According to Theorem 3.1, if the above equation admits a solution $P(\cdot)$, then there may be infinitely many optimal controls, and any optimal control has the following form:

$$u_{Y,z}(t) = [-R(t)^\dagger B(t)'P(t) + Y(t) - R(t)^\dagger R(t)Y(t)]x(t) + z(t) - R(t)^\dagger R(t)z(t), \tag{3.10}$$

where $Y(\cdot) \in L^2(s,T;\mathbf{R}^{n_u \times n})$ and $z(\cdot) \in L^2(s,T;\mathbf{R}^{n_u})$.

4. Necessity of the GRE. In the previous section, we proved that the solvability of GRE (2.5) is *sufficient* for the well-posedness of the stochastic LQ problem (2.1)–(2.3), and that optimal feedback control laws can be constructed based on the solution to the Riccati equation. In particular, if (2.5) admits a solution, then there must be an optimal *linear feedback* control, obtained by taking $Y(t) \equiv 0$ and $z(t) \equiv 0$ in (3.1). In this section we shall show that the solvability of the GRE is also *necessary* for there to exist an optimal *linear feedback* control for the LQ problem.

4.1. A linear feedback control formulation. If a linear feedback control is optimal for the LQ problem (2.1)–(2.3), then it must be optimal also in the class of linear feedback controls of the following form:

$$u(t) = K(t)x(t), \qquad K(t) \in \mathbf{R}^{n_u \times n}. \tag{4.1}$$

The corresponding closed-loop system with the initial $(s, y) = (0, x_0)$ is

$$\begin{cases} dx(t) &= [A(t) + B(t)K(t)]x(t)dt + [C(t) + D(t)K(t)]x(t)dW(t), \\ x(0) &= x_0 \in \mathbf{R}^n. \end{cases} \tag{4.2}$$

Now, if $x(\cdot)$ satisfies (4.2), then by Itô's formula the matrix $X(t) \equiv E[x(t)x(t)']$ satisfies the differential matrix equation

$$\begin{cases} \dot{X}(t) = [A(t) + B(t)K(t)]X(t) + X(t)[A(t) + B(t)K(t)]' \\ \qquad\qquad + [C(t) + D(t)K(t)]X(t)[C(t) + D(t)K(t)]', \\ X(0) = X_0 \equiv E[x_0 x_0'] \in \mathcal{S}_n^+, \end{cases} \tag{4.3}$$

with the associated cost function J expressed equivalently as

$$J(K(\cdot)) \equiv \int_0^T \mathbf{Tr}[(Q(t) + K'(t)R(t)K(t))X(t)]dt + \mathbf{Tr}(HX(T)). \tag{4.4}$$

To summarize, if we consider only the class of linear feedback controls for the original LQ problem with the initial $x(0) = x_0$, then the problem reduces to the following deterministic optimal control problem:

$$\begin{cases} \text{Minimize}_{K(\cdot)} & \displaystyle\int_0^T \mathbf{Tr}[(Q + K'RK)X]dt + \mathbf{Tr}(HX(T)), \\ \text{subject to} & (4.3). \end{cases} \tag{4.5}$$

4.2. Matrix minimum principle. For the reader's convenience, let us state the matrix minimum principle (see [5]) here. We start by defining the gradient matrix. Let $f(\cdot)$ be a function from $\mathbf{R}^{p \times q}$ to $\mathbf{R}$. Then the gradient matrix of f is a $p \times q$ matrix, denoted by $\frac{\partial f(X)}{\partial X}$, with the ijth component $(\frac{\partial f(X)}{\partial X})_{ij} = \frac{\partial f(X)}{\partial x_{ij}}$.

Consider an $n \times n$ matrix differential system

$$\begin{cases} \dot{X} = F(X(t), U(t), t), \\ X(t_0) = X_0, \end{cases} \tag{4.6}$$

where the control $U(\cdot)$ is a measurable mapping from $[t_0, T]$ to a prescribed set $\Omega \subseteq \mathbf{R}^{n_u \times n}$. With T fixed, consider the cost function

$$J(X_0, U(\cdot)) = \int_{t_0}^T L(X(t), U(t), t)dt + G(X(T)), \tag{4.7}$$

where G and L are scalar-valued functions, satisfying the usual smooth conditions. Let $P(t) \in \mathbf{R}^{n \times n}$ be the costate (adjoint) matrix. Then, the Hamiltonian function is defined as

$$H(X(t), P(t), U(t), t) = L(X(t), U(t), t) + \mathbf{Tr}(F(X(t), U(t), t)P(t)'). \tag{4.8}$$

Now, we present the matrix minimum principle in the form stated in [5].

PROPOSITION 4.1. *If $(X^*(\cdot), U^*(\cdot))$ is optimal for (4.6)–(4.7), then there exists a costate matrix $P^*(t)$ satisfying the costate (adjoint) equation*

(4.9)
$$\begin{cases} \dot{P}^*(t) = -\dfrac{\partial}{\partial X^*(t)} L(X^*(t), U^*(t), t) - \dfrac{\partial}{\partial X^*(t)} \mathbf{Tr}(F(X^*(t), U^*(t), t) P^*(t)'), \\ P^*(T) = \dfrac{\partial}{\partial X^*(T)} G(X^*(T)) \end{cases}$$

such that

$$H(X^*(t), P^*(t), U^*(t), t) \le H(X^*(t), P^*(t), U, t) \ \ \forall U \in \Omega, \ \text{ a.e. } t \in [t_0, T]. \tag{4.10}$$

Note that if $U(\cdot)$ is unconstrained, then (4.10) is equivalent to $\frac{\partial H}{\partial U^*(t)} = 0$.

4.3. Necessity of the GRE. We are going to use the matrix minimum principle to show that if there exists an optimal linear feedback control for the original LQ problem (2.1)–(2.3), then GRE (2.5) must have a solution. Furthermore, we will show that any optimal linear feedback control law has the form (3.1) with $z(t) \equiv 0$.

First we give the following necessary condition.

THEOREM 4.2. *Assume that the LQ problem (2.1)–(2.3) is well-posed. For any $s \in [0, T)$, if there exists $P(\cdot)$ such that*

(4.11)
$$\begin{cases} \dot{P} + PA + A'P + C'PC - (PB + C'PD)(R + D'PD)^\dagger (B'P + D'PC) + Q = 0, \\ P(T) = H, \\ (R + D'PD)(R + D'PD)^\dagger (B'P + D'PC) - B'P - D'PC = 0, \ \text{ a.e. } t \in [s, T], \end{cases}$$

then P must satisfy

$$R + D'PD \ge 0, \ \text{ a.e. } t \in [s, T].$$

Proof. Let $\lambda(t)$ be any fixed eigenvalue of the matrix $R(t) + D(t)'P(t)D(t)$, $t \in [s, T]$. We will show that $\mathbf{mes}(\{t \in [s, T] | \lambda(t) < 0\}) = 0$, where $\mathbf{mes}$ denotes the Lebesgue measure. Let $v_\lambda(t)$ be a unit eigenvector (i.e., $v_\lambda(t)' v_\lambda(t) = 1$) associated with the eigenvalue $\lambda(t)$. Define $I_n(\cdot)$ as the indicator function of the set $\{t \in [s, T] | \lambda(t) < -\frac{1}{n}\}$, $n = 1, 2, \ldots$. Fix a scalar $\delta \in \mathbf{R}$ and consider the state trajectory $x(\cdot)$ of system (2.1) under the feedback control

(4.12)
$$u(t) = \begin{cases} 0 & \text{if } \lambda(t) = 0, \\ \dfrac{\delta I_n(t)}{|\lambda(t)|^{1/2}} v_\lambda(t) & \\ -[R(t) + D(t)'P(t)D(t)]^\dagger [B(t)'P(t) + D(t)'P(t)C(t)]x(t) & \text{if } \lambda(t) \ne 0. \end{cases}$$

Clearly, $u(\cdot) \in L^2_{\mathcal{F}}(s, T; \mathbf{R}^{n_u})$. Now,

$$\begin{aligned} J(s, y; u(\cdot)) = y'P(s)y + E\int_s^T \big[u + (R + D'PD)^\dagger (B'P + D'PC)x\big]'(R + D'PD) \\ \times \big[u + (R + D'PD)^\dagger (B'P + D'PC)x\big](t)dt. \end{aligned}$$

It follows from $\lambda(t) \neq 0$ that $|\lambda(t)|^{-1} I_n(t)(R(t) + D(t)'P(t)D(t))v_\lambda(t) = -I_n(t)v_\lambda(t)$. Hence

$$
\begin{aligned}
J(s, y; u(\cdot)) &= y'P(s)y - \delta^2 \int_s^T I_n(t)dt \\
&= y'P(s)y - \delta^2 \mathbf{mes}\left(\left\{t \in [s,T] | \lambda(t) < -\frac{1}{n}\right\}\right).
\end{aligned} \tag{4.13}
$$

If $\mathbf{mes}(\{t \in [s,T] | \lambda(t) < -\frac{1}{n}\}) > 0$, then by letting $\delta \to \infty$ in (4.13) we obtain $J(s, y; u(\cdot)) \to -\infty$, which contradicts the well-posedness of the LQ problem. Hence $\mathbf{mes}(\{t \in [s,T] | \lambda(t) < -\frac{1}{n}\}) = 0$. Since

$$
\{t \in [s,T] | \lambda(t) < 0\} = \bigcup_{n \in \mathbf{N}} \left\{t \in [s,T] | \lambda(t) < -\frac{1}{n}\right\},
$$

we conclude that $\mathbf{mes}(\{t \in [s,T] | \lambda(t) < 0\}) = 0$, completing the proof. □

THEOREM 4.3. *If a given linear feedback control $u(t) = K(t)x(t)$ is optimal for the LQ problem (2.1)–(2.3) with respect to the initial $(s, y) = (0, x_0)$, then GRE (2.5) must have a solution $P(\cdot)$. Moreover, the optimal feedback control $u(t) = K(t)x(t)$ can be represented via (3.1) with $z(t) \equiv 0$. In particular, the feedback law $u(t) = K(t)x(t)$ must be optimal with respect to any initial $(s, y) \in [0, T) \times \mathbf{R}^n$.*

Proof. Since the given feedback control $u(t) = K(t)x(t)$ is optimal over the set of all admissible controls, it must in particular be optimal over the class of all linear feedback controls. Therefore, as shown earlier, $K(\cdot)$ must solve the following deterministic optimal control problem:

$$
\begin{cases}
\min\limits_{K(\cdot)} & \displaystyle\int_0^T \mathbf{Tr}[(Q + K'RK)X](t)dt + \mathbf{Tr}(HX(T)), \\
\text{subject to} & \begin{cases} \dot{X}(t) = (A + BK)X + X(A + BK)' + (C + DK)X(C + DK)', \\ X(0) = X_0, \ \ X_0 \in \mathcal{S}_n^+. \end{cases}
\end{cases} \tag{4.14}
$$

By the minimum principle, Proposition 4.1, we conclude that the Hamiltonian

$$
\mathbf{Tr}\Big((Q + K'RK)X + [(A + BK)X + X(A + BK)' + (C + DK)X(C + DK)']P'\Big)
$$

is pointwise (in t) minimized at $K(t)$ over the space of $\mathbf{R}^{n_u \times n}$. This, together with the costate equation (4.9), leads to the following:

$$
\begin{cases}
\dot{P} = -Q - K'RK - (C + DK)'P(C + DK) - P(A + BK) - (A + BK)'P, \\
P(T) = H, \\
0 = RKX' + RKX + B'PX' + B'P'X + D'PDKX' + D'PDKX \\
\qquad + D'PCX' + D'P'CX.
\end{cases} \tag{4.15}
$$

Note that in the above calculation we have used the following formulae:

$$
\frac{\partial}{\partial X}\mathbf{Tr}(AX) = A', \ \ \frac{\partial}{\partial X}\mathbf{Tr}(AX') = A, \ \ \frac{\partial}{\partial X}\mathbf{Tr}(AXBX') = A'XB' + AXB.
$$

Since X and P are symmetric, (4.15) is reduced to

(4.16)
$$\begin{cases} \dot{P} = -Q - K'RK - (C + DK)'P(C + DK) - P(A + BK) - (A + BK)'P, \\ P(T) = H, \\ 0 = (R + D'PD)K + B'P + D'PC. \end{cases}$$

Now, we apply Lemma 2.7 to the equation $(R + D'PD)K + B'P + D'PC = 0$. First of all, we know a priori that it does have a solution K. Thus condition (2.9) must hold, which in the present case specializes to

$$(R + D'PD)(R + D'PD)^{\dagger}(B'P + D'PC) = B'P + D'PC.$$

Moreover, by (2.10), K has the following form:

$$K = -(R + D'PD)^{\dagger}(B'P + D'PC) + Y - (R + D'PD)^{\dagger}(R + D'PD)Y. \tag{4.17}$$

Substituting K into the first equation of (4.16), we can see by a simple calculation that P satisfies

$$\dot{P} + PA + A'P + C'PC - (PB + C'PD)(R + D'PD)^{\dagger}(B'P + D'PC) + Q = 0.$$

Noting that Theorem 4.2 implies that $R + D'PD \geq 0$, we conclude that $P(\cdot)$ solves (2.5). The representation of K is given by (4.17). Finally, the last assertion of the theorem follows from Theorem 3.1. □

5. Open-loop optimal controls. In the previous analysis we have shown that the solvability of the GRE is equivalent to the condition that the LQ problem is solvable by linear feedback controls. In this section we further prove that the solvability of the GRE is also equivalent to the case in which the LQ problem is solvable by continuous *open-loop* controls.

First we need the following lemma.

LEMMA 5.1. *Assume that the LQ problem* (2.1)–(2.3) *is well-posed. Then there exists a symmetric matrix function* $P(\cdot)$ *such that*

$$V(s, y) = y'P(s)y \quad \forall (s, y) \in [0, T] \times \mathbf{R}^n. \tag{5.1}$$

Moreover, assume that $Q(t)$ *and* $R(t)$ *are continuous in* t*, and for any initial* $(s, y) \in [0, T] \times \mathbf{R}^n$ *the LQ problem* (2.1)–(2.3) *has an optimal open-loop control that is continuous in* t*; then the matrix function* $P(\cdot)$ *satisfying* (5.1) *is differentiable on* $[0, T]$.

Proof. First, (5.1) can be shown by a simple adaptation of the well-known result in the deterministic case (see, e.g., [10, 4]). Moreover, since the value function $V(s, y)$ is continuous in s, so is $P(\cdot)$. Next, fix (s, y) and let $(u_*(\cdot), x_*(\cdot))$ be an optimal solution of (2.1)–(2.3) with respect to the initial condition $x(s) = y$ with $u_*(\cdot)$ continuous. Then the dynamic programming optimality principle yields

(5.2)
$$V(s, y) = E\left\{ \int_s^{s+h} [x_*(t)'Q(t)x_*(t) + u_*(t)'R(t)u_*(t)]dt + V(s + h, x_*(s + h)) \right\} \forall h \geq 0.$$

Making use of (5.1)–(5.2), we have

$$\begin{aligned}\tfrac{1}{h}[y'P(s+h)y - y'P(s)y] &= \tfrac{1}{h}E[y'P(s+h)y - x_*(s+h)'P(s+h)y]\\ &\quad + \tfrac{1}{h}E[x_*(s+h)'P(s+h)y - x_*(s+h)'P(s+h)x_*(s+h)]\\ &\quad - \tfrac{1}{h}E\textstyle\int_s^{s+h}[x_*(t)'Q(t)x_*(t) + u_*(t)'R(t)u_*(t)]dt.\end{aligned}$$

Noting that $P(\cdot)$ and $x_*(\cdot)$ are continuous and the integrand above is continuous in t by the assumptions, we can show by a standard argument that the limit of each of the three terms on the right-hand side of the above equation exists as h goes to zero. Therefore $\lim_{h\to 0}\frac{1}{h}[y'P(s+h)y - y'P(s)y]$ exists. Since y is arbitrary, $P(s)$ is differentiable at $s \in [0,T]$. □

The assumption that the optimal control is continuous in t is a rather technical one. From the above proof we can see that only the continuity of the control at the initial time s is actually needed. On the other hand, if we assume that $B(t), C(t), D(t)$, and $R(t)$ are continuous, then by (3.1) the existence of a continuous optimal open-loop control is really *necessary* for the solvability of GRE (2.5).

Consider the following convex set of differentiable symmetric matrix functions on $[0,T]$:

$$\mathcal{P} \triangleq \left\{ P(\cdot)\Big| \quad \left[\begin{array}{c|c} \dot P + A'P + PA + C'PC + Q & PB + C'PD \\ \hline B'P + D'PC & R + D'PD \end{array}\right] \geq 0, \right. \\ \left. \text{a.e. } t \in [0,T],\ P(T) \leq H \right\}. \tag{5.3}$$

The following result provides a sufficient condition for the well-posedness of the LQ problem.

THEOREM 5.2. *The LQ problem* (2.1)–(2.3) *is well-posed if the set* $\mathcal{P}$ *is nonempty.*

Proof. Let $P(\cdot) \in \mathcal{P}$. Applying Lemma 2.4, we have, for any admissible (open-loop) control $u(\cdot)$ and any initial $(s,y) \in [0,T) \times \mathbf{R}^n$,

$$\begin{aligned} J(s,y;u(\cdot)) &= y'P(s)y + E[x(T)(H - P(T))x(T)]\\ &\quad + E\int_s^T \begin{pmatrix} x \\ u \end{pmatrix}' \left[\begin{array}{c|c} \dot P + A'P + PA + C'PC + Q & PB + C'PD \\ \hline B'P + D'PC & R + D'PD \end{array}\right] \begin{pmatrix} x \\ u \end{pmatrix}(t)dt. \end{aligned} \tag{5.4}$$

Thus $J(s,y;u(\cdot)) \geq y'P(s)y$, implying $V(s,y) > -\infty\ \ \forall (s,y) \in [0,T) \times \mathbf{R}^n$. □

The following is the main result of this section.

THEOREM 5.3. *Assume that* $B(t), C(t), D(t), Q(t)$, *and* $R(t)$ *are continuous in* t. *Then the LQ problem* (2.1)–(2.3) *has an continuous optimal open-loop control for any initial* $(s,y) \in [0,T] \times \mathbf{R}^n$ *if and only if GRE* (2.5) *has a solution* $P(\cdot)$.

Proof. The "if" part follows from Theorem 3.1. Let us now show the "only if" part. First, since the LQ problem is well-posed, Lemma 5.1 yields that there exists a symmetric matrix function $P(\cdot)$ such that

$$V(s,y) = y'P(s)y\ \ \forall (s,y) \in [0,T) \times \mathbf{R}^n.$$

Moreover, by the assumption and Lemma 5.1, $P(\cdot)$ is differentiable. On the other hand, the dynamic programming principle yields

$$\begin{aligned} V(s,y) \leq\ & E\left\{ \int_s^{s+h} [x(t)'Q(t)x(t) + u(t)'R(t)u(t)]dt + V(s+h, x(s+h)) \right\} \\ & \forall h \geq 0\ \ \forall u(\cdot) \in U_{ad}. \end{aligned}$$

Applying Itô's formula to $V(t,x(t)) \equiv x(t)'P(t)x(t)$, using the above inequality, and employing Lemma 2.4, we obtain

$$E\int_s^{s+h} \begin{pmatrix} x \\ u \end{pmatrix}' \left[\begin{array}{c|c} \dot{P}+A'P+PA+C'PC+Q & PB+C'PD \\ \hline B'P+D'PC & R+D'PD \end{array}\right] \begin{pmatrix} x \\ u \end{pmatrix}(t)dt \geq 0.$$

Taking $u(t) \equiv \bar{u} \in \mathbf{R}^{n_u}$, and then dividing both sides by h and letting $h \to 0$, we obtain

$$\begin{pmatrix} y \\ \bar{u} \end{pmatrix}' \left[\begin{array}{c|c} \dot{P}+A'P+PA+C'PC+Q & PB+C'PD \\ \hline B'P+D'PC & R+D'PD \end{array}\right](s) \begin{pmatrix} y \\ \bar{u} \end{pmatrix} \geq 0, \quad \text{a.e. } s \in [0,T].$$

Since $y \in \mathbf{R}^n$ and $\bar{u} \in \mathbf{R}^{n_u}$ are arbitrary, we obtain

$$\left[\begin{array}{c|c} \dot{P}+A'P+PA+C'PC+Q & PB+C'PD \\ \hline B'P+D'PC & R+D'PD \end{array}\right] \geq 0, \quad \text{a.e. } t \in [0,T]. \tag{5.5}$$

Applying Lemma 2.6 to (5.5), we have

$$\begin{cases} \dot{P}+PA+A'P+C'PC-(PB+C'PD)(R+D'PD)^\dagger(B'P+D'PC)+Q \geq 0, \\ (R+D'PD)(R+D'PD)^\dagger(B'P+D'PC)-B'P-D'PC=0, \\ R+D'PD \geq 0, \quad \text{a.e. } t \in [0,T]. \end{cases} \tag{5.6}$$

Now, let $(x_*(\cdot),u_*(\cdot))$ be an optimal open-loop control for (2.1)–(2.3) with respect to the initial condition $x(s)=y$. Applying Lemma 2.4 to $P(\cdot)$, we have

$$\begin{aligned} V(s,y) = y'P(s)y \; &+ E\int_s^T [x_*'\big(\dot{P}+PA+A'P+C'PC+Q \\ &\qquad -(PB+C'PD)(R+D'PD)^\dagger(B'P+D'PC)\big)x_*](t)dt \\ &+ E\int_s^T [u_*+(R+D'PD)^\dagger(B'P+D'PC)x_*]' \\ &\qquad \times (R+D'PD)[u_*+(R+D'PD)^\dagger(B'P+D'PC)x_*](t)dt. \end{aligned} \tag{5.7}$$

By virtue of the relation $V(s,y)=y'P(s)y$ and (5.6)–(5.7), we obtain

$$\dot{P}+PA+A'P+C'PC-(PB+C'PD)(R+D'PD)^\dagger(B'P+D'PC)+Q=0.$$

This completes the proof. □

Theorem 5.1 says that the nonemptiness of the set $\mathcal{P}$ is sufficient for the well-posedness of the original LQ problem. The following result stipulates that the nonemptiness of the set $\mathcal{P}$ is also *necessary* for the attainability of the LQ problem.

THEOREM 5.4. *Under the same assumption of Theorem* 5.3, *the LQ problem* (2.1)–(2.3) *has a continuous optimal open-loop control for any initial* $(s,y) \in [0,T] \times \mathbf{R}^n$ *only if the set* $\mathcal{P}$ *is nonempty.*

Proof. This is seen from (5.5). □

6. An example. In this section we give an example in which the singularity of $R+D'PD$ does occur, but the LQ problem is well-posed and attainable. Moreover, the example shows that a stochastic LQ problem can be well-posed even when *both* Q and R are negative.

Consider the following one-dimensional LQ problem:

$$\begin{aligned} &\text{Minimize} \quad J = E\left\{\int_0^1 [qx(t)^2 + r(t)u(t)^2]dt + hx(1)^2\right\}, \\ &\text{subject to} \quad \begin{cases} dx(t) = [ax(t) + bu(t)]dt + [cx(t) + \delta u(t)]dW(t), \\ x(0) = x_0, \end{cases} \end{aligned} \tag{6.1}$$

where the coefficients are chosen such that $\delta \neq 0$, $b+\delta c = 0$, $q < 0$, and $2a+c^2+q > 0$. Take $r(t) = -\delta^2 p(t)$, where

$$p(t) = \frac{e^{(2a+c^2)(1-t)}(2ha + hc^2 + q) - q}{2a + c^2} \tag{6.2}$$

is the solution to the following equation:

$$\dot{p}(t) + (2a + c^2)p(t) + q = 0, \qquad p(1) = h. \tag{6.3}$$

Incidentally, Example 1.1 in section 1 is a special case of this example. It is easy to verify directly that (6.3) is exactly the GRE in the present case. (Note that the singularity arises because $r(t)+\delta^2 p(t) \equiv 0$.) Therefore, by Theorem 3.1 and Corollary 3.1(i), the LQ problem is well-posed, and any admissible control is optimal with an optimal cost $p(s)y^2$.

It is interesting to look at the sign of the solution to the Riccati equation (6.3). First assume that $h < 0$. In this case, since $2a + c^2 > 0$ and $q < 0$, we have from (6.2) that $p(t) \leq h < 0 \ \forall t \in [0, 1]$. Hence, the solution to the Riccati equation could be *negative*, which is quite contrary to the deterministic LQ case. On the other hand, if $h > 0$ is large enough so that $2ha + hc^2 + q > 0$, then $p(t) \geq h > 0$ and $r(t) = -\delta^2 p(t) < 0$. In this case, both q and $r(t)$ are *negative* but the LQ problem is well-posed. Again, this is different from the deterministic situation. The essential reason behind this phenomenon is that the positive terminal cost $hx(1)^2$ *outweighs* the negative running cost.

7. Conclusion. Standard LQ theory, which has proved so useful for control applications in the last decades, has been extended here to signal models with multiplicative noises in both state and control and with quadratic weights that are fundamentally different from those in the literature. Such models better approximate nonlinear stochastic systems and arise naturally in areas of current interest such as in finance. A new Riccati equation is introduced in this paper as an appropriate vehicle for identifying optimal controls and calculating the optimal cost value.

Other properties concerning the existence, uniqueness, and asymptotic behavior of solutions to the GRE associated with an indefinite LQ problem are studied in a companion paper [1], which complements results derived in this paper.

ROBUST CONTROLLER SYNTHESIS FOR UNCERTAIN TIME-VARYING SYSTEMS*

CAROL PIRIE† AND GEIR E. DULLERUD†

Abstract. In this paper we develop and present new convex synthesis conditions for robust performance in linear time-varying systems, subject to time-varying perturbations. In particular, these results are *exact* for sensitivity minimization in the presence of multiplicative perturbations. The methods apply to a number of additional robust performance problems and are always both necessary and sufficient when the system plant is periodic. Otherwise, the conditions provided are *always* sufficient, and a controller can be directly constructed when this condition holds.

Key words. uncertain system, time-varying system, discrete-time system, controller synthesis, convex methods, linear matrix inequality

1. Introduction.

The focus of this paper is the development of synthesis tools for robust performance of linear time-varying (LTV) systems. The primary engineering motivation for this work is its application to nonlinear trajectory tracking, where the LTV model arises from linearization of the nonlinear model around a nominal trajectory. This is the generalization of linearizing a nonlinear model around an equilibrium point to obtain a linear time-invariant (LTI) model. The work is also applicable to systems which naturally have time-varying dynamics, such as periodic multirate or sampled-data systems [2, 4].

The main result of the paper is a convex synthesis condition for the existence of a controller, which provides robust *performance* to either additive or multiplicative LTV perturbations; this condition is both necessary and sufficient. When the above existence condition is satisfied we indicate how an explicit controller can be computed for implementation via a convex program. As far as we are aware, these are the first synthesis results for *exact* robust performance of LTV systems; namely, the condition obtained is both necessary and sufficient and convex. The methods developed apply to a more general class of robust synthesis problems and are always both necessary and sufficient when the nominal LTV system is either periodic or satisfies a partitioning condition.

The approach used in the paper combines the LTI results reported in [7, 8] with the LTV framework developed in [9]; for independent, closely related LTV tools see [1, 12, 13]. This work builds on work which considered synthesis of LTI discrete-time systems subject to spatial constraints on the inputs and outputs. As shown in [7], some robust control problems, such as sensitivity minimization with multiplicative uncertainty, may be cast in terms of analysis of systems with spatial constraints. We show that a similar theory holds for LTV systems. We remark that a related robustness problem is solved in [22] for LTI systems, with LTI perturbations, and the obtained results were convex but infinite dimensional in general. The general

machinery used here has its roots in the related papers [11, 15]. The work presented here is based on [18].

The results are given in terms of linear operator inequalities, which always have a convex solution space, but in general are infinite dimensional. When the initial LTV plant is periodic, or the synthesis problem is only considered over a finite horizon, these conditions reduce to linear matrix inequalities (LMIs). Namely, in these two important cases the results become finite dimensional and convex and thus readily computable.

The paper is organized as follows: section 2 introduces the notation used and the basic LTV machinery; in section 3 we provide a solution to the square ℓ_2 optimization problem, which is a generalization of the H_∞ control problem; in section 4 we show how this synthesis result can be used for robust synthesis.

2. Background.

2.1. Notation and definitions. Given a normed linear space $\mathcal{X}$, we denote the closed unit ball by $\mathcal{B}\mathcal{X}$. If $\mathcal{W}$ is also a normed linear space, the space of bounded linear operators mapping $\mathcal{X}$ to $\mathcal{W}$ will be denoted by $\mathcal{L}(\mathcal{X}, \mathcal{W})$. The induced norm of an operator A in this space will be denoted $\|A\|_{\mathcal{X}\to\mathcal{W}}$; we suppress the subscripts when the spaces are clear. We use A^* to denote the adjoint operator.

We will use the abbreviation $\mathcal{L}(\mathcal{X})$ for $\mathcal{L}(\mathcal{X}, \mathcal{X})$, and we say that an operator in this set is invertible if the algebraic inverse exists and is a bounded operator on $\mathcal{X}$. We state the following standard small-gain result for later reference.

PROPOSITION 2.1. *Suppose $\mathcal{X}$ is a Banach space and $A \in \mathcal{L}(\mathcal{X})$. If $\|A\|_{\mathcal{X}\to\mathcal{X}} < 1$, then $I - A$ is invertible, and further $\|(I-A)^{-1}\|_{\mathcal{X}\to\mathcal{X}} \le \frac{1}{1-\|A\|_{\mathcal{X}\to\mathcal{X}}}$.*

If $\mathcal{X}$ is a Hilbert space and an operator A is self-adjoint, we use $A > 0$ to mean that there exists an $\epsilon > 0$ such that

$$\langle x, Ax\rangle_{\mathcal{X}} \ge \epsilon \|x\|_{\mathcal{X}}^2 \qquad \text{for every } x \in \mathcal{X}.$$

A useful result is the following.

PROPOSITION 2.2 (Schur complement formula). *Suppose $X \in \mathcal{L}(\mathcal{X})$, $Y \in \mathcal{L}(\mathcal{Y})$, $W \in \mathcal{L}(\mathcal{Y}, \mathcal{X})$, and X and Y are self-adjoint. Then*

$$\begin{bmatrix} X & W \\ W^* & Y \end{bmatrix} < 0$$

if and only if $Y < 0$ and $X - WY^{-1}W^* < 0$.

Given a Hilbert space $\mathcal{X}$, we will denote by $\ell_2(\mathcal{X})$ the Hilbert space of square summable sequences of elements of $\mathcal{X}$ with the usual inner product; that is, $x, y \in \ell_2(\mathcal{X})$; then

$$\langle x, y\rangle = \sum_{k=1}^{\infty} \langle x_k, y_k\rangle_{\mathcal{X}},$$

where $x_k, y_k \in \mathcal{X}$. For simplicity we will denote $\ell_2(\mathbb{C}^n)$ by ℓ_2 regardless of the spatial dimension n. Additionally, we will use $\|x\|$ to denote $\sqrt{\langle x, x\rangle}$, the standard norm on this space.

The upper and lower linear fractional transformations of operators in $\mathcal{L}(\ell_2)$ are $\mathcal{F}_u(M, N) = M_{22} + M_{21}N(I - M_{11}N)^{-1}M_{12}$ and $\mathcal{F}_\ell(M, N) = M_{11} + M_{12}N(I - M_{22}N)^{-1}M_{21}$, respectively, where M is partitioned compatibly with N.

2.2. Memoryless operators. Our goal in this section is to define a particular type of operator and an important associated operation which makes working with LTV state space systems nearly identical to operations on LTI state space systems. See [9] for a complete treatment of memoryless operators and their use in LTV systems.

We make the following definition.

DEFINITION 2.3. *A bounded operator Q on $\ell_2(\mathcal{X})$ is* memoryless *if there exists a sequence of operators Q_k in $\mathcal{L}(\mathcal{X})$ such that, for all w, z, if $z = Qw$, then $z_k = Q_k w_k$. Then Q has the representation*

$$\begin{bmatrix} Q_0 & & & 0 \\ & Q_1 & & \\ & & Q_2 & \\ 0 & & & \ddots \end{bmatrix}.$$

Further, if $P_k \in \mathcal{L}(\mathcal{X})$ is a uniformly bounded sequence of operators, we say $P = \operatorname{diag}(P_0, P_1, \dots)$ is the memoryless operator for P_k, and conversely, given that P is a memoryless operator, the blocks are denoted by P_k for $k \in \mathbb{N}_0$.

Suppose F, G, R, and S are memoryless operators, and let A be a *partitioned operator*, each of whose elements is a memoryless operator such as

$$A = \begin{bmatrix} F & G \\ R & S \end{bmatrix}.$$

We now define the following notation:

$$\left[\!\!\left[\begin{array}{cc} F & G \\ R & S \end{array} \right]\!\!\right] = \operatorname{diag}\left(\begin{bmatrix} F_0 & G_0 \\ R_0 & S_0 \end{bmatrix}, \begin{bmatrix} F_1 & G_1 \\ R_1 & S_1 \end{bmatrix}, \dots, \right),$$

which we call the *memoryless realization* of A. Clearly, for any given operator A of this particular structure, $[\![A]\!]$ is simply A with the rows and columns permuted appropriately so that

$$\left[\!\!\left[\begin{array}{cc} F & G \\ R & S \end{array} \right]\!\!\right]_k = \begin{bmatrix} F_k & G_k \\ R_k & S_k \end{bmatrix}.$$

The following is immediate.

PROPOSITION 2.4. *For any real number β and any partitioned operator A consisting of elements which are memoryless, $A < \beta I$ holds if and only if $[\![A]\!] < \beta I$. That is, positivity is preserved under permutation.*

Two further useful facts for the above permutations are the following.

PROPOSITION 2.5.

(i) *Suppose that A and B are partitioned operators consisting of memoryless elements and that their structures are the same. Then*

$$[\![A + B]\!] = [\![A]\!] + [\![B]\!].$$

(ii) *Suppose that A and C are partitioned operators, each of which consists of elements which are memoryless. Further suppose that the block structures are compatible so that the product $\hat{A}\hat{C}$ is memoryless for any operators $\hat{A}$ and $\hat{C}$ with the same block structures as A and C. Then*

$$[\![AC]\!] = [\![A]\!]\,[\![C]\!].$$

2.3. LTV systems. Although the analysis results presented in this paper will apply to any LTV system, the synthesis result (Theorem 3.10) applies only to state space systems. For this reason we briefly review LTV state space systems; see [9] for an in-depth treatment of the theory. Suppose we are considering the time-varying difference equation

$$\begin{aligned} x_{k+1} &= A_k x_k + B_k u_k, \qquad x_0 = 0, \\ y_k &= C_k x_k + D_k u_k, \end{aligned}$$

where A_k, B_k, C_k, and D_k are bounded *real* matrix sequences. Then clearly these sequences define memoryless operators A, B, C, and D, and therefore the above system may be written more compactly in operator form as

$$\begin{aligned} x &= ZAx + ZBu, \\ y &= Cx + Du, \end{aligned}$$

where Z is the shift, or delay, operator on ℓ_2. Thus we can write the map from u to y formally as

$$u \mapsto y = C(I - ZA)^{-1}ZB + D.$$

It is possible to show that the operator $I - ZA$ is invertible exactly when the state space LTV system is exponentially stable. Throughout the paper we will say an open- or closed-loop LTV state space system is *stable* when its A-operator satisfies the above invertibility condition.

A special case of LTV systems which will be of interest to us are the periodic systems. An operator $M \in \mathcal{L}(\ell_2)$ is said to be n-periodic if $Z^n M = M Z^n$.

3. Time-varying square ℓ_2 synthesis. The square ℓ_2 control problem involves the system depicted in Figure 3.1, where the input signal w and the output signal z are partitioned spatially into n_w and n_z *vector-valued* channels, respectively. Let P_i be the operator which projects onto the ith vector-valued channel of w, and similarly, let Q_j be the operator which projects onto the jth vector-valued channel of z. The standard problem of minimizing the ℓ_2-induced norm of the system, considered in [9], does not directly address such additional spatial system structure. Considering such structure will allow us to formulate a number of robust synthesis problems and may also be more representative of physical situations to place constraints on the norm of each channel of w independently. With this objective in mind, we define the square ℓ_2 problem.

PROBLEM 3.1. *Define the square ℓ_2 induced norm of a system M to be*

$$\|M\|_{sq} = \sup_{\|P_i w\| \le 1} \sum_{j=1}^{n_z} \|Q_j M w\|,$$

and let $\gamma_{opt} = \inf_K \|\mathcal{F}_\ell(G,K)\|_{sq}$. Given $\gamma > 0$, the suboptimal square ℓ_2 problem is to determine whether $\gamma > \gamma_{opt}$ and then, where possible, to find a controller K such that

$$\|\mathcal{F}_\ell(G,K)\|_{sq} < \gamma.$$

The choice of the norm $\sum_{j=1}^{n_z} \|Q_j z\|$ on the output z allows the robust control problem of section 4 to be incorporated into the square ℓ_2 framework.

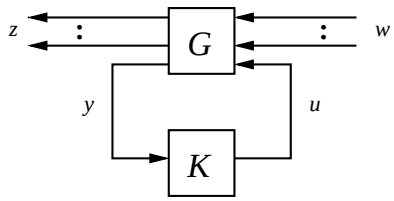

FIG. 3.1. *Square ℓ_2 synthesis arrangement.*

The square ℓ_2 problem is treated for time-invariant systems in [7, 8]. Here we extend its treatment to time-varying systems. The first task is to provide for analysis of a given stable system M; i.e., given γ, is $\|M\|_{sq} < \gamma$? A sufficient condition for M to be contractive with respect to the square norm is given as a scaled small-gain condition on the system, and this condition is further shown to be exact (necessary as well as sufficient) for systems which are *either* periodic or satisfy $n_w \cdot n_z \leq 3$. For a larger class of systems, a related small-gain condition is shown to be necessary for the system to be contractive; however, this condition is not sufficient. A sufficient synthesis which is convex but in general infinite dimensional is then considered for Problem 3.1.

To work effectively with the square norm performance criterion, we introduce a new set of norms on the space ℓ_2. We define the input space $\mathcal{W}_p$ to consist of the elements of ℓ_2, equipped with the norm

$$\|w\|_{\mathcal{W}_p} = |(\|P_1 w\|, \ldots, \|P_{n_w} w\|)|_p,$$

where $|\cdot|_p$ denotes the standard p-norm on $\mathbb{C}^{n_w}$. We similarly define the output space $\mathcal{Z}_p$ via the projections Q_j. For later reference we state the following elementary facts about these new spaces.

PROPOSITION 3.2. *Suppose $1 \leq p \leq \infty$. Then the following hold:*

(a) *The norm $\|\cdot\|_{\mathcal{W}_p}$ is equivalent to the ℓ_2-norm; in particular, $\|w\| \leq \sqrt{n_w}\|w\|_{\mathcal{W}_\infty}$.*
(b) *The mapping A is in $\mathcal{L}(\mathcal{W}_p)$ if and only if $A \in \mathcal{L}(\ell_2)$.*
(c) *If $1 < q \leq \infty$ satisfies $q^{-1} + p^{-1} = 1$, then $\mathcal{W}_q$ represents the normed dual space of $\mathcal{W}_p$ via the ℓ_2 inner product. That is, if f is a linear functional in $\mathcal{L}(\mathcal{W}_p, \mathbb{C})$ with norm α, then there exists $v \in \mathcal{W}_q$ with norm α such that*

$$f(w) = \langle v, w \rangle \qquad \text{for each } w \in \mathcal{W}_p.$$

The analogous statements hold for $\mathcal{Z}_p$.

The above follows from standard analysis, and the proof is omitted.

Having defined these new spaces it is routine to verify that

$$\|M\|_{sq} = \|M\|_{\mathcal{W}_\infty \to \mathcal{Z}_1}. \tag{3.1}$$

That is, the square performance norm is an induced norm.

To simplify the presentation, we define the properties required for the scaling operators in the scaled small-gain conditions of this section.

DEFINITION 3.3. *For a given γ, the time-invariant memoryless operators S, $T \in \mathcal{L}(\ell_2)$ are* γ-admissible scales *if they are of the form*

$$[\![S]\!]_k = \begin{bmatrix} s_1 I & & \\ & \ddots & \\ & & s_{n_w} I \end{bmatrix}, \quad [\![T]\!]_k = \begin{bmatrix} t_1 I & & \\ & \ddots & \\ & & t_{n_z} I \end{bmatrix}$$

and satisfy the condition

$$\sum_{i=1}^{n_w} s_i + \sum_{j=1}^{n_z} t_j < 2\gamma, \text{ where every } s_i > 0 \text{ and } t_j > 0.$$

Note, therefore, that $S = \sum_{i=1}^{n_w} s_i P_i^* P_i$ and $T = \sum_{j=1}^{n_z} t_j Q_j^* Q_j$. The following provides sufficiency in the form of a scaled small-gain condition for contractiveness in the square norm.

THEOREM 3.4. *Suppose that $M \in \mathcal{L}(\ell_2)$ and γ is given. Then if there exist γ-admissible scales S and T such that*

$$\left\| T^{-\frac{1}{2}} M S^{-\frac{1}{2}} \right\|_{\ell_2 \to \ell_2} < 1,$$

then

$$\|M\|_{sq} < \gamma.$$

Proof. The result will be proven for $\gamma = 1$ since in the general case the γ may be absorbed into the plant M. Since the sum of the s_i and t_j is less than 2 by hypothesis, it is routine to see that there must exist an $\alpha > 0$ such that

$$\alpha \sum_{i=1}^{n_w} s_i < 1 \text{ and } \alpha^{-1} \sum_{j=1}^{n_z} t_j < 1.$$

To begin, recall that $\mathcal{Z}_\infty$ represents the normed dual space of $\mathcal{Z}_1$ via the inner product on ℓ_2. Thus we have that the square norm satisfies

$$\|M\|_{\mathcal{W}_\infty \to \mathcal{Z}_1} = \sup_{v \in \mathcal{B}\mathcal{Z}_\infty,\, w \in \mathcal{B}\mathcal{W}_\infty} \operatorname{Re} \langle v, Mw \rangle .$$

We now show that $\mathcal{B}\mathcal{W}_\infty \subset \alpha^{-1} S^{-\frac{1}{2}} \mathcal{B}\ell_2$. To see this, choose $w \in \mathcal{B}\mathcal{W}_\infty$, and set $u = \alpha S^{\frac{1}{2}} w$. Then clearly $w = \alpha^{-1} S^{-\frac{1}{2}} u$ and

$$\|u\|^2 = \alpha s_1 \|P_1 w\|^2 + \cdots + \alpha s_{n_w} \|P_{n_w} w\|^2 < 1,$$

since by definition each $\|P_j w\| \le 1$. An identical argument shows $\mathcal{B}\mathcal{Z}_\infty \subset \alpha T^{-\frac{1}{2}} \mathcal{B}\ell_2$.

Now, returning to the above supremum condition, we get

$$\begin{aligned} \sup_{v \in \mathcal{B}\mathcal{Z}_\infty,\, w \in \mathcal{B}\mathcal{W}_\infty} \operatorname{Re} \langle v, Mw \rangle &\le \sup_{v \in \mathcal{B}\ell_2,\, w \in \mathcal{B}\ell_2} \operatorname{Re} \left\langle \alpha T^{-\frac{1}{2}} v, \alpha^{-1} M S^{-\frac{1}{2}} w \right\rangle \\ &= \sup_{v \in \mathcal{B}\ell_2,\, w \in \mathcal{B}\ell_2} \operatorname{Re} \left\langle v, T^{-\frac{1}{2}} M S^{-\frac{1}{2}} w \right\rangle . \end{aligned}$$

We conclude by observing that the right-hand side is equal to $\|T^{-\frac{1}{2}} M S^{-\frac{1}{2}}\|_{\ell_2 \to \ell_2}$. ∎

Theorem 3.4 provides sufficiency of the scaled small-gain condition $\|T^{-\frac{1}{2}} M S^{-\frac{1}{2}}\|_{\ell_2 \to \ell_2} < 1$ for any operator, and we now investigate necessity. For either periodic systems or systems which satisfy $n_w \cdot n_z \le 3$, we obtain exactness of the scaled small-gain condition through the following result.

THEOREM 3.5. *Suppose $M \in \mathcal{L}(\ell_2)$ and satisfies $\|M\|_{sq} < \gamma$. If either*
(a) *M is periodic, or*
(b) *the product $n_w \cdot n_z \leq 3$,*
then there exist γ-admissible scales S and T such that $\|T^{-\frac{1}{2}} M S^{-\frac{1}{2}}\|_{\ell_2 \to \ell_2} < 1$.

The proof of this theorem is lengthy and is provided in Appendix A. A proof of the time-invariant case is outlined in [7, Theorem 2].

REMARK 3.6. *Here we are working with the complex space $\ell_2(\mathbb{C}^n)$. If instead sequences in the real space $\ell_2(\mathbb{R}^n)$ are considered, a version of Theorem* 3.5 *still holds; however, the inequality in condition* (b) *must be replaced by the more restrictive condition $n_w \cdot n_z \leq 2$. See Remark* A.5.

A more general necessary condition may be developed for time-varying systems which fail to be periodic but which demonstrate a periodic behavior after an initial transient period.

DEFINITION 3.7. *A system M is* eventually periodic *if there is a $k \in \mathbb{N}$ such that the system $Z^{*k} M Z^k$ is periodic.*

With this observation the following generalization of Theorem 3.5 is almost immediate.

PROPOSITION 3.8. *Suppose M is eventually periodic and $\|M\|_{sq} < \gamma$. Then there exist γ-admissible scales S and T such that*

$$\left\| T^{-\frac{1}{2}} \left\{ Z^{*k} M Z^k \right\} S^{-\frac{1}{2}} \right\|_{\ell_2 \to \ell_2} < 1.$$

Proof. We employ the submultiplicative inequality to get

$$\|Z^{*k} M Z^k\|_{\mathcal{W}_\infty \to \mathcal{Z}_1} \leq \|Z^{*k}\|_{\mathcal{Z}_1 \to \mathcal{Z}_1} \|M\|_{\mathcal{W}_\infty \to \mathcal{Z}_1} \|Z^k\|_{\mathcal{W}_\infty \to \mathcal{W}_\infty} = \|M\|_{\mathcal{W}_\infty \to \mathcal{Z}_1} < \gamma.$$

By hypothesis, $Z^{*k} M Z^k$ is periodic; thus the necessity of the scaled small-gain condition follows directly from Theorem 3.5. ∎

Given a system which is eventually periodic but not periodic, this proposition allows a lower bound on the square norm of M to be found. If the scaled small-gain condition of Theorem 3.4 fails for a given value of γ, no conclusion may be made as to whether $\|M\|_{sq} < \gamma$; however, if there are no γ-admissible scales such that $\|T^{-\frac{1}{2}} \{Z^{*k} M Z^k\} S^{-\frac{1}{2}}\|_{\ell_2 \to \ell_2} < 1$, then necessarily $\|M\|_{sq} \geq \gamma$.

To address Problem 3.1, we apply the analysis result of Theorem 3.4 to the closed loop. If, for a given controller K, there exist γ-admissible scales such that

$$\left\| T^{-\frac{1}{2}} \mathcal{F}_\ell(G, K) S^{-\frac{1}{2}} \right\|_{\ell_2 \to \ell_2} < 1, \tag{3.2}$$

then K provides a synthesis such that the closed loop is contractive in the square norm. The key point in solving the synthesis problem is that for fixed scales S and T, finding a K satisfying (3.2) is exactly the problem of finding a controller which makes the closed loop contractive in the induced ℓ_2-norm for the system

$$\hat{G} = \left[\begin{array}{c|cc} \hat{A} & \hat{B}_1 & \hat{B}_2 \\ \hline \hat{C}_1 & \hat{D}_{11} & \hat{D}_{12} \\ \hat{C}_2 & \hat{D}_{21} & 0 \end{array}\right] \equiv \left[\begin{array}{c|cc} A & B_1 S^{-\frac{1}{2}} & B_2 \\ \hline T^{-\frac{1}{2}} C_1 & T^{-\frac{1}{2}} D_{11} S^{-\frac{1}{2}} & T^{-\frac{1}{2}} D_{12} \\ C_2 & D_{21} S^{-\frac{1}{2}} & 0 \end{array}\right],$$

where the notation

$$\left[\begin{array}{c|c} A & B \\ \hline C & D \end{array}\right]$$

signifies the LTV system defined by the memoryless operators A, B, C, D. The proof of the next result uses this idea and the solution from [9] to the induced ℓ_2 synthesis problem and uses the LTI proof in [8] as a formal template.

LEMMA 3.9. *Suppose S and T are γ-admissible scales. There exists a controller K such that the closed loop is internally stable and $\|T^{-\frac{1}{2}}\mathcal{F}_\ell(G,K)S^{-\frac{1}{2}}\|_{\ell_2\to\ell_2} < 1$ if and only if there exist memoryless operators P, Q, $X > 0$, and $Y > 0$ satisfying*

$$N_X^*\left\{\begin{bmatrix} A & B_1 \\ C_1 & D_{11}\end{bmatrix}\begin{bmatrix} X & 0 \\ 0 & P\end{bmatrix}\begin{bmatrix} A & B_1 \\ C_1 & D_{11}\end{bmatrix}^* - \begin{bmatrix} Z^*XZ & 0 \\ 0 & T\end{bmatrix}\right\}N_X < 0, \tag{3.3}$$

$$N_Y^*\left\{\begin{bmatrix} ZA & ZB_1 \\ C_1 & D_{11}\end{bmatrix}^*\begin{bmatrix} Y & 0 \\ 0 & Q\end{bmatrix}\begin{bmatrix} ZA & ZB_1 \\ C_1 & D_{11}\end{bmatrix} - \begin{bmatrix} Y & 0 \\ 0 & S\end{bmatrix}\right\}N_Y < 0, \tag{3.4}$$

$$\begin{bmatrix} X & I \\ I & Y\end{bmatrix} \geq 0, \quad \begin{bmatrix} P & I \\ I & S\end{bmatrix} \geq 0, \quad \begin{bmatrix} Q & I \\ I & T\end{bmatrix} \geq 0, \tag{3.5}$$

where

$$\mathrm{Im}N_X = \ker\begin{bmatrix} B_2^* & D_{12}^*\end{bmatrix}, \quad N_X^*N_X = I,$$
$$\mathrm{Im}N_Y = \ker\begin{bmatrix} C_2 & D_{21}\end{bmatrix}, \quad N_Y^*N_Y = I.$$

Proof. Suppose there is a solution, K, for the scaled synthesis problem. Applying the time-varying induced ℓ_2 synthesis to the system $\hat{G}$ defined above, $\|\mathcal{F}_\ell(\hat{G},K)\|_{\ell_2\to\ell_2} < 1$ if and only if there are memoryless operators $X > 0$ and $Y > 0$ which solve the three operator inequalities

$$\hat{N}_X^*\left\{\begin{bmatrix} \hat{A} & \hat{B}_1 \\ \hat{C}_1 & \hat{D}_{11}\end{bmatrix}\begin{bmatrix} X & 0 \\ 0 & I\end{bmatrix}\begin{bmatrix} \hat{A} & \hat{B}_1 \\ \hat{C}_1 & \hat{D}_{11}\end{bmatrix}^* - \begin{bmatrix} Z^*XZ & 0 \\ 0 & I\end{bmatrix}\right\}\hat{N}_X < 0, \tag{3.6}$$

$$\hat{N}_Y^*\left\{\begin{bmatrix} Z\hat{A} & Z\hat{B}_1 \\ \hat{C}_1 & \hat{D}_{11}\end{bmatrix}^*\begin{bmatrix} Y & 0 \\ 0 & I\end{bmatrix}\begin{bmatrix} Z\hat{A} & Z\hat{B}_1 \\ \hat{C}_1 & \hat{D}_{11}\end{bmatrix} - \begin{bmatrix} Y & 0 \\ 0 & I\end{bmatrix}\right\}\hat{N}_Y < 0, \tag{3.7}$$

$$\begin{bmatrix} X & I \\ I & Y\end{bmatrix} \geq 0, \tag{3.8}$$

where $\mathrm{Im}\hat{N}_X = \ker\begin{bmatrix} B_2^* & D_{12}^*T^{-\frac{1}{2}}\end{bmatrix}$ and $\mathrm{Im}\hat{N}_Y = \ker\begin{bmatrix} C_2 & D_{21}S^{-\frac{1}{2}}\end{bmatrix}$. Concentrating on the inequality (3.6) and factoring out the scales S and T, we may rewrite it as

$$\hat{N}_X^*\begin{bmatrix} I & 0 \\ 0 & T^{-\frac{1}{2}}\end{bmatrix}\left\{\begin{bmatrix} A & B_1 \\ C_1 & D_{11}\end{bmatrix}\begin{bmatrix} X & 0 \\ 0 & S^{-1}\end{bmatrix}\begin{bmatrix} A & B_1 \\ C_1 & D_{11}\end{bmatrix}^* - \begin{bmatrix} Z^*XZ & 0 \\ 0 & T\end{bmatrix}\right\}\begin{bmatrix} I & 0 \\ 0 & T^{-\frac{1}{2}}\end{bmatrix}\hat{N}_X < 0.$$

Noting that

$$\mathrm{Im}\left(\hat{N}_X\begin{bmatrix} I & 0 \\ 0 & T^{-\frac{1}{2}}\end{bmatrix}\right) = \ker\begin{bmatrix} B_2^* & D_{12}^*\end{bmatrix} = \mathrm{Im}N_X,$$

this inequality has the equivalent form

$$N_X^*\left\{\begin{bmatrix} A & B_1 \\ C_1 & D_{11}\end{bmatrix}\begin{bmatrix} X & 0 \\ 0 & S^{-1}\end{bmatrix}\begin{bmatrix} A & B_1 \\ C_1 & D_{11}\end{bmatrix}^* - \begin{bmatrix} Z^*XZ & 0 \\ 0 & T\end{bmatrix}\right\}N_X < 0.$$

A similar procedure allows (3.7) to be expressed as

$$N_Y^* \left\{ \begin{bmatrix} ZA & ZB_1 \\ C_1 & D_{11} \end{bmatrix}^* \begin{bmatrix} Y & 0 \\ 0 & T^{-1} \end{bmatrix} \begin{bmatrix} ZA & ZB_1 \\ C_1 & D_{11} \end{bmatrix} - \begin{bmatrix} Y & 0 \\ 0 & S \end{bmatrix} \right\} N_Y < 0.$$

Taking $P = S^{-1}$ and $Q = T^{-1}$, immediately X, Y, P, and Q satisfy (3.3)–(3.5) for the given values of S and T.

Conversely, suppose there is a solution to the inequalities (3.3)–(3.5). Applying Schur complements to (3.5) results in $P \geq S^{-1}$ and $Q \geq T^{-1}$. Thus

$$\begin{bmatrix} X & 0 \\ 0 & S^{-1} \end{bmatrix} \leq \begin{bmatrix} X & 0 \\ 0 & P \end{bmatrix},$$

so

$$\begin{bmatrix} A & B_1 \\ C_1 & D_{11} \end{bmatrix} \begin{bmatrix} X & 0 \\ 0 & S^{-1} \end{bmatrix} \begin{bmatrix} A & B_1 \\ C_1 & D_{11} \end{bmatrix}^* \leq \begin{bmatrix} A & B_1 \\ C_1 & D_{11} \end{bmatrix} \begin{bmatrix} X & 0 \\ 0 & P \end{bmatrix} \begin{bmatrix} A & B_1 \\ C_1 & D_{11} \end{bmatrix}^*,$$

and hence

$$\begin{aligned} &N_X^* \left\{ \begin{bmatrix} A & B_1 \\ C_1 & D_{11} \end{bmatrix} \begin{bmatrix} X & 0 \\ 0 & S^{-1} \end{bmatrix} \begin{bmatrix} A & B_1 \\ C_1 & D_{11} \end{bmatrix}^* - \begin{bmatrix} Z^*XZ & 0 \\ 0 & T \end{bmatrix} \right\} N_X \\ &\leq N_X^* \left\{ \begin{bmatrix} A & B_1 \\ C_1 & D_{11} \end{bmatrix} \begin{bmatrix} X & 0 \\ 0 & P \end{bmatrix} \begin{bmatrix} A & B_1 \\ C_1 & D_{11} \end{bmatrix}^* - \begin{bmatrix} Z^*XZ & 0 \\ 0 & T \end{bmatrix} \right\} N_X < 0. \end{aligned}$$

Similarly, since $Q \geq T^{-1}$,

$$N_Y^* \left\{ \begin{bmatrix} ZA & ZB_1 \\ C_1 & D_{11} \end{bmatrix}^* \begin{bmatrix} Y & 0 \\ 0 & T^{-1} \end{bmatrix} \begin{bmatrix} ZA & ZB_1 \\ C_1 & D_{11} \end{bmatrix} - \begin{bmatrix} Y & 0 \\ 0 & S \end{bmatrix} \right\} N_Y < 0.$$

The ℓ_2 synthesis may be applied again to show that

$$\left\| \mathcal{F}_\ell \left(\hat{G}, K \right) \right\|_{\ell_2 \to \ell_2} = \left\| T^{-\frac{1}{2}} \mathcal{F}_\ell \left(G, K \right) S^{-\frac{1}{2}} \right\|_{\ell_2 \to \ell_2} < 1. \qquad \square$$

A synthesis which is sufficient for $\|\mathcal{F}_\ell(G,K)\|_{sq} < \gamma$ is now immediate.

THEOREM 3.10. *If there exist γ-admissible scales S and T and memoryless operators P, Q, $X > 0$, and $Y > 0$ satisfying inequalities* (3.3)–(3.5)*, then there exists a stabilizing controller K such that $\|\mathcal{F}_\ell(G,K)\|_{sq} < \gamma$.*

Proof. By Lemma 3.9 and the existence of a solution to the inequalities (3.3)–(3.5),

$$\left\| T^{-\frac{1}{2}} \mathcal{F}_\ell \left(G, K \right) S^{-\frac{1}{2}} \right\|_{\ell_2 \to \ell_2} < \gamma.$$

Applying Theorem 3.4, $\|\mathcal{F}_\ell(G,K)\|_{sq} < 1$. $\square$

Theorem 3.10 provides a sufficient test to determine the existence of a controller synthesis such that $\|\mathcal{F}_\ell(G,K)\|_{sq} < \gamma$. To construct such a controller, in the case that the operator inequalities (3.3)–(3.5) have a solution X, Y, P, Q, S, and T, a controller realization may be obtained by forming the system $\hat{G}$ and proceeding to solve the synthesis operator inequalities for the time-varying ℓ_2 problem; see [9]. It follows that determining feasibility and constructing an admissible controller are both convex, though infinite dimensional, problems. As Theorem 3.10 provides (in general) only a sufficient test, infeasibility of the inequalities (3.3)–(3.5) does not allow any

conclusion to be made as to the existence of an admissible controller. This test is, however, exact for systems which are either periodic or $n_w \cdot n_z \leq 3$ since the analysis condition was shown in Theorem 3.5 to be exact.

It should be noted that the operator inequalities of Theorem 3.10 reduce to finite dimensional LMIs when the system is either periodic or the problem is considered only over a finite horizon. For finite horizon problems the reduction in dimension is immediate since the system realization may be taken to be zero at all time steps after the horizon of the problem. The operator inequalities may be written as a countable collection of coupled LMIs by considering the memoryless realization of the inequalities, and, due to the system realization being zero after the horizon all but a finite number of these LMIs are trivial. Denoting the horizon by k_o the problem thus reduces to the LMIs

$$1.\quad N_{X,k}^* \left\{ \begin{bmatrix} A_k & B_{1,k} \\ C_{1,k} & D_{11,k} \end{bmatrix} \begin{bmatrix} X_k & 0 \\ 0 & P_k \end{bmatrix} \begin{bmatrix} A_k & B_{1,k} \\ C_{1,k} & D_{11,k} \end{bmatrix}^* - \begin{bmatrix} X_{k+1} & 0 \\ 0 & T \end{bmatrix} \right\} N_{X,k} < 0 \quad \text{for } 0 \leq k \leq k_o,$$

$$2.\quad N_{Y,k}^* \left\{ \begin{bmatrix} A_k & B_{1,k} \\ C_{1,k} & D_{11,k} \end{bmatrix}^* \begin{bmatrix} Y_{k+1} & 0 \\ 0 & Q_k \end{bmatrix} \begin{bmatrix} A_k & B_{1,k} \\ C_{1,k} & D_{11,k} \end{bmatrix} - \begin{bmatrix} Y_k & 0 \\ 0 & S \end{bmatrix} \right\} N_{Y,k} < 0 \quad \text{for } 0 \leq k \leq k_o,$$

$$3.\quad \begin{bmatrix} X_k & I \\ I & Y_k \end{bmatrix} \geq 0 \quad \text{for } 0 \leq k \leq k_o + 1,$$

$$4.\quad \begin{bmatrix} P_k & I \\ I & S \end{bmatrix} \geq 0, \begin{bmatrix} Q_k & I \\ I & T \end{bmatrix} \geq 0 \quad \text{for } 0 \leq k \leq k_o,$$

where S and T are now *constant* matrices satisfying the γ-admissible scale properties, and the following conditions on the matrix variables are satisfied:

$$\begin{aligned} X_k > 0, \quad Y_k > 0 \quad & \text{for } 0 \leq k \leq k_o + 1, \\ P_k > 0, \quad Q_k > 0 \quad & \text{for } 0 \leq k \leq k_o. \end{aligned}$$

Note that due to the presence of the shift operator in the original inequalities, the $k_o + 1$ blocks of X and Y are constrained in these LMIs.

For periodic systems the reduction to finite dimensions is a result of an LMI solution to the ℓ_2 problem for periodic systems given in [9]. Applying the same methodology as in Lemma 3.9 and Theorem 3.10 and using the LMI solution in place of the operator inequalities will immediately produce an LMI solution which is exact for the periodic square ℓ_2 synthesis problem. Define the *cyclic shift operator*

$$\tilde{Z} = \begin{bmatrix} 0 & \cdots & 0 & I \\ I & \ddots & & 0 \\ & \ddots & & \vdots \\ & & I & 0 \end{bmatrix},$$

and for a periodic operator F define the first period truncation to be

$$\tilde{F} = \begin{bmatrix} F_0 & & & \\ & \ddots & & \\ & & & F_{n-1} \end{bmatrix}.$$

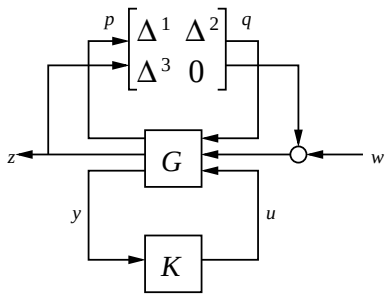

FIG. 4.1. *Structured uncertainty system interconnection.*

COROLLARY 3.11. *There exist γ-admissible scales $\tilde{S}$ and $\tilde{T}$ and matrices $\tilde{P}$, $\tilde{Q}$, $\tilde{X} > 0$, and $\tilde{Y} > 0$ satisfying the LMIs obtained from* (3.3)–(3.5) *by formally replacing the shift operator with the cyclic shift and the other operators with their first period truncations if and only if there exists a stabilizing controller K such that $\|\mathcal{F}_\ell(G,K)\|_{sq} < 1$. Furthermore, this controller may be chosen to be periodic.*

4. Robust synthesis for structured uncertainty. The structured uncertainty control problem of interest involves the system interconnection shown in Figure 4.1, where the input signal w, the output z, and the signals p and q are partitioned into n_w, n_z, n_p, and n_q vector-valued channels, respectively. The uncertainty Δ is assumed to be in $\bar{\mathbf{\Delta}}$, where

$$\bar{\mathbf{\Delta}} = \left\{ \begin{bmatrix} \Delta^1 & \Delta^2 \\ \Delta^3 & 0 \end{bmatrix} : \Delta^1 \in \mathbf{\Delta}_{n_q,n_p}, \Delta^2 \in \mathbf{\Delta}_{n_q,n_z}, \Delta^3 \in \mathbf{\Delta}_{n_w,n_p} \right\}$$

and

$$\mathbf{\Delta}_{n,m} = \left\{ \Delta \in \mathcal{L}(\ell_2) : \|\Delta_{ij}\|_{\ell_2 \to \ell_2} \le 1, i = 1, \dots, n, j = 1, \dots, m \right\}.$$

This uncertainty class encompasses a number of common uncertainty arrangements, and we illustrate this with two specific examples in what follows; see also [7]. Most of the results presented in this section appear in [6, 7]; here we provide alternative proofs in our current context that are concise and complete.

We begin with several definitions.

DEFINITION 4.1. *A linear operator $M \in \mathcal{L}(\ell_2)$ is* robustly stable *to an uncertainty set $\mathbf{\Delta}$ if $I - M\Delta$ is invertible on ℓ_2 for every $\Delta \in \mathbf{\Delta}$. An operator M is* uniformly robustly stable *to $\mathbf{\Delta}$ if, in addition to being robustly stable,*

$$\sup_{\Delta \in \mathbf{\Delta}} \left\| (I - M\Delta)^{-1} \right\|_{\ell_2 \to \ell_2} < \infty.$$

Given operators G and K, we say that K uniformly robustly stabilizes G if $\mathcal{F}_\ell(G,K)$ is uniformly robustly stable. Note that the above definitions remain unchanged if the ℓ_2-norm is replaced by the $\mathcal{Z}_p$-norm since all these norms are equivalent for all p.

The suboptimal robust control problem follows.

PROBLEM 4.2. *Given the structured uncertainty set $\bar{\mathbf{\Delta}}$, a linear system G on ℓ_2, and a desired performance level γ, construct a controller K such that the nominal system $\mathcal{F}_\ell(G,K)$ is uniformly robustly stable and*

$$\sup_{\Delta \in \bar{\mathbf{\Delta}}} \|T_{wz}\|_{sq} < \gamma,$$

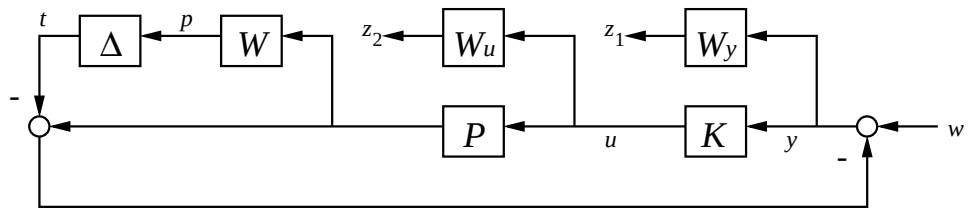

FIG. 4.2. *Generalized sensitivity minimization.*

where $T_{wz} = (I - \mathcal{F}_\ell(G,K)\,\Delta)^{-1}\,\mathcal{F}_\ell(G,K)$ *is the closed-loop map from* w *to* z *in Figure* 4.1.

In the case where $n_w = n_z = 1$, this problem reduces to

$$\sup_{\Delta \in \bar{\mathbf{\Delta}}} \|T_{wz}\|_{\ell_2 \to \ell_2} < \gamma.$$

Structured uncertainty may be transformed to block diagonal uncertainty (to which most existing theory applies) by appropriately redefining the plant G, although at some expense in the size of the problem. However, in the case of Problem 4.2 a direct analysis of the structured uncertainty is more tractable due an underlying connection with the square ℓ_2 problem, which we have shown to have a convex solution. Demonstrating this connection is the topic of this section. It should be noted that not all robust control problems may be formulated as in Figure 4.1 and Problem 4.2. To provide some concreteness the following example demonstrates how to formulate a problem under this framework.

Example. The generalized sensitivity minimization problem is depicted in Figure 4.2, where the aim is to minimize $\|z_1\| + \|z_2\|$ subject to the uncertainty $\|\Delta\|_{\ell_2 \to \ell_2} \le 1$ and $\|w\| \le 1$. Note that this is exactly the standard sensitivity minimization problem if the weight $W_u = 0$. This system may be reconfigured to fit the correct formulation by finding the operator which maps from $t + w$ and u to p, z, and y. From Figure 4.2,

$$\begin{aligned} p &= WPu, \\ z_1 &= W_y(w+t) - W_yPu, \\ z_2 &= W_uu, \\ y &= (w+t) - Pu. \end{aligned}$$

Thus this system is equivalent to the one in Figure 4.3, where

$$G = \begin{bmatrix} 0 & WP \\ \begin{bmatrix} W_y \\ 0 \end{bmatrix} & \begin{bmatrix} -W_yP \\ W_u \end{bmatrix} \\ I & -P \end{bmatrix}.$$

The problem may now be restated as follows: find a uniformly robustly stabilizing controller K such that

$$\sup_{\|\Delta\|_{\ell_2 \to \ell_2} \le 1} \sup_{\|w\| \le 1} \sum_{j=1}^{2} \|Q_j z\| < 1. \tag{4.1}$$

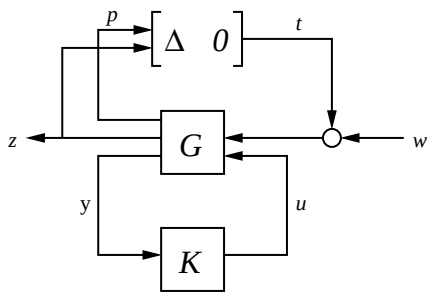

FIG. 4.3. *Reformulation of sensitivity minimization problem.*

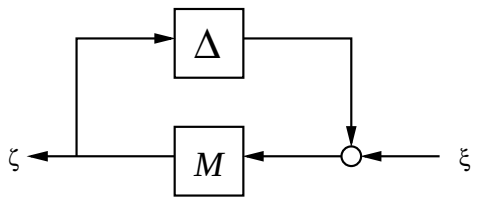

FIG. 4.4. *System for robust stability analysis.*

Thus we see that $n_z = 2$ and $n_w = 1$. To explicitly see that this example is in the framework of Figure 4.1, augment $\begin{bmatrix} \Delta & 0 \end{bmatrix}$ to get

$$\Delta' = \begin{bmatrix} \Delta^1 & \Delta^2 \\ \Delta & 0 \end{bmatrix},$$

where $\|\Delta^k\|_{\ell_2 \to \ell_2} \leq 1$, and augment G to obtain

$$G' = \begin{bmatrix} 0 & 0 & WP \\ \begin{bmatrix} 0 \\ 0 \end{bmatrix} & \begin{bmatrix} W_y \\ 0 \end{bmatrix} & \begin{bmatrix} -W_y P \\ W_u \end{bmatrix} \\ 0 & I & -P \end{bmatrix}.$$

REMARK 4.3. *Note that, from Theorem* 3.5*, we can solve the above example exactly using the methods of this paper since here* $n_w \cdot n_z = 2$.

As an initial step in reformulating Problem 4.2 as a square ℓ_2 problem, we consider robust stability analysis of a related full structured uncertainty. Consider the system depicted in Figure 4.4, where ξ is partitioned into $n_\xi = n_q + n_w$ channels and ζ is partitioned into $n_\zeta = n_z + n_p$ channels.

THEOREM 4.4. *A system* M *is uniformly robustly stable with respect to the full-block structured uncertainty set* $\mathbf{\Delta} = \mathbf{\Delta}_{n_\xi, n_\zeta}$ *if and only if* $\|M\|_{sq} < 1$.

Proof. (If:) Start by choosing $\Delta \in \mathbf{\Delta}$. It is sufficient to show that the inverse $(I - M\Delta)^{-1}$ exists in $\mathcal{L}(\mathcal{Z}_1)$ and is bounded by a constant independent of Δ.

We begin by showing that $\|\Delta\|_{\mathcal{Z}_1 \to \mathcal{W}_\infty} \leq 1$. Take any $q \in \mathcal{Z}_1$. Then

$$\|P_i \Delta q\| = \left\| \sum_{j=1}^{n_\zeta} \Delta_{ij} Q_j q \right\| \leq \sum_{j=1}^{n_\zeta} \|\Delta_{ij}\|_{\ell_2 \to \ell_2} \|Q_j q\| \leq \sum_{j=1}^{n_\zeta} \|Q_j q\| = \|q\|_{\mathcal{Z}_1}.$$

Thus we conclude that $\|\Delta q\|_{\mathcal{W}_\infty} \leq \|q\|_{\mathcal{Z}_1}$, and so Δ is a contractive element of $\mathcal{L}(\mathcal{Z}_1, \mathcal{W}_\infty)$.

Using this and applying the submultiplicative inequality, we have

$$\|M\Delta\|_{\mathcal{Z}_1\to\mathcal{Z}_1} \le \|M\|_{\mathcal{W}_\infty\to\mathcal{Z}_1}\|\Delta\|_{\mathcal{Z}_1\to\mathcal{W}_\infty} \le \|M\|_{\mathcal{W}_\infty\to\mathcal{Z}_1} < 1.$$

Invoking Proposition 2.1, we see that $(I-M\Delta)^{-1}$ exists and that $\|(I-M\Delta)^{-1}\|_{\mathcal{Z}_1\to\mathcal{Z}_1} \le \frac{1}{1-\|M\|_{sq}}$.

(Only if:) This part of the proof is by contradiction. Suppose that M is uniformly robustly stable, and suppose, on the contrary, that $\|M\|_{sq} \ge 1$. Then it suffices to show that, given any $\epsilon > 0$, there exist $\xi \in \mathcal{W}_\infty$, with norm $\|\xi\|_{\mathcal{W}_\infty} = 1$, and $\Delta \in \mathbf{\Delta} = \mathbf{\Delta}_{n_\xi,n_\zeta}$ such that

$$\|(I - \Delta M)\xi\|_{\mathcal{W}_\infty} \le \epsilon.$$

Fix $\epsilon > 0$, and choose $\xi \in \mathcal{W}_\infty$, with norm $\|\xi\|_{\mathcal{W}_\infty} = 1$, such that $\|M\xi\|_{\mathcal{Z}_1} > 1 - \epsilon$.

Let $\alpha = \|M\xi\|_{\mathcal{Z}_1}$, and define the full structured perturbation Δ by

$$\Delta_{ij}(x) = \begin{cases} \frac{1-\epsilon}{\alpha\|Q_jM\xi\|}\langle Q_jM\xi, x\rangle P_i\xi & \text{if } Q_jM\xi \ne 0, \\ 0 & \text{if } Q_jM\xi = 0. \end{cases}$$

For notational simplicity, assume that $Q_jM\xi \ne 0$ for each j. Then, since $1 - \epsilon < \sum_{j=1}^{n_\zeta}\|Q_jM\xi\| = \alpha$ and using the Cauchy–Schwarz inequality,

$$\begin{aligned}\|\Delta_{ij}\|_{\ell_2\to\ell_2} &\le \frac{1-\epsilon}{\alpha\,\|Q_jM\xi\|}\,\|Q_jM\xi\|\,\|P_i\xi\| \\ &= \frac{1-\epsilon}{\alpha}\,\|P_i\xi\| < 1,\end{aligned}$$

so $\Delta \in \mathbf{\Delta} = \mathbf{\Delta}_{n_\xi,n_\zeta}$. Further,

$$\begin{aligned}P_i\Delta M\xi &= \sum_{j=1}^{n_\zeta}\Delta_{ij}\,(Q_jM\xi) \\ &= \sum_{j=1}^{n_\zeta}\frac{1-\epsilon}{\alpha\,\|Q_jM\xi\|}\,\langle Q_jM\xi, Q_jM\xi\rangle\,P_i\xi \\ &= (1-\epsilon)P_i\xi\left(\frac{1}{\alpha}\sum_{j=1}^{n_\zeta}\|Q_jM\xi\|\right) \\ &= (1-\epsilon)P_i\xi,\end{aligned}$$

and hence $\Delta M\xi = (1-\epsilon)\xi$. Thus $\|\,(I - \Delta M)\,\xi\|_{\mathcal{W}_\infty} = \epsilon$. □

Theorem 4.4 reformulates robust stability as a square ℓ_2 analysis problem, and so the problem of finding a robustly stabilizing controller immediately reduces to the square ℓ_2 synthesis problem: find a stabilizing K such that $\|\mathcal{F}_\ell\,(G,K)\|_{sq} < 1$. Problem 4.2 requires further reformulation before the square ℓ_2 results apply, and a technical result is first needed.

COROLLARY 4.5. *Let $\mathcal{A}$ be a set of operators on ℓ_2. Then $\sup_{A\in\mathcal{A}}\|A\|_{sq} < 1$ if and only if $\sup_{\Delta\in\mathbf{\Delta},A\in\mathcal{A}}\left\|(I - A\Delta)^{-1}\right\|_{\ell_2\to\ell_2} < \infty$.*

Proof. The proof of this result is nearly identical to the proof of Theorem 4.4, and the details are omitted. □

We now present an analogue to the so-called main loop theorem from μ theory; see [16]. In this result we show that uniform robust performance is equivalent to

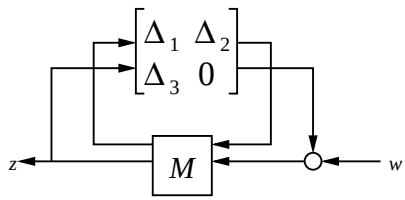

FIG. 4.5. *System for robust performance analysis.*

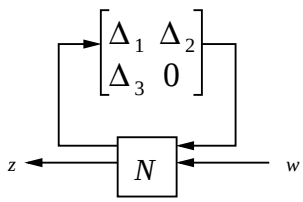

FIG. 4.6. *Equivalent system for robust performance analysis.*

uniform robust stability in an augmented uncertainty structure. This square version of the main loop theorem will provide the basis for the reformulation of Problem 4.2 as a square ℓ_2 problem.

PROPOSITION 4.6. *Define the augmented uncertainty set*

$$\mathbf{\Delta}_p = \left\{ \begin{bmatrix} \bar{\Delta} & 0 \\ 0 & \Delta_4 \end{bmatrix} : \bar{\Delta} \in \bar{\mathbf{\Delta}}, \Delta_4 \in \mathbf{\Delta}_{n_w,n_z} \right\}.$$

With N partitioned compatibly with the inputs and outputs,

$$\sup_{\bar{\Delta}\in\bar{\mathbf{\Delta}}} \left\| \left(I - N_{11}\bar{\Delta}\right)^{-1} \right\|_{\ell_2\to\ell_2} < \infty \text{ and } \sup_{\bar{\Delta}\in\bar{\mathbf{\Delta}}} \left\| \mathcal{F}_u\left(N, \bar{\Delta}\right) \right\|_{sq} < 1$$

if and only if

$$\sup_{\Delta_p\in\mathbf{\Delta}_p} \left\| (I - N\Delta_p)^{-1} \right\|_{\ell_2\to\ell_2} < \infty.$$

The proof of this proposition is a routine modification of the usual main loop theorem proof and is accordingly omitted.

The next theorem is the reformulation of Problem 4.2.

THEOREM 4.7. *Given a system $M \in \mathcal{L}(\ell_2)$, M is uniformly robustly stable to $\bar{\mathbf{\Delta}}$ and $\sup_{\bar{\Delta}\in\bar{\mathbf{\Delta}}} \|T_{wz}\|_{sq} < 1$, where $T_{wz} = \left(I - M\bar{\Delta}\right)^{-1} M$ is the closed-loop map from w to z in Figure 4.5 if and only if $\|M\|_{sq} < 1$.*

Proof. First notice that the systems in Figures 4.5 and 4.6 define the same mapping from w to z, where

$$N_{11} = M, \quad N_{12} = \begin{bmatrix} M_{12} \\ M_{22} \end{bmatrix}, \quad N_{21} = \begin{bmatrix} M_{21} & M_{22} \end{bmatrix}, \quad N_{22} = M_{22}.$$

Thus M is uniformly robustly stable to $\bar{\mathbf{\Delta}}$ and $\sup_{\bar{\Delta}\in\bar{\mathbf{\Delta}}} \|T_{wz}\|_{sq} < 1$ if and only if the inequalities $\sup_{\bar{\Delta}\in\bar{\mathbf{\Delta}}} \|(I - N_{11}\bar{\Delta})^{-1}\|_{l_2\to l_2} < \infty$ and $\sup_{\bar{\Delta}\in\bar{\mathbf{\Delta}}} \left\| \mathcal{F}_u\left(N, \bar{\Delta}\right) \right\|_{sq} < 1$ hold.

Applying Proposition 4.6, this holds if and only if $\sup_{\Delta_p \in \mathbf{\Delta}_p} \|(I - N\Delta_p)^{-1}\|_{l_2 \to l_2} < \infty$. Defining the operators

$$S = \begin{bmatrix} I & 0 \\ 0 & I \\ 0 & I \end{bmatrix}$$

and

$$T = MS^*\Delta_p = \begin{bmatrix} M_{11} & M_{12} \\ M_{21} & M_{22} \end{bmatrix} \begin{bmatrix} I & 0 & 0 \\ 0 & I & I \end{bmatrix} \begin{bmatrix} \Delta_1 & \Delta_2 & 0 \\ \Delta_3 & 0 & 0 \\ 0 & 0 & \Delta_4 \end{bmatrix},$$

then we see that $I - ST = I - N\Delta_p$ is invertible if and only if $I - TS = I - M\Delta$ is invertible, where

$$\Delta = \begin{bmatrix} \Delta_1 & \Delta_2 \\ \Delta_3 & \Delta_4 \end{bmatrix} \in \mathbf{\Delta} = \{S^*\Delta_p S : \Delta_p \in \mathbf{\Delta}_p\},$$

and further,

$$\begin{aligned} (I - M\Delta)^{-1} &= I + T(I - ST)^{-1} S \\ &= I + MS^*\Delta_p (I - N\Delta_p)^{-1} S. \end{aligned}$$

Thus $\sup_{\Delta_p \in \mathbf{\Delta}_p} \|(I - N\Delta_p)^{-1}\|_{l_2 \to l_2} < \infty$ holds if and only if $\sup_{\Delta \in \mathbf{\Delta}} \|(I - M\Delta)^{-1}\|_{l_2 \to l_2} < \infty$. Equivalently, applying Theorem 4.4, $\|M\|_{sq} < 1$. □

To summarize, Problem 4.2 requires a controller K which provides a robust performance level of γ, that is, such that $\sup_{\bar{\Delta} \in \bar{\mathbf{\Delta}}} \|T_{wz}\|_{sq} < \gamma$. Applying Theorem 4.7, it is sufficient to find a synthesis for the square ℓ_2 problem $\|\mathcal{F}_\ell(G, K)\|_{sq} < \gamma$, and through the development of section 3 we have given a sufficient controller synthesis for this problem as a set of operator inequalities.

5. Numerical example. Returning to the generalized sensitivity minimization, we now give an example to numerically demonstrate our results; it is without physical significance. Consider the standard sensitivity minimization, obtained by taking $W_u = 0$. Set $W_y = W = I$, and let the plant P be SISO with the following realization in which B, C, and D are not time-varying:

$$A_1 = \begin{bmatrix} 2 & 0 \\ 0 & 2 \end{bmatrix}, \quad A_2 = \begin{bmatrix} 0 & 2 \\ -2 & 0 \end{bmatrix}, \quad A_3 = \begin{bmatrix} -2 & 0 \\ 0 & -2 \end{bmatrix}, \quad A_4 = \begin{bmatrix} 0 & -2 \\ 2 & 0 \end{bmatrix},$$

$$B = \begin{bmatrix} 2 \\ 1 \end{bmatrix}, \quad C = \begin{bmatrix} 1 & 2 \end{bmatrix}, \quad D = 0.$$

Then the system G has the realization

$$G = \left[\begin{array}{c|cc} A & 0 & B \\ \hline WC & 0 & 0 \\ -W_yC & W_y & 0 \\ -C & I & 0 \end{array}\right] = \left[\begin{array}{c|cc} A & B_1 & B_2 \\ \hline C_1 & D_{11} & D_{12} \\ C_2 & D_{21} & 0 \end{array}\right]$$

with

$$B_1 = \begin{bmatrix} 0 \\ 0 \end{bmatrix}, \quad B_2 = B, \quad C_1 = \begin{bmatrix} WC \\ -W_y C \end{bmatrix}, \quad C_2 = -C,$$
$$D_{11} = \begin{bmatrix} 0 \\ W_y \end{bmatrix}, \quad D_{12} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}, \quad D_{21} = I.$$

Recall that the uncertainty block has the form $[\Delta \quad 0]$ so in this problem, $n_w = 1$ and $n_z = 2$. Treating the system as a finite horizon problem with a horizon of 4 gives $\gamma_{opt} = 1.0010$, and treating it as a periodic system with a period of 4 gives $\gamma_{opt} = 17.4473$.

6. Conclusions. In this paper we have extended work on LTI robust synthesis to LTV systems. The tools required were generalizations of results for LTI systems with spatial constraints [7, 8] to operators in $\mathcal{L}(\ell_2)$, the framework for LTV state space systems from [9], and the powerful results in [10, 21] on the S-procedure. We have demonstrated how a typical control problem (robust sensitivity minimization) may be handled using this machinery.

This theory has been experimentally applied to robust trajectory tracking on a flexible beam as reported in [19]. Software which performs square ℓ_2 synthesis for periodic and finite horizon systems is available at http://epic.me.uiuc.edu/∼dullerud.

Future work includes weakening the constraints of uniform robust stability to robust stability and further developing a general necessary condition for the controller synthesis. Computational issues arise when trying to solve the LMIs for a large horizon problem due to the size of the problem and the number of decision variables it involves. Advances in LMI solution methods and investigation into exploiting the particular structure of these LMIs would be beneficial.

The framework and proof machinery presented here provide a streamlined way to treat generalized ℓ_2-synthesis and thus may find wider application in generalizing LTI results to both the LTV and distributed control settings.

Appendix. Proof of Theorem 3.5. Here we will prove Theorem 3.5 using the technique of quadratic forms and constraints. We remark that the periodic case of this result could be obtained readily from the proofs in [7, 8] by first applying a lifting technique to the periodic system. To obtain the general LTV results proved here a different approach is required. In fact, the proof given, when restricted to the LTI case, gives a more direct and transparent demonstration than specialized LTI proofs in [7, 8]. Thus it may be useful for extending the latter LTI work to more general classes of systems (e.g., infinite dimensional, distributed control architectures).

As with the proof of Theorem 3.4, γ will be taken to be 1 as this causes no loss in generality. For simplicity we will restrict our proof to the case where either M is periodic or $n_w n_z \leq 2$ holds. See Remark A.4 at the end of this appendix for the routine extension to the $n_w n_z \leq 3$ case.

Thus for the remainder of the section we have the standing assumptions that $\|M\|_{sq} < 1$ and either (a) M is periodic or (b) $n_w n_z \leq 2$ holds.

Our constructions will be based on the following duality-based characterization of the square norm:

$$\|M\|_{sq} = \sup_{w,v \neq 0} \frac{\mathrm{Re}\langle v, Mw \rangle}{\|v\|_{\mathcal{Z}_\infty} \|w\|_{\mathcal{W}_\infty}}.$$

Having made this observation, we define the quadratic forms

$$\psi_i(w,v) = \left\langle \begin{bmatrix} v \\ w \end{bmatrix}, \begin{bmatrix} 0 & \frac{1}{2}M \\ \frac{1}{2}M^* & -P_i^*P_i \end{bmatrix} \begin{bmatrix} v \\ w \end{bmatrix} \right\rangle = \mathrm{Re}\langle v, Mw\rangle - \|P_i w\|^2 \text{ for } i = 1, \dots, n_w,$$

$$\psi_i(w,v) = \left\langle \begin{bmatrix} v \\ w \end{bmatrix}, \begin{bmatrix} -Q_i^*Q_i & \frac{1}{2}M \\ \frac{1}{2}M^* & 0 \end{bmatrix} \begin{bmatrix} v \\ w \end{bmatrix} \right\rangle = \mathrm{Re}\langle v, Mw\rangle - \|Q_i v\|^2 \text{ for } i = n_w+1, \dots, n_w+n_z$$

on the space $\ell_2 \times \ell_2$. For convenience set $\Psi(w,v) = (\psi_1(w,v), \dots, \psi_{n_w+n_z}(w,v))$, and define the set

$$\nabla = \{\Psi(w,v) : \ w, v \in \ell_2 \text{ and } \|w\|^2 + \|v\|^2 = 1\} \subset \mathbb{R}^{n_w+n_z},$$

and the nonnegative orthant $\Pi = \{(a_1, \dots, a_{n_w+n_z}) : \text{each } a_i \geq 0\} \subset \mathbb{R}^{n_w+n_z}$.

LEMMA A.1. *The closure* $\bar{\nabla}$ *is strictly separated from* Π.

Proof. Choose $(w,v) \in \ell_2 \times \ell_2$ satisfying $\|w\|^2 + \|v\|^2 = 1$. It is sufficient to show that for some $1 \leq k_0 \leq n_w + n_z$ the inequality $\psi_{k_0}(w,v) \leq (\|M\|_{sq} - 1)(n_w + n_z)^{-1}$ holds.

Set $\alpha = \|M\|_{sq}$, and thus we have

$$\mathrm{Re}\langle v, Mw\rangle \leq \alpha \|v\|_{\mathcal{Z}_\infty} \|w\|_{\mathcal{W}_\infty}.$$

Now let $\gamma = \max\{\|v\|^2_{\mathcal{Z}_\infty}, \|w\|^2_{\mathcal{W}_\infty}\}$, and then conclude

$$\mathrm{Re}\langle v, Mw\rangle - \gamma \leq (\alpha - 1)\gamma.$$

By equivalence of norms we have that $\gamma \geq (n_w + n_z)^{-1}(\|w\|^2 + \|v\|^2) = (n_w + n_z)^{-1}$, and so

$$\mathrm{Re}\langle v, Mw\rangle - \gamma \leq (\alpha - 1)(n_w + n_z)^{-1}.$$

By definition of the $\mathcal{W}_\infty$- and $\mathcal{Z}_\infty$-norms, there exists $1 \leq k_0 \leq n_w + n_z$ such that the left-hand side above is equal to $\psi_{k_0}(w,v)$. ∎

LEMMA A.2. *The closure of the convex hull* $\mathrm{co}(\bar{\nabla})$ *is strictly separated from* Π.

Proof. We consider the cases (a) M is periodic and (b) $n_w \cdot n_z \leq 2$ separately.

The first case is where M is q-periodic, in which case we prove that the closure $\bar{\nabla} = \mathrm{co}(\bar{\nabla})$, and thus by Lemma A.1 the conclusion follows. The fact that $\bar{\nabla}$ is convex follows directly from the main result in [14] on shift invariant quadratic forms by simply replacing the shift operator with Z^q and will not be reproduced here; the basic facts required in the proof are that $\psi(v,w) = \psi(Z^{qk}v, Z^{qk}w)$ and that Z^{qk} tends weakly to zero as k tends to infinity. See [17] for a proof in the style of this appendix; see also [18].

When M is not periodic but $n_w \cdot n_z \leq 2$ holds, we have at most *three* quadratic forms ψ_k or, equivalently, $\nabla \subset \mathbb{R}^3$. In this case we can appeal to [10], which states exactly the claim of the lemma for any three quadratic forms on a complex inner product space. Note that this result is essentially equivalent to the well-known μ-theory result, which says that the structured singular value is equal to its upper bound for three full-block uncertainties; see [16]. ∎

LEMMA A.3. *There exist* 1*-admissible scales* T *and* S *such that*

$$\begin{bmatrix} -T & M \\ M^* & -S \end{bmatrix} < 0. \tag{A.1}$$

Proof. By the separating hyperplane theorem and Lemma A.2, there exist vectors $\sigma \in \mathbb{R}^{n_w}$, $\tau \in \mathbb{R}^{n_z}$ and scalars ϵ, β such that

$$\begin{bmatrix}\sigma\\ \tau\end{bmatrix}^* x < -\epsilon < \beta < \begin{bmatrix}\sigma\\ \tau\end{bmatrix}^* a \qquad \text{for all } x \in \mathrm{co}(\bar{\nabla}) \text{ and } a \in \Pi.$$

From the properties of Π it is routine to verify that $\sigma_i, \tau_i \geq 0$ and that $\epsilon > 0$. Now $\mathrm{co}(\bar{\nabla})$ is compact, and so without loss of generality we may assume the strict inequalities $\sigma_i, \tau_i > 0$ so that

$$\begin{bmatrix}\sigma\\ \tau\end{bmatrix}^* x < -\epsilon \text{ still holds for each } x \in \mathrm{co}(\bar{\nabla}).$$

Using the definition of ∇, we have, in particular, that

$$\begin{bmatrix}\sigma\\ \tau\end{bmatrix}^* \Psi(w,v) = \sum_{i=1}^{n_w} \sigma_i(\mathrm{Re}\langle v, Mw\rangle - \|P_i w\|^2) + \sum_{i=1}^{n_z} \tau_i(\mathrm{Re}\langle v, Mw\rangle - \|Q_i v\|^2) < -\epsilon$$

for all $(w,v) \in \ell_2 \times \ell_2$ satisfying $\|w\|^2 + \|v\|^2 = 1$. Defining $\gamma = \sum_{i=1}^{n_w} \sigma_i + \sum_{i=1}^{n_z} \tau_i$ and multiplying the inequality through by $2\gamma^{-1}$, we get

$$2\mathrm{Re}\langle v, Mw\rangle - 2\gamma^{-1} \sum_{i=1}^{n_w} \sigma_i \|P_i w\|^2 - 2\gamma^{-1} \sum_{i=1}^{n_z} \tau_i \|Q_i v\|^2 < -2\gamma^{-1}\epsilon.$$

By setting $S = 2\gamma^{-1} \sum_{i=1}^{n_w} \sigma_i P_i^* P_i$ and $T = 2\gamma^{-1} \sum_{i=1}^{n_z} \tau_i Q_i^* Q_i$ we can rewrite this as

$$\left\langle \begin{bmatrix}v\\ w\end{bmatrix}, \begin{bmatrix}-T & M\\ M^* & -S\end{bmatrix} \begin{bmatrix}v\\ w\end{bmatrix} \right\rangle < -2\gamma^{-1}\epsilon.$$

This holds for any $(w,v) \in \ell_2 \times \ell_2$ with the unit norm constraint $\|w\|^2 + \|v\|^2 = 1$; therefore, inequality (A.1) holds.

To complete the proof notice that $\sum_{i=1}^{n_w} s_i + \sum_{i=1}^{n_z} t_i = 2$, and we can therefore perturb $s_1 > 0$ slightly to get $\sum_{i=1}^{n_w} s_i + \sum_{i=1}^{n_z} t_i < 2$ while still maintaining inequality (A.1). ∎

Proof of Theorem 3.5. Invoke Lemma A.3, and apply the Schur complement formula to (A.1) to get

$$M^* T^{-1} M - S < 0,$$

which implies $S^{-\frac{1}{2}} M^* T^{-1} M S^{-\frac{1}{2}} - I < 0$. Clearly, this means $\|T^{-\frac{1}{2}} M S^{-\frac{1}{2}}\| < 1$, and from Lemma A.3 we have directly that T and S are 1-admissible. ∎

REMARK A.4. *So far we have proved only the theorem for the case of $n_w \cdot n_z \leq 2$. For the remaining case of $n_w \cdot n_z \leq 3$, the above argument can again be employed, using instead the quadratic forms*

$$\psi(w) = \|Mw\|^2 - \|P_i w\|^2 \text{ for } i = 1, \ldots, n_w \text{ when } n_z = 1,$$

and $\psi(v) = \|M^* v\|^2 - \|Q_i v\|^2$ for $i = 1, \ldots, n_z$ when $n_w = 1$.

REMARK A.5. *If we replace the space of $\ell_2(\mathbb{C}^n)$ in the formulation of this paper with the real space $\ell_2(\mathbb{R}^n)$, condition* (b) *in the statement of Theorem* 3.5 *must be weakened to to $n_w \cdot n_z \leq 2$. This is because the result of* [10] *used in the proof of Lemma* A.2 *holds only for quadratic forms on complex spaces; however, the work in* [21] *says that* $\mathrm{co}(\bar{\nabla})$ *is strictly separated from* Π *if there are at most two real forms. This will be the case when $n_w \cdot n_z \leq 2$ and the forms from Remark* A.4 *are used.*

ON AUTOMATON RECOGNIZABILITY OF ABNORMAL EXTREMALS*

UGO BOSCAIN† AND BENEDETTO PICCOLI‡

Abstract. For a generic single-input planar control system $\dot{x} = F(x) + uG(x)$, $x \in \mathbb{R}^2$, $u \in [-1, 1]$, $F(0) = 0$, we analyze the properties of abnormal extremals for the minimum time stabilization to the origin. We prove that abnormal extremals are finite concatenations of bang arcs with switchings occurring on the set in which the vector fields F and G are collinear. Moreover, all the generic singularities of one parametric family of extremal trajectories near to abnormal extremals are studied. In particular, we prove that all possible sequences of these singularities, and hence all generic abnormal extremals, can be classified by a set of words recognizable by an automaton.

Key words. optimal control, abnormal extremals, synthesis theory, generic planar systems

1. Introduction.

In this paper we deal with the minimum time stabilization problem to the origin for the planar single-input system $\dot{x} = F(x) + uG(x)$, $x \in \mathbb{R}^2$, $u \in [-1, 1]$, $F(0) = 0$. The Pontryagin maximum principle (PMP) [12, 19] provides a necessary condition for optimality, and trajectories satisfying it are called extremals. Abnormal extremals are extremals corresponding to the zero level of the Hamiltonian given by the PMP; see [1, 2].

The aim of this paper is to analyze completely the generic properties of abnormal extremals. We prove that these are finite concatenations of bang arcs (that is, corresponding to constant ± 1 control). Moreover, the switchings (discontinuity points of the control) happen exactly when the abnormal extremal crosses the set of zeros of the function $\Delta_A = F \wedge G$. In many cases, an abnormal extremal is formed by fold points; that is, there are two sheets of the cotangent bundle covered by extremal trajectories that project onto the same region of the plane, and the boundary of this region is the projection of the abnormal extremal.

The set of possible singularities along abnormal extremals is formed of 28 (equivalence classes of) singular points, but not all sequences of singularities can be realized. We aim to provide a classification of all possible sequences of singularities. A good classification is obtained if one can put the possible sequences in bijective correspondence with some algebraic or combinatorial object Ω with simple structure. If all possible sequences of singularities were admitted, then this classification could be done choosing Ω to be the set of all words formed with letters from the alphabet $\{1, \dots, 28\}$, with the meaning that each number corresponds to a singularity. This is not the case; however, we can still have some regular structure. More precisely, Ω can be chosen as a set of words recognizable by an automaton, and this is the most natural classification for this problem; see rules R1, R2, and R3 of section 5. We recall that a set of words Ω from a given finite alphabet is recognizable if there exists an automaton

that generates exactly the words of Ω. An automaton is, roughly speaking, a graph with labelled edges, and one constructs words considering all paths starting from a given set of points and ending to another fixed set of points. The recognizable sets of words share a regular structure used in theoretical computer science; see [10, 11]. Since the sequence of singularities completely describes the abnormal extremal, we obtain that abnormal extremals are recognizable by an automaton.

In [15, 16, 22, 23], the authors studied the properties of extremal trajectories and via a finite dimensional reduction, obtained using the PMP, proved the existence of a regular optimal synthesis. Roughly speaking, an optimal synthesis is a function associating to each point an optimal trajectory. It happens that the synthesis is indeed generated by a feedback that is smooth on each strata of a Whitney stratification of the plane. For synthesis theory we refer also to [3, 9, 18]. In a series of papers [7, 8, 16, 17], the existence of a structurally stable optimal synthesis for generic smooth systems was proved, and complete classifications of the corresponding (nonsmooth) flows and relative singularities were given, in the same spirit of the work of Peixoto for two dimensional dynamical systems. For results in three dimensions, see [20, 21].

An alternative approach is used here and in [4, 5, 13, 14]. This amounts to constructing all extremals, that is, trajectory-covector pairs satisfying the PMP, and projecting the obtained set onto the plane. This approach is more involved but sheds more light on the links between synthesis singularities and the singularities of the minimum time function; see [6]. Moreover, the supports of extremals form a Whitney stratified set of dimension three in the cotangent bundle (see [5]). After normalization of the covector, one obtains a two dimensional stratified set in $\mathbb{R}^2 \times S^1$. The projection singularities can be classified in topological sense. Beside the classical folds and cusps (see [24]), new singularities appear. Some, called vertical, are due to the fact that the target (the origin) is of codimension two, while others are stable and independent of the target properties. These new singularities are called bifold and ribbon. In particular, the ribbon singularity can appear only along abnormal extremals.

All possible generic singularities of the synthesis on the plane occurring along (projections of) abnormal extremals are classified in section 4. However, one has to prove that all singularities indeed appear for some generic system, in particular, those corresponding to the new projection singularities, namely, bifold and ribbon. As a byproduct, we obtain the existence of systems presenting singular points corresponding to projection singularities of bifold and ribbon type (see Theorem 35).

The paper is organized in the following way. Section 2 introduces basic definitions and main results. The third section is dedicated to formulating and proving the main propositions about the switching strategy of abnormal extremals. In section 4 we describe the synthesis singularities (on the plane) occurring along abnormal extremals. Finally, in section 5 we describe the classification of abnormal extremals via a recognizable set of words and the corresponding automaton. Moreover, in section 5 we show that the ribbon singularity is realized, and we give an example of a synthesis containing a singularity of this kind.

2. Basic definitions and statement of the main result. Let Ξ be the set of all couples of $\mathcal{C}^\infty$ vector fields (F, G) such that the origin is an equilibrium point for F, that is, $F(0) = 0$. From now on we endow Ξ with the $\mathcal{C}^3$ topology induced by the norm

$$\|(F,G)\| = \sup \left\{ \left| \frac{\partial^{\alpha_1+\alpha_2} F_i(x)}{\partial x_1^{\alpha_1} \partial x_2^{\alpha_2}} \right|, \left| \frac{\partial^{\alpha_1+\alpha_2} G_i(x)}{\partial x_1^{\alpha_1} \partial x_2^{\alpha_2}} \right| :
$$

$$x \in \mathbb{R}^2;\ i = 1, 2;\ \alpha_1, \alpha_2 \in \mathbf{N} \cup \{0\}; \alpha_1 + \alpha_2 \leq 3 \Big\}.$$

We say that a subset of Ξ is generic if it contains an open and dense set. Analogously, a property P is said to be generic if the set satisfying P is generic.

For every $(F, G) \in \Xi$ we consider the minimum time stabilization problem to the origin for the control system

$$\dot{x} = F(x) + uG(x), \qquad x \in \mathbb{R}^2, \quad u \in [-1, 1]. \tag{1}$$

Reversing time, we deal with the equivalent problem of reaching every point of the plane in minimum time from the origin.

Given a measurable function $u : [a, b] \to [-1, 1]$, a trajectory of (1) corresponding to u is an absolutely continuous map $\gamma : [a, b] \to \mathbb{R}^2$ such that $\dot{\gamma}(t) = F(\gamma(t)) + u(t)G(\gamma(t))$ for almost every $t \in [a, b]$. Since the system is autonomous, we can always assume that $Dom(\gamma) = [0, a]$ for some $a \in \mathbb{R}$, $a > 0$, where Dom denotes the domain. Moreover, we denote by $\mathrm{Supp}(\gamma)$ the set $\gamma([a, b])$. A trajectory $\gamma : [0, a] \to \mathbb{R}^2$ is (time) optimal if for every trajectory $\gamma' : [0, b] \to \mathbb{R}^2$ with $\gamma(a) = \gamma'(b)$ we have $a \leq b$. A trajectory γ corresponding to a constant control ± 1 is called a *bang arc*. A *bang-bang* trajectory is a finite concatenation of bang arcs, and a time where the control changes sign is called *switching time*.

The well-known PMP in this special case states the following. Define for every $(x, p, u) \in \mathbb{R}^2 \times (\mathbb{R}^2)_* \times [-1, 1]$, where $(\mathbb{R}^2)_*$ is the set of row vectors,

$$\mathcal{H}(x, p, u) = p \cdot F(x) + u\, p \cdot G(x) \tag{2}$$

and

$$H(x, p) = \max\{p \cdot F(x) + u\, p \cdot G(x) : u \in [-1, 1]\}. \tag{3}$$

If $\gamma : [0, a] \to \mathbb{R}^2$ is a (time) optimal trajectory corresponding to a control $u : [0, a] \to [-1, 1]$, then there exist a nontrivial *field of covectors along* γ, that is, a function $\lambda : [0, a] \to (\mathbb{R}^2)_*$ never vanishing, and a constant $\lambda_0 \leq 0$ such that

(i) $\dot{\lambda}(t) = -\lambda(t) \cdot (\nabla F + u(t)\nabla G)(\gamma(t))$,
(ii) $\mathcal{H}(\gamma(t), \lambda(t), u(t)) + \lambda_0 = 0$ for almost every $t \in Dom(\gamma)$,
(iii) $\mathcal{H}(\gamma(t), \lambda(t), u(t)) = H(\gamma(t), \lambda(t))$ for almost every $t \in Dom(\gamma)$.

In this case we say that the pair (γ, λ) is extremal. If γ is optimal, we say that the pair (γ, λ) is optimal.

Given an extremal pair (γ, λ), one easily checks that for every $\alpha \in \mathbb{R}$, $\alpha > 0$, the pair $(\gamma, \alpha\lambda)$ is also extremal.

Definition 1. *Let (γ, λ) be an extremal pair. If the corresponding Hamiltonian satisfies $\mathcal{H}(\gamma(t), \lambda(t), u(t)) = 0$ for almost every $t \in Dom(\gamma)$ (i.e., if λ_0 in* (i) *above vanishes), we say that (γ, λ) is an abnormal extremal.*

The following theorem, proved in section 5, describes the set of generic abnormal extremals.

Theorem 2. *The set of abnormal extremals for control systems* (1)*, in a generic set of Ξ, can be classified through a set of words recognizable by an automaton.*

In the following we introduce some notation also used in [7, 16, 17]. Set

$$Y = F + G, \qquad X = F - G.$$

Let $\gamma : [t_1, t_2] \to \mathbb{R}^2$ be a trajectory of (1). If γ corresponds to constant control $+1$ (resp., -1) on $[t_1, t_2]$, we say that $\gamma|_{[t_1,t_2]}$ is a Y-trajectory (resp., X-trajectory), and we write $\gamma|_{[t_1,t_2]} \in \text{Traj}(Y)$ (resp., $\gamma|_{[t_1,t_2]} \in \text{Traj}(X)$). We say that $\gamma|_{[t_1,t_2]}$ is a Z-trajectory, and we write $\gamma|_{[t_1,t_2]} \in \text{Traj}(Z)$ if γ on $[t_1, t_2]$ corresponds to the control (called singular)

$$\varphi(x) = -\frac{\nabla \Delta_B(x) \cdot F(x)}{\nabla \Delta_B(x) \cdot G(x)}, \tag{4}$$

where

$$\Delta_B(x) = G(x) \wedge [F, G](x) = G_1(x)[F, G]_2(x) - G_2(x)[F, G]_1(x),$$

and $[F, G]$ is the Lie bracket of F and G. For later use we also define the function

$$\Delta_A(x) = F(x) \wedge G(x) = F_1(x)G_2(x) - F_2(x)G_1(x).$$

DEFINITION 3. *If $\gamma_1 : [t_1, t_2] \to \mathbb{R}^2$, $\gamma_2 : [t_2, t_3] \to \mathbb{R}^2$ $(t_1 < t_2 < t_3)$ are two trajectories of* (1) *with $\gamma_1(t_2) = \gamma_2(t_2)$, we set $(\gamma_2 * \gamma_1)(t) := \gamma_1(t)$ if $t \in [t_1, t_2[$ and $(\gamma_2 * \gamma_1)(t) := \gamma_2(t)$ if $t \in [t_2, t_3]$. Given an extremal trajectory γ, we denote by $n(\gamma)$ the smallest integer such that there exist $\gamma_i \in$ Traj(X)$\cup$Traj(Y) $\cup$Traj(Z), $i = 1, \dots, n(\gamma)$, satisfying $\gamma = \gamma_{n(\gamma)} * \cdots * \gamma_1$. The function $n(\gamma)$ is called the* number of arcs *of γ.*

In the following, we assume the following generic conditions:

(P1) The vectors $G(0)$ and $[F, G](0)$ are linearly independent.

