SOLUTION SENSITIVITY FROM GENERAL PRINCIPLES*

ADAM B. LEVY†

Abstract. We present a generic approach for the sensitivity analysis of solutions to parameterized finite-dimensional optimization problems. We study differentiability and continuity properties of quasi-solutions (stationary points or stationary point-multiplier pairs), as well as their existence and uniqueness, and the issue of when quasi-solutions are actually optimal solutions. Our approach is founded on a few general rules that can all be viewed as generalizations of the classical inverse mapping theorem, and sensitivity analyses of particular optimization models can be made by computing certain generalized derivatives in order to translate the general rules into the terminology of the particular model. The useful application of this approach hinges on an inverse mapping theorem that allows us to compute derivatives of solution mappings without computing solutions, which is crucial since numerical solutions to sensitive problems are fundamentally unreliable. We illustrate how this process works for parameterized nonlinear programs, but the generality of the rules on which our approach is based means that a similar sensitivity analysis is possible for practically any finite-dimensional optimization problem. Our approach is distinguished not only by its broad applicability but by its separate treatment of different issues that are frequently treated in tandem. In particular, meaningful generalized derivatives can be computed and continuity properties can be established even in cases of multiple or no quasi-solutions (or optimal solutions) for some parameters. This approach has not only produced unprecedented and computable conditions for traditional properties in well-studied situations, but has also characterized interesting new properties that might otherwise have remained unexplored.

1. Introduction.

Even the most basic parameterized optimization problems can exhibit poor solution behavior; there can be more than one solution for some parameters, or no solutions for some parameters, or the solutions can be sensitive to perturbations of the parameter. These same difficulties persist for quasi-solutions (stationary points or stationary point-multiplier pairs) both in the case when quasi-solutions and optimal solutions coincide, and in the case when they do not. To illustrate this, we consider the minimization over $x \in \mathbb{R}$ of three different parameterized objective functions: (A) $x^2/2 - wx$, (B) $x^3/3 - wx$, and (C) $x^4/4 - wx$. The stationary point mappings associated with each of these three problems are plotted against the parameter $w \in \mathbb{R}$ in Figure 1.1. The mapping in (A) behaves about as well as can be hoped; there exists a unique stationary point for each parameter, and the dependence of the stationary points on the parameters is linear. On the other hand, the mapping in (B) is very poorly behaved; there are either two stationary points or none for all parameters but $w = 0$, and moreover the vertical slope at zero indicates that very small perturbations from $w = 0$ cause dramatic changes in the stationary points. Finally, the mapping in (C) has mixed behavior; there exist unique stationary points for all parameters, however, there is again the sensitivity indicated by the vertical slope at zero. Notice also that the optimal solutions coincide with the stationary points in both cases (A) and (C), but not in (B), where the optimal solution mapping consists

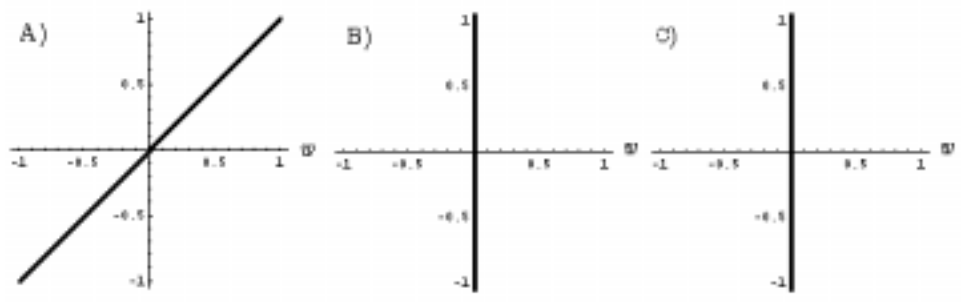

FIG. 1.2. *Derivatives of stationary point mappings.*

of only the upper branch of the square-root.

Simple examples like the three above are unusual among optimization problems generally, since the optimal solutions above can be calculated explicitly. It is more typical that numerical methods are used to identify solutions, and this fact provides motivation for the kind of sensitivity analysis that we present in this paper. In sensitive problems, small perturbations of parameters produce relatively large changes in solutions, so numerically computed solutions are fundamentally unreliable. It follows that any broadly useful sensitivity analysis of solutions should rest on tests that are independent of the computation of solutions. For the approach outlined in this paper, this paradox is handled by a kind of inverse mapping theorem that relates derivatives of the quasi-solution mapping to derivatives of the original data. For the simple examples above, the inverse mapping theorem gives a generalized derivative of the stationary point mapping at $w = 0$, as the inverse mapping associated with the second derivative in x of the objective function at $(x, w) = (0, 0)$. The second derivatives above are easy to compute and the inverse mapping theorem in these cases gives the generalized derivatives of the stationary point mappings displayed in Figure 1.2. In all of these cases, the graph of the generalized derivative is the tangent line to the stationary point mapping at $w = 0$, and any other reasonable generalized first derivative would be expected to produce the same thing for these examples.

The Fermat rule of differential calculus (the gradient is zero at a stationary point) is a very familiar example of a general rule which can be applied in different particular situations to obtain results about optimality, and it served to unify centuries of work on particular optimization problems. This kind of result is extraordinary in optimiza-

tion, the more typical generalization being an extension from some well-understood model. Our approach in this paper relies on general principles from variational analysis that are very much in the spirit of the Fermat rule. In fact, all of the general principles we use are different kinds of generalizations of the classical inverse mapping theorem.

CLASSICAL INVERSE MAPPING THEOREM. *For a single-valued $\mathcal{C}^1$ mapping $x : \mathbb{R}^d \to \mathbb{R}^n$ and any points $\bar{w} \in \mathbb{R}^d$ and $\bar{x} := x(\bar{w})$ the following are equivalent:*

(i) *$w' = 0$ is the only vector in $\mathbb{R}^d$ for which the Jacobian image $\nabla x(\bar{w}) \cdot w'$ equals zero.*

(ii) *There exists a neighborhood W of $\bar{w} \in \mathbb{R}^d$ and a neighborhood X of $\bar{x} \in \mathbb{R}^n$ such that the restriction of x to W is a bijection onto X with $\mathcal{C}^1$ inverse $w : X \to \mathbb{R}^d$, and moreover the Jacobians satisfy*

$$\nabla w(\bar{x}) = \big(\nabla x(\bar{w})\big)^{-1}. \tag{1.1}$$

We already alluded to one version of a generalization of this result, where an analogue to the identity (1.1) is obtained in a much less restrictive setting. The other generalizations that we use in this paper all characterize weaker properties than (ii) using generalized versions of (i).

We focus first on the most abstract and general objects, so that the specific applications become a second-stage matter of translating the abstract results into the language of the particular optimization problem at hand. We sometimes need to impose additional structure when we translate our results into verifiable conditions involving familiar terms of particular models, but these compromises are made after the fundamental rules have already been established, so their consequences and degree of necessity can be clarified. In this paper, we do not attempt to minimize the compromises we make to translate the general results, but instead we adopt reasonably standard assumptions so that the reader can see how the entire process works in a familiar setting. Of course, our approach is amenable to any desired refinement of the assumptions (e.g., reduced differentiability conditions on the original data) since it is based on completely general characterizations. Moreover, even under the standard assumptions, some of the sufficient conditions generated by our approach are unprecedented (even in cases of well-studied models like nonlinear programs), and our approach has identified interesting new properties that might otherwise have remained unexplored. We do not attempt to give a complete survey of the general principles underlying the sensitivity analysis of solutions, but rather we focus on a few principles and sensitivity properties that provide a basis for a reasonably complete sensitivity analysis.

One important aspect of our approach is that the general principles on which it is based are *characterizations* of certain desirable sensitivity properties. It follows that anyone who seeks derivative conditions for these sensitivity properties in connection with a particular optimization model must essentially reprove the general principles in their special case. Thus, anyone desiring to carry out such a sensitivity analysis need not create a new strategy from the ground up, and would be well served to translate the general principles for their particular case. In fact, one of the goals of this paper is to encourage others to work with the general principles presented here in order to carry out sensitivity analyses in more cases of interest.

To develop our general results, we study the variational properties of multifunctions (set-valued mappings) $S : \mathbb{R}^d \rightrightarrows \mathbb{R}^n$, and then specialize these results to the cases

where S represents stationary points or stationary point-multiplier pairs associated with the parameterized optimization problem

$$\min\{f(x,w)\} \text{ over all } x \in \mathbb{R}^n, \tag{1.2}$$

where f is a proper (so it is not identically equal to ∞ and nowhere equal to $-\infty$) extended real-valued function of $x \in \mathbb{R}^n$ and the parameter $w \in \mathbb{R}^d$. This is a completely generic finite-dimensional model which even includes constrained optimization problems since constraints can be incorporated through penalties into the objective function f. For instance, nonlinear programs like

$$\min\{g_0(x,w)\} \text{ over all } x \in C(w) := \left\{ x \;\middle|\; \begin{array}{ll} g_i(x,w) \le 0 & \text{for } i = 1,\dots,s, \\ g_i(x,w) = 0 & \text{for } i = s+1,\dots,m \end{array} \right\} \tag{1.3}$$

fit this model when the objective f is defined by

$$f(x,w) = \begin{cases} g_0(x,w) & \text{if } x \in C(w), \\ \infty & \text{otherwise.} \end{cases} \tag{1.4}$$

Throughout the paper, we illustrate how our approach applies to the analysis of the parametric sensitivity of general nonlinear programs.

As we already saw in the three simple examples at the beginning of this section, different issues are involved in solution sensitivity, including existence and uniqueness of solutions, as well as their continuity and differentiability properties. Another important issue is whether or not all stationary points are optimal solutions (every optimal solution is of course a stationary point, since the latter are defined by necessary conditions for optimality). Much of the sensitivity analysis carried out so far has followed the traditional hierarchy that has existence and uniqueness as the initial properties to be established (or assumed), followed by continuity properties, which in turn are followed by differentiability properties. In our approach, this hierarchy is inverted since these various properties depend on one another in new ways. For instance, the differentiability property that we use provides important sensitivity information even without uniqueness or existence for some parameters. Interestingly, existence and uniqueness properties cannot be characterized via first derivative objects in the absence of stability; this phenomenon is illustrated by the fact that the derivatives of the stationary point mappings above in cases (B) and (C) are the same even though the existence/uniqueness properties of the corresponding stationary point mappings are different. The unorthodox organization of the paper reflects the new hierarchy demanded by this situation; we begin with a discussion of differentiability properties, then move to continuity properties, and finally to questions of existence and uniqueness.

Sensitivity analysis has a long history, and many important contributions have been made over the years, both via the approach espoused here as well as by other approaches. The references at the end of this paper give some of the names of the major contributors; however, the purpose of this paper is not to provide a complete survey of the results in this area. Nor is its primary purpose to add particular results to the vast accumulation, but instead to frame certain kinds of sensitivity analyses generally in terms of a few basic principles that have been identified through this approach. One point of this paper then is that all analyses of certain sensitivity properties have at their core some general principle of variation. This means that any past or future attempt to characterize certain continuity or differentiability properties

of solutions in terms of derivatives of the original data of the problem must essentially involve the same general principles. It follows that translating these general principles to obtain particular results of interest is perhaps the most direct path to these results; and in any case it is an approach to results for new problems that has a head start, since it rests on already established general principles of variation.

Nonlinear programs have been studied so extensively that many of their important sensitivity properties have been well-understood long before this paper. In light of this extensive history as well as the fact that nonlinear programs are not the main focus of this paper, it is not feasible to give here an exhaustive description of past work in this area. When results presented here are apparently genuinely new, we do give some indication of that, but the default understanding in the applications sections is that similar results likely have been obtained before by other means. Nor are most aspects of the basic approach presented here new to this paper, and we try to indicate particular contributions along these lines where appropriate. Of particular note, the continuity and differentiability properties used here have been studied previously, and we refer the interested reader to [52] and [3] for a more complete treatment of these and related properties and their calculus. We also try to give some credit where it is due in the concluding section of the paper, where we describe some related solution sensitivity results obtained through the same basic approach, and compare our results to some obtained by fundamentally different approaches to solution sensitivity analysis.

2. Differentiability. One differentiability property frequently sought in connection with the sensitivity analysis of solutions is called B-differentiability: A single-valued mapping $f : \mathbb{R}^d \to \mathbb{R}^n$ is B-differentiable at $\bar{x} \in \mathbb{R}^d$ if it is directionally differentiable at $\bar{x}$ and the mapping $x \mapsto f(\bar{x}) + Df(\bar{x})(x - \bar{x})$ is a first-order approximation of f near $\bar{x}$. The differentiability property that we will use can be viewed as a direct generalization to multifunctions of B-differentiability for locally Lipschitz single-valued mappings, and it provides important sensitivity information even in the case of a true multifunction when the B-differentiability is not appropriate. This is important because there are many situations where there exist multiple or no solutions to a parameterized optimization problem. In addition, the property we use gives meaningful sensitivity information for single-valued mappings that are not B-differentiable.

We wish to study the differential properties of solutions associated with optimization problems (1.2), without making a priori assumptions about existence or uniqueness. This leads us naturally to generalized derivatives of multifunctions $S : \mathbb{R}^d \rightrightarrows \mathbb{R}^n$, since, for example, we can define a multifunction by

$$S(w) := \{x | x \text{ gives an optimal solution to (1.2) with parameter } w\}.$$

The primary generalized derivative that we use here is the *outer graphical derivative of S at $\bar{w}$ for $\bar{x}$* denoted $DS(\bar{w}|\bar{x}) : \mathbb{R}^d \rightrightarrows \mathbb{R}^n$ and defined as follows:

$$DS(\bar{w}|\bar{x})(w') = \left\{ x' \;\middle|\; \begin{array}{l} \exists w'_\nu \to w', \tau_\nu \downarrow 0 \text{ with } (\tilde{x}_\nu - \bar{x})/\tau_\nu \to x' \\ \text{for some } \tilde{x}_\nu \in S(\bar{w} + \tau_\nu w'_\nu) \end{array} \right\}.$$

The outer graphical derivative gets its name from the fact that it is the outer graphical limit as $t \downarrow 0$ of the sequence of difference quotient multifunctions defined for $t > 0$ by

$$w' \mapsto \frac{S(\bar{w} + tw') - \bar{x}}{t}.$$

The *outer graphical limit* of a sequence of multifunctions $\{G_t\}$ is the multifunction whose graph equals the set of all points obtained as limits of points in the sets $\operatorname{gph} G_{t_n}$

for some sequence $t_n \downarrow 0$. The outer graphical derivative always exists, though it may have empty values for some points.

A property called *protodifferentiability at $\bar{w}$ for $\bar{x}$* occurs when every element (w', x') in the graph of the outer graphical derivative $DS(\bar{x}, \bar{w})$ can actually be obtained as a limit

$$(w', x') = \lim_{t \downarrow 0} \frac{(w(t), x(t)) - (\bar{w}, \bar{x})}{t} \tag{2.1}$$

for some selection mapping $t \mapsto \big(w(t), x(t)\big) : [0, \epsilon] \to \operatorname{gph} S$ with $\epsilon > 0$. The concept of protodifferentiability is a generalization of B-differentiability [49] for single-valued mappings: A (single-valued) continuous mapping $S : \mathbb{R}^d \to \mathbb{R}^n$ is *B-differentiable at* $\bar{w}$ if the difference quotient mappings

$$w \mapsto \frac{S(\bar{w} + tw) - S(\bar{w})}{t} \quad \text{for} \quad t > 0$$

converge pointwise as $t \downarrow 0$ to a continuous (B-derivative) mapping $H : \mathbb{R}^d \to \mathbb{R}^n$ and do so uniformly on bounded sets.

Proposition 2.0.1 (see Proposition 2.2 of [27] and Proposition 3.5 of [29]). *Let O be an open neighborhood of a point $\bar{w} \in \mathbb{R}^d$ and consider a continuous single-valued mapping $S : O \to \mathbb{R}^n$. Then S is B-differentiable at $\bar{w}$ for $\bar{x} = S(\bar{w})$ if and only if S is protodifferentiable at $\bar{w}$ with $DS(\bar{w}|\bar{x})$ single-valued.*

When S happens to be Lipschitz continuous around $\bar{w}$, then S is B-differentiable at $\bar{w}$ if and only if S is protodifferentiable at $\bar{w}$ (and the single-valuedness of $DS(\bar{w}|\bar{x})$ is automatic under either of these equivalent conditions).

In either of these situations, the outer graphical derivative $DS(\bar{w}|\bar{x})$ is the same as the B-derivative, and one has the local expansion

$$S(\bar{w} + tw) = S(\bar{w}) + tDS(\bar{w}|\bar{x})(w) + o(t|w|) \quad \textit{for} \quad t > 0.$$

Remark. Since local Lipschitz continuity of solution mappings is traditionally established or assumed before studying differentiability properties, our approach using the outer graphical derivative and the concept of protodifferentiability covers at least as much ground as the traditional approaches to B-differentiability. However, the outer graphical derivative provides important sensitivity information even when S is genuinely set-valued, so our approach covers new ground too. From an analytical point of view, the image of the outer graphical derivative $DS(\bar{w}|\bar{x})(w')$ contains all the cluster points of sequences considered in the (uniform) limit defining the B-derivative. The situation when a single-valued mapping S fails to be B-differentiable at $\bar{w}$ thus corresponds to the case of the image set $DS(\bar{w}|\bar{x})(w')$ containing either multiple or no points. So the outer graphical derivative captures exactly the kind of derivative information that is usually desired, but which is often unnecessarily lost when attention is restricted to more traditional notions of differentiability. Protodifferentiability also signals an interesting geometric property where the graph of the multifunction is the image under an invertible nonlinear transformation of the graph of a B-differentiable single-valued mapping (see [29] for more details on this).

The following inverse mapping theorems for outer graphical derivatives form the theoretical basis for many of the computations in what follows.

Theorem 2.1 (see Theorem 4.1 of [26] and Theorem 3.1 of [23]). *For any multifunction $M : \mathbb{R}^n \times \mathbb{R}^d \rightrightarrows \mathbb{R}^n$ and any triple of points $(\bar{v}, \bar{w}, \bar{x})$ satisfying $\bar{v} \in$*

$M(\bar{x},\bar{w})$, consider the partial inverse multifunction $S:\mathbb{R}^n\times\mathbb{R}^d\rightrightarrows\mathbb{R}^n$ defined by

$$S(v,w):=\{x|v\in M(x,w)\} \tag{2.2}$$

and its restriction $S_0:\mathbb{R}^d\rightrightarrows\mathbb{R}^n$ defined by $S_0(w):=S(0,w)$. The outer graphical derivative of S at $(\bar{v},\bar{w})$ for $\bar{x}$ satisfies

$$DS(\bar{v},\bar{w}|\bar{x})(v',w')=\{x'|v'\in DM(\bar{x},\bar{w}|\bar{v})(x',w')\}, \tag{2.3}$$

and the outer graphical derivative of S_0 at $\bar{w}$ for $\bar{x}$ satisfies

$$DS_0(\bar{w}|\bar{x})(w')\subseteq\{x'|0\in DM(\bar{x},\bar{w}|0)(x',w')\}.$$

If the multifunction M is protodifferentiable at $(\bar{x},\bar{w})$ for $\bar{v}\in M(\bar{x},\bar{w})$, then the partial inverse multifunction S is protodifferentiable at $(\bar{v},\bar{w})$ for $\bar{x}$.

Remark. The explicit presence of the parameter v in the partial inverse multifunction S is essential for obtaining either the identity (2.3) or the protodifferentiability result. In the case when the mapping M satisfies the conditions of the classical inverse mapping theorem, Theorem 2.1 essentially reproduces the classical result (though obviously without the classical differentiability conclusions).

2.1. Differentiability of stationary points. A necessary condition for optimality in (1.2) that generalizes the Fermat rule is the inclusion $0\in\partial_x f(x,w)$ in terms of the partial subgradient multifunction $\partial_x f:\mathbb{R}^{n+d}\rightrightarrows\mathbb{R}^n$ (see [52, Theorem 10.1]). Recall from [52] that a vector $v\in\mathbb{R}^n$ is an element of the image set $\partial_x f(x,w)$ if and only if there exist sequences $v_n\to v$ and $x_n\to x$ such that $f(x_n,w)\to f(x,w)$, and for each fixed x'

$$f(x',w)\geq f(x_n,w)+\langle v_n,x'-x_n\rangle+o(|x'-x_n|).$$

Using the necessary condition for optimality $0\in\partial_x f(x,w)$ as a basis, the set of stationary points associated with (1.2) for with the parameter $w\in\mathbb{R}^d$ is the image set of the *stationary point multifunction* defined by

$$SP(w):=\{x|0\in\partial_x f(x,w)\}. \tag{2.4}$$

Notice that this multifunction is of the type S_0 covered by Theorem 2.1, so we know that its outer graphical derivative satisfies the estimate

$$D\big(SP\big)(\bar{w}|\bar{x})(w')\subseteq\{x'|0\in D\big(\partial_x f\big)(\bar{x},\bar{w}|0)(x',w')\} \tag{2.5}$$

in terms of the outer graphical derivative of the partial subgradient mapping. According to Theorem 2.1, if the partial subgradient multifunction is protodifferentiable, then the stationary point multifunction associated with a slightly modified problem is protodifferentiable too, and, moreover, in this case, the inclusion corresponding to (2.5) is an equality. The necessary modification involves a new parameter $v\in\mathbb{R}^n$ which serves to tilt the graph of the objective function:

$$\min\{f(x,w)-\langle v,x\rangle\}\text{ over }x\in\mathbb{R}^n. \tag{2.6}$$

Note that the new tilt parameter is precisely the kind of parameterization we saw for the simple examples considered in the introduction (though there we used the general parameter label w since there were no other parameters).

COROLLARY 2.1.1. *If the multifunction $\partial_x f$ is protodifferentiable at $(\bar{x}, \bar{w})$ for $\bar{v} \in \partial_x f(\bar{x}, \bar{w})$, then the stationary point multifunction associated with the problem* (2.6)

$$SP_{tilt}(v, w) := \{x | v \in \partial_x f(x, w)\} \tag{2.7}$$

is protodifferentiable at $(\bar{v}, \bar{w})$ for $\bar{x}$ and the identity holds that

$$D\big(SP_{tilt}\big)(\bar{v}, \bar{w}|\bar{x})(v', w') = \{x' | v' \in D\big(\partial_x f\big)(\bar{x}, \bar{w}|\bar{v})(x', w')\}.$$

Notice that Corollary 2.1.1 does not say anything directly about the protodifferentiability of the stationary point multifunction (2.4) associated with the original "untilted" optimization problem. However, indirect information about the differential properties of SP is available from the protodifferentiability of SP_{tilt} recorded in Corollary 2.1.1, and it can be extracted from $D\big(SP_{tilt}\big)$ according to the particular situation. In traditional situations when SP_{tilt} is B-differentiable, this procedure is trivial and the B-differentiability of SP follows immediately.

PROPOSITION 2.1.1. *If the stationary point multifunction SP_{tilt}* (2.7) *is (single-valued) continuous near $(0, \bar{w})$, the partial subgradient multifunction $\partial_x f$ is protodifferentiable at $(\bar{x}, \bar{w})$ for $0 \in \partial_x f(\bar{x}, \bar{w})$ and the outer graphical derivative mapping*

$$D\big(SP_{tilt}\big)(0, \bar{w}|\bar{x})(v', w') = \{x' | v' \in D\big(\partial_x f\big)(\bar{x}, \bar{w}|0)(x', w')\} \tag{2.8}$$

is single-valued, then SP_{tilt} is actually B-differentiable at $(0, \bar{w})$ with B-derivative given by (2.8).

If SP_{tilt} is Lipschitz continuous near $(0, \bar{w})$, then the same result holds without the assumption about the single-valuedness of (2.8) *(which single-valuedness is in this event assured by the B-differentiability).*

Moreover, in either of these situations, the stationary point mapping SP (2.4) *associated with the untilted problem is also B-differentiable at $\bar{w}$ with B-derivative given by*

$$D\big(SP\big)(\bar{w}|\bar{x})(w') = \{x' | 0 \in D\big(\partial_x f\big)(\bar{x}, \bar{w}|0)(x', w')\}.$$

Proof. This follows from Proposition 2.0.1 and Corollary 2.1.1 since $SP(w)$ is the same as $SP_{tilt}(0, w)$, so the joint B-differentiability of SP_{tilt} implies B-differentiability of the stationary point mapping SP. □

Remark. In the classical case when f is a twice differentiable function of x alone, both results in this section say that the stationary point mapping associated with the tilted minimization of f is protodifferentiable, and that its protoderivative is given by the inverse mapping associated with the Hessian $\nabla^2 f$.

2.2. Differentiability in the case of fully amenable functions. According to Corollary 2.1.1 and Proposition 2.1.1, the protodifferentiability of the partial subgradient multifunction $\partial_x f$ is the key to establishing differentiability properties for stationary point multifunctions. One particularly important class of composite functions in optimization has been shown to have protodifferentiable partial subgradient multifunctions.

Definition. A proper extended real-valued function g on $\mathbb{R}^m$ is called *piecewise linear-quadratic* if its effective domain $\operatorname{dom} g := \{y \in \mathbb{R}^m | g(y) < \infty\}$ can be represented as the union of finitely many polyhedral sets, relative to each of which $g(y)$ is

given by an expression of the form $\langle y, Ay\rangle/2 + \langle a, y\rangle + \alpha$ for some scalar $\alpha \in \mathbb{R}$, vector $a \in \mathbb{R}^m$, and symmetric matrix $A \in \mathbb{R}^{m\times m}$.

A proper extended real-valued function f on $\mathbb{R}^{n+d}$ is called *amenable in x at $\bar{x}$ with compatible parameterization in w at $\bar{w}$* if $f(\bar{x}, \bar{w})$ is finite and on some neighborhood $X \times W \subseteq \mathbb{R}^{n+d}$ of $(\bar{x}, \bar{w})$ there is a representation $f(x, w) = g\big(G(x, w)\big)$ in which G is a $\mathcal{C}^1$ mapping from $X \times W$ into $\mathbb{R}^m$, while g is a proper, lower semicontinuous, convex function on $\mathbb{R}^m$, such that the following constraint qualification is fulfilled:

$$0 \in \operatorname{int}\Big(\operatorname{dom} g - \big[G(\bar{x}, \bar{w}) + \nabla_x G(\bar{x}, \bar{w})\mathbb{R}^n\big]\Big). \tag{2.9}$$

If in addition such a representation exists with G not just $\mathcal{C}^1$ but $\mathcal{C}^2$ and with g piecewise linear-quadratic, then f is said to be *fully amenable in x at $\bar{x}$ with compatible parameterization in w at $\bar{w}$*.

The class of fully amenable functions covers many of the functions commonly involved in finite-dimensional optimization (see [52]), including maxima of finitely many $\mathcal{C}^2$ functions, as well as the essential objective associated with a nonlinear program (1.4) under the Mangasarian–Fromovitz constraint qualification. In [28], fully amenable functions with compatible parameterization were shown to have protodifferentiable partial subgradient multifunctions.

PROPOSITION 2.2.1 (see Theorem 1.1 of [28]). *If f is fully amenable in x at $\bar{x}$ with compatible parameterization in w at $\bar{w}$, then for all $(x, w) \in \mathbb{R}^{n+d}$ sufficiently close to $(\bar{x}, \bar{w})$ the partial subgradient multifunction $\partial_x f$ is protodifferentiable at (x, w) for $v \in \partial_x f(x, w)$. Moreover, in this case, the image sets of the outer graphical derivative $D\big(\partial_x f\big)(x, w|v)$ can be computed by taking the union over all $u \in \mathbb{R}^d$ satisfying $(v, u) \in \partial f(x, w)$ (for the full subgradient multifunction) of the projections onto $\mathbb{R}^n$ of the image sets for the outer graphical derivatives $D\big(\partial f\big)(x, w|v, u)$.*

Remark. In [43], this result was extended to a more general class of amenable functions where the function g is allowed to have $\mathcal{C}^2$ pieces in place of quadratic ones.

According to Proposition 2.2.1 fully amenable functions have protodifferentiable partial subgradient mappings, so the results of the previous section apply to give sensitivity information about the stationary points associated with the minimization of fully amenable functions. In the following section, we explore this further for one important particular case of fully amenable minimization.

2.3. Differentiability of stationary points for nonlinear programs. In [41] and [42], chain rules for the outer graphical derivatives of the full subgradient multifunction are worked out, and these can be combined with Proposition 2.2.1 to obtain more specific formulas for the outer graphical derivatives of the partial subgradient multifunction in particular cases that fit the model covered by Proposition 2.2.1. For example, this process was carried out in [27] for the case of the nonlinear program (1.3) with $\mathcal{C}^2$ functions g_i for $i = 0, \ldots, m$, and we will outline these results here under the same assumptions. The formulas obtained in [27] involved the polyhedral cone $Q(x, w) \subset \mathbb{R}^{n+d}$ defined by

$$Q(x, w) := \left\{(x', w') : \begin{array}{l} \langle \nabla g_i(x, w), (x', w')\rangle \le 0 \text{ for } i \in [1, s] \text{ with } g_i(x, w) = 0, \\ \langle \nabla g_i(x, w), (x', w')\rangle = 0 \text{ for } i \in [s+1, m] \end{array}\right\}, \tag{2.10}$$

the mapping

$$G(x, w) := \big(g_1(x, w), \ldots, g_m(x, w)\big), \tag{2.11}$$

the set

$$K := \{z \in \mathbb{R}^m | z_i \leq 0 \text{ for } i = 1, \ldots, s \text{ and } z_i = 0 \text{ for } i = s+1, \ldots, m\}, \tag{2.12}$$

its associated convex normal cone mapping $N_K : \mathbb{R}^m \rightrightarrows \mathbb{R}^m$, which is empty-valued at $z \notin K$ and is defined at $z \in K$ by

$$N_K(z) = \{y \in \mathbb{R}^m | \langle y, k - z\rangle \leq 0 \text{ for all } k \in K\}, \tag{2.13}$$

and the usual Lagrangian mapping $L : \mathbb{R}^n \times \mathbb{R}^m \times \mathbb{R}^d$ defined by

$$L(x, y, w) := g_0(x, w) + y_1 g_1(x, w) + \cdots + y_m g_m(x, w).$$

To state the result from [27] we also need certain sets of multiplier vectors, first the bounded, polyhedral set

$$Y(x, w, v, u) := \big\{y = (y_1, \ldots, y_m) \in N_K\big(G(x, w)\big) : \nabla_{(x,w)} L(x, y, w) = (v, u)\big\} \tag{2.14}$$

and its face

$$Y_{\max}(x, w, v, u; x', w') = \underset{y \in Y(x,w,v,u)}{\arg\max} \left\langle (x', w'), \nabla^2_{(x,w)(x,w)} L(x, y, w) \cdot (x', w') \right\rangle \tag{2.15}$$

and then the polyhedral cone

$$Y'(x, w; x', w') = \left\{ \begin{array}{r} y' = (y'_1, \ldots, y'_m) \in N_K\big(G(x, w)\big) : \\ y'_i = 0 \text{ for } i \text{ with } \left\langle \nabla g_i(x, w), (x', w') \right\rangle \neq 0 \end{array} \right\}. \tag{2.16}$$

Remark. Notice that in the case when the constraint functions are affine, the face (2.15) is the entire set of multipliers $Y(x, w, v, u)$.

Another special case is when the parameterization $w = (w_1, w_2)$ includes the "canonical" parameter $w_2 \in \mathbb{R}^m$ which perturbs the constraint functions as follows: $g_i(x, w_1) + \big[w_2\big]_i$. In this case, the multiplier set $Y(x, w, v, u)$ for $u = (u_1, u_2)$ is empty unless u_2 is in the normal cone $N_K\big(G(x, w)\big)$ and $u_1 = \nabla_{w_1} g_0(x, w_1) - u_2 \cdot \nabla_{w_1} G(x, w)$, in which case $Y(x, w, v, u)$ reduces to the singleton $\{u_2\}$. It follows that in this case the face $Y_{\max}(x, w, v, u; x', w')$ is the same as the set $Y(x, w, v, u)$ regardless of the choice of x' and w'. However, the set $Y_{\max}(x, w, v, u; x', w')$ is frequently a proper subset of the set of all multipliers as in the case of the following example.

Example program. Consider the minimization problem

$$\min\{g_0(x_1, x_2, w) := (x_1)^2 - x_1 + (x_2)^2\} \text{ over all } x \in C(w),$$

where the constraint set is defined as follows:

$$C(w) := \{x \in \mathbb{R}^2 : g_1(x_1, x_2, w) := x_1 - x_2^2 + w^2 \leq 0 \text{ and } g_2(x_1, x_2, w) := x_1 - w^2 \leq 0\}.$$

For the base values $x = (0, 0)$, $w = 0$, and $v = (0, 0)$, the set of Lagrange multipliers is empty unless $u = 0$ in which case it consists of the $y \in \mathbb{R}^2_+$ satisfying $y_1 + y_2 = 1$, and the Hessian $\nabla^2_{(x,w)(x,w)} L\left((0, 0), y, 0\right)$ is the matrix

$$\begin{bmatrix} 2 & 0 & 0 \\ 0 & 2(1 - y_1) & 0 \\ 0 & 0 & 2(y_1 - y_2) \end{bmatrix}.$$

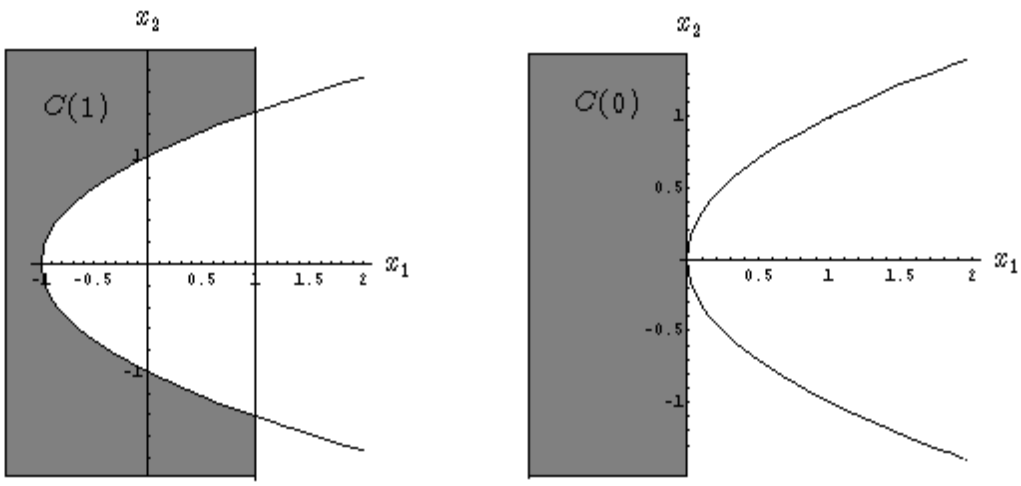

FIG. 2.1. *Constraint set for example program.*

It follows that the inner product defining the face $Y_{\max}\left((0,0),0,(0,0),0;x',w'\right)$ reduces to $2(x_1')^2 + 2(1-y_1)(x_2')^2 + 2(y_1-y_2)(w')^2$ which is maximized at the unique multiplier pair $(1,0)$ for any choice of $x' = (x_1', x_2')$ and w' with $x_2' = 0$ and $w' \neq 0$ or $x_2' \leq w' \neq 0$; thus in these cases, the face $Y_{\max}\left((0,0),0,(0,0),0;x',w'\right)$ contains only the pair $(1,0)$. On the other hand, if $w' = 0$ and $x_2' \neq 0$ or $0 \neq x_2' > w'$, then the face $Y_{\max}\left((0,0),0,(0,0),0;x',w'\right)$ consists solely of the multiplier pair $(0,1)$. Finally, if both $w' = 0$ and $x_2' = 0$, then the face $Y_{\max}\left((0,0),0,(0,0),0;x',w'\right)$ is the entire set of multipliers.

PROPOSITION 2.3.1 (see Theorem 3.2 of [27]). *For the nonlinear program* (1.3) *and its associated essential objective function* f (1.4)*, if the Mangasarian–Fromovitz constraint qualification holds at* $(\bar{x},\bar{w})$*,*

$$\nexists y = (y_1,\ldots,y_m) \in N_K\big(G(\bar{x},\bar{w})\big) \text{ with} \quad y_1\nabla_x g_1(\bar{x},\bar{w}) + \cdots + y_m\nabla_x g_m(\bar{x},\bar{w}) = 0, \text{ except } y = 0, \tag{2.17}$$

then for all pairs (x,w) *sufficiently close to* $(\bar{x},\bar{w})$ *and all* $v \in \partial_x f(x,w)$*, the partial subgradient multifunction for the essential objective function* (1.4) *is protodifferentiable at* (x,w) *for* v *and its outer graphical derivative can be computed as follows: For* $(x',w') \notin Q(x,w)$*, the set* $D\big(\partial_x f\big)(x,w|v)(x',w')$ *is empty. But for* $(x',w') \in Q(x,w)$*, the outer graphical derivative image set* $D\big(\partial_x f\big)(x,w|v)(x',w')$ *consists of all vectors*

$$\nabla^2_{x(x,w)} L(x,y,w)(x',w') + \sum_{i=1}^{m} y_i'\nabla_x g_i(x,w) - y_0'\big(v - \nabla_x g_0(x,w)\big)$$

generated by $y' \in Y'(x,w;x',w')$ *and* $y_0' \in \mathbb{R}$ *along with choices of* y *for which there exists* $u \in \mathbb{R}^d$ *with* $\langle (v,u),(x',w')\rangle = \langle \nabla g_0(x,w),(x',w')\rangle$ *such that* y *is an element of* $Y_{\max}(x,w,v,u;x',w')$*. (If no such choice of* y *is possible, then again* $D\big(\partial_x f\big)(x,w|v)(x',w')$ *is empty.)*

The characterization in Proposition 2.3.1 of the outer graphical derivative can be combined with the results in Corollary 2.1.1 and Proposition 2.1.1 to obtain the following formulas for the outer graphical derivatives of the stationary point multifunctions

associated with the nonlinear program (1.3):

$$SP(w) := \big\{x | \exists y \in N_K\big(G(x,w)\big) \text{ with } 0 = \nabla_x L(x,y,w)\big\} \tag{2.18}$$

and

$$SP_{tilt}(v,w) := \big\{x | \exists y \in N_K\big(G(x,w)\big) \text{ with } v = \nabla_x L(x,y,w)\big\}. \tag{2.19}$$

PROPOSITION 2.3.2 (see Theorem 3.1 of [27]). *For the nonlinear program* (1.3) *and its associated stationary point multifunctions SP* (2.18) *and* SP_{tilt} (2.19)*, if the Mangasarian–Fromovitz constraint qualification* (2.17) *holds at* $(\bar{x},\bar{w})$ *with* $\bar{x} \in SP(\bar{w})$*, then* SP_{tilt} *is protodifferentiable at* $(0,\bar{w})$ *for* $\bar{x}$ *and the image set of the outer graphical derivative* $D\big(SP_{tilt}\big)(0,\bar{w}|\bar{x})(v',w')$ *is equal to the set of* x' *such that* $(x',w') \in Q(\bar{x},\bar{w})$ *and there exist* $y' \in Y'(\bar{x},\bar{w};x',w')$*,* $y'_0 \in \mathbb{R}$*,* $\bar{u} \in \mathbb{R}^d$ *with* $\langle \bar{u}, w'\rangle = \langle \nabla g_0(\bar{x},\bar{w}), (x',w')\rangle$*, and* $\bar{y} \in Y_{\max}(\bar{x},\bar{w},0,\bar{u};x',w')$ *which together satisfy*

$$v' = \nabla^2_{x(x,w)} L(\bar{x},\bar{y},\bar{w}) \cdot (x',w') + y'_0 \nabla_x g_0(\bar{x},\bar{w}) + \sum_{i=1}^{m} y'_i \nabla_x g_i(\bar{x},\bar{w}). \tag{2.20}$$

Moreover, the image set of the outer graphical derivative $D\big(SP\big)(\bar{w}|\bar{x})(w')$ *is included in the set* $D\big(SP_{tilt}\big)(0,\bar{w}|\bar{x})(0,w')$ *from above.*

Proof. This follows from Corollary 2.1.1 and the inclusion (2.5) using the formula for the outer graphical derivative of $\partial_x f$ given in Proposition 2.3.1. □

Example program revisited. For the example program given at the beginning of this section and for $\bar{x} = (0,0)$ and $\bar{w} = 0$, both constraints are active and their gradients in x are both equal to $(1,0)$ so the Mangasarian–Fromovitz constraint qualification is satisfied, and Proposition 2.3.2 applies. In this case, the cone $Q(\bar{x},\bar{w})$ is the set of triples (x'_1,x'_2,w') with $x'_1 \le 0$, and $Y_{\max}(\bar{x},\bar{w},0,\bar{u};x',w')$ is empty unless $\bar{u} = 0$. When $\bar{u} = 0$, the condition

$$\langle \bar{u}, w'\rangle = \langle \nabla g_0(\bar{x},\bar{w}), (x',w')\rangle$$

reduces to $x'_1 = 0$, which implies that $Y'(\bar{x},\bar{w};x',w') = \mathbb{R}^2_+$. The identity (2.20) then reduces to

$$\begin{aligned} v'_1 &= -y'_0 + y'_1 + y'_2, \\ v'_2 &= 2(1-\bar{y}_1)x'_2 \end{aligned} \tag{2.21}$$

for some choices of $\bar{y} \in Y_{\max}(\bar{x},\bar{w},0,\bar{u};x',w')$, $y'_0 \in \mathbb{R}$, and $y' \in \mathbb{R}^2_+$. No matter what $v'_1 \in \mathbb{R}$ is, the first identity can be satisfied by choosing $y'_0 = -v'_1$ and $y'_1 = y'_2 = 0$. The form of the outer graphical derivative $D\big(SP_{tilt}\big)(0,\bar{w}|\bar{x})(v',w')$ thus depends entirely on the values of v'_2 and w'. We already have established that this outer graphical derivative has zero first component $x'_1 = 0$, and it remains to compute the possible second components x'_2 in this situation.

If $v'_2 = 0$, then the second identity in (2.21) is satisfied only when $\bar{y}_1 = 1$ or when $x'_2 = 0$. From our earlier analysis of the face $Y_{\max}(\bar{x},\bar{w},0,\bar{u};x',w')$, we know that $\bar{y}_1 = 1$ only when $x'_2 = 0$ or $x'_2 \le w' \ne 0$.

If $v'_2 \ne 0$, then the second identity in (2.21) is satisfied only when $\bar{y}_1 \ne 1$ in which case $x'_2 = v'_2/2(1-\bar{y}_1)$. From our earlier analysis of the face $Y_{\max}(\bar{x},\bar{w},0,\bar{u};x',w')$, it is clear that $\bar{y}_1 = 0$ is the only feasible option, in which case $x'_2 = v'_2/2$. This only

occurs, however, if $w' = 0$ or $v_2' > 2w'$. It follows that the outer graphical derivative for the tilted stationary point mapping associated with this example satisfies

$$D\big(SP_{tilt}\big)(0,\bar{w}|\bar{x})(v_1',v_2',w') = \begin{cases} \{0\}\times(\{0\}\cup(-\infty,w']) & \text{if } w'\neq 0 \text{ and } v_2'=0,\\ \{0\}\times\{v_2'/2\} & \text{if } w'=0 \text{ or } 0\neq v_2'>2w',\\ \emptyset & \text{otherwise.}\end{cases}$$

Moreover, the outer graphical derivative for the untilted stationary point mapping associated with this example satisfies

$$D\big(SP\big)(\bar{w}|\bar{x})(w') \subseteq \begin{cases} \{0\}\times(\{0\}\cup(-\infty,w']) & \text{if } w'\neq 0,\\ \{0\}\times\{0\} & \text{if } w'=0.\end{cases}$$

Notice that the derivative formulas for this example were computed without first computing the stationary points, so sensitivity information about stationary points is available without the stationary points themselves.

The next result is just the translation of Proposition 2.1.1 using the formula in Proposition 2.3.1.

PROPOSITION 2.3.3 (see Theorem 3.3 of [27]). *If in addition to the assumptions of Proposition* 2.3.2*, the stationary point multifunction SP_{tilt} is (single-valued) continuous near $(0,\bar{w})$, then it is B-differentiable at $(0,\bar{w})$ if for every pair (v',w') there is only one point x' for which $(x',w')\in Q(\bar{x},\bar{w})$ and there exist $y'\in Y'(\bar{x},\bar{w};x',w')$, $y_0'\in\mathbb{R}$, $\bar{u}\in\mathbb{R}^d$ with $\langle\bar{u},w'\rangle = \langle\nabla g_0(\bar{x},\bar{w}),(x',w')\rangle$, and $\bar{y}\in Y_{\max}(\bar{x},\bar{w},0,\bar{u};x',w')$ which together satisfy* (2.20)*.*

If SP_{tilt} is Lipschitz continuous near $(0,\bar{w})$, then it is automatically B-differentiable without any assumptions about uniqueness of solutions to (2.20) *(which uniqueness is in this event assured by the B-differentiability).*

Moreover, under either of these assumptions on SP_{tilt}, the stationary point mapping SP (2.18) *is B-differentiable at $\bar{w}$ with B-derivative $D\big(SP\big)(\bar{w}|SP(\bar{w}))(w')$ equal to the (unique) point x' for which $(x',w')\in Q(\bar{x},\bar{w})$ and for which there exist $y'\in Y'(\bar{x},\bar{w};x',w')$, $y_0'\in\mathbb{R}$, $\bar{u}\in\mathbb{R}^d$ with $\langle\bar{u},w'\rangle = \langle\nabla g_0(\bar{x},\bar{w}),(x',w')\rangle$, and $\bar{y}$ and element of $Y_{\max}(\bar{x},\bar{w},0,\bar{u};x',w')$ which together satisfy*

$$0 = \nabla^2_{x(x,w)}L(\bar{x},\bar{y},\bar{w})\cdot(x',w') + y_0'\nabla_x g_0(\bar{x},\bar{w}) + \sum_{i=1}^m y_i'\nabla_x g_i(\bar{x},\bar{w}).$$

2.4. Differentiability of Karush–Kuhn–Tucker pairs. In this section, we return to the study of general tilted optimization problems (2.6) but now where the objective function f takes the special form of a sum of a $\mathcal{C}^1$ function g_0 and an amenable function $g\big(G(x,w)+v_2\big)$ perturbed inside the composition by $v_2\in\mathbb{R}^m$ (see section 2.2 for the definition of amenability):

$$\min\{g_0(x,w) + g\big(G(x,w)+v_2\big) - \langle v_1,x\rangle\} \text{ over } x\in\mathbb{R}^n. \tag{2.22}$$

This optimization problem is a generalization of a canonically perturbed (by v_1 and v_2) nonlinear program since that model is covered by the mapping G (2.11) and the function g equal to the "indicator function" δ_K associated with the set K (2.12):

$$g(z) = \delta_K(z) := \begin{cases} 0 & \text{if } z\in K,\\ \infty & \text{otherwise.}\end{cases}$$

Of course, we lose nothing by explicitly including canonical perturbations, since sensitivity information for the unperturbed problem

$$\min\{g_0(x,w) + g\big(G(x,w)\big)\} \text{ over } x \in \mathbb{R}^n \tag{2.23}$$

can be recovered from the canonically perturbed model with $(v_1, v_2) = (0,0)$.

We can define a generalized Lagrangian function on $\mathbb{R}^{n+m+d}$ by

$$L(x,y,w) := g_0(x,w) + \langle y, G(x,w)\rangle,$$

as well as the generalized Karush–Kuhn–Tucker (KKT) pairs associated with parameters $(v,w) = (v_1, v_2, w) \in \mathbb{R}^{n+m} \times \mathbb{R}^d$, which are the pairs $(x,y) \in \mathbb{R}^{n+m}$ satisfying

$$\begin{aligned} &\nabla_x L(x,y,w) - v_1 = 0 \text{ and} \\ &G(x,w) + v_2 \in \big(\partial g\big)^{-1}(y), \end{aligned}$$

where $\big(\partial g\big)^{-1}(y)$ denotes the set of vectors $z \in \mathbb{R}^m$ for which $y \in \partial g(z)$. Under the constraint qualification (2.9) stipulated by amenability, stationary points x for the problem (2.22) for parameters (v,w) close to $(0,\bar{w})$ can always be paired with a multiplier vector $y \in \mathbb{R}^m$ so that the pair (x,y) is a KKT pair for (v,w) (see [52, Exercise 10.26]). To study these stationary point-multiplier pairs, we define the KKT pair multifunction whose value at (v,w) is the set of KKT pairs for (v,w)

$$KKT(v,w) := \left\{(x,y) | v \in \Big(\nabla_x L(x,y,w), -G(x,w)\Big) + \Big(\{0\}^n \times \big(\partial g\big)^{-1}(y)\Big)\right\}. \tag{2.24}$$

From this formulation, the role of the canonical perturbations is clear; since the parameter v appears explicitly, the KKT pair multifunction belongs to the class of multifunctions S covered by our basic Theorem 2.1. According to Theorem 2.1 then, the protodifferentiability of the KKT pair multifunction is assured under the protodifferentiability of the multifunction

$$M(x,y,w) := \Big(\nabla_x L(x,y,w), -G(x,w)\Big) + \Big(\{0\}^n \times \big(\partial g\big)^{-1}(y)\Big). \tag{2.25}$$

Proposition 2.4.1. *If the mapping $\nabla_x L$ is B-differentiable at $(\bar{x},\bar{y},\bar{w})$ and the subgradient multifunction ∂g is protodifferentiable at $\bar{z} := \bar{v}_2 + G(\bar{x},\bar{w})$ for $\bar{y} \in \partial g(\bar{z})$, then the KKT pair multifunction* (2.24) *is protodifferentiable at $(\bar{v},\bar{w})$ for $(\bar{x},\bar{y})$ and the image set of its outer graphical derivative $D\big(KKT\big)(\bar{v},\bar{w}|\bar{x},\bar{y})(v_1', v_2', w')$ is given by*

$$\left\{(x',y') \;\middle|\; \begin{array}{l} v_1' = D\left(\nabla_x L\right)(\bar{x},\bar{y},\bar{w}|\nabla_x L(\bar{x},\bar{y},\bar{w}))\,(x',y',w') \\ v_2' + \nabla G(\bar{x},\bar{w})\cdot(x',w') \in D\left(\big(\partial g\big)^{-1}\right)\big(\bar{y}|\bar{z}\big)(y') \end{array}\right\}. \tag{2.26}$$

Moreover, the image set at $w' \in \mathbb{R}^d$ of the outer graphical derivative at $\bar{w}$ for $(\bar{x},\bar{y})$ of the KKT pair multifunction $w \mapsto KKT(0,w)$ associated with the unperturbed problem (2.23) *is contained in the set*

$$\left\{(x',y') \;\middle|\; \begin{array}{l} 0 = D\left(\nabla_x L\right)(\bar{x},\bar{y},\bar{w}|\nabla_x L(\bar{x},\bar{y},\bar{w}))\,(x',y',w') \\ \nabla G(\bar{x},\bar{w})\cdot(x',w') \in D\left(\big(\partial g\big)^{-1}\right)\big(\bar{y}|G(\bar{x},\bar{w})\big)(y') \end{array}\right\}. \tag{2.27}$$

Proof. This follows from Theorem 2.1 since according to [26, Propositions 2.2 and 3.4], the protodifferentiability of M (2.25) is ensured by the assumptions. To show the formula (2.26) for the outer graphical derivative, we define the multifunction

$$M_2(x, y, w) := -G(x, w) + \big(\partial g\big)^{-1}(y)$$

so that the outer graphical derivative $DM(\bar{x}, \bar{y}, \bar{w}|\bar{v})(x', y', w')$ is the set

$$\Big(D\left(\nabla_x L\right)(\bar{x}, \bar{y}, \bar{w}|\nabla_x L(\bar{x}, \bar{y}, \bar{w}))\,(x', y', w'), DM_2(\bar{x}, \bar{y}, \bar{w}|\bar{v}_2)(x', y', w')\Big) \tag{2.28}$$

and the outer graphical derivative of M_2 is given by

$$DM_2(\bar{x}, \bar{y}, \bar{w}|\bar{v})(x', y', w') = -\nabla G(\bar{x}, \bar{w}) \cdot (x', w') + D\Big(\big(\partial g\big)^{-1}\Big)(\bar{y}|\bar{z})(y'). \tag{2.29}$$

The formula for the outer graphical derivative then follows directly from Theorem 2.1. ∎

Remark. Proposition 2.4.1 is quite broad since many optimization problems satisfy its assumptions: The mapping $\nabla_x L$ is B-differentiable under very mild additional assumptions on the function g_0 and the mapping G, and there are many known protodifferentiable subgradient multifunctions associated with convex functions g, including all cases when g is piecewise linear-quadratic.

A result similar to Proposition 2.4.1 but covering a slightly different model was obtained in [51], where the formula for the outer graphical derivative was given in terms of the solutions to an auxiliary optimization problem.

Following the approach outlined in section 2.1, we can study the B-differentiability of KKT pairs associated with the unperturbed and untilted problem (where $v = 0$) from the outer graphical derivative formula in Proposition 2.4.1.

PROPOSITION 2.4.2. *Under the assumptions of Proposition* 2.4.1 *with* $\bar{v} = 0$*, if either the KKT pair multifunction* (2.24) *is Lipschitz continuous near* $(0, \bar{w})$ *or it is (single-valued) continuous near* $(0, \bar{w})$ *and the outer graphical derivative* $D\big(KKT\big)$ *at* $(0, \bar{w})$ *for* $(\bar{x}, \bar{y})$ *is single-valued, then the KKT pair multifunction* (2.24) *is B-differentiable at* $(0, \bar{w})$*.*

Moreover, under either of these conditions, the KKT pair mapping $w \mapsto KKT(0, w)$ *associated with the optimization problem* (2.23) *is B-differentiable at* $\bar{w}$ *with B-derivative evaluated at* $w' \in \mathbb{R}^d$ *equal to the unique pair* $(x', y') \in \mathbb{R}^{n+m}$ *in the set* (2.27)*.*

2.5. Differentiability of KKT pairs for nonlinear programs. In this section, we move again to our most specific level by translating the results in section 2.4 into the case of nonlinear programs with canonical perturbations v_1 and v_2

$$\min\{g_0(x, w) - \langle v_1, x\rangle + \delta_K\big(G(x, w) + v_2\big)\}, \tag{2.30}$$

where the set K given by (2.12) and $\mathcal{C}^2$ functions g_i for $i = 0, \ldots, m$ define the mapping G given by (2.11). The Lagrangian function associated with this program is automatically $\mathcal{C}^2$, so the key to accessing the differentiability results in section 2.4 is the protodifferentiability of the subgradient multifunction associated with the indicator function $g(z) = \delta_K(z)$. The subgradient multifunction associated with δ_K is just the convex normal cone mapping $N_K : \mathbb{R}^m \rightrightarrows \mathbb{R}^m$ (2.13), which according to Proposition (2.2.1) is protodifferentiable under the Mangasarian–Fromovitz constraint qualification (2.17). Moreover, at any $\bar{z} \in K$ and for $\bar{y} \in N_K(\bar{z})$ the outer graphical

derivative of N_K is empty-valued at $z' \in \mathbb{R}^m$ unless $z' \in Z(\bar{z}, \bar{y})$, where

$$Z(\bar{z}, \bar{y}) := \left\{ z' \in \mathbb{R}^m \;\middle|\; \begin{array}{ll} z'_i \leq 0 & \text{for } i \in [1,s] \text{ with } \bar{z}_i = 0 \text{ and } \bar{y}_i = 0 \\ z'_i = 0 & \text{for } i \in [1,s] \text{ with } \bar{z}_i = 0 \text{ and } \bar{y}_i > 0 \\ z'_i = 0 & \text{for } i \in [s+1,m] \end{array} \right\},$$

in which case it satisfies

$$D\left(N_K\right)(\bar{z}|\bar{y})(z') = \left\{ y' \in \mathbb{R}^m \;\middle|\; \begin{array}{ll} y'_i \geq 0 & \text{for } i \in [1,s] \text{ with } \bar{z}_i = 0, \bar{y}_i = 0, \text{ and } z'_i = 0 \\ y'_i = 0 & \text{for } i \in [1,s] \text{ with } \bar{z}_i = 0, \bar{y}_i = 0, \text{ and } z'_i < 0 \\ y'_i = 0 & \text{for } i \in [1,s] \text{ with } \bar{z}_i < 0 \end{array} \right\}. \tag{2.31}$$

The next result follows from these facts and uses the following sets of indices:

$$\begin{aligned} I_1 &:= \{i \in [s+1,m] \text{ and } i \in [1,s] \text{ with } \bar{y}_i > 0 = g_i(\bar{x}, \bar{w})\}, \\ I_2 &:= \{i \in [1,s] \text{ with } \bar{y}_i = 0 = g_i(\bar{x}, \bar{w})\}, \\ I_3 &:= \{i \in [1,s] \text{ with } \bar{y}_i = 0 > g_i(\bar{x}, \bar{w})\}. \end{aligned} \tag{2.32}$$

Proposition 2.5.1. *For the canonically perturbed nonlinear program* (2.30) *and its associated KKT pair multifunction*

$$KKT(v,w) := \left\{ (x,y) | v \in \Big(\nabla_x L(x,y,w), -G(x,w) \Big) + \Big(\{0\}^n \times \left(N_K\right)^{-1}(y) \Big) \right\}, \tag{2.33}$$

if the Mangasarian–Fromovitz constraint qualification (2.17) *holds at* $(\bar{x}, \bar{w})$ *with* $(\bar{x}, \bar{y}) \in KKT(0, \bar{w})$*, then the KKT pair multifunction is protodifferentiable at* $(0, \bar{w})$ *for* $(\bar{x}, \bar{y}) \in KKT(0, \bar{w})$*, and the image set of outer graphical derivative*

$$D\big(KKT\big)(0, \bar{w} | \bar{x}, \bar{y})(v'_1, v'_2, w')$$

is the set of pairs $(x', y') \in \mathbb{R}^{n+m}$ *that satisfy*

$$\begin{aligned} & v'_1 = \nabla^2_{x(x,y,w)} L(\bar{x}, \bar{y}, \bar{w}) \cdot (x', y', w'), \\ & y'_i \geq 0 \text{ for } i \in [1,s] \text{ with } \bar{y}_i = 0, \\ & y'_i = 0 \text{ for } i \in I_3, \\ & \langle \nabla g_i(\bar{x}, \bar{w}), (x', w') \rangle + \Big[v'_2 \Big]_i \leq 0 \text{ for } i \in I_2 \text{ with } y'_i = 0, \\ & \langle \nabla g_i(\bar{x}, \bar{w}), (x', w') \rangle + \Big[v'_2 \Big]_i = 0 \text{ for } i \in I_2 \text{ with } y'_i > 0, \\ & \langle \nabla g_i(\bar{x}, \bar{w}), (x', w') \rangle + \Big[v'_2 \Big]_i = 0 \text{ for } i \in I_1. \end{aligned} \tag{2.34}$$

Moreover, the image set at $w' \in \mathbb{R}^d$ *of the outer graphical derivative at* $\bar{w}$ *for* $(\bar{x}, \bar{y})$ *of the KKT pair multifunction* $w \mapsto KKT(0, w)$ *associated with the nonlinear program* (1.3) *without canonical perturbations is contained in the set of pairs* $(x', y') \in \mathbb{R}^{n+m}$ *that satisfy the same six conditions* (2.34) *but with* $v'_1 = 0$ *and* $v'_2 = 0$.

Proof. According to the preceding discussion, the protodifferentiability of the KKT pair mapping follows from Proposition 2.4.1, as do the formulas for the outer graphical derivatives once we develop a formula for the outer graphical derivative of the inverse of the normal cone multifunction N_K. Since the outer graphical derivative of any multifunction S is defined in terms of the graph of S, the outer graphical derivative of the inverse multifunction S^{-1} is just the inverse of the outer graphical

derivative of S. It follows from the formula (2.31) for the outer graphical derivative of N_K then that the outer graphical derivative of $\big(N_k\big)^{-1}$ at $\bar{y}$ for $G(\bar{x},\bar{w})$ is empty-valued at $y' \in \mathbb{R}^m$ unless y' satisfies $y'_i \geq 0$ for $i \in [1,s]$ with $\bar{y}_i = 0$ and $y'_i = 0$ for $i \in I_3$, in which case the image set of the outer graphical derivative is equal to

$$\left\{ z' \in \mathbb{R}^m \;\middle|\; \begin{array}{ll} z'_i \leq 0 & \text{for } i \in I_2 \text{ with } y'_i = 0 \\ z'_i = 0 & \text{for } i \in I_2 \text{ with } y'_i > 0 \\ z'_i = 0 & \text{for } i \in I_1 \end{array} \right\}. \tag{2.35}$$

The formula claimed then follows from Proposition 2.4.1 after substituting $z' = v' + \nabla G(\bar{x},\bar{w}) \cdot (x', w')$. □

Example program revisited. We consider again the example program from section 2.3, but this time with canonical perturbations included.

$$\min\{(x_1)^2 - x_1 + (x_2)^2 - [v_1]_1 x_1 - [v_1]_2 x_2\} \text{ over all } x \in C(w, v_2),$$

where the constraint set is defined as follows:

$$C(w, v_2) := \{x \in \mathbb{R}^2 : x_1 - x_2^2 + w^2 + [v_2]_1 \leq 0 \text{ and } x_1 - w^2 + [v_2]_2 \leq 0\}.$$

The functions g_0, g_1, and g_2 and the Lagrangian are the same as in section 2.3, and we use the same base points $\bar{x} = (0,0)$ and $\bar{w} = 0$. There are a variety of $\bar{y}$ which can be paired with $\bar{x}$ to form a KKT pair in this case; namely, any $\bar{y} \in \mathbb{R}^2_+$ satisfying $\bar{y}_1 + \bar{y}_2 = 1$. The matrix $\nabla^2_{x(x,y,w)} L(\bar{x},\bar{y},\bar{x})$ is given by

$$\begin{bmatrix} 2 & 0 & 1 & 1 & 0 \\ 0 & 2(1-\bar{y}_1) & 0 & 0 & 0 \end{bmatrix}$$

and the index set I_3 is always empty for our choice of $(\bar{x},\bar{w})$. If we choose $\bar{y} = (1,0)$, the other index sets satisfy $I_1 = \{1\}$ and $I_2 = \{2\}$, and the six conditions in Proposition 2.5.1 become

$$\begin{aligned} &[v'_1]_1 = 2x'_1 + y'_1 + y'_2, \\ &[v'_1]_2 = 0, \\ &y'_2 \geq 0, \\ &x'_1 + [v'_2]_2 \leq 0 \text{ if } y'_2 = 0, \\ &x'_1 + [v'_2]_2 = 0 \text{ if } y'_2 > 0, \\ &x'_1 + [v'_2]_1 = 0. \end{aligned}$$

Thus Proposition 2.5.1 says that the outer graphical derivative

$$D\big(KKT\big)(0,\bar{w}|\bar{x},\bar{y})(v'_1, v'_2, w')$$

for $\bar{y} = (1,0)$ is empty unless $[v'_1]_2 = 0$ and $[v'_2]_2 \leq [v'_2]_1$, in which case it equals the set

$$\big\{(x', y') \in \mathbb{R}^2 \times \mathbb{R}^2 \,|\quad x'_1 = -[v'_2]_1, \quad y' = ([v'_1]_1 + 2[v'_2]_1, 0)\big\}$$

if $[v'_2]_2 < [v'_2]_1$, but instead equals the set

$$\big\{(x', y') \in \mathbb{R}^2 \times \mathbb{R}^2 \,|\quad x'_1 = -[v'_2]_1, \quad y'_2 \geq 0, \quad y'_1 = [v'_1]_1 + 2[v'_2]_1 - y'_2\big\}$$

in the case that $[v_2']_2 = [v_2']_1$.

If we consider instead the multiplier $\bar{y} = (0, 1)$, the index sets satisfy $I_1 = \{2\}$ and $I_2 = \{1\}$, and the same set of conditions work out as

$$\begin{aligned}
&[v_1']_1 = 2x_1' + y_1' + y_2',\\
&[v_1']_2 = 2x_2',\\
&y_1' \geq 0,\\
&x_1' + [v_2']_1 \leq 0 \text{ if } y_1' = 0,\\
&x_1' + [v_2']_1 = 0 \text{ if } y_1' > 0,\\
&x_1' + [v_2']_2 = 0.
\end{aligned}$$

Thus Proposition 2.5.1 says that the outer graphical derivative

$$D\big(KKT\big)(0, \bar{w}|\bar{x}, \bar{y})(v_1', v_2', w')$$

for $\bar{y} = (0, 1)$ equals the set

$$\left\{(x', y') \in \mathbb{R}^2 \times \mathbb{R}^2 \,|\quad x' = (-[v_2']_2, [v_1']_2/2)\,,\quad y' = (0, [v_1']_1 + 2[v_2']_2)\right\}$$

if $[v_2']_1 < [v_2']_2$ but instead equals the set

$$\left\{(x', y') \in \mathbb{R}^2 \times \mathbb{R}^2 \,|\quad x' = (-[v_2']_2, [v_1']_2/2)\,,\quad y_1' \geq 0,\quad y_2' = [v_1']_1 + 2[v_2']_2 - y_1'\right\}$$

in the case that $[v_2']_1 = [v_2']_2$ and is empty if $[v_2']_1 > [v_2']_2$.

For any other choice of multiplier $\bar{y}$, the index set I_2 is empty and $I_1 = \{1, 2\}$, so the conditions work out as

$$\begin{aligned}
&[v_1']_1 = 2x_1' + y_1' + y_2',\\
&[v_1']_2 = 2(1 - \bar{y}_1)x_2',\\
&x_1' + [v_2']_1 = 0,\\
&x_1' + [v_2']_2 = 0.
\end{aligned}$$

Thus Proposition 2.5.1 says that the outer graphical derivative

$$D\big(KKT\big)(0, \bar{w}|\bar{x}, \bar{y})(v_1', v_2', w')$$

in this case is empty unless $[v_2']_1 = [v_2']_2$, in which case it equals the set

$$\left\{(x', y') \in \mathbb{R}^2 \times \mathbb{R}^2 \,|\quad x' = (-[v_2']_1, [v_1']_2/\left(2(1 - \bar{y}_1)\right))\,,\ y_1' = [v_1']_1 + 2[v_2']_1 - y_2',\ y_2' \in \mathbb{R}\right\}.$$

The result in Proposition 2.5.1 for the case without the canonical perturbations is simpler for this example, and implies that the outer graphical derivative at $\bar{w}$ for $(\bar{x}, \bar{y})$ of the KKT pair multifunction $w \mapsto KKT(0, w)$ for the different possible choices of $\bar{y}$ is contained in the sets

$$\begin{aligned}
&\{(x', y') \in \mathbb{R}^2 \times \mathbb{R}^2 \,|\quad x_1' = 0,\quad y_1' \leq 0,\quad y_2' = -y_1'\} \text{ when } \bar{y} = (1, 0),\\
&\{(x', y') \in \mathbb{R}^2 \times \mathbb{R}^2 \,|\quad x_1' = 0,\quad x_2' = 0,\quad y_1' \geq 0,\quad y_2' = -y_1'\} \text{ when } \bar{y} = (0, 1),\\
&\{(x', y') \in \mathbb{R}^2 \times \mathbb{R}^2 \,|\quad x_1' = 0,\quad x_2' = 0,\quad y_1' \in \mathbb{R},\quad y_2' = -y_1'\} \text{ for other } \bar{y}.
\end{aligned}$$

Notice again that the derivative formulas for this example were computed without first computing the KKT pairs, so sensitivity information is available without the KKT pairs themselves.

Finally, we apply Proposition 2.4.2 to the canonically perturbed nonlinear program (2.30) to get the following sufficient conditions for B-differentiability of KKT pairs associated with the nonlinear program without the canonical perturbations.

PROPOSITION 2.5.2. *Under the Mangasarian–Fromovitz constraint qualification* (2.17)*, if either the KKT pair multifunction* (2.33) *is Lipschitz continuous near* $(0, \bar{w})$ *or it is (single-valued) continuous near* $(0, \bar{w})$ *and its outer graphical derivative* $D\big(KKT\big)(0, \bar{w}|\bar{x}, \bar{y})$ *is single-valued, then the KKT pair multifunction is B-differentiable at* $(0, \bar{w})$.

Moreover, the KKT pair multifunction $w \mapsto KKT(0, w)$ *associated with the nonlinear program* (1.3) *is B-differentiable at* $\bar{w}$ *with B-derivative evaluated at* $w' \in \mathbb{R}^d$ *equal to the unique pair* $(x', y') \in \mathbb{R}^{n+m}$ *satisfying the six conditions* (2.34) *with* $v_1' = v_2' = 0$.

3. Continuity. The continuity property on which we focus is a slightly restricted form of local Lipschitz continuity called "calmness." A function $x(w)$ on $\mathbb{R}^d$ is *calm at* $\bar{w}$ if there is a constant $L > 0$ such that for all w near $\bar{w}$, the function satisfies $|x(w) - x(\bar{w})| \leq L|w - \bar{w}|$. Notice that this is the same as the usual local Lipschitz continuity except that the base point $\bar{w}$ is always one of the points of comparison. A multifunction $S : \mathbb{R}^d \rightrightarrows \mathbb{R}^n$ is said to have *calm selections near* $(\bar{w}, \bar{x})$ if there exist neighborhoods $W \subseteq \mathbb{R}^d$ of $\bar{w}$ and $X \subseteq \mathbb{R}^n$ of $\bar{x}$ together with a constant $L > 0$ such that any local selection $x(w) \in S(w) \cap X$ for $w \in W$ satisfies

$$|x(w) - \bar{x}| \leq L|w - \bar{w}|. \tag{3.1}$$

Calmness is an important property to study when analyzing solutions to parameterized optimization problems since it gives a Lipschitz bound on the distance between perturbed and unperturbed solutions. The term "calmness" was used by Clarke [6] to describe an optimization problem whose optimal value function obeyed a Lipschitz bound with a fixed base point as in (3.1), and our use of this terminology was inspired by the earlier notion. Note also that property we are calling local selection calmness has been widely studied under various labels. In [23] it was called "local upper Lipschitz continuity," in [7] it was called "upper Lipschitz continuity at a point," and in [4] it was called "semistability" in the context of variational inequalities. Finally, in [40], [39], and [12] the term "stability" was used to indicate when certain multifunctions associated with nonlinear equations satisfied condition (ii) and at the same time had nonempty local image sets $S(w) \cap X$.

The results in this section are based on the following generalization of the classical inverse mapping theorem that gives a characterization of the calmness of selections in terms of the outer graphical derivative.

THEOREM 3.1 (see Proposition 4.1 of [23]). *For any multifunction* $S : \mathbb{R}^d \rightrightarrows \mathbb{R}^n$ *and any pair* $(\bar{w}, \bar{x}) \in \operatorname{gph} S$*, the following are equivalent:*

(i) *The outer graphical derivative image set* $DS(\bar{w}|\bar{x})(0)$ *equals the trivial set* $\{0\}$.

(ii) S *has calm selections near* $(\bar{w}, \bar{x})$.

Remark. Note that the implication (i) $\Rightarrow$ (ii) was shown first in [13, Proposition 2.1]. Theorem 3.1 has the advantage over the classical inverse mapping theorem that the outer graphical derivative exists for all multifunctions. This means that we can rule in or out useful Lipschitz bounds in practically any situation we might encounter simply by computing the outer graphical derivative in the nonsingularity condition (i) above. This is very important in terms of sensitivity analysis of quasi-solutions to optimization problems, since verifying calmness directly demands that quasi-solutions are reliably known (which is not typical if the problems are sensitive),

whereas the nonsingularity condition (i) demands only that we be able to compute a generalized derivative (which we can do as in the preceding chapter). Moreover, since the nonsingularity condition (i) characterizes the local selection calmness property (ii), any other sufficient condition for local selection calmness must essentially also involve the nonsingularity condition (i), so it makes sense to focus our attention on (i).

Example program revisited. In section 2.3, we computed outer graphical derivative estimates for stationary point mappings associated with both tilted and untilted versions of a parameterized nonlinear program. We can use these estimates to apply Theorem 3.1 to deduce whether those stationary point mappings have calm selections. From the formulas worked out in section 2.3, it is clear that the outer graphical derivative of the tilted stationary point mapping $D\left(SP_{tilt}\right)(0,\bar{w}|\bar{x})(0,0,0)$ equals the trivial set $\{0\}\times\{0\}$, so Theorem 3.1 guarantees calm selections near $(0,\bar{w},\bar{x})$. Likewise, the estimate for the outer graphical derivative of the untilted stationary point mapping ensures that $D\left(SP\right)(\bar{w}|\bar{x})(0)$ is contained in the trivial set $\{0\}\times\{0\}$, and since the trivial set is included in the image of any outer graphical derivative evaluated at 0, we can again apply Theorem 3.1 to deduce that the untilted stationary point mapping has calm selections near $(\bar{w},\bar{x})$. Of course, the untilted stationary point mapping is a restriction of the tilted stationary point mapping, so calm selections for the former are expected in the presence of calm selections for the latter.

In general, it is not necessary to compute the full outer graphical derivative mapping in order to decide whether a certain mapping has calm selections, since only the image at 0 is required by Theorem 3.1. In the following sections, we use the general formulas for outer graphical derivatives computed in the previous sections to translate Theorem 3.1 in some cases of particularly important mappings S. As in the previous chapter then, we use a fundamental general result (in this case Theorem 3.1) as the starting point for progressively more specific results. Along the way, layers of complication are added and restrictions are made as we pass from the general Theorem 3.1 to the language of the particular applications.

3.1. Continuity of stationary points. According to the estimate (2.5) for the outer graphical derivative of the stationary point mapping, the following sufficient condition for the local selection calmness property is immediate from Theorem 3.1.

PROPOSITION 3.1.1. *For the stationary point multifunction* SP (2.4) *and any pair* $(\bar{x},\bar{w})\in\mathbb{R}^{n+d}$ *with* $0\in\partial_x f(\bar{x},\bar{w})$*, if* $x'=0$ *is the only vector in* $\mathbb{R}^n$ *satisfying*

$$0\in D\big(\partial_x f\big)(\bar{x},\bar{w}|0)(x',0),$$

then SP *has calm selections near* $(\bar{w},\bar{x})$*.*

The gap between the sufficient condition in Proposition 3.1.1 and the local selection calmness property for the stationary point mapping SP is evident from the following proposition characterizing this same property for SP_{tilt} (2.7).

PROPOSITION 3.1.2. *For the stationary point multifunction* SP_{tilt} (2.7) *and any pair* $(\bar{x},\bar{w})\in\mathbb{R}^{n+d}$ *with* $0\in\partial_x f(\bar{x},\bar{w})$*, the following are equivalent:*

(i) $x'=0$ *is the only vector in* $\mathbb{R}^n$ *satisfying* $0\in D\big(\partial_x f\big)(\bar{x},\bar{w}|0)(x',0)$.

(ii) SP_{tilt} *has calm selections near* $(0,\bar{w},\bar{x})$*.*

Proof. This follows directly from Theorem 3.1 and the remark following Theorem 2.1. □

Remark. According to Proposition 3.1.2, the sufficient condition in Proposition 3.1.1 for local selection calmness for the stationary point mapping SP is equivalent to the local selection calmness of the tilted stationary point mapping SP_{tilt}. Thus

the gap between the sufficient condition (i) and the local selection calmness property for SP is filled precisely by the stationary point mappings SP that have calm local selections even though SP_{tilt} does not. An easy example that belongs in this category involves the unconstrained minimization of the smooth function $f(x,w) = x^4/4$. The lone stationary point for this function (for all parameters w) is $x = 0$, but as we saw in the introduction, the stationary point for the tilted minimization $\min\{x^4/4 - v\cdot x\}$ is $x = v^{1/3}$. In this case, the stationary point multifunction $SP(w) = 0$ is trivially calm at 0 while the mapping $SP_{tilt}(v,w) = v^{1/3}$ is not. Notice that the outer graphical derivative in this case satisfies $D\big(\partial_x f\big)(0,\bar{w}|0) = \nabla^2_{x(x,w)} f(0) = (0,0)$, so condition (i) above is certainly not satisfied.

3.2. Continuity of stationary points for nonlinear programs. In the case of the nonlinear program (1.3), the results in the preceding section can be translated into more familiar terms using the formulas for the outer graphical derivative of $\partial_x f$ from Proposition 2.3.1.

PROPOSITION 3.2.1 (see Theorem 5.1 of [24]). *For the nonlinear program* (1.3) *and its associated stationary point multifunction SP* (2.18)*, if the Mangasarian–Fromovitz constraint qualification* (2.17) *holds at* $(\bar{x},\bar{w})$ *with* $\bar{x} \in SP(\bar{w})$*, then SP has calm selections near* $(\bar{w},\bar{x})$ *if the condition holds that*

(i) $x' = 0$ *is the only vector satisfying* $(x',0) \in Q(\bar{x},\bar{w})$ (2.10)*,* $\nabla_x g_0(\bar{x},\bar{w})\cdot x' = 0$*, and*

$$0 = \nabla^2_{xx} L(\bar{x},\bar{y},\bar{w})\cdot x' + \sum_{i=1}^{m} y_i' \nabla_x g_i(\bar{x},\bar{w}) + y_0' \nabla_x g_0(\bar{x},\bar{w}) \tag{3.2}$$

for some $y' \in Y'(\bar{x},\bar{w};x',0)$ (2.16) *and* $y_0' \in \mathbb{R}$ *along with a vector* $\bar{y}$ *for which there exists* $\bar{u} \in \mathbb{R}^d$ *such that* $\bar{y} \in Y_{\max}(\bar{x},\bar{w},0,\bar{u};x',0)$ (2.15)*.*

Moreover, condition (i) *is equivalent to the stationary point multifunction* SP_{tilt} (2.19) *having calm selections near* $(0,\bar{w},\bar{x})$*.*

Remark. Notice that condition (i) is equivalent to $x' = 0$ being the only vector in $\mathbb{R}^n$ that is a stationary point (i.e., satisfies the KKT conditions) for any of the auxiliary problems with constraint system $(x',0) \in Q(\bar{x},\bar{w})$ with $\nabla_x g_0(\bar{x},\bar{w})\cdot x' = 0$ and with objective functions $x' \mapsto \langle x', \nabla^2_{xx} L(\bar{x},\bar{y},\bar{w})\cdot x'\rangle$, where $\bar{y}$ is any vector in the set $Y_{\max}(\bar{x},\bar{w},0,\bar{u};x',0)$ defined by any $\bar{u} \in \mathbb{R}^d$.

In the special case where the canonical constraint perturbation $w_2 \in \mathbb{R}^m$ is present $g_i(x,w_1) + [w_2]_i$, any Lagrange multiplier $\bar{y}$ (so $\bar{y} \in N_K\big(G(x,w)\big)$ with $\nabla_x L(x,y,w) = 0$) can be realized as an element of $Y_{\max}(\bar{x},\bar{w},0,\bar{u};x',0)$ for some $\bar{u} \in \mathbb{R}^d$, so the condition in Proposition 3.2.1 is equivalent to $x' = 0$ being the only vector in $\mathbb{R}^n$ that is a stationary point for any of the auxiliary problems with constraint system $(x',0) \in Q(\bar{x},\bar{w})$ with $\nabla_x g_0(\bar{x},\bar{w})\cdot x' = 0$ and with objective functions $x' \mapsto \langle x', \nabla^2_{xx} L(\bar{x},\bar{y},\bar{w})\cdot x'\rangle$ where $\bar{y}$ is any Lagrange multiplier. A flawed version of this result was stated in [10, Theorem 3.1] and a correct version was subsequently proved in [15] where the authors translated Theorem 3.1 for "generalized Kojima-functions" whose zeroes can be identified, for instance, with the stationary points of the nonlinear program (1.3).

If we take the product of x' with each side of (3.2), we can derive an even more familiar form of sufficient condition.

PROPOSITION 3.2.2 (see Corollary 5.2 of [24]). *Condition* (i) *from Proposition* 3.2.1 *holds if the condition*

$$\max_{y \in Y(\bar{x},\bar{w},0,\bar{u})} \langle x', \nabla^2_{xx} L(\bar{x},y,\bar{w})\cdot x'\rangle > 0$$

holds for all $\bar{u} \in \mathbb{R}^d$ *such that* $Y(\bar{x}, \bar{w}, 0, \bar{u}) \neq \emptyset$ (2.14) *and all nonzero* x' *satisfying* $(x', 0) \in Q(\bar{x}, \bar{w})$ (2.10) *and* $\nabla_x g_0(\bar{x}, \bar{w}) \cdot x' = 0$.

Remark. Notice that there is a larger gap between the condition in Proposition 3.2.2 and the local selection calmness property for SP than the one associated with condition (i) of Proposition 3.2.1. In particular, the condition in Proposition 3.2.2 demands the positive-definiteness of $\nabla_{xx} L(\bar{x}, y, \bar{w})$ while condition (i) also holds if $\nabla_{xx} L(\bar{x}, y, \bar{w})$ is negative-definite. Assuming a positive-definite $\nabla_{xx} L(\bar{x}, y, \bar{w})$ of course also addresses the issue of the stationary points being optimal solutions to the original minimization problem, which is one reason why conditions like the one in Proposition 3.2.2 are more typical in the literature. However, our approach yields a condition (i) that is closer to characterizing the desired property of local selection calmness, and so our approach more closely captures the essence of the stability property in which we are interested.

Example program revisited. At the beginning of section 3, we showed that the nonlinear program first introduced in section 2.3 has calm local selections from its stationary point mappings. We will show now that this example program, moreover, satisfies the conditions of Proposition 3.2.2 for the base point $\bar{x} = (0, 0)$ and the base parameter $\bar{w} = 0$. In this case, the Hessian matrix $\nabla_{xx} L(\bar{x}, y, \bar{w})$ is just

$$\begin{bmatrix} 2 & 0 \\ 0 & 2(1 - y_1) \end{bmatrix}$$

and the set $Y(\bar{x}, \bar{w}, 0, \bar{u})$ is only nonempty when $\bar{u} = 0$, in which case it equals the set of $y \in \mathbb{R}^2_+$ with $y_1 + y_2 = 1$. The cone $Q(\bar{x}, \bar{w})$ is just $\mathbb{R}_- \times \mathbb{R}^2$ and the condition $\nabla_x g_0(\bar{x}, \bar{w}) \cdot x' = 0$ is satisfied only by $x' = (x'_1, x'_2)$ with $x'_1 = 0$. It follows that the inner product in Proposition 3.2.2 reduces to $2(1 - y_1)(x'_2)^2$ which is maximized over $Y(\bar{x}, \bar{w}, 0, \bar{u})$ when $y_1 = 0$, with maximum value $2(x'_2)^2$. This maximum value is clearly nonzero as long as x'_2 is nonzero, so the condition in Proposition 3.2.2 is satisfied.

It is interesting to note that the Hessian of the Lagrangian for this example is not positive definite for all multipliers in $Y(\bar{x}, \bar{w}, 0, \bar{u})$ (when $y = (1, 0)$ the Hessian matrix is only positive semidefinite), so this program does not satisfy many of the standard second-order sufficient conditions for stability available prior to Proposition 3.2.2.

3.3. Continuity of KKT pairs. We return to the optimization model with canonical perturbations $v = (v_1, v_2)$

$$\min\{g_0(x, w) + g\big(G(x, w) + v_2\big) - \langle v_1, x\rangle\} \text{ over } x \in \mathbb{R}^n$$

from section 2.4, but now with an eye toward studying the continuity of its KKT pairs. As in the preceding two sections, Theorem 3.1 is the basis for the results here.

PROPOSITION 3.3.1. *If the mapping* $\nabla_x L$ *is B-differentiable at* $(\bar{x}, \bar{y}, \bar{w})$ *and the subgradient multifunction* ∂g *is protodifferentiable at* $G(\bar{x}, \bar{w})$ *for* $\bar{y} \in \partial g\big(G(\bar{x}, \bar{w})\big)$, *then for the KKT pair multifunction* (2.24), *the following are equivalent:*

(i) *The pair* $(x', y') = (0, 0)$ *is the only solution to the conditions*

$$0 = D\left(\nabla_x L\right)(\bar{x}, \bar{y}, \bar{w} | \nabla_x L(\bar{x}, \bar{y}, \bar{w}))(x') + \sum_{i=1}^{m} y'_i \nabla_x g_i(\bar{x}, \bar{w})$$

$$\nabla_x G(\bar{x}, \bar{w}) \cdot x' \in D\left(\left(\partial g\right)^{-1}\right)\left(\bar{y} | G(\bar{x}, \bar{w})\right)(y'). \tag{3.3}$$

(ii) *KKT has calm selections near* $(0, \bar{w}, \bar{x}, \bar{y})$.

Proof. This follows directly from Theorem 3.1 and Proposition 2.4.1. ∎

3.4. Continuity of KKT pairs for nonlinear programs. For nonlinear programs with canonical perturbations (2.30), the results of section 3.3 can be translated into even more specific terms. Again we use the index sets (2.32).

PROPOSITION 3.4.1. *For the canonically perturbed nonlinear program* (2.30) *and its associated KKT pair multifunction* (2.33)*, if the Mangasarian–Fromovitz constraint qualification* (2.17) *holds at* $(\bar{x}, \bar{w})$ *with* $(\bar{x}, \bar{y}) \in KKT(0, \bar{w})$*, then the following are equivalent:*

(i) *The pair* $(x', y') = (0, 0)$ *is the only solution to the conditions*

$$\begin{aligned}
&0 = \nabla^2_{xx} L(\bar{x}, \bar{y}, \bar{w}) \cdot x' + \sum_{i=1}^{m} y'_i \nabla_x g_i(\bar{x}, \bar{w}),\\
&y'_i \geq 0 \text{ for } i \in [1, s] \text{ with } \bar{y}_i = 0,\\
&y'_i = 0 \text{ for } i \in I_3,\\
&\langle \nabla_x g_i(\bar{x}, \bar{w}), x' \rangle \leq 0 \text{ for } i \in I_2 \text{ with } y'_i = 0,\\
&\langle \nabla_x g_i(\bar{x}, \bar{w}), x' \rangle = 0 \text{ for } i \in I_2 \text{ with } y'_i > 0,\\
&\langle \nabla_x g_i(\bar{x}, \bar{w}), x' \rangle = 0 \text{ for } i \in I_1.
\end{aligned}$$

(ii) KKT *has calm selections near* $(0, \bar{w}, \bar{x}, \bar{y})$.

Proof. This follows directly from Proposition 3.3.1 and the formula (2.35) for the outer graphical derivative of the inverse of N_K. □

The continuity property (ii) characterized in Proposition 3.4.1 is of course stronger than the property (ii) characterized in Proposition 3.2.1, since condition (ii) here stipulates joint calmness with respect to both stationary points and multipliers, whereas (ii) of Proposition 3.2.1 deals exclusively with stationary points. However, it is not as obvious that condition (i) of Proposition 3.2.1 is implied by (i) of Proposition 3.4.1 (which it must be if these characterizations are consistent), so we briefly show this fact here.

Proof of Proposition 3.4.1 (i) ⇒ *Proposition* 3.2.1 (i). Suppose x' satisfies $(x', 0) \in Q(\bar{x}, \bar{w}), \nabla_x g_0(\bar{x}, \bar{w}) \cdot x' = 0$, and

$$0 = \nabla^2_{xx} L(\bar{x}, \bar{y}, \bar{w}) \cdot x' + \sum_{i=1}^{m} y'_i \nabla_x g_i(\bar{x}, \bar{w}) + y'_0 \nabla_x g_0(\bar{x}, \bar{w})$$

as in Proposition 3.2.1 (i) for some $y' \in Y'(\bar{x}, \bar{w}; x', 0)$ and $y'_0 \in \mathbb{R}$ along with a vector $\bar{y}$ for which there exists $\bar{u}$ such that $\bar{y} \in Y_{\max}(\bar{x}, \bar{w}, 0, \bar{u}; x', 0)$. According to Proposition 3.4.1, under (i) (which is equivalent to (ii)) there is only one multiplier $\bar{y}$ such that $(\bar{x}, \bar{y}) \in KKT(0, \bar{w})$, so this is the only vector for which there exists $\bar{u}$ such that $\bar{y} \in Y_{\max}(\bar{x}, \bar{w}, 0, \bar{u}; x', 0)$. The conditions from Proposition 3.2.1 (i) then become

$$\begin{aligned}
&\langle \nabla_x g_i(\bar{x}, \bar{w}), x' \rangle \leq 0 \text{ for } i \in I_1 \cup I_2,\\
&\langle \nabla_x g_i(\bar{x}, \bar{w}), x' \rangle = 0 \text{ for } i \in [s+1, m] \cup \{0\},\\
&0 = \nabla^2_{xx} L(\bar{x}, \bar{y}, \bar{w}) \cdot x' + \sum_{i=1}^{m} y'_i \nabla_x g_i(\bar{x}, \bar{w}) + y'_0 \nabla_x g_0(\bar{x}, \bar{w})
\end{aligned}$$

for some $y'_0 \in \mathbb{R}$ and some $y' \in N_K\big(G(\bar{x}, \bar{w})\big)$ satisfying $y'_i \nabla_x g_i(\bar{x}, \bar{w}) \cdot x' = 0$ for $i \in [1, m]$. If we define $\tilde{y}' := y' - y_{0'} \bar{y}$ and use the fact that

$$0 = \nabla_x g_0(\bar{x}, \bar{w}) + \sum_{i=1}^{m} \bar{y}_i \nabla_x g_i(\bar{x}, \bar{w}),$$

we conclude that $\tilde{y}'$ satisfies

$$0 = \nabla^2_{xx} L(\bar{x}, \bar{y}, \bar{w}) \cdot x' + \sum_{i=1}^{m} \tilde{y}'_i \nabla_x g_i(\bar{x}, \bar{w}). \tag{3.4}$$

Since both $\bar{y}$ and y' are in the set $N_K\big(G(\bar{x}, \bar{w})\big)$, we know that $\tilde{y}'$ also satisfies

$$\tilde{y}'_i = 0 \text{ for } i \in I_3. \tag{3.5}$$

Finally, since $\tilde{y}'_i = y'_i$ if $\bar{y}_i = 0$, we also know that $\tilde{y}'$ satisfies

$$\tilde{y}'_i \geq 0 \text{ for } i \in [1, s] \text{ with } \bar{y}_i = 0 \tag{3.6}$$

and

$$\langle \nabla_x g_i(\bar{x}, \bar{w}), x' \rangle = 0 \text{ for } i \in I_2 \text{ with } \tilde{y}'_i > 0. \tag{3.7}$$

The conditions (3.4)–(3.7) show that the pair $(x', \tilde{y}')$ satisfies the system in condition (i) of Proposition 3.4.1. It follows from this condition that x' must equal zero, so condition (i) of Proposition 3.2.1 is verified. □

It follows directly from Proposition 3.4.1 that its condition (i) is sufficient to ensure the local selection calmness property for the KKT pairs associated with the nonlinear program (1.3) without the canonical perturbations.

PROPOSITION 3.4.2. *For the KKT pair multifunction* (2.33)*, if the Mangasarian–Fromovitz constraint qualification* (2.17) *holds at* $(\bar{x}, \bar{w})$ *with* $(\bar{x}, \bar{y}) \in KKT(0, \bar{w})$*, then either of the equivalent conditions in Proposition* 3.4.1 *is enough to ensure the existence of neighborhoods* $X \times Y \subseteq \mathbb{R}^{n+m}$ *of* $(\bar{x}, \bar{y})$ *and* $W \subseteq \mathbb{R}^d$ *of* $\bar{w}$ *as well as a constant* $L > 0$ *such that any local selection* $\big(x(w), y(w)\big) \in KKT(0, w) \cap \big(X \times Y\big)$ *of KKT pairs for the nonlinear program* (1.3) *for* $w \in W$ *satisfies the estimate*

$$|\big(x(w), y(w)\big) - (\bar{x}, \bar{y})| \leq L|w - \bar{w}|.$$

Example program revisited. In section 2.5, we added canonical perturbations to our example program and computed the outer graphical derivatives of the associated KKT pair multifunction at the different possible multipliers associated with $\bar{x} = (0, 0)$. The conditions in Proposition 3.4.1 are of course just the result of evaluating these outer graphical derivatives at zero, so they too work out differently for the different possible multipliers $\bar{y}$: When $\bar{y} = (1, 0)$, the conditions in Proposition 3.4.1 are satisfied by any element of the set

$$\left\{(x', y') \in \mathbb{R}^2 \times \mathbb{R}^2 | \quad x'_1 = 0, \quad y'_2 \geq 0, \quad y'_1 = -y'_2\right\},$$

but when $\bar{y} = (0, 1)$, the conditions in Proposition 3.4.1 are satisfied by any element of the set

$$\left\{(x', y') \in \mathbb{R}^2 \times \mathbb{R}^2 | \quad x' = (0, 0), \quad y'_1 \geq 0, \quad y'_2 = -y'_1\right\},$$

and when $\bar{y}$ is any other multiplier, the conditions in Proposition 3.4.1 are satisfied by any element of the set

$$\left\{(x', y') \in \mathbb{R}^2 \times \mathbb{R}^2 | \quad x' = (0, 0), \quad y'_1 = -y'_2\right\}.$$

Since none of these sets is trivial, it follows from Proposition 3.4.1 that the KKT pair multifunction does not have calm selections near $(0, \bar{w}, \bar{x}, \bar{y})$ at any of the possible KKT pairs $(\bar{x}, \bar{y})$ associated with the base point $\bar{x} = (0, 0)$ and the base parameter $\bar{w} = 0$. Notice that we cannot deduce anything from Proposition 3.4.2 about the calmness of selections from the KKT pair multifunction $w \mapsto KKT(0, w)$ for the program without the canonical perturbations, since we know only that a sufficient condition for this property is violated.

It is interesting to note that this example program did have calm selections from its associated stationary point mappings where multipliers were not involved directly, so this example highlights the gap between Propositions 3.2.1 and 3.4.1.

4. Existence and uniqueness. In contrast to our experience with continuity and differentiability properties, it has proven to be more difficult to characterize the properties of existence and uniqueness in terms of simple, verifiable conditions on generalized derivatives. In the introduction, we already discussed why it is not possible to use derivatives to characterize existence and uniqueness properties without involving stability properties at the same time. To discuss such combinations of properties, we introduce some additional generalized derivative concepts. One of these is the coderivative developed by Mordukhovich [31]. For a multifunction $S : \mathbb{R}^d \rightrightarrows \mathbb{R}^n$, the *coderivative of S at $\bar{w}$ for an element $\bar{x} \in S(\bar{w})$* is the multifunction $D^*S(\bar{w}|\bar{x}) : \mathbb{R}^n \rightrightarrows \mathbb{R}^d$ whose graph is obtained by the following transformation of the set $N_{\operatorname{gph} S}(\bar{w}, \bar{x})$ of normals to $\operatorname{gph} S := \{(w, x) : x \in S(w)\}$ at $(\bar{w}, \bar{x})$ (this normal cone $N_{\operatorname{gph} S}(\bar{w}, \bar{x})$ is equal to the subgradient of the indicator function $\delta_{\operatorname{gph} S}$ associated with the set $\operatorname{gph} S$; see [31] or [52]):

$$w' \in D^*S(\bar{w}|\bar{x})(x') \Leftrightarrow (w', -x') \in N_{\operatorname{gph} S}(\bar{w}, \bar{x}).$$

In the case of a single-valued mapping $x : \mathbb{R}^d \to \mathbb{R}^n$ that is $\mathcal{C}^1$ near $\bar{w}$, the coderivative coincides with the adjoint of the Jacobian $\nabla x(\bar{w})^*$. A calculus for the coderivative was developed by Mordukhovich in [37], and, moreover, the coderivative can be used to characterize a generalized Lipschitz property for multifunctions whose graphs are locally closed sets near a base point. A set K is *locally closed at c* if $K \cap C$ is closed for some closed neighborhood C of c (see [52]).

THEOREM 4.1 (see Theorem 5.4 of [32]).[1] *For any multifunction $S : \mathbb{R}^d \rightrightarrows \mathbb{R}^n$ and any pair $(\bar{w}, \bar{x})$ satisfying $\bar{x} \in S(\bar{w})$, if the set $\operatorname{gph} S$ is locally closed at $(\bar{w}, \bar{x})$, then the following are equivalent:*

(i) *The coderivative image set $D^*S(\bar{w}|\bar{x})(0)$ equals the trivial set $\{0\}$.*

(ii) *There exist neighborhoods $X \subseteq \mathbb{R}^n$ of $\bar{x}$ and $W \subseteq \mathbb{R}^d$ of $\bar{w}$ together with a constant $L > 0$ such that*

$$S(w) \cap X \subseteq S(w') + L|w - w'|\mathbb{B} \text{ for all } w, w' \in W, \tag{4.1}$$

where $\mathbb{B}$ denotes the unit ball in $\mathbb{R}^n$.

Remark. The continuity property in condition (ii) was originally called "pseudo Lipschitz continuity" in [1], and has also been referred to as the "Aubin property" [52] and "Aubin continuity" [21]. In [2], a sufficient condition for condition (ii) was given in terms of outer graphical derivatives, and Theorem 4.1 can be viewed as a kind of dual version of this result. Note that the existence of a local selection

[1] The first complete proof of this result appeared in [33], where there is also a thorough discussion of equivalent criteria and particular special cases.

$x(w) \in S(w)$ for $w \in W$ is guaranteed under this condition, and that in the case when S is actually a single-valued mapping $x : \mathbb{R}^d \to \mathbb{R}^n$, condition (ii) is the same as local Lipschitz continuity. The continuity property (ii) has been much studied for general multifunctions as well as for certain special cases. One example of the latter can be found in [8] where the multifunction S represents the solutions to certain parameterized generalized equations.

For a nice survey of coderivatives, their calculus, and applications, see [52] (for finite-dimensional spaces only) and [38] (for more general spaces).

To study uniqueness, yet another generalized derivative has proven to be useful. For any multifunction $S : \mathbb{R}^d \rightrightarrows \mathbb{R}^n$ and any pair $(\bar{w}, \bar{x})$ satisfying $\bar{x} \in S(\bar{w})$, the *strict derivative* $D_*S(\bar{w}|\bar{x}) : \mathbb{R}^d \rightrightarrows \mathbb{R}^n$ of S at $\bar{w}$ for $\bar{x}$ is defined for any $w' \in \mathbb{R}^d$ by

$$D_*S(\bar{w}|\bar{x})(w') = \left\{ x' \;\middle|\; \begin{array}{l} \exists w_\nu \to \bar{w}, x_\nu \in S(w_\nu), x_\nu \to \bar{x}, w'_\nu \to w', \tau_\nu \downarrow 0 \text{ with} \\ (\tilde{x}_\nu - x_\nu)/\tau_\nu \to x' \text{ for some } \tilde{x}_\nu \in S(w_\nu + \tau_\nu w'_\nu) \end{array} \right\}.$$

This derivative was used first in [53], but only for Lipschitz functions f. It was consequently called "Thibault's limit set" in [17], where it was used to prove an inverse function theorem for Lipschitz functions. The next theorem is a generalization of [17, Theorem 1.1] (use $S = f^{-1}$ below), and it shows that a nonsingular strict derivative characterizes the uniqueness of local selections in tandem with their Lipschitz continuity.

THEOREM 4.2 (see Theorem 1.3 of [19]). *For any multifunction $S : \mathbb{R}^d \rightrightarrows \mathbb{R}^n$ and any pair $(\bar{w}, \bar{x})$ satisfying $\bar{x} \in S(\bar{w})$, the following are equivalent:*

(i) *The strict derivative image set $D_*S(\bar{w}|\bar{x})(0)$ equals the trivial set $\{0\}$.*

(ii) *There exist neighborhoods $X \subseteq \mathbb{R}^n$ of $\bar{x}$ and $W \subseteq \mathbb{R}^d$ of $\bar{w}$ and a constant $L > 0$ such that there is at most one element $x(w)$ in the local image set $S(w) \cap X$ for $w \in W$ and it satisfies*

$$|x(w) - x(w')| \le L|w - w'| \quad \text{for} \quad w, w' \in W.$$

Remark. Notice that the gap between the nonsingularity condition (i) and the uniqueness property is identified precisely by the additional property of Lipschitz continuity in condition (ii) of Theorem 4.2.

For one important class of multifunctions, the existence of a Lipschitz local selection is also guaranteed by the nonsingularity condition (i) on the strict derivative. This class is studied in [21], where it is defined to consist of all multifunctions $S : \mathbb{R}^n \to \mathbb{R}^n$ whose graph near a base pair $(\bar{w}, \bar{x}) \in \operatorname{gph} S$ is the same set as $A \operatorname{gph} F$ for some Lipschitz continuous mapping $F : \mathbb{R}^n \to \mathbb{R}^n$ and a matrix $A \in \mathbb{R}^{2n \times 2n}$ of the form

$$\begin{bmatrix} 0 & A_2 \\ A_3 & A_4 \end{bmatrix}$$

for invertible $n \times n$ matrices A_2 and A_3. The graph of such a multifunction is said to be a *kernel inverting Lipschitzian manifold near* $(\bar{w}, \bar{x})$. For example, the graph of the inverse of any Lipschitzian mapping F is a kernel inverting Lipschitzian manifold under the matrix defined by $A_2 = A_3 = I$ and $A_4 = 0$. In particular, when this matrix is applied to the graph of the function $F(x) = 0$, the result is the graph of the multifunction F^{-1} which looks exactly like the derivative mapping (B) displayed in the introduction.

PROPOSITION 4.0.3 (see Theorem 2.1 of [21]). *For any multifunction $S : \mathbb{R}^n \to \mathbb{R}^n$ having $\operatorname{gph} S$ a kernel inverting Lipschitzian manifold near $(\bar{w}, \bar{x}) \in \operatorname{gph} S$, the following are equivalent:*

(i) *The strict derivative image set* $D_*S(\bar{w}|\bar{x})(0)$ *equals the trivial set* $\{0\}$.

(ii) *There exist neighborhoods* $X \subseteq \mathbb{R}^n$ *of* $\bar{x}$ *and* $W \subseteq \mathbb{R}^d$ *of* $\bar{w}$ *such that there exists a unique element* $x(w)$ *in* $S(w) \cap X$ *for* $w \in W$, *and in addition there is a constant* $L > 0$ *such that* $x(w)$ *is Lipschitz continuous with modulus* L *on* W.

Thus, for multifunctions satisfying the assumptions of Proposition 4.0.3, the nonsingularity condition on the strict derivative (i) guarantees not only the Lipschitz continuity and uniqueness of local selections (as in Theorem 4.2) but even guarantees their existence. We have already seen that for any Lipschitzian mapping, the multifunction F^{-1} is covered by Proposition 4.0.3, and we will see in a later section that Proposition 4.0.3 also covers KKT pair multifunctions. More generally, Proposition 4.0.3 applies to any solution mapping associated with a monotone generalized equation $0 \in F(x, w) + Q(x)$ for a monotone multifunction $Q : \mathbb{R}^n \rightrightarrows \mathbb{R}^n$. The Lipschitz continuity (as in (ii) above) of this important particular solution mapping is also characterized by a coderivative nonsingularity condition [35].

As in the case of the outer graphical derivative, there are calculus rules for coderivatives and strict derivatives that help us apply the results in this section.

THEOREM 4.3 (see Corollary 4.4 of [37] and Exercise 10.43 of [52]). *For any multifunction* $M : \mathbb{R}^n \times \mathbb{R}^d \rightrightarrows \mathbb{R}^n$ *and any triple* $(\bar{x}, \bar{v}, \bar{w})$ *satisfying* $\bar{v} \in M(\bar{x}, \bar{w})$, *the following identities hold for the inverse multifunction* $S(v, w) := \{x | v \in M(x, w)\}$:

$$D^*S(\bar{v}, \bar{w}|\bar{x})(x') = \{(v', w') | (-x', w') \in D^*M(\bar{x}, \bar{w}|\bar{v})(-v')\},$$
$$D_*S(\bar{v}, \bar{w}|\bar{x})(v', w') = \{x' | v' \in D_*M(\bar{x}, \bar{w}|\bar{v})(x', w')\}.$$

For any multifunction $M : \mathbb{R}^d \rightrightarrows \mathbb{R}^n$, *any mapping* $F : \mathbb{R}^d \to \mathbb{R}^n$, *and any points* $\bar{w}$, $\bar{x}_0 \in M(\bar{w})$, *and* $\bar{x} := \bar{x}_0 + F(\bar{w})$, *if* F *is* $\mathcal{C}^1$ *near* $\bar{w}$, *then the sum* $M + F$ *satisfies*

$$D^*\big(M + F\big)(\bar{w}|\bar{x})(x) = D^*M(\bar{w}|\bar{x}_0)(x) + \nabla F(\bar{w})^* \cdot x,$$
$$D_*\big(M + F\big)(\bar{w}|\bar{x})(w) = D_*M(\bar{w}|\bar{x}_0)(w) + \nabla F(\bar{w}) \cdot w.$$

Proof. Both of the first identities follow easily from the fact that the graph of S is a permutation of the arguments of the graph of M. The third identity was established in [37, Corollary 4.4], and the last follows from [52, Exercise 10.43]. □

4.1. Existence and uniqueness of stationary points. In this section, we apply the results in the preceding section to the stationary point mapping to obtain the following sufficient conditions for the existence and uniqueness of stationary points.

PROPOSITION 4.1.1. *For the stationary point multifunction* SP_{tilt} (2.7) *and any pair* $(\bar{x}, \bar{w}) \in \mathbb{R}^{n+d}$ *satisfying* $0 \in \partial_x f(\bar{x}, \bar{w})$ *we have*

(Existence.) If the set $\operatorname{gph} SP_{tilt}$ *is locally closed at* $\big((0, \bar{w}), \bar{x}\big)$ *and* $(v', w') = 0$ *is the only vector in* $\mathbb{R}^{n+d}$ *satisfying*

$$(0, w') \in D^*\big(\partial_x f\big)(\bar{x}, \bar{w}|0)(-v'),$$

then there exist neighborhoods $X \subseteq \mathbb{R}^n$ *of* $\bar{x}$, $W \subseteq \mathbb{R}^d$ *of* $\bar{w}$, *and* $V \subseteq \mathbb{R}^n$ *of 0 such that the stationary point sets* $SP_{tilt}(v, w) \cap X$ *are nonempty for all pairs* $(v, w) \in V \times W$.

(Uniqueness.) If $x' = 0$ *is the only vector in* $\mathbb{R}^n$ *satisfying*

$$0 \in D_*\big(\partial_x f\big)(\bar{x}, \bar{w}|0)(x', 0),$$

then there exist neighborhoods $X \subseteq \mathbb{R}^n$ *of* $\bar{x}$, $W \subseteq \mathbb{R}^d$ *of* $\bar{w}$, *and* $V \subseteq \mathbb{R}^n$ *of 0 such that for all pairs* $(v, w) \in V \times W$, *there is at most one stationary point in the set* $SP_{tilt}(v, w) \cap X$.

Proof. This follows immediately from Theorems 4.1, 4.2, and 4.3. ∎

Remark. Notice that the conditions in Proposition 4.1.1 are also sufficient conditions for the existence and uniqueness of stationary points associated with the untilted problem (1.2), since these points are represented by the mapping SP (2.4) which satisfies $SP(w) = SP_{tilt}(0, w)$.

Recall from Theorem 4.2 that the gap created by the sufficient condition in Proposition 4.1.1 for the uniqueness of stationary points contains exactly the stationary point mappings that violate the Lipschitz continuity property.

When paired with the assumption that there exists a unique locally optimal solution to the unperturbed problem

$$\min\{f(x, \bar{w})\} \text{ over all } x \in \mathbb{R}^n,$$

the sufficient condition for uniqueness from Proposition 4.1.1 actually characterizes a much stronger property where, in particular, the stationary points are optimal solutions.

PROPOSITION 4.1.2 (see Theorem 5.2 of [19]). *For a lower semicontinuous function $f : \mathbb{R}^{n+d} \to \mathbb{R} \cup \{\infty\}$ and a pair $(\bar{x}, \bar{w}) \in \mathbb{R}^{n+w}$ satisfying $0 \in \partial_x f(\bar{x}, \bar{w})$ as well as the constraint qualification*

$$(y, 0) \in \partial^\infty f(\bar{w}, \bar{x}) \Rightarrow y = 0,$$

in terms of the set $\partial^\infty f(\bar{w}, \bar{x})$ of horizon subgradients of f at $(\bar{w}, \bar{x})$, the following are equivalent:

(i) *The pair of conditions hold that*

(a) *There exists a neighborhood $X \subseteq \mathbb{R}^n$ of $\bar{x}$ such that $\bar{x}$ is the only solution to the unperturbed problem*

$$\min\{f(x, \bar{w})\} \text{ over all } x \in X;$$

(b) $0 \in D_*\big(\partial_x f\big)(\bar{x}, \bar{w}|0)(x', 0)$ *only for* $x' = 0$,

(ii) *There exist neighborhoods $X \subseteq \mathbb{R}^n$ of $\bar{x}$, $V \subseteq \mathbb{R}^n$ of 0, and $W \subseteq \mathbb{R}^d$ of $\bar{w}$ such that for every parameter pair $(v, w) \in V \times W$, there is exactly one optimal solution $x(v, w)$ to*

$$\min\{f(x, w) - \langle v, x\rangle\} \text{ over all } x \in X$$

and, moreover, this function $x(v, w)$ is Lipschitz continuous on $V \times W$. In addition, the optimal solution $x(v, w)$ is also the unique stationary point $x(v, w) = SP_{tilt}(v, w) \cap X$ for $(v, w) \in V \times W$.

Remark. Insight into condition (i)(b) of Proposition 4.1.2 can be gained by considering the case when f is twice continuously differentiable. In this situation, condition (i)(b) reduces to the demand that the kernel of the Hessian $\nabla^2_{xx} f(\bar{x}, \bar{w})$ be trivial. It follows that the pair of conditions (i)(a) and (i)(b) in Proposition 4.1.2 is equivalent in this case to the positive-definiteness of the Hessian $\nabla^2_{xx} f(\bar{x}, \bar{w})$.

The constraint qualification used in Proposition 4.1.2 is a generalization of the constraint qualification (2.9) used in the definition of fully amenable functions with compatible parameterization (see [25]), so this proposition certainly covers those functions. We will see some similar characterizations in the next section, but they all cover smaller classes of functions than does Proposition 4.1.2.

4.2. Existence and uniqueness in the case of fully amenable functions. The calculus for the coderivative and the strict derivative is less developed than that for the outer graphical derivative, so it is at present more difficult to apply the results in section 4.1 directly to some particular cases, including the stationary point multifunction associated with a nonlinear program. Fortunately, for this important particular case and others, there is an alternative characterization of the existence and uniqueness of stationary points in terms of the outer graphical derivative at x for $v \in \partial_x f(x,w)$ of the multifunction $x \mapsto \partial_x f(x,w)$. The generalized derivative that results from this construction maps points in $\mathbb{R}^n$ to sets in $\mathbb{R}^n$ and is denoted by $D_{xx}f(x,w|v)$. If we "strengthen" this derivative by taking the outer graphical limit as $x \to \bar{x}$, $w \to \bar{w}$, and $v \to \bar{v}$ of the sequence of multifunctions $D_{xx}f(x,w|v)$, we obtain the *strong partial outer graphical derivative of f at $\bar{x}$ for $\bar{v} \in \partial_x f(\bar{x},\bar{w})$*, which we denote by $\tilde{D}^2_{xx}f(\bar{x},\bar{w}|\bar{v})$. Both $D_{xx}f(\bar{x},\bar{w}|\bar{v})$ and its strengthening $\tilde{D}^2_{xx}f(\bar{x},\bar{w}|\bar{v})$ are generalizations of the Hessian mapping $x' \mapsto \nabla_{xx}f(\bar{x},\bar{w}) \cdot x'$.

PROPOSITION 4.2.1 (see Proposition 3.4 of [20]). *If f is fully amenable in x at $\bar{x}$ with compatible parameterization in w at $\bar{w}$ and if $0 \in \partial_x f(\bar{x},\bar{w})$, then the following are equivalent:*

(i) *The pair of conditions holds that*

(a) *There exist neighborhoods $X \subseteq \mathbb{R}^n$ of $\bar{x}$, $V \subseteq \mathbb{R}^n$ of 0, and $W \subseteq \mathbb{R}^d$ of $\bar{w}$ such that for every parameter pair $(v,w) \in V \times W$, there is exactly one stationary point $x(v,w)$ in the set $SP_{tilt}(v,w) \cap X$;*

(b) *There is a constant $L > 0$ such that for any fixed $w \in W$, the (single-valued) mapping $v \mapsto SP_{tilt}(v,w) \cap X$ is monotone and Lipschitz continuous with modulus L on V.*

(ii) *The strong partial outer graphical derivative of f at $\bar{x}$ for 0 is positive-definite in the sense that*

$$v' \in \tilde{D}^2_{xx}f(\bar{x},\bar{w}|0)(x') \Rightarrow \langle v', x' \rangle > 0 \text{ unless } x' = 0.$$

Moreover, under either of these equivalent conditions and for any parameter pair $(v,w) \in V \times W$, the unique stationary point $x(v,w)$ in the set $SP_{tilt}(v,w) \cap X$ is also the unique optimal solution to

$$\min\{f(x,w) - \langle v, x \rangle\} \text{ over all } x \in X.$$

Remark. Notice that just as we have seen previously, even though Proposition 4.2.1 involves the tilted stationary point mapping SP_{tilt} (2.7), its condition (ii) is automatically a sufficient condition for existence and uniqueness of the stationary points associated with the untilted problem (1.2), since these points are represented by the mapping SP (2.4) which satisfies $SP(w) = SP_{tilt}(0,w)$. Moreover, the gap between the sufficient condition (ii) and the existence and uniqueness of stationary points is identified by Proposition 4.2.1 via the properties given in condition (i).

Notice finally that Proposition 4.2.1 also identifies conditions which guarantee that stationary points are locally optimal solutions.

If we combine Propositions 4.2.1 and 3.1.2, we get the following stability result for optimal solutions.

COROLLARY 4.2.1 (see Theorem 1.1 of [20]). *If f is fully amenable in x at $\bar{x}$ with compatible parameterization in w at $\bar{w}$ and if $0 \in \partial_x f(\bar{x},\bar{w})$, then under the second-order conditions* (ii) *of Proposition* 4.2.1 *and* (i) *of Proposition* 3.1.2, *there exist neighborhoods $X \subseteq \mathbb{R}^n$ of $\bar{x}$ and $W \in \mathbb{R}^d$ of $\bar{w}$ such that for each parameter*

$w \in W$, there exists a unique solution $x(w)$ to

$$\min\{f(x,w)\} \text{ over all } x \in X,$$

and this solution function $x(w)$ is calm in the sense of (3.1)*. Moreover, $x(w)$ is also the unique stationary point in the set $SP(w) \cap X$.*

Remark. We have stated both Proposition 4.2.1 and Corollary 4.2.1 in terms of the fully amenable essential objective functions we studied in section 2.2; however, they were developed in [20] for an even broader class of objective functions (though one not as broad as those covered by Proposition 4.1.2). A similar result was developed in [25] where second-order coderivative conditions were used instead, and the stronger property of Lipschitz continuity was obtained.

4.3. Existence and uniqueness of solutions to nonlinear programs. In the case of the nonlinear program (1.3), the results in the preceding section can be translated into more familiar terms using the formula for the outer graphical derivative of $\partial_x f$ from Proposition 2.3.1.

PROPOSITION 4.3.1 (see Theorem 4.2 of [20]). *For the nonlinear program* (1.3) *and its associated stationary point multifunction SP* (2.18)*, suppose the Mangasarian–Fromovitz constraint qualification* (2.17) *holds at $(\bar{x}, \bar{w})$ with $\bar{x} \in SP(\bar{w})$, and the second-order condition holds that:*

(i) *For any sequences $x \to \bar{x}$, $w \to \bar{w}$, and $v \to 0$ with $x \in C(w)$, and any convergent sequence of points $x' \in \cap_{i\in[1,m]}$ with $_{g_i(x,w)=0}\nabla_x g_i(x,w)^\perp$ with nonzero limit $\bar{x}'$, together with any corresponding convergent sequence of multipliers y which each maximizes the value $\langle x'\nabla^2_{xx}L(x,y,w)\cdot x'\rangle$ over all choices of multipliers $y \in N_K\big(G(x,w)\big)$ with $\nabla_x L(x,y,w) = v$, the Hessian at the limit multiplier $\bar{y}$ satisfies $\langle \bar{x}', \nabla^2_{xx}L(\bar{x},\bar{y},\bar{w})\bar{x}'\rangle > 0$.*

Then there exist neighborhoods $X \subseteq \mathbb{R}^n$ of $\bar{x}$ and $W \subseteq \mathbb{R}^d$ of $\bar{w}$ such that for every parameter $w \in W$, there is exactly one stationary point in the set $SP(w) \cap X$, and it is, moreover, the unique solution to the problem

$$\min\{g_0(x,w)\} \text{ over all } x \in C(w) \cap X.$$

Moreover, condition (i) *above is equivalent to the pair of conditions* (i)(a) *and* (i)(b) *from Proposition* 4.2.1 *applied to the associated stationary point mapping SP_{tilt}* (2.19)*.*

If in addition the second-order condition (i) *of Proposition* 3.2.1 *holds, then the function $x(w)$ is calm in the sense of* (3.1)*.*

Remark. Together, the second-order conditions (i) in Propositions 4.3.1 and 3.2.1 actually characterize a slightly stronger stability property than calmness (see [20]), so the gap between these conditions and the calmness property is known. Moreover, it is shown in [20] that the second-order conditions in Propositions 4.3.1 and 3.2.1 are both weaker than the general strong second-order condition (from [11]):

> For every multiplier $y \in Y(\bar{x},\bar{w},0,u)$ for some $u \in \mathbb{R}^d$, the Hessian $\nabla^2_{xx}L(\bar{x},\bar{y},\bar{w})$ is positive-definite on the subspace of vectors perpendicular to every $\nabla_x g_i(\bar{x},\bar{w})$ with $i \in I_1$ (2.32).

This general strong second-order condition when paired with the Mangasarian–Fromovitz constraint qualification has been known for some time (via [48] and [16]) to imply the calmness property, and the fact that the conditions in Proposition 4.3.1 are weaker than the general strong second-order condition means that this proposition is an improvement on this previous sufficient condition for calmness.

Example program revisited. We return once more to the nonlinear program introduced in section 2.3, but this time to see how the condition (i) in Proposition 4.3.1 works out for this example. Notice that in this case, the final inner product whose positivity needs to be verified satisfies

$$\langle \bar{x}', \nabla^2_{xx} L(\bar{x}, \bar{y}, \bar{w}) \bar{x}' \rangle = 2(\bar{x}'_1)^2 + 2(1 - \bar{y}_1)(\bar{x}'_2)^2, \tag{4.2}$$

and that $\bar{y}_1 \in [0, 1]$. We consider only nonzero limit points $\bar{x}'$, and notice that in the case when $\bar{x}'_1 \neq 0$, the inner product (4.2) is positive no matter what the choice of multiplier since $\bar{y}_1 \in [0, 1]$. On the other hand, if $\bar{x}'_1 = 0$, then $\bar{x}'$ being nonzero implies that $\bar{x}'_2 \neq 0$, which means that we can assume $x'_2 \neq 0$ for the whole sequence of $x' \to \bar{x}'$. In this case, since the inner product to be maximized by the multiplier y is given by

$$\langle x', \nabla^2_{xx} L(x, y, w) x' \rangle = 2(x'_1)^2 + 2(1 - y_1)(x'_2)^2$$

we can conclude that $y_1 = 0$ for each multiplier in the sequence, so the limit multiplier $\bar{y}$ satisfies $\bar{y}_1 = 0$. It follows that in this case too, the inner product (4.2) is positive, so this example program satisfies the conditions of Proposition 4.3.1, and as a result has exactly one stationary point (and this stationary point also happens to be a locally optimal solution) for all values of w near $\bar{w} = 0$.

It is interesting to note that the general strong second-order condition does not hold for this example program (for the multiplier $\bar{y} = (1, 0)$, the Hessian $\nabla^2_{xx} L(\bar{x}, \bar{y}, \bar{w})$ is only positive semidefinite on the appropriate subspace), so this optimization problem falls in the gap between that sufficient condition and the stability properties promised by Proposition 4.3.1.

Remark. Of course it would be nice if the condition (i) from Proposition 4.3.1 could be refined in such a way as to depend only on information at the base point like the general strong second-order condition and not on the limits of nearby parameter values. In particular, such a refinement would likely make condition (i) less daunting to verify in many situations. However, such refinements are generally not possible without creating a gap and sacrificing the characterization. This fact can be seen by considering two different parameterizations of any well-behaved unperturbed problem: One parameterization is trivial, with each perturbed problem being the same as the unperturbed model, and the other parameterization is anything that creates a lack of the kind of stability covered by Proposition 4.3.1. For instance, consider the objective function $g_0(x_1, x_2) := x_1^2/2$ with parameterized constraint set

$$C(w) := \{(x_1, x_2) \in \mathbb{R}^2 : g_1(x, w) := x_2 - w^{2k} \leq 0 \text{ and } g_2(x, w) := -x_2 - w^{2k} \leq 0\}$$

for any positive integer k. For the unperturbed problem with $\bar{w} = 0$, the constraint set reduces to $C(0) = \{(x_1, x_2) \in \mathbb{R}^2 : x_2 = 0\}$, and the minimization of g_0 over $C(0)$ has a unique solution at $\bar{x} = (0, 0)$. Of course the trivially parameterized problem also has this property, so it exhibits the kind of stability covered by Proposition 4.3.1, and it even satisfies the general strong second-order condition. However, the minimization of g_0 over $C(w)$ for $w \neq 0$ has multiple solutions, so it fails to be stable at $\bar{w}$ in the sense of Proposition 4.3.1. In this case, only the derivatives of order $2k$ with respect to w of g_1 and g_2 evaluated at the base point $(\bar{x}, \bar{w})$ distinguish the two different parameterizations. Since k is any positive integer, no test using only derivatives evaluated at the base point will be able to distinguish the stability discrepancies illustrated in this example.

4.4. Existence and uniqueness of KKT pairs. We again consider the KKT pairs associated with the optimization model from section 2.4

$$\min\{g_0(x,w) + g\big(G(x,w)+v_2\big) - \langle v_1, x\rangle\} \text{ over } x \in \mathbb{R}^n.$$

Unlike the multifunctions studied in the preceding two sections, the particular structure of the KKT pair multifunction allows us to directly apply the fundamental characterizations in terms of the coderivative and strict derivative from section 4. In fact, for the KKT pair multifunction, the different characterizations from section 4 are both equivalent to each other and to the existence of a unique local selection that is Lipschitz continuous.

PROPOSITION 4.4.1. *If the mapping $\nabla_x L$ is $\mathcal{C}^1$ at $(\bar{x},\bar{y},\bar{w})$ and $(\bar{x},\bar{y}) \in KKT(0,\bar{w})$ for the KKT pair multifunction* (2.24)*, then the following are equivalent:*

(i) *The pair $(v',w') = (0,0)$ is the only solution in $\mathbb{R}^{n+m+d}$ to the system*

$$\begin{aligned}
\nabla_{xx}L(\bar{x},\bar{y},\bar{w})^* \cdot v_1' &= \nabla_x G(\bar{x},\bar{w})^* \cdot v_2',\\
\nabla_{xy}L(\bar{x},\bar{y},\bar{w})^* \cdot v_1' &\in D^*\Big(\big(\partial g\big)^{-1}\Big)\big(\bar{y}|G(\bar{x},\bar{w})\big)(-v_2'),\\
w' + \nabla_{xw}L(\bar{x},\bar{y},\bar{w})^* \cdot v_1' &= \nabla_w G(\bar{x},\bar{w})^* \cdot v_2'.
\end{aligned}$$

(ii) *The pair $(x',y') = (0,0)$ is the only solution in $\mathbb{R}^{n+m}$ to the system*

$$\begin{aligned}
0 &= \nabla^2_{xx}L(\bar{x},\bar{y},\bar{w})\cdot x' + \sum_{i=1}^m y_i' \nabla_x g_i(\bar{x},\bar{w}),\\
\nabla_x G(\bar{x},\bar{w})\cdot x' &\in D_*\Big(\big(\partial g\big)^{-1}\Big)\big(\bar{y}|G(\bar{x},\bar{w})\big)(y').
\end{aligned}$$

(iii) *There exist neighborhoods $X \times Y$ of $(\bar{x},\bar{y}) \in \mathbb{R}^{n+m}$ and $V \times W$ of $(0,\bar{w})$ in $\mathbb{R}^{n+d}$ such that for all pairs $(v,w) \in V \times W$, there is exactly one KKT pair $\big(x(v,w),y(v,w)\big)$ in the set $KKT(v,w) \cap (X \times Y)$, and, moreover, this KKT pair function is Lipschitz continuous on $V \times W$.*

Moreover, under any of these equivalent conditions, if the subgradient multifunction ∂g is protodifferentiable at $G(\bar{x},\bar{w})$ for $\bar{y} \in \partial g\big(G(\bar{x},\bar{w})\big)$, then the KKT pair $\big(x(v,w),y(v,w)\big)$ is B-differentiable at $(0,\bar{w})$.

Proof. The equivalence between (i) and (iii) follows from Theorem 4.1 and [9, Theorem 3] since the coderivative image set $D^*\big(KKT\big)(0,\bar{w}|\bar{x},\bar{y})(x',y')$ consists of all pairs $(v',w') \in \mathbb{R}^{n+d}$ that satisfy the system

$$\begin{aligned}
-x' &= -\nabla_{xx}L(\bar{x},\bar{y},\bar{w})^* \cdot v_1' + \nabla_x G(\bar{x},\bar{w})^* \cdot v_2',\\
-y' &\in -\nabla_{xy}L(\bar{x},\bar{y},\bar{w})^* \cdot v_1' + D^*\Big(\big(\partial g\big)^{-1}\Big)\big(\bar{y}|G(\bar{x},\bar{w})\big)(-v_2'),\\
w' &= -\nabla_{xw}L(\bar{x},\bar{y},\bar{w})^* \cdot v_1' + \nabla_w G(\bar{x},\bar{w})^* \cdot v_2'.
\end{aligned}$$

To prove the equivalence between (ii) and (iii), we use a certain linearization $L_{KKT} : \mathbb{R}^n \rightrightarrows \mathbb{R}^{n+m}$ of the KKT pair multifunction:

$$L_{KKT}(v) := \big\{(x,y) : v \in H(\bar{x},\bar{y},\bar{w}) + \nabla_{xy}H(\bar{x},\bar{y},\bar{w})\cdot\big((x,y)-(\bar{x},\bar{y})\big) + N(x,y)\big\},$$

where the mapping $H : \mathbb{R}^{n+m+d} \to \mathbb{R}^{n+m}$ is defined by

$$H(x,y,w) := \Big(\nabla_x L(x,y,w), -G(x,w)\Big)$$

and the multifunction $N : \mathbb{R}^{n+m} \rightrightarrows \mathbb{R}^{n+m}$ is defined by

$$N(x,y) := \Big(\{0\}^n \times \big(\partial g\big)^{-1}(y)\Big).$$

Notice that the multifunction L_{KKT} is the same as the KKT pair multifunction except that the former uses a linearization of H instead of H itself. Moreover, the graph of L_{KKT} is a kernel inverting Lipschitzian manifold (see [21]) so it is covered by our Proposition 4.0.3. In [21, Theorem 4.1] and [9, Propositions 1 and 2] it was shown that property (iii) above for the KKT pair multifunction is equivalent to the same property for the linearization L_{KKT}, and in [21, Theorem 4.1] it was shown that the nonsingularity condition (ii) is equivalent to the same condition applied to the linearization multifunction L_{KKT}. This means that the characterization recorded in Proposition 4.0.3 also holds for the KKT pair multifunction, so the result here follows from the calculus rules in Theorem 4.3, which allow us to deduce that the strict derivative image set $D_*\big(KKT\big)(0,\bar w|\bar x,\bar y)(v',w')$ consists of all pairs $(x',y') \in \mathbb{R}^{n+m}$ that satisfy the system

$$\begin{aligned} v_1' &= \nabla_{x(x,y,w)} L(\bar x,\bar y,\bar w)\cdot(x',y',w'),\\ v_2' &\in -\nabla G(\bar x,\bar w)\cdot(x',w') + D_*\Big(\big(\partial g\big)^{-1}\Big)\big(\bar y|G(\bar x,\bar w)\big)(y'). \end{aligned}$$

The B-differentiability follows immediately from Proposition 2.4.2. □

Remark. Notice the similarity between condition (ii) here and condition (i) from Proposition 3.3.1 characterizing the calmness of local KKT pair selections: The only difference is that the generalized derivative used in Proposition 3.3.1 is the outer graphical derivative. This reflects the fact that these arose from similar nonsingularity conditions which were derived in terms of the different generalized derivatives.

4.5. Existence and uniqueness of KKT pairs for nonlinear programs. For nonlinear programs with canonical perturbations (2.30), the results of the preceding section can be translated into even more specific terms by working out formulas for either the coderivative or strict derivative of the inverse of the normal cone multifunction N_K (2.13). We again use the sets of indices (2.32).

PROPOSITION 4.5.1. *For the canonically perturbed nonlinear program* (2.30) *and its associated KKT pair multifunction* (2.33)*, if the Mangasarian–Fromovitz constraint qualification* (2.17) *holds at* $(\bar x,\bar w)$ *with* $(\bar x,\bar y) \in KKT(0,\bar w)$*, then the following are equivalent:*

(i) *The pair of conditions hold that*

(a) *The vectors* $\nabla_x g_i(\bar x,\bar w)$ *for* $i \in I_1 \cup I_2$ *are linearly independent;*

(b) *For each partition of* $\{1,\dots,m\}$ *into index sets* I_1', I_2', I_3' *with* $I_1 \subseteq I_1' \subseteq I_1 \cup I_2$ *and* $I_3 \subseteq I_3' \subseteq I_3 \cup I_2$*, the cone* $K(I_1',I_2') \subseteq \mathbb{R}^n$ *consisting of all vectors* x' *satisfying*

$$\langle \nabla_x g_i(\bar x,\bar w), x'\rangle \begin{cases} = 0 & \text{for } i \in I_1',\\ \le 0 & \text{for } i \in I_2', \end{cases}$$

should be such that

$$x' \in K(I_1',I_2') \text{ and } \nabla^2_{xx} L(\bar x,\bar y,\bar w)\cdot x' \in K(I_1',I_2')^* \quad \Rightarrow \quad x' = 0.$$

(ii) *The pair* $(x',y') = (0,0)$ *is the only solution in* $\mathbb{R}^{n+m}$ *to the system*

$$0 = \nabla^2_{xx} L(\bar x,\bar y,\bar w)\cdot x' + \sum_{i=1}^m y_i' \nabla_x g_i(\bar x,\bar w),$$

$$\langle \nabla_x g_i(\bar{x}, \bar{w}), x' \rangle = 0 \text{ for } i \in I_1,$$
$$y_i' \langle \nabla_x g_i(\bar{x}, \bar{w}), x' \rangle \geq 0 \text{ for } i \in I_2,$$
$$y_i' = 0 \text{ for } i \in I_3.$$

(iii) *There exist neighborhoods $X \times Y$ of $(\bar{x}, \bar{y}) \in \mathbb{R}^{n+m}$ and $V \times W$ of $(0, \bar{w})$ in $\mathbb{R}^{n+d}$ such that for all pairs $(v, w) \in V \times W$, there is exactly one KKT pair $\big(x(v,w), y(v,w)\big)$ in the set $KKT(v,w) \cap (X \times Y)$, and, moreover, this KKT pair function is Lipschitz continuous on $V \times W$.*

Moreover, under any of these equivalent conditions, the KKT pair $\big(x(v,w), y(v,w)\big)$ is B-differentiable at $(0, \bar{w})$.

Proof. The equivalence between (i) and (iii) was established in [9, Theorem 5], where it was essentially shown that condition (i) above is equivalent to condition (i) from our Proposition 4.4.1. The equivalence between (ii) and (iii) follows directly from our Proposition 4.4.1 since the strict derivative of the inverse of N_K has $z' \in D_*((N_K)^{-1})(\bar{y}|G(\bar{x}, \bar{w}))(y')$ if and only if

$$y_i' = 0 \text{ for } i \in I_1,$$
$$y_i' \, z_i' \geq 0 \text{ for } i \in I_2,$$
$$z_i' = 0 \text{ for } i \in I_3,$$

(see [23]) and since the assumption that $(\bar{x}, \bar{y})$ is a KKT pair for $(0, \bar{w})$ implies that for $i \in [1, s]$, $g_i(\bar{x}, \bar{w}) \leq 0$ and $\bar{y}$ satisfies $\bar{y}_i \, g_i(\bar{x}, \bar{w}) = 0$ with $\bar{y}_i \geq 0$. □

Notice that the assumed satisfaction of the Mangasarian–Fromovitz constraint qualification is guaranteed by the linear independence condition (i)(a). It is an easy exercise to show that any pair satisfying the system in condition (i) of Proposition 3.4.1 also satisfies the system in condition (ii) above. This is consistent with the fact that condition (i) of Proposition 3.4.1 characterizes the calmness of local selections of KKT pairs, which is a weaker property than (iii) of Proposition 4.5.1. Notice that Proposition 4.5.1 does not address the issue of the primal component of the KKT pair being a locally optimal solution. For this, we need a positive-definiteness assumption.

PROPOSITION 4.5.2 (see Theorem 6 of [9]). *Under the assumptions of Proposition* 4.5.1*, the following are equivalent:*

(i) *There exist neighborhoods $X \times Y$ of $(\bar{x}, \bar{y}) \in \mathbb{R}^{n+m}$ and $V \times W$ of $(0, \bar{w})$ in $\mathbb{R}^{n+d}$ such that for all pairs $(v, w) \in V \times W$, there is exactly one KKT pair $\big(x(v,w), y(v,w)\big)$ in the set $KKT(v,w) \cap (X \times Y)$, this KKT pair function is Lipschitz continuous on $V \times W$, and, moreover, $x(v,w)$ is a locally optimal solution to the canonically perturbed nonlinear program* (2.30).

(ii) *The constraint gradients $\nabla_x g_i(\bar{x}, \bar{w})$ for $i \in I_1 \cup I_2$ are linearly independent and the strong second-order sufficient condition for local optimality holds that $\nabla^2_{xx} L(\bar{x}, \bar{y}, \bar{w})$ is positive-definite on the subspace of vectors perpendicular to all constraint gradients $\nabla_x g_i(\bar{x}, \bar{w})$ for $i \in I_1$.*

Moreover, under either of these equivalent conditions, the KKT pair $(x(v,w), y(v,w))$ is B-differentiable at $(0, \bar{w})$.

Remark. Notice that under the linear independence assumption in (ii), there is only one multiplier $\bar{y}$ which can be paired with $\bar{x}$ as a KKT pair for the parameters $(0, \bar{w})$ (which condition is equivalent to the strict Mangasarian–Fromovitz constraint qualification). Under these circumstances, the strong second-order sufficient condition here is equivalent to Robinson's general strong second-order condition (see section 4.3), so condition (ii) of Proposition 4.5.2 is stronger than the assumptions in Proposition 4.3.1. This is consistent with the fact that the properties identified in condition

(i) of Proposition 4.5.2 are stronger than the calmness of the unique local stationary point selection guaranteed by Proposition 4.3.1 (recall that under the Mangasarian–Fromovitz constraint qualification, each of the stationary points associated with the nonlinear program (1.4) can be paired with a multiplier to form a KKT pair).

5. Conclusions and related work. Each of the main three sections in the body of this paper follow the same basic pattern: The most general principles are established first (e.g., Theorems 2.1, 3.1, 4.1, and 4.2), and the rest of the work is computing the appropriate generalized derivatives in order to translate the general principles into verifiable conditions in the language of a particular optimization model (e.g., nonlinear programming). The results for stationary points and stationary point-multiplier pairs mirror each other because they are based on the same general principles; however, they are different too because the generalized derivatives work out differently in each of these situations. One common trick used in the sections involving stationary points is to characterize the sensitivity properties of the tilted version of the optimization problem (2.6) first and then to translate these characterizations into sufficient conditions for the untilted case. A similar approach is used in sections involving KKT stationary point-multiplier pairs, where the presence of canonical perturbations is exploited. We can always recover results about the untilted (or uncanonically perturbed) model by setting the new parameters equal to zero, and, moreover, the gap created by the resulting sufficient condition is precisely identified in terms of the augmented model.

Others who have used outer graphical derivatives to obtain results about the calmness of local selections include Qiu and Magnanti [44], [18], and Klatte and Kummer [15]. A good survey of sensitivity results in nonlinear programming obtained via this and similar methods can be found in [10], and a survey of other results in nonlinear programming obtained by these and more traditional approaches can be found in [11]. There has also been some interest recently in sensitivity results for nonlinear programs under relaxed differentiability assumptions (see [14], for example). Of course the generality of our approach means that our results could be applied in such cases by computing the appropriate generalized derivatives under the new assumptions.

A slightly different but complementary approach to studying the sensitivity properties of inverse multifunctions is based on the work of Robinson [46] and [47]. Instead of using the outer graphical derivative, this work relies on a different kind of linearization of the inverse multifunction (we actually use this linearization in our proof of Proposition 4.4.1). For many important cases of interest (including the KKT pair multifunction), the local single-valuedness and Lipschitz continuity of the linearization implies the same properties for the original inverse multifunction. The focus of this approach then is on establishing conditions under which the linearization is locally single-valued and Lipschitz continuous, a property which Robinson called "strong regularity." This approach has also yielded B-differentiability results for certain inverse multifunctions when they are single-valued [50], as well as results about when stationary points for optimization problems are optimal solutions.

In Theorem 4.1, we recorded Mordukhovich's characterization of "Aubin continuity" in terms of coderivatives [32, Theorem 5.4], but since our focus in the present paper is on the continuity property of selection calmness, we did not exploit this fundamental characterization more. Coderivatives and the characterization [32, Theorem 5.4] have been used effectively to develop conditions guaranteeing Lipschitzian properties of optimal solutions, stationary points, and related objects (see, for exam-

ple, [32], [34], [35], [36], [38], [52], and [25]). Many of these results depend on the coderivative calculus developed in [37].

A good example of a fundamentally different approach to sensitivity analysis is surveyed in [5], where quite different sensitivity properties are studied. These authors start from a generalized nonlinear program, and give sufficient conditions for directional differentiability and calmness of nearly optimal solutions along fixed parameter directions.

One very satisfying aspect of our approach is that even when applied to the well-studied case of nonlinear programming, our fundamental rules have generated new conditions for previously sought conditions. For example, Propositions 3.2.1 and 3.2.2 provide unprecedented conditions guaranteeing the calmness of local stationary point selections. Proposition 4.3.1 is also unprecedented, and improves the combined results of [48] and [16] giving the existence, uniqueness, and calmness of local solutions. Related results giving true Lipschitz continuity include a theorem of Robinson's [47] which stated that the linear independence of the gradients of all the binding constraints, together with the general strong second-order condition, were enough to ensure the existence, uniqueness, and Lipschitz continuity of locally optimal solutions. A long-standing question in this area (posed formally by Robinson in [48]) is whether a weaker constraint qualification can replace linear independence and still ensure this kind of solution stability. One answer to this question was provided in Liu [30] and Ralph and Dempe [45] where a "constant rank condition" combined with the Mangasarian–Fromovitz constraint qualification and the general strong second-order condition were shown to ensure the existence, uniqueness, and Lipschitz continuity of locally optimal solutions to the nonlinear program (1.3). Proposition 4.3.1 shows that the Mangasarian–Fromovitz constraint qualification together with a pair of weaker second-order conditions suffice to ensure the slightly weaker stability property of calmness. However, Robinson [48] provided an example to show that the assumptions in Proposition 4.3.1 are not enough to ensure the local Lipschitz continuity of locally optimal solutions to (1.3).

Finally, the success of our approach is not limited to the nonlinear programs on which we have focused our attention here. As another example, the same basic approach has been applied successfully to carry out a reasonably complete sensitivity analysis of solutions to parameterized nonlinear complementarity problems [22].

Acknowledgments. The author is grateful to Asen Dontchev and Boris Mordukhovich for their comments during the preparation of this paper.

A REMARK ON NULL EXACT CONTROLLABILITY OF THE HEAT EQUATION*

XU ZHANG†

Abstract. It is well known that the heat equation $u_t - \Delta u = f\chi_\omega$ in $(0,T)\times\Omega$ with homogeneous Dirichlet boundary conditions is null exactly controllable for any $T > 0$ and any open nonempty subset ω of Ω. In this note we show that this property may be obtained as a singular limit of the exact controllability properties of singularly perturbed damped wave equations with a changing controller.

Key words. controllability, singular perturbation, heat equation, wave equation

1. Introduction and main result.

Let us consider the following controlled heat equation:

$$\begin{cases} u_t - \Delta u = f\chi_\omega & \text{in} \quad Q, \\ u = 0 & \text{on} \quad \Sigma, \\ u(0) = u^0 & \text{in} \quad \Omega. \end{cases} \tag{1.1}$$

In (1.1), $Q \triangleq (0,T)\times\Omega$ and $\Sigma \triangleq (0,T)\times\Gamma$, where $T > 0$ and Ω is a bounded domain of $\mathbb{R}^n$ with C^∞ boundary $\Gamma \triangleq \partial\Omega$, $u = u(t,x)$ is the *state*, $f = f(t,x)$ is the *control*, and χ_ω denotes the characteristic function of the open nonempty subset ω of Ω where the control is supported.

It is well known (see [4] and [6]) that (1.1) is null exactly controllable for any given $T > 0$ and any nonempty open subset ω of Ω; i.e., for any given $u^0 \in L^2(\Omega)$, one can find a control $f \in L^2((0,T)\times\omega)$ such that the weak solution $u(\cdot) \in C([0,T]; L^2(\Omega)) \cap C((0,T]; H_0^1(\Omega))$ of (1.1) satisfies

$$u(T) = 0. \tag{1.2}$$

The corresponding f is called a null-control for (1.1) with initial state u^0.

In this note we will show that the above property of (1.1) may be obtained as a singular limit of the exact controllability properties of the following damped, singularly perturbed wave equation with a *changing* controller ω_ε:

$$\begin{cases} \varepsilon u_{\varepsilon,tt} - \Delta u_\varepsilon + u_{\varepsilon,t} = f_\varepsilon \chi_{\omega_\varepsilon} & \text{in} \quad Q, \\ u_\varepsilon = 0 & \text{on} \quad \Sigma, \\ u_\varepsilon(0) = u^0,\ u_{\varepsilon,t}(0) = u^1 & \text{in} \quad \Omega. \end{cases} \tag{1.3}$$

In (1.3), $\varepsilon > 0$ is a *small* parameter (which is devoted to tend to zero), $(u_\varepsilon, u_{\varepsilon,t}) = \big(u_\varepsilon(t,x), u_{\varepsilon,t}(t,x)\big)$ is the *state*, $f_\varepsilon = f_\varepsilon(t,x)$ is the *control*, and ω_ε is an open nonempty

subset of Ω where the control is supported. The exact controllability of (1.3) is formulated as follows: For any given (u^0, u^1), $(v^0, v^1) \in H_0^1(\Omega) \times L^2(\Omega)$, one can find a control $f_\varepsilon \in L^2((0,T) \times \omega_\varepsilon)$ such that the weak solution $u_\varepsilon(\cdot) \in C([0,T]; H_0^1(\Omega)) \cap C^1([0,T]; L^2(\Omega))$ of (1.3) satisfies

$$u_\varepsilon(T) = v^0, \qquad u_{\varepsilon,t}(T) = v^1. \tag{1.4}$$

If the final state (v^0, v^1) is $(0,0)$, the corresponding f_ε is called a null-control of (1.3) with initial state (u^0, u^1). We refer the reader to [7], [3], [11], and the references therein for an extensive study of the theory of exact controllability.

In the case $\omega_\varepsilon \equiv \omega$, i.e., the controller of system (1.3) is fixed, [9] considered the above singular pertubation problem under the following geometric control condition: [1]

$$\omega = \Omega \cap \mathcal{O}_\delta(\Gamma(x_0)), \tag{1.5}$$

where $\delta > 0$ is a constant, $\Gamma(x_0) = \{x \in \Gamma \,|\, (x - x_0) \cdot \nu(x) > 0\}$, $x_0 \in \mathbb{R}^n$, $\nu(x)$ denotes the outward unit normal to Ω at $x \in \Gamma$, and $\cdot$ denotes the scalar product in $\mathbb{R}^n$. More precisely, [9] proved the following result.

THEOREM A. *Let $T > 0$ and Ω be a bounded domain of $\mathbb{R}^n$ of class C^∞. Let $\omega_\varepsilon \equiv \omega$ with ω being given by* (1.5)*. Then, there exists an $\varepsilon_0 = \varepsilon_0(T, \Omega, \omega) > 0$ such that for any $0 < \varepsilon < \varepsilon_0$, system* (1.3) *is uniformly exactly controllable in time T. Furthermore, for any fixed $(u^0, u^1) \in H_0^1(\Omega) \times L^2(\Omega)$, the null-controls f_ε of* (1.3) *may be chosen such that*

$$f_\varepsilon \to f \text{ in } L^2((0,T) \times \omega) \text{ as } \varepsilon \to 0, \tag{1.6}$$

f being a null-control for the limit heat equation (1.1) *with initial datum u^0.*

Very recently, [10] generalized Theorem A by considering a more general geometric control condition introduced in [8]. It is also expected that Theorem A still holds under the sharp geometric control condition of [1] on ω although this is as of now an open problem.

However, we note that for the fixed controller case, according to the result in [1], some geometric conditions are needed on ω, the so-called *geometric optics condition*, to guarantee the exact controllability of (1.3). Therefore one may not expect the result of Theorem A to hold for any open nonempty subset ω of Ω.

In this note, we will allow the controller ω_ε of (1.3) to change as ε tends to zero. More precisely, for any given open nonempty subset ω of Ω, we suitably select a family of controllers ω_ε such that (1.3) with this controller is exactly controllable and

$$\lim_{\varepsilon \to 0} \omega_\varepsilon \setminus \omega = \emptyset.$$

Then, we can obtain the null exact controllability of (1.1) by considering the singular limit of the exact controllability properties of (1.3) with these controllers ω_ε.

This is precisely the main result of this note.

THEOREM B. *Let $T > 0$ and Ω be a bounded domain of $\mathbb{R}^n$ with C^∞ boundary Γ. Let ω be any given open nonempty subset of Ω and $\omega_\varepsilon = \omega \cup \big(\Omega \cap \mathcal{O}_\varepsilon(\Gamma)\big)$. Then, for any $(u^0, u^1) \in H_0^1(\Omega) \times L^2(\Omega)$ fixed, one can choose the null-controls f_ε of* (1.3) *such that*

$$f_\varepsilon \chi_{\omega_\varepsilon} \to f \chi_\omega \text{ in } L^2(Q) \text{ as } \varepsilon \to 0, \tag{1.7}$$

[1] For any $M \subseteq \mathbb{R}^n$ and $\eta > 0$, we put $\mathcal{O}_\eta(M) = \{y \in \mathbb{R}^n \,|\, |y - x| < \eta \text{ for some } x \in M\}$.

where f is a null-control for (1.1) *with initial datum u^0. Furthermore, it holds that*

$$\begin{array}{l} u_\varepsilon \to u \text{ strongly in } L^2(0,T;H_0^1(\Omega)) \cap C([0,T];L^2(\Omega)), \\ u_{\varepsilon,t} \to u_t \text{ strongly in } L^2(Q), \end{array} \tag{1.8}$$

where u_ε and u are the corresponding solutions of (1.3) *and* (1.1)*, respectively.*

Remark 1.1. Of course, one can select the controllers ω_ε of (1.3) in a different way. For example, we may take $\omega_\varepsilon = \omega \cup \big(\Omega \cap \mathcal{O}_\varepsilon(\Gamma(x_0))\big)$, where x_0 is a given point in $\mathbb{R}^n$.

Remark 1.2. As noted in [9], Theorem B provides the null-control of the limit heat equation only when $u^0 \in H_0^1(\Omega)$. However, due to the regularizing effect of the heat equation, as soon as we let the heat equation evolve freely (without control) during an arbitrarily short time interval, even if the initial datum lies in $L^2(\Omega)$, the solution enters $H_0^1(\Omega)$, and then the result above applies.

The proof of Theorem B follows the main steps developed in [9]. When doing this we need the following observability estimate for the solutions of the adjoint system:

$$\left\{ \begin{array}{lll} \varepsilon\varphi_{tt} - \Delta\varphi - \varphi_t = 0 & \text{in} & Q, \\ \varphi = 0 & \text{on} & \Sigma, \\ \varphi(T) = \varphi_0,\ \varphi_t(T) = \varphi_1 & \text{in} & \Omega. \end{array} \right. \tag{1.9}$$

THEOREM C. *Let Ω be a bounded domain of $\mathbb{R}^n$ with C^2 boundary Γ. Then for any $T > 0$ there exist two positive constants $\varepsilon_2 = \varepsilon_2(T,\Omega)$ and $C = C(T,\Omega)$ such that*

$$|\varphi_0|^2_{L^2(\Omega)} + \varepsilon|\varphi_1|^2_{H^{-1}(\Omega)} \le Ce^{C/\sqrt{\varepsilon}} \int_0^T \int_{\Omega\cap\mathcal{O}_\varepsilon(\Gamma)} \varphi^2 dxdt \tag{1.10}$$

for all $0 < \varepsilon < \varepsilon_2$ and every solution of (1.9).

The rest of this paper is organized as follows. In section 2, we reduce the proof of Theorem B to the explicit observability estimate (1.10) (in Theorem C). In section 3, we give the proof of Theorem C, which is performed using global Carleman inequalities.

2. Proof of Theorem B. This section is devoted to proving Theorem B. Similar to [9], we will reduce our problem to the sharp observability estimate on the eigenfunctions of the Laplacian in [6] and the explicit observability estimate in our Theorem C. For the reader's convenience, we will give the outline of the proof.

Step 1. *Some notations.*

First of all, we introduce the spectrum of the Laplacian

$$\left\{ \begin{array}{ll} -\Delta e_k = \mu_k e_k & \text{in} \quad \Omega, \\ e_k = 0 & \text{on} \quad \Gamma. \end{array} \right. \tag{2.1}$$

We know that (2.1) admits an increasing sequence of positive eigenvalues of finite multiplicity

$$0 < \mu_1 < \mu_2 \le \cdots \le \mu_k \le \cdots$$

tending to infinity. The eigenfunctions $\{e_k\}_{k\ge1}$ may be chosen to constitute an orthonormal basis of $L^2(\Omega)$.

Next, let us re-endow the Hilbert space $H = H_0^1(\Omega) \times L^2(\Omega)$ with the norm

$$|(u,v)|^2_{H_0^1(\Omega)\times L^2(\Omega)} = |u|^2_{H_0^1(\Omega)} + \varepsilon|v|^2_{L^2(\Omega)}. \tag{2.2}$$

We shall denote the norm (2.2) as $|\cdot|_{H^\varepsilon}$ to make explicit its dependence on ε. The space H endowed with this norm will be denoted by H^ε.

Finally, let us introduce the following subspaces of the space H^ε:

$$H_p^\varepsilon = \{U = (u, v) \in H^\varepsilon : u, v \in \text{span}_{1\le k\le k(\varepsilon)}(e_k)\}, \text{ where } k(\varepsilon) \text{ is such that}$$

$$\frac{1}{4\mu_{k(\varepsilon)+1}} < \varepsilon \le \frac{1}{4\mu_{k(\varepsilon)}};$$

$$H_h^\varepsilon = \{U = (u, v) \in H^\varepsilon : u, v \in \text{span}_{k\ge k(\varepsilon)+1}(e_k)\}, \text{ where } k(\varepsilon) \text{ is as above.}$$

Given $(u, v) \in H^\varepsilon$ we denote its orthogonal projections over H_p^ε by $\pi_p^\varepsilon(u, v)$.

Step 2. *Some preliminaries.*

First of all, we need the following theorem, which concerns the uniform boundedness of the controls of the parabolic component of solutions of (1.3), which is proved in [9] by means of the estimate of [6].

THEOREM 2.1. *Let Ω be a bounded domain of $\mathbb{R}^n$ of class C^∞. Let ω be any open nonempty subset of Ω. Then, there exist two positive constants $\varepsilon_3 = \varepsilon_3(T, \Omega, \omega)$ and $C = C(T, \Omega, \omega)$ such that for all $0 < \varepsilon < \varepsilon_3$ and $(u^0, u^1) \in H^\varepsilon$, there exists a control $f_\varepsilon \in L^2((0, T) \times \omega)$ such that the solution u_ε of*

$$\left\{\begin{array}{lll} \varepsilon u_{\varepsilon,tt} - \Delta u_\varepsilon + u_{\varepsilon,t} = f_\varepsilon \chi_\omega & in & Q, \\ u_\varepsilon = 0 & on & \Sigma, \\ u_\varepsilon(0) = u^0,\ u_{\varepsilon,t}(0) = u^1 & in & \Omega \end{array}\right. \tag{2.3}$$

satisfies

$$\pi_p^\varepsilon(u_\varepsilon(T), u_{\varepsilon,t}(T)) = 0 \tag{2.4}$$

and

$$|f_\varepsilon|_{L^2((0,T)\times\omega)} \le C|(u^0, u^1)|_{H^\varepsilon} \quad \forall\ (u^0, u^1) \in H^\varepsilon. \tag{2.5}$$

Next, let us recall the following known result (see [9]), which is devoted to analyzing the dissipativity of (1.3) over the solutions whose parabolic component vanishes.

THEOREM 2.2. *Let u_ε be a solution of* (1.3) *with $f_\varepsilon \equiv 0$ with initial data $(u^0, u^1) \in H_h^\varepsilon$. Then $(u_\varepsilon(t), u_{\varepsilon,t}(t)) \in H_h^\varepsilon$ for all $t \ge 0$ and*

$$|(u_\varepsilon(t), u_{\varepsilon,t}(t))|_{H^\varepsilon} \le 2^{3/2} e^{-\frac{t}{4\varepsilon}} |(u^0, u^1)|_{H^\varepsilon}. \tag{2.6}$$

Finally, by means of Theorem C (see section 3 for its proof), similar to the proof of Proposition 5.1 in [9], one gets the following result.

THEOREM 2.3. *Let Ω be a bounded domain of $\mathbb{R}^n$ of class C^2. Then, there exists a positive constant $C = C(T, \Omega)$ such that for all $0 < \varepsilon < \varepsilon_2$ (recall Theorem C for ε_2) and $(u^0, u^1) \in H^\varepsilon$, there exists a control $f_\varepsilon \in L^2((0, T) \times (\Omega \cap \mathcal{O}_\varepsilon(\Gamma)))$ such that the solution u_ε of*

$$\left\{\begin{array}{lll} \varepsilon u_{\varepsilon,tt} - \Delta u_\varepsilon + u_{\varepsilon,t} = f_\varepsilon \chi_{\Omega\cap\mathcal{O}_\varepsilon(\Gamma)} & in & Q, \\ u_\varepsilon = 0 & on & \Sigma, \\ u_\varepsilon(0) = u^0,\ u_{\varepsilon,t}(0) = u^1 & in & \Omega \end{array}\right. \tag{2.7}$$

satisfies

$$u_\varepsilon(T) = u_{\varepsilon,t}(T) = 0 \tag{2.8}$$

and

$$|f_\varepsilon|_{L^2((0,T)\times(\Omega\cap\mathcal{O}_\varepsilon(\Gamma)))} \le Ce^{C/\sqrt{\varepsilon}}|(u^0,u^1)|_{H^\varepsilon} \quad \forall\, (u^0,u^1)\in H^\varepsilon. \tag{2.9}$$

Step 3. *Description of the control strategy.*

Let us describe our control strategy. Given $T>0$, denote (recall Theorem 2.1 and Theorem 2.3 for ε_3 and ε_2, respectively)

$$\varepsilon_1 = \varepsilon_1(T,\Omega,\omega) \stackrel{\triangle}{=} \min(\varepsilon_2(T/3,\Omega), \varepsilon_3(T/3,\Omega,\omega)). \tag{2.10}$$

We divide the time interval $[0,T]$ in three subintervals $[0,T] = I_1\cup I_2\cup I_3$ with $I_1=[0,T/3]$, $I_2=[T/3,2T/3]$, and $I_3=[2T/3,T]$. Given an initial datum $(u^0,u^1)\in H_0^1(\Omega)\times L^2(\Omega)$ to be controlled, we proceed as follows.

• **First step.** In the first time interval I_1 we control the parabolic component of the solutions. By Theorem 2.1, for any $\varepsilon\in(0,\varepsilon_1)$ we can build a control $f_{1,\varepsilon}\in L^2((0,T/3)\times\omega)$ such that the solution of

$$\begin{cases} \varepsilon u_{\varepsilon,tt} - \Delta u_\varepsilon + u_{\varepsilon,t} = f_{1,\varepsilon}\chi_\omega & \text{in} \quad (0,T/3)\times\Omega,\\ u_\varepsilon = 0 & \text{on} \quad (0,T/3)\times\Gamma,\\ u_\varepsilon(0)=u^0,\ u_{\varepsilon,t}(0)=u^1 & \text{in} \quad \Omega \end{cases} \tag{2.11}$$

satisfies

$$\pi_p^\varepsilon(u_\varepsilon(T/3),\, u_{\varepsilon,t}(T/3)) = 0 \tag{2.12}$$

and

$$|f_{1,\varepsilon}|_{L^2(\omega\times(0,T/3))} \le C|(u^0,u^1)|_{H^\varepsilon} \quad \forall\,(u^0,u^1)\in H^\varepsilon, \quad \forall\, 0<\varepsilon<\varepsilon_1 \tag{2.13}$$

for some constant $C=C(T,\Omega,\omega)>0$.

In view of the uniform bound (2.13) of the control, by classical energy estimates, we have

$$|(u_\varepsilon(T/3),u_{\varepsilon,t}(T/3))|_{H^\varepsilon} \le C|(u^0,u^1)|_{H^\varepsilon} \quad \forall\,(u^0,u^1)\in H^\varepsilon, \quad \forall\, 0<\varepsilon<\varepsilon_1. \tag{2.14}$$

• **Second step.** In the time interval I_2 we let the equation evolve freely; i.e., we solve

$$\begin{cases} \varepsilon u_{\varepsilon,tt} - \Delta u_\varepsilon + u_{\varepsilon,t} = 0 & \text{in} \quad (T/3,2T/3)\times\Omega,\\ u_\varepsilon = 0 & \text{on} \quad (T/3,2T/3)\times\Gamma,\\ u_\varepsilon(T/3) = v_\varepsilon^0 \stackrel{\triangle}{=} u_\varepsilon(T/3), \quad u_{\varepsilon,t}(T/3) = v_\varepsilon^1 \stackrel{\triangle}{=} u_{\varepsilon,t}(T/3) & \text{in} \quad \Omega. \end{cases} \tag{2.15}$$

By Theorem 2.2, we see that

$$\pi_p^\varepsilon(u_\varepsilon(t),\, u_{\varepsilon,t}(t)) = 0 \quad \forall\, T/3\le t\le 2T/3 \tag{2.16}$$

and

$$|(u_\varepsilon(t),\, u_{\varepsilon,t}(t))|_{H^\varepsilon} \le Ce^{-\frac{(t-T/3)}{4\varepsilon}}|(v_\varepsilon^0,v_\varepsilon^1)|_{H^\varepsilon} \quad \forall\, T/3\le t\le 2T/3, \quad \forall\, 0<\varepsilon<\varepsilon_1 \tag{2.17}$$

for some generic constant $C > 0$. Thus, according to (2.14), we get

$$|(u_\varepsilon(2T/3),\, u_{\varepsilon,t}(2T/3))|_{H^\varepsilon} \le Ce^{\frac{-T}{12\varepsilon}}|(u^0,\, u^1)|_{H^\varepsilon} \quad \forall\, 0 < \varepsilon < \varepsilon_1. \tag{2.18}$$

• **Third step.** In this last step we control the whole solution to zero. By Theorem 2.3, for any $\varepsilon \in (0, \varepsilon_1)$, one can find a control $f_{2,\varepsilon} \in L^2((2T/3, T) \times (\Omega \cap \mathcal{O}_\varepsilon(\Gamma)))$ such that the solution of

$$\begin{cases} \varepsilon u_{\varepsilon,tt} - \Delta u_\varepsilon + u_{\varepsilon,t} = f_{2,\varepsilon}\chi_{\Omega\cap\mathcal{O}_\varepsilon(\Gamma)} & \text{in} \quad (2T/3, T) \times \Omega, \\ u_\varepsilon = 0 & \text{on} \quad (2T/3, T) \times \Gamma, \\ u_\varepsilon(2T/3) = w_\varepsilon^0 \triangleq u_\varepsilon(2T/3), \quad u_{\varepsilon,t}(2T/3) = w_\varepsilon^1 \triangleq u_{\varepsilon,t}(2T/3) & \text{in} \quad \Omega \end{cases} \tag{2.19}$$

satisfies

$$u_\varepsilon(T) \equiv u_{\varepsilon,t}(T) \equiv 0 \tag{2.20}$$

and

$$|f_{2,\varepsilon}|_{L^2(\omega\times(2T/3,T))} \le Ce^{C/\sqrt{\varepsilon}}|(w_\varepsilon^0, w_\varepsilon^1)|_{H^\varepsilon} \quad \forall\, 0 < \varepsilon < \varepsilon_1 \tag{2.21}$$

for some constant $C = C(T, \Omega) > 0$.

Combining (2.18) and (2.21), we get

$$|f_{2,\varepsilon}|_{L^2((2T/3,T)\times(\Omega\cap\mathcal{O}_\varepsilon(\Gamma)))} \le Ce^{C/\sqrt{\varepsilon}}e^{\frac{-T}{12\varepsilon}}|(u^0, u^1)|_{H^\varepsilon} \quad \forall\, 0 < \varepsilon < \varepsilon_1 \tag{2.22}$$

for all initial data $(u^0, u^1) \in H^\varepsilon$.

This shows that the control

$$f_\varepsilon = \begin{cases} f_{1,\varepsilon}, & 0 \le t \le T/3, \\ 0, & T/3 \le t \le 2T/3, \\ f_{2,\varepsilon}, & 2T/3 \le t \le T, \end{cases} \tag{2.23}$$

is such that the null controllability condition (2.20) holds and, according to (2.13) and (2.22),

$$|f_\varepsilon\chi_{\omega_\varepsilon}|_{L^2(Q)} \le C|(u^0, u^1)|_{H^\varepsilon}. \tag{2.24}$$

Thus we get the uniformly exact controllability of system (1.3).

Step 4. *Completion of the proof.*

Now, by means of the uniform estimate (2.24), proceeding exactly as section 7 in [9], one gets (1.7). Also, similar to Appendix D in [9] (with numerous but small changes), it is easy to obtain (1.8). Thus, the proof of Theorem B is completed. □

3. Proof of Theorem C. We now prove Theorem C.

We first observe that by the change of the time variable $t \to \tau = (T - t)/\sqrt{\varepsilon}$, system (1.9) becomes

$$\begin{cases} \varphi_{\tau\tau} - \Delta\varphi + \frac{1}{\sqrt{\varepsilon}}\varphi_\tau = 0 & \text{in} \quad (0, \widehat{T}) \times \Omega, \\ \varphi = 0 & \text{on} \quad (0, \widehat{T}) \times \Gamma, \\ \varphi(0) = \varphi_0, \quad \varphi_\tau(0) = -\sqrt{\varepsilon}\varphi_1 & \text{in} \quad \Omega, \end{cases} \tag{3.1}$$

where $\widehat{T} = \frac{T}{\sqrt{\varepsilon}}$. To simplify the notation we rewrite it as

$$\begin{cases} w_{tt} - \Delta w + kw_t = 0 & \text{in} \quad Q, \\ w = 0 & \text{on} \quad \Sigma, \\ w(0) = w_0, \quad w_t(0) = w_1 & \text{in} \quad \Omega. \end{cases} \tag{3.2}$$

It is sufficient to derive the following estimate.

THEOREM 3.1. *Let $t_0 \in (2\mathrm{diam}\,\Omega, \infty)$ be given. Then there is a positive constant $C = C(t_0, \Omega)$ such that*

$$|w_0|^2_{L^2(\Omega)} + |w_1|^2_{H^{-1}(\Omega)} \le C\delta^{-6}e^{Ck}\int_0^T\int_{\Omega\cap\mathcal{O}_\delta(\Gamma)} w^2 dxdt \tag{3.3}$$
$$\forall\, k > 0, T \ge t_0, \delta > 0, \text{ and } (w_0, w_1) \in L^2(\Omega)\times H^{-1}(\Omega),$$

where $w(\cdot) \in C([0,T]; L^2(\Omega)) \cap C^1([0,T]; H^{-1}(\Omega))$ is the weak solution of (3.2).

In order to prove Theorem 3.1, we need some preliminaries.

In what follows, we use the notations

$$f_i = f_i(x) \triangleq \frac{\partial f(x)}{\partial x_i},\ i = 1, 2, \dots, n;\ \sum_i \triangleq \sum_{i=1}^n;\ \sum_{i,j} \triangleq \sum_{i,j=1}^n.$$

(On the other hand, x_i is always the ith coordinate of the point x.)

The following three lemmas can be found, for example, in [9] and [10].

LEMMA 3.2. *Let $\lambda > 0$, $\alpha \in (0,1)$, and $k \in \mathbb{R}$ be constant. Let $x_0 \in \mathbb{R}^n$, $T > 0$, and*

$$\begin{cases} \phi(t,s,x) = \frac{1}{2}\left[|x-x_0|^2 - \alpha(t-T/2)^2 - \alpha(s-T/2)^2\right], \\ \ell = \lambda\phi, \\ \Psi = (n-1+\alpha)\lambda. \end{cases} \tag{3.4}$$

Let $z = z(t,s,x) \in C^2(\mathbb{R}^{2+n})$. Denote

$$v \triangleq \theta z \quad \text{with} \quad \theta = e^{\ell}. \tag{3.5}$$

Then

$$\begin{aligned} &\theta^2|z_{tt} + z_{ss} - \Delta z + k(z_t + z_s)|^2 \\ &\ge \Big[(k-2\ell_t)(v_t^2 - v_s^2 + \textstyle\sum_j v_j^2) + 2(k-2\ell_s)v_tv_s \\ &\qquad +4\textstyle\sum_j(\ell_j v_t v_j) + 2\Psi v_t v + (k-2\ell_t)(A+\Psi)v^2\Big]_t \\ &\quad +\Big[(k-2\ell_s)(v_s^2 - v_t^2 + \textstyle\sum_j v_j^2) + 2(k-2\ell_t)v_tv_s \\ &\qquad +4\textstyle\sum_j(\ell_j v_s v_j) + 2\Psi v_s v + (k-2\ell_s)(A+\Psi)v^2\Big]_s \\ &\quad -2\textstyle\sum_j\Big[2\sum_i(\ell_i v_i v_j) - \ell_j\sum_i v_i^2 + (k-2\ell_t)v_tv_j + (k-2\ell_s)v_sv_j \\ &\qquad +\Psi v_j v + \ell_j(v_t^2 + v_s^2) - (A+\Psi)\ell_j v^2\Big]_j \\ &\quad +2(1-\alpha)\lambda\Big(v_t^2 + v_s^2 + \textstyle\sum_j v_j^2\Big) + Bv^2, \end{aligned} \tag{3.6}$$

where

$$\begin{aligned} A = {}&\lambda^2\left[\alpha^2(t-T/2)^2 + \alpha^2(s-T/2)^2 - |x-x_0|^2\right] \\ &+\alpha\lambda k(t+s-T) + (1+\alpha)\lambda \end{aligned} \tag{3.7}$$

and

$$\begin{aligned} B = {}&2(3+\alpha)\lambda^3|x-x_0|^2 - 2\alpha^2\lambda^3(1+3\alpha)\left[(t-T/2)^2 + (s-T/2)^2\right] \\ &-2\alpha\lambda k^2 - 2\alpha\lambda^2 k(1+3\alpha)(t+s-T) - \left[n^2 + 4\alpha n + 1 + 2\alpha + 5\alpha^2\right]\lambda^2. \end{aligned} \tag{3.8}$$

LEMMA 3.3. *Let $0 \le S_1 < S_2 < T_2 < T_1 \le T$ and $k \in \mathbb{R}$ be given. Then there is a constant $C > 0$, which is independent of k, such that*

$$\int_{S_2}^{T_2} |w_t(t,\cdot)|^2_{H^{-1}(\Omega)} dt \le C(1+k^2) \int_{S_1}^{T_1} |w(t,\cdot)|^2_{L^2(\Omega)} dt, \tag{3.9}$$

where $w(\cdot)$ is the weak solution of system (3.2).

LEMMA 3.4. *For any $k \in \mathbb{R}$, it holds that*

$$E(t) \le E(s) e^{2|k|T} \qquad \forall\, t, s \in [0,T], \tag{3.10}$$

where

$$E(t) \triangleq \frac{1}{2} \left(|w_t(t,\cdot)|^2_{H^{-1}(\Omega)} + |w(t,\cdot)|^2_{L^2(\Omega)} \right), \tag{3.11}$$

with $w(\cdot)$ being the weak solution of system (3.2).

The following lemma can be found, for example, in [2].

LEMMA 3.5. *If X is an open nonempty subset in $\mathbb{R}^n$ and K is a compact subset of X, then one can find $\xi \in C_0^\infty(X)$ with $0 \le \xi \le 1$ so that $\xi = 1$ on a neighborhood of K. And it holds that*

$$\sup_{x \in X} |\partial^\beta \xi(x)| \le C_\beta \delta^{-|\beta|}, \tag{3.12}$$

where $\beta = (\beta_1, \dots, \beta_n)$ is a multi-index with nonnegative integer components and $|\beta| = \beta_1 + \cdots + \beta_n$, $\delta = \operatorname{dist}(K, \partial X)/4$ and C_β depends only on β and n.

Now, let us prove Theorem 3.1.

Proof of Theorem 3.1. We divide the proof into several steps.

Step 1. *Selection of pseudoconvex function.*

First of all, we see easily that it suffices to prove Theorem 3.1 under the condition

$$T = t_0.$$

The main idea of our proof is to use the pointwise estimate (3.6) in Lemma 3.2. For this purpose, we need to choose some suitable pseudoconvex function ϕ, that is, to choose x_0 and α.

By $T > 2\operatorname{diam}\Omega$, one can find a point $x_0 \in \mathbb{R}^n \backslash \overline{\Omega}$ such that $T > 2\max_{x\in\Omega} |x - x_0|$. Put

$$R_0 \triangleq \min_{x\in\Omega} |x - x_0|, \qquad R_1 \triangleq \max_{x\in\Omega} |x - x_0|. \tag{3.13}$$

Then $R_0 > 0$ and $T > 2R_1$. Thus we can choose an $\alpha \in (3/4, 1)$ such that

$$R_1^2 < \alpha (T/2)^2. \tag{3.14}$$

Having chosen x_0 and α as above, we next introduce the desired pseudoconvex function ϕ by setting

$$\phi = \phi(t,s,x) \triangleq \frac{1}{2} \left[|x - x_0|^2 - \alpha (t - T/2)^2 - \alpha (s - T/2)^2 \right]. \tag{3.15}$$

Step 2. *Some notations and transformations.*
We need the following notations. Denote

$$\begin{cases} \mathcal{Q} \triangleq (0,T)\times Q, \quad \mathcal{S} \triangleq (0,T)\times \Sigma, \\ T_i \triangleq T/2 - b_i T, \quad T_i' \triangleq T/2 + b_i T, \\ \mathcal{Q}_i \triangleq (T_i,T_i')\times(T_i,T_i')\times\Omega, \quad \mathcal{S}_i \triangleq (T_i,T_i')\times(T_i,T_i')\times\Gamma \end{cases} \tag{3.16}$$

and

$$\Lambda_j \triangleq \left\{ (t,s,x)\in \mathcal{Q} \;\middle|\; 2\phi(t,s,x) \geq \frac{R_0^2}{j+2} \right\}, \tag{3.17}$$

where $i = 0,1,2,3$; $j = 0,1,2$ and $0 < b_0 < b_1 < b_2 < b_3 < 1/2$ will be given below.

In order to determine b_i $(i = 0,1,2,3)$, we need an idea in [5]. First of all, by (3.13)–(3.15), one sees that

$$\phi(0,s,x) = \phi(T,s,x) \leq \frac{1}{2}\left(R_1^2 - \frac{\alpha T^2}{4}\right) < 0 \quad \forall\, (s,x)\in Q. \tag{3.18}$$

Thus, one can find a $b_1 \in (0,1/2)$ (close to $1/2$) such that (recall (3.16)–(3.17) for $\mathcal{Q}_1$, T_1, T_1', and Λ_2)

$$\Lambda_2 \subset \mathcal{Q}_1 \tag{3.19}$$

and for any $(t,s,x) \in (((0,T_1)\cup(T_1',T))\times Q)\cup((0,T)\times((0,T_1)\cup(T_1',T))\times\Omega)$ it holds that

$$\phi(t,s,x) < 0. \tag{3.20}$$

Next, noting that $R_0 > 0$ and $\{T/2\}\times\{T/2\}\times\Omega \subset \Lambda_0$, thus one finds a small $b_0 \in (0,b_1)$ such that (recall (3.17) and (3.16) for Λ_0 and $\mathcal{Q}_0$, respectively)

$$\mathcal{Q}_0 \subset \Lambda_0. \tag{3.21}$$

Finally, we fix any two numbers b_2 and b_3 satisfying $b_1 < b_2 < b_3 < 1/2$.

Now, we note that (recall (3.8) for B)

$$B = B\chi_{\Lambda_2}(t,s,x) + B\chi_{\mathcal{Q}\setminus\Lambda_2}(t,s,x). \tag{3.22}$$

First, we will prove Theorem 3.1 under the condition $k > 0$ being big enough. For this purpose, let us take

$$k = \beta\lambda, \tag{3.23}$$

where $\beta \in (0,1)$ is a constant to be determined later. Note that by (3.8) and (3.23), we have

$$\begin{aligned} B\chi_{\Lambda_2}(t,s,x) &\geq \Big\{ 2\alpha(1+3\alpha)\Big[|x-x_0|^2 - \alpha(t-T/2)^2 - \alpha(s-T/2)^2\Big]\lambda^3 \\ &\quad -2\alpha[\beta + (1+3\alpha)(t+s-T)]\beta\lambda^3 \\ &\quad -[n^2 + 4\alpha n + 1 + 2\alpha + 5\alpha^2]\lambda^2\Big\}\chi_{\Lambda_2}(t,s,x) \\ &\geq \Big\{ \tfrac{1}{2}\alpha(1+3\alpha)R_0^2\lambda^3 - C\beta\lambda^3 - \Big[n^2 + 4\alpha n + 1 + 2\alpha + 5\alpha^2\Big]\lambda^2\Big\}\chi_{\Lambda_2}(t,s,x), \end{aligned} \tag{3.24}$$

where $C = C(\alpha, T) > 0$ is a constant, independent of β. Thus, by (3.23)–(3.24) and (3.8), one sees easily that there exist a sufficiently small constant $\beta \in (0,1)$ and a sufficiently large constant $\lambda_1 > 1$ such that for any $\lambda > \lambda_1$, it holds that

$$B\chi_{\Lambda_2}(t,s,x) \geq c_0\lambda^3\chi_{\Lambda_2}(t,s,x) \tag{3.25}$$

and

$$\left|B\chi_{\mathcal{Q}\setminus\Lambda_2}(t,s,x)\right| \leq C\lambda^3 \tag{3.26}$$

for some constants $c_0 > 0$ and $C > 0$.

Finally, we need some transformations. For any fixed $\delta > 0$, by Lemma 3.5, we can choose a function $\xi \in C_0^\infty(\mathbb{R}^n; [0,1])$ such that

$$\begin{cases} \xi \equiv 1 & \text{on } \Omega \setminus \mathcal{O}_{\delta/2}(\Gamma); \\ \xi \equiv 0 & \text{on } \Omega \cap \mathcal{O}_{\delta/3}(\Gamma). \end{cases} \tag{3.27}$$

Set

$$p = p(t,x) \triangleq \xi(x)w(t,x), \quad (t,x) \in Q, \tag{3.28}$$

where w is the weak solution of (3.2). Then by (3.2), it is easy to see that

$$\begin{cases} p_{tt} - \Delta p + kp_t = -w\Delta\xi - 2(\nabla w)\cdot(\nabla\xi) & \text{in } Q, \\ p = 0 & \text{on } \Sigma, \\ p \equiv 0 & \text{in } (0,T)\times(\Omega\cap\mathcal{O}_{\delta/3}(\Gamma)). \end{cases} \tag{3.29}$$

The following simple transformations will play an important role in what follows. Put

$$z(t,s,x) \triangleq \int_s^t p(\tau,x)d\tau, \qquad Z(t,s,x) \triangleq \int_s^t w(\tau,x)d\tau. \tag{3.30}$$

Then $z(\cdot)$ satisfies (recall (3.16) for $\mathcal{Q}$ and $\mathcal{S}$)

$$\begin{cases} z_{tt} + z_{ss} - \Delta z + k(z_t + z_s) = -Z\Delta\xi - 2(\nabla Z)\cdot(\nabla\xi) & \text{in } \mathcal{Q}, \\ z = 0 & \text{on } \mathcal{S}, \\ z \equiv 0 & \text{in } (0,T)^2\times(\Omega\cap\mathcal{O}_{\delta/3}(\Gamma)). \end{cases} \tag{3.31}$$

Step 3. *Carleman-type estimate.*

For any given $\tau \in (T_2, T_1)$ and $\tau' \in (T_1', T_2')$ (recall (3.16) for T_i and T_i'), denote

$$\mathcal{Q}_\tau^{\tau'} \triangleq (\tau,\tau')\times(\tau,\tau')\times\Omega. \tag{3.32}$$

Let us observe (3.6), where z is given by (3.30) and ϕ is given by (3.15). Integrating (3.6) on $\mathcal{Q}_\tau^{\tau'}$, using integration by parts, and taking (3.31) into account, we arrive at the following (recall (3.5) for v and θ, and recall (3.16) for $\mathcal{Q}_2$, T_2, and T_2'):

$$\begin{aligned}
&2(1-\alpha)\lambda\textstyle\int_{\mathcal{Q}_\tau^{\tau'}}(v_t^2 + v_s^2 + \sum_i v_i^2)dxdtds + \int_{\mathcal{Q}_\tau^{\tau'}} Bv^2dxdtds \\
&\leq \textstyle\int_{\mathcal{Q}_2}\theta^2\left|Z\Delta\xi + 2(\nabla Z)\cdot(\nabla\xi)\right|^2dxdtds \\
&\quad + C\lambda^3\Big[\textstyle\int_{T_2}^{T_2'}\int_\Omega\Big(|v(\tau,s,x)|^2 + |v_t(\tau,s,x)|^2 + |v_s(\tau,s,x)|^2 + \sum_i|v_i(\tau,s,x)|^2 \\
&\quad + |v(\tau',s,x)|^2 + |v_t(\tau',s,x)|^2 + |v_s(\tau',s,x)|^2 + \textstyle\sum_i|v_i(\tau',s,x)|^2\Big)dxds \\
&\quad + \textstyle\int_{T_2}^{T_2'}\int_\Omega\Big(|v(t,\tau,x)|^2 + |v_t(t,\tau,x)|^2 + |v_s(t,\tau,x)|^2 + \sum_i|v_i(t,\tau,x)|^2 \\
&\quad + |v(t,\tau',x)|^2 + |v_t(t,\tau',x)|^2 + |v_s(t,\tau',x)|^2 + \textstyle\sum_i|v_i(t,\tau',x)|^2\Big)dxdt\Big] \quad \forall\,\lambda > \lambda_1.
\end{aligned} \tag{3.33}$$

However, recalling $v=\theta z$ with $\theta=e^{\ell}$, by (3.15) and (3.20), we get

$$
\begin{aligned}
&\int_{T_2}^{T_2'}\int_\Omega \Big(|v(\tau,s,x)|^2+|v_t(\tau,s,x)|^2+|v_s(\tau,s,x)|^2+\textstyle\sum_i|v_i(\tau,s,x)|^2\\
&\quad+|v(\tau',s,x)|^2+|v_t(\tau',s,x)|^2+|v_s(\tau',s,x)|^2+\textstyle\sum_i|v_i(\tau',s,x)|^2\Big)dxds\\
&\quad+\int_{T_2}^{T_2'}\int_\Omega \Big(|v(t,\tau,x)|^2+|v_t(t,\tau,x)|^2+|v_s(t,\tau,x)|^2+\textstyle\sum_i|v_i(t,\tau,x)|^2\\
&\quad+|v(t,\tau',x)|^2+|v_t(t,\tau',x)|^2+|v_s(t,\tau',x)|^2+\textstyle\sum_i|v_i(t,\tau',x)|^2\Big)dxdt\\
&\le C\lambda^2\Big[\int_{T_2}^{T_2'}\int_\Omega \Big(|z(\tau,s,x)|^2+|z_t(\tau,s,x)|^2+|z_s(\tau,s,x)|^2+\textstyle\sum_i|z_i(\tau,s,x)|^2\\
&\quad+|z(\tau',s,x)|^2+|z_t(\tau',s,x)|^2+|z_s(\tau',s,x)|^2+\textstyle\sum_i|z_i(\tau',s,x)|^2\Big)dxds\\
&\quad+\int_{T_2}^{T_2'}\int_\Omega \Big(|z(t,\tau,x)|^2+|z_t(t,\tau,x)|^2+|z_s(t,\tau,x)|^2+\textstyle\sum_i|z_i(t,\tau,x)|^2\\
&\quad+|z(t,\tau',x)|^2+|z_t(t,\tau',x)|^2+|z_s(t,\tau',x)|^2+\textstyle\sum_i|z_i(t,\tau',x)|^2\Big)dxdt\Big].
\end{aligned}
\tag{3.34}
$$

Further, by (3.17), (3.4)–(3.5), (3.15), and (3.25)–(3.26), we get

$$
\begin{aligned}
\int_{\mathcal{Q}_\tau^{\tau'}}Bv^2dxdtds &= \int_{\mathcal{Q}_\tau^{\tau'}\cap\Lambda_2}Bv^2dxdtds+\int_{\mathcal{Q}_\tau^{\tau'}\setminus\Lambda_2}Bv^2dxdtds\\
&\ge c_0\lambda^3\int_{\mathcal{Q}_\tau^{\tau'}\cap\Lambda_2}v^2dxdtds-C\lambda^3e^{R_0^2\lambda/4}\int_{\mathcal{Q}}z^2dxdtds\quad\forall\,\lambda>\lambda_1.
\end{aligned}
\tag{3.35}
$$

Note that by (3.17), (3.19), and (3.32), we have $\mathcal{Q}_\tau^{\tau'}\supset\Lambda_1$. Thus, by (3.35), for any $\lambda>\lambda_1$, we have

$$
\begin{aligned}
&2(1-\alpha)\lambda\int_{\mathcal{Q}_\tau^{\tau'}}(v_t^2+v_s^2+\textstyle\sum_i v_i^2)dxdtds+\int_{\mathcal{Q}_\tau^{\tau'}}Bv^2dxdtds\\
&\ge c_1\Big[\lambda\int_{\Lambda_1}(v_t^2+v_s^2+\textstyle\sum_i v_i^2)dxdtds+\lambda^3\int_{\Lambda_1}v^2dxdtds\Big]-C\lambda^3e^{R_0^2\lambda/4}\int_{\mathcal{Q}}z^2dxdtds,
\end{aligned}
\tag{3.36}
$$

where $c_1>0$ and $C>0$ are two constants, independent of λ.

Now, combining (3.33)–(3.34) and (3.36), we conclude that for any $\lambda>\lambda_1$, it holds that

$$
\begin{aligned}
&\int_{\Lambda_1}(v_t^2+v_s^2+\textstyle\sum_i v_i^2)dxdtds+\lambda^2\int_{\Lambda_1}\theta^2v^2dxdtds\\
&\le C\lambda^{-1}\Big\{e^{C\lambda}\int_{\mathcal{Q}_2}|Z\Delta\xi+2(\nabla Z)\cdot(\nabla\xi)|^2dxdtds\\
&\quad+\lambda^5\Big[\int_{T_2}^{T_2'}\int_\Omega \Big(|z(\tau,s,x)|^2+|z_t(\tau,s,x)|^2+|z_s(\tau,s,x)|^2+\textstyle\sum_i|z_i(\tau,s,x)|^2\\
&\quad+|z(\tau',s,x)|^2+|z_t(\tau',s,x)|^2+|z_s(\tau',s,x)|^2+\textstyle\sum_i|z_i(\tau',s,x)|^2\Big)dxds\\
&\quad+\int_{T_2}^{T_2'}\int_\Omega \Big(|z(t,\tau,x)|^2+|z_t(t,\tau,x)|^2+|z_s(t,\tau,x)|^2+\textstyle\sum_i|z_i(t,\tau,x)|^2\\
&\quad+|z(t,\tau',x)|^2+|z_t(t,\tau',x)|^2+|z_s(t,\tau',x)|^2+\textstyle\sum_i|z_i(t,\tau',x)|^2\Big)dxdt\Big]\\
&\quad+\lambda^3e^{R_0^2\lambda/4}\int_{\mathcal{Q}}z^2dxdtds\Big\}.
\end{aligned}
\tag{3.37}
$$

Integrating (3.37) with respect to τ and τ' from T_2 to T_1 and from T_1' to T_2', respectively, we get

$$
\begin{aligned}
&\int_{\Lambda_1}(v_t^2+v_s^2+\textstyle\sum_i v_i^2)dxdtds+\lambda^2\int_{\Lambda_1}v^2dxdtds\\
&\le C\lambda^{-1}\Big\{e^{C\lambda}\int_{\mathcal{Q}_2}|Z\Delta\xi+2(\nabla Z)\cdot(\nabla\xi)|^2dxdtds\\
&\qquad+\lambda^5\int_{\mathcal{Q}_2}\Big(z^2+z_t^2+z_s^2+\textstyle\sum_i z_i^2\Big)dxdtds+\lambda^3e^{R_0^2\lambda/4}\int_{\mathcal{Q}}z^2dxdtds\Big\}.
\end{aligned}
\tag{3.38}
$$

Consequently, by (3.4)–(3.5) and (3.15), and using (3.38), we see that for any $\lambda>\lambda_1$,

it holds that

$$\begin{aligned}&\int_{\Lambda_1}\theta^2(z_t^2+z_s^2+\textstyle\sum_i z_i^2)dxdtds\\ &\le C\lambda^{-1}\Big\{e^{C\lambda}\int_{\mathcal{Q}_2}|Z\Delta\xi+2(\nabla Z)\cdot(\nabla\xi)|^2dxdtds\\ &\qquad+\lambda^5\int_{\mathcal{Q}_2}\Big(z^2+z_t^2+z_s^2+\textstyle\sum_i z_i^2\Big)dxdtds+\lambda^3e^{R_0^2\lambda/4}\int_{\mathcal{Q}}z^2dxdtds\Big\}.\end{aligned}\tag{3.39}$$

Note that by (3.17) and (3.21), we have

$$\int_{\Lambda_1}\theta^2(z_t^2+z_s^2)dxdtds\ge\int_{\Lambda_0}\theta^2(z_t^2+z_s^2)dxdtds\ge e^{R_0^2\lambda/2}\int_{\mathcal{Q}_0}(z_t^2+z_s^2)dxdsdt.\tag{3.40}$$

Thus, by (3.39)–(3.40), we see that for any $\lambda>\lambda_1$ it holds that

$$\begin{aligned}&\int_{\mathcal{Q}_0}(z_t^2+z_s^2)dxdtds\\ &\le C_1\lambda^{-1}\Big\{e^{C_1\lambda}\int_{\mathcal{Q}_2}|Z\Delta\xi+2(\nabla Z)\cdot(\nabla\xi)|^2dxdtds\\ &\qquad+\lambda^5e^{-R_0^2\lambda/2}\int_{\mathcal{Q}_2}\Big(z^2+z_t^2+z_s^2+\textstyle\sum_i z_i^2\Big)dxdtds+\lambda^3e^{-R_0^2\lambda/4}\int_{\mathcal{Q}}z^2dxdtds\Big\},\end{aligned}\tag{3.41}$$

where $C_1>0$ is a generic constant.

Step 4. *Estimate on* $\int_{\mathcal{Q}_2}\sum_i z_i^2dxdsdt$.

Denote

$$\eta\triangleq(t-T_3)(T_3'-t)(s-T_3)(T_3'-s).\tag{3.42}$$

Multiplying the first equation of (3.31) by ηz, integrating it on $\mathcal{Q}_3$ (recall (3.16) for $\mathcal{Q}_3$), using integration by parts, by (3.23), and noting that

$$\eta(t,s)\ge(T_2-T_3)^2(T_3'-T_2)^2\quad\forall\,t\,,s\in(T_2,T_2'),$$

we get

$$\int_{\mathcal{Q}_2}\sum_i z_i^2dxdsdt\le C\left[\lambda\int_{\mathcal{Q}_3}(z_t^2+z_s^2+z^2)dxdsdt+\int_{\mathcal{Q}_3}|Z\Delta\xi+2(\nabla Z)\cdot(\nabla\xi)|^2dxdsdt\right].\tag{3.43}$$

Thus, by (3.41) and (3.43), we conclude that there is a constant $\lambda_2>\lambda_1$, which depends only on C_1 (in (3.41)) and R_0, such that

$$\begin{aligned}\int_{\mathcal{Q}_0}(z_t^2+z_s^2)dxdtds\le C\Big\{&\lambda^{-3}e^{C\lambda}\int_{\mathcal{Q}_3}|Z\Delta\xi+2(\nabla Z)\cdot(\nabla\xi)|^2dxdtds\\ &+\lambda^{-2}e^{-R_0^2\lambda/8}\int_{\mathcal{Q}}(z^2+z_t^2+z_s^2)dxdsdt\Big\}\quad\forall\,\lambda>\lambda_2.\end{aligned}\tag{3.44}$$

Step 5. *Estimate on* $\int_{\mathcal{Q}_3}|Z\Delta\xi+2(\nabla Z)\cdot(\nabla\xi)|^2dxdtds$.

Note that by (3.16), (3.27), and Lemma 3.5, using Poincáre's inequality, we have

$$\begin{aligned}\int_{\mathcal{Q}_3}|Z\Delta\xi+2(\nabla Z)\cdot(\nabla\xi)|^2dxdtds&=\int_{T_3}^{T_3'}\int_{T_3}^{T_3'}\int_{\Omega\cap\mathcal{O}_{\delta/2}(\Gamma)}|Z\Delta\xi+2(\nabla Z)\cdot(\nabla\xi)|^2dxdtds\\ &\le C\delta^{-4}\int_{T_3}^{T_3'}\int_{T_3}^{T_3'}\int_{\Omega\cap\mathcal{O}_{\delta/2}(\Gamma)}|\nabla Z|^2dxdtds.\end{aligned}\tag{3.45}$$

We need to estimate $\int_{T_3}^{T_3'}\int_{T_3}^{T_3'}\int_{\Omega\cap\mathcal{O}_{\delta/2}(\Gamma)}|\nabla Z|^2dxdsdt$. By (3.30) and (3.2), we see that $Z(\cdot)$ satisfies

$$\begin{cases}Z_{tt}+Z_{ss}-\Delta Z+k(Z_t+Z_s)=0 & \text{in }\mathcal{Q},\\ Z=0 & \text{on }\mathcal{S}.\end{cases}\tag{3.46}$$

By Lemma 3.5, we can choose a function $\zeta \in C_0^\infty(\mathbb{R}^n;[0,1])$ such that

$$\begin{cases} \zeta \equiv 1 & \text{on } \Omega \setminus \mathcal{O}_{2\delta/3}(\Gamma); \\ \zeta \equiv 0 & \text{on } \Omega \cap \mathcal{O}_{\delta/2}(\Gamma). \end{cases} \tag{3.47}$$

Denote

$$\psi \triangleq t(T-t)s(T-s)(1-\zeta). \tag{3.48}$$

Multiplying the first equation of (3.46) by $\psi^2 Z$, integrating it on $\mathcal{Q}$, by (3.46)–(3.47) and using integration by parts, and noting (3.23), we get for any $\lambda > 1$

$$\begin{aligned} &\int_{\mathcal{Q}} \psi^2 |\nabla Z|^2 dxdsdt \\ &= -\int_{\mathcal{Q}} \psi^2 \Big[Z_{tt} + Z_{ss} + k(Z_t + Z_s) \Big] Z dxdsdt - 2\int_{\mathcal{Q}} (\nabla Z)\cdot(\nabla\psi)\psi Z dxdsdt \\ &= 2\int_{\mathcal{Q}} \psi(\psi_t Z_t + \psi_s Z_s) Z dxdsdt + \int_{\mathcal{Q}} \psi^2 (Z_t^2 + Z_s^2) dxdsdt \\ &\quad -k\int_{\mathcal{Q}} \psi^2 (Z_t + Z_s) Z dxdsdt - 2\int_{\mathcal{Q}} \psi (\nabla Z)\cdot(\nabla\psi) Z dxdsdt \\ &\le C\lambda \int_{\mathcal{Q}} (1-\zeta)(Z^2 + Z_t^2 + Z_s^2) dxdsdt + C\int_{\mathcal{Q}} |\nabla\psi|^2 Z^2 dxdsdt \\ &\quad + \tfrac{1}{2}\int_{\mathcal{Q}} \psi^2 |\nabla Z|^2 dxdsdt. \end{aligned} \tag{3.49}$$

Note that by (3.47) and Lemma 3.5, we have

$$\begin{aligned} &\int_{\mathcal{Q}} |\nabla\psi|^2 Z^2 dxdsdt \le C\int_{\mathcal{Q}} |\nabla(1-\zeta)|^2 Z^2 dxdsdt \\ &= C\int_0^T \int_0^T \int_{\Omega\cap\mathcal{O}_\delta(\Gamma)} |\nabla\zeta|^2 Z^2 dxdsdt \le C\delta^{-2}\int_0^T \int_0^T \int_{\Omega\cap\mathcal{O}_\delta(\Gamma)} Z^2 dxdsdt. \end{aligned} \tag{3.50}$$

Thus, combining (3.49)–(3.50), noting (3.48), we get

$$\begin{aligned} &\int_{T_3}^{T_3'} \int_{T_3}^{T_3'} \int_{\Omega\cap\mathcal{O}_{\delta/2}(\Gamma)} |\nabla Z|^2 dxdsdt \\ &\le C(\lambda + \delta^{-2}) \int_0^T \int_0^T \int_{\Omega\cap\mathcal{O}_\delta(\Gamma)} (Z^2 + Z_t^2 + Z_s^2) dxdsdt. \end{aligned} \tag{3.51}$$

Combining (3.45) and (3.51), we get

$$\begin{aligned} &\int_{\mathcal{Q}_3} |Z\Delta\xi + 2(\nabla Z)\cdot(\nabla\xi)|^2 dxdtds \\ &\le C\delta^{-4}(\lambda + \delta^{-2}) \int_0^T \int_0^T \int_{\Omega\cap\mathcal{O}_\delta(\Gamma)} (Z^2 + Z_t^2 + Z_s^2) dxdsdt. \end{aligned} \tag{3.52}$$

Now, by (3.44) and (3.52), and noting that $\delta \in (0,1)$ and $\lambda_2 > 1$, we get

$$\begin{aligned} \int_{\mathcal{Q}_0} (z_t^2 + z_s^2) dxdtds \le C\lambda^{-2} \Big\{ &\delta^{-6} e^{C\lambda} \int_0^T \int_0^T \int_{\Omega\cap\mathcal{O}_\delta(\Gamma)} (Z^2 + Z_t^2 + Z_s^2) dxdsdt \\ &+ e^{-R_0^2\lambda/8} \int_{\mathcal{Q}} (z^2 + z_t^2 + z_s^2) dxdsdt \Big\} \quad \forall\, \lambda > \lambda_2. \end{aligned} \tag{3.53}$$

Step 6. *Completion of the proof when k large enough.*

Let us return to "w." By (3.53), (3.16), (3.28), and (3.30), one arrives at

$$\begin{aligned} \int_{T_0}^{T_0'} \int_{\Omega\setminus\mathcal{O}_{\delta/2}(\Gamma)} w^2 dxdt \le C\lambda^{-2} \Big[&\delta^{-6} e^{C\lambda} \int_0^T \int_{\Omega\cap\mathcal{O}_\delta(\Gamma)} w^2 dxdt \\ &+ e^{-R_0^2\lambda/8} \int_0^T \int_\Omega w^2 dxdt \Big] \quad \forall\, \lambda > \lambda_2. \end{aligned} \tag{3.54}$$

Now, adding both sides of (3.54) by $\int_{T_0}^{T_0'} \int_{\Omega\cap\mathcal{O}_{\delta/2}(\Gamma)} w^2 dxdt$, we conclude that

$$\begin{aligned} \int_{T_0}^{T_0'} \int_\Omega w^2 dxdt \le C\lambda^{-2} \Big[&\delta^{-6} e^{C\lambda} \int_0^T \int_{\Omega\cap\mathcal{O}_\delta(\Gamma)} w^2 dxdt \\ &+ e^{-R_0^2\lambda/8} \int_0^T E(t) dxdt \Big] \quad \forall\, \lambda > \lambda_2, \end{aligned} \tag{3.55}$$

where $E(t)$ is defined by (3.11).

However, taking two numbers S_0 and S_0' such that $T_0 < S_0 < S_0' < T_0'$, using Lemma 3.3, and noting (3.23), we see that

$$\int_{S_0}^{S_0'} E(s)ds \le C(1+\lambda^2)\int_{T_0}^{T_0'}\int_\Omega w^2 dxdt. \tag{3.56}$$

Combining (3.55) and (3.56), we arrive at

$$\int_{S_0}^{S_0'} E(s)ds \le C\left[\delta^{-6}e^{C\lambda}\int_0^T\int_{\Omega\cap\mathcal{O}_\delta(\Gamma)} w^2 dxdt + e^{-R_0^2\lambda/8}\int_0^T E(t)dxdt\right] \quad \forall\,\lambda>\lambda_2. \tag{3.57}$$

On the other hand, by Lemma 3.4 and (3.57), and noting (3.23), we get

$$E(0) \le C\left[\delta^{-6}e^{C\lambda}\int_0^T\int_{\Omega\cap\mathcal{O}_\delta(\Gamma)} w^2 dxdt + e^{(4T\beta-R_0^2/8)\lambda}E(0)\right] \quad \forall\,\lambda>\lambda_2. \tag{3.58}$$

Note that we can take $\beta>0$ small enough such that $4T\beta < R_0^2/12$. Thus by (3.58), we see that

$$E(0) \le C_2\left[\delta^{-6}e^{C_2\lambda}\int_0^T\int_{\Omega\cap\mathcal{O}_\delta(\Gamma)} w^2 dxdt + e^{-R_0^2\lambda/24}E(0)\right] \quad \forall\,\lambda>\lambda_2, \tag{3.59}$$

where $C_2>0$ is a generic constant.

Now, let us take a constant $\lambda_3>\lambda_2$ such that

$$C_2 e^{-R_0^2\lambda_3/24} < 1/2. \tag{3.60}$$

Then, by (3.59)–(3.60), we conclude that

$$E(0) \le C\delta^{-6}e^{C\lambda}\int_0^T\int_{\Omega\cap\mathcal{O}_\delta(\Gamma)} w^2 dxdt \quad \forall\,\lambda>\lambda_3. \tag{3.61}$$

Now, combining (3.61) and (3.23), we obtain the desired estimate under the condition $\lambda>\lambda_3$, or $k>k_0\triangleq\beta\lambda_3$ (recall (3.23)).

Step 7. *Completion of the proof when* $0<k\le k_0$.

Finally, let us consider the case $0<k\le k_0$. It is easy to see that (3.25)–(3.26) remains true in this case. Thus, proceeding as in (3.25)–(3.61) of the previous case the proof may be completed easily. □

A CONJUGATE POINTS THEORY FOR A NONLINEAR PROGRAMMING PROBLEM*

H. KAWASAKI†

Abstract. The conjugate point is an important global concept in the calculus of variations and optimal control. In these extremal problems, the variable is not a vector in R^n but a function. So a simple and natural question arises. Is it possible to establish a conjugate points theory for a nonlinear programming problem, Min $f(x)$ on $x \in R^n$? This paper positively answers this question. We introduce the Jacobi equation and conjugate points for the nonlinear programming problem, and we describe necessary and sufficient optimality conditions in terms of conjugate points.

Key words. conjugate points, strict conjugate points, Jacobi equation, Legendre condition, positive-definite, shortest path problem, Sylvester's criterion, principal minors

1. Introduction. In this paper, we establish a conjugate points theory for a nonlinear programming problem,

$$\text{(P)} \qquad \text{Min} \quad f(x) \quad \text{on} \quad x \in R^n,$$

where $f : R^n \to R$ is assumed to be twice continuously differentiable. We will define conjugate points for (P) based on the insight in Gelfand and Fomin [1] by comparing (P) with the simplest problem in the calculus of variations,

$$\text{(SP)} \quad \begin{array}{l} \text{Min} \displaystyle\int_0^T f(t, x(t), \dot{x}(t))dt \\ \text{subject to} \quad x(0) = A,\ x(T) = B, \end{array}$$

where A and B are given points in R^n, $T > 0$ fixed, and f is a smooth function. So, we first review the classical conjugate points theory for (SP) in brief. Let $\bar{x}(t)$ be a weak minimum for (SP). Then it satisfies the Euler equation $df_{\dot{x}}(t, \bar{x}(t), \dot{\bar{x}}(t))/dt = f_x(t, \bar{x}(t), \dot{\bar{x}}(t))$ (1744) and the Legendre condition $f_{\dot{x}\dot{x}}(t, \bar{x}(t), \dot{\bar{x}}(t)) \geq 0$ (1786). Legendre attempted to prove its inverse; that is, he expected that if a feasible solution $\bar{x}(t)$ satisfies the Euler equation and the strengthened Legendre condition $f_{\dot{x}\dot{x}}(t, \bar{x}(t), \dot{\bar{x}}(t)) > 0$, then $\bar{x}(t)$ would be a weak minimum. However, his conjecture was false. Jacobi solved this problem by introducing conjugate points in 1837. For a feasible solution $\bar{x}(t)$ of (SP), conjugate points are defined via the Jacobi equation

$$\frac{d}{dt}\{\bar{f}_{\dot{x}x}(t)y(t) + \bar{f}_{\dot{x}\dot{x}}(t)\dot{y}(t)\} = \bar{f}_{xx}(t)y(t) + \bar{f}_{x\dot{x}}(t)\dot{y}(t), \tag{1.1}$$

where $\bar{f}_{\dot{x}\dot{x}}(t) := f_{\dot{x}\dot{x}}(t, \bar{x}(t), \dot{\bar{x}}(t))$, etc. A point $c \in (0, T]$ is said to be *conjugate to* $t = 0$ if there exists a nontrivial solution $y(t)$ of the Jacobi equation (1.1) on $[0, c]$ and $y(0) = y(c) = 0$.

THEOREM 1.1 (Jacobi). *If $\bar{x}(t)$ is a weak minimum for the simplest problem* (SP) *and it satisfies the strengthened Legendre condition, then there is no point conjugate to $t = 0$ on $[0, T)$. Conversely, if $\bar{x}(t)$ satisfies the Euler equation and the strengthened Legendre condition, and if there is no point conjugate to $t = 0$ on $[0, T]$, then $\bar{x}(t)$ is a weak minimum.*

Recently, conjugate points have been extended to complex extremal problems such as optimal control problems and variational problems with state constraints; see, for example, [3, 4, 6, 7, 8, 9, 10, 11]. The present paper is outside of this trend. We deal with the elementary extremal problem (P). It seems to the author that one reason why researchers have not paid much attention to conjugate points for (P) lies in the following elementary results.

THEOREM 1.2. *If $\bar{x}$ is a minimum for* (P)*, then it satisfies $f'(\bar{x}) = 0$ and $f''(\bar{x}) \geq 0$. Conversely, if $\bar{x}$ satisfies $f'(\bar{x}) = 0$ and $f''(\bar{x}) > 0$, then it is a minimum for* (P)*, where $\geq$ and $>$ stand for nonnegative definite and positive-definite, respectively.*

Theorem 1.2 seems to assert that there is no room for conjugate points to play a role in (P). However, an interesting connection between Jacobi's condition and the theory of quadratic forms in R^n was discussed in Gelfand and Fomin [1, p. 125]; see section 2 of the present paper. Furthermore, the author [2, p. 8] recently found a stimulating example that strongly indicates the possibility to establish a conjugate points theory for (P).

EXAMPLE 1.1. *Let us first consider the shortest path problem on the unit sphere S in R^3. It is finding a shortest path on S joining $A = (1, 0, 0)$ and $B = (\cos T, \sin T, 0)$, where $0 < T < 2\pi$ is given. When $T > \pi$, the equatorial arc, say, AB in Figure* 1.1*, is not a weak minimum. Indeed, take another great circle arc (the broken curve in Figure* 1.1*) joining A and $C = (-1, 0, 0)$, say, AC, and join AC and the equatorial arc CB. Then it has the same length as the equatorial arc AB. However, we get a shorter curve by taking a short cut around C.*

FIG. 1.1.

According to the classical conjugate point theory, C is conjugate to A. Next, let us approximate the shortest path problem by an extremal problem in a finite-dimensional space as follows.

1. *Take a finite number of equally located longitudes ℓ_0, $\ell_1, \ldots, \ell_{n+1}$, where we assume that $A \in \ell_0$ and $B \in \ell_{n+1}$; see Figure* 1.2*.*
2. *Choose one point, say, X_k, on each ℓ_k for $k = 1, 2, \ldots n$.*
3. *Minimize the length of the polygonal curve joining $A, X_1, \ldots, X_n, B$.*

FIG. 1.2.

FIG. 1.3.

Then the above observation on the classical shortest path problem can be also applied to this extremal problem in R^n. In fact, by taking a short cut around C in Figure 1.3*, we obtain a shorter polygonal curve. Hence C can be regarded as a conjugate point in the finite-dimensional analogue.*

Though Theorem 1.2 seems to negatively answer our question, Example 1.1 seems to positively answer. In this paper, we show that the latter is right. In section 2, we first clarify the trick that Theorem 1.2 seems to negatively answer. Next, we introduce the Jacobi equation and conjugate points for (P), and we give a sufficient optimality condition in terms of conjugate points. In section 3, we define strict conjugate points, and we give a necessary optimality condition in terms of strict conjugate points. In section 4, we provide three examples and compute conjugate points. Readers will see that our conjugate points theory works very well.

2. The Jacobi equation and conjugate points: Sufficiency. In this section, we define the Jacobi equation and conjugate points for (P), and we describe sufficient optimality conditions in terms of conjugate points. In order to investigate conjugate points for (P), we should start with clarifying what corresponds to the Euler equation and the (strengthened) Legendre condition in (P), respectively. The point to achieve this purpose is that both of them are local properties. Namely, they are derived by giving a minimum $\bar{x}(t)$ an increment $\Delta x(t)$ that takes nonzero value only on a neighborhood of t. Since the variable t corresponds to the index k and the index set

$\{1,\dots,n\}$ is discrete, we may take the singleton $\{k\}$ as the smallest neighborhood of k. Hence the increment becomes $\Delta x := (0,\dots,0,\Delta x_k,0,\dots,0)$. So, defining $F(\Delta x_k) := f(\bar{x}+\Delta x)$ for any fixed index k, we get $F'(0) = f_{x_k}(\bar{x})$ and $F''(0) = f_{x_k x_k}(\bar{x})$. Therefore, we conclude that

(a) the Euler equation corresponds to $f_{x_k}(\bar{x}) = 0 \quad \forall k = 1,\dots,n$,
(b) the Legendre condition corresponds to $f_{x_k x_k}(\bar{x}) \geq 0 \quad \forall k = 1,\dots,n$,
(c) the strengthened Legendre condition corresponds to $f_{x_k x_k}(\bar{x}) > 0 \ \forall k = 1,\dots,n$.

Since there is a gap between (c) and $f''(\bar{x}) > 0$, there does exist room for conjugate points to play a role in (P).

So, let us now discuss the positive-definiteness of symmetric matrices. According to Sylvester's criterion, an $n \times n$-symmetric matrix $A = (a_{ij})$ is positive-definite if and only if its descending principal minors $|A_k|$, $(k = 1,\dots,n)$ are positive, where

$$A_k := \begin{pmatrix} a_{11} & \cdots & a_{1k} \\ \vdots & \ddots & \vdots \\ a_{k1} & \cdots & a_{kk} \end{pmatrix}.$$

The following lemma shows that the determinant of any square matrix is expanded with respect to the descending principal minors.

LEMMA 2.1. *For any $n \times n$-matrix $A = (a_{ij})$, its determinant is expanded as*

$$|A| = \sum_{k=0}^{n-1} \sum_{\rho} \varepsilon(\rho) a_{k+1\rho(k+1)} a_{k+2\rho(k+2)} \cdots a_{n\rho(n)} |A_k|, \tag{2.1}$$

where $|A_0| := 1$, $\varepsilon(\rho)$ denotes the sign of ρ, and the summation is taken over all permutations ρ on $\{k+1,\dots,n\}$ satisfying that there is no $\ell > k$ such that ρ is closed on $\{\ell+1,\dots,n\}$.

Proof. For any permutation σ on $\{1,\dots,n\}$, put $k := \max\{0 \leq \ell \leq n-1 : \sigma(\{\ell+1,\dots,n\}) = \{\ell+1,\dots,n\}\}$, $\tau := \sigma|_{\{1,\dots,k\}}$, and $\rho := \sigma|_{\{k+1,\dots,n\}}$, where τ is empty when $k = 0$. Then $\sigma = \tau \circ \rho$, and ρ is closed on $\{k+1,\dots,n\}$. But there is no $\ell > k$ such that ρ is closed on $\{\ell+1,\dots,n\}$. Hence

$$\begin{aligned} |A| &= \sum_{k=0}^{n-1} \sum_{\rho} \varepsilon(\rho) \left\{ \sum_{\tau} \varepsilon(\tau) a_{1\tau(1)} \cdots a_{k\tau(k)} \right\} a_{k+1\rho(k+1)} \cdots a_{n\rho(n)} \\ &= \sum_{k=0}^{n-1} \sum_{\rho} \varepsilon(\rho) a_{k+1\rho(k+1)} \cdots a_{n\rho(n)} |A_k|. \end{aligned}$$

This completes the proof. □

EXAMPLE 2.1. *When $A = (A_{ij})$ is a tridiagonal matrix*

$$\begin{pmatrix} a_1 & b_1 & & \\ b_1 & a_2 & \ddots & \\ & \ddots & \ddots & b_{n-1} \\ & & b_{n-1} & a_n \end{pmatrix}, \tag{2.2}$$

the expansion (2.1) *reduces to*

$$|A_k| = a_k |A_{k-1}| - b_{k-1}^2 |A_{k-2}|, \tag{2.3}$$

which coincides with (81) *in Gelfand and Fomin* [1, p. 127].

In this paper, we call the expansion (2.1) the *Jacobi equation* for (P). In the following, we show the reason. A connection between Jacobi's condition and the theory of quadratic forms in R^n was discussed in [1, p. 127] as follows. According to the classical conjugate point theory, the quadratic functional

$$\int_0^T (P\dot{y}^2 + Ry^2)dt, \tag{2.4}$$

where $P(t) > 0$, is positive for all $y(t)$ such that $y(0) = y(T) = 0$ if and only if $[0, T]$ contains no point conjugate to 0, where the corresponding Jacobi equation is

$$\frac{d}{dt}(P\dot{y}) = Ry$$

(see [1, p. 111]). By introducing the points $0 = t_0 < t_1 < \cdots < t_n < t_{n+1} = T$, we get $n + 1$ equal parts of length $\Delta t := T/(n + 1)$. Then the quadratic functional (2.4) is approximated by the quadratic form

$$\sum_{k=0}^{n} \left\{ P_k \left(\frac{y_{k+1} - y_k}{\Delta t} \right)^2 + R_k y_k^2 \right\} \Delta t, \tag{2.5}$$

where $P_k := P(t_k)$, $R_k := R(t_k)$, $y_k := y(t_k)$, and $y_0 = y_{n+1} = 0$. By putting $a_k := R_k\Delta t + (P_{k-1} + P_k)/\Delta t$, $b_k := -P_{k-1}/\Delta t$, $y = (y_1, \ldots, y_n)$, and A as (2.2), the quadratic form (2.5) is expressed as $y^T Ay$. Furthermore, by making the change of variables

$$Y_0 := 0, \quad Y_1 := \Delta t, \quad Y_{k+1} := \frac{(\Delta t)^{k+1}|A_k|}{P_1 \cdots P_k}, \quad k = 1, \ldots, n,$$

the recursion relation (2.3) reduces to

$$\frac{P_k \frac{Y_{i+1} - Y_k}{\Delta t} - P_{k-1} \frac{Y_k - Y_{k-1}}{\Delta t}}{\Delta t} = R_k Y_k. \tag{2.6}$$

Tending $\Delta t \to 0$ in (2.6), we get the Jacobi equation $d(P\dot{Y})/dt = RY$. Therefore, the expansion (2.1) can be regarded as the Jacobi equation for (P).

Additionally, when A_{k-1} is nonsingular, the expansion (2.1) is simplified as below.

LEMMA 2.2. *Divide A_k as follows:*

$$A_k = \begin{pmatrix} A_{k-1} & a \\ a^T & a_{kk} \end{pmatrix}. \tag{2.7}$$

If A_{k-1} is nonsingular, then it holds that $|A_k| = |A_{k-1}|(a_{kk} - a^T A_{k-1}^{-1} a)$. Furthermore, when all of $|A_1|, \ldots, |A_{k-1}|$ are positive, the necessary and sufficient condition for $|A_k|$ to be positive is that $a_{kk} - a^T A_{k-1}^{-1} a > 0$.

Proof. Our assertion follows from

$$A_k = \begin{pmatrix} I_{k-1} & 0 \\ a^T A_{k-1}^{-1} & 1 \end{pmatrix} \begin{pmatrix} A_{k-1} & 0 \\ 0 & a_{kk} - a^T A_{k-1}^{-1} a \end{pmatrix} \begin{pmatrix} I_{k-1} & A_{k-1}^{-1} a \\ 0 & 1 \end{pmatrix}, \tag{2.8}$$

where I_{k-1} denotes the $(k - 1) \times (k - 1)$ identity matrix. □

DEFINITION 2.3. *For any symmetric matrix A, we call the recursion relation on $\{y_i\}$*

$$y_k = \sum_{i=0}^{k-1} \sum_{\rho} \varepsilon(\rho) a_{i+1\rho(i+1)} a_{i+2\rho(i+2)} \cdots a_{k\rho(k)} y_i, \qquad k = 1, \ldots, n, \tag{2.9}$$

the Jacobi equation for A. We say that k is conjugate to 1 if the solution $\{y_i\}$ of the Jacobi equation with $y_0 > 0$ changes the sign from positive to nonpositive at $i = k$. Namely,

$$y_0 > 0, y_1 > 0, \ldots, y_{k-1} > 0, \text{ and } y_k \leq 0. \tag{2.10}$$

When A_{k-1} is nonsingular, $a_{kk} - a^T A_{k-1}^{-1} a$ is called the kth pivot of A for $k = 2, \ldots, n$. $|A_1| = a_{11}$ is called the first pivot.

THEOREM 2.4. *For any $n \times n$-symmetric matrix A, the following three conditions are equivalent.*

(a) *A is positive-definite.*

(b) *There is no point conjugate to 1.*

(c) *All the pivots ($k = 1, 2, \ldots, n$) are positive.*

Proof. The assertion follows from Sylvester's criterion, Lemma 2.2, and Definition 2.3. □

DEFINITION 2.5. *Let $\bar{x} \in R^n$ be any extremal for* (P)*; that is, it satisfies $f'(\bar{x}) = 0$. By taking $f''(\bar{x})$ as A in Definition* 2.3*, we define the Jacobi equation, conjugate points, and the* kth *pivot for* (P) *at $\bar{x}$.*

Combining Theorems 1.2, 2.4, and Definition 2.5, we readily get the following theorem.

THEOREM 2.6. *A sufficient condition for an extremal $\bar{x}$ to be a minimum for* (P) *is that there is no point conjugate to* 1.

REMARK 2.1. *Since each variable x_k ($1 \leq k \leq n$) plays the same role with one another in* (P)*, there is no reason to start with index* 1 *to define conjugate points. Indeed, let σ be an arbitrary permutation on $\{1, \ldots, n\}$, and denote by A^σ the matrix whose (i, j)-component is a $(\sigma(i), \sigma(j))$-component of A. Then we can define conjugate points as well as above, and Theorems* 2.4 *and* 2.6 *remain valid. However, concerning sufficient optimality conditions, such an extension is redundant, since it suffices to test the descending principal minors $|A_1|, \ldots, |A_n|$.*

3. Strict conjugate points: Necessity. In this section, we describe a necessary optimality condition for (P) in terms of conjugate points. Since the descending principal minors $|A_1|, \ldots, |A_n|$ are not enough to characterize $A \geq 0$, the situation is slightly different from the sufficiency case. Namely, though the implication $A \geq 0 \Rightarrow |A_k| \geq 0$ ($1 \leq k \leq n$) is true, its inverse is not true in general.

DEFINITION 3.1. *Let $A = (a_{ij})$ be an $n \times n$-symmetric matrix, and let $1 \leq i,\ j \leq n$ be two distinct integers. Then we say that j is strictly conjugate to i if there exist a permutation σ and $1 < k \leq n$ such that $\sigma(1) = i$, $\sigma(k) = j$, and if a solution $\{y_i\}$ of the Jacobi equation* (2.9) *for A^σ with $y_0 > 0$ changes the sign from nonnegative to negative at k; that is,*

$$y_0 > 0, y_1 \geq 0, \ldots, y_{k-1} \geq 0, \text{ and } y_k < 0, \tag{3.1}$$

where A^σ is defined as in Remark 2.1.

THEOREM 3.2. *Let A be a symmetric matrix. Then $A \geq 0$ if and only if there is no pair $1 \leq i,\ j \leq n$ of integers such that j is strictly conjugate to i.*

Proof. It is well known that $A \geq 0$ if and only if all of the principal minors of A are nonnegative; see, e.g., [5]. Hence our assertion is a direct consequence of Definition 3.1. □

DEFINITION 3.3. *Let $\bar{x} \in R^n$ be any extremal for* (P)*, and take $f''(\bar{x})$ as A. Then we say that j is conjugate to i at $\bar{x}$ if j is conjugate to i in the sense of Definition* 3.1.

Combining Theorems 1.2, 3.2, and Definition 3.3, we readily get the following theorem.

THEOREM 3.4. *A necessary condition for an extremal $\bar{x}$ to be a minimum for* (P) *is that there is no pair $1 \leq i,\ j \leq n$ of positive integers such that j is strictly conjugate to i.*

We close this section with showing the relationship between conjugate points and strict conjugate points.

PROPOSITION 3.5. *If j is strictly conjugate to i, then there exist a permutation σ and $m \geq 1$ such that m is conjugate to* 1 *concerning the matrix A^σ defined in Remark* 2.1.

Proof. By definition, there exist a permutation σ and $1 < k \leq n$ such that $\sigma(1) = i$, $\sigma(k) = j$, and a solution $\{y_i\}$ of the Jacobi equation (2.9) for A^σ with $y_0 > 0$ satisfies (3.1). Putting $m := \min\{1 \leq \ell \leq n\ :\ y_\ell \leq 0\}$, we have $y_0 > 0, \ldots, y_{m-1} > 0$, and $y_m \leq 0$. □

4. Examples. In this section, we give three examples and show that the preceding results work very well. Each example is derived from the classical shortest path problem on a surface S in R^3 by approximating the arc $X(t) = (x(t), y(t), z(t)) \in S$ by a polygonal curve. This approximation is done by the following procedure.

(i) Introduce the points $0 = t_0 < t_1 < \cdots < t_n < t_{n+1} = T$, and divide the interval $[0, T]$ into $n+1$ equal parts of length $\Delta t := T/(n+1)$.
(ii) For each feasible arc $X(t)$, put $X_k := X(t_k)$.
(iii) Approximate the length of the arc $X(t)$ by the length of the polygonal curve joining $n+2$ points $X_0, X_1, \ldots, X_{n+1}$.
(iv) Minimize the length of the polygonal curve.

EXAMPLE 4.1. *This example is same as Example* 1.1. *Here we compute conjugate points for the finite-dimensional analogue. By means of the spherical coordinates, any point on the* kth *longitude ℓ_k is expressed as*

$$X_k = (\sin\theta(t_k)\cos t_k, \sin\theta(t_k)\sin t_k, \cos\theta(t_k)).$$

Hence the minimization problem of the length of the polygonal arc joining $n+2$ points $A = X_0,\ X_1, \ldots, X_{n+1} = B$ is formulated as follows:

$$(\mathrm{P}_1) \quad \text{Min} \quad f(\theta_1, \ldots, \theta_n) := \sum_{k=0}^{n} \sqrt{2(1 - \cos\Delta t \sin\theta_{k+1}\sin\theta_k - \cos\theta_{k+1}\cos\theta_k)},$$

where $\theta_0 = \theta_{n+1} = \pi/2$. The variable $\theta \in R^n$ that corresponds to the equatorial arc $\bar{\theta}(t) \equiv \pi/2$ is $\bar{\theta} := (\pi/2, \ldots, \pi/2)$. Then the Hesse matrix of f at $\bar{\theta}$ is

$$f''(\bar{\theta}) = \frac{1}{\sqrt{2(1-c)}} \begin{pmatrix} 2c & -1 & & \\ -1 & 2c & \ddots & \\ & \ddots & \ddots & -1 \\ & & -1 & 2c \end{pmatrix}, \tag{4.1}$$

where $c := \cos\Delta t$. *It follows from Lemma* 4.1 *below that the principle minor of size* k *of* (4.1) *is positive if* $(k+1)\Delta t < \pi$. *Since* $\Delta t = T/(n+1)$, *we conclude that*

(a) *when* $T < \pi$, *there is no point conjugate to* 1, *and*

(b) *when* $T \geq \pi$, *the first number* k *satisfying* $(k+1)/(n+1) \geq \pi/T$ *is conjugate to* 1,

which matches the classical result.

The following lemma is easily proved by induction.

LEMMA 4.1. *For* $c = \cos\Delta t$, *define* $k \times k$*-matrices*

$$A_k := \begin{pmatrix} 2c & -1 & & \\ -1 & 2c & \ddots & \\ & \ddots & \ddots & -1 \\ & & -1 & 2c \end{pmatrix}, \qquad B_k := \begin{pmatrix} c & -1 & & \\ -1 & 2c & \ddots & \\ & \ddots & \ddots & -1 \\ & & -1 & 2c \end{pmatrix}. \tag{4.2}$$

Then their determinants are given by $|A_k| = \sin(k+1)\Delta t/\sin\Delta t$ *and* $|B_k| = \cos k\Delta t$, *respectively.*

EXAMPLE 4.2. *This example is a finite-dimensional analogue to the initial-free shortest path problem on the unit sphere* S, *that is, finding a shortest path joining the initial longitude* $\ell_0 := \{(\sin\alpha, 0, \cos\alpha) : \ 0 \leq \alpha \leq \pi\}$ *and the point* $B = (\cos T, \sin T, 0)$.

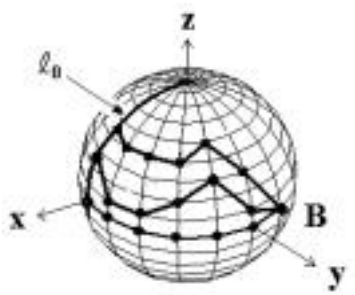

FIG. 4.1.

As well as in Example 4.1, *the finite-dimensional analogue is formulated as*

$$(\mathrm{P}_2) \quad \mathrm{Min} \quad f(\theta_0, \theta_1, \ldots, \theta_n) := \sum_{k=0}^{n} \sqrt{2(1 - \cos\Delta t \sin\theta_{k+1} \sin\theta_k - \cos\theta_{k+1}\cos\theta_k)},$$

where $\theta_{n+1} := \pi/2$. *The variable* $\theta \in R^{n+1}$ *that corresponds to the equatorial arc* $\bar\theta(t) \equiv \pi/2$ *is* $\bar\theta := (\pi/2, \ldots, \pi/2)$. *Then*

$$f''(\bar\theta) = \frac{1}{\sqrt{2(1-c)}} \left.\begin{pmatrix} c & -1 & & \\ -1 & 2c & \ddots & \\ & \ddots & \ddots & -1 \\ & & -1 & 2c \end{pmatrix}\right\} n+1, \tag{4.3}$$

where $c := \cos\Delta t$. *It follows from Lemma* 4.1 *that the principle minor of size* k *of* (4.3) *is positive if* $k\Delta t < \pi/2$. *Since* $\Delta t = T/(n+1)$, *we conclude that*

(a) *when* $T < \pi/2$, *there is no point conjugate to* 1, *and*
(b) *when* $T \geq \pi/2$, *the first number* k *satisfying* $kT/(n+1) \geq \pi/2$ *is conjugate to* 1,

which matches the classical result.

EXAMPLE 4.3. *The original variational problem is finding a shortest path on the cylinder* $S := \{(x, y, z) : x^2 + y^2 = 1,\ z \in R\}$ *joining* $A = (1, 0, 0)$ *and* $B = (\cos T, \sin T, \gamma)$, *where* $\gamma \in R$ *is given.*

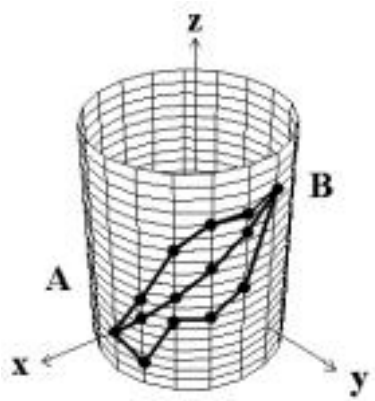

FIG. 4.2.

By applying the procedure (i)–(iv) *above to it, we get its finite-dimensional analogue*

$$(\mathrm{P}_3) \quad \text{Min} \quad f(z_1, \ldots, z_n) := \sum_{k=0}^{n} \sqrt{(z_{k+1} - z_k)^2 + 4 \sin^2 \frac{\Delta t}{2}},$$

where $z_0 := 0,\ z_{n+1} := \gamma$. *Furthermore, the variable* $z \in R^n$ *that corresponds to the spiral* $\bar{z}(t) = t\gamma/T$ *is* $\bar{z} := (\gamma/(n+1), \ldots, n\gamma/(n+1))$. *Then the Hesse matrix of* f *at* $\bar{z}$ *is*

$$f''(\bar{z}) = s(s+d)^{-3/2} \begin{pmatrix} 2 & -1 & & \\ -1 & 2 & \ddots & \\ & \ddots & \ddots & -1 \\ & & -1 & 2 \end{pmatrix}, \tag{4.4}$$

where $s := 4 \sin^2(\Delta t/2)$ *and* $d := \gamma^2/(n+1)^2$. *Since* $|A_k| = \{s(s+d)^{-3/2}\}^k (k+1) > 0$, *there is no point conjugate to* 1, *which matches the classical result.*

STOCK TRADING: AN OPTIMAL SELLING RULE*

Q. ZHANG†

Abstract. Trading in stock markets consists of three major steps: select a stock, purchase a number of shares, and eventually sell them to make a profit. The timing to buy and sell is extremely crucial. A selling rule can be specified by two preselected levels: a target price and a stop-loss limit. This paper is concerned with an optimal selling rule based on the model characterized by a number of geometric Brownian motions coupled by a finite-state Markov chain. Such a policy can be obtained by solving a set of two-point boundary value differential equations. Moreover, the corresponding expected target period and probability of making money and that of losing money are derived. Analytic solutions are obtained in one- and two-dimensional cases. Finally, a numerical example is considered to demonstrate the effectiveness of our method.

Key words. optimal selling rule, geometric Brownian motion, Markov switching, two-point boundary value problem

1. Introduction.

Trading in stocks consists of three major steps: (a) select a stock based on certain criteria; (b) buy a number of shares at the right time (usually associated with the so-called pivot points; see Livermore [14] and O'Neil [18]); (c) hold the position for a period of time and then sell it to make a profit. A selling (liquidation) decision can be made when the price of the underlying stock reaches a target price or a stop-loss limit.

To analyze and study the performance of a stock, it is important to establish a mathematical model to characterize its price movement. In mathematical finance, the price of a stock is often modeled as a geometric Brownian motion (see Merton [15]) which is determined by two parameters: the expected return and volatility (see Elliott and Kopp [7], Karatzas [11], and Karatzas and Shreve [12] for analysis of the model and applications). Such parameters are usually assumed to be deterministic when analyzing option pricing; see Duffie [6] and Hull [10]. As a result, such a model is good only for a relatively short period because it wouldn't respond to random changes in these parameters. Some modifications with random parameters are available in the literature in which the volatility is dictated by additional stochastic differential equations; see Fouque, Papanicolaou, and Ronnie [9], Hull [10], and Musiela and Rutkowski [16], among others, for related results.

A major factor that dominates the movement of an individual stock is the trends of the general market. If the overall market moves up, most stocks go up; if the general market goes down, most follow. By and large, the movements of a market can be viewed as a composition of a primary movement and secondary movement. Such a classification is summarized in Table 1.

In order to incorporate the broad trend of a stock market, it is necessary to revise and modify the geometric Brownian motion model to allow the expected return and volatility parameters to depend on general market movements. In view of this, it is

TABLE 1
Major movements of a stock market.

Market movements	Market trends	Duration
Primary	Broad upward or downward	Several years
Secondary	Significant decline in a great bull market or strong recovery in a great bear market	Several weeks to a few months

natural to introduce a finite-state Markov chain $\alpha(\cdot)$ representing the general market direction. For example, one may consider $\alpha(t) = (\alpha_1(t), \alpha_2(t))$, where $\alpha_1(t) \in \{1, 2\}$ represents the primary market trend (here the state 1 represents up-trend and 2 down-trend) and $\alpha_2(t) \in \{1, 2\}$ represents the secondary market movement indicator. In this case, we may consider the Markov chain

$$\alpha(t) \in \{(2,2), (1,2), (2,1), (1,1)\} \tag{1}$$

with a generator given by

$$Q = \begin{pmatrix} -\lambda_1 & \lambda_1 & 0 & 0 \\ \lambda_2 & -\lambda_2 & 0 & 0 \\ 0 & 0 & -\lambda_1 & \lambda_1 \\ 0 & 0 & \lambda_2 & -\lambda_2 \end{pmatrix} + \begin{pmatrix} -\mu_1 & 0 & \mu_1 & 0 \\ 0 & -\mu_1 & 0 & \mu_1 \\ \mu_2 & 0 & -\mu_2 & 0 \\ 0 & \mu_2 & 0 & -\mu_2 \end{pmatrix},$$

where λ_1 and μ_1 are the transition rates of going up and λ_2 and μ_2 the rates of going down. If a great bull market lasts for 5 years and a bear market for 3 years, then $\lambda_1 = 1/3$ and $\lambda_2 = 1/5$ when time is measured in years. Similarly, we can take $\mu_1 = 4$ and $\mu_2 = 12$ representing a recovery in a bear market which lasts for a quarter of a year and a decline in a bull market that runs for about 4–5 weeks. Clearly, it is more realistic to include the random process $\alpha(\cdot)$ in the model. In this paper, we consider a model with a single stock and its price observes a switching geometric Brownian motion. Moreover, the stock pays no dividends. Given the current price of a stock, a selling rule in this paper consists of a target price and a stop-loss limit. A selling decision is made whenever the price reaches either the target price or the stop-loss limit. The timing to sell is as important as that of buying. The primary goal of investing is to make a profit. However, in reality, one often picks up the wrong stock or purchases it at the wrong time. In this case, it is necessary to sell it sooner to stop loss. In practice, a target price is typically around a gain of 20% to 50% and a stop-loss limit generally varies from 10% to 30% depending on the risk an investor is willing to take. Clearly, it is not a good idea to adopt uniform profit-taking or cut-loss rates. Each stock is different and has its own trait. It should be treated differently with different liquidation rules.

In this paper, we consider a set of target prices and stop-loss limits. Our goal is to choose a target price and a stop-loss limit in that set in order to maximize an expected reward function. We aim at deriving these price limits. In addition, we obtain the expected target period (holding duration) and the probability of making money and that of losing money.

In practice, an often used criterion for measuring the performance of a portfolio is that of percentage return per unit time. However, such a criterion leads to frequent transactions because it encourages small profit taking within short holding time τ_0

(say, a few minutes to a couple of days). Clearly, such a criterion is not suitable to many individual investors because of limited time available for trading and additional transaction costs. A discounted reward, on the other hand, rules out too frequent transactions because the time factor $(1/\tau_0)$ is replaced by a discount rate $e^{-\rho\tau_0}$ (see section 6 for discussions on selection of $\rho > 0$). Such a discounted reward function is natural in many financial problems. Moreover, the resulting selling rule involves only a set of ordinary differential equations (ODEs) rather than a number of partial differential equations (PDEs), which makes the corresponding computation much easier. Our optimal selling rule can be determined by solving a set of ODEs with two-point boundary conditions. In this paper, we prove the existence and uniqueness of the solution to these equations. Examples with one-dimensional (1-D) and two-dimensional (2-D) models are considered. Analytic solutions are obtained in these cases. Finally, daily closes of the Microsoft Corp. stock in 1999 are used to demonstrate the effectiveness of our results.

The paper is organized as follows. In the next section, we formulate the optimization problem under consideration. In sections 3 and 4, we derive an optimal selling policy under the model formulated and assumptions imposed in this paper. We also obtain expected exit time and profit and loss probabilities. In section 5, analytic solutions of these policies are obtained in both 1-D and 2-D cases. A numerical example is reported in section 6. All proofs of results are postponed and given in the appendix.

2. Problem formulation. Let $\mathcal{M} = \{1, 2, \ldots, m\}$ denote the state space of the Markov chain $\alpha(\cdot)$. Note that each element in $\mathcal{M}$ is an index and may be used to represent a vector as in (1). Let $Q = (q_{ij})_{m\times m}$ be the generator of $\alpha(\cdot)$ with $q_{ij} \geq 0$ for $i \neq j$ and $\sum_{j=1}^{m} q_{ij} = 0$ for each $i \in \mathcal{M}$. In this paper, the market-trend indicator process $\alpha(t)$ is not necessarily observable. Only the generator and its initial distribution $\{p_i = P(\alpha(0) = i) \text{ for } i \in \mathcal{M}\}$ are available.

Let $S(t)$ denote the price of a stock at time t. It satisfies the equation

$$\begin{cases} dS(t) = \mu(\alpha(t))S(t)dt + \sigma(\alpha(t))S(t)dw(t), \\ S(0) = S_0,\ t \geq 0, \end{cases} \tag{2}$$

where $S_0 > 0$ is the initial price; $\mu(i)$, $i \in \mathcal{M}$, is the expected return; $\sigma(i)$, $i \in \mathcal{M}$, represents the stock volatility; and $w(\cdot)$ is a standard Brownian motion. The processes $\alpha(\cdot)$ and $w(\cdot)$ are independent. In addition, we assume $\sigma^2(i) > 0$ for $i \in \mathcal{M}$.

This paper is concerned with a stock selling rule. A commonly used selling rule in practice is of the form

$$\tau_0 = \inf\Big\{t > 0 :\ S(t) \notin (A, B)\Big\}, \tag{3}$$

i.e., to sell a stock at time τ_0 for prespecified $A \leq S_0 \leq B$.

In this paper, we study only those strategies with $A > 0$ and $B < \infty$.

The condition $A > 0$ is mainly motivated by practical considerations. In fact, the lower bound A prescribes the maximum risk level of an investment. Cutting a loss short is crucial to preserve the capital. This is especially important during a sharp market downturn. An often used cut-loss level is 10–30% for active traders, which corresponds to $A = S_0(1\text{–}10\%)$ to $A = S_0(1\text{–}30\%)$. W. J. O'Neil, the founder of *Investor's Business Daily*, suggests an even more conservative limit of 8% in [18]. In addition, Dammon and Spatt [4] have shown that an optimal selling rule should include $A = x_L > 0$ when transaction costs (commissions) and capital gain taxes are added to the picture. Similar results are obtained in Cadenillas and Pliska [2] when

$\mu > \sigma^2$ with constant μ and σ. However, from a purely mathematical point of view, it is possible to have $A = 0$ as an optimal lower bound. This is demonstrated by Øksendal [17, p. 199] using an optimal stopping approach. This condition means that an investor needs to risk the entire capital to maximize a potential future return.

The condition $B < \infty$ is imposed mainly for theoretical convenience (used in the proof of Theorem 3.2). It is shown in [17] that the optimal upper bound $B = x_0 < \infty$. In addition, even in the presence of capital gain taxes and transactions costs, the optimal B should be finite when $\sigma^2/2 < \mu < \sigma^2$ (see [2]). Furthermore, our numerical study in this paper indicates that the optimal $B < \infty$; see Remark 5.1 and Tables 6 and 8 in which the optimal $B(= S_0 e^{z_2^*})$ is bounded with fixed discount factor ρ. However, when $\mu > \sigma^2$, it is proved in [2] that the optimal $B = \infty$. Infinite upper bound is also obtained in [4]. Intuitively, the condition $B = \infty$ suggests that one should never sell his position no matter how high its price goes. However, in reality, a stock's price often rests at a certain level (or goes sideways) after substantial advances during a period of time. In this case, a predetermined $B < \infty$ (say 20–50% annual return) would help an investor lock in real profit following these price advances and move the money elsewhere for other investment opportunities. In view of this, such a predetermined rule is more desirable for a relatively short-term (several months to a year) investment.

Clearly, an optimal time to sell depends on the reward (utility) function and system parameters. It may also depend on transaction costs and capital gain taxes if these factors are included in the model. By and large, including commission and tax factors in the model typically makes transactions less frequent, which corresponds to smaller A and larger B. We refer the reader to [2], [3], and [4], among others, for further discussions on models with these factors.

Assumption (A). In this paper, we consider the selling rule (3) with

$$A_1 \le A \le A_2 \text{ and } B_1 \le B \le B_2$$

for any given $0 < A_1 < A_2 < S_0 < B_1 < B_2 < \infty$.

Our goal is to find an optimal pair (A, B) under this assumption for a given reward function.

For convenience, we choose a_1, a_2, b_1, b_2 such that

$$A_1 = S_0 e^{-b_1},\ A_2 = S_0 e^{-a_1},\ B_1 = S_0 e^{a_2},\ B_2 = S_0 e^{b_2}.$$

It is easy to see that $0 < a_1 \le b_1 < \infty$ and $0 < a_2 \le b_2 < \infty$. Moreover, choose z_1 and z_2 such that

$$A = S_0 e^{-z_1} \text{ and } B = S_0 e^{z_2}$$

for some z_1 and z_2. Let $\mathcal{I} = [a_1, b_1] \times [a_2, b_2]$. We consider $(z_1, z_2) \in \mathcal{I}$.

Here the target price is given by $B = S_0 e^{z_2}$ and the stop-loss limit is $A = S_0 e^{-z_1}$. A selling rule is determined by (z_1, z_2). For example, taking $z_1 = -\log 0.9$ and $z_2 = \log 1.2$ corresponds to a target price of 20% gain and a stop limit of 10% loss.

Let

$$X(t) = \int_0^t \left(\mu(\alpha(s)) - \frac{\sigma^2(\alpha(s))}{2}\right) ds + \int_0^t \sigma(\alpha(s)) dw(s),$$

where the stochastic integral

$$\int_0^t \sigma(\alpha(s)) dw(s) = \sum_{n=0}^{\infty} \sigma(\alpha_n)(w(t_{n+1}) - w(t_n))$$

with random jump times $0 = t_0 < t_1 < \cdots < t_n < \cdots$ of $\alpha(\cdot)$ and $\alpha(t) = \alpha_n$ for $t \in [t_n, t_{n+1})$, $n = 0, 1, 2, \ldots$. Note that $\alpha(\cdot)$ is a Markov chain with generator Q. It follows that $\lim_{n\to\infty} t_n = \infty$ with probability one; see Davis [5, p. 60]. Using $X(t)$, we can write $S(t)$ as follows:

$$S(t) = S_0 \exp X(t).$$

Moreover, τ_0 can be defined in terms of $X(\cdot)$:

$$\tau_0 = \inf\Big\{t > 0 : \ X(t) \notin (-z_1, z_2)\Big\}.$$

The objective of the problem is to find $(z_1, z_2) \in \mathcal{I}$ to maximize

$$V = V(z_1, z_2) := \sum_{i=1}^{m} p_i E[\Phi(X(\tau_0))e^{-\rho\tau_0}|\alpha(0) = i],$$

where $\rho > 0$ is a discount factor and $\Phi(x)$ is a function of x. For example, we may consider a discounted reward

$$E\left[\left(\frac{S(\tau_0) - S_0}{S_0}\right)e^{-\rho\tau_0}\right], \tag{4}$$

which corresponds to $\Phi(x) = e^x - 1$. This reward function will be used in our numerical example in section 6.

3. An optimal policy. Given $x \in [-z_1, z_2] \in \mathcal{I}$, consider the switching diffusion

$$\begin{cases} d\xi(t) = r(\alpha(t))dt + \sigma(\alpha(t))dw(t), \\ \xi(0) = x, \end{cases} \tag{5}$$

where $r(i) = \mu(i) - \sigma^2(i)/2$ for $i \in \mathcal{M}$ represents a continuously compounded return rate. It follows that

$$\xi(t) = x + X(t).$$

For $x \in [-z_1, z_2]$, we define

$$\tau(x) = \inf\Big\{t \geq 0 : \ \xi(t) \notin (-z_1, z_2)\Big\}.$$

Given $\alpha(0) = i$ and $\xi(0) = x$, let $v(x, i)$ denote the value function

$$v(x, i) = E[\Phi(\xi(\tau(x)))e^{-\rho\tau(x)}].$$

Then $\tau_0 = \tau(0)$ and $E[\Phi(X(\tau_0))e^{-\rho\tau_0}|\alpha(0) = i] = v(0, i)$. The corresponding reward function

$$V = V(z_1, z_2) = \sum_{i=1}^{m} p_i v(0, i). \tag{6}$$

In order to evaluate V, one has only to find $v(x, i)$. Formally, $v(x, i)$ satisfies the following differential equations:

$$\begin{cases} \dfrac{\sigma^2(i)}{2}\dfrac{\partial^2 v(x,i)}{\partial x^2} + r(i)\dfrac{\partial v(x,i)}{\partial x} - \rho v(x, i) + Qv(x, \cdot)(i) = 0, \\ v(-z_1, i) = \Phi(-z_1), \ v(z_2, i) = \Phi(z_2) \ \text{ for } x \in (-z_1, z_2), \ i \in \mathcal{M}, \end{cases} \tag{7}$$

where $Qf(\cdot)(i) = \sum_{j \neq i} q_{ij}(f(j) - f(i))$ for any function f on $\mathcal{M}$. In fact, if (7) has a smooth solution $v(x, i)$, then using Dynkin's formula (see Fleming and Soner [8]), we can show that $v(x, i) = E[\Phi(\xi(\tau(x)))e^{-\rho\tau(x)}]$, which in turn proves the uniqueness of the solution.

Remark 3.1. Solving the differential equations in (7) consists of a two-point boundary value (TPBV) problem. In general, such a problem may not have a solution. For example, the equation $\ddot{y} + y = 0$ with $y(0) = 0$ and $y(\pi) = 1$ does not have a solution.

Let $C^2[-z_1, z_2]$ denote the space of functions that are twice continuously differentiable on $[-z_1, z_2]$. The next theorem is concerned with the existence of a C^2 solution and optimal (z_1, z_2). All proofs of results are given in the appendix.

THEOREM 3.2. *Under Assumption* (A)*, the following assertions hold:*

(a) *For each* $i \in \mathcal{M}$, $v(x, i) \in C^2[-z_1, z_2]$ *and is the unique solution to* (7).

(b) *For each fixed* (x, i), $v(x, i)$ *is a continuous function of* (z_1, z_2) *on* $\mathcal{I}$.

(c) *There exists an optimal selling policy determined by* (z_1^*, z_2^*) *with the target price* $S_0 e^{z_2^*}$ *and stop-loss limit* $S_0 e^{-z_1^*}$.

Remark 3.3. One may also consider a model involving a time variable in the differential equation. In this case, the class of ODEs in (7) becomes a set of PDEs which is much more difficult to deal with. From the computational point of view, it is easier to work with an ODE than with a PDE. In addition, the existence of a time dependent v typically requires $\Phi \in C^3$; see Krylov [13]. Such a condition is not suitable when evaluating exit probabilities in the next section because the corresponding $\Phi(x)$ is merely Borel measurable; see Remark 4.4.

4. Expected exit time and probabilities. In this section, we compute the expected holding time $E\tau_0$, the profit probability $P(S(\tau_0) \geq S_0 e^{z_2^*})$, and the loss probability $P(S(\tau_0) \leq S_0 e^{-z_1^*})$, where (z_1^*, z_2^*) is determined by the optimal policy given in Theorem 3.2.

Expected Holding Time $E\tau_0$. We first consider τ_0. Given z_1 and z_2, define

$$T(x, i) = E[\tau(x) | \xi(0) = x, \alpha(0) = i].$$

The next lemma is concerned with the uniform boundedness of T.

LEMMA 4.1. *Given* $(z_1, z_2) \in \mathcal{I}$, *there exists a constant* K *such that*

$$T(x, i) \leq K$$

for all $x \in [-z_1, z_2]$ *and* $i \in \mathcal{M}$.

The boundedness of T and Dynkin's formula lead to the following theorem.

THEOREM 4.2. *For each* $i \in \mathcal{M}$, $T(x, i) \in C^2[-z_1, z_2]$ *and is the unique solution to the following equation:*

$$\begin{cases} \dfrac{\sigma^2(i)}{2}\dfrac{\partial^2 T(x,i)}{\partial x^2} + r(i)\dfrac{\partial T(x,i)}{\partial x} + QT(x,\cdot)(i) + 1 = 0, \\ T(-z_1, i) = T(z_2, i) = 0 \text{ for } x \in (-z_1, z_2),\ i \in \mathcal{M}. \end{cases} \tag{8}$$

The expected exit time is given by

$$E\tau_0 = \sum_{i=1}^{m} p_i E[\tau_0 | \alpha(0) = i] = \sum_{i=1}^{m} p_i E[\tau(0) | \xi(0) = 0, \alpha(0) = i] = \sum_{i=1}^{m} p_i T(0, i).$$

Remark 4.3. Note that the ODEs in (8) corresponds to the HJB equation in a "control" problem with the cost function

$$J(x,i) = E\left[\int_0^{\tau(x)} dt \Big| \xi(0) = x, \alpha(0) = i\right].$$

Of course, there is no control variable involved.

Profit Probability $P(S(\tau_0) \geq S_0 e^{z_2})$. Let

$$P_1(x,i) = P(\xi(\tau(x)) \geq z_2 | \xi(0) = x, \alpha(0) = i).$$

Then it is easy to see that

$$P(S(\tau_0) \geq S_0 e^{z_2} | \alpha(0) = i) = P_1(0,i).$$

Moreover, P_1 should satisfy the following equations:

$$\text{(9)} \qquad \begin{cases} \dfrac{\sigma^2(i)}{2}\dfrac{\partial^2 P_1(x,i)}{\partial x^2} + r(i)\dfrac{\partial P_1(x,i)}{\partial x} + QP_1(x,\cdot)(i) = 0, \\ P_1(-z_1,i) = 0,\ P_1(z_2,i) = 1 \text{ for } x \in (-z_1, z_2),\ i \in \mathcal{M}. \end{cases}$$

Remark 4.4. Similarly, the ODEs in (9) correspond to the HJB equation of a control problem with the cost function

$$J(x,i) = E\left[e^{-\rho\tau}\Phi(\xi(\tau)) \Big| \xi(0) = x, \alpha(0) = i\right]$$

with no (or fixed) control variable. Here $\Phi(x) = I_{\{x=z_2\}}$, which is *not* differentiable.

THEOREM 4.5. *For each $i \in \mathcal{M}$, $P_1(x,i) \in C^2[-z_1, z_2]$ and is the unique solution to* (9).

The profit probability is

$$P_1^* := P(S(\tau_0) \geq S_0 e^{z_2}) = \sum_{i=1}^m p_i P_1(0,i).$$

Loss Probability $P(S(\tau_0) \leq S_0 e^{-z_1})$. Similarly, let

$$P_2(x,i) = P(\xi(\tau(x)) \leq -z_1 | x(0) = x, \alpha(0) = i).$$

Then we have

$$P(S(\tau_0) \leq S_0 e^{-z_1} | \alpha(0) = i) = P_2(0,i).$$

Moreover, P_2 satisfies

$$\text{(10)} \qquad \begin{cases} \dfrac{\sigma^2(i)}{2}\dfrac{\partial^2 P_2(x,i)}{\partial x^2} + r(i)\dfrac{\partial P_2(x,i)}{\partial x} + QP_2(x,\cdot)(i) = 0, \\ P_2(-z_1,i) = 1,\ P_2(z_2,i) = 0 \text{ for } x \in (-z_1, z_2),\ i \in \mathcal{M}. \end{cases}$$

THEOREM 4.6. *For each $i \in \mathcal{M}$, $P_2(x,i) \in C^2[-z_1, z_2]$ and is the unique solution to* (10).

Then the loss probability is

$$P_2^* := P(S(\tau_0) \leq S_0 e^{-z_1}) = \sum_{i=1}^m p_i P_2(0,i).$$

5. Analytic solutions with $m = 1, 2$. In this section, we consider the simple cases with $m = 1$ and $m = 2$. We aim at deriving analytic solutions.

1-D Case ($m = 1$). We consider the 1-D case, i.e., $m = 1$. Let $\sigma = \sigma(1)$ and $r = r(1)$. We assume $r \neq 0$. Then, the differential equations in (7) become

$$\begin{cases} \dfrac{\sigma^2}{2}\ddot{v}(x) + r\dot{v}(x) - \rho v(x) = 0, \ x \in (-z_1, z_2), \\ v(-z_1) = \Phi(-z_1), \ v(z_2) = \Phi(z_2), \end{cases}$$

where $\dot{f}(x) = df(x)/dx$ and $\ddot{f}(x) = d^2 f(x)/dx^2$. Solve this equation to obtain

$$\begin{aligned} v(x) = & \left(\frac{e^{\eta_1 z_1 - \eta_2(z_1+z_2)}\Phi(z_2) - e^{\eta_1 z_1}\Phi(-z_1)}{e^{(\eta_1-\eta_2)(z_1+z_2)} - 1} \right) e^{\eta_1 x} \\ & + \left(\frac{-e^{-\eta_2 z_2}\Phi(z_2) + e^{\eta_1 z_1 + (\eta_1-\eta_2)z_2}\Phi(-z_1)}{e^{(\eta_1-\eta_2)(z_1+z_2)} - 1} \right) e^{\eta_2 x}, \end{aligned}$$

where

$$\begin{cases} \eta_1 = \dfrac{-r + \sqrt{r^2 + 2\rho\sigma^2}}{\sigma^2}, \\ \eta_2 = \dfrac{-r - \sqrt{r^2 + 2\rho\sigma^2}}{\sigma^2}. \end{cases}$$

The objective is to choose $(z_1, z_2) \in \mathcal{I}$ to maximize

$$V = v(0) = \frac{(e^{\eta_1 z_1 + (\eta_1-\eta_2)z_2} - e^{\eta_1 z_1})\Phi(-z_1) + (e^{(\eta_1-\eta_2)z_1 - \eta_2 z_2} - e^{-\eta_2 z_2})\Phi(z_2)}{e^{(\eta_1-\eta_2)(z_1+z_2)} - 1}.$$

We next compute $E\tau_0$. The corresponding differential equation is

$$\begin{cases} \dfrac{\sigma^2}{2}\ddot{T}(x) + r\dot{T}(x) + 1 = 0, \\ T(-z_1) = T(z_2) = 0. \end{cases}$$

Let $\eta_0 = -2r/\sigma^2$. Then

$$T(x) = \frac{z_1 + z_2}{r(e^{\eta_0 z_2} - e^{-\eta_0 z_1})} e^{\eta_0 x} - \frac{x}{r} - \frac{z_1 e^{\eta_0 z_2} + z_2 e^{-\eta_0 z_1}}{r(e^{\eta_0 z_2} - e^{-\eta_0 z_1})}.$$

It follows that

$$E\tau_0 = T(0) = \frac{z_1 + z_2}{r(e^{\eta_0 z_2} - e^{-\eta_0 z_1})} - \frac{z_1 e^{\eta_0 z_2} + z_2 e^{-\eta_0 z_1}}{r(e^{\eta_0 z_2} - e^{-\eta_0 z_1})}.$$

To compute $P(S(\tau_0) \geq S_0 e^{z_2})$ and $P(S(\tau_0) \leq S_0 e^{-z_1})$, we solve the corresponding equations (9) and (10) and obtain

$$\begin{cases} P_1(x) = \dfrac{e^{-\eta_0 z_1} - e^{\eta_0 x}}{e^{-\eta_0 z_1} - e^{\eta_0 z_2}}, \\ P_2(x) = \dfrac{e^{\eta_0 x} - e^{\eta_0 z_2}}{e^{-\eta_0 z_1} - e^{\eta_0 z_2}}. \end{cases}$$

TABLE 2
Cases when $\rho = 4$ and $\sigma = 0.3$.

r	0.1	0.2	0.3	0.4	0.5

$E\tau_0$	0.46	0.43	0.43	0.42	0.40
P_1^*	0.83	0.90	0.94	0.97	0.98
P_2^*	0.17	0.10	0.06	0.03	0.02

TABLE 3
Cases when $\rho = 4$ and $r = 0.15$.

σ	0.1	0.2	0.3	0.4	0.5
$(-z_1^*, z_2^*)$	(−0.36,0.06)	(−0.36,0.09)	(−0.36,0.13)	(−0.36,0.16)	(−0.36,0.20)
$E\tau_0$	0.39	0.51	0.43	0.34	0.27
P_1^*	1.00	0.97	0.87	0.79	0.72
P_2^*	0.00	0.03	0.12	0.21	0.28

TABLE 4
Dependence of (z_1^*, z_2^*) on b_1.

b_1	0.5	1	2	3	4	5
$(-z_1^*, z_2^*)$	$(-0.5, 0.30)$	$(-1, 0.30)$	$(-2, 0.30)$	$(-2.81, 0.30)$	$(-3.77, 0.30)$	$(-4.06, 0.31)$

Setting $x = 0$, we have

$$\begin{cases} P_1^* = P_1(0) = \dfrac{e^{-\eta_0 z_1} - 1}{e^{-\eta_0 z_1} - e^{\eta_0 z_2}}, \\ P_2^* = P_2(0) = \dfrac{1 - e^{\eta_0 z_2}}{e^{-\eta_0 z_1} - e^{\eta_0 z_2}}. \end{cases}$$

If we choose $\mathcal{I} = [0.01, 0.36] \times [0.01, 2.3]$, then $b_1 = 0.36$ which limits the maximum risk to 30% and $b_2 = 2.3$ which indicates a maximal 900% return.

Intuitively, stocks with larger expected return rate r correspond to bigger z_2^*, with shorter holding time and higher probability of making profit. This can be seen from Table 2 with fixed $\rho = 4$ and $\sigma = 0.3$.

On the other hand, for stocks with higher volatility, the corresponding z_2^* should be bigger to create more room for higher returns. In the meantime, this brings with it higher risk and therefore smaller probability of making money. This can be seen from Table 3.

Note that $z_1^* = 0.36$ in all of these cases. This means in general an optimal cut-loss level (30%) should be the maximum risk one is willing to take.

Remark 5.1. In addition, we also examine the dependence of (z_1^*, z_2^*) on the choice of b_1 and b_2. For this purpose, we choose $\rho = 4$, $r = 0.75$, and $\sigma = 0.38$ (which will be used in section 6). According to our numerical tests, if $b_2 \leq 0.30$, then $z_2^* = b_2$. For $b_2 > 0.30$, $z_2^* = 0.30$. Therefore, the optimal level z_2^* is mainly determined by other parameters, such as $r(i)$ and $\sigma(i)$, which is not sensitive to the choice of b_2 when it is greater than 0.3. Fixing $b_2 = 5$, we next examine the dependence of (z_1^*, z_2^*) on b_1. The results are summarized in Table 4.

These results tell us that $z_1^* \sim b_1$; it means the larger the b_1, the higher the risk is allowed, and that usually yields better expected return.

2-D Case ($m = 2$). The 2-D case ($m = 2$) corresponds to the model with Markov switching. Let the generator of $\alpha(\cdot)$ have the form

$$Q = \begin{pmatrix} -\lambda_1 & \lambda_1 \\ \lambda_2 & -\lambda_2 \end{pmatrix}$$

for $\lambda_1 > 0$ and $\lambda_2 > 0$. The corresponding stationary distribution is

$$(\nu_1, \nu_2) = \left(\frac{\lambda_2}{\lambda_1 + \lambda_2}, \frac{\lambda_1}{\lambda_1 + \lambda_2} \right).$$

In this example, we consider the market with two trends: up and down. Here $r(1) > 0$ corresponds to the up-trend return rate and $r(2) < 0$ the down-trend return rate. Let $\tilde{r} = r(1)\lambda_2 + r(2)\lambda_1$. Then the long-term average rate is given by

$$r(1)\nu_1 + r(2)\nu_2 = (\lambda_1 + \lambda_2)^{-1}\tilde{r} \tag{11}$$

which is typically greater than 0 in practice.

The corresponding differential equations are given by

$$\begin{cases} \dfrac{\sigma^2(1)}{2}\dfrac{\partial^2 v(x,1)}{\partial x^2} + r(1)\dfrac{\partial v(x,1)}{\partial x} - \rho v(x,1) + \lambda_1(v(x,2) - v(x,1)) = 0, \\ \dfrac{\sigma^2(2)}{2}\dfrac{\partial^2 v(x,2)}{\partial x^2} + r(2)\dfrac{\partial v(x,2)}{\partial x} - \rho v(x,2) + \lambda_2(v(x,1) - v(x,2)) = 0, \\ v(-z_1, 1) = \Phi(-z_1),\ v(-z_1, 2) = \Phi(-z_1), \\ v(z_2, 1) = \Phi(z_2),\ v(z_2, 2) = \Phi(z_2) \end{cases} \tag{12}$$

for $-z_1 < x < z_2$. Using the first equation, we obtain

$$v(x,2) = \frac{1}{\lambda_1}\left(-\frac{\sigma^2(1)}{2}\frac{\partial^2 v(x,1)}{\partial x^2} - r(1)\frac{\partial v(x,1)}{\partial x} + (\rho + \lambda_1)v(x,1) \right).$$

Substituting this into the second equation leads to

$$\begin{aligned} &\left(\frac{\sigma^2(1)\sigma^2(2)}{4}\right)\frac{\partial^4 v(x,1)}{\partial x^4} + \left(\frac{\sigma^2(1)r(2) + \sigma^2(2)r(1)}{2}\right)\frac{\partial^3 v(x,1)}{\partial x^3} \\ &\quad + \left(r(1)r(2) - \frac{\sigma^2(1)(\rho + \lambda_2) + \sigma^2(2)(\rho + \lambda_1)}{2} \right)\frac{\partial^2 v(x,1)}{\partial x^2} \\ &\quad - \Big(r(1)(\rho + \lambda_2) + r(2)(\rho + \lambda_1) \Big)\frac{\partial v(x,1)}{\partial x} + (\rho^2 + \rho(\lambda_1 + \lambda_2))v(x,1) = 0. \end{aligned}$$

The corresponding characteristic equation is given by

$$\begin{aligned} \psi(\eta) = \ & \frac{\sigma^2(1)\sigma^2(2)}{4}\eta^4 + \frac{\sigma^2(1)r(2) + \sigma^2(2)r(1)}{2}\eta^3 \\ & + \left(r(1)r(2) - \frac{\sigma^2(1)(\rho + \lambda_2) + \sigma^2(2)(\rho + \lambda_1)}{2} \right)\eta^2 \\ & - \Big(r(1)(\rho + \lambda_2) + r(2)(\rho + \lambda_1) \Big)\eta + \rho^2 + \rho(\lambda_1 + \lambda_2) = 0. \end{aligned} \tag{13}$$

It is easy to show that ψ can be written as

$$\begin{aligned} \psi(\eta) = \frac{\sigma^2(1)\sigma^2(2)}{4}\Bigg\{ & \left(\eta^2 + \frac{2r(1)}{\sigma^2(1)}\eta - \frac{2(\rho + \lambda_1)}{\sigma^2(1)} \right) \\ & \times \left(\eta^2 + \frac{2r(2)}{\sigma^2(2)}\eta - \frac{2(\rho + \lambda_2)}{\sigma^2(2)} \right) - \frac{4\lambda_1\lambda_2}{\sigma^2(1)\sigma^2(2)} \Bigg\}. \end{aligned}$$

Note that $\psi(\infty) = \psi(-\infty) = \infty$ and $\psi(0) > 0$. Moreover, let $\eta^+ > 0$ and $\eta^- < 0$ denote the zeros of

$$\eta^2 + \frac{2r(1)}{\sigma^2(1)}\eta - \frac{2(\rho+\lambda_1)}{\sigma^2(1)}.$$

One may also take $\eta^+ > 0$ and $\eta^- < 0$ to be the zeros of

$$\eta^2 + \frac{2r(2)}{\sigma^2(2)}\eta - \frac{2(\rho+\lambda_2)}{\sigma^2(2)}.$$

Then both $\psi(\eta^+)$ and $\psi(\eta^-)$ are less than zero. Therefore, in view of the intermediate value property, $\psi(\eta)$ should have four real zeros denoted by η_i, $i = 1, 2, 3, 4$. Hence, there are constants c_i, $i = 1, 2, 3, 4$, such that

$$\begin{cases} v(x,1) = \sum_{i=1}^{4} c_i e^{\eta_i(x+z_1)}, \\ v(x,2) = \sum_{i=1}^{4} c_i \kappa_i e^{\eta_i(x+z_1)}, \end{cases}$$

where

$$\kappa_i = \frac{1}{\lambda_1}\left(-\frac{\sigma^2(1)}{2}\eta_i^2 - r(1)\eta_i + \rho + \lambda_1\right).$$

Using the initial conditions, we have

$$\begin{pmatrix} 1 & 1 & 1 & 1 \\ \kappa_1 & \kappa_2 & \kappa_3 & \kappa_4 \\ e^{\eta_1(z_1+z_2)} & e^{\eta_2(z_1+z_2)} & e^{\eta_3(z_1+z_2)} & e^{\eta_4(z_1+z_2)} \\ \kappa_1 e^{\eta_1(z_1+z_2)} & \kappa_2 e^{\eta_2(z_1+z_2)} & \kappa_3 e^{\eta_3(z_1+z_2)} & \kappa_4 e^{\eta_4(z_1+z_2)} \end{pmatrix} \begin{pmatrix} c_1 \\ c_2 \\ c_3 \\ c_4 \end{pmatrix} = \begin{pmatrix} \Phi(-z_1) \\ \Phi(-z_1) \\ \Phi(z_2) \\ \Phi(z_2) \end{pmatrix}.$$

In view of Theorem 3.2, the above equation has a unique solution (c_1, c_2, c_3, c_4).

The objective is to choose (z_1, z_2) to maximize

$$V := p_1 v(0,1) + p_2 v(0,2) = \sum_{i=1}^{4} c_i(p_1 + \kappa_i p_2) e^{\eta_i z_1}.$$

We next compute $T(x,i)$. The corresponding differential equations are given by

$$\begin{cases} \frac{\sigma^2(1)}{2}\frac{\partial^2 T(x,1)}{\partial x^2} + r(1)\frac{\partial T(x,1)}{\partial x} + \lambda_1(T(x,2) - T(x,1)) + 1 = 0, \\ \frac{\sigma^2(2)}{2}\frac{\partial^2 T(x,2)}{\partial x^2} + r(2)\frac{\partial T(x,2)}{\partial x} + \lambda_2(T(x,1) - T(x,2)) + 1 = 0, \\ T(-z_1,1) = T(-z_1,2) = T(z_2,1) = T(z_2,2) = 0 \text{ for } -z_1 < x < z_2. \end{cases} \tag{14}$$

Following a similar procedure as in solving (12), we can show that the corresponding characteristic function $\psi^0(\eta)$ is identical to the one in (13) with $\rho = 0$. In view of (11), we consider only the case when $\tilde{r} := r(1)\lambda_2 + r(2)\lambda_1 \neq 0$. Note that $\dot{\psi}^0(0) = -\tilde{r}$. Therefore, ψ^0 has zeros

$$\begin{array}{l} \eta_1^0 < 0,\ \eta_2^0 < 0,\ \eta_3^0 > 0,\ \eta_4^0 = 0 \ \text{ if } \tilde{r} > 0, \\ \eta_1^0 < 0,\ \eta_2^0 > 0,\ \eta_3^0 > 0,\ \eta_4^0 = 0 \ \text{ if } \tilde{r} < 0. \end{array}$$

Thus we have

$$\begin{cases} T(x,1) = \sum_{i=1}^{3} c_i e^{\eta_i^0(x+z_1)} + c_4 - \dfrac{(\lambda_1+\lambda_2)x}{\tilde{r}}, \\ T(x,2) = \sum_{i=1}^{3} c_i \kappa_i^0 e^{\eta_i^0(x+z_1)} + c_4 - \dfrac{(\lambda_1+\lambda_2)x - (r(1)-r(2))}{\tilde{r}}, \end{cases}$$

where

$$\kappa_i^0 = \frac{1}{\lambda_1}\left(-\frac{\sigma^2(1)}{2}(\eta_i^0)^2 - r(1)\eta_i^0 + \lambda_1\right),\ i = 1,2,3.$$

In view of the initial conditions in (14), the following equation has a unique solution:

$$\begin{pmatrix} 1 & 1 & 1 & 1 \\ \kappa_1^0 & \kappa_2^0 & \kappa_3^0 & 1 \\ e^{\eta_1^0(z_1+z_2)} & e^{\eta_2^0(z_1+z_2)} & e^{\eta_3^0(z_1+z_2)} & 1 \\ \kappa_1^0 e^{\eta_1^0(z_1+z_2)} & \kappa_2^0 e^{\eta_2^0(z_1+z_2)} & \kappa_3^0 e^{\eta_3^0(z_1+z_2)} & 1 \end{pmatrix} \begin{pmatrix} c_1 \\ c_2 \\ c_3 \\ c_4 \end{pmatrix} = \frac{1}{\tilde{r}} \begin{pmatrix} -(\lambda_1+\lambda_2)z_1 \\ -(\lambda_1+\lambda_2)z_1 - (r(1)-r(2)) \\ (\lambda_1+\lambda_2)z_2 \\ (\lambda_1+\lambda_2)z_2 - (r(1)-r(2)) \end{pmatrix}.$$

Hence the expected exit time is given by

$$E\tau_0 = p_1 T(0,1) + p_2 T(0,2) = \sum_{i=1}^{3} c_i(p_1 + \kappa_i^0 p_2)e^{\eta_i^0 z_1} + c_4 + \frac{p_2(r(1)-r(2))}{\tilde{r}}.$$

We now compute $P_1(x,i)$. The corresponding differential equation is

$$\begin{cases} \dfrac{\sigma^2(1)}{2}\dfrac{\partial^2 P_1(x,1)}{\partial x^2} + r(1)\dfrac{\partial P_1(x,1)}{\partial x} + \lambda_1(P_1(x,2) - P_1(x,1)) = 0, \\ \dfrac{\sigma^2(2)}{2}\dfrac{\partial^2 P_1(x,2)}{\partial x^2} + r(2)\dfrac{\partial P_1(x,2)}{\partial x} + \lambda_2(P_1(x,1) - P_1(x,2)) = 0, \\ P_1(-z_1,1) = P_1(-z_1,2) = 0,\ P_1(z_2,1) = P_1(z_2,2) = 1 \end{cases} \tag{15}$$

for $-z_1 < x < z_2$.

Similarly, we can show

$$\begin{cases} P_1(x,1) = \sum_{i=1}^{3} c_i e^{\eta_i^0(x+z_1)} + c_4, \\ P_1(x,2) = \sum_{i=1}^{3} c_i \kappa_i^0 e^{\eta_i^0(x+z_1)} + c_4, \end{cases}$$

where, using the initial conditions in (15), (c_1,c_2,c_3,c_4) is determined by

$$\begin{pmatrix} 1 & 1 & 1 & 1 \\ \kappa_1^0 & \kappa_2^0 & \kappa_3^0 & 1 \\ e^{\eta_1^0(z_1+z_2)} & e^{\eta_2^0(z_1+z_2)} & e^{\eta_3^0(z_1+z_2)} & 1 \\ \kappa_1^0 e^{\eta_1^0(z_1+z_2)} & \kappa_2^0 e^{\eta_2^0(z_1+z_2)} & \kappa_3^0 e^{\eta_3^0(z_1+z_2)} & 1 \end{pmatrix} \begin{pmatrix} c_1 \\ c_2 \\ c_3 \\ c_4 \end{pmatrix} = \begin{pmatrix} 0 \\ 0 \\ 1 \\ 1 \end{pmatrix}.$$

Therefore, we obtain

$$P_1^* = P(S(\tau_0) \geq S_0 e^{z_2}) = p_1 P_1(0,1) + p_2 P_1(0,2) = \sum_{i=1}^{3} c_i (p_1 + \kappa_i^0 p_2) e^{\eta_i^0 z_1} + c_4.$$

Finally, we compute $P_2(x,i)$. The corresponding differential equation is identical to that in (15) except the boundary conditions become

$$P_1(-z_1,1) = P_1(-z_1,2) = 1,\ P_1(z_2,1) = P_1(z_2,2) = 0.$$

Similarly, the loss probabilities given $\alpha = 1,2$ can be written as

$$\begin{cases} P_2(x,1) = \sum_{i=1}^{3} c_i e^{\eta_i^0 (x+z_1)} + c_4, \\ P_2(x,2) = \sum_{i=1}^{3} c_i \kappa_i^0 e^{\eta_i^0 (x+z_1)} + c_4, \end{cases}$$

where the constants c_i, $i = 1,2,3,4$, are determined by

$$\begin{pmatrix} 1 & 1 & 1 & 1 \\ \kappa_1^0 & \kappa_2^0 & \kappa_3^0 & 1 \\ e^{\eta_1^0(z_1+z_2)} & e^{\eta_2^0(z_1+z_2)} & e^{\eta_3^0(z_1+z_2)} & 1 \\ \kappa_1^0 e^{\eta_1^0(z_1+z_2)} & \kappa_2^0 e^{\eta_2^0(z_1+z_2)} & \kappa_3^0 e^{\eta_3^0(z_1+z_2)} & 1 \end{pmatrix} \begin{pmatrix} c_1 \\ c_2 \\ c_3 \\ c_4 \end{pmatrix} = \begin{pmatrix} 1 \\ 1 \\ 0 \\ 0 \end{pmatrix}.$$

The loss probability is

$$P_2^* = P(S(\tau_0) \leq S_0 e^{-z_1}) = p_1 P_2(0,1) + p_2 P_2(0,2) = \sum_{i=1}^{3} c_i (p_1 + \kappa_i^0 p_2) e^{\eta_i^0 z_1} + c_4.$$

Remark 5.2. It would be interesting to study the sensitivity (or robustness) of the solution with respect to these parameters. Our numerical experiments indicate that the solution (z_1^*, z_2^*) is not sensitive with respect to small changes in $(\lambda_i, r(i), \sigma(i))$ in both the 1-D and 2-D cases. However, there is no straightforward way to prove this even in these simple cases. The main difficulty seems due to the fact that a maximizer of a function is not necessarily continuous with respect to these parameters.

6. A numerical example. In this section, we consider a numerical example with the reward function $\Phi(x) = e^x - 1$ given in (4). We begin with related computational issues. In this paper, the time is measured in years.

Estimation of $r(i)$ and $\sigma(i)$. To use the results in this paper, one needs to estimate $r(i)$ and $\sigma(i)$. We first consider a 1-D case. In this case, $r = r(1)$ and $\sigma = \sigma(1)$. The following procedure is standard for estimating the so-called historical volatility; see Hull [10].

Let S_i, $i = 0,1,\ldots,n$, denote the daily closing price of a stock and let

$$\zeta_i = \log S_i - \log S_{i-1},\ i = 1,2,\ldots,n.$$

Let $t_i = i/N_0$, where $N_0 = 252$ equals the number of trading days per annum. Then

$$\zeta_i = r(t_i - t_{i-1}) + \sigma(w(t_i) - w(t_{i-1})) \sim N\left(\frac{r}{N_0}, \frac{\sigma^2}{N_0}\right).$$

Let

$$\overline{\zeta} = \frac{\zeta_1 + \cdots + \zeta_n}{n}.$$

Then in view of the law of large numbers, the mean $r = N_0\overline{\zeta}$. Moreover, the standard deviation

$$\frac{\sigma}{\sqrt{N_0}} = \sqrt{\frac{1}{n-1}\sum_{i=1}^{n}(\zeta_i - \overline{\zeta})^2}.$$

Therefore, the volatility rate

$$\sigma = \sqrt{N_0} \cdot \sqrt{\frac{1}{n-1}\sum_{i=1}^{n}(\zeta_i - \overline{\zeta})^2}. \tag{16}$$

In the 2-D case, we start from a major market index such as the DJIA, NASDAQ, or S&P 500 to determine the market trends (up- or down-trends during a period of time) in the past 52 weeks. The jump rates λ_1 and λ_2 can be determined using one of these indices. Next we split the entire historical stock price data into two parts: the up-trend part consists of the price during the market up-trend periods and the down-trend part includes the price during the down-trend periods. Then we treat the up-trend and down-trend parts separately as in the 1-D case to obtain the up-trend volatility $\sigma(1)$ and down-trend volatility $\sigma(2)$.

To estimate the expected return rates, in the up-trend part let S_0^{up} denote the initial price, N^{up} the total points gained during the entire combined periods, and n^{up} the total number of trading days of the up-trend periods. Similarly, let S_0^{down}, N^{down}, and n^{down} denote the initial price, total points declined, and number of trading days in the down-trend periods, respectively. We choose

$$r(1) = N_0\left(\frac{\log(S_0^{\mathrm{up}} + N^{\mathrm{up}}) - \log S_0^{\mathrm{up}}}{n^{\mathrm{up}}}\right),$$
$$r(2) = N_0\left(\frac{\log(S_0^{\mathrm{down}} - N^{\mathrm{down}}) - \log S_0^{\mathrm{down}}}{n^{\mathrm{down}}}\right).$$

Remark 6.1. There are several other approaches available for estimating the parameters $r(i)$ and $\sigma(i)$ with constant $\alpha(t)$ (no switching). For example, linear filtering theory [17, p. 93] can be used to estimate the expected return $r(i)$. Another volatility estimation method uses daily price spreads (daily highs vs. daily lows). The larger the averaged spread the more volatile the stock. Interestingly, such an estimate is quite consistent with the estimate in (16); see Tompkins [19].

We next apply our method to daily closes of Microsoft stock (NASDAQ-MSFT) in 1999 (see Figure 1) based on the closes in the year 1998.

We use the NASDAQ Composite Index from 1998 to determine the general market movement which is given as follows:

Up-trend	1/2–4/22	6/16–7/20	9/11–9/23	10/9–12/31
Down-trend	4/23–6/15	7/21–9/10	9/24–10/8	

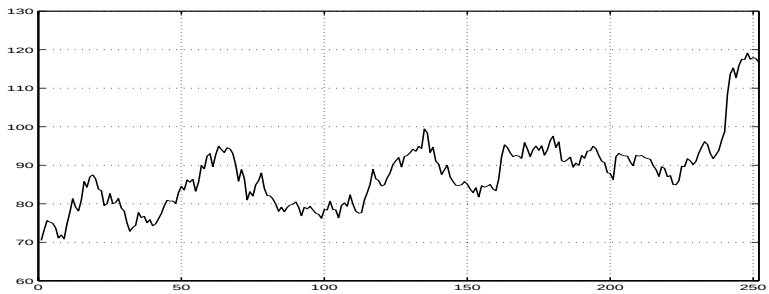

FIG. 1. *Adjusted closing price of MSFT (Jan. 4–Dec. 31, 1999).*

Moreover, the total number of "up" trading days is 167 and that of "down" days is 85. Thus, the average up (and average down, respectively) duration time is

$$\frac{1}{\lambda_1} = \frac{167}{252} \cdot \frac{1}{4}$$

and

$$\left(\frac{1}{\lambda_2} = \frac{85}{252} \cdot \frac{1}{3}, \text{ respectively} \right).$$

This gives the jump rates of $\alpha(\cdot)$

$$\lambda_1 = 6.04, \ \lambda_2 = 8.90.$$

Remark 6.2. We would like to point out that the switching $\alpha(t)$ can also be used to characterize the trends of an industrial group index or even that of an individual stock.

In addition, we obtain

$$r(1) = 1.50, \quad r(2) = -1.61, \quad \sigma(1) = 0.44, \quad \sigma(2) = 0.63.$$

We choose $p_1 = p_2 = 0.5$ because the market had rallied long enough since September 1998 that a market correction was possible. We choose $\mathcal{I} = [0.01, 0.36] \times [0.01, 2.3]$. Moreover, we take the initial value $S_0 = 70.5$, which is the closing price on January 4, 1999.

Selection of ρ. Note that the expected holding time $E\tau_0$ and the probability ratio P_1^*/P_2^* depend on the discount factor ρ. Typically, $E\tau_0$ provides a time period that capital has to be tied to the investment. On the other hand, P_1^*/P_2^* gives the likelihood of profitability. Clearly, these are two important factors in trading decision making. Intuitively, larger ρ discounts more on a future return, which leads to shorter holding time and larger probability of making a profit (see Table 5). In view of this, the discount factor ρ should be chosen according to how long investment capital is available and/or the outlook of profit probability. For example, if one plans to invest the capital for half a year, then one should choose ρ such that $E\tau_0 \sim 0.5$. Or one may choose ρ so that the probability ratio

$$P^* := \frac{P_1^*}{P_2^*} \geq k_0$$

TABLE 5
Dependence of $E\tau_0$ and P_1^*/P_2^* on ρ in 2-D model.

ρ	1	2	3	4	5	6	7	8	9	10
$E\tau_0$	2.07	1.23	1.00	0.51	0.44	0.39	0.35	0.33	0.30	0.29
P_1^*/P_2^*	1.58	2.59	3.51	5.21	6.42	7.76	9.10	10.24	11.84	13.0

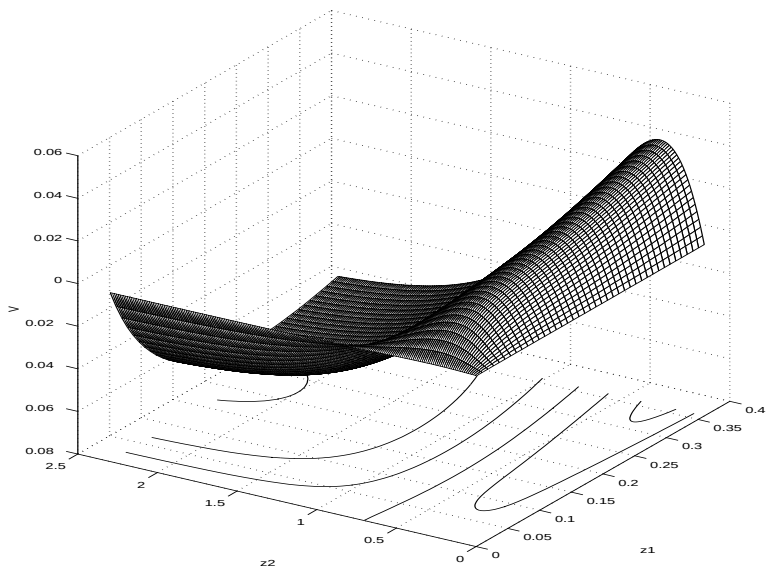

FIG. 2. *2-D reward function: MSFT (Jan. 2–Dec. 30, 1998).*

for a predetermined $k_0 > 0$. These two criteria can also be used jointly if so desired. To illustrate this idea, we compute $E\tau_0$ and P_1^*/P_2^* for $\rho = 1, 2, \ldots, 10$. Table 5 gives the dependence of these quantities on ρ.

Suppose, for example, we plan to invest capital for half a year and want the corresponding profit probability greater than 0.8 (or $P_1^*/P_2^* \geq 4$). Then we should choose $\rho = 4$. Using $\rho = 4$, the graph of the reward function V is given in Figure 2, which indicates the maximum occurs at $(z_1^*, z_2^*) = (0.36, 0.28)$.

If one decides to observe our selling rule, then, according to Figure 1, sell on January 20, 1999 at 81 if choosing $\rho = 10$, sell on January 26, 1999 at 81.48 if $\rho = 9$, and so on. These selling dates are listed in Table 6, in which $\overline{\tau}_0$ is the actual holding time if sold at or above the target price $S_0 e^{z_2^*}$ at closing. In Table 6, "*" means the target price has not yet been reached. Since the target period $E\tau_0 = 2.07$ is a little more than two years, one expects the corresponding target 195.18 to be reached around the beginning of year 2001.

One may also use the 1-D formula for similar calculations. In this case, $r = 0.75$ and $\sigma = 0.38$. The corresponding 1-D reward function (with $\rho = 4$) is given in Figure 3. As in Tables 5 and 6, Tables 7 and 8 provide corresponding results in the 1-D setting.

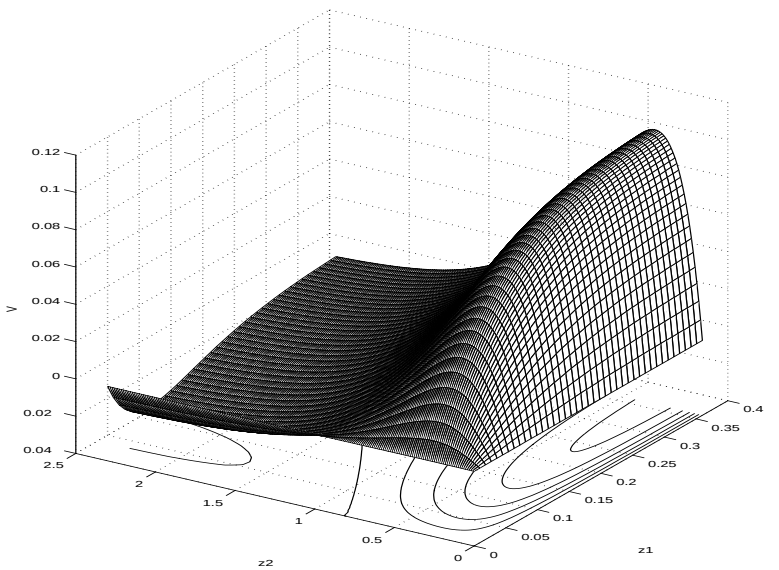

FIG. 3. 1-*D reward function: MSFT* (*Jan.* 2–*Dec.* 30, 1998).

TABLE 6
2-*D model: Comparisons with real data.*

ρ	1	2	3	4	5	6	7	8	9	10
$S_0 e^{z_2^*}$	195.18	116.35	100.20	92.99	88.81	85.80	83.85	82.89	81.48	81.00
sold on	*	12/22	12/15	4/5	3/25	1/26	1/26	1/26	1/26	1/20
$\overline{\tau}_0$	*	0.98	0.96	0.25	0.23	0.064	0.064	0.064	0.064	0.048
$\lvert E\tau_0 - \overline{\tau}_0 \rvert$	*	0.25	0.04	0.26	0.21	0.33	0.29	0.27	0.24	0.24

TABLE 7
Dependence of $E\tau_0$ *and* P_1^*/P_2^* *on* ρ *in* 1-*D model.*

ρ	1	2	3	4	5	6	7	8	9	10
$E\tau_0$	2.34	0.78	0.50	0.38	0.31	0.26	0.23	0.20	0.19	0.17
P_1^*/P_2^*	41.08	41.16	41.80	43.01	44.72	46.49	48.20	50.57	52.10	53.93

Looking at Tables 6 and 8, it can be seen that the 2-D model provides more realistic target prices. As for the expected holding times, the 1-D model provides better estimates for larger $\rho(\geq 5)$, which corresponds to smaller $E\tau_0$. On the other hand, the 2-D model yields better estimates for smaller $\rho(\leq 4)$. In addition, the 1-D model in Table 7 produces a much greater probability ratio estimate P_1^*/P_2^*.

7. Concluding remarks. Selling a stock is a crucial step to nail down real profit or to cut loss short. But emotions may come into play when selling. A rigorous selling rule would help an investor to control human emotion and consistently make profits. The results obtained in this paper, including the predetermined target price, stop-loss limit, target period, and the corresponding probabilities, could be used as a

guide to actual trading.

Appendix. In this appendix, we provide proofs of the results in this paper. We also give two technical lemmas required in the proofs.

Proof of Theorem 3.2. To show (a), it suffices to show the equation has a C^2 solution. Then following from Dynkin's formula, we have

$$v(x,i) = E[e^{-\rho\tau(x)}\Phi(\xi(\tau(x)))|\alpha(0) = i],$$

which implies the uniqueness of the solution.

Let $\phi(x) = (v(x,1),\dots,v(x,m))' \in \mathbb{R}^{1\times m}$. Then the differential equations (7) can be written as

$$\frac{1}{2}\mathrm{diag}(\sigma^2(1),\dots,\sigma^2(m))\ddot{\phi} + \mathrm{diag}(r(1),\dots,r(m))\dot{\phi} - \rho\phi + Q\phi = 0. \tag{17}$$

Let

$$\Gamma = \mathrm{diag}\left(\frac{r(1)}{\sigma^2(1)},\dots,\frac{r(m)}{\sigma^2(m)}\right),$$

$$\Sigma = \mathrm{diag}\left(\frac{1}{\sigma^2(1)},\dots,\frac{1}{\sigma^2(m)}\right).$$

Then (17) can be written as

$$\ddot{\phi} + 2\Gamma\dot{\phi} - 2\rho\Sigma\phi + 2\Sigma Q\phi = 0.$$

Let $\theta \in [0,1]$, $a, b \in \mathbb{R}^m$. Consider the differential equation

$$\begin{cases} \ddot{\phi} + 2\Gamma\dot{\phi} - 2\rho\Sigma\phi + 2\theta\Sigma Q\phi = 0, \\ \phi(-z_1) = a,\ \phi(z_2) = b. \end{cases} \tag{18}$$

Let

$$y(x) = (\phi'(x), \dot{\phi}'(x))' = \left(v(x,1),\dots,v(x,m), \frac{\partial v(x,1)}{\partial x},\dots,\frac{\partial v(x,m)}{\partial x}\right)'$$

and

$$A^\theta = \begin{pmatrix} 0_{m\times m} & I_{m\times m} \\ 2\Sigma(\rho I - \theta Q) & -2\Gamma \end{pmatrix}.$$

Then the differential equation (18) is equivalent to

$$\dot{y} = A^\theta y,\ \phi(-z_1) = a,\ \phi(z_2) = b. \tag{19}$$

Let

$$\Theta = \Big\{\theta \in [0,1] : \text{ such that (18) (or (19)) has a solution for all } a, b \in \mathbb{R}^m\Big\}.$$

Using the condition $\phi(-z_1) = a$, we can write

$$y(x) = \exp(A^\theta(x+z_1)) \begin{pmatrix} a \\ c \end{pmatrix},$$

where $c \in \mathbb{R}^m$ needs to be determined by the condition $\phi(z_2) = b$. Write

$$\exp(A^\theta(x+z_1)) = \begin{pmatrix} F_{11}^\theta(x+z_1) & F_{12}^\theta(x+z_1) \\ F_{21}^\theta(x+z_1) & F_{22}^\theta(x+z_1) \end{pmatrix},$$

such that $F_{ij}^\theta \in \mathbb{R}^{m\times m}$ for $i,j = 1,2$. Then (19) has a solution for all $b \in \mathbb{R}^m$ if and only if $F_{12}^\theta(z_1+z_2)$ is invertible.