(P2) Zero is a regular value for Δ_A and Δ_B.

(P3) The set $\Delta_A^{-1}(0) \cap \Delta_B^{-1}(0)$ is locally finite.

Let Tan_A be the set of points $x \in \Delta_A^{-1}(0)$ such that $X(x)$ or $Y(x)$ is tangent to $\Delta_A^{-1}(0)$. Define Tan_B in the same way using Δ_B rather than Δ_A.

(P4) Tan_A and Tan_B are locally finite sets.

Let $Bad := (\Delta_A^{-1}(0) \cap \Delta_B^{-1}(0)) \cup \text{Tan}_A \cup \text{Tan}_B$.

(P5) Bad is locally finite.

Notice that (P5) is a consequence of (P3) and (P4).

(P6) If $x \in Bad$ and $G(x) = 0$, then $F(x) \cdot \nabla(\Delta_A)(x) \neq 0$ and $F(x) \cdot \nabla(\Delta_B)(x) \neq 0$.

(P7) If $x \in Bad$, $G(x) \neq 0$, $x \in (\Delta_A^{-1}(0) \cap \Delta_B^{-1}(0)) \cap \text{Tan}_A$, and say, $X(x) \cdot \nabla \Delta_A(x) = 0$, then $\partial_y (X \cdot \nabla \Delta_A)|_{y=x} \neq 0$, $X(y) \neq 0$, and $Y(y) \neq 0$, where y takes values on $\Delta_A^{-1}(0)$ in a neighborhood of x.

(P8) If $x \in Bad$ and $x \in \text{Tan}_B$, then $\Delta_A(x) \neq 0$.

(P9) If $x \in Bad$, $G(x) \neq 0$, $X(x) = 0$, or $Y(x) = 0$, then $\Delta_B(x) \neq 0$.

The generic conditions (P6), (P7), and (P8) are clarified in Figure 2.1.

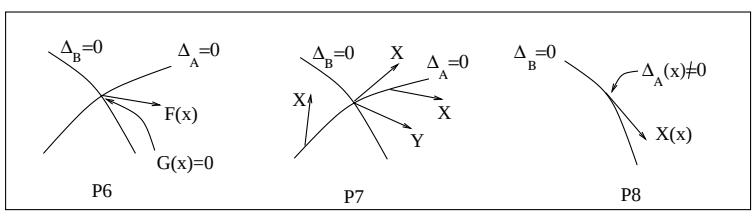

FIG. 2.1.

In [16] the following proposition was proved.

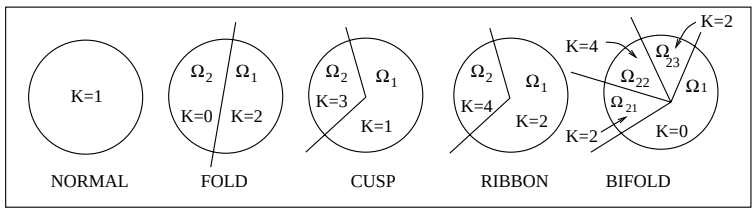

FIG. 2.2.

PROPOSITION 4. *If* (P1)–(P9) *hold, then each extremal trajectory* γ *can always be written in the form* $\gamma = \gamma_{n(\gamma)} * \cdots * \gamma_1$ *with* $n(\gamma) < \infty$*, and each arc is bang or singular (that is, a* Z*–trajectory).*

Let $\tau > 0$. We call the *reachable set* within time τ the set $\mathcal{R}(\tau) := \{x \in \mathbb{R}^2 :$ there exists $t \in [0,\tau]$ and a trajectory $\gamma : [0,\tau] \to \mathbb{R}^2$ of (1) such that $\gamma(0) = 0$, $\gamma(t) = x\}$. In [16] the following lemma was shown.

LEMMA 5. *Under the generic conditions* (P1)–(P9) $\gamma_i \in$ *Traj(Z) iff* $\mathrm{Supp}(\gamma_i) \subset \Delta_B^{-1}(0)$.

In the case in which $\gamma_i \in \mathrm{Traj}(Z)$ we say that $\mathrm{Supp}(\gamma_i)$ is a *turnpike*. We call $\gamma^{\pm} : [0, t_f^{\pm}] \to \mathbb{R}^2$ the extremal trajectories originating at 0 and corresponding to constant control ± 1 with $t_f^{\pm}$ the last times in which $\gamma^{\pm}$ are extremal (if they are less than τ) or τ (otherwise). Under generic assumptions, every extremal trajectory exits the origin with constant control $+1$ or -1.

DEFINITION 6. *Let* $(\gamma, \lambda) : [0,\tau] \to \mathbb{R}^2$ *be an extremal pair. The corresponding switching function is defined as* $\phi(t) := \lambda(t) \cdot G(\gamma(t))$.

We immediately have the following lemma.

LEMMA 7. *Let* $(\gamma, \lambda) : [0,\tau] \to \mathbb{R}^2$ *be an extremal pair, and* $[t_1, t_2] \subseteq [0,\tau]$ $(t_1 < t_2)$*. Then*

- *on* $[t_1, t_2]$, γ *corresponds to constant control* $+1$ *(resp.,* -1*) iff for each* $t \in [t_1, t_2]$ *we have* $\phi(t) \geq 0$ *(resp.,* $\phi(t) \leq 0$*) and meas*$(\{t \in [t_1, t_2] : \phi(t) = 0\}) = 0$*;*
- *on* $[t_1, t_2]$, γ *corresponds to the singular control* φ *(defined in* (4)*) iff for each* $t \in [t_1, t_2]$ *we have* $\phi(t) = 0$.

In [22] the following lemma was proved.

LEMMA 8. *Let* γ *be an extremal trajectory and* $\bar{t} \in Dom(\gamma)$ *a switching time. Let* $\bar{x} = \gamma(\bar{t})$*, and suppose that* $\bar{x} \notin \Delta_A^{-1}(0) \cup \Delta_B^{-1}(0)$*. Then* $\bar{t}$ *is a switching time from* X *to* Y *iff* $-\Delta_A(\bar{x})/\Delta_B(\bar{x}) > 0$*, and* $\bar{t}$ *is a switching time from* Y *to* X *iff* $-\Delta_A(\bar{x})/\Delta_B(\bar{x}) < 0$.

We now introduce some definitions to describe the projection singularities we encounter along abnormal extremals. Fix $\bar{x} \in \mathcal{R}(\tau)$ and an extremal trajectory $\bar{\gamma} : [0, \bar{a}] \to \mathcal{R}(\tau)$ such that $\bar{\gamma}(0) = 0$, $\bar{\gamma}(\bar{a}) = \bar{x}$, and define the function

$$K_\varepsilon^{\bar{x},\bar{\gamma}}(x) := \sharp\{\text{extremal trajectory } \gamma : \ \gamma(0) = 0,\ \gamma(a) = x,\ |\gamma(t) - \bar{\gamma}(t)| < \varepsilon \quad \forall\, t \in [0, \min(a,\bar{a})],\ |a - \bar{a}| < \varepsilon\}, \tag{5}$$

where $\sharp$ denotes the cardinality of a set. Referring to Figure 2.2, we introduce the following key definition.

DEFINITION 9. *Fix* $\bar{x} \in \mathcal{R}(\tau)$ *and an extremal trajectory* $\bar{\gamma} : [0, \bar{a}] \to \mathcal{R}(\tau)$ *such that* $\bar{\gamma}(0) = 0$ *and* $\bar{\gamma}(\bar{a}) = \bar{x}$.

- *We say that $\bar{x}$ is a* normal *point along $\bar{\gamma}$ if for ε sufficiently small there exists a neighborhood U of $\bar{x}$ such that $K_\varepsilon^{\bar{x},\bar{\gamma}}(U) = 1$.*
- *We say that $\bar{x}$ is a* fold *point along $\bar{\gamma}$ if there exists a one dimensional piecewise–$\mathcal{C}^1$ manifold l, with $\bar{x} \in l$, satisfying the following. For ε sufficiently small there exists a neighborhood U of $\bar{x}$ divided by l into two connected components Ω_1, Ω_2 such that $K_\varepsilon^{\bar{x},\bar{\gamma}}(\Omega_1) = 2$, $K_\varepsilon^{\bar{x},\bar{\gamma}}(\Omega_2) = 0$, $K_\varepsilon^{\bar{x},\bar{\gamma}}(l) = 1$.*
- *If l, $U(\varepsilon)$, Ω_1, Ω_2 are as above, then if $K_\varepsilon^{\bar{x},\bar{\gamma}}(\Omega_1) = 1$, $K_\varepsilon^{\bar{x},\bar{\gamma}}(\Omega_2) = 3$, and $K_\varepsilon^{\bar{x},\bar{\gamma}}(l) = 2$, we say that $\bar{x}$ is a* cusp point *along $\bar{\gamma}$.*
- *If l, $U(\varepsilon)$, Ω_1, Ω_2 are as above, then if $K_\varepsilon^{\bar{x},\bar{\gamma}}(\Omega_1) = 2$, $K_\varepsilon^{\bar{x},\bar{\gamma}}(\Omega_2) = 4$, and $K_\varepsilon^{\bar{x},\bar{\gamma}}(l) = 3$, we say that $\bar{x}$ is a* ribbon point *along $\bar{\gamma}$.*
- *We say that $\bar{x}$ is a* bifold point *along $\bar{\gamma}$ if there exists a one dimensional connected piecewise $\mathcal{C}^1$ embedded manifold l and two connected $\mathcal{C}^1$ embedded manifolds l_1 and l_2 satisfying the following.*
  1. *$l \cap \partial l_i = \{\bar{x}\}$ $(i = 1, 2)$; $\partial l_1 \cap \partial l_2 = \{\bar{x}\}$.*
  2. *For ε sufficiently small there exists a neighborhood U of x satisfying the following. The set $U \setminus l$ has two connected components Ω_1, Ω_2, and the set $\Omega_2 \setminus \{l_1 \cup l_2\}$ has three connected components Ω_{21}, Ω_{22}, and Ω_{23} (the names are chosen as in Figure 2.2) such that $K_\varepsilon^{\bar{x},\bar{\gamma}}(\Omega_1) = 0$, $K_\varepsilon^{\bar{x},\bar{\gamma}}(\Omega_{21}) = 2$, $K_\varepsilon^{\bar{x},\bar{\gamma}}(\Omega_{22}) = 4$, $K_\varepsilon^{\bar{x},\bar{\gamma}}(\Omega_{23}) = 2$, $K_\varepsilon^{\bar{x},\bar{\gamma}}(l) = 1$, and $K_\varepsilon^{\bar{x},\bar{\gamma}}(l_i) = 3$ $(i = 1, 2)$.*

Notice that this definition describes projection singularities. Indeed, the trajectories reaching the same point in the plane correspond to different lifts in the cotangent bundle.

Our aim is to prove that these are the only projection singularities that may happen along abnormal extremals and show that they are in fact realized for some control systems.

The behavior of abnormal extremals is individuated by the singularities it meets. To describe all possible singularities, we start describing those encountered in the optimal case. In [7, 16, 17], dealing with the optimal synthesis, it was proved that $\mathcal{R}(\tau)$ is a stratified subset of $\mathbb{R}^2$, and the one and zero dimensional strata that are singularities of the optimal flow are called, respectively, *frame curves* and *frame points* (FCs and FPs). Moreover, the authors use the letters X, Y, C, S, and K to indicate, respectively, the FCs corresponding to subsets of $\mathrm{Supp}(\gamma^+)$, subsets of $\mathrm{Supp}(\gamma^-)$, curves made of switching points (switching curves, see Figure 2.3 case 1), turnpikes and overlaps, that is, curves made of points reached optimally by two distinct trajectories. In [17], it was proved that these are generically all possible FCs. An FP x that is the intersection of two FCs F_1 and F_2 is called an (F_1, F_2) FP. Considering the extremal trajectories instead of the optimal ones, we do not have any K FC, but we have the following new FCs:

- an FC called $\bar{C}$ made of switching points on which X and Y point to opposite sides (see Figure 2.3, case 2);
- an FC called W that is an arc of an extremal trajectory characterized by the fact that all its points are fold points (see Figure 2.3, case 3).
- an FC called γ_0 that is an arc of an extremal trajectory that "transports" some special information, e.g., it switches every time it meets the locus $\Delta_A^{-1}(0)$, or it evolves into a W FC.

More details on the FCs W and γ^0 are given below.

To understand in detail the structure of abnormal extremals, we describe the set of all extremals, that is organized in one parameter families, called strips. Let Γ be

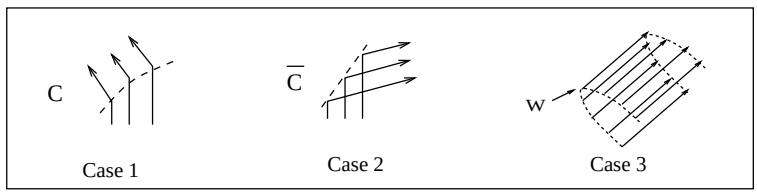

FIG. 2.3. *The FCs C, $\bar{C}$, W.*

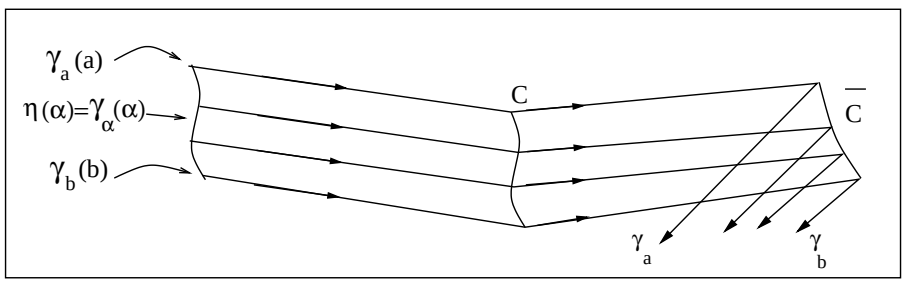

FIG. 2.4. *Strip.*

the set of all the extremal trajectories for the control problem (1) up to time $\tau > 0$. Again, under generic assumptions, extremals are finite concatenations of bang and singular arcs, so Γ can be obtained by a constructive algorithm that makes inductive steps on the number of arcs of extremal trajectories. We outline such an algorithm, described in detail in [5].

Outline of the algorithm. First, one constructs all the extremal trajectories in a neighborhood of $\gamma^{\pm}$. Then the set of extremal trajectories is subdivided into "strips." Each strip is a one dimensional continuous parametric family of extremal bang-bang trajectories having the same switching strategy. The evolution of each strip must be studied. In order to do that, the evolution of the boundary of strips must be analyzed separately. The more delicate case is that of abnormal extremals that here we treat in detail. The evolution of the interior of a strip may create new strips and cause the subdivision of each strip into smaller strips. This case is treated in [5], where the whole construction is completed.

Let us give the precise definition of strip.

DEFINITION 10. *Let a, b be two real numbers s.t. $0 \le a < b \le \tau$ and $x \in \mathcal{R}(\tau)$. A set of trajectories $\mathcal{S}^{a,b,x} = \{\gamma_\alpha : \ \alpha \in [a,b],\ \gamma_a(a) = x\}$ is called a strip if*

(i) $\forall\ \alpha \in [a,b],\ \ \gamma_\alpha : [0, \tau(\alpha)] \to \mathbb{R}^2$, *$\tau(\alpha) > \alpha$ is an extremal trajectory for the control problem* (1). *Moreover, there exists $\varepsilon > 0$ s.t. $\gamma_{[\alpha,\alpha+\varepsilon]}$ corresponds to a constant control ± 1;*

(ii) $\forall\ \alpha \in]a,b[,\ \ \gamma_\alpha$ *does not switch on $\Delta_A^{-1}(0) \cup \Delta_B^{-1}(0)$ after time α;*

(iii) *the set $\mathcal{B}^{a,b,x} = \{y \in \mathcal{R}(\tau) : \ \exists\ \alpha \in\ ]a,b[$ and $t \in]\alpha, \tau(\alpha)[$ s.t. $y = \gamma_\alpha(t)$, t is a switching time for $\gamma_\alpha\}$ is never tangent to X or Y.*

(iv) *the map $\eta : \ \alpha \in\ [a,b] \mapsto \gamma_\alpha(\alpha) \in \mathbb{R}^2$ is a bang or singular arc and $\gamma_\alpha|_{[0,\alpha']} = \gamma_{\alpha'}|_{[0,\alpha']}$ if $a \le \alpha' \le \alpha \le b$.*

The function $\eta : [a,b] \to \mathbb{R}^2$ is called the *base* of the strip, $\overset{\circ}{\mathcal{S}}{}^{a,b,x} := \{\gamma_\alpha : \ \alpha \in]a,b[\}$ is called an open strip, and $\partial\mathcal{S}^{a,b,x} := \{\gamma_a,\ \gamma_b\}$ is called the *strip border.* See Figure 2.4 for a graphical description of a strip.

Notice that in [7, 16] a similar algorithm was used to construct the optimal synthesis that can be organized as a finite collection of optimal strips. Also in this case the algorithm constructs Γ as a finite union of strips. The set of borders of strips is called $\partial\Gamma$. We clearly have the following lemma.

LEMMA 11. *Under generic assumptions, $\partial\Gamma$ is a finite set.*

Moreover, by construction, every border belongs to two different strips, and adjacent strips correspond locally to the same control. More precisely, the following lemma holds.

LEMMA 12. *Let $\gamma \in \partial\Gamma$, let $\mathcal{S}^1$ and $\mathcal{S}^2$ be the two strips such that $\{\gamma\} = \mathcal{S}^1 \cap \mathcal{S}^2$, and let $\bar{t}$ be a switching time for γ. Then the switching loci of $\mathcal{S}^1$ and $\mathcal{S}^2$, passing through $\gamma(\bar{t})$, correspond both to switchings from X to Y or both to switchings from Y to X.*

The algorithm produces the FCs in the following way:

- the FCs of kinds C and $\bar{C}$ lie in the interior of the strips;
- the borders of strips contain FCs of kinds W, γ^0, X, Y;
- the bases of strips contain FCs of kinds X, Y, S.

In fact, the FCs of kinds γ^0 and W are borders of strips, i.e., as follows.

DEFINITION 13. *Let $\gamma \in \partial\Gamma$, and suppose that it corresponds to a constant control in the interval $]b, c[$ $(0 < b < c \leq \tau)$.*

- *We say that in $]b, c[$ γ is a strip border of kind W if, for every $t \in\ ]b, c[$, $x := \gamma(t)$ is a fold point.*
- *Vice versa if, for every $t \in\ ]b, c[$ $\gamma(t)$ is a normal point, we say that in $]b, c[$ γ is a strip border of kind γ_0.*

By construction, we have the following lemma.

LEMMA 14. *If $\gamma \in \partial\Gamma$ and γ is of kind W in $]a, b[$ and of kind γ_0 in $]b, c[$ $(0 \leq a < b < c \leq \tau)$ or vice versa, then b is a switching time for γ.*

In the next section we see that in the case of abnormal extremals we need a more precise definition for FCs of kind W.

Given an extremal trajectory γ, let us define $v^\gamma(v_0, t_0; t)$ to be the solution to the Cauchy problem

$$\begin{cases} \dot{v^\gamma}(v_0, t_0; t) &= (\nabla F + u(t)\nabla G)(\gamma(t)) \cdot v^\gamma(v_0, t_0; t), \\ v^\gamma(v_0, t_0; t_0) &= v_0, \end{cases} \tag{6}$$

where $u(t)$ is the control corresponding to γ. In [16], denoting $\bar{v}^\gamma(t) := v^\gamma(G(\gamma(t)), t; 0)$, the following function was defined:

$$\theta^\gamma :\ Dom(\gamma) \to\ [-\pi, \pi], \quad \theta^\gamma(t) := \arg(\bar{v}^\gamma(0), \bar{v}^\gamma(t)), \tag{7}$$

where arg is the angle measured counterclockwise. We have the following.

LEMMA 15. *For fixed t_0, t, the map $f_{t_0,t} : v_0 \mapsto v^\gamma(v_0, t_0; t)$ is linear and injective. Moreover, let $\gamma : [a, b] \to \mathbb{R}^2$ be an extremal trajectory of (1) corresponding to a constant control $\bar{u}$. Then for every $t, t_0 \in [a, b]$ it holds that $v^\gamma((F+\bar{u}G)(\gamma(t_0)), t_0; t) = (F + \bar{u}G)(\gamma(t))$.*

In the following we use the notation $\theta^\pm(t) := \theta^{\gamma^\pm}(t)$ and $v^\pm := v^{\gamma^\pm}$. From Lemma 15 we have, for every $t \in [0, t_f^\pm]$, $v^\pm((F \pm G)(\gamma^\pm(t)), t; 0) = (F \pm G)(0) = \pm G(0)$. We consider the following generic conditions:

(GC1) For every $t \in [0, t_f^+]$, $G(\gamma^+(t)) \neq 0$.

(GC2) $\dot{\theta}^+(0) \neq 0$, $\dot{\theta}^+(t_f^+) \neq 0$.

(GC3) If $\dot{\theta}^+(t) = 0$, then $\theta^+(t) \neq 0$, $\ddot{\theta}^+(t) \neq 0$.

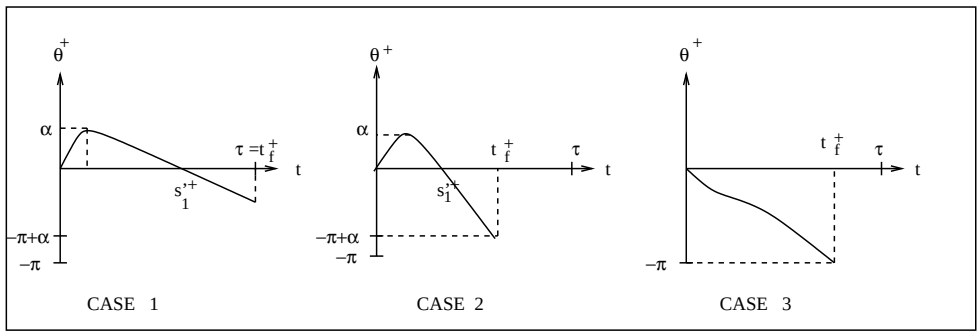

FIG. 2.5.

(GC4) If $t \neq s$ and $\dot\theta^+(s) = \dot\theta^+(t) = 0$, then $\theta^+(s) \neq \theta^+(t)$.
(GC5) If $t_f^+ = \tau$, then $\max\{|\theta^+(t) - \theta^+(\tau)|, \quad t \in [0,\tau]\} < \pi$.
In [7, 16] the following lemma was shown.

LEMMA 16. *We have the following:*

(A) $t_f^+ = \begin{cases} \tau \text{ if } |\theta^+(a) - \theta^+(b)| < \pi \quad \forall \quad a,\ b \in [0,\tau], \\ \min\{t \in [0,\tau] : \quad |\theta^+(a) - \theta^+(b)| = \pi \text{ for some } a,\ b \in [0,t]\} \text{ otherwise}; \end{cases}$

(B) *let γ be an extremal trajectory; then for almost every $t \in Dom(\gamma)$ we have $sgn(\dot\theta^\gamma(t)) = sgn(\Delta_B(\gamma(t))$;*
(C) *let γ be an extremal trajectory; then for each $t \in Dom(\gamma)$ the conditions $\phi(t) = \lambda(t) \cdot G(\gamma(t)) = 0, \quad \dot\theta^\gamma(t) \neq 0$ imply that t is a switching time for γ.*

We single out the following times:

$$s_1^+ := \min\{t \in]0, t_f^+] : \quad \theta^+(t) = 0, \dot\theta^+(0) < 0\},$$
$$s_1'^+ := \min\{t \in]0, t_f^+] : \quad \theta^+(t) = 0, \dot\theta^+(0) > 0\}.$$

The times s_1^-, $s_1'^-$ were defined similarly. From now on we assume the generic condition

(GAτ) (i) $\tau \notin \{s_i^\pm, s_i'^\pm\}$.
(ii) Let (γ, λ) be an extremal pairs. Then $\phi(\tau) = \lambda(\tau) \cdot G(\gamma(\tau)) = 0$ implies $\gamma(\tau) \notin \Delta_A^{-1}(0)$.

Observation 1. We can have three situations (cfr. Figure 2.5).
(1) $|\theta^\pm(a) - \theta^\pm(b)| < \pi$ for every $a, b \in [0,\tau]$. In this case $t_f^\pm = \tau$ and $|\theta^\pm(t_f^\pm)| < \pi$.
(2) $|\theta^\pm(a) - \theta^\pm(b)| = \pi$ for some $a, b \in]0,\tau]$. In this case, $|\theta^\pm(t_f^\pm)| < \pi$, $\theta^\pm$ has a maximum or a minimum in $]0, t_f^\pm[$, and either $s_1^\pm \neq 0$ or $s_1'^\pm \neq 0$.
(3) $|\theta^\pm(t_f^\pm)| = \pi$. In this case, $s_1^\pm$ and $s_1'^\pm$ are not defined, and generically we get $t_f^\pm < \tau$.

3. Generic properties of abnormal extremals. In this section we state and prove the main results about the switching strategies of abnormal extremals.

DEFINITION 17. *Let $\gamma : [0,\tau] \to \mathbb{R}^2$ be (the first component of) an abnormal extremal for the control problem* (1) *such that it switches at least one time, and let t_1 be its first switching time. We refer to the couples (γ, t_1) as nontrivial abnormal extremal (NTAE). By definition an NTAE is maximal if defined on $[0,\tau]$.*

DEFINITION 18. *Let $\gamma : [0,\tau] \to \mathbb{R}^2$ be an NTAE, and let $t_1 < t_2 < \cdots < t_{n(\gamma)-1} < t_{n(\gamma)} := \tau$ be the sequence of switching times. We set $AA(i) = \mathrm{Supp}\left(\gamma|_{[t_i,t_{i+1}]}\right)$ $(i = 1,\cdots,n(\gamma)-1)$, and we call it an* abnormal arc.

PROPOSITION 19. *Let $\gamma : [0,\tau] \to \mathbb{R}^2$ be an extremal trajectory for the control problem* (1) *such that it switches at least one time, let $\lambda : [0,\tau] \to \mathbb{R}_2$ be the corresponding covector, and let $t_1 < t_2 < \cdots < t_{n(\gamma)-1} < t_{n(\gamma)} := \tau$ be the sequence of switching times. Then the following hold:*

(A) *$\lambda(.)$ is unique (up to the multiplication by a positive constant);*

(B) *under generic assumptions the following conditions are equivalent:*

(a) *(γ, t_1) is an NTAE;*

(b) *$\gamma(t_i) \in \Delta_A^{-1}(0)$ for some $i \in \{1,\dots,n(\gamma)-1\}$;*

(c) *$\gamma(t_i) \in \Delta_A^{-1}(0)$ for each $i \in \{1,\dots,n(\gamma)-1\}$;*

(d) *$\gamma(\bar t) \in \Delta_A^{-1}(0)$ $(\bar t \in Dom(\gamma))$ iff $\bar t = t_i$ for some $i \in \{1,\dots n(\gamma)-1\}$;*

(C) *under generic assumptions,* (a) *(or, equivalently,* (b) *or* (c) *or* (d)*) implies that for every interval $[a,b] \subset [0,\tau]$ $(a < b)$, γ does not correspond to the singular control φ.*

Proof. (A) The covector associated to an extremal trajectory is completely determined after the first switching. From $n(\gamma) \geq 2$ it follows that $\lambda(.)$ is unique up to a positive constant.

Proof that (a) *implies* (c). Let (γ,λ) be an abnormal extremal such that $n(\gamma) \geq 2$. For each t_i $(i = 1,\dots,n(\gamma)-1)$ we have $\lambda(t_i)\cdot G(\gamma(t_i)) = 0$, and there exists a sequence $t'_m \nearrow t_i$ such that

$$\mathcal{H}(\gamma(t'_m),\lambda(t'_m),u(t'_m)) = \lambda(t'_m)\cdot(F + u(t'_m)G)(\gamma(t'_m)) = 0.$$

Hence $\lambda(t'_m)\cdot F(\gamma(t'_m)) \to 0$, and $\lambda(t_i)\cdot F(\gamma(t_i)) = 0$. We can conclude that $F(\gamma(t_i))$ and $G(\gamma(t_i))$ are parallel, $\lambda(t_i)$ being not equal to 0. (c) follows.

Proof of (C). From (P3), $\Delta_A^{-1}(0) \cap \Delta_B^{-1}(0) \cap \mathcal{R}(\tau)$ is a finite set. Generically γ does not switch on $\Delta_A^{-1}(0) \cap \Delta_B^{-1}(0)$ Using Lemma 5, we conclude.

Proof that (b) *implies* (a). Assume now that $\Delta_A(\gamma(t_i)) = 0$ for some $i \in \{1,\dots,n(\gamma)-1\}$. We have $\lambda(t_i)\cdot G(\gamma(t_i)) = 0$, and from $\Delta_A(\gamma(t_i)) = 0$ we get $\lambda(t_i)\cdot F(\gamma(t_i)) = 0$. There exists a sequence $t'_m \nearrow t_i$ such that

$$\mathcal{H}(\gamma(t'_m),\lambda(t'_m),u(t'_m)) = \lambda(t'_m)\cdot(F + u(t'_m)G)(\gamma(t'_m)) \to 0.$$

From the PMP we know that $\mathcal{H}$ is almost everywhere equal to a fixed constant in $Dom(\gamma)$; hence we can conclude $\mathcal{H}(\gamma(t),\lambda(t),u(t)) = 0$ almost everywhere.

Proof that (a) *implies* (d). Fix $\bar t$ such that $\gamma(\bar t) \in \Delta_A^{-1}(0)$. We have $F(\gamma(\bar t)) = \beta G(\gamma(\bar t))$ (by genericity we may assume $\beta \neq 0, \pm 1$), and there exists a sequence $t'_m \nearrow \bar t$ such that $|u(t'_m)| = 1$ and

$$\mathcal{H}(\gamma(t'_m),\lambda(t'_m),u(t'_m)) = \lambda(t'_m)\cdot(F + u(t'_m)G)(\gamma(t'_m)) = 0.$$

Hence $(1 + u(t'_m)\beta)\lambda(t'_m)\cdot G(t'_m) \to 0$ and, being that $\lim_{m\to\infty} u(t'_m) = \pm 1$, we have $\lambda(\bar t)\cdot G(\bar t) = 0$. From (C), $\Delta_B(\gamma(\bar t)) \neq 0$; thus $\dot\theta^\gamma(\bar t) \neq 0$, and $\bar t$ is a switching time (see Lemma 16). Vice versa, since (a) implies (c), we get that $\Delta_A(\gamma(t_i)) = 0$ for each i. Thus we are done.

The implications (c)⇒(b), (d)⇒(b) are obvious. This concludes the proof. ∎

We have the following lemma.

LEMMA 20. *Let (γ, t_1) be an NTAE; then $\gamma \in \partial\Gamma$.*

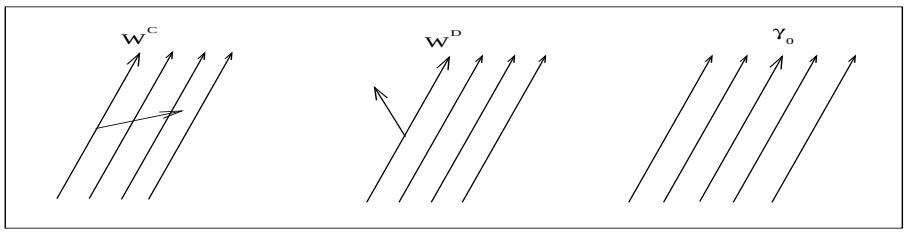

FIG. 3.1. *The abnormal extremals of type W^C, W^D, and γ_0.*

Proof. Let (γ, t_1) be an NTAE. From Proposition 19, $\gamma(t_1) \in \Delta_A^{-1}(0)$. Hence condition (ii) of Definition 10 is violated, so γ cannot be in the interior of a strip. ∎

Then it is natural to define $\partial\Gamma_A = \{\gamma \in \partial\Gamma,\ \gamma \text{ is an abnormal extremal}\}$.

DEFINITION 21. *Let $x \in \Delta_A^{-1}(0)$ be a switching point for an NTAE; then clearly $X(x) \neq 0$, $Y(x) \neq 0$, and $(F+G)(x) = \alpha(F-G)(x)$ for some $\alpha \neq 0$. If $\alpha > 0$ (resp., $\alpha < 0$), we say that* at *x, $\Delta_A^{-1}(0)$* is direct *(resp.,* inverse*).*

From Lemma 20 it follows that any $AA(i)$ is a strip border of kind γ_0 or W, but for abnormal extremals a more precise definition for the strip borders of kind W is necessary.

DEFINITION 22. *We refer to Figure* 3.1. *Let $\gamma \in \partial\Gamma_A$, and suppose that it corresponds to a constant control (say, $+1$) in the interval $]b, c[$ $(0 < b < c \leq \tau)$. Let $\mathcal{S}^1$ and $\mathcal{S}^2$ be the two strips such that $\{\gamma\} = \mathcal{S}^1 \cap \mathcal{S}^2$, and suppose that in the interval $]b, c[$ γ is a strip border of kind W.*

- *We say that in $]b, c[$ γ is a strip border of kind W^C if $\mathcal{S}^1$ and $\mathcal{S}^2$ both lie on the right (resp., on the left) of $\gamma|_{]b,c[}$ and X points to the right (resp., to the left) of $\gamma|_{]b,c[}$ at every point of* $\mathrm{Supp}(\gamma|_{]b,c[})$.
- *We say that in $]b, c[$ γ is a strip border of kind W^D if $\mathcal{S}^1$ and $\mathcal{S}^2$ both lie on the right (resp., on the left) of $\gamma|_{]b,c[}$ and X points to the left (resp., to the right) of $\gamma|_{]b,c[}$ at every points of* $\mathrm{Supp}(\gamma|_{]b,c[})$.

From Proposition 19 we have the following.

LEMMA 23. *Let $A_1, A_2 \in \{W^C, W^D, \gamma_0\}$ and $\gamma \in \partial\Gamma_A$. If γ is of kind A_1 in $]a, b[$ and of kind A_2 in $]b, c[$ $(A_1 \neq A_2,\ 0 < a < b < c \leq \tau)$, then b is a switching time for γ.*

Now the meaning of this more fine definition in the case of abnormal extremal strip borders is clear. An abnormal extremal can be of kind W^C (resp., W^D) on $[t-\varepsilon, t]$, $\varepsilon > 0$ and of kind W^D (resp., W^C) on $[t, t+\varepsilon]$, only if t is a switching time. On the contrary, in the case of strip borders that are not abnormal extremals the change from W^C to W^D or vice versa can occur without switching, and so the difference between W^C and W^D is not useful.

PROPOSITION 24. *Let γ be an NTAE, let $t_1 < t_2 < \cdots < t_{n(\gamma)-1} < t_{n(\gamma)} := \tau$ be the sequence of its switching times, and set $t_0 = 0$. From* (C) *of Proposition* 19, *generically $G(\gamma(t_i)) \neq 0$. If $F(\gamma(t_i)) = \beta_i G(\gamma(t_i))$, then clearly $\beta_i \neq \pm 1$. (Otherwise, $X(\gamma(t_i)) = 0$ or $Y(\gamma(t_i)) = 0$.) For all $i = 0, \ldots, n(\gamma) - 2$ it holds that*

$$v^\gamma(G(\gamma(t_{i+1})), t_{i+1}; 0) = (\beta_i + 1)/(\beta_{i+1} + 1) v^\gamma(G(\gamma(t_i)), t_i; 0)$$
if γ corresponds to control $+1$ on $[t_i, t_{i+1}]$,

$$v^\gamma(G(\gamma(t_{i+1})), t_{i+1}; 0) = (\beta_i - 1)/(\beta_{i+1} - 1) v^\gamma(G(\gamma(t_i)), t_i; 0)$$
if γ corresponds to control -1 on $[t_i, t_{i+1}]$.

Proof. Fix i, and suppose that γ corresponds to constant control $+1$ in $[t_i, t_{i+1}]$, the opposite case being similar. From $F(\gamma(t_{i+1})) = \beta_{i+1} G(\gamma(t_{i+1}))$, recalling Lemma 15, we have

$$\begin{aligned} F(\gamma(t_i)) + G(\gamma(t_i)) &= v^\gamma(F(\gamma(t_{i+1})) + G(\gamma(t_{i+1})), t_{i+1}; t_i) \\ &= (1+\beta_{i+1}) v^\gamma(G(\gamma(t_{i+1})), t_{i+1}; t_i). \end{aligned}$$

Now from $F(\gamma(t_i)) = \beta_i G(\gamma(t_i))$ (notice that in the case when $i = 0$ we have $F(0) = 0$, and hence $\beta_0 = 0$) and using again Lemma 15, we have

$$(1+\beta_i) v^\gamma(G(\gamma(t_i)), t_i; 0) = (1+\beta_{i+1}) v^\gamma(G(\gamma(t_{i+1})), t_{i+1}; 0),$$

which concludes the proof. □

PROPOSITION 25. *Let $\gamma : [0, \tau] \to \mathbb{R}^2$ be an extremal trajectory for the control problem* (1) *that switches at least one time, let θ^γ be the corresponding function defined in* (7)*, and let $t_1 < t_2 < \cdots < t_{n(\gamma)-1} < t_n(\gamma) := \tau$ be the sequence of switching times. Then under generic assumptions the following conditions are equivalent:*

(a) (γ, t_1) *is an NTAE;*
(b) $\theta^\gamma(t_i) \in \{0, \pm\pi\}$ *for some* $i \in \{1, \dots, n(\gamma) - 1\}$*;*
(c) $\theta^\gamma(t_i) \in \{0, \pm\pi\}$ *for each* $i \in \{1, \dots, n(\gamma) - 1\}$*;*
(d) $\theta^\gamma(\bar t) \in \{0, \pm\pi\}$, $(\bar t \in Dom(\gamma))$ *iff* $\bar t = t_i$ *for some* $i \in \{1, \dots n(\gamma) - 1\}$.

Proof. Proof that (a) *implies* (c). By definition $\theta^\gamma(0) = 0$. Proposition 24 implies that the vectors $v^\gamma(G(\gamma(t_{i+1}), t_{i+1}; 0)$ and $v^\gamma(G(\gamma(t_i), t_i; 0)$ are parallel. Since $\theta^\gamma(t_{i+1})$ and $\theta^\gamma(t_i)$ measure precisely the angle between those vectors and $G(0)$, we have $\theta^\gamma(t_{i+1}) = \theta^\gamma(t_i) \pm \pi$.

Proof that (c) *implies* (a). From (c) we have $\theta^\gamma(t_1) \in \{0, \pm\pi\}$; then for some $b \in \mathbb{R}$ (which by genericity we may assume different from 0 and 1) it holds that $v^\gamma(G(\gamma(t_1)), t_1; 0) = bG(\gamma(0))$. Now if we suppose that γ corresponds to constant control $+1$ in the interval $[0, t_1]$ (the opposite case being similar), we have $bG(\gamma(0)) = b(F+G)(\gamma(0)) = v^\gamma(b(F+G)(\gamma(t_1)), t_1; 0)$. From the injectivity of the map $v_0 \to v^\gamma(v_0, t_0; t_1)$ we obtain $\gamma(t_1) \in \Delta_A^{-1}(0)$. Using Proposition 19 (a) follows.

Proof that (b) *implies* (c) *and vice versa.* Clearly (b) follows from (c); let us prove the opposite. Let λ be the covector associated to γ. From (b) we have that $\lambda(0)$ is orthogonal to $G(0)$, and hence γ switches iff $\theta^\gamma \in \{0, \pm\pi\}$. Thus (c) follows.

Proof that (a) *implies* (d). It is a consequence of the generic condition $\theta^\gamma(\bar t) = 0 \Rightarrow \dot\theta^\gamma(\bar t) \neq 0$.

The implication (d)⇒(c) is obvious. This concludes the proof. □

PROPOSITION 26. *Let (γ, t_1) be an NTAE, and let $0 =: t_0 < t_1 < t_2 < \cdots < t_{n(\gamma)-1} < t_{n(\gamma)} := \tau$ be the sequence of switching times. Suppose that for some $i \in \{0, 1, \dots, n(\gamma)-2\}$, $\Delta_A^{-1}(0)$ is inverse at the points $\gamma(t_i)$, $\gamma(t_{i+1})$. Then $\theta^\gamma(t_{i+1}) = \theta^\gamma(t_i)$.*

Proof. Set $(F+G)(\gamma(t_i)) = \alpha_i (F-G)(\gamma(t_i))$ and $F(\gamma(t_i)) = \beta_i G(\gamma(t_i))$. Under generic assumptions, α_i and β_i are well defined for each $i = 1, \dots, n(\gamma) - 1$ and it holds that

$$\alpha_0 = -1, \quad \beta_0 = 0, \text{ and } \alpha_i, \beta_i \notin \{0, \pm 1\}, \quad \beta_i = \frac{1+\alpha_i}{1-\alpha_i}, \quad i \in \{1, ..., n(\gamma) - 1\}.$$

Now if $\Delta_A^{-1}(0)$ is inverse at both points $\gamma(t_i), \gamma(t_{i+1})$ ($i \in \{0, \dots, n(\gamma) - 2\}$, then $\alpha_i, \alpha_{i+1} < 0$ and we have $\beta_i, \beta_{i+1} \in]-1, 1[$ (see Figure 3.2). Recalling the definition of θ^γ, from Proposition 24 the conclusion follows. □

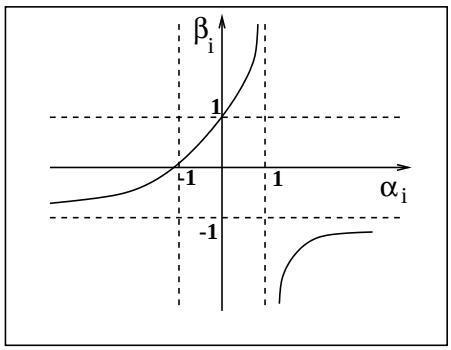

FIG. 3.2.

From Propositions 19 and 25, using the definitions of the times s_1^+, $s_1'^+$, t_f^+, s_1^-, $s_1'^-$, t_f^-, we have the following corollary.

COROLLARY 27. *Let γ be an extremal trajectory exiting the origin with control $+1$; then its first switching can occur on $\Delta_A^{-1}(0)$ only if $s_1 \neq 0$ (condition* (A)*) or $s_1' \neq 0$ (condition* (B)*) or $|\theta^+(t_f^+)| = \pi$ (condition* (C)*). Moreover, at most one of the conditions* (A), (B), (C) *holds, and the corresponding time is the first switching time of γ and the first time at which γ^+ intersect $\Delta_A^{-1}(0)$. A similar result holds for γ^- and for the times s_1^-, $s_1'^-$, t_f^-.*

Referring to conditions 1, 2, 3 of Observation 1, conditions A and B correspond either to case 2 or case 1 (with $s_1^+ \neq 0$ or $s_1'^+ \neq 0$), and condition C corresponds to case 3. Moreover, it is clear that for an NTAE (γ, t_1), t_1 is the first time at which γ reaches $\Delta_A^{-1}(0)$. In particular, if the trajectory exits the origin with control $+1$, we have $t_1 = s_1^+$ or $t_1 = s_1'^+$ or $t_1 = t_f^+$. In the case when $s_1^+ = 0$ and $s_1'^+$ are not defined or vice versa and $|\theta^+(t_f^+)| < \pi$ (which implies $t_f^+ = \tau$), there are no NTAEs exiting the origin with control $+1$. (An abnormal extremal exists but it never switches.) This case corresponds to case 1 of Observation 1 with $s_1^+ = 0$ and s'^+ not defined or vice versa. These observations are collected in the following.

COROLLARY 28. *There are at most two maximal NTAE. Moreover,*

(♠) *one exits the origin with control $+1$, and its first switching is at*

- s_1^+ *iff* $s_1^+ \neq 0$;
- $s_1'^+$ *iff* $s_1'^+ \neq 0$;
- t_f^+ *iff* $|\theta^+(t_f^+)| = \pi$;

(♣) *the other exits the origin with control -1, and its first switching is at*

- s_1^- *iff* $s_1^- \neq 0$;
- $s_1'^-$ *iff* $s_1'^- \neq 0$;
- t_f^- *iff* $|\theta^-(t_f^-)| = \pi$.

Finally, if $|\theta^\pm(t_f^\pm)| = \pi$, then $\Delta_A^{-1}(0)$ is direct at $\gamma(t_f^\pm)$.

The following two propositions describe the position of the switching curves of the strips whose borders are abnormal extremals.

PROPOSITION 29. *Let (γ, t_1) be an NTAE, let t_i and t_{i+1} be two consecutive switching times, let $\mathcal{S}$ be a strip such that $\gamma \in \partial S$, and let U^i, U^{i+1} be two sufficiently small neighborhoods of $\gamma(t_i)$ and $(\gamma(t_{i+1})$. Moreover, let U_{in}^i and U_{out}^i (resp., U_{in}^{i+1}, U_{out}^{i+1}) be the two connected components of $U^i \setminus \Delta_A^{-1}(0)$ (resp., $U^{i+1} \setminus \Delta_A^{-1}(0)$) chosen in such a way that γ enters U_{in}^i (resp., U_{in}^{i+1}). Under generic conditions we have the following cases:*

(1) $\theta^\gamma(t_i) = \theta^\gamma(t_{i+1})$ *and* $\Delta_A^{-1}(0)$ *direct at* $\gamma(t_i)$. *In this case if the switching locus of* $\mathcal{S}$ *passing through* $\gamma(t_i)$ *lies in* U^i_{in} *(resp.,* U^i_{out}*), then the switching locus of* $\mathcal{S}$ *passing through* $\gamma(t_{i+1})$ *lies in* U^{i+1}_{out} *(resp.,* U^{i+1}_{in}*).*

(2) $\theta^\gamma(t_i) = \theta^\gamma(t_{i+1})$ *and* $\Delta_A^{-1}(0)$ *inverse at* $\gamma(t_i)$. *In this case if the switching locus of* $\mathcal{S}$ *passing through* $\gamma(t_i)$ *lies in* U^i_{in} *(resp.,* U^i_{out}*), then the switching locus of* $\mathcal{S}$ *passing through* $\gamma(t_{i+1})$ *lies in* U^{i+1}_{in} *(resp.,* U^{i+1}_{out}*).*

(3) $\theta^\gamma(t_i) = \theta^\gamma(t_{i+1}) \pm \pi$ *and* $\Delta_A^{-1}(0)$ *direct at* $\gamma(t_i)$. *In this case we have the same conclusion as in case* (2).

(4) $\theta^\gamma(t_i) = \theta^\gamma(t_{i+1}) \pm \pi$ *and* $\Delta_A^{-1}(0)$ *inverse at* $\gamma(t_i)$. *In this case we have the same conclusion as in case* (1).

Proof. Let f_i (resp., A_i) be the sign of $-\Delta_B/\Delta_A$ (resp., Δ_A) on U^i_{in}, and let B_i be the sign of Δ_B on U^i. By hypothesis, taking U^i sufficiently small, these quantities are well defined and we have $f_i = -A_iB_i$. Moreover, set $\theta_i = +1$ if $\theta^\gamma(t_i) = \theta^\gamma(t_{i+1}) \pm \pi$ and $\theta_i = -1$ if $\theta^\gamma(t_i) = \theta^\gamma(t_{i+1})$.

Claim. $B_{i+1} = \theta_i B_i$.

Proof of the Claim. From $sgn(\dot\theta^\gamma(t)) = sgn(\Delta_B(\gamma(t)))$ we have that $\bar v^\gamma(t)$ (see formula (7)) is a vector rotating counterclockwise in U^i (resp., U^{i+1}) iff $B_i > 0$ (resp., $B_{i+1} > 0$). Recalling that $\theta^\gamma(t_i), \theta^\gamma(t_{i+1}) \in \{0, \pm\pi\}$ it is clear that B_i and B_{i+1} have the same sign iff $\theta^\gamma(t_{i+1}) = \theta^\gamma(t_i) \pm \pi$. The claim is proved.

Case 1. First suppose Δ_A is direct at $\gamma(t_i)$. In this case from Proposition 19 we clearly have $A_{i+1} = -A_i$. Now if the switching loci of $\mathcal{S}$ lie one in U^i_{in} and one in U^{i+1}_{in} (resp., U^i_{out} and U^{i+1}_{out}), then, from Lemma 8 we have $f_i = -f_{i+1}$. This occurs iff $-A_iB_i = +A_{i+1}B_{i+1} = -A_iB_i\theta_i$, from which it follows that $\theta_i = +1$.

On the other hand, if the switching loci of $\mathcal{S}$ lie one in U^i_{in} and one in U^{i+1}_{out} (resp., U^i_{out} and U^{i+1}_{in}), then $f_i = +f_{i+1}$, which occurs iff $\theta_i = -1$.

Case 2. If Δ_A is inverse at $\gamma(t_i)$, we have $A_{i+1} = +A_i$. Now if the switching loci of $\mathcal{S}$ lie one in U^i_{in} and one in U^{i+1}_{in} (resp., U^i_{out} and U^{i+1}_{out}), we have $f_i = -f_{i+1}$. This occurs iff $\theta_i = -1$.

On the other hand, if the switching loci of $\mathcal{S}$ lie one in U^i_{in} and U^{i+1}_{out} (resp., U^i_{out} and U^{i+1}_{in}), then $f_i = +f_{i+1}$, which occurs iff $\theta_i = +1$. □

PROPOSITION 30. *Let* (γ, t_1) *be an NTAE, and let* $\mathcal{S}^1$ *and* $\mathcal{S}^2$ *be two strips such that* $\{\gamma\} = \mathcal{S}^1 \cap \mathcal{S}^2$. *Let* $\bar t$ *be a switching time for* γ, *and let* U *be a small neighborhood of* $\gamma(\bar t)$ *such that* $U \setminus \Delta_A^{-1}(0)$ *has two connected components* U_{in} *and* U_{out}, *chosen in such a way that* γ *enters* U *from* U_{in}. *Then, under generic conditions, the switching loci of* $\mathcal{S}^1$ *and* $\mathcal{S}^2$ *passing through* $\gamma(\bar t)$ *satisfy the following:*

(a) *they both lie in* U_{in} *or both lie in* U_{out};

(b) *they are tangent to* $\mathrm{supp}(\gamma)$ *in* $\gamma(\bar t)$.

Proof of (a). By the analysis of the singularities at the first switching time (see Figure 4.1) we know that (a) is true in the special case $\bar t = t_1$. Using Proposition 29 and by induction the thesis follows.

Proof of (b). We prove (b) by induction on the switching time. We start considering the first switching time and treat only the case in which γ exits the origin with constant control $+1$, the opposite case being similar. First suppose that $\bar t$ is the first switching time for γ, and assume $s_1^+ > 0$ (i.e., $\bar t = s_1^+$), the case $s_1'^+ > 0$ and $|\theta^+(t_f^+)| = \pi$ being similar. Set $x = (x_1, x_2)$, and choose a local system of coordinates in such a way that

$$Y \equiv \begin{pmatrix} 1 \\ 0 \end{pmatrix} \quad X(x) = \begin{pmatrix} -1 + a_1x_1 + a_2x_2 + O(|x|^2) \\ b_1x_1 + b_2x_2 + O(|x|^2) \end{pmatrix},$$

$$X(x) = \begin{pmatrix} c_0 + c_1(x_1 - s_1^+) + c_2 x_2 + O(|x - (s_1^+, 0)|^2) \\ d_1(x_1 - s_1^+) + d_2 x_2 + O(|x - (s_1^+, 0)|^2) \end{pmatrix}.$$

Generically $\Delta_B(\gamma^+(s_1^+)) \neq 0$, and thus a switching curve generates at $\gamma^+(s_1^+)$.

Let $(\bar\gamma, \bar\lambda)$ be an extremal trajectory of (1) corresponding to constant control -1 in the interval $[0, \tau_1[$ and to constant control $+1$ in the interval $[\tau_1, \tau_2]$. We consider the trajectories $\bar\gamma$ that are near to γ, that is, those corresponding to (τ_1, τ_2) in a neighborhood of $(0, s_1^+)$. We have

$$\bar\gamma(\tau_1) = \begin{pmatrix} -\tau_1 + O(\tau_1^2) \\ -\frac{1}{2} b_1 \tau_1^2 + O(\tau_1^3) \end{pmatrix}, \quad \bar\gamma(\tau_2) = \begin{pmatrix} -\tau_1 + \tau_2 + O(\tau_1^2) \\ -\frac{1}{2} b_1 \tau_1^2 + O(\tau_1^3) \end{pmatrix}.$$

Now if τ_1, τ_2 are switching times for $\bar\gamma$, we must have

$$\bar\lambda(\tau_1) \cdot G(\bar\gamma(\tau_1)) = 0, \tag{8}$$

$$\bar\lambda(\tau_2) \cdot G(\bar\gamma(\tau_2)) = 0. \tag{9}$$

Moreover, from equation (i) of the PMP we have $\bar\lambda(\tau_1) = \bar\lambda(\tau_2) =: \bar\lambda$. Finally, set $\bar\lambda = (\bar\lambda_1, \bar\lambda_2)$, and normalize $\bar\lambda$ in such a way $\bar\lambda_2 = \sqrt{1 - \bar\lambda_1}$. Equations (8) and (9) become

$$f_1(\lambda_1, \tau_1, \tau_2) := \bar\lambda_1(1 + a_1\tau_1) + \sqrt{1 - \bar\lambda_1}\left(\frac{1}{2} b_1 \tau_1\right) + O(\tau_1^2) = 0,$$

$$f_2(\lambda_1, \tau_1, \tau_2) := \bar\lambda_1\left(\frac{1}{2}(1 - c_0) - c_1(-\tau_1 + (\tau_2 - s_1^+))\right) + \sqrt{1 - \bar\lambda_1}\left(-\frac{1}{2} d_1(-\tau_1 + (\tau_2 - s_1^+))\right) + O(\tau_1^2) + O((\tau_2 - s_1^+)^2) = 0.$$

These are two equations for the variable $(\bar\lambda_1, \tau_1, \tau_2)$, and $(0, 0, s_1^+)$ is a solution. We compute the 2×2 Jacobian matrix of partial derivatives of f_1 and f_2 with respect to (λ_1, λ_2) and check that its determinant at the point $(0, 0, s_1^+)$ is equal to $-d_1/2$. Under the generic assumption $d_1 \neq 0$, we can solve the system in a neighborhood of $(0, 0, s_1^+)$ expressing $(\bar\lambda_1, \tau_2)$ as a function of τ_1. This yields

$$\left.\frac{\partial \tau_2}{\partial \tau_1}\right|_{(0,0,s_1^+)} = -\frac{(b_1(1 - c_0) - 2d_1)}{2d_1} =: m; \tag{10}$$

hence $\tau_2 = s_1^+ + m\tau_1 + O(\tau_1^2)$, and under the generic condition $m \neq 1$ the parametric expression for the switching curve starting at $(s_1^+, 0)$ is

$$x_1(\tau_1) = s_1^+ + (m - 1)\tau_1 + O(\tau_1^2),$$
$$x_2(\tau_1) = -\frac{1}{2} b_1 \tau_1^2 + O(\tau_1^3).$$

If $m \neq 0$, we can use τ_2 as a parameter, so

$$x_1(\tau_2) = s_1^+ + \frac{m - 1}{m}(\tau_2 - s_1^+) + O((\tau_2 - s_1^+)^2),$$
$$x_2(\tau_2) = -\frac{b_1}{2m^2}(\tau_2 - s_1^+)^2 + O((\tau_2 - s_1^+)^3).$$

Assuming the generic condition $c_0 \neq 1$ and $b_1 \neq 0$, we may express x_2 as a function of x_1:

$$x_2 = -\frac{2d_1^2}{b_1(1-c_0)^2}(x_1 - s_1^+)^2 + O((x_1 - s_1^+)^3). \tag{11}$$

Notice that this curve can be of kind C or $\bar{C}$. This proves that the switching curve starting at the first switching time is tangent to $\mathrm{Supp}(\gamma)$.

Now we have to prove the induction step; that is, if t_n, t_{n+1} are two consequent switching times for γ and the switching curve passing through t_n is tangent to γ, then the switching curve passing through t_{n+1} is tangent to γ as well. Let us consider only the case in which γ corresponds to the constant control $+1$ on $[t_n, t_{n+1}]$, the opposite case being similar. Choose a local system of coordinates, and rescale the time in such a way that

$$\begin{aligned}
&t_n = 0, \quad \gamma(t_n) = 0,\\
&Y \equiv \begin{pmatrix} 1 \\ 0 \end{pmatrix} \quad X(x) = \begin{pmatrix} e_0 + e_1 x_1 + e_2 x_2 + O(|x|^2) \\ f_1 x_1 + f_2 x_2 + O(|x|^2) \end{pmatrix},\\
&X(x) = \begin{pmatrix} g_0 + g_1(x_1 - t_{n+1}) + g_2 x_2 + O(|x - (t_{n+1}, 0)|^2) \\ h_1(x_1 - t_{n+1}) + h_2 x_2 + O(|x - (t_{n+1}, 0)|^2) \end{pmatrix}.
\end{aligned}$$

We can parameterize the switching curve C_n through $\gamma(t_n)$ in the following way. Given $x \in C_n$, there exists (γ_x, λ_x) extremal that switches at x at time $\tau_n(x)$. By induction we may assume that τ_n is invertible for x near $\gamma(t_n)$ and parameterize C_n by τ_n:

$$\begin{aligned}
x_1(\tau_n) &= \alpha_n \tau_n + O(\tau_n^2),\\
x_2(\tau_n) &= \beta_n \tau_n^2 + O(\tau_n^3)
\end{aligned}$$

for some α_n, β_n that by genericity we may assume different from zero.

Let $(\tilde{\gamma}, \tilde{\lambda}) := (\tilde{\gamma}, \tilde{\lambda})_{\tau_n}$ be the extremal trajectory of (1) switching at τ_n on C_n, and let τ_{n+1} be the next switching time. We have

$$\tilde{\gamma}(\tau_n) = \begin{pmatrix} \alpha_n \tau_n + O(\tau_n^2) \\ \beta_n \tau_n^2 + O(\tau_n^3) \end{pmatrix}, \quad \tilde{\gamma}(\tau_{n+1}) = \begin{pmatrix} \alpha_n \tau_n + \tau_{n+1} + O(\tau_n^2) \\ \beta_n \tau_n^2 + O(\tau_n^3) \end{pmatrix}$$

and

$$\tilde{\lambda}(\tau_n) \cdot G(\tilde{\gamma}(\tau_n)) = 0, \tag{12}$$

$$\tilde{\lambda}(\tau_{n+1}) \cdot G(\tilde{\gamma}(\tau_{n+1})) = 0. \tag{13}$$

With computations entirely similar to the previous ones, using similar generic conditions we conclude that the switching curve passing through $\gamma(t_{n+1})$ has the expression

$$\begin{aligned}
x_1(\tau_{n+1}) &= t_{n+1} + \alpha_{n+1}(\tau_{n+1} - t_{n+1}) + O((\tau_{n+1} - t_{n+1})^2),\\
x_2(\tau_{n+1}) &= \beta_{n+1}(\tau_{n+1} - t_{n+1})^2 + O((\tau_{n+1} - t_{n+1})^3)
\end{aligned}$$

for some $\alpha_{n+1}, \beta_{n+1} \neq 0$. This conclude the proof. □

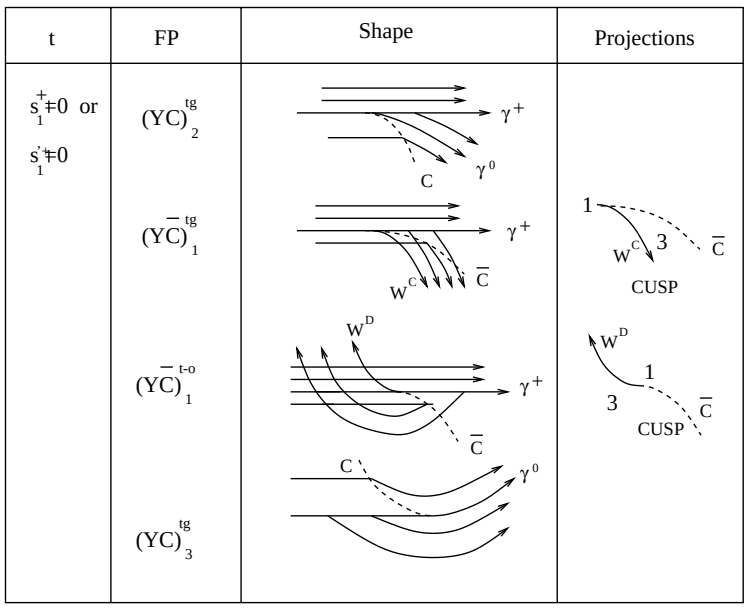

FIG. 4.1.

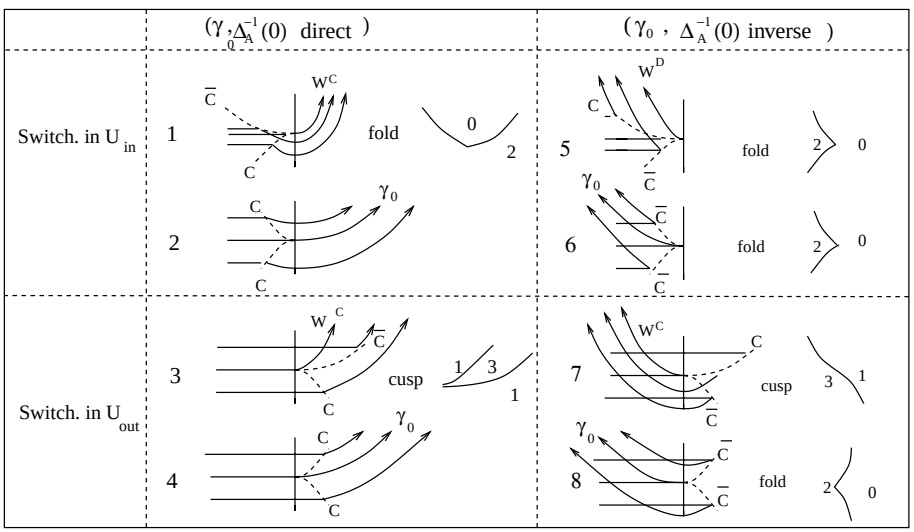

FIG. 4.2.

4. Singularities. In this section we describe all possible FPs occurring along an NTAE.

We start to describe the first singularity for the NTAE exiting the origin with control $+1$, the opposite case being similar. We refer to Figure 4.1, where all extremal trajectories are depicted in a neighborhood of the FPs. Following Corollary 28, an NTAE generates at time s_1^+ (iff $s_1^+ \neq 0$), or at time $s_1'^+$ (iff $s_1'^+ \neq 0$), or at time t_f^+ (iff $|\theta^+(t_f^+)| = \pi$). Assume $s_1^+ \neq 0$; then a switching curve tangent to $\mathrm{Supp}(\gamma^+)$ bifurcates from $\gamma^+(s_1^+)$. Recall formula (11) of the proof of (b) of Proposition 30. Using the

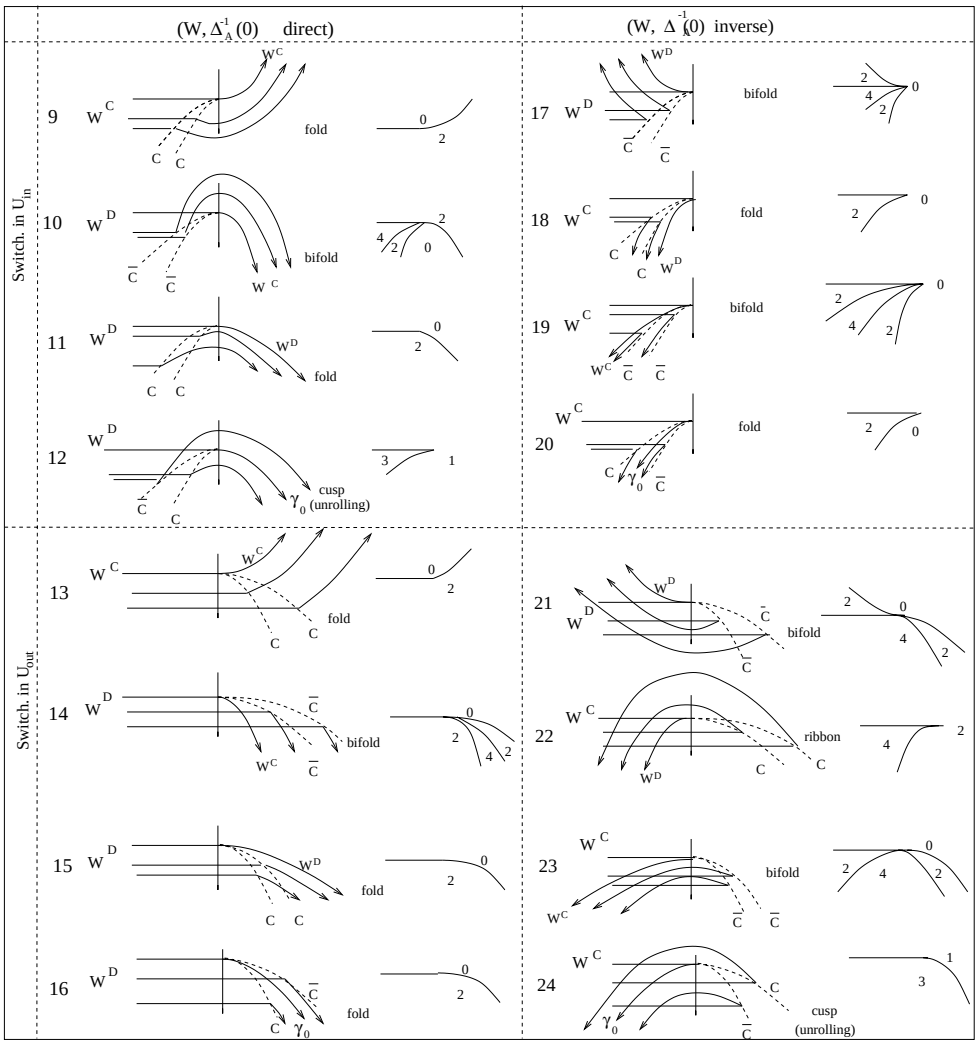

FIG. 4.3.

definition of θ^+ and s_1^+, as in Proposition 3.1 of [7], one gets that $b_1 > 0,\ d_1 < 0$ (we would have $b_1 < 0,\ d_1 > 0$, if $s_1^+ \neq 0$), and $c_0 < 1$. Hence the switching curve is bifurcating to the right of $\mathrm{Supp}(\gamma^+)$. Moreover, it follows that m, defined in formula (10), is bigger than 1, and being that $t_1 > 0$, we have (in formula (11)) $x_1 > s_1^+$. If the switching curve is of kind C, we call the singularity $(Y, C)_2^{tg}$. If the switching curve is of kind $\bar{C}$ and $\Delta_A^{-1}(0)$ is direct at $\gamma^+(s_1^+)$, we call the singularity $(Y, \bar{C})_1^{tg}$. Finally, if the switching curve is of kind $\bar{C}$ and $\Delta_A^{-1}(0)$ is inverse at $\gamma^+(s_1^+)$, we call the singularity $(Y, \bar{C})_1^{t-o}$. These names are chosen in accordance with [5, 17]. The case in which $s_1'^+ \neq 0$ is entirely similar.

The case in which the NTAE starts at $\gamma(t_f^+)$ (that happens iff $|\theta^+(t_f^+)| = \pi$) is again described by formula (11) with s_1^+ replaced by t_f^+. In this case, reasoning as in [7], we get $c_0 > 1$ and $b_1 d_1 < 0$. It follows that the switching curve bifurcates to the right, $m < 1$, and in formula (11) we have $x_1 < t_f^+$. Moreover, at t_f^+, γ^+ stops to be

extremal and $\Delta_A^{-1}(0)$ is direct at $\gamma(t_f^+)$ (see Proposition 26). We call this singularity $(Y, C)_3^{tg}$.

To classify the other generic singularities involving an NTAE, we consider at the FPs

- $\Delta_A^{-1}(0)$ direct or inverse;
- switching in U_{in} or U_{out} according to Proposition 29;
- all the *essentially different* directions of the exiting abnormal trajectory.

We obtain 24 types of singularities. The singularities with entering abnormal extremals of kind γ_0 are shown in Figure 4.2, while in Figure 4.3 all the possible singularities for an NTAE of the kinds W^C and W^D are listed. In these figures we also indicate the labels *fold, cusp, bifold,* or *ribbon* in accordance with Definition 9.

5. Classification of abnormal extremals. In this section we prove Theorem 2.

From now on we fix a positive time $\tau > 0$. Using Corollary 28, we have that for each system $(F, G) \in \Xi$ there exists exactly two maximal abnormal extremals $\gamma_A^{\pm} = \gamma_A^{\pm}((F, G), \tau)$ in time τ exiting the origin, respectively, with control ± 1.

DEFINITION 31. *We say that a set A provides a generic classification of abnormal extremals (in time τ) if there exist a generic subset Π of Ξ and a map $\Phi : \Pi \to A$ such that $\Phi((F, G)) = \Phi((F', G'))$, $(F, G), (F', G') \in \Pi$ iff the corresponding maximal abnormal extremals present the same finite sequence of generic singularities.*

Remark. From section 4, we know the structure of the set of extremal trajectories near each generic singularity. Hence, if two abnormal extremals present the same sequence of singularities, then the synthesis near them is exactly the same.

We provide a generic classification through a set of words A recognizable by an *automaton*. Therefore, proving Theorem 2 amounts precisely to constructing an automaton describing all possible sequences of generic singularities along an NTAE.

First, we build an automaton, naturally associated to a system, with the simplest possible set of edges. By this automaton we can prove that the ribbon and the bifold singularities are realized, but more than one sequence of singularities may correspond to a recognizable word. Then we build a more complicated automaton that has the required property; i.e., to every recognizable word it corresponds one and only one sequence of generic singularities.

Let us first recall some definitions from automata theory. For a more extensive and detailed treatment of the subject we refer to [10, 11].

DEFINITION 32. *Let Σ be a finite set, and consider the set Σ^* of ordered n-tuples $s = (\sigma_1, \dots, \sigma_k)$, $\sigma_i \in \Sigma$ $(i = 1, \dots, k)$, $k \geq 0$. We call Σ the* alphabet, *$\sigma \in \Sigma$ a* letter, *$s = (\sigma_1, \dots, \sigma_k) \in \Sigma^*$ a* word of length *k, and Σ^* the set of words generated by Σ.*

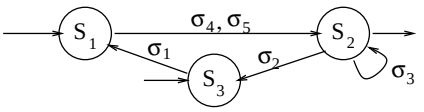
The set of words generated by an alphabet is a set with a simple structure, and a classification based on such a set is quite satisfying. Such a kind of classification was given, for example, for the sequence of generic singularities along $\gamma^{\pm}$ in [15]. For abnormal extremals we have to use a set with a more complicated structure.

DEFINITION 33. *Let Σ be a finite* alphabet*; an* automaton *$\mathcal{A}$ over Σ consists of the following:*

- *a finite set $\mathbb{S}$ whose elements are called* states*;*
- *a set of* initial states *$\mathbb{I} \subseteq \mathbb{S}$;*
- *a set of* terminal states *$\mathbb{T} \subseteq \mathbb{S}$;*
- *a set of* edges*, that is, a subset $\mathbb{E} \subseteq \mathbb{S} \times \Sigma \times \mathbb{S}$. An* edge *is indicated as (S_1, σ, S_2), and we say that it begins at S_1, it ends at S_2, and it carries the*

label σ.

Usually an *automaton* is represented by a set of circles (states) and a set of arrows that connect the circles (the edges). The initial (resp., final) states are labelled by arrows pointing toward (resp., away from) the circle. If there are several edges beginning and ending at the same states, they are replaced by a single arrow carrying several labels.



A *path* in $\mathcal{A}$ is a finite sequence of edges of the type $(S_1, \sigma_1, S_2)(S_2, \sigma_2, S_3), \dots, (S_k, \sigma_k, S_{k+1})$. If $S_1 \in \mathbb{I}$ and $S_{k+1} \in \mathbb{T}$, we say that the *path* is successful.

DEFINITION 34. *A set of words* $\Omega \subset \Sigma^*$ *is said to be recognizable by* $\mathcal{A}$ *if for every word* $(\sigma_1, \sigma_2, \dots, \sigma_m) \in \Omega$ *of length* m *there exists* $S_1, \dots, S_{m+1} \in \mathbb{S}$ *such that*

- $(S_i, \sigma_i, S_{i+1}) \in \mathbb{E}$ *for every* $i = 1, \dots, m$*;*
- $(S_1, \sigma_1, S_2)(S_2, \sigma_2, S_3), \dots, (S_m, \sigma_m, S_{m+1})$ *is a successful path.*

The set of words recognizable by an automaton share some regularity properties; in particular, they are studied in automata theory (see [10, 11]). Let us resume all the information on the switching strategy of an abnormal extremal via three rules. Let (γ, t_1) be an NTAE, and let $t_1 < t_2, \dots, < t_{n(\gamma)-1} < t_{n(\gamma)} := \tau$ be the sequence of its switching times.

R1. Let $\mathcal{S}^1$ and $\mathcal{S}^2$ be the two strips such that $\gamma \in \mathcal{S}^1 \cap \mathcal{S}^2$, and let $\bar{\mathcal{S}} := \mathcal{S}^1 \cup \mathcal{S}^2$. We have the following cases:

(1) $\theta^\gamma(t_i) = \theta^\gamma(t_{i+1})$ and $\Delta_A^{-1}(0)$ direct at $\gamma(t_i)$. In this case if the switching locus of $\bar{\mathcal{S}}$ passing through $\gamma(t_i)$ lies in U^i_{in} (resp., U^i_{out}), then the switching locus of $\bar{\mathcal{S}}$ passing through $\gamma(t_{i+1})$ lies in U^{i+1}_{out} (resp., U^{i+1}_{in}).

(2) $\theta^\gamma(t_i) = \theta^\gamma(t_{i+1})$ and $\Delta_A^{-1}(0)$ inverse at $\gamma(t_i)$. In this case if the switching locus of $\bar{\mathcal{S}}$ passing through $\gamma(t_i)$ lies in U^i_{in} (resp., U^i_{out}), then the switching locus of $\bar{\mathcal{S}}$ passing through $\gamma(t_{i+1})$ lies in U^{i+1}_{in} (resp., U^{i+1}_{out}).

(3) $\theta^\gamma(t_i) = \theta^\gamma(t_{i+1}) \pm \pi$ and $\Delta_A^{-1}(0)$ direct at $\gamma(t_i)$. In this case we have the same conclusion as in case (2).

(4) $\theta^\gamma(t_i) = \theta^\gamma(t_{i+1}) \pm \pi$ and $\Delta_A^{-1}(0)$ inverse at $\gamma(t_i)$. In this case we have the same conclusion as in case (1).

The rule R1 is a direct consequence of Propositions 29 and 30(a).

R2. If $\Delta_A^{-1}(0)$ is inverse at t_i and t_{i+1}, then $\theta^\gamma(t_{i+1}) = \theta^\gamma(t_i)$. The rule R2 follows from Proposition 26.

R3. Only the following consecutive singularities are possible:

Singularity at t_i	Possible singularity at t_{i+1}	AA(i)
$(YC)^{tg}_2$,$(YC)^{tg}_3$,2,4,6,8,12,16,20,24	1,2,3,4,5,6,7,8	γ^0
$(Y\bar{C})^{tg}_1$,1,3,7,9,10,13,14,19,23	9,13,18,19,20,22,23,24	W^C
$(Y\bar{C})^{t-o}_1$,5,11,15,17,18,21,22	10,11,12,14,15,16,17,21	W^D

Clearly, if an abnormal arc of kind γ^0 (resp., W^C, W^D) exits the singularity $\gamma(t_i)$ $(i = 1, \dots, n(\gamma) - 1)$, then an abnormal arc of kind γ^0 (resp., W^C, W^D) enters the singularity $\gamma(t_{i+1})$. Thus R3 can be directly checked using Figures 4.1, 4.2, and 4.3.

We now are ready to build an automaton $\mathcal{A}$. For us the set of *states* is the set of the 28 singularities

$$\mathbb{S} := \{(YC)^{tg}_2, (Y\bar{C})^{tg}_1, (Y\bar{C})^{t-o}_1, (YC)^{tg}_3,$$

TABLE A.

22	14,15,16,21	10,11,12
23	13,22,23,24	9
24	3,4,7,8	1,2

$$1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 21, 22, 23, 24\},$$

and the alphabet is

$$\Sigma := \{0, \pi\},$$

that is (if we are considering two singularities at t_i and t_{i+1}), the set of values assumed by the function $\Delta\theta_i^\gamma := |\theta^\gamma(t_{i+1}) - \theta^\gamma(t_i)|$. The set of *initial states* is constituted by the singularities $(YC)_2^{tg}, (Y\bar{C})_1^{tg}, (Y\bar{C})_1^{t-o}, (YC)_3^{tg}$, and the set of *terminal states* coincides with $\mathbb{S}$. Using rules R1–R3, we obtain Table A, which shows how the *edges* connect the *states*; that is, it describes the set of edges $\mathbb{E}$. For example, from the *state* (singularity) 18, using the *letter* π, we may reach the states $14, 15, 16$. This means that the edges of $\mathbb{E}$ with label π that start at the state 18 are $(18, \pi, 14), (18, \pi, 15), (18, \pi, 16)$. It is clear that for this automaton every word of Σ^* is recognizable, but $\mathcal{A}$ does not provide a generic classification because a word corresponds to more than one sequence of singularities. However, it describes in a simple way the set of abnormal extremals, and, in particular, from Table A we have the following theorem.

THEOREM 35. *All states* 1–24 *can be reached with at most two edges. More precisely, only the singularity* 17 *needs, in fact, two edges. Moreover, the singularity number* 22 *(the ribbon) can be realized with the edge* $((Y\bar{C})_1^{tg}, \pi, 22)$ *and the singularity number* 10 *(which is a bifold) with the edge* $((Y\bar{C})_1^{t-o}, \pi, 10)$.

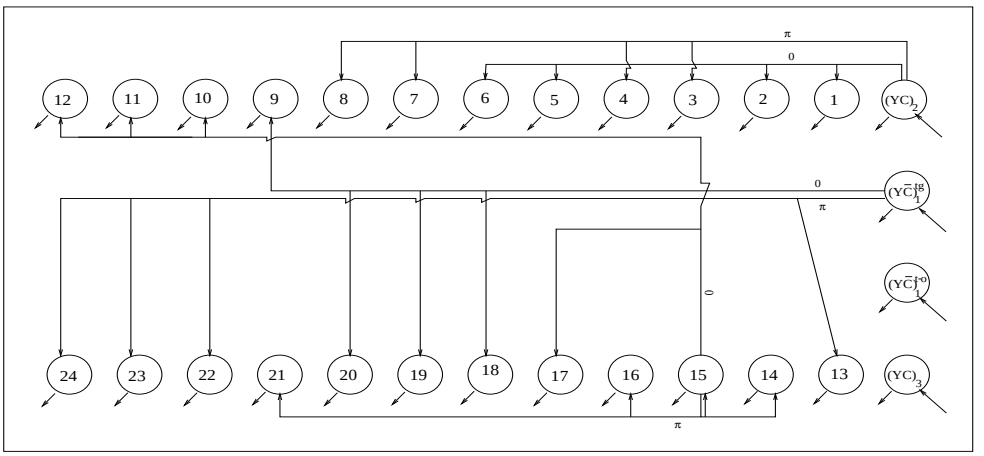

FIG. 5.1. *The automaton. (Some edges are omitted.)*

TABLE B *(first part).*

Letters→ states ↓	$(0, D, \gamma^0)$	$(0, D, W^C)$	$(0, D, W^D)$	$(0, I, \gamma^0)$	$(0, I, W^C)$	$(0, I, W^D)$

22	16	14	15	–	–	21
23	–	13	–	24	23	22
24	4	3	–	8	7	–

Figure 5.1 shows the automaton with all states but only the edges of the kind $((YC)_2^{tg}, ., .)$, $((Y\bar{C})_1^{tg}, ., .)$, $(15, ., .)$.

To build a new automaton $\mathcal{A}'$ that provides a generic classification, we need to include more information in the alphabet. First, we assign a label to the entry arrows I_1, I_2, I_3, I_4, corresponding, respectively, to the singularities $(YC)_2^{tg}$, $(Y\bar{C})_1^{tg}$, $(Y\bar{C})_1^{t-o}$, $(YC)_3^{tg}$. Then we introduce more information in the letters; i.e., we need a bigger alphabet. To do this, given a generic singularity on an NTAE, we want to

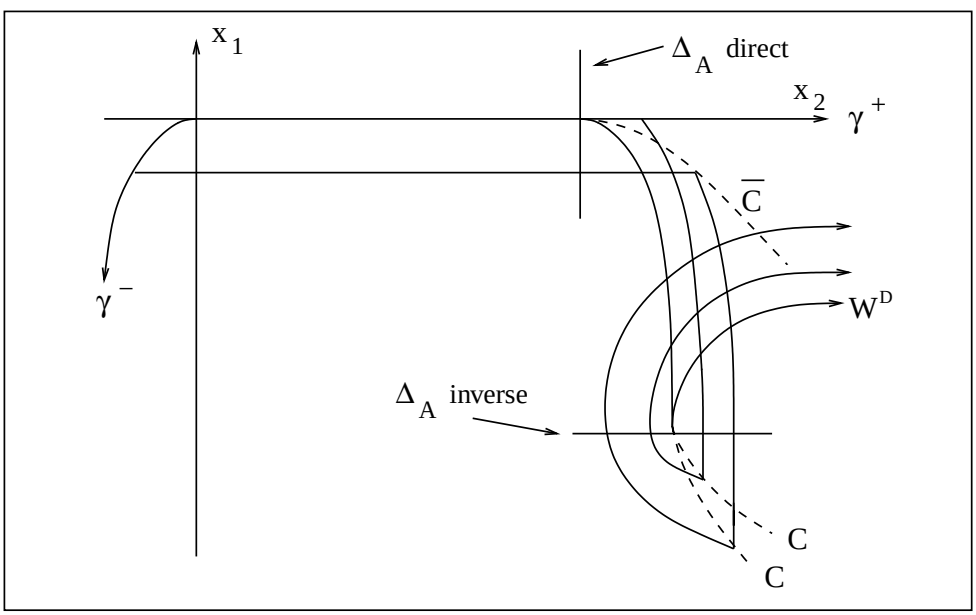

FIG. 5.2. *An example of a synthesis involving a* ribbon singularity.

include the following data relative to the subsequent singularity:

- $\Delta_A^{-1}(0)$ direct or inverse (indicated by D and I, resp.)

- the kind of exiting abnormal arc (i.e., γ^0, W^C or W^D).

In this way, the automaton $\mathcal{A}'$ is formed by $\mathbb{S}' = \mathbb{S}$, $\Sigma' = \{0, \pi\} \times \{D, I\} \times \{\gamma^0, W^C, W^D\} \cup \Sigma'_1$, where $\Sigma'_1 = \{I_1, I_2, I_3, I_4\}$ and set of edges $\mathbb{E}'$. Every element of Σ' (that is not in Σ'_1) is indicated by a triplet (. , . , .). In Table B the set of edges $\mathbb{E}'$ (with labels not in Σ'_1) is completely described. Notice that not all words of $(\Sigma')^*$ are recognizable by $\mathcal{A}'$. For example, the word $I_2(\pi, I, W^D)(0, D, W^C)$ is recognizable, and it corresponds to the sequence of singularities $(Y\bar{C})_1^{tg} \to 22 \to 14$, while the word $I_1(0, I, W^C)$ is not recognizable.

With these definitions, to every word recognizable by $\mathcal{A}'$ corresponds one and only one possible sequence of generic singularities along a NTAE. Theorem 2 is therefore proved.

We refer to Figure 5.2 for a graphic example of synthesis involving a *ribbon* singularity.

VISCOSITY SOLUTIONS OF THE BELLMAN EQUATION FOR EXIT TIME OPTIMAL CONTROL PROBLEMS WITH VANISHING LAGRANGIANS*

MICHAEL MALISOFF†

Abstract. We study the Hamilton–Jacobi–Bellman equation for undiscounted exit time optimal control problems for fully nonlinear systems and fully nonlinear singular Lagrangians using the dynamic programming approach. We prove a local uniqueness theorem characterizing the value functions for these problems as the unique viscosity solutions of the corresponding Hamilton–Jacobi–Bellman equations that satisfy appropriate boundary conditions. The novelty of this theorem is in the relaxed hypotheses on the lower bound on the Lagrangian and the very general assumptions on the target set. As a corollary, we show that the value function for the Fuller problem is the unique viscosity solution of the corresponding Hamilton–Jacobi–Bellman equation that vanishes at the origin and satisfies certain growth conditions. This implies as special cases first that the value function of this problem is the unique proper viscosity solution of the corresponding Hamilton–Jacobi–Bellman equation, in the class of all functions which are continuous in the plane and null at the origin, and second that this value function is the unique viscosity solution of that equation in a class which includes functions which are not bounded below. We also apply our results to the degenerate eikonal equation of geometric optics and to the shape-from-shading equations in image processing. Our theorem also applies to problems with noncompact targets and unbounded control sets whose Lagrangians take negative values.

1. Introduction.

This paper studies Hamilton–Jacobi–Bellman equations (HJBEs) for a large class of unbounded optimal control problems for fully nonlinear systems having the form

$$\begin{cases} y'(t) \;=\; f(y(t),\alpha(t)), \qquad t \geq 0, \quad \alpha(t) \in A, \\ y(0) \;=\; x. \end{cases} \tag{1.1}$$

Our hypotheses will be such that (1.1) has a unique solution trajectory which is defined on $[0,\infty)$ for each input α and $x \in \mathbb{R}^N$. The optimal control problems are of the form

$$\text{Minimize} \;\; J(x,\alpha) \;\; \text{over} \;\; \alpha \in \mathcal{A}^f(x), \tag{1.2}$$

where $y_x(\cdot,\alpha)$ is the solution of (1.1) for each input $\alpha \in \mathcal{A} := \{$ measurable functions $[0,\infty) \to A\}$, $t_x(\alpha)$ is the infimum of those times t at which $y_x(t,\alpha)$ lies in a given

*Received by the editors February 28, 2000; accepted for publication (in revised form) May 26, 2000; published electronically January 9, 2002. This research was supported in part by NSF grant DMS95-00798. This work was done while the author was a Louis Bevier Graduate Fellow in the Department of Mathematics at Rutgers University. It includes part of the author's dissertation under the direction of Professor Héctor J. Sussmann. Some of this work was presented during the session "Optimal Control I" of the 38th IEEE Conference on Decision and Control in Phoenix, AZ on December 7, 1999, and published in preliminary form in the conference proceedings.

closed set $\mathcal{T} \subseteq \mathbb{R}^N$, $\mathcal{A}^f(x)$ is the set of inputs α for which $t_x(\alpha) < \infty$, and

$$J(x,\alpha) := \int_0^{t_x(\alpha)} \ell(y_x(s,\alpha),\alpha(s))\, ds \;+\; g\left(y_x(t_x(\alpha),\alpha)\right) \quad \forall\, x \in \mathbb{R}^N \text{ and } \alpha \in \mathcal{A}^f(x).$$

We refer to the function ℓ as the Lagrangian (or instantaneous cost) of (1.2). We refer to $\mathcal{T}$ as a target, and thus (1.2) is a problem of minimizing the cost of reaching a target.

The value function of (1.2) will be denoted by v, and $\mathcal{R}$ denotes the set of all points x that can be brought to $\mathcal{T}$ in finite time using the evolution (1.1) and some input α in $\mathcal{A}$. Thus,

$$v(x) \;:=\; \begin{cases} \inf\left\{J(x,\alpha) :\; \alpha \in \mathcal{A}^f(x)\right\} & \text{if } x \in \mathcal{R}, \\ +\infty, & \text{otherwise.} \end{cases}$$

The class of problems we consider includes the Fuller problem (FP) and other well-known physical applications (cf. [14], [23], [26], and section 4), as well as problems for which the control set A and $\partial\mathcal{T}$ are both unbounded. The HJBE for (1.2) is

$$\sup_{a \in A} \left\{ -f(x,a) \cdot Du(x) \;-\; \ell(x,a) \right\} \;=\; 0, \tag{1.3}$$

which we wish to solve on $\Omega \setminus \mathcal{T}$, where Ω is a suitable open subset of $\mathbb{R}^N$. We will study (1.3) in the framework of viscosity solutions and relaxed controls (cf. [1] and [2]).

We will prove a local uniqueness theorem which characterizes the value functions for (1.2) as the unique viscosity solutions of the associated HJBEs on open sets of the form $\Omega \setminus \mathcal{T}$ that satisfy appropriate boundary and growth conditions. As a consequence, we show that the FP value function is the unique viscosity solution of the corresponding HJBE in the class of functions which are zero at the origin, are continuous in the plane, and satisfy a certain growth regularity condition. This regularity condition is a generalization of properness, i.e., of the condition $w(x) \to +\infty$ as $||x|| \to \infty$, which can also be satisfied by functions which are not bounded below (cf. Remark 2.8).

Uniqueness characterizations of this kind have been studied and applied by many authors for a large number of stochastic and deterministic optimal control problems and for differential games. Recent work in these areas may be found in [2], [9], and in the hundreds of references therein. For a detailed account of uniqueness questions for the HJBE for exit time problems with Lagrangians which are bounded below by positive constants on $\mathbb{R}^N \setminus \mathcal{T}$, see [5] and [16]. Also, uniqueness characterizations for HJBEs have been used to study the convergence of numerical schemes for approximating value functions and differential game values (cf. [4] and [19]) and also in the study of H^∞ control, singular perturbations, and much more.

However, Fuller's exit time problem is not covered by these results, since its Lagrangian ℓ vanishes at some points outside $\mathcal{T}$. For example, see [2], where the main comparison results for exit time problems require $\ell \geq m > 0$, and [16], where this requirement is relaxed to requiring[1] that for each $\varepsilon > 0$ there be a constant C_ε such that

$$\ell(x,a) \geq C_\varepsilon > 0 \qquad \forall a \in A \quad \text{and} \quad x \in \mathbb{R}^n \setminus B(\mathcal{T},\varepsilon). \tag{1.4}$$

[1] We set $\operatorname{dist}(p,S) := \inf\{||p-s|| : s \in S\}$ and $B(S,\varepsilon) := \{x \in \mathbb{R}^N :\ \operatorname{dist}(x,S) < \varepsilon\}$ for any $S \subseteq \mathbb{R}^N$, $p \in \mathbb{R}^N$, and $\varepsilon > 0$. For cases where $S = \{x\}$, we sometimes write $B_\varepsilon(x)$ instead of $B(\{x\},\varepsilon)$.

Also, the earlier results do not cover important Bellman equations for shape-from-shading problems and many eikonal equations from physics (cf. section 4). In fact, one easily finds HJBEs for optimal control problems with exit times that have several proper viscosity solutions when the lower bound requirement (1.4) is violated. For example, use the system

$$\dot{x}(t) \ = \ u(t) \ \in \ [-1,1],$$

choose

$$\ell(x,a) \ := \ (x+2)^2\,(x-2)^2\,x^2\,(x+1)^2\,(x-1)^2,$$

and set $g \equiv 0$. Let v_1 and v_2 denote the value functions for the associated problem (1.2) with the targets $\mathcal{T}_1 = \{0\}$ and $\mathcal{T}_2 = \{0, 2, -2\}$, respectively. One can easily check that v_1 and v_2 are both proper and that both are viscosity solutions of the associated HJBE (1.3) on $\mathbb{R} \setminus \mathcal{T}$ with $\mathcal{T} := \mathcal{T}_1$. Also, with the target $\mathcal{T} = \{0\}$, the problem satisfies all the hypotheses of the well-known theorems which characterize value functions of exit time control problems as the unique proper viscosity solutions of (1.3) in the class of all functions which are zero on $\mathcal{T}$, save for the fact that the positive lower bound requirement (1.4) on ℓ is not satisfied.

One may notice that the ingredient missing from this example is an optimal control analogue of the La Salle invariance condition, which we will specify below. This condition will guarantee that there are no spurious solutions for the HJBE for the FP. Roughly stated, the condition says that each trajectory of (1.1) "immediately leaves" any subset of the state space outside the target in which the running cost is null along some trajectory (cf. section 2). This condition would not be satisfied for the problem in the previous paragraph, since the constant trajectories at ± 2 accumulate zero costs. Our approach is therefore based on the properties of the trajectories $t \mapsto y_x(t,\alpha)$ of (1.1) at times close to zero. For a very different treatment of (1.3) based on the asymptotic behavior of trajectories as $t \to \infty$ and which characterizes value functions for exit time problems as the unique nonnegative viscosity solutions of the corresponding HJBEs that satisfy appropriate boundary conditions, see [17] and [18].

Our work is part of a larger research program which generalizes uniqueness results for viscosity solutions to versions that cover well-known optimal control problems whose dynamics do not necessarily admit unique trajectories for some choices of open loop controls and initial positions, or whose Lagrangians violate the usual boundedness requirements. For uniqueness characterizations for the Bellman equation for linear-quadratic problems, see [3] (which covers finite horizon cases) and [7] (which covers the infinite horizon case). A uniqueness characterization for (1.3) for exit time problems whose dynamics are continuous but not Lipschitz continuous, including Sussmann's reflected brachystochrone problem (cf. [21] and [22]), appears in [12]. For results for exit problems where f and ℓ are bounded under other special conditions that are generally not satisfied in the problems we consider below, see [25].

This paper is organized as follows. In section 2, we list assumptions on the data which will be in force in most of what follows, and we give definitions needed to specify a class of functions in which the value function v will be the unique viscosity solution. We also review the definitions of viscosity solutions and relaxed controls. In section 3, we state our main results, and section 4 shows how to apply them to a variety of physical problems, including the FP, geometric optics, and image processing. This is followed in section 5 with statements of certain converse dynamic

programming principles used to prove our uniqueness characterizations, a lemma on weak-$\star$ convergence of sequences of relaxed controls, and proofs of our main results. In section 6, we show how to extend these results so that they cover cases where the assumptions of section 2 are not satisfied, including cases where the control set A is unbounded and the Lagrangian ℓ takes negative values.

2. Assumptions and definitions. Let us make the following assumptions:

- (A_0) The control set A is a compact metric space.
- (A_1) The dynamics $f : \mathbb{R}^N \times A \to \mathbb{R}^N$ is continuous, and there exists a constant $L > 0$ such that $||f(x,a) - f(y,a)|| \leq L\,||x-y||$ for all $x, y \in \mathbb{R}^N$ and all $a \in A$.
- (A_2) The target $\mathcal{T} \subseteq \mathbb{R}^N$ is closed, $\mathcal{T} \neq \emptyset$, $g \in C(\mathcal{T})$, and g is bounded below.[2]
- (A_3) The Lagrangian $\ell : \mathbb{R}^N \times A \to \mathbb{R}$ is continuous.

The compactness requirement (A_0) is included to simplify the exposition. We will consider the case where A is noncompact separately in section 6.3 below. Roughly speaking, all of our results still hold when A is unbounded if we replace the inputs $\alpha \in \mathcal{A}$ with vector field valued inputs and add mild assumptions on the dynamics f and the Lagrangian ℓ. Alternatively, we can extend our results to cover problems with noncompact control sets by adding assumptions on f and ℓ from [3] that penalize "large" control values (cf. (A_4)–(A_5) below). We emphasize that, unlike in the usual treatments of exit time problems, $\partial\mathcal{T}$ is not required to be compact or smooth, f and ℓ need not be bounded, and ℓ need not be bounded below.

By an elementary application of the Schauder fixed point theorem (cf. [2]), conditions (A_0)–(A_1) will guarantee that for each input $\alpha \in \mathcal{A}$ and each point $x \in \mathbb{R}^N$ there is a unique solution $y_x(\cdot,\alpha)$ of the dynamics (1.1) which is defined on $[0,\infty)$. Moreover, the following estimates easily follow from (A_0)–(A_1):

- ($\mathcal{E}_1$) $\quad ||y_x(t,\alpha) - x|| \leq M_x\, t \ \text{ for all } \ t \in [0, 1/M_x]$,
- ($\mathcal{E}_2$) $\quad ||y_x(t,\alpha)|| \leq (||x|| + \sqrt{2Kt})e^{Kt} \ \text{ for all } \ t \geq 0 \ \text{ and } \ \alpha \in \mathcal{A}$,

where $M_x := \sup\{||f(z,a)|| : z \in B_1(x), a \in A\}$ when this supremum is nonzero, $M_x = 1$ otherwise, and $K := \sup\{||f(0,a)|| : a \in A\}$. (Recall from the footnote in section 1 that $B_1(x)$ is the open unit ball centered at x.) The preceding estimates are shown in [2].

Since A is a compact metric space, we can view our controls $\alpha \in \mathcal{A}$ as members of the larger class $\mathcal{A}^r$ of relaxed controls (cf. [2] and [24]). Thus,

$$\mathcal{A}^r := \{ \text{ measurable functions } [0,\infty) \to A^r \},$$

where A^r is the set of Radon probability measures on A (i.e., the probability measures on the smallest σ-algebra on A containing all the open sets of A). We topologize A^r as a subset of the dual of $C(A)$ with the topology of weak-$\star$ convergence. By identifying $\mathcal{A}$ with the set of Dirac probability measures on A (i.e., probability measures that put weight one on a single point in the control set at each time), we will view $\mathcal{A}$ as a subset of $\mathcal{A}^r$. The topology on $\mathcal{A}^r$ will be such that each sequence in $\mathcal{A}^r$ has a weak-$\star$ convergent subsequence in $\mathcal{A}^r$ (cf. Lemma 5.3). By $\mathcal{A}^r \ni \alpha_n \to \bar{\alpha} \in \mathcal{A}^r$ weak-$\star$ we mean

[2] We let $C(U)$ denote the set of continuous real-valued functions on any space U. For cases in which U is an open subset of a Euclidean space, $C^1(U)$ denotes the set of continuous real-valued functions on U with one continuous derivative.

$$\int_0^\tau \int_A (h(s))(a)\, d(\alpha_n(s))(a)\, ds \quad \to \quad \int_0^\tau \int_A (h(s))(a)\, d(\bar{\alpha}(s))(a)\, ds \quad \text{as} \quad n \to \infty \tag{2.1}$$

for each Lebesgue integrable function $h : [0, \tau] \to C(A)$ and each $\tau > 0$.

Define $\ell^r : \mathbb{R}^N \times A^r \to \mathbb{R}$ and $f^r : \mathbb{R}^N \times A^r \to \mathbb{R}^N$ by

$$\ell^r(x, m) := \int_A \ell(x, a)\, dm(a) \quad \text{and} \quad f^r(x, m) := \int_A f(x, a)\, dm(a). \tag{2.2}$$

One checks that f^r and ℓ^r satisfy (A_1) and (A_3), respectively, and that A^r is compact. We leave the details to the reader (cf. [2]). We can therefore define $y_x^r(\cdot, \alpha) : [0, \infty) \to \mathbb{R}^N$ to be the unique trajectory of $y'(s) = f^r(y(s), \alpha(s))$ starting at x for each $\alpha \in \mathcal{A}^r$. We will refer to $y_x^r(\cdot, \alpha)$ as a relaxed trajectory. Define the *Hamiltonian* $H : \mathbb{R}^N \times \mathbb{R}^N \to \mathbb{R}$ by

$$H(x, p) = \sup_{a \in A} \{ -f(x, a) \cdot p - \ell(x, a) \} \tag{2.3}$$

and set

$$P := \left\{ x \in \mathbb{R}^N : \int_0^t \ell^r(y_x^r(s, \alpha), \alpha(s)) ds > 0 \quad \forall\ t \in (0, \infty],\ \alpha \in \mathcal{A}^r \right\},$$

where we allow the integral to diverge to $+\infty$ in the definition of P. We sometimes write H_A instead of H to emphasize the control set. Notice that assumptions (A_0)–(A_3) guarantee that $H(x, p)$ is always a finite supremum. Notice also that we could have $P \supseteq \mathcal{R} \setminus \mathcal{T}$ even if $\ell(x, a) = 0$ for some $x \in \mathcal{R} \setminus \mathcal{T}$ and $a \in A$, since the dynamics (1.1) could be such that points in the state space that give zero values for the Lagrangians are "immediately" brought out of the null sets of the vector fields $\ell(\cdot, a)$, producing positive running costs. This will be the case for the FP (cf. section 4.1). For this problem, as well as for the other examples we give below, condition (1.4) is violated, but $P \supseteq \mathcal{R} \setminus \mathcal{T}$ (cf. section 4).

We will prove that for suitable open sets S, there is at most one viscosity solution $w \in C(S)$ of HJBE (1.3) on $S \setminus \mathcal{T}$ that satisfies a certain growth property and a certain compatibility property (cf. Definition 2.1 and Definition 2.6). In particular, we give uniqueness characterizations for viscosity solutions $w \in C(\mathcal{R})$ of (1.3) on $\mathcal{R} \setminus \mathcal{T}$. For the case of the FP, these side conditions reduce to properness or some generalized notion of properness (cf. Remark 2.7 and section 6). In particular, we show that the value function for the FP is the unique viscosity solution of the corresponding HJBE in a class which includes functions which are not bounded below. We also apply our results to degenerate eikonal equations and to the equations of shape-from-shading problems (cf. sections 4.2–4.3).

We use the following definition of viscosity solutions.

DEFINITION 2.1. *Let $\mathcal{G} \subseteq \mathbb{R}^N$ be open, let $S \supseteq \mathcal{G}$, let $F : \mathbb{R}^N \times \mathbb{R}^N \to \mathbb{R}$ be continuous, and let $w : S \to \mathbb{R}$.*

1. *We call w a* (semicontinuous) viscosity supersolution *of $F(x, Dw(x)) = 0$ on $\mathcal{G}$ if* (i) *w is lower semicontinuous on $\mathcal{G}$ and* (ii) *for all $\gamma \in C^1(\mathcal{G})$ and all local minima $x_o \in \mathcal{G}$ of $w - \gamma$ we have $F(x_o, D\gamma(x_o)) \geq 0$.*
2. *We call w a* (semicontinuous) viscosity subsolution *of $F(x, Dw(x)) = 0$ on $\mathcal{G}$ if* (i) *w is upper semicontinuous on $\mathcal{G}$ and* (ii) *for all $\lambda \in C^1(\mathcal{G})$ and all local maxima $x_1 \in \mathcal{G}$ of $w - \lambda$, we have $F(x_1, D\lambda(x_1)) \leq 0$.*

3. *We call w a* viscosity solution *of $F(x, Dw(x)) = 0$ on $\mathcal{G}$ if it is simultaneously a (semicontinuous) viscosity supersolution and a (semicontinuous) viscosity subsolution of this equation on $\mathcal{G}$.*

This definition of viscosity solutions is elementarily equivalent to the definition of viscosity solutions based on super- and subdifferentials used in [7] (cf. [2]). Also, by a denseness argument, the above definition is equivalent to the one obtained by replacing $C^1(\mathcal{G})$ with $C^\infty(\mathcal{G})$ (i.e., infinitely differentiable functions on $\mathcal{G}$). Most of what follows is based on the viscosity solution definition given above, so we omit the definition based on semidifferentials. We also use the following notions of quick growth and boundary levelness.

DEFINITION 2.2. *Let $S \subset \mathbb{R}^N$ be open, let $w : S \to \mathbb{R}$ be continuous, and let $\omega_o \in \mathbb{R} \cup \{+\infty\}$.*

1. *We say w is* quickly growing *with respect to S and write $w \in QG(S)$, provided the following:*
   $QG(S)$ *For each pair (x, y) with $x \in S$ and $y \in \partial S$, there exists an $\varepsilon > 0$ such that if $p \in S$ and if $|| p - y || < \varepsilon$, then $w(x) < w(p)$.*
2. *We say w is* boundary level *for S and ω_o and write $w \in BC_{\omega_o}(S)$, provided the following:*
   $BC_{\omega_o}(S)$ *For each $x \in S$, we have $w(x) < \omega_o$. In addition, for each $x_o \in \partial S$, we have $w(x) \to \omega_o$ as $S \ni x \to x_o$.*

We will show that if $w \in QG(\Omega)$ is a viscosity subsolution of (1.3) on $\Omega \setminus \mathcal{T}$, where Ω is an open set containing $\mathcal{T}$, and if $\Omega \setminus \mathcal{T} \subseteq P$, then $w \le v$ on $\Omega \setminus \mathcal{T}$ (but see section 6.4 for cases where $\Omega \setminus \mathcal{T} \not\subseteq P$). This is done in Proposition 5.4. This inequality is an easy consequence of the dynamic programming principle for cases where $\Omega = \mathcal{R}$ but nontrivial for other cases, because we must then consider trajectories which reach $\mathcal{T}$ in finite time but exit Ω before reaching $\mathcal{T}$.

Notice that condition $QG(S)$ is weaker than the standard requirement $BC_{\omega_o}(S)$ in the known uniqueness characterizations for cases where S is bounded (cf. [2], [5], and [16]). Notice also that the condition $QG(S)$ does not require the function w to be defined on ∂S, while for $\omega_o \neq +\infty$, $BC_{\omega_o}(S)$ holds if S is the ω_o-sublevel set of w and w is continuous on $\bar{S}$. In some of what follows, we will take $S = \mathcal{R} = \mathbb{R}^N$ and $\omega_o = +\infty$, in which case $QG(S)$ and $BC_{\omega_o}(S)$ are satisfied vacuously. We will do this when we consider Fuller's example.

We will be especially interested in viscosity solutions on sets which can be decomposed into smaller sets with "controllable boundaries." This controllability condition will guarantee the nondegeneracy of the Hamiltonian H, which is needed for our uniqueness characterizations. The controllability condition we need is as follows.

DEFINITION 2.3. *Let $\mathcal{O} \subseteq \mathbb{R}^N$ and assume* (A_0)–(A_3) *are satisfied. We say that $\mathcal{O}$ satisfies the* strong small time control condition *with respect to $\mathcal{T}$ and write SSTC($\mathcal{O}$, $\mathcal{T}$) if there is a sequence of bounded open sets $\{\Omega_j\}$ such that the following conditions hold:*

($SSTC_1$) The Ω_j's increase to $\mathcal{O}$, i.e., $\Omega_j \subseteq \Omega_{j+1}$ for all j and $\mathcal{O} = \bigcup_{j=1}^{\infty} \Omega_j$.

($SSTC_2$) If $T_j : \Omega_j \setminus \mathcal{T} \to \mathbb{R} \cup \{+\infty\}$ is defined by
$$T_j(x) := \inf\{t : y_x(t, \alpha) \in \partial(\Omega_j \setminus \mathcal{T}),\ \alpha \in \mathcal{A}\} \quad \text{for} \quad j = 1, 2, \ldots,$$
and if $\Omega_j \setminus \mathcal{T} \ni x \to x_0 \in \partial(\Omega_j \setminus \mathcal{T})$, then $T_j(x) \to 0$.

When these conditions hold, $\{\Omega_j\}$ is called the associated controllability sequence.

The following example illustrates the SSTC requirements.

Example 2.4. Take $N = 2$, $A = [-1, +1]$, $f(x, y, a) = (y, a)$, and $\mathcal{T} = \{\vec{0}\} \subseteq \mathbb{R}^2$. As we will show below, we can then satisfy SSTC($\mathbb{R}^2 \setminus \{0\}, \{0\}$) by taking Ω_j to be the open set bounded by the trajectory from $(0, j)$ to $(0, -j)$ using the constant control $a \equiv -1/2$, followed by the trajectory back to $(0, j)$ using the constant control $a \equiv +1/2$ with the origin removed. If we now choose $\ell(x, y, a) = x^2$, then we get the usual FP. We discuss the FP more fully in section 4.1, where we prove a uniqueness characterization for the FP Bellman equation.

Remark 2.5. Uniqueness of viscosity solutions requires nondegeneracy of the Hamiltonian, i.e., extra assumptions on the dynamics, which is implied by SSTC. Using proximal normals, we can characterize this nondegeneracy in terms of $f(x, a)$ and the boundary of the domain, as follows. Since the boundaries $\partial(\Omega_j \setminus \mathcal{T})$ in Definition 2.3 may not be smooth, we use generalized exterior normals (cf. [2]). Recall that for any closed nonempty set $S \subset \mathbb{R}^N$, the *(generalized) exterior normal* to S at $z \in \partial S$, which is denoted by $N(z)$, is defined to be the set of all unit vectors ν for which there exists $x \notin S$ satisfying

$$x = z + \operatorname{dist}(x, S)\nu \qquad \text{and} \qquad \{z\} = \mathcal{P}(x),$$

where $\mathcal{P}(x) := \{z \in \partial S : \operatorname{dist}(x, S) = ||x - z||\}$. Condition $(SSTC_2)$ is then satisfied if the following holds:

$(SSTC_3)$ For each $j \in \mathbb{N}$ and $\bar{x} \in \partial(\Omega_j \setminus \mathcal{T})$ there exist $s > 0$ and $\delta > 0$ such that

$$\inf_{a \in A} f(\bar{x}, a) \cdot \nu \ \leq \ -\delta$$

for any $\nu \in N(x)$ with $x \in \partial(\Omega_j \setminus \mathcal{T}) \cap B_s(\bar{x})$

(cf. [2, Chapter IV]). This of course reduces to a standard "outer field" condition in terms of outer normals when the sets $\Omega_j \setminus \mathcal{T}$ have piecewise smooth boundaries. Also, for the special case in which $\Omega_j \equiv \mathcal{O}$, we have nondegeneracy in terms of $f(x, a)$ and the boundary $\partial(\mathcal{O} \setminus \mathcal{T})$ of the domain.

One can also express the nondegeneracy in terms of the standard small-time controllability condition from [15]. Recall that for any $\mathcal{U} \subseteq \mathbb{R}^N$, $STC\mathcal{U}$ is defined to be the requirement that $\mathcal{U} \subset \text{Interior}\, \mathcal{R}(\varepsilon)$ for all $\varepsilon > 0$, where

$$\mathcal{R}(\varepsilon) \ := \ \left\{x \ \in \ \mathbb{R}^N : \ \exists\, t \ \in \ [0, \varepsilon) \ \text{and} \ \alpha \ \in \ \mathcal{A} \ \ \text{s.t.} \ \ y_x(t, \alpha) \ \in \ \mathcal{U}\right\}.$$

The condition $STC\mathcal{U}$ is satisfied when suitable assumptions are made on the directions of the vector field f and of its Lie brackets at $\partial\mathcal{U}$ (cf. [20]). Condition $(SSTC_2)$ is then satisfied if the following holds:

$(SSTC_4)$ The condition $\text{STC}(\Omega_j^c) \wedge \text{STC}\mathcal{T}$ holds for $j = 1, 2, \ldots$.

Condition $(SSTC_4)$ says that the dynamics (1.1) can be controlled to $\partial\mathcal{T}$ or $\partial(\Omega_j)$ for any $j \in \mathbb{N}$. This condition is stronger than $(SSTC_2)$ for cases in which $\mathcal{T} \cap \partial\Omega_j \neq \emptyset$ for some j, since $(SSTC_2)$ does not require controllability to the portions of $\partial(\Omega_j)$ in $\mathcal{T}$.

Finally, we use the following generalized notion of properness.

Definition 2.6. *Assume* (A_0)–(A_3) *and SSTC($\mathcal{O}$, $\mathcal{T}$). Let* $\{\Omega_j\}$ *denote the associated controllability sequence, and let* $w : \mathcal{O} \to \mathbb{R}$ *and* $\omega_o \in \mathbb{R} \cup \{+\infty\}$ *be given. We say that* w *is* $(\mathcal{O}, \mathcal{T}, \omega_o)$-compatible *if the following conditions hold:*

1. $\partial(\Omega_j) \setminus \mathcal{T} \subseteq \mathcal{O}$ *for all* j*;*
2. $\lim_{j \to \infty} \min\{w(p) : \ p \in \partial(\Omega_j) \setminus \mathcal{T}\} = \omega_o$.

Remark 2.7. The preceding compatibility conditions can be easily verified when $\mathcal{T} = \{0\}$. For example, any proper function is $(\mathbb{R}^N \setminus \{0\}, \{0\}, +\infty)$-compatible if $STC\{0\}$ and $STC(\Omega_j^c)$ hold for an increasing sequence Ω_j of bounded open sets that satisfy $\min\{||x|| : x \in \partial(\Omega_j), x \neq 0\} \to \infty$ and whose union is $\mathbb{R}^N \setminus \{0\}$. However, $(\mathcal{O}, \mathcal{T}, \omega_o)$-compatibility is a much more general properness condition, since it allows functions which are not proper and cases where $\mathcal{O}$ is bounded.

Remark 2.8. Notice for future reference that $(\mathcal{O}, \mathcal{T}, \omega_o)$-compatibility does not put any restrictions on the behavior of compatible functions at points which are not on the boundaries of any of the sets Ω_j in the controllability sequences. In particular, we allow $(\mathcal{O}, \mathcal{T}, +\infty)$-compatible functions which are not bounded below. We will generally be concerned with functions that are compatible in the sense of the preceding definition. (But see section 6.2 for analogues of our main results, which characterize the value function of (1.2) as a unique viscosity solution of (1.3) in a class of functions satisfying an even more general notion of properness than the one given by Definition 2.6.)

3. Statements of main results. We will prove the following theorem.

THEOREM 3.1. *Assume that* (1.2) *satisfies* (A_0)–(A_3), *that* $\Omega \subseteq \mathbb{R}^N$ *is an open set containing* $\mathcal{T}$, *that* $\omega_o \in \mathbb{R} \cup \{+\infty\}$, *and that* $w \in BC_{\omega_o}(\Omega)$ *is a viscosity solution of* [3]

$$\begin{cases} H(x, Dw(x)) \;=\; 0, & x \in \Omega \setminus \mathcal{T}, \\ w(x) \;=\; g(x), & x \in \mathcal{T}. \end{cases} \tag{3.1}$$

Assume $\Omega \setminus \mathcal{T} \subseteq P$ *and that* w *is* $(\Omega \cap P,\ \mathcal{T}, \omega_o)$*-compatible. Then* $w \equiv v$ *on* Ω.

Remark 3.2. The hypothesis that $w \in BC_{\omega_o}(\Omega)$, which is unnecessarily strong, is used to simplify the statement of the theorem. As we will show in section 5.2, Theorem 3.1 remains true if we weaken the assumption that $w \in BC_{\omega_o}(\Omega)$ to the assumptions that $w < \omega_o$ on Ω and $w \in QG(\Omega)$ (cf. Definition 2.2).

Remark 3.3. Let us compare the assumptions of Theorem 3.1 to those of the previously known uniqueness characterizations for exit time problems, and let us show how the assumptions of the theorem can easily be verified. As we explained in the introduction, the earlier results assume (1.4), i.e., positive lower bounds on the Lagrangian ℓ outside neighborhoods of the target. This is much more restrictive than requiring $\Omega \setminus \mathcal{T} \subseteq P$. For example, it could be that ℓ depends only on the state, and $\int_0^t \ell(y_x(s,\beta))\,ds > 0$ even though $\ell(y_x(s,\beta)) = 0$ for some values $s \in [0,t]$. This will be the case for the FP (cf. Example 2.4 and section 4.1), since the Lagrangian vanishes along the y-axis but all the trajectories starting outside $\vec{0}$ and running for positive time give positive running costs. The condition $\Omega \setminus \mathcal{T} \subseteq P$ is a control analogue of the La Salle invariance principle, and as we show in Remark 4.3, this condition cannot be omitted from the theorem. The condition $\Omega \setminus \mathcal{T} \subseteq P$ also allows cases where ℓ is always positive, or null only for state space points in the target, but still violates (1.4) because $\liminf_{||x|| \to \infty} \ell(x,a) = 0$ for certain control values a while $\mathcal{T}$ is bounded. This will be the case for the shape-from-shading and degenerate eikonal equations (cf. sections 4.2–4.3). As discussed in Remark 2.7, condition $BC_{\omega_o}(\Omega)$ is standard (cf. [2], [5], and [16]), and $(\mathbb{R}^N \setminus \mathcal{T}, \mathcal{T}, +\infty)$-compatibility holds for any proper continuous function as long as $STC\mathcal{T}$ and $STC(\Omega_j)$ hold along a suitable increasing sequence Ω_j

[3] By a viscosity solution of (3.1) we will mean a viscosity solution of $H(x, Dw(x)) = 0$ on $\Omega \setminus \mathcal{T}$ which equals g on $\mathcal{T}$. Notice that since we assume $\mathcal{T} \subset \Omega$, the target condition $w(x) = g(x)$ in (3.1) holds on all of $\mathcal{T}$.

of bounded open sets. This observation is the basis for our uniqueness result for the FP.

In the context of Theorem 3.1, we of course have $\Omega \subseteq \{x \in \mathbb{R}^N : v(x) < \omega_o\}$, since $w \equiv v$ on Ω. Also, while the condition $\Omega \setminus \mathcal{T} \subseteq P$ of the theorem implies that

$$\int_0^t \ell(y_p(s,\alpha),\alpha(s))\,ds \geq 0 \quad \forall \alpha \in \mathcal{A},\ t \geq 0, \ \text{ and } \ p \in \Omega \setminus \mathcal{T}, \tag{3.2}$$

this nonnegativity can fail for trajectories starting outside Ω, since (1.4) is not assumed. This suggests that a slight strengthening of the condition $\Omega \setminus \mathcal{T} \subseteq P$ to require nonnegativity of costs for trajectories running *outside* Ω might guarantee that $\Omega = \{x \in \mathbb{R}^N : v(x) < \omega_o\}$. This motivates the following corollary.

COROLLARY 3.4. *Under the assumptions of Theorem* 3.1*, with ℓ nonnegative,* $\Omega = \{x \in \mathbb{R}^N : v(x) < \omega_o\}$.

Remark 3.5. As we will show in the proof of Corollary 3.4, the assumption that ℓ is nonnegative can be relaxed to the following requirement:

($\sharp$) If $p \in \mathbb{R}^N$, and if $\alpha \in \mathcal{A}$ and $t > 0$ are such that $y_p(t,\alpha) \in \partial\Omega$, then $\int_0^t \ell(y_p(s,\alpha),\alpha(s))\,ds \geq 0$.

This is a strengthening of (3.2), since ($\sharp$) requires the nonnegativity of costs for trajectories starting outside of $\Omega \setminus \mathcal{T}$, while (3.2) requires only the nonnegativity of these costs for initial values on $\Omega \setminus \mathcal{T}$. Of course, ($\sharp$) may hold even if (1.4) fails (cf. the examples in section 4 below). Corollary 3.4 extends the local uniqueness characterizations based on (1.4) (cf. [2, Chapter 2] and [16]), which prove the uniqueness of viscosity solutions of HJBE (1.3) on neighborhoods Ω of $\mathcal{T}$ and which then characterize the neighborhoods containing proper viscosity solutions as sublevel sets of v. We will prove Corollary 3.4 in section 5.2.

The following corollary will be an immediate consequence of the fact that the value function v of (1.2) is a viscosity solution of the HJBE (1.3) on $\mathcal{R} \setminus \mathcal{T}$.

COROLLARY 3.6. *Assume* (A_0)–(A_3)*, $\mathcal{R}$ open, and $v \in QG(\mathcal{R})$. If $\mathcal{R} \setminus \mathcal{T} \subseteq P$ and v is $(\mathcal{R} \cap P, \mathcal{T}, +\infty)$-compatible, then v is the unique viscosity solution of*

$$\begin{cases} H(x, Dw(x)) \ = \ 0, & x \in \mathcal{R} \setminus \mathcal{T}, \\ w(x) \ = \ g(x), & x \in \mathcal{T}, \end{cases} \tag{3.3}$$

in the class of all $(\mathcal{R} \cap P, \mathcal{T}, +\infty)$-compatible functions $w \in QG(\mathcal{R})$.

The hypotheses of this corollary are especially easy to check when $\mathcal{R} = \mathbb{R}^N$, $\mathcal{T} = \{0\}$, and v is proper, since then $QG(\mathcal{R})$ holds vacuously and it suffices to check $SSTC(P)$ for a sequence Ω_j satisfying $\min\{||x|| : x \in \partial(\Omega_j), x \neq 0\} \to \infty$ and $\partial\Omega_j \setminus \mathcal{T} \subseteq P$ to get the uniqueness characterization.

Remark 3.7. The novelty of these results is that we do not need to assume that the Lagrangian ℓ satisfies condition (1.4) or that ℓ is even bounded below, that $\mathcal{T}$ can be very general, and that the uniqueness characterization is within a class which contains functions which are not bounded below. For the special cases in which $\omega_o = +\infty$, Corollary 3.4 characterizes the reachability set $\mathcal{R}$ as the unique set Ω for which there exists a function w satisfying the hypotheses of the theorem. By replacing the inputs $t \mapsto \alpha(t)$ with vector field valued inputs $t \mapsto (f(\cdot,\alpha(t)), \ell(\cdot,\alpha(t)))$ and adding standard assumptions on the input choice map $a \mapsto f(\cdot,a) \times \ell(\cdot,a)$, we can generalize Theorem 3.1 so that it also covers exit time problems with closed but not necessarily compact control sets (cf. section 6.3). One can also relax the assumption $\Omega \setminus \mathcal{T} \subseteq P$ and allow problems where ℓ takes negative values (cf. section 6.4).

4. Physical applications. Before proving our main results, we show how they apply to physical problems. Our uniqueness results apply to a variety of first-order equations which can be expressed in the HJBE form (1.3) but which are not tractable using the uniqueness results requiring (1.4). These include the Bellman equation of the FP (cf. [26]), degenerate eikonal equations from geometric optics (cf. [17]), and shape-from-shading problems in image processing (cf. [11]). This section discusses these applications.

4.1. The Fuller problem. We explain how the results of section 3 give uniqueness characterizations for the HJBE of the FP. Recall that the FP (with exponent q) is

$$\text{Infimize} \quad \int_0^{t_p(\alpha)} |y_{1,p}(t,\alpha)|^q \, dt \quad \text{over all} \quad \alpha \in \mathcal{A}^f(p) \tag{4.1}$$

for each $p \in \mathbb{R}^2$, where $t \mapsto y_p(t,u) := (y_{1,p}(t,u), y_{2,p}(t,u))'$ is defined to be the trajectory of

$$\begin{cases} \dot{x}(t) \;=\; y(t), \;\; \dot{y}(t) \;=\; u(t) \;\in\; A := [-1,+1], \\ (x(0),y(0))' \;=\; p, \end{cases}$$

and $t_p(u)$ is the first time this trajectory reaches the target $\mathcal{T} := \{0\} \subseteq \mathbb{R}^2$. (We use 0 to denote $0 \in \mathbb{R}$ or $\vec{0} \in \mathbb{R}^2$.) We allow any $q > 1$, but we fix q in what follows. From [26], we know that (4.1) has an optimal control for each initial state. In particular, $\mathcal{R} = \mathbb{R}^2$. We will verify the hypotheses of Corollary 3.6.

We first verify condition $SSTC(\mathbb{R}^2 \setminus \{0\}, \{0\})$. Let $\eta > 0$ be given. The FP trajectory ϕ_1 from $(0,\eta)'$ using the constant control $u \equiv -1/2$ reaches the point $(0,-\eta)'$ at time 4η. The FP trajectory ϕ_2 from $(0,-\eta)'$ using $u \equiv 1/2$ reaches $(0,\eta)'$ at time 4η. Let ζ_η denote the concatenation of the corresponding restrictions $\phi_1 : [0,4\eta] \to \mathbb{R}^2$ followed by $\phi_2 : [0,4\eta] \to \mathbb{R}^2$, and let G_η denote the open set bounded by this concatenation with the origin removed. By elementary calculations of trajectories, one sees that $STC(G_\eta^c)$ holds for each $\eta > 0$. The calculation is based on the fact that ϕ_1 solves $x = \eta^2 - y^2$, and ϕ_2 solves $x = y^2 - \eta^2$. From [15], we know that $STC(\{0\})$ holds. Since the G_η's engulf $\mathbb{R}^2 \setminus \{0\}$, it follows from Remark 2.5 that condition SSTC($\mathbb{R}^2 \setminus \{0\}, \{0\}$) holds.

For the case of the FP, we have $\int_0^t |y_{1,p}^r(s,\alpha)|^q \, ds > 0$ for all $\alpha \in \mathcal{A}^r$, $p \neq 0$, and $t > 0$, since $\dot{x} \equiv y$ is continuous along any FP trajectory (which implies that $|x(t)| > 0$ for a positive measure of small times whenever $y(0) \neq 0$). This establishes the condition $\mathcal{R} \setminus \mathcal{T} \subseteq P$. Next we verify that the FP value function v is $(\mathbb{R}^2 \setminus \{0\}, \{0\}, +\infty)$-compatible, which will be a consequence of the fact that v is proper (i.e., that it satisfies $\lim_{||x|| \to \infty} v(x) = +\infty$). The fact that v is proper is an elementary consequence of the dilation symmetries of the problem. Indeed, suppose

$$\lim_{m \to \infty} ||(x_m, y_m)'|| = \infty \quad \text{and} \quad v((x_n,y_n)') \leq M < \infty \quad \forall\, n.$$

For large n, pick a $\lambda_n > 0$ so that

$$\Lambda_n \;:=\; (\lambda_n^2 x_n, \lambda_n y_n)' \;\in\; \partial\,[B_1(0)]\,, \tag{4.2}$$

and thus $\lambda_n \to 0$. Assume $t \mapsto (x_n(t), y_n(t))'$ is an optimal FP trajectory for the initial point $(x_n, y_n)'$. Since $t \mapsto (\lambda_n^2 x_n(t/\lambda_n), \lambda_n y_n(t/\lambda_n))'$ is optimal for the initial

point Λ_n for each n (cf. [26]), it follows that

$$M \geq \int_0^\infty |x_n(t)|^q \, dt = \int_0^\infty \left|\lambda_n^2 \, x_n(u/\lambda_n)\right|^q \frac{1}{\lambda_n^{1+2q}} du = \frac{v(\Lambda_n)}{\lambda_n^{1+2q}} \quad \forall n. \tag{4.3}$$

Since $\partial[B_1(0)]$ is compact and v is continuous and positive definite, it follows that v is bounded away from 0 on $\partial[B_1(0)]$. To show that v is continuous, notice that v is strictly convex on $\mathbb{R}^2$ (cf. [26] and p. 81 of [13]), which follows from the fact that the FP admits optimal controls for each initial position and the convexity of $x \mapsto |x|^q$. Since (4.3) would mean that $v(\Lambda_n) \to 0$ as $n \to \infty$, we arrive at a contradiction with (4.2). Therefore, the FP value function is proper. Since the minimum norm of any point on $\partial(G_\eta) \setminus \{0\}$ increases without bound as $\eta \to +\infty$, it follows that the FP value function is $(\mathbb{R}^2 \setminus \{0\}, \{0\}, +\infty)$-compatible (with the controllability sequence defined by $\Omega_j = G_j$). Corollary 3.6 therefore gives the following.

COROLLARY 4.1. *For each $q > 1$, the value function v_q for the FP with exponent q is the unique viscosity solution of the Bellman equation*

$$-y(Dw((x,y)'))_1 + |(Dw((x,y)'))_2| - |x|^q = 0 \tag{4.4}$$

on $\mathbb{R}^2 \setminus \{0\}$ in the class of proper functions $w \in C(\mathbb{R}^2)$ that satisfy $w(0) = 0$. Moreover, v_q is the unique $(\mathbb{R}^2 \setminus \{0\}, \{0\}, +\infty)$-compatible viscosity solution $w \in C(\mathbb{R}^2)$ of (4.4) on $\mathbb{R}^2 \setminus \{0\}$ that vanishes at 0.

Remark 4.2. Since the FP Lagrangians ℓ vanish outside $\mathcal{T}$, this result does not follow from the earlier uniqueness results for viscosity solutions of HJBEs. Notice also that Corollary 3.6 actually gives a uniqueness characterization for (4.4) in a class containing functions which are not bounded below, as explained in Remark 2.8. Moreover, the FP value function is the unique viscosity solution of (4.4) on $\mathbb{R}^2 \setminus \{0\}$ in the class of functions $w \in C(\mathbb{R}^2)$ which are null at 0 and satisfy the even more general regularity condition (REG) of section 6.2 with $\Omega = \mathbb{R}^2$.

4.2. Degenerate eikonal equations. Our results also apply to equations from physics which do not arise as exit time problem HJBEs but which can be expressed in that form. For example, in geometric optics, the propagation of light is described by equations of the form

$$\sum_{i,j=1}^N a_{i,j}(x) \, u_{x_i}(x) \, u_{x_j}(x) + \sum_{i=1}^N 2 \, b_i(x) \, u_{x_i}(x) - h^2(x) = 0, \tag{4.5}$$

where $a_{i,j} = \sum_{k=1}^N \sigma_{i,k}\sigma_{j,k}$ and $\sigma = [\sigma_{i,j}]$ is a symmetric matrix. Such equations are called *degenerate eikonal equations*, and the viscosity solutions of (4.5) have been studied and applied extensively in physics (cf. [6]). The function $h : \mathbb{R}^N \to (0,1)$ represents the refraction index of the medium. Under the standard assumption that $b(x) = 2\sigma(x)\bar{b}(x)$ for some vector field $\bar{b}$, (4.5) is equivalent to

$$\left|\left|\sigma(x) \, Du(x) + \bar{b}(x)\right|\right| = \left[h^2(x) + \left|\left|\bar{b}\right|\right|^2(x)\right]^{1/2}.$$

This includes as a special case

$$\sup_{||a||=1} \{ -a \cdot Du(x) - |h(x)| \} = 0, \tag{4.6}$$

which is an HJBE for an exit problem for any closed target $\mathcal{T}$ with the dynamics $f(x,a) = a \in \partial B_1(0)$ and the Lagrangian $\ell(x,a) = |h(x)|$. (Recall from section 1 that $B_\varepsilon(p) := \{x \in \mathbb{R}^M : ||x-p|| < \varepsilon\}$ for all $\varepsilon > 0$ and $p \in \mathbb{R}^M$.) Equation (4.6) is satisfied by the travel time in geometric optics if $1/|h(x)|$ is the speed of the medium. Now take $\mathcal{T}$ to be bounded and choose any continuous refraction index h satisfying (i) $h(x) = \tilde{h}(||x||)$ for some decreasing function $\tilde{h} : \mathbb{R}_+ \to (0,1)$, (ii) $h(x) \to 0$ as $||x|| \to \infty$, and (iii) $||x||h(x) \to +\infty$ as $||x|| \to \infty$, e.g., take $\ell(x,a) \equiv h(x) = (1+||x||)^{-\beta}$ for any $\beta \in (0,1)$, so that (1.4) is violated. (One can also allow cases where h takes the value zero at some points in $\mathcal{T}$.) This defines an exit time problem with the control set $\partial B_1(0) \subseteq \mathbb{R}^N$ and the final cost $g \equiv 0$, and one can check that the structural assumptions of Theorem 3.1 apply to this problem. Using the fact that $t_p(\alpha) \geq ||p||/2$ for $||p||$ large and any input α that drives p to $\mathcal{T}$, the calculation

$$\int_0^{t_p(\alpha)} \tilde{h}(||y_p(s,\alpha)||)ds \;\geq\; \int_0^{||p||/2} \tilde{h}(3||p||/2)ds \;=\; \frac{1}{3}\left[\frac{3||p||}{2}\tilde{h}(3||p||/2)\right] \;\to\; +\infty$$

shows that the value functions for the exit time problems defined in this way are proper, and they are also continuous. Therefore, we can take the sets Ω_j in the SSTC($\mathbb{R}^N, \mathcal{T}$) definition to be the sublevel sets $\{x : v(x) < j\}$ of such value functions. This gives a characterization of the value function of the exit time problem, i.e., the travel time function, as the unique proper viscosity solution of (4.6) on $\mathbb{R}^N \setminus \mathcal{T}$ that vanishes on $\mathcal{T}$. In this case, ℓ is bounded below by positive constants on compact sets, so the result follows from the uniqueness results in [16], applied on the increasing sequence of bounded open sublevel sets of any continuous proper function. Theorem 3.1 also gives a uniqueness characterization for (4.6) on sublevel sets of the corresponding value function v which contain $\mathcal{T}$.

Remark 4.3. Since the set of relaxed trajectories for $f(x,a) = a \in \partial B_1(0) \subseteq \mathbb{R}^N$ includes all constant trajectories, we cannot allow eikonal equations in which h vanishes at points outside the target, although we can still allow degenerate cases in which h has a very general zero set in $\mathcal{T}$. Indeed, if h vanished at a point $\bar{p} \notin \mathcal{T}$, then the constant relaxed trajectory at $\bar{p}$ would generate zero running costs, which would violate the requirement $\mathbb{R}^N \setminus \mathcal{T} \subseteq P$. In fact, as shown in [17], the eikonal equation

$$||Du(x)||^2 \;=\; x^2(1-x^2)^2 \tag{4.7}$$

has *two* proper viscosity solutions on $\mathbb{R} \setminus \{0\}$ that vanish at 0. This shows that if we set

$$\tilde{P} := \left\{ x \in \mathbb{R}^N : \int_0^t \ell(y_x(s,\alpha),\alpha(s))\,ds > 0 \quad \forall t \in (0,\infty),\ \alpha \in \mathcal{A} \right\},$$

then the statement of Theorem 3.1 becomes false if $\Omega \setminus \mathcal{T} \subseteq P$ is replaced with $\Omega \setminus \mathcal{T} \subseteq \tilde{P}$. However, our results show that there is only one $(\mathbb{R}\setminus\{-1,0,+1\}, \{-1,0,+1\}, +\infty)$-compatible viscosity solution $w \in C(\mathbb{R})$ of (4.7) on $\mathbb{R} \setminus \{-1,0,+1\}$ which is null on $\{-1,0,1\}$. This extends a result from section 2 of [17].

4.3. Shape-from-shading equations. Our results also apply to equations of the form

$$I(x)\,\Psi(Du(x)) \;-\; b(x)\cdot Du(x) \;-\; h^2(x) \;=\; 0$$

for I nonnegative and Ψ a convex function with $\Psi(0) = 0$. This equation is studied in [17]. Taking the Legendre transform $\Psi^\star$ of Ψ, which is nonnegative, we can rewrite

this equation as

$$\max_{a \in \text{domain}(\Psi^\star)} \left\{ -\left(b(x) - I(x)a\right) \cdot Du(x) \; - \; \left[h^2(x) \; + \; I(x)\Psi^\star(a)\right] \right\} \; = \; 0.$$

A particular case of this equation is

$$I(x) \left[1 + ||Du(x)||^2\right]^{1/2} \; - \; 1 \; = \; 0, \quad x \in \Omega \subseteq \mathbb{R}^2, \tag{4.8}$$

for open sets Ω, which can in fact (cf. [17]) be written as

$$\max_{||a|| \leq 1} \left\{ I(x)\, a \cdot Du(x) \; - \; \left[1 \; - \; I(x) \left(1 - ||a||^2\right)^{1/2}\right] \right\} \; = \; 0. \tag{4.9}$$

Equation (4.9) arises in shape-from-shading models in image processing, where $I(x) \in [0, 1)$ is the intensity of light reflected by an object (cf. [11]). The objective in image processing is to reconstruct the unknown function u, representing the height of the surface over some subset Ω of the plane, from the brightness of a single two-dimensional image of the surface. As shown in [11], for the case of a Lambertian surface which is not self-shadowing and which is illuminated by a single distant vertical light source, the height u satisfies (4.9). Now take any positive Lipschitz continuous intensity function $I(x)$ for which $\lim_{||x|| \to \infty} I(x) = 1$, e.g.,

$$I(x) \; = \; 1 \; - \; \alpha\, e^{-||x||^2}, \qquad 0 < \alpha < 1. \tag{4.10}$$

Just as before, (4.9) is a Bellman equation for an exit time problem with the dynamics $f(x, a) = -I(x)a$ for any compact target $\mathcal{T}$ and the Lagrangian $\ell(x, a) = 1 - I(x)(1 - ||a||^2)^{1/2}$, which violates (1.4). However, with the choice of (4.10), we can use our theorem to get a global uniqueness characterization for viscosity solutions of (4.9) on $\mathbb{R}^N \setminus \mathcal{T}$ if the height u is $(\mathbb{R}^2, \mathcal{T}, \omega_o)$-compatible for some $\omega_o \in \mathbb{R} \cup \{+\infty\}$, continuous, and null on $\mathcal{T}$. This compatibility will hold if, for example, there is a positive constant ω_o so that (i) $u(x) < \omega_o$ for all x and (ii) $u(x) \to \omega_o$ as $||x|| \to \infty$. More generally, the compatibility requirement can be relaxed to the requirement (REG) in section 6.2 with $\Omega = \mathbb{R}^2$, $w = u$, and $P = \mathbb{R}^N$. These results also do not follow from the earlier uniqueness characterizations from [17], where the uniqueness results for (4.9) require $I(x) \leq C < 1$ for C constant. We also get local uniqueness characterizations on sublevel sets of the height function (cf. Theorem 3.1).

Remark 4.4. As discussed above, uniqueness characterizations for HJBEs form the basis for numerical schemes for approximating viscosity solutions. For example, in [11], uniqueness characterizations for (4.8) are used to give stable, robust numerical algorithms for finding the surface. Also, there is a large literature on approximating the minimal time function for exit problems with $\ell \equiv 1$ (cf. [2], [4], and the many references therein). One question which should be considered but which will not be discussed here is how the new uniqueness results for HJBEs can be used to study the convergence of schemes for approximating value functions for cases such as the FP, where $\ell(x, a)$ vanishes for certain $x \notin \mathcal{T}$ and $a \in A$. This type of result could have physical applications. This question will be addressed by the author in a separate paper.

5. Main lemmas and proof of main results. In this section, we recall well-known results from dynamic programming and relaxed controls. These are used to prove Theorem 3.1 and Corollary 3.4.

5.1. Main lemmas. Under (A_0)–(A_3) and $STC\mathcal{T}$, one easily proves that the value function v is a viscosity solution of the HJBE (1.3) on $\mathcal{R}\setminus\mathcal{T}$. The proof follows, since v satisfies the dynamic programming equality

$$v(x) = \inf_{\alpha\in\mathcal{A}}\left\{\int_0^t \ell(y_x(s,\alpha),\alpha(s))\,ds \;+\; v(y_x(t,\alpha))\right\} \quad \forall x\in\mathcal{R},\ t\in[0,\inf_\alpha t_x(\alpha)). \tag{5.1}$$

Our main results are based on the following representation lemmas, which say that viscosity solutions of (1.3) on $\mathcal{R}\setminus\mathcal{T}$ satisfy analogues of (5.1). The proofs of these lemmas are based on uniqueness characterizations for finite horizon problems (cf. [2, Chapter 3] or [10], and for generalizations, see [17] and [18]).

LEMMA 5.1. *Assume that conditions* (A_0)–(A_3) *are satisfied and that* $u\in C(\bar E)$ *is a viscosity subsolution of* $H(x,Du(x))=0$ *on* E, *where* $E\subset\mathbb{R}^N$ *is bounded and open. If we set*

$$\tau_q(\beta) \;=\; \inf\{\,t\ge 0:\ y_q(t,\beta)\ \in\ \partial E\}$$

for each $\beta\in\mathcal{A}$ *and* $q\in E$, *then, for all* $\beta\in\mathcal{A}$ *and* $q\in E$, *we have*

$$u(q) \;\le\; \int_0^r \ell(y_q(s,\beta),\beta(s))\,ds \;+\; u(y_q(r,\beta)) \tag{5.2}$$

for $0\le r<\tau_q(\beta)$.

LEMMA 5.2. *Assume* (A_0)–(A_3) *hold and assume* $w\in C(\bar B)$ *is a viscosity supersolution of* (1.3) *on* B, *where* B *is open and bounded. Set*

$$T_\delta(p) \;:=\; \inf\{\,t:\operatorname{dist}(y_p(t,\alpha),\ \partial B)\le\delta,\ \alpha\in\mathcal{A}\}$$

for each $p\in B$ *and* $\delta>0$. *Then for any* $p\in B$ *and any* $\delta\in(0,\operatorname{dist}(p,\partial B)/2]$, *we have*

$$w(p) \;\ge\; \inf_{\alpha\in\mathcal{A}}\left\{\int_0^t \ell(y_p(s,\alpha),\alpha(s))\,ds \;+\; w(y_p(t,\alpha))\right\} \tag{5.3}$$

for all $t\in(0,T_\delta(p))$.

Notice that we can put $r=\tau_q(\beta)$ in (5.2) when $\tau_q(\beta)<\infty$. We also need the following elementary consequence of the Gronwall inequality and the sequential compactness of $\mathcal{A}^r$ (cf. [24]).

LEMMA 5.3. *Let* A *be a compact metric space, let* $\{\alpha_n\}$ *be a sequence in* $\mathcal{A}^r$, *and let* $c>0$. *Assume that* $f:\mathbb{R}^N\times A\to\mathbb{R}^N$ *satisfies the condition* (A_1). *Then there exists a subsequence of* $\{\alpha_n\}$ *(which we do not relabel) and an* $\alpha\in\mathcal{A}^r$ *such that the following conditions hold:*

1. $\alpha_n\to\alpha$ *weak-*$\star$ *on* $[0,c]$.
2. *If* $x_n\to x$ *in* $\mathbb{R}^N$, *then* $y^r_{x_n}(\cdot,\alpha_n)\to y^r_x(\cdot,\alpha)$ *uniformly on* $[0,c]$.

We sometimes apply Lemma 5.3 to sequences in $\mathcal{A}$ identified with Dirac measure valued relaxed controls.

5.2. Proof of main results. Corollary 3.6 follows from Theorem 3.1 because v is a viscosity solution of the associated HJBE, which is shown by first establishing that v satisfies the dynamic programming equality (5.1) (cf. [2]). We leave the details to the reader and prove only Theorem 3.1 and Corollary 3.4.

5.2.1. Proof of Theorem 3.1. The inequality "$w \leq v$" follows from the following more general prolongation result.

PROPOSITION 5.4. *Assume that* (1.2) *satisfies* (A_0)–(A_3)*, that* $\Omega \subseteq \mathbb{R}^N$ *is an open set containing* $\mathcal{T}$ *which satisfies* $\Omega \setminus \mathcal{T} \subseteq P$*, and that* $w \in QG(\Omega)$ *is a viscosity subsolution of* (3.1)*. Then* $w \leq v$ *on* Ω*.*

Proof. Let $x \in \Omega \setminus \mathcal{T}$ be given, and let B be any bounded open subset of Ω that contains x and is such that $\bar{B} \subseteq \Omega \setminus \mathcal{T}$. Then w is also a viscosity subsolution of the HJBE (1.3) on B. Since $w \in C(\overline{B})$, it follows from Lemma 5.1 that

$$w(x) \;\leq\; \int_0^t \ell(y_x(s,\alpha),\alpha(s))\,ds \;+\; w(y_x(t,\alpha)) \tag{5.4}$$

for all $\alpha \in \mathcal{A}$ and $t \in [0, \tau_x(\alpha))$, where the $\tau_x(\alpha) := \inf\{t \geq 0 : y_x(t,\alpha) \notin B\} \in [0, +\infty]$. Moreover, we can put $t = \tau_x(\alpha)$ in (5.4) when $\tau_x(\alpha) < \infty$.

Suppose that $w(x) > v(x)$. By the definition of the infimum, there is an $\tilde{\alpha} \in \mathcal{A}^f(x)$ such that

$$\int_0^{t_x(\tilde{\alpha})} \ell(y_x(s,\tilde{\alpha}),\tilde{\alpha}(s))\,ds \;+\; g(y_x(t_x(\tilde{\alpha}),\tilde{\alpha})) < w(x). \tag{5.5}$$

If $y_x(s,\tilde{\alpha}) \in \Omega$ for all $s \in [0, t_x(\tilde{\alpha})]$, then $t_x(\tilde{\alpha})$ is a limit of exit times from sets $B = B_k$, as above, as $k \to \infty$. For example, take B_k to be an open tube around the restriction of the trace of $y_x(\cdot,\tilde{\alpha})$ to $[0,\, t_x(\tilde{\alpha}) - 1/k]$ for k large enough. In that case we arrive at a contradiction once we put $\alpha = \tilde{\alpha}$ and $t = t_x^k(\tilde{\alpha})$ in (5.4), where $t_x^k(\alpha) := \inf\{t \geq 0 : y_x(t,\alpha) \notin B_k\}$, and pass to the limit as $k \to \infty$. Otherwise, let $\hat{\tau}$ be the last time in $(0, t_x(\tilde{\alpha}))$ that $y_x(\cdot,\tilde{\alpha})$ is in $\partial\Omega$, and apply Lemma 5.1 with the choices

$$q = z_n := y_x(\hat{\tau} + 1/n, \tilde{\alpha}), \quad \beta(\cdot) = \alpha_n(\cdot) := \tilde{\alpha}(\cdot + \hat{\tau} + 1/n), \quad r = t_{z_n}(\tilde{\alpha}(\cdot + \hat{\tau} + 1/n)),$$

and with E chosen to be a tube in Ω which contains a portion of the trajectory $y_x(\cdot,\tilde{\alpha})$ that runs from z_n to $\mathcal{T}$. We then get $w(z_n) < w(x)$ for all n. Indeed, (5.5) would give

$$\begin{aligned} w(x) &> \int_0^{\hat{\tau}+1/n} \ell(y_x(s,\tilde{\alpha}),\tilde{\alpha}(s))\,ds \;+\; \int_0^{t_x(\tilde{\alpha})-\hat{\tau}-1/n} \ell(y_{z_n}(s,\alpha_n),\alpha_n(s))\,ds \\ &\quad + w(y_x(t_x(\tilde{\alpha}),\tilde{\alpha})) \\ &\geq \int_0^{\hat{\tau}+1/n} \ell(y_x(s,\tilde{\alpha}),\tilde{\alpha}(s))\,ds + w(z_n). \end{aligned} \tag{5.6}$$

Since $x \in \Omega \setminus \mathcal{T} \subseteq P$, the last integral is nonnegative for all n, so we get $w(x) > w(z_n)$ for large n. But $\Omega \ni z_n \to y_x(\hat{\tau},\tilde{\alpha}) \in \partial\Omega$, and this contradicts the assumption $w \in QG(\Omega)$. Since $w \equiv v$ on $\mathcal{T}$, the result follows. □

We turn next to the proof of the inequality "$w \geq v$." Fix $x \in \Omega \setminus \mathcal{T}$. Since $\Omega \setminus \mathcal{T} \subseteq P$, we know that $x \in \Omega_j \setminus \mathcal{T}$ for large enough j, and for such a j we set $\mathcal{S} = \Omega_j$. We later put some restrictions on the value of j. We now use (5.3) of Lemma 5.2 (with $B = \mathcal{S} \setminus \mathcal{T}$) to prove the existence of a trajectory which starts at x and reaches $\mathcal{T}$ in finite time. The lemma applies since $\overline{\mathcal{S} \setminus \mathcal{T}} \subseteq \mathcal{S} \setminus \mathcal{T} \cup \partial\mathcal{S} \cup \partial\mathcal{T} \subseteq \Omega$ (by the compatibility assumption) and w is continuous on Ω.

We will first assume that $\omega_0 < \infty$. The proof is similar in spirit to the proof of Theorem IV.3.15 in [2] and arguments in [8], but we use a weak-$\star$ convergence

and strong controllability argument to replace the assumptions that w is bounded below and ℓ is bounded away from zero. We will apply inequality (5.3) of Lemma 5.2 repeatedly to a sequence of points $p = x_1, x_2, \dots$ in $\mathcal{S} \setminus \mathcal{T}$. We will assume that all of the corresponding δ's in the lemma can be chosen to be 1. The general case then follows by replacing the corresponding $1/k$'s with δ_k/k's for a suitable sequence $\delta_k \searrow 0$ in the argument below. In what follows, we set

$$I(x,t,\alpha) \;=\; \int_0^t \ell(y_x(s,\alpha),\alpha(s))ds \;+\; w(y_x(t,\alpha)).$$

Given $\varepsilon > 0$, let us begin by constructing an $\hat{\alpha} \in \mathcal{A}$ such that $\tau_x(\hat{\alpha}) < +\infty$ and such that

$$w(x) \;\geq\; \int_0^{\tau_x(\hat{\alpha})} \ell(y_x(s,\hat{\alpha}),\hat{\alpha}(s))\,ds \;+\; \lambda_x(\hat{\alpha}) \;-\; \varepsilon, \tag{5.7}$$

where

$$\tau_x(\alpha) \;:=\; \inf\{t \geq 0 : y_x(t,\alpha) \notin \mathcal{S} \setminus \mathcal{T}\}$$

and

$$\lambda_x(\alpha) := \begin{cases} \dfrac{w(x)+\omega_0}{2}, & t_x(\alpha) \neq \tau_x(\alpha), \\ w\left(y_x(\tau_x(\alpha),\alpha)\right), & t_x(\alpha) = \tau_x(\alpha). \end{cases}$$

Setting

$$T_\delta(p) \;=\; \inf\left\{t \geq 0 : \operatorname{dist}\left(y_p(t,\alpha), \partial(\mathcal{S} \setminus \mathcal{T})\right) < \delta, \alpha \in \mathcal{A}\right\} \quad \forall\; p \in \mathbb{R}^N,\; \delta > 0,$$

we define $x_1 := x$, $\tau_1 := T_1(x_1)$ when $T_1(x_1) < +\infty$, and $\tau_1{:=}10$ when $T_1(x_1) = +\infty$. Since $w \in C(\Omega)$ and $\overline{\mathcal{S} \setminus \mathcal{T}} \subseteq \Omega$, we can use (5.3) of Lemma 5.2 to get an α_1 such that $w(x_1) \geq I(x_1,\tau_1,\alpha_1) - \varepsilon/4$. Note that $y_{x_1}(\tau_1,\alpha_1) \in \mathcal{S} \setminus \mathcal{T}$. By induction, we define

$$x_k \;:=\; y_{x_{k-1}}(\tau_{k-1},\alpha_{k-1}) \;\in\; \mathcal{S} \setminus \mathcal{T} \quad \text{for} \quad k = 2,3,\dots, \tag{5.8}$$

where

$$\tau_k \;:=\; \begin{cases} T_{1/k}(x_k) & \text{if } T_{1/k}(x_k) < +\infty, \\ 10^k, & \text{otherwise.} \end{cases}$$

Since $x_k \in \mathcal{S} \setminus \mathcal{T}$, we can use (5.3) to get an $\alpha_k \in \mathcal{A}$ such that

$$w(x_k) \;\geq\; I(x_k,\tau_k,\alpha_k) \;-\; 2^{-(k+1)}\varepsilon \;\;\forall\;\; k. \tag{5.9}$$

We also set $\sigma_k := \tau_1 + \cdots + \tau_k$, $\bar{\sigma} = \limsup_k \sigma_k$, and, for an arbitrary $\bar{a} \in A$,

$$\bar{\alpha}(s) := \begin{cases} \alpha_1(s) & \text{if } 0 \leq s < \sigma_1, \\ \alpha_2(s-\sigma_1) & \text{if } \sigma_1 \leq s < \sigma_2, \\ \vdots & \\ \alpha_k(s-\sigma_{k-1}) & \text{if } \sigma_{k-1} \leq s < \sigma_k, \\ \vdots & \\ \bar{a} & \text{if } \bar{\sigma} \leq s, \end{cases}$$

with the last line used if $\bar{\sigma} < +\infty$. From the definitions of x_k, P, and $\bar{\alpha}$, we know that

$$y_x(s,\bar{\alpha}) \;=\; y_{x_k}(s-\sigma_{k-1},\alpha_k) \;\in\; \mathcal{S}\setminus\mathcal{T}\subseteq P \quad \text{when} \quad s<\bar{\sigma} \tag{5.10}$$

and

$$\int_0^{\tau_k}\ell(y_{x_k}(s,\alpha_k),\alpha_k(s))\,ds \;=\; \int_{\sigma_{k-1}}^{\sigma_k}\ell(y_x(s,\bar{\alpha}),\bar{\alpha}(s))ds \;\geq\; 0 \;\forall\; k. \tag{5.11}$$

Applying (5.9) repeatedly, we therefore get

$$\begin{aligned} w(x) &\geq \int_0^{\tau_1}\ell(y_x(s,\bar{\alpha}),\bar{\alpha}(s))\,ds + w(x_2) - \frac{\varepsilon}{4} \\ &\geq \int_0^{\sigma_2}\ell(y_x(s,\bar{\alpha}),\bar{\alpha}(s))\,ds + w(x_3) - \varepsilon\left(\frac{1}{4}+\frac{1}{8}\right) \\ &\geq \cdots \\ &\geq I(x,\sigma_k,\bar{\alpha}) - \frac{\varepsilon}{2}\left(1-\frac{1}{2^k}\right) \qquad \forall k. \end{aligned} \tag{5.12}$$

By (5.8) and the boundedness of $\mathcal{S}\in\{\Omega_j\}$, we know that $\{x_k\}$ is bounded and therefore clusters. Let $\bar{x}$ be a cluster point of the x_k's, and assume without loss of generality (w.l.o.g.) that $x_k\to\bar{x}$ (by passing to a subsequence without relabeling). Then $\bar{x}\in\overline{\mathcal{S}\setminus\mathcal{T}}$. We will need the following minimality property of $\bar{x}$.

PROPOSITION 5.5. *In the above notation,* $\bar{\tau} := \inf\{\tau_{\bar{x}}(\alpha) : \alpha\in\mathcal{A}\} \;\leq\; \limsup_k \tau_k$.

Proof. First assume $\bar{\tau}<\infty$. Let $\delta>0$ be given, and suppose that, for k as large as desired, we have $\tau_k < \bar{\tau}-\delta$. Passing to a subsequence, we assume that $\tau_k\to z\in[0,\bar{\tau}-\delta]$. There would then exist a sequence $\tilde{\tau}_k\to z$ and a control $u\in\mathcal{A}^r$ such that

$$\operatorname{dist}(y^r_{\bar{x}}(z,u),\partial(\mathcal{S}\setminus\mathcal{T})) \;\leftarrow\; \operatorname{dist}(y_{x_k}(\tilde{\tau}_k,u_k),\partial(\mathcal{S}\setminus\mathcal{T})) \;\leq\; \frac{1}{k}\to 0 \;\text{ as }\; k\to+\infty. \tag{5.13}$$

The u_k's and the $\tilde{\tau}_k$'s are chosen using the definition of the infima τ_k, and u is a weak-$\star$ limit of some subsequence of the u_j's. The existence of such a control u follows from Lemma 5.3 with c chosen to be some upper bound of the $\tilde{\tau}_k$'s. To check (5.13), note that

$$||y^r_{\bar{x}}(z,u)-y_{x_k}(\tilde{\tau}_k,u_k)|| \;\leq\; ||y^r_{\bar{x}}(z,u)-y^r_{\bar{x}}(\tilde{\tau}_k,u)|| \;+\; ||y^r_{\bar{x}}(\tilde{\tau}_k,u)-y_{x_k}(\tilde{\tau}_k,u_k)|| \;\to\; 0$$

and that $\operatorname{dist}(\cdot,\partial(\mathcal{S}\setminus\mathcal{T}))$ is continuous. The standard trajectories $y_{\bar{x}}(\cdot,u_k)$ converge uniformly to $y^r_{\bar{x}}(\cdot,u)$ on $[0,z+1]$ (by Lemma 5.3), and (5.13) gives

$$y^r_{\bar{x}}(\tilde{\tau}_k,u) \quad\to\quad y^r_{\bar{x}}(z,u) \quad\in\quad \partial(\mathcal{S}\setminus\mathcal{T}) \quad \text{as} \quad k\;\to\;\infty. \tag{5.14}$$

Therefore, for large k, we know that $y_{\bar{x}}(\tilde{\tau}_k,u_k)$ lies in $\mathcal{S}\setminus\mathcal{T}$ (since we are supposing that $\tilde{\tau}_k<\bar{\tau}$ for all k) and can be brought to $\partial(\mathcal{S}\setminus\mathcal{T})$ by some standard control $\tilde{u}$ in time less than $\delta/2$ (by the SSTC condition and (5.14)). If we concatenate a control u_k for such a k and a corresponding control $\tilde{u}$, we get a (standard) trajectory which brings $\bar{x}$ to $\partial(\mathcal{S}\setminus\mathcal{T})$ in time $\leq\bar{\tau}-\delta/4$, which stands in contradiction to the definition of $\bar{\tau}$. We conclude that $\tau_k\geq\bar{\tau}-\delta$ for k large enough, which establishes the result

if $\bar\tau < \infty$. If $\bar\tau = +\infty$, then replace $\bar\tau - \delta$ in the argument above with any positive number to get the result. ∎

Passing to a further subsequence without relabeling, fix $l \geq \bar\tau$ so that $\tau_k \uparrow l \in [0, +\infty]$. By the estimate $(\mathcal{E}_1)$, we know that $\bar\tau = 0$ iff $\bar x \in \partial(\mathcal{S} \setminus \mathcal{T})$. (Indeed, if $\bar x \notin \partial(\mathcal{S} \setminus \mathcal{T})$, then $\bar x \in \mathcal{S} \setminus \mathcal{T}$, so $B(\{\bar x\}, \mu) \subseteq \mathcal{S} \setminus \mathcal{T}$ for some $\mu > 0$. By $(\mathcal{E}_1)$, there is a $\gamma > 0$ so that all trajectories which start at $\bar x$ and run for time $\leq \gamma$ stay in $B(\{\bar x\}, \mu)$, and thus $\bar\tau \geq \gamma > 0$. The converse is trivial.) We use the following corollary, which is a consequence of Proposition 5.5.

COROLLARY 5.6. *With the above notation, we have* $\bar x \in \partial(\mathcal{S} \setminus \mathcal{T})$.

Proof. Let $M \in (0, l)$, and let $\tilde\alpha \in \mathcal{A}^r$ be a weak-$\star$ limit of a subsequence of the α_k's in $\mathcal{A}^r$ on $[0, M]$, which we assume to be the sequence itself for brevity (cf. Lemma 5.3). We conclude from (5.11) that

$$0 \leftarrow \int_{\sigma_{k-1}}^{\sigma_k \wedge \{\sigma_{k-1}+M\}} \ell(y_x(s, \bar\alpha), \bar\alpha(s))\, ds = \int_0^{\tau_k \wedge M} \ell(y_{x_k}(s, \alpha_k), \alpha_k(s))\, ds \;\to\; \int_0^{l \wedge M} \ell^r(y^r_{\bar x}(s, \tilde\alpha), \tilde\alpha(s))\, ds. \tag{5.15}$$

The left arrow is by the divergence test applied to the last integral in (5.12), since w is bounded below on $\bar{\mathcal{S}}$ and $x_k \in \mathcal{S} \setminus \mathcal{T} \subseteq P$ for all k. To justify the right arrow, apply Lemma 5.3 to get an $\tilde\alpha \in \mathcal{A}^r$ such that

$$y^r_{x_k}(s, \alpha_k) \;\to\; y^r_{\bar x}(s, \tilde\alpha) \quad \text{uniformly on} \quad [0, M]. \tag{5.16}$$

Let $\alpha_{k,s}(\cdot)$ (resp., $\tilde\alpha_s(\cdot)$) denote the Radon measures $\alpha_k(s)$ (resp., $\tilde\alpha(s)$) for each k. Then,

$$\begin{aligned} &\left| \int_0^M \left[\ell^r(y^r_{\bar x}(s, \tilde\alpha), \tilde\alpha(s)) - \ell^r(y^r_{x_k}(s, \alpha_k), \alpha_k(s)) \right] ds \right| \\ &\leq \left| \int_0^M \int_A \ell(y^r_{\bar x}(s, \tilde\alpha), a)\, d\tilde\alpha_s(a)\, ds - \int_0^M \int_A \ell(y^r_{\bar x}(s, \tilde\alpha), a)\, d\alpha_{k,s}(a)\, ds \right| \\ &\quad + \left| \int_0^M \int_A \left[\ell(y^r_{\bar x}(s, \tilde\alpha), a) - \ell(y^r_{x_k}(s, \alpha_k), a) \right] d\alpha_{k,s}(a)\, ds \right|. \end{aligned}$$

The first term on the right-hand side (RHS) $\to 0$ because $\alpha_k \to \tilde\alpha$ weak-$\star$ on the interval $[0, M]$ and because we can set $(h(s))(a) := \ell(y^r_{\bar x}(s, \tilde\alpha), a)$ in (2.1).[4] The second RHS term $\to 0$ by (5.16) and the assumption (A_3). This justifies the right arrow in (5.15), because $\tau_k \wedge M = M$ for large k, since $M < l$ and $\tau_k \to l$.

If we had $\int_0^{\bar\tau} \ell^r(y^r_{\bar x}(s, \tilde\alpha), \tilde\alpha(s))\, ds > 0$, then we have $\int_0^G \ell^r(y^r_{\bar x}(s, \tilde\alpha), \tilde\alpha(s))\, ds > 0$ for some $G \in (0, \bar\tau)$. Since $l \geq \bar\tau$ (cf. Proposition 5.5), we would reach a contradiction by putting $M = G$ in (5.15). Therefore, $\bar\tau = 0$, or $\bar x$ is not in P. If $\bar\tau = 0$, then $\bar x \in \partial(\mathcal{S} \setminus \mathcal{T})$, as explained above. Assume $\bar x \notin P$. Since $\bar x \in \overline{\mathcal{S} \setminus \mathcal{T}}$ by construction, and $\mathcal{S} \setminus \mathcal{T} \subset P$ by assumption, we again conclude that $\bar x \in \partial(\mathcal{S} \setminus \mathcal{T})$, as needed. ∎

We can therefore find $\bar n$ such that for each $k > \bar n$ there exists a $\beta_k \in \mathcal{A}$ which drives x_k to a point $\tilde x \in \partial(\mathcal{S} \setminus \mathcal{T})$ (depending on k) and which is such that

$$\int_0^{\tau_{x_k}(\beta_k)} \ell(y_{x_k}(s, \beta_k), \beta_k(s))\, ds \;<\; \varepsilon/4. \tag{5.17}$$

[4] We are using the fact that ℓ is continuous in the control set value.

To see why, let F be a bounded set containing $\{y_{x_k}(s,\beta) : \beta \in \mathcal{A}, 0 \leq s \leq 1, k \in \mathbb{N}\}$. Such a set exists by the estimate $(\mathcal{E}_2)$ and the boundedness of the x_k's. Set $\bar{\kappa} = 1 + \sup \ell\lceil [F \times A]$. This is finite since A is compact and ℓ is continuous. By the SSTC assumption and the fact that $\{x_k\}$ converges to a point in $\partial(\mathcal{S} \setminus \mathcal{T})$, we can find $\bar{n} \in \mathbb{N}$ so that if $k > \bar{n}$, then x_k can be brought to $\partial(\mathcal{S} \setminus \mathcal{T})$ in time $< \varepsilon/(4\bar{\kappa}) \wedge 1$. This establishes (5.17) for $k \geq \bar{n}$.

For $k > \bar{n}$, the construction (5.12) therefore gives

$$w(x) \ \geq \ I(x, \sigma_{k-1}, \bar{\alpha}) \ + \ \int_0^{\tau_{x_k}(\beta_k)} \ell(y_{x_k}(s,\beta_k), \beta_k(s))\, ds \ - \ \varepsilon/2\,(1 - 2^{-(k-1)} + 1/2). \tag{5.18}$$

Since $\partial(\mathcal{S}\setminus\mathcal{T}) \subseteq \mathcal{T} \cup (\partial\mathcal{S}\setminus\mathcal{T})$, we now separately consider the case in which $\tilde{x} \in \mathcal{T}$ and the case in which $\tilde{x} \in (\partial\mathcal{S}\setminus\mathcal{T})$. For large k, it follows that if $\tilde{x} \in \mathcal{T}$, then

$$w(x_k) \ + \ \varepsilon/4 \ \ > \ \ w(\tilde{x}). \tag{5.19}$$

To see why, first recall that $w \in C(\Omega)$ and $\mathcal{T} \subseteq \Omega$. By choosing small enough running times for the paths from x_k to $\tilde{x} \in \partial(\mathcal{S} \setminus \mathcal{T})$, we can use the estimate $(\mathcal{E}_1)$ from section 2 to ensure that $||x_k - \tilde{x}|| < \delta$, where $\delta > 0$ is chosen so that $|w(p) - w(a)| < \varepsilon/4$ for all $a \in \mathcal{T} \cap \bar{\mathcal{S}}$ and $p \in B(\mathcal{T} \cap \bar{\mathcal{S}}, \delta)$. By the SSTC assumption, these running times can be made as small as desired by taking k to be large. Such a δ exists since w is continuous on the compact set $\bar{\mathcal{S}} \cap \mathcal{T}$. The estimate (5.19) now follows by choosing $a = \tilde{x}$ and $p = x_k$.

If, on the other hand, we have $\tilde{x} \in \partial\mathcal{S} \setminus \mathcal{T}$, then we get $w(x_k) \geq 1/2\,(w(x) + \omega_0)$ for large k, since $w(x) < \omega_o$ and, by the compatibility condition, we can assume that the j we choose is so large that $w(p) > \frac{1}{4}w(x) + \frac{3}{4}w_0$ for $p \in \mathcal{S} \setminus \mathcal{T}$ sufficiently close to $\partial\mathcal{S} \setminus \mathcal{T}$. (The closeness of x_k to $\tilde{x}$ is achieved by choosing k large, as explained in the previous paragraph.) In the former case, we add and subtract $\varepsilon/4$ in (5.18). We can therefore take $\hat{\alpha}$ to be the concatenation

$$\hat{\alpha}(s) \ := \ \begin{cases} \bar{\alpha}(s) & \text{if } \ 0 \leq s \leq \sigma_{k-1}, \\ \\ \beta_k(s - \sigma_{k-1}) & \text{if } \ \sigma_{k-1} \leq s < \infty \end{cases}$$

for k large enough.

Thus, when $\omega_0 \in \mathbb{R}$, our construction always gives us a control $\hat{\alpha}$ which satisfies the condition $\tau_x(\hat{\alpha}) < +\infty$ and which satisfies the requirement (5.7). Since $\varepsilon > 0$ was arbitrary, we conclude that

$$w(x) \geq \inf_{\alpha} \left\{ \int_0^{\tau_x(\alpha)} \ell(y_x(s,\alpha), \alpha(s)) ds \ + \ \lambda_x(\alpha) : \ \ \tau_x(\alpha) \ < \ +\infty \right\}. \tag{5.20}$$

If $\alpha \in \mathcal{A}$ is such that $\tau_x(\alpha) \neq t_x(\alpha)$, then the corresponding infimand in (5.20) is

$$\int_0^{\tau_x(\alpha)} \ell(y_x(s,\alpha), \alpha(s))\, ds \ + \ \frac{1}{2}\,(\omega_0 + w(x)) \ \ > \ \ w(x),$$

since $w(x) < w_0$ for all $x \in \Omega$ and $x \in \mathcal{S} \setminus \mathcal{T} \subseteq P$, and thus such a control is irrelevant for the infimum. Since $g = w = v$ on $\mathcal{T}$, this establishes that $w \geq v$ on Ω for the case in which $\omega_o < \infty$.

The proof for the $w_0 = +\infty$ case is similar to this. We view a fixed $x \in \Omega \setminus \mathcal{T}$ as a member of $\Omega_j \setminus \mathcal{T}$, where j is large enough so that values of w on $\partial(\Omega_j) \setminus \mathcal{T}$ majorize $w(x)$, and then we construct a trajectory that reaches $\partial(\Omega_j)$ or $\mathcal{T}$ in finite time. By the above, the controls α for which $\tau_x(\alpha) \neq t_x(\alpha)$ are irrelevant for the calculation of the infimum in (5.20), and thus $w \geq v$ as before. This gives $w = v$ on Ω.

5.2.2. Proof of Corollary 3.4. It remains to prove the sublevel set characterization $\Omega = \{x \in \mathbb{R}^N : v(x) < \omega_o\}$ under the added assumption (♯). The inclusion "$\subseteq$" holds, since $w \equiv v$ on Ω and $w < \omega_o$ on Ω. Suppose $x \notin \Omega$ and $v(x) < \omega_o$, for the sake of obtaining a contradiction. Using the definition of the infimum, we can then find a $\bar{\beta} \in \mathcal{A}$ and a $K < \omega_o$ so that $t_x(\bar{\beta}) < \infty$ and so that

$$\int_0^{t_x(\bar{\beta})} \ell(y_x(s,\bar{\beta}),\bar{\beta}(s))ds \;+\; g(y_x(t_x(\bar{\beta}),\bar{\beta})) \;\;=\;\; K.$$

Since $\mathcal{T} \subset \Omega$ is closed and Ω is open, we have

$$\bar{t} := \sup\big\{t \in [0, t_x(\bar{\beta})) : y_x(t,\bar{\beta}) \in \partial\Omega\big\} \;\;<\;\; t_x(\bar{\beta}).$$

Set $z_n := y_x(\bar{t} + 1/n, \bar{\beta})$ for $n \in \mathbb{N}$ and let $\{\Omega_j\}$ be the controllability sequence from the compatibility hypothesis. We can assume $\bar{t} + 1/n < t_x(\bar{\beta})$ for all n. Since $z := y_x(\bar{t},\bar{\beta}) \notin \mathcal{T}$ and $\Omega \cap P \supseteq \Omega \setminus \mathcal{T} \ni z_n \to z$, it follows that for each sufficiently large n there is an $m(n) \in \mathbb{N}$ such that $z_n \in \Omega_{m(n)} \setminus \mathcal{T}$. Recall that $\{\Omega_j\}$ is an increasing sequence. If $\{m(n)\}$ can be taken to be bounded, then it follows that $\{z_n\}$ accumulates in some $\overline{\Omega_{\bar{m}}}$, and thus $z \in \overline{\Omega_{\bar{m}}} \setminus \mathcal{T} \subseteq \Omega$. Since $z \in \partial\Omega$, this contradicts the fact that Ω is open.

Therefore, for each n, we can find a $k(n) \in (0, \frac{1}{n})$ so that $z_n' := y_x(\bar{t} + k(n), \bar{\beta}) \in \partial\left(\Omega_{m(n)}\right) \setminus \mathcal{T}$, namely, $k(n) := \inf\{t \in [0, 1/n] : y_x(\bar{t} + t, \bar{\beta}) \in \partial(\Omega_{m(n)})\}$. By the definition of compatibility,

$$\limsup_{n\to\infty} w(z_n') \;\geq\; \omega_o. \tag{5.21}$$

On the other hand, by setting $\bar{\alpha}_n(\cdot) = \bar{\beta}(\cdot + \bar{t} + k(n))$ and applying Lemma 5.1 as before, we get

$$\begin{aligned} w(z_n') &\leq \int_0^{t_{z_n'}(\bar{\alpha}_n)} \ell(y_{z_n'}(s,\bar{\alpha}_n),\bar{\alpha}_n(s))ds + g(y_x(t_x(\bar{\beta}),\bar{\beta})) \\ &\leq \int_0^{t_{z_n'}(\bar{\alpha}_n)} \ell(y_{z_n'}(s,\bar{\alpha}_n),\bar{\alpha}_n(s))ds + g(y_x(t_x(\bar{\beta}),\bar{\beta})) \\ &\quad + \int_0^{\bar{t}} \ell(y_x(s,\bar{\beta}),\bar{\beta}(s))\,ds \leq K \end{aligned}$$

for n sufficiently large. The second inequality follows from (♯), and the last one follows from the fact that $\Omega \setminus \mathcal{T} \subseteq P$ and from the definition of $z \in \mathcal{T}^c$, which guarantees that

$$\int_{\bar{t}}^{\bar{t}+k(n)} \ell(y_x(s,\bar{\beta}),\bar{\beta}(s))\,ds \;\geq\; 0,$$

as a limit of the nonnegative running costs from points $y_x(\bar{t} + 1/m, \bar{\beta}) \in \Omega \setminus \mathcal{T} \subseteq P$ as $m \to \infty$. Therefore,

$$\limsup_{n\to\infty}\, w(z_n') \;\;\leq\;\; K \;\;<\;\; \omega_o,$$

which contradicts (5.21). This proves the sublevel set characterization. Corollary 3.4 now follows.

6. Extensions. We close with remarks on how to extend the results of section 3. We show how to relax the requirements that the control set A be bounded and that $\Omega \setminus \mathcal{T} \subseteq P$. We also show how to improve the theorem to get a uniqueness characterization within a class of functions satisfying more general notions of properness.

6.1. A further property of controllability sequences. For the Fuller example, there is a controllability sequence Ω_j for which $\mathcal{T} \subseteq \partial(\Omega_j)$ for all j. However, Theorem 3.1 allows controllability sequences for which this condition fails. On the other hand, if Ω, w, and so forth are as in the hypotheses of the theorem, and if $x \in \Omega \setminus \mathcal{T}$ and k are chosen so that $x \in \Omega_k$ and so that $\min\{w(p) : p \in \partial(\Omega_k) \setminus \mathcal{T}\} > w(x)$, then the argument of Theorem 3.1 gives a trajectory from x to $\mathcal{T}$ which lies completely in $\bar{\Omega}_k$. Indeed, given a point $x \in \Omega \setminus \mathcal{T}$, the hypotheses of Theorem 3.1 guarantee the existence of a trajectory which remains in $\bar{\Omega}_k$ and which reaches $\partial(\Omega_k) \setminus \mathcal{T}$ or $\mathcal{T}$ in finite time. The proof shows that if there is no trajectory whose exit time from $\Omega_k \setminus \mathcal{T}$ is an exit time from $\mathcal{T}^c$, then all the infimands in (5.20) are $> w(x)$, which is a contradiction. In particular, $\bar{\Omega}_k \cap \mathcal{T} \neq \emptyset$.

6.2. Generalized properness notions. As mentioned in section 2, the uniqueness conclusion "$w = v$" of Theorem 3.1 remains true if the compatibility assumption of the theorem is replaced by the assumption that w satisfies an even more general properness assumption (and all the other hypotheses are kept the same). For example, we can replace the compatibility requirement with the following:

(REG) Condition STC$\mathcal{T}$ holds, and for each $x \in \Omega \cap P$ there is a bounded open set $\Omega_x \subseteq \Omega \setminus \mathcal{T}$ which contains x and a $\omega_{o,x} \in \mathbb{R} \cup \{+\infty\}$ such that
- (REG_1) $w(p) < \omega_{o,x}$ for all $p \in \Omega_x$,
- (REG_2) $w(p) \to \omega_{o,x}$ as $\Omega_x \ni p \to x_o$ for all $x_o \in \partial(\Omega_x)$, and
- (REG_3) STC(Ω_x^c) and $\bar{\Omega}_x \setminus \mathcal{T} \subseteq \Omega \cap P$.

The proof follows from the argument we gave above, once we replace $\mathcal{S} = \Omega_j$ with the set Ω_x, and the argument will show that $\bar{\Omega}_x \cap \mathcal{T} \neq \emptyset$ for all x. The novelty here is that there may be uncountably many Ω_x's and that one does not need subcollections of the Ω_x's to form increasing sets (cf. Definition 2.3).

6.3. Problems with unbounded control sets. One can relax the compactness requirement (A_0) in Theorem 3.1 in various ways. One way to do this is to replace the inputs $t \mapsto \alpha(t)$ with vector field valued inputs $[0, \infty[\ni t \mapsto f(\cdot, \alpha(t)) \times \ell(\cdot, \alpha(t))$ and then add assumptions on f and ℓ which guarantee that the control set for the vector field valued inputs is compact. The details are as follows. We assume that A is a closed subset of a Euclidean space, for simplicity, but the argument also holds for more general control sets. We equip $C(\mathbb{R}^N, \mathbb{R}^{N+1})$ with the *metrizable* topology of compact convergence. We make the following assumptions on f and ℓ:

- (NC_1) $M_\ell := \sup\{\ell(0, a) : a \in A\} < \infty$.
- (NC_2) $\{f(\cdot, a) \times \ell(\cdot, a) : a \in A\}$ is a closed subset of $C(\mathbb{R}^N, \mathbb{R}^{N+1})$.
- (NC_3) $f : \mathbb{R}^N \times A \to \mathbb{R}^N$ satisfies condition (A_1) and is bounded on $B_R(0) \times A$ for all $R > 0$.
- (NC_4) $\ell : \mathbb{R}^N \times A \to \mathbb{R}$ is continuous and bounded below, and there is a modulus ω such that for all $x, y \in \mathbb{R}^N$ and all $a \in A$, $|\ell(y, a) - \ell(x, a)| \leq \omega(|| x - y ||)$.

We will also find it convenient to assume the additional condition:

(NC_5) $f(\cdot,a)\times\ell(\cdot,a)\equiv f(\cdot,b)\times\ell(\cdot,b)\Rightarrow a=b$, i.e., the mapping $a\overset{\mu}{\mapsto} f(\cdot,a)\times\ell(\cdot,a)$ is one-to-one.

However, (NC_5) is not necessary if we restate the condition $\Omega\setminus\mathcal{T}\subseteq P$ in terms of vector field valued inputs (see the discussion below). In (NC_3), a modulus is a continuous nondecreasing function $\omega:\mathbb{R}_+\to\mathbb{R}_+$ which satisfies $\omega(0)=0$. The vector field $\ell(0,\cdot)$ in (NC_1) can be replaced by $\ell(p,\cdot)$ for any $p\in\mathbb{R}^N$ (by assumption (NC_4)). Notice that under assumption (NC_1), the mappings f^r and ℓ^r defined in (2.2) are still well-defined functions. Also, (NC_3) guarantees that $y_x(\cdot,\alpha)$ is defined on $[0,\infty)$ for all $\alpha\in\mathcal{A}$ and $x\in\mathbb{R}^N$ and satisfies ($\mathcal{E}_1$)–($\mathcal{E}_2$) (cf. [2]). All the weak-$\star$ convergence in what follows takes place in $\mathcal{K}^r$ (i.e., the relaxed controls on K), where K is a suitable compact set of vector fields defined below, and we topologize K^r and $\mathcal{K}^r$ as before. In particular, K^r is topologized as a subset of the dual space of $C(K)$, and $\mathcal{K}^r\ni\alpha_n\to\bar\alpha\in\mathcal{K}^r$ means that (2.1) holds, with A replaced by K, for all Lebesgue integrable functions $h:[0,\tau]\to C(K)$ and all $\tau>0$. Condition (NC_5) guarantees that $\mu\lceil\ \overline{B_R(0)}\ $ has a continuous inverse for each $R>0$, where we write $B_R(0)$ to mean $B_R(0)\cap A$, to simplify the notation. (Indeed, assume $a_n,a\in B_R(0)$ for all n and $\mu(a_n)\to\mu(a)$. If $\varepsilon>0$ is such that $||a_{n'}-a||\geq\varepsilon$ along some sequence $a_{n'}$, then we can pass to a further subsequence without relabeling to get $a_{n'}\to\bar a\in\ \overline{B_R(0)}$. Since μ is continuous, we get $\mu(a_{n'})\to\mu(\bar a)$. By ($NC_5$), $\bar a=a$, which is a contradiction.)

In particular, if $S\subseteq A$ is closed, then

$$\begin{aligned}\mu(S) &= \bigcup_{n=1}^{\infty}\mu\left(S\bigcap\left[\ \overline{B_n(0)}\ \setminus\ B_{n-1}(0)\ \right]\right)\\ &= \bigcup_{n=1}^{\infty}\left\{\left[\mu\lceil\ \overline{B_n(0)}\ \right]^{-1}\right\}^{-1}\left(S\bigcap\left[\ \overline{B_n(0)}\ \setminus\ B_{n-1}(0)\ \right]\right)\end{aligned}$$

is a union of closed sets and therefore measurable. It follows that μ sends Borel subsets of A to Borel subsets of K, and in particular, we conclude that $m\circ\mu\in A^r$ for all $m\in K^r$. We can therefore topologize A^r (differently from before) by declaring that

$$\mathcal{O}\subset A^r\text{ is open}\quad\Longleftrightarrow\quad\{m\in K^r:m\circ\mu\in\mathcal{O}\}\text{ is open.}$$

The choice of the topology on A^r will guarantee that $s\mapsto k(s)\mapsto k(s)\circ\mu\in A^r$ is measurable when $s\mapsto k(s)\in K^r$ is measurable. This will allow us to apply the condition in the definition of the set P to relaxed controls in $\mathcal{K}^r$ (cf. (6.1) below). We remark that condition (NC_5) can be dropped if we replace the positivity set P with the analogue for vector field valued inputs (i.e., if we replace ℓ and $\mathcal{A}^r$ with Λ and $\mathcal{K}^r$, respectively, in the definition of P, where the notation is as defined below).

We now show how to prove an analogue of Theorem 3.1 for problems with noncompact control sets. We assume that $A\subset\mathbb{R}^M$ is closed and that conditions (A_2) from section 2 and (NC_1)–(NC_5) are satisfied. Let w satisfy the assumptions of the theorem. Let m_ℓ be a lower bound for ℓ. Let $\hat K$ be any collection of continuous functions $\phi\times\lambda:\mathbb{R}^N\to\mathbb{R}^N\times\mathbb{R}$ each of whose members satisfies

1. $\sup\{||\phi(x)||:x\in B_R(0)\}\leq\sup\{||f(x,a)||:a\in A,x\in B_R(0)\}$ for all $R>0$,
2. $||\phi(x)-\phi(y)||\ \leq\ L\,||x-y||$ for all $x,y\in\mathbb{R}^N$,
3. $|\lambda(x)-\lambda(y)|\ \leq\ \omega(||x-y||)$ for all $x,y\in\mathbb{R}^N$,
4. $m_\ell\ \leq\ \lambda(0)\ \leq\ M_\ell$.

These conditions guarantee that $\hat K$ is equicontinuous and pointwise bounded. Applying Ascoli's theorem, it follows that $\hat K$ is precompact in $C(\mathbb{R}^N,\mathbb{R}^{N+1})$. It now follows

from assumption (NC_2) that $K := \{h_a(\cdot) := f(\cdot,a) \times \ell(\cdot,a) : a \in A\}$ is a compact subset of the metric space $C(\mathbb{R}^N, \mathbb{R}^{N+1})$. We use K as our new control set. Set

$$\Phi(x,k) = (\Pi_{\mathbb{R}^N} \circ k)(x) \quad \text{and} \quad \Lambda(x,k) := (\Pi_{\mathbb{R}} \circ k)(x) \ \ \forall \ \ k \in K,$$

where $\Pi_{\mathbb{R}^N}$ (resp., $\Pi_{\mathbb{R}}$) is the projection from K to its first N components (resp., last component). Then Φ and Λ satisfy (A_1) and (A_3), with f replaced by Φ, ℓ replaced by Λ, and A replaced by K. Set

$$\tilde{\mathcal{A}} \ = \ \{[0,\infty) \ni t \mapsto h_{\alpha(t)} : \alpha \in \mathcal{A}\}.$$

Since $a \mapsto h_a$ is continuous, this is a subset of the measurable mappings of $[0,\infty)$ into K.

Note that for each $p \in \mathbb{R}^N$, the trajectories of Φ with controls in $\tilde{\mathcal{A}}$ starting at p are exactly the trajectories of f with controls in $\mathcal{A}$ starting at p. The proof of Theorem 3.1 under the new hypotheses is then exactly as before but with ℓ replaced by Λ (using controls in $\tilde{\mathcal{A}}$ that bring points to $\mathcal{T}$ in finite time) up to (but not including) the proof that $\bar{x} \in \partial(\mathcal{S} \setminus \mathcal{T})$. We then follow the argument of Corollary 5.6, except that the weak-$\star$ limits k^r we obtain are K^r-valued. Then $\bar{x} \in \partial(\mathcal{S} \setminus \mathcal{T})$ follows since

$$\int_0^t \int_K \Lambda(\phi_x^r(s,\beta),k)\, d\beta_s(k)\, ds \ = \ \int_0^t \int_A \ell(y_x^r(s,\beta\circ\mu),a)\, d(\beta_s \circ \mu)(a)\, ds \ > \ 0 \tag{6.1}$$

for all $\beta \in \mathcal{K}^r$, $x \in P$, and $t > 0$, where $\phi_x^r(\cdot,\beta)$ is the relaxed trajectory for the relaxed dynamics Φ^r and the control $s \mapsto \beta_s$ which starts at x. We leave the proof that $\phi_x^r(\cdot,\beta) \equiv y_x^r(\cdot,\beta\circ\mu)$ to the reader.

Another approach to extending Theorem 3.1 to problems with noncompact control sets is as follows. We assume that $0 \in A \subseteq \mathbb{R}^M$, with A closed but not necessarily compact. Following [3] and [7], we also add the following hypotheses on f and ℓ, which we assume in addition to (A_1) and (A_3):

- (A_4) There exists a $\sigma \geq 1$ and, for each compact subset $\mathcal{F} \subset \mathbb{R}^N$, a constant $f_{\mathcal{F}} > 0$ so that
$$||f(x,a)|| \ \leq \ f_{\mathcal{F}}(1 + ||a||^\sigma) \ \ \forall \ \ (x,a) \in \mathcal{F} \times A.$$
- (A_5) There exist $\ell_o > 0$, $C_o \geq 0$, $\beta \in (0,1]$, $\delta_2 \geq 0$, $\bar{\ell} \geq 0$, and $\delta_1 \geq 0$ such that the following conditions hold for all $x, y \in \mathbb{R}^N$ and all $a \in A$:
  (a) $\ell(x,a) \ \geq \ \ell_o||a||^{\delta_1} - C_o$,
  (b) $|\ell(x,a) - \ell(y,a)| \ \leq \ \bar{\ell}||x-y||^\beta \left(1 + ||a||^{\delta_1} + ||x||^{\delta_2} + ||y||^{\delta_2}\right)$.

We further assume that $\delta_1 > \sigma$. Assumptions (A_4)–(A_5) are satisfied for exit time problems with linear-quadratic (LQ) data. These assumptions penalize the use of control set values of large norm.

Let $\Omega \subset \mathbb{R}^N$ be an open set containing $\mathcal{T}$, let $w \in QG(\Omega)$ be a viscosity solution of (3.1), and assume that conditions (A_1)–(A_5) are satisfied. Since A is not necessarily compact, we cannot use the weak-$\star$ convergence argument from the proof of Theorem 3.1. Instead of replacing A with a compact set of vector fields as we did above, we will apply Lemma 5.3 to compact subsets of A. We use the positivity set

$$P^\sharp \ = \ \left\{ \begin{array}{l} x \in \mathbb{R}^N : \ \int_0^t \ell^r(y_x^r(s,\alpha),\alpha(s))\, ds > 0 \ \ \text{for all} \\ t \in (0,\infty], \ \alpha \in \mathcal{K}^r, \ \text{and compact sets } K \subseteq A \end{array} \right\}$$

in place of P, and we assume that w is $(\Omega \cap P^\sharp, \mathcal{T}, \omega_o)$-compatible for some $\omega_o \in \mathbb{R} \cup \{+\infty\}$ and has locally bounded subdifferentials (cf. [2]). We recall that the *subdifferential* of a function w on a set $S \subseteq \mathbb{R}^N$ is the set-valued map $D^- w : S \to \mathcal{P}(\mathbb{R}^N)$ defined by

$$D^- w(x) \;=\; \left\{ p \in \mathbb{R}^N : \liminf_{S \ni y \to x} \frac{w(y) - w(x) - p \cdot (y - x)}{||x - y||} \geq 0 \right\},$$

and we say w has locally bounded subdifferentials, provided that for each compact set $K_1 \subseteq S$ there is a compact set $K_2 \subseteq \mathbb{R}^N$ for which $\cup \{D^- w(x) : x \in K_1\} \subseteq K_2$. Let us remark that locally Lipschitz continuous functions have locally bounded subdifferentials (cf. [2]). Let $\{\Omega_j\}$ denote the corresponding controllability sequence. We next need the following lemma, which is an immediate consequence of the proof of Proposition 2.1 of [3].

LEMMA 6.1. *Let $A \subset \mathbb{R}^M$ be a closed set containing $\vec{0}$, and assume that conditions* (A_1)–(A_5) *hold. Let w be an $(\Omega \cap P^\sharp, \mathcal{T}, \omega_o)$-compatible viscosity solution of* (3.1) *with locally bounded subdifferentials, and let $\{\Omega_j\}$ denote the associated controllability sequence. Then for each $j \in \mathbb{N}$ there exists a compact subset $K_j \subseteq A$ such that w is also a viscosity supersolution of*

$$\begin{cases} \sup\limits_{a \in K_j} \{-f(x,a) \cdot Dw(x) - \ell(x,a)\} = 0, & x \in \Omega_j \setminus \mathcal{T}, \\ w(x) = g(x), & x \in \mathcal{T}, \end{cases}$$

for each j (i.e., a supersolution of $H_{K_j}(x, Dw(x)) = 0$ on $\Omega_j \setminus \mathcal{T}$ equalling g on $\mathcal{T}$, in the notation of section 2) .

This lemma follows since there are compact sets $K_j \subseteq A$ such that $H_A \lceil [\Omega_j \times \mathcal{D}_j] \equiv H_{K_j} \lceil [\Omega_j \times \mathcal{D}_j]$, where $\mathcal{D}_j$ is a compact set large enough to contain the subdifferentials of $w \lceil \Omega_j$ (cf. section 2 for the notation). Now let $x \in \left[\Omega \cap P^\sharp\right] \setminus \mathcal{T}$, and choose a $j \in \mathbb{N}$ so that $x \in \Omega_j$ and so that the values of w near $\partial(\Omega_j) \setminus \mathcal{T}$ majorize $w(x)$, as in the proof of Theorem 3.1. Assume further that (NC_3)–(NC_4) hold, and thus $(\mathcal{E}_1)$–$(\mathcal{E}_2)$ also hold. The argument now proceeds exactly as in the "$w \geq v$" part of that proof, up through the proof of $\bar{\tau} = 0$ but with the control set A replaced by the compact set K_j, so now all the weak-$\star$ limits are well-defined K_j^r-valued relaxed controls. Then we follow the part of the proof of that theorem after the $\bar{\tau} = 0$ proof as originally stated, to get $w(x) \geq v(x)$. Noting that the compactness assumption on A can be replaced by (NC_3)–(NC_4) in the proof of Proposition 5.4 (cf. [2]), we can therefore summarize our results for problems with noncompact control sets as follows.

COROLLARY 6.2. *Let* (A_2) *hold, and let $A \subseteq \mathbb{R}^M$ be a closed set containing $\vec{0}$. Let $\Omega \subseteq \mathbb{R}^N$ be an open set containing $\mathcal{T}$, let $\omega_o \in \mathbb{R} \cup \{+\infty\}$, and let $w \in BC_{\omega_o}(\Omega)$ be a viscosity solution of* (3.1) *with locally bounded subdifferentials. Assume the following:*

1. *$\Omega \setminus \mathcal{T} \subseteq P^\sharp$.*
2. *w is $(\Omega \cap P^\sharp, \mathcal{T}, \omega_0)$-compatible, and (NC_3)–(NC_4) hold.*
3. *Either (NC_1), (NC_2), and (NC_5) hold, or else* (A_1)–(A_5) *hold with $\delta_1 > \sigma$.*

Then $w \equiv v$ on Ω.

Remark 6.3. Just as before, we can relax the hypothesis that $w \in BC_{\omega_o}(\Omega)$ to the requirements that $w \in QG(\Omega)$ and $w < \omega_o$ on Ω. Note that even if w is $(\Omega \cap P^\sharp, \mathcal{T}, \omega_o)$-compatible with the controllability sequence $\{\Omega_j\}$, the condition $(SSTC_2)$ can fail if we replace the control set A with some compact set $\tilde{K} \subset A$. On the other hand, one can show that if $SSTC(P^\sharp \cap \Omega, \mathcal{T})$ holds with A replaced by some compact set $J \subseteq A$, and if the other assumptions of Corollary 6.2 are satisfied with (A_1)–(A_5) and $\delta_1 > \sigma$,

then the restriction of v to any of the sets Ω_j coincides with the value function $v_{K_j \cup J}$ gotten by replacing the control set A with $K_j \cup J$, where the K_j are as in Lemma 6.1. Indeed, the condition $SSTC(P^\sharp \cap \Omega, \mathcal{T})$ holds for controls in $K_j \cup J$. Therefore, we can carry out the "$w \geq v$" part of the proof of Theorem 3.1 with A replaced by $K_j \cup J$ to get $w \geq v_{K_j \cup J}$ on Ω_j. Also, we have $w \leq v$ on Ω_j as before. Therefore, we get $v \geq v_{K_j \cup J} \geq v$ on Ω_j, and thus $v \equiv v_{K_j \cup J}$ on Ω_j, as claimed.

6.4. Problems with negative Lagrangians. The equality "$w = v$" in Theorem 3.1 remains true if we drop the assumption that $\Omega \setminus \mathcal{T} \subseteq P$, as long as the Lagrangian ℓ is "not very negative" and the remaining assumptions of the theorem are satisfied. By "not very negative," we mean that the following additional conditions are satisfied:

- (NVN_1) If $x \in \mathbb{R}^N$, if $\alpha \in \mathcal{A}^f(x)$, if $\{t \geq 0 : t \leq t_x(\alpha) \text{ and } y_x(t,\alpha) \notin \Omega\} \neq \emptyset$, and if we set $\lambda := \sup\{t \geq 0 : \ t \leq t_x(\alpha) \ \text{ and } \ y_x(t,\alpha) \notin \Omega\}$, then $\int_0^\lambda \ell(y_x(s,\alpha),\alpha(s))\, ds$ is nonnegative.
- (NVN_2) For each $x \in \Omega \setminus [P \cup \mathcal{T}]$, there is a bounded open set $B \subseteq \Omega$ containing x so that $\bar{B} \subseteq \Omega \setminus \mathcal{T}$ and a positive number

$$\Psi \ < \ \inf_{\alpha \in \mathcal{A}} \left\{ t > 0 : \ \mathrm{dist}(y_x(t,\alpha), \partial B) \leq \frac{1}{2} \mathrm{dist}(x, \partial B) \right\}$$

such that $y_x(\Psi,\alpha) \in P \cap \Omega$ and $\int_0^\Psi \ell(y_x(s,\alpha),\alpha(s))\, ds \geq 0$ for all $\alpha \in \mathcal{A}$.

Condition (NVN_1) takes the place of the condition $\Omega \setminus \mathcal{T} \subseteq P$ in the proof of the inequality "$w \leq v$" (cf. Proposition 5.4). The details are as follows. In the left-hand side of (5.6), we can replace $w(x)$ with $w(x) - \delta$ for some $\delta > 0$, and condition (NVN_1) guarantees that the last integral in (5.6) is $\geq -\delta$ for large enough n. This gives $w(x) \geq w(z_n)$ for large n, and then the contradiction is as before.

Condition (NVN_2) roughly means that for each $x \in \Omega \setminus [P \cup \mathcal{T}]$, there is a time Ψ such that all trajectories starting at x are in $P \cap \Omega$ at time Ψ. The proof of the reverse inequality "$w \geq v$" for cases in which $\Omega \setminus \mathcal{T} \not\subseteq P$ relies on (NVN_2). Indeed, the proof of Theorem 3.1 shows that $w(x) \geq v(x)$ for all $x \in [\Omega \cap P] \setminus \mathcal{T}$. On the other hand, if $x \in \Omega \setminus [P \cup \mathcal{T}]$, we write

$$w(x) \ = \ [w(x) \ - \ w(y_x(\Psi,\alpha'))] \ + \ w(y_x(\Psi,\alpha'))$$

for some $\alpha' \in \mathcal{A}$ and $\Psi > 0$ such that $y_x(\Psi,\alpha') \in P \cap \Omega$ and such that

$$w(x) \ - \ w(y_x(\Psi,\alpha')) \ \geq \ \int_0^\Psi \ell(y_x(s,\alpha'),\alpha'(s))\, ds \ - \ \varepsilon$$

(using Lemma 5.2). The $\hat{\alpha}$ we choose to satisfy requirement (5.7) is then the concatenation of $\alpha' \lceil [0,\Psi]$, followed by the control constructed in the proof of Theorem 3.1 for the point $y_x(\Psi,\alpha') \in P$. Note that the condition (NVN_1) holds vacuously if $\Omega = \mathcal{R} = \mathbb{R}^N$. In this way, we can extend Theorem 3.1 to cases in which $\Omega \setminus \mathcal{T} \subseteq P$ is not satisfied but the Lagrangian is "not very negative."

Acknowledgements. I would like to thank Professor H. J. Sussmann for suggesting these problems, and I would like to thank all the members of my doctoral dissertation committee, Professors D. J. Ocone, H. M. Soner, E. D. Sontag, and H. J. Sussmann, for helpful discussions and good advice.

A SINGULAR PERTURBATION APPROACH TO A RECURSIVE DECONVOLUTION PROBLEM*

FABIO FAGNANI† AND LUCIANO PANDOLFI†

Abstract. Following the approach described by A. V. Kryazhimskii and Yu. S. Osipov, we present a *recursive* algorithm which can be applied to solve the deconvolution problem of linear finite dimensional input output systems. The method gives an on line approximation of the unknown input, based on approximate samples of the output. Key features of this approach are the introduction of an associated singularly perturbed system and the use of a *quasi canonical* form due to Morse.

Key words. approximation, deconvolution, input identification, inverse problems, linear systems, singular perturbations

1. Description of the problem. In this paper we study a recursive version of the deconvolution problem for a linear finite dimensional system,

$$\dot{x} = Ax + Bu\,, \qquad y = Cx, \tag{1}$$

where $x \in \mathbb{R}^q$, $u \in \mathbb{R}^m$, and $y \in \mathbb{R}^p$. The matrices have consistent dimensions and are constant. The point of view of this paper is as follows: we assume that the initial condition $x(0)$ is known. Instead, *the input function u represents an unknown input, often a disturbance, which must be (at least approximately) identified on the basis of measurements taken on the output y during a time interval* $[0, T]$. Measurements of y are available only at times $\tau_k = kT/n$, $1 \le k \le n-1$, where n is a given number, and they may be corrupted by noise. The information at time τ_k will be written as $\xi_k = y(\tau_k) + \theta_k$, where θ_k is an (unavoidable) error. We assume that the tolerance h of the error is known, i.e., that $||\theta_k|| < h$ for every k.

The input output relation which is obtained from system (1), with the initial condition $x(0) = 0$, is

$$y(t) = \int_0^t H(t,s)u(s)\ ds\,, \qquad H(t,s) = Ce^{A(t-s)}B,$$

so that our deconvolution problem fits into the framework described in [24] (see p. 3, but we shall not assume smoothness of the input u). An analogous problem is also described in [5, 18] in the context of medical applications. In fact, the deconvolution problem is ubiquitous from medical to astrophysical or geological applications.

Our analysis, however, will quite depart from what is done in the above-mentioned literature. On one hand, our assumptions are more stringent: the input output map is causal (this rules out, for example, applications as image reconstruction; see [4]); and we are assuming that the weight function is the impulse response of a time

invariant *finite dimensional* system. Our class of systems is thus smaller than the one considered, for instance, in [18, 24, 21], where more general convolution kernels are considered. Actually, if $C = I$, full state observation, the method in this paper can also be applied to some classes of distributed systems; see [14, 15]. Instead, in this paper, we are particularly interested in the case $C \neq I$, i.e., partial state observation. In our setting we will be able to use the very rich geometrical structure of linear time invariant systems, which will be exploited, in particular, in section 5. On the other hand, while in the literature the deconvolution problem is in general solved off line as a smoothing problem, we will here enforce *time recursivity*. Namely, we will impose that the reconstruction of the input u at a certain instant t will use only samples of y up to time t and, moreover, will not be updated in the future. We thus expect new and more precise results which, however, will be mostly applicable in the context of signal and control theory (see also [3, 16] and the recent paper [20]).

The recursive identification method that we are going to present is inspired by ideas of the Russian school; see [8, 9, 10, 12, 13]. Two distinctive features of this method are the introduction of a *model system* which is used in order to test candidate approximations of the input and the use of a *penalization technique*. Model systems have been used since the very beginning of identification theory (see [1, 11]). On the other hand, penalization techniques have been widely used in solving the deconvolution problem; see [18, 19, 22, 23, 24]. Differently than in [10], we shall not make any assumption on the unknown input u, a part square integrability.

Input identification is possible (at least with observations at *each* time) if and only if the map $u \to y$ is injective and this condition is equivalent to the following geometric property: the maximal controllability subspace $\mathcal{R}_*$ contained in $\ker C$ is $\{0\}$ (which implies *unknown input* state *reconstructibility*; see [3, p. 233]) and $\ker B = \{0\}$ (which allows the reconstruction of the input from the state). From now on, we will assume that these two conditions are satisfied. We notice that the subspace $\mathcal{R}_*$ can be computed using known algorithms.

In the remainder of this section we give a brief illustration of the identification algorithm we will study. We start with a "model" of our system:

$$\dot{w} = Aw + Bv\,, \qquad z = Cw\,. \tag{2}$$

As usual in identification problems, we shall compare the output z of the model to the measures ξ_k's taken on the output of the system in order to make an "optimal" choice for a function v, which should approximate the input u. The definition of v is recursive and "natural": on $[\tau_k, \tau_{k+1})$ it is defined to minimize a suitable functional of $||\xi_k - w(\tau_{k+1})||$ and $\alpha||v||_2$ (the penalization term). This is described in section 3. We stress the fact that we shall not make any a priori assumption on the magnitude or regularity of the unknown input.

A key issue which we will study in this paper is *consistency*. Our identification algorithm produces a signal v depending on n, h, and the *penalization parameter* α. We will study whether when h converges to 0, n to ∞, and α to 0, then v converges to the real input. More precisely, we will distinguish two different limiting processes: The first one is the limit for $n \to +\infty$ and $h \to 0$ and is treated in section 3. The second one for $\alpha \to 0$ is instead considered in section 4, which also contains explicit convergence estimates for the two limits. We prove, in particular, that both limits always exist, and, in particular, the second one exists thanks to the presence of a key *singular perturbation* in the underlying differential equations. (This explains the title of the paper.) This limit will be the unknown input for the special class of systems

of relative degree 1, i.e., such that $\ker CB = \{0\}$. The general case will be treated in section 5: it consists of an iteration of the basic deconvolution procedure described in sections 3 and 4, and it uses a special "quasi canonical form" proposed by Morse in [17].

2. The robustness issue. The consistency condition discussed in previous section is a fundamental property of any identification algorithm. In our setting, it ensures robustness with respect to the perturbation in the observation and to the sampling. The fact that robustness is indeed a delicate issue here can easily be seen by taking $A = 0$ in our system. The deconvolution problem then reduces to the problem of numerical differentiation, which is well known to be an ill posed problem (see [2]).

To emphasize the robustness issue, we examine in the next example the following apparently natural algorithm. Assume that (1) is controllable, and consider the following method: on the interval $[\tau_k, \tau_{k+1})$ we take the input v with minimal norm among those inputs driving the output of the model from ξ_k to ξ_{k+1}.

Example 1. We apply the proposed algorithm to the system

$$\dot{x} = u, \qquad y = x, \qquad x(0) = 0.$$

There is a unique input u which produces the given output. Let the observation interval be $[0, 1]$, and let the input, unknown to us, be $u(t) \equiv 0$. We observe at times $\tau_k = k/n$, and we get the observations $\xi_k = x(\tau_k) + \theta_k = \theta_k$, where θ_k is a disturbance unknown to us but such that $||\theta_k|| \leq 1/n$. In fact, the "real" output is $y(t) \equiv 0$. We define v_n on $[\tau_k, \tau_{k+1})$ as that control of minimal norm which transfers ξ_k to ξ_{k+1}.

It is easily computed that

$$v_{n|_{[\tau_k, \tau_{k+1})}}(t) = n[\theta_{k+1} - \theta_k]\,.$$

Now we compute v_n explicitly in the following cases: the case that $\theta_k = 1/n$ for each k or $\theta_k = (-1)^k/n$. In the first case we have

$$v_n(t) \equiv 0\,.$$

This is exactly the sought-for input u, so it seems that the proposed identification procedure is very efficient. However, in the second case we obtain

$$v_n(t) = \begin{cases} -2 & \text{on } [\tau_{2k}, \tau_{2k+1}), \\ +2 & \text{on } [\tau_{2k+1}, \tau_{2k+2}), \end{cases}$$

and this sequence of functions does not converge either pointwise or in the L^2-norm to $u(t) \equiv 0$. In fact, it converges to $u(t) \equiv 0$ but only weakly in $L^2(0, 1)$.

3. The construction of a sequence of inputs. For clarity, we collect here the standing assumptions (already described). The system we consider is

$$\dot{x} = Ax + Bu\,, \qquad y = Cx. \tag{3}$$

The matrices A, B, C are constant and known, and the unknown input u is square integrable. The initial condition x_0 is known, so it is not restrictive to assume $x_0 = 0$. Observations are available only at times $\tau_k = kT/n$ and are denoted by

$$\xi_k = y(\tau_k) + \theta_k, \qquad ||\theta_k|| < h.$$

The map from u to y is injective; i.e., the explicitly computable geometric conditions $\mathcal{R}_* = \{0\}$ (only used in section 5) and $\ker B = \{0\}$ hold. We shall also impose the (nonrestrictive) condition that C is surjective.

We now *fix* a positive number $\alpha < 1$ which, will be the penalization parameter. The quantities that we are going to construct do depend on n, h, and α. However, for the sake of simplicity, in this section dependence on α, which is fixed, will not be explicitly noted. It is also convenient to introduce $\delta = \delta_n = T/n$.

We use M in order to denote a generic constant which does not depend on n, h, α. We shall introduce also two particular constants, which do not depend on n, h, α, but which play a special role: they will be denoted by ω and η. (The constant η is introduced in the next section.)

In this section we present an algorithm which produces a candidate approximation v of the unknown input u. In order to use a simpler notation, v_n instead of $v_{n,h}$, we relate h to n, $h = h_n$. We assume $\lim h_n = 0$.

Remark 2. Notice that we are not assuming any particular functional relation between h and n since $\{h_n\}$ can be *any* infinitesimal sequence. Hence our analysis of the behavior of v is done for $n \to +\infty$ and $h \to 0$ independently. The convergence estimates at the end of section 4 will depend on n and h separately.

As said already, we are going to compare the observed quantities ξ_k's and the output z of the model system

$$\dot{w} = Aw + Bv\,, \qquad z = Cw\,. \tag{4}$$

Let us assume that we are at the instant $\tau_0 = 0$. We have the information that $x(0) = 0$ so that we shall also impose $w(0) = 0$. No further information will be available until time τ_1, and, consequently, the choice of $v_{|_{(0,\tau_1)}} \in L^2(0,\tau_1)$ will be

$$v_{|_{(0,\tau_1)}} = \arg\min \left\{ ||z(\tau_1) - 0||^2 + \alpha \int_0^{\tau_1} ||v(s)||^2 \, ds \right\}.$$

It is clear that $v_{|_{(0,\tau_1)}}$=0. We now proceed recursively. Assume we already constructed v on $(0,\tau_k)$; we *extend* it to the next interval (τ_k,τ_{k+1}) as follows: we feed v to (4) on the interval $[0,\tau_k]$, and we compute $w(\tau_k)$. Then we define v in the next interval by

$$v_{|_{(\tau_k,\tau_{k+1})}} = \arg\min \left\{ ||z(\tau_{k+1}) - \xi_k||^2 + \alpha \int_{\tau_k}^{\tau_{k+1}} ||v(s)||^2 \, ds \right\}. \tag{5}$$

It is clear that the number α is a penalization constant, as in [19, 22, 23].

In this way we construct a function v on $[0,T]$. This function does depend on n and h. As we said before, we denote it simply as v_n.

At the same time as v_n, we also construct the functions w_n and $z_n = Cw_n$, respectively, the state and output functions of the model system (4).

In order to better describe the sequences $\{v_n\}$ and $\{w_n\}$, we introduce the operators $\Lambda_{(k)}$: $L^2(\tau_k,\tau_{k+1}) \to \mathbb{R}^p$ and the adjoints $\Lambda^*_{(k)}$: $\mathbb{R}^p \to L^2(\tau_k,\tau_{k+1})$:

$$\Lambda_{(k)} v = \int_{\tau_k}^{\tau_{k+1}} Ce^{A(\tau_{k+1}-s)} Bv(s)\, ds, \qquad (\Lambda^*_{(k)} z)(t) = B^* e^{A^*(\tau_{k+1}-t)} C^* z.$$

In order to simplify some notation, we denote by $v_{(k)}$ the restriction of v_n to (τ_k,τ_{k+1}).

It is clear that $z(\tau_{k+1}) = Ce^{A\delta}w(\tau_k) + \left(\Lambda_{(k)}v_{(k)}\right)(\tau_{k+1})$ so that

$$v_{(k)} = -[\alpha I + \Lambda^*_{(k)}\Lambda_{(k)}]^{-1}\Lambda^*_{(k)}[Ce^{A\delta}w(\tau_k) - \xi_k]. \tag{6}$$

The following lemma is proved by direct computation.

LEMMA 3. *The following formulas hold:*

1. *the operator $\Lambda^*_{(k)}\Lambda_{(k)}$ acts from $L^2(\tau_k, \tau_{k+1})$ into itself and is given by*

$$[\Lambda^*_{(k)}\Lambda_{(k)}v](t) = B^*e^{A^*(\tau_{k+1}-t)}C^* \int_{\tau_k}^{\tau_{k+1}} Ce^{A(\tau_{k+1}-s)}Bv(s)\ \mathrm{d}s;$$

2. *the operator $\Lambda_{(k)}\Lambda^*_{(k)}$ acts from $\mathbb{R}^q$ into itself and is given by*

$$\Lambda_{(k)}\Lambda^*_{(k)} = \int_0^\delta Ce^{As}BB^*e^{A^*s}C^*\ \mathrm{d}s = R,$$

   independent of k *(but it does depend on n since it depends on $\delta = T/n$, $R = R_n$);*

3. $[\alpha I + \Lambda^*_{(k)}\Lambda_{(k)}]^{-1}\Lambda^*_{(k)} = \Lambda^*_{(k)}[\alpha I + \Lambda_{(k)}\Lambda^*_{(k)}]^{-1}$.

With the notation just introduced, the equation of the model on (τ_k, τ_{k+1}) is given by

$$\dot{w}_n = Aw_n - B[\alpha I + \Lambda^*_{(k)}\Lambda_{(k)}]^{-1}\Lambda^*_{(k)}[Ce^{A\delta}w_n(\tau_k) - \xi_k], \qquad z_n(t) = Cw_n(t). \tag{7}$$

We analyze the behavior of the sequence $\{w_n\}$ at the sampling times τ_k.

$$\begin{aligned}
&w_n(\tau_{k+1}) = e^{A\delta}w_n(\tau_k)\\
&-\textstyle\int_{\tau_k}^{\tau_{k+1}} e^{A(\tau_{k+1}-s)}B\left([\alpha I + \Lambda^*_{(k)}\Lambda_{(k)}]^{-1}\Lambda^*_{(k)}[Ce^{A\delta}w_n(\tau_k) - \xi_k]\right)(s)\ ds\\
&= e^{A\delta}w_n(\tau_k)\\
&-\textstyle\int_{\tau_k}^{\tau_{k+1}} e^{A(\tau_{k+1}-s)}B\left(\Lambda^*_{(k)}[\alpha I + \Lambda_{(k)}\Lambda^*_{(k)}]^{-1}[Ce^{A\delta}w_n(\tau_k) - \xi_k]\right)(s)\ ds\\
&= e^{A\delta}w_n(\tau_k)\\
&-\left(\textstyle\int_{\tau_k}^{\tau_{k+1}} e^{A(\tau_{k+1}-s)}BB^*e^{A^*(\tau_{k+1}-s)}C^*\ ds\right)\cdot\left([\alpha I + R]^{-1}[Ce^{A\delta}w_n(\tau_k) - \xi_k]\right)\\
&= \{I - KC^*[\alpha I + R]^{-1}C\}e^{A\delta}w_n(\tau_k) - KC^*(\alpha I + R)^{-1}\xi_k,
\end{aligned} \tag{8}$$

where K is the controllability operator,

$$K = \int_0^\delta e^{As}BB^*e^{A^*s}\ ds.$$

We note that K, as well as R, depends on δ, i.e., on n and that $||K|| < M \cdot \delta = M/n$.