We first show that Θ is not empty. In fact, $0 \in \Theta$. To show this, we note that when $\theta = 0$

$$\exp(A^0 x) = \begin{pmatrix} \operatorname{diag}(e^{\eta_1^1 x}, \dots, e^{\eta_m^1 x}) & \operatorname{diag}(e^{\eta_1^2 x}, \dots, e^{\eta_m^2 x}) \\ \operatorname{diag}(\eta_1^1 e^{\eta_1^1 x}, \dots, \eta_m^1 e^{\eta_m^1 x}) & \operatorname{diag}(\eta_1^2 e^{\eta_1^2 x}, \dots, \eta_m^2 e^{\eta_m^2 x}) \end{pmatrix} \times \begin{pmatrix} I_{m\times m} & I_{m\times m} \\ \operatorname{diag}(\eta_1^1, \dots, \eta_m^1) & \operatorname{diag}(\eta_1^2, \dots, \eta_m^2) \end{pmatrix}^{-1},$$

where η_i^1 and η_i^2 are the eigenvalues of A^0 given by

$$\begin{cases} \eta_i^1 = -\dfrac{r(i)}{\sigma^2(i)} - \sqrt{\left(\dfrac{\mu(i)}{\sigma^2(i)}\right)^2 + \dfrac{2\rho}{\sigma^2(i)}}, \\ \eta_i^2 = -\dfrac{r(i)}{\sigma^2(i)} + \sqrt{\left(\dfrac{\mu(i)}{\sigma^2(i)}\right)^2 + \dfrac{2\rho}{\sigma^2(i)}}, \end{cases}$$

$i = 1, \dots, m$.

$$F_{12}^0(z_1+z_2) = \operatorname{diag}\left(\frac{e^{\eta_1^2(z_1+z_2)} - e^{\eta_1^1(z_1+z_2)}}{\eta_1^2 - \eta_1^1}, \dots, \frac{e^{\eta_m^2(z_1+z_2)} - e^{\eta_m^1(z_1+z_2)}}{\eta_m^2 - \eta_m^1}\right),$$

which is invertible.

Next, let

$$\theta^* = \sup\Big\{\theta : \ [0,\theta] \subset \Theta\Big\}.$$

Clearly, $\theta^* \geq 0$. We show that $\theta^* = 1$. Note that if we can show $\theta^* \in \Theta$, then $F_{12}^{\theta^*}(z_1+z_2)$ is invertible, which implies, for any $\delta > 0$,

$$\exp(A^{\theta^*+\delta}(z_1+z_2)) = \exp(A^{\theta^*}(z_1+z_2)) + O(\delta),$$

because

$$A^{\theta^*+\delta}(z_1+z_2) = A^{\theta^*}(z_1+z_2) + \delta \begin{pmatrix} 0_{m\times m} & 0_{m\times m} \\ -2\Sigma Q & 0_{m\times m} \end{pmatrix}.$$

Thus for δ small enough, $F_{12}^{\theta}(z_1+z_2))$ is invertible. Following a similar argument, it is easy to see that $[0,\delta)\subset\Theta$. Therefore, $\theta^*>0$. If $\theta^*<1$, then it follows $(\theta^*+\delta)\in\Theta$, which contradicts the definition of θ^*. It remains to show $\theta^*\in\Theta$. By the definition of θ^*, there exists a sequence $\{\theta_n\}\subset\Theta$ such that $\theta_n\to\theta^*$ as $n\to\infty$. For any $a=(a_1,\ldots,a_m)'$ and $b=(b_1,\ldots,b_m)'$, let $\phi_n(x)\in C^2[-z_1,z_2]$ be the corresponding solutions with terminal reward function

$$\Phi(x,i)=\frac{b_i-a_i}{z_1+z_2}(x-z_2)+b_i.$$

Then it can be shown that ϕ_n is uniformly bounded by applying Dynkin's formula to

$$e^{-\rho t}\phi_n(\xi_n(t),\alpha_n(t)),$$

which leads to

$$\phi_n(x)=\Big(E[e^{-\rho\tau(x)}\Phi(\xi_n(\tau(x)))|\alpha_n(0)=1],\ldots,E[e^{-\rho\tau(x)}\Phi(\xi_n(\tau(x)))|\alpha_n(0)=m]\Big)',$$

where $\alpha_n(t)$ is a Markov chain generated by θ_nQ and $\xi_n(t)$ is the corresponding diffusion given in (5).

Integrating twice the differential equation (18) from $-z_1$ to x yields

$$\begin{cases}\phi_n(x)=a+(x+z_1)\dot{\phi}_n(-z_1)+g_n(x),\\ b=a+(z_1+z_2)\dot{\phi}_n(-z_1)+g_n(z_2),\end{cases}$$

where

$$g_n(x)=-2\Gamma\int_{-z_1}^{x}(\phi_n(r)-a)dr+2\rho\Sigma\int_{-z_1}^{x}\int_{-z_1}^{u}\phi_n(r)drdu-2\theta_n\Sigma Q\int_{-z_1}^{x}\int_{-z_1}^{u}\phi_n(r)drdu.$$

In view of the uniform boundedness of ϕ_n, there exists a subsequence $\{n_k\}$ such that $\int_{-z_1}^{x}\phi_{n_k}(r)dr$ converges in sup-norm. Thus $g_{n_k}(-z_1)$ converges which in turn implies $\dot{\phi}_{n_k}(-z_1)$ converges. Therefore, $\phi_{n_k}(x)$ converges in sup-norm. Hence, for all $a,b\in\mathbb{R}^m$, (18) has a solution when $\theta=\theta^*$. It follows that $\theta^*\in\Theta$.

We next show that $\phi(x,i)=\phi_{z_1,z_2}(x,i)$ is continuous. This can be seen from

$$\begin{aligned}\phi(x)=F_{11}^{1}(x+z_1)\Phi(-z_1)\mathbb{1}+F_{12}^{1}(x+z_1)(F_{12}^{1}(z_1+z_2))^{-1}\\ \times\left(\Phi(z_2)\mathbb{1}-F_{11}^{1}(z_1+z_2)\Phi(-z_1)\mathbb{1}\right),\end{aligned}$$

where $\mathbb{1}=(1,\ldots,1)'\in\mathbb{R}^m$.

Given (x,i), the continuity of $v(x,i)$ in (z_1,z_2) implies the continuity of V in (z_1,z_2). The existence of (z_1^*,z_2^*) maximizing V follows from the compactness of $\mathcal{I}$.

This completes the proof. □

Remark A.1. Note that a key condition that guarantees the existence is the uniform boundedness of $\phi(x)$. The proof does not go through without such a condition. For example, consider

$$\ddot{y}+\eta^2y=0,$$

with $0\le\eta\le1$, $y(0)=a$, and $y(\pi)=b$. Then

$$y(x)=\left(\frac{b-a\cos\eta\pi}{\sin\eta\pi}\right)\sin\eta x+a\cos\eta x,$$

which is not uniformly bounded as $\eta \to 1$. Consequently,

$$e^{Ax} = \begin{pmatrix} \cos \eta x & \dfrac{\sin \eta x}{\eta} \\ -\eta \sin \eta x & \cos \eta x \end{pmatrix}.$$

$F_{12} = (\sin \eta x)/\eta$ is not invertible at $x = \pi$ when $\eta = 1$.

Recall the independence condition of $\alpha(\cdot)$ and $w(\cdot)$. We have the following lemma.

LEMMA A.2. *Let $\mathcal{D}$ denote the sigma-algebra generated by $\{\alpha(s) : s \le T\}$. Then*

$$E\left[\int_0^T \sigma(\alpha(s))dw(s)\Big|\mathcal{D}\right] = 0.$$

Proof. Given a positive integer n, let $t_k = kT/n$ for $k = 0, 1, \ldots, n$. Define

$$\alpha^n(t) = \alpha(t_k) \text{ if } t \in [t_k, t_{k+1}),\ k = 0, 1, \ldots, n,$$

and $\alpha^n(T) = \alpha(T)$. Then it follows that, as $n \to \infty$,

$$\int_0^T \Big(\sigma(\alpha(s)) - \sigma(\alpha^n(s))\Big)^2 ds \to 0 \text{ a.s.}$$

Since $\mathcal{M}$ is finite, $\sigma(i)$ is bounded. The Lebesgue dominated convergence theorem implies

$$E\int_0^T \Big(\sigma(\alpha(s)) - \sigma(\alpha^n(s))\Big)^2 ds \to 0.$$

We next show that, for each fixed n,

$$E\left[\int_0^T \sigma(\alpha^n(s))dw(s)\Big|\mathcal{D}\right] = 0 \text{ a.s.}$$

In fact, let $y^n(t) = y_k$ if $t \in [t_k, t_{k+1})$ for given $(y_0, y_1, \ldots, y_n) \in \mathbb{R}^{n+1}$. Define

$$f(y_0, y_1, \ldots, y_n, \omega) = \int_0^T \sigma(y^n(s))dw(s)(\omega).$$

We have

$$g(y_0, y_1, \ldots, y_n) := E[f(y_0, y_1, \ldots, y_n, \omega)|\mathcal{D}] = 0.$$

It follows that, in view of the martingale property,

$$g(\alpha(t_0), \alpha(t_1), \ldots, \alpha(t_n)) = Ef(\alpha(t_0), \alpha(t_1), \ldots, \alpha(t_n), \omega) = 0.$$

Moreover, using Jensen's inequality, we have

$$\left(E\left[\int_0^T \Big(\sigma(\alpha(s)) - \sigma(\alpha^n(s))\Big)dw(s)\Big|\mathcal{D}\right]\right)^2$$
$$\le E\left[\left(\int_0^T \Big(\sigma(\alpha(s)) - \sigma(\alpha^n(s))\Big)dw(s)\right)^2 \Big|\mathcal{D}\right].$$

Therefore, we obtain

$$E\left(E\left[\int_0^T \sigma(\alpha(s))dw(s)\Big|\mathcal{D}\right] - E\left[\int_0^T \sigma(\alpha^n(s))dw(s)\Big|\mathcal{D}\right]\right)^2$$
$$\leq E\int_0^T \Big(\sigma(\alpha(s)) - \sigma(\alpha^n(s))\Big)^2 ds \to 0.$$

Hence we have

$$E\left[\int_0^T \sigma(\alpha(s))dw(s)\Big|\mathcal{D}\right] = 0 \text{ a.s.} \qquad \square$$

The next lemma will be needed in the proof of Lemma 4.1.

LEMMA A.3. *Given $z > 0$, there exist $s_0 > 0$ and $\delta_0 > 0$ such that*

$$P(|\xi(s_0)| \geq z | \xi(0) = x, \alpha(0) = i) \geq \delta_0 \tag{20}$$

for all $|x| \leq z$ and $i \in \mathcal{M}$.

Proof. If (20) does not hold, then, for some $z_0 > 0$, there exist $|x_0| \leq z_0$ and $i_0 \in \mathcal{M}$ such that, for all s_0 and δ_0,

$$P(|\xi(s_0)| \geq z_0 | \xi(0) = x_0, \alpha(0) = i_0) < \delta_0,$$

which implies $P(|\xi(s_0)| \geq z_0 | \xi(0) = x_0, \alpha(0) = i_0) = 0$ and hence $|\xi(s_0)| < z_0$ a.s. Therefore,

$$|\xi(s_0) - x_0| \leq z_0 + |x_0| \text{ a.s.} \tag{21}$$

In view of Lemma A.2, we have

$$E\left[\int_0^{s_0} r(\alpha(s))ds \int_0^{s_0} \sigma(\alpha(s))dw(s)\right]$$
$$= E\left\{\int_0^{s_0} r(\alpha(s))ds E\left[\int_0^{s_0} \sigma(\alpha(s))dw(s)\Big|\mathcal{D}\right]\right\} = 0.$$

It follows that

$$E(\xi(s_0) - x_0)^2 = E\left(\int_0^{s_0} r(\alpha(s))ds\right)^2 + E\left(\int_0^{s_0} \sigma(\alpha(s))dw(s)\right)^2$$
$$\geq E\int_0^{s_0} (\sigma(\alpha(s)))^2 ds.$$

Moreover, it is well known that for $i_1 \in \mathcal{M}$,

$$\nu_i := \lim_{s\to\infty} P(\alpha(s) = i | \alpha(0) = i_1) \text{ exists.}$$

It is easy to see that $\nu_i \geq 0$ and $\nu_1 + \cdots + \nu_m = 1$. Therefore,

$$\frac{1}{s_0} E\int_0^{s_0} (\sigma(\alpha(s)))^2 ds = \frac{1}{s_0}\int_0^{s_0} \sum_{i=1}^m \sigma^2(i) P(\alpha(s) = i | \alpha(0) = i_1) ds$$
$$\to \sum_{i=1}^m \sigma^2(i)\nu_i ds > 0.$$

This contradicts (21) because

$$\frac{E(\xi(s_0)-x_0)^2}{s_0} \le \frac{(z_0+|x_0|)^2}{s_0} \to 0 \text{ as } s_0 \to \infty. \qquad \square$$

Proof of 4.1. Let $z = \max\{z_1, z_2\}$. Then in view of Lemma A.3, there exist s_0 and δ_0 such that

$$P(|\xi(s_0)| \ge z | \xi(0) = x, \alpha(0) = i) \ge \delta_0$$

for all $|x| \le z$ and $i \in \mathcal{M}$.

Using this inequality, we have

$$\begin{aligned} P(\tau_0 > s_0) \le & \quad P(|\xi(s_0)| < z | \xi(0) = x, \alpha(0) = i) \\ \le & \quad 1 - P(|\xi(s_0)| \ge z | \xi(0) = x, \alpha(0) = i) \\ \le & \quad 1 - \delta_0. \end{aligned}$$

Similarly, we have

$$\begin{aligned} P(\tau_0 > 2s_0) \le & \quad P(|\xi(2s_0)| < z, |\xi(s_0)| < z | \xi(0) = x, \alpha(0) = i) \\ = & \quad \sum_{j=1}^{m} \int_{-z}^{z} P(|\xi(2s_0)| < z | \xi(s_0) = y, \alpha(s_0) = j) \\ & \qquad \times P(\xi(s_0) \in dy, \alpha(s_0) = j | \xi(0) = x, \alpha(0) = i) \\ \le & \quad (1-\delta_0) P(|\xi(s_0)| < z | \xi(0) = x, \alpha(0) = i) \\ \le & \quad (1-\delta_0)^2. \end{aligned}$$

In general, we can show, for each $n = 1, 2, \ldots$,

$$P(\tau_0 > n s_0) \le (1-\delta_0)^n.$$

Following the proof of Chow and Teicher [1, Corollary 4.1.3], we have

$$E\tau(x) \le s_0 \sum_{n=0}^{\infty} P(\tau_0 > n s_0) \le s_0 \sum_{n=0}^{\infty} (1-\delta_0)^n = \frac{s_0}{\delta_0}. \qquad \square$$

Proof of Theorem 4.2. The proof is similar to that of Theorem 3.2 except that if $T(x,i)$ is a solution to (8), then by Dynkin's formula,

$$T(x,i) = E[\tau(x) | \xi(0) = x, \alpha(0) = i] \le K. \qquad \square$$

Proof of Theorem 4.5. The proof follows that of Theorem 3.2 except by taking $\Phi(x) = I_{\{x=z_2\}}$, $\rho = 0$, and noting that

$$P_1(x,i) = E[\Phi(\xi(\tau(x)))| \alpha(0) = i]. \qquad \square$$

Proof of Theorem 4.6. This is similar to the proof of Theorem 4.5. $\square$

ON THE BOUNDEDNESS AND CONTINUITY OF THE SPECTRAL FACTORIZATION MAPPING*

BIRGIT JACOB† AND JONATHAN R. PARTINGTON†

Abstract. It is known that the spectral factorization mapping is bounded, but not continuous, on L_∞, the space of essentially bounded measurable functions on the unit circle. In this article we study the spectral factorization mapping on decomposing Banach algebras. The most important example of a decomposing Banach algebra is the Wiener algebra, the space of all absolutely convergent Fourier series. It is shown that the spectral factorization mapping is locally Lipschitz continuous, but not bounded, on all decomposing Banach algebras in consideration. An application is given to the construction of approximate normalized coprime factorization.

Key words. spectral factorization, continuity of the factorization, boundedness of the factorization, normalized coprime factorization, decomposing Banach algebras

1. Introduction.

Spectral factorization is the process by which a (possibly matrix-valued) function G is written as $G = W^*W$; that is, $G(e^{i\theta}) = W(e^{i\theta})^*W(e^{i\theta})$ for $\theta \in [0, 2\pi]$, or $G(i\omega) = W(i\omega)^*W(i\omega)$ for $\omega \in \mathbb{R}$. It is a procedure arising in many system-theoretic applications: for example, it is linked to H_∞ robust control, linear quadratic optimal control, and linear quadratic Gaussian (LQG) optimal control by the solution of Riccati equations [6, 8, 9, 19, 27, 29, 30]. Again, it is also seen in robust control via the construction of normalized coprime factorizations [30, 8].

For finite dimensional linear systems, the required spectral factors are generally rational functions, and there are well-established algebraic techniques for their solution. In the infinite dimensional case, it is common to proceed by approximation procedures (cf. [20, 11]), in which case it is important to know whether the operation of taking spectral factors is continuous and to be able to provide error estimates. The answer to this question depends crucially on which normed spaces one is using, as we shall see later. We shall build on work of Clancey and Gohberg [7], which we relate to work of Peller and Khrushchev [23], in order to give a systematic approach to this problem.

It is also important to know under what circumstances the norms of the spectral factors can be bounded in terms of the norm of the function being factorized. One application that we mention here is in the work of Patil on recovery of Hardy class functions from their values on a limited bandwidth [22, 21], where a sequence of spectral factorizations is employed. Similar calculations arise in the context of band-limited identification [2]. The boundedness problem turns out to be independent of the question of the continuity of the factorization. We shall see that, in most of the function spaces considered in systems theory (excepting the obvious case of the L_∞ norm), spectral factorization is actually unbounded.

In this paper we study only the scalar case. However, all the results obtained in this paper can be generalized without any problems to the matrix case.

The outline of this paper is as follows. In section 2 we review the notion of a decomposing Banach algebra and present some important examples. Spectral factorization is discussed in section 3, and its continuity in decomposing Banach algebras is the subject of section 4. The more difficult issue of boundedness is analyzed in section 5. Most of the results are presented originally for discrete-time systems (spectral factorization on the unit circle): a brief discussion of the half-plane case is given in section 6.

2. Decomposing Banach algebras. In this section we recall the notion of decomposing Banach algebras and we give many examples of these Banach algebras. We start by recalling some facts about Banach algebras which are frequently used in this paper.

By $\mathbb{T}$ we denote the unit circle $\{z \in \mathbb{C} \mid |z| = 1\}$ and by $\mathbb{D}$ the disc $\{z \in \mathbb{C} \mid |z| < 1\}$. Let $L_p(\mathbb{T})$, $1 < p < \infty$, be the Banach space of p-integrable functions on $\mathbb{T}$.

Let $\mathcal{B}$ be a commutative Banach algebra satisfying $\mathcal{B} \subset L_2(\mathbb{T})$. We will denote the norm of $\mathcal{B}$ by $\|\cdot\|_{\mathcal{B}}$ and let $\mathcal{GB}$ be the set of all invertible elements of $\mathcal{B}$. If $f \in \mathcal{B}$, we define the exponential by $e^f := \sum_{n=0}^{\infty} \frac{f^n}{n!}$. Then $e^f \in \mathcal{GB}$. By $\exp \mathcal{B}$ we denote the set $\{f \in \mathcal{B} \mid f = e^g, g \in \mathcal{B}\}$. Note that $\exp \mathcal{B}$ coincides with the component of $\mathcal{GB}$ which contains the identity, which is denoted by 1. Another important subset of $\mathcal{B}$ is

$$\mathcal{B}_{\text{pos}} := \{f \in \mathcal{B} \mid f(t) > 0 \text{ for every } t \in \mathbb{T}\}.$$

For more information on Banach algebras we refer the reader to Rickart [24], Larsen [18], and Bonsall and Duncan [5].

Next we will recall the notion of decomposing Banach algebras. For every $f \in L_2(\mathbb{T})$ we can define a function $Pf \in L_2(\mathbb{T})$ by

$$(Pf)(z) = \frac{1}{2\pi i} \int_{\mathbb{T}} \frac{f(\omega)}{\omega - z}\, d\omega.$$

P is the projection from $L_2(\mathbb{T})$ to the Hardy class $H_2(\mathbb{D})$, the space of all functions in $L_2(\mathbb{T})$ which are holomorphic within the unit disc; see, for example, Hoffman [13, p. 151]. Moreover, P is the projection from $L_p(\mathbb{T})$ onto $H_p(\mathbb{D})$ if $p \in (1, \infty)$; see Hoffman [13, p. 151].

DEFINITION 2.1. *A commutative Banach algebra $\mathcal{B} \subset L_2(\mathbb{T})$ is called a* decomposing Banach algebra *if*

- (A1) *$f \in \mathcal{B}$ implies $\bar{f} \in \mathcal{B}$ and $Pf \in \mathcal{B}$;*
- (A2) *$\mathcal{B}$ is a Banach algebra with respect to pointwise multiplication on $\mathbb{T}$;*
- (A3) *the set of trigonometric polynomials is dense in $\mathcal{B}$;*
- (A4) *every nonzero multiplicative functional on $\mathcal{B}$ coincides with a functional $f \mapsto f(t)$ defined as the value at some point $t \in \mathbb{T}$ (note that $\varphi : \mathcal{B} \to \mathbb{C}$ is a multiplicative functional if φ is a linear functional and $\varphi(ab) = \varphi(a)\varphi(b)$, $a, b \in \mathcal{B}$).*

This class of Banach algebras coincides with a class of Banach algebras introduced by Peller and Khrushchev [23] in order to study the problem of best approximation by analytic functions. Clancey and Gohberg [7] gave a more general definition of a decomposing Banach algebra, although they then imposed extra conditions in order to guarantee the existence of factorizations. The following proposition has been proved by Peller and Khrushchev [23].

PROPOSITION 2.2. *Let $\mathcal{B}$ be a decomposing Banach algebra. Then $\mathcal{B}$ is continuously embedded in $C(\mathbb{T})$, the space of maximal ideals of the algebra $\mathcal{B}$ coincides with $\mathbb{T}$, and $P \in \mathcal{L}(\mathcal{B})$.*

From now on, the symbol $\mathcal{B}$ will invariably denote a decomposing Banach algebra. The following proposition follows directly from the Beurling–Gel'fand theorem (see, for example, Larsen [18, p. 79 ff]).

PROPOSITION 2.3. *Every $f \in \mathcal{B}$, such that $f(t) \neq 0$ for all $t \in \mathbb{T}$, is an element of $\mathcal{GB}$.*

Using Proposition 2.3, we get $\mathcal{B}_{\rm pos} \subseteq \exp \mathcal{B}$, because an element $f \in \mathcal{B}_{\rm pos}$ can be joined to the identity via the path $\lambda + (1-\lambda)f$. As usual, for a function $f \in L_1(\mathbb{T})$ and $n \in \mathbb{Z}$, we write $\hat{f}(n)$ for the nth Fourier coefficient of f. Let $\mathcal{B}_+$ be defined by

$$\mathcal{B}_+ := \{f \in \mathcal{B} \mid \hat{f}(n) = 0 \text{ for all } n < 0\}.$$

For a decomposing Banach algebra $\mathcal{B}$, the set $\mathcal{B}_+$ is the set of all functions f in $\mathcal{B}$ that can be written as $f = Pg$ for some $g \in \mathcal{B}$; that is, P is the projection from $\mathcal{B}$ onto $\mathcal{B}_+$. By $Q \in \mathcal{L}(\mathcal{B})$ we denote the operator $Q := I - P$. Note that by this definition $1(t) = 1$ is an element of $\mathcal{B}_+$. An important property of $\mathcal{B}_+$ is that $\mathcal{B}_+$ is a Banach algebra.

Besides decomposing Banach algebras $\mathcal{B}$, we consider the Banach algebras $L_\infty(\mathbb{T})$ and $C(\mathbb{T})$. By $L_\infty(\mathbb{T})$ we denote the space of measurable and essentially bounded functions on $\mathbb{T}$. Clearly $L_\infty(\mathbb{T})$ satisfies (A2) and $L_\infty(\mathbb{T})_+$ is given by $H_\infty(\mathbb{D})$, the space of holomorphic and bounded functions within the unit disc $\mathbb{D}$. However, $L_\infty(\mathbb{T})$ does not satisfy the second part of (A1); see, for example, Hoffman [13, p. 155]. Let $C(\mathbb{T})$ be the Banach space of continuous functions on $\mathbb{T}$. The algebra $C(\mathbb{T})$ satisfies (A2)–(A4), but the second part of (A1) does not hold. Note that the space $C(\mathbb{T})_+$ coincides with the disc algebra $A(\mathbb{D})$, the Banach space of all continuous functions on $\bar{\mathbb{D}}$ which are holomorphic within the unit disc. Finally, we define

$$\begin{aligned}(L_\infty(\mathbb{T}))_{\rm pos} &:= \{f \in L_\infty(\mathbb{T}) \mid f^{-1} \in L_\infty(\mathbb{T}) \text{ and } f(t) > 0 \text{ for almost every } t \in \mathbb{T}\},\\ (C(\mathbb{T}))_{\rm pos} &:= \{f \in C(\mathbb{T}) \mid f(t) > 0 \text{ for } t \in \mathbb{T}\}.\end{aligned}$$

Thus $L_\infty(\mathbb{T})$ and $C(\mathbb{T})$ are Banach algebras, but not decomposing Banach algebras. Moreover, Proposition 2.2 implies that a decomposing Banach algebra cannot be a C*-algebra. Otherwise, the Gel'fand–Naimark theorem [18, p. 277] implies $\mathcal{B} = C(\mathbb{T})$, which cannot hold since $C(\mathbb{T})$ is not a decomposing Banach algebra.

All Banach algebras presented in the following are decomposing Banach algebras. The proofs can be found in Peller and Khrushchev [23]. One of the most important examples is the Wiener algebra.

Example 2.4. The *Wiener algebra* W consists of all absolutely convergent Fourier series

$$f(e^{it}) = \sum_{n\in\mathbb{Z}} a_n e^{int} \tag{2.1}$$

and is equipped with the norm

$$\|f\|_W := \sum_{n\in\mathbb{Z}} |a_n| < \infty.$$

The next example shows that it is also possible to introduce a weighted version of the Wiener algebra.

Example 2.5. Let $\omega = \{\omega_n\}_{n=0}^\infty$ be a sequence of numbers satisfying

$$\omega_{|n|} > 0 \quad \text{and} \quad \omega_{|n|} \leq \omega_{|n-k|}\omega_{|k|}, \qquad n, k \in \mathbb{Z}, \tag{2.2}$$

and

$$\overline{\lim}_{n\to+\infty}\omega_n^{1/n} = 1. \tag{2.3}$$

Then $W(\omega)$ denotes the *weighted Wiener algebra* with respect to the weights ω, which consists of all Fourier series f, given by (2.1), with

$$\|f\|_{W(\omega)} := \sum_{n\in\mathbb{Z}} \omega_{|n|}|a_n| < \infty.$$

Note that

$$\omega_{|n|} \le \omega_{|n-n|}\omega_{|n|}$$

implies $\omega_0 \ge 1$, and thus

$$\omega_{|0|} \le \omega_{|0-k|}\omega_{|k|} = \omega_{|k|}^2$$

shows $\inf_{k\ge0}\omega_k \ge 1 > 0$.

Choosing the sequence $\omega_n := 1$, we get $W(\omega) = W$.

Example 2.6. Let $p \in (1,\infty)$ and $\omega = \{\omega_n\}_{n\in\mathbb{N}_0}$ be a sequence of numbers satisfying

$$\sup_{m\in\mathbb{Z}}\left(\sum_{k+j=m}\left(\frac{\omega_{|m|}}{\omega_{|k|}\omega_{|j|}}\right)^{p'}\right)^{1/p'} < \infty \tag{2.4}$$

and (2.3), where $1/p + 1/p' = 1$. Then $\mathcal{F}\ell_p(\omega)$ denotes the space of all Fourier series f, given by (2.1), which satisfy

$$\|f\|_{\mathcal{F}\ell_p(\omega)} := \left(\sum_{n\in\mathbb{Z}}\omega_{|n|}^p|a_n|^p\right)^{1/p} < \infty.$$

Using $\omega_0 = \|e^{nit}e^{-nit}\|_{\mathcal{F}\ell_p(\omega)} \le \|e^{nit}\|_{\mathcal{F}\ell_p(\omega)}\|e^{-nit}\|_{\mathcal{F}\ell_p(\omega)} = \omega_n^2$, we get $\inf_{n\ge0}\omega_n > 0$. Finally, using (2.4), we see $\sup_{n\ge0}\omega_n = \infty$.

Another quite important example is the Hölder continuous functions of order α.

Example 2.7. By λ_α, $\alpha > 0$, we denote the Banach algebra of *Hölder continuous functions of order* α. If $\alpha \in (0,1]$, then λ_α is the closure of the set of trigonometric polynomials under the norm

$$\|f\|_{\lambda_\alpha} := \|f\|_\infty + \sup_{s,t\in\mathbb{T},s\ne t}\frac{|f(s)-f(t)|}{|s-t|^\alpha}.$$

λ_1 is also known as the *Lipschitz class*. If $\alpha > 1$, then λ_α is the Banach algebra given by the closure of the set of trigonometric polynomials under the norm

$$\|f\|_{\lambda_\alpha} := \sum_{j=0}^{n}\frac{1}{j!}\|f^{(j)}\|_\infty + \|f^{(n)}\|_{\lambda_{\alpha-n}},$$

where n is the integer for which $n < \alpha \le n+1$.

Example 2.8. For $q \in (1,\infty)$, $p \in [1,\infty]$, and $\alpha \in (1/p,\infty)$, or $q = 1$, $p \in [1,\infty]$, and $\alpha = 1/p$, the *Besov class* B^α_{pq} is defined by

$$B^\alpha_{pq} := \left\{ f \in L_p \mid \|f\|_{B^\alpha_{pq}} := \int_0^{2\pi} \frac{\|\Delta_t^n f\|^q_{L_p(\mathbb{T})}}{|t|^{1+\alpha q}}\, dt < \infty \right\},$$

where n is an integer such that $\alpha < n$, and $\Delta_t^n := \Delta_t \Delta_t^{n-1}$ with $(\Delta_t f)(e^{is}) := f(e^{i(s+t)}) - f(e^{is})$. This definition does not depend on the choice of n, $n > \alpha$.

Example 2.9. Let $\mathcal{L}^s_p$, $p \in [1,\infty)$, and $s > 1/p$, denote the *Sobolev spaces* of order s, which denotes the space of all Fourier series f, given by (2.1), which satisfy

$$\|f\|_{\mathcal{L}^s_p} := \left(\sum_{n\in\mathbb{Z}} (1+|n|)^{sp} |a_n|^p \right)^{1/p} < \infty.$$

If s is an integer, then an equivalent norm on $\mathcal{L}^s_2$ is given by

$$\|f\|_{\mathcal{L}^s_2} := \left(\sum_{j=0}^n \|f^{(j)}\|^2_{L_2(\mathbb{T})} \right)^{1/2}, \qquad f \in \mathcal{L}^s_2,$$

and $(\mathcal{L}^s_2)_+$ coincides with the Hardy–Sobolev space on the disc; see, for example, Baratchart and Zerner [3].

Example 2.10. Let Z be one of the spaces VMO, $A(\mathbb{D}) + \overline{A(\mathbb{D})}$, $H_1(\mathbb{D}) + \overline{H_1(\mathbb{D})}$, or $L_1(\mathbb{T}) + \widetilde{L_1(\mathbb{T})}$. Here VMO is the space of functions of vanishing mean oscillation, i.e.,

$$VMO := \left\{ f \in L_1(\mathbb{T}) \mid \lim_{a \searrow 0} \sup_{\lambda(I)\le a} \frac{1}{\lambda(I)} \int_I |f - f_I| d\lambda = 0 \right\},$$

where I is an arc of $\mathbb{T}$, λ is the normalized Lebesgue measure on $\mathbb{T}$, and $f_I := \frac{1}{\lambda(I)} \int_I f d\lambda$ is the mean value on I. A suitable norm on VMO is given by

$$\|f\|_* = |\hat{f}(0)| + \sup_I \frac{1}{\lambda(I)} \int_I |f - f_I| d\lambda.$$

If f is a function on $\mathbb{T}$, then $\bar{f}$ denotes the function given by $\bar{f}(t) := \overline{f(t)}$, and $\tilde{f}$ denotes the harmonic conjugate of f. Note that for every $f \in L_1(\mathbb{T})$ there exists a harmonic conjugate $\tilde{f}$; see Zygmund [31]. By $Z^{(n)}$, $n \in \mathbb{N}$, we denote the space

$$Z^{(n)} := \{ f \text{ a distribution on } \mathbb{T} \mid f^{(n)} \in Z \}$$

provided with the norm

$$\|f\|_{Z^{(n)}} := \sum_{j=0}^n \frac{1}{j!} \|f^{(j)}\|_Z.$$

If Z is one of the spaces VMO, $A(\mathbb{D}) + \overline{A(\mathbb{D})}$, $H_1(\mathbb{D}) + \overline{H_1(\mathbb{D})}$, then $Z^{(n)}$, $n \in \mathbb{N}$, is a decomposing Banach algebra. Moreover, if $n \ge 2$, then $(L_1(\mathbb{T}) + \widetilde{L_1(\mathbb{T})})^{(n)}$ is a decomposing Banach algebra.

Example 2.11. Let $\mathcal{C}$ be a decomposing Banach algebra, and let Q be a positive constant. Furthermore, let $\{M_n\}_{n\geq 0}$ be an increasing and logarithmically convex sequence with $M_0 = 1$ for which there exists a constant $k > 0$ such that

$$\liminf_{n\to\infty} \frac{M_n}{nM_{n-k}} > 0.$$

Then the *Carleman class* $C_Q(\mathcal{C}, \{M_n\})$, the space of all infinitely differentiable functions f on $\mathbb{T}$ with

$$\lim_{n\to\infty} \frac{\|f^{(n)}\|_{\mathcal{C}}}{Q^n n! M_n} = 0,$$

equipped with the norm

$$\|f\|_{C_Q(\mathcal{C},\{M_n\})} := \sup_{n\geq 0} \frac{\|f^{(n)}\|_{\mathcal{C}}}{Q^n n! M_n},$$

is a decomposing Banach algebra.

3. Spectral factorization. Next we recall the definitions of spectral densities and spectral factors, and we show that every spectral density that is positive and bounded away from zero admits a spectral factor. Let $\mathcal{A}$ denote $L_\infty(\mathbb{T})$, $C(\mathbb{T})$, or a decomposing Banach algebra $\mathcal{B}$.

Definition 3.1. *We call $f \in \mathcal{A}$ a* spectral density *if there exists a function $h \in \mathcal{GA}_+ := \mathcal{G}(\mathcal{A}_+)$ such that*

$$f(e^{it}) = |h(e^{it})|^2.$$

h is called a spectral factor *of f.*

If $f \in \mathcal{A}$ is a spectral density, then the spectral factor is unique up to a constant of modulus 1. Next we consider whether every $f \in \mathcal{A}_{\text{pos}}$ is a spectral density.

Proposition 3.2. *Every $f \in (L_\infty(\mathbb{T}))_{\text{pos}}$ is a spectral density, and one spectral factor is given by*

$$h(z) := \exp\left\{\frac{1}{2}\frac{1}{2\pi}\int_0^{2\pi} \frac{e^{it}+z}{e^{it}-z} \log f(e^{it})\, dt\right\}. \tag{3.1}$$

Proof. h and h^{-1} are holomorphic within the disc [13, p. 61], and $f(e^{it}) = |h(e^{it})|^2$ [13, pp. 30, 32], which proves the statement. ∎

However, Treil [28] showed that there exist functions $f \in (C(\mathbb{T}))_{\text{pos}}$ for which there is no continuous spectral factor.

Proposition 3.3. *Every $f \in \mathcal{B}_{\text{pos}}$ is a spectral density, and one spectral factor is given by* (3.1).

Proof. We have $f(e^{it}) = |h(e^{it})|^2$ [13, pp. 30, 32]. We write $f = e^g$ with $g \in \mathcal{B}$. Using

$$\frac{e^{it}+z}{e^{it}-z} = \frac{2e^{it}}{e^{it}-z} - 1,$$

we get

$$\begin{aligned} h(z) &= \exp\left\{-\frac{1}{2}(P(\log f))(0)\right\} \exp\{(P(\log f))(z)\} \\ &= \exp\left\{-\frac{1}{2}(Pg)(0)\right\} \exp\{(Pg)(z)\}. \end{aligned} \tag{3.2}$$

Since $Pg \in \mathcal{B}_+$ and $\mathcal{B}_+$ is a Banach algebra, this shows $h \in \mathcal{GB}_+$. Thus the proof is completed. □

Note that it is easy to see that, for $\mathcal{A} = L_\infty$ or $\mathcal{B}$, this sufficient condition is also a necessary condition, i.e., $f \in \mathcal{A}$ is a spectral density if and only if $f \in \mathcal{A}_{\rm pos}$. We now consider the mapping $\Phi : \mathcal{A}_{\rm pos} \to \mathcal{A}_+$, given by

$$\Phi(f)(z) := \exp\left\{\frac{1}{2}\frac{1}{2\pi}\int_0^{2\pi}\frac{e^{it}+z}{e^{it}-z}\log f(e^{it})\,dt\right\}.$$

Thus Φf is a spectral factor of f, and we have

$$\Phi(f)\Phi(f) = f, \quad f \in \mathcal{A}_{\rm pos}. \tag{3.3}$$

We call the mapping Φ the *spectral factorization mapping*. We also could define the spectral factorization mapping for $\mathcal{A} = C(\mathbb{T})$. However, in this case Φ only maps from $C(\mathbb{T})_{\rm pos}$ to $H_\infty(\mathbb{D}) = L_\infty(\mathbb{T})_+$ and not to $A(\mathbb{D}) = C(\mathbb{T})_+$.

4. Continuity of the spectral factorization. In this section we discuss the continuity of the spectral factorization mapping.

DEFINITION 4.1. *We say the spectral factorization mapping is* continuous *if for every converging sequence $\{f_n\}_n \in \mathcal{A}_{\rm pos}$ with limit in $\mathcal{A}_{\rm pos}$ the sequence of corresponding spectral factors converges.*

Anderson [1] showed that the spectral factorization mapping is not continuous in $L_\infty(\mathbb{T})$ and in $C(\mathbb{T})$. This result also follows from the example given by Treil [28] of a continuous spectral density with discontinuous spectral factor. However, we shall show that the spectral factorization mapping is locally Lipschitz continuous in decomposing Banach algebra. The next lemma is taken from Clancey and Gohberg [7, Theorem 1.1, p. 35].

LEMMA 4.2. *If $f \in \mathcal{B}_{\rm pos}$, then the operators $T_f, R_f \in \mathcal{L}(\mathcal{B})$, given by*

$$T_f(x) := P(fx) + Q(x) \qquad \text{and} \qquad R_f(x) := P(x) + Q(fx), \quad x \in \mathcal{B},$$

are invertible. Moreover, $e^{-Pg} = T_f^{-1}1$ and $e^{-Qg} = R_f^{-1}1$, where $f = e^g$.

A further useful result is the following.

LEMMA 4.3. *There exists a constant $m > 0$ such that*

$$\|\overline{g}\|_{\mathcal{B}} \le m\|g\|_{\mathcal{B}}, \qquad g \in \mathcal{B}. \tag{4.1}$$

Proof. The supremum-norm $\|\cdot\|_\infty$ is also a norm on $\mathcal{B}$, and we have $\|\bar{f}f\|_\infty = \|f\|_\infty^2$. Thus $\mathcal{B}$ is a A^*-algebra. For more information on A^*-algebras we refer the reader to Rickart [24]. Since the involution is continuous on A^*-algebras (see Rickart [24, p. 187]), we get (4.1). Thus the lemma is proved. □

Our next result is a continuity result for spectral factorization. It is a stronger form of the results of Clancey and Gohberg [7, p. 205], and we provide more complete arguments than they did.

THEOREM 4.4. *The spectral factorization mapping is locally Lipschitz continuous on $\mathcal{B}$. More precisely, for every $f \in \mathcal{B}_{\rm pos}$ there exist constants $\rho, c > 0$ such that for all $f_1, f_2 \in B_\rho(f) := \{g \in \mathcal{B}_{\rm pos} \mid \|g - f\|_{\mathcal{B}} < \rho\}$ we have that f_1, f_2 are spectral densities and that*

$$\|\Phi(f_1) - \Phi(f_2)\|_{\mathcal{B}} \le c\|f_1 - f_2\|_{\mathcal{B}}, \|\Phi(f_1)^{-1} - \Phi(f_2)^{-1}\|_{\mathcal{B}} \le c\|f_1 - f_2\|_{\mathcal{B}},$$

$$\|\overline{\Phi(f_1)} - \overline{\Phi(f_2)}\|_{\mathcal{B}} \le c\|f_1 - f_2\|_{\mathcal{B}}, \|\overline{\Phi(f_1)}^{-1} - \overline{\Phi(f_2)}^{-1}\|_{\mathcal{B}} \le c\|f_1 - f_2\|_{\mathcal{B}}.$$

Proof. Let $f \in \mathcal{B}_{\text{pos}}$ be arbitrary. Using a standard result about the continuity of inversion (which, for example, can be found in Hille and Phillips [12, Theorem 2.2, p. 118]), there exist constants $\rho_1, m > 0$ such that for every $f_1, f_2 \in B_{\rho_1}(f)$, we have that f_1, f_2 are spectral densities, and $\|f_1^{-1}\|_{\mathcal{B}}, \|f_2^{-1}\|_{\mathcal{B}} \leq m$. Let $f_1, f_2 \in B_{\rho_1}(f)$ be arbitrary, and choose $g_1, g_2 \in \mathcal{B}$ such that $f_1 = e^{g_1}$ and $f_2 = e^{g_2}$. Since f_1 and f_2 are spectral densities, Lemma 4.2 shows that the operators T_{f_1} and T_{f_2} are invertible. Moreover, we have $\|T_{f_1} - T_{f_2}\| \leq \|P\|\|f_1 - f_2\|_{\mathcal{B}}$.

Using again the theorem of inversion, there exist constants $\rho_2 \in (0, \rho_1]$ and $d_0, d_1 > 0$ such that for every $f_1, f_2 \in B_{\rho_2}(f)$, we have $\|T_{f_1}^{-1}\|_{\mathcal{B}}, \|T_{f_2}^{-1}\|_{\mathcal{B}} \leq d_0$ and $\|T_{f_1}^{-1} - T_{f_2}^{-1}\| \leq d_1\|f_1 - f_2\|_{\mathcal{B}}$. Especially, $\|T_{f_1}^{-1}(1) - T_{f_2}^{-1}(1)\|_{\mathcal{B}} \leq d_1\|1\|_{\mathcal{B}}\|f_1 - f_2\|_{\mathcal{B}}$, and thus by Lemma 4.2 we get

$$\|e^{-Pg_1} - e^{-Pg_2}\|_{\mathcal{B}} \leq d_1\|1\|_{\mathcal{B}}\|f_1 - f_2\|_{\mathcal{B}}.$$

In a similar manner it can be proved that there exist constants $\rho \in (0, \rho_2]$ and $d_2, d_3 > 0$ such that for every $f_1, f_2 \in B_\rho(f)$, we have $\|e^{-Qg_1}\|_{\mathcal{B}}, \|e^{-Qg_2}\|_{\mathcal{B}} \leq d_2$ and $\|e^{-Qg_1} - e^{-Qg_2}\| \leq d_3\|f_1 - f_2\|_{\mathcal{B}}$.

Using $e^{Pg_1} = f_1 e^{-Qg_1}$ and $e^{Pg_2} = f_2 e^{-Qg_2}$, there now exists a constant $d_4 > 0$ such that for every $f_1, f_2 \in B_\rho(f)$ we have

$$\|e^{Pg_1} - e^{Pg_2}\|_{\mathcal{B}} \leq d_4\|f_1 - f_2\|_{\mathcal{B}}.$$

Since $\mathcal{B}$ is continuously embedded into $C(\mathbb{T})$, we get

$$|e^{Pg_1}(0) - e^{Pg_2}(0)| \leq \|e^{Pg_1} - e^{Pg_2}\|_{C(\mathbb{T})} \leq c\|e^{Pg_1} - e^{Pg_2}\|_{\mathcal{B}} \leq cd_4\|f_1 - f_2\|_{\mathcal{B}},$$

and thus $\inf\{|e^{-Pg_1}(0)| \mid f_1 \in B_\rho(f)\} > 0$. In a similar way it can be shown that $\inf\{|e^{Pg_1}(0)| \mid f_1 \in B_\rho(f)\} > 0$. Thus there exists a constant $d_5 > 0$, such that for every $f_1, f_2 \in B_\rho(f)$, we have

$$\left|\sqrt{e^{Pg_1}(0)} - \sqrt{e^{Pg_2}(0)}\right| \leq d_5\|f_1 - f_2\|_{\mathcal{B}}$$

and

$$\left|\sqrt{e^{-Pg_1}(0)} - \sqrt{e^{-Pg_2}(0)}\right| \leq d_5\|f_1 - f_2\|_{\mathcal{B}}.$$

Finally, using (3.2) and Lemma 4.3, the theorem is proved. □

We conclude this section with the following corollary concerning normalized coprime factorization. In the special situation that the decomposing Banach algebra $\mathcal{B}$ equals the Wiener algebra W, this result can already be found in Mäkilä and Partington [20]. We say the functions $(N, D) \in \mathcal{B}_+ \times \mathcal{B}_+$ are *coprime factors* of $G : \mathbb{D} \to \mathbb{C} \cup \{\infty\}$ if D is not identically 0, $G = N/D$, and there exist $U, V \in \mathcal{B}_+$ such that

$$UN + VD = 1 \qquad \text{on } \mathbb{D}.$$

Moreover, the functions $(N, D) \in \mathcal{B}_+ \times \mathcal{B}_+$ are called *normalized coprime factors* of $G : \mathbb{D} \to \mathbb{C} \cup \{\infty\}$ if D is not identically 0, $G = N/D$, and

$$|N|^2 + |D|^2 = 1 \qquad \text{on } \mathbb{T}.$$

COROLLARY 4.5. *Let $(N_k, D_k) \in \mathcal{B}_+ \times \mathcal{B}_+$, $k \in \mathbb{N}_0$, be coprime factors. If $N_k \to N_0$ and $D_k \to D_0$ as k tends to ∞, then there exist normalized coprime factors $(\tilde{N}_k, \tilde{D}_k) \in \mathcal{B}_+ \times \mathcal{B}_+$ of N_k/D_k such that $\tilde{N}_k \to \tilde{N}_0$ and $\tilde{D}_k \to \tilde{D}_0$ as k tends to ∞. Moreover, the convergence is locally Lipschitz continuous, i.e., for every coprime factor N, D there exist constants $\rho, c > 0$ such that for all $N_1, N_2 \in B_\rho(N) := \{g \in \mathcal{B}_+ \mid \|g - N\| < \rho\}$ and $D_1, D_2 \in B_\rho(D)$ with (N_i, D_i), $i = 1, 2$, are coprime factors; there exist normalized coprime factors $(\tilde{N}_i, \tilde{D}_i)$ of N_i/D_i, $i = 1, 2$, such that*

$$\|\tilde{N}_1 - \tilde{N}_2\|_{\mathcal{B}} \le c \max\{\|N_1 - N_2\|_{\mathcal{B}}, \|D_1 - D_2\|_{\mathcal{B}}\},$$
$$\|\tilde{D}_1 - \tilde{D}_2\|_{\mathcal{B}} \le c \max\{\|N_1 - N_2\|_{\mathcal{B}}, \|D_1 - D_2\|_{\mathcal{B}}\}.$$

Proof. Let N, D be coprime factors. Then there exist constants $\rho, c_1 > 0$ such that $\|n\|, \|d\| < c_1$ if $n \in B_\rho(N)$ and $d \in B_\rho(D)$. We now choose $N_1, N_2 \in B_\rho(N)$ and $D_1, D_2 \in B_\rho(D)$ such that (N_i, D_i), $i = 1, 2$, are coprime factors and define $F_i(e^{it}) := |N_i(e^{it})|^2 + |D_i(e^{it})|^2$, $t \in [0, 2\pi)$ and $i = 1, 2$. Thus there exists a constant $c_2 > 0$ such that

$$\|F_1 - F_2\| \le c_2 \max\{\|N_1 - N_2\|, \|D_1 - D_2\|\}. \tag{4.2}$$

The coprimeness of N_i and D_i implies that $F_i \in \mathcal{B}_{\rm pos}$. Thus F_i is a spectral density, and so there exist functions $H_i \in \mathcal{GB}_+$ with $F_i(e^{it}) = |H_i(e^{it})|^2$, $t \in [0, 2\pi)$. Defining $\tilde{N}_i := N_i H_i^{-1}$ and $\tilde{D}_i := D_i H_i^{-1}$, we get $|\tilde{N}_i(e^{it})|^2 + |\tilde{D}_i(e^{it})|^2 = 1$, and $(\tilde{N}_i, \tilde{D}_i)$ are normalized coprime factors of N_i/D_i, $i = 1, 2$. Now (4.2) together with the previous theorem completes the proof. ∎

5. Boundedness of the spectral factorization. In this section we are concerned with the question whether or not the spectral factorization mapping is bounded. Boundedness of the spectral factorization mapping guarantees that the norm of the spectral factor is small if the spectral densities are small in norm. Thus the spectral factorization mapping is bounded if and only if it is continuous at the point 0. Note that boundedness is not included in the definition of continuity, since 0 is not an element of $\mathcal{A}_{\rm pos}$. We will see in this section that in general boundedness does not imply continuity and continuity does not imply boundedness.

DEFINITION 5.1. *We say that the spectral factorization mapping is* bounded *if for every bounded sequence $\{f_n\}_n \in \mathcal{A}_{\rm pos}$ the sequence of the corresponding spectral factors $\{\Phi f_n\}_n$ is bounded.*

Clearly, the spectral factorization mapping is bounded on $L_\infty(\mathbb{T})$ and on $C(\mathbb{T})$. However, we show in this section that on almost every decomposing Banach algebra the spectral factorization mapping is unbounded. In the next proposition we give a simple equivalent condition for the spectral factorization mapping to be bounded.

PROPOSITION 5.2. *The spectral factorization mapping is bounded on the decomposing Banach algebra $\mathcal{B}$ if and only if there exists a constant $M > 0$ such that*

$$\|f\|_{\mathcal{B}}^2 \le M \|f \bar{f}\|_{\mathcal{B}}, \quad f \in \mathcal{GB}_+. \tag{5.1}$$

Proof. Since $\mathcal{B}$ is separable, the spectral factorization mapping is bounded if and only if there is a constant $M_1 > 0$ such that

$$\|\Phi f\|_{\mathcal{B}}^2 \le M_1 \|f\|_{\mathcal{B}}, \qquad f \in \mathcal{B}_{\rm pos}. \tag{5.2}$$

Thus we need to show that (5.1) is equivalent to (5.2). Assume (5.1) holds. Then for $f \in \mathcal{B}_{\rm pos}$ we have $\Phi f \in \mathcal{GB}_+$. Using (3.3), we thus get (5.2).

We now assume that (5.2) holds. Let $f \in \mathcal{GB}_+$. Defining $g := f\bar{f}$, we get $g \in \mathcal{B}_{\mathrm{pos}}$. Using (5.2) for g and the definition of a spectral factor, we get (5.1). ∎

Note that the condition (5.1) is required only for $f \in \mathcal{GB}_+$ and not for every f in $\mathcal{B}$. In a C*-algebra, condition (5.1) is even satisfied for every $f \in \mathcal{B}$ and with $M = 1$ (see, for example, Rickart [24, p. 190]). However, Rickart [24, p. 190] shows that in a decomposing Banach algebra the condition (5.1) cannot be satisfied for every $f \in \mathcal{B}$, since it would imply that $\mathcal{B}$ is isomorphic to $C(\mathbb{T})$.

Recalling the formula $\Phi(f)\overline{\Phi(f)} = f$, $f \in \mathcal{B}_{\mathrm{pos}}$ (see (3.3)), a definition of the boundedness of the spectral factorization mapping should also include that the sequence $\{\overline{\Phi f_n}\}_n$ is bounded if $\{f_n\}_n \in \mathcal{B}_{\mathrm{pos}}$ is bounded. However, this is already included in our definition, as the following proposition shows.

PROPOSITION 5.3. *Assuming that the spectral factorization mapping is bounded on $\mathcal{B}$, for every bounded sequence $\{f_n\}_n \in \mathcal{B}_{\mathrm{pos}}$ the sequence $\{\overline{\Phi f_n}\}_n$ is bounded.*

Proof. The proof follows from Lemma 4.3. ∎

The next theorem provides us with an easy, checkable sufficient condition for the spectral factorization mapping to be unbounded on a decomposing Banach algebra $\mathcal{B}$.

THEOREM 5.4. *If the spectral factorization mapping is bounded on $\mathcal{B}$, then the Wiener algebra W can be continuously embedded into $\mathcal{B}$, i.e., $W \subset \mathcal{B}$ and*

$$\|f\|_{\mathcal{B}} \le c\|f\|_W, \qquad f \in W,$$

for some constant $c > 0$.

Proof. Since the spectral factorization mapping is bounded on $\mathcal{B}$, there exists a constant $M > 0$ such that (5.1) holds. Equation (4.1) shows that there exists a constant $m > 0$ such that

$$\|e^{-in\cdot}\|_{\mathcal{B}} \le m\|e^{in\cdot}\|_{\mathcal{B}}, \qquad n > 0. \tag{5.3}$$

Defining $f_n \in \mathcal{GB}_+$ by

$$f_n(e^{it}) := 2 + e^{int}, \qquad t \in [0, 2\pi],$$

we get

$$(\|e^{in\cdot}\|_{\mathcal{B}} - 2) \le \|f_n\|_{\mathcal{B}} \le M^{1/2}\|f_n\bar{f}_n\|_{\mathcal{B}}^{1/2} \le M^{1/2}(5 + 2(1+m)\|e^{in\cdot}\|_{\mathcal{B}})^{1/2}, \quad n > 0.$$

However, this can only hold if $\sup_{n\ge 0}\|e^{in\cdot}\|_{\mathcal{B}} < \infty$. This, together with (5.3), implies

$$c := \sup_{n\in\mathbb{Z}}\|e^{in\cdot}\|_{\mathcal{B}} < \infty.$$

Choosing an arbitrary trigonometric polynomial p, i.e.,

$$p(e^{it}) = \sum_{n=-N}^{N} a_n e^{int}, \quad t \in [0, 2\pi],$$

we get

$$\|p\|_{\mathcal{B}} \le \sum_{n=-N}^{N} |a_n|\|e^{in\cdot}\|_{\mathcal{B}} \le c\|p\|_W.$$

Since the trigonometric polynomials are dense in W and $\mathcal{B}$, the theorem is proved. ∎

COROLLARY 5.5. *If* $\lim_{n\to+\infty}\|e^{in\cdot}\|_{\mathcal{B}}=\infty$, *then the spectral factorization mapping is unbounded on* $\mathcal{B}$.

COROLLARY 5.6. *The spectral factorization mapping is not bounded on the following decomposing Banach algebras:*

1. $W(\omega)$ *if* $\sup_{n\in\mathbb{N}_0}\omega_n=\infty$.
2. $\mathcal{F}\ell_p(\omega)$, $p\in(1,\infty)$.
3. λ_α, $\alpha\in(0,\infty)$.
4. B^α_{pq}, $q\in(1,\infty)$, $p\in[1,\infty]$, *and* $\alpha\in(1/p,\infty)$.
5. $\mathcal{L}^s_p$, $p\in[1,\infty)$, *and* $s>1/p$.
6. $VMO^{(n)}$, $(A(\mathbb{D})+\overline{A(\mathbb{D})})^{(n)}$, $(H_1(\mathbb{D})+\overline{H_1(\mathbb{D})})^{(n)}$, *and* $(L_1(\mathbb{T})+\widetilde{L_1(\mathbb{T})})^{(k)}$, *if* $n\geq 1$ *and* $k\geq 2$.
7. $C_Q(\mathcal{C},\{M_n\})$.

Proof. Let us first consider the space λ_α for $\alpha\in(0,1]$. In order to show that the spectral factorization mapping is not bounded on λ_α, it remains to show

$$\lim_{n\to+\infty}\|e^{in\cdot}\|_{\lambda_\alpha}=\infty;$$

see the previous corollary. However, this follows from the calculation

$$\|e^{in\cdot}\|_{\lambda_\alpha}\geq\sup_{s,t\in[0,2\pi],s\neq t}\frac{|e^{ins}-e^{int}|}{|e^{is}-e^{it}|}|e^{is}-e^{it}|^{1-\alpha}=2^{1-\alpha}n.$$

Since $\lambda_\alpha\subset\lambda_1$, $\alpha\in(1,\infty)$, part 3 holds. In Peller and Khrushchev [23] it is proved that $\mathcal{L}^s_p\subset\lambda_\beta$, $\beta\in(0,s-1/p)$, and $B^\alpha_{pq}\subset\lambda_\beta$, $\beta\in(0,\alpha-1/p)$. Thus parts 4 and 5 hold. Finally, parts 1 and 2 follow from Corollary 5.5, and parts 6 and 7 are easy to see. □

In order to show that on $B^{1/p}_{p1}$, $p\in[1,\infty]$, the spectral factorization mapping is not bounded, we give another easy, checkable sufficient condition.

PROPOSITION 5.7. *If there exists a constant* $m>0$ *such that*

$$\|\bar f f\|_{\mathcal{B}}\leq m\|f^2\|_{\mathcal{B}},\qquad f\in\mathcal{GB}_+, \tag{5.4}$$

then the spectral factorization mapping is unbounded on $\mathcal{B}$.

Proof. We assume that the spectral factorization mapping is bounded, i.e., there exists a constant $M>0$ (Proposition 5.2) such that

$$\|f\|^2_{\mathcal{B}}\leq M\|f\bar f\|_{\mathcal{B}},\qquad f\in\mathcal{GB}_+.$$

This, together with (5.4), implies

$$\|f\|^2_{\mathcal{B}}\leq c\|f^2\|_{\mathcal{B}},\qquad f\in\mathcal{GB}_+,$$

where $c:=mM$. Applying this estimate repeatedly, we get for $f\in\mathcal{GB}_+$

$$\|f\|_{\mathcal{B}}\leq c^{1/2}\|f^2\|^{1/2}_{\mathcal{B}}\leq c^{1/2}c^{1/4}\|f^4\|^{1/4}_{\mathcal{B}}\leq\cdots\leq c\|f^{2^n}\|^{1/2^n}_{\mathcal{B}},$$

and thus by the spectral radius formula, that is, $\|f\|_\infty=\lim_{n\to\infty}\|f^n\|^{1/n}_{\mathcal{B}}$, we get $\|f\|_{\mathcal{B}}\leq c\|f\|_\infty$ for $f\in\mathcal{GB}_+$. Next we extend this estimate to all functions $f\in\mathcal{B}_+$. Let $f\in\mathcal{B}_+$. Then for $\delta\in(\|f\|_\infty,\|f\|_{\mathcal{B}})$ we get that δ is not in the spectrum of f, and thus $f+\delta\in\mathcal{GB}_+$. This implies

$$\|f\|_{\mathcal{B}}-\delta\leq\|f+\delta\|_{\mathcal{B}}\leq c\|f+\delta\|_\infty\leq c(\|f\|_\infty+\delta).$$

Thus we get $\|f\|_{\mathcal{B}} - \delta \le c(\|f\|_\infty + \delta)$, and, taking the limit $\delta \to \|f\|_\infty$, we get

$$\|f\|_{\mathcal{B}} \le (2c+1)\|f\|_\infty.$$

Thus $\|\cdot\|_{\mathcal{B}}$ and $\|\cdot\|_\infty$ are equivalent norms on $\mathcal{B}_+$. Next we show that $\mathcal{B} = C(\mathbb{T})$. Since we have assumed that the spectral factorization mapping is bounded on $\mathcal{B}$, Corollary 5.5 and Lemma 4.3 show

$$d := \sup_{n\in\mathbb{Z}} \|e^{in\cdot}\|_{\mathcal{B}} < \infty.$$

For an arbitrary trigonometric polynomial p, i.e.,

$$p(e^{it}) := \sum_{n=-N}^{N} a_n e^{int}, \qquad t \in [0, 2\pi],$$

we get

$$\begin{aligned}\|p\|_{\mathcal{B}} &= \|e^{-iN\cdot} e^{iN\cdot} p\|_{\mathcal{B}} \le d\|e^{iN\cdot} p\|_{\mathcal{B}} \\ &\le d(2c+1)\|e^{iN\cdot} p\|_\infty = d(2c+1)\|p\|_\infty.\end{aligned}$$

The trigonometric polynomials are dense in $\mathcal{B}$ and in $C(\mathbb{T})$, and $\mathcal{B} \subset C(\mathbb{T})$, and so we get $\mathcal{B} = C(\mathbb{T})$. Since $C(\mathbb{T})$ is not a decomposing Banach algebra, our assumption can no longer hold, and so the spectral factorization mapping is not bounded on $\mathcal{B}$. □

COROLLARY 5.8. *The spectral factorization mapping is unbounded on $B_{p,1}^{1/p}$, where $p \in [1, \infty]$.*

Proof. Using the triangle inequality

$$||a|^2 - |b|^2| \le |a^2 - b^2|, \qquad a, b \in \mathbb{C},$$

it is easy to see that the Banach algebras $B_{p,1}^{1/p}$ satisfy (5.4), and so, using Theorem 5.7, the spectral factorization mapping is not bounded on these decomposing Banach algebras. □

However, Theorem 5.7 does not imply that the spectral factorization mapping is unbounded on any decomposing Banach algebra, since (5.4) is not satisfied by every decomposing Banach algebra. In the next example we show that the Wiener algebra does not satisfy (5.4).

Example 5.9. Let the sequence $(p_n)_{n\in\mathbb{N}_0}$ of trigonometric polynomials be given by

$$\begin{aligned}p_0(e^{it}) &:= 1, \\ p_{n+1}(e^{it}) &:= p_n(e^{it})\big(8 - 4e^{i2\cdot 7^n t} - 2e^{i4\cdot 7^n t} - e^{i6\cdot 7^n t}\big).\end{aligned}$$

It is easy to see that $p_n \in \mathcal{G}W_+$. Moreover, we get

$$\begin{aligned}(p_{n+1}(e^{it}))^2 = (p_n(e^{it}))^2\big(&64 - 64e^{i2\cdot 7^n t} - 16e^{i4\cdot 7^n t} \\ &+12e^{i8\cdot 7^n t} + 4e^{i10\cdot 7^n t} + e^{i12\cdot 7^n t}\big)\end{aligned}$$

and

$$\begin{aligned}|p_{n+1}(e^{it})|^2 = |p_n(e^{it})|^2(&-8e^{-i6\cdot 7^n t} - 12e^{-i4\cdot 7^n t} - 22e^{-i2\cdot 7^n t} \\ &+85 - 22e^{i2\cdot 7^n t} - 12e^{i4\cdot 7^n t} - 8e^{i6\cdot 7^n t}).\end{aligned}$$

Noting that p_n is a polynomial of degree $7^n - 1$, it is easy to see that

$$\|(p_n(e^{it}))^2\|_W = 161\|(p_{n-1}(e^{it}))^2\|_W = 161^n$$

and

$$\| \, |p_n(e^{it})|^2\|_W = 169\| \, |p_{n-1}(e^{it})|^2\|_W = 169^n,$$

and so

$$\||p_n(e^{it})|^2\|_W = \left(\frac{169}{161}\right)^n \| \, (p_n(e^{it}))^2\|_W.$$

This shows that (5.4) does not hold for the Wiener class.

The only decomposing Banach algebra considered in section 2 which can be embedded into W and which does not satisfy (5.4) is the weighted Wiener algebra $W(\omega)$ with $\sup_{n\in\mathbb{N}_0} \omega_n < \infty$. However, the next theorem shows that the spectral factorization mapping is not bounded on $W(\omega)$.

THEOREM 5.10. *The spectral factorization mapping is not bounded on $W(\omega)$ with $\sup_{n\in\mathbb{N}_0} \omega_n < \infty$. In particular, the spectral factorization mapping is not bounded on W.*

Proof. $\sup_{n\in\mathbb{N}_0} \omega_n < \infty$ implies $W = W(\omega)$ and

$$k\|f\|_W \le \|f\|_{W(\omega)} \le K\|f\|_W, \qquad f \in W,$$

for some constants $k, K > 0$, and so it remains to show that the spectral factorization mapping is not bounded on W.

Rudin [25] and Shapiro [26] showed independently of each other that there exist polynomials

$$\tilde{h}_n(e^{it}) = \sum_{j=1}^{n} a_j e^{ijt}, \qquad t \in [0, 2\pi], n \in \mathbb{N},$$

such that $\{a_j\}_{j\in\mathbb{N}} \subseteq \{-1, 1\}$ and $\|\tilde{h}_n\|_{H_\infty} < 5n^{1/2}$. These polynomials are also called Rudin–Shapiro polynomials [17]. Clearly, $\tilde{h}_n \in W_+$ and $\|\tilde{h}_n\|_W = n$. We now define

$$h_n := 10n^{-1/4} + \frac{1}{n^{3/4}}\tilde{h}_n.$$

By this definition, we get $h_n \in W_+$, $\|h_n\|_{H_\infty} < 15n^{-1/4}$, and $\|\tilde{h}_n\|_W = 10n^{-1/4} + n^{1/4}$. Moreover, $|h_n(t)| \ge 5n^{-1/4}$, and so $h_n \in \mathcal{G}W_+$.

We now define $f_n \in W$ by $f_n(e^{it}) = |h_n(e^{it})|^2 = \overline{h_n(e^{it})}h_n(e^{it})$. This definition implies $f_n(t) > 0$, $t \in \mathbb{T}$, and so f_n is a spectral density and $\Phi f_n = b_n h_n$ for some constant b_n of modulus 1. We get that $\|f_n\|_{L_\infty(\mathbb{T})} < 225n^{-1/2}$ and $\|f_n\|_{L_2(\mathbb{T})} < \sqrt{2\pi}225n^{-1/2}$. This implies

$$\|f_n\|_W \le \|f_n\|_{L_2(\mathbb{T})} \left(\sum_{j=-n}^{n} 1^2\right)^{1/2} \le 225\sqrt{2\pi}\left(2 + \frac{1}{n}\right)^{1/2}.$$

This proves that the sequence $\{f_n\}_n$ is bounded in W, whereas the corresponding sequence of spectral factors is not bounded in W. Thus the spectral factorization mapping is not bounded in W. ∎

6. Spectral factorization on the right half-plane. Up until now we have studied the spectral factorization mapping on the disc. In what follows we will see that similar results are available on the right half-plane. Some of the results below can be obtained by transforming to the disc by a Möbius mapping such as $z = (1-s)/(1+s)$; for example, it was shown [4] that for $W(i\mathbb{R})$, the Wiener algebra on the imaginary axis, the transformed algebra is a decomposing Banach algebra on the circle. (This was used in order to prove various properties of the Nehari extension.) However, it is possible to proceed directly, and we do this now.

In order to define decomposing Banach algebras on the imaginary line, we need to introduce some definitions. By $\mathbb{C}_+$ we denote the right half-plane $\{z \in \mathbb{C} \mid \operatorname{Re} z > 0\}$, and by $BMO(\mathbb{R})$ we denote the set of all locally integrable functions f defined on $\mathbb{R}$ such that

$$\sup_I \frac{1}{|I|} \int_I |f(\omega) - f_I| \, d\omega < \infty,$$

where the supremum is taken over all intervals I of finite positive measure, and

$$f_I = \frac{1}{|I|} \int_I f(\omega) \, d\omega.$$

Moreover, by $BMOA(\mathbb{C}_+)$ we denote the set of all holomorphic functions $h : \mathbb{C}_+ \to \mathbb{C}$ such that $h(z)/(1+z)$ is an element of $H_2(\mathbb{C}_+)$ and the boundary function $h(i\omega)$ is in $BMO(\mathbb{R})$. For every function $f \in L_\infty(i\mathbb{R})$ there exists a function $h \in BMOA(\mathbb{C}_+)$ such that

$$h(s) - h(\beta) = \frac{1}{2\pi} \int_{\mathbb{R}} f(i\omega) \left[\frac{1}{i\omega - s} - \frac{1}{i\omega - \beta} \right] d\omega. \tag{6.1}$$

h is determined to within a constant. More information on the spaces $BMO(\mathbb{R})$ and $BMOA(\mathbb{C}_+)$ can be found in the books of Garnett [10] and Koosis [16].

DEFINITION 6.1. *A commutative Banach algebra $\mathcal{H} \subset L_\infty(i\mathbb{R})$ is called a* decomposing Banach algebra on the imaginary line *if the following hold.*

(H1) *$f \in \mathcal{H}$ implies $\bar{f} \in \mathcal{H}$ and $h \in \mathcal{H}$, where h is given by* (6.1).

(H2) *$\mathcal{H}$ is a unital Banach algebra with respect to pointwise multiplication on $i\mathbb{R}$.*

(H3) *The set of rational functions in $C(i\mathbb{R} \cap \{\infty\})$ is dense in $\mathcal{H}$.*

(H4) *Every multiplicative functional on $\mathcal{H}$ coincides with a functional $f \mapsto f(i\omega)$ defined as the value at some point $\omega \in \mathbb{R} \cup \{\infty\}$.*

Let $P \in \mathcal{L}(\mathcal{H})$ be given by $Pf := h$, where h is given by (6.1) with $h(i\infty) = f(i\infty)$. Similar to Proposition 2.2 and Proposition 2.3, we get the following proposition.

PROPOSITION 6.2. *$\mathcal{H}$ is continuously embedded in $C(i\mathbb{R} \cup \{i\infty\})$, the space of maximal ideals of the algebra $\mathcal{H}$ coincides with $i\mathbb{R} \cup \{i\infty\}$, and every $f \in \mathcal{H}$ with $f(i\omega) > 0$ for $\omega \in \mathbb{R} \cup \{\infty\}$ is an element of $\mathcal{GH}$.*

As in the case on the circle, there are many examples for decomposing Banach algebras on the imaginary line available. Here we introduce only one of the most important examples: the Wiener algebra on the imaginary line. For $g \in L_1(\mathbb{R})$ we denote by $\hat{g}$ the *two-sided Laplace transform* of g, which is given by

$$\hat{g}(s) := \int_{-\infty}^{\infty} e^{-st} g(t) \, dt, \qquad s \in i\mathbb{R}.$$

The two-sided Laplace transform of a function $g \in L_1(\mathbb{R})$ is an element of $C(i\mathbb{R} \cup \{i\infty\})$.

Example 6.3. The *Wiener algebra* $W(i\mathbb{R})$ *(on the imaginary line)* is the algebra of functions $f \in C(i\mathbb{R} \cup \{i\infty\})$ of the form

$$f = \hat{g} + c,$$

where c is a constant and $g \in L_1(\mathbb{R})$, and the norm of f is given by

$$\|f\|_{W(i\mathbb{R})} := |c| + \|g\|_{L_1(\mathbb{R})}.$$

Clancey and Gohberg [7] showed that $W(i\mathbb{R})$ is indeed a decomposing Banach algebra on the imaginary line.

Besides decomposing Banach algebras on the imaginary line, the spectral factorization can be defined on $L_\infty(i\mathbb{R})$ and $C(i\mathbb{R})$. Let $\mathcal{K}$ denote $L_\infty(i\mathbb{R})$, $C(i\mathbb{R})$, or a decomposing Banach algebra $\mathcal{H}$. In a similar way as on the circle, we define $\mathcal{K}_+$ and $\mathcal{K}_{\rm pos}$.

DEFINITION 6.4. *We call* $f \in \mathcal{K}$ *a* spectral density *if there exists a function* $h \in G\mathcal{K}_+$ *such that*

$$f(i\omega) = |h(i\omega)|^2.$$

h is called a spectral factor *of f.*

If $f \in \mathcal{K}$ is a spectral density, then the spectral factor is unique up to a constant of modulus 1. The following proposition can be proved in a similar way as Theorem 3.5 and Corollary 3.6 in Jacob, Winkin, Zwart [15].

PROPOSITION 6.5. *Let* $\mathcal{K} = L_\infty(i\mathbb{R})$ *or* $\mathcal{H}$. *Then every* $f \in \mathcal{K}_{pos}$ *is a spectral density, and one spectral factor is given by*

$$h(s) = \exp\left\{\frac{1}{2\pi}\int_{-\infty}^{\infty} \frac{i\omega s - 1}{i\omega - s}\,\frac{1}{1+\omega^2}\log f(i\omega)\,d\omega\right\}, \quad \operatorname{Re} s > 0. \tag{6.2}$$

As on the circle, there exist functions $C(i\mathbb{R})_{\rm pos}$ for which there is no continuous spectral factor.

For $\mathcal{K} = L_\infty(i\mathbb{R})$ or $\mathcal{H}$, we define the spectral factorization mapping $\Phi : \mathcal{K}_{pos} \to \mathcal{K}_+$ on the right half-plane by

$$\Phi(f) := h,$$

where h is given by (6.2). We also could define the spectral factorization mapping for $\mathcal{K} = C(i\mathbb{R})$. However, in this case, Φ maps only from $C(\mathbb{T})_{\rm pos}$ to $L_\infty(\mathbb{T})_+$.

The continuity and boundedness of the spectral factorization mapping on the right half-plane is defined in a similar way as on the circle.

In Jacob, Winkin, and Zwart [14] it is shown that the spectral factorization mapping is not continuous on $L_\infty(i\mathbb{R})$ and on $C(i\mathbb{R})$, and in Jacob, Winkin, and Zwart [15] it is shown that the spectral factorization mapping is continuous on $W(i\mathbb{R})$. Following the line of Theorem 4.5 in [15], we see that the spectral factorization mapping is continuous on decomposing Banach algebras on the imaginary axis.

As on the circle, it is easy to see that the spectral factorization mapping is bounded on $L_\infty(i\mathbb{R})$ and on $C(i\mathbb{R})$. In the remaining part of this section we study the boundedness of the spectral factorization mapping on decomposing Banach algebras.

PROPOSITION 6.6. *If*

$$\sup_{n\in\mathbb{N}} \left\| \frac{1}{(\cdot+1)^n} \right\|_{\mathcal{H}} = \infty,$$

then the spectral factorization mapping is not bounded on $\mathcal{H}$.

Proof. We assume that the spectral factorization mapping is bounded on $\mathcal{H}$, i.e., there exists a constant $M > 0$ such that

$$\|f\|_{\mathcal{H}}^2 \le M\|f\bar{f}\|_{\mathcal{H}}, \qquad f \in \mathcal{GH}_+.$$

Similar to Lemma 4.3, it can be proved that there exists a constant $m > 0$ such that

$$\left\|\frac{1}{(\cdot+1)^n}\right\|_{\mathcal{H}} \le m\left\|\frac{1}{(-\cdot+1)^n}\right\|_{\mathcal{H}}, \qquad n > 0.$$

Defining $f_n \in \mathcal{GH}_+$ by

$$f_n(i\omega) := 2 + \frac{1}{(i\omega+1)^n}, \qquad \omega \in \mathbb{R},$$

we get

$$\begin{aligned}\left(\left\|\frac{1}{(\cdot+1)^n}\right\|_{\mathcal{H}} - 2\right) &\le \|f_n\|_{\mathcal{H}} \le M^{1/2}\|f_n\bar{f}_n\|_{\mathcal{H}}^{1/2} \\ &\le M^{1/2}\left(5 + 2(1+m)\left\|\frac{1}{(\cdot+1)^n}\right\|_{\mathcal{H}}\right)^{1/2}, \quad n > 0.\end{aligned}$$

However, this can only hold if $\sup_{n\ge 0}\|\frac{1}{(\cdot+1)^n}\|_{\mathcal{H}} < \infty$. Thus the proposition is proved. □

As on the circle, this sufficient condition excludes most of the examples of a decomposing Banach algebra on the imaginary line from having a bounded spectral factorization mapping, as the Hölder classes, the Sobolev classes, the Carleman classes, etc. We close this section by showing that the spectral factorization mapping is not bounded on the Wiener algebra $W(i\mathbb{R})$. The proof is based on an idea used in Rudin [25].

PROPOSITION 6.7. *The spectral factorization mapping is unbounded on $W(i\mathbb{R})$.*

Proof. First, we consider the sequences $\{q_n\}_{n\in\mathbb{N}_0}, \{p_n\}_{n\in\mathbb{N}_0} \subset L_1(\mathbb{R})$ defined by

$$\begin{aligned} q_0(t) := p_0(t) &:= \begin{cases} 1 \ , & t \in [0,1], \\ 0 \ , & \text{otherwise}, \end{cases} \\ p_{n+1} &:= p_n + q_n(\cdot - 2^n), \\ q_{n+1} &:= p_n - q_n(\cdot - 2^n). \end{aligned}$$

By this definition $\|p_n\|_{L_1(\mathbb{R})} = \|q_n\|_{L_1(\mathbb{R})} = 2^n$. Moreover, we define the sequences $\{k_n\}_{n\in\mathbb{N}_0}, \{l_n\}_{n\in\mathbb{N}_0} \subset W(i\mathbb{R})_+$ by $k_n := \hat{p}_n$ and $l_n := \hat{q}_n$. Thus $\|k_n\|_{W(i\mathbb{R})} = 2^n$, and the parallelogram law

$$|a+b|^2 + |a-b|^2 = 2|a|^2 + 2|b|^2$$

shows

$$\begin{aligned} &|k_{n+1}(i\omega)|^2 + |l_{n+1}(i\omega)|^2 \\ &= |\hat{p}_n(i\omega) + q_n\widehat{(\cdot - 2^n)}(i\omega)|^2 + |\hat{p}_n(i\omega) - q_n\widehat{(\cdot - 2^n)}(i\omega)|^2 \\ &= 2|\hat{p}_n(i\omega)|^2 + 2|q_n\widehat{(\cdot - 2^n)}(i\omega)|^2 = 2|k_n(i\omega)|^2 + 2|l_n(i\omega)|^2. \end{aligned}$$

Thus

$$|k_n(i\omega)|^2 \le |k_n(i\omega)|^2 + |l_n(i\omega)|^2 = 2^n(|k_0(i\omega)|^2 + |l_0(i\omega)|^2) = 2^{n+1}|k_0(i\omega)|^2.$$

An easy calculation shows

$$|k_0(i\omega)| = \frac{2}{|\omega|}\left|\sin\frac{\omega}{2}\right|,$$

and thus $\|k_0\bar{k}_0\|_{L_2(i\mathbb{R})} = \sqrt{\frac{2\pi}{3}}$, and

$$\|k_n\bar{k}_n\|_{L_2(i\mathbb{R})} \le \sqrt{\frac{2\pi}{3}}2^{n+1}.$$

Moreover,

$$\|k_n\|_{L_\infty(i\mathbb{R})} \le 2^{(n+1)/2}\|k_0\|_{L_\infty(i\mathbb{R})} \le 2^{(n+1)/2}\|k_0\|_{W(i\mathbb{R})} \le 2^{(n+1)/2}.$$

We now define

$$h_n := 2\cdot 2^{-n/4} + 2^{-(3n)/4}k_n.$$

By this definition, we get $h_n \in W(i\mathbb{R})_+$, and $\|h_n\|_{W(i\mathbb{R})} = 2\cdot 2^{-n/4} + 2^{n/4}$. Moreover, $|h_n(i\omega)| \ge (2-\sqrt{2})\cdot 2^{-n/4}$, and so $h_n \in \mathcal{G}W(i\mathbb{R})_+$.

We now define $f_n \in W(i\mathbb{R})$ by $f_n = |h_n|^2 = \overline{h_n}h_n$. This definition implies $f_n(t) > 0$, $t \in \mathbb{T}$, and so f_n is a spectral density, and $\Phi f_n = b_n h_n$ for some constant b_n of modulus 1. This implies

$$\begin{aligned}
\|f_n\|_{W(i\mathbb{R})} &= \|4\cdot 2^{-n/2} + 2\cdot 2^{-n}(k_n + \bar{k}_n) + 2^{-(3n)/2}k_n\bar{k}_n\|_{W(i\mathbb{R})}\\
&\le 2^{2-n/2} + 2^{1-n}\|k_n + \bar{k}_n\|_{W(i\mathbb{R})} + 2^{-(3n)/2}\|k_n\bar{k}_n\|_{W(i\mathbb{R})}\\
&\le 2^{2-n/2} + 4 + 2^{-(3n)/2}\|p_n * p_n(-\cdot)\|_{L_1(\mathbb{R})}\\
&\le 2^{2-n/2} + 4 + 2^{-(3n)/2}\left(\int_{-2^n}^{2^n} 1\,dt\right)^{1/2}\|p_n * p_n(-\cdot)\|_{L_2(\mathbb{R})}\\
&\le 2^{2-n/2} + 4 + 2^{1/2-n}\|p_n * p_n(-\cdot)\|_{L_2(\mathbb{R})}\\
&= 2^{2-n/2} + 4 + \frac{2^{1/2-n}}{\sqrt{2\pi}}\|k_n\bar{k}_n\|_{L_2(i\mathbb{R})}\\
&\le 2^{2-n/2} + 4 + \frac{2^{-n}}{\sqrt{\pi}}\sqrt{\frac{2\pi}{3}}2^{n+1} \le 10.
\end{aligned}$$

This proves that the sequence $\{f_n\}_n$ is bounded in $W(i\mathbb{R})$, whereas the corresponding sequence of spectral factors is not bounded in $W(i\mathbb{R})$. Thus the spectral factorization mapping is not bounded in $W(i\mathbb{R})$. □

7. Conclusions. We presented in this paper a detailed study of two properties of the spectral factorization mapping on L_∞ and C as well as on decomposing Banach algebras: continuity and boundedness. We showed that these two properties are quite different. On L_∞ and C the spectral factorization mapping is bounded but not

continuous, whereas on all decomposing Banach algebras under consideration this mapping is continuous and not bounded.

One of our main results concerning the boundedness of the spectral factorization mapping on decomposing Banach algebras was that the mapping can be bounded only if the Wiener algebra W can be continuously embedded into the decomposing Banach algebra $\mathcal{B}$ and $\mathcal{B} \neq W$. However, it is an open problem whether there exists a decomposing Banach algebra $\mathcal{B} \neq W$ such that W can be continuously embedded into $\mathcal{B}$.

TRAJECTORY CONTROL AND INTERCONNECTION OF 1D AND nD SYSTEMS*

P. ROCHA† AND J. WOOD‡

Abstract. In this paper we examine the relationship between control viewed as concatenation of trajectories and control viewed as interconnection of systems. We show that, for one-dimensional linear time-invariant systems, the ability to obtain a given subsystem by regular interconnection (a prerequisite for any feedback-type structure) is equivalent to the ability to drive any trajectory into that subsystem. However, in the case of multidimensional systems, the former is a stronger property than the latter. Trajectory controllability can, however, be expressed as a regular interconnection of behaviors in an extended variable space by introducing latent or auxiliary variables. This leads as a by-product to the notion of controlling a system by means of latent variables.

Key words. behavioral approach, multidimensional systems, controllability, regular interconnection, set-controllability

1. Introduction.

The notion of feedback is ubiquitous in modern control theory. However, feedback interconnections of systems are based (albeit implicitly) on the still more fundamental concept of regular interconnection, formally introduced by Willems in the context of the behavioral approach [32]. As we will see in section 3, an interconnection is regular if the additional restrictions imposed on the plant by the controller are independent of the restrictions already present (e.g., only system inputs are restricted, as in a feedback loop). Given a plant and a desired subsystem which is a regular interconnection of the plant and some controller, we will say that the given subsystem is "achievable from the plant by regular interconnection."

Another fundamental concept in control systems theory is that of controllability. According to the behavioral definition, or the related state space definition of Kalman, controllability is the ability to drive any system trajectory into any other system trajectory (in finite time). Thus "controllability" is concerned with the driving of trajectories, whereas feedback "control" is concerned with the interconnection of systems. Clearly the two must be related. Indeed, for a one-dimensional (1D) linear state space model, controllability à la Kalman is necessary and sufficient to place a system's poles arbitrarily using state feedback. In the 1D behavioral context, Willems has shown that controllability is equivalent to achievability of any subsystem by regular interconnection.

Since many of the results in this paper answer open questions for standard 1D behaviors, our contribution is not only at the level of generalization of existing results in the 1D behavioral approach. However, most of our attention is given to the multidimensional (nD) case, in which every system trajectory is a function of two or more independent variables (rather than just one, usually time, in the standard 1D case). Such systems have classical applications in areas such as paper rolling, seismology,

iterative learning control, and image processing, or, more generally, in the analysis of any system described by PDEs or difference equations. The theory of control for general linear nD systems is to date not very far developed, and we hope here to provide a helpful foundation for future work.

The structure of the paper is as follows. We begin by introducing some necessary background from the field of 1D/nD behavioral theory. Most of this material is standard, centering around concepts such as autonomy, controllability and input/output structures. Also, in section 2.4 we look at the structure and representation of factor behaviors, which will be crucial in what follows. Section 3 is devoted to an exposition of the theory of regular interconnection for 1D and nD systems, including the recently discovered equivalence to feedback interconnection. This section concludes with an algorithm, based on recent work by Bisiacco and Valcher, for testing achievability by regular interconnection and constructing a controller.

Then in section 4 we introduce the notion of set-controllability, which describes the ability to concatenate any trajectory of a given behavior with some trajectory of a prescribed subset. Thus this definition captures the "trajectory driving" aspect of control. We look at the characterization of set-controllability and the relationship between it and regular interconnection. In particular, we show that, for a 1D linear time-invariant system, a behavior $\mathcal{B}$ is set-controllable to a subbehavior $\mathcal{B}'$ if and only if $\mathcal{B}'$ is achievable from $\mathcal{B}$ by regular interconnection. In the nD case, however, achievability by regular interconnection is strictly stronger and is generally a very strong requirement.

We unify these two concepts in section 5 by introducing "regular extended interconnection," which is regular interconnection of extended behaviors obtained by introducing latent or auxiliary variables (i.e., through an autoregressive moving average (ARMA)–type representation of the system). This use of variables other than those which we wish to control is also a basic idea in recent work of Polderman and Mareels [16] and Trentelman and Willems [23, 24]. One of our main results is that achievability of a given subbehavior by regular extended interconnection is equivalent to set-controllability to that subbehavior in both the 1D and nD cases.

A preliminary version of this work was presented in [22].

2. Differential/difference behaviors. In this section we introduce the necessary background material on behavioral theory. Except where explicitly indicated, all of this material has appeared previously in the literature.

2.1. Behaviors, representations, and admissible signal spaces. We define a *system* to be a triple $(\mathcal{A}, q, \mathcal{B})$, where $\mathcal{A}$ is a set called the *signal space*, $q \in \mathbb{Z}_+$, and $\mathcal{B} \subseteq \mathcal{A}^q$ is called the system *behavior* [29, 30]. The elements of $\mathcal{B}$ or, more generally, of $\mathcal{A}^q$ are called *trajectories*. Throughout this paper, $\mathcal{A}$ will be some space of functions or distributions on some *signal domain* T and taking values in a field k taken to be $\mathbb{R}$ or $\mathbb{C}$. In the 1D case, $T = \mathbb{N}, \mathbb{Z}$, or $\mathbb{R}$; in the nD case, $T = \mathbb{N}^n, \mathbb{Z}^n$, or $\mathbb{R}^n$.

Our behaviors will be specified by sets of linear differential equations (or difference equations) with constant coefficients. Denote by $\mathcal{D}$ the polynomial ring $k[z_1, \ldots, z_n]$ in n indeterminates, and let $R \in \mathcal{D}^{g,q}$ for some $g, q \in \mathbb{Z}_+$ be a polynomial matrix. Let $\mathcal{A} = \mathcal{C}^\infty(\mathbb{R}^n, k)$ or $\mathcal{D}'(\mathbb{R}^n, k)$. Then the *differential behavior* defined by R is given by

$$\mathcal{B} \;=\; \ker R \;:=\; \left\{ w \in \mathcal{A}^q \;\middle|\; R\left(\frac{\partial}{\partial t_1}, \ldots, \frac{\partial}{\partial t_n}\right) w = 0 \right\}, \tag{2.1}$$

and R is said to be a *kernel representation* of $\mathcal{B}$.

In case of behaviors specified by difference equations, which we will consider simultaneously, $\mathcal{A}$ is equal to $k^{\mathbb{Z}^n}$ or $k^{\mathbb{N}^n}$, and the *difference behavior* defined by R is given by

$$\mathcal{B} \;=\; \ker R \;:=\; \{w \in \mathcal{A}^q \mid R(\sigma_1, \ldots, \sigma_n)\, w = 0\}\,, \tag{2.2}$$

where each σ_i is a backward shift operator, defined on a given trajectory w by

$$(\sigma_i w)(t_1, \ldots, t_n) \;:=\; w(t_1, \ldots, t_i + 1, \ldots, t_n). \tag{2.3}$$

We again say that R is a *kernel representation* of $\mathcal{B}$. In order to consider both differential and difference behaviors simultaneously, we will drop the operator notation and simply write $Rw = R(z_1, \ldots, z_n)w$ for a given polynomial matrix R applied to a given trajectory w, where the meaning is understood to be given by substitution in R of partial derivative or shift operators according to $\mathcal{A}$.

As an example, the two-dimensional (2D) differential behavior with three variables described by the single PDE

$$\frac{\partial w_1}{\partial t_1}(t_1, t_2) + \frac{\partial w_1}{\partial t_2}(t_1, t_2) - \frac{\partial^2 w_2}{\partial t_1 t_2}(t_1, t_2) - 2\frac{\partial^3 w_3}{\partial t_1^3}(t_1, t_2) + w_3(t_1, t_2) \;=\; 0,$$

with signal space $\mathcal{A} = \mathcal{C}^\infty(\mathbb{R}^2, \mathbb{R})$, can be written as

$$\mathcal{B} \;=\; \ker R, \qquad R \;=\; \begin{pmatrix} (z_1 + z_2) & (-z_1 z_2) & (1 - 2z_1^3) \end{pmatrix}.$$

For the case $\mathcal{A} = k^{\mathbb{Z}^n}$, the shift operators σ_i are invertible, and so we consider the polynomial matrices to have entries in the ring $k[z_1, \ldots, z_n, z_1^{-1}, \ldots, z_n^{-1}]$ of Laurent polynomials; that is, in this case only we take $\mathcal{D} = k[z_1, \ldots, z_n, z_1^{-1}, \ldots, z_n^{-1}]$ throughout. We will not refer to the Laurent polynomial ring again; however, it should be borne in mind that Laurent polynomials replace polynomials for this particular signal space.

The two continuous and two discrete signal spaces listed above all possess certain important abstract properties which give our behaviors a far richer structure than would otherwise be the case, as explained in the ground-breaking work of Oberst [14]. Throughout the remainder of the paper, we take $\mathcal{A}$ to be one of these four spaces, and all behaviors considered will be differential or difference behaviors as defined by (2.1) or (2.2) according to $\mathcal{A}$. Thus, when we write "$\mathcal{B} \subseteq \mathcal{A}^q$," we implicitly assume not only that $\mathcal{A}$ is one of the listed signal spaces but also that $\mathcal{B}$ can be described by differential or difference equations as above. In particular, all behaviors are given by linear equations with constant coefficients.

It will occasionally be necessary to refer to module-theoretic properties of behaviors. For any $r \in \mathcal{D}$ and any $w \in \mathcal{A}^q$, rw is an element of $\mathcal{A}^q$ defined as $(rI_q)w$, where rI_q is that polynomial matrix given by r times the identity.

Given a differential or difference behavior $\mathcal{B} \subseteq \mathcal{A}^q$, it will sometimes be necessary to refer to the *orthogonal module* $\mathcal{B}^\perp$, defined by

$$\mathcal{B}^\perp \;=\; \{v \in \mathcal{D}^{1,q} \mid vw \;=\; 0 \;\forall\, w \in \mathcal{B}\}, \tag{2.4}$$

where the meaning of vw is simply the $1 \times q$ polynomial matrix v applied to the trajectory w in the usual way. Thus $\mathcal{B}^\perp$ is the set (actually a submodule of $\mathcal{D}^{1,q}$) of all polynomial equations satisfied by the behavior. Given a kernel representation

$\mathcal{B} = \ker R$, we in fact have that $\mathcal{B}^\perp$ is the set of all $\mathcal{D}$-linear combinations of the rows of R.

The following important result effectively says that an inclusion of behaviors is equivalent to the reverse inclusion of the corresponding orthogonal modules.

THEOREM 2.1 (see [14, 2.61], [19, Prop. II.9]). *Let $\mathcal{B}_1 = \ker R_1$, $\mathcal{B}_2 = \ker R_2$ be two behaviors in $\mathcal{A}^q$ for some q. Then $\mathcal{B}_1$ is a* subbehavior *of $\mathcal{B}_2$ (i.e., $\mathcal{B}_1 \subseteq \mathcal{B}_2$) if and only if there exists a polynomial matrix L with $R_2 = LR_1$.*

For a behavior $\mathcal{B} \subseteq \mathcal{A}^q$, we also say that a given matrix $M \in \mathcal{D}^{q,l}$ is an *image representation* of $\mathcal{B}$ if

$$\mathcal{B} \;=\; \operatorname{im} M \;:=\; \{w \in \mathcal{A}^q \mid w = Mv \text{ for some } v \in \mathcal{A}^l\}. \tag{2.5}$$

Not all behaviors have image representations.

2.2. Free variables, autonomous behaviors, and regular behaviors.

DEFINITION 2.2 (see [19, Def. III.11]). *Let $\mathcal{B} \subseteq \mathcal{A}^q$. The set of variables $\{w_i \,|\, i \in \Phi\}$ for some subset Φ of $\{1, \ldots, q\}$ is said to be a* set of free variables *if the mapping $\rho : \mathcal{B} \to \mathcal{A}^\Phi$, which projects a trajectory onto the components of Φ, is surjective.*

The maximum size of a set of free variables is called the number of free variables *of $\mathcal{B}$ and is denoted by $m(\mathcal{B})$.*

We will often abuse this nomenclature somewhat by referring to certain variables w_i as free when we actually mean that the set of such variables is free.

If R is a kernel representation of $\mathcal{B}$, then $m(\mathcal{B}) = q - \operatorname{rank} R$ (where the rank is defined over the ring $\mathcal{D}$ or, equivalently, over the field $k(z_1, \ldots, z_n)$); see [14, Thm. 2.69]. It can also be shown [35, remarks following Def. 6] that for any behavior $\mathcal{B}$ with subbehavior $\mathcal{B}'$, we have

$$m(\mathcal{B}) \;=\; m(\mathcal{B}') + m(\mathcal{B}/\mathcal{B}'); \tag{2.6}$$

the meaning of $\mathcal{B}/\mathcal{B}'$ will be discussed in section 2.4. Now it is a well-known algebraic fact that $\mathcal{B} + \overline{\mathcal{B}}$ is isomorphic (as a module) to the factor of $\mathcal{B} \oplus \overline{\mathcal{B}}$ by $\mathcal{B} \cap \overline{\mathcal{B}}$. Consequently, we have the following equation for any $\mathcal{B}, \overline{\mathcal{B}} \subseteq \mathcal{A}^q$:

$$m(\mathcal{B}) + m(\overline{\mathcal{B}}) \;=\; m(\mathcal{B} + \overline{\mathcal{B}}) + m(\mathcal{B} \cap \overline{\mathcal{B}}). \tag{2.7}$$

We will use the following definition of autonomous systems; an equivalent condition in terms of trajectories is given for discrete behaviors in [7, 35].

DEFINITION 2.3. *A behavior $\mathcal{B}$ is called* autonomous *if it has no free variables, i.e., if $m(\mathcal{B}) = 0$.*

LEMMA 2.4 (see [7, 35]). *The following are equivalent for any behavior $\mathcal{B} = \ker R$.*

1. *$\mathcal{B}$ is autonomous.*
2. *There exists a nonzero polynomial r with $rw = 0$ for all $w \in \mathcal{B}$.*
3. *R has full column rank.*

A behavior is said to be *regular* if it has a full row rank kernel representation [19]. For $n = 1$, all behaviors are regular; this fails for $n \geq 2$, as can be seen from the simple 2D differential behavior

$$\mathcal{B} \;=\; \ker \begin{pmatrix} z_1 \\ z_2 \end{pmatrix},$$

consisting of all constant functions, which cannot be described as the kernel of a single polynomial operator.

2.3. Input/output structures and controllability. Inputs (assumed to be free) and outputs are defined in the behavioral framework as follows.

DEFINITION 2.5 (see [14, Thm. 2.69], [19, Def. IV.8], [30, Def. VIII.3], [35, Def. 12]). *A* (free) input/output structure *on the behavior $\mathcal{B}$ is a partitioning of the system variables $w = (u, y)$, such that the set of variables u is free and the* zero-input behavior $\mathcal{B}_{0,y}$*, defined by*

$$\mathcal{B}_{0,y} \;=\; \{(u, y) \in \mathcal{B} \;\mid\; u = 0\}, \tag{2.8}$$

is autonomous.

Equivalently, we can consider a partitioning $R = (-Q\ P)$ of any kernel representation R of $\mathcal{B}$ (to within a column permutation), where the columns of Q correspond to the input variables u and the columns of P correspond to the output variables y, and we have the condition

$$\text{rank } R \;=\; \text{rank } P \;=\; \text{number of columns of } P. \tag{2.9}$$

It is easy to show that the number of inputs is equal to m, the number of free variables. In particular, the number of inputs and number of outputs of a behavior are independent of the input/output structure. We will denote the number of outputs of a behavior $\mathcal{B} \subseteq \mathcal{A}^q$ by $p(\mathcal{B}) = q - m(\mathcal{B})$; then for $\mathcal{B} = \ker R$ we have

$$p(\mathcal{B}) \;=\; \text{rank } R. \tag{2.10}$$

For a given free input/output structure, any behavior $\mathcal{B}$ has a unique *transfer (function) matrix* $G \in k(z_1, \dots, z_n)^{p,m}$ characterized by the equation $PG = Q$; see [14, Thm. 2.69] and also [19, p. 75], [30] for the 2D/1D cases. Collecting together all behaviors with a given input/output structure (i.e., which have the same number of system variables and both admit the given partitioning of those variables into inputs and outputs) and the same transfer matrix with respect to that input/output structure, we obtain a *transfer class*. The transfer class turns out to be independent of the input/output structure and resulting transfer matrix, and the transfer classes partition the set of behaviors. Furthermore, each transfer class has a unique element which is minimal with respect to set inclusion [14, Thm. 7.21], [19, p. 76].

Next, recall the notion of a minimal left annihilator (MLA) [19, p. 24]. The following is not the usual definition but is equivalent to it [35, Lem. 7].

DEFINITION 2.6. *Suppose that $R \in \mathcal{D}^{g,q}$. Then R is called an MLA (of M) if there exists a matrix $M \in \mathcal{D}^{q,h}$ for some h with* $\ker R = \text{im } M$.

Every polynomial matrix has an MLA [14, Lem. 2.27], [35, Lem. 7].

It is also shown in [35, Lem. 10] that a given matrix E is an MLA (of some matrix) precisely when it satisfies the condition of generalized factor left primeness introduced in [14, Thm. 7.21], [38]. Furthermore, a full row rank matrix $E \in \mathcal{D}^{g,q}$ is an MLA precisely when E is minor left prime, i.e., when the gth order minors of E have no nontrivial common factor.

We can now define and characterize controllability. It will be convenient to first introduce the notion of concatenability of trajectories.

DEFINITION 2.7. *Let $\mathcal{B}$ be a behavior, $w^{(1)}, w^{(2)} \in \mathcal{B}$, and let T_1, T_2 be subsets of the signal domain T. We say that $w^{(1)}$ and $w^{(2)}$ are* concatenable in $\mathcal{B}$ with respect to (T_1, T_2) *if the following condition, dependent on the signal space $\mathcal{A}$, holds.*

$\mathcal{A} = \mathcal{C}^\infty(\mathbb{R}^n, k)$ or $\mathcal{A} = \mathcal{D}'(\mathbb{R}^n, k)$. There exists $w^{(0)} \in \mathcal{B}$ such that $w^{(0)}$ agrees with $w^{(1)}$ on T_1 and with $w^{(2)}$ on T_2.

$\mathcal{A} = k^T, T = \mathbb{N}^n$ or $\mathbb{Z}^n$. For any $b_1, b_2 \in T$, there exists $w^{(0)} \in \mathcal{B}$ with

$$w^{(0)}(t) = \begin{cases} w^{(1)}(t-b_1), & t \in T_1 \text{ and } t-b_1 \in T, \\ w^{(2)}(t-b_2), & t \in T_2 \text{ and } t-b_2 \in T. \end{cases} \tag{2.11}$$

Concatenability therefore expresses the possibility of being able to find a trajectory $w^{(0)}$ which looks like the trajectory $w^{(1)}$ on the set T_1 and like $w^{(2)}$ on T_2. In the discrete case, we further require that this should be possible with $w^{(1)}$ and $w^{(2)}$ "positioned anywhere" within the signal domain, i.e., with the origins of their coordinate systems located at any points b_1, b_2. This is necessary in the case $T = \mathbb{N}^n$ to allow for the possibility that the behavior may not be forward shift-invariant [36].

The behavioral definition of controllability is due to Willems in the 1D case [30] and to various authors in the nD discrete/continuous cases [15, 19, 21, 35, 36]. The metric $d(\cdot,\cdot)$ on the signal domain T in the discrete case can be arbitrary.

DEFINITION 2.8. *A differential behavior $\mathcal{B}$ is* controllable *if, for any two open sets $T_1, T_2 \subseteq \mathbb{R}^n$ with disjoint closures, any pair of trajectories of $\mathcal{B}$ are concatenable in $\mathcal{B}$ with respect to (T_1, T_2).*

A difference behavior $\mathcal{B}$ with signal domain $T = \mathbb{Z}^n$ or $T = \mathbb{N}^n$ is controllable (with separation distance ρ) *if $\rho > 0$ has the property that for any sets $T_1, T_2 \subseteq T$ with $d(T_1, T_2) > \rho$, any pair of trajectories of $\mathcal{B}$ are concatenable in $\mathcal{B}$ with respect to (T_1, T_2).*

For the purposes of the definition of controllability, in the discrete case $T = \mathbb{N}^n$ we need consider only $b_1 = 0$ in Definition 2.7, whereas for $T = \mathbb{Z}^n$ we can take $b_1 = b_2 = 0$ without loss of generality [36].

The characterization of controllability is due to many authors [4, 14, 15, 17, 19, 21, 30, 35, 36, 38].

THEOREM 2.9. *The following are equivalent for a behavior $\mathcal{B} \subseteq \mathcal{A}^q$ with kernel representation R.*

1. *$\mathcal{B}$ is controllable.*
2. *$\mathcal{B}$ is minimal in its transfer class.*
3. *$\mathcal{B}$ has an image representation.*
4. *R is an MLA.*
5. *$\mathcal{B}$ is a divisible module, i.e., for any nonzero $r \in \mathcal{D}$ and any $w \in \mathcal{B}$, there exists $w' \in \mathcal{B}$ with $rw' = w$.*
6. *$\mathcal{B}$ has no proper subbehaviors with the same number of free variables.*

Any behavior has a "controllable-autonomous decomposition" $\mathcal{B} = \mathcal{B}^c + \mathcal{B}^a$ [35, Thm. 7]; the argument given in that paper applies equally well to continuous systems. In this decomposition, the *controllable part* $\mathcal{B}^c \subseteq \mathcal{B}$ is uniquely determined as the minimal element of the transfer class of $\mathcal{B}$. An example of an *autonomous part* is $\mathcal{B}_{0,y}$ for any free input/output structure (u, y) on $\mathcal{B}$ [34, Lem. 3.9]. Note that in the nD context we do not require $\mathcal{B}^c \cap \mathcal{B}^a = 0$.

The following result has not previously appeared in the literature.

COROLLARY 2.10. *The following are equivalent for any subbehavior $\mathcal{B}'$ of $\mathcal{B}$.*

1. *$\mathcal{B}'$ contains the controllable part $\mathcal{B}^c$ of $\mathcal{B}$.*
2. *$\mathcal{B}'$ and $\mathcal{B}$ have the same number of free variables.*
3. *$\mathcal{B}'$ and $\mathcal{B}$ are in the same transfer class.*

Proof. We prove $1 \Rightarrow 2 \Rightarrow 3 \Rightarrow 1$. Suppose first that $\mathcal{B}'$ contains $\mathcal{B}^c$. Then we must have $m(\mathcal{B}^c) \leq m(\mathcal{B}') \leq m(\mathcal{B})$. However, since $\mathcal{B}^c$ is in the same transfer class as $\mathcal{B}$, it in particular has the same number of free variables, and therefore $m(\mathcal{B}) = m(\mathcal{B}')$

also. Now let $(\mathcal{B}')^c$ denote the controllable part of $\mathcal{B}'$; this is in the transfer class of $\mathcal{B}'$, so has the same number of free variables, and we find

$$m((\mathcal{B}')^c) \;=\; m(\mathcal{B}') \;=\; m(\mathcal{B}).$$

However, by [33, Thm. 7], $\mathcal{B}^c$ is the unique controllable subbehavior of $\mathcal{B}$ with the same number of free variables as $\mathcal{B}$; therefore, $\mathcal{B}^c = (\mathcal{B}')^c$. Since $\mathcal{B}'$ and $\mathcal{B}$ have the same controllable part, they are in the same transfer class. Finally, if $\mathcal{B}'$ and $\mathcal{B}$ are in the same transfer class, then they have the same controllable part, and so, in particular, $\mathcal{B}^c \subseteq \mathcal{B}'$. □

The following definition is not the original one given for strong controllability [19], which has not yet been usefully extended from 2D to nD or to the continuous case.

DEFINITION 2.11. *A matrix $R \in \mathcal{D}^{g,q}$ is called* zero left prime *if its gth order minors generate $\mathcal{D}$ as an ideal. A behavior $\mathcal{B}$ is called* strongly controllable *if it has a zero left prime kernel representation.*

LEMMA 2.12. *A behavior $\mathcal{B} \subseteq \mathcal{A}^q$ is strongly controllable if and only if it is a direct summand of $\mathcal{A}^q$ (the complementary summand being also a differential/difference behavior).*

Proof. Suppose that $\mathcal{B} = \ker R$ with R zero left prime. Then it is well known that R has a right inverse Y over $\mathcal{D}$, and it is now routine to show that $\mathcal{A}^q = \ker R \oplus \operatorname{im} Y$. Conversely, if $\mathcal{B}$ is a direct summand of $\mathcal{A}^q$, then the "orthogonal module" $\mathcal{B}^\perp$ of all system equations is a direct summand of $\mathcal{D}^{1,q}$. A standard algebraic argument now yields that there exists a polynomial matrix R which is zero left prime such that the rows of R generate $\mathcal{B}^\perp$. Hence $\ker R = \mathcal{B}$. □

Any zero left prime matrix is minor left prime so, in particular, an MLA; therefore, any strongly controllable behavior is also controllable. Since minor left primeness and zero left primeness are equivalent in the 1D case, the converse holds for 1D systems but not for $n \geq 2$. Strong controllability as defined above has previously been termed "rectifiability" and is equivalent to the concepts of free-controllability and flatness due to Fliess and coworkers (e.g., [6, 12]).

2.4. Factors and sums of behaviors. Due to the categorical duality of Oberst, if $\mathcal{B}' \subseteq \mathcal{B} \subseteq \mathcal{A}^q$ are behaviors, then the factor space (module) $\mathcal{B}/\mathcal{B}'$ also admits the structure of a behavior [14, Thm. 2.56(iii)]. This can be seen by choosing a kernel representation $R' \in \mathcal{D}^{g',q}$ for $\mathcal{B}'$. The restriction of this operator map from $\mathcal{A}^q$ to $\mathcal{B}$ has kernel $\mathcal{B}'$, and so its image is isomorphic to $\mathcal{B}/\mathcal{B}'$:

$$R'\mathcal{B} \;\cong\; \mathcal{B}/\mathcal{B}'. \tag{2.12}$$

This is an isomorphism of behaviors in the sense that it is the dual of an isomorphism of the corresponding finitely generated modules [33, Sect. 2.5]. Such isomorphisms preserve many important system-theoretic properties such as controllability, strong controllability, autonomy, number of free variables, etc., and for most purposes we may consider them to be "the same behavior." Note that $R'\mathcal{B}$ is dependent upon the choice of R'; different $R'\mathcal{B}$'s may even have different numbers of system variables.

The next result, adapted from [34, Thm. 5.7], demonstrates the construction of a kernel representation for a factor behavior.

LEMMA 2.13. *Let $\mathcal{B}' \subseteq \mathcal{B}$ be behaviors, where $\mathcal{B}'$ has the kernel representation R', and KR' is a kernel representation of $\mathcal{B}$ for some K. Let C be an MLA of R', and set*

$$L \;=\; \begin{pmatrix} K \\ C \end{pmatrix}.$$

Then L is a kernel representation of $R'\mathcal{B} \cong \mathcal{B}/\mathcal{B}'$. In the case where R' has full row rank, K itself is a kernel representation of $R'\mathcal{B} \cong \mathcal{B}/\mathcal{B}'$.

Proof. For the first claim, follow the first part of the proof of [34, Thm. 5.7], which does not depend upon the special choice $\mathcal{B}' = \mathcal{B}^c$ in that result. The second claim is immediate from the fact that a full row rank matrix has 0 as an MLA. ∎

Alternatively, if given two kernel representations $\mathcal{B} = \ker R, \mathcal{B}' = \ker R'$, construct an MLA $(C\ C')$ of $\binom{R'}{R}$. By the procedure for elimination of variables [8], [14, Cor. 2.38], $\ker C = R'\mathcal{B}$.

Of particular interest are the factors of controllable or autonomous behaviors. If $\mathcal{B}$ is controllable and $\mathcal{B}'$ is a subbehavior of $\mathcal{B}$, then it is easy to show from the divisibility characterization in Theorem 2.9 that $\mathcal{B}/\mathcal{B}'$ is also controllable. Similarly, from condition 2 in Lemma 2.4 we find that if $\mathcal{B}$ is autonomous, then so is $\mathcal{B}/\mathcal{B}'$.

We can also construct a representation for the sum of two given behaviors; this technique is implicit in some of the work of Valcher, e.g., [25, Lem. 4.3].

LEMMA 2.14. *Suppose $\mathcal{B} = \ker R, \overline{\mathcal{B}} = \ker \overline{R}$ are subbehaviors of $\mathcal{A}^q$. Let $(C\ \overline{C})$ be an MLA of $\binom{R}{\overline{R}}$. Then $CR = -\overline{C}\,\overline{R}$ is a kernel representation of $\mathcal{B} + \overline{\mathcal{B}}$.*

Proof. Let $R, \overline{R}, C$, and $\overline{C}$ be as stated. Suppose first that $CRw = 0$. Then

$$\begin{pmatrix} Rw \\ 0 \end{pmatrix} \in \ker (C\ \overline{C}) = \operatorname{im} \begin{pmatrix} R \\ \overline{R} \end{pmatrix},$$

so there exists w' with $Rw = Rw'$ and $\overline{R}w' = 0$. Hence $w = (w - w') + w'$ with $w - w' \in \mathcal{B}$ and $w' \in \overline{\mathcal{B}}$. Conversely if $w = w_1 + w_2$, $w_1 \in \mathcal{B}$, $w_2 \in \overline{\mathcal{B}}$, then $CRw = CRw_2 = -\overline{C}\,\overline{R}w_2 = 0$. Hence $\mathcal{B} + \overline{\mathcal{B}} = \ker CR$. ∎

3. Regular interconnection. In the behavioral approach, interconnections of systems are described by intersections of the corresponding behaviors (e.g., [3, 30, 32]). Thus if $\mathcal{B} = \ker R$ and $\overline{\mathcal{B}} = \ker \overline{R}$, then $\mathcal{B} \cap \overline{\mathcal{B}} = \ker \frac{R}{\overline{R}}$ is the behavior of the system obtained by interconnecting $\mathcal{B}$ and $\overline{\mathcal{B}}$. In some cases, the physical interconnection is not along all input/output channels, e.g., in a series interconnection. Such an interconnection can, however, still be represented in this framework by extending each of the original systems to include the variables of the other (without constraints). Such variations are discussed in detail in the work of Weiland and Stoorvogel [27, 28]. Various types of interconnections have also been discussed and related to the module-theoretic approach by Fliess and Bourlès [5]. In this dual domain, interconnection is described as a fibered sum of modules [5].

A prerequisite for an interconnection to be describable in terms of feedback is that it should be "regular" [32]. This has nothing to do with the concept of a "regular" behavior. The definition that we give here is different from the original definition of Willems, but the two are equivalent in both 1D and nD cases.

Throughout this section and the remainder of the paper, $\mathcal{B}', \mathcal{B}$, and $\overline{\mathcal{B}}$ denote three (linear, shift-invariant) differential/difference behaviors in the same space $\mathcal{A}^q$. $\mathcal{B}$ can be thought of as the plant, $\overline{\mathcal{B}}$ as the controller, and $\mathcal{B}'$ as the controlled system.

DEFINITION 3.1. *The interconnection $\mathcal{B} \cap \overline{\mathcal{B}}$ is said to be a* regular interconnection *if the sets $\mathcal{B}^\perp$ and $\overline{\mathcal{B}}^\perp$ of system equations intersect trivially.*

If $\mathcal{B}' \subseteq \mathcal{B}$ and there exists $\overline{\mathcal{B}}$ such that $\mathcal{B}' = \mathcal{B} \cap \overline{\mathcal{B}}$ and this is a regular interconnection, we say that $\mathcal{B}'$ is achievable from $\mathcal{B}$ by regular interconnection.

With this new definition, regular interconnection expresses the idea of "restricting what is not yet restricted." In a regular interconnection, the controller imposes new restrictions on the plant; it does not reimpose restrictions that are already present. In

this sense, the controller in a regular interconnection has no redundancy. A feedback controller is a simple example of a regular interconnection; the controller imposes restrictions only on the plant input, which is unrestricted in the plant. Feedback interconnections (with no assumptions of causality) can be formally defined in the current framework as follows.

DEFINITION 3.2 (see [20, 32]). *The interconnection $\mathcal{B} \cap \overline{\mathcal{B}}$ is said to be* implementable as a feedback interconnection *if there exist input/output structures (u, y) on $\mathcal{B}$ and $(\overline{u}, \overline{y})$ on $\overline{\mathcal{B}}$ such that y and $\overline{y}$ are disjoint sets of variables, and $(u \cap \overline{u}, y \cup \overline{y})$ is an input/output structure on $\mathcal{B} \cap \overline{\mathcal{B}}$.*

We now give a number of conditions characterizing regular interconnection; in particular, we show that Definition 3.1 is equivalent to the original definition given in [32]. The last condition, established in [20], shows that regular interconnection is both necessary and sufficient for the existence of a feedback control structure.

LEMMA 3.3. *Take $\mathcal{B} = \ker R$, $\overline{\mathcal{B}} = \ker \overline{R}$. Then the following are equivalent.*

1. *$\mathcal{B} \cap \overline{\mathcal{B}}$ is a regular interconnection.*
2. *$p(\mathcal{B}) + p(\overline{\mathcal{B}}) = p(\mathcal{B} \cap \overline{\mathcal{B}})$.*
3. *$\operatorname{rank} R + \operatorname{rank} \overline{R} = \operatorname{rank} \left(\begin{smallmatrix} R \\ \overline{R} \end{smallmatrix}\right)$.*
4. *$\mathcal{B} + \overline{\mathcal{B}} = \mathcal{A}^q$.*
5. *$\mathcal{B} \cap \overline{\mathcal{B}}$ can be implemented as a feedback interconnection.*

Proof. The equivalence of conditions 2 and 3 is obvious from the equality of the rank and the number of outputs. Now subtract $2q$ from each side of (2.7) to obtain

$$p(\mathcal{B} \cap \overline{\mathcal{B}}) + p(\mathcal{B} + \overline{\mathcal{B}}) = p(\mathcal{B}) + p(\overline{\mathcal{B}}). \tag{3.1}$$

This holds for any $\mathcal{B}, \overline{\mathcal{B}}$. Thus condition 2 is equivalent to the condition

$$p(\mathcal{B} + \overline{\mathcal{B}}) = 0,$$

which is trivially equivalent to the condition 4. Next, note that any equation satisfied by both $\mathcal{B}$ and $\overline{\mathcal{B}}$ is satisfied by $\mathcal{B}+\overline{\mathcal{B}}$, and vice versa. Since $\mathcal{A}^q$ is the only (linear, shift-invariant) differential/difference behavior satisfying no nontrivial system equation, conditions 1 and 4 are equivalent.

Finally, equivalence of conditions 1 and 5 is shown in [20] for the case $\mathcal{A} = k^{\mathbb{Z}^n}$; the proof techniques given there apply also to the other signal spaces. □

Note that an interconnection satisfying the conditions of Lemma 3.3 is called a feedback interconnection in [10, 31], where the term regular (feedback) interconnection is reserved for something more specific. Weiland and Stoorvogel [27, 28] have another nonequivalent definition of regular interconnection. The term "achievable" is used in a similar way by Polderman and Mareels [16] but not in the context of *regular* interconnections.

Condition 3 in Lemma 3.3 provides an algorithmic test for the regularity of a given interconnection. Condition 2 intuitively says that the plant and controller cannot share output variables in a regular interconnection (though this interpretation depends upon a suitable choice of input/output structures and is hard to formalize). Condition 4 says that any q-tuple of signals can be decomposed as a sum of a plant trajectory and a controller trajectory; further interpretation of this is still open. One immediate consequence of condition 4 is that regularity of interconnection is preserved by extending either the plant or the controller behavior. This condition provides us with an alternative test of regularity of an interconnection: if $\mathcal{B} = \ker R$, $\overline{\mathcal{B}} = \ker \overline{R}$, and $(C\ \overline{C})$ is an MLA of $\left(\begin{smallmatrix} R \\ \overline{R} \end{smallmatrix}\right)$, then by Lemma 2.14 $\mathcal{B} \cap \overline{\mathcal{B}}$ is a regular interconnection

if and only if $CR = 0$. This test says that $\mathcal{B} \cap \overline{\mathcal{B}}$ is a regular interconnection precisely when any relation on the rows of $\left(\begin{smallmatrix} R \\ \overline{R} \end{smallmatrix}\right)$ can be decomposed into a relation on the rows of R and a relation on the rows of $\overline{R}$.

Lemma 3.3 shows that regular and feedback interconnections are equal in a certain sense. Moreover, it is shown in [20] (following [32] for the 1D case) that if $\mathcal{B}' \subseteq \mathcal{B}$ is achievable from $\mathcal{B}$ by regular interconnection and if input/output structures on $\mathcal{B}'$ and $\mathcal{B}$ are given, where the inputs of $\mathcal{B}'$ are a subset of the inputs of $\mathcal{B}$, then $\mathcal{B}'$ can be achieved from $\mathcal{B}$ by control in a standard feedback loop. In other words, achievability by regular interconnection is sufficient for the existence of a feedback controller, even when inputs and outputs for plant and controlled system are assigned a priori. Since we have no new observations to make on the subject of feedback, we will discuss it no further in this paper; see [20] for further details.

Example 3.4. 1. We begin with a 1D example, taken over the signal space $\mathcal{A} = \mathcal{C}^\infty(\mathbb{R}, \mathbb{R})$. Consider the behavior $\mathcal{B}$ and subbehavior $\mathcal{B}'$ given by

$$\mathcal{B} = \ker R, \quad R = \begin{pmatrix} z-1 & z-1 & z^2+z-2 \end{pmatrix},$$
$$\mathcal{B}' = \ker R', \quad R' = \begin{pmatrix} -z & 1 & 1 \\ z-1 & 0 & z-1 \end{pmatrix}.$$

We can achieve $\mathcal{B}'$ by interconnection with the following controller:

$$\overline{\mathcal{B}} = \ker \overline{R}, \quad \overline{R} = \begin{pmatrix} -z^2 & z & z \\ z-1 & 0 & z-1 \end{pmatrix}.$$

In fact, we have

$$\begin{pmatrix} R \\ \overline{R} \end{pmatrix} = \hat{L} R', \quad R' = \hat{K} \begin{pmatrix} R \\ \overline{R} \end{pmatrix}$$

with

$$\hat{L} = \begin{pmatrix} z-1 & z+1 \\ z & 0 \\ 0 & 1 \end{pmatrix}, \quad \hat{K} = \begin{pmatrix} -1 & 1 & z+1 \\ 0 & 0 & 1 \end{pmatrix}.$$

Unfortunately, $\mathcal{B}$ has rank $R = 1$ output, and $\overline{\mathcal{B}}$ has rank $\overline{R} = 2$ outputs, whereas $\mathcal{B} \cap \overline{\mathcal{B}} = \mathcal{B}'$ has rank $R' = 2$ outputs. The interconnection is therefore not regular, and a feedback structure connecting $\mathcal{B}$ and $\overline{\mathcal{B}}$ cannot exist.

2. For $\mathcal{A} = \mathcal{C}^\infty(\mathbb{R}^3, \mathbb{R})$, consider the interconnection

$$\mathcal{B} \cap \overline{\mathcal{B}} = \ker \left(\begin{array}{ccc} 0 & z_1 & -z_2 \\ -z_1 & 0 & z_3 \\ \hline 0 & z_2 & z_1 z_2 \\ 0 & z_3 & z_1 z_3 \end{array} \right).$$

It is easy from the rank condition to check that this interconnection is regular. The interconnection may be implemented by means of a feedback loop: take the first two variables to be outputs in $\mathcal{B}$ and inputs in $\overline{\mathcal{B}}$, and the third variable to be an input in $\mathcal{B}$ and an output in $\overline{\mathcal{B}}$; all three variables are then outputs in the intersection.

3. For the same signal space and behavior $\mathcal{B}$, look at the following interconnection with a different controller $\overline{\mathcal{B}}$:

$$\mathcal{B} \cap \overline{\mathcal{B}} = \ker \left(\begin{array}{ccc} 0 & z_1 & -z_2 \\ -z_1 & 0 & z_3 \\ \hline z_2 & -z_3 & 0 \end{array} \right).$$

The interconnected system is given by the *curl* or *rot* operator, which is singular. Since the ranks of the representations of $\mathcal{B}$ and $\overline{\mathcal{B}}$ add to up $3 > 2$, the interconnection is not regular. Indeed, $(z_1 z_2 \ -z_1 z_3 \ 0)w = 0$ is a system equation of both $\mathcal{B}$ and $\overline{\mathcal{B}}$. This interconnection cannot be implemented through feedback: the intersection has an input, which should therefore be a common input to both plant and controller, and by counting we find this is impossible without the nonfeedback phenomenon of a common output.

We now consider the condition of achievability by regular interconnection.

LEMMA 3.5. *Suppose $\mathcal{B}' \subseteq \mathcal{B} \subseteq \mathcal{A}^q$. Then the following are equivalent.*

1. *$\mathcal{B}'$ is achievable from $\mathcal{B}$ by regular interconnection.*
2. *$\mathcal{B}/\mathcal{B}'$ is a direct summand of $\mathcal{A}^q/\mathcal{B}'$.*

In the case where $\mathcal{B}'$ is a regular behavior, a further equivalent condition is that $\mathcal{B}/\mathcal{B}'$ is strongly controllable.

Also, for any $\mathcal{B}$ the following are equivalent.

(i) *$\mathcal{B}$ is strongly controllable.*

(ii) *Any $\mathcal{B}' \subseteq \mathcal{B}$ is achievable from $\mathcal{B}$ by regular interconnection.*

(iii) *The subbehavior $\{0\}$ is achievable from $\mathcal{B}$ by regular interconnection.*

Proof. If $\mathcal{B}'$ can be achieved from $\mathcal{B}$ by regular interconnection, then there exists a $\overline{\mathcal{B}} \subseteq \mathcal{A}^q$ with $\mathcal{B} \cap \overline{\mathcal{B}} = \mathcal{B}'$ and $\mathcal{B} + \overline{\mathcal{B}} = \mathcal{A}^q$. It follows immediately that $\mathcal{B}/\mathcal{B}' \cap \overline{\mathcal{B}}/\mathcal{B}' = \{0\}$ and $\mathcal{B}/\mathcal{B}' + \overline{\mathcal{B}}/\mathcal{B}' = \mathcal{A}^q/\mathcal{B}'$, i.e., $\mathcal{B}/\mathcal{B}'$ is a direct summand of $\mathcal{A}^q/\mathcal{B}'$ and conversely. Now suppose that $\mathcal{B}'$ is a regular behavior with a full row rank kernel representation R'. Then, as discussed in section 2.4, $\mathcal{B}/\mathcal{B}'$ can be identified with $R'\mathcal{B}$, and $\mathcal{A}^q/\mathcal{B}' = \operatorname{im} R'$, which by [14, pp. 24–25] equals $\mathcal{A}^{p(\mathcal{B}')}$, as R' has full row rank. Furthermore, there is a natural one-to-one correspondence between the subbehaviors of $\mathcal{A}^{p(\mathcal{B}')}$ and the subbehaviors of $\mathcal{A}^q/\mathcal{B}'$. Hence $\mathcal{B}/\mathcal{B}'$ is a direct summand of $\mathcal{A}^q/\mathcal{B}'$ if and only if $R'\mathcal{B}$ is a direct summand of $\mathcal{A}^{p(\mathcal{B}')}$, and by Lemma 2.12 this is precisely the condition of strong controllability of $R'\mathcal{B} \cong \mathcal{B}/\mathcal{B}'$.

Next, if $\mathcal{B}$ is strongly controllable, then $\mathcal{B}$ is a direct summand of $\mathcal{A}^q$, and so $\{0\}$ is achievable from $\mathcal{B}$ by regular interconnection, say, $\{0\} = \mathcal{B} \cap \overline{\mathcal{B}}$, $\mathcal{B} + \overline{\mathcal{B}} = \mathcal{A}^q$, and conversely. Hence (i) and (iii) are equivalent. Given such a controller $\overline{\mathcal{B}}$, for any given $\mathcal{B}' \subseteq \mathcal{B}$ we have $\mathcal{B} \cap (\overline{\mathcal{B}} + \mathcal{B}') = \mathcal{B}'$. Since $\mathcal{B} + (\overline{\mathcal{B}} + \mathcal{B}') = \mathcal{A}^q$, this interconnection is regular, and so $\mathcal{B}'$ is achievable from $\mathcal{B}'$ by regular interconnection. Hence (ii) and (iii) are equivalent. ∎

Note that in the 1D case every behavior is regular, and so $\mathcal{B}'$ is achievable from $\mathcal{B}$ by regular interconnection if and only if $\mathcal{B}/\mathcal{B}'$ is strongly controllable. In the nD case this is not so, and the condition does not generally apply. For example, take $\mathcal{B} = \mathcal{A}^q$. Then for any $\ker R' = \mathcal{B}' \subseteq \mathcal{B}$, $\mathcal{B}'$ is certainly achievable from $\mathcal{B}$ by regular interconnection (take the controller $\overline{\mathcal{B}} = \mathcal{B}'$), whereas $\mathcal{B}/\mathcal{B}' \cong \operatorname{im} R'$ is controllable but not in general strongly controllable.

Recall that for 1D systems controllability and strong controllability are equivalent. Equivalence of (i)–(iii) in Lemma 3.5 therefore gives us again the 1D result [32] that any subbehavior of a given 1D behavior $\mathcal{B}$ is achievable from $\mathcal{B}$ by regular interconnection if and only if $\mathcal{B}$ is controllable. In the nD case, even for $n = 2$, controllability and strong controllability are no longer equivalent, and we find that achievability by regular interconnection is generally a strong property. In particular, not every autonomous part, or even every minimal autonomous part, of a given behavior $\mathcal{B}$ can be achieved from $\mathcal{B}$ by regular interconnection, even when $\mathcal{B}$ is controllable. We see this by taking $\mathcal{B}$ to be a controllable but not strongly controllable behavior, e.g.,

$$\mathcal{B} \ = \ \ker \begin{pmatrix} z_1 - 1 & z_2 - 1 \end{pmatrix}.$$

Then $\mathcal{B}' = \{0\}$ cannot be achieved from $\mathcal{B}$ by regular interconnection.

We provide examples of behaviors which can and cannot be achieved by regular interconnection in the next section.

3.1. Constructing controllers. As shown in Lemma 3.5, achievability by regular interconnection can be tested through a direct summand condition. Conditions and an algorithm for testing whether one behavior is a direct summand of another have recently been given by Bisiacco and Valcher [2], extending some previous work of Valcher [26, Thm. 3.4]. Furthermore, this work is constructive in that it allows the construction of a complementary direct summand when one exists.

Using these techniques, we can test for achievability by regular interconnection and construct a suitable controller as follows. For brevity, we omit some of the details, which can be found by inspecting the results and proofs in [2].

1. Suppose we are given $\mathcal{B} = \ker R$ and $\mathcal{B}' = \ker R'$ with $\mathcal{B}' \subseteq \mathcal{B} \subseteq \mathcal{A}^q$. Begin by constructing a kernel representation L of $R'\mathcal{B} \cong \mathcal{B}/\mathcal{B}'$, as described in Lemma 2.13. Construct also an MLA C of R', so that $\ker C \cong \mathcal{A}^q/\mathcal{B}'$. Then we must find whether $\ker L$ is a direct summand of $\ker C$.

2. Apply the method of Bisiacco and Valcher. Construct a matrix K with $KL = C$, and extend K to $\hat{K}$ by adding rows which form an MLA of C. Now $\ker L$ is a direct summand of $\ker C$ if and only if $\hat{K}$ and L are *internally zero skew-prime*, i.e., there exists polynomial matrices X, Y with $X\hat{K} + LY = I$.

3. Internal zero skew-primeness can be tested using Gröbner basis techniques, since $X\hat{K} + LY = I$ is a system of linear equations in the entries of X and Y, and we simply want to know whether a solution exists and to find one if it does. Accordingly, if no such X, Y exist, then $\mathcal{B}'$ is not achievable from $\mathcal{B}$ by regular interconnection.

4. If, on the other hand, we can compute X and Y with $X\hat{K} + LY = I$, then we can extend this equation to a "doubly coprime factorization"

$$\begin{pmatrix} X & L \\ W_1 & W_2 \end{pmatrix} \begin{pmatrix} \hat{K} & Z_1 \\ Y & Z_2 \end{pmatrix} = \begin{pmatrix} I & 0 \\ 0 & I \end{pmatrix},$$

in which the two matrices on the left-hand side are mutual unimodular inverses (a unimodular matrix being a square matrix with an inverse over the polynomial ring). Since $\binom{L}{W_2}$ is zero right prime, $\ker L \cap \ker W_2 = 0$. Furthermore, $(\hat{K}\ Z_1)$ must be an MLA of $\binom{L}{W_2}$, so from Lemma 2.14 we find that $\hat{K}L$ is a kernel representation of $\ker L + \ker W_2$. However, by definition of $\hat{K}$ we have that $\ker \hat{K}L = \ker C$, so $\ker W_2$ is the complementary summand of $\ker L$ in $\ker C$.

5. Set $\overline{\mathcal{B}} = \ker W_2 R'$. It is now easy to check that $\mathcal{B} \cap \overline{\mathcal{B}} = \mathcal{B}'$ and $\mathcal{B} + \overline{\mathcal{B}} = \mathcal{A}^q$. Hence this interconnection is regular.

In the case where $\mathcal{B}'$ is regular, a simpler algorithm can be applied; we need only construct $R'\mathcal{B}$ and test to see whether it is strongly controllable. In the case where it is, we can find a full row rank kernel representation L of $R'\mathcal{B}$, which must be zero left prime. We then construct a matrix W_2 such that $\binom{L}{W_2}$ is unimodular (see, e.g., [1, 9]), and $W_2 R'$ gives us the required controller as in the above algorithm.

Example 3.6. 1. If (u, y) is a free input/output structure on $\mathcal{B}$, then $\mathcal{B}_{0,y}$ is achievable from $\mathcal{B}$ by regular interconnection. A suitable controller is

$$\overline{\mathcal{B}} := \left\{ \begin{pmatrix} u \\ y \end{pmatrix} \in \mathcal{A}^{m+p} \;\middle|\; u = 0 \right\}.$$

It is easy to see that $\mathcal{B} + \overline{\mathcal{B}} = \mathcal{A}^q$; from this we find by Lemma 3.3 that $\mathcal{B} \cap \overline{\mathcal{B}} = \mathcal{B}_{0,y}$ is a regular interconnection.

2. Let us return to the 1D example in 3.4.1, in which we previously found a nonregular interconnection:

$$\mathcal{B} = \ker R, \quad R = \begin{pmatrix} z-1 & z-1 & z^2+z-2 \end{pmatrix},$$
$$\mathcal{B}' = \ker R', \quad R' = \begin{pmatrix} -z & 1 & 1 \\ z-1 & 0 & z-1 \end{pmatrix}.$$

The given kernel representations for the behaviors $\mathcal{B}$ and $\mathcal{B}'$ are related by

$$R = LR', \quad L = \begin{pmatrix} z-1 & z+1 \end{pmatrix}.$$

Since R' has full row rank, L is a kernel representation for $R'\mathcal{B}$. It is zero left prime, proving that $R'\mathcal{B}$ is controllable or, equivalently, strongly controllable, and is therefore extendable by the Quillen–Suslin theorem to a unimodular matrix, e.g.,

$$\begin{pmatrix} L \\ \overline{L} \end{pmatrix} = \begin{pmatrix} z-1 & z+1 \\ 1 & 1 \end{pmatrix}.$$

A suitable controller is given by

$$\overline{\mathcal{B}} = \ker \overline{L} R' = \ker \begin{pmatrix} -1 & 1 & z \end{pmatrix},$$

which has a single output. We have $p(\mathcal{B}) + p(\overline{\mathcal{B}}) = p(\mathcal{B}')$, so the interconnection is regular. It can be implemented via a feedback loop: choose the first variable to be an input in $\overline{\mathcal{B}}$ and an output in $\mathcal{B}, \mathcal{B}'$, the second variable to be an input in $\mathcal{B}$ and an output in $\overline{\mathcal{B}}, \mathcal{B}'$, and the third variable to be an input in all three behaviors.

3. Consider the 2D behaviors given by the matrices

$$\mathcal{B} = \ker R, \quad \mathcal{B}' = \ker R', \quad R = \begin{pmatrix} z_1^2 - 1 & z_1 - z_2 \end{pmatrix}, \quad R' = \begin{pmatrix} z_1 + 1 & z_2 \\ 0 & -z_1 \end{pmatrix}.$$

In this case, R' has full row rank, and so from Lemma 3.5 we have that $\mathcal{B}'$ is achievable from $\mathcal{B}$ by regular interconnection if and only if $\mathcal{B}/\mathcal{B}'$ is strongly controllable. We have

$$R = LR', \qquad L = \begin{pmatrix} z_1 - 1 & z_2 - 1 \end{pmatrix},$$

from which L is a kernel representation of $R'\mathcal{B} \cong \mathcal{B}/\mathcal{B}'$. Since L is not zero left prime, $\mathcal{B}/\mathcal{B}'$ is not strongly controllable, and so $\mathcal{B}'$ is not achievable from $\mathcal{B}$ by regular interconnection, even though $\mathcal{B}$ is controllable.

4. Now look at the following 2D behaviors: $\mathcal{B} = \ker R, \mathcal{B}' = \ker R'$, where

$$R = \begin{pmatrix} z_1 z_2 & z_1 + 1 & z_2 \end{pmatrix}, \qquad R' = \begin{pmatrix} 0 & z_1 + z_2 + 1 & z_2 \\ z_1 z_2 & -z_1^2 - z_1 z_2 + 1 & -z_1 z_2 + z_2 \\ -z_1^2 - z_1 z_2 & z_1 + z_2 & 0 \end{pmatrix}.$$

Again we compute a kernel representation of $R'\mathcal{B}$,

$$R'\mathcal{B} = \ker L, \qquad L = \begin{pmatrix} z_1 & 1 & 0 \\ z_1^2 + z_1 z_2 - z_1 - z_2 & z_1 + z_2 & z_2 \end{pmatrix},$$

and an MLA C of R', which is given by the second row of L. Since R' is not full row rank (moreover $\mathcal{B}'$ is not regular), we proceed by applying the method of Bisiacco and Valcher. We have $\ker L \subseteq \ker C$, and we wish to know whether $\ker L$ is a direct

summand of $\ker C$. A kernel representation of $L(\ker C)$ is $\hat{K} = (0 \;\; 1)$, and we have that $\mathcal{B}'$ is achievable from $\mathcal{B}$ by regular interconnection if and only if $\hat{K}$ and L are internally zero skew-prime. This is indeed the case; we have

$$\left(\begin{array}{c|ccc} -1 & z_1 & 1 & 0 \\ 1 & z_1^2+z_1z_2-z_1-z_2 & z_1+z_2 & z_2 \end{array}\right) \left(\begin{array}{cc} 0 & 1 \\ \hline 1-z_2 & 1-z_2 \\ z_1z_2-z_1+1 & z_1z_2-z_1+1 \\ -z_1-z_2 & -z_1-z_2 \end{array}\right) \;=\; I,$$

and the matrix W_2 in the algorithm above is accordingly constructed as

$$\left(\begin{array}{ccc} z_1z_2 - z_1 + 1 & z_2 - 1 & 0 \\ z_1^2 + z_1 - 1 & z_1 + 1 & 1 \end{array}\right),$$

from which we obtain, as a suitable controller,

$$\overline{\mathcal{B}} \;=\; \ker \overline{R}, \qquad \overline{R} = W_2R' \;=\; \left(\begin{array}{ccc} z_1z_2^2 - z_1z_2 & z_1z_2 + 2z_2 & z_2^2 \\ z_1^2z_2 - z_1^2 & z_1^2 + 2z_1 & z_1z_2 \end{array}\right).$$

Since the ranks of R, $\overline{R}$, and $\left(\frac{R}{\overline{R}}\right)$ are 1, 1, and 2, respectively, $\mathcal{B} \cap \overline{\mathcal{B}}$ is certainly a regular interconnection. It remains to confirm that $\mathcal{B} \cap \overline{\mathcal{B}} = \mathcal{B}'$. However, we find

$$\left(\begin{array}{c} R \\ \overline{R} \end{array}\right) \;=\; U \left(\begin{array}{ccc} 0 & z_1 + z_2 + 1 & z_2 \\ z_1z_2 & -z_1^2 - z_1z_2 + 1 & -z_1z_2 + z_2 \\ -z_1^2 - z_1z_2 & z_1 + z_2 & 0 \end{array}\right) \;=\; UR',$$

where

$$U \;=\; \left(\begin{array}{ccc} z_1 & 1 & 0 \\ z_1z_2 - z_1 + 1 & z_2 - 1 & 0 \\ z_1^2 + z_1 - 1 & z_1 + 1 & 1 \end{array}\right)$$

is a unimodular matrix, proving that $\mathcal{B} \cap \overline{\mathcal{B}} = \mathcal{B}'$, as predicted by the theory.

Lomadze and Zerz [11] have recently provided a direct method for testing for achievability by regular interconnection and controller construction. Their algorithms address the problem more directly, but we will not discuss their work here, since the homological techniques involved are beyond the scope of this paper.

4. Set-controllability. In this section we introduce and characterize the new concept of set-controllability, which formalizes the idea of being able to drive any system trajectory into a prescribed trajectory set, in practice a subbehavior $\mathcal{B}'$. This concept has not previously appeared in the literature, even in the 1D case. The formalization is necessarily slightly different for the different signal spaces of interest.

DEFINITION 4.1. *Let $\mathcal{B}' \subseteq \mathcal{B} \subseteq \mathcal{A}^q$. Then we say that $\mathcal{B}$ is* set-controllable to $\mathcal{B}'$ *if the following condition, dependent on the signal space $\mathcal{A}$, holds.*

$\mathcal{A} = \mathcal{C}^\infty(\mathbb{R}^n, k)$ or $\mathcal{A} = \mathcal{D}'(\mathbb{R}^n, k)$: For any $w \in \mathcal{B}$, there exists $w' \in \mathcal{B}'$ such that, for any open sets $T_1, T_2 \subseteq \mathbb{R}^n$ with disjoint closures, w and w' are concatenable in $\mathcal{B}$ with respect to (T_1, T_2).

$\mathcal{A} = k^T, T = \mathbb{N}^n$ or $\mathbb{Z}^n$: There exists a $\rho > 0$ such that for any $w \in \mathcal{B}$, there exists $w' \in \mathcal{B}'$ such that, for any $T_1, T_2 \subseteq T$ with $d(T_1, T_2) \geq \rho$, w and w' are concatenable in $\mathcal{B}$ with respect to (T_1, T_2).

In the above definition, $w \in \mathcal{B}$ is interpreted as the given system trajectory, and $w' \in \mathcal{B}'$ is some trajectory in the desired subsystem into which w can be controlled,

by means of some driving trajectory $w^* \in \mathcal{B}$ (the concatenating trajectory $w^{(0)}$ in Definition 2.7). As in the definition of controllability, it is sufficient for the definition of set-controllability in the discrete case to consider only $b_1 = 0$ in Definition 2.7, and for $T = \mathbb{Z}^n$ we can take $b_2 = 0$ as well.

In each case, note that $w' \in \mathcal{B}'$ can be chosen independently of the regions T_1 and T_2. This sounds like a very stringent requirement, but as we will now show, set-controllability as defined above admits a variety of interesting characterizations.

4.1. Characterizing set-controllability. Here follows one of our main results.

THEOREM 4.2. *Let $\mathcal{B}' \subseteq \mathcal{B}$. The following are equivalent.*

1. *$\mathcal{B}$ is set-controllable to $\mathcal{B}'$.*
2. *$\mathcal{B}/\mathcal{B}'$ is controllable.*
3. *$\mathcal{B} = \mathcal{B}^c + \mathcal{B}'$.*
4. *Any autonomous part of $\mathcal{B}'$ is also an autonomous part of $\mathcal{B}$.*
5. *$\mathcal{B}$ has no proper subbehaviors with the same number of free variables which contain $\mathcal{B}'$.*
6. *$\mathcal{B}$ has no proper subbehaviors in the same transfer class which contain $\mathcal{B}'$.*

Proof. 1 $\Rightarrow$ 2. Suppose that $\mathcal{B}$ is set-controllable to $\mathcal{B}'$, and let R' be any kernel representation of $\mathcal{B}'$. We will prove that the behavior $R'\mathcal{B}$ is controllable. Since $R'\mathcal{B} \cong \mathcal{B}/\mathcal{B}'$, and controllability is (by the divisibility condition in Theorem 2.9) preserved by isomorphism, this is sufficient. We treat the discrete and continuous cases in turn.

The case $\mathcal{A} = k^T, T = \mathbb{N}^n$ or $\mathbb{Z}^n$: Let $\rho > 0$ be the distance given in the definition of set-controllability, and take $d(t_1, t_2) := \sum_{i=1}^n |(t_1)_i - (t_2)_i|$. Note that without loss of generality we can take R' to have entries in $\mathcal{D}$ regardless of T. Hence we can use the notation

$$R' \;=\; \sum_{a \in \mathbb{N}^n} R'_a z_1^{a_1} \cdots z_n^{a_n}$$

with coefficient matrices R'_a over k:

$$\operatorname{supp}(R') := \{a \in \mathbb{N}^n : R'_a \neq 0\}.$$

Set

$$\Delta := \max\{d(0, a) \mid a \in \operatorname{supp}(R')\}$$

and $\tau := \rho + 2\Delta$. We will prove that $R'\mathcal{B}$ is controllable with separation distance τ.

Let $v \in R'\mathcal{B}$ be arbitrary, say, $v = R'w$ for some $w \in \mathcal{B}$. Now there exists $w' \in \mathcal{B}'$ with the property given in the definition of set-controllability. Let $T_1, T_2 \in T$ be such that $d(T_1, T_2) \geq \tau$. It suffices by linearity to prove that v and 0 are concatenable in $R'\mathcal{B}$ with respect to (T_1, T_2). Therefore, choose $b_1, b_2 \in T$ arbitrarily, and extend T_1 and T_2 to T_3 and T_4, respectively, according to

$$T_3 \;:=\; \{t + a \mid t \in T_1, a \in \operatorname{supp}(R')\},$$

and similarly for T_4. Now for any $t_1 + a_1 \in T_3$, $t_2 + a_2 \in T_4$ with $t_1 \in T_1$, $t_2 \in T_2$, $a_1, a_2 \in \operatorname{supp}(R')$, we have

$$d(t_1, t_2) \;\leq\; d(t_1, t_1 + a_1) + d(t_1 + a_1, t_2 + a_2) + d(t_2 + a_2, t_2),$$

and, consequently, $d(T_3, T_4) \geq \rho$. Hence, by set-controllability, there exists $w^* \in \mathcal{B}$ satisfying

$$w^*(t) \;=\; \begin{cases} w(t-b_1) & \text{if } t \in T_3 \text{ and } t-b_1 \in T, \\ w'(t-b_2) & \text{if } t \in T_4 \text{ and } t-b_2 \in T. \end{cases} \tag{4.1}$$

Set $v^* = R'w^*$; we now find that for any $t \in T_1$ with $t - b_1 \in T$, we have

$$v^*(t) \;=\; \sum_{a \in \operatorname{supp}(R')} R'_a w^*(t+a).$$

Now $t + a - b_1$ must be in T for any $a \in \operatorname{supp}(R')$, and $t + a \in T_3$, which by (4.1) gives us

$$\begin{aligned} v^*(t) &= \sum_{a \in \operatorname{supp}(R')} R'_a w(t+a-b_1) \\ &= (R'w)(t-b_1) \\ &= v(t-b_1). \end{aligned}$$

Similarly, for any $t \in T_2$ with $t - b_2 \in T$, we have

$$v^*(t) \;=\; (R'w')(t-b_2) \;=\; 0.$$

Hence v^* drives the given trajectory v to the zero trajectory. This is sufficient to prove that $R'\mathcal{B}$ is controllable.

The case $\mathcal{A} = \mathcal{C}^\infty(\mathbb{R}^n, k)$ or $\mathcal{A} = \mathcal{D}'(\mathbb{R}^n, k)$: Let U be any open subset of $\mathbb{R}^n$, and let V be any closed subset whose interior contains the closure of U. Let $v \in R'\mathcal{B}$ be arbitrary, say, $v = R'w$ for some $w \in \mathcal{B}$. Since $\mathcal{B}$ is set-controllable to $\mathcal{B}'$, $\exists w' \in \mathcal{B}'$ and $w^* \in \mathcal{B}$ such that w^* agrees with w on U and with w' on V^c, the complement of V. Now define $v^* = R'w^* \in R'\mathcal{B}$. Since the support of $R'(w^* - w')$ is contained in the support of $w^* - w'$ (the differential operator R' is a local operator), we have that $v^* = R'(w^* - w')$ vanishes on V^c. On the other hand, $v - v^* = R'(w - w^*)$ vanishes on U, so v^* agrees with v on U. This proves that v has a "cutoff" $v^* \in R'\mathcal{B}$ with respect to U and V, which by [15, Lemma 3.3] is sufficient to prove that $R'\mathcal{B}$ is controllable.

$2 \Rightarrow 3$. Now suppose that $\mathcal{B}/\mathcal{B}'$ is controllable, and consider the behavior $\mathcal{B}/(\mathcal{B}^c + \mathcal{B}')$. This behavior is a factor of $\mathcal{B}/\mathcal{B}'$ but is also a factor of the behavior $\mathcal{B}/\mathcal{B}^c$. However, $\mathcal{B}/\mathcal{B}^c$ is autonomous by (2.6). By the remarks in section 2.4, $\mathcal{B}/(\mathcal{B}^c + \mathcal{B}')$ is therefore both controllable and autonomous, and therefore equal to $\{0\}$.

$3 \Rightarrow 1$. Suppose that $\mathcal{B} = \mathcal{B}^c + \mathcal{B}'$. Then any trajectory $w = w^c + w'$ of $\mathcal{B}$ can be driven to $\mathcal{B}'$ by driving w^c to 0. Hence $\mathcal{B}$ is set-controllable to $\mathcal{B}'$.

$3 \Leftrightarrow 4$. Let $\mathcal{B}'^a$ be an autonomous part of $\mathcal{B}'$, and let $\mathcal{B}'^c$ be the controllable part. We argue as follows:

$$\mathcal{B} \;=\; \mathcal{B}^c + \mathcal{B}' \;=\; \mathcal{B}^c + \mathcal{B}'^c + \mathcal{B}'^a. \tag{4.2}$$

Now $\mathcal{B}^c + \mathcal{B}'^c$ contains $\mathcal{B}^c$ and is contained in $\mathcal{B}$ so by Corollary 2.10 has the same number of free variables as $\mathcal{B}$ and $\mathcal{B}^c$. But it is easy to see that $\mathcal{B}^c + \mathcal{B}'^c$ is itself controllable, which by condition 6 of Theorem 2.9 implies that we must have $\mathcal{B}^c = \mathcal{B}^c + \mathcal{B}'^c$. Equation (4.2) now becomes $\mathcal{B} = \mathcal{B}^c + \mathcal{B}'^a$, i.e., $\mathcal{B}'^a$ is an autonomous part of $\mathcal{B}$. The converse is easy.

$2 \Leftrightarrow 5 \Leftrightarrow 6$. By condition 6 of Theorem 2.9, controllability of $\mathcal{B}/\mathcal{B}'$ means that no proper subbehavior of $\mathcal{B}/\mathcal{B}'$ can have the same number of free variables as $\mathcal{B}/\mathcal{B}'$.

By (2.6), an equivalent statement is 5, and the equivalence of 5 and 6 is immediate from Corollary 2.10. □

Condition 2 in Theorem 4.2 suggests that we can think of set-controllability to $\mathcal{B}'$ as "controllability to within $\mathcal{B}'$." We will use this characterization heavily in what follows.

Next, note that any $\mathcal{B}$ is set-controllable to $\mathcal{B}$. In fact, this is the only possibility for set-controllability when $\mathcal{B}$ is autonomous. Indeed, the condition "$\mathcal{B}$ is set-controllable to $\mathcal{B}' \Rightarrow \mathcal{B}' = \mathcal{B}$" characterizes autonomy. Controllability may also be characterized in terms of set-controllability (compare with Lemma 3.5 (i)–(iii)).

COROLLARY 4.3. *The following are equivalent.*

1. $\mathcal{B}$ *is controllable.*
2. $\mathcal{B}$ *is set-controllable to* $\mathcal{B}'$ *for any subbehavior* $\mathcal{B}'$.
3. $\mathcal{B}$ *is set-controllable to* $\{0\}$.

Thus controllability expresses the ability to control a given system in the above sense into any desired subsystem. Notice a more general property: if $\mathcal{B}$ is set-controllable to $\mathcal{B}'$, and $\mathcal{B}' \subseteq \mathcal{B}'' \subseteq \mathcal{B}$, then $\mathcal{B}$ is also set-controllable to $\mathcal{B}''$.

Example 4.4. 1. From condition 3 in Theorem 4.2, $\mathcal{B}$ is set-controllable to $\mathcal{B}'$ for any autonomous part $\mathcal{B}'$ of $\mathcal{B}$. In particular, $\mathcal{B}$ is set-controllable to $\mathcal{B}_{0,y}$ for any free input/output structure (u, y) (any trajectory is driven into $\mathcal{B}_{0,y}$ by setting the inputs to 0).

2. In Example 3.6.3, the subbehavior $\mathcal{B}'$ was shown not to be achievable from the controllable $\mathcal{B}$ by regular interconnection. However, we showed that $\mathcal{B}/\mathcal{B}' \cong \ker (z_1 - 1 \quad z_2 - 1)$, which by Theorem 4.2 demonstrates that $\mathcal{B}$ is set-controllable to $\mathcal{B}'$, as predicted by Corollary 4.3.

From condition 2 of Theorem 4.2 and (for example) the divisibility characterization of controllability, we can easily prove the intuitive result that set-controllability is transitive. In particular, if a behavior is set-controllable to a controllable subbehavior, then it must itself be controllable.

It is interesting to consider set-controllability of $\mathcal{B}$ to $\mathcal{B}'$ from the point of view of the subbehavior $\mathcal{B}'$. For any behavior $\mathcal{B}$, Theorem 4.2 tells us that $\mathcal{B}^c + \mathcal{B}'$ is set-controllable to $\mathcal{B}'$. This behavior $\mathcal{B}^c + \mathcal{B}'$ is also easily shown to be in the same transfer class as $\mathcal{B}$. Furthermore, there cannot be another behavior $\mathcal{B}^*$ in this transfer class which is also set-controllable to $\mathcal{B}'$, since $\mathcal{B}^*$ and $\mathcal{B}$ must have the same controllable part, and condition 3 of Theorem 4.2 therefore requires that $\mathcal{B}^* = \mathcal{B}^c + \mathcal{B}'$. This means that each transfer class contains at most one element which is set-controllable to $\mathcal{B}'$ for fixed $\mathcal{B}'$. When $\mathcal{B}'$ is autonomous, each transfer class contains exactly one such element. It follows that two distinct elements in the same transfer class cannot both be set-controllable to $\mathcal{B}'$ for any $\mathcal{B}'$, i.e., they have in a sense no controllability properties in common!

From these observations, we might go on to define a "$\mathcal{B}'$-transfer class" for fixed $\mathcal{B}'$, being a subset of an ordinary transfer class consisting of all those behaviors which contain $\mathcal{B}'$. Then each $\mathcal{B}'$-transfer class has a unique minimal element, and such elements are precisely the behaviors set-controllable to $\mathcal{B}'$.

It seems reasonable to assume set-controllability to $\mathcal{B}'$ as at least a necessary condition for control under any paradigm. Not only the plant, but also the controller, must be set-controllable to $\mathcal{B}'$, where $\mathcal{B}'$ is the controlled system. This means that, when designing a controller for a given problem, it suffices to identify the transfer class of that controller, for then the controller itself is uniquely identified as the single behavior in that transfer class which is set-controllable to $\mathcal{B}'$. This suggests that the

transfer function matrix approach may be an appropriate initial tool in nD controller design.

4.2. Testing for set-controllability. We now discuss algorithmic tests for set-controllability. These are based on conditions 2 and 3 in Theorem 4.2. We have the isomorphism

$$R'\mathcal{B} \cong \mathcal{B}/\mathcal{B}',$$

which enables us to test for set-controllability to $\mathcal{B}'$ by constructing a kernel representation E for $R'\mathcal{B}$ and testing to see whether E is an MLA. If E is an MLA, then $R'\mathcal{B}$ is controllable and so $\mathcal{B}$ is set-controllable to $\mathcal{B}'$, and conversely. Methods for finding a kernel representation of $R'\mathcal{B}$ have been discussed in section 2.4.

An alternative method for testing for set-controllability of $\mathcal{B}$ to $\mathcal{B}'$, which may be more efficient when a representation R^c of $\mathcal{B}^c$ is already given, is to test for the inclusion $\mathcal{B} \subseteq \mathcal{B}^c + \mathcal{B}'$. By Lemma 2.14, a kernel representation of $\mathcal{B}^c + \mathcal{B}'$ is given as $CR^c = -C'R'$, where $(C\ C')$ is an MLA of $\binom{R^c}{R'}$.

These algorithms require procedures for the following basic problems:

1. construction of a minimal left/right annihilator of a given matrix;
2. construction of a kernel representation for the controllable part of a given $\ker R$;
3. a test for inclusion $\ker R_1 \subseteq \ker R_2$, and the construction of a matrix L with $LR_1 = R_2$ when the inclusion holds;
4. a test to see whether a given R is an MLA.

The first problem is effectively the problem of constructing a syzygy module in commutative algebra, which can be solved through Gröbner basis techniques. The second problem is solved for a given R by constructing a minimal right annihilator M; the controllable part is then $\operatorname{im} M$, a kernel representation of which can be found as any MLA R^c of M. This algorithm is explained in [14, pp. 144–145], [35, 38]; see also the related algorithms in [18, section 4]. The third problem is another standard Gröbner basis problem, while the last reduces to the previous three, as it is equivalent to testing $\ker R \subseteq \ker R^c$.

4.3. Regular interconnection and set-controllability. We have now examined in outline two different paradigms for the control of 1D/nD systems. Regular interconnection is based on the notion of adding restrictions to systems and is related to classical feedback. Set-controllability, on the other hand, formalizes the concept of "on-line" control by steering system trajectories. For a 1D system, we know from the work of Willems [32] that controllability is equivalent to achievability of any subbehavior by means of regular interconnection. This leads to two immediate questions.

- What happens when the given behavior $\mathcal{B}$ is not controllable? In particular, if $\mathcal{B}$ is a 1D behavior which is set-controllable to some subbehavior $\mathcal{B}'$ (but not necessarily actually controllable), is this sufficient for $\mathcal{B}'$ to be achievable from $\mathcal{B}$ by regular interconnection? What about the converse?
- What is the situation for nD behaviors?

The next result answers these questions.

THEOREM 4.5. *If $\mathcal{B}'$ can be achieved from $\mathcal{B}$ by regular interconnection, then $\mathcal{B}$ is set-controllable to $\mathcal{B}'$. The converse holds for $n = 1$ but not for $n \geq 2$.*

Proof. Suppose that $\mathcal{B}'$ can be achieved from $\mathcal{B}$ by regular interconnection. Then by Lemma 3.5, $\mathcal{B}/\mathcal{B}'$ is a direct summand of the controllable behavior $\mathcal{A}^q/\mathcal{B}'$ and so is isomorphic to a factor of it. By the divisibility condition, any factor of a controllable

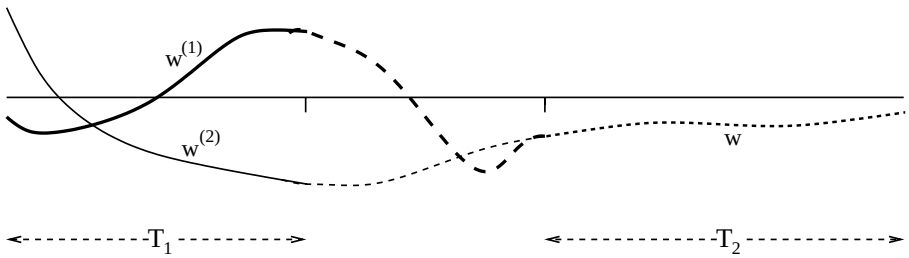

FIG. 4.1. *Mergeable behaviors.*

behavior is controllable, and so $\mathcal{B}$ is set-controllable to $\mathcal{B}'$. In the 1D case, suppose, conversely, that $\mathcal{B}$ is set-controllable to $\mathcal{B}'$. Then $\mathcal{B}/\mathcal{B}'$ is controllable, or, equivalently, strongly controllable, $\mathcal{B}'$ is regular, and so by Lemma 3.5 $\mathcal{B}'$ is achievable from $\mathcal{B}$ by regular interconnection. For any $n \geq 2$, the following is a controllable but not strongly controllable behavior:

$$\mathcal{B} \;=\; \ker\,(z_1 - 1 \;\; z_2 - 1).$$

Hence $\{0\}$ is not achievable from $\mathcal{B}$ by regular interconnection, although $\mathcal{B}$ is set-controllable to $\{0\}$. □

More generally, we have seen at the end of section 3 that not every autonomous part is achievable from a given (controllable) system by regular interconnection. On the other hand, a given behavior is set-controllable to any autonomous part.

The conclusion here is that "on-line" control to a desired subsystem is often possible in situations where there exists no suitable controller forming a regular interconnection with the plant. On the other hand, for a 1D system set-controllable to a given subsystem, it is always possible to construct a (not necessarily causal) feedback controller resulting in that subsystem.

4.4. Mergeable behaviors. We now discuss briefly a related controllability-type concept, which describes the possibility of interconnecting two systems on-line (e.g., a plant and controller) by steering their given trajectories to a common trajectory. This is a third possible paradigm for control of nD systems. While this concept has, to our knowledge, not previously appeared in the literature, similar ideas are the notions of a *compliance-free interconnection* [30] and *interconnectability with finite lag* [27, 28].

DEFINITION 4.6. *Let $\mathcal{B}$ and $\overline{\mathcal{B}}$ be two subbehaviors of $\mathcal{A}^q$. Then we say that $\mathcal{B}$ and $\overline{\mathcal{B}}$ are* mergeable *if the following condition, dependent on the signal space $\mathcal{A}$, holds.*

$\mathcal{A} = \mathcal{C}^\infty(\mathbb{R}^n, k)$ or $\mathcal{A} = \mathcal{D}'(\mathbb{R}^n, k)$. For any $w^{(1)} \in \mathcal{B}$, $w^{(2)} \in \mathcal{B}^{(2)}$, there exists $w \in \mathcal{B} \cap \overline{\mathcal{B}}$ such that for any open sets T_1, T_2 with disjoint closures, $w^{(1)}$ and w are concatenable in $\mathcal{B}$ with respect to (T_1, T_2), and $w^{(2)}$ and w are concatenable in $\overline{\mathcal{B}}$ with respect to (T_1, T_2).

$\mathcal{A} = k^T, T = \mathbb{N}^n$ or $\mathbb{Z}^n$. There exists a $\rho > 0$ such that, for any $w^{(1)} \in \mathcal{B}$, $w^{(2)} \in \mathcal{B}^{(2)}$, there exists $w \in \mathcal{B} \cap \overline{\mathcal{B}}$ such that for any $T_1, T_2 \subseteq T$ with $d(T_1, T_2) \geq \rho$, there exists $w \in \mathcal{B} \cap \overline{\mathcal{B}}$ such that $w^{(1)}$ and w are concatenable in $\mathcal{B}$ with respect to (T_1, T_2), and $w^{(2)}$ and w are concatenable in $\overline{\mathcal{B}}$ with respect to (T_1, T_2).

Thus mergeability formalizes the idea that any two trajectories in the given behaviors $\mathcal{B}$ and $\overline{\mathcal{B}}$ can be controlled to the same trajectory "in finite time." This concept is illustrated in the 1D case by Figure 4.1.

The next result characterizes mergeability and is new even in the 1D case; it also illustrates the usefulness of the set-controllability concept.

THEOREM 4.7. *Let $\mathcal{B}, \overline{\mathcal{B}} \subseteq \mathcal{A}^q$. Then $\mathcal{B}$ and $\overline{\mathcal{B}}$ are mergeable if and only if $\mathcal{B} + \overline{\mathcal{B}}$ is controllable.*

Proof. Consider the behavior $\mathcal{B} \oplus \overline{\mathcal{B}}$, which is naturally a subbehavior of $\mathcal{A}^{2q}$. Now $\mathcal{B} \cap \overline{\mathcal{B}}$ can be treated as a subbehavior of $\mathcal{B} \oplus \overline{\mathcal{B}}$ under the map $\iota : w \mapsto (w, w)$. With this embedding in mind, it is clear that $\mathcal{B}$ and $\overline{\mathcal{B}}$ are mergeable if and only if $\mathcal{B} \oplus \overline{\mathcal{B}}$ is set-controllable to $(\mathcal{B} \cap \overline{\mathcal{B}})$.

Now the image of the map ι is equal to the kernel of the projection $\pi : \mathcal{B} \oplus \overline{\mathcal{B}} \mapsto \mathcal{B} + \overline{\mathcal{B}}$, $(w^{(1)}, w^{(2)}) \mapsto w^{(1)} - w^{(2)}$, and therefore $\mathcal{B} + \overline{\mathcal{B}}$ is naturally isomorphic to the factor $(\mathcal{B} \oplus \overline{\mathcal{B}})/(\mathcal{B} \cap \overline{\mathcal{B}})$. The result now follows from condition 2 of Theorem 4.2. ∎

It can be seen that behaviors which are regularly interconnectable are mergeable, but not conversely. Also, a pair of mergeable behaviors are each set-controllable to their intersection, though this condition is not sufficient for mergeability.

5. Regular extended interconnection. In this section we will extend the framework of regular interconnection to include a concept equivalent in the nD case to set-controllability. The key is to introduce additional variables and to construct controllers in the extended variable space. We can think of these additional control variables as being variables internal to the system, which cannot be directly affected by means of a regular interconnection. By allowing restrictions to be placed directly on such internal variables, we can achieve a larger set of controlled behaviors than is possible through regular interconnection. In the 1D case, however, no additional power is gained through the ability to restrict latent or internal variables. This seems to be due to the fact that, in the 1D case, we can always choose our latent variable descriptions (see below) to be observable, so that the values of the latent variables can be determined from those of the system variables. Restrictions on such latent variables are therefore equivalent to restrictions on the manifest variables.

An idea similar to the use of latent variables is the partitioning of system variables in the plant $\mathcal{B}$ into variables w, which we wish to control, and variables v, which we are not interested in controlling but which we can nevertheless influence by interconnection. This framework has been used by Polderman and Mareels [16] and by Trentelman and Willems [23, 24] as a starting point for more advanced control theories in the behavioral context. In this paper we take the complementary approach of starting with the variables w, which we wish to control, and introducing the additional variables v, which we can also influence.

Recall that a behavior $\mathcal{B}_{w,v} \subseteq \mathcal{A}^{q+l}$ is said to be a *latent variable description* of a behavior $\mathcal{B}_w$ if

$$\mathcal{B}_w \;=\; \{w \in \mathcal{A}^q \mid \exists\, v \in \mathcal{A}^l \text{ such that } (w, v) \in \mathcal{B}_{w,v}\}. \tag{5.1}$$

The variables w are called *manifest variables*, and the variables v are called *latent variables* or auxiliary variables. Latent variable descriptions are often represented in "ARMA form" as

$$\mathcal{B}_{w,v} \;=\; \ker\,(-\hat{R}\;M) \;=\; \{(w, v) \in \mathcal{A}^{q+l} \mid \hat{R}w \;=\; Mv\} \tag{5.2}$$

for some polynomial matrices $\hat{R}$, M. These ideas are described in [8, 19, 21, 30]. The *manifest behavior* $\mathcal{B}_w$ can be constructed from the *full behavior* $\mathcal{B}_{w,v}$ as follows [8], [14, Cor. 2.38]: if E is an MLA of M, then $\mathcal{B}_w = \ker E\hat{R}$. Note our use of $\hat{R}$ rather than

the conventional R; this is to avoid the suggestion that the kernel of the left-hand operator is equal to our $\mathcal{B} = \mathcal{B}_w$. However, we do of course have that $\ker \hat{R} \subseteq \mathcal{B}_w$. Analogously to (5.1), we define the behavior $\mathcal{B}_v$.

5.1. Free latent variable descriptions. If we wish to perform a control action to drive a system trajectory into some desired subbehavior, our first problem is that we can normally affect only free variables. Control of the free input variables of the system unfortunately can only determine the controlled trajectory to within $\mathcal{B}_{0,y}$, and this may not be good enough. It therefore becomes necessary to look for free latent variables, which leads us to introduce the following concept.

DEFINITION 5.1. *A latent variable description $\mathcal{B}_{w,v} \subseteq \mathcal{A}^{q+l}$ is said to be a* free latent variable description *if the variables v are free variables, i.e., if $\mathcal{B}_v = \mathcal{A}^l$.*

We can characterize free latent variable descriptions as follows.

LEMMA 5.2. *Let $\mathcal{B}_{w,v} = \ker(-\hat{R}\ M)$ be a latent variable description of the behavior $\mathcal{B} = \mathcal{B}_w$. Then the following are equivalent.*

1. *$\mathcal{B}_{w,v}$ is a free latent variable description.*
2. *$\operatorname{rank} \hat{R} = \operatorname{rank}(-\hat{R}\ M)$.*
3. *$\operatorname{im} M \subseteq \operatorname{im} \hat{R}$.*
4. *M is an image representation of $\hat{R}\mathcal{B}$.*

Proof. $1 \Rightarrow 2$. Suppose $\mathcal{B}_{w,v}$ is a free latent variable representation. Then $m(\mathcal{B}_v) = l$, the number of variables v. Now $\mathcal{B}_v = \mathcal{B}_{w,v}/\mathcal{B}_{w,0}$, so by additivity of the number of free variables we have $m(\mathcal{B}_{w,v}) - m(\mathcal{B}_{w,0}) = l$. However, $m(\mathcal{B}_{w,v}) = (q+l) - \operatorname{rank}(-\hat{R}\ M)$, and $m(\mathcal{B}_{w,0}) = q - \operatorname{rank} \hat{R}$, from which $\operatorname{rank} \hat{R} = \operatorname{rank}(-\hat{R}\ M)$ as required.

$2 \Rightarrow 3$. Suppose that $\operatorname{rank} \hat{R} = \operatorname{rank}(-\hat{R}\ M)$. Then every column of M is linearly dependent on the columns of $\hat{R}$, i.e., there exist a nonsingular diagonal polynomial matrix D and a polynomial matrix X such that $\hat{R}X = MD$. Since D has full row rank, $\operatorname{im} D = \mathcal{A}^l$ by [14, pp. 24–25], and consequently $\operatorname{im} M = \operatorname{im} \hat{R}X \subseteq \operatorname{im} \hat{R}$ as required.

$3 \Rightarrow 4$. Suppose that $\operatorname{im} M \subseteq \operatorname{im} \hat{R}$. Then for any $x \in \operatorname{im} M$, $x = Mv = \hat{R}w$ for some w, v, which implies $w \in \mathcal{B}$, and so $x \in \hat{R}\mathcal{B}$. Conversely, if $x \in \hat{R}\mathcal{B}$, then $x = \hat{R}w$ for some $w \in \mathcal{B}$, so there must exist v with $x = \hat{R}w = Mv$, and now $x \in \operatorname{im} M$. This proves that $\operatorname{im} M = \hat{R}\mathcal{B}$.

$4 \Rightarrow 1$. Suppose that M is an image representation of $\hat{R}\mathcal{B}$. Then for any $v \in \mathcal{A}^l$, $Mv \in \hat{R}\mathcal{B}$, and so $v \in \mathcal{B}_v$. Hence $\mathcal{B}_{w,v}$ is a free latent variable representation as required. □

We now look at some interesting special cases of free latent variable descriptions.

Example 5.3. 1. Free input/output structures: A behavior $\mathcal{B} = \mathcal{B}_{y,u}$ with a given free input/output structure is clearly a free latent variable description of the manifest output behavior $\mathcal{B}_y$. Conversely, in the case where $\hat{R}w = Mv$ defines a free latent variable description and the behavior $\ker \hat{R}$ is furthermore autonomous, we have a free input/output structure on $\mathcal{B}_{w,v}$ with inputs v and outputs w. An interesting open question is whether the resulting transfer matrix and minimal element of the transfer class then have any interpretation in terms of the latent variable description.

2. A latent variable description arising from a controllable-autonomous decomposition $\mathcal{B} = \mathcal{B}^c + \mathcal{B}^a$, $\mathcal{B}^c = \operatorname{im} M$, $\mathcal{B}^a = \ker \hat{R}$ of $\mathcal{B}$: In this situation,

$$\hat{R}w \ = \ \hat{R}Mv$$

defines a free latent variable description of $\mathcal{B}$. It is a latent variable description of $\mathcal{B}$

since if $\hat{R}w = \hat{R}Mv$, then $w - Mv \in \ker \hat{R}$, so $w \in \operatorname{im} M + \ker \hat{R}$, and conversely. The latent variables v are free from the fact that $\operatorname{im} M = \mathcal{B}^c \subseteq \mathcal{B}$.

3. Consider a classical 1D state-space model, given in the form

$$\begin{pmatrix} B & 0 \\ D & -I \end{pmatrix} \begin{pmatrix} u \\ y \end{pmatrix} = \begin{pmatrix} zI - A \\ -C \end{pmatrix} x, \tag{5.3}$$

where the matrices A, B, C, and D are matrices over the field k. This is a latent variable description of the manifest behavior $\mathcal{B}_{u,y}$ (the behavior of the input and output variables only). By Lemma 5.2, it is free precisely when

$$\operatorname{rank} \begin{pmatrix} zI - A & -B & 0 \\ -C & -D & I \end{pmatrix} = \operatorname{rank} \begin{pmatrix} -B & 0 \\ -D & I \end{pmatrix}. \tag{5.4}$$

However, the rank of the left-hand side is equal to the number of output variables plus the number of state variables, whereas the rank of the right-hand side is equal to the number of output variables plus the rank of B. Therefore, (5.3) is a free latent variable description of $\mathcal{B}_{u,y}$ if and only if B has full row rank.

5.2. Extended interconnection. Having introduced an appropriate class of latent variable descriptions, we now discuss interconnections on the extended variable spaces given by latent variable descriptions.

DEFINITION 5.4. *Suppose that $\mathcal{B}' \subseteq \mathcal{B} \subseteq \mathcal{A}^q$. If there exists a latent variable description $\mathcal{B}_{w,v} \subseteq \mathcal{A}^{q+l}$ of $\mathcal{B}$ such that*

$$\mathcal{B}'_{w,v} = \mathcal{B}_{w,v} \cap \overline{\mathcal{B}_{w,v}} \tag{5.5}$$

for some $\overline{\mathcal{B}_{w,v}}, \mathcal{B}'_{w,v} \subseteq \mathcal{A}^{q+l}$ with $\mathcal{B}'$ equal to the manifest behavior $\mathcal{B}'_w$ of $\mathcal{B}'_{w,v}$, then we say that $\mathcal{B}'$ is achievable from $\mathcal{B}$ by extended interconnection*, and we call* (5.5) *an* extended interconnection*. If the variables w are free in $\overline{\mathcal{B}_{w,v}}$, then* (5.5) *is called a* latent interconnection*, and $\overline{\mathcal{B}_{w,v}}$ is called a* latent controller*. If* (5.5) *is a regular interconnection, i.e., if*

$$p(\mathcal{B}'_{w,v}) = p(\mathcal{B}_{w,v}) + p(\overline{\mathcal{B}_{w,v}}),$$

then it is called a regular extended interconnection *or a* regular latent interconnection*, appropriately. Hence we define* achievability by regular extended/latent interconnection*.*

Achievability by regular extended interconnection therefore describes the possibility of achieving the desired subsystem by extending the variable space using some latent variable description, applying a regular interconnection, and then projecting onto the manifest variables. Latent interconnections are extended interconnections in which the only restrictions applied are on the latent variables. To make a clear distinction, we will refer to an "ordinary" interconnection (i.e., one which restricts only the manifest variables w) as a *manifest interconnection*, and, similarly, we will refer to *manifest controllers*. Latent and manifest controllers are investigated by Kuijper in [10].

Given a latent variable description represented by the formula $\hat{R}w = Mv$, a general extended interconnection is described by the polynomial matrix

$$\left(\begin{array}{cc} -\hat{R} & M \\ \hline N_1 & N_2 \end{array}\right).$$

The case $N_2 = 0$ describes a manifest interconnection in extended interconnection form, and the case $N_1 = 0$ is an important special case of a latent interconnection.

Any manifest interconnection can therefore be expressed trivially as an extended interconnection. Also, any latent interconnection is equivalent to some manifest interconnection (in the sense that there exists a manifest interconnection resulting in the same controlled manifest behavior). To see this, note that any latent controller $N_2 v = 0$ is equivalent in this sense to a latent controller of the form $(LM)v = 0$, which is in turn equivalent to the manifest controller $(L\hat{R})w = 0$. However, we can obtain any subbehavior of the full behavior $\mathcal{B}_w$ by some manifest interconnection, whereas only those subbehaviors containing $\ker \hat{R}$ are achievable by latent interconnection (see [16, 23, 24] for discussions along these lines). For a *fixed* latent variable description, more behaviors can generally be achieved by manifest interconnection than by latent interconnection.

However, any manifest interconnection can be expressed as a latent interconnection on *some* suitably chosen latent variable description, e.g., the behavior $\mathcal{B} = \ker R$ can be extended to the latent variable description given by

$$\begin{pmatrix} I \\ 0 \end{pmatrix} w \;=\; \begin{pmatrix} I \\ R \end{pmatrix} v,$$

and the manifest controller $\overline{R}w = 0$ is equivalent to the latent controller $\overline{R}v = 0$. Furthermore, any regular interconnection becomes a regular latent interconnection in this way. In particular, any subbehavior achievable from $\mathcal{B}$ by regular interconnection is achievable from $\mathcal{B}$ by regular latent interconnection. We will shortly see that the converse of this is not true.

It is important to make a distinction between the behavior $\mathcal{B}'_{w,v}$ obtained by extended interconnection and the behavior

$$\mathcal{B}^*_{w,v} \;:=\; \{(w,v) \in \mathcal{B}_{w,v} \mid w \in \mathcal{B}'_w\}$$

obtained from the manifest $\mathcal{B}' = \mathcal{B}'_w$. It can be easily shown that the latter is equal to $\mathcal{B}'_{w,v} + \mathcal{B}_{0,v}$. Another trap is to suppose that the manifest controlled behavior $\mathcal{B}'_w$ is given by the intersection of the original manifest behavior $\mathcal{B}_w$ and the manifest behavior $\overline{\mathcal{B}_w}$ of the controller. This is generally not the case, e.g., for a latent interconnection we have $\overline{\mathcal{B}_w} = \mathcal{A}^q$, and certainly $\mathcal{B}_w \cap \mathcal{A}^q \neq \mathcal{B}'_w$, except when the interconnection is trivial.

Example 5.5. 1. Consider the behaviors $\mathcal{B}, \mathcal{B}'$ from Example 3.6.3. We saw there that $\mathcal{B}'$ is not achievable from $\mathcal{B}$ by regular interconnection. Now a free latent variable description of $\mathcal{B}$ is given by

$$\begin{pmatrix} z_1 + 1 & 0 \\ 0 & z_2 \\ 0 & -z_1 \end{pmatrix} w \;=\; \begin{pmatrix} z_2 - z_1 \\ z_2(z_1 - 1) \\ -z_1(z_1 - 1) \end{pmatrix} v.$$

It is easy to verify that the compound matrix $(-\hat{R}\ M)$ in this case has rank 2, so that condition 2 of Lemma 5.2 holds. Now consider the controller (which restricts both manifest and latent variables) given by

$$\begin{pmatrix} 0 & z_1(z_2 - 1) \\ 0 & z_1(z_1 - 1) \end{pmatrix} w \;=\; \begin{pmatrix} z_1^2(z_2 - 1) \\ z_1^2(z_1 - 1) \end{pmatrix} v.$$

We can see that this is a regular extended interconnection. The resulting manifest controlled behavior is computed by elimination of latent variables as the subbehavior $\mathcal{B}'$ specified earlier.

Free latent variable descriptions are particularly simple as regards latent interconnection:

LEMMA 5.6. *Any latent interconnection on a free latent variable description is regular.*

Proof. Suppose that $\mathcal{B}_{w,v} \subseteq \mathcal{A}^{q+l}$ is a free latent variable description of $\mathcal{B}_w$, and that $\mathcal{B}'_{w,v} = \mathcal{B}_{w,v} \cap \overline{\mathcal{B}_{w,v}}$ is a latent interconnection. Then the variables v are free in $\mathcal{B}_{w,v}$, and the variables w are free in $\overline{\mathcal{B}_{w,v}}$. Hence $\mathcal{B}_{w,v} + \overline{\mathcal{B}_{w,v}} = \mathcal{A}^{q+l}$, so by Lemma 3.3 the latent interconnection is regular. ∎

5.3. Set-controllability and extended interconnection. Our final main result shows that set-controllability is precisely equivalent to regular interconnection using latent variables.

THEOREM 5.7. *Let $\mathcal{B}' \subseteq \mathcal{B}$. The following are equivalent.*

1. *$\mathcal{B}$ is set-controllable to $\mathcal{B}'$.*
2. *$\mathcal{B}$ admits a free latent variable description $R'w = Mv$ with $\ker R' = \mathcal{B}'$.*
3. *$\mathcal{B}'$ is achievable from $\mathcal{B}$ by latent interconnection on a free latent variable description.*
4. *$\mathcal{B}'$ is achievable from $\mathcal{B}$ by regular latent interconnection on a free latent variable description.*
5. *$\mathcal{B}'$ is achievable from $\mathcal{B}$ by regular latent interconnection.*
6. *$\mathcal{B}'$ is achievable from $\mathcal{B}$ by regular extended interconnection.*

Proof. Suppose that $\mathcal{B}$ is set-controllable to $\mathcal{B}'$, and let R' be an image representation of $\mathcal{B}'$. Then by Theorem 4.2 $R'\mathcal{B} \cong \mathcal{B}/\mathcal{B}'$ is controllable and so admits an image representation M. Now the manifest behavior of $R'w = Mv$ is equal to $\mathcal{B}$, since $R'w = Mv \;\Rightarrow\; R'w \in R'\mathcal{B} \;\Rightarrow\; w \in \mathcal{B} + \mathcal{B}' = \mathcal{B}$, whereas $w \in \mathcal{B}$ implies $R'w \in \operatorname{im} M$. Hence $R'w = Mv$ is a latent variable description of $\mathcal{B}$ and is free by Lemma 5.2. This establishes condition 2. Given that condition, we achieve $\mathcal{B}'$ through the trivial latent interconnection $Iv = 0$. By Lemma 5.6, this is a regular latent (extended) interconnection. This establishes $1 \Rightarrow 2 \Rightarrow 3 \Rightarrow 4 \Rightarrow 5 \Rightarrow 6$. Finally, suppose that $\mathcal{B}'$ is achievable from $\mathcal{B}$ by regular extended interconnection, and let $\mathcal{B}'_{w,v}$ and $\mathcal{B}_{w,v}$ be the corresponding extended behaviors. By Theorem 4.5, $\mathcal{B}_{w,v}$ is set-controllable to $\mathcal{B}'_{w,v}$, and it follows from the definition of set-controllability that $\mathcal{B}_w$ is set-controllable to $\mathcal{B}'_w$, i.e., $\mathcal{B}$ is set-controllable to $\mathcal{B}'$. This completes the proof. ∎

The proof of Theorem 5.7 shows that $\mathcal{B}' = \ker R'$ can be achieved by regular extended or latent interconnection on the free latent variable description $R'w = Mv$ for some M. In fact, the choice of free latent variable descriptions allowing control to $\mathcal{B}'$ is much wider.

LEMMA 5.8. *If $\mathcal{B}$ is set-controllable to $\mathcal{B}'$, then $\mathcal{B}'$ is achievable from $\mathcal{B}$ by regular latent interconnection on any free latent variable description of $\mathcal{B}$ given by an equation of the form*

$$\hat{R}w \;=\; Mv,$$

where $\ker \hat{R} \subseteq \mathcal{B}'$.

Proof. Let $\hat{R}$ be such that $\hat{R}w = Mv$ is a free latent variable description of $\mathcal{B}$, and also $\ker \hat{R} \subseteq \mathcal{B}'$. There must exist an L with $\ker L\hat{R} = \mathcal{B}'$. Now imposition of the controller $LMv = 0$ on the extended behavior is a latent interconnection and regular

by Lemma 5.6. The manifest behavior of the controlled system is then

$$\begin{aligned}\{w \in \mathcal{A}^q \mid \exists\ v \text{ with } \hat{R}w = Mv,\ LMv = 0\} \\ = \{w \in \mathcal{A}^q \mid \exists\ v \text{ with } \hat{R}w = Mv,\ L\hat{R}w = 0\} \\ = \mathcal{B}'.\end{aligned}$$

Hence $\mathcal{B}'$ is achievable by regular latent interconnection on $\hat{R}w = Mv$. □

Example 5.9. 1. Returning to the 1D state-space model in item 3 in Example 5.3, we see that if the matrix B has full row rank, then the full behavior $\mathcal{B}_{x,u,y}$ is set-controllable to $\mathcal{B}_{0,u,y}$, i.e., to the subbehavior of all trajectories for which the state variables remain 0.

An interesting extension of the results in this section would be the consideration of which manifest behaviors can be achieved by restricting only the free latent variables in a (not necessarily free) latent variable description. We expect that this again gives only the subbehaviors to which $\mathcal{B}_w$ is set-controllable.

5.4. On-line control. We have seen that a behavior $\mathcal{B}$ is set-controllable to a given subbehavior $\mathcal{B}'$ if and only if $\mathcal{B}$ has a latent variable description of the form

$$R'w = Mv, \qquad \ker R' = \mathcal{B}', \tag{5.6}$$

in which the latent variables v are free. The question then arises: how can we actually perform the control, i.e., if we are given a trajectory $w \in \mathcal{B}$ in the region $T_1 \subseteq T$, how can we drive w into the desired subbehavior $\mathcal{B}'$ in the region $T_2 \subseteq T$? The obvious answer is by setting the variables v to 0 in T_2.

Unfortunately, the obvious answer is wrong. Setting v to 0 on T_2 enforces only $R'w = 0$ on T_2, which remarkably is not enough to establish that w agrees on T_2 with a trajectory of $\mathcal{B}'$. For example, with $\mathcal{A} = \mathbb{R}^{\mathbb{Z}^n}$, $n = 2$, we might have the behavior $\mathcal{B}' = \ker(z_1 - 1)$ consisting of functions which are constant in the t_1-direction. Take $T_2 = \mathbb{Z}^2 \backslash \{(0,0)\}$, and take w^* to be a trajectory given by

$$w^*(t_1, t_2) = \begin{cases} 1 & \text{if } t_1 \geq 1 \text{ and } t_2 = 0, \\ 0 & \text{elsewhere.} \end{cases}$$

Then $(z_1 - 1)w^*$ clearly vanishes on T_2, although w^* does not agree on T_2 with any trajectory of $\mathcal{B}'$. We can easily manufacture continuous and even 1D examples of this phenomenon.

We can get around this problem by making a change of latent variables. Suppose we are considering a free latent variable description of $\mathcal{B}$ of the form

$$\hat{R}w = Mv, \tag{5.7}$$

where, of course, $\ker \hat{R}$ is contained in the desired subbehavior $\mathcal{B}'$. By condition 2 of Lemma 5.2, the columns of M must be linearly dependent (over the ring $\mathcal{D}$) on the columns of $\hat{R}$. Hence there exists a diagonal nonsingular polynomial matrix D and a polynomial matrix L satisfying $\hat{R}L = MD$. Since D has full row rank, it follows that $\operatorname{im} MD = \operatorname{im} M$, and so

$$\hat{R}w = \hat{R}Lv \tag{5.8}$$

is another free latent variable description of $\mathcal{B}$. For such a latent variable description, a given trajectory w can be steered into the subbehavior $\mathcal{B}'$ by control of the variables

v. Since if we can drive a trajectory into $\ker \hat{R}$, we can certainly drive it into any larger behavior $\mathcal{B}'$, it suffices to prove this in the case $\hat{R} = R'$, $\ker R' = \mathcal{B}'$. In this case, the control action is the setting of the latent variables v to 0 in a suitable region. The next result demonstrates this; for brevity it is stated and proved in the continuous case only.

LEMMA 5.10. *Let $\mathcal{A} = \mathcal{C}^\infty(\mathbb{R}^n, k)$ or $\mathcal{A} = \mathcal{D}'(\mathbb{R}^n, k)$. Suppose that $\mathcal{B}$ has a free latent variable description of the form*

$$R'w \;=\; R'Lv,$$

where L has l columns and $\mathcal{B}' = \ker R'$. Then $\mathcal{B}$ is set-controllable to $\mathcal{B}'$, and, furthermore, any given trajectory of $\mathcal{B}$ can be driven into $\mathcal{B}'$ by control of the variables v.

More formally, let $w \in \mathcal{B}$, and suppose $v \in \mathcal{A}^l$ is such that $R'w = R'Lv$. Then for any open sets $T_1, T_2 \subseteq \mathbb{R}^n$ with disjoint closures, there exists a trajectory $v^* \in \mathcal{A}^l$ which agrees with v on T_1, such that for any $w^* \in \mathcal{B}$ satisfying the conditions

1. *$R'w^* = R'Lv^*$, and*
2. *w^* agrees with w on T_1,*

w^* agrees with a trajectory of $\mathcal{B}'$ on T_2.

Proof. The fact that $\mathcal{B}$ is set-controllable to $\mathcal{B}'$ is immediate from Theorem 5.7. Now let $w \in \mathcal{B}$ and $v \in \mathcal{A}^l$ satisfy $R'w = R'Lv$. Let $v^* \in \mathcal{A}^l$ be any trajectory which agrees with v on T_1 and vanishes on T_2; v^* exists because $\mathcal{A}^l$ is controllable. Now let w^* be a trajectory agreeing with w on T_1 and satisfying $R'w^* = R'Lv^*$; note that $w^* \in \mathcal{B}$. For any $t_2 \in T_2$ we now have

$$w^*(t_2) \;=\; (w^* - Lv^*)(t_2) + (Lv^*)(t_2) \;=\; (w^* - Lv^*)(t_2).$$

Since $w^* - Lv^* \in \ker R' = \mathcal{B}'$, we have that w^* agrees with a trajectory of $\mathcal{B}'$ on T_2. ∎

The interpretation of the various trajectories in the statement of Lemma 5.10 is as follows. The initial system trajectory is w, and v is some corresponding latent variable trajectory. Now w is controlled by setting v appropriately outside the region T_1. (This is formalized by having v^* agree with v on T_1, so that v^* is the latent trajectory "that actually occurs".) The trajectory w^* is required to fit the given "initial data" w on T_1 and is assumed to result from the given controlled latent variable trajectory v^*, so it must also satisfy $R'w^* = R'Lv^*$. The lemma now guarantees that any such w^* will agree with a trajectory of the subbehavior $\mathcal{B}'$ on the region T_2. Therefore, the control action of choosing v^* appropriately is guaranteed to steer w^* into $\mathcal{B}'$ on T_2.

It is worth noting that when adjusting Lemma 5.10 to the discrete case, it is necessary that v^* should agree with v on a suitably large extension of T_1. Note also that in the proof of Lemma 5.10, the resulting trajectory $w' = w^* - Lv^* \in \mathcal{B}'$ depends upon the choice of T_1, unlike in the definition of set-controllability.

6. Conclusions. We have looked at "control" from two points of view: as regular interconnection and as the ability to drive trajectories. We have seen that for 1D systems theory these paradigms are essentially different perspectives on the same phenomenon, whereas in the nD case they differ. Regular interconnection of nD systems appears to be a very strong condition. However, we have shown that the subsystems to which a given system is set-controllable are precisely those which are obtainable by regular interconnection in an extended trajectory space. In order to control nD trajectories by interconnection, it seems necessary to introduce these latent variables.

One important issue to be addressed in the future is that of causality. In the nD framework, this is most naturally defined with respect to a cone [15, 25]; a cohesive theory of 2D causality in the behavioral framework is emerging in the work of Napoli and Zampieri [13, 37]. Combining the causality theory with the theory of regular interconnections will surely be a difficult but important step in the future development of nD control theory.

Acknowledgment. We would like to thank two anonymous reviewers for their very helpful comments and suggestions.

OPTIMAL SEQUENTIAL VECTOR QUANTIZATION OF MARKOV SOURCES*

VIVEK S. BORKAR†, SANJOY K. MITTER‡, AND SEKHAR TATIKONDA§

Abstract. The problem of sequential vector quantization of a stationary Markov source is cast as an equivalent stochastic control problem with partial observations. This problem is analyzed using the techniques of dynamic programming, leading to a characterization of optimal encoding schemes.

Key words. optimal vector quantization, sequential source coding, Markov sources, control under partial observations, dynamic programming

1. Introduction.

In this paper, we consider the problem of optimal sequential vector quantization of stationary Markov sources. In the traditional rate distortion framework, the well-known result of Shannon shows that one can achieve entropy rates arbitrarily close to the rate distortion function for suitably long lossy block codes [9]. Unfortunately, long block codes imply long delays in communication systems. In particular, control applications require causal coding and decoding schemes.

These concerns are not new, and there is a sizable body of literature addressing these issues. We shall briefly mention a few key contributions. Witsenhausen [24] looked at the optimal finite horizon sequential quantization problem for finite state encoders and decoders. His encoder had a fixed number of levels. He showed that the optimal encoder for a kth order Markov source depends on at most the last k symbols and the present state of the decoder's memory. Walrand and Varaiya [23] looked at the infinite horizon sequential quantization problem for sources with finite alphabets. Using Markov decision theory, they were able to show that the optimal encoder for a Markov source depends only on the current input and the current state of the decoder. Gaarder and Slepian [12] look at sequential quantization over classes of finite state encoders and decoders. Though they lay down several useful definitions, their results, by their own admission, are incomplete. Other related works include a neural network based scheme [17] and a study of optimality properties of codes in specific cases [3], [10]. Some abstract theoretical results are given in [19].

A formulation similar in spirit to ours (insofar as it aims to minimize a "Lagrangian distortion measure" described below) is studied in [7], [8]. They show empirically that one can make gains in performance by entropy coding the codewords. In [7] the entropy constrained vector quantization problem for a block is formulated and a Max–Lloyd-type algorithm is introduced. In [8] they introduce the conditional entropy constrained vector quantization problem and show that one should use conditional entropy coders when the codewords are not independent from block to block. In these papers there is more emphasis on synthesizing algorithms and less emphasis on proving rigorously the optimality of the schemes proposed. Along with this work there is a large literature on differential predictive coding, where one encodes the innovation. Other than the Gauss–Markov case, though, it is not apparent how one may prove the optimality of such innovation coding schemes. Herein we emphasize, through the dynamic programming formulation, the optimality properties of the sequential quantization scheme. This leads the way for the application of many powerful approximate dynamic programming tools.

In this paper we do not impose a fixed number of levels on the quantizer. The aim is to somehow jointly optimize the entropy rate of the quantized process (in order to obtain a better compression rate) as well as a suitable distortion measure. The traditional rate distortion framework [9] calls for the minimization of the former with a hard constraint on the latter. We shall, however, consider the analytically more tractable Lagrangian distortion measure of [7], [8], which is a weighted combination of the two. We approach the problem from a stochastic control viewpoint, treating the choice of the sequential quantizer as a control choice. The correct "state space" then turns out to be the space of conditional laws of the underlying process given the quantizer outputs, these conditional laws serving as the "state" or "sufficient statistics." The "state dynamics" is then given by the appropriate nonlinear filter. While this is very reminiscent of the finite state quantizers studied, e.g., in [16], the state space here is not finite, and the state process has the familiar stochastic control interpretation as the output of a nonlinear filter. We then consider the "separated" or "certainty equivalent" control problem of controlling this nonlinear filter so as to minimize an appropriately transformed Lagrangian distortion measure. This problem can be analyzed in the traditional dynamic programming framework. This in turn can be made a basis for computational schemes for near-optimal code design.

To summarize, the main contributions of this paper are as follows.

(i) We formulate a stochastic control problem equivalent to the optimal vector quantization problem. In the process, we make precise the passage from the source output to its encoded version in a manner that ensures the well-posedness of the control problem.

(ii) We underscore the crucial role of the process of conditional laws of the source given the quantized process as the correct "sufficient statistics" for the problem.

(iii) We analyze the equivalent control problem by using the methodology of Markov decision theory. This opens up the possibility of using the computational machinery of Markov decision theory for code design.

Specifically, we consider a pair of a "state process" $\{X_n\}$ and an associated "observation process" $\{Y_n\}$, given by the dynamics

$$X_{n+1} = g(X_n, \xi_n),\ Y_{n+1} = h(X_n, \xi'_n),$$

where $\{\xi_n\}, \{\xi'_n\}$ are independently and identically distributed (i.i.d.) driving noise processes. We quantize Y_{n+1} into its quantized version q_{n+1} that has a finite range and

is selected based on the "history" $q^n \triangleq [q_0, q_1, \ldots, q_n]$. The aim then is to minimize the long run average of the Lagrangian distortion measure $R_n = E[H(q_{n+1}/q^n) + \lambda||Y_n - \bar{q}_n||^2]$, where $\lambda > 0$ is a prescribed constant, $H(\cdot/\cdot)$ is the conditional entropy, and $\bar{q}_n$ is the best estimate of Y_n given q_n.

Let π_n be the regular conditional law of X_n given q^n for $n \geq 0$. From π_n, one can easily derive the regular conditional law of Y_{n+1} given q^n. Using Bayes's rule, $\{\pi_n\}$ can be evaluated recursively by a nonlinear filter. Furthermore, one can express R_n as the expected value of a function of π_n and a "control" process Q_n alone. ($\{Q_n\}$ is, in fact, the finite set depicting the range of the vector quantization of Y_{n+1} prior to its encoding into a fixed finite alphabet.) This allows us to consider the equivalent problem of controlling $\{\pi_n\}$ with the aim of minimizing the long run average of the R_n recast as above. This then fits the framework of traditional Markov decision theory and can be approached by dynamic programming. As usual, one has to derive the dynamic programming equations for the average cost control problem by a "vanishing discount" argument applied to the associated infinite horizon discounted control problem for which the dynamic programming equation is easier to justify.

The structure of the paper is as follows. In section 2, we describe the sequential quantization problem and introduce the formalism. Section 3 derives the equivalent control problem. This is analyzed in section 4 using the formalism of Markov decision theory.

2. Sequential quantization. This section formulates the sequential vector quantization problem. In particular, it describes the passage from the observation process to its quantized version, which in turn gets mapped into its encoding with respect to a fixed alphabet. We also lay down our key assumptions which, apart from making the coding scheme robust, also make its subsequent control formulation well-posed. The section concludes with a precise statement of this "long run average cost" control problem with partial observations that is equivalent to our original vector quantization problem.

Throughout, for a Polish (i.e., complete separable metric) space $X, P(X)$ will denote the Polish space of probability measures on X with Prohorov topology [6, Chapter 2]. For a random process $\{Z_m\}$, set $Z^n = \{Z_m, 0 \leq m \leq n\}$, its past up to time n. Finally, K will denote a finite positive constant, depending on the context.

Let $\{X_n\}$ be an ergodic Markov process taking values in $R^s, s \geq 1$, with an associated "observation process" $\{Y_n\}$ taking values in $R^d, d \geq 1$. ($\{Y_n\}$ thus is the actual process being observed.) Their joint evolution is governed by a transition kernel $x \in R^s \to p(x, dz, dy) \in P(R^s \times R^d)$, as described below. We assume this map to be continuous and further, that $p(x, dz, dy) = \varphi(y, z|x)dzdy$ for a density $\varphi(\cdot, \cdot|\cdot) : R^d \times R^s \times R^s \to R^+$ that is continuous and strictly positive, and furthermore, $\varphi(y, z|\cdot)$ is Lipschitz uniformly in y, z.

The evolution law is as follows. For $A \subset R^s, B \subset R^d$ Borel,

$$P(X_{n+1} \in A, Y_{n+1} \in B/X^n, Y^n) = \int_{A \times B} p(X_n, dx, dy)$$
$$= \int_A \int_B \varphi(y, z|X_n)dydz.$$

Following [13], we call the pair $(\{X_n\}, \{Y_n\})$ a Markov source, though the terminology "hidden Markov model" is more common nowadays. We impose on $(\{X_n\}, \{Y_n\})$ the condition of "asymptotic flatness" described next. We assume that these processes

are given recursively by the dynamics

$$X_{n+1} = g(X_n, \xi_n), \tag{2.1}$$

$$Y_{n+1} = h(X_n, \xi'_n), \tag{2.2}$$

where $\{\xi_n\}, \{\xi'_n\}$ are i.i.d. R^m-valued (say) random variables independent of each other and of X_0, and $g : R^s \times R^m \to R^s$, $h : R^s \times R^m \to R^d$ are prescribed measurable maps satisfying

$$||g(x,y)||, ||h(x,y)|| \leq K(1 + ||x||) \ \ \forall\ y.$$

Equations (2.1) and (2.2) and the laws of $\{\xi_n\}, \{\xi'_n\}$ completely specify $p(x, dz, dy)$, and therefore the conditions we impose on the latter will implicitly restrict the choice of the former.

Let $(\{X_n(x)\}, \{Y_n(x)\}), (\{X_n(y)\}, \{Y_n(y)\})$ denote the solutions to (2.1), (2.2) for $X_0 = x$, respectively, y with the *same* driving noises $\{\xi_n\}, \{\xi'_n\}$. The assumption of asymptotic flatness then is that there exist $K > 0, 0 < \beta < 1$, such that

$$E[||X_n(x) - X_n(y)||] \leq K\beta^n ||x - y||, n \geq 0.$$

A simple example would be the case when $g(x,u) = \bar{g}(x) + u, h(x,u) = \bar{h}(x) + u$ for all x, u, where $\bar{g} : R^s \to R^s$ is a contraction with respect to some equivalent norm on R^s. This covers, e.g., the usual linear quadratic Gaussian (LQG) case when the state process is stable. Another example would be a discretization of continuous time asymptotically flat processes considered in [1], where a Lyapunov-type sufficient condition for asymptotic flatness is given. This assumption, one must add, is not required for our formulation of the optimization problem per se but will play a key role in our derivation of the dynamic programming equations in section 4.

Let $\sum = \{\alpha_1, \alpha_2, \ldots, \alpha_N\}$ be an ordered set that will serve as the alphabet for our vector quantizer. Let $\{q_n\}$ denote the $\sum$-valued process that stands for the "vector quantized" version of $\{Y_n\}$. The passage from $\{Y_n\}$ to $\{q_n\}$ is described below.

Let D denote the set of finite nonempty subsets of R^d with cardinality at most $N \geq 1$, satisfying the following.

(†) There exist $M > 0$ ("large") and $\triangle > 0$ ("small") such that

(i) $x \in A \in D$ implies $||x|| \leq M$,

(ii) $x = [x_1, \ldots, x_d], y = [y_1, \ldots, y_d]$ for $x, y \in A \in D$, $x \neq y$, implies $|x_i - y_i| > \triangle$ for all i.

We endow D with the Hausdorff metric which renders it a compact Polish space. For $A \in D$, let $l_A : R^d \to A$ denote the map that maps $x \in R^d$ to the element of A nearest to it with reference to the Euclidean norm $||\cdot||$, any tie being resolved according to some fixed priority rule. Let $i_A : A \to \sum$ denote the map that first orders the elements $\{a_1, \ldots, a_m\}$ of A lexicographically and then maps them to $\{\alpha_1, \ldots, \alpha_m\}$ preserving the order.

Let $\sum^\infty = \sum \times \sum \times \cdots$ (i.e., a one-sided countably infinite product. Analogous notation will be used elsewhere.) At each time n, a measurable map $\eta_n : \sum^{n+1} \to D$ is chosen. With $Q_n \stackrel{\Delta}{=} \eta_n(q^n)$, one sets

$$q_{n+1} = i_{Q_n}(l_{Q_n}(Y_{n+1})).$$

This defines $\{q_n\}$ recursively as the quantized process that is to be encoded and transmitted across a communication channel.

The explanation of this scheme is as follows. In case of a fixed quantizer, the finite subset of R^d to which the signal gets mapped can itself be identified with the alphabet $\sum$. In our case, however, this set will vary from one instant to another and therefore must be mapped to a fixed alphabet $\sum$ in a uniquely invertible manner. This is achieved through the map i_A. Assuming that the receiver knows ahead of time the deterministic maps $\{n_n(\cdot)\}$ (later on we argue that a single fixed $\eta(\cdot)$ will suffice), she can reconstruct Q_n as $\eta_n(q^n)$ on having received q^n by time n. In turn, she can reconstruct $i_{Q_n}^{-1}(q_{n+1}) = l_{Q_n}(Y_{n+1})$ as the vector quantized version of Y_{n+1}. The main contribution of the condition (†) is to render the map $A = \{a_1, \ldots, a_m\} \in D \to \{i_A(a_1), \ldots, i_A(a_m)\} \in \sum^*$ continuous. Not only does this make sense from the point of view of robust decoding, but it also makes the control problem we formulate later well-posed.

As mentioned in the introduction, our aim will be to jointly optimize over the choice of $\{\eta_n(\cdot)\}$ the average entropy rate of $\{q_n\}$ ($\approx$ the average code length if the encoding is done optimally) and the average distortion. The conventional rate distortion theoretic formulation would be to minimize the average entropy rate

$$\limsup_{n\to\infty} \frac{1}{n} \sum_{m=0}^{n-1} E[H(q_{m+1}/q^m)],$$

$H(\cdot)$ being the (conditional) Shannon entropy, subject to a hard constraint on the distortion

$$\limsup_{n\to\infty} \frac{1}{n} \sum_{m=0}^{n-1} E[||Y_m - \bar{q}_m||^2] \le K,$$

where $\bar{q}_m = i_{Q_{m-1}}^{-1}(q_m) = l_{Q_{m-1}}(Y_m)$. We shall, however, consider the simpler problem of minimizing the Lagrangian distortion measure

$$\limsup_{n\to\infty} \frac{1}{n} \sum_{m=0}^{n-1} E[H(q_{m+1}/q^m) + \lambda||Y_m - \bar{q}_m||^2], \tag{2.3}$$

where $\lambda > 0$ is a prescribed constant. One may think of λ as a Lagrange multiplier, though, strictly speaking, such an interpretation is lacking given our arbitrary choice thereof.

3. Reduction to the control problem. This section derives the "completely observed" optimal stochastic control problem equivalent to the optimal vector quantization problem described above. In this, we follow the usual "separation" idea of stochastic control by identifying the regular conditional law of state given past observations (in our case, past encodings of the actual observations) as the new state process for the completely observed control problem. The original cost function is rewritten in an equivalent form that displays it as a function of the new state and control processes alone. Under the assumptions of the previous section on the permissible vector quantization schemes (as reflected in our definition of D), the above controlled Markov process is shown to have a transition kernel continuous in the initial state and control. Finally, a relaxation of this control problem is outlined, which allows for a larger class of controls. This is purely a technical convenience required for the proofs of the next section and does not affect our control problem in any essential manner.

Let $\pi_n(dx) \in P(R^s)$ denote the conditional law of X_n given $q^n, n \geq 0$. A standard application of the Bayes rule shows that $\{\pi_n\}$ is given recursively by the nonlinear filter

$$\pi_{n+1}(dx') = \frac{\int\int I\{i_{Q_n}(l_{Q_n}(y)) = q_{n+1}\}\varphi(y, x'|x)dydx'\pi_n(dx)}{\int\int\int I\{i_{Q_n}(l_{Q_n}(y)) = q_{n+1}\}\varphi(y, z|x)dydz\pi_n(dx)}. \tag{3.1}$$

By (†), $l_A^{-1}(i_A^{-1}(a))$ contains an open subset of R^d for any a, A. Given this fact and the condition that $\varphi(\cdot, \cdot|\cdot) > 0$, it follows that the denominator above is strictly positive, and hence the ratio is well defined. The initial condition for the recursion (3.1) is $\pi_0 =$ the conditional law of X_0 given q_0. We assume q_0 to be the trivial quantizer, i.e., $q_0 \equiv 0$, say, so that $\pi_0 =$ the law of X_0. Thus defined, $\{\pi_n\}$ can be viewed as a $P(R^s)$-valued controlled Markov process with a D-valued "control" process $\{Q_n\}$. To complete the description of the control problem, we need to define our cost (2.3) in terms of $\{\pi_n\}, \{Q_n\}$. For this purpose, let $\bar{\varphi}(y|x) \stackrel{\Delta}{=} \int \varphi(y, z|x)dz$ for all $(x, y) \in R^s \times R^d$. Note that for $a \in \sum$,

$$\begin{aligned} P(q_{n+1} = a/q^n) &= E[E[I\{q_{n+1} = a\}/q^n, X^n]/q^n] \\ &= E\left[\int p(X_n, R^s, dy)I\{q_{n+1} = a\}/q^n\right] \\ &= \int \pi_n(dx) \int \bar{\varphi}(y|x)I\{i_{\eta_n(q^n)}(l_{\eta_n(q^n)}(y)) = a\}dy \\ &\stackrel{\Delta}{=} h_a(\pi_n, Q_n), \end{aligned}$$

where $h_a : P(R^s) \times D \to R$ is defined by

$$h_a(\pi, A) = \int \pi(dx)f_a(x, A)$$

with

$$f_a(x, A) = \int \bar{\varphi}(y|x)I\{i_A(l_A(y)) = a\}dy.$$

Also define

$$\begin{aligned} \hat{f}(x, A) &= \int \bar{\varphi}(y|x)||y - l_A(y)||^2 dy, \\ k(\pi, A) &= -\sum_a h_a(\pi, A) \log h_a(\pi, A), \\ r(\pi, A) &= \int \pi(dx)\hat{f}(x, A), \end{aligned}$$

where the logarithm is to the base 2. We assume $f_a(\cdot, A), \hat{f}(\cdot, A)$ to be Lipschitz uniformly in a, A. This would be implied in particular by the condition that $\bar{\varphi}(y/\cdot)$ be Lipschitz uniformly in y. Now (2.3) can be rewritten as

$$\limsup_{n\to\infty} \frac{1}{n} \sum_{m=0}^{n-1} E[k(\pi_m, Q_m) + \lambda r(\pi_m, Q_m)]. \tag{3.2}$$

Strictly speaking, we should consider the problem of controlling $\{\pi_n\}$ given by (3.1) so as to minimize the cost (3.2). We shall, however, introduce some further

simplifications, thereby replacing (3.2) by an approximation of the same. Let $\frac{1}{N} > \epsilon^\star > 0$ be a small positive constant. For $n \geq 1$, let $P_n^\star$ denote the simplex of probability vectors in R^n which have each component bounded from below by $\epsilon^\star$. That is,

$$P_n^\star = \left\{ x = [x_1, \ldots, x_n] \in R^n : x_i \in [\epsilon^\star, 1] \ \ \forall\ i, \quad \sum_i x_i = 1 \right\}.$$

Similarly, let

$$P_n = \left\{ x = [x_1, \ldots, x_n] \in R^n : x_i \in [0, 1] \ \ \forall\ i, \quad \sum_i x_i = 1 \right\}$$

denote the entire simplex of probability vectors in R^n. Let $\Pi_n : P_n \to P_n^\star$ denote the projection map. Let $h(\pi, A) = [h_{a_1}(\pi, A), \ldots, h_{a_m}(\pi, A)]$ for $A = \{a_1, \ldots, a_m\}$ and

$$\begin{aligned} \tilde{h}(\pi, A) &= \Pi_{|A|}(h(\pi, A)) \\ &\triangleq [\tilde{h}_{a_1}(\pi, A), \ldots, \tilde{h}_{a_m}(\pi, A)]. \end{aligned}$$

Note that

$$|\log \tilde{h}_a(\pi, A)| \leq -\log \epsilon^\star < \infty \quad \forall\ a, \pi, A. \tag{3.3}$$

Finally, let

$$\tilde{k}(\pi, A) = -\sum_a \tilde{h}_a(\pi, A) \log \tilde{h}_a(\pi, A).$$

The control problem we consider is that of controlling $\{\pi_n\}$ so as to minimize the cost

$$\limsup_{n \to \infty} \frac{1}{n} \sum_{m=0}^{n-1} E[\tilde{k}(\pi_n, Q_n) + \lambda r(\pi_n, Q_n)]. \tag{3.4}$$

Replacing $k(\cdot, \cdot)$ by $\tilde{k}(\cdot, \cdot)$ is a purely technical convenience to suit the needs of the developments to come in section 4. We believe that it should be possible to obtain the same results directly for (3.2), though possibly at the expense of a considerable additional technical overhead.

We shall analyze this problem using techniques of Markov decision processes. With this in mind, call $\{Q_n\}$ a stationary control policy if $Q_n = v(\pi_n)$ for all n for a measurable $v : P(R^s) \to D$. The map $v(\cdot)$ itself may be referred to as the stationary control policy by a standard abuse of notation. Let $(\pi, A) \in P(R^s) \times D \to \phi(\pi, A, d\pi') = P(P(R^s))$ denote the transition kernel of the controlled Markov process $\{\pi_n\}$.

LEMMA 3.1. *The map $\phi(\cdot, \cdot, d\pi')$ is continuous.*

Proof. It suffices to check that for $f \in C_b(P(R^s))$, the map $\int f(y)\phi(\cdot, \cdot, dy)$ is continuous. Let $(\mu_n, A_n) \to (\mu_\infty, A_\infty)$ in $P(R^s) \times D$. Then $\{\mu_n\}$ are tight, and therefore, for any $\epsilon > 0$, we can find a compact $S_\epsilon \subset R^s$ such that $\mu_n(S_\epsilon) > 1 - \epsilon$ for $n = 1, 2, \ldots, \infty$. Fix $\epsilon > 0$ and $S_\epsilon \subset R^s$. By the Stone–Weierstrass theorem, any $f \in C_b(P(R^s))$ can be approximated uniformly on S_ϵ by $\bar{f} \in C_b(P(R^s))$ of the form

$$\bar{f}(\mu) = F\left(\int f_1 d\mu, \ldots, \int f_l d\mu \right)$$

for some $l \geq 1, f_1, \ldots, f_l \in C_b(R^s)$ and $F \in C_b(R^l)$. Then

$$\left| \int f(y)\phi(\mu_n, A_n, dy) - \int f(y)\phi(\mu_\infty, A_\infty, dy) \right| \leq 4\epsilon K + \sup_{\mu \in S_\epsilon} |f(\mu) - \bar{f}(\mu)| + \left| \int \bar{f}(y)\phi(\mu_n, A_n, dy) - \int \bar{f}(y)\phi(\mu_\infty, A_\infty, dy) \right|. \tag{3.5}$$

Let

$$\nu_{ai}(\pi, A) = \int\int f_i(y) I\{i_A(l_A(y)) = a\} \bar{\varphi}(y|x) dy \pi(dx)$$

for $a \in \sum, 1 \leq i \leq l$. Direct verification leads to

$$\int \bar{f}(y)\phi(\pi, A, dy) = \sum_a h_a(\pi, A) F\left(\frac{\nu_{a1}(\pi, A)}{h_a(\pi, A)}, \ldots, \frac{\nu_{al}(\pi, A)}{h_a(\pi, A)} \right). \tag{3.6}$$

Note that for all a,

$$I\{i_{A_n}(l_{A_n}(y)) = a\} \to I\{i_{A_\infty}(l_{A_\infty}(y)) = 0\} \text{ almost everywhere (a.e.),}$$

because this convergence fails only on the boundaries of the regions $l^{-1}_{A_\infty}(b)$, $b \in A_\infty$, which have zero Lebesgue measure. (These are the so called *Voronoi* regions in vector quantization literature, viz., sets in the partition generated by the quantizer $l_{A_\infty}(\cdot)$.) Therefore, for all a, j,

$$f_j(y) I\{i_{A_n}(l_{A_n}(y)) = a\} \to f_j(y) I\{i_{A_\infty}(l_{A_\infty}(y)) = a\} \text{ a.e.}$$

If $x_n \to x_\infty$ in R^s, $\bar{\varphi}(y|x_n) \to \bar{\varphi}(y|x_\infty)$ for all y. Then by Scheffe's theorem [6, p. 26],

$$\bar{\varphi}(y|x_n)dy \to \bar{\varphi}(y|x_\infty)dy$$

in total variation. Hence for any a, j,

$$\int f_j(y) I\{i_{A_n}(l_{A_n}(y)) = a\} \bar{\varphi}(y|x_n) dy \to \int f_j(y) I\{i_{A_\infty}(l_{A_\infty}(y)) = a\} \bar{\varphi}(y|x_\infty) dy.$$

That is, the map

$$(x, A) \to \int f_j(y) I\{i_A(l_A(y)) = a\} \bar{\varphi}(y|x) dy$$

is continuous. It is clearly bounded. The continuity of $\nu_{ia}(\cdot, \cdot)$ follows. That of $h_a(\cdot, \cdot)$ follows similarly. The continuity of the sum in (3.6) then follows by one more application of Scheffe's theorem. Thus the last term on the right-hand side (RHS) of (3.5) tends to zero as $n \to \infty$. Since $\epsilon > 0$ was arbitrary and the second term on the RHS of (3.5) can be made arbitrarily small by a suitable choice of $\bar{f}$, the claim follows. □

We conclude this section with a description of a certain relaxation of this control problem wherein we permit a larger class of control policies, the so-called wide sense admissible controls used in [11]. Let $(\Omega, \mathcal{F}, P)$ denote the underlying probability space, where, without loss of generality, we may suppose that $\mathcal{F} = V_n \mathcal{F}_n$ for $\mathcal{F}_n = \sigma(X_i, Y_i, \xi_i, \xi_i', Q_i, i \leq n)$, $n \geq 0$. Define a new probability measure P_0 on $(\Omega, \mathcal{F})$ as

follows. Let $\psi_n : \sum^{n+1} \times R^m \to P(\sum)$ denote the regular conditional law of q_{n+1} given (q^n, Y_{n+1}) for $n \geq 0$. (Thus we are now allowing for a randomized choice of Q_n, i.e., Q_n is not necessarily a deterministic function of (q^n, Y_{n+1}).) Let $\Gamma \in P(\sum)$ be any fixed probability measure with full support. If, for $n \geq 0, P_n, P_{0n}$, we denote the restrictions of P, P_0 to $(\Omega, \mathcal{F}_n)$, respectively, then $P_n << P_{0n}$ with

$$\frac{dP_n}{dP_{0n}} = \prod_{m=0}^{n-1} \frac{\psi_n(q^m, Y_{m+1})(\{q_{m+1}\})}{\Gamma(\{q_{m+1}\})}, \quad n \geq 1.$$

Then, under $P_0, \{q_n\}$ are independent of $\{X_n, Y_n, \xi_n, \xi_n'\}$ and are i.i.d. with law Γ. We say that $\{Q_n\}$ is a wide sense admissible control if under $P_0, (q_{n+1}, q_{n+2}, \ldots)$ is independent of (q^n, Q^n) for $n \geq 0$. Note that this includes $\{Q_n\}$ of the type $Q_n = \eta_n(q^n)$ for suitable maps $\{\eta_n(\cdot)\}$.

It should be kept in mind that this allows explicit randomization in the choice of $\{Q_n\}$, whence the entropy rate expression in (3.2) or (3.4) is no longer valid. Nevertheless, we continue with wide sense admissible controls in the context of (3.1)–(3.4) because, for us, this is strictly a temporary technical device to facilitate proofs. The dynamic programming formulation that we shall finally arrive at in section 4 will permit us to return without any loss of generality to the apparently more restrictive class of $\{Q_n\}$ we started out with.

4. The vanishing discount limit. This section derives the dynamic programming equations for the equivalent "separated control problem" by extending the traditional "vanishing discount" argument to the present setup. Deriving the dynamic programming equations for the long run average cost control of the separated control problem has been an outstanding open problem in the general case. We solve it here by using in a crucial manner the asymptotic flatness assumption introduced earlier. It should be noted that this assumption was not required at all in the development thus far and is included purely for facilitating the vanishing discount limit argument that follows. In particular, it could be dispensed with altogether were we to consider the finite horizon or infinite horizon discounted cost. For an alternative set of conditions (also strong) under which the dynamic programming equations for the average cost control under partial observations have been derived, see [21].

Our first step will be to modify the construction at the end of section 3 so as to construct on a common probability space two controlled nonlinear filters with a common control process but differing in their initial condition. This allows us to compare discounted cost value functions for two different initial laws. In turn, this allows us to show that their difference, with one of the two initial laws fixed arbitrarily, remains bounded and equicontinuous with respect to a certain complete metric on the space of probability measures, as the discount factor approaches unity. (This is where one uses the condition of asymptotic flatness.) The rest of the derivation mimics the classical arguments in this field.

For $\alpha \in (0, 1)$, consider the discounted control problem of minimizing

$$J_\alpha(\pi_0, \{Q_n\}) = E\left[\sum_{n=0}^{\infty} \alpha^n (\tilde{k}(\pi_n, Q_n) + \lambda r(\pi_n, Q_n))\right] \tag{4.1}$$

over $\Phi \triangleq$ the set of all wide sense admissible controls, with the prescribed π_0. Define the associated value function $V_\alpha : P(R^s) \to R$ by

$$V_\alpha(\pi_0) = \inf_{\Phi} J(\pi_0, \{Q_n\}).$$

Standard dynamic programming arguments show that $V_\alpha(\cdot)$ satisfies

$$V_\alpha(\pi) = \min_A \left[k(\pi, A) + \lambda r(\pi, A) + \beta \int \phi(\pi, A, d\pi') V_\alpha(\pi') \right] \tag{4.2}$$

for $\pi \in P(R^s)$. We shall arrive at the dynamic programming equation for our original problem by taking a "vanishing discount" limit of a variant of (4.2). For this purpose, we need to compare $V_\alpha(\cdot)$ for two distinct values of its argument. In order to do so, we first set up a framework for comparing (4.1) for two choices of π_0 but with a "common" wide sense admissible control $\{Q_n\}$. This will be done by modifying the construction at the end of the preceding section. Let $(\Omega, \mathcal{F}, P_0)$ be a probability space on which we have (i) R^s-valued, possibly dependent random variables $\hat{X}_0, \tilde{X}_0$, with laws π_0, π_0', respectively; (ii) R^m-valued i.i.d. random processes $\{\xi_m\}, \{\xi_m'\}$, independent of each other and of $[\hat{X}_0, \tilde{X}_0]$ with laws as in (2.1), (2.2); and (iii) $\sum$-valued i.i.d. random sequences $\{\hat{q}_m\}, \{\tilde{q}_m\}$ with law Γ. Also defined on $(\Omega, \mathcal{F}, P_0)$ is a D-valued process $\{Q_n\}$ independent of $([\hat{X}_0, \tilde{X}_0], \{\xi_n\}, \{\xi_n'\}, \{\tilde{q}_n\})$ and satisfying the following. For $n \geq 0$, $(\hat{q}_{n+1}, \hat{q}_{n+2}, \ldots)$ is independent of $Q^n, \hat{q}^n$. Let $(\hat{X}_n, \hat{Y}_n), (\tilde{X}_n, \tilde{Y}_n)$ be solutions to (2.1), (2.2) with $\hat{X}_0, \tilde{X}_0$ as above. Without loss of generality, we may suppose that $\mathcal{F} = V_n \mathcal{F}_n$ with $\mathcal{F}_n = \sigma(\hat{X}^n, \tilde{X}^n, \hat{Y}^n, \tilde{Y}^n, \hat{q}^n, \tilde{q}^n, Q^n), n \geq 0$. Define a new probability measure P on $(\Omega, \mathcal{F})$ as follows. If P_n, P_{0n} denote the restrictions of P, P_0, respectively, to $(\Omega, \mathcal{F}_n), n \geq 0$, then $P_n << P_{0n}$ with

$$\frac{dP_n}{dP_{0n}} = \prod_{m=0}^{n-1} \frac{\psi_n(\hat{q}^n, \hat{Y}_{n+1})(\{\hat{q}_{n+1}, \}) \psi_n'(\tilde{q}^n, \tilde{Y}_{n+1})(\{\tilde{q}_{n+1}\})}{\Gamma(\{\hat{q}_{n+1}\}) \Gamma(\{\tilde{q}_{n+1}\})},$$

where the ψ_n (respectively, ψ_n') are the regular conditional laws of $Q_n(\hat{Y}_{n+1})$ given $(\hat{q}^n, \hat{Y}_{n+1})$ (respectively, of $Q_n(\tilde{Y}_{n+1})$ given $(\tilde{q}^n, \tilde{Y}_{n+1})$) for $n \geq 0$.

What this construction achieves is the identification of each wide sense admissible control $\{Q_n\}$ for initial law $\hat{\pi}_0$ with one wide sense admissible control for $\tilde{\pi}_0$. (This identification can be many-one.) By a symmetric argument that interchanges the roles of $\hat{\pi}_0$ and $\tilde{\pi}_0$, we can identify each wide sense admissible control for $\tilde{\pi}_0$ with one for $\hat{\pi}_0$. Now suppose that $V_\alpha(\hat{\pi}_0) \leq V_\alpha(\tilde{\pi}_0)$. Then for a wide sense admissible control $\{Q_n\}$ that is optimal for $\hat{\pi}_0$ (existence of this follows by standard dynamic programming arguments), we have

$$\begin{aligned} |V_\alpha(\hat{\pi}_0) - V_\alpha(\tilde{\pi}_0)| &= V_\alpha(\tilde{\pi}_0) - V_\alpha(\hat{\pi}_0) \\ &\leq J_\alpha(\tilde{\pi}_0, \{Q_n\}) - J_\alpha(\hat{\pi}_0, \{Q_n\}) \\ &\leq \sup_\Phi |J_\alpha(\tilde{\pi}_0, \{Q_n\}) - J_\alpha(\hat{\pi}_0, \{Q_n\})|, \end{aligned}$$

where we use the above identification. If $V_\alpha(\hat{\pi}_0) \geq V_\alpha(\tilde{\pi}_0)$, a symmetric argument applies. Thus we have proved the following lemma.

LEMMA 4.1.

$$|V_\alpha(\hat{\pi}_0) - V_\alpha(\tilde{\pi}_0)| \leq \sup_\Phi |J_\alpha(\hat{\pi}_0, \{Q_n\}) - J_\alpha(\tilde{\pi}_0, \{Q_n\})|.$$

Next, let $P_1(R^s) = \{\mu \in P(R^s) : \int ||x|| \mu(dx) < \infty\}$, topologized by the (complete) Vasserstein metric [20]

$$\rho(\mu_1, \mu_2) = \inf E[||X - Y||],$$

where the infimum is over all joint laws of (X, Y) such that the law of X (respectively, Y) is μ_1 (respectively, μ_2). We shall assume from now on that $\pi_0 \in P_1(R^s)$. Given the linear growth condition on $g(\cdot, y), h(\cdot, y)$ of (2.1), (2.2), uniformly in y, it is then easily deduced that $E[||X_n||] < \infty$ for all n and therefore $\pi_n \in P_1(R^s)$ almost surely (a.s.) for all n. Thus we may and do view $\{\pi_n\}$ as a $P_1(R^s)$-valued process. We then have the following lemma.

LEMMA 4.2. *For $\hat{\pi}_0, \tilde{\pi}_0 \in P_1(R^s)$ and $\alpha > 0, |V_\alpha(\hat{\pi}_0) - V_\alpha(\tilde{\pi}_0)| \le K\rho(\hat{\pi}_0, \tilde{\pi}_0)$.*

Proof. Let $\{\hat{\pi}_n\}, \{\tilde{\pi}_n\}$ be solutions to (3.1) with initial conditions $\hat{\pi}_0, \tilde{\pi}_0$, respectively, and a "common" wide sense admissible control $\{Q_n\} \in \Phi$. Then for $\{\hat{X}_n\}, \{\tilde{X}_n\}$ as above (with K denoting a generic positive constant that may change from step to step)

$$\begin{aligned}
&|E[r(\hat{\pi}_n, Q_n)] - E[r(\tilde{\pi}_n, Q_n]| \\
&\quad = |E[\hat{f}(\hat{X}_n, Q_n)] - E[\hat{f}(\tilde{X}_n, Q_n)]| \\
&\quad \le E[|\hat{f}(\hat{X}_n, Q_n) - \hat{f}(\tilde{X}_n, Q_n)|] \\
&\quad \le KE[||\hat{X}_n - \tilde{X}_n||]
\end{aligned}$$

(by the Lipschitz condition on $\hat{f}$)

$$\le K\beta^n E[||\hat{X}_0 - \tilde{X}_0||]$$

(by asymptotic flatness).

Now consider

$$|E[\tilde{k}(\hat{\pi}_n, Q_n)] - E[\tilde{k}(\tilde{\pi}_n, Q_n]|.$$

Suppose that $E[\tilde{k}(\hat{\pi}_n, Q_n)] \ge E[\tilde{k}(\tilde{\pi}_n, Q_n)]$. Then

$$\begin{aligned}
&|E[\tilde{k}(\hat{\pi}_n, Q_n)] - E[\tilde{k}(\tilde{\pi}_n, Q_n)]| \\
&\quad = E[\tilde{k}(\hat{\pi}_n, Q_n)] - E[\tilde{k}(\tilde{\pi}_n, Q_n)] \\
&\quad = E\left[\sum_a \tilde{h}_a(\tilde{\pi}_n, Q_n) \log \tilde{h}_a(\tilde{\pi}_n, Q_n)\right] - E\left[\sum_a \tilde{h}_a(\hat{\pi}_n, Q_n) \log \tilde{h}_a(\hat{\pi}_n, Q_n)\right] \\
&\quad = E\left[\sum_a \left(\tilde{h}_a(\tilde{\pi}_n, Q_n) \log \tilde{h}_a(\tilde{\pi}_n, Q_n) - \tilde{h}_a(\hat{\pi}_n, Q_n) \log \tilde{h}_a(\tilde{\pi}_n, Q_n)\right.\right. \\
&\qquad \left.\left. + \tilde{h}_a(\hat{\pi}_n, Q_n) \log \frac{\tilde{h}_a(\tilde{\pi}_n, Q_n)}{\tilde{h}_a(\hat{\pi}_n, Q_n)}\right)\right] \\
&\quad \le E\left[\sum_a (\tilde{h}_a(\tilde{\pi}_n, Q_n) - \tilde{h}_a(\hat{\pi}_n, Q_n)) \log \tilde{h}_a(\tilde{\pi}_n, Q_n))\right]
\end{aligned}$$

(by Jensen's inequality)

$$\begin{aligned}
&\le E\left[\sum_a (f_a(\tilde{X}_n, Q_n) - f_a(\hat{X}_n, Q_n)) \log \tilde{h}_a(\tilde{\pi}_n, Q_n))\right] \\
&\le KE[||\tilde{X}_n - \hat{X}_n||] \\
&\le K\beta^n E[||\tilde{X}_0 - \hat{X}_0||],
\end{aligned}$$

where we use (3.3) to arrive at the second to last inequality. A symmetric argument works if $E[\tilde{k}(\hat{\pi}_n, Q_n)] \le E[\tilde{k}(\tilde{\pi}_n, Q_n)]$, leading to the same conclusion. Combining

everything, we have

$$|E[\tilde{k}(\tilde{\pi}_n, Q_n) + \lambda r(\tilde{\pi}_n, Q_n)] - E[\tilde{k}(\hat{\pi}_n, Q_n) + \lambda r(\hat{\pi}_n, Q_n)]| \leq K\beta^n E[||\hat{X}_0 - \tilde{X}_0||].$$

Therefore, by Lemma 4.1,

$$|V_\alpha(\hat{\pi}_0) - V_\alpha(\tilde{\pi}_0)| \leq K \sum_n \beta^n \alpha^n E[||\hat{X}_0 - \tilde{X}_0||] \leq \frac{K}{1-\beta} E[||\hat{X}_0 - \tilde{X}_0||].$$

For any $\epsilon > 0$, we can render

$$E[||\hat{X}_0 - \tilde{X}_0||] \leq \rho(\hat{\pi}_0, \tilde{\pi}_0) + \epsilon$$

by suitably choosing the joint law of $(\hat{X}_0, \tilde{X}_0)$. Since $\epsilon > 0$ is arbitrary, the claim follows. □

Fix $\pi^\star \in P(R^s)$ and define $\bar{V}_\alpha(\pi) = V_\alpha(\pi) - V_\alpha(\pi^\star)$ for $\pi \in P(R^s), \alpha \in (0,1)$. By the above lemma, $\bar{V}_\alpha(\cdot)$ is bounded equicontinuous. Letting $\alpha \to 1$, we use the Arzela–Ascoli theorem to conclude that $\bar{V}_\alpha(\cdot)$ converges in $C(P_1(R^s))$ to some $V(\cdot)$ along a subsequence $\{\alpha(n)\}, \alpha(n) \to 1$. By dropping to a further subsequence if necessary, we may also suppose that $\{(1-\alpha(n))V_{\alpha(n)}(\pi^*)\}$, which is clearly bounded, converges to some $\gamma \in R$ as $n \to \infty$. These $V(\cdot), \gamma$ will turn out to be, respectively, the value function and optimal cost for our original control problem.

Our main result is the following theorem.

THEOREM 4.3.

(i) *$(V(\cdot), \gamma)$ solve the dynamic programming equation*

$$V(\pi) = \min_u \left(\tilde{k}(\pi, u) + \lambda r(\pi, u) + \int \phi(\pi, u, d\pi') V(\pi') - \gamma \right). \tag{4.3}$$

(ii) *γ is the optimal cost, independent of the initial condition. Furthermore, a stationary policy $v(\cdot)$ is optimal for any initial condition if*

$$v(\pi) \in \text{Argmin} \left(\tilde{k}(\pi, \cdot) + \lambda r(\pi, \cdot) + \int \phi(\pi, \cdot, d\pi') V(\pi') \right) \quad \forall\ \pi.$$

In particular, an optimal stationary policy exists.

(iii) *If $v(\cdot)$ is an optimal stationary policy and μ is a corresponding ergodic probability measure for $\{\pi_n\}$, then*

$$V(\pi) = \tilde{k}(\pi, v(\pi)) + \lambda r(\pi, v(\pi)) + \int \phi(\pi, v(\pi), d\pi') V(\pi') - \gamma, \ \mu\text{-a.s.}$$

Proof. For (i) rewrite (4.2) as

$$\bar{V}_\alpha(\pi) = \min_u \left(\tilde{k}(\pi, u) + \lambda r(\pi, u) + \alpha \int \phi(\pi, u, d\pi') \bar{V}_\alpha(\pi') - (1-\alpha) V_\alpha(\pi^\star) \right).$$

Let $\alpha \to 1$ along $\{\alpha(n)\}$ to obtain (4.3).

For (ii) note that the first two statements follow by a standard argument which may be found, e.g., in [15, Theorem 5.2.4, pp. 80–81]. The last claim follows from a standard measurable selection theorem—see, e.g., [22].

For (iii) note that the claim holds if "=" is replaced by "≤". If the claim is false, we can integrate both sides with respect to μ to obtain

$$\gamma < \int (\tilde{k}(\pi, v(\pi)) + \lambda r(\pi, v(\pi)))\mu(d\pi).$$

The RHS is the cost under $v(\cdot)$, whereby this inequality contradicts the optimality of $v(\cdot)$. The claim follows. □

This result opens up the possibility of exploiting the computational machinery of Markov decision theory (see, e.g., [2], [18], [21]) for code design.

Finally, we briefly consider the decoder's problem. If transmission is error free, the decoder can construct $\{\pi_n\}$ recursively given $\{q_n\}$ and the stationary policy $v(\cdot)$. Then $\{X_n\}, \{Y_n\}$ may be estimated by the maximum a posteriori (MAP) estimates:

$$\hat{X}_n = \text{argmax } \pi_n(\cdot),$$
$$\hat{Y}_n = \text{argmax} \left(\iint I\{i_{Q_{n-1}}(l_{Q_{n-1}}(\cdot)) = q_{n+1}\}\varphi(\cdot, z|x)dz \ \pi_{n-1}(dx) \right).$$

Suppose the decoder receives $\{q_n\}$ through a noisy but memoryless channel with input alphabet $\sum$ and output alphabet another finite set O, with transition probabilities $\tilde{p}(i,j), i \in D, j \in O$. Thus $\tilde{p}(i,j) \geq 0, \sum_l \tilde{p}(i,l) = 1$ for all i, j. Let d_n be the channel output at time n.

The decoder can estimate (X_n, Y_n) given $d^n, n \geq 0$, but this is no longer easy because we cannot reconstruct $\{Q_n\}$ exactly in absence of his knowledge of $\{\pi_n\}, \{q_n\}$. Thus he should estimate $\{q_n\}$ by $\{\hat{q}_n\}$, say (e.g., by maximum likelihood), given $\{d_n\}$ and use these estimates in place of $\{q_n\}$ in the nonlinear filter for $\{\pi_n\}$, giving an approximation $\{\hat{\pi}_n\}$ to $\{\pi_n\}$. The guess for Q_n then is $v(\hat{\pi}_n), n \geq 0$.

5. Conclusions and extensions. In this paper we have considered the problem of optimal sequential vector quantization of a stationary Markov source. We have formulated the problem as a stochastic control problem. We have used the methodology of Markov decision theory. Further, we have shown that the conditional law of the source given the quantized past is a sufficient statistic for the problem. Thus the optimal encoding scheme has a separated structure. The conditional laws are given recursively by the nonlinear filter described in (3.1). The optimal policy is characterized by Theorem 4.3.

The next step is to apply traditional Markov decision problem approximation techniques to compute approximate schemes. If we have access to training data, then we can use the tools of reinforcement learning. Here the idea is to parametrize the value function space or the control law itself and apply stochastic approximation techniques to optimize those parameters.

In general, the nonlinear filter recursion is very complicated. In the literature people have approximated this by a linear prediction of the mean. These linear predictive methods can be considered an approximation to the general nonlinear filter.

EXPONENTIAL STABILITY OF AN ABSTRACT NONDISSIPATIVE LINEAR SYSTEM*

KANGSHENG LIU†, ZHUANGYI LIU‡, AND BOPENG RAO§

Abstract. In this paper we consider an abstract linear system with perturbation of the form

$$\frac{dy}{dt} = Ay + \varepsilon By$$

on a Hilbert space $\mathcal{H}$, where A is skew-adjoint, B is bounded, and ε is a positive parameter. Motivated by a work of Freitas and Zuazua on the one-dimensional wave equation with indefinite viscous damping [P. Freitas and E. Zuazua, *J. Differential Equations*, 132 (1996), pp. 338–352], we obtain a sufficient condition for exponential stability of the above system when B is not a dissipative operator. We also obtain a Hautus-type criterion for exact controllability of system (A, G), where G is a bounded linear operator from another Hilbert space to $\mathcal{H}$. Our result about the stability is then applied to establish the exponential stability of several elastic systems with indefinite viscous damping, as well as the exponential stabilization of the elastic systems with noncolocated observation and control.

Key words. linear elastic system, exponential stability, exact controllability, Hautus-type criterion, indefinite damping, stabilization

1. Introduction.

We consider a linear evolution equation

$$\begin{cases} \dfrac{d}{dt}y(t) = \mathcal{A}_\varepsilon y(t) \equiv (A + \varepsilon B)y(t), \\ y(0) = y_0 \end{cases} \tag{1.1}$$

in a Hilbert space $\mathcal{H}$, where A is a densely defined, closed linear operator with domain $\mathcal{D}(\mathcal{A})$. We assume that

(H1) A is skew-adjoint ($A^* = -A$) and has a compact resolvent, and

(H2) B is a bounded linear operator on $\mathcal{H}$ with $\|B\| = N_b$.

Under assumptions (H1) and (H2), we know that the operator $\mathcal{A}_\varepsilon$ generates a C_0 semigroup $S_\varepsilon(t)$ on $\mathcal{H}$ (see [9]). In this paper we study mainly the exponential stability of the above system, i.e., that there exist $\mu > 0$ and $M \geq 1$ such that

$$\|S_\varepsilon(t)\| \leq Me^{-\mu t} \quad \forall\, t \geq 0. \tag{1.2}$$

When $\varepsilon = 1$, this problem has been investigated extensively for both bounded and unbounded operator B. These works are based on the assumption of the *dissipativeness* of B,

$$\mathrm{Re}\langle By, y\rangle \leq 0 \quad \forall\, y \in \mathcal{D}(A), \tag{1.3}$$

which implies that the energy of the system, $E(t) = \|S_\varepsilon(t)\|^2$, is a decreasing function of time. Clearly, this is not a necessary condition for $E(t)$ being upper bounded by a function which tends to zero exponentially. A natural question to ask is the following. Without the dissipativeness of B, can we still obtain (1.2) under some extra conditions? This problem is quite significant in the control theory for distributed parameter systems because

(a) the optimality systems resulting from the regulators are nondissipative;
(b) the closed-loop systems by feedback with noncolocated sensors and actuators are nondissipative;
(c) the perturbations arising from undetermined parts of models are nondissipative in general.

Such a question was first raised in [2] for the one-dimensional wave equation

$$\begin{cases} w_{tt}(x,t) = w_{xx}(x,t) - d(x)w_t(x,t), \quad 0 < x < 1, \quad t > 0, \\ w(0,t) = w(1,t) = 0, \quad t > 0, \\ w(x,0) = w_0(x), \ \ w_t(x,0) = w_1(x), \quad 0 < x < 1, \end{cases} \tag{1.4}$$

where d is a smooth function and changes sign on $(0,1)$. It was conjectured that (1.2) holds if

$$I_n \equiv \int_0^1 d(x) \sin^2 n\pi x \mathrm{d}x \geq C_0 > 0, \quad n = 1, 2, \ldots. \tag{1.5}$$

It turns out that (1.5) is not enough to ensure exponential stability. When $\|d\|_{L^\infty}$ becomes large enough, there will be eigenvalues of the system (1.2) with positive real part (see [3]). Thus, in order to have exponential stability, the damping coefficient must not only satisfy (1.5), but also has a small L^∞ norm. Later on, Freitas and Zuazua [4] considered the modified system of (1.4):

$$\begin{cases} w_{tt}(x,t) = w_{xx}(x,t) - \varepsilon d(x)w_t(x,t), \quad 0 < x < 1, \quad t > 0, \\ w(0,t) = w(1,t) = 0, \quad t > 0, \\ w(0,t) = w_0(x), \ w_t(x,0) = w_1(x), \quad 0 < x < 1. \end{cases} \tag{1.6}$$

They proved that if $d \in BV(0,1)$ and the condition (1.5) holds, then there exist positive constants ε_0, M, ω, depending only on the function d, such that for all $0 < \varepsilon < \varepsilon_0$,

$$E(t) = \int_0^1 (|w_x|^2 + |w_t|^2)\mathrm{d}x \leq Me^{-\varepsilon\omega t}E(0) \ \ \forall t > 0, \tag{1.7}$$

for every finite energy solution of (1.6). Their result was further extended in [1] to the equation

$$w_{tt} = w_{xx} - 2\varepsilon d(x)w_t - b(x)w, \tag{1.8}$$

where $b \in L^1(0,1)$.

These works lead us to the current study in this paper. Instead of working on a particular PDE system, we would like to obtain a general result along the line developed in [2]. Although the shooting method used in [4] and [1] is no longer applicable to our abstract problem, the analysis in these papers does provide us with valuable information on how to impose additional conditions in order to guarantee (1.2). In the next section, we estimate the growth rate of the semigroup $S_\varepsilon(t)$, by

a formula for the type of a C_0 semigroup on a Hilbert space due to Huang [7] and Prüss [10]. The exponential stability of the semigroup follows from a negative growth rate. It is well known that the exponential stability of a linear system reversible in time is always connected with exact controllability of the corresponding system. Thanks to the fact that our sufficient condition for exponential stability of (1.1) is also necessary when $-B$ is symmetrical and nonnegative, in section 3 we obtain a Hautus-type criterion for exact controllability of system (A, G), where G is a bounded linear operator from another Hilbert space to $\mathcal{H}$. In section 4, we apply the result on exponential stability to several elastic systems (such as string, Euler–Bernoulli beam, Timoshenko beam, and two-dimensional Schrödinger equations) with indefinite viscous damping or nondissipative perturbation arising from feedback by noncolocated observation and control.

2. Sufficient condition for exponential stability. Under the condition (H1), there is an orthonormal base of $\mathcal{H}$ consisting of eigenvectors of A,

$$\{\phi_n \mid n = 1, 2, \ldots\}, \tag{2.1}$$

such that

$$\begin{cases} A\phi_n = \boldsymbol{i}\beta_n\phi_n, \quad n = 1, 2, \ldots, \ \beta_n \in \mathbb{R}, \\ 0 \le |\beta_1| \le |\beta_2| \le \cdots \le |\beta_n| \le |\beta_{n+1}| \to \infty. \end{cases} \tag{2.2}$$

We have taken multiple eigenvalues into account. Every eigenvalue has a finite multiplicity.

For each $\gamma > 0$, set

$$\Sigma_\gamma = \left\{ \psi = \sum_{n \in I_{\gamma,m}} a_n\phi_n \;\Big|\; \sum_{n \in I_{\gamma,m}} |a_n|^2 = 1, \ m \in \mathbb{N}, \ a_n \in \mathbb{C} \right\}, \tag{2.3}$$

where

$$I_{\gamma,m} = \{n \in \mathbb{N} | \quad |\beta_n - \beta_m| < \gamma\}. \tag{2.4}$$

Let

$$C_\gamma = \inf_{\psi \in \Sigma_\gamma} \mathrm{Re}\langle -B\psi, \psi\rangle. \tag{2.5}$$

Note that $I_{\gamma,m} = I_{\gamma,l}$ if $\beta_m = \beta_l$ and $C_{\gamma_1} \ge C_{\gamma_2}$ for $0 < \gamma_1 < \gamma_2$. We further assume that

$$C_\gamma > 0 \qquad \text{for some} \quad \gamma > 0. \tag{H3}$$

Denote the type of semigroup $S_\varepsilon(t)$ by

$$\omega_0(\mathcal{A}_\varepsilon) = \lim_{t \to \infty} \frac{\ln \|S_\varepsilon(t)\|}{t} \tag{2.6}$$

and the spectral bound of $\mathcal{A}_\varepsilon$ by

$$\sigma_0(\mathcal{A}_\varepsilon) = \sup\{\mathrm{Re}\lambda | \ \lambda \in \sigma(\mathcal{A}_\varepsilon)\}. \tag{2.7}$$

We shall use a result in [7, 10] which states

$$\omega_0(\mathcal{A}_\varepsilon) = \inf \left\{ s > \sigma_0(\mathcal{A}_\varepsilon) \mid \sup_{\mathrm{Re}\lambda = s} \|(\lambda I - \mathcal{A}_\varepsilon)^{-1}\| < +\infty \right\}. \tag{2.8}$$

THEOREM 2.1. *Under the assumptions* (H1)–(H3), *for every* $C \in [0, C_\gamma)$ *it holds that*

$$\omega_0(\mathcal{A}_\varepsilon) < -\varepsilon C \tag{2.9}$$

whenever

$$0 < \varepsilon < \frac{\gamma(\sqrt{N_b^2 + C_\gamma(C_\gamma - C)} - N_b)}{2C_\gamma\sqrt{N_b^2 - C^2}}. \tag{2.10}$$

In particular, $S_\varepsilon(t)$ *is exponentially stable if*

$$0 < \varepsilon < \frac{\gamma}{2N_bC_\gamma}\left(\sqrt{N_b^2 + C_\gamma^2} - N_b\right). \tag{2.11}$$

Proof. We will prove that for every $\sigma \geq -C$ there exists $\delta_\varepsilon > 0$ such that

$$\|(\varepsilon\sigma + \boldsymbol{i}\tau)y - \mathcal{A}_\varepsilon y\| \geq \delta_\varepsilon\|y\| \qquad \forall\ \tau \in \mathbb{R},\ y \in \mathcal{D}(\mathcal{A}_\varepsilon). \tag{2.12}$$

Since for $y \in \mathcal{D}(A)$, $\sigma, \tau \in \mathbb{R}$,

$$\|(\varepsilon\sigma + \boldsymbol{i}\tau)y - \mathcal{A}_\varepsilon y\|\|y\| \geq \mathrm{Re}\langle(\varepsilon\sigma + \boldsymbol{i}\tau)y - \mathcal{A}_\varepsilon y\ ,\ y\rangle \geq \varepsilon(\sigma - N_b)\|y\|^2,$$

(2.12) holds for all $\sigma > N_b$. If (2.12) is false for some $\sigma \in [-C, N_b]$, then there exist a sequence of real numbers τ_p and a sequence of normalized vectors $y_p \in \mathcal{D}(\mathcal{A}_\varepsilon)$ such that

$$((\varepsilon\sigma + \boldsymbol{i}\tau_p)I - \mathcal{A}_\varepsilon)y_p \equiv f_p \to 0 \quad \text{in} \quad \mathcal{H} \quad \text{as} \quad p \to +\infty. \tag{2.13}$$

From (2.13) we have

$$\sigma = \frac{1}{\varepsilon}\langle f_p - (\boldsymbol{i}\tau_p I - A)y_p + \varepsilon By_p\ ,\ y_p\rangle = \lim_{p\to+\infty}\mathrm{Re}\langle By_p, y_p\rangle. \tag{2.14}$$

Moreover, (2.13)–(2.14) imply that

$$\begin{aligned}\|(\boldsymbol{i}\tau_p I - A)y_p\|^2 &= \|f_p - \varepsilon(\sigma I - B)y_p\|^2\\ &\leq \|f_p\|^2 + 2\varepsilon\|\sigma I - B\|\|f_p\| + \varepsilon^2\|(\sigma I - B)y_p\|^2\\ &= o(1) + \varepsilon^2(\sigma^2 - 2\sigma\mathrm{Re}\langle By_p, y_p\rangle + \|By_p\|^2)\\ &\leq \varepsilon^2(N_b^2 - \sigma^2) + o(1).\end{aligned}$$

Thus for any $\delta > 0$ there exists $N \in \mathbb{N}$ such that

$$\|(\boldsymbol{i}\tau_p I - A)y_p\|^2 \leq \varepsilon^2(N_b^2 - \sigma^2 + \delta) \quad \forall\ p > N. \tag{2.15}$$

We expand y_p for $p > N$ in the eigenvectors of A:

$$y_p = \sum_{n=1}^{\infty}\langle y_p, \phi_n\rangle\phi_n. \tag{2.16}$$

Substituting (2.16) into (2.15) yields

$$\sum_{n=1}^{\infty}|\tau_p - \beta_n|^2|\langle y_p, \phi_n\rangle|^2 \leq \varepsilon^2(N_b^2 - \sigma^2 + \delta). \tag{2.17}$$

Choose $m = m(p)$ such that

$$|\tau_p - \beta_m| = \min\{|\tau_p - \beta_n| \mid n \in \mathbb{N}\}. \tag{2.18}$$

Then we have

$$\frac{\gamma}{2} < |\tau_p - \beta_n| \qquad \forall n \notin I_{\gamma,m}. \tag{2.19}$$

In fact, if $|\tau_p - \beta_m| \geq \frac{\gamma}{2}$, (2.19) holds obviously. If $|\tau_p - \beta_m| < \frac{\gamma}{2}$, then (2.19) follows from $|\tau_p - \beta_n| \geq |\beta_n - \beta_m| - |\tau_p - \beta_m|$. Combination of (2.17) and (2.19) gives that

$$\frac{\gamma^2}{4} \sum_{n \notin I_{\gamma,m}} |\langle y_p, \phi_n \rangle|^2 \leq \varepsilon^2 (N_b^2 - \sigma^2 + \delta). \tag{2.20}$$

Define

$$z_p = \sum_{n \in I_{\gamma,m}} \langle y_p, \phi_n \rangle \phi_n, \qquad p > N. \tag{2.21}$$

Then (2.20) implies that

$$\|y_p - z_p\| \leq \frac{2\varepsilon}{\gamma} \sqrt{N_b^2 - \sigma^2 + \delta}, \qquad 1 \geq \|z_p\|^2 \geq 1 - \frac{4\varepsilon^2}{\gamma^2}(N_b^2 - \sigma^2 + \delta). \tag{2.22}$$

Note that $-\sigma \leq C < C_\gamma \leq N_b$. Since the function

$$g(x) \equiv \frac{\sqrt{N_b^2 + C_\gamma(C_\gamma + x)} - N_b}{\sqrt{N_b^2 - x^2}} \tag{2.23}$$

is monotonically increasing on $(-C_\gamma, N_b)$ (see Supplement 1), the inequality (2.10) implies (2.11) and, therefore,

$$2N_b\varepsilon/\gamma < \frac{\sqrt{N_b^2 + C_\gamma^2} - N_b}{C_\gamma} = \frac{C_\gamma}{\sqrt{N_b^2 + C_\gamma^2} + N_b} < 1.$$

From (2.22) we know $z_p \neq 0$ if δ is small enough. Hence we have $z_p/\|z_p\| \in \Sigma_\gamma$ and

$$-\mathrm{Re}\langle Bz_p, z_p \rangle \geq C_\gamma \|z_p\|^2 \geq C_\gamma \left(1 - \frac{4\varepsilon^2}{\gamma^2}(N_b^2 - \sigma^2 + \delta)\right). \tag{2.24}$$

It follows from (2.14), (2.22), and (2.24) that

$$\begin{aligned}
\sigma &= \lim_{p \to +\infty} \mathrm{Re}\langle By_p, y_p \rangle \\
&\leq \sup_{p>N} [\mathrm{Re}\langle Bz_p, z_p \rangle + \mathrm{Re}\langle B(y_p - z_p), y_p \rangle + \mathrm{Re}\langle Bz_p, y_p - z_p \rangle] \\
&\leq \sup_{p>N} [-C_\gamma \|z_p\|^2 + (1 + \|z_p\|)\|B\|\|y_p - z_p\|] \\
&\leq -C_\gamma \left(1 - \frac{4\varepsilon^2}{\gamma^2}(N_b^2 - \sigma^2 + \delta)\right) + \frac{4N_b\varepsilon}{\gamma} \sqrt{N_b^2 - \sigma^2 + \delta}. \qquad (2.25)
\end{aligned}$$

We take $\delta \to 0$ in (2.25) to get

$$C_\gamma + \sigma \le 4C_\gamma \left(\frac{\varepsilon}{\gamma}\sqrt{N_b^2 - \sigma^2}\right)^2 + 4N_b \left(\frac{\varepsilon}{\gamma}\sqrt{N_b^2 - \sigma^2}\right). \tag{2.26}$$

If $\sigma = N_b$, then (2.26) is an obvious contradiction. For $-C \le \sigma < N_b$, (2.26) implies

$$\varepsilon \ge \frac{\gamma}{2C_\gamma} g(\sigma) \ge \frac{\gamma}{2C_\gamma} g(-C), \tag{2.27}$$

which contradicts (2.10).

Since $\mathcal{A}_\varepsilon$ also has a compact resolvent, from (2.12) we deduce that the resolvent of $\mathcal{A}_\varepsilon$ is bounded on $\varepsilon\sigma + \boldsymbol{i}\mathbb{R}$ for all $\sigma \ge -C$. By the resolvent equation, the resolvent is bounded on $\{\varepsilon\sigma + \boldsymbol{i}\tau \,|\, \sigma \ge -C - \delta, \tau \in \mathbb{R}\}$ for some $\delta > 0$ small enough. The proof is complete from (2.8). □

It is easy to see that (H3) is satisfied with $\gamma = \gamma_0$ when the following conditions hold.

(H4) The spectrum of A satisfies the gap condition

$$\inf\{|\beta_j - \beta_k| : j, k = 1, 2, \ldots, \beta_j \ne \beta_k\} \equiv \gamma_0 > 0. \tag{2.28}$$

(H5) For any normalized eigenvector ϕ of A,

$$-\mathrm{Re}\langle B\phi, \phi\rangle \ge C_0 > 0. \tag{2.29}$$

Corollary 2.2. *Assume that the conditions* (H1), (H2), (H4), *and* (H5) *hold. Then the semigroup $S_\varepsilon(t)$ is exponentially stable if*

$$0 < \varepsilon < \frac{\gamma_0}{2N_bC_0}\left(\sqrt{N_b^2 + C_0^2} - N_b\right). \tag{2.30}$$

Moreover, for every $C \in (0, C_0)$, it holds that

$$\omega_0(\mathcal{A}_\varepsilon) < -\varepsilon C \quad \forall\, 0 < \varepsilon < \frac{\gamma_0(\sqrt{N_b^2 + C_0(C_0 - C)} - N_b)}{2C_0\sqrt{N_b^2 - C^2}}. \tag{2.31}$$

Proof. This follows from Theorem 2.1 with $\gamma = \gamma_0$, $C_\gamma \ge C_0$, and the fact that the function

$$g_1(x) = \frac{\sqrt{N_b^2 + x(x - C)} - N_b}{x} = \left(\frac{N_b}{x - C} + \sqrt{\left(\frac{N_b}{x - C}\right)^2 + \frac{C}{x - C} + 1}\right)^{-1}$$

is monotonically increasing for $x > C \ge 0$. □

Remark 2.1. In the analysis above, we provided not only the sufficient conditions for the exponential stability of semigroup $S_\varepsilon(t)$ but also an explicit negative bound of the type $\omega_0(\mathcal{A}_\varepsilon)$ of semigroup $S_\varepsilon(t)$ with the perturbation parameter ε in an explicit range.

Remark 2.2. Chen et al. [2] discussed the exponential stability of (1.1) with $\varepsilon = 1$ and the dissipative operator B. In addition to assumptions similar to (H1)–(H3), they needed the condition that $\mathrm{Re}\langle By_p, y_p\rangle \to 0$ implies $By_p \to 0$ for any sequence of normalized vectors y_p. This condition does not hold generally if B is nondissipative. On the other hand, if $-B$ is symmetrical and nonnegative, i.e., $-B = -B^* \ge 0$, then

the assumption (H3) is necessary for the exponential stability of semigroup $S_\varepsilon(t)$ (see the proof of Theorem 3.1).

Remark 2.3. The spectral gap condition (H4) is very restrictive. Corollary 2.2 applies primarily to the one-dimensional problems. Actually, as we will see in section 4, the condition (H4) can be absent even for some PDE system on the region of one spatial dimension. Roughly speaking, (H5) means that the damping operator B is uniformly effective for all the normalized eigenvectors. When the spectral gap condition fails, (H3) means that the damping operator B is uniformly effective for all the normalized linear combinations of eigenvectors corresponding to the eigenvalues located in the γ-neighborhood of any eigenvalue.

3. Hautus-type criterion for exact controllability. Let $\mathcal{H}$ and U be Hilbert spaces. Consider the control system (A, G)

$$y(u,t) = e^{tA}y_0 + \int_0^t e^{(t-s)A}Gu(s)ds, \tag{3.1}$$

where A generates a C_0 semigroup e^{tA} on $\mathcal{H}$, $G \in \mathcal{L}(U;\mathcal{H})$, $y_0 \in \mathcal{H}$. When $\mathcal{H} = \mathbb{C}^n$ and $U = \mathbb{C}^m$ are finite dimensional, the famous Hautus lemma [6] says that the system (A, G) is controllable if and only if

$$\mathrm{Rank}[\lambda I - A,\ G] = n \qquad \forall\ \lambda \in \sigma(A), \tag{3.2}$$

or, equivalently,

$$\|(\lambda I - A)^* y\| + \|G^* y\|_U > 0 \qquad \forall\ \lambda \in \sigma(A),\ \|y\| = 1. \tag{3.3}$$

When $A^* = -A$, (3.3) is equivalent to

$$\|G^*\phi\|_U > 0 \qquad \forall\ \phi \text{ being normalized eigenvectors of } A. \tag{3.4}$$

In this section, we will give a counterpart of the special Hautus criterion (3.4) for infinite dimensional systems. We need the following Lemma given in Liu [8, Thm. 2.3]. Concerning the definitions of exact controllability and exponential stabilizability of (A, G), we refer the reader to [8].

LEMMA 3.1. *Let $A^* = -A$, $G \in \mathcal{L}(U;\mathcal{H})$. Then the following propositions are equivalent.*

(a) *The system (A, G) is exactly controllable.*
(b) *The system (A, G) is exponentially stabilizable.*
(c) *For every positive-definite self-adjoint $K \in \mathcal{L}(U)$ the operator $A - GKG^*$ generates an exponentially stable C_0 semigroup on $\mathcal{H}$.*

By Lemma 3.1 and the frequency domain condition for exponential stability [7, 10], Liu [8] gave a Hautus-type criterion for exact controllability of the second order conservative systems in Hilbert spaces. Also by Lemma 3.1, Zhou and Yamamoto [11] gave a counterpart of (3.3) for the conservative system (A, G), $A^* = -A$. Our result is the following.

THEOREM 3.2. *Suppose that the assumption* (H1) *holds and $G \in \mathcal{L}(U;\mathcal{H})$. Then the following propositions are equivalent.*

(a) *The system (A, G) is exactly controllable.*
(b) *The assumption* (H3) *holds for $B = -GG^*$; that is,*

$$\lim_{\gamma \to 0^+} \inf_{\psi \in \Sigma_\gamma} \|G^*\psi\|_U > 0. \tag{3.5}$$

(c) *There exists $F \in \mathcal{L}(\mathcal{H};U)$ such that the assumption* (H3) *holds for $B = GF$.*

Proof. The implication (b)⇒(c) is trivial; (c)⇒(a) follows readily from Theorem 2.1 and Lemma 3.1.

(a)⇒(b). By Lemma 3.1, the exact controllability of (A, G) is equivalent to the exponential stability of the semigroup $S_\varepsilon(t)$ with $B = -GG^*$, $\varepsilon > 0$. Thus it suffices to prove that (H3) is necessary for the exponential stability of $S_\varepsilon(t)$ when $-B = -B^* \geq 0$. In this case, $C_\gamma \geq 0$ for all $\gamma > 0$. If for any $\gamma > 0$, $C_\gamma = 0$, then there exist β_m and a normalized vector of the form

$$\psi_\gamma = \sum_{n \in I_{\gamma,m}} a_n \phi_n \tag{3.6}$$

such that

$$\|B\psi_\gamma\| \leq \|(-B)^{\frac{1}{2}}\| \langle -B\psi_\gamma, \psi_\gamma \rangle^{\frac{1}{2}} < \gamma.$$

Thus

$$\|(\boldsymbol{i}\beta_m I - \mathcal{A}_\varepsilon)\psi_\gamma\| \leq \varepsilon\gamma + \left\| \sum_{n \in I_{\gamma,m}} (\beta_m - \beta_n)\boldsymbol{i} a_n \phi_n \right\| \leq (1+\varepsilon)\gamma. \tag{3.7}$$

This means that the resolvent of $\mathcal{A}_\varepsilon$ is unbounded on $\boldsymbol{i}\mathbb{R}$ if it exists. Thus $S_\varepsilon(t)$ is not exponentially stable. □

Remark 3.1. If the spectral gap condition (H4) holds, then the condition (3.5) takes the form

$$\|G^*\phi\|_U \geq \delta > 0 \qquad \forall\ \phi \text{ being normalized eigenvectors of } A. \tag{3.8}$$

This is just a counterpart of the finite dimensional case (3.4).

4. Applications. In this section, we apply our result about exponential stability to the wave, beam, and two-dimensional Shrödinger equations with indefinite viscous damping or nondissipative perturbation arising from feedback by noncolocated observation and control.

Example 1. We consider the following one-dimensional wave equation with indefinite viscous damping:

$$\begin{cases} w_{tt}(x,t) = w_{xx}(x,t) - \varepsilon d(x) w_t(x,t), & 0 < x < 1, \quad t > 0, \\ w(0,t) = w_x(1,t) = 0, & t > 0, \\ w(0,t) = w_0(x), \quad w_t(x,0) = w_1(x), & 0 < x < 1, \end{cases} \tag{4.1}$$

where $d \in L^\infty(0,1)$ is real-valued. The underlying Hilbert space is

$$\mathcal{H} = \left\{ \begin{bmatrix} w \\ v \end{bmatrix} \in H^1(0,1) \times L^2(0,L) \Big| \ w(0) = 0 \right\}$$

with the inner product

$$\left\langle \begin{bmatrix} w_1 \\ v_1 \end{bmatrix}, \begin{bmatrix} w_2 \\ v_2 \end{bmatrix} \right\rangle = \int_0^1 [w_1' \bar{w}_2' + v_1 \bar{v}_2] \mathrm{d}x.$$

Define

$$\mathcal{D}(A) = \left\{ \begin{bmatrix} w \\ v \end{bmatrix} \Big| \ w \in H^2(0,1), v \in H^1(0,1), w(0) = v(0) = w'(1) = 0 \right\},$$

$$A = \begin{bmatrix} 0 & I \\ \partial_x^2 & 0 \end{bmatrix}, \quad B = \begin{bmatrix} 0 & 0 \\ 0 & -d(x) \end{bmatrix}, \quad y = \begin{bmatrix} w \\ w_t \end{bmatrix}.$$

Then the system (4.1) can be rewritten as (1.1). A has a complete orthonormal set of eigenfunctions

$$\phi_n^{\pm} = \frac{1}{(n+\frac{1}{2})\pi} \begin{bmatrix} \sin(n+\frac{1}{2})\pi x \\ \pm \boldsymbol{i}(n+\frac{1}{2})\pi \sin(n+\frac{1}{2})\pi x \end{bmatrix}$$

with eigenvalues

$$\boldsymbol{i}\beta_n^{\pm} = \pm \boldsymbol{i}\left(n+\frac{1}{2}\right)\pi, \qquad n = 0, 1, 2, \ldots.$$

It is easy to see that (H1), (H2), and (H4) are satisfied with $\gamma_0 = \pi$, and

$$-\langle B\phi_n^{\pm}, \phi_n^{\pm}\rangle = \int_0^1 d(x)\sin^2\left(n+\frac{1}{2}\right)\pi x \mathrm{d}x. \tag{4.2}$$

Thus (H5) holds if and only if

$$\inf_{n\geq 0}\int_0^1 d(x)[1-\cos(2n+1)\pi x]\mathrm{d}x > 0. \tag{4.3}$$

For example, we take

$$d(x) = 1 + \alpha\cos 2k\pi x, \quad \alpha \in \mathbb{R}, \tag{4.4}$$

with k being any positive integer. Then

$$\gamma_0 = \pi, \quad N_b = 1 + |\alpha|, \quad -\langle B\phi_n^{\pm}, \phi_n^{\pm}\rangle = \frac{1}{2} \quad \forall\, n \geq 0.$$

Therefore, $S_\varepsilon(t)$ is exponentially stable if

$$0 < \varepsilon < \frac{\pi}{2(1+|\alpha|)}\Big(\sqrt{4(1+|\alpha|)^2+1} - 2(1+|\alpha|)\Big). \tag{4.5}$$

Moreover, for every $C \in (0, \frac{1}{2})$, it holds that

$$\omega_0(\mathcal{A}_\varepsilon) < -\varepsilon C \qquad \forall\ 0 < \varepsilon < \frac{\pi(\sqrt{4(1+|\alpha|)^2+1-2C} - 2(1+|\alpha|))}{2\sqrt{(1+|\alpha|)^2 - C^2}}. \tag{4.6}$$

We can also choose $d(x)$ with local support, such as

$$d(x) = \begin{cases} \sin 4\pi x, & \frac{1}{4} \leq x \leq \frac{1}{2}, \\ 2\sin 4\pi x, & \frac{1}{2} \leq x \leq \frac{3}{4}, \\ 0, & \text{otherwise.} \end{cases} \tag{4.7}$$

For this case,

$$-\langle B\phi_n^{\pm}, \phi_n^{\pm}\rangle \geq \frac{3}{20\pi} \quad \forall\, n \geq 0.$$

Example 2. Let us consider the following system with distributed control and locally distributed observation:

$$\begin{cases} w_{tt}(x,t) + w_{xxxx}(x,t) = f(x,t), & 0 < x < 1, \quad t > 0, \\ w(0,t) = w(1,t) = w_{xx}(0,t) = w_{xx}(1,t) = 0, & t > 0, \\ w(0,t) = w_0(x), \ \ w_t(x,0) = w_1(x), & 0 < x < 1, \quad t > 0, \\ h(x,t) = w_t(x,t), & x \in (\frac{1}{2}, 1), \quad t > 0. \end{cases} \tag{4.8}$$

Our purpose is to find a bounded linear operator K from $L^2(\frac{1}{2},1)$ to $L^2(0,1)$ so that the feedback control law

$$f(\cdot,t) = -\varepsilon K h(\cdot,t), \qquad t>0, \tag{4.9}$$

stablizes the system (4.8) for some $\varepsilon>0$. The simplest form of operator K would be

$$[Kh](x) = \begin{cases} 2c(x)h(1-x), & 0<x<\frac{1}{2}, \\ 2d(x)h(x), & \frac{1}{2}<x<1, \end{cases} \tag{4.10}$$

where $c\in L^\infty(0,\frac{1}{2})$, $d\in L^\infty(\frac{1}{2},1)$ are real-valued. The underlying Hilbert space is

$$\mathcal{H} = [H^2(0,1)\cap H_0^1(0,1)]\times L^2(0,1)$$

with the inner product

$$\left\langle \begin{bmatrix} w_1 \\ v_1 \end{bmatrix}, \begin{bmatrix} w_2 \\ v_2 \end{bmatrix} \right\rangle = \int_0^1 [w_1''\bar{w}_2'' + v_1\bar{v}_2]\mathrm{d}x.$$

Define

$$\mathcal{D}(A) = \left\{ \begin{bmatrix} w \\ v \end{bmatrix} \,\middle|\, w\in H^4(0,1), v\in H^2(0,1), w,v\in H_0^1(0,1), w''(0)=w''(1)=0 \right\},$$

$$A = \begin{bmatrix} 0 & I \\ -\partial_x^4 & 0 \end{bmatrix}, \quad B = \begin{bmatrix} 0 & 0 \\ 0 & -KI_0 \end{bmatrix}, \quad y = \begin{bmatrix} w \\ w_t \end{bmatrix},$$

where I_0 is the embedding from $L^2(0,1)$ to $L^2(\frac{1}{2},1)$. Then the closed-loop system (4.8)–(4.9) can be rewritten as (1.1). A has a complete orthonormal set of eigenfunctions

$$\phi_n^\pm = \frac{1}{n^2\pi^2}\begin{bmatrix} \sin n\pi x \\ \pm \boldsymbol{i} n^2\pi^2 \sin n\pi x \end{bmatrix}$$

with eigenvalues

$$\boldsymbol{i}\beta_n^\pm = \pm \boldsymbol{i} n^2\pi^2, \qquad n=1,2,\ldots.$$

It is easy to see that (H1), (H2), and (H4) are satisfied with $\gamma_0 = 3\pi^2$. For K defined in (4.10), we have

$$\begin{aligned} -\langle B\phi_n^\pm, \phi_n^\pm\rangle &= 2\int_0^{\frac{1}{2}} c(x)\sin n\pi(1-x)\sin n\pi x\mathrm{d}x + 2\int_{\frac{1}{2}}^1 d(x)\sin^2 n\pi x\mathrm{d}x \\ &= \int_0^{\frac{1}{2}} [d(1-x)+(-1)^{n+1}c(x)](1-\cos 2n\pi x)\mathrm{d}x. \end{aligned} \tag{4.11}$$

Thus (H5) holds if and only if

$$\inf_{n\ge 1}\int_0^{\frac{1}{2}} [d(1-x)+(-1)^{n+1}c(x)](1-\cos 2n\pi x)\mathrm{d}x > 0. \tag{4.12}$$

For example, we take

$$c(x) = \cos 4\pi x, \quad d(x) = \frac{1}{2} + \cos 4\pi x. \tag{4.13}$$

Then

$$N_b = 3, \quad -\langle B\phi_n^{\pm}, \phi_n^{\pm}\rangle = \frac{1}{4} \quad \forall\, n \geq 1.$$

Therefore, $S_\varepsilon(t)$ is exponentially stable if

$$0 < \varepsilon < \frac{\pi^2}{2}\Big(\sqrt{145} - 12\Big). \tag{4.14}$$

Moreover, for every $C \in (0, \frac{1}{4})$, it holds that

$$\omega_0(\mathcal{A}_\varepsilon) < -\varepsilon C \qquad \forall\ 0 < \varepsilon < \frac{3\pi^2\Big(\sqrt{145 - 4C} - 12\Big)}{2\sqrt{9 - C^2}}. \tag{4.15}$$

Remark 4.1. Let $d \equiv 0$ in (4.10); then the observation and control are completely noncolocated. In this case, by (4.11) we know that K can be uniformly effective only for finite many eigenmodes. The problem of whether there exists $K \in \mathcal{L}(L^2(\frac{1}{2}, 1), L^2(0, 1))$ with $\mathrm{supp}Kh \subset (0, \frac{1}{2})$ for any $h \in L^2(\frac{1}{2}, 1)$ such that (H5) holds remains open.

Example 3. We consider the following two-dimensional Schrödinger equation with distributed control and locally distributed observation:

$$\begin{cases} \dfrac{\partial y}{\partial t}(x,t) = \boldsymbol{i}\Delta y(x,t) + f(x,t), \quad x \in \Omega = (0,a)\times(0,b), \quad t > 0, \\ y|_{\partial\Omega} = 0, \quad t > 0, \quad y(x,0) = y_0(x), \quad x \in \Omega, \\ h(x,t) = y(x,t), \qquad x \in \Omega_1 = (\frac{a}{2}, a)\times(0,b), \quad t > 0. \end{cases} \tag{4.16}$$

Let

$$\mathcal{H} = L^2(\Omega)$$

with the standard L^2 (complex) inner product. Define

$$A = \boldsymbol{i}\Delta, \quad \mathcal{D}(A) = H^2(\Omega) \cap H_0^1(\Omega). \tag{4.17}$$

Then the operator A is skew-adjoint and has eigenvalues

$$\lambda_{k,l} = \boldsymbol{i}\beta_{k,l} = \boldsymbol{i}\left(\frac{k^2}{a^2} + \frac{l^2}{b^2}\right)\pi^2, \quad k, l \in \mathbb{N},$$

and the corresponding normalized eigenfunctions

$$\phi_{k,l}(x) = \frac{2}{\sqrt{ab}} \sin\frac{k\pi x_1}{a} \sin\frac{l\pi x_2}{b}, \quad k, l \in \mathbb{N}.$$

Set the feedback control law

$$f(\cdot, t) = -\varepsilon K h(\cdot, t), \qquad K \in \mathcal{L}(L^2(\Omega_1), L^2(\Omega), \tag{4.18}$$

$$[Kh](x) = \begin{cases} c(x_1)h(a - x_1, x_2), & 0 < x_1 < \frac{a}{2},\ 0 < x_2 < b, \\ d(x_1)h(x), & \frac{a}{2} < x_1 < a,\ 0 < x_2 < b, \end{cases} \tag{4.19}$$

where $c \in L^\infty(0, \frac{a}{2})$, $d \in L^\infty(\frac{a}{2}, a)$ are real-valued. Then the closed-loop system (4.16)–(4.18) can be rewritten as (1.1) with $B = -KI_1$, where I_1 is the embedding from $L^2(\Omega)$ to $L^2(\Omega_1)$. When a/b is a rational number, the gap condition (H4) is true, but there are multiple eigenvalues. While a/b is an irrational number, the gap condition (H4) is false (see [2]). So, we have to check the condition (H3). We recount the eigenvalues and the corresponding normalized eigenfunctions:

$$\boldsymbol{i}\beta_n = \boldsymbol{i}\beta_{k_n,l_n}, \quad \beta_n \le \beta_{n+1}, \qquad \phi_n = \phi_{k_n,l_n}, \quad n \in \mathbb{N}.$$

Choose $\gamma = (\frac{\pi}{a})^2$; then

$$I_{\gamma,m} = \left\{ n \in \mathbb{N} \;\middle|\; \left| \frac{k_n^2 - k_m^2}{a^2} + \frac{l_n^2 - l_m^2}{b^2} \right| < \frac{1}{a^2} \right\}.$$

We note that for $p, q \in I_{\gamma,m}$, $p = q$ if and only if $l_p = l_q$ for any $\psi \in \Sigma_\gamma$,

$$\psi = \sum_{n \in I_{\gamma,m}} a_n \phi_n = \sum_{n \in I_{\gamma,m}} \frac{2a_n}{\sqrt{ab}} \sin\frac{k_n \pi x_1}{a} \sin\frac{l_n \pi x_2}{b}, \quad \sum_{n \in I_{\gamma,m}} |a_n|^2 = 1. \tag{4.20}$$

Using the orthogonality of $\{\sin(l\pi x_2/b)\}_{l=1}^\infty$ in $L^2(0,b)$, we have

$$\begin{aligned} -\langle B\psi, \psi\rangle &= \int_0^{\frac{a}{2}} c(x_1) \int_0^b \sum_{p,q \in I_{\gamma,m}} a_p \bar{a}_q \phi_p(a - x_1, x_2) \phi_q(x_1, x_2) \mathrm{d}x_2 \mathrm{d}x_1 \\ &\quad + \int_{\frac{a}{2}}^a d(x_1) \int_0^b \left| \sum_{n \in I_{\gamma,m}} \frac{2a_n}{\sqrt{ab}} \sin\frac{k_n \pi x_1}{a} \sin\frac{l_n \pi x_2}{b} \right|^2 \mathrm{d}x_2 \mathrm{d}x_1 \\ &= \frac{2}{a} \sum_{n \in I_{\gamma,m}} |a_n|^2 \int_0^{\frac{a}{2}} [d(a - x_1) + (-1)^{1+k_n} c(x_1)] \sin^2\frac{k_n \pi x_1}{a} \mathrm{d}x_1. \end{aligned} \tag{4.21}$$

Thus (H3) holds if and only if

$$\inf_{k \in \mathbb{N}} \int_0^{\frac{a}{2}} [d(a - x_1) + (-1)^{1+k} c(x_1)] \sin^2\frac{k\pi x_1}{a} \mathrm{d}x_1 > 0. \tag{4.22}$$

The sufficiency follows from (4.21). If (4.22) is false, then there exists a sequence ξ_n of positive integers such that

$$\lim_{n \to +\infty} \int_0^{\frac{a}{2}} [d(a - x_1) + (-1)^{1+\xi_n} c(x_1)] \sin^2\frac{\xi_n \pi x_1}{a} \mathrm{d}x_1 = \alpha \le 0.$$

Thus for the sequence $\phi_{\xi_n,1}$ of normalized eigenfunctions of A we have

$$-\langle B\phi_{\xi_n,1}\ ,\ \phi_{\xi_n,1}\rangle = \frac{2}{a} \int_0^{\frac{a}{2}} [d(a - x_1) + (-1)^{1+\xi_n} c(x_1)] \sin^2\frac{\xi_n \pi x_1}{a} \mathrm{d}x_1 \to \frac{2\alpha}{a} \le 0,$$

which implies that (H3) is false. For example, we take

$$c(x_1) = \cos\frac{4\pi x_1}{a}, \quad d(x_1) = \frac{1}{2} + \cos\frac{4\pi x_1}{a}. \tag{4.23}$$

Then

$$N_b = \frac{3}{2}, \qquad \gamma = \left(\frac{\pi}{a}\right)^2, \qquad C_\gamma = \frac{1}{4}.$$

Therefore, $S_\varepsilon(t)$ is exponentially stable if

$$0 < \varepsilon < \frac{\pi^2}{3a^2}\left(\sqrt{37} - 6\right). \tag{4.24}$$

Moreover, for every $C \in (0, \frac{1}{4})$, it holds that

$$\omega_0(\mathcal{A}_\varepsilon) < -\varepsilon C \qquad \forall\ 0 < \varepsilon < \frac{\pi^2\left(\sqrt{37 - 4C} - 6\right)}{a^2\sqrt{9 - 4C^2}}. \tag{4.25}$$

Example 4. We consider the following Timoshenko beam equation with indefinite viscous damping:

$$\begin{cases} u_{tt} = pu_{xx} - p\phi_x - \varepsilon d_1(x)u_t, & 0 < x < \pi,\ t > 0, \\ \phi_{tt} = q\phi_{xx} + pu_x - p\phi - \varepsilon d_2(x)\phi_t, & 0 < x < \pi,\ t > 0, \\ u(0,t) = u(\pi,t) = \phi_x(0,t) = \phi_x(\pi,t) = 0, & t > 0, \\ u(x,0) = u_0,\ u_t(x,0) = u_1,\ \phi(x,0) = \phi_0,\ \phi_t(x,0) = \phi_1, & 0 < x < \pi, \end{cases} \tag{4.26}$$

where $p,\ q > 0$ are constants and $d_1,\ d_2 \in L^\infty(0,\pi)$ are real-valued.

The underlying Hilbert space is

$$\mathcal{H} = H_0^1(0,\pi) \times L^2(0,\pi) \times H^1(0,\pi) \times L^2(0,\pi)$$

with the inner-product induced by the quadratic form of energy,

$$\|[u,v,\phi,\psi]^T\|^2 = \int_0^\pi \left(p|u_x - \phi|^2 + q|\phi_x|^2 + |v|^2 + |\psi|^2\right) \mathrm{d}x.$$

Define in $\mathcal{H}$

$$\mathcal{D}(A) = \{[u,v,\phi,\psi]^T \mid u, v, \in H_0^1(0,\pi),\ u, \phi \in H^2(0,\pi),\ \psi \in H^1(0,\pi)\},$$

$$A = \begin{bmatrix} 0 & I & 0 & 0 \\ p\partial_x^2 & 0 & -p\partial_x & 0 \\ 0 & 0 & I & 0 \\ p\partial_x & 0 & q\partial_x^2 - pI & 0 \end{bmatrix}, \qquad B = \begin{bmatrix} 0 & 0 & 0 & 0 \\ 0 & -d_1(x) & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & -d_2(x) \end{bmatrix}.$$

Then the system (4.26) can be rewritten as (1.1) by setting $y = [u, u_t, \phi, \phi_t]^T$. It is easy to verify that (H1) and (H2) are satisfied. To compute the eigenvalues of A, we solve the eigenequation

$$A[u,v,\phi,\psi]^T = \lambda[u,v,\phi,\psi]^T, \quad [u,v,\phi,\psi]^T \in \mathcal{D}(A).$$

Eliminating the unknowns v, ϕ, ψ, we obtain

$$\begin{cases} pqu_{xxxx} - (p+q)\lambda^2 u_{xx} + \lambda^2(\lambda^2 + p)u = 0, \\ u(0) = u(\pi) = u_{xx}(0) = u_{xx}(\pi) = 0. \end{cases}$$

A straightforward calculation leads to

$$\text{(4.27)}\qquad \begin{cases} \lambda_{n,1}^2 = -\frac{1}{2}[(p+q)n^2+p] + \frac{1}{2}\sqrt{[(p-q)n^2+p]^2+4pqn^2}, \\ \lambda_{n,2}^2 = -\frac{1}{2}[(p+q)n^2+p] - \frac{1}{2}\sqrt{[(p-q)n^2+p]^2+4pqn^2}, \end{cases}$$

$$\lambda_{n,i}^{\pm} = \pm \boldsymbol{i}\sqrt{-\lambda_{n,i}^2} \quad \text{(counting multiple eigenvalues)},$$

and the corresponding normalized eigenvectors

$$Z_{n,i}^{\pm} = \frac{1}{R_{n,i}}[\sin nx,\ \lambda_{n,i}^{\pm}\sin nx,\ S_{n,i}\cos nx,\ \lambda_{n,i}^{\pm}S_{n,i}\cos nx]^T, \qquad i=1,\ 2; \quad n\in\mathbb{N},$$

where

$$\begin{aligned} S_{n,i} &= \frac{1}{n}\left(n^2 + \frac{1}{p}\lambda_{n,i}^2\right) \quad (\neq 0) \\ &= \frac{1}{2pn}\left([(p-q)n^2-p] + (-1)^{1+i}\sqrt{[(p-q)n^2+p]^2+4pqn^2}\right), \end{aligned} \tag{4.28}$$

$$R_{n,i} = \sqrt{\frac{\pi}{2}}\left[p(n-S_{n,i})^2 + qn^2S_{n,i}^2 - \lambda_{n,i}^2 - \lambda_{n,i}^2S_{n,i}^2\right]^{\frac{1}{2}}. \tag{4.29}$$

These sequences have asymptotic expansions:

$$\text{(4.30)}\qquad \text{for } p=q, \qquad \begin{cases} \lambda_{n,j}^{\pm} = \pm\boldsymbol{i}\sqrt{p}(n + \frac{(-1)^j}{2} + O(\frac{1}{n})), & S_{n,j}^2 = 1 + O(\frac{1}{n}), \\ R_{n,j}^2 = 2\pi pn^2 + O(n), & j=1,\ 2, \end{cases}$$

$$\text{(4.31)}\qquad \text{for } p\neq q, \qquad \begin{cases} (i,j)=(1,2) \text{ for } p>q, & (i,j)=(2,1) \text{ for } p<q, \\ \lambda_{n,i}^2 = -qn^2 + O(1), & \lambda_{n,j}^2 = -pn^2 + O(1), \\ S_{n,i}^2 = (1-\frac{q}{p})^2n^2 + O(1), & S_{n,j}^2 = O(\frac{1}{n^2}), \\ R_{n,i}^2 = \pi q(1-\frac{q}{p})^2n^4 + O(n^2), & R_{n,j}^2 = \pi pn^2 + O(1). \end{cases}$$

In order to verify condition (H3), we need the following observations of the eigenvalues.

1. Each of the two branches of eigenvalues is distinct within itself. This can be verified by showing that $-\lambda_{n,i}^2, i=1,2$, are strictly monotonically increasing functions of n^2; see Supplement 2. Moreover, $\inf_{n\geq 1}|\lambda_{n+1,i}^{\pm} - \lambda_{n,i}^{\pm}| = \gamma_i > 0,\ i=1,2$, by the asymptotic expansions (4.30) and (4.31).
2. $\inf_{n\geq 1}|\lambda_{n,1}^{\pm} - \lambda_{n,2}^{\pm}| = \gamma_3 > 0$. This follows from the fact that $\lambda_{n,1}^2 - \lambda_{n,2}^2 > 0$ for all $n\geq 1$ and the asymptotic expansions (4.30) and (4.31).
3. Multiplicity of each eigenvalue is less than two. For any $1\leq m<n$, there exists $r=p/q$ such that $\lambda_{n,1}=\lambda_{m,2}$, i.e., double eigenvalues occur. This can be verified by showing that the function $f(r)=(\lambda_{n,1}^2-\lambda_{m,2}^2)/q$ changes sign on $(0,\infty)$ (see Supplement 3).
4. When $p\neq q$, the gap condition (H4) never holds. In fact, if $\sqrt{p/q}=k/l,\ k,l\in\mathbb{N}$, is a rational number, we have $\lambda_{kj,1}^2 - \lambda_{lj,2}^2 = O(1)$ for $p>q$ and $\lambda_{lj,1}^2 - \lambda_{kj,2}^2 = O(1)$ for $p<q$ as $j\to\infty$. See Supplement 4 for the case when $\sqrt{p/q}$ is an irrational number.

Choose $\gamma = \min\{\gamma_1, \gamma_2, \gamma_3, 2|\lambda_{1,1}^+|\}$. From the above observations, we know that

(4.32)
$$\Sigma_\gamma = \{c_1 Z_{n,1}^\pm + c_2 Z_{m,2}^\pm \mid |c_1|^2 + |c_2|^2 = 1,\ |\lambda_{n,1}^\pm - \lambda_{m,2}^\pm| < \gamma,\ m, n \in \mathbb{N},\ c_1, c_2 \in \mathbb{C}\}.$$

For any $c_1 Z_{n,1}^\pm + c_2 Z_{m,2}^\pm \in \Sigma_\gamma$, by $\gamma \le \gamma_3$ we have $n \neq m$, and

$$\begin{aligned}\Gamma(m, n, c_1, c_2) &\equiv -\langle B(c_1 Z_{n,1}^\pm + c_2 Z_{m,2}^\pm)\ ,\ c_1 Z_{n,1}^\pm + c_2 Z_{m,2}^\pm\rangle \\ &= \int_0^\pi d_1(x) \left| \frac{c_1 \lambda_{n,1}^+}{R_{n,1}} \sin nx + \frac{c_2 \lambda_{m,2}^+}{R_{m,2}} \sin mx \right|^2 \mathrm{d}x \\ &\quad + \int_0^\pi d_2(x) \left| \frac{c_1 \lambda_{n,1}^+ S_{n,1}}{R_{n,1}} \cos nx + \frac{c_2 \lambda_{m,2}^+ S_{m,2}}{R_{m,2}} \cos mx \right|^2 \mathrm{d}x. \qquad (4.33)\end{aligned}$$

Thus (H3) holds if and only if

$$\inf\{\Gamma(m, n, c_1, c_2) \mid m \neq n, |c_1|^2 + |c_2|^2 = 1, m, n \in \mathbb{N}, c_1, c_2 \in \mathbb{C}\} > 0. \qquad (4.34)$$

For example, we take

(4.35)
$$d_i(x) = \alpha_i(1 + \beta_i \cos k_i x), \quad \alpha_i \ge 0,\ \alpha_1^2 + \alpha_2^2 \neq 0,\ |\beta_i| < 2,\ k_i \in \mathbb{N},\ \ i = 1,\ 2.$$

Using

$$\left| \int_0^\pi \cos k_2 x \cos nx \cos mx \mathrm{d}x \right| \le \frac{\pi}{4},$$

$$\left| \int_0^\pi \cos k_1 x \sin nx \sin mx \mathrm{d}x \right| \begin{cases} = 0, & k_1 = 2n \text{ or } 2m, \\ \le \frac{\pi}{4}, & \text{otherwise}, \end{cases}$$

we deduce that

$$\begin{aligned}\Gamma(m, n, c_1, c_2) &\ge \frac{\pi}{2}\alpha_1 \left(1 - \frac{|\beta_1|}{2}\right) \left(\frac{-\lambda_{n,1}^2}{R_{n,1}^2}|c_1|^2 + \frac{-\lambda_{m,2}^2}{R_{m,2}^2}|c_2|^2 \right) \\ &\quad + \frac{\pi}{2}\alpha_2 \left(1 - \frac{|\beta_2|}{2}\right) \left(\frac{-\lambda_{n,1}^2 S_{n,1}^2}{R_{n,1}^2}|c_1|^2 + \frac{-\lambda_{m,2}^2 S_{m,2}^2}{R_{m,2}^2}|c_2|^2 \right) \\ &\ge \frac{\pi}{2} \min(\eta_1, \eta_2),\end{aligned}$$

where we have put

$$\eta_1 = \inf_{n \ge 1} \left(\alpha_1 \left(1 - \frac{|\beta_1|}{2}\right) \frac{-\lambda_{n,1}^2}{R_{n,1}^2} + \alpha_2 \left(1 - \frac{|\beta_2|}{2}\right) \frac{-\lambda_{n,1}^2 S_{n,1}^2}{R_{n,1}^2} \right),$$

$$\eta_2 = \inf_{m \ge 1} \left(\alpha_1 \left(1 - \frac{|\beta_1|}{2}\right) \frac{-\lambda_{m,2}^2}{R_{m,2}^2} + \alpha_2 \left(1 - \frac{|\beta_2|}{2}\right) \frac{-\lambda_{m,2}^2 S_{m,2}^2}{R_{m,2}^2} \right).$$

Now, using the asymptotic expansions (4.30) and (4.31), we can easily conclude the following.

1. When $p = q$, (H3) holds even if either α_1 or α_2 is zero. Therefore, by Theorem 2.1, $S_\varepsilon(t)$ is exponentially stable if ε is small enough. This means that when the two wave speeds are the same, only one displacement or rotation angle damping is sufficient for the exponential energy decay in the Timoshenko beam.
2. When $p \neq q$, (H3) holds if both α_1 and α_2 are positive. Therefore, $S_\varepsilon(t)$ is exponentially stable if ε is small enough. On the other hand, for $d_1(x) \equiv 0$ or $d_2(x) \equiv 0$, it is easy to see that $S_\varepsilon(t)$ is not exponentially stable for any $\varepsilon > 0$. This means that when the two wave speeds are different, the displacement and rotation angle dampings are necessary for the exponential energy decay in the Timoshenko beam.

5. Technical supplements.

SUPPLEMENT 1. *Let* $0 < C_\gamma \leq N_b$, *and*

$$g(x) = \frac{\sqrt{N_b^2 + C_\gamma(C_\gamma + x)} - N_b}{\sqrt{N_b^2 - x^2}}.$$

Then g *is a monotonically increasing function on* $(-C_\gamma, N_b)$.

Proof. Write the function g in the following form:

$$g(x) = \frac{C_\gamma}{\sqrt{N_b - x}}\sqrt{1 - \frac{N_b - C_\gamma}{N_b + x}}\left(\sqrt{\frac{N_b^2}{C_\gamma + x} + C_\gamma} + \frac{N_b}{\sqrt{C_\gamma + x}}\right)^{-1}.$$

Then the monotony of g follows from the fact that all the factors are positive monotonically increasing functions on $(-C_\gamma, N_b)$. □

SUPPLEMENT 2. $-\lambda_{n,i}^2$, $i = 1, 2$, *are monotonic increasing functions of* n^2.

Proof. It is obvious that the conclusion holds for $-\lambda_{n,2}^2$. Let

$$\begin{aligned} f(x) &= (p+q)x + p - \sqrt{[(p-q)x + p]^2 + 4pqx} \\ &= (p+q)x + p - \sqrt{[(p+q)x + p]^2 - 4pqx^2}. \end{aligned}$$

Then $2f(n^2) = -\lambda_{n,2}^2$. Since

$$\begin{aligned} f'(x) &= (p+q) - \frac{[(p+q)x + p](p+q) - 4pqx}{\sqrt{[(p+q)x + p]^2 - 4pqx^2}} \\ &= (p+q)\left[1 - \frac{(p+q)x + p - 4pq(p+q)^{-1}x}{\sqrt{[(p+q)x + p]^2 - 4pqx^2}}\right] \end{aligned}$$

and the fraction in the bracket is strictly less than one, we know that $f'(x) > 0$ for all $x > 0$. □

SUPPLEMENT 3. *For any* $1 \leq m < n$, *there exist* $p, q > 0$ *such that* $\lambda_{n,1}^2 = \lambda_{m,2}^2$.

Proof. Let $r = p/q$, and

$$\begin{aligned} f(r) &= \frac{1}{q}(\lambda_{n,1}^2 - \lambda_{m,2}^2) \\ &= (r+1)(m^2 - n^2) + \sqrt{[(r-1)n^2 + r]^2 + 4rn^2} + \sqrt{[(r-1)m^2 + r]^2 + 4rm^2}, \end{aligned}$$

which is continuous for $r \in (0, +\infty)$. Moreover, we have

$$\lim_{r\to 0^+} f(r) = m^2 - n^2 < 0, \qquad \lim_{r\to+\infty} f(r) = +\infty. \tag{5.1}$$

This proves that for a certain ratio of p and q, there exist double eigenvalues. □

SUPPLEMENT 4. *Let $\sqrt{p/q}$ be an irrational number; then there exist sequences of integers $k_j \to +\infty$, $l_j \to +\infty$, such that $qk_j^2 - pl_j^2 = O(1)$.*

Proof. By a result in number theory [5, p. 140], for any $j \geq 1$, there exists a rational number $\frac{k_j}{l_j}$ with $l_j > j$ such that

$$\left|\sqrt{\frac{p}{q}} - \frac{k_j}{l_j}\right| \leq \frac{1}{l_j^2}, \quad \text{i.e.,} \quad \left|l_j\sqrt{\frac{p}{q}} - k_j\right| \leq \frac{1}{l_j}.$$

Thus

$$\begin{aligned} |qk_j^2 - pl_j^2| &= q\left(l_j\sqrt{\frac{p}{q}} + k_j\right)\left|l_j\sqrt{\frac{p}{q}} - k_j\right| \\ &\leq ql_j\left(2\sqrt{\frac{p}{q}} + 1\right)\frac{1}{l_j} = 2\sqrt{pq} + q. \end{aligned}$$ □

SERIES EXPANSIONS FOR THE EVOLUTION OF MECHANICAL CONTROL SYSTEMS*

FRANCESCO BULLO†

Abstract. This paper presents a series expansion that describes the evolution of a mechanical system starting at rest and subject to a time-varying external force. Mechanical systems are presented as second-order systems on a configuration manifold via the notion of affine connections. The series expansion is derived by exploiting the homogeneity property of mechanical systems and the variations of constant formula. A convergence analysis is obtained using some analytic functions and combinatorial analysis results. This expansion provides a rigorous means of analyzing locomotion gaits in robotics and lays the foundation for the design of motion control algorithms for a large class of underactuated mechanical systems.

Key words. series expansions, control of mechanical systems, nonlinear controllability

1. Introduction.

The general purpose of this work is to develop an innovative and powerful control and analysis method for underactuated mechanical control systems. This paper introduces a series expansion that characterizes the evolution of a mechanical system starting at rest and subject to an open loop time-varying force. This tool should prove useful in the study of robotic locomotion and in the design of motion control algorithms.

1.1. Series expansions and their control applications.

Original works on perturbation methods and series expansions in mechanics go back to Poincaré and Lagrange. Magnus [33] describes the evolution of systems on a Lie group. Chen [14], Fliess [17], and Sussmann [42] develop a general framework to describe the evolution of a nonlinear system via the so-called Chen–Fliess series and its factorization. Related work on the "chronological calculus" formalism was developed by Agrachev and Gamkrelidze [2].

Within the context of modern geometric control theory, series expansions play a key role in the study of nonlinear controllability. Small-time local controllability (STLC) was studied, for example, by Sussmann [41, 43], Agrachev and Gamkrelidze [3], and Kawski [22, 24]. Controllability along trajectories was investigated by Bianchini and Stefani in [8]. Finally, the work by Lewis and Murray [32] on configuration controllability for mechanical control systems is much related to this work.

Motion planning problems provide a second important use of series expansions. A rich literature is available on the motion planning problem for kinematic systems, that is, systems without drift. Numerous approaches include algorithms for chained systems by Murray and Sastry [36], for systems on Lie groups by Leonard and Krishnaprasad [30] and Kolmanovsky and McClamroch [26], and the very general solution

proposed by Lafferriere and Sussmann [28]. These works rely on the following observation: an explicit expression for the "input history to final displacement" map simplifies dramatically the two-point boundary value problem that defines the motion planning task. In other words, whenever an explicit expression (provided by a series expansion) for the evolution of the control system is available, the two-point boundary value problem is reduced to a low dimensional nonlinear program. Accordingly, motion control algorithms are designed by inverting this "input history to final displacement" map.

Finally, series expansions and the techniques developed in this paper have potential relevance in several areas including averaging and vibrational stabilization [6, 10], high-order variations for use in optimal control [25], digital multirate sampling of nonlinear systems [18], and model reduction [19].

Series expansions that specifically exploit the structure of mechanical systems have so far not been computed. However, some preliminary progress in this direction has been obtained by Bullo, Leonard, and Lewis [12, 13] via a perturbation analysis. Under the assumption of small amplitude forcing, the authors compute the initial terms of a Taylor series describing the forced evolution. The results are then found to be in agreement with the controllability analysis in [32]. A different but related research direction has focused on open loop vibrational control and the recent progress we described in [10] is related to this paper. A preliminary short version of this work appeared in [11].

1.2. Summary of results. The main contribution of this paper is a series that describes the evolution of a forced mechanical system starting from rest. Mechanical systems are characterized as second-order systems on a configuration manifold using the theory of affine connections. By exploiting the problem's structure, the system's evolution is described as a flow on the configuration space (n-dimensional) instead of a series on the full phase space ($2n$-dimensional).

The treatment relies on some differential geometric tools to describe the homogeneity properties of nonlinear mechanical systems and the variations of constants formula; see [2] and [23]. The homogeneous structure of nonlinear mechanical systems leads to a recursive procedure to compute the forced solution to a mechanical system. The terms in the series are computed recursively via time integrals and certain Lie brackets called symmetric products [32].

The series is guaranteed to convergence in a strong sense for small amplitude inputs and bounded final time. The convergence analysis is sophisticated and relies on various concepts from complex and combinatorial analysis. Following the analysis by Agrachev and Gamkrelidze in [2, Proposition 2.1], a bound is computed for every term of the series so that a notion of order is established. However, as opposed to [2], only a recursive expression for the series terms is available, and this much complicates the treatment. The key idea is to obtain a recursive bound not only on the terms of the expansion but also on their partial derivative.

The series expansion can be computed in simplified fashion in two settings. For simple Hamiltonian systems with integrable forces, the main theorem can be interpreted as a statement on gradient and Hamilton flows: the flow of a Hamiltonian system forced from rest can be written as a (time-varying) gradient flow. For invariant systems on groups, the series can be computed via algebraic manipulations (no differentiations). In other words, the computations are performed on the corresponding Lie algebra, and the theorem reduces to a statement on the flow of polynomial control systems. These results agree with and supersede the preliminary results in

in [12, 13].

Finally, some numerical simulations of a three degree of freedom robotic manipulator are performed. Truncating the series expansion at increasingly higher order, various approximations are obtained, and their accuracy is illustrated via some numerical data.

1.3. Organization. The paper is organized as follows. In section 2 we present the model and the homogeneity properties of a large class of mechanical control systems. Most ideas are common in the literature; some are not. In section 3 we present the main result of the paper, that is, a convergent series describing the evolution of a forced mechanical system. Section 4 contains some applications and extensions, including the simple Hamiltonian and the invariant system settings, as well as some simulations. We present our conclusions in section 5.

2. Some geometric and analytical properties of mechanical systems. We present a geometric definition of mechanical control systems, study their homogeneous properties, and provide bounds using analytic function theory.

2.1. Natural objects on manifolds. We review some basic definitions to fix some notation; see [1]. All the objects we consider are smooth in the sense of analytic. Let Q be a finite dimensional, Hausdorff, second countable manifold, let q be a point on it, let v_q be a point on TQ, let $I \subset \mathbb{R}$ be a real interval, and let $\gamma : I \to Q$ be a curve on Q. We let 0_q denote the zero velocity tangent vector on the tangent space T_qQ. Let $\pi : TQ \to Q$ denote the usual projection on the tangent bundle, that is, $\pi(v_q) = q$. On the manifold Q, we will define scalar functions $q \mapsto f(q) \in \mathbb{R}$ and vector fields $q \mapsto X(q) \in T_qQ$. Lie derivatives of functions and Lie brackets of vector fields are denoted by

$$\mathcal{L}_X f \qquad \text{and} \qquad \mathcal{L}_X Y = [X, Y].$$

2.2. Variation of constants formula in geometric terms. This section presents a quick review of the variation of constants formula within the chronological calculus formalism introduced in [2]; see also [38]. Given a vector field Y and a diffeomorphism ϕ, the *pull-back of* Y *along* ϕ, denoted ϕ^*Y, is a vector field defined by

$$(\phi^*Y)(q) \triangleq T_q\phi^{-1} \circ Y \circ \phi,$$

where $T_q\phi^{-1}$ is the tangent map to ϕ^{-1}; see [1]. In a system of local coordinates $(q^1, \ldots, q^n)$, a vector field is written as $Y(q) = Y^i(q)\ \partial/\partial q^i$, and the pull-back of Y along ϕ is

$$(\phi^*Y)^i(q) = \frac{\partial(\phi^{-1})^i}{\partial q^j} Y^j(\phi(q)),$$

where the summation convention is enforced here and in what follows.

A time-varying vector field $(q, t) \mapsto X(q, t)$ gives rise to the initial value problem

$$\dot{q}(t) = X(q, t), \qquad q(0) = q_0,$$

and its solution at time T, which we refer to as the flow of X, is denoted by $q(T) = \Phi^X_{0,T}(q_0)$. We shall usually assume time-varying quantities to be integrable with respect to time. Given a time-varying vector field $X(q, t)$, we denote its definite time

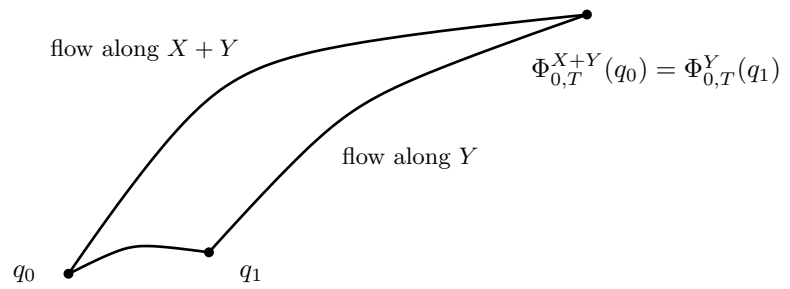

FIG. 2.1. *The flow along $X+Y$ is written as the flow along Y with initial condition q_q. The "variation" q_1 is computed via the variation of constants formula as the flow along $(\Phi_{0,t}^{Y})^* X$ for time $[0,T]$ with initial condition q_0.*

integral from time 0 to time T by

$$\overline{X}(q,T) = \int_0^T X(q,\tau)d\tau. \tag{2.1}$$

The integral takes place over the linear space T_qQ at fixed $q \in Q$. This operation can be defined in two ways. Given a coordinates chart about q, the integral is well defined in the coordinate system. (This definition suffices for the purpose of this paper, since the analysis is local.) A global coordinate-free definition is obtained, providing sufficient conditions in order for T_qQ to be a Banach space and introducing the Cauchy–Bochner integral; see [1, p. 61].

Next, consider the initial value problem

$$\dot{q}(t) = X(q,t) + Y(q,t), \qquad q(0) = q_0, \tag{2.2}$$

where X and Y are analytic time-varying vector fields. If we regard X as a perturbation to the vector field Y, we can describe the flow of $X+Y$ in terms of a nominal and perturbed flow. The following relationship is referred to as the *variation of constants* formula and describes the perturbed flow:

$$\Phi_{0,t}^{X+Y} = \Phi_{0,t}^{Y} \circ \Phi_{0,t}^{(\Phi_{0,t}^{Y})^* X}. \tag{2.3}$$

The result is illustrated in Figure 2.1 and proven in [2, equation (3.15)]; see also [10, Appendix A.1]. The result can be alternatively stated as follows. For all $T \geq 0$, the final value $q(T)$ of the curve $q : [0,T] \to M$ solution to the initial value problem (2.2) is also the final value of the curve solution to

$$\dot{q}(s) = Y(q,s), \qquad q(0) = z(T), \tag{2.4}$$

where $z : [0,T] \to M$ is the solution to the initial value problem

$$\dot{z}(s) = \left((\Phi_{0,s}^{Y})^* X\right)(z), \qquad z(0) = q_0. \tag{2.5}$$

The differential equation (2.5) is referred to as the "pulled back" or the "adjoint" system in [20]. If both X and Y are time invariant, then the classic infinitesimal Campbell–Backer–Hausdorff formula (see [21]) provides a means of computing the

pull-back:

$$(\Phi^Y_{0,t})^* X = \sum_{k=0}^{\infty} \mathrm{ad}^k_Y X \, \frac{t^k}{k!}.$$

If instead X and Y are time-varying, a generalized expression is (see [2])

$$(\Phi^Y_{0,t})^* X(q,t) = X(q,t) + \sum_{k=1}^{\infty} \int_0^t \cdots \int_0^{s_{k-1}} \left(\mathrm{ad}_{Y(q,s_k)} \ldots \mathrm{ad}_{Y(q,s_1)} X(q,t)\right) \, ds_k \ldots ds_1. \tag{2.6}$$

Just like in the classic Campbell–Backer–Hausdorff formula (see [44]), the convergence of the series expansion in the previous equation is a delicate manner. Sufficient conditions for local convergence are given in [2, Propositions 2.1 and 3.1]. For our analysis, the following straightforward statement suffices. If all the Lie brackets $\mathrm{ad}_{Y(s_k)} \ldots \mathrm{ad}_{Y(s_1)} X$ vanish for all k greater than a given N, then the series in (2.6) becomes a finite sum, and it readily converges.

2.3. Affine connections. We refer to [16, 29] for a comprehensive treatment on affine connections and Riemannian geometry. An *affine connection* on Q is a smooth map that assigns to a pair of vector fields X, Y a vector field $\nabla_X Y$ such that for any function f and for any third vector field Z

(i) $\nabla_{fX+Y} Z = f \nabla_X Z + \nabla_Y Z$,
(ii) $\nabla_X (fY + Z) = (\mathcal{L}_X f) Y + f \nabla_X Y + \nabla_X Z$.

We also say that $\nabla_X Y$ is the covariant derivative of Y with respect to X. Vector fields can also be covariantly differentiated along curves, and this concept will be instrumental in writing the Euler–Lagrange equations. Consider a smooth curve $\gamma : [0,1] \to Q$ and a vector field along γ, that is, a map $v : [0,1] \to TQ$ such that $\pi(v(t)) = \gamma(t)$ for all $t \in [0,1]$. Let V be a smooth vector field satisfying $V(\gamma(t)) = v(t)$. The covariant derivative of the vector field v along γ is defined by

$$\frac{Dv(t)}{dt} \triangleq \nabla_{\dot\gamma(t)} v(t) = \nabla_{\dot\gamma(t)} V(q)\big|_{q=\gamma(t)}.$$

It can be shown that this definition is independent of the choice of V. In a system of local coordinates $(q^1, \ldots, q^n)$, an affine connection is uniquely determined by its Christoffel symbols[1] Γ^i_{ij},

$$\nabla_{\frac{\partial}{\partial q^i}} \left(\frac{\partial}{\partial q^j} \right) = \Gamma^k_{ij} \frac{\partial}{\partial q^k},$$

and, accordingly, the covariant derivative of a vector field is written as

$$\nabla_X Y = \left(\frac{\partial Y^i}{\partial q^j} X^j + \Gamma^i_{jk} X^j Y^k \right) \frac{\partial}{\partial q^i}.$$

[1] We here refer to the Γ^k_{ij} functions as Christoffel symbols, even without requiring ∇ to be a Levi–Civita connection.

2.4. Control systems described by affine connections. We introduce a class of control systems that is a generalization of Lagrangian control systems. This approach to the modeling of vehicles and robotic manipulators is common to a number of recent works; see [9, 32, 31, 10]. A *control system described by an affine connection* is defined by the following objects:

(i) an n-dimensional configuration manifold Q, with $q \in Q$ being the configuration of the system and $v_q \in T_qQ$ being the system's velocity,

(ii) an affine connection ∇ on Q, whose Christoffel symbols are $\{\Gamma^i_{jk} : i, j, k \in \{1, \dots, n\}\}$,

(iii) a time-varying vector field Y on Q defining the input force.

The corresponding equations of motion are written as

$$\frac{Dv_q}{dt} = Y(q, t) \tag{2.7}$$

or, equivalently, in coordinates as

$$\dot{q}^i = v^i, \qquad \dot{v}^i + \Gamma^i_{jk}(q) v^j v^k = Y^i(q, t), \tag{2.8}$$

where the indices i, j, k run from 1 to n and where $v_q = v^i \frac{\partial}{\partial q^i}$. These equations are a generalized form of the Euler–Lagrange equations.

Remark 2.1. This definition of control systems described by an affine connection provides a convenient means of treating various classes of Lagrangian mechanical systems. For example, systems with nonholonomic constraints are described within this framework in [31]. We will treat in more details "simple Hamiltonian systems" in section 4.2 and "invariant systems on Lie groups" in section 4.3. A more detailed exposition is presented in [10].

The second-order system in (2.7) can be written as a first-order differential equation on the tangent bundle TQ. Using $\{\frac{\partial}{\partial q^i}, \frac{\partial}{\partial v^i}\}$ as a basis for the tangent bundle to TQ, we define

$$Z(v_q) = v^i \frac{\partial}{\partial q^i} - \Gamma(q)^i_{jk} v^j v^k \frac{\partial}{\partial v^i} \quad \text{and} \quad Y^{\text{lift}}(v_q, t) = Y^i(q, t) \frac{\partial}{\partial v^i},$$

so that the control system is rewritten as

$$\dot{v}_q = Z(v_q) + Y^{\text{lift}}(v_q, t). \tag{2.9}$$

We refer to [32, 29] for coordinate independent definitions of the lifting operation $Y \to Y^{\text{lift}}$ and of the drift vector field Z.

2.5. Homogeneity and Lie algebraic structure. One fundamental structure of the control system in (2.7) is the polynomial dependence of the vector fields Z and Y^{lift} on the velocity variables v^i_q. This structure is reflected in the Lie brackets computations involving Z and Y^{lift}; see related ideas in [40, 10].

We here rely on the notion of *geometric homogeneity*[2] as described in [23]. Given two vector fields X and X_E, we say that the vector field X is homogeneous with degree m with respect to X_E if

$$[X_E, X] = mX.$$

[2]Geometric homogeneity corresponds to the existence of an (infinitesimal) symmetry in the equations of motion. For control systems described by an affine connection the symmetry is invariance under affine time-scaling transformations.

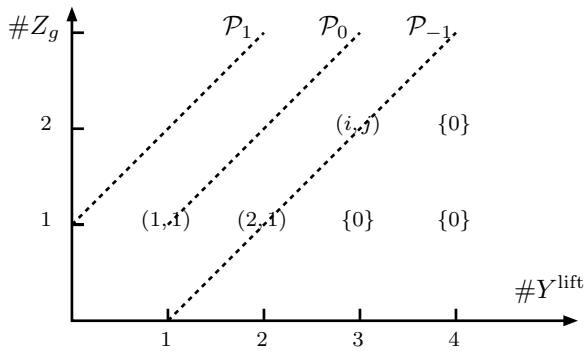

FIG. 2.2. *Table of Lie brackets between the drift vector field Z and the input vector field Y^{lift}. The (i,j)th position contains Lie brackets with i copies of Y^{lift} and j copies of Z. The corresponding homogeneous degree is $j-i$. All Lie brackets to the right of $\mathcal{P}_{-1}$ exactly vanish. All Lie brackets to the left of $\mathcal{P}_{-1}$ vanish when evaluated at $v_q = 0_q$.*

For control systems described by an affine connection, we introduce the Liouville vector field on TQ (see [7, pp. 19 and 29]) as

$$L(v_q) = v^i \frac{\partial}{\partial v^i},$$

where we recall $v_q = v^i \frac{\partial}{\partial q^i}$. The key mathematical relationships between vector fields on TQ are

$$[L, Z] = (+1)Z \quad \text{and} \quad [L, Y^{\text{lift}}] = (-1)Y^{\text{lift}}.$$

Hence the vector field Z is homogeneous of degree $+1$, and the vector field Y^{lift} is homogeneous of degree -1 with respect to the Liouville vector field. Let $\mathcal{P}_j$ be the set of vector fields on TQ of homogeneous degree j, so that

$$Z \in \mathcal{P}_1 \quad \text{and} \quad Y^{\text{lift}} \in \mathcal{P}_{-1}.$$

The sets $\mathcal{P}_j$ enjoy various interesting properties. Figure 2.2 illustrates them, their proof is via direct computation, and they are listed as follows:

(i) $[\mathcal{P}_i, \mathcal{P}_j] \subset \mathcal{P}_{i+j}$, that is, the Lie bracket between a vector field in $\mathcal{P}_i$ and a vector field in $\mathcal{P}_j$ belongs to $\mathcal{P}_{i+j}$.
(ii) $\mathcal{P}_k = \{0\}$ for all $k \leq -2$.
(iii) For all $X \in \mathcal{P}_k$ with $k \geq 1$, $X(0_q) = 0_q$.
(iv) Every $X \in \mathcal{P}_{-1}$ is the lift of a vector field on Q.

It is helpful to provide an interpretation of $\mathcal{P}_i$ in coordinates. In a system of local coordinates, let $\mathcal{H}_i(q, v_q)$ be the set of scalar functions on $TQ = \mathbb{R}^{2n}$, which are arbitrary functions of q and which are homogeneous polynomials in $\{v^1, \ldots, v^n\}$ of degree i. $\mathcal{P}_i$ is the set of vector fields on $\mathbb{R}^{2n}$ with the first n components in $\mathcal{H}_i$ and the second n components in $\mathcal{H}_{i+1}$.

Finally, it is of interest to focus on the Lie bracket $[Y_b^{\text{lift}}, [Z, Y_a^{\text{lift}}]]$, where Y_a, Y_b are two vector fields on Q. This operation will play an important role in later computations. Since this Lie bracket belongs to $\mathcal{P}_{-1}$, there must exist a vector field on Q, which we denote $\langle Y_a : Y_b \rangle$, such that

$$\langle Y_a : Y_b \rangle^{\text{lift}} = [Y_b^{\text{lift}}, [Z, Y_a^{\text{lift}}]].$$

Such a vector field is called the *symmetric product* between Y_b and Y_a, and a direct computation shows that it satisfies

$$\langle Y_b : Y_a \rangle = \nabla_{Y_a} Y_b + \nabla_{Y_b} Y_a,$$

or, equivalently, in coordinates

$$\langle Y_b : Y_a \rangle^i = \frac{\partial Y_a^i}{\partial q^j} Y_b^j + \frac{\partial Y_b^i}{\partial q^j} Y_a^j + \Gamma_{jk}^i \left(Y_a^j Y_b^k + Y_a^k Y_b^j \right).$$

The adjective "symmetric" comes from the equality $\langle Y_a : Y_b \rangle = \langle Y_b : Y_a \rangle$.

2.6. Integrable flows. Here we compute solutions to a few differential equations defined by certain homogeneous vector fields. In particular, significant simplifications take place in the following two cases. First, let $(q,t) \mapsto X(q,t)$ be a time-varying vector field on Q, and consider the differential equation on TQ

$$\dot{v}_q = X^{\text{lift}}(v_q, t) \tag{2.10}$$

with initial condition $v_q(0) = v_0 \in T_{q_0}Q$. It can be seen that

$$\Phi_{0,t}^{X^{\text{lift}}}(v_0) = v_0 + \int_0^t X(q_0, s) ds, \tag{2.11}$$

that is, in coordinates

$$\Phi_{0,t}^{X^{\text{lift}}} \left(\begin{bmatrix} q_0 \\ v_0 \end{bmatrix} \right) = \begin{bmatrix} q_0 \\ v_0 + \int_0^t X(q_0, s) ds \end{bmatrix}.$$

Next, let $X_0 \in \mathcal{P}_0$ and $X_1 \in \mathcal{P}_1$, and consider the differential equation

$$\dot{v}_q = X_0(v_q, t) + X_1(v_q, t) \tag{2.12}$$

with initial condition $v_q(0) = 0_{q_0} \in T_{q_0}Q$. Define the vector field $X_{0,1}$ on Q and its flow $\zeta : [0,T] \mapsto Q$ via

$$\begin{aligned} X_{0,1} &= T\pi \circ X_0, \\ \zeta(t) &= \Phi_{0,t}^{X_{0,1}}(q_0), \end{aligned}$$

where $T\pi : TTQ \to TQ$ is the tangent map to the projection map $\pi : TQ \to Q$. In coordinates, this vector field consists of the first n components of the vector field $X_0 = \begin{bmatrix} X_{0,1}(q,t)', & X_{0,2}(q,v,t)' \end{bmatrix}'$ on TQ. It can be seen that

$$\Phi_{0,t}^{X_0 + X_1}(0_{q_0}) = 0_{\zeta(t)},$$

that is, in coordinates

$$\Phi_{0,t}^{X_0 + X_1} \left(\begin{bmatrix} q_0 \\ 0 \end{bmatrix} \right) = \begin{bmatrix} \zeta(t) \\ 0 \end{bmatrix}.$$

The key observation in proving this statement is that the components of $X_{0,2}$ and X_1 are polynomials in $\{v^1, \ldots, v^n\}$ of degree at least 1. Since the initial velocity is assumed to be zero, v_q remains zero for all time.

2.7. Analyticity and bounds over complex neighborhoods. In this section we introduce a norm on the set of analytic vector fields over a compact subset of Q. We also provide bounds to partial derivatives of analytic functions. The bounds are *not* coordinate-free, i.e., they depend on the specific selection of a coordinate system. Accordingly, the treatment here assumes $Q = \mathbb{R}^n$.

Let q_0 be a point on $\mathbb{R}^n$, let σ be a positive scalar, and define the complex σ-neighborhood of q_0 in $\mathbb{C}^n$ as

$$B_\sigma(q_0) = \{z \in \mathbb{C}^n : \|z - q_0\| < \sigma\}.$$

Let f be a real analytic function on $\mathbb{R}^n$ that admits a bounded analytic continuation over $B_\sigma(q_0)$. The norm of f is defined as

$$\|f\|_\sigma \triangleq \max_{z \in B_\sigma(q_0)} |f(z)|,$$

where f denotes both the function over $\mathbb{R}^n$ and its analytic continuation. Given a time-varying vector field $(q,t) \mapsto Y(q,t) = Y_t(q)$, let Y_t^i be its ith component with respect to the usual basis on $\mathbb{R}^n$. Assuming $t \in [0,T]$ and assuming that every component function Y_t^i is analytic over $B_\sigma(q_0)$, we define the norm of Y as

$$\|Y\|_{\sigma,T} \triangleq \max_{t\in[0,T]} \max_{i\in\{1,\dots,n\}} \|Y_t^i\|_\sigma.$$

In what follows, we will often simplify notation by neglecting the subscript T in the norm of a time-varying vector field. Finally, given an affine connection ∇ with Christoffel symbols $\{\Gamma_{jk}^i : i,j,k \in \{1,\dots,n\}\}$, we introduce the notation

$$\|\Gamma\|_\sigma \triangleq \max_{ijk} \left\|\Gamma_{jk}^i\right\|_\sigma .$$

Next, we examine the norm of partial derivatives of these objects. Recall that the Cauchy integral representation of analytic functions leads to bounds on high-order derivatives of analytic functions in terms of the norm of the functions themselves; see the so-called Cauchy estimates in [27, section 2.3] and [37]. Let $(i_1,\dots,i_m)$ be a collection of integers belonging to $\{1,\dots,n\}$, and let σ' be a positive real strictly less than σ. It is known that

$$\|\partial^m f\|_{\sigma'} \triangleq \max_{i_1,\dots,i_m} \left\| \frac{\partial^m f}{\partial q_{i_1} \cdots \partial q_{i_m}} \right\|_{\sigma'} \leq m!\, \delta^m \|f\|_\sigma,$$

where $\delta = n/(\sigma - \sigma')$. The quantity $\partial^m f / \partial q_{i_1} \cdots \partial q_{i_m}$ is a real function; it is bounded by bounding its analytic continuation over $B_\sigma(q_0)$. Similarly, for vector fields

$$\|\partial^m Y\|_{\sigma'} \triangleq \max_{t\in[0,T]} \max_{i,i_1,\dots,i_m} \left\| \frac{\partial^m Y_t^i}{\partial q_{i_1} \cdots \partial q_{i_m}} \right\|_{\sigma'} \leq m!\, \delta^m \|Y\|_\sigma,$$

and for the Christoffel symbols

$$\|\partial^m \Gamma\|_{\sigma'} \triangleq \max_{i,j,k,i_1,\dots,i_m} \left\| \frac{\partial^m \Gamma_{jk}^i}{\partial q_{i_1} \cdots \partial q_{i_m}} \right\|_{\sigma'} \leq m!\, \delta^m \|\Gamma\|_\sigma.$$

3. A series expansion for mechanical control systems. This section describes first a preliminary bound, and then the main result of the paper, that is, a series expansion describing the evolution of a forced control system starting at rest.

Problem 3.1. Assume that the functions $q \mapsto \Gamma^i_{jk}(q)$ and the vector field $(q,t) \mapsto Y(q,t)$ are analytic in $q \in Q$ and integrable in $t \in [0,T]$ for some positive time T. Let $\gamma : [0,T] \mapsto Q$ be the solution to the differential equation (2.7) with initial condition $\dot\gamma(0) = 0_{q_0}$. Characterize γ as a series expansion containing iterated symmetric products and time integrals of Y.

We start with a conservative bound.

LEMMA 3.2 (bound on evolution). *Consider the system as described in Problem* 3.1. *Select a coordinate system about the point $q_0 \in Q$, and let σ be a positive constant. A sufficient condition for $\gamma([0,T])$ to be a subset of $B_\sigma(q_0)$ is that*

$$\|Y\|_\sigma T^2 < \frac{\eta^2(\sigma n^2 \|\Gamma\|_\sigma)}{n^2\|\Gamma\|_\sigma}, \tag{3.1}$$

where the function $\eta : x \in \mathbb{R}_+ \to [0,\pi/2]$ is the unique solution to $\eta\tan(\eta) = x$.

Proof. Let $T_0 < T$ be the smallest time at which the solution γ reaches the distance $\|\gamma(T_0) - q_0\| = \sigma$. If the solution never reaches this distance, then $\gamma([0,T])$ is obviously a subset of $B_\sigma(q_0)$. Since $\gamma([0,T_0]) \subset B_\sigma(q_0)$ for all $t \in [0,T_0]$, we have the bound $\|\dot\gamma(t)\| \le y(t)$, where

$$\dot y = n^2\|\Gamma\|_\sigma y^2 + \|Y\|_\sigma, \qquad y(0) = 0.$$

The solution to this initial value problem is

$$y(t) = \sqrt{\frac{\|Y\|_\sigma}{n^2\|\Gamma\|_\sigma}}\tan\left(\sqrt{\|Y\|_\sigma n^2\|\Gamma\|_\sigma}\, t\right).$$

Straightforward manipulations show that the condition in (3.1) is equivalent to $Ty(T) < \sigma$. But since y is a monotone function, $T_0 y(T_0) < \sigma$ also. Note that $\|\gamma(0) - q_0\| = 0$ and

$$\frac{d}{dt}\|\gamma(t) - q_0\| \le \|\dot\gamma\| \le y(t) < \sigma/T_0$$

for all $t \in [0,T_0]$. Therefore, $\|\gamma(T_0) - q_0\| < T_0\sigma/T_0$, and the contradiction is now immediate. □

We are now ready to present the main theorem.

THEOREM 3.3 (evolution of a forced mechanical system starting at rest). *Consider the system as described in Problem* 3.1. *Define recursively the time-varying vector fields V_k:*

$$V_1(q,t) = \int_0^t Y(q,s)ds, \tag{3.2}$$

$$V_k(q,t) = -\frac{1}{2}\sum_{j=1}^{k-1}\int_0^t \langle V_j(q,s)\; V_{k-j}(q,s)\rangle ds, \qquad k \ge 2. \tag{3.3}$$

Select a coordinate system about the point $q_0 \in Q$, let $\sigma > \sigma'$ be two positive constants, and assume that

$$\|Y\|_\sigma T^2 < L \triangleq \min\left\{\frac{\sigma - \sigma'}{2^4 n^2(n+1)}, \frac{1}{2^4 n(n+1)\|\Gamma\|_\sigma}, \frac{\eta^2(\sigma' n^2\|\Gamma\|_{\sigma'})}{n^2\|\Gamma\|_{\sigma'}}\right\}. \tag{3.4}$$

Then the solution $\gamma : [0,T] \to Q$ satisfies

$$\dot\gamma(t) = \sum_{k=1}^{+\infty} V_k(\gamma(t),t), \tag{3.5}$$

where V_k satisfies the bound

$$\|V_k\|_{\sigma'} \leq L^{1-k}\, \|Y\|_\sigma^k\, t^{2k-1}, \tag{3.6}$$

and the series $(q,t) \mapsto \sum_{k=1}^\infty V_k(q,t)$ converges absolutely and uniformly for $q \in B_{\sigma'}(q_0)$ and for $t \in [0,T]$.

A few comments on the various steps of the proof are appropriate. First, we investigate how to write the flow of a mechanical control system as the composition of more elementary flows. Two observations play a key role: the homogeneity of system (2.7) renders the computations tractable, and the simplifying procedure can be easily repeated giving rise to an iterative procedure. Second, we prove absolute and uniform convergence of the series expansion resulting from the first formal part of the proof. The proof of the bounds is inspired by the treatment in [2, Proposition 2.1], but it is considerably more complicated here by the recursive nature of the series expansion. Once the series is formally derived and it is proven to be convergent, a limiting argument leads to the final statement in (3.5).

Proof. Part I. *Here we write the solution to* (2.7) *as composition of the flow of two separate vector fields, one of which is defined recursively.*

Let k be a strictly positive integer, let X_k, Y_k, W_k be time-varying vector fields on Q, and let $v_{q,k}$ be a smooth curve on TQ that satisfies the differential equation

$$\begin{aligned} \dot v_{q,k} &= \left(Z + [X_k^{\mathrm{lift}}, Z] + Y_k^{\mathrm{lift}} + W_k^{\mathrm{lift}}\right)(v_{q,k},t), \\ v_{q,k}(0) &= 0_{q_0}. \end{aligned} \tag{3.7}$$

The mechanical system in (2.7) corresponds to setting $k=1$, $X_1 = W_1 = 0$, $Y_1 = Y(q,t)$, and, accordingly, $\dot\gamma(t) = v_{q,1}(t)$. Using the formula in (2.4) and (2.5) discussed in section 2.2, we set

$$v_{q,k}(t) = \Phi_{0,t}^{Y_k^{\mathrm{lift}}}(v_{q,k+1}(t)) \tag{3.8}$$

and

$$\begin{aligned} \dot v_{q,k+1} &= \left(\left(\Phi_{0,t}^{Y_k^{\mathrm{lift}}}\right)^* (Z + [X_k^{\mathrm{lift}}, Z] + W_k^{\mathrm{lift}})\right)(v_{q,k+1}), \\ v_{q,k+1}(0) &= 0_{q_0}, \end{aligned} \tag{3.9}$$

where we compute the pull-back along the flow by means of the infinite series in (2.6). Remarkably, this series reduces to a finite sum. From the discussion in section 2.5 on the Lie algebraic structure of the various vector fields, we have

$$\begin{gathered} \mathrm{ad}_{Y_k^{\mathrm{lift}}}^{m+2} Z = 0, \\ \mathrm{ad}_{Y_k^{\mathrm{lift}}}^{m+1} [X_k^{\mathrm{lift}}, Z] = 0, \quad \mathrm{ad}_{Y_k^{\mathrm{lift}}}^{m} W_k^{\mathrm{lift}} = 0 \end{gathered}$$

for all $m \geq 1$. With a little bookkeeping we can exploit these equalities and compute

$$\begin{aligned}
&\left(\Phi_{0,t}^{Y_k^{\text{lift}}}\right)^* (Z+[X_k^{\text{lift}}, Z] + W_k^{\text{lift}}) \\
&\qquad = Z + [X_k^{\text{lift}}, Z] + W_k^{\text{lift}} + \int_0^t [Y_k^{\text{lift}}(s), \big(Z + [X_k^{\text{lift}}, Z]\big)]ds \\
&\qquad\qquad + \int_0^t \int_0^{s_1} [Y_k^{\text{lift}}(s_2), [Y_k^{\text{lift}}(s_1), Z]]ds_2 ds_1 \\
&\qquad = Z + [X_k^{\text{lift}} + \overline{Y}_k^{\text{lift}}, Z] + [\overline{Y}_k^{\text{lift}}(s), [X_k^{\text{lift}}, Z]] + W_k^{\text{lift}} \\
&\qquad\qquad + \int_0^t \int_0^{s_1} [Y_k^{\text{lift}}(s_2), [Y_k^{\text{lift}}(s_1), Z]]ds_2 ds_1 \\
&\qquad = Z + [X_k^{\text{lift}} + \overline{Y}_k^{\text{lift}}, Z] - \left\langle \overline{Y}_k : X_k \right\rangle^{\text{lift}} + W_k^{\text{lift}} - \frac{1}{2} \left\langle \overline{Y}_k : \overline{Y}_k \right\rangle^{\text{lift}},
\end{aligned}$$

where we have used the $\bar{\cdot}$ notation introduced in (2.1). The last equality also relies on

$$\int_0^t \int_0^{s_1} [Y_k^{\text{lift}}(s_2), [Y_k^{\text{lift}}(s_1), Z]]ds_2 ds_1 = -\frac{1}{2} \left\langle \overline{Y}_k : \overline{Y}_k \right\rangle^{\text{lift}},$$

which follows from an integration by parts and the symmetry of the symmetric product. Remarkably, the differential equation describing the evolution of $v_{k+1}(t)$ is of the same form as (3.7) describing the evolution of $v_{q,k}(t)$, where

$$\begin{aligned}
X_{k+1} &= X_k + \overline{Y}_k, \\
Y_{k+1} + W_{k+1} &= -\left\langle \overline{Y}_k \ : \ X_k + \tfrac{1}{2}\overline{Y}_k \right\rangle + W_k.
\end{aligned}$$

The vector field X_k can be computed and substituted in as

$$\begin{aligned}
X_k &= \sum_{j=1}^{k-1} \overline{Y}_j, \\
Y_{k+1} + W_{k+1} &= -\left\langle \overline{Y}_k \ : \ \sum_{j=1}^{k-1} \overline{Y}_j + \frac{1}{2}\overline{Y}_k \right\rangle + W_k. \qquad (3.10)
\end{aligned}$$

Notice that the quantities Y_k and W_k are not yet uniquely determined. Equation (3.10) is verified for all k if and only if for all m

$$(Y_2 + Y_3 + \cdots + Y_{m+1}) + W_{m+1} = -\sum_{k=1}^{m} \left\langle \overline{Y}_k : \sum_{j=1}^{k-1} \overline{Y}_j + \frac{1}{2}\overline{Y}_k \right\rangle, \qquad (3.11)$$

where we used $W_1 = 0$. Some further manipulation leads to

$$\begin{aligned}
\sum_{k=1}^{m} \left\langle \overline{Y}_k : \sum_{j=1}^{k-1} \overline{Y}_j + \frac{1}{2}\overline{Y}_k \right\rangle &= \sum_{k=1}^{m} \sum_{j=1}^{k-1} \left\langle \overline{Y}_k : \overline{Y}_j \right\rangle + \frac{1}{2} \sum_{k=1}^{m} \left\langle \overline{Y}_k : \overline{Y}_k \right\rangle \\
&= \frac{1}{2} \sum_{j,k=1, j\neq k}^{m} \left\langle \overline{Y}_k : \overline{Y}_j \right\rangle + \frac{1}{2} \sum_{k=1}^{m} \left\langle \overline{Y}_k : \overline{Y}_k \right\rangle \\
&= \frac{1}{2} \sum_{j,k=1}^{m} \left\langle \overline{Y}_k : \overline{Y}_j \right\rangle.
\end{aligned}$$

A selection of $\{Y_i : i \in \{1,\dots,m\}\}$, and W_{m+1} that satisfies (3.11) is

$$Y_i = -\frac{1}{2} \sum_{j,k=1, j+k=i}^{m} \left\langle \overline{Y}_k : \overline{Y}_j \right\rangle = -\frac{1}{2} \sum_{j=1}^{i-1} \left\langle \overline{Y}_j : \overline{Y}_{i-j} \right\rangle, \tag{3.12}$$

$$W_{m+1} = -\frac{1}{2} \sum_{j,k=1, j+k>m}^{m} \left\langle \overline{Y}_k : \overline{Y}_j \right\rangle.$$

Note that (3.12) is a well-defined recursive relationship, and note that the recursive definition of V_k in (3.3) and (3.2) inside the theorem statement corresponds to setting $V_k(q,t) = \overline{Y}_k(q,t)$. The iteration procedure proves that, for any $k \geq 2$, the solution to the original mechanical system $\dot\gamma = v_{q,1} : [0,T] \mapsto TQ$ satisfies

$$\dot\gamma(t) = \left(\Phi_{0,t}^{Y_1^{\text{lift}}} \circ \Phi_{0,t}^{Y_2^{\text{lift}}} \circ \cdots \circ \Phi_{0,t}^{Y_{k-1}^{\text{lift}}} \right) (v_{q,k}(t)),$$

where $v_{q,k} : [0,T] \mapsto TQ$ is the solution to (3.7). The flow $\dot\gamma$ is now written as the composition of k flows, and a first simplification is immediate. For all integers i, j and for all times s_1, s_2 the vector fields Y_i^{lift} and Y_j^{lift} commute, that is,

$$[Y_i^{\text{lift}}(v_q, s_1), Y_j^{\text{lift}}(v_q, s_2)] = 0,$$

so that γ is the solution to

$$\dot\gamma(t) = \Phi_{0,t}^{\sum_{j=1}^{k-1} Y_j^{\text{lift}}} (v_{q,k}(t)). \tag{3.13}$$

A second simplification is also straightforward. The vector field in (3.13) is homogeneous of degree 0, i.e., it is in the form of (2.10). According to the result in (2.11), we have for all $t \in [0,T]$

$$\dot\gamma(t) = v_{q,k}(t) + \sum_{j=1}^{k-1} \overline{Y}_j(\pi(v_{q,k}(t)), t), \tag{3.14}$$

where the sequence of vector fields Y_j is defined via (3.12) and where the curve $v_{q,k} : [0,T] \mapsto TQ$ is the solution to

$$\frac{dv_{q,k}}{dt} = \left(Z + \left[\sum_{j=1}^{k-1} \overline{Y}_j^{\text{lift}},\, Z \right] + Y_k^{\text{lift}} + W_k^{\text{lift}} \right) (v_{q,k}, t), \tag{3.15}$$

$$v_{q,k}(0) = 0_{q_0}.$$

Part II. *Here we show absolute and uniform convergence of the series* $\sum_{k=1}^{\infty} Y_k(q,t)$ *over all* q *in a compact neighborhood of* q_0 *and for all* $t \leq T$.

Given the vector field Y, let $\Omega_1 = \{Y\}$, and define recursively the set Ω_k to be the collection of vector fields $-\frac{1}{2} \left\langle \overline{B}_i : \overline{B}_{k-i} \right\rangle$ for all $B_i \in \Omega_i$ and $B_{k-i} \in \Omega_{k-i}$. The first few sets are

$$\Omega_1 = \{Y\}, \quad \Omega_2 = \left\{ -\frac{1}{2} \left\langle \overline{Y} : \overline{Y} \right\rangle \right\}, \quad \Omega_3 = \left\{ \frac{1}{4} \left\langle \overline{Y} : \overline{\left\langle \overline{Y} : \overline{Y} \right\rangle} \right\rangle \right\}, \tag{3.16}$$

$$\Omega_4 = \left\{ -\frac{1}{8} \left\langle \overline{Y} : \overline{\left\langle \overline{Y} : \overline{\left\langle \overline{Y} : \overline{Y} \right\rangle} \right\rangle} \right\rangle, -\frac{1}{8} \left\langle \overline{\left\langle \overline{Y} : \overline{Y} \right\rangle} : \overline{\left\langle \overline{Y} : \overline{Y} \right\rangle} \right\rangle \right\}.$$

Next, we prove by induction that, for all k, the vector field Y_k is the sum of N_k vector fields belonging to Ω_k. The statement is true at $k = 1$ with $N_1 = 1$. We assume it is true for all $j < k$ and prove it for k. Because of the induction assumption, we write $Y_j = \sum_{a=1}^{N_j} B_{j,a}$, where the $B_{j,a}$ are elements in Ω_j. We compute

$$\begin{aligned} Y_k &= -\frac{1}{2}\sum_{j=1}^{k-1} \left\langle \overline{Y}_j : \overline{Y}_{k-j} \right\rangle \\ &= -\frac{1}{2}\sum_{j=1}^{k-1} \left\langle \sum_{a=1}^{N_j} \overline{B_{j,a}} : \sum_{b=1}^{N_{k-j}} \overline{B_{k-j,b}} \right\rangle \\ &= \sum_{j=1}^{k-1}\sum_{a=1}^{N_j}\sum_{b=1}^{N_{k-j}} \underbrace{-\frac{1}{2}\left\langle \overline{B_{j,a}} : \overline{B_{k-j,b}} \right\rangle}_{\in\ \Omega_k}. \end{aligned}$$

This concludes the proof by induction, and the recursive relation on N_k is

$$N_1 = 1, \qquad N_k = \sum_{j=1}^{k-1} N_j N_{k-j}, \quad k \geq 2. \tag{3.17}$$

As we discuss in the appendix, the sequence N_k can be explicitly computed and bounded as

$$N_k = \frac{1}{k}\binom{2k-2}{k-1} \leq \frac{2^{2(k-1)}}{k-\frac{1}{2}}. \tag{3.18}$$

We now focus our attention on bounding the generic time-varying vector field $(q, s) \mapsto B_k(q, s)$ in Ω_k. Recall the symbols $\delta, \|\cdot\|_\sigma, \|\partial^m \cdot\|_\sigma$ introduced in section 2.7. We claim that there exist sequences of real and integer coefficients $\{c_k : k \in \mathbb{R}\}$ and $\{d_k : k \in \mathbb{N}\}$ such that

$$\|\partial^m B_k\|_{\sigma'} \leq c_k \frac{(m+d_k)!}{d_k!}\, \delta^{m+k-1} \|Y\|_\sigma^k t^{2(k-1)}. \tag{3.19}$$

For convenience, we redefine δ to $\delta = \max\{\frac{n}{\sigma-\sigma'}, \|\Gamma\|_\sigma\}$, so that $\|\partial^m \Gamma\|_{\sigma'} \leq m!\, \delta^{m+1}$. As discussed in that section, the bound in (3.19) is satisfied at $k = 1$ for all $m \in \mathbb{N}$, with $c_1 = 1$, $d_1 = 0$. In what follows we provide a proof by induction on $k \geq 2$.

Any time-varying vector field B_k at $k \geq 2$ can be written as $B_k = -\frac{1}{2}\left\langle \overline{B_a} : \overline{B_b} \right\rangle$ for some $1 \leq a, b \leq k-1, a + b = k$ and $B_a \in \Omega_a$, $B_b \in \Omega_b$. Accordingly, we compute

$$\begin{aligned} &\|\partial^m \left\langle \overline{B_a} : \overline{B_b} \right\rangle\|_{\sigma'} \\ &\quad = \max_{i, i_1, \dots, i_m} \left\| \frac{\partial^m}{\partial q_{i_1} \cdots \partial q_{i_m}} \left(\frac{\partial \overline{B_a^i}}{\partial q^j} \overline{B_b^j} + \frac{\partial \overline{B_b^i}}{\partial q^j} \overline{B_a^j} + \Gamma_{jl}^i (\overline{B_a^j}\, \overline{B_b^l} + \overline{B_b^j}\, \overline{B_a^l}) \right) \right\|_{\sigma'} \\ &\quad \leq \max_i \left(\left\| \partial^m \left(\frac{\partial \overline{B_a^i}}{\partial q^j} \overline{B_b^j} \right) \right\|_{\sigma'} + \left\| \partial^m \left(\frac{\partial \overline{B_b^i}}{\partial q^j} \overline{B_a^j} \right) \right\|_{\sigma'} + 2 \left\| \partial^m \left(\Gamma_{jl}^i \overline{B_a^j}\, \overline{B_b^l} \right) \right\|_{\sigma'} \right). \end{aligned}$$

Relying on the equality

$$\frac{d^m}{dx^m} f(x) g(x) = \sum_{\alpha=0}^{m} \binom{m}{\alpha} \frac{d^\alpha f(x)}{dx^\alpha} \frac{d^{m-\alpha} g(x)}{dx^{m-\alpha}},$$

the first term is bounded according to

$$\begin{aligned}
\left\| \partial^m \left(\frac{\partial \overline{B_a^i}}{\partial q^j} \overline{B_b^j} \right) \right\|_{\sigma'} &\leq n \sum_{\alpha=0}^{m} \frac{m!}{\alpha!(m-\alpha)!} \left\| \partial^{\alpha+1} \overline{B_a} \right\|_{\sigma'} \left\| \partial^{m-\alpha} \overline{B_b} \right\|_{\sigma'} \\
&\leq n \sum_{\alpha=0}^{m} \frac{m!}{\alpha!(m-\alpha)!} \left(c_a \frac{(\alpha+1+d_a)!}{d_a!} \delta^{\alpha+a} \|Y\|_\sigma^a \frac{t^{2a-1}}{2a-1} \right) \\
&\qquad \cdot \left(c_b \frac{(m-\alpha+d_b)!}{d_b!} \delta^{m-\alpha+b-1} \|Y\|_\sigma^b \frac{t^{2b-1}}{2b-1} \right) \\
&= \frac{n c_a c_b}{(2a-1)(2b-1)} \left(\frac{m!}{d_a! d_b!} \sum_{\alpha=0}^{m} \frac{(\alpha+1+d_a)!(m-\alpha+d_b)!}{\alpha!(m-\alpha)!} \right) \\
&\qquad \cdot \delta^{m+a+b-1} \|Y\|_\sigma^{a+b} t^{2(a+b-1)}.
\end{aligned}$$

The third term is bounded according to

$$\begin{aligned}
\left\| \partial^m \left(\Gamma_{jl}^i \overline{B_a^j} \, \overline{B_b^l} \right) \right\|_{\sigma'} &\leq n^2 \sum_{\alpha=0}^{m} \sum_{\beta=0}^{\alpha} \frac{m! \left\| \partial^{m-\alpha} \Gamma \right\|_{\sigma'}}{(m-\alpha)!\beta!(\alpha-\beta)!} \left\| \partial^\beta \overline{B_a} \right\|_{\sigma'} \left\| \partial^{\alpha-\beta} \overline{B_b} \right\|_{\sigma'} \\
&\leq n^2 \sum_{\alpha=0}^{m} \sum_{\beta=0}^{\alpha} \frac{m!}{(m-\alpha)!\beta!(\alpha-\beta)!} \left((m-\alpha)! \, \delta^{m-\alpha+1} \right) \\
&\qquad \cdot \left(c_a \frac{(\beta+d_a)!}{d_a!} \delta^{\beta+a-1} \|Y\|_\sigma^a \frac{t^{2a-1}}{2a-1} \right) \\
&\qquad \cdot \left(c_b \frac{(\alpha-\beta+d_b)!}{d_b!} \delta^{\alpha-\beta+b-1} \|Y\|_\sigma^b \frac{t^{2b-1}}{2b-1} \right) \\
&\leq \frac{n^2 c_a c_b}{(2a-1)(2b-1)} \left(\frac{m!}{d_a! d_b!} \sum_{\alpha=0}^{m} \sum_{\beta=0}^{\alpha} \frac{(\beta+d_a)!(\alpha-\beta+d_b)!}{\beta!(\alpha-\beta)!} \right) \\
&\qquad \cdot \delta^{m+a+b-1} \|Y\|_\sigma^{a+b} t^{2(a+b-1)}.
\end{aligned}$$

To simplify notation, let us define

$$S(l, d_1, d_2) \triangleq \sum_{a=0}^{l} \frac{(a+d_1)!(l-a+d_2)!}{a!(l-a)!}.$$

Putting it all together,

$$\begin{aligned}
\left\| \partial^m \left\langle \overline{B_a} : \overline{B_b} \right\rangle \right\|_{\sigma'} &\leq \frac{n c_a c_b}{(2a-1)(2b-1)} \frac{m!}{d_a! d_b!} \, \delta^{m+a+b-1} \|Y\|_\sigma^{a+b} t^{2(a+b-1)} \\
&\qquad \cdot \left(S(m, d_a+1, d_b) + S(m, d_a, d_b+1) + 2n \sum_{\alpha=0}^{m} S(\alpha, d_a, d_b) \right).
\end{aligned}$$

Equation (A.2) in the appendix implies that

$$S(l, d_1, d_2) = \frac{d_1! d_2! (l+1+d_1+d_2)!}{l!(1+d_1+d_2)!}, \tag{3.20}$$

so that we compute

$$\begin{aligned}
&\frac{m!}{d_a!d_b!}\left(S(m,d_a+1,d_b)+S(m,d_a,d_b+1)+2n\sum_{\alpha=0}^{m}S(\alpha,d_a,d_b)\right)\\
&\quad=\frac{m!}{d_a!d_b!}\left(\Big((d_a+1)!d_b!+d_a!(d_b+1)!\Big)\frac{(m+2+d_a+d_b)!}{m!(2+d_a+d_b)!}\right.\\
&\qquad\left.+2n\sum_{\alpha=0}^{m}\frac{d_a!d_b!(\alpha+1+d_a+d_b)!}{\alpha!(1+d_a+d_b)!}\right)\\
&\quad=\frac{(m+2+d_a+d_b)!}{(1+d_a+d_b)!}+\frac{2nm!}{(1+d_a+d_b)!}\underbrace{\sum_{\alpha=0}^{m}\frac{(\alpha+1+d_a+d_b)!}{\alpha!}}_{S(m,1+d_a+d_b,0)},
\end{aligned}$$

and again applying (3.20) with $(l,d_1,d_2)=(m,1+d_a+d_b,0)$

$$\begin{aligned}
&=\frac{(m+2+d_a+d_b)!}{(1+d_a+d_b)!}+\frac{2nm!}{(1+d_a+d_b)!}\frac{(1+d_a+d_b)!(m+2+d_a+d_b)!}{m!(2+d_a+d_b)!}\\
&=\frac{(m+2+d_a+d_b)!}{(2+d_a+d_b)!}\left(2+2n+d_a+d_b\right).
\end{aligned}$$

Substitute in

$$\begin{aligned}
&\|\partial^m\left\langle\overline{B_a}:\overline{B_b}\right\rangle\|_{\sigma'}\\
&\qquad\le\frac{nc_ac_b(2+2n+d_a+d_b)(m+2+d_a+d_b)!}{(2a-1)(2b-1)(2+d_a+d_b)!}\,\delta^{m+a+b-1}\,\|Y\|_\sigma^{a+b}\,t^{2(a+b-1)}.
\end{aligned}$$

Next, we express everything back in terms of $k=a+b$ and $B_k=-\frac{1}{2}\left\langle\overline{B_a}:\overline{B_b}\right\rangle$. We have that

$$\|\partial^m B_k\|_{\sigma'}\le\max_{a+b=k}\left(\frac{nc_ac_b(2+2n+d_a+d_b)}{2(2a-1)(2b-1)}\,\frac{(m+2+d_a+d_b)!}{(2+d_a+d_b)!}\right)\delta^{m+k-1}\,\|Y\|_\sigma^{k}\,t^{2(k-1)}.$$

Equation (3.19) is proven by defining sequences c_k and d_k such that $c_1=1$, $d_1=0$, together with

$$\begin{aligned}
d_k&\ge\max_{a+b=k}2+d_a+d_b,\\
c_k&\ge\max_{a+b=k}\frac{nc_ac_b(2+2n+d_a+d_b)}{2(2a-1)(2b-1)}.
\end{aligned}$$

It is immediate to see that $d_k=2(k-1)$ satisfies the recursive requirement, so that we require c_k to satisfy $c_1=1$, together with the requirement

$$c_k\ge\max_{a+b=k}\frac{n(k+n-1)c_ac_b}{(2a-1)(2b-1)}=\max_{a\in\{1,\dots k-1\}}\frac{n(k+n-1)c_ac_{k-a}}{(2a-1)(2k-2a-1)}.$$

Consider the polynomial $p(a)=(2a-1)(2k-2a-1)$ in $a\in[1,k-1]$; it assumes its minimum value $(2k-3)$ at $a=1$, or, equivalently, $a=k-1$. Accordingly, a stricter requirement on c_k is

$$c_k\ge\max_{a\in\{1,\dots k-1\}}\frac{n(k+n-1)}{2k-3}c_ac_{k-a}.$$

Since $(k-1)/(2k-3) \leq 1$ and $n/(2k-3) \leq n$ for all $k \geq 2$, a conservative selection of c_k that satisfies this requirement is provided by the sequence

$$c_1 = 1, \qquad c_k = n(1+n) \sum_{a=1}^{k-1} c_a c_{k-a}, \quad k \geq 2.$$

Recalling the definition in (3.17), one can show that $c_k = (n(1+n))^{k-1} N_k$.

Finally, we summarize all the analysis in Part II and prove convergence. Evaluating at $m = 0$ the bound in (3.19), we have

$$\|B_k\|_{\sigma'} \leq (n(1+n))^{k-1} N_k \, \delta^{k-1} \|Y\|_\sigma^k \, t^{2(k-1)},$$

and recalling the bound in (3.18), we compute

$$\begin{aligned} \|Y_k\|_{\sigma'} &\leq N_k \, \|B_k\|_{\sigma'} \leq (n(1+n))^{k-1} N_k^2 \, \delta^{k-1} \, \|Y\|_\sigma^k \, t^{2(k-1)} \\ &\leq \frac{(2^4 n(1+n)\,\delta)^{k-1}}{(k-1/2)^2} \, \|Y\|_\sigma^k \, t^{2(k-1)}. \end{aligned}$$

An immediate consequence is that for $(2^4 n(n+1)\delta) \, \|Y\|_\sigma T^2 < 1$, the series

$$Y_\infty(q,t) \triangleq \lim_{K \to \infty} \sum_{k=1}^{K} Y_k(q,t)$$

converges absolutely and uniformly in $t \in [0,T]$ and $q \in B_{\sigma'}(q_0)$.

Part III. *Here we provide the final limiting argument by collecting various results in Parts* I *and* II *and in Lemma* 3.2.

We start by studying the behavior as $k \to \infty$ of (3.14) and of the initial value problem (3.15) from Part I. We shall exploit a variation of a standard result on the continuous dependence of solutions of differential equations with respect to parameter changes; see [15, chapter I, section 3]. Uniform convergence of the vector field describing a differential equation, say, for example, $\sum_{k=1}^{K} Y_k$, implies the uniform convergence of the solution to the Kth differential equation to the solution of the limiting differential equation. In order to apply this result to the differential equation (3.15), we need to ensure that the vector field on right-hand side converges uniformly and absolutely.

Assume that the time length T and input vector field Y satisfy the bound in (3.4) inside the theorem statement. Then Lemma 3.2 guarantees that $\gamma([0,T]) \subset B_{\sigma'}(q_0)$, and the analysis in Part II guarantees that series $\sum_{k=1}^{\infty} Y_k$ converges absolutely and uniformly over $q \in B_{\sigma'}(q_0)$. Therefore, the series converges uniformly and absolutely along the curve γ. From (3.14) one can deduce that $\gamma(t) = \pi\,(v_{q,k}(t))$, so that the series $\sum_{k=1}^{\infty} Y_k$ converges also along $\pi \circ v_{q,k} : [0,T] \mapsto Q$. Accordingly, we can take the limit as $k \to \infty$ in (3.15).

Notice that uniformly in $t \in [0,T]$ and $q \in B_{\sigma'}(q_0)$

$$\lim_{k \to \infty} Y_k(q,t) = 0 \qquad \text{and} \qquad \lim_{k \to \infty} W_k(q,t) = 0,$$

and define the time-varying vector field

$$V_\infty = \sum_{k=1}^{\infty} V_k = \sum_{k=1}^{\infty} \overline{Y}_k.$$

Taking the limit as $k \to \infty$ in (3.14) and (3.15), one obtains

$$\dot\gamma(t) = v_{q,\infty}(t) + V_\infty(\pi(v_{q,\infty}(t)), t),$$

where the curve $v_{q,\infty} : [0, T] \mapsto TQ$ is the solution to

$$\begin{aligned} \frac{dv_{q,\infty}}{dt} &= \left(Z + \left[V_\infty^{\text{lift}}, Z\right]\right)(v_{q,\infty}, t), \\ v_{q,\infty}(0) &= 0_{q_0}. \end{aligned} \tag{3.21}$$

According to the discussion in section 2.6, the initial value problem in (3.21) can be explicitly integrated. Because $Z \in \mathcal{P}_1$, $[V_\infty^{\text{lift}}, Z] \in \mathcal{P}_0$, and because of the equality

$$T\pi \circ \left[V_\infty^{\text{lift}}, Z\right] = V_\infty,$$

the curve $v_{q,\infty}$ satisfies

$$v_{q,\infty}(t) = 0_{\zeta(t)}, \text{ where } \zeta(t) = \Phi_{0,t}^{V_\infty}(q_0),$$

and therefore

$$\dot\gamma(t) = 0_{\zeta(t)} + V_\infty(\pi(0_{\zeta(t)}), t) = V_\infty(\zeta(t), t).$$

The last two statements imply $\gamma = \zeta$ and are equivalent to (3.5). □

Two brief comments are appropriate. First, it is interesting to emphasize an intermediate result proved in Part II: the V_k term in the series is the sum of the known number of vector fields belonging to the set Ω_k; see the definition preceding (3.16). This additional structure might be useful in controllability or motion planning studies. Second, it is unpleasant to remark that while the series expansion is stated in a coordinate-free context, its convergence properties rely on the introduction of a coordinate system.

4. Applications and extensions. We present a few diverse comments in order to relate the theorem to various earlier works as well as to obtain stronger results under specific additional assumptions on the system.

4.1. The first few order terms and small amplitude forcing. Equation (3.5) is well defined in the sense that, at fixed q, the integration is performed with respect to the time variable. Using the abbreviated notation introduced in (2.1), the first few terms of the sequence $\{V_k : k \in \mathbb{N}\}$ are computed as

$$\begin{aligned} V_1 &= \overline{Y}, \\ V_2 &= -\frac{1}{2}\overline{\langle \overline{Y} : \overline{Y} \rangle}, \\ V_3 &= \frac{1}{2}\overline{\left\langle \overline{\langle \overline{Y} : \overline{Y} \rangle} : \overline{Y} \right\rangle}, \\ V_4 &= -\frac{1}{2}\overline{\left\langle \left\langle \overline{\langle \overline{Y} : \overline{Y} \rangle} : \overline{Y} \right\rangle : \overline{Y} \right\rangle} - \frac{1}{8}\overline{\left\langle \overline{\langle \overline{Y} : \overline{Y} \rangle} : \overline{\langle \overline{Y} : \overline{Y} \rangle} \right\rangle}, \end{aligned}$$

so that we can write

$$\begin{aligned} \dot\gamma(t) = \overline{Y}(\gamma, t) &- \frac{1}{2}\overline{\langle \overline{Y} : \overline{Y} \rangle}(\gamma, t) + \frac{1}{2}\overline{\left\langle \overline{\langle \overline{Y} : \overline{Y} \rangle} : \overline{Y} \right\rangle}(\gamma, t) \\ &- \frac{1}{2}\overline{\left\langle \left\langle \overline{\langle \overline{Y} : \overline{Y} \rangle} : \overline{Y} \right\rangle : \overline{Y} \right\rangle}(\gamma, t) - \frac{1}{8}\overline{\left\langle \overline{\langle \overline{Y} : \overline{Y} \rangle} : \overline{\langle \overline{Y} : \overline{Y} \rangle} \right\rangle}(\gamma, t) + O(\|Y\|^5 t^9). \end{aligned}$$

This series converges under the assumption that the product of final time T and input magnitude $\|Y\|_\sigma$ is small. Typically, in controllability studies [41], it is the final time that is assumed to be small (the famous acronym STLC stands for STLC). Within the context of motion planning problems [30, 13], it is instead convenient to study the small input magnitude case. Motivated by the treatment in [13], let ϵ be a small positive constant, and consider a total acceleration of the form

$$Y(q,t,\epsilon) = \epsilon X_1(q,t) + \epsilon^2 X_2(q,t) + \epsilon^3 X_3(q,t), \qquad t \in [0,1].$$

Accordingly, (3.5) is equivalent to

$$\begin{aligned}\dot\gamma(t) = \epsilon\overline{X}_1(\gamma,t) + \epsilon^2\left(\overline{X}_2 - \frac{1}{2}\overline{\langle \overline{X}_1 : \overline{X}_1\rangle}\right)(\gamma,t) \\ + \epsilon^3\left(\overline{X}_3 - \frac{1}{2}\overline{\langle \overline{X}_1 : \overline{X}_2\rangle} + \frac{1}{2}\overline{\left\langle \overline{\langle \overline{X}_1 : \overline{X}_1\rangle} : \overline{X}_1\right\rangle}\right)(\gamma,t) + O(\epsilon^4).\end{aligned}$$

This expression generalizes the results presented in Proposition 4.1 in [13]. Note that those results were proven via a perturbation theory argument that is not as general and powerful as the treatment in Theorem 3.3.

4.2. Simple Hamiltonian systems with integrable forces. In this and the following section we analyze systems with more structure both in the affine connections ∇ as well as in the input forces Y. Here we consider systems with Lagrangian equal to "kinetic minus potential" and with integrable forces. In the interest of brevity, we refer to the textbooks [16, 34] for a detailed presentation and review here only the necessary notation. The affine connection of a simple system is the Levi–Civita connection associated with the kinetic energy matrix M; that is, the Christoffel symbols are defined according to the usual relationship

$$\Gamma_{ij}^k = \frac{1}{2}M^{mk}\left(\frac{\partial M_{mj}}{\partial q^i} + \frac{\partial M_{mi}}{\partial q^j} - \frac{\partial M_{ij}}{\partial q^m}\right), \tag{4.1}$$

where M_{ij} and M^{mk} are the components of the matrix representation of M and of its inverse. An integrable time-varying force is written as

$$Y(q,t) = \operatorname{grad}\varphi(q,t), \qquad \text{where} \qquad (\operatorname{grad}\varphi)^i = M^{ij}\frac{\partial\varphi}{\partial q_j}, \tag{4.2}$$

and where φ is a scalar function on $\mathbb{R}^n \times \mathbb{R}$.

One remarkable simplification takes place for a simple system described by a Levi–Civita connection: the set of gradient vector fields is closed under the operation of a symmetric product. Let φ_1, φ_2 be scalar functions on $\mathbb{R}^n$, and define a symmetric product between functions according to

$$\langle \varphi_1 : \varphi_2\rangle \triangleq \frac{\partial\varphi_1}{\partial q}M^{-1}\frac{\partial\varphi_2}{\partial q}. \tag{4.3}$$

Then the symmetric product of the corresponding gradient vector fields equals the gradient of the symmetric product of the functions. In equations,

$$\langle \operatorname{grad}\varphi_1 : \operatorname{grad}\varphi_2\rangle = \operatorname{grad}\langle \varphi_1 : \varphi_2\rangle .$$

We refer to [10] for the proof. Accordingly, the main theorem can be restated as follows.

THEOREM 4.1. *Consider the system as described in Problem* 3.1. *Additionally, let the Christoffel symbols and the input vector field be defined as in* (4.1) *and* (4.2). *Define recursively the time-varying functions*

$$\varphi_1(q,t) = \int_0^t \varphi(q,s)ds,$$
$$\varphi_k(q,t) = -\frac{1}{2}\sum_{j=1}^{k-1}\int_0^t \Big\langle \varphi_j(q,s) :\ \varphi_{k-j}(q,s)\Big\rangle ds, \qquad k \geq 2.$$

Then the solution $\gamma : [0,T] \to Q$ *satisfies*

$$\dot\gamma(t) = \operatorname{grad} \sum_{k=1}^{+\infty} \varphi_k(\gamma(t),t). \tag{4.4}$$

In other words, the flow of a simple Hamiltonian system forced from rest is written as a (time-varying) gradient flow. For completeness, we include a convergence treatment derived from the one in the main theorem.

Remark 4.2. Given $0 < \sigma'' < \sigma' < \sigma$, we assume M and φ to be analytic in a neighborhood $B_\sigma(q_0)$ of q_0 and uniformly integrable in $t \in [0,T]$. Two immediate bounds are

$$\|\operatorname{grad}\varphi\|_{\sigma'} \leq n\|M^{-1}\|_{\sigma'}\left\|\frac{\partial\varphi}{\partial q}\right\|_{\sigma'},$$
$$\|\Gamma\|_{\sigma'} \leq A \triangleq \frac{3n^2}{2(\sigma-\sigma')}\|M^{-1}\|_{\sigma'}\|M\|_\sigma.$$

Accordingly, the bounds in the main theorem can be restated (in a more conservative manner) as follows. If

$$\left\|\frac{\partial\varphi}{\partial q}\right\|_{\sigma'} T^2 < \frac{1}{n\|M^{-1}\|_{\sigma'}}\min\left\{\frac{\sigma'-\sigma''}{2^4n^2(n+1)}, \frac{1}{2^4n(n+1)A}, \frac{\eta^2(n^2\sigma''A)}{n^2A}\right\},$$

the series $\sum_{k=1}^\infty \varphi_k(q,t)$ converges absolutely and uniformly in t and q for all $t \in [0,T]$ and for all q in a neighborhood $B_{\sigma''}(q_0)$ of q_0.

4.3. Invariant systems on Lie groups. In this section we briefly investigate systems with kinetic energy and input forces invariant under a certain group action. These systems have a configuration space G with the structure of an n-dimensional matrix Lie group. Systems in this class include satellites, hovercraft, and underwater vehicles.

The equation of motion (2.7) decouples into a kinematic and dynamic equation in the configuration variable $g \in G$ and the body velocity[3] $v \in \mathbb{R}^n$. The kinematic equation can be written as a matrix differential equation[4] using matrix group notation

[3] More precisely, the body velocity v lives in the Lie algebra of the group G.

[4] Alternatively, the kinematic equation can be written in a system of local coordinates q (e.g., Euler angles in the case of rotation matrices) as $\dot q = J(q)v$, where $J(q)$ is an appropriate Jacobian matrix.

TABLE 4.1
Numerical comparison of various degrees of approximations. The entries in the table are the error values $e_{\epsilon,N}$ that provide a measure of the accuracy of the Nth-order truncated approximation.

ϵ	1	.1	.01
$N=1$	$5.3\cdot 10^{-3}$	$4.6\cdot 10^{-5}$	$4.5\cdot 10^{-7}$
$N=2$	$2.4\cdot 10^{-4}$	$4.2\cdot 10^{-7}$	$4.2\cdot 10^{-10}$
$N=3$	$1.4\cdot 10^{-4}$	$3.0\cdot 10^{-9}$	$2.3\cdot 10^{-13}$
$N=4$	$5.2\cdot 10^{-5}$	$2.4\cdot 10^{-10}$	$3.5\cdot 10^{-15}$

$\dot g = g\widehat v$; we refer to [35] for the details. The dynamic equation, sometimes referred to as Euler–Poincaré, is

$$\dot v^i + \gamma^i_{jk} v^j v^k = y^i(t), \tag{4.5}$$

where the coefficients γ^i_{jk} are determined by the group and metric structure. The curve $y : [0,T] \mapsto \mathbb{R}^n$ denotes the time-varying forcing.

Within this setting, the result in Theorem 3.3 is summarized as follows. The solution to (4.5) with initial condition $v(0) = 0$ is $v(t) = \sum_{k=1}^{\infty} v_k(t)$, where

$$v_1(t) = \int_0^t y(s)ds,$$
$$v_k(t) = -\frac{1}{2}\sum_{j=1}^{k-1}\int_0^t \Big\langle v_j(s) :\ v_{k-j}(s)\Big\rangle ds, \qquad k \geq 2,$$

and where the symmetric product between velocity vectors is $\langle x : y\rangle^i = -2\gamma^i_{jk} x^j y^k$. Local convergence for the series expansion can be easily established in this setting.

This result agrees with and indeed supersedes the ones presented in [13] obtained via the perturbation method. The relationship of this case to the more general setting studied in Theorem 3.3 is clarified via the notion of invariant connection; see [5, Appendix B] and [39, section 27, "Variations on a theme by Euler"] for more details.

4.4. Simulations for a three degree of freedom manipulator. In this section we illustrate the approximations derived in Theorem 3.3 by applying them to an example system. We consider a three-link planar manipulator. The configuration is described by three angles $(\theta_1, \theta_2, \theta_3)$. A constant (integrable) force is applied to the first variable. Specifically, we set $\varphi(q,t) = \epsilon\theta_1$, and we let the parameter ϵ vary in the range 10^{-2} to 1. The integration time is $T = 1$ seconds. Setting all lengths, masses, and moments of inertia to unity, the kinetic energy matrix is

$$M = \frac{1}{16}\begin{bmatrix} 25 & 6\cos(\theta_1-\theta_2) & 2\cos(\theta_1-\theta_3) \\ 6\cos(\theta_1-\theta_2) & 21 & 2\cos(\theta_2-\theta_3) \\ 2\cos(\theta_1-\theta_3) & 2\cos(\theta_2-\theta_3) & 17 \end{bmatrix}.$$

The initial condition is assumed to be $q(0) = (0, \pi/4, 0)$. We investigate the error value $e_{\epsilon,N} = \|\gamma(T) - \gamma_N(T)\|$, where γ_N is the solution to the Nth order truncation: $\dot\gamma_N(t) = \operatorname{grad}\sum_{k=1}^{N}\varphi_k(\gamma_N, t)$. An empirical forecast of the $e_{\epsilon,N}$ is computed as follows. Since $T = 1$ and $\|Y\| = O(\epsilon)$, there exist two constants c, d such that the kth term in the series is bounded by $c(d\epsilon)^k$. Summing the neglected contributions from $k = N+1$ to infinity and assuming that $d\epsilon \ll 1$, one can compute $e_{\epsilon,N} \approx c(d\epsilon)^{N+1}$.

We summarize the results of the numerical investigation[5] in Table 4.1. The results are in qualitative agreement with the theoretical forecasts.

5. Conclusions. We have presented a series expansion that describes the evolution of a forced mechanical system. Our result provides a first-order description to the solutions of a second-order initial value problem. Both the series and the proof method provide insight into the geometry of mechanical control systems. The treatment expands on our previous work [10] on high-amplitude high-frequency averaging and vibrational stabilization.

Series expansions are the underlying technique for controllability and motion planning. For mechanical systems moving in the low-velocity regime, these two problems have been tackled with various degrees of success in [32, 13]. Future research will rely on the contributions in this work to develop more general motion planning algorithms than the ones in [13] and sharper sufficient controllability tests than the ones in [32].

Appendix. Some basic identities in combinatorial analysis. We here present a basic result and derive a useful expression that is needed in the proof of the main theorem. The main reference is the method of generating functions as described in section 3.4 in [4]. The first identity is explicitly proven in the reference. If $N_1 = 1$ and

$$N_k = \sum_{j=1}^{k-1} N_j N_{k-j}, \qquad k \geq 2,$$

then

$$N_k = \frac{1}{k}\binom{2k-2}{k-1} = \frac{2^k}{(4k-2)}\frac{1\cdot 3\cdot 5\cdots(2k-1)}{1\cdot 2\cdot 3\cdots k} \leq \frac{4^k}{4k-2}. \tag{A.1}$$

The second equality needed in the proof of Theorem 3.3 is

$$\sum_{a=0}^{k}\binom{a+d_1}{d_1}\binom{k-a+d_2}{d_2} = \binom{k+1+d_1+d_2}{k}. \tag{A.2}$$

To prove it we use the method of generating functions; see [4]. We claim that, for all real x with $|x| < 1$,

$$\sum_{k=0}^{\infty}\left(\sum_{a=0}^{k}\binom{a+d_1}{d_1}\binom{k-a+d_2}{d_2}\right)x^k = \sum_{k=0}^{\infty}\binom{k+1+d_1+d_2}{k}x^k. \tag{A.3}$$

The first step is to notice that

$$\begin{aligned}\sum_{k=0}^{\infty}\left(\sum_{a=0}^{k}\binom{a+d_1}{d_1}\binom{k-a+d_2}{d_2}\right)x^k &= \sum_{k=0}^{\infty}\sum_{m+n=k}\binom{n+d_1}{d_1}\binom{m+d_2}{d_2}x^{n+m}\\ &= \left(\sum_{n=0}^{\infty}\binom{n+d_1}{d_1}x^n\right)\left(\sum_{m=0}^{\infty}\binom{m+d_2}{d_2}x^m\right).\end{aligned}$$

[5] The numerical integration is performed inside the Mathematica environment, specifying 16 digits of accuracy and 32 digits of working precision.

Accordingly, we define

$$f_a(x) = \sum_{m=0}^{\infty} \binom{m+a}{a} x^m, \tag{A.4}$$

and the thesis in (A.3) is equivalent to proving that

$$f_{d_1}(x) f_{d_2}(x) = f_{d_1+d_2+1}(x). \tag{A.5}$$

In passing, we also note that the convergence radius of f is $|x| < 1$.

The second step is to study the properties of f. First of all,

$$\begin{aligned} f_a(x) &= \sum_{m=0}^{\infty} \frac{(m+a)!}{m!a!} x^m = \frac{1}{a!} \sum_{m=0}^{\infty} (m+a) \cdots (m+1) x^m \\ &= \frac{1}{a!} \frac{d^a}{dx^a} \sum_{m=0}^{\infty} x^{m+a} = \frac{1}{a!} \frac{d^a}{dx^a} \left(x^a \sum_{m=0}^{\infty} x^m \right) = \frac{1}{a!} \frac{d^a}{dx^a} \frac{x^a}{1-x}. \end{aligned}$$

Additionally, it is immediate to see that

$$f_0(x) = \frac{1}{1-x}, \qquad x f_0(x) = f_0(x) - 1,$$

and, consequently,

$$f_a(x) = \frac{1}{a!} \frac{d^a}{dx^a} \frac{1}{1-x} = \frac{1}{a!} \frac{d^a}{dx^a} f_0(x).$$

Finally, we prove by induction that

$$f_a(x) = f_0(x)^{a+1}. \tag{A.6}$$

At $a = 0$ the statement is obvious. We assume it is true up to a and compute

$$\begin{aligned} f_{a+1}(x) &= \frac{1}{(a+1)!} \frac{d^{a+1}}{dx^{a+1}} \frac{1}{1-x} = \frac{1}{(a+1)!} \frac{d^a}{dx^a} \left(\frac{1}{1-x} \right)^2 \\ &= \frac{1}{(a+1)!} \sum_{b=0}^{a} \binom{a}{b} \left(\frac{d^b}{dx^b} \frac{1}{1-x} \right) \left(\frac{d^{a-b}}{dx^{a-b}} \frac{1}{1-x} \right) \\ &= \frac{a!}{(a+1)!} \sum_{b=0}^{a} \left(\frac{1}{b!} \frac{d^b}{dx^b} \frac{1}{1-x} \right) \left(\frac{1}{(a-b)!} \frac{d^{a-b}}{dx^{a-b}} \frac{1}{1-x} \right) \\ &= \frac{1}{a+1} \sum_{b=0}^{a} \left(\frac{1}{1-x} \right)^{b+1} \left(\frac{1}{1-x} \right)^{a-b+1} = \left(\frac{1}{1-x} \right)^{a+2}. \end{aligned}$$

This concludes the proof of (A.6), which immediately implies (A.5) and the main thesis in (A.3).

Acknowledgments. The author thanks Jim Radford and Andrew D. Lewis for helpful and stimulating discussions.

SMOOTH FEEDBACK, GLOBAL STABILIZATION, AND DISTURBANCE ATTENUATION OF NONLINEAR SYSTEMS WITH UNCONTROLLABLE LINEARIZATION*

CHUNJIANG QIAN†, WEI LIN†, AND W. P. DAYAWANSA‡

Abstract. Problems of global asymptotic stabilization and disturbance attenuation are addressed for a class of highly nonlinear systems that are comprised of a lower dimensional zero-dynamics subsystem and a chain of power integrators perturbed by a *nontriangular* vector field. It is shown in this paper that global stabilization and disturbance attenuation are solvable by *smooth* state feedback if one takes full advantage of the characteristics of the system in the feedback design to dominate the nonlinearity rather than to cancel it. A systematic design procedure which is based upon, but generalizes, the recent technique of *adding a power integrator* is developed for the explicit construction of the smooth controllers. Several examples are presented to demonstrate the key features of the proposed nonlinear control schemes.

Key words. adding a power integrator, smooth state feedback, global asymptotic stabilization, disturbance attenuation, high-order nonlinear systems, uncontrollable linearization

1. Introduction.

Most of the practical control systems are usually nonlinear with uncertainties or disturbances. One of the important problems in nonlinear control theory is to design a smooth state feedback control law that globally stabilizes the system in the absence of additive disturbances and attenuates the effect of the disturbances on the system output to an arbitrary degree of accuracy in the presence of disturbances. To address this issue, new ideas and powerful concepts have been developed over the last decade, leading to the development of a number of systematic design methods for global synthesis of *affine* systems. Among the proposed approaches, a Lyapunov-like design technique called adding a linear integrator [3, 30], also known as backstepping [16, 24], has been proved to be one of the effective control methods in studying the problems such as global stabilization and disturbance attenuation for a class of nonlinear systems in the so-called normal form [11, 13, 23, 12]

$$\begin{aligned}
&\dot{z} = f_0(z, x_1) + \phi_0(z, x_1)w,\\
&\dot{x}_i = x_{i+1} + f_i(z, x_1, \cdots, x_i) + \phi_i(z, x_1, \cdots, x_i)w, \quad i = 1, \cdots, r, \quad x_{r+1} := v,\\
&y = x_1,
\end{aligned} \tag{1.1}$$

where v, y, and w are the system input, output, and disturbance, respectively.

There are three key features exhibited in system (1.1): (i) The Jacobian linearization of the x-subsystem of (1.1) at the origin is *controllable*. Hence, when $w = 0$ and dim $z = 0$, (1.1) is *feedback linearizable*. (ii) The system is *affine* in the control

input v. (iii) (1.1) is of a *lower-triangular* form. These assumptions have been commonly used in most of the existing control schemes that were based on the integrator backstepping design. They guarantee that for system (1.1) the problem of global stabilization when $w = 0$ [11, 17, 18, 16, 24] or the problem of global disturbance attenuation with internal stability when $w \neq 0$ [11, 13, 23, 12, 31] is solvable by smooth state feedback. A globally stabilizing controller can be constructed by using the technique of adding a linear integrator [3, 30] and dealing with a design problem for a "one dimension system" every time. In fact, it was proved in [3, 30] that the cascade system

$$\begin{aligned} \dot{z} &= f(z) + y f_1(z, y), \\ \dot{y} &= u + g_1(z, y) \end{aligned} \tag{1.2}$$

is globally asymptotically stabilizable by smooth state feedback if there exists a positive definite and proper Lyapunov function V such that $L_f V(z) < 0 \; \forall z \neq 0$. The proof was based on the design of a Lyapunov function $U(z, y) = V(z) + \frac{y^2}{2}$ and a smooth controller $u(z, y) = -g_1(z, y) - y - L_{f_1} V$, making $\dot{U} = L_f V(z) - y^2 < 0 \quad \forall (z, y) \neq (0, 0)$. The crucial point here is to use $u(z, y)$ to cancel the nonlinear terms $g_1(z, y)$ and $L_{f_1} V$ in the equation $\dot{U} = L_f V + y L_{f_1} V + y(u + g_1(z, y))$. As illustrated by Theorem 9.2.3 in [11], global stabilization of minimum-phase systems (1.1) with $w = 0$ can then be achieved by repeatedly using this backstepping construct r times.

Many existing design methodologies on global stabilization and disturbance attenuation use this aforementioned construct [11, 3, 30, 16, 23, 1]; hence it becomes clear that they rely essentially on *feedback cancelation* and therefore can only be applied to a class of lower-triangular systems of the form (1.1).

An important question that remains largely open is to what extent the three structural conditions of (1.1)—*feedback linearizability, affine structure, and lower-triangularity*—can be significantly relaxed so that global stabilization and disturbance attenuation are still solvable by *smooth* state feedback for a larger class of highly nonlinear systems (even possibly nonaffine systems) with *uncontrollable* Jacobian linearization. In this paper we shall address this question and provide a partial answer. Specifically, we shall first consider the problem of global stabilization via *smooth* state feedback for a class of nonlinear systems of the form

$$\begin{aligned} \dot{z} &= f_0(z, x_1), \\ \dot{x}_i &= x_{i+1}^{p_i} + f_i(z, x_1, \ldots, x_i, x_{i+1}), \qquad i = 1, \ldots, r, \qquad x_{r+1} := u, \end{aligned} \tag{1.3}$$

where $z \in \mathbb{R}^{n-r}$ and $x = (x_1, \ldots, x_r)^T$ are the states, $u \in \mathbb{R}$ and $y \in \mathbb{R}$ are the system input and output, respectively, and p_i, $i = 1, \ldots, r$, are positive integers. The functions $f_i : R^{n-r+i+1} \to \mathbb{R}$ and $f_0 : \mathbb{R}^{n-r+1} \to \mathbb{R}^{n-r}$ are smooth and evaluate to zero at $(z, x_1, \ldots, x_r) = (0, 0, \ldots, 0)$. The system above can be regarded as a lower dimensional zero-dynamics driven by a nonlinear subsystem that consists of a chain of power integrators perturbed by a *nonstrict-triangular* vector field.

The notable characteristics of system (1.3) are that it is neither feedback linearizable (even partially) nor affine in the control input when $p_i > 1$. More significantly, (1.3) is not in a lower-triangular form due to the appearance of x_{i+1} in f_i. All these make global stabilization of system (1.3) challenging and unsolvable via the existing design methods, such as feedback linearization and backstepping. Actually, one may try to apply the adding a linear integrator method to system (1.3). However, a more careful examination indicates that in the high-order case, the conventional

backstepping design results in a possibly *nonsmooth* control law. To make this point clear, consider system (1.2) with a *nonaffine* input, e.g., $u = v^3$. If the adding a linear integrator method were applied, the resulting control law would be given by $v = -(g_1(z,y) + y + L_{f_1}V)^{\frac{1}{3}}$, which, in general, is only C^0. Therefore, no more integrators can be added in the next step of the recursive design. The same difficulty would be faced in the problem of disturbance attenuation. Therefore, a new synthesis tool that goes beyond the adding a linear integrator design must be developed in order to handle inherently nonlinear systems like (1.3).

Motivated by the theory of homogeneous systems [8, 1, 9, 10, 14, 15] and the subsequent works [6, 7, 5, 25, 19, 27], we develop in this paper a *new* design tool which is based upon, but substantially extends, the adding a power integrator technique proposed in [20]. The new design method enables us to relax, in addition to the removal of feedback linearizability and affineness, the *lower-triangularity* condition assumed in [20], hence enlarging the class of nonlinear systems for which global stabilization and disturbance attenuation are still solvable by *smooth* state feedback. There are, however, some major differences from the work in [20]. One of them is that the current paper deals with the *nonstrict-triangular* system (1.3) rather than a lower-triangular system, and several technical issues arise immediately. For example, when the system is not in the lower-triangular form, the adding a power integrator technique developed in [20] encounters two obstacles, namely, that at every step it is necessary to guarantee the existence of a *smooth* virtual controller, and that a method has to be developed to carry out an iterative design for sequentially adding a power integrator. Solving these problems will be one of the main contributions of this paper. The other key difference from [20] is that a constructive solution to the global stabilization of nontriangular systems is sought, which requires subtle but important changes in the stability analysis. Finally, due to the nature of the nontriangular structure, it is more difficult to identify suitable growth conditions for global stabilization and disturbance attenuation to be solvable via smooth state feedback. As we shall see in what follows, the new *adding a power integrator* technique proposed in this paper takes full advantage of the characteristics of the dynamic system in the feedback design, particularly, using feedback to *dominate* the high-order nonlinearities of the system. This is in sharp contrast to the classical adding a linear integrator approach [3, 30], which relies upon exact cancelation of terms. As illustrated above, designs which rely on exact cancelation may result in a *nondifferentiable* controller, which makes an iterative design exceptionally difficult. Our generalized adding a power integrator design overcomes not only this difficulty but also enables us to solve, in a unified manner, the problems of global stabilization and disturbance attenuation via *static smooth* feedback for nonlinear systems (1.3) which are neither feedback linearizable nor transformable to a lower-triangular form.

A byproduct of the new adding a power integrator design is the development of sufficient conditions for the problem of global disturbance attenuation to be solvable by *smooth* state feedback, and the explicit construction of smooth state feedback control laws. The robust control results thus obtained incorporate and significantly generalize the existing disturbance attenuation results [22, 23, 12], which are only applicable to a class of feedback linearizable systems having a lower-triangular structure (1.1).

2. Global asymptotic stabilization via smooth state feedback. For the sake of simplicity, in this section we concentrate on the situation where the nonlinear system (1.3) involves no zero-dynamics, i.e., dim $z = 0$. In this case, system (1.3)

reduces to

$$\begin{aligned}
\dot{x}_1 &= x_2^{p_1} + f_1(x_1, x_2),\\
&\vdots\\
\dot{x}_{n-1} &= x_n^{p_{n-1}} + f_{n-1}(x_1, \cdots, x_n),\\
\dot{x}_n &= u^{p_n} + f_n(x_1, \cdots, x_n, u).
\end{aligned} \tag{2.1}$$

Our objective is to investigate conditions under which the problem of global asymptotic stabilization is solvable by *smooth* state feedback. It is worth noticing that, compared to the system considered in [20], the high-order system (2.1) is not in a triangular form due to the existence of x_{i+1} in $f_i(x_1, \ldots, x_{i+1})$. This new feature, together with the nonaffineness and uncontrollability of the Jacobian linearization, makes the existing nonlinear feedback design methods inapplicable. Moreover, the technique of adding a power integrator, proposed recently in [20], is only applicable to a class of *strict-triangular* systems. In what follows, we shall show how a *generalized adding a power integrator* technique can be further developed, enabling us to construct a smooth state feedback control law that renders system (2.1) globally asymptotically stable (GAS) at the equilibrium $(x_1, \ldots, x_n) = (0, \ldots, 0)$.

We begin with two assumptions that characterize the subclass of nonlinear systems (2.1).

Assumption 2.1. $p_1 \geq p_2 \geq \cdots \geq p_n \geq 1$ are *odd* integers.

Assumption 2.2. For $i = 1, \ldots, n$,

$$f_i(x_1, \ldots, x_{i+1}) = \sum_{l=0}^{p_i - 1} a_{i,l}(x_1, \ldots, x_i) x_{i+1}^l, \tag{2.2}$$

$$|a_{i,l}(x_1, \ldots, x_i)| \leq (|x_1|^{p_i - l} + \cdots + |x_i|^{p_i - l}) \gamma_{i,l}(x_1, \ldots, x_i), \quad l = 0, \ldots, p_i - 1, \tag{2.3}$$

where $x_{n+1} := u$ and $\gamma_{i,l}(\cdot)$ is a smooth and nonnegative function.

Under Assumptions 2.1–2.2, it is possible to prove the following global stabilization theorem, which is one of the main results of the paper.

THEOREM 2.3. *Suppose the nonlinear system* (2.1) *satisfies Assumptions* 2.1–2.2. *Then there exists a* C^∞ *state feedback control law* $u = u(x_1, \ldots, x_n)$ *with* $u(0, \ldots, 0) = 0$, *such that the closed-loop system is GAS at the equilibrium* $x = 0$.

The proof of Theorem 2.3 relies crucially on the following simple but useful lemma.

LEMMA 2.4. *Let* $\mathcal{X}$, $\mathcal{Y}$, *and* $\mathcal{Z}_i$, $i = 1, \ldots, l$, *be real variables. Assume that* $g_1 : \mathbb{R} \to \mathbb{R}$ *and* $g_2 : \mathbb{R}^{l+1} \to \mathbb{R}$ *are smooth mappings. Then, for any positive integers* m, n, *and real number* $N > 0$, *there exist two nonnegative smooth functions* $h_1 : \mathbb{R}^2 \to \mathbb{R}$ *and* $h_2 : \mathbb{R}^{l+1} \to \mathbb{R}$, *such that*

(i) $|\mathcal{X}^m[(\mathcal{Y} + \mathcal{X} g_1(\mathcal{X}))^n - (\mathcal{X} g_1(\mathcal{X}))^n]| \leq \frac{|\mathcal{X}|^{m+n}}{N} + |\mathcal{Y}|^{m+n} h_1(\mathcal{X}, \mathcal{Y})$,

(ii) $|\mathcal{Y}^n(\mathcal{Z}_1^m + \cdots + \mathcal{Z}_l^m + \mathcal{Y}^m) g_2(\mathcal{Z}_1, \ldots, \mathcal{Z}_l, \mathcal{Y})|$
$\leq \frac{|\mathcal{Z}_1|^{m+n} + \cdots + |\mathcal{Z}_l|^{m+n}}{N} + |\mathcal{Y}|^{m+n} h_2(\mathcal{Z}_1, \ldots, \mathcal{Z}_l, \mathcal{Y})$.

Proof. For any positive integers m, n and any real-valued smooth function $\gamma(\mathcal{X}, \mathcal{Y}) > 0$, set

$$\begin{aligned}
a &= |\mathcal{X}|^m \gamma^{\frac{m}{m+n}}, & b &= |\mathcal{Y}|^n \gamma^{-\frac{m}{m+n}},\\
p &= \tfrac{m+n}{m}, & q &= \tfrac{m+n}{n}.
\end{aligned}$$

Then, using Young's inequality

$$|ab| \leq \frac{|a|^p}{p} + \frac{|b|^q}{q}$$

yields

$$|\mathcal{X}|^m|\mathcal{Y}|^n \le \frac{m}{m+n}\gamma(\mathcal{X},\mathcal{Y})|\mathcal{X}|^{m+n} + \frac{n}{m+n}\gamma^{-\frac{m}{n}}(\mathcal{X},\mathcal{Y})|\mathcal{Y}|^{m+n}. \tag{2.4}$$

From (2.4) it is straightforward to deduce the inequality (ii) by choosing appropriate $\gamma(\cdot)$ in (2.4). To deduce (i), first expand the expression $\mathcal{X}^m[(\mathcal{Y}+\mathcal{X}g_1(\mathcal{X}))^n - (\mathcal{X}g_1(\mathcal{X}))^n]$, and apply (2.4) to each term. □

With the aid of Lemma 2.4, a constructive solution to the global stabilization problem can be obtained by repeatedly using a *generalized adding a power integrator* technique, which is based upon, but substantially extends, the design method proposed in [20].

Proof of Theorem 2.3. *Initial step.* Consider the x_1-subsystem of (2.1). Let $V_1(x_1) = \frac{x_1^2}{2}$. Then

$$\begin{aligned}\dot{V}_1(x_1) &= x_1\left[x_2^{p_1} + f_1(x_1,x_2)\right]\\ &= x_1\left[x_2^{p_1} - x_2^{*p_1} + f_1(x_1,x_2) - f_1(x_1,x_2^*)\right] + x_1\left(x_2^{*p_1} + f_1(x_1,x_2^*)\right)\end{aligned}$$

for arbitrary x_2^*. By Assumption 2.2 and Lemma 2.4, there are smooth functions $\gamma_{1,l}(x_1) \ge 0,\ \rho_{1,l}(x_1) \ge 0,\ l = 0,\dots,p_1-1$, such that

$$\begin{aligned}|f_1(x_1,x_2)| &\le \sum_{l=0}^{p_1-1}|x_1|^{p_1-l}\gamma_{1,l}(x_1)|x_2|^l \le \sum_{l=0}^{p_1-1}\left(\frac{|x_2|^{p_1}}{2p_1} + |x_1|^{p_1}\rho_{1,l}(x_1)\right)\\ &\le \frac{|x_2|^{p_1}}{2} + |x_1|^{p_1}\hat{\rho}_1(x_1), \quad \hat{\rho}_1(x_1) := \sum_{l=0}^{p_1-1}\rho_{1,l}(x_1) \ge 0.\end{aligned} \tag{2.5}$$

Using this estimate, we have

$$\dot{V}_1(x_1) \le x_1\left[x_2^{p_1} - x_2^{*p_1} + f_1(x_1,x_2) - f_1(x_1,x_2^*)\right] + x_1x_2^{*p_1} + \frac{|x_1x_2^{*p_1}|}{2} + x_1^{p_1+1}\hat{\rho}_1(x_1).$$

Clearly, the virtual smooth controller

$$x_2^*(x_1) = -x_1\alpha_1(x_1), \quad \alpha_1(x_1) := (2n + 2\hat{\rho}_1(x_1))^{\frac{1}{p_1}} > 0, \tag{2.6}$$

is such that

$$\dot{V}_1(x_1) \le -nx_1^{p_1+1} + x_1\left[x_2^{p_1} - x_2^{*p_1} + f_1(x_1,x_2) - f_1(x_1,x_2^*)\right]. \tag{2.7}$$

Inductive step. Suppose at step k there exist a C^∞ global change of coordinates

$$\xi_1 = x_1 - x_1^*, \quad \xi_2 = x_2 - x_2^*(x_1), \dots, \quad \xi_k = x_k - x_k^*(x_1,\dots,x_{k-1}) \tag{2.8}$$

(where $x_1^* = 0,\ x_m^*(x_1,\dots,x_m)$ with $x_m^*(0,\dots,0) = 0,\ m = 2,\dots,k$, are smooth functions), a Lyapunov function

$$V_k(\xi_1,\dots,\xi_k) = \sum_{j=1}^{k}\frac{\xi_j^{p_1-p_j+2}}{p_1-p_j+2},$$

and a smooth state feedback control law of the form

$$x_{k+1}^*(x_1,\dots,x_k) = -\xi_k\alpha_k(\xi_1,\dots,\xi_k), \qquad \xi_m = x_m - x_m^*,\ m = 1,\dots,k, \tag{2.9}$$

with $\alpha_k(\cdot) > 0$ being *smooth*, such that

$$\begin{aligned}\dot{V}_k(\xi_1,\dots,\xi_k) \le& -(n-k+1)(\xi_1^{p_1+1}+\cdots+\xi_k^{p_1+1})\\ &+\xi_k^{p_1-p_k+1}[x_{k+1}^{p_k}-{x_{k+1}^*}^{p_k}+f_k(x_1,\dots,x_{k+1})-f_k(x_1,\dots,x_k,x_{k+1}^*)].\end{aligned}\tag{2.10}$$

We claim that (2.10) also holds at step $k+1$. To see this, define

$$\xi_{k+1} = x_{k+1} - x_{k+1}^*(x_1,\dots,x_k).$$

Then

$$\dot{\xi}_{k+1} = x_{k+2}^{p_{k+1}} + F_{k+1}(x_1,\dots,x_{k+2}),\tag{2.11}$$

where

$$\begin{aligned}F_{k+1}(x_1,\dots,x_{k+1},x_{k+2}) &= f_{k+1}(x_1,\dots,x_{k+1},x_{k+2})\\ &\quad-\sum_{m=1}^{k}\frac{\partial x_{k+1}^*}{\partial x_m}\left(x_{m+1}^{p_m}+f_m(x_1,\dots,x_{m+1})\right)\\ &= \sum_{l=0}^{p_{k+1}-1}\tilde{a}_{k+1,l}(x_1,\dots,x_{k+1})x_{k+2}^l,\\ \tilde{a}_{k+1,l}(x_1,\dots,x_{k+1}) &= a_{k+1,l}(x_1,\dots,x_{k+1}),\qquad l=1,\dots,p_{k+1}-1,\\ \tilde{a}_{k+1,0}(x_1,\dots,x_{k+1}) &= a_{k+1,0}(x_1,\dots,x_{k+1})\\ &\quad-\sum_{m=1}^{k}\frac{\partial x_{k+1}^*}{\partial x_m}\left(x_{m+1}^{p_m}+f_m(x_1,\dots,x_{m+1})\right).\end{aligned}$$

Assumption 2.2 implies that for $l=1,\dots,p_{k+1}-1$, there are C^∞ functions $\tilde{\gamma}_{k+1,l}(\cdot)\ge 0$ such that

$$\begin{aligned}|\tilde{a}_{k+1,l}(x_1,\dots,x_{k+1})| &\le (|x_1|^{p_{k+1}-l}+\cdots+|x_{k+1}|^{p_{k+1}-l})\gamma_{k+1,l}(x_1,\dots,x_{k+1})\\ &\le (|\xi_1|^{p_{k+1}-l}+\cdots+|\xi_{k+1}|^{p_{k+1}-l})\tilde{\gamma}_{k+1,l}(\xi_1,\dots,\xi_{k+1}).\end{aligned}\tag{2.12}$$

By definition,

$$\begin{aligned}|\tilde{a}_{k+1,0}(x_1,\dots,x_{k+1})| &\le |a_{k+1,0}(x_1,\dots,x_{k+1})|\\ &\quad+\sum_{m=1}^{k}\left|\frac{\partial x_{k+1}^*}{\partial x_m}\right|\left(|x_{m+1}^{p_m}|+|f_m(x_1,\dots,x_{m+1})|\right)\\ &\le (|x_1|^{p_{k+1}}+\cdots+|x_{k+1}|^{p_{k+1}})\gamma_{k+1,0}(x_1,\dots,x_{k+1})\\ &\quad+\sum_{m=1}^{k}\left|\frac{\partial x_{k+1}^*}{\partial x_m}\right|(|x_1|^{p_m}+\cdots+|x_{m+1}|^{p_m})\,r_m(x_1,\dots,x_m).\end{aligned}$$

Note that $p_{k+1}\le p_k\le\cdots\le p_1$ and $x_m^*(0)=0,\ m=1,\dots,k$. Thus we have

$$|\tilde{a}_{k+1,0}(\cdot)| \le (|\xi_1|^{p_{k+1}}+\cdots+|\xi_{k+1}|^{p_{k+1}})\tilde{\gamma}_{k+1,0}(\xi_1,\dots,\xi_{k+1})\tag{2.13}$$

for a C^∞ function $\tilde{\gamma}_{k+1,0}(\cdot)\ge 0$. Putting (2.12) and (2.13) together, it is deduced from Lemma 2.4 that

$$|F_{k+1}(x_1,\dots,x_{k+2})| \le \sum_{l=0}^{p_{k+1}-1}(|\xi_1|^{p_{k+1}-l}+\cdots+|\xi_{k+1}|^{p_{k+1}-l})\tilde{\gamma}_{k+1,l}(\cdot)|x_{k+2}|^l$$

$$\leq \sum_{l=0}^{p_{k+1}-1} \left(\frac{|x_{k+2}|^{p_{k+1}}}{2p_{k+1}} + (|\xi_1|^{p_{k+1}} + \cdots + |\xi_{k+1}|^{p_{k+1}})\rho_{k+1,l}(\xi_1, \ldots, \xi_{k+1}) \right)$$
$$= \frac{|x_{k+2}|^{p_{k+1}}}{2} + (|\xi_1|^{p_{k+1}} + \cdots + |\xi_{k+1}|^{p_{k+1}})\bar{\rho}_{k+1}(\xi_1, \ldots, \xi_{k+1}),$$

where $\rho_{k+1,l}(\xi_1, \ldots, \xi_{k+1}) \geq 0,\ l = 0, \ldots, p_{k+1} - 1$, and $\bar{\rho}_{k+1}(\xi_1, \ldots, \xi_{k+1}) \geq 0$ are smooth functions. Consequently (by Lemma 2.4(ii)),

$$|\xi_{k+1}^{p_1 - p_{k+1}+1} F_{k+1}(x_1, \ldots, x_{k+2})| \leq \frac{|\xi_{k+1}^{p_1 - p_{k+1}+1} x_{k+2}^{p_{k+1}}|}{2} + \frac{\xi_1^{p_1+1} + \cdots + \xi_k^{p_1+1}}{2} + \xi_{k+1}^{p_1+1} \hat{\rho}_{k+1}(\xi_1, \ldots, \xi_{k+1}), \tag{2.14}$$

for a $C^\infty \hat{\rho}_{k+1}(\cdot) \geq 0$.

Now construct the smooth Lyapunov function

$$V_{k+1}(\xi_1, \ldots, \xi_{k+1}) = V_k(\xi_1, \ldots, \xi_k) + \frac{\xi_{k+1}^{p_1 - p_{k+1}+2}}{p_1 - p_{k+1} + 2}, \tag{2.15}$$

which is positive definite and proper. Clearly, it follows from (2.10) that

(2.16)

$$\begin{aligned}
\dot{V}_{k+1}(\xi_1, \ldots, \xi_{k+1}) &= \dot{V}_k(\xi_1, \ldots, \xi_k) + \xi_{k+1}^{p_1 - p_{k+1}+1} \dot{\xi}_{k+1} \\
&\leq \xi_k^{p_1 - p_k + 1}[(\xi_{k+1} + x_{k+1}^*)^{p_k} - {x_{k+1}^*}^{p_k} + f_k(x_1, \ldots, x_k, \xi_{k+1} + x_{k+1}^*) \\
&\quad - f_k(x_1, \ldots, x_k, x_{k+1}^*)] - (n - k + 1)(x_1^{p_1+1} + \cdots + \xi_k^{p_1+1}) \\
&\quad + \xi_{k+1}^{p_1 - p_{k+1}+1}[x_{k+2}^{p_{k+1}} + F_{k+1}(x_1, \ldots, x_{k+2})] \\
&\leq \xi_k^{p_1 - p_k + 1}[(\xi_{k+1} + x_{k+1}^*)^{p_k} \\
&\quad - {x_{k+1}^*}^{p_k} + f_k(x_1, \ldots, x_k, \xi_{k+1} + x_{k+1}^*) - f_k(x_1, \ldots, x_k, x_{k+1}^*)] \\
&\quad - (n - k + 1)(x_1^{p_1+1} + \cdots + \xi_k^{p_1+1}) \\
&\quad + \xi_{k+1}^{p_1 - p_{k+1}+1}[{x_{k+2}^*}^{p_{k+1}} + F_{k+1}(x_1, \ldots, x_{k+2}^*)] \\
&\quad + \xi_{k+1}^{p_1 - p_{k+1}+1}[x_{k+2}^{p_{k+1}} - {x_{k+2}^*}^{p_{k+1}} + f_{k+1}(x_1, \ldots, x_{k+2}) \\
&\quad - f_{k+1}(x_1, \ldots, x_{k+2}^*)].
\end{aligned}$$

Since $x_{k+1}^* = -\xi_k \alpha_k(\xi_1, \ldots, \xi_k)$, it can be shown that

$$|(\xi_{k+1} + x_{k+1}^*)^l - {x_{k+1}^*}^l| \leq |\xi_{k+1}|(|\xi_{k+1}|^{l-1} + |\xi_k|^{l-1})\beta_{k+1,l}(\xi_1, \ldots, \xi_{k+1}) \tag{2.17}$$

for a $C^\infty\ \beta_{k+1,l}(\cdot) \geq 0$. Hence

$$\begin{aligned}
&\xi_k^{p_1 - p_k + 1}\ [\ f_k(x_1, \ldots, x_k, \xi_{k+1} + x_{k+1}^*) - f_k(x_1, \ldots, x_k, x_{k+1}^*)] \\
&\quad \leq |\xi_{k+1}|(|\xi_1|^{p_1} + \cdots + |\xi_{k+1}|^{p_1}) \sum_{l=1}^{p_k - 1} 2k^2 \beta_{k+1,l}(\cdot)\gamma_{k+1,l}(\cdot) \\
&\quad \leq \frac{\xi_1^{p_1+1} + \cdots + \xi_k^{p_1+1}}{4} + \xi_{k+1}^{p_1+1} \tilde{\rho}_{k+1,2}(\xi_1, \ldots, \xi_{k+1})
\end{aligned} \tag{2.18}$$

for a $C^\infty\ \tilde{\rho}_{k+1,2}(\cdot) \geq 0$. This, together with Lemma 2.4, implies that there exists a *smooth* function $\tilde{\rho}_{k+1}(\cdot) \geq 0$, such that

$$\begin{aligned}(2.19)\qquad \xi_k^{p_1-p_k+1}\ &\big[(\xi_{k+1}+x_{k+1}^*)^{p_k}-x_{k+1}^{*p_k}+f_k(x_1,\dots,x_k,\xi_{k+1}+x_{k+1}^*)\\ &\quad -f_k(x_1,\dots,x_k,x_{k+1}^*)\big]\\ &\le \frac{\xi_1^{p_1+1}+\cdots+\xi_k^{p_1+1}}{2}+\xi_{k+1}^{p_1+1}\tilde\rho_{k+1}(\xi_1,\dots,\xi_{k+1}).\end{aligned}$$

Substituting (2.14) and (2.19) into (2.16) yields

$$\begin{aligned}(2.20)\quad \dot V_{k+1}(\xi_1,\dots,\xi_{k+1})\le\ &-(n-k)(\xi_1^{p_1+1}+\cdots+\xi_k^{p_1+1})\\ &+\xi_{k+1}^{p_1-p_{k+1}+1}[x_{k+2}^{p_k}-{x_{k+2}^*}^{p_k}+f_{k+1}(x_1,\dots,x_{k+2})\\ &-f_{k+1}(x_1,\dots,x_{k+1},x_{k+2}^*)]\\ &+\xi_{k+1}^{p_1-p_{k+1}+1}{x_{k+2}^*}^{p_{k+1}}+\frac{|\xi_{k+1}^{p_1-p_{k+1}+1}{x_{k+2}^*}^{p_{k+1}}|}{2}\\ &+\xi_{k+1}^{p_1+1}\left(\tilde\rho_{k+1}(\cdot)+\hat\rho_{k+1}(\cdot)\right).\end{aligned}$$

Clearly, the *smooth state* feedback control law

$$x_{k+2}^*(x_1,\dots,x_{k+1})=-\xi_{k+1}\alpha_{k+1}(\xi_1,\dots,\xi_{k+1}),\qquad \xi_m=x_m-x_m^*,\ m=1,\dots,k+1,\tag{2.21}$$

with $\alpha_{k+1}(\xi_1,\dots,\xi_{k+1})=[2n-2k+2\tilde\rho_{k+1}(\cdot)+2\hat\rho_{k+1}(\cdot)]^{\frac{1}{p_{k+1}}}>0$, is such that

$$\begin{aligned}\dot V_{k+1}(\xi_1,\dots,\xi_{k+1})\le\ &-(n-k)(\xi_1^{p_1+1}+\cdots+\xi_{k+1}^{p_1+1})\\ &+\xi_{k+1}^{p_1-p_{k+1}+1}[x_{k+2}^{p_{k+1}}-x_{k+2}^{*p_{k+1}}+f_{k+1}(x_1,\dots,x_{k+2})\\ &-f_{k+1}(x_1,\dots,x_{k+1},x_{k+2}^*)].\end{aligned}$$

This completes the inductive proof.

Repeatedly using the above inductive argument, it is easy to prove, at the nth step, that one can explicitly construct a change of coordinates $(\xi_1,\dots,\xi_n)$ of the form (2.8), a *smooth* state feedback law

$$u=x_{n+1}^*=-\xi_n\alpha_n(\xi_1,\dots,\xi_n),\qquad \alpha_n(\cdot)>0,\tag{2.22}$$

and a positive definite and proper Lyapunov function $V_n(\xi_1,\dots,\xi_n)$ of the form (2.15), such that

$$\dot V_n(\xi_1,\dots,\xi_n)\le-(\xi_1^{p_1+1}+\cdots+\xi_n^{p_1+1}).\tag{2.23}$$

Since the change of coordinates (2.8) is a global diffeomorphism, we conclude from (2.23) that system (2.1) is globally asymptotically stabilizable at the equilibrium $(x_1,\dots,x_n)=(0,\dots,0)$ by the smooth state feedback control law (2.22). □

Remark 2.5. When $a_{i,l}(x_1,\dots,x_i)=0$, $i=1,\dots,n$, and $l=1,\cdots,p_i-1$, system (2.1) reduces to a lower-triangular system considered in [20]. Therefore, Theorem 2.3 includes the previous global stabilization result for a high-order lower-triangular system as a special case. The technique used in the proof of Theorem 2.3 is a generalized version of the adding a power integrator technique proposed in [20].

We conclude this section with an example that demonstrates how a smooth controller can be designed for a two-dimensional nonlinear system in the form (2.1).

Example 2.6. Consider the planar system

$$\begin{aligned}\dot x_1&=x_2^3+x_1^2x_2+x_1^3,\\ \dot x_2&=u^3.\end{aligned}\tag{2.24}$$

Obviously, this system is of the form (2.1) with $p_1 = p_2 = 3$. Hence Assumption 2.1 holds. A simple calculation shows that $f_1(x_1, x_2) = a_{1,0}(x_1) + a_{1,1}(x_1)x_2$ with $a_{1,0}(x_1) = x_1^3$ and $a_{1,1}(x_1) = x_1^2$. Clearly,

$$|a_{1,0}(x_1)| \le |x_1|^3, \qquad |a_{1,1}(x_1)| \le |x_1|^2,$$

which implies that Assumption 2.2 is also fulfilled. By Theorem 2.3, there exists a smooth controller that renders the equilibrium $(x_1, x_2) = (0, 0)$ of (2.24) GAS. The controller can be explicitly constructed by following the design procedure in Theorem 2.3.

First, choose $V_1 = \frac{x_1^2}{2}$. Then the virtual controller

$$x_2^* = -\sqrt[3]{\frac{11}{2}}x_1 \tag{2.25}$$

renders

$$\dot{V}_1 \le -2x_1^4 + x_1(x_2^3 - x_2^{*3}) + x_1^3(x_2 - x_2^*). \tag{2.26}$$

Next consider the Lyapunov function

$$V_2 = \frac{x_1^2}{2} + \frac{\left(x_2 + \sqrt[3]{\frac{11}{2}}x_1\right)^2}{2}.$$

Using an argument similar to the proof of Theorem 2.3, it is easy to see that the smooth controller

$$u = -38\left(x_2 + \sqrt[3]{\frac{11}{2}}x_1\right)$$

is such that

$$\dot{V}_2 \le -x_1^4 - \left(x_2 + \sqrt[3]{\frac{11}{2}}x_1\right)^4,$$

thus stabilizing the system (2.24) in the large.

3. Necessity of Assumptions 2.1–2.2. In this section, we discuss to what extent the sufficient conditions Assumptions 2.1 and 2.2 given in the previous section are *necessary* for global stabilization via *smooth* state feedback. We give examples to illustrate that smooth stabilization of the system (2.1) is not possible if either Assumption 2.1 or Assumption 2.2 fails to be satisfied.

First, we show that Assumption 2.1 is somewhat necessary for solving the stabilization problem of high-order nonlinear systems (2.1).

Example 3.1. Consider the two-dimensional nonlinear system

$$\begin{aligned} \dot{x}_1 &= x_2^3 + x_1^2x_2 + x_1^3, \\ \dot{x}_2 &= u^p. \end{aligned} \tag{3.1}$$

When $p = 3$ or $p = 1$, the system satisfies the hypotheses Assumptions 2.1 and 2.2. By Theorem 2.3, there is a smooth static state feedback control law that globally

asymptotically stabilizes (3.1) at $(x_1, x_2) = (0, 0)$. An explicit smooth controller has been given in Example 2.6.

If $p \geq 5$ is an odd integer, system (3.1) satisfies Assumption 2.2 but not Assumption 2.1. Then one can prove the following claim: system (3.1) with $p = 5$ cannot be stabilized, even locally, by any *smooth static* state feedback.

Proof. The claim is proved by contradiction. Suppose there is a smooth state feedback $\alpha(x)$, with $\alpha(0) = 0$ and $x = (x_1, x_2)^T$, such that system (3.1) is locally asymptotically stable at $(0, 0)$. Then $\forall \varepsilon \in (0, 1)$, there is a $\delta \in (0, \varepsilon)$ such that $\|x(0)\| < \delta \Rightarrow \|x(t, x(0))\| < \varepsilon \ \forall t \geq 0$.

Now consider the domain $\Omega_\varepsilon = \{x| \ \|x\| \leq \varepsilon, x_1 \geq 0, x_1 \geq -2x_2\}$ shown in Figure 3.1. Choose an initial condition $(x_1(0), x_2(0))$ in the interior of Ω_ε and $0 < \|x(0)\| < \delta$. Let $x(t, x(0))$ be a trajectory starting from $x(0)$. In the interior of Ω_ε, $1 > x_1 > -2x_2$ and $x_1 > 0$, which implies $\dot{x}_1 > 0$, $(x_1, x_2) \in$ interior of Ω_ε.

In fact, when $x_2 \geq 0$ it is clear that $\dot{x}_1 > 0$. In the case when $x_2 < 0$, a direct calculation gives

$$\dot{x}_1 = x_2^3 + x_1^2 x_2 + x_1^3 \geq x_2^3 + x_1^3 - \frac{2x_1^3}{3} - \frac{|x_2|^3}{3} = \frac{4x_2^3 + x_1^3}{3} > \frac{(2x_2)^3 + x_1^3}{3} \geq 0.$$

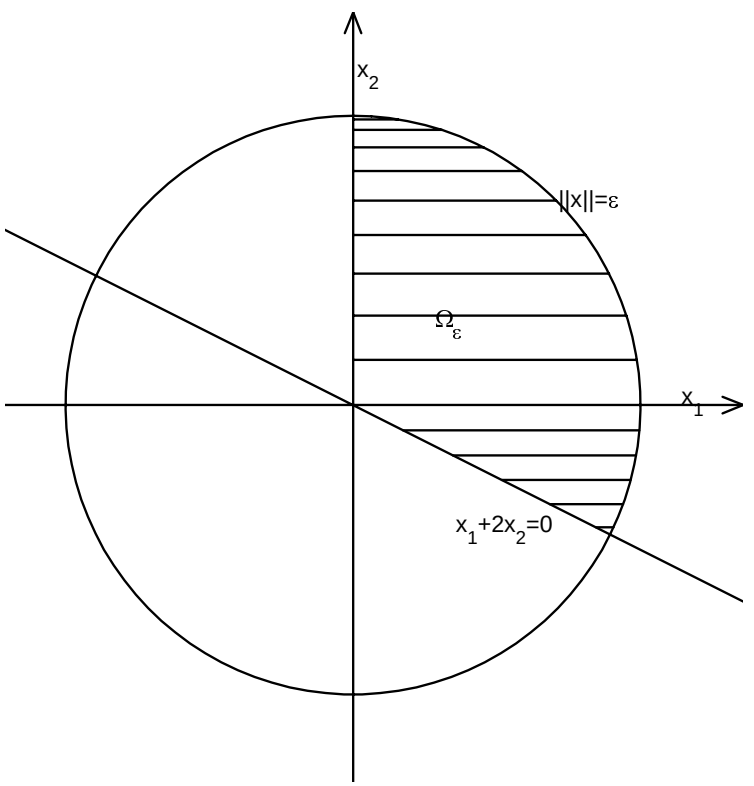

FIG. 3.1. *The domain of* Ω_ε.

Therefore, $x(t)$ cannot remain in Ω_ε forever if the origin is asymptotically stabilizable. In other words, the trajectory of (3.1) must cross the boundaries of Ω_ε in finite time. By assumption, $\|x(t, x(0))\| < \varepsilon \ \ \forall t \geq 0$. Thus the trajectory cannot cross the boundary $\Omega_\varepsilon \bigcap \{x| \ \|x\| = \varepsilon\}$. Note that the trajectory cannot cross

$\Omega_\varepsilon \bigcap \{x|\ x_1 = 0, x_2 \neq 0\}$ as on that boundary $\dot{x}_1 > 0$. In conclusion, the trajectory $x(t, x(0))$ of (3.1) must cross the line $\Omega_\varepsilon \bigcap \{x|\ x_1 + 2x_2 = 0\}$. In other words, there exists a point $x^* = (x_1^*, x_2^*)$ on $\Omega_\varepsilon \bigcap \{x|\ x_1 + 2x_2 = 0\}$ such that

$$-2\alpha^5(x^*) \geq {x_1^*}^3 + {x_1^*}^2 x_2^* + {x_2^*}^3, \qquad x_1^* = -2x_2^*, \qquad \|x^*\| < \varepsilon. \tag{3.2}$$

Since $x_1(0) > 0$ and $\dot{x}_1(t) > 0$ in the interior of Ω_ε, $x_1^* \geq x_1(0) > 0$.

From the argument above it is concluded that for every $\varepsilon_i \in (0, 1)$, there exists a $x_1^* = \theta_i > 0$ such that (3.2) holds. Choose $\varepsilon_1 = \varepsilon$ and $\varepsilon_i = \frac{\theta_{i-1}}{2}$, $i = 2, 3, \ldots$. In this way, we have generated a monotone, strictly decreasing sequence $\{\theta_i > 0\}_{i=1}^{\infty}$, having the properties that $\theta_i \to 0$ as $i \to \infty$ and

$$-2\alpha^5\left(\theta_i, \frac{-\theta_i}{2}\right) \geq \theta_i^3 + \theta_i^2\left(\frac{-\theta_i}{2}\right) + \left(\frac{-\theta_i}{2}\right)^3 = \frac{3\theta_i^3}{8} > 0, \quad i = 1, 2, \ldots.$$

This implies that

$$\frac{|\alpha(\theta_i, \frac{-\theta_i}{2}) - \alpha(0,0)|}{\|(\theta_i, \frac{-\theta_i}{2}) - (0,0)\|} = \frac{|\alpha(\theta_i, \frac{-\theta_i}{2})|}{\sqrt{\theta_i^2 + \frac{\theta_i^2}{4}}} \geq \frac{\sqrt[5]{6}}{\sqrt{5}}\theta_i^{-\frac{2}{5}} \to \infty \quad \text{as} \quad i \to \infty.$$

Therefore, the controller $u = \alpha(x)$ is not differentiable at $(0, 0)$, which is a contradiction. □

The next example demonstrates that the condition (2.3) is also crucial for the problem of smooth stabilization to be solvable.

Example 3.2. Consider the scalar system

$$\dot{x} = u^5 + u^2 x^p, \tag{3.3}$$

where p is a nonnegative integer.

This system always satisfies Assumption 2.1 and (2.2). However, if $p < 3$, $|a_{1,2}(x)| = |x^p|$ cannot be bounded by $|x|^3\rho(x)$, where $\rho(x) \geq 0$ is a smooth function. Thus (2.3) is not satisfied. In this case, it can be shown that there is no smooth controller, making the equilibrium $x = 0$ of system (3.3) locally asymptotically stable. To this end, suppose that there exists a stabilizing smooth controller $u(x)$ with $u(0) = 0$ and $u(x) \neq 0\ \forall x \in N - \{0\}$, where N is an open neighborhood of $x = 0$. By smoothness, $u(x) = xh(x)$ for a smooth function $h(x)$. Let δ be a real number in $(0, 1)$. Then, for $0 < x \leq \delta$ and sufficiently small δ, $x^p + u^3 = x^p + x^3h^3(x) > 0$ and $u(x) \neq 0$. This implies that for $V(x) = x$,

$$\dot{V} = u^2(x^p + u^3) > 0, \qquad x \in \{x \mid V(x) > 0, |x| \leq \delta\}.$$

By the Lyapunov instability theorem, the closed-loop system is unstable at the equilibrium $x = 0$.

When $p \geq 3$, (2.3) holds. By Theorem 2.3, there does exist a smooth state stabilizer. A smooth controller can be constructed as

$$u = -x\left(\frac{5}{3} + (1 + x^2)^{\frac{5(p-3)}{6}}\right)^{1/5}. \tag{3.4}$$

It is straightforward to verify that the time derivative of $V = x^2/2$ along the trajectory of the closed-loop system (3.3)–(3.4) satisfies

$$\dot{V} \leq -x^6.$$

Finally, the necessity of hypothesis (2.2) can be illustrated by the simple example below.

Example 3.3. Consider the planar system

$$\begin{aligned} \dot{x}_1 &= x_2^3 + x_2^3 x_1, \\ \dot{x}_2 &= u^3, \end{aligned} \tag{3.5}$$

for which Assumption 2.1 and (2.3) are fulfilled. However, (2.2) is violated as the order of x_2 in the decomposition term is equal to $p_1 = 3$. We claim that the system cannot be GAS by smooth state feedback, for observe that $x_1 = -1$ makes the first component of the vector field vanish. Thus, regardless of the choice of $u = u(x_1, x_2)$, the vertical line $x_1 = -1$ in the phase-plane is an invariant set which cannot be crossed by any trajectory. Indeed, for any $x_1(0) \leq -1$ there exists no feedback controller that can steer $x_1(t)$ to zero as $t \to \infty$.

4. Synthesis of cascade systems.

A. Global stabilization by smooth feedback. Now we show how the smooth feedback stabilization result developed in section 2 can be extended to the class of nonlinear systems of the form (1.3). We begin by listing three assumptions.

Assumption 4.1. $p_1 \geq p_2 \geq \cdots \geq p_r \geq 1$ are odd integers.

Assumption 4.2. For $i = 1, \ldots, r$,

$$f_i(z, x_1, \ldots, x_i, x_{i+1}) = \sum_{j=0}^{p_i - 1} C_{i,j}(z, x_1, \ldots, x_i) x_{i+1}^j,$$

$$|C_{i,j}(z, x_1, \ldots, x_i)| \leq (\|z\|^{p_i - j} + |x_1|^{p_i - j} + \cdots + |x_i|^{p_i - j}) \rho_{i,j}(z, x_1, \ldots, x_i), \tag{4.1}$$

where $x_{r+1} := u$ and $\rho_{i,j}(\cdot) \geq 0$ is a known smooth function.

Assumption 4.3. Assume that there is a real-valued, nonnegative smooth function $\gamma_0(z, x_1)$ such that

$$\|f_0(z, x_1)\| \leq (\|z\|^{p_1} + |x_1|^{p_1}) \gamma_0(z, x_1).$$

Using Assumptions 4.1–4.3, it is possible to prove the following global stabilization result.

THEOREM 4.4. *Consider the nonlinear system* (1.3) *satisfying Assumptions* 4.1–4.3. *Suppose there exist a smooth function* $x_1 = v^*(z)$ *with* $v^*(0) = 0$, *and a smooth Lyapunov function* $V(z)$, *which is positive definite and proper, such that*

$$\frac{\partial V}{\partial z} f_0(z, v^*(z)) \leq -\|z\|^{p_0 + 1} W(z), \qquad W(z) > 0, \quad \forall z, \tag{4.2}$$

$$\left\| \frac{\partial V}{\partial z} \frac{\partial f_0(z, x_1)}{\partial x_1} \right\| \leq (\|z\|^{p_0} + |x_1|^{p_0}) \gamma_1(z, x_1), \quad \gamma_1(\cdot) \geq 0, \tag{4.3}$$

where $p_0 \geq p_1$ *is an odd integer and* $W(z)$ *and* $\gamma_1(\cdot)$ *are smooth functions. Then system* (1.3) *is globally asymptotically stabilizable at* $(z, x_1, \ldots, x_r) = 0$ *by a smooth static controller* $u = u(z, x_1, \ldots, x_r)$ *with* $u(0, 0, \ldots, 0) = 0$.

Proof. The theorem can be proved in a fashion similar to the proof of Theorem 2.3 by using the generalized adding a power integrator technique. The major difference lies in the first step. For this reason, in what follows we consider only the case where $r = 1$ in system (1.3), i.e.,

$$\begin{aligned} \dot{z} &= f_0(z, x_1), \\ \dot{x}_1 &= u^{p_1} + f_1(z, x_1, u). \end{aligned} \tag{4.4}$$

This system can be rewritten as

$$\begin{aligned} \dot{z} &= f_0(z, v^*(z)) + \Delta(z, x_1), \\ \dot{x}_1 &= u^{p_1} + f_1(z, x_1, u) \end{aligned} \tag{4.5}$$

with

$$\Delta(z, x_1) = f_0(z, x_1) - f_0(z, v^*(z)). \tag{4.6}$$

For system (4.5), consider the Lyapunov function

$$U(z, x_1) = V(z) + \frac{(x_1 - v^*(z))^{p_0 - p_1 + 2}}{p_0 - p_1 + 2},$$

which is positive definite and proper. Then a direct calculation gives

$$\begin{aligned} \dot{U}(z, x_1)|_{(4.5)} \le & -\|z\|^{p_0+1} W(z) + \frac{\partial V(z)}{\partial z} \Delta(z, x_1) + \xi^{p_0 - p_1 + 1} u^{p_1} \\ & + \xi^{p_0 - p_1 + 1} \phi(z, \xi, u), \end{aligned} \tag{4.7}$$

where

$$\xi = x_1 - v^*(z) \equiv x_1 - z^T \alpha(z) \ \text{ for a } C^\infty, \quad \alpha(z) \in R^m,$$

$$\phi(z, \xi, u) = f_1(z, \xi + v^*(z), u) - \frac{\partial v^*}{\partial z} f_0(z, \xi + v^*(z)).$$

Using Assumption 4.2 and Lemma 2.4(i), we have

$$\begin{aligned} |\phi(z, \xi, u)| \le & \sum_{j=0}^{p_1 - 1} (\|z\|^{p_1 - j} + |\xi + v^*|^{p_1 - j}) \rho_{1,j}(z, \xi + v^*(z)) |u^j| \\ & + (\|z\|^{p_1} + |\xi + v^*|^{p_1}) \left| \frac{\partial v^*}{\partial z} \right| \gamma_0(z, \xi + v^*) \\ \le & \sum_{j=0}^{p_1 - 1} \left\| \begin{matrix} z \\ \xi \end{matrix} \right\|^{p_1 - j} |u^j| \hat{\rho}_{1,j}(z, \xi) + (\|z\|^{p_1} + |\xi + v^*|^{p_1}) \left| \frac{\partial v^*}{\partial z} \right| \gamma_0(z, \xi + v^*) \\ \le & \frac{|u|^{p_1}}{2} + (\|z\|^{p_1} + |\xi|^{p_1}) \gamma(z, \xi) \end{aligned} \tag{4.8}$$

for a smooth $\gamma(z, \xi) \ge 0$. By (4.8) and Lemma 2.4, there exists a smooth nonnegative function $\rho_1(z, \xi)$ such that

$$|\xi^{p_0 - p_1 + 1} \phi(z, \xi, u)| \le \frac{\|z\|^{p_0+1} W(z)}{4} + \xi^{p_0+1} \rho_1(z, \xi) + \frac{1}{2} |\xi|^{p_0 - p_1 + 1} |u|^{p_1}. \tag{4.9}$$

Using (4.3), (4.6), and the Taylor expansion formula, one has

$$\begin{aligned} \left| \frac{\partial V(z)}{\partial z} \Delta(z, x_1) \right| &\equiv \left| \frac{\partial V}{\partial z} \left(\int_0^1 \left. \frac{\partial f_0}{\partial x_1} \right|_{x_1 = v^* + \lambda\xi} d\lambda \right) \xi \right| \\ &\le |\xi| \int_0^1 (\|z\|^{p_0} + |v^* + \lambda\xi|^{p_0}) \gamma_1(\cdot) d\lambda \\ &\le |\xi| \int_0^1 (\|z\|^{p_0} + |\lambda\xi|^{p_0}) \tilde{\gamma}(z, v^* + \lambda\xi) d\lambda \\ &\le |\xi| \, (\|z\|^{p_0} + |\xi|^{p_0}) \int_0^1 \tilde{\gamma}(z, v^* + \lambda\xi) d\lambda, \end{aligned}$$

where $\tilde{\gamma}(\cdot) \geq 0$ is a smooth function.

The last inequality, together with Lemma 2.4(i), implies

$$\left|\frac{\partial V(z)}{\partial z}\Delta(z,x_1)\right| \leq \frac{\|z\|^{p_0+1}W(z)}{4} + \xi^{p_0+1}\rho_2(z,\xi) \tag{4.10}$$

for an appropriate nonnegative smooth function $\rho_2(z,\xi)$.

Substituting (4.9) and (4.10) into (4.7), we arrive at

$$\begin{aligned}\dot{U}(z,x_1)|_{(4.5)} \leq & -\frac{\|z\|^{p_0+1}W(z)}{2} + \xi^{p_0-p_1+1}u^{p_1} \\ & +\frac{1}{2}|\xi|^{p_0-p_1+1}|u|^{p_1} + \xi^{p_0+1}[\rho_1(z,\xi)+\rho_2(z,\xi)].\end{aligned} \tag{4.11}$$

Choose a smooth controller of the form

$$u = -2\xi\left[\frac{W(z)}{2} + \rho_1(z,\xi) + \rho_2(z,\xi)\right]^{\frac{1}{p_1}}. \tag{4.12}$$

Clearly, the proposed controller renders

$$\dot{U}(z,x_1)|_{(4.5)} \leq -\left(\|z\|^{p_0+1} + \xi^{p_0+1}\right)\frac{W(z)}{2}.$$

Thus Theorem 4.4 is true when $r = 1$.

If $r > 1$, Theorem 4.4 can be proved by repeatedly using the technique of adding a power integrator, as done in the proof of Theorem 2.3. □

In the remainder of this section, we use several examples to illustrate some of the interesting features of Theorem 4.4 and its applications to the smooth feedback stabilization problem. First, we illustrate how Theorem 4.4 can be used to deal with a general system which is not in a lower-triangular form.

Example 4.5. Consider the nonlinear system

$$\begin{aligned}\dot{z}_1 &= z_2^3 - 2z_1x_1^2, \\ \dot{z}_2 &= x_1^5 - z_2^5, \\ \dot{x}_1 &= u^3 + u^2\sin x_1 + uz_1z_2,\end{aligned} \tag{4.13}$$

which is not feedback linearizable, as the linearized system is not controllable. Moreover, the system is neither in a lower-triangular form nor affine in u; thus it cannot be handled by [20].

On the other hand, the system is of the form (1.3). The zero-dynamics (z_1, z_2) of (4.13) is GAS by $x_1 = v^*(z_1,z_2) = -z_1$. In fact, let $V(z_1,z_2) = \frac{z_1^4+2z_2^2}{4}$. A direct calculation gives

$$\dot{V}|_{x_1=v^*(z_1,z_2)} \leq -\frac{1}{3}(z_1^6 + z_2^6).$$

For $p_0 = 5$, $p_1 = 3$, it is easy to see that (4.2) and (4.3) are satisfied. Since $f_1(z_1,z_2,x_1,u) = u^3 + u^2\sin x_1 + uz_1z_2$, Assumption 4.2 also holds. Therefore, by Theorem 4.4 system (4.13) is GAS by smooth state feedback.

It has been known that achieving global stabilizability for a nonlinear system whose zero-dynamics depend on more than one component of x (i.e., x_1) is usually

difficult [29, 4]. It is of interest to point out that this may not be the case when dealing with high-order nonlinear systems. In fact, one can extend Theorem 4.4 to a more general class of nonlinear systems (than (1.3)), in which the zero-dynamics $\dot{z} = f_0(z, x_1)$ are replaced by

$$\dot{z} = f_0(z, x_1) + \sum_{j=1}^{p_1-1} a_j(z, x_1) x_2^j. \tag{4.14}$$

COROLLARY 4.6. *Consider the nonlinear system* (1.3)*, where the z-equation is replaced by* (4.14)*. Suppose all the hypotheses of Theorem* 4.4 *are fulfilled. In addition, assume the following:*

$$a_j(z, v^*(z)) = 0, \quad \left|\frac{\partial a_j(z, x_1)}{\partial x_1}\right| \le (\|z\|^{p_1-1-j} + |x_1|^{p_1-1-j})\hat{r}_j(z, x_1), \quad j = 1, \dots, p_1 - 1, \tag{4.15}$$

where $\hat{r}_j(z, x_1) \ge 0$ *is smooth. Then the system is globally asymptotically stabilizable by smooth state feedback.*

The proof of this result is strongly reminiscent of the proof of Theorem 4.4 and is therefore left to the reader as an exercise. The example below demonstrates an appealing application of Corollary 4.6 to a high-order nonlinear system that is not in the form (1.3).

Example 4.7. The nonlinear system

$$\begin{aligned} \dot{z} &= x_2^2 z + x_2^2 x_1 + x_1^3, \\ \dot{x}_1 &= x_2^3, \\ \dot{x}_2 &= u^3 \end{aligned} \tag{4.16}$$

satisfies the assumptions of Corollary 4.6, and therefore a globally stabilizing *smooth* controller exists.

To construct such a smooth feedback law, let $\xi = x_1 + z$ and $V = \frac{z^2+\xi^2}{2}$. Then the time derivative of V along the trajectory of (z, x_1)-subsystem of (4.16) is

$$\begin{aligned} \dot{V} &= -z^4 + z((\xi - z)^3 + z^3) + z\xi x_2^2 + \xi(x_2^3 + (\xi - z)^3 + x_2^2\xi) \\ &= -z^4 - 2\xi^3 z + 2\xi z^3 + \xi x_2^3 + z\xi x_2^2 + x_2^2\xi^2 + \xi^4. \end{aligned}$$

By Lemma 2.4(i), it is clear that

$$\begin{aligned} x_2^2\xi^2 &\le |\xi| \left(\frac{4}{3}|\xi|^3 + \frac{1}{3}|x_2|^3\right), \\ |\xi z x_2^2| &\le |\xi| \left(\frac{4}{3}|z|^3 + \frac{1}{3}|x_2|^3\right). \end{aligned}$$

Hence

$$\dot{V} \le -z^4 + 2|z\xi^3| + \frac{10}{3}|\xi z^3| + \xi x_2^3 + \frac{2}{3}|\xi x_2^3| + \frac{7}{3}\xi^4. \tag{4.17}$$

Note that

$$\begin{aligned} 2|z\xi^3| &\le \frac{1}{8}z^4 + 3\xi^4, \\ \frac{10}{3}|\xi z^3| &\le \frac{5}{8}z^4 + \frac{160}{3}\xi^4. \end{aligned}$$

Substituting the estimates above into (4.17), we have

$$\dot{V} \leq -\frac{1}{4}z^4 + \xi x_2^3 + \frac{2}{3}|\xi x_2^3| + \xi^4\left(\frac{7}{3} + 3 + \frac{160}{3}\right).$$

Obviously, the virtual smooth controller

$$x_2 = x_2^* = -(177)^{1/3}\xi$$

renders

$$\dot{V}|_{x_2=x_2^*} \leq -\frac{1}{4}(z^4 + \xi^4).$$

Therefore, a globally stabilizing smooth controller for (4.16) can be derived directly by adding one more power integrator $\dot{x}_2 = u^3$.

B. Disturbance attenuation with stability. So far we have studied the global stabilization problem for nonlinear systems in the absence of disturbances. When a nonlinear system under consideration involves an undesired input or disturbance that is additive to the system, it is no longer possible nor meaningful to asymptotically stabilize the system, due to the shift of the equilibrium of the system caused by additive external disturbances. Therefore, in the presence of external disturbances, a more realistic problem to be addressed is the so-called problem of disturbance attenuation. That is, the problem of seeking a *smooth* state feedback control law so that the influence of the disturbance on the output is as small as possible. Of course, such a feedback law should also guarantee global asymptotic stability of the system in the absence of disturbances.

The problem of disturbance attenuation of this type was first formulated, in terms of L_2-gain, for linear systems in [32]. For nonlinear systems, the problem has been one of the important subjects in nonlinear control theory over the last decade; see, for instance, the books [11, 26, 31]. To the best of our knowledge, the first work on the disturbance attenuation problem was reported in [22]. The solution presented in [22] is characterized in terms of the L_∞ induced norm from the disturbance inputs to the outputs. A drawback of [22] is that it did not consider the *internal stability* which is crucial for a meaningful application or a practical implementation. The stability issue was addressed later in [23], where a novel design technique based on adding a linear integrator [3, 30] was presented, resulting in an elegant solution to the global disturbance attenuation problem with internal stability, for minimum-phase nonlinear systems of the form (1.1). The disturbance attenuation result obtained in [23] has been generalized to a larger class of minimum-phase and nonminimum-phase nonlinear systems [3, 12, 13]. Notice that all the above-mentioned papers assume that the controlled plants are feedback linearizable and have a lower-triangular structure. As a result, most of the disturbance attenuation results in the literature can only be applied to affine systems that are globally diffeomorphic to (1.1).

In a recent work [28], the disturbance attenuation problem has been studied for a class of lower-triangular systems which are neither feedback linearizable nor affine in the control input. In what follows, we show how the result of [28] can be extended, with the aid of the *generalized adding a power integrator* technique, to the *nonstrict-triangular* cascade system

$$
\begin{aligned}
\dot{z} &= f_0(z, x_1) + \phi_0(z, x_1)w, \\
\dot{x}_1 &= x_2^{p_1} + f_1(z, x_1, x_2) + \phi_1(z, x_1)w, \\
&\vdots \\
\dot{x}_r &= u^{p_r} + f_r(z, x_1, \ldots, x_r, u) + \phi_r(z, x_1, \ldots, x_r)w, \\
y &= h(z, x_1),
\end{aligned} \tag{4.18}
$$

where $w \in \mathbb{R}^s$ represents a disturbance signal, the functions $f_i(\cdot)$, $i = 0, 1, \ldots, r$, are defined as in (1.3), $\phi_0 : \mathbb{R}^{n-r+1} \to \mathbb{R}^{1\times s}$, $\phi_i : \mathbb{R}^{n-r+i} \to \mathbb{R}^{1\times s}$, $i = 1, \ldots, r$, are smooth functions which do not necessarily vanish at the origin, and $h : \mathbb{R}^{n-r+1} \to \mathbb{R}$ is a smooth output function with $h(0, 0) = 0$.

Our goal is to construct, under appropriate conditions, a *smooth* state feedback control law

$$u = u(x) \qquad \text{with} \quad u(0) = 0, \tag{4.19}$$

such that for any real number $\gamma > 0$, the closed-loop system (4.18)–(4.19) satisfies the following:

(1) When $w = 0$, the closed-loop system (4.18)–(4.19) is GAS at $x = 0$.
(2) For every disturbance $w(t) \in L_2$, the response of the closed-loop system (4.18)–(4.19) starting from the initial state $x(0) = 0$ is such that

$$\int_0^t |y(s)|^{2p} ds \le \gamma^2 \int_0^t \|w(s)\|^2 ds \quad \forall t \ge 0, \quad \text{for some integer } p \ge 1. \tag{4.20}$$

□

Here, the problem of disturbance attenuation with internal stability is formulated in terms of an L_2–L_{2p}-gain (rather than a conventional L_2-gain) for cascade nonlinear systems (4.18). This is due to the consideration that the standard L_2-gain formulation is usually *not well-posed* in the case of high-order nonlinear systems. As a matter of fact, for cascade nonlinear system (4.18) an L_2 input signal may not necessarily produce an L_2 output signal. As shown in [28], an L_2 input signal is likely to yield an L_{2p} output signal, where p may be varying and depending on a structure of the system or the output of the system. In the case of feedback linearizable systems, $p = 1$. Then, the formulation above reduces to the standard L_2-gain characterization.

The following theorem gives a constructive solution to the disturbance attenuation problem characterized by an L_2–L_{2p}-gain for the cascade nonlinear system (4.18).

THEOREM 4.8. *Consider the nonlinear system* (4.18). *Suppose there exists a smooth Lyapunov function $V(z)$, which is positive definite and proper, such that*

$$
\begin{aligned}
&\left\| \frac{\partial V}{\partial z} \phi_0(z, x_1) \right\| \le (\|z\|^{p_0} + |x_1|^{p_0}) r_0(z, x_1), \qquad r_0(z, x_1) \ge 0, \\
&\left\| \frac{\partial V}{\partial z} \frac{\partial f_0(z, x_1)}{\partial x_1} \right\| \le (\|z\|^{2p_0 - 1} + |x_1|^{2p_0 - 1}) \tilde{r}_0(z, x_1), \qquad \tilde{r}_0(z, x_1) \ge 0,
\end{aligned} \tag{4.21}
$$

and

$$\frac{\partial V}{\partial z} f_0(z, v^*(z)) + \frac{1}{4\gamma^2} \left(\frac{\partial V}{\partial z} \phi_0(z, v^*(z)) \right)^2 + h^{2p_0}(z, v^*(z)) \le -\|z\|^{2p_0} W(z) \tag{4.22}$$

for a C^∞ $W(z) > 0$, where $p_0 \ge p_1$ is an odd integer, $v^*(z)$ is a smooth real-valued function with $v^*(0) = 0$, and the functions $r_0(\cdot)$, $\tilde{r}_0(\cdot)$, and $W(z)$ are smooth. Then

the disturbance attenuation problem with internal stability is solvable via smooth state feedback, if the hypotheses in Assumptions 4.1– 4.3 *hold.*

The proof of this result again relies on the *generalized adding a power integrator* technique. To begin with, we first introduce an important technical lemma which shows that the Hamilton–Jacobi–Isaacs (HJI) partial differential inequality (4.22) arising from the disturbance attenuation problem implies a dissipation inequality at the first step and can be propagated through adding a power integrator at each step.

LEMMA 4.9. *Consider a nonlinear system described by equations of the form*

$$\begin{cases} \dot{z} = f_0(z,\zeta) + \phi_0(z,\zeta)w, \\ \dot{\zeta} = u^{p_1} + f_1(z,\zeta,u) + \phi_1(z,\zeta)w, \\ y = h(z,\zeta), \end{cases} \tag{4.23}$$

in which $z \in \mathbb{R}^{n-r}$ *and* $\zeta \in \mathbb{R}$. *Suppose there exists a smooth Lyapunov function* $V(z)$, *which is positive definite and proper, such that*

$$\left\| \frac{\partial V}{\partial z}\phi_0(z,\zeta) \right\| \le (\|z\|^{p_0} + |\zeta|^{p_0}) r_0(z,\zeta), \qquad r_0(z,\zeta) \ge 0, \tag{4.24}$$

$$\left\| \frac{\partial V}{\partial z}\frac{\partial f_0(z,\zeta)}{\partial \zeta} \right\| \le (\|z\|^{2p_0-1} + |\zeta|^{2p_0-1}) \tilde{r}_0(z,\zeta), \qquad \tilde{r}_0(z,\zeta) \ge 0, \tag{4.25}$$

and

$$\frac{\partial V}{\partial z} f_0(z, v^*(z)) + \frac{1}{4\gamma^2}\left(\frac{\partial V}{\partial z}\phi_0(z, v^*(z))\right)^2 + h^{2p_0}(z, v^*(z)) \le -\|z\|^{2p_0} W(z), \;\; W(z) > 0, \tag{4.26}$$

where $p_0 \ge p_1$ *is an odd integer,* $v^*(z)$ *is a smooth function with* $v^*(0) = 0$, *and the functions* $r_0(\cdot)$, $\tilde{r}_0(\cdot)$, *and* $W(z)$ *are smooth. Under Assumptions* 4.2 *and* 4.3 *(with* $r = 1$, $\zeta = x_1$*), there are a smooth state feedback law* $u(z,\zeta)$ *with* $u(0,0) = 0$ *and a smooth Lyapunov function* $U(z,\zeta)$, *which is positive definite and proper, such that*

$$L_F U(z,\zeta) + \frac{1}{4\gamma^2}\left(L_\Phi U(z,\zeta)\right)^2 + h^{2p_0}(z,\zeta) \le -\left(\|z\|^{2p_0} + \|\zeta\|^{2p_0}\right)\mathcal{W}(z,\zeta)$$

for a C^∞ $\mathcal{W}(z,\zeta) > 0$, *where*

$$F(z,\zeta) = \begin{pmatrix} f_0(z,\zeta) \\ u^{p_1}(z,\zeta) + f_1(z,\zeta,u(z,\zeta)) \end{pmatrix}, \qquad \Phi(z,\zeta) = \begin{pmatrix} \phi_0(z,\zeta) \\ \phi_1(z,\zeta) \end{pmatrix}.$$

The proof of Lemma 4.9 is analogous to that of Theorem 4.4 with an appropriate modification. However, a different Lyapunov function $U(z,\zeta) = V(z) + \frac{(\zeta - v^*(z))^{2p_0-p_1+1}}{2p_0-p_1+1}$ must be used to carry out the proof.

Proof of Theorem 4.8. By Lemma 4.9, it is clear that Theorem 4.8 holds when $r = 1$. In the case where $r > 1$, Theorem 4.8 can be proved by repeatedly using Lemma 4.9. In fact, it can be easily verified that all the conditions of Lemma 4.9 are fulfilled when adding a power integrator each time. At the last step, one can prove that there are a smooth Lyapunov function $\tilde{U}(z,x)$, which is positive definite and proper, and a smooth state feedback law $u(z,x)$ with $u(0,0) = 0$, such that system (4.18) satisfies

$$L_{\tilde{F}}\tilde{U}(z,x) + \frac{1}{4\gamma^2}\left(L_{\tilde{\Phi}}\tilde{U}(z,x)\right)^2 + h^{2p_0}(z,x_1) \le -\left(\|z\|^{2p_0} + \|x\|^{2p_0}\right)\tilde{W}(z,x)$$

for a C^∞ $\tilde{W}(z,x) > 0$, where

$$\tilde{F}(z,x) = \begin{pmatrix} f_0(z,x_1) \\ x_2^{p_1} + f_1(z,x_1,x_2) \\ \vdots \\ u^{p_r}(z,x) + f_r(z,x_1,\ldots,x_r,u(z,x)) \end{pmatrix},$$

$$\tilde{\Phi}(z,\zeta) = \begin{pmatrix} \phi_0(z,x_1) \\ \phi_1(z,x_1) \\ \vdots \\ \phi_r(z,x_1,\ldots,x_r) \end{pmatrix}.$$

It is straightforward to prove that the HJI inequality above implies

$$\dot{\tilde{U}} + y^{2p_0} - \gamma^2 w^2 \le -\left(\|z\|^{2p_0} + \|x\|^{2p_0}\right)\tilde{W}(z,x). \tag{4.27}$$

Therefore, Theorem 4.8 follows immediately from the dissipation inequality (4.27). Indeed, (4.27) implies that system (4.18) is GAS by the smooth state feedback $u = u(z,x)$ when $w = 0$. Moreover, in the presence of an L_2 disturbance signal $w(t)$, the disturbance attenuation problem, characterized in term of an $L_2 - L_{2p_0}$-gain, is solved by *smooth* state feedback. □

As a consequence of Theorem 4.8, we arrive at the following important conclusion.

COROLLARY 4.10. *Consider the nonlinear system* (4.18) *with trivial zero-dynamics, i.e.,* $\dim z = 0$. *Under the hypotheses in Assumptions* 4.1–4.2 *with* $z = 0$, *the disturbance attenuation problem with* $p = p_1$ *is solvable by smooth state feedback.*

OBSERVABILITY AND CONTROL OF SCHRÖDINGER EQUATIONS*

K.-D. PHUNG†

Abstract. We propose an exact controllability result for Schrödinger equations in bounded domains under the Bardos–Lebeau–Rauch geometric control condition with an estimate of the control which is explicit with respect to the time of controllability. Also, we prove an explicit in time logarithmic observability estimate for the Schrödinger equation, where no geometrical conditions are supposed on the domain.

Key words. observability, controllability

1. Introduction.

Let Ω be a bounded domain of $\mathbb{R}^n$, $n \geq 1$, with a smooth boundary $\partial\Omega$. We consider a nonempty open subset ω of Ω. The question we wish to address is that of controllability for Schrödinger equations with an explicit in time bound of the cost of the following control function. Given a time $\varepsilon > 0$ and considering initial data w_o in some appropriate space X, can we find a control $\vartheta \in L^1(0,\varepsilon;X)$ such that the solution of the system

$$\left\{\begin{array}{r} i\partial_t w + \Delta w = \vartheta_{|\omega} \quad \text{in } \Omega \times]0,\varepsilon[\,, \\ w = 0 \quad \text{on } \partial\Omega \times]0,\varepsilon[\,, \\ w(\cdot,0) = w_o \quad \text{in } \Omega \end{array}\right. \tag{1.1}$$

satisfies $w(\cdot,\varepsilon) \equiv 0$ in Ω, with an estimate of the control ϑ

$$\frac{1}{\sqrt{\varepsilon}} \left\| \vartheta_{|\omega} \right\|_{L^1(0,\varepsilon;X)} \leq \mathcal{C}(\varepsilon) \left\| w_o \right\|_X , \tag{1.2}$$

where $\mathcal{C}$ is an explicit function of ε?

From the work of Lions [Li] on the control for distributed systems, such a result can be obtained with the Hilbert uniqueness method (HUM) by solving the dual observability problem: in the case where $X = L^2(\Omega)$, under which hypothesis the solution of the homogenous Schrödinger equation

$$\left\{\begin{array}{r} i\partial_t u + \Delta u = 0 \quad \text{in } \Omega \times \mathbb{R}_t, \\ u = 0 \quad \text{on } \partial\Omega \times \mathbb{R}_t, \\ u(\cdot,0) = u_o \quad \text{in } \Omega \end{array}\right. \tag{1.3}$$

satisfies

$$\forall \varepsilon > 0, \quad \forall u_o \in L^2(\Omega), \quad \left\| u_o \right\|_{L^2(\Omega)} \leq \mathcal{C}(\varepsilon) \left\| u \right\|_{L^2(\omega\times]0,\varepsilon[)} . \tag{1.4}$$

The relation (1.4) concerns any initial data but may need suitable geometric conditions on ω. Also, we can establish such an observability estimate which is true for

†17 rue Léonard Mafrand, 92320 Chatillon, France (phung@cmla.ens-cachan.fr).

any geometric situation but carries information only when $\|u_o\|_{H^s(\Omega)} = O(\|u_o\|_{L^2(\Omega)})$ for some $s \geq 1$. The problem becomes the following. For all $\omega \subset \Omega$, can we find a positive continuous and strictly increasing function $\mathcal{F} : \mathbb{R}_+^* \to \mathbb{R}_+^*$ which satisfies the relation $\lim_{x\to 0}\mathcal{F}(x) = 0$ such that one has the assertion

(1.5)

$$\forall \varepsilon > 0, \quad \forall u_o \in H^s(\Omega) \cap H_0^1(\Omega), \quad \|u_o\|^2_{L^2(\Omega)} \leq \mathcal{D}(\varepsilon)\ \mathcal{F}\left(\frac{\|u\|^2_{L^2(\omega\times]0,\varepsilon[)}}{\|u_o\|^2_{L^2(\Omega)}}\right)\|u_o\|^2_{H^s(\Omega)},$$

where $\mathcal{D}$ is an explicit positive function of ε?

These exact controllability and observability problems were already investigated in [M], [F], and in [LT], [M], [Le], [B], [T] if the control acts on a part of the boundary, but $\mathcal{C}(\varepsilon)$ was not calculated explicitly. The observability problem arises also in the context of parabolic [FI], [F-CZ], [LR1] or hyperbolic [Li], [BLR] systems. In [FI] and [LR1], an exact null controllability result for parabolic problems is established with no restriction on the time of control or on the support of the control function. Also, Fernandez-Cara and Zuazua [F-CZ] proved an explicit in time observability estimate for the heat equation. In [Ru], Russell used a transformation to show that a null controllability result for the heat equation for any time can be obtained from the exact controllability result for the wave equation in some time. Concerning hyperbolic systems, Bardos, Lebeau, and Rauch [BLR] show a link between the propagation of rays of geometric optics and the problem of exact controllability for hyperbolic problems. They give a geometrical control condition which is sufficient and almost necessary to obtain the observability for hyperbolic problems. Without this geometrical control condition, Robbiano [Ro] proved a logarithmic observability estimate for hyperbolic problems (but where ε must be large enough because of the finite speed of propagation) and showed how to use it to obtain an approximate control result with an estimation of the cost of the control.

In this paper, we give simple techniques and results which try to answer the three previous questions in different geometrical situations. Our strategy is to obtain results for the Schrödinger equation from well-known works on observation and controllability for parabolic and hyperbolic problems. Also, we will describe a method to have an exact control result for Schrödinger equations in bounded domain in $\mathbb{R}^n$, $n > 1$, from an observability result for the Schrödinger equation in one space dimension. Even if our approach does not give optimal results, we hope it can be used in other control problems. Let us now state the different results of this paper in the next section. The first result concerns the problem of observability for the Schrödinger equation when no geometrical conditions are required on ω. We give a logarithmic observability estimate. Then we study the case where the Bardos–Lebeau–Rauch geometric control hypothesis [BLR] holds. The second result is about the particular one-dimensional situation. The third result concerns the problem of exact control for the Schrödinger equation in a bounded domain of $\mathbb{R}^n$, $n > 1$.

2. The main results and some remarks. When no geometrical condition is assumed, we propose a logarithmic explicit in time observability estimate.

THEOREM 2.1. *Suppose $\Omega \subset \mathbb{R}^n$, $n \geq 1$, is of class C^∞. Let ω be a nonempty open subset of Ω. Then there exists $C > 0$ such that for all $\varepsilon > 0$, for all initial data $u_o \in H^2(\Omega) \cap H_0^1(\Omega)$, the solution of the homogenous Schrödinger equation* (1.3)

satisfies

$$\|u_o\|^2_{L^2(\Omega)} \leq \frac{C\,(1+1/\varepsilon)}{\ln\left(2+\frac{\|u_o\|^2_{L^2(\Omega)}}{\|u\|^2_{L^2(\omega\times]0,\varepsilon[)}}\right)}\ \|\Delta u_o\|^2_{L^2(\Omega)}\,. \tag{2.1}$$

The following second result is about the Schrödinger equation in one space dimension. We give an explicit in time observability estimate.

THEOREM 2.2. *Suppose $\Omega \subset \mathbb{R}^n$, $n = 1$. Let ω be a nonempty open subset of Ω. Then there exists $C > 0$ such that for all $\varepsilon > 0$, for all initial data $u_o \in L^2(\Omega)$, the solution of the homogenous Schrödinger equation* (1.3) *satisfies*

$$\|u_o\|^2_{L^2(\Omega)} \leq e^{C\left(1+1/\varepsilon^2\right)}\,\|u\|^2_{L^2(\omega\times]0,\varepsilon[)}\,. \tag{2.2}$$

The last result concerns the problem of exact control for the Schrödinger equation in a bounded domain of $\mathbb{R}^n$, $n > 1$. We estimate the size of the control.

THEOREM 2.3. *Suppose $\Omega \subset \mathbb{R}^n$, $n > 1$, is of class C^∞, and there is no infinite order of contact between the boundary $\partial\Omega$ and the bicharacteristics of $\partial_t^2 - \Delta$. If all generalized bicharacteristic rays meet $\omega \times]0, T_c[$ for some $0 < T_c < +\infty$, then for all $\varepsilon > 0$, for all initial conditions $w_o \in H_0^1(\Omega)$, there is a control $\vartheta = \vartheta_\varepsilon \in L^1\left(0,\varepsilon; L^2(\Omega)\right)$ such that the solution $w \in C\left([0,\varepsilon]; L^2(\Omega)\right)$ of the Schrödinger problem* (1.1) *satisfies $w(\cdot,\varepsilon) \equiv 0$ in Ω . Furthermore there exists a constant $C > 0$, such that for all $\varepsilon > 0$, we have*

$$\|\nabla w(\cdot,t)\|_{L^2(\Omega)} \leq \left(\frac{C}{\sqrt{t}} + e^{C\left(1+1/\varepsilon^2\right)}\right)\|\nabla w_o\|_{L^2(\Omega)} \qquad \forall t > 0 \tag{2.3}$$

with an estimate of the control ϑ_ε as follows:

$$\frac{1}{\sqrt{\varepsilon}}\,\|\vartheta_\varepsilon\|_{L^1(0,\varepsilon;L^2(\omega))} \leq \left(C+\sqrt{\varepsilon}\right)e^{C\left(1+1/\varepsilon^2\right)}\,\|\nabla w_o\|_{L^2(\Omega)}\,. \tag{2.4}$$

Let us make some comments.

1. Theorem 2.1 expresses a unique continuation property for the Schrödinger equation. Our approach to proving Theorem 2.1 consists of using an explicit in time observability estimate for parabolic equations obtained by Fernandez-Cara and Zuazua [F-CZ]. Next we introduce a Gaussian transformation to return to the solution of the Schrödinger equation. The logarithmic observability estimate (2.1) is equivalent to the following interpolation inequality:

$$\exists C > 0, \quad \forall \varepsilon, \delta > 0, \quad \|u_o\|^2_{L^2(\Omega)} \leq \exp\left(C\left(1+\frac{1}{\varepsilon}\right)\delta\right)\|u\|^2_{L^2(\omega\times]0,\varepsilon[)} + \frac{1}{\delta}\,\|\Delta u_o\|^2_{L^2(\Omega)}\,. \tag{2.5}$$

2. Theorem 2.2 asserts that we have an exact controllability result for the Schrödinger equation in one space dimension, due to the HUM of Lions [Li]. The proof of Theorem 2.2 combines multiplier techniques [M], [F] and interpolation inequalities. The interpolation estimates which are similar to (2.5) allow us to absorb the terms of lower order. The estimate (2.2) of Theorem 2.2 is also true for $n > 1$ if we suppose $\omega \subset \Omega \subset \mathbb{R}^n$ to be a neighborhood of $\overline{\Gamma_o}$, where $\Gamma_o = \{x \in \partial\Omega \,/\, (x - x_o)\cdot\nu(x) > 0\}$ is either equal to $\partial\Omega$ or is such that the boundary $\partial\Omega \setminus \Gamma_o$ is included in a hyperplan (see [F]), when x_o is a fixed point of $\mathbb{R}^n$, and $\nu(x)$ is the unit outward normal vector.

The author is indebted to Professor Zuazua, who called his attention to the papers [MZ], [I] and who pointed out that Theorem 2.2 can also be obtained from [MZ, Thm. 3.4], [I, Thm. 1], and a Fourier analysis.

3. Lebeau [Le] has proved the exact boundary controllability for the Schrödinger equation with an analytic boundary under the geometrical control condition of the work of Bardos, Lebeau, and Rauch on exact controllability for the wave equation [BLR]. Moreover, Burq [B] has proved the existence of open subsets of $\partial\Omega$ which do not geometrically control Ω for the wave equation in which it is possible to construct an exact boundary control for the Schrödinger equation if initial data are more regular than those with finite energy. Here the result of Theorem 2.3 is not optimal in norm in the sense that it should be enough to choose the initial condition in $w_o \in L^2(\Omega)$ to obtain a result of exact controllability for the Schrödinger equation with a control in $L^2(\omega \times]0,\varepsilon[)$ when it satisfies suitable geometric conditions (see the previous comment or the multiplier techniques [M], [F]). Also, Theorem 2.3 only implies the following observability estimate under the geometric control condition:

$$\forall \varepsilon > 0, \quad \forall u_o \in L^2(\Omega), \quad \|u_o\|_{H^{-1}(\Omega)} \leq \mathcal{C}(\varepsilon) \sup_{[0,\varepsilon]} \|u\|_{L^2(\omega)}. \tag{2.6}$$

4. Here our construction of the control given by Theorem 2.3 provides more precise information on the cost of the control. We propose a proof based on the theorem of Bardos, Lebeau, and Rauch [BLR] on exact controllability for hyperbolic equations, and a transformation inspired from the work of Boutet de Monvel [BdM] on the propagation of singularities in Schrödinger-type equations (see also [KS]). We will also use the estimate (2.2) of Theorem 2.2 in one space dimension to establish an explicit estimate on the size of the control function for the problem of exact controllability for the Schrödinger equation in $\Omega \subset \mathbb{R}^n$, $n > 1$, when the control region ω controls geometrically Ω. Furthermore, our method described (in section 5) below also applies to the case of Schrödinger equations with nonconstant principal part [HL]. We have the following control result.

THEOREM 2.4. *Let $\Delta_{\mathcal{A}} = \sum_{i,j=1}^n \frac{\partial}{\partial x_i} a_{ij}(x) \frac{\partial}{\partial x_j} + a_o(x)$, where the coefficients of $\Delta_{\mathcal{A}}$ are real, smooth, and satisfy the following conditions: $a_{ij}(x) = a_{ji}(x)$ and $\sum_{i,j=1}^n a_{ij}(x)\xi_i\xi_j \geq c|\xi|^2$. Suppose $\Omega \subset \mathbb{R}^n$, $n > 1$, of class C^∞, and there is no infinite order of contact between the boundary $\partial\Omega$ and the bicharacteristics of $\partial_t^2 - \Delta_{\mathcal{A}}$. If all generalized bicharacteristic rays of $\partial_t^2 - \Delta_{\mathcal{A}}$ meet $\omega \times]0,T_c[$ for some $0 < T_c < +\infty$, then for all $\varepsilon > 0$, for all initial conditions $w_o \in H_0^1(\Omega)$, there is a control $\vartheta_\varepsilon \in L^1\left(0,\varepsilon; L^2(\Omega)\right)$ such that the solution $w \in C\left([0,\varepsilon]; L^2(\Omega)\right)$ of the Schrödinger problem*

$$\begin{cases} i\partial_t w + \Delta_{\mathcal{A}} w = \vartheta_{\varepsilon\,|\omega} & \text{in } \Omega \times]0,\varepsilon[, \\ w = 0 \quad \text{on } \partial\Omega \times]0,\varepsilon[, \\ w(\cdot,0) = w_o \quad \text{in } \Omega \end{cases} \tag{2.7}$$

satisfies $w(\cdot,\varepsilon) \equiv 0$ in Ω. Furthermore, there exists a constant $C > 0$, such that for all $\varepsilon > 0$, the estimates (2.3)–(2.4) hold.

5. The main goal of this paper is to point out that an observability result for the heat equation gives a logarithmic observability estimate for the Schrödinger equation but also that an exact control result for the wave equation gives the exact controllability for the Schrödinger equation. Moreover, we show that an exact control result for the Schrödinger equation in one space dimension implies the exact controllability

for the Schrödinger equation in bounded domain $\Omega \subset \mathbb{R}^n$, $n > 1$, when a geometrical condition is assumed. The observability results for the Schrödinger equation are established under two different kinds of geometry: either when no geometrical hypothesis is assumed (Theorem 2.1) or when the Bardos–Lebeau–Rauch geometric control condition is satisfied (Theorem 2.2 ($n = 1$) and Theorem 2.3 ($n > 1$); see (2.6) in comment 3). Also, these techniques allow us to have explicit estimates with respect to the time of controllability.

The paper is organized in the following way. The proofs of Theorems 2.1 and 2.2 (see comment 2) rest on interpolation estimates which are established in section 3. These interpolation estimates can be seen as low frequency estimates. The proof of Theorem 2.1 is then easily described. In section 4, we prove Theorem 2.2. Section 5 is devoted to the construction of the control stated in Theorem 2.3.

3. Low frequency estimates. In this section, we first state interpolation inequalities in Theorem 3.1 below, which are the key results to prove Theorems 2.1 and 2.2 (see comment 2). Next, we recall some results on the observability for parabolic problems obtained by Fernandez-Cara and Zuazua [F-CZ]. Finally, we prove Theorem 3.1.

3.1. Interpolation inequalities and the proof of Theorem 2.1. We have the following interpolation inequalities.

THEOREM 3.1. *Suppose $\Omega \subset \mathbb{R}^n$, $n \geq 1$, is of class C^∞. Let ω be a nonempty open set included in Ω. Then there exist $C > 0$, $\varepsilon_o > 0$, $\mu_o > 0$, such that for all $\varepsilon \leq \varepsilon_o$, for all $\mu \geq \mu_o$, for all initial data $u_o \in H^2(\Omega) \cap H_0^1(\Omega)$, the solution of the homogenous Schrödinger equation* (1.3) *satisfies*

$$\int_\Omega |u_o(x)|^2 \, dx \leq \exp\left(\frac{C\mu}{\varepsilon}\right) \int_\omega \int_0^\varepsilon |u(x,t)|^2 \, dtdx + \frac{\varepsilon^3}{\mu} \int_\Omega |\Delta u_o(x)|^2 \, dx. \tag{3.1}$$

Furthermore, there exist $C > 0$, $\varepsilon_o > 0$, $\mu_o > 0$, such that for all $\varepsilon \leq \varepsilon_o$, for all $\mu \geq \mu_o$, for all initial data $u_o \in H^2(\Omega) \cap H_0^1(\Omega)$, the solution of the homogenous Schrödinger equation (1.3) *satisfies*

$$\int_\Omega |u_o(x)|^2 \, dx \leq \exp\left(\frac{C\mu}{\varepsilon}\right) \int_\omega \int_0^\varepsilon |\Delta u(x,t)|^2 \, dtdx + \frac{\varepsilon^3}{\mu} \int_\Omega |\Delta u_o(x)|^2 \, dx. \tag{3.2}$$

Let us assume that the interpolation inequality (3.1) holds in order to prove Theorem 2.1. The proof of Theorem 3.1 will be given at the end of section 3.

Proof of Theorem 2.1. By taking μ such that $\mu = C_0 \frac{\int_\Omega |\Delta u_0|^2 dx}{\int_\Omega |u_0|^2 dx} \geq \mu_o$, the estimate (3.1) becomes

$$\int_\Omega |u_0|^2 \, dx \leq \exp\left(\frac{CC_0}{\varepsilon} \frac{\int_\Omega |\Delta u_0|^2 \, dx}{\int_\Omega |u_0|^2 \, dx}\right) \int_\omega \int_0^\varepsilon |u|^2 \, dtdx + \frac{\varepsilon^3}{C_0} \int_\Omega |u_0|^2 \, dx. \tag{3.3}$$

So, $\exists C > 0$, $\exists \varepsilon_o > 0$, for all $\varepsilon \leq \varepsilon_o$,

$$\int_\Omega |u_0|^2 \, dx \leq \exp\left(\frac{C}{\varepsilon} \frac{\int_\Omega |\Delta u_0|^2 \, dx}{\int_\Omega |u_0|^2 \, dx}\right) \int_\omega \int_0^\varepsilon |u|^2 \, dtdx.$$

And also, $\exists C > 0$, for all $\varepsilon > 0$,

$$\int_\Omega |u_0|^2 \, dx \leq \exp\left(C\left(1 + \frac{1}{\varepsilon}\right) \frac{\int_\Omega |\Delta u_0|^2 \, dx}{\int_\Omega |u_0|^2 \, dx}\right) \int_\omega \int_0^\varepsilon |u|^2 \, dtdx. \tag{3.4}$$

The estimate (2.1) of Theorem 2.1 is equivalent to (3.4) by using properties of the logarithmic and exponential functions. That concludes the proof of Theorem 2.1. Let us remark here that we obtain (2.5) from (3.4) by studying the case where either $\|\Delta u_o\| \leq \delta \|u_o\|$ or $\|\Delta u_o\| > \delta \|u_o\|$ (see comment 1). □

It will be useful to recall some explicit in time observability results for parabolic problems before proving Theorem 3.1.

3.2. Observability for the parabolic problem. We recall the result in [F-CZ] in the particular case of a null potential.

Theorem [F-CZ]. Let Ω be a connected bounded domain in $\mathbb{R}^n$, with smooth boundary. Let v be the solution of the following adjoint parabolic equation:

$$\begin{cases} \partial_t v + \Delta v = 0 & \text{in } \Omega\times]0,T[, \\ v = 0 & \text{on } \partial\Omega\times]0,T[. \end{cases} \tag{3.5}$$

Then there is $C > 0$, such that for all $T > 0$,

$$\int_\Omega |v(x,0)|^2 \, dx \leq \exp\left(C\left(1+\frac{1}{T}\right)\right) \int_\omega \int_0^T |v|^2 \, dtdx. \tag{3.6}$$

Remark 3.2. Theorem [F-CZ] is obtained from the works of Fursikov and Imanuvilov [FI] on Carleman estimates for adjoint parabolic equations. Another approach, based on the work of Lebeau and Robbiano [LR1] on the exact controllability of the heat equation on a Riemannian compact manifold with boundary, and Dirichlet boundary conditions, in both cases of interior or boundary controls, gives us the estimates (3.6) but not explicitly in time. Nevertheless, a logarithmic boundary observability estimate for the Schrödinger equation is presented with that approach in [P].

We deduce from Theorem [F-CZ] the following corollary.

Corollary 3.3. *Let W be the solution of the following adjoint parabolic problem:*

$$\begin{cases} \partial_t W + \Delta W = f & \text{in } \Omega\times]0,T[, \\ W = 0 & \text{on } \partial\Omega\times]0,T[, \\ W(\cdot,T) \in L^2(\Omega). \end{cases} \tag{3.7}$$

Then

$$\exists C_T > 0, \qquad \int_\Omega |W(x,0)|^2 \, dx \leq C_T \left(\int_\omega \int_0^T |W|^2 \, dtdx + \int_\Omega \int_0^T |f|^2 \, dtdx \right). \tag{3.8}$$

If, moreover, $W(\cdot,T) \in H^2 \cap H_0^1(\Omega)$, then

$$\exists C_T > 0, \qquad \int_\Omega |W(x,0)|^2 \, dx \leq C_T \left(\int_\omega \int_0^T |\Delta W|^2 \, dtdx + \int_\Omega \int_0^T |f|^2 \, dtdx \right). \tag{3.9}$$

Here, the constant C_T of the estimates (3.8), (3.9) *is of the order of*

$$C_T = \exp\left(C\left(1+\frac{1}{T}\right)\right), \tag{3.10}$$

where $C > 0$ is a constant independent of $T > 0$.

Proof of Corollary 3.3. It is easy to see that (3.8) holds from (3.6) with a classical energy method. Let us prove (3.9). We consider $z(x,t) = W(x,t) - a(x,t)$, where

$$\left\{\begin{array}{rl} \partial_t a + \Delta a = f & \text{in } \Omega\times]0,T[, \\ a = 0 & \text{on } \partial\Omega\times]0,T[, \\ a(\cdot,T) = 0 & \text{in } \Omega. \end{array}\right. \tag{3.11}$$

As $\partial_t z$ is a solution of (3.5), the regularity of $W(\cdot,T)$ and (3.6) allow us to obtain the estimate

$$\int_\Omega |\Delta z(x,0)|^2\,dx \le \exp\left(C\left(1+\frac{1}{T}\right)\right)\int_\omega\int_0^T |\partial_t z|^2\,dtdx. \tag{3.12}$$

Now we give equalities on the solution a by a classical energy method:

$$\begin{aligned} &\frac{1}{2}\int_\Omega |a(x,0)|^2\,dx + \int_0^T\int_\Omega |\nabla a|^2\,dxdt = -\int_0^T\int_\Omega fa\,dxdt, \\ &\frac{1}{2}\int_\Omega |\nabla a(x,0)|^2\,dx + \int_0^T\int_\Omega |\partial_t a|^2\,dxdt = \int_0^T\int_\Omega f\partial_t a\,dxdt. \end{aligned} \tag{3.13}$$

By Cauchy–Schwarz and Poincaré inequalities and from (3.13) we have

$$\int_\Omega |a(x,0)|^2\,dx + \int_0^T\int_\Omega |\partial_t a|^2\,dxdt \le c\int_0^T\int_\Omega |f|^2\,dxdt. \tag{3.14}$$

We obtain from (3.12) and (3.14)

(3.15)

$$\begin{aligned} \int_\Omega |W(x,0)|^2\,dx &\le 2\int_\Omega |z(x,0)|^2\,dx + 2\int_\Omega |a(x,0)|^2\,dx \\ &\le c\int_\Omega |\Delta z(x,0)|^2\,dx + 2\int_\Omega |a(x,0)|^2\,dx \\ &\le \exp\left(C\left(1+\frac{1}{T}\right)\right)\int_\omega\int_0^T |\partial_t z|^2\,dtdx + c\int_0^T\int_\Omega |f|^2\,dxdt \\ &\le \exp\left(C\left(1+\frac{1}{T}\right)\right)\left(\int_\omega\int_0^T |\partial_t W|^2\,dtdx + c\int_0^T\int_\Omega |f|^2\,dxdt\right) \\ &\quad + c\int_0^T\int_\Omega |f|^2\,dxdt \\ &\le \exp\left(C\left(1+\frac{1}{T}\right)\right)\left(\int_\omega\int_0^T |\Delta W|^2\,dtdx + c\int_0^T\int_\Omega |f|^2\,dxdt\right) \\ &\quad + c\int_0^T\int_\Omega |f|^2\,dxdt. \end{aligned}$$

That concludes the proof of (3.9) and Corollary 3.3. □

3.3. Proof of Theorem 3.1. We begin to prove (3.1) as follows.

Let $F(z) = \frac{1}{2\pi}\int_{\mathbb{R}} e^{iz\tau}e^{-\tau^2}\,d\tau$; then $F(z) = \frac{\sqrt{\pi}}{2\pi}e^{\frac{1}{4}\left(|\operatorname{Im} z|^2 - |\operatorname{Re} z|^2\right)}e^{-\frac{i}{2}(\operatorname{Im} z \operatorname{Re} z)}$. Also, with $\lambda > 0$, let us consider

$$F_\lambda(z) = \lambda F(\lambda z) = \frac{1}{2\pi}\int_{\mathbb{R}} e^{iz\tau}e^{-\left(\frac{\tau}{\lambda}\right)^2}\,d\tau.$$

We have

$$|F_\lambda(z)| = \frac{\sqrt{\pi}}{2\pi}\lambda e^{\frac{\lambda^2}{4}\left(|\mathrm{Im}\, z|^2 - |\mathrm{Re}\, z|^2\right)}. \tag{3.16}$$

Let $s, \ell_0 \in \mathbb{R}$, and

$$W_{\ell_0,\lambda}(s,x) = \int_{\mathbb{R}} F_\lambda(\ell_0 + is - \ell)\Phi(\ell)u(x,\ell)d\ell, \tag{3.17}$$

where $\Phi \in C_0^\infty(\mathbb{R})$. The Gaussian transformation (3.17) is inspired from the Fourier–Bros–Iagolnitzer transformation in [LR2]. We remark that $\partial_s F_\lambda(\ell_0 + is - \ell) = -i\partial_\ell F_\lambda(\ell_0 + is - \ell)$, so

$$\begin{aligned}\partial_s W_{\ell_0,\lambda}(s,x) &= \int_{\mathbb{R}} -i\partial_\ell F_\lambda(\ell_0 + is - \ell)\Phi(\ell)u(x,\ell)d\ell \\ &= \int_{\mathbb{R}} iF_\lambda(\ell_0 + is - \ell)\left\{\frac{d}{d\ell}\Phi(\ell)u(x,\ell) + \Phi(\ell)\frac{\partial}{\partial\ell}u(x,\ell)\right\}d\ell.\end{aligned}$$

As $u : (x,t) \longmapsto u(x,t)$ is the solution of (1.3), $W_{\ell_0,\lambda}$ satisfies

$$\begin{cases} \partial_s W_{\ell_0,\lambda}(s,x) + \Delta W_{\ell_0,\lambda}(s,x) = \displaystyle\int_{\mathbb{R}} iF_\lambda(\ell_0 + is - \ell)\Phi'(\ell)u(x,\ell)d\ell, \\ W_{\ell_0,\lambda}(s,x) = 0 \quad \forall x \in \partial\Omega, \\ W_{\ell_0,\lambda}(0,x) = \left(F_\lambda * \Phi u(x,\cdot)\right)(\ell_0) \quad \forall x \in \Omega. \end{cases} \tag{3.18}$$

We define $\Phi \in C_0^\infty(\mathbb{R})$ such that the following holds. Let $L > 0$, and we choose $\Phi \in C_0^\infty(]0, L[)$, $0 \le \Phi \le 1$, $\Phi \equiv 1$ on $\left[\frac{L}{4}; \frac{3L}{4}\right]$ and such that $|\Phi'| \le \frac{8}{L}$. We take $K = \left[0; \frac{L}{4}\right] \cup \left[\frac{3L}{4}; L\right]$ and $K_0 = \left[\frac{3L}{8}; \frac{5L}{8}\right]$. So, $\mathrm{mes} K_0 = \frac{L}{4}$, $\mathrm{mes} K = \frac{L}{2}$, $\mathrm{supp}(\Phi') = K$, and $\mathrm{dist}(K; K_o) = \frac{L}{8}$. We will choose $\ell_0 \in K_0$.

As an application of (3.8), $W_{\ell_0,\lambda}$ satisfies the following estimate:

(3.19)

$$\begin{aligned}\int_\Omega \left|\left(F_\lambda * \Phi u(x,\cdot)\right)(\ell_0)\right|^2 dx &\le C_T \int_\omega \int_0^T |W_{\ell_0,\lambda}(s,x)|^2 \, dsdx \\ &\quad + C_T \int_\Omega \int_0^T \left|\int_{\mathbb{R}} iF_\lambda(\ell_0 + is - \ell)\Phi'(\ell)u(x,\ell)d\ell\right|^2 dsdx.\end{aligned}$$

On the other hand, from (3.16)

$$\begin{aligned}\int_\omega \int_0^T |W_{\ell_0,\lambda}(s,x)|^2 \, dsdx &= \int_\omega \int_0^T \left|\int_{\mathbb{R}} F_\lambda(\ell_0 + is - \ell)\Phi(\ell)u(x,\ell)d\ell\right|^2 dsdx \\ &\le \int_0^T \int_\omega \left|\int_{\mathbb{R}} \frac{\sqrt{\pi}}{2\pi}\lambda e^{\frac{\lambda^2}{4}\left(s^2 - |\ell_0 - \ell|^2\right)}\Phi(\ell)\left|u(x,\ell)\right|d\ell\right|^2 dxds \\ &\le \frac{\lambda^2}{4\pi}\left(\int_0^T e^{\frac{\lambda^2}{2}s^2}ds\right)|\sup\Phi|^2 \int_\omega \left|\int_0^L |u(x,\ell)|\, d\ell\right|^2 dx \\ &\le \frac{\lambda^2}{4\pi}e^{\frac{\lambda^2}{2}T^2}T \ \ |\sup\Phi|^2 \ \ L\int_\omega \int_0^L |u(x,\ell)|^2 \, d\ell dx\end{aligned}$$

and

$$\begin{aligned}
&\int_\Omega \int_0^T \left| \int_{\mathbb{R}} iF_\lambda(\ell_0 + is - \ell)\Phi'(\ell)u(x,\ell)d\ell \right|^2 dsdx \\
&\leq \int_0^T \int_\Omega \left| \int_{\mathbb{R}} \frac{\sqrt{\pi}}{2\pi} \lambda e^{\frac{\lambda^2}{4}\left(s^2 - |\ell_0 - \ell|^2\right)} |\Phi'(\ell)| \, |u(x,\ell)| \, d\ell \right|^2 dxds \\
&\leq \frac{\lambda^2}{4\pi} e^{\frac{\lambda^2}{2}T^2} T \int_\Omega \left(\int_K e^{-\frac{\lambda^2}{2}|\ell_0 - \ell|^2} |\Phi'(\ell)|^2 \, |u(x,\ell)|^2 \, d\ell \right) \mathrm{mes}\,(K)\, dx \\
&\leq \frac{\lambda^2}{4\pi} e^{\frac{\lambda^2}{2}T^2} T \; e^{-\frac{\lambda^2}{2}\mathrm{dist}(K,K_0)^2} \; \sup |\Phi'(\ell)|^2 \, \mathrm{mes}\,(K) \int_\Omega \int_K |u(x,\ell)|^2 \, d\ell dx \\
&\leq \frac{\lambda^2}{4\pi} e^{\frac{\lambda^2}{2}T^2} T \; e^{-\frac{\lambda^2}{2}\mathrm{dist}(K,K_0)^2} \; \sup |\Phi'(\ell)|^2 \, \mathrm{mes}\,(K)^2 \int_\Omega |u_o|^2 \, dx \\
&\leq \frac{\lambda^2 T}{4\pi} \exp\left[\frac{\lambda^2}{2} \left(T^2 - \left(\frac{L}{8} \right)^2 \right) \right] \; \frac{8^2}{L^2} \frac{L^2}{4} \int_\Omega |u_o|^2 \, dx \\
&\leq \frac{4\lambda^2 T}{\pi} \exp\left[\frac{\lambda^2}{2} \left(T^2 - \left(\frac{L}{8} \right)^2 \right) \right] \int_\Omega |u_o|^2 \, dx.
\end{aligned}$$

So, the inequality (3.19) becomes

$$\begin{aligned}
\int_\Omega \left| \left(F_\lambda * \Phi u(x,\cdot) \right)(\ell_0) \right|^2 dx &\leq C_T \frac{\lambda^2 TL}{4\pi} \exp\left(\frac{\lambda^2}{2} T^2 \right) \int_\omega \int_0^L |u(x,\ell)|^2 \, d\ell dx \\
&\quad + C_T \frac{4\lambda^2 T}{\pi} \exp\left[\frac{\lambda^2}{2} \left(T^2 - \left(\frac{L}{8} \right)^2 \right) \right] \int_\Omega |u_o|^2 \, dx. \qquad (3.20)
\end{aligned}$$

With the Parseval relation, we have

$$\begin{aligned}
&\int_{\mathbb{R}} \left| \Phi(\ell_0) u\,(x,\ell_0) - \left(F_\lambda * \Phi u\,(x,\cdot) \right)(\ell_0) \right|^2 d\ell_0 \\
&= \frac{1}{2\pi} \int_{\mathbb{R}} \left| \widehat{\Phi(\ell_0) u\,(x)}, \ell_0)(\tau) \right|^2 \left(1 - e^{-\left(\frac{\tau}{\lambda}\right)^2} \right)^2 d\tau \\
&\leq \frac{1}{\pi\lambda^2} \int_{\mathbb{R}} \left| \tau \widehat{\Phi(\ell_0) u\,(x)}, \ell_0)(\tau) \right|^2 d\tau \\
&\leq \frac{2}{\lambda^2} \int_{\mathbb{R}} \left| \Phi'(\ell_0) u\,(x,\ell_0) + \Phi(\ell_0) \partial_{\ell_0} u\,(x,\ell_0) \right|^2 d\ell_0 \\
&\leq \frac{4}{\lambda^2} \left[\frac{8^2}{L^2} \int_K |u(x,\ell_0)|^2 \, d\ell_0 + \int_0^L |\partial_{\ell_0} u(x,\ell_0)|^2 \, d\ell_0 \right].
\end{aligned}$$

By integrating on Ω, we obtain

$$\begin{aligned}
&\int_\Omega \int_{\mathbb{R}} \left| \Phi(\ell_0) u\,(x,\ell_0) - \left(F_\lambda * \Phi u\,(x,\cdot) \right)(\ell_0) \right|^2 d\ell_0 dx \qquad (3.21) \\
&\leq \frac{4}{\lambda^2} \left[\frac{c^2}{L^2} \int_K \int_\Omega |u(x,\ell_0)|^2 \, d\ell_0 dx + \int_0^L \int_\Omega |\partial_{\ell_0} u(x,\ell_0)|^2 \, d\ell_0 dx \right] \\
&\leq \frac{4}{\lambda^2} \left[\frac{8^2}{L^2} \frac{L}{2} \int_\Omega |u_o|^2 \, dx + L \int_\Omega |\Delta u_o|^2 \, dx \right].
\end{aligned}$$

So, with (3.20) and (3.21),

$$\begin{aligned}\operatorname{mes}(K_0)\int_\Omega |u_o|^2\,dx &= \int_{K_0}\int_\Omega |\Phi(\ell_0)u(x,\ell_0)|^2\,dx d\ell_0\\ &\le \operatorname{mes}(K_0)\,C_T\frac{\lambda^2 TL}{4\pi}\exp\left(\frac{\lambda^2}{2}T^2\right)\int_\omega\int_0^L |u(x,\ell)|^2\,d\ell dx\\ &+ \operatorname{mes}(K_0)\,C_T\frac{4\lambda^2 T}{\pi}\exp\left[\frac{\lambda^2}{2}\left(T^2-\left(\frac{L}{8}\right)^2\right)\right]\int_\Omega |u_o|^2\,dx\\ &+ \frac{4}{\lambda^2}\left[\frac{8^2}{L^2}\frac{L}{2}\int_\Omega |u_o|^2\,dx + L\int_\Omega |\Delta u_o|^2\,dx\right].\end{aligned}$$

Finally,

$$\begin{aligned}\int_\Omega |u_o|^2\,dx &\le C_T\frac{\lambda^2 TL}{4\pi}\exp\left(\frac{\lambda^2}{2}T^2\right)\int_\omega\int_0^L |u(x,\ell)|^2\,d\ell dx\\ &+ C_T\frac{4\lambda^2 T}{\pi}\exp\left[\frac{\lambda^2}{2}\left(T^2-\left(\frac{L}{8}\right)^2\right)\right]\int_\Omega |u_o|^2\,dx\\ &+ \frac{1}{\lambda^2}\frac{4^2}{L}\left[\frac{8^2}{2L}\int_\Omega |u_o|^2\,dx + L\int_\Omega |\Delta u_o|^2\,dx\right].\end{aligned}$$

Let us consider $A>0$ real such that $\left(1-A^2\right)<0$. By choosing $L=8AT$, it becomes

$$\begin{aligned}\int_\Omega |u_o|^2\,dx \le \frac{2A}{\pi}C_T\lambda^2T^2\exp\left(\frac{\lambda^2T^2}{2}\right)\int_\omega\int_0^{8AT}|u(x,\ell)|^2\,d\ell dx + 16\frac{1}{\lambda^2}\int_\Omega |\Delta u_o|^2\,dx\\ + \left[\frac{8}{A^2}\frac{1}{\lambda^2T^2} + \frac{4}{\pi}C_T\lambda^2T\exp\left(-\frac{A^2-1}{2}\lambda^2T^2\right)\right]\int_\Omega |u_o|^2\,dx.\end{aligned}$$

With the relation (3.10), we have the following uniform in time interpolation estimate:

$$\begin{aligned}\int_\Omega |u_o|^2\,dx &\le Ae^Ce^{C/T}\lambda^2T^2\exp\left(\frac{\lambda^2T^2}{2}\right)\int_\omega\int_0^{8AT}|u(x,\ell)|^2\,d\ell dx\\ &+ \left[\frac{C}{A^2}\frac{1}{\lambda^2T^2} + e^Ce^{C/T}\lambda^2T\exp\left(-\frac{A^2-1}{2}\lambda^2T^2\right)\right]\int_\Omega |u_o|^2\,dx\\ &+ \frac{16}{\lambda^2}\int_\Omega |\Delta u_o|^2\,dx.\end{aligned}$$

We introduce $\lambda^2=\frac{\mu}{T^3}$. Let $\alpha>0$ be real such that $\left(2\alpha+1-A^2\right)<0$; hence,

$$\begin{aligned}\int_\Omega |u_o|^2\,dx &\le Ae^Ce^{C/T}\frac{\mu}{T}\exp\left(\frac{\mu}{2T}\right)\int_\omega\int_0^{8AT}|u(x,\ell)|^2\,d\ell dx\\ &+ \left[\frac{C}{A^2}\frac{T}{\mu} + e^Ce^{C/T}\frac{\mu}{T^2}\exp\left(-\frac{A^2-1}{2}\frac{\mu}{T}\right)\right]\int_\Omega |u_o|^2\,dx\\ &+ 16\frac{T^3}{\mu}\int_\Omega |\Delta u_o|^2\,dx\\ &\le Ae^Ce^{C/T}\frac{\mu}{T}\exp\left(\frac{\mu}{2T}\right)\int_\omega\int_0^{8AT}|u(x,\ell)|^2\,d\ell dx\end{aligned}$$

$$+\left[\frac{C}{A^2}\frac{T}{\mu}+e^C e^{C/T}\frac{1}{\mu}\frac{4}{\alpha^2}\exp\left(-\frac{A^2-1-2\alpha}{2}\frac{\mu}{T}\right)\right]\int_\Omega |u_o|^2\,dx$$
$$+16\frac{T^3}{\mu}\int_\Omega |\Delta u_o|^2\,dx.$$

We take $\mu > \frac{2C}{A^2-1-2\alpha}$, so

$$\int_\Omega |u_o|^2\,dx \le Ae^C\frac{\mu}{T}\exp\left(\frac{A^2\mu}{2T}\right)\int_\omega\int_0^{8AT}|u(x,\ell)|^2\,d\ell dx$$
$$+\left[\frac{C}{A^2}\frac{T}{\mu}+e^C\frac{4}{\alpha^2}\frac{1}{\mu}\right]\int_\Omega |u_o|^2\,dx+16\frac{T^3}{\mu}\int_\Omega |\Delta u_o|^2\,dx,$$

$$\int_\Omega |u_o|^2\,dx \le \frac{e^C}{A}\exp\left(\frac{A^2\mu}{2T}\right)\int_\omega\int_0^{8AT}|u(x,\ell)|^2\,d\ell dx \tag{3.22}$$
$$+\left[\frac{CT}{A^2}+\frac{4e^C}{\alpha^2}\right]\frac{1}{\mu}\int_\Omega |u_o|^2\,dx+16\frac{T^3}{\mu}\int_\Omega |\Delta u_o|^2\,dx,$$

and with $\mu_o = \max(\frac{2C}{A^2-1-2\alpha}; 2(\frac{C}{A^2}+\frac{4e^C}{\alpha^2}))$

$$\forall T\le 1,\quad \forall \mu>\mu_o,\qquad \frac{1}{2}\int_\Omega |u_o|^2\,dx \tag{3.23}$$
$$\le \frac{e^C}{A}\exp\left(\frac{A^2\mu}{2T}\right)\int_\omega\int_0^{8AT}|u(x,\ell)|^2\,d\ell dx+16\frac{T^3}{\mu}\int_\Omega |\Delta u_o|^2\,dx.$$

Therefore, (3.1) is proved by choosing $T=\frac{\varepsilon}{8A}\le 1$.

The proof of (3.2) follows the same approach by using (3.9).

As application of (3.9), $W_{\ell_0,\lambda}$ satisfies the following estimate:

(3.24)
$$\int_\Omega |(F_\lambda * \Phi u(x,\cdot))(\ell_0)|^2\,dx \le C_T\int_\omega\int_0^T |\Delta W_{\ell_0,\lambda}(s,x)|^2\,dsdx$$
$$+C_T\int_\omega\int_0^T\left|\int_{\mathbb{R}} iF_\lambda(\ell_0+is-\ell)\Phi'(\ell)u(x,\ell)d\ell\right|^2 dsdx.$$

On the other hand, from (3.16)

$$\int_\omega\int_0^T |\Delta W_{\ell_0,\lambda}(s,x)|^2\,dsdx \le \frac{\lambda^2}{4\pi}e^{\frac{\lambda^2}{2}T^2}T\ |\sup\Phi|^2\ L\int_\omega\int_0^L |\Delta u(x,\ell)|^2\,d\ell dx.$$

Consequently, the inequality (3.24) becomes

$$\int_\Omega |(F_\lambda * \Phi u(x,\cdot))(\ell_0)|^2\,dx \le C_T\frac{\lambda^2 TL}{4\pi}\exp\left(\frac{\lambda^2}{2}T^2\right)\int_\omega\int_0^L |\Delta u(x,\ell)|^2\,d\ell dx$$
$$+C_T\frac{4\lambda^2 T}{\pi}\exp\left[\frac{\lambda^2}{2}\left(T^2-\left(\frac{L}{8}\right)^2\right)\right]\int_\Omega |u_o|^2\,dx. \tag{3.25}$$

Now, due to (3.25) and (3.21), for $\left(1-A^2\right)<0$ and $T\le 1$, we have

$$\int_\Omega |u_o|^2\,dx \le Ae^C e^{C/T}\lambda^2T^2\exp\left(\frac{\lambda^2T^2}{2}\right)\int_\omega\int_0^{8AT}|\Delta u(x,\ell)|^2\,d\ell dx+\frac{16}{\lambda^2}\int_\Omega |\Delta u_o|^2\,dx$$

$$+\left[\frac{C}{A^2}\frac{1}{\lambda^2T^2}+e^Ce^{C/T}\lambda^2T\exp\left(-\frac{A^2-1}{2}\lambda^2T^2\right)\right]\int_\Omega|u_o|^2\,dx.$$

We introduce $\lambda^2=\frac{\mu}{T^3}$ and $0<\alpha<\frac{1}{2}\left(A^2-1\right)$, so that

$$\begin{aligned}\int_\Omega|u_o|^2\,dx &\le Ae^{C/T}\frac{\mu}{T}\exp\left(\frac{\mu}{2T}\right)\int_\omega\int_0^{8AT}|\Delta u(x,\ell)|^2\,d\ell dx+16\frac{T^3}{\mu}\int_\Omega|\Delta u_o|^2\,dx\\ &+\left[\frac{C}{A^2}T+e^Ce^{C/T}\left(\frac{\mu}{T}\right)^2\exp\left(-\frac{A^2-1}{2}\frac{\mu}{T}\right)\right]\frac{1}{\mu}\int_\Omega|u_o|^2\,dx\\ &\le Ae^{C/T}\frac{\mu}{T}\exp\left(\frac{\mu}{2T}\right)\int_\omega\int_0^{8AT}|\Delta u(x,\ell)|^2\,d\ell dx+16\frac{T^3}{\mu}\int_\Omega|\Delta u_o|^2\,dx\\ &+\left[\frac{C}{A^2}T+e^Ce^{C/T}\frac{4}{\alpha^2}\exp\left(-\frac{A^2-1-2\alpha}{2}\frac{\mu}{T}\right)\right]\frac{1}{\mu}\int_\Omega|u_o|^2\,dx.\end{aligned}$$

We choose μ large enough such that

$$\int_\Omega|u_o|^2\,dx\le Ae^{C/T}\frac{\mu}{T}\exp\left(\frac{A\mu}{2T}\right)\int_\omega\int_0^{8AT}|\Delta u(x,\ell)|^2\,d\ell dx+C\frac{T^3}{\mu}\int_\Omega|\Delta u_o|^2\,dx.$$

Consequently, we have the following assertion: $\exists C>0$, $\exists\mu_o>0$, for all $T\le1$, for all $\mu>\mu_o$,

$$\int_\Omega|u_o|^2\,dx\le C\exp\left(\frac{A\mu}{T}\right)\int_\omega\int_0^{8AT}|\Delta u(x,\ell)|^2\,d\ell dx+C\frac{T^3}{\mu}\int_\Omega|\Delta u_o|^2\,dx. \tag{3.26}$$

That concludes the proof of Theorem 3.1. □

4. Proof of Theorem 2.2. We now prove Theorem 2.2 by using (3.2) when $n=1$ and multiplier techniques. Let A, B, β, ε be four reals such that $A<B$, $0<2\beta<B-A$, and $\varepsilon>0$. Let $\varphi:(t,s)\in\left]0,\varepsilon\right[\times\left]A,B\right[\longmapsto\varphi(t,s)$ be the solution of the Schrödinger equation in one space dimension:

$$\left\{\begin{array}{l} i\partial_t\varphi+\partial_s^2\varphi=0\quad\text{in }\left]0,\varepsilon\right[\times\left]A,B\right[,\\ \varphi(\cdot,A)=\varphi(\cdot,B)=0\quad\text{on }\left]0,\varepsilon\right[,\\ \varphi(0,\cdot)=\varphi_o\quad\text{in }\left]A,B\right[.\end{array}\right. \tag{4.1}$$

We will prove the following stable observability estimate: $\exists C>0,$ for all $\varepsilon>0$,

$$\int_A^B\left|\partial_s^2\varphi_o\right|^2ds\le e^{C\left(1+1/\varepsilon^2\right)}\int_{B-2\beta}^{B-\beta}\int_0^\varepsilon\left|\partial_s^2\varphi\right|^2dtds. \tag{4.2}$$

Indeed, let $q\in C^2\left([A,B]\right)$ be a real function

$$\begin{aligned}iq\frac{d}{dt}\left(\partial_s\varphi\partial_s^2\overline{\varphi}\right) &=q\left(i\frac{d}{dt}\partial_s\varphi\partial_s^2\overline{\varphi}+i\partial_s\varphi\frac{d}{dt}\partial_s^2\overline{\varphi}\right)\\ &=q\left(-\partial_s^3\varphi\partial_s^2\overline{\varphi}+\partial_s\varphi\partial_s^4\overline{\varphi}\right)\\ &=q\left(-\partial_s^3\varphi\partial_s^2\overline{\varphi}+\partial_s\left(\partial_s\varphi\partial_s^3\overline{\varphi}\right)-\partial_s^2\varphi\partial_s^3\overline{\varphi}\right)\\ &=-q\partial_s\left(\partial_s^2\varphi\partial_s^2\overline{\varphi}\right)+q\partial_s\left(\partial_s\varphi\partial_s^3\overline{\varphi}\right).\end{aligned}$$

So

$$\begin{aligned}\int_0^\varepsilon\int_A^B iq\frac{d}{dt}\left(\partial_s\varphi\partial_s^2\overline{\varphi}\right)dsdt &= -\int_0^\varepsilon\int_A^B q\partial_s\left|\partial_s^2\varphi\right|^2+\int_0^\varepsilon\int_A^B q\partial_s\left(\partial_s\varphi\partial_s^3\overline{\varphi}\right)\\ &= -\int_0^\varepsilon\left[q\left|\partial_s^2\varphi\right|^2\right]_A^B+\int_0^\varepsilon\int_A^B q'\left|\partial_s^2\varphi\right|^2\\ &+\int_0^\varepsilon\left[q\partial_s\varphi\partial_s^3\overline{\varphi}\right]_A^B-\int_0^\varepsilon\int_A^B q'\left(\partial_s\varphi\partial_s^3\overline{\varphi}\right)\\ &= \int_0^\varepsilon\int_A^B q'\left|\partial_s^2\varphi\right|^2+\int_0^\varepsilon\left[q\partial_s\varphi\partial_s^3\overline{\varphi}\right]_A^B\\ &-\int_0^\varepsilon\left[q'\partial_s\varphi\partial_s^2\overline{\varphi}\right]_A^B+\int_0^\varepsilon\int_A^B\left(q''\partial_s\varphi+q'\partial_s^2\varphi\right)\partial_s^2\overline{\varphi}\\ &= \int_0^\varepsilon\left[q\partial_s\varphi\partial_s^3\overline{\varphi}\right]_A^B+2\int_0^\varepsilon\int_A^B q'\left|\partial_s^2\varphi\right|^2+\int_0^\varepsilon\int_A^B q''\partial_s\varphi\partial_s^2\overline{\varphi}.\end{aligned}$$

Finally,

$$\begin{aligned}\int_A^B\left[iq\partial_s\varphi\partial_s^2\overline{\varphi}\right]_0^\varepsilon ds &= \int_0^\varepsilon\left[q\partial_s\varphi\partial_s^3\overline{\varphi}\right]_A^B dt\\ &+2\int_0^\varepsilon\int_A^B q'\left|\partial_s^2\varphi\right|^2 dsdt+\int_0^\varepsilon\int_A^B q''\partial_s\varphi\partial_s^2\overline{\varphi}dsdt.\end{aligned}\tag{4.3}$$

Consequently, by taking the real part of (4.3), we obtain

$$\begin{aligned}&2\int_0^\varepsilon\int_A^B q'\left|\partial_s^2\varphi\right|^2 dsdt+\mathrm{Re}\int_0^\varepsilon\left[q\partial_s\varphi\partial_s^3\overline{\varphi}\right]_A^B dt\\ &=-\mathrm{Im}\int_A^B\left[q\partial_s\varphi\partial_s^2\overline{\varphi}\right]_0^\varepsilon ds-\mathrm{Re}\int_0^\varepsilon\int_A^B q''\partial_s\varphi\partial_s^2\overline{\varphi}dsdt.\end{aligned}$$

By choosing $q(s)=s-A$, we have

$$\begin{aligned}2\int_0^\varepsilon\int_A^B\left|\partial_s^2\varphi\right|^2 dsdt &= -(B-A)\,\mathrm{Re}\int_0^\varepsilon\partial_s\varphi(t,B)\,\partial_s^3\overline{\varphi}(t,B)\,dt\\ &-\mathrm{Im}\int_A^B\left[(s-A)\,\partial_s\varphi\partial_s^2\overline{\varphi}\right]_0^\varepsilon ds.\end{aligned}\tag{4.4}$$

By choosing $q(s)=\chi(s)$ with $\mathrm{supp}\chi\subset[B-2\beta,B]$ and $\chi(B)\neq 0$, we have

$$\begin{aligned}-\chi(B)\,\mathrm{Re}\int_0^\varepsilon\partial_s\varphi(t,B)\,\partial_s^3\overline{\varphi}(t,B)\,dt &= 2\int_0^\varepsilon\int_A^B\chi'(s)\left|\partial_s^2\varphi\right|^2 dsdt\\ &+\mathrm{Im}\int_A^B\left[\chi(s)\,\partial_s\varphi\partial_s^2\overline{\varphi}\right]_0^\varepsilon ds+\mathrm{Re}\int_0^\varepsilon\int_A^B\chi''(s)\,\partial_s\varphi\partial_s^2\overline{\varphi}dsdt.\end{aligned}\tag{4.5}$$

Due to (4.4) and (4.5), if, moreover, $\mathrm{supp}\chi'\subset[B-2\beta,B-\beta]$, we obtain the following assertion:

$\exists c > 0, \quad \forall \varepsilon > 0,$

$$\int_0^\varepsilon \int_A^B \left|\partial_s^2 \varphi\right|^2 ds dt \leq c \left(\int_0^\varepsilon \int_{B-2\beta}^{B-\beta} \left|\partial_s^2 \varphi\right|^2 ds dt + (1+\varepsilon) \left\|\partial_s \varphi_o\right\| \left\|\partial_s^2 \varphi_o\right\|_{L^2(]A,B[)} \right).$$

Hence

$$\int_A^B \left|\partial_s^2 \varphi_o\right|^2 ds \leq \frac{c}{\varepsilon} \int_{B-2\beta}^{B-\beta} \int_0^\varepsilon \left|\partial_s^2 \varphi\right|^2 ds dt + c \left(1 + \frac{1}{\varepsilon}\right) \left\|\partial_s \varphi_o\right\|_{L^2(]A,B[)} \left\|\partial_s^2 \varphi_o\right\|_{L^2(]A,B[)}.$$

Finally,

$$\exists c > 0, \quad \forall \varepsilon \leq 1, \qquad \int_A^B \left|\partial_s^2 \varphi_o\right|^2 ds \leq \frac{c}{\varepsilon} \int_{B-2\beta}^{B-\beta} \int_0^\varepsilon \left|\partial_s^2 \varphi\right|^2 dt ds + \frac{c}{\varepsilon^2} \left\|\partial_s \varphi_o\right\|^2_{L^2(]A,B[)}.$$

By interpolation, we have

(4.6)

$$\exists c > 0, \quad \forall \varepsilon \leq 1, \qquad \int_A^B \left|\partial_s^2 \varphi_o\right|^2 ds \leq \frac{c}{\varepsilon} \int_{B-2\beta}^{B-\beta} \int_0^\varepsilon \left|\partial_s^2 \varphi\right|^2 dt ds + \frac{c}{\varepsilon^4} \left\|\varphi_o\right\|^2_{L^2(]A,B[)}.$$

But the interpolation inequality (3.2) of Theorem 3.1 in the one-dimensional case implies that

$\exists C > 0, \exists \varepsilon_o > 0, \exists \mu_o > 0, \forall \varepsilon \leq \varepsilon_o, \forall \mu \geq \mu_o,$

$$\int_A^B \left|\varphi_o\right|^2 ds \leq \exp\left(C \frac{\mu}{\varepsilon}\right) \int_{B-2\beta}^{B-\beta} \int_0^\varepsilon \left|\partial_s^2 \varphi\right|^2 dt ds + \frac{\varepsilon^3}{\mu} \int_A^B \left|\partial_s^2 \varphi_o\right|^2 ds. \tag{4.7}$$

Let D_o be real such that $D_o = \max(2; \frac{\min(1;\varepsilon_o)\mu_o}{c})$. By choosing $\mu = D_o \frac{c}{\varepsilon} \geq \mu_o$, we conclude the proof of (4.2) from (4.7) and (4.6). And, in a standard way [Li], [F], we also have $\exists C > 0$, for all $\varepsilon > 0$,

$$\int_A^B \left|\varphi_o\right|^2 ds \leq e^{C\left(1+1/\varepsilon^2\right)} \int_{B-2\beta}^{B-\beta} \int_0^\varepsilon \left|\varphi\right|^2 dt ds. \tag{4.8}$$

That concludes the proof of Theorem 2.2. □

Remark 4.1. To prove (2.2), we used the multiplier methods and we absorbed the terms of lower order with the interpolation inequality (3.2) for $n = 1$. The same method can be used for $n > 1$ (see comment 2). Indeed, from the equality (1.21) of the work of Fabre [F, Lemma 1.9] on the exact internal controllability of the Schrödinger equation, we choose $\theta = g^2(t)$, where $g \in C_0^\infty(]0, \varepsilon[)$, $g = 1$ in $]\varepsilon/3; 2\varepsilon/3[$, and $0 \leq g \leq 1$, to obtain with standard bootstrap arguments the following assertion:

$$\exists c > 0, \quad \forall \varepsilon \leq 1, \qquad \int_\Omega \left|\Delta u_o\right|^2 dx dt \leq \frac{c}{\varepsilon} \int_0^\varepsilon \int_\omega \left|\Delta u\right|^2 dx dt + \frac{c}{\varepsilon^2} \left\|u_o\right\|^2_{H^1(\Omega)}. \tag{4.9}$$

Under the hypothesis of Lemma 1.9 of the work of Fabre [F, p. 350],we have (2.2) for $n > 1$ by applying the interpolation inequality (3.2) of Theorem 3.1.

5. Proof of Theorem 2.3. This section is devoted to proving the exact control result for Schrödinger equations with an explicit in time estimate of the control. We proceed in three steps.

5.1. Step 1. The Schrödinger equation on $\mathbb{R}$. In this section, we prove the existence of the following solution of the Schrödinger equation on $\mathbb{R}$.

PROPOSITION 5.1. *Let $T > 0$ be real, and let δ be the Dirac measure. There exists a distribution $f = f(t,s)$ defined on $]0,\varepsilon[\times \mathbb{R}_s$ such that $f_t : s \in \mathbb{R}_s \longmapsto f(t,s)$ has a support included in $J = (]-\infty,-2T[\cup]2T,+\infty[)$ and the solution $F : (t,s) \in [0,\varepsilon] \times \mathbb{R}_s \longmapsto F(t,s)$ of the Schrödinger equation*

$$\left\{ \begin{array}{l} i\partial_t F + \partial_s^2 F = f_{|J} \quad \text{in }]0,\varepsilon[\times \mathbb{R}_s, \\ F(0,\cdot) = \delta(\cdot) \quad \text{in } \mathbb{R}_s \end{array} \right. \tag{5.1}$$

satisfies $F(\varepsilon,\cdot) \equiv 0$ in $[-T,T]$. Moreover, if $H = F - E$, where E is the fundamental solution of the Schrödinger equation in one space dimension, then

$$\exists C > 0, \quad \forall \varepsilon > 0, \qquad \|H\|_{L^\infty(0,\varepsilon;L^2(]-T,T[))} \leq e^{C\left(1+1/\varepsilon^2\right)}. \tag{5.2}$$

Remark 5.2. The result of Proposition 5.1 simply says that the Schrödinger equation on the whole line can be controlled to zero with a control concentrated in the exterior of the ball. This is also true in several dimensions. The proof of this can be easily obtained from the result on a bounded domain by a cut-off argument (see also [Z]). In our case, we obtain an explicit estimate with respect to the time ε of controllability. Here T does not denote time, and let us adopt the variables $(t,s) \in [0,\varepsilon] \times \mathbb{R}_s$ when we consider the one-dimensional case.

Proof of Proposition 5.1. Using the HUM of Lions [Li] and estimate (2.2) of Theorem 2.2, we know that for all data $v_\varepsilon \in L^2(]-3T,4T[$, there exists a control $h \in L^2(]0,\varepsilon[\times]3T,4T[)$ such that the solution $v : (t,s) \longmapsto v(t,s) \in C([0,\varepsilon];L^2(]-3T,4T[))$ satisfies

$$\left\{ \begin{array}{l} i\partial_t v + \partial_s^2 v = h_{|]3T,4T[} \quad \text{in }]0,\varepsilon[\times]-3T,4T[, \\ v(\cdot,-3T) = 0,\ v(\cdot,4T) = 0 \quad \text{on }]0,\varepsilon[, \\ v(0,\cdot) = 0 \quad \text{in }]-3T,4T[, \\ v(\varepsilon,\cdot) = v_\varepsilon \quad \text{in }]-3T,4T[\end{array} \right. \tag{5.3}$$

and

$$\frac{1}{\sqrt{\varepsilon}} \|h\|_{L^1(0,\varepsilon;L^2(]3T,4T[))} \leq \|h\|_{L^2(]0,\varepsilon[\times]3T,4T[)} \leq e^{C\left(1+1/\varepsilon^2\right)} \|v_\varepsilon\|_{L^2(]-3T,4T[)}. \tag{5.4}$$

In particular, we take $v_\varepsilon(\varepsilon,s) = -\chi(s) \frac{e^{-i\frac{\pi}{4}}}{\sqrt{4\pi\varepsilon}} e^{i\frac{s^2}{4\varepsilon}}$, where $s \in]-3T,4T[$, $\chi \in C_0^\infty(]-3T,4T[)$, $0 \leq \chi \leq 1$, $\chi_{|[-T,T]} = 1$. So

$$\|v\|_{L^\infty(0,\varepsilon;L^2(]-3T,4T[))} \leq 2\|h\|_{L^1(0,\varepsilon;L^2(]3T,4T[))} \leq Ce^{C\left(1+1/\varepsilon^2\right)}. \tag{5.5}$$

Let us consider

$$H(t,s) = \left| \begin{array}{ll} v(t,s) & \text{in } [0,\varepsilon] \times [-3T,4T], \\ 0 & \text{in } [0,\varepsilon] \times (]-\infty,-3T[\cup]4T,+\infty[), \end{array} \right. \tag{5.6}$$

where v is the solution of (5.3). So

$$\left\{ \begin{array}{l} i\partial_t H + \partial_s^2 H = h_{|]3T,4T[} - \partial_s v \otimes \delta(s-4T) + \partial_s v \otimes \delta(s+3T) \quad \text{in }]0,\varepsilon[\times \mathbb{R}_s, \\ H(0,\cdot) = 0 \quad \text{in } \mathbb{R}_s, \\ H(\varepsilon,s) = -\chi(s) \frac{e^{-i\frac{\pi}{4}}}{\sqrt{4\pi\varepsilon}} e^{i\frac{s^2}{4\varepsilon}} \end{array} \right. \tag{5.7}$$

and

$$\exists C>0,\quad \forall \varepsilon>0,\qquad \|H\|_{L^\infty(0,\varepsilon;L^2(]-3T,4T[))}\leq e^{C\left(1+1/\varepsilon^2\right)}. \tag{5.8}$$

Let E be the fundamental solution of the Schrödinger equation on the whole line

$$E(t,s)=\frac{e^{-i\frac{\pi}{4}}}{\sqrt{4\pi t}}e^{i\frac{s^2}{4t}}. \tag{5.9}$$

The solution $E\in C^\infty(\{t>0\}\times\mathbb{R}_s)\cap C\left([0,+\infty[\,;H^{-1/2-\epsilon}(\mathbb{R}_s)\right)$ satisfies

$$\begin{cases} i\partial_t E+\partial_s^2 E=0 \quad \text{in } \{t>0\}\times\mathbb{R}_s,\\ E(0,\cdot)=\delta(\cdot)\in H^{-1/2-\epsilon}(\mathbb{R}_s). \end{cases} \tag{5.10}$$

We finally consider $f=h_{|]3T,4T[}-\partial_s v\otimes\delta(s-4T)+\partial_s v\otimes\delta(s+3T)$ such that the solution $F=E+H$ satisfies

$$\begin{cases} i\partial_t F+\partial_s^2 F=f_{|J} \quad \text{in }]0,\varepsilon[\times\mathbb{R}_s,\\ i\partial_t F+\partial_s^2 F=0 \quad \text{in }]0,\varepsilon[\times[-T,T],\\ F(0,\cdot)=\delta(\cdot) \quad \text{in } \mathbb{R}_s,\\ F(\varepsilon,\cdot)\equiv 0 \quad \text{in } [-T,T]. \end{cases} \tag{5.11}$$

That concludes the proof of Proposition 5.1. □

5.2. Step 2. Controllability for the hyperbolic problem. The following exact controllability result holds.

LEMMA 5.3. *Suppose $\Omega\subset\mathbb{R}^n$, $n\geq 1$, is of class C^∞, and there is no infinite order of contact between the boundary $\partial\Omega$ and the bicharacteristics of $\partial_t^2-\Delta$. If all generalized bicharacteristic rays meet $\omega\times]0,T_c[$ for some $0<T_c<+\infty$, then for all $T>T_c$, for all initial condition $w_o\in H_0^1(\Omega)$, there exists a control $g\in L^2(\Omega\times]-T,T[)$ such that the solution $y\in C\left(\mathbb{R}_t;H_0^1(\Omega)\right)\cap C^1\left(\mathbb{R}_t;L^2(\Omega)\right)$ satisfies*

$$\begin{cases} \partial_t^2 y-\Delta y=g_{|\omega\times]-T,T[} \quad \text{in } \Omega\times\mathbb{R}_t,\\ y=0 \quad \text{on } \partial\Omega\times\mathbb{R}_t,\\ y(\cdot,0)=w_o,\ \partial_t y(\cdot,0)=0 \quad \text{in } \Omega,\\ y\equiv 0 \quad \text{in } \Omega\times(]-\infty,-T]\cup[T,+\infty[) \end{cases} \tag{5.12}$$

and

$$\|g\|_{L^2(\omega\times]-T,T[)}\leq C_{\omega,T}\|\nabla w_o\|_{L^2(\Omega)}. \tag{5.13}$$

Remark 5.4. The result of Lemma 5.3 holds by a simple reflection argument as a consequence of the theorem of Bardos, Lebeau, and Rauch [BLR] on the exact controllability for hyperbolic equations which are obtained with microlocal techniques and propagation of singularities of the solution of hyperbolic systems. We recall their result to be complete.

Theorem [BLR]. Suppose $\Omega\subset\mathbb{R}^n$, $n\geq 1$, is of class C^∞, and there is no infinite order of contact between the boundary $\partial\Omega$ and the bicharacteristics of $\partial_t^2-\Delta$. If all generalized bicharacteristic rays meet $\omega\times]0,T_c[$ for some $0<T_c<+\infty$, then for all $T>T_c$, for all $\theta\in C_0^\infty(]0,T[)$, for all initial conditions $(w_o,w_1)\in H_0^1(\Omega)\times L^2(\Omega)$, there exists a control $\varrho\in L^2(\Omega\times\mathbb{R}_t)$ such that the solution $\Psi\in C\left(\mathbb{R}_t;H_0^1(\Omega)\right)\cap C^1\left(\mathbb{R}_t;L^2(\Omega)\right)$ satisfies

$$\begin{cases} \partial_t^2\Psi-\Delta\Psi=\theta\varrho_{|\omega} \quad \text{in } \Omega\times\mathbb{R}_t,\\ \Psi=0 \quad \text{on } \partial\Omega\times\mathbb{R}_t,\\ \Psi(\cdot,0)=w_o,\ \partial_t\Psi(\cdot,0)=w_1 \quad \text{in } \Omega,\\ \Psi(\cdot,T)=\partial_t\Psi(\cdot,T)=0 \quad \text{in } \Omega \end{cases}$$

and

$$\|\theta\varrho\|_{L^2(\omega\times]0,T[)} \leq C_{\omega,T}\,\|(\nabla w_o, w_1)\|_{L^2(\Omega)}\,.$$

Proof of Lemma 5.3. We choose $w_1 = 0$ and extend Ψ in a symmetric way by taking

$$y\,(x,t) = \left|\begin{array}{ll} \Psi\,(x,t) & \text{in } \Omega\times[0,T]\,,\\ \Psi\,(x,-t) & \text{in } \Omega\times[-T,0[\,. \end{array}\right.$$

The control g will be given by

(5.14)
$$g\,(x,t)_{|\omega\times]-T,T[} = \theta\,(t)\,\varrho\,(x,t)_{|\omega\times]0,T[} + \theta\,(-t)\,\varrho\,(x,-t)_{|\omega\times]-T,0[} \quad \text{in } \Omega\times\,]-T,T[\,,$$

where $\theta \in C_0^\infty\,(]0,T[)$ so that $g\,(\cdot,-T) = g\,(\cdot,0) = g\,(\cdot,T) = 0$. □

5.3. Step 3. Construction of the control. Now we are able to construct and estimate the control of Theorem 2.3 as follows.

We define $w : (x,t) \in \Omega\times[0,\varepsilon] \longmapsto w\,(x,t)$ such that

$$w\,(x,t) = \int_{\mathbb{R}} F\,(t,\ell)\,y\,(x,\ell)\,d\ell, \tag{5.15}$$

where $F : (t,\ell) \in [0,\varepsilon]\times\mathbb{R}_\ell \longmapsto F\,(t,\ell)$ is obtained from Proposition 5.1:

$$\left\{\begin{array}{l} i\partial_t F + \partial_\ell^2 F = f_{|J} \quad \text{in } \,]0,\varepsilon[\,\times\mathbb{R}_\ell,\\ i\partial_t F + \partial_\ell^2 F = 0 \quad \text{in } \,]0,\varepsilon[\,\times[-T,T]\,,\\ \qquad F\,(0,\cdot) = \delta\,(\cdot) \quad \text{in } \mathbb{R}_\ell,\\ \qquad F\,(\varepsilon,\cdot) \equiv 0 \quad \text{in } \,[-T,T]\,, \end{array}\right. \tag{5.16}$$

and $y : (x,\ell) \in \Omega\times\mathbb{R}_\ell \longmapsto y\,(x,\ell)$ given by Lemma 5.3 satisfies

$$\left\{\begin{array}{l} \partial_\ell^2 y - \Delta y = g_{|\omega\times]-T,T[} \quad \text{in } \Omega\times\mathbb{R}_\ell,\\ \qquad y = 0 \quad \text{on } \partial\Omega\times\mathbb{R}_\ell,\\ \quad y(\cdot,0) = w_o \in H_0^1\,(\Omega)\,,\ \partial_\ell y(\cdot,0) = 0 \quad \text{in } \Omega,\\ \qquad y \equiv 0 \quad \text{in } \Omega\times(]-\infty,-T]\cup[T,+\infty[)\,. \end{array}\right. \tag{5.17}$$

Let us calculate $i\partial_t w\,(x,t)$:

$$\begin{aligned} i\partial_t w\,(x,t) &= \int_{\mathbb{R}} i\partial_t F\,(t,\ell)\,y\,(x,\ell)\,d\ell\\ &= \int_{\mathbb{R}} \left[-\partial_\ell^2 F\,(t,\ell) + f_{|J}\right] y\,(x,\ell)\,d\ell\\ &= \int_{\mathbb{R}} -F\,(t,\ell)\,\partial_\ell^2 y\,(x,\ell)\,d\ell + \int_{-T}^{T} \left[f_{|J}\right] y\,(x,\ell)\,d\ell\\ &= \int_{\mathbb{R}} F\,(t,\ell)\left[-\Delta y\,(x,\ell) - g\,(x,\ell)_{|\omega\times]-T,T[}\right] d\ell. \end{aligned}$$

Remark 5.5. The key point is that the solution $y : (x,\ell) \longmapsto y\,(x,\ell)$, where $\ell \in \mathbb{R}$, is identically null for ℓ out of the domain $]-T,T[$. Next, we need that the solution $F : (t,\ell) \longmapsto F\,(t,\ell)$ is defined for $\ell \in \mathbb{R}$. Moreover, F must satisfy $F\,(0,\cdot) = \delta\,(\cdot)$

in $\mathbb{R}$, $F(\varepsilon,\cdot)\equiv 0$ in $[-T,T]$, and also the homogenous Schrödinger equation in the domain $]0,\varepsilon[\times[-T,T]$. Out of the domain $[-T,T]$, F is solution of the Schrödinger equation with a second member f, but we do not see it in the integrations by parts because y is null on the support of f.

Our conclusion is

$$\left\{\begin{array}{r} i\partial_t w+\Delta w=\vartheta_{\varepsilon|\omega} \quad \text{in } \Omega\times]0,\varepsilon[\,,\\ w=0 \quad \text{on } \partial\Omega\times]0,\varepsilon[\,,\\ w(\cdot,0)=w_o \quad \text{in } \Omega,\\ w(\cdot,\varepsilon)=0 \quad \text{in } \Omega \end{array}\right. \tag{5.18}$$

with an estimate of the control ϑ_ε in $\omega\times]0,\varepsilon[$, given by

$$\begin{aligned} \vartheta_\varepsilon(x,t) &= \int_{-T}^{T} -F(t,\ell)\,g(x,\ell)\,d\ell\\ &= \int_{-T}^{T} -(E+H)(t,\ell)\,g(x,\ell)\,d\ell\\ &= \vartheta_{\varepsilon,1}(x,t)+\vartheta_{\varepsilon,2}(x,t), \end{aligned} \tag{5.19}$$

where, from Proposition 5.1, (5.2), and (5.13), we have

$$\begin{aligned} \|\vartheta_{\varepsilon,1}(\cdot,t)\|_{L^2(\omega)} &= \left(\int_\omega \left|\int_{-T}^{T} E(t,\ell)\,g(x,\ell)\,d\ell\right|^2 dx\right)^{1/2}\\ &\le c\left(\int_\omega \left|\frac{1}{\sqrt{t}}\,\|g\|_{L^2(]-T,T[)}\right|^2 dx\right)^{1/2}\\ &\le \frac{1}{\sqrt{t}} C_{\omega,T}\,\|\nabla w_o\|_{L^2(\Omega),} \end{aligned} \tag{5.20}$$

$$\begin{aligned} \|\vartheta_{\varepsilon,2}(\cdot,t)\|_{L^2(\omega)} &= \left(\int_\omega \left|\int_{-T}^{T} H(t,\ell)\,g(x,\ell)\,d\ell\right|^2 dx\right)^{1/2}\\ &\le \left(\|H(t,\cdot)\|^2_{L^2(]-T,T[)}\int_\omega \|g(x,\cdot)\|^2_{L^2(]-T,T[)}\,dx\right)^{1/2}\\ &\le e^{C\left(1+1/\varepsilon^2\right)}\ C_{\omega,T}\,\|\nabla w_o\|_{L^2(\Omega).} \end{aligned} \tag{5.21}$$

We conclude with an estimate of $(\int_\Omega |\nabla w(x,t)|^2dx)^{1/2} = (\int_\Omega |\int_{\mathbb{R}}(E+H)(t,\ell)\nabla y(x,\ell)d\ell|^2dx)^{1/2}$:

$$\begin{aligned} \left(\int_\Omega \left|\int_{\mathbb{R}} E(t,\ell)\,\nabla y(x,\ell)\,d\ell\right|^2 dx\right)^{1/2} &= \left(\int_\Omega \left|\int_{-T}^{T} E(t,\ell)\,\nabla y(x,\ell)\,d\ell\right|^2 dx\right)^{1/2}\\ &\le c\left(\int_\Omega \left|\frac{1}{\sqrt{t}}\,\|\nabla y(x,\cdot)\|_{L^2(]-T,T[)}\right|^2 dx\right)^{1/2}\\ &\le \frac{1}{\sqrt{t}} C_{\omega,T}\,\|\nabla w_o\|_{L^2(\Omega)}, \end{aligned} \tag{5.22}$$

(5.23)

$$\left(\int_\Omega \left|\int_{\mathbb{R}} H(t,\ell)\,\nabla y(x,\ell)\,d\ell\right|^2 dx\right)^{1/2} = \left(\int_\Omega \left|\int_{-T}^{T} H(t,\ell)\,\nabla y(x,\ell)\,d\ell\right|^2 dx\right)^{1/2}$$
$$\leq \left(\|H(t,\cdot)\|^2_{L^2(]-T,T[)} \int_\Omega \|\nabla y(x,\cdot)\|^2_{L^2(]-T,T[)}\,dx\right)^{1/2}$$
$$\leq e^{C\left(1+1/\varepsilon^2\right)}\, C_{\omega,T}\,\|\nabla w_o\|_{L^2(\Omega)}\,.$$

Remark 5.6. If we choose $w(x,t) = \int_{\mathbb{R}} F(t,\ell)\,y(x,\ell)\,d\ell$ with F given by (5.16) and y given by (5.17) where the operator Δ is replaced by $\Delta_{\mathcal{A}}$, then w is solution of (2.7).

Acknowledgments. The author would like to thank Professor C. Bardos and Professor E. Zuazua for their encouragement and for very useful criticism which allowed for the significant improvement of the presentation of the paper.

MOBILE POINT CONTROLS VERSUS LOCALLY DISTRIBUTED ONES FOR THE CONTROLLABILITY OF THE SEMILINEAR PARABOLIC EQUATION*

ALEXANDER KHAPALOV†

Abstract. It is well known now that a rather general semilinear parabolic equation with globally Lipschitz nonlinear term is both approximately and exactly null-controllable in $L^2(\Omega)$, when governed in a bounded domain by the locally distributed controls. In this paper we intend to show that, in fact, in one space dimension ($\Omega = (0,1)$) the very same results can be achieved by employing *at most* two mobile point controls with support on the curves properly selected within an arbitrary subdomain of $Q_T = (0,1) \times (0,T)$. We will show that such curves can be described by a certain differential inequality and the explicit examples are provided. We also discuss some extensions of our main results to the superlinear terms and to the case of several dimensions.

Key words. linear and semilinear parabolic equations, controllability, observability, point controls

1. Introduction.

1.1. Problem description. In modeling physical processes in bounded domains by controlled PDEs two types of controls—boundary and internal—are typically used. The boundary controls act upon the system from outside, while the internal controls act in the interior of the system's space domain. Each of these controls can be both distributed (i.e., depending both on x and t) and lumped (depending on t only). In general, it seems obvious that the former ones are more powerful. However, the latter ones seem more preferred in terms of applications. In this paper we are interested in the following question arising in this context: *Do the locally distributed controls really (always) work "better" than the internal point ones?*

We consider the Dirichlet initial-boundary value problem for the following one-dimensional parabolic equation:

$$u_t = u_{xx} + b(x,t)u_x + a(x,t)u + f(u) + (Bv)(x,t) \ \text{ in } Q_T = \Omega \times (0,T) = (0,1) \times (0,T),$$

$$\text{(S)} \qquad u(0,t) = u(1,t) = 0 \quad \text{in } \ (0,T), \quad u \ |_{t=0} = u_0 \in L^2(0,T),$$

$$a \in C(\bar{Q}_T), \ \ b \in C^{0,1}(\bar{Q}_T).$$

Here the term $(Bv)(x,t)$ models an internal control: B denotes the control operator (it describes how the "control mechanism" acts and is "fixed"), and v is the value of control.

Accordingly, in the case of locally distributed controls we have

$$(Bv)(x,t) = \chi_\omega(x)v(x,t), \tag{1.1}$$

where $\omega = (l_1, l_2)$ is the given subdomain of $\Omega = (0,1)$ on which control v is supported (so $\chi_\omega(x)$ is the characteristic function of ω), and $v = v(x,t)$ is the function of *both* the time and space variables.

To the contrary, the *lumped* controls, as it follows from their name, are the functions of *time only.* Typically two kinds of internal lumped controls are employed:

(a) *the point controls*

$$(Bv)(x,t) = v(t)\delta(x - s(t)), \tag{1.2}$$

where $s(t)$ is the preassigned point support of control $v = v(t)$ at time t (so $\delta(x-s(t))$ denotes Dirac's mass concentrated at $s(t)$); and

(b) *the averaged (or zone) controls*

$$(Bv)(x,t) = v(t)\chi_{\omega(t)}(x), \tag{1.3}$$

where $\omega(t) \subset \Omega$ is the given support of control $v = v(t)$ at time t. Note that in the latter case (1.3) the *same* value $v(t)$ of the control function applies at every point of the set $\omega(t)$.

If $s(t) \equiv x_0$ in (1.2) and $\omega(t) \equiv \omega$ in (1.3) for all $t \in (0,T)$, the lumped controls are "static"; otherwise, they are called "mobile" or "scanning."

The lumped controls are strongly motivated by numerous applications. They can be regarded as a degenerate class of locally distributed ones. (The latter in turn can be viewed as a collection of infinitely many former ones.) To analyze these two types of control, one usually needs quite different methods. For example, the controllability property by means of the locally distributed controls is essentially based on the unique continuation property of solutions to the linear parabolic equation from an *open* set. This property cannot, obviously, be associated with the case of lumped controls.

Generally, one cannot expect equally strong results for these two types of controls. Nonetheless, *we intend to show below that for a rather general system like* (S)*, whenever* (S) *is globally controllable by the locally distributed controls* (1.1) *supported in* $\omega \times (0,T)$*, it is also globally controllable by means of at most two mobile point controls* (1.2) *(see* (1.6) *below), which are supported on the curves* $s_1(\cdot)$ *and* $s_2(\cdot)$ *suitably selected within the very same set* $\omega \times (0,T)$. Our special concern is their explicit description.

Let us recall in this respect that the geometry of control support is critical for controllability by means of lumped controls. Namely, unlike the locally distributed ones, the outcome in terms of controllability for the lumped controls is generally *unstable* with respect to their support. For example, it is well known (see [4], [7], [26]) that the standard heat equation in $\Omega = (0,1)$ with the static point control $v(t)\delta(x - x_0), x_0 \in (0,1)$, is *not* controllable for any rational location x_0. However, it becomes approximately controllable in $L^2(0,1)$ at any positive time T for x_0 being any irrational number and exactly null-controllable for almost all irrational x_0. (These results are based on the explicit Fourier series approach and do not apply to a *linear* system like (S) with $f = 0$, convection term, and time-varying coefficients.) In this respect, nonetheless, our main results below deal with quite feasible geometric Assumptions 1.1–1.3 that are "stable" with respect to either the C-, or, at most, $C^{2,1}$-topology for the choice of control curves.

Before we proceed any further, let us recall the classical definitions of controllability.

Assume that system (S) has a unique solution in the space $C([0,T];H)$ for any $u_0 \in H$ and $v \in V$, where H and V are some Banach spaces.

DEFINITION 1.1. *Given $T > 0$, system* (S) *is said to be approximately controllable in H at time T if for an arbitrary $\varepsilon > 0$ and $u_0, u_T \in H$, there is a suitable $v \in V$ such that for the corresponding solution to* (S) *we have*

$$\| u(\cdot, T) - u_T \|_H \leq \varepsilon. \tag{1.4}$$

DEFINITION 1.2. *Assume $f(0) = 0$. Given $T > 0$, system* (S) *is said to be exactly null-controllable in H at time T if for an arbitrary $u_0 \in H$ there is a suitable $v \in V$ such that the corresponding solution to* (S) *reaches the zero state (the equilibrium of* (S)*) at time T; that is,*

$$u(\cdot, T) = 0. \tag{1.5}$$

Everywhere below we deal with $H = L^2(0,1)$ and controls either in $L^2(\omega \times (0,T))$ in the case of locally distributed controls or in $L^2(0,T)$ in the case of point controls.

1.2. Main results. We further assume that the control term Bv is represented by no more than two point controls as follows:

$$(Bv)(x,t) = v_1(t)\delta(x - s_1(t)) + v_2(t)\delta(x - s_2(t)). \tag{1.6}$$

To ensure both the mathematical well-posedness of the system at hand (see Theorem A1, below) and to preserve the physical meaning of $s_1(\cdot)$ and $s_2(\cdot)$ as of the trajectories for the point controls, the following conditions are assumed throughout the remainder of this paper.

Assumption 1.1. (i) The functions $s_1 = s_1(t)$ and $s_2 = s_2(t)$ are defined on some segments lying in $[0,T]$ and are continuous functions with values in $[0,1]$. (This means that the actual controls act only where s_i's are defined and are inactive otherwise.)

(ii) Any "horizontal" line $\{(x,t) \mid t = t_*\}$ can cross any of the trajectories $s_i(\cdot)$ at most at *one* point. (Indeed, if $s_i(\cdot), i = 1,2$ represent the paths of point controls, then at every moment of time these controls can be supported at the single points only; see Figures 1.1 and 1.2.)

Our first two results—Theorems 1.1 and 1.2—deal with the linear version of system (S) and are, respectively, about the approximate and exact null-controllability properties. Theorem 1.1 employs the following additional geometric condition.

Assumption 1.2. (meeting condition). There is an interval $[t_1, t_2] \subset [0,T)$ such that the functions $x = s_1(t)$ and $x = s_2(t)$ are continuous and one-to-one on it with values in $[0,1]$ and

$$s_1(t_2) = s_2(t_2), \quad s_1(t) < s_2(t) \quad \forall t \in [t_1, t_2).$$

This condition means that the two control point controls at hand arrive ("meet") at time t_2 at the same point, as shown in Figure 1.2, for example.

THEOREM 1.1 (approximate controllability). *Let $T > 0$ be given, and let Assumptions* 1.1 *and* 1.2 *hold. Then the linear version of system* (S)*, namely, with $f = 0$ and Bv as in* (1.6) *(or, system* (2.2) *below, which is the same) is approximately controllable in $L^2(0,1)$ at time T. In turn its dual system* (2.5) *with two point sensors is observable (in the sense described in* (2.7) *below).*

Our next exact null-controllability result makes use of the following conditions.

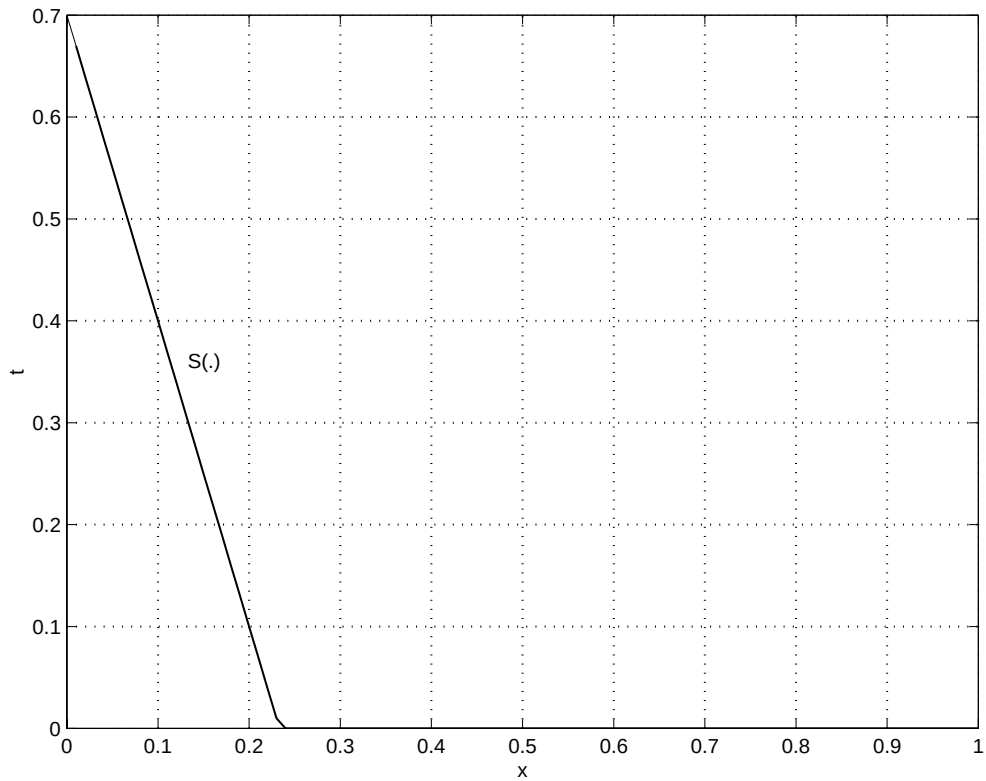

FIG. 1.1. *One point control.*

Assumption 1.3. (i) In addition to Assumption 1.2, assume that on the interval $[t_1, t_2] \subset [0, T]$ the functions $s_1(\cdot)$ and $s_2(\cdot)$ are, respectively, strictly monotone increasing and decreasing.

(ii) Assume that the connected geometric curve $s(\cdot)$ in $\bar{Q}_T \subset R^2$, composed from $s_1(\cdot)$ and $s_2(\cdot)$ on the interval $[t_1, t_2]$ (recall that they "meet" at t_2 by Assumption 1.2), is smooth and admits the following representation:

$$s(\cdot) = \{(x,t) \mid (x,t) \in \mathcal{A},\ F(x,t) = 0\},$$

where $\mathcal{A} = \{(x,t) \mid x \in [0,1], t \in [t_1, t_2]\}$ and F is an element of $C^{2,1}(\mathcal{A})$ and

$$-F_t(x,t) + 2b(x,t)F_x(x,t) - \{b(x,t)F(x,t)\}_x + F_{xx}(x,t) \le 0 \quad \forall (x,t) \in \mathcal{A}^*, \tag{1.7}$$

$$F(x,t) > 0 \quad \forall (x,t) \in \operatorname{int}\{\mathcal{A}^*\}, \quad F(x,t) \le 0 \quad \forall (x,t) \in \mathcal{A} \backslash \mathcal{A}^*, \tag{1.8}$$

where $\mathcal{A}^* = \{(x,t) \mid s_1(t) \le x \le s_2(t),\ t \in [t_1, t_2]\}$.

Assumption 1.3(i) means that any "vertical" line ($x =$ constant) within the layer $\mathcal{A}$ crosses at most one of the curves $s_1(\cdot), s_2(\cdot)$ at no more than one point. This assumption (as well as (ii)) can be relaxed somewhat: we assume it to simplify our further integration by parts. Several explicit examples illustrating Assumption 1.3 are given in section 6 below.

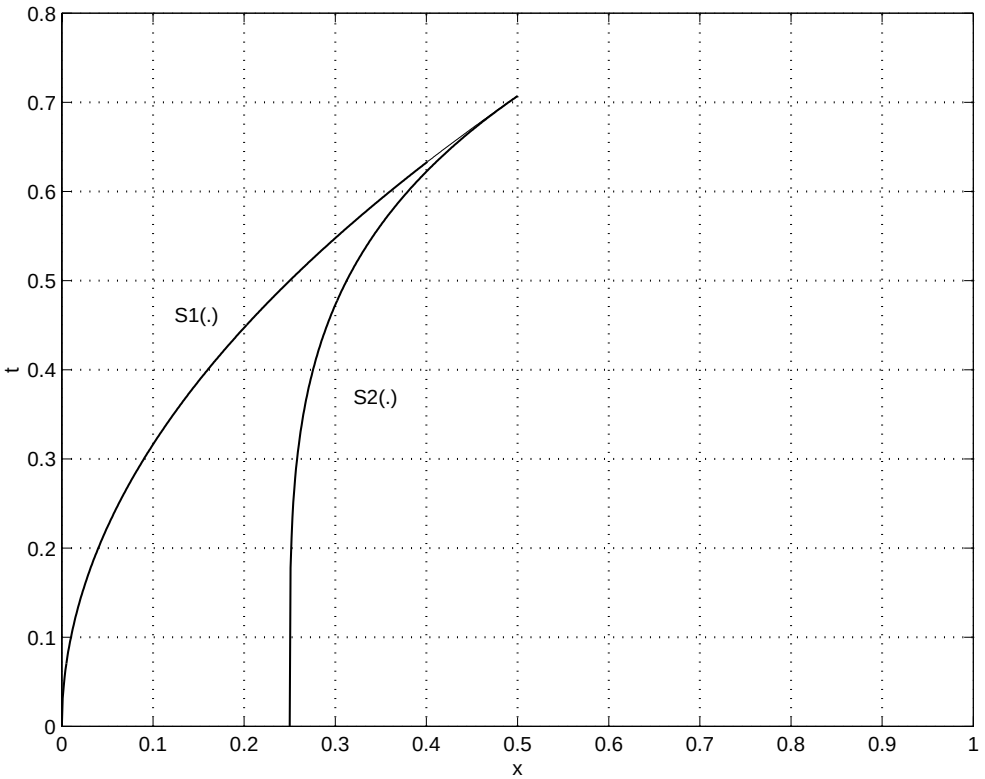

FIG. 1.2. *Two point controls.*

THEOREM 1.2 (exact null-controllability). *Let $T > 0$ be given, and let Assumptions* 1.1–1.3 *hold. Then the linear version of system* (S)*, namely, with $f = 0$ and Bv as in* (1.6) *(see system* (2.2) *below), is exactly null-controllable in $L^2(\Omega)$ at time T.*

The approximate and exact null-controllability properties of a system like (S) with globally Lipschitz f and the locally distributed controls were established (in several space dimensions) in [14], [13], based on the method of Carleman estimates (see also [24] for the case of the standard heat equation). For a different variational approach relevant solely to the issue of approximate controllability we refer to [6]. In this respect we have the following "lumped" result.

THEOREM 1.3 (the semilinear case). *Suppose that f is globally Lipschitz, differentiable at zero, and vanishes at zero: $f(0) = 0$. Let $T > 0$ be given, and let Assumptions* 1.1–1.3 *hold. Then system* (S) *with Bv as in* (1.6) *(or,* (5.1) *below, which is the same) is exactly null-controllable in $L^2(\Omega)$ at time T.*

Remark 1.1.

- In Corollaries 2.1 and 5.1 and in Remark 2.1 we distinguish the cases when all the above results hold with a single point control active only.
- In section 7.4 we also discuss possible extensions of Theorem 1.3 to some superlinear growth rates for f, which were the subject of the recent works [16], [8], [20], [21], [9], [2], [1], [11] dealing with the locally distributed controls.
- For the one-dimensional semilinear heat equation with the *uniformly bounded* globally Lipschitz term, governed by the static point controls like in (1.2)

with $s(t) \equiv x_0$, the approximate controllability was shown in [28].

- In [19] the approximate controllability was established for the *static* zone lumped controls like in (1.3), assuming that either (a) f is a sublinear $\log^r \mid u \mid$-like function or (b) it is superlinear like $\mid f(x,t,u,u_x) \mid \leq \beta(t)(\mid u \mid^{r_1} + \mid u_x \mid^{r_2})$, where r_1, r_2 can exceed 1 and $\beta(t) \to 0$ faster than any of $e^{-\nu/t}$, $\nu > 0$ as $t \to 0$, *and* the dissipativity condition holds for such f. In [22] the last restriction on the growth of f in t was avoided, assuming that $b = 0$, $a = a(t)$ in (S), and, in addition to the locally distributed control (1.3), one can use the coefficient $a = a(t)$ as an extra bilinear control.

In the appendix we prove the following supporting existence and regularity result which insures the well-posedness of the boundary problem (S), (1.6). (To separate it from our main controllability results and to indicate that its proof is delegated to the appendix, we mark it as "A.1.")

THEOREM A.1. *Let Assumption* 1.1 *hold, let f be globally Lipshitz, and let $f(0) = 0$. Then system* (S), (1.6) *admits a unique generalized solution in $C([0,T]; L^2(0,1)) \bigcap L^2(0,T; H_0^1(0,1))$ for which the following two estimates hold:*

$$\| u \|_{L^6(Q_T)} \leq c(T) \left(\| u_0 \|_{L^2(\Omega)} + \| v_1 \|_{L^2(0,T)} + \| v_2 \|_{L^2(0,T)} \right), \tag{1.9a}$$

$$\| u \|_{C([0,T];L^2(0,1))} + \left(\int_0^T \int_0^1 u_x^2 \, dxdt \right)^{1/2} \leq c(T) \left(\| u_0 \|_{L^2(\Omega)} + \| v_1 \|_{L^2(0,T)} + \| v_2 \|_{L^2(0,T)} \right), \tag{1.9b}$$

where $c(T)$ is nondecreasing and depends also on the $C(\bar{Q}_T)$-norms of $a(x,t)$ and $b(x,t)$ and the Lipschitz constant of f.

The remainder of the paper is organized as follows. In sections 2–4 we deal with the case when (S) is linear. Sections 4 and 5 consider the semilinear case with globally Lipschitz f. Several explicit examples are given in section 6. In section 7 we analyze some possible extensions of our main results.

2. The linear case: The dual observed system. In the linear case, to separate two types of controls, we represent (S) with the locally distributed controls as

$$p_t \ = \ p_{xx} \ + \ b(x,t)p_x \ + \ a(x,t)p \ + \ v(x,t)\chi_\omega(x) \quad \text{in} \quad Q_T, \tag{2.1}$$

$$p(0,t) = p(1,t) = 0 \quad \text{in} \ (0,T), \quad p \mid_{t=0} = p_0 \in L^2(0,1), \ \ v \in L^2(\omega \times (0,T)),$$

while with *two* point controls (1.6) system (S) will look as follows:

$$\begin{aligned} u_t \ &= u_{xx} + b(x,t)u_x \ + \ a(x,t)u \ + \ v_1(t)\delta(x - s_1(t)) \\ &\quad + \ v_2(t)\delta(x - s_2(t)) \quad \text{in} \quad Q_T, \end{aligned} \tag{2.2}$$

$$u(0,t) = u(1,t) = 0 \quad \text{in} \ (0,T), \quad u \mid_{t=0} = u_0 \in L^2(0,1), \ \ v_1, v_2 \in L^2(0,T).$$

It is known for (2.1) (and (2.5); see, e.g., [23]) and it is shown in the appendix for (2.2) that these systems possess unique solutions in the space $\Xi = C([0,T]; L^2(0,1)) \bigcap L^2(0,T; H_0^1(0,1))$, which we further endow with the norm

$$\| z \|_\Xi = \| z \|_{C([0,T];L^2(0,1))} \ + \ \left(\int_0^T \int_0^1 z_x^2 \, dxdt \right)^{1/2}, \tag{2.3}$$

and the estimates like (1.9a) and (1.9b) hold.

2.1. Approximate controllability: The linear case. Clearly, to analyze this property in this case, it is sufficient to do it when the initial data is the zero-state:

$$p_0 = 0 \ \text{ for } \ (2.1) \ \text{ and } \ u_0 = 0 \ \text{ for } \ (2.2). \tag{2.4}$$

Then, as is well known (see, e.g., [5]), the issue of global approximate controllability of systems (2.1) and (2.2) is tantamount to the observability property of the corresponding dual boundary problem:

$$y_t \ = \ y_{xx} \ - \ (b(x,T-t)y)_x \ + \ a(x,T-t)y \quad \text{ in } \ Q_T, \tag{2.5}$$

$$y(0,t) = y(1,t) = 0, \quad y \ |_{t=0} = y_0 \in L^2(0,1).$$

Namely, for (2.1) (or, for (2.1), (2.4), which is the same) system (2.5) must be *observable* with respect to the locally distributed observation over $\omega \times (0,T)$; that is,

$$y \equiv 0 \ \text{ in } \ \omega \times (0,T) \ \ \Longrightarrow \ \ y \equiv 0 \ \text{ in } \ Q_T. \tag{2.6}$$

In turn, for system (2.2) the *dual* observability property means that

$$y \equiv 0 \ \text{ along } \ s_1(T-\cdot), s_2(T-\cdot) \ \ \Longrightarrow \ \ y \equiv 0 \ \text{ in } \ Q_T. \tag{2.7}$$

This classical conclusion follows from the duality relations

$$\int_0^1 p(x,T)y_0(x)dx \ = \ \int_0^T \int_\omega v(x,t)y(x,T-t)dxdt,$$

$$\int_0^1 u(x,T)y_0(x)\,dx \ = \ \int_0^T v_1(t)y(s_1(t),T-t)\,dt \ + \ \int_0^T v_2(t)y(s_2(t),T-t)\,dt,$$

which can be derived by multiplying accordingly (2.1), (2.4) and (2.2), (2.4) by $y(x,T-t)$ and further integration by parts over Q_T.

Note now that the statement (2.6) is equivalent to the unique continuation property of solutions to (2.5) (also possessing the backward uniqueness property, e.g., [3]) from $\omega \times (0,T)$ to Q_T, which holds for any nondegenerate interval $\omega = (l_1, l_2)$.

We now intend to show that for any nondegenerate $\omega = (l_1, l_2) \subseteq (0,1)$ one can select two curves $s_1(\cdot)$ and $s_2(\cdot)$, lying in $\omega \times (0,T)$, which ensure (2.7), and hence the approximate controllability of (2.2). Our results here are linked to the geometric Assumptions 1.2 and 1.3 on these curves. In this subsection we employ the former.

We start with the discussion of the well-posedness of point observations.

Note that we have $(b(\cdot,T-\cdot)y)_x, a(\cdot,T-\cdot)y \in L^2(Q_T)$, while by the smoothing effect $u(\cdot,t_*) \in H_0^1(0,1)$ for any $t_* \in (0,T]$ (see, e.g., [23, pp. 178–180], [25]). Hence solutions to (2.5) on (t_*,T) can be viewed as the ones of the standard heat equation with the source term in $L^2((0,1)\times(t_*,T))$ and the initial data in $H_0^1(0,1)$. Hence they are continuous on any $[0,1]\times[t_*,T]$, i.e., on $[0,1]\times(0,T]$ for all $y_0 \in L^2(0,1)$. Moreover, the following estimate holds for any $t_* \in (0,T)$ (e.g., [25]):

$$\| \, y \, \|_{C([0,1]\times[t_*,T])} \le \ c(t_*) \left(\| \, y(\cdot,t_*) \, \|_{H_0^1(0,1)} \ + \ \| \, (b(\cdot,T-\cdot)y)_x + a(\cdot,T-\cdot)y \, \|_{L^2(Q_T)} \right), \tag{2.8a}$$

where the symbol $c(s)$ denotes any generic (i.e., they can be different) finite positive function of $s > 0$. (The symbol C is reserved for a generic positive constant.)

On the other hand, from the classical regularity results (based on the Fourier series approach) it is known (again viewing (2.5) as the standard heat equation with the source term in $L^2(Q_T)$) that

$$\| y(\cdot,t_*) \|_{H_0^1(0,1)} \le c(t_*) \big(\| y_0 \|_{L^2(0,1)} + \| (b(\cdot,T-\cdot)y)_x + a(\cdot,T-\cdot)y \|_{L^2(Q_T)} \big) \le c(t_*) \| y_0 \|_{L^2(0,1)}, \tag{2.8b}$$

(recall $c(\cdot)$ is generic), where we also used the following classical estimate for solutions of (2.5) (see (1.9a), (1.9b), and (2.3)):

$$\| y \|_{\Xi} \le c(T) \| y_0 \|_{L^2(\Omega)} .$$

Combining all of the above, we obtain

$$\| y \|_{C([0,1]\times[t_*,T])} \le c(t_*) \| y_0 \|_{L^2(0,1)} \quad \forall t_* \in (0,T), \tag{2.9}$$

which ensures the well-posedness of point observation.

Note also that for any continuous curve $s(t) \in (0,1), t \in (0,T)$ satisfying Assumption 1.1, by the continuity of embedding $H_0^1(0,1) \subset C[0,1]$, and by Poincaré–Friedrichs's inequality, we have

$$\| y(s(T-\cdot),\cdot) \|_{L^2(0,T)} \le C \| y \|_{L^2(0,T;H_0^1(0,1))} .$$

We are now ready to prove Theorem 1.1.

Proof of Theorem 1.1. *The case of the standard heat equation.* Note that by the smoothing effect, the solutions to (2.5) are classical in the cylinder

$$\mathcal{B} = \{(x,t) \mid x \in [0,1], t \in [T-t_2, T-t_1]\} = \{(x,t) \mid (x,T-t) \in \mathcal{A}\}$$

for any $y_0 \in L^2(0,1)$. This permits us to apply the classical maximum principle in it, which states that the maximum and minimum of y in (the closed set) $\mathcal{B}$ are attained on the boundary

$$\Gamma_{T-t_2,T-t_1} = \{(x,t) \mid x = 0,1; t \in [T-t_2, T-t_1]\} \bigcup \{(x,t) \mid t = T-t_2, x \in [0,1]\}$$

of this cylinder. Now we would like to remind the reader of the classical proof of this statement in order to show that it remains true for the set

$$\mathcal{B}^* = \{(x,t) \mid (x,T-t) \in \mathcal{A}^*\}$$

in place of $\mathcal{B}$ as well.

Assume it is false, e.g., that y reaches its maximum in $\mathcal{B}$, say, M, at the point $(x_0,t_0) \in \mathcal{B} \backslash \Gamma_{T-t_2,T-t_1}$, where $M = m + \varepsilon$, $m = \max\{y(x,t) \mid (x,t) \in \Gamma_{T-t_1,T-t_2}\}$, and $\varepsilon > 0$. Introduce an auxiliary function $v(x,t) = y(x,t) + k(t_0 - t)$.

Now select a positive parameter k sufficiently small to ensure that

$$\| y - v \|_{C(\mathcal{B})} \le \varepsilon/2.$$

Then v also reaches its maximum in $\mathcal{B}$, say, at the point $(x_1,t_1) \in \mathcal{B} \backslash \Gamma_{T-t_2,T-t_1}$, because

$$v(x_1,t_1) \ge v(x_0,t_0) = m + \varepsilon,$$

while v cannot exceed $m+\varepsilon/2$ on $\Gamma_{T-t_2,T-t_1}$. At the maximum point (x_1,t_1) we have

$$y_{xx}(x_1,t_1)=v_{xx}(x_1,t_1)\ \le\ 0\ \le\ v_t(x_1,t_1)=y_t(x_1,t_1)-k.$$

Therefore, the heat equation does not hold at (x_1,t_1), which is a contradiction.

Analyzing this proof, the reader can see that, under Assumptions 1.1 and 1.2, it holds true without any changes for the set $\mathcal{B}^*=\{(x,t)\mid s_1(T-t)\le x\le s_2(T-t),\ t\in[T-t_2,T-t_1]\}$ in place of $\mathcal{B}$ and for the combined *connected* (by Assumption 1.2) geometric curve $s(\cdot)=s_1(T-\cdot)\bigcup s_2(T-\cdot)$ in place of $\Gamma_{T-t_2,T-t_1}$ as well. Thus we establish the following:

$$\begin{aligned}\|\ y\ \|_{C(\mathcal{B}^*)}\ &\le\ \max_{i=1,2}\{\|\ y(s_i(T-\cdot),\cdot)\ \|_{C[T-t_2,T-t_1]}\}\\ &=\ \max_{i=1,2}\{\|\ y(s_i(\cdot),T-\cdot)\ \|_{C[t_1,t_2]}\}.\end{aligned}\tag{2.10}$$

In other words, if the solution y to (2.5) vanishes on the curves $s_1(T-t)$ and $s_2(T-t),t\in[T-t_2,T-t_1]$, "emitted" from the point $(s_1(t_2)=s_1(t_2),T-t_2)$, then y vanishes everywhere in $\mathcal{B}^*$.

Furthermore, by the unique continuation property (e.g., [27]) y vanishes in the horizontal layer $\mathcal{B}$. By backward (and forward) uniqueness this solution vanishes in Q_T. Thus we have (2.7) and hence the approximate controllability of dual (2.2).

The general case. Step 1. Represent the equation in (2.5) as follows:

$$y_t\ =\ y_{xx}\ -\ b(x,T-t)y_x\ +\ d(x,T-t)y,$$

where $d(x,T-t)=a(x,T-t)-b_x(x,T-t)$.

We know (see (2.8a–b)–(2.9)) that $y(x,T-t_2)\in H_0^1(0,1)$. Let us assume for a while that $y(x,T-t_2)$ and the coefficients $b(x,T-t)$ and $d(x,T-t)$ are infinitely many times continuously differentiable in $\mathcal{B}$. Then y will be the classical solution to (2.5) in the latter set; see, e.g., [12, p. 65].

Moreover, without loss of generality, we can assume that $d(x,T-t)\le 0$ in $\mathcal{B}$. (Indeed, this can be achieved by a simple change of variable $\hat{y}\to y:\ \hat{y}=e^{\lambda t}y$ with properly selected parameter λ.) If so, y satisfies the maximum principle in any set $\mathcal{P}_{(t)}=\mathcal{B}^*\bigcap\{(x,t)\mid t\ge t_*\}$, where $t_*\in(T-t_2,T-t_1]$ (see [12], pp. 34–35); that is, $|\ y(x,t)\ |$ reaches its maximum on the lower boundary of the set $\mathcal{P}_{(t)}$:

$$|\ y(x,t)\ |\le\ \max\{\|\ y(s_i(T-\cdot),\cdot)\ \|_{C[T-t_*,T-t_1]},\ i=1,2;\ \max_{r\in[s_1(T-t_*,s_2(T-t_*)]}|\ y(r,t_*)\ |\}$$

$$\forall(x,t)\in\mathcal{P}_{(t)};$$

see Figure 2.1. Since $s_1(t_2)=s_2(t_2)$ with $t_*\to T-t_2$, this estimate implies (2.10) whenever y is the classical solution.

Step 2. Consider now any solution to (2.5). Similar to the argument leading to (2.9), we can show that it can be approximated in the $C(\mathcal{B})$-norm by a sequence of the classical solutions to the boundary problem

$$y_{jt}\ =\ y_{jxx}\ -\ b_j(x,T-t)y_{jx}\ +\ d_j(x,T-t)y_j\quad\text{in}\ \ \mathcal{B},$$

$$y_j(0,t)=y_j(1,t)=0,\quad y_j\ |_{t=T-t_2}=y_{j0},$$

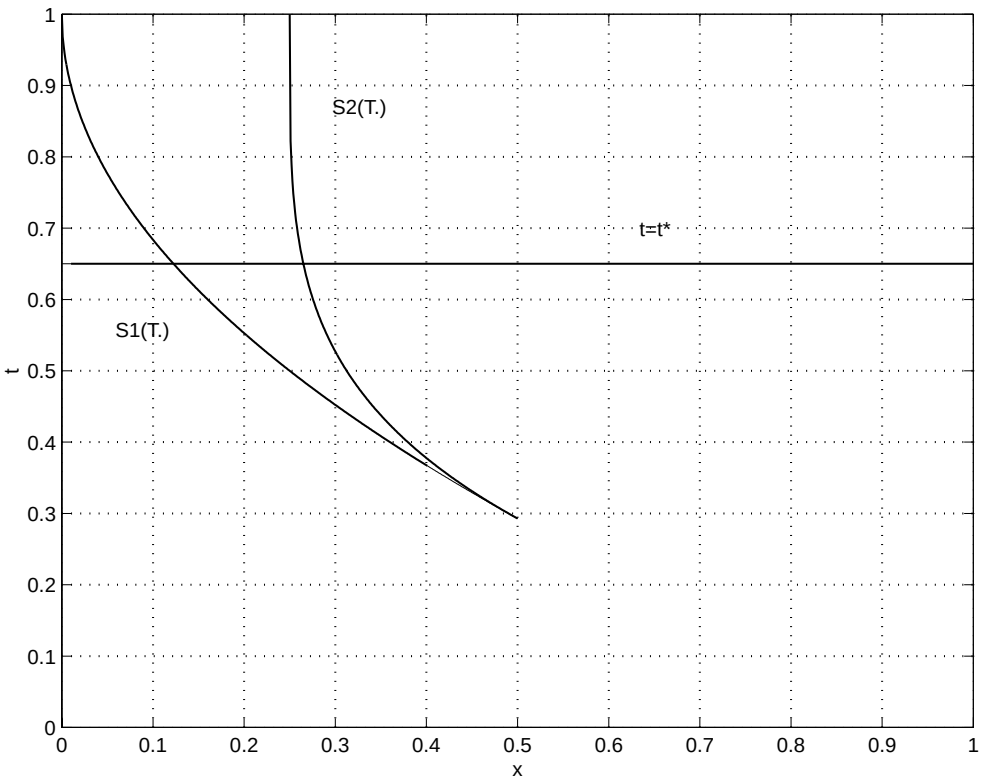

FIG. 2.1.

where $b_j(x, T-t), d_j(x, T-t)$, and $y_{j0}(x)$ are infinitely many times continuously differentiable functions converging, respectively, in the $C(\mathcal{B})$-norm to $b(x, T-t)$ and $d(x, T-t)$, and in the $H_0^1(0,1)$-norm to $y_0^*(x) = y(x, T-t_2)$. Moreover, d_j's can be selected to preserve the inequality $d_j(x, T-t) \leq 0$ in $\mathcal{B}$ for all $j = 1, \ldots$.

Indeed, to approximate the coefficients, one may first continuously extend their domain to a larger set and then use a suitable averaging procedure. To ensure the above-mentioned inequality for d_j's, if necessary, $d(x, T-t)$ should be approximated first by a sequence of continuous functions for which this inequality is strict in $\mathcal{B}$. To approximate y_0^*, it is sufficient to recall that the infinitely many times continuously differentiable functions with compact support in $(0,1)$ are dense in $H_0^1(0,1)$.

Then, for the difference $z_j = y - y_j$, we have the following boundary problem:

$$z_{jt} \;=\; z_{jxx} \;-\; b_j(x, T-t) z_{jx} \;+\; d_j(x, T-t) z_j \;+ f_j \quad \text{in} \quad \mathcal{B}, \tag{2.11}$$

$$z_j(0,t) = z_j(1,t) = 0, \quad z_j \;|_{t=T-t_2} = y_0^* - y_{j0},$$

where $f_j(x,t) = -(b(x, T-t) - b_j(x, T-t)) y_x + (d(x, T-t) - d_j(x, T-t)) y$. An estimate like (1.9a)–(1.9b) applied to (2.5) implies that

$$\| f_j \|_{L^2(\mathcal{B})} \leq \; C \left(\| b - b_j \|_{C(\mathcal{A})} + \| d - d_j \|_{C(\mathcal{A})} \right) \| y_0 \|_{L^2(0,1)}$$

for some $C > 0$.

Similar to (2.8a) and (2.8b), that is, viewing (2.11) as the standard heat equation with the source term $-b_j(x,T-t)z_{jx}+d_j(x,T-t)z_j+f_j(x,t)$ in $L^2(\mathcal{B})$, we obtain that

$$\| z_j \|_{C(\mathcal{B})}$$

$$\leq C_1 \left(\| z_j(\cdot,T-t_2) \|_{H_0^1(0,1)} + \| -b_j(\cdot,T-t)z_{jx}+d_j(\cdot,T-t)z_j+f_j \|_{L^2(\mathcal{B})} \right)$$

$$\leq C_2(\| z_j(\cdot,T-t_2) \|_{H_0^1(0,1)} + (\| b_j \|_{C(\mathcal{A})} + \| d_j \|_{C(\mathcal{A})}) \| z_j \|_{\Xi(\mathcal{B})}$$

$$+ \left(\| b-b_j \|_{C(\mathcal{A})} + \| d-d_j \|_{C(\mathcal{A})}\right) \| y_0 \|_{L^2(0,1)}])$$

for some positive constants $C_i, i=1,2$, where $\Xi(\mathcal{B})$ is the restriction of the space Ξ defined on Q_T to $\mathcal{B}$). Now, applying the estimates like (1.9a) and (1.9b) to z_j as the solution of (2.11), we derive that

$$\| z_j \|_{\Xi(\mathcal{B})} \leq C \left(\| z_j(\cdot,T-t_2) \|_{L^2(0,1)} + \| f_j \|_{L^2(\mathcal{B})} \right)$$

for some $C>0$, with $\| f_j \|_{L^2(\mathcal{B})}$ already evaluated in the above. Hence

$$\lim_{j\to\infty} \| z_j \|_{C(\mathcal{B})} = \lim_{j\to\infty} \| y-y_j \|_{C(\mathcal{B})} = 0. \tag{2.12}$$

Step 3. Now, if y vanishes on the curves $s_1(T-t)$ and $s_2(T-t)$, $t\in[T-t_2,T-t_1]$, lying in $\mathcal{B}$, then, by (2.12),

$$\lim_{j\to\infty} \max_{i=1,2} \{ \| y_k(s_i(T-\cdot),\cdot) \|_{C[T-t_2,T-t_1]} \} = 0. \tag{2.13}$$

Combining (2.13) with (2.10) applied to the classical solutions $y_j, j=1,\dots$ (see Step 1), yields that

$$\lim_{j\to\infty} \| y_j \|_{C(\mathcal{B}^*)} = 0,$$

which in view of (2.12) means that y vanishes in $\mathcal{B}^*$.

The end of the proof in the general case of (2.5) is identical to the case of the standard heat equation in the above with one correction: in the general case we don't have enough regularity to make use of the unique continuation result of [27]. Instead, we will use the estimate (4.4) below with $D = \operatorname{int}\mathcal{B}^*$, which gives $y|_{t=T}=0$ and, by duality discussed in the beginning of this subsection, the approximate controllability of (2.2). To obtain (2.7), one needs also to use the backward uniqueness property of solutions to (2.5) (e.g., [3]). This completes the proof of Theorem 1.1. □

Corollary 2.1. *Note that, due to the zero boundary condition in* (2.5) *(i.e., y vanishes on the lines $x=0$ and $x=1$), the conclusion of Theorem* 1.1 *also holds when we have just one point control, whose trajectory "hits" the boundary of* $(0,1)$ *at some time t_2, while approaching it from the interior of $\Omega=(0,1)$. (The actual proof of Theorem* 1.1 *is given below for this case.)*

2.2. Exact null-controllability: The linear case. For a system like (2.1) with varying coefficients and the locally distributed controls this property was shown in [14], [13] (see [24] for the standard heat equation). The methods of these works employ Carleman's estimates to enhance the unique continuation property, namely, by establishing the following estimate for the solutions to (2.5):

$$\| y(\cdot,T) \|_{L^2(0,1)} \leq C \| y \|_{L^2(\omega\times(0,T))} . \tag{2.14}$$

Note that (2.14) also provides the unique continuation property of y from $\omega\times(0,T)$ to Q_T, and hence the approximate controllability of (2.1). However, it means more, namely, that the operator which maps the trace y on $\omega \times (0,T)$ to $y(\cdot,T)$ on $(0,1)$ is well defined and continuous with respect to the spaces in (2.14). By duality, this classically yields the exact null-controllability of (2.1) in $L^2(0,1)$ at time T.

In this respect our next goal is to derive an estimate analogous to (2.14) for two point sensors "dual" of the two point controls in (2.2), which, by duality, is tantamount to Theorem 1.2. Our main result here is as follows.

THEOREM 2.2 (observability estimate). *Let $T > 0$ be given, and let Assumptions* 1.1–1.3 *hold. Then for any solution to the system* (2.5) *we have the following observability estimate (also implying* (2.7)*)*:

$$\| y(\cdot,T) \|_{L^2(0,1)} \leq C \left(\int_{T-t_2}^{T-t_1} (y^2(s_1(T-t),t) + y^2(s_2(T-t),t))dt \right)^{1/2} . \tag{2.15}$$

The proof of Theorem 2.2 is given in the next two sections.

Remark 2.1. Both Theorems 2.2 and 1.2 can be extended as in Corollary 2.1.

3. An auxiliary observability estimate (3.6). In this section our goal is to derive the estimate (3.6) under the assumptions of Theorem 2.2. For simplicity we will further assume that $t_1 = 0, t_2 = T$ and formally set $s_1(t) = 0$ for $t \in [0,T]$ (as in Corollary 2.1; otherwise, see Remark 3.1).

Let

$$\| a(x,t) \|_{C(\bar{Q}_T)} = L. \tag{3.1}$$

Let F be as in Assumption 1.3. Given $T > 0$, put

$$\varphi(x,t) = \begin{cases} F(x,T-t) & \text{for } (x,t) \in \mathcal{B}^*, \\ 0 & \text{for } (x,t) \in \mathcal{B}\backslash\mathcal{B}^*. \end{cases} \tag{3.2a}$$

Under Assumption 1.3, $\varphi \in C^{2,1}(\mathcal{B}^*)$ is nonnegative, vanishes in $\mathcal{B}\backslash\mathcal{B}^*$, and

$$\varphi = 0 \ \text{ on } \ s_2(T-\cdot) \ \text{ and } \ \varphi > 0 \ \text{ in } \ \operatorname{int}\{\mathcal{B}^*\}. \tag{3.2b}$$

Multiplication of (2.5) by φy and further integration by parts over Q_t (for all $t \in [0,T]$) or over the set $\mathcal{B}_t^* = \mathcal{B}^* \bigcap \{(x,\tau) \mid 0 < \tau < t\}$, which is the same, yield

$$\frac{1}{2}\int_0^1 \varphi(x,t)y^2(x,t)dx$$

$$= \int_0^t \int_0^1 \left(a(x,T-\tau)\varphi y^2 + \frac{1}{2}\varphi_\tau y^2 + y_{xx}\varphi y \ - \ (b(x,T-\tau)y)_x y\varphi \right) dxd\tau$$

$$= \int\int_{\mathcal{B}_t^*} a(x,T-\tau)\varphi y^2 dxd\tau \; - \; \frac{1}{2}\int\int_{\mathcal{B}_t^*} \varphi_x (y^2)_x dxd\tau$$

$$- \int\int_{\mathcal{B}_t^*} \varphi y_x^2 dxd\tau \; + \; \frac{1}{2}\int\int_{\mathcal{B}_t^*} (\varphi_\tau y^2 + 2b(x,T-\tau)\varphi_x y^2 + b(x,T-\tau)\varphi(y^2)_x) dxd\tau$$

$$\leq \; L\int\int_{\mathcal{B}_t^*} \varphi y^2 dxd\tau \; - \; \frac{1}{2}\int\int_{\mathcal{B}_t^*} \varphi_x (y^2)_x dxd\tau$$

$$+ \frac{1}{2}\int\int_{\mathcal{B}_t^*} \{\varphi_\tau + 2b(x,T-\tau)\varphi_x - (b(x,T-\tau)\varphi)_x\}\, y^2 dxd\tau. \tag{3.3}$$

From (3.2a) we derive, using Green's formula, that

$$-\int\int_{\mathcal{B}_t^*} \varphi_x (y^2)_x dxd\tau \; \leq \; \int\int_{\mathcal{B}_t^*} \varphi_{xx} y^2 dxd\tau + \int_0^t \mid \varphi_x(s_2(T-\tau),\tau) \mid y^2(s_2(T-\tau),\tau)d\tau. \tag{3.4}$$

Combining further (3.4) with (3.3), we obtain

$$\int_0^1 \varphi(x,t)y^2(x,t)dx \; \leq \; 2L\int_0^t\int_0^1 \varphi y^2 dxd\tau + \max_{(x,t)\in\bar{s}(T-\cdot)} \mid \varphi_x \mid \int_0^T y^2(s_2(T-\tau),\tau)d\tau$$

$$+ \int\int_{\mathcal{B}_t^*} (\varphi_\tau + 2b(x,T-\tau)\varphi_x - (b(x,T-\tau)\varphi)_x + \varphi_{xx}) y^2 dxd\tau.$$

In turn, recalling (3.2a) and (1.7) yields

$$\int_0^1 \varphi(x,t)y^2(x,t)dx$$

$$\leq \; 2L\int_0^t\int_0^1 \varphi y^2 dxd\tau \; + \; \max_{(x,t)\in\bar{\omega}(\cdot)} \mid F_x \mid \int_0^T y^2(s_2(T-\tau),\tau)d\tau. \tag{3.5}$$

Making use of Bellman–Gronwall's lemma, we can obtain from (3.5) that

$$\int_0^1 F(x,T-t)y^2(x,t)dx \; \leq \; e^{2LT} \max_{(x,t)\in\bar{s}(\cdot)} \mid F_x \mid \int_0^T y^2(s_2(T-\tau),\tau)d\tau \quad \forall t \in (0,T).$$

Hence, by (3.2b), there is an open subset D_* in Q_T (say, near the line $\{(x,t) \mid t = T\}$) for which

$$\int_{D_*} y^2(x,t)dxdt \; \leq \; Me^{2\|a\|_{C(\bar{Q}_T)}T} \int_0^T y^2(s_2(T-t),t)dt, \tag{3.6}$$

where M is a positive constant, which does not depend on $a(x,t)$. (This circumstance is critical for the fixed point argument in section 5.)

Remark 3.1. In the general case (i.e., when $s_1(\cdot)$ is present) in the above proof we will have just one more term similar to that in the above containing $s_2(T-\cdot)$ for the other branch of the curve $s(\cdot)$ defined in Assumption 1.3.

4. Auxiliary observability estimate for locally distributed support. It was shown in [14], [13, p. 24] that system (2.1) is exactly null-controllable from any $p_0 \in H_0^1(0,1)$ at any positive time T by using a locally distributed control whose magnitude is bounded as follows:

$$\| v \|_{L^2(\omega\times(0,T))} \le C \| p_0 \|_{H_0^1(0,1)}, \tag{4.1}$$

where C depends on $\omega \times (0,T)$.

The same result is also true for $p_0 \in L^2(0,1)$ and the locally distributed controls supported on any open subset of Q_T. Indeed, it is sufficient to show this for a control support like $\Upsilon = (l_1,l_2)\times(t_1,t_2)$, where $(l_1,l_2) \subset (0,1)$, $0 < t_1 < t_2 < T$ (i.e., with control $v = v(x,t)$ vanishing on $Q_T \backslash \Upsilon$).

Indeed, by the regularity of solutions to (2.1) with $p_0 \in L^2(0,1)$ and $v = 0$ on $(0,t_1)$, we have (similar to (2.8a) and (2.8b)) that

$$\| p(\cdot,t_1) \|_{H_0^1(0,1)} \le C \| p_0 \|_{L^2(0,1)} . \tag{4.2}$$

Applying the above exact null-controllability result on the time-interval (t_1,t_2) yields that there is a control $v = v(x,t)$ with support on Υ such that $p(\cdot,t_2) = 0$, while (4.1) holds with (t_1,t_2) in place of $(0,T)$ and $p(\cdot,t_1)$ in place of p_0. Hence, with $v = 0$ on (t_2,T), $p(\cdot,T) = 0$ also. Combining this with (4.2), we derive the estimate

$$\| v \|_{L^2(\Upsilon)} \le C(\Upsilon) \| p_0 \|_{L^2(0,1)}, \tag{4.3}$$

in which Υ can thus be any open subset of Q_T.

By the classical duality argument (4.3) implies the following dual observability estimate for (2.5):

$$\| y(\cdot,T) \|_{L^2(0,1)} \le C(D) \| y \|_{L^2(D)}, \tag{4.4}$$

where, again, $D = \{(x,t) \mid (x,T-t) \in \Upsilon\}$ can be any open subset of Q_T.

If one selects $D = D_*$ as in (3.6), then combining (4.4) and (3.6) provides the conclusion of Theorem 2.2.

Remark 4.1. Estimates (4.3) and (4.4) are immediate "adjustments" of the corresponding results in the above-cited works [14] and [13, p. 24]. The reader can find much more refined estimates of this type in [10]. (They were applied to the semilinear case in [11].)

5. The semilinear case.

Proof of Theorem 1.3. Let us give first the explicit form of system (S), (1.6) in Theorem 1.3, which is as follows:

$$u_t = u_{xx} + b(x,t)u_x + a(x,t)u + f(u) + v_1(t)\delta(x-s_1(t)) + v_2(t)\delta(x-s_2(t)) \quad \text{in } Q_T, \tag{5.1}$$

$$u(0,t) = u(1,t) = 0 \quad \text{in } (0,T), \quad u\,|_{t=0} = u_0 \in L^2(0,1), \;\; v_1, v_2 \in L^2(0,T).$$

Now note that the proof of Theorem 1.3 follows, in fact, from Theorems 2.2 and 1.2 by the fixed point argument (see, e.g., [6], [14], [13]). Its idea is to seek a suitable solution u to (5.1) satisfying (1.5) as a special ("fixed point") solution to the linear system like (2.2) with the potential $a(x,t) + f(z(x,t))/z(x,t)$ in place of $a(x,t)$ when z runs over $L^2(Q_T)$, namely, for which $z = u$. In its abstract operator form, this argument, based

on the estimate (1.9a)–(1.9b) and Theorems 2.2 and 1.2, is principally the same as for the locally distributed controls [18]. Therefore, we omit it here. □

Remark 5.1. Theorem 1.3 can easily be extended to the case of $f = f(x,t,u)$ for which the properties described in it hold uniformly in x and t.

COROLLARY 5.1. *The result of Theorem* 1.3 *holds with respect to approximate controllability, provided* $t_2 = T$ *in Assumption* 1.3.

This is an immediate traditional "structural" consequence of the exact null-controllability; see, e.g., [13, pp. 35–38]. Indeed, fix any $\varepsilon > 0$, and select any two initial and target states u_0 and u_1 in $L^2(0,1)$ for (5.1). Then, by the continuity of solutions to (5.1) in time (see, e.g., Theorem A.1), we can find T_* close enough to T and u_* close enough to u_1 such that the solution to (5.1) on (T_*, T), which we denote by $\bar{u}$ with the "initial" state $\bar{u}(\cdot, T_*) = u_*$ and $v_1 = v_2 = 0$, satisfies

$$\| \bar{u}(\cdot, T) - u_1 \|_{L^2(0,1)} \leq \varepsilon. \tag{5.2}$$

We build the control required to obtain (1.4) as follows.

On $(0, T_*)$ we apply the zero controls, while on (T_*, T) we employ controls v_1 and v_2, which solve the following auxiliary exact null-controllability problem:

$$\hat{u}_t = \hat{u}_{xx} + b(x,t)\hat{u}_x + a(x,t)\hat{u} + f(\hat{u} + \bar{u}) - f(\bar{u}) + v_1(t)\delta(x - s_1(t))$$

$$+ v_2(t)\delta(x - s_2(t)) \quad \text{in} \quad (0,1) \times (T_*, T),$$

$$\hat{u}(0,t) = \hat{u}(1,t) = 0 \quad \text{in} \ (T_*, T), \quad \hat{u} \mid_{t=T_*} = u(\cdot, T_*) - u_*,$$

$$\hat{u}(\cdot, T) = 0 \quad \text{in} \ (0,1). \tag{5.3}$$

This is possible due to Theorem 1.3 applied on (T_*, T) (recall we assumed that $s_1(\cdot)$ and $s_2(\cdot)$ "meet" at $t_2 = T$) for the function $f(x,t,s) = f(s + \bar{u}(x,t)) - f(\bar{u}(x,t))$ satisfying the assumptions of Theorem 1.3 along with Remark 5.1. Then on (T_*, T) we have

$$u = \hat{u} + \bar{u},$$

and hence, since $u(\cdot, T) = \bar{u}(\cdot, T)$, (5.3) and (5.2) imply (1.4).