We write the equality of the expression in (8) as follows:

$$w_n(\tau_{k+1}) = Hw_n(\tau_k) + f_k, \qquad \text{where}$$

$$\begin{cases} H &= \{I - KC^*[\alpha I + R]^{-1}C\}e^{A\delta},\\ f_k &= -KC^*(\alpha I + R)^{-1}\xi_k. \end{cases}$$

The crucial fact is that $\sup_k ||\xi_k|| < M$, independent of n, h, α. This implies that we can write

$$||f_k|| \le \frac{M}{n\alpha} \qquad \forall\, n\,,\ \alpha. \tag{9}$$

In order to estimate H, we consider the following inequality which will be repeatedly used in what follows:

$$||e^{A^* s} - I|| \leq \frac{M}{n} \qquad \forall s \in (0, 1/n). \tag{10}$$

We obtain

$$\begin{cases} ||H|| \leq 1 + \frac{\omega}{\alpha n} & \text{in general,} \\ ||H|| \leq 1 + \frac{M}{n} & \text{if } C = I. \end{cases} \tag{11}$$

The first inequality follows from (10), and the second follows from (10) and the fact that when $C = I$ the matrix $\{I - KC^*[\alpha I + R]^{-1}C\} = \{I - K[\alpha I + K]^{-1}\}$ is a contraction.

We are now ready to prove the following result.

THEOREM 4. *For every fixed $\alpha < 1$, the sequence $\{w_n(\tau_k)\}$ is uniformly bounded in n and k, and, for every $k < n$, we have the following estimates, where M and ω do not depend on n, h, α:*

$$\begin{cases} ||w_n(\tau_k)|| \leq M e^{\omega/\alpha} & \textit{in general,} \\ ||w_n(\tau_k)|| \leq M/\alpha & \textit{if } C = I. \end{cases} \tag{12}$$

Proof. We prove the inequality in the general case. We have

$$||w_n(\tau_k)|| \leq \big(\sup_k ||f_k||\big) \cdot \sum_{j=0}^{k} ||H||^j.$$

Using inequalities (11) and (9), we obtain

$$\begin{aligned} ||w_n(\tau_k)|| &\leq \frac{M}{\alpha n} \cdot \sum_{j=0}^{k} \Big(1 + \frac{\omega}{\alpha n}\Big)^j = \frac{M}{\alpha n} \cdot (\alpha n) \cdot \frac{(1 + \frac{\omega}{\alpha n})^{k+1} - 1}{\omega} \\ &\leq \frac{M}{\omega} \cdot \Big(1 + \frac{\omega}{\alpha n}\Big)^{k+1} \leq \frac{M}{\omega} \cdot \Big(1 + \frac{\omega}{\alpha n}\Big)^{n} \leq \frac{M}{\omega} e^{\omega/\alpha}, \end{aligned}$$

as wanted.

The proof in the case $C = I$ follows in a similar way by using the second inequality in (11). □

Remark 5.

(a) Estimate (12) in the case when $C \neq I$ is very weak. It will be used only for theoretical reasons since we shall prove in section 5 that the general case $C \neq I$ can be reduced to the study of a chain of simplest cases in which $C = I$. Hence, for practical purposes only, the second inequality in (12) is relevant.

(b) Inequality (12) was given only for $k < n$. If $k = n$, a further factor $[1+\omega/(\alpha n)]$ appears which, however, will not create any problem since the case of interest is when α converges to zero slowly (see Remarks 12 and 26).

In order to study the asymptotics of the whole sequence $\{w_n\}$, it is convenient to introduce further operators and to establish a number of continuity results for them.

We define Λ_n: $L^2(0,T) \to \mathbb{R}^{nq}$ as

$$(\Lambda_n f) = \mathrm{col}[\Lambda_{(0)} f_{|_{(0,\tau_1)}}, \ldots, \Lambda_{(n-1)} f_{|_{(\tau_{n-1},T)}}],$$

and we compute Λ_n^*: $\mathbb{R}^{nq} \to L^2(0,T)$:

$$\Lambda_n^*(x_0,\dots,x_{n-1}) = \bigwedge_{k=0}^{n-1} \Lambda_{(k)}^* x_k,$$

where the wedge $\wedge$ denotes concatenation. It follows the equality

$$(\Lambda_n^*\Lambda_n f)_{|_{(\tau_k,\tau_{k+1})}} = \Lambda_{(k)}^*\Lambda_{(k)} f_{|_{(\tau_k,\tau_{k+1})}}.$$

Next we introduce the space $\mathcal{K}_n(0,T)$ of the q-vector valued functions which are piecewise constant, with n jumps at most, located at the points τ_k. This space is a subspace of $L^2(0,T)$ isomorphic to $\mathbb{R}^{nq}$. We now introduce the operator $\Gamma_n : \mathcal{K}_n(0,T) \to \mathbb{R}^{qn}$, defined as follows. We fix arbitrary points $s_k \in (\tau_k, \tau_{k+1})$, and we put

$$\Gamma_n f = \mathrm{col}[f(s_0), f(s_1), \dots, f(s_{n-1})]. \tag{13}$$

We note that the space over which the operator Γ_n is defined is itself a function of n and that we have

$$||\Gamma_n f||_{\mathbb{R}^{nq}} = \sqrt{n}||f||_2. \tag{14}$$

We now study the properties of these operators. We have the following lemma.

LEMMA 6. *Consider a sequence of functions $\{g_n\}$ with $g_n \in \mathcal{K}_n(0,T)$. We have the following:*

1. *if the sequence $\{g_n\}$ is uniformly bounded on $[0,T]$, then the sequence $\{\Lambda_n^*\Gamma_n g_n\}$ is also uniformly bounded on $[0,T]$;*
2. *if there exists a bounded function g such that $\sup_t ||g_n(t) - g(t)|| \le M_0$, then*

$$\sup_t ||(\Lambda_n^*\Gamma_n g_n)(t) - B^*C^*g(t)|| \le M \cdot \left\{ \frac{1}{n} + M_0 \right\}.$$

Proof. We prove item 1. We have, from (13),

$$\begin{aligned} &\sup_t ||\left(\Lambda_n^*\Gamma_n g_n\right)(t)|| = \sup_k \sup_{t\in(\tau_k,\tau_{k+1})} ||\Lambda_{(k)}^* g_n(s_k)|| \\ &= \sup_k \sup_{t\in(\tau_k,\tau_{k+1})} ||B^* e^{A^*(\tau_{k+1}-t)} C^* g_n(s_k)|| \le M \cdot ||B|| \cdot ||C|| \sup_{s\in(0,\delta)} ||e^{A^*s}||, \end{aligned}$$

as wanted.

Now we prove item 2. We have

$$\begin{aligned} &||(\Lambda_n^*\Gamma_n g_n)(t) - B^*C^*g(t)|| \le ||(\Lambda_n^*\Gamma_n g_n)(t) - B^*C^*g_n(t)|| \\ &+||B^*C^*[g_n(t) - g(t)]||. \end{aligned} \tag{15}$$

The first addendum is equal to $||B^*(e^{A^*(\tau_{k+1}-t)} - I)C^*g_n(t)||$. (We recall that g_n is constant on (τ_k, τ_{k+1}).) Using (15) and (10) and the fact that $\{g_n\}$ is uniformly bounded, we obtain that, on each interval (τ_k, τ_{k+1}),

$$||(\Lambda_n^*\Gamma_n g_n)(t) - B^*C^*g(t)|| \le M \cdot \left\{ \frac{1}{n} + \sup_{t\in[0,T]} ||g_n(t) - g(t)|| \right\}, \tag{16}$$

as wanted. ∎

LEMMA 7. *The operators* $\Lambda_n : L^2(0,T) \to \mathbb{R}^{nq}$ *satisfy the following:*

1. $||\Lambda_n|| \to 0$.
2. *There exists a constant* M *such that* $\sup_{n,t} ||(\Lambda_n^* X)(t)|| \le M||X||$ *for every vector* $X \in \mathbb{R}^{nq}$. *The constant* M *does not depend on* n, h, α.

Proof. In order to prove item 1, we estimate $||\Lambda_n^*||$ first. Let $X = \mathrm{col}(x_0, x_1, \ldots, x_{n-1})$ be a unitary vector. We have

$$||\Lambda_n^* X||_2^2 = \sum_{k=0}^{n-1} ||\Lambda_{(k)}^* x_k||_2^2 = \sum_{k=0}^{n-1} \int_{\tau_k}^{\tau_{k+1}} ||B^* e^{A^*(\tau_{k+1}-s)} C^* x_k||^2 \, ds$$

$$\le \delta \sum_{k=0}^{n-1} \sup_{s\in[\tau_k,\tau_{k+1}]} \left(||B^* e^{A^*(\tau_{k+1}-s)} C^*||\right)^2 \cdot ||x_k||^2 \le M \cdot \delta \cdot ||X||^2 . \tag{17}$$

This yields

$$||\Lambda_n|| = ||\Lambda_n^*|| \le \frac{M}{n} \to 0 . \tag{18}$$

The second statement has an analogous proof. □

Finally, we prove a further pointwise estimate.

LEMMA 8. *Let* $\{g_n\}$ *be a sequence of functions,* $g_n \in \mathcal{K}_n(0,T)$. *We have the following:*

1. *If the sequence* $\{g_n\}$ *is uniformly bounded, then* $[\alpha I + \Lambda_n^* \Lambda_n]^{-1} g_n$ *is a piecewise continuous function and*

$$\sup_t ||([\alpha I + \Lambda_n^* \Lambda_n]^{-1} g_n)(t)|| < M \cdot \left(\frac{1}{\alpha} + \frac{1}{\sqrt{n}\alpha^2}\right) \cdot ||g_n||_2 .$$

   The constant M *does not depend on* n, h, α.
2. *If* $\{g_n\}$ *uniformly converges to* $g \in C(0,T)$, *then the sequence* $\{[\alpha I + \Lambda_n^* \Lambda_n]^{-1} g_n\}$ *converges to* $\frac{1}{\alpha} g$ *uniformly on* $[0,T]$.

Proof. Let $\psi_n = [\alpha I + \Lambda_n^* \Lambda_n]^{-1} g_n$. We have

$$\alpha \psi_n + \Lambda_n^* \Lambda_n \psi_n = g_n \tag{19}$$

so that ψ_n is a piecewise continuous function.

Taking the L^2 inner product of (19) by ψ_n and using the positivity of $\Lambda_n^* \Lambda_n$, we get

$$||\psi_n||_2 \le \frac{||g_n||_2}{\alpha}.$$

If $t \in (\tau_k, \tau_{k+1})$, we have

$$||(\Lambda_n^* \Lambda_n \psi_n)(t)|| = \left|\left| B^* e^{A^*(\tau_{k+1}-t)} C^* \int_{\tau_k}^{\tau_{k+1}} C e^{A(\tau_{k+1}-s)} B \psi_n(s) \, ds \right|\right|$$

$$\le M \cdot \sqrt{\delta} \cdot ||\psi_n||_2 \le \frac{M \cdot \sqrt{\delta}}{\alpha} ||g_n||_2. \tag{20}$$

It follows from (19) and (20) that

$$||\psi_n(t)|| \le M \left(\frac{1}{\alpha} + \frac{\sqrt{\delta}}{\alpha^2}\right) ||g_n||_2.$$

This proves item 1.

To prove item 2, we evaluate

$$\alpha\psi_n - g = [\alpha\psi_n - g_n] + [g_n - g] = -[\Lambda_n^*\Lambda_n\psi_n] + [g_n - g]. \tag{21}$$

It follows from (20), considering that $||g_n||_2$ is bounded, that

$$\sup_t ||(\Lambda_n^*\Lambda_n\psi_n)(t)|| \le \frac{M}{\alpha\sqrt{n}}. \tag{22}$$

From (21) and (22), we obtain the explicit estimate

$$\left|\left| [\,(\alpha I + \Lambda_n^*\Lambda_n)^{-1}g_n](t) - \frac{1}{\alpha}g(t)\right|\right| \le \frac{M}{\alpha^2\sqrt{n}} + \frac{1}{\alpha}\sup_t ||g_n(t) - g(t)||. \tag{23}$$

The right-hand side converges to zero for $n \to +\infty$ for each fixed α. □

Now we can study the sequence $\{w_n\}$. We prove the following theorem.

THEOREM 9. *The sequence $\{w_n\}$ is relatively compact in $C(0,T)$.*

Proof. We consider again equality (7). This can be written as

$$\dot{w}_n = Aw_n - B[\alpha I + \Lambda_n^*\Lambda_n]^{-1}\Lambda_n^*\Gamma_n f_n, \tag{24}$$

where $f_n \in \mathcal{K}_n(0,T)$ is given by

$$f_{n\,|_{(\tau_k,\tau_{k+1})}} = Ce^{A\delta}w_n(\tau_k) - \xi_k. \tag{25}$$

We know from Theorem 4 that $\{w_n(\tau_k)\}$ is bounded (for fixed α) so that $\{f_n\}$ is bounded too. Using Lemma 6, item 1, and Lemma 8, item 1, we see that the affine term in (24) is bounded. This implies that the sequence $\{w_n\}$ and, therefore, also $\{\dot{w}_n\}$, is uniformly bounded. Compactness then follows from the Ascoli–Arzelà theorem. □

For future use we note the explicit inequality

$$||\dot{w}_n(t)|| \le K = K(\alpha). \tag{26}$$

Finally, we prove the following theorem.

THEOREM 10. *The sequence $\{w_n\}$ converges uniformly to the unique solution w^α of the problem*

$$\dot{w} = \left[A - \frac{BB^*C^*C}{\alpha}\right]w + \frac{BB^*C^*C}{\alpha}x, \qquad w(0) = 0. \tag{27}$$

Proof. We show that every limit point in $C(0,T)$ of $\{w_n\}$ coincides with w^α. We consider a subsequence of $\{w_n\}$, still denoted $\{w_n\}$, which converges to a limit w.

Since $w_n(0) = 0$, we can write

$$w_n(t) = \int_0^t e^{A(t-s)}\left[\frac{B}{\alpha}\left[I + \frac{1}{\alpha}\Lambda_n^*\Lambda_n\right]^{-1}\Lambda_n^*\Gamma_n f_n\right]\,ds.$$

(The sequence $\{f_n\}$ is defined in (25).)

Consider now the bounded sequence $\{f_n\}$. We prove that

$$\lim_n \sup_{t\in[0,T]} ||f_n(t) - Cw(t) - y(t)|| = 0\,. \tag{28}$$

In fact, the supremum in (28) is less than

$$\sup_k \sup_{t\in(\tau_k,\tau_{k+1})} ||C[e^{A\delta}w_n(\tau_k) - w(t)]|| + \sup_k \sup_{t\in(\tau_k,\tau_{k+1})} ||\xi_k - y(t)||\,.$$

On one hand, if t belongs to (τ_k, τ_{k+1}), we have

$$||e^{A\delta}w_n(\tau_k) - w(t)|| \le ||e^{A\delta}w_n(\tau_k) - w_n(t)|| + ||w_n(t) - w(t)||,$$

and both right-hand terms converge uniformly to zero because $w_n \to w$ uniformly by assumption, $e^{A\delta} = e^{A/n} \to I$, and the sequence of functions $\{w_n\}$ is bounded and equicontinuous, thanks to (26).

On the other hand,

$$||\xi_k - y(t)|| \le ||\xi_k - y(\tau_k)|| + ||y(\tau_k) - y(t)||\,.$$

The first addendum converges to zero since it is dominated by $h_n \to 0$. The second term converges to zero because the integral $C\int_0^t e^{A(t-s)}Bu(s)\ ds$ is absolutely continuous on $[0,T]$. This proves (28).

We recall that we are considering a convergent subsequence (in the uniform norm), still denoted $\{w_n\}$, which converges to w. We apply Lemma 6, and we see that

$$\Lambda_n^*\Gamma_n f_n \to B^*C^*[Cw - y]$$

uniformly. Hence, from Lemma 7, we have that the integral converges to the solution of (27), as wanted. □

We can also give a pointwise estimate of the convergence illustrated in Theorem 10 as follows.

LEMMA 11. *For each $\alpha < 1$ and for each $t \in [0,T]$ we have*

$$\text{(29)}\qquad \begin{cases} ||w_n(t) - w^\alpha(t)|| \le \frac{Me^{\omega/\alpha}}{\sqrt{n\alpha}} & \text{in general,} \\ ||w_n(t) - w^\alpha(t)|| \le \frac{M}{\sqrt{n\alpha^2}} & \text{if } C = I. \end{cases}$$

Proof. We compute

$$w_n(t) - w^\alpha(t) = \lim_m \int_0^t e^{A(t-s)}B\big\{[\alpha I + \Lambda_n^*\Lambda_n]^{-1} - [\alpha I + \Lambda_m^*\Lambda_m]^{-1}\big\}\Lambda_n^*\Gamma_n f_n\ ds + \int_0^t e^{A(t-s)}B[\alpha I + \Lambda_m^*\Lambda_m^*]^{-1}\left\{\Lambda_n^*\Gamma_n f_n - \Lambda_m^*\Gamma_m f_n\right\}\ ds.$$

Let $s_k \in (\tau_k, \tau_{k+1})$ as in (13). For $m > n$ we have the following estimates (we use (18) and (14), (25), and Theorem 4):

$$\begin{aligned} &\left|\left|\int_0^t e^{A(t-s)}B\left\{[\alpha I + \Lambda_n^*\Lambda_n]^{-1} - [\alpha I + \Lambda_m^*\Lambda_m]^{-1}\right\}\Lambda_n^*\Gamma_n f_n\ ds\right|\right| \\ &\le M\big\{||(\alpha I + \Lambda_n^*\Lambda_n)^{-1}|| + ||[\alpha I + \Lambda_m^*\Lambda_m]^{-1}||\big\}||\Lambda_n^*\Gamma_n f_n||_2 \\ &\le \frac{2M}{\alpha}\frac{1}{n}||\Gamma_n f_n||_2 \le \frac{2M}{\alpha\sqrt{n}}e^{\omega/\alpha}, \end{aligned}$$

where we used $||w_n(\tau_k)|| + ||\xi_k|| \le Me^{\omega/\alpha}$ for $\alpha < 1$.

The second addendum is estimated as follows:

$$\left|\left|\int_0^t e^{A(t-s)}B[\alpha I+\Lambda_m^*\Lambda_m]^{-1}\{\Lambda_n^*\Gamma_n f_n-\Lambda_m^*\Gamma_m f_m\}\,ds\right|\right|$$
$$\leq \frac{M}{\alpha n}\{||\Gamma_n f_n||+||\Gamma_m f_m||\}\leq \frac{2M}{\sqrt{n}\alpha}e^{\omega/\alpha}.$$

In both the estimates we replace $e^{\omega/\alpha}$ with $1/\alpha$ if $C=I$. The required estimates follow. □

Remark 12. The previous lemma implies, in particular, that if α converges to zero slowly in such a way that $\alpha^2\sqrt{n}>M>0$, then, in the case when $C=I$, the sequence $\{w_n\}$ remains bounded. This strengthens the result in Theorem 4.

We now consider the sequence $\{v_n\}$. Taking into account the definition (6) of $v_{(k)}$ and the definitions of Γ_n, Λ_n, we can write

$$v_n=-[\alpha I+\Lambda_n^*\Lambda_n]^{-1}\Lambda_n^*\Gamma_n f_n. \tag{30}$$

It follows from Lemma 6 that, for $n\to+\infty$, $\Lambda_n^*\Gamma_n f_n\to B^*C^*C[w^\alpha-x]$, and it follows from Lemma 7 that $||\Lambda_n^*\Lambda_n||\to 0$. This yields the following result.

THEOREM 13. *We have*

$$\lim_n v_n=v_\alpha,\qquad \textit{where}\qquad v_\alpha=-\frac{1}{\alpha}B^*C^*C[w^\alpha-x]\,. \tag{31}$$

Convergence in the previous theorem is meant to be in $L^2(0,T)$, but later we shall also give pointwise estimates.

4. Input identification in a special case. In this section we consider the convergence of the solutions of system (27) when $\alpha\to 0$. We put

$$\tilde{J}=BB^*C^*C.$$

With this notation, the "error" $e^\alpha=w^\alpha-x$ satisfies the system with *singular perturbations*

$$\dot{e}^\alpha=\dot{w}^\alpha-\dot{x}=\left(A-\frac{\tilde{J}}{\alpha}\right)e^\alpha-Bu. \tag{32}$$

We study the convergence properties of e^α when $\alpha\to 0$.

It is easy to see that the matrix $\tilde{J}=BB^*C^*C$ is diagonalizable and its eigenvalues are nonnegative. With no loss of generality, we thus assume that $\tilde{J}$ is diagonal, and we decompose

$$\tilde{J}=\begin{bmatrix} J & 0\\ 0 & 0\end{bmatrix},$$

where the matrix J is diagonal and has *positive* determinant. We represent, accordingly,

$$A=\begin{bmatrix} A_{11} & A_{12}\\ A_{21} & A_{22}\end{bmatrix},\qquad B=\begin{bmatrix} B_+\\ B_-\end{bmatrix}.$$

We recall the Wintner–Ważeski inequalities (see [6, p. 25]): if G is any square matrix and σ_-, σ_+ are the minimum and maximum eigenvalues of $(G+G^*)/2$, then we have, for each $t \geq 0$,

$$e^{\sigma_- t} \leq ||e^{Gt}|| \leq e^{\sigma_+ t}.$$

First we prove the following lemma.

LEMMA 14. *There exists a positive number M such that*

$$||e^{\alpha}(t)|| \leq M \qquad \forall t \in [0,T], \quad \forall \alpha > 0.$$

Proof. We apply the Wintner–Ważeski inequalities to the matrix $G = A - \frac{1}{\alpha}\tilde{J}$. The largest eigenvalue of $[(A-\frac{1}{\alpha}\tilde{J})+(A-\frac{1}{\alpha}\tilde{J})^*]/2$ is smaller than the largest eigenvalue of the matrix $(A+A^*)/2$, call it μ, for every α. Hence we have

$$||e^{[A-\frac{1}{\alpha}\tilde{J}]t}|| \leq e^{\mu t} \qquad \forall t \in [0,T], \quad \forall \alpha > 0. \tag{33}$$

The result follows since the input u is fixed. □

We decouple (32) as

$$\begin{cases} \dot{e}_+^{\alpha} = (A_{11} - \frac{1}{\alpha}J)e_+^{\alpha} + A_{12}e_-^{\alpha} - g_+, \\ \dot{e}_-^{\alpha} = A_{21}e_+^{\alpha} + A_{22}e_-^{\alpha} - g_-, \end{cases} \quad \text{where} \quad g = \begin{bmatrix} g_+ \\ g_- \end{bmatrix} = Bu. \tag{34}$$

We now investigate the behavior of e_+^{α} and of e_-^{α} for $\alpha \to 0$. We shall repeatedly use the next result.

LEMMA 15. *There exists a number $\eta > 0$ such that for each $t > 0$, $\alpha > 0$ small enough, we have*

$$||e^{(A_{11}-J/\alpha)t}|| \leq e^{-(\eta/\alpha)t}.$$

Proof. We apply the Wintner–Ważeski inequalities to the matrix $A_{11} - J/\alpha$. Notice that $\frac{1}{2}\{[A_{11}-J/\alpha]+[A_{11}-J/\alpha]^*\} = \frac{1}{\alpha}[-J+\alpha(A_{11}+A_{11}^*)]$ is *negative definite* for small α, and its maximum eigenvalue $-\mu$ can be estimated as follows: $-\mu < -\eta/\alpha$, where $\eta > 0$ is any number less than all the eigenvalues of J. This gives the required estimate. □

Now we prove the following lemma.

LEMMA 16.

$$\lim_{\alpha \to 0} e_+^{\alpha}(t) = 0$$

uniformly in $[0,T]$.

Proof. It follows from Lemmas 14 and 15 and from an application of the Schwarz inequality that

$$||e_+^{\alpha}(t)|| = \left|\left| \int_0^t e^{[A_{11}-J/\alpha](t-s)}[A_{12}e_-^{\alpha}(s) - g_+(s)]\, ds \right|\right| \leq M \cdot \sqrt{\alpha}. \tag{35}$$

□

Now define e_-^0 as the solution of

$$\dot{e} = A_{22}e - g_-, \qquad e(0) = 0. \tag{36}$$

We have the following result.

LEMMA 17.

$$\lim_{\alpha\to 0} e_-^\alpha = e_-^0, \qquad \lim_{\alpha\to 0} \dot{e}_-^\alpha = \dot{e}_-^0$$

uniformly on $[0,T]$.

Proof. It follows from Lemma 16 that

$$e_-^\alpha(t) = \int_0^t e^{A_{22}(t-s)}\{A_{21}e_+^\alpha(s) - g_-(s)\} \to -\int_0^t e^{A_{22}(t-s)}g_-(s)\ ds. \tag{37}$$

This proves that e_-^α converges uniformly to e_-^0 on $[0,T]$. Convergence of the derivatives follows (37), Lemma 16, and (34). □

We now focus on the limit of $\frac{1}{\alpha}e^\alpha(t)$. The following is the main result of this section.

THEOREM 18. *We have*

$$\lim_{\alpha\to 0}\left[-\frac{1}{\alpha}Je_+^\alpha\right] = g_+ - A_{12}e_-^0.$$

The convergence is

- *in* $L^2(0,T)$ *if* u *is square integrable,*
- *uniform on* $[\epsilon,T]$ *for every* $\epsilon > 0$ *if* u *is absolutely continuous,*
- *uniform on* $[0,T]$ *if* u *is absolutely continuous and* $u(0) = 0$.

Proof. We proceed in a number of steps, first for absolutely continuous inputs and then for square integrable inputs.

Absolutely continuous inputs. In this case u and, consequently, g are *bounded* on $[0,T]$.

We start with a preliminary lemma.

LEMMA 19. *Let* g *be bounded. Then there exists a constant* M *such that*

$$\left|\left|\frac{1}{\alpha}e_+^\alpha(t)\right|\right| \le M \qquad \forall t\in[0,T], \quad \forall\alpha > 0.$$

Consequently,

$$||\dot{e}_+^\alpha(t)|| \le M \qquad \forall t\in[0,T], \quad \forall\alpha > 0.$$

Proof. In the following computation we use Lemma 15.

$$\begin{aligned}\left|\left|\frac{1}{\alpha}e_+^\alpha(t)\right|\right| &= \left|\left|\int_0^t \frac{1}{\alpha}e^{(A_{11}-\frac{1}{\alpha}J)(t-s)}[A_{12}e_-^\alpha(s) - g_+(s)]\ ds\right|\right| \\ &\le \int_0^t \frac{1}{\alpha}e^{-\eta(t-s)/\alpha}||A_{12}e_-^\alpha(s) - g_+(s)||\ ds \\ &\le \frac{1}{k}[1-e^{-\eta t/\alpha}]\sup_{s\in[0,T]}||A_{12}e_-^\alpha(s) - g_+(s)||.\end{aligned}$$

This is bounded since g_+ is bounded by assumption and e_-^α is bounded on $[0,T]$ from Lemma 14. Finally, boundedness of the derivative follows from (34). □

Remark 20. Lemma 19 and (37) give, when u is bounded,

$$||e_-^\alpha(t) - e_-^0(t)|| \le M\cdot\alpha \qquad \forall t\in[0,T], \quad \forall\alpha > 0. \tag{38}$$

Now we are ready to prove Theorem 18 for absolutely continuous inputs. We write the equation of e_+^α as

$$\dot{e}_+^\alpha = -\frac{1}{\alpha} J e_+^\alpha + \{-g_+ + A_{11} e_+^\alpha + A_{12} e_-^\alpha\}.$$

We have

$$\begin{aligned}
&\frac{1}{\alpha} J e_+^\alpha(t) = \int_0^t \left[\frac{d}{ds} e^{-\frac{1}{\alpha} J(t-s)}\right] \left[A_{11} e_+^\alpha(s) + A_{12} e_-^\alpha(s) - g_+(s)\right] \, ds \\
&= A_{11} e_+^\alpha(t) + A_{12} e_-^\alpha(t) - g_+(t) + e^{-\frac{1}{\alpha} Jt} g_+(0) \\
&- \int_0^t e^{-\frac{1}{\alpha} J(t-s)} \left[A_{11} \dot{e}_+^\alpha(s) + A_{12} \dot{e}_-^\alpha(s) - \dot{g}_+(s)\right] \, ds. \qquad (39)
\end{aligned}$$

As in the proof of Lemma 16, we see that the integral converges to zero uniformly on $[0,T]$. On the other hand, we know from Lemma 16 that e_+^α converges to zero uniformly on $[0,T]$ and, from Lemma 17, that e_-^α converges uniformly to e_-^0. Hence we have convergence to $-g_+ + A_{12} e_-^0$ uniformly on $[\epsilon, T]$ for any $\epsilon > 0$ and on $[0,T]$ if $u(0)$; hence $g_+(0)$, is zero.

The previous computation, combined with Lemma 19 and (38), gives the following pointwise estimate when $u \in W^{1,2}$:

$$\left|\left| \frac{1}{\alpha} J e_+^\alpha(t) + g_+(t) - A_{12} e_-^0(t) \right|\right| \leq M \cdot \left(\sqrt{\alpha} + e^{-\eta t/\alpha} ||g_+(0)||\right). \qquad (40)$$

Square integrable inputs. We now prove Theorem 18 for inputs which are assumed only to be in $L^2(0,T)$. We introduce the functions

$$(41) \begin{cases} z^\alpha(t) = -g_+(t) + A_{11} e_+^\alpha(t) + A_{12} e_-^\alpha(t), \quad t \in [0,T], \quad z^\alpha(t) = 0 \text{ otherwise;} \\ z^0(t) = -g_+(t) + A_{12} e_-^0(t), \quad t \in [0,T], \quad z^0(t) = 0 \text{ otherwise;} \\ \zeta^\alpha(t) = \frac{1}{\alpha} \int_0^t J e^{-\frac{J}{\alpha}(t-s)} z^\alpha(s) ds, \qquad t \in \mathbb{R}. \end{cases}$$

By definition, z^α converges to z^0 in $L^2(\mathbb{R})$, and ζ^α is the convolution of z^α with the function which is zero for $t < 0$ and $\frac{1}{\alpha} J e^{-Jt/\alpha}$ for $t > 0$. The function ζ^α belongs to $L^2(\mathbb{R})$ since the eigenvalues of J are *positive* and $\alpha > 0$.

We must prove that ζ^α converges to z^0 in $L^2(0,T)$, and this is implied by the $L^2(-\infty, +\infty)$ convergence of $\chi\zeta^\alpha$ to χz^0, where $\chi(t) = e^{-rt}$, since both $\zeta^\alpha(t)$ and $z^0(t)$ are zero for $t < 0$. Here r is a *fixed* positive number.

In order to prove $L^2(-\infty, +\infty)$ time domain convergence, we prove equivalently $L^2(-\infty, +\infty)$ convergence of the trace on the imaginary axis of the Laplace transforms. The trace of the Laplace transform of $\chi\zeta^\alpha$ is the function

$$\frac{1}{\alpha} J \left[(i\omega + r) I + \frac{J}{\alpha}\right]^{-1} \hat{z}^\alpha(i\omega + r).$$

We must prove

$$\lim_{\alpha \to 0} \int_{-\infty}^{+\infty} \left|\left| \mathcal{L}[e^{-r\cdot} \zeta^\alpha(\cdot) - e^{-r\cdot} z^0(\cdot)] \right|\right|^2 \, d\omega = 0. \qquad (42)$$

We have

$$\left[\int_{-\infty}^{+\infty} \left|\left|\mathcal{L}[e^{-r\cdot}\zeta^\alpha(\cdot) - e^{-r\cdot}z^0(\cdot)]\right|\right|^2 \, d\omega\right]^{1/2} \tag{43}$$

$$\leq \left[\int_{-\infty}^{+\infty} \left|\left| \frac{1}{\alpha} J \left[(i\omega + r)I + \frac{J}{\alpha}\right]^{-1} \left[\hat{z}^\alpha(i\omega + r) - \hat{z}^0(i\omega + r)\right] \right|\right|^2 \, d\omega\right]^{1/2} \tag{44}$$

$$+\left[\int_{-\infty}^{+\infty} \left|\left| \left[\frac{1}{\alpha} J \left[(i\omega + r)I + \frac{J}{\alpha}\right]^{-1} - I\right] \hat{z}^0(i\omega + r) \right|\right|^2 \, d\omega\right]^{1/2}. \tag{45}$$

We prove a lemma first.

LEMMA 21. *There exists a number M such that for every λ with $\Re e\, \lambda > 0$ and every $\alpha > 0$ we have*

$$\left|\left| \frac{1}{\alpha} J \left[\lambda I + \frac{J}{\alpha}\right]^{-1} \right|\right| \leq M. \tag{46}$$

Proof. We use a reference system where J is diagonal. (We recall that the eigenvalues of J are positive.) In this reference system we have $||\frac{1}{\alpha} J \left[\lambda I + \frac{J}{\alpha}\right]^{-1}|| < 1$, as it is simply seen because the matrix $\frac{1}{\alpha} J \left[\lambda I + \frac{J}{\alpha}\right]^{-1}$ is diagonal, its entries being of the form $j/(j + \lambda\alpha)$, where j is *positive* since it is an eigenvalue of J. □

It follows from Lemma 21 and the fact that $\hat{z}^\alpha(\cdot + r)$ converges to $\hat{z}^0(\cdot + r)$ in $L^2(-\infty, +\infty)$ (see (41) and Lemmas 16 and 17) that the first integral (44) converges to zero for $\alpha \to 0$.

In order to prove that the second integral (45) converges to zero, we need a further lemma.

LEMMA 22. *We have*

$$\lim_{\alpha \to 0} \frac{1}{\alpha} J \left[\lambda I + \frac{J}{\alpha}\right]^{-1} = I\,,$$

uniformly for λ in compact sets of $\Re e\, \lambda > 0$.

Proof. We note that

$$\frac{1}{\alpha} J \left[\lambda I + \frac{J}{\alpha}\right]^{-1} - I = [-\lambda\alpha J^{-1}] \frac{1}{\alpha} J \left[\lambda I + \frac{J}{\alpha}\right]^{-1}.$$

The result now follows easily from Lemma 21. □

Now we split (45) into the sum of the two integrals

$$\int_{\mathbb{R} - [h,h]} \left|\left| \left[\frac{1}{\alpha} J \left[(i\omega + r)I + \frac{J}{\alpha}\right]^{-1} - I\right] \right|\right| \cdot ||\hat{z}^0(i\omega + r)||^2 \, d\omega, \tag{47}$$

$$\int_{-h}^{+h} \left|\left| \left[\frac{1}{\alpha} J \left[(i\omega + r)I + \frac{J}{\alpha}\right]^{-1} - I\right] \right|\right| \cdot ||\hat{z}^0(i\omega + r)||^2 \, d\omega. \tag{48}$$

Using standard techniques and Lemma 22, we obtain that both integrals converge to 0. This proves (42) and *completes the proof* of Theorem 18.

It is clear from Theorem 18 that, in general, Bv_α does not converge to Bu since $A_{12}e^0_-$ in general will not be zero. We have the following result.

THEOREM 23. *The following conditions are equivalent:*
(a) $\lim_{\alpha\to 0} Bv_\alpha = Bu$ *and* $\lim_{\alpha\to 0} w_\alpha = x$ *for every input* u.
(b) $B_- = 0$.
(c) $\ker CB = \{0\}$.

Proof. (a)⇒(b). It immediately follows from the definition of v_α and the structure of the matrix $\hat{J}$.

(b)⇒(a). If (b) holds, then from (36) we see that $e_-^0 = 0$. The result then follows from Theorem 18.

(b)⇒(c). Since $\ker B = \{0\}$ and $B_- = 0$, we have that $\ker B_+ = \{0\}$. Multiplying $\hat{J}$ on the left by B^* and on the right by B, we get

$$[B^*B]B^*C^*[CB] = B_+^* J B_+.$$

Now $B_+^* J B_+$ is invertible since $\ker B_+ = \{0\}$ and $J = J^* > 0$. Hence CB is injective.

(c)⇒(b). We recall that $\hat{J} = BB^*C^*C = \operatorname{diag}[J, 0]$ and that $B = \operatorname{col}[B_+, B_-]$. We must prove $B_- = 0$. This is true because

$$B[B^*C^*CB] = [BB^*C^*C]B = \begin{bmatrix} JB_+ \\ 0 \end{bmatrix}.$$

As CB is injective, we have that B^*C^*CB is invertible so that

$$B = \begin{bmatrix} JB_+ \\ 0 \end{bmatrix} \cdot [B^*C^*CB]^{-1} = \begin{bmatrix} ? \\ 0 \end{bmatrix},$$

which was our claim. □

Remark 24. Property (c) in Theorem 23 is a condition of relative degree one on the system. This condition has a relevant role in robustness analysis; see [7]. When it is not satisfied, we need to carry on a more refined analysis, which is the content of next section.

Theorem 23 gives a necessary and sufficient condition under which the proposed recursive identification method really identifies both the input u and the evolution x of system (3). Notice, however, that we described the identification process as a double limiting process: first a limit with respect to n and h and next a limit with respect to α. In fact, there exists a small value of α such that $||Bv_\alpha - Bu||_2$ is less than $\epsilon/2$ for a prescribed ϵ; with such an α, we have that $||Bv_{n,\alpha} - Bv_\alpha||_2 < \epsilon/2$ for large n and small h. In this way we get that $Bv_{n,\alpha}$ approximate Bu within a tolerance ϵ (we denote by $v_{n,\alpha}$ the function defined in (30)). We present explicit convergence estimates in the case when u is differentiable. These estimates, which we prove in the special case $\ker CB = \{0\}$, will be crucial for the extension to the general case presented in the next section. Our standing assumption is $\ker B = \{0\}$ so that we can equivalently give an estimate for $g = Bu$.

We put ourselves in the case described by Theorem 23, and we assume that the input u, hence also $g = Bu$, is differentiable. In this case we can give estimates which explicitly show the dependence on n, h, and α. As we said, we denote by $v_{n,\alpha}$ the input which was simply denoted by v_n in section 3 and by $w_{n,\alpha}$ the corresponding solution to (27). The expression of $v_{n,\alpha}$ is given by (30).

We use

$$||Bv_{n,\alpha}(t) - Bu(t)|| \le ||Bv_{n,\alpha}(t) - Bv_\alpha(t)|| + ||Bv_\alpha(t) - Bu(t)||, \tag{49}$$

and we give asymptotic estimates for both terms on the right-hand side.

We use the pointwise estimate (40) (which concerns $||Bv_\alpha(t) - Bu(t)||$ since e_-^0 is now zero), and we get

$$||Bv_\alpha(t) - Bu(t)|| \leq M \cdot \left(e^{-\frac{\eta t}{\alpha}} ||u(0)|| + \sqrt{\alpha} \right). \tag{50}$$

The value of the constant depends on the values of u and $\dot{u}$.

Now we observe (see (30) and (31)) that

$$\begin{aligned} & v_{n,\alpha}(t) - v_\alpha(t) \\ & = -\left\{ [\alpha I + \Lambda_n^* \Lambda_n]^{-1} \Lambda_n^* \Gamma_n C e^{A\delta} w_{n,\alpha}(\tau_k) - \frac{1}{\alpha} B^* C^* C w^\alpha(t) \right\} \qquad (51) \\ & + \left\{ [\alpha I + \Lambda_n^* \Lambda_n]^{-1} \Lambda_n^* \Gamma_n \xi_k - \frac{1}{\alpha} B^* C^* C x(t) \right\}. \qquad (52) \end{aligned}$$

□

We want to give an estimate of this difference for α fixed and large n.

The sequence of piecewise constant functions Ξ_n, $\Xi_n(t) = \xi_k$ for $t \in [\tau_k, \tau_{k+1})$, converges uniformly to the Lipschitz function Cx (the output of the system) on $[0, T]$ and

$$||\Xi_n(t) - Cx(t)|| < h + \frac{M}{n}. \tag{53}$$

Hence, from the explicit estimates (16), we have

$$||(\Lambda_n^* \Gamma_n \Xi_n)(t) - B^* C^* C x(t)|| \leq M \cdot \left[h + \frac{1}{n} \right].$$

We use now the explicit estimate (23), and we get

$$\left|\left| \left([\alpha I + \Lambda_n^* \Lambda_n]^{-1} \Lambda_n^* \Gamma_n \Xi_n \right)(t) - \frac{1}{\alpha} B^* C^* C x(t) \right|\right| \leq M \cdot \left(\frac{1}{\alpha^2 \sqrt{n}} + \frac{1}{\alpha n} + \frac{h}{\alpha} \right).$$

We estimate (51) with the following sum:

$$\begin{aligned} & \left|\left| [\alpha I + \Lambda_n^* \Lambda_n]^{-1} \Lambda_n^* \Gamma_n C [e^{A\delta} - I] w_{n,\alpha}(\tau_k) \right|\right| \\ & + \left|\left| [\alpha I + \Lambda_n^* \Lambda_n]^{-1} \Lambda_n^* \Gamma_n C w_{n,\alpha}(\tau_k) - \frac{1}{\alpha} B^* C^* C w^\alpha(\tau_k) \right|\right| \\ & + \frac{1}{\alpha} \left|\left| B^* C^* C [w^\alpha(\tau_k) - w^\alpha(t)] \right|\right|. \end{aligned}$$

The inequalities in Lemma 8, Theorem 4, and (10) show that the first addendum is less than

$$\frac{M}{n^{3/2}} \left(\frac{1}{\alpha} + \frac{1}{\sqrt{n} \alpha^2} \right) e^{\omega/\alpha}.$$

The second addendum is estimated from the inequalities (23), (29). It is less than

$$M \left(\frac{1}{\alpha^2 \sqrt{n}} + \frac{1}{\alpha n} + \frac{1}{\alpha^2 \sqrt{n}} e^{\omega/\alpha} \right).$$

In order to estimate the third term, we use (32), Lemma 14, and the boundedness of u. We get that the third term is less than

$$\frac{M}{n\alpha}.$$

According to Theorem 4 and Lemma 11, the factor $e^{\omega/\alpha}$ in the previous inequalities must be replaced by $1/\alpha$ if $C = I$.

We collect the estimates above and we get the following theorem.

THEOREM 25. *Let the unknown input u be of class $W^{1,2}$ and let the condition $\ker CB = \{0\}$ hold. Then there exist numbers M, η, and ω, which do not depend on α, n, h, such that, for every $t \in [0,T]$,*

$$\begin{aligned} ||Bv_{n,\alpha}(t) - Bu(t)|| \le M \Big\{ &\left(e^{-\frac{\eta t}{\alpha}} ||u(0)|| + \sqrt{\alpha}\right) \\ &+ \left(\tfrac{1}{\alpha n} + \tfrac{1}{\alpha^2\sqrt{n}} + \tfrac{h}{\alpha}\right) + \left(\tfrac{1}{\alpha^2\sqrt{n}} + \tfrac{1}{\alpha n^{3/2}} + \tfrac{1}{\alpha^2 n^2}\right) \cdot e^{\omega/\alpha} \Big\}. \end{aligned} \tag{54}$$

In the special case when $C = I$ and $u(0) = 0$, the previous inequality is replaced by

$$||Bv_{n,\alpha}(t) - Bu(t)|| \le M \left(\sqrt{\alpha} + \frac{1}{\alpha n} + \frac{1}{\alpha^2\sqrt{n}} + \frac{h}{\alpha} + \frac{1}{\alpha^3\sqrt{n}}\right). \tag{55}$$

Remark 26.

(a) We observe that the explicit estimate shows that, naturally, if we want a good estimate, the penalization coefficient α should converge to zero not too quickly. Moreover, the right-hand sides of (54) and (55) show explicitly the dependence on n and h separately.

(b) The book [10] studies an even more general input identification problem for nonlinear systems under a condition which, in the linear case, is exactly $\ker CB = \{0\}$ (see, in particular, section 18.4). However, it is assumed there that the unknown input takes values in a known compact set explicitly used in the solution. Moreover, in contrast with (55), only L^2 estimates are given.

5. Input identification in the general case. In this section we extend the identification method described in previous sections to the general case when $\ker CB \neq \{0\}$ (maintaining, of course, the assumptions $\mathcal{R}_* = \{0\}$ and $\ker B = \{0\}$).

To clarify our approach, we first consider an example.

Example 27. Assume that the system matrices have the following special form:

$$A = \left[\begin{array}{ccc|ccc} 0 & 1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 \\ a_{3,1} & a_{3,2} & a_{3,3} & a_{3,4} & a_{3,5} & a_{3,6} \\ \hline 0 & 0 & 0 & 0 & 1 & 0 \\ a_{5,1} & a_{5,2} & a_{5,3} & a_{5,4} & a_{5,5} & a_{5,6} \\ \hline a_{6,1} & a_{6,2} & a_{6,3} & a_{6,4} & a_{6,5} & a_{6,6} \end{array}\right], \quad B = \left[\begin{array}{ccc} 0 & 0 & 0 \\ 0 & 0 & 0 \\ 1 & 0 & 0 \\ \hline 0 & 0 & 0 \\ 0 & 1 & 0 \\ \hline 0 & 0 & 1 \end{array}\right], \tag{56}$$

$$C = \left[\begin{array}{ccc|ccc} 1 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 \end{array}\right].$$

A system which has the previous representation but with $a_{3,i} = 0$, $a_{5,i} = 0$, $a_{6,i} = 0$ for each i is just a tandem connection of integrators. It is said to be in "prime" canonical form; see [17].

We represent $x = \mathrm{col}[x_i]$, $u = \mathrm{col}[u_i]$, and $y = \mathrm{col}[y_i]$ consistently with the structure of the matrices.

We now repeatedly apply the identification method described in previous sections. Consider first the subsystem

$$\left\{ \begin{array}{rcl} \dot{x}_1 &=& x_2, \\ \dot{x}_4 &=& x_5, \end{array} \right. \qquad y = \left[\begin{array}{c} x_1 \\ x_4 \end{array} \right].$$

Our recursive identification method gives an estimate of "inputs" x_2, x_5 *because the equivalent conditions of Theorem* 23 *are satisfied.* We observe that the "inputs" x_2, x_5 are differentiable and zero for $t = 0$. Hence Theorem 25 gives a pointwise estimate for the error, which holds *uniformly* on $[0, T]$.

We use the estimate given in Theorem 25 as a new "tolerance" h, and we consider the subsystem

$$\dot{x}_2 = x_3, \qquad y_1 = x_2.$$

We proceed analogously, and we approximate x_3, which will be considered as a new "input" in the last step. The approximation to x_3 is uniform on $[0, T]$.

In the last step we consider the subsystem

$$\left\{ \begin{array}{rcllll} \dot{x}_3 &=& a_{3,3}x_3 + a_{3,5}x_5 + a_{3,6}x_6 & +\rho_1, & & \\ \dot{x}_5 &=& a_{5,3}x_3 + a_{5,5}x_5 + a_{5,6}x_6 & +\rho_2, & y_2 = & \left[\begin{array}{c} x_3 \\ x_5 \\ x_6 \end{array} \right] \\ \dot{x}_6 &=& a_{6,3}x_3 + a_{6,5}x_5 + a_{6,6}x_6 & +\rho_3, & & \end{array} \right.$$

and

$$\rho = \left[\begin{array}{c} \rho_1 \\ \rho_2 \\ \rho_3 \end{array} \right] = \left[\begin{array}{c} a_{3,1}x_1 + a_{3,2}x_2 + a_{3,4}x_4 \\ a_{5,1}x_1 + a_{5,2}x_2 + a_{5,4}x_4 \\ a_{6,1}x_1 + a_{6,2}x_2 + a_{6,4}x_4 \end{array} \right] + \left[\begin{array}{c} u_1 \\ u_2 \\ u_3 \end{array} \right].$$

At this point, the "output" y_2 is known, within a certain tolerance, and the assumptions of Theorem 23 are satisfied. Hence we can apply our procedure for the identification of the "input" ρ, i.e., of the real input u, since we already estimated the first addendum of ρ within a certain tolerance.

We observe that we do not need to perform the procedure just described sequentially in three steps hence in a nonrecursive way. In fact, let n be fixed. Once the first observation time τ_1 is elapsed, we have an estimate for the new "outputs" $x_2(t)$, $x_5(t)$ for $t \in [0, \tau_1]$. Hence we can start the identification procedure for x_3, and, at time τ_3, we can start the identification procedure for u. We also observe that each step of the previous procedure studies a system for which $C = I$. Hence the exponential term $e^{\omega/\alpha}$ does not affect the rate of convergence.

The previous example may look quite special. In fact, it is completely general. In order to see this, we introduce a special "quasi canonical" form due to Morse; see [17]. This form resembles Kalman decomposition, but it goes far deeper. It is an extension of Brunovski canonical form and, in particular, it shows precisely the coupling between inputs and outputs.

According to [17], in the special case $\mathcal{R}_* = \{0\}$, there exist a state feedback F, an input injection L, and suitable reference frames in the state, input, and output spaces such that $A + BF + LC$, B, and C take the following forms:

$$A+BF+LC = \left[\begin{array}{ccc} A_0 & 0 & 0 \\ 0 & A_1 & 0 \\ 0 & 0 & A_2 \end{array} \right], \qquad B = \left[\begin{array}{c} 0 \\ 0 \\ B_2 \end{array} \right], \qquad C = \left[\begin{array}{ccc} 0 & C_1 & 0 \\ 0 & 0 & C_2 \end{array} \right]. \tag{57}$$

Moreover, the triple A_2, B_2, C_2 is in "prime" canonical form. This means

$$A_2 = \operatorname{diag}[N_i]\,, \qquad B_2 = \operatorname{diag}[b_i]\,, \qquad c_2 = \operatorname{diag}[c_i]\,,$$

$$N_i = \begin{bmatrix} 0 & 1 & 0 & \dots & 0 \\ 0 & 0 & 1 & \dots & 0 \\ \vdots & & & & \\ 0 & 0 & 0 & \dots & 1 \\ 0 & 0 & 0 & \dots & 0 \end{bmatrix}, \qquad b_i = \begin{bmatrix} 0 \\ 0 \\ \vdots \\ 0 \\ 1 \end{bmatrix}, \qquad c_i = \begin{bmatrix} 1 & 0 & 0 & \dots & 0 \end{bmatrix}.$$

If $\mathcal{R}_* \neq \{0\}$, then a further block would appear in the matrices $A + BF + LC$, and a further column would appear in the matrix B. This column would correspond to inputs that cannot be reconstructed.

Morse form can be used as follows in the deconvolution problem. We represent system (3) as

$$\begin{aligned} \dot{x} &= \{(A + BF)x + Ly\} + Bu - (BFx + Ly) \\ &= (A + BF + LC)x + Bu - BFx - Ly\,, \qquad y = Cx, \end{aligned}$$

and we put ourselves in that reference system in which the matrices have the form described above.

The matrices F and L (which can be explicitly computed) have the block forms

$$F = \begin{bmatrix} F_0 & F_1 & F_2 \end{bmatrix}, \qquad L = \begin{bmatrix} L_0' & L_0'' \\ L_1' & L_1'' \\ L_2' & L_2'' \end{bmatrix}.$$

Hence the system takes the following form:

$$\text{(58)} \qquad \begin{cases} \dot{x}_0 = A_0x_0 - \{L_0'C_1x_1 + L_0''C_2x_2\} \\ \qquad\;\; = A_0x_0 - \{L_0'y_1 + L_0''y_2\}, \\ \qquad\qquad\qquad\qquad\qquad\qquad y_1 = C_1x_1, \\ \dot{x}_1 = A_1x_1 - \{L_1'C_1x_1 + L_1''C_2x_2\} \\ \qquad\;\; = A_1x_1 - \{L_1'y_1 + L_1''y_2\} \end{cases}$$

and

$$\text{(59)} \qquad \begin{aligned} \dot{x}_2 &= A_2x_2 - \{L_2'C_1x_1 + L_2''C_2x_2\} - B_2Fx + B_2u \\ &= (A_2x_2 - B_2F_2)x_2 - \{L_2'y_1 + L_2''y_2\} \\ &+ B_2\{u - F_0x_0 - F_1x_1\}\,, \qquad\qquad y_2 = C_2x_2. \end{aligned}$$

The functions y_1 and y_2 are measured (at the sample times τ_k and with known error). They enter as regular perturbations in the previous differential equations so that we can compute x_0 and x_1 on $[0, T]$ (with a tolerance which tends to zero for $h \to 0$ and $\delta \to 0$).

Now we look more closely to the subsystem (59). This system has a block form similar to the one in Example 27. In fact, due to the prime-type structure of the matrices A_2 and B_2, the matrix $A_2 + B_2F_2$ has the same form as the matrix A in (56) (in general with more blocks) and B_2, C_2 have forms similar to those in (56), with more blocks. Hence we can apply the identification algorithm to systems of the form

$$\dot{x}_i = x_{i+1} - \mu_i,$$

where μ_i, due to the addendum $-\{L_1' y_1 + L_2'' y_2\}$, is approximately known. So the next component x_{i+1} can be approximately identified.

We do this for the system of the first components of the vectors which correspond to blocks of dimensions larger then 1. We consider the next component in a second step, as in Example 27, until we remain with the vectors whose entries correspond to the last rows of the blocks of $A_2 + B_2 F$. We get a system of differential equations, each one of the form

$$\dot{x}^k_{r_k} = a^{kk}_{k,r_k} x^k_{r_k} + \{\mu_r + \nu_r + u_r\} + \sum_{(i,j)\neq(k,r_k)} a^k_{ij} x^k_{ij},$$

where μ_r is due to the output injection (hence it is directly measured); ν_r denotes the contribution of x_0, x_1, which can be computed; the terms of the last sum are computed in the preceding steps. Hence all these terms are (approximately) known. Hence a last application of the identification algorithm gives an estimate of the unknown input $u = \mathrm{col}[u_r]$.

We observe that in order to iterate the first step on the second block of variables, we do not need to wait until time T is elapsed: once that time $t_0 > \tau$ is elapsed, we can apply the process to the second block of variables on the interval $[0, t_0]$. Hence also the identification method in the general case is recursive.

In conclusion, a recursive identification process can be applied to the most general case in which input identification is possible.

We do not insist on giving explicit convergence estimates for each step of the iteration. These estimates can be obtained by a repeated application of Theorem 25. We observe the importance of the pointwise estimate (55). In fact, even if we could have perfect observation, at the second step the new "output" is the estimate of the variables $x_{i,2}$ obtained in the previous step with an error given by (55).

We note that at each step, with the exception of the last one, *the pointwise estimates are uniform on* $[0, T]$ *even if the unknown input* u *is not differentiable. In fact, the fictitious inputs that must be estimated at each step, except the last one, are differentiable and zero for* $t = 0$*; and, moreover, at each step we work with a system for which* $C = I$ *so that the exponential factor* $e^{\omega/\alpha}$ *is replaced by* $1/\alpha$ *in the estimate for the convergence rate.*

Acknowledgments. We thank the referees for the careful reading of the paper. Their observations helped us in putting the paper in the proper perspective of the deconvolution problem.

LOSSLESS AND DISSIPATIVE DISTRIBUTED SYSTEMS*

HARISH K. PILLAI† AND JAN C. WILLEMS‡

Abstract. This paper deals with linear shift-invariant distributed systems. By this we mean systems described by constant coefficient linear partial differential equations. We define dissipativity with respect to a quadratic differential form, i.e., a quadratic functional in the system variables and their partial derivatives. The main result states the equivalence of dissipativity and the existence of a storage function or a dissipation rate. The proof of this result involves the construction of the dissipation rate. We show that this problem can be reduced to Hilbert's 17th problem on the representation of a nonnegative rational function as a sum of squares of rational functions.

Key words. quadratic differential forms, linear multidimensional systems, behavioral theory, polynomial matrices, lossless systems, positivity, dissipativeness, storage functions

1. Introduction.

One of the very useful concepts in systems theory is the notion of a dissipative system. It lies at the root of most of the stability results and on the synthesis of robust controllers. The theory of dissipative systems has been developed until now as a system theoretic concept for dynamical systems, i.e., for systems in which the independent variable is time. However, many if not most models of physical systems are distributed, involving both time and space variables. The purpose of this paper is to develop the theory of dissipative systems for systems described by partial differential equations.

The central problem in the theory of dissipative systems is the construction of an internal function called the storage function. Instances of functions that play the role of storage functions are Lyapunov functions in stability analysis, the internal energy, and entropy in thermodynamics, etc. The construction of storage functions for dynamical systems is reasonably well understood [23, Part 1] for general nonlinear systems and in much detail for linear systems with quadratic supply rates [23, Part 2] [25]. As we shall see, analogous results may be obtained, as far as existence is concerned, for distributed systems described by linear constant coefficient partial differential equations and with quadratic differential forms (QDFs) as supply rates. However, there are important differences in the resulting theory, the most important one being the fact that for distributed systems the storage functions need to be (in general) a function of unobservable ("hidden") latent variables.

Several recent papers [2, 12, 13] dealing with conservative and dissipative systems have been brought to our notice. In these papers, the authors consider an input/state/output framework for the multidimensional systems involved. The results in these papers are clearly related to the results presented in this paper. While the

results in [2, 12, 13] are more general (in the sense that they consider more general signal spaces—Hilbert spaces), they are far less structured (in the sense that they tackle only problems that admit a type of state formulation—the Roesser model). On the other hand, the results in this paper are more structured in the sense that it deals with systems that arise as solutions of constant coefficient partial differential equations (without assuming "states," etc.), though the signal spaces used are not as general. The mathematics involved in the two approaches are also substantially different.

An interesting feature of the results presented in this paper is the mathematics that underlies the construction of the storage function (for linear systems with quadratic supply rates). In the context of lumped dynamical systems the construction of a storage function involves, as we shall see, the factorization of a real polynomial matrix Φ in one indeterminate into the product $\Phi(\xi) = F^T(-\xi)F(\xi)$ with F also a real polynomial matrix. This factorization is readily seen to be possible if and only if $\Phi(\xi) = \Phi^T(-\xi)$ and $\Phi(i\omega) \geq 0$ for all $\omega \in \mathbb{R}$. However, in the case of distributed systems, Φ is a polynomial matrix in n indeterminates. In this case, the factorization $\Phi(\xi) = F^T(-\xi)F(\xi)$ is not always possible with F as a real polynomial matrix but it is possible with F as a matrix of rational functions. This factorization, it turns out, is known as *Hilbert's* 17*th problem*, and it is most stimulating indeed to see this problem emerge in a basic system theoretic question!

First, a few words about notation. We use the standard notation $\mathbb{R}^n$, $\mathbb{R}^{n_1 \times n_2}$, etc., for finite-dimensional vectors and matrices. When the dimension is not specified (but, of course, finite), we write $\mathbb{R}^\bullet$, $\mathbb{R}^{n \times \bullet}$, $\mathbb{R}^{\bullet \times \bullet}$, etc. In order to enhance readability, we typically use the notation $\mathbb{R}^{\mathtt{w}}$ when functions taking their values in that vector space are denoted by w. Real polynomials in the indeterminates $\xi = (\xi_1, \xi_2, \ldots, \xi_n)$ are denoted by $\mathbb{R}[\xi]$ and real rational functions by $\mathbb{R}(\xi)$, with obvious modifications for the matrix case. The space of infinitely differentiable functions with domain $\mathbb{R}^n$ and codomain $\mathbb{R}^{\mathtt{w}}$ is denoted by $\mathfrak{C}^\infty(\mathbb{R}^n, \mathbb{R}^{\mathtt{w}})$ and its subspace containing elements with compact support by $\mathfrak{D}(\mathbb{R}^n, \mathbb{R}^{\mathtt{w}})$.

The proofs of the results are collected in the appendix.

2. Multidimensional systems. We view a system as a family of trajectories mapping a set of "independent" variables into a set of "dependent" variables. See [20] for an elaboration of this with examples. Thus a *system* Σ is defined as a triple $\Sigma = (\mathbb{T}, \mathbb{W}, \mathfrak{B})$, where $\mathbb{T}$ is the indexing set, the set of independent variables, $\mathbb{W}$ is the signal space, the set of dependent variables, and $\mathfrak{B} \subset \mathbb{W}^{\mathbb{T}}$ is the behavior. In the present paper we consider systems with $\mathbb{T} = \mathbb{R}$ (we call these *lumped dynamical* systems or one-dimensional (1D) systems) and systems with $\mathbb{T} = \mathbb{R}^n$ (we call these *distributed* systems—they are commonly called nD systems). Also, we assume throughout that $\mathbb{W}$ is a finite-dimensional real vector space, $\mathbb{W} = \mathbb{R}^{\mathtt{w}}$.

A system $\Sigma = (\mathbb{R}^n, \mathbb{R}^{\mathtt{w}}, \mathfrak{B})$ is said to be *linear* if $\mathfrak{B}$ is a linear subspace of $(\mathbb{R}^{\mathtt{w}})^{\mathbb{R}^n}$ and *shift-invariant* if $\mathfrak{B} = \sigma^{x'}\mathfrak{B}$ for all $x' = (x'_1, \ldots, x'_n) \in \mathbb{R}^n$, where $\sigma^{x'} : (\mathbb{R}^{\mathtt{w}})^{\mathbb{R}^n} \to (\mathbb{R}^{\mathtt{w}})^{\mathbb{R}^n}$ denotes the x'-shift defined for $x' = (x'_1, \ldots, x'_n)$ by $\sigma^{x'} f(x_1, \ldots, x_n) = f(x_1 + x'_1, \ldots, x_n + x'_n)$. We call Σ a linear shift-invariant differential system if $\mathfrak{B}$ is the solution set of a system of linear constant coefficient partial differential equations. More precisely, if there exists a real polynomial matrix $R \in \mathbb{R}^{\bullet \times \mathtt{w}}[\xi]$ in n indeterminates, $\xi = (\xi_1, \ldots, \xi_n)$, such that $\mathfrak{B}$ consists of the $\mathfrak{C}^\infty(\mathbb{R}^n, \mathbb{R}^{\mathtt{w}})$-solutions of

$$R\left(\frac{d}{d\mathbf{x}}\right) w = 0, \tag{1}$$

where $\frac{d}{d\mathbf{x}} = (\frac{\partial}{\partial x_1}, \frac{\partial}{\partial x_2}, \ldots, \frac{\partial}{\partial x_n})$. The assumption that we consider only $\mathfrak{C}^\infty$-solutions is made for the ease of exposition, and the results remain valid for other solution concepts—for example, for distributions. We denote the family of linear shift-invariant differential systems $\Sigma = (\mathbb{R}^n, \mathbb{R}^{\mathtt{w}}, \mathfrak{B})$ as $\mathfrak{L}_n^{\mathtt{w}}$. We also denote $(\mathbb{R}^n, \mathbb{R}^{\mathtt{w}}, \mathfrak{B}) \in \mathfrak{L}_n^{\mathtt{w}}$ as $\mathfrak{B} \in \mathfrak{L}_n^{\mathtt{w}}$ since the indexing set and the signal space are then obvious from the context.

A system $\mathfrak{B} \in \mathfrak{L}_n^{\mathtt{w}}$ is uniquely specified by its annihilators, defined by

$$\mathfrak{N}_{\mathfrak{B}} = \left\{ p \in \mathbb{R}^{1\times \mathtt{w}}[\xi] \mid p\left(\frac{d}{d\mathbf{x}}\right)\mathfrak{B} = 0 \right\}.$$

It is easy to see that $\mathfrak{N}_{\mathfrak{B}}$ is a submodule of $\mathbb{R}^{1\times \mathtt{w}}[\xi]$ viewed as a module over $\mathbb{R}[\xi]$. In fact, there is a one-to-one relation between $\mathfrak{L}_n^{\mathtt{w}}$ and the submodules of $\mathbb{R}^{1\times \mathtt{w}}[\xi]$. Thus, whereas $R \in \mathbb{R}^{\bullet\times \mathtt{w}}[\xi]$ uniquely specifies a behavior $\mathfrak{B} \in \mathfrak{L}_n^{\mathtt{w}}$ through (1) with $\mathfrak{N}_{\mathfrak{B}}$ the module generated by the rows of R, any other polynomial matrix whose rows generate the same submodule define the same behavior.

The family of systems $\mathfrak{L}_n^{\mathtt{w}}$ enjoys many convenient properties, and this has been studied in detail in [19]. An important feature is the elimination theorem, which is the consequence of the following. Let $F \in \mathbb{R}^{\mathtt{w}_1\times \mathtt{w}_2}[\xi]$. Then $\mathfrak{B}_2 \in \mathfrak{L}_n^{\mathtt{w}_2}$ implies $F(\frac{d}{d\mathbf{x}})\mathfrak{B}_2 \in \mathfrak{L}_n^{\mathtt{w}_1}$ and $\mathfrak{B}_1 \in \mathfrak{L}_n^{\mathtt{w}_1}$ implies $(F(\frac{d}{d\mathbf{x}}))^{-1}\mathfrak{B}_1 \in \mathfrak{L}_n^{\mathtt{w}_2}$. This, in particular, implies that if $\mathfrak{B}_1, \mathfrak{B}_2 \in \mathfrak{L}_n^{\mathtt{w}}$, then $\mathfrak{B}_1 \cap \mathfrak{B}_2 \in \mathfrak{L}_n^{\mathtt{w}}$ and $\mathfrak{B}_1 + \mathfrak{B}_2 \in \mathfrak{L}_n^{\mathtt{w}}$. It also implies the elimination theorem that states that, for any $\mathfrak{B} \in \mathfrak{L}_n^{\mathtt{w}_1+\mathtt{w}_2}$, the set

$$\{w_1 \in \mathfrak{C}^\infty(\mathbb{R}^n, \mathbb{R}^{\mathtt{w}_1}) \mid \exists w_2 \in \mathfrak{C}^\infty(\mathbb{R}^n, \mathbb{R}^{\mathtt{w}_2}) : (w_1, w_2) \in \mathfrak{B}\}$$

is itself an element of $\mathfrak{L}_n^{\mathtt{w}_1}$. The elimination theorem and its variations follow from the important *fundamental principle* that states that the system of partial differential equations

$$A\left(\frac{d}{d\mathbf{x}}\right) f = g,$$

with $A \in \mathbb{R}^{\mathtt{w}_1\times \mathtt{w}_2}[\xi]$ and $g \in \mathfrak{C}^\infty(\mathbb{R}^n, \mathbb{R}^{\mathtt{w}_1})$ given, is solvable for $f \in \mathfrak{C}^\infty(\mathbb{R}^n, \mathbb{R}^{\mathtt{w}_2})$ if and only if whenever $p \in \mathbb{R}^{1\times \mathtt{w}_1}[\xi]$ satisfies $pA = 0$, then there must hold that $p(\frac{d}{d\mathbf{x}})g = 0$.

Whereas we have *defined* the behavior of a system in $\mathfrak{L}_n^{\mathtt{w}}$ as the set of solutions of a system of partial differential equations in the system variables, often, in practical applications, the specification of the behavior involves other, auxiliary variables, which we call *latent variables*. Specifically, consider the system of partial differential equations

$$R\left(\frac{d}{dx}\right) w = M\left(\frac{d}{dx}\right) \ell \tag{2}$$

with $w \in \mathfrak{C}^\infty(\mathbb{R}^n, \mathbb{R}^{\mathtt{w}})$ and $\ell \in \mathfrak{C}^\infty(\mathbb{R}^n, \mathbb{R}^\ell)$ and with $R \in \mathbb{R}^{\bullet\times \mathtt{w}}[\xi]$ and $M \in \mathbb{R}^{\bullet\times \ell}[\xi]$ polynomial matrices with the same number of rows. The set

$$\mathfrak{B}_f = \{(w, \ell) \in \mathfrak{C}^\infty(\mathbb{R}^n, \mathbb{R}^{\mathtt{w}+\ell}) \mid (2) \text{ holds}\} \tag{3}$$

obviously belongs to $\mathfrak{L}_n^{\mathtt{w}+\ell}$. It immediately follows from the elimination theorem that the set

$$\{w \in \mathfrak{C}^\infty(\mathbb{R}^n, \mathbb{R}^{\mathtt{w}}) \mid \exists \ell \in \mathfrak{C}^\infty(\mathbb{R}^n, \mathbb{R}^\ell) : (w, \ell) \in \mathfrak{B}_f\} \tag{4}$$

belongs to $\mathfrak{L}_n^{\mathbb{w}}$. We call (2) a latent variable representation, with manifest variables w and latent variables ℓ, of the system with full behavior (3) and manifest behavior (4). Correspondingly, we call (1) a kernel representation of the system with the behavior $\ker(R(\frac{d}{d\mathbf{x}}))$. We shall soon meet another sort of representation, the image representations, in the context of controllability.

3. Controllability and observability. Two very influential classical properties of dynamical systems are those of controllability and observability. In [24] these properties have been lifted to lumped dynamical systems in a behavioral setting, while in [19] generalizations to distributed systems have been introduced. We discuss these concepts here exclusively in the context of systems described by linear constant coefficient partial differential equations.

DEFINITION 1. *A system $\mathfrak{B} \in \mathfrak{L}_n^{\mathbb{w}}$ is said to be* controllable *if for all $w_1, w_2 \in \mathfrak{B}$ and for all sets $U_1, U_2 \subset \mathbb{R}^n$ with disjoint closure, there exists a $w \in \mathfrak{B}$ such that $w\,|_{U_1} = w_1\,|_{U_1}$ and $w\,|_{U_2} = w_2\,|_{U_2}$.*

Thus controllable partial differential equations are those in which the solutions can be "patched up" from solutions on subsets: in a sense there is no "action of a distance." There are a number of characterizations of controllability. In terms of its submodule of annihilators, $\mathfrak{N}_{\mathfrak{B}}$, $\mathfrak{B} \in \mathfrak{L}_n^{\mathbb{w}}$, is controllable if and only if the module $\mathbb{R}^{1\times \mathbb{w}}[\xi]/\mathfrak{N}_{\mathfrak{B}}$ is torsion-free [19].

More useful for our purposes is the equivalence of controllability with the existence of an image representation. Consider the following special latent variable representation:

$$w = M\left(\frac{d}{d\mathbf{x}}\right)\ell \tag{5}$$

with $M \in \mathbb{R}^{\mathbb{w}\times \ell}[\xi]$. Obviously, by the elimination theorem, its manifest behavior $\mathfrak{B} \in \mathfrak{L}_n^{\mathbb{w}}$. Such special latent variable representations often appear in physics, where the latent variables involved in such a representation are called *potentials*. Obviously, $\mathfrak{B} = \mathrm{im}(M(\frac{d}{d\mathbf{x}}))$ with $M(\frac{d}{d\mathbf{x}})$ viewed as a map from $\mathfrak{C}^\infty(\mathbb{R}^n, \mathbb{R}^\ell)$ to $\mathfrak{C}^\infty(\mathbb{R}^n, \mathbb{R}^{\mathbb{w}})$. For this reason, we call (5) an *image representation* of its manifest behavior. Whereas every $\mathfrak{B} \in \mathfrak{L}_n^{\mathbb{w}}$ allows (by definition) a kernel representation and hence trivially a latent variable representation, not every $\mathfrak{B} \in \mathfrak{L}_n^{\mathbb{w}}$ allows an image representation. In fact, see the following theorem.

THEOREM 2. *$\mathfrak{B} \in \mathfrak{L}_n^{\mathbb{w}}$ admits an image representation if and only if it is controllable.*

We denote the set of controllable systems in $\mathfrak{L}_n^{\mathbb{w}}$ by $\mathfrak{L}_{n,\mathrm{cont}}^{\mathbb{w}}$.

Observability is the property of systems that have two kinds of variables; the first set of variables are the "observed" set of variables, and the second set of variables are the ones that are "to-be-deduced" from the observed variables. Every variable that can be deduced uniquely from the manifest variables of a given behavior will be called an *observable*. So observability is not an intrinsic property of a given behavior. One has to be given a partition of the variables in the behavior into two classes before one can say whether one class of variables in the behavior can actually be deduced from the other class of variables (which were observed).

DEFINITION 3. *Let $w = (w_1, w_2)$ be a partition of the variables in $\Sigma = (\mathbb{R}^n, \mathbb{R}^{\mathbb{w}_1+\mathbb{w}_2}, \mathfrak{B})$. Then w_2 is said to be* observable *from w_1 in $\mathfrak{B}$ if given any two trajectories $(w_1', w_2'), (w_1'', w_2'') \in \mathfrak{B}$ such that $w_1' = w_1''$; then $w_2' = w_2''$.*

A natural situation to use observability is when one looks at the latent variable representation of a behavior. Then one may ask whether the latent variables are

observable from the manifest variables. If this is the case, then we call the latent variable representation *observable*.

As we have already mentioned, every controllable behavior has an image representation. In the case of 1D systems, it can be shown that every controllable behavior has an observable image representation. This is not true for nD systems.

4. QDFs. In [25, 26] a theory was developed for linear (1D) differential systems and quadratic functionals associated with these systems. It was shown that for systems described by *one-variable* polynomial matrices, the appropriate tool to express quadratic functionals are *two-variable* polynomial matrices. In the same vein, in this paper we will use polynomial matrices in $2n$ variables to express quadratic functionals for functions of n variables.

For convenience, let ζ denote $(\zeta_1, \dots, \zeta_n)$, and let η denote $(\eta_1, \dots, \eta_n)$. Let $\mathbb{R}^{\mathtt{w}_1 \times \mathtt{w}_2}[\zeta, \eta]$ denote the set of real polynomial matrices in the $2n$ indeterminates ζ and η. We will consider quadratic forms of the type $\Phi \in \mathbb{R}^{\mathtt{w}_1 \times \mathtt{w}_2}[\zeta, \eta]$. Explicitly,

$$\Phi(\zeta, \eta) = \sum_{\mathbf{k},\mathbf{l}} \Phi_{\mathbf{k},\mathbf{l}} \zeta^{\mathbf{k}} \eta^{\mathbf{l}}.$$

The sum above ranges over all nonnegative multi-indices $\mathbf{k} = (k_1, k_2, \dots, k_n), \mathbf{l} = (l_1, l_2, \dots, l_n) \in \mathbb{N}^n$, and the sum is assumed to be finite. Moreover, $\Phi_{\mathbf{k},\mathbf{l}} \in \mathbb{R}^{\mathtt{w}_1 \times \mathtt{w}_2}$. The polynomial matrix Φ induces a *bilinear differential form* (BLDF), that is, the map

$$L_\Phi : \mathfrak{C}^\infty(\mathbb{R}^n, \mathbb{R}^{\mathtt{w}_1}) \times \mathfrak{C}^\infty(\mathbb{R}^n, \mathbb{R}^{\mathtt{w}_2}) \to \mathfrak{C}^\infty(\mathbb{R}^n, \mathbb{R})$$

defined by

$$L_\Phi(v, w)(\mathbf{x}) := \sum_{\mathbf{k},\mathbf{l}} \left(\frac{d^{\mathbf{k}} v}{d\mathbf{x}^{\mathbf{k}}}(\mathbf{x}) \right)^T \Phi_{\mathbf{k},\mathbf{l}} \left(\frac{d^{\mathbf{l}} w}{d\mathbf{x}^{\mathbf{l}}}(\mathbf{x}) \right),$$

where $\frac{d^{\mathbf{k}}}{d\mathbf{x}^{\mathbf{k}}} = \frac{\partial^{k_1}}{\partial x_1^{k_1}} \frac{\partial^{k_2}}{\partial x_2^{k_2}} \cdots \frac{\partial^{k_n}}{\partial x_n^{k_n}}$ and analogously for $\frac{d^{\mathbf{l}}}{d\mathbf{x}^{\mathbf{l}}}$. Note that ζ corresponds to differentiation of terms to the left, and η refers to differentiation of the terms to the right.

If $\mathtt{w}_1 = \mathtt{w}_2 = \mathtt{w}$, then Φ induces the QDF

$$Q_\Phi : \mathfrak{C}^\infty(\mathbb{R}^n, \mathbb{R}^{\mathtt{w}}) \to \mathfrak{C}^\infty(\mathbb{R}^n, \mathbb{R})$$

defined by

$$Q_\Phi(w) := L_\Phi(w, w).$$

Define the * operator

$$^* : \mathbb{R}^{\mathtt{w} \times \mathtt{w}}[\zeta, \eta] \to \mathbb{R}^{\mathtt{w} \times \mathtt{w}}[\zeta, \eta]$$

by

$$\Phi^*(\zeta, \eta) := \Phi^T(\eta, \zeta).$$

If $\Phi = \Phi^*$, then Φ is called *symmetric*. For the purposes of QDFs induced by polynomial matrices, it suffices to consider the symmetric QDFs since $Q_\Phi = Q_{\Phi^*} = Q_{\frac{1}{2}(\Phi + \Phi^*)}$.

We also consider vectors $\Psi \in (\mathbb{R}^{\mathtt{w}\times\mathtt{w}}[\zeta,\eta])^n$, i.e., $\Psi = (\Psi_1,\dots,\Psi_n)$. Analogous to the QDF induced by Φ, Ψ induces a *vector of quadratic differential forms* (VQDF)

$$Q_\Psi(w) : \mathfrak{C}^\infty(\mathbb{R}^n,\mathbb{R}^{\mathtt{w}}) \to (\mathfrak{C}^\infty(\mathbb{R}^n,\mathbb{R}))^n$$

defined by $Q_\Psi = (Q_{\Psi_1},\dots,Q_{\Psi_n})$.

Finally, we define the "div" (divergence) operator that associates with the VQDF induced by Ψ, the scalar QDF:

$$(\text{div } Q_\Psi)(w) := \frac{\partial}{\partial x_1} Q_{\Psi_1}(w) + \cdots + \frac{\partial}{\partial x_n} Q_{\Psi_n}(w).$$

The theory of QDFs has been developed in much detail in [25, 26] for 1D systems. In the next section, we put forward those aspects which are useful in the construction of storage function for distributive systems.

5. Path independence. Consider the integral

$$\int_\Omega Q_\Phi(w)d\mathbf{x}, \tag{6}$$

where Ω is a closed bounded subset of $\mathbb{R}^n$ with a nonempty interior. This integral is said to be independent of the "path" w (or a *path integral*) if the integral depends only on the value of w and its derivatives on the boundary of Ω, denoted by $\partial\Omega$. More precisely, if for any $w_1, w_2 \in \mathfrak{C}^\infty(\mathbb{R}^n,\mathbb{R}^{\mathtt{w}})$ such that $\frac{d^{\mathbf{k}}w_1}{d\mathbf{x}^{\mathbf{k}}}(\mathbf{x}) = \frac{d^{\mathbf{k}}w_2}{d\mathbf{x}^{\mathbf{k}}}(\mathbf{x})$ for all $\mathbf{x}\in\partial\Omega$ and all $\mathbf{k}\in\mathbb{N}^n$, there holds

$$\int_\Omega Q_\Phi(w_1)d\mathbf{x} \;=\; \int_\Omega Q_\Phi(w_2)d\mathbf{x}.$$

Instead of some $\Omega\subset\mathbb{R}^n$, if we consider the integral (6) over all of $\mathbb{R}^n$, then the integral need not be well defined for all $w\in\mathfrak{C}^\infty(\mathbb{R}^n,\mathbb{R}^{\mathtt{w}})$. We can overcome this by considering it only for w's of compact support. This yields the functional

$$\int Q_\Phi : \mathfrak{D}(\mathbb{R}^n,\mathbb{R}^{\mathtt{w}}) \to \mathbb{R}$$

defined by

$$\int Q_\Phi(w) := \int_{\mathbb{R}^n} Q_\Phi(w)d\mathbf{x},$$

which evaluates the integral over all of $\mathbb{R}^n$.

The following theorem gives several conditions that are equivalent to path independence.

THEOREM 4. *Let $\Phi\in\mathbb{R}^{\mathtt{w}\times\mathtt{w}}[\zeta,\eta]$. Then the following statements are equivalent:*

1. *$\int_\Omega Q_\Phi$ is independent of path for all closed bounded subsets Ω of $\mathbb{R}^n$.*
2. *$\int Q_\Phi = 0$.*
3. *$\Phi(-\xi,\xi) = 0$.*
4. *There exist $\Psi_1,\dots,\Psi_n\in\mathbb{R}^{\mathtt{w}\times\mathtt{w}}[\zeta,\eta]$ such that*

$$\Phi(\zeta,\eta) = (\zeta_1+\eta_1)\Psi_1(\zeta,\eta) + \cdots + (\zeta_n+\eta_n)\Psi_n(\zeta,\eta).$$

5. *There exists a* $\Psi \in (\mathbb{R}^{\mathtt{w}\times\mathtt{w}}[\zeta,\eta])^n$ *such that*

$$\operatorname{div} Q_\Psi = Q_\Phi$$

for all $w \in \mathfrak{C}^\infty(\mathbb{R}^n, \mathbb{R}^{\mathtt{w}})$.

At this point we would like to point out an important difference for the cases $n = 1$ and $n > 1$. Although the above theorem holds for all values of n, more can be said in the case when $n = 1$. In the case when $n = 1$, the last condition of the above theorem can be strengthened to state that there exists a unique Ψ such that $\frac{d}{dt}Q_\Psi = Q_\Phi$ (assuming t is the independent variable). This uniqueness of Ψ does not hold when $n > 1$. This will become clear from the subsequent proposition, which will help us in classifying this nonuniqueness. If Ψ_1 and Ψ_2 induce two VQDFs such that

$$Q_\Phi = \operatorname{div} Q_{\Psi_1} = \operatorname{div} Q_{\Psi_2}, \tag{7}$$

then $\Psi = \Psi_1 - \Psi_2$ defines a VQDF such that $\operatorname{div} Q_\Psi(w) = 0$ for all $w \in \mathfrak{C}^\infty(\mathbb{R}^n, \mathbb{R}^{\mathtt{w}})$. Such a VQDF is said to have *null divergence*. Thus it is obvious that given a $\Phi \in \mathbb{R}^{\mathtt{w}\times\mathtt{w}}[\zeta,\eta]$ which defines a path integral and a VQDF induced by $\Psi \in (\mathbb{R}^{\mathtt{w}\times\mathtt{w}}[\zeta,\eta])^n$ such that $\operatorname{div} Q_\Psi(w) = Q_\Phi(w)$, it is possible to obtain other VQDFs that satisfy this property by adding VQDFs that have null divergence to the already obtained VQDF Ψ. We now characterize those VQDFs that have null divergence.

PROPOSITION 5. *A VQDF induced by* $\Psi = (\Psi_1, \dots, \Psi_n) \in (\mathbb{R}^{\mathtt{w}\times\mathtt{w}}[\zeta,\eta])^n$ *has null divergence if and only if there exists a family of* n^2 *QDFs induced by* $\Delta_{ij} \in \mathbb{R}^{\mathtt{w}\times\mathtt{w}}[\zeta,\eta]$, $i = 1, \dots, n$, $j = 1, \dots, n$, *with* $\Delta_{ij} = -\Delta_{ji}$ *such that*

$$\Psi_i = (\zeta_1 + \eta_1)\Delta_{i1} + (\zeta_2 + \eta_2)\Delta_{i2} + \cdots + (\zeta_n + \eta_n)\Delta_{in}.$$

From the above proposition, it is clear that $\Delta_{ii} = 0$. Thus for 1D systems, the QDF induced by Δ_{11} is the zero QDF, and so there exists no nonzero 1D (V)QDFs that have null divergence. Hence the Ψ obtained in Theorem 4 for 1D systems is unique [26, Theorem 3.1]. In fact, $\Psi(\zeta,\eta) = \frac{\Phi(\zeta,\eta)}{\zeta+\eta}$ in 1D systems. In nD systems with $n > 1$, the Ψ obtained in Theorem 4 is no longer unique since there exist nonzero VQDFs that give rise to null divergences. The above proposition completely classifies the nonuniqueness of these VQDFs. Hence, for every path independent QDF induced by $\Phi \in \mathbb{R}^{\mathtt{w}\times\mathtt{w}}[\zeta,\eta]$, one obtains an equivalence class of VQDFs such that (7) holds. The members of an equivalence class are exactly those that differ by a VQDF that has null divergence.

6. Lossless systems. In this section, we study the notion of path independence generalized to controllable systems $\mathfrak{B} \in \mathfrak{L}^{\mathtt{w}}_{n,\mathrm{cont}}$. We cast this in the context of conservative systems.

Let $\Phi = \Phi^* \in \mathbb{R}^{\mathtt{w}\times\mathtt{w}}[\zeta,\eta]$ and $\mathfrak{B} \in \mathfrak{L}^{\mathtt{w}}_{n,\mathrm{cont}}$. Now consider the QDF $Q_\Phi(w)$ for trajectories $w \in \mathfrak{B}$. We consider $Q_\Phi(w)(\mathbf{x})$ (with $\mathbf{x} \in \mathbb{R}^n$) as the rate of supply of some physical quantity (for example, energy) delivered to the system at the point $\mathbf{x}$ (whence positive when the system absorbs supply).

DEFINITION 6. *The system* $\mathfrak{B} \in \mathfrak{L}^{\mathtt{w}}_{n,\mathrm{cont}}$ *is said to be* lossless *with respect to the supply rate* Q_Φ *induced by* $\Phi = \Phi^* \in \mathbb{R}^{\mathtt{w}\times\mathtt{w}}[\zeta,\eta]$ *if* $\int_{\mathbb{R}^n} Q_\Phi(w)d\mathbf{x} = 0$ *for all* $w \in \mathfrak{B} \cap \mathfrak{D}(\mathbb{R}^n, \mathbb{R}^{\mathtt{w}})$.

The interpretation of this condition is that $\int_{\mathbb{R}^n} Q_\Phi(w)d\mathbf{x}$ denotes the net amount of supply that the system absorbs integrated over "time" and "space." Whence the system is lossless if this integral is zero: any supply absorbed at some time or place is temporarily stored but eventually recovered perhaps at some other time or place.

A related notion is that of path independence along a behavior. Let Ω be a closed and bounded subset of $\mathbb{R}^n$. The integral $\int_\Omega Q_\Phi(w)d\mathbf{x}$ is said to be independent of path for trajectories $w \in \mathfrak{B}$ if whenever $w_1, w_2 \in \mathfrak{B}$ and $\frac{d^{\mathbf{k}}w_1}{d\mathbf{x}^{\mathbf{k}}}(\mathbf{x}) = \frac{d^{\mathbf{k}}w_2}{d\mathbf{x}^{\mathbf{k}}}(\mathbf{x})$ for $\mathbf{x} \in \partial\Omega$ and all $\mathbf{k} \in \mathbb{N}^n$, then

$$\int_\Omega Q_\Phi(w_1)d\mathbf{x} \;=\; \int_\Omega Q_\Phi(w_2)d\mathbf{x}.$$

Define the * operator mapping from $\mathbb{R}^{\mathtt{w}_1\times\mathtt{w}_2}[\xi]$ to $\mathbb{R}^{\mathtt{w}_2\times\mathtt{w}_1}[\xi]$ by $X^\star(\xi) := X^T(-\xi)$. In other words, if we look at $X(\frac{d}{d\mathbf{x}})$ as a partial differential operator, then $X^\star(\frac{d}{d\mathbf{x}})$ is the (formal) adjoint operator.

The following theorem gives a number of equivalent conditions for a system to be lossless.

THEOREM 7. *Let $\mathfrak{B} \in \mathfrak{L}^{\mathtt{w}}_{n,\mathrm{cont}}$. Let $R \in \mathbb{R}^{\bullet\times\mathtt{w}}[\xi]$ and $M \in \mathbb{R}^{\mathtt{w}\times\bullet}[\xi]$ induce, respectively, a kernel and image representation of $\mathfrak{B}$; i.e., $\mathfrak{B} = \ker(R(\frac{d}{d\mathbf{x}})) = \mathrm{im}(M(\frac{d}{d\mathbf{x}}))$. Let $\Phi = \Phi^* \in \mathbb{R}^{\mathtt{w}\times\mathtt{w}}[\zeta,\eta]$ induce a QDF on $\mathfrak{B}$. Then the following conditions are equivalent:*

1. *$\mathfrak{B}$ is lossless with respect to the QDF Q_Φ;*
2. *The QDF induced by Φ is independent of path on $\mathfrak{B}$, i.e., $\int_\Omega Q_\Phi(w)d\mathbf{x}$ is independent of path for all bounded and closed subsets Ω in $\mathbb{R}^n$ with a nonempty interior;*
3. *the QDF corresponding to Φ' is a path integral, where Φ' is given by $\Phi'(\zeta,\eta) := M^T(\zeta)\Phi(\zeta,\eta)M(\eta)$;*
4. *$\Phi'(-\xi,\xi) = 0$;*
5. *there exists a VQDF Q_Ψ, with $\Psi \in (\mathbb{R}^{m\times m}[\zeta,\eta])^n$, where m is the number of columns of M such that*

$$\mathrm{div}\, Q_\Psi(\ell) = Q_{\Phi'}(\ell) = Q_\Phi(w) \tag{8}$$

for all $\ell \in \mathfrak{C}^\infty(\mathbb{R}^n,\mathbb{R}^m)$ and $w = M(\frac{d}{d\mathbf{x}})\ell$.

We focus our attention for a moment on the equivalence of conditions 1 and 5 of the above theorem. It states that $\mathfrak{B}$ is lossless with respect to Q_Φ, i.e., that

$$\int_{\mathbb{R}^n} Q_\Phi(w)d\mathbf{x} = 0 \tag{9}$$

for all $w \in \mathfrak{B}$ of compact support if and only if $\mathfrak{B}$ admits an image representation $w = M(\frac{d}{d\mathbf{x}})\ell$ and there exists some VQDF Ψ such that

$$\mathrm{div}\; Q_\Psi(\ell) = Q_\Phi(w) \tag{10}$$

for all $w \in \mathfrak{B}$ and ℓ such that $w = M(\frac{d}{d\mathbf{x}})\ell$.

The equivalence of the global version of losslessness (9) with the local version (10) is a recurrent theme in the theory of dissipative systems. The local version states that there is a function $Q_\Psi(\ell)(\mathbf{x})$ that plays the role of the amount of supply stored at $\mathbf{x} \in \mathbb{R}^n$. Thus (10) says that for lossless systems, it is possible to define a *storage function* Q_Ψ such that the *conservation equation*

$$\mathrm{div}\; Q_\Psi(\ell) = Q_\Phi(w) \tag{11}$$

is satisfied for all w, ℓ such that $w = M(\frac{d}{d\mathbf{x}})\ell$. Note here that since $\Phi' = \mathrm{div}\;\Psi$, by the Stokes theorem

$$\int_{\partial\Omega}\sum_{i=1}^n (-1)^{i-1}Q_{\Psi_i}(\ell)dx_1\wedge\cdots\wedge\widehat{dx_i}\wedge\cdots\wedge dx_n = \int_\Omega Q_{\Phi'}(\ell)dx_1\wedge\cdots\wedge dx_n$$

(for any $\Omega \subseteq \mathbb{R}^n$ with a reasonable boundary). We can then think of the above as an integral form of the conservation equation (11).

Two important features, both specific to the case when $n > 1$, are worth emphasizing. First is the fact that the storage $Q_\Psi(\ell)$ depends on the latent variable ℓ from the image representation $w = M(\frac{d}{d\mathbf{x}})\ell$. Since $\mathfrak{B} \in \mathfrak{L}^{\mathbb{W}}_{n,\text{cont}}$ may not have an observable image representation, there may not exist a storage function of the form $Q_\Psi(w)$ that depends on the manifest variables $w \in \mathfrak{B}$. Hence the storage in (11) involves "hidden" (i.e., nonobservable) variables. Second, the nonuniqueness of the VQDF Q_Ψ that solves $\operatorname{div} Q_\Psi(\ell) = Q_\Phi(M(\frac{d}{d\mathbf{x}})\ell) = Q_{\Phi'}(\ell)$. Hence, even when the ℓ's have acquired a "physical significance," there will be many possible storage functions. We shall see in the next section that this nonuniqueness is important already in basic physics.

We would like to mention at this point that in many practical examples the independent variables are time and space variables. So, for example, the indexing set would be $\mathbb{R} \times \mathbb{R}^3$. In this case, we will use the notation t, x, y, z to stand for the independent variables (time coordinate and the three space coordinates, respectively), and the partial derivatives with respect to these variables are denoted by $\frac{\partial}{\partial t}, \frac{\partial}{\partial x}, \frac{\partial}{\partial y}, \frac{\partial}{\partial z}$, respectively. It is important to interpret the storage function Q_Ψ in this context. In the case mentioned above, we denote $\Psi = (\Psi_t, \Psi_x, \Psi_y, \Psi_z)$ and $Q_\Psi = (u, \mathbf{S})$. Here u is the QDF Q_{Ψ_t}, which is the "*internal storage*" and the VQDF $\mathbf{S} := (Q_{\Psi_x}, Q_{\Psi_y}, Q_{\Psi_z})$ is the "*flux*." This interpretation will be useful in the next section. With the above notation, (8) now becomes

$$\frac{\partial}{\partial t} u(\ell) + \nabla \cdot \mathbf{S}(\ell) = Q_\Phi(w),$$

where ∇ is the spatial divergence operator.

7. Maxwell's equations. The prototypical example of a linear shift-invariant differential system is provided by Maxwell's equations in free space:

$$\begin{aligned} \nabla \cdot \mathbf{E} - \frac{\rho}{\epsilon_0} &= 0, \\ \nabla \times \mathbf{E} + \frac{\partial \mathbf{B}}{\partial t} &= 0, \\ c^2 \nabla \times \mathbf{B} - \frac{\partial \mathbf{E}}{\partial t} - \frac{\mathbf{j}}{\epsilon_0} &= 0, \\ \nabla \cdot \mathbf{B} &= 0. \end{aligned} \tag{12}$$

This describes the relation between the electrical field $\mathbf{E} : \mathbb{R} \times \mathbb{R}^3 \to \mathbb{R}^3$, the magnetic field $\mathbf{B} : \mathbb{R} \times \mathbb{R}^3 \to \mathbb{R}^3$, the current density $\mathbf{j} : \mathbb{R} \times \mathbb{R}^3 \to \mathbb{R}^3$, and the charge density $\rho : \mathbb{R} \times \mathbb{R}^3 \to \mathbb{R}$. In the above equations, the constants c and ϵ_0 stand for the speed of light in vacuum and the electric constant, respectively. Hence (12) defines a system $\mathfrak{B}_{ME} \in \mathfrak{L}^{10}_4$. It is well known that $\mathfrak{B}_{ME}$ can be described in terms of the vector potential $\mathbf{A} : \mathbb{R} \times \mathbb{R}^3 \to \mathbb{R}^3$ and the scalar potential $\phi : \mathbb{R} \times \mathbb{R}^3 \to \mathbb{R}$ by

$$\begin{aligned} \mathbf{E} &= -\frac{\partial \mathbf{A}}{\partial t} - \nabla \phi, \\ \rho &= -\epsilon_0 \nabla \cdot \frac{\partial \mathbf{A}}{\partial t} - \epsilon_0 \nabla^2 \phi, \\ \mathbf{B} &= \nabla \times \mathbf{A}, \\ \mathbf{j} &= \epsilon_0 \frac{\partial^2 \mathbf{A}}{\partial t^2} - \epsilon_0 c^2 \nabla^2 \mathbf{A} + \epsilon_0 c^2 \nabla(\nabla \cdot \mathbf{A}) + \epsilon_0 \nabla \frac{\partial \phi}{\partial t}. \end{aligned} \tag{13}$$

It is important to note that (13) is an image representation of $\mathfrak{B}_{ME}$. Hence, by Theorem 2, Maxwell's equations define a controllable system. It is also important to note that (13) is an unobservable image representation of $\mathfrak{B}_{ME}$. In fact, there *do not exist* observable image representations of $\mathfrak{B}_{ME}$.

Strictly speaking, the vector potential $\mathbf{A}$ and the scalar potential ϕ are "free" latent variables (i.e., they are allowed to take on any values in the relevant space of trajectories). Note that we can change $\mathbf{A}$ and ϕ to $\mathbf{A}' = \mathbf{A} + \nabla\psi$ and $\phi' = \phi - \frac{\partial\psi}{\partial t}$ (where ψ is some other arbitrary scalar function) without changing the resulting $\mathbf{E}$, $\mathbf{B}$, ρ, and $\mathbf{j}$. These are called *gauge transformations*. Additional conditions may be imposed on $\mathbf{A}$ and ϕ without changing the fact that the image in (13) remains $\mathfrak{B}_{ME}$. For example, the Lorentz condition

$$\nabla \cdot \mathbf{A} = -\frac{1}{c^2}\frac{\partial \phi}{\partial t} \tag{14}$$

can be imposed on the potentials to obtain symmetry in the representation (13). In this case, the last two terms of the last equation in (13) disappear, thus displaying a symmetry in the equations. Moreover, these new equations then remain invariant under Lorentz transformations of the independent variables. There are other possibilities. The important point is that the gauge transformations and imposition of such conditions like the Lorentz condition do not change the set of $(\mathbf{E}, \mathbf{B}, \mathbf{j}, \rho)$ obtained as solutions to the Maxwell equations. In other words, (13) and (14) together provide a latent variable representation of $\mathfrak{B}_{ME}$. We will not consider such transformations further in this paper.

We are interested in studying the exchange of electrical energy between the environment and the electromagnetic field in free space. This exchange of energy only involves the electrical variables $(\mathbf{E}, \mathbf{j})$. The laws that are described by these variables define, by the elimination theorem, a system $\mathfrak{B}_{\mathrm{E}} \in \mathfrak{L}_4^6$. Consider, therefore, in Maxwell's equations the magnetic field $\mathbf{B}$ and the charge density ρ as latent variables. Then, by eliminating these latent variables, we obtain

$$\begin{aligned} \frac{\partial}{\partial t}\nabla \cdot \mathbf{E} + \frac{1}{\epsilon_0}\nabla \cdot \mathbf{j} &= 0, \\ \frac{\partial^2 \mathbf{E}}{\partial t^2} + c^2 \nabla \times (\nabla \times \mathbf{E}) + \frac{1}{\epsilon_0}\frac{\partial \mathbf{j}}{\partial t} &= 0. \end{aligned} \tag{15}$$

The above equations give a kernel representation for the behavior $\mathfrak{B}_{\mathrm{E}}$ consisting of all trajectories $(\mathbf{E}, \mathbf{j}) \in \mathfrak{C}^\infty(\mathbb{R}^4, \mathbb{R}^6)$ which are compatible with the solutions of Maxwell's equations. Since $\mathfrak{B}_{\mathrm{ME}}$ is controllable, so is $\mathfrak{B}_{\mathrm{E}}$, and so one can obtain an image representation of it.

$$\begin{aligned} \mathbf{E} &= -\nabla\phi - \frac{\partial \mathbf{A}}{\partial t}, \\ \mathbf{j} &= \epsilon_0 \frac{\partial}{\partial t}\nabla\phi + \epsilon_0 \frac{\partial^2 \mathbf{A}}{\partial t^2} + \epsilon_0 c^2 \nabla \times (\nabla \times \mathbf{A}). \end{aligned} \tag{16}$$

Here $\mathbf{A}$ and ϕ are again the vector and scalar potentials, respectively [10].

Consider the QDF $Q_\Phi(\mathbf{E}, \mathbf{j}) = \mathbf{E} \cdot \mathbf{j}$ for all $w \in \mathfrak{B}_{\mathrm{ME}}$. This quantity defines the rate of work done by the field on each unit volume [10].

It is well known that Maxwell's equations define a lossless system. This also follows from Theorem 7. Indeed, by identifying the matrix Φ corresponding to the QDF $Q_\Phi(\mathbf{E}, \mathbf{j}) = \mathbf{E} \cdot \mathbf{j}$ and the M matrix corresponding to the image representation

(13), we can compute $\Phi'(\zeta,\eta) := M^T(\zeta)\Phi(\zeta,\eta)M(\eta)$. It is easily seen that $\Phi'(-\xi,\xi) = 0$. Losslessness follows from Theorem 7. The QDF induced by Φ' is a path integral on the potentials, which in turn implies that Φ is a path integral on the solutions of Maxwell's equations. By Theorem 7, there exists a VQDF, $\Psi \in (\mathbb{R}^{4\times 4}[\zeta,\eta])^4$, such that $\operatorname{div} Q_\Psi(\phi,\mathbf{A}) = Q_\Phi(\mathbf{E},\mathbf{j}) = \mathbf{E}\cdot\mathbf{j}$. By the terminology defined at the end of last section, we can write the VQDF Q_Ψ as $(-u,-\mathbf{S})$ (the negative signs are purely a matter of convention). Then we have

$$\mathbf{E}\cdot\mathbf{j} = \operatorname{div} Q_\Psi(\phi,\mathbf{A}) = -\frac{\partial u(\phi,\mathbf{A})}{\partial t} - \nabla\cdot\mathbf{S}(\phi,\mathbf{A}).$$

On substituting $\mathbf{B} = \nabla\times\mathbf{A}$ and $\mathbf{E} = -\nabla\phi - \frac{\partial\mathbf{A}}{\partial t}$, we obtain

$$\begin{aligned} u &= \frac{\epsilon_0}{2}\mathbf{E}\cdot\mathbf{E} + \frac{\epsilon_0 c^2}{2}\mathbf{B}\cdot\mathbf{B}, \\ \mathbf{S} &= \epsilon_0 c^2 \mathbf{E}\times\mathbf{B}. \end{aligned} \tag{17}$$

This u defines the *energy density* in the field, and $\mathbf{S}$ represents the *energy flux* of the field. The vector $\mathbf{S}$ is known as the "Poynting vector." Thus (8) gives a "conservation law" for Maxwell's equations. It states that the rate at which the field does work on an infinitesimal volume ($Q_\Phi(\mathbf{E},\mathbf{j}) = \mathbf{E}\cdot\mathbf{j}$) is equal to the rate of decrease in the energy density ($-\frac{\partial u}{\partial t}$) and the energy flux ($-\nabla\cdot\mathbf{S}$) that flows into the infinitesimal volume under consideration. Thus (8) states that the total energy is conserved.

We now interpret these results about Maxwell's equations in terms of the theory developed earlier. There are two points that we would like to emphasize.

1. The problem under consideration may be viewed as finding out if the system given by (15) (the behavior $\mathfrak{B}_{\mathrm{E}}$) is lossless with respect to $Q_\Phi(\mathbf{E},\mathbf{j}) = \mathbf{E}\cdot\mathbf{j}$, and if so, finding a storage function for it. Verification of losslessness involves a straightforward calculation. Also, a storage function $(u,\mathbf{S})$ was derived in terms of $\mathbf{E}$ and $\mathbf{B}$ (17). Note that this storage function depends on $\mathbf{E}$ and $\mathbf{B}$. The latter is a latent variable with respect to the electrical quantities $(\mathbf{E},\mathbf{j})$ involved in (15). In fact, $\mathbf{B}$ is not observable from $(\mathbf{E},\mathbf{j})$ in Maxwell's equations. Hence already in this elementary example the storage functions involve hidden variables.
   From Theorem 7 and the example of Maxwell's equations, it is seen that the VQDF acts on some latent variables. These latent variables are related to the latent variables that appear in an image representation of a given controllable behavior. For example, in Maxwell's equations, $\mathbf{B}$ is related to $\mathbf{A}$. One would like the VQDF to act only on the manifest variables. A sufficient condition for the existence of such a VQDF is that the controllable behavior has an observable image representation. In 1D systems, every controllable system has an observable image representation. As a result, in the 1D case, given a QDF induced by Φ which is independent of path on $\mathfrak{B}$, we can actually find a QDF Ψ such that
   $$\frac{d}{dt}Q_\Psi(w) = Q_\Phi(w)$$
   for all $w\in\mathfrak{B}$. In the nD case, a controllable behavior need not necessarily have an observable image representation. So for the nD case, when the QDF induced by Φ is independent of path on $\mathfrak{B}$, it is sufficient for $\mathfrak{B}$ to have

observable potentials for us to find a VQDF Ψ such that

$$\operatorname{div} Q_\Psi(w) = Q_\Phi(w)$$

for all $w \in \mathfrak{B}$.

2. We would also like to make a comment on the nonuniqueness of the VQDF that appears in the conservation equation (8). With reference to Maxwell's equations, we quote from [10], "All we did was to find a *possible* "u" and a *possible* "$\mathbf{S}$." How do we know that juggling the terms around some more we couldn't find another formula for "u" and "$\mathbf{S}$"? ... It's possible. ... There are, in fact, an infinite number of possibilities for u and $\mathbf{S}$, and so far no one has thought of an experiment to tell which one is right!"
We found that this nonuniqueness of the storage function is an intrinsic feature of storage functions for conservative nD systems with $n > 1$. The result in Proposition 5 characterizes the nonuniqueness of the VQDF that goes with a given QDF induced by Φ which is independent of path on all trajectories in $\mathfrak{C}^\infty(\mathbb{R}^n, \mathbb{R}^\ell)$.

8. Supply, storage, and dissipation. In the previous section, we considered QDFs such that $\int Q_\Phi$ is zero when restricted to some behavior $\mathfrak{B}$: the lossless systems. As we have seen, such QDFs define conservation laws. In this section, we consider QDFs where the integral $\int Q_\Phi$ is nonnegative. In the spirit of [23, 26], we refer to these as dissipative systems. We justify the use of this terminology later.

Our plan is as follows. We first introduce the concepts for general controllable behaviors $\mathfrak{B} \in \mathfrak{L}^{\mathtt{w}}_{n,\mathrm{cont}}$. Subsequently, we analyze the situation $\mathfrak{B} = \mathfrak{C}^\infty(\mathbb{R}^n, \mathbb{R}^{\mathtt{w}})$. We will see that this leads to the problem of factorization of polynomial matrices in several variables. We subsequently return to general controllable behaviors.

DEFINITION 8. *Let $\mathfrak{B} \in \mathfrak{L}^{\mathtt{w}}_{n,\mathrm{cont}}$ and $\Phi = \Phi^* \in \mathbb{R}^{\mathtt{w}\times\mathtt{w}}[\zeta, \eta]$. Consider the QDF Q_Φ induced by Φ. We call* $\mathfrak{B}$ dissipative with respect to Q_Φ *(briefly Φ-dissipative) if*

$$\int_{\mathbb{R}^n} Q_\Phi(w) d\mathbf{x} \geq 0$$

for all $w \in \mathfrak{B}$ with compact support.

The intuitive interpretation is that $Q_\Phi(w)$ is the rate of supply (Q_Φ is called the *supply rate*) absorbed by the system. Dissipativity hence means that the net supply that is absorbed by the system is nonnegative for any trajectory $w \in \mathfrak{B}$ that is of compact support.

Two related notions are those of storage functions and dissipation rate. As we have already seen in the context of lossless systems, the storage function is in general a function of unobservable latent variables, more specifically of the latent variables that appear in an image representation (thus depending on "potentials"). We incorporate this in the definitions.

DEFINITION 9. *Let $\mathfrak{B} \in \mathfrak{L}^{\mathtt{w}}_{n,\mathrm{cont}}$, $\Phi = \Phi^* \in \mathbb{R}^{\mathtt{w}\times\mathtt{w}}[\zeta, \eta]$, and $w = M(\frac{d}{d\mathbf{x}})\ell$ be an image representation of $\mathfrak{B}$ with $M \in \mathbb{R}^{\mathtt{w}\times\ell}[\xi]$. Let $\Psi = (\Psi_1, \Psi_2, \ldots, \Psi_n)$ with $\Psi_k = \Psi_k^* \in \mathbb{R}^{\ell\times\ell}[\zeta, \eta]$ for $k = 1, 2, \ldots, n$. The VQDF Q_Ψ is said to be a* storage function *for $\mathfrak{B}$ with respect to Q_Φ if*

$$\operatorname{div} Q_\Psi(\ell) \leq Q_\Phi(w) \tag{18}$$

for all $\ell \in \mathfrak{D}(\mathbb{R}^n, \mathbb{R}^\ell)$ and $w = M(\frac{d}{d\mathbf{x}})\ell$.