6. Examples.

Example 6.1. Let $\Omega = (0,1)$ and the equation in (2.2) has the form

$$u_t = u_{xx} + bu_x + v(t)\delta(x - \alpha(T - t)) \quad \text{in} \quad Q_T, \quad v \in L^2(0,T). \tag{6.1}$$

We assume that $\alpha > 0$ and the velocity of convection b is positive and constant. Thus (6.1) is the case of the point control, which moves across Ω from the point $x = \min\{1, \alpha T\}$ to the left end-point $x = 0$ of the space domain Ω at the constant speed α; see Figure 1.1.

Put

$$F(x,t) = -x + \alpha(T - t),$$

$$\mathcal{A}^* = \{(x,t) \in \bar{Q}_T \mid x \leq \alpha(T - t)\}.$$

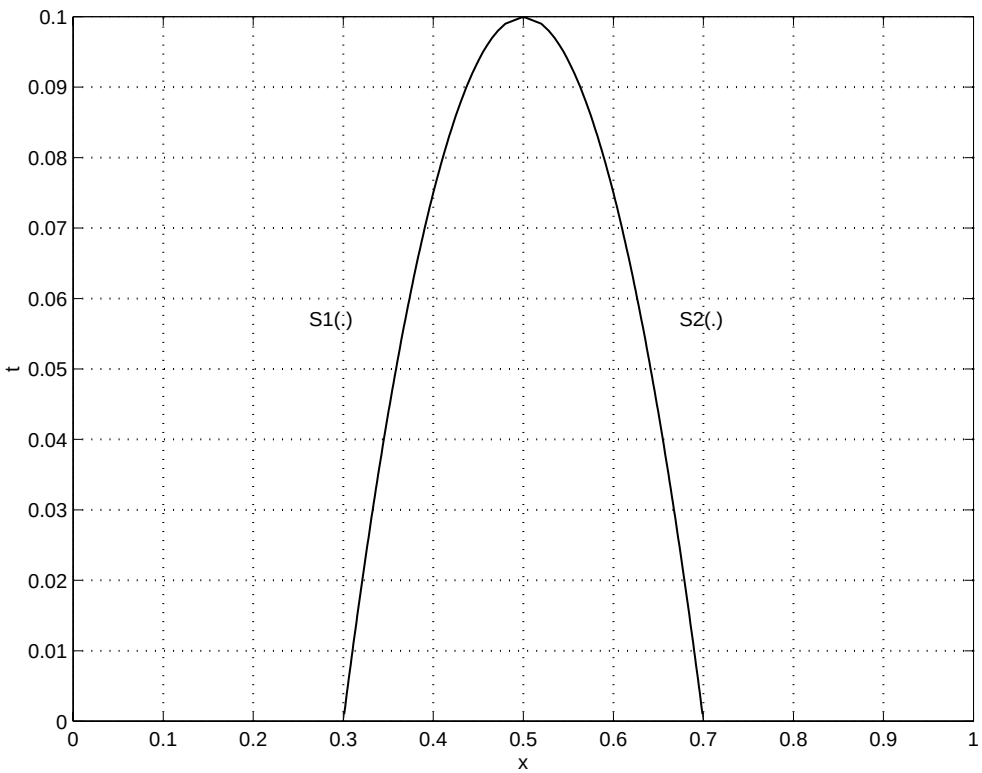

FIG. 6.1.

Take any $0 < T < 1/\alpha$. In turn, condition (1.7) gives

$$\alpha \ \leq \ b.$$

Hence, to make Theorem 1.2 work along Remark 2.1 with a *single point control*, we need the latter to move in the direction of convection with a speed which does not exceed that of convection. Note that our point control moves within the interval $[0, \alpha T]$.

Example 6.2. In Example 6.1, one can consider a parabolic trajectory $F(x,t) = -(x-0.5)^2 + \alpha(T-t) \ = \ 0$, whose two branches on the left and on the right of the line $x = 0.5$ form the control curves for two point controls:

$$s_1(t) = 0.5 - \sqrt{\alpha(T-t)}, \ \ s_2(t) = 0.5 + \sqrt{\alpha(T-t)}, \ \ t \in (0,T);$$

see Figure 6.1.

To satisfy Theorem 1.2, one may select, e.g., $\alpha \in (0,2]$, $T < 0.25/\alpha$, while setting $b = 0$, i.e., omitting convection. Note that our point controls move within the interval $[0.5 - \sqrt{\alpha T}, 0.5 + \sqrt{\alpha T}]$. (For instance, for $\alpha = 0.4, T = 0.1$ this interval will be $[0.3, 0.7]$.)

Example 6.3. The parabolic trajectories as in Example 6.2 will satisfy any a and b described in (S). Indeed, in this case (1.8) holds as before, and (1.7) is as follows:

$$\alpha T \ + \ b(x,t)(-2(x-0.5)) \ - \ b_x(x,t)(-(x-0.5)^2 + \alpha(T-t)) \ - 2 \ \leq \ 0.$$

The estimate will hold if, e.g., $t_2 = T$, while αT and $t_2 - t_1$ are sufficiently small positive numbers.

Examples 6.1–6.3 admit immediate extension to the semilinear case like in Theorem 1.3.

7. Concluding remarks. The above results can be extended in a number of ways.

7.1. More general coefficients. In (S) we may introduce a varying coefficient for the leading term; that is, $q(x,t)u_{xx}, q(x,t) > 0$ instead of u_{xx}. In particular, along the scheme of section 3 dealing with the integration by parts, this will change the condition (1.7) to the following:

$$-F_t(x,t) \ + \ 2b(x,t)F_x(x,t) - \{b(x,t)F(x,t)\}_x \ + \ (q(x,t)F)_{xx} \ \le 0 \quad \forall (x,t) \in \mathcal{A}^*.$$

7.2. Alternative $L^\infty(\varepsilon, T)$-estimates. Note that if $[t_1 = 0, t_2] \subset [0, T)$, then by (2.9) the trace of y on the curve $s(\cdot)$ in Assumption 1.3 is a continuous function. Hence (2.15), derived for two point sensors, implies

$$\| \, y(\cdot, T) \, \|_{L^2(0,1)} \le \ C(\varepsilon) \, \| \, y(s(T - \cdot), \cdot) \, \|_{L^\infty(\varepsilon, T)}, \tag{7.1}$$

where $\varepsilon = T - t_2$.

The same type of estimates was the subject of the works [15] and [17], where the path $s(\cdot)$ for a *single* point sensor was selected within Q_T following a certain algorithmic optimization procedure with infinitely many steps. Unlike the results of this paper, the method of [15] and [17] did not provide the explicit description of $s(\cdot)$.

The idea of [15] and [17] was to select (a) a countable set of solutions $\{y_1, \ldots\}$ to (2.5) which is dense (in suitable sense) in the set of all possible solutions to (2.5) and (b) an arbitrary sequence of moments $0 < t_1 < t_2 \ldots$ in (ε, T), and then (c) to associate them with a sequence of points $x_k \in (0,1)$ such that

$$\| \, y_k(\cdot, T) \, \|_{L^2(0,1)} \le \ C \mid y_k(x_k, t_k) \mid$$

for the same $C > 0$ for all $k = 1, \ldots$. The latter was achieved making use of the maximum principle in [15] and its generalized version in [17]. Then to have (7.1), $s(\cdot)$ is to be selected as any continuous curve passing through all the points $(t_k, x_k), k = 1, \ldots$.

The estimate (7.1) yields the observability in the sense of (2.7) of system (2.5) for the corresponding $s(\cdot)$ and hence, as it was described in section 2, the approximate controllability of (2.2) by means of $L^2(0,T)$-controls. Moreover, in the dual fashion leading to Theorem 1.2, the estimate (7.1) also provides a similar exact null-controllability result *but* with controls from the space dual of $L^\infty(\varepsilon, T)$.

It seems plausible that the results of [15] and [17] can be extended to narrow the (implicit) selection of the trajectories $s(\cdot)$ to those lying within any open set $\omega \times (\varepsilon, T)$, based on the technique of section 4 in the above, making use of the estimate (4.4) instead of the maximum principle as in these works. However, one should expect a highly irregular ("impractical") behavior of such curves when following this strategy.

7.3. The case of several dimensions. The just-mentioned "linear" results of [15] and [17] for single point sensors actually hold in the several space dimensions as well, in which case solutions to the dual linear system like (2.2) with $(L^\infty(0,T))'$-controls can be defined by the duality technique. It is *not* so in the semilinear case like (5.1).

It should also be noted that in several space dimensions the well-posedness of the point observations requires more regularity than $L^2(\Omega)$ for the initial data. Hence the dual controllability of the corresponding multidimensional version of (2.2) can be achieved only in the spaces that are weaker than $L^2(\Omega)$. This explains, in particular, why in the above we focused on the one-dimensional case.

On the other hand, the results of this paper for the controllability in $L^2(\Omega)$ can easily be extended to the case of several dimensions in the sense that in n space dimensions we should use controls that are supported on the surfaces of dimension $[n-1]$. In this way in [15] we established the exact null-controllability of the semilinear reaction-diffusion-convection equation with the superlinear reaction term like $f(u) = -\mid u \mid u^r, r > 0$ and the additive linear convection term, assuming that the control supporting surface (a) satisfies a differential inequality like (1.7) *and* (b) separates the top of the cylinder Q_T from its bottom.

7.4. Superlinear growth. In the series of recent works [16], [8], [20], [21], [9], [2], [1], [11], [22] the global exact null- and/or approximate controllability of a multidimensional system like (S) were shown by means of locally distributed controls for various types of superlinear growth of nonlinear terms.

- *Superlinear logarithmic growth.* In [8] the exact null-controllability property was shown in $L^2(\Omega)$ (or appropriate Sobolev space) assuming that f can grow superlinearly at the rate $\lim_{|p|\to\infty} f(p)/(p \log \mid p \mid) = 0$. This result was improved in [2] to the rate $\lim_{|p|\to\infty} f(p)/(p(\log \mid p \mid)^{3/2}) = 0$ under the additional dissipativity condition that $-f(u)u \geq -cu^2$, where $c > 0$. In [9], [11] it was shown that the latter condition can be avoided, both in terms of exact null- and approximate controllability. Interestingly, [9], [11] deal with the system which admits blow-up.
- *Polynomial growth.* It is well known that if f is dissipative and admits the polynomial growth at infinity, then, in general, it is *not* globally controllable in any of $L^p(\Omega)$-type spaces; see [13], [6], and the references therein. Nonetheless, it was shown in [20] that this property indeed holds in some spaces that are weaker than any of the above-mentioned L^p-spaces. Alternatively, the global approximate controllability in $L^2(\Omega)$ can be achieved for such systems by using an additional bilinear lumped control [22] (see also Remark 1.1). The result of [21] extends that of [19] for the superlinear time-dependent nonlinearities with "fast" convergence to zero as $t \to 0$ to the n-dimensional case with the locally distributed controls in place of the lumped ones as in (1.3) in the one-dimensional case; see Remark 1.1.
- *Polynomial growth: Finite dimensional controllability.* The local aspects at an equilibrium of this property for dissipative nonlinearities were analyzed in [29]. For the global aspects we refer to [20].

The extension of our Theorem 1.3 to the above-listed superlinear terms is an open question. On the one hand, since in this article we reduce the issue of controllability with the point controls to that with the locally distributed ones (namely, (2.15) follows from (3.6) and (4.4)), this extension does not seem impossible, at least in some situations. On the other hand, there are many serious difficulties, both technical and conceptual, in this direction. Let us mention just two of them here.

- The existence of a solution to (S) with the point control (1.2) seems to be a highly technical issue and can intrinsically be ill-posed (involving potential blow-up) when the dissipativity condition is not assumed (see, [8], [9], [11]).
- In the superlinear case the uniqueness of solutions to the boundary problem

at hand typically is not guaranteed. This means that Definitions 1.1 and 1.2 are ill-posed, which requires their certain generalization. In the works [8], [9], [11], and [2] these properties were established in the sense that there is at least one solution to the PDE at hand for which either (1.4) or (1.5) holds. In [16], [20], [21], and [22] controllability was achieved by selecting a control that can uniformly steer all possible multiple solutions.

Appendix A. In this section we prove Theorem A.1 formulated at the end of subsection 1.2. For simplicity of notations our proof deals with the system (S) or (5.1), which is the same, and one point control as in (1.2).

Proof of Theorem A.1. The uniqueness follows by the standard technique.

Our proof of existence is based on that of the corresponding existence result in [23, pp. 467–474], established there for (5.1) in the absence of the control term $v(t)\delta(x-s(t))$. The degenerate nature of the latter is the crux here.

For simplicity we further omit the coefficient a, assuming that it is incorporated into the globally Lipschitz f.

First of all, let us recall that we deal here with generalized solutions, understood in the sense of the following identity, obtained by formal integration by parts of (5.1) multiplied by an arbitrary smooth test function ψ, vanishing at $x = 0, 1$:

$$\int_0^t \int_\Omega (-u\psi_t - u_x\psi_x dxdt \ - \ bu_x\psi \ + \ f(u)\psi)dxdt$$

$$= \int_\Omega (\psi(x,0)u_0 - \psi(x,t)u(x,t))dx \ + \ \int_0^T v\psi(s(\tau))d\tau \quad \forall t \in [0,T]. \tag{A.1}$$

Here, by the Lipschitz property of f and the embedding theorems (e.g., [23]) $f(u) \in L^6(Q_T)$ for all $u \in \Xi$ and

$$\| \psi(s(\cdot),\cdot) \|_{L^2(0,T)} \leq \ C \| \psi \|_{L^2(0,T;H_0^1(0,1))} \tag{A.2}$$

for some positive constant C.

Following [23], we apply Galerkin's method. Namely, we look for an approximate solution u^N in the form

$$u^N(x,t) = \sum_{k=1}^N c_k^N(t)\psi_k(x),$$

where $\{\psi_k\}$ is a fundamental system in $H_0^1(Q_T)$, i.e., ψ_k's are linear independent and span the entire $H_0^1(Q_T)$, and

$$\int_\Omega \psi_k\psi_l dx \ = \ \delta_k^l \quad \text{and} \quad \| \psi_k, \ \psi_{kx} \|_{L^\infty(Q_T)} \leq \ c_k \quad k = 1, \dots .$$

The substitution of u^N into (5.1) provides the following system of ordinary differential equations in c_k^N's:

$$\frac{\partial c_k}{\partial t} = \int_\Omega \left(u_{x_i}^N\psi_{kx} \ + \ b(x,t)u_x^N\psi_k \ - \ f(u^N)\psi_k\right) dx \ + \ v(t)\psi_k(s(t),t), \quad k = 1, \dots, N, \tag{A.3}$$

with the initial conditions

$$c_k^N(0) = \int_\Omega u_0(x)\psi_k(x,0)dx, \quad k = 1, \dots, N.$$

Multiplication of the kth equation in (A.3) by $c_k^N(t)$ and summation of all the equations and integration over $(0,T)$ yield that

$$\frac{1}{2} \parallel u^N(x,t) \parallel^2_{L^2(\Omega)} \le \frac{1}{2} \parallel u^N(\cdot,0) \parallel^2_{L^2(\Omega)} - \int_0^t \int_\Omega (u_x^N)^2 dxd\tau$$

$$+ \max_{(x,t)\in\bar{Q}_T} \{\mid b(x,t) \mid\} \int_0^t \int_\Omega u_x^N u^N dxd\tau$$

$$+ L \int_0^t \int_\Omega (u^N)^2 dxdt + \parallel v \parallel_{L^2(0,T)} \parallel u^N(s(\cdot),\cdot) \parallel_{L^2(0,t)}, \tag{A.4}$$

where L is the Lipschitz constant for f.

Young's and Poincaré–Friedrichs's inequalities and (A.2) provide us with the following estimates, valid for any $s > 0$:

$$\parallel v \parallel_{L^2(0,T)} \parallel u^N(s(\cdot),\cdot) \parallel_{L^2(0,t)} \le \frac{1}{s} \parallel v \parallel^2_{L^2(0,T)} + s \parallel u^N(s(\cdot),\cdot) \parallel^2_{L^2(0,t)}$$

$$\le \frac{1}{s} \parallel v \parallel^2_{L^2(0,T)} + sC_* \int_0^t \int_\Omega (u_x^N)^2 dxd\tau \tag{A.5}$$

for some $C_* > 0$, and

$$\int_0^t \int_\Omega u_x^N u^N dxd\tau \le \frac{1}{s} \parallel u^N \parallel^2_{L^2(Q_t)} + s \int_0^t \int_\Omega (u_x^N)^2 dxd\tau. \tag{A.6}$$

Select $s > 0$ in (A.5) and (A.6) so that

$$1 - sC_* - s \max_{(x,t)\in\bar{Q}_T} \mid b(x,t) \mid > \frac{1}{2}.$$

Then we derive from (A.4)–(A.6) that

$$\max_{\tau\in[0,t]} \parallel u^N(\cdot,\tau) \parallel^2_{L^2(\Omega)} + \int_0^t \int_\Omega (u_x^N)^2 dxd\tau$$

$$\le 2 \Bigg[\parallel u^N(\cdot,0) \parallel^2_{L^2(\Omega)} + 2L \int_0^t \int_\Omega (u^N)^2 dxd\tau$$

$$+ 2 \max_{(x,t)\in\bar{Q}_T} \{b(x,t)\} \frac{1}{s} \int_0^t \int_\Omega (u^N)^2 dxd\tau + \frac{2}{s} \parallel v \parallel^2_{L^2(0,T)} \Bigg].$$

Since

$$\int_0^t \int_\Omega (u^N(x,\tau))^2 dx d\tau \;\le\; \int_0^t \left(\max_{s\in[0,\tau]} \| u^N(\cdot,s) \|^2_{L^2(\Omega)} \;+\; \int_0^\tau \int_\Omega (u^N_x)^2 dx ds \right) d\tau,$$

we further have

$$\max_{\tau\in[0,t]} \| u^N(\cdot,\tau) \|^2_{L^2(\Omega)} \;+\; \int_0^t \int_\Omega (u^N_x)^2 dx d\tau$$

$$\le\; 2 \| u^N(\cdot,0) \|^2_{L^2(\Omega)} \;+ \frac{4}{s} \| v \|^2_{L^2(0,T)}$$

$$+ c_0 \int_0^t \left(\max_{s\in[0,\tau]} \| u^N(\cdot,s) \|^2_{L^2(\Omega)} \;+\; \int_0^\tau \int_\Omega (u^N_x)^2 dx ds \right) d\tau$$

for $c_0 = 4(c_3 + \max_{(x,t)\in\bar{Q}_T}\{b(x,t)\}\frac{1}{s})$. Employing Bellman–Gronwall's lemma, we obtain

$$\| u^N \|_\Xi = \left(\max_{t\in[0,T]} \| u^N(x,t) \|^2_{L^2(\Omega)} \;+\; \int_0^t \int_\Omega (u^N_x)^2 dx dt \right)^{\frac{1}{2}}$$

$$\le\; c(T) \left(\| u^N(x,0) \|_{L^2(\Omega)} \;+\; \| v \|_{L^2(0,T)} \right) \tag{A.7}$$

for some constant $c(T)$, which does not depend on N and $a(x,t)$. This is exactly the estimate (6.47) in [23, p. 468] from which the rest of the proof of Theorem A.1 follows the lines of that of Theorem 6.7 in [23, Ch. V, pp. 466–474] (by appropriate limit passage). Note that (A.7) provides the second estimate in (1.9a) and (1.9b), while the first one follows by continuous embedding $\Xi \subset L^6(Q_T)$; see, e.g., [23, p. 466]. □

LIE-ALGEBRAIC STABILITY CRITERIA FOR SWITCHED SYSTEMS*

ANDREI A. AGRACHEV† AND DANIEL LIBERZON‡

Abstract. It was recently shown that a family of exponentially stable linear systems whose matrices generate a solvable Lie algebra possesses a quadratic common Lyapunov function, which implies that the corresponding switched linear system is exponentially stable for arbitrary switching. In this paper we prove that the same properties hold under the weaker condition that the Lie algebra generated by given matrices can be decomposed into a sum of a solvable ideal and a subalgebra with a compact Lie group. The corresponding local stability result for nonlinear switched systems is also established. Moreover, we demonstrate that if a Lie algebra fails to satisfy the above condition, then it can be generated by a family of stable matrices such that the corresponding switched linear system is not stable. Relevant facts from the theory of Lie algebras are collected at the end of the paper for easy reference.

1. Introduction.

A switched system can be described by a family of continuous-time subsystems and a rule that orchestrates the switching between them. Such systems arise, for example, when different controllers are being placed in the feedback loop with a given process, or when a given process exhibits a switching behavior caused by abrupt changes of the environment. For a discussion of various issues related to switched systems, see the recent survey article [13].

To define more precisely what we mean by a switched system, consider a family $\{f_p : p \in \mathcal{P}\}$ of sufficiently regular functions from $\mathbb{R}^n$ to $\mathbb{R}^n$, parameterized by some index set $\mathcal{P}$. Let $\sigma : [0, \infty) \to \mathcal{P}$ be a piecewise constant function of time, called a *switching signal*. A *switched system* is then given by the following system of differential equations in $\mathbb{R}^n$:

$$\dot{x} = f_\sigma(x). \tag{1}$$

We assume that the state of (1) does not jump at the switching instants, i.e., the solution $x(\cdot)$ is everywhere continuous. Note that infinitely fast switching (chattering), which calls for a concept of generalized solution, is not considered in this paper. In the particular case when all the individual subsystems are linear (i.e., $f_p(x) = A_p x$, where $A_p \in \mathbb{R}^{n \times n}$ for each $p \in \mathcal{P}$), we obtain a *switched linear system*

$$\dot{x} = A_\sigma x. \tag{2}$$

This paper is concerned with the following problem: find conditions on the individual subsystems which guarantee that the switched system is asymptotically stable

for an arbitrary switching signal σ. In fact, a somewhat stronger property is desirable, namely, asymptotic or even exponential stability that is uniform over the set of all switching signals. Clearly, all the individual subsystems must be asymptotically stable, and we will assume this to be the case throughout the paper. Note that it is not hard to construct examples where instability can be achieved by switching between asymptotically stable systems (section 4 contains one such example), so one needs to determine what additional requirements must be imposed. This question has recently generated considerable interest, as can be seen from the work reported in [9, 12, 16, 17, 18, 19, 21, 22].

Commutation relations among the individual subsystems play an important role in the context of the problem posed above. This can be illustrated with the help of the following example. Consider the switched linear system (2), take $\mathcal{P}$ to be a finite set, and suppose that the matrices A_p commute pairwise: $A_pA_q = A_qA_p$ for all $p, q \in \mathcal{P}$. Then it is easy to show directly that the switched linear system is exponentially stable, uniformly over all switching signals. Alternatively, one can construct a quadratic common Lyapunov function for the family of linear systems

$$\dot{x} = A_p x, \qquad p \in \mathcal{P}, \tag{3}$$

as shown in [18], which is well known to lead to the same conclusion.

In this paper we undertake a systematic study of the connection between the behavior of the switched system and the commutation relations among the individual subsystems. In the case of the switched linear system (2), a useful object that reveals the nature of these commutation relations is the Lie algebra $\mathfrak{g} := \{A_p : p \in \mathcal{P}\}_{LA}$ generated by the matrices A_p, $p \in \mathcal{P}$ (with respect to the standard Lie bracket $[A_p, A_q] := A_pA_q - A_qA_p$). The observation that the structure of this Lie algebra is relevant to stability of (2) goes back to the paper by Gurvits [9]. That paper studied the discrete-time counterpart of (2) taking the form

$$x(k+1) = A_{\sigma(k)}x(k), \tag{4}$$

where σ is a function from nonnegative integers to a finite index set $\mathcal{P}$ and $A_p = e^{L_p}$, $p \in \mathcal{P}$, for some matrices L_p. Gurvits conjectured that if the Lie algebra $\{L_p : p \in \mathcal{P}\}_{LA}$ is nilpotent (which means that Lie brackets of sufficiently high order equal zero), then the system (4) is asymptotically stable for any switching signal σ. He was able to prove this conjecture for the particular case when $\mathcal{P} = \{1, 2\}$ and the third-order Lie brackets vanish: $[L_1, [L_1, L_2]] = [L_2, [L_1, L_2]] = 0$.

It was recently shown in [12] that the switched linear system (2) is exponentially stable for arbitrary switching if the Lie algebra $\mathfrak{g}$ is solvable (see section A.3 for the definition). The proof relied on the facts that matrices in a solvable Lie algebra can be simultaneously put in the upper-triangular form (Lie's theorem) and that a family of linear systems with stable upper-triangular matrices has a quadratic common Lyapunov function. For the result to hold, the index set $\mathcal{P}$ does not need to be finite (although a suitable compactness assumption is required). One can derive the corresponding result for discrete-time systems in similar fashion, thereby confirming and directly generalizing the statement conjectured by Gurvits (because every nilpotent Lie algebra is solvable).

In the present paper we continue the line of work initiated in the above references. Our main theorem is a direct extension of the one proved in [12]. The new result states that one still has exponential stability for arbitrary switching if the Lie algebra $\mathfrak{g}$ is a semidirect sum of a solvable ideal and a subalgebra with a compact Lie group

(which amounts to saying that all the matrices in this second subalgebra have purely imaginary eigenvalues). The corresponding local stability result for the nonlinear switched system (1) is also established. Being formulated in terms of the original data, such Lie-algebraic stability criteria have an important advantage over results that depend on a particular choice of coordinates, such as the one reported in [16]. Moreover, we demonstrate that the above condition is in some sense the strongest one that can be given on the Lie algebra level. Loosely speaking, we show that if a Lie algebra does not satisfy this condition, then it could be generated by a switched linear system that is not stable.

More precisely, the main contributions of the paper can be summarized as follows. (See the appendix for an overview of relevant definitions and facts from the theory of Lie algebras.) Given a matrix Lie algebra $\hat{\mathfrak{g}}$ which contains the identity matrix, we are interested in the following question. Is it true that any set of stable generators for $\hat{\mathfrak{g}}$ gives rise to a switched system that is exponentially stable, uniformly over all switching signals? We discover that this property depends only on the structure of $\hat{\mathfrak{g}}$ as a Lie algebra and not on the choice of a particular matrix representation of $\hat{\mathfrak{g}}$. The following equivalent characterizations of the above property can be given.

1. The factor algebra $\hat{\mathfrak{g}}$ mod $\mathfrak{r}$, where $\mathfrak{r}$ denotes the radical, is a compact Lie algebra.
2. The Killing form is negative semidefinite on $[\hat{\mathfrak{g}}, \hat{\mathfrak{g}}]$.
3. The Lie algebra $\hat{\mathfrak{g}}$ does not contain any subalgebras isomorphic to $sl(2, \mathbb{R})$.

We will also show how the investigation of stability (in the above sense) of a switched linear system in $\mathbb{R}^n$, $n > 2$, whose associated Lie algebra is low-dimensional, can be reduced to the investigation of stability of a switched linear system in $\mathbb{R}^2$. For example, take $\mathcal{P} = \{1, 2\}$, and define $\tilde{A}_i := A_i - \frac{1}{n}\text{trace}(A_i)I$, $i = 1, 2$. Assume that all iterated Lie brackets of the matrices $\tilde{A}_1$ and $\tilde{A}_2$ are linear combinations of $\tilde{A}_1$, $\tilde{A}_2$, and $[\tilde{A}_1, \tilde{A}_2]$. This means that if we consider the Lie algebra $\mathfrak{g} = \{A_1, A_2\}_{LA}$ and add to it the identity matrix (if it is not already there), the resulting Lie algebra $\hat{\mathfrak{g}}$ has dimension at most 4. In this case, the following algorithm can be used to verify that the switched linear system generated by A_1 and A_2 is uniformly exponentially stable or, if this is not possible, to construct a second-order switched linear system whose uniform exponential stability is equivalent to that of the original one.

Step 1. If $[\tilde{A}_1, \tilde{A}_2]$ is a linear combination of $\tilde{A}_1$ and $\tilde{A}_2$, stop: the system is stable. Otherwise, write down the matrix of the Killing form for the Lie algebra $\tilde{\mathfrak{g}} := \{\tilde{A}_1, \tilde{A}_2\}_{LA}$ relative to the basis given by $\tilde{A}_1$, $\tilde{A}_2$, and $[\tilde{A}_1, \tilde{A}_2]$. (This is a symmetric 3×3 matrix; see section A.4 for the definition of the Killing form.)

Step 2. If this matrix is degenerate or negative definite, stop: the system is stable. Otherwise, continue.

Step 3. Find three matrices h, e, and f in $\tilde{\mathfrak{g}}$ with commutation relations $[h, e] = 2e$, $[h, f] = -2f$, and $[e, f] = h$ (this is always possible in the present case). We can then write $\tilde{A}_i = \beta_i e + \gamma_i f + \delta_i h$, where $\alpha_i, \beta_i, \gamma_i$ are constants, $i = 1, 2$.

Step 4. Compute the largest eigenvalue of h. It will be an integer; denote it by k. Then the given system is stable if and only if the switched linear system generated by the 2×2 matrices

$$\hat{A}_1 := \begin{pmatrix} \frac{\text{trace}(A_1)}{nk} - \delta_1 & -\beta_1 \\ -\gamma_1 & \frac{\text{trace}(A_1)}{nk} + \delta_1 \end{pmatrix}, \quad \hat{A}_2 := \begin{pmatrix} \frac{\text{trace}(A_2)}{nk} - \delta_2 & -\beta_2 \\ -\gamma_2 & \frac{\text{trace}(A_2)}{nk} + \delta_2 \end{pmatrix}$$

is stable.

All the steps in the above reduction procedure involve only elementary matrix operations (addition, multiplication, and computation of eigenvalues and eigenvectors). Details and justification are given in section 4.

Before closing the introduction, we make one more remark to further motivate the work reported here and point out its relationship to a more classical branch of control theory. Assume that $\mathcal{P}$ is a finite set, say, $\mathcal{P} = \{1, \dots, m\}$. The switched system (1) can then be recast as

$$\dot{x} = \sum_{i=1}^{m} f_i(x) u_i, \tag{5}$$

where the admissible controls are of the form $u_k = 1$, $u_i = 0 \; \forall i \neq k$. (This corresponds to $\sigma = k$.) In particular, the switched linear system (2) gives rise to the bilinear system

$$\dot{x} = \sum_{i=1}^{m} A_i x u_i.$$

It is intuitively clear that asymptotic stability of (1) for arbitrary switching corresponds to lack of controllability for (5). Indeed, it means that for any admissible control function the resulting solution trajectory must approach the origin. Lie-algebraic techniques have received a lot of attention in the context of the controllability problem for systems of the form (5). As for the literature on stability analysis of switched systems, despite the fact that it is vast and growing, Lie-algebraic methods do not yet seem to have penetrated it. The present work can be considered as a step towards filling this gap.

The rest of the paper is organized as follows. In section 2 we establish a sufficient condition for stability (Theorem 2) and discuss its various implications. In section 3 we prove a converse result (Theorem 4). Section 4 contains a detailed analysis of switched systems whose associated Lie algebras are isomorphic to the Lie algebra $gl(2, \mathbb{R})$ of real 2×2 matrices. This leads to, among other things, the reduction algorithm sketched above and to a different (and arguably more illuminating) proof of Theorem 4. To make the paper self-contained, in the appendix we provide an overview of relevant facts from the theory of Lie algebras.

2. Sufficient conditions for stability. The switched system (1) is called (locally) *uniformly exponentially stable* if there exist positive constants M, c, and μ such that for any switching signal σ the solution of (1) with $\|x(0)\| \leq M$ satisfies

$$\|x(t)\| \leq c e^{-\mu t} \|x(0)\| \quad \forall t \geq 0. \tag{6}$$

The term "uniform" is used here to describe uniformity with respect to switching signals. If there exist positive constants c and μ such that the estimate (6) holds for any switching signal σ and any initial condition $x(0)$, then the switched system is called *globally uniformly exponentially stable*. Similarly, one can also define the property of uniform *asymptotic* stability, local or global. For switched linear systems all the above concepts are equivalent (see [15]). In fact, as shown in [1], in the linear case global uniform exponential stability is equivalent to the seemingly weaker property of asymptotic stability for any switching signal.

In the context of the switched linear system (2), we will always assume that $\{A_p : p \in \mathcal{P}\}$ is a *compact* (with respect to the usual topology in $\mathbb{R}^{n \times n}$) set of real $n \times n$ matrices with eigenvalues in the open left half-plane. Let $\mathfrak{g}$ be the Lie algebra

defined by $\mathfrak{g} = \{A_p : p \in \mathcal{P}\}_{LA}$ as before. The following stability criterion was established in [12]. It will be crucial in proving Theorem 2 below.

THEOREM 1 (see [12]). *If $\mathfrak{g}$ is a solvable Lie algebra, then the switched linear system* (2) *is globally uniformly exponentially stable.*

Remark 1. The proof of this result given in [12] relies on a construction of a quadratic common Lyapunov function for the family of linear systems (3). The existence of such a function actually implies global uniform exponential stability of the time-varying system $\dot{x} = A_\sigma x$ with σ not necessarily piecewise constant. This observation will be used in the proof of Theorem 2.

The above condition can always be checked directly in a finite number of steps if $\mathcal{P}$ is a finite set. Alternatively, one can use the standard criterion for solvability in terms of the Killing form. Similar criteria exist for checking the other conditions to be presented in this paper—see sections A.3 and A.4 for details.

We now consider a Levi decomposition of $\mathfrak{g}$, i.e., we write $\mathfrak{g} = \mathfrak{r} \oplus \mathfrak{s}$, where $\mathfrak{r}$ is the radical and $\mathfrak{s}$ is a semisimple subalgebra (see section A.4). Our first result is the following generalization of Theorem 1.

THEOREM 2. *If $\mathfrak{s}$ is a compact Lie algebra, then the switched linear system* (2) *is globally uniformly exponentially stable.*

Proof. For an arbitrary $p \in \mathcal{P}$, write $A_p = r_p + s_p$ with $r_p \in \mathfrak{r}$ and $s_p \in \mathfrak{s}$. Let us show that r_p is a stable matrix. Writing

$$e^{(r_p+s_p)t} = e^{s_p t} B_p(t), \tag{7}$$

we have the following equation for $B_p(t)$:

$$\dot{B}_p(t) = e^{-s_p t} r_p e^{s_p t} B_p(t), \qquad B_p(0) = I. \tag{8}$$

To verify (8), differentiate the equality (7) with respect to t, which gives

$$(r_p + s_p) e^{(r_p+s_p)t} = s_p e^{s_p t} B_p + e^{s_p t} \dot{B}_p.$$

Using (7) again, we have

$$r_p e^{s_p t} B_p + s_p e^{s_p t} B_p = s_p e^{s_p t} B_p + e^{s_p t} \dot{B}_p;$$

hence (8) holds. Define $c_p(t) := e^{-s_p t} r_p e^{s_p t}$. Clearly, $\operatorname{spec}(c_p(t)) = \operatorname{spec}(r_p)$ for all t. It is well known that for any two matrices A and B one has

$$e^{-A} B e^{A} = e^{\operatorname{ad} A}(B) = B + [A, B] + \frac{1}{2}[A, [A, B]] + \cdots; \tag{9}$$

hence we obtain the expansion

$$c_p(t) = r_p + [s_p t, r_p] + \frac{1}{2}[s_p t, [s_p t, r_p]] + \cdots.$$

Since $[\mathfrak{s}, \mathfrak{r}] \subseteq \mathfrak{r}$, we see that $c_p(t) \in \mathfrak{r}$. According to Lie's theorem, there exists a basis in which all matrices from $\mathfrak{r}$ are upper-triangular. Combining the above facts, it is not hard to check that $\operatorname{spec}(B_p(t)) = e^{t \operatorname{spec}(r_p)}$. Now it follows from (8) that $\operatorname{spec}(r_p)$ lies in the open left half of the complex plane. Indeed, as $t \to \infty$, we have $e^{(r_p+s_p)t} \to 0$ because the matrix A_p is stable. Since $\mathfrak{s}$ is compact, there exists a constant $C > 0$ such that we have $|e^s x| \geq C|x|$ for all $s \in \mathfrak{s}$ and $x \in \mathbb{R}^n$; thus we cannot have $e^{s_p t} x \to 0$ for $x \neq 0$. Therefore, $B_p(t) \to 0$, and so r_p is stable.

Since $p \in \mathcal{P}$ was arbitrary, we see that all the matrices r_p, $p \in \mathcal{P}$, are stable. Theorem 1 implies that the switched linear system generated by these matrices is globally uniformly exponentially stable. Moreover, the same property holds for matrices in the extended set $\bar{\mathfrak{r}} := \{\bar{A} : \exists\, p \in \mathcal{P} \text{ and } s \in \mathfrak{s} \text{ such that } \bar{A} = e^{-s} r_p e^s\}$. This is true because the matrices in this set are stable and because they belong to $\mathfrak{r}$. (The last statement follows from the expansion (9) again since $[\mathfrak{s}, \mathfrak{r}] \subseteq \mathfrak{r}$.) Now the transition matrix of the original switched linear system (2) at time t takes the form

$$\Phi(t,0) = e^{(r_{p_k}+s_{p_k})t_k} \cdots e^{(r_{p_1}+s_{p_1})t_1} = e^{s_{p_k}t_k} B_{p_k}(t_k) \cdots e^{s_{p_1}t_1} B_{p_1}(t_1),$$

where t_1, t_1+t_2, $\ldots$, $t_1+t_2+\cdots+t_{k-1} < t$ are switching instants, $t_1+\cdots+t_k = t$, and, as before, $\dot{B}_{p_i}(t) = e^{-s_{p_i}t} r_{p_i} e^{s_{p_i}t} B_{p_i}(t)$, $i = 1, \ldots, k$. To simplify the notation, let $k = 2$. (In the general case one can adopt the same line of reasoning or use induction on k.) We can then write

$$\Phi(t,0) = e^{s_{p_2}t_2} e^{s_{p_1}t_1} e^{-s_{p_1}t_1} B_{p_2}(t_2) e^{s_{p_1}t_1} B_{p_1}(t_1) = e^{s_{p_2}t_2} e^{s_{p_1}t_1} \tilde{B}_{p_2}(t_2) B_{p_1}(t_1),$$

where $\tilde{B}_{p_2}(t) := e^{-s_{p_1}t_1} B_{p_2}(t) e^{s_{p_1}t_1}$. We have

$$\begin{aligned}
\frac{d}{dt}\tilde{B}_{p_2}(t) &= e^{-s_{p_1}t_1} e^{-s_{p_2}t} r_{p_2} e^{s_{p_2}t} B_{p_2}(t) e^{s_{p_1}t_1} \\
&= e^{-s_{p_1}t_1} e^{-s_{p_2}t} r_{p_2} e^{s_{p_2}t} e^{s_{p_1}t_1} e^{-s_{p_1}t_1} B_{p_2}(t) e^{s_{p_1}t_1} \\
&= e^{-s_{p_1}t_1} e^{-s_{p_2}t} r_{p_2} e^{s_{p_2}t} e^{s_{p_1}t_1} \tilde{B}_{p_2}(t).
\end{aligned}$$

Thus we see that

$$\Phi(t,0) = e^{s_{p_2}t_2} e^{s_{p_1}t_1} \cdot \bar{B}(t), \tag{10}$$

where $\bar{B}(t)$ is the transition matrix of a switched/time-varying system generated by matrices in $\bar{\mathfrak{r}}$, i.e., $\frac{d}{dt}\bar{B}(t) = \bar{A}(t)\bar{B}(t)$ with $\bar{A}(t) \in \bar{\mathfrak{r}}\ \forall t \geq 0$. The norm of the first term in the above product is bounded by compactness, while the norm of the second goes to zero exponentially by Theorem 1 (see also Remark 1), and the statement of the theorem follows. □

Remark 2. The fact that $\mathfrak{r}$ is the radical, implying that $\mathfrak{s}$ is semisimple, was not used in the proof. The statement of Theorem 2 remains valid for any decomposition of $\mathfrak{g}$ into the sum of a solvable ideal $\mathfrak{r}$ and a subalgebra $\mathfrak{s}$. Among all possible decompositions of this kind, the one considered above gives the strongest result. If $\mathfrak{g}$ is solvable, then $\mathfrak{s} = 0$ is of course compact, and we recover Theorem 1 as a special case.

Example 1. Suppose that the matrices A_p, $p \in \mathcal{P}$, take the form $A_p = -\lambda_p I + S_p$, where $\lambda_p > 0$ and $S_p^T = -S_p$ for all $p \in \mathcal{P}$. These are automatically stable matrices. Suppose also that $\operatorname{span}\{A_p, p \in \mathcal{P}\} \ni I$. Then the condition of Theorem 2 is satisfied. Indeed, take $\mathfrak{r} = \{\lambda I : \lambda \in \mathbb{R}\}$ (scalar multiples of the identity matrix) and observe that the Lie algebra $\{S_p : p \in \mathcal{P}\}_{LA}$ is compact because skew-symmetric matrices have purely imaginary eigenvalues.

In [12] the global uniform exponential stability property was deduced from the existence of a quadratic common Lyapunov function. In the present case we found it more convenient to obtain the desired result directly. However, under the hypothesis of Theorem 2, a quadratic common Lyapunov function for the family of linear systems (3) can also be constructed, as we now show. Let $\bar{V}(x) = x^T Q x$ be a quadratic

common Lyapunov function for the family of linear systems generated by matrices in $\bar{\mathfrak{r}}$ (which exists according to [12]). Define the function

$$V(x) := \int_{\mathcal{S}} \bar{V}(Sx)dS = x^T \cdot \int_{\mathcal{S}} S^T Q S dS \cdot x,$$

where $\mathcal{S}$ is the Lie group corresponding to $\mathfrak{s}$ and the integral is taken with respect to the Haar measure invariant under the right translation on $\mathcal{S}$ (see section A.4). Using (10), it is straightforward to show that the derivative of V along solutions of the switched linear system (2) satisfies

$$\begin{aligned}\frac{d}{dt}V(x(t)) &= \frac{d}{dt}\int_{\mathcal{S}} \bar{V}(S\bar{B}(t)x(0))dS \\ &= \int_{\mathcal{S}} x^T(0)\bar{B}^T(t)S^T((S\bar{A}(t)S^{-1})^T Q + QS\bar{A}(t)S^{-1})S\bar{B}(t)x(0)dS < 0.\end{aligned}$$

The first equality in the above formula follows from the invariance of the measure, and the last inequality holds because $S\bar{A}(t)S^{-1} \in \bar{\mathfrak{r}}$ for all $t \geq 0$ and all $S \in \mathcal{S}$.

Remark 3. It is now clear that the above results remain valid if piecewise constant switching signals are replaced by arbitrary measurable functions (cf. Remark 1).

The existence of a quadratic common Lyapunov function will be used to prove Corollary 3 below. It is also an interesting fact in its own right because, although the converse Lyapunov theorem proved in [15] implies that global uniform exponential stability always leads to the existence of a common Lyapunov function, in some cases it is not possible to find a quadratic one [4]. Incidentally, this clearly shows that the condition of Theorem 2 is not necessary for uniform exponential stability of the switched linear system (2). Another way to see this is to note that the property of uniform exponential stability is robust with respect to small perturbations of the parameters of the system, whereas the condition of Theorem 2 is not. In fact, no Lie-algebraic condition of the type considered here can possess the indicated robustness property. This follows from the fact, proved in section A.6, that in an arbitrarily small neighborhood of any pair of $n \times n$ matrices there exists a pair of matrices that generate the entire Lie algebra $gl(n, \mathbb{R})$.

We conclude this section with a local stability result for the nonlinear switched system (1). Let $f_p : D \to \mathbb{R}^n$ be continuously differentiable with $f_p(0) = 0$ for each $p \in \mathcal{P}$, where D is a neighborhood of the origin in $\mathbb{R}^n$. Consider the linearization matrices

$$F_p := \frac{\partial f_p}{\partial x}(0), \qquad p \in \mathcal{P}.$$

Assume that the matrices F_p are stable, that $\mathcal{P}$ is a compact subset of some topological space, and that $\frac{\partial f_p}{\partial x}(x)$ depends continuously on p for each $x \in D$. Consider the Lie algebra $\tilde{\mathfrak{g}} := \{F_p : p \in \mathcal{P}\}_{LA}$ and its Levi decomposition $\tilde{\mathfrak{g}} = \tilde{\mathfrak{r}} \oplus \tilde{\mathfrak{s}}$. The following statement is a generalization of [12, Corollary 5].

COROLLARY 3. *If $\tilde{\mathfrak{s}}$ is a compact Lie algebra, then the switched system* (1) *is uniformly exponentially stable.*

Proof. This is a relatively straightforward application of Lyapunov's first method (see, e.g., [11]). For each $p \in \mathcal{P}$ we can write $f_p(x) = F_p x + g_p(x)x$. Here $g_p(x) = \frac{\partial f_p}{\partial x}(z) - \frac{\partial f_p}{\partial x}(0)$, where z is a point on the line segment connecting x to the origin. We have $g_p(x) \to 0$ as $x \to 0$. Under the present assumptions, the family of linear systems $\dot{x} = F_p x$, $p \in \mathcal{P}$, has a quadratic common Lyapunov function. Because of

compactness of $\mathcal{P}$ and continuity of $\frac{\partial f_p}{\partial x}$ with respect to p, it is not difficult to verify that this function is a common Lyapunov function for the family of systems $\dot{x} = f_p(x)$, $p \in \mathcal{P}$, on a certain neighborhood $\bar{D}$ of the origin. Thus the switched system (1) is uniformly exponentially stable on $\bar{D}$. □

An important problem for future research is to investigate how the structure of the Lie algebra generated by the original nonlinear vector fields f_p, $p \in \mathcal{P}$, is related to stability properties of the switched system (1). Taking higher-order terms into account, one may hope to obtain conditions that guarantee stability of nonlinear switched systems when the above linearization test fails. A first step in this direction is the observation made in [21] that a finite family of commuting nonlinear vector fields giving rise to exponentially stable systems has a local common Lyapunov function. Imposing certain additional assumptions, it is possible to obtain analogues of Lie's theorem which yield triangular structure for families of nonlinear systems generating nilpotent or solvable Lie algebras (see [3, 10, 14]). However, the methods described in these papers require that the Lie algebra have full rank, and so typically they do not apply to families of systems with common equilibria of the type treated here.

3. A converse result. We already remarked that the condition of Theorem 2 is not necessary for uniform exponential stability of the switched linear system (2). It is natural to ask whether this condition can be improved. A more general question that arises is to what extent the structure of the Lie algebra can be used to distinguish between stable and unstable switched systems. The findings of this section will shed some light on these issues.

We find it useful to introduce a possibly larger Lie algebra $\hat{\mathfrak{g}}$ by adding to $\mathfrak{g}$ the scalar multiples of the identity matrix if necessary. In other words, define $\hat{\mathfrak{g}} := \{I, A_p : p \in \mathcal{P}\}_{LA}$. The Levi decomposition of $\hat{\mathfrak{g}}$ is given by $\hat{\mathfrak{g}} = \hat{\mathfrak{r}} \oplus \mathfrak{s}$ with $\hat{\mathfrak{r}} \supseteq \mathfrak{r}$ (because the subspace $\mathbb{R}I$ belongs to the radical of $\hat{\mathfrak{g}}$). Thus $\hat{\mathfrak{g}}$ satisfies the hypothesis of Theorem 2 if and only if $\mathfrak{g}$ does.

Our goal in this section is to show that if this hypothesis is not satisfied, then $\hat{\mathfrak{g}}$ can be generated by a family of stable matrices (which might in principle be different from $\{A_p : p \in \mathcal{P}\}$) with the property that the corresponding switched linear system is not stable. Such a statement could in some sense be interpreted as a converse of Theorem 2. It would imply that by working just with $\hat{\mathfrak{g}}$ it is not possible to obtain a stronger result than the one given in the previous section.

We will also see that there exists another set of stable generators for $\hat{\mathfrak{g}}$ which does give rise to a uniformly exponentially stable switched linear system. In fact, we will show that both generator sets can always be chosen in such a way that they contain the same number of elements as the original set that was used to generate $\hat{\mathfrak{g}}$. Thus, if the Lie algebra does not satisfy the hypothesis of Theorem 2, this Lie algebra alone (even together with the knowledge of how many stable matrices were used to generate it) does not provide enough information to determine whether or not the original switched linear system is stable.

Let $\{A_1, A_2, \ldots, A_m\}$ be any finite set of stable generators for $\hat{\mathfrak{g}}$. (If the index set $\mathcal{P}$ is infinite, a suitable finite subset can always be extracted from it.) Then the following holds.

THEOREM 4. *Suppose that $\mathfrak{s}$ is not a compact Lie algebra. Then there exists a set of m stable generators for $\hat{\mathfrak{g}}$ such that the corresponding switched linear system is not uniformly exponentially stable. There also exists another set of m stable generators for $\hat{\mathfrak{g}}$ such that the corresponding switched linear system is globally uniformly exponentially stable.*

Proof. To prove the second statement of the theorem, we simply subtract λI from each of the generators $A_1, A_2, \ldots, A_m$, where $\lambda > 0$ is large enough. Namely, take λ to be any number larger than the largest eigenvalue of $(A_i + A_i^T)/2$ for all $i = 1, \ldots, m$. Then it is easy to check that the linear systems defined by the matrices $A_1 - \lambda I, A_2 - \lambda I, \ldots, A_m - \lambda I$ all share the common Lyapunov function $V(x) = x^T x$. To prove that these matrices indeed generate $\hat{\mathfrak{g}}$, it is enough to show that the span of these matrices and their iterated Lie brackets contains the identity matrix I. We know that I can be written as a linear combination of the matrices $A_1, A_2, \ldots, A_m$, and their suitable Lie brackets. Replacing each A_i in this linear combination by $A_i - \lambda I$, we obtain a scalar multiple of I. If it is nonzero, we are done; otherwise, we just have to increase λ by an arbitrary amount.

We now turn to the first statement of the theorem. Since $\mathfrak{s}$ is not compact, it contains a subalgebra that is isomorphic to $sl(2, \mathbb{R})$. Such a subalgebra can be constructed as shown in section A.5. The existence of this subalgebra is the key property that we will explore.

It follows from basic properties of solutions to differential inclusions that if a family of matrices gives rise to a uniformly exponentially stable switched linear system, then all convex linear combinations of these matrices are stable. (This fact is easily seen to be true from the converse Lyapunov theorems of [15, 4], although in [15] it was actually used to prove the result; see also Remark 5 below.) To prove the theorem, we will first find a pair of stable matrices B_1, B_2 that lie in the subalgebra isomorphic to $sl(2, \mathbb{R})$ and have an unstable convex combination, and then we will use them to construct a desired set of generators for $\hat{\mathfrak{g}}$. (An alternative method of proof will be presented in the next section.)

Since every matrix representation of $sl(2, \mathbb{R})$ is a direct sum of irreducible ones, there is no loss of generality in considering only irreducible representations. Their complete classification in all dimensions (up to equivalence induced by linear coordinate transformations) is available. In particular, it is known that any irreducible representation of $sl(2, \mathbb{R})$ contains two matrices of the following form:

$$\tilde{B}_1 = \begin{pmatrix} 0 & \mu_1 & \cdots & 0 \\ \vdots & \ddots & \ddots & \vdots \\ \vdots & & \ddots & \mu_r \\ 0 & \cdots & \cdots & 0 \end{pmatrix} \quad \text{and} \quad \tilde{B}_2 = \begin{pmatrix} 0 & \cdots & \cdots & 0 \\ 1 & \ddots & & \vdots \\ \vdots & \ddots & \ddots & \vdots \\ 0 & \cdots & 1 & 0 \end{pmatrix}$$

(cf. section A.2). The matrix $\tilde{B}_1$ has positive entries $\mu_1, \ldots, \mu_r$ immediately above the main diagonal and zeros elsewhere, and the matrix $\tilde{B}_2$ has ones immediately below the main diagonal and zeros elsewhere.

It is not hard to check that the nonnegative matrix $\tilde{B} := (\tilde{B}_1 + \tilde{B}_2)/2$ is irreducible[1] and as such satisfies the assumptions of the Perron–Frobenius theorem (see, e.g., [6, Chapter XIII]). According to that theorem, $\tilde{B}$ has a positive eigenvalue. Then for a small enough $\epsilon > 0$ the matrix $B := \tilde{B} - \epsilon I$ also has a positive eigenvalue. We have $B = (\tilde{B}_1 - \epsilon I + \tilde{B}_2 - \epsilon I)/2$. This implies that a desired pair of matrices in the given irreducible matrix representation of $sl(2, \mathbb{R})$ can be defined by $B_1 := \tilde{B}_1 - \epsilon I$ and $B_2 := \tilde{B}_2 - \epsilon I$. Indeed, these matrices are stable, but their average B is not.

For $\alpha \geq 0$, define $A_1(\alpha) := B_1 + \alpha A_1$ and $A_2(\alpha) := B_2 + \alpha A_2$. If α is small enough, then $A_1(\alpha)$ and $A_2(\alpha)$ are stable matrices, while $(A_1(\alpha) + A_2(\alpha))/2$ is unstable. Thus

[1] A matrix is called *irreducible* if it has no proper invariant subspaces spanned by coordinate vectors.

the matrices $A_1(\alpha), A_2(\alpha), A_3, \ldots, A_m$ yield a switched system that is not uniformly exponentially stable. Moreover, it is not hard to show that for α small enough these matrices generate $\hat{\mathfrak{g}}$. Indeed, consider a basis for $\hat{\mathfrak{g}}$ formed by $A_1, \ldots, A_m$, and their suitable Lie brackets. Replacing A_1 and A_2 in these expressions by $A_1(\alpha)$ and $A_2(\alpha)$ and writing the coordinates of the resulting elements relative to this basis, we obtain a square matrix $\Delta(\alpha)$. Its determinant is a polynomial in α whose value tends to ∞ as $\alpha \to \infty$, and therefore it is not identically zero. Thus $\Delta(\alpha)$ is nondegenerate for all but finitely many values of α; in particular, we will have a basis for $\hat{\mathfrak{g}}$ if we take α sufficiently small. This completes the proof. □

Remark 4. Given the matrices B_1 and B_2 as in the above proof, it is of course quite easy to construct a set of stable generators for $\hat{\mathfrak{g}}$ giving rise to a switched linear system that is not uniformly exponentially stable: just take any set of generators for $\hat{\mathfrak{g}}$ containing $-I$, B_1, and B_2, and make them into stable ones by means of subtracting positive multiples of the identity if necessary. The above more careful construction has the advantage of producing a set of generators with the same number of elements as in the original generating set for $\hat{\mathfrak{g}}$.

Remark 5. The existence of an unstable convex combination actually leads to more specific conclusions than simply a lack of uniform exponential stability. Namely, one can find a sequence of solutions of the switched system that converges in a suitable sense to a trajectory of the unstable linear system associated with such a convex combination. This is a consequence of the so-called *relaxation theorem* which in our case says that the set of solutions to the differential inclusion $\dot{x} \in \{A_p x : p \in \mathcal{P}\}$ is dense in the set of solutions to the differential inclusion $\dot{x} \in \mathrm{co}\{A_p x : p \in \mathcal{P}\}$, where $\mathrm{co}(K)$ denotes the convex hull of a set $K \subset \mathbb{R}^n$. For details, see [2, 5].

The results that we have obtained so far reveal the following important fact: the property of $\hat{\mathfrak{g}}$ which is being investigated here, namely, global uniform exponential stability of any switched system whose associated Lie algebra is $\hat{\mathfrak{g}}$, depends only on the structure of $\hat{\mathfrak{g}}$ (i.e., on the commutation relations between its matrices) and is independent of the choice of a particular representation.

4. Switched linear systems with low-dimensional Lie algebras. In the proof of Theorem 4 in the previous section, we needed to construct a pair of stable matrices in a representation of $sl(2, \mathbb{R})$ which give rise to an unstable switched system. To achieve this, we relied on the fact that a switched system defined by two matrices is not stable if these matrices have an unstable convex combination. However, even if all convex combinations are stable, stability of the switched system is not guaranteed. As a simple example that illustrates this, consider the switched system in $\mathbb{R}^2$ defined by the matrices $A_1 := \tilde{A}_1 - \epsilon I$ and $A_2 := \tilde{A}_2 - \epsilon I$, where

$$\tilde{A}_1 := \begin{pmatrix} 0 & k \\ -1 & 0 \end{pmatrix}, \qquad \tilde{A}_2 := \begin{pmatrix} 0 & 1 \\ -k & 0 \end{pmatrix}$$

with $\epsilon > 0$ and $k > 1$. It is easy to check that all convex combinations of A_1 and A_2 are stable. When $\epsilon = 0$, the trajectories of the corresponding individual systems look as shown in Figure 1 (left) and Figure 1 (center), respectively. It is not hard to find a switching signal $\sigma : [0, \infty) \to \{1, 2\}$ that makes the switched system $\dot{x} = \tilde{A}_\sigma x$ unstable: simply let $\sigma = 1$ when $xy > 0$ and $\sigma = 2$ otherwise. For an arbitrary initial state, this results in the switched system $\dot{x} = \tilde{A}_{\sigma(t)} x$ whose solutions grow exponentially. Therefore, the original switched system $\dot{x} = A_\sigma x$ will also be destabilized by the same switching signal, provided that ϵ is sufficiently small.

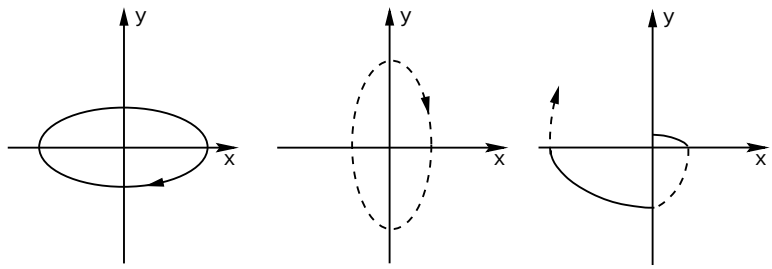

FIG. 1. *Unstable switched system in the plane.*

As a step toward understanding the behavior of switched systems in higher dimensions, in view of the findings of this paper it is natural to investigate the case when given matrices generate a Lie algebra that is isomorphic to one generated by 2×2 matrices. This is the goal of the present section.

Consider the Lie algebra $\mathfrak{g} := \{A_p : p \in \mathcal{P}\}_{LA}$, and assume that $\mathfrak{g} = \mathbb{R}I_{n\times n} \oplus sl(2,\mathbb{R})$. Here $sl(2,\mathbb{R})$ means an n-dimensional matrix representation, which we take to be irreducible. (As before, this will not introduce a loss of generality because every matrix representation of $sl(2,\mathbb{R})$ is a direct sum of irreducible ones.) Then for each $p \in \mathcal{P}$ we can write

$$A_p = (n-1)\alpha_p I_{n\times n} + \beta_p \phi(e) + \gamma_p \phi(f) + \delta_p \phi(h), \tag{11}$$

where $\beta_p, \gamma_p, \delta_p$ are constants, ϕ is the standard representation of $sl(2,\mathbb{R})$ constructed in section A.2 (n here corresponds to $k+1$ there), $\{e, h, f\}$ is the canonical basis for $sl(2,\mathbb{R})$, and $\alpha_p = \frac{1}{n(n-1)}\mathrm{trace}(A_p)$. For each $p \in \mathcal{P}$, define the following 2×2 matrix:

$$\hat{A}_p := \alpha_p I_{2\times 2} - \beta_p e - \gamma_p f - \delta_p h. \tag{12}$$

We now demonstrate that the task of investigating stability of the switched system generated by the matrices A_p, $p \in \mathcal{P}$, reduces to that of investigating stability of the two-dimensional switched system generated by the matrices $\hat{A}_p$, $p \in \mathcal{P}$.

PROPOSITION 5. *The switched linear system* (2) *with* A_p *given by* (11) *is globally uniformly exponentially stable if and only if the switched linear system* $\dot{x} = \hat{A}_\sigma x$ *with* $\hat{A}_p$ *given by* (12) *is globally uniformly exponentially stable.*

Proof. The transition matrix of the switched system (2) for any particular switching signal takes the form

$$\Phi(t,0) = e^{(n-1)(\alpha_{p_k}t_k + \cdots + \alpha_{p_1}t_1)I} e^{(\beta_{p_k}\phi(e) + \gamma_{p_k}\phi(f) + \delta_{p_k}\phi(h))t_k} \cdots e^{(\beta_{p_1}\phi(e) + \gamma_{p_1}\phi(f) + \delta_{p_1}\phi(h))t_1}.$$

Consider the (n-dimensional) linear space $P^{n-1}[x,y]$ of polynomials in x and y, homogeneous of degree $n-1$, with the basis chosen as in section A.2. Denote the elements of this basis by $p_1, \ldots, p_n$. (These are monomials in x and y.) Fix an arbitrary polynomial $p \in P^{n-1}[x,y]$, and let $a_1, \ldots, a_n$ be its coordinates relative to the above basis. As an immediate consequence of the calculations given in section A.2, for any values of x and y we have

$$\begin{pmatrix} a_1 & \cdots & a_n \end{pmatrix} \Phi(t,0) \begin{pmatrix} p_1 \\ \vdots \\ p_n \end{pmatrix} = p\left(\hat{\Phi}(t,0)\begin{pmatrix} x \\ y \end{pmatrix}\right),$$

where

$$\hat{\Phi}(t,0) = e^{(\alpha_{p_k} t_k + \cdots + \alpha_{p_1} t_1) I} e^{(-\beta_{p_1} e - \gamma_{p_1} f - \delta_{p_1} h) t_1} \cdots e^{(-\beta_{p_k} e - \gamma_{p_k} f - \delta_{p_k} h) t_k}.$$

Since the polynomial p was arbitrary, it is clear that $\Phi(t,0)$ approaches the zero matrix as $t \to \infty$, uniformly over the set of all switching signals, if and only if $\hat{\Phi}(t,0)$ does so. But $\hat{\Phi}(t,0)$ is the transition matrix of the switched system $\dot{x} = \hat{A}_\sigma x$, corresponding to the "reversed" switching signal on $[0,t]$. We conclude that this switched system is globally asymptotically stable, uniformly over σ, if and only if the same property holds for the original system (2). The statement of the proposition now follows from the fact that for switched linear systems, uniform asymptotic stability is equivalent to uniform exponential stability. □

We are now in position to justify the reduction procedure outlined in the introduction. Assume that $\hat{\mathfrak{g}}$ has dimension at most 4. We know from section A.5 that any noncompact semisimple Lie algebra contains a subalgebra isomorphic to $sl(2,\mathbb{R})$. Thus $\hat{\mathfrak{g}}$ contains a noncompact semisimple subalgebra if only if its dimension exactly equals 4 and the Killing form is nondegenerate and sign-indefinite on $\tilde{\mathfrak{g}} = \{\tilde{A}_1, \tilde{A}_2\}_{LA} = \hat{\mathfrak{g}} \bmod \mathbb{R}I$ (see section A.4). In this case $\tilde{g}$ is isomorphic to $sl(2,\mathbb{R})$. An $sl(2)$-triple $\{h,e,f\}$ can be constructed as explained in section A.5. (The procedure given there for a general noncompact semisimple Lie algebra certainly applies to $sl(2,\mathbb{R})$ itself.) Specifically, as h we can take any element of the subspace on which the Killing form is positive definite, normalized in such a way that the eigenvalues of $\mathrm{ad}h$ equal 2 and -2. The corresponding eigenvectors yield e and f. The resulting representation of $sl(2,\mathbb{R})$ is not necessarily irreducible; the dimension of the largest invariant subspace is equal to $k+1$, where k is the largest eigenvalue of h. If the switched linear system restricted to this invariant subspace is globally uniformly exponentially stable, then the same property holds for the switched linear system restricted to any other invariant subspace. This is true because, in view of the role of the scalar $k = n-1$ in the context of Proposition 5, the matrices of the reduced (second-order) system associated with the system evolving on the largest invariant subspace are obtained from those of the reduced system associated with the system evolving on another invariant subspace by subtracting positive multiples of the identity matrix, and this cannot introduce instability (to see why this last statement is true, one can appeal to the existence of a convex common Lyapunov function [15]). Note that we do not need to identify the invariant subspaces; we need to know only the dimension of the largest one. Thus the outcome of the algorithm depends on the matrix representation of $\hat{\mathfrak{g}}$ and not just on the structure of $\hat{\mathfrak{g}}$ as a Lie algebra, but it does so in a rather weak way.

As another application of Proposition 5, we can obtain an alternative proof of Theorem 4. Indeed, let the matrices $\tilde{B}_1$ and $\tilde{B}_2$ be as in the proof of Theorem 4 given in the previous section. (The existence of a subalgebra isomorphic to $sl(2,\mathbb{R})$ remains crucial.) Define the matrices $B_1 := -k\tilde{B}_1 + \tilde{B}_2 - \epsilon I$ and $B_2 := -\tilde{B}_1 + k\tilde{B}_2 - \epsilon I$, where $\epsilon > 0$ and $k > 1$. Then the switched system

$$\dot{x} = B_\sigma x, \qquad \sigma : [0,\infty) \to \{1,2\} \tag{13}$$

is not stable for ϵ small enough (even though all convex combinations of B_1 and B_2 are stable). This follows from Proposition 5 and from the example presented at the beginning of this section; in fact, a specific (periodic) destabilizing switching signal for the system (13) can be constructed with the help of that example. Interestingly,

it appears to be difficult to establish the same result by a direct analysis of (13). The rest of the proof of Theorem 4 can now proceed exactly as before.

It was shown by Shorten and Narendra in [22] that two stable two-dimensional linear systems $\dot{x} = A_1 x$ and $\dot{x} = A_2 x$ possess a quadratic common Lyapunov function if and only if all pairwise convex combinations of matrices from the set $\{A_1, A_2, A_1^{-1}, A_2^{-1}\}$ are stable. Combined with Proposition 5, this yields the following result.

COROLLARY 6. *Let $\mathcal{P} = \{1, 2\}$. Suppose that all pairwise convex combinations of matrices from the set $\{\hat{A}_1, \hat{A}_2, \hat{A}_1^{-1}, \hat{A}_2^{-1}\}$, with A_1 and A_2 given by* (12)*, are stable. Then the switched linear system* (2)*, with A_p given by* (11)*, is globally uniformly exponentially stable.*

The above corollary provides only sufficient and not necessary conditions for global uniform exponential stability of (2). This is due to the fact that, as we already mentioned earlier, it may happen that a switched linear system is globally uniformly exponentially stable while there is no quadratic common Lyapunov function for the individual subsystems (see the example in [4]).

Appendix. Basic facts about Lie algebras. In this appendix we give an informal overview of basic properties of Lie algebras. Only those facts that directly play a role in the developments of the previous sections are discussed. Most of the material is adopted from [8, 20], and the reader is referred to these and other standard references for more details.

A.1. Lie algebras and their representations. A *Lie algebra* $\mathfrak{g}$ is a finite-dimensional vector space equipped with a *Lie bracket*, i.e., a bilinear, skew-symmetric map $[\cdot, \cdot] : \mathfrak{g} \times \mathfrak{g} \to \mathfrak{g}$ satisfying the Jacobi identity $[a, [b, c]] + [b, [c, a]] + [c, [a, b]] = 0$. Any Lie algebra $\mathfrak{g}$ can be identified with a tangent space at the identity of a Lie group $\mathcal{G}$ (an analytic manifold with a group structure). If $\mathfrak{g}$ is a matrix Lie algebra, then the elements of $\mathcal{G}$ are given by products of the exponentials of the matrices from $\mathfrak{g}$. In particular, each element $A \in \mathfrak{g}$ generates the *one-parameter subgroup* $\{e^{At}, t \in \mathbb{R}\}$ in $\mathcal{G}$. For example, if $\mathfrak{g}$ is the Lie algebra $gl(n, \mathbb{R})$ of all real $n \times n$ matrices with the standard Lie bracket $[A, B] = AB - BA$, then the corresponding Lie group is given by the invertible matrices.

Given an abstract Lie algebra $\mathfrak{g}$, one can consider its (matrix) representations. A *representation* of $\mathfrak{g}$ on an n-dimensional vector space V is a homomorphism (i.e., a linear map that preserves the Lie bracket) $\phi : \mathfrak{g} \to gl(V)$. It assigns to each element $g \in \mathfrak{g}$ a linear operator $\phi(g)$ on V, which can be described by an $n \times n$ matrix. A representation ϕ is called *irreducible* if V contains no nontrivial subspaces invariant under the action of all $\phi(g)$, $g \in \mathfrak{g}$. A particularly useful representation is the *adjoint* one, denoted by "ad." The vector space V in this case is $\mathfrak{g}$ itself, and for $g \in \mathfrak{g}$ the operator $\mathrm{ad}g$ is defined by $\mathrm{ad}g(a) := [g, a]$, $a \in \mathfrak{g}$. There is also *Ado's theorem*, which says that every Lie algebra is isomorphic to a subalgebra of $gl(V)$ for some finite-dimensional vector space V. (Compare this with the adjoint representation which is in general not injective.)

A.2. Example: $sl(2, \mathbb{R})$ and $gl(2, \mathbb{R})$. The *special linear Lie algebra* $sl(2, \mathbb{R})$ consists of all real 2×2 matrices of trace 0. A canonical basis for this Lie algebra is given by the matrices

$$h := \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}, \qquad e := \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}, \qquad f := \begin{pmatrix} 0 & 0 \\ 1 & 0 \end{pmatrix}. \tag{14}$$

They satisfy the relations $[h,e]=2e$, $[h,f]=-2f$, $[e,f]=h$ and form what is sometimes called an $sl(2)$-*triple*. One can also consider other representations of $sl(2,\mathbb{R})$. Although all irreducible representations of $sl(2,\mathbb{R})$ can be classified by working with the Lie algebra directly (see [20, pp. 27–30]), for our purposes it is more useful to exploit the corresponding Lie group $SL(2,\mathbb{R})=\{S\in\mathbb{R}^{n\times n}:\det S=1\}$. Let $P^k[x,y]$ denote the space of polynomials in two indeterminates x and y that are homogeneous of degree k (where k is a positive integer). A homomorphism ϕ that makes $SL(2,\mathbb{R})$ act on $P^k[x,y]$ can be defined as

$$\phi(S)p\left(\begin{pmatrix}x\\y\end{pmatrix}\right)=p\left(S^{-1}\begin{pmatrix}x\\y\end{pmatrix}\right),$$

where $S\in SL(2,\mathbb{R})$ and $p\in P^k[x,y]$. The corresponding representation of the Lie algebra $sl(2,\mathbb{R})$, which we denote also by ϕ with slight abuse of notation, is obtained by considering the one-parameter subgroups of $SL(2,\mathbb{R})$ and differentiating the action defined above at $t=0$. For example, for e as in (14) we have

$$\phi(e)p\left(\begin{pmatrix}x\\y\end{pmatrix}\right)=\frac{d}{dt}\Big|_{t=0}p\left(e^{-et}\begin{pmatrix}x\\y\end{pmatrix}\right)=\frac{d}{dt}\Big|_{t=0}p\left(\begin{pmatrix}1&-t\\0&1\end{pmatrix}\begin{pmatrix}x\\y\end{pmatrix}\right)=-y\frac{\partial}{\partial x}p\left(\begin{pmatrix}x\\y\end{pmatrix}\right).$$

Similarly, $\phi(f)p=-x\frac{\partial}{\partial y}p$ and $\phi(h)p=(-x\frac{\partial}{\partial x}+y\frac{\partial}{\partial y})p$. With respect to the basis in $P^k[x,y]$ given by the monomials $y^k,-ky^{k-1}x,k(k-1)y^{k-2}x^2,\dots,(-1)^kk!x^k$, the corresponding differential operators are realized by the matrices

$$h\mapsto\begin{pmatrix}k&\cdots&\cdots&0\\\vdots&k-2&&\vdots\\\vdots&&\ddots&\vdots\\0&\cdots&\cdots&-k\end{pmatrix},\ e\mapsto\begin{pmatrix}0&\mu_1&\cdots&0\\\vdots&\ddots&\ddots&\vdots\\\vdots&&\ddots&\mu_k\\0&\cdots&\cdots&0\end{pmatrix},\ f\mapsto\begin{pmatrix}0&\cdots&\cdots&0\\1&\ddots&&\vdots\\\vdots&\ddots&\ddots&\vdots\\0&\cdots&1&0\end{pmatrix},$$

where $\mu_i=i(k-i+1)$, $i=1,\dots,k$. It turns out that any irreducible representation of $sl(2,\mathbb{R})$ of dimension $k+1$ is equivalent (under a linear change of coordinates) to the one just described. An arbitrary representation of $sl(2,\mathbb{R})$ is a direct sum of irreducible ones.

When working with $gl(2,\mathbb{R})$ rather than $sl(2,\mathbb{R})$, one also has the 2×2 identity matrix $I_{2\times 2}$. It corresponds to the operator $x\frac{\partial}{\partial x}+y\frac{\partial}{\partial y}$ on $P^k[x,y]$, whose associated matrix is $kI_{(k+1)\times(k+1)}$. One can thus naturally extend the above representation to $gl(2,\mathbb{R})$. The complementary subalgebras $\mathbb{R}I$ and $sl(2,\mathbb{R})$ are invariant under the resulting action.

A.3. Nilpotent and solvable Lie algebras. If $\mathfrak{g}_1$ and $\mathfrak{g}_2$ are linear subspaces of a Lie algebra $\mathfrak{g}$, one writes $[\mathfrak{g}_1,\mathfrak{g}_2]$ for the linear space spanned by all the products $[g_1,g_2]$ with $g_1\in\mathfrak{g}_1$ and $g_2\in\mathfrak{g}_2$. Given a Lie algebra $\mathfrak{g}$, the sequence $\mathfrak{g}^{(k)}$ is defined inductively as follows: $\mathfrak{g}^{(1)}:=\mathfrak{g}$, $\mathfrak{g}^{(k+1)}:=[\mathfrak{g}^{(k)},\mathfrak{g}^{(k)}]\subset\mathfrak{g}^{(k)}$. If $\mathfrak{g}^{(k)}=0$ for k sufficiently large, then $\mathfrak{g}$ is called *solvable*. Similarly, one defines the sequence $\mathfrak{g}^k$ by $\mathfrak{g}^1:=\mathfrak{g}$, $\mathfrak{g}^{k+1}:=[\mathfrak{g},\mathfrak{g}^k]\subset\mathfrak{g}^k$ and calls $\mathfrak{g}$ *nilpotent* if $\mathfrak{g}^k=0$ for k sufficiently large. For example, if $\mathfrak{g}$ is a Lie algebra generated by two matrices A and B, we have: $\mathfrak{g}^{(1)}=\mathfrak{g}^1=\mathfrak{g}=\operatorname{span}\{A,B,[A,B],[A,[A,B]],\dots\}$, $\mathfrak{g}^{(2)}=\mathfrak{g}^2=\operatorname{span}\{[A,B],[A,[A,B]],\dots\}$, $\mathfrak{g}^{(3)}=\operatorname{span}\{[[A,B],[A,[A,B]]],\dots\}\subset\mathfrak{g}^3=\operatorname{span}\{[A,[A,B]],[B,[A,B]],\dots\}$, and so on. Every nilpotent Lie algebra is solvable, but the converse is not true.

The *Killing form* on a Lie algebra $\mathfrak{g}$ is the symmetric bilinear form K given by $K(a,b):=\operatorname{tr}(\operatorname{ad}a\circ\operatorname{ad}b)$ for $a,b\in\mathfrak{g}$. *Cartan's 1st criterion* says that $\mathfrak{g}$ is solvable

if and only if its Killing form vanishes identically on $[\mathfrak{g},\mathfrak{g}]$. Let $\mathfrak{g}$ be a solvable Lie algebra over an algebraically closed field, and let ϕ be a representation of $\mathfrak{g}$ on a vector space V. *Lie's theorem* states that there exists a basis for V with respect to which all the matrices $\phi(g)$, $g \in \mathfrak{g}$, are upper-triangular.

A.4. Semisimple and compact Lie algebras. A subalgebra $\bar{\mathfrak{g}}$ of a Lie algebra $\mathfrak{g}$ is called an *ideal* if $[g,\bar{g}] \in \bar{\mathfrak{g}}$ for all $g \in \mathfrak{g}$ and $\bar{g} \in \bar{\mathfrak{g}}$. Any Lie algebra has a unique maximal solvable ideal $\mathfrak{r}$, the *radical*. A Lie algebra $\mathfrak{g}$ is called *semisimple* if its radical is 0. *Cartan's 2nd criterion* says that $\mathfrak{g}$ is semisimple if and only if its Killing form is nondegenerate (meaning that if for some $g \in \mathfrak{g}$ we have $K(g,a) = 0\ \forall a \in \mathfrak{g}$, then g must be 0).

A semisimple Lie algebra is called *compact* if its Killing form is negative definite. A general *compact Lie algebra* is a direct sum of a semisimple compact Lie algebra and a commutative Lie algebra (with the Killing form vanishing on the latter). This terminology is justified by the facts that the tangent algebra of any compact Lie group is compact according to this definition, and that for any compact Lie algebra $\mathfrak{g}$ there exists a connected compact Lie group $\mathcal{G}$ with tangent algebra $\mathfrak{g}$. Compactness of a semisimple matrix Lie algebra $\mathfrak{g}$ amounts to the property that the eigenvalues of all matrices in $\mathfrak{g}$ lie on the imaginary axis. If $\mathcal{G}$ is a compact Lie group, one can associate to any continuous function $f : \mathcal{G} \to \mathbb{R}$ a real number $\int_{\mathcal{G}} f(G)dG$ so as to have $\int_{\mathcal{G}} 1dG = 1$ and $\int_{\mathcal{G}} f(AGB)dG = \int_{\mathcal{G}} f(G)dG \quad \forall A, B \in \mathcal{G}$ (left and right invariance). The measure dG is called the *Haar measure*.

An arbitrary Lie algebra $\mathfrak{g}$ can be decomposed into the semidirect sum $\mathfrak{g} = \mathfrak{r} \oplus \mathfrak{s}$, where $\mathfrak{r}$ is the radical, $\mathfrak{s}$ is a semisimple subalgebra, and $[\mathfrak{s},\mathfrak{r}] \subseteq \mathfrak{r}$ because $\mathfrak{r}$ is an ideal. This is known as a *Levi decomposition*. To compute $\mathfrak{r}$ and $\mathfrak{s}$, switch to a basis in which the Killing form K is diagonalized. The subspace on which K is not identically zero corresponds to $\mathfrak{s} \oplus (\mathfrak{r} \bmod \mathfrak{n})$, where $\mathfrak{n}$ is the maximal nilpotent subalgebra of $\mathfrak{r}$. Construct the Killing form $\bar{K}$ for the factor algebra $\mathfrak{s} \oplus (\mathfrak{r} \bmod \mathfrak{n})$. This form will vanish identically on $(\mathfrak{r} \bmod \mathfrak{n})$ and will be nondegenerate on $\mathfrak{s}$. The subalgebra $\mathfrak{s}$ identified in this way is compact if and only if $\bar{K}$ is negative definite on it. For more details on this construction and examples, see [7, pp. 256–258].

A.5. Subalgebras isomorphic to $sl(2,\mathbb{R})$. Let $\mathfrak{g}$ be a real, noncompact, semisimple Lie algebra. Our goal here is to show that $\mathfrak{g}$ has a subalgebra isomorphic to $sl(2,\mathbb{R})$. To this end, consider a *Cartan decomposition* $\mathfrak{g} = \mathfrak{k} \oplus \mathfrak{p}$, where $\mathfrak{k}$ is a maximal compact subalgebra of $\mathfrak{g}$ and $\mathfrak{p}$ is its orthogonal complement with respect to K. The Killing form K is negative definite on $\mathfrak{k}$ and positive definite on $\mathfrak{p}$. Let $\mathfrak{a}$ be a maximal commuting subalgebra of $\mathfrak{p}$. Then it is easy to check using the Jacobi identity that the operators $\mathrm{ad}a$, $a \in \mathfrak{a}$, are commuting. These operators are also symmetric with respect to a suitable inner product on $\mathfrak{g}$ (for $a, b \in \mathfrak{g}$ this inner product is given by $-K(a,\Theta b)$, where Θ is the map sending $k + p$, with $k \in \mathfrak{k}$ and $p \in \mathfrak{p}$, to $k - p$), and hence they are simultaneously diagonalizable. Thus $\mathfrak{g}$ can be decomposed into a direct sum of subspaces invariant under $\mathrm{ad}a$, $a \in \mathfrak{a}$, on each of which every operator $\mathrm{ad}a$ has exactly one eigenvalue. The unique eigenvalue of $\mathrm{ad}a$ on each of these invariant subspaces is given by a linear function λ on $\mathfrak{a}$, and accordingly the corresponding subspace is denoted by $\mathfrak{g}_\lambda$. Since $\mathfrak{p} \neq 0$ (because $\mathfrak{g}$ is not compact) and since K is positive definite on $\mathfrak{p}$, the subspace $\mathfrak{g}_0$ associated with λ being identically zero cannot be the entire $\mathfrak{g}$. Summarizing, we have

$$\mathfrak{g} = \mathfrak{g}_0 \oplus \big(\bigoplus\nolimits_{\lambda \in \Sigma} \mathfrak{g}_\lambda\big),$$

where Σ is a finite set of nonzero linear functions on $\mathfrak{a}$ (which are called the *roots*) and $\mathfrak{g}_\lambda = \{g \in \mathfrak{g} : \mathrm{ad}a(g) = \lambda(a)g \ \forall a \in \mathfrak{a}\}$. Using the Jacobi identity, one can show that $[\mathfrak{g}_\lambda, \mathfrak{g}_\mu]$ is a subspace of $\mathfrak{g}_{\lambda+\mu}$ if $\lambda + \mu \in \Sigma \cup \{0\}$, and equals 0 otherwise. This implies that the subspaces $\mathfrak{g}_\lambda$ and $\mathfrak{g}_\mu$ are orthogonal with respect to K unless $\lambda + \mu = 0$ (cf. [20, p. 38]). Since K is nondegenerate on $\mathfrak{g}$, it follows that if λ is a root, then so is $-\lambda$. Moreover, the subspace $[\mathfrak{g}_\lambda, \mathfrak{g}_{-\lambda}]$ of $\mathfrak{g}_0$ has dimension 1, and λ is not identically zero on it (cf. [20, pp. 39–40]). This means that there exist some elements $e \in \mathfrak{g}_\lambda$ and $f \in \mathfrak{g}_{-\lambda}$ such that $h := [e, f] \neq 0$. It is now easy to see that, multiplying e, f, and h by constants if necessary, we obtain an $sl(2)$-triple. Alternatively, we could finish the argument by noting that if $g \in \mathfrak{g}_\lambda$ for some $\lambda \in \Sigma$, then the operator $\mathrm{ad}g$ is nilpotent (because it maps each $\mathfrak{g}_\mu$ to $\mathfrak{g}_{\mu+\lambda}$, to $\mathfrak{g}_{\mu+2\lambda}$, and eventually to 0 since Σ is a finite set), and the existence of a subalgebra isomorphic to $sl(2, \mathbb{R})$ is guaranteed by the Jacobson–Morozov theorem.

A.6. Generators for $gl(2, \mathbb{R})$. This subsection is devoted to showing that in an arbitrarily small neighborhood of any pair of $n \times n$ matrices one can find another pair of matrices that generate the entire Lie algebra $gl(n, \mathbb{R})$. This fact demonstrates that Lie-algebraic stability conditions considered in the previous sections are never robust with respect to small perturbations of the matrices that define the switched system. Constructions like the one presented here have certainly appeared in the literature, but we are not aware of a specific reference.

We begin by finding some matrices B_1, B_2 that generate $gl(n, \mathbb{R})$. Let B_1 be a diagonal matrix $B_1 = \mathrm{diag}(b_1, b_2, \ldots, b_n)$ satisfying the following two properties.

1. $b_i - b_j \neq b_k - b_l$ if $(i, j) \neq (k, l)$.
2. $\sum_{i=1}^n b_i \neq 0$.

Denote by $od(n, \mathbb{R})$ the space of matrices with zero elements on the main diagonal. Let B_2 be any matrix in $od(n, \mathbb{R})$ such that all its off-diagonal elements are nonzero. It is easy to check that if $E_{i,j}$ is a matrix whose ijth element is 1 and all other elements are 0, where $i \neq j$, then $[B_1, E_{i,j}] = (b_i - b_j)E_{i,j}$. Thus it follows from property 1 above that B_2 does not belong to any proper subspace of $od(n, \mathbb{R})$ that is invariant with respect to the operator $\mathrm{ad}B_1$. Therefore, the linear space spanned by the iterated brackets $ad^k B_1(B_2)$ is the entire $od(n, \mathbb{R})$. Taking brackets of the form $[E_{i,j}, E_{j,i}]$, we generate all traceless diagonal matrices (cf. the example $[e, f] = h$ in section A.2). Since B_1 has a nonzero trace by property 2 above, we conclude that $\{B_1, B_2\}_{LA} = gl(n, \mathbb{R})$.

Now let A_1 and A_2 be two arbitrary $n \times n$ matrices. Using the matrices B_1 and B_2 just constructed, we can define $A_1(\alpha) := A_1 + \alpha B_1$ and $A_2(\alpha) := A_2 + \alpha B_2$, where $\alpha \geq 0$. The two matrices $A_1(\alpha)$ and $A_2(\alpha)$ generate $gl(n, \mathbb{R})$ for any sufficiently small α, as can be shown by using the same argument as the one employed at the end of the proof of Theorem 4. Thus one can take $(A_1(\alpha), A_2(\alpha))$ as a desired pair of matrices in a neighborhood of (A_1, A_2).

Acknowledgments. The second author is grateful to Steve Morse for constant encouragement and interest in this work and to Victor Protsak for helpful discussions on Lie algebras.

OPTIMAL CONTROL FOR CONTINUOUS-TIME LINEAR QUADRATIC PROBLEMS WITH INFINITE MARKOV JUMP PARAMETERS*

MARCELO D. FRAGOSO† AND JACK BACZYNSKI‡

Abstract. The subject matter of this paper is the optimal control problem for continuous-time linear systems subject to Markovian jumps in the parameters and the usual infinite-time horizon quadratic cost. What essentially distinguishes our problem from previous ones, inter alia, is that the Markov chain takes values on a countably infinite set. To tackle our problem, we make use of powerful tools from semigroup theory in Banach space and a decomplexification technique. The solution for the problem relies, in part, on the study of a countably infinite set of coupled algebraic Riccati equations (ICARE). Conditions for existence and uniqueness of a positive semidefinite solution of the ICARE are obtained via the extended concepts of stochastic stabilizability (SS) and stochastic detectability (SD). These concepts are couched into the theory of operators in Banach space and, parallel to the classical linear quadratic (LQ) case, bound up with the spectrum of a certain infinite dimensional linear operator.

1. Introduction.

Our main concern in this paper is with the so-called class of continuous-time linear systems with Markovian jump parameters (LSMJP). The usual infinite-time horizon quadratic cost is considered, and we assume that both the state and the Markov jump are accessible to the controller. (It is perhaps worth mentioning that although in engineering problems the Markov state is not often at hand, there are enough cases where this indeed happens. An illustrative list of such situations is found in [12].) Recent advances in LSMJP have greatly increased its power and led to new applications in many different fields. Potential applications include, inter alia, safety-critical and high-integrity systems (e.g., aircraft, chemical plants, nuclear power stations, robotic manipulator systems, large-scale flexible structures for space stations such as antennae, solar arrays, etc.). Without any intention of being exhaustive here, we mention [6], [7], [10], [12], [13], [14], [16], [17], [18], [19], [20], [22], [26], [27], [28], [33], [34], [35], [39], [40], [41], [42], [46], and [49], as a small sample of works dealing with different aspects of control problems. We mention also [5], [17], [30], [38], [40] (and references therein), and [46] as works dealing with applications of this class. In addition, the connection between linear dynamically varying (LDV) systems and jump linear systems, which has been exploited in [8] and [9], will certainly give a new impetus to LSMJP in the coming years. LDV controllers have been introduced as a technique to control systems with complicated dynamics (nonlinear dynamical

systems that run over compact sets and have such features as nontrivial recurrence and periodic and aperiodic orbits).

What essentially distinguishes our problem from previous ones is that the Markov chain takes values in a countably infinite set. This, associated with the continuous-time feature of the problem, requires the use of operator theory, particularly, powerful tools from semigroup theory. Semigroup theory laid the basis for establishing here the equivalence between the conditions for stochastic stabilizability (SS) and stochastic detectability (SD) and the spectrum of a certain infinite dimensional linear operator. Operator theory was essential to allowing us to frame the whole problem into an infinite dimensional Banach space setting that lead us to the optimal solution which, analogously to the classical LQ case (see for instance [49]), boils down essentially to questions of existence and uniqueness of solution to a certain countably infinite set of coupled algebraic Riccati equations (ICARE).

In its content, this paper is closely related to [12]. However, technically they are rather different. For instance, beside the tools mentioned above, we have to introduce a natural adaptation of the decomplexification concept described in [1, section 18] for nonlinear complex functions with range in $\mathbb{R}$. This is required to establish a certain version of the gradient concept and, from that, the linear approximation to nonholomorphic functionals. This has allowed us to conveniently specify the semigroup of the Markov process $\{x, \theta\}$ applied to a certain (nonholomorphic) quadratic functional with domain in the complex space $\mathbb{C}^n$. In this way, we have preserved a more general (complex) framework to the problem, as in [12]. It is noteworthy that this framework is not only important for the sake of generalization, but because it allows us a self-adjoint matrix decomposition (refer to Remarks 2.3 and 2.5), as it is effectively required in the proof of the important Lemma 6.6. In addition, it is tacitly usual to work in the complex setting when using an operator theoretical approach.

Of course, it is too early to predict the full extent to which the theory developed here will be applied. However, from the outset we can envisage some situations in which model (3.1) can be naturally applied. For instance, applications to a nonlinear plant for which there is a conceivably infinite countable number of operating points, each of them characterized by a corresponding linearized model, where the abrupt changes would represent the dynamics of the system moving from one operating point to another, are suggested in [12]. This could probably also happen in economics and finance, where the complexity of the system, including the fact that the future is uncertain, is such that you have to consider infinitely many conceivable economical scenarios in order to have a more accurate model. ([3] gives practical-oriented-motivation for the use of infinite dimensional analysis in economics, and [17] gives practical-oriented-motivation for the use of LSJMP in economics.)

Finally, it is worth mentioning that if we specialize our results to the setting in which the state space of the Markov chain is finite, this paper still provides an important contribution in that the conditions in Theorem 6.13 below can be seen as a relaxation of those in Theorem 5 of [33], i.e., Theorem 5 of [33] uses the concept of observability, while we use the concept of SD. Indeed, if we consider the single state case (no jumps), SD reduces to detectability in the usual sense (see Remark 6.14), while the observability concept used in Theorem 5 of [33] (see also Definition 3 of [33]) reduces to observability in the usual sense.

An outline of the content of this paper is as follows. In section 2 we provide the bare essentials of notations and fundamental remarks. The model description is stated in section 3. Some preliminaries are given in section 4. The bulk of the results

in control are exhibited in sections 5 and 6.

2. Notations and initial remarks. As usual, $\mathbb{C}^n$ (respectively, $\mathbb{R}^n$) stands for the n-dimensional Euclidean space over the field of complex (respectively, real) numbers $\mathbb{C}$ (respectively, $\mathbb{R}$) and $\mathbb{N} = \{1, 2, \dots\}$. We denote $\mathbb{M}(\mathbb{C}^m, \mathbb{C}^n)$ as the normed linear space of all n by m complex matrices and, for simplicity, write $\mathbb{M}(\mathbb{C}^n)$ whenever $n = m$. We use the superscripts $^-$, $'$, and * for complex conjugate, transpose, and conjugate transpose, respectively. The notation $L \geq 0$ and $L > 0$ is adopted if a self-adjoint matrix is positive semidefinite or positive definite, respectively. We denote $\mathbb{M}(\mathbb{C}^n)^+ = \{L \in \mathbb{M}(\mathbb{C}^n); L = L^* \geq 0\}$ and write $\|\cdot\|_L$ for the norm in $\mathbb{C}^n$ induced by the inner product $\langle x, y\rangle_L = x^*Ly$ whenever the matrix $L = L^* \geq 0$. Furthermore, $\|\cdot\|_Y$ indicates a norm in the space Y. Except when otherwise mentioned, $\|\cdot\|$ represents either the Euclidean norm in $\mathbb{C}^n$ or the spectral induced norm in $\mathbb{M}(\mathbb{C}^n)$. To avoid notational confusion with the summation index i and j, we denote by ι the pure imaginary complex number. For $z \in \mathbb{C}$, we write z_{Re}(and sometimes $\mathrm{Re}(z)$) and z_{Im} for the real and imaginary parts of z, respectively, so that $z = z_{\mathrm{Re}} + \iota z_{\mathrm{Im}}$. For $x \in \mathbb{C}^n$ we denote the real vectors $x_{\mathrm{Re}} := (x_{1\,\mathrm{Re}}, \dots, x_{n\,\mathrm{Re}})'$ and $x_{\mathrm{Im}} := (x_{1\,\mathrm{Im}}, \dots, x_{n\,\mathrm{Im}})'$, which we call the real and imaginary parts of $x \in \mathbb{C}^n$, and we may write $x = x_{\mathrm{Re}} + \iota x_{\mathrm{Im}}$. (The notation $x_{j\,\mathrm{Re}}$ and $x_{j\,\mathrm{Im}}$ abbreviates the more precise notation $(x_j)_{\mathrm{Re}}$ and $(x_j)_{\mathrm{Im}}$, respectively, $j = 1, \dots, n$.) In addition, by the decomplexification of an arbitrary $x \in \mathbb{C}^n$, we mean the operation $\mathbb{C}^n \ni x \mapsto {}^{\mathrm{R}}x = (x_{\mathrm{Re}}\ x_{\mathrm{Im}})' \in \mathbb{R}^{2n}$, and by the decomplexification of a generic operator $g : [0, \infty) \times \mathbb{C}^n \mapsto \mathbb{R}$, we mean the operator ${}^{\mathrm{R}}g : [0, \infty) \times \mathbb{R}^{2n} \mapsto \mathbb{R}$ that coincides with g pointwise, i.e.,

$$ {}^{\mathrm{R}}g\left(t, {}^{\mathrm{R}}x\right) = g(t, x) \text{ for all } t \in [0, \infty) \text{ and } x \in \mathbb{C}^n, \tag{2.1} $$

which is a natural adaptation of the concept devised in [1].

Remark 2.1. From the above definition, ${}^{\mathrm{R}}\mathbb{C}^n = \mathbb{R}^{2n}$, ${}^{\mathrm{R}}(x + y) = {}^{\mathrm{R}}x + {}^{\mathrm{R}}y$, ${}^{\mathrm{R}}(cx) = c\,{}^{\mathrm{R}}(x)$, and $\|x\| = \left\|{}^{\mathrm{R}}x\right\|$ for $x, y \in \mathbb{C}^n$, c a real number.

Remark 2.2. For every $L \in \mathbb{M}(\mathbb{C}^n)^+$, there is a unique $L^{1/2} \in \mathbb{M}(\mathbb{C}^n)^+$ such that $(L^{1/2})^2 = L$. The absolute value of $L \in \mathbb{M}(\mathbb{C}^n)$, denoted by $|L|$, is defined as $|L| = (L^*L)^{1/2}$. It is easy to verify that $\|L\| = \||L|\|$.

Remark 2.3. Every element in $\mathbb{M}(\mathbb{C}^n)$ has a Cartesian self-adjoint decomposition (see, e.g., [44, p. 376]) and every self-adjoint operator in $\mathbb{M}(\mathbb{C}^n)$ can be decomposed in positive and negative parts [44, p. 464]. Thus, for any $L \in \mathbb{M}(\mathbb{C}^n)$, there exist X^+, X^-, Y^+, Y^- in $\mathbb{M}(\mathbb{C}^n)^+$ such that $L = (X^+ - X^-) + \iota\,(Y^+ - Y^-)$. Moreover, $X^+ \leq X^+ + X^- = (L + L^*)/2$, and thus $\|X^+\| \leq \|L\|$. Similarly, $\|X^-\| \leq \|L\|$, $\|Y^+\| \leq \|L\|$, and $\|Y^-\| \leq \|L\|$.

Set $\mathcal{H}_1^{m,n}$ (respectively, $\mathcal{H}_\infty^{m,n}$) as the linear space made up of all infinite sequences of complex matrices $H = (H_1, H_2, \dots)$, $H_i \in \mathbb{M}(\mathbb{C}^m, \mathbb{C}^n)$, such that $\sum_{i=1}^\infty \|H_i\| < \infty$ (respectively, $\sup\{\|H_i\|,\ i = 1, 2, \dots\} < \infty$). For $H \in \mathcal{H}_1^{m,n}$ (respectively, $H \in \mathcal{H}_\infty^{m,n}$) we define a norm in $\mathcal{H}_1^{m,n}$ (respectively, $\mathcal{H}_\infty^{m,n}$) by $\|H\|_1 = \sum_{i=1}^\infty \|H_i\|$ (respectively, $\|H\|_\infty = \sup\{\|H_i\|,\ i = 1, 2, \dots\}$). We shall write $\mathcal{H}_1^n$ and $\mathcal{H}_\infty^n$ whenever $n = m$ and denote $\mathcal{H}_1^{n^+} = \{H \in \mathcal{H}_1^n,\ H_i \in \mathbb{M}(\mathbb{C}^n)^+,\ i = 1, 2, \dots\}$ and $\mathcal{H}_\infty^{n^+} = \{H \in \mathcal{H}_\infty^n,\ H_i \in \mathbb{M}(\mathbb{C}^n)^+,\ i = 1, 2, \dots\}$ as the class of positive semidefinite elements of $\mathcal{H}_1^n$ and $\mathcal{H}_\infty^n$, respectively. For $H = (H_1, H_2, \dots)$ and $L = (L_1, L_2, \dots)$ in $\mathcal{H}_1^{n^+}$ we shall use the notation $H \leq L$ to indicate that $H_i \leq L_i$ for each i in $\mathbb{N}$. It is clear that

$$ H \leq L \Rightarrow \|H\|_1 \leq \|L\|_1 . \tag{2.2} $$

Furthermore, we shall use the notation H^* to indicate that each component H_i^* of H^* is the adjoint of H_i, $i = 1, 2, \dots$.

We shall denote $(l_1, \|\cdot\|_1)$, $(l_2, \|\cdot\|_2)$, and $(l_\infty, \|\cdot\|_\infty)$, respectively, as the sets made up of all infinite sequences of complex numbers $x = (x_1, x_2, \dots)$ such that $\sum_{i=1}^{\infty} |x_i| < \infty$, $\sum_{i=1}^{\infty} |x_i|^2 < \infty$, and $\sup\{|x_i|,\ i = 1, 2, \dots\} < \infty$, equipped with the usual norm $\|x\|_1 = \sum_{i=1}^{\infty} |x_i|$, $\|x\|_2 = \sum_{i=1}^{\infty} |x_i|^2$, and $\|x\|_\infty = \sup\{|x_i|,\ i = 1, 2, \dots\}$ and, in the case of $(l_2, \|\cdot\|_2)$, equipped with the usual internal product $\langle \cdot, \cdot \rangle$.

Remark 2.4. It is easy to verify that $(\mathcal{H}_1^{m,n}, \|\cdot\|_1)$ and $(l_1, \|\cdot\|_1)$ are uniformly homeomorphic. Similarly, $(\mathcal{H}_\infty^{m,n}, \|\cdot\|_\infty)$ and $(l_\infty, \|\cdot\|_\infty)$ can be shown to be uniformly homeomorphic. Since $(l_1, \|\cdot\|_1)$ and $(l_\infty, \|\cdot\|_\infty)$ are Banach spaces, we have that $(\mathcal{H}_1^{m,n}, \|\cdot\|_1)$ and $(\mathcal{H}_\infty^{m,n}, \|\cdot\|_\infty)$ are also Banach spaces.

Remark 2.5. Consider $Q = (Q_1, Q_2, \dots) \in \mathcal{H}_1^n$. From Remark 2.3, $Q_i = \left(X_i^+ - X_i^-\right) + \iota \left(Y_i^+ - Y_i^-\right)$, where X_i^+, X_i^-, Y_i^+, and Y_i^- belong to $\mathbb{M}(\mathbb{C}^n)^+$. Now define $X^+ = (X_1^+, X_2^+, \dots)$, $X^- = (X_1^-, X_2^-, \dots)$, $Y^+ = (Y_1^+, Y_2^+, \dots)$, and $Y^- = (Y_1^-, Y_2^-, \dots)$. Since $Q \in \mathcal{H}_1^n$, it follows, again from Remark 2.3, that X^+, X^-, Y^+, and Y^- also belong to $\mathcal{H}_1^n$. Therefore, Q can always be decomposed as

$$Q = \left(X^+ - X^-\right) + \iota \left(Y^+ - Y^-\right)$$

with X^+, X^-, Y^+, and Y^- in $\mathcal{H}_1^{n^+}$.

To support the sketch of the proof of Proposition 4.9, we define $\mathcal{W}_\infty^{m,n}$ as the Banach space made up of all infinite dimensional complex matrices of the type $\mathcal{C} = \operatorname{diag}(C_i)$, where $C_i \in \mathbb{M}(\mathbb{C}^m, \mathbb{C}^n)$, $i \in \mathcal{S}$, and $\sup_{i \in \mathcal{S}} \|C_i\| < \infty$. For $\mathcal{C} \in \mathcal{W}_\infty^{m,n}$ we define $\|\mathcal{C}\|_{\mathcal{W}_\infty} = \sup_{i \in \mathcal{S}} \|C_i\|$ as the norm in $\mathcal{W}_\infty^{m,n}$ and $\mathcal{C}^* = \operatorname{diag}(C_i^*) \in \mathcal{W}_\infty^{n,m}$, where C_i^* is the adjoint of C_i. We write $\mathcal{W}_\infty^n$ whenever $n = m$ and denote $\mathcal{W}_\infty^{n^+} = \{\mathcal{C} \in \mathcal{W}_\infty^n, C_i \in \mathbb{M}(\mathbb{C}^n)^+,\ i \in \mathcal{S}\}$ as the class of positive semidefinite elements of $\mathcal{W}_\infty^n$. For $\mathcal{B}, \mathcal{C} \in \mathcal{W}_\infty^{n+}$, we say that $\mathcal{B} \le \mathcal{C}$ if $B_i \le C_i$, $i \in \mathcal{S}$.

For any complex Banach space X, we denote by $Blt(X)$ the Banach space of all bounded linear transformations of X into X equipped with the uniform induced norm represented by $\|\cdot\|$, and for $L \in Blt(X)$ we denote by $\sigma(L)$ the spectrum of L.

Finally, we denote by $1_A\ \{.\}$ the Dirac measure, we write $\{\eta\}$ for any process $\{\eta(t),\ 0 \le t \le T\}$, whenever it is clear whether T is finite or not, and we adopt $E[\cdot]$ for the usual expectation. In addition, a function $f : Y \to \mathbb{R}$, Y a finite dimensional space, is denoted $o(\|r\|)$ if $\lim_{r \to 0} \frac{f(r)}{\|r\|_Y} = 0$ with r approaching zero by any path in Y. A function $f : [0, \infty) \to \mathbb{E}$, $\mathbb{E}$ standing for $\mathbb{R}$ or $\mathbb{C}$, is said to be $o(\delta)$ if $\lim_{\delta \downarrow 0} \frac{|f(\delta)|}{\delta} = 0$. A similar notation, namely, $o^n(\delta)$ (respectively, $o^{nn}(\delta)$), stands for a vector (respectively, matrix) valued function if the above limit holds for each entry. For $g : \mathbb{R}^n \to \mathbb{R}$ with partial derivatives $\frac{\partial g(x)}{\partial x_i}$, $i = 1, \dots, n$, we denote by $\nabla_x g(x) = (\frac{\partial g(x)}{\partial x_1} \dots \frac{\partial g(x)}{\partial x_n})'$ the gradient of g.

3. Problem statement. Let us fix an underlying complete probability space $(\Omega, \mathcal{F}, \mathcal{P})$ and, for arbitrary $s, T \in [0, \infty)$, consider the class of stochastic differential equations

$$\dot{x}(t) = A_{\theta(t)} x(t) + B_{\theta(t)} u(t), \quad s < t < T, \tag{3.1}$$

$$x(s) = x_s, \theta(s) = \theta_s, \tag{3.2}$$

where $x(t) \in \mathbb{C}^n$ denotes the state vector and $u(t) \in \mathbb{C}^m$ the control input. The system parameters are functions of a homogeneous Markov process $\{\theta(t), t \in [s, T]\}$ with right continuous trajectories and an infinite countable state space which, for convenience, we assign to the set $\mathcal{S} = \{1, 2, \dots\}$. We assume that $\{\theta\}$ has a stationary standard

transition probability matrix function (see [36, p. 138]) $\{P_\tau(i,j)\}_{i,j\in\mathcal{S}}$ in that, for $0 \le \tau \le T-t$,

$$P_\tau(i,j) = \mathcal{P}\{\theta(t+\tau) = j \mid \theta(t) = i\} = \begin{cases} \lambda_{ij}\tau + o_{ij}(\tau), & i \neq j, \\ 1 + \lambda_{ii}\tau + o_{ii}(\tau), & i = j, \end{cases} \tag{3.3}$$

with infinitesimal matrix $\Lambda = [\lambda_{ij}]_{i,j\in\mathcal{S}}$, where $\lambda_{ij} \ge 0$ for $i \neq j$. The Markov process $\{\theta\}$ is conservative and stable in that

$$\sum_{j=1, j\neq i}^{\infty} \lambda_{ij} = -\lambda_{ii} \le c < \infty, \quad i = 1, 2, \dots, \tag{3.4}$$

where c does not depend on i. We assume that $\left\{A_{(.)}, B_{(.)}\right\}$ are such that for any $j \in \mathcal{S}$ and for $\theta(t) = j$, $A_{\theta(t)} = A_j$ and $B_{\theta(t)} = B_j$, with A_j, B_j being constant matrices in $\mathbb{M}(\mathbb{C}^n)$ and $\mathbb{M}(\mathbb{C}^m, \mathbb{C}^n)$, respectively. In addition, the parameters are supposed norm-bounded in that $A = (A_1, A_2, \dots) \in \mathcal{H}_\infty^n$ and $B = (B_1, B_2, \dots) \in \mathcal{H}_\infty^{m,n}$. We consider x_s a second order random variable (r.v.) which may depend on the r.v. θ_s, and we shall denote $\vartheta_s = \vartheta_s(x_s, \theta_s)$ as the joint initial distribution of x_s and θ_s. By its turn, we assume the r.v.'s $\theta(t+\tau)$ are conditionally independent of x_s, given $\theta(t)$, for $s \le t < T$, $0 < \tau < T - t$.

In order to tackle our main problem, we begin by studying the auxiliary finite-time control problem as defined below.

We assume that the class of admissible control policies, $\mathcal{U}^{s,T}$ ($\mathcal{U}^{0,T} \equiv \mathcal{U}^T$ for short), is the class of all Borel measurable functions $u : \{[s,T], \mathbb{C}^n, \mathcal{S}\} \to \mathbb{C}^m$ such that, for some constant c, which might depend on u, the following hold.

C1. For every z, $y \in \mathbb{C}^n$, $t \in [s,T]$, and each $i \in \mathcal{S}$,
   (a) $\|u(t,z,i) - u(t,y,i)\| \le c\,\|(z-y)\|$ (Lipschitz condition), and
   (b) $\|u(t,y,i)\| \le c(1 + \|y\|)$ (growth condition).

For starting time $0 \le s < T$, terminal cost condition $L \in \mathcal{H}_\infty^{n^+}$, and for each policy $u \in \mathcal{U}^{s,T}$, define the cost functional

$$\mathcal{J}_{[s,T],L}(\vartheta_s, u) = E\left[\int_s^T \left\|\mathcal{Q}^{1/2}x(t)\right\|^2 + \left\|\mathcal{R}^{1/2}u(t)\right\|^2 dt + x(T)^* L_{\theta(T)} x(T)\right], \tag{3.5}$$

where $x(t)$ is subject to (3.1), $\mathcal{R}, \mathcal{Q} \in \mathbb{M}(\mathbb{C}^n)^+$, and $\mathcal{R} > 0$. For the sake of simplicity, the cost matrices $\mathcal{Q}$ and $\mathcal{R}$ are jump independent. However, the results derived here carry over verbatim to the case $\mathcal{Q}_{\theta(t)}$ and $\mathcal{R}_{\theta(t)}$ when conveniently norm-bounded.

The finite-time optimal control problem consists in finding $\hat{u}^T \in \mathcal{U}^{s,T}$, which minimizes $\mathcal{J}_{[s,T],L}(\vartheta_s, u)$.

Our main problem consists then in analyzing the infinite-time control problem by considering the setup as above, where now $t \ge 0$ and $\mathcal{U} \equiv \mathcal{U}^{0,\infty}$ with the following additional conditions.

C2. Model (3.1) with $t \ge 0$ is mean square stable (MSS), i.e., $E[\|x(t)\|^2] \to 0$ as $t \to \infty$ for any distribution ϑ_0.

C3. The cost functional $\mathcal{J}(\vartheta_0, u)$, defined below, is finite for any distribution ϑ_0.

For each policy $u \in \mathcal{U}$, define the cost functional

$$\mathcal{J}(\vartheta_0, u) := E\left[\int_0^\infty \left(\left\|\mathcal{Q}^{1/2}x(t)\right\|^2 + \left\|\mathcal{R}^{1/2}u(t)\right\|^2\right) dt\right], \tag{3.6}$$

where $x(t)$ is subject to (3.1) with $t > 0$.

The infinite-time problem is then to derive an optimal control policy $\hat{u}$, within the class $\mathcal{U}$, that minimizes the above cost, i.e., such that

$$\mathcal{J}(\vartheta_0, \hat{u}) := \inf_{u \in \mathcal{U}} \mathcal{J}(\vartheta_0, u), \tag{3.7}$$

and to establish structural conditions under which the existence and uniqueness of such a solution are ensured.

Remark 3.1. Since $\{x(t), \theta(t)\}$ is a Markov process, (3.1) and (3.5) set a "Markov" problem, and therefore control policies of the form $u(t) = u(t, x(t), \theta(t))$ suffice vis-à-vis the more expanded class consisting of policies of the form $u(t) = u(t, \{x(s), \theta(s), s \le t\})$.

4. Preliminaries. The following propositions from semigroup theory are essential tools in this work (see, for instance, [45]).

PROPOSITION 4.1. *Let Y be a Banach space, and consider the homogeneous differential equation*

$$\begin{cases} \dot{y}(t) = \mathcal{A}y(t), & t > 0, \\ y(0) = y \end{cases} \tag{4.1}$$

with arbitrary initial data $y \in Y$, where $\mathcal{A}$ is a bounded linear operator defined on Y into Y. Then (4.1) *is satisfied by a unique Y-valued function, continuous for $t \ge 0$ and continuously differentiable for $t > 0$, given by*

$$t \to y(t) = T(t)y \in Y, \quad t \ge 0, \tag{4.2}$$

where $T(t) : Y \to Y$, $t \ge 0$, is the C_0-semigroup (actually a uniformly continuous semigroup) of bounded linear transformations generated by $\mathcal{A}$, its infinitesimal operator.

PROPOSITION 4.2. *Let Y be a Banach space, and, for finite $T > 0$, consider the inhomogeneous differential equation*

$$\begin{cases} \dot{y}(t) = \mathcal{A}y(t) + f(t), & 0 < t < T, \\ y(0) = y \end{cases} \tag{4.3}$$

with arbitrary initial data $y \in Y$, where $\mathcal{A}$ is a bounded linear operator defined from Y into Y and $f \in L_1([0,T], Y)$. Then, for every $y \in Y$, the initial value problem (4.3) *has at most one solution. If, for a certain $y \in Y$, it has a solution, it is given by*

$$y(t) = T(t)y + \int_0^t T(t-s)f(s)ds, \qquad t \in [0,T],$$

where $T(t)$ is the uniformly continuous semigroup as defined in the above proposition. Moreover, if $f \in L_1([0,T], Y)$ is continuously differentiable, then (4.3) *has, for every $y \in Y$, a unique continuous and continuously differentiable solution on $[0,T]$.*

The following lemma is, essentially, a combination of results from [45].

LEMMA 4.3. *Let $\mathcal{A} : \mathfrak{D}(\mathcal{A}) \to Y$ be the infinitesimal generator of a C_0 semigroup $T(t) : Y \to Y$, let Y be a Banach space, and let $\mathfrak{D}(\mathcal{A})$ be the domain of $\mathcal{A}$, and consider the following assertions.*

1. $\sup\{\operatorname{Re}\lambda : \lambda \in \sigma(\mathcal{A})\} < 0$.
2. *There are constants $M \ge 1$ and $\omega > 0$ such that $\|T(t)\| \le M \exp(-\omega t)$.*
3. $\int_0^\infty \|T(t)y\|\, dt < \infty$ *for every $y \in Y$.*

4. $\int_0^\infty \|T(t)\|\,dt < \infty$.

Then 2, 3, *and* 4 *are equivalent assertions and imply* 1. *Moreover, if* $T(t)$ *is analytic, all assertions are equivalent.*

Proof (sketch of proof). Implications ($2 \Rightarrow 4$) and ($4 \Rightarrow 3$) are straightforward and ($3 \Rightarrow 2$) is obtained, e.g., from Theorem 4.4.1 of [45]. For ($2 \Rightarrow 1$), note that the C_0 semigroup $S(t) = \exp(\omega t)T(t)$, $t \geq 0$, is such that $\|S(t)\| \leq M$ and so $\rho(\mathcal{A}_s) \supset \{\lambda \in \mathbb{C} : \operatorname{Re}\lambda > 0\}$, where $\rho(\mathcal{A}_s)$ is the resolvent set of the infinitesimal generator $\mathcal{A}_s$ of $S(t)$ (see, e.g., [45]). Since $\mathcal{A} = \mathcal{A}_s - \omega I$ and $\mathfrak{D}(\mathcal{A}) = \mathfrak{D}(\mathcal{A}_s)$, it follows that $\rho(\mathcal{A}) = \rho(\mathcal{A}_s) - \omega$ and so $\rho(\mathcal{A}) \supset \{\lambda \in \mathbb{C} : \operatorname{Re}\lambda > -\omega\}$, i.e., $\sup\{\operatorname{Re}\lambda : \lambda \in \sigma(\mathcal{A})\} < 0$. Finally, if $T(t)$ is an analytic semigroup, the exponential decay implication ($1 \Rightarrow 2$) follows, e.g., from Theorem 4.4.3 of [45]. For details, see [4]. □

Corollary 4.4. *If Assertion* 2 *of Lemma* 4.3 *holds, then* $\beta = \frac{M}{\omega}$ *(respectively,* $\beta\,\|y\|$*) is an upper bound for Assertion* 4 *(respectively, Assertion* 3*).*

For arbitrary initial condition (x_0, θ_0), let us now consider the homogeneous dynamic system

$$\begin{cases} \dot{x}(t) = F_{\theta(t)}x(t), \quad t > 0, \\ x(0) = x_0,\ \theta(0) = \theta_0, \end{cases} \tag{4.4}$$

where $F = (F_1, F_2, \dots) \in \mathcal{H}_\infty^n$, and define $Q(t) = (Q_1(t), Q_2(t), \dots)$, $t \geq 0$, where

$$Q_i(t) = E[x(t)x(t)^* 1_{\{\theta(t)=i\}}] \in \mathbb{M}(\mathbb{C}^n)^+, \quad i \in \mathcal{S}. \tag{4.5}$$

Furthermore, for $H = (H_1, H_2, \dots) \in \mathcal{H}_1^n$, let us define the operator $\mathcal{D}$, with $\mathcal{D}(H) = (\mathcal{D}_1(H), \mathcal{D}_2(H), \dots)$, such that

$$\mathcal{D}_i(H) = F_i H_i + H_i F_i^* + \sum_{j=1}^{\infty} \lambda_{ji} H_j, \quad i \in \mathcal{S}. \tag{4.6}$$

Proposition 4.5. $\mathcal{D} \in Blt\,(\mathcal{H}_1^n)$.

Proof. The proof follows standard arguments concerning bounded linear transformations in Banach spaces. □

Proposition 4.6. *Let* $x(t)$ *be given by* (4.4) *with arbitrary* $F \in \mathcal{H}_\infty^n$. *Then* $Q(t)$, $t \geq 0$, *defined as in* (4.5), *belongs to* $\mathcal{H}_1^{n^+}$ *and satisfies the Banach space linear differential equation*

$$\begin{cases} \dot{Q}(t) = \mathcal{D}(Q(t)), \quad t > 0, \\ Q(0) = Q^0 \in \mathcal{H}_1^{n^+}, Q_i^0 = E[x_0 x_0^* 1_{\{\theta_0=i\}}], \quad i \in \mathcal{S}, \end{cases} \tag{4.7}$$

or, equivalently, the infinite countable set of interconnected linear differential equations

$$\begin{cases} \dot{Q}_i(t) = \mathcal{D}_i(Q(t)), \quad t > 0, \\ Q_i(0) = Q_i^0 = E[x_0 x_0^* 1_{\{\theta_0=i\}}], \quad i \in \mathcal{S}, \end{cases} \tag{4.8}$$

where $\mathcal{D}$ *is given as in* (4.6).

Proof. We use (4.4) and (4.5) and the fact that $Q_i(t) \in \mathbb{M}(\mathbb{C}^n)^+$ to obtain that $Q(t) \in \mathcal{H}_1^{n^+}$, $t \geq 0$, and that, with probability one,

$$x(t+\delta) = x(t) + F_{\theta(t)}x(t)\delta + o^n(\delta), \quad t, \delta \geq 0. \tag{4.9}$$

Furthermore, some algebraic manipulation and standard results with respect to the existence of limits lead us to $\frac{d^+Q(t)}{dt} = \lim_{\delta \downarrow 0} \frac{Q(t+\delta)-Q(t)}{\delta} = \mathcal{D}(Q(t))$, $t > 0$. We notice further that $\mathcal{D}$ is the infinitesimal generator of a C_0-semigroup, and from an argument of the proof of Theorem 1.2.4 of [45], the proposition follows. ∎

Let us now define, for $H = (H_1, H_2, \dots) \in \mathcal{H}_\infty^{n^+}$, the linear operators $\mathcal{E}(H) = (\mathcal{E}_1(H), \mathcal{E}_2(H), \dots)$ and $\mathcal{G}(H) = (\mathcal{G}_1(H), \mathcal{G}_2(H), \dots)$ as well as the nonlinear operator $\mathcal{T}(H) = (\mathcal{T}_1(H), \mathcal{T}_2(H), \dots)$, where, for each $i \in \mathcal{S}$,

$$\mathcal{E}_i(H) = \sum_{j=1, j\neq i}^{\infty} \lambda_{ij} H_j, \quad \mathcal{G}_i(H) = \mathcal{R}^{-1} B_i^* H_i, \tag{4.10}$$

and

$$\mathcal{T}_i(H) = \mathcal{Q} + A_i^* H_i + H_i A_i - H_i B_i \mathcal{R}^{-1} B_i^* H_i + \lambda_{ii} H_i + \mathcal{E}_i(H). \tag{4.11}$$

PROPOSITION 4.7. *The operator $\mathcal{E}$ maps $\mathcal{H}_\infty^{n+}$ into $\mathcal{H}_\infty^{n^+}$, $\mathcal{T}$ maps $\mathcal{H}_\infty^{n+}$ into $\{Z \in \mathcal{H}_\infty^n : Z^* = Z\}$, and $\mathcal{G}$ maps $\mathcal{H}_\infty^{n^+}$ into $\mathcal{H}_\infty^{n,m}$.*

Proof. The proof is straightforward from standard arguments concerning normed spaces. ∎

With the operators $\mathcal{T}$, $\mathcal{E}$, and $\mathcal{G}$ in hand, let us now define, for finite $T$and $L \in \mathcal{H}_\infty^{n^+}$ arbitrarily fixed, the Banach space Riccati differential equation

$$\begin{cases} \dot{S}^T(t) + \mathcal{T}(S^T(t)) = 0, & t \in (0, T), \\ S^T(T) = L, \end{cases} \tag{4.12}$$

where $S^T(t) = (S_1^T(t), S_2^T(t), \dots)$.

Equation (4.12) may be written as the following infinite countable set of interconnected Riccati differential equations:

$$\begin{cases} \dot{S}_i^T(t) + \mathcal{T}_i(S^T(t)) = 0, & t \in (0, T), \\ S_i^T(T) = L_i, & i \in \mathcal{S}. \end{cases} \tag{4.13}$$

Remark 4.8. Although it may appear, prima facie, that the above equivalence is a tautology, we would like to point out that it relies on the fact that the induced norm by $\mathcal{H}_\infty^n$ on the linear subspace $\{(0, \dots, 0, H, 0, 0, \dots),\ H \in \mathbb{M}(\mathbb{C}^n)\}$ coincides with the usual norm $\|\cdot\|$ of $\mathbb{M}(\mathbb{C}^n)$ ((4.12) ⇒ (4.13)) and that $(\dot{S}_1^T(t), \dot{S}_2^T(t), \dots) \in \mathcal{H}_\infty^n$ ((4.13) ⇒ (4.12)). (For more information on the matter, see [43].) To see that $(\dot{S}_1^T(t), \dot{S}_2^T(t), \dots) \in \mathcal{H}_\infty^n$, note that for $S^T(t) \in \mathcal{H}_\infty^{n^+}$, we have from Proposition 4.7 and the definition of $\mathcal{T}$ that $\mathcal{T}(S^T(t)) = (\mathcal{T}_1(S^T(t)), \mathcal{T}_2(S^T(t)), \dots) \in \mathcal{H}_\infty^n$. In turn, this and (4.13) yield $(\dot{S}_1^T(t), \dot{S}_2^T(t), \dots) \in \mathcal{H}_\infty^n$.

The proposition that follows shows that the solution of the Riccati differential equation given by (4.12) exists and is unique.

PROPOSITION 4.9. *For $T \in [0, \infty)$ and terminal data $L \in \mathcal{H}_\infty^{n^+}$, arbitrarily fixed, there exists a solution $S^T(\cdot) : [0, T] \to \mathcal{H}_\infty^{n^+}$ for (4.12), continuous for $t \in [0, T]$ and continuously differentiable for $t \in (0, T)$. Moreover, this solution is unique (within the class of solutions with these properties).*

Proof (sketch of proof). Besides existence and uniqueness, we have to show that the solution to (4.12) is positive in the sense defined in section 2. This led us to an approach inspired, in part, by that in [49] for the finite dimensional scenario, in conjunction with standard results from the literature on semigroup, evolution equation,

and the Volterra equation in Banach space (see, e.g., [45], [37]). So, we define the infinite dimensional square matrix $\mathfrak{S}(t) = \text{diag}(S_i^T(t))$, $t \in [s,T]$, and shape (4.12) as

$$\dot{\mathfrak{S}}^T(t) + \Psi(\mathfrak{S}(t)) = 0, \qquad \mathfrak{S}(T) = \mathcal{L}, \ \ t \in (s,T), \tag{4.14}$$

where $\Psi(\mathfrak{S}) = \overline{\mathcal{A}}^* \mathfrak{S} + \mathfrak{S}\overline{\mathcal{A}} + \Pi(\mathfrak{S}) + \mathfrak{Q} - \mathfrak{S}\mathcal{B}\mathfrak{R}^{-1}\mathcal{B}^*\mathfrak{S}$, $\overline{\mathcal{A}} = \mathcal{A} + \frac{1}{2}\text{diag}(\lambda_{ii} I_n)$, $\mathcal{A} = \text{diag}(A_i) \in \mathcal{W}_\infty^n$, $\mathcal{B} = \text{diag}(B_i) \in \mathcal{W}_\infty^{m,n}$, $\mathfrak{R}^{-1} = \text{diag}(\mathcal{R}^{-1}) \in \mathcal{W}_\infty^{n^+}$, $\mathfrak{Q} = \text{diag}(\mathcal{Q}) \in \mathcal{W}_\infty^{m^+}$, and $\mathcal{L} = \text{diag}(L_i) \in \mathcal{W}_\infty^{n^+}$. In addition, $\Pi : \mathcal{W}_\infty^n \to \mathcal{W}_\infty^n$ is a bounded linear operator with $\Pi = \mathfrak{D} \circ \chi \circ \mathfrak{D}^{-1}$, where, for every $H \in \mathcal{H}_\infty^n$, $\chi = (\chi_1, \chi_2, \dots) : \mathcal{H}_\infty^n \to \mathcal{H}_\infty^n$ is such that $\chi_i(H) = \sum_{j=1, j\neq i}^{\infty} \lambda_{ij} H_j$, and $\mathfrak{D} : \mathcal{H}_\infty^n \to \mathcal{W}_\infty^n$ is such that $\mathfrak{D}(H) = \text{diag}(H_i)$. We proceed ensuring that every element in $\mathcal{W}_\infty^{:,:}$ is well defined as an operator in $Blt\,(\mathcal{W}_\infty^{:,:}, \mathcal{W}_\infty^{:,:})$, namely, that $\mathcal{C} \in \mathcal{W}_\infty^{m,n}$ implies $\mathcal{C} \in Blt\,(\mathcal{W}_\infty^{m,q}, \mathcal{W}_\infty^{q,n})$, $\|\mathcal{C}\| \leq \|\mathcal{C}\|_{\mathcal{W}_\infty}$, and $\|\mathcal{C}\| = \|\mathcal{C}\|_{\mathcal{W}_\infty}$ for $n = m = q$. Now, in the spirit of the technique of [49], we define a version of the differential equation (4.14), which is linear in $\mathfrak{S}$, and we obtain its Volterra equivalent. Picard's successive approximation method and the positiveness of Π (in that $\Pi(H) \geq 0$ if $H \geq 0$) give us that the unique solution to the Volterra equation is positive semidefinite, i.e., it belongs to $\mathcal{W}_\infty^{n^+}$. An important step now is to build a sequence of solutions $\mathfrak{S}_i(t)$ to the corresponding set of Volterra equations equipped with parameters $\mathcal{K}_1(t)$ (arbitrary) and $\mathcal{K}_i(t) = \mathfrak{R}^{-1}\mathcal{B}^*\mathfrak{S}_{i-1}(t)$, $i = 2, 3, \dots$, in that order. Then, exploring (i) a property of the minimum, (ii) a comparison theorem, and (iii) a standard result on semigroup theory, and applying the dominated convergence theorem, we show that, for each t, $\{\mathfrak{S}_i(t)\}$ is a monotone nonincreasing sequence of positive semidefinite elements that converges to a solution of (4.14). A Lipschitz condition gives us that this positive solution is unique. For details, see [4], [27]. □

5. The finite-time optimal control problem. Referring to the finite-time optimal control problem defined in section 3, we have from system (3.1) that $\{x(t), \theta(t)\}_{t\in[s,T]}$, is a Markov process evolving in $(\mathbb{C}^n, \mathcal{S})$ with sample paths that are continuous from the right. From this fact, and bearing in mind an argument from [1, p. 37], we have that $\{x(t), \theta(t)\}_{t\in[s,T]}$ has a stochastically continuous transition probability and consequently is characterized uniquely in terms of its infinitesimal generator, as follows. Let $\mathbb{B}(\mathcal{X}, \mathbb{R})$, $\mathcal{X} = ([s,T] \times \mathbb{C}^n \times \mathcal{S})$, be the Banach space of all bounded real valued measurable functions g, defined on $\mathcal{X}$, equipped with the norm $\|g\| := \sup\{|g(z)| : z \in \mathcal{X}\}$. The semigroup of linear Markov transition operators $T(h) : \mathbb{B}(\mathcal{X}, \mathbb{R}) \to \mathbb{B}(\mathcal{X}, \mathbb{R})$, $h \in [0, T-t]$, which characterizes $\{x(t), \theta(t)\}_{t\in[s,T]}$, is given by

$$(T(h)g)\,(t, x(t), \theta(t)) := E_{x(t),\theta(t)}[g(t+h, x(t+h), \theta(t+h))] \tag{5.1}$$

for every $(t, x(t), \theta(t)) \in \mathcal{X}$.

By the infinitesimal generator of a family of transition probabilities of the Markov process $\{x(t), \theta(t)\}_{t\in[s,T]}$, we mean the operator $\mathcal{L} : \mathfrak{D}(\mathcal{L}) \mapsto \mathbb{B}(\mathcal{X}, \mathbb{R})$, such that

$$(\mathcal{L}g)\,(t, x(t), \theta(t)) = \lim_{h \downarrow 0} \frac{(T(h)g)\,(t, x(t), \theta(t)) - (T(0)g)\,(t, x(t), \theta(t))}{h} \tag{5.2}$$

for every $(t, x(t), \theta(t)) \in \mathcal{X}$ and $g \in \mathfrak{D}(\mathcal{L})$ with $(T(h)g)\,(t, x(t), \theta(t))$ defined as in (5.1), where $\mathfrak{D}(\mathcal{L})$ is the set of functions $g \in \mathbb{B}(\mathcal{X}, \mathbb{R})$ for which the above limit exists. The limit required is the uniform limit with respect to $\mathcal{X}$. Furthermore, Dynkin's

formula reads as (see [32])

$$\begin{aligned} &g(s,x(s),\theta(s)) - E_{x(s),\theta(s)}\left[g(t,x(t),\theta(t))\right] \\ &\qquad = E_{x(s),\theta(s)}\left[\int_s^t -\left(\mathcal{L}g\right)(r,x(r),\theta(r))dr\right] \end{aligned} \tag{5.3}$$

for $g \in \mathfrak{D}(\mathcal{L})$. (Notice that, since all terms above are measurable and bounded, the integral and expectations above exist and are finite.)

Bearing in mind now the decomplexification concept in section 2, we get, in our scenario, a further derivation for the infinitesimal generator of the Markov process $\{x(t),\theta(t)\}_{t\in[s,T]}$. For this, let us start with the following proposition.

PROPOSITION 5.1. *For any continuous bounded function $g{:}\mathcal{X} \mapsto \mathbb{R}$, we have that*

$$\lim_{h\downarrow 0}\left(T(h)g\right)(t,x(t),\theta(t)) = g(t,x(t),\theta(t)). \tag{5.4}$$

Proof. The proof follows, mutatis mutandis, from [29] . □

We now define $C_b^{1,\mathrm{R}}(\mathcal{X})$ as the set of all functions $g \in \mathbb{B}(\mathcal{X},\mathbb{R})$ such that, for each $i \in \mathcal{S}$, the decomplexification ${}^{\mathrm{R}}g$ is (Fréchet-) continuously differentiable in the variables $t \in (s,T)$ and ${}^{\mathrm{R}}x \in \mathbb{R}^{2n}$.

PROPOSITION 5.2. *Consider system* (3.1) *with $u \in \mathcal{U}^{s,T}$, and let $g \in C_b^{1,\mathrm{R}}(\mathcal{X})$. Then $g \in \mathfrak{D}(\mathcal{L})$, and the infinitesimal operator* (5.2) *reads as*

$$\begin{aligned} \left(\mathcal{L}^u g\right)(t,x(t),\theta(t)) &= \frac{\partial}{\partial t}g(t,x(t),\theta(t)) + \nabla_{{}^{\mathrm{R}}x}\,{}^{\mathrm{R}}g(t,{}^{\mathrm{R}}x(t),\theta(t))'\,{}^{\mathrm{R}}(A_{\theta(t)}x(t) \\ &\quad + B_{\theta(t)}u(t)) + \sum_{j=1}^{\infty} g(t,x(t),j)\lambda_{\theta(t)j} \end{aligned} \tag{5.5}$$

for any $(t,x(t),\theta(t)) \in ((s,T)\times\mathbb{C}^n\times\mathcal{S})$.

Proof. The proof follows from (5.2), bearing in mind (3.1), (3.3), (5.1), and Lemma 7.1. That $g \in \mathfrak{D}(\mathcal{L})$ follows along the same lines of [21, p. 159]. □

Remark 5.3. Actually, $\mathfrak{D}(\mathcal{L})$ now is the set $C_b^{1,\mathrm{R}}(\mathcal{X})$ (see [1, p. 38]).

With $\mathcal{X}_o = ((s,T)\times X_o\times\mathcal{S})$ and X_o an arbitrary open and bounded set in $\mathbb{C}^n$, let us define $C^{1,\mathrm{R}}(\mathcal{X}_o)$ as the set of all real valued measurable functions g, well-defined on $\bar{\mathcal{X}}_o$ (the closure of $\mathcal{X}_o$), such that, for each $i \in \mathcal{S}$, the decomplexification ${}^{R}g$ is (Fréchet-) continuously differentiable in the variables $t \in (s,T)$ and ${}^{\mathrm{R}}x \in {}^{\mathrm{R}}X_o$. In this case, mutatis mutandis, as in [23, Ch. V, Lemma 5.1], the integral and expectations in the above equations exist and are finite, so that Dynkin's formula (5.3) may be applied. This is the setting of our next proposition.

PROPOSITION 5.4. *Let $g \in C^{1,\mathrm{R}}(\mathcal{X}_o)$ be such that*

$$g(t,x,i) = x^* S_i^T(t)x, \tag{5.6}$$

where $t \mapsto S^T(t) = (S_1^T(t), S_2^T(t)\dots) \in \mathcal{H}_\infty^{n^+}$ satisfies the Banach space Riccati differential equation given by (4.12) *with terminal condition $S^T(T) = L \in \mathcal{H}_\infty^{n^+}$. Then, for system* (3.1) *with $u \in \mathcal{U}^{s,T}$, the infinitesimal operator $\mathcal{L}^u$ is given by*

$$\begin{aligned} \left(\mathcal{L}^u g\right)(t,x(t),\theta(t)) &= x(t)^*\{-\mathcal{Q} + S_{\theta(t)}^T(t)B_{\theta(t)}\mathcal{R}^{-1}B_{\theta(t)}^* S_{\theta(t)}^T(t)\}x(t) \\ &\quad + u(t)^* B_{\theta(t)}^* S_{\theta(t)}^T(t)x(t) + x(t)^* S_{\theta(t)}^T(t)B_{\theta(t)}u(t) \end{aligned} \tag{5.7}$$

for any $(t, x(t), \theta(t)) \in ((s,T) \times X_o \times \mathcal{S})$. *Furthermore, Dynkin's formula* (5.3) *reads as*

$$\begin{aligned} & x(s)^* S^T_{\theta(s)}(s)x(s) - E_{x(s),\theta(s)}[x(t)^* S^T_{\theta(t)}(t)x(t)] \\ & = E_{x(s),\theta(s)} \left[\int_s^t x(r)^* \mathcal{Q} x(r) - x(r)^* S^T_{\theta(r)}(r) B_{\theta(r)} \mathcal{R}^{-1} B^*_{\theta(r)} S^T_{\theta(r)}(r) x(r) \right. \\ & \qquad \left. - u(r)^* B^*_{\theta(r)} S^T_{\theta(r)}(r) x(r) - x(r)^* S^T_{\theta(r)}(r) B_{\theta(r)} u(r) dr \right]. \end{aligned} \tag{5.8}$$

Proof. Bearing in mind [23, Chap. V, Lemma 5.1], we use (5.5) as well as Lemma 7.4. □

PROPOSITION 5.5. *The above result also holds if we consider Proposition* 5.4 *with* g *now defined on the hole domain* $\mathcal{X}$.

Proof. Note that g trivially satisfies a polynomial growth condition, namely, $\|g(t,x,i)\| \le c_1(1 + \|x\|^k)$ for every $(t,x,i) \in \mathcal{X}$ and some constants c_1 and k. Also note that g with $S^T(t)$ given by (4.12) is continuous on $\bar{\mathcal{X}}_o$. These facts, together with Lemma 7.7 in the Appendix, fulfill the conditions given in [23, Ch. V, Theorem 5.1] so that, along the same lines as in the proof of this theorem, Dynkin's formula (5.3) may still be applied (the integral and expectations therein exist) and the proposition follows. □

We now derive a cost expression for an arbitrary $u \in \mathcal{U}^{s,T}$ and the optimal solution for the finite-time case.

PROPOSITION 5.6. *For arbitrary* $u \in \mathcal{U}^{s,T}$, *the cost defined in* (3.5) *reads as follows.*

$$\begin{aligned} \mathcal{J}_{[s,T],L}(\vartheta_s, u) = E \Bigg[& x(s)^* S^T_{\theta(s)}(s) x(s) \\ & + \int_s^T \left\| B^*_{\theta(r)} S^T_{\theta(r)}(r) x(r) + \mathcal{R} u(r) \right\|^2_{\mathcal{R}^{-1}} dr \Bigg] \end{aligned} \tag{5.9}$$

with $S^T(r) \in \mathcal{H}^{n^+}_\infty$ *(uniquely) satisfying* (4.12).

Proof. From (3.5), we have that

$$\begin{aligned} \mathcal{J}_{[s,T],L}(\vartheta_s, u) = E \Bigg[& E_{x(s),\theta(s)} \left[\int_s^T (x(r)^* \mathcal{Q} x(r) + u(r)^* \mathcal{R} u(r)) dr \right] \\ & + E_{x(s),\theta(s)}[x(T)^* L_{\theta(T)} x(T)] \Bigg]. \end{aligned} \tag{5.10}$$

Now, from Proposition 5.5, setting $t = T$ in Dynkin's formula (5.8), we get

$$\begin{aligned} \mathcal{J}_{[s,T],L}(\vartheta_s, u) = E \Bigg[& x(s)^* S^T_{\theta(s)}(s) x(s) + E_{x(s),\theta(s)} \left[\int_s^T (u(r)^* \mathcal{R} u(r) \right. \\ & + x(r)^* S^T_{\theta(r)}(r) B_{\theta(r)} \mathcal{R}^{-1} B^*_{\theta(r)} S^T_{\theta(r)}(r) x(r) \\ & \left. + u(r)^* B^*_{\theta(r)} S^T_{\theta(r)}(r) x(r) + x(r)^* S^T_{\theta(r)}(r) B_{\theta(r)} u(r)) dr \right] \Bigg]. \end{aligned} \tag{5.11}$$

Now, since $\mathcal{R} = \mathcal{R}^*$, the expression under integration may be written as

$$u(r)^*\mathcal{R}^*\mathcal{R}^{-1}\mathcal{R}u(r) + x(r)^*S^T_{\theta(r)}(r)B_{\theta(r)}\mathcal{R}^{-1}B^*_{\theta(r)}S^T_{\theta(r)}(r)x(r)$$
$$+ (\mathcal{R}u(r))^*\mathcal{R}^{-1}B^*_{\theta(r)}S^T_{\theta(t)}(r)x(r) + x(r)^*S^T_{\theta(r)}(r)B_{\theta(r)}\mathcal{R}^{-1}\mathcal{R}u(r),$$

and, denoting $y = B^*_{\theta(r)}S^T_{\theta(r)}(r)x(r)$ and $w = \mathcal{R}u(r)$, it becomes

$$w^*\mathcal{R}^{-1}w + y^*\mathcal{R}^{-1}y + w^*\mathcal{R}^{-1}y + y^*\mathcal{R}^{-1}w = (y+w)^*\mathcal{R}^{-1}(y+w)$$
$$= \|y+w\|^2_{\mathcal{R}^{-1}} = \left\|B^*_{\theta(r)}S^T_{\theta(r)}(r)x(r) + \mathcal{R}u(r)\right\|^2_{\mathcal{R}^{-1}}.$$

Thus substitution in (5.11) yields

$$\mathcal{J}_{[s,T],L}(\vartheta_s, u) = E\left[x(s)^*S^T_{\theta(s)}(s)x(s) + \int_s^T \left\|B^*_{\theta(r)}S^T_{\theta(r)}(r)x(r) + \mathcal{R}u(r)\right\|^2_{\mathcal{R}^{-1}} dr\right],$$

(5.12)

which completes the proof.

Remark 5.7. Note that, instead of Proposition 5.5, we could also use Proposition 5.4 alone to deduce (5.11), bearing in mind that the process $\{x\}$ satisfies the differential equation (3.1), with $u \in \mathcal{U}^{s,T}$, and $E[\|x(r)\|^k]$ is bounded for each $k > 0$ and $s \le r \le T$ (see [23, p. 156]). □

PROPOSITION 5.8. *The optimal control in the admissible class $\mathcal{U}^{s,T}$ is given by*

$$\hat{u}^T(t) = -G^T_{\theta(t)}(t)x(t), \tag{5.13}$$

where $G^T(t) = (G^T_1(t), G^T_2(t), \dots) = \mathcal{G}(S^T(t)) \in \mathcal{H}^{n,m}_\infty$ ($G^T_i(t) = \mathcal{R}^{-1}B^*_iS^T_i(t)$) with $S^T(t) \in \mathcal{H}^{n^+}_\infty$ (uniquely) satisfying (4.12), *$t \in [s,T]$. Furthermore, the minimum cost reads as follows:*

$$\mathcal{J}_{[s,T],L}(\vartheta_s, \hat{u}^T) = \inf_{u\in\mathcal{U}^{s,T}} \mathcal{J}_{[s,T],L}(\vartheta_s, u) = E[x(s)^*S^T_{\theta(s)}(s)x(s)]. \tag{5.14}$$

Proof. The proof is immediate from (5.12). □

6. The infinite-time optimal control problem. In this section conditions for solving the infinite horizon optimal control problem are established. Parallel to the classical LQ problem, when dealing with the infinite-time optimal control problem(infinite horizon) two structural concepts turn out to be essential: SS and SD, defined as follows.

DEFINITION 6.1 (SS). *We say that the system (A, B, Λ) is SS if there exists $G \in \mathcal{H}^{n,m}_\infty$ such that for any joint initial distribution ϑ_0, we have that*

$$\int_0^\infty E[\|x(t)\|^2]dt < \infty, \tag{6.1}$$

where $x(t)$ is given by (3.1) *with $t \ge 0$ and $u(t) = -G_{\theta(t)}x(t)$, i.e.,*

$$\dot{x}(t) = F_{\theta(t)}x(t), \quad t > 0, \tag{6.2}$$

with $F_{\theta(t)} = A_{\theta(t)} - B_{\theta(t)}G_{\theta(t)}$. In this case we say that (6.2) *is stochastically stable and G stabilizes (A, B, Λ).*

DEFINITION 6.2 (SD). *Consider* $C = (C_1, C_2, \dots) \in \mathcal{H}_\infty^{n,r}$. *We say that the system* (C, A, Λ) *is SD if there exists* $K \in \mathcal{H}_\infty^{r,n}$ *such that for any joint initial distribution* ϑ_0, *we have that*

$$\int_0^\infty E[\|x(t)\|^2]dt < \infty, \tag{6.3}$$

where $x(t)$ *is given by*

$$\dot{x}(t) = F_{\theta(t)}x(t), \quad t > 0, \tag{6.4}$$

with $F_{\theta(t)} = A_{\theta(t)} - K_{\theta(t)}C_{\theta(t)}$.

Remark 6.3. The system (C, A, Λ) refers to

$$\begin{cases} \dot{r}(t) = A_{\theta(t)}r(t), \quad t > 0, \\ y(t) = C_{\theta(t)}r(t), \\ r(0) = x_0,\ \theta(0) = \theta_0, \end{cases} \tag{6.5}$$

and $x(t)$, given by (6.4), assigns the error of a K-based estimate of $r(t)$. We say then that this estimate detects $r(\cdot)$ in the sense of (6.3) and that K turns (C, A, Λ) detectable.

Remark 6.4 (SS versus MSS.). It has been shown in [22] that MSS and SS are equivalent if the Markov chain has a finite state space. For the countably infinite case, however, this equivalence is no longer true, as we can notice from the counterexample that follows. We denote $-b_{\theta(t)} = A_{\theta(t)}$ and consider the infinite-time scalar version of the random differential equation (3.1) with $u \equiv 0$, $\{\theta\}$ a Poisson process with parameter λ, and $b_i = \frac{\lambda}{2}\ln\left(\frac{i+1}{i}\right)$, $i \in \mathcal{S}$. In this case (see [11], [48]) the discontinuities of the sample paths are ordinary jumps with probability one, the sequence of jump times $\tau_0 = 0 < \tau_1 < \tau_2 \dots$ is infinite and such that $\lim_{n\to\infty}\tau_n = \infty$ almost surely (a.s.), and the sojourn times $\tau_n - \tau_{n-1}$, $n \in \mathbb{N}$, are independent r.v.'s with average $E[\tau_n - \tau_{n-1}] = 1/\lambda$ and density function given by $\lambda e^{-\lambda s}$, $s \geq 0$. Furthermore, the trajectories of the state process $\{x\}$ are decreasing and connected solution pieces of (3.1) given by $x(t) = a_n \exp(\ -b_{n+\theta_0-1}(\ t - \tau_{n-1}))$ a.s., $\tau_{n-1} \leq t < \tau_n$, $n \in \mathbb{N}$, where $a_1 = x_0$, and, from continuity, $a_n = x_0 \exp(\ -\sum_{i=1}^{n-1} b_{i+\theta_0-1}\ (\tau_i - \tau_{i-1}))$, $n = 2, 3, \dots$.

Now, for deterministic $x(0) = x_0 \in \mathbb{R}^n$, $x_0 \neq 0$, and $\theta(0) = \ell \in \mathcal{S}$, we have, using the Jensen inequality and Fubini, that

$$\int_0^\infty E[x(t)^2]dt = E\sum_{n=1}^\infty \int_{\tau_{n-1}}^{\tau_n^-} x(t)^2 dt \geq x_0^2 \sum_{n=1}^\infty \left(\frac{\theta_0}{n+\theta_0}\exp\left\{\int_0^\infty (\ln s)\lambda e^{-\lambda s}ds\right\}\right) = \infty.$$

By its turn, we have that $x(\tau_n) = a_{n+1}$ a.s., so that

$$\begin{aligned} E_{x_0,\theta_0}[x(\tau_n)^2] &= x_0^2 \prod_{i=1}^n \left\{\int_0^\infty \exp(-2b_{i+\theta_0-1}s).\lambda\exp(-\lambda s)ds\right\} \\ &= x_0^2\left(\prod_{i=1}^n\left(1 + \ln\left(\frac{i+\theta_0}{i+\theta_0-1}\right)\right)\right)^{-1} \to 0 \text{ as } n \to \infty. \end{aligned}$$

Moreover, since almost all trajectories of $\{x\}$ are decreasing, we have that $\lim_{t\to\infty} x(t)^2 = \lim_{n\to\infty} x(\tau_n)^2$ a.s.. Hence, using the Lebesgue monotone convergence theorem, we can write that $\lim_{t\to\infty} E[x(t)^2] = E[\lim_{n\to\infty} E_{x_0,\theta_0}[x(\tau_n)^2]] = 0$ for any joint distribution of (x_0, θ_0).

An important tool for solving our optimal control problem is an *equivalence lemma* which draws the connection between the above concepts and the spectrum of a certain infinite dimensional linear operator. We start with the following auxiliary proposition.

PROPOSITION 6.5. *Define $F = (F_1, F_2, \dots)$, where, referring to the SS (respectively, the SD) case, $F_i = A_i - B_iG_i$ (respectively, $F_i = A_i - K_iC_i$), $i \in \mathcal{S}$. Then $F \in \mathcal{H}_\infty^n$.*

Proof. See [4] for details. □

Now we have the equivalence lemma.

LEMMA 6.6. *Consider the operator $\mathcal{D}$ given by (4.6), some $G = (G_1, G_2, \dots) \in \mathcal{H}_\infty^{n,m}$, $C = (C_1, C_2, \dots) \in \mathcal{H}_\infty^{n,r}$, and $K = (K_1, K_2, \dots) \in \mathcal{H}_\infty^{r,n}$. Then the following hold.*

(E1) *The system (A, B, Λ) is SS with stabilizing G if and only if*

$$\sup\{\operatorname{Re}\lambda : \lambda \in \sigma(\mathcal{D})\} < 0, \quad F_i = A_i - B_iG_i, \quad i \in \mathcal{S}. \tag{6.6}$$

(E2) *Similarly, the system (C, A, Λ) is SD with K turning (C, A, Λ) detectable if and only if*

$$\sup\{\operatorname{Re}\lambda : \lambda \in \sigma(\mathcal{D})\} < 0, \quad F_i = A_i - K_iC_i, \quad i \in \mathcal{S}. \tag{6.7}$$

Proof. In order to carry out indistinctly the proof for (E1) or (E2), we shall consider $\mathcal{D}$ and (4.4) equipped either with $F_i = A_i - B_iG_i$ or with $F_i = A_i - K_iC_i$.

$\Rightarrow$*(Sufficiency).* We have that $Q(t)$ given by (4.5), with $x(t)$ satisfying (4.4), is continuous and continuously differentiable in $\mathcal{H}_1^n$. Also, from Proposition 4.6, $Q(t)$ satisfies (4.7). So, using Proposition 4.1, $Q(t) = T(t)Q^0$, $t \geq 0$, where $T(t)$ is the uniformly continuous semigroup generated by $\mathcal{D}$. Now, $\int_0^\infty \left\|T(t)Q^0\right\|_1 dt < \infty$ (see Lemma 4.3) and, since $E[\|x(t)\|^2] = tr(\sum_{i=1}^\infty E[x(t)x(t)^* 1_{\{\theta(t)=i\}}]) \leq n \|Q(t)\|_1$, it follows that $\int_0^\infty E[\|x(t)\|^2]dt < \infty$ for every initial condition r.v. (x_0, θ_0).

$\Leftarrow$ *(Necessity).* From the hypothesis, $\int_0^\infty E[\|x(t)\|^2]dt < \infty$ for every initial condition r.v. (x_0, θ_0) and $x(t)$ given by (4.4). This implies $\int_0^\infty \|Q(t)\|_1 dt < \infty$, where $Q(t)$ is given by (4.5). (Notice that $\|Q(t)\|_1 \leq \sum_{i=1}^\infty E[\|x(t)x(t)^*\| 1_{\{\theta(t)=i\}}] \leq E[\|x(t)\|^2]$.) Also, $Q(t)$ is continuous and continuously differentiable and, from Proposition 4.6, satisfies (4.7). So, using Proposition 4.1, we have that $Q(t) = T(t)Q^0$, $t \geq 0$, where $T(t)$ is the uniformly continuous semigroup generated by $\mathcal{D}$. Hence $\int_0^\infty \left\|T(t)Q^0\right\|_1 dt < \infty$ for every $Q^0 \in \mathcal{H}_1^{n^+}$. (This is justified since, for any $Q^0 \in \mathcal{H}_1^{n^+}$, we can always find r.v.'s x_0 and θ_0 that, subject to (4.5), produce Q^0.) Now, since our variables are defined in the field of the complex numbers, we may appeal to the Cartesian decomposition of Remark 2.5 so that there exist X^+, X^-, Y^+, and Y^- in $\mathcal{H}_1^{n^+}$ such that, for every $Q^0 \in \mathcal{H}_1^n$, $\int_0^\infty \|T(t)Q^0\|_1 dt = \int_0^\infty \|T(t)\{(X^+ - X^-) + \iota\,(Y^+ - Y^-)\}\|_1 dt < \infty$. The result follows from Lemma 4.3. □

Let us now turn our attention to the infinite-time optimal control problem. Since in this case there is no fixed "time horizon," we expect, parallel to the classical LQ problem, that the minimum cost (see (5.14)) should not depend on the starting time s whenever we preserve the same initial condition r.v.'s $(x(s), \theta(s))$. This suggests finding a constant function $[0, T] \ni t \mapsto S^T(t) = S$ satisfying (4.12) with terminal condition $S^T(T) = S$, a "matched" solution for the finite-time problem in the sense that it simulates the infinite-time case. Now we may notice that S satisfies (4.12) with terminal condition $S^T(T) = S$ if and only if it satisfies the ICARE $\mathcal{T}(S) = 0$. From this *liaison*, we should expect that the solution of our infinite-time problem

should hinge on the solution of the ICARE. This is indeed the case, as we shall show throughout the following propositions.

PROPOSITION 6.7. *$[0,T] \ni t \mapsto S^T(t) = S \in \mathcal{H}_1^n$ satisfies*

$$\begin{cases} \dot{S}^T(t) + \mathcal{T}(S^T(t)) = 0, \quad t \in (0,T), \\ S^T(T) = S \end{cases} \tag{6.8}$$

if and only if S satisfies $\mathcal{T}(S) = 0$.

Proof. The proof is a straightforward exercise. □

DEFINITION 6.8. *We say that $S = (S_1, S_2, \dots)$ is a positive semidefinite solution to the ICARE if $S \in \mathcal{H}_\infty^{n^+}$ and satisfies the ICARE*

$$\mathcal{T}(S) = 0. \tag{6.9}$$

Furthermore, S is a stabilizing solution to the ICARE if it is a positive semidefinite solution and $G = (G_1, G_2, \dots) = \mathcal{G}(S)$ stabilizes (A, B, Λ).

Proposition 6.9 below provides sufficient conditions for the existence of a solution to (6.9).

PROPOSITION 6.9. *Suppose (A, B, Λ) is SS. Then, for $L = 0 \in \mathcal{H}_\infty^{n^+}$, the value $S_i^T(0)$ of the (unique) solution $S^T(t) \in \mathcal{H}_\infty^{n^+}$, $t \in [0,T]$, to (4.12), converges to some $S_i \in \mathbb{M}(\mathbb{C}^n)^+$ as $T \to \infty$ for each $i \in \mathrm{S}$. Furthermore, $S = (S_1, S_2, \dots)$ belongs to $\mathcal{H}_\infty^{n^+}$ and satisfies the ICARE (6.9).*

Proof. From Proposition 4.9, the solution to (4.12) indeed exists and is unique for $T \in (0,\infty)$ and $L = 0 \in \mathcal{H}_\infty^{n^+}$. Let us now consider the finite-time control problem of section 5 with $s = 0$ and initial conditions $x(0) = x$ and $\theta(0) = i$, x and i deterministic and arbitrary in $\mathbb{C}^n$ and $\mathcal{S}$, respectively, time horizons $T_1, T_2 \in (0,\infty)$, $T_1 < T_2$, and terminal cost conditions $S^{T_1}(T_1) = S^{T_2}(T_2) = L = 0$. In this case, applying the definition (3.5) in (5.14), we have that

$$\begin{aligned} x^* S_i^{T_2}(0) x &\geq \min_{u \in \mathcal{U}^{T_2}} E\left[\int_0^{T_1} \left\|\mathcal{Q}^{1/2} x(t)\right\|^2 + \left\|\mathcal{R}^{1/2} u(t)\right\|^2 dt\right] \\ &\quad + \min_{u \in \mathcal{U}^{T_2}} E\left[\int_{T_1}^{T_2} \left\|\mathcal{Q}^{1/2} x(t)\right\|^2 + \left\|\mathcal{R}^{1/2} u(t)\right\|^2 dt\right] \\ &\geq \min_{u \in \mathcal{U}^{T_1}} E\left[\int_0^{T_1} \left\|\mathcal{Q}^{1/2} x(t)\right\|^2 + \left\|\mathcal{R}^{1/2} u(t)\right\|^2 dt\right] = x^* S_i^{T_1}(0) x, \end{aligned} \tag{6.10}$$

and since the above expression holds for every $x \in \mathbb{C}^n$,

$$0 \leq S_i^{T_1}(0) \leq S_i^{T_2}(0) \tag{6.11}$$

for every $T_1, T_2 \in (0,\infty)$, $T_1 < T_2$, and $i \in \mathcal{S}$. Let us assume for the moment that, for every $T \in (0,\infty)$ and $i \in \mathcal{S}$,

$$S_i^T(0) \leq dI \tag{6.12}$$

for some constant d which does not depend on i and T. This together with (6.11) allows us to apply Lemma 7.8 in the appendix, which proves the two first assertions of the proposition.

We shall now show that S satisfies $\mathcal{T}(S) = 0$. Bearing in mind Proposition 4.9 and Lemma 7.10 and arbitrarily fixing $a > 0$ and $T \in (a, \infty)$, let $S^T(t)$, $t \in [0, T]$, and $S^{T,-a}(t)$, $t \in [-a, T-a]$, respectively, be the solution to

$$\begin{cases} \dot{S}^T(t) + \mathcal{T}(S^T(t)) = 0, & t \in (0, T), \\ S^T(T) = 0 \end{cases} \tag{6.13}$$

and to

$$\begin{cases} \dot{S}^{T,-a}(t) + \mathcal{T}(S^{T,-a}(t)) = 0, & t \in (-a, T-a), \\ S^{T,-a}(T-a) = 0. \end{cases} \tag{6.14}$$

Since $S_i^T(0) \to S_i$ as $T \to \infty$, we have that $S_i^{T-a}(0) \to S_i$ as $T \to \infty$. Renaming T by $T - a$ in (6.13), it is clear that

$$S_i^{T,-a}(t) = S_i^{T-a}(t), \quad t \in [0, T-a], \tag{6.15}$$

so that $S_i^{T,-a}(0) \to S_i$ as $T \to \infty$. Now, from Lemma 7.10, we have that

$$S_i^T(a) = S_i^{T,-a}(0), \quad i \in \mathcal{S}. \tag{6.16}$$

Hence

$$\lim_{T\to\infty} S_i^T(a) = S_i, \quad i \in \mathcal{S}. \tag{6.17}$$

Rewriting (6.11) and (6.12) as $0 \le S_i^{T_1-a}(0) \le S_i^{T_2-a}(0)$ and $S_i^{T-a}(0) \le dI$, respectively, we have, from (6.15) and (6.16), that $0 \le S_i^{T_1}(a) \le S_i^{T_2}(a)$ and $S_i^T(a) \le dI$ for every $T, T_1, T_2 \in (a, \infty)$, $T_1 < T_2$, and $i \in \mathcal{S}$.

Now, from these two expressions in conjunction with (6.17), the fact that $S = (S_1, S_2, \dots) \in \mathcal{H}_\infty^{n^+}$, and assuming (6.12), we get via Lemma 7.9 of the appendix that

$$\lim_{T\to\infty} \mathcal{T}(S^T(a)) = \mathcal{T}(S). \tag{6.18}$$

Let us now define, for $(0, T) \ni t \mapsto S_i^T(t)$, the differential operator D such that $S_i^T(\cdot) \mapsto DS_i^T(\cdot) = \dot{S}_i^T(\cdot)$. From (6.17) and since $a > 0$ is arbitrary, we have that $\lim_{T\to\infty} S_i^T(t) = S_i$, $t \in (0, T)$. Therefore, from the continuity of D and viewing S_i as a constant function of t, we obtain $\lim_{T\to\infty} \dot{S}_i^T(t) = \lim_{T\to\infty} DS_i^T(t) = D(S_i) = 0$, $i \in \mathcal{S}$. Choosing $t = a$ in the above expression and in (6.13), we obtain

$$\lim_{T\to\infty} \dot{S}^T(a) = 0 \tag{6.19}$$

and

$$\dot{S}^T(a) + \mathcal{T}(S^T(a)) = 0. \tag{6.20}$$

Passing the above expression to the limit and using (6.18) and (6.19), we have that

$$0 = \lim_{T\to\infty} \dot{S}^T(a) + \lim_{T\to\infty} \mathcal{T}(S^T(a)) = \mathcal{T}(S). \tag{6.21}$$

Finally, let us show that $S_i^T(0) \le dI$, $i \in \mathcal{S}$, $T \in (0, \infty)$. This follows from the hypothesis that (A, B, Λ) is SS. Indeed, Definition 6.1 says that, in this case, there

exists $G \in \mathcal{H}_\infty^{m,n}$, which stabilizes (A, B, Λ). So let us define the stabilizing control policy $\overline{u}(t) = -G_{\theta(t)}x(t)$, $t \geq 0$, so that the dynamic (3.1) with $t \geq 0$ reads as $\dot{x}(t) = F_{\theta(t)}x(t)$, $t > 0$, with $F_{\theta(t)} = A_{\theta(t)} - B_{\theta(t)}G_{\theta(t)}$. We shall be interested in the specialized initial condition $x(0) = x$ and $\theta(0) = i$, where x and i are deterministic and arbitrary in $\mathbb{C}^n$ and $\mathcal{S}$, respectively.

From Lemma 6.6, we have that $\sup\{\mathrm{Re}\,\lambda : \lambda \in \sigma(\mathcal{D})\} < 0$ with $\mathcal{D}$ given by (4.6). Recalling that $\mathcal{D}$ generates a uniformly continuous semigroup, say, $T(t)$, we may invoke the equivalence among assertions 1, 2, and 3 of Lemma 4.3, as well as Corollary 4.4, so that, for some constant $\beta \in (0, \infty)$,

$$\int_0^\infty \left\|T(t)Q^0\right\|_1 dt \leq \beta \left\|Q^0\right\|_1 < \infty \tag{6.22}$$

for every $Q^0 \in \mathcal{H}_1^n$. Now, from semigroup theory, $Q(t) = T(t)Q^0, t \geq 0$, is the solution to the differential equation

$$\begin{cases} \dot{Q}(t) = \mathcal{D}(Q(t)), \quad t > 0, \\ Q(0) = Q^0 = (Q_1^0, Q_2^0, \dots) \in \mathcal{H}_1^n, \end{cases}$$

which, from Proposition 4.6, is expressed by (4.5) whenever the initial condition is such that

$$Q_i^0 = E[x(0)x(0)^* 1_{\{\theta(0)=i\}}] = xx^* 1_{\{\theta(0)=i\}}, \quad i \in \mathcal{S}. \tag{6.23}$$

Hence (6.22) reads as

$$\int_0^\infty \|Q(t)\|_1 \, dt \leq \beta \left\|Q^0\right\|_1 < \infty \tag{6.24}$$

for Q^0 satisfying (6.23). Now we have that $E[\|x(t)\|^2] \leq n \|Q(t)\|_1$and $\|Q^0\|_1 \leq E[\|x(0)\|^2] = \|x\|^2$, so that (6.24) becomes

$$\int_0^\infty E[\|x(t)\|^2]dt \leq n\beta \|x\|^2 < \infty. \tag{6.25}$$

Using Schwarz's inequality and Fubini and denoting $d = (\|\mathcal{Q}\| + \|\mathcal{R}\| \, \|G\|_\infty^2)n\beta$, the expression for the cost of policy $\overline{u}$ may be dominated from above as follows:

$$E\left[\int_0^\infty x(t)^*\mathcal{Q}x(t) + \overline{u}(t)^*\mathcal{R}\overline{u}(t)dt\right] \leq E\left[\int_0^\infty (\|\mathcal{Q}\| + \|\mathcal{R}\| \, \|G\|_\infty^2) \|x(t)\|^2 \, dt\right]$$
$$\leq (\|\mathcal{Q}\| + \|\mathcal{R}\| \, \|G\|_\infty^2)n\beta \|x\|^2 \leq d \|x\|^2 = x^* dI x.$$

Now, turning back to the finite-time control problem (see (6.10)), we have that

$$x^* S_i^T(0)x = \min_{u \in \mathcal{U}^T} E\left[\int_0^T x(t)^*\mathcal{Q}x(t) + u(t)^*\mathcal{R}u(t)dt\right]$$
$$\leq E\left[\int_0^\infty x(t)^*\mathcal{Q}x(t) + \overline{u}(t)^*\mathcal{R}\overline{u}(t)dt\right] \leq x^* dI x.$$

Since $T \in (0, \infty)$, $i \in \mathcal{S}$, and $x \in \mathbb{C}^n$ are arbitrary, $S_i^T(0) \leq dI$ for every T and i. □

Defining $\bar{\mathcal{Q}}^{1/2} = (\mathcal{Q}^{1/2}, \mathcal{Q}^{1/2}, \dots) \in \mathcal{H}_\infty^{n^+}$, the following proposition provides sufficient conditions for a solution of the ICARE to be stabilizing.

PROPOSITION 6.10. *Suppose* $(\bar{\mathcal{Q}}^{1/2}, A, \Lambda)$ *is SD and* S *is a positive semidefinite solution to the ICARE* (6.9). *Then* S *is a stabilizing solution to* (6.9).

Proof. For $x(t)$ given by (3.1) with $t \geq 0$ and $u(t) = -G_{\theta(t)}x(t)$, $G = (G_1, G_2, \dots) = \mathcal{G}(S) \in \mathcal{H}_\infty^{n,m}$, and arbitrary initial data (x_0, θ_0), let us consider the statistic $Q(t)$, $t \geq 0$, given by (4.5) with F replaced by $\bar{F} = (\bar{F}_1, \bar{F}_2, \dots)$, $\bar{F}_i = A_i - B_iG_i$. Furthermore, let us define the operators $\bar{\mathcal{D}}$ and $\hat{\mathcal{D}}$ as in (4.6), replacing F by $\bar{F}$ in the former and by $\hat{F} = (\hat{F}_1, \hat{F}_2, \dots)$ in the latter, where $\hat{F}_i = A_i - K_i\mathcal{Q}^{1/2}$ with $K = (K_1, K_2, \dots) \in \mathcal{H}_\infty^{r,n}$ such that $\sup\{\operatorname{Re}\lambda : \lambda \in \sigma(\hat{\mathcal{D}})\} < 0$ (such K exists, bearing in mind the SD hypothesis of the proposition).

The idea of the proof runs as follows. We must prove that $\int_0^\infty E[\,\|x(t)\|^2\,]dt < \infty$ for any initial data (x_0, θ_0). Proving this is tantamount to proving that $\int_0^\infty \|Q(t)\|_1\,dt < \infty$ for arbitrary initial data $Q^0 \in \mathcal{H}_1^{n^+}$, where $Q(t)$, given by (4.5), also satisfies the differential equation $\dot{Q}(t) = \bar{\mathcal{D}}(Q(t))$. This amounts then, essentially, to obtaining an adequate function that dominates $\|Q(t)\|_1$.

From Proposition 4.6 we may write

$$\begin{aligned}\dot{Q}_i(t) = \bar{\mathcal{D}}_i(Q(t)) &= \bar{F}_iQ_i(t) + Q_i(t)\bar{F}_i^* + \sum_{j=1}^{\infty}\lambda_{ji}Q_j(t)\\ &= \hat{F}_iQ_i(t) + Q_i(t)\hat{F}_i^* + \sum_{j=1}^{\infty}\lambda_{ji}Q_j(t) + \Delta_iQ_i(t) + Q_i(t)\Delta_i^*\\ &= \hat{\mathcal{D}}_i(Q(t)) + \Delta_iQ_i(t) + Q_i(t)\Delta_i^*, \qquad (6.26)\end{aligned}$$

where

$$\Delta_i = K_i\mathcal{Q}^{1/2} - B_iG_i. \qquad (6.27)$$

Now, for arbitrary $\varepsilon > 0$, $0 \leq \left(\varepsilon I - \frac{1}{\varepsilon}\Delta_i\right)Q_i(t)\left(\varepsilon I - \frac{1}{\varepsilon}\Delta_i\right)^*$, so that $\Delta_iQ_i(t) + Q_i(t)\,\Delta_i^* \leq \varepsilon^2Q_i(t) + \frac{1}{\varepsilon^2}\Delta_iQ_i(t)\Delta_i^*$. Thus, from (6.26),

$$\dot{Q}_i(t) \leq \hat{\mathcal{D}}_i(Q(t)) + \varepsilon^2Q_i(t) + \frac{1}{\varepsilon^2}\Delta_iQ_i(t)\Delta_i^*. \qquad (6.28)$$

Now, for $H = (H_1, H_2, \dots) \in \mathcal{H}_1^n$, let us define the operators $\tilde{\mathcal{D}}(H) = (\tilde{\mathcal{D}}_1(H), \tilde{\mathcal{D}}_2(H), \dots)$, $\Gamma(H) = (\Gamma_1(H), \Gamma_2(H), \dots)$, and $\mathcal{V}(H) = (\mathcal{V}_1(H), \mathcal{V}_2(H), \dots)$ in $Blt\,(\mathcal{H}_1^n)$, such that

$$\tilde{\mathcal{D}}_i(H) = \hat{\mathcal{D}}_i(H) + \varepsilon^2H_i, \quad \Gamma_i(H) = \Delta_iH_i\Delta_i^*, \qquad (6.29)$$

and

$$\mathcal{V}_i(H) = \left(\varepsilon I - \frac{1}{\varepsilon}\Delta_i\right)H_i\left(\varepsilon I - \frac{1}{\varepsilon}\Delta_i^*\right), \ \ i \in \mathcal{S}. \qquad (6.30)$$

From (6.29), we have that

$$\tilde{\mathcal{D}} = \hat{\mathcal{D}} + \varepsilon^2 I \qquad (6.31)$$

with I being the identity operator associated to $\mathcal{H}_1^n$. We can rewrite (6.28) as

$$\dot{Q}_i(t) \leq \tilde{\mathcal{D}}_i(Q(t)) + \frac{1}{\varepsilon^2}\Gamma_i(Q(t)). \qquad (6.32)$$

In order to use a comparison theorem, we consider now the nonhomogeneous differential equation

$$\begin{cases} \dot{R}_i(t) = \tilde{\mathcal{D}}_i(R(t)) + \frac{1}{\varepsilon^2}\Gamma_i(Q(t)), \\ R_i(0) = Q_i(0), \quad i \in \mathcal{S}, \end{cases} \tag{6.33}$$

or, equivalently, the Banach space differential equation

$$\begin{cases} \dot{R}(t) = \tilde{\mathcal{D}}(R(t)) + \frac{1}{\varepsilon^2}\Gamma\left(Q(t)\right), \\ R(0) = Q(0) \in \mathcal{H}_1^{n^+} \end{cases} \tag{6.34}$$

with $R(t) = (R_1(t), R_2(t), \dots)$. Now, for each finite T and time interval $[0,T]$, $Q(\cdot)$ and consequently $\frac{1}{\varepsilon^2}\Gamma\left(Q(\cdot)\right)$ belong to $L_1([0,T], \mathcal{H}_1^n)$ and are continuously differentiable. Thus Proposition 4.2 tells us that the unique solution $R(t) \in \mathcal{H}_1^n$ to (6.34) is given by

$$R(t) = T_{\tilde{\mathcal{D}}}(t)\left(Q(0)\right) + \frac{1}{\varepsilon^2}\int_0^t T_{\tilde{\mathcal{D}}}(t-s)(\Gamma(Q(s)))ds, \qquad t \in [0,T], \tag{6.35}$$

for any $Q(0) \in \mathcal{H}^{n^+}$, where $T_{\tilde{\mathcal{D}}}$ is the uniformly continuous semigroup generated by $\tilde{\mathcal{D}}$. Let us now define

$$U_i(t) = R_i(t) - Q_i(t), \quad i \in \mathcal{S}. \tag{6.36}$$

Then $U(t) = (U_1(t), U_2(t), \dots)$ belongs to $\mathcal{H}_1^n$ and satisfies the differential equation

$$\begin{cases} \dot{U}(t) = \tilde{\mathcal{D}}(U(t)) + \mathcal{V}\left(Q(t)\right), \\ U(0) = 0. \end{cases} \tag{6.37}$$

Indeed,

$$\begin{aligned} \dot{U}_i(t) &= \dot{R}_i(t) - \dot{Q}_i(t) = \tilde{\mathcal{D}}_i(R(t)) + \frac{1}{\varepsilon^2}\Delta_i Q_i(t)\Delta_i^* \ - \bar{\mathcal{D}}_i(Q(t)) \\ &= \hat{\mathcal{D}}_i(R(t)) + \varepsilon^2 R_i(t) + \frac{1}{\varepsilon^2}\Delta_i Q_i(t)\Delta_i^* \ - \left(\hat{\mathcal{D}}_i(Q(t)) + \Delta_i Q_i(t) + Q_i(t)\Delta_i^*\right) \\ &= \tilde{\mathcal{D}}_i(U(t)) + \left(\varepsilon I - \frac{1}{\varepsilon}\Delta_i\right) Q_i(t) \left(\varepsilon I - \frac{1}{\varepsilon}\Delta_i^*\right) = \tilde{\mathcal{D}}_i(U(t)) + \mathcal{V}_i(Q(t)). \end{aligned}$$

Now $Q(\cdot)$ and consequently $\mathcal{V}\left(Q(\cdot)\right)$ belong to $L_1([0,T], \mathcal{H}_1^n)$. Thus, from Proposition 4.2, $U(t) \in \mathcal{H}_1^n$ defined in (6.36) is the unique solution to (6.37) and is given by

$$U(t) = \int_0^t T_{\tilde{\mathcal{D}}}(t-s)\left(\mathcal{V}(Q(s))\right) ds, \qquad t \in [0,T].$$

Since $Q(s)$ and consequently $\mathcal{V}\left(Q(s)\right)$ belong to $\mathcal{H}_1^{n^+}$ and $\tilde{\mathcal{D}}$ is a bounded linear transformation, it follows that $T_{\tilde{\mathcal{D}}}(t-s)\mathcal{V}(Q(s)) = (\exp((t-s))\tilde{\mathcal{D}})\mathcal{V}(Q(s))$ belongs to $\mathcal{H}_1^{n^+}$. Hence $U(t) \in \mathcal{H}_1^{n^+}$, which, together with (6.36), sets our comparison result, i.e., $0 \le Q(t) \le R(t) \in \mathcal{H}_1^{n^+}$, $t \in [0,T]$, for arbitrary $Q(0) \in \mathcal{H}_1^{n^+}$ and each finite T. Now, using (6.35) and (2.2), we have that

$$\|Q(t)\|_1 \le \|T_{\tilde{\mathcal{D}}}(t)\left(Q(0)\right)\|_1 + \frac{1}{\varepsilon^2}\int_0^t \|T_{\tilde{\mathcal{D}}}(t-s)(\Gamma(Q(s)))\|_1 \, ds.$$

Hence integration on $[0,T]$ yields

(6.38)
$$\int_0^T \|Q(t)\|_1\,dt \le \int_0^T \|T_{\tilde{\mathcal{D}}}(t)\,(Q(0))\|_1\,dt + \frac{1}{\varepsilon^2}\int_0^T\int_0^t \|T_{\tilde{\mathcal{D}}}(t-s)(\Gamma(Q(s)))\|_1\,dsdt.$$

Referring to the last term of (6.38), let us define $l = t - s$ and

$$T^E_{\tilde{\mathcal{D}}}(r) = \begin{cases} T_{\tilde{\mathcal{D}}}(r) & \text{if } r \ge 0, \\ 0 & \text{if } r < 0, \end{cases}$$

so that

$$\int_0^T\int_0^t \|T_{\tilde{\mathcal{D}}}(t-s)(\Gamma(Q(s)))\|_1\,ds\;dt = \int_0^T\int_0^T \left\|T^E_{\tilde{\mathcal{D}}}(t-s)(\Gamma(Q(s)))\right\|_1\,dt\;ds$$

$$\le \int_0^T \|\Gamma(Q(s))\|_1 \int_0^{T-s} \|T_{\tilde{\mathcal{D}}}(l)\|\,dl\;ds \le \int_0^T \|\Gamma(Q(s))\|_1\,ds \int_0^T \|T_{\tilde{\mathcal{D}}}(l)\|\,dl. \tag{6.39}$$

Hence

$$\int_0^T \|Q(t)\|_1\,dt \le \left\{\|(Q(0))\|_1 + \frac{1}{\varepsilon^2}\int_0^T \|\Gamma(Q(s))\|_1\,ds\right\}\int_0^T \|T_{\tilde{\mathcal{D}}}(s)\|\,ds. \tag{6.40}$$

Let us now dominate $\|(\Gamma(Q(s)))\|_1$ from above. Using (6.27), (6.29), and defining $c = \max\{\|K\|^2_\infty, \|B\|^2_\infty\}$,

$$\begin{aligned}\|\Gamma_i(Q(s))\| &= \|(K_i\mathcal{Q}^{1/2} - B_iG_i)Q_i(s)(K_i\mathcal{Q}^{1/2} - B_iG_i)^*\| \\ &\le c(\|\mathcal{Q}^{1/2}Q_i(s)\mathcal{Q}^{1/2}\| + \|G_iQ_i(s)G_i^*\| + 2\|\mathcal{Q}^{1/2}Q_i(s)G_i^*\|).\end{aligned}$$

Now from (4.5),

$$\|\mathcal{Q}^{1/2}Q_i(s)\mathcal{Q}^{1/2}\| = \|\mathcal{Q}^{1/2}E[x(s)x(s)^*1_{\{\theta(s)=i\}}]\mathcal{Q}^{1/2}\| \le E[\|\mathcal{Q}^{1/2}x(s)1_{\{\theta(s)=i\}}\|^2].$$

Similarly, $\|G_iQ_i(s)G_i^*\| \le E[\|G_ix(s)1_{\{\theta(s)=i\}}\|^2]$ and, bearing in mind that $2ab \le a^2 + b^2$ for any real numbers a,b,

$$\begin{aligned}2\|\mathcal{Q}^{1/2}Q_i(s)G_i^*\| &\le 2E[\|\mathcal{Q}^{1/2}x(s)\,(G_ix(s))^*\,1_{\{\theta(s)=i\}}\|] \\ &\le 2E[\|\mathcal{Q}^{1/2}x(s)1_{\{\theta(s)=i\}}\|\|\,(G_ix(s))\,1_{\{\theta(s)=i\}}\|] \\ &\le E[\|\mathcal{Q}^{1/2}x(s)1_{\{\theta(s)=i\}}\|^2] + E[\|\,(G_ix(s))\,1_{\{\theta(s)=i\}}\|^2].\end{aligned}$$

Consequently,

$$\|\Gamma(Q(s))\|_1 = \sum_{i=1}^\infty \|\Gamma_i(Q(s))\| \le 2cE\left[\sum_{i=1}^\infty \left\{\left\|\mathcal{Q}^{1/2}x(s)\right\|^2 1_{\{\theta(s)=i\}}\right.\right.$$

$$\left.\left. + \left\|G_{\theta(s)}x(s)\right\|^2 1_{\{\theta(s)=i\}}\right\}\right] = 2cE[\|\mathcal{Q}^{1/2}x(s)\|^2 + \|G_{\theta(s)}x(s)\|^2],$$

and (6.40) becomes

$$\int_0^T \|Q(t)\|_1\,dt \le \left\{\|Q(0)\|_1 + \frac{2c}{\varepsilon^2}\int_0^T E[\|\mathcal{Q}^{1/2}x(s)\|^2\right.$$

$$\left. + \|G_{\theta(s)}x(s)\|^2]ds\right\}\int_0^T \|T_{\tilde{\mathcal{D}}}(t)\|\,dt \tag{6.41}$$

for arbitrary $T \in (0, \infty)$. At this point we shall use the two hypotheses of the proposition to obtain an adequate bound to the first integral on the right-hand side of (6.41). So let us first consider the finite-time optimal control problem in section 5 with matched termination cost $S^T(T) = L = S$ such that $\mathcal{T}(S) = 0$. Then it follows from Propositions 5.8 (with $s = 0$) and 6.7 that the optimal control reads as $\hat{u}^T(t) = -G_{\theta(t)}x(t)$ with $G = (G_1, G_2, \dots) = \mathcal{G}(S^T(t)) = \mathcal{G}(S) \in \mathcal{H}_\infty^{n,m}$. Moreover, from (3.5) and (5.14), and since norms are equivalent in finite dimensional spaces, we have that

$$\begin{aligned} &\|S\|_\infty E[\|x(0)\|^2] \geq E[x(0)^* S_{\theta(0)} x(0)] \\ &= E\left[\int_0^T (\|\mathcal{Q}^{1/2}x(t)\|^2 + \|G_{\theta(t)}x(t)\|_{\mathcal{R}}^2)dt + \|x(T)\|_{S_{\theta(T)}}^2\right] \\ &\geq \int_0^T E[\|\mathcal{Q}^{1/2}x(t)\|^2 + m_{\mathcal{R}}\|G_{\theta(t)}x(t)\|^2]dt \end{aligned} \tag{6.42}$$

for some $m_{\mathcal{R}} > 0$. Or else,

$$\int_0^T E[\|\mathcal{Q}^{1/2}x(t)\|^2 + \|G_{\theta(t)}x(t)\|^2]dt \leq d_1 E[\|x(0)\|^2] < \infty$$

for $d_1 = \|S\|_\infty (1 + \frac{1}{m_{\mathcal{R}}})$ which do not depend on T. Hence, using this expression to majorize the right-hand side of (6.41) and passing to the limit, we have that

$$\lim_{T\to\infty} \int_0^T \|Q(t)\|_1 \, dt \leq \left\{ \|(Q(0))\|_1 + \frac{2c}{\varepsilon^2} d_1 (E[\|x(0)\|]) \right\} \lim_{T\to\infty} \int_0^T \|T_{\tilde{\mathcal{D}}}(t)\| \, dt. \tag{6.43}$$

Now $\sup\{\operatorname{Re}\lambda : \lambda \in \sigma(\hat{\mathcal{D}})\} < 0$, and so, from continuity of the spectrum of $\tilde{\mathcal{D}}$ on ε (note, from (6.31), that $\sigma(\tilde{\mathcal{D}}) = \sigma(\hat{\mathcal{D}}) + \varepsilon^2$), we have that $\sup\{\operatorname{Re}\lambda : \lambda \in \sigma(\tilde{\mathcal{D}})\} < 0$ for some $\varepsilon > 0$ sufficiently small. Thus, from Lemma 4.3, $\lim_{T\to\infty} \int_0^T \|T_{\tilde{\mathcal{D}}}(t)\| \, dt < \infty$, where $T_{\tilde{\mathcal{D}}}(t)$ is the semigroup generated by the bounded linear operator $\tilde{\mathcal{D}}$, or else (see (6.43)) $\lim_{T\to\infty} \int_0^T \|Q(t)\|_1 \, dt < \infty$ whenever $Q(0) \in \mathcal{H}_1^{n^+}$. Moreover, $E[\|x(t)\|^2] \leq n \|Q(t)\|_1$ so that $\lim_{T\to\infty} \int_0^T E[\|x(t)\|^2]dt < \infty$ for any initial condition (x_0, θ_0). Hence $G = \mathcal{G}(S)$ stabilizes (A, B, Λ). □

The next proposition shows the uniqueness of stabilizing solutions to the ICARE (6.9) as well as the optimality of this solution.

PROPOSITION 6.11. *Suppose $S = (S_1, S_2, \dots)$ is a stabilizing solution to the ICARE* (6.9). *Then S is the unique stabilizing solution to* (6.9) *and, for any initial condition* $(x(0), \theta(0))$,

$$\begin{aligned} \inf_{u\in\mathcal{U}} \mathcal{J}(\vartheta_0, u) = \mathcal{J}(\vartheta_0, \hat{u}) &:= E\left[\int_0^\infty (\|\mathcal{Q}^{1/2}x(t)\|^2 + \|\mathcal{R}^{1/2}\hat{u}(t)\|^2)dt\right] \\ &= E[x(0)^* S_{\theta(0)} x(0)], \end{aligned} \tag{6.44}$$

where $\hat{u}(t) = -G_{\theta(t)}x(t)$ with $G = (G_1, G_2, \dots) = \mathcal{G}(S) \in \mathcal{H}_\infty^{n,m}$ and $x(t)$ is given by (3.1) *with $t \geq 0$ plugged with $\hat{u}$.*

Proof. First notice that $\hat{u}$, as defined above, stabilizes (A, B, Λ). Thus $\hat{u} \in \mathcal{U}$, so that $\mathcal{U}$ is nonempty. Now let us pick an arbitrary control strategy $u \in \mathcal{U}$ and, focusing on the finite time horizon case, let us define, for an arbitrary T, the matched cost termination $S^T(T) = L = S$ and the control policy u^T such that $[0, T] \ni t \mapsto u^T(t) = u(t) \in \mathbb{R}^m$. Clearly, $x^T(t) = x(t)$ for $t \in [0, T]$, where $x^T(t)$ satisfies system

(3.1) with $s = 0$ plugged with u^T, $x(t)$ satisfies (3.1) with $t \geq 0$ plugged with u, and the same initial data $(x(0), \theta(0))$ stands for both cases. Now, as a consequence of having $S^T(T) = L = S$, the solution to the Riccati equation (4.12) is $S^T(t) = S$, $t \in [0, T]$ (see Proposition 6.7), and, consequently, $S^T_{\theta(0)}(0) = S_{\theta(0)}$. Thus, from the cost definition (3.5) and Proposition 5.6, we have that

$$\begin{aligned} \mathcal{J}_{[0,T],S}(\vartheta_0, u^T) &= E\left[\int_0^T (\|\mathcal{Q}^{1/2}x(t)\|^2 + \|\mathcal{R}^{1/2}u(t)\|^2)dt\right] + E[x(T)^* S_{\theta(T)} x(T)] \\ &= E[x(0)^* S_{\theta(0)} x(0)] + E\left[\int_0^T \|B^*_{\theta(r)} S_{\theta(r)} x(r) + \mathcal{R}u(r)\|^2_{\mathcal{R}^{-1}} dr\right]. \end{aligned} \tag{6.45}$$

Now, since $u \in \mathcal{U}$, we have, from condition C2 in section 3, $0 \leq E[x(T)^* S_{\theta(T)}\, x(T)] \leq \|S\|_\infty E[\|x(T)\|^2] \to 0$ as $T \to \infty$. Thus, passing (6.45) to the limit and by inspection of (3.6), it turns out that

$$\begin{aligned} \mathcal{J}(\vartheta_0, u) &= \lim_{T\to\infty} \mathcal{J}_{[0,T],S}(\vartheta_0, u^T) = E\left[\int_0^\infty (\|\mathcal{Q}^{1/2}x(t)\|^2 + \|\mathcal{R}^{1/2}u(t)\|^2)dt\right] \\ &= E[x(0)^* S_{\theta(0)} x(0)] + E\left[\int_0^\infty \|B^*_{\theta(r)} S_{\theta(r)} x(r) + \mathcal{R}u(r)\|^2_{\mathcal{R}^{-1}} dr\right] \end{aligned} \tag{6.46}$$

for arbitrary $u \in \mathcal{U}$ and initial condition ϑ_0. Hence, bearing in mind that a stabilizing solution S to the ICARE (6.9) belongs to $\mathcal{U}$, the minimum of (6.46) over $u \in \mathcal{U}$ is achieved with $\hat{u}$, in which case the second term on the right-hand side of (6.46) is zero. (Recall from (4.10) that $\hat{u}(t) = \mathcal{R}^{-1} B^*_{\theta(t)} S_{\theta(t)} x(t)$.) Expression (6.44) then follows. Finally, let us suppose that there exists a stabilizing solution $V \neq S$ to the ICARE. As in the case of the stabilizing solution S, we shall arrive at the conclusion that $E[x(0)^* V_{\theta(0)} x(0)]$ is the minimum of $\mathcal{J}(\vartheta_0, u)$ over $u \in \mathcal{U}$. But the minimum clearly does not depend on S and V, so it follows that

$$E[x(0)^* S_{\theta(0)} x(0)] = E[x(0)^* V_{\theta(0)} x(0)]$$

for any initial condition r.v. $(x(0), \theta(0))$. Making $x(0) = x$ and $\theta(0) = i$, x and i deterministic and arbitrary in $\mathbb{C}^n$ and $\mathcal{S}$, respectively, the above equation becomes $x^* S_i x = x^* V_i x$. Since S_i and V_i are Hermitian for every $i \in \mathcal{S}$, $S = V$. ∎

PROPOSITION 6.12. *Suppose* (A, B, Λ) *is SS and* $(\bar{\mathcal{Q}}^{1/2}, A, \Lambda)$ *is SD. Then, for arbitrary terminal condition* $L \in \mathcal{H}^{n^+}_\infty$, *the value* $\tilde{S}^T_i(0)$ *of the unique solution* $\tilde{S}^T(t) \in \mathcal{H}^{n^+}_\infty$, $t \in [0, T]$, *to* (4.12) *converges to* $S_i \in \mathbb{M}(\mathbb{C}^n)^+$ *as* $T \to \infty$ *for each* $i \in \mathcal{S}$, *and* $S = (S_1, S_2, \dots)$ *is the stabilizing solution to the ICARE* (6.9).

Proof. The idea of the proof is to recast an essential result of Proposition 6.9, namely, that $\lim_{T\to\infty} S^T_i(0) = S_i$, $i \in \mathcal{S}$, where $S = (S_1, S_2, \dots)$ is a positive semidefinite solution to the ICARE (6.9) and $S^T(t)$, $t \in [0, T]$, satisfies (4.12) with null terminal condition.

Bearing in mind the finite-time control problem of section 5 with arbitrary terminal cost condition $L \in \mathcal{H}^{n^+}_\infty$ and specialized initial condition $x(0) = x$ and $\theta(0) = i$, x and i deterministic and arbitrary in $\mathbb{C}^n$ and $\mathcal{S}$, respectively, and using, in this order, Proposition 5.8 coupled with definition (3.5) with $s = 0$ and the last equality of (6.10),

we obtain that

$$x^*\tilde{S}_i^T(0)x = \min_{u\in\mathcal{U}^T} E\left[\int_0^T (\|\mathcal{Q}^{1/2}x(t)\|^2 + \|\mathcal{R}^{1/2}u(t)\|^2)dt + x(T)^*L_{\theta(T)}x(T)\right]$$

$$\geq \min_{u\in\mathcal{U}^T} E\left[\int_0^T (\|\mathcal{Q}^{1/2}x(t)\|^2 + \|\mathcal{R}^{1/2}u(t)\|^2)dt\right] = x^*S_i^T(0)x, \tag{6.47}$$

where $S_i^T(0)$, $i \in \mathcal{S}$, is as defined in Proposition 6.9. Taking the limit on both sides of (6.47), we have that

$$\liminf_{T\to\infty} x^*\tilde{S}_i^T(0)x \geq \liminf_{T\to\infty} x^*S_i^T(0)x = \lim_{T\to\infty} x^*S_i^T(0)x = x^*S_ix, \tag{6.48}$$

where, from Propositions 6.9, 6.10, and 6.11, $\lim_{T\to\infty} x^*S_i^T(0)x$ exists, and it is such that $S = (S_1, S_2, \dots)$ is the unique stabilizing solution to the ICARE (6.9).

Let us now select the policy $u(t) = -G_{\theta(t)}x(t)$, $t \geq 0$, where $G = (G_1, G_2, \dots) = \mathcal{G}(S) \in \mathcal{H}_\infty^{n,m}$. Since by assumption $\tilde{S}^T(T) = L$, $x^*\tilde{S}_i^T(0)x$ is the minimum cost for the finite-time control problem above. (See Proposition 5.8 with $s = 0$.) Hence, considering the restriction of $u(t)$ to the interval $[0, T]$ (which assigns an admissible policy in $\mathcal{U}^T$) and using definition (3.5), we have that

$$x^*\tilde{S}_i^T(0)x \leq E\left[\int_0^T (\|\mathcal{Q}^{1/2}x(t)\|^2 + \|\mathcal{R}^{1/2}u(t)\|^2)dt + x(T)^*L_{\theta(T)}x(T)\right]$$

$$\leq E\left[\int_0^T (\|\mathcal{Q}^{1/2}x(t)\|^2 + \|\mathcal{R}^{1/2}u(t)\|^2)dt\right] + \|L\|_\infty E[\|x(T)\|^2]. \tag{6.49}$$

Now, bearing in mind the infinite-time control problem, and since $S = (S_1, S_2, \dots)$ is stabilizing, we have that the limit of the integral in (6.49) exists and $E[\|x(T)\|^2] \to 0$ as $T \to \infty$. Therefore, taking limits in (6.49), it follows that

$$\limsup_{T\to\infty} x^*\tilde{S}_i^T(0)x \leq \lim_{T\to\infty} E\left[\int_0^T (\|\mathcal{Q}^{1/2}x(t)\|^2 + \|\mathcal{R}^{1/2}u(t)\|^2)dt\right]$$

$$= E\left[\int_0^\infty (\|\mathcal{Q}^{1/2}x(t)\|^2 + \|\mathcal{R}^{1/2}u(t)\|^2)dt\right] = x^*S_ix, \tag{6.50}$$

where the last equality above comes from Proposition 6.11. Now, (6.48) and (6.50) tell us that $\lim_{T\to\infty} x^*\tilde{S}_i^T(0)x = x^*S_ix$. Since x and i are arbitrary and S_i is Hermitian, $\lim_{T\to\infty} \tilde{S}_i^T(0) = S_i$ for each $i \in \mathcal{S}$ and arbitrary $L \in \mathcal{H}_\infty^{n^+}$. □

THEOREM 6.13. *Suppose (A, B, Λ) is SS. Then, for $L = 0 \in \mathcal{H}_\infty^{n^+}$, the value $S_i^T(0)$ of the unique solution $S^T(t) \in \mathcal{H}_\infty^{n^+}$, $t \in [0, T]$, to (4.12) converges to some $S_i \in \mathbb{M}(\mathbb{C}^n)^+$ as $T \to \infty$ for each $i \in \mathcal{S}$. Moreover, $S = (S_1, S_2, \dots)$ belongs to $\mathcal{H}_\infty^{n^+}$ and satisfies the ICARE (6.9). Suppose, in addition, that $(\bar{\mathcal{Q}}^{1/2}, A, \Lambda)$ is SD. Then S is stabilizing and the unique positive semidefinite solution to (6.9), and, for arbitrary terminal condition $L \in \mathcal{H}_\infty^{n^+}$, the value $\tilde{S}_i^T(0)$ of the unique solution $\tilde{S}^T(t) \in \mathcal{H}_\infty^{n^+}$, $t \in [0, T]$, to (4.12) converges to S_i as $T \to \infty$ for each $i \in \mathcal{S}$. Furthermore, the optimal control policy $\hat{u}$ is given by $\hat{u}(t) = -G_{\theta(t)}x(t)$ with $G = (G_1, G_2, \dots) = \mathcal{G}(S) \in \mathcal{H}_\infty^{n,m}$, and produces the cost $\mathcal{J}(\vartheta_0, \hat{u}) = \inf_{u\in\mathcal{U}} \mathcal{J}(\vartheta_0, u) = E[x(0)^*S_{\theta(0)}x(0)]$.*

Proof. The proof is a straightforward consequence of Propositions 4.9, 5.6, 5.8, 6.9, 6.10, 6.11, and 6.12. □

Remark 6.14. If we specialize our framework to the nonjump case, the definitions of SS and SD in section 6 recast the definitions of stabilizability and detectability of the standard linear/quadratic/deterministic case. Indeed, the definition of SS duly specialized to the single state case and with deterministic $x_0 \in \mathbb{C}^n$ means that $\int_0^\infty \|x(t)\|^2 \, dt < \infty$, where $\dot{x}(t) = Fx(t)$ with $F = A - BG \in \mathbb{M}(\mathbb{C}^n)$ for some $G \in \mathbb{M}(\mathbb{C}^n, \mathbb{C}^m)$ and arbitrary $x_0 \in \mathbb{C}^n$. Since F does not depend on $\{\theta\}$, and to remain in the operator theoretical context, let us view it as the infinitesimal generator of the semigroup $T_F(t)$ so that $x(t) = T_F(t)x_0$. We may then write that $\int_0^\infty \|T_F(t)x_0\|^2 \, dt < \infty$. Invoking Lemma 4.3 for this finite dimensional application, the latter expression is the same as saying that every eigenvalue of F is placed on the open left complex halfplane, i.e., (A, B) is stabilizable in the usual sense. The case of stochastic stability follows an analogous procedure.

7. Appendix.

7.1. Linear approximation of nonnecessarily holomorphic functionals, via a decomplexification concept. Based on the decomplexification concept defined in section 2, the following lemma provides the linear approximation of a complex function g.

LEMMA 7.1. *Assume the decomplexification* ${}^{\mathrm{R}}g : [0,\infty) \times \mathbb{R}^{2n} \mapsto \mathbb{R}$, *of* $g : [0,\infty) \times \mathbb{C}^n \mapsto \mathbb{R}$ *is (Fréchet-) differentiable. Then, for every* $(t,x) \in [0,\infty) \times \mathbb{C}^n$, g *has the linear approximation*

$$g(t+s, x+w) = g(t,x) + \frac{\partial}{\partial t} g(t,x)s + \nabla_{{}^{\mathrm{R}}x} {}^{\mathrm{R}}g(t, {}^{\mathrm{R}}x)' \, {}^{\mathrm{R}}w + o(\|(s,w)\|). \tag{7.1}$$

Proof. See [4] for details. □

Remark 7.2. Differentiability of ${}^{\mathrm{R}}g$ suffices to guarantee the existence of the linear approximation of g. More stringent conditions, such as g being holomorphic, are not required.

Remark 7.3. From the definition of decomplexification of $x \in \mathbb{C}^n$, as stated in section 2, it is clear that $\nabla_{{}^{\mathrm{R}}x} {}^{\mathrm{R}}g(t, {}^{\mathrm{R}}x)' {}^{\mathrm{R}}w = \nabla_{x_{\mathrm{Re}}} {}^{\mathrm{R}}g(t, {}^{\mathrm{R}}x)' \, w_{\mathrm{Re}} + \nabla_{x_{\mathrm{Im}}} {}^{\mathrm{R}}g(t, {}^{\mathrm{R}}x)' w_{\mathrm{Im}}$.

LEMMA 7.4. *Let* g *be the (nonholomorphic) function given by*

$$[0,T] \times \mathbb{C}^n \ni (t,x) \to g(t,x) = x^* S_m(t) x \in \mathbb{R} \tag{7.2}$$

with $S_m(t) = S_m(t)^* \in \mathbb{M}(\mathbb{C}^n)$ *differentiable for all* $t \in [0,T]$. *Then* $\frac{\partial}{\partial t} g(t,x) = x^* \dot{S}_m(t) x$, *and the differentiable function* ${}^{\mathrm{R}}g$ *is such that*

$$\nabla_{{}^{\mathrm{R}}x} {}^{\mathrm{R}}g(t, {}^{\mathrm{R}}x) = \begin{pmatrix} \nabla_{x_{\mathrm{Re}}} {}^{\mathrm{R}}g(t, {}^{\mathrm{R}}x) \\ \nabla_{x_{\mathrm{Im}}} {}^{\mathrm{R}}g(t, {}^{\mathrm{R}}x) \end{pmatrix} = 2 \begin{pmatrix} (S_m(t)x)_{\mathrm{Re}} \\ (S_m(t)x)_{\mathrm{Im}} \end{pmatrix}, \tag{7.3}$$

or else

$$\nabla_{{}^{\mathrm{R}}x} {}^{\mathrm{R}}g(t, {}^{\mathrm{R}}x)' \, {}^{\mathrm{R}}w = w^* S_m(t) x + x^* S_m(t) w. \tag{7.4}$$

Proof. See [4]. □

7.2. Support for the proof of Proposition 5.5. The following results are essential to the proof of Proposition 5.5.

LEMMA 7.5. *For arbitrary $\mathcal{Q},\mathcal{R} \in \mathbb{M}(\mathbb{C}^n)^+$ and $T \in \mathbb{M}(\mathbb{C}^m,\mathbb{C}^n)$, there exists $d_1 \geq 0$ such that, for every $(x,u) \in \mathbb{C}^n \times \mathbb{C}^m$, we have that*

$$d_1(x^*\mathcal{Q}x + u^*\mathcal{R}u) \geq u^*Tx + x^*T^*u.$$

Proof. See [4]. □

LEMMA 7.6. *$H \in \mathcal{H}_\infty^{n+} \Rightarrow H_i \leq H_0$ for some $H_0 \in \mathbb{M}(\mathbb{C}^n)^+$.*

Proof. Suppose, by contradiction, that there exists some sequence $\{H_{i_j}\}_{j\in\mathbb{N}}$, increasing and unbounded in the self-adjoint partial ordering. Hence there is $H_0^1 \in \mathbb{M}(\mathbb{C}^n)^+$ with $\left\|H_0^1\right\| \geq \|H\|_\infty$ and some $j_0 \in \mathbb{N}$ such that $H_{i_{j_0}} > H_0^1$, which leads us to $\left\|H_{i_{j_0}}\right\| > \left\|H_0^1\right\| \geq \|H\|_\infty \geq \left\|H_{i_{j_0}}\right\|$, which is a contradiction. □

LEMMA 7.7. *Let $\{x\}$ be given by (3.1) with $u \in \mathcal{U}^{s,T}$. Then, for $g(t,x,i) = x^*S_i^T(t)x$ defined on $\mathcal{X}$, there is some real valued function $M^u(x) \equiv M(x,u(t,x,i))$ defined on $\mathbb{C}^n \times \mathbb{C}^m$ with*

$$E_{s,x,i}\left[\int_s^t \mid M(x(r),u(r))dr \mid\right] < \infty, \tag{7.5}$$

and such that

$$\frac{\partial}{\partial t}g(t,x,i) + \left(\mathcal{L}^u g\right)(t,x,i) + M(x,u) \geq 0$$

for every $(t,x,i) \in ((s,T) \times \mathbb{C}^n \times \mathcal{S})$.

Proof. We use Lemmas 7.5 and 7.6. See [4] for details. □

7.3. Support for the proof of Proposition 6.9. The following results are essential to the proof of Proposition 6.9.

LEMMA 7.8. *For arbitrary $i \in \mathcal{S}$ and $H_i^T \in \mathbb{M}(\mathbb{C}^n)^+$, $T \in (0,\infty)$, suppose that $H_i^{T_1} \leq H_i^{T_2} \leq dI$ for every $T_1 < T_2$ and some constant $0 < d < \infty$ which does not depend on i, T_1, and T_2. Then there exists $H_i \in \mathbb{M}(\mathbb{C}^n)^+$ such that $H_i^T \to H_i$ as $T \to \infty$, $i \in \mathcal{S}$, and $H = (H_1, H_2, \dots) \in \mathcal{H}_\infty^{n+}$.*

Proof. The first assertion follows from a standard monotonicity result concerning positive semidefinite matrices. Now $\left\|H_i^T\right\| \leq d$ for every finite T. Hence $\|H_i\| \leq d$ for every $i \in \mathcal{S}$, which proves the second assertion. □

LEMMA 7.9. *For $H^T \in \mathcal{H}_\infty^{n+}$, $T \in (0,\infty)$, let us assume that*

1. *$H_i^T \to H_i \in \mathbb{M}(\mathbb{C}^n)^+$ as $T \to \infty$, $i \in \mathcal{S}$.*
2. *$H = (H_1, H_2, \dots) \in \mathcal{H}_\infty^{n+}$.*
3. *$H_i^{T_1} \leq H_i^{T_2} \leq dI$, $T_1, T_2 \in (0,\infty)$, $T_1 < T_2$, $i \in \mathcal{S}$, and some constant $0 < d < \infty$, which does not depend on i, T_1, and T_2.*

Then, with $\mathcal{T}$ given by (4.11), we get that

$$\lim_{T\to\infty} \mathcal{T}_i(H^T) = \mathcal{T}_i(H), \quad i \in \mathcal{S}, \quad \text{and} \quad \lim_{T\to\infty} \mathcal{T}(H^T) = \mathcal{T}(H). \tag{7.6}$$

Proof. From (4.11) we have that

$$\begin{aligned}
&\lim_{T\to\infty} \mathcal{T}_i(H^T) \\
&= \mathcal{Q} + A_i^* \lim_{T\to\infty} H_i^T + \left(\lim_{T\to\infty} H_i^T\right) A_i - \left(\lim_{T\to\infty} H_i^T\right) B_i\mathcal{R}^{-1}B_i^* \left(\lim_{T\to\infty} H_i^T\right) \\
&+ \lambda_{ii} \lim_{T\to\infty} H_i^T + \lim_{T\to\infty} \mathcal{E}_i(H^T) \\
&= \mathcal{Q} + A_i^*H_i + H_iA_i - H_iB_i\mathcal{R}^{-1}B_i^*H_i + \lambda_{ii}H_i + \lim_{T\to\infty} \mathcal{E}_i(H^T).
\end{aligned} \tag{7.7}$$

If we assume for the moment that $\lim_{T\to\infty}\mathcal{E}_i(H^T)=\mathcal{E}_i(H)$, then (7.6) follows immediately from (7.7). So, let us prove that the previous equation indeed holds, by first showing that, for arbitrary $x\in\mathbb{C}^n$, $\lim_{T\to\infty}x^*\mathcal{E}_i(H^T)x=x^*\mathcal{E}_i(H)x$. With this aim, we have from assertion 3 that $0\le\lambda_{ij}x^*H_j^{T_1}x\le\lambda_{ij}x^*H_j^{T_2}x\le\lambda_{ij}x^*dIx$ for every positive T_1,T_2, $T_1<T_2$, $i,j\in\mathcal{S}$, which implies that

$$0\le\lim_{M\to\infty}\sum_{j=1,j\neq i}^{M}\lambda_{ij}x^*H_j^{T_1}x\le\lim_{M\to\infty}\sum_{j=1,j\neq i}^{M}\lambda_{ij}x^*H_j^{T_2}x$$
$$\le\lim_{M\to\infty}\sum_{j=1,j\neq i}^{M}\lambda_{ij}x^*dIx=d\left\|x\right\|^2\left|\lambda_{ii}\right|.$$

Hence, from the monotonicity of the bounded function $g(M,T)=\sum_{j=1,j\neq i}^{M}\lambda_{ij}x^*H_j^Tx$ on M and T, and bearing in mind assertions 1 and 2, we may write that

$$\lim_{T\to\infty}x^*\mathcal{E}_i(H^T)x=\lim_{T\to\infty}x^*\left(\lim_{M\to\infty}\sum_{j=1,j\neq i}^{M}\lambda_{ij}H_j^T\right)x$$
$$=\lim_{M\to\infty}\lim_{T\to\infty}\sum_{j=1,j\neq i}^{M}\lambda_{ij}x^*H_j^Tx=\lim_{M\to\infty}\sum_{j=1,j\neq i}^{M}\lambda_{ij}x^*H_jx=x^*\mathcal{E}_i(H)x.$$

Since the above equation holds for every $x\in\mathbb{C}^n$ and $\mathcal{E}_i(H)$ is self-adjoint, $\lim_{T\to\infty}\mathcal{E}_i(H^T)=\mathcal{E}_i(H)$, so that the first expression of (7.6) follows. Consequently, bearing in mind Proposition 4.7, we get

$$\mathcal{H}_\infty^n\ni\mathcal{T}(H)=\left(\lim_{T\to\infty}\mathcal{T}_1(H^T),\lim_{T\to\infty}\mathcal{T}_2(H^T),\dots\right)$$
$$=\lim_{T\to\infty}(\mathcal{T}_1(H^T),\mathcal{T}_2(H^T),\dots)=\lim_{T\to\infty}\mathcal{T}(H^T).\qquad\square$$

LEMMA 7.10. *For finite T, $\Delta\in\mathbb{R}$, and $\mathcal{K}$ an operator from the Banach space X into X, let us consider the Banach space differential equation*

$$\begin{cases}\dot V(t)+\mathcal{K}(V(t))=0,\quad t\in(-\Delta,T-\Delta),\\ V(T-\Delta)=0,\end{cases}\tag{7.8}$$

and let $S^T(\cdot)\equiv S^{T,0}(\cdot)$ and $S^{T,-\Delta}(\cdot)$ be functions such that

$$S^{T,-\Delta}(t)=S^T(t+\Delta),\quad t\in[-\Delta,T-\Delta].\tag{7.9}$$

Then $S^{T,-\Delta}(\cdot)$ is a solution to (7.8) *if and only if $S^T(\cdot)$ is a solution to* (7.8) *with $\Delta=0$. If a solution to one system is unique, then it is the case of the other system too, and both solutions satisfy* (7.9).

Proof. The lemma is intuitive since it corresponds to a shift of T. Considering the "only if " part, let $S^{T,-\Delta}(\cdot)$ be such that

$$\begin{cases}\dot S^{T,-\Delta}(t)+\mathcal{K}(S^{T,-\Delta}(t))=0,\quad t\in(-\Delta,T-\Delta),\\ S^{T,-\Delta}(T-\Delta)=0.\end{cases}\tag{7.10}$$

Now, from (7.9), it follows that $\dot S^{T,-\Delta}(t)=\dot S^T(t+\Delta)$ and

$$S^{T,-\Delta}(T-\Delta)=S^T(T)=0,\tag{7.11}$$

so that substitution in (7.10) yields $\dot{S}^T\ (t+\Delta) + \mathcal{K}(S^T(\ t+\Delta)) = 0, \quad t \in (-\Delta, T-\Delta)$, i.e., $\dot{S}^T(t) + \mathcal{K}(S^T(t)) = 0, \quad t \in (0,T)$. This and (7.11) show that $S^T(\cdot)$ satisfies (7.8) with $\Delta = 0$. For the "if" part, an analogous procedure holds, and the uniqueness part of the proof is easily shown by contradiction. □

Acknowledgments. The authors would like to express their gratitude to the referees for their suggestions and helpful comments. The authors would also like to thank Professor J. B. do Val for invaluable conversation on the applications of our results in economics.

UNIFORM ROBUST PERFORMANCE AGAINST QUASI-LTI UNCERTAINTY IN SAMPLED-DATA SYSTEMS*

SEAN E. BOURDON† AND GEIR E. DULLERUD‡

Abstract. Uniform robust performance of sampled-data systems is studied in the context of arbitrarily slowly time-varying structured perturbations. Exact conditions for robustness are obtained. These conditions are convex but inherently infinite dimensional in nature.

Key words. sampled-data systems, quasi-LTI, structured uncertainty, periodic systems

AMS subject classifications. 93C57, 93D09

1. Introduction.

The main objective of this paper is to provide an exact characterization for uniform robust performance in *sampled-data systems* against a class of structured linear quasi-time-invariant (quasi-LTI) perturbations for systems with L_2 inputs. Motivated by the work of Poolla and Tikku [23] on standard time-invariant systems, we obtain separate conditions for uniform robust stability and uniform robust performance. The now ubiquitous use of digital hardware in the control of complex processes serves to underscore the importance of sampled-data and multirate systems, which, in turn, motivates the *exact* analysis presented herein. Although we focus primarily on sampled-data systems in what follows, this work has more general application to periodic continuous time systems such as multirate systems and jump systems. We therefore believe that this work may find wider application, in, for instance, control of networked systems.

We choose to work with a perturbation class of arbitrarily slowly time-varying operators. These operators, at least intuitively, closely approximate the set of linear time-invariant (LTI) operators and are therefore referred to as quasi-LTI. Moreover, this set seems to form a natural perturbation class in our framework. Our nominal model consists of a continuous time plant in feedback with a discrete time controller, both of which are LTI. However, this is necessarily an idealization since any physical system exhibits some degree of time-variation, no matter how modest.

Other perturbation classes have previously been considered in the same context. In Thompson et al. [27, 28], Hara, Nakajima, and Kabamba [16], and [13], conditions characterizing robustness to the class of LTI perturbations were obtained. The problem of finding exact conditions characterizing robust performance against periodically time-varying (PTV) perturbations has been worked on by Thompson et al. [27, 28], Sivashankar and Khargonekar [26], and Dullerud and Glover [14]. Also, linear time-varying (LTV) and quasi-PTV perturbations were considered in [12], where exact conditions for robust performance to these perturbation classes are provided.

The approach used in the paper uses the framework for sampled-data robustness of [12] and appeals to the lifting techniques of [5, 4, 29, 30]. The analytical robustness conditions we obtain are in terms of a convex optimization problem over an infinite dimensional set. Computational issues associated with the conditions are dealt with in a separate paper [9]. In particular, it is shown in [9] that converging upper and lower bounds on the stability radius of a sampled-data system can be computed within any desired accuracy using computations involving only linear (finite dimensional) matrix inequalities.

The exact nature of our robustness conditions is not totally unexpected given the results found in [12] on LTI perturbations. In fact, robustness of sampled-data systems is similar to that of purely continuous time LTI systems in that a greater degree of time variation in the perturbation class results in a simpler robustness test.

Finally, in proving the necessity of our robustness conditions, we generalize a result regarding the so-called S-procedure first proved by Megretski and Treil [18] from a finite dimensional space to one which has a countable basis. Our version is a special case, since it is well known that the result does not hold in general for a countable number of quadratic forms.

2. Mathematical preliminaries. We begin by introducing some concepts from mathematical analysis. Our treatment is kept brief. However, the material presented here is standard; see, e.g., [7, 17] for a more complete introduction. Throughout, we denote the nonnegative integers by $\mathbb{N}_{\mathrm{o}}$ and the real and complex numbers by $\mathbb{R}$ and $\mathbb{C}$, respectively.

Suppose E is a Hilbert space. We denote the norm on E by $\|\cdot\|_E$, although for convenience we frequently suppress the subscript. The space of bounded linear operators on E is written $\mathcal{L}(E)$, on which we will always put the norm topology; if X is in $\mathcal{L}(E)$, we denote the E to E induced norm of X by $\|X\|_{E\to E}$. Furthermore, the adjoint of X is written X^*, its spectrum $\mathrm{spec}(X)$ and its spectral radius $\mathrm{rad}(X)$. Given a subspace $\mathcal{X} \subset \mathcal{L}(E)$, we denote the *open* unit ball by $\mathcal{U}\mathcal{X}$.

We will be primarily concerned with three specific Hilbert spaces. The first of these is $L_2^m[0,\infty)$, which is the standard set of square integrable functions mapping $[0,\infty)$ to the Euclidean space $\mathbb{R}^m$. For simplicity we refer to this space as L_2 when convenient. Given a real number h, we can also define a compressed version of the space $L_2^m[0,\infty)$ on the interval $[0,h)$. We will use $\mathcal{K}_2$ to denote the space $L_2^m[0,h)$.

A third Hilbert space of interest is formed using a given Hilbert space E, the base space, and is denoted $\ell_2(E)$. It is the space of sequences mapping $\mathbb{N}_{\mathrm{o}}$ to E consisting of elements $(x_0, x_1, x_2, \dots)$ which satisfy

$$\sum_{k=0}^{\infty} \|x_k\|_E^2 < \infty.$$

If the base space E is not particularly relevant, we abbreviate further to ℓ_2. We say an operator is LTI on ℓ_2 if it commutes with the unilateral shift.

The *half-plane algebra*, which we denote $\mathcal{A}_{\mathbb{C}^+}$, is a frequency domain space which will also play an important role throughout this paper. It is comprised of functions that map the closed right half-plane $\overline{\mathbb{C}}^+$ to the $m \times p$ complex matrices $\mathbb{C}^{m\times p}$, are continuous on $\overline{\mathbb{C}}^+ \cup \{\infty\}$, and are analytic on the open half-plane $\mathbb{C}^+$, with the norm $\|\widehat{\Delta}\|_\infty := \sup_{\omega\in\mathbb{R}} \bar{\sigma}(\widehat{\Delta}(j\omega))$; here $\bar{\sigma}(\cdot)$ is the maximum singular value. The following lemma about the half-plane algebra is a result we shall appeal to a number of times.

PROPOSITION 2.1. *The set of stable, proper, rational functions $\mathcal{RH}_\infty$ is dense in $\mathcal{A}_{\mathbb{C}^+}$.*

So, given any $\widehat{D} \in \mathcal{A}_{\mathbb{C}^+}$ and $\varepsilon > 0$, there exist matrices $X_0, \ldots, X_n$ for some $n \geq 0$, so that with $\widehat{F}(s) = \sum_{k=0}^{n} X_k \left(\frac{1-s}{1+s}\right)^k$ we have

$$\|\widehat{D} - \widehat{F}\|_\infty < \varepsilon.$$

That is, any element of $\mathcal{A}_{\mathbb{C}^+}$ can be approximated by a finite sum of the above form.

Note that $\mathcal{A}_{\mathbb{C}^+}$ is a subspace of $\mathcal{H}_\infty$, and therefore any function $\widehat{\Delta}$ in $\mathcal{A}_{\mathbb{C}^+}$ defines a causal operator $\mathbf{\Delta}$ on L_2 through multiplication and the Laplace transform. Let $\mathcal{L}_{\mathcal{A}_{\mathbb{C}^+}}$ denote this subspace of $\mathcal{L}(L_2)$, whose elements have such transfer function representations in $\mathcal{A}_{\mathbb{C}^+}$.

We will also frequently make use of the operator-valued space $\mathcal{A}_{\mathbb{D}}$, the discrete time counterpart to $\mathcal{A}_{\mathbb{C}^+}$, called the *disc algebra*. This space consists of functions $\check{G} : \overline{\mathbb{D}} \to \mathcal{L}(\mathcal{K}_2)$, which are analytic in the unit disc $\mathbb{D}$, continuous on $\overline{\mathbb{D}}$, and for which the norm

$$\|\check{G}\|_\infty := \max_{\omega \in \mathbb{R}} \|\check{G}(e^{j\omega})\|_{\mathcal{K}_2 \to \mathcal{K}_2} = \max_{z \in \overline{\mathbb{D}}} \|\check{G}(z)\|_{\mathcal{K}_2 \to \mathcal{K}_2}$$

is finite.

3. Problem formulation. In this section, we pose the problem that is to be the main focus of this paper and provide a technical overview of our results. To begin, a brief introduction to uncertain sampled-data systems is presented. Next, we define the central notions of uniform robust stability and uniform robust performance for the systems under consideration, and then we define the particular perturbation sets of this paper and their associated scalings. Finally, we state the main results of the paper, whose proofs are covered in detail in section 5.

A standard configuration for uncertain sampled-data systems is depicted in Figure 3.1. This paradigm for studying robust performance, in our context of structured perturbations, was first introduced for continuous time systems by Doyle [11] and Safonov [25] and can incorporate many standard models of uncertainty; see also the survey article [21] on the structured singular value.

In the figure, the operator $\mathbf{G}$ represents a finite dimensional linear time-invariant (FDLTI) system with minimal state space realization (A, B, C, D). That is, $\mathbf{G}$ has a transfer function representation $\hat{G}(s) := C(sI - A)^{-1}B + D = \left[\begin{array}{c|c} A & B \\ \hline C & D \end{array}\right]$. Moreover, we will assume throughout the paper that the realization for our plant $\mathbf{G}$ has the form

$$\hat{G}(s) = \left[\begin{array}{c|ccc} A & B_1^1 & B_1^2 & B_2 \\ \hline C_1^1 & 0 & 0 & D_{12}^1 \\ C_1^2 & 0 & 0 & D_{12}^2 \\ C_2 & 0 & 0 & 0 \end{array}\right] =: \begin{bmatrix} \hat{G}_{11} & \hat{G}_{12} \\ \hat{G}_{21} & \hat{G}_{22} \end{bmatrix}, \tag{3.1}$$

where each of the matrices B, C, and D is partitioned with respect to its inputs and its outputs. Notice that the matrix $D_{21} = 0$. This ensures that the signal y is low-pass filtered. We have also set $D_{11} = 0$ and $D_{22} = 0$ for simplicity, although these restrictions can be relaxed without affecting our subsequent results.

Our plant $\mathbf{G}$ is in feedback with a discrete time FDLTI controller $\mathbf{K}_d$ through an *ideal sampler* $\mathbf{S}$ and a *zero-order hold operator* $\mathbf{H}$. These mappings satisfy

$$(\mathbf{S}u)[k] := u(kh),$$
$$(\mathbf{H}v)(t) := v[k] \text{ for } t \in [kh, (k+1)h),$$

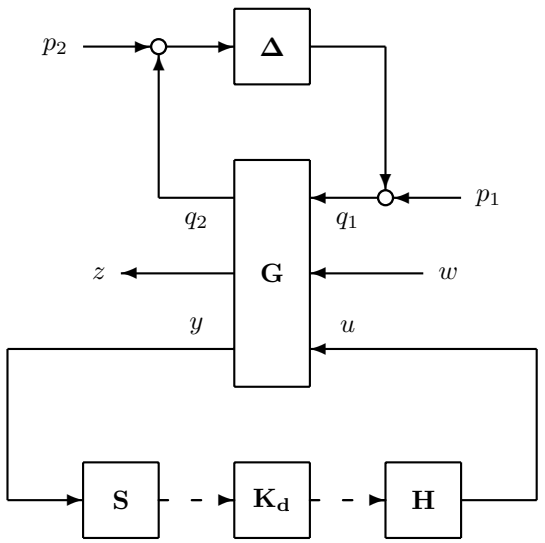

FIG. 3.1. *Uncertain sampled-data system.*

for each $u : [0, \infty) \to \mathbb{C}^n$, every sequence $v : \mathbb{N}_o \to \mathbb{C}^n$, and some real number $h > 0$, called the *sampling period* of the sampled-data system. Throughout the paper, we assume that the sample and hold devices are *synchronized* and that the sampling period h is *fixed*. We further assume that $(A_{K_d}, B_{K_d}, C_{K_d}, D_{K_d})$ is a minimal state space realization for $\mathbf{K}_d$.

The final assumption we place on our controller $\mathbf{K}_d$ is that it asymptotically stabilizes its nominal interconnection with our plant $\mathbf{G}$. For future reference, when $\mathbf{\Delta} = 0$, we call the mapping $\mathbf{M} : \begin{bmatrix} p_1 \\ w \end{bmatrix} \mapsto \begin{bmatrix} q_2 \\ z \end{bmatrix}$ from Figure 3.1 the *nominal sampled-data system*.

Assumption 3.1. Suppose that the signals w, p_1, and p_2 from Figure 3.1 are all zero. Further suppose that the operator $\mathbf{\Delta} = 0$. Then for any initial states $x_G(0)$ and $x_{K_d}[0]$ of the minimal state space realizations for $\mathbf{G}$ and $\mathbf{K}_d$, respectively, the limits $\lim_{t\to\infty} x_G(t) = 0$ and $\lim_{k\to\infty} x_{K_d}[k] = 0$ are both satisfied.

The above condition guarantees input-output stability of the nominal sampled-data system. However, it is also possible to make this condition equivalent to input-output stability; see [10].

The various signals appearing in Figure 3.1 are all physically meaningful. For instance, w represents all exogenous inputs to our system, such as disturbances, noise, and command signals. The regulated output z is the signal which is to be attenuated. The internal inputs to our system are given by p_1 and p_2. Of course, we require that our system be stable with respect to these inputs. The internal outputs are the signals q_1 and q_2. The signal u contains the controlled inputs to our system, whereas the measured outputs of the system are found in y.

Throughout the paper, we assume that the dimension of the signals p_1, p_2, q_1, and q_2 is m and that r denotes the dimension of w and z. Under these assumptions, we notice that the nominal closed-loop system is square. As with many of our other assumptions, this one is made out of convenience and our results will not be affected

if we choose to remove it. The final assumption we make on our signals is that the inputs w, p_1, and p_2 all belong to the space of bounded energy signals L_2.

Finally, the operator $\mathbf{\Delta}$ also appears in our system through a feedback loop and represents a perturbation to the nominal model. Its purpose is to encompass the uncertainty incurred by inaccuracies in the mathematical description. Recall that our nominal model is linear. However, by including uncertainty directly into our model description, our results are applicable to a much wider range of possibilities, including nonlinear and time-varying systems. The exact nature of quasi-LTI perturbations will be discussed below.

Recall that this paper is dedicated primarily to the study of uniform robust stabilization and performance of sampled-data systems against structured quasi-LTI perturbations. Intuitively, the system of Figure 3.1 has uniform robust stability to an uncertainty set $\mathcal{S}$ if it is internally stable given any perturbation $\mathbf{\Delta} \in \mathcal{S}$. This being the case, we say that our system has uniform robust performance to the set $\mathcal{S}$ if a performance inequality is also satisfied. The following definition makes these notions precise.

DEFINITION 3.2. *Suppose $\mathcal{X}$ is a subspace of $\mathcal{L}(L_2)$ and $\rho > 0$. Then the system in Figure* 3.1 *is said to have* uniform robust stability *against perturbations in the set $\rho\mathcal{UX}$ if the maps $\begin{bmatrix} w \\ p_1 \\ p_2 \end{bmatrix} \mapsto \begin{bmatrix} z \\ q_1 \\ q_2 \end{bmatrix}$ exist for each $\mathbf{\Delta} \in \rho\mathcal{UX}$ and are uniformly bounded in norm. If, in addition, the performance inequality $\rho \cdot \|w \mapsto z\| \leq 1$ is satisfied for all $\mathbf{\Delta} \in \rho\mathcal{UX}$, then the system in Figure* 3.1 *is said to have* uniform robust performance *with respect to that same perturbation set.*

Notice that both definitions are made with the same scaling constant ρ. In practice, however, we will usually set $\rho = 1$ for convenience when stating and proving results. This can be done without loss of generality since all of the systems we consider are linear and can hence be scaled appropriately a priori. Also note that a similar argument shows that the radius of the uncertainty set and the bound on the performance inequality can be varied independently by having first scaled $\mathbf{G}$. Having defined uniform robust stability and uniform robust performance, we can now introduce the set of quasi-LTI perturbations, which is the specific uncertainty set $\mathcal{S}$ that is the focus of this paper.

The perturbations we work with are assumed to be members of the spatially structured set

$$\mathcal{X}_s := \{\mathbf{\Delta} = \operatorname{diag}(\mathbf{\Delta}^1, \ldots, \mathbf{\Delta}^d) : \mathbf{\Delta}^k \in \mathcal{L}(L_2^{m_k}) \text{ for } 1 \leq k \leq d\},$$

where $\sum_{k=0}^{d} m_k = m$. Note that it is the Euclidean part of the elements of $\mathcal{X}_s$ on which the structure is imposed; given an operator $\mathbf{\Delta} = \operatorname{diag}(\mathbf{\Delta}^1, \ldots, \mathbf{\Delta}^d) \in \mathcal{X}_s$ and a signal $u = (u_1, \ldots, u_d) \in L_2^m$ with $u_k \in L_2^{m_k}$, we have $\mathbf{\Delta}u = (\mathbf{\Delta}^1 u_1, \ldots, \mathbf{\Delta}^d u_d)$. Also notice that the spatial blocks are all square. Again this is strictly for simplicity, and all of our results hold when this assumption is removed. This structured uncertainty arrangement is particularly useful in that it models uncertainty occurring simultaneously in various parts of the model in a nonconservative fashion. We refer to [3] and [20], which provide additional motivation for using this particular uncertainty arrangement from an engineering perspective.

Now let us define the set of quasi-LTI operators. By this, we mean perturbations $\mathbf{\Delta}$ lying in the set

$$\mathcal{L}_{LTI}(\nu) := \left\{ \mathbf{\Delta} \in \mathcal{L}(L_2^m) : \sup_{T>0} \frac{\|\mathbf{D}_T \mathbf{\Delta} - \mathbf{\Delta} \mathbf{D}_T\|}{T} \leq \nu, \mathbf{\Delta} \text{ causal} \right\},$$

where $\nu > 0$ and $\mathbf{D}_T$ is the T-shift on L_2. This set is precisely the continuous time analogue of the discrete time slowly time-varying set in [23] and is called quasi-LTI since, intuitively, less time variation is permitted as ν is decreased; indeed, the set $\mathcal{L}_{LTI}(0)$ corresponds to the set of all causal LTI operators on L_2. We can then define the set of quasi-LTI *structured* operators via

$$\mathcal{X}_{LTI}(\nu) := \mathcal{X}_s \cap \mathcal{L}_{LTI}(\nu).$$

In the case where $\mathcal{X}_{LTI}(\nu) = \mathcal{L}_{LTI}(\nu)$, we say that our perturbation set is *unstructured*.

Accordingly, we now define a particular class of so-called D-scaling sets, which will appear throughout what follows. Let $\mathfrak{D}^s_{LTI}$ be the set of all *nonsingular* operators in $\mathcal{L}_{\mathcal{A}_{\mathbb{C}^+}}$ whose spatial structure allows them to commute with all members of $\mathcal{X}_{LTI}(0)$. Specifically, we have

$$\mathfrak{D}^s_{LTI} = \{\mathbf{D} \in \mathcal{L}_{\mathcal{A}_{\mathbb{C}^+}} : \mathbf{D}\boldsymbol{\Delta} = \boldsymbol{\Delta}\mathbf{D} \text{ for each } \boldsymbol{\Delta} \in \mathcal{X}_{LTI}(0), \text{ and } 0 \notin \operatorname{spec}(\mathbf{D})\}.$$

That is, every $\mathbf{D} \in \mathfrak{D}^s_{LTI}$ has a corresponding transfer function representation $\hat{D} \in \mathcal{A}_{\mathbb{C}^+}$ of the form $\hat{D} = \operatorname{diag}(\hat{d}_1 I_{m_1}, \ldots, \hat{d}_d I_{m_d})$, where each scalar function $\hat{d}_k \in \mathcal{A}_{\mathbb{C}^+}$. Of course, if $\mathcal{X}_{LTI}(\nu) = \mathcal{L}_{LTI}(\nu)$, the transfer function $\hat{D}$ simply has the form $\hat{D} = \hat{d} I_m$, where $\hat{d} \in \mathcal{A}_{\mathbb{C}^+}$, and we write $\mathfrak{D}^u_{LTI}$ in lieu of $\mathfrak{D}^s_{LTI}$ for this particular case.

Recall that we defined the operator $\mathbf{M}$ to be the nominal closed-loop sampled-data system mapping $\begin{bmatrix} p_1 \\ w \end{bmatrix} \mapsto \begin{bmatrix} q_2 \\ z \end{bmatrix}$ when $\boldsymbol{\Delta} = 0$. Thus the system of Figure 3.1 is exactly that of Figure 3.2 below; the latter is more convenient to work with in our framework. Also notice that by Assumption 3.1, the operator $\mathbf{M}$ is bounded. If we compatibly partition $\mathbf{M} =: \begin{bmatrix} \mathbf{M}_{11} & \mathbf{M}_{12} \\ \mathbf{M}_{21} & \mathbf{M}_{22} \end{bmatrix}$ with respect to its inputs and outputs, we are in a position to state our first result regarding robust stabilization. The lemma, whose proof is straightforward, says that we need only verify the existence and boundedness of one of the component maps of Figure 3.2 (rather than all four) in appealing to our definition of uniform robust stability.

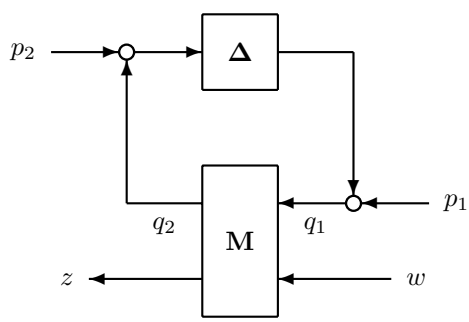

FIG. 3.2. *Robust performance configuration.*

LEMMA 3.3. *Suppose that $\mathcal{X}$ is a subspace of $\mathcal{L}(L_2)$ and $\rho > 0$. Then the system of Figure* 3.1 *has uniform robust stability to the perturbation set $\rho\mathcal{U}\mathcal{X}$ if and only if for each $\boldsymbol{\Delta} \in \rho\mathcal{U}\mathcal{X}$ the mapping $(\mathbf{I} - \mathbf{M}_{11}\boldsymbol{\Delta})^{-1}$ exists in $\mathcal{L}(L_2)$ and the family of maps $(\mathbf{I} - \mathbf{M}_{11}\boldsymbol{\Delta})^{-1}$ is uniformly bounded over $\mathcal{U}\mathcal{X}$.*

In light of the lemma, we see that uniform robust stability of a sampled-data system can be studied using the simplified configuration of Figure 3.3. Of course, we can use this framework to study uniform robust stability of the sampled-data system of Figure 3.2 by setting $\mathbf{M} = \mathbf{M}_{11}$ in Figure 3.3. This brings us to our main results.

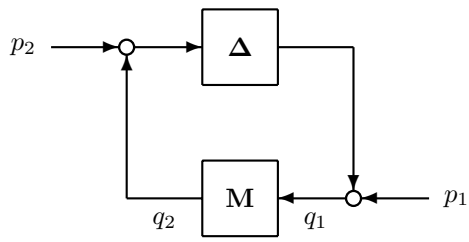

FIG. 3.3. *Robust stabilization configuration.*

THEOREM 3.4. *Suppose the nominal sampled-data closed-loop operator* $\mathbf{M} \in \mathcal{L}_{\mathcal{A}_{\mathbb{D}}}$. *Then, for every* $0 < \rho < 1$, *the system of Figure* 3.3 *has uniform robust stability against perturbations in* $\rho\mathcal{UX}_{LTI}(\nu)$ *for some* $\nu > 0$ *if and only if*

$$\inf_{\mathbf{D} \in \mathfrak{D}^s_{LTI}} \|\mathbf{D}\mathbf{M}\mathbf{D}^{-1}\|_{L_2 \to L_2} \leq 1.$$

An important feature of our robustness paradigm is that robust performance problems can be cast in a robust stability framework. See [8] for the details concerning this conversion. This then allows us to greatly expedite the proofs of our results as the framework established in proving robust stability results can be reused, modulo some technical modifications, to prove results concerning robust performance. To this end, we have Theorem 3.5 below, which constitutes the main result of the paper.

THEOREM 3.5. *Suppose the nominal sampled-data closed-loop operator* $\mathbf{M} \in \mathcal{L}_{\mathcal{A}_{\mathbb{D}}}$. *Then, for every* $0 < \rho < 1$, *the system of Figure* 3.1 *has uniform robust performance against perturbations in* $\rho\mathcal{UX}_{LTI}(\nu)$ *for some* $\nu > 0$ *if and only if*

$$\inf_{\mathbf{D} \in \mathfrak{D}^s_{LTI}} \left\| \begin{bmatrix} \mathbf{D} & 0 \\ 0 & \mathbf{I} \end{bmatrix} \mathbf{M} \begin{bmatrix} \mathbf{D} & 0 \\ 0 & \mathbf{I} \end{bmatrix}^{-1} \right\|_{L_2 \to L_2} \leq 1.$$

The theorem supplies us with a condition that guarantees uniform robust performance of the sampled-data system of Figure 3.1. Written in the operator formulation, the condition is precisely the same as the discrete time condition derived in [23].

Remark 3.6. Theorems 3.4 and 3.5 both involve the minimization of a scaled norm condition over the set $\mathfrak{D}^s_{LTI}$. Notice that by Proposition 2.1 we could have replaced this set by $\mathcal{L}_{\mathcal{RH}_\infty} \cap \mathfrak{D}^s_{LTI}$, where $\mathcal{L}_{\mathcal{RH}_\infty}$ is the subspace of linear operators on L_2 which have stable, proper, rational transfer function representations. Although all of our results still hold with this new set, it is more technically convenient to use $\mathfrak{D}^s_{LTI}$ in our proofs. Further, we point out that the results do *not* hold in general if $\mathcal{A}_{\mathbb{C}^+}$ and $\mathcal{A}_{\mathbb{D}}$ are replaced by their associated H_∞ spaces.

We now make a few comments regarding the results presented in this section. First, notice that our robustness conditions involve a minimization over the D-scaling set $\mathfrak{D}^s_{LTI}$. That we obtain D-scaling problems is not entirely surprising in light

of previous work in the area. In [12], it is shown that a structured singular value calculation is an exact test for robust stability of a sampled-data system to the set of LTI perturbations. It was also shown that if the perturbations are LTV, PTV, or quasi-PTV, then the test for robustness involves a D-scaling problem. Of course, it is well known that D-scaling problems form natural upper bounds to structured singular value calculations.

Having stated the main results of the paper, we now outline the related work contained within the next few sections. We begin by introducing a further set of tools and results required in proving our necessity results. In section 5, we prove a simplified version of Theorem 3.4 with $\mathcal{X}_{LTI}(\nu) = \mathcal{L}_{LTI}(\nu)$. Namely, we limit ourselves to the case where our perturbations are unstructured. The proofs for robustness to the class of structured quasi-LTI perturbations require mostly technical modifications from the results presented in section 5 and are omitted due to space considerations. Complete details concerning these extensions may be found in [8].

4. Analysis of sampled-data systems. In section 2, we focused on presenting mathematical tools which can be used to study any dynamical system. The goal of this section is to develop some further results that will simplify the proofs of the main results stated in the last section. The material presented below is collected in this section because the results are of independent interest. First, we examine some of the tools required in the analysis of sampled-data systems. Namely, we will introduce a lifting formalism for periodic operators as well as another operator-valued representation of our nominal system $\mathbf{M}$ called the sampled-data frequency response. We reserve the last subsection of this section for an introduction to the S-procedure.

4.1. Lifting of periodic systems. We begin our study of sampled-data systems by describing a technique for lifting periodic operators. The aim of this formalism, which was first developed in [5, 29, 30, 4] is to provide a framework in which the periodic system becomes time-invariant. Although the technique introduced applies to any periodic operator in $\mathcal{L}(L_2)$, we focus primarily on sampled-data systems.

The first step is to define the *sampled-data lifting operator* $\mathbf{W}$ as a mapping from $L_2[0,\infty)$ to $\ell_2(\mathcal{K}_2)$. Given $u \in L_2$, the sequence $\tilde{u} = \mathbf{W}u$ is defined via

$$(\tilde{u}[k])(\tau) := u(kh + \tau) \tag{4.1}$$

for $\tau \in [0,h)$ and $k \in \mathbb{N}_o$. From the definition, it is obvious that $\mathbf{W}^{-1}$ exists and that $\mathbf{W}$ is an isomorphism between L_2 and $\ell_2(\mathcal{K}_2)$. Hence, if $\mathbf{F} \in \mathcal{L}(L_2)$, then the mapping $\tilde{F} := \mathbf{W}\mathbf{F}\mathbf{W}^{-1}$ is a bounded linear operator on $\ell_2(\mathcal{K}_2)$; in fact, $\|\mathbf{F}\|_{L_2 \to L_2} = \|\tilde{F}\|_{\ell_2 \to \ell_2}$. Note the convention we have adopted here: if $u \in L_2$ and $\mathbf{F} \in \mathcal{L}(L_2)$, then the lifted signal and the lifted system are denoted by $\tilde{u}$ and $\tilde{F}$, respectively.

Using the sampled-data lifting operator and the Z-transform, we can obtain a transfer function representation for $\mathbf{M}$ of the form $\check{M}(z) = \check{C}z(I - zA_d)^{-1}\check{B} + \check{D}$. The explicit form of the operators on the right-hand side is in Appendix A. Using these expressions, it is then an easy matter to show that $\check{M}(z) \in \mathcal{A}_{\mathbb{D}}$. This property constitutes the starting point for subsection 4.2.1.

4.2. The sampled-data frequency response. The second tool we introduce in this section is the sampled-data frequency response, which provides us with another frequency domain representation for a class of operators in $\mathcal{L}(L_2)$. This new representation is at the heart of the necessity conditions proposed in Theorems 3.4 and 3.5, as is best seen later through Theorem 5.2. As the name suggests, the sampled-data frequency response plays an analogous role to the Fourier frequency response for

standard continuous time systems. This connection will become more obvious in what follows.

Our study of the sampled-data frequency response is split into three parts. We begin by defining the frequency response operator. We then focus on the class of LTI perturbations having transfer function representations in the half-plane algebra $\mathcal{A}_{\mathbb{C}^+}$. This allows us to define the D-scaling sets we will use to scale the frequency response of our sampled-data systems. In the second part, we dwell on an asymptotic property of the frequency response operator in proving two technical lemmas used in the proof of Theorem 3.4. Finally, in subsection 4.2.3, we discuss the continuity of the mappings introduced in defining the sampled-data frequency response operator of a system. Our presentation is based on that of [12], and we refer the reader to this book and the references cited therein for a more complete overview than the one presented here; see also [1, 2, 31].

4.2.1. Lifting in frequency domain. We begin by defining the set $\mathcal{L}_{\mathcal{A}_{\mathbb{D}}}$ to consist of operators $\mathbf{G} \in \mathcal{L}(L_2)$ for which there exists a function $\check{G}(z) \in \mathcal{A}_{\mathbb{D}}$ such that $\mathbf{G} = \mathbf{W}^{-1}Z^{-1}\check{G}Z\mathbf{W}$. Notice that at a fixed point $z_{\mathrm{o}} \in \overline{\mathbb{D}}$ the operator $\check{G}(z_{\mathrm{o}}) : \mathcal{K}_2 \to \mathcal{K}_2$. Clearly, every operator in the set $\mathcal{L}_{\mathcal{A}_{\mathbb{D}}}$ is h-periodic, although the set of all causal h-periodic operators on L_2 is isomorphic to the larger space $\mathcal{H}_\infty(\mathbb{D})$. For such an operator, we also have that

$$\|\mathbf{G}\| = \max_{z\in\mathbb{D}} \|\check{G}(z)\| = \sup_{\omega\in\mathbb{R}} \|\check{G}(e^{j\omega})\|,$$

where the second equality follows from a maximum modulus result. Thus it seems that when dealing with questions about robust stability and performance, we need only concern ourselves with the behavior of $\check{G}(z)$ along the boundary of the unit disc since this is where the function takes its "largest" values. As we will see later, this is precisely the case.

Let us now briefly discuss the space $\mathcal{K}_2$. It is not difficult to show that for any $\omega_{\mathrm{o}} \in (-\pi, \pi]$ the sequence $\{\psi_k\}$ forms a complete orthonormal basis for $\mathcal{K}_2$, where

$$\psi_k(t) := h^{-\frac{1}{2}} e^{jh^{-1}(2\pi\nu_k - \omega_{\mathrm{o}})t} \tag{4.2}$$

for $t \in [0, h)$, and ν_k is the kth element in the sequence $\{0, 1, -1, 2, -2, \dots\}$.

We now define a one-parameter family of operators $J_\omega : \mathcal{K}_2 \to \ell_2$ for $\omega \in (-\pi, \pi]$. Given $\psi \in \mathcal{K}_2$ with Fourier expansion $\psi = \sum_{k=0}^{\infty} a_k\psi_k$, we have

$$J_{\omega_{\mathrm{o}}}\psi := (a_0, a_1, a_2, \dots),$$

where $\omega_{\mathrm{o}} \in (-\pi, \pi]$ is the frequency at which the basis $\{\psi_k\}$ is defined. In this fashion, we can define an operator-valued function $J : \partial\mathbb{D} \to \mathcal{L}(\mathcal{K}_2, \ell_2)$ through the relationship

$$J(e^{j\omega}) := J_\omega.$$

From this definition, it is immediate that $J^{-1} = J^*$ at each point $\omega \in (-\pi, \pi]$ and that J is an isomorphism between the space of square integrable $\mathcal{K}_2$-valued functions on $\partial\mathbb{D}$ and the square integrable ℓ_2-valued functions on $\partial\mathbb{D}$.

The sampled-data frequency response of an operator $\mathbf{G} \in \mathcal{L}_{\mathcal{A}_{\mathbb{D}}}$ is then defined by

$$G(e^{j\omega}) := J_\omega \check{G}(e^{j\omega}) J_\omega^*. \tag{4.3}$$

Our above discussion allows us to conclude that $G : \partial\mathbb{D} \to \mathcal{L}(\ell_2)$ and that

$$\sup_{\omega\in(-\pi,\pi]} \|G(e^{j\omega})\|_{\ell_2\to\ell_2} = \sup_{\omega\in(-\pi,\pi]} \|\check{G}(e^{j\omega})\|_{\mathcal{K}_2\to\mathcal{K}_2} = \|\mathbf{G}\|_{L_2\to L_2}.$$

In the last section, we saw that for the sampled-data system of Figure 3.1, the transfer function $\check{M}(e^{j\omega}) = \check{C}e^{j\omega}(I - e^{j\omega}A_d)^{-1}\check{B} + \check{D}$. Using our mapping J, we can define new operators $\tilde{B} := \check{B}J_\omega^*$, $\tilde{C} := J_\omega\check{C}$, and $\tilde{D} := J_\omega\check{D}J_\omega^*$ so that

$$M(e^{j\omega}) = \tilde{C}e^{j\omega}(I - e^{j\omega}A_d)^{-1}\tilde{B} + \tilde{D}.$$

From these definitions, it is easy to see that $\tilde{B} : \ell_2 \to \mathbb{C}^{\tilde{n}}$, $\tilde{C} : \mathbb{C}^{\tilde{n}} \to \ell_2$, and $\tilde{D} : \ell_2 \to \ell_2$. Hence each operator can be viewed as an infinite dimensional "matrix." For example, we can write

$$\tilde{B} =: \begin{bmatrix}(\tilde{B})_0 & (\tilde{B})_1 & (\tilde{B})_2 & \cdots\end{bmatrix},$$

where the block $(\tilde{B})_k$ is simply a matrix acting on the kth element of a sequence in ℓ_2^m. Similar definitions can be made for $(\tilde{C})_l$ and $(\tilde{D})_{lk}$, the matrix components of $\tilde{C}$ and $\tilde{D}$, respectively. State space formulae for all of the above quantities can be found in Appendix A.

We end our introduction to the sampled-data frequency response with a closer examination of a special case. The results that we state can be found in [12] along with their proofs. Recall that $\mathcal{L}_{\mathcal{A}_{\mathbb{C}^+}}$ denotes the subspace of operators in $\mathcal{L}(L_2)$ which have transfer function representations in the half-plane algebra $\mathcal{A}_{\mathbb{C}^+}$. Suppose our perturbation $\mathbf{\Delta} \in \mathcal{X}_{LTI}(0) \cap \mathcal{L}_{\mathcal{A}_{\mathbb{C}^+}}$. That is, $\mathbf{\Delta}$ is LTI and lies in our spatially structured set, while its transfer function $\hat{\Delta} \in \mathcal{A}_{\mathbb{C}^+}$. By Proposition 2.1, this set is the closure of the FDLTI operators in the spatially structured set $\mathcal{X}_s$. For such a perturbation, it can be shown that

$$\Delta(e^{j\omega_\circ}) = \operatorname{diag}(\hat{\Delta}(j\theta_0), \hat{\Delta}(j\theta_1), \hat{\Delta}(j\theta_2), \dots),$$

where the frequency $\theta_k = \frac{2\pi\nu_k - \omega_\circ}{h}$. See [12]. Thus $\Delta(e^{j\omega_\circ})$ can be viewed as an infinite dimensional block diagonal matrix whose blocks inherit their spatial structure from $\mathcal{X}_s$. More precisely, by defining the set

$$\mathbf{\Delta}_{LTI} := \{\operatorname{diag}(\Delta_0, \Delta_1, \Delta_2, \dots) : \Delta_k \in \mathcal{X}\},$$

where the set of spatially structured matrices

$$\mathcal{X} := \{\operatorname{diag}(Q_1, Q_2, \dots, Q_d) : Q_k \in \mathbb{C}^{m_k\times m_k}\} \subset \mathbb{C}^{m\times m},$$

we see that $\Delta(e^{j\omega}) \in \mathbf{\Delta}_{LTI}$ at each frequency along the unit circle.

Finally, we can define the set of D-scaling operators for $M(e^{j\omega})$. This is done by analogy with our definitions of the sets $\mathfrak{D}^s_{LTI}$ and $\mathfrak{D}^u_{LTI}$. Let $\tilde{\mathfrak{D}}^s$ be the set of nonsingular operators which commute with each member of $\mathbf{\Delta}_{LTI}$. From this definition, it is easy to show that

$$\tilde{\mathfrak{D}}^s = \{\operatorname{diag}(\tilde{D}_0, \tilde{D}_1, \tilde{D}_2, \dots) : \tilde{D}_k = \operatorname{diag}(\tilde{d}_{k,1}I_{m_1}, \dots, \tilde{d}_{k,d}I_{m_d}),\ 0 \neq \tilde{d}_{k,l} \in \mathbb{C}\}.$$

Of course, we can similarly conclude that when $\tilde{\mathfrak{D}}^s = \tilde{\mathfrak{D}}^u$, each block $\tilde{D}_k = \tilde{d}_k I_m$ with $0 \neq \tilde{d}_k \in \mathbb{C}$. We now further restrict this set by appealing to the following elementary result.

PROPOSITION 4.1. *Given bounded linear operators M and D acting on some Hilbert space $\mathcal{H}$ with D invertible. Then for a scalar $\delta > 0$, the following are equivalent:*

(1) $\|DMD^{-1}\|^2 \leq \delta^2$.
(2) $M^*D^*DM - \delta^2 D^*D \leq 0$.

We therefore define the positive subsets

$$\mathfrak{D}^s = \{\mathrm{diag}(D_0, D_1, D_2, \dots) : D_k = \mathrm{diag}(d_{k,1}I_{m_1}, \dots, d_{k,d}I_{m_d}),\ 0 < d_{k,l} \in \mathbb{R}\} \tag{4.4}$$

and

$$\mathfrak{D}^u = \{\mathrm{diag}(d_0 I_m, d_1 I_m, d_2 I_m, \dots) : 0 < d_k \in \mathbb{R}\} \tag{4.5}$$

and will work with them instead of $\tilde{\mathfrak{D}}^s$ and $\tilde{\mathfrak{D}}^u$. With this, we conclude our introduction to the sampled-data frequency response. Further properties of this representation are discussed in the next two subsections.

4.2.2. Frequency response as an asymptotic limit. We now focus on another key property of the sampled-data frequency response operator. The results below provide us with a new means by which we can connect the original operator $\mathbf{M}$ to its frequency response function $M(e^{j\omega})$. The result will be used later when we prove the necessity of the condition of Theorem 3.4.

To begin with, we need to define a two-parameter set of scalar functions

$$\phi^q_{\omega_o}(t) := \begin{cases} \frac{1}{\sqrt{qh}} e^{j\omega_o t}, & 0 \leq t < qh, \\ 0, & t \geq qh, \end{cases} \tag{4.6}$$

where $\omega_o \in \mathbb{R}$ and $q \in \mathbb{N}_o$. Notice that any such function always has unit norm. These functions have a useful property in connection with the frequency response operator, as is seen in the following lemma.

LEMMA 4.2. *Given $b_0, \dots, b_N \in \mathbb{C}^m$, a frequency $\theta_o \in (-\pi, \pi]$, and the sequence $\nu_k = \{0, 1, -1, 2, -2, \dots\}$. Let $\omega_l := \frac{2\pi\nu_l - \theta_o}{h}$ for every $l \in \mathbb{N}_o$. Then*

$$\|z^q - \mathbf{M}w^q\|_{L_2} \longrightarrow 0 \text{ as } q \to \infty,$$

where $\mathbf{M}$ is the nominal sampled-data system of Figure 3.1, $w^q(t) = \sum_{l=0}^N b_l \phi^q_{\omega_l}(t)$, and $z^q(t) = \sum_{l=0}^N \sum_{p=0}^\infty \left(M_{p,l}(e^{j\theta_o})b_l\right) \phi^q_{\omega_p}(t)$.

The lemma states that each of the $N+1$ harmonics $\omega_0, \dots, \omega_N$ generates a countable number of aliased harmonics whose sizes are determined from the frequency response operator $M(e^{j\omega})$; in interpreting this result, observe for a fixed q that the functions $\phi^q_{\omega_l}$ form an orthonormal sequence in L_2.

4.2.3. Continuity properties. We end our introduction to the sampled-data frequency response with a look at an important continuity property of the frequency response operator $M(e^{j\omega})$ defined in subsection 4.2.1. Let us begin by defining the operator $X \in \mathcal{L}(\ell_2)$ via

$$(b_0, b_1, b_2, \dots) \xrightarrow{X} (b_{\eta_0}, b_{\eta_1}, b_{\eta_2}, \dots),$$

where η_k is the sequence $\{2, 0, 4, 1, 6, 3, 8, 5, 10, 7, 12, 9, \dots\}$.

Recall that $M(e^{j\omega})$ provides an alternative representation for the multiplication operator $\check{M}(z)$ on the unit circle $\partial\mathbb{D}$. The interesting thing to note is that although the transfer function $\check{M}(\cdot)$ is continuous on $\partial\mathbb{D}$, Proposition 4.3 implies that its counterpart $M(\cdot)$ does not always share this property in general. Nonetheless, we still have the following result, which says that a discontinuity can occur at only one point on $\partial\mathbb{D}$.

PROPOSITION 4.3. *The frequency response of the nominal sampled-data system* **M** *of Figure* 3.1 *satisfies the following two properties.*

(i) $M(e^{j\omega})$ *is continuous on* $(-\pi, \pi)$ *and left continuous at* π.

(ii) $\lim_{\omega\to-\pi^+} \|M(e^{j\omega}) - X^*M(-1)X\|_{\ell_2\to\ell_2} = 0$.

The proof results from an easy application of the triangle inequality and the continuity of the lifting operator J_ω. See [12].

4.3. The S-procedure. The final topic we will cover in this section is the S-procedure [18]. In our presentation we provide a new result, which generalizes earlier work from a finite to a countable number of quadratic forms under special conditions. It is worth noting that the general result for a countable number of quadratic forms does not hold.

It is in this vein that we introduce time-invariant quadratic forms on ℓ_2: a mapping $\psi : \ell_2 \to \mathbb{R}$ is called a time-invariant quadratic form if there exist two time-invariant operators X and Y in $\mathcal{L}(\ell_2)$ satisfying

$$\psi(u) = \|Xu\|_2^2 - \|Yu\|_2^2$$

for each $u \in \ell_2$.

In the work that follows, we will work exclusively with sequences of time-invariant operators on ℓ_2. However, our study will be limited to those sequences which satisfy the following condition.

Condition 4.4. A sequence $\{X_k\}$ of time-invariant operators on ℓ_2 satisfies this condition if $\sum_{k=0}^{\infty} \|X_k u\|_2^2$ is finite for every $u \in \ell_2$ with $\|u\|_2 = 1$.

Note, in particular, that any such sequence X_k tends strongly to zero.

Suppose we have two sequences $\{X_k\}$ and $\{Y_k\}$ of time-invariant operators on ℓ_2 which satisfy Condition 4.4. We then define the set

$$\nabla := \{(\psi_0(u), \psi_1(u), \dots) : u \in \ell_2,\ \|u\|_2 = 1\} \subset \ell_\infty, \tag{4.7}$$

where $\psi_k(u) = \|X_k u\|_2^2 - \|Y_k u\|_2^2$ for $k \in \mathbb{N}_o$ and ℓ_∞ is the set of bounded real-valued sequences. Lemma 4.5 below states an important property of the set ∇.

LEMMA 4.5. *Suppose* $\{X_k\}$ *and* $\{Y_k\}$ *are sequences of time-invariant operators on* ℓ_2 *which satisfy Condition* 4.4*, and* ∇ *is the corresponding subset of* ℓ_∞ *defined in* (4.7)*. Then* ∇ *is a subset of* ℓ_1*, the set of absolutely summable sequences, and its closure* $\overline{\nabla}$ *is convex.*

The proof of this result can be found in [8] along with the proofs of the other results of this section; it is an extension of the proof of an analogous result found in [18] and adopts the presentation of [22].

In what follows, we denote the positive orthant of ℓ_1 by

$$\Pi^+ := \{x \in \ell_1 : x = (x_0, x_1, \dots), x_k \geq 0 \text{ for each } k \in \mathbb{N}_o\}.$$

This definition in hand, we are now set to present the key result in this section. The proof relies on the strong separation theorem for normed spaces and the fact that the normed dual space of ℓ_1 is isomorphic to ℓ_∞.

THEOREM 4.6. *Suppose* $\{X_k\}$ *and* $\{Y_k\}$ *are sequences of time-invariant operators in* $\mathcal{L}(\ell_2)$ *such that* ∇*, the corresponding set defined by* (4.7)*, is a bounded subset of* ℓ_1*. Then the following statements are equivalent.*

(i) *The inequality* $\inf_{x\in\nabla,\ y\in\Pi^+} \|x-y\|_{\ell_1} > 0$ *is satisfied.*

(ii) *There exists a bounded sequence of real scalars* $d_\infty, d_0, d_1, d_2, \ldots > \beta > 0$ *for some* $\beta > 0$*, such that* $d_0\psi_0(u) + d_1\psi_1(u) + \cdots \le -d_\infty$ *for all* $u \in \ell_2$ *with* $\|u\|_2 = 1$*.*

We now begin the process of narrowing our focus by specializing this last result to our sampled-data framework. For each $l \in \mathbb{N}_{\mathrm{o}}$, we define the projection operator E_l on ℓ_2 to be the operator whose representation is

$$E_l = \operatorname{diag}(\underbrace{0, 0, \ldots, 0}_{l \text{ zeros}}, I_m, 0, \ldots),$$

where I_m is the $m \times m$ identity matrix. Now consider the space $\ell_2(\ell_2^m)$. Suppose $L \in \mathcal{L}(\ell_2^m)$. We define the *memoryless* operator $T_L : \ell_2(\ell_2^m) \to \ell_2(\ell_2^m)$ as the mapping satisfying

$$(T_L u)_k := L u_k$$

for each $k \in \mathbb{N}_{\mathrm{o}}$. Given an LTI operator V on $\ell_2(\ell_2)$ and an integer $N \in \mathbb{N}_{\mathrm{o}}$, we define the special set of quadratic forms

$$\psi_l(u) := \begin{cases} \|T_{E_l} V u\|_2^2 - \|T_{E_l} u\|_2^2, & l = 0, \ldots, N, \\ \|T_{Q_N} V u\|_2^2 - \|T_{Q_N} u\|_2^2, & l = N+1, \\ 0, & l > N+1, \end{cases} \tag{4.8}$$

where $u \in \ell_2(\ell_2)$ and the projection operator $Q_n : \ell_2 \to \ell_2$ is defined by

$$Q_n(a_0, \ldots, a_n, a_{n+1}, \ldots) = (0, \ldots, 0, a_{n+1}, a_{n+2}, \ldots)$$

for each $a \in \ell_2$ and $n \in \mathbb{N}_{\mathrm{o}}$. Having made this definition, we are now able to state our next result. It relates condition (i) from the last theorem to an equivalent D-scaling problem over the set $\mathfrak{D}_n^u \subset \mathfrak{D}^u$ defined by

$$\mathfrak{D}_n^u = \{D = \operatorname{diag}(d_0 I_m, d_1 I_m, \ldots) \in \mathfrak{D}^u : d_l = d_{N+1} \text{ for } l > N+1\},$$

where $\mathfrak{D}^u$ is the D-scaling set defined in (4.5); thus note that $\mathfrak{D}_n^u$ is a subset of $\mathfrak{D}^u$.

COROLLARY 4.7. *Given a time-invariant operator* $V \in \mathcal{L}(\ell_2(\ell_2))$ *and the corresponding set of time-invariant quadratic forms defined in* (4.8)*. Then the inequality* $\inf_{x\in\nabla,\ y\in\Pi^+} \|x-y\|_{\ell_1} > 0$ *holds if and only if*

$$\inf_{D\in\mathfrak{D}_n^u} \|T_D V T_{D^{-1}}\|_{\ell_2(\ell_2)\to\ell_2(\ell_2)} < 1.$$

This simplified version of Theorem 4.6 is sufficient for our purposes since there is only a finite number of nonzero quadratic forms defined in (4.8). However, the full result may have wider application.

The following corollary is the final result of this section. It links the quadratic forms defined in (4.8) to the D-scaling set $\mathfrak{D}^u$ and is precisely the result we will appeal to later in proving the main theorems of the paper.

COROLLARY 4.8. *If the inequality*

$$\inf_{D\in\mathfrak{D}^u} \|DM(e^{j\omega_o})D^{-1}\|_{\ell_2\to\ell_2} > 1$$

holds for some frequency $\omega_o \in (-\pi,\pi]$, *then for each integer* $n > 0$ *there exist* $u \in \ell_2(\ell_2^m)$ *with* $\|u\| = 1$ *and* $\gamma > 1$ *such that*

$$\gamma\|T_{E_l}u\|_{\ell_2(\ell_2)} \le \|T_{E_l}T_M u\|_{\ell_2(\ell_2)}$$

for each $l = 0,\dots,n$, *and*

$$\gamma\|T_{Q_n}u\|_{\ell_2(\ell_2)} \le \|T_{Q_n}T_M u\|_{\ell_2(\ell_2)}.$$

Note here that T_M above, short for $T_{M(e^{j\omega_o})}$, is time-invariant.

We now have a complete set of tools with which to study our problems. We shall make extensive use of the techniques developed here in section 5, where we prove the necessity and sufficiency results of section 3.

5. Uniform robust stability: Unstructured perturbations. The proofs for Theorems 3.4 and 3.5 are quite lengthy. For the purposes of this paper, we will therefore concentrate on the following specialized result. Namely, we shall focus on characterizing uniform robust stability against the set of *unstructured* perturbations, $\mathcal{UL}_{LTI}(\nu)$. The extensions to Theorems 3.4 and 3.5 are routine; details are in [8].

THEOREM 5.1. *Suppose the nominal sampled-data closed-loop operator* $\mathbf{M} \in \mathcal{L}_{\mathcal{A}_\mathbb{D}}$, *and the frequency response* $M(e^{j\omega_o})$ *is a compact operator at each frequency* $\omega_o \in (-\pi,\pi]$. *Then, for every* $0 < \rho < 1$, *the system of Figure* 3.3 *has uniform robust stability against perturbations in* $\rho\mathcal{UL}_{LTI}(\nu)$ *for some* $\nu > 0$ *if and only if*

$$\inf_{\mathbf{D}\in\mathfrak{D}^u_{LTI}} \|\mathbf{DMD}^{-1}\|_{L_2\to L_2} \le 1.$$

The closed loop operator $\mathbf{M}$ defined in section 3 will always satisfy the supposition of the theorem; see the state space formula of Appendix A. Thus the above result holds for a more general class of periodic systems.

5.1. Necessity. We begin our proof of Theorem 5.1 by showing that the D-scaling condition put forward is necessary in order to guarantee uniform robust stability of our sampled-data system. The result stated next is key. It allows us to convert our original D-scaling condition to a D-scaling condition involving the sampled-data frequency response operator introduced last section.

THEOREM 5.2. *Suppose* $M(e^{j\omega})$ *is continuous and compact at each* $\omega \in \mathbb{R}$. *Then*

$$\inf_{\mathbf{D}\in\mathfrak{D}^u_{LTI}} \|\mathbf{DMD}^{-1}\| = \sup_{\omega\in\mathbb{R}} \inf_{D\in\mathfrak{D}^u} \|DM(e^{j\omega})D^{-1}\|.$$

The proof of this result is located in Appendix B. At first, it appears that there is no distinct advantage to this new formulation since the representations involved remain infinite dimensional. However, the properties of the sampled-data frequency response operator that were introduced in the last section make this new representation more amenable to constructing the required proof. Moreover, the computational framework we develop in [9] is entirely based on the interchangeability of the two representations.

Lemma 5.3 below is the main necessity result that we shall prove in this paper. By Theorem 5.2, it is precisely the contrapositive of the desired result. Now, although we

significantly bolstered our set of tools in the last section, we still require an additional technical result which will help us construct the destabilizing perturbation required in the proof of the theorem. We state the main result here and then briefly digress before returning to the proof in subsection 5.1.2.

LEMMA 5.3. *Suppose* $\mathbf{M} \in \mathcal{L}_{\mathcal{A}_{\mathbb{D}}}$, *and* $M(e^{j\omega_o})$ *is a compact operator at each frequency* $\omega_o \in (-\pi, \pi]$. *If*

$$\sup_{\omega\in(-\pi,\pi]} \inf_{D\in\mathfrak{D}^u} \|DM(e^{j\omega})D^{-1}\|_{\ell_2\to\ell_2} > 1,$$

then the sampled-data system in Figure 3.3 *does not have uniform robust stability to the perturbation sets* $\mathcal{UL}_{LTI}(\nu)$ *for any* $\nu > 0$.

5.1.1. Constructing destabilizing perturbations. Here we present a number of lemmas. The key result of this subsection is concerned with the maximal rate of time variation required for an operator to move power across frequencies while maintaining a set of power inequalities. The basic construction parallels that in [23].

Our first result gives an asymptotic property of an operator in the set $\mathcal{L}_{\mathcal{A}_{\mathbb{C}+}}$ and is nothing more than a special case of an asymptotic frequency response result presented in section 4. Since the result is standard in linear systems theory, no proof is presented.

LEMMA 5.4. *Suppose* $\Omega \in \mathbb{R}$ *and* $\mathbf{Q} \in \mathcal{L}_{\mathcal{A}_{\mathbb{C}+}}$. *Then the following limit is satisfied:*

$$\lim_{q\to\infty} \|\hat{Q}(j\Omega)\phi_\Omega^q - \mathbf{Q}\phi_\Omega^q\| = 0,$$

where the function ϕ_Ω^q *is defined in* (4.6).

Our next lemma is concerned with filtering a signal consisting of $N+1$ countable sets of aliased frequencies. The construction is based on a result first proved by Rudin [24] and the asymptotic property presented in our last result.

LEMMA 5.5. *Suppose* (a) *the frequencies* $-\pi < \omega_0 < \cdots < \omega_N < \omega_0 + \pi$, *and* (b) *the corresponding sequences* $a_0, \ldots, a_N$ *are in* ℓ_2. *Then there exists* $\mathbf{Q} \in \mathcal{L}_{\mathcal{A}_{\mathbb{C}+}}$ *with* $\|\mathbf{Q}\| = 1$ *such that*

$$\lim_{q\to\infty} \|\mathbf{Q}z^q - v^q\| = 0,$$

where $z^q = \sum_{k=0}^N \sum_{l=0}^\infty a_k^l \phi_{\omega_k^l}^q$, $v^q = \sum_{k=0}^N \sum_{l=0}^n a_k^l \phi_{\omega_k^l}^q$, *and* $\omega_k^l = \frac{2\pi\nu_l - \omega_k}{h}$.

Lemma 5.6 is the key result in this section. It provides an upper bound for the rate of change required for an operator $\mathbf{\Delta}$ to move power across frequencies. Once again, due to space limitations, the proof is omitted. We refer the reader to [8].

LEMMA 5.6. *Suppose* (i) $a_k^l, b_k^l \in \mathbb{C}^m$ *for* $0 \le l \le n$ *and* $0 \le k \le N$, (ii) $-\pi < \omega_0 < \cdots < \omega_N < \omega_0 + \pi$, $\omega_i \ne -\omega_j$ *for* $i, j = 0, \ldots, N$, *and* (iii) *for some* $\gamma > 1$, *the finite sequences* a^l *and* b^l *satisfy* $|a^l|_2 \ge \gamma |b^l|_2$ *for each* $0 \le l \le n$. *Then there exists* $\mathbf{\Delta} \in \mathcal{UL}_{LTI}(\nu_o)$, *with* $\nu_o := \frac{\omega_N - \omega_0}{h}$, *such that*

$$\lim_{q\to\infty} \|\mathbf{\Delta}z^q - w^q\| = 0,$$

where $z^q = \sum_{k=0}^N \sum_{l=0}^n a_k^l \phi_{\omega_k^l}^q$, $w^q = \sum_{k=0}^N \sum_{l=0}^n b_k^l \phi_{\omega_k^l}^q$, *and* $\omega_k^l = \frac{2\pi\nu_l - \omega_k}{h}$.

Remark 5.7. The convention introduced in the statement of Lemma 5.6 shall be used throughout the remainder of the paper. Namely, given a sequence of sequences, $a = (a_0, a_1, \ldots,)$, we shall use a_k^l to denote the lth component of the kth sequence.

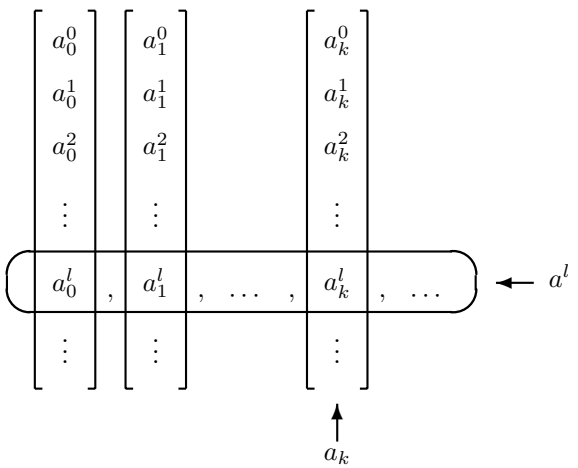

FIG. 5.1. *Typical element of* $\ell_2(\ell_2)$.

Also, we will denote the sequence $(a_0^l, a_1^l, a_2^l, \dots,)$ by a^l. Figure 5.1 illustrates the use of this notation when $a \in \ell_2(\ell_2)$.

Remark 5.8. In the hypotheses of Lemma 5.6, we have assumed that the frequencies $\omega_0, \dots, \omega_N$ are chosen so that $\omega_i \neq -\omega_j$. Although this assumption is never explicitly used in our construction, it is necessary to have it in place when the perturbation $\mathbf{\Delta}$ is required to map real signals back onto real signals.

Corollary 5.9 below is the result needed to construct the destabilizing perturbation required in the proof of Lemma 5.3.

COROLLARY 5.9. *Suppose* (i) $a_k, b_k \in \ell_2$ *for* $0 \leq k \leq N$, (ii) $-\pi < \omega_0 < \cdots < \omega_N < \omega_0 + \pi$, $\omega_i \neq -\omega_j$ *for* $i, j = 0, \dots, N$, *and* (iii) *there exists* $\gamma > 1$ *such that for each* $0 \leq l \leq n$, *we have* $|a^l|_2 \geq \gamma |b^l|_2$. *Then there exists* $\mathbf{\Delta} \in \mathcal{UL}(\nu_o)$ *with* $\nu_o = \frac{\omega_N - \omega_0}{h}$, *such that*

$$\lim_{q \to \infty} \|\mathbf{\Delta} z^q - w^q\| = 0,$$

where $z^q = \sum_{k=0}^{N} \sum_{l=0}^{\infty} a_k^l \phi_{\omega_k^l}^q$, $w^q = \sum_{k=0}^{N} \sum_{l=0}^{n} b_k^l \phi_{\omega_k^l}^q$, *and* $\omega_k^l = \frac{2\pi\nu_l - \omega_k}{h}$.

Having established this last result, we are now in a position to prove Lemma 5.3, which we do next.

5.1.2. Proof of Lemma 5.3. Choose any $\nu_o > 0$. It is sufficient to show that given this choice of ν_o and any $\varepsilon > 0$, we can construct a perturbation $\mathbf{\Delta} \in \mathcal{UL}_{LTI}(\nu_o)$ and a corresponding signal $z \in L_2$ of unit norm such that $\|(\mathbf{I} - \mathbf{M}\mathbf{\Delta})z\| < \varepsilon$.

Let $\varepsilon > 0$. By hypothesis, there exists a $\theta_o \in (-\pi, \pi]$ so that

$$\inf_{D \in \mathfrak{D}^u} \|DM(e^{j\theta_o})D^{-1}\| > 1. \tag{5.1}$$

Next, choose $N \in \mathbb{N}_o$ large enough so that

$$\|P_N M(e^{j\theta_o}) - M(e^{j\theta_o})\| < \frac{\varepsilon}{3\|\mathbf{M}\|}, \tag{5.2}$$

where the projection operator $P_n = I - Q_n$ is defined by

$$P_n(a_0, \dots, a_n, a_{n+1}, \dots) = (a_0, \dots, a_n, 0, 0, \dots)$$

for each $a \in \ell_2$ and $n \in \mathbb{N}_o$. Note that by compactness of $M(e^{j\theta_o})$, such an integer N always exists [15]. Moreover, by continuity of $M(\cdot)$, there exists an interval I about θ_o such that $\|P_N M(e^{j\omega}) - M(e^{j\omega})\| < \frac{\varepsilon}{3\|\mathbf{M}\|}$ for all $\omega \in I$.

Now recall our earlier work on the S-procedure. By Corollary 4.8, condition (5.1) implies that there exist $\gamma > 1$ and $b \in \ell_2(\ell_2)$ with $\|b\| = 1$ so that by defining $a' := T_M b$, we have

$$\gamma \|T_{E_l} b\|_2 \le \|T_{E_l} a'\|_2 = \sqrt{\sum_{k=0}^{\infty} \|E_l M(e^{j\theta_o}) b_k\|_2^2} \tag{5.3}$$

for $l = 0, \dots, N$ and

$$\gamma \|T_{Q_N} b\|_2 \le \|T_{Q_N} a'\|_2 = \sqrt{\sum_{k=0}^{\infty} \|Q_N M(e^{j\theta_o}) b_k\|_2^2}. \tag{5.4}$$

Since T_M is a memoryless operator, we can assume, without loss of generality, that (5.3) and (5.4) are satisfied for b with finite support. Let $K+1$ be the support length of b.

Using (5.3), (5.4), and the continuity of $M(e^{j\omega})$, we can choose $K+1$ distinct frequencies $-\pi < \omega_0 < \cdots < \omega_K < \omega_0 + \pi$, each in the interval I, so that by defining $a_k := M(e^{j\omega_k}) b_k$, we have

(i) $\dfrac{\omega_K - \omega_0}{h} < \nu_o$,

(ii) $\omega_i \neq -\omega_j$ for all $i, j = 0, \dots, K$,

(iii) $$\gamma' \sqrt{\sum_{k=0}^{K} \|E_l b_k\|_2^2} = \gamma' \|T_{E_l} b\|_2 \le \|T_{E_l} a\|_2 = \sqrt{\sum_{k=0}^{K} \|E_l M(e^{j\omega_k}) b_k\|_2^2} \tag{5.5}$$
for each $l = 0, \dots, N$, and

(iv) $$\gamma' \sqrt{\sum_{k=0}^{K} \|Q_N b_k\|_2^2} = \gamma' \|T_{Q_N} b\|_2 \le \|T_{Q_N} a\|_2 = \sqrt{\sum_{k=0}^{K} \|Q_N M(e^{j\omega_k}) b_k\|_2^2} \tag{5.6}$$

for some $1 < \gamma' < \gamma$. Furthermore, without loss of generality, we can also assume that the frequencies $\omega_0, \dots, \omega_K$ are all rational numbers.

We now seek to make use of Corollary 5.9 in order to construct our destabilizing perturbation. Let

$$z^q := \sum_{k=0}^{K} \sum_{l=0}^{\infty} a_k^l \phi_{\omega_k^l}^q, \; u^q := \sum_{k=0}^{K} \sum_{l=0}^{\infty} b_k^l \phi_{\omega_k^l}^q, \text{ and } w^q := \sum_{k=0}^{K} \sum_{l=0}^{N} b_k^l \phi_{\omega_k^l}^q.$$

Henceforth, we shall also assume for simplicity that the integer q in the above definitions is always chosen from the set $\Omega := \{n \in \mathbb{N}_o : n\omega_k \in \mathbb{Z} \text{ for } k = 1, \dots, K\}$. Under

this assumption and the conditions given in (5.6) and (5.2), we then have that

$$\begin{aligned}\|u^q - w^q\|_{L_2}^2 &= \sum_{k=0}^{K} \sum_{l=N+1}^{\infty} \|b_k^l\|_2^2 \\ &= \sum_{k=0}^{K} \|Q_N b_k\|_{\ell_2}^2 \\ &\leq \sum_{k=0}^{K} \|Q_N M(e^{j\omega_k})\|_{\ell_2 \to \ell_2}^2 \cdot \|b_k\|_{\ell_2}^2 \\ &< \left(\frac{\varepsilon}{3\|\mathbf{M}\|}\right)^2 \sum_{k=0}^{K} \|b_k\|_{\ell_2}^2 \\ &= \left(\frac{\varepsilon}{3\|\mathbf{M}\|}\right)^2, \end{aligned} \tag{5.7}$$

since $\|b\| = 1$.

We will now show that $\|\mathbf{M}\boldsymbol{\Delta} z^q - z^q\| < \varepsilon$ for $q \in \Omega$ large enough in order to complete this part of the proof. By Corollary 5.9 and (5.5), we know there exists $\boldsymbol{\Delta} \in \mathcal{UL}_{LTI}(\nu_o)$ so that $\|\boldsymbol{\Delta} z^q - w^q\| \longrightarrow 0$ as $q \to \infty$. Using (5.7) and the triangle inequality, we find that for q sufficiently large $\|\boldsymbol{\Delta} z^q - u^q\| < \frac{\varepsilon}{3\|\mathbf{M}\|}$. The submultiplicative inequality then implies that

$$\|\mathbf{M}\boldsymbol{\Delta} z^q - \mathbf{M}u^q\| < \frac{\varepsilon}{3} \tag{5.8}$$

for $q \in \Omega$ sufficiently large. Also, from the definition of w^q and Lemma 4.2, we see that

$$\left\| \mathbf{M}w^q - \sum_{k=0}^{K} \sum_{l=0}^{N} \sum_{p=0}^{\infty} (M_{p,l}(e^{j\omega_k}) b_k^l) \phi^q_{\omega_k^p} \right\| \longrightarrow 0 \text{ as } q \to \infty.$$

With the help of the triangle and submultiplicative inequalities, it is not difficult to use (5.7) to deduce that

$$\left\| \mathbf{M}u^q - \sum_{k=0}^{K} \sum_{l=0}^{N} \sum_{p=0}^{\infty} (M_{p,l}(e^{j\omega_k}) b_k^l) \phi^q_{\omega_k^p} \right\| < \frac{\varepsilon}{3} \tag{5.9}$$

for q sufficiently large. Finally, from the definition of z^q, we have

$$z^q = \sum_{k=0}^{K} \sum_{l=0}^{\infty} E_l M(e^{j\omega_k}) b_k \phi^q_{\omega_k^l} = \sum_{k=0}^{K} \sum_{p=0}^{\infty} \sum_{l=0}^{\infty} M_{l,p}(e^{j\omega_k}) b_k^p \phi^q_{\omega_k^l},$$

from which it follows that

$$\begin{aligned}\left\| z^q - \sum_{k=0}^{K}\sum_{l=0}^{N}\sum_{p=0}^{\infty}(M_{p,l}(e^{j\omega_k})b_k^l)\phi^q_{\omega_k^p}\right\|_{L_2}^2 &= \left\| \sum_{k=0}^{K}\sum_{l=N+1}^{\infty}\sum_{p=0}^{\infty}(M_{p,l}(e^{j\omega_k})b_k^l)\phi^q_{\omega_k^p}\right\|_{L_2}^2 \\ &= \sum_{k=0}^{K}\|M(e^{j\omega_k})Q_N b_k\|_{\ell_2}^2 \\ &\le \|\mathbf{M}\|^2\sum_{k=0}^{K}\|Q_N b_k\|_{\ell_2}^2 \\ &< \left(\frac{\varepsilon}{3}\right)^2, \qquad (5.10)\end{aligned}$$

just as in the derivation of (5.7).

Using (5.8), (5.9), and (5.10) along with the triangle inequality, we see that

$$\|\mathbf{M}\boldsymbol{\Delta}z^q - z^q\| < \varepsilon$$

for q sufficiently large. Now set $z := \frac{z^q}{\|z^q\|}$, where q is chosen as above. Note that since $\|b\| = 1$, (5.5) and (5.6) guarantee that $1 \le \|z^q\| \le \infty$ and hence that $\|\mathbf{M}\boldsymbol{\Delta}z - z\| < \varepsilon$, as required. □

5.2. Sufficiency. Having established the necessity of our robustness condition, we now focus on proving that the inequality stated in Theorem 5.1 is sufficient in order to guarantee uniform robust stability against perturbations in the class $\mathcal{L}_{LTI}(\nu)$ for some $\nu > 0$.

Our aim in this part is to prove Lemma 5.10, which is a generalization of a similar result from [23].

LEMMA 5.10. *Suppose* $\mathbf{M} \in \mathcal{L}_{\mathcal{A}_{\mathbb{D}}}$. *If*

$$\inf_{\mathbf{D}\in\mathfrak{D}^u_{LTI}} \|\mathbf{D}\mathbf{M}\mathbf{D}^{-1}\| < 1,$$

then the sampled-data system of Figure 3.3 *has uniform robust stability to perturbations in the set* $\mathcal{UL}_{LTI}(\nu)$ *for some* $\nu > 0$.

In proving our result, we will introduce a second definition for the class of quasi-LTI operators and prove that it is weaker than our original definition. This new class, which is introduced below, is more technically convenient to work with in our context. We should also point out that Lemma 5.10 is not specific to our sampled-data arrangement since $\mathbf{M}$ can be any arbitrarily LTV operator.

The proof of the above theorem is rendered much simpler if we choose to work with an expanded class of quasi-LTI operators. Namely, define the set

$$\mathcal{P}(\varepsilon) := \{\boldsymbol{\Delta} \in L_2^m : \|\boldsymbol{\Theta}\boldsymbol{\Delta} - \boldsymbol{\Delta}\boldsymbol{\Theta}\| \le \varepsilon,\ \boldsymbol{\Delta} \text{ causal}\},$$

where $\varepsilon > 0$ and $\boldsymbol{\Theta} \in \mathcal{L}(L_2^m)$ is the operator whose transfer function representation in $\mathcal{A}_{\mathbb{C}^+}$ is $\hat{\Theta}(s) = \frac{1-s}{1+s}$. Lemma 5.11 below states that this new definition is in fact weaker than our first.

LEMMA 5.11. *Given* $\varepsilon > 0$, *there exists* $\nu > 0$ *such that*

$$\mathcal{UL}_{LTI}(\nu) \subseteq \mathcal{UP}(\varepsilon).$$

Proof. We sketch the details for the proof of the above result here and refer the reader to [8] for the complete version. The first step in proving that our new definition for the class of slowly time-varying operators is weaker than the first is to notice that given an $\varepsilon > 0$, the inequality $\|\mathbf{\Theta\Delta} - \mathbf{\Delta\Theta}\| \leq \varepsilon$ holds if and only if $\|\mathbf{\Lambda\Delta} - \mathbf{\Delta\Lambda}\| \leq \varepsilon$, where $\mathbf{\Lambda} \in \mathcal{L}(L_2)$ represents convolution with the function $\lambda(t) := 2e^{-t}$. Now, given $\delta > 0$ and an input $u \in L_2$, we can choose $N \in \mathbb{N}_{\mathrm{o}}$ and $\tau > 0$ large enough so that the inequality $\|\mathbf{\Psi}_{N,\tau}u - \mathbf{\Lambda}u\| < \delta$ is satisfied. The operator $\mathbf{\Psi}_{N,\tau}$ simply represents convolution with the piecewise constant function $\psi_{N,\tau}(t) := 2\sum_{k=0}^{N-1} e^{-k\tau} w_{k\tau,\tau}(t)$, where the family of window functions $w_{T,\tau}$ is defined by

$$w_{T,\tau}(t) := \begin{cases} 1, & T < t < T + \tau, \\ 0 & \text{otherwise} \end{cases}$$

for $T, \tau > 0$. The idea behind this construction can easily be seen through Figure 5.2 below.

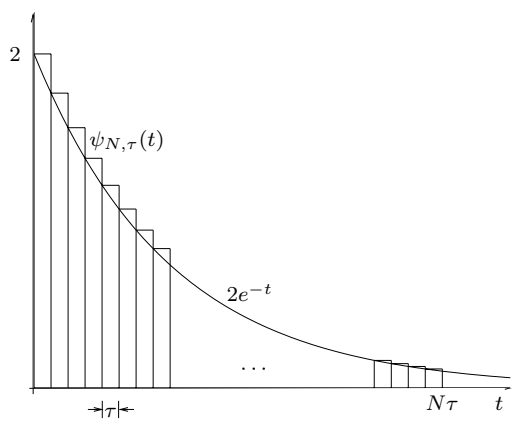

FIG. 5.2. *Piecewise constant function approximation to* $\lambda(t) = 2e^{-t}$.

Now, without loss of generality, we could have chosen the above τ small enough so that the inequality $\|\mathbf{W}_{T,\tau}u - \mathbf{D}_T u\| < \frac{\delta}{4}$ also holds independent of the value of $T > 0$. Here $\mathbf{W}_{T,\tau}$ represents a convolution with the function $\frac{1}{\tau} w_{T,\tau}(t)$, and $\mathbf{D}_T$ is the T-shift on L_2. Having made this choice, we can be assured that $\|\mathbf{\Xi}u - \mathbf{\Psi}_{N,\tau}u\| < \delta$, where the operator $\mathbf{\Xi}$ is defined by $\mathbf{\Xi} := 2\sum_{k=0}^{N-1} \tau e^{-k\tau} \mathbf{D}_{k\tau}$.

From the definition of the set $\mathcal{L}_{LTI}(\nu)$, we can conclude that if $\mathbf{\Delta} \in \mathcal{UL}_{LTI}(\nu)$, then $\|\mathbf{D}_T\mathbf{\Delta} - \mathbf{\Delta}\mathbf{D}_T\| < \nu T$ for every $T > 0$. Let $\delta = \frac{\varepsilon}{5}$. Then, using the above fact, along with the triangle and submultiplicative inequalities, it can be shown that $\|\mathbf{\Theta\Delta} - \mathbf{\Delta\Theta}\| \leq \frac{4\varepsilon}{5} + 2\nu$. Now choose $0 < \nu < \frac{\varepsilon}{10}$ in order to complete the proof. ∎

Finally, we present a technical result which is used in the proof of Lemma 5.10. Its proof is straightforward and is hence omitted.

LEMMA 5.12. *If* $\mathbf{\Delta} \in \mathcal{UP}(\varepsilon)$, *then* $\|\mathbf{\Theta}^k\mathbf{\Delta} - \mathbf{\Delta}\mathbf{\Theta}^k\| \leq k\varepsilon$ *for any* $k \in \mathbb{N}_{\mathrm{o}}$.

Proof of Lemma 5.10. Here we assume that $\mathbf{M}$ is not the zero operator on L_2^m; otherwise, the result is trivial. By hypothesis, there exists $\mathbf{D} \in \mathfrak{D}_{LTI}^u$ satisfying the inequality $\|\mathbf{DMD}^{-1}\| < 1$. Choose $\eta > 0$ so that $\|\mathbf{DMD}^{-1}\| + \eta < 1$.

By definition of the set $\mathfrak{D}^u_{LTI}$, we know that the operator $\mathbf{D}^{-1}$ has a corresponding transfer function $\hat{D}^{-1} \in \mathcal{A}_{\mathbb{C}^+}$. Now functions in the half-plane algebra are isomorphic to those in the disc algebra via the bilinear transformation $z = \frac{1-s}{1+s}$. By Proposition 2.1, we can choose scalars $x_0, x_1, \ldots, x_n$ so that, for any $\eta > 0$, we have

$$\left\| \mathbf{D}^{-1} - \sum_{k=0}^{n} x_k \mathbf{\Theta}^k \right\| = \left\| \hat{D}^{-1} - \sum_{k=0}^{n} x_k \left(\frac{1-s}{1+s} \right)^k \right\|_\infty < \eta,$$

provided, of course, that we choose n large enough.

Set $\mathbf{T}_n = \sum_{k=0}^{n} x_k \mathbf{\Theta}^k$, and choose n sufficiently large so that

$$\|\mathbf{D}^{-1} - \mathbf{T}_n\| < \frac{1}{3}\eta \, \frac{1}{\|\mathbf{DM}\|}.$$

Then $\|\mathbf{DMD}^{-1} - \mathbf{DMT}_n\| \leq \|\mathbf{DM}\| \, \|\mathbf{D}^{-1} - \mathbf{T}_n\| < \frac{1}{3}\eta$. Choose $\varepsilon_{\mathrm{o}} > 0$ so that $\|\mathbf{DM}\| \, \varepsilon_{\mathrm{o}} \sum_{k=1}^{n} k|x_k| < \frac{1}{3}\eta$. Since $\|\mathbf{\Delta}\| \leq 1$ for any $\mathbf{\Delta} \in \mathcal{UP}(\varepsilon_{\mathrm{o}})$, we deduce that

$$\|\mathbf{DMD}^{-1}\mathbf{\Delta} - \mathbf{DMT}_n\mathbf{\Delta}\| < \frac{1}{3}\eta \, \|\mathbf{\Delta}\| \leq \frac{1}{3}\eta. \tag{5.11}$$

Using our last lemma, we find that the following inequalities hold for all perturbations $\mathbf{\Delta} \in \mathcal{UP}(\varepsilon_{\mathrm{o}})$:

$$\begin{aligned} \|\mathbf{T}_n\mathbf{\Delta} - \mathbf{\Delta}\mathbf{T}_n\| &= \Big\| \sum_{k=0}^{n} x_k \mathbf{\Theta}^k \mathbf{\Delta} - \mathbf{\Delta} \sum_{k=0}^{n} x_k \mathbf{\Theta}^k \Big\| \\ &\leq \sum_{k=1}^{n} |x_k| \, \|\mathbf{\Theta}^k\mathbf{\Delta} - \mathbf{\Delta}\mathbf{\Theta}^k\| \\ &\leq \varepsilon_{\mathrm{o}} \sum_{k=1}^{n} k|x_k| \\ &< \frac{1}{3}\eta \, \frac{1}{\|\mathbf{DM}\|}, \end{aligned}$$

where the last inequality follows by our choice of $\varepsilon_{\mathrm{o}} > 0$.