$\Delta = \Delta^* \in \mathbb{R}^{\ell\times\ell}[\zeta,\eta]$ *is said to be a* dissipation rate *for* $\mathfrak{B}$ *with respect to* Q_Φ *if*

$$Q_\Delta \geq 0 \text{ and } \int_{\mathbb{R}^n} Q_\Delta(\ell)d\mathbf{x} = \int_{\mathbb{R}^n} Q_\Phi(w)d\mathbf{x}$$

for all $\ell \in \mathfrak{D}(\mathbb{R}^n,\mathbb{R}^\ell)$ *and* $w = M(\frac{d}{d\mathbf{x}})\ell$.

We define $Q_\Delta \geq 0$ if $Q_\Delta(w(\mathbf{x})) \geq 0$ for all $w \in \mathfrak{D}(\mathbb{R}^n,\mathbb{R}^w)$ evaluated at every $\mathbf{x} \in \mathbb{R}^n$. This defines a pointwise positivity condition. Thus $\int_\Omega Q_\Delta(w)d\mathbf{x} \geq 0$ for every $\Omega \subset \mathbb{R}^n$ if $Q_\Delta \geq 0$.

It is easy to see that there is a relation between a storage function for $\mathfrak{B}$ with respect to Q_Φ and a dissipation rate for $\mathfrak{B}$ with respect to Q_Φ, given by

$$Q_\Delta(\ell) = Q_\Phi\left(M\left(\frac{d}{d\mathbf{x}}\right)\ell\right) - \text{div } Q_\Psi(\ell). \tag{19}$$

The definitions of the storage function and the dissipation rate, combined with (19), yield intuitive interpretations. The dissipation rate can be thought of as the rate of supply that is dissipated in the system and the storage function as the rate of supply stored in the system. Intuitively, we could think of the QDF Q_Φ as measuring the power going into the system. In many practical examples, the power is indeed a QDF of some system variables. (For example, $-\mathbf{E}\cdot\mathbf{j}$ is the rate of work done on the system in the case of Maxwell's equations, or, as mentioned earlier, $\mathbf{E}\cdot\mathbf{j}$ is the rate of work done by the field.) Φ-dissipativity would imply that the net power flowing into a system is nonnegative, which in turn implies that the system dissipates energy. Of course, locally the flow of energy could be positive or negative, leading to variations in energy density and fluxes. The energy density and fluxes could be thought of as a storage function for the energy. (Again see the section on Maxwell's equations.) If the system is dissipative, then the rate of change of energy density and fluxes cannot exceed the power delivered into the system. This is captured by the inequality (18) in Definition 9. The excess is precisely what is lost (or dissipated). This interaction between supply, storage, and dissipation is formalized by (19).

When the independent variables are time and space, we can write (19) as

$$\frac{\partial u(\ell)}{\partial t} = Q_\Phi\left(M\left(\frac{d}{d\mathbf{x}}\right)\ell\right) - \nabla\cdot\mathbf{S}(\ell) - Q_\Delta(\ell), \tag{20}$$

where, as before, we use $Q_\Psi = (u,\mathbf{S})$, with u the stored energy and $\mathbf{S}$ the flux. Moreover, $w = M(\frac{d}{d\mathbf{x}})\ell$. Thus (20) states that the change in the stored energy $(\frac{\partial u(\ell)}{\partial t})$ in an infinitesimal volume is exactly equal to the difference between the energy supplied $(Q_\Phi(w))$ into the infinitesimal volume and the energy lost by the infinitesimal volume by means of energy flux flowing out of the volume $(\nabla\cdot\mathbf{S}(\ell))$ and the energy dissipated $(Q_\Delta(\ell))$ within the volume.

The problem we address is the equivalence of (i) dissipativeness of $\mathfrak{B}$ with respect to Q_Φ, (ii) the existence of a storage function, and (iii) the existence of a dissipation rate. Note that this problem also involves the construction of an appropriate image representation. We first consider the case where $\mathfrak{B} = \mathfrak{C}^\infty(\mathbb{R}^n,\mathbb{R}^{\mathbb{w}})$. In this case, the definition of the dissipation rate requires that for all $\ell \in \mathfrak{D}(\mathbb{R}^n,\mathbb{R}^\ell)$

$$\int_{\mathbb{R}^n} Q_\Phi(w)d\mathbf{x} = \int_{\mathbb{R}^n} Q_\Delta(\ell)d\mathbf{x} \tag{21}$$

with $w = M(\frac{d}{d\mathbf{x}})\ell$; $M(\frac{d}{d\mathbf{x}})$ a surjective partial differential operator and $Q_\Delta(\ell) \geq 0$ for all $\ell \in \mathfrak{D}(\mathbb{R}^n,\mathbb{R}^\ell)$. This latter condition is seen to be equivalent to the existence of

a polynomial matrix $D \in \mathbb{R}^{\bullet\times\ell}[\xi]$ such that $\Delta(\zeta,\eta) = D^T(\zeta)D(\eta)$. One direction of the previous claim is trivial. For the other direction, we think of the operator $\Delta(\zeta,\eta)$ as acting on the space of ℓ and its derivatives (the jet space). The operator $\Delta(\zeta,\eta)$ then becomes a symmetric matrix with real entries that acts on this jet space. The condition $Q_\Delta \geq 0$ is a pointwise condition, and so one obtains the matrix $D(\xi)$ in the obvious way. Using Theorem 7, it follows that (21) is equivalent to the factorization equation

$$M^T(-\xi)\Phi(-\xi,\xi)M(\xi) = D^T(-\xi)D(\xi).$$

This equation with $\Phi = \Phi^* \in \mathbb{R}^{\mathtt{w}\times\mathtt{w}}[\zeta,\eta]$ given and $M \in \mathbb{R}^{\mathtt{w}\times\bullet}[\xi]$ and $D \in \mathbb{R}^{\bullet\times\bullet}[\xi]$ unknown is discussed in the next section.

9. Factorization of polynomial matrices. In this section, we discuss the following problem. Let $\Gamma \in \mathbb{R}^{\mathtt{w}\times\mathtt{w}}[\xi]$ be a polynomial matrix in n commuting variables, $\xi = (\xi_1, \xi_2, \ldots, \xi_n)$. Can it be factored as

$$\Gamma(\xi) = F^T(-\xi)F(\xi). \tag{22}$$

We are interested in both the case when $F \in \mathbb{R}^{\bullet\times\mathtt{w}}[\xi]$ is itself a polynomial matrix and the case when $F \in \mathbb{R}^{\bullet\times\mathtt{w}}(\xi)$ is a matrix of rational functions.

Note that $\Gamma^\star = \Gamma$ and $\Gamma(i\omega) \geq 0$ for all $\omega \in \mathbb{R}^n$ are obviously necessary conditions for the existence of a factor $F \in \mathbb{R}^{\bullet\times\mathtt{w}}[\xi]$. The problem is whether these conditions are also sufficient. At this point, it is convenient to discuss the cases when $n = 1$ and $n > 1$ separately.

9.1. The case $n = 1$. In the case when $n = 1$, it is well known that (22) admits a solution $F \in \mathbb{R}^{\bullet\times\mathtt{w}}[\xi]$ if and only if $\Gamma^\star = \Gamma$ and $\Gamma(i\omega) \geq 0$ for all $\omega \in \mathbb{R}$. In fact, there even exist square factors $F \in \mathbb{R}^{\mathtt{w}\times\mathtt{w}}[\xi]$ that are, moreover, Hurwitz (i.e., with the roots of $\det(F)$ in the closed left half of the complex plane) and square factors that are anti-Hurwitz (i.e., with the roots of $\det(F)$ in the closed right half of the complex plane). These factors are called *spectral factors*. Several algorithms exist for obtaining such factorizations [6, 8, 15, 21].

9.2. The case $n > 1$. We start with the scalar case, i.e., when $\Gamma \in \mathbb{R}[\xi]$. So we need to find $F \in \mathbb{R}^{\bullet\times 1}[\xi]$ or $F \in \mathbb{R}^{\bullet\times 1}(\xi)$ such that $\Gamma(\xi) = F^T(-\xi)F(\xi)$. Substituting $i\omega$ for ξ, the above problem reduces to finding F such that

$$\Gamma(i\omega) = F^\star(i\omega)F(i\omega). \tag{23}$$

If $F(i\omega)$ is decomposed into real and imaginary parts as $F(i\omega) = A(\omega) + iB(\omega)$, then (23) becomes $\Gamma(i\omega) = A^2(\omega) + B^2(\omega)$. Thus the problem reduces to the case of finding a sum of "two" squares which add up to a given positive (or nonnegative) polynomial. This problem has a very venerable history. It is Hilbert's 17th problem that he posed at the International Congress of Mathematicians in 1900. It deals with the representation of positive definite functions as sums of squares [18]. This investigation of positive definite functions began in the year 1888 with the following "negative" result of Hilbert: If $f(\xi) \in \mathbb{R}[\xi]$ is a positive definite polynomial in n variables, then f need not be a sum of squares of polynomials in $\mathbb{R}[\xi]$, except in the case when $n = 1$. Several examples of such positive definite polynomials which cannot be expressed as sum of squares of polynomials are available in the literature; for example, the polynomial

$$\xi_1^2\xi_2^2(\xi_1^2 + \xi_2^2 - 1) + 1$$

is not factorizable as a sum of squares of polynomials [4].

Thus the factorization we were looking for in nD systems (in the form stated above) is not solvable for polynomial factors, not even in the scalar case. However, several results on Hilbert's 17th problem allow us to solve the factorization problem (22) with F as a rational function. Indeed,

- if $\Gamma(\xi) \in \mathbb{R}(\xi)$ and $\Gamma \geq 0$ (i.e., $\Gamma(\xi) \geq 0$ for all $\xi \in \mathbb{R}^n$), then there exists some natural number r such that $\Gamma(\xi)$ is the sum of r squares of rational functions in $\mathbb{R}(\xi)$ (shown by Artin [1]);
- there is a sharp upper bound on the number r; it is $r = 2^n$, shown by Pfister [17, 18].

This leads to the following result, which plays a central role in the rest of this paper.

THEOREM 10. *Assume that* $\Gamma \in \mathbb{R}^{\mathtt{w}\times\mathtt{w}}[\xi]$ *satisfies* $\Gamma^\star = \Gamma$ *and* $\Gamma(i\omega) \geq 0$ *for all* $\omega \in \mathbb{R}^n$. *Then there exists an* $F \in \mathbb{R}^{\bullet\times\mathtt{w}}(\xi)$ *such that* $\Gamma(\xi) = F^T(-\xi)F(\xi)$.

Note that even when Γ is a polynomial matrix, the entries of the matrix F are rational functions in n-indeterminates with real coefficients, whereas for the 1D case one can obtain an F with polynomial entries. Several results related to this factorization problem for the two-dimensional (2D) case (with some additional conditions like holomorphicity on certain complex half planes or unit polydiscs) exist in the literature [3, 11, 14, 16]. A different factorization problem involving symmetric nD matrices is shown in [5].

10. Main results. We now return to the problem of existence of a storage function and a dissipation rate for a Φ-dissipative system $\mathfrak{B} \in \mathfrak{L}^{\mathtt{w}}_{n,\mathrm{cont}}$. For the sake of clarity, we first consider the case of $\mathfrak{B} = \mathfrak{C}^\infty(\mathbb{R}^n, \mathbb{R}^{\mathtt{w}})$ and subsequently the case of a general $\mathfrak{B} \in \mathfrak{L}^{\mathtt{w}}_{n,\mathrm{cont}}$. We start with a proposition that gives a condition on Φ for $\int Q_\Phi$ to be nonnegative.

PROPOSITION 11. *Let* $\Phi = \Phi^* \in \mathbb{R}^{\mathtt{w}\times\mathtt{w}}[\zeta, \eta]$. *Then* $(\int Q_\Phi \geq 0)$ *if and only if* $(\Phi(-i\omega, i\omega) \geq 0$ for all $\omega \in \mathbb{R}^n)$.

Proposition 11 and the factorizability implied by Theorem 10 readily lead to the following theorem.

THEOREM 12. *Let* $\Phi = \Phi^* \in \mathbb{R}^{\mathtt{w}\times\mathtt{w}}[\zeta, \eta]$. *Then the following conditions are equivalent:*

1. $\int_{\mathbb{R}^n} Q_\Phi(w) d\mathbf{x} \geq 0$ *for all* $w \in \mathfrak{D}(\mathbb{R}^n, \mathbb{R}^{\mathtt{w}})$.
2. *There exists a polynomial matrix* $M \in \mathbb{R}^{\mathtt{w}\times\mathtt{w}}[\xi]$ *such that* $M(\frac{d}{d\mathbf{x}})$ *is surjective and* $\Psi = (\Psi_1, \Psi_2, \ldots, \Psi_n)$ *with* $\Psi_k = \Psi_k^* \in \mathbb{R}^{\mathtt{w}\times\mathtt{w}}[\zeta, \eta]$ *for* $k = 1, 2, \ldots, n$ *such that the VQDF* Q_Ψ *is a storage function, i.e.,*

$$\operatorname{div}\ Q_\Psi(\ell) \leq Q_\Phi(w)$$

   for all $\ell \in \mathfrak{D}(\mathbb{R}^n, \mathbb{R}^{\mathtt{w}})$ *and* $w = M(\frac{d}{d\mathbf{x}})\ell$.
3. *There exists a polynomial matrix* $M \in \mathbb{R}^{\mathtt{w}\times\mathtt{w}}[\xi]$ *such that* $M(\frac{d}{d\mathbf{x}})$ *is surjective and a* $\Delta = \Delta^* \in \mathbb{R}^{\mathtt{w}\times\mathtt{w}}[\zeta, \eta]$ *such that* Q_Δ *is a dissipation rate, i.e.,*

$$Q_\Delta \geq 0 \text{ and } \int_{\mathbb{R}^n} Q_\Delta(\ell) d\mathbf{x} = \int_{\mathbb{R}^n} Q_\Phi(w) d\mathbf{x}$$

   for all $\ell \in \mathfrak{D}(\mathbb{R}^n, \mathbb{R}^{\mathtt{w}})$ *and* $w = M(\frac{d}{d\mathbf{x}})\ell$.
4. *There exists a polynomial matrix* $M \in \mathbb{R}^{\mathtt{w}\times\mathtt{w}}[\xi]$ *such that* $M(\frac{d}{d\mathbf{x}})$ *is surjective, a* $\Psi = (\Psi_1, \Psi_2, \ldots, \Psi_n)$ *with* $\Psi_k = \Psi_k^* \in \mathbb{R}^{\mathtt{w}\times\mathtt{w}}[\zeta, \eta]$ *for* $k = 1, 2, \ldots, n$, *and a*

$\Delta = \Delta^* \in \mathbb{R}^{\mathtt{w}\times\mathtt{w}}[\zeta,\eta]$ *such that*

$$Q_\Delta \geq 0$$
$$\textit{and}$$
$$\operatorname{div} Q_\Psi(\ell) = Q_\Phi(w) - Q_\Delta(\ell) \tag{24}$$

for all $\ell \in \mathfrak{C}^\infty(\mathbb{R}^n, \mathbb{R}^{\mathtt{w}})$ *and* $w = M(\frac{d}{d\mathbf{x}})\ell$. *Note that this states that the VQDF* Q_Ψ *is a storage function and that* Q_Δ *is a dissipation rate.*

It follows from the proof of Theorem 12 that several Δ's may satisfy the same dissipation condition; i.e., several Δ's may be present, all of them satisfying $Q_\Delta \geq 0$ and $\int_{\mathbb{R}^n} Q_\Delta(\ell)d\mathbf{x} = \int_{\mathbb{R}^n} Q_\Phi(w)d\mathbf{x}$ for all $\ell \in \mathfrak{D}(\mathbb{R}^n, \mathbb{R}^{\mathtt{w}})$ and satisfying the equation

$$w = M\left(\frac{d}{d\mathbf{x}}\right)\ell$$

for some $M \in \mathbb{R}^{\mathtt{w}\times\mathtt{w}}[\xi]$. The first part of this nonuniqueness comes from the factorization of the matrix $\Phi(-\xi,\xi)$. Choosing a particular factorization of the matrix $\Phi(-\xi,\xi)$ still leaves us with a choice for Δ depending on the M we choose. Also note that unlike the 1D case, there is no one-to-one correspondence between storage and dissipation functions. Given a supply QDF and an associated dissipation QDF, one can find several VQDFs that satisfy (24). One should also note the unavoidable emergence of latent variables in the dissipation equation (24) for the nD case. In the 1D case, the dissipation equation can be written in terms of manifest variables alone, whereas in the nD case, this is only possible if the latent variables that appear in the dissipation equation are observable.

The case of an arbitrary $\mathfrak{B} \in \mathfrak{L}^{\mathtt{w}}_{n,\mathrm{cont}}$ is easily reduced to the free case by considering an image representation for $\mathfrak{B}$. This leads to the following theorem, which is the main result of the paper.

THEOREM 13. *Let* $\mathfrak{B} \in \mathfrak{L}^{\mathtt{w}}_{n,\mathrm{cont}}$ *and* $\Phi = \Phi^* \in \mathbb{R}^{\mathtt{w}\times\mathtt{w}}[\zeta,\eta]$. *The following conditions are equivalent:*

1. $\mathfrak{B}$ *is* Φ*-dissipative; i.e.,* $\int_{\mathbb{R}^n} Q_\Phi(w)d\mathbf{x} \geq 0$ *for all* $w \in \mathfrak{B} \cap \mathfrak{D}(\mathbb{R}^n, \mathbb{R}^{\mathtt{w}})$.
2. *There exists an integer* $\mathtt{l} \in \mathbb{N}$, *a polynomial matrix* $M \in \mathbb{R}^{\mathtt{w}\times\mathtt{l}}[\xi]$ *such that* $M(\frac{d}{d\mathbf{x}})$ *is an image representation of* $\mathfrak{B}$, *a* $\Psi = (\Psi_1, \Psi_2, \ldots, \Psi_n)$ *with* $\Psi_k = \Psi_k^* \in \mathbb{R}^{\mathtt{l}\times\mathtt{l}}[\zeta,\eta]$ *for* $k = 1, 2, \ldots, n$, *and a* $\Delta = \Delta^* \in \mathbb{R}^{\mathtt{l}\times\mathtt{l}}[\zeta,\eta]$ *such that*

$$Q_\Delta \geq 0$$
$$\textit{and}$$
$$\operatorname{div} Q_\Psi(\ell) = Q_\Phi(w) - Q_\Delta(\ell)$$

with $w = M(\frac{d}{d\mathbf{x}})\ell$.

11. Conclusions. In this paper, we dealt with distributed systems described by constant coefficient linear partial differential equations. We started by defining controllability for such systems in terms of patching up of feasible trajectories. We then explained that it is exactly the controllable systems which allow an image representation, i.e., a representation in terms of what in physics is called a potential function. Subsequently, we turned to lossless and dissipative systems.

For lossless systems, we proved the equivalence with the existence of a conservation law involving the storage function. Important features of the storage function are (i) the fact that it depends on latent variables that are in general hidden (i.e.,

nonobservable) and (ii) its nonuniqueness. We have illustrated these features by demonstrating that they are already present in Maxwell's equations.

For dissipative systems, we proved the equivalence with the existence of a storage function and a dissipation rate. The problem of constructing a dissipation rate led to the question of factorizability of certain polynomial matrices in n variables. We reduced this problem to Hilbert's 17th problem, the representation of a nonnegative rational function in n variables as a sum of squares of rational functions.

12. Appendix. We collect the proofs in this appendix.

Proof of Theorem 2. Please refer to [19, Theorem 3]. ∎

Proof of Theorem 4. First we show the equivalence of the first three statements. Then we will show the equivalence of the last two statements. Finally, we link up these two sets of conditions.

(1) ⇔ (3) If two trajectories w_1 and w_2 agree along with all their derivatives on the boundary $\partial\Omega$ of some arbitrary closed bounded subset $\Omega \subset \mathbb{R}^n$ (with nonempty interior), then $w = w_1 - w_2$ can be thought of as a trajectory with its support strictly in the interior of Ω. Thus $w \in \mathfrak{D}(\mathbb{R}^n, \mathbb{R}^{\mathbb{w}})$. Since

$$Q_\Phi(w_1) = Q_\Phi(w_2) + Q_\Phi(w) + 2L_\Phi(w_2, w),$$

we conclude that $\int_\Omega Q_\Phi$ is independent of path for all Ω if and only if

$$\int_\Omega Q_\Phi(w)d\mathbf{x} + 2\int_\Omega L_\Phi(w, v)d\mathbf{x} = 0 \tag{25}$$

for any $w \in \mathfrak{D}(\mathbb{R}^n, \mathbb{R}^{\mathbb{w}})$ with support in Ω, any $v \in \mathfrak{C}^\infty(\mathbb{R}^n, \mathbb{R}^{\mathbb{w}})$, and any closed bounded subset Ω in $\mathbb{R}^n$ with nonempty interior.

In particular, if we choose v in (25) to be zero, we obtain $\int_\Omega Q_\Phi(w)d\mathbf{x} = 0$, which in turn implies $\int Q_\Phi = 0$. Thus (25) yields $\int_\Omega L_\Phi(w, v)d\mathbf{x} = 0$. But

$$L_\Phi(w, v)(\mathbf{x}) = \sum_{\mathbf{k},\mathbf{l}} \left(\frac{d^{\mathbf{k}} w}{d\mathbf{x}^{\mathbf{k}}}(\mathbf{x})\right)^T \Phi_{\mathbf{k},\mathbf{l}} \left(\frac{d^{\mathbf{l}} v}{d\mathbf{x}^{\mathbf{l}}}(\mathbf{x})\right).$$

Now on integrating each of these terms by parts, we obtain

$$\int_\Omega L_\Phi(w, v)d\mathbf{x} = \int_\Omega w \cdot \left[\sum_{\mathbf{k},\mathbf{l}} \Phi_{\mathbf{k},\mathbf{l}} \left((-1)^{\mathbf{k}} \frac{(d)^{\mathbf{k}}}{d\mathbf{x}^{\mathbf{k}}} \left(\frac{d^{\mathbf{l}} v}{d\mathbf{x}^{\mathbf{l}}}\right)\right)\right] = 0$$

for every $w \in \mathfrak{D}(\mathbb{R}^n, \mathbb{R}^{\mathbb{w}})$ with support in the interior of $\Omega \subset \mathbb{R}^n$ and for every such Ω. This can hold if and only if $\sum_{\mathbf{k},\mathbf{l}} \Phi_{\mathbf{k},\mathbf{l}}((-1)^{\mathbf{k}} \frac{(d)^{\mathbf{k}}}{d\mathbf{x}^{\mathbf{k}}}(\frac{d^{\mathbf{l}} v}{d\mathbf{x}^{\mathbf{l}}})) = 0$ or, equivalently, $\Phi(-\xi, \xi) = 0$. A simple reversal of arguments shows that (3) ⇒ (1).

(2) ⇔ (3) If $\Phi(-\xi, \xi) = 0$, then using integration by parts it is clear that $\int Q_\Phi = 0$. Conversely, if $\int Q_\Phi = 0$, then, using integration by parts, we obtain the condition $\sum_{\mathbf{k},\mathbf{l}} \Phi_{\mathbf{k},\mathbf{l}}((-1)^{\mathbf{k}} \frac{(d)^{\mathbf{k}}}{d\mathbf{x}^{\mathbf{k}}}(\frac{d^{\mathbf{l}} w}{d\mathbf{x}^{\mathbf{l}}})) = 0$ for every $w \in \mathfrak{D}(\mathbb{R}^n, \mathbb{R}^{\mathbb{w}})$. This is only possible if $\Phi(-\xi, \xi) = 0$.

(4) ⇔ (5) As mentioned earlier,

$$(\text{div } Q_\Psi)(w) = \frac{\partial}{\partial x_1} Q_{\Psi_1}(w) + \cdots + \frac{\partial}{\partial x_n} Q_{\Psi_n}(w).$$

It is easy to see that $\frac{\partial}{\partial x_1} Q_{\Psi_1}(w) = L_{\Psi_1}(\frac{\partial w}{\partial x_1}, w) + L_{\Psi_1}(w, \frac{\partial w}{\partial x_1}) = Q_{\Psi_1'}(w)$, where $\Psi_1' = (\zeta_1 + \eta_1)\Psi_1$. Now the equivalence of (4) and (5) is obvious.

(4) $\Rightarrow$ (3) This is obvious from substitution.

(3) $\Rightarrow$ (4) Given a $\Phi \in \mathbb{R}^{\mathtt{w}\times\mathtt{w}}[\zeta, \eta]$, which contains polynomials in $2n$ variables, we can rewrite this matrix as a polynomial matrix in the $2n$ new variables given by $\gamma_i = \zeta_i + \eta_i$ and $\gamma_{i+n} = \zeta_i - \eta_i$ for $i = 1, \ldots, n$. Now setting $-\zeta = \eta = \xi$ translates to setting $\gamma_i = 0$ for $i = 1, \ldots, n$. Thus if $\Phi(-\xi, \xi) = 0$, then each term in the matrix can be written as polynomials in γ_i, $i = 1, \ldots, n$, without the free term. By the very definition of these γ_i's and the symmetry of the matrices, we have the result. ∎

Proof of Proposition 5. ($\Leftarrow$): Let

$$\Psi_i = (\zeta_1 + \eta_1)\Delta_{i1} + \cdots + (\zeta_n + \eta_n)\Delta_{in}$$

with $\Delta_{ij} = -\Delta_{ji}$ as given in the statement of the proposition. Let Φ be such that $Q_\Phi = \operatorname{div} Q_\Psi$. Then

$$\begin{aligned}
\Phi &= (\zeta_1 + \eta_1)\Psi_1 + \cdots + (\zeta_n + \eta_n)\Psi_n \\
&= \sum_{i=1}^{n} (\zeta_i + \eta_i)\Psi_i \\
&= \sum_{i=1}^{n} (\zeta_i + \eta_i) \sum_{j=1}^{n} (\zeta_j + \eta_j)\Delta_{ij} \\
&= \sum_{i=1}^{n} \sum_{j=1}^{n} (\zeta_i\zeta_j + \zeta_i\eta_j + \eta_i\zeta_j + \eta_i\eta_j)\Delta_{ij} \\
&= 0 \quad \text{since } \Delta_{ij} = -\Delta_{ji}.
\end{aligned}$$

($\Rightarrow$): Let $\Psi \in (\mathbb{R}^{\mathtt{w}\times\mathtt{w}}[\zeta, \eta])^n$ define a VQDF with null divergence, that is, div $Q_\Psi = 0$. Clearly, it is enough to just consider any (k, l)th entry of the corresponding QDFs since the same arguments would apply to all other entries. For simplicity, let us denote by p_i the (k, l)th entry of the QDF Ψ_i.

As in the proof of Theorem 4, we will again employ a change of variables. Let $\gamma_i = \zeta_i + \eta_i$ and $\gamma_{i+n} = \zeta_i - \eta_i$ for $i = 1, \ldots, n$. Since Ψ defines a null divergence,

$$\sum_{i=1}^{n} \gamma_i p_i = 0. \tag{26}$$

Setting all γ_i's except γ_j to zero in (26), we conclude that p_j can be written as

$$p_j = \sum_{i=1, i\neq j}^{n} f_{ji}\gamma_i$$

for some arbitrary polynomials f_{ji} in the $2n$ variables γ_i. Now reverting back to ζ_i's and η_i's, this precisely means that $\Psi_j = (\zeta_1 + \eta_1)\Delta_{j1} + \cdots + (\zeta_n + \eta_n)\Delta_{jn}$ with the entries of Δ_{ji}'s being the corresponding f_{ji}'s. Note that f_{ii}'s are all zero; that is, $\Delta_{ii} = 0$ for $i = 1, \ldots, n$.

We can rearrange the terms of Δ_{ij}'s to obtain $\Delta_{ij} = -\Delta_{ji}$. This is in some sense similar to the stepping stone algorithm in operations research. We give an outline of the proof here. For a proof of this, we return to the variables γ_i's. Again, it is enough to consider any (k, l)th entry. As before, let p_i be the (k, l)th entry

of Ψ_i. Let $p_i = \sum_{\mathbf{k}} f_{i,\mathbf{k}} \gamma^{\mathbf{k}}$, where γ is a monomial in terms of γ_i's, $i = 1, \ldots, n$. Thus $\gamma^{\mathbf{k}} = \gamma_1^{k_1} \cdots \gamma_n^{k_n}$, where the multi-index $\mathbf{k} = (k_1, \cdots, k_n)$. Note that $f_{i,\mathbf{k}}$ are polynomials in γ_{i+n}'s, $i = 1, \ldots, n$. Let $\mathbf{k_j} = (k_1, \ldots, k_{j-1}, k_j - 1, k_{j+1}, \ldots, k_n)$, and similarly $\mathbf{k_{ij}}$ is a multi-index defined in the obvious way. Fix a multi-index $\mathbf{k}$ and hence a monomial $\gamma^{\mathbf{k}}$. We shall demonstrate how to rearrange the terms for this particular monomial, and similar operations should be carried out for each such monomial. From the condition $\sum_{i=1}^n \gamma_i p_i = 0$, we can conclude that $\sum_{i=1}^n f_{i,\mathbf{k_i}} = 0$ (since they are the coordinates of the monomial $\gamma^{\mathbf{k}}$). Note that some of these $f_{i,\mathbf{k_i}}$'s may be zero. Set the coordinate of $\gamma^{\mathbf{k_{12}}}$ in the corresponding term ((k,l)th term) in Δ_{12} to be $f_{1,\mathbf{k_1}}$. We force the coordinate of $\gamma^{\mathbf{k_{12}}}$ in the (k,l)th term of Δ_{21} to be $-f_{1,\mathbf{k_1}}$ and the coordinate of $\gamma^{\mathbf{k_{23}}}$ in the (k,l)th term of Δ_{23} to be $f_{2,\mathbf{k_2}} + f_{1,\mathbf{k_1}}$ and so on. We perform the above operation for every multi-index $\mathbf{k}$ that might be involved. (These are finite in number.) Then $p_j = \sum_{i=1}^n \gamma_i g_{ji}$, where g_{ji} are the polynomials obtained by the above procedure and are the (k,l)th terms of the corresponding Δ_{ji}'s. We can easily check the entries of $\Delta_{ij} = -\Delta_{ji}$. Thus we have demonstrated how to construct the required Δ_{ij}'s that satisfy the conditions of the proposition. □

Proof of Theorem 7. (2) ⇒ (1) Following the lines of the proof of Theorem 4, we can conclude that $\int_\Omega Q_\Phi(w) d\mathbf{x}$ is independent of path on $\mathfrak{B}$ if and only if

$$\int_\Omega Q_\Phi(w) d\mathbf{x} + 2 \int_\Omega L_\Phi(w, v) d\mathbf{x} = 0 \tag{27}$$

for any $w \in \mathfrak{D}(\mathbb{R}^n, \mathbb{R}^{\mathbb{w}}) \cap \mathfrak{B}$ with support in Ω, any $v \in \mathfrak{C}^\infty(\mathbb{R}^n, \mathbb{R}^{\mathbb{w}}) \cap \mathfrak{B}$, and any closed bounded set $\Omega \subset \mathbb{R}^n$. Again, since $v = 0$ is a trajectory in $\mathfrak{B}$, we can conclude that $\int_\Omega Q_\Phi(w) d\mathbf{x} = 0$ for any $w \in \mathfrak{D}(\mathbb{R}^n, \mathbb{R}^{\mathbb{w}}) \cap \mathfrak{B}$ with support in Ω. Thus $\mathfrak{B}$ is lossless with respect to the QDF Q_Φ.

(1) ⇒ (4) Since $\int_\Omega Q_\Phi(w) d\mathbf{x} = 0$ for any $w \in \mathfrak{B} \cap \mathfrak{D}(\mathbb{R}^n, \mathbb{R}^{\mathbb{w}})$ with support in Ω, from (27) we can conclude that $\int_\Omega L_\Phi(w, v) d\mathbf{x} = 0$ for all $w \in \mathfrak{D}(\mathbb{R}^n, \mathbb{R}^{\mathbb{w}}) \cap \mathfrak{B}$ with support in Ω and all $v \in \mathfrak{C}^\infty(\mathbb{R}^n, \mathbb{R}^{\mathbb{w}}) \cap \mathfrak{B}$. Using integration by parts, it is easy to see that the integral $\int_\Omega (w^T f) d\mathbf{x}$ equals zero for all $w \in \mathfrak{D}(\mathbb{R}^n, \mathbb{R}^{\mathbb{w}}) \cap \mathfrak{B}$ with support in Ω if f is in the image of the operator $R^T(-\frac{d}{d\mathbf{x}})$. In $L_\Phi(w, v)$, every v we consider is of the form $v = M(\frac{d}{d\mathbf{x}})\ell$, and so we conclude that $\Phi(-\xi, \xi) M(\xi) = R^T(-\xi) Y(\xi)$ for some Y. Now premultiplying by $M^T(-\xi)$, we obtain $\Phi'(-\xi, \xi) = M^T(-\xi)\Phi(-\xi, \xi) M(\xi) = M^T(-\xi) R^T(-\xi) Y(\xi) = 0$ since $R(\xi) M(\xi) = 0$.

(4) ⇒ (2) From [22], we know that, given a controllable behavior $\mathfrak{B}$, there exists some operator $M_1(\xi)$ such that $\mathfrak{B} = \{w : w = M_1(\frac{d}{d\mathbf{x}})\ell\}$ with the additional property that every $w \in \mathfrak{B} \cap \mathfrak{D}(\mathbb{R}^n, \mathbb{R}^{\mathbb{w}})$ can be obtained as the image of some ℓ which is itself compactly supported. It can be shown that if $\Phi'(-\xi, \xi) = M^T(-\xi)\Phi(-\xi, \xi) M(\xi) = 0$ for some image representation of $M(\xi)$, then $M'^T(-\xi)\Phi(-\xi, \xi) M'(\xi) = 0$ for every image representation $M'(\frac{d}{d\mathbf{x}})$ of the controllable behavior $\mathfrak{B}$. In particular, $\Phi_1(\zeta, \eta) = M_1^T(\zeta)\Phi(\zeta, \eta) M_1(\eta)$ has the property that $\Phi_1(-\xi, \xi) = 0$. Using integration by parts, we can now show that $\int_\Omega L_\Phi(w, v) d\mathbf{x} = \int_\Omega L_{\Phi_1}(\ell_1, \ell_2) d\mathbf{x} = 0$ for any $w \in \mathfrak{D}(\mathbb{R}^n, \mathbb{R}^{\mathbb{w}}) \cap \mathfrak{B}$ with support in Ω, $w = M_1(\frac{d}{d\mathbf{x}})\ell_1$ with ℓ_1 having compact support, and $v = M_1(\frac{d}{d\mathbf{x}})\ell_2$. A similar argument also proves that $\int_\Omega Q_\Phi(w) d\mathbf{x} = 0$ for all $w \in \mathfrak{D}(\mathbb{R}^n, \mathbb{R}^{\mathbb{w}}) \cap \mathfrak{B}$ with support in Ω. From (27), we then conclude that the QDF induced by Φ is independent of path on $\mathfrak{B}$.

(3) ⇔ (4) This is already shown in Theorem 4.

(4) ⇔ (5) From Theorem 4, it is clear that there exists $\Psi \in (\mathbb{R}^{m \times m}[\zeta, \eta])^n$ such that $\mathrm{div} Q_\Psi(\ell) = Q_{\Phi'}(\ell)$ for all $\ell \in \mathfrak{C}^\infty(\mathbb{R}^n, \mathbb{R}^m)$. Moreover, since $M(\frac{d}{d\mathbf{x}})$ gives an

image representation of the behavior $\mathfrak{B}$, $Q_\Phi(w) = Q_{\Phi'}(\ell)$ for all w and ℓ related by $w = M(\frac{d}{dx})\ell$. □

Proof of Theorem 10. We will start by considering the scalar case. Let $\Gamma \in \mathbb{R}[\xi]$ with $\Gamma^\star = \Gamma$ and $\Gamma(i\omega) \geq 0$ for all $\omega \in \mathbb{R}^n$. From the above data, we can conclude that the polynomial p defined as $p(\omega) := \Gamma(i\omega)$ is a positive definite (or nonnegative) function. Using the result from Hilbert's 17th problem [1], we can write

$$p(\omega) = \sum_{i=1}^{r} \left(f_i(\omega)\right)^2,$$

where each $f_i \in \mathbb{R}(\omega)$; i.e., f_i's are rational functions in ω. Now consider each of these f_i's. We can write them as

$$f_i(\omega) = f_{i+}(\omega) + f_{i-}(\omega),$$

where

$$f_{i+}(\omega) = \frac{f_i(\omega) + f_i(-\omega)}{2},$$
$$f_{i-}(\omega) = \frac{f_i(\omega) - f_i(-\omega)}{2}.$$

Thus we separate the even and odd parts of the functions f_i. Now

$$\begin{aligned} p(\omega) &= \sum_{i=1}^{r} \left(f_{i+}(\omega) + f_{i-}(\omega)\right)^2 \\ &= \sum_{i=1}^{r} \left[\left(f_{i+}(\omega)\right)^2 + \left(f_{i-}(\omega)\right)^2 + 2f_{i+}(\omega)f_{i-}(\omega)\right], \end{aligned}$$

and

$$\begin{aligned} p(-\omega) &= \sum_{i=1}^{r} \left(f_{i+}(-\omega) + f_{i-}(-\omega)\right)^2 \\ &= \sum_{i=1}^{r} \left[\left(f_{i+}(\omega)\right)^2 + \left(f_{i-}(\omega)\right)^2 - 2f_{i+}(\omega)f_{i-}(\omega)\right]. \end{aligned}$$

Since $p(\omega) = p(-\omega)$ (from the initial assumption on Γ), we can conclude $\sum_{i=1}^{r} f_{i+}(\omega)f_{i-}(\omega) = 0$, and so

$$\begin{aligned} p(\omega) &= \sum_{i=1}^{r} \left[\left(f_{i+}(\omega)\right)^2 + \left(f_{i-}(\omega)\right)^2\right] \\ &= \sum_{i=1}^{r} \left[f_{i+}(\omega) + if_{i-}(\omega)\right]\left[f_{i+}(\omega) - if_{i-}(\omega)\right] \\ &= \sum_{i=1}^{r} \left[f_{i+}(\omega) + if_{i-}(\omega)\right]\left[f_{i+}(-\omega) + if_{i-}(-\omega)\right]. \end{aligned}$$

Thus note that p has now been written down as the sum of r terms, each of which is a product of a function evaluated at ω and $-\omega$. Construct an $r \times 1$ matrix E

whose $(i,1)$th entry is $(f_{i+} + if_{i-})$. Then $\Gamma(i\omega) = p(\omega) = E^T(-\omega)E(\omega)$, which in turn implies that $\Gamma(\xi) = F^T(-\xi)F(\xi)$, where F is obtained from E by the obvious substitution; i.e., the $(i,1)$th entry of F is $(f_{i+} + f_{i-})$.

We now tackle the case where $\Gamma \in \mathbb{R}^{\mathtt{w}\times\mathtt{w}}[\xi]$ with the properties $\Gamma^T(-\xi) = \Gamma(\xi)$ and $\Gamma(i\omega) \geq 0$ for all $\omega \in \mathbb{R}^n$. Let $\Gamma(\xi) = [a_{ij}(\xi)]$; i.e., let the polynomial in the (i,j)th coordinate of Γ be denoted by a_{ij}. Clearly, all diagonal elements a_{ii} are even polynomials in ξ since $\Gamma^T(-\xi) = \Gamma(\xi)$. Let $I = \{i : a_{ii}(\xi) = 0\}$. Consider the submatrix obtained from Γ by choosing elements a_{ij}, where both $i, j \in I$. Let us call this matrix $H(\xi) = [a_{ij}(\xi)]_{i,j\in I}$. Observe that $\Gamma(i\omega)$ (and hence $H(i\omega)$) are Hermetian matrices for any $\omega \in \mathbb{R}^n$. Since the trace of $H(i\omega)$ is zero, we can conclude that $H(i\omega)$ has a negative real eigenvalue (provided $H(i\omega)$ has nonzero entries). In this case, $H(i\omega) \not\geq 0$, and hence $\Gamma(i\omega) \not\geq 0$. However, this contradicts the assumption that $\Gamma(i\omega) \geq 0$. Hence we conclude that $H(\xi) = 0$.

We now construct a 2×2 submatrix of $\Gamma(\xi)$, denoted by $H_1(\xi)$, by considering the four elements $a_{ij}(\xi) \in \Gamma(\xi)$, where $i \in I$ and $j \notin I$ are fixed. Clearly, the determinant of $H_1(\xi)$ is given by $-a_{ij}(\xi)a_{ji}(\xi) = -a_{ij}(\xi)a_{ij}(-\xi)$, and this is an even polynomial in ξ. Substituting $i\omega$ for ξ, we obtain $H_1(i\omega)$—a 2×2 Hermetian matrix with a negative determinant. This implies a negative real eigenvalue, and hence $H_1(i\omega) \not\geq 0$. But since $\Gamma(i\omega) \geq 0$, we conclude that $a_{ij}(\xi) = a_{ji}(\xi) = 0$. From the above discussion, we conclude that the rows and columns corresponding to $i \in I$ have only zero entries.

We now define and prove an algorithmic step. In this step, we take as an input a $\mathtt{w}\times\mathtt{w}$ matrix Γ that has the following properties: (i) $\Gamma^\star = \Gamma$ and (ii) $\Gamma(i\omega) \geq 0$ for all $\omega \in \mathbb{R}^n$. The outputs of this algorithmic step are two matrices, which we call E and Q. E has the same number of columns as Γ. The matrix Q has the same properties as Γ but is a $(\mathtt{w}-1)\times(\mathtt{w}-1)$ matrix. Let

$$\Gamma = \begin{bmatrix} a_{11} & \gamma \\ \gamma^\star & \Gamma_{\mathtt{w}-1} \end{bmatrix}.$$

If $a_{11} \neq 0$, then construct $F_1(\xi)$ such that $a_{11}(\xi) = F_1^T(-\xi)F_1(\xi)$. Define the matrix $E = \begin{bmatrix} F_1 & F_1 a_{11}^{-1}\gamma \end{bmatrix}$. Clearly,

$$\begin{bmatrix} F_1^\star \\ \gamma^\star(a_{11}^{-1})^\star F_1^\star \end{bmatrix} \begin{bmatrix} F_1 & F_1 a_{11}^{-1}\gamma \end{bmatrix} = \begin{bmatrix} a_{11} & \gamma \\ \gamma^\star & \gamma^\star(a_{11}^{-1})^\star\gamma \end{bmatrix}.$$

Note that $(a_{11}^{-1})^\star = a_{11}^{-1}$. On the other hand, if $a_{11} = 0$, from the discussion above we know $\gamma = 0$. In this case, define the matrix $E = \begin{bmatrix} 0_{1\times 1} & 0_{1\times\{\mathtt{w}-1\}} \end{bmatrix}$. Define the $(\mathtt{w}-1)\times(\mathtt{w}-1)$ matrix

$$Q = \begin{cases} \Gamma_{\mathtt{w}-1} - \gamma^\star a_{11}^{-1}\gamma & \text{when} \quad a_{11}, \neq 0 \\ \Gamma_{\mathtt{w}-1} & \text{when} \quad a_{11} = 0. \end{cases}$$

(When $a_{11} \neq 0$, then the above matrix Q is known in the literature as the Schur complement of a_{11} in Γ; see [7, 9].) Clearly, the matrix Q is such that $Q^T(-\xi) = Q(\xi)$. Moreover, we claim that $Q(i\omega) \geq 0$ for all $\omega \in \mathbb{R}^n$. This is clear for the case when $a_{11} = 0$. For the case when $a_{11} \neq 0$, we have $Q = \Gamma_{\mathtt{w}-1} - \gamma^\star a_{11}^{-1}\gamma$. Suppose $Q(i\omega) \not\geq 0$ for some $\omega \in \mathbb{R}^n$. This implies that there exists a vector a such that $a^T Q(i\omega)a < 0$. Consider the vector

$$v = \begin{bmatrix} -(a_{11}^{-1}(i\omega)\gamma(i\omega)a \\ a \end{bmatrix}.$$

Then $v^T\Gamma(i\omega)v = a^TQ(i\omega)a < 0$, and this contradicts $\Gamma(i\omega) \geq 0$ for all $\omega \in \mathbb{R}^n$. Hence we have a $(\mathtt{w}-1)\times(\mathtt{w}-1)$ matrix Q such that $Q^T(-\xi) = Q(\xi)$ and $Q(i\omega) \geq 0$ for all $\omega \in \mathbb{R}^n$.

We now give the algorithm to construct F such that $\Gamma = F^T(-\xi)F(\xi)$.

1. Set $Q_0 = \Gamma$. Set $i = 0$.
2. Invoke the algorithmic step defined above with input Q_i to obtain outputs E and Q. Set $E_{i+1} = E$ and $Q_{i+1} = Q$.
3. If $Q_{i+1} \neq 0$, increment i and go back to step 2.
4. Construct

$$F = \begin{bmatrix} E_1 & \\ 0_{\bullet\times 1} & E_2 \\ 0_{\bullet\times 2} & E_3 \\ \vdots & \vdots \\ 0_{\bullet\times i} & E_i \end{bmatrix}.$$

It is now easy to check that $\Gamma = F^T(-\xi)F(\xi)$. □

Proof of Proposition 11. ($\Leftarrow$) Since $w \in \mathfrak{D}(\mathbb{R}^n, \mathbb{R}^{\mathtt{w}})$, we can take the multidimensional Fourier transform. Let $\hat{w}$ denote the multidimensional Fourier transform of w. Then, using Parseval's theorem, we have

$$\int_{\mathbb{R}^n} Q_\Phi(w)d\mathbf{x} = \frac{1}{(2\pi)^n}\int_{\mathbb{R}^n} \hat{w}(-i\omega)\Phi(-i\omega, i\omega)\hat{w}(i\omega)d\omega, \tag{28}$$

where $\omega \in \mathbb{R}^n$. Then ($\Leftarrow$) is clear.

($\Rightarrow$) Consider a compactly supported function $u(\mathbf{x})$, where the variables can be separated, i.e., $u(\mathbf{x}) = v_1(x_1)v_2(x_2)\cdots v_n(x_n)$. Let $\int_{\mathbb{R}^n} Q_\Phi(u)d\mathbf{x} = E$. Suppose $\Phi(-i\omega, i\omega) \not\geq 0$ for all $\omega \in \mathbb{R}^n$. Let $a \in \mathbb{C}^q$ and $\omega_0 = (\omega_1, \ldots, \omega_n) \in \mathbb{R}^n$ be such that $a^T\Phi(-i\omega_0, i\omega_0)a < 0$. Without loss of generality, we will assume that $\omega_1 \neq 0$. Then we can choose functions $u_N(\mathbf{x})$ given by $u_N(\mathbf{x}) = v_{1,N}(x_1)v_{2,N}(x_2)\cdots v_{n,N}(x_n)$, where

$$v_{1,N}(x_1) = \begin{cases} e^{i<\omega_1, x_1>}a, & |\, x_1 \,| \leq \frac{2\pi N}{\omega_1}, \\ v_1(x_1 + \frac{2\pi N}{\omega_1}), & x_1 < -\frac{2\pi N}{\omega_1}, \\ v_1(x_1 - \frac{2\pi N}{\omega_1}), & x_1 > \frac{2\pi N}{\omega_1}, \end{cases} \tag{29}$$

and for $i = 2, \ldots, n$ and $\omega_i \neq 0$,

$$v_{i,N}(x_i) = \begin{cases} e^{i<\omega_i, x_i>}[1, 1, \ldots, 1]^T, & |\, x_i \,| \leq \frac{2\pi N}{\omega_i}, \\ v_i(x_i + \frac{2\pi N}{\omega_i}), & x_i < -\frac{2\pi N}{\omega_i}, \\ v_i(x_i - \frac{2\pi N}{\omega_i}), & x_i > \frac{2\pi N}{\omega_i}, \end{cases} \tag{30}$$

and for $i = 2, \ldots, n$ with $\omega_i = 0$, we have

$$v_{i,N}(x_i) = v_i(x_i). \tag{31}$$

Then, on evaluating $\int_{\mathbb{R}^n} Q_\Phi(u_N)d\mathbf{x}$, one gets a negative term that depends on N and another term that is independent of N. Then, by choosing N large enough, this integral can be made negative and hence we obtain a contradiction to $\int Q_\Phi \geq 0$. □

Proof of Theorem 12. Note that (4) is a statement that combines (2) and (3). So we first we show the equivalence of the first three statements. Then we show how statement (4) is equivalent.

(1) $\Rightarrow$ (3) Let $\Phi = \Phi^* \in \mathbb{R}^{\mathtt{w}\times\mathtt{w}}[\zeta,\eta]$. By Proposition 11, we know that $\int Q_\Phi \geq 0$ implies that $\Phi(-i\omega, i\omega) \geq 0$ for all $\omega \in \mathbb{R}^n$. Thus $\Phi(-\xi,\xi)$ satisfies all the conditions on Γ in Theorem 10, and hence $\Phi(-\xi,\xi) = F^T(-\xi)F(\xi)$ for some $F \in \mathbb{R}^{\bullet\times\mathtt{w}}(\xi)$.

Let us now consider the matrix $F \in \mathbb{R}^{r\times\mathtt{w}}(\xi)$. (Here we assume that the number of rows of F is some arbitrary (finite) number r.) It is easy to show that $F = DM^{-1}$, where $D \in \mathbb{R}^{r\times\mathtt{w}}[\xi]$ and $M \in \mathbb{R}^{\mathtt{w}\times\mathtt{w}}[\xi]$. Note that both D and M are now matrices with polynomial entries. Moreover, we can choose M such that it is a diagonal matrix (and hence the operator $M(\frac{d}{d\mathbf{x}})$ is surjective). We can now define latent variables ℓ related to the manifest variables w by the equation $w = M(\frac{d}{d\mathbf{x}})\ell$. Now consider $\Delta \in \mathbb{R}^{\mathtt{w}\times\mathtt{w}}[\zeta,\eta]$ given by the matrix $\Delta(\zeta,\eta) = D^T(\zeta)D(\eta)$. Obviously, $Q_\Delta \geq 0$. Now for all $\ell \in \mathfrak{D}(\mathbb{R}^n,\mathbb{R}^{\mathtt{w}})$ we have $M(\frac{d}{d\mathbf{x}})\ell = w \in \mathfrak{D}(\mathbb{R}^n,\mathbb{R}^{\mathtt{w}})$. Hence it follows that

$$\begin{aligned}\int_{\mathbb{R}^n} Q_\Phi(w)d\mathbf{x} &= \int_{\mathbb{R}^n} (w)^T \left(\Phi\left(-\frac{d}{d\mathbf{x}},\frac{d}{d\mathbf{x}}\right)w\right)d\mathbf{x}\\ &= \int_{\mathbb{R}^n} \left(M\left(\frac{d}{d\mathbf{x}}\right)\ell\right)^T \left(\Phi\left(-\frac{d}{d\mathbf{x}},\frac{d}{d\mathbf{x}}\right)M\left(\frac{d}{d\mathbf{x}}\right)\ell\right)d\mathbf{x}\\ &= \int_{\mathbb{R}^n} Q_\Delta(\ell)d\mathbf{x}.\end{aligned}$$

Thus the matrix $\Delta(\zeta,\eta) = D^T(\zeta)D(\eta)$ induces a QDF, which defines a dissipation function for the given Φ.

(3) $\Rightarrow$ (2) Let $\Delta \in \mathbb{R}^{\mathtt{w}\times\mathtt{w}}[\zeta,\eta]$ induce a QDF on the latent variables ℓ such that Q_Δ is a dissipation function associated to the given Φ. Moreover, let $M \in \mathbb{R}^{\mathtt{w}\times\mathtt{w}}[\xi]$ induce a surjective operator, such that $w = M(\frac{d}{d\mathbf{x}})\ell$. Consider the system defined by $w - M(\frac{d}{d\mathbf{x}})\ell = 0$ in the variables (w,ℓ) with a QDF induced by

$$\begin{bmatrix}\Phi & 0\\ 0 & -\Delta\end{bmatrix} \in \mathbb{R}^{(2\mathtt{w})\times(2\mathtt{w})}[\zeta,\eta].$$

Note that the system given by $w - M(\frac{d}{d\mathbf{x}})\ell = 0$ is a controllable system. In fact, this system has an observable image representation given by

$$\begin{bmatrix} w\\ \ell\end{bmatrix} = \begin{bmatrix} M(\frac{d}{d\mathbf{x}})\\ I\end{bmatrix}\ell$$

(for details see [19]). The QDF defined above gives

$$\int_{\mathbb{R}^n} [Q_\Phi(w) - Q_\Delta(\ell)]\, d\mathbf{x} = 0$$

on every compactly supported trajectory in the full behavior involving both w and ℓ, and so, applying Theorem 7, we obtain a QDF $\Phi'(\zeta,\eta) = M^T(\zeta)\Phi(\zeta,\eta)M(\eta) - \Delta(\zeta,\eta)$ which acts on the variables ℓ. Since $\Phi'(-\xi,\xi) = 0$, we can find a corresponding VQDF Q_Ψ acting on the latent variables ℓ such that $Q_\Phi(w) - Q_\Delta(\ell) = \operatorname{div} Q_\Psi(\ell)$. This VQDF can now, in turn, be interpreted as a storage function for the original Φ since $\operatorname{div} Q_\Psi(\ell) \leq Q_\Phi(w)$ for all $\ell \in \mathfrak{D}(\mathbb{R}^n,\mathbb{R}^{\mathtt{w}})$.

(2) $\Rightarrow$ (1) Let Φ admit a storage function. So $\operatorname{div} Q_\Psi(\ell) \leq Q_\Phi(w)$ for all $\ell \in \mathfrak{D}(\mathbb{R}^n,\mathbb{R}^{\mathtt{w}})$ and $w = M(\frac{d}{d\mathbf{x}})\ell$. On integrating this inequality over all of $\mathbb{R}^n$, we get $0 \leq \int_{\mathbb{R}^n} Q_\Phi(w)d\mathbf{x}$. Now consider any $w \in \mathfrak{D}(\mathbb{R}^n,\mathbb{R}^{\mathtt{w}})$. Since $M(\frac{d}{d\mathbf{x}})$ is surjective, there exist some $\ell_0 \in \mathfrak{C}^\infty(\mathbb{R}^n,\mathbb{R}^{\mathtt{w}})$ such that $w = M(\frac{d}{d\mathbf{x}})\ell_0$. Choose a sequence of $\ell_i \in$

$\mathfrak{D}(\mathbb{R}^n, \mathbb{R}^{\mathtt{w}})$ such that $\lim_{i\to\infty} \ell_i = \ell_0$. Let $w_i = M(\frac{d}{d\mathbf{x}})\ell_i$. Clearly, $w_i \in \mathfrak{D}(\mathbb{R}^n, \mathbb{R}^{\mathtt{w}})$. Hence, by continuity, we conclude that $\int_{\mathbb{R}^n} Q_\Phi(w)d\mathbf{x} \geq 0$. Thus $\int Q_\Phi \geq 0$.

(1) $\Rightarrow$ (4) Given a Φ, the steps in (1) $\Rightarrow$ (3) above explain how Δ can be obtained. The proof of (3) $\Rightarrow$ (2) explains how Ψ can be obtained. Observe that the latent variables involved in the construction of Ψ are the latent variables ℓ. These are the latent variables associated with the image representation of the controllable behavior given by $w - M(\frac{d}{d\mathbf{x}})\ell = 0$. Thus we obtain the equation

$$\operatorname{div} Q_\Psi(\ell) = Q_\Phi(w) - Q_\Delta(\ell).$$

Note that the same set of latent variables is associated to storage and dissipation.

(4) $\Rightarrow$ (1) This is obvious from (2) $\Rightarrow$ (1). ∎

Proof of Theorem 13. (1) $\Rightarrow$ (2) First, we convert the problem into a problem on a free behavior by using the image representation of the behavior. Let $M' \in \mathbb{R}^{\mathtt{w}\times\mathtt{l}}[\xi]$ define an operator $M'(\frac{d}{d\mathbf{x}})$ that defines an image representation of the given behavior $\mathfrak{B} \in \mathfrak{L}^{\mathtt{w}}_{n,\mathrm{cont}}$. Define $\Phi' := M'^T(\zeta)\Phi(\zeta,\eta)M'(\eta)$, and look at the action of the QDF induced by Φ' on the full space of latent variables ℓ' that appear in the image representation of $\mathfrak{B}$ (i.e., $\mathfrak{B} = \{w \mid w = M'(\frac{d}{d\mathbf{x}})\ell'\}$). Clearly, $\int_{\mathbb{R}^n} Q_{\Phi'}(\ell') \geq 0$ for all $\ell' \in \mathfrak{D}(\mathbb{R}^n, \mathbb{R}^\ell)$. By Theorem 12, we can find $\Psi = (\Psi_1, \Psi_2, \ldots, \Psi_n)$ with $\Psi_k = \Psi_k^* \in \mathbb{R}^{\mathtt{l}\times\mathtt{l}}[\zeta,\eta]$ for $k = 1, 2, \ldots, n$ and $\Delta = \Delta^* \in \mathbb{R}^{\mathtt{l}\times\mathtt{l}}[\zeta,\eta]$ such that

$$\operatorname{div} Q_\Psi(\ell) = Q_{\Phi'}(\ell') - Q_\Delta(\ell)$$

with ℓ' and ℓ related by $\ell' = M(\frac{d}{d\mathbf{x}})\ell$ and $M \in \mathbb{R}^{\mathtt{l}\times\mathtt{l}}[\xi]$. Observe that by definition $Q_\Phi(w) = Q_{\Phi'}(\ell')$, where $w = M'(\frac{d}{d\mathbf{x}})\ell'$. Hence we obtain the required result with w and ℓ related by $w = M'(\frac{d}{d\mathbf{x}})M(\frac{d}{d\mathbf{x}})\ell$, which is also an image representation of $\mathfrak{B}$, since $M(\frac{d}{d\mathbf{x}})$ is surjective (Theorem 12).

(2) $\Rightarrow$ (1) Consider any $w \in \mathfrak{B} \cap \mathfrak{D}(\mathbb{R}^n, \mathbb{R}^{\mathtt{w}})$. Then $w = M(\frac{d}{d\mathbf{x}})\ell$ for some $\ell \in \mathfrak{C}^\infty(\mathbb{R}^n, \mathbb{R}^\ell)$. Clearly, if $\ell \in \mathfrak{D}(\mathbb{R}^n, \mathbb{R}^\ell)$, then

$$0 = \int_{\mathbb{R}^n} \operatorname{div} Q_\Psi(\ell)d\mathbf{x} = \int_{\mathbb{R}^n} Q_\Phi(w)d\mathbf{x} - \int_{\mathbb{R}^n} Q_\Delta(\ell)d\mathbf{x}.$$

Thus $\int_{\mathbb{R}^n} Q_\Phi(w)d\mathbf{x} = \int_{\mathbb{R}^n} Q_\Delta(\ell)d\mathbf{x} \geq 0$. If $\ell \notin \mathfrak{D}(\mathbb{R}^n, \mathbb{R}^\ell)$, then one can find a sequence of $\ell_i \in \mathfrak{D}(\mathbb{R}^n, \mathbb{R}^\ell)$ that converges to ℓ. Then, by continuity, we obtain $\int_{\mathbb{R}^n} Q_\Phi(w)d\mathbf{x} \geq 0$ for all $w \in \mathfrak{B} \cap \mathfrak{D}(\mathbb{R}^n, \mathbb{R}^{\mathtt{w}})$. ∎

SECOND ORDER OPTIMALITY CONDITIONS FOR SEMILINEAR ELLIPTIC CONTROL PROBLEMS WITH FINITELY MANY STATE CONSTRAINTS*

EDUARDO CASAS† AND MARIANO MATEOS‡

Abstract. This paper deals with necessary and sufficient optimality conditions for control problems governed by semilinear elliptic partial differential equations with finitely many equality and inequality state constraints. Some recent results on this topic for optimal control problems based upon results for abstract optimization problems are compared with some new results using methods adapted to the control problems. Meanwhile, the Lagrangian formulation is followed to provide the optimality conditions in the first case; the Lagrangian and Hamiltonian functions are used in the second statement. Finally, we prove the equivalence of both formulations.

Key words. necessary and sufficient optimality conditions, control of elliptic equations, state constraints

1. Introduction.

The first goal of this paper is to provide some new second order optimality conditions for control problems of semilinear elliptic partial differential equations with finitely many state constraints. These conditions involve the Lagrangian and the Hamiltonian functions. Therefore, they are not a consequence of some abstract theorems in optimization theory but are proved by using arguments valid only in the framework of control theory. The second goal is to compare these conditions with those obtained recently for the same type of problems by using theorems for abstract optimization in infinite-dimensional spaces.

While there exists a very extensive literature about first order optimality conditions for control problems of partial differential equations, only a few papers are devoted to second order conditions. However, some progress has been made in the last few years. Most of the papers have been devoted to the study of sufficient second order optimality conditions; see Goldberg and Tröltzsch [13], Casas, Tröltzsch, and Unger [9], [10], Raymond and Tröltzsch [20]. Such sufficient optimality conditions are useful for carrying out the numerical analysis of a control problem, for obtaining error estimates in the numerical discretization, and for analyzing the sequential quadratic programming algorithms applied to control problems. However, we also have to study the second order necessary conditions and compare them with the sufficient ones in order to check if there is a reasonable gap between them. This was studied by Casas and Tröltzsch [7], [8] and Casas, Mateos, and Fernández [5] for some control problems. In the last papers, the authors proved the results by using some methods of abstract optimization theory and by stating some new results in this abstract framework. The gap between the established necessary and the sufficient conditions was very small.

Bonnans and Zidani [2] extended the results for finite-dimensional optimization problems to control problems by assuming that the second derivative with respect to the control of the Lagrangian function is a Legendre form. This is the natural way of doing such an extension, but the inconvenience is that the hypothesis about the Lagrangian function works in only a few cases. In this paper, instead of assuming that the second derivative of the Lagrangian function is a Legendre form, we assume a strict positivity condition on the second derivative of the Hamiltonian function with respect to the control, which is quite close to the necessary relaxed positivity.

The plan of the paper is as follows. In the next section, the control problem is formulated and some derivability results of the functionals are stated. In section 3, we reformulate the control problem as an infinite-dimensional optimization problem with constraints and we apply the second order conditions as deduced in [7] to our particular situation. Finally, in section 4 we deduce necessary and sufficient second order conditions involving the Lagrangian and the Hamiltonian functions and compare them with those established in section 3.

2. The control problem. Let Ω be an open bounded set in $\mathbb{R}^N$ with a boundary Γ of class C^1, and A an elliptic operator of the form

$$Ay = -\sum_{i,j=1}^{N} \partial_{x_j}\left[a_{ij}\partial_{x_i} y\right] + a_0 y,$$

where the coefficients a_{ij} belong to $C(\bar{\Omega})$ and satisfy

$$m\|\xi\|^2 \le \sum_{i,j=1}^{N} a_{ij}(x)\xi_i\xi_j \le M\|\xi\|^2 \ \forall \xi \in \mathbb{R}^N \text{ and } \forall x \in \Omega$$

for some $m, M > 0$ and $a_0 \in L^r(\Omega)$ is not identically zero, with $r \ge Np/(N+p)$ for some $p > N$ fixed, $a_0(x) \ge 0$ in Ω. Let f and L be Carathéodory functions $f : \Omega \times \mathbb{R}^2 \to \mathbb{R}$ and $L : \Omega \times \mathbb{R}^2 \longrightarrow \mathbb{R}$, n_e and n_i be nonnegative integers, and for every $1 \le j \le n_e + n_i$ let us consider a function $F_j : W^{1,p}(\Omega) \longrightarrow \mathbb{R}$.

The control problem is formulated as follows:

$$(\mathbf{P}) \begin{cases} \text{Minimize } J(u) = \int_\Omega L(x, y_u(x), u(x))dx, \\ u_a(x) \le u(x) \le u_b(x) \text{ a.e. } x \in \Omega, \\ F_j(y_u) = 0, \ 1 \le j \le n_e, \\ F_j(y_u) \le 0, \ n_e + 1 \le j \le n_e + n_i, \end{cases}$$

where y_u is the solution of

$$\begin{cases} Ay_u = f(x, y_u, u) & \text{in } \Omega, \\ \partial_{n_A} y_u = g & \text{on } \Gamma, \end{cases} \tag{2.1}$$

$g \in L^{p(1-1/N)}(\Gamma)$ and u_a, $u_b \in L^\infty(\Omega)$, $u_a(x) \le u_b(x)$ for almost every (a.e.) $x \in \Omega$. Let us state the following assumptions on the functional F_j, L, and f.

(A1) f is of class C^2 with respect to the second and third variables,

$$f(\cdot, 0, 0) \in L^{Np/(N+p)}(\Omega), \qquad \frac{\partial f}{\partial y}(x, y, u) \le 0,$$

and for all $M > 0$ there exists a constant $C_{f,M} > 0$ such that

$$\left|\frac{\partial f}{\partial y}(x, y, u)\right| + \left|\frac{\partial f}{\partial u}(x, y, u)\right| + \left|\frac{\partial^2 f}{\partial y^2}(x, y, u)\right| + \left|\frac{\partial^2 f}{\partial y \partial u}(x, y, u)\right| + \left|\frac{\partial^2 f}{\partial u^2}(x, y, u)\right| \le C_{f,M}$$

for a.e. $x \in \Omega$ and $|y|, |u| \le M$. Moreover, given $\rho > 0$ arbitrary, for every $\varepsilon > 0$ there exists $\delta > 0$ such that for almost every point $x \in \Omega$ and $|y_i|, |u_i| \le \rho$, $i = 1, 2$, we have

$$|D^2_{(y,u)} f(x, y_2, u_2) - D^2_{(y,u)} f(x, y_1, u_1)| < \varepsilon \ \text{ if } \ |y_2 - y_1| < \delta, \ |u_2 - u_1| < \delta,$$

where $D^2_{(y,u)} f$ denotes the second derivative of f with respect to (y, u).

(A2) $L : \Omega \times \mathbb{R} \times \mathbb{R} \longrightarrow \mathbb{R}$ is of class C^2 with respect to the second and third variables, $|L(\cdot, 0, 0)| \in L^1(\Omega)$, and for all $M > 0$ there exists a constant $C_M > 0$ and functions $\psi_M \in L^{Np/(N+p)}(\Omega)$ and $\psi^*_M \in L^2(\Omega)$ such that

$$\left|\frac{\partial L}{\partial y}(x, y, u)\right| \le \psi_M(x), \ \left|\frac{\partial L}{\partial u}(x, y, u)\right| \le \psi^*_M(x),$$

and

$$\left|\frac{\partial^2 L}{\partial y^2}(x, y, u)\right| + \left|\frac{\partial^2 L}{\partial y \partial u}(x, y, u)\right| + \left|\frac{\partial^2 L}{\partial u^2}(x, y, u)\right| \le C_M$$

for a.e. $x \in \Omega$ and $|y|, |u| \le M$. Finally, given $\rho > 0$ arbitrary, for every $\varepsilon > 0$ there exists $\delta > 0$ such that for almost every point $x \in \Omega$ and $|y_i|, |u_i| \le \rho$, $i = 1, 2$, we have

$$|D^2_{(y,u)} L(x, y_2, u_2) - D^2_{(y,u)} L(x, y_1, u_1)| < \varepsilon \ \text{ if } \ |y_2 - y_1| < \delta, \ |u_2 - u_1| < \delta,$$

where $D^2_{(y,u)} L$ denotes the second derivative of L with respect to (y, u).

(A3) For every $1 \le j \le n_e + n_i$, F_j is of class C^1 in $W^{1,s}(\Omega)$ and of class C^2 in $W^{1,q}(\Omega)$, where $s \in [1, \frac{N}{N-1})$, $q \in [\max\{s, \frac{2N}{N+2}\}, \frac{2N}{N-2})$, and $q \le p$.

Remark 2.1. The continuity assumption on the coefficients a_{ij} and the C^1 regularity of the boundary of the domain will allow us to consider integral state constraints involving the derivatives of the state. Nevertheless, if the coefficients a_{ij} are only bounded and the boundary Γ is Lipschitz, some results similar to those obtained here can be derived if the constraints do not involve the gradient of the state.

Let us show some examples of state constraints included in the previous formulation.

EXAMPLE 2.2. *Integral constraints on the state.* Given $g_j : \Omega \times \mathbb{R} \longrightarrow \mathbb{R}$, we define $F_j(y) = \int_\Omega g_j(x, y(x))dx$. Assumption **(A3)** is satisfied if we make the following hypotheses: g_j is of class C^2 with respect to the second variable and measurable with respect to the first one, $g_j(\cdot, 0) \in L^1(\Omega)$, and for every $M > 0$ there exist $\psi_M \in L^{Ns/([N+1]s-N)}(\Omega)$, for some $s < N/(N-1)$, and $\psi^*_M \in L^\alpha(\Omega)$, with $\alpha = 1$ if $N < 4$ and $\alpha > N/4$ otherwise, such that for every $y, y_1, y_2 \in [-M, +M]$ and almost every $x \in \Omega$

$$\left|\frac{\partial g_j}{\partial y}(x, y)\right| \le \psi_M(x), \quad \left|\frac{\partial^2 g_j}{\partial y^2}(x, y)\right| \le \psi^*_M(x),$$

$$\forall \varepsilon > 0 \ \exists \delta > 0 \ \text{ such that } \ \left|\frac{\partial^2 g_j}{\partial y^2}(x, y_2) - \frac{\partial^2 g_j}{\partial y^2}(x, y_1)\right| \le \varepsilon \ \text{ if } |y_2 - y_1| < \delta.$$

(A3) holds for $q = \min\{p, 2N/(N-2) - \beta\} > N$ for some $\beta > 0$ small enough.

EXAMPLE 2.3. *Integral constraints on the derivatives of the state.* Given $g_j : \Omega \times \mathbb{R}^N \longrightarrow \mathbb{R}$, we now define $F_j(y) = \int_\Omega g_j(x, \nabla y(x))dx$. Then assumption **(A3)** is

fulfilled if g_j is of class C^2 with respect to the second variable and measurable with respect to the first one, $g_j(\cdot,0) \in L^1(\Omega)$, there exist $C>0$, $r<2p/N$, $\psi \in L^{s'}(\Omega)$ for some $s<N/(N-1)$, and $\psi^* \in L^\alpha(\Omega)$ with $\alpha > N/2$, such that

$$\left|\frac{\partial g_j}{\partial \eta}(x,\eta)\right| \le \psi(x) + C|\eta|^{p(s-1)/s}, \quad \left|\frac{\partial^2 g_j}{\partial \eta^2}(x,\eta)\right| \le \psi^*(x) + C|\eta|^r, \text{ for a.e. } x \in \Omega,$$

and finally, for every $M>0$ and $\varepsilon>0$ there exists $\delta=\delta(\varepsilon,M)>0$ such that

$$\left|\frac{\partial^2 g_j}{\partial \eta^2}(x,\eta_2) - \frac{\partial^2 g_j}{\partial \eta^2}(x,\eta_1)\right| \le \varepsilon \text{ if } |\eta_2-\eta_1|<\delta \text{ and } |\eta_1|,|\eta_2| \le M, \text{ for a.e. } x \in \Omega.$$

Once again, **(A3)** is fulfilled for $q=\min\{p, 2N/(N-2)-\beta\}$ for $\beta>0$ small enough. The reader is referred to [5] for the study of this type of constraints.

The solution of (2.1) must be understood in a variational sense. Let us clarify this point. We define the variational form associated to the operator A in the usual way:

$$a(y,z) = \sum_{i,j=1}^N \int_\Omega a_{ij}(x)\partial_{x_i} y(x) \partial_{x_j} z(x)\,dx + \int_\Omega a_0(x) y(x) z(x)\,dx.$$

Then given $1<r<+\infty$, $\hat f \in (W^{1,r'}(\Omega))'$, and $\hat g \in W^{-\frac{1}{r},r}(\Gamma)$, we say that $y \in W^{1,r}(\Omega)$ is a solution of

$$\left\{ \begin{array}{rcll} Ay & = & \hat f & \text{in } \Omega, \\ \partial_{n_A} y & = & \hat g & \text{on } \Gamma, \end{array} \right. \tag{2.2}$$

if

$$a(y,z) = \langle \hat f, z\rangle_{(W^{1,r'}(\Omega))'\times W^{1,r'}(\Omega)} + \langle \hat g, \gamma z\rangle_{W^{-\frac{1}{r},r}(\Gamma)\times W^{\frac{1}{r},r'}(\Gamma)} \quad \forall z \in W^{1,r'}(\Omega),$$

where $\gamma : W^{1,r'}(\Omega) \to W^{\frac{1}{r},r'}(\Gamma)$ is the trace operator. The following known result deals with the solvability of (2.2); see Mateos [17] for the details, as well as Morrey [19] and Troianiello [21].

LEMMA 2.4. *Let $1<r<+\infty$, $\hat f \in (W^{1,r'}(\Omega))'$, and $\hat g \in W^{-\frac{1}{r},r}(\Gamma)$. Then there exists a unique variational solution $y \in W^{1,r}(\Omega)$ of Neumann's problem* (2.2). *Moreover, the following estimate is satisfied:*

$$\|y\|_{W^{1,r}(\Omega)} \le C\left(\|\hat f\|_{(W^{1,r'}(\Omega))'} + \|\hat g\|_{W^{-\frac{1}{r},r}(\Gamma)}\right), \tag{2.3}$$

where $C>0$ is a constant only depending on r, the dimension N, the operator A, and the domain Ω.

The semilinear case is a consequence of the previous lemma. In particular, $y_u \in W^{1,p}(\Omega)$ is said to be a solution of (2.1) if it satisfies the above variational equation with $\hat f = f(\cdot, y_u, u) \in (W^{1,p'}(\Omega))'$ and $\hat g = g \in L^{p(1-1/N)}(\Gamma) \subset W^{-1/p,p}(\Gamma)$. The next theorem states the existence and uniqueness of the solution of (2.1) as well as the differentiability of the relation between the control u and the associated state y_u.

THEOREM 2.5. *Suppose that* **(A1)** *holds. Then for every $u \in L^\infty(\Omega)$ there exists a unique solution $y_u \in W^{1,p}(\Omega)$ of the state equation* (2.1) *and*

$$\forall M>0\ \exists C_M>0 \text{ such that } \|y_u\|_{W^{1,p}(\Omega)} \le C_M \text{ if } \|u\|_{L^\infty(\Omega)} \le M.$$

The mapping $G : L^\infty(\Omega) \longrightarrow W^{1,p}(\Omega)$, defined by $G(u) = y_u$ is of class C^2 and for all $h, u \in L^\infty(\Omega)$, $z_h = G'(u)h$ is defined as the solution of

$$\left\{ \begin{array}{rcll} Az_h & = & \dfrac{\partial f}{\partial y}(x, y_u, u)z_h + \dfrac{\partial f}{\partial u}(x, y_u, u)h & \text{in } \Omega, \\ \partial_{n_A} z_h & = & 0 & \text{on } \Gamma. \end{array} \right. \tag{2.4}$$

Finally, for every $h_1, h_2 \in L^\infty(\Omega)$, $z_{h_1h_2} = G''(u)h_1h_2$ is the solution of

$$\left\{ \begin{array}{rcl} Az_{h_1h_2} = & \dfrac{\partial f}{\partial y}(x, y_u, u)z_{h_1h_2} + \dfrac{\partial^2 f}{\partial y^2}(x, y_u, u)z_{h_1}z_{h_2} & \\ & + \dfrac{\partial^2 f}{\partial u \partial y}(x, y_u, u)(z_{h_1}h_2 + z_{h_2}h_1) + \dfrac{\partial^2 f}{\partial u^2}(x, y_u, u)h_1h_2 & \text{in } \Omega, \\ \partial_{n_A} z_{h_1h_2} = & 0 \quad \text{on } \Gamma. & \end{array} \right. \tag{2.5}$$

Proof. The proof of the existence, uniqueness, and estimate of the solution of (2.1) is standard. Let us prove the differentiability. For that let us start with a homogeneous boundary condition, $g = 0$. We consider the space

$$V(A) = \Big\{ y \in W^{1,p}(\Omega) : \ Ay \in L^{Np/(N+p)}(\Omega), \ \partial_{n_A} y = 0 \Big\}$$

endowed with the norm

$$\|y\|_{V(A)} = \|y\|_{W^{1,p}(\Omega)} + \|Ay\|_{L^{Np/(N+p)}(\Omega)}.$$

Let us now define the function

$$F : V(A) \times L^\infty(\Omega) \to L^{Np/(N+p)}(\Omega), \quad F(y, u) = Ay - f(\cdot, y, u).$$

Thanks to assumption **(A1)**, F is of class C^2. Moreover, from Lemma 2.4 it follows that

$$\frac{\partial F}{\partial y}(y, u) = A - \frac{\partial f}{\partial y}(\cdot, y, u)$$

is an isomorphism from $V(A)$ to $L^{Np/(N+p)}(\Omega)$. Taking into account that $F(x, y, u) = 0$ if and only if $y = G(u)$, we can apply the implicit function theorem (see, for instance, [3]) to deduce that G is of class C^2 and satisfies $F(G(u), u) = 0$. From this identity, (2.4) and (2.5) follow easily.

If $g \neq 0$, then we can write $G(u) = y_u^0 + y_g = G_0(u) + y_g$, with y_u^0 and y_g solutions of the problems

$$\left\{ \begin{array}{rcll} Ay_g & = & 0 & \text{in } \Omega, \\ \partial_{n_A} y_g & = & g & \text{on } \Gamma, \end{array} \right.$$

$$\left\{ \begin{array}{rcll} Ay_u^0 & = & f^0(x, y_u^0, u) & \text{in } \Omega, \\ \partial_{n_A} y_u^0 & = & 0 & \text{on } \Gamma, \end{array} \right.$$

where $f^0(x, y, u) = f(x, y + y_g(x), u)$. From the previous argument we have that G_0 is of class C^2 and consequently G is C^2 too, with $G' = G_0'$ and $G'' = G_0''$, which concludes the proof. ∎

As a consequence of this theorem we will get the differentiability of the functionals J and $G_j = F_j \circ G$ in the next two theorems.

THEOREM 2.6. *Let us suppose that* **(A1)** *and* **(A2)** *hold. Then the functional* $J : L^\infty(\Omega) \to \mathbb{R}$ *is of class* C^2. *Moreover, for every* $u, h, h_1, h_2 \in L^\infty(\Omega)$,

$$J'(u)h = \int_\Omega \left(\frac{\partial L}{\partial u}(x, y_u, u) + \varphi_{0u} \frac{\partial f}{\partial u}(x, y_u, u) \right) h \, dx \tag{2.6}$$

and

$$\begin{aligned} J''(u)h_1h_2 = \int_\Omega \Bigg[& \frac{\partial^2 L}{\partial y^2}(x, y_u, u) z_1 z_2 + \frac{\partial^2 L}{\partial y \partial u}(x, y_u, u)(z_1 h_2 + z_2 h_1) \\ & + \frac{\partial^2 L}{\partial u^2}(x, y_u, u) h_1 h_2 + \varphi_{0u} \left(\frac{\partial^2 f}{\partial y^2}(x, y_u, u) z_1 z_2 \right. \\ & \left. + \frac{\partial^2 f}{\partial y \partial u}(x, y_u, u)(z_1 h_2 + z_2 h_1) + \frac{\partial^2 f}{\partial u^2}(x, y_u, u) h_1 h_2 \right) \Bigg] \, dx, \end{aligned} \tag{2.7}$$

where $y_u = G(u)$, $\varphi_{0u} \in W^{1,p}(\Omega)$ *is the unique solution of the problem*

$$\begin{cases} A^*\varphi &= \dfrac{\partial f}{\partial y}(x, y_u, u)\varphi + \dfrac{\partial L}{\partial y}(x, y_u, u) & \text{in } \Omega, \\ \partial_{n_{A^*}}\varphi &= 0 & \text{on } \Gamma, \end{cases} \tag{2.8}$$

where A^* *is the adjoint operator of* A *and* $z_i = G'(u)h_i$, $i = 1, 2$.

Proof. Let us consider the function $F_0 : C(\bar\Omega) \times L^\infty(\Omega) \to \mathbb{R}$ defined by

$$F_0(y, u) = \int_\Omega L(x, y(x), u(x)) \, dx.$$

Due to the assumptions on L it is straightforward to prove that F_0 is of class C^2. Now, applying the chain rule to $J(u) = F_0(G(u), u)$ and using Theorem 2.5 and the fact that $W^{1,p}(\Omega) \subset C(\bar\Omega)$ for every $p > N$, we get that J is of class C^2 and

$$J'(u)h = \int_\Omega \left(\frac{\partial L}{\partial y}(x, y_u, u) z_h + \frac{\partial L}{\partial u}(x, y_u, u) h \right) dx.$$

Taking φ_{0u} as the solution of (2.8), we deduce (2.6) from previous identity and (2.4). Let us remark that the assumptions on f and L imply the regularity of φ_{0u}. The second derivative can be deduced in a similar way, making use of Theorem 2.5 once more. ∎

THEOREM 2.7. *Let us suppose that* **(A1)** *and* **(A3)** *hold. Then for each* j, *the functional* $G_j = F_j \circ G : L^\infty(\Omega) \to \mathbb{R}$ *is of class* C^2. *Moreover, for every* $u, h, h_1, h_2 \in L^\infty(\Omega)$,

$$G_j'(u)h = \int_\Omega \varphi_{ju} \frac{\partial f}{\partial u}(x, y_u, u) h \, dx \tag{2.9}$$

and

$$\begin{aligned} G_j''(u)h_1h_2 = F_j''(y_u) z_1 z_2 \\ + \int_\Omega \varphi_{ju} \left(\frac{\partial^2 f}{\partial y^2}(x, y_u, u) z_1 z_2 + \frac{\partial^2 f}{\partial y \partial u}(x, y_u, u)(z_1 h_2 + z_2 h_1) + \frac{\partial^2 f}{\partial u^2}(x, y_u, u) h_1 h_2 \right) dx, \end{aligned} \tag{2.10}$$

where $y_u = G(u)$, $\varphi_{ju} \in W^{1,s'}(\Omega)$ *is the unique solution of the problem*

$$\left\{ \begin{array}{rcll} A^*\varphi_{ju} & = & \dfrac{\partial f}{\partial y}(x, y_u, u)\varphi_{ju} + F_j'(y_u) & \text{in } \Omega, \\ \partial_{n_{A^*}}\varphi_{ju} & = & 0 & \text{on } \Gamma, \end{array} \right. \tag{2.11}$$

and $z_i = G'(u)h_i$, $i = 1, 2$.

The proof of this theorem is very similar to that of Theorem 2.6. Nevertheless we have to make a comment about (2.11). From assumption **(A3)** we have that $F'(\bar{y}) \in (W^{1,s}(\Omega))'$; then the boundary problem (2.11) has a unique solution in $W^{1,s'}(\Omega)$ in the variational sense, analogous to that of (2.2); see Lemma 2.4. Finally recall that $s < N/(N-1)$; then $s' > N$ and therefore $\varphi_{ju} \in W^{1,s'}(\Omega) \subset C(\bar{\Omega})$.

3. First and second order optimality conditions in the Lagrangian form. Let us start this section by reformulating problem **(P)** as follows:

$$(\mathbf{P}) \left\{ \begin{array}{l} \text{Minimize } J(u), \\ u_a(x) \le u(x) \le u_b(x) \text{ for a.e. } x \in \Omega, \\ G_j(u) = 0, \ 1 \le j \le n_e, \\ G_j(u) \le 0, \ n_e + 1 \le j \le n_e + n_i, \end{array} \right.$$

where we are using the functions introduced in the previous section $G_j = F_j \circ G$. We now apply the results obtained in [7]. In order to deduce the first and second order optimality conditions of an optimization problem, it is necessary to make a regularity assumption. This is our first goal. Given $\varepsilon > 0$, we denote the set of *ε-inactive constraints* by

$$\Omega_\varepsilon = \{x \in \Omega : u_a(x) + \varepsilon \le \bar{u}(x) \le u_b(x) - \varepsilon\}.$$

We say that a feasible control $\bar{u}$ is regular if the following assumption is fulfilled:

$$\left\{ \begin{array}{l} \exists \varepsilon_{\bar{u}} > 0 \text{ and } \{\bar{h}_j\}_{j \in I_0} \subset L^\infty(\Omega), \text{ with } \operatorname{supp} \bar{h}_j \subset \Omega_{\varepsilon_{\bar{u}}}, \text{ such that} \\ G_i'(\bar{u})\bar{h}_j = \delta_{ij}, \quad i, j \in I_0, \end{array} \right. \tag{3.1}$$

where

$$I_0 = \{j \le m \,|\, G_j(\bar{u}) = 0\}.$$

I_0 is the set of indices corresponding to active constraints. Associated to **(P)** we define the Lagrangian function

$$\mathcal{L}(u, \lambda) = J(u) + \sum_{j=1}^{n_e+n_i} \lambda_j G_j(u).$$

Obviously (3.1) is equivalent to the independence of the derivatives $\{G_j'(\bar{u})\}_{j \in I_0}$ in $L^1(\Omega_{\varepsilon_{\bar{u}}})$. Under this assumption we can derive the first order necessary conditions for optimality in a qualified form. For the proof the reader is referred to Bonnans and Casas [1] or Clarke [11]; see also Mateos [17].

THEOREM 3.1. *Let us assume that* $\bar{u}$ *is a local solution of* **(P)** *and* (3.1) *holds. Then there exist real numbers* $\{\bar{\lambda}_j\}_{j=1}^{n_e+n_i}$ *such that*

$$\bar{\lambda}_j \ge 0, \quad n_e + 1 \le j \le n_e + n_i, \ \bar{\lambda}_j = 0 \text{ if } G_j(\bar{u}) < 0; \tag{3.2}$$

$$\frac{\partial \mathcal{L}}{\partial u}(\bar{u},\bar{\lambda})(u-\bar{u}) \geq 0 \quad \textit{for all } u_a \leq u \leq u_b. \tag{3.3}$$

Denoting by $\bar{\varphi}_0$ and $\bar{\varphi}_j$ the solutions of (2.8) and (2.11) corresponding to $\bar{u}$ and setting

$$\bar{\varphi} = \bar{\varphi}_0 + \sum_{j=1}^{n_e+n_i} \bar{\lambda}_j \bar{\varphi}_j, \tag{3.4}$$

we deduce from Theorems 2.6 and 2.7 and the definition of $\mathcal{L}$ that

$$\begin{aligned}\frac{\partial \mathcal{L}}{\partial u}(\bar{u},\bar{\lambda})h &= \int_\Omega \left(\frac{\partial L}{\partial u}(x,\bar{y},\bar{u}) + \bar{\varphi}_0 \frac{\partial f}{\partial u}(x,\bar{y},\bar{u})\right) h\,dx \;+\; \sum_{j=1}^{n_e+n_i} \bar{\lambda}_j \int_\Omega \bar{\varphi}_j \frac{\partial f}{\partial u}(x,\bar{y},\bar{u}) h\,dx \\ &= \int_\Omega \left(\frac{\partial L}{\partial u}(x,\bar{y},\bar{u}) + \bar{\varphi} \frac{\partial f}{\partial u}(x,\bar{y},\bar{u})\right) h\,dx \\ &= \int_\Omega d(x)h(x)\,dx \quad \forall h \in L^\infty(\Omega), \end{aligned} \tag{3.5}$$

where $\bar{y} = G(\bar{u}) = y_{\bar{u}}$ and

$$d(x) = \frac{\partial L}{\partial u}(x,\bar{y}(x),\bar{u}(x)) + \bar{\varphi}(x)\frac{\partial f}{\partial u}(x,\bar{y}(x),\bar{u}(x)) = \frac{\partial H}{\partial u}(x,\bar{y}(x),\bar{u}(x),\bar{\varphi}(x)), \tag{3.6}$$

$H : \Omega \times \mathbb{R}^3 \longrightarrow \mathbb{R}$ being the Hamiltonian associated to the control problem **(P)**,

$$H(x,y,u,\varphi) = L(x,y,u) + \varphi f(x,y,u).$$

From (3.3) we deduce that

$$d(x) = \begin{cases} 0 & \text{for a.e. } x \in \Omega, \text{ where } u_a(x) < \bar{u}(x) < u_b(x), \\ \geq 0 & \text{for a.e. } x \in \Omega, \text{ where } \bar{u}(x) = u_a(x), \\ \leq 0 & \text{for a.e. } x \in \Omega, \text{ where } \bar{u}(x) = u_b(x). \end{cases} \tag{3.7}$$

Remark 3.2. From (3.3), (3.7), and assumption (3.1) we get

$$\int_\Omega \left(\frac{\partial L}{\partial u}(x,\bar{y}(x),\bar{u}(x)) + \bar{\varphi}_0(x)\frac{\partial f}{\partial u}(x,\bar{y}(x),\bar{u}(x))\right)\bar{h}_j(x)\,dx + \bar{\lambda}_j = \frac{\partial \mathcal{L}}{\partial u}(\bar{u},\bar{\lambda})\bar{h}_j = 0,$$

which implies the uniqueness of the Lagrange multipliers provided in Theorem 3.1.

Associated with d we set

$$\Omega^0 = \{x \in \Omega : |d(x)| > 0\}. \tag{3.8}$$

Given $\{\bar{\lambda}_j\}_{j=1}^{n_e+n_i}$ by Theorem 3.1 we define the *cone of critical directions*

$$C_{\bar{u}}^0 = \{h \in L^\infty(\Omega) \text{ satisfying (3.10) and } h(x) = 0 \text{ for a.e. } x \in \Omega^0\}, \tag{3.9}$$

with

$$\begin{cases} G_j'(\bar{u})h = 0 \text{ if } (j \leq n_e) \text{ or } (j > n_e,\ G_j(\bar{u}) = 0, \text{ and } \bar{\lambda}_j > 0); \\ G_j'(\bar{u})h \leq 0 \text{ if } j > n_e,\ G_j(\bar{u}) = 0, \text{ and } \bar{\lambda}_j = 0; \\ h(x) = \begin{cases} \geq 0 & \text{if } \bar{u}(x) = u_a(x); \\ \leq 0 & \text{if } \bar{u}(x) = u_b(x). \end{cases} \end{cases} \tag{3.10}$$

Now we are ready to state the second order necessary optimality conditions.

THEOREM 3.3. *Let us assume that $\bar{u}$ is a local solution of* **(P)**, (3.1) *holds, and* $\{\bar{\lambda}_j\}_{j=1}^{n_e+n_i}$ *are the Lagrange multipliers satisfying* (3.2) *and* (3.3). *Then the following inequality is satisfied:*

$$\frac{\partial^2 \mathcal{L}}{\partial u^2}(\bar{u},\bar{\lambda})h^2 \geq 0 \quad \forall h \in C^0_{\bar{u}}. \tag{3.11}$$

This theorem follows from Theorem 2.2 of [7]. Indeed it is enough to check the assumptions **(A1)** and **(A2)** of such a paper. **(A1)** says that $J'(\bar{u})$ and $G_j'(\bar{u})$ must be continuous functionals on $L^2(\Omega)$, which is an immediate consequence of Theorems 2.6 and 2.7. Assumption **(A2)** of [7] says that

$$\frac{\partial^2 \mathcal{L}}{\partial u^2}(\bar{u},\bar{\lambda})h_k^2 \longrightarrow \frac{\partial^2 \mathcal{L}}{\partial u^2}(\bar{u},\bar{\lambda})h^2$$

whenever $\{h_k\}_{k=1}^{\infty}$ is bounded in $L^\infty(\Omega)$ and $h_k(x) \to h(x)$ a.e. in Ω. Taking into account that

$$\begin{aligned}\frac{\partial^2 \mathcal{L}}{\partial u^2}(\bar{u},\bar{\lambda})h^2 = &\sum_{j=1}^{n_e+n_i} \bar{\lambda}_j F_j''(\bar{y})z_h^2 \\ &+ \int_\Omega \left(\frac{\partial^2 L}{\partial y^2}(x,\bar{y},\bar{u}) + \bar{\varphi}\frac{\partial^2 f}{\partial y^2}(x,\bar{y},\bar{u})\right) z_h^2\,dx \\ &+ \int_\Omega \left(\frac{\partial^2 L}{\partial y \partial u}(x,\bar{y},\bar{u}) + \bar{\varphi}\frac{\partial^2 f}{\partial y \partial u}(x,\bar{y},\bar{u})\right) z_h h\,dx \\ &+ \int_\Omega \left(\frac{\partial^2 L}{\partial u^2}(x,\bar{y},\bar{u}) + \bar{\varphi}\frac{\partial^2 f}{\partial u^2}(x,\bar{y},\bar{u})\right) h^2\,dx,\end{aligned} \tag{3.12}$$

where z_h is the solution of (2.4) corresponding to the pair $(\bar{y},\bar{u})$, the desired convergence property follows from the boundedness of the second derivatives of L and f along with the convergence $z_{h_k} \to z_h$ in $W^{1,q}(\Omega) \subset L^2(\Omega)$ and our assumption **(A3)**.

In order to obtain the sufficient second order optimality conditions for problem **(P)**, we need to check some additional properties of the first and second derivatives of J and G_j. Let us take a ball in $L^\infty(\Omega)$, $B_\rho(\bar{u})$. From Theorem 2.5, we deduce the existence of a constant $C_\rho > 0$ such that $\{y_u\}_{u\in B_\rho(\bar{u})}$ is uniformly bounded by C_ρ in the $W^{1,p}(\Omega)$ norm and therefore in the $L^\infty(\Omega)$ norm too. This implies the uniform boundedness of the derivatives of f at every point (y_u,u), for $u \in B_\rho(\bar{u})$, as well as the boundedness of the second derivatives of L and the domination of the first derivatives by some functions $\psi_\rho \in L^{Np/(N+p)}(\Omega)$ and $\psi_\rho^* \in L^2(\Omega)$. Then from Lemma 2.4 we deduce that $\{\varphi_{ju}\}_{u\in B_\rho(\bar{u})}$ are bounded in $W^{1,p}(\Omega) \subset L^\infty(\Omega)$ for $j=0$ and $W^{1,s'}(\Omega) \subset L^\infty(\Omega)$ for $1 \leq j \leq n_e+n_i$, respectively. Finally, using Lemma 2.4 once more, we get that

$$\|z_h\|_{W^{1,q}(\Omega)} \leq C\|h\|_{L^2(\Omega)},$$

which follows from the imbedding $L^2(\Omega) \subset (W^{1,q'}(\Omega))'$ due to the fact $q < 2N/(N-2)$. Collecting all these things, we get the existence of constants $M_{j,1}, M_{j,2} > 0$, with

$0 \le j \le n_e + n_i$, such that for every $u \in B_\rho(\bar u)$ and all $h, h_1, h_2 \in L^\infty(\Omega)$ we have

$$\begin{cases} |J'(u)h| \le M_{0,1}\|h\|_{L^2(\Omega)}, \quad |G_j'(u)h| \le M_{j,1}\|h\|_{L^2(\Omega)}, \\ |J''(u)h_1h_2| \le M_{0,2}\|h_1\|_{L^2(\Omega)}\|h_2\|_{L^2(\Omega)}, \\ |G_j''(u)h_1h_2| \le M_{j,2}\|h_1\|_{L^2(\Omega)}\|h_2\|_{L^2(\Omega)}. \end{cases} \tag{3.13}$$

We have to check a last condition, which is established in the following lemma.

LEMMA 3.4. *For every $\delta > 0$ there exists $\varepsilon \in (0, \rho)$ such that for every $h \in L^\infty(\Omega)$ and $\|u - \bar u\|_\infty < \varepsilon$ the following inequality is fulfilled:*

$$\left| \left[\frac{\partial^2 \mathcal{L}}{\partial u^2}(u, \bar\lambda) - \frac{\partial^2 \mathcal{L}}{\partial u^2}(\bar u, \bar\lambda) \right] h^2 \right| \le \delta \, \|h\|^2_{L^2(\Omega)}. \tag{3.14}$$

Proof. Let us take $h \in L^\infty(\Omega)$ and $\delta > 0$. We are going to check that

$$\begin{aligned} &\left| \left[\frac{\partial^2 \mathcal{L}}{\partial u^2}(v, \bar\lambda) - \frac{\partial^2 \mathcal{L}}{\partial u^2}(\bar u, \bar\lambda) \right] h^2 \right| \\ &\le \int_\Omega \left| \frac{\partial^2 L}{\partial u^2}(x, y_v, v) + \varphi_v \frac{\partial^2 f}{\partial u^2}(x, y_v, v) - \frac{\partial^2 L}{\partial u^2}(x, \bar y, \bar u) - \bar\varphi \frac{\partial^2 f}{\partial u^2}(x, \bar y, \bar u) \right| h^2 \, dx \\ &\quad + \int_\Omega \left| \left(\frac{\partial^2 L}{\partial y \partial u}(x, y_v, v) + \varphi_v \frac{\partial^2 f}{\partial y \partial u}(x, y_v, v) \right) z_h \right. \\ &\quad \left. - \left(\frac{\partial^2 L}{\partial y \partial u}(x, \bar y, \bar u) + \bar\varphi \frac{\partial^2 f}{\partial y \partial u}(x, \bar y, \bar u) \right) \bar z_h \right| |h| \, dx \\ &\quad + \int_\Omega \left| \left(\frac{\partial^2 L}{\partial y^2}(x, y_v, v) + \varphi_v \frac{\partial^2 f}{\partial y^2}(x, y_v, v) \right) z_h^2 \right. \\ &\quad \left. - \left(\frac{\partial^2 L}{\partial y^2}(x, \bar y, \bar u) + \bar\varphi \frac{\partial^2 f}{\partial y^2}(x, \bar y, \bar u) \right) \bar z_h^2 \right| dx \\ &\quad + \sum_{j=1}^{n_i + ni} |\bar\lambda_j| \left| F_j''(y_v) z_h^2 - F_j''(\bar y) \bar z_h^2 \right| \le \delta \|h\|^2_{L^2(\Omega)}, \end{aligned} \tag{3.15}$$

supposing $\|v - \bar u\|_{L^\infty(\Omega)} < \varepsilon$ with ε small enough, where

$$\begin{cases} Az_h &= \dfrac{\partial f}{\partial y}(x, y_v, v) z_h + \dfrac{\partial f}{\partial u}(x, y_v, v) h & \text{in } \Omega, \\ \partial_{n_A} z_h &= 0 & \text{on } \Gamma, \end{cases}$$

and

$$\begin{cases} A\bar z_h &= \dfrac{\partial f}{\partial y}(x, \bar y, \bar u) \bar z_h + \dfrac{\partial f}{\partial u}(x, \bar y, \bar u) h & \text{in } \Omega, \\ \partial_{n_A} \bar z_h &= 0 & \text{on } \Gamma. \end{cases}$$

We discuss every term in a separate way. The inequality

$$\left\| \frac{\partial^2 L}{\partial u^2}(x, y_v, v) + \varphi_v \frac{\partial^2 f}{\partial u^2}(x, y_v, v) - \frac{\partial^2 L}{\partial u^2}(x, \bar y, \bar u) - \bar\varphi \frac{\partial^2 f}{\partial u^2}(x, \bar y, \bar u) \right\|_{L^\infty(\Omega)} < \frac{\delta}{4}$$

is a direct consequence of the continuity $v \in L^\infty(\Omega) \longrightarrow \varphi_v \in W^{1,\min\{s',p\}}(\Omega) \subset C(\bar\Omega)$ (see Lemma 2.4 and Theorems 2.6 and 2.7) and the continuity properties of the second derivatives of f and L assumed in **(A1)** and **(A2)**, as well as assumption **(A3)**.

Let us study the second term of (3.15). Hölder's inequality leads us to

$$\begin{aligned}
&\int_\Omega \left| \left(\frac{\partial^2 L}{\partial y \partial u}(x, y_v, v) + \varphi_v \frac{\partial^2 f}{\partial y \partial u}(x, y_v, v) \right) z_h \right. \\
&\qquad \left. - \left(\frac{\partial^2 L}{\partial y \partial u}(x, \bar y, \bar u) + \bar\varphi \frac{\partial^2 f}{\partial y \partial u}(x, \bar y, \bar u) \right) \bar z_h \right| |h| \, dx \\
&\le \|h\|_{L^2(\Omega)} \left(\left\| \frac{\partial^2 L}{\partial y \partial u}(x, y_v, v) - \frac{\partial^2 L}{\partial y \partial u}(x, \bar y, \bar u) \right\|_{L^\infty(\Omega)} \|z_h\|_{L^2(\Omega)} \right. \\
&\qquad + \left\| \frac{\partial^2 L}{\partial y \partial u}(x, \bar y, \bar u) \right\|_{L^\infty(\Omega)} \|z_h - \bar z_h\|_{L^2(\Omega)} \\
&\qquad + \left\| \varphi_v \frac{\partial^2 f}{\partial y \partial u}(x, y_v, v) - \bar\varphi \frac{\partial^2 f}{\partial y \partial u}(x, \bar y, \bar u) \right\|_{L^\infty(\Omega)} \|z_h\|_{L^2(\Omega)} \\
&\qquad \left. + \left\| \bar\varphi \frac{\partial^2 f}{\partial y \partial u}(x, \bar y, \bar u) \right\|_{L^\infty(\Omega)} \|z_h - \bar z_h\|_{L^2(\Omega)} \right) < \frac{\delta}{4} \|h\|^2_{L^2(\Omega)},
\end{aligned}$$

the last inequality being a consequence of **(A1)** and **(A2)** along with the estimates

$$\|z_h\|_{L^2(\Omega)} + \|\bar z_h\|_{L^2(\Omega)} \le C_1 \left(\|z_h\|_{W^{1,q}(\Omega)} + \|\bar z_h\|_{W^{1,q}(\Omega)} \right) \le C_2 \|h\|_{L^2(\Omega)} \tag{3.16}$$

and

$$\|z_h - \bar z_h\|_{L^2(\Omega)} \le C_1 \|z_h - \bar z_h\|_{W^{1,q}(\Omega)} \le O(\varepsilon) \|h\|_{L^2(\Omega)}, \tag{3.17}$$

with $O(\varepsilon) \to 0$ when $\varepsilon \to 0$. Let us notice that (3.16) follows from the inequalities $2N/(N+2) \le q < 2N/(N-2)$, Sobolev imbeddings, and Lemma 2.4.

Analogously we have

$$\begin{aligned}
&\int_\Omega \left| \left(\frac{\partial^2 L}{\partial y^2}(x, y_v, v) + \varphi_v \frac{\partial^2 f}{\partial y^2}(x, y_v, v) \right) z_h^2 - \left(\frac{\partial^2 L}{\partial y^2}(x, \bar y, \bar u) + \bar\varphi \frac{\partial^2 f}{\partial y^2}(x, \bar y, \bar u) \right) \bar z_h^2 \right| dx \\
&\le \left\| \frac{\partial^2 L}{\partial y^2}(x, y_v, v) - \frac{\partial^2 L}{\partial y^2}(x, \bar y, \bar u) \right\|_{L^\infty(\Omega)} \|z_h\|^2_{L^2(\Omega)} \\
&\quad + \left\| \frac{\partial^2 L}{\partial y^2}(x, \bar y, \bar u) \right\|_{L^\infty(\Omega)} \|z_h - \bar z_h\|_{L^2(\Omega)} \|z_h + \bar z_h\|_{L^2(\Omega)} \\
&\quad + \left\| \varphi_v \frac{\partial^2 f}{\partial y^2}(x, y_v, v) - \bar\varphi \frac{\partial^2 f}{\partial y^2}(x, \bar y, \bar u) \right\|_{L^\infty(\Omega)} \|z_h\|^2_{L^2(\Omega)} \\
&\quad + \left\| \bar\varphi \frac{\partial^2 f}{\partial y^2}(x, \bar y, \bar u) \right\|_{L^\infty(\Omega)} \|z_h - \bar z_h\|_{L^2(\Omega)} \|z_h + \bar z_h\|_{L^2(\Omega)} < \frac{\delta}{4} \|h\|^2_{L^2(\Omega)},
\end{aligned}$$

thanks again to **(A1)**, **(A2)**, (3.16), and (3.17).

For the fourth term of (3.15) it is enough to take into account assumption **(A3)**, and once more (3.16) and (3.17), and to use the inequality

$$\begin{aligned}
|F_j''(y_v) z_h^2 - F_j''(\bar y) \bar z_h^2| &= |F_j''(y_v)(z_h^2 - \bar z_h^2) + (F_j''(y_v) - F_j''(\bar y)) \bar z_h^2| \\
&\le |F_j''(y_v)(z_h + \bar z_h)(z_h - \bar z_h)| + |(F_j''(y_v) - F_j''(\bar y)) \bar z_h^2|. \qquad \square
\end{aligned}$$

Before writing the sufficient optimality conditions, we have to fix some notation. Analogously to (3.8) and (3.9), we define for every $\tau > 0$

$$\Omega^\tau = \{x \in \Omega : |d(x)| > \tau\} \tag{3.18}$$

and

$$C_{\bar u}^\tau = \{h \in L^\infty(\Omega) \text{ satisfying (3.10) and } h(x) = 0 \text{ for a.e. } x \in \Omega^\tau\}. \tag{3.19}$$

The next theorem provides the second order sufficient optimality conditions of problem **(P)**.

THEOREM 3.5. *Let $\bar u$ be a feasible point for problem* **(P)** *satisfying* (3.2) *and* (3.3) *and let us suppose that assumption* (3.1) *holds. Let us also assume that*

$$\frac{\partial^2 \mathcal{L}}{\partial u^2}(\bar u, \bar\lambda)h^2 \ge \delta \|h\|^2_{L^2(\Omega)} \quad \forall h \in C_{\bar u}^\tau \tag{3.20}$$

for some $\delta > 0$ and $\tau > 0$ given. Then there exist $\varepsilon > 0$ and $\alpha > 0$ such that $J(\bar u) + \alpha\|u - \bar u\|^2_{L^2(\Omega)} \le J(u)$ for every feasible point u for **(P)**, *with $\|u - \bar u\|_{L^\infty(\Omega)} < \varepsilon$.*

Relations (3.13) and (3.14) prove that the hypotheses of Corollary 3.3 of [7] are fulfilled, which leads straightforwardly to the above theorem. In that paper it is also proved that we can not relax the sufficient condition by taking $\tau = 0$; see also Dunn [12].

The last two theorems concerning the necessary and sufficient second order optimality conditions involve two norms: those of $L^2(\Omega)$ and $L^\infty(\Omega)$. This is motivated by the so-called two norms discrepancy; see, for instance; A. Ioffe [15] and H. Maurer [18]. In particular, the cones $C_{\bar u}^\tau$, for $\tau \ge 0$, as defined in (3.8) and (3.19), are subsets of $L^\infty(\Omega)$, but only the $L^2(\Omega)$-norm of the elements of $C_{\bar u}^\tau$ is involved in the optimality conditions (3.11) and (3.20). Now there is a natural question. Let us define for each $\tau \ge 0$

$$C_{\bar u, L^2(\Omega)}^\tau = \{h \in L^2(\Omega) \text{ satisfying (3.10) and } h(x) = 0 \text{ for a.e. } x \in \Omega^\tau\}. \tag{3.21}$$

Can we replace $C_{\bar u}^\tau$ by $C_{\bar u, L^2(\Omega)}^\tau$ in Theorems 3.3 and 3.5? The next proposition provides a positive answer.

PROPOSITION 3.6. *Let us assume that* (3.1) *holds. Then $C_{\bar u, L^2(\Omega)}^\tau = \bar C_{\bar u}^\tau$, where $\bar C_{\bar u}^\tau$ denotes the closure of $C_{\bar u}^\tau$ in $L^2(\Omega)$.*

Proof. Since $C_{\bar u, L^2(\Omega)}^\tau$ is closed in $L^2(\Omega)$, we obviously have $\bar C_{\bar u}^\tau \subset C_{\bar u, L^2(\Omega)}^\tau$. Let us prove the reverse inclusion. Let $h \in C_{\bar u, L^2(\Omega)}^\tau$. We are going to obtain a sequence $\{h_k\}_{k=1}^\infty \subset C_{\bar u}^\tau$ such that $h_k \to h$ in $L^2(\Omega)$. Let us take

$$\hat h_k = \begin{cases} +k & \text{if } h(x) > +k, \\ h(x) & \text{if } |h(x)| \le k, \\ -k & \text{if } h(x) < -k. \end{cases}$$

For every $j \in I_0$ let us set

$$\alpha_{kj} = G_j'(\bar u)\hat h_k - G_j'(\bar u)h.$$

It is clear that $\hat h_k \to h$ in $L^2(\Omega)$ and $\alpha_{kj} \to 0$ for every $j \in I_0$. Finally we define

$$h_k = \hat h_k - \sum_{j \in I_0} \alpha_{kj} \bar h_j,$$

where $\bar{h}_j$ is given in (3.1). It is obvious that $h_k \to h$ in $L^2(\Omega)$ and $\{h_k\}_{k=1}^{\infty} \subset L^\infty(\Omega)$. Let us prove that $h_k \in C^\tau_{\bar{u}}$ for every k. First of all, $h_k(x) = 0$ for almost every $x \in \Omega^\tau$. Indeed, since $h \in C^\tau_{\bar{u},L^2(\Omega)}$, then $h(x) = 0$ for almost every $x \in \Omega^\tau$; consequently $\hat{h}_k$ keeps the same property. On the other hand, the support of $\bar{h}_j$ is in $\Omega_{\varepsilon_{\bar{u}}}$, and $d(x) = 0$ for almost every $x \in \Omega_{\varepsilon_{\bar{u}}}$; therefore $\bar{h}_j(x) = 0$ for almost all $x \in \Omega^\tau$. Hence $h_k(x)$ also vanishes almost everywhere in Ω^τ. Moreover, since h and $\hat{h}_k$ have the same sign, it follows that $h_k(x) = \hat{h}_k(x) \geq 0$ if $\bar{u}(x) = u_a(x)$. Analogously, if $\bar{u}(x) = u_b(x)$, then $h_k(x) = \hat{h}_k(x) \leq 0$. Finally, let us fix $j \in I_0$

$$G'_j(\bar{u})h_k = G'_j(\bar{u})\hat{h}_k - \sum_{i\in I_0} \alpha_{ki} G'_j(\bar{u})\bar{h}_i = G'_j(\bar{u})\hat{h}_k - \alpha_{kj} = G'_j(\bar{u})h.$$

Using the fact that h is in the cone of critical directions of $L^2(\Omega)$, we deduce that h_k satisfies in the same way as h the conditions on the derivatives of G_j, for every j, which proves that $h_k \in C^\tau_{\bar{u}}$. □

Remark 3.7. As a consequence of the previous proposition and the fact that $\frac{\partial^2 \mathcal{L}}{\partial u^2}(\bar{u}, \bar{\lambda})$ is a bilinear and continuous form in $L^2(\Omega)$, we get the following equivalences:

$$\frac{\partial^2 \mathcal{L}}{\partial u^2}(\bar{u}, \bar{\lambda})h^2 \geq 0 \ \ \forall h \in C^0_{\bar{u}} \iff \frac{\partial^2 \mathcal{L}}{\partial u^2}(\bar{u}, \bar{\lambda})h^2 \geq 0 \ \ \forall h \in C^0_{\bar{u},L^2(\Omega)}$$

and

$$\frac{\partial^2 \mathcal{L}}{\partial u^2}(\bar{u}, \bar{\lambda})h^2 \geq \delta\|h\|^2_{L^2(\Omega)} \ \ \forall h \in C^\tau_{\bar{u}} \iff \frac{\partial^2 \mathcal{L}}{\partial u^2}(\bar{u}, \bar{\lambda})h^2 \geq \delta\|h\|^2_{L^2(\Omega)} \ \ \forall h \in C^\tau_{\bar{u},L^2(\Omega)}.$$

4. First and second order optimality conditions involving the Hamiltonian. As in the previous section, we denote with $H : \Omega \times \mathbb{R}^3 \longrightarrow \mathbb{R}$ the Hamiltonian associated to the control problem **(P)**:

$$H(x, y, u, \varphi) = L(x, y, u) + \varphi f(x, y, u).$$

Pontryagin's principle for **(P)** is formulated in terms of H in the next proposition.

PROPOSITION 4.1. *Let $\bar{u}$ be a solution of* (**P**). *Suppose that the assumptions* **(A1)**–**(A3)** *and* (3.1) *hold. Then there exist real numbers $\bar{\lambda}_j$, $j = 1, \ldots, n_i + n_e$, and functions $\bar{y} \in W^{1,p}(\Omega)$, $\bar{\varphi} \in W^{1,\min\{s',p\}}(\Omega)$ such that*

$$\bar{\lambda}_j \geq 0, \quad n_e + 1 \leq j \leq n_e + n_i, \quad \bar{\lambda}_j F_j(\bar{y}) = 0, \tag{4.1}$$

$$\begin{cases} A\bar{y} = f(x, \bar{y}(x), \bar{u}(x)) & \text{in } \Omega, \\ \partial_{n_A}\bar{y} = 0 & \text{on } \Gamma, \end{cases} \tag{4.2}$$

$$\begin{cases} A^*\bar{\varphi} = \dfrac{\partial f}{\partial y}(x, \bar{y}, \bar{u})\bar{\varphi} + \dfrac{\partial L}{\partial y}(x, \bar{y}, \bar{u}) + \displaystyle\sum_{j=1}^{n_e+n_i} \bar{\lambda}_j F'_j(\bar{y}) & \text{in } \Omega, \\ \partial_{n_{A^*}}\bar{\varphi} = 0 & \text{on } \Gamma, \end{cases} \tag{4.3}$$

and for a.e. $x \in \Omega$

$$H(x, \bar{y}(x), \bar{u}(x), \bar{\varphi}(x)) = \min_{k\in[u_a(x),u_b(x)]} H(x, \bar{y}(x), k, \bar{\varphi}(x)). \tag{4.4}$$

Proof. Let us define $H_\nu : \Omega \times \mathbb{R}^3 \longrightarrow \mathbb{R}$ by

$$H_\nu(x,y,u,\varphi) = \nu L(x,y,u) + \varphi f(x,y,u).$$

It is known (see Casas [4], Casas, Raymond, and Zidani [6], Li and Yong [16], or Mateos [17]) that there exist $\bar\nu \ge 0$, $\bar\lambda = (\bar\lambda_j)_{1\le j\le n_i+n_e}$, and functions $\bar y \in W^{1,p}(\Omega)$, $\bar\varphi \in W^{1,\min\{s',p\}}(\Omega)$ such that $(\bar\nu,\bar\lambda) \ne 0$, (4.1) and (4.2) hold, and

$$\text{(4.5)}\quad \begin{cases} A^*\bar\varphi &= \dfrac{\partial f}{\partial y}(x,\bar y,\bar u)\bar\varphi + \bar\nu\dfrac{\partial L}{\partial y}(x,\bar y,\bar u) + \displaystyle\sum_{j=1}^{n_e+n_i}\bar\lambda_j F_j'(\bar y) & \text{in } \Omega,\\ \partial_{n_{A^*}}\bar\varphi &= 0 & \text{on } \Gamma, \end{cases}$$

and

$$\text{(4.6)}\quad H_{\bar\nu}(x,\bar y(x),\bar u(x),\bar\varphi(x)) = \min_{k\in[u_a(x),u_b(x)]} H_{\bar\nu}(x,\bar y(x),k,\bar\varphi(x)) \ \text{ for a.e. } x\in\Omega.$$

In the case $\bar\nu > 0$, we can rename $\bar\lambda/\bar\nu$ by $\bar\lambda$ and obtain (4.1)–(4.5). So it is enough to prove that $\bar\nu \ne 0$. Let us argue by contradiction and let us suppose that $\bar\nu = 0$. Since $H_{\bar\nu}$ is C^1 with respect to $(y,u) \in \mathbb{R}\times\mathbb{R}$, we deduce from (4.6) and Theorem 2.7 that for every $u_a \le u \le u_b$

$$\sum_{j=1}^{n_i+n_e}\bar\lambda_j G_j'(\bar u)(u-\bar u) = \int_\Omega \frac{\partial H_{\bar\nu}}{\partial u}(x,\bar y(x),\bar u(x),\bar\varphi(x))(u(x)-\bar u(x))\,dx \ge 0.$$

Let us take $\bar h_j$ as defined in assumption (3.1) and $|\rho| < \varepsilon$ small enough such that $u_a \le u = \bar u + \rho\bar h_j \le u_b$; then

$$\rho\bar\lambda_j = \sum_{i=1}^{n_i+n_e}\bar\lambda_i G_i'(\bar u)(u-\bar u) \ge 0.$$

By taking ρ positive and negative, respectively, we get that $\bar\lambda_j = 0$ for every $j \in I_0$. So we have the contradiction with the fact that $(\bar\nu,\bar\lambda) \ne 0$. ∎

Let us notice that

$$\text{(4.7)}\quad \begin{cases} d(x) = \dfrac{\partial H}{\partial u}(x,\bar y(x),\bar u(x),\bar\varphi(x)),\\[2ex] \dfrac{\partial\mathcal{L}}{\partial u}(\bar u,\bar\lambda)h = \displaystyle\int_\Omega \frac{\partial H}{\partial u}(x,\bar y(x),\bar u(x),\bar\varphi(x))h(x)\,dx. \end{cases}$$

As an immediate consequence of Pontryagin's principle, Theorem 3.1, and Remark 3.7, we obtain the necessary first and second order optimality conditions as follows.

COROLLARY 4.2. *Suppose that $\bar u$ is a local solution for problem* (**P**). *Suppose also that assumptions* **(A1)**–**(A3)** *and the regularity assumption* (3.1) *hold. Then there exist real numbers $\bar\lambda_j$, $j = 1,\dots,n_i+n_e$, and functions $\bar y \in W^{1,p}(\Omega)$, $\bar\varphi \in W^{1,\min\{s',p\}}(\Omega)$ such that* (4.1)–(4.3) *hold as well as the following relations:*

$$\text{(4.8)}\quad \frac{\partial H}{\partial u}(x,\bar y(x),\bar u(x),\bar\varphi(x))(k-\bar u(x)) \ge 0 \ \textit{for all } u_a(x)\le k\le u_b(x), \ \textit{for a.e. } x\in\Omega,$$

$$\text{(4.9)}\quad \frac{\partial^2\mathcal{L}}{\partial u^2}(\bar u,\bar\lambda)h^2 \ge 0 \ \textit{for all } h\in C^0_{\bar u,L^2(\Omega)},$$

and

$$\frac{\partial^2 H}{\partial u^2}(x,\bar{y}(x),\bar{u}(x),\bar{\varphi}(x)) \geq 0 \text{ for a.e. } x \in \Omega \setminus \Omega^0. \tag{4.10}$$

Let us notice that

$$\frac{\partial H}{\partial u}(x,\bar{y}(x),\bar{u}(x),\bar{\varphi}(x)) = d(x) = 0, \quad x \in \Omega \setminus \Omega^0.$$

Then it is enough to use elementary calculus to deduce (4.10) from (4.4) and the above equality.

In finite dimension, the first order optimality conditions and the strict positivity of the second derivative of the Lagrangian with respect to u on $C^0_{\bar{u}}$ are sufficient conditions for a local minimum. The argument of the proof uses in an essential way the compactness of the balls in finite dimension. To extend this argumentation to infinite-dimensional optimization problems, Bonnans and Zidani [2] made the assumption that the second derivative of the Lagrangian with respect to u was a Legendre form. Let us recall that a quadratic form Q on a Hilbert space X is said to be a Legendre form if it is weakly lower semicontinuous, and for every sequence $\{x_k\} \subset X$ that converges weakly $x_k \rightharpoonup x$ and such that $Q(x_k) \to Q(x)$, we have that $x_k \to x$ strongly. Unfortunately this assumption is not fulfilled, in general, in the context of control theory. We follow a different approach to achieve the same result. Along with the strict positivity of the second derivative of the Lagrangian, we assume that the second derivative of the Hamiltonian with respect to u is strictly positive on $\Omega \setminus \Omega^\tau$, for $\tau > 0$, which is not far from the necessary condition provided in (4.10). More precisely, we have the following result.

THEOREM 4.3. *Let $\bar{u}$ be an admissible control for problem* (**P**) *satisfying* **(A1)**–**(A3)**, *the regularity assumption* (3.1), *and* (4.1)–(4.4) *for some $\bar{\lambda}_j$, $j = 1, \dots, n_i + n_e$. Let us suppose also that there exist $\omega > 0$ and $\tau > 0$ such that*

$$\begin{cases} \dfrac{\partial^2 H}{\partial u^2}(x,\bar{y}(x),\bar{u}(x),\bar{\varphi}(x)) \geq \omega \text{ for a.e. } x \in \Omega \setminus \Omega^\tau, \\ \\ \dfrac{\partial^2 \mathcal{L}}{\partial u^2}(\bar{u},\bar{\lambda})h^2 > 0 \text{ for all } h \in C^0_{\bar{u},L^2(\Omega)} \setminus \{0\}. \end{cases} \tag{4.11}$$

Then there exist $\varepsilon > 0$ and $\alpha > 0$ such that $J(\bar{u}) + \alpha\|u - \bar{u}\|^2_{L^2(\Omega)} \leq J(u)$ for all admissible control u with $\|u - \bar{u}\|_{L^\infty(\Omega)} \leq \varepsilon$.

Proof. We will argue by contradiction. The proof is divided into five steps.

(i) *Definition of a sequence $\{h_k\}$ of the unit sphere of $L^2(\Omega)$ converging weakly to h.* Let us suppose that the theorem is false. Then there exists a sequence $\{u_k\}$ of admissible controls with $u_k \to \bar{u}$ in $L^\infty(\Omega)$ such that

$$J(\bar{u}) + \frac{1}{k}\|u_k - \bar{u}\|^2_{L^2(\Omega)} > J(u_k). \tag{4.12}$$

Let us set $\delta_k = \|u_k - \bar{u}\|_{L^2(\Omega)}$ and

$$h_k = \frac{u_k - \bar{u}}{\delta_k}.$$

Since $\|h_k\|_{L^2(\Omega)} = 1$ for every k, there exists a subsequence of $\{h_k\}$, which will be denoted in the same way, and $h \in L^2(\Omega)$ such that $h_k \rightharpoonup h$ weakly in $L^2(\Omega)$.

(ii) $\frac{\partial \mathcal{L}}{\partial u}(\bar{u},\bar{\lambda})h = 0$. Let us denote $y_k = y_{u_k}$. Since u_k is admissible, we have that

$$F_j(y_k) = 0 \ \text{ if } \ 1 \le j \le n_e$$

and

$$F_j(y_k) \le 0 \ \text{ if } \ n_e + 1 \le j \le n_e + n_i.$$

Since $\bar{\lambda}_j \ge 0$ if $n_e + 1 \le j \le n_e + n_i$, we have that

$$\bar{\lambda}_j F_j(y_k) \le 0 \ \text{ for } \ 1 \le j \le n_e + n_i.$$

On the other hand $\bar{\lambda}_j F_j(\bar{y}) = 0$. Hence (4.12) implies

$$\mathcal{L}(\bar{u},\bar{\lambda}) + \frac{1}{k}\|u_k - \bar{u}\|^2_{L^2(\Omega)} > \mathcal{L}(u_k,\bar{\lambda}). \tag{4.13}$$

Moreover, h satisfies the sign condition in (3.10), because every h_k satisfies it, and the set of functions that satisfy the sign condition in (3.10) is convex and closed in $L^2(\Omega)$, and therefore weakly closed. Furthermore

$$\mathcal{L}(u_k,\bar{\lambda}) = \mathcal{L}(\bar{u},\bar{\lambda}) + \delta_k \frac{\partial \mathcal{L}}{\partial u}(v_k,\bar{\lambda})h_k,$$

where v_k is an intermediate point between $\bar{u}$ and u_k. Using (4.13) and that $\delta_k > 0$, we have that

$$\frac{\partial \mathcal{L}}{\partial u}(v_k,\bar{\lambda})h_k < \frac{1}{k\delta_k}\|u_k - \bar{u}\|^2_{L^2(\Omega)} = \frac{1}{k}\|u_k - \bar{u}\|_{L^2(\Omega)}.$$

This expression can be written as follows:

$$\int_\Omega \left(\frac{\partial L}{\partial u}(x, y_{v_k}, v_k) + \varphi_{v_k} \frac{\partial f}{\partial u}(x, y_{v_k}, v_k) \right) h_k dx < \frac{1}{k}\|u_k - \bar{u}\|_{L^2(\Omega)}, \tag{4.14}$$

where y_{v_k} and φ_{v_k} are, respectively, the state and adjoint state associated to v_k. The conditions imposed on F_j and the uniform convergence $v_k \to \bar{u}$ imply the convergences $y_{v_k} \to \bar{y}$ uniformly and $\varphi_{v_k} \to \bar{\varphi}$ in $L^2(\Omega)$. Using **(A1)**, **(A2)**, and the weak convergence $h_k \rightharpoonup h$ in $L^2(\Omega)$, we can pass to the limit in (4.14) and obtain

$$\frac{\partial \mathcal{L}}{\partial u}(\bar{u},\bar{\lambda})h \le 0. \tag{4.15}$$

On the other hand, from (4.7), (4.8), and $h_k = (u_k - \bar{u})/\delta_k$, with $\delta_k > 0$ and $u_a \le u_k \le u_b$, we get

$$\frac{\partial \mathcal{L}}{\partial u}(\bar{u},\bar{\lambda})h_k \ge 0.$$

Taking the limit we obtain

$$\frac{\partial \mathcal{L}}{\partial u}(\bar{u},\bar{\lambda})h \ge 0. \tag{4.16}$$

So (4.15) and (4.16) lead to

$$\frac{\partial \mathcal{L}}{\partial u}(\bar{u},\bar{\lambda})h = 0. \tag{4.17}$$

(iii) $h \in C^0_{\bar{u},L^2(\Omega)}$. First we check that

$$F_j'(\bar{y})z_h = 0 \text{ if } \begin{cases} j \le n_e \\ \text{or} \\ j > n_e,\ F_j(\bar{y}) = 0,\ \bar{\lambda}_j > 0, \end{cases}$$

and

$$F_j'(\bar{y})z_h \le 0 \text{ if } j > n_e,\ F_j(\bar{y}) = 0,\ \bar{\lambda}_j = 0.$$

If $j \le n_e$, then $F_j(y_k) = F_j(y_{\bar{u}+\delta_k h_k}) = 0$ and $F_j(\bar{y}) = 0$. Therefore

$$0 = \frac{F_j(y_{\bar{u}+\delta_k h_k}) - F_j(\bar{y})}{\delta_k},$$

and taking the limit we obtain with the help of assumption **(A3)**

$$F_j'(\bar{y})z_h = 0.$$

If $j > n_e$ and $F_j(\bar{y}) = 0$, we have that $F_j(y_k) = F_j(y_{\bar{u}+\delta_k h_k}) \le 0$. So

$$0 \ge \frac{F_j(y_{\bar{u}+\delta_k h_k}) - F_j(\bar{y})}{\delta_k},$$

and once again taking the limit as before we deduce

$$F_j'(\bar{y})z_h \le 0.$$

Let us see what happens when $\bar{\lambda}_j > 0$. Taking into account (4.12) and that $\delta_k = \|u_k - \bar{u}\|_{L^2(\Omega)}$, we get

$$\frac{\delta_k}{k} \ge \frac{J(u_k) - J(\bar{u})}{\delta_k} = \frac{J(\bar{u} + \delta_k h_k) - J(\bar{u})}{\delta_k}.$$

Since $\delta_k \to 0$, by passing to the limit in this expression, it follows that

$$0 \ge J'(\bar{u})h.$$

Using (4.17) and the expression for the derivative of the Lagrangian, we now have that

$$0 = J'(\bar{u})h + \sum_{j=1}^{n_e+n_i} \bar{\lambda}_j F_j'(\bar{y})z_h.$$

Taking into account that if $j \le n_e$, then we have already proved the equalities $F_j'(\bar{y})z_h = 0$, and that if $F_j(\bar{y}) < 0$, then $\bar{\lambda}_j = 0$, we have that

$$0 = J'(\bar{u})h + \sum_{j \in I_1} \bar{\lambda}_j F_j'(\bar{y})z_h,$$

where

$$I_1 = \{j : n_e < j \le n_e + n_i;\ F_j(\bar{y}) = 0;\ \bar{\lambda}_j > 0\}.$$

So

$$0 \le -J'(\bar u)h = \sum_{j\in I_1} \bar\lambda_j F_j'(\bar y) z_h \le 0.$$

Thus, if $j \in I_1$, then necessarily $F_j'(\bar y)z_h = 0$. To conclude the proof of the inclusion $h \in C^0_{\bar u, L^2(\Omega)}$ it remains to check that $h(x) = 0$ for a.e. $x \in \Omega^0$. As signaled above, h satisfies the sign condition; then we have that $d(x)h(x) \ge 0$ for a.e. $x \in \Omega$; recall (3.7). Therefore

$$\int_\Omega |d(x)h(x)|\,dx = \int_\Omega d(x)h(x)\,dx = \frac{\partial \mathcal{L}}{\partial u}(\bar u, \bar\lambda)h = 0,$$

which implies $h(x) = 0$ in a.e. Ω^0 and $h \in C^0_{\bar u, L^2(\Omega)}$.

(iv) $h = 0$. Due to the assumption of the theorem, we have that

$$\frac{\partial^2 \mathcal{L}}{\partial u^2}(\bar u, \bar\lambda)h^2 > 0 \quad \text{if} \quad h \ne 0. \tag{4.18}$$

Let us prove that the reverse inequality is satisfied, which will lead to the identity $h = 0$. By applying the mean value theorem we get

$$\mathcal{L}(u_k, \bar\lambda) = \mathcal{L}(\bar u, \bar\lambda) + \delta_k \frac{\partial \mathcal{L}}{\partial u}(\bar u, \bar\lambda)h_k + \frac{\delta_k^2}{2}\frac{\partial^2 \mathcal{L}}{\partial u^2}(w_k, \bar\lambda)h_k^2, \tag{4.19}$$

where w_k is an intermediate point between u_k and $\bar u$. In order to simplify the expression of the derivatives of $\mathcal{L}$, let us introduce some notation:

$$\bar H_u(x) = \frac{\partial H}{\partial u}(x, \bar y(x), \bar u(x), \bar\varphi(x)),$$

$$\bar H_{uu}(x) = \frac{\partial^2 H}{\partial u^2}(x, \bar y(x), \bar u(x), \bar\varphi(x)).$$

Analogously we define $\bar H_{uy}$ or $\bar H_{yy}$. Inserting this notation into the expressions of the derivatives of $\mathcal{L}$ given in (3.5) and (3.12), we get

$$\delta_k \frac{\partial \mathcal{L}}{\partial u}(\bar u, \bar\lambda)h_k + \frac{\delta_k^2}{2}\frac{\partial^2 \mathcal{L}}{\partial u^2}(\bar u, \bar\lambda)h_k^2 = \delta_k \int_\Omega \bar H_u(x)h_k(x)\,dx + \frac{\delta_k^2}{2}\int_\Omega \bar H_{uu}(x)h_k^2(x)\,dx$$

$$+ \frac{\delta_k^2}{2}\left[\int_\Omega \bar H_{yy}(x)z_{h_k}^2(x)\,dx + 2\int_\Omega \bar H_{yu}(x)h_k(x)z_{h_k}(x)\,dx + \sum_{j=1}^{n_e+n_i} \bar\lambda_j F_j''(\bar y)z_{h_k}^2\right].$$

Taking into account that $\bar H_u(x) = d(x) = 0$ in $\Omega \setminus \Omega^0$,

$$A_k = \delta_k \int_\Omega \bar H_u(x)h_k(x)\,dx + \frac{\delta_k^2}{2}\int_\Omega \bar H_{uu}(x)h_k^2(x)\,dx = \delta_k \int_{\Omega^0\setminus\Omega^\tau} \bar H_u(x)h_k(x)\,dx$$

$$+ \delta_k \int_{\Omega^\tau} \bar H_u(x)h_k(x)\,dx + \frac{\delta_k^2}{2}\int_{\Omega^\tau} \bar H_{uu}(x)h_k^2(x)\,dx + \frac{\delta_k^2}{2}\int_{\Omega\setminus\Omega^\tau} \bar H_{uu}(x)h_k^2(x)\,dx.$$

Using now that $\bar{H}_u(x)h_k(x) \geq 0$ for a.e. $x \in \Omega$ and $\bar{H}_u(x) \geq \tau$ for a.e. $x \in \Omega^\tau$, we have that

$$A_k \geq \delta_k \tau \int_{\Omega^\tau} |h_k(x)|\, dx + \frac{\delta_k^2}{2} \int_{\Omega^\tau} \bar{H}_{uu}(x) h_k^2(x)\, dx + \frac{\delta_k^2}{2} \int_{\Omega \setminus \Omega^\tau} \bar{H}_{uu}(x) h_k^2(x)\, dx.$$

Since $\|\delta_k h_k\|_{L^\infty(\Omega)} = \|u_k - \bar{u}\|_{L^\infty(\Omega)} < \varepsilon$, then for a.e. $x \in \Omega$, $\delta_k |h_k(x)| \leq \varepsilon$. Therefore

$$\frac{\delta_k^2 h_k^2(x)}{\varepsilon} \leq \delta_k |h_k(x)|.$$

Hence

$$A_k \geq \frac{\delta_k^2}{2} \int_{\Omega^\tau} \left(\frac{2\tau}{\varepsilon} + \bar{H}_{uu}(x) \right) h_k^2(x)\, dx + \frac{\delta_k^2}{2} \int_{\Omega \setminus \Omega^\tau} \bar{H}_{uu}(x) h_k^2(x)\, dx.$$

Now, from (4.13), (4.19) and taking into account the previous considerations, we have

$$\begin{aligned} \frac{\delta_k^2}{k} &> \delta_k \frac{\partial \mathcal{L}}{\partial u}(\bar{u}, \bar{\lambda}) h_k + \frac{\delta_k^2}{2} \frac{\partial^2 \mathcal{L}}{\partial u^2}(w_k, \bar{\lambda}) h_k^2 \\ &= \delta_k \frac{\partial \mathcal{L}}{\partial u}(\bar{u}, \bar{\lambda}) h_k + \frac{\delta_k^2}{2} \frac{\partial^2 \mathcal{L}}{\partial u^2}(\bar{u}, \bar{\lambda}) h_k^2 + \frac{\delta_k^2}{2} \left[\frac{\partial^2 \mathcal{L}}{\partial u^2}(w_k, \bar{\lambda}) h_k^2 - \frac{\partial^2 \mathcal{L}}{\partial u^2}(\bar{u}, \bar{\lambda}) h_k^2 \right] \\ &\geq \frac{\delta_k^2}{2} \int_{\Omega^\tau} \left(\frac{2\tau}{\varepsilon} + \bar{H}_{uu}(x) \right) h_k^2(x)\, dx + \frac{\delta_k^2}{2} \int_{\Omega \setminus \Omega^\tau} \bar{H}_{uu}(x) h_k^2(x) dx \\ &+ \frac{\delta_k^2}{2} \left[\int_\Omega \bar{H}_{yy}(x) z_{h_k}^2(x)\, dx + 2 \int_\Omega \bar{H}_{yu}(x) h_k(x) z_{h_k}(x)\, dx + \sum_{j=1}^{n_e+n_i} \bar{\lambda}_j F''(\bar{y}) z_{h_k}^2 \right] \\ &+ \frac{\delta_k^2}{2} \left[\frac{\partial^2 \mathcal{L}}{\partial u^2}(w_k, \bar{\lambda}) h_k^2 - \frac{\partial^2 \mathcal{L}}{\partial u^2}(\bar{u}, \bar{\lambda}) h_k^2 \right]. \end{aligned} \tag{4.20}$$

Taking into account the assumptions made on the second derivatives of the functions, there exists a constant $C_H > 0$ such that $\bar{H}_{uu}(x) \geq -C_H$ for a.e. $x \in \Omega$. So, taking ε small enough, we have that

$$\frac{2\tau}{\varepsilon} + \bar{H}_{uu}(x) \geq \frac{2\tau}{\varepsilon} - C_H > 0 \text{ for a.e. } x \in \Omega.$$

Thus

$$\liminf_{k \to \infty} \int_{\Omega^\tau} \left(\frac{2\tau}{\varepsilon} + \bar{H}_{uu}(x) \right) h_k^2(x) dx \geq \int_{\Omega^\tau} \left(\frac{2\tau}{\varepsilon} + \bar{H}_{uu}(x) \right) h^2(x) dx.$$

Moreover, in $\Omega \setminus \Omega^\tau$, $\bar{H}_{uu}(x) > \omega > 0$, and then

$$\liminf_{k \to \infty} \int_{\Omega \setminus \Omega^\tau} \bar{H}_{uu}(x) h_k^2(x)\, dx \geq \int_{\Omega \setminus \Omega^\tau} \bar{H}_{uu}(x) h^2(x)\, dx.$$

Now dividing (4.20) by $\delta_k^2/2$ and using (3.14) and assumption **(A3)**, we can take the lower limit of the resulting expression and obtain

$$\begin{aligned} 0 &\geq \int_{\Omega^\tau} \left(\frac{2\tau}{\varepsilon} + \bar{H}_{uu}(x) \right) h^2(x)\, dx + \int_{\Omega \setminus \Omega^\tau} \bar{H}_{uu}(x) h^2(x)\, dx \\ &+ \int_\Omega \bar{H}_{yy}(x) z_h^2(x)\, dx + 2 \int_\Omega \bar{H}_{yu}(x) h(x) z_h(x)\, dx + \sum_{j=1}^{n_e+n_i} \bar{\lambda}_j F_j''(\bar{y}) z_h^2 \\ &= \frac{2\tau}{\varepsilon} \int_\Omega h^2(x)\, dx + \frac{\partial^2 \mathcal{L}}{\partial u^2}(\bar{u}, \bar{\lambda}) h^2. \end{aligned}$$

Combining this inequality with (4.18) we deduce that $h = 0$.

(v) $h_k \to 0$ *strongly in* $L^2(\Omega)$. We have that $h_k \rightharpoonup h = 0$ weakly in $L^2(\Omega)$, and consequently $z_{h_k} \to 0$ strongly in $W^{1,q}(\Omega)$. Therefore again dividing (4.20) by $\delta_k^2/2$ and using (3.14) we get

$$\begin{aligned}
&\min\left\{\omega, \frac{2\tau}{\varepsilon} - C_H\right\} \limsup_{k\to\infty} \int_\Omega h_k^2(x)dx \\
&\leq \limsup_{k\to\infty} \left\{ \int_{\Omega^\tau} \left(\frac{2\tau}{\varepsilon} + \bar{H}_{uu}(x)\right) h_k^2(x)\,dx + \int_{\Omega\setminus\Omega^\tau} \bar{H}_{uu}(x) h_k^2(x)dx \right\} \\
&\leq \limsup_{k\to\infty} \left\{ \frac{1}{k} - \left[\int_\Omega \bar{H}_{yy}(x) z_{h_k}^2(x)\,dx + 2\int_\Omega \bar{H}_{yu}(x) h_k(x) z_{h_k}(x)\,dx + \sum_{j=1}^{n_e+n_i} \bar{\lambda}_j F''(\bar{y}) z_{h_k}^2 \right] \right. \\
&\qquad \left. - \left[\frac{\partial^2 \mathcal{L}}{\partial u^2}(w_k, \bar{\lambda}) h_k^2 - \frac{\partial^2 \mathcal{L}}{\partial u^2}(\bar{u}, \bar{\lambda}) h_k^2 \right] \right\} = 0.
\end{aligned}$$

Hence

$$\lim_{k\to\infty} \|h_k\|_{L^2(\Omega)} = 0.$$

But $\|h_k\|_{L^2(\Omega)} = 1$ for every k. So we have achieved the contradiction. ∎

The next theorem shows the equivalence of (3.20) and (4.11).

THEOREM 4.4. *Let $\bar{u}$ be an admissible control for problem* (**P**) *that satisfies* **(A1)**–**(A3)**, *the regularity assumption* (3.1), *and* (4.1)–(4.4). *Then the following two statements are equivalent:*

(1) *There exist $\delta > 0$ and $\tau' > 0$ such that*

$$\frac{\partial^2 \mathcal{L}}{\partial u^2}(\bar{u}, \bar{\lambda}) h^2 \geq \delta \|h\|_{L^2(\Omega)}^2 \text{ for all } h \in C_{\bar{u}, L^2(\Omega)}^{\tau'}. \tag{4.21}$$

(2) *There exist $\omega > 0$ and $\tau > 0$ such that*

$$\begin{cases} \dfrac{\partial^2 H}{\partial u^2}(x, \bar{y}(x), \bar{u}(x), \bar{\varphi}(x)) \geq \omega \text{ for a.e. } x \in \Omega \setminus \Omega^\tau, \\ \dfrac{\partial^2 \mathcal{L}}{\partial u^2}(\bar{u}, \bar{\lambda}) h^2 > 0 \text{ for all } h \in C_{\bar{u}, L^2(\Omega)}^0 \setminus \{0\}. \end{cases} \tag{4.22}$$

Proof. (1) $\Longrightarrow$ (2). Since $C_{\bar{u}, L^2(\Omega)}^0 \subset C_{\bar{u}, L^2(\Omega)}^{\tau'}$, the second inequality of (4.22) is an obvious consequence of (4.21). Let us prove the existence of ω and τ satisfying the first inequality of (4.22). Let us take $\alpha > 0$ and $\varepsilon > 0$, as in Theorem 3.5, and consider the problem

$$(P_\alpha) \begin{cases} \text{Minimize } J_\alpha(u) = J(u) - \frac{\alpha}{2}\|u - \bar{u}\|_{L^2(\Omega)}^2, \\ u_a(x) \leq u(x) \leq u_b(x) \text{ for a.e. } x \in \Omega, \\ G_j(u) = 0,\ 1 \leq j \leq n_e, \\ G_j(u) \leq 0,\ n_e + 1 \leq j \leq n_e + n_i. \end{cases}$$

Then for any feasible point u of this problem, with $\|u - \bar{u}\|_\infty < \varepsilon$ and $u \neq \bar{u}$, we have

$$J_\alpha(\bar{u}) = J(\bar{u}) \leq J(u) - \alpha\|u - \bar{u}\|_{L^2(\Omega)}^2 < J(u) - \frac{\alpha}{2}\|u - \bar{u}\|_{L^2(\Omega)}^2 = J_\alpha(u).$$

Then $\bar{u}$ is the unique solution of (P_α) in the $L^\infty(\Omega)$-ball $B_\varepsilon(\bar{u})$. The Hamiltonian for problem (P_α) is

$$H^\alpha(x,y,u,\varphi) = H(x,y,u,\varphi) - \frac{\alpha}{2}(u-\bar{u}(x))^2.$$

Therefore we can apply Corollary 4.2 to (P_α) and deduce, with the notation of the proof of Theorem 4.3, that

$$\bar{H}_{uu}(x) - \alpha = \bar{H}^\alpha_{uu}(x) \geq 0 \quad \text{for a.e. } x \in \Omega \setminus \Omega^0,$$

which implies

$$\bar{H}_{uu}(x) \geq \alpha > 0 \quad \text{for a.e. } x \in \Omega \setminus \Omega^0. \tag{4.23}$$

In the case in which the bound constraints on the control are not active, i.e., $u_a(x) < \bar{u}(x) < u_b(x)$ a.e., then the Lebesgue measure of Ω^0 is zero; hence (4.23) implies the first inequality of (4.22). Let us analyze the case where Ω^0 has a strictly positive Lebesgue measure. We will proceed by contradiction and we assume that there exist no $\omega > 0$ and $\tau > 0$ such that (4.22) is satisfied. Then we define for every $k \geq 1$

$$\hat{h}_k(x) = \begin{cases} +1 & \text{if } |d(x)| \leq 1/k,\ \bar{H}_{uu}(x) < 1/k, \text{ and } \bar{u}(x) = u_a(x), \\ -1 & \text{if } |d(x)| \leq 1/k,\ \bar{H}_{uu}(x) < 1/k, \text{ and } \bar{u}(x) = u_b(x), \\ 0 & \text{otherwise.} \end{cases}$$

Since (4.22) is not satisfied for $\omega = 1/k$ and $\tau = 1/k$, with arbitrarily large k, and the measure of Ω^0 is not zero, we have that $\hat{h}_k \neq 0$. Then we define $\tilde{h}_k = \hat{h}_k / \|\hat{h}_k\|_{L^2(\Omega)}$. Let us prove that $\tilde{h}_k \rightharpoonup 0$ weakly in $L^2(\Omega)$. From (4.23) we deduce that the set

$$B = \{x \in \Omega : |d(x)| = 0 \ \text{ and } \ \bar{H}_{uu}(x) \leq 0\}$$

has zero Lebesgue measure. Therefore

$$\bigcap_{k=1}^{\infty} \mathrm{supp}\{\tilde{h}_k\} \subset B \Rightarrow \mathrm{measure}\left(\bigcap_{k=1}^{\infty} \mathrm{supp}\{\tilde{h}_k\}\right) \leq \mathrm{measure}(B) = 0.$$

Taking into account that $\mathrm{supp}\{\tilde{h}_k\} \subset \mathrm{supp}\{\tilde{h}_{k'}\}$ for every $k > k'$, we deduce that $\tilde{h}_k(x) \to 0$ pointwise a.e. in Ω. On the other hand, $\{\tilde{h}_k\}_{k=1}^\infty$ is bounded in $L^2(\Omega)$; consequently $\tilde{h}_k \rightharpoonup 0$ weakly in $L^2(\Omega)$; see Hewitt and Stromberg [14, p. 207]. Furthermore for $\tau' > 1/k$ we have that $\tilde{h}_k(x) = 0$ for every $x \in \Omega^{\tau'}$ and $\tilde{h}_k$ satisfies the sign condition of (3.10). Let us define a new function $h_k \in C^{\tau'}_{\bar{u},L^2(\Omega)}$ close to $\tilde{h}_k$. Using the functions $\{\bar{h}_j\}_{j\in I_0}$ introduced in (3.1), we set

$$h_k = \tilde{h}_k - \sum_{j\in I_0} \alpha_{kj}\bar{h}_j, \quad \text{with } \ \alpha_{kj} = G'_j(\bar{u})\tilde{h}_k.$$

As in the proof of Proposition 3.6, we deduce that $h_k \in C^{\tau'}_{\bar{u},L^2(\Omega)}$ for every $k > 1/\tau'$. Moreover, since $\tilde{h}_k \rightharpoonup 0$ weakly in $L^2(\Omega)$, we deduce that $\alpha_{kj} \to 0$, and therefore $h_k \rightharpoonup 0$ weakly in $L^2(\Omega)$. On the other hand, since $\mathrm{supp}\{\tilde{h}_k\}$ is included in the set

of points of Ω where the bound constraints on the control are active, which has an empty intersection with the support of each $\bar{h}_j$ $(j \in I_0)$,

$$\|h_k\|_{L^2(\Omega)} = \left\{ \int_{\operatorname{supp}\{\tilde{h}_k\}} h_k^2 \, dx + \int_{\Omega \setminus \operatorname{supp}\{\tilde{h}_k\}} h_k^2 \, dx \right\}^{\frac{1}{2}}$$

$$= \left\{ \int_{\operatorname{supp}\{\tilde{h}_k\}} \tilde{h}_k^2 \, dx + \int_{\Omega \setminus \operatorname{supp}\{\tilde{h}_k\}} \left(\sum_{j \in I_0} \alpha_{kj} \bar{h}_j \right)^2 dx \right\}^{\frac{1}{2}}$$

$$= \left\{ \|\tilde{h}_k\|^2_{L^2(\Omega)} + \| \sum_{j \in I_0} \alpha_{kj} \bar{h}_j \|^2_{L^2(\Omega)} \right\}^{\frac{1}{2}} \geq \left\{ 1 - 2 \sum_{j \in I_0} \alpha_{kj}^2 \|\bar{h}_j\|^2_{L^2(\Omega)} \right\}^{\frac{1}{2}} \overset{k \to \infty}{\longrightarrow} 1.$$

From this relation and (4.21) with $h = h_k$, we get

$$\delta \leq \delta \liminf_{k \to \infty} \|h_k\|^2_{L^2(\Omega)} \leq \liminf_{k \to \infty} \frac{\partial^2 \mathcal{L}}{\partial u^2}(\bar{u}, \bar{\lambda}) h_k^2. \tag{4.24}$$

On the other hand, the weak convergence $h_k \rightharpoonup 0$ in $L^2(\Omega)$ implies the strong convergence in $(W^{1,q'}(\Omega))'$, and thanks to Lemma 2.4 we deduce $z_{h_k} \to 0$ in $W^{1,q}(\Omega) \subset L^2(\Omega)$ strongly. Writing the second derivative of the Lagrangian in terms of the derivatives of the Hamiltonian, as was done in the proof of Theorem 4.3, and taking into account that $\bar{H}_{uu}(x) < 1/k$ in the support of $\tilde{h}_k$ and $\alpha_{kj} \to 0$, we get

$$\liminf_{k \to \infty} \frac{\partial^2 \mathcal{L}}{\partial u^2}(\bar{u}, \bar{\lambda}) h_k^2 \leq \limsup_{k \to \infty} \int_\Omega \bar{H}_{uu}(x) h_k^2(x) \, dx + \limsup_{k \to \infty} \int_\Omega \bar{H}_{yy}(x) z_{h_k}^2(x) \, dx$$

$$+ 2 \limsup_{k \to \infty} \int_\Omega \bar{H}_{yu}(x) h_k(x) z_{h_k}(x) \, dx + \limsup_{k \to \infty} \left(\sum_{j=1}^{n_e + n_i} \bar{\lambda}_j F_j''(\bar{y}) z_{h_k}^2 \right)$$

$$\leq \limsup_{k \to \infty} \int_{\operatorname{supp}\{\tilde{h}_k\}} \bar{H}_{uu}(x) h_k^2(x) \, dx + \limsup_{k \to \infty} \int_{\Omega \setminus \operatorname{supp}\{\tilde{h}_k\}} \bar{H}_{uu}(x) h_k^2(x) \, dx$$

$$\leq \limsup_{k \to \infty} \frac{1}{k} \int_{\operatorname{supp}\{\tilde{h}_k\}} \tilde{h}_k^2(x) \, dx + \limsup_{k \to \infty} \int_{\Omega \setminus \operatorname{supp}\{\tilde{h}_k\}} \bar{H}_{uu}(x) \left[\sum_{j \in I_0} \alpha_{kj} \bar{h}_j(x) \right]^2 dx$$

$$= \limsup_{k \to \infty} \frac{1}{k} \int_\Omega \tilde{h}_k^2(x) \, dx = \lim_{k \to \infty} \frac{1}{k} = 0,$$

which contradicts (4.24).

(2) $\Longrightarrow$ (1). Let us suppose that (4.21) is not satisfied. Then for every $\tau' > 0$ there exists $h_{\tau'} \in C^{\tau'}_{\bar{u}, L^2(\Omega)}$ such that $\|h_{\tau'}\|_{L^2(\Omega)} = 1$ and

$$\frac{\partial^2 \mathcal{L}}{\partial u^2}(\bar{u}, \bar{\lambda}) h_{\tau'}^2 < \tau'.$$

Since $\{h_{\tau'}\}$ is bounded in $L^2(\Omega)$, there exists a subsequence, denoted in the same way, such that $h_{\tau'} \rightharpoonup h$ weakly in $L^2(\Omega)$. We have that $h \in C^0_{\bar{u}, L^2(\Omega)}$. Indeed relations (3.10) are obtained for h by passing to the limit in the corresponding ones satisfied

by $h_{\tau'}$. Let us see that $h(x) = 0$ in Ω^0:

$$\int_\Omega |h(x)||d(x)|\,dx = \int_\Omega h(x)d(x)\,dx = \lim_{\tau'\to 0}\int_\Omega h_{\tau'}(x)d(x)\,dx$$
$$= \lim_{\tau'\to 0}\int_{\Omega\setminus\Omega^{\tau'}} |h_{\tau'}(x)||d(x)|\,dx$$
$$\le \lim_{\tau'\to 0}\tau'\int_\Omega |h_{\tau'}(x)|\,dx \le \lim_{\tau'\to 0}\tau'\sqrt{m(\Omega)}\|h_{\tau'}\|_{L^2(\Omega)} = 0;$$

hence $h(x)d(x) = 0$, and therefore $h(x) = 0$ for a.e. $x \in \Omega^0$.

Since $\bar H_{uu}(x) \ge \omega > 0$ in $\Omega \setminus \Omega^\tau$, $(\Omega \setminus \Omega^{\tau'}) \subset (\Omega \setminus \Omega^\tau)$ for $\tau' < \tau$, and $h_{\tau'} = 0$ in $\Omega_{\tau'}$, we have that

$$\liminf_{k\to\infty}\int_\Omega \bar H_{uu}(x)h^2_{\tau'}(x)dx = \liminf_{k\to\infty}\int_{\Omega\setminus\Omega^{\tau'}} \bar H_{uu}(x)h^2_{\tau'}(x)dx$$
$$\ge \int_{\Omega\setminus\Omega^{\tau'}} \bar H_{uu}(x)h^2(x)dx = \int_\Omega \bar H_{uu}(x)h^2(x)dx.$$

Therefore, using the definition of $h_{\tau'}$ along with the strong convergence $z_{h_{\tau'}} \to z_h$ in $W^{1,q}(\Omega)$, we get

$$0 \ge \limsup_{\tau'\to 0}\frac{\partial^2\mathcal{L}}{\partial u^2}(\bar u,\bar\lambda)h^2_{\tau'} \ge \liminf_{\tau'\to 0}\frac{\partial^2\mathcal{L}}{\partial u^2}(\bar u,\bar\lambda)h^2_{\tau'}$$
$$= \liminf_{\tau'\to 0}\left\{\int_\Omega \bar H_{uu}(x)h^2_{\tau'}(x)\,dx + \int_\Omega \bar H_{yy}(x)z^2_{h_{\tau'}}(x)\,dx\right.$$
$$\left. + 2\int_\Omega \bar H_{yu}(x)h_{\tau'}(x)z_{h_{\tau'}}(x)\,dx + \sum_{j=1}^{n_e+n_i}\bar\lambda_j F_j''(\bar y)z^2_{h_{\tau'}}\right\} \ge \frac{\partial^2\mathcal{L}}{\partial u^2}(\bar u,\bar\lambda)h^2,$$

which, together with (4.22), implies that $h = 0$. Finally, using the weak convergence $h_{\tau'} \rightharpoonup 0$ in $L^2(\Omega)$ and the strong convergence $z_{h_{\tau'}} \to 0$ in $W^{1,q}(\Omega)$, we conclude that

$$\omega = \omega\limsup_{\tau'\to 0}\|h_{\tau'}\|^2_{L^2(\Omega)} \le \limsup_{\tau'\to 0}\int_\Omega \bar H_{uu}(x)h^2_{\tau'}(x)dx$$
$$\le \limsup_{\tau'\to 0}\left\{\frac{\partial^2\mathcal{L}}{\partial u^2}(\bar u,\bar\lambda)h^2_{\tau'}dx - \int_\Omega \bar H_{yy}(x)z^2_{h_{\tau'}}(x)\,dx\right.$$
$$\left. - 2\int_\Omega \bar H_{yu}(x)h_{\tau'}(x)z_{h_{\tau'}}(x)\,dx - \sum_{j=1}^{n_e+n_i}\bar\lambda_j F_j''(\bar y)z^2_{h_{\tau'}}\right\} \le 0,$$

and we have a contradiction. ∎

OPTIMAL CONTROL OF THE SOLID FUEL IGNITION MODEL WITH H^1-COST*

KAZUFUMI ITO† AND KARL KUNISCH‡

Abstract. Optimal control problems for the stationary as well as the time-dependent solid fuel ignition model are investigated. Existence of optimal controls is proved, and optimality systems are derived. The analysis is based on a closedness lemma for the exponential function in L^1 and a generalization of Aubin's lemma.

Key words. optimal control, control of exponential nonlinearity, explosion phenomena, optimality conditions

1. Introduction.

This paper is concerned with optimal control problems for systems governed by

$$y_t = \Delta y + \delta e^y + u \tag{1.1}$$

on the time-space domain $(0,T] \times \Omega$, together with appropriate initial and boundary conditions. Here δ is a fixed positive constant, and u denotes the control. System (1.1) arises, for example, in the theory of combustion, where it is referred to as the solid fuel ignition model [BE]. More precisely, combustion models describe rapid exothermic chemical reactions in combustible materials. The modeling process is based upon conservation of mass, species, momentum, and energy. Due to the Arrhenius law relating the production rate of reactants to their concentration and to temperature, exponential terms enter these models. Even for single one-step irreversible reactions involving fuel and an oxidant, the resulting model is a complicated system of partial differential equations for the variables temperature, density, pressure, and oxidant mass fraction; see [BE, p. 6]. The model can be significantly simplified if, instead of considering a compressible gas, one focuses on the thermal reaction formulated for a nondeformable material of constant density. Expressed in dimensionless form, this results in the following system of equations describing the combustion of a solid fuel [BE]:

$$\begin{cases} T_t = \Delta T + \epsilon\delta v^m \exp\left(\frac{T-1}{\epsilon T}\right), \\ v_t = \beta\Delta v - \epsilon\delta\Gamma v^m \exp\left(\frac{T-1}{\epsilon T}\right), \end{cases} \tag{1.2}$$

with initial and boundary conditions given, e.g., by

$$\begin{cases} T(0,\cdot) = T_0,\ v(0,\cdot) = v_0 \ \text{ in } \ \Omega, \\ T(t,x) = 1,\ \frac{\partial v}{\partial n}(t,x) = 0 \ \text{ on } \ (0,\infty) \times \partial\Omega, \end{cases} \tag{1.3}$$

where T and v denote the temperature and oxidant mass fraction, respectively. Further, β, Γ, and δ are nonnegative constants, m is the mass of a single molecule, $\frac{\partial v}{\partial n}$ stands for the outer normal to $\partial\Omega$, and $\epsilon = \frac{RT_0}{E}$, with R the gas constant, E the total energy of the system, and T_0 the temperature corresponding to an equilibrium state. Under appropriate conditions (see [BE, BK]), a first-order approximation with respect to changes in T and v is justified. We set $T = 1 + \epsilon\, y$ and $v = 1 - \epsilon\, c$, where y and c are two auxiliary quantities expressing temperature and oxidant mass fraction changes. If, further, $\epsilon \ll 1$, the equations in y and c decouple and the equation for y is obtained:

$$\begin{cases} y_t = \Delta y + \delta \exp y, \\ y(0,\cdot) = y_0 \ \text{ in } \ \Omega, \quad y(t,x) = 0 \ \text{ on } \ (0,\infty) \times \partial\Omega. \end{cases} \tag{1.4}$$

This is the uncontrolled solid fuel ignition model. In (1.1) we added a source term to describe the control mechanism. The stationary version of (1.4) is called the steady state solid fuel ignition model [BE] and is given by

$$\begin{cases} \Delta y + \delta \exp y = 0 \ \text{ in } \Omega, \\ y = 0 \ \text{ on } \partial\Omega. \end{cases} \tag{1.5}$$

Let us mention that (1.4)–(1.5) also play an important role in the study of stellar structures; we refer to [FK] and the references given there.

An additional motivation for the study of optimal control problems involving (1.1) is the recent development of diverse numerical methods for solving open loop optimal control problems for nonlinear partial differential equations. Due to the strong nonlinearity in (1.1) it serves as an excellent test example. The choice of a numerical method is guided by, among other considerations, a proper function space framework for the nonlinear optimal control problem. For (1.1) this choice is not evident. For numerical results concerning optimal control of (1.1) and its stationary version we refer to [BK, GH, KK].

Problems of existence and uniqueness for (1.4) as well as the qualitative behavior of the solutions to (1.1) are rather well understood; see [BE, F] and the references given there. Depending on δ and the dimension of Ω, the solutions to (1.4) typically exist only locally and exhibit finite time blow-up at a distinct point within the spatial domain Ω. The stationary uncontrolled equation (1.5) is also well investigated. To give the reader a taste of the multitude of properties linked with (1.5), we recall a specific result for the case in which Ω is the unit ball in $\mathbb{R}^2$: There exists a real number $\delta^* > 0$ (see [BE, F]) such that (i) if $\delta > \delta^*$, then (1.5) admits no solution; (ii) if $\delta \in (0, \delta^*)$, then there exist exactly two solutions; (iii) if $\delta = \delta^*$, then there exists exactly one solution to (1.5). Related results also hold in general domains.

Optimal control of equations with the property that they admit multiple states in the stationary case and finite blow-up in the evolutionary case are called singular control problems in [L]. Thus studying optimal control for the control system (1.1) means analyzing a singular control problem with the most severe nonlinearity. The techniques developed in [L] are not applicable to the optimal control problems of this paper. In fact most of the work in [L] is concerned with nonlinearities of the power-law type ($\pm y^3$). In this case, existence of optimal controls and optimality systems can be derived if the cost functionals are coercive (radially unbounded) in appropriate L^p-norms, with $p > 2$. This would suggest using cost functionals that are coercive with respect to the L^∞-norm. Such a choice would, however, be neither practical from the point of view of discretization and numerical realization nor mathematically

appealing. We shall demonstrate that it is possible to obtain the existence of optimal controls as well as to derive optimality conditions for the stationary and for the evolutionary case for cost functionals which are coercive in a Hilbert-space setting involving H^1-norms. Let us also point out that optimal control for (1.1) was posed as an open problem in [L, problem 25, p. 501]. The difficulty of studying just the existence problem for optimal control of (1.1) arises from the fact that a priori bounds on the control u do not imply appropriate bounds on the state y. Even if bounds on both u and y are implied by the choice of the cost functional, it is difficult to pass to the limit on minimizing subsequences in (1.1), which appears as a constraint in the optimal control problem. It is worth observing that the introduction of controls into (1.4)–(1.5) gives additional freedom since it allows the existence of control-state pairs satisfying (1.4) (resp., (1.5)) for δ values for which the uncontrolled equation does not admit a solution. Concerning optimal control of (1.1), the dynamical system behavior of (1.4) suggests that we distinguish two classes of problems. The first class of problems excludes the situation in which blow-up actually occurs. Control can be used to avoid blow-up entirely or to steer close to blow-up, but actual blow-up is avoided. Typical optimal control formulations result in tracking-type problems. The second conceivable class of control problems is the one which allows blow-up and uses control to influence blow-up time or location. No research effort so far has focused on the second class of problems.

Thus, optimal control for (1.1) is a rich subject for a well-motivated class of problems. Nevertheless only little attention has been paid to it so far. We are only aware of the two contributions [CKP] and [KK]. To cope with the exponential nonlinearity in (1.1), the cost functionals in [KK] are chosen such that they contain an exponential term. In the present paper we do not utilize such a technique. The formulation in [CKP] uses an implicit constraint on the state variable which allows the determination of an a priori bound on $\exp(y)$ for admissible (y, u) pairs if $n \geq 3$. The analysis in [CKP] is restricted to the stationary case with distributed controls. Let us also mention [GH], in which optimal control techniques based on a linearization of (1.1) are studied numerically. Newton methods for optimal control of (1.1) are treated in [IK].

The present paper develops a different framework for optimal control of (1.1), which we believe to be more practical than those in [CKP] and [KK], and which avoids linearization as used in [GH]. It is based on cost functionals that are coercive with respect to the $L^2((0,T)\times\Omega)$-norm for the control and the $L^2(0,T;H_0^1(\Omega))$-norm for the state. The impossibility of obtaining a priori estimates on y in terms of u in (1.1) requires us to employ several nonstandard methods to guarantee existence for the optimal control problems that we formulate. In the stationary case the essential technical tool consists of a closedness lemma of the exponential function in L^1-spaces; for the evolutionary case a generalization of Aubin's lemma is developed. To derive optimality systems we use a perturbation argument as well as the Zowe–Kurcyusz Lagrangian theory. Both distributed as well as boundary control problems are considered. Section 2 is devoted to optimal control problems for the time-independent version of (1.1). Section 3 focuses on optimal control for (1.1). The analysis of multigrid methods applied to the optimality systems obtained in this paper and a comparison to the approach taken in [KK] is given in [BK].

2. Stationary optimal control problems. This section is devoted to the stationary control problem

$$\min\ J(y,u) \tag{2.1}$$

subject to $(y,u) \in H_0^1(\Omega) \times L^2(\Omega)$ and

$$\left\{ \begin{array}{l} -\Delta y - \delta e^y = u \ \text{ in } \Omega, \\ y = 0 \ \text{ on } \partial\Omega, \end{array} \right. \tag{2.2}$$

with Ω a bounded domain in $\mathbb{R}^n$ with smooth boundary $\partial\Omega$ and $\delta > 0$.

It is assumed that

$$\left\{ \begin{array}{l} J : H^1(\Omega) \times L^2(\Omega) \to \mathbb{R} \text{ is bounded from below, weakly} \\ \text{ lower semicontinuous, and coercive, in the sense that} \\ J(y,u) \to \infty \ \text{ if } \ |y|_{H_0^1(\Omega)} \to \infty \text{ or } |u|_{L^2(\Omega)} \to \infty. \end{array} \right. \tag{A1}$$

A typical example for a cost functional satisfying (A1) is given by tracking functionals of the form

$$J(y,u) = \frac{1}{2} \int_\Omega |\nabla(y-z)|^2 dx + \frac{\alpha}{2} \int_\Omega |u|^2 dx,$$

with $\alpha > 0$ and $z \in H^1(\Omega)$.

The notion of a solution to (2.2) is defined next. Let $\mathcal{D}(\Omega)$ denote the space of functions in $C^\infty(\Omega)$ with compact support in Ω, endowed with the usual topology, and let $\mathcal{D}'(\Omega)$ be its topological dual. The duality pairing between $\mathcal{D}(\Omega)$ and $\mathcal{D}'(\Omega)$ is denoted by $(\cdot,\cdot)_{\mathcal{D}',\mathcal{D}}$.

DEFINITION 2.1. *For $u \in L^2(\Omega)$ a function $y \in H_0^1(\Omega)$ is called a solution to equation* (2.2) *if $e^y \in \mathcal{D}'(\Omega)$ and*

$$(\nabla y, \nabla v)_{L_n^2} - \delta(e^y, v)_{\mathcal{D}',\mathcal{D}} = (u,v) \ \text{ for all } v \in \mathcal{D}(\Omega). \tag{2.3}$$

Note that if y is a solution to (2.2), then necessarily

$$e^y \in H^{-1}(\Omega) \cap L^1(\Omega).$$

In fact $e^y \in H^{-1}(\Omega)$ follows from (2.3) and the density of $\mathcal{D}(\Omega)$ in $H_0^1(\Omega)$. Moreover, e^y is measurable and nonnegative so that $e^y \in L^1(\Omega)$, provided that $\int_\Omega e^y dx < \infty$. Set $\Omega_1 = \{x \in \Omega : y(x) \le 1\}$ and observe that from (2.3) with $v = |y|$ we have $\int_\Omega |y e^y| dx < \infty$. It follows that

$$\int_\Omega e^y dx \le \int_{\Omega_1} e^y dx + \int_{\Omega \setminus \Omega_1} \frac{1}{y} y e^y dx \le \text{ meas } \Omega + \int_\Omega |y e^y| dx < \infty,$$

and hence $e^y \in L^1(\Omega)$.

For the proof of existence of a solution to (2.1)–(2.2) we require the following lemma on maximal monotone operators in $L^1(\Omega)$ (see [Br, p. 126]).

LEMMA 2.2. *Let γ be a maximal monotone graph in $\mathbb{R} \times \mathbb{R}$, and let f_n and v_n be measurable functions from Ω to $\mathbb{R}$. Assume that $v_n \to v$ a.e. on Ω, and $f_n \to f$ weakly in $L^1(\Omega)$. If $f_n(x) \in \gamma(v_n(x))$ a.e. on Ω, then $f(x) \in \gamma(v(x))$ a.e. on Ω.*

THEOREM 2.3. *If* (A1) *holds, then* (2.1)–(2.2) *admits a solution $(y^*, u^*) \in H_0^1(\Omega) \times L^2(\Omega)$ with $e^{y^*} \in H^{-1}(\Omega) \cap L^1(\Omega)$.*

Proof. There exists a pair $(y,u) \in H_0^1(\Omega) \times L^2(\Omega)$ satisfying (2.2), and hence the feasible set for (2.1)–(2.2) is nonempty. Since by (A1) the functional J is bounded from below, there exists a minimizing sequence $(y_n, u_n) \in H_0^1(\Omega) \times L^2(\Omega)$ to (2.1)–(2.2). Due to the coercivity of J, it follows that $\{(y_n,u_n)\}_{n=1}^\infty$ is bounded in $H_0^1(\Omega) \times L^2(\Omega)$.

Since y_n is a solution to (2.2), with u replaced by u_n for every n, it follows that $\{e^{y_n}\}_{n=1}^{\infty}$ is bounded in $H^{-1}(\Omega)$. Hence there exist a subsequence of $\{(y_n, u_n, e^{y_n})\}$, denoted by the same symbol, and $(y^*, u^*, w^*) \in H_0^1(\Omega) \times L^2(\Omega) \times H^{-1}(\Omega)$ such that $y_n \rightharpoonup y^*$ in $H_0^1(\Omega), u_n^* \rightharpoonup u^*$ in $L^2(\Omega), y_n \to y^*$ a.e. in Ω, and $e^{y_n} \rightharpoonup w$ in H^{-1}. Due to the weak lower semicontinuity of J we have

$$J(y^*, u^*) \le \liminf_{n\to\infty} J(y_n, u_n),$$

and hence the proof will be complete if we show that y^* is a solution to (2.2) with $u = u^*$.

For this purpose we show that $e^{y_n} \rightharpoonup w^*$ weakly in $L^1(\Omega)$ by utilizing the Dunford–Pettis theorem. This requires us to show that the integrals $\int_\Omega |e^{y_n}| dx$ are uniformly absolutely convergent. Due to the boundedness of $\{(y_n, u_n)\}_{n=1}^{\infty}$ in $H_0^1(\Omega) \times L^2(\Omega)$ and (2.2) there exists C such that $\int_\Omega e^{y_n} y_n dx \le C$ for all n. Let $\epsilon > 0$ be arbitrary, set $R = \frac{2C}{\epsilon}$, and choose $\delta < \frac{\epsilon}{2}\, e^{-2C/\epsilon}$. Then for every measurable set E with $|E| < \delta$ we find

$$\begin{aligned}\int_E e^{y_n} dx &= \int_{E\cap\{y_n \le R\}} e^{y_n} dx + \int_{E\cap\{y_n > R\}} e^{y_n} dx \\ &\le |E| e^R + \int_{E\cap\{y > R\}} \frac{e^{y_n}}{y_n} y_n dx \le |E| e^R + \frac{C}{R} < \frac{\epsilon}{2} + \frac{\epsilon}{2} = \epsilon,\end{aligned}$$

where $\{y_n < R\}$ is short for $\{x\colon y_n(x) < R \text{ a.e.}\}$. Hence the integrals $\int_\Omega |e^{y_n}| dx$ are uniformly absolutely continuous, and there exists a subsequence of $\{y_n\}$, again denoted by $\{y_n\}$, such that $e^{y_n} \rightharpoonup \widetilde{w}$ weakly in $L^1(\Omega)$. Since $e^{y_n} \rightharpoonup w^*$ in $H^{-1}(\Omega)$, we have $e^{y_n} \rightharpoonup w^*$ weakly in $L^1(\Omega)$. Lemma 2.2 implies that $w^* = e^{y^*}$, and thus $e^{y_n} \rightharpoonup e^{y^*}$ weakly in $L^1(\Omega)$. Now we can take the limit in

$$(\nabla y_n, \nabla v)_{L_n^2} - \delta(e^{y_n}, v)_{\mathcal{D}',\mathcal{D}} = (u_n, v) \text{ for all } v \in \mathcal{D}(\Omega)$$

and obtain

$$(\nabla y^*, \nabla v)_{L_n^2} - \delta(e^{y^*}, v)_{\mathcal{D}',\mathcal{D}} = (u^*, v) \text{ for all } v \in \mathcal{D}(\Omega).$$

Hence y^* is a solution to (2.2) with $u = u^*$, and the proof is complete. □

We turn to optimality conditions satisfied by a solution (y^*, u^*) of (2.1)–(2.2). It is simple to formally derive the first-order conditions

$$\text{(2.4)} \qquad \begin{cases} -\Delta y^* - \delta e^{y^*} = u^* & \text{in } \Omega, \\ y^* = 0 & \text{on } \partial\Omega, \\ -\Delta \lambda^* - \delta e^{y^*} \lambda^* = J_y(y^*, u^*) & \text{in } \Omega, \\ \lambda^* = 0 & \text{on } \partial\Omega, \\ \lambda^* = J_u(y^*, u^*) & \text{in } \Omega, \end{cases}$$

where J_y and J_u denote the Riesz representative of the partial derivatives of J. We next verify (2.4) in the case in which $\Omega \subset \mathbb{R}^2$.

For this purpose let (y^*, u^*) denote a solution to (2.1)–(2.2). We recall from [GT, p. 155] that

$$\text{(2.5)} \qquad \begin{aligned}&\{|e^y|_{L^4}\colon y \in \mathcal{B}\} \text{ is bounded for every bounded set } \mathcal{B} \subset H_0^1(\Omega), \\ &\text{with } \Omega \subset \mathbb{R}^2.\end{aligned}$$

For this result the restriction to $n = 2$ is essential. It follows in particular that $e^{y^*} \in L^4(\Omega)$ and, utilizing (2.2) and [T, Theorem 2.2.7], we conclude that $y^* \in L^\infty(\Omega) \cap H_0^1(\Omega)$. Let $G: H_0^1(\Omega) \to H^{-1}$ denote the operator

$$Gy = -\Delta y - \delta e^{y^*} y.$$

Note that G is an operator with compact resolvent so that its spectrum consists of eigenvalues only. We shall require the following assumptions.

(A2) $$0 \text{ is not an eigenvalue of } G.$$

To interpret (A2) recall that, because (1.5) is a singular system (see [L]), the existence of a solution to the nonlinear control system, given by the first two equations in (2.4) here, does not imply well-posedness of the linearized system $Gy = g$, with $y \in H_0^1(\Omega)$, $g \in H^{-1}$. The simple structure of the linearization admits a straightforward characterization of the well-posedness condition by means of (A2). In the evolution case such a condition will not be necessary.

(A3) $$\begin{cases} J: H_0^1(\Omega) \times L^2(\Omega) \to \mathbb{R} \text{ is continuously Fréchet-differentiable} \\ \text{in a neighborhood } U(y^*, u^*) \subset H_0^1(\Omega) \times L^2(\Omega) \text{ of } (y^*, u^*). \end{cases}$$

The tracking functional specified below (A1) satisfies (A3).

THEOREM 2.4. *If* (A1)–(A3) *hold,* $n = 2$, *and* (y^*, u^*) *is a solution to* (2.1)–(2.2), *then there exists* $\lambda^* \in H_0^1(\Omega)$ *such that* (2.4) *holds.*

Proof. (i) We first argue by means of the implicit function theorem that there exists a convex neighborhood $U(u^*) \subset L^2(\Omega)$ of u^* and a constant k such that (2.2) has a solution $y(u)$ for every $u \in U(u^*)$ and

$$|y(u) - y^*|_{H_0^1} \le k|u - u^*|_{L^2} \quad \text{for all } u \in U(u^*), \tag{2.6}$$

where $y^* = y(u^*)$. The implicit function theorem is applied to the mapping $g: H_0^1 \times L^2(\Omega) \to H^{-1}(\Omega)$ defined by

$$g(y, u) = -\Delta y - \delta e^y - u.$$

Since (y^*, u^*) is a solution to (2.1)–(2.2), we have $g(y^*, u^*) = 0$. Moreover, by (2.5) the mapping g is continuous and Fréchet-differentiable with respect to y, with Fréchet derivative

$$g_y(y, u)\delta y = -\Delta \delta y - \delta e^y \delta y.$$

Note that $g_y(y^*, u^*) = G$. By (A2) the operator G is continuously invertible from $H^{-1}(\Omega)$ to $H_0^1(\Omega)$, and hence the implicit function theorem allows us to ascertain the existence of $U(u^*)$ and k such that (2.6) holds.

(ii) Let $u \in U(u^*)$ be arbitrary, and set $v = u - u^*$ and $y(t) = y(u^* + tv)$ for $t \in [0, 1]$. Observe that

$$\begin{aligned} 0 &= g(y(t), u^* + tv) - g(y^*, u^*) \\ &= -\Delta(y(t) - y^*) - tv - \delta e^{y(t)} + \delta e^{y^*}. \end{aligned} \tag{2.7}$$

Since by assumption $J_y(y^*, u^*) \in H^{-1}$ and due to (A2), there exists $\lambda^* \in H_0^1(\Omega)$ such that the third and fourth equations in (2.4) hold. Observe that

$$\begin{aligned} &0 \le J(y(t), u^* + tv) - J(y^*, u^*) = J_y(y^*, u^*)(y(t) - y^*) + tJ_u(y^*, u^*)v \\ &+ \textstyle\int_0^1 [J'(y^* + s(y(t) - y^*), u^* + stv) - J'(y^*, u^*)](y(t) - y^*, tv)ds, \end{aligned}$$

and hence by (2.6) and the definition of $y(t)$

$$0 \le \liminf_{t\to 0^+} \tfrac{1}{t}\,\{J_y(y^*,u^*)(y(t)-y^*) + t\,J_u(y^*,u^*)v\}.$$

By (2.7) we obtain

$$\begin{aligned} 0 \le \liminf_{t\to 0^+} \tfrac{1}{t}\,\big\{ & J_y(y^*,u^*)(y(t)-y^*) + t\,J_u(y^*,u^*)v \\ & - \langle y(t)-y^*, \Delta\lambda^*\rangle_{H_0^1,H^{-1}} - t(v,\lambda^*)_{L^2} \\ & - \delta\left(\textstyle\int_0^1 (e^{y^*+s(y(t)-y^*)} - e^{y^*})(y(t)-y^*)ds, \lambda^*\right)_{L^2} \\ & - \delta(e^{y^*}(y(t)-y^*),\lambda^*)_{L^2}\big\}. \end{aligned}$$

Using (2.4), (2.6), and (2.7), we can pass to the limit in this last inequality to obtain $0 \le J_u(y^*,u^*)v - (v,\lambda^*)_{L^2}$.

Since $u \in U(u^*)$ was arbitrary, it follows that

$$\lambda^* = J_u(y^*,u^*).$$

Here we do not distinguish in notation between the Fréchet-derivative and its Riesz representative in $L^2(\Omega)$. □

Let us turn to the boundary control problem

$$\min\ J(y,u) \tag{2.8}$$

subject to $(y,u) \in H^1(\Omega)\times L^2(\partial\Omega)$ and

$$\begin{cases} -\Delta y - \delta e^y = f & \text{in } \Omega, \\ \frac{\partial y}{\partial n} = u & \text{on } \partial\Omega, \end{cases} \tag{2.9}$$

where $f \in L^2(\Omega)$ is fixed, $\Omega \subset \mathbb{R}^2$, and (2.9) is understood in the variational sense, i.e.,

$$(\nabla y, \nabla v)_{L_n^2} - \delta(e^y, v)_{L^2} = (f,v)_{L^2} + (u,v)_{\partial\Omega} \ \text{ for all } \ v \in H^1(\Omega). \tag{2.10}$$

We shall require the following modifications of (A1)–(A3).

(A1′) This is (A1) with $L^2(\Omega)$ replaced by $L^2(\partial\Omega)$.

(A2′) $\begin{cases} \text{This is (A2) with } G \text{ replaced by } \widetilde{G}\colon H^1(\Omega) \to H^1(\Omega)^*, \\ \text{where } \widetilde{G}(\delta y) \text{ is the element of } H^1(\Omega)^* \text{ characterized by} \\ v \to (\nabla\delta y, \nabla v)_{L_n^2} - \delta(e^{y^*}\delta y, v) \text{ for all } v \in H^1(\Omega). \end{cases}$

(A3′) This is (A3) with $H_0^1(\Omega)\times L^2(\Omega)$ replaced by $H^1(\Omega)\times L^2(\partial\Omega)$.

If (A1′) holds, then assuming that the feasible set is nonempty, it is simple to argue the existence of a solution $(y^*,u^*) \in H^1(\Omega)\times L^2(\partial\Omega)$ with $e^{y^*} \in H^1(\Omega)^* \cap L^1(\Omega)$. The formal first-order necessary optimality condition for (2.8)–(2.9) is given by

$$\begin{cases} -\Delta y^* - \delta e^{y^*} = f & \text{in } \Omega, \\ \frac{\partial y^*}{\partial n} = u^* & \text{on } \partial\Omega, \\ -\Delta\lambda^* - \delta e^{y^*}\lambda^* = J_y(y^*,u^*) & \text{in } \Omega, \\ \frac{\partial\lambda^*}{\partial n} = 0 & \text{on } \partial\Omega, \\ \lambda^* = J_u(y^*,u^*) & \text{on } \partial\Omega. \end{cases} \tag{2.11}$$

THEOREM 2.5. *If* (A1′)–(A3′) *hold,* $n = 2$*, and* (y^*, u^*) *is a solution to* (2.8)–(2.9)*, then there exists* $\lambda^* \in H^1(\Omega)$ *such that* (2.11) *holds.*

Proof. The proof is similar to that of Theorem 2.4, so we only give the necessary changes. For $\widetilde{g}\colon H^1(\Omega) \times L^2(\partial\Omega) \to (H^1(\Omega))^*$ defined by

$$\widetilde{g}(y,u) = (\nabla y, \nabla v)_{L^2_n} - \delta(e^y, v)_{L^2} - (u,v)_{L^2(\partial\Omega)} \quad \text{for all} \quad v \in H^1(\Omega),$$

one argues that due to (A2′) and (2.5) the implicit function theorem is applicable, and thus there exists a neighborhood $U(u^*)$ of u^* in $L^2(\partial\Omega)$ and a constant $k > 0$ such that for all $u \in U(u^*)$ there exists a solution $y(u) \in H^1(\Omega)$ to (2.9) and

$$|y(u) - y^*|_{H^1} \le |u - u^*|_{L^2(\partial\Omega)} \quad \text{for all} \quad u \in U(u^*).$$

Due to (A2′) there exists a solution λ^* to the variational form of the third and fourth equations in (2.11), i.e., $(\nabla\lambda^*, \nabla v)_{L^2_n} - \delta(e^{y^*}\lambda^*, v)_{L^2} = \langle J_y(y^*, u^*), v\rangle_{(H^1)^*, H^1}$ for all $v \in H^1(\Omega)$.

For arbitrary $u \in U(u^*)$ we find, as in (ii) of the proof of Theorem 2.4,

$$\begin{aligned} 0 \le \liminf_{t\to 0^+} \tfrac{1}{t}\, & J_y(y^*,u^*)(y(t)-y^*) + t\, J_u(y^*,u^*)(u-u^*) \\ & + (\nabla(y(t)-y^*), \nabla\lambda^*)_{L^2_n} - t\,(u-u^*, \lambda^*)_{L^2(\partial\Omega)} \\ & - \delta\left(\int_0^1 (e^{y^* + s(y(t)-y^*)} - e^{y^*})(y(t)-y^*)ds, \lambda^*\right)_{L^2} - \delta(e^{y^*}(y(t)-y^*), \lambda^*)_{L^2} \\ = {} & J_u(y^*,u^*)(u-u^*) - (u-u^*, \lambda^*)_{L^2(\partial\Omega)}, \end{aligned}$$

and thus (2.11) follows.

3. Evolutionary optimal control problems. This section is devoted to optimal control problems of the type

$$\min J(y, y(T,\cdot), u) \tag{3.1}$$

subject to $(y, y(T,\cdot), u) \in W \times L^2(\Omega) \times L^2(Q)$ and

$$\begin{cases} y_t = \Delta y + \delta e^y + u & \text{in } Q = (0,T] \times \Omega, \\ y(0,\cdot) = \varphi & \text{in } \Omega, \\ y = 0 & \text{on } \Sigma = (0,T] \times \partial\Omega, \end{cases} \tag{3.2}$$

where Ω is a bounded domain in $\mathbb{R}^n$ with smooth boundary $\partial\Omega$, $\varphi \in L^2(\Omega)$, and

$$W = \{y \in L^2(0,T; H^1_0(\Omega))\colon y_t \in L^1(0,T; X_1^*)\}$$

endowed with $|y|_W = |y|_{L^2(H^1_0(\Omega))} + |y_t|_{L^1(x_1^*)}$ as norm. Here $|y|_{L^2(H^1_0(\Omega))}$ stands for $|y|_{L^2(0,T;H^1_0(\Omega))}$. X_1^* denotes the topological dual of a reflexive Banach space X_1 with the property that

$$\mathcal{D}(\Omega) \hookrightarrow X_1 \hookrightarrow (L^\infty(\Omega) \cap H^1_0(\Omega))$$

with continuous and dense injections. It follows that $(L^1(\Omega) \cup H^{-1}(\Omega)) \hookrightarrow X_1^* \subset \mathcal{D}'(\Omega)$ with continuous and dense injections as well. The choice $X_1 = W^{1,p}_0(\Omega)$, $p > n$, satisfies the specified properties. Henceforth u is assumed to be an element of $L^2(Q)$. Contents permitting, $L^p(X)$ stands for $L^p(0,T;X)$ with X a Banach space and $p \in [1,\infty]$.

DEFINITION 3.1. *A function $y \in W$ is called a solution to* (3.2) *if* $e^y \in L^1(Q)$ *and*

$$\text{(3.3)} \qquad \begin{cases} (y_t, v)_{L^1(X_1^*),L^\infty(X_1)} + (\nabla y, \nabla v)_{L^2(L^2_n)} = \delta(e^y, v)_{L^1(Q),L^\infty(Q)} \\ \qquad\qquad + (u, v)_{L^2(Q)} \quad \textit{for all } v \in L^\infty(0,T;X_1), \\ y(0,\cdot) = \varphi. \end{cases}$$

Recall that every element of W, and hence every solution to (3.2), can be identified a.e. with respect to $t \in [0,T]$ with a function in $C([0,T];X_1^*)$; see [Ba]. Since $L^\infty(0,T;X_1)$ is the dual space to $L^1(0,T;X_1^*)$, a function $y \in W$ is a solution to (3.2) if and only if $e^y \in L^1(Q)$, $y(0,\cdot) = \varphi$, and

$$\text{(3.4)} \qquad y_t = \Delta y + \delta e^y + u \text{ in } L^1(0,T;X_1^*).$$

We shall require the following a priori bound on $e^y y$ when y is a solution to (3.2).

PROPOSITION 3.2. *Let $u \in L^2(Q)$ and let $y = y(u)$ be a solution to* (3.2) *with $y(T,\cdot) \in L^2(\Omega)$. Then $e^y y \in L^1(Q)$ and*

$$\text{(3.5)} \qquad \begin{aligned} &\delta \textstyle\int_Q e^y y dx + \frac{1}{2}|\varphi|^2_{L^2(\Omega)} \\ &\le \tfrac{1}{2}|y(T,\cdot)|^2_{L^2(\Omega)} + |y|^2_{L^2(0,T;H_0^1)} + \tfrac{1}{2}|u|^2_{L^2(Q)} + \tfrac{1}{2}|y|^2_{L^2(Q)}. \end{aligned}$$

Formally, (3.5) is obtained by taking the inner product in $L^2(Q)$ of (3.4) with y. A detailed proof is given in the appendix.

To establish the existence of a solution to (3.1)–(3.2) the following assumption is required:

$$\text{(A4)} \qquad \begin{cases} J\colon \mathcal{X} = L^2(0,T;H_0^1(\Omega)) \times L^2(\Omega) \times L^2(Q) \to \mathbb{R} \text{ is bounded from} \\ \text{below, weakly lower semicontinuous, and coercive in the sense that} \\ J(y, y(T,\cdot), u) \to \infty \text{ if } |y|_{L^2(0,T;H_0^1)} \to \infty \text{ or } |y(T)|_{L^2(\Omega)} \to \infty \\ \text{or } |u|_{L^2(Q)} \to \infty. \end{cases}$$

THEOREM 3.3. *If* (A4) *holds, then* (3.1)–(3.2) *admits a solution* $(y^*, y^*(T,\cdot), u^*) \in W \times L^2(\Omega) \times L^2(Q)$.

Proof. The set of feasible points for (3.1)–(3.2) is nonempty. By assumption (A4) the functional J is bounded from below and there exists a minimizing sequence $\{(y_n, y_n(T,\cdot), u_n\}_{n=1}^\infty \in W \times L^2(\Omega) \times L^2(Q)$ for (3.1)–(3.2). Due to (A4) there exists a subsequence, denoted by the same symbol, and $(y^*, z^*, u^*) \in \mathcal{X}$ such that

$$\text{(3.6)} \qquad (y_n, y_n(T,\cdot), u_n) \rightharpoonup (y^*, z^*, u^*) \text{ in } \mathcal{X}.$$

From (3.5), moreover,

$$\text{(3.7)} \qquad \{e^{y_n} y_n\}_{n=1}^\infty \text{ is bounded in } L^1(Q).$$

Due to the weak lower semicontinuity of J we have

$$J(y^*, y^*(T,\cdot), u^*) \le J(y, y(T,\cdot), u)$$

for all pairs $(y, y(T,\cdot), u) \in W \times L^2(\Omega) \times L^2(Q)$ which satisfy (3.2). It thus remains to show that $(y^*, u^*) \in W \times L^2(Q)$ satisfies (3.2). Since $\{y_n\}_{n=1}^\infty$ is bounded in $L^2(0,T;H_0^1(\Omega))$ and since (3.7) with $y_n = y(u_n)$ a solution to (3.2) holds, a generalization of Aubin's lemma given in Lemma 3.4 below implies the existence of a subsequence of $\{y_n\}_{n=1}^\infty$ denoted by the same symbol and of an element $\tilde{y} \in L^1(0,T;L^2(\Omega))$

such that $y_n \to \tilde{y}$ in $L^1(0,T;L^2(\Omega))$. Since $y_n \rightharpoonup y^*$ in $L^2(0,T;H_0^1(\Omega))$, it follows that

$$y_n \rightharpoonup y^* \text{ in } L^1(0,T;L^2(\Omega)). \tag{3.8}$$

As a consequence there exists a further subsequence, again denoted by y_n, converging a.e. in Q to y^*. Due to (3.7) the Dunford–Pettis theorem can be used as in the proof of Theorem 2.3 to argue that

$$e^{y_n} \rightharpoonup e^{y^*} \text{ in } L^1(Q). \tag{3.9}$$

Finally, we consider the convergence of $\{\frac{d}{dt}y_n\}_{n=1}^{\infty}$. Due to (3.6), (3.9), and (3.4), with u replaced by u_n, there exists $z \in L^1(0,T;X_1^*)$ such that

$$\frac{d}{dt}y_n \rightharpoonup z \text{ in } L^1(0,T;X_1^*). \tag{3.10}$$

To argue that $z = \frac{d}{dt}y^*$, we introduce the differentiation operator

$$D\colon \text{dom } (D) \subset L^1(0,T;X_1^*) \to L^1(0,T;X_1^*),$$

with dom $(D) = \{y \in L^1(0,T;X_1^*), \frac{d}{dt}y \in L^1(0,T;X_1^*), y(0) = 0\}$. Since the inverse of D is a bounded linear operator, D is closed. Due to (3.8) and (3.10),

$$y_n - \varphi \to y^* - \varphi \quad \text{and} \quad \frac{d}{dt}y_n \rightharpoonup z \text{ in } L^1(0,T;X_1^*),$$

and hence $y^* = z$ and

$$\frac{d}{dt}y_n \rightharpoonup z \text{ in } L^1(0,T;X_1^*). \tag{3.11}$$

Taking the limit in

$$\begin{cases} (\frac{d}{dt}y_n, v)_{L^1(X_1^*),L^\infty(X_1)} + (\nabla y_n, \nabla v)_{L^2(L_n^2)} = \delta(e^{y_n}, v)_{L^1(Q),L^\infty(Q)} + (u,v)_{L^2(Q)} \\ \qquad\qquad \text{for all } v \in L^\infty(0,T;X_1), \\ y_n(0,\cdot) = \varphi, \end{cases}$$

and utilizing (3.6), (3.9), and (3.11), we find

$$\begin{cases} (\frac{d}{dt}y^*, v)_{L^1(X_1^*),L^\infty(X_1)} + (\nabla y^*, \nabla v)_{L^2(L_n^2)} = \delta(e^{y^*}, v)_{L^1(Q),L^\infty(Q)} + (u,v)_{L^2(Q)} \\ \qquad\qquad \text{for all } v \in L^\infty(0,T;X_1), \\ y^*(0,\cdot) = \varphi. \end{cases}$$

Thus y^* is a solution to (3.2) with $u = u^*$ as desired.

LEMMA 3.4. *Let y_n denote solutions to* (3.2) *with u replaced by $u_n \in L^2(Q)$, $n \in \mathbb{N}$, and assume that $\{u_n\}_{n=1}^{\infty}$ is bounded in $L^2(Q)$, that $\{y_n\}_{n=1}^{\infty}$ is bounded in $L^2(0,T;H_0^1(\Omega))$, and that $\{e^{y_n}y_n\}_{n=1}^{\infty}$ is bounded in $L^1(Q)$. Then there exists a subsequence $\{y_{n_k}\}_{k=1}^{\infty}$ of $\{y_n\}_{n=1}^{\infty}$ and $y^* \in L^2(0,T;H_0^1)$ such that $y_{n_k} \to y^*$ in $L^1(0,T;L^2(\Omega))$ as $k \to \infty$.*

Proof. For the proof we follow essentially an Aubin-lemma argument [CF].

(i) Since $H_0^1(\Omega) \subset L^2(\Omega) \subset X_1^*$ with $H_0^1(\Omega)$, compact in $L^2(\Omega)$, there exists for every $\epsilon > 0$ a constant $c_\epsilon > 0$ such that

$$|y|_{L^2(\Omega)} \le \epsilon |y|_{H_0^1(\Omega)} + c_\epsilon |y|_{X_1^*} \text{ for all } y \in H_0^1(\Omega). \tag{3.12}$$

(ii) Due to the assumptions on the boundedness of $\{y_n\}_{n=1}^{\infty}$, there exists $y^* \in L^2(0,T;H_0^1)$ and a subsequence of $\{y_n\}$, denoted by the same symbol, such that $y_n \rightharpoonup y^*$ in $L^2(0,T;H_0^1)$. We need to show that $y_n \to y^*$ in $L^1(0,T;L^2(\Omega))$. By assumption there exists a constant $C>0$ such that

$$|y_n|_{L^2(H_0^1(\Omega))} \le C, \quad |u_n|_{L^2(Q)} \le C, \quad \text{and} \quad |e^{y_n} y_n|_{L^1(Q)} \le C \tag{3.13}$$

for all $n \in \mathbb{N}$. Due to (3.12) and (3.13) we have for every $\epsilon > 0$

$$\begin{aligned} &\textstyle\int_0^T |y_n - y^*|_{L^2(\Omega)} dt \le \epsilon \int_0^T |y_n - y^*|_{H_0^1(\Omega)} dt + c_\epsilon \int_0^T |y_n - y^*|_{X_1^*} dt \\ &\le \epsilon\sqrt{T}\left(C + |y^*|_{L^2(H_0^1(\Omega))}\right) + c_\epsilon \textstyle\int_0^T |y_n - y^*|_{X_1^*} dt \text{ for all } n. \end{aligned} \tag{3.14}$$

(iii) We next show that $y_n(t) \to y^*(t)$ in X_1^* for almost every $t \in (0,T)$. First observe that for every interval $I \subset [0,T]$

$$\int_I y_n(t,\cdot)dt \to \int_I y^*(t,\cdot)dt \text{ in } L^2(\Omega). \tag{3.15}$$

In fact, let χ_I denote the characteristic function of I and let $\ell \in H^{-1}(\Omega)$ be arbitrary. Then

$$\left(\int_I (y_n(t,\cdot) - y^*(t,\cdot))dt, \ell\right)_{H_0^1, H^{-1}} = \int_0^T (y_n(t,\cdot) - y^*(t,\cdot), \ell)_{H_0^1, H^{-1}} \chi_I \, dt \to 0,$$

since $y_n \rightharpoonup y^*$ in $L^2(0,T;H_0^1)$. Hence $\int_I y_n(t,\cdot)dt \rightharpoonup \int_I y^*(t,\cdot)dt$ in $H_0^1(\Omega)$, and (3.15) follows by the compactness of $H_0^1(\Omega)$ in $L^2(\Omega)$. To verify that $y_n(t) \to y^*(t)$ in X_1^* for almost every $t \in (0,T)$, let $\delta > o$ be arbitrary. We have the following equation in X_1^*:

$$y_n(t) = \frac{1}{\delta}\int_{t-\delta}^t y_n(s)ds + \frac{1}{\delta}\int_{t-\delta}^t (s-t+\delta)\frac{d}{ds}\, y_n(s)ds. \tag{3.16}$$

We turn to the second term on the right-hand side of (3.16). Utilizing (3.15) with u replaced by u_n, and denoting by k the embedding constant of $L^1(\Omega)$ as well as $H^{-1}(\Omega)$ into X_1^*, we find

$$\begin{aligned} &\tfrac{1}{\delta}\left|\textstyle\int_{t-\delta}^t (s-t+\delta)\frac{d}{ds} y_n(s)ds\right|_{X_1^*} \le \tfrac{k}{\delta}\textstyle\int_{t-\delta}^t |(s-t+\delta)\Delta y_n(s)|_{H^{-1}}\, ds \\ &+ \tfrac{k}{\delta}\textstyle\int_{t-\delta}^t |(s-t+\delta)e^{y_n(s)}|_{L^1} ds + \tfrac{k}{\delta}\textstyle\int_{t-\delta}^t |(s-t+\delta)u_n(s)|_{L^2}\, ds \\ &\le \tfrac{k}{\delta}\Big[(\textstyle\int_{t-\delta}^t (s-t+\delta)^2 ds)^{1/2}((\int_{t-\delta}^t |\Delta y_n(s)|_{H^{-1}}^2 ds)^{1/2} + (\int_{t-\delta}^t |u_n(s)|_{L^2}^2 ds)^{1/2}) \\ &\qquad + \textstyle\int_{t-\delta}^t |(s-t+\delta)e^{y_n(s)}|_{L^1} ds\Big] \\ &\le \tfrac{k}{\delta}\left[(\tfrac{\delta^3}{3})^{1/2} C(1+|\Omega|^{1/2}) + \int_0^\delta \left|\tfrac{s}{y_n(t+s-\delta)}\, e^{y_n(t+s-\delta)}\, y_n(t+s-\delta)\right|_{L^1} ds\right], \end{aligned}$$

where we used (3.13). For $R>0$ we decompose Q into $Q_R = \{(t,x) \in Q : y_n(t,x) \le R\}$, where the dependence of Q_R on n is supressed, and its complement. Utilizing the last inequality in (3.13), we obtain

$$\begin{aligned} &\tfrac{1}{\delta}\left|\textstyle\int_{t-\delta}^t (s-t+\delta)\frac{d}{ds}\, y_n(s)ds\right|_{X_1^*} \le \tfrac{kC}{\sqrt{3}}\sqrt{\delta}(1+|\Omega|^{1/2}) \\ &+ \tfrac{k}{\delta}\big[\textstyle\int_0^\delta s \int_\Omega e^R dx\, ds + \frac{1}{R}\int_0^\delta \int_\Omega y_n(t+s-\delta)e^{y_n(t+s-\delta)} ds\big] \\ &\le \tfrac{kC}{\sqrt{3}}\sqrt{\delta}(1+|\Omega|^{1/2}) + \tfrac{1}{2}\delta e^R|\Omega| + \tfrac{C}{R}. \end{aligned} \tag{3.17}$$

Henceforth let t be a Lebesgue point for y^*, so that

$$\lim_{\delta\to 0^+} \frac{1}{\delta}\int_{t-\delta}^{t} y^*(s)ds = y^*(t). \tag{3.18}$$

Let $\epsilon > 0$ be arbitrary. Due to (3.17) and (3.18), one can choose R and subsequently δ such that $\frac{1}{\delta}|\int_{t-\delta}^{t}(s-t+\delta)\frac{d}{ds}\, y_n(s)ds|_{X_1^*} \le \epsilon_0$ and $|\frac{1}{\delta}\int_{t-\delta}^{t} y^*(s)ds - y^*(t)| \le \epsilon$ for all n. Combined with (3.16) we find $|y_n(t)-y^*(t)|_{X_1^*} \le |\frac{1}{\delta}\int_{t-\delta}^{t}(y_n(s)-y^*(s))ds|_{X_1^*} + 2\epsilon_0$, and, since δ is fixed in this last inequality, (3.15) implies that $y_n(t) \to y^*(t)$ in X_1^*. The set of Lebesgue points of y^* is dense in $(0,T)$, and thus $y_n(t) \to y^*(t)$ in X_1^* for almost every $t \in (0,T)$.

(iv) Due to (3.16) and (3.17) Lebesgue's bounded convergence theorem is applicable to passing to the limit on the right-hand side of (3.14). This implies the desired result. □

Lemma 3.4 differs from the classical Aubin lemma [CF] in that $\{\frac{d}{dt}\, y_n\}_{n=1}^{\infty}$ is not bounded in $L^p(0,T;X_1^*)$ for some $p > 1$. Rather, the boundedness of $\{e^{y_n}y_n\}_{n=1}^{\infty}$ in $L^1(Q)$ is used as well as the assumption that the functions y_n are solutions of (3.2).

We turn to a modification of (3.1)–(3.2) and consider a cost functional without atom at T as in (3.1). For this purpose we define

$$W_G = \left\{y \in L^2(0,T;H_0^1(\Omega))\colon y_t \in L_G^1(0,T;X_1^*)\right\},$$

where

$$L_G^1(0,T;X_1^*) = \left\{y\colon (0,T) \to X_1^* \text{ measurable} : \int_0^T |y(t)|_{X_1^*}(T-t)dt < \infty\right\}.$$

For $u \in L^2(Q)$ a function $y = y(u) \in W_G$ is called the solution in W_G of (3.2) if $e^y \in L_G^1$ and

$$\left\{\begin{array}{rcl} y_t & = & \Delta y + \delta e^y + u \text{ in } L_G^1, \\ y(0) & = & \varphi. \end{array}\right. \tag{3.19}$$

Let us consider

$$\left\{\begin{array}{l} \min J(y,u) \\ \text{ subject to } (y,u) \in W_G \times L^2(Q) \text{ with } y \text{ a solution to (3.2)}, \end{array}\right. \tag{3.20}$$

where Ω satisfies the properties specified at the beginning of this section and $\varphi \in L^2(\Omega)$. We require

$$\left\{\begin{array}{l} J\colon L^2(0,T;H_0^1(\Omega)) \times L^2(Q) \to \mathbb{R} \text{ is bounded from below,} \\ \text{ weakly lower semicontinuous, and coercive in the sense that} \\ J(y,u) \to \infty \text{ if } |y|_{L^2(0,T;H_0^1)} \to \infty \text{ or } |u|_{L^2(Q)} \to \infty. \end{array}\right. \tag{A5}$$

THEOREM 3.5. *If* (A5) *holds, then* (3.20) *admits a solution* $(y^*,u^*) \in W_G \times L^2(Q)$.

Proof. The set of feasible points is nonempty. By (A5) there exists a minimizing sequence $\{(y_n,u_n)\} \in L^2(0,T;H_0^1(\Omega)) \times L^2(Q)$ for (3.20). Moreover, there exists a subsequence, denoted by the same symbol, as well as $(y^*,u^*) \in L^2(0,T;H_0^1(\Omega)) \times L^2(Q)$ such that

$$(y_n,u_n) \rightharpoonup (y^*,u^*) \text{ in } L^2(0,T;H_0^1(\Omega)) \times L^2(Q). \tag{3.21}$$

Due to the weak lower semicontinuity of J,

$$J(y^*, u^*) \leq J(y, u)$$

for all (y, u) satisfying (3.2). It thus remains to show that $y^* \in W_G$ and that (y^*, u^*) is a solution to (3.2).

Let $y = y(u)$ with $u \in L^2(Q)$ be a solution to (3.2). Taking the inner product of (3.2) in $L^2(Q)$ with $(T-t)y$, one computes that

$$\begin{aligned} &\delta \textstyle\int_Q e^y y(T-T)dQ + \frac{T}{2}|\varphi|^2_{L^2(\Omega)} \\ &\leq |y|^2_{L^2(0,T;H_0^1)} + |y|^2_{L^2(Q)} + \tfrac{T^2}{2}|u|^2_{L^2(Q)}. \end{aligned} \tag{3.22}$$

The detailed proof is similar to that of Proposition 3.2. Let k^0 be such that $T \geq \frac{1}{k_0}$. From (3.22) it follows that $\{e^{y_n} y_n|_{(0,T-\frac{1}{k})}\}_{n=1}^{\infty}$ is bounded in $L^2(0, T-\frac{1}{k}; H_0^1(\Omega))$ for every $k \geq k_0$. By construction, $\{y_n|_{(0,T-\frac{1}{k})}\}_{n=1}^{\infty}$ is bounded in $L^2(0, T-\frac{1}{k}; H_0^1(\Omega))$ for every $k \geq k_0$ as well. Arguing as in the proof of Theorem 3.3, there exists a nested sequence of subsequences satisfying $\{n_{k+1}\} \prec \{n_k\} \prec \{n\}, k \geq k_0$, and

$$\begin{aligned} y_{n_k} &\rightharpoonup y^* \text{ in } L^1\left(0, T-\frac{1}{k}; L^2(\Omega)\right), \\ e^{y_{n_k}} &\rightharpoonup e^{y^*} \text{ in } L^1\left(\left(0, T-\frac{1}{k}\right) \times \Omega\right), \\ \frac{d}{dt} y_{n_k} &\rightharpoonup \frac{d}{dt} y^* \text{ in } L^1\left(0, T-\frac{1}{k}; X_1^*\right) \text{ as } n_k \to \infty, \end{aligned}$$

and y^* is a solution to (3.2) on $(0, T-\frac{1}{k})$ for $k \geq k_0$. In particular, this implies that $\frac{d}{dt}y^* = \Delta y^* + \delta e^{y^*} + u^*$ for almost every $t \in [0,T]$, and $y^*(0) = \varphi$. It remains to argue that $y^* \in W_G$. Since $y^*|_{(0,T-\frac{1}{k})}$ is a solution to (3.2) on $(0, T-\frac{1}{k})$, for $k \geq k_0$, one argues as for (3.22) to obtain for every $k \geq k_0$

$$\begin{aligned} \delta \int_0^{T-\frac{1}{k}} \int_\Omega \left| e^{y^*} y^* \left(T - \tfrac{1}{k} - t\right)\right| dxdt + \tfrac{T-\frac{1}{k}}{2}|\varphi|^2_{L^2(\Omega)} \\ \leq |y^*|^2_{L^2(0,T;H_0^1)} + |y^*|^2_{L^2(Q)} + \tfrac{T^2}{2}|u^*|^2_{L^2(Q)}. \end{aligned}$$

Taking the limit with respect to k, we find

$$\delta \int_Q e^{y^*} y^*(T-t)dQ + \tfrac{T}{2}|\varphi|^2_{L^2(\Omega)} \leq |y^*|^2_{L^2(0,T;H_0^1)} + |y^*|^2_{L^2(Q)} + \tfrac{T^2}{2}|u^*|^2_{L^2(Q)},$$

and consequently $\int_Q e^{y^*}(T-t)dQ < \infty$. Since $y^* \in L^2(0,T;H_0^1(\Omega)$, it follows that $y^* \in W_G$ and $\frac{d}{dt}y^* = \Delta y^* + \delta e^{y^*} + u^*$ in $L^1_G(0,T;x_1^*)$, as desired. ∎

3.1. Optimality conditions. We turn to the optimality condition satisfied by a solution $(y^*, y^*(T,\cdot), u^*)$ to (3.1)–(3.2). Again it is simple to formally derive first-order optimality conditions:

$$\begin{cases} y_t^* = \Delta y^* + \delta e^{y^*} + u^* \text{ in } Q, \\ y^*(0,\cdot) = \varphi \text{ in } \Omega, \quad y^* = 0 \text{ on } \Sigma, \\ -\lambda_t^* = \Delta\lambda^* + \delta e^{y^*}\lambda^* - J_y(y^*, y^*(T,\cdot), u^*) \text{ in } Q, \\ \lambda^*(T,\cdot) = J_{y(T,\cdot)}(y^*, y^*(T,\cdot), u^*) \text{ in } \Omega, \quad \lambda^* = 0 \text{ on } \Sigma, \\ \lambda^* = J_u(y^*, y^*(T,\cdot), u^*) \text{ in } Q. \end{cases} \tag{3.23}$$

We shall use (3.23)(i) to denote the first equation in (3.23), and similarly for the other equations in (3.23). Next (3.23) is justified in special cases. We recall the definition of $\mathcal{X}$ in (A4) and introduce a further assumption:

$$\text{(A6)} \quad \begin{cases} J\colon \mathcal{X} \to \mathbb{R} \text{ is continuously Fréchet-differentiable in a neighborhood} \\ U(y^*, y^*(T,\cdot), u^*) \subset \mathcal{X} \text{ of } (y^*, y^*(T,\cdot), u^*). \end{cases}$$

We set $\mathcal{W} = \{y \in L^2(0,T; H_0^1(\Omega))\colon y_t \in L^2(0,T; H^{-1}(\Omega))\}$, and recall from the theory of parabolic equations that there exists a solution $\lambda^* \in \mathcal{W}$ to (3.23)(iii) and (iv), provided that e^{y^*} is sufficiently smooth.

THEOREM 3.6. *If* (A4) *and* (A6) *hold,* $n \le 2, \varphi \in H_0^1(\Omega)$, *and* $(y^*, y^*(T,\cdot), u^*)$ *is a solution to* (3.1)–(3.2) *with* $e^{y^*} \in L^2(Q)$, *then there exists* $\lambda^* \in \mathcal{W}$ *such that* (3.23) *holds.*

Proof. For the proof we require the space

$$W^{2,1} = \{y \in L^2(0,T; H^2(\Omega) \cap H_0^1(\Omega))\colon y_t \in L^2(0,T; L^2(\Omega))\},$$

endowed with the natural Hilbert-space norm. Recall that $W^{2,1}$ is continuously embedded in $C(0,T; H_0^1(\Omega))$, and hence for $y \in W^{2,1}$ we find $e^y \in C(0,T; L^4(\Omega))$. The assumptions $e^{y^*} \in L^2(Q)$ and $\varphi \in H_0^1(\Omega)$ imply that $y^* \in W^{2,1}$.

(i) We now follow the proof of Theorem 2.4 and argue that there exists a convex neighborhood $U(u^*) \subset L^2(Q)$ of u^* and a constant k such that (3.2) has a solution $y(u)$ for every $u \in U(u^*)$ and

$$|y(u) - y^*|_{W^{2,1}} \le k|u - u^*|_{L^2(Q)} \text{ for every } u \in U(u^*). \tag{3.24}$$

The implicit function theorem is applied to the mapping $g\colon W^{2,1} \times L^2(Q) \to L^2(Q) \times L^2(\Omega)$ defined by

$$g(y,u) = (y_t - \Delta y - \delta e^y - u, y(0,\cdot) - \varphi).$$

Note that $g(y^*, u^*) = 0$. Utilizing (2.5), one can show (see, e.g., [KK]) that $y \to e^y$ is continuously Fréchet-differentiable from $W^{2,1}$ to $L^\infty(0,T; L^4(\Omega))$. It follows that g is continuously Fréchet-differentiable with its partial derivative with respect to y given by

$$g_y(y,u)\delta y = ((\delta y)_t - \Delta \delta y - \delta e^y \delta y, \delta y(0,\cdot)).$$

The theory of parabolic equations implies that $g_y(y^*, u^*)\colon \mathcal{W} \to L^2(Q) \times L^2(\Omega)$ is continuously invertible, and hence (3.24) follows.