The submultiplicative inequality then allows us to conclude that

$$\|\mathbf{DMT}_n\mathbf{\Delta} - \mathbf{DM\Delta T}_n\| \leq \|\mathbf{DM}\| \, \|\mathbf{T}_n\mathbf{\Delta} - \mathbf{\Delta}\mathbf{T}_n\| < \frac{1}{3}\eta. \tag{5.12}$$

Using (5.11), (5.12), and the triangle inequality, we have

$$\|\mathbf{DMD}^{-1}\mathbf{\Delta} - \mathbf{DM\Delta T}_n\| < \frac{2}{3}\eta. \tag{5.13}$$

Notice from our definition of $\mathbf{T}_n$ that we have

$$\|\mathbf{DM\Delta T}_n - \mathbf{DM\Delta D}^{-1}\| \leq \|\mathbf{DM}\| \, \|\mathbf{\Delta}\| \, \|\mathbf{D}^{-1} - \mathbf{T}_n\| \leq \frac{1}{3}\eta. \tag{5.14}$$

Finally, using (5.13), (5.14), and the triangle inequality, we see that

$$\big| \|\mathbf{DMD}^{-1}\mathbf{\Delta}\| - \|\mathbf{DM\Delta D}^{-1}\| \big| \leq \|\mathbf{DMD}^{-1}\mathbf{\Delta} - \mathbf{DM\Delta D}^{-1}\| < \eta.$$

Thus

$$\|\mathbf{DM\Delta D}^{-1}\| < \|\mathbf{DMD}^{-1}\mathbf{\Delta}\| + \eta \leq \|\mathbf{DMD}^{-1}\| + \eta < 1$$

by our choice of η. Since

$$\mathrm{rad}(\mathbf{M\Delta}) = \mathrm{rad}(\mathbf{DM\Delta D}^{-1}) \leq \|\mathbf{DM\Delta D}^{-1}\| < 1,$$

we conclude that $\mathbf{I} - \mathbf{M\Delta}$ is an invertible operator on L_2 for every $\mathbf{\Delta} \in \mathcal{UP}(\varepsilon_o)$ with ε_o as chosen above. Finally, by Lemma 5.11, we know there exists $\nu > 0$ such that $\mathbf{I} - \mathbf{M\Delta}$ is invertible for every $\mathbf{\Delta} \in \mathcal{UL}_{LTI}(\nu)$.

In order to complete our proof, we need only show that the family of maps $(\mathbf{I} - \mathbf{M\Delta})^{-1}$ is uniformly bounded for all $\mathbf{\Delta} \in \mathcal{UL}_{LTI}(\nu)$. From an earlier part of the proof, we already know that by our choice of $\mathbf{D}$, $\|\mathbf{DM\Delta D}^{-1}\| =: \beta < 1$ for every $\mathbf{\Delta} \in \mathcal{UL}_{LTI}(\nu)$. Using a Neumann series expansion (see, for instance, [19]), we can conclude that $\|\mathbf{D}^{-1}(\mathbf{I} - \mathbf{M\Delta})^{-1}\mathbf{D}\| = \|(\mathbf{I} - \mathbf{DM\Delta D}^{-1})^{-1}\| \leq \frac{1}{1-\beta}$ for every $\mathbf{\Delta} \in \mathcal{UL}_{LTI}(\nu)$. By appealing to the submultiplicative inequality, we then find that

$$\begin{aligned}\|(\mathbf{I} - \mathbf{M\Delta})^{-1}\| &= \|\mathbf{DD}^{-1}(\mathbf{I} - \mathbf{M\Delta})^{-1}\mathbf{DD}^{-1}\| \\ &\leq \|\mathbf{D}\| \cdot \|\mathbf{D}^{-1}(\mathbf{I} - \mathbf{M\Delta})^{-1}\mathbf{D}\| \cdot \|\mathbf{D}^{-1}\| \\ &\leq \frac{1}{1-\beta} \cdot \|\mathbf{D}\| \cdot \|\mathbf{D}^{-1}\|\end{aligned}$$

for every $\mathbf{\Delta} \in \mathcal{UL}_{LTI}(\nu)$. Finally, since both $\|\mathbf{D}\|$ and $\|\mathbf{D}^{-1}\|$ are finite, our proof is complete. □

6. Conclusions and future considerations. This paper establishes the theoretical framework for the analysis of quasi-LTI uncertainty in sampled-data systems, and the main contribution of this paper was to provide an exact characterization of uniform robust performance against the set of quasi-LTI perturbations. Having completed this analysis, we now make a few concluding remarks.

Computation of the stability radius, from the conditions presented here, of a given sampled-data system subject to quasi-LTI uncertainty is an important related problem for applying the methods of this paper. Theorem 5.2 is used as the starting point in [9], where we develop a framework for obtaining upper and lower bounds to the stability radius using only convex matrix calculations.

Although the emphasis was placed on sampled-data systems in this paper, we should mention once again that many of the results we present apply to a larger class of periodic continuous time systems. Specifically, suppose an h-periodic (closed-loop) system is specified by an exponentially stable realization $(A(t), B(t), C(t), D(t) = 0)$ with all these functions being bounded and h-periodic. Then, via lifting, it is possible to explicitly write an equivalent frequency response representation $M(e^{j\omega})$ for the system, which has the same continuity properties required in this paper. Further, at each frequency, $M(e^{j\omega})$ is the sum of a finite rank operator and an integral operator; this integral operator is necessarily compact, and thus the analysis of this paper immediately generalizes.

As a comment, we conjecture that uniform robust performance against quasi-LTI perturbations is equivalent to robust performance in the context of the sampled-data systems studied here.

It should also be noted that the procedure outlined in Appendix B can serve as a guideline for constructing appropriate D-scaling operators in a process such as D-K iteration, providing a robust synthesis heuristic similar to that for standard LTI systems.

Finally, the results of this paper, together with previously published work, provide a complete set of tests for *all* of the standard types of dynamic uncertainty sets encountered in robust control analysis. We believe that the tools and techniques developed in this body of research will allow for a straightforward generalization of the *integral quadratic constraint* (IQC) framework to sampled-data and multirate systems.

Appendix A. State space formulae. In this appendix, we provide state space realizations for several representations of the operator $\mathbf{M}$. In particular, we make explicit the operators $\tilde{M}$, $\tilde{M}(e^{j\omega})$, and $M(e^{j\omega_\circ})$. The details concerning the derivation of the formulae can be found in [12] or in [8].

Recall from section 3 that our plant $\mathbf{G}$ has been conformably partitioned to satisfy equations of the form

$$\begin{bmatrix} z \\ y \end{bmatrix} = \begin{bmatrix} \mathbf{G}_{11} & \mathbf{G}_{12} \\ \mathbf{G}_{21} & \mathbf{G}_{22} \end{bmatrix} \begin{bmatrix} w \\ u \end{bmatrix}.$$

We also provided a state space realization for $\mathbf{G}$,

$$\hat{G}(s) = \left[\begin{array}{c|cc} A & B_1 & B_2 \\ \hline C_1 & 0 & D_{12} \\ C_2 & 0 & 0 \end{array}\right],$$

while the matrices $(A_{K_d}, B_{K_d}, C_{K_d}, D_{K_d})$ constituted a minimal realization for our discrete time controller $\mathbf{K}_d$. Using the above information and referring back to Figure 3.1, we see that the equations

$$\begin{aligned} z &= \mathbf{M}w, \\ u &= \mathbf{H}\mathbf{K}_d\mathbf{S}y \end{aligned}$$

represent the behavior of our sampled-data system.

The procedure for obtaining $\tilde{M}$ now proceeds as follows. First, provide a state space realization for the last system of equations and integrate over the interval $[kh, kh+\tau)$. Next, use the procedure described in section 4.1 to lift the input and output signals to the operator $\mathbf{M}$. Set $\tilde{w} = \mathbf{W}w$ and $\tilde{z} = \mathbf{W}z$, where $\mathbf{W}$ is the operator defined by (4.1). Recall that we are also using the shorthand $\tilde{w}[k]$, $\tilde{z}[k]$ to represent the functions $(\tilde{w}[k])(\tau) = w(\tau + kh)$ and $(\tilde{z}[k])(\tau) = z(\tau + kh)$, respectively, for $\tau \in [0, h)$. These definitions in hand, it can be shown that

$$\begin{aligned} \begin{bmatrix} x_G((k+1)h) \\ x_{K_d}[k+1] \end{bmatrix} &= A_d \begin{bmatrix} x_G(kh) \\ x_{K_d}[k] \end{bmatrix} + \check{B}\tilde{w}[k], \qquad \begin{bmatrix} x_G(0) \\ x_{K_d}[0] \end{bmatrix} = 0, \\ \tilde{z}[k] &= \check{C} \begin{bmatrix} x_G(kh) \\ x_{K_d}[k] \end{bmatrix} + \check{D}\tilde{w}[k], \end{aligned} \tag{A.1}$$

where the operators $A_d \in \mathbb{C}^{\tilde{n}\times\tilde{n}}$, $\check{B} : \mathcal{K}_2 \to \mathbb{C}^{\tilde{n}}$, $\check{C} : \mathbb{C}^{\tilde{n}} \to \mathcal{K}_2$, and $\check{D} : \mathcal{K}_2 \to \mathcal{K}_2$ are

defined as follows:

$$A_d := \begin{bmatrix} e^{Ah} + \int_0^h e^{A(h-\eta)}\, d\eta B_2 D_{K_d} C_2 & \int_0^h e^{A(h-\eta)}\, d\eta B_2 C_{K_d} \\ B_{K_d} C_2 & A_{K_d} \end{bmatrix},$$

$$\check{B}\psi := \begin{bmatrix} \int_0^h e^{A(h-\eta)} B_1 \psi(\eta)\, d\eta \\ 0 \end{bmatrix},$$

$$(\check{C}\xi)(\tau) := \begin{bmatrix} C_1 e^{A\tau} & C_1 \int_0^h e^{A(\tau-\eta)}\, d\eta B_2 + D_{12} \end{bmatrix} \begin{bmatrix} I & 0 \\ D_{K_d} & C_{K_d} \end{bmatrix} \xi,$$

$$(\check{D}\psi)(\tau) := C_1 \int_0^h e^{A(\tau-\eta)} B_1 \psi(\eta)\, d\eta.$$

The lifted system $\tilde{M} = \mathbf{W}\mathbf{M}\mathbf{W}^{-1}$ is then given by (A.1), whereas the operator $\check{M}(e^{j\omega}) = \check{C} e^{j\omega}(I - e^{j\omega} A_d)^{-1} \check{B} + \check{D}$.

Finally, we expand the operators $\check{B}$, $\check{C}$, and $\check{D}$ with respect to the basis $\{\psi_k\}$ defined in (4.2) in order to obtain the matrices $(\tilde{B})_k := \check{B} J^*_{\omega_o}$, $(\tilde{C})_l := J_{\omega_o} \check{C}$, and $(\tilde{D})_{lk} := J_{\omega_o} \check{D} J^*_{\omega_o}$, which make up the frequency response operator $M(e^{j\omega_o})$. They are

$$(\tilde{B})_k = h^{-1/2} \begin{bmatrix} I \\ 0 \end{bmatrix} e^{Ah} \int_0^h e^{(j\theta_k I - A)\tau}\, d\tau B_1,$$

$$(\tilde{C})_l = h^{-1/2} \begin{bmatrix} C_1 & D_{12} \end{bmatrix} \int_0^h \exp\left(\begin{bmatrix} A - j\theta_l I & B_2 \\ 0 & -j\theta_l I \end{bmatrix} \tau \right) d\tau \begin{bmatrix} I & 0 \\ D_{K_d} C_2 & C_{K_d} \end{bmatrix},$$

$$(\tilde{D})_{lk} = h^{-1} C_1 \int_0^h e^{(A - j\theta_l I)\tau} \int_0^h e^{(j\theta_k I - A)\eta}\, d\eta\, d\tau B_1,$$

where the frequency $\theta_k = \frac{2\pi\nu_k - \omega_o}{h}$ and ν_k is the sequence $\{0, 1, -1, 2, -2, \dots\}$.

Appendix B. Proof of Theorem 5.2. We now concern ourselves with the proof of Theorem 5.2. Of course this means that we will be dealing with the class of unstructured operators only. The proof presented here can be changed to deal with the class of structured operators with modest technical difficulty. We begin by restating the result for convenience.

THEOREM 5.2. *The following equality holds:*

$$\sup_{\omega \in (-\pi, \pi]} \inf_{D \in \mathfrak{D}^u} \|DM(e^{j\omega})D^{-1}\| = \inf_{\mathbf{D} \in \mathfrak{D}^u_{LTI}} \|\mathbf{D}\mathbf{M}\mathbf{D}^{-1}\|.$$

An outline of the proof of the result spans this entire appendix. Notice that a number of lemmas are pursued within the proof. Their purpose is to help divide the presentation into more manageable pieces. We refer the interested reader to [8] for additional details concerning the omitted proofs.

Proof. Since the frequency response $D(e^{j\omega})$ of a D-scaling operator $\mathbf{D} \in \mathfrak{D}^u_{LTI}$ takes its values in the set $\mathfrak{D}^u$, it readily follows that

$$\begin{aligned} \inf_{\mathbf{D} \in \mathfrak{D}^u_{LTI}} \|\mathbf{D}\mathbf{M}\mathbf{D}^{-1}\| &= \inf_{D \in \mathfrak{D}^u_{LTI}} \sup_{\omega \in (-\pi, \pi]} \|D(e^{j\omega})M(e^{j\omega})D^{-1}(e^{j\omega})\| \\ &\geq \sup_{\omega \in (-\pi, \pi]} \inf_{\mathbf{D} \in \mathfrak{D}^u_{LTI}} \|D(e^{j\omega})M(e^{j\omega})D^{-1}(e^{j\omega})\| \\ &\geq \sup_{\omega \in (-\pi, \pi]} \inf_{D \in \mathfrak{D}^u} \|DM(e^{j\omega})D^{-1}\|. \end{aligned}$$

The reverse inequality is significantly more challenging to prove. The approach we adopt is based on work found in [6] and the sampled-data framework and tools introduced so far. We begin by constructing a smooth operator-valued function mapping the interval $(-\pi, \pi]$ to $\mathfrak{D}^u$, which satisfies our norm condition. We then use this smooth D-scaling operator in order to define a smooth function on the boundary of the closed right half-plane, whose behavior we approximate by a proper real rational function which lies in the half-plane algebra $\mathcal{A}_{\mathbb{C}^+}$. The D-scaling operator we are ultimately interested in is simply that which has this real rational function as its transfer function representation in the half-plane algebra.

Now, in order to show the inequality, we will prove that given any $\alpha > 0$,

$$\text{if} \sup_{\omega\in(-\pi,\pi]} \inf_{D\in\mathfrak{D}^u} \|DM(e^{j\omega})D^{-1}\| < \alpha, \text{ then } \inf_{\mathbf{D}\in\mathfrak{D}^u_{LTI}} \|\mathbf{DMD}^{-1}\| < \alpha \text{ also.}$$

The first step in validating this assertion is to prove that we can choose a smooth function that satisfies our norm constraint. The construction proceeds in two steps. First, we show that we can partition the interval $(-\pi, \pi]$ into a finite number of subintervals on which the D-scaling function can be chosen constant. In addition, we can choose the D-scales from the set

$$\overline{\mathfrak{D}}_k := \left\{ D = \begin{bmatrix} \Pi_k Y(\Pi_k)^* & 0 \\ 0 & I \end{bmatrix} : Y \in \mathfrak{D}^u \right\}$$

for some choice of $k \in \mathbb{N}_{\mathrm{o}}$, where the truncation operator $\Pi_k : L_2 \to \mathbb{R}_k$ is defined by

$$\Pi_k(a_0, a_1, \dots) := (a_0, \dots, a_k).$$

Namely, the set $\overline{\mathfrak{D}}_k$ is the subset of $\mathfrak{D}^u$ which consists of D-scales in which only the first $k+1$ blocks are not prespecified to be the identity. This process is the subject of the next lemma. Finally, in a second lemma, we smoothly join our constant D-scaling operators to form an infinitely differentiable D-scaling operator on the interval $(-\pi, \pi]$.

LEMMA B.1. *Suppose that* $\sup_{\omega\in(-\pi,\pi]} \inf_{D\in\mathfrak{D}^u} \|DM(e^{j\omega})D^{-1}\| < \alpha$. *Then, for some pair of integers* n *and* k, *there exists a partition*

$$-\pi < a_1 < b_1 < a_2 < \cdots < a_n < b_n < \pi$$

of the interval $(-\pi, \pi]$ *along with a corresponding set of invertible* D*-scaling operators* $D_0, D_0^{-1}, \dots, D_n, D_n^{-1} \in \overline{\mathfrak{D}}_k$ *such that*

$$\|D_l M(e^{j\omega})D_l^{-1}\| < \alpha \text{ is satisfied for } \begin{cases} \omega \in (-\pi, a_1], & l = 0, \\ \omega \in [b_l, a_{l+1}], & l = 1, \dots, n-1, \\ \omega \in [b_l, \pi], & l = n. \end{cases}$$

Moreover, we can choose these frequencies and the D*-scales so that for a fixed* $l = 1, \dots, n$ *the inequalities*

$$\|D_l M(e^{j\omega})D_l^{-1}\| < \alpha \text{ and } \|D_{l-1} M(e^{j\omega})D_{l-1}^{-1}\| < \alpha$$

are simultaneously satisfied for every $\omega \in (a_l, b_l)$.

The construction described in the statement of the lemma is shown pictorially in Figure B.1 below.

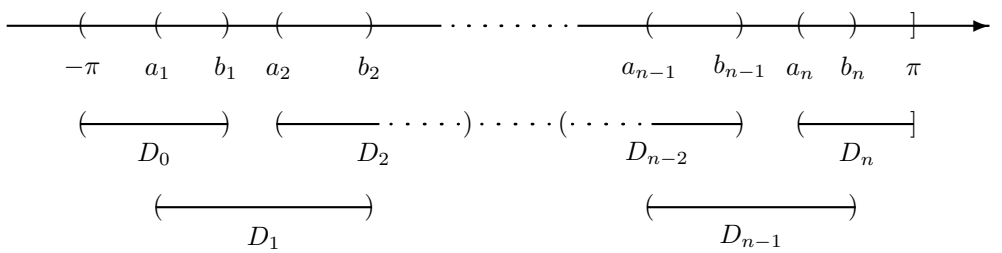

FIG. B.1. *Finite partition of* $(-\pi, \pi]$.

The proof of this first result makes use of the continuity of the sampled-data frequency response operator $M(\cdot)$ and Lemma 4.3. When combined, these two properties allow us to show that the domain of the frequency response operator, the interval $(-\pi, \pi]$, exhibits many properties shared by compact intervals on the real line, which in turn enables the above construction.

The next step in our proof is to smoothly join our newly defined D-scales. We begin by appealing to the function

$$\lambda(t) = \begin{cases} 0, & t \leq 0, \\ e^{-\frac{1}{t}}, & t > 0. \end{cases}$$

It is easy to verify that $\lambda(t)$ is smooth on $\mathbb{R}$. We now use this first definition in order to introduce the "bump" function $\phi_{(a,b)}$ via

$$\phi_{(a,b)}(t) := \frac{\lambda(t-a)}{\lambda(t-a) + \lambda(b-t)}.$$

It is routine to verify that $\phi_{(a,b)}(t) = 0$ for $t \leq a$, $\phi_{(a,b)}(t) = 1$ for $t \geq b$, and that $\phi_{(a,b)}(t)$ is smooth for all $t \in \mathbb{R}$.

We are now in a position to define our smooth D-scaling function. Let $N(e^{j\omega})$ be given by

$$N^2(e^{j\omega}) := \begin{cases} D_0^* D_0, & \omega \in (-\pi, a_1], \\ D_l^* D_l, & \omega \in [b_l, a_{l+1}],\ l = 1, 2, \ldots, n-1, \\ D_n^* D_n, & \omega \in [b_n, \pi], \\ D_{l-1}^* D_{l-1} + (D_l^* D_l - D_{l-1}^* D_{l-1})\phi_{(a_l, b_l)}(\omega), & \\ & \omega \in (a_l, b_l),\ l = 1, 2, \ldots, n, \end{cases} \tag{B.1}$$

where D_l denotes the D-scaling operator defined in the previous lemma for each $l = 0, \ldots, n$. In defining N, we have made use of the bump function in the intervals (a_l, b_l), where two constant D-scales overlap. The function allows us smoothly interpolate the constant D-scales. The process (in the scalar case) is illustrated in Figure B.2.

It is easy to see that such an N is positive and is also a smooth function of ω. Hence we need only demonstrate that our norm constraint still holds using this new function in order to complete our construction. This is done in the following lemma whose proof follows by the definition of N and repeated application of Proposition 4.1.

LEMMA B.2. *Given the function* $N : (-\pi, \pi] \to \mathfrak{D}^u$ *defined in* (B.1)*, the following inequality is satisfied:*

$$\sup_{\omega \in (-\pi, \pi]} \|N(e^{j\omega}) M(e^{j\omega}) N^{-1}(e^{j\omega})\| < \alpha.$$

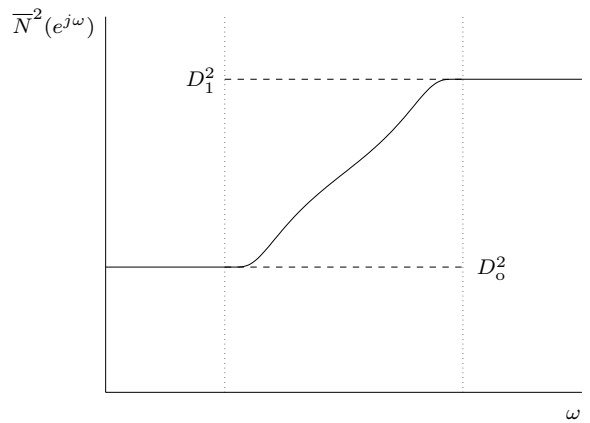

FIG. B.2. *Creating a smooth D-scale.*

The goal now is to show that we can use the function N to help us define a D-scaling operator $\mathbf{D}_o \in \mathfrak{D}^u_{LTI}$ which satisfies the inequality $\|\mathbf{D}_o\mathbf{M}\mathbf{D}_o\|_{L_2\to L_2} < \alpha$. Begin by defining the scalar function $\hat{n} : j\mathbb{R} \to (0,\infty)$ via

$$N(e^{j\omega}) = \operatorname{diag}(\hat{n}(j\omega_0)I_m, \hat{n}(j\omega_1)I_m, \dots), \tag{B.2}$$

where $\omega_k = \frac{2\pi\nu_k - \omega}{h}$ for $\omega \in (-\pi,\pi]$. Using the properties of N, we can easily see that $\hat{n}(j\theta)$ is a positive and bounded function on $j\mathbb{R}$ and that for θ sufficiently large, $\hat{n}(j\theta) = 1$. Moreover, it follows that $\|\hat{n}\|_\infty = \sup_{\omega\in(-\pi,\pi]} \|N(e^{j\omega})\|_{\ell_2\to\ell_2}$. Hence we can conclude that $\hat{n} \in \mathcal{L}_\infty(j\mathbb{R})$, the set of complex-valued functions bounded on the imaginary axis.

Let us now discuss the continuity of $\hat{n}$. Since $N(e^{j\omega})$ is smooth on $(-\pi,\pi]$, we see that $\hat{n}(j\theta)$ is smooth on $[\frac{2\pi\nu_l-\pi}{h}, \frac{2\pi\nu_l+\pi}{h})$ for every $l \in \mathbb{N}_o$. Now, from the definition of N and Proposition 4.3, we have that

$$\lim_{\omega\to-\pi^+} N(e^{j\omega}) = X^*N(-1)X = X^*\begin{bmatrix} \hat{n}(j\frac{2\pi\nu_0-\pi}{h})I_m & & 0 \\ & \hat{n}(j\frac{2\pi\nu_1-\pi}{h})I_m & \\ 0 & & \ddots \end{bmatrix} X,$$

from which it follows that $\hat{n}(j\theta)$ (and hence $N(e^{j\omega})$ also) is smooth on $\mathbb{R}$.

Now, given any function $\mathbf{D} \in \mathfrak{D}^u_{LTI}$, we similarly have [12] that

$$D(e^{j\omega}) = \begin{bmatrix} \hat{d}(j\omega_0)I_m & & 0 \\ & \hat{d}(j\omega_1)I_m & \\ 0 & & \ddots \end{bmatrix},$$

where $D(e^{j\omega})$ is the frequency response of $\mathbf{D}$ and $\hat{d}(s)I_m$ is its transfer function representation in $\mathcal{A}_{\mathbb{C}^+}$. The following lemma says that if $\hat{d}$ closely approximates $\hat{n}$, then $\mathbf{D}$ is the D-scaling operator we require in order to complete the proof.

LEMMA B.3. *Suppose* $\sup_{\omega\in(-\pi,\pi]} \|N(e^{j\omega})M(e^{j\omega})N^{-1}(e^{j\omega})\| < \alpha$, *where* N *is the operator defined in* (B.1). *Then there exists an* $\varepsilon > 0$ *such that if* $\mathbf{D} \in \mathfrak{D}^u_{LTI}$ *and satisfies*

$$\sup_{\theta\in\mathbb{R}} |\hat{d}(j\theta) - \hat{n}(j\theta)| < \varepsilon,$$

we have

$$\sup_{\omega\in(-\pi,\pi]} \|D(e^{j\omega})M(e^{j\omega})D^{-1}(e^{j\omega})\| < \alpha.$$

The proof, which is also omitted, relies on nothing more than the triangle and submultiplicative inequalities along with the fact that N and $\hat{n}$, and D and $\hat{d}$, are isomorphic pairs of operators.

The following lemma is the final result that we present and is easily proved using two important properties of the function space $\mathcal{RL}_\infty(j\mathbb{R})$. This space, consisting of all proper real rational functions with no poles on the imaginary axis, is dense in $\mathcal{L}_\infty(j\mathbb{R})$. Moreover, for any function $\hat{q} \in \mathcal{RL}_\infty(j\mathbb{R})$, there exists a spectral factorization $\hat{q} = \hat{d}^*\hat{d}$, where $\hat{d}$ and $\hat{d}^{-1}$ lie in the space $\mathcal{RH}_\infty$. Using these facts, we can interpolate our function $\hat{n}$ to any desired accuracy using a proper real rational function in the half-plane algebra.

LEMMA B.4. *Given the smooth function $\hat{n}$ defined through* (B.2). *For every $\varepsilon > 0$, there exists a function $\hat{d} \in \mathcal{RH}_\infty$ with $\hat{d}^{-1} \in \mathcal{RH}_\infty$ such that*

$$\left\| |\hat{d}| - \hat{n} \right\|_\infty < \varepsilon.$$

Now, for every $\varepsilon > 0$, there exists an operator $\mathbf{D} \in \mathfrak{D}^u_{LTI}$ such that $\left\| |\hat{d}_\mathrm{o}| - \hat{n} \right\|_\infty < \varepsilon$ by Lemma B.4. Lemma B.3 then says that we can choose the above $\varepsilon > 0$ small enough so that

$$\sup_{\omega\in(-\pi,\pi]} \|D(e^{j\omega})M(e^{j\omega})D^{-1}(e^{j\omega})\| < \alpha,$$

where the operator-valued function

$$D(e^{j\omega}) := \begin{bmatrix} |\hat{d}_\mathrm{o}(j\omega_0)|I_m & & 0 \\ & |\hat{d}_\mathrm{o}(j\omega_1)|I_m & \\ 0 & & \ddots \end{bmatrix}.$$

Let $\mathbf{D}_\mathrm{o}$ be the operator in the space $\mathfrak{D}^u_{LTI}$ whose transfer function representation in the half-plane algebra $\mathcal{A}_{\mathbb{C}^+}$ is $\hat{D}_\mathrm{o} := \hat{d}_\mathrm{o} I_m$. Its frequency response $D_\mathrm{o}(e^{j\omega})$ then satisfies

$$D_\mathrm{o}(e^{j\omega}) = \begin{bmatrix} \hat{d}_\mathrm{o}(j\omega_0)I_m & & 0 \\ & \hat{d}_\mathrm{o}(j\omega_1)I_m & \\ 0 & & \ddots \end{bmatrix} = D(e^{j\omega})\Xi(e^{j\omega}),$$

where $\Xi(e^{j\omega_\mathrm{o}})$ is a unitary operator on ℓ_2 at each frequency $\omega_\mathrm{o} \in (-\pi, \pi]$. It then follows that

$$\|D_\mathrm{o}(e^{j\omega})M(e^{j\omega})D_\mathrm{o}^{-1}(e^{j\omega})\| = \|D(e^{j\omega})M(e^{j\omega})D^{-1}(e^{j\omega})\|$$

for each $\omega \in (-\pi, \pi]$. Finally, using the above definitions, we can see that

$$\begin{aligned} \inf_{\mathbf{D}\in\mathfrak{D}^u_{LTI}} \|\mathbf{DMD}^{-1}\|_{L_2\to L_2} &\le \|\mathbf{D}_\mathrm{o}\mathbf{M}\mathbf{D}_\mathrm{o}^{-1}\|_{L_2\to L_2} \\ &= \sup_{\omega\in(-\pi,\pi]} \|D_\mathrm{o}(e^{j\omega})M(e^{j\omega})D_\mathrm{o}^{-1}(e^{j\omega})\|_{\ell_2\to\ell_2} \\ &= \sup_{\omega\in(-\pi,\pi]} \|D(e^{j\omega})M(e^{j\omega})D^{-1}(e^{j\omega})\|_{\ell_2\to\ell_2} \\ &< \alpha. \end{aligned}$$

Hence our proof is now complete. □

COMMENT ON AN EXISTENCE RESULT FOR A NONCOERCIVE NONCONVEX VARIATIONAL PROBLEM*

ERIK J. BALDER†

Abstract. An essential improvement is given of a recent existence result of Crasta [G. Crasta, *SIAM J. Control Optim.*, 38 (1999), pp. 237–253] for a nonconvex, noncoercive variational problem whose integrand does not depend on the state variable. This is shown to follow by the methods based on Fatou's lemma in several dimensions of [E. J. Balder, *J. Math. Anal. Appl.*, 101 (1984), pp. 527–539]. The associated Euler–Lagrange inclusions follow from well-known optimality conditions for such problems [V. M. Alekseev, V. M. Tichimirov, and S. V. Fomin, *Optimal Control*, Consultants Bureau, New York, 1987; V. I. Arkin and V. L. Levin, *Uspekhi Mat. Nauk*, 27 (1972), pp. 21–77].

Key words. nonconvex variational problems, existence, Fatou's lemma in several dimensions, measurable selections

1. An existence result.

In [15] Crasta considers the following variational problem:

$$\text{(P)} \qquad \min_{v\in AC([0,R])^d)} \left\{ \int_0^R g(t,v'(t))dt : v(R)=0 \right\}.$$

In Theorem 3.2, the main result of [15], he proves the existence of an optimal solution for problem (P) by means of a complicated proof with several intermediate steps, such as an Euler–Lagrange inclusion for a convexified version of the above problem and an L_∞-truncation procedure (see [15, pp. 245–250]). In [15] this result is subsequently applied to radially symmetric variational problems. To be precise, that main result is as follows. Let $[0,R]$ be equipped with the Lebesgue σ-algebra and Lebesgue measure, and let $\mathbf{R}^2$ have the Borel σ-algebra. Let $g : [0,R]\times\mathbf{R}^d \to (-\infty,+\infty]$ be given as above. Let $g^{**}(t,\cdot)$ $[g^*(t,\cdot)]$ be the Fenchel-biconjugate (Fenchel-conjugate) of $g(t,\cdot)$, and let $\partial g^*(t,p)$ be the subdifferential of $g^*(t,\cdot)$ at the point $p\in\mathbf{R}^d$. The following conditions are needed in [15, Theorem 3.2].

- (G1′) g is product-measurable and such that $g(t,\cdot)$ is lower semicontinuous on $\mathbf{R}^d$ for almost every (a.e.) t in $[0,R]$.
- (G1″) $g^{**}(t,x) < +\infty$ for a.e. t in $[0,R]$ and for all $x\in\mathbf{R}^d$.
- (G2) $g^{**}(\cdot,0)$ is integrable on $[0,R]$.
- (G3) There exist $m>0$ and $b\in\mathcal{L}_1([0,R])$ such that $g^{**}(t,x)\geq m|x|-b(t)$ for a.e. t in $[0,R]$ and for all $x\in\mathbf{R}^d$.
- (G4) For every $r_1>0$ there exists $r_2>0$ such that for a.e. t in $[0,R]$ and every $p\in\mathbf{R}^d$ the following implication holds:

$$\partial g^*(t,p)\cap\{x\in\mathbf{R}^d : |x|\leq r_1\}\neq\emptyset \Rightarrow \partial g^*(t,p)\subset\{x\in\mathbf{R}^d : |x|<r_2\}.$$

- (G5) $g(\cdot,\xi)$ is integrable on $[0,R]$ for every $\xi\in\mathbf{R}^d$.

The following theorem improves Theorem 3.2 of [15]. It shows that (G1″) and the technical polar condition (G4) are redundant and that much less is needed in (G5), bringing it exactly in line with (G2). Furthermore, we work with a general dimension d, whereas Crasta's approach really uses $d = 1$. Our approach will also show that problem (P) can be handled directly without the intervention of (P**). The latter is a relaxation of problem (P), obtained by replacing g with g^{**}.

THEOREM 1.1. (i) *Under* (G1′), (G2), *and* (G3) *the problem* (P**) *has an optimal solution* $\bar{v} \in AC([0,R])^d$, $\bar{v}(R) = 0$, *that satisfies the Euler–Lagrange inclusion*

$$0 \in \partial g^{**}(t, \bar{v}'(t)) \text{ for a.e. } t \text{ in } [0,R].$$

(ii) *Moreover, already if* (G5) *just holds for* $\xi = 0$, *then* $\bar{v}$ *satisfies* $g(t,\bar{v}'(t)) = g^{**}(t,\bar{v}'(t))$ *a.e. and is also an optimal solution to* (P).

By the substitution $v(t) = -\int_t^R u(s)ds$, problem (P) is evidently equivalent to the following unconstrained optimal control problem:

$$(\text{CP}) \qquad \min_{u \in \mathcal{L}_1([0,R])^d} \int_0^R g(t,u(t))dt,$$

and a similar reformulation holds for (P**); the latter optimal control problem is indicated by (CP**). Problems (CP) and (CP**) are particular, unconstrained instances of a *Lyapunov-type* optimization problem. Such problems have been studied extensively [1, 3, 5, 6, 7, 9, 11], both for their existence aspects and optimality conditions. Seen from that body of knowledge, Theorem 1.1 is entirely standard. For instance, already by introducing the singular component $\bar{y}_u(t) := \int_0^t g(s,u(s))ds$, the existence part of Theorem 1.1 follows directly from Corollary 2.9 in [7][1] (see also [13] for related results). However, since we wish to stress the general background of problem (P), we have chosen two quite general tools. The first of these is Fatou's lemma in several dimensions; see Theorem 2.1. The second general result is the reduction Theorem 2.2, which is a well-known measurable selection result about "switching infima and integral signs."

2. Proof of Theorem 1. Let $(T,\mathcal{T},\mu)$ be a finite and complete measure space. By $\mathcal{L}_1(T)^m$ we denote the set of all functions from T into $\mathbf{R}^m$ with μ-integrable component functions. The unifying Fatou lemma in several dimensions of [6] is as follows.

THEOREM 2.1 (see [6]). *Suppose* $(f_k)_k \subset \mathcal{L}_1(T)^m$ *is such that* $(\max(0,-f_k^i))_k$ *is uniformly* μ*-integrable,* $i =, \ldots, m$, *and such that* $a := \lim_k \int f_k \, d\mu$ *exists in* $\mathbf{R}^m$. *Then there exists* $f_* \in \mathcal{L}_1(T)^m$ *such that* $\int f_* \, d\mu \le a$ *(coordinatewise) and*

$$f_*(t) \text{ is a limit point of } (f_k(t))_k \text{ for } \mu\text{-a.e. } t \text{ in } T.$$

This result extends similar results in [5, 11, 4, 22]. The following version of the reduction theorem comes from [8, Appendix B], which essentially mimics [12, VII]. Similar results can also be found in [5, 19, 21].

THEOREM 2.2 (see [8, Theorem B.1]). *Let* X *be a Suslin space. For every* $\mathcal{T} \times \mathcal{B}(X)$*-measurable function* $f : T \times X \to [-\infty, +\infty]$ *and every decomposable*[2] *set*

[1] Namely, set $a, \bar{a} \equiv 0$, $b \equiv 0$, $\bar{b} \equiv 1$, $\bar{c} := g$, and $J(u) := \bar{y}_u(R)$ in [7].

[2] That is, for every $A \in \mathcal{T}$, $u \in \mathcal{U}$ and every $(\mathcal{T},\mathcal{B}(X))$-measurable $b : T \to X$ with $b(T) \subset X$ relatively compact, the concatenation $1_A b + 1_{T \setminus A} u$ belongs to $\mathcal{U}$.

$\mathcal{U}$ of $(\mathcal{T}, \mathcal{B}(X))$-measurable functions

$$\inf_{u\in\mathcal{U}} I_f(u) = \int_T \left(\inf_{x\in X} f(t,x)\right)\mu(dt),$$

provided that the left-hand side does not equal $+\infty$.

Above the integrals $I_f(u) := \int_T f(t,u(t))\mu(dt)$ must be interpreted with the following *convention*: $I_f(u) := \int_T \max(f(t,u(t)),0)\mu(dt) - \int_T \max(-f(t,u(t)),0)\mu(dt)$, where the "tie" $(+\infty)-(+\infty)$ has to be read as $+\infty$. (This coincides precisely with convention VII.7 in [12].) A similar convention also applies to the integral on the right, whose integrand is already $\mathcal{T}$-measurable by the measurable projection theorem. (Apply [12, III.39].)

Proof of Theorem 1.1. Let T be the set $[0,R]\backslash N$, where N is the union of the exceptional null sets in (G1′) and (G3). We equip T with its Lebesgue σ-algebra $\mathcal{T}$ and the Lebesgue measure μ.

(i) Define $\iota := \inf(\mathrm{CP}^{**}) \geq -\int_T b$. (Use (G3).) By (G2), (CP**) is feasible, so ι is a finite number. Let $(u_k)_k \subset \mathcal{L}_1(T)^d$ be a minimizing sequence for (CP**). Then by (G3) the sequence $(\int_T |u_k|d\mu)_k$ is bounded, so without loss of generality we can suppose that $\ell := \lim_k \int_T |u_k|\, d\mu$ exists in $\mathbf{R}$. Form $(f_k)_k \subset \mathcal{L}_1(T)^2$ by setting $f_k(t) := (g^{**}(t,u_k(t)), |u_k(t)|)$. Then the above yields $\int_T f_k\, d\mu \to (\iota,\ell)$. Also, observe that $\max(0,-f_k^i)$ is uniformly integrable for each i: for $i=1$ this follows by $\max(0,-f_k^1(t)) \leq \max(0,-b(t))$, because of (G3), and for $i=2$ it is trivial. By Theorem 2.1 there exists $f_* := (f_*^1, f_*^2) \in \mathcal{L}^1(T)^2$ such that (a) $\int_T f_*\, d\mu \leq (\iota,\ell)$ and (b) $f_*(t)$ is a limit point of $(g^{**}(t,u_k(t),u_k(t)))_k$ for μ-a.e. t in T. According to (b), for a.e. t there is a subsequence (k_t) of (k) such that $(g^{**}(t,u_{k_t}(t)) \to f_*^1(t)$ and $|u_{k_t}(t)| \to f_*^2(t)$. The latter implies that a further subsequence of $(u_{k_t})_{k_t}$ converges in $\mathbf{R}^d$ to some limit point $u_{*,t}$. By lower semicontinuity of $g^{**}(t,\cdot)$, the preceding implies $f_*^1(t) \geq g^{**}(t,u_{*,t})$ for a.e. t. By continuity of $|\cdot|$, the same also implies $f_*^2(t) = |u_{*,t}|$. By the implicit measurable function result in [12, III.38][3] there exists a measurable function $\bar{u} : T \to \mathbf{R}^d$ such that $f_*^1(t) \geq g^{**}(t,\bar{u}(t))$ and $f_*^2(t) = |\bar{u}(t)|$ for a.e. t. By $\int_T f_*^2 d\mu \leq \ell < +\infty$ (see (a)) we obtain $\bar{u} \in \mathcal{L}_1(T)^d$, and by $\int_T f_*^1 d\mu \leq \iota$ the optimality of $\bar{u}$ for (CP**) follows. Next, recall from [12] that $\mathcal{L}_1([0,R])^d$ is decomposable. Again using (G2), Theorem 2.2 gives $I_{g^{**}}(\bar{u}) = \inf(CP^{**}) = \int_T \inf_{x\in\mathbf{R}^d} g^{**}(t,x)dt$, which is clearly equivalent to $g^{**}(t,\bar{u}(t)) = \inf_{x\in\mathbf{R}^d} g^{**}(t,x)$ a.e. This amounts to the stated Euler–Lagrange equation, because $\bar{v}(t) := -\int_t^R \bar{u}$ defines an optimal solution of (P**), for which $\bar{v}' = \bar{u}$ a.e.

(ii) The proof of existence of an optimal solution u^* of (CP) by means of Theorem 2.1 is precisely the same as the one given above. By Theorem 2.2 and (G5) (for $\xi = 0$) we have $+\infty > I_g(u^*) = \inf_{u\in\mathcal{L}_1([0,R])^d} I_g(u) = \int_T \phi(t)dt$ with $\phi(t) := \inf_{x\in\mathbf{R}} g(t,x)dt$. Because of this and (G2), ϕ belongs to $\mathcal{L}^1(T)$. So the identity $\int_T [g(t,u^*(t)) - \phi(t)]dt = 0$, where the integrand is clearly nonnegative, gives $g(t,u^*(t)) = \phi(t)$ a.e. By elementary properties of Fenchel conjugation, (G3) implies that $-\infty < \inf_{x\in\mathbf{R}^d} g(t,x) = \inf_{x\in\mathbf{R}^d} g^{**}(t,x)$ for all (or a.e.) t. So u^* satisfies $g^{**}(t,u^*(t)) \leq g(t,u^*(t)) = \inf_{x\in\mathbf{R}} g^{**}(t,x)$ a.e. Evidently, this implies that u^* is also optimal for (CP). The corresponding optimal solution of (P) and (P**) is given jointly by $v^*(t) := -\int_t^R u^*$. □

[3] On p. 85 of [12] one should substitute $\Sigma \equiv \mathbf{R}^d$ and $\Theta(t) := \{x \in \mathbf{R}^d : g^{**}(t,x) \leq f_*^1(t), |x| = f_*^2(t)\}$.

3. Epilogue. Let us present some observations and remarks about Theorem 1.1. Observe that our proof does not use the convexity of $g^{**}(t,\cdot)$, which is unlike [15]. This also explains why we could prove part (ii) independently from part (i). Moreover, in contrast to [15], Theorem 1.1 and its proof extend immediately to the situation where the place of $\mathbf{R}^d$ is taken by a separable reflexive Banach space X. (Replace $|\cdot|$ by the norm of X, but equip X with the weak topology.) Further, for the variational problem (P) in its equivalent form (CP), we can work with a finite measure space instead of $[0,R]$. Also, by using well-known Kuhn–Tucker-type optimality characterizations for (Q), which involve Theorem 2.2 in connection with scalar multipliers, we could have dealt with constrained versions of problem (P). This is because (P) is of so-called *Lyapunov-type*, as studied in [2, 18] and in [1, 4.3.1]. See [10] for some additional comments on how to handle the situation where the measure space may have atoms.

Finally, we wish to observe that the proof of Theorem 3.2 in [15] seems to have been inspired by the approach in the earlier paper [14], which, in turn, has been inspired by work by Olech [20]. However, [14, Theorem 3.1] deals with a more difficult existence problem, which is for the following variant of (P):

$$(\mathrm{P}') \qquad \min_{v\in AC([0,R])^d}\left\{\int_0^R g(t,v'(t))dt : v(0)=v_0, v(R)=v_1\right\}.$$

The reformulation of this as an optimal control problem is

$$(\mathrm{CP}') \qquad \min_{u\in\mathcal{L}_1([0,R])^d}\left\{\int_0^R g(t,u(t))dt : \int_0^R u(t)dt = v_1-v_0\right\}.$$

This problem cannot be treated by the general apparatus for Lyapunov-type optimization problems, because the uniform integrability condition for negative parts in Theorem 2.1 fails to hold under the conditions of [14]. In terms of the proof of Theorem 1.1(i), this can be seen by observing that the adapted proof would have to use $f_k(t) := (g^{**}(t,u_k(t)), |u_k(t)|, u_k(t))$ or something similar. This fails because $(\max(0,-u_k^i))_k$ is not uniformly integrable, given Crasta's slow growth conditions for g^{**}. In other words, we conclude that the method of proof followed in [14] is quite appropriate for the problem (P') but that the related proof in [15] for the much simpler problem (P) falls short.

After the submission of this note it was pointed out to the present author that in [16, Theorem 3.10] Crasta has obtained an existence result for a more general Bolza problem that, when specialized to the setting of the present note, gives precisely the existence result of Theorem 1.1. Also, in [17] much more general results have been given for the problem (P^{**}) by exploiting the associated Euler–Lagrange equations in connection with fixed point results.

Acknowledgments. The author is indebted to two anonymous referees for helpful references and suggestions about the presentation of this note.

CHARACTERIZATION OF EXTREMAL CONTROLS FOR INFINITE DIMENSIONAL TIME-VARYING SYSTEMS*

DIOMEDES BARCENAS† AND HUGO LEIVA†

Abstract. In this paper we prove some properties of attainable sets for time-varying infinite dimensional linear control systems with time-varying constrained controls and target sets. We also characterize the extremal controls and give necessary and sufficient conditions for the normality of the system. Moreover, we prove an existence theorem for the time optimal control, establishing two maximum principles.

Key words. attainable sets, extremal control, time optimal control, normal system

1. Introduction. The time optimal control problem has been studied by many authors; while Lee–Markus [24] and Hermes–Lassalle [16] conform a good reference for the finite dimensional cases, for infinite dimensional linear systems it is worth mentioning the contributions of authors such as Ahmed [1], Ahmed–Teo [2], Curtain–Pritchard [8], Fattorini [12], [13], [14], Friedman [15], Hoppe [19], Raymond–Zidani [32], Li–Yong [25], and Papageorgiou [29] among others. All of these references, except [29], have the particularity of working with a constant target and hypotheses like reflexivity to obtain the corresponding time optimal control and maximum principle.

One of the purposes of this paper is to remove these hypotheses and the continuity of the adjoint evolution operator generated by the system as we indicate below.

Here we consider the general system

$$\begin{aligned} &\dot{x}(t) = A(t)x(t) + B(t)u(t), \quad t > 0, \\ &x(0) = x_0 \in X, \quad u(t) \in \mathcal{U}(t) \subset U, \quad x(t^*) \in G(t^*), \end{aligned} \tag{1.1}$$

for some $t^* > 0$ minimum, where the state $x(t) \in X$ and X and U are nonnecessarily separable Banach spaces. The family of unbounded operators $A(t)$ generates a strongly continuous evolution operator $S(t,s)$ according to [30] and [8], such that for each $t > 0$ the mapping $s \to S^*(t,s)$ is strongly continuous on $[0,t)$ and $B \in L^\infty_{loc}(0,+\infty; L(U,X))$, where $L(U,X)$ is the space of linear and bounded operators $T : U \to X$, and the controls values $\mathcal{U}(t)$ and the target set $G(t) \subset X$ are time-varying. For this class of systems, we get the results announced in the abstract.

As we have pointed out at the beginning of this introduction, the problem for infinite dimensional linear systems has been studied by several authors. For example, Friedman [15] established the existence of time optimal control for a class of time-invariant linear systems for which the target set is a singleton; and Ahmed–Teo [1] established the same where the target set is just $\{0\}$ and the system is time-varying. A generalization of Friedman's work can be found in Fattorini [13], where some hypotheses are relaxed.

More recently, Papageorgiou [29] extends part of these mentioned works for infinite dimensional time-varying systems, removing some restrictive hypotheses like invertibility of the evolution operator in [1], [12], [15], and target sets time-varying with a nonempty interior, which makes a different treatment to the problem since it does not include the case when the target set is a singleton.

The key hypothesis in Papageorgiou's work is the strong continuity of the adjoint evolution operator, which, incidentally, also generalizes some works of Peichl–Schappacher [31] and Barcenas–Leiva [5], in the sense that the space X does not need to be reflexive as in [5] and [31].

In this paper, inspired by Papageorgiou [29] and Barcenas–Diestel [3], using only the uniform integrability of the Bochner integral, we remove the continuity of the adjoint evolution operator at $s = t$, incorporating into the subject an important class of partial differential equations such as diffusion processes in nonreflexive Banach spaces; our target sets are time-varying and upper semicontinuous (USC) instead of continuous in the Hausdorff metric as in [29].

The paper is organized as follows. In section 3, a time optimal control theorem is obtained, where, as indicated, our target set is not continuous as in [29], and neither is the state space X reflexive as in [25] and [32]; this last reference deals with second order elliptic operators in the reflexive Banach space L^s $(s > 2)$, and, consequently, the adjoint of the associated strongly continuous semigroup is strongly continuous. As we can see in Example 6.1, our existence theorem (Theorem 3.1) applies to a one dimensional heat equation in nonreflexive Banach spaces, which is a case out of range of previous works since, as it is shown in this example, the adjoint evolution operator $S^*(t,s) = T^*_{t-s}$ is not strongly continuous at $t = s$; while this important example illustrates a time-invariant system, Example 6.2 exhibits a case of a time-varying system where Theorem 3.1 can be applied.

In section 4, we obtain a maximum principle (Theorem 4.1) which is different from that in Papageorgiou's paper; in fact, since the hypothesis in [29] requires $\operatorname{int} G(t) \neq \emptyset$, we observe that its maximum principle does not include the important case of a singleton $G(t) = \{x_0\}$. We also have that Theorem 4.1 applies only in the special case in which X is a reflexive Banach space and Theorem 4.2 is a generalization of Papageorgiou's maximum principle (Theorem 4.1 of [29]); to this end, we would like to remark that Theorem 4.1 is different from Theorem 4.2 since the latter requires the sets of attainable points to have nonempty interior. For this reason we prove Theorem 4.1 rather than Theorem 4.2.

We also would like to remark on the difference of our two maximum principles from those found in Li–Yong [25]. Several maximum principles are found in [25, Chapters V and VII] without any allusion to reflexivity in the respective hypotheses; however, we can see that the corresponding maximum principles stated on pages 170, 188, 203, and 212 of [25] ensure the associated solution in a suitable reflexive space (actually a Sobolev space), while the maximum principle given on page 292 (Chapter VII) of the same reference requires the existence of the optimal time t^* as a hypothesis, and such an existence is proved under the reflexivity assumption (see Theorem 5.9 of [25]). So the presence of reflexivity means that these results are comparable only with Theorem 4.1 of this paper; here we notice that in the case of time invariant systems the Li–Yong treatment is more general than this one since the only requirement is $\operatorname{Codim}(K(t) - G(t)) < \infty$. However, our conclusion allows us to characterize the extremal controls.

We also notice that the Raymond–Zidani maximum principle is stated in reflexive

Banach spaces.

In section 5 we extend the notion of normality from finite dimensional systems [24] to infinite dimensional systems, and we get the strict convexity of the attainable sets, a characterization of normality, and a bang-bang principle.

In the last section of this work we provide some examples where our results can be applied in several familiar situations.

Finally, we want to make the following remark. When we study a time-varying system

$$\dot{x}(t) = A(t)x(t), \quad x \in X, \quad t \geq 0, \tag{1.2}$$

we can try to transform the system (1.2) into a time-independent system by increasing the dimension of the phase space in the following way:

$$\begin{cases} \dot{x}(t) & = A(t)x, \quad t \in \mathbb{R}_+, \\ \dot{t} & = 1. \end{cases} \tag{1.3}$$

The system (1.3) generates a semigroup (semiflow) $\{\pi_t\}_{t\geq 0}$ on the space $X \times \mathbb{R}$ given by $\pi_t(x,s) = (T(t+s,s,)x, s+t)$, $t \geq 0$, where $T(t,s)$ is the evolution operator associated with (1.2). Although this approach is good for some time dependent dynamical systems, we do not know anything about the adjoint evolution operator. So the techniques illustrated here may not be applied.

2. Preliminaries. Even though in this paper we will work with the Lebesgue measure on the real line, we start our preliminaries in a general form. Let X and U be arbitrary Banach spaces, and let (Ω, Σ, μ) be a nonnegative, complete, finite measure space. We will use the following notations.

$$P_{f(c)}(U) =: \{A \subset U : \quad A \text{ closed (convex)}, \quad A \neq \emptyset\},$$

$$P_{wkc}(X) =: \{A \subset X : \quad A \neq \emptyset; \quad \text{weakly compact convex}\}.$$

The following definition comes from [4].

DEFINITION 2.1. *A multifunction $F : \Omega \to P_f(U)$ is called μ-measurable if there is a sequence $f_n : \Omega \to U$ of measurable functions and $N \in \Sigma$ with $\mu(N) = 0$ so that*

$$F(\omega) = \overline{\{f_n(\omega) : n \geq 1\}} \quad \forall \omega \in \Omega \setminus N.$$

As it is shown in [4], this definition coincides with the classical one when U is a separable Banach space.

DEFINITION 2.2. *A measurable selector of F is a μ-measurable function $f : \Omega \to U$ such that*

$$f(\omega) \in F(\omega) \quad \mu \text{ almost everywhere (a.e.).}$$

We denote

$$S_F^1 = \{f : f \in L_U^1(\mu); f \text{ is a measurable selector of } F\}.$$

DEFINITION 2.3. *A μ-measurable multifunction $F : \Omega \to U$ is called integrably bounded if there is $g \in L^1(\mu)$ such that*

$$\int_\Omega \|f(\omega)\| d\omega \leq \int_\Omega g d\mu$$

for every μ-measurable selector f of F.

DEFINITION 2.4. *On $P_f(U)$ the Hausdorff metric is defined by setting*

$$h(A,B) = \max\left\{\sup_{a\in A} d(a,B), \sup_{b\in B} d(A,b)\right\}.$$

The metric space $(P_f(U), h)$ is complete, and $P_{f(c)}(U)$ is a closed subspace of it.

DEFINITION 2.5. *If V is a Hausdorff topological space, the multifunction $F : V \to P_f(U)$ is continuous if it is a continuous function with the Hausdorff metric.*

F is called USC if for each nonempty open subset $\mathcal{A}$ of U, the set

$$F^{-1}(\mathcal{A}) = \{v \in V : F(v) \subset \mathcal{A}\}$$

is open in V.

3. Time optimal control problem. In this section we shall study the time optimal control problem associated with the linear system (1.1) which can be written in the following way using the foregoing notation:

$$\begin{aligned} &\dot{x}(t) = A(t)x(t) + B(t)u(t), \quad t > 0, \\ &x(0) = x_0, \quad u \in S^1_{\mathcal{U}}, \quad x(t^*) \in G(t^*), \end{aligned} \tag{3.1}$$

where $\mathcal{U} : [0,\infty) \to P_{wkc}(U)$ is an integrably bounded multifunction.

A mild solution of (3.1) is a function $x_u(\cdot) : [0,\infty) \to X$ defined by

$$x_u(t) = S(t,0)x_0 + \int_0^t S(t,\alpha)B(\alpha)u(\alpha)d\alpha, \quad t \geq 0, \tag{3.2}$$

where $u \in S^1_{\mathcal{U}}$.

DEFINITION 3.1. *For $t_1 > 0$ the set of admissible controls on $[0,t_1]$ is defined by*

$$C(t_1) = \{u \in L^1(0,t_1;U) : u(t) \in \mathcal{U}(t) \ \text{ a.e. in } \ [0,t_1]\} = S^1_{\mathcal{U}_{t_1}},$$

and the corresponding set of attainable points is defined by

$$K(t_1) = \{x_u(t_1) : x_u(\cdot) \ \text{ is a mild solution of } \ (3.1), \ u \in C(t_1)\},$$

where $\mathcal{U}_{t_1}$ is the restriction of $\mathcal{U}$ over $[0,t_1]$.

The following definition is a generalization of the similar one given in [24, p. 73].

DEFINITION 3.2. *A control $u \in C(t_1)$ is called an* extremal control *if the corresponding solution x_u of (3.1) satisfies $x_u(t_1) \in \partial K(t_1)$.*

DEFINITION 3.3. *For each $t \geq 0$, consider a target set $G(t) \subset X$. Suppose $t^* > 0$ and $u^* \in C(t^*)$ such that $x^*(t^*) \in G(t^*)$. Then u^* is called an optimal control if*

$$t^* = \inf\{t \in [0,\infty) : K(t) \cap G(t) \neq \emptyset\}.$$

The goal of this section is to provide the existence of optimal control for (3.1) under the hypothesis of upper semicontinuity on the target set. The importance of this result (Theorem 3.1) is that, even with constant target, it applies to linear partial differential equations in nonreflexive Banach spaces. In order to do that, we need to prove some propositions.

PROPOSITION 3.1. *$K(t_1)$ is convex and weakly compact in X.*

Proof. Define the multifunction

$$\Gamma : [0, t_1] \to P(X) \quad \text{by} \quad \Gamma(s) = S(t_1, s)B(s)\mathcal{U}(s).$$

The multifunction Γ is measurable, convex, a.e. weakly compact valued, and integrably bounded. By Theorem 3.2 of [4], S^1_Γ is weakly compact in $L^1(0, t_1; X)$.

Since $K(t_1)$ is merely a translation of $\int_0^{t_1} S^1_\Gamma$ and the integration is a bounded linear operator, the conclusion follows. □

PROPOSITION 3.2. *$K(t)$ is continuous in $t \in [0, T]$ with respect to the Hausdorff metric if $\bigcap_{t\in(0,T]} \mathcal{U}(t) \neq \emptyset$.*

Proof. Let $t_1 > 0$ be fixed and $\epsilon > 0$. We must find $\delta > 0$ such that

$$\text{if} \quad |t_1 - t_2| < \delta, \quad \text{then} \quad h(K(t_1), \quad K(t_2)) < \epsilon.$$

Let $t_2 \in (0, T)$ be with $0 < t_2 - t_1 < t_1$. If $x \in K(t_1)$, there exists $u \in C(t_1)$ such that

$$x = S(t_1, 0)x_0 + \int_0^{t_1} S(t_1, \alpha)\, B(\alpha)u(\alpha)d\alpha.$$

Define

$$\bar{u}(t) = \begin{cases} u(t) & \text{if } 0 \le t \le t_1, \\ v & \text{if } t > t_1, \end{cases}$$

where $v \in \bigcap_{t\in(0,T]} \mathcal{U}(t)$. Then

$$y = S(t_2, 0)x_0 + \int_0^{t_2} S(t_2, \alpha)B(\alpha)\bar{u}(\alpha)d\alpha \in K(t_2)$$

by the strong continuity of the evolution operator $S(t, s)$, the absolute continuity of the Bochner integral, and the Lebesgue dominated convergence theorem; given $\epsilon > 0$, there exists $\delta > 0$ such that, if $t_2 - t_1 < \delta$, then

$$\begin{aligned} \|x - y\| &\le \|S(t_2, 0)x_0 - S(t_1, 0)x_0\| + \left\| \int_{t_1}^{t_2} S(t_2, \alpha)B(\alpha)\bar{u}(\alpha)d\alpha \right\| \\ &\quad + \int_0^{t_1} \|S(t_2, \alpha)B(\alpha)u(\alpha) - S(t_1, \alpha)B(\alpha)u(\alpha)\|d\alpha \\ &< \frac{\epsilon}{3} + \frac{\epsilon}{3} + \frac{\epsilon}{3} = \epsilon. \end{aligned}$$

If $t_2 < t_1$, the conclusion is immediate. □

Even though the following corollary is an infinite dimensional version of the one found in Lee–Markus [24], our proof is very simple.

COROLLARY 3.1. *If $p \in \text{int}K(t_1)$ and $\bigcap_{t>0} \mathcal{U}(t) \neq \emptyset$, then there is a neighborhood N of p and $\delta > 0$ such that $N \subset K(t_2)$ for $|t_2 - t_1| < \delta$.*

Proof. Since $p \in \text{int}K(t_1)$, there is $r > 0$ such that $\overline{B(p, r)} \subset K(t_1)$ and

$$\alpha = \inf\{\|x - y\| : x \in \partial B(p, r), \quad y \in \partial K(t_1)\} > 0.$$

On the other hand, from Proposition 3.2, there exists $\delta > 0$ such that

$$|t - t_1| < \delta \Longrightarrow \text{h}(K(t_1), K(t)) < \frac{\alpha}{2}. \tag{3.3}$$

Now suppose that there exists $x_0 \in B(p,r) \setminus K(t)$ for some $t \in (t_1-\delta, t_1+\delta)$. Then for $y \in \partial K(t_1)$ and $x \in K(t)$ we have

$$\alpha < \mathrm{d}(x_0, y) \leq \mathrm{d}(x, y) + \mathrm{d}(x, x_0).$$

Hence

$$\begin{aligned}
\alpha &< \inf_{x\in K(t)} \mathrm{d}(x,y) + \inf_{x\in K(t)} \mathrm{d}(x_0,x) \\
&= \mathrm{d}(K(t),y) + \mathrm{d}(K(t),x_0) \\
&\leq \sup_{y\in K(t_1)} \mathrm{d}(K(t),y) + \frac{\alpha}{2} \\
&< \frac{\alpha}{2} + \frac{\alpha}{2} = \alpha,
\end{aligned}$$

which is in contradiction to (3.3). Therefore, $B(p,r) \subset K(t)$ for $|t-t_1| < \delta$. □

THEOREM 3.1 (existence of the time optimal control). *Suppose the target $G(t)$ is convex, closed, and USC with respect to the Hausdorff metric. If there is a control $u \in C(t_1)$ such that $x_u(t_1) \in G(t_1)$, then there exists a time optimal control $u^* \in C(t^*)$.*

Proof. Put

$$H = \{t \in [0, t_1] : K(t) \cap G(t) \neq \emptyset\}$$

and $t^* = \inf H$. Then there is a decreasing sequence $\{t_n\} \subseteq H$ such that $\lim_{n\to\infty} t_n = t^*$, which implies the existence of a sequence $\{u_n\} \subset S^1_{\mathcal{U}_{t_1}}$ such that

$$S(t_n, 0)x_0 + \int_0^{t_n} S(t_n, s)B(s)u_n(s)ds \in G(t_n).$$

Since for each $n \in \mathbb{N}$

$$\int_0^{t_n} S(t_n,s)B(s)u_n(s)ds = \int_0^{t^*} S(t_n,s)B(s)u_n(s)ds + \int_{t^*}^{t_n} S(t_n,s)B(s)u_n(s)ds,$$

$\mathcal{U}$ is integrably bounded, and $t_n \to t^*$, then by the absolute continuity of the Bochner integral, given $\epsilon > 0$, there is $n_0 \in \mathbb{N}$ such that, if $n \geq n_0$, we have

$$\left\| \int_0^{t_n} S(t_n,s)B(s)u_n(s)ds - \int_0^{t^*} S(t_n,s)B(s)u_n(s)ds \right\| < \epsilon.$$

Since $S^1_{\mathcal{U}_{t^*}}$ is weakly compact in $L^1(0,t^*;U)$, then we can choose $\{u_n\}_{n\geq 1}$ converging weakly in $L^1(0,t^*;U)$ to some $u \in S^1_{\mathcal{U}_{t^*}}$.

On the other hand, if we define the multifunction

$$F : [0, t^*] \to P_{wkc}(X)$$

by the formula

$$F(s) = S(t^*, s)B(s)\mathcal{U}(s),$$

then S^1_F is weakly compact in $L^1(0,t^*;X)$. Hence there is $f \in S^1_F$ such that $S(t^*,\cdot)B(\cdot)u_n(\cdot)$ converges in the weak topology of $L^1(0,t^*;X)$ to f.

Suppose $f \neq S(t^*,\cdot)B(\cdot)u(\cdot)$ a.e.. Then by Diestel–Uhl [10, Corollary II.2.5], there is $E \in \Sigma$ such that

$$\int_E f d\mu \neq \int_E S(t^*,\cdot)B(\cdot)u(\cdot)ds.$$

Now, given $\eta = \int_E \|f - S(t^*,\cdot)B(\cdot)u(\cdot)\|ds$, there is $\delta > 0$ such that

$$t^* - t^{**} < \delta \Rightarrow \int_{t^{**}}^{t^*} \|S(t^*,s)B(s)u(s)\|ds < \frac{\eta}{4} \text{ uniformly in } u \in S^1_{\mathcal{U}}$$

and $\int_{t^{**}}^{t^*} \|f(s)\|ds < \frac{\eta}{4}$. So, if $x^* \in X^*$ and $\|x^*\| = 1$, then

$$\begin{aligned}
&\left|\left\langle x^*, \int_0^{t^*} (S(t^*,s)B(s)u(s) - f(s))ds \right\rangle\right| \\
&\quad \leq \left|\left\langle x^*, \int_0^{t^{**}} (S(t^*,s)B(s)u(s) - f(s))ds \right\rangle\right| + \frac{\eta}{2} \\
&= \lim_{n\to\infty} \left| \int_0^{t^{**}} \langle x^*, S(t^*,s)B(s)u(s) - S(t^*,s)B(s)u_n(s)\rangle \, ds \right| + \frac{\eta}{2} \\
&= \lim_{n\to\infty} \left| \int_0^{t^{**}} \langle B^*(s)S^*(t^*,s)x^*, u(s) - u_n(s)\rangle \, ds \right| + \frac{\eta}{2}.
\end{aligned}$$

Since $S^*(t^*,\cdot)x^*$ is continuous in $[0,t^{**}]$, we conclude that

$$B^*(\cdot)S^*(t^*,\cdot)x^* \in L^\infty(0,t^{**};U^*) \subset \left(L^1(0,t^{**};U)\right)^*,$$

and since u_n weakly converges to u in $L^1(0,t^{**};U)$, the above limit is equal to zero. So, we get that $S(t^*,\cdot)B(\cdot)u_n(\cdot)$ weakly converges to $S(t^*,\cdot)B(\cdot)u(\cdot)$ in $L^1(0,t^*;X)$.

Since

$$\begin{aligned}
\int_0^{t_n} S(t_n,s)B(s)u_n(s)ds &= \int_0^{t^*} S(t_n,s)B(s)u_n(s)ds \\
&\quad + \int_{t^*}^{t_n} S(t_n,s)B(s)u_n(s)ds
\end{aligned}$$

and

$$\int_{t^*}^{t_n} S(t_n,s)B(s)u_n(s)ds \to 0, \quad \text{as} \quad n \to \infty,$$

we shall concentrate our attention on the first right-hand side of the foregoing equality. Since $0 \leq s \leq t^* \leq t_n$, we get

$$\int_0^{t^*} S(t_n,s)B(s)u_n(s)ds = S(t_n,t^*) \int_0^{t^*} S(t^*,s)B(s)u_n(s)ds.$$

Therefore,

$$\lim_{n\to\infty} \left\langle x^*, \int_0^{t^*} S(t_n,s)B(s)u_n(s)ds \right\rangle = \left\langle x^*, \int_0^{t^*} S(t^*,s)B(s)u(s)ds \right\rangle.$$

Hence

$$\begin{aligned}\text{w-}\lim_{n\to\infty} x(t_n) &= \text{w-}\lim_{n\to\infty}\left[S(t_n,0)x_0 + \int_0^{t_n} S(t_n,s)B(s)u_n(s)ds\right]\\ &= S(t^*,0)x_0 + \int_0^{t^*} S(t^*,s)B(s)u(s)ds\\ &= x(t^*).\end{aligned}$$

Since $x(t_n)\in G(t_n)$ and G is USC, then Theorem 2.4 of [21] implies that $x(t^*)\in G(t^*)$ and the control $u\in S^1_{\mathcal{U}_{t_1}}$ is a required optimal control. □

The following corollary contains Lemma 2.1 of Fattorini [13] since this reference uses the hypothesis $L^\infty(X) = L^1(X^*)^*$, which implies reflexivity.

COROLLARY 3.2. *If $A = A(t)$ is the infinitesimal generator of a strongly continuous semigroup, if $L^\infty(0,T;X^*) = L^1(0,T;X)^*$ for $T>0$, if the target $G(t)$ is USC, and if $K(t)\cap G(t)\neq\emptyset$ for some $t\in(0,T]$, then the system* (3.1) *has an optimal solution.*

Proof. $L^\infty(0,T;X^*) = L^1(0,T;X)^*$ if and only if X^* has the Radon–Nikodym property [10]. In this case A generates a strongly continuous semigroup $\{T_t\}_{t\geq 0}$ whose adjoint semigroup is strongly continuous on $(0,+\infty)$ [3], [27]. If we put $S(t,s) = T_{t-s}$, then the conclusion follows by applying the foregoing theorem. □

4. The maximum principle. Two maximum principles are given in this section; the first one holds in reflexive Banach spaces since $\text{int}K(t)\neq\emptyset$. It is so because in this case, 0 has a relative weakly compact neighborhood, which implies that X is reflexive (see [11, p. 425]).

THEOREM 4.1. *Suppose* $\text{int}K(t)\neq\emptyset$ *for $t>0$. If $u^*\in C(t^*)$ is an optimal control and the target $G(t)$ is convex and continuous in the Hausdorff metric, then there is $x^*\neq 0$ such that*

$$m(s) = \max_{u(s)\in\mathcal{U}(s)}\langle x^*, S(t^*,s)Bu(s)\rangle = \langle x^*, S(t^*,s)Bu^*(t)\rangle$$

a.e. on $[0,t^*]$ whenever $\bigcap_{t\in(0,t^*+\epsilon]}\mathcal{U}(t)\neq\emptyset$.

Proof. $G(t^*)\cap\text{int}K(t^*) = \emptyset$. In fact, for the purpose of contradiction, let us suppose that there exists $p\in G(t^*)\cap\text{int}K(t^*)$. Then by Corollary 3.1 there is an open subset N containing p and $\delta>0$ such that

$$t^*-\delta < t < t^* \Rightarrow N\subset K(t)\Rightarrow G(t)\subset N^c.$$

On the other hand,

$$0<d = \text{dist}(p,N^c)\leq \inf_{x\in G(t)}\|p-x\|,\quad t\in(t^*-\delta,t).$$

Hence $\text{h}(G(t^*),G(t))\geq d$, which contradicts the continuity of $G(t)$ with respect to the Hausdorff metric. So the statement is proved.

Applying the Hahn Banach theorem, we find $x^*\in X^*,\ x^*\neq 0$, such that

$$\sup x^*(K(t^*))\leq\inf x^*(G(t^*)).$$

Then

$$\sup_{u\in S^1_{\mathcal{U}_{t^*}}}\left\langle x^*, S(t^*,0)x_0 + \int_0^{t^*} S(t^*,s)B(s)u(s)ds\right\rangle$$

$$\leq \left\langle x^*, S(t^*,0)x_0 + \int_0^{t^*} S(t^*,s)B(s)u^*(s)ds \right\rangle,$$

where u^* is an optimal control as in Theorem 3.1.

Therefore,

$$\sup_{u\in S^1_{\mathcal{U}_{t^*}}} \int_0^{t^*} x^*S(t^*,s)B(s)u(s)ds = \int_0^{t^*} x^*S(t^*,s)B(s)u^*(s)ds.$$

From Theorem 2.2 of Hiai–Umegaki [17] we get

$$\begin{aligned}\sup_{u\in S^1_{\mathcal{U}_{t^*}}} \int_0^{t^*} x^*S(t^*,s)B(s)u(s)ds &= \int_0^{t^*} \sup_{u(s)\in\mathcal{U}(s)} \langle x^*, S(t^*,s)B(s)u(s)\rangle\, ds \\ &= \int_0^{t^*} x^*S(t^*,s)B(s)u^*(s)ds.\end{aligned}$$

Hence

$$\sup_{u(s)\in\mathcal{U}(s)} \langle x^*, S(t^*,s)B(s)u(s)\rangle = \langle x^*, S(t^*,s)B(s)u^*(s)\rangle.$$

Since $S(t^*,s)B(s)\mathcal{U}(s)$ is weakly compact for each $s\in[0,t^*]$, then James's weak compactness theorem [20] implies that

$$\max_{u(s)\in\mathcal{U}(s)} \langle x^*, S(t^*,s)B(s)u(s)\rangle = \langle x^*, S(t^*,s)B(s)u^*(s)\rangle \quad \text{a.e.}$$

This completes the proof. □

In the proof of Theorem 4.1 we used some ideas from Theorem 4.1 of [29]. Here we shall state a similar result to that one without assuming the strong continuity at $s=t^*$ of the adjoint evolution operator $S^*(t^*,s)$. Since the proof of it is essentially the same, we will omit it.

THEOREM 4.2. *If $G(t)$ is convex and continuous with respect to the Hausdorff metric and* $\operatorname{int}G(t)\neq\emptyset\ \forall t\in[0,t^*]$, *and if u^* is an optimal control and X is separable, then there is $x^*\in X^*\setminus\{0\}$ so that*

$$m(s) = \max_{u(s)\in\mathcal{U}(s)} \langle x^*, S(t^*,s)B(s)u(s)\rangle = \langle x^*, S(t^*,s)B(s)u^*(s)\rangle \ \ a.e.$$

Remark 4.1. Theorems 4.1 and 4.2 admit comparison only when X is reflexive and separable. In fact, suppose the hypotheses of Theorem 4.1 hold. Since $K(t)$ is weakly compact and $\operatorname{int}K(t)\neq\emptyset$, then the Banach space X must be reflexive. So apparently, Theorem 4.2 is more general than Theorem 4.1. However, the hypothesis $\operatorname{int}G(t)\neq\emptyset$ is too restrictive and does not include the simple case $G(t)=\{x_1\}$, even in finite dimensional systems. We recall that the hypothesis of "$S^*(t^*,s)$" having been strongly continuous on $0\leq s<t^*$ allows us to incorporate into the subject the study of the heat equation in nonreflexive Banach spaces, a case which is not considered in [29].

THEOREM 4.3. *Suppose that the hypothesis of Theorem* 4.1 *holds. Then a control $u^*\in C(t^*)$ is extremal if and only if there is $x^*\in X^*\setminus\{0\}$ so that*

$$\max_{u(s)\in\mathcal{U}(s)} \langle x^*, S(t^*,s)B(s)u(s)\rangle = \langle x^*, S(t^*,s)B(s)u^*(s)\rangle \ \ a.e.$$

Proof. If u^* is an extremal control, then the corresponding solution $x(\cdot)$ of (3.1) satisfies $x(t^*) \in \partial K(t^*)$. Since $K(t^*)$ is convex and weakly compact, and since $\text{int}K(t^*) \neq \emptyset$, there exists $x^* \in X^* \setminus \{0\}$ such that

$$\sup_{x \in K(t^*)} \langle x^*, x \rangle = \langle x^*, x(t^*) \rangle .$$

So,

$$\sup_{u \in S^1_{\mathcal{U}_{t^*}}} \left\langle x^*, \int_0^{t^*} S(t^*, s)B(s)u(s)ds \right\rangle = \left\langle x^*, \int_0^{t^*} S(t^*, s)B(s)u^*(s)ds \right\rangle,$$

and the proof follows as in Theorem 4.1.

For the converse, if $u^* \in C(t^*)$, $x^* \in X^* \setminus \{0\}$,

$$\langle x^*, S(t^*, s)B(s)u^*(s) \rangle = \max_{u(s) \in \mathcal{U}(s)} \langle x^*, S(t^*, s)B(s)u(s) \rangle$$

a.e. on $[0, t^*]$ and $x(\cdot)$ is the solution of (1.1) corresponding to u^*, then for each $\hat{x}(t^*) \in K(t^*)$ there exists $\hat{u} \in C(t^*)$ such that

$$\hat{x}(t^*) = S(t^*, 0)x_0 + \int_0^{t^*} S(t^*, s)B(s)\hat{u}(s)ds.$$

Hence

$$\langle x^*, \hat{x}(t^*) - x(t^*) \rangle = \int_0^{t^*} \langle x^*, S(t^*, s)B(s)(\hat{u}(s) - u^*(s)) \rangle ds \leq 0,$$

which implies that $x(t^*) \in \partial K(t^*)$. □

Remark 4.2. The hypothesis $\text{int}K(t) \neq 0$ in the converse portion of the Theorem 4.3 is not necessary.

5. Normal systems. The following definition is a generalization of Lee–Markus [24, p. 79].

DEFINITION 5.1. *The control system* (1.1) *is called* normal *if the following implication holds. If* $u_1, u_2 \in C(t_1)$ *transfer* x_0 *to the same* $p \in \partial K(t_1)$*, then* $u_1 = u_2$ *a.e. on* $[0, t_1]$.

We recall that a convex set K in a Banach space X is strictly convex if each support hyperplane meets K in at most one point. This notion was introduced by Clarkson [7], and a nice study of it can be found in Diestel [9].

THEOREM 5.1. *Under the hypotheses of Theorems* 4.1 *and* 4.2*, if the control system* (1.1) *is normal, then* $K(t_1)$ *is strictly convex.*

Proof. Suppose that Π_{t_1} is a support hyperplane for $K(t_1)$ such that $p_a, p_b \in \Pi_{t_1} \cap K(t_1)$ with $p_a \neq p_b$ and $u_a, u_b \in C(t_1)$ as their corresponding controls.

We now consider the Banach space $Y = X \times X$ with the norm

$$\|y\|_Y = \| \begin{pmatrix} x_1 \\ x_2 \end{pmatrix} \| = \|x_1\|_X + \|x_2\|_X$$

and the function

$$f(t) = \begin{pmatrix} S(t_1, s)B(s)u_a(s) \\ S(t_1, s)B(s)u_b(s) \end{pmatrix}, \quad s \in [0, t_1],$$

with values in Y. Clearly $f \in L^1(0,t_1,Y)$. By Lyapunov's convexity theorem [33] the set

$$F = \left\{ w(D) = \int_D f(t)dt : D \subset [0,t_1] \ \text{ is measurable} \right\}$$

has convex closure. Thus

$$\frac{1}{2}w([0,t_1]) = \frac{1}{2}w([0,t_1]) + \frac{1}{2}w(\emptyset) \in \bar{F}.$$

Therefore, there exists a sequence $\{w(D_n)\}$ contained in F such that

$$\lim_{n\to\infty} w(D_n) = \frac{1}{2}w([0,t_1]), \quad \lim_{n\to\infty} w([0,t_1] \setminus D_n) = \frac{1}{2}w([0,t_1]).$$

Consider the controls

$$u_n^{(1)}(s) = \begin{cases} u_a(s), & s \in D_n, \\ u_b(t), & s \in [0,t_1] \setminus D_n, \end{cases}$$

$$u_n^{(2)}(s) = \begin{cases} u_a(s), & s \in [0,t_1] \setminus D_n, \\ u_b(t), & s \in D_n, \end{cases}$$

with corresponding solutions $x_n^{(1)}(\cdot)$ and $x_n^{(2)}(\cdot)$. It is easy to see that

$$\lim_{n\to\infty} x_n^{(1)}(t_1) = \lim_{n\to\infty} x_n^{(2)}(t_1) = \frac{1}{2}p_a + \frac{1}{2}p_b.$$

Since $C(t_1)$ is weakly compact in $L^1(0,t_1;U)$, we can suppose that the sequences $\{u_n^{(1)}\}$ and $\{u_n^{(2)}\}$ weakly converge to the controls $u_1, u_2 \in C(t_1)$, respectively.

Since $S^*(t_1,s)$ is strongly continuous in $s \in [0,t_1)$, then for each $x^* \in X^*$ and $\alpha \in (0,t_1)$ we have that

$$B^*(\cdot)S^*(t_1,\cdot)x^*u_n^{(i)}(\cdot) \ \text{ weakly converges to } \ B^*(\cdot)S^*(t_1,\cdot)x^*u_i(\cdot), \quad i = 1,2,$$

in $L^1(0,\alpha;\mathbb{R})$. If we take $\alpha_m \to t_1$, we see that

$$B^*(\cdot)S^*(t_1,\cdot)x^*u_n^{(i)}(\cdot)\mathcal{X}_{[0,\alpha_m]} \ \text{ converges to } \ B^*(\cdot)S^*(t_1,\cdot)x^*u^i(\cdot)\mathcal{X}_{[0,t_1]}, \quad i = 1,2,$$

on $[0,t_1]$. Since $\mathcal{U}$ is integrably bounded we get

$$\|B^*(\cdot)S^*(t_1,\cdot)x^*u^i\|_{L^1} \le \sup_{s\in[0,t_1)} \|S(t_1,s)\|\|x^*\|\|B\|_\infty \|g\|_{L^1},$$

where $g \in L^1[0,t_1]$ and $\|u(s)\| \le g(s)$, a.e. $\forall u \in S^1_{\mathcal{U}_{t_1}}$.

Thus, by applying the Lebesgue dominated convergence theorem, we get that

$$B^*(\cdot)S^*(t_1,\cdot)x^*u_n^{(i)}(\cdot) \ \text{ converges to } \ B^*(\cdot)S^*(t_1,\cdot)x^*u^{(i)}(\cdot), \quad i = 1,2,$$

in the weak topology of $L^1(0,t_1;U)$. Hence

$$\begin{aligned} \lim_{n\to\infty} \left\langle x^*, x_n^1(t_1) \right\rangle &= \langle x^*, S(t_1,0)x_0 \rangle + \left\langle x^*, \int_0^{t_1} S(t_1,s)B(s)u^1(s)ds \right\rangle \\ &= \left\langle x^*, \frac{1}{2}(p_a + p_b) \right\rangle = \left\langle x^*, S(t_1,0)x_0 + \int_0^{t_1} S(t_1,s)B(s)u^2(s)ds \right\rangle \\ &= \lim_{n\to\infty} \left\langle x^*, x_n^2(t_1) \right\rangle. \end{aligned}$$

Since this happens for each $x^* \in X^*$, we conclude that

$$S(t_1,0)x_0 + \int_0^{t_1} S(t_1,s)B(s)u^1(s)ds = S(t_1,0)x_0 + \int_0^{t_1} S(t_1,s)B(s)u^2(s)ds,$$

and by the normality of the system (3.1), we obtain

$$u_1(t) = u_2(t) \ \text{ a.e on } \ [0,t_1]. \tag{5.1}$$

Since $C(t_1) \subset L^1(0,t_1;U)$ is weakly compact, from the equality (5.1) we get

$$\lim_{n\to\infty} \left\langle u^*, u_n^{(1)} - u_n^{(2)} \right\rangle = 0 \ \text{ for each } \ u^* \in \left(L^1(0,t_1;U)\right)^*.$$

Therefore, by the definition of u_n^1 and u_n^2 we get $\langle u^*, u_a - u_b\rangle = 0$. Thus $u_a(t) = u_b(t)$ a.e. on $J = [0,t_1]$, and, consequently, $p_a = p_b$, which is a contradiction. This concludes the proof. □

THEOREM 5.2. *Suppose the hypothesis in Theorem* 4.1 *holds. Then the control system* (3.1) *is normal if and only if for each* $x^* \in X^* \setminus \{0\}$ *and a pair of controls* $u_1, u_2 \in C(t_1)$*, such that*

$$\begin{aligned} &\langle\ x^*, S(t_1,s)B(s)u_1(s)\rangle = \langle x^*, S(t_1,s)B(s)u_2(s)\rangle \\ &= \max_{u(s)\in\mathcal{U}(s)} \langle x^*, S(t_1,s)B(s)u(s)\rangle \ \ \textit{a.e on } \ [0,t_1] \end{aligned} \tag{5.2}$$

implies $u_1 = u_2$ *a.e. on* $[0,t_1]$.

Proof. Suppose the system (4.1) is normal; consider $x^* \in X^* \setminus \{0\}$, and let $u_1(\cdot), u_2(\cdot)$ be controls in $C(t_1)$ with the corresponding solutions $x_1(\cdot), x_2(\cdot)$, such that

$$\begin{aligned} &\langle\ x^*, S(t_1,s)B(s)u_1(s)\rangle = \langle x^*, S(t_1,s)B(s)u_2(s)\rangle \\ &= \max_{u(s)\in\mathcal{U}(s)} \langle x^*, S(t_1,s)B(s)u(s)\rangle \ \text{ a.e. on } \ [0,t_1]. \end{aligned}$$

Let Π be the hyperplane defined by

$$\Pi = \{x \in X : \langle x^*, x - x_1(t_1)\rangle = 0\}.$$

Π supports $K(t_1)$ at $x_1(t_1)$ and $x_2(t_1)$, and by the foregoing theorem $x_1(t_1) = x_2(t_1)$. Since (4.1) is normal, $u_1(t) = u_2(t)$ a.e. on $[0,t_1]$.

Conversely, let u_1, u_2 be controls belonging $C(t_1)$ which transfer x_0 to p. Then, by Theorem 4.3,

$$\begin{aligned} &\langle x^*, S(t_1,s)B(s)u_1(s)\rangle = \langle x^*, S(t_1,s)B(s)u_2(s)\rangle \\ &= \max_{u(s)\in\mathcal{U}(s)} \langle x^*, S(t_1,s)B(s)u(s)\rangle \ \text{ a.e. on } \ [0,t_1]. \end{aligned}$$

Therefore, by (5.2) we obtain $u_1(t) = u_2(t)$ a.e. on $[0,t_1]$. Hence the system (1.1) is normal. □

THEOREM 5.3. *If for almost all* s, $\mathcal{U}(s)$ *is strictly convex and* $\mathrm{Ker}B^*(s)S^*(t^*,s) = \{0\}$*, then the system* (1.1) *is normal.*

Proof. Suppose $x^* \in X^* \setminus \{0\}$. Then $x_s^* = B^*(s)S^*(t^*,s)x^* \neq 0$. Since $\mathcal{U}(s)$ is weakly compact and strictly convex, x_s^* attains its maximum at a unique point in $\mathcal{U}(s)$.

So, if $u_1,\ u_2 \in C(t^*)$ with

$$\begin{aligned}&\langle x^*, S(t^*,s)B(s)u_1(s)\rangle = \langle x^*, S(t^*,s)B(s)u_2(s)\rangle\\ &= \max_{u(s)\in\mathcal{U}(s)} \langle x^*, S(t^*,s)B(s)u(s)\rangle \ \text{ a.e. on } \ [0,t_1],\end{aligned}$$

then $u_1 = u_2$ a.e. and the system (1.1) is normal by Theorem 5.2. □

As a consequence we get the following corollary.

COROLLARY 5.1 (bang-bang principle). *Under the hypothesis of the former theorem, the optimal control u^* is unique and $u^*(t) \in \partial\mathcal{U}(t)$ a.e.*

6. Examples. In this section we shall show how some of our results can be applied in many evolution processes.

Example 6.1. Consider the one dimensional heat equation

$$\text{(6.1)}\qquad \begin{cases} x_t(t,\xi) = x_{\xi\xi}(t,\xi) + bu(t,\xi), \quad 0<\xi<1, \quad t>0,\\ x(t,0) = x(t,1), \quad x_\xi(t,0) = x_\xi(t,1), \quad t\geq 0,\\ x(0,\xi) = x_0(x), \end{cases}$$

as shown in Pazy [30, section 8.2]; if we associate with (6.1) the operator $A\phi = \phi_{\xi\xi}$, then A generates a strongly continuous semigroup $\{T_t\}_{t\geq 0}$ of compact operators on the nonreflexive Banach spaces $X = U = C_p[0,1]$ of all continuous and periodic functions with period 1 and the supremum norm.

Since T_t is compact, it is continuous in the uniform topology of $L(X)$ for $t>0$, and therefore the adjoint semigroup T_t^* is strongly continuous away from 0, and Theorem 3.1 can be applied with any target satisfying the hypothesis of that theorem.

We will show that T_t^* fails to be strongly continuous at $t=0$, and, consequently, this example does not fit in the theory developed in the cited references by simply putting $S(t,s) = T_{t-s}$.

In fact, since T_t is compact for $t>0$, then X is a sun-reflexive Banach space under the action of T_t (see [27], [28]). Therefore, X^* is a weakly compact generated Banach space [28]. Now a theorem from Kuo [23] shows that X^* has the Radon–Nikodym property, which is lacked by X^* in our present case.

We recall that a Banach space X has the Radon–Nikodym property when every X-valued, countably additive, and bounded variation vector measure has a Bochner integrable Radon–Nikodym derivative.

Example 6.2. If A is the generator of a strongly continuous semigroup T_t which is uniformly continuous for $t>0$ and $F \in L^\infty(0,T;L(X))$, then the evolution operator $S(t,s)$ generated by $A+F(s)$ is uniformly continuous in s for $0\leq s<t$ and is given by

$$S(t,s)x = T_{t-s}x + \int_s^t T_{t-r}F(r)S(t,r)dr.$$

The uniform continuity of $S(t,s)$ comes from the uniform integrability of

$$\{T_{t-(\cdot)}F(\cdot)S(t,\cdot)x : \quad \|x\|\leq 1\};$$

this implies that the adjoint evolution operator is strongly (actually uniformly) continuous in $0\leq s<t$.

Actually, if T_t is compact for $t>0$, and X^* is not weakly compactly generated, then as in Example 6.1 we can show that T_t^* is not strongly continuous at $t=0$. Hence, if $S(t,s) = T_{t-s}$, then $S^*(t,s)$ is not strongly continuous at $t=s$.

These kinds of examples appear in optimal control periodic problems and are studied in Li–Yong [25, pp. 160–164] in the particular case when T_t is compact for $t > 0$. However, neither time optimal control nor maximum principle is considered for this particular case.

Example 6.3. If we consider the Schrodinger operator $A\phi = i\Delta\phi$ in the Hilbert space $X = L^2(\mathbb{R}^n)$, then it is proved in Pazy [30, Chapter VII] that the operator A generates a strongly continuous group in X. If $B \in L^\infty(0,T;X)$ such that $B(t)$ is invertible a.e., then

$$\mathrm{Ker}B^*(s)S^*(t-s) = \{0\} \quad \mu. \text{ a.e.},$$

and defining the multifunction

$$\begin{aligned} \mathcal{U} : [0,T] &\to X, \\ s &\to sB_X, \end{aligned}$$

where $B_X = \{x \in X : \|x\| \le 1\}$, then $\mathcal{U}(t)$ is strictly convex for every $s \in [0,T]$ and so the system (1.1) is normal by Theorem 5.3.

Example 6.4. Consider the following evolution system:

$$x_t(t,\xi) = k\Delta x(t,\xi) + b(t,\xi)u(t,\xi), \quad t \ge 0, \quad \xi \in \Omega. \tag{6.2}$$

If $\Omega = \mathbb{R}^n$ (no boundary conditions), then we work in the space $X = L^1(\mathbb{R}^n)$. In this case the operator $A\phi = \Delta\phi$ also generates a strongly continuous semigroup $\{T_t\}_{t\ge 0}$ given by

$$T_t\phi(\xi) = \frac{1}{2^n(\pi kt)^{n/2}} \int_{\mathbb{R}^n} \exp\left(\frac{-|\xi-\eta|^2}{4kt}\right)\phi(\eta)d\eta, \quad t > 0.$$

As is shown in [13], the adjoint semigroup is strongly continuous away from zero. If this semigroup were continuous at $t = 0$, then it would be strongly continuous on $L^\infty(\mathbb{R}^n)$, and so by Lotz [26], T_t^* has a bounded generator which implies that T_t has a bounded generator also, which is a plain contradiction.

Acknowledgments. We want to thank the referees for their comments which helped us to improve the presentation of this paper.

LIMITING DISCOUNTED-COST CONTROL OF PARTIALLY OBSERVABLE STOCHASTIC SYSTEMS*

ONÉSIMO HERNÁNDEZ-LERMA† AND ROSARIO ROMERA‡

Abstract. This paper presents two main results on partially observable (PO) stochastic systems. In the first one, we consider a general PO system

$$x_{t+1} = F(x_t, a_t, \xi_t), \quad y_t = G(x_t, \eta_t) \quad (t = 0, 1, \dots) \qquad (*)$$

on Borel spaces, with possibly unbounded cost-per-stage functions, and we give conditions for the existence of α-discount optimal control policies ($0 < \alpha < 1$). In the second result we specialize $(*)$ to additive-noise systems

$$x_{t+1} = F_n(x_t, a_t) + \xi_t, \quad y_t = G_n(x_t) + \eta_t \quad (t = 0, 1, \dots)$$

in Euclidean spaces with $F_n(x, a)$ and $G_n(x)$ converging pointwise to functions $F_\infty(x, a)$ and $G_\infty(x)$, respectively, and we give conditions for the limiting PO model

$$x_{t+1} = F_\infty(x_t, a_t) + \xi_t, \quad y_t = G_\infty(x_t) + \eta_t$$

to have an α-discount optimal policy.

Key words. partially observable control systems, partially observable Markov control processes, hidden Markov models, discounted cost criterion

1. Introduction.

In this paper we consider a nonlinear, time-varying, partially observable (PO) stochastic control system with state process $\{x_t\}$ evolving according to the equation

$$x_{t+1} = F_t(x_t, a_t) + \xi_t\ , \quad t \in \mathbb{N}, \qquad (1.1)$$

where $\mathbb{N} := \{0, 1, \dots\}$, and observations $\{y_t\}$ are of the form

$$y_t = G_t(x_t) + \eta_t, \quad t \in \mathbb{N}. \qquad (1.2)$$

Assuming that the functions F_t and G_t converge pointwise to functions F_∞ and G_∞, that is, as $t \to \infty$

$$F_t(x, a) \to F_\infty(x, a) \quad \text{and} \quad G_t(x) \to G_\infty(x) \qquad (1.3)$$

for all (x, a) and x, respectively, we investigate the existence of optimal control policies for the *limiting PO system*

$$x_{t+1} = F_\infty(x_t, a_t) + \xi_t, \quad y_t = G_\infty(x_t) + \eta_t, \qquad (1.4)$$

when the optimality criterion is the α-*discounted cost* ($0 < \alpha < 1$).

In fact, we present two main results. In the first one, we consider a *general PO system*

$$x_{t+1} = F(x_t, a_t, \xi_t), \quad y_t = G(x_t, \eta_t), \tag{1.5}$$

in which the *state space* X and the *observation set* Y are *Borel spaces* (that is, Borel subsets of complete and separable metric spaces). Similarly, the state and observation disturbances ξ_t and η_t take values in Borel spaces S and S', respectively, whereas the control actions a_t are taken from a compact metric space A. In this setting, we give conditions for the existence of α-discount optimal policies, allowing the cost-per-stage to be possibly *unbounded*. (See Theorem 2.5.)

In the second main result (Theorem 3.4), we consider the additive-noise case (1.1), (1.2) and the limiting system (1.4) on the spaces $\mathrm{X} = S = \mathbb{R}^{d_1}$ and $\mathrm{Y} = S' = \mathbb{R}^{d_2}$. Assuming (1.3), we give conditions ensuring the existence of an optimal control policy for (1.4).

To prove these results we begin by writing (1.5) as a PO Markov control (or decision) process (MCP), also known as a controlled "hidden Markov model" [6]. In other words, we work with a *general state transition law* and a *general observation kernel*, as in (2.10) and (2.11), respectively, which can be specialized in the obvious manner to (1.5), say. (See (2.12) and (2.13).) The formulation (2.10), (2.11) has, of course, technical advantages, but what is even more important is that it includes a class of models larger than (1.5). Namely, there are many applications in control of queues, fisheries, learning processes, and others (see [4, 6, 7, 13, 18, 20, 21]) described by "stochastic kernels" as in (2.10) and (2.11), on possibly finite or countable spaces, rather than by a "difference equation" model such as (1.5).

Our original motivation to study the limiting control problem, which naturally led us to consider the general system (1.5), was our interest in some biotechnological processes and other *time-varying* systems, as in (1.1), (1.2), but for which it is known that their "coefficients" tend to stabilize in the sense of (1.3); see [1, 16]. Alternatively, if the disturbances ξ_t and η_t have zero means, then (1.3) is equivalent to the convergence of the expected values

$$F_t(x, a) = E(x_{t+1} | x_t = x, a_t = a) \text{ and } G_t(x) = E(y_t | x_t = x). \tag{1.6}$$

Thus our Theorem 3.4 can also be interpreted as a result on the adaptive control of (1.4) when the terms $F_\infty(x, a)$ and $G_\infty(x)$ are *unknown* but they are being estimated by the conditional expectations in (1.6). Similarly, using (2.10) and (2.11), Theorem 3.4 is easily related to results on either the approximation or the adaptive control of PO systems with unknown state transition law and observation kernel [4, 6, 7, 9, 13, 14, 25]. This interpretation of Theorem 3.4 is valid, of course, for the *completely observable* (CO) case which results when $y_t = x_t$ for all time index t; see [5, 9, 15, 19, 22]. Similarly, in the *noncontrolled* case (namely, when the control space A is a one-point set, say), our results on (1.1)–(1.4) can be seen as stating the convergence of filtering models—see Lemma 5.1.

Our approach is somewhat related to the CO case considered in [15], but the technical requirements are quite different. This is due to the fact that the analysis of (1.5) requires us to introduce an equivalent CO system with values in a set of probability measures (see (2.5)–(2.7)). Thus, for instance, some "pointwise" statements in [15] in our present setting turn out to be statements on the convergence of measures in some suitable sense.

The remainder of the paper is organized as follows. In section 2 we state our assumptions and main result (Theorem 2.5) on the general PO system (1.5). Section 3 consists of two parts. In the first we consider the additive-noise system (3.1) and show that the assumptions in section 2 can be replaced with conditions on (3.1) itself. This is important to keep in mind because one of those assumptions (Assumption 2.4) is imposed on a "transformed" PO system, whereas the conditions in section 3 (Hypotheses A to D) are all on the original PO system (3.1), and so—at least in principle—they are easier to verify. In the second part of section 3 we state our result (Theorem 3.4) on the limiting PO system (1.4). Sections 4 and 5 contain the proofs of Theorem 2.5 and 3.4, respectively, and, finally, we conclude in section 6 with some general comments.

2. The general PO system. We begin with the following remark on the terminology and notation we shall use and then proceed to state the optimal control problem we are concerned with.

REMARK 2.1. (a) *Given a Borel space* X*, we denote by* $\mathcal{B}(\mathrm{X})$ *its Borel* σ*-algebra, and by* $\mathbb{P}(\mathrm{X})$ *the family of probability measures on* X*, endowed with the usual weak topology* $\sigma(\mathbb{P}(\mathrm{X}), C_b(\mathrm{X}))$*, where* $C_b(\mathrm{X})$ *stands for the Banach space of continuous bounded functions* u *on* X *with the sup norm* $\|u\| := \sup_x |u(x)|$*. Thus a sequence* $\{\mu_k\}$ *in* $\mathbb{P}(\mathrm{X})$ *is said to converge weakly to* μ *if*

$$\int_{\mathrm{X}} u d\mu_k \to \int_{\mathrm{X}} u d\mu \quad \forall u \in C_b(\mathrm{X}). \tag{2.1}$$

As X *is a Borel space, so is* $\mathbb{P}(\mathrm{X})$*. (See* [2, 3, 23]*, for instance.)*

(b) *Let* X *and* Y *be Borel spaces. A measurable function* $q : \mathrm{Y} \to \mathbb{P}(\mathrm{X})$ *is called a* stochastic kernel *on* X *given* Y*, and we denote by* $\mathbb{P}(\mathrm{X}|\mathrm{Y})$ *the family of all those stochastic kernels. Equivalently,* $q(dx|y)$ *is in* $\mathbb{P}(\mathrm{X}|\mathrm{Y})$ *if* $q(\cdot\,|y)$ *is a probability measure on* X *for each fixed* $y \in \mathrm{Y}$*, and* $q(B|\cdot\,)$ *is a measurable function on* Y *for each fixed* $B \in \mathcal{B}(\mathrm{X})$*. If* $\mathrm{X} = \mathrm{Y}$*, then a stochastic kernel is called a* Markov transition probability.

Throughout the paper we suppose the following.

ASSUMPTION 2.2. *All the stochastic processes considered below are defined on an underlying probability space* $(\Omega, \mathcal{F}, P)$*. In addition, the following hold.*

(a) *The state space* X*, the observation set* Y*, and the disturbance spaces* S *and* S' *are all Borel spaces.*

(b) *The control (or action) set* A *is a compact metric space.*

(c) *The state and observation disturbances* ξ_t *and* $\eta_t, t \in \mathbb{N}$*, form independent sequences of independent and identically distributed (i.i.d.) random variables with values in* S *and* S'*, respectively. These sequences are also independent of the initial state* x_0*. We denote by* $\mu \in \mathbb{P}(S)$ *and* $\nu \in \mathbb{P}(S')$ *the common distributions of* ξ_t *and* η_t*, respectively.*

(d) *The functions* $F(x, a, s)$ *and* $G(x, s')$ *in* (1.5) *are continuous.*

(e) *The cost-per-stage function* $c : \mathrm{X} \times A \to \mathbb{R}$ *is* (e_1) *nonnegative and lower semicontinuous (l.s.c.), and* (e_2) $c(x, a)$ *is continuous in* $x \in \mathrm{X}$ *uniformly on* A*.*

(f) *There exists a constant* C *and a continuous function* $w \geq 1$ *on* X *such that* $c(x, a) \leq Cw(x)$ *for all* $x \in \mathrm{X}$ *and* $a \in A$*.*

For examples of cost functions $c(x, a)$ that satisfy Assumptions 2.2(e) and (f), see, for instance, [11, 17, 20]. In particular, both assumptions trivially hold if A is a finite set (as in [7, 18, 21, 24]), whereas (e_2) holds if $c(x, a) = c_1(x) + c_2(a)$, where c_1 and c_2 are nonnegative functions with $c_1(x)$ continuous and $c_2(a)$ l.s.c.

The PO control problem. Let $\mathcal{Y}_t := \sigma(y_0, \dots, y_t)$ be the σ-algebra generated by the observations up to time t. By an *admissible control policy* (or simply a *policy*) we mean a sequence $\pi = \{a_t\}$ of A-valued random variables such that a_t is $\mathcal{Y}_t$-measurable for each $t \in \mathbb{N}$. We shall denote by Π the set of all such policies.

Let $\alpha \in (0,1)$ be a fixed "discount factor." For each policy $\pi \in \Pi$ and initial distribution $\varphi \in \mathbb{P}(\mathrm{X})$ (that is, φ is the a priori distribution of x_0), the corresponding α-discounted cost is defined as

$$V(\pi, \varphi) := \sum_{t=0}^{\infty} \alpha^t E_\varphi^\pi \left[c(x_t, a_t) \right], \tag{2.2}$$

where E_φ^π denotes the expectation operator with respect to the probability measure P_φ^π induced by π and φ. Let

$$V^*(\varphi) := \inf_\pi V(\pi, \varphi) \quad \text{for} \quad \varphi \in \mathbb{P}(\mathrm{X}) \tag{2.3}$$

be the *optimal* α-discounted cost. The *PO optimal control problem* is then to find an optimal policy π^*, that is, a policy such that

$$V(\pi^*, \varphi) = V^*(\varphi) \quad \forall \varphi \in \mathbb{P}(\mathrm{X}). \tag{2.4}$$

The CO control problem. To study the PO control problem we shall follow the standard procedure in which the PO problem is transformed into a CO problem using the *filtering process* $\{\varphi_t\}$ in $\mathbb{P}(\mathrm{X})$ defined as follows. For each policy $\pi \in \Pi$ and initial distribution $\varphi \in \mathbb{P}(\mathrm{X})$,

$$\varphi_0(B) := P_\varphi^\pi(x_0 \in B) = \varphi(B), \tag{2.5}$$

$$\varphi_t(B) := P_\varphi^\pi(x_t \in B | \mathcal{Y}_t) \quad \text{for} \quad t \geq 1, \tag{2.6}$$

which are defined for all B in $\mathcal{B}(\mathrm{X})$. The filtering process depends, of course, on the policy π and the initial distribution φ, and so, strictly speaking, we should write φ_t as $\varphi_{t,\varphi}^\pi$, for instance. However, we shall use the simpler notation in (2.5) and (2.6) unless we need to remark which π and φ are being used.

To continue with the description of the PO problem, we use the well-known fact (see, for instance, [2, 6, 25, 27, 28] and (3.5), (3.6) below) that there exists a measurable function $H : \mathbb{P}(\mathrm{X}) \times A \times \mathrm{Y} \to \mathbb{P}(\mathrm{X})$ such that (2.6) can be written as

$$\varphi_{t+1} = H(\varphi_t, a_t, y_{t+1}) \quad \forall t \in \mathbb{N} \tag{2.7}$$

with initial condition (2.5). (Note that, by Remark 2.1(b), H is a stochastic kernel on $\mathbb{P}(\mathrm{X})$ given $\mathbb{P}(\mathrm{X}) \times A \times \mathrm{Y}$.) Moreover, using the notation

$$\widehat{c}(\varphi, a) := \int_{\mathrm{X}} c(x, a) \varphi(dx) \quad \text{for} \quad \varphi \in \mathbb{P}(\mathrm{X}),\ a \in A, \tag{2.8}$$

we can rewrite the α-discounted cost in (2.2) as

$$V(\pi, \varphi) = \sum_{t=0}^{\infty} \alpha^t E_\varphi^\pi \left[\widehat{c}(\varphi_t, a_t) \right]. \tag{2.9}$$

Finally, the *CO problem* is to minimize (2.9) over all $\pi \in \Pi$, subject to (2.5) and (2.6), and this problem is equivalent to the original PO problem in the sense that an optimal policy for CO is optimal for PO.

Solution of the CO problem. To state our first main result we need some notation. Let $P \in \mathbb{P}(\mathrm{X}|\mathrm{X} \times A)$ and $Q \in \mathbb{P}(\mathrm{Y}|\mathrm{X})$ be the *state transition law* and the *observation kernel* corresponding to (1.5), that is,

$$P(B|x,a) := \mathrm{Prob}(x_{t+1} \in B | x_t = x, a_t = a) \tag{2.10}$$

and

$$Q(C|x) := \mathrm{Prob}(y_t \in C | x_t = x) \tag{2.11}$$

for each $B \in \mathcal{B}(\mathrm{X}), C \in \mathcal{B}(\mathrm{Y}), x \in \mathrm{X}, a \in A$, and $t \in \mathbb{N}$. More explicitly, in view of (1.5) and Assumption 2.2(c), we have that

$$P(B|x,a) = \int_S I_B\left[F(x,a,s)\right]\mu(ds), \tag{2.12}$$

where I_B denotes the indicator function of a set B, and, similarly,

$$Q(C|x) = \int_{S'} I_C\left[G(x,s')\right]\nu(ds'). \tag{2.13}$$

From (2.12) and (2.13), together with the bounded convergence theorem, it follows that P and Q are both *weakly continuous*; that is, if $x^n \to x$ and $a^n \to a$, then

$$\int_{\mathrm{X}} u(x')P(dx'|x^n,a^n) \to \int_{\mathrm{X}} u(x')P(dx'|x,a) \quad \forall u \in C_b(\mathrm{X}), \tag{2.14}$$

and

$$\int_{\mathrm{Y}} v(y)Q(dy|x^n) \to \int_{\mathrm{Y}} v(y)Q(dy|x) \quad \forall v \in C_b(\mathrm{Y}). \tag{2.15}$$

We also require the following conditions on the state transition law P.

ASSUMPTION 2.3. (a) *If $a^n \to a$, then $P(\cdot|x,a^n) \to P(\cdot|x,a)$ weakly, uniformly in $x \in \mathrm{X}$.*

(b) *If $(\varphi^n, a^n) \to (\varphi, a)$, then there exists an integer $N = N_{\varphi,a}$ and a finite measure $\zeta = \zeta_{\varphi,a}$ such that*

$$\int_{\mathrm{X}} P(\cdot\,|x,a^n)\varphi^n(dx) \le \zeta(\cdot) \quad \forall n \ge N.$$

The existence of a "majorant" measure ζ as in Assumption 2.3(b), which we will use in conjunction with Lemma 4.5, below, is discussed at the end of this section; see Remark 2.6 and Example 2.7. On the other hand, to verify Assumption 2.3(a) one may try to use one of the several metrics that metrize the weak convergence, such as the Dudley metric [29, Corollary 4.3.6]. For instance, suppose that $\mathrm{X} = \mathbb{R}^d$ and that $F(x,a,s)$ is of the form $F(x,a,s) = F_1(x) + F_2(a,s)$, where F_2 is a continuous bounded function on $A \times S$. Now choose an arbitrary Lipschitz bounded function $u : \mathrm{X} \to \mathbb{R}$ with Lipschitz constant $\overline{u}$, that is, $|u(x) - u(x')| \le \overline{u}|x - x'|$. Then, by (2.12), if $a^n \to a$, we obtain

$$\begin{aligned}
&\Big|\int_X u(x')P(dx'|x,a^n) - \int_X u(x')P(dx'|x,a)\Big| \\
&\quad \le \int_S |u[F(x,a^n,s)] - u[F(x,a,s)]|\mu(ds) \\
&\quad \le \overline{u}\int_S |F_2(a^n,s) - F_2(a,s)|\mu(ds) \\
&\quad \to 0 \quad \text{uniformly in} \quad x \in \mathrm{X}.
\end{aligned}$$

Hence, as the choice of u was arbitrary, $P(\cdot|x,a^n) \to P(\cdot|x,a)$ converges in the Dudley metric [29], uniformly in $x \in \mathrm{X}$, and so Assumption 2.3(a) follows. A similar conclusion holds, of course, if F is of the form $F(x,a,s) = F_1(x,s) + F_2(a)$, where F_2 is a continuous function on A. (For the additive-noise case, see (3.10).)

Now, for each $C \in \mathcal{B}(\mathrm{Y}), \varphi \in \mathbb{P}(\mathrm{X})$, and $a \in A$, consider the stochastic kernel

$$\widehat{q}(C|\varphi,a) := \mathrm{Prob}(y_{t+1} \in C|\varphi_t = \varphi, a_t = a), \tag{2.16}$$

which, using (2.10)–(2.13), can be written as

$$\begin{aligned}\widehat{q}(C|\varphi,a) &= \int_{\mathrm{X}}\int_{\mathrm{X}} Q(C|x')P(dx'|x,a)\varphi(dx) \\ &= \int_{\mathrm{X}}\int_{S}\int_{S'} I_C\left[G(F(x,a,s),s')\right]\nu(ds')\mu(ds)\varphi(dx).\end{aligned} \tag{2.17}$$

Finally, for each $D \in \mathcal{B}(\mathbb{P}(\mathrm{X})), \varphi \in \mathbb{P}(\mathrm{X}), a \in A,$ and $t \in \mathbb{N}$, let

$$\widehat{P}(D|\varphi,a) := \mathrm{Prob}(\varphi_{t+1} \in D|\varphi_t = \varphi, a_t = a)$$

be the *transition law of the filtering process* (2.7), which we can also write as

$$\widehat{P}(D|\varphi,a) = \int_{\mathrm{Y}} I_D\left[H(\varphi,a,y)\right]\widehat{q}(dy|\varphi,a). \tag{2.18}$$

ASSUMPTION 2.4. *Let H and $w \geq 1$ be as in* (2.7) *and Assumption* 2.2(f)*, respectively, and define $\widehat{w} : \mathbb{P}(\mathrm{X}) \to \mathbb{R}$ as $\widehat{w}(\varphi) := \int_{\mathrm{X}} w(x)\varphi(dx)$.*

(a) *H is continuous.*

(b) *There is a number $1 \leq \beta < 1/\alpha$ such that*

$$\int_{\mathbb{P}(\mathrm{X})} \widehat{w}(\varphi')\widehat{P}(d\varphi'|\varphi,a) \leq \beta\widehat{w}(\varphi) \quad \forall\varphi \in \mathbb{P}(\mathrm{X}), \quad a \in A. \tag{2.19}$$

Observe that the property "$w \geq 1$" of w is inherited by $\widehat{w}$ because

$$\widehat{w}(\varphi) := \int_{\mathrm{X}} w d\varphi \geq \varphi(\mathrm{X}) = 1 \quad \forall\varphi \in \mathbb{P}(\mathrm{X}).$$

We shall denote by $\mathbb{B}_w(\mathbb{P}(\mathrm{X}))$ the (vector) space of all real-valued measurable functions u on $\mathbb{P}(\mathrm{X})$ such that

$$\|u\|_w := \sup_{\varphi} |u(\varphi)|/\widehat{w}(\varphi) < \infty.$$

We can now state our first optimality result as follows.

THEOREM 2.5. *If Assumptions* 2.2, 2.3, *and* 2.4 *are satisfied, then the following hold.*

(a) *The optimal cost function $V^*(\varphi) := \inf_\pi V(\pi,\varphi)$, with $V(\pi,\varphi)$ as in* (2.9)*, is the unique solution in $\mathbb{B}_w(\mathbb{P}(\mathrm{X}))$ of the Bellman (or dynamic programming) equation*

$$V^*(\varphi) = \min_{a\in A}\left[\widehat{c}(\varphi,a) + \alpha\int_{\mathbb{P}(\mathrm{X})} V^*(\varphi')\widehat{P}(d\varphi'|\varphi,a)\right] \tag{2.20}$$

for all $\varphi \in \mathbb{P}(\mathrm{X})$.

(b) *Moreover, V^* is l.s.c.*

(c) *There exists a measurable function $f^* : \mathbb{P}(\mathrm{X}) \to A$ that attains the minimum in* (2.20)*, i.e., for all $\varphi \in \mathbb{P}(\mathrm{X})$*

$$V^*(\varphi) = \widehat{c}(\varphi, f^*(\varphi)) + \alpha \int_{\mathbb{P}(\mathrm{X})} V^*(\varphi')\widehat{P}(d\varphi'|\varphi, f^*(\varphi)), \tag{2.21}$$

and f^* determines an optimal control policy $\pi^* = \{a_t^*\}$ given by

$$a_t^* := f^*(\varphi_t) \quad \forall t \in \mathbb{N},$$

where $\{\varphi_t\}$ is the filtering process.

Theorem 2.5, which is proved in section 4, is essentially standard except for the fact that we are allowing a *general* PO system (1.5) and a possibly *unbounded* cost-per-stage $c(x, a)$, as in Assumption 2.2(e), (f). To the best of our knowledge, the only case studied in the literature in which $c(x, a)$ is unbounded is for the so-called *linear-quadratic-Gaussian* (*LQG*) PO system. Furthermore, the existence of the "filtering function" H in (2.7) depends only on the state transition law and the observation kernel in (2.10) and (2.11), not on the particular PO model (1.5). This means, in other words, that Theorem 2.5 is valid for general PO systems on Borel spaces, and so, in particular, it includes systems on *countable* spaces, which are very common in applications; see [4, 6, 7, 13, 18, 20, 21, 24, 25].

On the other hand, it goes without saying that in Theorem 2.5 the most restrictive hypothesis is Assumption 2.4 because it is stated in terms of the components H and $\widehat{P}$ of the CO problem—in contrast to Assumptions 2.2 and 2.3 that are given on the *original PO system*, and so, in principle, they are "easier" to verify in particular PO models. In the following section we show, among other things, that Assumptions 2.3 and 2.4 hold for additive-noise models under reasonably mild conditions.

We conclude this section with some comments on Assumption 2.3(b) which are used in the following sections.

REMARK 2.6. (a) *Let* X *be an arbitrary Borel space, and let* Γ *be an arbitrary subfamily of* $\mathbb{P}(\mathrm{X})$*. A measure* γ^m *on* X *is said to be a* majorant *of* Γ *if* $\gamma^m(\cdot) \geq \gamma(\cdot)$ *for all* $\gamma \in \Gamma$*. If* Γ *has a* finite *majorant, we then say that* Γ *is* order-bounded from above [30, 31].

(b) *A family* $\Gamma \subset \mathbb{P}(\mathrm{X})$ *always has an* upper envelope*, that is, a majorant* γ^u *such that* $\gamma^u(\cdot) \leq \gamma^m(\cdot)$ *for any majorant* γ^m *of* Γ*. The construction of* γ^u*, which is used in the proof of Lemma* 5.1*, is as follows. Let* ρ^u *be the set function defined as*

$$\rho^u(B) := \sup\{\gamma(B)|\gamma \in \Gamma\} \quad \forall\, B \in \mathcal{B}(\mathrm{X}). \tag{2.22}$$

Then, as in Theorem 2.2 *in* [8]*, for instance, the upper envelope of* Γ *is the measure* γ^u *on* $\mathcal{B}(\mathrm{X})$ *given by*

$$\gamma^u(B) := \sup\left\{\sum_{k=1}^{\infty} \rho^u(B_k)|\{B_k\} \subset \mathcal{B}(\mathrm{X}) \quad \textit{is a partition of } B\right\}. \tag{2.23}$$

(There are more "explicit" ways of constructing γ^u *if* Γ *is a countable family* [8*, Remark* 2.4]*.) Clearly,* Γ *is order-bounded from above if and only if* γ^u *is a finite measure, i.e.,*

$$\gamma^u(\mathrm{X}) < \infty. \tag{2.24}$$

(c) *Let* $\| \lambda \|_{TV} := |\lambda|(\mathrm{X})$ *be the total variation norm of a finite signed measure* λ *on* X*, where* $|\lambda| = \lambda^+ + \lambda^-$ *denotes the variation measure. Let* $\{\gamma_n\}$ *be a sequence in* $\mathbb{P}(\mathrm{X})$ *such that* $\| \gamma_n - \gamma \|_{TV} \to 0$*. Then (by the definition of order-convergence—see* [31, Definition 2, p. 366]*) there exists a nonincreasing sequence of finite measures* $\widehat{\gamma}_n$ *on* X *such that* $\widehat{\gamma}_n(\mathrm{X}) \downarrow 0$ *and*

$$|\gamma_n - \gamma| \le \widehat{\gamma}_n \quad \forall\, n = 1, 2, \dots . \tag{2.25}$$

Now choose an arbitrary integer N *(for instance, such that* $\widehat{\gamma}_N(\mathrm{X}) \le \varepsilon$ *for some* $\varepsilon > 0$*.) It follows from* (2.25) *that*

$$\gamma_n(\cdot) \le \gamma(\cdot) + \widehat{\gamma}_N(\cdot) \quad \forall\, n \ge N. \tag{2.26}$$

In other words, if $\lambda_n \to \lambda$ *in the total variation norm, then, for any* $N > 0$*, the sequence* $\{\gamma_n, n \ge N\}$ *has the finite majorant* $\gamma(\cdot) + \widehat{\gamma}_N(\cdot)$*.*

For additional criteria for order-boundedness of measures, see, e.g., [30]. On the other hand, an obvious sufficient condition for Assumption 2.3(b) is that the whole family $\{P(\cdot|x,a) : x \in \mathrm{X}, a \in A\}$ is order-bounded from above, i.e.,

$$P(\cdot|x,a) \le \zeta(\cdot) \quad \forall\, x \in \mathrm{X},\ a \in A, \tag{2.27}$$

for some finite measure $\zeta(\cdot)$. This is the case in the following well-known example.

Example 2.7 (see, e.g., [32, 33, 34]). *Consider the additive-noise system*

$$x_{t+1} = F(x_t, a_t) + \xi_t \tag{2.28}$$

with state space $\mathrm{X} = \mathbb{R}^{d_1}$*, say. Suppose that* $F : \mathrm{X} \times A \to \mathrm{X}$ *is continuous and bounded and that the i.i.d. disturbances* ξ_t *have a continuous and bounded density* g_ξ *with respect to the Lebesgue measure* λ_1 *on* X*. Then, by* (2.10) *and* (2.12)*,*

$$P(B|x,a) = \int_B g_\xi(s - F(x,a))\lambda_1(ds). \tag{2.29}$$

Then, as the closure of the set $\{F(x,a)|x \in \mathrm{X}, a \in A\}$ *is compact in* X *and the function* $w \to g_\xi(s-w)$ *is continuous for each* s*, there is a bounded,* λ_1*-integrable function* $\widehat{g}_\xi$ *on* X *such that* $g_\xi(s - F(x,a)) \le \widehat{g}_\xi(s)$ *for all* s, x, a*. Hence* (2.27) *holds with*

$$\zeta(B) := \int_B \widehat{g}_\xi(s)\lambda_1(ds).$$

Remark 2.8. (a) *An argument as in Example* 2.7 *shows that* (2.27) *holds, for instance, for the nonadditive-noise models in Examples* 8.6.2 *and* 8.6.4 *in* [11].

(b) *Consider an additive-noise* observation process

$$y_t = G(x_t) + \eta_t \tag{2.30}$$

on $Y := \mathbb{R}^{d_2}$ *with i.i.d. disturbances* η_t*, which have a density* g_η *with respect to the Lebesgue measure* λ_2 *on* $\mathbb{R}^{d_2}$*. Then, by* (2.11) *and* (2.13)*,*

$$Q(C|x) = \int_C g_\eta(s' - G(x))\lambda_2(ds'), \tag{2.31}$$

and, as in Example 2.7*, it follows that if* g_η *and* G *are continuous bounded functions (on their corresponding domains), then there exists a finite measure* γ *on* Y *such that*

$$Q(\cdot|x) \le \gamma(\cdot) \quad \forall\, x \in \mathrm{X}.$$

(c) *The additive-noise systems in* (b) *and Example* 2.7 *with continuous bounded "drifts"* $G(x)$ *and* $F(x,a)$*, respectively, are also* order-bounded from below [32, 33, 34]*; that is, there exist nontrivial substochastic measures* γ_1^l *on* Y *and* γ_2^l *and* X *such that*

$$Q(\cdot|x) \ge \gamma_1^l(\cdot) \quad \text{and} \quad P(\cdot|x,a) \ge \gamma_2^l(\cdot) \quad \forall\, x, a. \tag{2.32}$$

For additional conditions ensuring order-boundedness from below, see [9, 11, 30, 34, 35]*, for instance.*

3. Additive-noise models and the limiting PO system. The main objective in this section is to study the limiting system (1.4). With this in mind, we first study the general additive-noise system (3.1), below, which serves several purposes. It illustrates the concepts introduced in section 2; it gives conditions ensuring that Assumptions 2.3 and 2.4 are satisfied; and it is an introduction to our main result (Theorem 3.4) on (1.4).

Additive-noise models. Consider the PO additive-noise system

$$x_{t+1} = F(x_t, a_t) + \xi_t, \quad y_t = G(x_t) + \eta_t, \quad t \in \mathbb{N}, \tag{3.1}$$

with $\mathrm{X} = S = \mathbb{R}^{d_1}, \mathrm{Y} = S' = \mathbb{R}^{d_2}$, and A a compact metric; see Assumptions 2.2(a), (b). In addition, the disturbances $\{\xi_t\}$ and $\{\eta_t\}$ are as in Assumption 2.2(c), except that now we also suppose the following.

Hypothesis A. *The noise distributions* μ *and* ν *are absolutely continuous, say,*

$$\mu(ds) = g_\xi(s)\lambda_1(ds) \quad \textit{and} \quad \nu(ds') = g_\eta(s')\lambda_2(ds'), \tag{3.2}$$

where λ_i $(i = 1, 2)$ *denotes the Lebesgue measure on* $\mathbb{R}^{d_i}$*, and, moreover,* g_ξ *and* g_η *are* continuous bounded *density functions.*

Then, as in (2.29) and (2.31), the state transition law and the observation kernel are given by

$$P(B|x,a) = \int_B g_\xi(s - F(x,a))\lambda_1(ds) \tag{3.3}$$

and

$$Q(C|x) = \int_C g_\eta(s' - G(x))\lambda_2(ds'), \tag{3.4}$$

respectively. On the other hand, as is well known [4, 9, 14, 24, 25, 27], the filtering function H in (2.7) is of the form

$$H(\varphi, a, y)(B) = \sigma(\varphi, a, y)(B)/\sigma(\varphi, a, y)(\mathrm{X}) \quad \forall B \in \mathcal{B}(\mathrm{X}) \tag{3.5}$$

with

$$\begin{aligned} \sigma(\varphi, a, y)(B) &= \int_B g_\eta(y - G(x')) \int_{\mathrm{X}} P(dx'|x,a)\varphi(dx) \\ &= \int_{\mathrm{X}} \left[\int_B g_\eta(y - G(x'))P(dx'|x,a) \right] \varphi(dx) \\ &= \int_{\mathrm{X}} \left[\int_B g_\eta(y - G(x'))g_\xi(x' - F(x,a))\lambda_1(dx') \right] \varphi(dx), \end{aligned} \tag{3.6}$$

by (3.3).

On the other hand, Assumption 2.2(d) reduces to the following.

HYPOTHESIS B. *The functions* $F : \mathrm{X} \times A \to \mathrm{X}$ *and* $G : \mathrm{X} \to \mathrm{Y}$ *in* (3.1) *are continuous.*

Let us denote by $\|\cdot\|_{TV}$ the *total variation norm* for measures and suppose that $x^n \to x$ and $a^n \to a$. Then, by (3.3), Hypotheses A and B, and Scheffé's theorem (see, for instance, pp. 223–224 in [3]), we have that

$$\|P(\cdot\,|x^n, a^n) - P(\cdot\,|x, a)\|_{TV} \to 0, \tag{3.7}$$

which is of course a lot stronger than (2.14). Similarly, by (3.4),

$$\|Q(\cdot\,|x^n) - Q(\cdot\,|x)\|_{TV} \to 0. \tag{3.8}$$

On the other hand, in addition to the cases that we have already mentioned in section 2, to obtain Assumption 2.3 we may suppose, for example, the following.

HYPOTHESIS C. (a) *If* $a^n \to a$, *then* $\|P(\cdot\,|x, a^n) - P(\cdot\,|x, a)\|_{TV} \to 0$ *uniformly on X.*

(b) *If* $(\varphi^n, a^n) \to (\varphi, a)$, *then there exist an integer* $N = N_{\varphi,a}$ *and a* λ_1*-integrable function* $\widehat{g} = \widehat{g}_{\varphi,a} \geq 0$ *such that*

$$\int_{\mathrm{X}} g_\xi(s - F(x, a^n))\varphi^n(dx) \leq \widehat{g}(s) \quad \forall s \in \mathrm{X} \text{ and } n \geq N. \tag{3.9}$$

Hypothesis C(a) holds, for instance, if $F(x, a)$ is "separable" in x and a, say,

$$F(x, a) = F_1(x) + F_2(a), \tag{3.10}$$

where F_1 and F_2 are continuous functions. This follows from (3.3) and using the change of variable $y := s - F_1(x)$. In fact, (3.10) is similar to the "separable" case in the paragraph after Assumption 2.3, and it covers many control models. For example, (3.10) appears in the *cash-balance model* of Hordijk and Yushkevich [17, section 6], in which the state process, the "cash balance," follows the scalar linear equation

$$x_{t+1} = x_t + a_t + \xi_t. \tag{3.11}$$

In (3.11), the disturbances ξ_t are i.i.d. standard Gaussian variables, and the control action $a_t = a$ corresponds to a withdrawal of money of size $-a$ if $a < 0$, or to a supply a if $a > 0$. The control set is a given compact interval, say, $A = [-M, M]$. In this setting, (3.9) also holds if the probability measure φ^n satisfies that, for some constant k, $\int \exp(x^2)\varphi^n(dx) \leq k$ for all n sufficiently large (see [17, p. 445]). Observe that (3.11) does not satisfy the boundedness of $F(x, a)$ used in Example 2.7.

PROPOSITION 3.1. *Hypothesis C implies Assumption* 2.3.

Proof. It is evident that Hypothesis C(a) implies Assumption 2.3(a). Now, to obtain Assumption 2.3(b), note that (3.3) and (3.9) yield

$$\begin{aligned}\int_{\mathrm{X}} P(B|x, a^n)\varphi^n(dx) &= \int_B \int_{\mathrm{X}} g_\xi(s - F(x, a^n))\varphi^n(dx)\lambda_1(ds) \\ &\leq \int_B \widehat{g}(s)\lambda_1(ds)\end{aligned}$$

for all $n \geq N$. Thus the measure $\zeta(B) := \int I_B(s)\widehat{g}(s)\lambda_1(ds)$ satisfies that

$$\int_{\mathrm{X}} P(\cdot\,|x, a^n)\varphi^n(dx) \leq \zeta(\cdot) \quad \forall n \geq N, \tag{3.12}$$

and Assumption 2.3(b) follows. □

We next show that Hypothesis C also yields Assumption 2.4(a).

PROPOSITION 3.2. *If Hypothesis C holds, then so does Assumption* 2.4(a).

Proof. Let H be as in (3.5) and suppose that $(\varphi^n, a^n, y^n) \to (\varphi, a, y)$. We wish to prove that

$$H(\varphi^n, a^n, y^n)(\cdot) \to H(\varphi, a, y)(\cdot) \ \text{ weakly.} \tag{3.13}$$

To prove this, let

$$\mu_n(\cdot) := \int_{\mathrm{X}} P(\cdot\,|x, a^n)\varphi^n(dx) \ \text{ and } \ \mu(\cdot) := \int_{\mathrm{X}} P(\cdot\,|x, a)\varphi(dx). \tag{3.14}$$

We will first show that

$$\mu_n(\cdot) \to \mu(\cdot) \ \text{ setwise.} \tag{3.15}$$

By (3.12) and Lemma 4.5 below (in which $\widehat{\mathrm{X}} := \mathbb{P}(\mathrm{X})$), to get (3.15) it suffices to show that $\mu_n \to \mu$ *weakly*. Thus choose an arbitrary function u in $C_b(\mathrm{X})$ and use (3.14) to write

$$\Big|\int_{\mathrm{X}} u d\mu_n - \int_{\mathrm{X}} u d\mu\Big| \leq f(n) + g(n) \tag{3.16}$$

with

$$f(n) := \Big|\int_{\mathrm{X}}\int_{\mathrm{X}} u(x')[P(dx'|x, a^n) - P(dx'|x, a)]\varphi^n(dx)\Big|$$

and

$$g(n) := \Big|\int_{\mathrm{X}}\int_{\mathrm{X}} u(x')P(dx'|x, a)\varphi^n(dx) - \int_{\mathrm{X}}\int_{\mathrm{X}} u(x')P(dx'|x, a)\varphi(dx)\Big|.$$

By (3.3), the integral $\int u(x')P(dx'|x, a)$ is, in particular, continuous in $x \in \mathrm{X}$ for each $a \in A$. Therefore, $g(n) \to 0$. On the other hand, by Hypothesis C(a),

$$f(n) \leq \|u\| \sup_x \|P(\cdot\,|x, a^n) - P(\cdot\,|x, a)\|_{TV} \to 0 \ \text{ as } \ n \to \infty.$$

Hence from (3.16) we conclude that $\mu_n \to \mu$ weakly, which, as was already noted, together with (3.12) and Lemma 4.5, gives (3.15).

Now, going back to (3.13), let u be an arbitrary function in $C_b(\mathrm{X})$, and use (3.14) and (3.6) to write

$$\int_{\mathrm{X}} u(x)\sigma(\varphi^n, a^n, y^n)(dx) = \int_{\mathrm{X}} u(x)g_\eta(y^n - G(x))\mu_n(dx). \tag{3.17}$$

Therefore, as $g_\eta(y^n - G(x)) \to g_\eta(y - G(x))$ for all $x \in \mathrm{X}$, from (3.15) and Lemma 4.4(c) we obtain that

$$\sigma(\varphi^n, a^n, y^n) \to \sigma(\varphi, a, y) \ \text{ weakly.} \tag{3.18}$$

Moreover, taking $u(\cdot) \equiv 1$ in (3.17), we get $\sigma(\varphi^n, a^n, y^n)(\mathrm{X}) \to \sigma(\varphi, a, y)(\mathrm{X})$. This latter fact, combined with (3.18) and (3.5), gives (3.13). □

Finally, we will show that the following hypothesis implies (2.19).

HYPOTHESIS D. *There exist positive constants* $\bar{\alpha}$ *and* $\bar{\sigma}$ *such that*
(a) $g_\eta(y - G(x))/\sigma(\varphi, a, y)(\mathrm{X}) \le \bar{\sigma}$ for all φ, a, y, x,
(b) $\int_{\mathrm{X}} w(x')P(dx'|x,a) \le \bar{\alpha} w(x)$ for all x, a, *and*
(c) $1 \le \bar{\alpha}\bar{\sigma} < 1/\alpha$, *where* α *is the discount factor in* (2.9) (or (2.2)).

For examples satisfying condition (b), see [11 (Chapter 8), 17, 20] and their references. Concerning (a), see Remark 3.6.

PROPOSITION 3.3. *Hypothesis D implies Assumption* 2.4(b) *with* $\beta := \bar{\alpha}\bar{\sigma}$.

Proof. As $\widehat{w}(\varphi) := \int w(x)\varphi(dx)$, writing $\mathbb{P}(\mathrm{X})$ as $\widehat{\mathrm{X}}$, the left-hand side of (2.19) becomes

$$\int_{\widehat{\mathrm{X}}} \widehat{w}(\varphi')\widehat{P}(d\varphi'|\varphi, a) = \int_{\mathrm{X}} w(x) \int_{\widehat{\mathrm{X}}} \varphi'(dx)\widehat{P}(d\varphi'|\varphi, a),$$

and so, using (2.18),

$$\int_{\widehat{\mathrm{X}}} \widehat{w}(\varphi')\widehat{P}(d\varphi'|\varphi, a) = \int_{\mathrm{X}} w(x) \int_{\mathrm{Y}} H(\varphi, a, y)(dx)\widehat{q}(dy|\varphi, a). \tag{3.19}$$

On the other hand, by (3.5), (3.6), and Hypothesis D(a),

$$H(\varphi, a, y)(\cdot\,) \le \bar{\sigma} \int_{\mathrm{X}} P(\cdot\,|x, a)\varphi(dx).$$

This inequality and (3.19) yield

$$\begin{aligned}\int_{\widehat{\mathrm{X}}} \widehat{w}(\varphi')\widehat{P}(d\varphi'|\varphi, a) &\le \bar{\sigma} \int_{\mathrm{X}} \left[\int_{\mathrm{X}} w(x')P(dx'|x, a)\right] \varphi(dx) \\ &\le \bar{\alpha}\bar{\sigma} \int_{\mathrm{X}} w(x)\varphi(dx) \ \text{[by Hypothesis D(b)]} \\ &= \bar{\alpha}\bar{\sigma}\widehat{w}(\varphi).\end{aligned}$$

That is, (2.19) holds with $\beta := \bar{\alpha}\bar{\sigma}$. □

Summarizing, *Hypotheses A to D imply Assumptions* 2.3 *and* 2.4.

The limiting PO system. For each $n \in \mathbb{N}_\infty$, consider the PO control system

$$x_{t+1} = F_n(x_t, a_t) + \xi_t, \quad y_t = G_n(x_t) + \eta_t, \tag{3.20}$$

where $F_n(x, a)$ and $G_n(x)$ are functions that satisfy (1.3). For $n = \infty$, we have the limiting PO system (1.4). We will use a subindex "n" to indicate functions and probabilities corresponding to the model in (3.20). For instance, the α-discounted cost and the optimal cost function in (2.2) and (2.3) become

$$V_n(\pi, \varphi) := \sum_{t=0}^{\infty} \alpha^t E^\pi_{n,\varphi}\left[c(x_t, a_t)\right]$$

and

$$V_n^*(\varphi) := \inf_\pi V_n(\pi, \varphi),$$

respectively.

THEOREM 3.4. *Suppose that for each* finite $n \in \mathbb{N}$, (3.20) *satisfies Assumption* 2.2 *as well as Hypotheses A to D. Moreover, in addition to* (1.3) *we suppose that the*

limiting functions $F_\infty(x,a)$ *and* $G_\infty(x)$ *are continuous. Then Theorem* 2.5 *holds for* $n=\infty$.

Theorem 3.4 is proved in section 5. In the meantime, we may observe that Theorem 3.4 yields an optimal control policy for the limiting system, $n=\infty$, as follows.

For each $n=1,2,\dots$, let f_n^* be an optimal control policy for the nth control model, obtained as in (2.21); that is,

$$V_n^*(\varphi)=\widehat{c}(\varphi,f_n^*(\varphi))+\alpha\int_{\mathbb{P}(\mathrm{X})}V_n^*(\varphi')\widehat{P}_n(d\varphi'|\varphi,f_n^*(\varphi)) \tag{3.21}$$

for all $\varphi\in\mathbb{P}(\mathrm{X})$.

COROLLARY 3.5. *Under the hypotheses of Theorem* 3.4*, there exists a measurable function* $f_\infty^*:\mathbb{P}(\mathrm{X})\to A$ *such that the following hold.*

(a) *For each* $\varphi\in\mathbb{P}(\mathrm{X})$, $f_\infty^*(\varphi)$ *is an accumulation point of the sequence* $\{f_n^*(\varphi)\}$.

(b) f_∞^* *is an optimal control policy for the limiting control model with* $n=\infty$.

Proof. (a) This is a consequence of a result of Schäl [26] (reproduced in [10, Proposition D.7] and also in [11, p. 65]). Part (b) follows from (a) and from an argument as in the proof of Theorem 4.6.5 in [10], for instance. □

Moreover, if for each finite n there is a *unique* policy f_n^* as in (3.21), which is the case for some "convex" control problems, then in Corollary 3.5(a) we obtain that *the whole sequence* $\{f_n^*(\varphi)\}$ converges to $f_\infty^*(\varphi)$ for each φ in $\mathbb{P}(\mathrm{X})$.

We conclude this section with some comments on Hypothesis D(a).

REMARK 3.6. *As* g_η *is bounded, that is,* $g_\eta(y-G(x))\le\|\ g_\eta\ \|$ *for all* x,y*, Hypothesis* D(a) *holds if there is a constant* $\overline{\sigma}$ *such that*

$$\sigma(\varphi,a,y)(\mathrm{X})\ge\|\ g_\eta\ \|/\overline{\sigma}\quad\forall\,\varphi,a,y.$$

On the other hand, if $P(\cdot|x,a)$ *is order-bounded from below, say, as in* (2.32)*, then by* (3.6)

$$\sigma(\varphi,a,y)(\mathrm{X})\ge\int_{\mathrm{X}}g_\eta(y-G(x'))\gamma_2^l(dx')=:\widehat{g}_\eta(y)\quad\forall\,\varphi,a,y. \tag{3.22}$$

Therefore, another sufficient condition for Hypothesis D(a) *is the existence of a constant* $\overline{\sigma}$ *such that*

$$g_\eta(y-G(x))\le\overline{\sigma}\,\widehat{g}_\eta(y)\quad\forall\,x,y. \tag{3.23}$$

Observe that (3.22) *and* (3.23) *are both verifiable for the cases in Example* 2.7 *and Remark* 2.8(b).

4. Proof of Theorem 2.5. To prove Theorem 2.5 let us first write the CO problem (2.7)–(2.9) as an MCP. Thus (as in [2, 9, 10, 11], for instance) consider the control model

$$(\widehat{\mathrm{X}},\widehat{A},\widehat{P},\widehat{c}) \tag{4.1}$$

with *state space* $\widehat{\mathrm{X}}:=\mathbb{P}(\mathrm{X})$ and *control set* $\widehat{A}:=A$. The "state" *transition law* $\widehat{P}$ and the *running cost* $\widehat{c}$ are as in (2.18) and (2.8), respectively. Then Theorem 2.5 will follow from the results in section 8.5 (and section 8.3) of [11] if we show that the MCP in (4.1) satisfies Assumptions 8.5.1 and 8.5.2 in [11], which are reproduced below as Conditions

4.1 and 4.2, respectively. (Under our present Assumption 2.2(e), the running cost or cost-per-stage $c(x,a)$ is *nonnegative,* and, therefore, so is $\widehat{c}(\varphi,a)$. This means that here we do *not* require Assumption 8.5.3 in [11], whereas in Assumption 8.5.2 we need only $\widehat{w}(\varphi)$ to be l.s.c. rather than continuous, where $\widehat{w}(\varphi) := \int w(x)\varphi(dx)$ is the function in Assumption 2.4 above.)

CONDITION 4.1 (see Assumption 8.5.1 in [11]).

(a) $\widehat{\mathrm{X}} := \mathbb{P}(\mathrm{X})$ *is a Borel space, and* $\widehat{A} := A$ *is a compact metric space.*

(b) $\widehat{c}$ *is l.s.c. and nonnegative on* $\mathbb{K} := \widehat{\mathrm{X}} \times \widehat{A}$.

(c) $\widehat{P}$ *is weakly continuous on* $\mathbb{K}$*; that is, if* $(\varphi^n, a^n) \to (\varphi, a)$*, then*

$$\int_{\widehat{\mathrm{X}}} u(\varphi')\widehat{P}(d\varphi'|\varphi^n, a^n) \to \int_{\widehat{\mathrm{X}}} u(\varphi')\widehat{P}(d\varphi'|\varphi, a) \quad \forall u \in C_b(\widehat{\mathrm{X}}).$$

CONDITION 4.2 (see Assumptions 8.5.2 and 8.3.2 in [11]). *There exist nonnegative constants* C *and* β*, with* $1 \le \beta < 1/\alpha$*, and an l.s.c. function* $\widehat{w} \ge 1$ *on* $\widehat{\mathrm{X}}$ *such that for each "state"* $\varphi \in \widehat{\mathrm{X}}$

(a) $\sup_{a\in A} \widehat{c}(\varphi,a) \le C\widehat{w}(\varphi)$*, and*

(b) $\sup_{a\in A} \int_{\mathrm{X}} \widehat{w}(\varphi')\widehat{P}(d\varphi'|\varphi,a) \le \beta\widehat{w}(\varphi)$. *(See* (2.19)*.)*

Comparing these conditions with our Assumptions 2.2, 2.3, and 2.4, we see that to prove Theorem 2.5 it suffices to show that (in order of difficulty)

(i) $\widehat{w}(\varphi) \ge 1$ for all $\varphi \in \mathrm{X}$, and $\widehat{w}$ is l.s.c.,

(ii) $\widehat{c}(\varphi,a)$ satisfies Conditions 4.1(b) and 4.2(a), and

(iii) $\widehat{P}$ satisfies Condition 4.1(c).

Proof of (i). We already noted (after Assumption 2.4) that $\widehat{w} \ge 1$, whereas the lower semicontinuity of $\widehat{w}$ follows from the general well-known fact (see, for instance, statement (12.3.37) on p. 225 of [11]) that *if* φ^n *converges weakly to* φ *and* $v : \mathrm{X} \to \mathbb{R}$ *is l.s.c. and bounded below, then*

$$\liminf_{n\to\infty} \int_{\mathrm{X}} v(x)\varphi^n(dx) \ge \int_{\mathrm{X}} v(x)\varphi(dx). \tag{4.2}$$

Hence, as $w \ge 1$ is continuous (Assumption 2.2(f)), taking $v = w$ in (4.2), we get that $\widehat{w}$ is l.s.c. □

Proof of (ii). Condition 4.2(a) obviously follows from (2.8) and Assumption 2.2(f). Now, to prove that $\widehat{c}(\varphi,a)$ is l.s.c., suppose that $(\varphi^n, a^n) \to (\varphi, a)$. Let

$$\bar{c}_j(x) := \inf_{i\ge j} c(x, a^i) \quad \text{for each } \ j = 1, 2, \dots, \tag{4.3}$$

and observe that $\bar{c}_j(\cdot)$ is continuous (by Assumption 2.2(e_2)) and that

$$c(x, a^n) \ge \bar{c}_j(x) \quad \forall x \in \mathrm{X} \text{ and } \ n \ge j.$$

Therefore, for each $j = 1, 2, \dots$ and $n \ge j$ we have

$$\widehat{c}(\varphi^n, a^n) := \int_{\mathrm{X}} c(x, a^n)\varphi^n(dx) \ge \int_{\mathrm{X}} \bar{c}_j(x)\varphi^n(dx),$$

and taking the limit infimum as $n \to \infty$, from (4.2) we obtain

$$\liminf_{n\to\infty} \widehat{c}(\varphi^n, a^n) \ge \int_{\mathrm{X}} \bar{c}_j(x)\varphi(dx). \tag{4.4}$$

Finally, as $\bar{c_j}(\cdot)$ is nondecreasing and (by Assumption 2.2(e_1))

$$\lim_{j\to\infty} \bar{c_j}(x) = \liminf_{n\to\infty} c(x, a^n) \geq c(x, a),$$

letting $j \to \infty$ in (4.4), we get (by monotone convergence)

$$\liminf_{n\to\infty} \widehat{c}(\varphi^n, a^n) \geq \int_{\mathrm{X}} c(x, a)\varphi(dx) = \widehat{c}(\varphi, a). \tag{4.5}$$

This completes the proof of (ii). □

To prove (iii) we will first state some general preliminary facts in which X stands for an arbitrary Borel space, and $\widehat{\mathrm{X}} := \mathbb{P}(\mathrm{X})$.

LEMMA 4.3. *Let $\{u_n\}$ and $\{\mu_n\}$ be sequences in $C_b(\mathrm{X})$ and $\widehat{\mathrm{X}}$, respectively, such that*

(a) *$u_n \to u$ uniformly on* X*, and*

(b) *$\mu_n \to \mu$ weakly.*

Then

$$\lim_{n\to\infty} \int u_n d\mu_n = \int u d\mu.$$

Proof. By (a), the function u is in $C_b(X)$, and so, by (b),

$$\int u d\mu_n \to \int u d\mu. \tag{4.6}$$

Therefore, as $u_n \leq \| u_n - u \| + u$ we get

$$\limsup_{n\to\infty} \int u_n d\mu_n \leq \int u d\mu. \tag{4.7}$$

Similarly, (4.6) and the inequality $u_n \geq - \| u_n - u \| + u$ yield

$$\liminf_{n\to\infty} \int u_n d\mu_n \geq \int u d\mu.$$

The latter fact and (4.7) give the lemma. □

LEMMA 4.4. *Let u and u_n $(n \in \mathbb{N})$ be measurable functions on* X*, and let $\{\mu_n\}$ be a sequence in $\widehat{\mathrm{X}}$. If μ_n converges setwise to μ, i.e.,*

$$\mu_n(B) \to \mu(B) \quad \forall B \in \mathcal{B}(\mathrm{X}), \tag{4.8}$$

and u and $\{u_n\}$ are bounded below, then

(a) $\liminf \int u d\mu_n \geq \int u d\mu$, *and*

(b) $\liminf \int u_n d\mu_n \geq \int (\liminf u_n) d\mu$. *Therefore,*

(c) *if $\{u_n\}$ is a bounded sequence of measurable functions such that $u_n \to u$, then $\lim \int u_n d\mu_n = \int u d\mu$.*

Proof. (a) As u is bounded below, we have that $u + N \geq 0$ for some constant N. Thus, without loss of generality, we may assume that u is *nonnegative*. Moreover, by (4.8), part (a) holds for indicator functions $u = I_B$ of Borel subsets B of X and also of course for "simple" functions u (that is, finite linear combinations of indicator functions of Borel sets). Now choose an arbitrary measurable function $u \geq 0$, and let

$\{v_k\}$ be a sequence of simple functions such that $v_k(x) \uparrow u(x)$ for all $x \in \mathrm{X}$. Then, for each k,

$$\liminf_{n\to\infty} \int u d\mu_n \geq \liminf_{n\to\infty} \int v_k d\mu_n = \int v_k d\mu,$$

and letting $k \to \infty$, we obtain (a).

(b) This part follows from (a) and an argument as in (4.3)–(4.5). That is, define $\overline{u}_j := \inf_{n\geq j} u_n$ and note that

$$\int u_n d\mu_n \geq \int \overline{u}_j d\mu_n \quad \text{for each} \quad j \quad \text{and} \quad n \geq j.$$

Hence, by (a),

$$\liminf_{n\to\infty} \int u_n d\mu_n \geq \int \overline{u}_j d\mu \quad \text{for each} \quad j,$$

and letting $j \to \infty$, we get (b).

(c) Applying (b) to both u_n and $-u_n$, we get (c). □

The following result is a special case of Proposition 2.3(a) in [12].

LEMMA 4.5. *Let $\{\mu_n\}$ be a sequence in $\widehat{\mathrm{X}}$ and suppose that*

(a) *$\mu_n \to \mu$ weakly, and*

(b) *there is an integer N and a finite measure γ on X such that $\mu_n(\cdot) \leq \gamma(\cdot)$ for all $n \geq N$.*

Then $\mu_n \to \mu$ setwise.

For an example of a sequence $\{\mu_n\}$ that satisfies part (a) in Lemma 4.5 but not part (b), see Remark 3.3 in [8], for instance.

LEMMA 4.6. *Under Assumption* 2.3(a)*, the stochastic kernel $\widehat{q}$ in* (2.17) *is weakly continuous; that is, if $(\varphi^n, a^n) \to (\varphi, a)$, then*

$$\int_{\mathrm{Y}} v(y)\widehat{q}(dy|\varphi^n, a^n) \to \int_{\mathrm{Y}} v(y)\widehat{q}(dy|\varphi, a) \quad \forall v \in C_b(\mathrm{Y}). \tag{4.9}$$

If in addition Assumption 2.3(b) *holds, then*

$$\widehat{q}(\cdot\,|\varphi^n, a^n) \to \widehat{q}(\cdot\,|\varphi, a) \ \textit{ setwise.} \tag{4.10}$$

Proof. Choose an arbitrary function v in $C_b(\mathrm{Y})$, and let

$$v'(x') := \int_{\mathrm{Y}} v(y)Q(dy|x') \quad \forall x' \in \mathrm{X}.$$

By (2.15), $v'(\cdot)$ is in $C_b(\mathrm{X})$, and, therefore, by (2.14), the function

$$v''(x, a) := \int_{\mathrm{X}}\int_{\mathrm{Y}} v(y)Q(dy|x')P(dx'|x, a) \tag{4.11}$$

is in $C_b(\mathrm{X} \times A)$. Suppose now that $(\varphi^n, a^n) \to (\varphi, a)$ and use (4.11) and (2.17) to write

$$\int_{\mathrm{Y}} v(y)\widehat{q}(dy|\varphi^n, a^n) = \int_{\mathrm{X}} v''(x, a^n)\varphi^n(dx). \tag{4.12}$$

Thus, since Assumption 2.3(a) yields that

$$v''(\cdot\,, a^n) \to v''(\cdot\,, a) \ \text{ uniformly on } \ \mathrm{X},$$

from (4.12) and Lemma 4.3 we get (4.9).

To obtain (4.10) observe that (2.17) and Assumption 2.3(b) together give

$$\begin{aligned} \widehat{q}(\cdot\,|\varphi^n, a^n) &= \int_{\mathrm{X}} \int_{\mathrm{X}} Q(\cdot\,|x') P(dx'|x, a^n) \varphi^n(dx) \\ &\le \int_{\mathrm{X}} Q(\cdot\,|x') \beta(dx') =: \gamma(\cdot\,) \end{aligned} \tag{4.13}$$

for all $n \ge N$, and for some integer $N = N_{\varphi,a}$. Hence, as the measure γ in (4.13) is finite, from (4.13), (4.9), and Lemma 4.5 we obtain the setwise convergence in (4.10). □

From these lemmas we can now prove (iii), that is, Condition 4.1(c), as follows.

Proof of (iii). Suppose that $(\varphi^n, a^n) \to (\varphi, a)$ and choose an arbitrary function u in $C_b(\mathrm{X})$. Then, by (2.18),

$$\int_{\widehat{\mathrm{X}}} u(\varphi') \widehat{P}(d\varphi'|\varphi^n, a^n) = \int_{\mathrm{Y}} u\left[H(\varphi^n, a^n, y)\right] \widehat{q}(dy|\varphi^n, a^n), \tag{4.14}$$

and by Assumption 2.4(a)

$$u\left[H(\varphi^n, a^n, y)\right] \to u\left[H(\varphi, a, y)\right] \quad \forall y \in \mathrm{Y}.$$

This fact, combined with (4.14), (4.10), and Lemma 4.4(c), yields Condition 4.1(c). □

As was already mentioned (after Condition 4.2), from (i), (ii), and (iii) we obtain Theorem 2.5.

5. Proof of Theorem 3.4. For each *finite* $n \in \mathbb{N}$, the Bellman equation (2.20) becomes

$$V_n^*(\varphi) = \min_{a \in A} \left[\widehat{c}(\varphi, a) + \alpha \int_{\widehat{\mathrm{X}}} V_n^*(\varphi') \widehat{P}_n(d\varphi'|\varphi, a) \right] \tag{5.1}$$

with $\widehat{\mathrm{X}} := \mathbb{P}(\mathrm{X})$. Thus to prove Theorem 3.4 it suffices to show that V_∞^* satisfies (5.1), i.e.,

$$V_\infty^*(\varphi) = \min_{a \in A} \left[\widehat{c}(\varphi, a) + \alpha \int_{\widehat{\mathrm{X}}} V_\infty^*(\varphi') \widehat{P}_\infty(d\varphi'|\varphi, a) \right], \tag{5.2}$$

because then the desired conclusion follows from the "uniqueness of solutions" in Theorem 2.5(a).

Now, to prove (5.2), let

$$\underline{u}(\varphi) := \liminf_{n \to \infty} V_n^*(\varphi) \quad \text{and} \quad \overline{u}(\varphi) := \limsup_{n \to \infty} V_n^*(\varphi).$$

We wish to show that

$$\underline{u}(\varphi) = \overline{u}(\varphi) = V_\infty^*(\varphi) \quad \forall \varphi \in \widehat{\mathrm{X}}. \tag{5.3}$$

To prove this, let us first note the following.

LEMMA 5.1. *As $n \to \infty$, the following hold.*

(a) $\|\widehat{q}_n(\cdot\,|\varphi,a) - \widehat{q}_\infty(\cdot\,|\varphi,a)\|_{TV} \to 0$ *for each* (φ,a) *in* $\widehat{\mathrm{X}} \times A$, *where* $\|\cdot\|_{TV}$ *denotes the total variation norm.*

(b) $\|H_n(\varphi,a,y)(\cdot\,) - H_\infty(\varphi,a,y)(\cdot\,)\|_{TV} \to 0$ *for all* (φ,a,y) *in* $\widehat{\mathrm{X}} \times A \times \mathrm{Y}$, *where* H_n *is the filtering function in* (3.5), (3.6).

(c) $\widehat{P}_n(\cdot\,|\varphi,a) \to \widehat{P}_\infty(\cdot\,|\varphi,a)$ *weakly for each* (φ,a).

(d) *Furthermore, for each pair* (φ,a) *in* $\widehat{\mathrm{X}} \times A$, *there exists an integer* $N = N_{\varphi,a}$ *and a finite measure* $\gamma = \gamma_{\varphi,a}$ *on* $\mathcal{B}(\widehat{\mathrm{X}})$ *such that* $\widehat{P}_n(\cdot|\varphi,a) \le \gamma(\cdot)$ *for all* $n \ge N$.

(e) *The convergence in* (c) *holds setwise.*

Proof. (a) For each $n \in \mathbb{N}_\infty$, let $P_n(\cdot\,|x,a)$ and $Q_n(\cdot\,|x)$ be as in (3.3) and (3.4); that is,

$$P_n(B|x,a) = \int_B g_\xi(s - F_n(x,a))\lambda_1(ds)$$

and

$$Q_n(C|x) = \int_C g_\eta(s' - G_n(x))\lambda_2(ds').$$

As $g_\xi(s - F_n(x,a)) \to g_\xi(s - F_\infty(x,a))$ for all (x,a,s), it follows from Scheffé's theorem that

$$\|P_n(\cdot\,|x,a) - P_\infty(\cdot\,|x,a)\|_{TV} \to 0 \quad \forall (x,a) \in \mathrm{X} \times A. \tag{5.4}$$

Similarly, as $g_\eta(s' - G_n(x)) \to g_\eta(s' - G_\infty(x))$, we have

$$\|Q_n(\cdot\,|x) - Q_\infty(\cdot\,|x)\|_{TV} \to 0 \quad \forall x \in \mathrm{X}. \tag{5.5}$$

Therefore, by (2.17),

$$\begin{aligned}
\widehat{q}_n(\cdot\,|\varphi,a) &= \int_{\mathrm{X}}\int_{\mathrm{X}} Q_n(\cdot\,|x')P_n(dx'|x,a)\varphi(dx) \\
&= \int_{\mathrm{X}}\int_{\mathrm{X}} [Q_n(\cdot|x') - Q_\infty(\cdot|x')]P_n(dx'|x,a)\varphi(dx) \\
&\quad + \int_{\mathrm{X}}\int_{\mathrm{X}} Q_\infty(\cdot|x')[P_n(dx'|x,a) - P_\infty(dx'|x,a)]\varphi(dx) \\
&\quad + \widehat{q}_\infty(\cdot|\varphi,a),
\end{aligned}$$

and then a straightforward calculation using (5.4) and (5.5) yields (a).

(b) By (3.5) and (3.6), to prove (b) it suffices to show that, for all (φ,a,y),

$$\sigma_n(\varphi,a,y)(B) = \int_{\mathrm{X}} \left[\int_B g_\eta(y - G_n(x'))P_n(dx'|x,a)\right]\varphi(dx)$$

converges to $\sigma_\infty(\varphi,a,y)(B)$ in the total variation norm. To do this, observe that, for all $B \in \mathcal{B}(\mathrm{X})$,

$$\left|\int_B g_\eta(y - G_n(x'))P_n(dx'|x,a) - \int_B g_\eta(y - G_\infty(x'))P_\infty(dx'|x,a)\right|$$

$$\leq \|g_\eta\|\ \|P_n(\cdot\,|x,a) - P_\infty(\cdot\,|x,a)\|_{TV} + \int_{\mathrm{X}} |g_\eta(y - G_n(x')) - g_\eta(y - G_\infty(x'))| P_\infty(dx'|x,a)$$

$$\to 0 \quad \text{as} \quad n \to \infty,$$

and the latter convergence is, of course, uniform in $B \in \mathcal{B}(\mathrm{X})$. This clearly implies

$$\|\sigma_n(\varphi,a,y)(\cdot) - \sigma_\infty(\varphi,a,y)(\cdot)\|_{TV} \to 0 \quad \text{as} \quad n \to \infty,$$

and (b) follows.

(c) Choose an arbitrary function u in $C_b(\widehat{\mathrm{X}})$. Then, by (2.18),

$$\int_{\widehat{\mathrm{X}}} u(\varphi')\widehat{P}_n(d\varphi'|\varphi,a) = \int_{\mathrm{Y}} u\,[H_n(\varphi,a,y)]\,\widehat{q}_n(dy|\varphi,a). \tag{5.6}$$

Now observe that the integrand $u[H_n(\varphi,a,y)]$ is bounded by $\|u\|$ for all n. Therefore, (c) follows from (5.6) together with parts (a) and (b), and Lemma 4.4(c).

(d) Fix an arbitrary pair (φ,a) in $\widehat{\mathrm{X}} \times A$. By part (a) and the Remark 2.6(c), there is an integer $N = N_{\varphi,a}$ and a finite measure $q^* = q^*_{N,\varphi,a}$ on Y such that

$$\widehat{q}_n(\cdot|\varphi,a) \leq q^*(\cdot) \quad \forall\, n \geq N. \tag{5.7}$$

For notational ease, let

$$\widehat{P}_n(\cdot) := \widehat{P}_n(\cdot|\varphi,a), \ \ \widehat{q}_n(\cdot) := \widehat{q}_n(\cdot|\varphi,a), \ \ H_n(y) := H_n(\varphi,a,y).$$

Moreover, for each Borel set $D \subset \widehat{\mathrm{X}}$ let

$$\Delta_n(D) := \{y \in Y | H_n(y) \in D\},$$

so that, replacing u in (5.6) with the indicator function I_D, we get

$$\widehat{P}_n(D) = \int_Y I_D[H_n(y)]\widehat{q}_n(dy) = \widehat{q}_n[\Delta_n(D)]. \tag{5.8}$$

We will now use (2.22) and (2.23) to show that $\Gamma := \{\widehat{P}_n, n \geq n\}$ has a finite upper envelope, which will complete the proof of (d). Let ρ^u be the set function

$$\rho^u(D) := \sup_{n \geq N} \widehat{P}_n(D),$$

and (as in (2.23)) let γ^u be the upper envelope of Γ, i.e.,

$$\gamma^u(D) := \sup\left\{\sum_{k=1}^{\infty} \rho^u(D_k) | \{D_k\} \subset \mathcal{B}(\widehat{\mathrm{X}}) \quad \text{is a partition of } D\right\}$$

for each $D \in \mathcal{B}(\widehat{\mathrm{X}})$. Note that, by (5.8) and (5.7),

$$\rho^u(D) \leq \sup_{n \geq N} q^*[\Delta_n(D)] \leq q^*\left[\bigcup_{n \geq N} \Delta_n(D)\right] \leq q^*(Y) < \infty. \tag{5.9}$$

Moreover, writing $\bigcup_{n\geq N}\Delta_n(D)$ as a union of *disjoint* sets $\Delta'_n(D)$, we have

$$\rho^u(D)\leq q^*\left[\bigcup_{n=N}^{\infty}\Delta_n(D)\right]=\sum_{n=N}^{\infty}q^*[\Delta'_n(D)].$$

Therefore, for any partition $\{D_k\}\subset\mathcal{B}(\widehat{\mathrm{X}})$ of D,

$$\begin{aligned}\sum_{k=1}^{\infty}\rho^u(D_k)&\leq\sum_{k=1}^{\infty}\sum_{n=N}^{\infty}q^*[\Delta'_n(D_k)]\\&=\sum_{n=N}^{\infty}\sum_{k=1}^{\infty}q^*[\Delta'_n(D_k)]\\&=\sum_{n=N}^{\infty}q^*[\Delta'_n(D)]\\&\leq q^*(Y)<\infty\qquad\text{(by (5.9))}.\end{aligned}$$

Hence, as the partition $\{D_k\}$ was arbitrary, it follows that $\gamma^u(D)$ is bounded above by $q^*(Y)<\infty$ for any D in $\mathcal{B}(\widehat{\mathrm{X}})$; thus γ^u is a finite measure, which can be taken as the measure $\gamma=\gamma_{\varphi,a}$ in (d).

(e) This is a consequence of (c), (d), and Lemma 4.5. □

We now go back to the proof of (5.3). First note that using the interchange of infima we get from (5.1) that

$$\inf_{n\geq k}V_n^*(\varphi)=\min_{a\in A}\left[\widehat{c}(\varphi,a)+\alpha\cdot\inf_{n\geq k}\int_{\widehat{\mathrm{X}}}V_n^*(\varphi')\widehat{P}_n(d\varphi'|\varphi,a)\right].$$

Therefore, taking the lim inf in both sides of (5.1) and using Lemmas 5.1(e) and 4.4(b), we obtain

$$\underline{u}(\varphi)\geq\min_{a\in A}\left[\widehat{c}(\varphi,a)+\alpha\int_{\widehat{\mathrm{X}}}\underline{u}(\varphi')\widehat{P}_\infty(d\varphi'|x,a)\right].$$

Therefore, by a standard dynamic programming argument (see, for instance, Lemma 4.2.7 in [10])

$$\underline{u}(\varphi)\geq V_\infty^*(\varphi)\quad\forall\varphi\in\widehat{\mathrm{X}}.\tag{5.10}$$

To complete the proof of (5.3), we next show that

$$\overline{u}(\varphi)\leq V_\infty^*(\varphi)\quad\forall\varphi\in\widehat{\mathrm{X}},\tag{5.11}$$

which, together with (5.10), yields (5.3). To obtain (5.11) we see from (5.1) that

$$V_n^*(\varphi)\leq\widehat{c}(\varphi,a)+\alpha\int_{\widehat{\mathrm{X}}}V_n^*(\varphi')\widehat{P}_n(d\varphi'|\varphi,a)\tag{5.12}$$

for all (φ,a) in $\widehat{\mathrm{X}}\times A$. Furthermore, by Lemma 5.1(e), $\widehat{P}_n(\cdot\,|\varphi,a)$ converges setwise to $\widehat{P}_\infty(\cdot\,|\varphi,a)$, and in addition (by the inequality (8.3.33) in [11], p.52), the sequence $V_n^*(\varphi)$ is uniformly bounded by $C\widehat{w}(\varphi)/(1-\beta)$, where C and $\beta:=\bar{\alpha}\bar{\sigma}$ are the constants in Assumption 2.2(f) and Proposition 3.3, respectively. It follows that the extended

Fatou lemma, Lemma 8.3.7(b) in [11], is applicable to (5.12), so that taking the lim sup as $n \to \infty$, we get

$$\overline{u}(\varphi) \leq \widehat{c}(\varphi, a) + \alpha \int_{\widehat{\mathrm{X}}} \overline{u}(\varphi')\widehat{P}_\infty(d\varphi'|\varphi, a).$$

This implies that

$$\overline{u}(\varphi) \leq \min_{a \in A} \left[\widehat{c}(\varphi, a) + \alpha \int_{\widehat{\mathrm{X}}} \overline{u}(\varphi')\widehat{P}_\infty(d\varphi'|\varphi, a) \right],$$

which in turn, by Lemma 4.2.7 in [10], for instance, yields (5.11).

6. Concluding remarks. As was already mentioned, the results in Theorem 2.5 are essentially well known except for the fact that $c(x, a)$ is allowed to be unbounded and for the generality of the PO system (1.5). However, to our knowledge, the proof itself is new, even for the case of a bounded cost function $c(x, a)$, that is, when $w(\cdot) \equiv 1$ in Assumption 2.2(f). Similarly, parts (a) and (b) in Lemma 5.1, which concern the *total variation norm*, are new.

On the other hand, Theorem 2.5 includes the important case in which the state space X and the observation set Y are *countable*, as occurs in many applications [4, 6, 7, 18, 20, 21, 24, ...]. In such a case, the filtering function H turns out to be similar to (3.5) with

$$\sigma(\varphi, a, y)(x') = Q(y|x') \sum_x P(x'|x, a)\varphi(x)$$

(compare with (3.6)), and so Assumptions 2.2, 2.3, and 2.4 can be simplified in the obvious manner.

LIE ALGEBRAIC OBSTRUCTIONS TO Γ-CONVERGENCE OF OPTIMAL CONTROL PROBLEMS*

ARIELA BRIANI† AND FRANCO RAMPAZZO‡

Abstract. We investigate the possibility of describing the "limit problem" of a sequence of optimal control problems $(\mathcal{P})_{(b_n)}$, each of which is characterized by the presence of a time dependent vector valued coefficient $b_n = (b_{n_1}, \dots, b_{n_M})$. The notion of "limit problem" is intended in the sense of Γ-convergence, which, roughly speaking, prescribes the convergence of both the minimizers and the infimum values. Due to the type of growth involved in each problem $(\mathcal{P})_{(b_n)}$ the (weak) limit of the functions $(b^2_{n_1}, \dots, b^2_{n_M})$—beside the limit $(b_1, \dots, b_M)$ of the $(b_{n_1}, \dots, b_{n_M})$—is crucial for the description of the limit problem. Of course, since the b_n are L^2 maps, the limit of the $(b^2_{n_1}, \dots, b^2_{n_M})$ may well be a (vector valued) measure $\mu = (\mu_1, \dots, \mu_M)$. It happens that when the problems $(\mathcal{P})_{(b_n)}$ enjoy a certain commutativity property, then the pair (b, μ) is sufficient to characterize the limit problem.

This is no longer true when the commutativity property is not in force. Indeed, we construct two sequences of problems $(\mathcal{P})_{(b_n)}$ and $(\mathcal{P})_{(\tilde{b}_n)}$ which are equal except for the coefficient $b_n(\cdot)$ and $\tilde{b}_n(\cdot)$, respectively. Moreover, both the sequences (b_n, b_n^2) and $(\tilde{b}_n, \tilde{b}_n^2)$ converge to the same pair (b, μ). However, the infimum values of the problems $(\mathcal{P})_{(b_n)}$ tend to a value which is different from the limit of the infimum values of the $(\mathcal{P})_{(\tilde{b}_n)}$. This means that the mere information contained in the pair (b, μ) is not sufficient to characterize the limit problem. We overcome this drawback by embedding the problems in a more general setting where limit problems can be characterized by triples of functions (B_0, B, γ) with $B_0 \geq 0$.

Key words. Γ-convergence, optimal control problems, Lie brackets

1. Introduction.

The general goal in the various theories of variational convergence consists in singling out a notion of limit problem $(\mathcal{P})$ for a sequence of minimum problems $(\mathcal{P}_n)$. Loosely speaking, this means that both the minimizers (provided they exist) of the problems $(\mathcal{P}_n)$ and the corresponding minimum values should converge (in some sense) to the minimizers and the minimum value of $(\mathcal{P})$, respectively.

In this paper we shall deal with the case where the minimum problems $(\mathcal{P}_n)$ have the form of the optimal control problems $(\mathcal{P})_{(b_n)}$ considered below. More precisely, the dependence on n follows by the fact that the dynamics of these problems contain n-dependent time functions b_n. We are motivated to study this particular problem essentially for two reasons. The first one is related to the general problem of homogenization (see, e.g., [BLP78], [LPV85], [SP80]). More specifically, for a control system one could think to the case where the dynamic contains a quite irregular time dependent coefficient. This would motivate the interest in looking for suitable topologies such that the approximation of this coefficient with regular functions would provide a "good" approximation of the given optimal control problem.

The second reason why we are studying the particular class of problems specified below is twofold. On one hand, this class of problems is general enough to display

the pathology related to Lie brackets of the involved vector fields (see below). On the other hand, the relatively simple structure of these problems allows one to avoid unessential technicalities which would obscure the nature of the question at issue.

Referring to the appendix for some basic tools of the general issue of variational convergence, let us specify the class of optimal control problems we are going to deal with.

Let $g_0, g_1, \dots, g_M$ be smooth vector fields, and let l, k_i, h_i be given real functions. We shall consider sequences of optimal control problems of the form

$(\mathcal{P})_{(b_n)}$

$$\begin{cases} \dot{x} = g_0(t,x) + \displaystyle\sum_{i=1}^{M} g_i(x) b_{n_i}(t) u_i(t), \quad x(0) = x_0, \\ \min\limits_{u} \left\{ J(x,u) = \displaystyle\int_0^T \left(l(t,x) + \sum_{i=1}^{M} k_i(t,x) b_{n_i}(t) u_i(t) + \sum_{i=1}^{M} h_i^2(x) u_i^2(t) \right) dt \right\}, \end{cases}$$

where $(b_n)_{n\in\mathbb{N}}$ is a sequence of $\mathbb{R}^M$-valued, time dependent coefficients.

We will investigate the Γ-limit (see the appendix) of problems $(\mathcal{P})_{(b_n)}$ when

$$\begin{array}{ll} \lim\limits_{n\to\infty} b_{n_i}(\cdot) = b_i(\cdot) & \text{weakly in } L^2(0,T), \\ \lim\limits_{n\to\infty} b_{n_i}^2(\cdot) = \mu_i(\cdot) & \text{weakly}^* \text{ in } \mathcal{M}([0,T]) \end{array} \tag{1.1}$$

for $i = 1, \dots, M$ (where $L^2(0,T)$ and $\mathcal{M}([0,T])$ denote the space of 2-integrable functions and the space of Borel measures, respectively).

We shall assume the following set of hypotheses on the data.

(Hg0) The function $g_0 : (0,T) \times \mathbb{R}^N \to \mathbb{R}^N$ is continuous. Moreover, for every compact subset $Q \subset \mathbb{R}^N$ there exists a continuous function $\gamma_0(t)$ such that, for every $t \in [0,T]$ and for every $x, y \in Q$, one has

$$|g_0(t,x) - g_0(t,y)| \le \gamma_0(t)|x-y|.$$

(Hg1) For each $i = 1, \dots, M$ the vector fields g_i from $\mathbb{R}^N$ into $\mathbb{R}^N$ are of class C^2, and the trajectories of the equations $\dot{x} = g_i(x)$ exist globally.

(Hb) For each $n \in N$, $b_n(t) = (b_{n_1}(t), \dots, b_{n_M}(t)) \in L^2(0,T;\mathbb{R}^M)$.

(Hu) The controls $u(t) = (u_1(t), \dots, u_M(t))$ belong to $L^2(0,T;\mathbb{R}^M)$.

(Hl) The function $l : [0,T] \times \mathbb{R}^N \to [0,\infty]$ is a Borel function, and for every compact subset $Q \subset \mathbb{R}^N$ there exists an L^1 function $\eta(t)$ such that, for every $t \in [0,T]$ and for every $x, y \in Q$,

$$|l(t,x) - l(t,y)| \le \eta(t)\,|x-y|\,.$$

Moreover, the function $l(t,0)$ belongs to $L^1(0,T)$.

(Hk) For each $i = 1, \dots, M$, $k_i : [0,T] \times \mathbb{R}^N \to [0,\infty]$ is a continuous function. There exists a constant $C > 0$ such that, for each $t \in [0,T]$ and for each $y \in \mathbb{R}^N$

$$|k_i(t,y)| \le C, \qquad i = 1, \dots, M. \tag{1.2}$$

Moreover, there exists a constant $L_k > 0$ such that, for each $t \in [0,T]$ and for each $y, z \in \mathbb{R}^N$,

$$|k_i(t,y) - k_i(t,z)| \le L_k |y-z|, \qquad i = 1, \dots, M. \tag{1.3}$$

(Hh) For each $i = 1, \dots, M$, $h_i : \mathbb{R}^N \to [0, \infty]$ is a Borel function, and for every compact subset $Q \subset \mathbb{R}^N$ there exists a constant L_h such that

$$|h_i(x) - h_i(y)| \leq L_h |x - y|, \quad i = 1, \dots, M$$

for every $x, y \in Q$. Moreover, we assume the following *coercivity* hypothesis. There exists a constant $K > 0$ such that, for every $x \in \mathbb{R}^N$,

$$\sum_{i=1}^{M} h_i^2(x) u_i^2 \geq K |u|^2$$

for every $u \in L^2(0, T)$.

Remark 1.1. Some of these hypotheses can be weakened further. For example, in view of section 5, the constants C and L_k in (1.2), (1.3) may be replaced by two functions in $L^1(0, T)$. Moreover, at the cost of some technical complications in the computation of the Γ-limit in Definition 2.3 below, the maps l, h_i, and k_i may be allowed to depend on n as well.

Let us begin by remarking that some authors (see, e.g., [BC89], [BF93], [Fr98]) studied this problem when the maps $g_1, \dots, g_M$, $h_1, \dots, h_M$ are *constant* and $k_i = 0$, $i = 1, \dots, M$. In particular, in [BF93], [Fr98] one studies the limit of these problems when the L^2 structural parameters $b_n(\cdot) = (b_{n_1}, \dots, b_{n_M})(\cdot)$ converge, say, weakly, to an L^2 map $b(\cdot) = (b_1, \dots, b_M)(\cdot)$. It turns out that in order to single out the limit problem one needs to know the (weak) limit $\mu = (\mu_1, \dots, \mu_M)(\cdot)$ of the maps $b_n^2 = (b_{n_1}^2, \dots, b_{n_M}^2)(\cdot)$ as well. Let us recall that this limit, when it exists, can well be different from $b^2(\cdot)$. (Actually, one has $\mu \geq b^2$.) Moreover, in general, it is not an L^1 function. Actually, it is a measure on $[0, T]$. The main point established in the quoted papers consists in the fact that the pair (b, μ) does single out the limit problem. This result relies upon a crucial assumption, namely, the fact that the g_i and the h_i are independent of x, which, in turn, allows one to regard the limit equation and the limit payoff as relations *in measure*. On the contrary, as soon as the g_i actually depend on x—and a certain commutativity assumption (see below) is not verified—the measure-theoretical approach does not work, as shown by the simple example in section 3.

In this paper we shall study the limit of problem $(\mathcal{P})_{(b_n)}$ when both *the g_i and the h_i can depend on x* and the k_i do not vanish.

Our aim is threefold. To begin with, in section 2 we assume a *commutativity* hypothesis, which generalizes the case where the g_i are constant. Namely, we assume that $[g_i, g_j] = 0$ for all $i, j = 1, \dots, M$ (plus the fact that the k_i and h_i are constant), where $[g_i, g_j]$ denotes the Lie bracket of the fields g_i and g_j. It is remarkable that, under this assumption, one can prove the same result as in the case where the g_i are x-independent. In other words, the limit problem of the $(\mathcal{P})_{(b_n)}$ is still singled out by the limit (b, μ) of the pairs (b_n, b_n^2). This limit is denoted by $\Phi^{-1}(Q_{(b,\mu)})$, for it is the preimage of a simpler problem $(\mathcal{Q})_{(b,\mu)}$ via a diffeomorphism Φ, which, in turn, is determined by the (commutative) fields g_i. The result in this section allows one to get a geometric insight into the results in [BC89], [BF93], [Fr98] as well, for, while the property of "being independent of x" is not chart-invariant, commutativity has an intrinsic meaning.

Second, in section 3 we present an example that reveals the crucial difference between the case with vanishing Lie brackets and the general case. Actually, in this example (the Lie brackets do not vanish and) two sequences $((b_n, b_n^2))_{n \in N}$ and

$((\tilde{b}_n, \tilde{b}_n^2))_{n\in N}$ converge to the *same* pair (b, μ), while the corresponding problems $(\mathcal{P})_{(\tilde{b}_n)}$ and $(\mathcal{P})_{(\tilde{b}_n)}$ converge to *different* limit problems. Hence, provided a limit problem exists (in some possibly extended sense), in order to characterize it one needs some "extra information" beside that contained in the assignment of the pair (b, μ).

The construction of an extended setting for problems with no commutativity assumptions is, in fact, the third aim of the paper. We pursue this objective in section 4 by redefining the minimum problems in the space of the graphs. Within this extended setting every minimum problem is identified by a triple of functions (B_0, B, γ) defined on $[0, 1]$, this triple replacing the role of the pair (b, μ). The map B_0, whose square root is the derivative of time t with respect to a *pseudotime parameter* s in the interval $[0, 1]$, assumes values greater than or equal to zero. A particular case is represented by the original problems $(\mathcal{P})_{(b_n)}$, which are identified with problems corresponding to triples of the form (B_{0_n}, B_n, B_n^2) with B_{0_n} *strictly greater than zero almost everywhere (a.e.) in* $[0, 1]$ and $B_n \doteq b_n B_{0_n}$. On the other hand, the extra information needed in order to single out the limit problem is provided by the restriction of γ to the subintervals of $[0, 1]$, where B_0 is equal to zero.

Last, in section 5 we prove some statements aiming to compose the (apparent) discrepancy between the case with vanishing Lie brackets—which is treated in section 2 in terms of the original time t—and the general case—which is addressed in section 4 in an extended framework. The key points consist in a projection of the set of triples (B_0, B, γ) onto the set of the pairs (b, μ) and in the consequent partition of the set of triples. Roughly speaking, when the commutativity hypothesis holds, all extended problems in a class of this partition correspond to a unique problem, namely, the one singled out by the (unique) projection (b, μ) of the triples in the class.

For the sake of self-consistency we conclude the paper with an appendix, where some basic facts from the general theory of Γ-convergence are briefly recalled.

Let us point out that a reader interested only in the case with vanishing Lie brackets may read just section 2. On the other hand, the construction of the extended setting for the general case, which is performed in section 4, is self-contained and independent of the antecedent material of the paper.

Notation. We will write $L^p(0, T; \mathbb{R}^M)$ to denote the space of p-integrable functions from $[0, T]$ into $\mathbb{R}^M$ endowed with the usual norm $\|\cdot\|_p$. Moreover, $\mathcal{M}([0, T]; \mathbb{R}^M)$ and $BV([0, T]; \mathbb{R}^M)$ will denote the space of $\mathbb{R}^M$-valued Borel measure on $[0, T]$ and the space of $\mathbb{R}^M$-valued functions with bounded variation on $[0, T]$, respectively. If $M = 1$, we write $L^p(0, T)$, $\mathcal{M}([0, T])$, $BV([0, T])$ instead of $L^p(0, T; \mathbb{R})$, $\mathcal{M}([0, T]; \mathbb{R})$, $BV([0, T]; \mathbb{R})$, respectively.

If $\mu \in \mathcal{M}([0, T])$, μ^a and μ^s stand for the absolutely continuous and the singular part of μ with respect to the Lebesgue measure dt, respectively. If μ_1 and μ_2 are a vector measure and a scalar measure on $[0, T]$, respectively, we write $\mu_1 << \mu_2$ to mean that μ_1 is absolutely continuous with respect to μ_2. Moreover, we denote the derivative of μ_1 with respect to μ_2 (in the sense of the Radon–Nikodym theorem) by $\frac{d\mu_1}{d\mu_2}$. Finally, by $\operatorname{supp}\mu$ we mean the support of the measure μ.

2. Null Lie brackets. We assume here the *commutativity condition* (HC) below, which, in particular, states that all Lie brackets $[g_i, g_j]$, $i, j = 1, \ldots, M$, are identically equal to zero. This hypothesis is crucial in order to prove a result of Γ-convergence (see the appendix for the definition of Γ-limit) analogous to the one proved in [Fr98], where the vectors multiplying the control were assumed x-independent. This fact allows one to get a geometric insight into the question, since the case with constant g_i

is nothing but a particular occurrence of the commutativity condition. We will see in the next sections that such a result does not hold when the commutativity assumption is not assumed.

Commutativity condition (HC). For every $i, j = 1, \dots, M$ the Lie bracket

$$[g_i, g_j](x) = Dg_j(x)g_i(x) - Dg_i(x)g_j(x)$$

(where $Dg(x)$ denotes the derivative of g at x) is identically equal to zero. Moreover, the maps h_i and k_i are constant. (See Remark 2.12 below for a comment on this latter condition.)

In order to define the Γ-limit, we introduce a suitable coordinate transformation which is induced by the fields $g_1, \dots, g_M$. This transformation is made possible by the crucial commutativity assumption (HC). Let us begin by adding the auxiliary equations $z_i(t) = \int_0^t b_{n_i}(s)u_i(s)ds$, $i = 1, \dots, M$. Then the state equation of $(\mathcal{P})_{(b_n)}$ reads as

$$\begin{pmatrix} \dot{z} \\ \dot{x} \end{pmatrix} = \tilde{g}_0(t, x) + \sum_{i=1}^{M} \tilde{g}_i(x) b_{n_i}(t) u_i(t),$$

where

$$\begin{array}{rccc} \tilde{g}_0 : & [0,T] \times \mathbb{R}^N & \to & \mathbb{R}^M \times \mathbb{R}^N, \\ & (t, x) & \mapsto & \begin{pmatrix} 0_M \\ g_0^1(t,x) \\ . \\ . \\ g_0^N(t,x) \end{pmatrix}, \end{array}$$

and, for every $i = 1, \dots, M$,

$$\begin{array}{rccc} \tilde{g}_i : & \mathbb{R}^N & \to & \mathbb{R}^M \times \mathbb{R}^N, \\ & x & \mapsto & \begin{pmatrix} e_i \\ g_i^1(x) \\ . \\ . \\ g_i^N(x) \end{pmatrix}, \end{array}$$

0_M and e_i being the zero vector and the ith (column) vector of the canonical basis in $\mathbb{R}^M$, respectively.

In the extended state space $\mathbb{R}^M \times \mathbb{R}^N$, problem $(\mathcal{P})_{(b_n)}$ is now formulated as

$$(\mathcal{P})_{(b_n)} \quad \begin{cases} \begin{pmatrix} \dot{z} \\ \dot{x} \end{pmatrix} = \tilde{g}_0(t, x) + \displaystyle\sum_{i=1}^{M} \tilde{g}_i(x) b_{n_i}(t) u_i(t), \ (z(0), x(0)) = (0, x_0), \\ \min\limits_{u} \left\{ J_n((z, x), u) = \displaystyle\int_0^T \left(l(t, x) + \sum_{i=1}^{M} k_i b_{n_i}(t) u_i(t) + \sum_{i=1}^{M} h_i^2 u_i^2(t) \right) dt \right\}. \end{cases}$$

(Notice that we use the same notation, namely, $(\mathcal{P})_{(b_n)}$, to mean both the problem in $\mathbb{R}^N$ and the corresponding one in $\mathbb{R}^M \times \mathbb{R}^N$.)

Let us set

$$\begin{aligned} &\Phi_1(z, x) = z, \\ &\Phi_2(z, x) = \exp(-z_M g_M) \circ \cdots \circ \exp(-z_1 g_1)x \end{aligned}$$

(where $\exp(sg)x$ stands for the value at time s of the solution of the Cauchy problem $\dot{y}(s) = g(y(s))$, $y(0) = x$), and let us consider the map Φ defined by

$$\begin{pmatrix} z \\ y \end{pmatrix} = \Phi(z,x) \doteq \begin{pmatrix} \Phi_1(z,x) \\ \Phi_2(z,x) \end{pmatrix}.$$

We shall also use the notations $(z, x(z,y))$ and $(z, y(z,x))$ instead of $\Phi^{-1}(z,y)$ and $\Phi(z,x)$, respectively. Notice that, since the maps g_i are of class C^2, Φ is a local diffeomorphism. Actually, Φ is a global diffeomorphism.

Let us define the vector fields $\check{g}_0 : (0,T) \times \mathbb{R}^M \times \mathbb{R}^N \to \mathbb{R}^M \times \mathbb{R}^N$ and $\check{g}_i : \mathbb{R}^M \times \mathbb{R}^N \to \mathbb{R}^M \times \mathbb{R}^N$, $i = 1, \dots, M$, by setting

$$\begin{aligned} \check{g}_0(t,z,y) &\doteq D\Phi(z,x)\, \tilde{g}_0(t,x), \\ \check{g}_i(z,y) &\doteq D\Phi(z,x)\, \tilde{g}_i(x), \end{aligned}$$

where $(z,x) = \Phi^{-1}(z,y)$. Notice that $\check{g}_0$ and $\check{g}_i$ are the expressions of $\tilde{g}_0$ and $\tilde{g}_i$, respectively, in the new coordinate (z,y).

PROPOSITION 2.1. *The first components of the vector field $\check{g}_0 : (0,T) \times \mathbb{R}^M \times \mathbb{R}^N \to \mathbb{R}^M \times \mathbb{R}^N$ are equal to zero, that is,*

$$\check{g}_0(t,z,y) = \begin{pmatrix} 0_M \\ g_0^\sharp(t,z,y) \end{pmatrix},$$

where the (column) vector field $g_0^\sharp(t,z,y)$ is given by $g_0^\sharp(t,z,y) = D_x\Phi_2(z,x)\tilde{g}_0(t,x)$ with $(z,x) = \Phi^{-1}(z,y)$. In particular, $\check{g}_0$ verifies (Hg0) *(with N replaced by $M+N$). Moreover, one has, for $i = 1, \dots, M$,*

$$\check{g}_i(z,y) = \begin{pmatrix} e_i \\ 0_N \end{pmatrix},$$

where 0_N stands for the (column) zero vector of $\mathbb{R}^N$.

A proof of this trivial proposition can be found in [BR91].

By means of this coordinate change, problem $(\mathcal{P})_{(b_n)}$ is transformed into the problem

$$(\mathcal{Q})_{(b_n)} \qquad \begin{cases} \begin{pmatrix} \dot{z} \\ \dot{y} \end{pmatrix} = \check{g}_0(t,z,y) + \displaystyle\sum_{i=1}^{M} \check{g}_i b_{n_i}(t) u_i(t), \qquad (z(0), y(0)) = (0, x_0), \\ \min\limits_u \left\{ \check{J}_n((z,y),u) \right\}, \end{cases}$$

$$\check{J}_n((z,y),u) = \int_0^T \left(l(t, x(z,y)) + \sum_{i=1}^{M} k_i b_{n_i}(t) u_i(t) + \sum_{i=1}^{M} h_i^2 u_i^2(t) \right) dt,$$

which, thanks to Proposition 2.1, displays the following, particularly simple, form:

$$(\mathcal{Q})_{(b_n)} \qquad \begin{cases} \dot{z}_1(t) = b_{n_1}(t) u_1(t), \\ \cdot \\ \cdot \\ \dot{z}_M(t) = b_{n_M}(t) u_M(t), \\ \\ \dot{y}(t) = g_0^\sharp(t,z,y), \\ \\ \min\limits_u \left\{ \check{J}_n((z,y),u) \right\}. \end{cases}$$

Remark 2.2. By saying that "$(\mathcal{P})_{(b_n)}$ is transformed into $(\mathcal{Q})_{(b_n)}$" we mean the following.

(i) A trajectory-control pair $((z,y),u)$ is admissible for the problem $(\mathcal{Q})_{(b_n)}$ if and only if the trajectory-control pair $((z,x),u) \doteq (\Phi^{-1}(z,y),u)$ is admissible for $(\mathcal{P})_{(b_n)}$.

(ii) For each trajectory-control pair $((z,y),u)$, if $((z,x),u) \doteq (\Phi^{-1}(z,y),u)$, then

$$J_n((z,x),u) = \check{J}_n(\Phi(z,x),u)$$

for every $u \in L^2(0,T;\mathbb{R}^M)$.

In particular, a trajectory-control pair $((z^\sharp,x^\sharp),u^\sharp)$ is optimal for $(\mathcal{P})_{(b_n)}$ if and only if $((z^\sharp,y^\sharp),u^\sharp)$ is optimal for $(\mathcal{Q})_{(b_n)}$, where $y^\sharp = \Phi_2(z^\sharp,x^\sharp)$.

In order to provide a representation of the Γ-limit of problems $(\mathcal{P})_{(b_n)}$ we shall be concerned with the set of *data pairs*

$$A = \left\{(b,\mu) \in L^2(0,T;\mathbb{R}^M) \times \mathcal{M}([0,T];\mathbb{R}^M) \ : \ \mu \geq b^2\right\},$$

where $\mu = (\mu_1,\dots,\mu_M)$, $b = (b_1,\dots,b_M)$, and the inequality has to be interpreted as $\mu_i \geq b_i^2$ for all $i = 1,\dots,M$ (in the measure-theoretical sense). In particular, we shall consider the subset $A_s \subset A$ defined by

$$A_s = \left\{(b,\mu) \in A \ : \ \mu = b^2\right\},$$

which we call the subset of *simple data pairs* of A. (We recall that b^2 denotes the vector $(b_1^2,\dots,b_M^2)$.)

DEFINITION 2.3. *Let $(b,\mu) \in A$, and let us set $\sigma = \sum_{i=1}^M \mu_i^s$. We consider the variational problem*

$$(\mathcal{Q})_{(b,\mu)} \qquad \min_{((z,y),u)} \left\{\check{J}((z,y),u) \ : \ \dot{z} << dt + \sigma, \quad \dot{y} = g_0^\sharp(t,z,y)\right\},$$

where the minimum is searched over the trajectory-control pairs $((z,y),u)$ in $BV([0,T];\mathbb{R}^M \times \mathbb{R}^N) \times L^2(0,T;\mathbb{R}^M)$ and the cost functional $\check{J}$ is defined by

$$\begin{aligned}
&\check{J}((z,y),u) \\
&\quad \doteq \int_0^T \left[l(t,w) + \sum_{i=1}^M \left(k_i \dot{z}_i^a(t) + h_i^2 u_i^2(t) + h_i^2 \frac{(b_i(t)u_i(t) - \dot{z}_i^a(t))^2}{(\mu_i^a(t) - b_i^2(t))} \right) \right] dt \\
&\quad + \int_{\Omega_s \setminus \{0,T\}} \sum_{i=1}^M \left(h_i^2 \left| \frac{d\dot{z}_i^s}{d\sigma} \right|^2 + k_i \left| \frac{d\dot{z}_i^s}{d\sigma} \right| \right) d\sigma \\
&\quad + \sum_{i=1}^M \left(h_i^2 \frac{|z_i(0^+) - z_i(0^-)|^2}{\sigma(\{0\})} + k_i \left| z_i(0^+) - z_i(0^-) \right| \right) \\
&\quad + \sum_{i=1}^M \left(h_i^2 \frac{|z_i(T) - z_i(T^-)|^2}{\sigma(\{T\})} + k_i \left| z_i(T^+) - z_i(T^-) \right| \right),
\end{aligned}$$

where we have set $w = x(z,y)$ and $\Omega_s = \operatorname{supp}\sigma$. (See section 1 for the notations in the above formula.)

Remark 2.4. We adopt here the convention (already used in [BC89], [BF93], [Fr98]) according to which the fractions appearing in the definition of $\check{J}$ are zero as soon as their denominators are zero.

Remark 2.5. If one has $b_i^2 = \mu_i$ for $i = 1, \dots, M$, then the limit problem $(\mathcal{Q})_{(b,\mu)}$ reduces to the standard form

$$\begin{cases} \begin{pmatrix} \dot z \\ \dot y \end{pmatrix} = \check g_0(t,z,y) + \sum_{i=1}^{M} \check g_i(z,y) b_i(t) u_i(t), \quad (z(0), y(0)) = (0, x_0), \\ \min\limits_u \big\{ \check J((z,y),u) \big\}, \end{cases}$$

$$\check J((z,y),u) = \int_0^T \left(l(t, x(z,y)) + \sum_{i=1}^{M} k_i b_i(t) u_i(t) + \sum_{i=1}^{M} h_i^2 u_i^2(t) \right) dt.$$

Definition 2.6. *Let us rewrite problem* $(\mathcal{Q})_{(b,\mu)}$ *in the form*

$$(\mathcal{Q})_{(b,\mu)} \qquad \min \left\{ \check F((z,y),u) : (z,y) \in BV([0,T]; \mathbb{R}^M \times \mathbb{R}^N),\ u \in L^2(0,T;\mathbb{R}^M) \right\},$$

where $\check F((z,y),u) \doteq \check J\,((z,y),u) + \chi_{\{\dot z << dt + \sigma\,,\ \dot y = g_0^\sharp(t,w)\}}$. *We define problem* $\Phi^{-1}((\mathcal{Q})_{(b,\mu)})$ *as follows:*

$$\Phi^{-1}((\mathcal{Q})_{(b,\mu)}) \qquad \min\{ \check F(\Phi((z,x)),u) : (z,x) \in BV([0,T]; \mathbb{R}^M \times \mathbb{R}^N), u \in L^2(0,T;\mathbb{R}^M) \}.$$

The next result states that problems $(\mathcal{P})_{(b_n)}$ converge to the variational problem $\Phi^{-1}((\mathcal{Q})_{(b,\mu)})$. For the basic facts concerning the Γ-convergence, see the appendix and the references therein.

Theorem 2.7. *If the* (b_n, b_n^2) *converge to* (b,μ) *as in* (1.1)*, then the problems* $(\mathcal{P})_{(b_n)}$ Γ*-converge to* $\Phi^{-1}((\mathcal{Q})_{(b,\mu)})$.

Proof. In view of Lemma 2.8 below we have to prove only that the $(\mathcal{Q})_{(b_n)}$ Γ-converge to $(\mathcal{Q})_{(b,\mu)}$. Now the optimal control problems $(\mathcal{Q})_{(b_n)}$ verify hypotheses (7.1)–(7.5) in [Fr98]. Moreover, assumption (1.1) here implies (7.17) and (7.18) therein. Hence, in view of the results in [Fr98], problems $((\mathcal{Q})_{(b_n)})_{n\in N}$ Γ-converge to the problem $(\mathcal{Q})_{(b,\mu)}$ introduced in Definition 2.3. □

Lemma 2.8. *If the sequence of problems* $((\mathcal{Q})_{(b_n)})_{n\in N}$ Γ*-converges to* $(\mathcal{Q})_{(b,\mu)}$*, then the sequence* $((\mathcal{P})_{(b_n)})_{n\in N}$ Γ*-converges to* $\Phi^{-1}((\mathcal{Q})_{(b,\mu)})$.

Proof. To begin with, for each $n \in N$ we set

$$\check F_n((z,y),u) \doteq \check J_n((z,y),u) + \chi_{\check C_n}((z,y),u),$$

where $\check C_n$ is the set of admissible trajectory-control pairs for $(\mathcal{Q})_{(b_n)}$ (see the appendix). By assumption we have (see Definition A.3 in the appendix)

$$\Gamma(N, U^-, Y^-) \lim_{n\to\infty} \check F_n((z,y),u) = \check F((z,y),u). \tag{2.1}$$

Now (see Remark 2.2)

$$\begin{aligned} F_n((z,x),u) &\doteq J_n((z,x),u) + \chi_{C_n}((z,x),u) \\ &= \check J_n(\Phi(z,x),u) + \chi_{\check C_n}(\Phi(z,x),u)) = \check F_n(\Phi(z,x),u), \end{aligned}$$

where C_n is the set of admissible trajectory-control pairs for $(\mathcal{P})_{(b_n)}$. Hence, by (2.1),

$$\begin{aligned} &\Gamma(N, U^-, Y^-) \lim_{n\to\infty} F_n((z,x),u) \\ &\quad = \Gamma(N, U^-, Y^-) \lim_{n\to\infty} \check F_n(\Phi(z,x),u) = \check F(\Phi(z,x),u), \end{aligned}$$

which proves the lemma. □

Theorem 2.7 says that the Γ-limit of a sequence of problems $(\mathcal{P})_{(b_n)}$ has the form $\Phi^{-1}((\mathcal{Q})_{(b,\mu)})$. Conversely, we have the following.

THEOREM 2.9. *For each problem* $\Phi^{-1}((\mathcal{Q})_{(b,\mu)})$ *with* $(b,\mu) \in A$, *there exists a sequence of problems* $((\mathcal{P})_{(b_n)})_{n\in N}$ *which* Γ*-converges to* $\Phi^{-1}((\mathcal{Q})_{(b,\mu)})$.

In order to prove this theorem, we need the following result.

LEMMA 2.10. *For each* $(b,\mu) \in A$ *(with* $M = 1$*) there exists a sequence* $(b_n)_{n\in N} \in L^2(0,T)$ *such that* $b_n \to b$ *weakly in* $L^2(0,T)$ *and* $b_n^2 \to \mu$ *weakly* in* $\mathcal{M}([0,T])$.

In the case where μ is an L^∞-function we can sharpen the above result as follows.

LEMMA 2.11. *If* $(b,\mu) \in A$ *(with* $M = 1$*) and* $\mu \in L^\infty(0,T)$, *then there exists a sequence* $(b_n)_{n\in N} \in L^2(0,T)$ *such that* $b_n \to b$ *weakly in* $L^2(0,T)$ *and* $b_n^2 \to \mu$ *weakly* in* $L^\infty(0,T)$.

We omit the proofs of both Lemmas 2.10 and 2.11, for they are mostly based on the same arguments as in the proof of Theorem 3.2 in [BR93].

Proof of Theorem 2.9. In view of Lemma 2.10, for each $(b,\mu) \in L^2(0,T;\mathbb{R}^M) \times \mathcal{M}([0,T];\mathbb{R}^M)$ such that $(b,\mu) \in A$ there exist sequences $(b_{n_i})_{n\in N}$ in $L^2(0,T)$ such that $b_{n_i} \to b_i$ weakly in $L^2(0,T)$ and $b_{n_i}^2 \to \mu_i$ weakly* in $\mathcal{M}([0,T])$ for $i = 1,\dots,M$. Hence, in view of Theorem 2.7, the sequence of problems $((\mathcal{P})_{(b_n)})_{n\in N}$ Γ-converges to $\Phi^{-1}((\mathcal{P})_{(b,\mu)})$. □

Remark 2.12. By the above arguments it is clear that we could replace hypothesis (HC) with the following more general assumption (GHC), which, on one hand, does not assume that the functions k_i and h_i are constant and, on the other hand, involves these functions in the zero-Lie bracket condition.

Generalized commutativity condition (GHC). For every $\alpha,\beta = 1,\dots,2M$

$$[\gamma_\alpha,\gamma_\beta] = 0,$$

where the vector fields γ_δ are defined on $\mathbb{R}^{N+2}$ by

$$\gamma_\delta = \begin{pmatrix} g_i^1 \\ . \\ . \\ g_i^N \\ k_\delta \\ 0 \end{pmatrix}$$

when $\delta = 1,\dots,M$, and

$$\gamma_\delta = \begin{pmatrix} 0 \\ . \\ . \\ 0 \\ 0 \\ h_\delta \end{pmatrix}$$

when $\delta = M+1,\dots,2M$.

3. Nonvanishing Lie brackets: An example. In the previous section it has been shown that whenever the vector fields commute the Γ-limit of problems $(\mathcal{P})_{(b_n)}$ for (b_n, b_n^2) converging to (b,μ) *does exist*. However, this is no longer true whenever some Lie bracket is not vanishing, as shown in the example below. In the next sections

we will provide a theoretical framework from which it will be clear that, in general, there exist infinitely many limit problems corresponding to the pair (b, μ).

In order to get rid of the suspicion that having a state's dimension larger than the control's dimension might matter with the convergence question, the state in this example is one-dimensional.

Let $N = 1$, $M = 2$, and consider the state equation

$$\begin{cases} \dot{x}(t) = b_{n_1}(t)u_1(t) + a(x(t))b_{n_2}(t)u_2(t), \\ x(0) = 0, \end{cases}$$

where $a(x)$ is a bounded C^2 function coinciding with the identity map in the interval $[-4, 4]$. Hence $g_1(x)$ coincides with the constant 1, and $g_2(x) = a(x)$. Let us assume (Hb), (Hu), $T = 1$, and let us consider the cost functional

$$J_{b_n}(x, u) = \int_0^1 \left(|u(t)|^2 + b_{n_1}(t)u_1(t) + a(x(t))b_{n_2}(t)u_2(t)\right) dt \left(= \int_0^1 |u(t)|^2 \, dt + x(1)\right).$$

If we set $h_1(x) = 1$, $h_2(x) = 1$, $k_1(t, x) = 1$, $k_2(t, x) = a(x)$, and $l(t, x) = 0$, the hypotheses in section 2 turns out to be satisfied.

Since $[g_1, g_2](0) = -1$, neither the commutativity condition (HC) nor its generalization (GHC) are fulfilled.

Let us consider the two sequences of coefficients

$$(b_{n_1}(t), b_{n_2}(t)) \doteq \left(\sqrt{2n}, 0\right) \mathbf{I}_{\left[1-\frac{1}{n}, 1-\frac{1}{2n}\right]}(t) + \left(0, \sqrt{2n}\right) \mathbf{I}_{\left[1-\frac{1}{2n}, 1\right]}(t),$$

$$\left(\tilde{b}_{n_1}(t), \tilde{b}_{n_2}(t)\right) \doteq \left(0, \sqrt{2n}\right) \mathbf{I}_{\left[1-\frac{1}{n}, 1-\frac{1}{2n}\right]}(t) + \left(\sqrt{2n}, 0\right) \mathbf{I}_{\left[1-\frac{1}{2n}, 1\right]}(t),$$

where $\mathbf{I}_{[a,b]} = 1$ if $t \in [a, b]$ and $\mathbf{I}_{[a,b]} = 0$ if $t \notin [a, b]$. Let us observe that

$$(b_{n_1}(t), b_{n_2}(t)) \to (0, 0) \qquad \text{weakly in } L^2(0, T),$$

$$\left(\tilde{b}_{n_1}(t), \tilde{b}_{n_2}(t)\right) \to (0, 0) \qquad \text{weakly in } L^2(0, T),$$

$$\left(b^2_{n_1}(t), b^2_{n_2}(t)\right) \to (\delta_1, \delta_1) \qquad \text{weakly}^* \text{ in } \mathcal{M}([0, T]),$$

$$\left(\tilde{b}^2_{n_1}(t), \tilde{b}^2_{n_2}(t)\right) \to (\delta_1, \delta_1) \qquad \text{weakly}^* \text{ in } \mathcal{M}([0, T]),$$

where δ_1 denotes the Dirac measure at $T = 1$. Hence the two sequences fulfill the convergence assumption (1.1) with the *same* limit $(b_1, b_2) = (0, 0)$ and $(\mu_1, \mu_2) = (\delta_1, \delta_1)$. Yet the corresponding sequences $((\mathcal{P})_{(b_n)})_{n\in N}$ and $((\mathcal{P})_{(\tilde{b}_n)})_{n\in N}$ *cannot* converge to the same Γ-limit. Indeed, if we implement the control

$$(u_1^n(t), u_2^n(t)) = \left(-\sqrt{\frac{n}{2}} \, \mathbf{I}_{\left[1-\frac{1}{n}, 1-\frac{1}{2n}\right]}(t), 0\right) + \left(0, \sqrt{n} \, \mathbf{I}_{\left[1-\frac{1}{2n}, 1\right]}(t)\right)$$

in the system driven by the (b_n), we obtain a trajectory x_n verifying

$$x_n(1) = -\frac{1}{2} \exp(2^{-1/2}).$$

Thus

$$J_{b_n}(x_n, u_n) = K \doteq -\frac{1}{2}\exp(2^{-1/2}) + \frac{3}{4}\left(< -\frac{1}{4}\right).$$

On the contrary, if we consider $(\mathcal{P})_{(\tilde{b}_n)}$, a simple application of the Pontryagin maximum principle shows that

$$(\hat{u}_1^n(t), \hat{u}_2^n(t)) = \left(-\frac{1}{2}\,\tilde{b}_{n_1}, 0\right)$$

is an optimal control. The corresponding optimal trajectory $\hat{x}_n$ solves

$$\dot{\hat{x}}_n(t) = -\frac{1}{2}\,\tilde{b}^2_{n_1}, \qquad \hat{x}_n(0) = 0.$$

Hence

$$-\frac{1}{4} = J_{\tilde{b}_n}(\hat{x}_n, \hat{u}_n) = \min_u\{J_{\tilde{b}_n}(x, u)\}.$$

In particular, one has

$$\liminf_{n\to\infty}\left(\inf_u\{J_{b_n}(x,u)\}\right) \le K < -\frac{1}{4} = \liminf_{n\to\infty}\left(\min_u\{J_{\tilde{b}_n}(x,u)\}\right).$$

Hence, although the (b_{n_1}, b_{n_2}) and $(\tilde{b}_{n_1}, \tilde{b}_{n_2})$ converge to the same (b, μ) in the sense of (1.1), in view of Theorem A.2 in the appendix the Γ-limit of the $(\mathcal{P})_{(b_n)}$ and $(\mathcal{P})_{(\tilde{b}_n)}$ are necessarily different.

4. Nonvanishing Lie brackets: An extended setting. In this section we still assume hypotheses (Hg0), (Hg1), (Hl), (Hk), and (Hh), but we *do not* assume the commutativity hypothesis (HC) made in section 2. The previous example shows that in order to determine the limit problem *it is not enough* to assume that $b_n \to b$ weakly in $L^2(0,T;\mathbb{R}^M)$ and $b_n^2 \to \mu$ weakly* in $\mathcal{M}([0,T];\mathbb{R}^M)$. In fact, due to the noncommutativity of the vector fields g_i $(i = 1, \dots, M)$, some extra information—related to the choice of the particular sequence (b_n, b_n^2) approximating (b, μ)—is needed. It turns out that this extra information can be represented neatly by first embedding the problem in the (t, x)-space and then reparameterizing time with a nondecreasing map whose derivative is zero for those values of t where μ is concentrated. In particular, this embedding allows one to keep track of the particular sequence (b_n, b_n^2) approximating (b, μ).

Let us begin with some definitions.

Definition 4.1. *The set of* data triples *is defined as*

$$\mathcal{A} \doteq \Bigg\{(B_0, B, \gamma) :\ B_0 : [0,1] \to \mathbb{R}^+ \cup \{0\}\ ,\ B : [0,1] \to \mathbb{R}^M,$$

$$\gamma : [0,1] \to (\mathbb{R}^+ \cup \{0\})^M \textit{ are Borel functions in } L^\infty(0,T;\mathbb{R}^M)\ :$$
$$\gamma_i \ge B_i^2 \ \textit{ for all } i = 1, \dots, M \textit{ and } \int_0^1 B_0^2(s)ds = T\Bigg\}.$$

The subset A_{NI} *of* nonimpulsive data triples *is defined as*

$$\mathcal{A}_{NI} \doteq \{(B_0, B, \gamma) \in \mathcal{A} \ :\ B_0 > 0 \ \textit{a.e. on } [0,1]\}.$$

The subset of simple data triples *is defined as*

$$\mathcal{A}_s \doteq \left\{(B_0, B, \gamma) \in \mathcal{A} \,:\, \gamma_i = B_i^2 \text{ a.e. on } [0,1]\,,\ i = 1, \dots, M\ \right\}.$$

We will denote the vector $(B_1^2, \dots, B_M^2)$ by B^2.

For each triple $(B_0, B, \gamma) \in \mathcal{A}$ let us consider the *space-time* optimal control problem

$$(\mathcal{P})_{(B_0,B,\gamma)} \qquad \begin{cases} y'(s) = g_0(s,y)B_0^2(s) + \displaystyle\sum_{i=1}^{M} g_i(y)V_i(s), \quad y(0) = y_0, \\ \min\limits_{U,V} \left\{\hat{J}(y,U,V)\right\}, \end{cases}$$

$$\begin{aligned} \hat{J}(y,U,V) \;=\; & \int_0^1 \left(l(s,y)B_0^2(s) + \sum_{i=1}^{M} k_i(s,y)V_i(s) + \sum_{i=1}^{M} h_i^2(y)U_i^2(s) \right. \\ & \left. +\ \sum_{i=1}^{M} h_i^2(y) \frac{(B_i(s)U_i(s) - V_i(s))^2}{(\gamma_i(s) - B_i^2(s))} \right) ds, \end{aligned}$$

where $U \in L^2(0,1;\mathbb{R}^M)$ and $V \in L^2(0,1;\mathbb{R}^M)$.

Remark 4.2. When $(B_0, B, \gamma) \in \mathcal{A}_s$, that is, $\gamma_i = B_i^2$, $i = 1, \dots, M$, the optimal control problem $(\mathcal{P})_{(B_0,B,\gamma)}$ reduces to the following standard form:

$$(\mathcal{P})_{(B_0,B,B^2)} \qquad \begin{cases} y'(s) = g_0(s,y)B_0^2(s) + \displaystyle\sum_{i=1}^{M} g_i(y)B_i(s)U_i(s), \quad y(0) = y_0, \\ \min\limits_{U} \left\{\hat{J}(y,U)\right\}, \end{cases}$$

$$\hat{J}(y,U) = \int_0^1 \left(l(s,y)B_0^2(s) + \sum_{i=1}^{M} k_i(s,y)B_i(s)U_i(s) + \sum_{i=1}^{M} h_i^2(y)U_i^2(s) \right) ds.$$

We shall show that the class of problems $(\mathcal{P})_{(b)}$—where $(\mathcal{P})_{(b)}$ stands for a problem like $(\mathcal{P})_{(b_n)}$ when b_n is replaced by b—can be put into one-to-one correspondence with the class of space-time problems $\{(\mathcal{P})_{(B_0,B,B^2)} \,:\, (B_0, B, B^2) \in \mathcal{A}_s \cap \mathcal{A}_{NI}\}$. Then we shall give sufficient conditions for the Γ-convergence of a sequence of problems $(\mathcal{P})_{(B_{0_n},B_n,B_n^2)}$ to a problem $(\mathcal{P})_{(B_0,B,\gamma)}$. Last, we shall see that *every* such problem is the Γ-limit of a suitable sequence of problems $(\mathcal{P})_{(B_{0_n},B_n,B_n^2)}$.

DEFINITION 4.3. *Given* $(B_0, B, \gamma) \in \mathcal{A}$, *let us define* $\alpha(B_0, B, \gamma) \doteq (b, \mu)$ *by setting the following.*

(i) $$t(s) \doteq \int_0^s B_0^2(u)du,$$

and, whenever there exists $\delta > 0$ *such that* $B_0 > 0$ *a.e. on* $[s-\delta, s+\delta] \cap [0,1]$,

$$b_i(t(s)) \doteq \frac{B_i(s)}{B_0(s)} \qquad (i = 1, \dots, M).$$

(ii) *For each Borel subset* $E \subseteq [0,T]$

$$\mu_i(E) \doteq \int_I \gamma_i(s)ds \qquad (i = 1, \dots, M)$$

when $E = t(I)$.

Remark 4.4. (a) The function $b(\cdot)$ is well defined. Indeed, the set of values of t such that t^{-1} is not a singleton is at most countable.

(b) For each $(B_0, B, \gamma) \in \mathcal{A}$ the pair $(b, \mu) = \alpha(B_0, B, \gamma)$ is in A; in particular, if $(B_0, B, B^2) \in \mathcal{A}_{NI} \cap \mathcal{A}_s$, then $\alpha(B_0, B, B^2) = (b, b^2) \in A_s$.

(c) The definition of μ is equivalent to

$$\int_{[0,T]} \phi(t)d\mu = \int_0^1 \langle \gamma_i(s), \phi(t(s))\rangle ds \quad \text{for all } \phi \in C([0,T]; \mathbb{R}^M), \tag{4.1}$$

where $\langle \cdot, \cdot \rangle$ denotes the scalar product in $\mathbb{R}^M$.

(d) The map α is not injective, unless it is restricted to $\mathcal{A}_{NI} \cap \mathcal{A}_s$. Let us show that it is surjective. Indeed, for every (b, μ) let us set

$$s(t) = \begin{cases} 0 & t = 0, \\ \dfrac{t + \int_{]0,t]} d\mu}{T + \int_{]0,T]} d\mu} & 0 < t < T, \\ 1 & t = T, \end{cases}$$

and let us define $t(s)$ as the unique nondecreasing continuous map such that $t \circ s(\tau) = \tau$ for all $\tau \in [0,T]$. Correspondingly, let us set $B_0^2(s) = t'(s)$, $B_i(s) = b_i(t(s))B_0(s)$, $s \in [0,1]$, $i = 1, \dots, M$. Finally, let us choose $\gamma_i(s)$ such that

$$\int_{s_1}^{s_2} \gamma_i(s)ds = \int_{t(s_1,s_2)} d\mu_i, \quad i = 1, \dots, M,$$

for each subinterval (s_1, s_2) of $[0,1]$. Then $\alpha(B_0, B, \gamma) = (b, \mu)$. We will call this data triple *the canonical preimage* of (b, μ). Let us notice that for every (b, μ), $\alpha^{-1}(b, \mu)$ turns out to be the class of data triples in $\mathcal{A}$ such that

$$(B_0, B, \gamma), (\tilde{B}_0, \tilde{B}, \tilde{\gamma}) \in \alpha^{-1}(b, \mu) \quad \Leftrightarrow \quad \begin{cases} B_0 = \tilde{B}_0 \text{ a.e. }, \\ B = \tilde{B} \text{ a.e. }, \\ \gamma_i(s) = \tilde{\gamma}_i(s) \text{ for a.e. } s \in [0,1] \setminus \cup I_j \\ \text{ and } \displaystyle\int_{I_j} \gamma_i(s)ds = \int_{I_j} \tilde{\gamma}_i(s)ds \quad \text{for all } j, \end{cases}$$

where $\{I_j\}$ is the (countable) family of (disjoint) subintervals of $[0,1]$ such that $B_0 = \tilde{B}_0 = 0$ on each I_j.

In the following two theorems we establish a one-to-one correspondence between the class of problems $(\mathcal{P})_{(b)}$, $b \in L^2(0,T;\mathbb{R}^M)$, and the class of problems $(\mathcal{P})_{(B_0,B,\gamma)}$, $(B_0, B, \gamma) \in \mathcal{A}_{NI} \cap \mathcal{A}_s$ (i.e., $B^2 = \gamma$ and $B_0 > 0$). Before stating these results let us notice that α is one-to-one from $\mathcal{A}_{NI} \cap \mathcal{A}_s$ onto A_s.

THEOREM 4.5. *Let* b *and* u *satisfy* (Hb) *and* (Hu), *and let* $x(\cdot)$ *be the corresponding solution of the state equation of* $(\mathcal{P})_{(b)}$

$$\begin{cases} \dot{x} = g_0(t,x) + \displaystyle\sum_{i=1}^M g_i(x)b_i(t)u_i(t), \\ x(0) = x_0. \end{cases} \tag{4.2}$$

Let $(B_0, B, B^2) = \alpha^{-1}(b, b^2)$*, and set* $U(s) \doteq [u \circ t(s)]B_0(s)$*. Let* y *be the solution of the state equation of* $(\mathcal{P})_{(B_0,B,B^2)}$

$$\begin{cases} y'(s) = g_0(s,y)B_0^2(s) + \sum_{i=1}^{M} g_i(y)B_i(s)U_i(s), \\ y(0) = y_0. \end{cases} \tag{4.3}$$

Then

$$y(s) = x(t(s)) \quad \text{for all } s \in [0,1].$$

Conversely, let $(B_0, B, B^2) \in \mathcal{A}_s \cap \mathcal{A}_{NI}$*,* $U \in L^2(0,1;\mathbb{R}^M)$*, and let* $y(\cdot)$ *be the corresponding solution of* (4.3)*. Setting* $(b, b^2) = \alpha(B_0, B, B^2)$*, let us define*

$$u_i(t) \doteq \frac{U_i(s(t))}{B_0(s(t))}, \quad i = 1, \dots, M.$$

If $x(\cdot)$ *is the solution of* (4.2) *corresponding to these* b_i *and* u_i*, then*

$$x(t) = y(s(t)) \quad \text{for all } t \in [0,T].$$

Proof. The proof of this theorem relies essentially on the uniqueness properties of (4.2) and (4.3). For this reason we omit it. □

An analogous result holds for the payoffs J and $\hat{J}$.

THEOREM 4.6. *Consider* b, u, x, B_0, B, U*, and* y *as in the first part of Theorem* 4.5*, and set*

$$J(x,u) = \int_0^T \left(l(t,x) + \sum_{i=1}^{M} k_i(t,x)b_i(t)u_i(t) + \sum_{i=1}^{M} h_i^2(x)u_i^2(t) \right) dt,$$

$$\hat{J}(y,U) = \int_0^1 \left(l(s,y)B_0(s) + \sum_{i=1}^{M} k_i(s,y)B_i(s)U_i(s) + \sum_{i=1}^{M} h_i^2(y)U_i^2(s) \right) ds.$$

Then $\hat{J}(y,U) = J(x,u)$*. Conversely, if* B_0, B, U, y *and* b, u, x *are as in the second part of Theorem* 4.5*, then* $J(x,u) = \hat{J}(y,U)$*.*

Proof. In view of Theorem 4.5 the proof of this theorem is straightforward. □

When the problems $(\mathcal{P})_{(b)}$ and $(\mathcal{P})_{(B_0,B,B^2)}$ are related as in the previous result, we say that they are *isomorphic*. In view of Theorems 4.5 and 4.6 the map $(\mathcal{P})_{(b)} \mapsto (\mathcal{P})_{(B_0,B,B^2)}$ with $\alpha(B_0, B, B^2) = (b, b^2)$ establishes a *one-to-one correspondence between the class of problems* $\{(\mathcal{P})_{(b)}\ ,\ b \in L^2(0,T;\mathbb{R}^M)\}$ *and the subset* $\{(\mathcal{P})_{(B_0,B,\gamma)}\ ,\ (B_0, B, \gamma) \in \mathcal{A}_s \cap \mathcal{A}_{NI}\} \subset \{(\mathcal{P})_{(B_0,B,\gamma)}\ ,\ (B_0, B, \gamma) \in \mathcal{A}\}$. This one-to-one correspondence can be regarded as an embedding of the original class of problems $\{(\mathcal{P})_{(b)}\ :\ b \in L^2(0,T;\mathbb{R}^M)\}$ in the larger class $\{(\mathcal{P})_{(B_0,B,\gamma)}\ ,\ (B_0, B, \gamma) \in \mathcal{A}\}$. In this extended setting we are now able to provide a convergence result, so giving an answer to the question raised with the example in section 3. In other words, we are going to replace the assumptions on the sequence $((\mathcal{P})_{(b_n)})_{n\in N}$ with hypotheses on the sequence of isomorphic problems $(\mathcal{P}_{(B_{0_n},B_n,B_n^2)})_{n\in N}$. And assigning the limit of the triples (B_{0_n}, B_n, B_n^2), we actually provide the extra information whose lack was revealed by the example of section 3.

Here is the main result.

THEOREM 4.7. *Let* $(B_{0_n}, B_n, B_n^2) \in \mathcal{A}_s \cap \mathcal{A}_{NI}$ *and* $(B_0, B, \gamma) \in \mathcal{A}$ *verify*

$$\lim_{n\to\infty} B_{0_n}(\cdot) = B_0(\cdot) \text{ a.e. on } [0,1], \tag{4.4}$$

$$\lim_{n\to\infty} B_n(\cdot) = B(\cdot) \text{ weakly in } L^1(0,1;\mathbb{R}^M), \tag{4.5}$$

$$\lim_{n\to\infty} B_n^2(\cdot) = \gamma(\cdot) \text{ weakly in } L^1(0,1;\mathbb{R}^M). \tag{4.6}$$

Then problems $\mathcal{P}_{(B_{0_n},B_n,B_n^2)}$ Γ*-converge to problem* $(\mathcal{P})_{(B_0,B,\gamma)}$.

Remark 4.8. In the previous statement one possibly has $\alpha(B_{0_n}, B_n, B_n^2) = (b_n, b_n^2)$ with $b_n \in L^2(0,T;\mathbb{R}^M)$. So, in particular, Theorem 4.7 can be regarded as a convergence result concerning the original problems $(\mathcal{P})_{(b_n)}$.

Proof of Theorem 4.7. Thanks to the performed rescaling of the problem, we can exploit the general results proved by Buttazzo and Cavazzuti in [BC89]. Actually, hypotheses (Hg0), (Hg1), (Hl), (Hk), (Hh), and (4.4)–(4.6) imply (3.6)–(3.10) and (3.12)–(3.15) in [BC89], respectively. Hence Propositions 3.2 and 3.3 of [BC89] state that $(\mathcal{P})_{(B_0,B,\gamma)}$ is the Γ-limit of the $\mathcal{P}_{(B_{0_n},B_n,B_n^2)}$. □

Similarly to what has been done in the case where the Lie brackets vanish, we now prove that *each* problem $(\mathcal{P})_{(B_0,B,\gamma)}$ with $(B_0, B, \gamma) \in \mathcal{A}$ is indeed the Γ-limit of a sequence of problems of the form $\mathcal{P}_{(B_{0_n},B_n,B_n^2)}$ with $B_{0_n} > 0$ (which, up to the introduced one-to-one correspondence, means that $(\mathcal{P})_{(B_0,B,\gamma)}$ is the Γ-limit of problems $(\mathcal{P})_{(b_n)}$ with $(b_n, b_n^2) = \alpha(B_{0_n}, B_n, B_n^2)$).

THEOREM 4.9. *For every* $(B_0, B, \gamma) \in \mathcal{A}$*, the problem* $(\mathcal{P})_{(B_0,B,\gamma)}$ *is the* Γ*-limit of a suitable sequence* $(\mathcal{P}_{(B_{0_n},B_n,B_n^2)})_{n\in N}$ *with* $(B_{0_n}, B_n, B_n^2) \in \mathcal{A}_s \cap \mathcal{A}_{NI}$.

Proof. By Lemma 2.11 for each $(B_0, B, \gamma) \in A$ there is a sequence $((B_0, B_n, B_n^2))_{n\in N}$ $(\in \mathcal{A}_s)$ such that $B_{n_i} \to B_i$ weakly in $L^2(0,1)$ and $B_{n_i}^2 \to \gamma_i$ weakly in $L^1(0,1)$ for $i = 1, \dots, M$.

Moreover, by setting

$$B_{0_n}(s) = \sqrt{\frac{T}{T + \frac{1}{n}} \left(B_0^2(s) + \frac{1}{n} \right)},$$

we find that the triples (B_{0_n}, B_n, B_n^2) (belong to $\mathcal{A}_s \cap \mathcal{A}_{NI}$ and) verify (4.4)–(4.6). Hence one concludes by Theorem 4.7. □

5. Revisiting sections 2 and 3 in the light of the extended setting. On one hand, sections 2 and 3 reveal a crucial discrepancy between the case when all the brackets $[g_i, g_j]$ vanish identically and the general case. On the other hand, in section 4 we have introduced an extended setting in order to state a convergence result in the general case. In this section we are going to revisit both the positive result of section 2 and the counterexample of section 3 in light of the theory developed in section 4. Let us recall that the map $\alpha : \mathcal{A} \to A$ induces a one-to-one correspondence between the subset $\mathcal{A}_{NI} \cap \mathcal{A}_s \subset \mathcal{A}$ and $A_s \subset A$.

Null Lie brackets. In Theorem 5.1 below we show—under the commutativity hypothesis (HC) in section 2—that when problems $(\mathcal{P})_{(B_{0_n},B_n,B_n^2)}$ Γ-converge to a problem $(\mathcal{P})_{(B_0,B,\gamma)}$, then the space-projected problems $(\mathcal{P})_{(b_n)}$ with $(b_n, b_n^2) = \alpha(B_{0_n}, B_n, B_n^2)$ Γ-converge to the projected limit $\Phi^{-1}((\mathcal{Q})_{(b,\mu)})$, where $(b, \mu) = \alpha(B_0, B, \gamma)$.

The most relevant point of this theorem consists in the fact that two sequences $(B_{0_n}, B_n, B_n^2), (\tilde{B}_{0_n}, \tilde{B}_n, \tilde{B}_n^2)$ converging to two *different* triples $(B_0, B, \gamma), (\tilde{B}_0, \tilde{B}, \tilde{\gamma})$ such that $(b, \mu) = \alpha(B_0, B, \gamma) = \alpha(\tilde{B}_0, \tilde{B}, \tilde{\gamma})$ give rise to problems $(\mathcal{P})_{(b_n)}$ and $(\mathcal{P})_{(\tilde{b}_n)}$ Γ-converging to the *same* limit problem $\Phi^{-1}((\mathcal{Q})_{(b,\mu)})$. In particular, this explains why as soon as all the brackets vanish there is in fact no need of the extended setting.

THEOREM 5.1. *Let us assume the hypotheses of section* 2 *(in particular, the commutativity hypothesis* (HC)*). Given* $(B_0, B, \gamma) \in \mathcal{A}$*, let us consider* any *sequence* $(B_{0_n}, B_n, B_n^2) \in \mathcal{A}_{NI} \cap \mathcal{A}_s$ *such that the* B_{0_n} *are equibounded and*

$$\lim_{n\to\infty} B_{0_n}(\cdot) = B_0(\cdot) \text{ a.e. on } [0,1], \tag{5.1}$$

$$\lim_{n\to\infty} B_n(\cdot) = B(\cdot) \text{ weakly in } L^1(0,1;\mathbb{R}^M), \tag{5.2}$$

$$\lim_{n\to\infty} B_n^2(\cdot) = \gamma(\cdot) \text{ weakly in } L^1(0,1;\mathbb{R}^M) \tag{5.3}$$

(so that, by Theorem 4.7, $(\mathcal{P})_{(B_{0_n}, B_n, B_n^2)}$ Γ*-converges to* $(\mathcal{P})_{(B_0,B,\gamma)}$*). Then, setting* $(b_n, b_n^2) = \alpha(B_{0_n}, B_n, B_n^2)$ *and* $(b, \mu) = \alpha(B_0, B, \gamma)$*, one has that the problems* $(\mathcal{P})_{(b_n)}$ Γ*-converge to* $\Phi^{-1}((\mathcal{Q})_{(b,\mu)})$.

Proof. In view of Theorem 2.7, we have to prove only that

$$b_n \to b \text{ weakly in } L^2(0,T;\mathbb{R}^M), \tag{5.4}$$

$$b_n^2 \to \mu \text{ weakly}^* \text{ in } \mathcal{M}([0,T];\mathbb{R}^M). \tag{5.5}$$

We begin by observing that hypotheses (5.1)–(5.3) imply

$$\lim_{n\to\infty} B_{0_n}^2(\cdot) = B_0^2(\cdot) \text{ a.e. on } (0,1),$$

$$\lim_{n\to\infty} B_n(\cdot)B_{0_n}(\cdot) = B(\cdot)B_0(\cdot) \text{ weakly in } L^1(0,1;\mathbb{R}^M),$$

and

$$\lim_{n\to\infty} B_n^2(\cdot) = \gamma(\cdot) \text{ weakly in } L^1(0,T;\mathbb{R}^M).$$

Set

$$t_n(s) = \int_0^s B_{0_n}^2(u)du \quad \text{and} \quad t(s) = \int_0^s B_0^2(u)du.$$

Since the t_n tend to t pointwise and each t_n is increasing, the t_n tend to t uniformly on [0,1]. Hence, for each $\varphi \in C([0,T];\mathbb{R}^M)$,

$$\lim_{n\to\infty} \left| \int_0^T \langle b_n^2(t), \varphi(t)\rangle dt - \int_{[0,T]} \varphi(t)d\mu \right|$$
$$= \lim_{n\to\infty} \left| \int_0^1 \langle B_n^2(s), \varphi(t_n(s))\rangle ds - \int_0^1 \langle \gamma(s), \varphi(t(s))\rangle ds \right| = 0,$$

which proves (5.5).

In order to prove (5.4), let us observe that for any function $\varphi \in C_c^\infty(0,T;\mathbb{R}^M)$

$$\lim_{n\to\infty}\left|\int_0^T \langle b_n(t),\varphi(t)\rangle dt - \int_0^T \langle b(t),\varphi(t)\rangle dt\right| = \lim_{n\to\infty}\left|\int_0^1 \langle B_n(s)B_{0_n}(s),\varphi(s)\rangle ds - \int_0^1 \langle B(s)B_0(s),\varphi(s)\rangle ds\right| = 0.$$

Since the B_n are uniformly bounded in $L^2(0,T;\mathbb{R}^M)$, (5.4) follows by the density of $C_c^\infty(0,T;\mathbb{R}^M)$ in $L^2(0,T;\mathbb{R}^M)$. □

A compactness result. We now examine the converse situation, where a sequence $(b_n)_{n\in N}$ is given such that $((b_n,b_n^2))_{n\in N}$ converges—with some regularity—to $(b,\mu)\in A$. We do not assume here that the Lie brackets vanish. It turns out that a subsequence of the corresponding triples (B_{0_n},B_n,B_n^2) converges to an element $(B_0,B,\gamma)\in\alpha^{-1}(b,\mu)$.

THEOREM 5.2. *Assume the hypotheses of section* 2, *with the exclusion of the commutativity hypothesis* (HC). *Let* $\mathcal{T}=\{t_i, i\in N\}$, *a (countable) subset of* $[0,T]$, *and let* $(b,\mu)\in A$ *and* $(b_n)_{n\in N}$ *be given such that*

(i) $\mu = b^2+\mu^\tau$ *with* μ^τ *a (positive) measure concentrated in* $\mathcal{T}$;

(ii) *for each* $n\in N$, $b_n\in C([0,T]\setminus\mathcal{T};\mathbb{R}^M)$, *and*

$$b_n(\cdot)\to b(\cdot) \text{ uniformly on the compact subsets of } [0,T]\setminus\mathcal{T}, \tag{5.6}$$

$$b_n \to b \text{ weakly in } L^2(0,T;\mathbb{R}^M),$$

$$b_n^2 \to \mu \text{ weakly}^* \text{ in } \mathcal{M}([0,T];\mathbb{R}^M). \tag{5.7}$$

(So, if the commutative hypothesis (HC) *is in force,* $(\mathcal{P})_{(b_n)}\Gamma$*-converges to* $(\mathcal{P})_{(b,\mu)}$.*) Then, setting* $(B_{0_n},B_n,B_n^2)\doteq\alpha^{-1}(b_n,b_n^2)$, *there exists a subsequence* $(\check{B}_{0_n},\check{B}_n,\check{B}_n^2)$ *and a data triple* $(B_0,B,\gamma)\in\alpha^{-1}(b,\mu)$, *such that the problems* $(\mathcal{P})_{(\check{B}_{0_n},\check{B}_n,\check{B}_n^2)}$ Γ*-converge to* $(\mathcal{P})_{(B_0,B,\gamma)}$.

The proof of this theorem relies essentially on the following lemma.

LEMMA 5.3. *Assume the hypotheses of Theorem* 5.2. *Let us set*

$$s(t)\doteq\begin{cases}0, & t=0,\\ \dfrac{t+\int_{]0,t]}d\mu}{T+\int_{]0,T]}d\mu}, & 0<t<T,\\ 1, & t=T,\end{cases}$$

$$s_n(t)\doteq\frac{\int_0^t(1+|b_n|^2(s))ds}{\int_0^T(1+|b_n|^2(s))ds},$$

and let us define $t_n(s)$ *and* $t(s)$ *as the inverse of* $s_n(t)$ *and the unique nondecreasing continuous map such that* $t\circ s(\tau)=id_{[0,T]}$, *respectively. Then* $t_n(\cdot)$ *and* $t(\cdot)$ *are equi-Lipschitz continuous and*

$$\lim_{n\to\infty} t_n(s)=t(s) \tag{5.8}$$

uniformly on $[0,1]$. *Moreover, setting* $B_0(s) \doteq \sqrt{t'(s)}$, *one has*

$$B_0(s) = 0 \quad \textit{for all } s \in \mathrm{int}(t^{-1}(\mathcal{T})) \tag{5.9}$$

and

$$B_{0_n}(s) \to B_0 \ \textit{a.e. on } [0,1]. \tag{5.10}$$

Proof. Since $t^{-1}(\mathcal{T}) = \cup_{t_i \in \mathcal{T}} t^{-1}(t_i)$, we immediately obtain (5.9). Let us observe that hypothesis (5.7) implies that

$$\lim_{n\to\infty} s_n(t) = s(t) \quad \text{a.e. on } [0,T]$$

(see, e.g., Proposition 7.19 in [Fo84]).

Actually, by the continuity of $s(t)$ on $[0,T] \setminus \mathcal{T}$, one has

$$\lim_{n\to\infty} s_n(t) = s(t) \quad \text{for all } t \in [0,T] \setminus \mathcal{T}.$$

Moreover, by the monotonicity of the $s_n(\cdot)$ and of $s(\cdot)$, it follows that

$$\lim_{\varepsilon\to 0} \lim_{n\to\infty} (s_n(t+\varepsilon) - s_n(t-\varepsilon)) = s(t^+) - s(t^-),$$

which yields

$$\lim_{n\to\infty} t_n(s) = t(s) \quad \text{uniformly on } [0,1]. \tag{5.11}$$

Since $B^2_{0_n} = t'_n \geq 0$ for every n, there exists a subsequence, still denoted with $(B_{0_n})_{n\in N}$, such that

$$B^2_{0_n} = t'_n \to 0 \quad \text{a.e. on } \mathrm{int}(t^{-1}(\mathcal{T})).$$

The convergence of B_{0_n} to B_0 on the set $\mathrm{int}(t^{-1}(\mathcal{T}))$ is proved. In order to conclude, let us prove this convergence for every $s \in [0,1] \setminus t^{-1}(\mathcal{T})$. Indeed, by (5.6) and (5.11) one has

$$\lim_{n\to\infty} B^2_{0_n}(s) = \lim_{n\to\infty} t'_n(s) = \lim_{n\to\infty} \frac{1}{\dot{s}(t_n(s))} = \lim_{n\to\infty} \frac{\int_0^T (1+b_n(u)^2)du}{1+b_n^2(t_n(s))}$$

$$= \frac{T + \int_{[0,T]} d\mu}{1+b^2(t(s))} = B_0^2(s).$$

The lemma is proved. □

Proof of Theorem 5.2. By Theorem 4.7 in section 4 we have to prove only that the there exists a subsequence $(\check{B}_{0_n}, \check{B}_n, \check{B}^2_n)$ of (B_{0_n}, B_n, B^2_n) and a data triple $(B_0, B, \gamma) \in \alpha^{-1}(b,\mu)$ such that

$$\lim_{n\to\infty} \check{B}_{0_n}(\cdot) = B_0(\cdot) \text{ a.e. on } [0,1], \tag{5.12}$$

$$\lim_{n\to\infty} \check{B}_n(\cdot) = B(\cdot) \text{ weakly in } L^1(0,1;\mathbb{R}^M), \tag{5.13}$$

$$\lim_{n\to\infty} \check{B}^2_n(\cdot) = \gamma(\cdot) \text{ weakly in } L^1(0,1;\mathbb{R}^M). \tag{5.14}$$

Let us define B_0 as in Lemma 5.3, which yields (5.12).

Moreover, since the B_n are equibounded, there is a subsequence $(\tilde{B}_n)_{n\in N}$ of $(B_n)_{n\in N}$ converging to a map B weakly in $L^1(0,1;\mathbb{R}^M)$.

By Ascoli–Arzela's theorem there exists a subsequence $(\phi_n)_{n\in N}$ of

$$\tilde{\phi}_n(s) \doteq \int_0^s \tilde{B}_n(\sigma)^2 d\sigma$$

converging to a Lipschitz continuous map ϕ. Then the subsequence $\check{B}^2_n(s) \doteq \frac{d\phi_n(s)}{ds}$ converges weakly* in $L^\infty(0,T;\mathbb{R}^M)$ to $\gamma(s) \doteq \frac{d\phi(s)}{ds}$, which implies (5.14).

We claim that $(B_0, B, \gamma) \in \alpha^{-1}(b,\mu)$. Indeed, $\check{B}_{0_n}(s)$ tends to $B_0(s)$ for every s such that $B_0 > 0$ a.e. on $[s-\delta, s+\delta]$ for a sufficiently small δ. Moreover, thanks to (5.11) and hypothesis (5.6), $b_n(t_n(s))$ converges to $b(t(s))$ for every such point s. Since $\check{B}_n(s)$ tends a.e. to $B(s)$, (i) in the definition of the mapping α (Definition 4.3) turns out to be satisfied. Finally, in view of (5.14) and (4.1), (ii) in the definition of α holds true as well. □

Revisiting the example of section 3. Let us conclude by framing the example of section 3 in the extended setting. This will clarify that the distinct limiting behavior of problems $(\mathcal{P})_{(b_n)}$ and problems $(\mathcal{P})_{(\tilde{b}_n)}$ arises from the fact that the corresponding triples $(B_{0_n}, B_n, B^2_n), (\tilde{B}_{0_n}, \tilde{B}_n, \tilde{B}^2_n)$ converge to different limits.

Let us recall that the state equation and the cost functional were given by

$$\begin{cases} \dot{x}(t) = b_{n_1}(t)u_1(t) + a(x(t))b_{n_2}(t)u_2(t), \\ x(0) = 0 \end{cases}$$

and

$$J_n(x,u) = \int_0^1 \left(|u(t)|^2 + b_{n_1}(t)u_1(t) + a(x(t))b_{n_2}(t)u_2(t)\right) dt \left(= \int_0^1 |u(t)|^2 dt + x(1)\right),$$

respectively. The problem of minimizing $J_n(x,u)$ over the controls $u \in L^2(0,T)$ was denoted by $(\mathcal{P})_{(b_n)}$ and $(\mathcal{P})_{(\tilde{b}_n)}$ when the parameters were identified with

$$(b_{n_1}(t), b_{n_2}(t)) = \left(\sqrt{2n}, 0\right)\mathbf{I}_{\left[1-\frac{1}{n}, 1-\frac{1}{2n}\right]}(t) + \left(0, \sqrt{2n}\right)\mathbf{I}_{\left[1-\frac{1}{2n}, 1\right]}(t)$$

and

$$\left(\tilde{b}_{n_1}(t), \tilde{b}_{n_2}(t)\right) = \left(0, \sqrt{2n}\right)\mathbf{I}_{\left[1-\frac{1}{n}, 1-\frac{1}{2n}\right]}(t) + \left(\sqrt{2n}, 0\right)\mathbf{I}_{\left[1-\frac{1}{2n}, 1\right]}(t),$$

respectively. Following the construction performed in section 4, let us compute the isomorphic problems $\mathcal{P}_{(B_0, B_n, B^2_n)}$ and $\mathcal{P}_{(\tilde{B}_0, \tilde{B}_n, \tilde{B}^2_n)}$ with $(B_0, B_n, B^2_n) = \alpha^{-1}(b_n, b^2_n)$ and $(\tilde{B}_0, \tilde{B}_n, \tilde{B}^2_n) = \alpha^{-1}(\tilde{b}_n, \tilde{b}^2_n)$. In both cases the optimal control problem turns out to have the form

$$\begin{cases} y'(s) = B_{n_1}(s)U_1(s) + a(y(s))B_{n_2}(s)U_2(s)\ ,\ y(0) = 0, \\ \min\limits_U \{\hat{J}_n(y,U)\}, \end{cases}$$

$$\hat{J}_n(y,U) = \int_0^1 \left(|U(s)|^2 + B_{n_1}(s)U_1(s) + a(y(s))B_{n_2}(s)U_2(s)\right) ds$$

with the parameters B identified with

$$\begin{aligned} B_{0_n}(s) &= \sqrt{3}\,\mathrm{I}_{\left[0,\frac{1}{3}\left(1-\frac{1}{n}\right)\right]} + \sqrt{\frac{3}{1+2n}}\,\mathrm{I}_{\left[\frac{1}{3}\left(1-\frac{1}{n}\right),1\right]}, \\ B_n(s) &= (B_{n_1}(s), B_{n_2}(s)) \\ &= \left(\sqrt{\frac{6n}{1+2n}}, 0\right)\,\mathrm{I}_{\left[\frac{1}{3}\left(1-\frac{1}{n}\right),\frac{1}{3}\left(2-\frac{1}{2n}\right)\right]} + \left(0, \sqrt{\frac{6n}{1+2n}}\right)\,\mathrm{I}_{\left[\frac{1}{3}\left(2-\frac{1}{2n}\right),1\right]}, \end{aligned}$$

and

$$\begin{aligned} \tilde{B}_{0_n}(s) &= \sqrt{3}\,\mathrm{I}_{\left[0,\frac{1}{3}\left(1-\frac{1}{n}\right)\right]} + \sqrt{\frac{3}{1+2n}}\,\mathrm{I}_{\left[\frac{1}{3}\left(1-\frac{1}{n}\right),1\right]}, \\ \tilde{B}_n(s) &= (\tilde{B}_{n_1}(s), \tilde{B}_{n_2}(s)) \\ &= \left(0, \sqrt{\frac{6n}{1+2n}}\right)\,\mathrm{I}_{\left[\frac{1}{3}\left(1-\frac{1}{n}\right),\frac{1}{3}\left(2-\frac{1}{2n}\right)\right]} + \left(\sqrt{\frac{6n}{1+2n}}, 0\right)\,\mathrm{I}_{\left[\frac{1}{3}\left(2-\frac{1}{2n}\right),1\right]}, \end{aligned}$$

respectively. In order to find the Γ-limit of problems $\mathcal{P}_{(B_0,B_n,B_n^2)}$ and $\mathcal{P}_{(\tilde{B}_0,\tilde{B}_n,\tilde{B}_n^2)}$, we need to compute the limits appearing in hypotheses (4.4), (4.5), and (4.6).

For the data triples (B_0, B_n, B_n^2), we obtain

$$\begin{aligned} \lim_{n\to\infty} B_{0_n}(s) = \quad & B_0(s) \doteq \sqrt{3}\,\mathrm{I}_{[0,1/3]} && \text{a.e. } [0,1], \\ \lim_{n\to\infty} B_{n_1}(s) = \quad & B_1(s) \doteq \sqrt{3}\,\mathrm{I}_{[1/3,2/3]} && \text{in } L^1(0,1), \\ \lim_{n\to\infty} B_{n_2}(s) = \quad & B_2(s) \doteq \sqrt{3}\,\mathrm{I}_{[2/3,1]} && \text{in } L^1(0,1), \\ \lim_{n\to\infty} B_{n_1}^2(s) = \quad & B_1^2(s) = 3\ \mathrm{I}_{[1/3,2/3]} && \text{in } L^1(0,1), \\ \lim_{n\to\infty} B_{n_2}^2(s) = \quad & B_2^2(s) = 3\,\mathrm{I}_{[2/3,1]} && \text{in } L^1(0,1), \end{aligned}$$

while, for the data triples $(\tilde{B}_0, \tilde{B}_n, \tilde{B}_n^2)$, we have

$$\begin{aligned} \lim_{n\to\infty} \tilde{B}_{0_n}(s) = \quad & \tilde{B}_0(s) \doteq \sqrt{3}\,\mathrm{I}_{[0,1/3]} && \text{a.e. } [0,1], \\ \lim_{n\to\infty} \tilde{B}_{n_1}(s) = \quad & \tilde{B}_1(s) \doteq \sqrt{3}\,\mathrm{I}_{[2/3,1]} && \text{in } L^1(0,1), \\ \lim_{n\to\infty} \tilde{B}_{n_2}(s) = \quad & \tilde{B}_2(s) \doteq \sqrt{3}\,\mathrm{I}_{[1/3,2/3]} && \text{in } L^1(0,1), \\ \lim_{n\to\infty} \tilde{B}_{n_1}^2(s) = \quad & \tilde{B}_1^2(s) = 3\,\mathrm{I}_{[2/3,1]} && \text{in } L^1(0,1), \\ \lim_{n\to\infty} \tilde{B}_{n_2}^2(s) = \quad & \tilde{B}_2^2(s) = 3\,\mathrm{I}_{[1/3,2/3]} && \text{in } L^1(0,1). \end{aligned}$$

Let us remark that the limits of (B_0, B_n, B_n^2) and $(\tilde{B}_0, \tilde{B}_n, \tilde{B}_n^2)$ are *different*. This explains why problems $(\mathcal{P})_{(b_n)}$ and $(\mathcal{P})_{(\tilde{b}_n)}$ in the example cannot converge to the same limit problem. More precisely, in view of Theorem 4.7, problems $\mathcal{P}_{(B_0,B_n,B_n^2)}$ and $\mathcal{P}_{(\tilde{B}_0,\tilde{B}_n,\tilde{B}_n^2)}$ Γ-converge to the optimal control problems

$$\begin{cases} y'(s) = B_1(s)U_1(s) + a(y(s))B_2(s)U_2(s), \quad y(0) = 0, \\ \min\limits_U \{\hat{J}(y,U)\}, \end{cases}$$

$$\hat{J}(y,U) = \int_0^1 \left(|U(s)|^2 + B_1(s)U_1(s) + a(y(s))B_2(s)U_2(s)\right) ds$$

and

$$\begin{cases} y'(s) = \tilde{B}_1(s)U_1(s) + a(y(s))\tilde{B}_2(s)U_2(s), \quad y(0) = 0, \\ \min\limits_{U}\{\hat{J}(y,U)\}, \end{cases}$$

$$\hat{J}(y,U) = \int_0^1 \big(|U(s)|^2 + \tilde{B}_1(s)U_1(s) + a(y(s))\tilde{B}_2(s)U_2(s)\big)ds,$$

respectively.

Appendix. Basic tools from Γ-convergence applied to control theory. Since the work of Wijsman [Wi64], [Wi66], many different concepts of convergence for sequences of functionals and operators have been appearing in the literature. These concepts were especially designed to approach the limit of sequences of variational problems. Each type of variational problem (minimization, maximization, min-max, etc.) has been associated to a particular concept of convergence.

In the case of the *minimization problem,* the first concept of convergence was the so-called *epiconvergence.* The epiconvergence of a sequence of functionals is equivalent to set-convergence of the corresponding epigraphs.

In turn, this concept was placed in the general framework of Γ-convergence theory by De Giorgi. The theory of Γ-convergence aims to deduce the asymptotic behavior of the solutions of a sequence of variational problems from the asymptotic behavior of the corresponding functionals. Typical examples of applications of Γ-convergence are the theories of homogenization, of singular perturbations, and of the limit behavior of elliptic problems with various obstacles. (We refer, e.g., to the books of Attouch [At84], Bensoussan, Lions, and Papanicolau [BLP78], Sanchez-Palencia [SP80], Dal Maso [DM93], and Buttazzo [Bu89].)

In this paper we have studied the Γ-convergence of sequences of optimal control problems. Let us sketch the general framework of this branch of the theory of Γ-convergence. For each $n \in N$ let $C_n \subseteq Y \times \mathcal{U}$ denote the set of *admissible trajectory-control pairs* defined by

$$C_n \doteq \{(y,u) \in Y \times \mathcal{U} \,:\, A_n(y) = B_n(u)\},$$

where A_n and B_n map Y and $\mathcal{U}$, respectively, in a third topological space V. Correspondingly, let us consider the optimal control problems

$$(\mathcal{P}_n) \qquad \min\{J_n(y,u) \,:\, (y,u) \in C_n\},$$

where J_n is a real operator defined on $Y \times \mathcal{U}$.

Setting $F_n(y,u) = J_n(y,u) + \chi_{C_n}(y,u)$ (where χ_E is 1 on E and $+\infty$ on $(Y \times \mathcal{U}) \setminus E$), let us rephrase problems $(\mathcal{P}_n)$ as follows:

$$(\mathcal{P}_n) \qquad \min\{F_n(y,u) \,:\, (y,u) \in Y \times \mathcal{U}\}.$$

We will say that (y_n, u_n) is an *optimal pair* for the problem $(\mathcal{P}_n)$ if

$$F_n(y_n,u_n) = \min_{Y\times\mathcal{U}} F_n.$$

Via Theorem A.2 below, the theory of Γ-convergence provides a notion of the limit problem guaranteeing the following property. *If (y_n, u_n) is an optimal pair of*

$(\mathcal{P}_n)$, or simply a minimizing sequence, and if (y_n, u_n) tends to (y, u) in $Y \times \mathcal{U}$, then (y, u) is an optimal pair for the limit problem $(\mathcal{P})$.

Theorem A.2 below provides a notion of Γ-*limit* problem $(\mathcal{P})$ such that this property holds. In order to state this theorem, we recall the definition of the multiple Γ-limit operator (see [BDM82]). We shall denote the "sup" and the "inf" operators by $Z(+)$ and $Z(-)$, respectively.

DEFINITION A.1. *Let X and W be two topological spaces, and let $F_n : X \times W \to \overline{\mathbb{R}}$ be a sequence of functions. For every $x \in X$, $w \in W$, and $\alpha, \beta, \gamma \in \{+, -\}$, let us define the* Γ-limit of the F_n *by setting*

$$\Gamma(N^\alpha, X^\beta, W^\gamma) \lim_{n\to\infty} F_n(w, x) = \mathop{\mathrm{Z}(\beta)}_{(x_n)\in S(x)} \mathop{\mathrm{Z}(\gamma)}_{(w_n)\in S(w)} \mathop{\mathrm{Z}(-\alpha)}_{k\in N} \mathop{\mathrm{Z}(\alpha)}_{n\geq k} F_n(w_n, x_n),$$

where $S(x)$ and $S(w)$ denote the sets of all sequences $x_n \to x$ in X and $w_n \to w$ in W, respectively. When the Γ*-limit does not depend on the sign $+$ or $-$, this sign is omitted. For example, if*

$$\Gamma(N^+, X^-, W^+) \lim_{n\to\infty} F_n(w, x) = \Gamma(N^+, X^+, W^+) \lim_{n\to\infty} F_n(w, x),$$

their common value will be indicated by $\Gamma(N^+, X, W^+) \lim_{n\to\infty} F_n(w, x)$.

In particular,

$$\Gamma(N, \mathcal{U}^-, Y^-) \lim_{n\to\infty} F_n(y, u) = \inf_{(u_n)\in S(u)} \inf_{(y_n)\in S(y)} \lim_{n\to\infty} F_n(y_n, u_n).$$

THEOREM A.2. *Let Y and $\mathcal{U}$ be two topological spaces, and let $F_n \colon Y \times \mathcal{U} \to \overline{\mathbb{R}}$ be a sequence of functions. For each $n \in N$, let (y_n, u_n) be a minimum point for F_n or simply a pair such that*

$$\lim_{n\to\infty} F_n(y_n, u_n) = \lim_{n\to\infty} [\inf_{Y\times\mathcal{U}} F_n].$$

Assume that the (y_n, u_n) converge to (y, u) in $Y \times \mathcal{U}$ and there exists

$$F(y, u) \doteq \Gamma(N, \mathcal{U}^-, Y^-) \lim_{n\to\infty} F_n(y_n, u_n). \tag{A.1}$$

Then

(i) *(y, u) is a minimum point for F on $Y \times \mathcal{U}$;*

(ii) $\lim_{n\to\infty} [\inf_{Y\times\mathcal{U}} F_n] = \min_{Y\times\mathcal{U}} F(y, u)$.

(For the proof see [BDM82, Proposition 2.1, p. 388].)

Note that if $F_n(y, u) \doteq F(u)$, then the Γ-limit $F(y, u)$ in (A.1) coincides with the so-called relaxed functional $\overline{F}$ (see, e.g., [Bu89]).

The above theorem motivates the following definition of the Γ-limit problem.

DEFINITION A.3. *When* (A.1) *is verified we say that the problem*

$$\min \{F(y, u) \,:\, (y, u) \in Y \times \mathcal{U}\} \tag{$\mathcal{P}$}$$

is the Γ-limit of problems $(\mathcal{P}_n)$.

See, e.g., [BDM82], [BC89], [BF93], [BF95], and [Fr98] for the explicit calculation of the Γ-limits in various interesting situations.

CONVERGENCE OF THE OPTIMAL FEEDBACK POLICIES IN A NUMERICAL METHOD FOR A CLASS OF DETERMINISTIC OPTIMAL CONTROL PROBLEMS*

PAUL DUPUIS† AND ADAM SZPIRO‡

Abstract. We consider a Markov chain based numerical approximation method for a class of deterministic nonlinear optimal control problems. It is known that methods of this type yield convergent approximations to the value function on the entire domain. These results do not easily extend to the optimal control, which need not be uniquely defined on the entire domain. There are, however, regions of strong regularity on which the optimal control is well defined and smooth. Typically, the union of these regions is open and dense in the domain. Using probabilistic methods, we prove that, on the regions of strong regularity, the Markov chain method yields a convergent sequence of approximations to the optimal feedback control. The result is illustrated with several examples.

Key words. optimal control, numerical approximation, rate of convergence, Markov chain approximation, feedback controls, finite difference approximation

1. Introduction.

In this paper, we prove that an efficient Markov chain based numerical approximation method for a general class of nonlinear optimal control problems yields feedback controls which converge (on most of the domain) to the optimal feedback control for the problem that is being approximated. We consider an infinite time horizon problem on a finite domain in $\mathbb{R}^n$ with deterministic dynamics which are affine in the control variable. The running cost $L(x,u)$ is quadratic in the control variable u and is fully nonlinear in the state variable x, and there is no exit cost. Any problem in this class can be reduced by a simple change of variables to one with dynamics of calculus of variations type, and we find it convenient in our analysis to consider that form.

In general, one cannot explicitly evaluate either the value function or the optimal control, so accurate numerical approximation methods are needed. The quantity of interest for applications is typically the optimal control, and considerations of robustness in implementation make it important to have the optimal control in feedback form. Furthermore, for many recent applications, including robust control [3] and problems in computer vision [11, 20], approximations to the optimal feedback control and to the closely related gradient of the value function are needed. Given the fact that the control need not be uniquely defined, however, almost all of the literature focuses on approximating the value function, which, under our assumptions, is well defined and Lipschitz on the entire domain.

A natural class of numerical methods, first described by Kushner [18], involves replacing the limit control problem with an approximating problem whose state variable takes values on a finite grid. The deterministic dynamics are replaced by a Markov chain so that movement in an arbitrary direction can be approximated by appropriate probabilities of jumping to neighboring gridpoints. As the underlying grid is refined, the value function for the Markov chain control problem becomes an increasingly good approximation to the value function for the limit problem.

As we noted earlier, the optimal feedback control for the limit problem is not uniquely defined at all points, and this makes it difficult to construct an approximate optimal control on the entire domain. However, there are large subsets of the domain, called regions of strong regularity, on which it is uniquely defined, smooth, and in feedback form. Our main theorem states that the numerical method described in [5] yields a convergent sequence of approximations to the limit optimal feedback control in the regions of strong regularity.

We remark that our proof is applicable to a larger class of control problems than the one considered here. The quadratic structure of the running cost is not essential and can be replaced by suitable smoothness and convexity conditions. We restrict our attention to the quadratic case in order to streamline the presentation. Furthermore, the class of problems that we consider is important in that the infima in the discrete dynamic programming equation (DPE) can be evaluated analytically, eliminating the need for computationally intensive numerical minimizations.

To our knowledge, there are no other general results of this type. Almost all of the literature, both probabilistic [5, 18, 19] and analytic using viscosity solution methods [1, 8], is dedicated to proving convergence of the value functions on the entire domain, and convergence of the controls does not follow naturally from those proofs. That is not surprising, since our proof strongly exploits smoothness properties which hold only in the regions of strong regularity. Some results regarding the convergence of controls in the Markov chain approximation method have been obtained in [12], but the situation there is quite specialized and is restricted to one dimension. In general, one dimensional problems are qualitatively easier to deal with because the control can point only in two directions, while the number of possible directions for $n \geq 2$ is uncountable. In fact, for the present problem, the following startling result can be shown for the case where $n = 1$. For any point x at which the limit problem is regular and for a sufficiently refined grid, the optimal feedback control for the approximating problem is exactly equal to the limit value! This follows from the fact that identical one dimensional quadratic equations for the gradients of the limit and prelimit value functions can be obtained from the DPEs (2.3) and (3.5) by solving for the optimal feedback policies in terms of the respective gradients. Although this observation has limited practical value, it does serve as a powerful reminder of the unique nature of one dimensional problems.

In our development, we draw liberally on ideas presented by Fleming in [14]. There, a similar problem is considered with a small variance Brownian motion perturbation of the deterministic dynamics taking the place of the Markov chain approximations in our problem. In a future paper, we will apply the present result to obtain a full asymptotic expansion of the limit value function in the regions of strong regularity, analogous to the expansion obtained in [14]. Using this expansion, we will present a new numerical method which, under some additional assumptions, will be proved to yield approximations which are second order accurate in the regions of strong regularity.

The outline of this paper is as follows. In section 2, we state our assumptions, introduce the limit optimal control problem, and define the regions of strong regularity on which our results will hold. Section 3 is dedicated to defining the approximating optimal control problems and their associated Markov chain dynamics, while in section 4 we establish some preliminary convergence results. The main theorem is stated and proved in section 5, and we conclude in section 6 with computational examples.

We end this section with some notation. Let $\mathbb{R}^n$ be an n-dimensional Euclidian space, and let $\mathbb{Z}^n$ be the subset of $\mathbb{R}^n$ consisting of n-tuples of integers. For vectors $x, y \in \mathbb{R}^n$, $\langle x, y\rangle$ is the scalar product, $\|x\| = \sqrt{\langle x, x\rangle}$ is the Euclidean norm, $\|x\|_1 = \Sigma_{i=0}^n |x_i|$ is the l^1-vector norm, and $|x| = (|x_1|, \ldots, |x_n|)$ is the componentwise absolute value. For a process $X(\cdot)$ taking values in $\mathbb{R}^n$ and for $S < +\infty$, $\|X(\cdot)\|_S = \int_0^S \|X(t)\| dt$ is the integrated l^2-norm, and $\|\!| X(\cdot) |\!\|_S = \sup_{0\le t\le S} \|X(t)\|$ is the uniform l^2-norm. For any two subsets A and A' of $\mathbb{R}^n$, $d(A, A')$ denotes minimum Euclidean distance between $\bar{A}$ and $\bar{A}'$, while $B_\varepsilon(A)$ is the open ball of radius ε around A.

For a smooth function f mapping $\mathbb{R}^n$ to $\mathbb{R}$, $D_i f(x) = \frac{\partial}{\partial x_i} f(x)$, and the gradient is $Df(x) = (D_1 f(x), \ldots, D_n f(x))$. For $h > 0$, the operators $D^{h,\pm}$ are finite difference approximations to the gradient operator. So the ith component of $D^{h,+} f(x)$ is

$$D_i^{h,+} f(x) = \frac{f(x + he_i) - f(x)}{h},$$

while the ith component of $D^{h,-} f(x)$ is

$$D_i^{h,-} f(x) = \frac{f(x) - f(x - he_i)}{h}.$$

The positive part of a scalar is $a^+ = \max(a, 0)$, and its negative part is $a^- = -\min(a, 0)$. For a vector, the positive and negative parts are taken componentwise, so that $x^\pm = (x_1^\pm, \ldots, x_n^\pm)$.

2. Deterministic control problem. In this section we describe a deterministic optimal control problem on a bounded domain with zero exit cost. Since our goal is to obtain the solution to this problem as the limit of numerical approximations, we will refer to it as the limit problem. Let $G \subset \mathbb{R}^n$ be open with compact closure, and assume that G satisfies uniform interior and exterior cone conditions (see [5] for definitions). Let b and c be C^∞ functions from $\mathbb{R}^n$ to $\mathbb{R}$, and let a be a C^∞ function from $\mathbb{R}^n$ to the space of symmetric positive definite $n \times n$ matrices. Notice that a is uniformly positive definite on G. Assume that $c(x) \ge c_0 > 0$ on G. For a control $\underline{u}^0(t)$ which is in $L^2([0, S]; \mathbb{R}^n)$ for all $S < +\infty$ and for an initial condition $x \in G$, we define $\underline{X}^0(t)$ by the dynamics

$$\underline{X}^0(t) = x + \int_0^t \underline{u}^0(s) ds, \tag{2.1}$$

up to the time when it exits from the domain G. We define the exit time $\underline{\tau}^0 = \inf[t : \underline{X}^0(t) \notin G]$. For the running cost

$$L(x, u) = \frac{1}{2}\Big\langle (u - b(x)), a^{-1}(x)(u - b(x))\Big\rangle + c(x),$$

we define the payoff functional

$$J^0(x, \underline{u}^0) = \int_0^{\underline{\tau}^0} L(\underline{X}^0(t), \underline{u}^0(t)) dt.$$

The problem is to minimize the payoff by choosing a suitable control. Define the value function

$$V^0(x) = \inf_{\underline{u}^0} J^0(x, \underline{u}^0),$$

where the infimum is over controls $\underline{u}^0$ which are in $L^2([0,S];\mathbb{R}^n)$ for all $S < +\infty$. We employ the underscore notation here to indicate trajectories which are obtained from an arbitrary control. The same notations, without the underscores, will be used later to refer to trajectories which are obtained through the application of an optimal control.

We note that our analysis subsumes a much larger class of deterministic control problems. Namely, any problem with smooth dynamics which depend affinely on the control variable u and with a cost structure of the type described above can be made to fit within our framework by a simple change of variables.

The dynamics in (2.1) involve an open loop control $\underline{u}^0(t)$, which is defined for all $t > 0$. It is generally desirable, from the point of view of robustness and for convenience of implementation, to consider controls which can be represented in the feedback form

$$\underline{X}^0(t) = x + \int_0^t \underline{u}^0(\underline{X}^0(s))ds. \tag{2.2}$$

A key feature of the regions of strong regularity is that the optimal open loop controls for all initial conditions in a region of strong regularity correspond to a unique smooth feedback function $u^0(x)$. That is the quantity that we wish to approximate.

The following lemma allows us to regard the limit control problem as one with a finite time horizon and a compact control space, when it is convenient to do so. Thus it follows from [2, Theorem 6.1] that V^0 is the unique nonnegative viscosity solution on G to the DPE

$$\inf_u \left[\langle u, DV^0(x)\rangle + L(x,u)\right] = 0 \tag{2.3}$$

with the continuous boundary condition $V^0(x) = 0$ on ∂G. See [1] and [15] for a thorough account of the relationship between viscosity solutions of Hamilton–Jacobi PDEs and the value functions for various types of optimal control problems.

LEMMA 2.1. *$V^0(x)$ is bounded and uniformly Lipschitz on G, and there exists $T < +\infty$ such that every optimal trajectory exits from G by time $T-1$. Furthermore, there exists $U^0 < +\infty$ such that the norm of every optimal open loop control is bounded by U^0 for each $0 \le t \le T-1$.*

Proof. We begin by observing that the fact that $a(x)$ is uniformly positive definite implies that it is possible to move with unit velocity in any direction with bounded running cost. It follows immediately from this observation that the value function $V^0(x)$ is bounded uniformly by a finite multiple of $\sup_{x\in G} d(x, \partial G)$. Furthermore, the principle of optimality thus implies for all $x, y \in G$ the relation $V^0(x) \le V^0(y) + C\|y - x\|$ for some fixed $C < +\infty$, and this gives a uniform Lipschitz property.

To obtain the bound on the optimal controls, it suffices to find $U^0 < +\infty$ such that any control $\underline{u}^0(t)$ which has norm exceeding U^0 on some measurable set $A \subset [0, +\infty)$ can be replaced by one with a smaller maximum norm, resulting in a lower cost. Since the running cost $L(x,u)$ is uniformly convex in the control variable u, we can

accomplish this for U^0 sufficiently large by constructing a modified control $\tilde{u}^0(t)$ as follows. Let

$$s(t) = \int_0^t \left[I_{A^c}(r) + \frac{1}{2} I_A(r) \right] dr,$$

where $I_{A'}(\cdot)$ is the indicator function for a set A'. Now define

$$\tilde{u}^0(t) = u^0(s(t)) I_{A^c}(s(t)) + \frac{1}{2} u^0(s(t)) I_A(s(t)).$$

This results in following the same trajectory at a slower speed, and a straightforward calculation indicates that it yields a lower cost. □

It turns out that V^0 is smooth on most of the domain G. Let Q be a relatively open subset of $\bar{G}$. We call Q a region of strong regularity if the following hold.

1. For each initial condition $x \in Q$, there is a unique optimal open loop control, and the corresponding trajectory is contained in Q up to its exit time. The optimal trajectory meets ∂G nontangentially.
2. $V^0 \in C^\infty(Q)$.
3. There is a unique $u^0 \in C^\infty(Q)$ such that the optimal control can be represented in feedback form and is given by $u^0(x)$ for each $x \in Q$.

For a discussion of the classical method of characteristics and its application to proving the existence of regions of strong regularity for the present problem, see the appendices in [14] and [16]. At least in the case where ∂G is of class C^∞, the union of the regions of strong regularity is open and dense in the domain [16]. Detailed information on the structure of the singularity sets for closely related problems can be found in [13], [7], and [6]. Since V^0 is a classical solution to the DPE (2.3) on the regions of strong regularity, the optimal feedback control can be explicitly evaluated there:

$$u^0(x) = -a(x) DV^0(x) + b(x). \tag{2.4}$$

Let B_0 be a subset of $\bar{G}$ such that $\bar{B}_0 \subset Q$, and consider a nested sequence of three regions of strong regularity B, N, and Q such that

$$\bar{B}_0 \subset B \subset \bar{B} \subset N \subset \bar{N} \subset Q.$$

The main convergence results will be stated in terms of uniform limits on the set B_0. We assume the following.

ASSUMPTION 2.2. *The boundary section $Q \cap \partial G$ is parallel to one of the coordinate hyperplanes. Furthermore, the minimum distance in the outward normal direction from $Q \cap \partial G$ to $\partial G / Q$ is equal to $\tilde{\delta} > 0$.*

The foregoing assumption is a significant restriction in that it limits our results to regions Q such that $Q \cap \partial G$ is flat and such that ∂G does not make an acute angle at any of the extremal points of $Q \cap \partial G$. We suspect that the assumption about $Q \cap \partial G$ being flat can be relaxed. With regard to acute angles at the corners, we note that Assumption 2.2 does not preclude ∂G itself from making an acute angle, and it does not even preclude showing that the optimal controls converge for points arbitrarily close to such a corner. It does, however, restrict our uniform convergence estimates to regions which are bounded away from such corners.

It is convenient to have $u^0(x)$ defined and Lipschitz on all of $\mathbb{R}^n$, so we abuse notation by extending $u^0(x)$ to $\mathbb{R}^n$ and changing its values on the complement of $\bar{N}$. Let $\delta > 0$ be such that $\delta < d(N, \partial Q \cap G)$ and such that $\delta \leq \tilde{\delta}$, where $\tilde{\delta}$ is as in

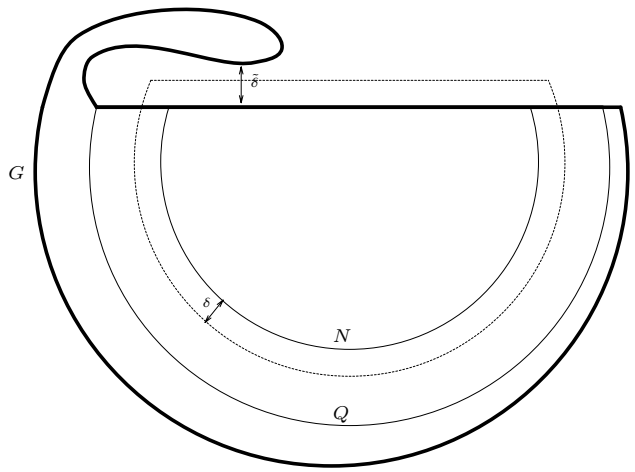

FIG. 1. *Region for smooth extension of* u^0.

Assumption 2.2; see Figure 1. We can define a Lipschitz function $\tilde{u}^0(x)$ on $B_\delta(\bar{N})$ by setting $\tilde{u}^0(x) = u^0(x)$ on $B_\delta(\bar{N}) \cap G$ and by extending it to be constant across the boundary section $Q \cap \partial G$. Now let $\phi(x)$ be a C^∞ function on $\mathbb{R}^n$ taking values in $[0,1]$ such that $\phi(x) = 1$ on $B_{\delta/2}(\bar{N})$ and $\phi(x) = 0$ outside of $B_\delta(\bar{N})$. Such a function can be constructed by standard methods using a smooth convolution kernel [17, Theorem 0.17]. We can now redefine $u^0(x)$ to be equal to $\phi(x)\tilde{u}^0(x)$ on $B_\delta(\bar{N})$ and zero everywhere else. This new $u^0(x)$ is Lipschitz on $\mathbb{R}^n$ and satisfies (2.4) on the region N. Furthermore, $\|u^0(x)\| \le U^0$ for each $x \in \mathbb{R}^n$, where $U^0 < +\infty$ is the bound from Lemma 2.1.

For any $x \in N$, let $X_x^0(t)$ be the trajectory obtained by applying the optimal feedback control u^0 with initial condition x. Since we use the extended version of u^0, we can define $X_x^0(t)$ by (2.2) for all $t \ge 0$. Let τ_x^0 be the first exit time of $X_x^0(t)$ from G, and let z_x^0 be its exit location. Notice that the definition of regions of strong regularity implies that $z_x^0 \in N$ for each $x \in N$ and that τ_x^0 is also the first exit time from the interior of N. We will often suppress the initial conditions in the subscripts of these notations.

LEMMA 2.3. *For each sufficiently small* $\varepsilon > 0$, *there exists* $\eta > 0$ *such that the following holds. Let* X *be a trajectory with initial condition in* N, *and let* τ_N *and* z_N *be its exit time and location from the interior of* N. *If* $\| X - X_x^0 \|_T \le \eta$ *holds for some* $x \in N$, *then* $\tau_N \le \tau_x^0 + \varepsilon$. *If, in addition,* $x \in B$, *then it also follows that* $|\tau_N - \tau_x^0| \le \varepsilon$ *and* $\|z_N - z_x^0\| \le \varepsilon$.

Proof. We first consider the case $x \in N$. Recall from Lemma 2.1 the bounds T and U^0 on the exit times and on the optimal controls, respectively. Given the way we extended u^0 beyond N and given the nontangential exit property for the regions of strong regularity, we have that

$$X_x^0(t) \in B_{\delta/2}(N)/G$$

for all $\tau_x^0 \le t \le \tau_x^0 + \Delta$, where $\Delta = \min(1, \delta/2U^0)$. Furthermore, there is $0 < \gamma \le \delta/2$ such that the component of $\dot{X}_x^0(t)$ in the outward normal direction away from the boundary segment $Q \cap \partial G$ is at least equal to γ for $\tau_x^0 \le t < \tau_x^0 + \Delta$. On account of

the second part of Assumption 2.2, it follows that

$$d(X_x^0(t), G) \geq \gamma(t - \tau_x^0)$$

for $\tau_x^0 \leq t < \tau_x^0 + \Delta$; see Figure 1. Thus, if $\| X - X_x^0 \|_T < \gamma\varepsilon$, then $\tau_N \leq \tau_x^0 + \varepsilon$. For the remainder of this proof, we consider only those η such that $\eta \leq \gamma\varepsilon$, so we may assume that $\tau_N \leq \tau_x^0 + \varepsilon$.

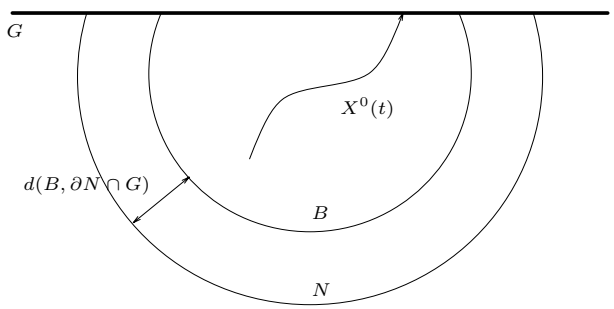

FIG. 2. *Regions of strong regularity.*

Suppose now that $x \in B$. To establish the lower bound for τ_N, we begin by observing that the nontangential exit property for regions of strong regularity implies

$$d(X_x^0(t), \partial N \cap G) \geq d(B, \partial N \cap G) - \varepsilon U^0$$

for all $0 \leq t \leq \tau_x^0 + \varepsilon$; see Figure 2. Thus, if $\varepsilon > 0$ is sufficiently small and if

$$\| X - X_x^0 \|_T < d(B, \partial N \cap G) - \varepsilon U^0,$$

then it follows that $X(\tau_N) \in \partial G$. We observe that $\tau_y^0 \leq C d(y, \partial G)$ holds for any $y \in G$, where $C = \sup_{x \in G} V^0(x)/c_0$ and $c_0 > 0$ is the lower bound on the running cost. Thus, if $\| X - X_x^0 \|_T < \varepsilon/C$, then the previous display implies

$$\tau_x^0 \leq \tau_N + C d(X_x^0(\tau_N), \partial G) \leq \tau_N + \varepsilon.$$

We have shown that $|\tau_N - \tau_x^0| \leq \varepsilon$ is satisfied for sufficiently small $\eta > 0$. Now we observe that

$$\begin{aligned} \|z_N - z_x^0\| &\leq \|X(\tau_N) - X_x^0(\tau_N)\| + \|X_x^0(\tau_N) - X_x^0(\tau_x^0)\| \\ &\leq \eta + U^0 |\tau_N - \tau_x^0|. \end{aligned}$$

Thus we can use the above argument to select a possibly smaller $\eta > 0$ such that $|\tau_N - \tau_x^0| < (\varepsilon - \eta)/U^0$ and so establish the bound $\|z_N - z_x^0\| \leq \varepsilon$. □

The following lemma deals with the continuity of the trajectories with respect to the initial condition. It will be useful in establishing uniformity in the pathwise convergence results of section 4.

LEMMA 2.4. *Let $x_k \in B$ be such that $x_k \to x \in B$, and let T be as in Lemma 2.1. Then*

$$\| X_{x_k}^0 - X_x^0 \|_T, \quad \|u^0(X_{x_k}^0) - u^0(X_x^0)\|_T, \quad |\tau_{x_k}^0 - \tau_x^0|, \quad \textit{and} \quad \|z_{x_k}^0 - z_x^0\|$$

all converge to zero as $k \to \infty$.

Proof. Since the vector field u^0 is globally Lipschitz, the convergence of $\| X^0_{x_k} - X^0_x \|_T$ to zero can be established by a routine application of Gronwall's inequality to the dynamics in (2.2). Given that, the remaining parts of the lemma follow from the uniform continuity of the feedback control u^0 and from Lemma 2.3. □

3. Markov chain approximations. We employ the method of approximating Markov chains developed by Kushner [18] to compute approximate solutions to the deterministic optimal control problem described above. For an up-to-date treatment of this subject, see the book of Kushner and Dupuis [19]. Our approximation is essentially the one used by Boué and Dupuis in [5]. In order to numerically approximate the value function V^0 and the optimal control u^0, we need to define a process which takes values on a finite lattice and which approximates the continuous dynamics. We circumvent the problem of only being able to move in the lattice directions by introducing jump probabilities which give rise to arbitrary mean velocities. The value function corresponding to this process, with the same cost structure as above, satisfies on the lattice a DPE analogous to (2.3). Thus it is possible to numerically compute the value function and the optimal feedback control for the approximating problem. We will show that, at least in the compact set B_0, these are good approximations to V^0 and u^0.

Let $h > 0$ be a discretization parameter, and define the discrete domain $G^h = h\mathbb{Z}^n \cap G$. For any $A \subset \mathbb{R}^n$, we define $A^h = h\mathbb{Z}^n \cap A^o$, where A^o is the interior of A. We consider limits as $h \to 0$ with the h chosen such that the hyperplane in which the boundary section $Q \cap \partial G$ lies lines up with the lattice $\mathbb{Z}^h$ (see Assumption 2.2). We will construct a continuous time controlled jump Markov process on G^h which approximates the deterministic dynamics in (2.2). This process will give rise to the same DPE obtained in [5] by using a discrete time Markov chain. For our purposes, however, it is more convenient to work with a continuous time jump Markov process.

Let $\underline{u}^h$ be any feedback control on G^h, and extend $\underline{u}^h$ to be equal to u^0 on $\mathbb{Z}^h/G^h$. Let $\underline{X}^h$ be the Markov process with controlled generator given by

$$\mathcal{L}^h_u f = \langle u^+, D^{h,+} f \rangle - \langle u^-, D^{h,-} f \rangle \tag{3.1}$$

for any smooth function f mapping $\mathbb{R}^n$ to $\mathbb{R}$. See section 1 for the notation in this definition. The stochastic dynamics corresponding to this generator will be called the h-dynamics. As in the description of the limit problem, we employ the underscore notation to indicate objects which are obtained from the application of an arbitrary possibly suboptimal feedback control.

Since we consider only feedback controls, it is straightforward to construct $\underline{X}^h$, as in section 4.3 of [19] and in [9]. We define a sequence of independent and identically distributed exponential random fields parameterized by u with mean values specified as follows:

$$\overline{\Delta t}^h(u) = \begin{cases} \frac{h}{\|u\|_1}, & u \neq 0, \\ h, & u = 0. \end{cases}$$

Suppose that after $m-1$ jumps, $\underline{X}^h(s)$ is defined for $0 \le s \le t$ and that $\underline{X}^h(t) = x$. Then we take $\underline{X}^h(s) = x$ for all $t \le s < t + \eta$, where the waiting time η is the exponential random variable obtained by evaluating the mth random field with the parameter value $u = \underline{u}^h(\underline{X}^h(s))$. If $u = 0$, then $\underline{X}^h(t + \eta) = x$, but otherwise it is

conditionally distributed according to the jump probabilities

$$p^h(x,y|u) = \begin{cases} \frac{u_i^{\pm}}{\|u\|_1} & \text{if } y = x \pm he_i, \\ 0 & \text{otherwise.} \end{cases}$$

It is easy to verify that the mean velocity of $\underline{X}^h$ at time t conditioned on $\underline{X}^h(t) = x$ is equal to $\underline{u}^h(x)$, so this is a consistent approximation to the limit dynamics in (2.2).

We consider the semimartingale decomposition of $\underline{X}^h$. For a given feedback control $\underline{u}^h$ and fixed initial condition $x \in G^h$, we write

$$\underline{X}^h(t) = \underline{Y}^h(t) + \underline{m}^h(t), \tag{3.2}$$

where the stochastic process $\underline{Y}^h$ is defined with probability one (w.p.1) by

$$\underline{Y}^h(t) = x + \int_0^t \underline{u}^h(\underline{X}^h(s))ds.$$

The consistency of the jump dynamics guarantees that $\underline{m}^h(t)$ is a martingale with mean zero. Furthermore, the variance of $\underline{m}^h(t)$ is controlled by the parameter h. That is the content of the following lemma.

LEMMA 3.1. *Fix $h > 0$, and let $\underline{u}^h$ be any feedback control which satisfies $\|\underline{u}^h(x)\| \le K < +\infty$ for all $x \in h\mathbb{Z}^n$. Then the bound*

$$E_x\|\underline{m}^h(\sigma)\|^2 \le hKE_x\sigma$$

holds for any bounded stopping time σ.

Proof. The triple $(\underline{m}^h, \underline{X}^h, \underline{Y}^h)$ is Markov and measurable with respect to the σ-algebra generated by $\underline{X}^h$. We consider its generator $\tilde{\mathcal{L}}^h$. Since $\underline{m}^h = \underline{X}^h - \underline{Y}^h$, we have

$$\tilde{\mathcal{L}}^h f = \langle \underline{u}^{h,+}(\underline{X}^h), D^{h,+}f\rangle - \langle \underline{u}^{h,-}(\underline{X}^h), D^{h,-}f\rangle - \langle \underline{u}^h(\underline{X}^h), Df\rangle$$

for any smooth function of the form $f(m,x,y) = f(m)$. Given the fact that $\underline{m}^h(t)$ takes values in a bounded set for bounded values of $t \ge 0$, the general theory of piecewise deterministic processes [9, Theorem 5.5] implies that for any smooth function f on $\mathbb{R}^n$, for any initial condition $x \in G$, and for any bounded stopping time σ,

$$E_x\left[f(\underline{m}^h(\sigma)) - f(0) - \int_0^\sigma \tilde{\mathcal{L}}^h f(\underline{m}^h(t))dt\right] = 0. \tag{3.3}$$

Taking $f(m) = \|m\|^2$, we use (3.3) and the fact that for this choice of f,

$$|\tilde{\mathcal{L}}^h f(\underline{m}^h(s))| \le 2h\|\underline{u}^h(\underline{X}^h(s))\|_1$$

to obtain

$$E_x\|\underline{m}^h(\sigma)\|^2 \le 2hE_x\int_0^\sigma \|\underline{u}^h(\underline{X}^h(s))\|_1 ds.$$

Given the bound on $\|\underline{u}^h\|$, this completes the proof. □

We now formulate the discrete approximation to the optimal control problem discussed in section 2. Define the value function

$$V^h(x) = \inf_{\underline{u}^h} E_x\int_0^{\underline{\tau}^h} L(\underline{X}^h(t), \underline{u}^h(\underline{X}^h(t)))dt, \tag{3.4}$$

where the exit time is $\underline{\tau}^h = \inf[t : \underline{X}^h(t) \notin G^h]$, and the infimum is over feedback controls $\underline{u}^h$. Using standard methods [19, section 4.3] it can be shown that V^h is the unique solution on G^h to the DPE

$$\inf_u \left[\left\langle u^+, D^{h,+}V^h(x) \right\rangle - \left\langle u^-, D^{h,-}V^h(x) \right\rangle + L(x,u) \right] = 0 \tag{3.5}$$

with zero boundary condition on $h\mathbb{Z}^n/G^h$. It is straightforward to verify that (3.5) is equivalent to

$$V^h(x) = \inf_u \left[\sum_{y \in \mathbb{R}^n} p^h(x,y|u)V^h(y) + \overline{\Delta t}^h(u)L(x,u) \right] \tag{3.6}$$

for $x \in G^h$, and that the minimizing values of u are the same for these two equations. As suggested by the form of (3.6), the fixed point and an optimal feedback control can be found numerically using either Jacobi or Gauss–Seidel iteration schemes. We note that (3.6) is the DPE for a different approximating control problem, where a discrete time Markov chain is used to approximate the deterministic dynamics. That is the approach taken in [5], where the time step $\overline{\Delta t}^h(u)$ is used to interpolate the Markov chain into continuous time. As discussed in [5], the choice of one-sided transition probabilities and of a control dependent time step facilitates rapid convergence of the iterative schemes used to solve (3.6), and the required infima at each step can be evaluated analytically.

The DPE (3.5) gives rise to an optimal feedback control u^h on G^h. It is convenient at this point to abuse notation and to redefine u^h to be equal to u^0 on $h\mathbb{Z}^n/N^h$. Then, for each initial condition $x \in N^h$, there is a unique process X_x^h defined for all $t \geq 0$ which is optimally controlled by u^h until it exits from N^h. We define the exit time $\tau_{x,N}^h = \inf[t : X_x^h(t) \notin N^h]$ and the exit location $z_{x,N}^h = X_x^h(\tau_{x,N}^h)$. Recall that N^h is defined to be $h\mathbb{Z}^n \cap N^o$, where N^o is the interior of N. Let m_x^h be the martingale part of the decomposition for X_x^h given by (3.2). As in the limit problem, we will often suppress the initial conditions in the subscripts of all of these notations.

The following remark and lemma simplify some of the analysis by allowing us to consider a compact domain and a compact control space.

REMARK 3.2. *We extended $u^0(x)$ to all of $\mathbb{R}^n$ in such a way that it is equal to zero off of the neighborhood $B_\delta(N)$. Thus the same is now true of $u^h(x)$. Consequently, for all initial conditions $x \in N$, the trajectories X_x^0 and X_x^h never leave the closed neighborhood $\overline{B_{\delta+h}(N)}$.*

LEMMA 3.3. *There exists a compact set $U \subset \mathbb{R}^n$ such that the extended optimal feedback controls $u^0(x)$ and $u^h(x)$ take values in U for all $h > 0$ and for all $x \in \mathbb{R}^n$ on which they are defined. Furthermore, the value functions $V^0(x)$ and $V^h(x)$ are bounded, uniformly in h and x.*

Proof. Recall from Lemma 2.1 that we obtained $U^0 < +\infty$ such that $\|u^0(x)\| \leq U^0$ for all $x \in \mathbb{R}^n$. From the DPE (3.5), it follows that for $x \in G^h$, each component of $u^h(x)$ either is equal to zero or is given by a bounded linear functional of $D^{h,\pm}V^h(x)$. Thus, in order to find the set U, it suffices to establish a bound on $D^{h,\pm}V^h(x)$ which is uniform for all $h > 0$ and $x \in G^h$.

Without loss of generality, we consider the case of bounding $D_i^{h,+}V^h(x)$. The principle of optimality implies that the minimal cost starting at $x \in G^h$ can be no larger than the minimal cost starting at $x + he_i$ plus the expected cost of getting from x to $x + he_i$ under any suboptimal control. The fact that a is uniformly positive

definite while b and c are bounded implies that there exists a constant $K < \infty$ such that $L(x,u) \le K$ whenever $\|u\| = 1$. Taking $u = he_i$, we obtain $V^h(x) \le V^h(x+he_i) + KE_x\eta$, where the waiting time η is exponential with mean h. Thus we have shown $V^h(x) \le V^h(x+he_i)+hK$. The reverse inequality is established by using $x+he_i$ as the initial condition, and it follows that $|D_i^{h,+}V^h(x)| < K$. That concludes the proof for the optimal controls. A uniform bound on the value functions $V^h(x)$ follows from the above argument and from the boundedness of the domain G. Along with the bound on $V^0(x)$ from Lemma 2.1, this finishes the proof. □

4. Preliminary convergence results. The main results of this section are contained in Lemma 4.1. It states that in the region of strong regularity B, the optimal trajectories, open loop controls, exit times, and exit locations converge in probability, uniformly with respect to initial conditions. Since the limit objects are deterministic, we are able to use convergence in distribution arguments to establish the desired convergence in probability. Uniformity with respect to initial conditions is a consequence of the continuity properties in Lemma 2.4.