(ii) Proceeding as in the proof of Theorem 2.4, we choose $u \in U(u^*)$ arbitrarily and set $v = u - u^*$ and $y(t) = y(u^* + tv)$ for $t \in [0,1]$. Observe that

$$0 = g(y(t), u^* + tv) - g(y^*, u^*) = \frac{d}{dt}(y(t) - y^*) - \Delta(y(t) - y^*) - tv - \delta e^{y(t)} + \delta e^{y^*(t)}. \tag{3.25}$$

By assumption, $J_y(y^*, y^*(T,\cdot), u^*) \in L^2(0,T; H^{-1}(\Omega))$, and hence there exists $\lambda^* \in \mathcal{W}$ such that (3.23)(iii) and (iv) hold. It remains to verify the last equation of (3.23). Due to (A6) and (3.25) we find

$$
\begin{aligned}
0 \le \liminf_{t\to 0^+} \tfrac{1}{t} \Big\{ & J_y(y^*, y^*(T,\cdot), u^*)(y(t) - y^*) \\
& + J_{y(T,\cdot)}(y^*, y^*(T,\cdot), u^*)(y(t)(T,\cdot) - y^*(T,\cdot)) + tJ_u(y^*, y^*(T,\cdot), u^*)v \\
& + (y(t)(T,\cdot) - y^*(T,\cdot), \lambda^*(T,\cdot))_{L^2(\Omega)} \\
& - \langle y(t) - y^*, \lambda_t^* \rangle_{L^2(0,T;H_0^1), L^2(0,T;H^{-1})} \\
& - \langle y(t) - y^*, \Delta\lambda^* \rangle_{L^2(0,T;H_0^1), L^2(0,T;H^{-1})} - t(v, \lambda^*)_{L^2(Q)} \\
& - \delta \left(\textstyle\int_0^1 (e^{y^* + s(y(t)-y^*)} - e^{y^*})(y(t) - y^*) ds, \lambda^* \right)_{L^2(Q)} \\
& - \delta (e^{y^*}(y(t) - y^*), \lambda^*)_{L^2(Q)} \Big\} = J_u(y^*, y^*(T,\cdot), u^*)v - (v, \lambda^*)_{L^2(Q)},
\end{aligned}
$$

where we used (3.23)(iii) and (iv) and the fact that $\{|e^{(y^* + s(y(t)-y^*))(\sigma,\cdot)}|_{L^4(\Omega)}: s \in [0,1], \sigma, t \in [0,T]\}$ is bounded. Since $u \in U(u^*)$ is chosen arbitrarily, the last equation in (3.23) holds as well. □

We next consider a variation of problem (3.1)–(3.2) aimed at eliminating the regularity condition $e^{y^*} \in L^2(Q)$ in Theorem 3.6. This can be achieved at the expense of introducing the bound

$$\int_\Omega |\nabla y(t,\cdot)|^2 dx \le M \text{ a.e. } t \in [0,T],$$

for some $M > 0$, to (3.1)–(3.2). This implies that the optimal state is necessarily an element of $W^{2,1}$. This motivates us to consider

$$\min J(y,u) \tag{3.26}$$

subject to $(y,u) \in W^{2,1} \times L^2(Q)$, and

$$\begin{cases} (y,u) \text{ satisfies (3.2) with} \\ \int_\Omega |\nabla y(t,\cdot)|^2 dx \le M \text{ for almost every } t \in [0,T]. \end{cases} \tag{3.27}$$

Here $n = 2, M > 0$ is fixed, and $\varphi \in H_0^1(\Omega)$ with $|\nabla\varphi|_{L_n^2} \le M$. Let (y^*, u^*) denote a solution to (3.26)–(3.27), which is readily shown to exist if $J: W^{2,1} \times L^2(Q)$ is bounded below, weakly lower semicontinuous, and radially unbounded in the sense that $J(y,u) \to \infty$ if $|y|_{W^{2,1}} \to \infty$ or $|u|_{L^2} \to \infty$. We require

$$\begin{cases} J: W^{2,1} \to \mathbb{R} \text{ is continuously Fréchet-differentiable in a} \\ \text{neighborhood } U(y^*, u^*) \subset W^{2,1} \times L^2(Q) \text{ of } (y^*, u^*). \end{cases} \tag{A7}$$

THEOREM 3.7. *If (y^*, u^*) is a solution to* (3.26)–(3.27) *and* (A7) *is satisfied, then there exists $\lambda^* \in L^2(Q)$ such that* (3.23)(i), (ii), *and* (v) *hold, while* (iii) *and* (iv) *are replaced by*

$$J_y(y^*, u^*)(y - y^*) + (\lambda^*, (y - y^*)_t - \Delta(y - y^*) - \delta e^{y^*}(y - y^*))_{L^2(Q)} \ge 0 \tag{3.28}$$

for all $y \in W^{2,1}$ with $\int_\Omega |\nabla y(t,\cdot)|^2 \le M$ for almost every $t \in [0,T]$, and $y = y(0,\cdot) = \varphi$.

Proof. The result follows from an abstract theorem on the existence of Lagrange multipliers for optimization problems [ZK]. Here a Lagrange multiplier is only introduced for the constraint $g: W^{2,1} \times L^2(Q) \to L^2(Q)$, given by

$$g(y,u) = y_t - \Delta y - \delta e^y - u,$$

while $y(0,\cdot) = \varphi$ and $|\nabla y(t,\cdot)|^2_{L^2_n} \leq M$, for almost every $t \in [0,T]$, are treated as explicit constraints. Since $W^{2,1}$ is continuously embedded in $C(0,T;H^1_0(\Omega))$, it follows that $\{y \in W^{2,1}: y(0,\cdot) = \varphi, |\nabla y(t,\cdot)|^2_{L^2_n} \leq M \text{ a.e. } t \in [0,T]\}$ is a closed convex subset of $W^{2,1}$. Moreover $g_u: L^2(Q) \to L^2(Q)$ is surjective, and hence (3.28) follows from Theorem 3.3 in [ZK]. □

As a direct consequence of Theorem 3.6, we observe that if (y^*, u^*) is a solution to (3.26)–(3.27) such that $|\nabla y^*(t,\cdot)|^2 < M$ for all t and (A7) holds, then (y^*, u^*) satisfies the optimality system (3.23).

Let us close the section with a remark on boundary control problems.

Remark 3.8. The technique of Theorem 3.3 is also applicable to the treatment of certain boundary control problems. Let us consider

$$\min J(y, y(T,\cdot), u) \tag{3.29}$$

subject to $(y, y(T,\cdot), u) \in \widetilde{W} \times L^2(\Omega) \times L^2(\Sigma)$ and

$$\begin{cases} y_t = \Delta y + \delta e^y & \text{in } Q, \\ \frac{\partial y}{\partial n} = u & \text{on } \Sigma, \\ y(0,\cdot) = \varphi & \text{in } \Omega, \end{cases} \tag{3.30}$$

where

$$\widetilde{W} = \{y \in L^2(0,T;H^1(\Omega)): y_t \in L^1(0,T;X_1^*)\}.$$

For $u \in L^2(\Sigma)$ a function y is called a solution to (3.30) if $e^y \in L^1(Q)$ and

$$\begin{cases} (y_t, v)_{L^1(X_1^*),L^\infty(X_1)} + (\nabla y, \nabla v)_{L^2(L^2_n)} = \delta(e^y, v)_{L^1(Q),L^\infty(Q)} \\ \qquad\qquad + (u, v)_{L^2(\Sigma)} \quad \text{for all } v \in L^\infty(0,T;X_1), \\ y(0,\cdot) = \varphi. \end{cases} \tag{3.31}$$

We introduce the condition

$$\begin{cases} J: L^2(0,T;H^1(\Omega)) \times L^2(\Omega) \times L^2(\Sigma) \to \mathbb{R} \text{ is bounded from below,} \\ \text{weakly lower semicontinuous, and coercive in the sense that} \\ J(y, y(T,\cdot), u) \to \infty \text{ if } |y|_{L^2(0,T;H^1)} \to \infty \text{ or } |y(T,\cdot)|_{L^2(\Omega)} \to \infty \text{ or} \\ |u|_{L^2(\Sigma)} \to \infty. \end{cases} \tag{A8}$$

If (A8) holds and there exists $u \in L^2(\Sigma)$ such that (3.30) admits a solution $y(u)$, then there exists a solution $(y^*, y^*(T,\cdot), u^*) \in \widetilde{W} \times L^2(\Omega) \times L^1(\Sigma)$. In fact, one first argues, in a manner similar to that used for Proposition 3.2, that every solution y to (3.30) satisfies

$$\begin{aligned} &\delta \textstyle\int_Q e^y y dQ + \frac{1}{2}|\varphi|^2_{L^2(\Omega)} \\ &\leq \tfrac{1}{2}|y(T,\cdot)|^2_{L^2(\Omega)} + |\nabla y|^2_{L^2(L^2_n)} + \tfrac{1}{2}|u|^2_{L^2(\Sigma)} + \tfrac{K}{2}|y|^2_{L^2(H^1)}, \end{aligned} \tag{3.32}$$

where K is the embedding constant of $L^2(\partial\Omega)$ into $H^1(\Omega)$. The existence proof is then quite similar to that of Theorem 3.3, with $H^1_0(\Omega)$ and W replaced by $H^1(\Omega)$ and $\widetilde{W}$. Formally it simple to derive a first-order optimality condition for (3.29)–(3.30). The detailed analysis of optimality conditions for boundary control problems is not within the scope of this paper, however.

Appendix. *Proof of Proposition* 3.2. Let $\{S_\epsilon : \epsilon > 0\}$ denote the semigroup generated by the Laplacian with homogenous Dirichlet boundary conditions in $L^1(\Omega)$. Recall that $S_\epsilon(L^1(\Omega)) \subset L^\infty(\Omega)$ for every $\epsilon > 0$. The restriction of S_ϵ to $L^2(\Omega)$ will be denoted by S_ϵ as well. S_ϵ is used as a spatial smoothing operation. For the temporal smoothing we use

$$T_\epsilon : L^1(0,T;X_1^*) \to W^{1,1}(0,T;X_1^*)$$

given by

$$T_\epsilon v(t) = \frac{1}{\epsilon}\int_t^{t+\epsilon} v(s)\,ds,$$

where v is extended by 0 for $s > T$. Applying $T_\epsilon S_\epsilon$ to (3.4), we obtain for every $\epsilon > 0$

$$(T_\epsilon S_\epsilon y)_t = \Delta(T_\epsilon S_\epsilon y) + \delta T_\epsilon S_\epsilon e^y + T_\epsilon S_\epsilon u, \tag{A.1}$$

where $T_\epsilon S_\epsilon y \in W^{1,2}(0,T;H_0^1 \cap L^\infty)$. In fact, $y \in L^2(0,T;H_0^1), S_\epsilon y \in L^2(0,T;H_0^1 \cap L^\infty)$, and hence $T_\epsilon S_\epsilon y \in W^{1,2}(0,T;H_0^1 \cap L^\infty)$. In addition we have $\Delta(T_\epsilon S_\epsilon y) \in L^2(0,T;L^2), T_\epsilon S_\epsilon u \in L^2(0,T;L^2)$, and $T_\epsilon S_\epsilon e^y \in L^\infty(Q)$. Set $z_\epsilon = T_\epsilon S_\epsilon y \in L^\infty(Q)$ and note that z_ϵ can be identified a.e. with an element of $H^1(Q)$. Since the positive part z_ϵ^+ of z_ϵ is an element of $H^1(Q)$ and $L^2(0,T;H_0^1)$ as well, we can integrate (A.1) against z^+ on Q. Let us first consider

$$\int_Q z_\epsilon z_{\epsilon,t}^+ = \int_\Omega \int_0^T z_\epsilon z_{\epsilon,t}^+ = \frac{1}{2}\int_\Omega |z_\epsilon^+(T,\cdot)|^2 - \frac{1}{2}\int_\Omega |z_\epsilon^+(0,\cdot)|^2.$$

We thus obtain from (A.1)

$$\begin{aligned}
&\delta \textstyle\int_Q T_\epsilon S_\epsilon e^y (T_\epsilon S_\epsilon y)^+ dx\,dt + \frac{1}{2}\int_\Omega |z_\epsilon^+(0,\cdot)|^2 dx \\
&\le \tfrac{1}{2}\textstyle\int_\Omega |z_\epsilon^+(T,\cdot)|^2 dx + \int_0^T (\nabla z_\epsilon, \nabla z_\epsilon^+)_{L_n^2(\Omega)} dt \\
&\qquad - \textstyle\int_0^T (T_\epsilon S_\epsilon u, z_\epsilon^+)_{L^2(\Omega)} dt.
\end{aligned}$$

Applying Fatou's lemma, we obtain

$$\begin{aligned}
&\delta \textstyle\int_Q e^y y^+ dx\,dt + \frac{1}{2}\int_\Omega |\varphi^+|^2 dx \\
&\le \liminf_{\epsilon \to 0^+} \Big[\tfrac{1}{2}\textstyle\int_\Omega |z_\epsilon^+(T,\cdot)|^2 dx + \int_0^T (\nabla z_\epsilon, \nabla z_\epsilon^+)_{L_n^2(\Omega)} dt \\
&\qquad - \textstyle\int_0^T (T_\epsilon S_\epsilon u, z_\epsilon^+)_{L^2(\Omega)} dt \Big].
\end{aligned} \tag{A.2}$$

Next Lebesque's bounded convergence theorem is applied to the right-hand side of (A.2). It is applicable, since S_ϵ is a contraction semigroup and T_ϵ is a contraction as well. To pass to the limit in the expression $(\nabla z_\epsilon(t,\cdot), \nabla z_\epsilon^+(t,\cdot))_{L_n^2(\Omega)}$ for fixed $t > 0$, we recall that the mapping $u \to u^+$ is continuous from $H^1(\Omega)$ to itself (see [T, p. 79]). Hence we have

$$\begin{aligned}
&\delta \textstyle\int_Q e^y y\,dx\,dt + \frac{1}{2}\int_\Omega |\varphi^+|^2 dx \\
&\le \tfrac{1}{2}\textstyle\int_\Omega |y^+(T,\cdot)|^2_{L^2(\Omega)} dx + \int_0^T |\nabla y^+|^2_{L_n^2(\Omega)} dt - \int_0^T (u, y^+)_{L^2(\Omega)} dt.
\end{aligned} \tag{A.3}$$

The analogous estimate holds for y^-, and hence (3.5) follows. ∎

VARIATIONAL PROBLEMS WITH NONCONVEX, NONCOERCIVE, HIGHLY DISCONTINUOUS INTEGRANDS: CHARACTERIZATION AND EXISTENCE OF MINIMIZERS*

CRISTINA MARCELLI†

Abstract. We consider the functional $F(v) = \int_a^b f(t, v'(t))dt$ in $\mathcal{H}_p = \{v \in W^{1,p} : v(a) = 0, v(b) = d\}$, $p \in [1, +\infty]$. Under only the assumption that the integrand is $\mathcal{L} \otimes \mathcal{B}_n$-measurable, we prove characterizations of strong and weak minimizers both in terms of the minimizers of the relaxed functional and by means of the Euler–Lagrange inclusion.

As an application, we provide necessary and sufficient conditions for the existence of the minimum, expressed in terms of a limitation on the width of the slope d.

Key words. strong and weak minimizers, Euler–Lagrange condition, convexification, subdifferential

1. Introduction.

The study of nonsmooth and nonconvex variational problems has been widely developed in recent years, with regard to both necessary conditions for optimality and sufficient conditions for existence of minimizers. The development of nonsmooth analysis has allowed researchers to deal with nonregular problems. In particular, the introduction of various types of subdifferentials that are sharper and sharper, starting with Clarke's and continuing with the more refined Mordukhovich's subdifferential, permitted the achievement of nonsmooth versions of the classical Euler–Lagrange condition (see [7], [8], [12], [13], [21], [22], [23], [24] [25], [31]). In particular, in the paper by Ioffe and Rockafellar [13], which deals with nonsmooth integrands $f = f(t, v(t), v'(t))$ everywhere finite, the Euler–Lagrange condition is proved for weak local minimizers (w.l.m.) by means of this last type of subdifferential.

In the same paper the authors also prove the Weierstrass condition for minimizers in the $W^{1,1}$-norm (see [13, Theorem 1]), which are usually called *intermediate minimizers*. Of course, this condition can not hold in general for w.l.m., since it has a global character.

In this paper we consider the optimization problem

$$\text{minimize} \quad F(v) = \int_a^b f(t, v'(t))dt$$

in the class

$$\mathcal{H}_p = \left\{ v \in W^{1,p}([a,b]; \mathbb{R}^n) : \int_a^b f(t, v'(t))dt \text{ is well-defined in } \tilde{\mathbb{R}}, v(a) = 0, v(b) = d \right\}$$

for $p \in [1, +\infty]$, where $\tilde{\mathbb{R}} = \mathbb{R} \cup \{\pm\infty\}$ and the integrand $f : [a,b] \times \mathbb{R}^n \to \mathbb{R} \cup \{+\infty\}$ is assumed to be only $\mathcal{L} \bigotimes \mathcal{B}_n$-measurable, hence, in general, neither convex nor coercive nor continuous.

†Dipartimento di Matematica "V. Volterra," Universitá di Ancona, Via Brecce Bianche, 60131 Ancona, Italy (marcelli@dipmat.unian.it).

The first aim of this paper is to provide, under these minimal assumptions, a localized version of the Weierstrass condition for w.l.m., which allows us to obtain a Euler–Lagrange inclusion expressed in terms of a localized version of the subdifferential in the sense of convex analysis. This type of subgradient, which in general is strictly contained in the other types of subdifferential, is the best one in this context in which the integrand is of the type $f = f(t, v'(t))$. Indeed, the present version of the Euler–Lagrange condition also provides a sufficient condition for optimality.

In order to provide more detail, our first main result (see Theorem 3.2) is a characterization of $W^{1,p}$-strong local minimizers, that is, functions $u_0 \in W^{1,1}$ for which there exists $\delta > 0$ such that $F(u_0) \leq F(v)$ for every $v \in u_0 + W_0^{1,p}$ with $|v(t) - u_0(t)| < \delta$ for every $t \in [a, b]$. In particular, we prove that $u_0 \in \mathcal{H}_1$ is a $W^{1,p}$-strong local minimizer if and only if $F(u_0) = \min_{v \in \mathcal{H}_p} \int_a^b f^{**}(t, v'(t))dt$, and this condition is equivalent to the Euler–Lagrange inclusion $c \in \partial f(t, u_0'(t))$ a.e. in $[a, b]$, where $\partial f(t, \cdot)$ denotes the usual subgradient in the sense of convex analysis.

As a consequence, note that if u_0 is a $W^{1,p}$-strong local minimizer, then it is also a global minimizer. Moreover, when the minimum exists, the integrand f coincides with its convex envelope along the minimizer, even if it is nonconvex and highly discontinuous. Furthermore, the Euler–Lagrange inclusion involves the usual subgradient in the sense of convex analysis, even if the integrand is not convex in general. Finally, this characterization extends a result in [1] where the Euler–Lagrange inclusion is obtained for nonconvex integrands, but under a suitable growth assumption.

We also obtain a similar characterization for w.l.m., that is, functions u_0 such that $F(u_0) \leq F(v)$ for every $v \in u_0 + W_0^{1,p}$ with $|v'(t) - u_0'(t)| < \epsilon$, for almost every $t \in [a, b]$, for some $\epsilon > 0$, by means of a localization of the subgradient (see Corollary 3.4).

We wish to underline that, with regard to the regularity of the integrand, we only assume the measurability with respect to the last variable, contrary to most of the papers on this subject, in which lower semicontinuity and limitations by summable functions are needed, such as in [13], [17]. In particular, in [17] a version of the Euler–Lagrange condition in terms of the subdifferential of convex analysis is obtained for complete integrands $f = f(t, v(t), v'(t))$, everywhere finite. In the present paper, we limit ourselves to dealing with integrands of the type $f = f(t, v'(t))$, taking values on $\mathbb{R} \cup \{+\infty\}$, for which we require weaker regularity assumptions.

As a consequence of these results, we are able to prove a general existence theorem for nonconvex problems, which will allow us to get many applications concerning the existence of minimizers in the second part of the paper.

In more detail, denoting by $C_t = \{z \in \mathbb{R}^n : f(t, z) = f^{**}(t, z)\}$ the set where $f(t, \cdot)$ coincides with its convex envelope, we prove (see Theorem 3.5) that the functional F admits a minimum in $\mathcal{H}_p$ if and only if there exists $u_0 \in \mathcal{H}_p$ such that $\int_a^b f^{**}(t, u_0'(t))dt = \min_{v \in \mathcal{H}_p} \int_a^b f^{**}(t, v'(t))dt$ and $u_0'(t) \in co(C_t)$ a.e. in $[a, b]$. By applying this result, we are able to give very operative necessary and sufficient conditions for the existence of the minimum in the scalar case ($n = 1$).

We recall that in [18] Marcellini proved the existence of the minimum for the functional F under the assumption that $f(t, \cdot)$ is coercive but not necessarily convex. As is well known, when the integrand is not coercive the functional F could admit no minimum. A classical example is provided by the weighed length functional, whose integrand has the form $f(t, z) = \phi(t)\sqrt{1 + z^2}$. For such a functional, Kaiser proved in [14] that the existence of the minimum depends on the width of the slope d. More precisely, he obtained a necessary and sufficient condition for the existence of the

minimum, expressed in terms of a limitation on the slope d.

This result was extended by Brandi in [4] to the case of more general convex integrands. Subsequently in [15] a necessary and sufficient condition for the existence of the minimum of the functional F with integrand convex but not coercive was established. This condition consists of a limitation on the slope d in such a way that the range of the values of d for which the minimum exists is exactly determined.

Such results take a boundary condition (the width of d) into consideration as a specific parameter of the variational problem. This approach to the existence of the minimum is quite different from the classical *direct method*, which indeed presents well-known limitations in the treatment of noncoercive or nonconvex problems.

The importance of the role played by boundary conditions and other specific parameters of the problem is discussed by Mordukhovich in [26], where *individual existence theorems* are presented in the setting of optimal control problems, together with examples, a survey, and a wide bibliography on this subject.

In this paper we are able to discuss the existence of the minimum related to the parameter d in the case of nonconvex and noncoercive integrands. Indeed, we exactly determine the set $D = \{d \in \mathbb{R} : F(v) \text{ admits minimum}\}$ (see Theorem 4.2).

The result we obtain becomes particularly expressive when the integrand has the structure $f(t,z) = \phi(t)h(z)$. Indeed, set $C = \{z : h(z) = h^{**}(z)\}$, and in general we have $D \subset co(C)$, but strict inclusion may occur, as we show in Example 4.1.

More precisely, for the case in which h is not convex at ∞, i.e., the set C is bounded, we show that if h^{**} is strictly convex in C, then D is strictly contained in $co(C)$. Whereas, when h^{**} is affine in $co(C)$, it can happen that $D = co(C)$. We prove that this situation occurs if and only if a precise relation, which links the minimum and the maximum of the function $\phi(t)$ and the left and right derivatives of h^{**} in $\min C$, $\max C$, is satisfied (see Corollary 4.5).

Finally, in the case when $f^{**}(t,\cdot)$ is strictly convex at ∞ (but not necessarily coercive), we show that the range D is exactly the same as that obtained for the convex case in [15].

With regard to the methodology used in order to prove our main result about the characterization of minimizers, we wish to remark that a key tool is a localized version of classical relaxation theorems. Specifically, set $S_p(u_0,\epsilon) = \{v \in u_0 + W_0^{1,p} : |u_0(t) - v(t)| < \epsilon \text{ for every } t \in [a,b]\}$; we prove (see Theorem 2.1)

$$\inf_{v \in S_p(u_0,\epsilon)} F(v) = \inf_{v \in S_q(u_0,\epsilon)} \int_a^b f^{**}(t, v'(t))dt \qquad \text{for every } \ \epsilon > 0, \quad p, q \in [1, +\infty],$$

from which one deduces, as a particular case, $\inf_{v \in \mathcal{H}_p} F(v) = \inf_{v \in \mathcal{H}_p} \int_a^b f^{**}(t, v'(t))dt$.

2. Notations and relaxation theorem. Let $f : [a,b] \times \mathbb{R}^n \to \mathbb{R} \cup \{+\infty\}$ be a given $\mathcal{L} \bigotimes \mathcal{B}_n$-measurable function, where $\mathcal{L}$, $\mathcal{B}_n$ denote, respectively, the Lebesgue and Borel σ-fields in $[a,b]$ and $\mathbb{R}^n$. As usual, we denote by $\mathrm{dom} f = \{(t,z) : f(t,z) < +\infty\}$ and by $\mathrm{dom} f(t,\cdot) = \{z \in \mathbb{R}^n : f(t,z) < +\infty\}$.

Let $f^{**}(t,\cdot)$ and $\mathcal{C}f(t,\cdot)$ be the bipolar function and the convex envelope of the function $f(t,\cdot)$, respectively. As is well known (see, e.g., [29, Corollary 17.1.5]), we have

$$\mathcal{C}f(t,z) = \inf \left\{ \sum_{j=1}^{n+1} \lambda_j f(t,\xi_j) : \lambda_j \in [0,1], \ \sum_{j=1}^{n+1} \lambda_j = 1, \ \sum_{j=1}^{n+1} \lambda_j \xi_j = z \right\}. \tag{2.1}$$

Moreover, f^{**} is convex and lower semicontinuous; hence we have

$$f^{**}(t,\cdot) \le \mathcal{C}f(t,\cdot) \le f(t,\cdot), \tag{2.2}$$

and if dom $f(t,\cdot) = \mathbb{R}^n$, then we have $f^{**} \equiv \mathcal{C}f$ (see, e.g., [10, Theorem 2.2.5]). But note that in general we have

$$\mathcal{C}f(t,z) = f^{**}(t,z) \quad \text{for every } z \in \text{int}(\text{co}(\text{dom}f(t,\cdot))).$$

Of course, dom $f^{**}(t,\cdot) = \overline{co}(\text{dom}f(t,\cdot))$, where $\overline{co}(\cdot)$ denotes the closure of the convex hull.

We denote by $\partial f(t,z)$ the subgradient of $f(t,\cdot)$ at the point z in the sense of convex analysis, i.e.,

$$\partial f(t,z) = \{\zeta \in \mathbb{R}^n \ : \ f(t,w) \ge f(t,z) + \langle \zeta, w - z\rangle \ \text{ for every } \ w \in \mathbb{R}^n\}.$$

In what follows we consider for $p \in [1,+\infty]$ the classes

$$\mathcal{H}_p = \left\{ v \in W^{1,p} \ : \ \int_a^b f(t,v'(t))dt \text{ is well-defined in } \tilde{\mathbb{R}}, v(a) = 0, v(b) = d \right\}.$$

Let $F : \mathcal{H}_1 \to \tilde{\mathbb{R}}$ be the functional defined by $F(v) = \int_a^b f(t,v'(t))dt$.

Let $u_0 \in \mathcal{H}_1$ be given. For every $\epsilon > 0$, we denote by

$$S_p(u_0,\epsilon) = \{v \in u_0 + W_0^{1,p} : |u_0(t) - v(t)| < \epsilon \quad \text{for every } t \in [a,b]\},$$

$$W_p(u_0,\epsilon) = \{v \in u_0 + W_0^{1,p} : \|u_0 - v\|_{W_0^{1,p}} < \epsilon\}$$

the strong and weak ϵ-neighborhoods of u_0.

Recall that a function $u_0 \in W^{1,p}(a,b)$ is said to be a *(global) minimizer* for the functional F in $\mathcal{H}_p$ if $F(u_0) \le F(v)$ for every $v \in \mathcal{H}_p$, whereas it is said to be a $W^{1,q}$*-strong* (respectively, $W^{1,q}$*-weak*) *local minimizer*, with $q \ge p$, if a constant $\epsilon > 0$ exists such that $F(u_0) \le F(v)$ for every $v \in S_q(u_0,\epsilon)$ (respectively, $v \in W_q(u_0,\epsilon)$).

Functions u_0, which are $W^{1,\infty}$-weak local minimizers, are usually simply called *w.l.m.* In contrast, $W^{1,p}$-weak local minimizers for $p < +\infty$ are called *intermediate local minimizers*. In [25], [30] the relation between strong, intermediate, and weak local minimizers is discussed, showing that they are different concepts in general.

In the present paper we characterize strong and weak local minimizers.

The following theorem is a relaxation-type result for infima taken over strong neighborhoods.

THEOREM 2.1. *Let* $f : [a,b] \times \mathbb{R}^n \to \mathbb{R} \cup \{+\infty\}$ *be a* $\mathcal{L} \bigotimes \mathcal{B}_n$*-measurable function such that* dom$f(t,\cdot)$ *is a convex set for almost every* $t \in [a,b]$.

Assume that some $u_0 \in W^{1,1}(a,b)$ *satisfies both* $F(u_0) < +\infty$ *and*

$$u_0'(t) \in \text{int } (\text{dom}f(t,\cdot)) \qquad \text{a.e. in } [a,b]. \tag{2.3}$$

Then, for every $p,q \in [1,+\infty]$ *and every* $\epsilon > 0$,

$$\inf_{v \in S_p(u_0,\epsilon)} F(v) = \inf_{v \in S_q(u_0,\epsilon)} \int_a^b f^{**}(t,v'(t))dt.$$

In particular,

$$\inf_{v\in\mathcal{H}_p} F(v) = \inf_{v\in\mathcal{H}_p} \int_a^b f^{**}(t, v'(t))dt.$$

Let us now recall a classical Lyapunov-type result, whose proof can be found in [6, Theorem 16.1.v], which will play a fundamental role in the proof of Theorem 2.1.

LYAPUNOV THEOREM. *Let $g_j : A \to \mathbb{R}^m$, $j = 1, \dots, h$, be L-integrable functions on a set $A \subset \mathbb{R}$ with finite measure, and let $\lambda_j : A \to [0, 1]$, $j = 1, \dots, h$, be measurable weight functions with $\sum_{j=1}^h \lambda_j(t) = 1$.*

Then, there exists a decomposition $E_1, \dots, E_h$ of A into disjoint measurable subsets such that

$$\sum_{j=1}^h \int_{E_j} g_j(t)dt = \int_A \sum_{j=1}^h \lambda_j(t) g_j(t)dt.$$

Proof of Theorem 2.1. Taking equation (2.2) into account, it suffices to show that $\inf_{v\in S_p(u_0,\epsilon)} F(v) \le \inf_{v\in S_q(u_0,\epsilon)} \int_a^b f^{**}(t, v'(t))dt$ for every $\epsilon > 0$ and every $p, q \in [1, +\infty]$.

Let us assume, for contradiction, that for some $\epsilon > 0$ and some $p, q \in [1, +\infty]$ there exists $w \in S_q(u_0, \epsilon)$ such that

$$\int_a^b f^{**}(t, w'(t))dt < \inf_{v\in S_p(u_0,\epsilon)} F(v).$$

Let α, β be two real numbers such that

$$\int_a^b f^{**}(t, w'(t))dt < \alpha < \beta < \inf_{v\in S_p(u_0,\epsilon)} F(v).$$

Let $\delta \in]0, 1/2[$ be such that $B(w(t), \delta) \subset B(u_0(t), \epsilon)$ for every $t \in [0, 1]$ and

$$(1-\delta)\int_a^b f^{**}(t, w'(t))dt + \delta \int_a^b f^{**}(t, u_0'(t))dt < \alpha,$$

with obvious meaning in the case $\int_a^b f^{**}(t, w'(t))dt = -\infty$ or $\int_a^b f^{**}(t, u_0'(t))dt = -\infty$. (Notice that both of the previous integrals are less than $+\infty$.)

For $\tilde{w}(t) := (1-\delta)w(t) + \delta u_0(t)$, we have that $B(\tilde{w}(t), \delta) \subset B(u_0(t), \epsilon)$ for every $t \in [a, b]$, and by the convexity of the function f^{**} we deduce that

$$\int_a^b f^{**}(t, \tilde{w}'(t))dt \le (1-\delta)\int_a^b f^{**}(t, w'(t))dt + \delta \int_a^b f^{**}(t, u_0'(t))dt < \alpha.$$

Moreover, since $w'(t) \in \mathrm{dom} f^{**}(t, \cdot)$ for almost all t, by virtue of the convexity of $\mathrm{dom} f(t, \cdot)$ and by (2.3) we have that $\tilde{w}'(t) \in \mathrm{int}(\mathrm{dom} f(t, \cdot))$ a.e. in $[a, b]$. Hence,

$$f^{**}(t, \tilde{w}'(t)) = \mathcal{C}f(t, \tilde{w}'(t)) \quad \text{for a.a. (almost all) } t \in [a, b]. \tag{2.4}$$

Let $g : [a, b] \to \mathbb{R}$ be a summable function such that $g(t) > f^{**}(t, \tilde{w}'(t))$ and

$$\int_a^b g(t)dt < \alpha.$$

Combining (2.1) with (2.4) shows that the multifunction $Q : t \in [a,b] \mapsto Q(t) \subset [0,1]^{n+1} \times \mathbb{R}^{n(n+1)}$ defined by

$$Q(t) = \left\{ (\lambda, \xi) \ : \ \sum_{j=1}^{n+1} \lambda_j = 1, \sum_{j=1}^{n+1} \lambda_j \xi_j = \tilde{w}'(t), \sum_{j=1}^{n+1} \lambda_j f(t, \xi_j) \leq g(t), \ f(t, \xi_j) < +\infty \right\}$$

has nonempty values and is measurable. By virtue of the Aumann selection theorem [8, Theorem 7.2.1], there exist measurable functions $\lambda_j : [a,b] \to [0,1]$, $\xi_j : [a,b] \to \mathbb{R}^n$, $j = 1, \dots, n+1$, such that $\sum_{j=1}^{n+1} \lambda_j(t)\xi_j(t) = \tilde{w}'(t)$ and

$$\sum_{j=1}^{n+1} \lambda_j(t) f(t, \xi_j(t)) \leq g(t) \quad \text{a.e. in } [a,b]. \tag{2.5}$$

Let $\rho > 0$ be a real number such that for every set $E \subset [a,b]$ with $|E| < 2\rho$ we have

$$\int_E (|u_0'(t)| + |\tilde{w}'(t)|)dt < \frac{\delta}{3}, \tag{2.6}$$

$$\int_E |f(t, u_0'(t))|dt < \frac{1}{2}(\beta - \alpha), \tag{2.7}$$

$$\int_{[a,b]\setminus E} g(t)dt < \alpha. \tag{2.8}$$

Let $r \in]0,1[$ be such that for $G = \{t : \overline{B(\tilde{w}'(t), nr)} \subset \mathrm{dom} f(t, \cdot)\}$ we have $|G| > b - a - \rho/2$.

Let $C \subset G$ be a compact set with $(b-a) - \rho < |C| < b - a$, and let $L > 0$ be a constant such that for almost every $t \in C$ and every $\lambda \in \mathbb{R}^n$ with $\lambda_i \in \{\tilde{w}_i'(t), \tilde{w}_i'(t) + r, \tilde{w}_i'(t) - r\}$, $i = 1, \dots, n$, we have

$$|u_0'(t)| + |\tilde{w}'(t)| + \sum_{j=1}^{n+1} |\xi_j(t)| + \sum_{j=1}^{n+1} |f(t, \xi_j(t))| + |f(t, \lambda)| \leq L. \tag{2.9}$$

Put $\sigma := \min\{\frac{\beta - \alpha}{2L}, \rho, |C|, \delta/3n\}$, let $A \subset [a,b] \setminus C$ be a set, and let $N > 0$ be a constant such that we have

$$\sum_{j=1}^{n+1} (|f(t, \xi_j(t))| + |\xi_j(t)|) + |\tilde{w}'(t)| + |u_0'(t)| \leq N \ \text{ for a.a. } t \in [a,b] \setminus (A \cup C), \tag{2.10}$$

$$\int_A |\tilde{w}'(t) - u_0'(t)|dt \leq r\sigma. \tag{2.11}$$

Let $C^* \subset C$ be a set with $|C^*| = \sigma$. Set $B = [a,b] \setminus (A \cup C^*)$ and let $B_1, \dots, B_s$ be a finite partition of B into disjoint measurable subsets such that

$$|B_k| < \rho, \quad \sup B_k \leq \inf B_{k+1}, \qquad k = 1, \dots, s,$$

and

$$\int_{B_k}\left(|\tilde{w}'(t)|+\sum_{j=1}^{n+1}|\xi_j(t)|\right)dt\le\frac{\delta}{3},\quad k=1,\dots,s. \tag{2.12}$$

For every $k\in\{1,\dots,s\}$ we can apply the Lyapunov theorem to the functions $h_j:B_k\to\mathbb{R}^{n+1}$, $j=1,\dots,n+1$, defined by $h_j(t)=(\xi_j(t),f(t,\xi_j(t)))$ to deduce that for every $k=1,\dots,s$ there exist disjoint sets $E_1^k,\dots,E_{n+1}^k\subset B_k$ such that for $\phi(t)=\sum_{k=1}^{s}\sum_{j=1}^{n+1}\chi_{E_j^k}(t)\xi_j(t)$, where $\chi_D(\cdot)$ denotes the characteristic function of the set D, we have

$$\int_{B_k}\phi(t)dt=\int_{B_k}\sum_{j=1}^{n+1}\lambda_j(t)\xi_j(t)dt=\int_{B_k}\tilde{w}'(t)dt,\quad k=1,\dots,s. \tag{2.13}$$

Notice that, taking (2.5), (2.8) into account,

$$\int_B f(t,\phi(t))dt=\int_B\sum_{j=1}^{n+1}\lambda_j(t)f(t,\xi_j(t))dt\le\int_B g(t)dt<\alpha. \tag{2.14}$$

For every $i\in\{1,\dots,n\}$ set $\gamma_i:=\int_A[\tilde{w}_i'(t)-u_{0i}'(t)]dt$. By (2.11) we can choose a set $C_i^*\subset C^*$ such that $|C_i^*|=|\gamma_i|/r$.

Finally, for every $i\in\{1,\dots,n\}$, set

$$\psi_i(t):=\begin{cases}u_{0i}'(t), & t\in A,\\ \phi_i(t), & t\in B,\\ \tilde{w}_i'(t)+r\ \operatorname{sgn}(\gamma_i), & t\in C_i^*,\\ \tilde{w}_i'(t), & t\in C^*\setminus C_i^*,\end{cases}$$

and let $\tilde{v}(t):=\int_a^t\psi(\tau)d\tau$. Note that by (2.9) we have $|f(t,\psi(t))|\le L$ for almost every $t\in C^*$. Moreover, from (2.13) it follows that

$$\int_a^b\tilde{v}_i'(t)dt=\int_A u_{0i}'(t)dt+\int_B\phi_i(t)dt+\int_{C^*}\tilde{w}_i'(t)dt+|\gamma_i|\operatorname{sgn}(\gamma_i)=\int_a^b\tilde{w}_i'(t)dt.$$

Hence, by (2.9) and (2.10) we have $u_0-\tilde{v}\in W_0^{1,\infty}(a,b)$.

Moreover, by (2.6), (2.12), (2.13), for every $t\in[a,b]$ we have

$$|\tilde{v}(t)-\tilde{w}(t)|\le\int_A|u_0'(\tau)-\tilde{w}'(\tau)|d\tau+\int_{B_k}|\phi(\tau)-\tilde{w}'(\tau)|d\tau+n\sigma\le\frac{\delta}{3}+\frac{\delta}{3}+\frac{\delta}{3},$$

where $k\in\{1,\dots,s\}$ is such that $\sup B_{k-1}<t\le\sup B_k$, and $B_0=\{a\}$.

Hence, $\tilde{v}\in S_p(u_0,\epsilon)$. Finally, from (2.7), (2.14) we deduce

$$F(\tilde{v})=\int_a^b f(t,\tilde{v}'(t))dt=\int_A f(t,u_0'(t))dt+\int_B f(t,\phi(t))dt+\int_{C^*}f(t,\psi(t))dt$$

$$<\frac{1}{2}(\beta-\alpha)+\alpha+L\sigma\le\beta<\inf_{v\in S_p(u_0,\epsilon)}F(v),$$

a contradiction. □

Remark 2.2. Assumption (2.3) in Theorem 2.1 can be weakened as follows:

$$\operatorname{meas}\{t:u_0'(t)\in\ \operatorname{int}\ (\operatorname{dom}\ f(t,\cdot))\}>0, \tag{2.3′}$$

provided we replace f^{**} with $\mathcal{C}f$ in the assertion. In fact, in view of the proof, in this case it suffices if we ensure that $C^*\subset G$, and this is possible, provided $|G|>0$.

3. Characterization of minimizers. As a consequence of the relaxation theorem, we now prove a characterization for strong minimizers both in terms of minimizers of the relaxed functional and in terms of the Euler–Lagrange inclusion. This will generalize the following result by Ambrosio, Ascenzi, and Buttazzo [1], which concerns convex integrands.

THEOREM 3.1 (see [1, Theorem 3.1]). *Let $f : [0,1] \times \mathbb{R}^n \to [0,+\infty]$ be an $\mathcal{L} \bigotimes \mathcal{B}_n$-measurable function lower semicontinuous and convex with respect to the last variable.*

Let $u_0 \in W^{1,1}(0,1)$ be a w.l.m. for the functional F such that

$$u_0'(t) \in \text{int } (\text{dom } f(t,\cdot)) \qquad a.e.\ in\ \ [0,1].$$

Then, there exists $c \in \mathbb{R}^n$ with

$$c \in \partial f(t, u_0'(t)) \qquad a.e.\ in\ [0,1].$$

In the next theorem, we consider nonconvex integrands which are only assumed to be $\mathcal{L} \bigotimes \mathcal{B}_n$-measurable. By using Theorem 2.1, we show that the Euler–Lagrange inclusion is a necessary and sufficient condition for the existence of the minimum.

THEOREM 3.2. *Let $f : [a,b] \times \mathbb{R}^n \to \mathbb{R} \cup \{+\infty\}$ be a given $\mathcal{L} \bigotimes \mathcal{B}_n$-measurable function such that* dom $f(t,\cdot)$ *is a convex set for almost every $t \in [a,b]$.*

Let $u_0 \in \mathcal{H}_1$ be such that $F(u_0) \in \mathbb{R}$ and

$$u_0'(t) \in \text{int } (\text{dom} f(t,\cdot)) \qquad a.e.\ in\ [a,b]. \tag{3.1}$$

Then, the following conditions are equivalent:

(i) *u_0 is a $W^{1,p}$-strong local minimizer for F;*

(ii) *$F(u_0) = \int_a^b f^{**}(t, u_0'(t))dt = \min_{v \in \mathcal{H}_p} \int_a^b f^{**}(t, v'(t))dt$;*

(iii) *a constant $c \in \mathbb{R}^n$ exists such that $c \in \partial f(t, u_0'(t))$ a.e. in $[a,b]$.*

Proof. The implication (i) $\Rightarrow$ (ii) is an immediate consequence of Theorem 2.1, taking the convexity of f^{**} into account.

Let us now prove the implication (ii) $\Rightarrow$ (iii). Set

$$\tilde{f}(t,z) := \max\{f^{**}(t,z), f^{**}(t,u_0'(t)) - 1\} - [f^{**}(t,u_0'(t)) - 1]$$

and $\tilde{F}(v) = \int_a^b \tilde{f}(t, v'(t))dt$.

Of course $\tilde{f}$ is a nonnegative function, convex and lower semicontinuous in the second argument. Moreover, since $\tilde{f}(t,z) \geq f^{**}(t,z) - f^{**}(t,u_0'(t)) + 1$, it is easy to see that $\tilde{F}(u_0) = \min_{v \in \mathcal{H}_p} \tilde{F}(v)$. Hence, we can apply Theorem 3.1 to deduce that a constant $c \in \mathbb{R}^n$ exists such that $c \in \partial \tilde{f}(t, u_0'(t))$ a.e. in $[a,b]$, i.e.,

$$\max\{f^{**}(t,z), f^{**}(t,u_0'(t)) - 1\} \geq f^{**}(t,u_0'(t)) + \langle c, z - u_0'(t)\rangle, \quad z \in \mathbb{R}^n, \text{ a.e. } t \in [a,b].$$

Therefore, for almost every $t \in [a,b]$ there exists a real number $\rho > 0$ such that

$$f^{**}(t,z) \geq f^{**}(t,u_0'(t)) + \langle c, z - u_0'(t)\rangle \qquad \text{for every } z \in B(u_0'(t), \rho);$$

hence, taking the convexity of f^{**} into account, we deduce that $c \in \partial f^{**}(t, u_0'(t))$ a.e. in $[a,b]$. Now, the assertion follows immediately, since

$$f(t,z) \geq f^{**}(t,z) \geq f^{**}(t,u_0'(t)) + \langle c, z - u_0'(t)\rangle = f(t,u_0'(t)) + \langle c, z - u_0'(t)\rangle.$$

(iii) $\Rightarrow$ (i). For every $v \in \mathcal{H}_p$, the subgradient inequality gives

$$\int_a^b f(t,v'(t))dt \geq \int_a^b f(t,u_0'(t))dt + \int_a^b \langle c, v'(t) - u_0'(t)\rangle dt = \int_a^b f(t,u_0'(t))dt. \qquad \square$$

Remark 3.3. The previous theorem also improves an analogous result established in [1] (see Proposition 3.6) for nonconvex integrands f which are $\mathcal{L}\bigotimes\mathcal{B}_n$-measurable, but under the following additional hypothesis:

$$(*) \qquad |z|^p \leq f(t,z) \leq K(1+|z|^p) \quad \text{for some } p > 1.$$

Now we will apply Theorem 3.2 to obtain an analogous equivalence result for w.l.m. as well.

For a given subset $S \subset \mathbb{R}^n$, let $\delta_S(\cdot)$ be the indicator function; that is, $\delta_S(z) = 0$ if $z \in S$, $\delta_S(z) = +\infty$ otherwise. If u_0 is a w.l.m. for functional F with respect to the weak ϵ-neighborhood $W_\infty(u_0,\epsilon)$, set

$$\tilde{f}_\epsilon(t,z) := f(t,z) + \delta_{B(u_0'(t),\epsilon)}(z) \quad \text{and} \quad \tilde{F}_\epsilon(u) := \int_a^b \tilde{f}_\epsilon(t,u'(t))dt;$$

then u_0 is a global minimizer for functional $\tilde{F}_\epsilon$. Hence, we have the following result.

COROLLARY 3.4. *Under the same assumptions of Theorem* 3.2, *the function* $u_0 \in \mathcal{H}_1$ *is a w.l.m. for the functional* F *in the weak* ϵ*-neighborhood* $W_\infty(u_0,\epsilon)$ *if and only if a constant* $c \in \mathbb{R}^n$ *exists such that for almost every* $t \in [a,b]$

$$c \in \partial\tilde{f}_\epsilon(t,u_0'(t)) = \{\zeta : f(t,w) \geq f(t,u_0'(t)) + \langle \zeta, w - u_0'(t)\rangle \text{ for every } w \in B(u_0'(t),\epsilon)\}.$$

Now we wish to note that, as an application of Theorem 3.2, the following result holds, which can be seen to be an extension to the case of integrands $f(t,z)$ of a classical result known for integrands of the type $f = f(z)$ (see [10, Theorem 5.2.6]).

THEOREM 3.5. *Let* $f : [a,b] \times \mathbb{R}^n \to [0,+\infty[$ *be an* $\mathcal{L}\bigotimes\mathcal{B}_n$*-measurable integrand. Denote by*

$$C_t = \{z \in \mathbb{R}^n : f(t,z) = f^{**}(t,z)\}$$

the set where $f(t,\cdot)$ *coincides with its convex envelope, and assume that there exists a function* $m \in L^p(a,b)$ *such that*

$$(3.2) \qquad Bd(C_t) \subset B(0,m(t)) \quad \text{for almost every } t \in [a,b],$$

where $Bd(C_t)$ *denotes the boundary of the set* C_t.

Then, the functional F *admits a minimum in* $\mathcal{H}_p$ *if and only if there exists* $u_0 \in \mathcal{H}_p$ *such that* $\int_a^b f^{**}(t,u_0'(t))dt = \min_{v\in\mathcal{H}_p}\int_a^b f^{**}(t,v'(t))dt$ *and*

$$(3.3) \qquad u_0'(t) \in co(C_t) \text{ a.e. in } [a,b].$$

Proof. The necessary part is contained in Theorem 3.2.

As regards the sufficient part, by (3.3) there exist measurable functions $\lambda_j : [a,b] \to [0,1]$, $\xi_j : [a,b] \to \mathbb{R}^n$, with $\xi_j(t) \in C_t$, $j = 1,\dots,n+1$, such that $\sum_{j=1}^{n+1}\lambda_j(t)\xi_j(t) = u_0'(t)$ and $f^{**}(t,\cdot)$ is affine in $co(\{\xi_j(t), j = 1,\dots,n+1\})$, a.e. in $[a,b]$. By applying the Lyapunov theorem to the functions $g_j(t) = (\xi_j(t), f^{**}(t,\xi_j(t)))$,

$j = 1, \dots, n+1$, we deduce that there exist measurable disjoint sets $E_1, \dots, E_{n+1}$ such that for $\phi(t) = \sum_{j=1}^{n+1} \chi_{E_j}(t)\xi_j(t)$ we have $\int_a^b \phi(t)dt = \int_a^b u_0'(t)dt$ and

$$\int_a^b f(t,\phi(t))dt = \sum_{j=1}^{n+1} \int_{E_j} f^{**}(t,\xi_j(t))dt = \int_a^b \sum_{j=1}^{n+1} \lambda_j(t) f^{**}(t,\xi_j(t))dt$$
$$= \int_a^b f^{**}(t,u_0'(t))dt.$$

Then the assertion follows, since by (3.2) we have $\phi(t) \in L^p$. □

We conclude this section by noting that, in view of Theorem 3.2, the Lipschitz regularity result established in [1, Theorem 3.2] can be extended to nonconvex integrands by using the same proof. (For the existence of the minimum, see Marcellini [18], Olech [28].)

THEOREM 3.6. *Let $f : [a,b] \times \mathbb{R}^n \to [0, +\infty[$ be an $\mathcal{L} \bigotimes \mathcal{B}_n$-measurable integrand. Assume that a function $\theta : \mathbb{R} \to \mathbb{R}$ exists with $\lim_{x\to+\infty} \theta(x)/x = +\infty$ such that*

$$f(t,z) \geq \theta(|z|) \quad \text{for every } z \in \mathbb{R}^n \text{ and almost every } t \in [a,b].$$

Moreover, assume that there exists $z_0 \in L^\infty(a,b)$ such that $f(t,z_0(t)) \in L^\infty(a,b)$.

Then, every (global) minimizer of the functional F is Lipschitz continuous on $[a,b]$.

4. Applications: Existence of the minimum for $f^{**}(t,\cdot)$ affine at ∞. Let $f : [0,1] \times \mathbb{R} \to \mathbb{R}$ be a normal integrand, that is, such that $f(t,\cdot)$ is lower semicontinuous for almost every t and there exists a Borel function $\tilde{f} : [0,1] \times \mathbb{R} \to \mathbb{R}$ such that $\tilde{f}(t,\cdot) = f(t,\cdot)$ for a.a. $t \in [0,1]$. Recall that a Carathéodory function is a normal integrand (see [11, Proposition 8.1.1]).

In what follows, for every $t \in [0,1]$ we denote by C_t the set where $f^{**}(t,\cdot)$ coincides with $f(t,\cdot)$, i.e.,

$$C_t = \{z \in \mathbb{R} : f^{**}(t,z) = f(t,z)\}, \quad t \in [0,1].$$

If the set C_t does not depend on t, we denote it by C.

As an immediate consequence of Theorem 3.2, it follows that if F admits a minimizer u_0, then the convex envelope $f^{**}(t,\cdot)$ takes real values and the set C_t is nonempty for almost every $t \in [0,1]$. For this reason, from now on we assume $C_t \neq \emptyset$ for almost every $t \in [0,1]$.

In this section we deal with the case of integrands whose convex envelope is affine at ∞. More precisely, we now assume that C_t is bounded for almost every $t \in [0,1]$. In this case, the convex envelope $f^{**}(t,\cdot)$ is affine outside the set C_t.

As is well known, if the integrand does not depend on t, i.e., $f(t,z) \equiv h(z)$, the minimum exists if and only if

$$\min C \leq d \leq \max C$$

(see [10, Theorem 5.2.6]). When the integrand also depends on t, from Theorem 3.1 it follows that a necessary condition for the existence of the minimum is

$$\int_0^1 [\min C_t]\ dt \leq d \leq \int_0^1 [\max C_t]\ dt, \tag{4.1}$$

provided that the integrals above are well-defined. But unfortunately, this condition is not sufficient in general, as the following example shows.

Example 4.1. Let $f(t,z) = \phi(t)h(z)$, where $h : \mathbb{R} \to \mathbb{R}$ is the function defined by

$$h(z) = \begin{cases} z^2 - 1 & \text{for } |z| \le 1, \\ \log|z|/|z| + |2z| - 2 & \text{for } |z| > 1, \end{cases}$$

and $\phi(t) = t + 1$, $t \in [0,1]$.

We have that

$$h^{**}(z) = \begin{cases} z^2 - 1 & \text{for } |z| \le 1, \\ |2z| - 2 & \text{for } |z| > 1 \end{cases}$$

is a C^1-function, and the set of coincidence points of h and h^{**} is given by $C = [-1,1]$.

Note that if F admits a minimum u_0, then $u_0'(t) \in [-1,1]$ and a constant c exists such that $c/(t+1) = h'(u_0'(t)) = 2u_0'(t)$ for almost every $t \in [0,1]$. Therefore, $c/(t+1) \in [-2,2]$ a.e. in $[0,1]$; hence $|c| \le 2$. Moreover,

$$|d| = \left| \int_0^1 u_0'(t)dt \right| = \frac{|c|}{2} \int_0^1 \frac{1}{(t+1)} dt = \frac{|c| \log 2}{2} \le \log 2 < 1.$$

Then, if $|d| > \log 2$, the minimum does not exist.

Our aim in this section is to establish the limitation on the slope d, stronger than (4.1), which is necessary and sufficient for the existence of the minimum. In other words, denote by

$$D = \{d \in \mathbb{R} \ : \ F(v) \text{ admits minimum}\}$$

the range of the value of d for which the minimum exists; we now exactly determine the set D.

In order to do this, let us introduce some notation.

Let $(f_z^{**})^+(t,\cdot), (f_z^{**})^-(t,\cdot)$ be the right and left derivatives of $f^{**}(t,\cdot)$. Set

$$\alpha(t) = (f_z^{**})^-(t, \min C_t), \quad \beta(t) = (f_z^{**})^+(t, \max C_t),$$

let $g^+, g^- : [0,1] \times \mathbb{R} \to \mathbb{R}$ be the functions defined by

$$g^+(t,\zeta) = \begin{cases} \max \partial f^*(t,\zeta) & \text{for } \zeta < \beta(t), \\ \max C_t & \text{for } \zeta \ge \beta(t), \end{cases}$$

$$g^-(t,\zeta) = \begin{cases} \min \partial f^*(t,\zeta) & \text{for } \zeta > \alpha(t), \\ \min C_t & \text{for } \zeta \le \alpha(t), \end{cases}$$

where $\partial f^*(t,\cdot)$ denotes the subgradient of $f^*(t,\cdot)$.

Note that when $\alpha(t) < \zeta < \beta(t)$, the functions g^+, g^-, respectively, are the right and left derivative of the polar function $f^*(t,\cdot)$. We cut off these functions in such a way that they assume values in $[\min C_t, \max C_t]$.

In spite of this modification, the functions g^+, g^- satisfy the same properties of the derivatives of $f^*(t,\cdot)$. More precisely (see [29]), $g^+(t,\cdot), g^-(t,\cdot)$ are monotone nondecreasing, and $g^+(t,\cdot)$ is right-continuous, whereas $g^-(t,\cdot)$ is left-continuous. Moreover, if $\zeta_1 < \zeta_2$, then $g^-(t,\zeta_1) \le g^+(t,\zeta_1) \le g^-(t,\zeta_2) \le g^+(t,\zeta_2)$.

Finally, note that $\min C_t \in \partial f^*(t, \alpha(t))$ and $\max C_t \in \partial f^*(t, \beta(t))$.

Set

$$l = \operatorname*{esssup}_{t\in[0,1]} (f_z^{**})^-(t, \min C_t), \quad L = \operatorname*{ess\,inf}_{t\in[0,1]} (f_z^{**})^+(t, \max C_t).$$

The necessary and sufficient condition for the existence of the minimum is expressed by the following result.

THEOREM 4.2. *Assume that C_t is bounded for almost every $t \in \mathbb{R}$ and $\max C_t$, $\min C_t \in L^p(0,1)$. Then, the functional F admits a minimum if and only if $l \le L$ and*

$$\int_0^1 g^-(t,l)dt \le d \le \int_0^1 g^+(t,L)dt. \tag{4.2}$$

This condition becomes more expressive when the integrand f has the particular structure $f(t,z) = \phi(t)h(z)$, with $\phi(t)$ measurable and nonnegative and h lower semicontinuous. Note that in this case the set C does not depend on t.

Set

$$m = \operatorname*{ess\,inf}_{t\in[0,1]} \phi(t), \quad M = \operatorname*{ess\,sup}_{t\in[0,1]} \phi(t), \quad h_1 = \lim_{z\to-\infty} (h^{**})'(z), \quad h_2 = \lim_{z\to+\infty} (h^{**})'(z).$$

Moreover, let $\tilde g^+, \tilde g^- : [h_1, h_2] \to \mathbb{R}$ be the functions defined by

$$\tilde g^+(\zeta) = \begin{cases} \max \partial h^*(\zeta) & \text{for } \zeta < h_2, \\ \max C & \text{for } \zeta = h_2, \end{cases}$$

$$\tilde g^-(\zeta) = \begin{cases} \min \partial h^*(\zeta) & \text{for } \zeta > h_1, \\ \min C & \text{for } \zeta = h_1. \end{cases}$$

In the following result we will assume $m > 0$. The case $m = 0$ will be tackled in Corollary 4.11.

COROLLARY 4.3. *Assume that C is bounded and $m = \operatorname{essinf}_{t\in[0,1]}\phi(t) > 0$. Then, the functional F admits a minimum if and only if the following condition* (4.3) *(expressed according to the sign of h_1, h_2) is satisfied:*

$$\int_0^1 \tilde g^- \left(\frac{mh_1}{\phi(t)}\right) dt \le d \le \int_0^1 \tilde g^+ \left(\frac{mh_2}{\phi(t)}\right) dt \qquad \text{if} \quad h_1 \le 0 \le h_2, \tag{4.3$_1$}$$

$$M < +\infty \quad \text{and} \quad \int_0^1 \tilde g^- \left(\frac{Mh_1}{\phi(t)}\right) dt \le d \le \int_0^1 \tilde g^+ \left(\frac{mh_2}{\phi(t)}\right) dt \ \text{if} \quad 0 < h_1 \le h_2, \tag{4.3$_2$}$$

$$M < +\infty \quad \text{and} \quad \int_0^1 \tilde g^- \left(\frac{mh_1}{\phi(t)}\right) dt \le d \le \int_0^1 \tilde g^+ \left(\frac{Mh_2}{\phi(t)}\right) dt \ \text{if} \quad h_1 \le h_2 < 0. \tag{4.3$_3$}$$

Moreover the minimum, if it exists, is Lipschitz continuous.

Remark 4.4. Taking into account the definition of the functions $\tilde g^+, \tilde g^-$, the integrands which appear in inequalities (4.3$_i$), $i = 1, 2, 3$, assume values in $[\min C, \max C]$. Note that if $h_1 = 0$, then the integral on the left-hand side of (4.3$_1$) coincides with $\min C$, whereas, if $h_2 = 0$, then the integral on the right-hand side coincides with $\max C$.

Moreover, when ϕ is not constant, if h^{**} is strictly convex in a left neighborhood of $\max C$, with $h_2 \neq 0$, then the integrals in the right-hand side of (4.3$_i$) are strictly less than $\max C$. Similarly, if h^{**} is strictly convex in a right neighborhood of $\min C$,

with $h_1 \neq 0$, then the integrals in the left-hand side of (4.3_i) are strictly greater than $\min C$. Hence, when these cases occur, conditions (4.3_i), $i = 1, 2, 3$, actually are more restrictive than (4.1), and then D is strictly contained in $co(C)$.

Whereas, when h^{**} is affine in $co(C)$ it can happen that conditions (4.3_i) coincide with (4.1), that is, the range D coincides with $co(C)$. The following result shows under what conditions this situation occurs.

COROLLARY 4.5. *Let C be bounded and $m = \operatorname{essinf}_{t\in[0,1]}\phi(t) > 0$. Moreover, let h^{**} be affine in $co(C)$ with slope h_0.*

Assume that the following condition (4.4) *holds (expressed according to the sign of h_1, h_2):*

$$mh_1 \leq Mh_0 \leq mh_2 \quad \text{if} \quad h_1 \leq 0 \leq h_2, \tag{4.4$_1$}$$

$$Mh_1 \leq mh_0 \leq Mh_0 \leq mh_2 \quad \text{if} \quad 0 < h_1 \leq h_2, \tag{4.4$_2$}$$

$$mh_1 \leq Mh_0 \leq mh_0 \leq Mh_2 \quad \text{if} \quad h_1 \leq h_2 < 0. \tag{4.4$_3$}$$

Then, the minimum exists if and only if $\min C \leq d \leq \max C$, i.e., $D = co(C)$.

Vice versa, if (4.4) *is not satisfied and C is not a singleton, then condition* (4.3) *is actually more restrictive than* (4.1)*, i.e., D is strictly contained in $co(C)$.*

Remark 4.6. In the case $h_1h_2 > 0$, according to (4.3_2), (4.3_3), $M < +\infty$ is a necessary condition for the existence of the minimum. Therefore, in (4.4_2), (4.4_3), M is assumed to be real.

When $h_1 \leq 0 \leq h_2$, M could be $+\infty$. Hence, in this case if $h_0 \neq 0$, then condition (4.4_1) is not satisfied, but if $h_0 = 0$, then it is, with the convention $+\infty \cdot 0 = 0$. In contrast, if h^{**} is constant in co(C), that is, $h_1 \leq h_0 = 0 \leq h_2$, condition (4.4_1) is satisfied whatever the function ϕ may be, and then $D = co(C)$.

We now provide some examples of applications of Corollaries 4.3, 4.5.

Example 4.7. Let $f(t, z)$ be the integrand defined in Example 4.1. We have $C = [-1, 1]$, $h_1 = -2$, $h_2 = 2$, $m = 1$. Moreover, since h^{**} is C^1, we have $g^-(\zeta) = g^+(\zeta) = \zeta/2$ for $|\zeta| < 2$. Hence, condition (4.3_1) becomes

$$|d| \leq \int_0^1 \frac{1}{(t+1)} dt = \log 2,$$

i.e., the minimum exists if and only if $|d| \leq \log 2$. Here, since h^{**} is strictly convex in C, the range D is a proper subset of C.

Example 4.8. If we modify the definition of function h by putting $h(z) = 1 - z^2$ in $[-1, 1]$, then $h^{**}(z) = 0$ for every $z \in [-1, 1]$. In this case, by virtue of Corollary 4.5 (see also Remark 4.6), the minimum exists if and only if $|d| \leq 1$.

Example 4.9. Let $h : \mathbb{R} \to \mathbb{R}$ be the function defined by

$$h(z) = \begin{cases} z^2 - 1 & \text{for } |z| \leq 1, \\ \log z/z + 2z - 2 & \text{for } z > 1, \\ \log |z|/|z| & \text{for } z < -1, \end{cases}$$

and let $\phi(t) = t + 1$, $t \in [0, 1]$. We have that

$$h^{**}(z) = \begin{cases} z^2 - 1 & \text{for } 0 \leq z \leq 1, \\ 2z - 2 & \text{for } z > 1, \\ -1 & \text{for } z < 0 \end{cases}$$

is a C^1-function and $C = [0, 1]$. In this case $h_1 = 0, h_2 = 2, m = 1$; hence by applying condition (4.3_1), we obtain

$$0 \leq d \leq \int_0^1 \frac{1}{(t+1)} dt = \log 2.$$

Example 4.10. Let $\tilde{h}(z) = h(z) + z$, where h is as in Example 4.8. In this case, we still have $co(C) = [-1, 1]$ and $\tilde{h}^{**}$ affine in $co(C)$ with slope $h_0 = 1$. Hence, by virtue of Corollary 4.5, if $\phi(t)$ is such that $M \leq 3m$, then the minimum exists if and only if $|d| \leq 1$, that is, the range D coincides with $co(C)$. In fact, we have $h_1 = -1$, $h_2 = 3$, and then condition (4.4_1) is satisfied. Whereas, if $M > 3m$, then D is strictly contained in $[-1, 1]$.

Let us now consider the case in which $C = \{z_0\}$ is a singleton. Of course, if the minimum u_0 exists, then necessarily we have $d = z_0$ and $u_0(t) = td$.

Note that in the case $h_1 \leq 0 \leq h_2$ the linear function is actually the minimizer since $0 \in \partial h^{**}(d)$. Whereas, in the case $0 < h_1 \leq h_2$ $(h_1 \leq h_2 < 0)$ it is the minimizer if and only if $Mh_1 \leq mh_2$ $(mh_1 \leq Mh_2)$. In fact, since $\partial h^{**}(d) = [h_1, h_2]$, we have $h_1\phi(t) \leq c \leq h_2\phi(t)$ for some constant c.

In the following result we will consider the case in which $m = \operatorname{essinf}_{t\in[0,1]} \phi(t) = 0$. In this case, the necessary and sufficient condition on the slope d is much more restrictive than the one obtained in the case $m > 0$.

COROLLARY 4.11. *Assume that C is bounded and*

$$0 = m < \phi(t) \quad \text{a.e. in } [0, 1]. \tag{4.5}$$

Then, the functional F admits a minimum if and only if

$$\min C \leq d \leq \max C \quad \text{and} \quad h^{**}(d) = \min_{z\in\mathbb{R}} h^{**}(z),$$

that is, $D = co(C) \cap \partial h^*(0)$.

As an application of this result, note that if we replace function $\phi(t) = t + 1$ with function $\tilde{\phi}(t) = t$ in Examples 4.7, 4.8, 4.9, the necessary and sufficient condition for the existence of the minimum becomes $d = 0$ for Examples 4.7 and 4.9, $|d| \leq 1$ for Example 4.8.

Remark 4.12. In the previous result we do not take into consideration the case in which the set $Z = \{t : \phi(t) = 0\}$ has positive measure (but is less than 1), since in this case the existence of the minimum does not depend on the value of the slope d.

In fact, it is easy to check that the functional F admits a minimum if and only if the function h admits a minimum, and a minimizer u_0 for F is the function such that $u_0'(t) = z_0$ for $t \notin Z$, $u_0'(t) = \frac{d - z_0(1-\mu)}{\mu}$ for $t \in Z$, where $\mu = \text{meas(Z)}$ and z_0 is any point such that $h(z_0) = \min_{z\in\mathbb{R}} h(z)$.

We conclude this section by providing proofs of the results stated above.

Proof of Theorem 4.2. (*Necessary condition*) By virtue of Theorem 3.2, if F admits a minimum, then a function u_0 and a constant c exist such that $\int_0^1 u_0'(t)dt = d$ and

$$c \in \partial f^{**}(t, u_0'(t)) \text{ a.e. in } [0, 1]. \tag{4.6}$$

Moreover, we have $u_0'(t) \in C_t$ a.e. in $[0, 1]$. Therefore,

$$\alpha(t) \leq (f_z^{**})^-(t, u_0'(t)) \leq c \leq (f_z^{**})^+(t, u_0'(t)) \leq \beta(t) \text{ a.e. in } [0, 1],$$

so $l \le c \le L$.

Finally, from (4.6) we have

$$g^-(t,l) \le g^-(t,c) \le u_0'(t) \le g^+(t,c) \le g^+(t,L),$$

from which (4.2) follows.

(*Sufficient condition*) Since g^+ and g^-, respectively, are right-continuous and left-continuous, we deduce that the functions $G^+(s) := \int_0^1 g^+(t,s)dt$ and $G^-(s) := \int_0^1 g^-(t,s)dt$, respectively, are right-continuous and left-continuous in $[l,L]$. Therefore, for

$$c = \sup\{s : G^-(s) \le d\}$$

we have

$$\int_0^1 g^-(t,c)dt \le d \le \int_0^1 g^+(t,c)dt.$$

Then, it is easy to prove that a constant $r \in [0,1]$ exists such that the function

$$\psi(t) = \begin{cases} g^-(t,c) & \text{for } t \in [0,r], \\ g^+(t,c) & \text{for } t \in [r,1] \end{cases}$$

satisfies $\int_0^1 \psi(t)dt = d$.

Set $u_0(t) := \int_0^t \psi(\tau)d\tau$. Then, from the definition of ψ it follows that $u_0'(t) \in \partial f^*(t,c)$, that is, $c \in \partial f^{**}(t,u_0'(t))$ for a.a. $t \in [0,1]$. Hence, by Theorem 3.5, we deduce that u_0 is a minimizer for functional F, and this concludes the proof. ∎

Proof of Corollary 4.3. When $h_1 \le 0 \le h_2$ we have $l = mh_1$ and $L = mh_2$. Moreover, it is easy to verify that $\partial f^*(t,\zeta) = \partial h^*(\frac{\zeta}{\phi(t)})$; then $g^+(t,\zeta) = \tilde{g}^+(\frac{\zeta}{\phi(t)})$ and $g^-(t,\zeta) = \tilde{g}^-(\frac{\zeta}{\phi(t)})$ for $\zeta \in [l,L]$ and a.a. $t \in [0,1]$. Therefore, condition (4.2) is equivalent to (4.3_1).

Assume now $h_1 > 0$. In this case we have $l = Mh_1$ and $L = mh_2$. Therefore, if $l \le L$, then $M < +\infty$. Moreover, by virtue of the observations above, we have $g^+(t,L) = \tilde{g}^+(\frac{mh_2}{\phi(t)})$ and $g^-(t,l) = \tilde{g}^-(\frac{Mh_1}{\phi(t)})$. As a consequence, (4.2) is equivalent to (4.3_2).

The case $h_2 < 0$ can be treated in a similar way.

Finally, since C is bounded, if a minimizer exists, it is Lipschitz continuous. ∎

Proof of Corollary 4.5. Assume $h_1 \le 0 \le h_2$; the other cases can be proved in a similar way.

If (4.4_1) holds, then $\frac{mh_2}{\phi(t)} \ge h_0$ for a.a. $t \in [0,1]$; hence $\tilde{g}^+(\frac{mh_2}{\phi(t)}) \ge \tilde{g}^+(h_0) \ge \max C$, that is, $\int_0^1 \tilde{g}^+(\frac{mh_2}{\phi(t)})dt = \max C$.

Similarly, we have $\frac{mh_1}{\phi(t)} \le h_0$ for a.a. $t \in [0,1]$. Hence, $\tilde{g}^-(\frac{mh_1}{\phi(t)}) \le \tilde{g}^-(h_0) \le \min C$, and the assertion is proved.

Finally, note that if (4.4_1) does not hold, for example if $mh_2 < Mh_0$, then we have $\tilde{g}^+(\frac{mh_2}{\phi(t)}) \le \tilde{g}^-(h_0) \le \min C < \max C$ in a set of positive measure. Hence we have $\int_0^1 \tilde{g}^+(\frac{mh_2}{\phi(t)})dt < \max C$, and condition (4.3_1) is more restrictive than (4.1). ∎

Proof of Corollary 4.11. (*Necessary condition*) First note that if F admits a minimum, then $h_1 \le 0 \le h_2$. In fact, if $h_1 > 0$, then $l = Mh_1 > 0 = L$, which is a contradiction by Theorem 4.2. Similarly we exclude that $h_2 < 0$.

Hence, since $l = mh_1 = 0 = mh_2 = L$, condition (4.2) becomes $\tilde{g}^-(0) \le d \le \tilde{g}^+(0)$; that is, $0 \in \partial h^{**}(d)$ and then $h^{**}(d) = \min_{z\in\mathbb{R}} h^{**}(z)$.

Finally, from (4.1) we deduce that $\min C \le d \le \max C$.

(*Sufficient condition*) From the assumptions it can be immediately verified that the linear function $u_0(t) = td$ is a minimizer for the relaxed functional F^{**}, and since $d \in co(C)$, the assertion follows from Theorem 3.5. □

5. Applications: Existence of the minimum for $f^{**}(t,\cdot)$ strictly convex at ∞. In this section we deal with integrands $f : [0,1] \times \mathbb{R} \to \mathbb{R}$ whose convex envelope is strictly convex at ∞. More precisely, we now assume that the set $\mathbb{R} \setminus C_t$ is bounded for a.a. $t \in \mathbb{R}$ and that $f(t,\cdot)$ is strictly convex outside the set $co(\mathbb{R} \setminus C_t)$.

We now give some notations.

Let $f_z^+(t,\cdot), f_z^-(t,\cdot)$ be the right and left derivatives of $f(t,\cdot)$, and let $f_\zeta^{*+}(t,\cdot)$, $f_\zeta^{*-}(t,\cdot)$ be the right and left derivatives of the polar function $f^*(t,\cdot)$.

Set $f_z^-(t,-\infty) = f_z^+(t,-\infty) = \lim_{\xi\to-\infty} f_z^-(t,\xi) = \lim_{\xi\to-\infty} f_z^+(t,\xi)$ and $f_z^-(t,+\infty) = f_z^+(t,+\infty) = \lim_{\xi\to+\infty} f_z^-(t,\xi) = \lim_{\xi\to+\infty} f_z^+(t,\xi)$.

Finally, let

$$l = \operatorname*{ess\,sup}_{t\in[0,1]} f_z^-(t,-\infty) \quad \text{and} \quad L = \operatorname*{ess\,inf}_{t\in[0,1]} f_z^+(t,+\infty),$$

$$T_p^+ = \{s \in [l,L] \cap \mathbb{R} : f_\zeta^{*+}(t,s) \in L^p(0,1)\},$$

$$T_p^- = \{s \in [l,L] \cap \mathbb{R} : f_\zeta^{*-}(t,s) \in L^p(0,1)\}.$$

The following result extends Theorem 3′ in [15] to the case of nonconvex integrands.

THEOREM 5.1. *Assume that $\mathbb{R} \setminus C_t$ is bounded for a.a. $t \in [0,1]$ with*

$$\min(\mathbb{R} \setminus C_t), \max(\mathbb{R} \setminus C_t) \in L^p(0,1) \tag{5.1}$$

and $f(t,\cdot)$ strictly convex outside the set $co(\mathbb{R} \setminus C_t)$.

Then, the functional F admits a minimum if and only if one of the following conditions is satisfied:

(a) $T_p^+ \cap T_p^- \neq \emptyset$ *and* $\displaystyle\inf_{s\in T_p^-} \int_0^1 f_\zeta^{*-}(t,s)dt < d < \sup_{s\in T_p^+} \int_0^1 f_\zeta^{*+}(t,s)dt,$

(b) $T_p^- \neq \emptyset$ *and* $\displaystyle d = \min_{s\in T_p^-} \int_0^1 f_\zeta^{*-}(t,s)dt,$

(c) $T_p^+ \neq \emptyset$ *and* $\displaystyle d = \max_{s\in T_p^+} \int_0^1 f_\zeta^{*+}(t,s)dt.$

We wish to remark that conditions (a), (b), (c) are exactly the same as those we obtained in the convex case in Theorem 3′ in [15].

Proof. First we observe that in [15] the function $f(t,\cdot)$ is assumed to be C^1, as well as convex. But, as we showed in [16], it is easy to prove that the assumption C^1 can be weakened by taking $f(t,\cdot)$ only continuous.

(*Sufficient condition*) By Theorem 3′ in [15] we deduce that the relaxed functional $F^{**}(v)$ admits a minimum v_0. Then, if we show that there exists a function $u_0 \in v_0 + W_0^{1,p}(0,1)$ such that $F(u_0) = F^{**}(v_0)$, the assertion will be proved.

Since the set $\mathbb{R} \setminus C_t$ is bounded, we have (see [11, Lemma 8.3.3])

$$f^{**}(t,z) = \min\{\lambda_1 f(t,\xi_1) + \lambda_2 f(t,\xi_2) \ : \ \lambda_1,\lambda_2 \in [0,1],\ \lambda_1+\lambda_2 = 1,\ \lambda_1\xi_1+\lambda_2\xi_2 = z\}.$$

Therefore, by virtue of Proposition 8.3.1 in [11], there exist measurable functions $\lambda_1, \lambda_2 : [0,1] \to [0,1]$, $\xi_1, \xi_2 : [0,1] \to \mathbb{R}$ such that

$$f^{**}(t, v_0'(t)) = \lambda_1(t) f(t, \xi_1(t)) + \lambda_2(t) f(t, \xi_2(t)), \quad \lambda_1(t)\xi_1(t) + \lambda_2(t)\xi_2(t) = v_0'(t).$$

Moreover, by (5.1) we deduce that $\xi_1, \xi_2 \in L^p(0,1)$.

Now, by applying the Lyapunov theorem to the functions $g_j(t) = (\xi_j(t), f(t, \xi_j(t)))$, $j = 1, 2$, we deduce that there exist two measurable disjoint sets E_1, E_2 such that for $\psi(t) = \chi_{E_1}(t)\xi_1(t) + \chi_{E_2}(t)\xi_2(t)$ we have $\int_0^1 \psi(t)dt = \int_0^1 v_0'(t)dt$ and

$$\int_0^1 f(t, \psi(t))dt = \int_{E_1} f(t, \xi_1(t))dt + \int_{E_2} f(t, \xi_2(t))dt$$

$$= \int_0^1 [\lambda_1(t) f(t, \xi_1(t)) + \lambda_2(t) f(t, \xi_2(t))]dt = \int_0^1 f^{**}(t, v_0'(t))dt = F^{**}(v_0).$$

Hence, for $u_0(t) = \int_0^t \psi(\tau)d\tau$ we have $u_0 \in v_0 + W_0^{1,p}(0,1)$ and $F(u_0) = F^{**}(v_0)$.

(*Necessary condition*) The necessary condition is an immediate consequence of Theorem 3.1 and of Theorem 3′ in [15], taking into account the relation $f^* = (f^{**})^*$. □

From this result it is possible to derive very operative necessary and sufficient conditions in the case in which the integrand has the particular structure $f(t,z) = \phi(t)h(z)$, as in [15]. In view of the present results, we can see that Theorems 5–9 in [15] hold even for nonconvex integrands, provided that the set $\mathbb{R} \setminus C$ is bounded and that h is strictly convex outside the set C.

These conditions emphasize a strict link between the exponent p, the behavior at ∞ of function h, and the infinitesimal order of $[\phi(t) - m]$.

We now quote only two significant results in a slightly less general setting, referring to [15] for proofs and details. For the sake of simplicity, in the following results the function ϕ is assumed to be continuous, and h to be C^1.

COROLLARY 5.2 (quasi-coercive case). *Assume that* $\min \phi = \phi(t_0) = 0$ *and* $\phi(t) > 0$ *for* $t \neq t_0$. *Moreover, let* h *be coercive.*

Furthermore, assume that $\phi \in O(\alpha)$ *when* $t \to t_0$ *and* $1/h' \in O(\beta)$ *when* $|z| \to +\infty$, *where* $O(\cdot)$ *denotes the infinitesimal order.*

Then, if $p\alpha < \beta$, *the functional* F *admits a minimum for every* $d \in \mathbb{R}$. *Whereas, if* $p\alpha \geq \beta$, *the minimum exists if and only if* $h^{**}(d) = \min_{z \in \mathbb{R}} h^{**}(z)$.

COROLLARY 5.3 (noncoercive case). *Set* $\lim_{z \to -\infty} h'(z) = h_1, \lim_{z \to +\infty} h'(z) = h_2$, *and assume that* $-\infty < h_1 < 0 < h_2 < +\infty$. *Moreover, assume that* $m = \min \phi(t) > 0$.

Finally, suppose that $[\phi(t) - m] \in O(\alpha)$ *and* $[h'(z) - h_2], [h'(z) - h_1] \in O(\beta)$.

Then, if $\alpha \geq \beta$, *the functional* F *admits a minimum for every* $d \in \mathbb{R}$. *Whereas, if* $\alpha < \beta$, *then the range* D *of the values of the slope* d *for which the minimum exists is a bounded interval.*

Remark 5.4. For the sake of brevity, we do not explicitly treat mixed cases, for example when h^{**} is strictly convex at $-\infty$ but is linear at $+\infty$, that is, when $\inf C = -\infty$ but $\sup C < +\infty$. In fact, we think it is now clear how to combine the conditions of Corollaries 4.3–4.5 and Theorem 5.1 in order to deal with these cases.

CONVEXITY IN ZERO-SUM DIFFERENTIAL GAMES*

RAFAL GOEBEL†

Abstract. A new approach to two-player zero-sum differential games with convex-concave cost function is presented. It employs the tools of convex and variational analysis. A necessary and sufficient condition on controls to be an open-loop saddle point of the game is given. Explicit formulas for saddle controls are derived in terms of the subdifferential of the function conjugate to the cost. Existence of saddle controls is concluded under very general assumptions, not requiring the compactness of control sets. A Hamiltonian inclusion, new to the field of differential games, is shown to describe equilibrium trajectories of the game.

Key words. two-player zero-sum differential games, open-loop controls, convex-concave functions, generalized Hamiltonian systems

1. Introduction.

Consider the following two-player zero-sum differential game. The trajectory of the game, $x(\cdot)$, is described by a linear differential equation

$$\dot{x}(t) = A(t)x(t) + B(t)u(t) + C(t)v(t), \tag{1}$$

and the initial condition is

$$x(\tau) = \xi \tag{2}$$

for some $\tau \in (-\infty, T]$ and $\xi \in \mathbb{R}^n$. Controls $u(\cdot)$ and $v(\cdot)$ are functions on $[\tau, T]$ chosen, respectively, by Player One and Player Two from some control sets $\mathcal{U}(\tau, \xi)$ and $\mathcal{V}(\tau, \xi)$, subject to the constraints

$$u(t) \in P(t) \text{ and } v(t) \in Q(t) \text{ for almost all } t \in [\tau, T], \tag{3}$$

for given convex sets $P(t) \in \mathbb{R}^k$, $Q(t) \in \mathbb{R}^l$. The cost functional $\Phi(\tau, \xi, \cdot, \cdot)$ is given by

$$\Phi(\tau, \xi, u(\cdot), v(\cdot)) = \int_\tau^T f(t, u(t), v(t))dt + d \cdot x(T). \tag{4}$$

Player One tries to minimize the cost $\Phi(\tau, \xi, u(\cdot), v(\cdot))$, while Player Two attempts to maximize it. The saddle value of the functional $\Phi(\tau, \xi, \cdot, \cdot)$ is called the value of the game. Controls $\bar{u}(\cdot)$ and $\bar{v}(\cdot)$, corresponding to a saddle point $(\bar{u}(\cdot), \bar{v}(\cdot))$ of this functional are referred to as saddle controls, or open-loop solutions of the game. The trajectory generated by them is an equilibrium trajectory.

Two-player zero-sum games and their generalization, N-player games, have seen extensive treatment in literature; a good reference is Basar and Olsder [1]. Assumptions of convexity of the cost for each player allowed Varaiya [14], Scalzo [11], and

Tolwinski [13] to obtain results on the existence of open-loop solutions for N-player games. Reference [13] contains a discussion of other related results. For two-player zero-sum games, an assumption of convexity of costs yields a convex-concave cost functional, which one player minimizes and the other maximizes. A special case of such a game was treated by Berkovitz [3].

All of the mentioned works rely on the compactness of sets of feasible control functions, achieved either by assumption of boundedness of control constraint sets, or by a priori integral bounds on control functions. This allows for the use of fixed point and saddle point theorems in infinite-dimensional function spaces to guarantee the existence of equilibrium trajectories. Here we approach the existence issue directly by analyzing explicit descriptions of saddle controls. We demonstrate that the strong assumptions of the compactness of control functions are not necessary in the convex-concave setting—sufficient "compactness-like" properties are guaranteed through the so-called Isaacs condition. In the language of convex analysis, finiteness of the saddle function conjugate to the cost reflects the desired growth properties of the cost function itself. Details are discussed in section 2.

In section 3 we show that for the controls $(\bar{u}(\cdot), \bar{v}(\cdot))$ to furnish a saddle point of the game, it is necessary and sufficient for $(\bar{u}(t), \bar{v}(t))$ to be a saddle point on $P(t) \times Q(t)$ of an auxiliary function

$$S(t,u,v) = f(t,u,v) + d \cdot \mathcal{A}(T,t)[B(t)u + C(t)v]. \tag{5}$$

The matrix $\mathcal{A}(T,t)$ is the fundamental matrix for $\dot{w}(t) = A(t)w(t)$, with $\mathcal{A}(T,T)$ being the identity matrix. In a different setting, a characterization of saddle controls as solutions of an instantaneous saddle problem involving a pre-Hamiltonian function was given by Subbotin [12]. A pre-Hamiltonian function has also been used by Berkovitz [2] to give a necessary condition for saddle controls and by Leitmann [5] to state a sufficient condition. The special properties of (5) when the cost is convex-concave seem not to have been analyzed, however.

We explore the convex-concave structure of (5) in section 4 and obtain explicit formulas for saddle points of this auxiliary function. This leads to expressions for saddle controls—see (14) and (15). Formula (15) is of special value, as it describes saddle controls as subgradients of a particular saddle function. Such a description seems more practical in our setting than any min/max expression. It leads, through the analysis of possible growth of subgradients of saddle functions, to results on the existence of saddle controls in Theorem 4.1 and, once the existence is guaranteed, allows for a detailed study of their structure. (See the comments at the end of section 4.) Let us also note that the saddle controls, when they exist, turn out not to depend on the initial condition.

A characterization of an equilibrium trajectory, new to the field of differential games, is given in Theorem 5.1 with the help of the associated Hamiltonian function $H(t,x,y)$. Much in the spirit of optimal control theory, solutions to a nonsmooth Hamiltonian dynamical system, posed in terms of the subgradients of $H(t,x,y)$, turn out to describe the equilibria of the game.

We conclude the introduction with remarks on differential games in the more standard setting of closed-loop controls. There, players choose strategies as functions of both time and state, $U : (-\infty, T] \times \mathbb{R}^n \to \mathbb{R}^k$ and $V : (-\infty, T] \times \mathbb{R}^n \to \mathbb{R}^l$. Given an initial condition (2), these strategies and the dynamics (1) determine the instantaneous controls by $u(t) = U(t, x(t))$ and $v(t) = V(t, x(t))$ and the cost $\Phi(\tau, \xi, U(\cdot,\cdot), V(\cdot,\cdot))$. The closed-loop solutions of the game are the strategies $U(\cdot,\cdot)$

and $V(\cdot,\cdot)$ that provide a saddle point of the cost functional for every (τ,ξ). It is known that if $\bar{u}(\cdot)$ and $\bar{v}(\cdot)$ are open-loop solutions of the game with a specified initial condition, then, by taking

$$U(t,x)=\bar{u}(t), \qquad V(t,x)=\bar{v}(t),$$

one obtains closed-loop saddle strategies for this game; see Berkovitz [3]. Our results yield open-loop controls independent of the initial condition, and so the above equations can be used to define closed-loop strategies on $(-\infty,T]\times\mathbb{R}^n$.

2. Assumptions. We now present the assumptions that are in effect in the remaining sections. The game described by (1)–(4) and the assumptions below will be referred to as $\mathcal{G}(\tau,\xi)$.

ASSUMPTION 2.1 (general assumptions). *The matrices $A(t)\in\mathbb{R}^{n\times n}$, $B(t)\in\mathbb{R}^{n\times k}$, and $C(t)\in\mathbb{R}^{n\times l}$ in (1) depend continuously on $t\in(-\infty,T]$. Control sets $\mathcal{U}(\tau,\xi)$ and $\mathcal{V}(\tau,\xi)$ are subsets of the space of measurable and locally integrable functions on $[\tau,T]$. The constraint sets in (3), $P(t)\subset\mathbb{R}^k$ and $Q(t)\subset\mathbb{R}^l$, are nonempty, closed (but not necessarily bounded), convex, and measurably dependent on t.*

Measurable dependence of sets on time is defined and discussed in chapter 14 of Rockafellar and Wets [9]. Sets depending continuously on time, constant sets in particular, have this property.

A natural generalization of the assumptions on the constraint sets P and Q might be to allow their dependence on the state variable, that is, to let $u(t)\in P(t,x(t))$ and $v(t)\in Q(t,x(t))$. However, this can lead to the set of feasible pairs of controls $(u(\cdot),v(\cdot))$ not being a product set in $\mathcal{U}(\tau,\xi)\times\mathcal{V}(\tau,\xi)$, as opposed to the case where the constraints have the form (3). For example, look at the game where $x(0)=0$, $\dot{x}(t)=u(t)$, and the controls are constrained by $u(t)\in[0,1]$ and $v(t)=x(t)$. In such cases, it is unclear what the notions of an equilibrium and the value of the game should be. We do not address this issue, preferring to work with the constraints given by (3).

The following assumption guarantees that the cost functional $\Phi(\tau,\xi,u(\cdot),v(\cdot))$ is convex in the control $u(\cdot)$ for fixed $(\tau,\xi,v(\cdot))$ and concave in the control $v(\cdot)$ for fixed $(\tau,\xi,u(\cdot))$.

ASSUMPTION 2.2 (convexity-concavity). *The function $f:(-\infty,T]\times P(t)\times Q(t)\to\mathbb{R}$ has the following properties: $f(t,u,v)$ is measurable in t for every fixed (u,v), continuous in $(u,v)\in P(t)\times Q(t)$ for every t, convex in u for every (t,v), and concave in v for every (t,u).*

For purposes of convex analysis, it is convenient to extend the function f to $(-\infty,T]\times\mathbb{R}^k\times\mathbb{R}^l$ by appropriately chosen infinite values. We define

$$\tilde{f}(t,u,v)=\begin{cases} f(t,u,v), & u\in P(t) \text{ and } v\in Q(t),\\ +\infty, & u\notin P(t),\\ -\infty, & u\in P(t) \text{ and } v\notin Q(t).\end{cases} \tag{6}$$

In what follows, we will often consider the function f on $(-\infty,T]\times\mathbb{R}^k\times\mathbb{R}^l$.

As a matter of fact, a game with linear dynamics and a cost function $\hat{f}(t,x,u,v)$ that is convex in (x,u) for fixed (t,v) and concave in (x,v) for fixed (t,u) can be reduced to a game with cost (4). Indeed, these properties imply that

$$\hat{f}(t,x,u,v)=\alpha(t)\cdot x(t)+f(t,u,v)$$

for some function α and a function $f(t,u,v)$ convex in u and concave in v. Skipping the technicalities, we point out that, through an inclusion of an additional one-dimensional variable in the dynamics, we can reformulate the game under discussion in the format of this paper.

ASSUMPTION 2.3 (finiteness of cost). *For any $u(\cdot) \in \mathcal{U}(\tau,\xi)$ and $v(\cdot) \in \mathcal{V}(\tau,\xi)$ satisfying* (3), $\int_\tau^T f(t,u(t),v(t))dt$ *is finite.*

This restrictive-looking assumption is satisfied, in particular, when $f(t,u,v)$ is continuous and the controls are essentially bounded or when $f(t,u,v)$ is a quadratic expression in u and v with bounded coefficients and the controls are L^2 functions.

Under these assumptions, the cost $\Phi(\tau,\xi,u(\cdot),v(\cdot))$ is well defined. A pair of controls $(\bar u(\cdot),\bar v(\cdot))$ is a saddle point (a Nash equilibrium) of $\Phi(\tau,\xi,u(\cdot),v(\cdot))$ over $\mathcal{U}(\tau,\xi)\times\mathcal{V}(\tau,\xi)$ if $(\bar u(\cdot),\bar v(\cdot)) \in \mathcal{U}(\tau,\xi)\times\mathcal{V}(\tau,\xi)$, and for any $(u(\cdot),v(\cdot)) \in \mathcal{U}(\tau,\xi)\times\mathcal{V}(\tau,\xi)$ the following is satisfied:

$$\Phi(\tau,\xi,\bar u(\cdot),v(\cdot)) \le \Phi(\tau,\xi,\bar u(\cdot),\bar v(\cdot)) \le \Phi(\tau,\xi,u(\cdot),\bar v(\cdot)). \tag{7}$$

ASSUMPTION 2.4 (Isaacs condition). *For every $t \in (-\infty,T]$ and every $(p,q) \in \mathbb{R}^k\times\mathbb{R}^l$*

$$\sup_{u\in P(t)}\inf_{v\in Q(t)}\{p\cdot u+q\cdot v-f(t,u,v)\} = \inf_{v\in Q(t)}\sup_{u\in P(t)}\{p\cdot u+q\cdot v-f(t,u,v)\}, \tag{8}$$

and the common value is finite.

The assumption is certainly satisfied whenever the sets $P(t)$, $Q(t)$ are compact (37.6.1 in [6]) but also holds in several other interesting cases.

Example 2.5. Let $P(t)=\mathbb{R}^k$, $Q(t)=\mathbb{R}^l$, and consider $f(t,u,v)=u\cdot v$. A direct calculation shows that both sides of (8) are equal $p\cdot q$. In particular, Assumption 2.4 holds. Note that not only the control constraint sets are unbounded, but the function $f(t,\cdot,\cdot)$ does not seem—at the first glance—to display favorable growth properties.

Example 2.6 (quadratic cost and polyhedral control constraints). Consider a game with polyhedral control constraint sets $P(t)$, $Q(t)$ and the cost function given by

$$f(t,u,v) = \frac{1}{2}u\cdot E(t)u - \frac{1}{2}v\cdot F(t)v + v\cdot G(t)u, \tag{9}$$

where $E(t)$, $F(t)$, and $G(t)$ are matrices of appropriate dimensions, with $E(t)$ and $F(t)$ symmetric and positive semidefinite. Note that a second order approximation of any smooth saddle cost would yield such a function. (We skip the linear terms for simplicity of presentation.) Consider the following condition:

$$\text{for every } t\le T, \qquad (P(t))^\infty \cap \ker E(t) = \{0\}, \qquad (Q(t))^\infty \cap \ker F(t) = \{0\}. \tag{10}$$

Above, C^∞ denotes the recession cone of a convex set C, defined as $\{y\in\mathbb{R}^m \mid C+y\subset C\}$. If (10) holds, then Assumption 2.4 is satisfied for the game under discussion. Indeed, pick any $\bar v(t)\in Q(t)$. We have

$$\begin{aligned}
&\inf_{v\in Q(t)}\sup_{u\in P(t)}\{p\cdot u+q\cdot v-f(t,u,v)\}\\
&\quad\le \sup_{u\in P(t)}\left\{p\cdot u+q\cdot v-\frac{1}{2}u\cdot E(t)u+\frac{1}{2}\bar v\cdot F(t)\bar v-\bar v\cdot G(t)u\right\}\\
&\quad= \frac{1}{2}\bar v\cdot F(t)\bar v+\sup_{u\in P(t)}\left\{(p-G^*(t)\bar v)\cdot u-\frac{1}{2}u\cdot E(t)u\right\}.
\end{aligned}$$

If Θ is a symmetric and positive semidefinite matrix and $\ker(\Theta) \cap C^\infty = \{0\}$, then for any $z \in \mathbb{R}^m$, $\sup_{y \in C}\{z \cdot y - \frac{1}{2} y \cdot \Theta y\}$ is finite; see 11.18 in Rockafellar and Wets [9]. Thus

$$\inf_{v \in Q(t)} \sup_{u \in P(t)} \{p \cdot u + q \cdot v - f(t,u,v)\} < +\infty.$$

A symmetric argument shows that $-\infty < \sup_{u \in P(t)} \inf_{v \in Q(t)} \{p \cdot u + q \cdot v - f(t,u,v)\}$, and since

$$\sup_{u \in P(t)} \inf_{v \in Q(t)} \{p \cdot u + q \cdot v - f(t,u,v)\} \leq \inf_{v \in Q(t)} \sup_{u \in P(t)} \{p \cdot u + q \cdot v - f(t,u,v)\},$$

both expressions are finite. This guarantees that they are actually equal to each other (34.2.1 in Rockafellar [6]).

Note that when matrices $E(t)$, $F(t)$, and $G(t)$ depend continuously on t and the sets $\mathcal{U}(\tau,\xi)$, $\mathcal{V}(\tau,\xi)$ are subsets of $L^2[\tau,T]$, Assumption 2.3 is satisfied (as well as Assumptions 2.1 and 2.2). Let us finish the discussion of this special case with two remarks.

- Conditions (10) are clearly satisfied when sets $P(t)$, $Q(t)$ are bounded (then their recession cones reduce to $\{0\}$) or when matrices $E(t)$, $F(t)$ are positive definite (and thus invertible).
- Conditions (10) take a particularly simple form when sets $P(t)$ and $Q(t)$ are cones: $P(t) \cap \ker E(t) = \{0\}$, $Q(t) \cap \ker F(t) = \{0\}$. Cones include the "nonnegative orthants" $\mathbb{R}^k_+$, $\mathbb{R}^l_+$, and, more generally, finite intersections of half-spaces given by linear (not just affine) subspaces.

A general result, describing all convex-concave functions for which Assumption 2.4 holds, will be given at the end of this section.

We now present the basic notions of convex analysis that will be heavily used in what follows. Extending the function f to $(-\infty,T] \times \mathbb{R}^k \times \mathbb{R}^l$, as described in (6), allows for defining the class of functions conjugate in the convex-concave sense to $f(t,\cdot,\cdot)$. Under the condition (8), this class consists of one function $f^* : (-\infty,T] \times \mathbb{R}^k \times \mathbb{R}^l \to \mathbb{R}$ given by

$$\begin{aligned} f^*(t,p,q) &= \sup_{u \in \mathbb{R}^k} \inf_{v \in \mathbb{R}^l} \{p \cdot u + q \cdot v - \tilde{f}(t,u,v)\} \\ &= \inf_{v \in \mathbb{R}^l} \sup_{u \in \mathbb{R}^k} \{p \cdot u + q \cdot v - \tilde{f}(t,u,v)\}. \end{aligned}$$

Equivalently, $f^*(t,p,q)$ is the common value in (8). The function $f^*(t,p,q)$ is convex in p, concave in q, and locally Lipschitz continuous in (p,q).

The subdifferential $\partial\phi(\bar{p},\bar{q})$ of a convex-concave function $\phi(\cdot,\cdot)$, in the sense of Rockafellar [6], is defined as

$$\partial\phi(\bar{p},\bar{q}) = \partial_1\phi(\bar{p},\bar{q}) \times \partial_2\phi(\bar{p},\bar{q}),$$

where

$$\partial_1\phi(\bar{p},\bar{q}) = \{r \mid \phi(p,\bar{q}) \geq \phi(\bar{p},\bar{q}) + r \cdot (p - \bar{p})\}$$

is the subdifferential in the sense of convex analysis of the convex function $\phi(\cdot,\bar{q})$, and

$$\partial_2\phi(\bar{p},\bar{q}) = \{s \mid \phi(\bar{p},q) \leq \phi(\bar{p},\bar{q}) + s \cdot (q - \bar{q})\}$$

is the subdifferential of the concave function $\phi(\bar{p},\cdot)$. The subdifferential $\partial f^*(t,p,q)$ is then by definition the subdifferential of the convex-concave function $(p,q) \mapsto f^*(t,p,q)$. The function $f^*(t,p,q)$ is differentiable in (p,q), in particular when the cost function $f(t,u,v)$ is strictly convex in p and strictly concave in q. Then the subgradient $\partial f^*(t,p,q)$ equals $\nabla f^*(t,p,q)$, where the gradient is taken with respect to (p,q). If, in addition, the cost function is continuous in (t,u,v) and the sets $P(t)$ and $Q(t)$ evolve continuously in time, as is the case when they are constant, then both $f^*(t,p,q)$ and $\nabla f^*(t,p,q)$ are continuous in (t,p,q). An example where strict convexity and strict concavity are present is provided by quadratic cost function (9) with positive definite matrices $E(t)$ and $F(t)$. For a complete presentation of saddle function theory, see Rockafellar [6].

The section concludes with an equivalent, possibly more practical, condition for Assumption 2.4 to hold. A convex function $\alpha(\cdot)$ is called proper if it does not take on the value $-\infty$ and has a finite value at some point. It is called coercive if it is bounded from below and $\alpha(u)/|u| \to \infty$ as $|u| \to \infty$. An equivalent condition for coercivity of a convex function $\alpha(\cdot)$ is that its conjugate function, given by $\alpha^*(q) = \sup_u\{q\cdot u - \alpha(u)\}$, is finite. We will say that a concave function $\beta(\cdot)$ is proper or coercive if $-\beta(\cdot)$ is proper or coercive in the sense just described. Recall that $\tilde{f}$ is the extension of f to $(-\infty,T]\times\mathbb{R}^k\times\mathbb{R}^l$, defined in (6).

PROPOSITION 2.7 (finiteness of the conjugate function). *Assumption* 2.4 *holds if and only if, for every* $t \in (-\infty,T]$, *the convex function* $\alpha(u) = \sup_v \tilde{f}(t,u,v)$ *and the concave function* $\beta(v) = \inf_u \tilde{f}(t,u,v)$ *are both proper and coercive.*

Proof. For simplicity of notation, fix $t \in (-\infty,T]$. Suppose that Assumption 2.4 holds. Then, for functions $a(\cdot,\cdot)$ and $b(\cdot,\cdot)$ from $\mathbb{R}^k\times\mathbb{R}^l$ to $\overline{\mathbb{R}}$ defined by $a(u,q) = \sup_p\{u\cdot p - f^*(t,p,q)\}$, $b(p,v) = \inf_q\{v\cdot q - f^*(t,p,q)\}$, the following conditions hold: for every q, the convex function $a(\cdot,q)$ is proper and coercive, and for every p, the concave function $b(p,\cdot)$ is proper and coercive. But it is also true that $a(u,q) = \sup_v\{\tilde{f}(t,u,v) - v\cdot q\}$, $b(p,v) = \inf_u\{\tilde{f}(t,u,v) - u\cdot p\}$. Justification of these formulas can be found in Rockafellar [8]. In particular, the convex function $a(\cdot,0) = \alpha(\cdot)$ and the concave function $b(0,\cdot) = \beta(\cdot)$ are both proper and coercive.

Now assume that $\alpha(\cdot)$ and $\beta(\cdot)$ are proper and coercive. Then, for the lower conjugate of $\tilde{f}(t,\cdot,\cdot)$, we have

$$\begin{aligned}\underline{\tilde{f}}^*(t,p,0) &= \sup_{u\in\mathbb{R}^k}\inf_{v\in\mathbb{R}^l}\{p\cdot u - \tilde{f}(t,u,v)\} = \sup_{u\in\mathbb{R}^k}\{p\cdot u - \sup_{v\in\mathbb{R}^l}\tilde{f}(t,u,v)\}\\ &= \sup_{u\in\mathbb{R}^k}\{p\cdot u - \alpha(u)\},\end{aligned}$$

and the last quantity is finite, for every p. Similarly, for the upper conjugate function, we have

$$\overline{\tilde{f}}^*(t,0,q) = \inf_{v\in\mathbb{R}^l}\sup_{u\in\mathbb{R}^k}\{q\cdot v - \tilde{f}(t,u,v)\} = \inf_{v\in\mathbb{R}^l}\{q\cdot v - \beta(v)\},$$

and the last quantity is finite, for every q. Then also $\underline{\tilde{f}}^*(t,0,q) < +\infty$ for every q, which, combined with the finiteness of $\underline{\tilde{f}}^*(t,p,0)$ for every p, implies that the saddle function $\underline{\tilde{f}}^*(t,\cdot,\cdot)$ is proper. We can now apply 34.3 in [6] to deduce that $\underline{\tilde{f}}^*(t,\cdot,\cdot)$ is actually finite. Then 34.2.1 in [6] implies that Assumption 2.4 holds. □

3. Necessary and sufficient saddle condition. To proceed with reducing the saddle point problem for an integral functional to the saddle point problem for the

integrand function, we need the notion of decomposable sets of functions, which is a slight modification of the notion of decomposable spaces. This and other notions used in this section, like normal integrands and measurability of set valued mappings, are discussed in Rockafellar and Wets [9, Chapter 14].

Let Z be a set of measurable functions $z : [\tau, T] \to \mathbb{R}^m$, and let $R(t) \subset \mathbb{R}^m$ be a nonempty set depending measurably on t. Define Z_R to be the set of all $z \in Z$ such that $z(t) \in R(t)$ almost everywhere on $[\tau, T]$. The set Z is called decomposable with respect to $R(\cdot)$ if, for every function $z_0 \in Z_R$, every measurable set $W \subset [\tau, T]$, and any bounded, measurable function $z_1 : W \to \mathbb{R}^m$ such that $z_1(t) \in R(t)$ for almost every $t \in W$, Z contains the function given by

$$z(t) = \begin{cases} z_0(t) & \text{for } t \in [\tau, T] \setminus W, \\ z_1(t) & \text{for } t \in W. \end{cases}$$

If $R(t) = \mathbb{R}^m$ for almost all $t \in [\tau, T]$, we call the set Z decomposable. Note that, in such a case, Z is also decomposable with respect to any other constraint set $R'(\cdot)$. Decomposable spaces, as defined in [9], are decomposable sets. An example of decomposable spaces is provided by L^p spaces. On the other extreme, discrete sets of functions consisting of more than one function cannot be decomposable if $R(t)$ is convex and is not a singleton for almost every t.

Recall that the auxiliary saddle function $S(t, u, v)$, given by (5), is finite only for $(u, v) \in P(t) \times Q(t)$. Therefore, the saddle points of $S(t, u, v)$ over $P(t) \times Q(t)$ are the same as over $\mathbb{R}^k \times \mathbb{R}^l$; see 36.3 in Rockafellar [6]. The statement (11) in the following theorem can be understood in either sense.

THEOREM 3.1 (saddle point condition). *Any pair of controls* $(\bar{u}(\cdot), \bar{v}(\cdot)) \in \mathcal{U}(\tau, \xi) \times \mathcal{V}(\tau, \xi)$ *satisfying*

$$(\bar{u}(t), \bar{v}(t)) \text{ is a saddle point of } S(t, u, v) \text{ for almost all } t \in [\tau, T] \tag{11}$$

is a saddle point of $\Phi(\tau, \xi, u(\cdot), v(\cdot))$. *Conversely, if* $\mathcal{U}(\tau, \xi)$ *and* $\mathcal{V}(\tau, \xi)$ *are decomposable with respect to* $P(\cdot)$ *and* $Q(\cdot)$ *and if a saddle point* $(\bar{u}(\cdot), \bar{v}(\cdot))$ *of* $\Phi(\tau, \xi, u(\cdot), v(\cdot))$ *exists, then* (11) *holds.*

COROLLARY 3.2. *If* $\mathcal{U}(\tau, \xi)$ *and* $\mathcal{V}(\tau, \xi)$ *are decomposable with respect to* $P(\cdot)$ *and* $Q(\cdot)$, *as is the case when* $\mathcal{U}(\tau, \xi)$ *and* $\mathcal{V}(\tau, \xi)$ *are* L^p *spaces, the following statements are equivalent:*

(a) *Controls* $\bar{u}(\cdot) \in \mathcal{U}(\tau, \xi)$, $\bar{v}(\cdot) \in \mathcal{V}(\tau, \xi)$ *are open-loop solutions of the game* $\mathcal{G}(\tau, \xi)$.

(b) $(\bar{u}(t), \bar{v}(t))$ *is a saddle point of* $S(t, u, v)$ *for almost all* $t \in [\tau, T]$.

The proof of Theorem 3.1 is an application of the following facts, which easily follow from 14.60 in Rockafellar and Wets [9].

LEMMA 3.3. *Let* $\gamma : [a, b] \times \mathbb{R}^n \times \mathbb{R}^m \to \overline{\mathbb{R}}$ *be a function such that* $t \to \gamma(t, u(t), v(t))$ *is measurable for any* $u(\cdot) \in \mathcal{U}$, $v(\cdot) \in \mathcal{V}$, *where* $\mathcal{U}$ *and* $\mathcal{V}$ *are some sets of measurable functions. Define* $\Gamma(u(\cdot), v(\cdot)) = \int_a^b \gamma(t, u(t), v(t))dt$.