LEMMA 4.1. *Let T be the bound on the exit times from Lemma* 2.1. *For every $\varepsilon > 0$, there exists $h_0 > 0$ such that*

$$\text{(i)} \quad P_x\left[\|\!|\!|\, X_x^h - X_x^0 \,|\!|\!|_T > \varepsilon\right] < \varepsilon,$$

$$\text{(ii)} \quad P_x\left[\|u^h(X_x^h) - u^0(X_x^0)\|_T > \varepsilon\right] < \varepsilon,$$

$$\text{(iii)} \quad P_x\left[\tau_{x,N}^h > \tau_x + \varepsilon\right] < \varepsilon$$

holds for all $0 < h \le h_0$ and for all initial conditions $x \in N^h$, and such that

$$\text{(iv)} \quad P_x\left[|\tau_{x,N}^h - \tau_x^0| > \varepsilon\right] < \varepsilon,$$

$$\text{(v)} \quad P_x\left[\|z_{x,N}^h - z_x^0\| > \varepsilon\right] < \varepsilon$$

holds for all $0 < h \le h_0$ and for all initial conditions $x \in B^h$.

We will use the following convergence result [5]. In fact, we will repeat part of the argument to prove this theorem in our proof of Lemma 4.1, but the exposition is made more transparent by assuming convergence of the value functions.

THEOREM 4.2. (i) *Let $x^h \in G^h$ for $h > 0$ be such that $x^h \to x \in \bar{G}$ as $h \to 0$. Then $V^h(x^h) \to V^0(x)$ as $h \to 0$.* (ii) *For any $\varepsilon > 0$, there exists $h_0 > 0$ such that $|V^h(x) - V^0(x)| < \varepsilon$ for all $0 < h \le h_0$ and all $x \in G^h$.*

Proof. Part (i) is proved, in a somewhat more general setting, as Theorem 5.4 in [5]. If part (ii) is false, then there are $\varepsilon > 0$ and a sequence $x^h \in G^h$ with $h \to 0$ such that $|V^h(x^h) - V^0(x^h)| > \varepsilon$ for each h. Since $\bar{G}$ is compact and V^0 is uniformly continuous on $\bar{G}$, we can extract a subsequence such that $x^h \to x \in \bar{G}$ and $|V^h(x^h) - V^0(x)| > \varepsilon/2$ for each h, which contradicts part (i) of the theorem. □

To facilitate treating the optimal trajectories and controls in the framework of convergence in distribution, we adopt some standard definitions. We treat the processes X^h as random variables taking values in $\mathcal{D}([0,\infty);\mathbb{R}^n)$, the space of $\mathbb{R}^n$-valued functions that are continuous from the right and have limits on the left. With the Skorokhod metric, $\mathcal{D}([0,\infty);\mathbb{R}^n)$ is a complete separable metric space [4], and convergence of a sequence in $\mathcal{D}([0,\infty);\mathbb{R}^n)$ is equivalent to convergence of that sequence

in $\mathcal{D}([0,S];\mathbb{R}^n)$ for each $S<+\infty$. If a sequence in $\mathcal{D}([0,\infty);\mathbb{R}^n)$ converges to a continuous function under the Skorokhod metric, then it also converges in the uniform norm $|||\cdot|||_S$ for each $S<+\infty$.

We also consider the space of relaxed controls. A relaxed control is an element of $\mathcal{R}(U\times[0,\infty))$, the space of all Borel measures ν on $U\times[0,\infty)$ such that $\nu(\mathbb{R}^n\times[0,S])=S$ for each $S\le+\infty$, where $U\subset\mathbb{R}^n$ is the compact control set from Lemma 3.3. This space can be metrized as a complete separable metric space with a metric such that $\nu_k\to\nu$ if and only if the restriction of ν_k to $U\times[0,S]$ converges weakly to the restriction of ν to $U\times[0,S]$ for all $S\le+\infty$ [19, section 9.5]. The second marginal of any measure $\nu\in\mathcal{R}(U\times[0,\infty))$ is a Lebesgue measure, so the decomposition $\nu(du\times dt)=\nu_t(du)dt$ holds, where ν_t is a probability measure for each $t\ge0$. If ν is a random variable, then this decomposition can be done so that it holds almost surely and so that for all $t\ge0$, ν_t is a random variable. We note that the following version of Fatou's lemma holds [4, Theorems 5.1 and 5.3]. If $\nu_k\to\nu$, then

$$\liminf_{k\to\infty}\int_{U\times[0,S]}f\,d\nu_k\ge\int_{U\times[0,S]}f\,d\nu \tag{4.1}$$

for any $S<+\infty$ and for any continuous nonnegative function f on the space $U\times[0,\infty)$.

For $h>0$ and for each $t\ge0$, let $\nu_t^h=\delta_{u^h(X^h(t))}$, where δ_u is the probability measure on U that places unit mass at the point u, and u^h is the optimal feedback control for the prelimit problem with parameter h. The corresponding optimal relaxed control is the measure valued random variable given by $\nu^h(A\times A')=\int_{A'}\nu_t^h(A)dt$ for Borel sets $A\subset U$ and $A'\subset[0,\infty)$. In terms of the optimal relaxed control measures, the inequality

$$V^h(x)\ge E_x\int_{U\times[0,\tau_N^h]}L(X^h(t),u)\nu^h(du\times dt) \tag{4.2}$$

holds for each $x\in N^h$. Equality may not hold in (4.2) because it is possible to have $X^h(\tau_N^h)\notin\partial G$; for equality to hold, we would need to add $E_xV^h(X^h(\tau_N^h))\ge0$ to the right-hand side of expression (4.2). For initial conditions in the region of strong regularity N, we can similarly define ν^0 to be the measure in $\mathcal{R}(U\times[0,\infty))$ with first marginals $\nu_t^0=\delta_{u^0(X^0(t))}$. Since ν^0 is not a random variable, an analogue to (4.2) holds for V^0 without the expectation:

$$V^0(x)=\int_{U\times[0,\tau^0]}L(X^0(t),u)\nu^0(du\times dt). \tag{4.3}$$

Notice that the inequality in (4.2) is replaced by equality in (4.3) because τ^0 is the exit time of X^0 from G. The proof of the following lemma is nearly identical to the proof of Lemma 5.3 in [5]. The only necessary modification is to use the martingale estimate from Lemma 3.1 in place of an analogous estimate obtained by applying a standard conditioning argument to the discrete time processes in [5].

LEMMA 4.3. *For $h>0$, let $x^h\in N^h$ be such that $x^h\to x\in\bar N$ as $h\to0$. Then, using these initial conditions, the random variables (X^h,ν^h) are tight. Furthermore, for any subsequence along which the limit*

$$(X^h,\nu^h)\to(X,\nu)$$

holds in the sense of distributions,

$$X(\cdot) = x + \int_0^{\cdot} \int_U u\, \nu_s(du)ds \tag{4.4}$$

*is valid w.p.*1.

Given the tightness from Lemma 4.3 and the convergence of the value functions from Theorem 4.2, we can use the uniqueness of optimal trajectories in regions of strong regularity for the limit problem to prove that the optimal trajectories and controls converge in distribution to the appropriate limit quantities. That is the conclusion of the next lemma.

LEMMA 4.4. *Let $x^h \in N^h$ be such that $x^h \to x \in \bar{N}$ as $h \to 0$. Then, using these initial conditions, the limit $(X^h, \nu^h) \to (X^0, \nu^0)$ holds in the sense of distributions as $h \to 0$.*

Proof. We consider the τ_N^h as random variables taking values in the compactified space $[0, \infty]$. Then Lemma 4.3 implies that the random variables (X^h, ν^h, τ_N^h) are tight. Thus, given the continuity of the process in expression (4.4), for any subsequence there is a further subsequence along which the weak convergence $(X^h, \nu^h, \tau_N^h) \to (X, \nu, \tilde{\tau})$ holds for some limit random variable taking values in

$$\mathcal{C}([0,\infty); \mathbb{R}^n) \times \mathcal{R}(U \times [0,\infty)) \times [0,\infty].$$

We will show that for any such limit, (X, ν) is w.p.1 equal to (X^0, ν^0).

By the Skorokhod representation theorem [10], we can consider a probability space on which the convergence is w.p.1. Since the limit trajectory X is continuous, the convergence $X^h \to X$ is uniform on compact intervals. Thus it is easy to verify that w.p.1 $\tilde{\tau} \geq \tau_N$, where τ_N is the first exit time of $X(t)$ from the interior of N. We obtain the following series of inequalities, each line of which is explained after the display:

$$\begin{aligned}
V^0(x) &= \lim_{h\to 0} V^h(x^h) \\
&\geq \lim_{h\to 0} E_{x^h} \int_{U\times[0,\tau_N^h)} L(X^h(t), u)\nu^h(du \times dt) \\
&\geq E_x \int_{U\times[0,\tilde{\tau})} L(X(t), u)\nu(du \times dt) \\
&\geq E_x \int_{U\times[0,\tau_N)} L(X(t), u)\nu(du \times dt) \\
&\geq E_x \int_0^{\tau_N} L(X(t), \dot{X}(t))dt \\
&\geq V^0(x).
\end{aligned}$$

The first line is due to part (i) of Theorem 4.2; the second line comes from the representation in (4.2); the third line is obtained by applying (4.1) along with the standard version of Fatou's lemma; the fourth line uses the fact that w.p.1 $\tilde{\tau} \geq \tau_N$; the fifth line follows from Jensen's inequality and the relation (4.4); and the final line is a consequence of the definition of $V^0(x)$.

Evidently, all of the inequalities in the previous display are in fact equalities. Thus, given the uniqueness of optimal trajectories in the regions of strong regularity, the last line implies that w.p.1, $X(t) = X^0(t)$ for $0 \leq t \leq \tau_N = \tau^0$. Recall that for

equality to occur in Jensen's inequality with a strictly convex function, the probability measure must be a point mass. Thus equality in the fifth line implies that w.p.1 $\nu_t = \nu_t^0$ for almost every (a.e.) $0 \le t \le \tau^0$. It remains to show that w.p.1, $X(t) = X^0(t)$ and $\nu_t = \nu_t^0$ for a.e. $\tau^0 \le t \le T$.

Since $|||\ X^h - X^0\ |||_{\tau^0}$ converges to zero w.p.1 it follows that $\|X^h(\tau^0) - X^0(\tau^0)\|$ converges to zero w.p.1 and hence in probability. Thus we can use the optimality of X^h, along with a uniform Lipschitz type bound on the V^h (see Lemma 3.3) and the lower bound on the running cost, to conclude that $\tau_N^h - \tau^0$ is small with arbitrarily high probability. Since the optimal controls are bounded, it follows that with high probability $\|X^h(t) - X^0(t)\|$ is arbitrarily small up to time $\tau^0 \vee \tau_N^h$. Furthermore, since $u^h = u^0$ outside of N, Gronwall's inequality implies that if $\|X^h(\tau^0 \vee \tau_N^h) - X^0(\tau^0 \vee \tau_N^h)\|$ is small, if $X^h(t)$ stays uniformly close to its mean after the stopping time $\tau^0 \vee \tau_N^h$, and if X^h does not return to N after it exits, then $\|X^h(t) - X^0(t)\|$ is small for all $\tau^0 \vee \tau_N^h \le t \le T$. This event occurs with arbitrarily high probability, so we conclude that $X(t) = X^0(t)$ w.p.1 for all $\tau^0 \le t \le T$. The verification of the needed fact that with high probability X^h does not return to N after it exits uses the observation that the extended optimal controls u^0 and u^h point away from the region N near the boundary section $N \cap \partial G$ and that the h-dynamics are one sided, so that whenever X^h exits from N at a point in $N \cap \partial G$ (which happens with high probability), it reaches the region where $u^h = 0$ before returning to N; see Figure 1. Finally, $\nu_t = \nu_t^0$ for a.e. $\tau^0 \le t \le T$ follows from the above argument since $u^h = u^0$ outside of N and u^0 is uniformly Lipschitz on $\mathbb{R}^n$. □

Proof of Lemma 4.1. Suppose that part (i) of the lemma is false. Then there exists $\varepsilon > 0$ along with a sequence $x^h \in B^h$ with $h \to 0$ such that

$$P\left[|||\ X_{x^h}^h - X_{x^h}^0\ |||_T > \varepsilon\right] \ge \varepsilon$$

for each h. Using the continuity of X^0 as a function of its initial condition from Lemma 2.4, we can extract a subsequence such that $x^h \to x \in \bar{B}$ and

$$P\left[|||\ X_{x^h}^h - X_x^0\ |||_T > \varepsilon/2\right] \ge \varepsilon$$

for each h. This is a contradiction, since the convergence in distribution of $X_{x^h}^h$ to the deterministic limit X_x^0 in Lemma 4.4 implies that $|||\ X_{x^h}^h - X_x^0\ |||_T \to 0$ in probability. Parts (iii)–(v) follow from part (i) and from Lemma 2.3.

The proof of part (ii) is slightly more subtle because we need to parlay the convergence of relaxed control measures from Lemma 4.4 into a statement about the convergence in $L^2([0,T];\mathbb{R}^n)$ of the controls $u^h(X^h(t))$. Consider a sequence of initial conditions $x^h \in B^h$ such that $x^h \to x \in \bar{B}$ as $h \to 0$. Using Lemma 4.4 and the Skorokhod representation theorem, we consider a probability space on which $\nu^h \to \nu^0$ w.p.1. Since $\nu^0(du \times dt) = \delta_{u^0(X^0(t))}(du)dt$ and $\nu^h(du \times dt) = \delta_{u^h(X^h(t))}(du)dt$, the w.p.1 convergence $\nu^h \to \nu^0$ implies

$$\begin{aligned}\int_0^T \|u^h(X^h(t)) - u^0(X^0(t))\|^2 dt &= \int_{U\times[0,T]} \|u - u^0(X^0(t))\|^2 \nu^h(du \times dt) \\ &\longrightarrow \int_{U\times[0,T]} \|u - u^0(X^0(t))\|^2 \nu^0(du \times dt) \\ &= \int_0^T \|u^0(X^0(t)) - u^0(X^0(t))\|^2 dt \\ &= 0,\end{aligned}$$

where the limit in the second line holds as $h \to 0$ w.p.1. Thus, switching from the Skorokhod space back to the original random variables, we can conclude that $\|u^h(X^h) - u^0(X^0)\|_T$ converges to zero in probability for any sequence of initial conditions $x^h \in B^h$ such that $x^h \to x \in \bar{B}$ as $h \to 0$. Now, as in the proof of part (i), this implies the convergence asserted by the lemma. □

It is useful to identify the suboptimal processes obtained by applying the limit optimal feedback control u^0 in the h-dynamics. For an initial condition in N^h, let $X^{h,0}$ be the process obtained by taking $\underline{u}^h = u^0$ in section 3, and let $m^{h,0}$ and $Y^{h,0}$ be the corresponding martingale and bounded variation parts indicated by the decomposition (3.2). Finally, define the exit time $\tau_N^{h,0} = \inf[t : X^{h,0}(t) \notin N^h]$ and the exit location $z_N^{h,0} = X^{h,0}(\tau_N^{h,0})$.

LEMMA 4.5. *Let T be the bound on the exit times from Lemma* 2.1. *For every $\varepsilon > 0$, there exists $h_0 > 0$ such that*

$$\text{(i)} \qquad P_x\left[\|\!| X_x^{h,0} - X_x^0 |\!\|_T > \varepsilon\right] < \varepsilon,$$

$$\text{(ii)} \qquad P_x\left[\tau_{x,N}^{h,0} > \tau_x + \varepsilon\right] < \varepsilon$$

holds for all $0 < h \le h_0$ and for all initial conditions $x \in N^h$, and such that

$$\text{(iii)} \qquad P_x\left[|\tau_{x,N}^{h,0} - \tau_x^0| > \varepsilon\right] < \varepsilon,$$

$$\text{(iv)} \qquad P_x\left[\|z_{x,N}^{h,0} - z_x^0\| > \varepsilon\right] < \varepsilon$$

holds for all $0 < h \le h_0$ and for all initial conditions $x \in B^h$.

Proof. For an initial condition $x \in B^h$, let $Z^h(t) = X^{h,0}(t) - X^0(t)$. Then by (3.2) we have

$$Z^h(t) = \int_0^t \left[u^0(X^{h,0}(s)) - u^0(X^0(s))\right] ds + m^{h,0}(t)$$

holding w.p.1 for any $t < +\infty$. Thus, if K is the uniform Lipschitz constant for u^0, then for any $0 \le \sigma < +\infty$

$$\|Z^h(t)\| \le \int_0^t K\|Z^h(s)\| ds + \|\!| m^{h,0}(t) |\!\|_\sigma$$

holds w.p.1 for each $0 \le t \le \sigma$. We can apply a version of Gronwall's inequality [10, Theorem A.6.4] to get the w.p.1 bound

$$\| X^{h,0}(t) - X^0(t) \|_\sigma \le \| m^{h,0}(t) \|_\sigma e^{K\sigma}. \tag{4.5}$$

Now, letting $\sigma = T$ in (4.5) and applying Lemma 3.1 with a standard submartingale inequality, we obtain part (i) of the lemma. Parts (ii)–(iv) follow directly from part (i) and from Lemma 2.3. □

5. Convergence of the feedback controls. The main results of this paper are Theorem 5.5 and Corollary 5.6. They state that in the set B_0, the optimal feedback controls $u^h(x)$ for the approximating control problems converge uniformly to $u^0(x)$, the optimal feedback control for the limit problem. Once we establish the analogous convergence of the approximate gradients $D^{h,\pm}V^h(x)$ to $DV^0(x)$, we will be able to use the uniqueness of the optimal control $u^0(x)$ to prove Theorem 5.5. Thus most of this section is devoted to establishing the following lemma.

LEMMA 5.1. *Let $x^h \in B_0^h$ be such that $x^h \to x \in \bar{B}_0$ as $h \to 0$. Then, as $h \to 0$,*

$$D^{h,\pm}V^h(x^h) \to DV^0(x).$$

There are two main steps in the proof of Lemma 5.1. First, we obtain the convergence of $D^{h,\pm}V^h(x)$ to $DV^0(x)$ in a neighborhood of $B \cap \partial G$. Then we use representations of $V^0(x)$ and $V^h(x)$ in terms of integrals along optimal trajectories to obtain the convergence of the $D^{h,\pm}V^h(x)$ to $DV^0(x)$ on the interior of the smaller region B_0. Our arguments are very similar in spirit to those used in the proof of [14, Lemma 5.5]. It is useful in what follows to define a compact notation for the running cost under a feedback control $u(x)$ by

$$L_u(x) = L(x, u(x)). \tag{5.1}$$

The following lemma establishes a geometric bound on the difference between V^h and V^0 on the set B.

LEMMA 5.2. *For any $m > 0$, there exists $h_0 > 0$ such that*

$$(1-m)V^0(x) \;\le\; V^h(x) \;\le\; (1+m)V^0(x)$$

holds for all $0 < h \le h_0$ and for all $x \in B^h$.

Proof. We prove this lemma in two steps, first considering the upper bound on $V^h(x)$ and then the lower bound.

Upper bound. Let $\mu > m$, and put $W^0 = (1+\mu)V^0$. It follows from the DPE (2.3) that

$$\langle u^{0,+}, D^{h,+}W^0 \rangle - \langle u^{0,-}, D^{h,-}W^0 \rangle + \tilde{L}_{u^0} = 0 \tag{5.2}$$

holds on N, where the modified cost $\tilde{L}_{u^0}(x)$ is defined on N by

$$\tilde{L}_{u^0} = (1+\mu)L_{u^0} + \langle u^0, DW^0 \rangle - \langle u^{0,+}, D^{h,+}W^0 \rangle + \langle u^{0,-}, D^{h,-}W^0 \rangle.$$

Note that since $L_{u^0}(x) \ge c_0 > 0$ and $W^0(x)$ is smooth, $\tilde{L}_{u^0}(x) \ge L_{u^0}(x)$ for $h > 0$ sufficiently small and for all $x \in N$. Since the generator in (5.2) corresponds to applying the feedback control u^0 in the h-dynamics, we can use a standard verification argument to establish for all $x \in B^h$ the representation

$$W^0(x) = E_x \left[\int_0^{\tau_N^{h,0}} \tilde{L}_{u^0}(X^{h,0}) dt + W^0(z_N^{h,0}) \right]. \tag{5.3}$$

We use part (ii) of Lemma 4.5 to obtain the uniform integrability of $\tau_N^{h,0}$ needed for the right-hand side of (5.3) to be finite.

For $x \in B^h$, we define

$$V^{h,0}(x) = E_x \left[\int_0^{\tau_N^{h,0}} L_{u^0}(X^{h,0}) dt + V^h(z_N^{h,0}) \right]. \tag{5.4}$$

Since the feedback control u^0 is suboptimal in the control problem with the h-dynamics, it follows from the strong Markov property that $V^h(x) \leq V^{h,0}(x)$ for all $x \in B^h$. Thus it suffices to establish the bound $V^{h,0}(x) \leq (1+m)V^0(x)$.

Let K be the bound on $V^h(x)$ from Lemma 3.3. Then the following series of inequalities holds for all sufficiently small $h > 0$ and for all $x \in B^h$:

$$\begin{aligned} V^{h,0}(x) &\leq W^0(x) + E_x \left[V^h(z_N^{h,0}) - W^0(z_N^{h,0}) \right] \\ &\leq (1+\mu)V^0(x) + E_x V^h(z_N^{h,0}) \\ &\leq (1+\mu)V^0(x) + K P_x \left[z_N^{h,0} \in G \right]. \end{aligned} \tag{5.5}$$

The first line uses the representations (5.3) and (5.4), along with the fact that $\tilde{L}_{u^0}(x) \geq L_{u^0}(x)$ for all $x \in N$; the second line uses the definition of $W^0(x)$ and the nonnegativity of $W^0(x)$ for all $x \in G$; and the third line uses the fact that $V^h(x) = 0$ for all $x \in \partial G$.

We now turn our attention to bounding the final term in the last display. Let $\varepsilon > 0$ be equal to $d(B, \partial N \cap G)$, so that $z_N^{h,0} \in G$ implies that $z_N^{h,0}$ is at least a distance of ε away from $z^0 \in B$; see Figure 3 before Lemma 5.3. Choose $0 < \delta < \varepsilon/2$ such that once an optimal trajectory for the limit problem with initial condition $x \in B$ gets to within δ of the boundary ∂G, it can travel no further than distance $\varepsilon/2$ before exiting. The existence of such a $\delta > 0$ is guaranteed by the nontangential exit property for the regions of strong regularity. Finally, let $0 < \eta < \delta < \varepsilon/2$ be chosen so that the conclusions of Lemma 2.3 hold. We obtain the following series of inequalities holding for all $x \in B^h$, each line of which is explained after the display:

$$\begin{aligned} P_x \left[z_N^{h,0} \in G \right] &\leq P_x \left[\| z_N^{h,0} - z^0 \| > \varepsilon \right] \\ &\leq P_x \left[\| \! | X^{h,0} - X^0 | \! \|_{\tau_N^{h,0} \wedge T} \geq \eta \right] \\ &\leq P_x \left[\| \! | m^{h,0}(t) | \! \|_{\tau_N^{h,0} \wedge T} \geq \eta e^{-K'T} \right] \\ &\leq (\eta e^{-K'T})^{-2} E_x \left[\| m^{h,0}(\tau_N^{h,0} \wedge T) \|^2 \right] \\ &\leq hCE_x \tau_N^{h,0} \\ &\leq hc_0^{-1} C V^{h,0}(x). \end{aligned} \tag{5.6}$$

The first line is a consequence of the fact that $z_N^{h,0} \in G$ can occur only if $\| z_N^{h,0} - z^0 \| > \varepsilon$; the second line follows from the choice of δ and η; the third line follows from (4.5)

with K' equal to the Lipschitz constant for $u^0(x)$; the fourth line is obtained by a standard submartingale inequality; the fifth line follows from Lemma 3.1 with C a composite finite constant; and the last line is a consequence of the definition of $V^{h,0}$ and of the lower bound c_0 on the running cost. We can combine the last lines of (5.5) and (5.6) to obtain the bound

$$(1 - hc_0^{-1}CK)V^{h,0}(x) \leq (1+\mu)V^0(x)$$

for sufficiently small $h > 0$ and for all $x \in B^h$. Since $V^h(x) \leq V^{h,0}(x)$, we complete the proof of the upper bound by taking $h > 0$ sufficiently small so that $(1+\mu)/(1 - hc_0^{-1}CK) \leq 1 + m$.

Lower bound. Let $\mu < m$, and this time put $W^0 = (1-\mu)V^0$. It follows from the DPE (2.3) that the relation

$$\langle u^h, DV^0\rangle + L_{u^h} - \phi^h = 0$$

holds on N^h for some nonnegative function ϕ^h. This, in turn, implies that

$$\langle u^{h,+}, D^{h,+}W^0\rangle - \langle u^{h,-}, D^{h,-}W^0\rangle + \tilde{L}^h_{u^h} = 0, \tag{5.7}$$

where $\tilde{L}^h_{u^h}(x)$ is defined on N^h by

$$\begin{aligned}\tilde{L}^h_{u^h} &= (1-\mu)L_{u^h} - (1-\mu)\phi^h \\ &\quad + \langle u^h, DW^0\rangle - \langle u^{h,+}, D^{h,+}W^0\rangle + \langle u^{h,-}, D^{h,-}W^0\rangle.\end{aligned}$$

Since $L_{u^h}(x) \geq c_0 > 0$ and $W^0(x)$ is smooth, the nonnegativity of $\phi^h(x)$ implies that $L_{u^h}(x) \geq \tilde{L}^h_{u^h}(x)$ for $h > 0$ sufficiently small and for all $x \in N^h$. The generator in (5.7) corresponds to applying the feedback control u^h in the h-dynamics, so we can use a standard verification argument to establish for all $x \in B^h$ the representation

$$W^0(x) = E_x\left[\int_0^{\tau_N^h} \tilde{L}^h_{u^h}(X^h)dt + W^0(z_N^h)\right]. \tag{5.8}$$

We use part (iii) of Lemma 4.1 to obtain the uniform integrability of τ_N^h needed for the right-hand side to be finite. The strong Markov property implies the representation

$$V^h(x) = E_x\left[\int_0^{\tau_N^h} L_{u^h}(X^h)dt + V^h(z_N^h)\right]. \tag{5.9}$$

Thus the following series of inequalities holds for all sufficiently small $h > 0$ and for all $x \in B^h$:

$$\begin{aligned} V^h(x) &\geq W^0(x) + E_x\left[V^h(z_N^h) - W^0(z_N^h)\right] \\ &\geq (1-\mu)V^0(x) - \sup_{y\in G^h}\left|V^h(y) - V^0(y)\right| P_x\left[z_N^h \notin \partial G\right] \\ &= (1-\mu)V^0(x) - o_h(1)P_x\left[z_N^h \notin \partial G\right]. \end{aligned} \tag{5.10}$$

The first line follows from the representations (5.8) and (5.9), along with the fact that $L_{u^h}(x) \geq \tilde{L}^h_{u^h}(x)$ for all $x \in N^h$; the second line uses the definition of $W^0(x)$,

the nonnegativity of $V^0(x)$ for all $x \in G$, and the fact that $V^h(x) = V^0(x) = 0$ for all $x \in \partial G$; finally, the third line uses part (ii) of Theorem 4.2, and the $o_h(1)$ term converges to zero as $h \to 0$, uniformly for all $x \in B^h$.

Let $\varepsilon > 0$ be equal to $d(B, \partial N \cap G)/2$. Notice that any trajectory with an initial condition $x \in B$ must travel a distance of at least 2ε if it is to exit N at a point which is not in ∂G; see Figure 3. Let $K \geq \sup_{u \in U} \|u\|$ be such that $\varepsilon/K \leq T$. Then, given the semimartingale decomposition in (3.2), $z_N^h \in \partial G$ will follow if $\tau_N^h < \varepsilon/K \leq T$ and if $\| \, m^h \, \|_{\tau_N^h \wedge T} < \varepsilon$. By Chebyshev's inequality and by the lower bound c_0 on the running cost, for each $x \in B^h$ we have

$$\begin{aligned} P_x \left[\tau_N^h \geq \varepsilon/K \right] &\leq (\varepsilon/K)^{-1} E_x \tau_N^h \\ &\leq (\varepsilon c_0/K)^{-1} V^h(x). \end{aligned}$$

As in (5.6), we can use a standard submartingale inequality and Lemma 3.1 to verify that

$$P_x \left[\| \, m^h \, \|_{\tau_N^h \wedge T} \geq \varepsilon \right] \leq hCV^h(x)$$

for all $x \in B^h$, where C is a finite constant. Thus, for a composite constant C', we conclude that

$$P_x \left[z_N^h \notin \partial G \right] \leq C' V^h(x)$$

for all $x \in B^h$. Combining this last bound with (5.10), we obtain

$$(1 + o_h(1)) V^h(x) \geq (1 - \mu) V^0(x)$$

for all $h > 0$ sufficiently small and for all $x \in B^h$. By taking $h > 0$ sufficiently small so that $(1 - \mu)/(1 + o_h(1)) \geq 1 - m$ on B^h, we complete the proof of the lower bound. □

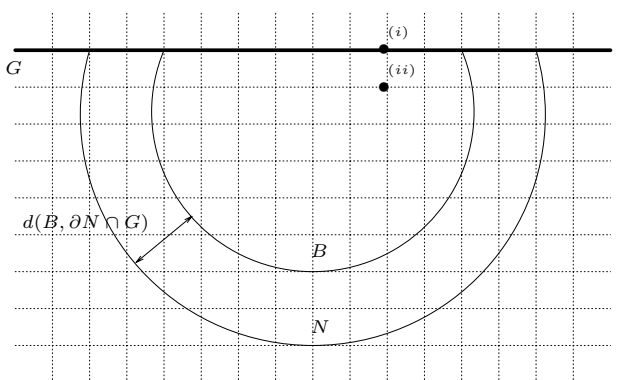

FIG. 3. *Boundary points.*

We are now able to prove that the approximations $D^{h,\pm} V^h(x)$ converge uniformly to the gradient $DV^0(x)$ at appropriate points x near the boundary of B. The two cases in the following lemma are illustrated in Figure 3.

LEMMA 5.3. *For $\varepsilon > 0$ there exists $h_0 > 0$ such that for all $0 < h \le h_0$ and for each $i = 1, \dots, n$,*

$$|D_i^{h,+}V^h(x) - D_iV^0(x)| \le \varepsilon \quad (resp.,\ |D_i^{h,-}V^h(x) - D_iV^0(x)| \le \varepsilon)$$

for each $x \in \mathbb{R}^n$ such that either (i) *$x \in \partial G$ and $x + he_i \in B^h$ (resp., $x - he_i \in B^h$), or* (ii) *$x \in B^h$ and $x + he_i \in \partial G$ (resp., $x - he_i \in \partial G$).*

Proof. For simplicity, we treat only case (i) with $x \in \partial G$ and $x + he_i \in B^h$. Given the smoothness of D_iV^0, the other cases follow easily from the same argument. Fix $\varepsilon > 0$, and let K be the uniform Lipschitz constant for $V^0(x)$. Then by Lemma 5.2, there exists $h_0 > 0$ such that

$$\left| \frac{V^h(x + he_i) - V^0(x + he_i)}{V^0(x + he_i)} \right| \le \frac{\varepsilon}{2} K^{-1} \tag{5.11}$$

for all $0 < h \le h_0$ and for all $x \in \mathbb{R}^n$ satisfying condition (i). For such x and h, put $y = x + he_i$. Then, using (5.11) along with the fact that $V^0(x)$ and $V^h(x)$ satisfy zero boundary conditions on ∂G, we obtain

$$\begin{aligned} |D_i^{h,+}V^h(x) - D_i^{h,+}V^0(x)| &= \left| \frac{V^h(y) - V^0(y)}{h} \right| \\ &= \left| \frac{V^0(y)}{h} \right| \left| \frac{V^h(y) - V^0(y)}{V^0(y)} \right| \\ &\le K \left| \frac{V^h(y) - V^0(y)}{V^0(y)} \right| \\ &\le \varepsilon/2. \end{aligned} \tag{5.12}$$

Now let $h_0 > 0$ be sufficiently small so that

$$|D_i^{h,+}V^0(x) - D_iV^0(x)| \le \varepsilon/2$$

for all $0 < h \le h_0$ and $x \in \bar{B}$. Then the result follows from (5.12). □

The first step in extending the result of Lemma 5.3 to the interior of B_0 is to establish a representation for $DV^0(x)$ in terms of an integral of the gradient in x of the running cost $L(x, u)$ along the optimal trajectories. The proof we give for this representation in the next lemma is fairly simple because it involves only deterministic trajectories. An analogous argument, involving stochastic trajectories, will be used to establish the convergence of $D^{h,\pm}V^h(x)$ to $DV^0(x)$ in the proof of Lemma 5.1. We also note that the representation in Lemma 5.4 can be obtained by the classical method of characteristics [13]. Recall the notation $L_u(x) = L(x, u(x))$ for a feedback control $u(x)$.

LEMMA 5.4. *The representation*

$$DV^0(x) = \int_0^{\tau_x^0} DL_{u^0}(X_x^0)dt + DV^0(z_x^0) \tag{5.13}$$

holds for all initial conditions $x \in \bar{B}_0$.

Proof. We fix $x \in \bar{B}_0$ and establish the representation separately for each component $D_iV^0(X)$ of the gradient $DV^0(x)$. Without loss of generality, assume that

$x + he_i \in N$ for all sufficiently small $h > 0$. Since $D_i^{h,+}V^0(x) \to D_iV^0(x)$ as $h \to 0$, we can establish the representation by proving separately the upper bound

$$\limsup_{h\to 0} D_i^{h,+}V^0(x) \le \int_0^{\tau_x^0} D_iL_{u^0}(X_x^0)dt + D_iV^0(z_x^0)$$

and the lower bound

$$\liminf_{h\to 0} D_i^{h,+}V^0(x) \ge \int_0^{\tau_x^0} D_iL_{u^0}(X_x^0)dt + D_iV^0(z_x^0).$$

Upper bound. Let $\hat{\tau}_h$ be the minimum of τ_x^0 and the first exit time from N of the shifted trajectory $X_x^0(t) + he_i$, and let $\hat{z}_h = X_x^0(\hat{\tau}_h)$. Using the fact that $X_x^0(t) + he_i$ is a suboptimal trajectory for the initial condition $x + he_i$, we obtain the relations

$$\begin{aligned} D_i^{h,+}V^0(x) &\le \frac{1}{h}\left[\int_0^{\hat{\tau}_h} L(X_x^0 + he_i, u^0(X_x^0))dt + V^0(\hat{z}_h + he_i)\right. \\ &\quad \left. - \int_0^{\hat{\tau}_h} L(X_x^0, u^0(X_x^0))dt - V^0(\hat{z}_h)\right] \\ &= \int_0^{\hat{\tau}_h} D_i^{h,+}L_{u^0}(X_x^0)dt + D_i^{h,+}V^0(\hat{z}_h). \end{aligned}$$

Lemma 2.3 implies that $|\hat{\tau}_h - \tau_x^0|$ and $\|\hat{z}_h - z_x^0\|$ both converge to zero as $h \to 0$, so we can apply the Lebesgue dominated convergence theorem to obtain the upper bound.

Lower bound. This time, let $\hat{\tau}_h$ be the minimum of $\tau_{x+he_i}^0$ and the first exit time from N of the shifted trajectory $X_{x+he_i}^0(t) - he_i$, and let $\hat{z}_h = X_{x+he_i}^0(\hat{\tau}_h)$. Using the fact that $X_{x+he_i}^0(t) - he_i$ is a suboptimal trajectory for the initial condition x, we obtain the relations

$$\begin{aligned} D_i^{h,+}V^0(x) &\ge \frac{1}{h}\left[\int_0^{\hat{\tau}_h} L(X_{x+he_i}^0, u^0(X_{x+he_i}^0))dt + V^0(\hat{z}_h)\right. \\ &\quad \left. - \int_0^{\hat{\tau}_h} L(X_{x+he_i}^0 - he_i, u^0(X_{x+he_i}^0))dt - V^0(\hat{z}_h - he_i)\right] \\ &= \int_0^{\hat{\tau}_h} D_i^{h,-}L_{u^0}(X_{x+he_i}^0)dt + D_i^{h,-}V^0(\hat{z}_h). \end{aligned}$$

By Lemma 2.4, $|||\, X_{x+he_i}^0 - X_x^0 \,|||_T$ converges to zero as $h \to 0$. Thus Lemma 2.3 implies that $|\hat{\tau}_h - \tau_x^0|$ and $\|\hat{z}_h - z_x^0\|$ both converge to zero as $h \to 0$, and we can apply the Lebesgue dominated convergence theorem to obtain the lower bound. □

We can now use the representation for $DV^0(x)$ obtained in Lemma 5.4 to prove Lemma 5.1. In fact, the proofs are essentially analogous. The primary difference is that the trajectories which arise in the proof of Lemma 5.1 are stochastic, so the analysis of the limits as $h \to 0$ is more involved.

Proof of Lemma 5.1. We give a detailed argument only for the convergence $D_i^{h,+}V^h(x^h) \to D_iV^0(x)$. Fix $x \in \bar{B}_0$, and let $x^h \in B_0^h$ be such that $x^h \to x$ as

$h \to 0$. As usual, we prove separately the upper bound

$$\limsup_{h\to 0} D_i^{h,+} V^h(x^h) \le D_i V^0(x)$$

and the lower bound

$$\liminf_{h\to 0} D_u^{h,+} V^h(x^h) \ge D_i V^0(x).$$

Upper bound. Let $\hat{\tau}_h$ be the minimum of $\tau^h_{x^h,N}$ and the first exit time from the interior of N of the shifted trajectory $X^h_{x^h}(t) + he_i$, and let $\hat{z}_h = X^h_{x^h}(\hat{\tau}_h)$. Using the fact that the trajectory $X^h_{x^h}(t) + he_i$ results when the suboptimal feedback control $\tilde{u}^h(\cdot) = u^h(\cdot - he_i)$ is applied in the h-dynamics with initial condition $x^h + e_i$, we obtain the relations

$$\begin{aligned} D_i^{h,+} V^h(x^h) &\le \frac{1}{h} E_x^h \left[\int_0^{\tilde{\tau}_h} L_{\tilde{u}^h}(X^h_{x^h} + he_i)dt + V^h(\tilde{z}_h + he_i) \right. \\ &\qquad \left. - \int_0^{\tilde{\tau}_h} L_{u^h}(X^h_{x^h})dt - V^h(\tilde{z}_h) \right] \\ &= E_{x^h} \left[\int_0^{\hat{\tau}_h} D_i^{h,+} L_{u^h}(X^h_{x^h})dt + D_i^{h,+} V^h(\hat{z}_h) \right]. \end{aligned}$$

In light of the representation (5.13), this implies that we can establish the upper bound by showing that

$$E_{x^h} \left| \int_0^{\hat{\tau}_h} D_i^{h,+} L(X^h_{x^h}, u^h(X^h_{x^h}))dt - \int_0^{\tau^0_x} D_i L(X^0_x, u^0(X^0_x))dt \right| \tag{5.14}$$

and

$$E_{x^h} \left| D_i^{h,+} V^h(\hat{z}_h) - D_i V^0(z^0_{x,N}) \right| \tag{5.15}$$

both converge to zero as $h \to 0$. Recall from Remark 3.2 and Lemma 3.3 that the pair $(X^h, u^h(X^h))$ takes values in a compact set for all initial conditions and for all $h \ge 0$. Thus the smoothness of L implies that we can use the triangle inequality to bound the quantity in (5.14) by a constant times

$$E_{x^h} \left[\|X^h_{x^h} - X^0_x\|_T + \|u^h(X^h_{x^h}) - u^0(X^0_x)\|_T + |\hat{\tau}_h - \tau^0_x| + hT \right]. \tag{5.16}$$

By combining parts (i) and (ii) of Lemma 4.1 with Lemma 2.4, we can establish that the first two terms in (5.16) converge to zero as $h \to 0$. Uniform integrability of the $\hat{\tau}_h$ follows from the strong Markov property and from the fact that Lemmas 2.3 and 2.4 together imply that $\hat{\tau}_h \le T$ with positive probability, uniformly in h. Thus, since $\hat{\tau}_h \to \tau^0_x$ in probability, the third term in (5.16) converges to zero as $h \to 0$, and this implies that the expression in (5.14) converges to zero as $h \to 0$.

Applying the triangle inequality to (5.15), we find that it is bounded by

$$E_{x^h} \left[|D_i^{h,+} V^h(\hat{z}_h) - D_i V^0(\hat{z}_h)| + |D_i V^0(\hat{z}_h) - D_i V^0(z^0_x)| \right]. \tag{5.17}$$

Combining part (i) of Lemma 4.1 with Lemmas 2.3 and 2.4, we conclude that $\hat{z_h}$ converges to z_x^0 in probability. The continuity result in Lemma 2.4 and the fact that B is a region of strong regularity imply that the set $\{z_y^0 : y \in \bar{B}_0\}$ is compactly contained in B, so the probability of $\hat{z}^h$ satisfying the conditions of Lemma 5.3 increases to one as $h \to 0$. Thus we can use Lemma 5.3 and the smoothness of $D_i V^0$ to conclude that each of the terms in (5.17) converges to zero as $h \to 0$. That, in turn, implies that (5.14) converges to zero as $h \to 0$ and completes the proof of the upper bound.

Lower bound. This time, we let $\hat{\tau}_h$ be the minimum of $\tau^h_{x+he_i}$ and the first exit time from N of the shifted trajectory $X^h_{x+he_i}(t) - he_i$, and we let $\hat{z}_h = X^h_{x+he_i}(\hat{\tau}_h)$. As in the proof of the upper bound, we obtain

$$D_i^{h,+}V^h(x^h) \quad \geq \quad E_{x^h}\left[\int_0^{\hat{\tau}_h} D_i^{h,-}L_{u^h}(X^h_{x^h+he_i})dt + D_i^{h,-}V^h(\hat{z}_h)\right].$$

See also the analogous relation which appears in the proof of the lower bound for Lemma 5.4. Just as in the proof of the upper bound, we show that the right-hand side of the above expression converges to $D_i V^0(x)$ as $h \to 0$. Notice that we need $x^h + he_1 \in B^h$ in order to apply Lemma 4.1. Since $x^h \in B_0$, this condition is satisfied for all sufficiently small $h > 0$. □

THEOREM 5.5. *Let $x^h \in B_0^h$ be such that $x^h \to x \in \bar{B}_0$ as $h \to 0$. Then, as $h \to 0$,*

$$u^h(x^h) \to u^0(x).$$

Proof. For each $u \in U$, we define

$$F^0(u) = \langle u, DV^0(x)\rangle + L(x,u)$$

and

$$F^h(u) = \langle u^+, D^{h,+}V^h(x^h)\rangle - \langle u^-, D^{h,-}V^h(x^h)\rangle + L(x^h,u).$$

Recall from Lemma 3.3 that the optimal controls u^0 and u^h take values in the compact set U. Thus there exists $\tilde{u} \in U$ such that in a subsequence, $u^h(x^h) \to \tilde{u}$ as $h \to 0$. It suffices to show that $\tilde{u} = u^0(x)$. Since x is in a region of strong regularity, it follows from the DPE (2.3) that the unique minimizer of $F^0(u)$ is given by $u^0(x)$. Similarly, the DPE (3.5) implies that $u^h(x^h)$ is a minimizer of $F^h(u)$. Also, notice that $F^0(u)$ is a continuous function of u and that Lemma 5.1 implies that $F^h(u)$ converges to $F^0(u)$ for each $u \in U$. Thus we obtain the following relations:

$$F^0(u^0(x)) \;=\; \lim_{h\to 0} F^h(u^0(x)) \;\geq\; \lim_{h\to 0} F^h(u^h(x^h)) \;=\; F^0(\tilde{u}).$$

Since $u^0(x)$ is the unique minimizer of F^0, it follows that $\tilde{u} = u^0(x)$. That completes the proof of the theorem. □

COROLLARY 5.6. *For any $\varepsilon > 0$, there exist $h_0 > 0$ such that*

$$\|u^h(x) - u^0(x)\| < \varepsilon$$

for all $0 < h \leq h_0$ and for all $x \in B_0^h$.

Proof. Since $u^0(x)$ is uniformly continuous on $\bar{B}_0$, the result follows from Theorem 5.5 and a standard argument by contradiction. □

FIG. 4. (a) *Exact solution;* (b) *approximate control.*

6. Computational examples. In this section, we present examples of approximations obtained by numerically solving the DPE (3.5) for the Markov chain optimal control problem. The fixed point of that equation is taken as the approximation to the value function $V^0(x)$, and the infimizing feedback control is taken as an approximate feedback control for the limit problem. The solution of (3.5) is obtained by using either Jacobi or Gauss–Seidel iteration in the equivalent equation (3.6), and we note that the infima at each step can be evaluated analytically [5]. When the Gauss–Seidel method is used, we observe in our examples that the number of iterations required to find the fixed point is essentially independent of the parameter h.

Example 1. Our first example is a minimum escape time problem on the unit square $G = [-1, 1] \times [-1, 1]$ in $\mathbb{R}^2$ with running cost

$$L(x, u) = \frac{1}{4}\|u\|^2 + 1.$$

The domain can be decomposed into four regions of strong regularity on which the value function is smooth and on which there is a smooth optimal feedback control. This decomposition and the optimal values are indicated in Figure 4(a). Arrows indicate the direction of the optimal velocity field. Figure 4(b) displays the values of the first component of the feedback control $u^h(x)$ for $h = 0.05$. We see that the discontinuities in the optimal control are resolved very sharply by our approximation scheme. In Table 1, we indicate errors in the approximations to the controls. The L^1 errors reported there are for the entire domain, while the L^∞ errors are for points inside the regions of strong regularity and a distance of at least 0.1 from the discontinuities. We also indicate the number of iterations required for the Gauss–Seidel method to achieve a residual of less than 10^{-8}, our standard tolerance. We see that the errors in the optimal controls become machine zero on the regions of strong regularity, which is in part a consequence of the fact that the value function is linear in those regions. Additionally, the optimal controls appear to converge in L^1 on the entire domain. Without detailed assumptions about the structure of the regions of strong regularity, our results do not necessarily predict that type of convergence. However, since we know for the present problem that the complement of the regions of strong regularity has Lebesgue measure zero, convergence in L^1 on the entire domain is, in fact, expected. Finally, similar error values are indicated in the second part of Table 1 for

TABLE 1
Escape time problem errors.

0.025	8	2.80 e − 01	2.31 e − 13	17	8.22 e − 01	3.94 e − 13

the escape time problem on the unit cube in $\mathbb{R}^3$.

Example 2. Our next example involves a value function which is obtained by perturbing the value function for the escape time problem in $\mathbb{R}^2$. We take care to modify the value function and the cost structure in such a way that we obtain a new problem with smooth data and with a solution that can be evaluated analytically. To that end, we introduce the C^∞ double bump function defined by

$$\chi(\xi) = \begin{cases} e^{-\lambda((\xi-m)^2-\sigma^2)^{-2}}, & \xi \in [m-\sigma, m+\sigma], \\ e^{-\lambda((-\xi-m)^2-\sigma^2)^{-2}}, & \xi \in [-m-\sigma, -m+\sigma], \\ 0 & \text{otherwise}, \end{cases}$$

where we use the parameter values $m = 0.7$, $\sigma = 0.5$, and $\lambda = 0.07$. Now we define a mollifier by

$$\Phi(x, y) = \chi(x + y)\chi(x - y)$$

for all (x, y) in the unit square, and then we define the value function $V^0(x, y)$ by multiplying the value function for the escape time problem by $1 + \Phi(x, y)$. The resulting function has the same regions of strong regularity as indicated in Figure 4(a), and it maintains the linear structure in a neighborhood of the discontinuities. In a similar spirit, we define

$$a(x, y) = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} + 3\sin(2\pi x)^2 \begin{bmatrix} 2 & 5 \\ 5 & 18 \end{bmatrix} \Phi(x, y)$$

and

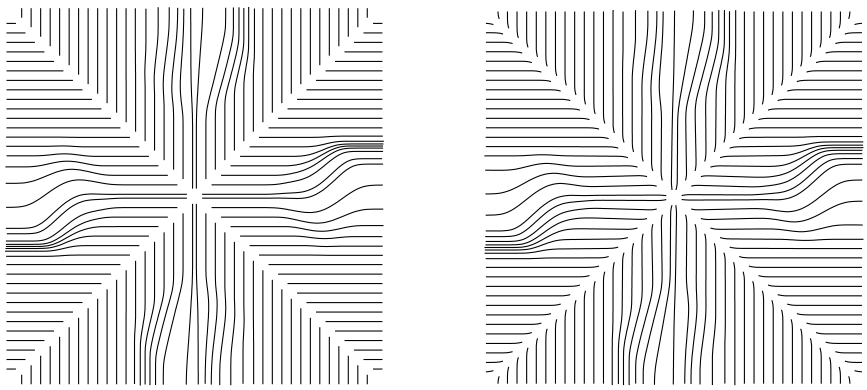
$$b(x, y) = \begin{bmatrix} 0 \\ 0 \end{bmatrix} + 5 \begin{bmatrix} x \\ y\sin((x^2 + y^2)^{1/2} - 1/2) \end{bmatrix} \Phi(x, y),$$

so that $a(x, y)$ is the identity and $b(x, y)$ is the zero vector in a neighborhood of the discontinuities. Now we define $c(x, y)$ on the regions of strong regularity by

$$c(x, y) = (1/2)\Big\langle DV^0(x, y), a(x, y)DV^0(x, y)\Big\rangle - \Big\langle b(x, y), DV^0(x, y)\Big\rangle.$$

Our use of a mollifier in defining all of the relevant functions ensures that the cost function $c(x, y)$ extends smoothly to $c(x, y) = 1$ at the discontinuities, and it turns out that $V^0(x)$ solves the limit control problem for the indicated cost structure.

The optimal trajectories for this problem are indicated in Figure 5(a), while trajectories computed using the approximate optimal controls with $h = 0.025$ are shown in Figure 5(b). Clearly, the controls computed with our algorithm yield an excellent approximation to the optimal trajectories. In Table 2, we exhibit error values for the



(a) (b)

FIG. 5. (a) *Characteristics;* (b) *approximate characteristics.*

TABLE 2
Perturbed escape time problem errors.

h	Iter	L^1	L^∞ RSR
0.1	10	5.83 e − 01	2.66 e − 01
0.05	12	3.24 e − 01	1.59 e − 01
0.025	12	1.72 e − 01	8.94 e − 02

0.00625	12	4.55 e − 02	2.54 e − 02

approximations to the optimal control with the L^1 errors being on the entire domain and the L^∞ errors being for points a distance of at least 0.1 from the discontinuities. Evidently, both measures of the error are approximately proportional to h, and it is also worth noting that the number of iterations required for the Gauss–Seidel procedure to converge to the fixed point is essentially constant. In Figure 6, we display an approximation to the first component of the optimal control with $h = 0.05$ and the errors in the approximation to the control for $h = 0.05$. The discontinuities are resolved very sharply, and we can see that the errors are uniformly small within the regions of strong regularity

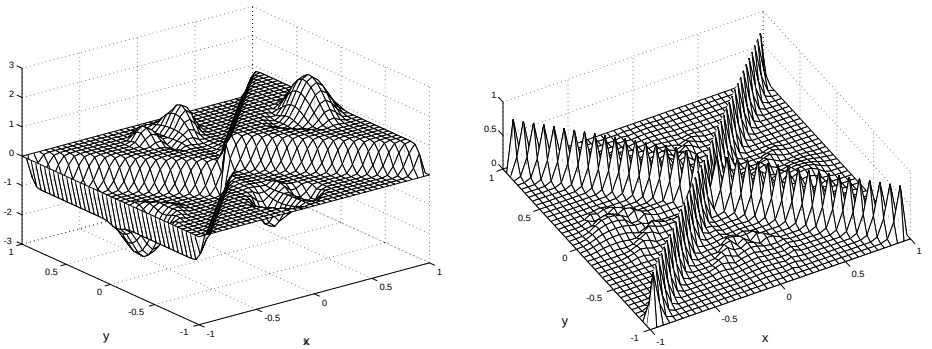
Example 3. Our final example is an application to the problem of finding geodesics on a surface, suggested in [20]. Given a surface $z(x, y)$ on the unit square in $\mathbb{R}^2$, the problem is to find the shortest path along the surface from a given point to the boundary. It is shown in [20, section 16.5] that the solution to this problem can be obtained from our optimal control problem with running cost specified by

$$a(x,y) = \begin{bmatrix} 1+z_y^2 & z_x z_y \\ z_x z_y & 1+z_x^2 \end{bmatrix}, \qquad b(x,y) = \begin{bmatrix} 0 \\ 0 \end{bmatrix},$$

and

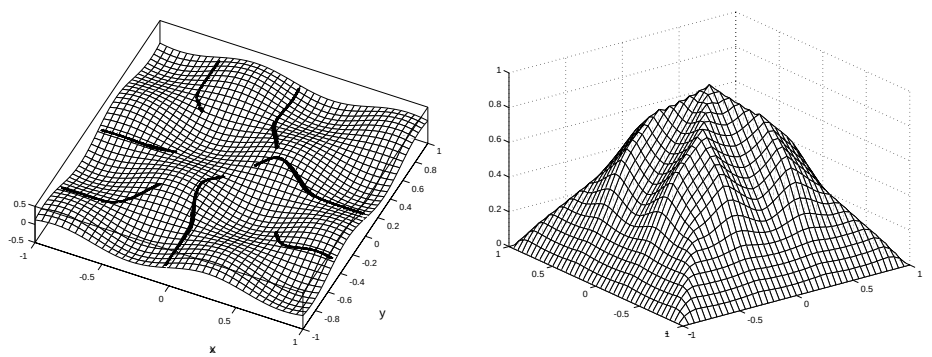
$$c(x,y) = (1/2)(1+z_x^2+z_y^2).$$

Geodesics are obtained by following the optimal trajectories from points on the interior of the unit square to the boundary. In Figure 7(a), we show several approximate



(a) (b)

FIG. 6. (a) *Approximate control;* (b) *control error.*



(a) (b)

FIG. 7. (a) *Geodesics;* (b) *value function.*

geodesics computed using our algorithm for the sinusoidal surface

$$z(x,y) = (1/4)\sin\left(\frac{7\pi}{4}x\right)\sin\left(\frac{7\pi}{4}y\right).$$

The approximate controls are computed on a grid with spacing $h = 0.05$, and the trajectories are integrated by a simple Euler method with linear interpolation. In Figure 7(b), we show the value function computed with $h = 0.05$ for the corresponding control problem, illustrating the fairly complex structure of the regions of strong regularity. Since we do not know the exact solution for this problem, it is not possible for us to present a numerical measure of accuracy for the approximate geodesics in Figure 7(a). However, Theorem 5.5 guarantees that for initial conditions in a region of strong regularity, the approximations will converge to the correct geodesics as $h \to 0$. Being that a more refined grid does not result in discernible changes to the paths indicated in Figure 7(a), we conclude that these are, in fact, good approximations to the exact geodesic curves.

ON A BOUNDARY CONTROL APPROACH TO DOMAIN EMBEDDING METHODS*

L. BADEA† AND P. DARIPA‡

Abstract. In this paper, we propose a domain embedding method associated with an optimal boundary control problem with boundary observations to solve elliptic problems. We prove that the optimal boundary control problem has a unique solution if the controls are taken in a finite dimensional subspace of the space of the boundary conditions on the auxiliary domain.

Using a controllability theorem due to J. L. Lions, we prove that the solutions of Dirichlet (or Neumann) problems can be approximated within any prescribed error, however small, by solutions of Dirichlet (or Neumann) problems in the auxiliary domain taking an appropriate subspace for such an optimal control problem. We also prove that the results obtained for the interior problems hold for the exterior problems. Some numerical examples are given for both the interior and the exterior Dirichlet problems.

1. Introduction.

The embedding or fictitious domain methods, which were developed especially in the seventies (see [6], [2], [34], [35], [28], or [14]), have been a very active area of research in recent years because of their appeal and potential for applications in solving problems in complicated domains very efficiently. In these methods, complicated domains ω, where solutions of problems may be sought, are embedded into larger domains Ω with simple enough boundaries so that solutions in these embedded domains can be constructed more efficiently. The use of these embedding methods is now commonplace for solving complicated problems arising in science and engineering. To this end, it is worth mentioning the domain embedding methods for Stokes equations (Borgers [5]), for fluid dynamics and electromagnetics (Dinh et al. [12]), and for the transonic flow calculation (Young et al. [36]).

In [3], an embedding method is associated with a distributed optimal control problem. There the problem is solved in an auxiliary domain Ω using a finite element method on a fairly structured mesh which allows the use of fast solvers. The auxiliary domain Ω contains the domain ω, and the solution in Ω is found as a solution of a distributed optimal control problem such that it satisfies the prescribed boundary conditions of the problem in the domain ω. The same idea is also used in [10], where a least squares method is used. In [13], an embedding method is proposed in which a combination of Fourier approximations and boundary integral equations is used. Essentially, there a Fourier approximation for a particular solution of the inhomogeneous equation in Ω is found, and then the solution in ω for the homogeneous equation is sought using the boundary integral methods.

In recent years, progress in this field has been substantial, especially in the use of the Lagrange multiplier techniques. In this connection, the works of Girault, Glowinski, Hesla, Joseph, Kuznetsov, Lopez, Pan, and Périaux (see [15], [16], [17], [18], and [19]) should be cited.

There are many problems for which an exact solution on some particular domains may be known or computed numerically within a good approximation very efficiently. In these cases, an embedding domain method associated with a boundary optimal control problem allows one to find solutions of the problems very efficiently in complicated domains. Specifically, the particular solution of the inhomogeneous equation can be used to reduce the problem to solving a homogeneous equation in ω subject to appropriate conditions on the boundary of the domain ω. This solution in the complicated domain ω can be obtained via an optimal boundary control problem where one finds the solution of the same homogeneous problem in the auxiliary domain Ω that would satisfy appropriate boundary conditions on the domain ω. We mention that the boundary control approach already has been used by Mäkinen, Neittaanmäki, and Tiba for optimal shape design and two-phase Stefan-type problems (see [29], [32]). Moreover, recently there has been enormous progress in shape optimization using the fictitious domain approaches. We can cite here, for instance, the works of Daňková, Haslinger, Klarbring, Makinen, Neittaanmäki, and Tiba (see [9], [22], [23], and [33]) among many others.

In section 2, an optimal boundary control problem involving an elliptic equation is formulated. In this formulation, the solution on the auxiliary domain Ω is sought such that it satisfies the boundary conditions on the domain ω. In general, such an optimal control problem leads to an ill posed problem, and, consequently, it may not have a solution.

Using a controllability theorem of J. L. Lions, it is proved here that the solutions of the problems in ω can be approximated within any specified error, however small, by the solutions of the problems in Ω for appropriate values of the boundary conditions. In section 3, it is shown that the optimal control problem has a unique solution in a finite dimensional space. Consequently, considering a family of finite dimensional subspaces with their union dense in the whole space of controls, we can approximate the solution of the problem in ω with the solutions of the problems in Ω using finite dimensional optimal boundary control problems. Since the values of the solutions in Ω are approximately calculated on the boundary of the domain ω, we study the optimal control problem with boundary observations in a finite dimensional subspace in section 4. In section 5, we extend the results obtained for the interior problems to the exterior problems. In section 6, we give some numerical examples for both bounded and unbounded domains. The numerical results are presented to show the validity and high accuracy of the method. Finally, in section 7 we provide some concluding remarks. There is still a large room for further improvement and numerical tests. In future works, we will apply this method in conjunction with fast algorithms (see [4], [7], [8]) to solve other elliptic problems in complicated domains.

2. Controllability. Let ω, $\Omega \in \mathcal{N}^{(1),1}$ (i.e., the maps defining the boundaries of the domains and their derivatives are Lipschitz continuous) be two bounded domains in $\mathbf{R}^N$ such that $\bar{\omega} \subset \Omega$. Their boundaries are denoted by γ and Γ, respectively.

In this paper, we use domain embedding and the optimal boundary control approach to solve the elliptic equation

$$Ay = f \quad \text{in } \omega, \tag{2.1}$$

subject to either Dirichlet boundary conditions

$$y = g_\gamma \quad \text{on } \gamma \tag{2.2}$$

or Neumann boundary conditions

$$\frac{\partial y}{\partial n_A(\omega)} = h_\gamma \quad \text{on } \gamma, \tag{2.3}$$

where $\frac{\partial}{\partial n_A(\omega)}$ is the outward conormal derivative associated with A.

We assume that the operator A is of the form

$$A = -\sum_{i,j=1}^{N} \frac{\partial}{\partial x_i}\left(a_{ij}\frac{\partial}{\partial x_j}\right) a_0$$

with $a_{ij} \in C^{(1),1}(\bar{\Omega})$, $a_0 \in C^{(0),1}(\bar{\Omega})$, $a_0 \geq 0$ in Ω, and there exists a constant $c > 0$ such that $\sum_{i,j=1}^{N} a_{ij}\xi_i\xi_j \geq c(\xi_1^2 + \cdots + \xi_N^2)$ in Ω for any $(\xi_1, \ldots, \xi_N) \in \mathbf{R}^N$. Also, we assume that $f \in L^2(\Omega)$, $g_\gamma \in L^2(\gamma)$, and $h_\gamma \in H^{-1}(\gamma)$.

For later use, we define the following. A function $y \in H^{1/2}(\omega)$ is called a solution of the Dirichlet problem (2.1)–(2.2) if it satisfies (2.1) in the sense of distributions and the boundary conditions (2.2) in the sense of traces in $L^2(\gamma)$. A function $y \in H^{1/2}(\omega)$ is called a solution of the Neumann problem (2.1), (2.3) if it satisfies (2.1) in the sense of distributions and the boundary conditions (2.3) in the sense of traces in $H^{-1}(\gamma)$ (see [27, Chap. 2, section 7]).

The Dirichlet problem (2.1)–(2.2) has a unique solution which depends continuously on the data

$$|y|_{H^{1/2}(\omega)} \leq C\{|f|_{L^2(\omega)} + |g_\gamma|_{L^2(\gamma)}\}. \tag{2.4}$$

If there exists a constant $c_0 > 0$ such that $a_0 \geq c_0$ in ω, then the Neumann problem (2.1), (2.3) has a unique solution which depends continuously on the data

$$|y|_{H^{1/2}(\omega)} \leq C\{|f|_{L^2(\omega)} + |h_\gamma|_{H^{-1}(\gamma)}\}. \tag{2.5}$$

If $a_0 = 0$ in ω, then the Neumann problem (2.1), (2.3) has a solution if

$$\int_\omega f + \int_\gamma h_\gamma = 0. \tag{2.6}$$

In this case, the problem has a unique solution in $H^{1/2}(\omega)/\mathbf{R}$ and

$$\inf_{r \in \mathbf{R}} |y + r|_{H^{1/2}(\omega)} \leq C\{|f|_{L^2(\omega)} + |h_\gamma|_{H^{-1}(\gamma)}\}. \tag{2.7}$$

We also remark that the solution of problem (2.1)–(2.2) can be viewed (see [27, Chap. 2, section 6]) as the solution of the problem

$$\begin{aligned} &y \in H^{1/2}(\omega) : \int_\omega yA^*\psi = \int_\omega f\psi - \int_\gamma g_\gamma \frac{\partial \psi}{\partial n_{A^*}(\omega)} \\ &\text{for any } \psi \in H^2(\omega),\ \psi = 0 \text{ on } \gamma, \end{aligned} \tag{2.8}$$

and that a solution of problem (2.1), (2.3) is also solution of the problem

$$\begin{aligned} &y \in H^{1/2}(\omega) : \int_\omega yA^*\psi = \int_\omega f\psi + \int_\gamma h_\gamma\psi \\ &\text{for any } \psi \in H^2(\omega),\ \frac{\partial \psi}{\partial n_{A^*}(\omega)} = 0 \text{ on } \gamma, \end{aligned} \tag{2.9}$$

where A^* is the adjoint operator of A given by

$$A^* = -\sum_{i,j=1}^{N} \frac{\partial}{\partial x_i}\left(a_{ji}\frac{\partial}{\partial x_j}\right) + a_0.$$

Evidently, the above results also hold for problems in the domain Ω.

We consider in the following only the cases in which the above problems have unique solutions, i.e., the Dirichlet problems, and we assume in the case of the Neumann problems that there exists a constant $c_0 > 0$ such that $a_0 \geq c_0$ in Ω.

Below we use the notations and the notions of optimal control from Lions [26]. First, we study the controllability of the solutions of the above two problems (defined by (2.1)–(2.3)) in ω with the solutions of a Dirichlet problem in Ω. Let

$$\mathcal{U} = L^2(\Gamma) \tag{2.10}$$

be the space of controls. The state of the system for a control $v \in L^2(\Gamma)$ is given by the solution $y(v) \in H^{1/2}(\Omega)$ of the following Dirichlet problem:

$$\begin{array}{lll} Ay(v) = f & \text{in} & \Omega, \\ y(v) = v & \text{on} & \Gamma. \end{array} \tag{2.11}$$

In the case of the Dirichlet problem (2.1)–(2.2), the space of observations is taken to be

$$\mathcal{H} = L^2(\gamma), \tag{2.12}$$

and the cost function is given by

$$J(v) = \frac{1}{2}|y(v) - g_\gamma|^2_{L^2(\gamma)}, \tag{2.13}$$

where $v \in L^2(\Gamma)$ and $y(v)$ is the solution of problem (2.11). For the Neumann problem given by (2.1) and (2.3), the space of observations is taken to be

$$\mathcal{H} = H^{-1}(\gamma), \tag{2.14}$$

and the cost function is given by

$$J(v) = \frac{1}{2}\left|\frac{\partial y(v)}{\partial n_A(\omega)} - h_\gamma\right|^2_{H^{-1}(\gamma)}. \tag{2.15}$$

Remark 2.1. Since $y(v) \in H^{1/2}(\Omega)$ and $Ay(u) = f \in L^2(\Omega)$, we have $y(v) \in H^2(D)$ for any domain D which satisfies $\bar{\omega} \subset D \subset \bar{D} \subset \Omega$ (see [30, Chap. 4, section 1.2, Theorem 1.3], for instance). Therefore, $y(v) \in H^{3/2}(\gamma)$ with the same values on both the sides of γ. Also, $\frac{\partial y(v)}{\partial n_A(\omega)} \in H^{1/2}(\gamma)$, $\frac{\partial y(v)}{\partial n_A(\Omega-\bar{\omega})} \in H^{1/2}(\gamma)$, and $\frac{\partial y(v)}{\partial n_A(\omega)} + \frac{\partial y(v)}{\partial n_A(\Omega-\bar{\omega})} = 0$. Consequently, the above two cost functions make sense.

PROPOSITION 2.1. *A control $u \in L^2(\Gamma)$ satisfies $J(u) = 0$, where the control function is given by* (2.13)*, if and only if the solution of* (2.11) *for $v = u$, $y(u) \in H^{1/2}(\Omega)$ satisfies*

$$\begin{array}{ll} Ay(u) = f & \text{in } \Omega - \bar{\omega}, \\ y(u) = y & \text{on } \gamma, \\ \frac{\partial y(u)}{\partial n_A(\Omega-\bar{\omega})} + \frac{\partial y}{\partial n_A(\omega)} = 0 & \text{on } \gamma, \end{array} \tag{2.16}$$

and

$$y(u) = y \quad \text{in } \omega, \tag{2.17}$$

where y is the solution of the Dirichlet problem defined by (2.1) *and* (2.2) *in the domain ω. The same result holds if the control function is given by* (2.15) *and y is the solution of the Neumann problem* (2.1) *and* (2.3).

Proof. Let $y(u) \in H^{1/2}(\Omega)$ be the solution of problem (2.11) corresponding to an $u \in L^2(\Gamma)$ such that $J(u) = 0$ with the control function given by (2.13). Consequently, $y(u)$ verifies (2.1) in the sense of distributions and the boundary condition (2.2) in the sense of traces. It gives $y(u) = y$ in ω. Since $y(u)$ satisfies (2.11) in $\Omega - \bar{\omega}$ in the sense of distributions, then, evidently, $y(u)$ is a solution of the equation in (2.16). From (2.17) and Remark 2.1, we obtain that $y(u)$ also satisfies the two boundary conditions of (2.16). The reverse implication is evident.

The same arguments also hold for the Neumann problem defined by (2.1) and (2.3) and the control function given by (2.15). □

Since (2.16) is not a properly posed problem, it follows from the above proposition that the optimal control might not exist. However, J. L. Lions proves in [26, Chap. 2, section 5.3, Theorem 5.1] a controllability theorem which can be directly applied to problem (2.11). We mention this theorem below.

LIONS'S CONTROLLABILITY THEOREM. *The set $\{\frac{\partial z_0(v)}{\partial n_A(\Omega-\bar{\omega})} \in H^{-1}(\gamma) : v \in L^2(\Gamma)\}$ is dense in $H^{-1}(\gamma)$, where $z_0(v) \in H^{1/2}(\Omega - \bar{\omega})$ is the solution of the problem*

$$\begin{aligned} &Az_0(v) = 0 && \text{in } \Omega - \bar{\omega}, \\ &z_0(v) = v && \text{on } \Gamma, \\ &z_0(v) = 0 && \text{on } \gamma. \end{aligned}$$

Now, we can easily prove the following lemma.

LEMMA 2.2. *For any $g \in L^2(\gamma)$, the set $\{\frac{\partial z(v)}{\partial n_A(\Omega-\bar{\omega})} \in H^{-1}(\gamma) : v \in L^2(\Gamma)\}$ is dense in $H^{-1}(\gamma)$, where $z(v) \in H^{1/2}(\Omega - \bar{\omega})$ is the solution of the problem*

$$\begin{aligned} &Az(v) = f && \text{in } \Omega - \bar{\omega}, \\ &z(v) = v && \text{on } \Gamma, \\ &z(v) = g && \text{on } \gamma. \end{aligned} \tag{2.18}$$

Proof. Let $z \in H^{1/2}(\Omega - \bar{\omega})$ be the solution of the problem

$$\begin{aligned} &Az = f && \text{in } \Omega - \bar{\omega}, \\ &z = 0 && \text{on } \Gamma, \\ &z = g && \text{on } \gamma. \end{aligned}$$

Using $z_0(v) = z(v) - z$ in the Lions controllability theorem, we get that the set $\{\frac{\partial(z(v)-z)}{\partial n_A(\Omega-\bar{\omega})} \in H^{-1}(\gamma) : v \in L^2(\Gamma)\}$ is dense in $H^{-1}(\gamma)$. Hence the lemma follows. □

The following theorem proves controllability of the solutions of problems in ω by the solutions of Dirichlet problems in Ω. In the proof of this theorem below, we use the spaces Ξ^s introduced in Lions and Magenes [27, Chap. 2, section 6.3]. For the sake of completeness, we give definitions of these spaces Ξ^s.

Let $\rho(x)$ be a function in $\mathcal{D}(\bar{\Omega})$ which is positive in Ω and vanishes on Γ. We also assume that for any $x_0 \in \Gamma$, the limit

$$\lim_{x \to x_0 \in \Gamma} \frac{\rho(x)}{d(x, \Gamma)}$$

exists and is positive, where $d(x,\Gamma)$ is the distance from $x \in \Omega$ to the boundary Γ. Then, for $s = 0, 1, 2, \ldots$, the space Ξ^s is defined by

$$\Xi^s(\Omega) = \{u : \rho^{|\alpha|} D^\alpha u \in L^2(\Omega), |\alpha| \le s\}.$$

With the norm

$$||u||_{\Xi^s(\Omega)} = \sum_{|\alpha| \le s} ||\rho^{|\alpha|} D^\alpha u||_{L^2(\Omega)},$$

the space $\Xi^s(\Omega)$ is a Hilbert space, and

$$\Xi^0(\Omega) = L^2(\Omega), \quad H^s(\Omega) \subset \Xi^s(\Omega) \subset L^2(\Omega), \quad \text{and} \quad \mathcal{D}(\Omega) \text{ is dense in } \Xi^s(\Omega).$$

Now, for a positive noninteger real $s = k+\theta$ with k the integer part of s and $0 < \theta < 1$, the space Ξ^s is, as in the case of the spaces H^s, the intermediate space

$$\Xi^s(\Omega) = [\Xi^{k+1}(\Omega), \Xi^k(\Omega)]_{1-\theta}.$$

Finally, for negative real values $-s$, $s > 0$, the space $\Xi^{-s}(\Omega)$ is the dual space of $\Xi^s(\Omega)$, $(\Xi^s(\Omega))'$.

THEOREM 2.3. *The set $\{y(v)_{|\omega} : v \in L^2(\Gamma)\}$ is dense, using the norm of $H^{1/2}(\omega)$, in $\{y \in H^{1/2}(\omega) : Ay = f \text{ in } \omega\}$, where $y(v) \in H^{1/2}(\Omega)$ is the solution of the Dirichlet problem* (2.11) *for a given $v \in L^2(\Gamma)$.*

Proof. Let us consider $y \in H^{1/2}(\omega)$ such that $Ay = f$ in ω, and a real number $\varepsilon > 0$. We denote the traces of y on γ by $y = g \in L^2(\gamma)$ and $\frac{\partial y}{\partial n_A(\omega)} = h \in H^{-1}(\gamma)$. From the previous lemma, it follows that there exists $v_\varepsilon \in L^2(\Gamma)$ such that the solution $z(v_\varepsilon) \in H^{1/2}(\Omega - \bar{\omega})$ of problem (2.18) satisfies

$$\left| \frac{\partial z(v_\varepsilon)}{\partial n_A(\Omega - \bar{\omega})} + h \right|_{H^{-1}(\gamma)} < \varepsilon.$$

Let $y(v_\varepsilon)$ be the solution of the Dirichlet problem (2.11) corresponding to v_ε, and let us define

$$y_\varepsilon = \begin{cases} y & \text{on } \omega, \\ z(v_\varepsilon) & \text{on } \Omega - \bar{\omega}. \end{cases}$$

Then $(y(v_\varepsilon) - y_\varepsilon) \in H^{1/2}(\Omega)$ and satisfies in the sense of distributions the equation

$$A(y(v_\varepsilon) - y_\varepsilon) = \tfrac{\partial z(v_\varepsilon)}{\partial n_A(\Omega - \bar{\omega})} + h \quad \text{in } \Omega$$

and the boundary conditions

$$y(v_\varepsilon) - y_\varepsilon = 0 \quad \text{on } \Gamma.$$

Consider, as in Remark 2.1, a fixed domain D such that $\bar{\omega} \subset D \subset \bar{D} \subset \Omega$. Then, for any $\psi \in \mathcal{D}(\Omega)$, we have $\int_\Omega A(y(v_\varepsilon) - y_\varepsilon)\psi = \int_\gamma (\frac{\partial z(v_\varepsilon)}{\partial n_A(\Omega - \bar{\omega})} + h)\psi \le |\frac{\partial z(v_\varepsilon)}{\partial n_A(\Omega - \bar{\omega})} + h|_{H^{-1}(\gamma)} |\psi|_{H^1(\gamma)} \le C(D)|\psi|_{H^{3/2}(D)}\varepsilon \le C(D)|\psi|_{\Xi^{3/2}(\Omega)}\varepsilon$, where $C(D)$ depends only on the domain D. Therefore,

$$|A(y(v_\varepsilon) - y_\varepsilon)|_{\Xi^{-3/2}(\Omega)} \le C(D)\varepsilon.$$

Taking into account the continuity of the solution on the data (see Lions and Magenes [27, Chap. 2, section 7.3, Theorem 7.4]), we get

$$|y(v_\varepsilon) - y_\varepsilon|_{H^{1/2}(\Omega)} \leq C(D)\varepsilon. \qquad \square$$

Below, the controllability of the solutions of the Dirichlet and the Neumann problems (given by (2.1), (2.2), and (2.1), (2.3), respectively) in ω by Neumann problems in Ω is discussed.

Now as a set of controls we can take the space

$$\mathcal{U} = H^{-1}(\Gamma), \tag{2.19}$$

and for a $v \in H^{-1}(\Gamma)$, the state of the system is the solution $y(v) \in H^{1/2}(\Omega)$ of the problem

$$\begin{aligned} Ay(v) &= f \quad \text{in} \quad \Omega, \\ \tfrac{\partial y(v)}{\partial n_A(\Omega)} &= v \quad \text{on} \quad \Gamma. \end{aligned} \tag{2.20}$$

We remark that

$$\begin{aligned} &i : \{y(v) \in H^{1/2}(\Omega) : v \in L^2(\Gamma),\ y(v) \text{ solution of problem (2.11)}\} \to \\ &\quad \{y(w) \in H^{1/2}(\Omega) : w \in H^{-1}(\Gamma),\ y(w) \text{ solution of problem (2.20)}\}, \\ &i(y(v)) = y(w) \Leftrightarrow y(v) = y(w) \text{ in } \Omega \end{aligned} \tag{2.21}$$

establish a bijective correspondence. Consequently, Proposition 2.1 also holds if the space of controls there is changed to $H^{-1}(\Gamma)$ and the states $y(v)$ of the system are solutions of problem (2.20). Theorem 2.3 in this case becomes the following theorem.

THEOREM 2.4. *The set* $\{y(v)_{|\omega} : v \in H^{-1}(\Gamma)\}$ *is dense, using the norm of* $H^{1/2}(\omega)$, *in* $\{y \in H^{1/2}(\omega) : Ay = f \text{ in } \omega\}$, *where* $y(v) \in H^{1/2}(\Omega)$ *is a solution of the Neumann problem* (2.20) *for a given* $v \in H^{-1}(\Gamma)$.

3. Controllability with finite dimensional spaces. Let $\{U_\lambda\}_\lambda$ be a family of finite dimensional subspaces of the space $L^2(\Gamma)$ such that, given (2.10) as a space of controls with the Dirichlet problems, we have

$$\bigcup_\lambda U_\lambda \text{ is dense in } \mathcal{U} = L^2(\Gamma). \tag{3.1}$$

For a $v \in L^2(\Gamma)$ we consider the solution $y'(v) \in H^{1/2}(\Omega)$ of the problem

$$\begin{aligned} Ay'(v) &= 0 \quad \text{in } \Omega, \\ y'(v) &= v \quad \text{on } \Gamma. \end{aligned} \tag{3.2}$$

We fix a U_λ. The cost functions J defined by (2.13) and (2.15) are differentiable and convex. Consequently, an optimal control

$$u_\lambda \in U_\lambda : J(u_\lambda) = \inf_{v \in U_\lambda} J(v) \tag{3.3}$$

exists if and only if it is a solution of the equation

$$u_\lambda \in U_\lambda : (y(u_\lambda), y'(v))_{L^2(\gamma)} = (g_\gamma, y'(v))_{L^2(\gamma)} \text{ for any } v \in U_\lambda, \tag{3.4}$$

when the control function is (2.13), and

$$u_\lambda \in U_\lambda : \left(\frac{\partial y(u_\lambda)}{\partial n_A(\omega)}, \frac{\partial y'(v)}{\partial n_A(\omega)}\right)_{H^{-1}(\gamma)} = \left(h_\gamma, \frac{\partial y'(v)}{\partial n_A(\omega)}\right)_{H^{-1}(\gamma)} \text{ for any } v \in U_\lambda, \tag{3.5}$$

when the control function is (2.15). Above, $y(u_\lambda)$ is the solution of problem (2.11) corresponding to u_λ, and $y'(v)$ is the solution of problem (3.2) corresponding to v. If $y_f \in H^2(\Omega)$ is the solution of the problem

$$\begin{array}{ll} Ay_f = f & \text{in } \Omega, \\ y_f = 0 & \text{on } \Gamma, \end{array} \tag{3.6}$$

then, for a $v \in L^2(\Gamma)$, we have

$$y(v) = y'(v) + y_f, \tag{3.7}$$

where $y(v)$ and $y'(v)$ are the solutions of problems (2.11) and (3.2), respectively. Therefore, we can rewrite problems (3.4) and (3.5) as

$$u_\lambda \in U_\lambda : (y'(u_\lambda), y'(v))_{L^2(\gamma)} = (g_\gamma - y_f, y'(v))_{L^2(\gamma)} \tag{3.8}$$

for any $v \in U_\lambda$, and

$$u_\lambda \in U_\lambda : \left(\frac{\partial y'(u_\lambda)}{\partial n_A(\omega)}, \frac{\partial y'(v)}{\partial n_A(\omega)}\right)_{H^{-1}(\gamma)} = \left(h_\gamma - \frac{\partial y_f}{\partial n_A(\omega)}, \frac{\partial y'(v)}{\partial n_A(\omega)}\right)_{H^{-1}(\gamma)} \tag{3.9}$$

for any $v \in U_\lambda$, respectively. Next, we prove the following lemma.

LEMMA 3.1. *For a fixed λ, let $\varphi_1, \ldots, \varphi_{n_\lambda}$, $n_\lambda \in \mathbf{N}$, be a basis of U_λ, and let $y'(\varphi_i)$ be the solution of problem* (3.2) *for $v = \varphi_i$, $i = 1, \ldots, n_\lambda$. Then $\{y'(\varphi_1)_{|\gamma}, \ldots, y'(\varphi_{n_\lambda})_{|\gamma}\}$ and $\{\frac{\partial y'(\varphi_1)}{\partial n_A(\omega)}|\gamma, \ldots, \frac{\partial y'(\varphi_{n_\lambda})}{\partial n_A(\omega)}|\gamma\}$ are linearly independent sets.*

Proof. From Remark 2.1, we have $y'(v) \in H^2(D)$ for any domain D which satisfies $\bar{\omega} \subset D \subset \bar{D} \subset \Omega$, and, consequently, $y'(v) \in H^{3/2}(\gamma)$ for any $v \in L^2(\Gamma)$. Assume that for $\xi_1, \ldots, \xi_{n_\lambda} \in \mathbf{R}$ we have $\xi_1 y'(\varphi_1) + \cdots + \xi_{n_\lambda} y'(\varphi_{n_\lambda}) = 0$ on γ. Then

$$y'(\xi_1\varphi_1 + \cdots + \xi_{n_\lambda}\varphi_{n_\lambda}) = 0 \quad \text{on } \gamma, \tag{3.10}$$

and therefore, $y'(\xi_1\varphi_1 + \cdots + \xi_{n_\lambda}\varphi_{n_\lambda}) = 0$ on ω. This implies that

$$\frac{\partial y'(\xi_1\varphi_1 + \cdots + \xi_{n_\lambda}\varphi_{n_\lambda})}{\partial n_A(\Omega - \bar{\omega})} = 0 \quad \text{on } \gamma. \tag{3.11}$$

From (3.10) and (3.11), we get $y'(\xi_1\varphi_1 + \cdots + \xi_{n_\lambda}\varphi_{n_\lambda}) = 0$ on $\Omega - \bar{\omega}$, and therefore, $\xi_1\varphi_1 + \cdots + \xi_{n_\lambda}\varphi_{n_\lambda} = y'(\xi_1\varphi_1 + \cdots + \xi_{n_\lambda}\varphi_{n_\lambda}) = 0$ on Γ, or $\xi_1 = \cdots = \xi_{n_\lambda} = 0$. The second part of the statement can be proved using similar arguments. □

The following proposition proves the existence and uniqueness of the optimal control when the states of the system are the solutions of the Dirichlet problems.

PROPOSITION 3.2. *Let us consider a fixed U_λ. Then problems* (3.8) *and* (3.9) *have unique solutions. Consequently, if the boundary conditions of Dirichlet problems* (2.11) *lie in the finite dimensional space U_λ, then there exists a unique optimal control of problem* (3.3) *corresponding to either the Dirichlet problem* (2.1), (2.2) *or the Neumann problem* (2.1), (2.3).

Proof. For a given λ, let V_λ denote the subspace of $L^2(\gamma)$ generated by $\{y'(\varphi_i)_{|\gamma}\}_{1 \le i \le n_\lambda}$, where $\{\varphi_i\}_{1 \le i \le n_\lambda}$ is a basis of U_λ, and $y'(\varphi_i)$ is the solution of problem (3.2) with $v = \varphi_i$. Since the norms $|\xi_1\varphi_1 + \cdots + \xi_{n_\lambda}\varphi_{n_\lambda}|_{L^2(\Gamma)}$ in U_λ, and $|\xi_1 y'(\varphi_1) + \cdots + \xi_{n_\lambda} y'(\varphi_{n_\lambda})|_{L^2(\gamma)}$ in V_λ are equivalent to the norm $(\xi_1^2 + \cdots + \xi_{n_\lambda}^2)^{1/2}$, the above lemma then implies that there exist two positive constants c and C such that

$$c|v|_{L^2(\Gamma)} \le |y'(v)|_{L^2(\gamma)} \le C|v|_{L^2(\Gamma)} \text{ for any } v \in U_\lambda.$$

Consequently, from the Lax–Milgram lemma we get that (3.8) has a unique solution. A similar reasoning proves that (3.9) also has a unique solution. This time we use the norm equivalence

$$c|v|_{L^2(\Gamma)} \leq \left| \frac{\partial y'(v)}{\partial n_A(\Omega - \bar{\omega})} \right|_{H^{-1}(\gamma)} \leq C|v|_{L^2(\Gamma)} \text{ for any } v \in U_\lambda$$

in the Lax–Milgram lemma. □

The following theorem proves the controllability of the solutions of the Dirichlet and Neumann problems in ω by the solutions of the Dirichlet problems in Ω.

THEOREM 3.3. *Let $\{U_\lambda\}_\lambda$ be a family of finite dimensional spaces satisfying* (3.1). *We associate the solution y of the Dirichlet problem* (2.1), (2.2) *in ω with problem* (3.3), *in which the cost function is given by* (2.13). *Also, the solution y of the Neumann problem* (2.1), (2.3) *is associated with problem* (3.3), *in which the cost function is given by* (2.15). *In both cases, there exists a positive constant C, and for any given $\varepsilon > 0$ there exists U_{λ_ε} such that*

$$|y(u_{\lambda_\varepsilon})_{|\omega} - y|_{H^{1/2}(\omega)} < C\varepsilon,$$

where $u_{\lambda_\varepsilon} \in U_{\lambda_\varepsilon}$ is the optimal control of the corresponding problem (3.3) *with $\lambda = \lambda_\varepsilon$, and $y(u_{\lambda_\varepsilon})$ is the solution of problem* (2.11) *with $v = u_{\lambda_\varepsilon}$.*

Proof. Let us consider an $\varepsilon > 0$ and $y \in H^{1/2}(\omega)$ as the solution of problem (2.1), (2.2). From Theorem 2.3, there exists $v_\varepsilon \in L^2(\Gamma)$ such that $y(v_\varepsilon) \in H^{1/2}(\Omega)$, the solution of problem (2.11) with $v = v_\varepsilon$, satisfies $|y - y(v_\varepsilon)_{|\omega}|_{H^{1/2}(\omega)} < \varepsilon$. Consequently, there exists a constant C_1 such that

$$|g_\gamma - y(v_\varepsilon)|_{L^2(\gamma)} < C_1\varepsilon. \tag{3.12}$$

Since $\cup_\lambda U_\lambda$ is dense in $L^2(\Gamma)$, there exist λ_ε and $v_{\lambda_\varepsilon} \in U_{\lambda_\varepsilon}$ such that $|v_\varepsilon - v_{\lambda_\varepsilon}|_{L^2(\Gamma)} < \varepsilon$, and then there exists a positive constant C_2 such that

$$|y(v_\varepsilon) - y(v_{\lambda_\varepsilon})|_{L^2(\gamma)} < C_2\varepsilon. \tag{3.13}$$

From (3.12) and (3.13) we get

$$|g_\gamma - y(v_{\lambda_\varepsilon})|_{L^2(\gamma)} < C_3\varepsilon$$

and, consequently,

$$|g_\gamma - y(u_{\lambda_\varepsilon})|_{L^2(\gamma)} < C_4\varepsilon,$$

where $u_{\lambda_\varepsilon} \in L^2(\Gamma)$ is the unique optimal control of problem (3.3) on U_{λ_ε} with the cost function given by (2.13). Therefore,

$$|y(u_{\lambda_\varepsilon})_{|\omega} - y|_{H^{1/2}(\omega)} < C\varepsilon.$$

A similar reasoning can be made for the solution $y \in H^{1/2}(\omega)$ of problem (2.1), (2.3). □

Using the basis $\varphi_1, \ldots, \varphi_{n_\lambda}$ of the space U_λ, we define the matrix

$$\Pi_\lambda = ((y'(\varphi_i), y'(\varphi_j))_{L^2(\gamma)})_{1 \leq i,j \leq n_\lambda} \tag{3.14}$$

and the vector

$$l_\lambda = ((g_\gamma - y_f, y'(\varphi_i))_{L^2(\gamma)})_{1 \leq i \leq n_\lambda}. \tag{3.15}$$

Then problem (3.8) can be written as

$$\xi_\lambda = (\xi_{\lambda,1}, \dots, \xi_{\lambda,n_\lambda}) \in \mathbf{R}^{n_\lambda} : \Pi_\lambda \xi_\lambda = l_\lambda. \tag{3.16}$$

Consequently, using Theorem 3.3, the solution y of problem (2.1), (2.2) can be obtained within any prescribed error by setting the restriction to ω of

$$y(u_\lambda) = \xi_{\lambda,1} y'(\varphi_1) + \cdots + \xi_{\lambda,n_\lambda} y'(\varphi_{n_\lambda}) + y_f, \tag{3.17}$$

where $\xi_\lambda = (\xi_{\lambda,1}, \dots, \xi_{\lambda,n_\lambda})$ is the solution of algebraic system (3.16). Above, y_f is the solution of problem (3.6), and $y'(\varphi_i)$ are the solutions of problems (3.2) with $v = \varphi_i$, $i = 1, \dots, n_\lambda$.

An algebraic system (3.16) is also obtained in the case of problem (3.9). This time the matrix of the system is given by

$$\Pi_\lambda = \left(\left(\frac{\partial y'(\varphi_i)}{\partial n_A(\omega)}, \frac{\partial y'(\varphi_j)}{\partial n_A(\omega)} \right)_{H^{-1}(\gamma)} \right)_{1 \le i,j \le n_\lambda}, \tag{3.18}$$

and the free term is

$$l_\lambda = \left(\left(h_\gamma - \frac{\partial y_f}{\partial n_A(\omega)}, \frac{\partial y'(\varphi_i)}{\partial n_A(\omega)} \right)_{H^{-1}(\gamma)} \right)_{1 \le i \le n_\lambda}. \tag{3.19}$$

Therefore, using Theorem 3.3, the solution y of problem (2.1), (2.3) can be estimated by (3.17). Also, y_f is the solution of problem (3.6), and $y'(\varphi_i)$ are the solutions of problems (3.2) with $v = \varphi_i$, $i = 1, \dots, n_\lambda$.

The case of the controllability with finite dimensional optimal controls for states of the system given by the solution of a Neumann problem is treated in a similar way. As in the previous section, the space of the controls is $\mathcal{U}$, given in (2.19), and the state of the system $y(v) \in H^{1/2}(\Omega)$ is given by the solution of Neumann problem (2.20) for a $v \in H^{-1}(\Gamma)$.

Let $\{U_\lambda\}_\lambda$ be a family of finite dimensional subspaces of the space $H^{-1}(\Gamma)$ such that

$$\bigcup_\lambda U_\lambda \text{ is dense in } \mathcal{U} = H^{-1}(\Gamma). \tag{3.20}$$

This time, the function $y'(v) \in H^{1/2}(\Omega)$ appearing in (3.4), (3.5), (3.8), and (3.9) is the solution of the problem

$$\begin{array}{ll} Ay'(v) = 0 & \text{in } \Omega, \\ \frac{\partial y'(v)}{\partial n_A(\Omega)} = v & \text{on } \Gamma \end{array} \tag{3.21}$$

for a $v \in H^{-1}(\Gamma)$. Also, $y_f \in H^2(\Omega)$ appearing in (3.7), (3.8), and (3.9) is the solution of the problem

$$\begin{array}{ll} Ay_f = f & \text{in } \Omega, \\ \frac{\partial y_f}{\partial n_A(\Omega)} = 0 & \text{on } \Gamma. \end{array} \tag{3.22}$$

With these changes, Lemma 3.1 also holds in this case, and the proof of the following proposition is similar to that of Proposition 3.2.

PROPOSITION 3.4. *For a given U_λ, the problems* (3.8) *and* (3.9) *have unique solutions. Consequently, if the boundary conditions of Neumann problems* (2.20) *lie in the finite dimensional space U_λ, then there exists a unique optimal control of problem* (3.3)*, corresponding to either Dirichlet problem* (2.1), (2.2) *or Neumann problem* (2.1), (2.3).

A proof similar to that given for Theorem 3.3 can also be given for the following theorem.

THEOREM 3.5. *Let $\{U_\lambda\}_\lambda$ be a family of finite dimensional spaces satisfying* (3.20). *We associate the solution $y \in H^{1/2}(\omega)$ of problem* (2.1), (2.2) *with problem* (3.3), *in which the cost function is given by* (2.13). *Also, the solution y of problem* (2.1), (2.3) *is associated with problem* (3.3), *in which the cost function is given by* (2.15). *In both cases, there exists a positive constant C, and for any given $\varepsilon > 0$ there exists λ_ε such that*

$$|y(u_{\lambda_\varepsilon})_{|\omega} - y|_{H^{1/2}(\omega)} < C\varepsilon,$$

where $u_{\lambda_\varepsilon} \in U_{\lambda_\varepsilon}$ is the optimal control of the corresponding problem (3.3) *with $\lambda = \lambda_\varepsilon$, and $y(u_{\lambda_\varepsilon})$ is the solution of problem* (2.20) *with $v = u_{\lambda_\varepsilon}$.*

Evidently, in the case of the controllability with solutions of Neumann problem (2.20) we can also write algebraic systems (3.16) using a basis $\varphi_1, \ldots, \varphi_{n_\lambda}$ of a given subspace U_λ of the space $\mathcal{U} = H^{-1}(\Gamma)$. As in the case of the controllability with solutions of the Dirichlet problem (2.11), these algebraic systems have unique solutions.

Theorems 3.3 and 3.5 prove the convergence of the embedding method associated with the optimal boundary control. An error analysis would be desirable, but it would go beyond the scope of this paper.

Remark 3.1. We have defined y_f as a solution of problems (3.6) or (3.22) in order to have $y(v) = y'(v) + y_f$ or $\frac{\partial y(v)}{\partial n_A(\Omega)} = \frac{\partial y'(v)}{\partial n_A(\Omega)} + \frac{\partial y_f}{\partial n_A(\Omega)}$, respectively, on the boundary Γ. In fact, we can replace $y(v)$ by $y'(v) + y_f$ in the cost functions (2.13) and (2.15) with $y_f \in H^2(\Omega)$ satisfying only

$$Ay_f = f \text{ in } \Omega, \tag{3.23}$$

and the results obtained in this section still hold.

Indeed, the two sets $\{y(v) = y'(v) + y_f \in H^{1/2}(\Omega) : v \in L^2(\Gamma)\}$ corresponding to y_f given by (3.23) and (3.6), $y'(v)$ being the solution of (3.2), are identical to the set $\{y(v) \in H^{1/2}(\Omega) : v \in L^2(\Gamma)\}$, $y(v)$ being the solution of (2.11). Also, the two sets $\{y(v) = y'(v) + y_f \in H^{1/2}(\Omega) : v \in H^{-1}(\Gamma)\}$ corresponding to y_f given by (3.23) and (3.22), $y'(v)$ being the solution of (3.21), are identical to the set $\{y(v) \in H^{1/2}(\Omega) : v \in H^{-1}(\Gamma)\}$, $y(v)$ being the solution of (2.20).

4. Approximate observations in finite dimensional spaces. In solving problems (3.8), (3.9), we require an appropriate interpolation which makes use of the values of $y'(v)$ computed only at some points on the boundary γ. We show below that using these interpolations, i.e., observations in finite dimensional subspaces, we can obtain the approximate solutions of problems (2.1), (2.2) and (2.1), (2.3).

As in the previous sections, we first deal with the case when the states of the system are given by the Dirichlet problem (2.11). Let U_λ be a fixed finite dimensional subspace of $\mathcal{U} = L^2(\Gamma)$ with the basis $\varphi_1, \ldots, \varphi_{n_\lambda}$.

Let us assume that for problem (2.1), (2.2), we choose a family of finite dimensional spaces $\{H_\mu\}_\mu$ such that

$$\bigcup_\mu H_\mu \text{ is dense in } \mathcal{H} = L^2(\gamma). \tag{4.1}$$

Similarly, for problem (2.1), (2.3) we choose the finite dimensional spaces $\{H_\mu\}_\mu$ such that

$$\bigcup_\mu H_\mu \text{ is dense in } \mathcal{H} = H^{-1}(\gamma). \tag{4.2}$$

The subspace H_μ given in (4.1) and (4.2) is a subspace of $\mathcal{H}$ given in (2.12) and (2.14), respectively.

An appropriate choice of H_μ is made based on the problem to be solved as discussed above. For a given φ_i, $i = 1, \dots, n_\lambda$, we consider below the solution $y'(\varphi_i)$ of problem (3.2) corresponding to $v = \varphi_i$, and we approximate its trace on γ by $y'_{\mu,i}$. Also, the approximation of $\frac{\partial y'(\varphi_i)}{\partial n_A(\omega)}$ on γ is denoted by $\frac{\partial y'_{\mu,i}}{\partial n_A(\omega)}$.

Since the system (3.16) has a unique solution, the determinants of the matrices Π_λ given in (3.14) and (3.18) are nonzero. Consequently, if $|y'(\varphi_i) - y'_{\mu,i}|_{L^2(\gamma)}$ or $|\frac{\partial y'(\varphi_i)}{\partial n_A(\omega)} - \frac{\partial y'_{\mu,i}}{\partial n_A(\omega)}|_{H^{-1}(\gamma)}$ are small enough, then the matrices

$$\Pi_{\lambda\mu} = ((y'_{\mu,i}, y'_{\mu,j})_{L^2(\gamma)})_{1\le i,j\le n_\lambda} \tag{4.3}$$

and

$$\Pi_{\lambda\mu} = \left(\left(\frac{\partial y'_{\mu,i}}{\partial n_A(\omega)}, \frac{\partial y'_{\mu,j}}{\partial n_A(\omega)} \right)_{H^{-1}(\gamma)} \right)_{1\le i,j\le n_\lambda} \tag{4.4}$$

have nonzero determinants. In this case, each of the algebraic systems

$$\xi_{\lambda\mu} = (\xi_{\lambda\mu,1}, \dots, \xi_{\lambda\mu,n_\lambda}) \in \mathbf{R}^{n_\lambda} : \Pi_{\lambda\mu}\xi_{\lambda\mu} = l_{\lambda\mu} \tag{4.5}$$

has a unique solution. In this system, the free term is

$$l_{\lambda\mu} = ((g_{\gamma\mu} - y_{f\mu}, y'_{\mu,i})_{L^2(\gamma)})_{1\le i\le n_\lambda} \tag{4.6}$$

if the matrix $\Pi_{\lambda\mu}$ is given by (4.3) and

$$l_{\lambda\mu} = \left(\left(h_{\gamma\mu} - \frac{\partial y_{f\mu}}{\partial n_A(\omega)}, \frac{\partial y'_{\mu,i}}{\partial n_A(\omega)} \right)_{H^{-1}(\gamma)} \right)_{1\le i\le n_\lambda} \tag{4.7}$$

if the matrix $\Pi_{\lambda\mu}$ is given by (4.4). Above, we have denoted by $g_{\gamma\mu}$ and $h_{\gamma\mu}$ some approximations in H_μ of g_γ and h_γ, respectively. Also, $y_{f\mu}$ and $\frac{\partial y_{f\mu}}{\partial n_A(\omega)}$ are some approximations of y_f and $\frac{\partial y_f}{\partial n_A(\omega)}$ in the corresponding H_μ of $L^2(\gamma)$ and $H^{-1}(\gamma)$, respectively, with $y_f \in H^2(\Omega)$ satisfying (3.23).

The solution y of problems (2.1), (2.2) and (2.1), (2.3) can be approximated with the restriction to ω of

$$y(u_{\lambda\mu}) = \xi_{\lambda\mu,1}y'(\varphi_1) + \cdots + \xi_{\lambda\mu,n_\lambda}y'(\varphi_{n_\lambda}) + y_f, \tag{4.8}$$

where $\xi_\lambda = (\xi_{\lambda\mu,1}, \dots, \xi_{\lambda\mu,n_\lambda})$ is the solution of appropriate algebraic system (4.5).

For a vector, $\xi = (\xi_1, \dots, \xi_{n_\lambda})$, we use the norm $|\xi| = \max_{1\le i\le n_\lambda} |\xi_i|$, and the corresponding matrix norm is denoted by $||\cdot||$. From (3.17) and (4.8) we have

$$|y(u_\lambda) - y(u_{\lambda\mu})|_{H^{1/2}(\omega)} \le C_\lambda |\xi_\lambda - \xi_{\lambda\mu}|, \tag{4.9}$$

where C_λ depends only on the basis in U_λ. From

$$||\Pi_\lambda^{-1} - \Pi_{\lambda\mu}^{-1}|| \leq \frac{||\Pi_\lambda^{-1}||||\Pi_\lambda - \Pi_{\lambda\mu}||}{1/||\Pi_\lambda^{-1}|| - ||\Pi_\lambda - \Pi_{\lambda\mu}||}$$

and algebraic systems (3.16) and (4.5), we have $\xi_\lambda = \Pi_\lambda^{-1} l_\lambda$ and $\xi_{\lambda\mu} = \Pi_{\lambda\mu}^{-1} l_{\lambda\mu}$ and we get that there exists $C_\lambda > 0$, depending on the basis in U_λ, such that

$$|\xi_\lambda - \xi_{\lambda\mu}| \leq C_\lambda \left(||\Pi_\lambda - \Pi_{\lambda\mu}|| + |l_\lambda - l_{\lambda\mu}|\right). \tag{4.10}$$

In the case of matrices (3.14) and (4.3) and the free terms (3.15) and (4.6), we have

$$\begin{aligned} ||\Pi_\lambda - \Pi_{\lambda\mu}|| &\leq C_\lambda \max_{1\leq i\leq n_\lambda} |y'(\varphi_i) - y'_{\mu,i}|_{L^2(\gamma)}, \\ |l_\lambda - l_{\lambda\mu}| &\leq C_\lambda \left(|g_\gamma - g_{\gamma\mu}|_{L^2(\gamma)} \right. \\ &\qquad \left. + |y_f - y_{f\mu}|_{L^2(\gamma)}\right) + C \max_{1\leq i\leq n_\lambda} |y'(\varphi_i) - y'_{\mu,i}|_{L^2(\gamma)}. \end{aligned} \tag{4.11}$$

Instead, if we take matrices (3.18) and (4.4) and the free terms (3.19) and (4.7), then we get

$$\begin{aligned} ||\Pi_\lambda - \Pi_{\lambda\mu}|| &\leq C_\lambda \max_{1\leq i\leq n_\lambda} \left|\frac{\partial y'(\varphi_i)}{\partial n_A(\omega)} - \frac{\partial y'_{\mu,i}}{\partial n_A(\omega)}\right|_{H^{-1}(\gamma)}, \\ |l_\lambda - l_{\lambda\mu}| &\leq C_\lambda \left(|h_\gamma - h_{\gamma\mu}|_{H^{-1}(\gamma)} + \left|\frac{\partial y_f}{\partial n_A(\omega)} - \frac{\partial y_{f\mu}}{\partial n_A(\omega)}\right|_{H^{-1}(\gamma)} \right) \\ &\qquad + C \max_{1\leq i\leq n_\lambda} |\frac{\partial y'(\varphi_i)}{\partial n_A(\omega)} - \frac{\partial y'_{\mu,i}}{\partial n_A(\omega)}|_{H^{-1}(\gamma)}, \end{aligned} \tag{4.12}$$

where C is a constant and C_λ depends on the basis in U_λ.

For states of the system given by the Neumann problem (2.20), U_λ is a subspace of $\mathcal{U} = H^{-1}(\Gamma)$. The material presented above for the case of the Dirichlet problems in Ω is applicable to the case of the Neumann problems in Ω, except for the difference that this time $y'(\varphi_i)$ are the solutions of problems (3.21) with $v = \varphi_i$, $i = 1, \ldots, n_\lambda$.

In both cases (i.e., when the control is affected via Dirichlet and Neumann problems), we obtain the following theorem from Theorems 3.3 and 3.5 and (4.9)–(4.12).

THEOREM 4.1. *Let $\{U_\lambda\}_\lambda$ be a family of finite dimensional spaces, either satisfying* (3.1) *if we consider problem* (2.11)*, or satisfying* (3.20) *if we consider problem* (2.20)*. Also, we associate problem* (2.1), (2.2) *or* (2.1), (2.3) *with a family of spaces $\{H_\mu\}_\mu$ satisfying* (4.1) *or* (4.2)*, respectively. Then, for any $\varepsilon > 0$, there exists λ_ε such that the following hold.*

(i) *If the space H_μ is taken such that $|y'(\varphi_i) - y'_{\mu,i}|_{L^2(\gamma)}$, $i = 1, \ldots, n_{\lambda_\varepsilon}$, are small enough, y is the solution of problem* (2.1)–(2.2)*, and $y(u_{\lambda_\varepsilon\mu})$ is given by* (4.8)*, in which $\xi_{\lambda\mu}$ is the solution of the algebraic system* (4.5) *with the matrix given by* (4.3) *and the free term given by* (4.6)*, then the algebraic system* (4.5) *has a unique solution and*

$$\begin{aligned} &|y(u_{\lambda_\varepsilon\mu})_{|\omega} - y|_{H^{1/2}(\omega)} < C\varepsilon \\ &+ C_{\lambda_\varepsilon} \left(|g_\gamma - g_{\gamma\mu}|_{L^2(\gamma)} + |y_f - y_{f\mu}|_{L^2(\gamma)} + \max_{1\leq i\leq n_\lambda} |y'(\varphi_i) - y'_{\mu,i}|_{L^2(\gamma)} \right). \end{aligned}$$

(ii) *If the space H_μ is taken such that $|\frac{\partial y'(\varphi_i)}{\partial n_A(\omega)} - \frac{\partial y'_{\mu,i}}{\partial n_A(\omega)}|_{H^{-1}(\gamma)}$, $i = 1, \ldots, n_{\lambda_\varepsilon}$, are small enough, y is the solution of problem* (2.1)–(2.3)*, and $y(u_{\lambda_\varepsilon\mu})$ is given by* (4.8) *in*

which $\xi_{\lambda\mu}$ is the solution of the algebraic system (4.5) *with the matrix given by* (4.4) *and the free term given by* (4.7)*, then the algebraic system* (4.5) *has a unique solution and*

$$\begin{aligned}&|y(u_{\lambda_\varepsilon\mu})_{|\omega} - y|_{H^{1/2}(\omega)} < C\varepsilon\\ &+ C_{\lambda_\varepsilon}\left(|h_\gamma - h_{\gamma\mu}|_{H^{-1}(\gamma)} + \left|\tfrac{\partial y_f}{\partial n_A(\omega)} - \tfrac{\partial y_{f\mu}}{\partial n_A(\omega)}\right|_{H^{-1}(\gamma)}\right.\\ &\left.+ \max_{1\le i\le n_\lambda}\left|\tfrac{\partial y'(\varphi_i)}{\partial n_A(\omega)} - \tfrac{\partial y'_{\mu,i}}{\partial n_A(\omega)}\right|_{H^{-1}(\gamma)}\right),\end{aligned}$$

where C is a constant and C_{λ_ε} depends on the basis of U_{λ_ε}.

Remark 4.1. Since the matrices $\Pi_{\lambda\mu}$ given by (4.3) and (4.4) are assumed to be nonsingular, it follows that $\{y'_{\mu,i}\}_{i=1,\dots,n_\lambda}$ and $\{\frac{\partial y'_{\mu,i}}{\partial n_A(\omega)}\}_{i=1,\dots,n_\lambda}$ are some linearly independent sets in $L^2(\gamma)$ and $H^{-1}(\gamma)$, respectively. Consequently, if m_μ is the dimension of the corresponding subspace H_μ, then $n_\lambda \le m_\mu$.

5. Exterior problems. In this section, we consider the domain $\omega \subset \mathbf{R}^N$ of problems (2.1), (2.2) and (2.1), (2.3) as the complement of the closure of a bounded domain, and it lies on only one side of its boundary. The same assumptions are made on the domain Ω of problems (2.11) and (2.20), and, evidently, $\omega \subset \Omega$. In order to retain continuity and to prove that the solutions of the problems in ω can be approximated by the solutions of problems in Ω, we have to specify the spaces in which the problems have solutions and also their correspondence with the trace spaces.

Since the domain $\Omega - \bar{\omega}$ is bounded, Lions's controllability theorem does not need to be extended to unbounded domains. Moreover, we see that the boundaries γ and Γ of the domains ω and Ω are bounded, and, consequently, we can use finite open covers of them (as for the bounded domains) to define the traces.

In order to avoid the use of the fractional spaces of the spaces in ω and Ω, we simply remark that if the controls in the Lions controllability theorem are taken in $H^{1/2}(\Gamma)$ instead of $L^2(\Gamma)$, then a similar proof of it gives the following.

The set $\{\frac{\partial z_0(v)}{\partial n_A(\Omega-\bar{\omega})} \in H^{-1/2}(\gamma) : v \in H^{1/2}(\Gamma)\}$ is dense in $H^{-1/2}(\gamma)$, where $z_0(v) \in H^1(\Omega - \bar{\omega})$ is the solution of the problem

$$\begin{aligned}&Az_0(v) = 0 \quad &&\text{in } \Omega - \bar{\omega},\\ &z_0(v) = v &&\text{on } \Gamma,\\ &z_0(v) = 0 &&\text{on } \gamma.\end{aligned}$$

Now we associate to the operator A the symmetric bilinear form

$$a(y,z) = \sum_{i,j=1}^{N}\int_\Omega a_{ij}\frac{\partial y}{\partial x_i}\frac{\partial z}{\partial x_j} + \int_\Omega a_0 yz \quad \text{for} \quad y,\ z \in H^1(\Omega),$$

which is continuous on $H^1(\Omega)\times H^1(\Omega)$. Evidently, a is also continuous on $H^1(\omega)\times H^1(\omega)$. Now if $f \in L^2(\omega)$, taking the boundary data $g_\gamma \in H^{1/2}(\gamma)$ and $h_\gamma \in H^{-1/2}(\gamma)$, then problems (2.1), (2.2) and (2.1), (2.3) can be written in the variational form

$$\begin{aligned}&y \in H^1(\omega) : a(y,z) = \textstyle\int_\omega fz \quad \text{for any} \quad z \in H_0^1(\omega),\\ &y = g_\gamma \text{ on } \gamma,\end{aligned} \tag{5.1}$$

and

$$y \in H^1(\omega) : a(y,z) = \int_\omega fz + \int_\gamma h_\gamma z \quad \text{for any} \quad z \in H^1(\omega), \tag{5.2}$$

respectively. Similar equations can also be written for problems (2.11) and (2.20).

Therefore, if there exists a constant $c_0 > 0$ such that $a_0 \geq c_0$ in Ω, then the bilinear form a is $H^1(\Omega)$-elliptic, i.e., there exists a constant $\alpha > 0$ such that $\alpha|y|^2_{H^1(\Omega)} \leq a(y,y)$ for any $y \in H^1(\Omega)$. It follows from the Lax–Milgram lemma that problems (2.11) and (2.20) have unique weak solutions in $H^1(\Omega)$. Naturally, problems (2.1), (2.2) and (2.1), (2.3) in ω also have unique weak solutions given by the solutions of problems (5.1) and (5.2), respectively.

We know that there exist an isomorphism and homeomorphism of $H^1(\Omega)/H^1_0(\Omega)$ onto $H^{1/2}(\Gamma)$ (see Theorem 7.53, p. 216, in [1], or Theorem 5.5, p. 99, and Theorem 5.7, p. 103, in [30]), i.e., there are two constants $k_1,\ k_2 > 0$ such that we have the following.

- For any $y \in H^1(\Omega)$, there exists $v \in H^{1/2}(\Gamma)$ such that $y = v$ on Γ and $\mid v \mid_{H^{1/2}(\Gamma)} \leq k_1 \mid y \mid_{H^1(\Omega)}$.
- For any $v \in H^{1/2}(\Gamma)$, there exists $y \in H^1(\Omega)$ such that $y = v$ on Γ and $\mid y \mid_{H^1(\Omega)} \leq k_2 \mid v \mid_{H^{1/2}(\Gamma)}$.

Using this correspondence, we can easily prove the continuous dependence of the solutions on data. For instance, for problems (2.1), (2.2) and (2.1), (2.3) we have

$$|y|_{H^1(\omega)} \leq C\{|f|_{L^2(\omega)} + |g_\gamma|_{H^{1/2}(\gamma)}\}$$

and

$$|y|_{H^1(\omega)} \leq C\{|f|_{L^2(\omega)} + |h_\gamma|_{H^{-1/2}(\gamma)}\},$$

respectively.

Therefore, if there exists a constant $c_0 > 0$ such that $a_0 \geq c_0$ in Ω, then we can proceed in the same manner and obtain similar results for the exterior problems to those obtained in the previous sections for the interior problems. Evidently, in this case we take

$$\mathcal{U} = H^{1/2}(\Gamma) \tag{5.3}$$

as a space of the controls for problem (2.11), in place of that given in (2.10), and the space of controls for problem (2.20) is taken as

$$\mathcal{U} = H^{-1/2}(\Gamma), \tag{5.4}$$

in place of the space given in (2.19).

If $a_0 = 0$ in Ω, the domain being unbounded, then the problems might not have solutions in the classical Sobolev spaces (see [11]), and we have to introduce the weighted spaces which take into account the particular behavior of the solutions at infinity.

For domains in $\mathbf{R}^2$, we use the weighted spaces introduced in [24], [25], specifically,

$$W^1(\Omega) = \{v \in \mathcal{D}'(\Omega) : (1+r^2)^{-1/2}(1+\log\sqrt{1+r^2})^{-1}v \in L^2(\Omega),\ \nabla v \in (L^2(\Omega))^2\},$$

where $\mathcal{D}'(\Omega)$ is the space of the distributions on Ω, and r denotes the distance from the origin. The norm on $W^1(\Omega)$ is given by

$$| v |_{W^1(\Omega)} = \left(| (1+r^2)^{-1/2}(1+\log\sqrt{1+r^2})^{-1} v |^2_{L^2(\Omega)} + | \nabla v |^2_{(L^2(\Omega))^2} \right)^{1/2}.$$

For domains in $\mathbf{R}^N$, $N \geq 3$, appropriate spaces, introduced in [21] and used in [20], [31], are

$$W^1(\Omega) = \{ v \in \mathcal{D}'(\Omega) : (1+r^2)^{-1/2} v \in L^2(\Omega),\ \nabla v \in (L^2(\Omega))^N \}$$

with the norm

$$| v |_{W^1(\Omega)} = \left(| (1+r^2)^{-1/2} v |^2_{L^2(\Omega)} + | \nabla v |^2_{(L^2(\Omega))^N} \right)^{1/2}.$$

We remark that the space $H^1(\Omega)$ is continuously embedded in $W^1(\Omega)$, and the two spaces coincide for the bounded domains. We use $W^1_0(\Omega)$ to denote the closure of $\mathcal{D}(\Omega)$ in $W^1(\Omega)$.

Concerning the space of the traces of the functions in $W^1(\Omega)$, we notice that, the boundary Γ being bounded, these traces lie in $H^{1/2}(\Gamma)$. This fact immediately follows from considering a bounded domain $D \subset \Omega$ such that $\Gamma \subset D$ and from taking into account that $W^1(D)$ and $H^1(D)$ are identical.

Assuming that

$$(1+r^2)^{1/2}(1+\log\sqrt{1+r^2}) f \in L^2(\Omega) \text{ if } N = 2,$$

$$(1+r^2)^{1/2} f \in L^2(\Omega) \text{ if } N \geq 3,$$

and using the spaces W^1 in place of the spaces H^1, we can rewrite the problems (5.1) and (5.2) and also similar equations for problems (2.11) and (2.20).

For $N = 2$, the bilinear form $a(y,z)$ generates on $W^1_0(\Omega)$ an equivalent norm with that induced by $W^1(\Omega)$ (see [24]). Also, the bilinear form $a(y,z)$ generates on $W^1(\Omega)/\mathbf{R}$ a norm which is equivalent to the standard norm.

For $N \geq 3$, the previously introduced norm on $W^1(\mathbf{R}^N)$ is equivalent to that generated by the bilinear form $a(.,.)$ (see [21]). Now if we extend the functions in $W^1_0(\Omega)$ with zero in $\mathbf{R}^N - \Omega$, we get that the bilinear form $a(y,z)$ also generates on $W^1_0(\Omega)$ a norm equivalent to that induced by $W^1(\Omega)$. Moreover, using the fact that the domain Ω is the complement of a bounded set, it can be proved that the bilinear form $a(y,z)$ generates in $W^1(\Omega)$ a norm equivalent to the above introduced norm.

Therefore, we can conclude that, in the case of $a_0 = 0$ on Ω, the exterior problems have unique solutions in the spaces W^1 if $N \geq 3$. If $N = 2$, the Dirichlet problems have unique solutions in W^1, and the Neumann problems have unique solutions in $W^1/\mathbf{R}$.

Using the fact that the spaces $W^1(D)$ and $H^1(D)$ coincide on the bounded domains D, the continuous embedding of $H^1(\Omega)$ in $W^1(\Omega)$, and the homeomorphism and isomorphism between $H^{1/2}(\Gamma)$ and $H^1(\Omega)/H^1_0(\Omega)$, we can easily prove that there exist a homeomorphism and isomorphism between $H^{1/2}(\Gamma)$ and $W^1(\Omega)/W^1_0(\Omega)$. Consequently, we get the following continuous dependence on the data of the solution y of problem (2.1), (2.2):

$$|y|_{W^1(\omega)} \leq C\{ |(1+r^2)^{1/2}(1+\log\sqrt{1+r^2}) f|_{L^2(\omega)} + |g_\gamma|_{H^{1/2}(\gamma)} \} \qquad \text{if } N = 2,$$

and

$$|y|_{W^1(\omega)} \le C\{|(1+r^2)^{1/2} f|_{L^2(\omega)} + |g_\gamma|_{H^{1/2}(\gamma)}\} \qquad \text{if } N \ge 3.$$

For the problem (2.1), (2.3), we have

$$\inf_{s\in\mathbf{R}} |y+s|_{W^1(\omega)} \le C\{|(1+r^2)^{1/2}(1+\log\sqrt{1+r^2}) f|_{L^2(\omega)} + |h_\gamma|_{H^{-1/2}(\gamma)}\} \qquad \text{if } N = 2,$$

and

$$|y|_{W^1(\omega)} \le C\{|(1+r^2)^{1/2} f|_{L^2(\omega)} + |h_\gamma|_{H^{-1/2}(\gamma)}\} \qquad \text{if } N \ge 3.$$

Therefore, we can prove in a manner similar to the previous sections that when $a_0 = 0$ on Ω and $N \ge 3$, the solutions of the Dirichlet and Neumann problems in ω can be approximated with solutions of both the Dirichlet and the Neumann problems in Ω. Naturally, the controls are taken in the appropriate space (5.3) or (5.4). If $a_0 = 0$ on Ω and $N = 2$, the solutions of the Dirichlet problems in ω can be approximated with solutions of the Dirichlet problem in Ω. The Neumann problems do not have unique solutions.

Since $y(v)$ and g_γ lie in $H^{1/2}(\gamma)$ in the case of problem (2.1), (2.2), and $\frac{\partial y(v)}{\partial n_A(\omega)}$ and h_γ lie in $H^{-1/2}(\gamma)$ when we solve (2.1), (2.3), the natural choices for the space of observations are

$$\mathcal{H} = H^{1/2}(\gamma) \tag{5.5}$$

and

$$\mathcal{H} = H^{-1/2}(\gamma), \tag{5.6}$$

respectively. Even if the convergence is assured for these spaces, their norms are numerically estimated with much difficulty. However, noticing that the inclusions $H^{1/2}(\gamma) \subset L^2(\gamma) \subset H^{-1/2}(\gamma) \subset H^{-1}(\gamma)$ are continuous, we can take the spaces of observations, as in the case of the bounded domains, given in (2.12) and (2.14). We mentioned earlier the need to avoid the use of the fractional Sobolev spaces for unbounded domains because of the lack of work on this subject (to the best of our knowledge), especially concerning the continuous dependence of the solution on the data of the problem. In the next section, we give a numerical example where the space of the controls is taken as for the bounded domains and the obtained results are accurate.

6. Numerical results. In this section, we choose some specific U_λ and H_μ. Hence we drop the subscripts λ and μ. First, we summarize the results obtained in the previous sections on the algebraic system we need to solve to obtain solutions, within a prescribed error, of problems (2.1), (2.2) or (2.1), (2.3), using the solutions of problems (2.11) or (2.20).

We recall that if, for both the bounded and unbounded domains, there exists a constant $c_0 > 0$ such that the coefficient a_0 of the operator A satisfies $a_0 \ge c_0$ in Ω, then the solutions of problems (2.1), (2.2) or (2.1), (2.3) can be approximated by the solutions of both problems (2.11) and (2.20). If $a_0 = 0$ in Ω, then the solutions of problems (2.1), (2.2) can be approximated by the solutions of problems (2.11) for both the bounded and the unbounded domains, and if also $N \ge 3$, then by the

solutions of problems (2.20) for unbounded domains only. If $a_0 = 0$ in Ω with the domains unbounded, then the solutions of problems (2.1), (2.3) can be obtained from the solutions of problems (2.11) and also from the solutions of (2.20) if $N \geq 3$.

Actually, we have to solve the algebraic system (4.5), which is rewritten as

$$\xi \in \mathbf{R}^n : \Pi\xi = l. \tag{6.1}$$

Some remarks on the computing of the elements of the matrix Π and the free term l are made below.

- Depending on the problem in Ω, we choose the space of controls $\mathcal{U}$ and a finite dimensional subspace of it, $U \subset \mathcal{U}$. Let $\varphi_1, \ldots, \varphi_n$, $n \in \mathbf{N}$, be the basis of U, and let $y'(\varphi_i)$, $i = 1, \ldots, n$ be the corresponding solutions of problems (3.2) or (3.21) if the problem in Ω is (2.11) or (2.20), respectively.
- If the problem in ω is (2.1), (2.2), then we calculate the values of $y'(\varphi_i)$, $i = 1, \ldots, n$, at the mesh points on γ. For the problem (2.1), (2.3) we calculate the values of $\frac{\partial y'(\varphi_i)}{\partial n_a(\omega)}$, $i = 1, \ldots, n$, at the mesh points on γ.
- Using the computed values of $y'(\varphi_i)$ or $\frac{\partial y'(\varphi_i)}{\partial n_a(\omega)}$, $i = 1, \ldots, n$, at the mesh points on γ, we compute the elements of the matrix Π which are some inner products either in $\mathcal{H} = L^2(\gamma)$ when we solve the problem (2.1), (2.2) or in $\mathcal{H} = H^{-1}(\gamma)$ when we solve the problem (2.1), (2.3). The finite dimensional subspace $H \subset \mathcal{H}$ depends on the numerical integration method that we use. We remark that the matrix Π is symmetric and full.
- The elements of the free term l are also some inner products in the space of observations $\mathcal{H}$. We use a solution y_f of (3.23) and the boundary data of the problem in ω (i.e., g_γ or h_γ if the problem is (2.1), (2.2) or (2.3), (2.1), respectively) in these inner products.
- For problem (2.1), (2.2), the matrix Π and the free term l are given by (4.3) and (4.6), respectively. Also, for problem (2.1), (2.3) the matrix Π and the free term l are given in (4.4) and (4.7), respectively. In these equations, y'_i and $\frac{\partial y'_i}{\partial n_A(\omega)}$ are some approximations in H of $y'(\varphi_i)$ and $\frac{\partial y'(\varphi_i)}{\partial n_A(\omega)}$, respectively. These approximations arise from the use of numerical integration on γ and numerical values of $y'(\varphi_i)$ and $\frac{\partial y'(\varphi_i}{\partial n_A(\omega)}$ at the mesh points on γ. These values can be found either by evaluating an algebraic expression or by interpolation. Indeed, when the finite element method or any other method is used with a mesh over Ω which does not fit with the boundary γ, the values of the functions y_f and $y'(\varphi_i)$, $i = 1, \ldots, n$ at some mesh points in γ are found by interpolation.

Finally, if $\xi = (\xi_1, \ldots, \xi_n)$ is the solution of algebraic system (6.1) and y is the solution of the problem we solve, then its approximation is the restriction to ω of

$$\xi_1 y'(\varphi_1) + \cdots + \xi_n y'(\varphi_n) + y_f. \tag{6.2}$$

We recall that the matrices Π_λ given in (3.14) and (3.18) are nonsingular, and therefore, each of the problems (3.16) has a unique solution. Also, algebraic systems (6.1) have unique solutions if their matrices and free terms are good approximations in H of the matrix and the free term of the algebraic systems (3.16), respectively. Also, from Remark 4.1 we must take $n \leq m$, n being the dimension of U and m the dimension of H. However, as we recall from section 2, the problem in infinite dimensional space may not have a solution. Consequently, for very large n, we might

obtain algebraic systems (3.16) that are almost singular. These algebraic systems can be solved by an iterative method such as the conjugate gradient method. However, we applied the Gauss elimination method in order to find out whether the algebraic system is singular or nonsingular. This is done by checking the diagonal elements during the elimination phase.

In the following two subsections, we give some numerical examples for both interior and exterior problems in which the solutions of the problems in Ω are found either directly by a formula, or by a method using a mesh over Ω.

6.1. Interior problems.

Example 6.1. The first numerical test refers to the Dirichlet problem

$$\begin{aligned} -\Delta y &= f \text{ in } \omega, \\ y &= g_\gamma \text{ on } \gamma, \end{aligned} \tag{6.3}$$

where $\omega \subset \mathbf{R}^2$ is a square centered at the origin with sides parallel to the axes and of length of 2 units. The approximate solution of this problem is given by the solution of the Dirichlet problem

$$\begin{aligned} -\Delta y(v) &= f \text{ in } \Omega, \\ y(v) &= v \text{ on } \Gamma, \end{aligned} \tag{6.4}$$

in which the domain Ω is the disc centered at the origin with radius equal to 2. The solutions of the homogeneous Dirichlet problems in Ω are found by the Poisson formula

$$y(v)(z) = \frac{1}{2\pi r} \int_{|\zeta|=r} v(\zeta) \frac{r^2 - |z|^2}{|z-\zeta|^2} dS_\zeta. \tag{6.5}$$

The circle Γ is discretized with n equidistant points, and $U \subset \mathcal{U} \equiv L^2(\Gamma)$ is taken as the space of the piecewise constant functions. Naturally, an element φ_i in the basis of H is a function defined on Γ which takes the value 1 between the nodes i and $i+1$ and vanishes in the rest of Γ. The square γ is also discretized with m equidistant points, and $H \subset \mathcal{H} \equiv L^2(\gamma)$ is taken as the space of the continuous piecewise linear functions. Evidently, the inclusions in (3.1) and (4.1) are dense because the union of the spaces (over some sequence of mesh size approaching zero) of continuous piecewise linear or piecewise constant functions is dense in L^2.

The values of the integrals in the Poisson formula at the points on γ are calculated using the numerical integration with three nodes. The integrals in the inner products in $L^2(\gamma)$ are calculated using an exact formula when H is the space of the continuous piecewise linear functions. In particular, if we have on γ two continuous piecewise linear functions y_1 and y_2 such that

$$\begin{aligned} y_1(x) &= m_1^k (x - x_k) + y_1^k, \\ y_2(x) &= m_2^k (x - x_k) + y_2^k \end{aligned} \tag{6.6}$$

for $x \in [x_k, x_{k+1}]$, $k = 1 \ldots, m$, then

$$\int_\gamma y_1 y_2 = h \sum_{k=1}^{m} \left[y_1^k y_2^k + \frac{h^2}{3} m_1^k m_2^k + \frac{h}{2} (m_1^k y_2^k + m_2^k y_1^k) \right], \tag{6.7}$$

where $h = x_{k+1} - x_k$ is the mesh size on γ.

TABLE 6.1

12	.29916E-10	.54208E-02
10	.94618E-02	.17096E-01

All computations below have been performed in fifteen digit arithmetics (double precision).

In the first example, we choose the exact solution to be $u(x_1, x_2) = x_1^2 + x_2^2$. Hence $g_\gamma(x_1, x_2) = x_1^2 + x_2^2$, and $f = -4$. We have taken $y_f = 2x_1^2$ as a solution of the inhomogeneous equation in Ω. It has been compared with the computed one at 19 equidistant points on a diagonal of the square: (-1.4,-1.4),. . .,(0,0),. . .,(1.4,1.4). Below $\mathrm{err_d}$ denotes the maximum of the relative errors between the exact and the computed solutions at these 19 considered points in the domain ω. A similar error only on the boundary γ is denoted by $\mathrm{err_b}$.

Table 6.1 shows errors $\mathrm{err_d}$ and $\mathrm{err_b}$ against n, the number of the equidistant points on Γ which is the dimension of the finite dimensional space U. Recall that Γ is boundary of the embedding domain Ω. All these computations use a mesh size of 0.1 on γ. It corresponds to $m = 80$, the number of equidistant points on γ, which is the dimension of the finite dimensional space H. The smallest diagonal element during the Gauss elimination method is of the order 10^{-17} for $n = 80$ and $n = 72$, and of the order 10^{-14} for $n = 60$. It is greater than 10^{-10} for $n = 10, \ldots, 45$. We should mention that in the cases when $n > 60$, where the last pivot is very small, we notice an increase in error. In all these cases the error $\mathrm{err_b}$, which can be calculated for any example even when the exact solution is not known, is a good indicator of the computational accuracy.

In the above example, the right-hand side f of the equation in ω is given by an exact algebraic formula, and it was extended in Ω by the same formula. Moreover, we have had for this simple example an exact solution y_f of the inhomogeneous equation in Ω, which could be exactly evaluated at the mesh points of the boundary γ of the domain ω. Also, the solutions of the homogeneous problems in Ω, given by the above Poisson formula, could be evaluated directly at these mesh points. In the following example we study the effect of various extensions of f in Ω on the computed solutions in ω. Therefore, in this example, the solution of the problem in Ω could be computed only at some nodes of a regular mesh over Ω, and their values at the mesh points on γ are calculated by interpolation.

Example 6.2. This example concerns the Dirichlet problem

$$\begin{aligned} &\Delta y - \sigma^2 y = f \text{ in } \omega, \\ &y = g_\gamma \text{ on } \gamma, \end{aligned} \tag{6.8}$$

where $\omega \subset \mathbf{R}^2$ is bounded by the straight lines $x_1 = -\pi/2$, $x_1 = \pi/2$, and $x_2 = -1.5$ and the curve $y = 0.5 + \cos(x + \pi/2)$. We approximate the solution of this problem by a solution of the Dirichlet problem

$$\begin{aligned} &\Delta y(v) - \sigma^2 y(v) = f \text{ in } \Omega, \\ &y(v) = v \text{ on } \Gamma, \end{aligned} \tag{6.9}$$

in which the domain Ω is the disc centered at the origin with the radius of 2.3 (see Figure 6.1 (a)). We have taken $\sigma^2 = 0.75$ in numerical computations.

We approximate the functions f and v by the discrete Fourier transforms

$$\begin{aligned} f(r,\theta) &= \sum_{k=-n/2}^{n/2-1} f_k(r) e^{ik\theta}, \\ v(\theta) &= \sum_{k=-n/2}^{n/2-1} v_k e^{ik\theta}. \end{aligned} \tag{6.10}$$

Then the solution of problem (6.9),

$$y(v) = y_f + y'(v), \tag{6.11}$$

can also be written as a discrete Fourier transform

$$\begin{aligned} y_f(r,\theta) &= \sum_{k=-n/2}^{n/2-1} y_k(r) e^{ik\theta}, \\ y'(v)(r,\theta) &= \sum_{k=-n/2}^{n/2-1} y'_k(r) e^{ik\theta}, \end{aligned} \tag{6.12}$$

where the Fourier coefficients $y_k(r)$ and $y'_k(r)$ are given by

$$\begin{aligned} y_k(r) = &- \int_0^r \rho K_k(\sigma r) I_k(\sigma\rho) f_k(\rho) d\rho - \int_r^R \rho I_k(\sigma r) K_k(\sigma\rho) f_k(\rho) d\rho \\ &+ \frac{I_k(\sigma r)}{I_k(\sigma R)} \int_0^R \rho K_k(\sigma R) I_k(\sigma\rho) f_k(\rho) d\rho, \\ y'_k(r) = &\frac{I_k(\sigma r)}{I_k(\sigma R)} v_k. \end{aligned} \tag{6.13}$$

Above, R is the radius of the disc, and I_k and K_k are the modified Bessel functions of the first and second kinds, respectively. We recall that $y'(v)$ and y_f in (6.11) are the solutions of problems (3.2) and (3.6), respectively. A fast algorithm is proposed in [4], which, using (6.13) and the fast Fourier transforms, evaluates y_f and $y'(v)$ in (6.12) at the nodes of a mesh on the disc Ω with n equidistant nodes in tangential direction and l equidistant nodes in the radial direction.

It is worth noting from (6.10) that the finite dimensional space of controls U is the space of real periodic functions defined on $[0, 2\pi]$ which can be written as a Fourier transform with the terms $-n/2, \ldots, 0, \ldots, n/2 - 1$. On the other hand, we have $\mathcal{U} = L^2(\Gamma) = L^2(0, 2\pi)$, and since the functions in $L^2(0, 2\pi)$ can be approximated by discrete Fourier transforms, we get that (3.1) holds with U as the above finite dimensional spaces. Since the controls v are real functions, it follows from (6.10)

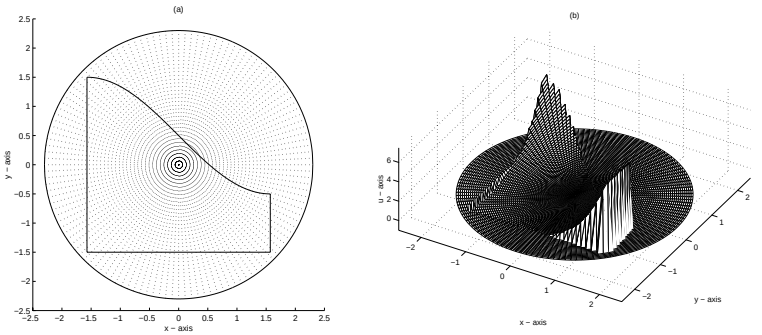

FIG. 6.1. (a) *Domains,* (b) *exact solution.*

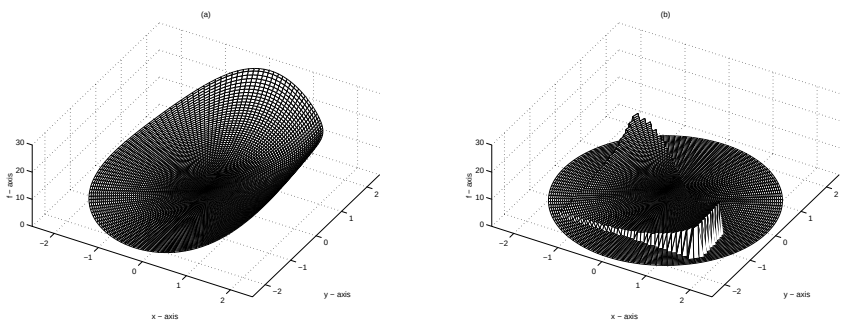

FIG. 6.2. *Extension of f by* (a) *the formula in the domain ω,* (b) *zero.*

that $v_i = \bar{v}_{-i}$ for $i = 1, \ldots, n/2 - 1$ and v_0 is real provided we choose $v_{-n/2} \in R$. Consequently, a basis of U is given by the functions: φ_0 which has the Fourier coefficient $v_0 = 1$, the other ones being zero, $\varphi_{-n/2}$ which has the Fourier coefficient $v_{-n/2} = 1$, the other ones being zero, and φ_j, $-n/2 + 1 \leq j \leq n/2 - 1$, $j \neq 0$, have the Fourier coefficients $v_j = 1 + i$, $v_{-j} = 1 - i$ with the rest being zero.

The boundary γ is discretized with m equidistant points, and, as in the previous example, H is taken to be the space of the piecewise linear functions. The integrals in the inner products in $L^2(\gamma)$ are calculated by the same formulae (6.7). We recall that the values of y_f and $y'(\varphi_)$ at the mesh points of the boundary γ were obtained by interpolation of function values at mesh points on Ω. Assuming that the point (r, θ) lies between the four mesh nodes (r_1, θ_1), (r_2, θ_1), (r_1, θ_2), (r_2, θ_2), we have linearly interpolated in radial direction first the values corresponding to (r_1, θ_1) and (r_2, θ_1), and then the values corresponding to (r_1, θ_2), (r_2, θ_2). Using the two obtained values, we have made a linear interpolation in the tangential direction.

For numerical purposes, we have taken $f(x_1, x_2) = (2 + x_1(1 - \sigma^2))e^{x_1} + (2 + x_2(1 - \sigma^2))e^{x_2}$ and $g_\gamma(x_1, x_2) = x_1 e^{x_1} + x_2 e^{x_2}$ in (6.8). Then problem (6.8) has the exact solution $y(x_1, x_2) = x_1 e^{x_1} + x_2 e^{x_2}$, which is shown in Figure 6.1 (b). In order to assess the effect of various extensions of the function f outside of ω on the numerical results, we have taken for this example only two types of extensions: (i) extending f using the above formula in ω; (ii) extending f by zero (see Figure 6.2).

Tables 6.2 through 6.5 show the arithmetic mean of the absolute errors between the exact and the computed solutions against various values of n (the number of the nodes in tangential direction, i.e., the number of nodes on Γ) and δ_r (the mesh size in radial direction), while keeping the number of mesh points on γ fixed at $m = 360$ for

all these computations. The results in Tables 6.2 and 6.3 have been obtained with the extension of f in Ω made with the formula in ω, and the results in Tables 6.4 and 6.5 have been obtained with the extension made by zero. In Tables 6.2 and 6.4, we show the errors computed on the boundary γ by taking the average over $m = 360$ boundary points. On the other hand, we show in Tables 6.3 and 6.5 the errors computed in the domain ω by taking the average over all mesh points in ω.

We notice in these tables that errors on the boundary γ are of the same order as in the domain ω, and the extension of the function f outside of ω with the formula in ω gives smaller errors than the extension by zero. It may be worth noting here that the errors for this example are higher than those for the previous example (see Table 6.1) because the values of y_f and $y(\varphi_i)$ on the boundary γ were found by interpolation in this example and by an exact algebraic expression in the previous example. Thus interpolation error is one of the possible sources of larger error in these tables for this example. Figure 6.3 shows absolute errors at the mesh nodes in the domain ω when $n = 128$ and $\delta_r = 0.01$ for the two extensions of f.

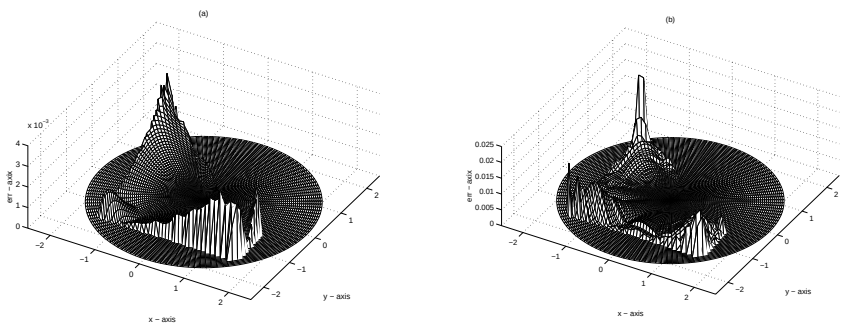

FIG. 6.3. *Errors in the domain when f is extended by* (a) *the formula in the domain* ω, (b) *zero.*

6.2. Exterior problems. Below, we show the performance of the method on two exterior problems.

Example 6.3. We solve the same problem as defined by (6.3) in Example 6.1 except that the domain ω is now the exterior of a square centered at the origin with sides parallel to the axes and of length of 2 units. For this problem, we consider exterior Dirichlet problem (6.4) with the embedding domain Ω as the exterior of a disc with its center at the origin and radius 0.99 unit.

Similar to Example 6.1, the solutions of the homogeneous Dirichlet problems in Ω are found by the Poisson formula

$$y(v)(z) = \frac{-1}{2\pi r} \int_{|\zeta|=r} v(\zeta) \frac{r^2 - |z|^2}{|z-\zeta|^2} dS_\zeta. \tag{6.14}$$

The spaces U, $\mathcal{U}$, H, and $\mathcal{H}$ are the same as in Example 6.1, and the integrals on the boundary γ use the same formula (6.7).

The problem in ω we have numerically solved has had $g_\gamma(x_1, x_2) = x_1 x_2$ and $f = 0$. Evidently, we take $y_f = 0$. In this case, we do not know the exact solution of the problem, but we recall from previous examples that the error on the boundary γ was very close to that in domain ω. Hence Table 6.6 shows the maximum relative errors between the exact prescribed data and the computed solutions on boundary γ against various values of n (the number of the nodes in tangential direction, i.e., number of nodes on Γ) while keeping the number of mesh points on γ fixed at $m = 120$ (corresponding to a mesh size of $1/15$ on γ) for all these computations.

We found that the smaller diagonal element during the Gauss elimination method is of the order 10^{-15} for $n = 120$ and of the order 10^{-14} for $n = 118$, and it is greater

TABLE 6.6

116	0.24253E-05
115	0.38082E-03
110	0.33003E-02
100	0.55797E-01
90	0.18828E+00
60	0.21087E+00
30	0.77558E+00

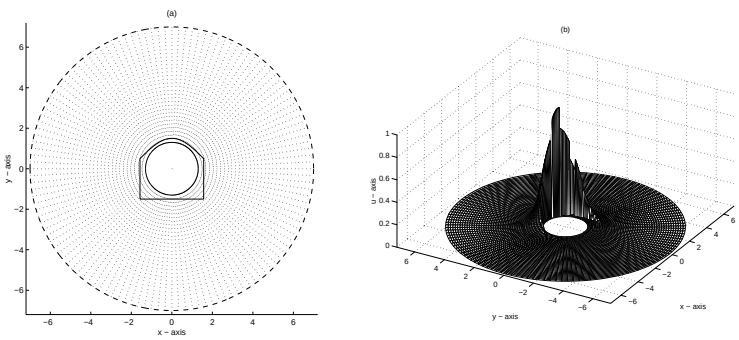

FIG. 6.4. (a) *Domains,* (b) *exact solution.*

than 10^{-12} for $n = 30, \ldots, 116$. We see in Table 6.6 that for $n > 116$, the error increases when the pivots in the Gauss elimination method become very small.

Example 6.4. Here we solve the same problem as defined by (6.8) in Example 6.2 except that the domain ω now is the open complement of the domain bounded by the straight lines $x_1 = -\pi/2$, $x_1 = \pi/2$, and $x_2 = -1.5$ and the curve $y = 0.5 + \cos(x)$. For this problem, the embedding domain Ω is taken to be the exterior of a disc with its center at the origin and radius 1.3 unit (see Figure 6.4, (a)).

We approximate the solution of this problem by a solution of the exterior Neumann problem

$$\begin{aligned} &\Delta y(v) - \sigma^2 y(v) = f \text{ in } \Omega, \\ &\tfrac{\partial y(v)}{\partial n_A(\Omega)} = v \text{ on } \Gamma, \end{aligned} \tag{6.15}$$

where Γ is the inner boundary of the embedding domain Ω. Similar to Example 6.2, we have taken $\sigma^2 = 0.75$ in numerical computations.

As before, functions f and v are approximated by the discrete Fourier transforms (6.10). Then the solution of problem (6.15) admits representation given by (6.11) and (6.12) except that the Fourier coefficients $y_k(r)$ and $y_k'(r)$ are now given by

$$\begin{aligned} y_k(r) = &- \int_R^r \rho K_k(\sigma r) I_k(\sigma\rho) f_k(\rho) d\rho - \int_r^\infty \rho I_k(\sigma r) K_k(\sigma\rho) f_k(\rho) d\rho \\ &- \frac{K_k(\sigma r)}{K_{k-1}(\sigma R) + K_{k+1}(\sigma R)} \int_R^\infty \rho [I_{k-1}(\sigma R) + I_{k+1}(\sigma R)] K_k(\sigma\rho) f_k(\rho) d\rho, \\ y_k'(r) = &\frac{K_k(\sigma r)}{K_{k-1}(\sigma R) + K_{k+1}(\sigma R)} \frac{2}{\sigma} v_k. \end{aligned} \tag{6.16}$$

Above, R is the radius of the disc whose complement is the domain Ω, and I_k and K_k are the modified Bessel functions of first and second kinds, respectively. In order to compute the solution of problem (6.15) at mesh points of the domain Ω with n equidistant nodes in the tangential direction and l equidistant nodes in the radial direction, we use the algorithm proposed in [4]. This algorithm uses (6.16) and the fast Fourier transforms to compute y_f and $y'(v)$ in (6.12). For numerical computations, the domain Ω is considered to be the annulus with the radii R and R_∞, where R_∞ is chosen very large so that its effect is minimal on the accuracy of the solutions.

The spaces U and H are the same as in Example 6.2. Also, the values of y_f and $y'(\varphi_)$ at the mesh points of the boundary γ were obtained by interpolating the values of the function at mesh points on Ω.

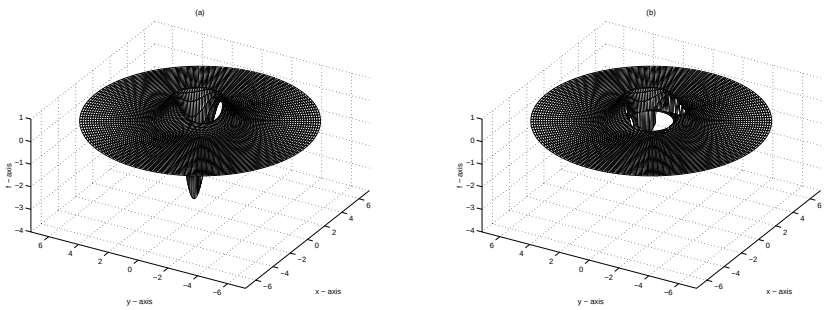

FIG. 6.5. *Extension of f by* (a) *the formula in the domain* ω, (b) *zero.*

For numerical purposes in this example, we have considered (6.8) with $f(x_1, x_2) = [4(x_1^2 + x_2^2 - x_1 - x_2) - 2 + \sigma^2]e^{-x_1^2 - x_2^2 + x_1 + x_2}$ and $g_\gamma(x_1, x_2) = e^{-x_1^2 - x_2^2 + x_1 + x_2}$. This problem has the exact solution $y(x_1, x_2) = e^{-x_1^2 - x_2^2 + x_1 + x_2}$ (it lies in $H^1(\omega)$ and satisfies the equation and the boundary conditions of problem (6.8)), which is plotted in Figure 6.4 (b).

Numerical computations show that $|y(r)| \leq 0.104E - 16$ for $r > 7$, where r is the distance of the point from the origin. Hence we have taken $R_\infty = 7$ in these computations. As in Example 6.2, we have extended f outside of ω in two different ways: (i) by the above formula, and (ii) by zero. These extensions are plotted in Figure 6.5. We have taken $m = 360$, the number of the mesh points on the boundary γ.

The error tables are similar to those in Example 6.2. Tables 6.7 and 6.8 correspond to the case when the extension of f in Ω is made with the formula in ω, and Tables 6.9 and 6.10 correspond to the extension made by zero. In Tables 6.7 and 6.9, we show the arithmetic mean of the absolute errors computed on the boundary γ by taking the average over $m = 360$ boundary points. On the other hand, we show in Tables 6.8 and 6.10 the errors computed in the domain ω by taking the average over all mesh points in ω. It is worth noting in these tables that, this time, the errors on the boundary γ are less than those in the domain ω, and the two extensions of f give solutions with

LINEAR-QUADRATIC CONTROL OF BACKWARD STOCHASTIC DIFFERENTIAL EQUATIONS*

ANDREW E. B. LIM† AND XUN YU ZHOU‡

Abstract. This paper is concerned with optimal control of linear backward stochastic differential equations (BSDEs) with a quadratic cost criteria, or backward linear-quadratic (BLQ) control. The solution of this problem is obtained completely and explicitly by using an approach which is based primarily on the completion-of-squares technique. Two alternative, though equivalent, expressions for the optimal control are obtained. The first of these involves a pair of Riccati-type equations, an uncontrolled BSDE, and an uncontrolled forward stochastic differential equation (SDE), while the second is in terms of a Hamiltonian system. Contrary to the deterministic or stochastic forward case, the optimal control is no longer a feedback of the *current* state; rather, it is a feedback of the *entire* history of the state. A key step in our derivation is a proof of global solvability of the aforementioned Riccati equations. Although of independent interest, this issue has particular relevance to the BLQ problem since these Riccati equations play a central role in our solution. Last but not least, it is demonstrated that the optimal control obtained coincides with the solution of a certain *forward* linear-quadratic (LQ) problem. This, in turn, reveals the origin of the Riccati equations introduced.

Key words. backward stochastic differential equations (BSDEs), linear-quadratic (LQ) optimal control, Riccati equations, completion of squares

1. Introduction.

A backward stochastic differential equation (BSDE) is an Ito stochastic differential equation (SDE) for which a *random terminal condition* on the state has been specified. The linear version of this type of equation was first introduced by Bismut [4] as the adjoint equation in the stochastic maximum principle (see also [3, 17, 20]). General nonlinear BSDEs, introduced independently by Pardoux and Peng [16] and Duffie and Epstein [9], have received considerable research attention in recent years due to their nice structure and wide applicability in a number of different areas, especially in mathematical finance (see, e.g., [7, 10, 11, 13, 15, 19]). For example, the Black–Scholes formula for options pricing can be recovered via a system of forward-backward stochastic differential equations (FBSDEs). In this case, the random terminal condition is related to the price of the underlying stock at a given terminal date. Unlike a (forward) SDE, the solution of a BSDE is a *pair* of adapted processes $(x(\cdot), z(\cdot))$. The additional term $z(\cdot)$ may be interpreted as a risk-adjustment factor and is required for the equation to have *adapted* solutions. This restriction of solutions to the class of *adapted processes* is necessary if the insights gained from the study of BSDEs are to be useful in applications. Adapted processes depend on *past* and *present* information but do *not* rely (clairvoyantly) on future knowledge. This is natural in virtually all applications; for example, the replicating portfolio for a contingent claim may depend at any particular time on past and present

stock prices but not, quite naturally, on future stock prices. For recent accounts on BSDE theory and applications, the reader is referred to the books [15, 19].

Since a BSDE is a well-defined dynamic system, it is very natural and appealing, first at the theoretical level, to consider the optimal control of the BSDE. As for applications, optimally controlled BSDEs promise to have a great potential. For example, an optimal control problem of a linear BSDE comes out in the process of solving a *forward* stochastic linear-quadratic (LQ) control problem in [6]. Moreover, controlled BSDEs are expected to have important applications in mathematical finance. For instance, a situation in which funds may be injected or withdrawn from the replication process of a contingent claim so as to achieve some other goal may be viewed quite naturally as an optimal BSDE control problem. However, the study on controlled BSDEs is quite lacking in literature. To our best knowledge there are only a few papers dealing with optimal control of BSDEs, including [18] and [8], which establish local and global maximum principles, respectively, and [11], in which a controlled BSDE with linear state drift is studied.

This paper is concerned with optimal control of a linear BSDE with a quadratic cost criteria, namely, a stochastic backward linear-quadratic (BLQ) problem. It is well known that LQ control is one of the most important classes of optimal control, and the solution of this problem has had a profound impact on many engineering applications. Stochastic forward LQ theory has been well established, especially with the recent development on the so-called *indefinite* stochastic LQ control [1, 5, 6, 14]. However, stochastic BLQ control remains an almost completely unexplored area. An attempt was made in [8], where a special stochastic BLQ problem without state cost was considered. An optimal control was derived, using the maximum principle obtained in the paper, under the assumption that a certain SDE admits a solution. This SDE, while it resembles the Riccati equation, is not exactly of Riccati type since it is *not* symmetric, and its solvability is hard to verify in general.

The main contribution of this paper is a complete solution of a general BLQ problem. As it turns out, the optimal control can no longer be expressed as a linear feedback of the *current* state as in the deterministic or stochastic forward case. Rather, it depends, in general, on the entire past history of the state pair $(x(\cdot), z(\cdot))$. It will be shown that this dependence is linear, and explicit formulas for the optimal control and the optimal cost in terms of a pair of Riccati equations, a Lyapunov equation, an uncontrolled BSDE, and an uncontrolled SDE are established. The basic idea is to first establish a lower bound to the optimal cost via the completion-of-squares technique and then to construct a control that achieves exactly this lower bound. A key part of our derivation is a proof of existence and uniqueness of solutions of the Riccati equations mentioned above. Although this issue is one which has independent interest, the proof of global solvability presented in this paper has direct relevance to the BLQ problem since these Riccati equations play a central role in our analysis.

It is interesting to remark that our original approach to solving the BLQ problem was inspired by [15, 12], where an (uncontrolled) BSDE is viewed as a *controlled forward* SDE. Extending this idea, we can show that the optimal control of the BLQ problem is the limit of a sequence of square integrable processes, obtained by solving a family of *forward* LQ problems. During this procedure, the key Riccati equations, along with other related equations, come out very naturally. What is more interesting is that once these equations are in place, one may forget about the forward formulation and limiting procedure, which is rather complicated, and instead use these equations *directly* along with the completion-of-squares technique to obtain the optimal control

for the original BLQ problem. Nevertheless, the forward formulation still represents an alternative and insightful approach to the backward control problem, and for this reason, an outline of this procedure is also presented in this paper.

The outline of this paper is as follows. In section 2, we formulate the BLQ problem. In section 3, we present the main result of the paper (with its proof deferred to section 5). In addition, we compare the solution of the stochastic BLQ problem with that of the deterministic case. A key ingredient in our analysis is the existence and uniqueness of solutions of certain Riccati equations, an issue which is addressed in section 4. A proof of the main result is carried out in section 5. In section 6, we explain, in a rather informal way, the origin of the key Riccati equations, and we present an alternative approach to the BLQ problem. In particular, we show that the optimal BLQ control, established in section 3, coincides with the limit of the solutions of a family of forward LQ problems. Finally, section 7 concludes the paper.

2. Problem formulation. We assume throughout that $(\Omega, \mathcal{F}, \{\mathcal{F}\}_{t\geq 0}, P)$ is a given and fixed complete filtered probability space and that $W(\cdot)$ is a scalar-valued Brownian motion on this space. (Our assumption that $W(\cdot)$ is scalar-valued is for the sake of simplicity. No essential difficulties are encountered when extending our analysis to the case of vector-valued Brownian motions). In addition, we assume that $\mathcal{F}_t$ is the augmentation of $\sigma\{W(s) \,|\, 0 \leq s \leq t\}$ by all the P-null sets of $\mathcal{F}$.

Throughout this paper, we denote the set of symmetric $n \times n$ matrices with real elements by S^n. If $M \in S^n$ is positive (semi)definite, we write $M > (\geq)\ 0$. Let X be a given Hilbert space. The set of X-valued continuous functions is denoted by $C(0, T; X)$. If $N(\cdot) \in C(0, T; S^n)$ and $N(t) > (\geq)\ 0$ for every $t \in [0, T]$, we say that $N(\cdot)$ is positive (semi)definite, which is denoted by $N(\cdot) > (\geq)\ 0$. Suppose $\eta : \Omega \to \mathbb{R}^n$ is an $\mathcal{F}_T$-random variable. We write $\eta \in L^2_{\mathcal{F}_T}(\Omega; \mathbb{R}^n)$ if η is square integrable (i.e., $E|\eta|^2 < \infty$). Consider now the case when $f : [0, T] \times \Omega \to \mathbb{R}^n$ is an $\{\mathcal{F}_t\}_{t\geq 0}$ adapted process. If $f(\cdot)$ is square integrable (i.e., $E \int_0^T |f(t)|^2\, dt < \infty$), we shall write $f(\cdot) \in L^2_{\mathcal{F}}(0, T; \mathbb{R}^n)$; if $f(\cdot)$ is uniformly bounded (i.e., ess $\sup_{(t,\, w)\in[0,\, T]\times\Omega} |f(t)| < \infty$), then $f(\cdot) \in L^\infty_{\mathcal{F}}(0, T; \mathbb{R}^n)$. If $f(\cdot)$ has (P-almost surely (a.s.)) continuous sample paths and $E \sup_{t\in[0,\, T]} |f(t)|^2 < \infty$, we write $f(\cdot) \in L^2_{\mathcal{F}}(0, T; C(0, T; \mathbb{R}^n))$; if ess $\sup_{w\in\Omega} \sup_{t\in[0,\, T]} |f(t)| < \infty$, then $f(\cdot) \in L^\infty_{\mathcal{F}}(0, T; C(0, T; \mathbb{R}^n))$. These definitions generalize in the obvious way to the case when $f(\cdot)$ is $\mathbb{R}^{n\times m}$—or S^n—valued. Finally, in cases where we are restricting ourselves to deterministic Borel measurable functions $f : [0, T] \to \mathbb{R}^n$, we shall drop the subscript $\mathcal{F}$ in the notation; for example, $L^\infty(0, T; \mathbb{R}^n)$.

Consider the BSDE

$$\left\{ \begin{array}{rcl} dx(t) &=& \{A(t)\, x(t) + B(t)\, u(t) + C(t) z(t)\}\ dt + z(t)\, dW(t), \\ x(T) &=& \xi, \end{array} \right. \tag{2.1}$$

where $u(\cdot)$ is the control process. The class of *admissible controls* for (2.1) is

$$\mathcal{U} = L^2_{\mathcal{F}}(0, T; \mathbb{R}^m). \tag{2.2}$$

Later, we shall state assumptions on the coefficients $A(\cdot)$, $B(\cdot)$, $C(\cdot)$, and the terminal condition ξ so as to guarantee the existence of a unique solution pair $(x(\cdot), z(\cdot)) \in L^2_{\mathcal{F}}(\Omega; C(0, T; \mathbb{R}^n)) \times L^2_{\mathcal{F}}(0, T; \mathbb{R}^n)$ of the BSDE (2.1) for every admissible control $u(\cdot) \in \mathcal{U}$. We refer to such a three-tuple $(x(\cdot), z(\cdot); u(\cdot))$ as an *admissible triple*. The

cost associated with an admissible triple $(x(\cdot),\, z(\cdot);\, u(\cdot))$ is given by

$$J(\xi; u(\cdot)) := E\,\frac{1}{2}\Bigg[x(0)'Hx(0) + \int_0^T \left(x(t)'Q(t)x(t) + z(t)'S(t)z(t) + u(t)'R(t)u(t)\right)\,dt\Bigg]. \tag{2.3}$$

The *BLQ control problem* can be stated as follows:

$$\begin{cases} \min J(\xi; u(\cdot)) \\ \text{subject to} \\ \quad u(\cdot) \in \mathcal{U}, \\ \quad (x(\cdot),\, z(\cdot);\, u(\cdot)) \text{ satisfies (2.1)}. \end{cases} \tag{2.4}$$

Throughout this paper, we shall assume the following:

Assumption (A1).

$$\begin{cases} A,\, C & \in & L^\infty(0,\, T;\, \mathbb{R}^{n\times n}), \\ B & \in & L^\infty(0,\, T;\, \mathbb{R}^{n\times m}), \\ Q,\, S & \in & L^\infty(0,\, T;\, S^n),\ Q,\, S \,\geq\, 0, \\ R & \in & L^\infty(0,\, T; S^m),\ R \,>\, 0, \\ H & \in & S^n,\ H \,\geq\, 0, \\ \xi & \in & L^2_{\mathcal{F}_T}(\Omega;\, \mathbb{R}^n). \end{cases}$$

In particular, Assumption (A1) is sufficient to guarantee the existence of a unique solution pair $(x(\cdot),\, z(\cdot)) \in L^2_{\mathcal{F}}(\Omega; C(0,\, T;\, \mathbb{R}^n)) \times L^2_{\mathcal{F}}(0,\, T;\, \mathbb{R}^n)$ of (2.1) for every admissible control $u(\cdot) \in \mathcal{U}$; see [19, Chapter 7].

3. Main result. Before we present the main result of the paper, which gives a complete solution to the above BLQ problem, let us see how one would solve the *deterministic* BLQ problem. This corresponds to $\xi \in \mathbb{R}^n$ being deterministic, $C = 0$, $S = 0$, and an admissible class $\mathcal{U}_d = L^2(0,\, T;\, \mathbb{R}^n)$. The other parameters satisfy (A1), while the cost and dynamics are given by

$$J_d(\xi; u(\cdot)) := \frac{1}{2}\,x(0)'Hx(0) + \frac{1}{2}\int_0^T \left(x(t)'Q(t)x(t) + u(t)'R(t)u(t)\right)\,dt,$$

$$\begin{cases} \dot{x}(t) = A(t)\,x(t) + B(t)\,u(t), \\ x(T) = \xi, \end{cases}$$

respectively. By reversing time,

$$\tau = T - t, \quad t \in [0,\, T],$$

we obtain an equivalent forward LQ problem that can be solved using a standard (Riccati) approach (see, e.g., [19, Chapter 6, section 2]). In particular, this gives us the following result.

Proposition 3.1 (deterministic BLQ problem). *The optimal cost and optimal feedback control for the deterministic BLQ problem are*

$$J_d^*(\xi) = \frac{1}{2}\xi'\,Z(T)\,\xi, \tag{3.1}$$

$$u(t) = R(t)^{-1}B(t)'Z(t)x(t), \tag{3.2}$$

respectively, where $Z(\cdot)$ is the unique solution of the Riccati equation

$$\begin{cases} \dot{Z}(t) + Z(t)A(t) + A(t)'Z(t) + Z(t)B(t)R(t)^{-1}B(t)'Z(t) - Q(t) = 0, \\ Z(0) = H, \end{cases} \tag{3.3}$$

and $x(\cdot)$ is the unique solution of the differential equation

$$\begin{cases} \dot{x}(t) = (A(t) + B(t)\, R(t)^{-1}B(t)'Z(t))\, x(t), \\ x(T) = \xi. \end{cases}$$

It is important to recognize that the above time reversal technique *cannot* be extended to the stochastic BLQ problem, (2.4), as it would destroy the adaptiveness which is essential in the model. In particular, a control obtained in this way will not, in general, be $\{\mathcal{F}_t\}_{t\geq 0}$-adapted and hence is not admissible.

It turns out that the solution to (2.4) is more involved. In the remainder of this section, we present two alternative expressions (which are later shown to be equivalent) for the solution of the optimal BLQ control. The first one is analogous to the solution to the deterministic BLQ problem just presented. It gives an explicit formula via a pair of Riccati equations, a Lyapunov equation, an uncontrolled BSDE, and an uncontrolled SDE.

First, consider the following Riccati-type equation:

$$\begin{cases} \dot{\Sigma}(t) - A(t)\Sigma(t) - \Sigma(t)A(t)' - \Sigma(t)Q(t)\Sigma(t) \\ \quad +B(t)R(t)^{-1}B(t)' + C(t)\Sigma(t)\left(S(t)\Sigma(t) + I\right)^{-1}C(t)' = 0, \\ \Sigma(T) = 0. \end{cases} \tag{3.4}$$

The existence and uniqueness of a solution to this equation will be addressed in section 4; see Theorem 4.5. Letting $\Sigma(\cdot)$ be the solution to (3.4), we define the following equations:

$$\begin{cases} \dot{Z}(t) + Z(t)A(t) + A(t)'Z(t) \\ \quad +Z(t)[B(t)R(t)^{-1}B(t)' \\ \quad +C(t)\Sigma(t)(I + S(t)\Sigma(t))^{-1}C(t)']Z(t) - Q(t) = 0, \\ Z(0) = H, \end{cases} \tag{3.5}$$

$$\begin{cases} \dot{N}(t) + N(t)(A(t) + \Sigma(t)Q(t)) + (A(t) + \Sigma(t)Q(t))'N(t) - Q(t) = 0, \\ N(0) = \frac{1}{2}\{H(I + \Sigma(0)H)^{-1} + (I + H\Sigma(0))^{-1}H\}, \end{cases} \tag{3.6}$$

$$\begin{cases} dh(t) = \{(A(t) + \Sigma(t)Q(t))h(t) + C(t)(I + \Sigma(t)S(t))^{-1}\,\eta(t)\}\,dt \\ \quad +\eta(t)\,dW(t), \\ h(T) = -\xi. \end{cases} \tag{3.7}$$

The first equation (3.5) is again a Riccati-type equation. It is a generalization of the Riccati equation (3.3) associated with the deterministic problem. The second equation is a Lyapunov equation, while the third is a linear BSDE. Based on the solutions $Z(\cdot)$ and $(h(\cdot), \eta(\cdot))$ to (3.5) and (3.7), respectively, we finally introduce

$$\begin{cases} dq(t) = \{-[A(t) + B(t)R(t)^{-1}B(t)'Z(t) + C(t)(I + \Sigma(t)S(t))^{-1}\Sigma(t)C(t)'Z(t)]'\, q(t) \\ \quad +Z(t)C(t)(I + \Sigma(t)S(t))^{-1}\eta(t)\}dt + \{(Z(t) - S(t))(I + \Sigma(t)S(t))^{-1}\eta(t) \\ \quad +(I + Z(t)\Sigma(t))(I + S(t)\Sigma(t))^{-1}C(t)'(I + Z(t)\Sigma(t))^{-1}(Z(t)h(t) - q(t))\}\,dW(t), \\ q(0) = 0. \end{cases} \tag{3.8}$$

The existence and uniqueness of the solutions of (3.5)–(3.8) will be discussed in section 4. It should be noted that (3.4), (3.6), (3.7), and (3.8) play no role in the solution of the deterministic BLQ problem.

THEOREM 3.2. *The BLQ problem* (2.4) *is uniquely solvable. Moreover, the control*

$$u(t) = R(t)^{-1}B(t)'(Z(t)x(t) + q(t)) \tag{3.9}$$

is optimal, where $Z(\cdot)$ *and* $q(\cdot)$ *are the solutions of* (3.5) *and* (3.8)*, respectively. The optimal state trajectory* $(x(\cdot), z(\cdot))$ *is the unique solution of the BSDE*

$$\begin{cases} dx(t) = \{(A(t) + B(t)\,R(t)^{-1}B(t)'Z(t))\,x(t) \\ \qquad\qquad +C(t)z(t) + B(t)\,R(t)^{-1}\,B(t)'\,q(t)\}\,dt + z(t)\,dW(t), \\ x(T) = \xi, \end{cases} \tag{3.10}$$

and the optimal cost is

$$J^*(\xi) := E\frac{1}{2}\Bigg\{\xi'N(T)\xi + \int_0^T \{\eta(t)'[(S(t)\Sigma(t) + I)^{-1}S(t) - N(t)]\eta(t) \\ -2\eta(t)'(I + S(t)\Sigma(t))^{-1}C(t)'N(t)h(t)\}\,dt\Bigg\}, \tag{3.11}$$

where $N(\cdot)$ *is the unique solution of* (3.6).

Remark 3.1. If we compare the two optimal controls, (3.2) and (3.9), for the deterministic and stochastic BLQ problems, respectively, we see that the latter involves an additional random nonhomogeneous term $q(\cdot)$. This addition disqualifies (3.9) from a feedback control of the *current* state, contrary to the deterministic BLQ (see Proposition 3.1) or stochastic forward LQ (see [5]) cases. The reason is because $q(\cdot)$ depends on $(h(\cdot), \eta(\cdot))$, which in turn depends on ξ, the terminal condition of part of the state variable, $x(\cdot)$. This is one of the major distinctive features of the stochastic BLQ problem. On the other hand, when ξ is nonrandom, $C = 0$ and $S = 0$, the optimal control (3.9) reduces to the solution (3.2) of the deterministic problem. In this case, it is easy to see (by the uniqueness of the solutions of (3.7)) that $\eta(t) \equiv 0$. This implies, in turn, that $q(t) \equiv 0$, and hence the optimal control (3.9) agrees with the solution (3.2) of the deterministic problem. In addition, since

$$N(t) = \frac{1}{2}[Z(t)(I + \Sigma(t)Z(t))^{-1} + (I + Z(t)\Sigma(t))^{-1}Z(t)]$$

(see Proposition 4.8), it follows that $N(T) = Z(T)$ and the optimal cost (3.11) reduces to (3.1) for the deterministic problem. Through the above comparison, we can also see that the fundamental difference between the solutions to the deterministic and stochastic BLQ problems lies in the introduction of (3.4).

Although for the stochastic BLQ problem the optimal control is no longer a feedback of the current state, it is indeed a linear state feedback of the *entire past history* of the state process $(x(\cdot), z(\cdot))$. This conclusion is a consequence of the second form of the optimal control we will present, which is in terms of the Hamiltonian system:

$$\begin{cases} dx(t) = \{A(t)x(t) - B(t)R(t)^{-1}B(t)'y(t) + C(t)z(t)\}dt + z(t)dW(t), \\ x(T) = \xi, \end{cases} \tag{3.12}$$

$$\begin{cases} dy(t) = \{-A(t)'y(t) - Q(t)x(t)\}dt + \{-C(t)'y(t) - S(t)z(t)\}dW(t), \\ y(0) = -Hx(0). \end{cases} \tag{3.13}$$

Notice that the combination of (3.12)–(3.13) does not qualify as a conventional FBSDE as defined in, say, [19, 15]. The subtle difference is that the forward and backward variables in (3.12)–(3.13) are directly related at the *initial* time, while those in the FBSDE are related at the *terminal* time. Moreover, one cannot transform between these two types of equations by reversing the time, due to the required adaptiveness. In what follows, we shall refer to any three-tuple of processes

$$(x(\cdot),\, z(\cdot),\, y(\cdot)) \in L^2_{\mathcal{F}}(\Omega;\, C(0,\, T;\, \mathbb{R}^n)) \times L^2_{\mathcal{F}}(0,\, T;\, \mathbb{R}^n) \times L^2_{\mathcal{F}}(\Omega;\, C(0,\, T;\, \mathbb{R}^n)),$$

which satisfies (3.12)–(3.13) as a *solution of the Hamiltonian system* (3.12)–(3.13).

THEOREM 3.3. *The Hamiltonian system* (3.12)–(3.13) *has a unique solution* $(x(\cdot),\, z(\cdot),\, y(\cdot))$. *Moreover, the BLQ problem* (2.4) *is uniquely solvable with the optimal control*

$$u(t) = -R(t)^{-1}B(t)'y(t), \tag{3.14}$$

and $(x(\cdot),\, z(\cdot))$ *as the corresponding optimal state process. The optimal cost is* (3.11).

Remark 3.2. If (3.14) is optimal, then (3.12)–(3.13) are exactly the corresponding state equation and adjoint equation; see [8]. This is the reason why we call (3.12)–(3.13) the Hamiltonian system.

Theorem 3.3 shows that the optimal control is linear in the process $y(\cdot)$. The following simple result further reveals that the optimal control is a linear feedback of the past and current values of the state process $(x(\cdot),\, z(\cdot))$.

PROPOSITION 3.4. *Let* $y(\cdot)$ *be the process obtained from the Hamiltonian system* (3.12)–(3.13). *Then*

$$\begin{aligned} y(t) = \Phi(t)\Bigg\{ & -Hx(0) + \int_0^t \Phi(s)^{-1}[Q(s)x(s) + C(s)'S(s)z(s)]\, ds \\ & - \int_0^t \Phi(s)^{-1}S(s)z(s)dW(s)\Bigg\}, \end{aligned}$$

where $\Phi(\cdot)$ *is the unique solution of the matrix SDE*

$$\begin{cases} d\Phi(t) &= -A(t)'\Phi(t)dt - C(t)'\Phi(t)dW(t), \\ \Phi(0) &= I. \end{cases}$$

Proof. This is an immediate consequence of the variation-of-constant formula; see [19, p. 47, Theorem 6.14]. □

Proofs of Theorems 3.2 and 3.3 are deferred to section 5.

4. Riccati equations. Before proving the main result formulated in the previous section, in this section we first study the existence and uniqueness of solutions to (3.4)–(3.8), mainly focusing on the Riccati equations (3.4) and (3.5).

To start, let us first consider the two equations

$$\begin{cases} \dot{\Sigma}(t) - A(t)\Sigma(t) - \Sigma(t)A(t)' - \Sigma(t)Q(t)\Sigma(t) \\ \quad +B(t)R(t)^{-1}B(t)' + C(t)\Sigma(t)(S(t)\Sigma(t) + I)^{-1}C(t)' = 0, \\ \Sigma(T) = M, \end{cases} \tag{4.1}$$

$$\begin{cases} \dot{P}(t) + P(t)A(t) + A(t)'P(t) \\ \quad -P(t)(B(t)R(t)^{-1}B(t)' + C(t)(S(t) + P(t))^{-1}C(t)')P(t) + Q(t) = 0, \\ P(T) = M^{-1}, \end{cases} \tag{4.2}$$

where M is a given symmetric $n \times n$ matrix in (4.1) and a nonsingular symmetric $n \times n$ matrix in (4.2). It will be seen from what follows that (4.2) is introduced as a means of dealing with the solvability of (4.1).

PROPOSITION 4.1. *Let M be a symmetric $n \times n$ matrix. If the Riccati equation* (4.1) *is solvable, then the solution is unique.*

Proof. Suppose that $\Sigma_1(\cdot)$, $\Sigma_2(\cdot) \in C(0, T; S^n)$ are two solutions of (4.1). Since $\Sigma_1(\cdot)$ and $\Sigma_2(\cdot)$ are continuous, it follows that $\Delta(\cdot) := \Sigma_1(\cdot) - \Sigma_2(\cdot)$ is uniformly bounded. It is easy to show that $\Delta(\cdot)$ is a solution of the equation

$$\begin{cases} \dot{\Delta}(t) = (A(t) + \Sigma_1(t)\,Q(t))\,\Delta(t) + \Delta(t)\,(A(t) + \Sigma_1(t)\,Q(t))' - \Delta(t)Q(t)\Delta(t) \\ \quad -C(t)[I - \Sigma_2(t)(S(t)\Sigma_2(t) + I)^{-1}S(t)]\Delta(t)(S(t)\Sigma_1(t) + I)^{-1}C(t)', \\ \Delta(T) = 0. \end{cases}$$

Integrating both sides of this equation from t to T, it follows from the uniform boundedness of $\Delta(\cdot)$ and all the coefficients that there is a constant $0 < K < \infty$ such that

$$\|\Delta(t)\| \le K \int_t^T \|\Delta(s)\|\,ds.$$

Hence, by Gronwall's inequality, it follows that $\Sigma_1(t) - \Sigma_2(t) = 0$ for all $t \in [0, T]$. □

Next we prove the existence of solutions to (4.1). We first consider the case when $S = 0$. In this case, the Riccati equations (4.1) and (4.2) become

$$\begin{cases} \dot{\Sigma}(t) - A(t)\Sigma(t) - \Sigma(t)A(t)' + C(t)\Sigma(t)C(t)' \\ \qquad -\Sigma(t)Q(t)\Sigma(t) + B(t)R(t)^{-1}B(t)' = 0, \\ \Sigma(T) = M, \end{cases} \tag{4.3}$$

$$\begin{cases} \dot{P}(t) + P(t)A(t) + A(t)'P(t) + Q(t) \\ \qquad -P(t)(B(t)R(t)^{-1}B(t)' + C(t)P(t)^{-1}C(t)')P(t) = 0, \\ P(T) = M^{-1}. \end{cases} \tag{4.4}$$

PROPOSITION 4.2. *Let $M \ge 0$ be a given symmetric $n \times n$ matrix. Then the Riccati equation* (4.3) *is uniquely solvable. Moreover,*

(i) *if $M > 0$, then the solution $\Sigma(\cdot) > 0$, and*

(ii) *if $M \ge 0$, then the solution $\Sigma(\cdot) \ge 0$.*

Proof. Case 1*: $M > 0$.* Consider first the case when $Q(t) > 0$ for almost every (a.e.) $t \in [0, T]$. Then (4.3) is a standard Riccati equation (arising in deterministic LQ control) and is uniquely solvable with the solution $\Sigma(\cdot) > 0$ (see, e.g., [2, 19]). Suppose now that we have only $Q(\cdot) \ge 0$. Define $Q_i := Q + (1/i)\,I$ for $i \in \mathbb{Z}^+$. Let $\Sigma_i(\cdot)$ be the unique positive definite solution of (4.3) when Q is replaced by Q_i. Note first that $\Sigma_i(\cdot)$ is uniformly bounded. To see this, consider the Lyapunov equation

$$\begin{cases} \dot{\bar{\Sigma}}(t) = A(t)\bar{\Sigma}(t) + \bar{\Sigma}(t)A(t)' - C(t)\bar{\Sigma}(t)C(t)' - B(t)R(t)^{-1}B(t)', \\ \bar{\Sigma}(T) = M. \end{cases} \tag{4.5}$$

Since (4.5) is a linear ordinary differential equation (ODE) with bounded coefficients, it follows that it has a unique solution $\bar{\Sigma}(\cdot)$ which is uniformly bounded. For any

$i \in \mathbb{Z}^+$, let $\bar{\Delta}_i(\cdot) := \bar{\Sigma}(\cdot) - \Sigma_i(\cdot)$. It is easy to show that $\bar{\Delta}_i(\cdot)$ is a solution of the Riccati equation

$$\begin{cases} \dot{\bar{\Delta}}_i(t) = A_i(t)\bar{\Delta}_i(t) + \bar{\Delta}_i(t)A_i(t)' - C(t)\bar{\Delta}_i(t)C(t)' \\ \qquad\qquad + \bar{\Delta}_i(t)Q_i(t)\bar{\Delta}_i(t) - \bar{\Sigma}(t)Q_i(t)\bar{\Sigma}(t), \\ \bar{\Delta}(T) = 0, \end{cases} \tag{4.6}$$

where $A_i(t) := A(t) + \Sigma_i(t)Q_i(t)$. This is again a standard Riccati equation which has a unique solution $\bar{\Delta}_i(\cdot) \geq 0$. Therefore, $0 \leq \Sigma_i(\cdot) \leq \bar{\Sigma}(\cdot)$, so $\Sigma_i(\cdot)$ is uniformly bounded, as claimed. Next, observe that $\Sigma_i(\cdot)$ is nondecreasing in i. To see this, suppose that $j < i$. Then $\Delta(\cdot) := \Sigma_i(\cdot) - \Sigma_j(\cdot)$ is the unique solution of the Riccati equation

$$\begin{cases} \dot{\Delta}(t) = \bar{A}(t)\Delta(t) + \Delta(t)\bar{A}(t)' - C(t)\Delta(t)C(t)' + \Delta(t)Q_i(t)\Delta(t) - (\frac{1}{j} - \frac{1}{i})\Sigma_j(t)\,\Sigma_j(t), \\ \Delta(T) = 0, \end{cases}$$

where $\bar{A} := A + \Sigma_j Q_i$. As before, $\Delta(\cdot)$ is positive semidefinite, and hence $\Sigma_i(\cdot) \geq \Sigma_j(\cdot)$. Since $\{\Sigma_i(\cdot)\}_{i\geq 1}$ is a nondecreasing, uniformly bounded sequence of functions, it follows that there is a function $\Sigma(\cdot)$ (which is not necessarily continuous) such that $\Sigma_i(t) \uparrow \Sigma(t)$ for every $t \in [0, T]$ as $i \uparrow \infty$. Therefore, $\Sigma(t)$ is symmetric, and $\Sigma(t) > 0$ for every $t \in [0, T]$. Finally, we show that $\Sigma(\cdot)$ is continuous and is a solution of (4.3). Observe first that by virtue of (4.3), the relation

$$\begin{aligned} \Sigma_i(t) = M - \int_t^T & (A(s)\Sigma_i(s) + \Sigma_i(s)A(s)' - C(s)\Sigma_i(s)C(s)' \\ & + \Sigma_i(s)Q_i(s)\Sigma_i(s) - B(s)R(s)^{-1}B(s)')\,ds \end{aligned}$$

holds. Since $\Sigma_i(t) \uparrow \Sigma(t)$ for every $t \in [0, T]$ as $i \uparrow \infty$, it follows from the bounded convergence theorem that

$$\begin{aligned} \Sigma(t) = M - \int_t^T & (A(s)\Sigma(s) + \Sigma(s)A(s)' - C(s)\Sigma(s)C(s)' \\ & + \Sigma(s)Q(s)\Sigma(s) - B(s)R(s)^{-1}B(s')\,ds. \end{aligned}$$

Therefore, $\Sigma(\cdot) \in C(0, T; S^n)$ is a solution of (4.3), and $\Sigma(\cdot) > 0$. Uniqueness follows from Proposition 4.1.

Case 2: $M \geq 0$. In this case, the one difference, when applying the argument above, is that $\Sigma(t) \geq 0$ instead of $\Sigma(t) > 0$ for all $t \in [0, T]$. □

PROPOSITION 4.3. *Let $M > 0$ be a given symmetric $n \times n$ matrix. Then the Riccati equation* (4.4) *is uniquely solvable with the solution $P(\cdot) > 0$.*

Proof. We begin by proving existence. By Proposition 4.2, (4.3) is uniquely solvable with the solution $\Sigma(\cdot) > 0$. It follows that $\Sigma(\cdot)^{-1}$ is well defined, symmetric, and positive definite. By evaluating $\frac{d}{dt}(\Sigma(t)\Sigma(t)^{-1}) = 0$, it can be shown that $P(\cdot) := \Sigma(\cdot)^{-1} \in C(0, T, S^n)$ is a solution of (4.4).

To prove uniqueness, let $P_i(\cdot)$, $i = 1, 2$, be solutions of (4.4). Since (4.4) involves $P_i(\cdot)^{-1}$, $P_i(t)$ is invertible for every $t \in [0, T]$, and $P_i(\cdot)^{-1}$ is differentiable. Since $P_i(\cdot)^{-1}$ is a solution of (4.3), the uniqueness property of (4.3) implies that $P_1(\cdot) = P_2(\cdot)$. □

Now we proceed to the general case when $S \geq 0$. We begin by proving global solvability of the Riccati equation (4.2) when $M > 0$. The following notions, introduced in [5], play an important role in our analysis. Let

$$\hat{\mathcal{K}} := \{K \in L^\infty(0,\, T;\, S^n) \,|\, K(t),\, K(t)^{-1} > 0, \\ \text{a.e. } t \in [0,\, T],\ \text{and } K(\cdot)^{-1} \in L^\infty(0,\, T;\, S^n)\}.$$

For every $K \in \hat{\mathcal{K}}$, the Riccati equation

$$\begin{cases} \dot{P}(t) + P(t)A(t) + A(t)'P(t) \\ \quad -P(t)(B(t)R(t)^{-1}B(t)' + C(t)K(t)^{-1}C(t)')P(t) + Q(t) = 0, \\ P(T) = M^{-1} \end{cases} \tag{4.7}$$

is a standard Riccati equation which is uniquely solvable, with the solution $P(\cdot) > 0$. Therefore, the mapping $\psi : \hat{\mathcal{K}} \to C(0,\, T;\, S^n)$, where $P = \psi(K)$ is the solution of (4.7) associated with K, is well defined. A sufficient condition for unique solvability of the Riccati equation (4.2) is the existence of $K \in \hat{\mathcal{K}}$ such that

$$S + \psi(K) \geq K; \tag{4.8}$$

see [5, Theorem 4.6]. Hence we have the following result.

THEOREM 4.4. *Let $M > 0$ be a given symmetric $n \times n$ matrix. Then the Riccati equation* (4.2) *has a unique solution $P(\cdot) \in C(0,\, T;\, S^n)$. Moreover, $P(\cdot) > 0$.*

Proof. Let $\bar{P}(\cdot) \in C(0,\, T;\, S^n)$ denote the solution of the Riccati equation (4.4). It follows from Proposition 4.3 that $\bar{P} \in \hat{\mathcal{K}}$ and $\bar{P} = \psi(\bar{P})$. Moreover, since $S \geq 0$, it is clear that (4.8) is satisfied with $K = \bar{P}$, and hence (4.2) is uniquely solvable (with solution $P(\cdot) \in C(0,\, T;\, S^n)$). To see that $P(t) \geq \bar{P}(t) > 0$ for all $t \in [0,\, T]$, observe that $x'P(t)x$ is the optimal cost associated with the optimal control problem [5]

$$\begin{cases} \min_{u(\cdot),\, v(\cdot)} E\int_t^T \{x(s)'Q(s)x(s) + u(s)'R(s)u(s) + v(s)'S(s)v(s)\}\, ds + x(T)'M^{-1}x(T) \\ \text{subject to} \\ \quad dx(s) = \{A(s)x(s) + B(s)u(s) + C(s)v(s)\}\, ds + v(s)\, dW(s), \quad s \in [t, T], \\ \quad x(t) = x, \\ \quad (u(\cdot),\, v(\cdot)) \in L^2_{\mathcal{F}}(0,\, T;\, \mathbb{R}^m) \times L^2_{\mathcal{F}}(0,\, T;\, \mathbb{R}^n), \end{cases} \tag{4.9}$$

while $x'\bar{P}(t)x$ is the optimal cost associated with

$$\begin{cases} \min_{u(\cdot),\, v(\cdot)} E\int_t^T \{x(s)'Q(s)x(s) + u(s)'R(s)u(s)\}\, ds + x(T)'M^{-1}x(T) \\ \text{subject to} \\ \quad dx(s) = \{A(s)x(s) + B(s)u(s) + C(s)v(s)\}\, ds + v(s)\, dW(s), \quad s \in [t, T], \\ \quad x(t) = x, \\ \quad (u(\cdot),\, v(\cdot)) \in L^2_{\mathcal{F}}(0,\, T;\, \mathbb{R}^m) \times L^2_{\mathcal{F}}(0,\, T;\, \mathbb{R}^n). \end{cases} \tag{4.10}$$

Since $S \geq 0$, it follows that $x'P(t)x \geq x'\bar{P}(t)x$ for all $(t,\, x) \in [0,\, T] \times \mathbb{R}^n$, from which the result follows. □

Remark 4.1. A special case of Theorem 4.4 is proved in [12, Theorem 4.2] under an additional assumption (inequality (4.3) in [12]).

THEOREM 4.5. *Let $M \geq 0$ be a given symmetric $n \times n$ matrix. Then the Riccati equation* (4.1) *is uniquely solvable. Moreover,*

(i) *if $M > 0$, then the solution $\Sigma(\cdot) > 0$, and*

(ii) *if $M \geq 0$, then the solution $\Sigma(\cdot) \geq 0$.*

Proof. We consider the issue of existence for the cases $M > 0$ and $M \geq 0$ separately. Uniqueness follows immediately from Proposition 4.1.

Case 1: $M > 0$. Let $P(\cdot)$ denote the solution of the Riccati equation (4.2). By Theorem 4.4, it follows that $P(t) > 0$ for all $t \in [0, T]$. Therefore, $P(t)^{-1}$ is well defined. Using the fact that $\frac{d}{dt}(P(t)^{-1}P(t)) = 0$ and $(S(t) + P(t))^{-1} = P(t)^{-1}(S(t)P(t)^{-1} + I)^{-1}$, it can be shown that $\Sigma(\cdot) := P(\cdot)^{-1}$ is a solution of (4.1). Clearly, $\Sigma(t) > 0$ for all $t \in [0, T]$.

Case 2: $M \geq 0$. Let $M_i := M + (1/i)I$ and $\Sigma_i(\cdot)$, $P_i(\cdot)$ denote the solutions of (4.1) and (4.2), respectively, corresponding to $M_i > 0$. Then $\Sigma_i(\cdot) = P_i(\cdot)^{-1} > 0$. Since $x'P_i(t)x$ is the optimal cost for the optimal control problem

$$\begin{cases} \min_{u(\cdot),\, v(\cdot)} E\int_t^T \{x(s)'Q(s)x(s) + u(s)'R(s)u(s) + v(s)'S(s)v(s)\}\, ds + x(T)'M_i^{-1}x(T) \\ \text{subject to} \\ \quad dx(s) = \{A(s)x(s) + B(s)u(s) + C(s)v(s)\}\, ds + v(s)\, dW(s), \quad s \in [t, T], \\ \quad x(t) = x, \\ \quad (u(\cdot),\, v(\cdot)) \in L^2_{\mathcal{F}}(0,\, T;\, \mathbb{R}^m) \times L^2_{\mathcal{F}}(0,\, T;\, \mathbb{R}^n), \end{cases}$$

it follows that $0 < P_i(t) \leq P_j(t)$ for all $i < j$, and hence $0 < \Sigma_j(t) \leq \Sigma_i(t)$. Therefore, $\Sigma_i(t)$ is a monotonically decreasing sequence that is bounded below and hence converges; that is, $\Sigma_i(t) \downarrow \Sigma(t) \geq 0$ for all $t \in [0, T]$. On the other hand,

$$\begin{aligned} \Sigma_i(t) = M + \frac{1}{i}I - \int_t^T \{&A(s)\Sigma_i(s) + \Sigma_i(s)A(s)' \\ &- B(s)R(s)^{-1}B(s)' - C(s)\Sigma_i(s)[S(s)\Sigma_i(s) + I]^{-1}C(s)' + \Sigma_i(s)Q(s)\Sigma_i(s)\}\, ds. \end{aligned}$$

Hence it follows from the bounded convergence theorem that

$$\begin{aligned} \Sigma(t) = M - \int_t^T \{&A(s)\Sigma(s) + \Sigma(s)A(s)' \\ &- B(s)R(s)^{-1}B(s)' - C(s)\Sigma(s)[S(s)\Sigma(s) + I]^{-1}C(s)' + \Sigma(s)Q(s)\Sigma(s)\}\, ds, \end{aligned}$$

so $\Sigma(\cdot)$ is a solution of (4.1). □

The above theorem implies, in particular, that (3.4) is uniquely solvable. Now we are in the position to prove the unique solvability of the Riccati equation (3.5).

COROLLARY 4.6. *Let* $\Sigma(\cdot)$ *denote the solution of* (3.4). *Then the Riccati equation* (3.5) *is uniquely solvable. Moreover,*

(i) *if* $H > 0$, *then the solution* $Z(\cdot) > 0$, *and*

(ii) *if* $H \geq 0$, *then the solution* $Z(\cdot) \geq 0$.

Proof. By making the time reversing transformation

$$\tau = T - t, \quad t \in [0, T],$$

the Riccati equation (3.5) is equivalent to

$$\begin{cases} \dot{Z}(t) - Z(t)A(t) - A(t)'Z(t) - Z(t)\left[B(t)R(t)^{-1}B(t)' \right. \\ \qquad\qquad \left. + C(t)\Sigma(t)(I + S(t)\Sigma(t))^{-1}C(t)'\right] Z(t) + Q(t) = 0, \\ Z(T) = H. \end{cases} \tag{4.11}$$

We now show that (4.11) is a special case of the Riccati equation (4.1). To see this, let $\Sigma_i(\cdot)$ and $P_i(\cdot)$ denote the solutions of (4.1) and (4.2) when $M = (1/i)I$. Since

$$\Sigma(t)(I + S(t)\Sigma(t))^{-1} = \lim_{i \uparrow \infty} \Sigma_i(t)(I + S(t)\Sigma_i(t))^{-1} = \lim_{i \uparrow \infty}(S(t) + P_i(t))^{-1},$$

which implies, in particular, that $B(t)R(t)^{-1}B(t)' + C(t)\Sigma(t)(I + S(t)\Sigma(t))^{-1}C(t)'$ is symmetric, and

$$Q(t) = (Q(t)^{\frac{1}{2}})\, I^{-1}\, (Q(t)^{\frac{1}{2}})',$$

it follows that (4.11) is an equation of the form (4.1). Therefore, Theorem 4.5 applies, and (3.5) is uniquely solvable. □

Now we have proved the unique solvability of the two Riccati equations (3.4) and (3.5). The unique solvability of (3.7) and (3.8), with the solutions $(h(\cdot), \eta(\cdot)) \in L^2_{\mathcal{F}}(\Omega; C(0, T; \mathbb{R}^n)) \times L^2_{\mathcal{F}}(0, T; \mathbb{R}^n)$ and $q(\cdot) \in L^2_{\mathcal{F}}(\Omega; C(0, T; \mathbb{R}^n))$, is evident as they are linear BSDE/SDE with bounded linear coefficients and square integrable nonhomogeneous terms; see, e.g., [19, Theorem 2.2, p. 349] and [19, Theorem 6.14, p. 47]. Finally, the unique solvability of the Lyapunov equation (3.6) is well known.

Next let us study the asymptotic behavior of some equations with respect to the terminal condition of those equations, which is important in proving the main results, Theorems 3.2 and 3.3. Let $M > 0$ be a symmetric $n \times n$ matrix. Consider the following equations parameterized by M:

$$\text{(4.12)} \quad \begin{cases} \dot{P}(t) + P(t)A(t) + A(t)'P(t) \\ \quad -P(t)[B(t)R(t)^{-1}B(t)' + C(t)(S(t) + P(t))^{-1}C(t)']P(t) + Q(t) = 0, \\ P(T) = M^{-1}, \end{cases}$$

$$\text{(4.13)} \quad \begin{cases} \dot{\Sigma}(t) - A(t)\Sigma(t) - \Sigma(t)A(t)' - \Sigma(t)Q(t)\Sigma(t) \\ \quad +B(t)R(t)^{-1}B(t)' + C(t)\Sigma(t)(S(t)\Sigma(t) + I)^{-1}C(t)' = 0, \\ \Sigma(T) = M, \end{cases}$$

$$\text{(4.14)} \quad \begin{cases} dh(t) = \{(A(t) + \Sigma(t)Q(t))h(t) + C(t)(I + \Sigma(t)S(t))^{-1}\, \eta(t)\}\, dt \\ \quad +\eta(t)\, dW(t), \\ h(T) = -\xi. \end{cases}$$

Notice that the $\Sigma(\cdot)$ appearing on the right-hand side of (4.14) is the solution to (4.13) which depends on M; hence (4.14) and (3.7) are *different*.

PROPOSITION 4.7. *Let M_i $(i \in \mathbb{Z}^+)$ and M be symmetric, $n \times n$, positive semidefinite matrices. Let $\Sigma_i(\cdot)$, $(h_i(\cdot), \eta_i(\cdot))$ and $\Sigma(\cdot)$, $(h(\cdot), \eta(\cdot))$ be solutions of* (4.13)–(4.14)*, corresponding to M_i and M, respectively. If $M_i \to M$, then $\Sigma_i(\cdot) \to \Sigma(\cdot)$, uniformly on $[0, T]$, and $(h_i(\cdot), \eta_i(\cdot)) \to (h(\cdot), \eta(\cdot))$ in $L^2_{\mathcal{F}}(\Omega; C(0, T; \mathbb{R}^n)) \times L^2_{\mathcal{F}}(0, T; \mathbb{R}^n)$, as $i \uparrow \infty$.*

Proof. Since every convergent sequence is bounded, there exists $0 < \bar{M} \in S^n$ such that $M_i \le \bar{M}$ and $M \le \bar{M}$. Therefore, $\Sigma(\cdot) \le \bar{\Sigma}(\cdot)$ and $\Sigma_i(\cdot) \le \bar{\Sigma}(\cdot)$, where $\bar{\Sigma}(\cdot)$ is the solution of (4.1) corresponding to $\bar{M}$. It follows that if $\Delta_i(\cdot) := \Sigma_i(\cdot) - \Sigma(\cdot)$, then $\|\Delta_i(t)\| \le C$ for every $t \in [0, T]$ uniformly in i, where $C < \infty$ is a constant independent of i. As in the proof of Proposition 4.1, it can be shown that

$$\Delta_i(t) := (M_i - M) - \int_t^T \{[A(s) + \Sigma(s)Q(s)]\Delta_i(s) + \Delta_i(s)[A(s) + \Sigma(s)Q(s)]'$$
$$+\Delta_i(s)Q(s)\Delta_i(s) - C(s)[I - \Sigma_i(s)(S(s)\Sigma_i(s) + I)^{-1}S(s)]\Delta_i(s)(S(s)\Sigma(s) + I)^{-1}C(s)'\}\, ds.$$

Since $\|\Delta_i(t)\| \le C$, uniformly in i, it follows that

$$\|\Delta_i(t)\| \le \|M_i - M\| + K \int_t^T \|\Delta_i(s)\|\, ds,$$

where $K < \infty$ is a constant independent of i. From Gronwall's inequality, it follows that $\|\Delta_i(t)\| \le \|M_i - M\| e^{KT}$, so $\Delta_i(\cdot) \to 0$ as $i \uparrow \infty$, uniformly on $[0, T]$.

To show convergence of $(h_i(\cdot), \eta_i(\cdot))$ to $(h(\cdot), \eta(\cdot))$, observe that

$$\begin{cases} d(h(t) - h_i(t)) = [(A(t) + \Sigma(t)Q(t))(h(t) - h_i(t)) \\ \qquad\qquad + C(t)(I + \Sigma(t)S(t))^{-1}(\eta(t) - \eta_i(t)) \\ \qquad\qquad + (\Sigma(t) - \Sigma_i(t))Q(t)h_i(t) \\ \qquad\qquad - C(t)(I + \Sigma(t)S(t))^{-1}(\Sigma(t) - \Sigma_i(t))S(t)(I + \Sigma_i(t)S(t))^{-1}\eta_i(t)]\, dt \\ \qquad\qquad + (\eta(t) - \eta_i(t))dW(t), \\ h(T) - h_i(T) = 0. \end{cases}$$

Since $(h(\cdot) - h_i(\cdot), \eta(\cdot) - \eta_i(\cdot))$ is the (unique) solution of a linear BSDE, it follows from [19, Theorem 2.2, p. 349] that

$$\begin{aligned} &E \sup_{t\in[0,\,T]} |h(t) - h_i(t)|^2 + E \int_0^T |\eta(t) - \eta_i(t)|^2\, dt \\ &\le K_1 E \int_0^T |(\Sigma(t) - \Sigma_i(t))Q(t)h_i(t) \\ &\quad -C(t)(I + \Sigma(t)S(t))^{-1}(\Sigma(t) - \Sigma_i(t))S(t)(I + \Sigma_i(t)S(t))^{-1}\eta_i(t)|^2\, dt, \\ &\le K_2 \|\Sigma(\cdot) - \Sigma_i(\cdot)\|^2 E \int_0^T (|h_i(t)|^2 + |\eta_i(t)|^2)\, dt \end{aligned}$$

for some constants K_1, $K_2 < \infty$ (which are independent of i). Finally, since $\Sigma_i(\cdot)$ is uniformly bounded in i, it can be shown (following the proof of [19, Theorem 2.2, p. 349]) that $E\int_0^T |h_i(t)|^2\, dt$ and $E\int_0^T |\eta_i(t)|^2\, dt$ are bounded, uniformly in i. Our result follows from the fact that $\Sigma_i(\cdot) \to \Sigma(\cdot)$ as $i \uparrow \infty$. □

Before we conclude this section, we present a representation result for the solution of the Lyapunov equation (3.6).

PROPOSITION 4.8. *The solution of the Lyapunov equation* (3.6) *is*

$$N(t) = \frac{1}{2}[Z(t)(I + \Sigma(t)Z(t))^{-1} + (I + Z(t)\Sigma(t))^{-1}Z(t)]. \tag{4.15}$$

Proof. Case 1: $H > 0$. In this case $Z(t) > 0$ for every $t \in [0, T]$; see Corollary 4.6. Therefore, $Z(t)^{-1}$ is well defined and (4.15) is equivalent to:

$$N(t) = (Z(t)^{-1} + \Sigma(t))^{-1}. \tag{4.16}$$

Thus it suffices to show that the right-hand side of (4.16) is a solution of (3.6). By evaluating $\frac{d}{dt}\{Z(t)Z(t)^{-1}\} = 0$, it is easy to show that

$$\begin{cases} \frac{d}{dt}\{Z(t)^{-1}\} = A(t)Z(t)^{-1} + Z(t)^{-1}A(t)' \\ \quad +B(t)R(t)^{-1}B(t)' + C(t)\Sigma(t)(I + S(t)\Sigma(t))^{-1}C(t)' - Z(t)^{-1}Q(t)Z(t)^{-1}, \\ Z(0)^{-1} = H^{-1}. \end{cases}$$

Therefore, $N(t)^{-1} = Z(t)^{-1} + \Sigma(t)$ is the solution of the ODE:

$$\begin{cases} \dfrac{d}{dt}\{N(t)^{-1}\} = (A(t) + \Sigma(t)Q(t))N(t)^{-1} + N(t)^{-1}(A(t) + \Sigma(t)Q(t))' \\ \qquad\qquad - N(t)^{-1}Q(t)N(t)^{-1}, \\ N(0)^{-1} = H^{-1} + \Sigma(0). \end{cases}$$

Finally, by evaluating $\frac{d}{dt}\{N(t)N(t)^{-1}\} = 0$, it is easy to show that the right-hand side of (4.16) (and hence that of (4.15)) is a solution of (3.6).

Case 2: $H \geq 0$. Let $Z(\cdot)$, $Z_i(\cdot)$ $(i \in \mathbb{Z}^+)$ be the solutions of (3.5) corresponding to H and $H_i := H + (1/i)I > 0$, respectively, where the $\Sigma(\cdot)$ in the coefficients of (3.5) is the solution to (3.4). Let

$$N_i(t) = \frac{1}{2}[Z_i(t)(I + \Sigma(t)Z_i(t))^{-1} + (I + Z_i(t)\Sigma(t))^{-1}Z_i(t)]. \tag{4.17}$$

It follows from Case 1 that $N_i(\cdot)$ is the unique solution of the Lyapunov equation

$$\begin{cases} \dot{N}_i(t) + N_i(t)(A(t) + \Sigma(t)Q(t)) + (A(t) + \Sigma(t)Q(t))'N_i(t) - Q(t) = 0, \\ N_i(0) = \frac{1}{2}\{H_i(I + \Sigma(0)H_i)^{-1} + (I + H_i\Sigma(0))^{-1}H_i\}. \end{cases}$$

On the other hand, we know from the continuity of solutions of linear ODEs with respect to initial conditions that $N_i(\cdot) \to N(\cdot)$, where $N(\cdot)$ is the solution of the ODE (3.6). Therefore, to prove that $N(\cdot)$ has the representation (4.15), we need only show that $Z_i(\cdot) \to Z(\cdot)$ since this will imply that the right-hand side of (4.17) converges to the right-hand side of (4.15). However, it follows from the fact that (3.5) is a special case of (3.4) (see the proof of Corollary 4.6) and the convergence properties of (3.4) (Proposition 4.7) that $Z_i(\cdot) \to Z(\cdot)$ as $i \uparrow \infty$. This proves our result. □

5. Proofs of Theorems 3.2 and 3.3. In this section we give proofs of the main results of the paper, Theorems 3.2 and 3.3. The basic idea is first to find a lower bound of the cost function (2.3) (see Lemma 5.1), and then to identify a control which achieves *exactly* this lower bound (see Proposition 5.3).

To obtain a lower bound of (2.3), we use the completion-of-squares technique. Consider (4.12)–(4.14) parameterized by $M > 0$. It has been shown in section 4 that these three equations have unique solutions $P_M(\cdot) > 0, \Sigma_M(\cdot) > 0$, and $(h_M(\cdot), \eta_M(\cdot)) \in L^2_{\mathcal{F}}(\Omega; C(0, T; \mathbb{R}^n)) \times L^2_{\mathcal{F}}(0, T; \mathbb{R}^n)$, respectively, for every $M > 0$, and $\Sigma_M(t) = P_M(t)^{-1}$ for all $t \in [0, T]$.

Let $(x(\cdot), z(\cdot))$ be the solution of the BSDE (2.1) corresponding to a control $u(\cdot) \in \mathcal{U}$. Applying Ito's formula to $(x(t) + h_M(t))'P_M(t)(x(t) + h_M(t))$, we obtain

$$\begin{aligned} &d\{(x + h_M)'P_M(x + h_M)\} \\ &= \{(x + h_M)'\,(P_MBR^{-1}B'P_M + P_MC(S + P_M)^{-1}C'P_M - Q)\,(x + h_M) \\ &\quad +2(x + h_M)'\,P_M\,(\Sigma_MQh_M + C(\Sigma_MS + I)^{-1}\eta_M - C\eta_M) \\ &\quad +(z + \eta_M)'P_M(z + \eta_M) + 2(z + \eta_M)'C'P_M(x + h_M) + 2u'B'P_M(x + h_M)\}\,dt \\ &\quad +\{\cdots\}\,dW. \end{aligned}$$

Integrating both sides with respect to t and taking expectations, we arrive at

$$\begin{aligned} 0 &= (x(0) + h_M(0))'P_M(0)(x(0) + h_M(0)) \\ &\quad +E\int_0^T \{(x + h_M)'(P_MBR^{-1}B'P_M + P_MC(S + P_M)^{-1}C'P_M - Q)(x + h_M) \\ &\quad +2(x + h_M)'\,P_M\,(\Sigma_MQh_M + C(\Sigma_MS + I)^{-1}\eta_M - C\eta_M) \\ &\quad +(z + \eta_M)'P_M(z + \eta_M) + 2(z + \eta_M)'C'P_M(x + h_M) + 2u'B'P_M(x + h_M)\}\,dt. \end{aligned} \tag{5.1}$$

Adding (5.1) to the right-hand side of (2.3), we obtain (after some manipulation)

$$\begin{aligned}J(\xi;u(\cdot)) = {}& \frac{1}{2}[x(0)+(\Sigma_M(0)H+I)^{-1}h_M(0)]'[H+P_M(0)][x(0)+(\Sigma_M(0)H+I)^{-1}h_M(0)]\\ &+\frac{1}{2}h_M(0)'(H\Sigma_M(0)+I)^{-1}Hh_M(0)+E\int_0^T\{h_M'Qh_M+\eta_M'(S\Sigma_M+I)^{-1}S\eta_M\}\,dt\\ &+E\frac{1}{2}\int_0^T\{[u+R^{-1}B'P_M(x+h_M)]'R[u+R^{-1}B'P_M(x+h_M)]\\ &+[z+(I+\Sigma_MS)^{-1}\eta_M+\Sigma_M(I+S\Sigma_M)^{-1}C'P_M(x+h_M)]'\\ &\times(S+P_M)[z+(I+\Sigma_MS)^{-1}\eta_M+\Sigma_M(I+S\Sigma_M)^{-1}C'P_M(x+h_M)]\}\,dt.\end{aligned}\tag{5.2}$$

In deriving this expression, we have used the fact that $\Sigma_M(t)=P_M(t)^{-1}$ together with the following simple relations:

$$\begin{aligned}&[H+P_M(0)]^{-1}P_M(0)=[\Sigma_M(0)H+I]^{-1},\\ &P_M(0)-P_M(0)(H+P_M(0))^{-1}P_M(0)=[H\Sigma_M(0)+I]^{-1}H,\\ &z+\eta_M+(I+\Sigma_MS)^{-1}\Sigma_M(C'P_M(x+h_M)-S\eta_M)\\ &\quad=z+(I+\Sigma_MS)^{-1}\eta_M+\Sigma_M(I+S\Sigma_M)^{-1}C'P_M(x+h_M).\end{aligned}$$

Since $H+P_M(0)>0$, $R>0$, and $S+P_M>0$, it follows from (5.2) that

$$\begin{aligned}J(\xi;u(\cdot))\geq{}&h_M(0)'[H\Sigma_M(0)+I]^{-1}Hh_M(0)\\ &+E\int_0^T\{h_M'Qh_M+\eta_M'(S\Sigma_M+I)^{-1}S\eta_M\}dt\end{aligned}\tag{5.3}$$

for any $u(\cdot)\in\mathcal{U}$. Note that the right-hand side of (5.3) depends on $\Sigma_M(\cdot)$ and $(h_M(\cdot),\eta_M(\cdot))$ (but does not depend on $P_M(\cdot)$). Therefore, it is well defined even when $M=0$. Thus we have the following result.

LEMMA 5.1. *We have*

$$\begin{aligned}J(\xi;u(\cdot))\geq{}&h(0)'[H\Sigma(0)+I]^{-1}Hh(0)\\ &+E\int_0^T\{h'Qh+\eta'(S\Sigma+I)^{-1}S\eta\}dt\ \forall u(\cdot)\in\mathcal{U},\end{aligned}\tag{5.4}$$

where $\Sigma(\cdot)$ *and* $(h(\cdot),\eta(\cdot))$ *are the solutions of* (3.4) *and* (3.7)*, respectively.*

Proof. Letting $M\to 0$ in (5.3) and appealing to Proposition 4.7, we obtain the result. □

Lemma 5.1 provides a lower bound on the cost function (2.3). Now we are to find a control that achieves this lower bound. To this end, recall the Hamiltonian system (3.12)–(3.13).

PROPOSITION 5.2. *The Hamiltonian system* (3.12)–(3.13) *has a unique solution* $(x(\cdot),z(\cdot),y(\cdot))$*. Moreover, the following relations are satisfied:*

$$\begin{cases}x(t)=\Sigma(t)y(t)-h(t),\\ z(t)=-\Sigma(t)(S(t)\Sigma(t)+I)^{-1}C(t)'y(t)-(\Sigma(t)S(t)+I)^{-1}\eta(t),\\ x(0)=-(\Sigma(0)H+I)^{-1}h(0),\end{cases}\tag{5.5}$$

where $\Sigma(\cdot)$ *and* $(h(\cdot),\eta(\cdot))$ *are the solutions of* (3.4) *and* (3.7)*, respectively.*

Proof. We begin by proving existence. Consider the following SDE:

$$\text{(5.6)}\quad \begin{cases} d\bar{y}(t) = [-(A(t)+\Sigma(t)Q(t))'\bar{y}(t) + Q(t)h(t)]\,dt \\ \quad\quad +[-(I+S(t)\Sigma(t))^{-1}C(t)'\bar{y}(t) + S(t)(I+\Sigma(t)S(t))^{-1}\eta(t)]\,dW(t), \\ \bar{y}(0) = H(\Sigma(0)H+I)^{-1}h(0). \end{cases}$$

Since (5.6) is a linear SDE with bounded coefficients and square integrable nonhomogeneous terms, it follows that it has a unique solution $\bar{y}(\cdot)$. On the other hand, we can define

$$\text{(5.7)}\qquad \bar{x}(t) := \Sigma(t)\bar{y}(t) - h(t).$$

By applying Ito's formula to (5.7), we obtain

$$\text{(5.8)}\quad \begin{cases} d\bar{x}(t) = [A(t)\bar{x}(t) - B(t)R(t)^{-1}B(t)'\bar{y}(t) \\ \quad\quad +C(t)(-(\Sigma(t)S(t)+I)^{-1}\eta(t) - \Sigma(t)(I+S(t)\Sigma(t))^{-1}C(t)'\bar{y}(t))]\,dt \\ \quad\quad +[-(\Sigma(t)S(t)+I)^{-1}\eta(t) - \Sigma(t)(I+S(t)\Sigma(t))^{-1}C(t)'\bar{y}(t)]\,dW(t), \\ \bar{x}(0) = -(\Sigma(0)H+I)^{-1}h(0). \end{cases}$$

Substituting

$$\text{(5.9)}\qquad \bar{z}(t) := -(\Sigma(t)S(t)+I)^{-1}\eta(t) - \Sigma(t)(I+S(t)\Sigma(t))^{-1}C(t)'\bar{y}(t)$$

into (5.8) and noting (from (5.7)) that $\bar{x}(T) = \xi$, it follows that

$$\text{(5.10)}\quad \begin{cases} d\bar{x}(t) = [A(t)\bar{x}(t) - B(t)R(t)^{-1}B(t)'\bar{y}(t) + C(t)\bar{z}(t)]\,dt + \bar{z}(t)\,dW(t), \\ \bar{x}(T) = \xi. \end{cases}$$

On the other hand, it follows from (5.9) that

$$\begin{aligned} &-C(t)'\bar{y}(t) - S(t)\bar{z}(t) \\ &= S(t)(\Sigma(t)S(t)+I)^{-1}\eta(t) \\ &\quad +[S(t)\Sigma(t) - (S(t)\Sigma(t)+I)](S(t)\Sigma(t)+I)^{-1}C(t)'\bar{y}(t) \\ &= S(t)(\Sigma(t)S(t)+I)^{-1}\eta(t) - (S(t)\Sigma(t)+I)^{-1}C(t)'\bar{y}(t). \end{aligned} \qquad \text{(5.11)}$$

Finally, substituting (5.7) and (5.11) into (5.6) and noting (from (5.8)) the initial value of $\bar{x}(0)$, it follows that $\bar{y}(t)$ is a solution of the differential equation

$$\text{(5.12)}\quad \begin{cases} d\bar{y}(t) = \{-A(t)'\bar{y}(t) - Q(t)\bar{x}(t)\}dt + \{-C(t)'\bar{y}(t) - S(t)\bar{z}(t)\}dW(t), \\ \bar{y}(0) = -H\bar{x}(0). \end{cases}$$

That is, $(\bar{x}(\cdot), \bar{z}(\cdot), \bar{y}(\cdot))$ is a solution of the system of equations (5.10), (5.12) and hence a solution of the Hamiltonian system (3.12)–(3.13). In addition, by virtue of (5.7), (5.8), and (5.9), the relations (5.5) are satisfied.

To prove uniqueness, suppose that $(x_1(\cdot), z_1(\cdot), y_1(\cdot))$ and $(x_2(\cdot), z_2(\cdot), y_2(\cdot))$ are solutions of (3.12)–(3.13). It follows that $(x(\cdot), z(\cdot), y(\cdot)) := (x_1(\cdot) - x_2(\cdot), z_1(\cdot) - z_2(\cdot), y_1(\cdot) - y_2(\cdot))$ is a solution of the Hamiltonian system

$$\text{(5.13)}\quad \begin{cases} dx(t) = \{A(t)x(t) - B(t)R(t)^{-1}B(t)'y(t) + C(t)z(t)\}dt + z(t)dW(t), \\ x(T) = 0, \end{cases}$$

$$\text{(5.14)}\quad \begin{cases} dy(t) = \{-A(t)'y(t) - Q(t)x(t)\}dt + \{-C(t)'y(t) - S(t)z(t)\}dW(t), \\ y(0) = -Hx(0). \end{cases}$$

By Ito's formula, we have

$$d\{x(t)'y(t)\} = \{ - x(t)'Q(t)x(t) - y(t)'B(t)R(t)^{-1}B(t)'y(t) - z(t)'S(t)z(t)\}dt + \{\cdots\}dW(t).$$

Integrating both sides from 0 to T and taking expectations, we obtain

$$x(0)'Hx(0) = -E\int_0^T (x(t)'Q(t)x(t) + y(t)'B(t)R(t)^{-1}B(t)'y(t) + z(t)'S(t)z(t))dt.$$

Since H, $Q(\cdot)$, $R(\cdot)$, and $S(\cdot)$ are all positive semidefinite (see (A1)), it follows that

$$E\int_0^T (x(t)'Q(t)x(t) + y(t)'B(t)R(t)^{-1}B(t)'y(t) + z(t)'S(t)z(t))dt = 0.$$

Finally, since $R(\cdot) > 0$, it follows that

$$B(t)'y(t) = 0, \quad \text{a.e. } t \in [0, T],\ P\text{-a.s..}$$

Substituting this into (5.13), it follows that $(x(\cdot), z(\cdot))$ is the solution of the linear BSDE:

$$\begin{cases} dx(t) = \{A(t)x(t) + C(t)z(t)\}dt + z(t)dW(t), \\ x(T) = 0, \end{cases}$$

and the uniqueness of solutions for linear BSDEs implies that $(x(\cdot), z(\cdot)) \equiv 0$. Substituting $(x(\cdot), z(\cdot)) \equiv 0$ into (5.14), it follows that $y(\cdot)$ is a solution of linear SDE

$$\begin{cases} dy(t) = -A(t)'y(t)dt - C(t)'y(t)dW(t), \\ y(0) = -Hx(0). \end{cases}$$

Hence it follows from the uniqueness again that $y(\cdot) \equiv 0$. This proves our result. □

Remark 5.1.We have shown, in fact, that $(x(\cdot), z(\cdot), y(\cdot))$ is the solution of the Hamiltonian system (3.12)–(3.13) if and only if $y(\cdot)$ is the solution of (5.6), $x(\cdot)$ is the solution of (5.8), and $z(\cdot)$ satisfies (5.9). This means that we may use the Hamiltonian system (3.12)–(3.13) or (5.6), (5.8), and (5.9) interchangeably to describe the processes $y(\cdot)$, $x(\cdot)$, and $z(\cdot)$. This is an important observation which simplifies much of our subsequent analysis.

PROPOSITION 5.3. *Let $(x(\cdot), z(\cdot), y(\cdot))$ be the solution of the Hamiltonian system* (3.12)–(3.13)*, and let $u(\cdot)$ be given by*

$$u(t) = -R(t)^{-1}B(t)'y(t). \tag{5.15}$$

Then $(x(\cdot), z(\cdot))$ is the solution of the BSDE (2.1) *corresponding to* (5.15) *and*

$$\begin{aligned} J(\xi; u(\cdot)) =& h(0)'[H\Sigma(0) + I]^{-1}Hh(0) \\ &+ E\int_0^T \{h'Qh + \eta'(S\Sigma + I)^{-1}S\eta\}\, dt \end{aligned} \tag{5.16}$$

is the associated cost.

Proof. Let $(x(\cdot), z(\cdot), y(\cdot))$ be the solution of the Hamiltonian system (3.12)–(3.13), and let $u(\cdot)$ be given by (5.15). It follows from Remark 5.1 that $y(\cdot)$ is also the unique solution of the SDE (5.6). Regarding $y(\cdot)$ in this way, it follows that $(x(\cdot), z(\cdot))$ (as determined from (3.12)–(3.13)) is also the solution of BSDE (2.1) when $u(\cdot)$ is given by (5.15).

To determine the cost associated with the control (5.15), we shall use the fact that $y(\cdot)$ is also the unique solution of the linear SDE (5.6). By Ito's formula, it can be shown that

$$\begin{aligned} d\{y'\,\Sigma\, y\} &= \{-y'[\Sigma Q\Sigma + BR^{-1}B' + C(\Sigma S + I)^{-1}\Sigma S\Sigma(S\Sigma + I)^{-1}C']y \\ &\quad -2\eta'(S\Sigma + I)^{-1}S\Sigma(S\Sigma + I)^{-1}C'y + 2y'\Sigma Qh \\ &\quad +\eta'(S\Sigma + I)^{-1}S\Sigma S(\Sigma S + I)^{-1}\eta\}\,dt + \{\cdots\}\,dW. \end{aligned}$$

Therefore,

$$\begin{aligned} &E\int_0^T \{y'[\Sigma Q\Sigma + BR^{-1}B' + C(\Sigma S + I)^{-1}\Sigma S\Sigma(S\Sigma + I)^{-1}C']\,y \\ &\quad +2\eta'(S\Sigma + I)^{-1}S\Sigma(S\Sigma + I)^{-1}C'y - 2y'\Sigma Qh\}\,dt \\ &= h(0)'(I + H\Sigma(0))^{-1}H\Sigma(0)H(I + \Sigma(0)H)^{-1}h(0) \\ &\quad +E\int_0^T \eta'(S\Sigma + I)^{-1}S\Sigma S(\Sigma S + I)^{-1}\eta\,dt. \end{aligned} \tag{5.17}$$

On the other hand, the cost associated with the control (5.15) can be obtained by substituting (5.5) and (5.15) into (2.3). By doing this, we obtain

$$\begin{aligned} J(\xi; u(\cdot)) &= h(0)'(I + H\Sigma(0))^{-1}H(I + \Sigma(0)H)^{-1}h(0) \\ &\quad +E\int_0^T \{\eta'(I + S\Sigma)^{-1}S(I + \Sigma S)^{-1}\eta + h'Qh \\ &\quad +y'[\Sigma Q\Sigma + BR^{-1}B' + C(\Sigma S + I)^{-1}\Sigma S\Sigma(S\Sigma + I)^{-1}C']\,y \\ &\quad +2\eta'(S\Sigma + I)^{-1}S\Sigma(S\Sigma + I)^{-1}C'y - 2y'\Sigma Qh\}\,dt. \end{aligned}$$

Hence it follows from (5.17) that

$$\begin{aligned} J(\xi; u(\cdot)) &= h(0)'(I + H\Sigma(0))^{-1}(H + H\Sigma(0)H)(I + \Sigma(0)H)^{-1}h(0) \\ &\quad +E\int_0^T \{h'Qh + \eta'(S\Sigma + I)^{-1}(S + S\Sigma S)(I + \Sigma S)^{-1}\eta\}\,dt \\ &= h(0)'[H\Sigma(0) + I]^{-1}Hh(0) + E\int_0^T \{h'Qh + \eta'(S\Sigma + I)^{-1}S\eta\}\,dt, \end{aligned}$$

which is precisely the expression (5.16). □

Proof of Theorem 3.3. The unique solvability of the Hamiltonian system (3.12)–(3.13) has been proved in Proposition 5.2. The optimality of (5.15) follows from the fact that the cost (5.16) associated with the control (5.15) is equal to a lower bound to the optimal cost; see Lemma 5.1. The expression (3.11) for the optimal cost can be obtained by applying Ito's formula to $h(t)'N(t)h(t)$. By doing this, we obtain the

relation

$$\begin{aligned} &h(0)'H(I+\Sigma(0)H)^{-1}h(0)+E\int_0^T\{h'Qh+\eta'(S\Sigma+I)^{-1}S\eta\}\,dt\\ &\quad=E\xi'N(T)\xi+E\int_0^T\{\eta(t)'[(S(t)\Sigma(t)+I)^{-1}S(t)-N(t)]\eta(t)\\ &\qquad-2\eta(t)'(I+S(t)\Sigma(t))^{-1}C(t)'N(t)h(t)\}\,dt. \end{aligned} \tag{5.18}$$

This yields the optimal cost (3.11). Finally, we are able to conclude that the control (5.15) is unique because the BLQ problem (2.4) is a (strictly) convex optimization problem. The set of admissible triples $(x(\cdot), z(\cdot), u(\cdot))$ associated with (2.1) is a convex set, and the cost (2.3) is a strictly convex function on this set. □

Now we proceed to prove Theorem 3.2. First we have the following lemma.

LEMMA 5.4. *Let $(x(\cdot), z(\cdot), y(\cdot))$ be the solution of the Hamiltonian system* (3.12)–(3.13)*, and let $q(\cdot)$ be the solution of the SDE* (3.8)*. Then*

$$y(t)=-Z(t)x(t)-q(t). \tag{5.19}$$

Proof. Let $(x(\cdot), z(\cdot), y(\cdot))$ denote the solution of the Hamiltonian system (3.12)–(3.13). We have already shown that $x(\cdot)=\bar{x}(\cdot)$, where $\bar{x}(\cdot)$ is the solution of the SDE (5.8); see also Remark 5.1. Therefore, we can prove (5.19) by showing that

$$y(t)=-Z(t)\bar{x}(t)-q(t). \tag{5.20}$$

Let $y(\cdot)$, $\bar{x}(\cdot)$, and $Z(\cdot)$ be solutions of (5.6), (5.8), and (3.5), respectively. Also, let us assume for the time being that $q(\cdot)$ is the unique solution of the SDE

$$\begin{cases} dq(t)=\{-[A(t)+B(t)R(t)^{-1}B(t)'Z(t)\\ \qquad\qquad +C(t)(I+\Sigma(t)S(t))^{-1}\Sigma(t)C(t)'Z(t)]'\,q(t)\\ \qquad +Z(t)C(t)(I+\Sigma(t)S(t))^{-1}\eta(t)\}dt+\{(Z(t)-S(t))(I+\Sigma(t)S(t))^{-1}\eta(t)\\ \qquad +(I+Z(t)\Sigma(t))(I+S(t)\Sigma(t))^{-1}C(t)'y(t)\}\,dW(t),\\ q(0)=0. \end{cases} \tag{5.21}$$

(Note that (3.8) and (5.21) differ only in their diffusion terms. It will be shown later that (3.8) and (5.21) have the same solution. In the meantime, however, it will be easier to work with (5.21)). Finally, by virtue of (5.5), $y(\cdot)$ is also the unique solution of the SDE

$$\begin{cases} dy(t)=\{-A(t)'y(t)-Q(t)\bar{x}(t)\}\,dt\\ \qquad +\{S(t)(I+\Sigma(t)S(t))^{-1}\eta(t)-(I+S(t)\Sigma(t))^{-1}C(t)'y(t)\}\,dW(t),\\ y(0)=H(\Sigma(0)H+I)^{-1}h(0). \end{cases} \tag{5.22}$$

With $q(\cdot)$ denoting the solution of (5.21), it is easy to show (using Ito's formula) that

$$\begin{cases} d\{y(t)+Z(t)\bar{x}(t)+q(t)\}\\ \qquad =[A(t)+B(t)R(t)^{-1}B(t)'Z(t)+C(t)(I+\Sigma(t)S(t))^{-1}\Sigma(t)C(t)'Z(t)]'\\ \qquad \times(y(t)+Z(t)\bar{x}(t)+q(t))\,dt,\\ y(0)+Z(0)\bar{x}(0)+q(0)=0. \end{cases} \tag{5.23}$$

Hence it follows from the uniqueness of solutions of linear SDEs that

$$y(t) + Z(t)x(t) + q(t) = y(t) + Z(t)\bar{x}(t) + q(t) = 0 \quad \forall\, t \in [0,\, T],\ P\text{-a.s.}, \tag{5.24}$$

where $q(\cdot)$ is the solution of (5.21). Finally, substituting (5.7) into (5.24), it is easy to show that

$$y(t) = (I + Z(t)\Sigma(t))^{-1}(Z(t)h(t) - q(t)). \tag{5.25}$$

Substituting (5.25) into (5.21), it follows that $q(\cdot)$ is the unique solution of both (5.21) and (3.8). □

Proof of Theorem 3.2. It follows immediately from Proposition 5.3 and Lemma 5.4. □

Finally, it is important to recognize that the expressions for the optimal control, as presented in Theorems 3.3 and 3.2, are equivalent expressions of the same process; that is, this does not contradict the uniqueness of optimal controls for (2.4).

6. Origin of idea: Forward formulation. In section 5, we obtained the solution of the BLQ problem (2.4) by showing that the control (3.14) or (3.9) achieves a lower bound to the cost function. In showing this result, (3.4)–(3.8), especially the Riccati equations (3.4) and (3.5), play a crucial role. In other words, once these equations are in place, then the whole derivation, albeit quite tedious, is essentially in the same spirit as the completion-of-squares technique commonly used in tackling forward LQ problems. However, the reader may be puzzled about how these (rather complicated) equations were obtained in the first place. This section serves to unfold the origin of those equations by presenting an alternative and intuitively appealing approach to the BLQ problem (2.4). The idea is basically inspired by [15, 12], where an (uncontrolled) BSDE is regarded as a *controlled forward* SDE. Here we go one step further to show that the BLQ problem can also be viewed as a (constrained) forward LQ problem, and that the solution (5.15) of the BLQ problem and the relationships (5.5) coincide with the limiting solution of a sequence of unconstrained forward LQ problems. In this process, the Riccati equations (3.4) and (3.5), along with other related equations, come out very naturally. It should be noted that our aim in this section is to highlight the origin of (3.4)–(3.8) as well as (5.5), and hence the material in this section will be presented in an informal way. For this reason, certain convergence results required in this derivation, for example, are taken for granted, although they can be verified rigorously using standard techniques from stochastic analysis, the details of which are left to the interested reader. (As a matter of fact, the first version of this paper *was* written rigorously using the forward formulation, but then we went for the current version finding that the presentation would be much simpler once all the necessary equations were identified.) Finally, for the sake of notational convenience, we shall assume throughout this section that $S = 0$. The extension to the case $S \geq 0$ can be obtained in a similar way.

Forward LQ problem.

Consider the following SDE:

$$\begin{cases} dx(t) &= \{A(t)x(t) + B(t)u(t) + C(t)v(t)\}dt + v(t)\, dW(t), \\ x(0) &= x^0. \end{cases} \tag{6.1}$$

We assume throughout that $x^0 \in \mathbb{R}^n$ and $(u(\cdot),\, v(\cdot)) \in \bar{\mathcal{U}}$, where

$$\bar{\mathcal{U}} = L^2_{\mathcal{F}}(0,\, T;\, \mathbb{R}^m) \times L^2_{\mathcal{F}}(0,\, T;\, \mathbb{R}^n).$$

For every $i \in \mathbb{Z}^+$ let

$$\begin{aligned} &J(x^0,\, u(\cdot),\, v(\cdot);\, i) \\ &:= E\frac{1}{2}\{x^{0\prime} H x^0 + \int_0^T (x(t)'Q(t)x(t) + u(t)'R(t)u(t))\, dt + i\,|x(T) - \xi|^2\}. \end{aligned} \tag{6.2}$$

The family of LQ problems, parameterized by i, is defined by

$$\begin{cases} \min_{x^0,\,(u(\cdot),\,v(\cdot))} J(x^0,\, u(\cdot),\, v(\cdot);\, i) \\ \text{subject to} \\ \quad (u(\cdot),\, v(\cdot)) \in \bar{\mathcal{U}},\ x^0 \in \mathbb{R}^n, \\ \quad (x^0,\, x(\cdot),\, u(\cdot),\, v(\cdot)) \text{ satisfies (6.1).} \end{cases} \tag{6.3}$$

Comparing (6.3) with the BLQ problem (2.4), it is clear that the control $v(\cdot)$ replaces the process $z(\cdot)$ in the BSDE, while the terminal condition $x(T) = \xi$ in (2.4) is replaced by a penalty term in the cost of the forward problem (6.3). One fundamental difference between (2.4) and (6.3) should be recognized. In the BLQ problem (2.4), the initial condition $x(0)$ and the process $z(\cdot)$ are part of the state process $(x(\cdot),\, z(\cdot))$; that is, once $u(\cdot)$ has been chosen, the pair $(x(\cdot),\, z(\cdot))$ (and hence $x(0)$) is uniquely determined. On the other hand, the pair $(u(\cdot),\, v(\cdot))$ and the initial condition $x(0)$ are decision variables in the forward problem (6.3). This additional degree of freedom is possible because the forward problem (6.3) does not involve a terminal condition on the state $x(\cdot)$. We shall show that the optimal solution of the BLQ problem (2.4), as stated in Theorems 3.3 and 3.2, can be obtained by solving the forward problem (6.3) and letting $i \uparrow \infty$.

Completion of squares. The solution of the forward problem (6.3) can be obtained by using a completion-of-squares approach via the Riccati equation studied in [5]. In particular, let $P_i(\cdot)$ and $(h_i(\cdot),\, \eta_i(\cdot))$ be the unique solutions of the following equations:

$$\begin{cases} \dot{P}_i(t) + P_i(t)A(t) + A(t)'P_i(t) \\ \quad -P_i(t)[B(t)R(t)^{-1}B(t)' + C(t)P_i(t)^{-1}C(t)']P_i(t) + Q(t) = 0, \\ P_i(T) = i\, I, \end{cases} \tag{6.4}$$

$$\begin{cases} dh_i(t) = \{(A(t) + P_i(t)^{-1}Q(t))h_i(t) + C(t)\,\eta_i(t)\}\, dt + \eta_i(t)\, dW(t), \\ h_i(T) = -\xi. \end{cases} \tag{6.5}$$

Note that (6.5) is introduced to cope with the linear term $E\{\, i\xi x(T)\}$ in the terminal cost part of (6.2). Evaluating $\Sigma_i(t) := P_i(t)^{-1}$, it turns out that $\Sigma_i(\cdot)$ is a solution of the Riccati equation

$$\begin{cases} \dot{\Sigma}_i(t) = A(t)\Sigma_i(t) + \Sigma_i(t)A(t)' - C(t)\Sigma_i(t)C(t)' \\ \qquad\qquad + \Sigma_i(t)Q(t)\Sigma_i(t) - B(t)R(t)^{-1}B(t)', \\ \Sigma_i(T) = \frac{1}{i} I. \end{cases} \tag{6.6}$$

(The above explains the origin of the key equations (4.1), (4.2), and (4.14).) Applying Ito's formula to $(x(t) + h_i(t))'P_i(t)(x(t) + h_i(t))$, it can be shown that

$$\begin{aligned} 0 &= (x(0) + h_i(0))'P_i(0)(x(0) + h_i(0)) \\ &\quad + E\int_0^T \{(x + h_i)'(P_iBR^{-1}B'P_i + P_iCP_i^{-1}C'P_i + Q)(x + h_i) + 2(x + h_i)'\Sigma_i Q h_i \\ &\quad + (z + \eta_i)'P_i(z + \eta_i) + 2(z + \eta_i)'C'P_i(x + h_i) + 2u'B'P_i(x + h_i)\}\, dt. \end{aligned}$$

Adding this to the right-hand side of the cost (6.2), we obtain (after some manipulation) that

$$\begin{aligned} J(x^0,\,u(\cdot),\,v(\cdot);\,i) &= \frac{1}{2}h_i(0)'(H\Sigma_i(0)+I)^{-1}Hh_i(0) + E\frac{1}{2}\int_0^T h_i(t)'Q(t)h_i(t)\,dt \\ &+\frac{1}{2}[x^0+(I+\Sigma_i(0)H)^{-1}h_i(0)]'[H+P_i(0)][x^0+(I+\Sigma_i(0)H)^{-1}h_i(0)] \\ &+E\frac{1}{2}\int_0^T [(u+R^{-1}B'P_i(x+h_i))'R(u+R^{-1}B'P_i(x+h_i)) \\ &+(v+\Sigma_iC'P_i(x+h_i)+\eta_i)'P_i(v+\Sigma_iC'P_i(x+h_i)+\eta_i)]\,dt. \end{aligned} \tag{6.7}$$

It is interesting to observe that the expression (6.7) for the cost of the forward LQ problem is similar to the expression (5.2) for the backwards LQ cost. Nevertheless, they are fundamentally different in that $(u(\cdot),\,v(\cdot))$ and $x(0)$ are free to be chosen in (6.7), while $x(0)$ and $z(\cdot)$ are uniquely determined in (5.2) once $u(\cdot)$ has been chosen. Clearly, the optimal cost for the forward LQ problem (6.3) is

$$J_i^*(\xi) = \frac{1}{2}h_i(0)'(H\Sigma_i(0)+I)^{-1}Hh_i(0) + E\frac{1}{2}\int_0^T h_i(t)'Q(t)h_i(t)\,dt, \tag{6.8}$$

which is obtained when

$$\begin{cases} u_i(t) = -R(t)^{-1}B(t)'P_i(t)(x_i(t)+h_i(t)), \\ v_i(t) = -\Sigma_i(t)C(t)'P_i(t)(x_i(t)+h_i(t)) - \eta_i(t), \\ x_i^0 = -(I+\Sigma_i(0)H)^{-1}h_i(0), \end{cases} \tag{6.9}$$

where $x_i(\cdot) \in L^2_{\mathcal{F}}(\Omega;\,C(0,\,T;\,\mathbb{R}^n))$, the optimal state trajectory, is the unique solution of the SDE

$$\begin{cases} dx_i(t) &= \{A(t)x_i(t) - B(t)R(t)^{-1}B(t)'P_i(t)(x_i(t)+h_i(t)) \\ &\quad -C(t)P_i(t)^{-1}C(t)'P_i(t)(x_i(t)+h_i(t)) - C(t)\eta_i(t)\}\,dt \\ &\quad -\{P_i(t)^{-1}C(t)'P_i(t)(x_i(t)+h_i(t)) + \eta_i(t)\}\,dW(t), \\ x_i(0) &= x_i^0. \end{cases} \tag{6.10}$$

Limiting solution: $i \uparrow \infty$. Let $y_i(\cdot)$ be defined by the relation

$$y_i(t) := P_i(t)(x_i(t)+h_i(t)). \tag{6.11}$$

It follows that

$$x_i(t) = \Sigma_i(t)y_i(t) - h_i(t), \tag{6.12}$$

where $x_i(\cdot)$ is the solution of (6.10). It is easy to show that

$$\begin{cases} dx_i(t) = \{A(t)x_i(t) - B(t)R(t)^{-1}B(t)'y_i(t) \\ \qquad\qquad + C(t)(-\Sigma_i(t)C(t)'y_i(t) - \eta_i(t))\}\,dt \\ \qquad\qquad +\{-\Sigma_i(t)C(t)'y_i(t) - \eta_i(t)\}\,dW(t), \\ x_i(0) = x_i^0 \end{cases} \tag{6.13}$$

$$\begin{cases} dy_i(t) = \{-(A(t)+\Sigma_i(t)Q(t))'y_i(t) + Q(t)h_i(t)\}\,dt \\ \qquad\qquad - C(t)'y_i(t)\,dW(t), \\ y_i(0) = H(\Sigma_i(0)H+I)^{-1}h_i(0). \end{cases} \tag{6.14}$$

Substituting (6.11) into (6.6), (6.8)–(6.10) and letting $i \uparrow \infty$, we obtain

$$\begin{cases} u(t) = -R(t)^{-1}B(t)'y(t), \\ x(t) = \Sigma(t)y(t) - h(t), \\ v(t) = -\Sigma(t)C(t)'y(t) - \eta(t), \\ x^0 = -(I + \Sigma(0)H)^{-1}h(0) \end{cases} \tag{6.15}$$

and

$$\begin{aligned} J^*(\xi) &= \frac{1}{2}h(0)'(H\Sigma(0) + I)^{-1}Hh(0) + E\frac{1}{2}\int_0^T h(t)'Q(t)h(t)\,dt \\ &= E\frac{1}{2}\left\{\xi' N(T)\xi - \int_0^T (\eta' N\eta + 2h'NC\eta)\,dt\right\}, \end{aligned} \tag{6.16}$$

where

$$\begin{cases} \dot{\Sigma}(t) = A(t)\Sigma(t) + \Sigma(t)A(t)' - C(t)\Sigma(t)C(t)' \\ \qquad\qquad + \Sigma(t)Q(t)\Sigma(t) - B(t)R(t)^{-1}B(t)', \\ \Sigma(T) = 0, \end{cases} \tag{6.17}$$

$$\begin{cases} \dot{N}(t) + N(t)(A(t) + \Sigma(t)Q(t)) + (A(t) + \Sigma(t)Q(t))'N(t) - Q(t) = 0, \\ N(0) = \frac{1}{2}\{H(I + \Sigma(0)H)^{-1} + (I + H\Sigma(0))^{-1}H\}, \end{cases} \tag{6.18}$$

$$\begin{cases} dh(t) = \{(A(t) + \Sigma(t)Q(t))h(t) + C(t)\,\eta(t)\}\,dt + \eta(t)\,dW(t), \\ h(T) = -\xi, \end{cases} \tag{6.19}$$

$$\begin{cases} dx(t) = \{A(t)x(t) - B(t)R(t)^{-1}B(t)'y(t) \\ \qquad\qquad + C(t)(-\Sigma(t)C(t)'y(t) - \eta(t))\}\,dt \\ \qquad\qquad + \{-\Sigma(t)C(t)'y(t) - \eta(t)\}\,dW(t), \\ x(0) = x^0, \end{cases} \tag{6.20}$$

$$\begin{cases} dy(t) = \{-(A(t) + \Sigma(t)Q(t))'y(t) + Q(t)h(t)\}\,dt - C(t)'y(t)\,dW(t), \\ y(0) = H(\Sigma(0)H + I)^{-1}h(0), \end{cases} \tag{6.21}$$

the second equality in (6.16) being obtained by using the identity (5.18). The Hamiltonian system (3.12)–(3.13) is obtained by substituting (6.15) into (6.20)–(6.21), together with the observation that

$$x(T) = \Sigma(T)y(T) - h(T) = \xi.$$

The optimal control (3.14), the optimal cost (3.11), and the relations (5.5) are recovered in (6.15)–(6.16). Hence the solution of the optimal BLQ control problem (2.4) as outlined in Theorem 3.3 coincides with the limiting solution of a family (6.3) of forward LQ problems. Theorem 3.2 can be recovered simply by applying the transformation as outlined in Lemma 5.4.

On the other hand, it is not surprising that the forward approach recovers the solution of the BLQ problem. In particular, it is clear that if

$$J(x^0, u(\cdot), v(\cdot)) = E\frac{1}{2}\left\{x^{0\prime}Hx^0 + \int_0^T (x(t)'Q(t)x(t) + u(t)'R(t)u(t))\,dt\right\}, \tag{6.22}$$

then the problem

$$\text{(6.23)} \qquad \begin{cases} J^* := \min_{x^0,\,(u(\cdot),\,v(\cdot))} J(x^0,\,u(\cdot),\,v(\cdot)) \\ \text{subject to} \\ \quad E\frac{1}{2}|x(T)-\xi|^2 = 0, \\ \quad (u(\cdot),\,v(\cdot)) \in \bar{\mathcal{U}},\ x^0 \in \mathbb{R}^n, \\ \quad (x^0,\,x(\cdot),\,u(\cdot),\,v(\cdot)) \text{ is admissible for (6.1)} \end{cases}$$

is equivalent to the BLQ problem (2.4). Moreover, the solution of (6.23) can be obtained by using a penalty function approach which coincides precisely with the unconstrained problem (6.3). This provides an alternative approach to (2.4), which, as mentioned, was our original idea for solving the BLQ problem. The details are left to the interested readers.

7. Conclusion. In this paper, the optimal control for the BLQ control problem is derived explicitly in terms of a pair of Riccati equations, a forward SDE, and a BSDE. Moreover, this optimal control coincides with the solution of a constrained forward LQ problem and is the limiting solution of a family of unconstrained forward LQ problems. A key part of our derivation is a proof of the existence and uniqueness of solutions of the Riccati equations. Although of independent interest, this proof of global solvability has direct relevance to the BLQ problem since the Riccati equations play a central role in the analysis.

An outstanding open problem to study is the BLQ problem where all the coefficients are random. In this case, the Riccati equations (3.4) and (3.5) both become (nonlinear) BSDEs (rather than ODEs as in this paper), the solvability of which is very challenging to prove.

Acknowledgments. The authors would like to thank the two anonymous referees for their careful reading and constructive comments that led to an improved version of the paper.

FLATNESS OF HEAVY CHAIN SYSTEMS*

NICOLAS PETIT† AND PIERRE ROUCHON†

Abstract. In this paper the *flatness* [M. Fliess, J. Lévine, P. Martin, and P. Rouchon, *Internat. J. Control*, 61 (1995), pp. 1327–1361, M. Fliess, J. Lévine, P. Martin, and P. Rouchon, *IEEE Trans. Automat. Control*, 44 (1999), pp. 922–937] of heavy chain systems, i.e., trolleys carrying a fixed length heavy chain that may carry a load, is addressed in the partial derivatives equations framework. We parameterize the system trajectories by the trajectories of its free end and solve the motion planning problem, namely, steering from one state to another state. When considered as a finite set of small pendulums, these systems were shown to be flat [R. M. Murray, in *Proceedings of the IFAC World Congress*, San Francisco, CA, 1996, pp. 395–400]. Our study is an extension to the infinite dimensional case.

Under small angle approximations, these heavy chain systems are described by a one-dimensional (1D) partial differential wave equation. Dealing with this infinite dimensional description, we show how to get the explicit parameterization of the chain trajectory using (distributed and punctual) advances and delays of its free end.

This parameterization results from symbolic computations. Replacing the time derivative by the Laplace variable s yields a second order differential equation in the spatial variable where s is a parameter. Its fundamental solution is, for each point considered along the chain, an entire function of s of exponential type. Moreover, for each, we show that, thanks to the Liouville transformation, this solution satisfies, modulo explicitly computable exponentials of s, the assumptions of the Paley–Wiener theorem. This solution is, in fact, the transfer function from the flat output (the position of the free end of the system) to the whole state of the system. Using an inverse Laplace transform, we end up with an explicit motion planning formula involving both distributed and punctual advances and delays operators.

Key words. wave equation, delay systems, flatness, motion planning

AMS subject classification. 99C20

Introduction. The notion of *flatness* [3, 4] has proven to be relevant in many problems where motion planning problems have been solved [10, 5]. The existence of a *flat output* is the key to explicit formulas that can be implemented as open-loop controllers. Many systems of engineering interest are flat. So far the dynamics under consideration have been nonlinear ordinary differential equations, constant of varying delay equations, or even partial differential equations. In these cases the open-loop controller expression involved algebraic computations, punctual advances and delays [11, 6, 12], distributed advance and delay operators [12, 5, 14, 16], composition of functions [15], etc. In this paper we use both distributed and punctual advances and delays operators.

The heavy chain systems under consideration in this paper are defined by a trolley carrying a fixed length heavy chain to which a load may be attached. The dynamics are studied in a fixed vertical plane. When approximated as a finite set of small pendulums, such heavy chain systems were shown to be flat (see [13]). Their trajectories can be explicitly parameterized by the trajectories of their free ends. These parameterizations involve numerous derivatives (twice as many as the number of pendulums). When this number goes to infinity, the derivative order goes to infinity as

well, yielding series expansions. This makes these relations difficult to handle and to use in practice.

In order to overcome these difficulties, we consider infinite dimensional descriptions of heavy chain systems. Around the stable vertical steady-state and under the small angle assumption, the dynamics are described by second order ordinary differential equations (dynamics of the load at position $y(t)$) coupled with one-dimensional (1D) wave equations (dynamics of the chain $X(x,t)$), where wave speed depends on x, the spatial variable along the chain length.

This combined ordinary and partial differential equation description turns out to be a significant shortcut to an explicit motion planning formula. Instead of an infinite number of derivatives, the explicit parameterization of the trajectories involves a small number of both distributed and punctual advances and delays. The controllability of such hybrid systems could be analyzed via Hilbert's uniqueness method [8, 9], as done in [7]. The work presented here is also a constructive proof of the controllability of these systems in the sense that it provides the open-loop control for steering the system from any given state to any other state. In a real application it should be used as a feedforward term complemented by a closed-loop controller using the energy method as proposed in [2].

In the case of a single homogeneous heavy chain as depicted in Figure 1.1 (see section 1 for details), our explicit parameterization shows that the general solution of

$$\frac{\partial}{\partial x}\left(gx\frac{\partial X}{\partial x}\right) - \frac{\partial^2 X}{\partial t^2} = 0$$

is given by the integral

$$X(x,t) = \frac{1}{2\pi}\int_{-\pi}^{\pi} y(t + 2\sqrt{x/g}\sin\theta)\ d\theta, \tag{0.1}$$

where $t \mapsto y(t)$ is any smooth-enough time function: $X(0,t) = y(t)$ corresponds then to the free end position; the control $u(t) = X(L,t)$ is the trolley position.

For the general cases, we show here that relationships similar to (0.1) exist. They are expressed by (2.2) and (3.2). The structure is similar, but the moving averages involve weights (i.e., kernels) depending on the mass distribution. More precisely, given any mass distribution along the chain and any punctual mass at $x = 0$, we prove that there is a one-to-one correspondence between the trajectory of the load $t \mapsto y(t) = X(0,t)$ and the trajectory of the whole system (namely, the cable and the trolley): $t \mapsto X(x,t)$ and $t \mapsto u(t) = X(L,t)$. This correspondence yields the explicit parameterization of the trajectories: $X(x,\cdot) = \mathcal{A}_x y$, where $\{\mathcal{A}_x\}$ is a set of operators including time derivations, advances, and delays. In other words, $(x,t) \mapsto (\mathcal{A}_x y)(t)$ verifies the system equations for any smooth function $t \mapsto y(t)$. For each x, the operator $\mathcal{A}_x$ admits compact support. Thus it is possible to steer the system from any initial point to any other point in finite time.

This parameterization results from symbolic computations. Replacing the time derivative by the Laplace variable s yields a second order differential equation in x with s as a parameter. For each x, its fundamental solution A_x is an entire function of s of exponential type. Furthermore, for each x we show, thanks to the Liouville transformation, that $s \mapsto A_x(s)$ satisfies the assumptions of the Paley–Wiener theorem, modulo explicitly computable exponentials of s.

The paper is organized as follows.

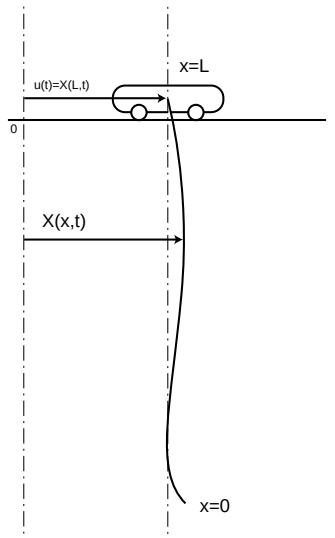

FIG. 1.1. *The homogeneous chain without any load.*

1. In section 1 we consider the case of a homogeneous chain without any load. Although it is the easiest case by far, it is explanatory, and it helps in understanding the meaning and control interest of our results.
2. In section 2 we address the case of an inhomogeneous chain without any load. The problem of the singularity at $x = 0$ of the second order differential equation receives special treatment. We prove the flatness of this system by Theorem 1.
3. In section 3 we solve the general problem of an inhomogeneous chain carrying a punctual load. By contrast with the previous case, the corresponding second order differential is not singular. Flatness of this system is proven by Theorem 2.

1. The homogeneous chain without any load. The computations are simple and explicit and summarize the goal of this paper.

Consider a heavy chain in stable position as depicted in Figure 1.1. Under the small angle approximation it is ruled by the dynamics[1]

$$\begin{cases} \dfrac{\partial}{\partial x}\left(gx\dfrac{\partial X}{\partial x}\right) - \dfrac{\partial^2 X}{\partial t^2} = 0, \\ X(L,t) = u(t), \end{cases} \tag{1.1}$$

where $x \in [0, L]$, $t \in \mathbb{R}$, $X(x,t) - X(L,t)$ is the deviation profile, g is the gravitational acceleration, and the control u is the trolley position.

Thanks to the classical mapping $y = 2\sqrt{\frac{x}{g}}$, we get

$$y\frac{\partial^2 X}{\partial y^2}(y,t) + \frac{\partial X}{\partial y}(y,t) - y\frac{\partial^2 X}{\partial t^2}(y,t) = 0.$$

[1]This model was used in the historical work of D. Bernoulli on a heavy chain system where the zero-order Bessel functions appear for the first time; see [18, pp. 3–4].

Use Laplace transform of X with respect to the variable t (denoted by $\hat{X}$ and with zero initial conditions, i.e., $X(.,0)=0$ and $\frac{\partial X}{\partial t}(.,0)=0$) to get

$$y\frac{\partial^2 \hat{X}}{\partial y^2}(y,s)+\frac{\partial \hat{X}}{\partial y}(y,s)-ys^2\hat{X}(y,s)=0.$$

Less classically, the mapping $z=\imath s y$ gives

$$z\frac{\partial^2 \hat{X}}{\partial z^2}(z,s)+\frac{\partial \hat{X}}{\partial z}(z,s)+z\hat{X}(z,s)=0. \tag{1.2}$$

This is a Bessel equation. Its solution writes in terms of J_0 and Y_0 the zero-order Bessel functions. Using the inverse mapping $z=2\imath s\sqrt{\frac{x}{g}}$, we get

$$\hat{X}(x,s)=A\ J_0(2\imath s\sqrt{x/g})+B\ Y_0(2\imath s\sqrt{x/g}).$$

Since we are looking for a bounded solution at $x=0$, we have $B=0$. Then

$$\hat{X}(x,s)=J_0(2\imath s\sqrt{x/g})\hat{X}(0,s), \tag{1.3}$$

where we can recognize the Clifford function $\mathcal{C}_\prime$ (see [1, p. 358]). Using Poisson's integral representation of J_0 [1, formula 9.1.18],

$$J_0(z)=\frac{1}{2\pi}\int_{-\pi}^{\pi}\exp(\imath z\sin\theta)\ d\theta,$$

we have

$$J_0(2\imath s\sqrt{x/g})=\frac{1}{2\pi}\int_{-\pi}^{\pi}\exp(2s\sqrt{x/g}\sin\theta)\ d\theta.$$

In terms of Laplace transforms, this last expression is a combination of delay operators. Turning (1.3) back into the time-domain, we get

$$X(x,t)=\frac{1}{2\pi}\int_{-\pi}^{\pi}y(t+2\sqrt{x/g}\sin\theta)\ d\theta \tag{1.4}$$

with $y(t)=X(0,t)$.

Relation (1.4) means that there is a one-to-one correspondence between the (smooth) solutions of (1.1) and the (smooth) functions $t\mapsto y(t)$. For each solution of (1.1), set $y(t)=X(0,t)$. For each function $t\mapsto y(t)$, set X by (1.4) and u as

$$u(t)=\frac{1}{2\pi}\int_{-\pi}^{\pi}y(t+2\sqrt{L/g}\sin\theta)\ d\theta \tag{1.5}$$

to obtain a solution of (1.1).

Finding $t\mapsto u(t)$, steering the system from the steady-state $X\equiv 0$ at $t=0$ to the other one $X\equiv D$ at $t=T$ becomes obvious. Our analysis shows that T must be larger than 2Δ, where $\Delta=2\sqrt{L/g}$ is the travelling time of a wave between $x=L$ and $x=0$. It consists only in finding $t\mapsto y(t)$ that is equal to 0 for $t\leq\Delta$ and to D for $t>T-\Delta$ and in computing u via (1.5).

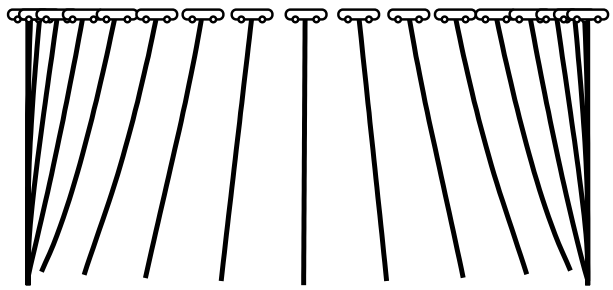

FIG. 1.2. *Steering from* 0 *to* $3L/2$ *in finite time* $T = 4\Delta$. *Regularly time-spaced positions of the heavy chain system are represented. The Matlab simulation code can be obtained from the second author via email.*

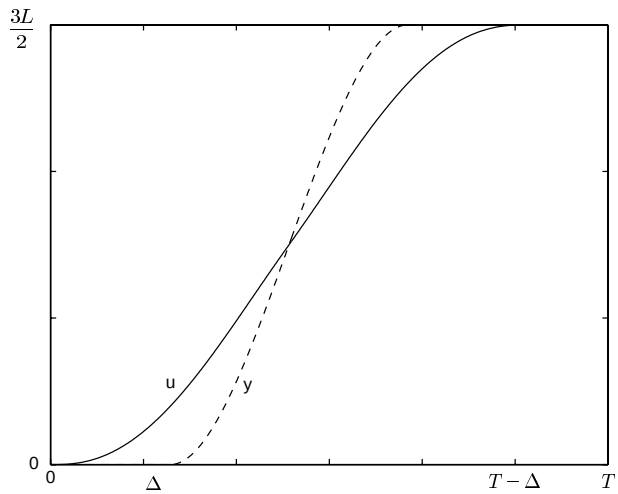

FIG. 1.3. *The steering control, trolley position* u, *and the "flat output," the free end* y.

Figure 1.2 illustrates computations based on (1.4) with

$$y(t) = \begin{cases} 0 \text{ if } t < \Delta, \\ \frac{3L}{2}\left(\frac{t-\Delta}{T-2\Delta}\right)^2\left(3-2\left(\frac{t-\Delta}{T-2\Delta}\right)\right) \text{ if } \Delta \le t \le T-\Delta, \\ \frac{3L}{2} \text{ if } t > T-\Delta, \end{cases}$$

where the chosen transfer time T equals 4Δ. For $t \le 0$ the chain is vertical at position 0. For $t \ge T$ the chain is vertical at position $D = 3L/2$.

Plots of Figure 1.3 show the control $[0,T] \ni t \mapsto u(t)$ required for such motion. Notice that the support of $\dot{u}$ is $[0,T]$, while the support of $\dot{y}$ is $[\Delta, T-\Delta]$. To be consistent with the small angle approximation, the horizontal acceleration of the end point $\ddot{y}$ must be much smaller than g. In our computations the maximum of $|\ddot{y}|$ is chosen rather large, $9g/16$. This is just for tutorial reasons. In practice, a reasonable transition time is $T = 5\Delta$ yielding $|\ddot{y}| \le g/4$.

2. The inhomogeneous (i.e., variable section) chain without any load. Formula (1.4) can be extended to a heavy chain with variable section and carrying no load (see Figure 2.1). Such an extension deserves special consideration because of the singularity of the partial differential system at $x = 0$.

Such a system is governed by the equations

$$\left\{\begin{array}{c} \dfrac{\partial}{\partial x}\left(\tau(x)\dfrac{\partial X}{\partial x}\right) - \dfrac{\tau'(x)}{g}\dfrac{\partial^2 X}{\partial t^2} = 0, \\ X(L,t) = u(t), \end{array}\right. \tag{2.1}$$

where $x \in [0, L]$, $t \in \mathbb{R}$, and u is the control. The tension of the chain is $\tau(x)$ with $\tau(0) = 0$ and $\tau(x) = gx + \mathcal{O}(x^2)$, while $\tau'(x)/g > 0$ is the mass distribution along the chain. Furthermore, we assume that there exists $a > 0$ such that $\tau(x) \geq ax \geq 0$.

THEOREM 1. *Consider* (2.1) *with* $[O, L] \ni x \mapsto \tau(x)$ *a smooth increasing function with* $\tau(0) = 0$ *and* $\tau' > 0$. *There is a one-to-one correspondence between the solutions* $[0, L] \times \mathbb{R} \ni (x, t) \mapsto (X(x, t), u(t))$ *that are* C^3 *in* t *and the* C^3 *functions* $\mathbb{R} \ni t \mapsto y(t)$ *via the formulas*

(2.2)

$$\begin{aligned} X(x,t) =& \frac{L^{1/4}\sqrt{g}}{2\pi^{3/2}(\tau(x)\tau'(x))^{1/4}}\sqrt{G(2\sqrt{\tau(x)/g})}\ \int_{-\pi}^{\pi} y\left(t + KG(2\sqrt{\tau(x)/g})\sin\theta\right) d\theta \\ &+ \frac{1}{(\tau(x)\tau'(x)/g)^{1/4}}\int_{-2\sqrt{\frac{\tau(x)}{ag}}}^{2\sqrt{\frac{\tau(x)}{ag}}} \mathcal{K}(G(2\sqrt{\tau(x)/g}), \xi)\ \dot{y}\,(t+\xi)\ d\xi, \\ u(t) =& X(L,t) \end{aligned}$$

with

$$y(t) = X(0,t),$$

where the constant K *and the functions* G *and* $\mathcal{K}$ *are defined by the function* τ *via formulas* (2.15) *and* (2.29).

The proof of this result is organized as follows.

1. A simple time-scaling simplifies the system. We shift from X to Y.
2. Symbolic computations where time derivatives are replaced by the Laplace variable s are performed.
3. The solution $Y(x, s)$ is factorized as $Y(x, s) = Y(0, s)A(x, s)$. A partial differential system is derived for $A(x, s)$.
4. A Liouville transformation is performed.
5. In these new coordinates the preceding transformed equation is compared to an equation that we have already solved in section 1, namely, the equation of a single homogeneous chain. We denote by $D(x, s)$ the difference between these two solutions.
6. $D(x, s)$ is proven to be an entire function of s and of exponential type.
7. A careful study of the Volterra equation satisfied by $D(x, s)$ shows that, for each x, the restriction to $D(x, s)/s$ to the imaginary axis is in L^2.
8. Thanks to the Paley–Wiener theorem, we prove that, for each x, $D(x, s)/s$ can be represented as a compact sum (discrete and continuous) of exponentials in s.
9. Gathering all the terms of $A(x, s)$, we get an expression involving the Bessel function J_0 (the solution for a homogeneous chain) and exponentials in s multiplied by s. This gives (2.2).

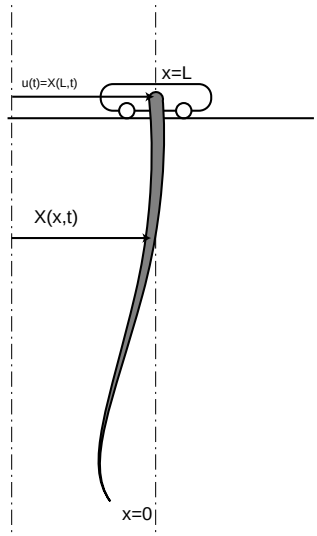

FIG. 2.1. *The inhomogeneous chain without any load.*

Proof. Simple change of coordinates Let[2] $Y(x,t) = X\left(\tau(x)/g, t\right)$.

[2]One may easily show the following result: if Y satisfies

$$\frac{\partial}{\partial x}\left(x\tau' \circ \tau^{-1}(gx)\frac{\partial Y}{\partial x}\right) - \frac{\partial^2 Y}{\partial t^2} = 0, \tag{2.3}$$

then $X(x,t) = Y(\tau(x)/g, t)$ satisfies

$$\frac{\partial}{\partial x}\left(\tau(x)\frac{\partial X}{\partial x}\right) - \frac{\tau'(x)}{g}\frac{\partial^2 X}{\partial t^2} = 0. \tag{2.4}$$

To show this, denote $\circ$ the composition operator with respect to the first variable. Thus $X = Y \circ (\tau/g)$. Then

$$\frac{\partial}{\partial x}\left(\tau\frac{\partial X}{\partial x}\right) = \frac{\partial}{\partial x}\left(\tau\tau'/g\frac{\partial Y}{\partial x} \circ (\tau/g)\right). \tag{2.5}$$

On the other hand, a factorization of (2.3) gives

$$\begin{aligned}\frac{\partial^2 Y}{\partial t^2} &= \frac{\partial}{\partial x}\left(\left(\tau/g\tau'\frac{\partial Y}{\partial x} \circ (\tau/g)\right) \circ \tau^{-1}(gx)\right)\\ &= \frac{\partial}{\partial x}\left(\tau^{-1}(gx)\right)\frac{\partial}{\partial x}\left(\tau\tau'/g\frac{\partial Y}{\partial x} \circ (\tau/g)\right) \circ \tau^{-1}(gx).\end{aligned}$$

So by using (2.5)

$$\frac{\partial}{\partial x}\left(\tau^{-1}(gx)\right)\frac{\partial}{\partial x}\left(\tau\frac{\partial X}{\partial x}\right) \circ \tau^{-1}(gx) = \frac{\partial^2 Y}{\partial t^2}.$$

Yet

$$\frac{\partial}{\partial x}\left(\tau^{-1}(gx)\right) = \frac{g}{\tau' \circ \tau^{-1}(gx)},$$

so

$$\frac{\partial}{\partial x}\left(\tau\frac{\partial X}{\partial x}\right) \circ \tau^{-1}(gx) = \frac{1}{g}\tau' \circ \tau^{-1}(gx)\frac{\partial^2 Y}{\partial t^2},$$

or, equivalently,

$$\frac{\partial}{\partial x}\left(\tau\frac{\partial X}{\partial x}\right) = \frac{\tau'}{g}\frac{\partial^2 Y}{\partial t^2} \circ (\tau/g) = \frac{\tau'}{g}\frac{\partial^2 X}{\partial t^2},$$

which gives the conclusion.

Now (2.1) gives

$$\frac{\partial}{\partial x}\left(\tau_1(x)\frac{\partial Y}{\partial x}\right)-\frac{\partial^2 Y}{\partial t^2}=0, \tag{2.6}$$

where $\tau_1(x)=x\tau'(\tau^{-1}(gx))$.

Symbolic computations. Replacing the time derivation by s gives

$$\frac{\partial}{\partial x}\left(\tau_1(x)\frac{\partial Y}{\partial x}\right)-s^2Y=0. \tag{2.7}$$

Factorization. It is very easy to check that $Y(x,s)=Y(0,s)A(x,s)$ is the solution of (2.7), provided that $A(x,s)$ is solution of the following partial differential system:

$$\begin{cases}\dfrac{\partial}{\partial x}\left(\tau_1(x)\dfrac{\partial A}{\partial x}\right)-s^2A=0,\\ \quad A(0,s)=1.\end{cases} \tag{2.8}$$

Existence of a solution. System (2.8) admits a smooth solution that is an entire function of exponential type in s. This solution reads

$$A(x,s)=\sum_{i\geq 0}\frac{s^{2i}}{i!}f_i(x), \tag{2.9}$$

where

$$\begin{cases}\quad f_0=1,\\ f_i(x)=\displaystyle\int_0^x\frac{1}{\tau_1(l)}\int_0^l if_{i-1}(s)ds\ dl.\end{cases} \tag{2.10}$$

It is very easy to check that, formally, $\sum_{i\geq 0}\frac{s^{2i}}{i!}f_i(x)$ is solution of (2.8): since

$$\frac{\partial}{\partial x}\left(\tau_1(x)\frac{\partial}{\partial x}f_i(x)\right)=if_{i-1}(x),$$

we can write

$$\begin{cases}\dfrac{\partial}{\partial x}\left(\tau_1(x)\dfrac{\partial}{\partial x}\displaystyle\sum_{i\geq 0}\frac{s^{2i}}{i!}f_i(x)\right)=s^2\sum_{i\geq 0}\frac{s^{2i}}{i!}f_i(x),\\ \quad\displaystyle\sum_{i\geq 0}\frac{s^{2i}}{i!}f_i(0)=f_0(0)=1.\end{cases} \tag{2.11}$$

Now let us address the convergence by proving that for all i

$$|f_i(x)|\leq\frac{1}{i!}\left(\frac{x}{a}\right)^i. \tag{2.12}$$

Suppose that (2.12) is true for a given i. (It is obviously the case for $i=0$.) Let us inductively prove that it is also true for $i+1$. From (2.10) we get

$$|f_{i+1}(x)|\leq\int_0^x\frac{l^{i+1}}{\tau_1(l)a^i i!}dl.$$

Yet $\tau' \geq a$, so $\tau_1(x) \geq ax \geq 0$, and then

$$|f_{i+1}(x)| \leq \int_0^x \frac{l^i}{a^{i+1} i!} dl \leq \frac{1}{(i+1)!} \left(\frac{x}{a}\right)^{i+1},$$

which is (2.12) at rank $i+1$.

So, gathering (2.9) and (2.12) and using $\frac{1}{(i!)^2} \leq \frac{2^{2i}}{(2i)!}$, we get

$$A(x,s) \leq \sum_{i\geq 0} \frac{s^{2i} x^i}{(i!)^2 a^i} \leq \sum_{i\geq 0} \frac{s^{2i} 2^{2i} x^i}{(2i)! a^i} \leq \exp\left(2s\sqrt{\frac{x}{a}}\right). \tag{2.13}$$

This proves that, for each x, $s \mapsto A(x,s)$ is an entire function of s of exponential type.

Liouville transformation. The Liouville transformation

$$(x, A) \mapsto (z, u)$$

(see, e.g., [19, p. 110]) turns equations of the form

$$\frac{d}{dx}\left(p(x)\frac{dA}{dx}\right) + (\lambda r(x) - q(x))\, A = 0$$

with $p(x) > 0$ into

$$\frac{d^2u}{dz^2} + (\rho^2 - h(z))u = 0,$$

where ρ is depending only on λ and can be considered as a parameter.

Here

$$p(x) = \tau_1(x), \quad \lambda = -s^2, \quad r(x) = 1, \quad q(x) = 0, \quad x \in [0, L],$$

and the transformation is defined for each $x > 0$. Nevertheless, it can be extended to $x = 0$ because around 0, $\tau_1(x) \approx gx$ with $g > 0$. It turns (2.8) into

$$\frac{d^2u}{dz^2} - K^2 s^2 u = \bar{h}(z) u \tag{2.14}$$

with

$$z = \frac{1}{K}\int_0^x \sqrt{\frac{1}{\tau_1}} \equiv G(2\sqrt{x}), \quad K = \frac{1}{\pi}\int_0^L \sqrt{\frac{1}{\tau_1}}, \tag{2.15}$$

$$u(z,s) = (\tau_1(x))^{1/4} A(x,s), \tag{2.16}$$

$$\bar{h}(z) = \frac{F''(z)}{F(z)} \quad \text{with } F(z) \equiv (\tau_1(x))^{1/4}. \tag{2.17}$$

Notice that since $\tau_1(x) \geq ax$ with $a > 0$, $\int_0^x 1/\tau_1$ is a smooth function of $\sqrt{x}$, and thus G is well defined and invertible. Similar arguments imply that $\bar{h}$ is, in fact, a function of z^2. Thus $\bar{h}(z) = h(z^2)$, and we have the following Laurent series around 0:

$$\bar{h}(z) = h(z^2) = \frac{-1}{4z^2} + \mathcal{O}(1).$$

Comparison to a simpler solution. We know from [1, formula 9.1.49, p. 362] that

$$u_0(z,s) = (Lg)^{1/4}\sqrt{\frac{z}{\pi}}\, J_0(iKsz) \tag{2.18}$$

satisfies

$$\frac{d^2u_0}{dz^2} - K^2s^2u_0 = \left(\frac{-1}{4z^2}\right)u_0. \tag{2.19}$$

According to the Laurent series of $\bar{h}$, we compare the solutions of (2.14), namely, $u(z,s)$, and (2.19), namely, $u_0(z,s)$. Let $D(z,s) = u(z,s) - u_0(z,s)$. We deduce from (2.14) and (2.19) that

$$\frac{d^2D}{dz^2} - K^2s^2D = \left(h(z^2) + \frac{1}{4z^2}\right)u_0 + h(z^2)D. \tag{2.20}$$

Since $z = G(2\sqrt{x})$ with G smooth and invertible, we have from (2.9) and (2.16)

$$u(z,s) = (Lg)^{1/4}\sqrt{\frac{z}{\pi}} + \mathcal{O}(z^{5/2}).$$

Then it is easy to check that for each s, D is a C^1 function of z around 0 with $D(0,s) = 0$ and $D'(0,s) = 0$. Equation (2.20) can be turned into the following integral equation (see [19, p. 111]):

$$\begin{aligned} D(z,s) =& \frac{1}{Ks}\int_0^z \sinh(Ks(z-t))\left(h(z^2) + \frac{1}{4t^2}\right)u_0(t,s)dt \\ &+ \frac{1}{Ks}\int_0^z \sinh(Ks(z-t))h(t^2)D(t,s)dt. \end{aligned} \tag{2.21}$$

Proving that $\mathbb{C} \ni s \mapsto D(z,s)$ is an entire function of exponential type. We already know that $A(x,s)$ and thus $u(z,s)$ (by (2.16)) are entire functions of exponential type in s. On the other hand, for each z, $s \mapsto u_0(z,s)$ is also an entire function of s of exponential type as J_0 is. This gives the conclusion.

Proving that $i\mathbb{R} \ni s \mapsto D(z,s)/s$ belongs to L^2. For each z, we need only an estimation of $D(z,iw)$ as w tends to ∞. For the sake of simplicity, we consider here $w \mapsto D(z,iw)$ for $w > 0$ large enough. The case $w < 0$ is similar. Classically (see, for instance, [19, p. 112]), let $M(z,w) = \sup_{0\le\zeta\le z}|D(\zeta,iw)|$. Using (2.21), we will get an estimation of $M(z,w)$. This gives

$$KwM(z,w) \le I_1(z,w) + I_2(z,w) \tag{2.22}$$

with

$$\begin{aligned} I_1(z,w) &= \int_0^z \left|h(t^2) + \frac{1}{4t^2}\right| |u_0(t,iw)|\, dt, \\ I_2(z,w) &= \int_0^z \left|h(t^2)\right| |D(t,iw)|\, dt. \end{aligned}$$

We know that

$$0 \le z \le \pi, \quad |u_0(t,iw)| \le (Lg)^{1/4}$$

since J_0 is bounded by 1 on the real axis. We know also that $h(t^2)+1/4t^2$ is bounded on $[0,\pi]$. Thus the integral I_1 is bounded by a constant $K_1 > 0$, independent of $z \in [0,\pi]$ and w,

$$I_1(z,w) \leq K_1. \tag{2.23}$$

Next, to majorate I_2 we split it into

$$I_2(z,w) = \underbrace{\int_0^{\gamma/w} \left|h(t^2)\right| |D(t,iw)|\, dt}_{I_2'(z,w)} + \underbrace{\int_{\gamma/w}^{z} \left|h(t^2)\right| |D(t,iw)|\, dt}_{I_2''(z,w)},$$

where $\gamma > 0$ is a parameter we will choose afterwards. A simple but quite tedious computation gives (using $J_0(z) = 1 - \frac{1}{4}z^2 + \circ(z^2)$)

$$D(z,s) = \sqrt{z}\ cs^2z^2(1+\mu(s^2z^2)),$$

where c is a constant and μ is a smooth function such that $\mu(0) = 0$. Using this last expression in I_2', we get

$$I_2'(z,w) \leq \sqrt{w}\frac{bc}{6}\gamma^{3/2}\left(1 + \sup_{|\xi|\leq\gamma^2} |\mu(\xi)|\right), \tag{2.24}$$

where $b > 0$ is such that $\left|h(t^2)\right| \leq b/(4t^2)$ for all $t \in]0,\pi]$. On the other hand, it is easy to check that

$$I_2''(z,w) \leq \frac{bw}{4\gamma} M(z,w). \tag{2.25}$$

Gathering (2.24) and (2.25), we get

$$I_2(z,w) \leq \sqrt{w}\frac{bc}{6}\gamma^{3/2}\left(1 + \sup_{|\xi|\leq\gamma^2} |\mu(\xi)|\right) + \frac{bw}{4\gamma} M(z,w). \tag{2.26}$$

Thanks to the majorations (2.23) and(2.26), we get

$$KwM(z,w) \leq K_1 + \sqrt{w}\frac{bc}{6}\gamma^{3/2}\left(1 + \sup_{|\xi|\leq\gamma^2} |\mu(\xi)|\right) + \frac{bw}{4\gamma} M(z,w).$$

This majoration is valid for $z \in]0,\pi]$, $w > 0$, and $\gamma > 0$ such that $\gamma/w \leq z$. Now we take

$$\gamma = \frac{b}{2K}.$$

Thus for each $z > 0$ and each $w > \gamma/z$, we have

$$(K - b/4\gamma)wM(z,w) \leq K_1 + \sqrt{w}\frac{bc}{6}\gamma^{3/2}\left(1 + \sup_{|\xi|\leq\gamma^2} |\mu(\xi)|\right).$$

Since $K - b/4\gamma = K/2$, we have

$$\frac{1}{2}\ KwM(z,w) \leq K_1 + \sqrt{w}\frac{bc}{6}\gamma^{3/2}\left(1 + \sup_{|\xi|\leq\gamma^2} |\mu(\xi)|\right). \tag{2.27}$$

Thus there exists $C_0 > 0$ such that for each $z \in]0, \pi]$ and for every $w > \gamma/z$,

$$|D(z, iw)| \leq \frac{C_0}{\sqrt{|w|}}. \tag{2.28}$$

Since $D(z, 0) \equiv 0$, we deduce for each $z > 0$ that $s \mapsto D(z, s)/s$ remains an entire function of s (of exponential type), and the above majoration says that $i\mathbb{R} \ni s \mapsto D(z, s)/s$ belongs to L^2.

Using the Paley–Wiener theorem. The Paley–Wiener theorem [17, p. 375] ensures that, for any $z \in [0, \pi]$, there exists $[-\frac{G^{-1}(z)}{\sqrt{a}}, \frac{G^{-1}(z)}{\sqrt{a}}] \ni t \mapsto \mathcal{K}(z, t)$ in L^2 such that

$$D(z, s)/s = \int_{-\frac{G^{-1}(z)}{\sqrt{a}}}^{\frac{G^{-1}(z)}{\sqrt{a}}} \mathcal{K}(z, \xi) \exp(s\xi) d\xi. \tag{2.29}$$

The integral bounds results from the following facts.

1. Via (2.16), $2\sqrt{x} = G^{-1}(z)$, and (2.13), we have
$$\forall s \in \mathbb{C}, \quad |(u(z, s)| \leq N(z) \exp\left(|s| \frac{G^{-1}(z)}{\sqrt{a}}\right)$$
for some $N(z) > 0$.
2. A well-known property on J_0 implies that
$$\forall s \in \mathbb{C}, \quad |(u_0(z, s)| \leq N_0(z) \exp(|s|\, zK)$$
for some $N_0(z) > 0$.
3. Since $\tau_1 x \geq ax$, (2.15) implies that $zK < \frac{G^{-1}(z)}{\sqrt{a}}$.
4. Thus
$$\forall s \in \mathbb{C}, \quad |D(z, s)| = |u(z, s) - u_0(z, s)| \leq (N(z) + N_0(z)) \exp\left(|s| \frac{G^{-1}(z)}{\sqrt{a}}\right).$$

Conclusion.

$$(u(z, s) - u_0(z, s))/s = \int_{-\frac{G^{-1}(z)}{\sqrt{a}}}^{\frac{G^{-1}(z)}{\sqrt{a}}} \mathcal{K}(z, \xi) \exp(s\xi) d\xi.$$

This gives

$$u(z, s) = \frac{(Lg)^{1/4}}{\sqrt{\pi}} \sqrt{z} J_0(iKsz) + \int_{-\frac{G^{-1}(z)}{\sqrt{a}}}^{\frac{G^{-1}(z)}{\sqrt{a}}} s\mathcal{K}(z, \xi) \exp(s\xi) d\xi.$$

Pulling back this relation in the (x, A) coordinates, we deduce using (2.16) that

$$\begin{aligned} A(x, s) =& \frac{(Lg)^{1/4}}{\sqrt{\pi}} \frac{1}{(\tau_1(x))^{1/4}} \sqrt{G(2\sqrt{x})} J_0(iKsG(2\sqrt{x})) \\ &+ \frac{1}{(\tau_1(x))^{1/4}} \int_{-2\sqrt{\frac{x}{a}}}^{2\sqrt{\frac{x}{a}}} s\mathcal{K}(G(2\sqrt{x}), \xi) \exp(s\xi) d\xi. \end{aligned}$$

Then we quickly get $Y(x,s) = Y(0,s)A(x,s)$. This gives in the time domain

$$\begin{aligned} Y(x,t) =& \frac{(Lg)^{1/4}}{\sqrt{\pi}} \frac{1}{(\tau_1(x))^{1/4}} \sqrt{G(2\sqrt{x})}\ \frac{1}{2\pi} \int_{-\pi}^{\pi} Y(0, t + KG(2\sqrt{x}) \sin\theta) d\theta \\ &+ \frac{1}{(\tau_1(x))^{1/4}} \int_{-2\sqrt{\frac{x}{a}}}^{2\sqrt{\frac{x}{a}}} \mathcal{K}(G(2\sqrt{x}), \xi) \left[\frac{\partial}{\partial t} Y(0, t+\xi) \right] d\xi. \end{aligned}$$

Then substituting

$$\begin{aligned} X(x,t) &= Y\left(\tau(x)/g, t\right), \\ Y(0,t) &= X(0,t), \\ \frac{\partial Y}{\partial t}(0,t) &= \frac{\partial X}{\partial t}(0,t), \end{aligned}$$

we get

(2.30)

$$\begin{aligned} X(x,t) =& \frac{L^{1/4}\sqrt{g}}{2\pi^{3/2}(\tau(x)\tau'(x))^{1/4}} \sqrt{G(2\sqrt{\tau(x)/g})}\ \int_{-\pi}^{\pi} y(t + KG(2\sqrt{\tau(x)/g}) \sin\theta) d\theta \\ &+ \frac{1}{(\tau(x)\tau'(x)/g)^{1/4}} \int_{-2\sqrt{\frac{\tau(x)}{ag}}}^{2\sqrt{\frac{\tau(x)}{ag}}} \mathcal{K}(G(2\sqrt{\tau(x)/g}), \xi)\ \dot{y}\left(t+\xi\right)\ d\xi \end{aligned}$$

with $y(t) = X(0,t)$. □

Remark. In the case of a homogeneous chain, we can substitute

$$\begin{aligned} &\tau(x) = gx, \quad \tau'(x) = g, \quad \tau_1(x) = gx = \tau(x), \\ &K = \frac{2}{\pi}\sqrt{\frac{L}{g}}, \quad z = G(2\sqrt{x}) = \pi\sqrt{\frac{x}{L}}, \mathcal{K} = 0, \end{aligned}$$

and (2.30) reads

$$X(x,t) = \frac{1}{2\pi} \int_{-\pi}^{\pi} y\left(t + 2\sqrt{\frac{x}{g}} \sin\theta\right) d\theta,$$

which is indeed identical to (1.4).

3. The inhomogeneous chain with punctual load. The system of Figure 3.1 consists of a heavy chain with a variable section carrying a punctual load m. Small deviations $X(x,t) - u(t)$ from the vertical position are described by the partial differential system

$$\left\{ \begin{aligned} &\frac{\partial}{\partial x}\left(\tau(x)\frac{\partial X}{\partial x}\right) - \frac{\tau'(x)}{g}\frac{\partial^2 X}{\partial t^2} = 0, \\ &\frac{\partial^2 X}{\partial t^2}(0,t) = g\frac{\partial X}{\partial x}(0,t), \\ &X(L,t) = u(t), \end{aligned} \right. \tag{3.1}$$

where u is the control. The tension in the chain writes $\tau(x)$: $\tau(0) = mg$, and $\tau'(x)/g > 0$ is the mass distribution along the chain.

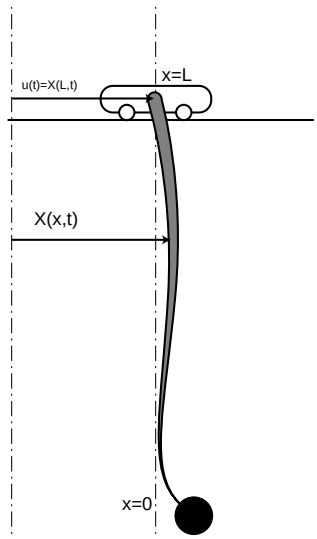

FIG. 3.1. *The inhomogeneous (variable section) chain with punctual load.*

THEOREM 2. *Consider* (3.1) *with* $[0,L] \ni x \mapsto \tau(x)$ *a smooth increasing function with* $\tau(0) = m$. *There is a one-to-one correspondence between the solutions* $[0,L]\times\mathbb{R} \ni (x,t) \mapsto (X(x,t), u(t))$ *that are* C^3 *in* t *and the* C^3 *functions* $\mathbb{R} \ni t \mapsto y(t)$ *via the following formulas:*

(3.2)
$$\begin{cases} X(x,t) = \phi(x)\ [y(t+\theta(x)) + y(t-\theta(x))] + \psi(x)\ [\dot{y}(t+\theta(x)) - \dot{y}(t-\theta(x))] \\ \qquad\qquad + \displaystyle\int_0^x \mathcal{B}(x,\xi)[y(t+\theta(\xi)) + y(t-\theta(\xi))]\ d\xi, \\ u(t) = X(L,t) \end{cases}$$

with

$$\begin{aligned} y(t) &= X(0,t), \\ \theta(x) &= \int_0^x \sqrt{\frac{\tau'}{g\tau}}, \\ \psi(x) &= \left(\frac{\tau(0)\tau'(0)}{\tau(x)\tau'(x)}\right)^{\frac{1}{4}} \frac{1}{2}\sqrt{\frac{\tau(0)}{g\tau'(0)}}, \\ \phi(x) &= \left(\frac{\tau(0)\tau'(0)}{\tau(x)\tau'(x)}\right)^{\frac{1}{4}} \cdots \\ &\quad \times \left[1 + \frac{1}{8}\sqrt{\frac{\tau(0)}{\tau'(0)}} \left(\left(\sqrt{\frac{\tau'}{\tau}} + \frac{\tau''}{\tau'}\sqrt{\frac{\tau}{\tau'}}\right)(x) - \left(\sqrt{\frac{\tau'}{\tau}} + \frac{\tau''}{\tau'}\sqrt{\frac{\tau}{\tau'}}\right)(0) \right.\right. \\ &\qquad\qquad \left.\left. + \cdots + \frac{1}{4}\int_0^x \left(\sqrt{\frac{\tau'}{\tau}} + \frac{\tau''}{\tau'}\sqrt{\frac{\tau}{\tau'}}\right)^2 \sqrt{\frac{\tau'}{\tau}}\right)\right], \end{aligned}$$

$B(x,\xi)$ a smooth function of x, and ξ defined by the function τ via formula (3.15).

Correspondence (3.2) defines a family of linear operators $\mathcal{A}_x$ with compact support such that, for any C^3 time function, $X(x,t) = \mathcal{A}_x y|_t$ is automatically the solution of (3.1) with $u(t) = X(L,t)$ and $X(0,t) = y(t)$.

The proof relies on the following points.

1. Symbolic computations where the time derivation is replaced by the Laplace variable s are performed. This yields a second order differential equation with nonconstant coefficients in the space variable x.
2. The solution $X(x,s)$ is factorized as $X(x,s) = X(0,s)A(x,s)$. A partial differential system is derived for $A(x,s)$.
3. The study of $s \mapsto A(x,s)$ is simplified by a Liouville transformation $(x,A) \mapsto (z,u)$.
4. The solution $A(x,s)$ of this differential equation is proven to be an entire function of s and of exponential type. (Volterra expansion and majoring series arguments are used.)
5. A careful study of the Volterra equation of the second kind satisfied by A shows that modulo some functions (exponentials of s, depending on x and explicitly calculated), for each x, the restriction of $A(x,s)$ to the imaginary axis is in L^2.
6. Thanks to the Paley–Wiener theorem and the last two properties of A, we prove that, for each x, A can be represented as a compact sum (discrete and continuous) of exponentials in s. This gives (3.2).

Proof. Symbolic computation. Replacing the time derivation by s gives

$$\begin{cases} \dfrac{\partial}{\partial x}\left(\tau(x)\dfrac{\partial X}{\partial x}\right) - \dfrac{\tau'(x)}{g}s^2 X = 0, \\ s^2 X(0,s) = gX'(0,s). \end{cases} \tag{3.3}$$

We do not consider the other boundary condition since u is the control and can be obtained explicitly from X via $u(t) = X(L,t)$.

Factorization. It is very easy to check that $X(x,s) = X(0,s)A(x,s)$ is the solution of (3.3), provided that $A(x,s)$ is the solution of the following partial differential system:

$$\begin{cases} \dfrac{\partial}{\partial x}\left(\tau(x)\dfrac{\partial A}{\partial x}\right) - \dfrac{\tau'(x)}{g}s^2 A = 0, \\ A(0,s) = 1, \\ gA'(0,s) = s^2. \end{cases} \tag{3.4}$$

Liouville transformation. This time we perform a Liouville transformation (already used in section 2)

$$(x,A) \mapsto (z,u)$$

with

$$p(x) = \tau(x), \quad \lambda = -\frac{s^2}{g}, \quad r(x) = \tau'(x), \quad q = 0, \quad x \in [0,L].$$

The new variables (z, u) are defined by the following formulas:

$$z = \frac{1}{K}\int_0^x \sqrt{\frac{\tau'}{\tau}}, \quad 0 \le z \le \pi, \quad K = \frac{1}{\pi}\int_0^L \sqrt{\frac{\tau'}{\tau}}, \tag{3.5}$$

$$u(z,s) = (\tau(x)\tau'(x))^{1/4} A(x,s). \tag{3.6}$$

System (3.4) is turned into

$$\frac{d^2u}{dz^2} + (\rho^2 - h(z))u = 0 \quad \text{with } \frac{du}{dz}(0) = (a + b\rho^2), \quad u(0) = 1, \tag{3.7}$$

where

$$\rho = \imath\, \frac{K}{\sqrt{g}} s, \quad \imath = \sqrt{-1},$$
$$h(z) = \frac{f''(z)}{f(z)} \quad \text{with } f(z) = (\tau(x)\tau'(x))^{1/4},$$
$$a = \frac{f'(0)}{f(0)}, \quad b = \frac{1}{K}\sqrt{\frac{\tau(0)}{\tau'(0)}}.$$

Proving that $\mathbb{C} \ni \rho \mapsto u(z,\rho)$ is an entire function of exponential type. We claim that, for each z, $\rho \mapsto u(z,\rho)$ is an entire function of exponential type.

Denote by $W(z,\rho)$ the 2×2 matrix solution of

$$\frac{dW}{dz} = \begin{pmatrix} 0 & 1 \\ h(z) - \rho^2 & 0 \end{pmatrix} W$$

with $W(0,\rho) = I$. Since

$$u(z,\rho) = \begin{pmatrix} 1 & 0 \end{pmatrix} W(z,\rho) \begin{pmatrix} 1 \\ a + b\rho^2 \end{pmatrix},$$

it suffices to prove that W is entire in ρ and of exponential type. Using the classical fixed point technique, W can be expressed as an absolutely convergent series of iterated integrals (Volterra expansion)

$$W(z,\rho) = \sum_{i \ge 0} W_i(z,\rho)$$

with

$$W_0(z,\rho) = I, \quad W_{i+1}(z) = \int_0^z \begin{pmatrix} 0 & 1 \\ h(\sigma) - \rho^2 & 0 \end{pmatrix} W_i(\sigma,\rho)\, d\sigma. \tag{3.8}$$

For each $i > 0$, $W_i(z,\rho)$ is a polynomial in ρ^2 of degree i with coefficients depending on z. Thus we have

$$\sum_{0 \le i \le k} W_i(z,\rho) = \sum_{0 \le j \le k} W^{j,k}(z)\, \rho^{2j}.$$

From step k to $k+1$, we add to $W^{j,k}(z)$ the coefficient of ρ^{2j} in W_{k+1}, say, $\mathcal{W}^{j,k+1}$, to obtain $W^{j,k+1}(z)$:

$$W^{j,k+1}(z) = W^{j,k}(z) + \mathcal{W}^{j,k+1}(z).$$

Let $\alpha = \sup_{[0,\pi]} |h|$. Then the absolute value of each entry of $W_i(z,\rho)$ is bounded by the corresponding entries in the following *majoring series* $M_i(z,\rho)$ defined by the induction (to be compared to (3.8)):

$$M_0(z,\rho) = I, \quad M_{i+1}(z) = \int_0^z \begin{pmatrix} 0 & 1 \\ \alpha+\rho^2 & 0 \end{pmatrix} M_i(\sigma,\rho)\, d\sigma. \tag{3.9}$$

As for W, we can define $M = \sum_{i\geq 0} M_i$ and, for each $k > 0$, the matrices $M^{j,k}$ and $\mathcal{M}^{j,k+1}$ satisfying

$$\sum_{0\leq i\leq k} M_i(z,\rho) = \sum_{0\leq j\leq k} M^{j,k}(z)\, \rho^{2j}, \quad M^{j,k+1}(z) = M^{j,k}(z) + \mathcal{M}^{j,k+1}(z).$$

Standard matrix computations show that

$$\begin{aligned} M(z,\rho) = I &+ \sum_{i>0} \frac{z^{2i}}{(2i)!} \begin{pmatrix} (\rho^2+\alpha)^i & 0 \\ 0 & (\rho^2+\alpha)^i \end{pmatrix} \\ &+ \sum_{i>0} \frac{z^{2i+1}}{(2i+1)!} \begin{pmatrix} 0 & (\rho^2+\alpha)^i \\ (\rho^2+\alpha)^{i+1} & 0 \end{pmatrix}. \end{aligned}$$

That is,

$$M(z,\rho) = \begin{pmatrix} \cosh(z\sqrt{\rho^2+\alpha}) & \sinh(z\sqrt{\rho^2+\alpha})/\sqrt{\rho^2+\alpha} \\ \sinh(z\sqrt{\rho^2+\alpha})\sqrt{\rho^2+\alpha} & \cosh(z\sqrt{\rho^2+\alpha}) \end{pmatrix}. \tag{3.10}$$

For each j, the matrices $M^{j,k} = \sum_{j\leq l\leq k-1} \mathcal{M}^{j,l}$ converge as k tends to ∞. Denote by M^j the limit. By construction, $M = \sum_{j\geq 0} M^j(z)\, \rho^{2j}$, and this series has an infinite radius of convergence in ρ, since, for each z, the functions $\rho \mapsto \cosh(z\sqrt{\rho^2+\alpha})$, $\rho \mapsto \sinh(z\sqrt{\rho^2+\alpha})/\sqrt{\rho^2+\alpha}$, and $\rho \mapsto \sinh(z\sqrt{\rho^2+\alpha})\sqrt{\rho^2+\alpha}$ are entire functions of ρ^2.

But, for each i, j, and k, the matrices $M^{j,k}$ and $\mathcal{M}^{j,k+1}$, whose entries are always nonnegative, dominate the absolute values of the entries of $W^{j,k}$ and $\mathcal{W}^{j,k+1}$, respectively. Thus for each j, the matrices $W^{j,k} = \sum_{j\leq l\leq k-1} \mathcal{W}^{j,l}$ converge as k tends to ∞. Denote by W^j the limit. By construction, $W = \sum_{j\geq 0} W^j(z)\rho^{2j}$, and this series has an infinite radius of convergence in ρ, since M has one. In other words, W is an entire function of ρ. Moreover, the entries of M are upper bounds of the entries of W. Thus W is of exponential type in ρ: for each $z \in [0,\pi]$, there exists $E > 0$ such that

$$\forall \rho \in \mathbb{C}, \quad |W(z,\rho)| \leq E \exp(z|\rho|).$$

We have proven that, for each $z \in [0,\pi]$, $u(z,\rho)$ is an entire function of ρ of exponential type with

$$\forall \rho \in \mathbb{C}, \quad |u(z,\rho)| \leq b(z) \exp(z|\rho|)$$

for some $b(z) > 0$ well-chosen.

Proving that "a part" of $\mathbb{R} \ni \rho \mapsto u(z,\rho)$ belongs to L^2. In general, $\mathbb{R} \ni \rho \mapsto u(z,\rho)$ does not belong to L^2. Thus the Paley–Wiener theorem does not apply directly. Removing some appropriate terms, the remaining is in L^2.

Let

$$v(z,\rho) = u(z,\rho) + b\rho\sin(\rho z) - \left(1 + \frac{b\int_0^z h}{2}\right)\ \cos(\rho z). \tag{3.11}$$

In the following we prove that this entire function of exponential type is such that $\mathbb{R} \ni \rho \mapsto v(z,\rho)$ belongs to L^2.

From the Volterra equation of the second kind satisfied by u (see [19, p. 111]),

$$u(z,\rho) = \left(\cos(\rho z) + (a - b\rho^2)\frac{\sin(\rho z)}{\rho}\right) + \frac{1}{\rho}\int_0^z \sin(\rho(z-\zeta))\ h(\zeta)\ u(\zeta,\rho)\ d\zeta,$$

we quickly derive a similar equation satisfied by v,

$$v(z,\rho) = \phi(z,\rho) + \frac{1}{\rho}\int_0^z \sin(\rho(z-\zeta))\ h(\zeta)\ v(\zeta,\rho)\ d\zeta,$$

where $\phi = \phi_1 - b\phi_2$ with

$$\begin{aligned}
\phi_1(z,\rho) =& a\frac{\sin(\rho z)}{\rho} + \frac{1}{\rho}\int_0^z \sin(\rho(z-\zeta))h(\zeta)\cos(\rho\zeta)\left(1 + (b/2)\int_0^\zeta h\right)\ d\zeta,\\
\phi_2(z,\rho) =& \cos(\rho z)\int_0^z h/2 + \int_0^z \sin(\rho(z-\zeta))h(\zeta)\sin(\zeta)\ d\zeta.
\end{aligned}$$

Clearly, there exists $D_1 > 0$ such that for all $z \in [0,\pi]$ and $\rho \in \mathbb{R}$,

$$|\phi_1(z,\rho)| \le \frac{D_1}{1+|\rho|}$$

(h is bounded). With $2\sin(\rho(z-\zeta))\sin(\zeta) = \cos(\rho(z-2\zeta)) - \cos(\rho z)$, we have

$$\phi_2(z,\rho) = \int_0^z \cos(\rho(z-2\zeta))h(\zeta)\ d\zeta.$$

The integration by part (by assumption τ is C^4 thus h is C^1)

$$\int_0^z \cos(\rho(z-2\zeta))h(\zeta)\ d\zeta = \frac{h(0)+h(z)}{2\rho}\sin(\rho z) + \frac{1}{2\rho}\ \int_0^z \sin(\rho(z-2\zeta))h'(\zeta)\ d\zeta$$

shows that for large $|\rho|$, ϕ_2 tends to zero at least as $1/|\rho|$. Thus there exists $D_2 > 0$ such that for all $z \in [0,\pi]$ and $\rho \in \mathbb{R}$,

$$|\phi_2(z,\rho)| \le \frac{D_2}{1+|\rho|}.$$

This proves that v satisfies

$$v(z,\rho) = \phi(z,\rho) + \frac{1}{\rho}\int_0^z \sin(\rho(z-\zeta))h(\zeta)v(\zeta,\rho)\ d\zeta \tag{3.12}$$

with $|\phi(z,\rho)| \le D/(1+|\rho|)$ for all $z \in [0,\pi]$ and $\rho \in \mathbb{R}$. ($D > 0$ is a well-chosen constant independent of z and ρ.)

This last inequality gives the desired conclusion by the following classical computation (see [19, p. 112], for instance).

Let $\beta(z,\rho) = \sup_{0\le\zeta\le z} |v(\zeta,\rho)|$. By (3.12) we have for each z_1 and z_2 in $[0,\pi]$, $z_1 \le z_2$

$$|v(z_1,\rho)| \le \frac{D}{1+|\rho|} + \frac{\alpha z_1 \beta(z_2,\rho)}{|\rho|} \le \frac{D}{1+|\rho|} + \frac{\alpha\pi}{|\rho|}\ \beta(z_2,\rho).$$

(Remember that $\alpha = \sup_{[0,\pi]} |h|$.) In particular, when $z_1 = z_2 = z$, we have

$$\beta(z,\rho)\left(1 - \frac{\alpha\pi}{|\rho|}\right) \le \frac{D}{1+|\rho|}. \tag{3.13}$$

Finally, for $|\rho| \ge 2\alpha\pi$, $\beta(z,\rho) \le 2D/(1+|\rho|)$. This proves that $\mathbb{R} \ni \rho \mapsto v(z,\rho)$ belongs to L^2.

Using the Paley–Wiener theorem. At last, the Paley–Wiener theorem ensures that the Fourier transform of $\rho \mapsto v(z,\rho)$ has a compact support included in $[-z,z]$ since for all $\rho \in \mathbb{C}, |v(z,\rho)| \le N\exp(z|\rho|)$ for some constant $N > 0$. This means that, for each $z \in [0,\pi]$, there exists $[-z,z] \ni \zeta \mapsto \mathcal{K}(z,\zeta)$ in $L^2([-z,z])$ such that

$$v(z,\rho) = \int_{-z}^{+z} \mathcal{K}(z,\zeta)\exp(\imath\zeta\rho)\ d\zeta.$$

Since v is an even function of ρ, $\mathcal{K}$ is also an even function of ζ. Thus we have, finally,

$$v(z,\rho) = \int_{0}^{+z} \mathcal{K}(z,\zeta)(\exp(\imath\zeta\rho) + \exp(-\imath\zeta\rho))\ d\zeta. \tag{3.14}$$

Conclusion. Pulling back this last relation in the (x,A) coordinates, noticing that $\rho = \imath Ks/\sqrt{g}$, that $\exp(-\theta s)$ is the Laplace transform of the θ-delay operator, and that $u(0,\rho)$ is, up to a constant, the Laplace transform of $X(0,t)$, we deduce after some standard but tedious computations formulae (3.2). The new function $\mathcal{B}(x,\xi)$ is related to $\mathcal{K}(z,\zeta)$ via

$$K\sqrt{\frac{\tau(\xi)}{\tau'(\xi)}}\ \mathcal{B}(x,\xi) = \left(\frac{\tau(0)\tau'(0)}{\tau(x)\tau'(x)}\right)^{\frac{1}{4}}\ \mathcal{K}\left(\frac{\sqrt{g}}{K}\theta(x), \frac{\sqrt{g}}{K}\theta(\xi)\right). \tag{3.15}$$

At last,

$$\begin{aligned} A(x,s) = \varphi(x)\,(\exp\theta(x)s + \exp\theta(x)s) + \psi(x)s\,(\exp\theta(x)s - \exp\theta(x)s) \\ + \int_0^x \mathcal{K}(x,\zeta)(\exp(\theta(\zeta)s) + \exp(-\theta(\zeta)s))\ d\zeta, \end{aligned}$$

so $X(x,s) = X(0,s)A(x,s)$ when turned back into the time-domain does give formulae (3.2). □

4. Conclusion. We have shown that, around the stable vertical position, heavy chain systems with or without load, with constant or variable section, are "flat": the trajectories of these systems are parameterizable by the trajectories of their free ends. Relations (1.4), (2.2), and (3.2) show that such parameterizations involve operators of compact supports.

It is surprising that such parameterizations can also be applied around the inverse and unstable vertical position. For the homogenous heavy chain, we have only to replace g by $-g$ to obtain a family of smooth solutions to the elliptic equation (singular at $x = 0$)

$$\frac{\partial}{\partial x}\left(gx\frac{\partial X}{\partial x}\right) + \frac{\partial^2 X}{\partial t^2} = 0$$

by the integral

$$X(x,t) = \frac{1}{2\pi}\int_{-\pi}^{\pi} y(t + 2\imath\sqrt{x/g}\sin\theta)\ d\theta,$$

where y is now a holomorphic function in $\mathbb{R} \times [-2\sqrt{L/g}, +2\sqrt{L/g}]$ that is real on the real axis. This parameterization can still be used to solve the motion planning problem in spite of the fact that the Cauchy problem associated to this elliptic equation is not well-posed in the sense of Hadamard.

Acknowledgments. The authors are indebted to Michel Fliess and Philippe Martin for fruitful discussions relative to the Paley–Wiener theorem, series expansions, majoring series arguments, and Liouville transformations.

A GENERALIZATION OF ZUBOV'S METHOD TO PERTURBED SYSTEMS*

FABIO CAMILLI†, LARS GRÜNE‡, AND FABIAN WIRTH§

Abstract. A generalization of Zubov's theorem on representing the domain of attraction via the solution of a suitable partial differential equation is presented for the case of perturbed systems with a singular fixed point. For the construction it is necessary to consider solutions in the viscosity sense. As a consequence, maximal robust Lyapunov functions can be characterized as viscosity solutions.

Key words. Zubov's method, robust stability, domain of attraction, viscosity solutions

1. Introduction.

The domain of attraction of an asymptotically stable fixed point has been one of the central objects in the study of continuous dynamical systems. In the late 1960's there was a particular surge of activity with a number of papers by Coleman [8], [9], Wilson [25], and Bhatia [6] analyzing properties of the domains. One of the celebrated results of that era was what came to be known as Zubov's method [26], which asserts that the domain of attraction of an asymptotically stable fixed point x^* of

$$\dot{x} = f(x)\,, \quad x \in \mathbb{R}^n,$$

may be characterized by solutions v of the partial differential equation

$$Dv(x) \cdot f(x) = -h(x)(1 - v(x))\sqrt{1 + \|f(x)\|^2}\,. \tag{1.1}$$

Namely, under suitable assumptions on h, the set $v^{-1}([0,1))$ is equal to the domain of attraction. These results are presented in several books; see [11] or [14]. For the case of real-analytic systems a constructive procedure is presented in [11] that allows for the approximation of the domain of attraction. This method was extended and simplified in [24], where again a constructive approach for the case of analytic systems is presented. The construction was extended to the case of asymptotically stable periodic orbits in [2].

In recent years much effort has been devoted to the development of numerical methods for the approximation of domains of attractions. Zubov's method also lends itself to the construction of such schemes; see [24], [13] and the paper [1], which considers a particular application.

In this paper our aim is to generalize Zubov's basic result by incorporating perturbations into the setup. That is, we consider systems of the form

$$\dot{x} = f(x, a)$$

with the property that the fixed point (which we take to be zero) is not perturbed under all perturbations. Under a local stability assumption, which guarantees that it is reasonable to consider domains of attraction we are interested in the set of points that is attracted to the fixed point regardless of the perturbation considered. This is what we call the robust domain of attraction. This subset of the domain of the unperturbed system $\dot{x} = f(x, a_0)$ is also studied in [18], [19], where, in particular, an approximation scheme for the robust domain of attraction is presented based on ideas of optimal control. In this paper we concentrate on proving an existence and uniqueness result for a Zubov-type equation and examining properties of the solutions that can be obtained. Numerical aspects and actual examples are presented in [7].

In section 2 we begin defining robust domains of attraction for the class of systems under consideration and state some fundamental properties. In section 3 we define the generalization of (1.1) suitable for our case and discuss the question of solvability of this equation. For this we turn to the methodology of viscosity solutions. We refer to [3] for an introduction to this theory in the context of optimal control. Using viscosity solutions, we obtain an existence and uniqueness result for the generalized equation. In sections 4 and 5 we note some properties of the constructed solutions. In particular, the solutions can be interpreted as robust Lyapunov functions for the perturbed system, and via suitable choices of the parameters this Lyapunov function can be guaranteed to be globally Lipschitz, or smooth, at least, on subsets of the robust domain of attraction. Finally, in section 6 we provide a simple example illustrating our results.

2. The robust domain of attraction. Let $\varphi(t, x_0, a)$ be the solution of

$$\begin{cases} \dot{x}(t) = f(x(t), a(t)), & t \in [0, \infty), \\ x(0) = x_0, \end{cases} \tag{2.1}$$

where $a(\cdot) \in \mathcal{A} = L^\infty([0, +\infty), A)$ and A is a compact subset of $\mathbb{R}^m$. Throughout the paper the map f is taken to be continuous and bounded in $\mathbb{R}^n \times A$ and locally Lipschitz in x uniformly in $a \in A$. Furthermore, we assume that the fixed point $x = 0$ is singular; that is, $f(0, a) = 0$ for any $a \in A$.

We assume that the singular point 0 is uniformly locally exponentially stable for the system (2.1), i.e.,

(H1) there exist constants $C, \sigma, r > 0$ such that $\|\varphi(t, x_0, a)\| \le Ce^{-\sigma t}\|x_0\|$ for any $x_0 \in B(0, r)$ and any $a \in \mathcal{A}$.

We now define the following sets which describe domains of attraction for the equilibrium $x = 0$ of the system (2.1).

DEFINITION 2.1. *For the system* (2.1) *satisfying* (H1) *we define the* robust domain of attraction *as*

$$\mathcal{D} = \{x_0 \in \mathbb{R}^n : \varphi(t, x_0, a) \to 0 \text{ as } t \to +\infty \text{ for any } a \in \mathcal{A}\}$$

and the uniform robust domain of attraction *by*

$$\mathcal{D}_0 = \left\{ x_0 \in \mathbb{R}^n : \begin{array}{l} \text{there exists a function } \beta(t) \to 0 \text{ as } t \to \infty \\ \text{such that } \|\varphi(t, x_0, a)\| \le \beta(t) \text{ for all } t > 0,\ a \in \mathcal{A} \end{array} \right\}.$$

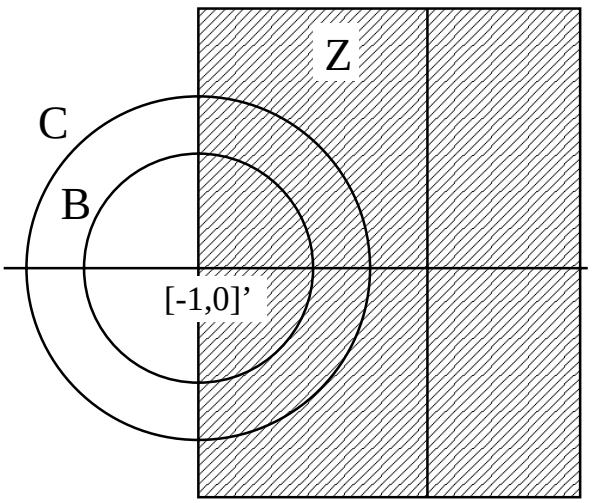

FIG. 2.1. *Sketch for Example* 2.1.

In order to obtain a different characterization of $\mathcal{D}_0$, we introduce the following "first hitting time" defined by $t(x,a) := \inf\{t > 0 : \ \varphi(t,x,a) \in B(0,r)\}$. Note that by the assumption on $B(0,r)$ there exists $T > 0$ independent of x and a such that $\varphi(t,x,a) \in B(0,r)$ for any $t \geq t(x,a) + T$.

LEMMA 2.2. *Assume* (H1); *then the robust domains of attraction* $\mathcal{D}$ *and* $\mathcal{D}_0$ *satisfy*

$$\mathcal{D} = \{x \in \mathbb{R}^n \, : \, t(x,a) < +\infty \text{ for any } a \in \mathcal{A}\} \, ,$$
$$\mathcal{D}_0 = \left\{ x \in \mathbb{R}^n \, : \, \sup_{a \in \mathcal{A}} \{t(x,a)\} < +\infty \right\} .$$

Proof. This is immediate from Definition 2.1. □

Before we begin analyzing some of the properties of $\mathcal{D}$ and $\mathcal{D}_0$, let us give an example that shows that for general nonlinear systems they are different.

Example 2.1. Let $n = 2$ and $y_0 = [\,-1\,,\,0\,]'$. We fix two discs around y_0 given by $B := B(y_0, 1/2)$ and $C := B(y_0, 3/4)$ and let $Z := \{x = [x_1, x_2] \in \mathbb{R}^2 \ : \ x_1 > -1\}$; see Figure 2.1.

Fix a C^∞ function $h : \mathbb{R}^2 \to \mathbb{R}$ such that

$$h \geq 0 \, , \quad h_{|B} \equiv 1 \, , \quad h_{|C^c} \equiv 0 \, .$$

Fix any $f : \mathbb{R}^2 \to \mathbb{R}^2$ such that $f_{|B} \equiv 0$, $f(0) = 0$, and such that the set $Z \setminus \operatorname{cl} B$ is contained in the domain of attraction of $x^* = 0$ for the system $\dot{x} = f(x)$. We may assume, furthermore, that for the first component function of f (denoted by f_1) we have $f_1(x) > 0$ on the annulus $C \setminus \operatorname{cl} B$. Now consider the system

$$\dot{x} = f(x) + h(x) \begin{bmatrix} (x_1+1)^2 + x_2^2 + 1 - a^2 \\ a \end{bmatrix} =: g(x,a) \, ,$$

where $a \in [-1,1]$. It is easy to see that for $x_0 \in B$ it holds that the first component of the solution $\varphi_1(t,x_0,a)$ is strictly increasing as long as $\varphi(t,x_0,a) \in B$. We even

have that for any $x_0 \in B \cap \operatorname{cl} Z$ and any $a \in \mathcal{A}$ there is a time $T = T(x_0, a)$ such that $\varphi(T, x_0, a) \notin B$. Also, by our assumption on f, h, and the construction of g, the first component of the solutions is strictly increasing on $C \setminus \operatorname{cl} B$. As a consequence, $y_0 \in \mathcal{D}$. On the other hand, for y_0 we have that for any time $t > 0$ and any $\varepsilon > 0$ there is some $a \in \mathcal{A}$ with $\|y_0 - \varphi(t, y_0, a)\| < \varepsilon$ by [12, Chap. 3, Theorem 6] as 0 is contained in the convex hull of $\{g(y_0, a) \ : \ a \in A\}$. Hence $t(y_0, a)$ is unbounded over $\mathcal{A}$, and so $y_0 \notin \mathcal{D}_0$.

In the following proposition we present some relevant properties of the (uniform) robust domain of attraction. Several of these bear a striking resemblance to those of the domain of attraction of an asymptotically stable fixed point of a time-invariant system; compare [11, Chap. IV]. It will frequently be convenient to consider the reachable set at time T from an initial condition $x_0 \in \mathbb{R}^n$ defined by

$$\mathcal{R}(x_0, T_0) := \{x \in \mathbb{R}^n \ : \ \exists\, 0 \le t \le T_0, a \in \mathcal{A} \text{ such that } x = \varphi(t, x_0, a)\}.$$

Note that by the boundedness of f it is immediate that the reachable set from a bounded set of initial conditions S given by

$$\mathcal{R}(S, T) := \bigcup_{x \in S} \mathcal{R}(x, T)$$

is bounded for any $T \ge 0$.

PROPOSITION 2.3. *Consider system* (2.1) *and assume* (H1)*; then the following hold.*

(i) $\operatorname{cl} B(0, r) \subset \mathcal{D}_0$.
(ii) $\mathcal{D}_0$ *is an open, connected, invariant set.* $\mathcal{D}$ *is a pathwise connected, invariant set.*
(iii) $\sup_{a \in \mathcal{A}}\{t(x, a)\} \to +\infty$ *for* $x \to x_0 \in \partial\mathcal{D}_0$ *or* $\|x\| \to \infty$.
(iv) $\mathcal{D} \subset \operatorname{cl} \mathcal{D}_0$.
(v) $\operatorname{cl} \mathcal{D}_0 = \operatorname{cl} \mathcal{D}$ *is an invariant set.*
(vi) $\mathcal{D}_0$, $\mathcal{D}$ *are contractible to* 0.
(vii) *If for some* $a_0 \in A$ $f(\cdot, a_0)$ *is of class* C^1*, then* $\mathcal{D}_0$ *is* C^1*-diffeomorphic to* $\mathbb{R}^n$.
(viii) *If for every* $x \in \partial\mathcal{D}_0$ *there exists* $a \in \mathcal{A}$ *such that* $\varphi(t, x, a) \in \partial\mathcal{D}_0$ *for all* $t \ge 0$*, then* $\mathcal{D} = \mathcal{D}_0$.
(ix) *If for all* $x \in \mathcal{D}$ *the set* $\{f(x, a) \ : \ a \in \mathcal{A}\}$ *is convex, then* $\mathcal{D}_0 = \mathcal{D}$.

Proof.

(i) This is a consequence of the exponential bound in (H1), which can easily be shown to extend to $\operatorname{cl} B(0, r)$.
(ii) Let $x_0 \in \mathcal{D}_0$ and $T_0 = \sup_{a \in \mathcal{A}}\{t(x_0, a)\}$. Then there exists T such that $\varphi(t, x_0, a) \in B(0, r/2C)$ for any $a \in \mathcal{A}$, $t \ge T$. Let δ be such that if $\|x_0 - x\| \le \delta$, then $\|\varphi(t, x_0, a) - \varphi(t, x, a)\| \le r/2C$ for any $t \le T$ and any $a \in \mathcal{A}$. Then $\varphi(t, x, a) \in B(0, r)$ for $t \ge T$ and $a \in \mathcal{A}$. Therefore, $x \in \mathcal{D}_0$, and it follows that $\mathcal{D}_0$ is open. By definition from each $x \in \mathcal{D}_0$ ($x \in \mathcal{D}$) there exists a trajectory $\varphi(\cdot, x, a)$ entering $B(0, r)$. This shows connectedness. To prove invariance assume that for some $x \in \mathcal{D}_0, a_1 \in \mathcal{A}$ there exists a $t > 0$ such that $y := \varphi(t, x, a_1) \notin \mathcal{D}_0$. This implies $\sup_{a \in \mathcal{A}}\{t(y, a)\} = \infty$. But clearly, $\sup_{a \in \mathcal{A}}\{t(x, a)\} \ge \sup_{a \in \mathcal{A}}\{t(y, a)\}$, contradicting the choice of x. A similar argument works for $\mathcal{D}$.
(iii) Let $x_n \to x_0 \in \partial\mathcal{D}_0$ and set $T_n = \sup_{a \in \mathcal{A}}\{t(x_n, a)\}$. If we assume that T_n is bounded and we take $r' < r$, we can find T such that, for any n, $\varphi(t, x_n, a) \in B(0, r')$ for any $t \ge T$ and for any $a \in \mathcal{A}$.

For any $\epsilon > 0$, there exists $\delta > 0$ such that if $\|x' - x''\| \leq \delta$, $\|\varphi(t, x', a) - \varphi(t, x'', a)\| \leq \epsilon$ for any $t \leq T$, for any $a \in \mathcal{A}$. Thus, setting $\epsilon = r - r'$ and choosing n sufficiently large such that $\|x_n - x_0\| \leq \delta$, we obtain that $\varphi(t, x_0, a) \in B(0, r)$ for any $t \geq T$ and for any $a \in \mathcal{A}$. Hence $x_0 \in \mathcal{D}_0$, which is a contradiction. The assertion is clear for $\|x_n\| \to \infty$, as our assumptions exclude solutions exploding in backward time.

(iv) The statement follows from an application of [20, Lemma III.2], which states that if $x \in \mathcal{D} \setminus \mathcal{D}_0$ or, equivalently, if $\sup_{a \in \mathcal{A}}\{t(x, a)\} = \infty$, while $t(x, a) < \infty$ for every $a \in \mathcal{A}$, then $x \in \partial\mathcal{D}$, as in every neighborhood of x there exists a point y and a control a_y such that $t(y, a_y) = \infty$.

(v) If for some $x \in \operatorname{cl}\mathcal{D}_0$ and $a \in \mathcal{A}$ we have $\varphi(t, x, a) \notin \operatorname{cl}\mathcal{D}_0$, then by continuous dependence on initial conditions we have that $\mathcal{D}_0$ is not invariant, contradicting (i). The equality of the two sets is an immediate consequence of (iv).

(vi) This follows by regarding the flow of $\dot{x} = f(x, a_0)$ for some $a_0 \in \mathcal{A}$.

(vii) In the proof we follow the outline given in [19]. Recall that a paracompact manifold M with the property that every compact subset of M has an open neighborhood that is diffeomorphic to $\mathbb{R}^n$ is itself diffeomorphic to $\mathbb{R}^n$; see [17, Lemma 3]. Let $K \subset \mathcal{D}_0$ be compact and consider a neighborhood U of K with $B(0, r) \subset U \subset \mathcal{D}_0$. Choose a relatively compact neighborhood U_2 of K with $B(0, r/2) \subset \operatorname{cl} U_2 \subset U$ and fix a C^∞ function $h : \mathbb{R}^n \to [0, 1]$ with $h_{|U_2} \equiv 1$ and $h_{|U^c} \equiv 0$. Now consider the system

$$\dot{x} = h(x) f(x, a_0)$$

with associated flow $\psi(t, x)$. It is clear that for some T large enough we have $K \subset \psi(-T, B(0, r/4)) \subset U$. This proves the assertion as $\psi(-T, B(0, r/4))$ is diffeomorphic to $B(0, r/4)$, which is in turn diffeomorphic to $\mathbb{R}^n$.

(viii) By the pathwise connectedness of $\mathcal{D}$ we have that $\mathcal{D} \cap \partial\mathcal{D}_0 \neq \emptyset$ if $\mathcal{D} \neq \mathcal{D}_0$. This contradicts our assumption.

(ix) Clearly, we need only show $\mathcal{D} \subset \mathcal{D}_0$. Assume that $x \in \mathcal{D}$ and there exist sequences $a_k \in \mathcal{A}$, $T_k \to \infty$ such that $\|\varphi(T_k, x, a_k)\| > r > 0$ for all $k \in \mathbb{N}$. By standard constructions there exists a subsequence (for which we use the index k again) which converges uniformly on compact time intervals to a solution $y(t)$ of the differential inclusion

$$\dot{y}(t) \in f(y(t), A)\,.$$

Now by convexity of $f(y(t), A), t \geq 0$, and Filippov's lemma [15, p. 267] there exists a control $a \in \mathcal{A}$ such that $y(t) = \varphi(t, x, a)$. By assumption there exists a t_0 such that $\|\varphi(t_0, x, a)\| < r/C$. As $\varphi(t_0, x, a_k) \to \varphi(t_0, x, a)$, this implies for all k large enough the inequality $\|\varphi(t, x, a_k)\| < r$ for $t \geq t_0$, which is a contradiction. □

3. Zubov's method for robust domains of attraction. It is our aim to show that the appropriate generalization of Zubov's equation (1.1) is given by

$$\inf_{a \in A}\{-Dv(x) f(x, a) - (1 - v(x)) g(x, a)\} = 0, \qquad x \in \mathbb{R}^n.$$

In this section we show the existence of a unique solution under a suitable "boundary condition" in the equilibrium $x = 0$. This solution will turn out to characterize the

uniform robust domain of attraction $\mathcal{D}_0$. Before turning to this equation, we introduce two optimal value functions and show certain properties of these functions.

Consider the following nonnegative, extended value function $V : \mathbb{R}^n \to \mathbb{R} \cup \{+\infty\}$ by

$$V(x) = \sup_{a \in \mathcal{A}} \int_0^{+\infty} g(\varphi(t, x, a), a(t))dt \tag{3.1}$$

and its transformation via the Kruzkov transform

$$v(x) = 1 - e^{-V(x)}. \tag{3.2}$$

The function $g : \mathbb{R}^n \times A \to \mathbb{R}$ is supposed to be continuous and satisfies the following.

(H2)
- (i) For any $a \in A$, $g(0, a) = 0$ and $g(x, a) > 0$ for $x \neq 0$.
- (ii) There exists a constant $g_0 > 0$ such that $\inf_{x \notin B(0,r),\, a \in A} g(x, a) \geq g_0$.
- (iii) For every $R > 0$ there exists a constant L_R such that $\|g(x, a) - g(y, a)\| \leq L_R \|x - y\|$ for all $\|x\|$, $\|y\| \leq R$, and all $a \in A$.

Since g is nonnegative, it is immediate that $V(x) \geq 0$ and $v(x) \in [0, 1]$ for all $x \in \mathbb{R}^n$. Furthermore, standard techniques from optimal control (see, e.g., [3, Chapter III]) imply that V and v satisfy the dynamic programming principle; i.e., for each $t > 0$ we have

$$V(x) = \sup_{a \in \mathcal{A}} \left\{ \int_0^t g(\varphi(\tau, x, a), a(\tau))d\tau + V(\varphi(t, x, a)) \right\} \tag{3.3}$$

and

$$v(x) = \sup_{a \in \mathcal{A}} \{(1 - G(x, t, a)) + G(x, t, a)v(\varphi(t, x, a))\} \tag{3.4}$$

with

$$G(x, t, a) := \exp\left(- \int_0^t g(\varphi(\tau, x, a), a(\tau))d\tau \right). \tag{3.5}$$

The relation between V and v is immediate; we have

$$\begin{array}{lcl} V(x) = 0 & \Leftrightarrow & v(x) = 0\,, \\ V(x) \in (0, +\infty) & \Leftrightarrow & v(x) \in (0, 1)\,, \\ V(x) = +\infty & \Leftrightarrow & v(x) = 1\,. \end{array} \tag{3.6}$$

In the next proposition we investigate the relation between $\mathcal{D}_0$ and V (and thus also v) and the continuity of V and v.

PROPOSITION 3.1. *Assume* (H1) and (H2). *Then the following hold.*

(i) $V(x) < +\infty$ *if and only if* $x \in \mathcal{D}_0$.
(ii) $V(0) = 0$ *if and only if* $x = 0$.
(iii) V *is continuous on* $\mathcal{D}_0$.
(iv) $V(x) \to +\infty$ *for* $x \to x_0 \in \partial\mathcal{D}_0$ *and for* $\|x\| \to \infty$.
(v) $v(x) < 1$ *if and only if* $x \in \mathcal{D}_0$.
(vi) $v(0) = 0$ *if and only if* $x = 0$.
(vii) v *is continuous on* $\mathbb{R}^n$.

(viii) $v(x) \to 1$ *for* $x \to x_0 \in \partial\mathcal{D}_0$ *and for* $\|x\| \to \infty$.

Proof. (i) To show that $V(x_0) < +\infty$ for $x_0 \in \mathcal{D}_0$, observe that by Lemma 2.2 for each $x_0 \in \mathcal{D}_0$ there exists $T_0 > 0$ such that $\varphi(t, x_0, a) \in B(0, r)$ for all $t \geq T_0$ and all $a \in \mathcal{A}$. Also, the closure of the reachable set $\operatorname{cl}\mathcal{R}(x_0, T_0)$ is compact. Thus for any $a \in \mathcal{A}$

$$\begin{aligned}\int_0^{+\infty} g(\varphi(t), a(t))dt &\leq \int_0^{T_0} g(\varphi(t), a(t))dt + L_r \int_{T_0}^{+\infty} \|\varphi(t)\|dt \\ &\leq T_0 \sup_{x\in\mathcal{R}(x_0,T_0),a\in A} g(x, a) + L_r C \int_{T_0}^{+\infty} e^{-\sigma t} r dt \leq \tilde{C}\end{aligned}$$

with $\tilde{C}$ independent of $a \in \mathcal{A}$, and therefore, $V(x_0) < +\infty$.

Now let $x_0 \notin \mathcal{D}_0$. Then there exists a sequence $a_n \in \mathcal{A}$ such that $t(x_0, a_n)$ tends to ∞. Then for any $n \in \mathbb{N}$

$$\int_0^{+\infty} g(\varphi(t), a_n(t))dt \geq \int_0^{t(x_0,a_n)} g(\varphi(t), a_n(t))dt \geq g_0 t(x_0, a_n)\,,$$

where $g_0 > 0$ is defined as in (H2) (ii). It follows that $V(x) = +\infty$.

(ii) The proof follows immediately from (3.1), (H2) (i), and $f(0, a) = 0$.

(iii) Observe that

$$\begin{aligned}|V(x) - V(y)| &= \left|\sup_{a\in\mathcal{A}} \int_0^{+\infty} g(\varphi(t, x, a), a(t))dt - \sup_{a\in\mathcal{A}} \int_0^{+\infty} g(\varphi(t, y, a), a(t))dt\right| \\ &\leq \sup_{a\in\mathcal{A}} \int_0^{+\infty} |g(\varphi(t, x, a), a(t)) - g(\varphi(t, y, a), a(t))|\, dt\,. \qquad (3.7)\end{aligned}$$

We first prove that V is continuous on $B(0, r/C)$.

Fix some $x_0 \in B(0, r/C)$. Then (H1) and (H2) (iii) imply

$$\begin{aligned}\int_0^{+\infty} g(\varphi(t, x_0, a), a(t))dt &\leq L_r \int_0^{+\infty} \|\varphi(t, x_0, a)\|dt \\ &\leq L_r C \int_0^{+\infty} e^{-\sigma t}\|x_0\|dt \leq C_1\|x_0\|.\end{aligned}$$

Fix $\epsilon > 0$. From (H1) we can conclude that there exists $T > 0$ such that $C_1\|\varphi(t, x, a)\| \leq \epsilon/4$ for all $t \geq T$ and all $x \in B(0, r/C)$. Abbreviate $L = L_{r/C}$. Then by Lipschitz continuity of f there exists a $\delta > 0$ such that $\|\varphi(t, x_0, a) - \varphi(t, y_0, a)\| < \epsilon/(2LT)$ for all $t \in [0, T]$ and all $y_0 \in B(0, r/C)$ with $\|x_0 - y_0\| < \delta$.

Putting this together yields for every $a \in \mathcal{A}$

$$\begin{aligned}&\int_0^{+\infty} |g(\varphi(t, x_0, a), a(t)) - g(\varphi(t, y_0, a), a(t))|\, dt \\ &\quad\leq \int_0^T L\,\|\varphi(t, x_0, a) - \varphi(t, y_0, a)\|\, dt + C_1\|\varphi(T, x_0, a)\| + C_1\|\varphi(T, y_0, a)\| \\ &\quad\leq \epsilon/2 + \epsilon/4 + \epsilon/4 \;\leq\; \epsilon\,,\end{aligned}$$

which by (3.7) implies continuity.

For $x_0 \in \mathcal{D}_0$ we can use openness of $\mathcal{D}_0$ in order to conclude that there exists an open neighborhood N of x_0 and $T > 0$ such that $\varphi(t, y_0, a) \in B(0, r/C)$ for all

$y_0 \in N$, all $a \in \mathcal{A}$, and all $t \geq T$. Thus (3.3) and the continuity on $B(0, r/C)$ imply continuity in x_0.

(iv) The proof follows immediately from Proposition 2.3 (iii) since $\mathcal{D}_0$ is open and $g(x) \geq g_0 > 0$ for x outside $B(0, r)$ as assumed in (H2).

(v) and (vi) follow immediately from (3.6), (i), and (ii); (vii) follows from (3.6), (iii), and (iv); and (viii) follows from (3.6) and (iv). □

We now turn to the formulation of suitable partial differential equations for which V and v form solutions. Since in general these functions will not be differentiable, we have to work with a more general solution concept, namely, viscosity solutions.

Let us recall the definition of viscosity solutions. (For more details about this theory we refer to [3].)

DEFINITION 3.2. *Given an open subset Ω of $\mathbb{R}^n$ and a continuous function $H : \Omega \times \mathbb{R} \times \mathbb{R}^n \to \mathbb{R}$, we say that a lower semicontinuous (l.s.c.) function $u : \Omega \to \mathbb{R}$ (resp., an upper semicontinuous (u.s.c.) function $v : \Omega \to \mathbb{R}$) is a viscosity supersolution (resp., subsolution) of the equation*

$$H(x, u, Du) = 0, \qquad x \in \Omega, \tag{3.8}$$

if for all $\phi \in C^1(\Omega)$ and $x \in \operatorname{argmin}_\Omega(u - \phi)$ (resp., $x \in \operatorname{argmax}_\Omega(v - \phi)$) we have

$$H(x, u(x), D\phi(x)) \geq 0 \qquad \big(\textit{resp., } H(x, v(x), D\phi(x)) \leq 0\big).$$

A continuous function $u : \Omega \to \mathbb{R}$ is said to be a viscosity solution of (3.8) *if u is a viscosity supersolution and a viscosity subsolution of* (3.8).

Remark 3.1. It is not difficult to see (cf. [3, Lemma II.1.7]) that the set of derivatives $D\phi(x)$ for $x \in \operatorname{argmin}_\Omega(u - \phi)$ coincides with the set

$$D^- u(x) := \{p \in \mathbb{R}^n \mid u(x) - u(y) - p(x - y) \geq -o(\|x - y\|) \text{ for all } y \in \mathbb{R}^n\}$$

and that the set of derivatives $D\phi(x)$ for $x \in \operatorname{argmax}_\Omega(v - \phi)$ equals

$$D^+ v(x) := \{p \in \mathbb{R}^n \mid v(x) - v(y) - p(x - y) \leq o(\|x - y\|) \text{ for all } y \in \mathbb{R}^n\}.$$

Hence one can alternatively define viscosity solutions via the sets D^- and D^+, the so called *sub- and superdifferentials*. Note that if a function $w : \Omega \to \mathbb{R}$ is differentiable in some $x \in \Omega$, the equality $D^+ w(x) = D^- w(x) = \{Dw(x)\}$ follows; hence for smooth functions viscosity solutions coincide with classical solutions.

Recalling that V is locally bounded in $\mathcal{D}_0$ and v is locally bounded on $\mathbb{R}^n$, the following proposition follows from an easy application of the dynamic programming principles (3.3) and (3.4); cf. [3, Chapter III].

PROPOSITION 3.3. *V is a viscosity solution of*

$$\inf_{a \in A} \{-DV(x) f(x, a) - g(x, a)\} = 0, \qquad x \in \mathcal{D}_0, \tag{3.9}$$

and v is a viscosity solution of

$$\inf_{a \in A} \{-Dv(x) f(x, a) - (1 - v(x)) g(x, a)\} = 0, \qquad x \in \mathbb{R}^n. \tag{3.10}$$

Observe that (3.10) is the straightforward generalization of the classical Zubov equation (1.1) [26] multiplied by -1, which is necessary in order to obtain the proper sign for viscosity sub- and supersolutions. Equation (3.9), however, shows that also our "auxiliary function" V can be characterized as the solution of a suitable PDE.

In order to get a uniqueness result, we use the following super- and suboptimality principles. Our approach is closely related to that of Soravia [21, 22]; we quote the following result from [21].

THEOREM 3.4 (see [21, Theorem 3.2 (i)]). *Consider the equation*

$$\sup_{a\in A}\{-Du(x)f(x,a) - h(x,a) + k(x,a)u(x)\} = 0\,. \tag{3.11}$$

Then if u is a u.s.c. subsolution of (3.11)*, then it satisfies the lower optimality principle*

$$u(x) = \inf_{a\in\mathcal{A}}\inf_{t\geq 0}\left[\int_0^t \exp\left(-\int_0^s k(\varphi(r),a(r))dr\right) h(\varphi(s),a(s))ds + \exp\left(-\int_0^t k(\varphi(t),a(t))ds\right) u(\varphi(t))\right].$$

Recalling the definition of G from (3.5), we see that this result has immediate applications for (3.9), (3.10).

PROPOSITION 3.5.

(i) *Let w be an l.s.c. supersolution of* (3.10) *in $\mathbb{R}^n$; then for any $x\in\mathbb{R}^n$*

$$w(x) = \sup_{a\in\mathcal{A}}\sup_{t\geq 0}\{(1-G(x,t,a)) + G(x,t,a)w(\varphi(t))\}\,. \tag{3.12}$$

(ii) *Let W be an l.s.c. supersolution of* (3.9) *in $\mathcal{D}_0$; then for any $x\in\mathcal{D}_0$*

$$W(x) = \sup_{a\in\mathcal{A}}\sup_{t\geq 0}\left\{\int_0^t g(\varphi(s),a(s))ds + W(\varphi(t))\right\}. \tag{3.13}$$

(iii) *Let u be a u.s.c. subsolution of* (3.10) *in $\mathbb{R}^n$, and let $\tilde{u}:\mathbb{R}^n\to\mathbb{R}$ be a continuous function with $u\leq\tilde{u}$. Then for any $x\in\mathbb{R}^n$ and any $T\geq 0$*

$$u(x) \leq \sup_{a\in\mathcal{A}}\inf_{t\in[0,T]}\{(1-G(x,t,a)) + G(x,t,a)\tilde{u}(\varphi(t))\}\,. \tag{3.14}$$

(iv) *Let U be a u.s.c. subsolution of* (3.9) *in $\mathcal{D}_0$, and let $\tilde{U}:\mathcal{D}_0\to\mathbb{R}$ be a continuous function with $U\leq\tilde{U}$. Then for any $x\in\mathcal{D}_0$ and any $T\geq 0$*

$$U(x) \leq \sup_{a\in\mathcal{A}}\inf_{t\in[0,T]}\left\{\int_0^t g(\varphi(s),a(s))ds + \tilde{U}(\varphi(t))\right\}. \tag{3.15}$$

Proof. If w is an l.s.c. supersolution of (3.10), then it follows by multiplication by -1 and an application of the definition that $-w$ is a u.s.c. subsolution of

$$\sup_{a\in A}\{-Du(x)f(x,a) + (1+u(x))g(x,a)\} = 0, \qquad x\in\mathbb{R}^n\,. \tag{3.16}$$

This implies that we can directly apply Theorem 3.4 for the special case $h\equiv -g, k\equiv g$ to obtain that $-w$ satisfies

$$-w(x) = \inf_{a\in\mathcal{A}}\inf_{t\geq 0}\left[-\int_0^t \exp\left(-\int_0^s g(\varphi(r),a(r))dr\right) g(\varphi(s),a(s))ds - \exp\left(-\int_0^t g(\varphi(t),a(t))ds\right) w(\varphi(t))\right].$$

Now the assertion follows upon multiplication by -1 and using the fact that

$$\int_0^t G(\varphi(s), s, a(s))g(\varphi(s), a(s))ds = 1 - G(x, t, a)\,.$$

(ii) follows by insertion of $k \equiv 0, h \equiv -g$ in (3.11).

For the proof of (iii) we follow the ideas of [21] with minor modifications. Let $u : \mathbb{R}^n \to \mathbb{R}$ be a u.s.c. subsolution of (3.10), let $\tilde{u} : \mathbb{R}^n \to \mathbb{R}$ be a continuous function with $u \le \tilde{u}$, and define $u^* := -u$ and $\tilde{u}^* := -\tilde{u}$. Again, a straightforward verification of the definition shows that u^* is an l.s.c. viscosity supersolution of

$$\sup_{a\in A}\{-Dw(x)f(x,a) + (1 + w(x))g(x,a)\} = 0, \qquad x \in \mathbb{R}^n. \tag{3.17}$$

From this equation it is easy to see that the auxiliary function $\bar{u} : \mathbb{R}^{n+2} \to \mathbb{R}$ given by $\bar{u}(x, r, s) = e^{-s}u^*(x) + r$ is an l.s.c. supersolution of

$$\sup_{a\in A}\left\{-e^{-s}D_x v(x,r,s)f(x,a) + D_r v(x,r,s)e^{-s}g(x,a) - D_s v(x,r,s)g(x,a)\right\} = 0$$

for $x \in \mathbb{R}^n$, r, $s \in \mathbb{R}$.

We now introduce a change of variables by choosing $\rho : \mathbb{R} \to \mathbb{R}_+$ smooth, bounded, and such that $0 < \dot{\rho} \le M$ and $\rho(s) \to 0$ as $s \to -\infty$. Now consider the function

$$U(z) = U(x, r, s) := \rho(\bar{u}(x, r, s)) = \rho(e^{-s}u^*(x) + r)\,.$$

By the rules for changes of variables (cf. [3, Proposition II.2.5]) it can be shown that U is an l.s.c. supersolution of

$$\sup_{a\in A}\{-D_z u(z)F(z,a)\} = 0\,, \quad z \in \mathbb{R}^{n+2}\,, \tag{3.18}$$

where the underlying dynamics is given by

$$\dot{z} = \begin{pmatrix} \dot{x} \\ \dot{r} \\ \dot{s} \end{pmatrix} = F(z(t), a(t)) = \begin{pmatrix} f(\varphi(t), a(t)) \\ -e^{-s(t)}g(\varphi(t), a(t)) \\ g(\varphi(t), a(t)) \end{pmatrix}. \tag{3.19}$$

Note that the solution to this system corresponding to an initial value $z = (x, 0, 0)$ is given by

$$z(t) = \left[\varphi(t, x, a), (G(t, x, a) - 1), \int_0^t g(\varphi(s), a(s))ds\right]'. \tag{3.20}$$

In order to apply results from [21, Appendix] we need that F satisfies a global Lipschitz condition. Since this is not true in general, we localize the problem by considering for $k \in \mathbb{N}$ the family of smooth functions $\zeta_k : \mathbb{R}^{n+2} \to \mathbb{R}$ with $0 \le \zeta_k \le 1$, $\zeta_k \equiv 1$ in $B(0, k) \subset \mathbb{R}^{n+2}$, $\zeta_k \equiv 0$ in $B(0, k + 1)^c$, $|D\zeta_k| \le 2$, and setting $F_k = \zeta_k F$.

Then from (3.18) we can conclude that for each $k \in \mathbb{N}$ the function U is also a supersolution of

$$\sup_{a\in A}\{-D_z u(z)F_k(z,a)\} = 0\,,$$

as the multiplication with the nonnegative function ζ_k does not affect the inequality that a supersolution has to fulfill.

Now consider the continuous function $\phi : \mathbb{R}^{n+2} \to \mathbb{R}\,, \phi(z) = \phi(x,s,r), x \in \mathbb{R}^n, s, r \in \mathbb{R}$,

$$\phi(z) = \rho(e^{-s}\tilde{u}^*(x) + r)\,.$$

Since $U \geq 0$ (by the choice of ρ), we obtain for any fixed $\lambda > 0$ that U is also a supersolution of

$$\lambda u + \min\left\{\sup_{a\in A}\{-D_z u(z) F_k(z,a)\}\,,\; u - (1+\lambda)\phi\right\} = 0. \tag{3.21}$$

This equation has a unique continuous viscosity solution and it can be shown [21, Appendix] that this solution is given by the value function

$$V_k^\lambda(z) := \inf_{a\in\mathcal{A}} \sup_{t\geq 0} e^{-\lambda t}\phi(z_k(t)),$$

where $z_k(\cdot)$ solves $\dot{z}_k(t) = F_k(z_k(t), a(t))$, $z_k(0) = z$. By the usual comparison theorem for semicontinuous viscosity solutions (see, e.g., [3, Chapter V]), we obtain $U \geq V_k^\lambda$ for each $\lambda > 0$ and each $k \in \mathbb{N}$. Hence letting $\lambda \to 0$ yields for all $k \in \mathbb{N}$ and all $T > 0$ the inequality

$$\rho(e^{-s}u^*(x) + r) = U(z) \geq \inf_{a\in\mathcal{A}} \sup_{t\in[0,T]} \phi(z_k(t)).$$

By the boundedness of f the reachable set $\mathcal{R}(x,T)$ is bounded for each $x \in \mathbb{R}^n, T > 0$. Hence for each $z = (x,0,0) \in \mathbb{R}^{n+2}$ and each $T > 0$ there exists a $k \in \mathbb{N}$ such that $z(t) \in B(0,k)$ for all $a \in \mathcal{A}$ and all $t \in [0,T]$. Furthermore, on $B(0,k)$ the trajectories $z(\cdot)$ and $z_k(\cdot)$ coincide, and thus we can conclude by (3.20) and by the definition of ϕ that

$$\rho(u^*(x)) = U(x,0,0) \geq \inf_{a\in\mathcal{A}} \sup_{t\in[0,T]} \phi(z(t))$$

$$= \inf_{a\in\mathcal{A}} \sup_{t\in[0,T]} \rho\left((G(x,t,a) - 1) + G(x,t,a)\tilde{u}^*(\varphi(t))\right).$$

Using the monotonicity of ρ, we obtain

$$u^*(x) \geq \inf_{a\in\mathcal{A}} \sup_{t\in[0,T]} \left\{(G(x,t,a) - 1) + G(x,t,a)\tilde{u}^*(\varphi(t))\right\},$$

and hence

$$u(x) \leq \sup_{a\in\mathcal{A}} \inf_{t\in[0,T]} \left\{(1 - G(x,t,a)) + G(x,t,a)\tilde{u}(\varphi(t))\right\}$$

holds for each $T \geq 0$, which shows (iii).

Assertion (iv) is proved analogously. □

We can now apply these principles to the generalized version of Zubov's equation (3.10).

PROPOSITION 3.6. *Let w be a bounded l.s.c. supersolution of* (3.10) *on $\mathbb{R}^n$ with $w(0) \geq 0$. Then $w \geq v$ for v as defined in* (3.2).

Proof. First observe that the lower semicontinuity of w and the assumption $w(0) \geq 0$ imply that for each $\epsilon > 0$ there exists a $\delta > 0$ such that

$$w(x) \geq -\epsilon \text{ for all } x \in \mathbb{R}^n \text{ with } \|x\| \leq \delta. \tag{3.22}$$

Furthermore, the upper optimality principle (3.12) implies

$$w(x_0) \geq \sup_{a \in \mathcal{A}} \inf_{t \geq 0} \{1 + G(x_0, t, a)(w(\varphi(t, x_0, a)) - 1)\} . \tag{3.23}$$

Now we distinguish two cases.

(i) $x_0 \in \mathcal{D}_0$. In this case we know that for each $a \in \mathcal{A}$ we have $\varphi(t, x_0, a) \to 0$ as $t \to \infty$. Thus from (3.22) and (3.23), and using the definition of v, we can conclude

$$w(x_0) \geq \sup_{a \in \mathcal{A}} \left\{ \lim_{t \to \infty} (1 - G(x_0, t, a)) \right\} = v(x_0) ,$$

which shows the claim.

(ii) $x_0 \notin \mathcal{D}_0$. In this case by (3.6) and Proposition 3.1(v) it is sufficient to show that $w(x_0) \geq 1$. By the definition of $\mathcal{D}_0$ we know that for each $T > 0$ that there exists $a_T \in \mathcal{A}$ such that $t(x_0, a_T) > T$, which implies $G(x_0, T, a_T) \leq \exp(-Tg_0)$, which tends to 0 as $T \to \infty$. Thus, denoting the bound on $|w|$ by $M > 0$, the inequality (3.23) implies

$$w(x_0) \geq (1 - \exp(-Tg_0)) - \exp(-Tg_0)M$$

for every $T > 0$, and hence $w(x_0) \geq 1$. □

PROPOSITION 3.7. *Let u be a bounded u.s.c. subsolution of* (3.10) *on $\mathbb{R}^n$ with $u(0) \leq 0$. Then $u \leq v$ for v defined in* (3.2).

Proof. By the upper semicontinuity of u and $u(0) \leq 0$ we obtain that for every $\epsilon > 0$ there exists a $\delta > 0$ with $u(x) \leq \epsilon$ for all $x \in \mathbb{R}^n$ with $\|x\| \leq \delta$. Thus for each $\epsilon > 0$ we find a bounded and continuous function $\tilde{u}_\epsilon : \mathbb{R}^n \to \mathbb{R}$ with

$$\tilde{u}_\epsilon(0) < \epsilon \text{ and } u \leq \tilde{u}_\epsilon. \tag{3.24}$$

Now the lower optimality principle (3.14) implies for every $t \geq 0$ that

$$u(x_0) \leq \sup_{a \in \mathcal{A}} \{1 + G(x_0, t, a)(\tilde{u}_\epsilon(\varphi(t, x_0, a)) - 1)\} . \tag{3.25}$$

Again, we distinguish two cases.

(i) $x_0 \in \mathcal{D}_0$. In this case $\|\varphi(t, x_0, a)\| \to 0$ as $t \to \infty$ uniformly in $a \in \mathcal{A}$. Hence for each $\epsilon > 0$ there exists $t_\epsilon > 0$ such that

$$\tilde{u}_\epsilon(\varphi(t_\epsilon, x_0, a)) \leq \epsilon \quad \text{and} \quad |G(x_0, t_\epsilon, a) - G(x_0, \infty, a)| \leq \epsilon$$

for all $a \in \mathcal{A}$. Thus from (3.24) and (3.25), and using the definition of v, we can conclude

$$u(x_0) \leq \sup_{a \in \mathcal{A}} \{1 - (1 - \epsilon)G(x_0, t_\epsilon, a)\} \leq v(x_0) + \epsilon(1 - v(x_0)) + \epsilon ,$$

which shows the claim since v is bounded and $\epsilon > 0$ was arbitrary.

(ii) $x_0 \notin \mathcal{D}_0$. In this case by (3.6) and Proposition 3.1(v) it is sufficient to show that $u(x_0) \leq 1$. By (i) we know that $u(y) \leq v(y) < 1$ for each $y \in \mathcal{D}_0$; hence, analogous to (3.24) for each $\epsilon > 0$, we can conclude the existence of a continuous $\tilde{u}_\epsilon$ with $u \leq \tilde{u}_\epsilon$ and $\tilde{u}_\epsilon(y) \leq 1 + \epsilon$ for each $y \in \mathcal{D}_0$. Since u is bounded by assumption, we may choose $\tilde{u}_\epsilon$ such that $M_\epsilon := \sup_{x \in \mathbb{R}^n} \tilde{u}_\epsilon(x) < \infty$. If $M_\epsilon \leq 1$ for some $\epsilon > 0$, we are done. Otherwise, fix $\epsilon > 0$ and consider a sequence $t_n \to \infty$. Then (3.25) implies that there exists a sequence $a_n \in \mathcal{A}$ with

$$u(x_0) - \epsilon \leq 1 + G(x_0, t_n, a_n)(\tilde{u}_\epsilon(\varphi(t_n, x_0, a_n)) - 1).$$

If $\varphi(t_n, x_0, a_n) \in \mathcal{D}_0$, we know that $\tilde{u}_\epsilon(\varphi(t_n, x_0, a_n)) \leq 1 + \epsilon$, and since $G \leq 1$, we obtain $u(x_0) - \epsilon \leq 1 + \epsilon$. If $\varphi(t_n, x_0, a_n) \notin \mathcal{D}_0$, then $G(x_0, t_n, a_n) \leq \exp(-g_0 t_n)$; thus

$$1 + G(x_0, t_n, a_n)(\tilde{u}_\epsilon(\varphi(t_n, x_0, a_n)) - 1) \leq 1 + \exp(-g_0 t_n)(M_\epsilon - 1).$$

Thus for each $n \in \mathbb{N}$ we obtain

$$u(x_0) \leq 2\epsilon + 1 + \exp(-g_0 t_n)(M_\epsilon - 1)\,,$$

which for $n \to \infty$ implies $u(x_0) \leq 1 + 2\epsilon$. This proves the assertion since $\epsilon > 0$ was arbitrary. □

Using these propositions, we can now formulate an existence and uniqueness theorem for the generalized version of Zubov's equation (3.10).

THEOREM 3.8. *Consider the system* (2.1) *and a function* $g : \mathbb{R}^n \times A \to \mathbb{R}$ *such that* (H1) *and* (H2) *are satisfied. Then* (3.10) *has a unique bounded and continuous viscosity solution* v *on* $\mathbb{R}^n$ *satisfying* $v(0) = 0$.

This function coincides with v *from* (3.2). *In particular, the characterization* $\mathcal{D}_0 = \{x \in \mathbb{R}^n \mid v(x) < 1\}$ *holds.*

Proof. This is immediate from Propositions 3.6 and 3.7. □

For the sake of completeness we state the following analogous result for (3.9), which is proved with the same techniques, using (3.13) and (3.15) instead of (3.12) and (3.14). Observe that this result corresponds to the one in [4].

THEOREM 3.9. *Consider the system* (2.1) *and a function* $g : \mathbb{R}^n \times A \to \mathbb{R}$. *Assume* (H1) *and* (H2). *Let* $\mathcal{O} \subset \mathbb{R}^n$ *be an open set containing the origin, and let* $U : \mathcal{O} \to \mathbb{R}$ *be a positive and continuous function which is a viscosity solution of* (3.9) *on* $\mathcal{O}$ *and satisfies* $U(0) = 0$ *and* $U(x) \to \infty$ *for* $x \to \partial\mathcal{O}$ *and for* $|x| \to \infty$.

Then U *coincides with* V *from* (3.1), *and* $\mathcal{O} = \mathcal{D}_0$. *In particular, the function* V *from* (3.1) *is the unique positive continuous viscosity solution of* (3.9) *on* $\mathcal{D}_0$ *with* $V(0) = 0$.

For practical purposes, Theorem 3.8 might be inconvenient since we have to compute (or verify) a solution of (3.10) on the whole $\mathbb{R}^n$. The following fact can be exploited to show that this is not always necessary.

Remark 3.2. The optimality principles (i) and (iii) of Proposition 3.5 also hold if we have viscosity sub- or supersolutions of (3.10), which are defined only on some proper open subset $\mathcal{O} \subset \mathbb{R}^n$, except that in this case the "inf" and "sup" over the time t is taken only up to the first time when the trajectory under consideration leaves $\mathcal{O}$. More precisely, (3.12) becomes

$$w(x) = \sup_{a \in \mathcal{A}} \sup_{t \in [0, \tau_x(a)]} \{(1 - G(x,t,a)) + G(x,t,a) w(\varphi(t))\}\,, \tag{3.26}$$

and (3.14) becomes

$$u(x) \leq \sup_{a \in \mathcal{A}} \inf_{t \in [0, \tau_x(a)]} \{(1 - G(x,t,a)) + G(x,t,a) \tilde{u}(\varphi(t))\}\,, \tag{3.27}$$

where $\tau_x(a) := \inf\{t \geq 0 \,|\, \varphi(t,x,a) \notin \mathcal{O}\}$. We refer to [22] for a proof using the same arguments as in the $\mathbb{R}^n$ case combined with a localization technique.

Using these "nonglobal" optimality principles, we are now able to state nonglobal versions of the Propositions 3.6 and 3.7.

PROPOSITION 3.10. *Consider some open set $\mathcal{O} \subset \mathbb{R}^n$. Let $w : \mathrm{cl}\,\mathcal{O} \to \mathbb{R}$ be a bounded l.s.c. supersolution of* (3.10) *on $\mathcal{O}$ with $w(0) \geq 0$ and $w(x) \geq 1$ for all $x \in \partial\mathcal{O}$. Then $w \geq v|_{\mathcal{O}}$ for v as defined in* (3.2).

Proof. The proof follows with the same techniques as the proof of Proposition 3.6 using (3.26) instead of (3.12). ∎

In contrast to Proposition 3.10, we have to strengthen the assumption of Proposition 3.7 in order to get the corresponding nonglobal result.

PROPOSITION 3.11. *Consider some open set $\mathcal{O} \subset \mathbb{R}^n$. Let $u : \mathrm{cl}\,\mathcal{O} \to \mathbb{R}$ be a bounded continuous subsolution of* (3.10) *on $\mathcal{O}$ with $u(0) \leq 0$ and $u(x) = 1$ for all $x \in \partial\mathcal{O}$. Then $u \leq v|_{\mathcal{O}}$ for v as defined in* (3.2).

Proof. It is sufficient to show that $\mathcal{D}_0 \subseteq \mathcal{O}$ since in this case we get $v|_{\partial\mathcal{O}} \equiv 1$ and thus obtain the assertion with the same techniques as in the proof of Proposition 3.7 using (3.27) instead of (3.14).

In order to show $\mathcal{D}_0 \subseteq \mathcal{O}$, assume that $\mathcal{D}_0 \not\subseteq \mathcal{O}$. Then we obtain

$$r_0 := \sup\{r > 0 \,|\, \{x \in \mathbb{R}^n \,|\, v(x) \leq r\} \subset \mathcal{O}\} < 1.$$

We set $S := \{x \in \mathbb{R}^n \,|\, v(x) \leq r_0\}$. Note that from the optimality principle (3.4) we immediately obtain that v is strictly decreasing along each trajectory $\varphi(t,x_0,a)$; hence $\varphi(t,x_0,a) \in \mathrm{int}S \subseteq \mathcal{O}$ for all $t > 0, a \in \mathcal{A}$. By definition of r_0 there exists $x_0 \in \partial\mathcal{O}$ with $v(x_0) = r_0$ and $u(x_0) = 1$; hence by continuity of u there exists $\epsilon > 0$ and $\eta > 0$ such that $u(x) > r_0 + \epsilon$ for all $x \in \mathcal{O} \cap B(x_0,\eta)$. Fixing some arbitrary $a^* \in \mathcal{A}$ and some $\tau > 0$ sufficiently small, we set $x_1 := \varphi(\tau,x_0,a^*) \in \mathcal{O} \cap B(x_0,\eta)$. Then $\varphi(t,x_1,a) \in \mathrm{int}S \subseteq \mathcal{O}$ for all $t \geq 0, a \in \mathcal{A}$; i.e., the trajectory never reaches $\partial\mathcal{O}$, implying that (3.27) coincides with (3.14). (Note that by continuity of u we can choose $\tilde{u} = u$.) Thus we obtain

$$r_0 + \epsilon \leq u(x_1) \leq \sup_{a\in\mathcal{A}} \inf_{t\in[0,T]} \{(1 - G(x,t,a)) + G(x,t,a)u(\varphi(t,x_1,a))\}$$

for all $T > 0$. Since u is continuous with $u(0) \leq 0$ and $\varphi(t,x_1,a) \to 0$ as $t \to \infty$, we obtain by letting $T \to \infty$

$$r_0 + \epsilon \leq u(x_1) \leq \lim_{t\to\infty} \sup_{a\in\mathcal{A}} \{(1 - G(x,t,a))\} = v(x_1) \leq r_0,$$

which is a contradiction and hence shows $\mathcal{D}_0 \subseteq \mathcal{O}$. ∎

From these propositions we can now easily deduce the following theorem. It shows that we can restrict ourselves to a proper open subset $\mathcal{O}$ of the state space and still obtain our solution v, provided $\mathcal{D}_0 \subseteq \mathcal{O}$. Conversely, if $\mathcal{D}_0 \not\subseteq \mathcal{O}$, then no viscosity solution v with $v(x) = 1$ for all $x \in \partial\mathcal{O}$ can exist.

THEOREM 3.12. *Consider the system* (2.1) *and a function $g : \mathbb{R}^n \times A \to \mathbb{R}$. Assume* (H1) *and* (H2). *Let $\mathcal{O} \subset \mathbb{R}^n$ be an open set containing the origin, and let $v : \mathrm{cl}\mathcal{O} \to \mathbb{R}$ be a bounded and continuous function which is a viscosity solution of* (3.10) *on $\mathcal{O}$ and satisfies $v(0) = 0$ and $v(x) = 1$ for all $x \in \partial\mathcal{O}$.*

Then v coincides with the restriction $v|_{\mathcal{O}}$ of the function v from (3.2). *In particular, the characterization $\mathcal{D}_0 = \{x \in \mathcal{O} \,|\, v(x) < 1\}$ holds.*

Proof. The proof follows immediately from Propositions 3.10 and 3.11. ∎

4. Further properties of the solution. In this section we collect several properties of the solution v of Zubov's equation from Theorem 3.8. In particular, we show that this solution is a robust Lyapunov function on $\mathcal{D}_0$ and that additional assumptions on g ensure Lipschitz continuity of v.

THEOREM 4.1. *The function v is a robust Lyapunov function for the system* (2.1). *More precisely, we have*

$$v(\varphi(t,x_0,a(\cdot)))-v(x_0) \le \left[1-\exp\left(-\int_0^t g(\varphi(\tau),a(\tau))d\tau\right)\right](v(\varphi(t,x_0,a(\cdot)))-1) < 0$$

for all $x_0 \in \mathcal{D}_0 \setminus \{0\}$ and all $a(\cdot) \in \mathcal{A}$. In particular, each sublevel set of v is positively invariant.

Proof. The dynamic programming principle (3.4) implies

$$v(x) \ge 1-\exp\left(\int_0^t g(\varphi(\tau,x,a),a(\tau))d\tau\right)+\exp\left(\int_0^t g(\varphi(\tau,x,a),a(\tau))d\tau\right)v(\varphi(t,x,a))$$

for each $a \in \mathcal{A}$. This immediately yields the assertion. ∎

Remark 4.1.

(i) If v is differentiable in some point $0 \neq x_0 \in \mathcal{D}_0$, this yields the more familiar inequality

$$\sup_{a\in A} Dv(x_0)f(x,a) \le (v(x_0)-1)g(x,a) < 0,$$

which, in fact, can also be directly derived from (3.10).

(ii) It follows immediately from Proposition 3.5 (ii) that any viscosity supersolution w of (3.10) with $w(0)=0$ is a robust Lyapunov function on its sublevel set $\{x \in \mathbb{R}^d \,|\, w(x) < 1\}$.

Now we investigate regularity properties for the function v. In general, we cannot expect this function to be differentiable. A suitable choice of g, however, guarantees Lipschitz continuity. We start by investigating this for the function V defined in (3.1).

PROPOSITION 4.2. *Assume* (H1) *and* (H2) *and that $f(\cdot,a)$ is locally Lipschitz continuous uniformly in a; i.e., for any $R>0$ there exists a constant M_R such that*

$$\|f(x,a)-f(y,a)\| \le M_R\|x-y\| \quad \text{for all } x,y \in B(0,R),\ a \in A\,.$$

Assume, furthermore, that there exists a neighborhood N of the origin such that for all x, $y \in N$ the inequality

$$|g(x,a)-g(y,a)| \le K\max\{\|x\|,\|y\|\}^s\|x-y\|$$

holds for some $K>0$ and $s > M_r/\sigma$ with $r>0, \sigma>0$ as in (H1). *Then V is locally Lipschitz in $\mathcal{D}_0$.*

Proof. Let $S \subset \mathcal{D}_0$ be compact. According to (H2), there exists a time $T>0$ such that $\varphi(t,x,a) \in N \cap B(0,r)$ for all $t \ge T, x \in S, a \in \mathcal{A}$. Furthermore, the set $\mathcal{R}(S,T)$ is bounded, and we may choose $R>0$ large enough so that $\mathcal{R}(S,T) \subset B(0,R)$. Now fix x, $y \in S$. Analogously to the proof of Proposition 3.1(iii), we obtain

$$\begin{aligned}|V(x)-V(y)| &\le \sup_{a\in\mathcal{A}} \int_0^{+\infty} |g(\varphi(t,x,a),a(t))-g(\varphi(t,y,a),a(t))|\,dt \\ &\le \sup_{a\in\mathcal{A}} \int_0^{T} |g(\varphi(t,x,a),a(t))-g(\varphi(t,y,a),a(t))|\,dt\end{aligned}$$

$$
\begin{aligned}
&+\sup_{a\in\mathcal{A}}\int_T^{+\infty}|g(\varphi(t,x,a),a(t))-g(\varphi(t,y,a),a(t))|\,dt\\
&\le\int_0^T L_R e^{M_R t}\|x-y\|dt\\
&\quad+\int_T^{+\infty}K\max\{\|\varphi(T)\|,\,\|y(T)\|\}^s C^s e^{-s\sigma(t-T)}e^{M_r t}\|x-y\|dt\\
&\le\underbrace{\left(L_R\frac{e^{M_R T}-1}{M_R}+Kr^sC^se^{\sigma T}\frac{e^{(M_r-s\sigma)T}}{s\sigma-M_r}\right)}_{=L_S}\|x-y\|\,.
\end{aligned}
$$

This shows the assertion. □

Obviously, this result immediately carries over to v on $\mathcal{D}_0$. In order to obtain Lipschitz continuity of v on the rest of $\mathbb{R}^n$, it is convenient to consider a generalization of the transformation (3.2) by defining

$$v_\delta(x):=1-\exp(-\delta V(x))$$

for $\delta>0$. Observe that this results in the equation

$$\inf_{a\in A}\{-f(x,a)Dv(x)-\delta(1-v(x))g(x,a)\}=0,\qquad x\in\mathbb{R}^n. \tag{4.1}$$

Thus this transformation is equivalent to an appropriate choice of g in (3.10). Observe that for $\delta\to 0$ the function v_δ converges to 0 on $\mathcal{D}_0$ and is equal to 1 outside $\mathcal{D}_0$. Note that this convergence to a piecewise constant function is a typical behavior of discounted optimal value functions, see, e.g., [10].

In the opposite case, i.e., for sufficiently large $\delta>0$, the following result holds for v_δ.

PROPOSITION 4.3. *Assume that $f(\cdot,a)$ and $g(\cdot,a)$ are globally Lipschitz continuous in $\mathbb{R}^n$, with constants L_f, $L_g>0$ independent of $a\in A$, and assume that there exists a neighborhood N of the origin such that for all x, $y\in N$ the inequality*

$$|g(x,a)-g(y,a)|\le K\max\{\|x\|,\,\|y\|\}^s\|x-y\|$$

holds for some $K>0$ and $s>L_f/\sigma$ with $\sigma>0$ given by (H1). *Then the function v_δ is Lipschitz continuous in $\mathbb{R}^n$ for all $\delta>0$ sufficiently large.*

Proof. Let L_0 denote the Lipschitz constant of V on $B(0,r)$ guaranteed by Proposition 4.2. For $x\in\mathcal{D}_0$, define $T_x=\sup\{t(x,a):a\in\mathcal{A}\}$ and observe that $V(x)\ge g_0T_x$, where $g_0>0$ is given by (H2). If x, $y\in\mathcal{D}_0$, then for any $\epsilon>0$, there exists a control $a\in\mathcal{A}$ such that

$$
\begin{aligned}
|V(x)-V(y)|&\le\int_0^{T_x\vee T_y}|g(\varphi(t,x,a),a(t))-g(\varphi(t,y,a),a(t))|dt\\
&\quad+|V(\varphi(T_x\vee T_y,x,a))-V(\varphi(T_x\vee T_y,y,a))|+\epsilon\\
&\le\int_0^{T_x\vee T_y}L_g\exp(L_ft)\|x-y\|dt+L_0\|x-y\|\exp(L_f(T_x\vee T_y))+\epsilon\\
&\le(L_0+L_g/L_f)\exp(L_fV(x)/g_0)\|x-y\|+\epsilon.
\end{aligned}
$$

So we see that V is locally Lipschitz continuous in $\mathcal{D}_0$ with a constant of the form $L\exp(L_fV(x)/g_0)$.

Let $\phi \in C^1(\mathbb{R}^n)$ be such that $v_\delta(x) - \phi$ has a local maximum at $x_0 \in \mathcal{D}_0$, where we may assume that $v_\delta(x_0) - \phi(x_0) = 0$ and $\phi(x) \le 1, \forall x \in \mathbb{R}^n$. Then $V - \psi$ has a local maximum at x_0 for $\psi(x) = -\ln(1 - \phi(x))/\delta$.

It follows that

$$|D\phi(x_0)| \le \delta |D\psi(x_0)| \exp(-\delta V(x)) \le L\delta \exp((L_f/g_0 - \delta)V(x)).$$

Hence, letting $\delta \ge L_f/g_0$ and recalling that $v_\delta \equiv 1$ in $\mathbb{R}^n \setminus \mathcal{D}_0$, we have that $|D\phi(x_0)| \le \delta L$ for any $x \in \mathbb{R}^n$ and for any $\phi \in C^1(\mathbb{R}^n)$ such that $v_\delta(x) - \phi$ has a local maximum at x. This implies that v_δ is Lipschitz continuous in $\mathbb{R}^n$ with Lipschitz constant δL, cf. [5, Lemma 2.10]. □

5. Smooth solutions. It is always of interest to know whether for a given stability property there are Lyapunov functions with certain regularity properties. In [16] it is shown that under the condition of global uniform asymptotic stability, that is, under the condition $\mathcal{D}_0 = \mathbb{R}^n$ in our terminology, there exists a C^∞ Lyapunov function $V : \mathbb{R}^n \to \mathbb{R}$ such that

$$DV(x)f(x,a) \le -\alpha_1(\|x\|) \tag{5.1}$$

for some class $\mathcal{K}_\infty$ function α_1. Furthermore, there exist class $\mathcal{K}_\infty$ functions α_2, α_3 such that

$$\alpha_2(\|x\|) \le V(x) \le \alpha_3(\|x\|). \tag{5.2}$$

(As usual in stability theory, we call a function $\alpha : [0,\infty) \to [0,\infty)$ of class $\mathcal{K}_\infty$ if it is continuous, strictly increasing, unbounded, and satisfies $\alpha(0) = 0$). By [23, Theorems 1 and 2, Proposition 3] it follows that if we add the assumption that $f(x, A)$ be convex for all $x \in \mathbb{R}^n$, then there exists a C^∞ Lyapunov function V on $\mathcal{D}_0$ (which is in this case equal to $\mathcal{D}$ by Proposition 2.3 (iii)). Assuming that $\omega : \mathcal{D} \to \mathbb{R}_{\ge 0}$ is continuous and satisfies $\omega(x) = 0$ if and only if $x = 0$, and that $\omega(x_n) \to \infty$ for any sequence $\{x_n\}$ with $\lim x_n \in \partial\mathcal{D}$ or $\lim \|x_n\| = \infty$, then V can be chosen in such a manner that it has the properties (5.1), (5.2), where $\|x\|$ has to be replaced by $\omega(x)$. It is of interest, and therefore the topic of our last section, to know whether we are able to reproduce these functions via our approach.

We first treat the case of global stability.

LEMMA 5.1. *Assume that system* (2.1) *is globally uniformly asymptotically stable at* 0*; then* $g(x,a)$ *can be chosen such that the corresponding solutions* V *of* (3.9) *and* v *of* (3.10) *are* C^∞*. Furthermore, for any smooth Lyapunov function* V *satisfying* (5.1) *and* (5.2) *there exists a function* $g : \mathbb{R}^n \to \mathbb{R}$ *such that* V *is the corresponding solution of* (3.9)*.*

Proof. By [16, Theorem 2.9, Remark 4.1] there exists a C^∞ Lyapunov function $V : \mathbb{R}^n \to \mathbb{R}$ for (2.1). Now define $v(x) = 1 - e^{-V(x)}$ as before, and

$$\begin{aligned} g(x,a) := g(x) &:= -\sup_{a\in\mathcal{A}} \frac{Dv(x)f(x,a)}{1 - v(x)} \\ &= -\sup_{a\in\mathcal{A}} \frac{e^{-V(x)}DV(x)f(x,a)}{e^{-V(x)}} = -\sup_{a\in A} DV(x)f(x,a)\,. \end{aligned} \tag{5.3}$$

It is clear that the function g thus defined satisfies condition (i) of (H2). By (5.1) we have $g(x) \ge \alpha_1(\|x\|)$, which implies (ii). The third condition is implied by the

Lipschitz continuity of f and smoothness of V. A straightforward computation yields that V and v are the respective (unique) solutions of (3.9) and (3.10).

The second statement is clear by the previous construction. □

It is now tempting to try to copy this argument for the nonglobal case by utilizing the smooth maximal Lyapunov functions defined on the domain of attraction which are obtained in [23]. In this way one might hope to construct smooth Lyapunov functions that are representable as suitable solutions of (3.9), respectively, (3.10). This approach, however, has one problem. It is by no means clear that g as defined in the proof of Lemma 5.1 can be continuously extended to $\mathbb{R}^n$ so that (H2) is satisfied. We can, however, reconstruct smooth solutions on any subset of $\mathcal{D}_0$ that is bounded away from $\partial\mathcal{D}_0$.

PROPOSITION 5.2. *Assume* (H1), (H2)*, and that $f(x, A)$ is convex for all $x \in \mathbb{R}^n$. Let $B \subset \mathcal{D}_0$ satisfy* $\operatorname{dist}(B, \partial\mathcal{D}_0) > 0$*; then there exists a function $g : \mathbb{R}^n \to \mathbb{R}$ such that the corresponding solution v of* (3.10) *is C^∞ on a neighborhood of B.*

Proof. Let V denote a smooth Lyapunov function for system (2.1) defined on $\mathcal{D}$. Let U be an open neighborhood of B contained in $\mathcal{D}_0$, and define $g_{|U}$ by (5.3). Then g can be extended to a continuous function on $\mathbb{R}^n$ satisfying (H2). The corresponding unique solution v of (3.10) is C^∞ on U. □

6. Example. In this section we illustrate our results by a simple example, where we explicitly verify a (nonsmooth) solution of the generalized version of Zubov's equation (3.10). Consider the system

$$\begin{aligned} \dot{x}_1 &= -x_1 + ax_1^2, \\ \dot{x}_2 &= -x_2 + ax_2^2 \end{aligned}$$

with $x = (x_1, x_2)^T \in \mathbb{R}^2$ and $A = [-1, 1]$. We claim that for $g(x, a) = \|x\|^2 = x_1^2 + x_2^2$ the function v defined by

$$v(x) = \begin{cases} 1 - e^{-V(x)}, & x \in (-1, 1)^2, \\ 1, & x \notin (-1, 1)^2, \end{cases}$$

where $V : (-1, 1)^2 \to \mathbb{R}$ is given by

$$V(x) = \begin{cases} -\ln(1 - x_1) - \ln(1 - x_2) - x_1 - x_2, & x_1 \geq -x_2, \\ -\ln(1 + x_1) - \ln(1 + x_2) + x_1 + x_2, & x_1 \leq -x_2, \end{cases}$$

solves (3.10).

Note that by Theorem 3.12 it suffices to verify (3.10) on $(-1, 1)^2$, since $v|_{(-1,1)^2}$ satisfies the assumptions of this theorem with $\mathcal{O} = (-1, 1)^2$.

Using Remark 3.1, we identify the set of possible derivatives of functions ϕ such that $v - \phi$ has a local extremum for $x \in (-1, 1)$. First note that v is smooth on $(-1, 1)^2 \setminus D_1$, where D_1 is the diagonal $\{x \in (-1, 1)^2 \mid x_1 = -x_2\}$. In this region $D\phi$ must coincide with Dv, which is computed to be

$$Dv(x) = \begin{cases} (x_1(1 - x_2)e^{+x_1+x_2},\ x_2(1 - x_1)e^{+x_1+x_2}), & x \in (-1, 1)^2,\ x_1 > -x_2, \\ (x_1(1 + x_2)e^{-x_1-x_2},\ x_2(1 + x_1)e^{-x_1-x_2}), & x \in (-1, 1)^2,\ x_1 < -x_2. \end{cases}$$

On D_1 (setting $x = (y, -y)^T$) one verifies that the superdifferential D^+v is empty, while the subdifferential D^-v satisfies

$$D^-v(y, -y) = \{\theta p_1 + (1 - \theta)p_2 \mid \theta \in [0, 1]\},$$

where

$$p_1 = (+y(y+1),\, +y(y-1))\,,$$
$$p_2 = (-y(y-1),\, -y(y+1))\,.$$

Using these computations, we obtain that on $(-1,1)^2$ (3.10) becomes

$$\min_{a\in[-1,1]} \{-e^{x_1+x_2}(1-a)(x_1^3+x_2^3-x_1x_2^3-x_1^3x_2)\} = 0 \quad \text{for } x_1 > -x_2,$$

$$\min_{a\in[-1,1]} \{e^{-x_1-x_2}(1+a)(x_1^3+x_2^3+x_1^3x_2+x_1x_2^3)\} = 0 \quad \text{for } x_1 < -x_2,$$

and

$$\min_{a\in[-1,1]} \{2(1-a+2\theta a)y^4)\} \geq 0 \quad \text{for } x_1 = -x_2 =: y.$$

It turns out that in the first case the minimizer is $a = 1$, and in the second case it is $a = -1$, while in the third case it is $a = 1$ for $\theta \in [0, 1/2)$, $a = -1$ for $\theta \in (1/2, 1]$, and any $a \in [-1, 1]$ for $\theta = 1/2$. In all cases we see that the desired (in)equalities are satisfied, which, in particular, shows that $\mathcal{D}_0 = (-1, 1)^2$.

Acknowledgments. The authors would like to thank Pierpaolo Soravia and Maurizio Falcone for useful discussions.

VARIATIONAL INEQUALITIES, SYSTEM OF FUNCTIONAL EQUATIONS, AND INCOMPLETE INFORMATION REPEATED GAMES*

RIDA LARAKI†

Abstract. We consider a pair of functional equations obtained by Mertens and Zamir (*Internat. J. Game Theory,* 1 (1971–72), pp. 39–64; *J. Math. Anal. Appl.* 60 (1977), pp. 550–558) to characterize the asymptotic value of a two person zero sum repeated with lack of information on both sides (Aumann and Maschler (*Repeated Games with Incomplete Information,* MIT Press, Cambridge, MA 1995)). We give a new proof for the convergence of the discounted values of the repeated game and a new characterization of the limit using variational inequalities. The same idea allows us to prove existence and uniqueness of a Lipschitz solution for the pair of functional equations in a general framework using an auxiliary game: "the splitting game," introduced by Sorin (*A First Course on Zero-Sum Repeated Games,* preprint).

Key words. incomplete information repeated games, variational inequalities, functional equations, convexification operator, convex-concave functions

Introduction. A two person zero sum repeated game with lack of information on both sides (Aumann and Maschler (1995)) is a multistage game where the payoff function depends on two parameters and where each player knows only one of the parameters (see section 1).

Mertens and Zamir (1971–1972) have shown that the sequence of the values converges when the length of the game grows to infinity, to the unique solution of the following system of functional equations with unknown v:

$$\begin{cases} v(p,q) = Cav_{p\in\Delta(K)}\left[\min(u,v)\right](p,q) & (S1)\,, \\ v(p,q) = Vex_{q\in\Delta(L)}\left[\max(u,v)\right](p,q) & (S2)\,. \end{cases} \qquad (S)$$

In this system, K and L are two finite sets, $\Delta(K)$ is the unit simplex of R^K, $\Delta(L)$ is the unit simplex of R^L, and u is the value of the average game (that is, the game where the players do not use their information). For a function φ and a convex set C, $Cav_C[\varphi]$ (resp., $Vex_C[\varphi]$) is the smallest concave function on C greater than φ (resp., the greatest convex function on C smaller than φ).

In fact, Mertens and Zamir (1977) also studied the "functional equations" (S) in a general framework without reference to game theoretical tools: u is not necessarily the value of a game, and $\Delta(K)$ and $\Delta(L)$ are replaced by any convex-compact sets C and D in finite dimension. Remark that when u does not depend on the first variable, the unique solution of (S) is $Vex_D[u]$. The example of Kruskal (1969) shows that the convexification operator does not conserve the continuity for any convex compact set D. (That is, $Vex_D[u]$ is not always continuous even if u is continuous.) This implies that the Mertens–Zamir system does not always admit a continuous solution

for arbitrary convex compact sets C and D. In a recent work (Laraki (2001a)), we studied necessary and sufficient conditions on the geometry of a convex-compact set X in order that the convexification operator on X conserves the continuity (resp., uniformly the Lipschitz property). In Laraki (2001b), we studied the existence of a continuous solution for (S) when C and D are in the class of convex-compact sets characterized in Laraki (2001b). This is the class of convex-compact sets X such that the convexification operator on X conserves the continuity.

In this paper we will consider the existence of a Lipschitz solution for (S) in a general framework. In Laraki (2001a) we proved that when X is a polytope in a normed real vector space, then the convexification operator conserves uniformly the Lipschitz property. We showed that in finite dimension, being a polytope is also a necessary condition to preserve uniformly the Lipschitz property. Hence it is natural to ask if (S) admits a Lipschitz solution when C and D are two polytopes in a normed real vector space and u is Lipschitz.

The main contributions of this paper are

- a new characterization ($P1$ and $P2$, below) equivalent to (S) in a very general framework;
- a new simple proof for the convergence of the discounted values of the repeated game with incomplete information on both sides by providing a game interpretation of $P1$ and $P2$ (section 2);
- the same idea allows us to show that (S) admits a Lipschitz solution (where C and D are two polytopes in a normed vector space and u is Lipschitz) by using an auxiliary (stochastic) game called the "splitting game" (introduced by Sorin (2000)) (see sections 3–4).

A function $f(p,q)$ is concave-convex if it is concave in p and convex in q.

More precisely, we prove that the limit of the discounted values is the unique continuous concave-convex function, $v(p,q)$, satisfying the following variational inequalities.

- $P1$: For all q_0, if $[p_0, v(p_0,q_0)]$ is an extreme point of (the hypograph) of $v(\cdot,q_0)$, then $v(p_0,q_0) \leq u(p_0,q_0)$.
- $P2$: For all q_0, if $[q_0, v(p_0,q_0)]$ is an extreme point of (the epigraph) of $v(q_0,\cdot)$, then $v(p_0,q_0) \geq u(p_0,q_0)$.

In section 2.1 we will show that any accumulation point, v, of the family of the discounted values $\{v_\lambda\}$ satisfies $P1$ and $P2$. This very simple proof translates the following intuitive idea: if p_0 is an extreme point of $v(\cdot,q_0)$, then " asymptotically" Player 1 must not use his information, and then Player 2 can guarantee asymptotically (just by not using his information) $u(p_0,q_0)$. This implies that $v(p_0,q_0) \leq u(p_0,q_0)$.

In section 2.2 we deduce the uniqueness of a continuous solution by proving a comparison theorem.

In section 3 we study the existence of a Lipschitz solution by using the splitting game.

Finally, we prove the equivalence with Mertens–Zamir's system in a very general framework (section 4).

1. Preliminary results. We recall here the framework of zero sum repeated games with incomplete information (Aumann and Maschler (1995)).

I and J are two finite sets, $X = \Delta(I)$ (the set of probabilities on I), and $Y = \Delta(J)$. $\left(A^{k,l}\right)_{k\in K, l\in L}$ is a family of $I \times J$-matrices (I rows and J columns).

DEFINITION 1. *For each $p \in \Delta(K)$ and $q \in \Delta(L)$, the game form $G_F(p,q)$ is as follows.*

- *At stage 0, k is chosen according to the probability p and announced to Player 1 only; l is chosen according to the probability q and announced to Player 2 only.*
- *At stage 1, Player 1 chooses a move $i_1 \in I$, Player 2 chooses a move $j_1 \in J$, and the couple (i_1, j_1) is told to both players. The payoff is $A^{k,l}_{i_1,j_1}$ but is not announced.*
- *Inductively, at stage m, knowing the past history $h_m = (i_1, j_1, \ldots, i_{m-1}, j_{m-1})$, Player 1 chooses a move $i_m \in I$, Player 2 chooses a move $j_m \in J$, and the new history $h_{m+1} = (h_m, i_m, j_m)$ is told to both players. The payoff is $A^{k,l}_{i_m,j_m}$ and is not announced.*
- *Both players know the above description (public knowledge).*

We denote by Σ (resp., Υ) the set of behavioral strategies of Player 1 (resp., Player 2).

Several games are associated to this game form and differ only in the way the stream of payoffs is evaluated. We will be interested in the λ-discounted game $G_\lambda(p,q)$ $(0 < \lambda < 1)$, where, if the play is $(k, l, (i_1, j_1), \ldots, (i_n, j_n), \ldots)$, Player 2 gives Player 1 the amount $\sum_{m=1}^{\infty} \lambda(1-\lambda)^{m-1} A^{k,l}_{i_m j_m}$. The stage payoff being uniformly bounded, the payoff function is jointly continuous and bilinear on $\Sigma \times \Upsilon$. Hence (Sion (1958)) this game has a value $v_\lambda(p,q)$.

Notations.

- Let $u(p,q)$ be the value of the one shot average game $G(p,q)$ with matrix payoff $A_{i,j}(p,q) = \sum_{k \in K} p^k q^l A^{k,l}_{ij}$. Then u is a Lipschitz function on $\Delta(K) \times \Delta(L)$ with constant $\|A\|_\infty = \max_{k,l,i,j} \left\| A^{k,l}_{i,j} \right\|$.
- Let us call a function $f(p,q)$ concave in p and convex in q a saddle function.
- Let F be the set of saddle Lipschitz functions on $\Delta(K) \times \Delta(L)$ with constant $\|A\|_\infty$.
- Fix $(p,q) \in \Delta(K) \times \Delta(L)$ initial probabilities and $(x,y) \in X^K \times Y^L$ one stage strategies of the players. Then, for all $(i,j) \in I \times J$, we define:
  $\overline{x}(i) = \sum_{k \in K} p^k x^k(i)$ (the total probability of playing i),
  $\overline{y}(j) = \sum_{l \in L} q^l y^l(j)$ (the total probability of playing j),
  $p(i)$: the conditional probability over K knowing i given by $p^k(i) = \frac{p^k x^k(i)}{\overline{x}(i)}$,
  $q(j)$: the conditional probability over L knowing j given by $q^l(j) = \frac{p^l y^l(j)}{\overline{y}(j)}$,
  $A_{x,y}(p,q) = \sum_{k,l,i,j} p^k q^l x^k(i) y^l(j) A^{k,l}_{i,j}$.

Then we have the following property (see Mertens, Sorin and Zamir (1994)).

PROPOSITION 1. *v_λ is in F and satisfies the following recursive formula:*

$$v_\lambda(p,q) = \max_{x \in X^K} \min_{y \in Y^l} \left[\lambda A_{x,y}(p,q) + (1-\lambda) \sum_{i \in I, j \in J} \overline{x}(i)\overline{y}(j) v_\lambda\left(p(i), q(j)\right) \right].$$

2. The convergence of v_λ. We prove in this section that the asymptotic value, $v = \lim_{\lambda \to 0} v_\lambda$, exists and is the unique saddle continuous function on $\Delta(K) \times \Delta(L)$ satisfying $P1$ and $P2$. In the first subsection we give a game theoretical interpretation of these properties by proving that any accumulation point of v_λ satisfies $P1$ and $P2$. In the second subsection we prove uniqueness via a comparison theorem.

2.1. Existence. We want to express mathematically the fact that if p_0 is an extreme point of $v(\cdot, q_0)$, then "asymptotically" Player 1 must not use his information. We will follow the operator approach of Rosenberg and Sorin (2001) to study repeated games with incomplete information. (We use here some of their notations.)

Define for $0 \leq \lambda \leq 1$ an operator $T(\lambda, \cdot)$ which associates to a function $f \in F$ the function $T(\lambda, f)$ defined by

$$T(\lambda, f)(p,q) = \max_{x \in X^K} \min_{y \in Y^L} \left[\lambda A_{x,y}(p,q) + (1-\lambda) \sum_{i,j} \overline{x}(i)\overline{y}(j) f\left(p(i), q(j)\right) \right]$$

$$= \min_{y \in Y^L} \max_{x \in X^K} \left[\lambda A_{x,y}(p,q) + (1-\lambda) \sum_{i,j} \overline{x}(i)\overline{y}(j) f\left(p(i), q(j)\right) \right].$$

Denote by $X_\lambda(f)(p,q)$ (resp., $Y_\lambda(f)(p,q)$) the set of optimal strategies of Player 1 (resp., Player 2) in the above one shot game.

We introduce NR_p^1, the set of nonrevealing strategies of Player 1, i.e., the set of $x \in X^K$ such that the conditional probability distribution on K induced by x is constant (thus equal to p), which is the case if and only if, for all $k \neq k'$ such that $p(k)p(k') > 0$, $x^k = x^{k'}$. NR_q^2 is defined in the same way.

For a function g defined on $\Delta(K)$, p is an extreme point of g if $g(p) = \alpha g(p_1) + (1-\alpha)\, g(p_2)$ with $p = \alpha p_1 + (1-\alpha)\, p_2$ and $0 < \alpha < 1$ implies $p_1 = p_2 = p$.

Because the family $\{v_\lambda\}$ is uniformly Lipschitz, there exist $v \in F$ and $(\lambda_n) \to 0$ such that v_{λ_n} converges uniformly to v. Such a v is called an accumulation point of the family $\{v_\lambda\}$.

We have the following properties.

PROPOSITION 2 (see Rosenberg and Sorin (2001)).

(i) $v_\lambda = T(\lambda, v_\lambda)$.

For all v, an accumulation point of $\{v_\lambda\}$, we have the following.

(ii) $v = T(0, v)$.

(iii) *If p_0 is an extreme point of $v(\cdot, q_0)$, then $X_0(v)(p_0, q_0) \subset NR_{p_0}^1$.*

(iv) *If q_0 is an extreme point of $v(p_0, \cdot)$, then $Y_0(v)(p_0, q_0) \subset NR_{q_0}^2$.*

Proof. (i) and (ii) are consequences of Proposition 1, the definition and the continuity of T.

For (iii), let $x^* \in X_0(v)(p_0, q_0)$. Then we have

$$v(p_0, q_0) = \min_{y \in Y^L} \left[\sum_{i,j} \overline{x}^*(i)\overline{y}(j) v\left(p_0(i), q_0(j)\right) \right]$$

$$\leq \min_{y \in Y} \left[\sum_{i} \overline{x}^*(i) v\left(p_0(i), q_0\right) \right]$$

$$\leq \sum_{i} \overline{x}^*(i) v\left(p_0(i), q_0\right).$$

But, as $v\left(\cdot, q_0\right)$ is concave, we have

$$v(p_0, q_0) = \sum_{i} \overline{x}^*(i) v\left(p_0(i), q_0\right).$$

Since p_0 is an extreme point of $v\left(\cdot, q_0\right)$, we deduce that $p_0(i) = p_0$ for all i. Thus $x^* \in NR_{p_0}^1$. ∎

Let us recall the basic variational inequalities $P1$ and $P2$ for a function v.

- $P1$: For all $q_0 \in \Delta(L)$, if $p_0 \in \Delta(K)$ is an extreme point of $v(\cdot, q_0)$, then $v(p_0, q_0) \leq u(p_0, q_0)$.
- $P2$: For all $p_0 \in \Delta(K)$, if $q_0 \in \Delta(L)$ is an extreme point of $v(q_0, \cdot)$, then $v(p_0, q_0) \geq u(p_0, q_0)$.

PROPOSITION 3. *Any accumulation point v of $\{v_\lambda\}$ satisfies $P1$ and $P2$.*

Proof. Let p_0 be an extreme point of $v(\cdot, q_0)$.

Denote $E_{x,y}[f](p_0, q_0) = \sum_{i\in I, j\in J} \overline{x}(i)\overline{y}(j) f(p_0(i), q_0(j))$. Then, we have

$$\begin{aligned}
&v_{\lambda_n}(p_0, q_0)\\
&= \max_{x\in X^K} \min_{y\in Y^l} \left[\lambda_n \left[A_{x,y}(p_0, q_0) - E_{x,y}\left[v_{\lambda_n}\right](p_0, q_0)\right] + E_{x,y}\left[v_{\lambda_n}\right](p_0, q_0)\right]\\
&= \max_{x\in X_{\lambda_n}(v_{\lambda_n})(p_0,q_0)} \min_{y\in Y^l} \left[\lambda_n \left[A_{x,y}(p_0, q_0) - E_{x,y}\left[v_{\lambda_n}\right](p_0, q_0)\right] + E_{x,y}\left[v_{\lambda_n}\right](p_0, q_0)\right]\\
&\leq \max_{x\in X_{\lambda_n}(v_{\lambda_n})(p_0,q_0)} \min_{y\in Y} \left[\begin{array}{c} \lambda_n \left[A_{x,y}(p_0, q_0) - \sum_{i\in I} \overline{x}(i) v_{\lambda_n}(p_0(i), q_0)\right] \\ + \sum_{i\in I} \overline{x}(i) v_{\lambda_n}(p_0(i), q_0) \end{array}\right].
\end{aligned}$$

Thus

$$\max_{x\in X_{\lambda_n}(v_{\lambda_n})(p_0,q_0)} \min_{y\in Y} \left(\lambda_n \left[A_{x,y}(p_0, q_0) - \sum_{i\in I} \overline{x}(i) v_{\lambda_n}(p_0(i), q_0)\right] + \sum_{i\in I} \overline{x}(i) v_{\lambda_n}(p_0(i), q_0) - v_{\lambda_n}(p_0, q_0)\right) \geq 0.$$

But v_{λ_n} concave yields

$$\sum_{i\in I} \overline{x}(i) v_{\lambda_n}(p_0(i), q_0) - v_{\lambda_n}(p_0, q_0) \leq 0,$$

so that

$$\max_{x\in X_{\lambda_n}(v_{\lambda_n})(p_0,q_0)} \min_{y\in Y} \lambda_n \left[A_{x,y}(p_0, q_0) - \sum_{i\in I} \overline{x}(i) v_{\lambda_n}(p_0(i), q_0)\right] \geq 0.$$

Since $\lambda_n > 0$, this gives

$$\max_{x\in X_{\lambda_n}(v_{\lambda_n})(p_0,q_0)} \min_{y\in Y} \left[A_{x,y}(p_0, q_0) - \sum_{i\in I} \overline{x}(i) v_{\lambda_n}(p_0(i), q_0)\right] \geq 0.$$

Now let $X^*(v)(p_0, q_0)$ be the set of accumulation points of $X_{\lambda_n}(v_{\lambda_n})(p_0, q_0)$. Since the correspondence $(\lambda, f) \to X_\lambda(f)$ is upper-semicontinuous, we deduce that

$$X^*(v)(p_0, q_0) \subset X_0(v)(p_0, q_0).$$

But p_0 is an extreme point of $v(\cdot, q_0)$; thus by (iii) in Proposition 2 we deduce that

$$X_0(v)(p_0, q_0) \subset NR^1_{p_0}.$$

Hence, letting $n \to \infty$ and using the uniform convergence of v_{λ_n} to v, we deduce that

$$\max_{x\in NR^1_{p_0}} \min_{y\in Y} \left[\sum_{k,l} p_0^k q_0^l x^k A^{k,l} y - v(p_0, q_0)\right] \geq 0.$$

Thus

$$\max_{x\in X}\min_{y\in Y}\left[\sum_{k,l}p_0^k q_0^l x A^{k,l} y - v\left(p_0,q_0\right)\right]\geq 0,$$

which implies that

$$u\left(p_0,q_0\right)\geq v\left(p_0,q_0\right).$$

Hence v satisfies $P1$ and, similarly, $P2$. □

2.2. Uniqueness. To show uniqueness, we use a comparison result and basically follow the idea of Mertens and Zamir (1971–72, 1977).

PROPOSITION 4. (maximum principle). *Let v_1 and v_2 be two saddle continuous functions satisfying $P1$ and $P2$, respectively. Then $v_1\leq v_2$.*

Proof. Let $\delta=\max_{p,q}\left[v_1(p,q)-v_2(p,q)\right]$. We will show that $\delta\leq 0$. Let $C=\operatorname{Argmax}_{p,q}\left[v_1(p,q)-v_2(p,q)\right]$. C is a nonempty compact set. □

We first prove the following.

LEMMA 2. *If (p_0,q_0) is an extreme point of the convex-hull of C, then p_0 is an extreme point of $v_1\left(\cdot,q_0\right)$ and q_0 is an extreme point of $v_2\left(p_0,\cdot\right)$.*

Proof. Assume that $v_1(p_0,q_0)=\alpha v_1(p_1,q_0)+\left(1-\alpha\right)v_1(p_2,q_0)$ with $p_0=\alpha p_1+\left(1-\alpha\right)p_2$ and $0<\alpha<1$.

Since v_2 is concave in p, we have

$$\alpha v_2(p_1,q_0)+\left(1-\alpha\right)v_2(p_2,q_0)\leq v_2(p_0,q_0),$$

so that

$$\begin{aligned}\alpha\left[v_1(p_1,q_0)-v_2(p_1,q_0)\right]+\left(1-\alpha\right)\left[v_1(p_2,q_0)-v_2(p_2,q_0)\right]\\ \geq v_1(p_0,q_0)-v_2(p_0,q_0)=\delta.\end{aligned}$$

Since $v_1(p,q)-v_2(p,q)\leq\delta$ for all (p,q), we necessarily have equality. Hence $(p_i,q_0)\in C$ for $i=1,2$, which is a contradiction.

Now we continue with the proof of the proposition.

Consider an extreme point (p_0,q_0) of the convex hull of C. By the previous lemma, $P1$, and $P2$, we deduce that $v_1(p_0,q_0)\leq u(p_0,q_0)$ and $v_2(p_0,q_0)\geq u(p_0,q_0)$.

Thus $\delta=v_1(p_0,q_0)-v_2(p_0,q_0)\leq u(p_0,q_0)-u(p_0,q_0)=0$. □

THEOREM 3. *v_λ converges uniformly to the unique continuous saddle function on $\Delta(K)\times\Delta(L)$ satisfying $P1$ and $P2$.*

Proof. The proof follows from the existence result (Proposition 3) and the comparison result (Proposition 4). □

3. The general case: Existence via the splitting game. Here H is a Lipschitz function on $C\times D$, where C and D are two polytopes in a normed real vector space.

We want to study the existence of a Lipschitz solution to the functional equations with unknown Ψ:

$$\begin{cases}\Psi(c,d)=Cav_{c\in C}\left[\min(H,\Psi)\right](c,d),\\ \Psi(c,d)=Vex_{d\in D}\left[\max(H,\Psi)\right](c,d).\end{cases}$$

In section 4 we will prove in a more general framework that this system is equivalent to the properties $P1[H,C,D]$ and $P2[H,C,D]$, below. Thus the comparaison theorem implies the uniqueness of a continuous solution. Here we use the same proof as

for a repeated game with incomplete information to prove the existence of a Lipschitz solution to the functional equations by considering an auxiliary stochastic game introduced by Sorin (2000) called the splitting game.

DEFINITION 4. *For each $(c_0, d_0) \in C \times D$, the splitting game $SG(c_0, d_0)$ is a zerosum stochastic game, described as follows.*

- *At stage 1 Player 1 chooses a probability P_{c_0} on C centered at c_0 and Player 2 chooses a probability Q_{d_0} on D centered at d_0. Then c_1 is selected according to P_{c_0}, and d_1 is selected according to Q_{d_0}. Finally, $h_1 = (c_0, d_0, c_1, d_1)$ is announced to both players. The stage payoff (from Player 2 to Player 1) is $H(c_1, d_1)$.*
- *Inductively, at stage $m+1$, knowing the past history h_m, Player 1 chooses a probability P_{c_m} on C centered at c_m, and Player 2 chooses a probability Q_{d_m} on D centered at d_m. Then c_{m+1} follows the low P_{c_m}, and d_{m+1} follows Q_{d_m}. Finally, $h_{m+1} = (h_m, c_{m+1}, d_{m+1})$ is announced to both players. The stage payoff is $H(c_{m+1}, d_{m+1})$.*

We consider the discounted evaluation $\sum_{m=1}^{\infty} \lambda(1-\lambda)^{m-1} H(c_m, d_m)$, where $0 < \lambda < 1$, and we call SG_λ the associated (discounted) splitting game.

PROPOSITION 5. *$SG_\lambda(c, d)$ has a value $V_\lambda(c, d)$.*

V_λ is a saddle function on $C \times D$ and satisfies the following recursive equation:

$$V_\lambda(c,d) = \max_{P \in \Delta_C(c)} \min_{Q \in \Delta_D(d)} \left[\int_{C \times D} \left[\lambda H(\widetilde{c}, \widetilde{d}) + (1-\lambda) V_\lambda(\widetilde{c}, \widetilde{d}) \right] dP(\widetilde{c}) dQ(\widetilde{d}) \right]$$
$$= \min_{Q \in \Delta_D(d)} \max_{P \in \Delta_C(c)} \left[\int_{C \times D} \left[\lambda H(\widetilde{c}, \widetilde{d}) + (1-\lambda) V_\lambda(\widetilde{c}, \widetilde{d}) \right] dP(\widetilde{c}) dQ(\widetilde{d}) \right],$$

where $\Delta_C(c)$ is the set of probabilities on C, centered at c, and $\Delta_D(d)$ is the set of probabilities on D, centered at d.

Moreover, there exists a norm on $C \times D$ with respect to which the family (V_λ) has the same Lipschitz constant as H.

Proof. Let $\mathcal{UL}$ be the space of real valued functions on $C \times D$ which are upper-semicontinuous–lower-semicontinuous, bounded by $\|H\|_\infty$. This space is complete for uniform convergence.

Let Φ be the splitting operator from $\mathcal{UL}$ to itself (Laraki (2001b)) defined by

$$\Phi[f](c,d) = \max_{P \in \Delta_C(c)} \min_{Q \in \Delta_D(d)} \left[\int_{C \times D} f(\widetilde{c}, \widetilde{d}) dP(\widetilde{c}) dQ(\widetilde{d}) \right]$$
$$= \min_{Q \in \Delta_D(d)} \max_{P \in \Delta_C(c)} \left[\int_{C \times D} f(\widetilde{c}, \widetilde{d}) dP(\widetilde{c}) dQ(\widetilde{d}) \right].$$

$f \to \Phi[\lambda H + (1-\lambda)\cdot]$ is contracting; hence it admits a fixed point $V_\lambda \in \mathcal{UL}$. It is standard and easy to show that both players can guarantee V_λ in the splitting game (see Mertens–Sorin–Zamir (1994)).

By Laraki (2001b) we deduce that V_λ is a saddle function.

Now, since C and D are polytopes, by Laraki (2001b) we deduce that there exists an equivalent norm on $C \times D$ ($\|\|\|_{C \times D}$) with respect to which the splitting operator conserves the Lipschitz constant. Hence, if M is the Lipschitz constant of H with respect to $\|\|\|_{C \times D}$, then the operator $f \to \Phi[\lambda H + (1-\lambda)\cdot]$ associates to an M-Lipschitz function an M-Lipschitz one. By the completeness of the space of uniformly Lipschitz functions, we deduce that the last operator admits a unique M-Lipschitz fixed point (which is V_λ, of course). ∎

DEFINITION 5. *A function φ on $C \times D$ satisfies*

- *$P1[H,C,D]$ if for all $d_0 \in D$, if $c_0 \in C$ is an extreme point of $\varphi(\cdot, d_0)$ in C, then $\varphi(p_0,q_0) \leq H(p_0,q_0)$;*
- *$P2[H,C,D]$ if for all $c_0 \in C$, if $d_0 \in D$ is an extreme point of $\varphi(c_0,\cdot)$ in D, then $\varphi(p_0,q_0) \geq H(p_0,q_0)$.*

PROPOSITION 6. *V_λ converges uniformly to the unique saddle continuous function V satisfying $P1[H,C,D]$ and $P2[H,C,D]$. In addition, for some equivalent norm depending (only) on C and D, V is Lipschitz with the same constant of Lipschitz as H.*

Proof. The proof here is exactly the same proof as in section 2. □

4. Equivalence with Mertens–Zamir's system. Here C and D are two convex-compact sets in a metric real vector space endowed with a locally convex topology.

LEMMA 6. *For all lower-semicontinuous bounded functions φ on D, there exists a unique lower-semicontinuous convex function (say, ψ) on D satisfying the following.*

(α) $\psi \leq \varphi$;

(β) If d_0 is an extreme point of ψ, then $\psi(d_0) \geq \varphi(d_0)$.

This function is $Vex_D[\varphi]$.

Proof. For a function f on D, $Epi(f)$ is the epigraph of f:

$$Epi(f) = \{(d,r) \in D \times BbbR : r \geq f(d)\}.$$

The property (β) and the fact that φ is bounded and lower-semicontinuous implies that $Epi(\psi) \subset Epi(\varphi)$. Since $Epi(\psi)$ is convex (since ψ is convex), we deduce that $Epi(\psi) \subset co[Epi(\varphi)] = Epi(Vex_D(\varphi))$. Hence $\psi \geq Vex_D[\varphi]$.

The property (α) and the fact that ψ is convex implies that $\psi \leq Vex_D[\varphi]$.

The fact that $(Vex_D[\varphi])$ satisfies (α) and (β) and is lower-semicontinuous is clear. □

PROPOSITION 7. *Let H and ψ be two upper-semicontinuous–lower-semicontinuous bounded functions on $C \times D$. Then the following hold.*

(i) *ψ is concave on C and satisfies $P1[H,C,D] \Leftrightarrow \psi = Cav_C[\min(H,\psi)]$.*

(ii) *ψ is convex on D and satisfies $P2[H,C,D] \Leftrightarrow \psi = Vex_D[\max(H,\psi)]$.*

Proof. Let us prove (ii) (the proof of (i) is similar).

It is clear that if $\psi = Vex_D[\max(H,\psi)]$, then the following hold.

- ψ is convex on D.
- If d_0 is an extreme point of $\psi(c_0,\cdot)$, then $\psi(c_0,d_0) = \max[H,\psi](c_0,d_0) \geq H(c_0,d_0)$.

Now suppose that ψ is convex on D and satisfies $P2[H,C,D]$. Let $c_0 \in C$ and put $\varphi(\cdot) = \max(H,\psi)(c_0,\cdot)$. Then it is clear that ψ satisfies (α) and (β) and is convex. By the last lemma we deduce that $\psi = Vex_D[\varphi]$. Hence $\psi = Vex_D[\max(H,\psi)]$. □

5. Concluding remarks.

- In fact, the last proposition can be deduced implicitly from the proof of Proposition 18 in Rosenberg and Sorin (2001). Our contribution is (a) how to extract properties $P1$ and $P2$ from the discounted games, and (b) their use to prove the existence of a Lipschitz solution of (S).
- The proof for the finitely repeated game (the study of $\lim v_n$) is much more complicated and needs all the machinery of the operator approach in Rosenberg and Sorin (2001). Since the goal in this paper is to give some new ideas with simple proofs, we omit this question.

- In fact, Mertens and Zamir (1971–1972) studied the asymptotic value in a more general framework where the private information received by the players is dependent. (The probability over the types is not necessarily the product of the marginals.) It is easy to see that our proof holds also in this case, but for clarity (because the formulation of the problem is very technical) we cover only the independent case.
- We remark that if the splitting operator does not conserve uniformly the Lipschitz property, then the familly (V_λ) will not be uniformly Lipschitz. Hence our proof does not apply directly in this case.
- In Laraki (2001b) we study the regularity properties of the splitting operator, and we address the problem of the existence of a continuous solution for the Mertens–Zamir system when C and D are in the class of convex-compact sets satisfying some necessary geometric conditions. (This class strictly contains the polytopes.)

Acknowledgment. My gratitude goes to Sylvain Sorin for supervising and motivating this work by his useful comments and advice.

A DYNAMIC PROGRAMMING ALGORITHM FOR THE OPTIMAL CONTROL OF PIECEWISE DETERMINISTIC MARKOV PROCESSES*

ANTHONY ALMUDEVAR†

Abstract. A piecewise deterministic Markov process (PDP) is a continuous time Markov process consisting of continuous, deterministic trajectories interrupted by random jumps. The trajectories may be controlled with the object of minimizing the expected costs associated with the process. A method of representing this controlled PDP as a discrete time decision process is presented, allowing the value function for the problem to be expressed as the fixed point of a dynamic programming operator. Decisions take the form of trajectory segments. The expected costs may then be minimized through a dynamic programming algorithm, rather than through the solution of the Bellman–Hamilton–Jacobi equation, assuming the trajectory segments are numerically tractable. The technique is applied to the optimal capacity expansion problem, that is, the problem of planning the construction of new production facilities to meet rising demand.

Key words. piecewise deterministic Markov process, dynamic programming, capacity expansion

1. Introduction.

In this paper a technique for minimizing expected costs associated with piecewise deterministic Markov processes (PDPs) is developed. Such processes may be described as continuous time Markov processes consisting of continuous, deterministic trajectories interrupted by random jumps. A comprehensive definition and theoretical development of these processes can be found in Davis [4]. Many problems in operations research can be naturally expressed in this framework; hence there is a great deal of interest in optimization problems associated with these processes.

A PDP is usually defined on a state space $E \subset \Re^p$ partitioned into a boundary E_δ and interior E_o, although the state space definition in [4] is somewhat more general. We let $\mathcal{E}$ denote the Borel subsets of E, and we will let $\mathcal{P}(E)$ be the space of probability measures on the measurable space $(E, \mathcal{E})$, endowed with the topology of weak convergence. Under suitable regularity conditions a PDP can be uniquely determined by a vector field $f : E \to \Re^p$, an intensity function $\lambda : E \to \Re^+$, and stochastic kernels $q_o : E_o \to \mathcal{P}(E)$ and $q_\delta : E_\delta \to \mathcal{P}(E)$. Between jumps the PDP $\hat{x}(t)$ obeys $d\hat{x}(t)/dt = f(\hat{x}(t))$, and jumps occur at rate $\lambda(x)$ when the process is at state x, independently of the process history. If a jump occurs at $x \in E_o$, the process is transferred immediately to a new state given randomly by probability measure $q_o(dx \mid x)$. If the process reaches the boundary at $x \in E_\delta$, the process is transferred immediately to a new state given randomly by probability measure $q_\delta(dx \mid x)$. We will always assume that $q_o(E_o \mid x) = 1$ and $q_\delta(E_o \mid x) = 1$.

A controlled PDP is defined when the quadruple $(f, \lambda, q_o, q_\delta)$ is allowed to depend on a control parameter u. In addition, cost is assumed at a rate $l_o(x, u)$ when the process is at $x \in E_o$ and control u is applied, and a discrete cost $l_\delta(x, u)$ is assumed

when the process reaches the boundary at $x \in E_\delta$ and control u is applied. A *control policy* Φ is equivalent to a specification for each $x \in E$ of an open loop continuous time control function to be applied from x until the next jump (Vermes [11]).

If we define $J_\Phi(x)$ to be the expected cost under control policy Φ from initial state x, possibly under geometric discounting, the *value function* is then defined as

$$J^*(x) = \inf_\Phi J_\Phi(x),$$

where the infimum is taken over all admissible control policies. The object is to find, if it exists, a control policy whose expected cost achieves this infimum.

In the existing literature the value function for this problem is typically given as a solution to a Bellman–Hamilton–Jacobi (BHJ) equation. In [11] a limiting form of the BHJ equation is given as a necessary and sufficient optimality condition. In Dempster and Ye [9] a generalized BHJ equation, expressed in terms of the generalized Clarke gradient (Clarke [3]), is given as a necessary and sufficient optimality condition. In Soner [10] a viscosity solution approach to the BHJ equation is proposed, and, more recently, the viscosity solution to the BHJ equation has been developed in Davis and Farid [8], which has advantages with respect to the availability of numerical methods for solution.

In this paper we use an approach similar to that introduced by Davis [5] and developed in [9] and Davis [6], in which the problem is reformulated in terms of an imbedded discrete time process, in which a stage consists of the intrajump deterministic portion of the process. The principal difference is that in the approach proposed in this article the problem remains in the discrete time domain up to and including the solution algorithm. The concept of a continuously applied control parameter will play no role. Instead, a discrete time decision process is defined in which a decision consists of the selection of a trajectory segment, in this way constructing the deterministic trajectory in a piecewise fashion. This means that the BHJ equation plays no role. Ultimately, the value function is calculable as a fixed point of a dynamic programming operator in discrete time. Here we do not admit direct control over the cost function and the jump rate, unlike the other models cited in the above literature, although in principle the methodology could be extended to incorporate the cost function and the jump rate into the action space.

Apart from the more limited control, this allows a more uniform approach to the calculation of optimal policies and a weakening of regularity conditions. For the generalized BHJ equation in [9], conditions are imposed which guarantee that the value function is Lipschitz, which excludes many problems of practical importance (see [6]). The viscosity solution approach allows milder assumptions. In [8] the state space is required to be bounded, and the cost rate and jump rate are assumed to be bounded and uniformly continuous. In comparison, in this article the state space need not be bounded, the jump rate is bounded but not necessarily uniformly continuous, and the cost rate may be lower semicontinuous and need not be bounded. In fact, conditions are placed only on suitably defined integrals of the cost rate (see section 2). As for the trajectory, in the context of the BHJ equation the vector field f is generally assumed to be Lipschitz. In the approach presented here there is no explicit vector field and no other restrictions other than that the path can be constructed in a piecewise manner from trajectories selected from a compact set. This admits a wider variety of control structures, including certain types of impulse controls.

In section 2, we define a discrete time decision process imbedded in the PDP and obtain conditions under which the resulting transition measure will be continuous

on the state-action product space. In section 3, we discuss some results for discrete time decision processes from Bertsekas and Shreve [1] which may be applied to the problem under consideration here. In addition, with some additional assumptions we show that the dynamic programming operator is a contraction mapping. In section 4 we show how this may be applied to the capacity expansion problem considered in Davis et al. [7]. Section 5 contains some concluding remarks and possible extensions of this work.

2. Reduction of a PDP to a discrete time process. Let $E \subset \Re^p$ be a state space containing a boundary E_δ. Let $E_o = E - E_\delta$ be the interior of E. Possibly, $E_\delta = \emptyset$, the empty set. We also have the intensity function and stochastic kernels (λ, q_o, q_δ) as defined in section 1, all assumed to be Borel measurable mappings.

Then let I_T be a time scale interval $[0, T]$ if $T < \infty$ and $[0, \infty)$ if $T = \infty$. Let A be an action space consisting of a family of continuous trajectories $\alpha : I_T \to \Re^p$ with $\alpha(0) = 0$. It will be assumed that A is a compact metric space in which convergence implies pointwise convergence. We define

$$B(x, \alpha) = \inf\{t \in I_T : x + \alpha(t) \in E_\delta\},$$

which is the time taken for the trajectory $x + \alpha(t)$ to reach the boundary, and let

$$t_f(x, \alpha) = \min\{B(x, \alpha), T\},$$

adopting the convention that $\inf \emptyset = \infty$. For each $x \in E$ let $A_x \subset A$ be a subset of trajectories available at state x, which gives the *state-action space*

$$\Gamma = \{(x, \alpha) \in E \times A : \alpha \in A_x\}.$$

We assume that $x + \alpha(t) \in E$ when $t \le t_f(x, \alpha)$ for all $(x, \alpha) \in \Gamma$. Generally, the following condition will be satisfied:

(A.1) $x+\alpha(t) = x+\alpha(B(x,\alpha))\,\forall\, t \ge B(x,\alpha), t \in I_T,$ when $(x, \alpha) \in \Gamma$ and $B(x, \alpha) < \infty$,

which implies that a trajectory comes to rest upon reaching the boundary. In addition, (A.1) implies $x+\alpha(B(x, \alpha)) \in E_\delta$ for all $(x, \alpha) \in \Gamma$ and that the only admissable action when $x \in E_\delta$ is $\alpha \equiv 0$.

We can define iteratively the continuous time process $\{\hat{x}(t) \in E : t \ge 0\}$ and the imbedded discrete time decision process $\{(\hat{x}_n, \hat{\alpha}_n) \in \Gamma : n \ge 0\}$ with the associated event time process $\{\hat{t}_n \ge 0 : n \ge 0\}$. Suppose we have state $\hat{x}_n \in E_o$, decision $\hat{\alpha}_n \in A_{x_n}$, and time $\hat{t}_n$. The process then follows the trajectory

$$\hat{x}(t) = \hat{x}_n + \hat{\alpha}_n(t - \hat{t}_n), \quad t \ge \hat{t}_n, \tag{2.1}$$

until time $\hat{t}_n + t_f(\hat{x}_n, \hat{\alpha}_n)$, unless a random jump occurs along the trajectory before then, say, at time $t' \in (\hat{t}_n, \hat{t}_n + t_f(\hat{x}_n, \hat{\alpha}_n))$, in which case (2.1) holds until t'. These jumps occur at rate $\lambda(x)$ when the process is in state $x \in E_o$, independently of the process history. If such a jump occurs at state x', then the new state $\hat{x}_{n+1} \in E_o$ is given randomly by the distribution $q_o(dx \mid x')$, and we set $\hat{t}_{n+1} = t'$. If no jump occurs before $\hat{t}_n + t_f(\hat{x}_n, \hat{\alpha}_n)$ then set $\hat{t}_{n+1} = \hat{t}_n + t_f(\hat{x}_n, \hat{\alpha}_n)$. In this case, if the process has reached the boundary at state $x' \in E_\delta$ (i.e., $B(\hat{x}_n, \hat{\alpha}_n) < \infty$), then the new state $\hat{x}_{n+1} \in E_o$ is given randomly by the distribution $q_\delta(dx \mid x')$. Otherwise, if the end of the trajectory segment $\hat{\alpha}_n$ has been reached before the boundary (i.e.,

$B(\hat{x}_n, \hat{\alpha}_n) = \infty$, $T < \infty$), then set $\hat{x}_{n+1} = \hat{x}_n + \hat{\alpha}_n(\hat{t}_{n+1} - \hat{t}_n)$. A new decision $\hat{\alpha}_{n+1} \in A_{\hat{x}_{n+1}}$ is then made. An initial state and decision $(\hat{x}_0, \hat{\alpha}_0) \in \Gamma$ is specified, with $\hat{t}_0 = 0$. If $\hat{x}_0 \in E_\delta$, we will set $\hat{t}_1 = \hat{t}_0 = 0$, $\hat{\alpha}_0 \equiv 0$, and $\hat{x}_1$ will be determined by $q_\delta(dx \mid \hat{x}_0)$. Then $\hat{x}_k \in E_o$ for $k \geq 1$.

This defines the transition measure $Q : \Gamma \to \mathcal{P}(E)$ for the process $(\hat{x}_n, \hat{\alpha}_n)$, where $Q(K \mid x, \alpha)$ is the probability that $\hat{x}_{n+1} \in K$ given that trajectory $\hat{\alpha}_n = \alpha$ is selected at state $\hat{x}_n = x$. Assuming (A.1) holds, this is given explicitly by

$$\begin{aligned} Q(K \mid x, \alpha) = &\int_0^{t_f(x,\alpha)} q_o(K \mid x + \alpha(t))\lambda(x + \alpha(t)) \exp(-\Lambda(t, x, \alpha))\, dt \\ &+ q_\delta(K \mid x + \alpha(B(x, \alpha))) \exp(-\Lambda(B(x, \alpha), x, \alpha)) I\{B(x, \alpha) < \infty\} \\ &+ I\{x + \alpha(T) \in K\} \exp(-\Lambda(T, x, \alpha)) I\{B(x, \alpha) = \infty, T < \infty\}, \end{aligned} \tag{2.2}$$

where

$$\Lambda(t, x, \alpha) = \int_0^t \lambda(x + \alpha(w))\, dw.$$

Here, $I\{S\}$ is the indicator function of set S. Since we assume $q_o(E_o \mid x) = 1$ and $q_\delta(E_o \mid x) = 1$, we necessarily have $Q(E_o \mid x, \alpha) = 1$ for $(x, \alpha) \in \Gamma$. Note also that if $x \in E_\delta$, we have $\alpha \equiv 0$, $t_f(x, \alpha) = B(x, \alpha) = 0$, and $Q(K \mid x, \alpha) = q_\delta(K \mid x)$. It will be useful to know when the transition measure is continuous with respect to weak convergence on Γ (with $E \times A$ assuming the product topology). We prove below that Q will be continuous under the following assumptions:

(B.1) $q_o(dx \mid x)$ is continuous on E_o with respect to weak convergence.

(B.2) $q_\delta(dx \mid x)$ is continuous on E_δ with respect to weak convergence.

(B.3) λ is continuous on E, $\lambda \leq M_\lambda$ for some $M_\lambda < \infty$.

(B.4) The sets $B_1 = \{(x, \alpha) \in \Gamma : B(x, \alpha) < \infty\}$ and $B_2 = \{(x, \alpha) \in \Gamma : B(x, \alpha) = \infty\}$ are both closed.

(B.5) $B(x, \alpha)$ is continuous on B_1.

Remark. If a nontrivial boundary is present, a special condition is typically necessary for the continuity of Q to hold. Generally, some assumption which governs the behavior of the trajectory near the boundary is required. Informally, these assumptions typically require that if a trajectory approaches the boundary, it does so in some direct manner. In [11] the minimum velocity in the direction normal to the boundary is bounded away from 0. This condition is weakened in [8] to require only that where the boundary is approachable it is approachable nontangentially. Assumptions (B.4) and (B.5) are used here to govern trajectory behavior near the boundary. They will not be natural to many problems and are not satisfied by the capacity expansion problem considered in [7]. However, we show in section 4 how a reasonable redefinition of the problem can force (B.4) and (B.5) to hold.

THEOREM 2.1. *If assumptions* (A.1) *and* (B.1)–(B.5) *hold, then* $Q(dx \mid x, \alpha)$ *is continuous on* Γ *with respect to weak convergence.*

Proof. Let $\gamma = \{(x_n, \alpha_n) : n \geq 1\}$ be a convergent sequence in Γ with limit (x_0, α_0). We then have

$$\lim_{n \to \infty} x_n + \alpha_n(t) = x_0 + \alpha_0(t) \quad \forall t \in I_T,$$

and hence by (B.3)

$$\lim_{n\to\infty} \lambda(x_n + \alpha_n(t)) = \lambda(x_0 + \alpha_0(t)) \quad \forall t \in I_T. \tag{2.3}$$

By (B.3) λ is bounded, so applying the dominated convergence theorem gives

$$\lim_{n\to\infty} \Lambda(t, x_n, \alpha_n) = \Lambda(t, x_0, \alpha_0) \quad \forall t \in I_T. \tag{2.4}$$

Next, recall that if $\{\mu_n : n \geq 1\}$ is any sequence of probability measures in $\mathcal{P}(E)$, an equivalent definition of weak convergence of the sequence to a probability measure μ_0 is

$$\liminf_{n\to\infty} \mu_n(K) \geq \mu_0(K) \quad \forall \text{ open sets } K$$

(see, for example, Theorem 29.1 in Billingsley [2]), so it suffices to show that

$$\liminf_{n\to\infty} Q(K \mid x_n, \alpha_n) \geq Q(K \mid x_0, \alpha_0) \quad \forall \text{ open sets } K \in \mathcal{E}, \tag{2.5}$$

for each convergent sequence γ. Since B_1 and B_2 are closed, we may assume that $\gamma \subset B_1$ or $\gamma \subset B_2$. We now examine separately the three following cases.

Case 1: $T = \infty$, $\gamma \subset B_2$. In this case we have

$$Q(K \mid x_n, \alpha_n) = \int_0^\infty q_o(K \mid x_n + \alpha_n(t))\lambda(x_n + \alpha_n(t)) \exp(-\Lambda(t, x_n, \alpha_n))\, dt.$$

By (B.1), (2.3), and (2.4) we may assert for open K

$$\begin{aligned} &\liminf_{n\to\infty} q_o(K \mid x_n + \alpha_n(t))\lambda(x_n + \alpha_n(t)) \exp(-\Lambda(t, x_n, \alpha_n)) \\ &\qquad \geq q_o(K \mid x_0 + \alpha_0(t))\lambda(x_0 + \alpha_0(t)) \exp(-\Lambda(t, x_0, \alpha_0)); \end{aligned} \tag{2.6}$$

hence (2.5) holds by Fatou's lemma.

Case 2: $T < \infty$, $\gamma \subset B_2$. In this case we have

$$\begin{aligned} Q(K \mid x_n, \alpha_n) = &\int_0^T q_o(K \mid x_n + \alpha_n(t))\lambda(x_n + \alpha_n(t)) \exp(-\Lambda(t, x_n, \alpha_n))\, dt \\ &+ I\{x_n + \alpha_n(T) \in K\} \exp(-\Lambda(T, x_n, \alpha_n)) \end{aligned} \tag{2.7}$$

for all $n \geq 0$. Using an argument similar to that used for Case 1, we have

$$\begin{aligned} &\liminf_{n\to\infty} \int_0^T q_o(K \mid x_n + \alpha_n(t))\lambda(x_n + \alpha_n(t)) \exp(-\Lambda(t, x_n, \alpha_n))\, dt \\ &\qquad \geq \int_0^T q_o(K \mid x_0 + \alpha_0(t))\lambda(x_0 + \alpha_0(t)) \exp(-\Lambda(t, x_0, \alpha_0))\, dt \end{aligned} \tag{2.8}$$

for all open sets $K \in \mathcal{E}$. Then

$$\liminf_{n\to\infty} I\{x_n + \alpha_n(T) \in K\} \geq I\{x_0 + \alpha_0(T) \in K\}$$

for open $K \in \mathcal{E}$, which, when combined with (2.4), (2.7), and (2.8), gives (2.5) for Case 2.

Case 3: $\gamma \subset B_1$. In this case we necessarily have $t_f(x_n, \alpha_n) = B(x_n, \alpha_n)$, $n \geq 0$, so that

$$Q(K \mid x_n, \alpha_n) = \int_0^{B(x_n,\alpha_n)} q_o(K \mid x_n + \alpha_n(t))\lambda(x_n + \alpha_n(t)) \exp(-\Lambda(t, x_n, \alpha_n))\, dt \\ + q_\delta(K \mid x_n + \alpha_n(B(x_n, \alpha_n))) \exp(-\Lambda(B(x_n, \alpha_n), x_n, \alpha_n))$$

for all $n \geq 0$. By assumption (B.5) $B(x_n, \alpha_n) \to_n B(x_0, \alpha_0)$. Then, using (2.6), we have

$$\liminf_{n\to\infty} q_o(K \mid x_n + \alpha_n(t))\lambda(x_n + \alpha_n(t)) \exp(-\Lambda(t, x_n, \alpha_n)) I\{t \leq B(x_n, \alpha_n)\} \\ \geq q_o(K \mid x_0 + \alpha_0(t))\lambda(x_0 + \alpha_0(t)) \exp(-\Lambda(t, x_0, \alpha_0)) I\{t < B(x_0, \alpha_0)\}$$

for open $K \in \mathcal{E}$, so by Fatou's lemma

$$\liminf_{n\to\infty} \int_0^{B(x_n,\alpha_n)} q_o(K \mid x_n + \alpha_n(t))\lambda(x_n + \alpha_n(t)) \exp(-\Lambda(t, x_n, \alpha_n))\, dt \\ \geq \int_0^{B(x_0,\alpha_0)} q_o(K \mid x_0 + \alpha_0(t))\lambda(x_0 + \alpha_0(t)) \exp(-\Lambda(t, x_0, \alpha_0))\, dt \tag{2.9}$$

for all open sets $K \in \mathcal{E}$. By assumption (A.1) we must have

$$\lim_{n\to\infty} x_n + \alpha_n(B(x_n, \alpha_n)) = x_0 + \alpha_0(B(x_0, \alpha_0)),$$

and by assumption (B.2)

$$\liminf_{n\to\infty} q_\delta(K \mid x_n + \alpha_n(B(x_n, \alpha_n))) \geq q_\delta(K \mid x_0 + \alpha_0(B(x_0, \alpha_0)))$$

for all open sets $K \in \mathcal{E}$. We then have

$$\lim_{n\to\infty} \lambda(x_n + \alpha_n(t)) I\{t \leq B(x_n, \alpha_n)\} = \lambda(x_0 + \alpha_0(t)) I\{t \leq B(x_0, \alpha_0)\},$$

except possibly at $t = B(x_0, \alpha_0)$. The sequence $\{B(x_n, \alpha_n) : n \geq 1\}$ is bounded since B_1 is closed. Then with assumption (B.3) the dominated convergence theorem applies, giving

$$\lim_{n\to\infty} \Lambda(B(x_n, \alpha_n), x_n, \alpha_n) = \Lambda(B(x_0, \alpha_0), x_0, \alpha_0),$$

so that

$$\liminf_{n\to\infty} q_\delta(K \mid x_n + \alpha_n(B(x_n, \alpha_n))) \exp(-\Lambda(B(x_n, \alpha_n), x_n, \alpha_n)) \\ \geq q_\delta(K \mid x_0 + \alpha_0(B(x_0, \alpha_0))) \exp(-\Lambda(B(x_0, \alpha_0), x_0, \alpha_0))$$

for all open sets $K \in \mathcal{E}$, which with (2.9) gives (2.5) for Case 3, which completes the proof. □

With respect to assumption (B.5), assumption (A.1) is sufficient to guarantee the lower semicontinuity of $B(x, \alpha)$ on B_1, as shown in Lemma 2.2 below, but upper semicontinuity must be verified separately.

LEMMA 2.2. *If assumption* (A.1) *holds,* $B(x, \alpha)$ *is lower semicontinuous on* B_1.

Proof. Suppose that $\gamma = \{(x_n, \alpha_n) : n \geq 1\}$ is a convergent sequence in B_1 with limit $(x_0, \alpha_0) \in B_1$. We show that

$$\liminf_{n\to\infty} B(x_n, \alpha_n) \geq B(x_0, \alpha_0) \tag{2.10}$$

for any such sequence. Suppose there exists an infinite subsequence $\{(x_{n_k}, \alpha_{n_k}) : k \geq 1\}$ and a $\beta < B(x_0, \alpha_0)$ such that $B(x_{n_k}, \alpha_{n_k}) \leq \beta$ for all $k \geq 1$. Then

$$\lim_{k\to\infty} x_{n_k} + \alpha_{n_k}(B(x_0, \alpha_0)) = x_0 + \alpha_0(B(x_0, \alpha_0)), \tag{2.11}$$

and by assumption (A.1) and the fact that $B(x_{n_k}, \alpha_{n_k}) \leq \beta < B(x_0, \alpha_0)$, $k \geq 1$, we must have

$$\begin{aligned} \lim_{k\to\infty} x_{n_k} + \alpha_{n_k}(B(x_0, \alpha_0)) &= \lim_{k\to\infty} x_{n_k} + \alpha_{n_k}(\beta) \\ &= x_0 + \alpha_0(\beta). \end{aligned} \tag{2.12}$$

However, (2.11) and (2.12) are contradictory since $x_0 + \alpha_0(B(x_0, \alpha_0)) \in E_\delta$, but $x_0 + \alpha_0(\beta) \in E_o$; hence any convergent sequence must satisfy (2.10). □

Finally, we assume there is a nonnegative expected cost $g : \Gamma \to \Re^+$ associated with each stage. This cost may be specified by letting C_T be the family of measurable functions $c : I_T \to \Re^+$. The cost of a stage is then determined by a mapping $h_o : \Gamma \to C_T$ which represents the rate at which cost is assumed at a time t after decision α is made from state x. We may also have a boundary cost $h_\delta(x)$, $x \in E_\delta$, assumed when the process reaches the boundary at x. Then if $W_{(x,\alpha)}$ is the random time spent in the stage, the cost assumed in the stage given $W_{(x,\alpha)} = w$ is

$$H_{(x,\alpha)}(w) = \int_0^w h_o(t \mid x, \alpha)\, dt + h_\delta(x + \alpha(B(x, \alpha)))I\{w = B(x, \alpha), B(x, \alpha) < \infty\}.$$

Then g is given by

$$\begin{aligned} g(x, \alpha) &= E[H_{(x,\alpha)}(W_{(x,\alpha)})] \\ &= \int_0^{t_f(x,\alpha)} h_o(t \mid x, \alpha) \exp(-\Lambda(t, x, \alpha))\, dt \end{aligned} \tag{2.13}$$

$$+ h_\delta(x + \alpha(B(x, \alpha))) \exp(-\Lambda(B(x, \alpha), x, \alpha))I\{B(x, \alpha) < \infty\}. \tag{2.14}$$

In the following discussion any regularity condition will be placed on g directly.

3. Optimization for lower semicontinuous costs. We give a general definition (following [1]) of a stochastic discrete time decision process $\{(\hat{x}_n, \hat{\alpha}_n) : n \geq 0\}$, where $\hat{x}_n$ and $\hat{\alpha}_n$ are elements of a state space and action space E and A, both assumed to be Borel spaces. Let $\mathcal{P}(E)$ and $\mathcal{P}(A)$ be the space of all probability measures on the Borel sets of E and A, respectively, endowed with the topology of weak convergence. For each $x \in E$ we assume that there is a set of available actions $A_x \subset A$. We then have state-action space

$$\Gamma = \{(x, \alpha) \in E \times A : \alpha \in A_x\},$$

where $E \times A$ is endowed with the product topology (and is also a Borel space). We assume there is a stochastic kernel $Q(dx \mid x, \alpha)$ which is a Borel measurable mapping

from Γ to $\mathcal{P}(E)$. Finally, we have a lower semianalytic cost function $g : \Gamma \to \Re^+$. Define a policy

$$\Phi = \{\tilde{\phi}_n : n \geq 0\}$$

as a sequence of stochastic kernels $\tilde{\phi}_n(dy \mid x_0, \alpha_0, \ldots, x_{n-1}, \alpha_{n-1}, x_n)$ which are universally measurable mappings from $(\times^n \Gamma) \times E$ to $\mathcal{P}(A)$ satisfying

$$\tilde{\phi}_n(A_{x_n} \mid x_0, \alpha_0, \ldots, x_{n-1}, \alpha_{n-1}, x_n) = 1,$$

and let Π be the class of all such policies. For a given policy $\Phi \in \Pi$ the process $(\hat{x}_n, \hat{\alpha}_n)$ can then be defined iteratively by considering a current state $\hat{x}_n$ and the process history $\{(\hat{x}_k, \hat{\alpha}_k) : k = 0, \ldots, n-1\}$. Decision $\hat{\alpha}_n$ is then given randomly by the distribution $\tilde{\phi}_n(dy \mid \hat{x}_0, \hat{\alpha}_0, \ldots, \hat{x}_{n-1}, \hat{\alpha}_{n-1}, \hat{x}_n)$, and then state $\hat{x}_{n+1}$ is given randomly by the distribution $Q(dx \mid \hat{x}_n, \hat{\alpha}_n)$. We are given an initial state $\hat{x}_0$. Then a cost of $\sum_n g(\hat{x}_n, \hat{\alpha}_n)$ is assumed. (We do not consider at this point geometric discounting.) Define

$$J_\Phi(x) = E\left[\sum_{n=0}^{\infty} g(\hat{x}_n, \hat{\alpha}_n) \mid \hat{x}_0 = x\right],$$

which denotes the expected cost assumed by the process under policy Φ with initial state $\hat{x}_0 = x$. If $\tilde{\phi}_n$ is parametrized by x_n only, then Φ is a Markov policy. Let Π_1 be the class of all mappings $\phi : E \to A$ with $\phi(x) \in A_x$ for all $x \in E$. We will be interested primarily in *nonrandomized stationary Markov policies*, that is, policies for which there is some $\phi \in \Pi_1$ such that for all $n \geq 0$, $\tilde{\phi}_n(dy \mid x_n)$ is a point mass at $\phi(x_n)$. (In this case we will simply write $\tilde{\phi}_n(dy \mid x_n) = \phi(x_n)$.)

We then define the problem:

(P) minimize $J_\Phi(x)$ over all policies $\Phi \in \Pi$ for each $x \in E$.

Define the value function

$$J^*(x) = \inf_{\Phi \in \Pi} J_\Phi(x), \quad x \in E.$$

For universally measurable $J : E \to \Re^+$ define the operator T mapping J to $TJ : E \to \Re^+$ by

$$(TJ)(x) = \inf_{\alpha \in A_x} \left(g(x, \alpha) + \int_E J(x') Q(dx' | x, \alpha) \right) \tag{3.1}$$

for all $x \in E$. For $\phi \in \Pi_1$, define the operator T_ϕ mapping universally measurable $J : E \to \Re^+$ to $T_\phi J : E \to \Re^+$ by

$$(T_\phi J)(x) = g(x, \phi(x)) + \int_E J(x') Q(dx' \mid x, \phi(x))$$

for all $x \in E$. Letting $J_0 \equiv 0$, define the sequence

$$J_{k+1} = TJ_k, \quad k \geq 0. \tag{3.2}$$

(The sequence is well defined, since if J is lower semianalytic, so is TJ. See [1, Section 8.2].)

It is easy to verify that $g \geq 0$ implies that T is monotone in the sense that $TJ_2 \geq TJ_1$ if $J_2 \geq J_1$. Then $J_1 \geq J_0$, and hence $J_2 = TJ_1 \geq TJ_0 = J_1$. By extending this argument we conclude that $\{J_k\}$ is increasing, so that the limit

$$J_\infty = \lim_{k\to\infty} J_k \tag{3.3}$$

exists.

The model defined in this section is a *lower semicontinuous model with positive cost* according to the definition given in [1, Definition 8.7, p. 208] if the following conditions hold:

(C.1) A is compact.

(C.2) Γ is a closed subset of $E \times A$.

(C.3) $g(x, \alpha)$ is lower semicontinuous on Γ.

(C.4) The transition measure $Q(dx \mid x, \alpha)$ is weakly continuous on Γ.

We summarize some results from [1, Proposition 8.6, Corollary 9.4.1, Proposition 9.8, Corollary 9.17.2, Proposition 9.18, pp. 209, 221, 225, 235, 236] in the following theorem.

THEOREM 3.1. *Under assumptions* (C.1)–(C.4), *the following hold.*

(i) *If $J \in \mathcal{J}$ is lower semicontinuous, then so is TJ (from proof of Proposition* 8.6*).*

(ii) *J^* is lower semianalytic, and $J^* = TJ^*$ (Corollary* 9.4.1*, Proposition* 9.8*).*

(iii) *There exists a Borel measurable nonrandomized stationary Markov policy Φ^* such that $J_{\Phi^*} = J^*$ (Corollary* 9.17.2*).*

(iv) *$J^* = J_\infty$, where J_∞ is lower semicontinuous (Corollary* 9.17.2*).*

(v) *There exists a sequence $\{\phi_k \in \Pi_1 : k \geq 0\}$, where ϕ_k is universally measurable, such that $T_{\phi_k} J_k = TJ_k$, $k \geq 0$. Each sequence $\{\phi_k(x)\}$, $x \in E$, has an accumulation point. If $\phi^* \in \Pi_1$ is universally measurable and $\phi^*(x)$ is an accumulation point of $\{\phi_k(x)\}$ when $J^*(x) < \infty$, then $\Phi^* = (\phi^*, \phi^*, \ldots)$ is an optimal policy (Proposition* 9.18*).*

Suppose the state space E contains a measurable set E_K such that once the process enters E_K it does not leave and it assumes no further cost. Let $\mathcal{J}_K$ be the set of all $J : E \to \Re^+$ with $J(x) = 0$ for all $x \in E_K$. We must then have $J_\Phi \in \mathcal{J}_K$ for any policy Φ. Furthermore, suppose there is some $r > 0$ such that from any state the probability of subsequently entering E_K is at least r for all $(x, \alpha) \in \Gamma$. Under these assumptions, it is shown below that T is a contraction mapping on $\mathcal{J}_K$; hence there is at most one fixed point of T in $\mathcal{J}_K$. This can be summarized by the following assumptions:

(D.1) $\exists r > 0$ such that $Q(E_K \mid x, \alpha) \geq r$ for all $(x, \alpha) \in \Gamma$.

(D.2) $Q(E_K \mid x, \alpha) = 1$ for all $x \in E_K, \alpha \in A$.

(D.3) $g(x, \alpha) = 0$ for all $x \in E_K, \alpha \in A$.

THEOREM 3.2. *Suppose* (D.1)–(D.3) *hold. Then T is a contraction mapping of universally measurable $J \in \mathcal{J}_K$ to $\mathcal{J}_K$ with contraction constant $1 - r$.*

Proof. By (D.2), (D.3), and the definition of T, if $J(x) = 0$ on E_K for universally measurable J, then $TJ \in \mathcal{J}_K$.

If $J_1, J_2 \in \mathcal{J}_K$ are universally measurable, then for any $\phi \in \Pi_1$ we have

$$\begin{aligned} \|T_\phi J_2 - T_\phi J_1\| &= \sup_{x\in E} \left| \int_E J_2(x') Q(dx' \mid x, \phi(x)) - \int_E J_1(x') Q(dx' \mid x, \phi(x)) \right| \\ &\leq \sup_{x\in E} \int_E |J_2(x') - J_1(x')| Q(dx' \mid x, \phi(x)) \end{aligned}$$

$$\begin{aligned}
&\leq \sup_{x\in E} \int_{E-E_K} |J_2(x') - J_1(x')| Q(dx' \mid x, \phi(x)) \\
&\leq \sup_{x\in E} \|J_2 - J_1\|(1 - Q(E_K \mid x, \phi(x))) \\
&\leq \|J_2 - J_1\|(1 - r)
\end{aligned}$$

since $|J_2(x) - J_1(x)| = 0$ when $x \in E_K$. For $\epsilon > 0$ we may select ϕ so that

$$T_\phi J_1 \leq TJ_1 + \epsilon,$$

and then

$$\begin{aligned}
TJ_2 - TJ_1 &\leq TJ_2 - T_\phi J_1 + \epsilon \\
&\leq T_\phi J_2 - T_\phi J_1 + \epsilon \\
&\leq \|J_2 - J_1\|(1 - r) + \epsilon.
\end{aligned}$$

This holds for all $\epsilon > 0$, so $TJ_2 - TJ_1 \leq \|J_2 - J_1\|(1 - r)$. A similar argument gives $TJ_1 - TJ_2 \leq \|J_2 - J_1\|(1 - r)$, completing the proof. □

The model discussed in this section is directly applicable to the imbedded discrete time decision process introduced in section 2. Using the notation of that section, if E and E_o are measurable subsets of $\Re^p$ and if A can be defined as a compact metric space, then E and A are both Borel spaces; then it remains to verify that Γ is closed. It must then be verified that the transition measure (2.2) is continuous on Γ, possibly through Theorem 2.1. Then the cost g must be lower semicontinuous on Γ. Under these conditions, assumptions (C.1)–(C.4) hold and Theorem 3.1 applies, and the optimum expected cost may be calculated through the dynamic programming algorithm (3.2)–(3.3). An optimal policy may be obtained as the limit defined in Theorem 3.1(v).

With respect to the process of section 2, assumption (D.1) will hold under various circumstances. Geometric discounting may be introduced by adding to E a kill state Δ and assuming that the process jumps to Δ at some fixed rate. If λ is bounded and $B(x, \alpha)$ is bounded away from 0, then assumption (D.1) will be satisfied. Alternatively, there may be some target set which the state-action space is constrained to reach in one stage within some bounded time, barring a jump. If the process remains in this set with no further costs, then assumption (D.1) will be satisfied.

4. The capacity expansion problem. We now consider the optimal capacity expansion problem considered by Davis et al. [7]. We suppose that for a certain commodity there is a demand rate d which increases in time according to a compound Poisson process with constant rate $\lambda > 0$. Suppose there are enough plants to supply the commodity at rate s. At any time a decision to build a new plant may be made, which requires a total cost of C. Let y be the amount already invested in the plant being currently built. If no plant is currently being built, then $y = 0$. The rate of investment will then be $\dot{y} \in [0, c]$, where c represents the maximum possible investment rate. Once a plant is completed, capacity s is increased by L units. We let $z = s - d$. If $z > 0$, then there is overcapacity, and if $z < 0$, there is undercapacity. Let $h : \Re \to \Re^+$ represent the rate at which cost is assumed due to overcapacity or undercapacity z with $h(0) = 0$.

The problem is to derive a policy, giving the investment rate at any state, which minimizes the total expected cost under geometric discounting. In [7] a technique for solving the BHJ equation for this problem is given. It should be noted that an

optimal solution does not necessarily exist. Examples are given in [7] of a problem in which for certain values of z it is ϵ-optimal to build the current plant to within a small amount β of completion, with the expected cost function improving as β approaches 0, but not optimal to complete it. This suggests introducing as a control constraint the requirement that a plant be completed if it is within some fixed amount of completion. It will be shown below that this constraint forces assumptions (B.4) and (B.5) to hold. It is also shown in [7] that any optimal policy will specify either maximum investment rate c or minimum investment rate 0.

We need to specify $E_\delta, E_o, A, \Gamma, \lambda, q_o, q_\delta, g$ as defined in section 2. The state space will be

$$\begin{aligned} E &= [0, C] \times \Re, \\ E_o &= [0, C) \times \Re, \\ E_\delta &= E - E_o. \end{aligned}$$

Then we interpret $(y, z) \in E$ as the state at which the current plant has y currently invested and $z = s - d$. As in [7], we will suppose that the investment rate is either 0 or c. Hence from a starting point (y, z) the decision will consist of determining how much to invest in the current plant at rate c. The action space A is then the family of parametric curves $\alpha : [0, \infty) \to \Re^2$ of the form

$$\alpha(t) = \begin{cases} (ct, 0), & 0 \le t < a/c, \\ (a, 0), & a/c \le t, \end{cases} \tag{4.1}$$

for $a \in [0, C]$. Thus we have $T = \infty$. The trajectories in (4.1) are homeomorphic to the interval $[0, C]$, so that A will subsequently be represented by $[0, C]$. We let β be a positive constant less than C. The action space will be constrained so that if $y \in (C - \beta, C]$, the project must be completed at rate c, and if $y \in [0, C - \beta]$, then an amount $a \le C - \beta - y$ or $a = C - y$ may be invested. Hence we have state-action space

$$\begin{aligned} \Gamma &= \Gamma_1 \cup \Gamma_2, \\ \Gamma_1 &= \{(y, z, a) \in E \times [0, C] : y + a = C\}, \\ \Gamma_2 &= \{(y, z, a) \in E \times [0, C] : y + a \le C - \beta\}. \end{aligned}$$

We introduce geometric discounting by adding to E a kill state Δ to which the process jumps at a rate $\eta > 0$. At this state no further costs are assumed. We can then define the overall jump intensity as $\lambda(y, z) \equiv \lambda + \eta$. If the magnitude of any demand jump equals in distribution some nonnegative random variable Z, let $P_Z(\cdot \mid y, z)$ be the probability measure of the random vector equal in distribution to $(y, z - Z) \in E$. Then

$$q_o(K \mid y, z) = \frac{\lambda}{\lambda + \eta} P_Z(K \mid y, z) + \frac{\eta}{\lambda + \eta} I\{\Delta \in K\}, \quad (y, z) \in E_o,$$

and

$$q_\delta(K \mid y, z) = I\{(0, z + L) \in K\}, \quad (y, z) \in E_\delta,$$

for any $K \in \mathcal{E}$, the Borel subsets of E. Then q_0 and q_δ are continuous on E_o and E_δ, respectively. We also have $B(y, z, a) < \infty$ in Γ_1 and $B(y, z, a) = \infty$ in Γ_2, which

are both closed sets. Assumptions (B.1)–(B.4) of Theorem 2.1 are then satisfied. Furthermore, $B(y,z,a) = a/c$ on Γ_1 so that assumption (B.5) of Theorem 2.1 is satisfied. Since assumption (A.1) also holds, we may conclude that the transition measure Q defined in (2.2) is continuous on Γ.

For state (y,z) and decision a we can then calculate the immediate stage cost g,

$$g(y,z,a) = \frac{h(z)+c}{\lambda+\eta}(1-\exp(-(\lambda+\eta)(a/c)))$$

for $(y,z,a) \in \Gamma_1$ and

$$g(y,z,a) = \frac{h(z)}{\lambda+\eta} + \frac{c}{\lambda+\eta}(1-\exp(-(\lambda+\eta)(a/c)))$$

for $(y,z,a) \in \Gamma_2$. If $h(z)$ is lower semicontinuous, then so is g on Γ. Then assumptions (C.1)–(C.4) are satisfied so that Theorem 3.1 applies and algorithm (3.2)–(3.3) becomes

$$J_0(y,z) \equiv 0, \tag{4.2}$$

$$J_{k+1}(y,z) = \inf_a \left(g(y,z,a) + \int_E J_k(y',z')Q(dy',dz' \mid y,z,a) \right) \tag{4.3}$$

for all $(y,z) \in E$, $k \geq 0$, where the infimum is taken over $a \in [0, C-\beta-y] \cup \{C-y\}$ if $y \leq C-\beta$, and over the singleton $\{C-y\}$ if $y > C-\beta$. Since at any state (C,z) the process transfers immediately to $(0, z+L)$, we may set $J_k(C,z) = J_k(0,z+L)$ for all $k \geq 1$, $z \in \Re$. Note that $J_k(\Delta) = 0$.

As an example, we will apply this algorithm to a case considered in [7], in which jumps in demand consist of one unit with probability one. The integral in (4.3) becomes

$$\begin{aligned}\int_E J_k(y',z')Q(dy',dz' \mid y,z,a) = &\int_0^{a/c} J_k(y+ct, z-1)\lambda \exp(-(\lambda+\eta)t)\,dt \\ &+ J_k(0, z+L)\exp(-(\lambda+\eta)(a/c))\end{aligned}$$

for $(y,z,a) \in \Gamma_1$, and

$$\begin{aligned}\int_E J_k(y',z')Q(dy',dz' \mid y,z,a) = &\int_0^{a/c} J_k(y+ct, z-1)\lambda \exp(-(\lambda+\eta)t)\,dt \\ &+ J_k(y+a, z-1)\frac{\lambda}{\lambda+\eta}\exp(-(\lambda+\eta)(a/c))\end{aligned}$$

for $(y,z,a) \in \Gamma_2$. Then let

$$J_{k+1}^a(y,z) = g(y,z,a) + \int_E J_k(y',z')Q(dy',dz' \mid y,z,a)$$

for all $(y,z,a) \in \Gamma$, $k \geq 0$. If L is an integer, then we may confine attention to a semigrid on E by constraining z to be an integer. We will discretize the problem by considering only states $\{(Ci/n, z) : i = 0,1,\ldots,n\}$ for some large n. Choose $\beta = C(i^*/n)$ for some positive integer $i^* < n$. Then (4.3) can be calculated for a

given J_k numerically. To reduce the number of calculations necessary we can evaluate the discretized version of (4.3) using backwards recursion by setting

$$J_{k+1}(C-\beta,z) = \min\{J^0_{k+1}(C-\beta,z), J^\beta_{k+1}(C-\beta,z)\},$$
$$J_{k+1}(C(1-i/n),z) = \min\{V_{wait}, V_{go}\}, \quad i = i^*+1,\dots n,$$

where

$$V_{wait} = \frac{h(z)+\lambda J_k(C(1-i/n),z-1)}{\lambda+\eta}, \tag{4.4}$$

$$V_{go} = \left(C\frac{h(z)+c}{nc} + J_{k+1}(C(1-(i-1)/n),z)\right)\exp(-(\lambda+\eta)C/(nc))$$
$$+ \lambda/(\lambda+\eta)J_k(C(1-i/n),z-1)(1-\exp(-(\lambda+\eta)C/(nc))). \tag{4.5}$$

Intuitively, when the process is in state $(C-\beta,z)$ there are only two options available: completing the project or waiting. So we calculate the expected cost for each option and set $J_{k+1}(C-\beta,z)$ to be the smaller value. Then consider state $(C-\beta-C/n,z)$. Again, there are two choices: either proceeding to point $(C-\beta,z)$ or waiting. Then V_{wait} in (4.4) with $i=i^*+1$ represents the expected cost of waiting. If the choice is to proceed, the assumption is that the process reaches state $(C-\beta,z)$ with probability $\exp(-(\lambda+\eta)C/(nc))$ and then assumes the optimal choice there. Otherwise, the process jumps to point $(C-\beta-C/n,z-1)$ or Δ, with probabilities $\lambda/(\lambda+\eta)$ and $\eta/(\lambda+\eta)$, respectively. For this choice V_{go} in (4.5) with $i=i^*+1$ represents the expected cost. Then set $J_{k+1}(C-\beta-C/n,z)$ to be the smaller of these two values. Continue in this manner, decreasing y by C/n, until J_{k+1} is calculated for state $(0,z)$, and then repeat this algorithm for all values of z. Then J_{k+1} is used to calculate J_{k+2} in the same manner, continuing in this way until convergence is achieved.

This algorithm was applied to a set of parameters $L=1$, $C=1$, $c=1$, $\lambda=0.8$, $\eta=0.05$, and $h(z)=1.5|z|$ on the range $10\le z\le 10$ with $n=50$ and $\beta=3/50$. Note that to calculate $J_{k+1}(y,z)$ the values of $J_k(y,z-1)$ and $J_k(0,z+1)$ are required; hence the range over which J_k can be calculated will decrease by one unit in each direction of z with each iteration. In [7] this is dealt with by setting appropriate boundary conditions. We do the same here with the constraint $J_k(y,-10)=250$, $k\ge 0$. This quantity is roughly the expected cost when construction continues indefinitely from state $(0,-10)$. We also assumed that it will be optimal to wait at all states $(y,10)$. These constraints allow the calculation of J_k on the entire range of interest.

It was found that the optimal policy could be expressed by the quantities $w(z)$, $z=-10,-9\dots,10$, where it will be optimal to construct as long as $y<1-w(z)$. The quantities found were $w(z)=0$ for $z=-10,\dots,-1$; $w(z)=1$ for $z=4,\dots,10$; and $w(0)=0.06$, $w(1)=0.06$, $w(2)=0.22$, and $w(3)=0.62$. Note that $0.06=\beta$. The same example calculated in [7] gives $w(1)=0.0158$, $w(2)=0.2225$, and $w(3)=0.6612$. Also in [7], for $z=0$ it was found that the expected cost improved as $w(0)\to 0$, but it was not optimal to set $w(0)=0$. Accordingly, the algorithm proposed here calculated $w(0)=\beta$. Similarly, where $w(1)=0.0158\le\beta$ in [7], $w(1)$ by the above algorithm was found to be β. The other values were the same using both methods. Convergence was achieved by 50 iterations.

It should be noted that the solution techniques used in [7] require some prior assumption about the form of the optimal policy. Two classes of policy are considered: the "invest until complete" (IUC) policy and the "follow realized demand" (FRD) policy. For an IUC policy there is nonincreasing $w(z)\in[0,C]$ such that construction

takes place when $y \geq 1-w(z)$. Essentially, a plant is completed once started under this policy. For an FRD policy there is nondecreasing $w(z) \in [0, C]$ such that construction takes place as long as $y < 1-w(z)$. (The optimal policy calculated in this section is an FRD policy.) Necessary and sufficient optimality conditions are developed separately for each class and are then investigated separately. No such distinction has to be made in the technique presented in this paper.

5. Concluding remarks. The problem of minimum cost piecewise deterministic processes under a broad class of controls was considered with the objective of verifying the existence of an optimal control and with proposing a unified approach to a numerical solution. The approach is fundamentally different from other discussions of this problem in the literature in that the control problem is presented as a discrete time decision process in which a decision consists of the selection of a trajectory segment from a compact space. The BHJ equation plays no role. If the action space is numerically tractable, a straightfoward fixed point algorithm based on a dynamic programming operator can be used to calculate the optimal control.

In the BHJ equation method the velocity field is commonly assumed to be Lipschitz-continuous. This means that a solution to the BHJ equation could also be constructed from a sequence of trajectory segments taken from a suitably defined compact space, making the theory presented here applicable also to control models treated in the literature cited above (although one would need to establish some smoothness conditions on an optimal trajectory as a necessary condition). The solution methodology, however, is more natural for problems in which the trajectory segments are parametrizable in finite dimensions, although the infinite dimension control could be approximated with splines. It is important to note that the discrete time decision process also admits more coarse varieties of control. For example, we may define piecewise linear control policies, which would have the effect of allowing control to be exerted only at regular time intervals.

It is anticipated that further work in this area will result in an expansion of the definition of the action space to include some control over jump rate and cost function. This would make the range of applicable models similar to that of methods based on the BHJ equation. It would also be of some value to allow trajectory time lengths to vary and hence be subject to control. This would significantly expand the classes of admissible control structures. A more complete treatment of, for example, impulse-type controls would then be possible.

NONNEGATIVE REALIZATION OF AUTONOMOUS SYSTEMS IN THE BEHAVIORAL APPROACH*

MARIA ELENA VALCHER†

Abstract. Nonnegative linear systems, which have traditionally been investigated within the state-space framework, have been recently introduced and analyzed by means of the behavioral approach. In a couple of recent papers [J. W. Nieuwenhuis, *Linear Algebra Appl.*, 281 (1998), pp. 43–58, M. E. Valcher, *Linear Algebra Appl.*, 319 (2000), pp. 147–162], several general definitions and results about nonnegative behaviors, as well as a complete analysis of nonnegativity property for autonomous behaviors, have been presented. In this contribution, by focusing our interest again on autonomous behaviors, we explore the nonnegative realization problem by deriving an extended set of necessary and sufficient (geometric) conditions for an autonomous behavior to be nonnegative realizable. In the scalar case, in particular, necessary and sufficient conditions for nonnegative realizability, which refer to the set of zeros of any polynomial involved in the kernel description of the behavior, are provided. Finally, a comparison between the nonnegative realizability property, here investigated, and K-realizability, addressed in [H. Maeda and S. Kodama, *IEEE Trans. Circuits, Systems* I *Fund. Theory Appl.*, CAS-281 (1981), pp. 39–47] is carried on.

Key words. autonomous behavior, most powerful unfalsified model (MPUM), nonnegative behavior, state-space realization, proper (polyhedral) cones left invariant by a linear transformation, nonnegative realization

1. Introduction.

Since the early seventies positive linear systems have attracted the interest of several researchers, both from a mathematical and from an engineering background. In fact, on the one hand, the theory of positive linear systems is deep and elegant and relies on a family of nice results that essentially draw on the celebrated Perron–Frobenius theorem [2]. On the other hand, concrete applications of this seemingly abstract theory arise in various fields, like econometrics, bioengineering, chemistry, and, generally speaking, in every context where the variables involved are intrinsically nonnegative. A fundamental reference for the elementary definitions and results of positive system theory, as well as a good source of examples where positive system modeling mostly finds interesting applications, is [13]. A very good and recent reference is [6].

A few years ago, there was a first attempt to develop a general theory of a positive linear system within the behavioral framework [17]. In a very nice paper [15], Nieuwenhuis has introduced the notion of nonnegative discrete behavior (whose trajectories are defined on the time axis $\mathbb{Z}_+$), based on the notion of most powerful unfalsified behavior [9, 24], and later given some preliminary results, mostly concerned with behaviors which are one-dimensional (namely, with trajectories in $(\mathbb{R})^{\mathbb{Z}_+}$) and autonomous, or two-dimensional (with trajectories in $(\mathbb{R}^2)^{\mathbb{Z}_+}$) and controllable. More recently, these definitions and results have stimulated a special interest in autonomous behaviors [20], thus leading to a rather complete characterization of nonnegative au-

tonomous behaviors, mostly based on geometric tools, like invariant cones, and on some new entities, as the nonnegative part of a behavior.

In this contribution, we aim to further extend our analysis of nonnegative autonomous behaviors by addressing what undoubtedly has been, and still is, the most challenging problem in positive system theory: the nonnegative realization problem [1, 4, 14]. In fact, the question we aim to answer is: given a nonnegative autonomous behavior $\mathfrak{B} \subseteq (\mathbb{R}^q)^{\mathbb{Z}_+}$, under what conditions does there exist a nonnegative (autonomous) state-space model

$$\begin{aligned} \mathbf{x}(t+1) &= A\mathbf{x}(t), \\ \mathbf{w}(t) &= C\mathbf{x}(t), \qquad t \in \mathbb{Z}_+, \end{aligned}$$

with A and C nonnegative matrices, such that $\mathfrak{B}$ can be characterized as the set of all trajectories $\mathbf{w}$ which are obtained from the above model, corresponding to the set of all possible initial conditions $\mathbf{x}(0)$?

As we will see, the above question finds quite an exhaustive answer. In fact, after having obtained a rather wide set of equivalent geometric conditions for the problem solvability, by resorting to some key results [1, 4, 11] about the nonnegative realizability of strictly proper transfer functions, we will derive, in the scalar case, a complete spectral characterization of those autonomous behaviors which are nonnegative realizable.

The paper is organized as follows: section 2 summarizes up the basic definitions and results about (linear, left shift-invariant, complete) behaviors whose trajectories are defined on $\mathbb{Z}_+$ and take values in $\mathbb{R}^q$. Also, the fundamental definitions required to introduce positive behaviors are recalled. In section 3, the nonnegativity property for autonomous systems, in the behavioral approach, is recalled, and necessary and sufficient conditions for an autonomous behavior to be nonnegative are presented [20]. Some of these conditions are stated in slightly different terms with respect to [20] in order to obtain more suitable statements for the following analysis. Moreover, some new conditions have been introduced. Finally, a necessary spectral condition, derived in [20] for the nonnegativity of a scalar autonomous behavior, is here strengthened, and proved to be also sufficient.

Section 4 analyzes the nonnegative realization problem for autonomous behaviors and, in section 5, a complete spectral characterization of scalar autonomous behaviors which are nonnegative realizable is given. To conclude the paper, a quick comparison with the notion of nonnegative realizability (K-realizability) previously introduced for scalar autonomous behaviors in [14] is carried on.

Throughout the paper we let $\mathbb{R}^n_+$ denote the nonnegative orthant, namely, the set of nonnegative vectors in the n-dimensional Euclidean space $\mathbb{R}^n$. A set $\mathcal{K} \subset \mathbb{R}^n$ is said to be a *cone* if all finite nonnegative linear combinations of elements of $\mathcal{K}$ belong to $\mathcal{K}$. A cone $\mathcal{K}$ is *convex* if it contains, with any two points, the line segment between them, namely, $\alpha\mathbf{v}_1 + (1-\alpha)\mathbf{v}_2 \in \mathcal{K}$, for every $\alpha \in [0,1]$ and every pair of vectors $\mathbf{v}_1$ and $\mathbf{v}_2$ in $\mathcal{K}$. A convex cone $\mathcal{K}$ is *solid* if it contains an open set (a ball) of $\mathbb{R}^n$, and it is *pointed* if $\mathcal{K} \cap \{-\mathcal{K}\} = \{0\}$. A closed, pointed, solid convex cone is called a *proper cone*. A cone $\mathcal{K}$ is said to be *polyhedral* if it can be expressed as the set of nonnegative linear combinations of a finite set of *generating vectors*. This amounts to saying that a positive integer r and r vectors in $\mathbb{R}^n$, $\mathbf{v}_1, \mathbf{v}_2, \ldots, \mathbf{v}_r$, can be found, such that $\mathcal{K}$ coincides with the set of nonnegative combinations of $\mathbf{v}_1, \mathbf{v}_2, \ldots, \mathbf{v}_r$. In this case, we adopt the notation $\mathcal{K} := \mathrm{Cone}(\mathbf{v}_1, \mathbf{v}_2, \ldots, \mathbf{v}_r)$. This notation can be extended to the case when the vectors $\mathbf{v}_1, \mathbf{v}_2, \ldots, \mathbf{v}_r$ are replaced by matrices $M_1, M_2, \ldots, M_r$ (with

the same number of rows). In this case, by $\text{Cone}(M_1, M_2, \ldots, M_r)$ we mean the set of nonnegative combinations of the columns of $M_1, M_2, \ldots, M_r$. Also, the extensions of the previous definitions to an arbitrary real vector space, on which it has been introduced some topology, are straightforward. The *dual* of a cone $\mathcal{K}$ in $\mathbb{R}^n$ is denoted by $\mathcal{K}^*$ and is defined as

$$\mathcal{K}^* := \{\mathbf{v} : \mathbf{w}^T\mathbf{v} \geq 0 \ \forall \ \mathbf{w} \in \mathcal{K}\}.$$

For further details we refer to [2].

If A is an $n \times n$ real matrix, we denote by $\sigma(A)$ its *spectrum* and by $\rho(A)$ its *spectral radius*, i.e., $\rho(A) := \max\{|\lambda| : \lambda \in \sigma(A)\}$. For every $\lambda \in \sigma(A)$, the *degree* of λ in A, $\deg \lambda$, is the size of the largest diagonal block in the Jordan canonical form of A which contains λ (i.e., the multiplicity of λ as a zero of $\psi_A(z)$, the (monic) minimal polynomial of A).

Given $A \in \mathbb{R}^{n\times n}$ and a cone $\mathcal{K} \subseteq \mathbb{R}^n$, we say that A *leaves* $\mathcal{K}$ *invariant* ($\mathcal{K}$ is A-invariant) if $A\mathcal{K} \subseteq \mathcal{K}$. If $A = [a_{ij}]$ is a matrix (in particular, a vector), we write

- $A \geq 0$ (A *nonnegative*) if $a_{ij} \geq 0$ for all i, j;
- $A > 0$ (A *nonzero nonnegative*) if $a_{ij} \geq 0$ for all i, j, and $a_{hk} > 0$ for at least one pair (h, k);
- $A \gg 0$ (A *positive*) if $a_{ij} > 0$ for all i, j.

Given any polynomial $r(z) \in \mathbb{R}[z]$, we denote by λ_R the greatest (if any) nonnegative real zero of r, namely, $\lambda_R := \max\{\lambda \in \mathbb{R}_+ : r(\lambda) = 0\}$. We say that λ_R is

- *dominant* if for any other zero of r, λ, we have $|\lambda| \leq \lambda_R$ and the multiplicity of λ is not greater than the multiplicity of λ_R as a zero of r;
- *strictly dominant* if for any other zero of r, $\lambda \neq \lambda_R$, we have $|\lambda| < \lambda_R$.

In the paper, all (discrete) sequences will be defined on the set $\mathbb{Z}_+$ of nonnegative integers. The right (forward) and the left (backward) shift operators on $(\mathbb{R}^q)^{\mathbb{Z}_+}$, the set of sequences defined on $\mathbb{Z}_+$ and taking values in $\mathbb{R}^q$, are defined as

$$\tau : (\mathbb{R}^q)^{\mathbb{Z}_+} \to (\mathbb{R}^q)^{\mathbb{Z}_+} : (\mathbf{v}_0, \mathbf{v}_1, \mathbf{v}_2, \cdots) \mapsto (0, \mathbf{v}_0, \mathbf{v}_1, \cdots),$$
$$\sigma : (\mathbb{R}^q)^{\mathbb{Z}_+} \to (\mathbb{R}^q)^{\mathbb{Z}_+} : (\mathbf{v}_0, \mathbf{v}_1, \mathbf{v}_2, \cdots) \mapsto (\mathbf{v}_1, \mathbf{v}_2, \mathbf{v}_3, \cdots).$$

As we will deal with sets of sequences (our *behaviors*) which are left shift-invariant, we can restrict our attention to the left shift operator σ. For every positive integer i, the ith power of σ is naturally defined by composition as $\sigma^i = \sigma\circ\sigma\circ\cdots\circ\sigma$ (i times).

Also, we can further extend the set of shift operators. Indeed, to every polynomial matrix $R(z) = \sum_{i=0}^{L} R_i z^i \in \mathbb{R}[z]^{p\times q}$ we can associate the polynomial matrix operator $R(\sigma) = \sum_{i=0}^{L} R_i\sigma^i$ (from $(\mathbb{R}^q)^{\mathbb{Z}_+}$ to $(\mathbb{R}^p)^{\mathbb{Z}_+}$), mapping every sequence $\{\mathbf{w}(t)\}_{t\in\mathbb{Z}_+}$ into the sequence $\{R(\sigma)\mathbf{w}(t)\}_{t\in\mathbb{Z}_+}$, where $R(\sigma)\mathbf{w}(t) = R_0\mathbf{w}(t) + R_1\mathbf{w}(t+1) + \cdots + R_L\mathbf{w}(t+L)$ for every $t \in \mathbb{Z}_+$. It can be proved that $R(\sigma)$ describes an injective map if and only if R is a right prime matrix, and a surjective map if and only if R is of full row rank.

2. Identifiability issues and nonnegativity property for a complete behavior. Before proceeding, we briefly summarize some basic definitions and results about behaviors whose trajectories have support in $\mathbb{Z}_+$. Further details on the subject can be found in [15, 18, 22].

In this paper, by a *dynamic system* we mean a triple $\Sigma = (\mathbb{Z}_+, \mathbb{R}^q, \mathfrak{B})$, where $\mathbb{Z}_+$ represents the *time set*, $\mathbb{R}^q$ is the *signal alphabet*, namely, the set where the system trajectories take values, and $\mathfrak{B} \subseteq (\mathbb{R}^q)^{\mathbb{Z}_+}$ is the *behavior*, namely, the set of trajectories

which are compatible with the system laws. A behavior $\mathfrak{B} \subseteq (\mathbb{R}^q)^{\mathbb{Z}_+}$ is said to be *linear* if it is a vector subspace (over $\mathbb{R}$) of $(\mathbb{R}^q)^{\mathbb{Z}_+}$ and *left shift-invariant* if $\sigma\mathfrak{B} \subseteq \mathfrak{B}$. A linear left shift-invariant behavior $\mathfrak{B} \subseteq (\mathbb{R}^q)^{\mathbb{Z}_+}$ is *complete* if for every sequence $\tilde{\mathbf{w}} \in (\mathbb{R}^q)^{\mathbb{Z}_+}$ the condition $\tilde{\mathbf{w}}|_{\mathcal{S}} \in \mathfrak{B}|_{\mathcal{S}}$ for every finite set $\mathcal{S} \subset \mathbb{Z}_+$ implies $\tilde{\mathbf{w}} \in \mathfrak{B}$, where $\tilde{\mathbf{w}}|_{\mathcal{S}}$ denotes the restriction to $\mathcal{S}$ of the trajectory $\tilde{\mathbf{w}}$ and $\mathfrak{B}|_{\mathcal{S}}$ the set of all restrictions to $\mathcal{S}$ of behavior trajectories.

Linear left shift-invariant complete behaviors are kernels of polynomial matrices in the left shift operator σ, which amounts to saying that the trajectories $\mathbf{w} = \{\mathbf{w}(t)\}_{t\in\mathbb{Z}_+}$ of $\mathfrak{B}$ can be identified with the set of solutions in $(\mathbb{R}^q)^{\mathbb{Z}_+}$ of a system of difference equations

$$R_0\mathbf{w}(t) + R_1\mathbf{w}(t+1) + \cdots + R_L\mathbf{w}(t+L) = 0, \qquad t \in \mathbb{Z}_+, \tag{2.1}$$

with $R_i \in \mathbb{R}^{p\times q}$, and hence described by the equation

$$R(\sigma)\mathbf{w} = 0, \tag{2.2}$$

where $R(z) := \sum_{i=0}^{L} R_i z^i$ belongs to $\mathbb{R}[z]^{p\times q}$. In what follows, a behavior $\mathfrak{B}$ described as in (2.2) will be denoted, for short, as $\mathfrak{B} = \ker(R(\sigma))$. Also, we will restrict our attention to linear, left shift-invariant, and complete behaviors $\mathfrak{B} \subseteq (\mathbb{R}^q)^{\mathbb{Z}_+}$, and we will refer to them simply as *behaviors*.

DEFINITION 2.1. *A behavior $\mathfrak{B} \subseteq (\mathbb{R}^q)^{\mathbb{Z}_+}$ is said to be* autonomous *if there exists $m \in \mathbb{Z}_+$ such that if $\mathbf{w}^1, \mathbf{w}^2 \in \mathfrak{B}$, and $\mathbf{w}^1|_{[0,m]} = \mathbf{w}^2|_{[0,m]}$, then $\mathbf{w}^1 = \mathbf{w}^2$.*

As is well known, a behavior $\mathfrak{B} = \ker(R(\sigma))$ with $R \in \mathbb{R}[z]^{p\times q}$ is autonomous if and only if it is a finite-dimensional vector subspace of $(\mathbb{R}^q)^{\mathbb{Z}_+}$, or, equivalently, if and only if R has full column rank q [22]. Any autonomous behavior can always be described as the kernel of a nonsingular square matrix, which is uniquely determined up to a left unimodular factor. So, in what follows, we will steadily assume that $R(z)$ is nonsingular square. The determinant of $R(z)$ (which is, of course, independent of the specific square representation, except for a multiplicative nonzero constant) is known as the *characteristic polynomial of* $\mathfrak{B}$, and its zeros as the *characteristic values of* $\mathfrak{B}$ [17]. For the sake of simplicity, we will also assume that $\det R(z)$ is a monic polynomial.

We now address certain identifiability issues which are fundamental in order to introduce the notion of positive behavior. Such concepts are only marginally touched upon here. For further details we refer the interested reader to [9, 15].

DEFINITION 2.2. *Let $\mathbf{w}^1, \mathbf{w}^2, \ldots, \mathbf{w}^m$ be m trajectories in $(\mathbb{R}^q)^{\mathbb{Z}_+}$. A behavior $\mathfrak{B} \subseteq (\mathbb{R}^q)^{\mathbb{Z}_+}$ is said to be* the most powerful unfalsified model (MPUM) explaining *$\mathbf{w}^1, \mathbf{w}^2, \ldots, \mathbf{w}^m$, if the following hold.*

- *$\mathbf{w}^1, \mathbf{w}^2, \ldots, \mathbf{w}^m$ belong to $\mathfrak{B}$.*
- *For any other behavior $\bar{\mathfrak{B}}$ having $\mathbf{w}^1, \mathbf{w}^2, \ldots, \mathbf{w}^m$ among its trajectories, we have $\mathfrak{B} \subseteq \bar{\mathfrak{B}}$.*

For every choice of the trajectories $\mathbf{w}^1, \mathbf{w}^2, \ldots, \mathbf{w}^m$, the MPUM explaining $\mathbf{w}^1, \mathbf{w}^2, \ldots, \mathbf{w}^m$, denoted by $\mathfrak{B}(\mathbf{w}^1, \mathbf{w}^2, \ldots, \mathbf{w}^m)$, exists and represents the smallest (linear left shift-invariant and complete) behavior including $\mathbf{w}^1, \mathbf{w}^2, \ldots, \mathbf{w}^m$.

A behavior $\mathfrak{B} \subseteq (\mathbb{R}^q)^{\mathbb{Z}_+}$ is said to be *identifiable* if there exists a finite number of its trajectories, say, $\mathbf{w}^1, \mathbf{w}^2, \ldots, \mathbf{w}^m$, such that $\mathfrak{B} \equiv \mathfrak{B}(\mathbf{w}^1, \mathbf{w}^2, \ldots, \mathbf{w}^m)$. Under the linearity, left shift-invariance and completeness assumptions we steadily adopt, every behavior is, indeed, identifiable.

By resorting to the notion of identifiability, Nieuwenhuis proposed in [15] the following definition of nonnegative behavior.

DEFINITION 2.3. *A behavior* $\mathfrak{B} \subseteq (\mathbb{R}^q)^{\mathbb{Z}_+}$ *is said to be* nonnegative *if there exist* $m \in \mathbb{N}$ *and nonnegative trajectories* $\mathbf{w}^1, \mathbf{w}^2, \ldots, \mathbf{w}^m$ *such that* $\mathfrak{B} \equiv \mathfrak{B}(\mathbf{w}^1, \mathbf{w}^2, \ldots, \mathbf{w}^m)$.

3. Nonnegative autonomous behaviors. A fundamental result we will resort to in the following analysis is the fact that every autonomous behavior can be "realized" by means of a state-space model [12, 23]. Indeed, if $\mathfrak{B} \subseteq (\mathbb{R}^q)^{\mathbb{Z}_+}$ is an autonomous behavior, then there exist $n \in \mathbb{N}$ and real matrices $A \in \mathbb{R}^{n\times n}$ and $C \in \mathbb{R}^{q\times n}$ such that

$$\mathfrak{B} = \left\{ \mathbf{w} \in (\mathbb{R}^q)^{\mathbb{Z}_+} : \ \exists\, \mathbf{x}(0) \text{ such that } \mathbf{x}(t+1) = A\mathbf{x}(t),\ \mathbf{w}(t) = C\mathbf{x}(t),\ t \in \mathbb{Z}_+ \right\}.$$

The pair (A, C) is an *n-dimensional realization of* $\mathfrak{B}$. Those realizations of $\mathfrak{B}$ for which n is minimal are called *minimal*. Minimal realizations of an autonomous behavior $\mathfrak{B}$ are those realizations of $\mathfrak{B}$ which are observable [20, 23].

The correspondence between kernel descriptions and state-space representations of an autonomous behavior has been explored in [12], where a certain number of algorithms have also been presented. A major role in this contribution is played by the relationship between the spectral properties of these two representations, namely, between the characteristic polynomial of $\mathfrak{B}$ and the characteristic polynomial of any matrix A appearing in the state space descriptions of $\mathfrak{B}$. Such a relationship is described in the following lemma.

LEMMA 3.1. *Let* $\mathfrak{B} = \ker(R(\sigma))$, *with* $R(z) \in \mathbb{R}[z]^{q\times q}$ *nonsingular square, be an autonomous behavior, and let* (A, C) *be an n-dimensional realization of* $\mathfrak{B}$. *Then the following hold.*

- $\det R \mid \det(zI_n - A)$, *and therefore* $\{\lambda : \det R(\lambda) = 0\} \subseteq \sigma(A)$.
- *If* (A, C) *is a minimal realization of* $\mathfrak{B}$, *then* $\det R$ *and* $\det(zI_n - A)$ *coincide, and hence* $\{\lambda : \det R(\lambda) = 0\} = \sigma(A)$.

Proof. As is well known [7, 12], if (A, C) is an n-dimensional realization of $\mathfrak{B}$ and $[\, V(z) \quad \bar{R}(z)\,]$ is a minimal left annihilator of the Popov–Belevich–Hautus (PBH) observability matrix (also known as the matrix of the Hautus observability test [10]) $\left[\begin{smallmatrix} zI_n - A \\ C \end{smallmatrix}\right]$, then (1) $\bar{R}$ is a nonsingular square matrix with $\det \bar{R} \mid \det(zI_n - A)$, and (2) $\mathfrak{B} = \ker(\bar{R}(\sigma))$. Since R and $\bar{R}$ provide two nonsingular square kernel representations of the same behavior, it follows that $\bar{R} = UR$ for some unimodular factor U. This proves the first part of the result. On the other hand, if (A, C) is a minimal, and hence observable realization, then $\left[\begin{smallmatrix} zI_n - A \\ C \end{smallmatrix}\right]$ is right prime, and hence $\det \bar{R}$ and $\det(zI_n - A)$ coincide. □

Of course, if λ is an eigenvalue of A which is not a characteristic value of $\mathfrak{B}$ (i.e., is not a zero of $\det R$), it must be an eigenvalue of the unobservable system alone [10].

Now we need to introduce a few important sets that will turn out to be useful in providing a complete characterization of both nonnegativity and, later, of nonnegative realizability. To this end, we need to consider a general (not necessarily autonomous) n-dimensional state space model with m inputs and p outputs:

$$\mathbf{x}(t+1) = A\mathbf{x}(t) + B\mathbf{u}(t), \tag{3.1}$$

$$\mathbf{w}(t) = C\mathbf{x}(t), \qquad t \in \mathbb{Z}_+. \tag{3.2}$$

Such a system is denoted, for the sake of brevity, by means of the triple (A, B, C).

DEFINITION 3.2 (see [3, 16]). *Given an n-dimensional state space model* (A, B, C) *with m inputs and p outputs, the* reachable cone *of the system (or, equivalently, of*

the pair (A, B)*) is the cone*

$$\mathcal{R}(A,B) := \overline{\text{Cone}}\{B, AB, A^2B, \ldots\}, \tag{3.3}$$

where the "upper bar" over the word "Cone" denotes the closure operation, while the observable cone *of the system (of the pair* (A, C)*) is the cone*

$$\begin{aligned} \mathcal{S}(C,A) &:= \{\mathbf{x} \in \mathbb{R}^n : CA^t\mathbf{x} \geq 0 \ \forall\ t \geq 0\} \\ &= \left(\text{Cone}\{C^T, A^TC^T, (A^T)^2C^T, \ldots\}\right)^*, \end{aligned} \tag{3.4}$$

where the symbol $*$ *denotes the "dual" of the indicated cone.*

Of course, both the reachable cone and the observable cone are always convex closed and, in general, infinitely generated. The reachable cone is solid if and only if the pair (A, B) is reachable (in the standard sense, i.e., $\text{rank}\,[\,B \quad AB \quad \ldots \quad A^{n-1}B\,] = n$); meanwhile, the observable cone is pointed if and only if the pair (A, C) is observable. Finally, the observable cone of the system (A, B, C) and the reachable cone of the dual system (A^T, C^T, B^T) are dual cones. All these results have been proved in [16] for the continuous time case, but their discrete time version is immediate.

Finally, we introduce the "positive part" of a behavior.

DEFINITION 3.3 (see [20]). *Given a behavior* $\mathfrak{B} \subseteq (\mathbb{R}^q)^{\mathbb{Z}_+}$*, we call the* positive part of $\mathfrak{B}$ *and denote it by* $\mathfrak{B}_+$*, the set of all nonnegative trajectories in* $\mathfrak{B}$*, namely,*

$$\mathfrak{B}_+ := \mathfrak{B} \cap (\mathbb{R}^q_+)^{\mathbb{Z}_+}. \tag{3.5}$$

Given any behavior $\mathfrak{B} \subseteq (\mathbb{R}^q)^{\mathbb{Z}_+}$, its positive part, $\mathfrak{B}_+$, is a convex and pointed cone in $(\mathbb{R}^q)^{\mathbb{Z}_+}$, and it is closed (with respect to the topology of the pointwise convergence). Also, $\mathfrak{B}_+$ is left shift-invariant, meaning that $\mathbf{w} \in \mathfrak{B}_+$ implies $\sigma\mathbf{w} \in \mathfrak{B}_+$.

By referring to a minimal realization of $\mathfrak{B}$, we can provide an efficient characterization of the nonnegativity property for autonomous behaviors, which refers to the aforementioned entities: the reachable cone, the observable cone, and the positive part of a behavior. The equivalence of most of the statements has been proved in [20]. There are some new statements, but their equivalence to at least one of the known statements is immediate.

THEOREM 3.4 (see [20]). *Let* $\mathfrak{B} \subseteq (\mathbb{R}^q)^{\mathbb{Z}_+}$ *be an autonomous behavior, let* $\mathfrak{B}_+$ *be its positive part, and let* (A, C) *be an* n*-dimensional and minimal realization of* $\mathfrak{B}$*. The following facts are equivalent:*

(1) $\mathfrak{B}$ *is a nonnegative behavior;*
(2) *there exists a positive integer* m *and some matrix* $X_0 \in \mathbb{R}^{n\times m}$ *such that*
  (2a) (A, X_0) *is a reachable pair, and*
  (2b) $CA^tX_0 \geq 0$ *for every* $t \geq 0$*;*
(3) *there exists a positive integer* m *and some matrix* $B \in \mathbb{R}^{n\times m}$ *such that*
  (3a) (A, B, C) *is a minimal realization of its transfer matrix* $W(z) := C(zI_n - A)^{-1}B$*, and*
  (3b) *the Markov coefficients of* $W(z)$*, i.e., the coefficients* W_t *of the power series expansion* $\sum_{t\geq 0} W_t\ z^{-t}$ *of* $W(z)$*, are all nonnegative matrices;*
(4) *there exists a positive integer* m *and some matrix* $B \in \mathbb{R}^{n\times m}$ *such that the reachable cone* $\mathcal{R}(A, B)$ *is proper and included in the observable cone* $\mathcal{S}(C, A)$*;*
(5) *there exists a proper* A*-invariant cone* $\mathcal{K} \subset \mathbb{R}^n$ *included in* $\mathcal{S}(C, A)$*;*
(6) *the observable cone* $\mathcal{S}(C, A)$ *is a proper cone;*
(7) $\mathfrak{B}$ *is the smallest (linear, left shift-invariant, and complete) behavior having* $\mathfrak{B}_+$ *as its positive part;*

(8) $\mathfrak{B}_+$ *generates an* n*-dimensional real vector space in* $(\mathbb{R}^q)^{\mathbb{Z}_+}$ *(equivalently,* $\mathfrak{B}_+$ *is a proper left shift-invariant cone in* $(\mathbb{R}^q)^{\mathbb{Z}_+}$*).*

Remarks. For a more exhaustive discussion on the previous set of characterizations, we refer the interested reader to [20]. Here we aim to introduce only a few specific comments which are relevant for the following analysis.

(i) It is well known that an autonomous behavior $\mathfrak{B} \subseteq (\mathbb{R}^q)^{\mathbb{Z}_+}$ is a finite-dimensional vector subspace of $(\mathbb{R}^q)^{\mathbb{Z}_+}$, whose dimension coincides with the dimension of a minimal realization of $\mathfrak{B}$. In fact, it is easily seen that, under the minimality (namely, observability) assumption on the pair (A, C), there exists a bijective correspondence between the set of behavior trajectories and the (vector) space $\mathbb{R}^n$ of initial conditions $\mathbf{x}(0)$. In particular, there exists a bijective correspondence between the positive part of a behavior $\mathfrak{B}$, $\mathfrak{B}_+$, and the observable cone $\mathcal{S}(C, A)$, which is just the set of initial conditions corresponding (by means of (A, C)) to the trajectories of $\mathfrak{B}_+$. Thus the above theorem states that the nonnegativity of $\mathfrak{B}$ corresponds to the fact that such a cone $\mathcal{S}(C, A)$ is a solid one, or, in a sense, is "dense" in $\mathbb{R}^n$, just as the nonnegativity of $\mathfrak{B}$ means that the set $\mathfrak{B}_+$ is rich enough to carry on all the information about $\mathfrak{B}$. In order to better understand this fact, the interested reader may refer to [20], where a few examples have been given.

(ii) Notice that for the special case of scalar autonomous behaviors, nonnegativity reduces (see Theorem 12 in [15]) to the possibility of determining one single nonnegative trajectory $w \in \mathfrak{B}$ such that $\mathfrak{B} = \mathfrak{B}(w)$. As a consequence, in the scalar case, the matrix X_0 (equivalently, the matrix B), if it exists, can always be assumed to be a simple column vector.

(iii) By Theorem 3.4, an autonomous behavior $\mathfrak{B}$, having (A, C) as an n-dimensional and minimal realization, is nonnegative if and only if there exists a proper A-invariant cone $\mathcal{K}$ included in the observable cone $\mathcal{S}(C, A)$. As is well known [2], an $n \times n$ matrix A leaves a proper cone invariant if and only if it satisfies the following two conditions (known as the *Perron–Schaefer conditions*):

(a) the spectral radius of A, $\rho(A)$, is an eigenvalue of A;

(b) any other eigenvalue λ of A whose modulus $|\lambda|$ is equal to $\rho(A)$ satisfies the inequality $\deg \lambda \leq \deg \rho(A)$ (and hence the size of the largest Jordan block corresponding to λ in the Jordan form of A is not bigger than the largest Jordan block corresponding to $\rho(A)$).

This amounts to saying that $\rho(A)$ is the greatest nonnegative real zero of $\psi_A(z)$, the minimal polynomial of A, and is dominant as a zero of ψ_A. (If A is cyclic, then $\psi_A(z) = \det(zI_n - A)$ and hence the same properties hold true in terms of the characteristic polynomial of A.)

This important characterization represents a necessary condition for an autonomous behavior to be nonnegative. In the scalar case, by resorting to different arguments, we can prove that this condition also becomes sufficient. Indeed, we have also seen that an autonomous behavior $\mathfrak{B}$, having (A, C) as a minimal (and n-dimensional) realization, is nonnegative if and only if the observable cone $\mathcal{S}(C, A)$ is proper. When $\mathfrak{B}$ is scalar autonomous, and hence C is a row vector, we can resort to (the discrete time version of) a result due to Ohta, Maeda, and Kodama (Theorem 3 in [16]) stating that, under the observability assumption on the pair (A, C), the cone $\mathcal{S}(C, A)$ is proper if and only if the $n \times n$ matrix A satisfies the Perron–Schaefer conditions. This important characterization allows us to obtain a complete spectral characterization of nonnegative scalar autonomous behaviors (which strengthens both the general result for the nonscalar case and Proposition 4.2 in [20]). It turns out that the nonnegativity

property for a scalar autonomous behavior $\mathfrak{B}$ depends only on the properties of the maximum modulus characteristic values of $\mathfrak{B}$.

PROPOSITION 3.5. *Let* $\mathfrak{B} = \ker(r(\sigma))$, *with* $r(z) = z^n + r_{n-1}z^{n-1} + \cdots + r_0 \in \mathbb{R}[z]$, *be a scalar autonomous behavior.* $\mathfrak{B}$ *is a nonnegative behavior if and only if the following two conditions hold true:*

(i) $r(z)$ *has a positive real root* λ_R *whose modulus is greater than or equal to the modulus of any other root of* $r(z)$, *namely,* $\lambda_R \geq |\lambda|$ *for any other* λ *such that* $r(\lambda) = 0$;

(ii) *any root* λ *of* $r(z)$, *with* $|\lambda| = \lambda_R$, *has multiplicity* $\mu(\lambda)$ *not greater than the multiplicity* $\mu(\lambda_R)$ *of* λ_R.

Proof. Let (A, C) be a minimal (and hence observable) realization of $\mathfrak{B}$. Since $\mathfrak{B}$ is scalar, then, by resorting to the aforementioned result by Ohta, Maeda, and Kodama, we get that $\mathfrak{B}$ is a nonnegative behavior if and only if A satisfies the Perron–Schaefer conditions. But since A is cyclic (i.e., $\psi_A(z) = \det(zI - A)$) and $r(z) = \det(zI_n - A)$, the Perron–Schaefer conditions are equivalent to (i) and (ii). □

4. Nonnegative realizability and equivalent characterizations. By following [15], we adopt the following, quite natural, definition of nonnegative realizable autonomous behavior.

DEFINITION 4.1 (see [15]). *An autonomous behavior* $\mathfrak{B} \subseteq (\mathbb{R}^q)^{\mathbb{Z}_+}$ *is said to be* nonnegative realizable *if there exists a realization of* $\mathfrak{B}$, *say,* (A_+, C_+), *with* A_+ *and* C_+ *nonnegative matrices.*

Nonnegative realizability admits a wide set of equivalent characterizations that strictly remind us of those obtained for nonnegativity and make use of the same distinguished sets: the reachable cone, the observable cone, and the positive part of the behavior.

THEOREM 4.2. *Let* $\mathfrak{B} \subseteq (\mathbb{R}^q)^{\mathbb{Z}_+}$ *be an autonomous behavior, let* $\mathfrak{B}_+$ *be its positive part, and let* (A, C) *be an* n*-dimensional and minimal realization of* $\mathfrak{B}$. *The following facts are equivalent:*

(1) $\mathfrak{B}$ *is a nonnegative realizable behavior;*

(2) *there exists a positive integer* m *and some matrix* $X_0 \in \mathbb{R}^{n \times m}$ *such that*
  (2a) *the reachable cone of the pair* (A, X_0) *is proper and polyhedral, and*
  (2b) $CA^t X_0 \geq 0$ *for every* $t \geq 0$;

(3) *there exists a positive integer* m *and some matrix* $B \in \mathbb{R}^{n \times m}$ *such that*
  (3a) (A, B, C) *is a minimal realization of its transfer matrix* $W(z) := C(zI_n - A)^{-1}B$,
  (3b) *the Markov coefficients of* $W(z)$, *i.e., the coefficients* W_t *of the power series expansion* $\sum_{t \geq 0} W_t\, z^{-t}$ *of* $W(z)$, *are all nonnegative matrices, and*
  (3c) *the reachable cone of the pair* (A, B) *is proper polyhedral;*

(4) *there exists a positive integer* m *and some matrix* $B \in \mathbb{R}^{n \times m}$ *such that the reachable cone of the pair* $\mathcal{R}(A, B)$ *is proper polyhedral and included in* $\mathcal{S}(C, A)$;

(5) *there exists an* A*-invariant proper polyhedral cone* $\mathcal{K} \subset \mathbb{R}^n$ *included in* $\mathcal{S}(C, A)$;

(6) *the set* $\mathfrak{B}_+$ *includes a proper polyhedral left shift-invariant cone.*

Proof. (1) ⇒ (2). Let (A_+, C_+) be an m-dimensional nonnegative realization of $\mathfrak{B}$, and let T be a nonsingular square matrix that reduces the pair to the standard nonobservable form [10]:

$$T^{-1}A_+T = \begin{bmatrix} A_{11} & 0 \\ A_{21} & A_{22} \end{bmatrix}, \qquad C_+T = [\, C_1 \quad 0 \,] \tag{4.1}$$

with (A_{11}, C_1) an observable pair. The pair (A_{11}, C_1) provides an observable and hence minimal (see comments at the beginning of section 3) realization of $\mathfrak{B}$. So, it entails no loss of generality, assuming $A_{11} = A$ and $C_1 = C$. Partition the nonsingular matrix T^{-1} as

$$T^{-1} = \begin{bmatrix} T_1 \\ T_2 \end{bmatrix} \begin{matrix} \}n, \\ \}m-n. \end{matrix}$$

We aim to show that by choosing $X_0 = T_1$ we satisfy both (2a) and (2b). Of course, the reachable cone generated by the pair (A_+, I_m) coincides with $\mathbb{R}^m_+ = \text{Cone}(I_m)$ and hence is a proper polyhedral cone. Consequently, the reachable cone generated by the pair $(T^{-1}A_+T, T^{-1})$ coincides with $\text{Cone}(T^{-1})$ and is, in turn, a proper polyhedral cone. Since

$$\begin{aligned} \text{Cone}\{T^{-1}, T^{-1}A_+, T^{-1}A_+^2, \ldots\} &= \text{Cone}\left\{T^{-1}, \begin{bmatrix} A & 0 \\ A_{21} & A_{22} \end{bmatrix} T^{-1}, \begin{bmatrix} A & 0 \\ A_{21} & A_{22} \end{bmatrix}^2 T^{-1}, \ldots\right\} \\ &= \text{Cone}\left\{\begin{bmatrix} T_1 \\ T_2 \end{bmatrix}, \begin{bmatrix} A & 0 \\ A_{21} & A_{22} \end{bmatrix}\begin{bmatrix} T_1 \\ T_2 \end{bmatrix}, \begin{bmatrix} A^2 & 0 \\ * & A_{22}^2 \end{bmatrix}\begin{bmatrix} T_1 \\ T_2 \end{bmatrix}, \cdots\right\}, \end{aligned}$$

where $*$ denotes an unspecified element, it follows that

$$\text{Cone}\left\{\ T_1, AT_1, A^2T_1, \ldots\right\}$$

is polyhedral, too. But this is just the reachability cone of the pair (A, T_1), and hence (2a) holds. This first part of the proof has been inspired by the proof of Theorem 2.1 in [1]. Finally, it remains to show that (2b) holds. By the nonnegativity of the pair (A_+, C_+) we have, for every $t \geq 0$,

$$0 \leq C_+A_+^t = (C_+T)(T^{-1}A_+T)^tT^{-1} = [\,C \quad 0\,]\begin{bmatrix} A & 0 \\ A_{21} & A_{22} \end{bmatrix}^t \begin{bmatrix} T_1 \\ T_2 \end{bmatrix}.$$

This ensures that $CA^tX_0 = CA^tT_1 \geq 0$ for every $t \geq 0$.

(2) $\Leftrightarrow$ (3). As (A, C) is a minimal realization for the autonomous behavior $\mathfrak{B}$, and hence is an observable pair, the equivalence of (2) and (3) is straightforward.

(2) $\Rightarrow$ (4) $\Rightarrow$ (5). This part of the proof is obvious.

(5) $\Leftrightarrow$ (6). We have remarked earlier that $\mathfrak{B}_+$ coincides with the set of behavior trajectories generated by the state-space model

$$\mathbf{x}(t+1) = A\mathbf{x}(t), \qquad \mathbf{w}(t) = C\mathbf{x}(t), \qquad t \in \mathbb{Z}_+,$$

corresponding to initial conditions, $\mathbf{x}(0)$, belonging to $\mathcal{S}(C, A)$. Due to the minimality of the state-space representation, there exists a bijective correspondence between trajectories of $\mathfrak{B}_+$ and initial conditions in $\mathcal{S}(C, A)$. This ensures that $\mathfrak{B}_+$ includes the proper polyhedral cone generated by the m trajectories $\mathbf{w}^1, \mathbf{w}^2, \ldots, \mathbf{w}^m$ if and only if $\mathcal{S}(C, A)$ includes the proper polyhedral cone generated by $\mathbf{x}_0^1, \mathbf{x}_0^2, \ldots, \mathbf{x}_0^m$, the initial conditions corresponding to $\mathbf{w}^1, \mathbf{w}^2, \ldots, \mathbf{w}^m$. Finally, the A-invariance of the cone in $\mathcal{S}(C, A)$ is, of course, the corresponding property of the left shift-invariance of the cone in $\mathfrak{B}_+$.

(5) $\Rightarrow$ (1). The proof is very similar to (one part of) the proof of Theorem 2.2 in [1]. Let P be a (full row rank) matrix with n rows, such that $\mathcal{K} = \text{Cone}(P)$. The A-invariance of $\mathcal{K}$ ensures the existence of some nonnegative matrix A_+ such that $AP = PA_+$. Set $C_+ := CP$. Condition $\mathcal{K} \subseteq \mathcal{S}(C, A)$ ensures, in particular, that

$CP \geq 0$, and hence C_+ is nonnegative. We aim to show that the pair (A_+, C_+) provides a nonnegative realization of $\mathfrak{B}$. In fact, by exploiting the fact that P is of full row rank, and hence the fact that for every vector $\mathbf{x}_0$ there exists some $\bar{\mathbf{x}}_0$ such that $\mathbf{x}_0 = P\bar{\mathbf{x}}_0$, we get

$$\begin{aligned} \mathbf{w} \in \mathfrak{B} &\Leftrightarrow \exists\ \mathbf{x}_0 \text{ such that } \mathbf{w}(t) = CA^t\mathbf{x}_0\ \forall t \in \mathbb{Z}_+ \\ &\Leftrightarrow \exists\ \bar{\mathbf{x}}_0 \text{ such that } \mathbf{w}(t) = CA^tP\bar{\mathbf{x}}_0 = CPA_+^t\bar{\mathbf{x}}_0 = C_+A_+^t\bar{\mathbf{x}}_0\ \forall t \in \mathbb{Z}_+. \end{aligned}$$

This completes the proof. □

Remarks. (i) It is immediately seen from the above theorem that every nonnegative realizable behavior is nonnegative. Simple examples can be given showing that the converse is not true in general (see Example 1, below).

(ii) Conditions (4) and (5) strictly remind us of analogous characterizations obtained for the nonnegative realizability of a strictly proper rational transfer function [1, 14]. In fact, if $w(z)$ is a strictly proper rational transfer function and (A, B, C) is an n-dimensional and minimal realization of $w(z)$, then $w(z)$ admits a nonnegative realization if and only if there exists an A-invariant proper polyhedral cone $\mathcal{K}$ satisfying

$$\mathcal{R}(A, B) \subseteq \mathcal{K} \subseteq \mathcal{S}(C, A).$$

(iii) Notice that the proof of (5) ⇒ (1) does not make explicit use of the minimality assumption on the realization (A, C). In fact, it holds also for an arbitrary realization of $\mathfrak{B}$. As a matter of fact, (1) ⇒ (5) also could be proved for an arbitrary realization by suitably adapting the proof of Theorem 1 in [11]. So, the equivalence of points (1) and (5) holds true for any realization (A, C).

(iv) It is immediately apparent from the proofs of (1) ⇒ (2) and (5) ⇒ (1) that when an autonomous behavior is nonnegative realizable, then the size of its minimal nonnegative realization coincides with the minimal number of extremal edges a proper polyhedral cone $\mathcal{K} \subseteq \mathbb{R}^n$ satisfying (5) possibly exhibits. (Notice that a proper polyhedral cone is, in particular, solid, and hence the number of its extremal edges is at least n.) A more straightforward proof could be obtained by suitably adapting that of Theorem 3 in [14].

(v) If $\mathfrak{B}$ is nonnegative realizable, then, by point (5) of the previous theorem, the matrix A appearing in a minimal realization of $\mathfrak{B}$ leaves a proper polyhedral cone $\mathcal{K}$ invariant. As a consequence [19, 21], A satisfies the following three conditions:

(a) the spectral radius of A, $\rho(A)$, is an eigenvalue of A, and, when $\rho(A) \neq 0$,

(b) $\lambda \in \sigma(A)$ with $|\lambda| = \rho(A)$ implies $\deg \lambda \leq \deg \rho(A) =: m$; namely, the size of the largest Jordan block corresponding to λ in the Jordan form of A is not bigger than the largest Jordan block corresponding to $\rho(A)$;

(c) $\lambda \in \sigma(A)$ with $|\lambda| = \rho(A)$ implies that $\lambda/\rho(A)$ is a root of unity.

As it happened for the nonnegativity property, we will see that, in the scalar case, this set of necessary conditions turns out to be sufficient also and can be tested directly on the kernel representation of the behavior.

Example 1. Consider the scalar autonomous behavior $\mathfrak{B} = \ker(r(\sigma))$, where $r(z) = (z-1)(z-e^{i\theta})(z-e^{-i\theta})$ and θ/π is not rational. Of course, by Proposition 3.5, $\mathfrak{B}$ is nonnegative. A minimal realization of $\mathfrak{B}$ is given by the pair

$$A = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 1 & -(2\cos\theta + 1) & 2\cos\theta + 1 \end{bmatrix}, \qquad C = [\,1 \quad 0 \quad 0\,].$$

So, by the previous remark, $\mathfrak{B}$ cannot be nonnegative realizable.

(vi) In Theorem 3.4, the nonnegativity property proves to be equivalent to the fact that $\mathcal{S}(C,A)$ is a proper cone or, alternatively, to the fact that $\mathfrak{B}_+$ is a proper cone in $(\mathbb{R}^q)^{\mathbb{Z}_+}$. In this respect, nonnegative realizability entails slightly weaker constraints on the sets $\mathcal{S}(C,A)$ and $\mathfrak{B}_+$ with respect to what we would expect. Indeed, it is equivalent to the fact that $\mathcal{S}(C,A)$ *includes* a proper polyhedral cone or, alternatively, to the fact that $\mathfrak{B}_+$ *includes* a proper polyhedral cone (in $(\mathbb{R}^q)^{\mathbb{Z}_+}$). As a matter of fact, we have the following result.

COROLLARY 4.3. *Given an autonomous behavior $\mathfrak{B} \subseteq (\mathbb{R}^q)^{\mathbb{Z}_+}$, let $\mathfrak{B}_+$ be its positive part, and let (A,C) be an n-dimensional and minimal realization of $\mathfrak{B}$. The following facts are equivalent:*

(i) *$\mathfrak{B}_+$ generates a proper polyhedral cone in $(\mathbb{R}^q_+)^{\mathbb{Z}_+}$;*

(ii) *the observable cone $\mathcal{S}(C,A)$ is a proper polyhedral cone.*

If either of the above equivalent conditions is satisfied, then $\mathfrak{B}$ is a nonnegative realizable behavior.

Proof. (i) $\Leftrightarrow$ (ii). See (5) $\Leftrightarrow$ (6) in the previous theorem. (Notice that, as previously remarked, $\mathcal{S}(C,A)$ is A-invariant, while $\mathfrak{B}_+$ is left shift-invariant.)

The final result follows from the fact that point (5) of Theorem 4.2 holds for $\mathcal{K} = \mathcal{S}(C,A)$ (equivalently, (6) of Theorem 4.2 holds ...), and hence $\mathfrak{B}$ is positive realizable. □

Notice that, in the scalar case, necessary and sufficient conditions for the reachable cone to be proper polyhedral have been given in [5]. So, by resorting to the duality relation existing between the reachable cone of a system and the observable cone of the dual system, we can translate the results of Theorems 1 and 2 in [5], thus obtaining a set of conditions on the matrix A for the properness and polyhedrality of the cone $\mathcal{S}(C,A)$. This way, we get a set of sufficient spectral conditions for a scalar autonomous behavior to be nonnegative realizable. Necessary *and* sufficient spectral conditions for a scalar autonomous behavior to be nonnegative realizable will be derived in the next section.

Example 2 (example on p. 373 in [5]). Consider the scalar autonomous behavior $\mathfrak{B} = \ker(r(\sigma))$, where $r(z) = (z-\lambda_1)(z-\lambda_2)(z-\lambda_3)$, and λ_1, λ_2, and λ_3 are distinct real zeros. Suppose also that λ_1 is positive and that the three zeros are ordered by decreasing order, so that $\lambda_1 > \lambda_2 > \lambda_3$. A minimal realization of $\mathfrak{B}$ is given by the pair

$$A = \begin{bmatrix} \lambda_1 & & \\ & \lambda_2 & \\ & & \lambda_3 \end{bmatrix}, \qquad C = [\,1 \quad 1 \quad 1\,].$$

We consider the same cases analyzed in [5] and make use of their results as far as the polyhedrality of the interested cones is concerned:

(a) $\lambda_1 > 0$, while $\lambda_2, \lambda_3 < 0$, and $\lambda_3 \neq -\lambda_1$. Then, as stated in the example,

$$\text{Cone}\{C^T, (A^T)C^T, (A^T)^2C^T, \ldots\}$$

is proper polyhedral and hence, a fortiori,

$$\overline{\text{Cone}}\{C^T, (A^T)C^T, (A^T)^2C^T, \ldots\}$$

and its dual, $\mathcal{S}(C,A)$.

(b) $\lambda_1 > \lambda_2 > \lambda_3 > 0$. In this case, $\mathcal{S}(C,A)$ not polyhedral. However, $\mathfrak{B}$ is trivially nonnegative realizable ((A,C) is, indeed, a nonnegative realization!).

(c) $\lambda_1 > \lambda_2 > 0$, $\lambda_3 < 0$ and $\lambda_3 \neq -\lambda_1$. In this case

$$\text{Cone}\{C^T, (A^T)C^T, (A^T)^2C^T, \ldots\}$$

is not proper polyhedral, while

$$\overline{\text{Cone}}\{C^T, (A^T)C^T, (A^T)^2C^T, \ldots\},$$

and hence also its dual, $\mathcal{S}(C, A)$, are proper polyhedral cones.

So, in all the above situations, $\mathfrak{B}$ is nonnegative realizable.

To conclude the section, it may be interesting to show how the characterization given by Nieuwenhuis in Theorem 15 of [15] for the nonnegative realizability of a scalar autonomous behavior can be easily obtained as an immediate corollary of Theorem 4.2. Indeed, if $\mathfrak{B} = \ker(r(\sigma))$, with $r(z) \in \mathbb{R}[z]$, is a scalar autonomous behavior, it entails no loss of generality assuming that $r(z)$ is monic, and hence can be represented as $r(z) = z^n + r_{n-1}z^{n-1} + \cdots + r_0$. A minimal realization of $\mathfrak{B}$ is given by the (observable) pair

$$A = \begin{bmatrix} 0 & 1 & 0 & & & \\ 0 & 0 & 1 & 0 & & \\ & & & \ddots & \ddots & \\ & & & & \ddots & 0 \\ & & & & & 1 \\ -r_0 & -r_1 & -r_2 & & & -r_{n-1} \end{bmatrix}, \qquad C = [\,1 \quad 0 \quad \ldots \quad 0\,]$$

(with A in companion form [10]). The operator P introduced in [15] and acting on the vectors of $\mathbb{R}^n$ as follows,

$$\begin{aligned} P \;:\; \mathbb{R}^n &\to \mathbb{R}^n \\ : \begin{bmatrix} v_1 \\ v_2 \\ \vdots \\ v_n \end{bmatrix} &\mapsto \begin{bmatrix} v_2 \\ v_3 \\ \vdots \\ -\sum_{i=0}^{n-1} r_i v_i \end{bmatrix}, \end{aligned}$$

corresponds, in fact, to the (left) product by the matrix A, namely, $P(\mathbf{v}) = A\mathbf{v}$ for every $\mathbf{v} \in \mathbb{R}^n$. Since $C = [\,1 \quad 0 \quad \ldots \quad 0\,]$, it is easily seen that condition (5) in Theorem 4.2 becomes equivalent to the fact that there exists a proper polyhedral A-invariant cone $\mathcal{K} \subseteq \mathbb{R}^n_+$, or, in other words, a polyhedral cone $\mathcal{K} \subseteq \mathbb{R}^n_+$ such that $P(\mathcal{K}) \subseteq \mathcal{K}$. In fact, if $\mathcal{K} = \text{Cone}(P)$ is an A-invariant proper polyhedral cone in $\mathbb{R}^n$, condition $\mathcal{K} \subseteq \mathcal{S}(C, A)$ implies, in particular, that $CA^tP \geq 0$ for $t = 0, 1, \ldots, n-1$, which, for the specific choice of the pair (A, C), means

$$\begin{bmatrix} 1 & & & \\ & 1 & & \\ & & \ddots & \\ & & & 1 \end{bmatrix} P \geq 0.$$

So, $P \geq 0$ and $\mathcal{K} \subseteq \mathbb{R}^n_+$. Conversely, if $\mathcal{K} = \text{Cone}(P)$ is an A-invariant proper polyhedral cone in $\mathbb{R}^n_+$, and hence $P \geq 0$, then A-invariance ensures that $AP = PA_+$ for some $A_+ \geq 0$. Consequently,

$$CA^tP = CPA_+^t = [\,1 \quad 0 \quad \ldots \quad 0\,]\,PA_+^t \geq 0 \qquad \forall\, t \geq 0.$$

This ensures that $\mathcal{K} = \text{Cone}(P) \subseteq \mathcal{S}(C, A)$. This way we have proved the following result.

PROPOSITION 4.4 (see [15]). *Let $\mathfrak{B} = \ker\,(r(\sigma))$, with $r(z) = z^n + r_{n-1}z^{n-1} + \cdots + r_0 \in \mathbb{R}[z]$, be a scalar autonomous behavior, and let P be the operator acting on the vectors of $\mathbb{R}^n$ as follows:*

$$P \;:\; \mathbb{R}^n \;\to\; \mathbb{R}^n$$

$$: \begin{bmatrix} v_1 \\ v_2 \\ \vdots \\ v_n \end{bmatrix} \mapsto \begin{bmatrix} v_2 \\ v_3 \\ \vdots \\ -\sum_{i=0}^{n-1} r_i v_i \end{bmatrix}.$$

$\mathfrak{B}$ is a nonnegative realizable behavior if and only if there exists a proper polyhedral cone $\mathcal{K} \subseteq \mathbb{R}^n_+$ such that $P(\mathcal{K}) \subseteq \mathcal{K}$.

5. The nonnegative realizability problem for scalar autonomous behaviors. In the previous section, we have provided geometric conditions which are necessary and sufficient for the nonnegative realizability of an autonomous behavior. By focusing our attention to the scalar case, we aim now to provide a complete spectral characterization of those scalar autonomous behaviors $\mathfrak{B}$ which admit a nonnegative realization. Not unexpectedly, such a characterization is, again, completely based on the properties of the maximum modulus characteristic values of $\mathfrak{B}$.

As a first step, by suitably applying both the results of the previous sections and the fundamental result (Theorem 4.1 and Corollary 4.1) obtained in [1], we can prove that nonnegative scalar autonomous behaviors, having a strictly dominant nonnegative real characteristic value, are nonnegative realizable.

THEOREM 5.1. *Let $\mathfrak{B} = \ker(r(\sigma))$, with $r(z) \in \mathbb{R}[z]$ monic of degree n, be an autonomous nonnegative behavior. If λ_R, the maximum nonnegative real characteristic value of $\mathfrak{B}$, is strictly dominant, then $\mathfrak{B}$ is nonnegative realizable.*

Proof. Let (A, C) be an n-dimensional and minimal realization of $\mathfrak{B}$. Since $\mathfrak{B}$ is nonnegative and scalar, then (see the remarks after Theorem 3.4) there exists some column vector b such that $\mathcal{R}(A, b)$ is a proper cone included in $\mathcal{S}(C, A)$, or, equivalently, there exists b such that (A, b, C) is a minimal realization of the transfer function with nonnegative Markov coefficients, $W(z) := C(zI_n - A)^{-1}b$. Notice that, since (A, b, C) is minimal, the poles of $W(z)$ coincide with the eigenvalues of A and hence (see Lemma 3.1) with the zeros of $r(z)$. So we have a strictly proper transfer function, $w(z)$, with nonnegative Markov coefficients and a positive real pole which is strictly dominant. This ensures, by Theorem 4.1 and Corollary 4.1 in [1], that $w(z)$ admits a nonnegative realization or, in other words, that there exists a proper polyhedral A-invariant cone $\mathcal{K}$, satisfying

$$\mathcal{R}(A, b) \subseteq \mathcal{K} \subseteq \mathcal{S}(C, A).$$

This ensures, in particular, that condition (5) of Theorem 4.2 is satisfied, and hence $\mathfrak{B}$ is nonnegative realizable. ∎

Notice that Theorem 5.1 assumes that the given scalar behavior is nonnegative. Such an assumption is by no means restrictive, as we have previously underlined that nonnegativity is a necessary condition for an autonomous behavior to be nonnegative realizable. On the other hand, in the specific scalar case we are addressing, such a property can be tested, due to the spectral characterization given in Proposition 3.5.

We aim now to provide a way for testing whether an arbitrary scalar autonomous nonnegative behavior is nonnegative realizable or not. Our proof has been inspired by [4, 11] and is based on the following technical lemma, which is easily proved along the same lines of the proof of Lemma 2 in [11].

LEMMA 5.2 (see [11]). *Let A and C be an $n\times n$ real matrix and a $q\times n$ real matrix, respectively, and let p be any positive integer. There exists a proper (polyhedral) A-invariant cone included in the observable cone $\mathcal{S}(C,A)$ if and only if there exists a proper (polyhedral) A^p-invariant cone included in the observable cone $\mathcal{S}(C,A^p)$.*

THEOREM 5.3. *Let $\mathfrak{B} = \ker(r(\sigma))$, with $r(z) \in \mathbb{R}[z]$ monic of degree n, be an autonomous nonnegative behavior. $\mathfrak{B}$ is nonnegative realizable if and only if the following conditions hold true:*

(i) *$r(z)$ has a positive real dominant root λ_R, which amounts to saying that $\lambda_R \geq |\lambda|$ for any other λ such that $r(\lambda) = 0$ and any root λ, with $|\lambda| = \lambda_R$, has multiplicity $\mu(\lambda)$ not greater than the multiplicity $\mu(\lambda_R)$ of λ_R;*

(ii) *for any root λ of $r(z)$ with $|\lambda| = \lambda_R$, we have that λ/λ_R is a root of unity.*

Proof. Let (A, C) be an n-dimensional and minimal realization of $\mathfrak{B}$. If $\mathfrak{B}$ is nonnegative realizable, then, as we previously remarked, A leaves a proper polyhedral cone invariant and hence satisfies the following three conditions:

(a) the spectral radius of A, $\rho(A)$, is an eigenvalue of A,

and, when $\rho(A) \neq 0$,

(b) $\lambda \in \sigma(A)$ with $|\lambda| = \rho(A)$ implies $\deg \lambda \leq \deg \rho(A) =: m$, namely, the size of the largest Jordan block corresponding to λ in the Jordan form of A is not bigger than the largest Jordan block corresponding to $\rho(A)$;

(c) $\lambda \in \sigma(A)$ with $|\lambda| = \rho(A)$ implies $\lambda/\rho(A)$ is a root of unity.

Since the given realization is a minimal one (and hence $\det(zI_n - A) = r(z)$) and, being in the scalar case, the matrix A is necessarily cyclic (namely, it exhibits one Jordan block for every eigenvalue), the above conditions on the Jordan form of A can be easily translated in terms of the polynomial $r(z)$, thus getting (i) and (ii).

Conversely, suppose that conditions (i) and (ii) hold, and let p be a positive integer such that for any root λ of $r(z)$ with $|\lambda| = \lambda_R$, λ/λ_R is a pth root of unity. Let $\mathfrak{B}_p$ be the scalar autonomous behavior having the pair (A^p, C) as an (n-dimensional) realization. We make the following observations:

- As $\mathfrak{B}$ is nonnegative, there exists a proper A-invariant cone included in $\mathcal{S}(C,A)$. By the previous lemma, then, there exists a proper A^p-invariant cone included in the observable cone $\mathcal{S}(C,A^p)$, and hence $\mathfrak{B}_p$ is nonnegative.
- By the assumption on p, the matrix A^p has a strictly dominant nonnegative real eigenvalue.
- Since the pair (A, C) is minimal and hence observable, then the pair (A^p, C) is either observable or, if not, $\rho(A)^p$ cannot be the eigenvalue of the unobservable system alone. In fact, by the observability of the pair (A, C) there exists a nonzero vector $\mathbf{v}$ such that $A\mathbf{v} = \rho(A)\mathbf{v}$ while $C\mathbf{v} \neq 0$. But then, the state-space model (A^p, C) corresponding to the initial condition $\mathbf{x}(0) = \mathbf{v}$ provides the (nontrivial) output trajectory

$$\mathbf{w}(t) = C(A^p)^t\mathbf{v} = CA^{pt}\mathbf{v} = \rho(A)^{pt}C\mathbf{v} \ \in \mathfrak{B}_p.$$

This ensures that $\rho(A)^p$ cannot be the eigenvalue of the unobservable system alone, and hence if we let $r_p(z)$ be the monic polynomial providing a kernel description of $\mathfrak{B}_p$, we have that $r_p(z)$ has a zero of maximum modulus in $\rho(A)^p$.

So we have that $\mathfrak{B}_p := \ker(r_p(\sigma))$ is nonnegative, and its characteristic polynomial, $r_p(z)$, has $\rho(A)^p$ as a strictly dominant nonnegative real zero. This ensures, by Theorem 5.1, that $\mathfrak{B}_p$ is nonnegative realizable. So, finally, by putting together Theorem 4.2 and Lemma 5.2, we obtain that $\mathfrak{B}$ is nonnegative realizable too. □

Remark. Notice that, with respect to the traditional nonnegative realization problem, here we have obtained a much more favorable situation. In fact, the solutions presently available of the nonnegative realization problem for proper rational transfer functions [1, 4, 8, 11] assume, as a steady assumption, the nonnegativity of the impulse response of the system. This is, of course, a necessary condition for the problem solution; however, up to now, no algorithm has been obtained to check this condition. The nonnegativity constraint on the impulse response is here replaced by the nonnegativity assumption on the scalar autonomous behavior. This property, however, in the scalar case, has been completely captured in terms of spectral conditions. Indeed, as stated in Proposition 3.5, $\mathfrak{B}$ is a nonnegative behavior if and only if the so-called "extended Perron–Schaefer conditions" hold true. Even more, nonnegative realizability has, in turn, obtained a complete spectral characterization in the scalar case. So, it seems that, at least in the scalar autonomous case, the properties here considered can be practically checked.

As we did for nonnegativity in [20], given a scalar autonomous behavior $\mathfrak{B}$, we can find the largest behavior $\mathfrak{B}^*$ included in $\mathfrak{B}$ which is nonnegative realizable. In fact, assume that $\mathfrak{B} = \ker(r(\sigma))$, with $r(z)$ (monic) in $\mathbb{R}[z]$, is a scalar autonomous behavior. Consider the set $\{\lambda \in \mathbb{R}_+ : r(\lambda) = 0\}$ and, in case it is nonempty, set

$$\lambda_R := \max\{\lambda \in \mathbb{R}_+ : r(\lambda) = 0\},$$

and let $\mu(\lambda)$ denote the multiplicity of λ as a zero of $r(z)$. Set, also,

$$p_1(z) := \prod_{\substack{\lambda: r(\lambda)=0 \\ |\lambda|>\lambda_R}} (z-\lambda)^{\mu(\lambda)},$$

$$p_2(z) := \prod_{\substack{\lambda: r(\lambda)=0, |\lambda|=\lambda_R \\ |\lambda|/\lambda_R \text{ a root of unity, } \mu(\lambda)>\mu(\lambda_R)}} (z-\lambda)^{\mu(\lambda)-\mu(\lambda_R)},$$

$$p_3(z) := \prod_{\substack{\lambda: r(\lambda)=0, |\lambda|=\lambda_R \\ |\lambda|/\lambda_R \text{ not a root of unity}}} (z-\lambda)^{\mu(\lambda)},$$

and correspondingly define

$$r^*(z) := \frac{r(z)}{p_1(z)p_2(z)p_3(z)}.$$

Then $\mathfrak{B}^* := \ker(r^*(\sigma))$ is the largest nonnegative realizable behavior included in $\mathfrak{B}$. For the sake of brevity, we skip the boring details of the proof.

6. Comparisons with the *K*-realizability notion. To conclude the paper, it is worthwhile to further deepen our analysis and make a quick comparison with a set of nice results presented in a celebrated paper by Maeda and Kodama. In [14] a different notion of realizability, called K-realizability, has been analyzed and characterized for scalar autonomous behaviors (as a matter of fact, for the set of solutions of a scalar linear time-invariant and homogeneous difference equation. The

paper was written in 1981, before the publication of Willems' papers). This was the only type of nonnegative realizability addressed in the literature until the paper by Nieuwenhuis [15].

Let $\mathfrak{B}$ be a scalar autonomous behavior, and let $\mathfrak{B}_+$ be its positive part. $\mathfrak{B}$ is said to be *K-realizable* if there exists a nonnegative autonomous state-space model

$$\begin{aligned} \mathbf{x}(t+1) &= A\mathbf{x}(t), \\ w(t) &= C\mathbf{x}(t), \qquad t \in \mathbb{Z}_+ \end{aligned}$$

(which is not necessarily a realization of $\mathfrak{B}$!!!), such that $\mathfrak{B}_+$ coincides with the set of all (nonnegative) trajectories produced by the nonnegative state-space model (A, C), corresponding to *nonnegative initial conditions*. In formulas

$$\mathfrak{B}_+ \equiv \{w \in \mathfrak{B} : \exists\ \mathbf{x}(0) \geq 0 \text{ such that } w(t) = CA^t\mathbf{x}(0)\ \forall\ t \geq 0\}. \tag{6.1}$$

In the general case, a K-realizable behavior is not necessarily nonnegative realizable.

Example 3. Consider the scalar autonomous behavior $\mathfrak{B} = \ker(r(\sigma))$, with $r(z) = (z+2)(z-1)$. Of course, by Proposition 3.5, $\mathfrak{B}$ is not nonnegative, as the maximum modulus zero of r is a negative one, and henceforth is not even nonnegative realizable. The positive part of $\mathfrak{B}_+$, by Theorem 4.3 in [20], coincides with the positive part of $\mathfrak{B}^* := \ker(\sigma - 1)$ and hence is

$$\mathfrak{B}_+ = \Big\{\{w(t)\}_{t\geq 0} = \{c\}_{t\geq 0} : c \geq 0\Big\}.$$

It is immediately apparent that the nonnegative system $A = C = 1$ makes condition (6.1) satisfied, and hence $\mathfrak{B}$ is K-realizable.

Under the nonnegativity assumption, however, K-realizable behaviors are always nonnegative realizable. In fact, upon resorting to the results obtained in [20] and in this paper, we can suitably translate into "behavioral terms" the results of Theorem 2 in [14].

THEOREM 2 (from [14]). *Suppose that $\mathfrak{B}$ is a scalar autonomous behavior and that $\mathfrak{B}_+$ generates an n-dimensional vector space in $\mathbb{R}^{\mathbb{Z}_+}$ (equivalently, by Theorem* 3.4, *$\mathfrak{B}$ is a nonnegative behavior). Let (A, C) be a minimal (and n-dimensional) realization of $\mathfrak{B}$. Then $\mathfrak{B}$ is K-realizable if and only if the observable cone $\mathcal{S}(C, A)$ is proper polyhedral.*

Notice that, in the original statement, $\mathcal{S}(C, A)$ is required only to be polyhedral. However, the nonnegativity assumption on $\mathfrak{B}$ ensures (see, again, Theorem 3.4) that the observable cone is proper. So, by comparing Corollary 4.3 with the previous result, we obtain that under the nonnegativity assumption on the scalar autonomous behavior (which, by the way, is a necessary condition for nonnegative realizability), K-realizability is equivalent to the polyhedrality of $\mathcal{S}(C, A)$ and hence implies nonnegative realizability. The converse, however, as it has been shown in Example 2, is not true.

STOCHASTIC FREQUENCY CHARACTERISTICS*

HANZHONG WU† AND XUN YU ZHOU‡

Abstract. This paper is concerned with stochastic linear-quadratic (LQ) problems in infinite time horizon with control-dependent diffusions and indefinite cost weighting matrices. The classical approach of frequency domain is employed to tackle the problem, starting with the introduction of a frequency characteristic. The equivalence is established among the unique solvability of the LQ problem, the solvability of the associated stochastic Riccati equation, the coercivity of some bilinear form in the Hilbert space of the admissible controls, and the uniformly positive definiteness of the frequency characteristic matrix.

Key words. indefinite stochastic linear-quadratic control, frequency characteristic, stochastic Riccati equation, bilinear form, stability, solvability

1. Introduction.

Linear-quadratic (LQ) control, pioneered by Kalman [9], is one of the most fundamental and useful tools in modern engineering and has developed into a major research field in control theory. In the LQ literature it is typically assumed (for a minimization problem) that the cost function has positive semidefinite weighting matrices for the control and the state. In fact, the positive semidefiniteness of the control cost matrix is *necessary* for the well-posedness of the *deterministic* LQ problem (see, e.g., [21, Chapter 6, Proposition 2.4]).

However, it was found in [4] for the first time that a stochastic LQ problem with an *indefinite* control cost may still be well-posed. This phenomenon, which occurs only when the diffusion term depends on the control, has to do with the deep nature of the uncertainty involved. By and large, in a stochastic environment the uncertainty or risk is *costly*, and this uncertainty/risk cost, which can be evaluated precisely via a stochastic Riccati equation, must be taken into consideration when one exercises the control. This, in turn, gives rise to a meaningful or well-posed LQ problem even when the control cost matrix is indefinite (and, in particular, negative definite).

Starting from [4], there have been extensive research efforts devoted to indefinite stochastic LQ control, and a systematic theory is being established; refer to [1, 2, 5, 6, 11, 20, 21]. In addition, computational algorithms to solve the problem were developed in [1, 20]. On the other hand, the theory provides a nice framework for many applications, especially in finance, as many finance problems can be formulated as stochastic LQ problems which are inherently indefinite [10, 22].

In the research on indefinite LQ problems so far, however, there is one important and deep issue that has not been addressed, i.e., what are the precise relations among the parameters of the problem (namely, the linear coefficient matrices in the dynamics

and the weighting matrices in the cost) so as to make a well-posed and solvable LQ problem? In [4], it was shown that the well-posedness and solvability of an LQ control problem boil down to certain conditions in terms of a Riccati equation, but it is hard to translate the conditions into ones that *directly* relate the parameters of the original LQ problem, due to the difficulty and complexity of the Riccati equation. For example, in [4] the following question was posed: if the control cost is allowed to be negative, then how negative can it be so that the LQ problem is still well-posed and solvable? An answer was given in [4], nevertheless only implicitly via the solution to the Riccati equation, which was not really an "answer" in that it was not easily verifiable. Another possible way of addressing the issue is to reformulate the stochastic LQ problem as a (minimizing) optimization problem of a bilinear form in a Hilbert space—the space of all admissible controls. From this perspective, whether or not the control cost is positive is not important in order for the LQ problem to be well-posed and solvable; what is important is that all the parameters must be given in such a way that the resulting infinite dimensional optimization problem is convex (see, e.g., [21, Chapter 6, Theorem 4.2]). This approach gives a deeper and more abstract view of the original LQ problem, but again the difficulty lies in interpreting the abstract convexity condition by the parameters of the LQ problem.

In the classical control literature there is a so-called frequency domain approach that describes the input-output or control-state relation via the Fourier transformation and uses some frequency characteristics to characterize the underlying LQ problem. For the deterministic finite-dimensional systems, Yakubovich [17] systematically established the frequency theory in both nondegenerate and degenerate forms. These results were later extended to infinite dimensions in [18, 19, 15, 16]. For the stochastic case, Dokuchaev [7] introduced a frequency characteristic for a certain (definite) LQ problem under the solvability of a linear matrix equation. However, in [7] the diffusion coefficient does not depend on the control variable, and the controls are taken as deterministic functions; hence the results and their derivations are very much parallel to the deterministic case. On the other hand, Ugrinovskii [14] established, via the frequency domain approach, the equivalence between the solvability of a matrix inequality and the nonnegativity of the aforementioned bilinear form in the control space. However, no frequency characteristic that can be computed explicitly through the parameter matrices of the LQ problem has been given in [14] to characterize the well-posedness/solvability of the original stochastic LQ problem. (For more details see Remark 7.3 below.)

In this paper, we introduce a new frequency characteristic for the indefinite stochastic LQ problem. This characteristic, which reduces to the one studied in [7] when the diffusion is control-independent, is a complex matrix that can be calculated directly from the given parameters of the LQ problem. Then we establish the equivalence of the following statements: (1) the LQ problem is solvable and has a unique optimal control; (2) the stochastic Riccati equation has a unique solution such that the induced feedback control is stabilizing; (3) the associated optimization problem of the bilinear form is coercive; and (4) the frequency characteristic matrix is uniformly positive definite. This way we completely characterize the solvability of the indefinite LQ problem via the frequency characteristic introduced, and we establish a grand unification of different approaches in dealing with the LQ problem. One of the implications of the above equivalence is that it is the overall coordination of *all* the parameters of the problem, rather than the positive definiteness of individual cost matrices, that is essential to the solvability of the LQ problem. This is the underlying

reason for the seemingly surprising phenomenon that one may solve a stochastic LQ problem even when the cost matrices are indefinite. An interesting by-product is that, by comparing and equating the frequency characteristics, the stochastic LQ problem is shown to be equivalent to a problem without a diffusion term but with different cost weighting matrices. In other words, the diffusion part of the problem can be transferred to the overall cost, which in turn implies that the uncertainty is nothing but a *part* of the cost. One can then clearly figure out how negative a control or state cost can be so as to make a meaningful LQ problem.

The remainder of the paper is organized as follows. In section 2 the indefinite stochastic LQ problem is formulated, and some preliminaries, including the important issue of stabilizability, are presented. In section 3 a frequency characteristic is introduced. Section 4 gives a link between the frequency characteristic and the bilinear form. Section 5 is devoted to the relationship between the stochastic Riccati equation and the LQ problem, while section 6 is devoted to that between the frequency characteristic and the LQ problem. In section 7 all the results obtained are unified to establish a grand equivalence theorem. Finally, section 8 concludes the paper.

2. Problem formulation and preliminaries. Let $(\Omega, \mathcal{F}, \mathcal{P}; \mathcal{F}_t)$ be a given standard filtered probability space with a standard scalar Brownian motion $w(t)$ on $[0, +\infty)$ (with $w(0) = 0$). The Brownian motion is assumed to be one-dimensional only for simplicity; there is no essential difficulty with the multidimensional case. Consider the controlled Itô differential equation

$$\begin{cases} dx(t) = [Ax(t) + Bu(t)]dt + [Cx(t) + Du(t)]dw(t), \\ x(0) = x_0 \in \mathbb{R}^n, \end{cases} \tag{2.1}$$

where A, B, C, and D are real matrices of sizes $n \times n$, $n \times m$, $n \times n$, and $n \times m$, respectively. The associated cost functional is

$$J(x_0; u(\cdot)) = E \int_0^{+\infty} [x(t)^T Q x(t) + 2u(t)^T S x(t) + u(t)^T R u(t)]\, dt, \tag{2.2}$$

where Q and R are real symmetric matrices and S is a real matrix of appropriate sizes.

Throughout this paper, the superscript "T" denotes the transpose of a matrix, while "*" denotes the adjoint of a (complex) matrix (i.e., the complex conjugate of the transpose). For a matrix or vector $X = (x_{ij})$, we define its norm by $|X| = (\sum_{i,j} |x_{ij}|^2)^{\frac{1}{2}}$. Moreover, we denote by $\|\cdot\|_H$ the underlying norm in a Hilbert space H. Set

$$L^2_{\mathcal{F}}(\mathbb{R}^k) \triangleq \begin{cases} \phi(\cdot) : [0, +\infty) \times \Omega \mapsto \mathbb{R}^k \mid \phi(\cdot) \text{ is } \mathcal{F}_t\text{-adapted, measurable,} \\ \text{and } E \displaystyle\int_0^{+\infty} |\phi(t, \omega)|^2\, dt < +\infty, \end{cases} \tag{2.3}$$

which is a Hilbert space with the inner product $E \int_0^{+\infty} \phi(t)^T \psi(t)\, dt$ for $\phi(\cdot)$, $\psi(\cdot) \in L^2_{\mathcal{F}}(\mathbb{R}^k)$. Define $\mathcal{U}(x_0) \subset L^2_{\mathcal{F}}(\mathbb{R}^m)$, the set of admissible controls (at x_0), as the collection of such $u(\cdot) \in L^2_{\mathcal{F}}(\mathbb{R}^m)$ that the corresponding solution $x(\cdot) \equiv x(\cdot; x_0, u(\cdot))$ of (2.1) satisfies $x(\cdot) \in L^2_{\mathcal{F}}(\mathbb{R}^n)$. In this case, $(u(\cdot), x(\cdot))$ is called an admissible pair (at x_0).

The (indefinite) stochastic LQ optimal control problem can be stated as follows.

Problem (LQ). For a given $x_0 \in \mathbb{R}^n$, find $u(\cdot) \in \mathcal{U}(x_0)$ so that the cost functional (2.2) is minimized.

We call the LQ problem under consideration in this paper *indefinite* in the sense that we do not impose any positive/positive semi- definiteness for the cost matrices Q and R. However, as it turns out, being indefinite does not rule out the possibility that the bilinear form of the stochastic LQ problem is "positive definite" so that the problem admits an optimal control (see Theorem 7.1). In fact, this is exactly the distinctive feature of the stochastic problem that motivates this paper to characterize the solvability of an indefinite stochastic LQ problem.

Since now the problem is indefinite, the infimum of the cost functional (2.2) could be negatively infinite. If it holds that

$$\inf_{u(\cdot)\in\mathcal{U}(x_0)} J(x_0; u(\cdot)) > -\infty, \tag{2.4}$$

then we say that Problem (LQ) is well-posed at $x_0 \in \mathbb{R}^n$. If there exists a $\bar{u}(\cdot) \in \mathcal{U}(x_0)$ such that

$$J(x_0; \bar{u}(\cdot)) = \inf_{u(\cdot)\in\mathcal{U}(x_0)} J(x_0; u(\cdot)) > -\infty, \tag{2.5}$$

then we say that Problem (LQ) is solvable at $x_0 \in \mathbb{R}^n$. In this case, we call the control $\bar{u}(\cdot)$ an optimal control and the pair $(\bar{u}(\cdot), \bar{x}(\cdot))$ an optimal pair. If there is only one optimal control satisfying (2.5), then Problem (LQ) is called uniquely solvable at $x_0 \in \mathbb{R}^n$.

Compared with optimality, an almost equally important term, due to the infinite time horizon, is the stability/stabilizability.

Definition 2.1. *The system* (2.1) *with a given admissible control* $u(\cdot)$ *is called (mean-square) stable at a given initial state* $x_0 \in \mathbb{R}^n$, *if* $\lim_{t\to+\infty} E|x(t)|^2 = 0$, *where* $x(\cdot)$ *is the corresponding state trajectory. The system* (2.1) *is called (mean-square) stabilizable if there exists a feedback control* $u(\cdot) = Kx(\cdot)$ *with a constant matrix* K, *such that the corresponding solution* $x(\cdot)$ *of the system* (2.1), *for any initial state* $x_0 \in \mathbb{R}^n$, *satisfies* $\lim_{t\to+\infty} E|x(t)|^2 = 0$. *In this case, the matrix* K *is called a (mean-square) stabilizing feedback operator, and the feedback control* $u(\cdot) = Kx(\cdot)$ *is called a (mean-square) stabilizing control.*

The following standard assumption is imposed throughout this paper.

Assumption (A1). The system (2.1) is stabilizable.

Remark 2.1. It is easy to see that Assumption (A1) implies the stabilizability of the pair (A, B) in the deterministic sense.

Remark 2.2. It follows from Theorems 4.1 and 4.2 of [13] that Assumption (A1) is equivalent to the nonemptiness of the admissible control set $\mathcal{U}(x_0)$ at *any* x_0. This is a very deep result, as the nonemptiness of $\mathcal{U}(x_0)$ is a rather weak statement. It also shows that (A1) is almost a minimum assumption.

Under Assumption (A1), we can further assume, without loss of generality, that the uncontrolled system of (2.1) (i.e., the system (2.1) with $u(t) \equiv 0$) is (mean-square) stable at any initial x_0. Indeed, let K be a stabilizing feedback operator, and put $u(\cdot) = Kx(\cdot) + v(\cdot)$ in (2.1). Then (2.1) is turned to

$$dx(t) = [A_1x(t) + Bv(t)]dt + [C_1x(t) + Dv(t)]dw(t), \quad x(0) = x_0, \tag{2.6}$$

where $A_1 = A + BK$ and $C_1 = C + DK$. So the system (2.6) with $v(t) \equiv 0$ is stable at any x_0.

Based on the above argument, we assume the following throughout this paper.

Assumption (A2). The uncontrolled system of (2.1) is stable at any initial x_0.

Remark 2.3. Similar to Remark 2.1, Assumption (A2) implies that the matrix A is Hurwitz (i.e., the real parts of all the eigenvalues of A are strictly negative).

LEMMA 2.1. *For any* $u(\cdot) \in \mathcal{U}(x_0)$, $E|x(t)|^2$ *is uniformly continuous on* $[0, +\infty)$ *and* $\lim_{t\to+\infty} E|x(t)|^2 = 0$.

Proof. By Itô's formula, $X(t) \triangleq E[x(t)x(t)^T]$ satisfies the differential equation

$$\frac{d}{dt}X(t) = AX(t) + X(t)A^T + CX(t)C^T + Y(t), \tag{2.7}$$

where

$$\begin{aligned} Y(t) \triangleq E[&Bu(t)x(t)^T + x(t)u(t)^T B^T + Du(t)x(t)^T C^T \\ &+ Cx(t)u(t)^T D^T + Du(t)u(t)^T D^T]. \end{aligned} \tag{2.8}$$

It follows from $u(\cdot) \in \mathcal{U}(x_0)$ that, for some constant $k > 0$,

$$\int_0^\infty |Y(t)|\, dt \le k[\|u(\cdot)\|^2_{L^2_{\mathcal{F}}(\mathbb{R}^m)} + \|x(\cdot)\|^2_{L^2_{\mathcal{F}}(\mathbb{R}^n)}] < +\infty. \tag{2.9}$$

On the other hand, by Assumption (A2), the solution to the homogeneous version of (2.7),

$$\frac{d}{dt}X(t) = AX(t) + X(t)A^T + CX(t)C^T, \tag{2.10}$$

is exponentially stable, i.e., there exist numbers $c, \varepsilon > 0$ such that $|X(t)| \le c|x_0|^2 e^{-\varepsilon t}$. Hence it can be easily verified by the variation-of-constant formula along with (2.9) that $E[x(t)x(t)^T] = X(t)$ is uniformly continuous. This also leads to $\lim_{t\to+\infty} E[x(t)x(t)^T] = 0$ since $x(\cdot) \in L^2_{\mathcal{F}}(\mathbb{R}^n)$. □

LEMMA 2.2. $\mathcal{U}(x_0) = L^2_{\mathcal{F}}(\mathbb{R}^m)$ *for any* $x_0 \in \mathbb{R}^n$.

Proof. It suffices to prove that for any $u(\cdot) \in L^2_{\mathcal{F}}(\mathbb{R}^m)$, the corresponding solution $x(\cdot)$ of (2.1) satisfies $x(\cdot) \in L^2_{\mathcal{F}}(\mathbb{R}^n)$. By Itô's formula, $X(t) \triangleq E[x(t)x(t)^T]$ satisfies the matrix-valued differential equation (2.7). It has been shown in the proof of Lemma 2.1 that there exist $c_1, \varepsilon_1 > 0$ such that the fundamental solution matrix (with a size of $n^2 \times n^2$) of the linear ODE (2.10), denoted by $M(t) \triangleq (m_{ij}(t))$, satisfies

$$|M(t)| = \left(\sum_{i,j} |m_{ij}(t)|^2\right)^{\frac{1}{2}} \le c_1 e^{-\varepsilon_1 t} \quad \forall t \in [0, +\infty). \tag{2.11}$$

By Young's inequality there exists a constant $c_2 > 0$ (independent of $t \in [0, +\infty)$) such that $Y(t)$ defined by (2.8) satisfies

$$|Y(t)| \le \frac{\varepsilon_1}{2c_1}|X(t)| + c_2 E|u(t)|^2 \quad \forall t \in [0, +\infty). \tag{2.12}$$

Hence, using the variation-of-constant formula, it follows from (2.11) and (2.12) that

the solution $X(\cdot)$ to (2.7) satisfies

$$\begin{aligned}|X(t)| &\le c_1 e^{-\varepsilon_1 t}|X(0)| + c_1 \int_0^t e^{-\varepsilon_1(t-s)}|Y(s)|\,ds \\ &\le c_1 e^{-\varepsilon_1 t}|X(0)| + c_1 c_2 \int_0^t e^{-\varepsilon_1(t-s)} E|u(s)|^2\,ds \\ &\quad + \frac{\varepsilon_1}{2}\int_0^t e^{-\varepsilon_1(t-s)}|X(s)|\,ds.\end{aligned}$$

Integrating from 0 to $j \in [0, +\infty)$ and employing Fubini's theorem, we obtain

$$\begin{aligned}\int_0^j |X(t)|\,dt &\le \frac{c_1}{\varepsilon_1}|X(0)| + c_1 c_2 \int_0^j \int_0^t e^{-\varepsilon_1(t-s)} E|u(s)|^2\,ds\,dt \\ &\quad + \frac{\varepsilon_1}{2}\int_0^j \int_0^t e^{-\varepsilon_1(t-s)}|X(s)|\,ds\,dt \\ &\le \frac{c_1}{\varepsilon_1}\left[|X(0)| + c_2 \int_0^{+\infty} E|u(t)|^2\,dt\right] + \frac{1}{2}\int_0^j |X(t)|\,dt.\end{aligned}$$

Noticing the arbitrariness of j and the fact that

$$\|x(\cdot)\|^2_{L^2_{\mathcal{F}}(\mathbb{R}^n)} = \int_0^{+\infty} \operatorname{Tr} X(t)\,dt,$$

we have, for some constant $k > 0$,

$$\|x(\cdot)\|_{L^2_{\mathcal{F}}(\mathbb{R}^n)} \le k[|x_0| + \|u(\cdot)\|_{L^2_{\mathcal{F}}(\mathbb{R}^m)}]. \tag{2.13}$$

This completes the proof. □

In view of Lemma 2.2, from now on we shall use $\mathcal{U}(x_0)$ and $L^2_{\mathcal{F}}(\mathbb{R}^m)$ interchangeably.

3. Frequency characteristic. Since A is a Hurwitz matrix (see Remark 2.3), the complex matrix-valued function

$$g(\lambda) \triangleq (i\lambda I - A)^{-1} \tag{3.1}$$

is well defined for any $\lambda \in \mathbb{R}$.

Now introduce the following matrix equation with the unknown Θ being a symmetric matrix:

$$\Theta = Q + \frac{1}{2\pi}\int_{-\infty}^{+\infty} C^T g(-\lambda)^T \Theta g(\lambda) C\,d\lambda. \tag{3.2}$$

This is a linear algebraic equation whose solvability is interesting in its own right. We shall study the solvability of this equation at the end of this section.

Suppose that (3.2) is solvable with a solution Θ. Define a complex matrix-valued function

$$\begin{aligned}\hat{\Phi}(\lambda) \triangleq & R + \frac{1}{2\pi} D^T \int_{-\infty}^{+\infty} g(-\lambda)^T \Theta g(\lambda)\,d\lambda D + B^T g(-\lambda)^T \Theta g(\lambda) B \\ & + B^T g(-\lambda)^T \left[S^T + \frac{1}{2\pi} C^T \int_{-\infty}^{+\infty} g(-\lambda)^T \Theta g(\lambda)\,d\lambda D\right] \\ & + \left[S + \frac{1}{2\pi} D^T \int_{-\infty}^{+\infty} g(-\lambda)^T \Theta g(\lambda)\,d\lambda C\right] g(\lambda) B \quad \forall \lambda \in \mathbb{R}.\end{aligned} \tag{3.3}$$

The above $\hat{\Phi}(\lambda)$ is called the frequency characteristic of Problem (LQ), which can be computed explicitly through the given parameters of the original stochastic LQ problem. Note that when $C = 0$ and $D = 0$, by Proposition 3.1(i) below, this frequency characteristic coincides with that in the deterministic case (see [16],[17],[18],[19]):

$$\hat{\Phi}(\lambda) \triangleq R + B^T g(-\lambda)^T Q g(\lambda) B + B^T g(-\lambda)^T S^T + S g(\lambda) B \quad \forall \lambda \in \mathbb{R}. \tag{3.4}$$

Let us now turn to the solvability of (3.2). First we investigate the scalar case.

Example 3.1. Consider Problem (LQ), where the state and control variables are both scalar. It is easy to verify that the solution $x(\cdot)$ to the uncontrolled system (2.1) satisfies $Ex(t)^2 = e^{(2A+C^2)t}x_0^2$. By the stability assumption (A2), we must have $2A + C^2 < 0$. On the other hand, (3.2) reduces to

$$\Theta = Q + \frac{1}{2\pi}\int_{-\infty}^{+\infty} \frac{C^2}{\lambda^2 + A^2} d\lambda \cdot \Theta = Q - \frac{C^2}{2A}\Theta.$$

This equation has a unique solution

$$\Theta = \frac{Q}{1 + \frac{C^2}{2A}} = \frac{2AQ}{2A + C^2}.$$

It is interesting to note that Θ and Q always have the same signs. Moreover, $\Theta \geq Q$ if and only if $Q \geq 0$.

For the general multidimensional case, we are now giving equivalent algebraic conditions for (3.2) to have solutions and a unique solution, respectively. First, with an $n \times n$ matrix $X = (x_{ij})$ we associate the n^2-dimensional column vector vec X defined by

$$\text{vec } X \triangleq (x_{11}, \dots, x_{n1}, x_{12}, \dots, x_{n2}, \dots, x_{1n}, \dots, x_{nn})^T.$$

Next, recall that for two $n \times n$ matrices $X = (x_{ij})$ and $Y = (y_{ij})$ we define the Kronecker product, denoted by $X \otimes Y$, by

$$X \otimes Y \triangleq \begin{pmatrix} x_{11}Y & \cdots & x_{1n}Y \\ \vdots & \cdots & \vdots \\ x_{n1}Y & \cdots & x_{nn}Y \end{pmatrix}.$$

THEOREM 3.1. *Equation* (3.2) *admits solutions if and only if*

$$\text{rank } (\Gamma \ \text{ vec } Q) = \text{rank } \Gamma,$$

where the $n^2 \times n^2$ *matrix* Γ *is given by*

$$\Gamma \triangleq I - \frac{1}{2\pi}\int_{-\infty}^{+\infty} (C^T g(\lambda)^T) \otimes (C^T g(-\lambda)^T) d\lambda.$$

Moreover, (3.2) *admits a unique solution if and only if* Γ *is nonsingular.*

Proof. Vectorizing both sides of (3.2) and noting the general formula vec $(XYZ) = (Z^T \otimes X)$vec Y (see p. 254, Lemma 4.3.1 of [8]), we have

$$\text{vec } \Theta = \text{vec } Q + \frac{1}{2\pi}\int_{-\infty}^{+\infty} (C^T g(\lambda)^T) \otimes (C^T g(-\lambda)^T) d\lambda \text{ vec } \Theta.$$

The desired results follow immediately. □

The following proposition further gives two easily verifiable *sufficient* conditions for the unique solvability of (3.2).

PROPOSITION 3.1. *Equation* (3.2) *admits a unique solution* Θ *in either of the following two cases.*

(i) $C = 0$ *(in which case* $\Theta = Q$*).*

(ii) A *and* C *satisfy*

$$\frac{1}{2\pi}\int_{-\infty}^{+\infty} |C^T g(-\lambda)^T||g(\lambda)C|\, d\lambda < 1.$$

Proof. Case (i) is straightforward. For (ii), denote by $\mathcal{S}^n$ the space of $n \times n$ symmetric matrices. Define a mapping $\mathcal{T} : \mathcal{S}^n \mapsto \mathcal{S}^n$ as follows:

$$\mathcal{T}\Theta \triangleq Q + \frac{1}{2\pi}\int_{-\infty}^{+\infty} C^T g(-\lambda)^T \Theta g(\lambda) C\, d\lambda \quad \forall \Theta \in \mathcal{S}^n.$$

The conclusion then follows immediately from the contraction mapping theorem. □

It should be noted that the case $C = 0$ is typically encountered in financial applications (see, e.g., [10, 22]).

4. Frequency characteristic and bilinear form. It is well known that an optimal LQ problem can be formulated as an optimization problem of a bilinear form in a Hilbert space. This formulation, in turn, gives insight on the LQ problem from the viewpoint of convex analysis in infinite dimensions. This section establishes the relation between the frequency characteristic and the bilinear form.

Define the bounded bilinear operators Φ and Γ on $L^2_{\mathcal{F}}(\mathbb{R}^m)$ and $\mathbb{R}^n$, respectively, as

$$\begin{aligned}\Phi(u(\cdot), v(\cdot)) \triangleq & E\int_0^{+\infty} [x(t;0,u(\cdot))^T Q x(t;0,v(\cdot)) + u(t)^T S x(t;0,v(\cdot)) \\ & + x(t;0,u(\cdot))^T S^T v(t) + u(t)^T R v(t)]\, dt \quad \forall u(\cdot), v(\cdot) \in \mathcal{U}(0),\end{aligned} \tag{4.1}$$

and

$$\Gamma(x_0) \triangleq E\int_0^{+\infty} x(t;x_0,0)^T Q x(t;x_0,0)\, dt. \tag{4.2}$$

Further, define the bounded bilinear operator Ψ on $L^2_{\mathcal{F}}(\mathbb{R}^m) \times \mathbb{R}^n$ by

$$\Psi(u(\cdot), x_0) \triangleq E\int_0^{+\infty} [x(t;0,u(\cdot))^T Q x(t;x_0,0) + u(t)^T S x(t;x_0,0)]\, dt. \tag{4.3}$$

The boundedness of the operators Φ, Γ, and Ψ follows from (2.13).

Then, the cost functional (2.2) can be represented as

$$J(x_0; u(\cdot)) = \Phi(u(\cdot), u(\cdot)) + 2\Psi(u(\cdot), x_0) + \Gamma(x_0). \tag{4.4}$$

Clearly, the first term on the right-hand side of (4.4), namely, the bilinear operator Φ, is crucial in determining the well-posedness and solvability of the optimization problem. To link the bilinear form introduced above to the frequency characteristic, we need to first recall the Fourier transformation on Hilbert spaces.

Let $Z \triangleq L^2(\Omega, \mathcal{F}, \mathcal{P}; \mathbb{R}^k)$ be the Hilbert space equipped with the inner product $\int_\Omega \phi(\omega)^T \psi(\omega) \mathcal{P}(\, d\omega)$ for any $\phi, \psi \in Z$. For $\phi(\cdot) \in L^2(-\infty, +\infty; Z)$, define its Fourier transformation as

$$\tilde{\phi}(\lambda) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} e^{-i\lambda t} \phi(t)\, dt \quad \forall \lambda \in \mathbb{R}. \tag{4.5}$$

If we denote

$$\tilde{\phi}_\alpha(\lambda) = \frac{1}{\sqrt{2\pi}} \int_{-\alpha}^{\alpha} e^{-i\lambda t} \phi(t)\, dt \quad \forall \lambda \in \mathbb{R}, \tag{4.6}$$

then obviously we have

$$\|\tilde{\phi}_\alpha(\cdot) - \tilde{\phi}(\cdot)\|_{L^2(-\infty, +\infty; Z)} \to 0 \tag{4.7}$$

as $\alpha \to +\infty$.

Now we turn to our system (2.1). For any $x(\cdot) \in L^2_{\mathcal{F}}(\mathbb{R}^n)$, we set $x(t) = 0$ for $t < 0$. We augment $u(\cdot) \in \mathcal{U}(0)$ in a similar way. In other words, we have the natural embedding $L^2_{\mathcal{F}}(\mathbb{R}^n) \subset L^2(-\infty, \infty; L^2(\Omega, \mathcal{F}, \mathcal{P}; \mathbb{R}^n))$ and $\mathcal{U}(0) \subset L^2(-\infty, \infty; L^2(\Omega, \mathcal{F}, \mathcal{P}; \mathbb{R}^m))$.

The following result, which represents the bilinear form through the frequency characteristic, plays a central role in this paper.

PROPOSITION 4.1. *Assume that the matrix equation* (3.2) *is solvable with a solution* Θ. *Then*

$$\Phi(u(\cdot), u(\cdot)) = E \int_{-\infty}^{+\infty} \tilde{u}(\lambda)^* \hat{\Phi}(\lambda) \tilde{u}(\lambda)\, d\lambda, \tag{4.8}$$

where Φ *and* $\hat{\Phi}(\lambda)$, $\lambda \in \mathbb{R}$, *are defined by* (4.1) *and* (3.3), *respectively.*

Proof. For $u(\cdot) \in \mathcal{U}(0)$, the system (2.1) with $x_0 = 0$ yields

$$\begin{aligned} &\int_0^\alpha e^{-i\lambda t}[Ax(t) + Bu(t)]\, dt + \int_0^\alpha e^{-i\lambda t}[Cx(t) + Du(t)]\, dw(t) \\ &= \int_0^\alpha e^{-i\lambda t}\, dx(t) = i\lambda \int_0^\alpha e^{-i\lambda t} x(t)\, dt + e^{-i\lambda\alpha} x(\alpha). \end{aligned}$$

It follows that

$$\tilde{x}_\alpha(\lambda) = (i\lambda - A)^{-1} \left[B\tilde{u}_\alpha(\lambda) + f_\alpha(\lambda) - \frac{1}{\sqrt{2\pi}} e^{-i\lambda\alpha} x(\alpha) \right], \tag{4.9}$$

where

$$f_\alpha(\lambda) = \frac{1}{\sqrt{2\pi}} \int_0^\alpha e^{-i\lambda t}[Cx(t) + Du(t)]\, dw(t), \quad g(\lambda) = (i\lambda I - A)^{-1}.$$

Now, for any symmetric matrix H,

$$\begin{aligned} E[\tilde{x}_\alpha(\lambda)^* H \tilde{x}_\alpha(\lambda)] = E \Big\{ &[g(\lambda) B\tilde{u}_\alpha(\lambda)]^* H g(\lambda) B\tilde{u}_\alpha(\lambda) \\ &- \frac{2}{\sqrt{2\pi}} \operatorname{Re}\{[g(\lambda) B\tilde{u}_\alpha(\lambda)]^* H g(\lambda) e^{-i\lambda\alpha} x(\alpha)\} \\ &+ \frac{1}{2\pi} [g(\lambda) e^{-i\lambda\alpha} x(\alpha)]^* H g(\lambda) e^{-i\lambda\alpha} x(\alpha) \\ &+ [g(\lambda) f_\alpha(\lambda)]^* H g(\lambda) f_\alpha(\lambda) \Big\}. \end{aligned} \tag{4.10}$$

Hence, for $\beta > 0$,

$$\begin{aligned}\int_{-\beta}^{\beta} E[\tilde{x}_\alpha(\lambda)^* H \tilde{x}_\alpha(\lambda)]\, d\lambda &= \int_{-\beta}^{\beta} E[\tilde{u}_\alpha(\lambda)^* B^T g(-\lambda)^T H g(\lambda) B \tilde{u}_\alpha(\lambda)]\, d\lambda \\ &\quad + \int_{-\beta}^{\beta} E\{[g(\lambda) f_\alpha(\lambda)]^* H g(\lambda) f_\alpha(\lambda)\}\, d\lambda + \rho(\alpha, \beta),\end{aligned} \tag{4.11}$$

where $\rho(\alpha, \beta)$ includes all the remainder terms. Noting that $\|x(\alpha)\|_{L^2(\Omega, \mathcal{F}, \mathcal{P}; \mathbb{R}^n)} \to 0$ as $\alpha \to +\infty$ due to Lemma 2.1, that $|g(\lambda)|$ is uniformly bounded due to the stability of (2.1), and that $|g(\lambda) B \tilde{u}_\alpha(\lambda)|$ is uniformly bounded due to (4.7), we conclude that $\rho(\alpha, \beta)$ converges to zero uniformly in β as $\alpha \to +\infty$.

By Itô's formula, we have

$$\begin{aligned}&\int_{-\beta}^{\beta} E\{[g(\lambda) f_\alpha(\lambda)]^* H g(\lambda) f_\alpha(\lambda)\}\, d\lambda \\ &= \int_{-\alpha}^{\alpha} E\left\{ [Cx(t) + Du(t)]^T \left[\frac{1}{2\pi} \int_{-\beta}^{\beta} g(-\lambda)^T H g(\lambda)\, d\lambda \right] [Cx(t) + Du(t)] \right\} dt.\end{aligned} \tag{4.12}$$

Letting $\alpha \to +\infty$ and $\beta \to +\infty$ in (4.11) and (4.12) and appealing to Parseval's equality, we obtain

$$\begin{aligned}&E \int_0^{+\infty} x(t)^T H x(t)\, dt = \frac{1}{2\pi} E \int_{-\infty}^{+\infty} \tilde{x}(\lambda)^* H \tilde{x}(\lambda)\, d\lambda \\ &= \frac{1}{2\pi} E \int_{-\infty}^{+\infty} \tilde{u}(\lambda)^* B^T g(-\lambda)^T H g(\lambda) B \tilde{u}(\lambda)\, d\lambda \\ &\quad + \frac{1}{2\pi} E \int_0^{+\infty} [Cx(t) + Du(t)]^T \left(\int_{-\infty}^{+\infty} g(-\lambda)^T H g(\lambda)\, d\lambda \right) [Cx(t) + Du(t)] dt.\end{aligned} \tag{4.13}$$

Similarly, it follows from (4.7), (4.9), and Lemma 2.1 that

$$E \int_0^{+\infty} u(t)^T S x(t)\, dt = \frac{1}{2\pi} E \int_0^{+\infty} \tilde{u}(\lambda)^* S g(\lambda) B \tilde{u}(\lambda)\, d\lambda. \tag{4.14}$$

Finally, Parseval's equality yields

$$E \int_0^{+\infty} u(t)^T R u(t)\, dt = \frac{1}{2\pi} E \int_{-\infty}^{+\infty} \tilde{u}(\lambda)^* R \tilde{u}(\lambda)\, d\lambda. \tag{4.15}$$

Combining (4.13), (4.14), and (4.15) and noting that Θ satisfies (3.2), we arrive at (4.8). □

THEOREM 4.1. *If there exists some constant $\sigma > 0$ such that*

$$\hat{\Phi}(\lambda) \geq \sigma I \quad \forall \lambda \in \mathbb{R}, \tag{4.16}$$

then

$$\Phi(u(\cdot), u(\cdot)) \geq \sigma E \int_0^{+\infty} |u(t)|^2\, dt \qquad \forall u(\cdot) \in L^2_{\mathcal{F}}(\mathbb{R}^m). \tag{4.17}$$

As a consequence, Problem (LQ) *is uniquely solvable at any initial state* $x_0 \in \mathbb{R}^n$.

Proof. It follows from (4.8) that

$$\Phi(u(\cdot),u(\cdot)) \geq \sigma E \int_{-\infty}^{+\infty} \tilde{u}(\lambda)^* \tilde{u}(\lambda)\, d\lambda = \sigma \|u(\cdot)\|^2_{L^2_{\mathcal{F}}(\mathbb{R}^m)}.$$

This coercivity of the bilinear form Φ further implies (see, e.g., [18, Lemma 1] or [21, Chapter 6, Theorem 4.2]) that Problem (LQ) is uniquely solvable at any initial state x_0. □

5. Riccati equation and LQ control. The Riccati equation is the primary approach in dealing with LQ problems. In this section we present the equivalent relation between the unique solvability of Problem (LQ) and the solvability of the following stochastic algebraic Riccati equation (SARE) introduced in [1]:

$$\begin{cases} A^TP + PA + C^TPC + Q \\ \qquad - (S^T + PB + C^TPD)(R + D^TPD)^{-1}(S + B^TP + D^TPC) = 0, \\ R + D^TPD > 0. \end{cases} \tag{5.1}$$

It should be noted that the second (positive definiteness) constraint in (5.1) is *part* of the equation and must be satisfied by any solution. This in turn gives rise to additional difficulty in solving the equation.

To cope with the possible singularity of $R + D^TPD$, we need to employ the notion of the pseudoinverse of a matrix. To be specific, for any matrix M, there exists a unique matrix $M^\dagger$ satisfying the following properties:

$$MM^\dagger M = M,\ \ M^\dagger MM^\dagger = M^\dagger,\ \ (M^\dagger M)^T = M^\dagger M,\ \ (MM^\dagger)^T = MM^\dagger. \tag{5.2}$$

$M^\dagger$ is called the Moore–Penrose pseudoinverse (see [12]) of M. When M is nonsingular, the pseudoinverse coincides with the usual inverse, i.e., $M^\dagger = M^{-1}$.

The generalized version of the SARE (5.1), when the matrix $R+D^TPD$ is allowed to be singular, is the following generalized algebraic Riccati equation (GARE), which was first introduced in [2]:

$$\begin{cases} \mathcal{M}(P) - \mathcal{L}(P)^T \mathcal{N}(P)^\dagger \mathcal{L}(P) = 0, \\ [I - \mathcal{N}(P)^\dagger \mathcal{N}(P)]\mathcal{L}(P) = 0, \\ \mathcal{N}(P) \geq 0, \end{cases} \tag{5.3}$$

where

$$\begin{cases} \mathcal{M}(P) \triangleq A^TP + PA + C^TPC + Q, \\ \mathcal{N}(P) \triangleq R + D^TPD, \\ \mathcal{L}(P) \triangleq S + B^TP + D^TPC. \end{cases} \tag{5.4}$$

LEMMA 5.1. *If Problem* (LQ) *is solvable at any* $x_0 \in \mathbb{R}$, *then the GARE* (5.3) *has a solution* $P = P^T$ *satisfying*

$$\inf_{u(\cdot)\in\mathcal{U}(x_0)} J(x_0;u(\cdot)) = x_0^TPx_0. \tag{5.5}$$

Proof. This is shown in the proof of [2, Theorem 4.1]. □

THEOREM 5.1. *Problem* (LQ) *is uniquely solvable at any initial state* $x_0 \in \mathbb{R}^n$ *if and only if the SARE* (5.1) *has one and only one such solution* $P = P^T$ *that the associated feedback operator*

$$\widetilde{K} \triangleq -(R + D^T P D)^{-1}[S + B^T P + D^T P C] \tag{5.6}$$

is (mean-square) stabilizing.

Proof. The "if" part is an immediate consequence of [2, Theorems 2.1, 4.1]. We now prove the "only if" part. By Lemma 5.1, the GARE (5.3) admits a solution $P = P^T$ satisfying (5.5). Let $u(\cdot) \in \mathcal{U}(x_0)$ be any admissible control, and let $x(\cdot) \in L^2_{\mathcal{F}}(\mathbb{R}^n)$ be the corresponding state trajectory. By applying Itô's formula to $x(t)^T P x(t)$ and integrating from 0 to $+\infty$, and then by combining it with the cost functional (2.2), we obtain

$$\begin{aligned} J(x_0; u(\cdot)) =& x_0^T P x_0 \\ &+ E \int_0^{+\infty} \{x(t)^T \mathcal{M}(P) x(t) + 2u(t)^T \mathcal{L}(P) x(t) + u(t)^T \mathcal{N}(P) u(t)\}\, dt. \end{aligned} \tag{5.7}$$

First, we show that

$$\mathcal{N}(P) \neq 0. \tag{5.8}$$

In fact, if $\mathcal{N}(P) = 0$, then the GARE (5.3) is reduced to

$$\mathcal{M}(P) = 0,\ \mathcal{L}(P) = 0,\ \mathcal{N}(P) = 0.$$

Hence it follows from (5.7) that

$$J(x_0; u(\cdot)) = 0 \qquad \forall u(\cdot) \in L^2_{\mathcal{F}}(\mathbb{R}^m),$$

which implies that any $u(\cdot) \in L^2_{\mathcal{F}}(\mathbb{R}^m)$ is optimal. This contradicts the assumption of the unique solvability of Problem (LQ), which proves (5.8).

Next we prove that $\mathcal{N}(P)$ is nonsingular. Indeed, if $\mathcal{N}(P) \neq 0$ is singular, then there is a symmetric matrix V with $VV^T = V^T V = I$ such that

$$\mathcal{N}(P) = V \begin{pmatrix} \Sigma & 0 \\ 0 & 0 \end{pmatrix} V^T, \tag{5.9}$$

where Σ is a positive definite diagonal matrix of order r with $0 < r < m$. Moreover,

$$\mathcal{N}(P)^\dagger = V \begin{pmatrix} \Sigma^{-1} & 0 \\ 0 & 0 \end{pmatrix} V^T. \tag{5.10}$$

Define $v(\cdot) \triangleq V^T u(\cdot)$. It follows from (5.7) and the GARE (5.3) that

$$\begin{aligned} J(x_0; u(\cdot)) &= x_0^T P x_0 + E \int_0^{+\infty} \left\{ x(t)^T \mathcal{L}(P)^T V \begin{pmatrix} \Sigma^{-1} & 0 \\ 0 & 0 \end{pmatrix} V^T \mathcal{L}(P) x(t) \right. \\ &\qquad \left. + 2v(t)^T V^T \mathcal{L}(P) x(t) + v(t)^T \begin{pmatrix} \Sigma & 0 \\ 0 & 0 \end{pmatrix} v(t) \right\} dt \\ &= x_0^T P x_0 + E \int_0^{+\infty} |(\Sigma^{\frac{1}{2}} \ \ 0)_{r\times m} v(t) + (\Sigma^{-\frac{1}{2}} \ \ 0)_{r\times m} V^T \mathcal{L}(P) x(t)|^2\, dt. \end{aligned} \tag{5.11}$$

Note that in equating the cross term of $v(t)$ and $x(t)$ in the last equality above, we have used the second equality of (5.3) as well as (5.9)–(5.10). In view of (5.5), $u(\cdot) \in L^2_{\mathcal{F}}(\mathbb{R}^m)$ is an optimal control of Problem (LQ) at $x_0 \in \mathbb{R}^n$ if and only if the integrand on the right-hand side of (5.11) is zero, i.e.,

$$u(\cdot) = Vv(\cdot) \equiv V\begin{pmatrix} v_r(\cdot) \\ v_{m-r}(\cdot) \end{pmatrix} = -V\begin{pmatrix} (\Sigma^{-1} \ \ 0)_{r\times m} V^T \mathcal{L}(P)x(\cdot) \\ v_{m-r}(\cdot) \end{pmatrix}, \tag{5.12}$$

where $v_{m-r}(\cdot) \in L^2_{\mathcal{F}}(\mathbb{R}^{m-r})$. With the above control, the dynamics (2.1) is reduced to

$$\begin{cases} dx(t) = [A_1 x(t) + B_1 v_{m-r}(t)]dt + [C_1 x(t) + D_1 v_{m-r}(t)]dw(t), \\ x(0) = x_0 \in \mathbb{R}^n, \end{cases} \tag{5.13}$$

where

$$\begin{cases} A_1 \triangleq A - B\mathcal{N}(P)^\dagger \mathcal{L}(P), \quad C_1 \triangleq C - D\mathcal{N}(P)^\dagger \mathcal{L}(P), \\ B_1 \triangleq -BV\begin{pmatrix} 0_{r\times(m-r)} \\ I_{(m-r)\times(m-r)} \end{pmatrix}, \quad D_1 \triangleq -DV\begin{pmatrix} 0_{r\times(m-r)} \\ I_{(m-r)\times(m-r)} \end{pmatrix}. \end{cases}$$

The above argument shows that any $v_{m-r}(\cdot) \in L^2_{\mathcal{F}}(\mathbb{R}^{m-r})$ applied to the system (5.13), as long as the corresponding state $x(\cdot) \in L^2_{\mathcal{F}}(\mathbb{R}^n)$, provides an optimal control for the original Problem (LQ) via (5.12). Now we are going to show that there are more than one such $v_{m-r}(\cdot)$. First note that at this point we *cannot* directly conclude the stabilizability of system (5.13) from that of system (2.1) because (5.13) is "smaller" than (2.1) in the sense that the admissible controls for (5.13) are confined to the form specified by (5.12). To get around this, let $(\bar{u}(\cdot), \bar{x}(\cdot)) \in L^2_{\mathcal{F}}(\mathbb{R}^m) \times L^2_{\mathcal{F}}(\mathbb{R}^n)$ be an optimal pair for the original Problem (LQ) at an initial x_0, which exists by assumption, and let $\bar{v}(\cdot) \equiv \binom{\bar{v}_r(\cdot)}{\bar{v}_{m-r}(\cdot)} = V^T \bar{u}(\cdot)$. Then it follows from (5.12) that

$$\bar{u}(\cdot) = -V\begin{pmatrix} (\Sigma^{-1} \ \ 0)_{r\times m} V^T \mathcal{L}(P)^T \bar{x}(\cdot) \\ \bar{v}_{m-r}(\cdot) \end{pmatrix},$$

where $\bar{v}_{m-r}(\cdot) \in L^2_{\mathcal{F}}(\mathbb{R}^{m-r})$. This implies that $\bar{x}(\cdot) \in L^2_{\mathcal{F}}(\mathbb{R}^n)$ is the trajectory to (5.13) under the admissible control $\bar{v}_{m-r}(\cdot) \in L^2_{\mathcal{F}}(\mathbb{R}^{m-r})$. Therefore, the set of admissible controls for (5.13) is nonempty at any initial state x_0. By Theorems 4.1 and 4.2 in [13], the SARE

$$\begin{aligned} &A_1^T P + PA_1 + C_1^T PC_1 + I \\ &\quad - (PB_1 + C_1^T PD_1)(I + D_1^T PD_1)^{-1}(B_1^T P + D_1^T PC_1) = 0 \end{aligned}$$

admits a solution $P_1 = P_1^T$ such that

$$\widetilde{K} \triangleq -(I + D_1^T P_1 D_1)^{-1}[B_1^T P_1 + D_1^T P_1 C_1]$$

is a stabilizing feedback operator. In other words, system (5.13) is stabilizable. Using the same argument as that in the proof of Lemma 2.2, we can show that the state $x(\cdot)$ of (5.13) corresponding to the control $v_{m-r}(\cdot) = Kx(\cdot) + \xi(\cdot)$, where $\xi(\cdot) \in L^2_{\mathcal{F}}(\mathbb{R}^{m-r})$ is arbitrary, must satisfy $x(\cdot) \in L^2_{\mathcal{F}}(\mathbb{R}^n)$. This implies that the original Problem (LQ) has more than one optimal control, which is a contradiction. Therefore, $\mathcal{N}(P)$ must be nonsingular. The desired results then follow from the fact that in this case the two Riccati equations, SARE (5.1) and GARE (5.3), coincide, and the optimal feedback operator given in (5.12) degenerates to (5.6). Finally, the uniqueness of such a solution P to (5.1) that (5.6) is stabilizing follows from [2, Theorem 2.3]. □

6. Frequency characteristic and LQ control. In this section, to close the loop of equivalence we establish the relationship between the frequency characteristic and LQ control. Throughout the section we assume that the matrix equation (3.2) is solvable.

PROPOSITION 6.1. *The cost functional* (2.2) *can be represented as*

$$J(x_0;u(\cdot)) = E\int_{-\infty}^{+\infty}\{\tilde{u}(\lambda)^*\hat{\Phi}(\lambda)\tilde{u}(\lambda) + 2\,\mathrm{Re}[\tilde{u}(\lambda)^*\hat{\Psi}(\lambda)x_0]\}\,d\lambda + \Gamma(x_0), \tag{6.1}$$

where

$$\hat{\Psi}(\lambda) \triangleq \left[B^T g(-\lambda)^T\Theta + \frac{1}{2\pi}D^T\int_{-\infty}^{+\infty} g(-\lambda)^T\Theta g(\lambda)\,d\lambda C + S\right] g(\lambda). \tag{6.2}$$

Proof. Similar to the argument in section 4, it follows from (4.7), (4.9), and Lemma 2.1 that

$$\begin{aligned} E\int_0^{+\infty} x(t;0,u(\cdot))^T\Theta x(t;x_0,0)\,dt &= E\int_{-\infty}^{+\infty}\tilde{u}(\lambda)^*B^Tg(-\lambda)^T\Theta g(\lambda)x_0\,d\lambda \\ &+ \frac{1}{2\pi}E\int_0^{+\infty}[Cx(t;0,u(\cdot)) + Du(t)]^T\int_{-\infty}^{+\infty} g(-\lambda)^T\Theta g(\lambda)\,d\lambda Cx(t;x_0,0)\,dt. \end{aligned}$$

Moreover, for any matrix $H \in \mathbb{R}^{m\times n}$,

$$E\int_0^{+\infty} u(t)^THx(t;x_0,0)\,dt = E\int_{-\infty}^{+\infty}\tilde{u}(\lambda)^*Hg(\lambda)x_0\,d\lambda.$$

Therefore,

$$\begin{aligned} &E\int_0^{+\infty} x(t;0,u)^TQx(t;x_0,0)\,dt \\ &= E\int_{-\infty}^{+\infty}\tilde{u}(\lambda)^*\left[B^Tg(-\lambda)^T\Theta + \frac{1}{2\pi}D^T\int_{-\infty}^{+\infty} g(-\lambda)^T\Theta g(\lambda)\,d\lambda C\right] g(\lambda)x_0\,d\lambda. \end{aligned}$$

We can then conclude from (4.3) that

$$\begin{aligned} &\Psi(u(\cdot),x_0) \\ &= E\int_{-\infty}^{+\infty}\tilde{u}(\lambda)^*\left[B^Tg(-\lambda)^T\Theta + \frac{1}{2\pi}D^T\int_{-\infty}^{+\infty} g(-\lambda)^T\Theta g(\lambda)\,d\lambda C + S\right] g(\lambda)x_0\,d\lambda. \end{aligned} \tag{6.3}$$

The desired result therefore follows from (4.1)–(4.4), (4.8), and (6.3). ∎

Next, based on the frequency characteristic, we construct an auxiliary stochastic LQ problem that does not have a diffusion part but is equivalent to the original stochastic LQ problem. To do this, define

$$\begin{aligned} &Q_1 \triangleq \Theta, \qquad S_1 \triangleq S + \frac{1}{2\pi}D^T\int_{-\infty}^{+\infty} g(-\lambda)^T\Theta g(\lambda)\,d\lambda C, \\ &R_1 \triangleq R + \frac{1}{2\pi}D^T\int_{-\infty}^{+\infty} g(-\lambda)^T\Theta g(\lambda)\,d\lambda D. \end{aligned} \tag{6.4}$$

Construct the following LQ problem with the cost functional

$$\bar{J}(x_0;u(\cdot)) = E\int_0^{+\infty} [x(t)^T Q_1 x(t) + 2u(t)^T S_1 x(t) + u(t)^T R_1 u(t)]\,dt, \tag{6.5}$$

subject to the dynamics

$$\begin{cases} \dfrac{d}{dt}x(t) = Ax(t) + Bu(t), \\ x(0) = x_0 \in \mathbb{R}^n, \end{cases} \tag{6.6}$$

where the admissible control set is $L^2_{\mathcal{F}}(\mathbb{R}^m)$.

From the way we constructed the LQ problem (6.5)–(6.6), it is clear that the problem has the same frequency characteristic as that of the original Problem (LQ). By an analogous argument to those in section 4 and the above in this section, it holds that

$$\bar{J}(x_0;u(\cdot)) = E\int_{-\infty}^{+\infty} \{\tilde{u}(\lambda)^*\hat{\Phi}(\lambda)\tilde{u}(\lambda) + 2\,\mathrm{Re}[\tilde{u}(\lambda)^*\hat{\Psi}(\lambda)x_0]\}\,d\lambda + \Gamma_1(x_0), \tag{6.7}$$

where

$$\Gamma_1(x_0) \triangleq E\int_0^{+\infty} x(t;x_0,0)^T Q_1 x(t;x_0,0)\,dt \tag{6.8}$$

for the solution $x(\cdot;x_0,0)$ of (6.6) with $u(\cdot)=0$.

LEMMA 6.1. *The LQ problem* (2.1)–(2.2) *is uniquely solvable at any* x_0 *if and only if the LQ problem* (6.5)–(6.6) *is uniquely solvable at any* x_0.

Proof. In view of (6.1) and (6.7), $J(x_0;u(\cdot))$ and $\bar{J}(x_0;u(\cdot))$ differ by a term which does not depend on the control variable $u(\cdot)$. The result then follows. □

Remark 6.1. Lemma 6.1 is of significant implications on its own. It suggests that the original Problem (LQ) is in fact equivalent to the auxiliary LQ problem (6.5)–(6.6) whose diffusion part in the dynamics is absent while the cost parameters are modified. More specifically, one can transfer the diffusion part (corresponding to the uncertainty/risk) of a stochastic system to the cost part. The new cost can be precisely calculated according to (6.4), which in turn draws the boundary of the possible indefiniteness of the original LQ problem. See Example 7.1 below for more details.

LEMMA 6.2. *If the LQ problem* (6.5)–(6.6) *is uniquely solvable at any initial state* $x_0 \in \mathbb{R}^n$, *then* $R_1 > 0$, *and the Riccati equation*

$$A^T P + PA + Q_1 - [B^T P + S_1]^T R_1^{-1}[B^T P + S_1] = 0 \tag{6.9}$$

admits a solution P_1 *with the matrix*

$$A - BR_1^{-1}[B^T P_1 + S_1] \tag{6.10}$$

being Hurwitz.

Proof. This follows from Theorem 5.1, in view of the fact that the LQ problem (6.5)–(6.6) is a special case of the original Problem (LQ). □

LEMMA 6.3. *Assume that the LQ problem* (6.5)–(6.6) *is uniquely solvable at any initial state* $x_0 \in \mathbb{R}^n$. *Then*

$$\hat{\Phi}(\lambda) = [I + E(\lambda)^*]R_1[I + E(\lambda)], \tag{6.11}$$

where

$$E(\lambda) \triangleq R_1^{-1}[B^T P_1 + S_1](i\lambda - A)^{-1}B. \tag{6.12}$$

Moreover, it holds that

$$I + E(\lambda) = [I - G(\lambda)B]^{-1} \tag{6.13}$$

with

$$G(\lambda) \triangleq R_1^{-1}[B^T P_1 + S_1]\{i\lambda - A + BR_1^{-1}[B^T P_1 + S_1]\}^{-1}. \tag{6.14}$$

Proof. It follows from (3.3) and (6.4) that

$$\begin{aligned}\hat{\Phi}(\lambda) = {} & R_1 + B^T(-i\lambda - A^T)^{-1}Q_1(i\lambda - A)^{-1}B \\ & + B^T(-i\lambda - A^T)^{-1}S_1^T + S_1(i\lambda - A)^{-1}B \quad \forall \lambda \in \mathbb{R}.\end{aligned} \tag{6.15}$$

By Lemma 6.2, the Riccati equation (6.9) admits a unique solution P_1. First we calculate

$$\begin{aligned}& -(-i\lambda - A^T)^{-1}A^T P_1(i\lambda - A)^{-1} - (-i\lambda - A^T)^{-1}P_1 A(i\lambda - A)^{-1} \\ & = P_1(i\lambda - A)^{-1} + i\lambda(-i\lambda - A^T)^{-1}P_1(i\lambda - A)^{-1} \\ & \quad + (-i\lambda - A^T)^{-1}P_1 - i\lambda(-i\lambda - A^T)^{-1}P_1(i\lambda - A)^{-1} \\ & = P_1(i\lambda - A)^{-1} + (-i\lambda - A^T)^{-1}P_1.\end{aligned}$$

Consequently,

$$\begin{aligned}& (-i\lambda - A^T)^{-1}Q_1(i\lambda - A)^{-1} \\ & = (-i\lambda - A^T)^{-1}(B^T P_1 + S_1)^T R_1^{-1}(B^T P_1 + S_1)(i\lambda - A)^{-1} \\ & \quad - (-i\lambda - A^T)^{-1}(A^T P_1 + P_1 A)(i\lambda - A)^{-1} \\ & = (-i\lambda - A^T)^{-1}(B^T P_1 + S_1)^T R_1^{-1}(B^T P_1 + S_1)(i\lambda - A)^{-1} \\ & \quad + P_1(i\lambda - A)^{-1} + (-i\lambda - A^T)^{-1}P_1.\end{aligned} \tag{6.16}$$

Plugging (6.16) in (6.15), we get (6.11).

By Lemma 6.2, the matrix

$$\pi(\lambda) \triangleq i\lambda - A + BR_1^{-1}(B^T P_1 + S_1)$$

is nonsingular for all $\lambda \in \mathbb{R}$, which in turn implies that $G(\lambda)$ in (6.14) is well defined. Now we compute

$$\begin{aligned}& E(\lambda)G(\lambda)B \\ & = R_1^{-1}(B^T P_1 + S_1)(i\lambda - A)^{-1}BR_1^{-1}(B^T P_1 + S_1)\pi(\lambda)^{-1}B \\ & = R_1^{-1}(B^T P_1 + S_1)(i\lambda - A)^{-1}[i\lambda - A + BR_1^{-1}(B^T P_1 + S_1)]\pi(\lambda)^{-1}B \\ & \quad - R_1^{-1}(B^T P_1 + S_1)\pi(\lambda)^{-1}B \\ & = E(\lambda) - G(\lambda)B.\end{aligned}$$

Thus

$$[I + E(\lambda)][I - G(\lambda)B] = I + E(\lambda) - G(\lambda)B - E(\lambda) + G(\lambda)B = I,$$

which yields (6.13). □

THEOREM 6.1. *If Problem* (LQ) *is uniquely solvable at any* x_0*, then there exists some constant* $\sigma > 0$ *such that*

$$\hat{\Phi}(\lambda) \geq \sigma I \quad \forall \lambda \in \mathbb{R}. \tag{6.17}$$

Proof. It follows from (6.10) that there exists a constant $k > 0$ satisfying

$$|[i\lambda - A + BR_1^{-1}(B^T P_1 + S_1)]^{-1}| \leq k \quad \forall \lambda \in \mathbb{R}.$$

Hence there exists a $k_1 > 0$ such that

$$|G(\lambda)| \leq k_1 \quad \forall \lambda \in \mathbb{R}.$$

For any $u \in \mathbb{C}^m$ (the set of m-dimensional complex vectors), let

$$v(\lambda) \triangleq [I + E(\lambda)]u = [I - G(\lambda)B]^{-1}u \quad \forall \lambda \in \mathbb{R}.$$

Then it holds that

$$|u| = |[I - G(\lambda)B]v(\lambda)| \leq (1 + k_1|B|)|v(\lambda)|.$$

Hence it follows from (6.11) that

$$\begin{aligned} u^* \hat{\Phi}(\lambda) u &= |R_1^{\frac{1}{2}}[I + E(\lambda)]u|^2 = |R_1^{\frac{1}{2}} v(\lambda)|^2 \\ &\geq k_2^2 |v(\lambda)|^2 \geq \left(\frac{k_2}{1 + k_1|B|}\right)^2 u^* u \quad \forall \lambda \in \mathbb{R}, \quad \forall u \in \mathbb{C}^m, \end{aligned}$$

where $k_2 > 0$ is the minimum eigenvalue of the positive-definite matrix $R_1^{\frac{1}{2}}$. This completes the proof. □

7. Synthesis. In this section, based on the results in the previous sections, we establish a grand unification of four statements for Problem (LQ) from different aspects: the LQ problem itself, the Riccati equation, the bilinear form, and the frequency characteristic.

THEOREM 7.1. *Assume that the matrix equation* (3.2) *is solvable. Then the following statements are equivalent.*

(I) *Problem* (LQ) *is uniquely solvable at any initial state* $x_0 \in \mathbb{R}^n$.

(II) *The SARE* (5.1) *admits only one such solution* P *such that* $P^T = P$ *and*

$$\widetilde{K} \triangleq -(R + D^T P D)^{-1}[S + B^T P + D^T P C] \tag{7.1}$$

is a (mean-square) stabilizing feedback operator.

(III) *There exists a constant* $\sigma > 0$ *such that*

$$\Phi(u(\cdot), u(\cdot)) \geq \sigma E \int_0^{+\infty} |u(t)|^2 \, dt \qquad \forall u(\cdot) \in L^2_{\mathcal{F}}(\mathbb{R}^m). \tag{7.2}$$

(IV) *There exists a constant* $\sigma > 0$ *such that*

$$\hat{\Phi}(\lambda) \geq \sigma I \quad \forall \lambda \in \mathbb{R}. \tag{7.3}$$

Proof. We have the following loop of implications.

(I) $\Longrightarrow$ (IV): Theorem 6.1; (IV) $\Longrightarrow$ (III) $\Longrightarrow$ (I): Theorem 3.1; (I) $\Longleftrightarrow$ (II): Theorem 5.1. □

Remark 7.1. The assumption of the solvability of the matrix equation (3.2) is not necessary for the equivalence between (I) and (II).

Remark 7.2. When (I) or (II) holds true, the unique optimal feedback control of Problem (LQ) is

$$\bar{u}(t) = -(R + D^T P D)^{-1}[S + B^T P + D^T P C]\bar{x}(t), \quad t \geq 0.$$

Remark 7.3. In [14], it was proved that the bilinear form $\Phi \geq 0$ if and only if there exists a symmetric matrix H such that the following inequality holds:

$$2\,\mathrm{Re}\, x^T H(Ax + Bu) + (Cx + Du)^T H(Cx + Du) + F(x, u) \geq 0 \quad \forall u \in \mathbb{R}^m, x \in \mathbb{R}^n,$$

where $F(x, u) = x^T Q x + 2u^T S x + u^T R u$. It was further mentioned in [14, Remark 2] that Φ can be estimated by a certain frequency-type inequality derived in [3], which is precisely as follows. Let $h_1(t)$ and $h_2(t)$ be functions such that $\int_0^{+\infty} |h_k(t)|^2\, dt < +\infty$ and $h_k(t) = 0$ for $t < 0$ $(k = 1, 2)$. The frequency inequality in [3] is the estimate

$$\begin{aligned}\int_0^{+\infty} E\left[\int_0^t h_1(t-\tau)u(\tau)\,d\tau + \int_0^t h_2(t-\tau)u(\tau)dw(\tau)\right] u(t)\,dt \\ \geq \int_{-\infty}^{+\infty} [\mathrm{Re}\, H_1(i\lambda) - G]E|\hat{u}(i\lambda)|^2\,d\lambda \;\forall u(\cdot) \in L^2_{\mathcal{F}}(\mathbb{R}^m),\end{aligned}$$

where $H_1(i\lambda) \triangleq \int_0^{+\infty} h_1(t)e^{i\lambda t}\,dt$ and $\hat{u}(i\lambda) \triangleq \int_0^{+\infty} u(t)e^{i\lambda t}\,dt$. Clearly, the above inequality is hard to verify via the original parameters of Problem (LQ).

Example 7.1. Continue with Example 3.1, where it has been shown that $\Theta = \frac{2AQ}{2A+C^2}$. We can then calculate the parameters in (6.4) as

$$Q_1 = \Theta = \frac{2AQ}{2A + C^2},$$

$$R_1 = R + \frac{1}{2\pi}\int_{-\infty}^{+\infty} \frac{D^2\Theta}{\lambda^2 + A^2} d\lambda = R - \frac{D^2\Theta}{2A} = R - \frac{D^2 Q}{2A + C^2},$$

$$S_1 = S - \frac{CDQ}{2A + C^2}.$$

The frequency characteristic is

$$\hat{\Phi}(\lambda) = \frac{2A}{\lambda^2 + A^2}\left[\frac{B^2 Q}{2A + C^2} - B\left(S - \frac{CDQ}{2A + C^2}\right)\right] + R - \frac{D^2 Q}{2A + C^2}.$$

Consequently, the underlying LQ problem is uniquely solvable if and only if the parameters satisfy the following:

$$\begin{cases} R - \dfrac{D^2 Q}{2A + C^2} > 0 & \text{if } \dfrac{B^2 Q}{2A + C^2} - B\left(S - \dfrac{CDQ}{2A + C^2}\right) \leq 0, \\ \dfrac{2}{A}\left[\dfrac{B^2 Q}{2A + C^2} - B\left(S - \dfrac{CDQ}{2A + C^2}\right)\right] + R - \dfrac{D^2 Q}{2A + C^2} > 0 \\ \qquad\qquad \text{if } \dfrac{B^2 Q}{2A + C^2} - B\left(S - \dfrac{CDQ}{2A + C^2}\right) > 0. \end{cases}$$

Next let us look at a two-dimensional example.

Example 7.2. Consider a two-dimensional LQ problem with the following data in the system dynamics,

$$A = \begin{pmatrix} -1 & 1 \\ 0 & -1 \end{pmatrix}, \quad B = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}, \quad C = \begin{pmatrix} 0 & 0 \\ 0 & 0 \end{pmatrix}, \quad D = \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix},$$

and with the cost weighting matrices

$$Q = \begin{pmatrix} 4 & 0 \\ 0 & -1 \end{pmatrix}, \quad S = \begin{pmatrix} 0 & 0 \\ 0 & 0 \end{pmatrix}, \quad R = \begin{pmatrix} -1 & 0 \\ 0 & 3 \end{pmatrix}.$$

Note that both Q and R are indefinite in this example. It is clear that the uncontrolled system (2.1) is mean-square stable. Moreover, $\Theta = Q$, and the corresponding frequency characteristic is

$$\begin{aligned} \hat{\Phi}(\lambda) &= \begin{pmatrix} 1 & 0 \\ 0 & 3 \end{pmatrix} + \frac{1}{(1+\lambda^2)^2} \begin{pmatrix} 4(1+\lambda^2) & 4(1-i\lambda) \\ 4(1+i\lambda) & 4-(1+\lambda^2) \end{pmatrix} \\ &\geq I \quad \forall \lambda \in \mathbb{R}, \end{aligned}$$

where the last inequality is obtained by directly evaluating the eigenvalues. Therefore, it follows from Theorem 7.1 that this LQ problem is uniquely solvable at any initial state, and the SARE (5.1) admits a unique solution.

8. Concluding remarks. In this paper we applied the frequency domain approach to the indefinite stochastic LQ problems. We introduced a new frequency characteristic and explored its links to the underlying LQ problem, the stochastic Riccati equation, and the bilinear form. It turned out that there are intrinsic equivalence relations among them. The frequency characteristic introduced is expressed explicitly through the parameters of the LQ problem and is easy to compute. More importantly, it gives new insights into the internal structure of an LQ problem and explains the fundamental reason why a stochastic LQ control problem can be indefinite.

Acknowledgment. The authors would like to thank the two anonymous referees for their careful reading and constructive comments that led to an improved version of the paper.

NEW SECOND-ORDER OPTIMALITY CONDITIONS FOR VARIATIONAL PROBLEMS WITH C^2-HAMILTONIANS*

VERA ZEIDAN†

Abstract. The generalized problem of Bolza with a C^2-Hamiltonian is considered. Necessary and sufficient conditions are obtained, respectively, in terms of the accessory problem, the existence of conjoined basis, and the existence of a solution to a Riccati equation with boundary conditions. No strengthened Legendre–Clebsch condition is required. When applied to a general optimal control problem, these results include and generalize known results.

Key words. generalized Bolza problem, optimal control, accessory problem, conjoined basis, Riccati equation, general boundary conditions, optimality criteria, strong, $W^{1,s}$- and L^s-weak local minima

AMS subject classifications. 49K05, 49K15

PII. S0363012999358725

1. Introduction.

Consider the generalized problem of Bolza,

$$\text{(P)} \qquad \text{minimize } J(x) = \ell(x(0), x(1)) + \int_0^1 L(t, x(t), \dot{x}(t))dt,$$

over all absolutely continuous functions (arcs)$x(\cdot) \in W^{1,1}[0,1]$ satisfying

$$\phi(x(0), x(1)) = 0, \tag{1.1}$$

where $\ell : \mathbb{R}^n \times \mathbb{R}^n \to \mathbb{R}$, $L : [0,1] \times \mathbb{R}^n \times \mathbb{R}^n \to \mathbb{R} \cup \{+\infty\}$, and $\phi : \mathbb{R}^n \times \mathbb{R}^n \to \mathbb{R}^r$, $r \leq 2n$. The norm in $W^{1,s}[0,1]$ is $\|x\|_{1,s} := |x(0)| + \|\dot{x}(\cdot)\|_s$. An arc is said to be *admissible* if it satisfies (1.1).

The Hamiltonian corresponding to the problem is

$$H(t,x,p) := \sup\{\langle p, v\rangle - L(t,x,v) : v \in \mathbb{R}^n\}. \tag{1.2}$$

The problem (P) was introduced by R. T. Rockafellar. It is more general than it appears to be, due to the fact that L is allowed to take the value $+\infty$. While this problem subsumes diverse constrained problems (e.g., calculus of variations and optimal control problems), it is distinguished from the classical setting by the lack of regularity of L. Nevertheless, the Hamiltonian itself may actually be well behaved for certain classes of problems. This was the reason for the program of studying the problem (P) from the point of view of the Hamiltonian H. In fact, existence theory involving conditions on H was obtained by Rockafellar [9], and first-order necessary conditions in terms of the Hamiltonian inclusions were developed by Clarke in [3] and [4]. Sufficiency criteria for optimality of zero, first and second order were derived in [14] and [16] for the case where $H(t,\cdot,\cdot)$ is not necessarily concave-convex. There, one state endpoint is assumed to be fixed, and the second-order sufficiency criterion

†Department of Mathematics, Michigan State University, East Lansing, MI 48824-1027 (zeidan@math.msu.edu). A part of this research was supported by the National Science Foundation under grant DMS-0072598.

assumes that $H(t,\cdot,\cdot)$ is $C^{1+}(C^{1,1})$, that is, has a Lipschitz gradient, and is phrased in terms of a certain Riccati inequality. However, the question of second-order necessary conditions in terms of the Hamiltonian remains an open question. By analogy with the classical calculus of variations setting, these conditions are expected to be expressed in terms of

(i) the accessory problem,
(ii) the coupled point theory,
(iii) a conjoined basis with appropriate boundary conditions, and
(iv) a certain Riccati-type equation with appropriate boundary conditions.

As opposed to the classical setting, these conditions must be phrased in terms of the Hamiltonian, which can be "nice" even when L is "bad."

Now consider the *optimal control* problem

$$\text{(C)} \qquad \text{minimize } J(x,u) := \ell(x(0),x(1)) + \int_0^1 g(t,x(t),u(t))dt \text{ subject to}$$

$$\text{(1.3)} \qquad \begin{cases} \dot{x}(t) = f(t,x(t),u(t)) \text{ almost everywhere (a.e.)}, \\ u(t) \in U \text{ a.e.}, \\ \phi(x(0),x(1)) = 0, \end{cases}$$

where $x(\cdot) \in W^{1,1}[0,1]$ and $u(\cdot)$ is measurable, ℓ and ϕ are as in the problem (P), $f : [0,1] \times \mathbb{R}^n \times \mathbb{R}^m \to \mathbb{R}^n$, and $g : [0,1] \times \mathbb{R}^n \times \mathbb{R}^m \to \mathbb{R}$. A pair (x,u) is called *admissible* if $x(\cdot) \in W^{1,1}[0,1]$, $u(\cdot)$ is measurable and (x,u) satisfies (1.3). An arc x is called *admissible* if there exists a measurable u for which (x,u) is admissible.

We shall assume the following.

$$\text{(A)} \qquad \begin{cases} \bullet\ f \text{ and } g \text{ are } (\mathcal{L} \times \mathcal{B})\text{-measurable and continuous in } (x,u), \\ \bullet\ U \text{ is closed}, \\ \bullet\ \ell \text{ is lower semicontinuous}. \end{cases}$$

The Hamiltonian associated with (C) is

$$\text{(1.4)} \qquad \mathcal{H}(t,x,p) := \sup\{p \cdot f(t,x,u) - g(t,x,u) \mid u \in U\}.$$

The program of studying the problem (C) from the point of view of the "true" Hamiltonian $\mathcal{H}$ is one step further along than that for (P). In fact, in addition to the existence theory of [9], the first-order necessary conditions in [4], and the sufficiency criteria up to the second order in [14] and [15] for the case where only one state endpoint varies, necessary conditions for (C) were obtained in [2, Theorem 5.1] in terms of the Riccati equation $(\mathcal{R})$ and (3.17). However, these conditions were derived for $W^{1,1}$-weak minimality and for the case where the initial state variable is *fixed* and the final one is free. There, a triplet $(\bar{x},\bar{u},\bar{p})$ satisfying the first-order necessary conditions is considered. It is assumed that $\nabla^2\ell$ is Lipschitz and $\nabla^2_{(x,p)}\mathcal{H}$ is Lipschitz at $(\bar{x},\bar{p})$ from L^∞ to L^1 (see Definition 2.2). The result states that if the Riccati equation $(\mathcal{R})$ and the boundary condition (3.17) have on $]t_c,t]$ for some $t_c \in (0,1)$, a solution that does not extend to t_c, and if the *strengthened Legendre–Clebsch* condition $(S\mathcal{L})$ holds near t_c and for $t < t_c$,

$$(S\mathcal{L}) \qquad \text{for some } \lambda > 0, \quad \mathcal{H}_{pp}(t,\bar{x}(t),\bar{p}(t)) \geq \lambda I \quad \text{a.e.},$$

and if

$$\sup_{t\in[t_c-\lambda,t_c]} \left|\nabla^2_{(x,p)}\mathcal{H}(t,\bar{x}(t),\bar{p}(t))\right| < \infty, \tag{1.5}$$

then $(\bar{x},\bar{u})$ is not a $W^{1,1}$-weak local minimum for (C). These assumptions (see Lemma 5.4 and Remark 5.2) imply that the problem (C) resembles the classical calculus of variations setting, which is quite restrictive. Also the question of necessary conditions of types (i)–(iii) remains open.

The aim of this paper is to *complete* the program of studying the problems (P) and (C) from the point of view of the "true" Hamiltonian. This is accomplished by answering the open necessity and sufficiency questions of types (i), (iii), and (iv). Conditions of type (ii) will be handled in a separate paper.

The paper is divided as follows. In section 2, preliminary results are derived concerning the $W^{1,s}$- and L^s-weak local optimality notions used in the manuscript and the connection with the classical ones. In the same section we recall known results on the connection between (P) and (C) and on the notion of M-controllability.

For the problem (P), necessary conditions in terms of the Hamiltonian H are obtained in section 3 for $W^{1,s}$-local optimality. The first condition takes the form of the accessory problem. The novelty of its proof lies in associating to (P) an optimal control problem ($\mathrm{C}_{\mathcal{H}}$) that inherits the optimality of (P). The accessory problem for ($\mathrm{C}_{\mathcal{H}}$) is what we call the accessory problem of (P). As a consequence and by means of the results in [17], we obtain necessary conditions of types (iii) and (iv) for the case when the endpoint costs and constraints are separable. In section 4 we develop a sufficiency optimality criterion in (P) for general endpoints conditions and another one when the endpoints cost and constraint are separable. This latter enjoys the distinction that it is as close as possible to the necessary conditions developed in section 3.

In section 5 we apply the results of sections 3 and 4 to the optimal control problem (C) to obtain necessary and sufficient conditions. Indeed, the necessary conditions are derived under two different sets of conditions depending on whether we write (C) in the framework of (P) or ($\mathrm{C}_{\mathcal{H}}$). Neither of the two sets requires the strengthened Legendre–Clebsch conditions ($S\mathcal{L}$). Hence, when specialized to the case considered in [2], our results are much more general. More specifically, part (1)(ii) of Theorem 5.2 of this paper extends [2, Theorem 5.1] to the case where the Hessians $\nabla^2\ell$ and $\nabla^2\mathcal{H}$ are not necessarily Lipschitz, (1.5) is not satisfied, or the strengthened Legendre–Clebsch ($S\mathcal{L}$) does not hold. This latter is replaced by a normality condition which is automatically satisfied when ($S\mathcal{L}$) holds. Example 5.1 shows that the normality condition can be satisfied when ($S\mathcal{L}$) fails, and hence it illustrates the utility of our generalization. Furthermore, part (1) of Theorem 5.2 applies equally to all $W^{1,s}$-weak local minimum for $s\in[1,\infty]$. Moreover, part (2) of Theorem 5.2 applies to all L^s-weak local minimum for $s\in[1,\infty]$. In addition to necessary conditions in terms of the Riccati equation ($\mathcal{R}$), Theorem 5.2 develops necessary conditions in terms of the accessory problem (Theorem 3.3) and a conjoint basis for (3.14)–(3.15) (Theorem 3.9).

In this paper we assume that $H(t,\cdot,\cdot)$ and $\mathcal{H}(t,\cdot,\cdot)$ are C^2. This assumption is appropriate for certain classes of optimal control problems (see, e.g., [2]). Furthermore, the results of this paper will serve as a principal stepping stone for a subsequent paper where this regularity assumption on H and $\mathcal{H}$ is weakened.

2. Preliminary results. The following three notions of local optimality apply to both problems (P) and (C).

DEFINITION 2.1. *In* (P) *(resp., in* (C)*), an admissible arc* $\bar{x}$ *is said to be*

(i) *a strong local minimum if there exists* $\varepsilon > 0$ *such that for any admissible arc* x *satisfying* $\|x - \bar{x}\|_\infty < \varepsilon$ *we have* $J(x) \geq J(\bar{x})$ *(resp.,* $J(x,u) \geq J(\bar{x},\bar{u})$*),*

(ii) *a* $W^{1,s}$*-weak local minimum for* $1 \leq s \leq \infty$ *if there exists* $\varepsilon > 0$ *such that for any admissible arc* x *for which* $\|x - \bar{x}\|_{1,s}$ *is defined and* $\|x - \bar{x}\|_{1,s} < \varepsilon$*, we have* $J(x) \geq J(\bar{x})$ *(resp.,* $J(x,u) \geq J(\bar{x},\bar{u})$*).*

Clearly, if $\bar{x}$ is a strong local minimum, then $\bar{x}$ is a $W^{1,s}$-weak local minimum for all $s \in [1,\infty]$. If for $s \in [1,\infty]$ $\bar{x}$ is a $W^{1,s}$-weak local minimum, then it is a $W^{1,\infty}$-weak local minimum.

In the control context the notion of strong local minimality coincides with the classical notion. On the other hand, the following *classical* notions of L^s-weak local minima are known for (C).

DEFINITION 2.2. *Let* $s \in [1,\infty]$*. An admissible pair* $(\bar{x},\bar{u})$ *for* (C) *is a classically* L^s*-weak local minimum if for some* $\varepsilon > 0$

$$J(x,u) \geq J(\bar{x},\bar{u})$$

for all admissible pairs (x,u) *satisfying*

$$\|x - \bar{x}\|_\infty + \|u - \bar{u}\|_s < \varepsilon.$$

We shall need the following notions. A function K on $[0,1] \times \mathbb{R}^k$ is $(\mathcal{L} \times \mathcal{B})$-*measurable* if it is measurable with respect to the σ-algebra generated by products of Lebesgue sets in $[0,1]$ and Borel sets in $\mathbb{R}^k$.

For $\bar{z} \in L^\infty[0,1]$ we give these definitions.

DEFINITION 2.3. *Let* $K : [0,1] \times \mathbb{R}^k \to \mathbb{R}$ *be* $(\mathcal{L} \times \mathcal{B})$*-measurable. For* $1 \leq s \leq \infty$*, we say that* K *is continuous at* $\bar{z}$ *from* L^∞ *to* L^s *if the map* $z(\cdot) \to K(\cdot, z(\cdot))$ *from* L^∞ *to* L^s *is continuous at* $\bar{z}$*. The function* K *is said to be Lipschitz near* $\bar{z}$ *from* L^∞ *to* L^s *if the map* $z(\cdot) \to K(\cdot, z(\cdot))$ *is Lipschitz near* $\bar{z}$ *from* L^∞ *to* L^s*.*

DEFINITION 2.4. *Let* $\bar{x} \in L^\infty$*,* $\bar{y} \in L^s$ *for* $s \in [1,\infty]$*, and let* $K : [0,1] \times \mathbb{R}^r \times \mathbb{R}^s \to \mathbb{R}$*. The function* K *is said to be continuous at* $(\bar{x},\bar{y})$ *from* $L^\infty \times L^s$ *to* L^s *if the map* $(x(\cdot), y(\cdot)) \to K(\cdot, x(\cdot), y(\cdot))$ *is continuous at* $(\bar{x},\bar{y})$ *from* $L^\infty \times L^s \to L^s$*.*

We say that K *is Lipschitz near* $(\bar{x},\bar{y})$ *from* $L^\infty \times L^s$ *to* L^s *if the map* $(x(\cdot), y(\cdot)) \to K(\cdot, x(\cdot), y(\cdot))$ *from* $L^\infty \times L^s$ *to* L^s *is Lipschitz near* $(\bar{x},\bar{y})$*.*

It is clear that the Lipschitz property of K yields the corresponding continuity property of K. However, as we shall see below, the continuity of the gradient $\nabla_z K$ yields the Lipschitz condition on K.

LEMMA 2.5. *Let* $K(t,\cdot)$ *be* C^1*, and let* $\bar{z} \in L^\infty$*. Assume that* $\nabla_z K(\cdot, \bar{z}(\cdot))$ *is* L^s *for some* s *in* $[1,\infty]$*. If* $\nabla_z K$ *is continuous at* $\bar{z}$ *from* L^∞ *to* L^s*, then* K *is Lipschitz near* $\bar{z}$ *from* L^∞ *to* L^s*.*

Proof. The continuity at $\bar{z}$ of $\nabla_z K$ from L^∞ to L^s yields the existence of $\delta > 0$ such that for all $z : \|z - \bar{z}\|_\infty < \delta$ we have

$$\|\nabla_z K(\cdot, z(\cdot)) - \nabla_z K(\cdot, \bar{z}(\cdot))\|_s < 1.$$

Then, for all z and z' with $\|z - \bar{z}\|_\infty < \delta$, $\|z' - \bar{z}\|_\infty < \delta$, the mean value theorem implies that for almost all t there exists $\tilde{z}_t$ satisfying $|\tilde{z}_t - \bar{z}(t)| < \delta$ and

$$\begin{aligned} |K(t,z(t)) - K(t,z'(t))| &\leq |\nabla_z K(t,\tilde{z}_t)| \cdot |z(t) - z'(t)| \\ &\leq |\nabla_z K(t,\tilde{z}_t) - \nabla_z K(t,\bar{z}(t))| \cdot \|z - z'\|_\infty \\ &\quad + |\nabla_z K(t,\bar{z}(t))| \cdot \|z - z'\|_\infty. \end{aligned}$$

Since $\nabla_z K(\cdot, \bar{z}(\cdot))$ is L^s, by the Minkowski inequality we get

$$\|K(\cdot, z(\cdot)) - K(\cdot, z'(\cdot))\|_s \leq (1 + \|\nabla_z K(\cdot, \bar{z}(\cdot))\|_s)\|z - z'\|_\infty.$$

Therefore, the result follows. □

The next result shows that, under natural hypotheses on the dynamics f, the $W^{1,s}$-weak local minimality in (C) implies the *classical* L^s-weak local minimality. This implication will play an important role in developing the results of this paper. The converse is shown to hold under more restrictive hypotheses on f and is not needed for this paper.

LEMMA 2.6. *Let* (A) *be satisfied, and let* $(\bar{x}, \bar{u})$ *be an admissible pair for* (C) *such that* $\bar{u} \in L^s$ *for* $s \in [1, \infty]$.

(a) *Assume that* $(\bar{x}, \bar{u})$ *is a* $W^{1,s}$*-weak local minimum for* (C). *If* f *is continuous at* $(\bar{x}, \bar{u})$ *from* $L^\infty \times L^\infty$ *to* L^s, *then* $(\bar{x}, \bar{u})$ *is a classically* L^∞*-weak local minimum for* (C). *If* f *is continuous at* $(\bar{x}, \bar{u})$ *from* $L^\infty \times L^s$ *to* L^s, *then* $(\bar{x}, \bar{u})$ *is a classically* L^s*-weak local minimum for* (C).

(b) *Conversely, let* $(\bar{x}, \bar{u})$ *be an* L^s*-weak local minimum for* (C). *Assume that the map* $x(\cdot) \to f(\cdot, x(\cdot), u(\cdot))$ *is continuous at* $\bar{x}(\cdot)$ *from* L^∞ *to* L^s *uniformly in* $u(\cdot) \in L^s$ *with* $u(t) \in U$ *a.e., and that there exists* $m > 0$ *such that for all* $u(\cdot) \in L^s$ *such that* $u(t) \in U$ *a.e.,*

$$\|f(\cdot, \bar{x}(\cdot), u(\cdot)) - f(\cdot, \bar{x}(\cdot), \bar{u}(\cdot))\|_s \geq m\|u - \bar{u}\|_s.$$

Then $(\bar{x}, \bar{u})$ *is a* $W^{1,s}$*-weak local minimum for* (C).

Proof. For (a), let $\varepsilon > 0$ be such that for any admissible pair (x, u) for which $\|x - \bar{x}\|_{1,s}$ is defined and $\|x - \bar{x}\|_{1,s} < \varepsilon$, we have $J(x, u) \geq J(\bar{x}, \bar{u})$. If f is continuous at $(\bar{x}, \bar{u})$ from $L^\infty \times L^\infty$ to L^s, there exists $\delta_0 > 0$ such that for $\|(x, u) - (\bar{x}, \bar{u})\|_\infty < \delta_0$ we have $\|f(\cdot, x(\cdot), u(\cdot)) - f(\cdot, \bar{x}(\cdot), \bar{u}(\cdot))\|_s < \frac{\varepsilon}{2}$. Set

$$\bar{\varepsilon} := \min\left\{\frac{\varepsilon}{2}, \delta_0\right\}.$$

Now let (x, u) be admissible for (C) with

$$\|x - \bar{x}\|_\infty + \|u - \bar{u}\|_\infty < \bar{\varepsilon};$$

it follows that

$$\|x - \bar{x}\|_{1,s} \leq |x(0) - \bar{x}(0)| + \|f(\cdot, x(\cdot), u(\cdot)) - f(\cdot, \bar{x}(\cdot), \bar{u}(\cdot))\|_s < \varepsilon,$$

whence

$$J(x, u) \geq J(\bar{x}, \bar{u}),$$

proving that $(\bar{x}, \bar{u})$ is *classically* L^∞-weak local minimum. On the other hand, if f is continuous at $(\bar{x}, \bar{u})$ from $L^\infty \times L^s$ to L^s, then there exists $\delta_0 > 0$ such that for $\|x - \bar{x}\|_\infty < \delta_0$ and $\|u - \bar{u}\|_s < \delta_0$ we have $\|f(\cdot, x(\cdot), u(\cdot)) - f(\cdot, \bar{x}(\cdot), \bar{u}(\cdot))\|_s < \frac{\varepsilon}{2}$. Set $\bar{\varepsilon} := \min\{\frac{\varepsilon}{2}, \delta_0\}$, and let (x, u) be admissible for (C) with

$$\|x - \bar{x}\|_\infty + \|u - \bar{u}\|_s < \bar{\varepsilon}.$$

Then $\|x - \bar{x}\|_{1,s} < \varepsilon$. Thus $J(x, u) \geq J(\bar{x}, \bar{u})$; that is, $(\bar{x}, \bar{u})$ is *a classically* L^s-weak local minimum.

For (b), the L^s-weak local minimality of $(\bar{x},\bar{u})$ for (C) yields the existence of $\varepsilon>0$ such that $J(x,u)\geq J(\bar{x},\bar{u})$ for all admissible pairs (x,u) satisfying

$$\|x-\bar{x}\|_\infty+\|u-\bar{u}\|_s<\varepsilon.$$

By the continuity assumption on f, there exists $\delta_0>0$ such that for $\|x-\bar{x}\|_\infty<\delta_0$,

$$\|f(\cdot,x(\cdot),u(\cdot))-f(\cdot,\bar{x}(\cdot),u(\cdot))\|_s<\frac{\varepsilon m}{4}$$

for all $u(\cdot)\in L^s$ with $u(t)\in U$ a.e., where m is the constant in the assumption.

Define $\bar{\varepsilon}=\min\{\frac{m\varepsilon}{4},\frac{\varepsilon}{2},\delta_0\}$. Let (x,u) be admissible for (C) with $\|x-\bar{x}\|_{1,s}<\bar{\varepsilon}$. Then $\|x-\bar{x}\|_\infty<\frac{\varepsilon}{2}$, and

$$\|f(\cdot,x(\cdot),u(\cdot))-f(\cdot,\bar{x}(\cdot),\bar{u}(\cdot))\|_s<\frac{m\varepsilon}{4}.$$

It results that

$$\begin{aligned}\frac{m\varepsilon}{4}&>\|f(\cdot,\bar{x}(\cdot),u(\cdot))-f(\cdot,\bar{x}(\cdot),\bar{u}(\cdot))+f(\cdot,x(\cdot),u(\cdot))-f(\cdot,\bar{x}(\cdot),u(\cdot))\|_s\\&\geq\|f(\cdot,\bar{x}(\cdot),u(\cdot))-f(\cdot,\bar{x}(\cdot),\bar{u}(\cdot))\|_s-\|f(\cdot,x(\cdot),u(\cdot))-f(\cdot,\bar{x}(\cdot),u(\cdot))\|_s\\&>m\|u-\bar{u}\|_s-\frac{m\varepsilon}{4}.\end{aligned}$$

Thus $\|u-\bar{u}\|_s<\frac{\varepsilon}{2}$, whence $J(x,u)\geq J(\bar{x},\bar{u})$, and, therefore, $(\bar{x},\bar{u})$ is a $W^{1,s}$-weak local minimum for (C). □

Let $\bar{x}\in C[0,1]$ and $\varepsilon>0$ be given. Define

$$T(\bar{x};\varepsilon):=\{(t,x)\in[0,1]\times\mathbb{R}^n:|x-\bar{x}(t)|<\varepsilon\}. \tag{2.1}$$

We say that an arc $x(\cdot)\in T(\bar{x};\varepsilon)$ when $(t,x(t))\in T(\bar{x};\varepsilon)$ for all t.

There are several ways to write (C) in the form of (P). Below we exhibit a general one. Set

$$L_C(t,x,v):=\begin{cases}\inf\{g(t,x,u)\;\big|\;v=f(t,x,u)\text{ and }u\in U\}&\text{if }(t,x)\in T(\bar{x};\varepsilon),\\+\infty&\text{otherwise .}\end{cases} \tag{2.2}$$

Clearly, $L_C(t,x,v)=+\infty$ when $\{u:v=f(t,x,u),u\in U\}=\emptyset$. Furthermore, even if $L_C(t,x,v)$ is finite, it can be discontinuous or nonsmooth. To problem (C) we can associate the following *generalized Bolza problem*:

$$(\mathrm{P_C})\qquad\text{minimize }J_C(x):=\ell(x(0),x(1))+\int_0^1 L_C(t,x(t),\dot{x}(t))dt\text{ subject to}$$

$$\phi(x(0),x(1))=0.$$

The Hamiltonian corresponding to $(\mathrm{P_C})$ on $T(\bar{x};\varepsilon)\times\mathbb{R}^n$ is

$$\begin{aligned}H_C(t,x,p)&:=\sup\{\langle p,v\rangle-L_C(t,x,v):v\in\mathbb{R}^n\}\\&=\sup_{u\in U}\{\langle p,f(t,x,u)\rangle-g(t,x,u)\}\\&=\mathcal{H}(t,x,p),\end{aligned}$$

the Hamiltonian corresponding to (C).

Remark 2.1. The first two assumptions in (A) imply that L_C, defined by (2.2), is $(\mathcal{L} \times \mathcal{B})$-measurable. Indeed, define a set-valued map by

$$\Gamma(t,x,v) := \{u \in U : v = f(t,x,u)\}. \tag{2.3}$$

By [3, Proposition 3.1.2], $\Gamma(\cdot)$ is measurable and closed. Using [1, Theorem 8.2.11], it follows that L_C is $(\mathcal{L} \times \mathcal{B})$-measurable.

Remark 2.2. Since $\int_0^1 L_C(t,x(t),\dot{x}(t))dt \le \int_0^1 g(t,x(t),u(t))dt$ for all (x,u) admissible for (C), it results that if $\bar{x}$ is a strong or a $W^{1,s}$-weak local minimum for $(\mathrm{P_C})$, and if there exists $\bar{u}$ such that $(\bar{x},\bar{u})$ is admissible for (C) and

$$L_C(t,\bar{x}(t),\dot{\bar{x}}(t)) = g(t,\bar{x}(t),\bar{u}(t)) \text{ a.e.},$$

then it follows that $(\bar{x},\bar{u})$ is, respectively, a strong, $W^{1,s}$-weak local minimum for (C).

For the converse, an extra hypothesis is needed. Assume the following.

$$(\bar{\mathrm{A}}) \qquad \begin{cases} \bullet \text{ For } (t,x) \in T(\bar{x};\varepsilon) \text{ and } v \in f(t,x,U), \\ \qquad \text{the infimum in (2.2) is attained,} \\ \bullet \ L_C \text{ is lower semicontinuous in } (x,v). \end{cases}$$

With minor modification of the proof of the equivalence theorem in [9], we obtain the following.

THEOREM 2.7 (see [9]). *If assumptions* (A) *and* $(\bar{\mathrm{A}})$ *are satisfied, then for all arcs* $x(\cdot)$ *in* $T(\bar{x};\varepsilon)$ *that are admissible for* $(\mathrm{P_C})$ *we have that* $J_C(x)$ *is well defined. Furthermore, if* $J_C(x) < +\infty$, *then*

$$J_C(x) = \min_{u(\cdot)\ measurable} \{J(x,u) \ \mid \ \dot{x}(t) = f(t,x(t),u(t)) \ a.e., \ and \ u(t) \in U \ a.e.\}.$$

That is, $\bar{x}$ *is strong, or, for some* $s \in [1,\infty]$, *a* $W^{1,s}$*-weak local minimum for* $(\mathrm{P_C})$ *iff there exists a control* $\bar{u}$ *corresponding to* $\bar{x}$ *such that* $(\bar{x},\bar{u})$ *is, respectively, strong, or a* $W^{1,s}$*-weak local minimum for* (C).

In applications it is important to have more verifiable conditions guaranteeing $(\bar{\mathrm{A}})$. We shall use the following assumption.

$(\mathcal{B})$ For every *bounded* set $V \subseteq \mathbb{R}^n$, the following set is bounded: $\{u \in U \mid \exists\, (t,x,v) \in T(\bar{x};\varepsilon) \times V : \ v = f(t,x,u)\}$.

Remark 2.3. Assumptions (A) and $(\mathcal{B})$ yield assumption $(\bar{\mathrm{A}})$(i). Furthermore, we have

$$L_C(t,x,v) = \begin{cases} \inf\{g(t,x,u) : u \in \Gamma(t,x,v)\} & \text{if } \ (t,x) \in T(\bar{x};\varepsilon) \text{ and } \Gamma(t,x,v) \neq \phi, \\ +\infty & \text{otherwise,} \end{cases}$$

where Γ is given by (2.3). From (A) it follows that $\Gamma(t,\cdot,\cdot)$ is upper semicontinuous and from (A) and $(\mathcal{B})$ it results that $\Gamma(t,x,v)$ is compact. Thus, using [1, Theorem 1.4.16(ii)] we obtain that $L_C(t,\cdot,\cdot)$ is lower semicontinuous. Therefore, (A) and $(\mathcal{B})$ imply $(\bar{\mathrm{A}})$. When U is compact, $(\mathcal{B})$ holds automatically.

In the rest of this section we present notions of controllability and normality that we shall use throughout this paper. For given L^1-matrix functions $A(\cdot) : [0,1] \to \mathbb{R}^{n\times n}$ and $R(\cdot) : [0,1] \to \mathbb{R}^{n\times m}$, consider the linear system

$$\dot{\eta}(t) = A(t)\eta(t) + R(t)v(t) \qquad \text{a.e.}, \tag{2.4}$$

where $v(\cdot) \in L^\infty[0,1]$.

DEFINITION 2.8. *Let M be in $\mathbb{R}^{r\times 2n}$, and let $[a,b]$ be an interval in $[0,1]$. The system (2.4) is M-controllable on $[a,b]$ when for all $\beta \in \mathbb{R}^r$ there exist $v_\beta(\cdot) \in L^\infty[a,b]$ and $\eta(\cdot) \in W^{1,1}[a,b]$ such that (η, v_β) solves (2.4) on $[a,b]$ and satisfies*

$$M \begin{pmatrix} \eta(a) \\ \eta(b) \end{pmatrix} = \beta.$$

(When $r = 0$, this condition is satisfied trivially.)

The M-controllability on $[a,b]$ amounts to saying that

$$\operatorname{Im} \Lambda = \mathbb{R}^r,$$

where

$$\Lambda \begin{pmatrix} \alpha \\ v(\cdot) \end{pmatrix} := M \begin{bmatrix} I \\ Z_b(a) \end{bmatrix} \alpha + M \begin{bmatrix} 0 \\ I \end{bmatrix} \int_a^b Z_b(\tau) R(\tau) v(\tau) d\tau,$$

and $Z_b(\cdot)$ is defined by $-\dot{Z}(t) = Z(t)A(t)$ a.e., $Z(b) = I$; here I is the $n \times n$-identity matrix.

When $b = 1$, we denote Z_1 by Z.

Remark 2.4. The M-controllability on $[a,b]$ of the system (2.4) is known to be equivalent to its *M-normality*; that is, $(y,\gamma) \equiv 0$ is the only solution on $[a,b]$ to

$$\text{(2.5)} \qquad \begin{cases} \dot{y}(t) = -A^T(t)y(t) & \text{a.e.,} \\ \begin{pmatrix} y(a) \\ -y(b) \end{pmatrix} = M^T\gamma, \\ R^T(t)y(t) = 0 & \text{a.e.} \end{cases}$$

When the endpoints of η in (2.4) are separated, then for some $r_0 \times n$-matrix M_0 and $r_1 \times n$-matrix M_1 we have $M = \left[\begin{smallmatrix} M_0 & 0 \\ 0 & M_1 \end{smallmatrix}\right]$. In this case, the M-normality is denoted by $(M_0 : M_1)$-normality and the vector γ in (2.5) takes the form $\gamma = \left(\begin{smallmatrix} \gamma_0 \\ \gamma_1 \end{smallmatrix}\right)$, where $\gamma_0 \in \mathbb{R}^{r_0}$ and $\gamma_1 \in \mathbb{R}^{r_1}$.

3. Necessary conditions for (P). In this section we present the first part of the main results of this paper. It concerns deriving three types of second-order necessary conditions for (weak or strong) optimality in the generalized problem of Bolza (P). The key feature resides in the fact that all these conditions are phrased in terms of the Hamiltonian H given in (1.2). The first condition takes the form of the accessory problem, that is, the nonnegativity of a certain quadratic functional. It plays a fundamental role in obtaining the other two.

Let $\bar{z} := (\bar{x}, \bar{p}) \in W^{1,1}[0,1]$ be given. Throughout the paper we denote by $\bar{\Phi}(t)$ the evaluation $\Phi(t, \bar{z}(t))$ and by Φ_x and Φ_p the partial derivatives of Φ with respect to x and p, respectively. Elements in $\mathbb{R}^n$ are considered to be column vectors, and gradients of real-valued maps evaluated at a point are considered row vectors. The notation $B_n(x_0;\varepsilon)$ refers to the ball in $\mathbb{R}^n$ centered at x_0 of radius ε. When $x_0 = 0$, we write $B_n(\varepsilon)$.

In this section we assume that ℓ and ϕ are C^1 on $B_{2n}((\bar{x}(0), \bar{x}(1)); \varepsilon)$ and L is $(\mathcal{L} \times \mathcal{B})$-measurable. Set

$$\bar{M} := \nabla\phi(\bar{x}(0), \bar{x}(1)).$$

In stating our main results, we will refer to the following assumptions concerning (P).

There exists $\varepsilon > 0$ such that the following hold.

($\mathcal{L}$) $L(t,x,\cdot)$ is convex and lower semicontinuous for $(t,x) \in T(\bar{x};\varepsilon)$.

(H_1)
$$\begin{cases} \bullet\ \forall\, t,\ H(t,\cdot) \text{ is } C^1 \text{ on } B_{2n}(\bar{z}(t);\varepsilon), \\ \bullet\ \bar{H}(\cdot) \text{ and } \overline{\nabla_z H}(\cdot) \text{ are integrable}, \\ \bullet\ \nabla_z H \text{ is continuous at } \bar{z} \text{ from } L^\infty \text{ to } L^1. \end{cases}$$

(H_p^s) H_p is continuous at $\bar{z}$ from L^∞ to L^s.

(H_2)
$$\begin{cases} \bullet\ \forall\, t,\ H(t,\cdot) \text{ is } C^2 \text{ on } B_{2n}(\bar{z}(t);\varepsilon), \\ \bullet\ \bar{H}(\cdot),\ \overline{\nabla_z H}(\cdot),\ \overline{\nabla_z^2 H}(\cdot) \text{ are integrable}, \\ \bullet\ \nabla_z^2 H \text{ is continuous at } \bar{z} \text{ from } L^\infty \text{ to } L^1, \\ \bullet\ \ell \text{ and } \phi \text{ are } C^2 \text{ on } B_{2n}((\bar{x}(0),\bar{x}(1));\varepsilon), \\ \bullet\ \bar{M} \text{ is of full rank.} \end{cases}$$

When $s = 1$, (H_p^s) is included in (H_1)(iii). From Lemma 2.5, (H_2)(iii) yields (H_1) (iii). Hence (H_2) implies (H_1). Also, if we have that $\nabla_z H_p$ is continuous from L^∞ to L^s and $\overline{\nabla_z H_p}(\cdot) \in L^s$, by Lemma 2.5 we get that (H_p^s) holds true.

The last condition in (H_2) holds trivially in the free-endpoints case, where $r = 0$.

DEFINITION 3.1. *Let $\bar{z} := (\bar{x},\bar{p}) \in W^{1,1}[0,1]$ at which (H_1) holds. The arc $\bar{z}$ is called a normal extremal for* (P) *if for some $\bar{\gamma} \in \mathbb{R}^r$, it satisfies the Hamiltonian equations and the transversality conditions*

(3.1)
$$\begin{cases} -\dot{\bar{p}}^T(t) = \bar{H}_x(t) \quad a.e., \\ \dot{\bar{x}}^T(t) = \bar{H}_p(t) \quad a.e., \\ (\bar{p}^T(0), -\bar{p}^T(1)) = \nabla \ell(\bar{x}(0),\bar{x}(1)) + \bar{\gamma}^T \bar{M}. \end{cases}$$

Note that when the matrix $\bar{M}$ is of full rank, at most one vector $\bar{\gamma} \in \mathbb{R}^r$ can satisfy (3.1).

Clarke showed in [3] that when problem (P) is calm, $L(t,\cdot,\cdot)$ satisfies certain assumptions including ($\mathcal{L}$), and when H satisfies the strong Lipschitz condition

$\exists\ K(\cdot) \in L^1[0,1],\ \exists\ \varepsilon > 0 : \forall\, p \in \mathbb{R}^n,\ \forall\,(t,y_1)$, and $(t,y_2) \in T(\bar{x};\varepsilon)$, one has $|H(t,y_1,p) - H(t,y_2,p)| \le K(t)(1+|p|)|y_1 - y_2|$,

then a necessary condition for the *strong* minimality of $\bar{x}$ is the existence of $\bar{p} \in W^{1,1}[0,1]$ satisfying the Hamiltonian inclusions and the transversality conditions, and thus, if $H(t,\cdot,\cdot)$ is C^1 near $\bar{z} := (\bar{x},\bar{p})$, then $\bar{z}$ satisfies (3.1). The result in [3] was generalized by Clarke in [4] and also by Loewen and Rockafellar in [6]. When $\bar{x}$ is an $W^{1,\infty}$-weak local minimum for (P), it is proved that there exists an arc $\bar{p} \in W^{1,1}[0,1]$ satisfying the *Euler equations* and the *transversality conditions*. Under extra hypotheses, and if $H(t,\cdot,\cdot)$ is C^1 near $\bar{z} := (\bar{x},\bar{p})$, these conditions are equivalent to (3.1), as was proved by Rockafellar in [10].

DEFINITION 3.2. *For a given normal extremal* $(\bar{x}, \bar{p})$ *with associated* $\bar{\gamma}$*, the accessory problem corresponding to* (P) *at* $(\bar{x}, \bar{p}, \bar{\gamma})$ *is defined to be*

$$\text{(AP)} \quad \textit{minimize} \;\; J_2(\eta, v) := \frac{1}{2}\left\langle \Gamma \begin{pmatrix} \eta(0) \\ \eta(1) \end{pmatrix}, \begin{pmatrix} \eta(0) \\ \eta(1) \end{pmatrix} \right\rangle + \frac{1}{2}\int_0^1 \left\{ \langle \bar{H}_{pp}(t)v(t), v(t)\rangle - \langle \bar{H}_{xx}(t)\eta(t), \eta(t)\rangle \right\} dt$$

over $(\eta, v) \in W^{1,1}[0,1] \times L^\infty[0,1]$ *solution of*

$$\dot{\eta}(t) = \bar{H}_{px}(t)\eta(t) + \bar{H}_{pp}(t)v(t) \quad \textit{a.e.}, \tag{3.2}$$

$$\bar{M}\begin{pmatrix} \eta(0) \\ \eta(1) \end{pmatrix} = 0,$$

where $\Gamma := \nabla^2(\ell + \phi^T\bar{\gamma})|_{(\bar{x}(0),\bar{x}(1))}$.

Necessary conditions for (P) involving the accessory problem are given by the following result.

THEOREM 3.3. *Assume that* $\bar{z} := (\bar{x}, \bar{p}) \in W^{1,1}[0,1]$ *satisfy* (H_2) *and* $(\mathcal{L})$*, and form together with* $\bar{\gamma} \in \mathbb{R}^r$ *a normal extremal for* (P)*. Suppose that for* $s \in [1, \infty]$*,* $\bar{x}$ *is a* $W^{1,s}$*-weak local minimum with* (H_p^s) *satisfied. Then either the minimum value of the accessory problem is zero or else the* $\bar{M}$*-controllability of* (3.2) *fails on* $[0,1]$*.*

Let $Z : [0,1] \to \mathbb{R}^{n\times n}$ *denote the fundamental matrix of the system*

$$\begin{cases} -\dot{Z}(t) = Z(t)\bar{H}_{px}(t) & \textit{a.e.}, \\ Z(1) = I = \textit{identity matrix in } \mathbb{R}^{n\times n}. \end{cases} \tag{3.3}$$

Remark 3.1. From Definition 2.8, system (3.2) is *not* $\bar{M}$-controllable on $[0,1]$, meaning that Im Λ is a proper linear subspace of $\mathbb{R}^r$, where $A(t) := \bar{H}_{px}(t)$, $R(t) := \bar{H}_{pp}(t)$, and $Z_b := Z$. Hence there exists $\gamma \in \mathbb{R}^r$, $\gamma \neq 0$ satisfying

$$\gamma^T\bar{M}\begin{bmatrix} I \\ Z(0) \end{bmatrix} = 0$$

and

$$\gamma^T\bar{M}\begin{bmatrix} 0 \\ I \end{bmatrix} Z(t)\bar{H}_{pp}(t) = 0, \quad t \in [0,1] \quad \text{a.e.}$$

This is equivalent to saying that there exists $(y, \gamma) \not\equiv 0$ a solution on $[0,1]$ of (2.5), where the equivalence is revealed by setting $y(t) := Z^T(t)\bar{M}_R^T\gamma$. $\bar{M}_R$ is the $r \times n$-matrix in the partition $\bar{M} = (\bar{M}_L\ \bar{M}_R)$. Hence, if the system (3.2) is $\bar{M}$-normal, then the accessory problem must have a zero minimum value. This is the case, for instance, if we have that $\bar{H}_{pp}(t)$ is positive definite and $\bar{M}$ is of full rank, since in this case $(y, \gamma) \equiv 0$ is the only solution to the corresponding system (2.5).

The proof of Theorem 3.3, which we present later, will involve the following variational problem.

$$(\mathrm{C}_{\mathcal{H}}) \qquad \text{minimize } J_C(x,p) := \ell(x(0),x(1)) + \int_0^1 \{\langle p(t), \dot{x}(t)\rangle - H(t,x(t),p(t))\}dt$$

subject to

$$\dot{x}^T(t) = H_p(t,x(t),p(t)) \quad \text{a.e.},$$
$$\phi(x(0),x(1)) = 0,$$

where $x(\cdot) \in W^{1,1}[0,1]$, $p(\cdot) \in L^\infty[0,1]$, and H is the Hamiltonian given by (1.2).

Note that the problem $(\mathrm{C}_{\mathcal{H}})$ is an *optimal control* problem, where $x(\cdot)$ is the state and $p(\cdot)$ is the control. Hence the optimality notions of strong and $W^{1,s}$-weak local minima introduced in section 2 and the corresponding classical notions given in Definition 2.2 apply to $(\mathrm{C}_{\mathcal{H}})$.

It is known that the objective function $J_C(x,p)$, when unconstrained, has no local minima nor maxima. However, as we shall see below, when constrained as in $(\mathrm{C}_{\mathcal{H}})$, $J_C(x,p)$ admits a (local) minimum whenever the generalized Bolza problem (P) does.

PROPOSITION 3.4. *Assume that there exists* $\bar{z} := (\bar{x},\bar{p}) \in W^{1,1}[0,1] \times L^\infty[0,1]$ *that satisfy* $(\mathcal{L})$, (H_1), *and* (3.1)(ii). *Then, for* x *near* $\bar{x}$, $J(x)$ *is well defined (possibly* $+\infty$*), and if* $\bar{x}$ *is a strong,* $W^{1,s}$*-weak local minimum for* (P) *for some* $s \in [1,\infty]$, *then* $(\bar{x},\bar{p})$ *is, respectively, a strong, or* $W^{1,s}$*-weak local minimum for* $(\mathrm{C}_{\mathcal{H}})$.

Proof. From the definition of H in (1.2) and hypothesis (H_1)(i) it follows that $H(t,x,\cdot)$ is convex and lower semicontinuous for all $(t,x) \in T(\bar{x};\varepsilon)$. Then, by $(\mathcal{L})$ we obtain, for $(t,x,v) \in T(\bar{x};\varepsilon) \times \mathbb{R}^n$,

$$L(t,x,v) = \sup\{\langle p,v\rangle - H(t,x,p) \mid p \in \mathbb{R}^n\}, \tag{3.4}$$

whence, by (H_1)(ii)–(iii) and Lemma 2.5 it results that there exist $\bar{\delta} > 0$ ($\bar{\delta} < \varepsilon$) and γ such that for $\|z - \bar{z}\|_\infty < \bar{\delta}$,

$$\int_0^1 |H(t,z(t))|dt \le \gamma. \tag{3.5}$$

Then by the $(\mathcal{L} \times \mathcal{B})$-measurability of L we get that for $x \in W^{1,1}[0,1]$ satisfying $\|x - \bar{x}\|_\infty < \bar{\delta}$

$$\int_0^1 L(t,x(t),\dot{x}(t))dt \ge \int_0^1 \langle \bar{p}(t),\dot{x}(t)\rangle dt - \gamma,$$

and thus $J(x)$ is well defined (possibly $+\infty$) near $\bar{x}$. Using (3.4) again, it follows that for such x

$$\begin{aligned} J(x) &:= \ell(x(0),x(1)) + \int_0^1 L(t,x(t),\dot{x}(t))dt \\ &= \ell(x(0),x(1)) + \int_0^1 \sup_{p\in\mathbb{R}^n} \{\langle p,\dot{x}(t)\rangle - H(t,x(t),p)\}dt. \end{aligned}$$

The convexity of $H(t,x,\cdot)$ and (3.1)(ii) yield that

$$\begin{aligned} J(\bar{x}) &= \ell(\bar{x}(0),\bar{x}(1)) + \int_0^1 \{\langle \bar{p}(t),\dot{\bar{x}}(t)\rangle - \bar{H}(t)\}dt \\ &= J_C(\bar{x},\bar{p}). \end{aligned}$$

Furthermore, for any (x,p) that is admissible for $(\mathrm{C}_{\mathcal{H}})$ with $\|x-\bar{x}\|_\infty < \bar{\delta}$ we have

$$J(x) = J_C(x,p).$$

Therefore, assume there exists $\varepsilon_0 > 0$ such that

$$J(x) \geq J(\bar{x})$$

for all arcs $x(\cdot)$ that are admissible for (P) and satisfying $\|x-\bar{x}\|_\infty < \varepsilon_0$, or $\|x-\bar{x}\|_{1,s} < \varepsilon_0$, for some $s \in [1,\infty]$. Then, for all (x,p) admissible in $(\mathrm{C}_{\mathcal{H}})$ with $\|x-\bar{x}\|_\infty < \bar{\varepsilon}$, or $\|x-\bar{x}\|_{1,s} < \bar{\varepsilon}$, respectively, we have

$$J_C(x,p) = J(x) \geq J(\bar{x}) = J_C(\bar{x},\bar{p}),$$

where $\bar{\varepsilon} = \min\{\bar{\delta}, \varepsilon_0\}$. □

Combining Lemma 2.6 and Proposition 3.4, we obtain the connection between optimality in (P) and *classical* optimality in $(\mathrm{C}_{\mathcal{H}})$.

COROLLARY 3.5. *Assume that $\bar{z} := (\bar{x},\bar{p})$ satisfy the conditions of Proposition* 3.1. *Then the following hold.*

(i) *If $\bar{x}$ is a strong local minimum for* (P), *then $(\bar{x},\bar{p})$ is a classically L^∞-weak local minimum for* $(\mathrm{C}_{\mathcal{H}})$. *If, in addition, for all t, $H(t,\cdot)$ is C^1 on $B_n(\bar{x}(t);\varepsilon)\times\mathbb{R}^n$, then $(\bar{x},\bar{p})$ is a strong local minimum for* $(\mathrm{C}_{\mathcal{H}})$.

(ii) *If, for $s \in [1,\infty]$, $\bar{x}$ is a $W^{1,s}$-weak local minimum for* (P) *and* (H_p^s) *holds, then $(\bar{x},\bar{p})$ is a classically L^∞-weak local minimum for* $(\mathrm{C}_{\mathcal{H}})$. *If, in addition, $H(t,\cdot)$ is C^1 on $B_n(\bar{x}(t);\varepsilon)\times\mathbb{R}^n$ and H_p is continuous at $(\bar{x},\bar{p})$ from $L^\infty\times L^s$ to L^s, then $(\bar{x},\bar{p})$ is a classically L^s-weak local minimum for* $(\mathrm{C}_{\mathcal{H}})$.

The next result shows that if system (3.2) is $\bar{M}$-controllable (see Definition 2.8) and $(\bar{x},\bar{p})$ is a classically L^∞-weak local minimum for the optimal control problem $(\mathrm{C}_{\mathcal{H}})$, then the adjoint variable $q(\cdot)$ corresponding to $(\bar{x},\bar{p})$ in the weak version of the Pontryagin maximum principle applied to $(\mathrm{C}_{\mathcal{H}})$ coincides with $\bar{p}$.

LEMMA 3.6. *Assume that $(\bar{x},\bar{p},q,\gamma)$ satisfy the weak version of the Pontryagin maximum principle applied to* $(\mathrm{C}_{\mathcal{H}})$. *If the system* (3.2) *is $\bar{M}$-controllable, $\bar{M}$ is of full rank, and $(\bar{x},\bar{p})$ satisfy* (3.1), *then the problem* $(\mathrm{C}_{\mathcal{H}})$ *is normal and $(q,\gamma) = (\bar{p},\bar{\gamma})$, up to scalar multiplication.*

Proof. Let $(\bar{x},\bar{p},q,\gamma)$ satisfy the weak version of the maximum principle corresponding to $(\mathrm{C}_{\mathcal{H}})$. Then there exists $\lambda_0 \geq 0$ such that λ_0,γ, and q are not all zero, and

$$-\dot{q}(t) = \bar{H}_{xp}(t)q(t) - \lambda_0[\bar{H}_{xp}(t)\bar{p}(t) - \bar{H}_x(t)] \quad \text{a.e.},$$

$$\bar{H}_{pp}(t)[q(t) - \lambda_0\bar{p}(t)] = 0 \quad \text{a.e.},$$

$$(q^T(0), -q^T(1)) = \lambda_0\nabla\ell(\bar{x}(0),\bar{x}(1)) + \gamma^T\bar{M}.$$

If $\lambda_0 = 0$, then (q,γ) satisfies system (2.5), where $A = \bar{H}_{xp}$ and $R = \bar{H}_{pp}$. By the $\bar{M}$-controllability of the system (3.2) and Remark 2.4 we get that $q \equiv 0$ and $\gamma = 0$. Since λ_0,γ, and q are not all zero, we conclude that $\lambda_0 \neq 0$.

Now, assume $\lambda_0 = 1$, and use in the above equations that $(\bar{x},\bar{p})$ satisfy (3.1); we obtain

$$-(\dot{q}(t) - \dot{\bar{p}}(t)) = \bar{H}_{xp}(t)(q(t) - \bar{p}(t)) \quad \text{a.e.},$$

$$\bar{H}_{pp}(t)(q(t) - \bar{p}(t)) = 0 \quad \text{a.e.},$$

$$(q^T(0) - \bar{p}^T(0), -(q^T(1) - \bar{p}^T(1))) = (\gamma^T - \bar{\gamma}^T)\bar{M}.$$

Using the $\bar{M}$-controllability, it follows that $q \equiv \bar{p}$. The full rank condition on $\bar{M}$ yields that $\gamma = \bar{\gamma}$. □

In order to prove Theorem 3.3, we shall establish the following result, which says that the necessary conditions given by Theorem 3.3 are in fact necessary for the L^∞-weak local minimality of $(\bar{x}, \bar{p})$ in $(\mathrm{C}_\mathcal{H})$.

THEOREM 3.7. *Assume that* $(\bar{x}, \bar{p}) \in W^{1,1}[0,1]$ *satisfies* (H_2). *If* $(\bar{x}, \bar{p})$ *is a classically* L^∞*-weak local minimum for* $(\mathrm{C}_\mathcal{H})$, *then the conclusions of Theorem* 3.3 *are satisfied.*

To prove Theorem 3.7 we intend to calculate the second variation of the optimal control problem $(\mathrm{C}_\mathcal{H})$. For achieving this goal, one could attempt to apply known second-order necessary conditions. However, all known results (see [8], [12], and the references therein) require the dynamics and the integrand to be at least *twice* directionally *differentiable*. Since $H_p(t,\cdot,\cdot)$ is only C^1 and is involved in both the dynamics and the integrand of $(\mathrm{C}_\mathcal{H})$, those results cannot be applied here. Nevertheless, as we shall see below in the proof of Theorem 3.7, the second variation of $(\mathrm{C}_\mathcal{H})$ can be derived by taking its special structure into consideration. We shall need the following result, which says that the $\bar{M}$-controllability of system (3.2) allows us to associate with each pair (η, v) solving that system, an admissible family $(x(\cdot,\alpha), p(\cdot,\alpha))_{\alpha\in(-\delta,\delta)}$ for the problem $(\mathrm{C}_\mathcal{H})$ which includes $(\bar{x}, \bar{p})$ at $\alpha = 0$ and has a first derivative with respect to α at $\alpha = 0$ equal to (η, v).

PROPOSITION 3.8. *Assume* (H_2) *to hold at the admissible pair* $\bar{z} = (\bar{x}, \bar{p})$ *and that the system* (3.2) *is* $\bar{M}$*-controllable. Then, for every* $(\eta, v) \in W^{1,1}[0,1] \times L^\infty[0,1]$ *satisfying system* (3.2) *and its boundary conditions, there exists an admissible family* $(x(\cdot;\alpha), p(\cdot;\alpha))_{\alpha\in(-\delta,\delta)}$ *for* $(\mathrm{C}_\mathcal{H})$ *such that* $(x(t;\cdot),\ p(t;\cdot))$ *is* C^1, $(\frac{\partial x}{\partial\alpha}, \frac{\partial p}{\partial\alpha})$ *is continuous at* 0 *from* $\mathbb{R}$ *to* L^∞, *and*

(i) $x(t;0) = \bar{x}(t),\ p(t;0) = \bar{p}(t) \quad \forall\, t \in [0,1]$,

(ii) $\frac{\partial x}{\partial\alpha}(t;0) = \eta(t),\ \frac{\partial p}{\partial\alpha}(t;0) = v(t) \quad \forall\, t \in [0,1]$.

Proof. Let $\beta_1, \ldots, \beta_r$ be r linearly independent vectors in $\mathbb{R}^r$. By the $\bar{M}$-controllability of system (3.2), there exist functions $v_1, \ldots, v_r \in L^\infty[0,1]$ and $\eta_1, \ldots, \eta_r$ in $W^{1,1}[0,1]$ satisfying

$$\left\{\begin{array}{l} \dot{\eta}_j(t) = \bar{H}_{px}(t)\eta_j(t) + \bar{H}_{pp}(t)v_j(t) \quad \text{a.e.,} \\ \bar{M}\begin{pmatrix} \eta_j(0) \\ \eta_j(1) \end{pmatrix} = \beta_j. \end{array}\right. \tag{3.6}$$

Define on $[0,1] \times \mathbb{R} \times \mathbb{R}^r$

$$p(t;\alpha,\lambda) := \bar{p}(t) + \alpha v(t) + \sum_{j=1}^{r} \lambda_j v_j(t). \tag{3.7}$$

Consider the system

$$\left\{\begin{array}{l} \dot{x}^T(t) = H_p(t, x(t), p(t,\alpha,\lambda)), \\ x(0) = \bar{x}(0) + \alpha\eta(0) + \sum_{j=1}^{r} \lambda_j \eta_j(0). \end{array}\right. \tag{3.8}$$

Clearly, when $(\alpha,\lambda) = (0,0)$, system (3.8) has $\bar{x}$ as the solution. Hypothesis (H_2) and Lemma 2.5 yield that for

$$F(t,x,\alpha,\lambda) := H_p(t,x,p(t,\alpha,\lambda))$$

F and $\nabla_{(x,\alpha,\lambda)}F$ are Carathéodory on some tube $T(\bar{x},(0,0);\varepsilon_0)$ for $\varepsilon_0 \leq \varepsilon$. Hence, by the embedding theorem of differential equations [11, II.4.11], it results that there exists $\bar{\delta} > 0$ ($\bar{\delta} < \varepsilon_0$) such that for $(\alpha,\lambda) \in B_{r+1}(\bar{\delta})$ and for $x_0 \in B_n(\bar{x}(0);\bar{\delta})$, the system (3.8)(i) has a unique solution $x(\cdot;x_0,\alpha,\lambda)$ in $W^{1,1}[0,1]$ satisfying $x(0;x_0,\alpha,\lambda) = x_0$. Furthermore, on $B_n(\bar{x}(0);\bar{\delta}) \times B_{r+1}(\bar{\delta})$, $x(t,\cdot,\cdot,\cdot)$ has a derivative that is continuous, L^∞-uniformly in t. However, by (3.8)(ii), there exists $\delta_0 > 0$ ($\delta_0 \leq \bar{\delta}$) such that for $(\alpha,\lambda) \in B_{r+1}(\delta_0)$, the unique solution to (3.8) $x(t;\alpha,\lambda) := x(t;x_{\alpha,\lambda},\alpha,\lambda)$, where $x_{\alpha,\lambda} := \bar{x}(0) + \alpha\eta(0) + \sum_{j=1}^r \lambda_j\eta_j(0)$, has a derivative with respect to (α,λ) that is continuous at 0 from $\mathbb{R}^{r+1}$ to L^∞.

Differentiate the system (3.8) with respect to (α,λ) and use (3.2), (3.6), and (3.7) to get

$$\text{(3.9)} \qquad \begin{cases} \dfrac{\partial x}{\partial \alpha}(\cdot;0,0) = \eta(\cdot), & \dfrac{\partial p}{\partial \alpha}(\cdot;0,0) = v(\cdot), \\ \dfrac{\partial x}{\partial \lambda_j}(\cdot;0,0) = \eta_j(\cdot), & \dfrac{\partial p}{\partial \lambda_j}(\cdot;0,0) = v_j(\cdot) \quad \forall\, j = 1,\dots,r. \end{cases}$$

Define $G : B(\delta_0) \times B_r(\delta_0) \to \mathbb{R}^r$ by

$$(\alpha,\lambda) \to G(\alpha,\lambda) := \phi(x(0;\alpha,\lambda), x(1;\alpha,\lambda)).$$

We have $G(0,0) = 0$, $\frac{\partial G(0,0)}{\partial \lambda_j} = \bar{M}\binom{\eta_j(0)}{\eta_j(1)} = \beta_j$, and thus $\frac{\partial G}{\partial \lambda}(0,0)$ is nonsingular. By the implicit function theorem, there exist $\delta < \delta_0$ and a C^1-function $\lambda(\cdot) : B(\delta) \to \mathbb{R}^r$ with $\lambda(0) = 0$, $\lambda(B(\delta)) \subset B(\delta_0)$, and

$$\text{(3.10)} \qquad \phi(x(0;\alpha,\lambda(\alpha)), x(1;\alpha,\lambda(\alpha))) = 0.$$

Differentiating (3.10) with respect to α at $\alpha = 0$ and using (3.9), (3.6), and the fact the (η, v) satisfies (3.2), we get $\sum_{j=1}^r \dot{\lambda}_j(0)\beta_j = 0$, which yields $\dot{\lambda}_j(0) = 0$ for all j.

Now, set on $[0,1] \times (-\delta,\delta)$

$$p(t;\alpha) := p(t;\alpha,\lambda(\alpha)),$$

$$x(t;\alpha) := x(t;\alpha,\lambda(\alpha)).$$

Using (3.7) and (3.9), we obtain the result of this proposition. □

We are now ready to prove Theorem 3.7. As we shall see in the proof, the map

$$\alpha \to J_C(x(\cdot;\alpha), p(\cdot;\alpha))$$

is twice differentiable at 0, even though the functions defining $J_C(x,p)$ are not themselves twice differentiable.

Proof of Theorem 3.7. Let $(\bar{x},\bar{p})$ satisfy (3.1).

Assume that system (3.2) is $\bar{M}$-controllable and that $(\bar{x},\bar{p})$ provides a classically L^∞-weak local minimum for $(C_\mathcal{H})$. Thus $(\bar{x},\bar{p})$ must satisfy the weak version of the Pontryagin maximum principle. By Lemma 3.6, we deduce that $(C_\mathcal{H})$ is normal, and the adjoint variable corresponding to $(\bar{x},\bar{p})$ is $\bar{p}$.

Let (η, v) satisfy system (3.2) and its boundary conditions. Then, by Proposition 3.8, there exists a family $(x(\cdot;\alpha), p(\cdot;\alpha))_{\alpha\in(-\delta,\delta)}$ that is admissible for $(C_\mathcal{H})$ and satisfies the conditions stated in Proposition 3.8. In particular, using Lemma 2.5, it

follows that there exist $\gamma > 0 (\gamma \leq \delta)$ and $\mu > 0$ such that, for almost all t and for $\alpha, \alpha' \in (-\gamma, \gamma)$,

$$|(x(t,\alpha), p(t,\alpha)) - (x(t;\alpha'), p(t,\alpha'))| \leq \mu|\alpha - \alpha'|. \tag{3.11}$$

Thus choose γ small enough so that $(\bar{x}, \bar{p})$ is optimal for J_C on $T(\bar{x}, \bar{p}; \mu\gamma)$. Hence, by setting $\mathbb{H}(t;\alpha) := H(t, x(t;\alpha), p(t;\alpha))$ and $\mathbb{J}_C(\alpha) := J_C(x(\cdot;\alpha), p(\cdot;\alpha))$, we get that $\alpha = 0$ is a minimum for $\mathbb{J}_C(\alpha)$ over $(-\gamma, \gamma)$. On the other hand, hypothesis (H_2) and Lemma 2.5 yield that there exists a neighborhood of 0, $(-\bar{\gamma}, \bar{\gamma})$, where $\mathbb{H}, \mathbb{H}_p$, and $\mathbb{H}_x$ are Lipschitz from $\mathbb{R}$ to L^1 and $\mathbb{H}_p(t;\cdot)$ is bounded by an integrable function of t. Set $\gamma_0 := \min(\gamma, \bar{\gamma})$. Thus, for $\alpha \in (-\gamma_0, \gamma_0)$, we have

$$\begin{aligned}
\mathbb{J}_C(\alpha) &:= \ell(x(0;\alpha), x(1;\alpha)) + \int_0^1 \{\mathbb{H}_p(t;\alpha)p(t;\alpha) - \mathbb{H}(t;\alpha)\}dt \\
&= \ell(x(0;\alpha), x(1;\alpha)) + \int_0^1 \{\mathbb{H}_p(t;\alpha)(p(t;\alpha) - \bar{p}(t)) + \dot{x}^T(t;\alpha)\bar{p}(t) - \mathbb{H}(t;\alpha)\}dt \\
&= \ell(x(0;\alpha), x(1;\alpha)) + \bar{p}^T(1)x(1;\alpha) - \bar{p}^T(0)x(0;\alpha) \\
&\quad + \int_0^1 \{\mathbb{H}_p(t;\alpha)(p(t;\alpha) - \bar{p}(t)) - \mathbb{H}(t;\alpha) - \dot{\bar{p}}^T(t)x(t;\alpha)\}dt.
\end{aligned}$$

We shall show that $\mathbb{J}_C(\cdot)$ is twice differentiable at 0. Since on $(-\gamma_0, \gamma_0)$, x and p are Lipschitz from $\mathbb{R}$ to L^∞ (see (3.11)), $\mathbb{H}$ and $\mathbb{H}_p$ are Lipschitz near 0 from $\mathbb{R}$ to L^1, $\mathbb{H}_p(t;\cdot)$ is bounded by an L^1-function of t, and ℓ is Lipschitz, it follows from the dominated convergence theorem and (3.1)(iii) that for $\bar{\alpha} \in (-\gamma_0, \gamma_0)$ and for $x_\alpha = \frac{\partial x}{\partial \alpha}$, $p_\alpha = \frac{\partial p}{\partial \alpha}$, we have

$$\begin{aligned}
\mathbb{J}'_C(\bar{\alpha}) &= (\nabla\ell(x(0;\bar{\alpha}), x(1;\bar{\alpha})) - \nabla\ell(\bar{x}(0), \bar{x}(1)) - \bar{\gamma}^T\bar{M}) \begin{pmatrix} x_\alpha(0;\bar{\alpha}) \\ x_\alpha(1;\bar{\alpha}) \end{pmatrix} \\
&\quad + \int_0^1 \big\{(\mathbb{H}_{px}(t;\bar{\alpha})x_\alpha(t;\bar{\alpha}) + \mathbb{H}_{pp}(t;\bar{\alpha})p_\alpha(t;\bar{\alpha}))^T(p(t;\bar{\alpha}) - \bar{p}(t)) \\
&\quad - (\mathbb{H}_x(t;\bar{\alpha}) + \dot{\bar{p}}^T(t))x_\alpha(t;\bar{\alpha})\big\}dt.
\end{aligned}$$

Using (3.1), system (3.2), and Proposition 3.8, we obtain

$$\mathbb{J}'_C(0) = 0.$$

Let us calculate $\mathbb{J}''_C(0)$. For $h \in (-\gamma_0, \gamma_0)$ and $i \in \{1, \ldots, r\}$ we have

$$\phi^i(x(0;h), x(1;h)) = 0;$$

hence

$$\nabla\phi^i(x(0;h), x(1;h)) \begin{bmatrix} x_\alpha(0;h) \\ x_\alpha(1;h) \end{bmatrix} = 0.$$

Thus, by the mean value theorem applied to each partial derivative $\partial_{x_j}\phi^i$ and $\partial_{x_j}\ell$, where $j = 1, \ldots, 2n$, it results that there exist h_j^i and $\tilde{h}_j$ in between 0 and h

such that, for $\tilde{h}_j$,

$$\bar{M} = \begin{bmatrix} \bar{M}^1 \\ \vdots \\ \bar{M}^r \end{bmatrix} \text{ and } x_\alpha = \begin{pmatrix} x_\alpha^1 \\ \vdots \\ x_\alpha^n \end{pmatrix}$$

we have

$$\begin{aligned} -\frac{\bar{M}^i}{h} \begin{pmatrix} x_\alpha(0;h) \\ x_\alpha(1;h) \end{pmatrix} &= \left[\frac{\nabla\phi^i(x(0;h),x(1;h)) - \bar{M}^i}{h}\right] \begin{pmatrix} x_\alpha(0;h) \\ x_\alpha(1;h) \end{pmatrix} \\ &= \sum_{j=1}^{n} x_\alpha^j(0;h) \nabla\partial_{x_j}\phi^i(x(0,h_j^i),x(1,h_j^i)) \begin{pmatrix} x_\alpha(0;h_j^i) \\ x_\alpha(1;h_j^i) \end{pmatrix} \\ &\quad + \sum_{j=n+1}^{2n} x_\alpha^{j-n}(1;h) \nabla\partial_{x_j}\phi^i(x(0,h_j^i),x(1,h_j^i)) \begin{pmatrix} x_\alpha(0;h_j^i) \\ x_\alpha(1;h_j^i) \end{pmatrix} \end{aligned}$$

and

$$\frac{\partial_{x_j}\ell(x(0;h),x(1;h)) - \partial_{x_j}\ell(\bar{x}(0),\bar{x}(1))}{h} = \nabla\partial_{x_j}\ell(x(0;\tilde{h}_j),x(1;\tilde{h}_j)) \begin{pmatrix} x_\alpha(0;\tilde{h}_j) \\ x_\alpha(1;\tilde{h}_j) \end{pmatrix},$$

whence

$$\begin{aligned} &\lim_{h\to 0} \frac{(\nabla\ell(x(0;h),x(1;h)) - \nabla\ell(\bar{x}(0),\bar{x}(1)) - \bar{\gamma}^T\bar{M})}{h} \begin{pmatrix} x_\alpha(0;h) \\ x_\alpha(1;h) \end{pmatrix} \\ &\qquad = \left\langle \Gamma \begin{pmatrix} \eta(0) \\ \eta(1) \end{pmatrix}, \begin{pmatrix} \eta(0) \\ \eta(1) \end{pmatrix} \right\rangle, \end{aligned}$$

where $\Gamma := \nabla^2(\ell + \phi^T\bar{\gamma})|_{(\bar{x}(0),\bar{x}(1))}$.

On the other hand, from (H_2) and the Lipschitz property of x and p in h obtained in Proposition 3.8, it results that the integrand

$$\begin{aligned} \int_0^1 \{(\mathbb{H}_{px}(t;h)x_\alpha(t;h) + \mathbb{H}_{pp}(t;h)p_\alpha(t;h))^T \frac{(p(t;h) - \bar{p}(t))}{h} \\ - \frac{(\mathbb{H}_x(t;h) - \mathbb{H}_x(t;0))}{h} x_\alpha(t;h)\} dt \end{aligned}$$

is bounded by an integrable function. Therefore, by the dominated convergence theorem we get

$$\begin{aligned} \mathbb{J}_C''(0) := \lim_{h\to 0} \frac{\mathbb{J}_C'(h)}{h} &= \left\langle \Gamma \begin{pmatrix} \eta(0) \\ \eta(1) \end{pmatrix}, \begin{pmatrix} \eta(0) \\ \eta(1) \end{pmatrix} \right\rangle \\ &\quad + \int_0^1 \{v^T(t)\bar{H}_{px}(t)\eta(t) + v^T(t)\bar{H}_{pp}(t)v(t) - \eta^T(t)\bar{H}_{xx}(t)\eta(t) \\ &\qquad - \eta^T(t)\bar{H}_{xp}(t)v(t)\} dt \\ &= 2J_2(\eta, v). \end{aligned}$$

Now, since $\min\{\mathbb{J}_C(\alpha) : \alpha \in (-\gamma_0, \gamma_0)\} = \mathbb{J}_C(0)$ and $\mathbb{J}'_C(0) = 0$,

$$\mathbb{J}''_C(0) \geq 0.$$

Therefore, the proof of the theorem is complete. □

Proof of Theorem 3.3. Let $s \in [1, \infty]$, and let $\bar{x}$ be $W^{1,s}$-weak local minimum for (P) with (H_p^s) satisfied. Consider $\bar{z} = (\bar{x}, \bar{p})$ as in the theorem. Then, by Corollary 3.5, it results that $(\bar{x}, \bar{p})$ provides a classically L^∞-weak local minimum for $(C_\mathcal{H})$. Therefore, by Theorem 3.7 the proof is complete. □

Now, for the rest of this section, assume that the endpoints cost and constraint in (P) are separable; that is,

$$\ell(x, y) := \ell_0(x) + \ell_1(y),$$

$$\phi(x, y) := \begin{pmatrix} \phi_0(x) \\ \phi_1(y) \end{pmatrix},$$

where $\phi_i : \mathbb{R}^n \to \mathbb{R}^{r_i}$ for $i = 0, 1$, and $r_0 + r_1 = r$.

In this case, the matrices $\bar{M}$ and Γ in the accessory problem (AP) take the form

$$\bar{M} = \begin{bmatrix} \bar{M}_0 & 0 \\ 0 & \bar{M}_1 \end{bmatrix} \text{ and } \Gamma = \begin{bmatrix} \Gamma_0 & 0 \\ 0 & \Gamma_1 \end{bmatrix},$$

where

$$\bar{M}_0 := \nabla\phi_0(\bar{x}(0)), \qquad \bar{M}_1 = \nabla\phi_1(\bar{x}(1)),$$

$$\Gamma_0 := \nabla^2(\ell_0 + \phi_0^T\bar{\gamma}_0)\big|_{x=\bar{x}(0)}, \qquad \Gamma_1 = \nabla^2(\ell_1 + \phi_1^T\bar{\gamma}_1)\big|_{x=\bar{x}(1)},$$

and

$$\begin{pmatrix} \gamma_0 \\ \gamma_1 \end{pmatrix} := \gamma.$$

Here $\bar{M}_0 \in \mathbb{R}^{r_0 \times n}$, $\bar{M}_1 \in \mathbb{R}^{r_1 \times n}$, $\gamma_0 \in \mathbb{R}^{r_0}$, and $\gamma_1 \in \mathbb{R}^{r_1}$.

Note that when no final constraint is present, that is, when $\phi_1 : \mathbb{R}^n \to \{0\}$, then $\bar{M}_1$ is automatically of full rank.

Without loss of generality we assume that $\bar{M}_0$ and $\bar{M}_1$ are in fact orthogonal projections in $\mathbb{R}^n$. This can easily be done by taking, instead of $\bar{M}_i$, the orthogonal projections

$$\bar{M}_i^T(\bar{M}_i\bar{M}_i^T)^{-1}\bar{M}_i, \quad i = 0, 1,$$

where the $\bar{M}_i$'s are of full rank, by (H_2)(v).

When system (3.2) is $(\bar{M}_0 : \bar{M}_1)$-normal, the optimality of (η, v) in (AP) yields the existence of an arc q and vectors γ_0 and γ_1 satisfying on $[0, 1]$

$$\begin{cases} \dot{\eta}(t) = A(t)\eta(t) + R(t)q(t) & \text{a.e.}, \\ -\dot{q}(t) = A^T(t)q(t) + P(t)\eta(t) & \text{a.e.}, \end{cases} \tag{3.12}$$

$$\begin{cases} q(0) = \Gamma_0\eta(0) + \bar{M}_0\gamma_0, \\ -q(1) = \Gamma_1\eta(1) + \bar{M}_1\gamma_1, \end{cases}$$

where

$$A(t) := \bar{H}_{px}(t), \quad R(t) := \bar{H}_{pp}(t), \quad \text{and} \quad P(t) := \bar{H}_{xx}(t). \tag{3.13}$$

Consider (U_1, V_1) the solution of the matrix system corresponding to (3.12),

$$\begin{cases} \dot{U}(t) = A(t)U(t) + R(t)V(t) \quad \text{a.e.}, \\ -\dot{V}(t) = A^T(t)V(t) + P(t)U(t) \quad \text{a.e.}, \end{cases} \tag{3.14}$$

with final conditions

$$\begin{cases} U(1) = I - \bar{M}_1, \\ V(1) = -\Gamma_1(I - \bar{M}_1) - \bar{M}_1. \end{cases} \tag{3.15}$$

The following result states that the existence of a conjoined basis on $[0,1]$ for (3.14) and (3.15) with certain initial conditions is *necessary* for the optimality in (P) or in $(C_{\mathcal{H}})$.

THEOREM 3.9. *Let $\bar{z} := (\bar{x}, \bar{p})$ satisfy the conclusions of Theorem* 3.3. *If, in addition, for all $c \in (0,1)$ the system* (3.2) *is $(\bar{M}_0 : I)$-normal on $[0,c]$ and $(I : \bar{M}_1)$-normal on $[c,1]$, then (U_1, V_1) satisfies*

(i) $U^TV = V^TU$ *on* $[0,1]$,

(ii) $\det U(t) \neq 0$ *on* $(0,1)$,

(iii) $U^T(0)(\Gamma_0U(0) - V(0)) \geq 0$ *on* $K := \{\alpha : \bar{M}_0U(0)\alpha = 0\}$,

and

(iv) $V(1) + \Gamma_1(I - \bar{M}_1) + \bar{M}_1 = 0$.

Proof. From the normality hypotheses it follows that the accessory problem (AP) has a minimum value equal to zero. Thus by [17, Theorem 4.1] the result of the theorem follows. □

An immediate consequence of the above theorem is an important result on necessary conditions concerning the Riccati equation.

COROLLARY 3.10. *Under the conditions of Theorem* 3.9, *there exists on* $(0,1)$ *a symmetric absolutely continuous solution W of*

$$\dot{W}(t) + A^T(t)W(t) + W(t)A(t) + W(t)R(t)W(t) + P(t) = 0 \tag{$\mathcal{R}$}$$

satisfying

$$\begin{cases} \lim\limits_{t\to 1} W(t)U_1(t) = -\Gamma_1(I - \bar{M}_1) - \bar{M}_1, \\ U_1^T(0) \lim\limits_{t\to 0^+} (\Gamma_0 - W(t))U_1(t) \geq 0, \\ \qquad\qquad \text{on } K := \{\alpha \mid \bar{M}_0U_1(0)\alpha = 0\}. \end{cases} \tag{3.16}$$

Remark 3.2. When the final state endpoint is free, $\bar{M}_1 = 0$ and (3.15) yield that $U_1(1) = I$. In this case the function W in Corollary 3.10 is defined on $(0,1]$, and (3.16)(i) reduces to

$$W(1) = -\Gamma_1. \tag{3.17}$$

If also the initial condition is fixed, then (3.16)(ii) is trivially satisfied, and thus (3.16) becomes simply (3.17).

By symmetry, we could define (U_0, V_0) as the solution of (3.14), and instead of (3.15),

$$U(0) = I - \bar{M}_0,$$

$$V(0) = \Gamma_0(I - \bar{M}_0) + \bar{M}_0.$$

Then necessary conditions for (P) and ($C_{\mathcal{H}}$) parallel to Theorem 3.9 and Corollary 3.10 could be phrased in terms of (U_0, V_0).

The following example illustrates the utility of the results in this section.

Example 3.1. Define on $[0,1] \times \mathbb{R} \times \mathbb{R}$ the function

$$L(t,x,v) := \begin{cases} x^3 + \dfrac{v^2}{(t-\frac{1}{2})^{2/3}} & \text{if } t \neq \dfrac{1}{2}, \\ x^3 & \text{if } t = \dfrac{1}{2} \text{ and } v = 0, \\ +\infty & \text{if } t = \dfrac{1}{2} \text{ and } v \neq 0. \end{cases}$$

Consider the problem

$$(P_0) \qquad \text{minimize} \qquad -\frac{5}{3}2^{5/3}x^2(1) + \int_0^1 L(t, x(t), \dot{x}(t))dt$$

$$\text{subject to} \qquad x(0) = 0.$$

The Hamiltonian corresponding to (P_0) is

$$H(t,x,p) = \sup_{v \in \mathbb{R}} \{pv - L(t,x,v)\} = -x^3 + \frac{p^2}{4}\left(t - \frac{1}{2}\right)^{2/3}.$$

Take $\bar{x} \equiv 0$ and $\bar{p} \equiv 0$. Then L satisfies ($\mathcal{L}$), and H satisfies hypotheses (H_2) and (H_p^s) for all $s \in [1, \infty]$. Here, $\bar{M}_0 = I$, $\bar{M}_1 = 0$. For $\bar{\gamma} = \binom{0}{0}$, $(\bar{x}, \bar{p})$ with $\bar{\gamma}$ form a normal extremal for (P_0). In this problem, $A(t) \equiv 0$, $R(t) = \frac{1}{2}(t - \frac{1}{2})^{2/3}$, and $P(t) = 0$. Since the system $\dot{y}(t) \equiv 0$ and $(t - \frac{1}{2})^{2/3}y(t) \equiv 0$ admits only $y \equiv 0$ as a solution on any interval $[a,b] \subset [0,1]$, the normality assumptions in Theorem 3.9 are satisfied.

The Riccati equation ($\mathcal{R}$) and the boundary condition (3.17) are equivalent here to

$$\dot{W}(t) + \frac{1}{2}\left(t - \frac{1}{2}\right)^{2/3} W^2(t) = 0 \quad \text{and} \quad W(1) = \frac{10}{3}2^{5/3}. \tag{3.18}$$

The solution is $W(t) = -\frac{10}{3(t-\frac{1}{2})^{5/3}}$, which exists on $(\frac{1}{2}, 1]$ and not on $(0,1]$. Hence the conclusion of Corollary 3.10 fails. Therefore, by Corollary 3.10, $\bar{x} \equiv 0$ is not a $W^{1,s}$-weak local minimum for (P_0), for any $s \in [1, \infty]$.

4. Sufficient conditions for (P). In this section we first derive for the generalized problem of Bolza (P) a sufficiency criterion for strong local optimality. The conditions therein involve the "Weierstrass-type" condition, and the Riccati equation $(\mathcal{R})$ of Corollary 3.10 whose coefficients are given by (3.13), together with the (joint) boundary conditions

$$\Gamma + \begin{bmatrix} -W(0) & 0 \\ 0 & W(1) \end{bmatrix} > 0 \quad \text{on} \quad \left\{(\alpha,\beta) : \bar{M}\begin{pmatrix} \alpha \\ \beta \end{pmatrix} = 0\right\}, \tag{4.1}$$

where $\Gamma = \nabla^2(\ell + \bar{\gamma}^T\phi)|_{(\bar{x}(0),\bar{x}(1))}$.

This result extends the corresponding results in [14] and [16] to the case when both endpoints of x vary (i.e., $\phi(x(0), x(1)) = 0$).

THEOREM 4.1. *Assume that L is $(\mathcal{L}\times\mathcal{B})$-measurable and that, for a vector $\bar{\gamma}\in\mathbb{R}^r$, $\bar{z} := (\bar{x},\bar{p})$ is a normal extremal for* (P) *at which* (H_2) *holds true. Suppose that*

(i) $L(t,\bar{x}(t),\dot{\bar{x}}(t)+v) - L(t,\bar{x}(t),\dot{\bar{x}}(t)) \geq \langle \bar{p}(t), v\rangle$ *for almost all* $t\in[0,1]$ *and for all* $v\in\mathbb{R}^n$;

(ii) *there exists a symmetric absolutely continuous solution on* $[0,1]$ *to the Riccati equation* $(\mathcal{R})$ *with the boundary conditions* (4.1).

Then $J(x)$ is well defined (possibly $+\infty$) near $\bar{x}$, and $\bar{x}$ provides a strict strong local minimum for (P). *Furthermore, there exist $\bar{\varepsilon}>0$ and $\bar{\delta}>0$ such that for all admissible arcs x satisfying $\|x-\bar{x}\|_\infty < \bar{\delta}$ we have*

$$J(x) - J(\bar{x}) \geq \bar{\varepsilon}\|x-\bar{x}\|_2^2.$$

Proof. Define $\bar{L}(t,x,v) := \sup\{\langle p,v\rangle - H(t,x,p) : p\in\mathbb{R}^n\}$. By hypothesis (H_2) and Lemma 2.5, it results that there exist $\bar{\delta}>0$ ($\bar{\delta}<\varepsilon$) and γ such that for $\|z-\bar{z}\|_\infty<\bar{\delta}$, (3.5) is satisfied. Hence, for $x\in W^{1,1}[0,1]$ with $\|x-\bar{x}\|_\infty<\bar{\delta}$,

$$\int_0^1 \bar{L}(t,x(t),\dot{x}(t))dt \geq \int_0^1 \langle \bar{p}(t),\dot{x}(t)\rangle dt - \gamma.$$

Since

$$L(t,x,v) \geq \bar{L}(t,x,v),$$

we conclude that $J(x)$ is well defined (possibly $+\infty$) near $\bar{x}$.

Now, by the embedding theorem of differential equations there exist $\varepsilon_0>0$ and $\bar{W}$ on $[0,1]$ such that

$$\dot{\bar{W}} + A^T\bar{W} + \bar{W}A + \bar{W}R\bar{W} + P = -\varepsilon_0 I \quad \text{for} \quad t\in[0,1] \text{ a.e.}$$

and

$$\Gamma + \begin{pmatrix} -\bar{W}(0) & 0 \\ 0 & \bar{W}(1) \end{pmatrix} > \varepsilon_0 I \quad \text{on} \quad \left\{(\alpha,\beta) : \bar{M}\begin{pmatrix} \alpha \\ \beta \end{pmatrix} = 0\right\}. \tag{4.2}$$

Set

$$p(t,x) := \bar{p}(t) + \bar{W}(t)(x-\bar{x}(t)),$$

and

$$F(x(\cdot)) := \int_0^1 \Big\{ H(t,x(t),p(t,x(t))) - \bar{H}(t) + \langle \dot{\bar{p}}(t), x(t)-\bar{x}(t)\rangle - \langle \dot{\bar{x}}(t), \bar{W}(t)(x(t)-\bar{x}(t))\rangle + \frac{1}{2}\langle x(t)-\bar{x}(t), \dot{\bar{W}}(t)(x(t)-\bar{x}(t))\rangle \Big\} dt, \tag{4.3}$$

where $x(\cdot)$ is continuous. We have that F is twice Gateaux differentiable near $\bar{x}$ with first and second derivatives in the direction $h(\cdot)$:

$$\delta F(x(\cdot);h(\cdot)) = \int_0^1 \langle H_x(t,x(t),p(t,x(t))) + H_p(t,x(t),p(t,x(t)))\bar{W}(t) + \dot{\bar{p}}^T(t) - \dot{\bar{x}}^T(t)\bar{W}(t) + (x(t)-\bar{x}(t))^T\dot{\bar{W}}(t), h(t)\rangle dt,$$

and

$$\delta^2 F(x(\cdot);h(\cdot)) = \int_0^1 \langle \{H_{xx}(t,x(t),p(t,x(t))) + H_{xp}(t,x(t),p(t,x(t)))\bar{W}(t) + \bar{W}(t)H_{px}(t,x(t),p(t,x(t))) + \bar{W}(t)H_{pp}(t,x(t),p(t,x(t)))\bar{W}(t) + \dot{\bar{W}}(t)\}h(t), h(t)\rangle dt.$$

Also, using (3.1) and the definition of $\bar{W}$, it results that, for all continuous $h(\cdot)$,

$$F(\bar{x}(\cdot)) = 0, \quad \delta F(\bar{x}(\cdot);h(\cdot)) = 0, \quad \text{and}$$

$$\delta^2 F(\bar{x}(\cdot);h(\cdot)) = -\varepsilon_0 \int_0^1 |h(t)|^2 dt.$$

Hypothesis (H_2) yields that there exists $\delta_0 > 0$ such that for all continuous $x(\cdot)$ and $h(\cdot)$ satisfying $\|x-\bar{x}\|_\infty < \delta_0$ we have

$$\delta^2 F(x(\cdot);h(\cdot)) \le -\frac{\varepsilon_0}{2}\int_0^1 |h(t)|^2 dt.$$

Therefore, by [18, Theorem 40 A], for all continuous $x(\cdot) : \|x-\bar{x}\|_\infty < \delta_0$, we have

$$F(x(\cdot)) - F(\bar{x}(\cdot)) \le -\frac{\varepsilon_0}{4}\|x-\bar{x}\|_2^2. \tag{4.4}$$

Now define

$$Q(t,x) := \langle \bar{p}(t), x-\bar{x}(t)\rangle + \frac{1}{2}\langle x-\bar{x}(t), \bar{W}(t)(x-\bar{x}(t))\rangle. \tag{4.5}$$

Let $\|x-\bar{x}\|_\infty < \delta_0$ with x admissible for (P). Then, using (4.3), (4.5), (1.2), and condition (i) of the theorem, we obtain

$$\int_0^1 \{(L(t,x(t),\dot{x}(t)) - L(t,\bar{x}(t),\dot{\bar{x}}(t))\}dt \ge F(\bar{x}(\cdot)) - F(x(\cdot)) + \int_0^1 \frac{d}{dt}\{Q(t,x(t))\}dt.$$

Thus, from (4.4) and (4.5) and by integrating the last term, we get

$$\begin{aligned} J(x) - J(\bar{x}) \geq\ & \ell(x(0), x(1)) - \ell(\bar{x}(0), \bar{x}(1)) \\ & + \langle \bar{p}(1), x(1) - \bar{x}(1) \rangle + \frac{1}{2} \langle x(1) - \bar{x}(1), \bar{W}(1)(x(1) - \bar{x}(1)) \rangle \\ & - \langle \bar{p}(0), x(0) - \bar{x}(0) \rangle - \frac{1}{2} \langle x(0) - \bar{x}(0), \bar{W}(0)(x(0) - \bar{x}(0)) \rangle \\ & + \frac{\varepsilon_0}{4} \|x - \bar{x}\|_2^2. \end{aligned}$$

Consider the problem

$$\begin{aligned} \text{minimize } f(x, y) :=\ & \ell(x, y) - \ell(\bar{x}(0), \bar{x}(1)) \\ & + \langle \bar{p}(1), y - \bar{x}(1) \rangle + \frac{1}{2} \langle y - \bar{x}(1), \bar{W}(1)(y - \bar{x}(1)) \rangle \\ & - \langle \bar{p}(0), x - \bar{x}(0) \rangle - \frac{1}{2} \langle x - \bar{x}(0), \bar{W}(0)(x - \bar{x}(0)) \rangle \end{aligned}$$

over $\phi(x, y) = 0$.

Using (3.1)(iii) it follows that

$$\nabla f(\bar{x}(0), \bar{x}(1)) + \bar{\gamma}^T \bar{M} = 0.$$

Furthermore, (4.2) is equivalent to saying that

$$\nabla^2 (f + \bar{g}^T \phi) \Big|_{(\bar{x}(0), \bar{x}(1))} > 0 \quad \text{on} \quad \left\{ (\alpha, \beta) : \bar{M} \begin{pmatrix} \alpha \\ \beta \end{pmatrix} = 0 \right\}.$$

Hence, by standard sufficiency criterion for the finite dimensional optimization problem (e.g., [7, p. 307]), we conclude that $(\bar{x}(0), \bar{x}(1))$ is a local minimum for $f(x, y)$ over $\phi(x, y) = 0$. Thus there exists $\bar{\delta} \leq \delta_0$ such that for any admissible x with $\|x - \bar{x}\|_\infty < \bar{\delta}$ we have

$$J(x) - J(\bar{x}) \geq \bar{\varepsilon} \|x - \bar{x}\|_2^2,$$

where $\bar{\varepsilon} := \frac{\varepsilon_0}{4}$. □

Remark 4.1. When the endpoints cost and constraint are separable, we have $\Gamma = \left[\begin{smallmatrix} \Gamma_0 & 0 \\ 0 & \Gamma_1 \end{smallmatrix}\right]$ and $\bar{M} = \left[\begin{smallmatrix} \bar{M}_0 & 0 \\ 0 & \bar{M}_1 \end{smallmatrix}\right]$, and in this case, the boundary conditions (4.1) become

$$\text{(4.6)} \qquad \begin{cases} \Gamma_0 - W(0) > 0 \text{ on } \{\alpha \neq 0 \big| \bar{M}_0 \alpha = 0\}, \\ \\ \Gamma_1 + W(1) > 0 \text{ on } \{\alpha \neq 0 \big| \bar{M}_1 \alpha = 0\}. \end{cases}$$

Note that in this setting the proof of Theorem 4.1 remains valid when (4.6)(ii) is replaced by

$$W(1) = -\Gamma_1 - \beta \bar{M}_1$$

for some β. In fact, by the embedding theorem of differential equations, a solution of $(\mathcal{R})$ satisfying (4.6)(i) and the above condition leads to a solution of $(\mathcal{R})$ satisfying

(4.6). By symmetry, we can replace in Theorem 4.1 condition (4.6)(i) by $W(0) = \Gamma_0 + \beta\bar{M}_0$.

In the remainder of this section we study the connection between the sufficiency criterion presented in Theorem 4.1 and the necessary conditions obtained in section 3 in terms of the accessory problem (i.e., Theorem 3.3), the existence of a conjoined basis (i.e., Theorem 3.9), and a solution to the Riccati equation ($\mathcal{R}$) with boundary conditions (3.16) (i.e., Corollary 3.10). Our study below works for any L^1-matrix functions $A(\cdot), R(\cdot)$, and $P(\cdot)$ from $[0,1]$ to $\mathbb{R}^{n\times n}$ and matrices $\Gamma \in \mathbb{R}^{n\times n}$ and $\bar{M} \in \mathbb{R}^{r\times 2n}$ and not only for the choice given by (3.13) through the data of the problem (P).

Define

$$J_2(\eta, v) := \frac{1}{2}\left\langle \Gamma\begin{pmatrix}\eta(0)\\ \eta(1)\end{pmatrix}, \begin{pmatrix}\eta(0)\\ \eta(1)\end{pmatrix}\right\rangle + \frac{1}{2}\int_0^1 \{\langle R(t)v(t), v(t)\rangle - \langle P(t)\eta(t), \eta(t)\rangle\}dt.$$

In [17, Theorem 5.1] it is shown that the existence of a solution to ($\mathcal{R}$) in $[0,1]$ satisfying condition (4.1), which is condition (ii) of Theorem 4.1, is in fact sufficient for the coercivity in η of the quadratic form J_2; that is, for some $\gamma_0 > 0$,

$$J_2(\eta, v) \geq \frac{\gamma_0}{2}\int_0^1 |\eta(t)|^2 dt \tag{4.7}$$

for all (η, v) satisfying (2.4) and the boundary conditions $\bar{M}\binom{\eta(0)}{\eta(1)} = 0$. Condition (4.7) is a natural strengthening of the necessary condition in Theorem 3.3. However, for the general case of joint boundary conditions on the state, the existence of a solution to $\mathcal{R}$ and (4.1) is sufficient but not necessary for the coercivity of $J_2(\eta, v)$. This latter condition or its equivalent ones are the best to be used in the sufficiency criteria, since the gap between necessary and sufficient conditions would be minimal. This can also be said about the natural strengthenings of the necessary conditions given by Theorem 3.9 and Corollary 3.10.

Now consider the case of separable state endpoints and costs conditions. Hence we have

$$\bar{M} = \begin{bmatrix} \bar{M}_0 & 0 \\ 0 & \bar{M}_1 \end{bmatrix} \quad \text{and} \quad \Gamma = \begin{bmatrix} \Gamma_0 & 0 \\ 0 & \Gamma_1 \end{bmatrix}.$$

It is important to find out whether in this case the existence of a solution to ($\mathcal{R}$) on $[0,1]$ satisfying (4.6) is only sufficient for the coercivity in (4.7) or that the two conditions are rather equivalent. As we shall see below, under a certain controllability assumption, they are indeed equivalent. Observe that the coercivity of J_2 is in η and not in v, due to the lack of the strengthened Legendre–Clebsch hypothesis. However, under the latter hypothesis this result is known. It is worth mentioning that in [17, Theorem 5.2] a result parallel to Theorem 4.2 is obtained for the *positivity* of J_2 in η and *not* for its *coercivity*.

THEOREM 4.2. *Assume that the system* (2.4) *is either* $(I : \bar{M}_1)$*-normal on* $[c, 1]$ *for all* $c \in [0, 1)$ *or* $(\bar{M}_0 : I)$*-normal on* $[0, c]$ *for all* $c \in (0, 1]$. *Then the following are equivalent.*

(1) $J_2(\eta, v)$ *is coercive in* η *for all* (η, v) *solving* (2.4) *and* $\bar{M}_0\eta(0) = \bar{M}_1\eta(1) = 0$.

(2) *There exists a solution* (U, V) *of* (3.14) *satisfying*

(i) $U^T V = V^T U$ *on* $[0, 1]$,

(ii) $\det U(t) \neq 0$ *on* $[0,1]$,
(iii) $U^T(0)[\Gamma_0 U(0) - V(0)] > 0$ *on* $\{\alpha \neq 0 \mid \bar{M}_0 U(0)\alpha = 0\}$, *and*
(iv) $U^T(1)[\Gamma_1 U(1) + V(1)] > 0$ *on* $\{\alpha \neq 0 \mid \bar{M}_1 U(1)\alpha = 0\}$.

(3) *There exists a symmetric absolutely continuous solution* W *on* $[0,1]$ *of* $(\mathcal{R})$ *satisfying* (4.6).

Proof. By taking $W = VU^{-1}$ it follows that condition (2) implies (3). Also from [17, Theorem 5.1], condition (3) implies (1). Thus it remains to show that condition (1) implies condition (2). Assume that (2.4) is $(I : \bar{M}_1)$-normal on $[c,1]$ for all $c \in [0,1)$. By symmetry, a similar argument holds when the $(\bar{M}_0 : I)$-normality occurs. From [17, Theorem 5.5], condition (1) implies that the solution (U_1, V_1) of (3.14) and (3.15) satisfies conditions 2(i), 2(iii),

$$\det U(t) \neq 0 \quad \text{on} \quad [0,1),$$

and

$$U^T(1)[\Gamma_1 U(1) + V(1)] = 0.$$

By [5, Theorem 3.1.2(v)], there exists $\delta_0 > 0$ such that for all $\delta \in (0, \delta_0]$, the matrix

$$U_\delta := (I - \bar{M}_1) + \delta(-\Gamma_1(I - \bar{M}_1) - \bar{M}_1) \tag{4.8}$$

is invertible. Consider the system (3.14) with boundary conditions

$$\begin{cases} U(1) = U_\delta, \\ V(1) = V_1(1) + \delta(\Gamma_1\Gamma_1(I - \bar{M}_1) + I). \end{cases} \tag{4.9}$$

Since for $\delta = 0$ the system (3.14) and (4.9) has (U_1, V_1) as a solution on $[0,1]$ and since from (4.9) we have

$$U^T(1)[V(1) + \Gamma_1 U(1)] = \delta I + \delta^2 \bar{S}$$

for $\bar{S} = [(I - \bar{M}_1)\Gamma_1 + \bar{M}_1][\Gamma_1 \bar{M}_1 - I]$, then by the embedding theorem, there exists $\delta_1 > 0$ ($\delta_1 < \delta_0$) such that for all $\delta \in (0, \delta_1]$ there exists a solution $(U_\delta(\cdot), V_\delta(\cdot))$ of (3.14) and (4.9) satisfying parts (i), (iii), and (iv) of condition (2).

It remains to show that for some $\delta \in (0, \delta_1]$ the solution to (3.14) and (4.9) also satisfies part (ii) of condition (2). Note that since U_δ, given by (4.8), is invertible, then for each $\delta \in (0, \delta_1]$ there exists $t_\delta \in [0,1)$ (minimal) such that $\det U_\delta(t) \neq 0$ on $(t_\delta, 1)$. Now suppose that our claim is not true; then there exists $t_m \in [0,1)$ (minimal) such that

$$\det U_{1/m}(t) \neq 0 \quad \text{on} \quad (t_m, 1] \quad \text{and } \det U_{1/m}(t_m) = 0.$$

Using (4.9) it follows that $(U_{1/m}, V_{1/m}) \underset{m\to\infty}{\longrightarrow} (U_1, V_1)$. However, since U_1 is invertible on $[0,1)$, we conclude that $t_m \to 0$. Let $\alpha_m \in \mathbb{R}^n$ with $|\alpha_m| = 1$ and

$$U_{1/m}(t_m)\alpha_m = 0. \tag{4.10}$$

By passing to a convergent subsequence, say, $\alpha_m \underset{m\to\infty}{\longrightarrow} \alpha$, and upon taking the limit in (4.10), it results that

$$U_1(0)\alpha = 0 \quad \text{and} \quad |\alpha| = 1.$$

This contradicts that $\det U_1(0) \neq 0$. Therefore, the proposition is proved. □

Note that in this setting, condition (ii) of Theorem 4.1 can be replaced by any of the equivalent conditions in Theorem 4.2, as long as the normality assumption of the theorem holds. Another consequence of this theorem is the following connection between condition (ii) of Theorem 4.1, that is, condition (3) of Theorem 4.2, and the necessary conditions in Theorem 3.9 and Corollary 3.10.

COROLLARY 4.3. *Assume that system* (2.4) *is* $(I : \bar{M}_1)$*-normal on* $[c, 1]$ *for all* $c \in [0, 1)$. *Then each of the three equivalent conditions of Theorem* 4.2 *is also equivalent to each of the following conditions.*

(a) *The solution* (U_1, V_1) *of* (3.14) *and* (3.15) *satisfies* (i) $U^T V = V^T U$, (ii) $\det U(t) \neq 0$ *on* $[0, 1)$, (iii) $U^T(0)(\Gamma_0 U(0) - V(0)) > 0$ *on* $\{\alpha \neq 0 \mid \bar{M}_0 U(0)\alpha = 0\}$, *and* $V(1) + \Gamma_1(I - \bar{M}_1) + \bar{M}_1 = 0$.

(b) *There exists a symmetric solution* W *to* $(\mathcal{R})$ *on* $[0, 1)$ *satisfying* (4.6)(i) *and*

$$\lim_{t \to 1^-} W(t)U_1(t) = -\Gamma_1(I - \bar{M}_1) - \bar{M}_1.$$

Proof. From [17, Theorem 5.2] we know that conditions (a) and (b) above are equivalent. Also, in the proof of Theorem 4.2 we showed the following implications:

$$(1) \Rightarrow \text{condition (a)} \Rightarrow (2) \Rightarrow (3) \Rightarrow (1),$$

which proves the corollary. □

Remark 4.2. The above result states that in Theorem 4.1 we can replace condition (ii) by either of conditions (a) or (b) of Corollary 4.3, since they imply the $(I : \bar{M}_1)$-normality required. Hence Corollary 4.3 shows that the sufficiency criterion of Theorem 4.1 is obtained as natural strengthening of the necessary conditions in either Theorem 3.9 or Corollary 3.10.

5. Application to optimal control problems. In this section we consider the optimal control problem (C) defined in the introduction. First, we intend to apply the results of the previous section to the generalized Bolza ($\mathrm{P_C}$) problem defined in section 2 and associated with (C), and hence sufficient conditions for strong local minimality in (C) will be obtained. Next, we plan to derive second-order necessary conditions for optimality in (C). In this regard we shall obtain results parallel to Theorem 3.3, Theorem 3.9, and Corollary 3.10 by either applying Theorem 3.3 to the generalized problem of Bolza ($\mathrm{P_C}$) associated to (C), or by using Theorem 3.7 directly. The former approach yields necessary conditions for $W^{1,s}$-local minimum and requires assuming condition $(\mathcal{B})$, given in section 2, and

$$(\mathcal{L}_C) \qquad \text{for } (t, x) \in T(\bar{x}; \varepsilon), \{(f(t, x, u), g(t, x, u) + r) : u \in U,\ r \geq 0\}$$

is convex and closed.

On the other hand, the second approach produces necessary conditions for $W^{1,s}$- and L^s-weak local minimality, where $s \in [1, \infty]$. For the first type of optimality this approach requires only that the supremum in (1.4) be attained at some $\mathbf{u}(t, x, p)$, while for the second type of optimality, regularity assumptions are needed on $\mathbf{u}$. Of course, all the results of this section apply for the (classical) strong local minimality in (C).

Assume throughout this section that f, g, ℓ, and U satisfy assumption (A), given in section 2; for $t \in [0, 1]$ and $u \in U$, $f(t, \cdot, u)$ and $g(t, \cdot, u)$ are differentiable on $B_n(\bar{x}(t); \varepsilon)$; and ℓ is differentiable on $B_{2n}(\bar{x}(0), \bar{x}(1); \varepsilon)$.

Let $(\bar{x}, \bar{u}, \bar{p}, \bar{\gamma})$ be given. We say that $(\bar{x}, \bar{u}, \bar{p}, \bar{\gamma})$ satisfies the *normal* version of the Pontryagin maximum principle if they satisfy

$$\text{(5.1)} \qquad \begin{cases} -\dot{\bar{p}} = f_x^T(t, \bar{x}(t), \bar{u}(t))\bar{p}(t) - g_x^T(t, \bar{x}(t), \bar{u}(t)), \\ (\bar{p}^T(0), -\bar{p}^T(1)) = \nabla \ell(\bar{x}(0), \bar{x}(1)) + \bar{\gamma}^T \bar{M}, \\ \max\{\bar{p}^T(t) f(t, \bar{x}(t), u) - g(t, \bar{x}(t), u) \mid u \in U\} \\ \text{is attained at } \bar{u}(t), \text{ for almost all } t. \end{cases}$$

Let the Hamiltonian $\mathcal{H}(t, \cdot, \cdot)$ be differentiable at $(\bar{x}, \bar{p})$. If $(\bar{x}, \bar{u})$ is admissible for (C) and (5.1) holds, then $(\bar{x}, \bar{u}, \bar{p}, \bar{\gamma})$ satisfies

$$\begin{aligned} -\dot{\bar{p}}(t) &= \bar{\mathcal{H}}_x(t) \quad \text{a.e.}, \\ \dot{\bar{x}}(t) &= \bar{\mathcal{H}}_p(t) \quad \text{a.e.}, \\ (\bar{p}^T(0), -\bar{p}^T(1)) &= \nabla \ell(\bar{x}(0), \bar{x}(1)) + \bar{\gamma}^T \bar{M}, \\ \mathcal{H}(t, \bar{x}(t), \bar{p}(t)) &= \langle \bar{p}(t), f(t, \bar{x}(t), \bar{u}(t)) \rangle - g(t, \bar{x}(t), \bar{u}(t)) \quad \text{a.e.} \end{aligned}$$

(see, e.g., [2, Proposition 3.2]).

The following result is an application of Theorem 4.1 to the optimal control setting. It extends the corresponding result in [14], [15], and [2] to the case where $\bar{x}$ is not necessarily C^1 and both endpoints of x vary (i.e., $\phi(x(0), x(1)) = 0$). When we specialize to the case considered in [2], that is, a fixed initial and a free final state constraints, our result assumes less regularity assumptions on the Hamiltonian $\mathcal{H}$ defined by (1.4) and on $\mathcal{H}_p$.

THEOREM 5.1. *Let $(\bar{x}, \bar{u})$ be admissible for* (C)*, $\bar{p} \in W^{1,1}[0,1]$ and $\bar{\gamma} \in \mathbb{R}^r$ such that $(\bar{x}, \bar{u}, \bar{p}, \bar{\gamma})$ satisfies the normal version of the Pontryagin maximum principle* (5.1)*. Let $\mathcal{H}$, the Hamiltonian of* (C)*, satisfy* (H_2) *for some $\varepsilon > 0$. Assume that there exists a symmetric, absolutely continuous solution on $[0,1]$ of* (4.1) *and the Riccati equation* ($\mathcal{R}$)*, where H is replaced by $\mathcal{H}$.*

Then there exist $\bar{\varepsilon} > 0$ and $\bar{\delta} > 0$ such that for all admissible pairs (x, u) with $\|x - \bar{x}\|_\infty < \bar{\delta}$ we have

$$J(x, u) \geq J(\bar{x}, \bar{u}) + \bar{\varepsilon} \|x - \bar{x}\|_2^2,$$

and $(\bar{x}, \bar{u})$ is a strong local minimum for (C)*.*

Proof. Define L_C via (2.2), where $T(\bar{x}; \varepsilon)$ is used. In order to prove this theorem, we use Remark 2.2. The maximality condition in (5.1) yields that

$$L_C(t, \bar{x}(t), \dot{\bar{x}}(t)) = g(t, \bar{x}(t), \bar{u}(t)) \quad \text{a.e.}$$

Let us show that $\bar{x}$ is a strong local minimum for (P_C). Again the maximum principle yields that

$$L_C(t, \bar{x}(t), \dot{\bar{x}}(t) + v) - L_C(t, \bar{x}(t), \dot{\bar{x}}(t)) \geq \langle \bar{p}(t), v \rangle$$

for almost all t and for all $v \in \mathbb{R}^n$. Equations (5.1) yield that $(\bar{x}, \bar{p})$ satisfies (3.1), where $H := \mathcal{H}$. Since the Hamiltonian $\mathcal{H}$ of the control problem (C) is the same as the Hamiltonian corresponding to (P_C), all the conditions of Theorem 4.1 are satisfied

for the problem ($\mathrm{P_C}$). It results that there exist $\bar\varepsilon > 0$ and $\bar\delta > 0$ such that for any x admissible for ($\mathrm{P_C}$) with $\|x - \bar x\|_\infty < \bar\delta$ we have

$$J_C(x) - J_C(\bar x) \ge \bar\varepsilon \|x - \bar x\|_2^2.$$

For (x, u) admissible for (C) Remark 2.2 implies that

$$J_C(x) \le J(x, u).$$

We also know that

$$J_C(\bar x) = J(\bar x, \bar u);$$

hence $(\bar x, \bar u)$ is a strong local minimum for (C) and for all admissible pairs (x, u) with $\|x - \bar x\|_\infty < \bar\delta$ we have

$$J(x, u) - J(\bar x, \bar u) \ge \bar\varepsilon \|x - \bar x\|_2^2. \qquad \square$$

Remark 5.1. Consider the case where the state endpoint costs and constraints are separable, that is,

$$\ell(x, y) := \ell_0(x) + \ell_1(y) \quad \text{and} \quad \phi(x, y) := \begin{pmatrix} \phi_0(x) \\ \phi_1(y) \end{pmatrix}. \tag{5.2}$$

Then Theorem 4.2 and Corollary 4.3 yield that the result of Theorem 5.1 remains valid for problem (C) when the assumption regarding the existence of a solution to $(\mathcal{R})$ and (4.1) is replaced by either condition (a) or condition (b) of Corollary 4.3, or by any of the equivalent conditions given in Theorem 4.2, provided that the normality hypothesis of that theorem holds.

Now we intend to derive necessary conditions for (C). This is done either by ensuring that the problem (C), the function $\mathrm{L_C}$, and the Hamiltonian $\mathcal{H}$ satisfy assumptions $(\bar A)$, $(\mathcal{L})$, and (H_2), and hence Theorem 3.3 will apply to ($\mathrm{P_C}$), or by connecting the two optimal control problems (C) and ($\mathrm{C}_\mathcal{H}$), and then ensuring that $H := \mathcal{H}$ satisfies the conditions of Theorem 3.7. Here ($\mathrm{C}_\mathcal{H}$) is exactly the problem ($\mathrm{C}_\mathcal{H}$) introduced in section 3 with $H := \mathcal{H}$. The first method leads to part (1)(i) of the theorem, and the second method is behind the rest of the theorem.

THEOREM 5.2. *Let f, g, and U satisfy* (A). *Suppose that $(\bar x, \bar u, \bar p, \bar\gamma)$ and $\mathcal{H}$ satisfy* (5.1) *and* (H_2). *Then for $H := \mathcal{H}$, the conclusions of Theorem* 3.3 *hold and Theorem* 3.9 *and Corollary* 3.10 *are valid if either of the conditions* (1) *or* (2) *is satisfied.*

(1) *For $s \in [1, \infty]$, $(\bar x, \bar u)$ is a $W^{1,s}$-weak local minimum with* (H_p^s) *satisfied, and either condition* (i) *or condition* (ii) *is in effect.*

(i) *Assumptions* $(\mathcal{L}_C)$ *and* $(\mathcal{B})$ *hold.*

(ii) *The supremum in* (1.4) *is attained for $(t, x, p) \in T(\bar x, \bar p; \varepsilon)$.*

(2) *For $s \in [1, \infty]$, $(\bar x, \bar u)$ is a classically L^s-weak local minimum with* (H_p^s) *satisfied, and the supremum in condition* (ii) *is attained at $\mathbf{u}(t, x, p)$ such that $\mathbf{u}(t, \bar x(t), \bar p(t)) = \bar u(t)$, and $\mathbf{u}$ is continuous at $\bar z := (\bar x, \bar p)$ from L^∞ to L^s.*

Remark 5.2. When U is compact, $(\mathcal{B})$ and condition (ii) of Theorem 5.2 hold automatically, and hence condition (i) is more restrictive than (ii). Thus, in this case, part (1) of the theorem disposes of conditions (i) and (ii). This shows that in this case the second-order necessary conditions obtained for (C) by passing through the associated generalized Bolza problem ($\mathrm{P_C}$) are weaker than those obtained by passing through ($\mathrm{C}_\mathcal{H}$).

The existence of a feedback-type function $\mathbf{u}$ as in part (2) of the theorem has been employed in [13] when deriving sufficient conditions for the strong local minimum.

Proof. Assumptions (A) yield that $\mathcal{H}$ is $(\mathcal{L}\times\mathcal{B})$-measurable. By Remark 2.1, L_C is also $(\mathcal{L}\times\mathcal{B})$-measurable.

For (1), assume that (i) holds. Then, by Remark 2.3, assumptions $(\bar{A})$ are satisfied. Thus, by applying Theorem 2.7, it results that $\bar{x}$ is $W^{1,s}$-weak local for $(\mathrm{P_C})$. We shall check whether the assumptions of Theorem 3.3 are met by $(\mathrm{P_C})$. As mentioned earlier, (5.1) yields that $(\bar{x},\bar{p},\bar{\gamma})$ is a normal extremal for $(\mathrm{P_C})$, whose Hamiltonian is $\mathcal{H}$. Assumption $(\mathcal{L}_{\mathrm{C}})$ implies that $L_C(t,x,\cdot)$ is convex, since for $(t,x)\in T(\bar{x};\varepsilon)$ the set defined in $(\mathcal{L}_{\mathrm{C}})$ is the epigraph of $L_C(t,x,\cdot)$. Thus Assumption $(\mathcal{L})$ is satisfied, whence the conclusions of Theorem 3.3 hold. Assume that ϕ and ℓ are separable, as in (5.2); then, under the normality assumptions therein, the results of Theorem 3.9 and Corollary 3.10 are valid.

To prove parts (1)(ii) and (2) of the theorem we shall use the following result that connects (C) with $(\mathrm{C}_{\mathcal{H}})$.

PROPOSITION 5.3. *Assume that f,g, and U satisfy* (A). *Suppose that condition* (ii) *of Theorem* 5.2 *holds and that $\mathcal{H}(t,\cdot,\cdot)$ is differentiable on $B_{2n}(\bar{x}(t),\bar{p}(t);\varepsilon)$. Let $(\bar{x},\bar{u},\bar{p})$ satisfy* (5.1)(iii). *If for $s\in[1,\infty]$, (H_p^s) holds and*

(a) *$(\bar{x},\bar{u})$ is a $W^{1,s}$-weak local minimum for* (C), *or*

(b) *$(\bar{x},\bar{u})$ is a classically L^s-weak local minimum and the supremum in condition* (ii) *of Theorem* 5.2 *is attained at some $\mathbf{u}(t,x,p)$ such that $\mathbf{u}(t,\bar{x}(t),\bar{p}(t))=\bar{u}(t)$, and $\mathbf{u}$ is continuous at $(\bar{x},\bar{p})$ from L^∞ to L^s,*

then $(\bar{x},\bar{p})$ is classically an L^∞-weak local minimum for $(C_{\mathcal{H}})$.

Proof. For (a), suppose that there exists $0<\varepsilon_0<\varepsilon$ such that $J(x,u)\geq J(\bar{x},\bar{u})$ for all admissible pairs (x,u) with $\|x-\bar{x}\|_{1,s}<\varepsilon_0$. Let (x,p) be admissible for $(\mathrm{C}_{\mathcal{H}})$ with $(x,p)\in T(\bar{x},\bar{p};\varepsilon)$ and $\|x-\bar{x}\|_{1,s}<\varepsilon_0$. Condition (ii) of Theorem 5.2 and the differentiability of $\mathcal{H}(t,\cdot,\cdot)$ yield that

$$\mathcal{H}_p(t,x(t),p(t))=f(t,x(t),A(t,x(t),p(t))),$$

where

$$A(t,x,p):=\{u\in U:\langle p,f(t,x,u)\rangle-g(t,x,u)=\mathcal{H}(t,x,p)\},$$

and $f(t,x,A(t,x,p))$ is a singleton. Hence, by the measurable selection theorem, there exists a measurable function u such that $u(t)\in A(t,x(t),p(t))$ for almost all t. Thus

$$\dot{x}(t)=f(t,x(t),u(t))=\mathcal{H}_p(t,x(t),p(t))\quad\text{a.e.,}\tag{5.3}$$

and

$$\langle p(t),f(t,x(t),u(t))\rangle-g(t,x(t),u(t))=\mathcal{H}(t,x(t),p(t))\quad\text{a.e.}\tag{5.4}$$

It follows that (x,u) is admissible for (C), and then

$$J(x,u)\geq J(\bar{x},\bar{u}).$$

However, using (5.3) and (5.4), we get

$$J_C(x,p)=J(x,u)\quad\text{and}\quad J_C(\bar{x},\bar{p})=J(\bar{x},\bar{u}).$$

Therefore, $(\bar{x},\bar{p})$ is a $W^{1,s}$-weak local minimum for $(\mathrm{C}_{\mathcal{H}})$. Now applying Lemma 2.6 to the problem $(\mathrm{C}_{\mathcal{H}})$, we conclude the result.

For (b), suppose for $0 < \varepsilon_0 < \varepsilon$ we have $J(x,u) \geq J(\bar{x},\bar{u})$ for $\|x-\bar{x}\|_\infty + \|u-\bar{u}\|_s < \varepsilon_0$. By continuity of $\mathbf{u}$, there exists $0 < \delta_0 < \frac{\varepsilon_0}{2}$ such that for $\|x-\bar{x}\|_\infty + \|p-\bar{p}\|_\infty < \delta_0$, we have

$$\|\mathbf{u}(\cdot, x(\cdot), p(\cdot)) - \mathbf{u}(\cdot, \bar{x}(\cdot), \bar{p}(\cdot))\|_s < \varepsilon_0/2.$$

Now let (x,p) be such that $\|x-\bar{x}\|_\infty + \|p-\bar{p}\|_\infty < \delta_0$ and (x,p) is admissible for $(\mathrm{C}_\mathcal{H})$. In this case, $\mathbf{u}(t,x(t),p(t))$ belongs to $A(t,x(t),p(t))$ defined above, and hence, for $u(\cdot) := \mathbf{u}(\cdot, x(\cdot), p(\cdot))$, (x,u) is admissible for (C). Since

$$\|x-\bar{x}\|_\infty + \|u-\bar{u}\|_s < \delta_0 + \frac{\varepsilon_0}{2} < \varepsilon_0,$$

it results that $J(x,u) \geq J(\bar{x},\bar{u})$. Arguments similar to those used for (a) yield that $J_\mathrm{C}(x,p) \geq J_\mathrm{C}(\bar{x},\bar{p})$. That is, $(\bar{x},\bar{p})$ is an L^∞-weak local minimum for $(\mathrm{C}_\mathcal{H})$. □

Return to the proof of part (1) of Theorem 5.2. Assume condition (ii) of the theorem holds. Then Proposition 5.3(a) and Theorem 3.7 yield that the conclusions of Theorem 3.3 hold, and thus each of Theorem 3.9 and Corollary 3.10 is valid. Part (2) of the theorem follows from Proposition 5.3(b) and Theorem 3.7. □

Remark 5.3. When the initial state value is fixed and the final state value is free, the problem (C) reduces to the one studied in [2]. In this case, ℓ and ϕ in (5.2) take the form $\ell(x,y) = \ell_1(y)$ and $\phi(x,y) = \phi_0(x) = x - x_0$. In this special setting necessary conditions in terms of the Riccati equation $(\mathcal{R})$ were derived in [2, Theorem 5.1] for the $W^{1,1}$-weak local minimum. On the other hand, specialized to this setting, part (1) of Theorem 5.2 here yields that, under hypotheses (A), (5.1), (H_2), and condition (ii) of Theorem 5.2, Corollary 3.10 holds true. Hence, by Remark 3.2, these assumptions yield necessary conditions in terms of a solution on $(0,1]$ to $(\mathcal{R})$ and (3.17). However, these assumptions are considerably weaker than those imposed in [2, Theorem 5.1]. This is so since we do *not* assume (1.5), $\nabla_z^2 \bar{\mathcal{H}}(\cdot)$ to be L^∞, $\nabla_z^2 \mathcal{H}$ to be Lipschitz near $\bar{z} = (\bar{x},\bar{p})$ from L^∞ to L^1, nor the strengthened Legendre–Clebsch condition $(S\mathcal{L})$ to hold. Also, our necessary conditions apply for the $W^{1,s}$-, or classically L^s-weak local minimum, where $s \in [1,\infty]$, and not only for the $W^{1,1}$-weak local minimum.

As we shall see below, the assumption $(S\mathcal{L})$ in [2] is very strong. In fact, it renders the corresponding function L_C to be locally C^1 in (x,v), and hence, the control problem (C) resembles a calculus of variations problem.

LEMMA 5.4. *Let $(\bar{x},\bar{p}) \in W^{1,\infty}[0,1] \times L^\infty[0,1]$ satisfy $\dot{\bar{x}}(t) = \bar{\mathcal{H}}_p(t)$ a.e., and let $\mathcal{H}$ satisfy (H_2), (H_p^∞), and $(S\mathcal{L})$. Assume that $\mathcal{H}_{pp}$ is continuous at $(\bar{x},\bar{p})$, from L^∞ to L^∞, and $\bar{\mathcal{H}}_p(\cdot)$ and $\mathcal{H}_{pp}(\cdot)$ are in L^∞.*

If L_C, defined by (2.2), satisfies $(\mathcal{L})$, then L_C is $(\mathcal{L}\times\mathcal{B})$-measurable and lower semicontinuous in (x,v), and there exists $\tilde{\varepsilon} > 0$ $(\tilde{\varepsilon} \leq \varepsilon)$ and $p(t,x,v)$ such that $p(t,\cdot,\cdot)$ is C^1 on $T(\bar{x},\dot{\bar{x}};\tilde{\varepsilon})$ and ∇p is continuous at $(\bar{x},\dot{\bar{x}})$, from L^∞ to L^∞, such that

$$L_C(t,x,v) = p(t,x,v)\cdot v - H(t,x,p(t,x,v)).$$

Proof. Since $\mathcal{H}$ is also the Hamiltonian corresponding to L_C, which is convex in v,

$$L_C(t,x,v) = \sup\{\langle p,v\rangle - \mathcal{H}(t,x,p) \mid p \in \mathbb{R}^n\}$$

for $(t,x) \in T(\bar{x};\varepsilon)$. Hence by [9], L_C is $(\mathcal{L}\times\mathcal{B})$-measurable and lower semicontinuous in (x,v). Consider the equation

$$v = \mathcal{H}_p(t,x,p). \tag{5.5}$$

We have that (5.5) is satisfied for almost all t, for $v = \dot{\bar{x}}(t)$, for $x = \bar{x}(t)$, and for $p = \bar{p}(t)$. Set

$$N(z(\cdot);\varepsilon) := \{x(\cdot) \in L^\infty[0,1] \mid \|z - x\|_\infty < \varepsilon\},$$

and define

$$\mathcal{F} : N(\bar{x};\varepsilon) \times N(\bar{p};\varepsilon) \to L^\infty[0,1],$$

$$(x(\cdot), p(\cdot)) \to v(\cdot) = \mathcal{F}(x(\cdot), p(\cdot)),$$

where

$$\mathcal{F}(x(\cdot), p(\cdot))(t) = \mathcal{H}_p(t, x(t), p(t)).$$

Consider the equation

$$v(\cdot) = \mathcal{F}(x(\cdot), p(\cdot)).$$

(i) For $x(\cdot) \in N(\bar{p};\varepsilon)$, $\mathcal{F}(x(\cdot),\cdot)$ is differentiable on $N(\bar{p};\varepsilon)$.

For, let $p(\cdot) \in N(\bar{p};\varepsilon)$ and $\bar{\varepsilon} > 0$ given. The continuity of $\mathcal{H}_{pp}$ from L^∞ to L^∞ yields the existence of $\delta > 0$ such that for $\|q - p\|_\infty < \delta$ we have

$$|\mathcal{H}_{pp}(t, x(t), q(t)) - \mathcal{H}_{pp}(t, x(t), p(t))| < \frac{\bar{\varepsilon}}{2} \text{ a.e.}$$

Let $\bar{q}(\cdot) \in N(p(\cdot);\delta)$. We shall show

$$\|\mathcal{F}(x(\cdot), \bar{q}(\cdot)) - \mathcal{F}(x(\cdot), p(\cdot)) - \mathcal{F}_p(x(\cdot), p(\cdot))(\bar{q}(\cdot) - p(\cdot))\|_\infty \le \bar{\varepsilon}\|\bar{q} - p\|_\infty.$$

By the mean value theorem for vector-valued functions applied to $\mathcal{H}_p(t, x(t), \cdot) - \mathcal{H}_{pp}(t, x(t), p(t))(\cdot)$ on the line segment joining $p(t)$ and $\bar{q}(t)$, there exists $\tilde{q}$ with $|\tilde{q}(t) - p(t)| < \delta$ such that

$$\begin{aligned}
&|\mathcal{H}_p(t, x(t), \bar{q}(t)) - \mathcal{H}_p(t, x(t), p(t)) - \mathcal{H}_{pp}(t, x(t), p(t))(\bar{q}(t) - p(t))| \\
&\quad \le \big|\big(\mathcal{H}_{pp}(t, x(t), \tilde{q}(t)) - \mathcal{H}_{pp}(t, x(t), p(t))\big)(\bar{q}(t) - p(t))\big| \\
&\quad \le \frac{\bar{\varepsilon}}{2}\|\bar{q} - p\|_\infty.
\end{aligned}$$

Set

$$\mathcal{F}_p(x(\cdot), p(\cdot))(t) := \mathcal{H}_{pp}(t, x(t), p(t)).$$

The result follows.

(ii) Let $\mathcal{B}(L^\infty, L^\infty)$ be the normed space of all bounded linear operators from L^∞ into L^∞. Then

$$\mathcal{F}_p : N(\bar{x};\varepsilon) \times N(\bar{p};\varepsilon) \to \mathcal{B}(L^\infty, L^\infty)$$

is continuous, since $\mathcal{H}_{pp}(t,\cdot,\cdot)$ is continuous on $N(\bar{x};\varepsilon) \times N(\bar{p};\varepsilon)$, L^∞-uniformly in t.

(iii) $\mathcal{F}_p(\bar{x},\bar{p})$ is a homeomorphism of L^∞ onto L^∞. The strengthened Legendre condition $(S\mathcal{L})$ yields that $\mathcal{F}_p(\bar{x},\bar{p})$ is a bijection and that $\bar{\mathcal{H}}_{pp}^{-1}(t)$ is essentially bounded. Since $\bar{\mathcal{H}}_{pp}(\cdot)\in L^\infty[0,1]$, we get that $\mathcal{F}_p(\bar{x},\bar{p})$ is a homeomorphism.

(i)–(iii) allow us to apply the implicit function theorem [11, II.3.8] to deduce the existence of $\varepsilon_0,\varepsilon_1>0$ and a unique C^1-function $\mathcal{P}$ such that

$$\mathcal{P}: N(\bar{x},\varepsilon_0)\times N(\dot{\bar{x}},\varepsilon_0)\to N(\bar{p},\varepsilon_1),$$

$$v(\cdot)=\mathcal{F}(x(\cdot),\mathcal{P}(x(\cdot),v(\cdot))),$$

and

$$\mathcal{P}(\bar{x},\dot{\bar{x}})=\bar{p}.$$

Let us construct $p(t,x,v)$ on $T(\bar{x},\dot{\bar{x}};\frac{\varepsilon_0}{2})$.

For given $(t,x,v)\in T(\bar{x},\dot{\bar{x}};\frac{\varepsilon_0}{2})$, set

$$x(s):=\bar{x}(s)+(\dot{\bar{x}}(t)-v)(t-s)+x-\bar{x}(t).$$

We have $x(t)=x$, and $\dot{x}(t)=v$. Define

$$p(t,x,v):=\mathcal{P}(x(\cdot),\dot{x}(\cdot))(t).$$

Then, on $T(\bar{x},\dot{\bar{x}};\frac{\varepsilon_0}{2})$, $p(\cdot,\cdot,\cdot)$ is well defined with values in $N(\bar{p},\varepsilon_1)$,

$$v=\mathcal{H}_p(t,x,p(t,x,v)), \tag{5.6}$$

and

$$p(t,\bar{x}(t),\dot{\bar{x}}(t))=\bar{p}(t).$$

Condition $(S\mathcal{L})$ yields that $p(\cdot,\cdot,\cdot)$ is unique. The C^1-property of $\mathcal{P}$ on $N(\bar{x};\varepsilon_0)\times N(\dot{\bar{x}},\varepsilon_0)$ implies that p is continuously differentiable from L^∞ to L^∞. Thus, by the convexity of $\mathcal{H}(t,x,\cdot)$, for (t,x,v) in $T(\bar{x},\dot{\bar{x}};\frac{\varepsilon_0}{2})$,

$$L_C(t,x,v)=p(t,x,v)\cdot v-\mathcal{H}(t,x,p(t,x,v)),$$

whence the result follows. □

The following example shows the power of the results of this section, as it produces information where previous work offered none.

Example 5.1. Consider the optimal control problem

$$(\mathrm{C}_0)\qquad \text{minimize } J(x,u):=-\frac{5}{3}2^{5/3}x^2(1)+\int_0^1 (x^3(t)+u^2(t))dt$$

subject to

$$\dot{x}(t)=\left(t-\frac{1}{2}\right)^{1/3}u(t),$$

$$x(0)=0,$$

$$u(t)\in\mathbb{R}\quad \text{a.e.}$$

The Hamiltonian corresponding to (C_0) is

$$\mathcal{H}(t,x,p) := \sup_{u\in\mathbb{R}} \left\{ p\left(t-\frac{1}{2}\right)^{1/3} u - x^3 - u^2 \right\}$$
$$= -x^3 + \frac{p^2}{4}\left(t-\frac{1}{2}\right)^{2/3},$$

and hence the supremum in $\mathcal{H}$ is attained for all $(t,x,p)\in[0,1]\times\mathbb{R}\times\mathbb{R}$ at

$$\mathbf{u}(t,x,p) = \frac{p}{2}\left(t-\frac{1}{2}\right)^{1/3}$$

with $\mathbf{u}$ continuous everywhere from $L^\infty \times L^\infty$ to L^∞. Moreover, $\mathcal{H}$ is the same Hamiltonian H of the problem (P_0) in Example 3.1.

Let $\bar{x}\equiv 0, \bar{u}\equiv 0, \bar{p}\equiv 0$, and $\bar{\gamma} = \binom{0}{0}$. Then $(\bar{x},\bar{p},\bar{u},\bar{\gamma})$ satisfy the normal version of the Pontryagin maximum principle (5.1). Furthermore, assumptions (A) and (H_2) hold, and, as seen in Example 3.1, the normality requirements of Theorem 3.9 are satisfied.

The Riccati equation $(\mathcal{R})$ for this problem with the boundary condition (3.17) is exactly given by (3.18). The solution $W(t) = -\frac{10}{3(t-\frac{1}{2})^{5/3}}$ exists on $(\frac{1}{2},1]$ and cannot be extended (by continuity) to $[\frac{1}{2},1]$. Even though (1.4) holds, the strengthened Legendre–Clebsch condition $(S\mathcal{L})$ required in the necessity theorem [2, Theorem 5.1] fails to hold near $t_c = \frac{1}{2}$, since

$$\bar{H}_{pp}(t) = \frac{1}{2}\left(t-\frac{1}{2}\right)^{2/3} \Rightarrow \inf_{\alpha\le t<t_c} \bar{H}_{pp}(t) = 0 \qquad \forall\ \ \alpha\in[0,t_c).$$

Therefore, the result in [2, Theorem 5.1] does not apply to this problem, and no information can be produced from [2] about the optimality of $(\bar{x},\bar{u})$ for (C_0).

On the other hand, as seen in Example 3.1, the conclusion of Corollary 3.10 does not hold since the solution W does not exist on $(0,1]$. Given that condition (ii) of part (1) of Theorem 5.2 is satisfied, it results from applying Theorem 5.2(1) that $(\bar{x},\bar{u})$ is not a $W^{1,s}$-weak local minimum for (C_0), for any $s\in[1,\infty]$. Since the assumptions for part (2) of Theorem 5.2 hold, we also conclude that $(\bar{x},\bar{u})$ is not a L^s-weak local minimum for (C_0), for any $s\in[1,\infty]$.

Acknowledgment. The author wishes to thank a referee for the thorough reading of the paper and for valuable remarks and comments that helped improve the presentation of the results.

A ROBUST CONTROL FRAMEWORK FOR LINEAR, TIME-INVARIANT, SPATIALLY DISTRIBUTED SYSTEMS*

J. REINSCHKE†, M. W. CANTONI‡, AND M. C. SMITH§

Abstract. A robust control framework for linear, time-invariant (LTI), spatially distributed systems is outlined in this paper. We adopt an input-output approach which takes account of the spatially distributed nature of the input and output signals for such systems. The approach is a generalization of H^∞ control in the sense that the 2-norm (in both time and space) is used to quantify the size of signals. It is shown that a frequency-domain representation, in the form of a graph symbol, exists for every LTI, spatially distributed system under very mild assumptions. The graph symbol gives rise to left and right coprime representations if the system is also stabilizable. We investigate fundamental issues of feedback control such as feedback stability and robust stability to plant and/or controller uncertainty quantified in the gap-metric. This includes a generalization of the Sefton–Ober gap formula to the infinite-dimensional operator case. A design example in which an electrostatically destabilized membrane is feedback-stabilized concludes the paper.

Key words. spatially distributed systems, distributed-parameter systems, robust stability, gap-metric, H^∞-control

1. Introduction.

1.1. Motivation. Robust control theory attempts to account for the fact that there is always some mismatch between any model of a physical plant and the actual physical plant itself. A fundamental problem in the theory is to find a suitable measure of the distance between two systems. A solution to this problem (initially only for finite-dimensional, lumped-parameter, linear, time-invariant (LTI) systems) was proposed in terms of the so-called *gap-metric,* which was introduced into the control literature by Zames and El-Sakkary [ZE] in 1980. In the 1980's and early 1990's a system- and control-theoretic framework for *finite-dimensional,* lumped-parameter, LTI systems emerged which, in particular, complemented the use of the gap-metric as a distance measure to quantify uncertainty; see, e.g., [DLMS], [VSF], [V1], [E], [VK], [G1], [GM], [GS1], [OS], [QD], [SO], [V3] as well as the monographs [V2], [F], [ZDG], and [V4]. Substantial parts of this robust control theory were subsequently generalized to certain classes of infinite-dimensional, lumped-parameter, LTI systems (see [C2] and [GS2], for example), to the case of linear, time-varying systems (see [DS], [FGS], [CG1], and [CG2]), and to the case of nonlinear systems (see [DGS], [G2], and [GS5], for example). In this paper we systematically generalize much of this theory to the class of LTI, spatially distributed systems. The results and proofs are in parts based on similar results available in the literature for finite-dimensional,

lumped-parameter, LTI systems; we refer, in particular, to [GS1], [GS3], and [SO]. As in [GS1] and [SO], we will use techniques that are mostly function-theoretic, relying on specific representations for the graph of an LTI, dynamical system. A more general, geometric framework based on operator-theoretic methods, in particular, the use of parallel projection operators, was presented in [FGS]. However, the results of [FGS] do not consider the shift-invariance or causality of systems, and hence the necessity parts of the robust stability results as stated here are not known to hold in the geometric framework.

We take an input-output view of spatially distributed systems in which the system's input and output signals are spatially distributed, i.e., the signals may depend on spatial variables as well as time. This view is motivated by the observation that there exist numerous examples of feedback control problems in which inputs, outputs, disturbances, etc. are naturally considered as spatially distributed signals. A common first step in analyzing spatially distributed systems is to reduce them to "lumped-parameter" form. By contrast, we seek to retain the spatial element of signals in the definition of input-output performance measures. In particular, we will make use of the 2-norm for both the space- and the time-dependence of signals and thereby define the induced norm of a system. As we are concerned with LTI systems, we can think interchangeably of signals and systems in the time and frequency domain. In this way our approach can be considered as a generalization of H^∞ control to spatially distributed systems. We will not be concerned with distributed systems in state-space form (as in [CZ]) but concentrate on input-output properties and issues such as the existence of graph symbols and coprime representations, feedback stability, robustness, etc.

The paper is organized as follows. In subsection 1.2 we discuss a simple example of a spatially distributed system to illustrate the input-output view taken. A number of mathematical results of complex analysis and operator theory needed in the remainder of the paper are gathered in section 1.3. In section 2 we present an abstract approach to spatially distributed systems and show that a frequency-domain representation exists for every spatially distributed LTI system under very mild assumptions. The representation takes the form of a graph symbol from which so-called *(normalized) right and left coprime representations* can be obtained if the system is stabilizable. In section 3 we generalize the Sefton–Ober gap formula [SO] to the infinite-dimensional operator case. In section 4 we present (generalized) robust stability results for feedback loops of shift-invariant systems in which the plant, or the controller, or both, may be uncertain with the uncertainty being measured in the gap-metric. Finally, in section 5 the use of the previously obtained results is illustrated by a controller design example.

1.2. Example. In this subsection we discuss a simple example of a spatially distributed system to illustrate the distributed input-output view taken, and the choice of signal spaces. Consider an elastic string stretched between $x=0$ and $x=1$ and clamped at both ends. Denote the string's deflection from the equilibrium position by $y(x,t)$, and assume the string is set in motion under the action of a distributed load $u(x,t)$ ($u(x,t)\equiv 0$ for $t<0$). The dynamics of the string are governed by the PDE

$$\frac{\partial^2 y(x,t)}{\partial t^2}+\delta\,\frac{\partial y(x,t)}{\partial t}-\tau\,\frac{\partial^2 y(x,t)}{\partial x^2}=u(x,t), \tag{1}$$

$x\in(0,1)$, $t\geq 0$, together with the boundary conditions $y(0,t)=y(1,t)=0$. In (1), $\delta>0$ is a frictional coefficient, and $\tau>0$ represents the tension per unit mass of the string.

We select spaces of input and output signals as follows. At any given time instant we assume that $u(x,t)$ is square-integrable in x over the spatial domain $\mathcal{D}^i=(0,1)$. That is, for fixed t, $u(.,t)\in L^2(\mathcal{D}^i)=:\mathscr{U}$, where $L^2(\mathcal{D}^i)$ is the standard Lebesgue space. Bringing in the time-dependence, we consider $u(.,t)=:u(t)$ to belong to the Lebesgue space of $\mathscr{U}$-valued, square-integrable functions, $L^2_{\mathscr{U}}[0,\infty)$, which is defined as

$$L^2_{\mathscr{U}}[0,\infty):=\left\{u:[0,\infty)\to\mathscr{U}\;\Big|\;\int_0^\infty\langle u(t),\,u(t)\rangle_{\mathscr{U}}\,\mathrm{d}t<\infty\right\},$$

where $\langle .,.\rangle_{\mathscr{U}}$ denotes the scalar product in $\mathscr{U}$. Similarly, a suitable space for the output signals is $L^2_{\mathscr{Y}}[0,\infty)$, where $\mathscr{Y}:=L^2(\mathcal{D}^o)$, and in this case the spatial domain is $\mathcal{D}^o=(0,1)$. Thus we consider the system (1) as defining an operator from $L^2_{\mathscr{U}}[0,\infty)$ to $L^2_{\mathscr{Y}}[0,\infty)$. In this example, $\mathcal{D}^i$ and $\mathcal{D}^o$ are both equal to $(0,1)$. In general, however, we allow for $\mathcal{D}^i$ and $\mathcal{D}^o$ to be different, which permits the description of plants with boundary controls or boundary observations, for example. Also, in the case of spatially multidimensional systems, $\mathcal{D}^i$ and $\mathcal{D}^o$ will be subsets of $\mathbb{R}^{n_u}$ and $\mathbb{R}^{n_y}$ with n_u, $n_y\in\mathbb{Z}_+$.

Taking Laplace transforms of (1) with zero initial conditions gives

$$\left((s^2+\delta\,s)-\tau\frac{\mathrm{d}^2}{\mathrm{d}x^2}\right)\hat{y}(x;s)=\hat{u}(x;s),$$

$x\in(0,1)$, $s\in\mathbb{C}$, plus the boundary conditions $\hat{y}(0;s)=\hat{y}(1;s)=0$. Then $\hat{u}(.;s)=:\hat{u}(s)$ may be regarded as the system's Laplace-transformed spatially distributed input variable and $\hat{y}(.;s)=:\hat{y}(s)$ as its Laplace-transformed spatially distributed output variable. After taking Laplace transforms, the input and output signal spaces become Hardy 2-spaces of $\mathscr{U}$- (respectively, $\mathscr{Y}$-) valued functions; see Definition 1.2 below. In the frequency-domain, the input-output relationship of a spatially distributed LTI plant can often be represented as

$$\hat{y}(x;s)=\int_{\mathcal{D}^i}\mathrm{d}\xi\;\kappa_{\hat{\mathbf{P}}}(x,\xi;s)\,\hat{u}(\xi;s),\quad x\in\mathcal{D}^o,$$

where $\kappa_{\hat{\mathbf{P}}}(x,\xi;s)$ denotes the kernel of an s-dependent, infinite-dimensional, integral operator. For the vibrating string, the integral kernel is given by $\kappa_{\hat{\mathbf{P}}}(x,\xi;s)=\sum_{k=1}^{\infty}2\sin(k\pi x)\big(s^2+\delta\,s+\tau\,(k\,\pi)^2\big)^{-1}\sin(k\pi\xi)$, which is the string's Laplace-transformed Green's function.

1.3. Mathematical preliminaries. In this subsection we introduce the notation and the mathematical background that will be used repeatedly in this paper. Except for Proposition 1.12, the material is taken from the literature (see especially [RR], [FF], and [N]).

Let $\mathbb{C}_+:=\big\{s\in\mathbb{C}\,|\,\mathrm{Re}(s)>0\big\}$. Let $\mathfrak{L}$ represent the Laplace-transform operator. $\mathbf{I}_{\mathscr{V}}$, $\|.\|_{\mathscr{V}}$, and $\langle .,.\rangle_{\mathscr{V}}$ denote the identity operator, the norm, and the scalar product in the Hilbert space $\mathscr{V}$. Throughout, Hilbert spaces will be assumed to be separable. Let $\mathscr{V}_1$ be a subspace of $\mathscr{V}$. The projection operator onto $\mathscr{V}_1$ is denoted by $\mathcal{P}_{\mathscr{V}_1}$. For $\mathscr{U}$, $\mathscr{Y}$ Banach spaces, let the space of all bounded, linear operators from $\mathscr{U}$ to $\mathscr{Y}$, equipped with the induced norm $\|.\|_{\mathrm{ind}}$, be denoted by $\mathscr{B}(\mathscr{U},\mathscr{Y})$. The domain, the null-space, and the range-space of an operator $T:\mathscr{U}\to\mathscr{Y}$ are denoted by $\mathrm{dom}(T):=\{u\in\mathscr{U}\,|\,T\,u\in\mathscr{Y}\}$, $\mathrm{null}(T):=\{u\in\mathscr{U}\,|\,T\,u=0\}$, and $\mathrm{ran}(T):=\{y\in\mathscr{Y}\,|\,y=T\,u,\;u\in\mathrm{dom}(T)\}$.

THEOREM 1.1 (see [H, Problem 52]). *Let $\mathscr{U}$, $\mathscr{Y}$ be Hilbert spaces. If $T\in\mathscr{B}(\mathscr{U},\mathscr{Y})$ is bounded from below (i.e., $\|Tu\|_{\mathscr{Y}}\geq\delta\|u\|_{\mathscr{U}}$ for all $u\in\mathscr{U}$ and some $\delta>0$) and has dense range, then T is boundedly invertible.*

DEFINITION 1.2 (Lebesgue 2-space, Hardy 2-space [RR]). *Let $\mathcal{V}$ be a Hilbert space. The* Lebesgue 2-space $L^2_{\mathcal{V}}(\jmath\mathbb{R})$ *is the Banach space of $\mathcal{V}$-valued functions $\hat{v}$ of a complex variable that are bounded in the norm* $\|\hat{v}\|_{L^2} := \left(\frac{1}{2\pi}\int_{-\infty}^{\infty} \left\|\hat{v}(\jmath\omega)\right\|^2_{\mathcal{V}} \mathrm{d}\omega\right)^{1/2}$. *By the* Hardy 2-space $H^2_{\mathcal{V}}(\mathbb{C}_+)$ *we mean the Banach space of $\mathcal{V}$-valued functions $\hat{v}$ of a complex variable that are analytic on $\mathbb{C}_+$ and bounded in the norm* $\|\hat{v}\|_{H^2} := \left(\sup_{\sigma>0} \frac{1}{2\pi}\int_{-\infty}^{\infty} \left\|\hat{v}(\sigma+\jmath\omega)\right\|^2_{\mathcal{V}} \mathrm{d}\omega\right)^{1/2}$. *If $\hat{v} \in H^2_{\mathcal{V}}(\mathbb{C}_+)$, then $\hat{v}$ can be extended to a boundary function on $\jmath\mathbb{R}$ and $\|\hat{v}\|_{L^2} = \|\hat{v}\|_{H^2}$. The Lebesgue 2-space $L^2_{\mathcal{V}}(\jmath\mathbb{R})$ and the Hardy 2-space $H^2_{\mathcal{V}}(\mathbb{C}_+)$ are Hilbert spaces with inner product* $\langle f, g\rangle_2 := \frac{1}{2\pi}\int_{-\infty}^{\infty} \langle f(\jmath\omega), g(\jmath\omega)\rangle_{\mathcal{V}} \mathrm{d}\omega$, *and $H^2_{\mathcal{V}}(\mathbb{C}_+) \subset L^2_{\mathcal{V}}(\jmath\mathbb{R})$.*

DEFINITION 1.3 (truncation and shift operators). *Let $\mathcal{V}$ be a Hilbert space. The (time-domain) truncation and shift operators, $\mathbf{T}^\tau$ and $\mathbf{S}^\tau$, on the signal space $L^2_{\mathcal{V}}[0,\infty)$ are defined by*

$$\mathbf{T}^\tau v(t) = \begin{cases} v(t) & \text{if } t < \tau, \\ 0 & \text{otherwise,} \end{cases} \qquad \text{and} \qquad \mathbf{S}^\tau v(t) = \begin{cases} v(t-\tau) & \text{if } \tau \le t, \\ 0 & \text{if } 0 \le t < \tau, \end{cases}$$

where $v \in L^2_{\mathcal{V}}[0,\infty)$. The (frequency-domain) shift operator $\hat{\mathbf{S}}^\tau$ on the signal space $H^2_{\mathcal{V}}(\mathbb{C}_+)$ is defined as $\hat{\mathbf{S}}^\tau := \mathcal{L}\mathbf{S}^\tau\mathcal{L}^{-1} = \mathrm{e}^{-\tau s}\,\mathbf{I}_{\mathcal{V}}$. On $L^2_{\mathcal{V}}(\jmath\mathbb{R})$, $\mathrm{e}^{-\jmath\omega\tau}\,\mathbf{I}_{\mathcal{V}}$ corresponds to the bilateral shift by τ.

DEFINITION 1.4 (Lebesgue ∞-space, Hardy ∞-space [RR]). *Let $\mathcal{U}$, $\mathcal{Y}$ be Hilbert spaces. The* Lebesgue ∞-space $L^\infty_{\mathcal{B}(\mathcal{U},\mathcal{Y})}(\jmath\mathbb{R})$ *is the Banach space of $\mathcal{B}(\mathcal{U},\mathcal{Y})$-valued functions T of a complex variable that are bounded in the norm* $\|T\|_{L^\infty} := \operatorname{ess\,sup}_{\omega\in\mathbb{R}} \{\|T(\jmath\omega)\|_{\mathrm{ind}}\}$. *The* Hardy ∞-space $H^\infty_{\mathcal{B}(\mathcal{U},\mathcal{Y})}(\mathbb{C}_+)$ *is the Banach space of $\mathcal{B}(\mathcal{U},\mathcal{Y})$-valued functions T of a complex variable that are analytic on $\mathbb{C}_+$ and bounded in the norm* $\|T\|_{H^\infty} := \sup_{s\in\mathbb{C}_+} \{\|T(s)\|_{\mathrm{ind}}\}$. *If $T \in H^\infty_{\mathcal{B}(\mathcal{U},\mathcal{Y})}(\mathbb{C}_+)$, then $\|T\|_{H^\infty} = \operatorname{ess\,sup}_{\omega\in\mathbb{R}} \|T(\jmath\omega)\|_{\mathrm{ind}}$, and hence we can identify the norms $\|.\|_{L^\infty}$ and $\|.\|_{H^\infty}$ with each other and write simply $\|.\|_\infty$, calling it the* ∞-norm.

DEFINITION 1.5 (multiplication operator [RR]). *Let $T \in H^\infty_{\mathcal{B}(\mathcal{U},\mathcal{Y})}(\mathbb{C}_+)$. The operator $\mathcal{M}_T : H^2_{\mathcal{U}}(\mathbb{C}_+) \to H^2_{\mathcal{Y}}(\mathbb{C}_+)$ defined by $\mathcal{M}_T : f \mapsto Tf$ for all $f \in H^2_{\mathcal{U}}(\mathbb{C}_+)$ is called the* multiplication operator with symbol T.

DEFINITION 1.6 (Laurent operator and para-hermitian conjugate). *Each $G \in L^\infty_{\mathcal{B}(\mathcal{U},\mathcal{Y})}(\jmath\mathbb{R})$ induces an operator $\mathcal{L}_G : L^2_{\mathcal{U}}(\jmath\mathbb{R}) \to L^2_{\mathcal{Y}}(\jmath\mathbb{R})$, called the* Laurent operator with symbol G, *and defined by $\mathcal{L}_G : g \mapsto Gg$ for all $g \in L^2_{\mathcal{U}}(\jmath\mathbb{R})$. The adjoint $\mathcal{L}_G^*$ is equal to the Laurent operator with symbol $G^\sim$, where $G^\sim$ is defined via $\langle f, Gg\rangle_2 = \langle G^\sim f, g\rangle_2$ for all $g \in L^2_{\mathcal{U}}(\jmath\mathbb{R})$, $f \in L^2_{\mathcal{Y}}(\jmath\mathbb{R})$. $G^\sim \in L^\infty_{\mathcal{B}(\mathcal{Y},\mathcal{U})}(\jmath\mathbb{R})$ is called the* para-hermitian conjugate *of G, and it is given by $G^\sim(s) = \left(G(-\overline{s})\right)^*$, where $(.)^*$ denotes the $\mathcal{B}(\mathcal{U},\mathcal{Y})$-adjoint and $\overline{s}$ is the complex-conjugate of s. If $G \in H^\infty_{\mathcal{B}(\mathcal{U},\mathcal{Y})}(\mathbb{C}_+)$, then $\|G\|_{H^\infty} = \sqrt{\|G^\sim G\|_{L^\infty}} = \sqrt{\|G\,G^\sim\|_{L^\infty}}$.*

THEOREM 1.7 ([FF, p. 235]). *Let $\mathcal{U}$, $\mathcal{Y}$ be Hilbert spaces. A bounded linear operator $M : H^2_{\mathcal{U}}(\mathbb{C}_+) \to H^2_{\mathcal{Y}}(\mathbb{C}_+)$ is shift-invariant iff $M = \mathcal{M}_G$ for some $G \in H^\infty_{\mathcal{B}(\mathcal{U},\mathcal{Y})}(\mathbb{C}_+)$. In this case, $\|M\|_{\mathrm{ind}} = \|G\|_\infty$. Similarly, a bounded linear operator $L : L^2_{\mathcal{U}}(\jmath\mathbb{R}) \to L^2_{\mathcal{Y}}(\jmath\mathbb{R})$ commutes with the bilateral shift iff $L = \mathcal{L}_K$ for some $K \in L^\infty_{\mathcal{B}(\mathcal{U},\mathcal{Y})}(\jmath\mathbb{R})$. In this case, $\|L\|_{\mathrm{ind}} = \|K\|_\infty$.*

DEFINITION 1.8 (invertible in H^∞). *An (operator-valued) function $T \in H^\infty_{\mathcal{B}(\mathcal{U},\mathcal{U})}(\mathbb{C}_+)$ is said to be* invertible in H^∞ *if there exists a function $T^{-1} \in H^\infty_{\mathcal{B}(\mathcal{U},\mathcal{U})}(\mathbb{C}_+)$ such that $T^{-1}T = TT^{-1} = \mathbf{I}_{\mathcal{U}}$. The terms* right invertible in H^∞ *and* left invertible in H^∞ *are defined analogously.*

DEFINITION 1.9 (inner and coinner functions [FF, p. 234]). *Let $\mathscr{U}$, $\mathscr{Y}$ be Hilbert spaces. A function $G \in H^\infty_{\mathscr{B}(\mathscr{U},\mathscr{Y})}(\mathbb{C}_+)$ is called* inner *if $G^\sim(\jmath\omega)\,G(\jmath\omega) = \mathbf{I}_\mathscr{U}$ for (almost) all $\omega \in \mathbb{R}$, and* coinner *if $G(\jmath\omega)\,G^\sim(\jmath\omega) = \mathbf{I}_\mathscr{Y}$ for (almost) all $\omega \in \mathbb{R}$.*

DEFINITION 1.10 (outer function [FF, p. 240]). *Let $\mathscr{U}$, $\mathscr{Y}$ be Hilbert spaces. $G_o \in H^\infty_{\mathscr{B}(\mathscr{U},\mathscr{Y})}(\mathbb{C}_+)$ is called an* outer function *(or simply* outer*) if $\operatorname{cl}\big(G_o\,H^2_\mathscr{U}(\mathbb{C}_+)\big) = H^2_\mathscr{Y}(\mathbb{C}_+)$, where* cl(.) *denotes "closure."*

THEOREM 1.11 (Szegö [RR, section 6.14]). *Let $\mathscr{Y}$ be a Hilbert space, and F a (weakly measurable) nonnegative $\mathscr{B}(\mathscr{Y},\mathscr{Y})$-valued function of $\omega \in \mathbb{R}$ that has invertible values for (almost) all $\omega \in \mathbb{R}$. Assume that*

$$\int_{-\infty}^{\infty} \frac{\log^+\|F(\jmath\omega)\|_{\mathrm{ind}}}{1+\omega^2}\,\mathrm{d}\omega < \infty \quad \textit{and} \quad \int_{-\infty}^{\infty} \frac{\log^+\|F^{-1}(\jmath\omega)\|_{\mathrm{ind}}}{1+\omega^2}\,\mathrm{d}\omega < \infty, \tag{2}$$

where $\log^+ t := \max(\log t, 0)$ for $t > 0$ and $\log^+ 0 := -\infty$. Then $F(\jmath\omega) = V^\sim(\jmath\omega)\,V(\jmath\omega)$ for (almost) all $\omega \in \mathbb{R}$, where $V(s)$, $s \in \mathbb{C}$, is a $\mathscr{B}(\mathscr{Y},\mathscr{Y}_1)$-valued outer function with $\mathscr{Y}_1$ being a closed subspace of $\mathscr{Y}$.

The following Proposition 1.12 on the spectral factorization of operator-valued L^∞-functions is a consequence of Szegö's theorem. A proof of the proposition is included as the authors were unable to find the result, as stated below, in the literature.

PROPOSITION 1.12 (spectral factorization). *Let $\mathscr{U}$, $\mathscr{Y}$ be Hilbert spaces.*

(i) *For every function $G \in L^\infty_{\mathscr{B}(\mathscr{U},\mathscr{Y})}(\jmath\mathbb{R})$ that has a left inverse in L^∞, there exists a function $X \in H^\infty_{\mathscr{B}(\mathscr{U},\mathscr{U})}(\mathbb{C}_+)$, which is invertible in H^∞, such that $G^\sim(\jmath\omega)\,G(\jmath\omega) = X^\sim(\jmath\omega)\,X(\jmath\omega)$ for (almost) all $\omega \in \mathbb{R}$.*

(ii) *For every function $\tilde{G} \in L^\infty_{\mathscr{B}(\mathscr{Y},\mathscr{U})}(\jmath\mathbb{R})$ that has a right inverse in L^∞, there exists a function $Y \in H^\infty_{\mathscr{B}(\mathscr{U},\mathscr{U})}(\mathbb{C}_+)$, which is invertible in H^∞, such that $\tilde{G}(\jmath\omega)\,\tilde{G}^\sim(\jmath\omega) = Y(\jmath\omega)\,Y^\sim(\jmath\omega)$ for (almost) all $\omega \in \mathbb{R}$.*

Proof. Given a function $K \in L^\infty_{\mathscr{B}(\mathscr{U},\mathscr{Y})}(\jmath\mathbb{R})$ that has a left inverse $L \in L^\infty_{\mathscr{B}(\mathscr{Y},\mathscr{U})}(\jmath\mathbb{R})$, set $F := K^\sim K$. Since $L\,K = \mathbf{I}_\mathscr{U}$, it follows that $\|K\,\hat{u}\|_2 \geq \|L\|_\infty^{-1}\,\|\hat{u}\|_2$, and hence, since $\|L\|_\infty^{-2}\langle\hat{u},\hat{u}\rangle_2 \leq \langle K\hat{u}, K\hat{u}\rangle_2 = \langle\hat{u}, F\hat{u}\rangle_2 \leq \|\hat{u}\|_2\,\|F\hat{u}\|_2$, we have $\|F\,\hat{u}\|_2 \geq \|L\|_\infty^{-2}\,\|\hat{u}\|_2$ for all $\hat{u} \in L^2_\mathscr{U}(\jmath\mathbb{R})$. Thus $\mathcal{L}_F\colon L^2_\mathscr{U}(\jmath\mathbb{R}) \to L^2_\mathscr{U}(\jmath\mathbb{R})$ is bounded from below. Since K is left invertible, $K^\sim$ is right invertible which means that $\mathcal{L}_{K^\sim}$ has full range. Since K is bounded below, $\operatorname{ran}(\mathcal{L}_K) = \operatorname{cl}\big(\operatorname{ran}(\mathcal{L}_K)\big) = \operatorname{null}(\mathcal{L}_{K^\sim})^\perp$. Hence $\operatorname{ran}(\mathcal{L}_F) = L^2_\mathscr{U}[0,\infty)$. This means that $\mathcal{L}_F$ is boundedly invertible by Theorem 1.1. Since $\mathcal{L}_F$ commutes with the bilateral shift, so does $\mathcal{L}_F^{-1}$, implying the existence of a function $F^{-1} \in L^\infty_{\mathscr{B}(\mathscr{U},\mathscr{U})}(\jmath\mathbb{R})$ such that $\mathcal{L}_F^{-1} = \mathcal{L}_{F^{-1}}$ by Theorem 1.7. Note that both F and F^{-1} satisfy the conditions (2) in Theorem 1.11. Consequently, there exist outer functions $V_1 \in H^\infty_{\mathscr{B}(\mathscr{U},\mathscr{U}_1)}(\mathbb{C}_+)$ and $V_2 \in H^\infty_{\mathscr{B}(\mathscr{U},\mathscr{U}_2)}(\mathbb{C}_+)$, with $\mathscr{U}_1$ and $\mathscr{U}_2$ being closed subspaces of $\mathscr{U}$, such that $F(\jmath\omega) = V_1^\sim(\jmath\omega)\,V_1(\jmath\omega)$ and $F^{-1}(\jmath\omega) = V_2^\sim(\jmath\omega)\,V_2(\jmath\omega)$ for (almost) all $\omega \in \mathbb{R}$. The multiplication operators $\mathcal{M}_{V_1}\colon H^2_\mathscr{U}(\mathbb{C}_+) \to H^2_{\mathscr{U}_1}(\mathbb{C}_+)$ and $\mathcal{M}_{V_2}\colon H^2_\mathscr{U}(\mathbb{C}_+) \to H^2_{\mathscr{U}_2}(\mathbb{C}_+)$ have dense range (since V_1 and V_2 are outer) and are bounded from below (since $\|F\hat{u}\|_2 = \|V_1^\sim\,V_1\,\hat{u}\|_2 \geq \|L\|_\infty^{-2}\,\|\hat{u}\|_2$ implies $\|V_1\,\hat{u}\|_2 \geq \|V_1\|_\infty^{-1}\,\|L\|_\infty^{-2}\,\|\hat{u}\|_2$, and similarly for V_2). Combining Theorems 1.1 and 1.7, it follows that both V_1 and V_2 are invertible in H^∞. Furthermore, $\dim\mathscr{U}_1 = \dim\mathscr{U}_2 = \dim\mathscr{U}$, i.e., both $\mathscr{U}_1$ and $\mathscr{U}_2$ are isometrically isomorphic to $\mathscr{U}$ [K2, p. 173], and therefore there exist (constant) isometric isomorphisms $T_1\colon \mathscr{U}_1 \to \mathscr{U}$ and $T_2\colon \mathscr{U}_2 \to \mathscr{U}$.

To prove part (i), set $K := G$ and $X := T_1\,V_1$. Now note that $X, X^{-1} \in H^\infty_{\mathscr{B}(\mathscr{U},\mathscr{U})}(\mathbb{C}_+)$ and that $G^\sim(\jmath\omega)\,G(\jmath\omega) = F(\jmath\omega) = V_1^\sim(\jmath\omega)\,V_1(\jmath\omega) = X^\sim(\jmath\omega)\,X(\jmath\omega)$ for (almost) all $\omega \in \mathbb{R}$.

To prove part (ii), set $K := \tilde{G}^{\sim}$ and $Y := \begin{pmatrix} T_2 \\ V_2 \end{pmatrix}^{-1}$. Now note that $Y, Y^{-1} \in H^{\infty}_{\mathscr{B}(\mathscr{U},\mathscr{U})}(\mathbb{C}_+)$ and that $\big(\tilde{G}(\jmath\omega)\,\tilde{G}^{\sim}(\jmath\omega)\big)^{-1} = F^{-1}(\jmath\omega) = V_2^{\sim}(\jmath\omega)\,V_2(\jmath\omega) = \big(Y(\jmath\omega)\,Y^{\sim}(\jmath\omega)\big)^{-1}$, i.e., $\tilde{G}(\jmath\omega)\,\tilde{G}^{\sim}(\jmath\omega) = Y(\jmath\omega)\,Y^{\sim}(\jmath\omega)$ for (almost) all $\omega \in \mathbb{R}$. □

2. System representations. Mathematical models for spatially distributed systems may arise in the form of PDEs, integral operators, or as a result of direct modelling techniques such as the finite element method. In this section we take an abstract approach to show that frequency domain representations exist for LTI, spatially distributed systems under very mild assumptions. The representation takes the form of a graph symbol. We will furthermore show that the graph symbol gives rise to so-called *(normalized) right and left coprime representations* if the system is (feedback-) stabilizable.

In the time-domain, a spatially distributed system is considered to be an operator

$$\mathbf{P} : \mathrm{dom}(\mathbf{P}) \subseteq L^2_{\mathscr{U}}[0,\infty) \to L^2_{\mathscr{Y}}[0,\infty),$$

where $\mathscr{U}$, $\mathscr{Y}$ are (infinite-dimensional) Hilbert spaces. The *graph* of $\mathbf{P}$ is defined by $\mathcal{G}_{\mathbf{P}} := \left[\begin{smallmatrix} \mathbf{I}_{\mathscr{U}} \\ \mathbf{P} \end{smallmatrix}\right] \mathrm{dom}(\mathbf{P}) \subseteq L^2_{\left[\begin{smallmatrix}\mathscr{U}\\ \mathscr{Y}\end{smallmatrix}\right]}[0,\infty)$. A system $\mathbf{P}$ is said to be *linear* if $\mathcal{G}_{\mathbf{P}}$ is a linear subspace of $L^2_{\left[\begin{smallmatrix}\mathscr{U}\\ \mathscr{Y}\end{smallmatrix}\right]}[0,\infty)$. A linear system $\mathbf{P}$ is said to be *stable* if $\mathrm{dom}(\mathbf{P}) = L^2_{\mathscr{U}}[0,\infty)$ and $\|\mathbf{P}\|_{\mathrm{ind}} < \infty$. A system $\mathbf{P}$ is said to be *shift-invariant* (or *time-invariant*) if, for all $\tau \in (0,\infty)$ and all $u \in \mathrm{dom}(\mathbf{P})$, $\mathbf{S}^{\tau}\,\mathbf{P}\,u = \mathbf{P}\,\mathbf{S}^{\tau}\,u$. This is equivalent to the graph $\mathcal{G}_{\mathbf{P}}$ being a shift-invariant subspace of $L^2_{\left[\begin{smallmatrix}\mathscr{U}\\ \mathscr{Y}\end{smallmatrix}\right]}[0,\infty)$, i.e., $\mathbf{S}^{\tau}\,\mathcal{G}_{\mathbf{P}} \subseteq \mathcal{G}_{\mathbf{P}}$ for all $\tau \in (0,\infty)$. A linear system $\mathbf{P}$ is said to be *causal* if, for all $\tau \in (0,\infty)$ and all $u_1, u_2 \in \mathrm{dom}(\mathbf{P})$, $\mathbf{T}^{\tau}\,u_1 = \mathbf{T}^{\tau}\,u_2$ implies $\mathbf{T}^{\tau}\,\mathbf{P}\,u_1 = \mathbf{T}^{\tau}\,\mathbf{P}\,u_2$. This is equivalent to the graph of $\mathbf{P}$ satisfying the following: $\left(\begin{smallmatrix} 0 \\ \hat{v} \end{smallmatrix}\right) \in \mathbf{T}^{\tau}\,\mathcal{G}_{\mathbf{P}}$ implies $\hat{v} = 0$ for all $\tau \in (0,\infty)$. A stable, linear system $\mathbf{P}$ is causal iff $\mathbf{T}^{\tau}\,\mathbf{P}\,u = \mathbf{T}^{\tau}\,\mathbf{P}\,\mathbf{T}^{\tau}\,u$ for all $u \in L^2_{\mathscr{U}}[0,\infty)$. Furthermore, it is a standard fact that every linear, stable, and shift-invariant system, which is defined on the singly infinite time axis $[0,\infty)$, is causal. A causal, linear system $\mathbf{P}$ is called *causally extendible* if $\mathbf{T}^{\tau}\,\mathrm{dom}(\mathbf{P}) = L^2_{\mathscr{U}}[0,\tau) := \mathbf{T}^{\tau} L^2_{\mathscr{U}}[0,\infty)$ for all $\tau \in (0,\infty)$. Causal extendibility means that, given any $\tau > 0$, we can choose the input to $\mathbf{P}$ arbitrarily over the interval $[0,\tau)$ and yet be able to continue the input to an element of $\mathrm{dom}(\mathbf{P})$.

Consider the LTI system $\mathbf{P} : \mathrm{dom}(\mathbf{P}) \subseteq L^2_{\mathscr{U}}[0,\infty) \to L^2_{\mathscr{Y}}[0,\infty)$ with input-output relationship given by $y = \mathbf{P}\,u$. Denote the Laplace-transforms of u and y by $\hat{u} := \mathcal{L}u$ and $\hat{y} := \mathcal{L}y$, respectively. In the "frequency domain," the system is represented by the operator $\hat{\mathbf{P}} : \mathrm{dom}(\hat{\mathbf{P}}) \subseteq H^2_{\mathscr{U}}(\mathbb{C}_+) \to H^2_{\mathscr{Y}}(\mathbb{C}_+)$, defined via $\hat{\mathbf{P}} := \mathcal{L}\mathbf{P}\mathcal{L}^{-1}$. The Laplace-transformed system graph is denoted by $\mathcal{G}_{\hat{\mathbf{P}}} := \mathcal{L}\mathcal{G}_{\mathbf{P}}$. It is well known that the Laplace-transform (of signals) is an isometric isomorphism between Hilbert spaces. Thus we can think interchangeably of operators defined in the "time domain" or the "frequency domain." The equivalence between "time domain" and "frequency domain" can be depicted in diagrammatic form:

$$\begin{array}{ccccc} L^2_{\mathscr{U}}[0,\infty) & \supseteq & \mathrm{dom}(\mathbf{P}) & \xrightarrow{\ \mathbf{P}\ } & L^2_{\mathscr{Y}}[0,\infty) \\ \mathcal{L} \Updownarrow \mathcal{L}^{-1} & & \mathcal{L} \Updownarrow \mathcal{L}^{-1} & & \mathcal{L} \Updownarrow \mathcal{L}^{-1} \\ H^2_{\mathscr{U}}[\mathbb{C}_+) & \supseteq & \mathrm{dom}(\hat{\mathbf{P}}) & \xrightarrow{\ \hat{\mathbf{P}}\ } & H^2_{\mathscr{Y}}[\mathbb{C}_+). \end{array}$$

The following result, which is a generalization of a fundamental result for lumped-parameter systems, states mild conditions under which the graph of a spatially distributed LTI system can be represented as the range of an operator-valued H^{∞}-function.

THEOREM 2.1. *Let $\mathscr{U}$, $\mathscr{Y}$ be (separable) Hilbert spaces. Consider a closed, linear, shift-invariant, causally extendible system* $\mathbf{P}\colon \operatorname{dom}(\mathbf{P}) \subseteq L^2_{\mathscr{U}}[0,\infty) \to L^2_{\mathscr{Y}}[0,\infty)$. *Then there exist (operator-valued) functions* $M \in H^\infty_{\mathscr{B}(\mathscr{U},\,\mathscr{U})}(\mathbb{C}_+)$ *and* $N \in H^\infty_{\mathscr{B}(\mathscr{U},\,\mathscr{Y})}(\mathbb{C}_+)$ *such that* $G := \left[\begin{smallmatrix} M \\ N \end{smallmatrix}\right]$ *is inner and satisfies* $\mathcal{G}_{\hat{\mathbf{P}}} = G\, H^2_{\mathscr{U}}(\mathbb{C}_+)$.

Proof (the proof is based on the proofs of Propositions 1 and 11 in [GS3]). Call $\mathscr{V} := \left[\begin{smallmatrix} \mathscr{U} \\ \mathscr{Y} \end{smallmatrix}\right]$. By assumption $\mathcal{G}_{\hat{\mathbf{P}}}$ is a closed, shift-invariant subspace of $H^2_{\mathscr{V}}(\mathbb{C}_+)$, and hence by the Beurling–Lax theorem [FF, p. 239] there exists an at most countably infinite-dimensional Hilbert space $\mathscr{Z}$ and an inner function $G' \in H^\infty_{\mathscr{B}(\mathscr{Z},\,\mathscr{V})}(\mathbb{C}_+)$ such that $\mathcal{G}_{\hat{\mathbf{P}}} = G'\, H^2_{\mathscr{Z}}(\mathbb{C}_+)$. We will show next that the assumption of causal extendibility of $\mathbf{P}$ implies that $\mathscr{Z}$ cannot be finite-dimensional if $\mathscr{U}$ is infinite-dimensional. Set $G' =: \left[\begin{smallmatrix} M' \\ N' \end{smallmatrix}\right]$, where $M' \in H^\infty_{\mathscr{B}(\mathscr{Z},\,\mathscr{U})}(\mathbb{C}_+)$ and $N' \in H^\infty_{\mathscr{B}(\mathscr{Z},\,\mathscr{Y})}(\mathbb{C}_+)$. $\mathbf{P}$ is causally extendible, meaning that for all $\tau > 0$ and all $\hat{u} \in H^2_{\mathscr{U}}(\mathbb{C}_+) \ominus \mathrm{e}^{-\tau s} H^2_{\mathscr{U}}(\mathbb{C}_+)$ there exists a $\hat{z} \in H^2_{\mathscr{Z}}(\mathbb{C}_+)$ such that $\hat{u} = \mathcal{P}_{H^2_{\mathscr{U}}(\mathbb{C}_+) \ominus \mathrm{e}^{-\tau s} H^2_{\mathscr{U}}(\mathbb{C}_+)} M'\, \hat{z}$. Equivalently, for every $\hat{u} \in H^2_{\mathscr{U}}(\mathbb{C}_+)$ and $\tau > 0$, $\hat{u} = M'\, \hat{w} - \mathrm{e}^{-\tau s}\, \hat{v} =: M'' \left(\begin{smallmatrix} \hat{w} \\ \hat{v} \end{smallmatrix}\right)$ has a solution $\left(\begin{smallmatrix} \hat{w} \\ \hat{v} \end{smallmatrix}\right) \in H^2_{\left[\begin{smallmatrix} \mathscr{Z} \\ \mathscr{U} \end{smallmatrix}\right]}(\mathbb{C}_+)$. This condition is satisfied iff $M'' H^2_{\left[\begin{smallmatrix} \mathscr{Z} \\ \mathscr{U} \end{smallmatrix}\right]}(\mathbb{C}_+) = H^2_{\mathscr{U}}(\mathbb{C}_+)$, i.e., the multiplication operator $\mathcal{M}_{M''} : H^2_{\left[\begin{smallmatrix} \mathscr{Z} \\ \mathscr{U} \end{smallmatrix}\right]}(\mathbb{C}_+) \to H^2_{\mathscr{U}}(\mathbb{C}_+)$ is onto. This implies that $\mathcal{M}_{M''}$ has a right inverse, which by [FF, Corollary VI.6.2, p. 218] can be expressed as a multiplication operator with symbol in H^∞. Hence $\big(M''(s)\big)^*$ is left invertible for fixed $s \in \mathbb{C}_+$. Moreover, $\big(M''(s)\big)^*$ is uniformly (in $\mathbb{C}_+$) bounded from below. Thus $\inf_{s \in \mathbb{C}_+} \left\langle \big(M''(s)\big)^* u,\, \big(M''(s)\big)^* u \right\rangle_{\left[\begin{smallmatrix} \mathscr{Z} \\ \mathscr{U} \end{smallmatrix}\right]} > 0$ for all $0 \neq u \in \mathscr{U}$, and hence

$$\inf_{s \in \mathbb{C}_+} \left(\left\langle \big(M'(s)\big)^* u,\, \big(M'(s)\big)^* u \right\rangle_{\mathscr{Z}} + \mathrm{e}^{-2\tau \mathrm{Re}(s)} \langle u,\, u \rangle_{\mathscr{U}} \right) > 0 \qquad \text{for all} \quad 0 \neq u \in \mathscr{U}. \tag{3}$$

Thus, for all $s \in \mathbb{C}_+$, the bounded linear operator $\big(M'(s)\big)^* : \mathscr{U} \to \mathscr{Z}$ has zero null-space, and hence $\dim \mathscr{U} = \dim \operatorname{ran} \big(M'(s)\big)^* \leq \dim \mathscr{Z}$. Therefore, if $\mathscr{U}$ is countably infinite-dimensional, so must be $\mathscr{Z}$. Since the Hilbert spaces $\mathscr{Z}$ and $\mathscr{U}$ have the same dimension, they are isometrically isomorphic ([K2, p. 173]), i.e., there exists a (constant) isometric isomorphism $U : \mathscr{U} \to \mathscr{Z}$. Finally, $G := G'\, U$ satisfies $\mathcal{G}_{\hat{\mathbf{P}}} = G\, H^2_{\mathscr{U}}(\mathbb{C}_+)$, where G so defined is inner since $G \in H^\infty_{\mathscr{B}(\mathscr{U},\,\left[\begin{smallmatrix} \mathscr{U} \\ \mathscr{Y} \end{smallmatrix}\right])}(\mathbb{C}_+)$ and $\big(G(\jmath\omega)\big)^{\sim} G(\jmath\omega) = U^* \big(G'(\jmath\omega)\big)^{\sim} G'(\jmath\omega)\, U = U^* \mathbf{I}_{\mathscr{Z}}\, U = \mathbf{I}_{\mathscr{U}}$ for (almost) all $\omega \in \mathbb{R}$. ∎

DEFINITION 2.2 (graph symbol). *Given a closed, linear, and shift-invariant system* $\mathbf{P}\colon\ L^2_{\mathscr{U}}[0,\infty) \to L^2_{\mathscr{Y}}[0,\infty)$, *a function* $G \in H^\infty_{\mathscr{B}(\mathscr{U},\,\left[\begin{smallmatrix} \mathscr{U} \\ \mathscr{Y} \end{smallmatrix}\right])}(\mathbb{C}_+)$ *satisfying* $\mathcal{G}_{\hat{\mathbf{P}}} = G\, H^2_{\mathscr{U}}(\mathbb{C}_+)$ *is called a* graph symbol *of* $\mathbf{P}$.

In the physical sciences and engineering it is often the case that the input-output behavior of a system can be represented in terms of an integral operator. Though we are not able to provide an existence theorem for such representations, based on fundamental system properties as in Theorem 2.1, we now briefly discuss the possible relationship between such representations and the graph symbol arising from Theorem 2.1. Suppose that $\mathbf{P}$ is a causal, linear, shift-invariant system with integral operator representation of the form

$$y(x,t) = \int_0^t \int_{\mathcal{D}^i} \kappa_{\mathbf{P}}(x,\xi,t-\tau)\, u(\xi,\tau)\, \mathrm{d}\xi\, \mathrm{d}\tau, \qquad x \in \mathcal{D}^o, \tag{4}$$

where $\mathcal{D}^i$ and $\mathcal{D}^o$ denote the input and output spatial domains. Taking Laplace-

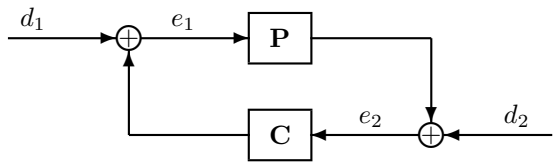

FIG. 1. *Standard feedback configuration* $[\mathbf{P}, \mathbf{C}]$ *of spatially distributed systems in the "time domain."*

transforms of (4) gives

$$\hat{y}(x;s) = \int_{\mathcal{D}^i} \kappa_{\hat{\mathbf{P}}}(x,\xi;s)\,\hat{u}(\xi;s)\,\mathrm{d}\xi, \qquad x \in \mathcal{D}^o,$$

where $\kappa_{\hat{\mathbf{P}}}(x,\xi;s)$ is the Laplace-transform of the system's Green's function $\kappa_{\mathbf{P}}(x,\xi;t)$. This leads to a "frequency domain" interpretation of $\mathbf{P}$ as a parameter-dependent (i.e., s-dependent) integral operator $P(s)$ with kernel $\kappa_{\hat{\mathbf{P}}}(x,\xi;s)$. Now suppose that $\mathbf{P}$ is closed and causally extendible, so that by Theorem 2.1 there exists an $M \in H^\infty_{\mathscr{B}(\mathscr{U},\mathscr{U})}(\mathbb{C}_+)$ and an $N \in H^\infty_{\mathscr{B}(\mathscr{U},\mathscr{Y})}(\mathbb{C}_+)$ such that $\mathcal{G}_{\hat{\mathbf{P}}} = G\,H^2_{\mathscr{U}}(\mathbb{C}_+)$, where $G =: \left[\begin{smallmatrix} M \\ N \end{smallmatrix}\right]$, $\mathscr{U} := L^2(\mathcal{D}^i)$, and $\mathscr{Y} := L^2(\mathcal{D}^o)$. If $\mathbf{P}$ is also bounded on the whole of $L^2_{\mathscr{U}}[0,\infty)$, then it can be shown that the corresponding M is invertible in $H^\infty_{\mathscr{B}(\mathscr{U},\mathscr{U})}(\mathbb{C}_+)$ and that $P(s) = N(s)M^{-1}(s)$. In general, however, although it can be shown that $\mathcal{M}_M$ is always injective, whether $(\mathcal{M}_M)^{-1}$ corresponds to multiplication by some operator-valued function (frequency-domain symbol) appears to be an open question. In such cases, the relationship between the integral operator representation and graph symbol needs further clarification.

Consider now the spatially distributed feedback system in Figure 1, which we denote by $[\mathbf{P}, \mathbf{C}]$, where $\mathbf{P} : \mathrm{dom}(\mathbf{P}) \subseteq L^2_{\mathscr{U}}[0,\infty) \to L^2_{\mathscr{Y}}[0,\infty)$ and $\mathbf{C} : \mathrm{dom}(\mathbf{C}) \subseteq L^2_{\mathscr{Y}}[0,\infty) \to L^2_{\mathscr{U}}[0,\infty)$ are linear operators.

DEFINITION 2.3 (feedback stability). *Consider the systems* $\mathbf{P} : \mathrm{dom}(\mathbf{P}) \subseteq L^2_{\mathscr{U}}[0,\infty) \to L^2_{\mathscr{Y}}[0,\infty)$ *and* $\mathbf{C} : \mathrm{dom}(\mathbf{C}) \subseteq L^2_{\mathscr{Y}}[0,\infty) \to L^2_{\mathscr{U}}[0,\infty)$*, where* $\mathscr{U}$ *and* $\mathscr{Y}$ *are Hilbert spaces. The standard feedback configuration* $[\mathbf{P}, \mathbf{C}]$ *in Figure* 1 *is said to be* stable *if*

$$\mathbf{F}(\mathbf{P},\mathbf{C}) := \begin{pmatrix} \mathbf{I}_{\mathscr{U}} & -\mathbf{C} \\ -\mathbf{P} & \mathbf{I}_{\mathscr{Y}} \end{pmatrix} : \ \mathrm{dom}(\mathbf{P}) \times \mathrm{dom}(\mathbf{C}) \subseteq L^2_{\left[\begin{smallmatrix}\mathscr{U}\\ \mathscr{Y}\end{smallmatrix}\right]}[0,\infty) \to L^2_{\left[\begin{smallmatrix}\mathscr{U}\\ \mathscr{Y}\end{smallmatrix}\right]}[0,\infty) : \ \begin{pmatrix} e_1 \\ e_2 \end{pmatrix} \mapsto \begin{pmatrix} d_1 \\ d_2 \end{pmatrix}$$

has a bounded inverse $\big(\mathbf{F}(\mathbf{P},\mathbf{C})\big)^{-1} =: \mathbf{H}(\mathbf{P},\mathbf{C})$ *on* $L^2_{\left[\begin{smallmatrix}\mathscr{U}\\ \mathscr{Y}\end{smallmatrix}\right]}[0,\infty)$.

The *inverse graph* of $\mathbf{C}$ is defined as $\mathcal{G}^{\mathrm{i}}_{\mathbf{C}} := \left[\begin{smallmatrix}\mathbf{C}\\ \mathbf{I}_{\mathscr{Y}}\end{smallmatrix}\right] \mathrm{dom}(\mathbf{C})$, and its frequency-domain equivalent is denoted by $\mathcal{G}^{\mathrm{i}}_{\hat{\mathbf{C}}} := \mathcal{L}\mathcal{G}^{\mathrm{i}}_{\mathbf{C}}$. The following result characterizes feedback stability in terms of the graphs of $\mathbf{P}$ and $\mathbf{C}$; see [FGS1, OS, GS3, FGS], for example.

PROPOSITION 2.4. *Consider the systems* $\mathbf{P} : \mathrm{dom}(\mathbf{P}) \subseteq L^2_{\mathscr{U}}[0,\infty) \to L^2_{\mathscr{Y}}[0,\infty)$ *and* $\mathbf{C} : \mathrm{dom}(\mathbf{C}) \subseteq L^2_{\mathscr{Y}}[0,\infty) \to L^2_{\mathscr{U}}[0,\infty)$*, where* $\mathscr{U}$ *and* $\mathscr{Y}$ *are Hilbert spaces. The*

feedback configuration $[\mathbf{P}, \mathbf{C}]$ *is stable iff* $\mathcal{G}_{\mathbf{P}}$, $\mathcal{G}^{\mathrm{i}}_{\mathbf{C}}$ *are closed subspaces of* $L^2_{\left[\begin{smallmatrix}\mathscr{U}\\ \mathscr{Y}\end{smallmatrix}\right]}[0,\infty)$,

$$\mathcal{G}_{\mathbf{P}} \cap \mathcal{G}^{\mathrm{i}}_{\mathbf{C}} = \{0\}, \tag{5}$$

$$\mathcal{G}_{\mathbf{P}} + \mathcal{G}^{\mathrm{i}}_{\mathbf{C}} = L^2_{\left[\begin{smallmatrix}\mathscr{U}\\ \mathscr{Y}\end{smallmatrix}\right]}[0,\infty). \tag{6}$$

On the basis of Theorem 2.1 and Definition 2.3, we now define the class of spatially distributed systems considered in this paper.

DEFINITION 2.5 (class of shift-invariant, spatially distributed systems). *Consider the Hilbert spaces* $\mathscr{U} := L^2(\mathcal{D}^i)$ *and* $\mathscr{Y} := L^2(\mathcal{D}^o)$, *where* $\mathcal{D}^i$ *and* $\mathcal{D}^o$ *are spatial domains. We define* $\mathcal{S}\big(\mathscr{U}, \mathscr{Y}; [0,\infty)\big)$ *to be the set of all closed, linear, shift-invariant, causally extendible operators* $\mathbf{P} : \mathrm{dom}(\mathbf{P}) \subseteq L^2_{\mathscr{U}}[0,\infty) \to L^2_{\mathscr{Y}}[0,\infty)$. *By* $\mathcal{SS}\big(\mathscr{U}, \mathscr{Y}; [0,\infty)\big)$ *we denote the subclass of* stabilizable *systems in* $\mathcal{S}\big(\mathscr{U}, \mathscr{Y}; [0,\infty)\big)$.

The requirement that the elements of $\mathcal{S}\big(\mathscr{U}, \mathscr{Y}; [0,\infty)\big)$ be closed operators (i.e., operators with closed graphs) is not a major restriction since, by Proposition 2.4, closedness of the system graph is necessary for the system to be stabilizable. We next define *coprime representations,* which are shown to exist for every system in $\mathcal{SS}\big(\mathscr{U}, \mathscr{Y}; [0,\infty)\big)$. Coprime representations have proved to be useful notions in feedback control, particularly in dealing with (open-loop) unstable systems, and as shown below they lead to a neat parameterization of stabilizing controllers. The following definition is adapted from [DS].

DEFINITION 2.6 (coprime representations). *Given a system* $\mathbf{P} \in \mathcal{S}\big(\mathscr{U}, \mathscr{Y}; [0,\infty)\big)$, $\left[\begin{smallmatrix}M\\ N\end{smallmatrix}\right]$ *is said to be a* right coprime representation *of* $\mathbf{P}$ *if* $M \in H^\infty_{\mathscr{B}(\mathscr{U},\mathscr{U})}(\mathbb{C}_+)$ *and* $N \in H^\infty_{\mathscr{B}(\mathscr{U},\mathscr{Y})}(\mathbb{C}_+)$ *satisfy* $\mathcal{G}_{\hat{\mathbf{P}}} = \left[\begin{smallmatrix}M\\ N\end{smallmatrix}\right] H^2_{\mathscr{U}}(\mathbb{C}_+)$, *and* $\left[\begin{smallmatrix}M\\ N\end{smallmatrix}\right]$ *is left invertible in* H^∞. *If, in addition,* $\left[\begin{smallmatrix}M\\ N\end{smallmatrix}\right]$ *is inner, then the right coprime representation is called* normalized. *Given* $\mathbf{P} \in \mathcal{S}\big(\mathscr{U}, \mathscr{Y}; [0,\infty)\big)$, $\begin{bmatrix}-\tilde{N} & \tilde{M}\end{bmatrix}$ *is said to be a* left coprime representation *of* $\mathbf{P}$ *if* $\tilde{M} \in H^\infty_{\mathscr{B}(\mathscr{Y},\mathscr{Y})}(\mathbb{C}_+)$ *and* $\tilde{N} \in H^\infty_{\mathscr{B}(\mathscr{U},\mathscr{Y})}(\mathbb{C}_+)$ *satisfy* $\mathcal{G}_{\hat{\mathbf{P}}} = \big\{\hat{v} \in H^2_{\left[\begin{smallmatrix}\mathscr{U}\\ \mathscr{Y}\end{smallmatrix}\right]}(\mathbb{C}_+) \;\big|\; \begin{bmatrix}-\tilde{N} & \tilde{M}\end{bmatrix} \hat{v} = 0\big\}$, *and* $\begin{bmatrix}-\tilde{N} & \tilde{M}\end{bmatrix}$ *is right invertible in* H^∞. *If, in addition,* $\begin{bmatrix}-\tilde{N} & \tilde{M}\end{bmatrix}$ *is coinner, then the left coprime representation is called* normalized.

THEOREM 2.7. *Every* $\mathbf{P} \in \mathcal{SS}\big(\mathscr{U}, \mathscr{Y}; [0,\infty)\big)$ *has normalized right and normalized left coprime representations* $\left[\begin{smallmatrix}M\\ N\end{smallmatrix}\right] \in H^\infty_{\mathscr{B}(\mathscr{U},\left[\begin{smallmatrix}\mathscr{U}\\ \mathscr{Y}\end{smallmatrix}\right])}(\mathbb{C}_+)$ *and* $\begin{bmatrix}-\tilde{N} & \tilde{M}\end{bmatrix} \in H^\infty_{\mathscr{B}(\left[\begin{smallmatrix}\mathscr{U}\\ \mathscr{Y}\end{smallmatrix}\right],\mathscr{Y})}(\mathbb{C}_+)$, *respectively.*

Proof. Suppose that $\mathbf{C} \in \mathcal{SS}\big(\mathscr{Y}, \mathscr{U}; [0,\infty)\big)$ stabilizes $\mathbf{P}$. By Theorem 2.1 there exist (operator-valued) inner functions $G \in H^\infty_{\mathscr{B}(\mathscr{U},\left[\begin{smallmatrix}\mathscr{U}\\ \mathscr{Y}\end{smallmatrix}\right])}(\mathbb{C}_+)$ and $K \in H^\infty_{\mathscr{B}(\mathscr{Y},\left[\begin{smallmatrix}\mathscr{U}\\ \mathscr{Y}\end{smallmatrix}\right])}(\mathbb{C}_+)$ such that $\mathcal{G}_{\hat{\mathbf{P}}} = GH^2_{\mathscr{U}}(\mathbb{C}_+)$ and $\mathcal{G}^{\mathrm{i}}_{\hat{\mathbf{C}}} = KH^2_{\mathscr{Y}}(\mathbb{C}_+)$. Let $T := (G, K)$. Then since $[\mathbf{P}, \mathbf{C}]$ is stable, it follows by Proposition 2.4 that

$$T\, H^2_{\left[\begin{smallmatrix}\mathscr{U}\\ \mathscr{Y}\end{smallmatrix}\right]}(\mathbb{C}_+) = GH^2_{\mathscr{U}}(\mathbb{C}_+) + KH^2_{\mathscr{Y}}(\mathbb{C}_+) = \mathcal{G}_{\hat{\mathbf{P}}} + \mathcal{G}^{\mathrm{i}}_{\hat{\mathbf{C}}} = H^2_{\left[\begin{smallmatrix}\mathscr{U}\\ \mathscr{Y}\end{smallmatrix}\right]}(\mathbb{C}_+).$$

Moreover, since $\mathrm{null}\big(\mathcal{M}_G\big) = \{0\}$ and $\mathrm{null}\big(\mathcal{M}_K\big) = \{0\}$, it follows from (5) that $\mathcal{M}_T : H^2_{\left[\begin{smallmatrix}\mathscr{U}\\ \mathscr{Y}\end{smallmatrix}\right]}(\mathbb{C}_+) \to H^2_{\left[\begin{smallmatrix}\mathscr{U}\\ \mathscr{Y}\end{smallmatrix}\right]}(\mathbb{C}_+)$ is also injective, and hence boundedly invertible. As the inverse is also shift-invariant, it follows by Theorem 1.7 that T is invertible in H^∞. Partition $T =: \left(\begin{smallmatrix}M & Y\\ N & X\end{smallmatrix}\right) \in H^\infty_{\mathscr{B}(\left[\begin{smallmatrix}\mathscr{U}\\ \mathscr{Y}\end{smallmatrix}\right],\left[\begin{smallmatrix}\mathscr{U}\\ \mathscr{Y}\end{smallmatrix}\right])}(\mathbb{C}_+)$ and $T^{-1} =: \left(\begin{smallmatrix}\tilde{X} & -\tilde{Y}\\ -\tilde{N} & \tilde{M}\end{smallmatrix}\right) \in H^\infty_{\mathscr{B}(\left[\begin{smallmatrix}\mathscr{U}\\ \mathscr{Y}\end{smallmatrix}\right],\left[\begin{smallmatrix}\mathscr{U}\\ \mathscr{Y}\end{smallmatrix}\right])}(\mathbb{C}_+)$. Clearly, $\begin{bmatrix}\tilde{X} & -\tilde{Y}\end{bmatrix}$ is a left inverse of $G = \left[\begin{smallmatrix}M\\ N\end{smallmatrix}\right]$, and correspondingly G is a right coprime representation of $\mathbf{P}$. Furthermore, it is normalized since G is inner.

We now show that $\tilde{G} := \begin{bmatrix}-\tilde{N} & \tilde{M}\end{bmatrix}$ is a left coprime representation of $\mathbf{P}$. First note that $\left[\begin{smallmatrix}Y\\ X\end{smallmatrix}\right]$ is a right inverse of $\tilde{G}$. Let $\hat{v}_1, \hat{v}_2 \in H^2_{\left[\begin{smallmatrix}\mathscr{U}\\ \mathscr{Y}\end{smallmatrix}\right]}(\mathbb{C}_+)$ satisfy $0 \neq \hat{v}_1 \in \mathcal{G}_{\hat{\mathbf{P}}}$ and

$0 \neq \hat{v}_2 \notin \mathcal{G}_{\hat{\mathbf{P}}}$, noting that there exist a $0 \neq \hat{u}_1 \in H^2_{\mathscr{U}}(\mathbb{C}_+)$ such that $\hat{v}_1 = \left[\begin{smallmatrix} M \\ N \end{smallmatrix}\right] \hat{u}_1$ and a $\hat{u}_2 \in H^2_{\mathscr{U}}(\mathbb{C}_+)$ and $0 \neq \hat{y} \in H^2_{\mathscr{Y}}(\mathbb{C}_+)$ such that $\hat{v}_2 = \left[\begin{smallmatrix} M \\ N \end{smallmatrix}\right] \hat{u}_2 + \left[\begin{smallmatrix} Y \\ X \end{smallmatrix}\right] \hat{y}$. It follows that $\tilde{G}\,\hat{v}_1 = \begin{bmatrix} -\tilde{N} & \tilde{M} \end{bmatrix} \left[\begin{smallmatrix} M \\ N \end{smallmatrix}\right] \hat{u}_1 = 0$ and $\tilde{G}\,\hat{v}_2 = \begin{bmatrix} -\tilde{N} & \tilde{M} \end{bmatrix} \left[\begin{smallmatrix} Y \\ X \end{smallmatrix}\right] \hat{y} = \hat{y} \neq 0$, which implies that $\mathcal{G}_{\hat{\mathbf{P}}} = \left\{ \hat{v} \in H^2_{\left[\begin{smallmatrix} \mathscr{U} \\ \mathscr{Y} \end{smallmatrix}\right]}(\mathbb{C}_+) \;\middle|\; \tilde{G}\,\hat{v} = 0 \right\}$. It remains to show that $\tilde{G}$ can be normalized. Since $\tilde{G}$ is right invertible, it follows by Proposition 1.12(ii) that there exists a function $Y \in H^\infty_{\mathscr{B}(\mathscr{Y},\,\mathscr{Y})}(\mathbb{C}_+)$, invertible in H^∞, such that $\tilde{G}(\jmath\omega)\,\tilde{G}^\sim(\jmath\omega) = Y(\jmath\omega)\,Y^\sim(\jmath\omega)$ for (almost) all $\omega \in \mathbb{R}$. It is now straightforward to verify that $(Y^{-1}\,\tilde{G})$ is a normalized left coprime representation of $\mathbf{P}$. □

PROPOSITION 2.8 (Youla-parametrization of all stabilizing controllers). *Let* $\mathbf{P} \in \mathcal{SS}\big(\mathscr{U}, \mathscr{Y}; [0,\infty)\big)$. *Consider any (operator-valued) functions* M, $\tilde{X} \in H^\infty_{\mathscr{B}(\mathscr{U},\,\mathscr{U})}(\mathbb{C}_+)$; Y, $\tilde{Y} \in H^\infty_{\mathscr{B}(\mathscr{Y},\,\mathscr{U})}(\mathbb{C}_+)$; N, $\tilde{N} \in H^\infty_{\mathscr{B}(\mathscr{U},\,\mathscr{Y})}(\mathbb{C}_+)$; *and* X, $\tilde{M} \in H^\infty_{\mathscr{B}(\mathscr{Y},\,\mathscr{Y})}(\mathbb{C}_+)$ *with* $\left[\begin{smallmatrix} M \\ N \end{smallmatrix}\right]$ *a right coprime representation of* $\mathbf{P}$ *and* $\begin{bmatrix} -\tilde{N} & \tilde{M} \end{bmatrix}$ *a left coprime representation of* $\mathbf{P}$ *such that the following double Bezout identity holds:*

$$\begin{pmatrix} M & Y \\ N & X \end{pmatrix} \begin{pmatrix} \tilde{X} & -\tilde{Y} \\ -\tilde{N} & \tilde{M} \end{pmatrix} = \begin{pmatrix} \tilde{X} & -\tilde{Y} \\ -\tilde{N} & \tilde{M} \end{pmatrix} \begin{pmatrix} M & Y \\ N & X \end{pmatrix} = \begin{pmatrix} \mathbf{I}_{\mathscr{U}} & 0 \\ 0 & \mathbf{I}_{\mathscr{Y}} \end{pmatrix}.$$

Then $\mathbf{C} \in \mathcal{SS}\big(\mathscr{Y}, \mathscr{U}; [0,\infty)\big)$ *stabilizes* $\mathbf{P}$ *iff* $\mathbf{C}$ *has a right coprime representation* $\left[\begin{smallmatrix} Y - M\,Q \\ X - N\,Q \end{smallmatrix}\right]$ *and a left coprime representation* $\begin{bmatrix} (-\tilde{Y} + Q\,\tilde{M}) & (\tilde{X} - Q\,\tilde{N}) \end{bmatrix}$ *for some* $Q \in H^\infty_{\mathscr{B}(\mathscr{Y},\,\mathscr{U})}(\mathbb{C}_+)$.

Proof. The result follows largely by arguments in [F], with extra care needed to ensure invertibility of certain frequency-domain symbols in H^∞, as in the first part of the proof of Theorem 2.7 above. □

3. The gap-metric. Consider two systems $\mathbf{P}_1, \mathbf{P}_2 \in \mathcal{SS}\big(\mathscr{U}, \mathscr{Y}; [0,\infty)\big)$. Let their (Laplace-transformed) graphs be denoted by $\mathcal{G}_1 := \mathcal{G}_{\hat{\mathbf{P}}_1}$ and $\mathcal{G}_2 := \mathcal{G}_{\hat{\mathbf{P}}_2}$, and let the inner functions G_1 and G_2 denote the respective graph symbols. The *gap* $\delta_g(.,.)$ between the two systems $\mathbf{P}_1$ and $\mathbf{P}_2$ is defined to be the aperture between their graphs (cf. [K1, p. 197ff] and [ZE]), i.e., $\delta_g(\mathbf{P}_1, \mathbf{P}_2) := \|\mathcal{P}_{\mathcal{G}_1} - \mathcal{P}_{\mathcal{G}_2}\|_{\mathrm{ind}}$, where $\mathcal{P}_{\mathcal{G}_1}$ and $\mathcal{P}_{\mathcal{G}_2}$ denote the projection operators from $H^2_{\left[\begin{smallmatrix} \mathscr{U} \\ \mathscr{Y} \end{smallmatrix}\right]}(\mathbb{C}_+)$ onto the (closed) graphs $\mathcal{G}_1$ and $\mathcal{G}_2$. It is easy to verify that the gap $\delta_g(.,.)$ so defined is a metric. Furthermore, $0 \leq \delta_g(\mathbf{P}_1, \mathbf{P}_2) \leq 1$. In [KVZRS, p. 205f], it was shown that $\delta_g(\mathbf{P}_1, \mathbf{P}_2) = \max\big\{\vec{\delta}_g(\mathbf{P}_1, \mathbf{P}_2), \vec{\delta}_g(\mathbf{P}_2, \mathbf{P}_1)\big\}$, where $\vec{\delta}_g(\mathbf{P}_1, \mathbf{P}_2) := \big\|\mathcal{P}_{\mathcal{G}_2^\perp}\,\mathcal{P}_{\mathcal{G}_1}\big\|_{\mathrm{ind}}$, which is termed the *directed gap*. In addition,

$$\delta_g(\mathbf{P}_1, \mathbf{P}_2) = \vec{\delta}_g(\mathbf{P}_1, \mathbf{P}_2) = \vec{\delta}_g(\mathbf{P}_2, \mathbf{P}_1) \qquad \text{if} \quad \delta_g(\mathbf{P}_1, \mathbf{P}_2) < 1. \tag{7}$$

Generalizing the result of [G1] to the infinite-dimensional, linear operator case, it was shown in [CG2, Theorem 3.3] that

$$\vec{\delta}_g(\mathbf{P}_1, \mathbf{P}_2) = \Big\|\mathcal{P}_{\mathcal{G}_2^\perp}\,\mathcal{P}_{\mathcal{G}_1}\Big\|_{\mathrm{ind}} = \inf_{Q \in H^\infty_{\mathscr{B}(\mathscr{U},\,\mathscr{U})}(\mathbb{C}_+)} \|G_1 - G_2\,Q\|_\infty. \tag{8}$$

Building on the result of [G1], Sefton and Ober [SO] derived a useful formula for the gap (as opposed to the directed gap) between lumped-parameter LTI systems, which is similar to (8) except that Q is restricted to being invertible in H^∞. In what follows the Sefton–Ober gap formula is generalized to the case of spatially distributed LTI systems.

THEOREM 3.1. *Let the inner functions* $\left[\begin{smallmatrix}M_1\\N_1\end{smallmatrix}\right], \left[\begin{smallmatrix}M_2\\N_2\end{smallmatrix}\right] \in H^\infty_{\mathscr{B}(\mathscr{U},\left[\begin{smallmatrix}\mathscr{Y}\\\mathscr{U}\end{smallmatrix}\right])}(\mathbb{C}_+)$ *be graph symbols of the systems* $\mathbf{P}_1, \mathbf{P}_2 \in \mathcal{S}\big(\mathscr{U}, \mathscr{Y}; [0,\infty)\big)$.

(i) *If there exists a* $\tilde{Q} \in H^\infty_{\mathscr{B}(\mathscr{U},\mathscr{U})}(\mathbb{C}_+)$ *such that* $\| \left[\begin{smallmatrix}M_1\\N_1\end{smallmatrix}\right] - \left[\begin{smallmatrix}M_2\\N_2\end{smallmatrix}\right] \tilde{Q}\|_\infty < 1$ *and* $\tilde{Q}$ *is not invertible in* H^∞, *then* $\delta_g(\mathbf{P}_1, \mathbf{P}_2) = 1$.

(ii) *If there exists a* $\tilde{Q} \in H^\infty_{\mathscr{B}(\mathscr{U},\mathscr{U})}(\mathbb{C}_+)$ *such that* $\|G_1 - G_2\,\tilde{Q}\|_\infty < 1$ *and* $\tilde{Q}^{-1} \in H^\infty_{\mathscr{B}(\mathscr{U},\mathscr{U})}(\mathbb{C}_+)$, *then* $\delta_g(\mathbf{P}_1, \mathbf{P}_2) < 1$.

Proof. (i) This part follows as shown in the proof of Proposition 4.6 in [SO], provided it can be shown that when $\tilde{Q} \in H^\infty_{\mathscr{B}(\mathscr{U},\mathscr{U})}(\mathbb{C}_+)$ satisfies

$$\left\| \begin{bmatrix} M_1 \\ N_1 \end{bmatrix} - \begin{bmatrix} M_2 \\ N_2 \end{bmatrix} \tilde{Q} \right\|_\infty < 1, \tag{9}$$

then taking an inner-outer factorization (see [FF, p. 241]), the outer part is invertible in H^∞. To see that this is the case, first note that for any $\tilde{Q} \in H^\infty_{\mathscr{B}(\mathscr{U},\mathscr{U})}(\mathbb{C}_+)$ satisfying (9), $\mathcal{M}_{\tilde{Q}} : H^2_{\mathscr{U}}(\mathbb{C}_+) \to H^2_{\mathscr{U}}(\mathbb{C}_+)$ is bounded from below. This follows by assuming the contrary and taking a sequence $\hat{v}_n \in H^2_{\mathscr{U}}(\mathbb{C}_+)$ such that $\|\hat{v}_n\|_2 = 1$ for $n \in \mathbb{Z}_+$ and $\lim_{n\to\infty} \|\tilde{Q}\hat{v}_n\|_2 = 0$. Then $\lim_{n\to\infty} \| \left[\begin{smallmatrix}M_1\\N_1\end{smallmatrix}\right] \hat{v}_n - \left[\begin{smallmatrix}M_2\\N_2\end{smallmatrix}\right] \tilde{Q}\hat{v}_n\|_2 = 1$, which contradicts (9). Now taking an inner-outer factorization $\tilde{Q} = \tilde{Q}_i\,\tilde{Q}_o$, where $\tilde{Q}_i \in H^\infty_{\mathscr{B}(\mathscr{V},\mathscr{U})}(\mathbb{C}_+)$ is inner, $\tilde{Q}_o \in H^\infty_{\mathscr{B}(\mathscr{U},\mathscr{V})}(\mathbb{C}_+)$ is outer, and $\mathscr{V}$ is a Hilbert space of suitable dimension, it follows that $\mathcal{M}_{\tilde{Q}_o} : H^2_{\mathscr{U}}(\mathbb{C}_+) \to H^2_{\mathscr{V}}(\mathbb{C}_+)$ is bounded from below, since $\mathcal{M}_{\tilde{Q}_i} : H^2_{\mathscr{V}}(\mathbb{C}_+) \to H^2_{\mathscr{U}}(\mathbb{C}_+)$ is isometric. But $\mathcal{M}_{\tilde{Q}_o}$ has dense range, since $\tilde{Q}_o$ is outer, which by Theorem 1.1 implies that $\mathcal{M}_{\tilde{Q}_o}$ is boundedly invertible. Hence, $\tilde{Q}_o$ is invertible in H^∞ by Theorem 1.7, as claimed.

(ii) This part of the result follows by the same arguments used to prove Theorem 4.7 in [SO]. ∎

The Sefton–Ober gap formula is a direct consequence of Theorem 3.1 as stated below.

COROLLARY 3.2. *Let the inner functions* $G_1, G_2 \in H^\infty_{\mathscr{B}(\mathscr{U},\left[\begin{smallmatrix}\mathscr{Y}\\\mathscr{U}\end{smallmatrix}\right])}(\mathbb{C}_+)$ *be graph symbols of the systems* $\mathbf{P}_1, \mathbf{P}_2 \in \mathcal{S}\big(\mathscr{U}, \mathscr{Y}; [0,\infty)\big)$. *Then* $\delta_g(\mathbf{P}_1, \mathbf{P}_2) = \inf_{Q,\, Q^{-1} \in H^\infty_{\mathscr{B}(\mathscr{U},\mathscr{U})}(\mathbb{C}_+)} \|G_1 - G_2\,Q\|_\infty$.

4. Robust feedback stability. In this section we establish a quantitative robust stability result for feedback loops comprised of spatially distributed LTI systems subject to gap-metric perturbations. First, we present a qualitative result which demonstrates that the gap-metric is a measure of the difference between open-loop systems with respect to variation in closed-loop performance.

PROPOSITION 4.1. *With* $\mathbf{P}, \mathbf{P}_i \in \mathcal{SS}\big(\mathscr{U}, \mathscr{Y}; [0,\infty)\big)$ *for* $i \in \mathbb{Z}_+$, *the following statements are equivalent:*

(a) $\delta_g(\mathbf{P}_i, \mathbf{P}) \to 0$ *as* $i \to \infty$;

(b) $\|\mathbf{H}(\mathbf{P}_i,\mathbf{C}) - \mathbf{H}(\mathbf{P},\mathbf{C})\|_{\text{ind}} \to 0$ *as* $i \to \infty$ *for any* $\mathbf{C}$ *stabilizing* $\mathbf{P}$;

(c) *there exist right coprime representations* $\left[\begin{smallmatrix}M_i\\N_i\end{smallmatrix}\right], \left[\begin{smallmatrix}M\\N\end{smallmatrix}\right]$ *of* $\mathbf{P}_i, \mathbf{P}$ *such that* $\left\| \left[\begin{smallmatrix}M_i\\N_i\end{smallmatrix}\right] - \left[\begin{smallmatrix}M\\N\end{smallmatrix}\right] \right\|_\infty \to 0$ *as* $i \to \infty$.

Proof. (a) ⇔ (b) is a direct consequence of Theorem 4.1 in [C1] and sufficiency of Theorem 3 in [FGS]. The equivalence (c) ⇔ (a) follows directly from Corollary 3.2. ∎

Suppose that $[\mathbf{P}, \mathbf{C}]$ is stable and that $\mathbf{P}$ has a right coprime representation $\left[\begin{smallmatrix}M\\N\end{smallmatrix}\right]$. By Proposition 4.1, every plant $\mathbf{P}'$, with a (perturbed) right coprime representation

$\left[\begin{smallmatrix} M' \\ N' \end{smallmatrix}\right] = \left[\begin{smallmatrix} M+\Delta_M \\ N+\Delta_N \end{smallmatrix}\right]$, will be stabilized by $\mathbf{C}$ provided that the perturbation $\left[\begin{smallmatrix} \Delta_M \\ \Delta_N \end{smallmatrix}\right]$, commonly referred to as the *(right) coprime factor uncertainty,* has a sufficiently small ∞-norm. The following result shows that a *normalized* coprime factor ball of systems is equivalent to a gap-metric ball of systems.

PROPOSITION 4.2. *Given* $\mathbf{P} \in \mathcal{SS}\big(\mathscr{U}, \mathscr{Y}; [0,\infty)\big)$, *let* $\left[\begin{smallmatrix} M \\ N \end{smallmatrix}\right]$ *be a normalized right coprime representation of* $\mathbf{P}$. *For all* $b:\ 0 < b \le 1$ *we have*

$$\begin{aligned} &\big\{\mathbf{P}' \in \mathcal{SS}\big(\mathscr{U}, \mathscr{Y}; [0,\infty)\big) \,\big|\, \delta_g(\mathbf{P}, \mathbf{P}') < b\big\} \\ &\quad = \big\{\mathbf{P}' \in \mathcal{SS}\big(\mathscr{U}, \mathscr{Y}; [0,\infty)\big) \,\big|\, \left[\begin{smallmatrix} M+\Delta_M \\ N+\Delta_N \end{smallmatrix}\right] \\ &\qquad \text{is a right coprime representation of } \mathbf{P}' \text{ with } \left\| \begin{smallmatrix} \Delta_M \\ \Delta_N \end{smallmatrix} \right\|_\infty < b\big\}. \end{aligned}$$

Proof. The proof is the same as that of Theorem 5.2 in [SO] for the lumped-parameter LTI case. □

Given $\mathbf{P} \in \mathcal{SS}\big(\mathscr{U}, \mathscr{Y}; [0,\infty)\big)$ and $\mathbf{C} \in \mathcal{SS}\big(\mathscr{Y}, \mathscr{U}; [0,\infty)\big)$ such that the standard feedback configuration $[\mathbf{P}, \mathbf{C}]$ in Figure 1 is stable, let

$$b_{\mathbf{P},\mathbf{C}} := \left\| \begin{bmatrix} \mathbf{I}_\mathscr{U} \\ \mathbf{P} \end{bmatrix} \begin{bmatrix} \big(\mathbf{I}_\mathscr{U} - \mathbf{C}\,\mathbf{P}\big)^{-1} & -\mathbf{C}\big(\mathbf{I}_\mathscr{Y} - \mathbf{P}\,\mathbf{C}\big)^{-1} \end{bmatrix} \right\|_{\mathrm{ind}}^{-1},$$

and define

$$b_{\mathrm{opt}}(\mathbf{P}) := \sup_{\mathbf{C} \in \mathcal{SS}(\mathscr{U}, \mathscr{Y}, [0,\infty))} b_{\mathbf{P},\mathbf{C}}. \tag{10}$$

With $G = \left[\begin{smallmatrix} M \\ N \end{smallmatrix}\right]$ as a normalized right coprime representation of $\mathbf{P}$ and $\begin{bmatrix} -\tilde{U} & \tilde{V} \end{bmatrix}$ as a left coprime representation of $\mathbf{C}$, setting $\tilde{K} := \begin{bmatrix} \tilde{V} & -\tilde{U} \end{bmatrix}$ it follows that $(\tilde{K}G)^{-1} \in H^\infty_{\mathscr{B}(\mathscr{U},\mathscr{U})}(\mathbb{C}_+) \Leftrightarrow [\mathbf{P}, \mathbf{C}]$ is stable, and $b_{\mathbf{P},\mathbf{C}} = \big\|\big(\tilde{K}G\big)^{-1}\tilde{K}\big\|_\infty^{-1}$. Furthermore, $b_{\mathbf{P},\mathbf{C}}$ satisfies (see, e.g., [FGS]) $0 \le b_{\mathbf{P},\mathbf{C}} \le 1$ and $b_{\mathbf{P},\mathbf{C}} = b_{\mathbf{C},\mathbf{P}}$. The number $b_{\mathbf{P},\mathbf{C}}$ is often called the *stability margin.* The reason for this terminology is evident from the following result.

THEOREM 4.3 (robustness under plant gap uncertainty). *Assume that* $\mathbf{P} \in \mathcal{SS}\big(\mathscr{U}, \mathscr{Y}; [0,\infty)\big)$ *and* $\mathbf{C} \in \mathcal{SS}\big(\mathscr{Y}, \mathscr{U}; [0,\infty)\big)$ *are such that* $[\mathbf{P}, \mathbf{C}]$ *is stable and* $0 < b_{\mathbf{P},\mathbf{C}} < b_{\mathrm{opt}}(\mathbf{P})$. *Then* $[\mathbf{P}', \mathbf{C}]$ *is stable for all* $\mathbf{P}' \in \mathcal{SS}\big(\mathscr{U}, \mathscr{Y}; [0,\infty)\big)$ *such that* $\delta_g(\mathbf{P}, \mathbf{P}') < b$ *iff* $b \le b_{\mathbf{P},\mathbf{C}}$.

Proof. (i) "if": Using Proposition 4.2, this can be proved as for lumped-parameter LTI systems (see Theorem 9.6 in [ZDG], for example). Alternatively, it follows from [FGS, Theorem 3].

(ii) "only if": Let $G := \left[\begin{smallmatrix} M \\ N \end{smallmatrix}\right]$, where $M \in H^\infty_{\mathscr{B}(\mathscr{U},\mathscr{U})}(\mathbb{C}_+)$ and $N \in H^\infty_{\mathscr{B}(\mathscr{U},\mathscr{Y})}(\mathbb{C}_+)$, be a normalized right coprime representation of $\mathbf{P}$. Also let $\begin{bmatrix} -\tilde{U} & \tilde{V} \end{bmatrix}$ be a left coprime representation of $\mathbf{C}$, and set $\tilde{K} := \begin{bmatrix} \tilde{V} & -\tilde{U} \end{bmatrix}$. Assuming that the claim does not hold, we now show that it is then possible to construct a right coprime representation of a system $\mathbf{P}' \in \mathcal{SS}\big(\mathscr{U}, \mathscr{Y}; [0,\infty)\big)$ such that $\delta_g(\mathbf{P}, \mathbf{P}') < b$ with $b_{\mathbf{P},\mathbf{C}} < b \le b_{\mathrm{opt}}(\mathbf{P})$ and $[\mathbf{P}', \mathbf{C}]$ unstable. The right coprime representation of the required $\mathbf{P}'$ takes the form $(G + \Delta) \in H^\infty_{\mathscr{B}(\mathscr{U},\left[\begin{smallmatrix} \mathscr{U} \\ \mathscr{Y} \end{smallmatrix}\right])}(\mathbb{C}_+)$, where $\|\Delta\|_\infty < b$ (cf. Proposition 4.2.)

Before going on to construct an appropriate Δ, we make the following observations. First, note that provided $\|\Delta\|_\infty < b_{\mathrm{opt}}(\mathbf{P})$, then $(G+\Delta) \in H^\infty_{\mathscr{B}(\mathscr{U},\left[\begin{smallmatrix} \mathscr{U} \\ \mathscr{Y} \end{smallmatrix}\right])}(\mathbb{C}_+)$ is left invertible in H^∞, which can be shown as follows. By the definition of $b_{\mathrm{opt}}(\mathbf{P})$, there exists a $\mathbf{C}_0$ with left coprime representation $\begin{bmatrix} -\tilde{U}_0 & \tilde{V}_0 \end{bmatrix}$ such that $\tilde{K}_0 := \begin{bmatrix} \tilde{V}_0 & -\tilde{U}_0 \end{bmatrix}$

satisfies $b_{\mathrm{opt}}^{-1}(\mathbf{P}) \le b_{\mathbf{P},\mathbf{C}_0}^{-1} = \left\|\left(\tilde{K}_0 G\right)^{-1}\tilde{K}_0\right\|_\infty < \|\Delta\|_\infty^{-1}$. Setting $X := \left(\tilde{K}_0 G\right)^{-1}\tilde{K}_0$, and noting that $X(G+\Delta) = \mathbf{I}_{\mathscr{U}} + X\Delta$, where $\|X\Delta\|_\infty \le \|X\|_\infty \|\Delta\|_\infty < 1$, it follows that $X(G+\Delta)$ is invertible in H^∞. Then $X_0 := \big(X(G+\Delta)\big)^{-1}X \in H^\infty_{\mathscr{B}(\left[\begin{smallmatrix}\mathscr{U}\\ \mathscr{Y}\end{smallmatrix}\right],\,\mathscr{U})}(\mathbb{C}_+)$ is a left inverse of $(G+\Delta)$. Second, note that if $(G+\Delta) \in H^\infty_{\mathscr{B}(\mathscr{U},\,\left[\begin{smallmatrix}\mathscr{U}\\ \mathscr{Y}\end{smallmatrix}\right])}(\mathbb{C}_+)$ is a right coprime representation of a system $\mathbf{P}' \in \mathcal{SS}\big(\mathscr{U}, \mathscr{Y}; [0,\infty)\big)$, then $[\mathbf{P}', \mathbf{C}]$ is stable iff $\big(\mathbf{I}_{\mathscr{U}} + (\tilde{K}G)^{-1}\tilde{K}\Delta\big)^{-1} \in H^\infty_{\mathscr{B}(\mathscr{U},\,\mathscr{U})}(\mathbb{C}_+)$. This follows from the fact that $\left(\tilde{K}\,G\right)^{-1}\tilde{K}$ is a left coprime representation of $\mathbf{C}$.

Now, since $\left\|\left(\tilde{K}G\right)^{-1}\tilde{K}\right\|_\infty = b_{\mathbf{P},\mathbf{C}}^{-1} > b^{-1}$, it follows that for arbitrary small $\sigma > 0$, there exists a frequency $\omega_0 \in (0,\infty)$ and a unit vector $\hat{v} \in \left[\begin{smallmatrix}\mathscr{U}\\ \mathscr{Y}\end{smallmatrix}\right]$ such that $\hat{u} := \big(\tilde{K}(\sigma+\jmath\omega_0)\,G(\sigma+\jmath\omega_0)\big)^{-1}\tilde{K}(\sigma+\jmath\omega_0)\,\hat{v}$ satisfies $b_{\mathbf{P},\mathbf{C}}^{-1} \ge \|\hat{u}\|_{\mathscr{U}} > b^{-1}$. Define $p(s) := \frac{s}{s^2+2\delta s+\omega_0^2}$ and $\Delta(s) := \frac{-p(s)}{p(\sigma+\jmath\omega_0)}\,\frac{\mathrm{e}^{-\alpha s}}{\mathrm{e}^{-\alpha(\sigma+\jmath\omega_0)}}\,\frac{\hat{v}}{\|\hat{u}\|_{\mathscr{U}}^2}\,\langle\hat{u},\,.\rangle_{\mathscr{U}}$, where $\delta > 0$ and $\alpha > 0$. It follows that $\|\Delta\|_\infty = \frac{|p(\jmath\omega_0)|}{|p(\sigma+\jmath\omega_0)|}\,\mathrm{e}^{\alpha\sigma}\,\|\hat{u}\|_{\mathscr{U}}^{-1}$. Since $\|\hat{u}\|_{\mathscr{U}}^{-1} < b$ and $\frac{|p(\jmath\omega_0)|}{|p(\sigma+\jmath\omega_0)|}\,\mathrm{e}^{\alpha\sigma} = \frac{\sqrt{(\sigma^2+2\delta\sigma)^2+4\omega_0^2(\sigma+\delta)^2}}{2\delta\sqrt{\sigma^2+\omega_0^2}}\,\mathrm{e}^{\alpha\sigma} \to 1$ as $\delta \to \infty$ and $\alpha \to 0$, we can choose $\delta > 0$ sufficiently large and $\alpha > 0$ sufficiently small so that $\|\Delta\|_\infty < b$. Furthermore, by construction

$$\Big(\mathbf{I}_{\mathscr{U}} + \big(\tilde{K}(\sigma+\jmath\omega_0)\,G(\sigma+\jmath\omega_0)\big)^{-1}\tilde{K}(\sigma+\jmath\omega_0)\,\Delta(\sigma+\jmath\omega_0)\Big)\,\hat{u} = 0,$$

and hence $(\mathbf{I}_{\mathscr{U}} + \left(\tilde{K}\,G\right)^{-1}\tilde{K}\,\Delta)$ cannot be invertible in H^∞. Therefore, if $\big(G+\Delta\big)$ corresponds to a right coprime representation of a system $\mathbf{P}' \in \mathcal{SS}\big(\mathscr{U}, \mathscr{Y}; [0,\infty)\big)$, then the feedback loop $[\mathbf{P}', \mathbf{C}]$ is unstable as claimed. The remainder of the proof is devoted to showing that indeed $\mathbf{P}' \in \mathcal{SS}\big(\mathscr{U}, \mathscr{Y}; [0,\infty)\big)$.

Since the perturbation constructed satisfies $\|\Delta\|_\infty < b_{\mathrm{opt}}(\mathbf{P}) \le 1$, it follows that $(G+\Delta)$ is a right coprime representation of a closed, linear, shift-invariant system $\mathbf{P}'$. Furthermore, using the result of part (i) and the fact that $\delta_g(\mathbf{P}, \mathbf{P}') < b_{\mathrm{opt}}(\mathbf{P})$ (cf. Proposition 4.2), we see that $\mathbf{P}'$ is also stabilizable. For $\mathbf{P}'$ to be in $\mathcal{SS}\big(\mathscr{U}, \mathscr{Y}; [0,\infty)\big)$ it remains to show that $\mathbf{P}'$ is causally extendible. The following proof that $\mathbf{P}'$ is causally extendible uses arguments similar to those in [CG2]. Partition $(G+\Delta) =: \left[\begin{smallmatrix}M'\\ N'\end{smallmatrix}\right]$ such that $M' \in H^\infty_{\mathscr{B}(\mathscr{U},\,\mathscr{U})}(\mathbb{C}_+)$ and $N' \in H^\infty_{\mathscr{B}(\mathscr{U},\,\mathscr{Y})}(\mathbb{C}_+)$. Define $\mathbf{M} := \mathcal{L}^{-1}\,\mathcal{M}_M\,\mathcal{L}$, $\mathbf{N} := \mathcal{L}^{-1}\,\mathcal{M}_N\,\mathcal{L}$, $\mathbf{M}' := \mathcal{L}^{-1}\,\mathcal{M}_{M'}\,\mathcal{L}$, and $\mathbf{N}' := \mathcal{L}^{-1}\,\mathcal{M}_{N'}\,\mathcal{L}$, and recall that for $\mathbf{P}'$ to be causally extendible, we must show that $\mathbf{P}'$ is causal and that $\mathbf{T}^\tau \mathrm{dom}(\mathbf{P}') = L^2_{\mathscr{U}}[0,\tau)$ for all $\tau > 0$. We will first show that $\mathbf{P}'$ is causal. Pick a $\tau > 0$ and a $v \in L^2_{\mathscr{U}}[0,\infty)$ such that $\mathbf{T}^\tau\,\mathbf{M}'\,v = 0$. Setting $\widetilde{\mathscr{U}} := L^2_{\mathscr{U}}[0,\alpha)$, define the time-lifting isomorphism $\mathcal{W}\colon L^2_{\mathscr{U}}[0,\infty) \to \ell^2_{\widetilde{\mathscr{U}}}[0,\infty)$ via

$$\widetilde{f}_k(\theta) := \big(\mathcal{W}f\big)_k(\theta) := f(k\,\alpha+\theta), \qquad f \in L^2_{\mathscr{U}}[0,\infty), \quad \theta \in [0,\alpha), \quad k = 0,1,2,\ldots\,.$$

Representing signals in $\ell^2_{\widetilde{\mathscr{U}}}[0,\infty)$ by (infinite-dimensional) column vectors with the kth entry corresponding to the value of the signal at the kth time instant, which

corresponds to the continuous-time interval $\big[k\,\alpha, (k+1)\,\alpha\big)$, we obtain

(11)

$$0 = \mathbf{T}^{\tau}\,\mathbf{M}'\,v = \mathbf{T}^{\tau}\,\mathcal{W}^{-1}\,[\mathcal{W}\,\mathbf{M}'\,\mathcal{W}^{-1}]\,[\mathcal{W}\,v] = \mathbf{T}^{\tau}\,\mathcal{W}^{-1}\begin{bmatrix} \overbrace{\begin{bmatrix} \widetilde{\mathbf{M}}'_0 & 0 & \cdots & 0 \\ \widetilde{\mathbf{M}}'_1 & \widetilde{\mathbf{M}}'_0 & \ddots & \vdots \\ \vdots & \ddots & \ddots & 0 \\ \widetilde{\mathbf{M}}'_N & \cdots & \widetilde{\mathbf{M}}'_1 & \widetilde{\mathbf{M}}'_0 \end{bmatrix}}^{=:\,\left[\widetilde{\mathbf{M}}'\right]_N} \begin{bmatrix} \widetilde{v}_0 \\ \widetilde{v}_1 \\ \vdots \\ \widetilde{v}_N \end{bmatrix} \\ \begin{matrix} 0 \\ \vdots \end{matrix} \end{bmatrix},$$

where $N :=$ the integer part of τ/α, $\widetilde{v}_k := (\mathcal{W}\,v)_k$, and $\widetilde{\mathbf{M}}'_k \colon \widetilde{\mathscr{U}} \to \widetilde{\mathscr{U}}$ is the kth entry of the sequence uniquely identifiable with the block-Toeplitz representation of the causal, discrete-time operator $\mathcal{W}\,\mathbf{M}'\,\mathcal{W}^{-1} \colon \ell^2_{\widetilde{\mathscr{U}}}[0,\infty) \to \ell^2_{\widetilde{\mathscr{U}}}[0,\infty)$. Now, noting that $\mathbf{M}' = \mathbf{M} + \mathbf{S}^{\alpha}\boldsymbol{\Delta}'$, where $\boldsymbol{\Delta}'$ is a causal system, it follows that $\widetilde{\mathbf{M}}'_0 = \widetilde{\mathbf{M}}_0$, where $\widetilde{\mathbf{M}}_0$ is the 0th entry of the block-Toeplitz representation of $\mathcal{W}\,\mathbf{M}\,\mathcal{W}^{-1}$. As such, $[\widetilde{\mathbf{M}}']_N$ defined in (11) is boundedly invertible because of its block lower triangular structure and since $\widetilde{\mathbf{M}}_0$ is boundedly invertible as shown next. First note that since $\mathbf{P}$ is causal, $\mathbf{T}^{\alpha}\,\mathbf{M}\,u = 0$ implies $\mathbf{T}^{\alpha}\,\mathbf{N}\,u = 0$ for all $u \in L^2_{\mathscr{U}}[0,\infty)$. Next, since $\left[\begin{smallmatrix} M \\ N \end{smallmatrix}\right]$ is a right *coprime* representation of $\mathbf{P}$, $\left[\begin{smallmatrix} \mathbf{M} \\ \mathbf{N} \end{smallmatrix}\right]$ has a bounded, shift-invariant (and hence causal) left inverse, $\mathbf{K}$. Therefore, $\mathbf{T}^{\alpha}\,u = \mathbf{T}^{\alpha}\,\mathbf{K}\left[\begin{smallmatrix} \mathbf{M} \\ \mathbf{N} \end{smallmatrix}\right] u = \mathbf{T}^{\alpha}\,\mathbf{K}\,\mathbf{T}^{\alpha}\left[\begin{smallmatrix} \mathbf{M} \\ \mathbf{N} \end{smallmatrix}\right] u = 0$ if $\mathbf{T}^{\alpha}\,\mathbf{M}\,u = \mathbf{T}^{\alpha}\,\mathbf{M}\,\mathbf{T}^{\alpha}\,u = 0$, which implies that $\widetilde{\mathbf{M}}_0 \colon \widetilde{\mathscr{U}} \to \widetilde{\mathscr{U}}$ is injective. Moreover, since $\mathbf{P}$ is causally extendible, we have that $\mathbf{T}^{\alpha}\,\mathbf{M}\,L^2_{\mathscr{U}}[0,\infty) = \mathbf{T}^{\alpha}\,\mathrm{dom}(\mathbf{P}) = \mathbf{T}^{\alpha}L^2_{\mathscr{U}}[0,\infty) = \widetilde{\mathscr{U}}$, implying that $\widetilde{\mathbf{M}}_0 \colon \widetilde{\mathscr{U}} \to \widetilde{\mathscr{U}}$ is surjective. Consequently, $\widetilde{\mathbf{M}}_0$, and hence $[\widetilde{\mathbf{M}}']_N$, are boundedly invertible. In view of this, (11) implies that $\mathbf{T}^{\tau}\,v = 0$, by which it follows that $\mathbf{T}^{\tau}\,\mathbf{N}'\,v = \mathbf{T}^{\tau}\,\mathbf{N}'\,\mathbf{T}^{\tau}\,v = 0$, where the first equality is a consequence of the fact that $\mathbf{N}'$ is a causal operator, since it is bounded and shift-invariant. Correspondingly, we have shown that, for all $\tau > 0$ and $v \in L^2_{\mathscr{U}}[0,\infty)$, $\mathbf{T}^{\tau}\left[\begin{smallmatrix} \mathbf{M}' \\ \mathbf{N}' \end{smallmatrix}\right] v = \left[\begin{smallmatrix} 0 \\ y \end{smallmatrix}\right]$ implies $y = 0$. That is, $\mathbf{P}'$ is causal. Causal extendibility of $\mathbf{P}'$ now follows by noting that, since $\left[\widetilde{\mathbf{M}}'\right]_N$ has full range for all $N = 0, 1, 2, \ldots$, for every $\tau > 0$ (taking $N > \tau/\alpha$)

$$\mathbf{T}^{\tau}\,\mathrm{dom}(\mathbf{P}') = \mathbf{T}^{\tau}\,\mathbf{M}'\,L^2_{\mathscr{U}}[0,\infty) = \mathbf{T}^{\tau}\,\mathcal{W}^{-1}\begin{bmatrix} \left[\widetilde{\mathbf{M}}'\right]_N \overbrace{\left(\widetilde{\mathscr{U}} \times \cdots \times \widetilde{\mathscr{U}}\right)}^{N \text{ times}} \\ 0 \\ \vdots \end{bmatrix} = \mathbf{T}^{\tau}\,L^2_{\mathscr{U}}[0, N\alpha)$$

$$= L^2_{\mathscr{U}}[0,\tau).$$

This completes the proof. □

COROLLARY 4.4 (robustness under controller gap uncertainty). *Let* $\mathbf{P} \in \mathcal{SS}\big(\mathscr{U}, \mathscr{Y}; [0,\infty)\big)$ *and* $\mathbf{C} \in \mathcal{SS}\big(\mathscr{Y}, \mathscr{U}; [0,\infty)\big)$ *be such that* $[\mathbf{P}, \mathbf{C}]$ *is stable and* $0 < b_{\mathbf{P},\mathbf{C}} < b_{\mathrm{opt}}(\mathbf{P})$. *Then* $b \le b_{\mathbf{P},\mathbf{C}}$ *iff* $[\mathbf{P}, \mathbf{C}']$ *is stable for all* $\mathbf{C}' \in \mathcal{SS}\big(\mathscr{U}, \mathscr{Y}; [0,\infty)\big)$ *with* $\delta_g(\mathbf{C}, \mathbf{C}') < b$.

Proof. Thinking of the plant and the controller interchanged and recalling that $b_{\mathbf{P},\mathbf{C}} = b_{\mathbf{C},\mathbf{P}}$, the result follows immediately by Theorem 4.3. □

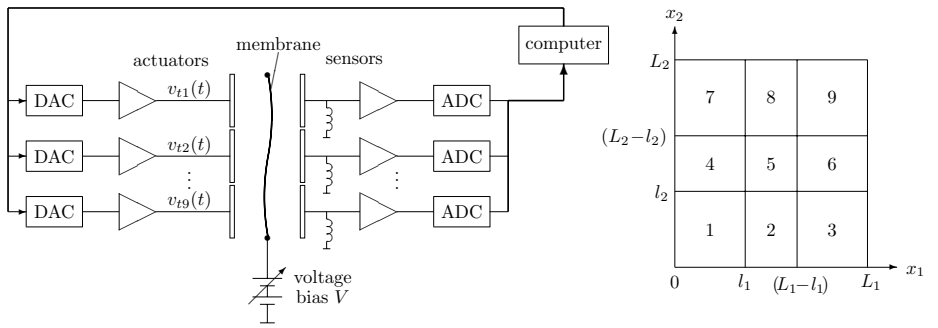

FIG. 2. *Left: Functional diagram of the electrostatically destabilized membrane with feedback arrangement for stabilization. Right: Geometry of actuator and sensor plates (assumed equal).*

For completeness, we quote a result on the stability of feedback loops with *simultaneous* plant and controller uncertainty, which was originally formulated for finite-dimensional, lumped-parameter, LTI systems in [QD], and which was later generalized to infinite-dimensional, time-varying systems in [FGS].

THEOREM 4.5 (robustness to plant and controller gap uncertainty [FGS]). *Given a plant* $\mathbf{P} \in \mathcal{SS}\big(\mathscr{U}, \mathscr{Y}; [0,\infty)\big)$ *and controller a* $\mathbf{C} \in \mathcal{SS}\big(\mathscr{Y}, \mathscr{U}; [0,\infty)\big)$*, fix nonnegative numbers* b_1 *and* b_2 *such that* $b_1^2 + b_2^2 < 1$*. Suppose that* $[\mathbf{P}, \mathbf{C}]$ *is stable and that* $b_1\sqrt{1-b_2^2} + b_2\sqrt{1-b_1^2} < b_{\mathbf{P},\mathbf{C}}$*. Then* $[\mathbf{P}', \mathbf{C}']$ *is stable for all* $\mathbf{P}' \in \mathcal{S}\big(\mathscr{U}, \mathscr{Y}; [0,\infty)\big)$ *and all* $\mathbf{C}' \in \mathcal{S}\big(\mathscr{Y}, \mathscr{U}; [0,\infty)\big)$ *which satisfy* $\delta_g(\mathbf{P}, \mathbf{P}') \le b_1$ *and* $\delta_g(\mathbf{C}, \mathbf{C}') \le b_2$*.*

5. Controller design example. Based on the control-theoretic framework described above, a controller design method was proposed in [R]. The design method, termed *coprime factor synthesis*, can be regarded as an extension or adaptation of "normalized coprime factor robust stabilization" [GM] and "H^∞ loop-shaping" [MG1, MG2] to the case of spatially distributed LTI systems. In the following we will briefly outline the method by means of a numerical example treating the feedback stabilization of an electrostatically destabilized, electrically conducting membrane. For details see [R].

The experimental setup is schematically depicted in Figure 2 and can be described as follows. A rectangular, flexible, electrically conducting membrane is suspended vertically, clamped at its boundaries, and biased by a high-voltage source V. The two spatial coordinates within the membrane plane shall be denoted by x_1 and x_2. Assuming the membrane deflection $\hat{y}(x_1, x_2; s)$ from the level-flat equilibrium position to be small, this (Laplace-transformed) quantity is governed by the PDE

$$\left(s^2\,\mu + s\,\delta - \frac{2\epsilon_0 V^2}{H^3}\right)\hat{y}(x_1,x_2;s) - \tau_1\,\frac{\partial^2\hat{y}(x_1,x_2;s)}{\partial x_1^2} - \tau_2\,\frac{\partial^2\hat{y}(x_1,x_2;s)}{\partial x_2^2} = -\frac{\epsilon_0\,V}{H^2}\,\hat{u}(x_1,x_2;s), \tag{12}$$

$\{x_1, x_2\} \in [0, L_1] \times [0, L_2]$, together with the boundary conditions $\hat{y}(x_1, x_2; s) = 0$ if $x_1 = 0$, or $x_1 = L_1$, or $x_2 = 0$, or $x_2 = L_1$. The distributed variable $\hat{u}(x_1, x_2; s)$ on the right-hand side of (12) stands for a distributed control voltage to be realized by the actuators. (The fact that the form of $\hat{u}(x_1, x_2; s)$ is restricted due to the discreteness of the actuators shall be disregarded for the moment.)

The parameters appearing in (12) have the following meaning and numerical values: membrane mass density $\mu = 0.033\,\mathrm{kg\,m^{-2}}$, viscous damping coefficient $\delta =$

$0.48\,\mathrm{kg\,m^{-2}\,s^{-1}}$, membrane tension in x_1-direction $\tau_1 = 8.4\,\mathrm{N/m}$, membrane tension in x_2-direction $\tau_2 = 7.8\,\mathrm{N/m}$, distance between membrane and actuator plates $H = 9.2\cdot 10^{-3}\,\mathrm{m}$, free space permittivity $\epsilon_0 = 8.85\cdot 10^{-12}\,\mathrm{As/V/m}$. The size of the actuator and sensor surfaces is assumed to be $L_1 \times L_2 = 1.04\,\mathrm{m} \times 1.12\,\mathrm{m}$.

The explicit input-output relationship of the system described by (12) is given by $\hat{y}(x_1, x_2; s) = \int_0^{L_1} \mathrm{d}\xi_1 \int_0^{L_2} \mathrm{d}\xi_2\, \kappa_{\hat{\mathbf{P}}^\infty}(x_1, x_2, \xi_1, \xi_2; s)\, \hat{u}(\xi_1, \xi_2; s)$, where

(13)
$$\kappa_{\hat{\mathbf{P}}^\infty}(x_1, x_2, \xi_1, \xi_2; s) = \sum_{j=1}^{\infty} \alpha_j(x_1, x_2) \left(-\frac{\epsilon_0 V}{H^2}\right) \left(s^2\,\mu + s\,\delta + \omega_j^2 - \Omega\right)^{-1} \beta_j(\xi_1, \xi_2)$$

with $\alpha_j(x_1, x_2) = \beta_j(x_1, x_2) := \frac{2}{\sqrt{L_1 L_2}} \sin(\frac{i\pi x_1}{L_1}) \sin(\frac{l\pi x_2}{L_2})$, $\omega_j := \sqrt{\tau_1 \left(\frac{i\pi}{L_1}\right)^2 + \tau_2 \left(\frac{l\pi}{L_2}\right)^2}$, and $\Omega := \frac{2\epsilon_0 V^2}{H^3}$. The mapping $(i, l) \mapsto j$ is defined such that $\{\omega_j\}_{j\in\mathbb{Z}_+}$ is an increasing sequence. From (13) it is clear that the first mode becomes unstable if V exceeds $\pi\sqrt{\frac{H^3}{2\epsilon_0}\left(\frac{\tau_1}{L_1^2} + \frac{\tau_2}{L_2^2}\right)} = 2460\,\mathrm{V}$; the second mode goes unstable at $V = 3760\,\mathrm{V}$, etc. We take $V = 2500\,\mathrm{V}$, whence precisely the first mode of the open-loop plant is unstable.

Let $\hat{\mathbf{P}}^\infty$ denote the integral operator whose kernel is given by (13); its finite-dimensional approximation, $\hat{\mathbf{P}}^{(10)}$, is obtained by truncating the infinite sum in (13) after the first $m = 10$ terms. We select the scalar, stable, stably invertible, weighting function $\hat{W}(s) = \frac{s+w_1}{s+w_2}$ with $w_1 = 3.1158 \cdot 10^6$ and $w_2 = 70$, and we define $\hat{\mathbf{P}}_W^\infty := \hat{\mathbf{P}}^\infty \cdot \hat{W}$ as well as $\hat{\mathbf{P}}_W^{(10)} := \hat{\mathbf{P}}^{(10)} \cdot \hat{W}$. Using the generalized Sefton–Ober gap formula (Corollary 3.2), the gap distance between the weighted infinite-dimensional plant model and the weighted finite-dimensional plant model can be evaluated as $\delta_g(\hat{\mathbf{P}}_W^\infty, \hat{\mathbf{P}}_W^{(10)}) = 0.0458$. By means of (10) and standard H^∞-techniques for finite-dimensional, lumped-parameter systems, the optimal stability margin of $\hat{\mathbf{P}}_W^{(10)}$ can be computed to be $b_{\mathrm{opt}}(\hat{\mathbf{P}}_W^{(10)}) = 0.3732$, where the optimally stabilizing controller, $\hat{\mathbf{C}}^{\mathrm{opt}}$, achieving this stability margin has a kernel of the form

$$\kappa_{\hat{\mathbf{C}}^{\mathrm{opt}}}(\xi_1, \xi_2, x_1, x_2; s) = E^\beta(\xi_1, \xi_2)\, \hat{C}^{\mathrm{opt}}(s) \left(E^\alpha(x_1, x_2)\right)^T$$

with $E^\alpha(x_1, x_2) := \big(\alpha_1(x_1, x_2), \ldots, \alpha_{10}(x_1, x_2)\big)$, $E^\beta(\xi_1, \xi_2) := \big(\beta_1(\xi_1, \xi_2), \ldots, \beta_{10}(\xi_1, \xi_2)\big)$, and $\hat{C}^{\mathrm{opt}}$ being a 10×10, finite-dimensional, lumped-parameter, transfer matrix.

The controller $\hat{\mathbf{C}}^{\mathrm{opt}}$ cannot be realized by the discrete sensors and actuators, as depicted in Figure 2. Therefore, we wish to find an implementable controller, $\hat{\mathbf{C}}^{\mathrm{imp}}$, whose kernel is of the form

$$\kappa_{\hat{\mathbf{C}}^{\mathrm{imp}}}(x_1, x_2, \xi_1, \xi_2, s) = E^{\alpha^c}(x_1, x_2)\, \hat{C}^{\mathrm{imp}}(s) \left(E^{\beta^c}(\xi_1, \xi_2)\right)^T,$$

where $E^{\alpha^c}(x_1, x_2) = E^{\beta^c}(x_1, x_2) = \big(\alpha_1^c(x_1, x_2), \ldots, \alpha_9^c(x_1, x_2)\big)$ with

$$\alpha_1^c(x_1, x_2) := \begin{cases} (l_1 \cdot l_2)^{-1/2} & \text{if } 0 < x_1 < l_1 \text{ and } 0 < x_2 < l_2, \\ 0 & \text{otherwise,} \end{cases}$$

etc. The parameters l_1 and l_2 as well as the 9×9, lumped-parameter, transfer matrix $\hat{C}^{\mathrm{imp}}(s)$ are to be determined such that the gap distance $\delta_g\big(\hat{\mathbf{C}}^{\mathrm{opt}}, \hat{\mathbf{C}}^{\mathrm{imp}}\big)$ is sufficiently small for the implementable controller to stabilize the weighted, infinite-dimensional, plant model $\hat{\mathbf{P}}_W^\infty$ according to Theorem 4.5. By means of a direct, global search in l_1

and l_2, in conjunction with standard H^∞-techniques for computing $\hat{C}^{\mathrm{imp}}(s)$, we found $l_1 = 0.20$, $l_2 = 0.22$, and $C^{\mathrm{imp}}(s)$ with (minimal) state-space realization $[A, B, C, D]$, where

$$A = \begin{pmatrix} -905.0798 & -193.9911 & -109.3168 \\ 193.9911 & -1.2967 & -5.4102 \\ -109.3168 & 5.4102 & -93.9223 \end{pmatrix},$$

$$B = \begin{pmatrix} -1.667 & -8.664 & -1.667 & -8.385 & -43.583 & -8.385 & -1.667 & -8.664 & -1.667 \\ 0.053 & 0.275 & 0.053 & 0.266 & 1.384 & 0.266 & 0.053 & 0.275 & 0.053 \\ -0.104 & -0.543 & -0.104 & -0.526 & -2.732 & -0.526 & -0.104 & -0.543 & -0.104 \end{pmatrix},$$

$$C = \begin{pmatrix} -1.6668 & -0.0530 & -0.1045 \\ -8.6642 & -0.2752 & -0.5432 \\ -1.6668 & -0.0530 & -0.1045 \\ -8.3847 & -0.2663 & -0.5256 \\ -43.5833 & -1.3838 & -2.7316 \\ -8.3847 & -0.2663 & -0.5256 \\ -1.6668 & -0.0530 & -0.1045 \\ -8.6642 & -0.2752 & -0.5432 \\ -1.6668 & -0.0530 & -0.1045 \end{pmatrix}, \qquad D = 0_{9\times 9},$$

to be nearly optimal. For the gap distance between optimal and implementable controllers we obtained $\delta_g(\hat{\mathbf{C}}^{\mathrm{opt}}, \hat{\mathbf{C}}^{\mathrm{imp}}) = 0.3195$, thus satisfying the inequality in Theorem 4.5. Since the weight $\hat{W}(s)$ is scalar, stable, and stably invertible, $\hat{\mathbf{C}}^{\mathrm{imp}}$ stabilizing $\hat{\mathbf{P}}_W^\infty$ implies that the implementable controller $\hat{\mathbf{C}}^{\mathrm{imp}} \cdot \hat{W}$ stabilizes the infinite-dimensional, open-loop unstable, spatially distributed plant $\hat{\mathbf{P}}^\infty$.

MULTIOBJECTIVE $\mathcal{H}_2/\mathcal{H}_\infty$ CONTROL DESIGN*

XIANG CHEN† AND KEMIN ZHOU‡

Abstract. An important question in feedback control design is how to achieve desired performance for dynamical systems subject to both model uncertainties and white noise. For this purpose, it is desirable to develop a systematic design technique that combines the good aspects of both $\mathcal{H}_2(LQG)$ and $\mathcal{H}_\infty$ methods, which provides the motivation for the development of multiobjective design framework in this paper. Encouraged by a time domain game approach for $\mathcal{H}_2/\mathcal{H}_\infty$ control design, two multiobjective control design problems are formulated and solved in the time domain. Results for both the finite time horizon and the infinite time horizon are presented. It is shown that all the results can be obtained by solving the corresponding set of coupled Riccati equations.

Key words. multiobjective control, $\mathcal{H}_2/\mathcal{H}_\infty$ control, $\mathcal{H}_\infty$ Gaussian control

1. Introduction.

It is probably fair to say that the most important objective of any control design is to achieve certain desired performance specifications in spite of external disturbances and noises, system parameter variations, and variations of system operating conditions. What a judicially designed feedback can usually achieve is to improve the system performance in one aspect by sacrificing the system performance in another aspect. Thus a feedback control design is a process of making trade-offs between conflicting objectives. Two prominent conflicting objectives in most feedback control designs are good transient response and robustness with respect to disturbances and system uncertainties. Usually a very robust control law tends to make the system's transient response poor [35, 36]. On the other hand, a system with an extremely good transient response for a nominal operation condition (or model) could be very sensitive to external disturbances and parameter variations [9]. In this case a good control design should be a compromise between good transient performance and robustness. It is generally agreed that a suitable linear quadratic Gaussian (LQG) or $\mathcal{H}_2$ criterion can be a good measure for transient performance, while the $\mathcal{H}_\infty$ optimal control design framework is developed primarily because of the robustness consideration. Thus it is natural to consider a design framework that can systematically make the design tradeoffs between these two design objectives. The development of such a multiobjective design framework is the main topic of this paper.

The multiobjective control problem has received much attention from the control research community in the past decade [3, 4, 6, 7, 8, 11, 12, 14, 17, 20, 22, 25, 26, 28, 27, 29, 30, 31, 34, 36]. Though there are many multiobjective approaches [32], the $\mathcal{H}_2/\mathcal{H}_\infty$ approach has a better physical interpretation and clearer motivation, as discussed above, and attracts a great number of researchers. It should be pointed out that the term $\mathcal{H}_2/\mathcal{H}_\infty$ usually refers to any multiobjective optimal design of which the

performance measures have both $\mathcal{H}_2(LQG)$ and $\mathcal{H}_\infty$ interpretations. Thus, under the big framework of $\mathcal{H}_2/\mathcal{H}_\infty$, there are many different ways to formulate the problem. It is more appropriate to call them multiobjective $\mathcal{H}_2/\mathcal{H}_\infty$ designs as is done in this paper.

Some major results about multiobjective control with an $\mathcal{H}_2/\mathcal{H}_\infty$ interpretation are summarized as follows (see also [32]):

1. Fixed-order controller design by minimizing an auxiliary cost functional [3, 17, 18]: This formulation minimizes an upper bound on the $\mathcal{H}_2$ norm of the closed-loop transfer function as the index functional which is subject to an $\mathcal{H}_\infty$ norm constraint and designs a fixed order controller for the formulated problem.

2. Convex optimization [20, 14, 19, 12, 8, 4]: There are several approaches in this category. In general, each approach uses (different) matrix inequalities as performance measures to characterize a convex optimization problem. The advantage of the convex optimization approach is that there exist effective and powerful algorithms for the solutions of these problems. However, it is difficult to generalize this approach to a nonlinear system or to apply this approach to systems with stochastic disturbances.

3. Optimizing an entropy cost functional [24, 25, 15]: This approach designs a controller to minimize the so-called closed-loop entropy which provides an upper bound of $\mathcal{H}_2$ cost, while guaranteeing the $\mathcal{H}_\infty$ performance. It turns out that this approach is equivalent to the approach of minimizing an auxiliary cost functional in [3] for the single external input case [24].

4. Bounded power characterization [11, 36]: This approach can treat systems with both white noise and bounded power disturbances. The design objective is to minimize the power of the output error signal. The problem solved by this approach is a dual to that solved in [3] in some sense [34]. This approach is interesting because it uses norms of power signals instead of norms of transfer functions to characterize the problem, which positions it as a time domain approach.

5. Nash game approach [21, 22, 28]: This approach uses the Nash equilibrium strategy [2] as a performance measure to characterize the problem with a very clear $\mathcal{H}_2/\mathcal{H}_\infty$ interpretation. It is also possible to generalize this approach to a nonlinear system [23]. However, only a state feedback problem was solved in [22], and the output feedback problem turns out to be very difficult [28].

As pointed out before, the clear $\mathcal{H}_2/\mathcal{H}_\infty$ interpretation plus the solvability through some standard algorithm makes the Nash game approach very attractive. Hence how to generalize this approach to the output feedback case is very interesting and important, considering that, in general, information of system state variables may not be available. The desire of developing output feedback mixed $\mathcal{H}_2/\mathcal{H}_\infty$ control using the game approach triggered our development of multiobjective control design in this paper. We shall adopt the observer-based controller structure for the proposed multiobjective control problems. As a result of this, we have to take the estimation of system states into account in the output feedback framework; hence the inclusion of the noise (usually Gaussian white noise) effect becomes necessary for the purpose of optimization as it does in classical LQG control. Because of this similarity, we call the second multiobjective control problem formulated in this paper "$\mathcal{H}_\infty$ Gaussian Control."

The paper is organized as follows: in section 2 the formulation of our problems is given; section 3 provides definitions and preliminary results about signals, systems, and constrained optimization required for sections 4 and 5, which are devoted to solving the main problems in both finite and infinite time horizons; some comments

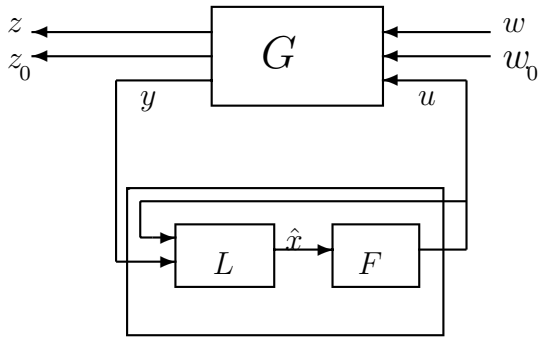

FIG. 1. *Multiobjective control design.*

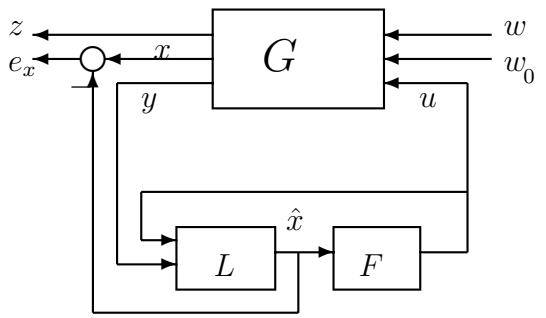

FIG. 2. H_∞ *Gaussian control design.*

and the conclusion can be found in sections 6 and 7.

The notations used in this paper are standard: I always denotes the identity matrix with dimensions determined in context; $E\{\cdot\}$ is the expectation operator; if A is a matrix or a vector, then A^T is its transpose and A^* is its conjugate transpose; if x is a complex number, then $Re(x)$ and $Im(x)$ are, respectively, its real and imaginary parts; $\mathbf{R}$ is the set of real numbers; $\mathcal{RH}_\infty$ is the space of all proper and real rational stable matrix transfer functions; if A is a square matrix, then trace (A) is the trace of A; $\|\cdot\|$ represents the Euclidean norm of a vector.

2. Formulation of main problems. As stated in the introduction, in this paper, we are interested in control design problems as shown in Figures 1 and 2.

From now on, we call the problem in Figure 1 *multiobjective control design* and the problem in Figure 2 $\mathcal{H}_\infty$ *Gaussian control design.* We shall first provide the definition of signal and system norms. Then we present the formulation of our problems.

2.1. Norms of signals and systems. There are two classes of stochastic signals which are used in this paper for the development of multiobjective control design: bounded power signals and white noise signals. It should be pointed out that a deterministic version of bounded power signals can also be defined (see [36, 13]), and the results obtained in this paper can be derived correspondingly.

Given a real vector stochastic signal $u(t)$,

$$u(t) = \left[\begin{array}{cccc} u_1(t) & u_2(t) & \cdots & u_m(t) \end{array}\right]^T \in \mathbf{R}^m \quad \forall t \in R,$$

where $u_i(t)$, $i = 1, \ldots, m$ are real stationary random processes, define the *mean* and

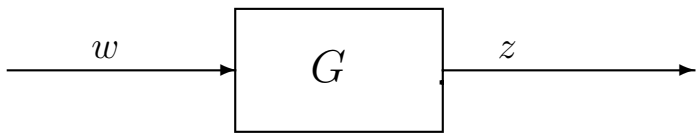

FIG. 3. *A stable system.*

autocorrelation matrices of $u(t)$, respectively, as follows:

$$E\{u\} := \left[\begin{array}{cccc} E\{u_1(t)\} & E\{u_2(t)\} & \cdots & E\{u_m(t)\} \end{array}\right]^T,$$

$$R_{uu}(\tau) := \lim_{T\to\infty} \frac{1}{T} \int_0^T E\{u(t+\tau)u^T(t)\}dt.$$

The Fourier transform of $R_{uu}(\tau)$, if exists, is $S_{uu} := \frac{1}{2\pi}\int_{-\infty}^{\infty} R_{uu}(\tau)e^{-j\omega\tau}d\tau$. The so-called bounded power signal is defined as follows.

DEFINITION 1. *A vector stationary stochastic signal u is said to have bounded power if*

1. *both R_{uu} and S_{uu} exist;*
2. $\lim_{T\to\infty} \frac{1}{T}\int_0^T E\|u(t)\|^2 dt < \infty$.

Let $\mathcal{P}$ be the space of all signals with bounded power. A seminorm can be defined on $\mathcal{P}$:

$$\|u\|_{\mathcal{P}} := \sqrt{\lim_{T\to\infty} \frac{1}{T} \int_0^T E\{\|u(t)\|^2\}dt} = \sqrt{\text{trace}[R_{uu}(0)]} \quad \forall u \in \mathcal{P}.$$

The well-known Gaussian white noise $w_0(t)$ is a stationary random process that satisfies $E\{w_0(t)\} \equiv 0$ and $E\{w_0(t)w_0^T(\tau)\} = Q(t)\delta(t-\tau)$, where $\delta(t)$ is Dirac δ function and $Q(t)$ is a positive definite matrix. In this paper, we shall assume, without loss of generality, that $Q(t) = I$, where I is an identity matrix, i.e., $w_0(t)$ is a zero mean stationary process with an identity power spectrum. A more rigorous description of the white noise process can be found in standard textbooks for stochastic processes (see, e.g., [33]). Independence between stochastic signals is defined as follows.

DEFINITION 2. *Two vector stationary stochastic signals $w_1(t)$ and $w_2(t)$ are said to be independent if, for any $t_1 \geq 0$ and $t_2 \geq 0$, we have*

$$E\{w_1(t_1)w_2^T(t_2)\} = E\{w_1(t_1)\}E\{w_2^T(t_2)\}.$$

A close relation exists between these two types of signals and the $\mathcal{H}_\infty$ and $\mathcal{H}_2$ norms of systems. Recall that, given a system $G(s) \in \mathcal{RH}_\infty$ in Figure 3 with a state space realization (A, B, C, D) and denoted by $G(s) = D + C(sI - A)^{-1}B := \left[\begin{array}{c|c} A & B \\ \hline C & D \end{array}\right]$, the $\mathcal{H}_\infty$ and $\mathcal{H}_2$ norms of this system are defined as

$$\|G(s)\|_\infty := \sup_\omega \bar{\sigma}\{G(j\omega)\}, \quad \|G(s)\|_2 := \sqrt{\frac{1}{2\pi}\int_{-\infty}^{\infty} \text{trace}[G^*(j\omega)G(j\omega)]d\omega},$$

where $\bar{\sigma}$ is the largest singular value of $G(s)$.

Let w be a bounded power signal. It can be proved that $\|G(s)\|_\infty = \sup_w \frac{\|z\|_{\mathcal{P}}}{\|w\|_{\mathcal{P}}}$ (see [36]). On the other hand, if $w = w_0(t)$ is a white noise signal, then it can be

proved that $\|G(s)\|_2 = \|z\|_{\mathcal{P}}$ (see [36]). On finite time horizon $[0,T]$, we define the 2-norm of a signal u as $\|u\|_{[0,T]} := \sqrt{\int_0^T E\|u\|^2 dt}$. Accordingly, we define the system norms

$$\|G(s)\|_{\infty,[0,T]} := \sup_w \frac{\|z\|_{[0,T]}}{\|w\|_{[0,T]}}, \quad \text{where } w \text{ is any bounded power signal,}$$

and

$$\|G(s)\|_{2,[0,T]} := \|z\|_{[0,T]}, \quad \text{where } w \text{ is a white noise signal.}$$

These definitions will be helpful for formulating our problems on the finite time horizon. Finally, note that it is easy to verify the following equivalencies:

$$\|G(s)\|_\infty < \gamma \iff 0 < \gamma^2\|w\|_{\mathcal{P}}^2 - \|z\|_{\mathcal{P}}^2 \quad \forall w \neq 0,$$

$$\|G(s)\|_{\infty,[0,T]} < \gamma \iff 0 < \gamma^2\|w\|_{[0,T]}^2 - \|z\|_{[0,T]}^2 \quad \forall w \neq 0.$$

2.2. Formulation of multiobjective control design. Consider a linear control system G in Figure 1 described by

$$\dot{x} = Ax + B_0 w_0 + B_1 w + B_2 u, \quad x(0) = 0, \tag{1}$$

$$y = C_2 x + D_{20} w_0, \quad R_0 := D_{20} D_{20}^T > 0, \tag{2}$$

$$z = C_1 x + D_{12} u, \quad R_1 = D_{12}^T D_{12}, \tag{3}$$

$$z_0 = C_0 x + D_{02} u, \quad R_{02} := D_{02}^T D_{02} > 0, \tag{4}$$

where w is a bounded power signal and w_0 is a white noise signal. Define the performance index functionals

$$J_1(u,w,w_0) := \gamma^2\|w\|_{[0,T]}^2 - \|z\|_{[0,T]}^2, \quad J_2(u,w,w_0) := \|z_0\|_{[0,T]}^2,$$

and

$$J_3(u,w,w_0) := \gamma^2\|w\|_{\mathcal{P}}^2 - \|z\|_{\mathcal{P}}^2, \quad J_4(u,w,w_0) := \|z_0\|_{\mathcal{P}}^2,$$

where u is the output feedback control law to be designed.

Then the *multiobjective control design* is formulated as follows: *Find an output feedback control law u_* such that it achieves*

$$J_1(u_*,w_*,w_0) \le J_1(u_*,w,w_0) \ \forall w \neq w_*, \ \ J_2(u_*,w_*,w_0) \le J_2(u,w_*,w_0)$$

for the finite time horizon case and

$$J_3(u_*,w_*,w_0) \le J_3(u_*,w,w_0) \ \ \forall w \neq w_*, \ \ J_4(u_*,w_*,w_0) \le J_4(u,w_*,w_0)$$

for the infinite time horizon case, where w_* is the worst possible disturbance signal to be determined.

It must be pointed out that the control law u (hence the optimal control law u_*) is supposed to have the following observer form:

$$\dot{\hat{x}} = \hat{A}\hat{x} + B_2 u - Ly, \hat{x}(0) = 0,$$
$$u = F\hat{x}.$$

2.3. Formulation of $\mathcal{H}_\infty$ Gaussian control. Consider a linear system in Figure 2 described by

$$\dot{x} = Ax + B_0 w_0 + B_1 w + B_2 u, \quad x(0) = 0, \tag{5}$$

$$z = C_1 x + D_{12} u, \quad R_1 := D_{12}^T D_{12} > 0, \tag{6}$$

$$y = C_2 x + D_{20} w_0, \quad R_0 := D_{20} D_{20}^T > 0, \tag{7}$$

where w is a bounded power signal and w_0 is a white noise signal. w and w_0 are independent. Let $\mathcal{P}_s$ be the subset of $\mathcal{P}$ consisting of all bounded power signals independent from w_0; hence $w \in \mathcal{P}_s$. The control law is supposed to take the observer form

$$\dot{\hat{x}} = \hat{A}\hat{x} + B_2 u - Ly, \hat{x}(0) = 0,$$
$$u = F\hat{x}.$$

Let $e_x := x - \hat{x}$, and define the following performance index functionals:

$$J_1(u, w, w_0) := \gamma^2 \|w\|_{[0,T]}^2 - \|z\|_{[0,T]}^2, \quad J_2(u, w, w_0) := \|e_x\|_{[0,T]}^2,$$

and

$$J_3(u, w, w_0) := \gamma^2 \|w\|_{\mathcal{P}}^2 - \|z\|_{\mathcal{P}}^2, \quad J_4(u, w, w_0) := \|e_x\|_{\mathcal{P}}^2.$$

Then the $\mathcal{H}_\infty$ *Gaussian control design* is formulated as follows: *Find a feedback control law u_* in the given form such that it achieves*

$$J_1(u_*, w_*, w_0) \le J_1(u_*, w, w_0) \quad \forall w \in \mathcal{P}_s, \quad J_2(u_*, w_*, w_0) \le J_2(u, w_*, w_0)$$

for the finite time horizon case and

$$J_3(u_*, w_*, w_0) \le J_3(u_*, w, w_0) \quad \forall w \in \mathcal{P}_s, \quad J_4(u_*, w_*, w_0) \le J_4(u, w_*, w_0)$$

for the infinite time horizon case, where w_* is called the worst disturbance signal.

Note that w_* may not be necessarily in $\mathcal{P}_s$, but it does guarantee that the performance index J_1 or J_3 has a lower bound.

3. Preliminaries. In this section, we present some preliminary results which will be applied to proving the main results in the subsequent sections.

LEMMA 3. *Let $R_{zw}(s)$ be the stable matrix transfer function from w (a bounded power signal) to z defined by*

$$\dot{x} = Ax + Bw, \quad x(0) = 0,$$
$$z = Cx.$$

Then the following two statements are equivalent:

1. $\|R_{zw}(s)\|_{\infty,[0,T]} < \gamma$, *i.e.*, $0 < \gamma^2 \|w\|_{[0,T]}^2 - \|z\|_{[0,T]}^2 \ \ \forall w \neq 0$;
2. *the solution of the Riccati equation*

$$-\dot{P}(t) = A^T P(t) + P(t)A - \gamma^{-2} P(t) B B^T P(t) - C^T C, \quad P(T) = 0,$$

has no finite escape time on $[0, T]$.

A proof of this lemma can be found in [22, Lemma 2].

LEMMA 4. *Consider the system*

$$\dot{x} = Ax + B_0 w_0 + B_1 w + B_2 u, \quad x(0) = 0,$$
$$y = C_2 x + D_{20} w_0,$$

where w_0 is a white noise and w is a stationary signal. Suppose w_0 and w are independent. Let the controller $K(s) = \bar{C}(sI - \bar{A})^{-1}\bar{B}$. Then we have

$$E\{x(t)w_0^T(t_1)\} = (e_{11}B_0 + e_{12}\bar{B}D_{20})/2, \ \ t_1 \le t, \quad or \quad E\{x(t)w_0^T(t_1)\} = 0, \quad t_1 > t,$$

where $\hat{A} = \begin{bmatrix} A & B_2\bar{C} \\ \bar{B}C_2 & \bar{A} \end{bmatrix}$ *and* $e^{\hat{A}(t-t_1)} = \begin{bmatrix} e_{11} & e_{12} \\ e_{21} & e_{22} \end{bmatrix}$.

Proof. Since $K(s) = \bar{C}(sI - \bar{A})^{-1}\bar{B}$, the closed-loop system becomes

$$\dot{\hat{x}} = \hat{A}\hat{x} + \hat{B}_0 w_0 + \hat{B}_1 w,$$

where $\hat{x} = [\ x^T \quad \bar{x}^T\ ]^T$, $\hat{B}_0 = [\ B_0^T \quad (\bar{B}D_{20})^T\ ]^T$, and $\hat{B}_1 = [\ B_1^T \quad 0\ ]^T$. Hence

$$\hat{x} = \int_0^t e^{\hat{A}(t-\tau)}[\hat{B}_0 w_0(\tau) + \hat{B}_1 w(\tau)]d\tau,$$

and

$$E[\ w_0(t_1)x^T(t) \quad w_0(t_1)\bar{x}^T(t)\ ]^T = E\left\{\int_0^t e^{\hat{A}(t-\tau)}[\hat{B}_0 w_0(\tau) + \hat{B}_1 w(\tau)]w_0^T(t_1)d\tau\right\}$$

$$= \int_0^t e^{\hat{A}(t-\tau)}\hat{B}_0 E\{w_0(\tau)w_0^T(t_1)\}d\tau = \int_0^t e^{\hat{A}(t-\tau)}\hat{B}_0\delta(\tau - t_1)d\tau,$$

which gives $E\{x(t)w_0^T(t_1)\} = (e_{11}B_0 + e_{12}\bar{B}D_{20})/2$ for $t_1 \le t$, or $E\{x(t)w_0^T(t_1)\} = 0$ for $t_1 > t$. ∎

LEMMA 5. *Consider the system*

$$\dot{x} = Ax + B_0 w_0 + B_1 w + B_2 u, \quad x(0) = 0,$$
$$y = C_2 x + D_{20} w_0,$$

where w_0 is a white noise and the controller $K(s)$ is of the form

$$\dot{\bar{x}} = \bar{A}\bar{x} + \bar{B}y, \quad \bar{x}(0) = 0,$$
$$u = \bar{C}\bar{x}.$$

Let $w = F\hat{x}$, where $\hat{x} = [\ x^T \quad \bar{x}^T\ ]^T$. Then we have

$$E\{x(t)w_0^T(t_1)\} = (e_{11}B_0 + e_{12}\bar{B}D_{20})/2, \ \ t_1 \le t, \quad or \quad E\{x(t)w_0^T(t_1)\} = 0, \quad t_1 > t,$$

where $\hat{A} = \begin{bmatrix} A & B_2\bar{C} \\ \bar{B}C_2 & \bar{A} \end{bmatrix} + B_1 F$ *and* $e^{\hat{A}(t-t_1)} = \begin{bmatrix} e_{11} & e_{12} \\ e_{21} & e_{22} \end{bmatrix}$.

Proof. The proof is similar to that of Lemma 4 and is omitted. ∎

A constrained optimization problem solved below plays the key role in the solution of our multiobjective control design. The sufficient conditions for the constrained optimization problem will be proved in this section, and the proof of necessary conditions will be given in the appendix of this paper.

Given $A \in \mathbf{R}^{n\times n}$, $B \in \mathbf{R}^{n\times r}$, $C \in \mathbf{R}^{p\times n}$, $D \in \mathbf{R}^{p\times r}$, and $R = DD^T > 0$, we define two index functionals:

1. $J_1(L(t)) = \text{trace}(\int_0^T Q(t)P(t)Q^T(t)dt)$, $T \geq 0$, where $Q(t)$ is any time-varying weighting matrix, and $P(t) = P^T(t) \geq 0$ on $[0,T]$ with $P(0) = 0$ satisfies

$$(A + L(t)C)P(t) + P(t)(A + L(t)C)^T + (B + L(t)D)(B + L(t)D)^T = \dot{P}(t). \tag{8}$$

2. $J_2(L) = \text{trace}(QPQ^T)$, where Q is any constant weighting matrix, $A + LC$ is Hurwitz, and $P = P^T \geq 0$ satisfies

$$(A + LC)P + P(A + LC)^T + (B + LD)(B + LD)^T = 0. \tag{9}$$

The constrained optimization problems on finite time and infinite time horizons can be stated as follows:

1. $\min_{L(t)} J_1(L(t)) = \min_{P(t)} \text{trace}(\int_0^T Q(t)P(t)Q^T(t)dt)$, where $L(t)$ and $P(t)$ are subject to the constraint (8).
2. $\min_L J_2(L) = \min_P \text{trace}(QPQ^T)$, where L and P are subject to the constraint (9).

The next two theorems provide solutions to these two optimization problems.

THEOREM 6. *Consider the constrained optimization problem defined on the finite time horizon; if there is a solution $P_*(t) \geq 0$ on $[0,T]$ with $P_*(0) = 0$ for*

$$(A - BD^TR^{-1}C)P_*(t) + P_*(t)(A - BD^TR^{-1}C)^T - P_*(t)C^TR^{-1}CP_*(t) + B(I - D^TR^{-1}D)B^T = \dot{P}_*(t),$$

then $J_1(L(t))$ achieves the minimum value at $L_*(t) = -(P_*(t)C^T + BD^T)R^{-1}$.

Conversely, if there are $L(t)$ and $P(t)$ such that

$$(A + L(t)C)P(t) + P(t)(A + L(t)C)^T + (B + L(t)D)(B + L(t)D)^T = \dot{P}(t)$$

and $J_1(L(t))$ is the minimum value, then there is a solution $P_*(t) \geq 0$ on $[0,T]$ with $P_*(0) = 0$ to

$$(A - BD^TR^{-1}C)P_*(t) + P_*(t)(A - BD^TR^{-1}C)^T - P_*(t)C^TR^{-1}CP_*(t) + B(I - D^TR^{-1}D)B^T = \dot{P}_*(t),$$

and the minimum value of $J(L(t))$ is also achieved at $L_*(t) = -(P_*(t)C^T + BD^T)R^{-1}$.

Proof (sufficiency). Take $\Delta P(t) = P(t) - P_*(t)$. Then

$$\Delta\dot{P}(t) = (A + L(t)C)\Delta P(t) + \Delta P(t)(A + L(t)C)^T + (L(t) - L_*(t))R(L(t) - L_*(t))^T,$$

where $L_*(t) = -(P_*(t)C^T + BD^T)R^{-1}$. Now let $\Phi(t,\tau)$ be the transition matrix of $A + L(t)C$. Then

$$\Delta P(t) = \int_0^t \Phi(t,s)(L(s) - L_*(s))R(L(s) - L_*(s))^T\Phi^T(t,s)ds \geq 0$$

for any $L(t)$ and $\Delta P(t) = 0$ if $L(t) = L_*(t)$. Therefore, $J(L(t)) - J(L_*(t)) \geq 0$ for any $L(t)$, which means that $J(L(t))$ achieves the minimum value at $L_*(t)$.

For the proof of necessity, please see the appendix. □

THEOREM 7. *Consider the constrained optimization problem, defined for infinite time horizon case; if there is a stabilizing solution $P_* \geq 0$ for*

$$(A-BD^TR^{-1}C)P_*+P_*(A-BD^TR^{-1}C)^T-P_*C^TR^{-1}CP_*+B(I-D^TR^{-1}D)B^T=0$$

i.e., $A-BD^TR^{-1}C-P_*C^TR^{-1}C$ is stable, then $J_2(L)$ achieves the minimum value at $L_*=-(P_*C^T+BD^T)R^{-1}$.

Conversely, let (C,A) be detectable. If there are L_1 and $P_1 \geq 0$, where $A+L_1C$ is stable and P_1 solves

$$(A+L_1C)P_1+P_1(A+L_1C)^T+(B+L_1D)(B+L_1D)^T=0$$

such that $J_2(L)$ is minimized, then there is a $P_* \geq 0$ solving

$$(A-BD^TR^{-1}C)P_*+P_*(A-BD^TR^{-1}C)^T-P_*C^TR^{-1}CP_*+B(I-D^TR^{-1}D)B^T=0.$$

Moreover, an optimal L_* can be obtained as $L_*=-(P_*C^T+BD^T)R^{-1}$ if $A+L_*C$ is Hurwitz.

Proof (sufficiency). Since P_* is a stabilizing solution, $A+L_*C$ is Hurwitz, where $L_*=-(P_*C^T+BD^T)R^{-1}$. For any L for which $A+LC$ is stable, we have $P \geq 0$ solving

$$(A+LC)P+P(A+LC)^T+(B+LD)(B+LD)^T=0.$$

Now take $\Delta P=P-P_*$. Then

$$(A+LC)\Delta P+\Delta P(A+LC)^T+(L-L_*)R(L-L_*)^T=0.$$

By the standard property of the Lyapunov equation, we have $\Delta P \geq 0$ and $\Delta P=0$ if and only if $L=L_*$. Hence $J(L)-J(L_*) \geq 0$ for any L, which means that $J(L)$ achieves the minimum value at L_*.

For the proof of necessity, please see the appendix. □

4. Multiobjective control design. In this section, we give the main theorems for the multiobjective control design problems formulated in section 2.2. To simplify the notations, the following abbreviations are assumed:

$$A_s=A-B_2R_{02}^{-1}D_{02}^TC_0, \quad A_f=A-B_0D_{20}^TR_0^{-1}C_2,$$

$$P:=B_0(I-D_{20}^TR_0^{-1}D_{20})B_0^T, \quad Q:=C_0^T(I-D_{02}R_{02}^{-1}D_{02}^T)C_0.$$

4.1. Multiobjective control design—finite time horizon. To motivate our output feedback design, we shall first present the state feedback design results, a simplified version of which can be found in [22].

THEOREM 8. *For the system G described by* (1)–(4) *and the associated cost functionals $J_1(u,w,w_0)$ and $J_2(u,w,w_0)$, there exist linear memoryless state feedback strategies (Nash equilibrium strategies) u_* and w_* such that*

$$0 \leq J_1(u_*,w_*,0) \leq J_1(u_*,w,0), \quad J_2(u_*,w_*,0) \leq J_2(u,w_*,0)$$

if and only if the coupled Riccati differential equations

$$-\dot{P}_1(t)=(A_s-B_2R_{02}^{-1}B_2^TP_2(t))^TP_1(t)+P_1(t)(A_s-B_2R_{02}^{-1}B_2^TP_2(t))+\gamma^{-2}P_1(t)B_1B_1^TP_1(t)$$

$$+[C_1 - D_{12}R_{02}^{-1}(D_{02}^T C_0 + B_2^T P_2(t))]^T[C_1 - D_{12}R_{02}^{-1}(D_{02}^T C_0 + B_2^T P_2(t))],$$

$$-\dot{P}_2(t) = (A_s + \gamma^{-2}B_1B_1^T P_1(t))^T P_2(t) + P_2(t)(A_s + \gamma^{-2}B_1B_1^T P_1(t))$$

$$-P_2(t)B_2R_{02}^{-1}B_2^T P_2(t) + Q$$

have solutions $P_1(t) \geq 0$ *and* $P_2(t) \geq 0$ *on* $[0,T]$ *with* $P_1(T) = 0$ *and* $P_2(T) = 0$. *Furthermore, if the solutions exist, we have* $w_* = \gamma^{-2}B_1^T P_1(t)x$ *and* $u_* = F_*(t)x$ *with* $F_* = -R_{02}^{-1}(D_{02}^T C_0 + B_2^T P_2(t))$.

The output feedback design are established in the following theorems for multiobjective control in finite time horizon.

THEOREM 9. *There exist a* w_* *and an output feedback control law* u_* *in the form of*

$$\begin{aligned}\dot{\hat{x}} &= (A + \gamma^{-2}B_1B_1^T P_1(t) + B_2F_*(t))\hat{x} + L_*(t)(C_2\hat{x} - y),\\ u_* &= F_*(t)\hat{x},\end{aligned}$$

such that $J_1(u_*, w_*, w_0) \leq J_1(u_*, w, w_0), J_2(u_*, w_*, w_0) \leq J_2(u, w_*, w_0)$ *if the coupled differential Riccati equations*

$$-\dot{P}_1(t) = (A_s - B_2R_{02}^{-1}B_2^T P_2(t))^T P_1(t) + P_1(t)(A_s - B_2R_{02}^{-1}B_2^T P_2(t)) + \gamma^{-2}P_1(t)B_1B_1^T P_1(t)$$