(a) *If* $\bar{u}(\cdot) \in \mathcal{U}$ *and* $\bar{v}(\cdot) \in \mathcal{V}$ *are such that* $(\bar{u}(t), \bar{v}(t))$ *is a saddle point of* $\gamma(t, \cdot, \cdot)$ *over* $\mathbb{R}^n \times \mathbb{R}^m$ *for almost all* $t \in [a, b]$, *then* $(\bar{u}(\cdot), \bar{v}(\cdot))$ *is a saddle point for* $\Gamma(\cdot, \cdot)$ *over* $\mathcal{U} \times \mathcal{V}$.

Assume additionally that $(t, u) \mapsto \gamma(t, u, v(t))$ *and* $(t, v) \mapsto -\gamma(t, u(t), v)$ *are normal integrands for any* $u(\cdot) \in \mathcal{U}$, $v(\cdot) \in \mathcal{V}$, *and that the following condition holds: for some sets* $U(t)$ *and* $V(t)$, *depending measurably on* t, *with the property that, for almost all* $t \in [a, b]$, $u(t) \in U(t)$ *and* $v(t) \in V(t)$ *whenever* $u(\cdot) \in \mathcal{U}$ *and* $v(\cdot) \in \mathcal{V}$, $\mathcal{U}$ *is*

decomposable with respect to $U(\cdot)$, and $\mathcal{V}$ is decomposable with respect to $V(\cdot)$. (This condition is automatically satisfied when $\mathcal{U}$ and $\mathcal{V}$ are decomposable.)

(b) *If $(\bar{u}(\cdot), \bar{v}(\cdot))$ is a saddle point for $\Gamma(\cdot,\cdot)$ over $\mathcal{U} \times \mathcal{V}$, and the saddle value is finite, then $(\bar{u}(t), \bar{v}(t))$ is a saddle point for $\gamma(t,\cdot,\cdot)$ over $\mathbb{R}^n \times \mathbb{R}^m$ for almost all $t \in [a,b]$.*

The additional assumption of normality of integrands preceding part (b) implies, in particular, that $t \mapsto \gamma(t, u(t), v(t))$ and $t \mapsto -\gamma(t, u(t), v(t))$ are measurable functions of t. An example of normal integrands is provided by Caratheodory integrands—functions $(t,z) \mapsto \eta(t,z)$ measurable in t and continuous in z. The other condition preceding (b) will later be invoked for the control sets $\mathcal{U} = \{u(\cdot) \in \mathcal{U}(\tau,\xi) \mid u(t) \in P(t)$ almost everywhere for $t \in [\tau,T]\}$ and $\mathcal{V} = \{v(\cdot) \in \mathcal{V}(\tau,\xi) \mid v(t) \in Q(t)$ almost everywhere for $t \in [\tau,T]\}$, with $P(\cdot)$ and $Q(\cdot)$ playing the role of $U(\cdot)$ and $V(\cdot)$.

PROPOSITION 3.4 (normal integrands). *The function $(t,u) \mapsto f(t,u,v(t))$ is a normal integrand for any measurable $v(\cdot)$ such that $v(t) \in Q(t)$ almost everywhere in $[\tau,T]$. Symmetrically, $(t,u) \mapsto -f(t,u(t),v)$ is a normal integrand for any measurable $u(\cdot)$ such that $u(t) \in P(t)$ almost everywhere in $[\tau,T]$.*

Proof. First, assume that $v(t) \in Q(t)$ almost everywhere in $[\tau,T]$. Then we have $f(\cdot,\cdot,v(\cdot)) = \tilde{f}(\cdot,\cdot,v(\cdot))$, where $\tilde{f}(t,u,v) = f(t,u,v)$ when $v \in Q(t)$ and $\tilde{f}(t,u,v) = +\infty$ elsewhere. We can view $\tilde{f}$ as a sum of a Caratheodory integrand $\hat{f}$ and an indicator of $P(t) \times Q(t)$; so, according to 14.32 in [9], $\tilde{f}$ is a normal integrand. The mentioned $\hat{f}$ can be, for example,

$$\hat{f}(t,u,v) = f\left(t, \Pi_{P(t)\times Q(t)}(u,v)\right),$$

where Π_S is the projection onto the set S. The expression $\Pi_{P(t)\times Q(t)}((u,v))$, by 14.17 in [9], is measurable in t, so $\hat{f}$ is also measurable in t for fixed (u,v). For a fixed time t, the projection is continuous in (u,v), so the same property holds for $\hat{f}$. Thus $\hat{f}$ is a Caratheodory integrand. The proof of the second part of the proposition is parallel. □

Proof of Theorem 3.1. Given the controls $u(\cdot)$ and $v(\cdot)$ and the initial condition (2), we obtain the trajectory

$$x(t) = \mathcal{A}(t,\tau)\xi + \int_\tau^t \mathcal{A}(t,s)\left(B(s)u(s) + C(s)v(s)\right) ds. \tag{12}$$

The cost (4) can be rewritten as

$$\int_\tau^T f(t,u(t),v(t))dt + d \cdot \left(\int_\tau^T \mathcal{A}(T,s)(B(s)u(s) + C(s)v(s))ds + \mathcal{A}(T,\tau)\xi \right)$$

$$= \int_\tau^T \left[f(t,u(t),v(t)) + d \cdot \mathcal{A}(T,t)(B(t)u(t) + C(t)v(t)) \right] dt + d \cdot \mathcal{A}(T,\tau)\xi. \tag{13}$$

The last term in the last expression is independent of the controls. To find the saddle point of (13), we can then concentrate on the integral part of this expression. Part (a) of Lemma 3.3 implies that condition (11) is sufficient. We now prove it is also necessary. The expression $d \cdot \mathcal{A}(T,t)(B(t)u + C(t)v)$ is continuous in (t,u,v). Thus it is a normal integrand in (t,u) for a fixed $v(\cdot)$, and its negative is a normal integrand in (t,v) for a fixed $u(\cdot)$. Similar properties hold for $f(t,u,v)$ by Lemma 3.4 and then also for the integrand in (13). The last statement follows from the fact that a

sum of normal integrands is a normal integrand. Let $(\bar{u}(\cdot), \bar{v}(\cdot))$ be a saddle point of $\Phi(\tau, \xi, u(\cdot), v(\cdot))$. Then $\bar{u}(\cdot)$ and $\bar{v}(\cdot)$ satisfy (3), and, by Assumption 2.3, the value of (13) for these controls is finite. The assumption of decomposability of $\mathcal{U}(\tau, \xi)$ with respect to $P(t)$ implies, in particular, that the set $\mathcal{U}$, as defined in the comments following Lemma 3.3, is decomposable with respect to $P(t)$. Symmetric statements can be made for $\mathcal{V}(\tau, \xi)$. Applying Lemma 3.3 to the control sets $\mathcal{U}$, $\mathcal{V}$ and the constraint sets $P(t)$, $Q(t)$ finishes the proof. □

4. Existence of saddle controls. The condition that $(\bar{u}(t), \bar{v}(t))$ is a saddle point of $S(t, u, v)$ is equivalent, by 37.4 in Rockafellar [6], to either of the following expressions:

$$(-B^*(t)\mathcal{A}^*(T,t)d, -C^*(t)\mathcal{A}^*(T,t)d) \in \partial f\,(t, \bar{u}(t), \bar{v}(t))\,, \tag{14}$$

$$(\bar{u}(t), \bar{v}(t)) \in \partial f^*(t, -B^*(t)\mathcal{A}^*(T,t)d, -C^*(t)\mathcal{A}^*(T,t)d). \tag{15}$$

In the above formulas and in what follows, $\mathcal{A}^*(T,t)$, $B^*(t)$, and $C^*(t)$ denote the transposes of the matrices $\mathcal{A}(T,t)$, $B(t)$, and $C(t)$.

THEOREM 4.1 (existence of saddle controls). *Measurable controls $u(\cdot)$ and $v(\cdot)$ satisfying* (15) *for $t \in (-\infty, T]$ exist.*

(a) *If, in addition, for every fixed (p, q), $f^*(t, p, q)$ is locally L^1 in t, the controls are locally L^1 functions.*

(b) *If, in addition, $f^*(t, p, q)$ is continuous in (t, p, q), then the controls are locally L^∞ functions.*

In the proof of the theorem, we will use following lemma, taken from Rockafellar and Wolenski [10]. We need a definition first: for a function $\gamma : \mathbb{R}^n \to \overline{\mathbb{R}}$ and a point x with $\gamma(x)$ finite, the general subdifferential $\partial^g\gamma(x)$ is the set of all y, such that there exist sequences $x^\nu \to x$, with $\gamma(x^\nu) \to \gamma(x)$, and $y^\nu \to y$, with each pair x^ν, y^ν satisfying the condition $\gamma(x') \geq \gamma(x^\nu) + y^\nu \cdot (x' - x^\nu) + o(|x' - x^\nu|)$.

LEMMA 4.2. *Let $h(\cdot, \cdot)$ be a finite, convex-concave function. Then*

$$\partial h(p, q) = \operatorname{con} \partial^g h(p, q). \tag{16}$$

Proof. By 12.27 in [9], the mapping $T(\cdot, \cdot)$ defined by $(u, -v) \in T(p, q)$ whenever $(u, v) \in \partial h(p, q)$ is maximal monotone. By 35.8 in [6], $T(p, q)$ is single valued if and only if $h(\cdot, \cdot)$ is differentiable at (p, q), and this is the case for almost all (p, q), since $h(\cdot, \cdot)$ is locally Lipschitz continuous. Then the structure of monotone mappings, as described in 12.67 in [9] implies that

$$T(p, q) = \operatorname{con}\{(u, -v) \mid \exists (p^\nu, q^\nu) \to (p, q) \text{with } \nabla h(p^\nu, q^\nu) \to (u, v)\}. \tag{17}$$

We can now apply 9.61 in [9] to conclude that $\partial h(p, q) = \operatorname{con} \partial^g h(p, q)$. □

Proof of Theorem 4.1. Since $f^*(t, p, q)$ is finite, the right side of the inclusion (15) is a nonempty compact convex set. We now argue that it depends measurably on t. For fixed p and q, $f^*(t, p, q)$ is measurable in t. It follows from the fact that conjugacy in the convex sense preserves measurability in time; applying this twice to $f(\cdot, u, v)$ gives us measurability of $f^*(t, p, q)$. Measurability in t and continuity in (p, q) mean that $f^*(t, p, q)$ is a Caratheodory integrand and so also a normal integrand. By Lemma 4.2

$$\partial f^*(t, B^*(t)y(t), C^*(t)y(t)) = \operatorname{con} \partial^g f^*(t, B^*(t)y(t), C^*(t)y(t)).$$

The subdifferential on the right side depends measurably on time, by 14.56 in [9]. Taking the convex hull preserves measurability, by 14.12 in [9]. Therefore, the right side of the inclusion (15) is measurable in time with nonempty compact convex values. By 14.6 in [9], there exists a measurable selection, that is, a pair of measurable functions $u(\cdot)$ and $v(\cdot)$ satisfying (15). Applying Lemma 3 from Rockafellar [7] to the function $f^*(t,p,q)$ implies part (a). If $f^*(t,p,q)$ is continuous, then it is epi/hypocontinuous in t, which implies the graphical continuity of $\partial f^*(t,\cdot,\cdot)$—see Rockafellar [8]. In particular, the graph of $\partial f^*(t,p,q)$ is locally bounded. For $t \in [\tau, T]$,

$$(t, -B^*(t)\mathcal{A}^*(T,t)d, -C^*(t)\mathcal{A}^*(T,t)d) \in K$$

for some compact set K, so the right side of the inclusion (15) is bounded. This implies part (b). □

If any pair of controls $(\bar{u}(\cdot), \bar{v}(\cdot))$ satisfying (15) is such that $\bar{u}(\cdot)$, $\bar{v}(\cdot)$ are in the desired control spaces $\mathcal{U}(\tau,\xi)$, $\mathcal{V}(\tau,\xi)$, the game $\mathcal{G}(\tau,\xi)$ has open-loop solutions; this is guaranteed by Theorem 3.1. General conditions guaranteeing that this is the case are as follows.

COROLLARY 4.3 (existence of open-loop solutions). *Under either of the following two conditions, the game $\mathcal{G}(\tau,\xi)$ has open-loop solutions.*

(a) *The condition in part* (a) *of Theorem* 4.1 *holds, and the control sets $\mathcal{U}(\tau,\xi)$ and $\mathcal{V}(\tau,\xi)$ contain all locally integrable functions.*

(b) *The condition of part* (b) *of Theorem* 4.1 *holds, and the control sets $\mathcal{U}(\tau,\xi)$ and $\mathcal{V}(\tau,\xi)$ contain all essentially bounded functions,*

The solutions are independent of τ and ξ in the following sense: there exist functions $\bar{u}_\infty : (-\infty, T] \mapsto \mathbb{R}^k$, $\bar{v}_\infty : (-\infty, T] \mapsto \mathbb{R}^l$ such that, for any (τ,ξ), the truncations of $\bar{u}_\infty$, $\bar{v}_\infty$ to $[\tau, T]$ are open-loop solutions to $\mathcal{G}(\tau,\xi)$.

In the case where $f(t,u,v) = g(t,u) - h(t,v)$ for some functions $g(t,u)$ and $h(t,v)$ convex in u and v, the conjugate function is $f^*(t,p,q) = g^*(t,p) - h^*(t,q)$. Here $g^*(t,\cdot)$ and $h^*(t,\cdot)$ denote convex functions conjugate to $g(t,\cdot)$ and $h(t,\cdot)$. Condition (15) can be written as

$$\bar{u}(t) \in \partial g^*(t, -B^*(t)\mathcal{A}^*(T,t)d) \quad \text{and} \quad -\bar{v}(t) \in \partial h^*(t, -C^*(t)\mathcal{A}^*(T,t)d).$$

In this case, not only do the saddle controls $\bar{u}(\cdot)$ and $\bar{v}(\cdot)$ not depend on τ and ξ, but they can be chosen independently of each other. Indeed, to choose $\bar{u}(\cdot)$, Player One needs only to know the function $g(\cdot,\cdot)$ and matrices A and B. That player's choice does not depend on $h(\cdot,\cdot)$ or C.

We now comment on the special structure of the inclusion (15) for the game discussed in Example 2.6 ($P(t)$, $Q(t)$ polyhedral, $f(t,\cdot,\cdot)$ quadratic, given by (9)). Let $N_C(y)$ denote the normal cone to the set C at y. (If C is polyhedral, then so is $N_C(y)$.) We have, for any $(u,v) \in P(t) \times Q(t)$,

$$\partial f(t,u,v) = \left\{E(t)u + G^*(t)v + N_{P(t)}(u)\right\} \times \left\{-F(t)v + G(t)u - N_{Q(t)}(v)\right\}.$$

For points $(u,v) \notin P(t) \times Q(t)$, the subdifferential of $f(t,\cdot,\cdot)$ is empty. The graph of the mapping $\partial f(t,\cdot,\cdot)$ is thus piecewise polyhedral—it consists of a union of finitely many polyhedral sets. The same holds for $\partial f^*(t,\cdot,\cdot)$, as $\partial f^*(t,\cdot,\cdot) = (\partial f(t,\cdot,\cdot))^{-1}$, and so the graphs of the two mappings are invertible linear images of one another. In particular, the right-hand side of the inclusion (15) is always a polyhedral set (possibly a singleton).

If the matrices defining f depend continuously on t, we can conclude that the right-hand side of (15) is locally bounded. Indeed, such an assumption guarantees the so-called epi/hypocontinuity of f in t, which in turn is equivalent to the graphical continuity of ∂f, as well as ∂f^*, in t. As the latter subdifferential is always nonempty, it must be locally bounded (in all variables). This allows us to conclude that the game in Example 2.6 has open-loop solutions when the control sets $\mathcal{U}(\tau,\xi)$ and $\mathcal{V}(\tau,\xi)$ contain all essentially bounded functions (as is the case when the control sets are L^2 spaces—a natural choice for games with quadratic costs).

Exploring the structure of the subdifferential of a saddle function, as described in (17), we can say the following: when the matrices E, F, G do not depend on t, the right-hand side of (15) can be written as $\operatorname{con}\{r_1(t), r_2(t), \dots, r_j(t)\}$ for some piecewise continuous functions $r_i(\cdot)$ (with the possibility that all r_i agree for some t). In particular, the right-hand side of (15) depends "piecewise continuously" on t.

5. Hamiltonian system. We define the Hamiltonian, namely, the function $H : (-\infty, T] \times \mathbb{R}^n \times \mathbb{R}^n \to \mathbb{R}$, as the saddle value of the concave-convex function $(u,v) \to y \cdot (A(t)x + B(t)u + C(t)v) - f(t,u,v)$; that is,

$$H(t,x,y) = \sup_u \inf_v \{y \cdot (A(t)x + B(t)u + C(t)v) - f(t,u,v)\}.$$

By the definition of f^*, we obtain

$$H(t,x,y) = y \cdot A(t)x + f^*(t, B^*(t)y, C^*(t)y). \tag{18}$$

We now give another characterization of saddle controls, in terms of Clarke subdifferential $\partial^c H$ of the Hamiltonian. For any locally Lipschitz function $\psi(\cdot)$,

$$\partial^c \psi(\bar{z}) = \operatorname{con}\{\lim \nabla \psi(z^\nu) \mid x^\nu \to x\}, \tag{19}$$

where the limits are taken over all sequences $\{x^\nu\}$ of points where ψ is differentiable (see Clarke [4] for details). Below, $\partial^c H(t,x,y)$ denotes the Clarke subdifferential of $H(t,\cdot,\cdot)$. Whenever $f^*(t,p,q)$ is differentiable in (p,q), the Hamiltonian is differentiable in (x,y), and $\partial^c H(t,x,y)$ reduces to $\nabla_x H(t,x,y) \times \nabla_y H(t,x,y)$. Note that, since $f(t,\cdot,\cdot)$ is a finite convex-concave function, the proof of Lemma 4.2 shows that $\partial f^*(t,p,q) = \partial^c f^*(t,p,q)$.

THEOREM 5.1 (generalized Hamiltonian system). *If the Hamiltonian inclusion*

$$(-\dot{y}(t), \dot{x}(t)) \in \partial^c H(t, x(t), y(t)) \tag{20}$$

holds for almost all $t \in [\tau, T]$ *and*

$$-y(T) = d, \tag{21}$$

then $x(\cdot)$ *satisfies the dynamics* (1) *for some controls* $u(\cdot)$ *and* $v(\cdot)$ *satisfying the saddle condition* (15). *If, for every* $t \in [\tau, T]$, *either* $f^*(t,p,\cdot)$ *is differentiable for every* p *or* $f^*(t,\cdot,q)$ *is differentiable for every* q, *then the reverse implication holds.*

Proof. Directly from the definition (19) we get that

$$\partial^c H(t,x,y) \subset (A^*(t)y, A(t)x + [B(t), C(t)]\, \partial^c f^*(t, B^*(t)y, C^*(t)y)), \tag{22}$$

where $\partial^c f^*(t,p,q)$ denotes the Clarke subdifferential of $f^*(t,p,q)$ in (p,q). The Hamiltonian condition (20) now reduces to

$$-\dot{y}(t) = A^*(t)y(t),$$

$$\dot{x}(t) \in A(t)x(t) + [B(t), C(t)]\, \partial^c f^*(t, B^*(t)y(t), C^*(t)y(t)).$$

The first equation, combined with the transversality condition (21) implies that $y(t) = -\mathcal{A}^*(T,t)d$. We now concentrate on the second inclusion. The Clarke subdifferential $\partial^c f^*(t,\cdot,\cdot)$ is equal to $\partial f^*(t,\cdot,\cdot)$. The inclusion becomes

$$\dot{x}(t) \in A(t)x(t) + [B(t), C(t)]\, \partial f^*(t, B^*(t)y(t), C^*(t)y(t)).$$

By remarks made in the proof of Theorem 4.1, $\partial f^*(t, B^*(t)y(t), C^*(t)y(t))$ is measurable in t. Let $E(t) = [B(t), C(t)]$. The mapping $(t,w) \to E(t)w$ is a Caratheodory mapping. For almost all $t \in [\tau, T]$, there exists a $w \in \partial f^*(t, B^*(t)y(t), C^*(t)y(t))$ such that $E(t)w \in \dot{x}(t) - A(t)x(t)$, and the mapping on the right side of the inclusion is single (so closed) valued and measurable. We can extend this mapping to the whole interval $[\tau, T]$ by assigning it an empty value whenever $\dot{x}(t)$ does not exist; this does not change the closed valuedness or measurability. Theorem 14.16 in [9] implies that there exists a measurable $w(\cdot)$ defined on a full measure subset $S \subset [\tau, T]$, with $w(t) \in \partial f^*(t, B^*(t)y(t), C^*(t)y(t))$, for all $t \in S$ such that

$$\dot{x}(t) = A(t)x(t) + E(t)w(t).$$

We can now write $w(t)$ as $(u(t), v(t))$, where $(u(\cdot), v(\cdot))$ satisfies (15), since $y(t) = -\mathcal{A}^*(T,t)d$. The first part of the theorem is proved.

Now assume that for a fixed t, $f^*(t,p,\cdot)$ is differentiable for every p. Then $f^*(t,\cdot,\cdot)$ is subdifferentially regular at $(B^*(t)y, C^*(t)y)$ in the sense of 7.25 in [9], and by 10.6 in [9], $[B(t), C(t)]\, \partial^c f^*(t, B^*(t)y, C^*(t)y)$ is the Clarke subdifferential of $f^*(t,\cdot,\cdot)$ at $(B^*(t)y, C^*(t)y)$ with respect to y. The inclusion (22) becomes an equation, and all of the above arguments can be reversed. If $f^*(t,\cdot,q)$ is differentiable, we can make an argument, similar to the one above, for the function $-f^*(t,\cdot,q)$. □

COROLLARY 5.2. *Assume that $x(\cdot)$ with $x(\tau) = \xi$ and $y(\cdot)$ with $-y(T) = d$ satisfy the Hamiltonian inclusion* (20) *for almost all $t \in [\tau, T]$. Then $x(\cdot)$ is an equilibrium trajectory of the game $\mathcal{G}(\tau, \xi)$.*

6. The value function. The value $W(\tau, \xi)$ of the game is defined to be the saddle value of the game $\mathcal{G}(\tau, \xi)$. Let $\mathcal{U}$ and $\mathcal{V}$ be some sets of controls on the interval $(-\infty, T]$, such that any measurable and locally integrable solution $(\bar{u}(\cdot), \bar{v}(\cdot))$ of (15) satisfies $\bar{u}(\cdot) \in \mathcal{U}$ and $\bar{v}(\cdot) \in \mathcal{V}$. Assume that, for every $(\tau, \xi) \in (-\infty, T] \times \mathbb{R}^n$, the control sets $\mathcal{U}(\tau, \xi)$ and $V(\tau, \xi)$ are the restrictions of $\mathcal{U}$ and $\mathcal{V}$ to the interval $[\tau, T]$. Then the value function $W(\cdot,\cdot)$ is well defined. In particular, there exist measurable and locally integrable functions $\bar{u}_\infty(\cdot)$ and $\bar{v}_\infty(\cdot)$ on $(-\infty, T]$ such that, for every (τ, ξ), the value function is given by $W(\tau, \xi) = \Phi(\tau, \xi, \bar{u}(\cdot), \bar{v}(\cdot))$, where $\bar{u}(\cdot)$ and $\bar{v}(\cdot)$ are the restrictions of $\bar{u}_\infty(\cdot)$ and $\bar{v}_\infty(\cdot)$ to $[\tau, T]$. Looking at the cost expression in (13), we get that, for almost all (τ, ξ),

$$\nabla_\xi W(\tau, \xi) = \mathcal{A}^*(T, \tau)d,$$

$$W_\tau(\tau, \xi) = -f(\tau, \bar{u}(\tau), \bar{v}(\tau)) - d \cdot \mathcal{A}(T, \tau)(A\xi + B\bar{u}(\tau) + C\bar{v}(\tau)).$$

Whenever both partial derivatives exist, the Hamilton–Jacobi equation holds:

$$-W_\tau(\tau, \xi) + H(\tau, \xi, -\nabla_\xi W(\tau, \xi)) = 0. \tag{23}$$

More can be said in the case where the functions $\bar{u}_\infty(\cdot)$ and $\bar{v}_\infty(\cdot)$ are continuous.

THEOREM 6.1. *Assume that $f^*(\cdot,\cdot,\cdot)$ is continuous in all three variables and, for all $t \in (-\infty, T]$, $f^*(t,\cdot,\cdot)$ is differentiable. Then the value function $W(\cdot,\cdot)$ is continuously differentiable and satisfies the Hamilton–Jacobi equation* (23).

The Hamilton–Jacobi equation allows us to rewrite the auxiliary saddle function (5) as

$$S(t,u,v) = f(t,u,v) + \nabla_\xi W(\tau,\xi)(B(t)u + C(t)v). \tag{24}$$

Theorem 11 states that any controls $\bar{u}(\cdot)$, $\bar{v}(\cdot)$ such that $(\bar{u}(t), \bar{v}(t))$ is a saddle point of (24) almost everywhere are saddle controls of the game. A similar result was obtained by Subbotin [12] under different assumptions and in the setting of closed-loop controls. A solution of (23) was used there to generate closed-loop saddle controls of the game, as saddle points of (24).

If, in addition to the assumptions of the above theorem, the Hamiltonian function is Lipschitz continuous in the y variable, the value function is the unique solution of (23) with the boundary condition

$$W(T,\xi) = d \cdot \xi \tag{25}$$

not only in the classical sense but in the minimax sense. For definitions and the proof, see Subbotin [12]. Note that the Hamiltonian is Lipschitz continuous in y, in particular when $f^*(t,\cdot,\cdot)$ has this property. We finish the paper with the characterization of this case, showing that $f^*(t,\cdot,\cdot)$ is globally Lipschitz continuous if and only if the control sets $P(t)$ and $Q(t)$ are bounded.

PROPOSITION 6.2 (Lipschitz continuity of the conjugate function). *Let $h(\cdot,\cdot)$ be a closed convex-concave function, and let K be the nonempty set where $h(\cdot,\cdot)$ is finite valued. The following statements are equivalent:*

(a) *The class of functions conjugate to $h(\cdot,\cdot)$ contains a globally Lipschitz continuous function $h^*(\cdot,\cdot)$. (Note that this actually implies that $h^*(\cdot,\cdot)$ is the unique function in the mentioned class.)*

(b) *The set K is bounded.*

Proof. Recall that the subdifferential $\partial h^*(\cdot,\cdot)$ of the saddle function $h^*(\cdot,\cdot)$ equals $\operatorname{con} \partial^g h^*(\cdot,\cdot)$, where $\partial^g h(\cdot,\cdot)$ is the generalized subdifferential in the sense of [9]. Also recall that if $h^*(\cdot,\cdot)$ is finite, then $\partial h^*(\cdot,\cdot)$, so also $\partial^g h^*(\cdot,\cdot)$, is locally bounded. This fact will allow us to use Theorem 9.13 of Rockafellar and Wets [9]. Note also that the boundedness of K implies that the class of functions conjugate to $h(\cdot,\cdot)$ consists of a unique finite function $h^*(\cdot,\cdot)$ and that the global Lipschitz continuity of the latter function entails its finiteness.

The boundedness of K is equivalent to the boundedness of $\operatorname{rge} \partial h^*(\cdot,\cdot)$, the range of the subdifferential mapping $\partial h^*(\cdot,\cdot)$, by Theorems 37.4 and 37.5 in Rockafellar [6]. This is equivalent to $\partial^g h^*(\cdot,\cdot)$ being globally bounded and, by Theorem 9.13 in [9], to the local Lipschitz modulus of $h^*(\cdot,\cdot)$ being globally bounded. This, in turn, is equivalent to $h^*(\cdot,\cdot)$ being globally Lipschitz continuous; see Theorem 9.2 in [9]. □

Acknowledgments. The author wishes to express his gratitude to Arkadii Kryazhimskii and Alexander Tarasiev for introducing him to the field of differential games during the author's stay at the International Institute for Applied Systems Analysis in Laxenburg, Austria.

DISSIPATIVE CONTROL OF MECHANICAL SYSTEMS: A GEOMETRIC APPROACH*

MIGUEL C. MUÑOZ-LECANDA† AND F. JAVIER YÁNIZ-FERNÁNDEZ†

Abstract. Dissipative and passive mechanical systems are studied from a geometric point of view. Since the natural geometric background is a Riemannian manifold, we begin by generalizing La Salle theorems about the stability of equilibrium points of dynamical systems to a complete Riemannian manifold. The stability of dissipative mechanical systems is studied using the particular geometric properties of the tangent bundle, and passivity based controls are designed to stabilize equilibrium points. The case of partially dissipative systems is formulated and used with a dynamical extension to design controls for bringing the system to a desired point of the phase space.

1. Introduction.

Although the specific properties of stability of the equilibrium points of dissipative systems have been well known for years, the systematic study of such systems is fairly recent. Indeed, the study of passivity control, based on these properties, has received wide attention, as is evident from the extensive scientific and technical literature on the subject.

The results and the usual methods, however, are only local; they use coordinate expressions and conceal the geometric properties of the state spaces and the vector fields defining the systems.

Furthermore, since the 1970s the use of geometric intrinsic methods has proven to be powerful for describing the interesting properties of control systems, shedding light on the relation between them, and improving the methods used to design the control. A look at the papers by Brockett, Millman, and Sussmann [5], Isidori [7], Nijmeijer and van der Schaft [9], or Lewis and Murray [8], and the references quoted there is enough to ensure that these methods are worthy of being studied and used.

In this paper we give a geometric intrinsic formulation of some aspects of mechanical dissipative systems and the use of these properties to design controls by passivity.

The natural geometric background for describing these systems is a Riemannian manifold, where dissipative vector fields are naturally formulated, including as a particular case those coming from a Rayleigh function. This Riemannian manifold is the *configuration space* of the system.

A mechanical system in a Riemannian manifold, (M, g), is given by a vector field, which is the external force field. The most simple case is that in which this vector field is the gradient of a function, the potential function, but the force often has additional components. We will suppose that one of these components is dissipative and the other contains the control forces. With these data we can write the equation of motion for

a mechanical system with controls, the commonly called *Newton equation*, which is equivalent to *Euler–Lagrange equations*. If, however, we wish to write this equation of motion as a dynamical system—that is, as the equation for the integral curves of a vector field in a manifold, since it is a second order differential equation—we must go to the tangent bundle of the initial configuration manifold. This tangent bundle is the *phase space* of coordinate-velocities of the mechanical system.

Taking this as the natural starting point, the aim of this paper is twofold: first, to describe geometrically the stability properties of equilibrium points of a dissipative vector field in a Riemannian manifold, and second, to use these properties to design passivity controls on mechanical systems in order to stabilize an equilibrium point or to bring the system to a desired working point. We have used [10], [12], [14], and the corresponding chapters of [11] and [13] as a natural guide to the problem in a classical context. They contain enough applications of the results of our study to assure the interest of our approximation to the problem.

The paper is organized as follows. Sections 2 and 3 are devoted to stating the systems we are going to use and the suitable notations for mechanical systems, dissipative and passive systems. In section 4, La Salle's theorem is generalized to a complete vector field in a complete Riemannian manifold, and in section 5 it is applied to passive systems. In section 6, we study the stability of equilibrium points in dissipative mechanical systems, including those which are partially dissipative. Finally, section 7 is devoted to stabilizing equilibrium points of mechanical systems using passivity controls, and to bringing the system to a desired point by means of a dynamical dissipative extension.

Throughout this paper we suppose that the manifolds and maps are differentiable, and differentiability means infinite differentiability. The manifolds are Hausdorff. As a reference for differential geometry, notation employed, and concepts, see [1] and [3].

2. Dynamical and control systems.

2.1. Dissipative mechanical systems. Let M be a differentiable manifold. A *dynamical system* on M is a vector field Y in M. M is called the *phase space* of the system. The differential equation associated to Y, that is, the equation of the integral curves of Y, is given by $Y \circ \gamma(t) = \dot{\gamma}(t)$, where γ is a curve in M. It is called the *evolution equation* of the system.

The vector field $Y \in \mathfrak{X}(M)$ defines a *dissipative system* if there exists a nonnegative function $S \in C^\infty(M)$ which is *decreasing* along the integral curves of Y; that is, $\mathcal{L}_Y S \leq 0$, where $\mathcal{L}_Y$ is the Lie derivative with respect to the vector field Y. S is called the *dissipation function* for Y. If $\mathcal{L}_Y S < 0$, that is, S is *strictly decreasing* along the integral curves of Y, then we call the system *strictly dissipative*.

2.2. Control systems and passive systems. A *control system* on a manifold M is given by a vector field X, called the *drift*, and the *control vector fields* $X_1, \ldots, X_m$. The vector field associated to the system is $Y = X + \sum_{i=1}^m X_i u_i$, where $u_i : M \longrightarrow \mathbb{R}$ are the *controls* or *inputs* of the system.

Usually, for a control system, in addition to the evolution equation, we have the *outputs* of the system, functions $y_1 = h_1, \ldots, y_m = h_m$, $h_i \in C^\infty(M)$, related to the observable variables of the system.

Following [4], we introduce the idea of *passivity* as the counterpart for control systems of a dissipative system. Consider a control system given by $Y = X + \sum_{i=1}^m X_i u_i$ on the manifold M with outputs $y_1, \ldots, y_m$. It is *passive* if there exists a nonnegative

function $S \in C^\infty(M)$ such that

$$S(\gamma(T)) - S(\gamma(0)) \leq \int_0^T \sum_{i=1}^m y_i(\gamma(s))u_i(\gamma(s))\,ds$$

for every solution $\gamma(t)$ with the given inputs $u_1, \ldots, u_m$. The function S is called the *storage function*. This last expression can be understood as an inequality in the evolution of the energy of the system and will be clarified when we apply these ideas to mechanical systems.

3. Mechanical systems. Let (Q, g) be a Riemannian manifold, $\dim Q = n$, and let ∇ be the Levi–Civita connection associated to the Riemannian metric g. A differentiable curve in Q, $\gamma\colon I \longrightarrow Q$, is a *trajectory*, or a *solution*, of the mechanical system associated to the vector field $F \in \mathfrak{X}(Q)$ if γ satisfies the differential equation

$$\nabla_{\dot\gamma}\dot\gamma = F \circ \gamma, \tag{1}$$

where $\dot\gamma(t)$ is the tangent vector of the curve γ at the point $\gamma(t)$ and $\nabla_{\dot\gamma}\dot\gamma$ is the covariant derivative of $\dot\gamma(t)$ with respect to the tangent vector $\dot\gamma(t)$. F is called the *external force* vector field. In local coordinates (q^i) on Q, the components $(\gamma^1, \ldots, \gamma^n)$ of γ satisfy the differential equations

$$\ddot\gamma^k + \sum_{i,j=1}^n \Gamma_{ij}^k \dot\gamma^i \dot\gamma^j = F^k(\gamma^1, \ldots, \gamma^n), \qquad k = 1, \ldots, n, \tag{2}$$

where $\{\Gamma_{ij}^k\}$ are the Christoffel symbols of the connection ∇ in the given coordinates. Equations (1) and (2) are the classical *Newton equations of movement*.

If there exists a differentiable function $U\colon Q \to \mathbb{R}$ such that the force field $F = -\operatorname{grad} U$, we call U the *potential function*. A *simple mechanical system* is given by a Riemannian manifold, (Q, g), the *configuration space*, and a force field $F = -\operatorname{grad} U$. We write such systems as (Q, g, U).

Let $\mathrm{T}Q$ be the tangent bundle of Q, with $\tau_Q\colon \mathrm{T}Q \mapsto Q$ the natural projection; the *kinetic energy* is the function $T\colon \mathrm{T}Q \longrightarrow \mathbb{R}$ given by $T(v_q) = \frac{1}{2} g_q(v_q, v_q)$. In local coordinates, its expression is $T(q^i, v^i) = \frac{1}{2} g_{ij}(q) v^i v^j$, where (q^i, v^i) are the natural local coordinates on $\mathrm{T}Q$ associated to the coordinates (q^i) on Q.

For simple mechanical systems, the *Lagrangian function* is defined by $L = T - \tau_Q^* U$. For simplicity we will write it as $L = T - U$.

Frequently, the force vector field, F, splits into two vector fields, and only one of these fields comes from a potential function. Then if $F = -\operatorname{grad} U + R$, the dynamical equations are written as

$$\nabla_{\dot\gamma}\dot\gamma = -\operatorname{grad} U \circ \gamma + R \circ \gamma, \tag{3}$$

and, using the Lagrangian function, $L = T - U$, the equivalent (see [1]) Euler–Lagrange equations are

$$\frac{d}{dt}\left.\frac{\partial L}{\partial v^i}\right|_{\dot\gamma} - \left.\frac{\partial L}{\partial q^i}\right|_{\dot\gamma} = \sum_{j=1}^n g_{ij} R^j \circ \gamma, \qquad i = 1, \ldots, n. \tag{4}$$

In this situation, the mechanical system is given by $\Sigma = (Q, g, U, R)$.

It is well known that the dynamical equations of mechanics are second order differential equations in the configuration manifold Q, so there is a corresponding first order equation in the tangent bundle $\mathrm{T}Q$, and we have a vector field $Y \in \mathfrak{X}(\mathrm{T}Q)$ associated to Newton equation (3) or to the equivalent Lagrange equations (4). In local coordinates (q^i, v^i) of $\mathrm{T}Q$, this vector field Y has the expression

$$\begin{aligned} Y &= \sum_{i=1}^{n} \left(v^i \frac{\partial}{\partial q^i} + \left(F^i - \sum_{j,k=1}^{n} \Gamma^i_{jk} v^j v^k \right) \frac{\partial}{\partial v^i} \right) \\ &= \sum_{i=1}^{n} \left(v^i \frac{\partial}{\partial q^i} - \sum_{j,k=1}^{n} \Gamma^i_{jk} v^j v^k \frac{\partial}{\partial v^i} \right) + \sum_{i=1}^{n} F^i \frac{\partial}{\partial v^i} = X_g + F^v, \end{aligned}$$

where X_g is the *geodesic field* of the Riemannian metric g, F^v is the vertical lift from Q to $\mathrm{T}Q$ of the force vector field F, $F = -\mathrm{grad}\, U + R$, and we have that $\sum_{j=1}^{n} g_{ij} F^j = -\frac{\partial U}{\partial q^i} + \sum_{j=1}^{n} g_{ij} R^j$. Notice that the vector field $Y \in \mathfrak{X}(\mathrm{T}Q)$ satisfies the second order condition. It is a holonomic vector field in TQ; hence its integral curves in $\mathrm{T}Q$ are canonical liftings of curves in the manifold Q. This tangent bundle, $\mathrm{T}Q$, is called the *phase space* of the mechanical system. See [1] for details on $\mathrm{T}Q$ and properties of the second order vector fields.

When working with mechanical systems, it is usual to consider forces which depend on the velocities. These are vector fields on the manifold Q along the projection $\tau_Q \colon \mathrm{T}Q \longrightarrow Q$; that is, mappings $R \colon \mathrm{T}Q \longrightarrow \mathrm{T}Q$ such that $\tau_Q \circ R = \tau_Q$. We denote by $\mathfrak{X}(Q, \tau_Q)$ the set of such fields.

The dynamical equations of a mechanical system with the force vector field given by $F = -\mathrm{grad}\, \mathrm{U} + R$ with $R \in \mathfrak{X}(Q, \tau_Q)$ are $\nabla_{\dot\gamma} \dot\gamma = -(\mathrm{grad}\, \mathrm{U}) \circ \gamma + R \circ \dot\gamma$. Observe that in this equation we have $R \circ \dot\gamma$ instead of $R \circ \gamma$, because R depends on the velocities.

3.1. Dissipative mechanical systems. Given $R \in \mathfrak{X}(Q, \tau_Q)$, we call it *dissipative* if it satisfies $g_p(R(v_q), v_q) \leq 0$ for every $v_q \in \mathrm{T}Q$. A *dissipative mechanical system* is a mechanical system, $\Sigma = (Q, g, U, R)$ with R dissipative. If $R \in \mathfrak{X}(Q, \tau_Q)$ verifies $g_q(R(v_q), v_q) \leq -\alpha g_q(v_q, v_q)$ for every $v_q \in \mathrm{T}Q$, with α a real number, $\alpha > 0$, then R is called *strictly dissipative* and Σ is a *strictly dissipative system.*

Recall that the energy associated to a mechanical system given by $\Sigma = (Q, g, U, R)$ is the function $E = T + \tau_Q^* U \in C^\infty(\mathrm{T}Q)$. The vector field R is called dissipative because of the following proposition.

PROPOSITION 3.1. *Let $\Sigma = (Q, g, U, R)$ be a mechanical system. If the vector field R is dissipative, then the energy decreases along the solutions. Moreover, if R is strictly dissipative and γ satisfies the condition that $\dot\gamma(t) \neq 0$ for all t, then E is strictly decreasing.*

Proof. Let $\gamma \colon I \longrightarrow Q$ be a trajectory of the mechanical system. Then we have that

$$\begin{aligned} \tfrac{d(E \circ \dot\gamma)}{dt} &= \nabla_{\dot\gamma}(E \circ \dot\gamma) = \nabla_{\dot\gamma}(T \circ \dot\gamma + (\tau_Q^\star U) \circ \dot\gamma) \\ &= \nabla_{\dot\gamma}(\tfrac{1}{2} g(\dot\gamma, \dot\gamma)) + \nabla_{\dot\gamma}(U \circ \gamma) = g(\nabla_{\dot\gamma}\dot\gamma, \dot\gamma) + \nabla_{\dot\gamma}(U \circ \gamma) \\ &= g(-(\mathrm{grad}\, U) \circ \gamma, \dot\gamma) + g(R(\dot\gamma), \dot\gamma) + \nabla_{\dot\gamma}(U \circ \gamma) \\ &= g(R \circ \dot\gamma, \dot\gamma) \leq 0. \qquad \square \end{aligned}$$

So if $\Sigma = (Q, g, U, R)$ is a mechanical system and R is a dissipative force, then the associated vector field $Y = X_g - (\mathrm{grad}\, U)^v + R^v$ defines a dissipative system

in the phase space $\mathrm{T}Q$, provided that $U(q) \geq 0$ for every $q \in Q$. In this case, the dissipation function is the total energy E. Observe that condition $U \geq 0$ is equivalent to supposing that the potential function is bounded below.

3.2. Mechanical systems with controls and passive mechanical systems. In *mechanical systems with controls*, the vector fields of control are forces, and the inputs are coefficients to modulate the strength of these forces. Then the equation of motion is

$$\nabla_{\dot\gamma}\dot\gamma = -(\operatorname{grad} U)\circ\gamma + (F_1u_1 + \cdots + F_mu_m)\circ\dot\gamma,$$

where $F_1, \ldots, F_m$ are the control forces, which often depend on the position and the velocity, and $u_i\colon \mathrm{T}Q \longrightarrow \mathbb{R}$ are the inputs.

The *natural outputs* (see [9]) of a mechanical system with controls are the functions $h_i(v_q) = g(F_i(v_q), v_q)$; that is, $h_i = \mathrm{i}(F_i)g$ for $i = 1, \ldots, m$, where $\mathrm{i}(F_i)g$ is the natural tensor contraction.

From now on, a simple mechanical control system with natural outputs will be denoted by $\Sigma = (Q, g, U, F_1, \ldots, F_m)$.

Consider now a mechanical system with a dissipative component R of the force and with controls denoted by $\Sigma = (Q, g, U, R, F_1, \ldots, F_m)$. According to the above definitions and comments, it can be regarded as a control system with the following characteristics:

–Phase space: $M = \mathrm{T}Q$.

–Vector field of the system: $Y = X_g + F^v + \sum_{i=1}^m u_iX_i$, with $F = -\operatorname{grad} U + R$ and $X_i = F_i^v$.

–Natural outputs: $y_i = h_i = \mathrm{i}(F_i)g \in C^\infty(\mathrm{T}Q)$, $j = 1, \ldots, m$.

As pointed out above, the vector field $Y \in \mathfrak{X}(\mathrm{T}Q)$ satisfies the second order condition on $\mathrm{T}Q$.

PROPOSITION 3.2. *Suppose that $U(q) \geq 0$ for every $q \in Q$, or equivalently, that U is bounded from below; then the system Σ is a passive system with the mechanical energy $E = T + U$ as a storage function.*

Proof. From Proposition 3.1 we have

$$\frac{d(E\circ\dot\gamma)}{dt} = g(R\circ\dot\gamma, \dot\gamma) + \sum_{i=1}^m (u_i\circ\dot\gamma)g(F_i, \dot\gamma).$$

By integration of this expression from 0 to t, it follows that

$$E(\dot\gamma(t)) - E(\dot\gamma(0)) = \int_0^t g(R\circ\dot\gamma, \dot\gamma) + \int_0^t \sum_{i=1}^m y_i(\dot\gamma(s))u_i(\dot\gamma(s)) \leq \int_0^t \sum_{i=1}^m y_i(\dot\gamma(s))u_i(\dot\gamma(s)),$$

which is the passivity condition for E. ∎

Observe that the last inequality is the balance of energy referred to in the above section. The right-hand side is the work of the external forces, and the left-hand side is the stored energy.

4. Stability of equilibrium points in complete Riemannian manifolds.

4.1. Statement of the problem. Let (M, g) be a Riemannian manifold. It is known that from the metric g we can define in M a distance d in such a way that the induced metric topology from d coincides with the original one in M. Then (M, g) is a complete manifold if the induced distance is complete. Throughout this section we

suppose that (M, g) is a complete Riemannian manifold. For equivalent conditions on the completeness of a Riemannian manifold, see [6].

Let $X \in \mathfrak{X}(M)$ and let $x_0 \in M$ be an equilibrium point of X. Consider the associated dynamical system $X \circ \gamma = \dot{\gamma}$, where $\gamma\colon (a, b) \longrightarrow M$ is a differentiable curve. We denote by $\gamma(t; x)$ the solution with initial condition $\gamma(0; x) = x \in M$. We say that a solution $\gamma(t; x)$ is *bounded* if its image is bounded as a subset of the metric space M.

The goal of this section is to find conditions for the stability of the equilibrium point x_0, in the case where the Riemann manifold (M, g) is complete and the vector field X is also complete. In order to achieve this, we shall generalize the results of La Salle in $\mathbb{R}^n$ to this situation. See [16] for more details concerning the results in $\mathbb{R}^n$.

Recall that an equilibrium point x_0 is *stable* if for every $\epsilon > 0$ there exists a $\delta > 0$ such that if $\mathrm{d}(x, x_0) \leq \delta$, then $\mathrm{d}(\gamma(t; x); x_0) \leq \epsilon$, and *asymptotically stable* if it is stable and there exists a neighborhood O of x_0 such that $\lim_{t\to\infty} \mathrm{d}(\gamma(t; x), x_0) = 0$ for all $x \in O$. If $O = M$, we say that x_0 is *globally asymptotically stable*.

4.2. Liapunov functions. If $x_0 \in M$ is an equilibrium point of $X \in \mathfrak{X}(M)$, we say that $V \in C^\infty(M)$ is a *Liapunov function* of X at x_0 if $V(x_0) = 0$, $V(x) > 0$ for all $x \neq x_0$, and $\mathcal{L}_X V(x) \leq 0$ for all $x \in M$.

PROPOSITION 4.1. *If there exists a Liapunov function $V \in C^\infty(M)$ of X at x_0, then x_0 is stable.*

Proof. Let $\partial B(x_0, r) = \{x \in M | \mathrm{d}(x, x_0) = r\}$. Obviously, it is a closed and bounded set. Since (M, g) is complete, the Hopf–Rinow theorem ensures that it is compact. Then let β be the minimum value of the Liapunov function V on this compact set.

Consider $K = \{x \in B(x_0, r) \mid V(x) \leq \alpha\}$, where $\alpha \in (0, \beta)$. Let us show that K is invariant under the flow of X. Take $x \in K$ and consider $\gamma(t; x)$. Since $V(\gamma(t; x))$ is a decreasing function, it satisfies $V(\gamma(t; x)) \leq V(\gamma(0; x)) \leq \alpha$, and as a consequence $\gamma(t; x) \in B(x_0, r)$ for $t \geq 0$ because $\alpha < \beta$. Then K is invariant, and therefore x_0 is stable. □

Note. From this proposition, we have that if X is a dissipative field and the dissipative function S has a strict absolute minimum at the equilibrium point x_0, then x_0 is stable, since $V = S - S(x_0)$ is a suitable Liapunov function.

4.3. La Salle's theorem. Let $X \in \mathfrak{X}(M)$ be a complete vector field on the complete Riemannian manifold (M, g). For $x \in M$, consider the set

$$W(x) = \left\{ y \in M \mid \exists\, (t_k) \subset \mathbb{R},\, t_k > 0,\, t_k \to \infty,\, \lim_{k\to\infty} \gamma(t_k; x) = y \right\}.$$

This is the set of limit points of the integral curve $\gamma(t; x)$.

LEMMA 4.2. *If the solution $\gamma(t; x)$ is bounded, then $W(x)$ is an invariant and compact subset of M and $\lim_{t\to\infty} \mathrm{D}(\gamma(t; x), W(x)) = 0$ (where* D *is the point-set distance).*

Proof. Let $\hat{x} \in W(x)$; then there exists (t_k) such that $\lim_{k\to\infty} \gamma(t_k; x) = \hat{x}$. In order to show that $W(x)$ is invariant under X, we must prove that $\gamma(t; \hat{x}) \in W(x)$ for all $t \in \mathbb{R}$. For every $t \in \mathbb{R}$, take the sequence $(t + t_k)$ from the existence and uniqueness of solutions of ODE $\gamma(t + t_k; x) = \gamma(t; \gamma(t_k; x))$. The flow box theorem implies that $\lim_{k\to\infty} \gamma(t; \gamma(t_k; x)) = \gamma(t; \hat{x})$; therefore $W(x)$ is invariant.

Since $\gamma(t; x)$ is bounded, $W(x)$ is also bounded. Thus, we need only to prove that it is closed because of the Hopf–Rinow theorem. Let $(x_n) \subset W(x)$ and assume

that $\lim_{n\to\infty} x_n = \hat{x}$. Since $x_n \in W(x)$ for all $n \in \mathbb{N}$, there exist (t_k^n) such that $\lim_{k\to\infty} \gamma(t_k^n; x) = x_n$ for all $n > 0$. Then we can find a sequence $(\hat{t}_m)$ of (t_k^n) such that $\lim_{m\to\infty} \mathrm{d}(\gamma(\hat{t}_m; x), \hat{x}) = 0$. Hence, $\lim_{m\to\infty} \gamma(\hat{t}_m; x) = \hat{x}$, and the result follows.

Suppose that $\lim_{t\to\infty} \mathrm{D}(\gamma(t; x), W(x)) \neq 0$; then there exists $\epsilon > 0$ and a sequence (t_m), with $t_m \longrightarrow \infty$, such that $\mathrm{d}(\gamma(t_m; x), y) \geq \epsilon$ for all $y \in W(x)$. However, the curve $\gamma(t; x)$ is contained in a compact set, since this solution is bounded and (M, g) is a complete manifold. Thus we can find a convergent partial sequence $(\gamma(\hat{t}_k; x))$ such that $\lim_{k\to\infty} \gamma(\hat{t}_k; x) = \hat{y}$ for some $\hat{y} \in W(x)$. However, this is not possible because $\hat{y} \in W(x)$ and $\mathrm{d}(\hat{y}, y) \geq \epsilon$ for all $y \in W(x)$. □

It is essential for the solution to be bounded. It is well known that there are dynamical systems in $\mathbb{R}^3$, a complete Riemannian manifold, which have unbounded solutions with chaotic behavior.

PROPOSITION 4.3 (La Salle's theorem). *Let $X \in \mathfrak{X}(M)$ be a complete vector field on a complete Riemannian manifold (M, g). Let x_0 be an equilibrium point of X and $V \in C^\infty(M)$ a Liapunov function of X at x_0. Suppose that $x \in M$ is such that $\gamma(t; x)$ is bounded. Then $W(x) \subseteq \{y \in M | \mathcal{L}_X V(y) = 0\}$.*

Proof. The function $v(t) = V(\gamma(t; x))$ is positive and decreasing; then $\lim_{t\to\infty} v(t) = \hat{v} \geq 0$. Take $y \in W(x)$; there exists (t_m) such that $\lim_{m\to\infty} \gamma(t_m; x) = y$. Since V is continuous, it follows that $V(y) = \lim_{m\to\infty} V(\gamma(t_m; x)) = \hat{v}$. As $W(x)$ is invariant, we have $V(\gamma(t; y)) = V(y)$. Therefore $\mathcal{L}_X V(y) = 0$. □

PROPOSITION 4.4. *Under the same conditions of Proposition 4.3, if $K \subseteq M$ is the maximal invariant set under the flow of X such that $K \subseteq \{y \in M | \mathcal{L}_X V(y) = 0\}$, we have that $\lim_{t\to\infty} \mathrm{D}(\gamma(t; x), K) = 0$.*

Proof. Suppose that $\lim_{t\to\infty} \mathrm{D}(\gamma(t; x), K) \neq 0$; then there exists $\epsilon > 0$ and a sequence (t_m) such that $\mathrm{d}(\gamma(t_m; x), y) \geq \epsilon$ for all $y \in K$. Since $\gamma(t; x)$ is contained in a compact set, a convergent partial subsequence $\gamma(\hat{t}_k; x)$ can be found such that $\lim_{k\to\infty} \gamma(\hat{t}_k; x) = \hat{y} \in W(x) \subseteq K$. But this is a contradiction, since $\mathrm{d}(\hat{y}, y) \geq \epsilon$ for all $y \in K$. □

COROLLARY 4.5. *Under the same conditions as in Proposition 4.3, if the integral curves of X are bounded and the Liapunov function V of X at x_0 satisfies $\mathcal{L}_X V(x) < 0$ for $x \neq x_0$, then x_0 is globally asymptotically stable.*

Proof. Since V is a Liapunov function, x_0 is a stable equilibrium point. On the other hand, the conditions that we have assumed imply that $K = \{x_0\}$, and from the previous proposition, $\lim_{t\to\infty} \mathrm{D}(\gamma(t; x), x_0) = 0$ for all $x \in M$. □

Note. If X is strictly dissipative, the integral curves are bounded, and the dissipation function has a strict absolute minimum in x_0, then x_0 is globally asymptotically stable (see the note following Proposition 4.1).

In order to assure that the integral curves are bounded, if M is not compact, it is enough for the Liapunov function to satisfy that $\lim_{d(q,x_0)\to\infty} V(q) = \infty$.

5. Applications to control systems. Consider now the dynamical control system on the complete Riemannian manifold (M, g) given by $Y = X + \sum_{i=1}^m X_i u_i$ with outputs $y_i = h_i \in C^\infty(M)$, $i = 1, \ldots, m$. Let x_0 be an equilibrium point of the drift field X.

PROPOSITION 5.1. *Suppose that the system is passive with storage function S with a strict absolute minimum at x_0. If there exists a function $\phi = (\phi_1, \ldots, \phi_m) \in C^\infty(\mathbb{R}^m, \mathbb{R}^m)$ such that $\sum_{i=1}^m y_i \phi_i(y_1, \ldots, y_m) \geq 0$ and $\phi_i(y_1(x_0), \ldots, y_m(x_0)) = 0$, $i = 1, \ldots, m$, then we can stabilize the equilibrium point x_0 by the feedback $u_i(v_q) = -\phi_i(y_1(v_q), \ldots, y_m(v_q))$.*

Proof. It is enough to prove that the storage function S is a Liapunov function of $Z = X - \sum_{i=1}^{m} X_i\phi_i(y_1, \dots, y_m)$. Without lost of generality, we can suppose that $S(x_0) = 0$. Since the control system is passive and satisfies $\sum_{i=1}^{m} y_i\phi_i(y_1, \dots, y_m) \geq 0$, the next inequalities hold:

$$S(\gamma(T)) - S(\gamma(0)) \leq -\int_0^T \sum_{i=1}^{m} y_i(\gamma(s))\phi_i(y_1(\gamma(s)), \dots, y_m(\gamma(s)))\, ds \leq 0,$$

where γ is an integral curve of the field Z. Hence S is decreasing along the integral curves of Z. Moreover, $S(x) > 0$ for $x \neq x_0$ and $S(x_0) = 0$. □

Remember that a dynamical control system is called *zero-stable detectable* at x_0 if for every $x \in M$ such that $h(\gamma(t; x)) = 0$ we have $\lim_{t\to\infty} \gamma(t; x) = x_0$.

PROPOSITION 5.2. *Suppose now that the system is zero-stable detectable, is passive where the storage function S has a strict absolute minimum at x_0, and the sets $S^{-1}([0, a])$ are bounded. If there exists a function $\phi = (\phi_1, \dots, \phi_m)$ such that $\sum_{i=1}^{m} y_i\phi_i(y_1, \dots, y_m) > 0$, $(y_1, \dots, y_m) \neq 0$, and $\phi_i(y_1(x_0), \dots, y_m(x_0)) = 0$, $i = 1, \dots, m$, then the feedback $u_i = -\phi_i(y_1(v_q), \dots, y_m(v_q))$ makes x_0 globally asymptotically stable.*

Note. The zero-stable detectable property assures that the outputs faithfully transmit the behavior of the system. See [10] and [11] for details on this notion and examples.

Proof. From the above proposition, we have that x_0 is a stable equilibrium point. Notice that $\gamma(t)$ is defined for all $t \geq 0$ because the energy is decreasing along the integral curves of $Z = X - \sum_{i=1}^{m} X_i\phi_i(y_1, \dots, y_m)$ and $\gamma(t) \subseteq S^{-1}([0, \alpha])$, where $S^{-1}([0, \alpha])$ are bounded and closed sets.

Consider an integral curve $\gamma(t; x)$ of Z. It follows that $\lim_{t\to\infty} S(\gamma(t; x)) = a_0 \geq 0$. Then $S(\hat{x}) = a_0$ for all $\hat{x} \in W(x)$ because of the continuity of the function S. Let $\hat{x} \in W(x)$; since $W(x)$ is an invariant set and the control system is passive, the next inequalities hold:

$$0 = S(\gamma(T; \hat{x})) - S(\gamma(0; \hat{x})) \leq -\int_0^T \sum_{i=1}^{m} y_i\phi_i(y_1, \dots, y_m)\, dt < 0.$$

Hence $\sum_{i=1}^{m} y_i(\gamma(t, \hat{x}))\phi_i(y_1(\gamma(t, \hat{x})), \dots, \gamma(t, \hat{x})) = 0$, and in consequence $y_i(\gamma(t, \hat{x})) = 0$, $t \geq 0$. However, as the system is zero-stable detectable, $\lim_{t\to\infty} \gamma(t; \hat{x}) = x_0$ and $S(\lim_{t\to\infty} \gamma(t, \hat{x})) = a_0 = S(x_0) = 0$. Then $\lim_{t\to\infty} S(\gamma(t; x)) = 0$ and $\lim_{t\to\infty} \gamma(t; x) = x_0$. □

Example. Consider the dynamical control system $\dot{x}_1 = x_2$, $\dot{x}_2 = -x_1$, $\dot{x}_3 = u$, $y = x_3$. It is passive with storage function $S = \frac{1}{2}x_3^2$, and the equilibrium point $(0, 0, 0)$ is stable, but not asymptotically stable, since it is not zero-stable detectable.

6. Stability of equilibrium points of mechanical dissipative systems. This section is devoted to the study of the stability of mechanical systems. Since vector fields on TQ correspond to mechanical systems, according to the foregoing sections, the tangent bundle of a complete Riemannian manifold Q must be provided with a complete Riemannian metric in order to establish the results in an overall context and to determine the conditions for one equilibrium point to be globally asymptotically stable. This is always possible if we take as a metric on TQ the Sasaki metric g^T. It is known that the topology induced by g^T coincides with the natural one in TQ. Moreover, g^T is Riemannian, and if g is complete, then g^T is also complete.

Therefore, $(\mathrm{T}Q, g^T)$ is a complete Riemannian manifold, and we can apply the results of the previous section. See [2] and [15] for more details. Obviously, $\mathrm{T}Q$ can be provided with other different metrics. The only problem is to select one which makes $\mathrm{T}Q$ a complete Riemannian manifold.

6.1. Dissipative systems. Consider a mechanical system $\Sigma = (Q, g, U, R)$, where (Q, g) is a complete Riemannian manifold and $R \in \mathfrak{X}(Q, \tau_Q)$ is dissipative. The equilibrium points of the system are of the form $0_{q^o} \in \mathrm{T}_{q^o}Q$, since the vector field associated to the system, $Y = X_g - (\operatorname{grad} U)^v + R^v$, satisfies the second order condition. We denote by 0_{q^o} the zero vector in $\mathrm{T}_{q^o}Q$. Moreover, if $R \in \mathfrak{X}(Q, \tau_Q)$ verifies that $R(0_q) = 0$ for every $q \in Q$, for example if R comes from a Rayleigh function, then q^o is a zero of the gradient of U.

It is known that if $U \in C^\infty(Q)$ is bounded from below and $R \in \mathfrak{X}(Q, \tau_Q)$ is dissipative, then $Y \in \mathfrak{X}(\mathrm{T}Q)$ is positive complete; see [1] for more details. Therefore, we can study the asymptotic behavior of any solution.

PROPOSITION 6.1. *Let (Q, g) be a complete Riemannian manifold, and consider a mechanical system $\Sigma = (Q, g, U, R)$ with $R \in \mathfrak{X}(Q, \tau_Q)$ dissipative. Suppose that q^o is a strict absolute minimum of U and $R(0_q) = 0$ for every $q \in Q$. Then we have that 0_{q^o} is stable.*

Moreover, if 0_{q^o} is the only equilibrium point, $R \in \mathfrak{X}(Q, \tau_Q)$ is strictly dissipative, and the solutions are bounded, then 0_{q^o} is globally asymptotically stable.

Proof. In order to prove the stability, it is enough to show that $\tilde{E} = T + \tau_Q^* U - U(q^o)$ is a Liapunov function; see Proposition 4.1. That is, $\tilde{E}(v_q) > 0$ for all $v_q \neq 0_{q^o}$ and $\mathcal{L}_Y \tilde{E}(v_q) \leq 0$. To prove the last assertion, let $\dot{\gamma}(t; v_q)$ be a solution of the system. Then, since R is dissipative, we have $\mathcal{L}_Y \tilde{E}(v_q) = g(R \circ \dot{\gamma}(t; v_q), \dot{\gamma}(t; v_q))|_{t=0} \leq 0$, as in Proposition 3.1.

Asymptotic stability follows from Proposition 4.3. Consider a solution of the system $\dot{\gamma}(t; v_q)$; then $\mathcal{L}_Y \tilde{E}(v_q) = g(R \circ \dot{\gamma}(t; v_q), \dot{\gamma}(t; v_q))|_{t=0} \leq -\alpha g(\dot{\gamma}(t; v_q), \dot{\gamma}(t; v_q))|_{t=0} = -\alpha g_q(v_q, v_q)$ for some $\alpha > 0$. So the maximal invariant set K, defined in Proposition 4.4, verifies $K \subseteq \{y \in \mathrm{T}Q | \mathcal{L}_X \tilde{E}(y) = 0\} \subseteq \{0_q | q \in Q\}$, and since there is only one equilibrium point, then $K = \{0_{q^o}\}$. Therefore, 0_{q^o} is globally asymptotically stable. □

6.2. Partially dissipative systems. Let (Q_1, g_1), (Q_2, g_2) be Riemannian manifolds with Levi–Civita connections ∇_1 and ∇_2. We can provide the manifold $Q = Q_1 \times Q_2$ with a natural Riemannian metric $g = g_1 \oplus g_2$, which is complete if g_1 and g_2 are also complete. For (Q, g) the Levi–Civita connection is $\nabla = \nabla^1 \oplus \nabla^2$; that is, $\nabla_{\dot{\gamma}} \dot{\gamma} = \nabla^1_{\dot{\gamma}_1} \dot{\gamma}_1 + \nabla^2_{\dot{\gamma}_2} \dot{\gamma}_2$, where $\gamma = (\gamma_1, \gamma_2)$ is a curve in Q.

From the above, the dynamical equations of the system $\Sigma = (Q, g, U, R)$ can be written as

$$\begin{aligned} \nabla^1_{\dot{\gamma}_1} \dot{\gamma}_1 &= -(\operatorname{grad}_1 U) \circ (\gamma_1, \gamma_2) + R_1 \circ (\dot{\gamma}_1, \dot{\gamma}_2), \\ \nabla^2_{\dot{\gamma}_2} \dot{\gamma}_2 &= -(\operatorname{grad}_2 U) \circ (\gamma_1, \gamma_2) + R_2 \circ (\dot{\gamma}_1, \dot{\gamma}_2), \end{aligned} \tag{5}$$

where $\mathrm{i}(\operatorname{grad}_i U) g_i = -\mathrm{d}_i U$ and d_i is the exterior differential operator in Q_i, $i = 1, 2$. Recall that if $X \in \mathfrak{X}(Q)$, then $X = X_1 + X_2$, where $X_i \in (Q, \pi_i)$ and $\pi_i : Q \to Q_i$ is the natural projection.

PROPOSITION 6.2. *Given a mechanical system $\Sigma = (Q = Q_1 \times Q_2, g = g_1 \oplus g_2, U, R)$ with $R = (0, R_2)$, $R_2 \in \mathfrak{X}(Q_2, \tau_{Q_2})$ a dissipative force, if $U \in C^\infty(Q)$ has a strict absolute minimum at $q^o \in Q$, then the equilibrium point 0_{q^o} is stable.*

Proof. The function $\tilde{E} = T + \tau_Q^* U - U(q^o)$ is a Liapunov function at 0_{q^o} because $\tilde{E} > 0$ for $v_q \neq 0_{q^o}$ and $\mathcal{L}_Y \tilde{E}(v_q) = g(R \circ \dot{\gamma}, \dot{\gamma}) = g_2(R_2 \circ \dot{\gamma}_2, \dot{\gamma}_2) \leq 0$. Therefore, 0_{q^o} is stable. □

The vector field $R \in \mathfrak{X}(Q, \tau_Q)$ is called *strictly partially dissipative* if it verifies $g(R \circ v_q, v_q) \leq -\alpha g_2(v_{q_2}, v_{q_2})$, with α a real number, $\alpha > 0$, for all $v_q \in \mathrm{T}_q Q$. This condition means that R is only strictly dissipative on (Q_2, g_2).

PROPOSITION 6.3. *Let $\Sigma = (Q = Q_1 \times Q_2, g = g_1 \oplus g_2, U, R)$ be a mechanical system with $R \in \mathfrak{X}(Q, \tau_Q)$ strictly partially dissipative and such that if $v_{q_2} = 0$, then $R(v_q) = 0$.*

Suppose that $U \in C^\infty(Q)$ has a strict absolute minimum at q^o and every solution $\gamma(t) = (\gamma_1, \gamma_2)$ such that $\dot{\gamma}_2 = 0$ and $(\mathrm{grad}_2 U) \circ \gamma = 0$ satisfies $\lim_{t\to\infty} \dot{\gamma}(t) = 0_{q^o}$. Then 0_{q^o} is globally asymptotically stable.

Proof. Notice that the solutions are defined for all $t \geq 0$, because the vector field associated to the system is dissipative, and then it is positive complete.

Consider a solution of the system Σ, $\dot{\gamma}(t; v_q)$, and take the function $\tilde{E} = T + U - U(q^o)$. Since $\tilde{E} \geq 0$ and it verifies

$$\frac{d(\tilde{E} \circ \dot{\gamma})}{dt} = g(R \circ \dot{\gamma}, \dot{\gamma}) \leq -\alpha g(\dot{\gamma}_2, \dot{\gamma}_2) \leq 0, \tag{6}$$

then $\lim_{t\to\infty} \tilde{E}(\dot{\gamma}(t; v_q)) = a_0 \geq 0$. By the continuity of $\tilde{E}$, $\tilde{E}(\hat{x}) = a_0$ for all $\hat{x} \in W(v_q)$, with the same notation as in section 4.3.

Consider now the solution $\dot{\gamma}(t; \hat{x})$, where $\hat{x} \in W(v_q)$. From inequality (6) and the invariance of $W(v_q)$, it is clear that $g_2(\dot{\gamma}_2(t; \hat{x}), \dot{\gamma}_2(t; \hat{x})) = 0$. Hence $\dot{\gamma}_2(t; \hat{x}) = 0, t \geq 0$.

Substitution of $\dot{\gamma}_2(t; \hat{x}) = 0$ into (5) gives that $(\mathrm{grad}_2 U)(\gamma(t; \hat{x})) = 0$ and then $\lim_{t\to\infty}(\dot{\gamma}(t; \hat{x})) = 0_{q^o}$. Hence $a_0 = E(\dot{\gamma}(t; \hat{x})) = 0$ and therefore $\lim_{t\to\infty} \dot{\gamma}(t; v_q) = 0_{q^o}$. □

7. Dissipative control of mechanical systems.

7.1. Stabilization on equilibrium points. Let (Q, g) be a complete Riemannian manifold and 0_{q^o} an equilibrium point of the simple mechanical system (Q, g, U). Consider the mechanical control system $\Sigma = (Q, g, U, F_1, \ldots, F_m)$ with the natural outputs. Then we have the following proposition.

PROPOSITION 7.1. *If the potential function U has a strict absolute minimum at q^o, then 0_{q^o} is a stable equilibrium point of the system $\widetilde{\Sigma} = (Q, g, U, R)$, where $R(v_q) = -\beta \sum_{i=1}^m F_i(v_q) g_q(F_i(v_q), v_q)$, $\beta > 0$.*

Note. The system $\widetilde{\Sigma}$ is obtained from Σ by the feedback $u_i(v_q) = -\beta h_i(v_q) = -\beta g_q(F_i(v_q), v_q)$, with β a real number, $\beta > 0$.

Proof. The function $\tilde{E} = T + U - U(q^o)$ is a Liapunov function for $\widetilde{\Sigma} = (Q, g, U, R)$, because $\tilde{E}(v_q) > 0$ for every $v_q \neq 0_{q^o}$ and $\mathcal{L}_Z \tilde{E}(v_q) = -\beta \sum (g(F_i(v_q), v_q))^2$, where $Z \in \mathfrak{X}(\mathrm{T}Q)$ is the dynamical vector field associated to the system $\widetilde{\Sigma} = (Q, g, U, R)$. □

COROLLARY 7.2. *Under the same condition of the above proposition, suppose there exist functions $\phi_1, \ldots, \phi_m \in C^\infty(\mathbb{R}^m, \mathbb{R})$ such that $\phi_i(0) = 0$, $i = 1, \ldots, m$, and $\sum_{i=1}^m y_i \phi_i(y_1, \ldots, y_m) \geq 0$. Then 0_{q^o} is a stable equilibrium point of $\widetilde{\Sigma} = (Q, g, U, R = -\sum_{i=1}^m F_i \phi_i(y_1, \ldots, y_m))$.*

7.2. Stabilization at an arbitrary point.

7.2.1. Dynamic extensions of a control system. Let Σ_p be a control system on the manifold M_p; that is, $\Sigma_p = (M_p, Y_p = X_p^0 + \sum_{i=1}^m F_i^p u_i^p)$, with controls $u_i^p \in C^\infty(M_p)$. Denote by Σ_c the couple made by a manifold M_c and a vector field $Y_c \in \mathfrak{X}(M_c, \pi_c)$, where $\pi_c \colon M_p \times M_c \longrightarrow M_c$. Then $\Sigma_c = (M_c, Y_c)$ is a system on M_c which depends on the states of M_p.

With Σ_p and Σ_c, we can define a new control system $\Sigma = (M, Y)$, which is called a *dynamic extension* of Σ_p, in the following way. As phase space consider the manifold $M = M_p \times M_c$ and the vector field on M given by $Y = (X_p^0, Y_c) + \sum_{i=1}^m (F_i^p, 0) u_i$, where the new controls $u_i \in C^\infty(M)$. Note that the controls u_i depend on the state variables of M_c and M_p. Moreover, if Σ_c has good properties, for instance if it is a dissipative system, then these properties can be used to stabilize Σ_p.

The notation comes from that usually employed in control theory, M_p for the "plant system," the system under study, and M_c for the "controller" (see [10]), and we say that $\Sigma = (M, Y)$ is a *dynamic extension* of Σ_p.

7.2.2. Mechanical systems. Consider the mechanical system with controls $\Sigma_p = (Q_p, g_p, U_p, F_1^p, \dots, F_{m_p}^p)$. We are interested in dynamic extensions of Σ_p.

Suppose that we have a Riemannian manifold (Q_c, g_c), a function $U_c \colon Q_p \times Q_c \longrightarrow \mathbb{R}$, and a vector field $R_c \in \mathfrak{X}(Q_c, \tau_c)$, where $\tau_c \colon \mathrm{T}Q_c \longrightarrow Q_c$ is the natural projection. Denote by Σ_c the set (Q_c, g_c, U_c, R_c). With Σ_p and Σ_c we can define Σ, a dynamic extension of Σ_p, given by $Q = Q_p \times Q_c$, $g = g_p \oplus g_c$, and $Y = (X_g^p, X_g^c) - (\mathrm{grad}_p U_p, \mathrm{grad}_c U_c)^v + R^v + \sum_{i=1}^{m_p} F_i^v u_i$, where $R = (0, R_c)$ and $F_i = (F_i^p, 0)$, with controls $u_i \in C^\infty(Q)$.

Once again the new controls depend on the states of Q_p and Q_c, not only on Q_p. Notice that Σ is not a mechanical system with controls, because we have neither a potential function $U \in C^\infty(Q)$ nor $\mathrm{grad}\, U$ as a force field.

7.2.3. Stabilization by dynamic extensions. Let the mechanical control system be $\Sigma_p = (Q_p, g_p, U_p, F_1^p, \dots, F_{m_p}^p)$. We will try to design controls to stabilize the system at a desired point q_p^o. The idea is to construct a suitable dynamic extension Σ such that the whole system given by the dynamic extension makes q_p^o stable by an appropriate feedback.

With this aim, consider that Σ is a dynamic extension of Σ_p given by $\Sigma_c = (Q_c, g_c, U_c, R_c)$, and suppose that $\mathrm{grad}_p U_c \in \langle F_1^p, \dots, F_{m_p}^p \rangle$. We have the following results.

PROPOSITION 7.3. *Suppose that $q^0 = (q_p^0, q_c^0)$ is a strict absolute minimum of $U = U_p + U_c$ and that $R_c \in \mathfrak{X}(Q_c, \tau_c)$ is a dissipative vector field such that $R_c(0_{q_c}) = 0$ for every $q_c \in Q_c$. Then the feedback $u_i \in C^\infty(Q)$, such that $\sum_{i=1}^{m_p} F_i u_i = \mathrm{grad}_{\mathrm{p}} U_c$, makes 0_{q^o} stable.*

Note. Observe that the system which results from Σ by the feedback previously described is the mechanical system $\overline{\Sigma} = (Q, g, U, R)$.

Proof. Note that if $R_c \in \mathfrak{X}(Q_c, \tau_{Q_c})$ is dissipative, that is, if it verifies that $g_c(R_c(v_c), v_c) \leq 0$, then $R = (0, R_c)$ is also dissipative with respect to the metric g, since $g(R(v_p, v_c), (v_p, v_c)) = g_p(0, v_p) + g_c(R_c(v_c), v_c) = g_c(R_c(v_c), v_c) \leq 0$.

Then the function $\tilde{E} = T + \tau_Q^* U - U(q^o)$ is a Liapunov function of $\overline{\Sigma}$ because $\tilde{E}(v_p, v_c) > 0$ for every $(v_p, v_c) \neq 0_{q^o}$, and $\mathcal{L}_Z \tilde{E}((v_p, v_c)) = g(R((v_p, v_c)), (v_p, v_c)) \leq 0$ with Z the dynamical vector field of the whole system. □

PROPOSITION 7.4. *Under the same conditions as in the above proposition, let us suppose that $R_c \in \mathfrak{X}(Q_c, \tau_c)$ is strictly dissipative and every solution $\gamma = (\gamma_p, \gamma_c)$*

of the system $\overline{\Sigma} = (Q, g, U, R)$ *such that* $\dot{\gamma}_c(t) = 0$ *and* $grad_c\, U_c(\gamma_p, \gamma_c) = 0$ *satisfies* $\lim_{t\to\infty} \dot{\gamma}(t) = 0_{p^o}$. *Then* 0_{p^o} *is a globally asymptotically stable point of the system* $\overline{\Sigma}$.

Comment. The last condition is related to the property of being zero-stable detectable. See section 5 or [10].

Proof. Since $R \in \mathfrak{X}(Q, \tau_Q)$ is partially dissipative, we have the conditions of Proposition 6.3. □

Note. Given the mechanical control system Σ_p, suppose that $q_p^0 \in Q_p$ is the point where we want to stabilize the system. According to the above propositions, it is enough to find a system Σ_c with the condition that the new potential function $U = U_p + U_c$ has a strict absolute minimum at (q_p^0, q_c^0), where q_c^0 can be any point of the manifold Q_c.

Observe that the process has two different parts:

1. to find the potential function U_c, with the purpose of obtaining a new one $U = U_p + U_c$ that has a strict absolute minimum at (q_p^0, q_c^0);
2. to design controls u_i with the aim of obtaining a dynamical extension which can stabilize the system in q_p^0 using the dissipative force associated to Σ_c.

See [10] for a local point of view, examples, and applications of all these results. Compare the above proposition with Theorem 3.1 in [10].

Acknowledgments. We wish to thank the anonymous referees for their careful reading of the manuscript. Their helpful comments are greatly appreciated. Thanks also to Mr. Jeff Palmer for his assistance in preparing the English version.

STATE-CONSTRAINED OPTIMAL CONTROL GOVERNED BY NON–WELL-POSED PARABOLIC DIFFERENTIAL EQUATIONS*

GENGSHENG WANG† AND LIJUAN WANG†

Abstract. This paper is concerned with a maximum principle of optimal control problems governed by some parabolic differential equations which could be non–well-posed. Both an integral-type state constraint and a two-point boundary (time variable) state constraint are considered.

Key words. optimal control, non–well-posed parabolic equation, state constraint

1. Introduction.

In this paper we shall study optimal control problems governed by some semilinear parabolic differential equations which, in particular, could be singular, i.e., have local solution only. We shall call such systems non–well-posed systems and call the optimal control problems governed by such systems non–well-posed optimal control problems.

Throughout this paper, we denote by $\Omega \subset R^n$, $n \geq 3$, a bounded open subset with smooth boundary $\partial\Omega$ (say, for instance, the class of C^2). Let $Q = \Omega \times (0,T)$ with $T > 0$ and $\sum = \partial\Omega \times (0,T)$. Let $a_{ij}(x) \in C^2(\bar{\Omega})$ with $a_{ij}(x) = a_{ji}(x)$ for all $x \in \bar{\Omega}$, satisfying $\sum_{i,j=1}^n a_{ij}(x)\xi_i\xi_j \geq \Lambda \sum_{i=1}^n \xi_i^2$ for all $\xi_i \in R, i = 1, \ldots, n$, and $x \in \bar{\Omega}$, where $\Lambda > 0$. Set $Ay(x,t) = -\sum_{i,j=1}^n \frac{\partial}{\partial x_i}(a_{ij}(x)\frac{\partial y(x,t)}{\partial x_j})$. We set

$$Y = \left\{ y \in L^2(0,T;H_0^1(\Omega)) \mid \frac{\partial y}{\partial t} + Ay \in L^2(Q) \right\}$$

and

$$\|y\|_Y = \left(\|y\|^2_{L^2(0,T;H_0^1(\Omega))} + \left\| \frac{\partial y}{\partial t} + Ay \right\|^2_{L^2(Q)} \right)^{\frac{1}{2}}.$$

Then, as we know (cf. [15]), Y endowed with the norm $\|\cdot\|_Y$ is a Hilbert space, and $Y = H^{2,1}(Q) \cap L^2(0,T;H_0^1(\Omega))$, where

$$H^{2,1}(Q) = \left\{ y \mid y, \frac{\partial y}{\partial t}, \frac{\partial y}{\partial x_i}, \frac{\partial^2 y}{\partial x_i \partial x_j} \in L^2(Q),\ i,j = 1, \ldots, n \right\}.$$

We set

$$H^{2,1}_{\frac{2n}{n+2}}(Q) = \left\{ y \in L^{\frac{2n}{n+2}}(Q) \mid \frac{\partial y}{\partial t}, \frac{\partial y}{\partial x_i}, \frac{\partial^2 y}{\partial x_i \partial x_j} \in L^{\frac{2n}{n+2}}(Q),\ i,j = 1, \ldots, n \right\}$$

and

$$W_0^{1,\frac{2n}{n+2}}(\Omega) = \left\{ w \in L^{\frac{2n}{n+2}}(\Omega) \mid \frac{\partial w}{\partial x_i} \in L^{\frac{2n}{n+2}}(\Omega),\ i = 1, \ldots, n,\ w = 0,\ \text{on } \partial\Omega \right\}.$$

†Department of Mathematics, Huazhong Normal University, Wuhan, Hubei, 430079, P.R. of China (wanggs@ccnu.edu.cn, kyc@ccnu.edu.cn).

The first problem (P_1) we study in this paper is as follows.

Inf $L(y,u) \equiv$ Inf $\int_0^T [g(t,y)+h(u)]dt$ over all $(y,u) \in Y \times L^2(Q)$ such that

$$\begin{cases} \frac{\partial y(x,t)}{\partial t} + Ay(x,t) + f(x,t,y(x,t)) = u(x,t), & \text{in } Q, \\ y(x,t) = 0, & \text{on } \sum, \\ y(x,0) = y_0(x), & \text{in } \Omega \end{cases} \tag{1.1}$$

and

$$F(y) \in W. \tag{1.2}$$

Here $y_0(x) \in L^2(\Omega)$, and we assume the following:

$\boldsymbol{(H_1)}$ $g : [0,T] \times L^2(\Omega) \to R^+$ is measurable in t, and for every $\delta > 0$ there exists $L_\delta > 0$ independent of t such that $g(t,0) \in L^\infty(0,T)$ and

$$|g(t,y_1) - g(t,y_2)| \le L_\delta \|y_1 - y_2\|_{L^2(\Omega)} \text{ for all } t \in [0,T], \quad \|y_1\|_{L^2(\Omega)} + \|y_2\|_{L^2(\Omega)} \le \delta.$$

$h : L^2(\Omega) \to \bar{R} = (-\infty, +\infty]$ is lower semicontinuous and convex with the following growth property:

$$h(u) \ge c_1 \|u\|^2_{L^2(\Omega)} + c_2,$$

where $c_1 > 0$ and $c_2 \in R$.

$\boldsymbol{(H_2)}$ $f : \bar{\Omega} \times [0,T] \times R \to R$ is continuous, and $f'_y(x,t,\cdot)$ is continuous. Moreover,

$$|f(x,t,y)| \le a_1(x,t) + b_1|y|^{r_1}$$

and

$$|f'_y(x,t,y)| \le \tilde{a}_1(x,t) + \tilde{b}_1|y|^{r_1 - 1},$$

where $a_1(x,t) \in L^2(Q), \tilde{a}_1(x,t) \in L^n(Q)$ with $a_1(x,t) \ge 0$ a.e. in Q, $\tilde{a}_1(x,t) \ge 0$ a.e. in Q; $b_1, \tilde{b}_1 \ge 0$ are two constants; and $r_1 \in R$ with $1 \le r_1 \le \frac{n}{n-2}$.

$\boldsymbol{(H_3)}$ X is a Banach space with X^* strictly convex, and $F : L^2(Q) \to X$ is in the class of C^1. $W \subset X$ is a convex and closed subset.

Let (y_1^*, u_1^*) be an optimal pair for problem (P_1), i.e., $(y_1^*, u_1^*) \in Y \times L^2(Q)$ and satisfies (1.1) and (1.2); moreover, $L(y_1^*, u_1^*) \le L(y,u)$ for all $(y,u) \in Y \times L^2(Q)$ satisfying (1.1) and (1.2). In addition to (H_1), (H_2), and (H_3), we assume the following:

$\boldsymbol{(H_4)}$ $F'(y_1^*)D_r - W$ has finite codimensionality in X for some $r > 0$, where $D_r = \{\, z \in Y \,:\, \|z\|_Y \le r \text{ and } z(x,0) = 0 \,\}$.

For the definition of finite codimensionality of a set and related results, we refer the reader to [13]. Note that $z(x,0)$ makes sense and belongs to $L^2(Q)$ because $z \in Y$ (cf. [15]). It is clear that for each $r > 0$, $D_r \ne \emptyset$ because $0 \in D_r$.

The second problem (P_2) we shall study in this paper is as follows.

Inf $L(y,u) \equiv$ Inf $\int_0^T [g(t,y)+h(u)]dt$ over all $(y,u) \in Y \times L^2(Q)$ such that

$$\begin{cases} \frac{\partial y(x,t)}{\partial t} + Ay(x,t) + f(x,t,y(x,t)) = u(x,t), & \text{in } Q, \\ y(x,t) = 0, & \text{on } \sum \end{cases} \tag{1.3}$$

and

$$(y(x,0), y(x,T)) \in S, \tag{1.4}$$

where the functionals g and h satisfy (H_1) and the function f satisfies (H_2). Moreover we assume the following:

(H_5) $S \subset L^2(\Omega) \times L^2(\Omega)$ is a closed convex subset.

Let (y_2^*, u_2^*) be an optimal pair for problem (P_2), i.e., $(y_2^*, u_2^*) \in Y \times L^2(Q)$ and satisfies (1.3) and (1.4); moreover, $L(y_2^*, u_2^*) \le L(y, u)$ for all $(y, u) \in Y \times L^2(Q)$ satisfying (1.3) and (1.4). We define, for $r_1, r_2, r_3 > 0$,

$$\begin{aligned} B_{r_1,r_2,r_3} = \{(z_0, z_1) \in L^2(\Omega) \times L^2(\Omega) \mid &\text{for all } y \in Y \text{ with } \|y - y_2^*\|_Y \le r_1, \\ &\exists\, (z, v) \in Y \times L^2(Q) \text{ with } \|z\|_Y \le r_2, \|v\|_{L^2(Q)} \le r_3 \\ &\text{such that } z(x,0) = z_0, z(x,T) = z_1 \text{ and} \\ &\tfrac{\partial z}{\partial t} + Az + f_y'(x,t,y)z = v \text{ in } Q \,\}. \end{aligned} \tag{1.5}$$

Observe that for all $r_1, r_2, r_3 > 0$, $B_{r_1,r_2,r_3} \neq \emptyset$, because $(0,0) \in B_{r_1,r_2,r_3}$. In addition to (H_1), (H_2), and (H_5), we assume this:

(H_6) There exist $r_1, r_2, r_3 > 0$ such that the set $(B_{r_1,r_2,r_3} - S)$ has finite codimensionality in $L^2(\Omega) \times L^2(\Omega)$.

By (H_1), (H_2), (H_3), and (H_4), we may get the necessary conditions for (y_1^*, u_1^*) to be optimal for problem (P_1), which is given by Theorem 1.1 below, and by (H_1), (H_2), (H_5), and (H_6) we may obtain the necessary conditions for (y_2^*, u_2^*) to be optimal for problem (P_2), which is presented by Theorem 1.2.

In order to get the existence of optimal pairs for problems (P_1) and (P_2), we need the additional assumptions that follow.

(H_7) There exist $\tilde{c}_1 > 0$ and $\tilde{c}_2 \ge 0$ such that

$$g(t,y) \ge \tilde{c}_1 |y|^{2\tilde{r}} + \tilde{c}_2 \quad \text{for all } (t,y) \in [0,T] \times R,$$

where $\tilde{r} = \frac{n}{n-2}$.

(H_8) $D_{ad} \neq \emptyset$, where

$$D_{ad} = \{(y,u) \in Y \times L^2(Q) : (y,u) \text{ satisfies (1.1) and (1.2)}\}.$$

(H_9) $\tilde{D}_{ad} \neq \emptyset$, where

$$\tilde{D}_{ad} = \{(y,u) \in Y \times L^2(Q) : (y,u) \text{ satisfies (1.3) and (1.4)}\}.$$

(H_{10}) The set $\{x_0 \in L^2(\Omega) : (x_0, x_1) \in S \text{ for some } x_1 \in L^2(\Omega)\}$ is bounded in $L^2(\Omega)$.

The following notation will be in effect throughout this paper. $[F'(y)]^*$ denotes the adjoint operator of operator $F'(y)$, where $y \in L^2(Q)$; $\partial g(t,y)$ and $\partial h(u)$ denote the subdifferential of g to the second variable at y in the sense of Clarke (cf. [9]) and the subdifferential of convex functional h at u (cf. [2]), respectively, where $y \in L^2(Q)$ and $u \in L^2(Q)$; $d_S(\cdot,\cdot)$ denotes the distance of $(\cdot,\cdot)$ to S in $L^2(Q) \times L^2(Q)$; and $\langle \cdot, \cdot \rangle$ and $\langle \cdot, \cdot \rangle_{X^*,X}$ denote the inner product in $L^2(\Omega)$ and the pairing between X^* and X, respectively.

From now on, we shall omit x, t in all functions of x, t if there is no ambiguity. The main results we obtain in this paper are presented as follows.

THEOREM 1.1. *Suppose that (H_1), (H_2), (H_3) hold. Let (y_1^*, u_1^*) be optimal for problem (P_1). We suppose further that (H_4) holds. Then there exist a triplet $(\lambda_0, \xi_0, p) \in R \times X^* \times H^{2,1}_{\frac{2n}{n+2}}(Q)$ with $(\lambda_0, \xi_0) \neq 0$ and a function $\alpha \in \partial g(t, y_1^*)$ a.e. in Q such that*

$$\begin{cases} -\frac{\partial p}{\partial t} + Ap + f_y'(x,t,y_1^*)p + \lambda_0 \alpha + [F'(y_1^*)]^* \xi_0 = 0, & \text{in } Q, \\ p(x,t) = 0, & \text{on } \sum, \\ p(x,T) = 0, & \text{in } \Omega, \end{cases} \tag{1.6}$$

$$p \in \lambda_0 \partial h(u_1^*) \ \ a.e.\ in\, Q, \tag{1.7}$$

$$\langle \xi_0, \psi - F(y_1^*)\rangle_{X^*,X} \le 0 \ \ for\ all\, \psi \in W. \tag{1.8}$$

Moreover, if $[F'(y_1^*)]^*$ *is injective, then* $\lambda_0 \neq 0$.

THEOREM 1.2. *Suppose that* (H_1), (H_2), *and* (H_5) *hold. Let* (y_2^*, u_2^*) *be optimal for problem* (P_2). *We further suppose that* (H_6) *holds. Then there exist a function* $p \in L^2(Q) \cap L^{\frac{2n}{n+2}}(0,T; W_0^{1,\frac{2n}{n+2}}(\Omega))$, *a function* $\alpha \in \partial g(t, y_2^*)$ *a.e. in* Q, *and* $\lambda_0 \in R$ *with* $\lambda_0 \neq 0$ *such that*

$$-\frac{\partial p}{\partial t} + Ap \in L^{\frac{2n}{n+2}}(Q), \tag{1.9}$$

$$\begin{cases} -\frac{\partial p}{\partial t} + Ap + f_y'(x,t,y_2^*)p + \lambda_0 \alpha = 0, & in\, Q, \\ p(x,t) = 0, & on\ \sum, \end{cases} \tag{1.10}$$

$$\langle p(x,0), x_0 - y_2^*(x,0)\rangle - \langle p(x,T), x_1 - y_2^*(x,T)\rangle \le 0 \ \ for\ all\, (x_0,x_1) \in S, \tag{1.11}$$

and

$$p \in \lambda_0 \partial h(u_2^*) \ \ a.e.\ in\, Q. \tag{1.12}$$

THEOREM 1.3. *Let* (H_1), (H_2), (H_3), (H_7), *and* (H_8) *hold. Then problem* (P_1) *has at least one solution.*

THEOREM 1.4. *Let* (H_1), (H_2), (H_5), (H_7), (H_9), *and* (H_{10}) *hold. Then problem* (P_2) *has at least one solution.*

Now we shall point out some special cases of state constraints covered by (1.2) and (1.4) and a special state system covered by (1.1), which is non–well-posed. We stress that the state constraint (1.2) is of the type of an integral. We do not deal with the pointwise state constraint in this paper, for which we refer the reader to [7] and [8].

Example 1.5. Let $X = R^m$ and $h_i \in L^2(Q)$ with $1 \le i \le m$, which are linearly independent in $L^2(Q)$.

Define $F(y) = (\int_Q y(x,t)h_1(x,t)dxdt, \ldots, \int_Q y(x,t)h_m(x,t)dxdt)$. It is clear that F is a linear and bounded operator from $L^2(Q)$ to R^m.

Let $W = ([a_1,b_1], \ldots, [a_m,b_m]) \subset R^m$, $a_i < b_i$, $i = 1, \ldots, m$; then W is convex and closed with finite codimensionality. Thus by Proposition 3.4 of Chapter 4 of [13], the set $(F_y'(y)D_r - W)$ has finite codimensionality in X for any $y \in L^2(Q)$ and $r > 0$.

Consider the state constraint of the form:

$$a_i \le \int_Q y(x,t)h_i(x,t)dxdt \le b_i, \qquad i = 1, \ldots, m. \tag{1.13}$$

It is clear that (1.13) is equivalent to (1.2).

On the other hand, $[F'(y)]^*\xi : R^m \to L^2(Q)$ can be defined by

$$[F'(y)]^*\xi = \sum_{i=1}^m \xi_i h_i \ \text{ for all } \xi = (\xi_1, \ldots, \xi_m) \in R^m.$$

Since $h_1, \ldots, h_m$ are linearly independent, $[F'(y)]^*$ is injective for each $y \in L^2(Q)$.

Example 1.6. Let $S = \{x_0\} \times S_1$, where $x_0 \in H_0^1(\Omega)$ and $S_1 \subset L^2(\Omega)$ has finite codimensionality in $L^2(\Omega)$. We assume that there exists a constant $r > 0$ such that for each $z_0 \in H_0^1(\Omega)$ with $\|z_0\|_{H_0^1(\Omega)} \le r$, and $y \in Y$ with $\|y - y_2^*\|_Y \le r$, the variational system

$$\begin{cases} \frac{\partial z}{\partial t} + Az + f_y'(x,t,y)z = v, & \text{in } Q, \\ z(x,t) = 0, & \text{on } \sum, \\ z(x,0) = z_0, & \text{in } \Omega \end{cases} \tag{1.14}$$

is null controllable, i.e., there exists $(z, v) \in Y \times L^2(Q)$ which satisfies (1.14) and $z(x,T) = 0$.

By Proposition 3.4 in Chapter 4 of [13], one can easily check that (H_6) holds in this case. In other words, state constraint (1.4) covers this case.

From this example, we may see that hypothesis (H_6) mixes some geometric assumptions on set S and some observability assumptions on the variational system corresponding to the state system around (y_2^*, u_2^*).

Example 1.7. Consider the following system:

$$\begin{cases} \frac{\partial y(x,t)}{\partial t} + Ay(x,t) = y^3(x,t) + u(x,t), & \text{in } Q, \\ y(x,t) = 0, & \text{on } \sum, \\ y(x,0) = 0, & \text{in } \Omega, \end{cases} \tag{1.15}$$

where $Q = \Omega \times (0,T)$, $\Omega \subset R^3$, is a bounded domain with smooth boundary. We consider the control set to be $L^2(Q)$.

Let $f(x,t,y) \equiv -y^3$. One can easily check that f satisfies the conditions in (H_2). As we know (cf. [14]), for each $u \in L^2(Q)$, system (1.15) has in general no global solution. This is an unstable or non–well-posed system.

More generally, we may consider the following system:

$$\begin{cases} \frac{\partial y(x,t)}{\partial t} + Ay(x,t) = y(x,t)|y(x,t)|^{q-1} + u(x,t), & \text{in } Q, \\ y(x,t) = 0, & \text{on } \sum, \\ y(x,0) = 0, & \text{in } \Omega, \end{cases}$$

where $1 \le q \le \frac{n}{n-2}$, $n \ge 3$.

Let $f(x,t,y) = -y|y|^{q-1}$; one can check that f satisfies all conditions in (H_2).

Due to their practical applications, there has been a great deal of work on optimal control problems governed by parabolic differential equations; see, for example, [1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 15, 16, 17, 18]. In all of this work, the state equations handled are well-posed. In [14], Lions studied a non–well-posed optimal control problem where the cost functional is given by

$$J(y,u) = \frac{1}{6}\|y - y_d\|_{L^6(Q)}^6 + \frac{N}{2}\|u\|_{L^2(Q)}^2 \tag{1.16}$$

and the state system reads

$$\begin{cases} \frac{\partial y}{\partial t} - \Delta y - y^3 = u, & \text{in } Q, \\ y(x,t) = 0, & \text{on } \sum, \\ y(x,0) = 0, & \text{in } \Omega. \end{cases} \tag{1.17}$$

Stimulated by [14], we study optimal control problems (P_1) and (P_2), where the state equations are more general than (1.17) and the cost functionals are more general than (1.16)—in particular, may be nonsmooth. The major novelty of this paper is the presence of state constraints under "finite codimensionality hypotheses" in the non–well-posed optimal control problems. To the best of our knowledge, the maximum principles for such problems have not been studied. The main purpose of this paper is to derive the maximum principles for problems (P_1) and (P_2). So the existence of optimal pairs for problems (P_1) and (P_2) are assumed when we study the maximum principles.

Since the state equations handled in this paper may be non–well-posed, we can not expect the same results for the sensitivity of the states to the controls as those in [1, 2, 8, and 11]. Thus we cannot apply the techniques in [1, 2, 8, and 11] to derive the maximum principles for problems (P_1) and (P_2). Because of the involvement of the state constraints in the non–well-posed optimal control problems and because the cost functionals may be nonsmooth, we cannot apply the approximate method, which was employed in [14], to obtain the maximum principles for problems (P_1) and (P_2). Our main idea for overcoming these difficulties is to transform the original control problems to the optimization problems of two variables y and u by considering the state system as another constraint composed of the state variable y and the control variable u. (There already exist a state constraint (1.2) for problem (P_1) and a state constraint (1.4) for problem (P_2).) More precisely, we introduce two kinds of penalty functionals, via which we may transform the original problems (P_1) and (P_2) into optimization problems (P_1^ε) and (P_2^ε) which have smooth cost functionals and have no constraints. We find optimal solutions for problems (P_1^ε) and (P_2^ε), which turn out to be close to the original optimal pairs of problems (P_1) and (P_2), respectively. Then we derive the necessary conditions for the optimal solutions of the approximate problems. Finally, by passing to the limits for $\varepsilon \to 0$, we may obtain the maximum principles for problems (P_1) and (P_2).

This paper is organized as follows. In the next section, we prove the maximum principle for problem (P_1), i.e., Theorem 1.1. In section 3, we show Theorem 1.2. In section 4, we prove the existence of optimal pairs for problems (P_1) and (P_2), i.e., Theorem 1.3 and Theorem 1.4.

2. Maximum principle for problem (P_1). Throughout this section, we shall assume that (H_1)–(H_4) hold. We start this section with an introduction to the approximations g^ε of g and h_ε of h. For the details, we refer the reader to [2]. Let

$$g^\varepsilon(t,y) = \int_{R^N} g(t, P_N y - \varepsilon \Lambda_N s)\rho(s)ds, \qquad \varepsilon > 0,$$

where ρ is a mollifier in R^N, $N = [\varepsilon^{-1}]$, $P_N : L^2(\Omega) \to X_N$ is the projection of $L^2(\Omega)$ on X_N, which is the finite dimensional space generated by $\{e_i\}_{i=1}^N$, where $\{e_i\}_{i=1}^\infty$ is an orthonormal basis in $L^2(\Omega)$. $\Lambda_N : R^N \to X_N$ is the operator defined by $\Lambda_N(s) = \sum_{i=1}^N s_i e_i$, $s = (s_1, \ldots, s_N)$.

Let $h_\varepsilon : L^2(\Omega) \to R$ be defined by

$$h_\varepsilon(u) = \inf \left\{ \frac{\|u - v\|^2_{L^2(\Omega)}}{2\varepsilon} + h(v) \ : \ v \in L^2(\Omega) \right\}, \ \ \varepsilon > 0.$$

We define penalty functional L_ε on $Y \times L^2(Q)$ by

$$
\begin{aligned}
L_\varepsilon(y,u) = \quad & \int_0^T [g^\varepsilon(t,y) + h_\varepsilon(u)]dt + \frac{1}{2}\int_Q |u-u_1^*|^2 dxdt + \frac{1}{2\tilde{r}}\int_Q |y-y_1^*|^{2\tilde{r}} dxdt \\
& + \tfrac{1}{2\varepsilon}\int_\Omega |y(x,0)-y_0(x)|^2 dx + \frac{1}{2\varepsilon}[\varepsilon + d_W(F(y))]^2 \\
& + \tfrac{1}{2\varepsilon}\int_Q \left|\frac{\partial y}{\partial t} + Ay + f(x,t,y) - u\right|^2 dxdt,
\end{aligned} \tag{2.1}
$$

where $\tilde{r} = \frac{n}{n-2}$. Note that as $y \in Y$, $y(x,0)$ makes sense and belongs to $L^2(\Omega)$ (cf. [15]). In addition, by Sobolev's imbedding theorem, $y \in L^{\frac{2n}{n-2}}(Q)$. Thus, for each $\varepsilon > 0$, L_ε is well defined. Then we may introduce an approximate problem (P_1^ε), for each $\varepsilon > 0$, as follows.

(P_1^ε) Inf $L_\varepsilon(y,u)$ over all $(y,u) \in Y \times L^2(Q)$.

The following two lemmas provide the existence of an optimal solution for approximate problem (P_1^ε) and the convergence of such optimal solutions.

LEMMA 2.1. *For each $\varepsilon > 0$, problem (P_1^ε) has at least one solution.*

Proof. Let $d = \mathrm{Inf}_{(y,u)\in Y\times L^2(Q)} L_\varepsilon(y,u)$. By (H_1), it is obvious that $d > -\infty$. Let $(y_m, u_m) \in Y \times L^2(Q)$ be such that

$$
d \le L_\varepsilon(y_m,u_m) \le d + \frac{1}{m}. \tag{2.2}
$$

By virtue of (2.1) and (2.2), $\{(y_m,u_m)\}$ is bounded in $L^{2\tilde{r}}(Q)\times L^2(Q)$, $\{y_m(x,0)\}$ is bounded in $L^2(\Omega)$, and $\{\frac{\partial y_m}{\partial t} + Ay_m + f(x,t,y_m) - u_m\}$ is bounded in $L^2(Q)$.

On the other hand, by (H_2) and by Sobolev's imbedding theorem, we get that

$$
\{f(x,t,y_m)\} \quad \text{is bounded in } L^2(Q). \tag{2.3}
$$

Thus $\{\frac{\partial y_m}{\partial t} + Ay_m\}$ is bounded in $L^2(Q)$. Then by the same argument as in [15], $\{y_m\}$ is bounded in Y, and so we may extract subsequences of $\{y_m\}$ and $\{u_m\}$, still denoted by themselves, such that

$$
\begin{cases}
u_m \to \tilde{u} \ \text{ weakly in } L^2(Q) \ \text{ as } m \to \infty, \\
y_m \to \tilde{y} \ \text{ weakly in } Y, \text{ strongly in } L^2(Q) \ \text{ as } m \to \infty, \\
y_m(x,t) \to \tilde{y}(x,t) \ \text{ a.e. in } Q \ \text{ as } m \to \infty, \\
y_m(x,0) \to \tilde{y}(x,0) \ \text{ weakly in } L^2(\Omega) \ \text{ as } m \to \infty.
\end{cases} \tag{2.4}
$$

Since f is continuous, we infer that

$$
f(x,t,y_m(x,t)) \to f(x,t,\tilde{y}(x,t)) \ \text{ a.e. in } Q. \tag{2.5}
$$

By (2.3) and (2.5), there exists a subsequence of $\{y_m\}$, still denoted by itself, such that

$$
f(x,t,y_m) \to f(x,t,\tilde{y}) \ \text{ weakly in } L^2(Q) \ \text{ as } m \to \infty, \tag{2.6}
$$

which together with (2.4) shows that

$$
\frac{\partial y_m}{\partial t} + Ay_m + f(x,t,y_m) - u_m \to \frac{\partial \tilde{y}}{\partial t} + A\tilde{y} + f(x,t,\tilde{y}) - \tilde{u} \ \text{ weakly in } L^2(Q). \tag{2.7}
$$

Then it follows from (2.4) and (2.7) that

(2.8)
$$\underline{\lim}_{m\to\infty}\left\|\frac{\partial y_m}{\partial t}+Ay_m+f(x,t,y_m)-u_m\right\|_{L^2(Q)}\geq\left\|\frac{\partial \tilde{y}}{\partial t}+A\tilde{y}+f(x,t,\tilde{y})-\tilde{u}\right\|_{L^2(Q)}$$

and

$$\underline{\lim}_{m\to\infty}\|y_m(x,0)-y_0(x)\|_{L^2(\Omega)}\geq\|\tilde{y}(x,0)-y_0(x)\|_{L^2(\Omega)}. \tag{2.9}$$

Since $y_m\to\tilde{y}$ strongly in $L^2(Q)$, and because of (H_3), we conclude that

$$\frac{1}{2\varepsilon}[\varepsilon+d_W(F(y_m))]^2\to\frac{1}{2\varepsilon}[\varepsilon+d_W(F(\tilde{y}))]^2\ \text{ as } m\to\infty. \tag{2.10}$$

On the other hand, by the same argument as in Chapter 5 of [2], we get that

(2.11)
$$\begin{aligned}&\underline{\lim}_{m\to\infty}\left\{\int_0^T[g^\varepsilon(t,y_m)+h_\varepsilon(u_m)]dt+\frac{1}{2}\int_Q|u_m-u_1^*|^2dxdt+\frac{1}{2\tilde{r}}\int_Q|y_m-y_1^*|^{2\tilde{r}}dxdt\right\}\\&\geq\int_0^T[g^\varepsilon(t,\tilde{y})+h_\varepsilon(\tilde{u})]dt+\frac{1}{2}\int_Q|\tilde{u}-u_1^*|^2dxdt+\frac{1}{2\tilde{r}}\int_Q|\tilde{y}-y_1^*|^{2\tilde{r}}dxdt.\end{aligned}$$

It follows immediately from (2.2) and (2.8)–(2.11) that $L_\varepsilon(\tilde{y},\tilde{u})=d$. This completes the proof. □

LEMMA 2.2. *Let $(y_\varepsilon,u_\varepsilon)$ be optimal for problem (P_1^ε). Then there exists a generalized subsequence of ε, still denoted by itself, such that*

$$y_\varepsilon\to y_1^*\ \textit{strongly in}\ Y\ \ \textit{as}\ \varepsilon\to 0$$

and

$$u_\varepsilon\to u_1^*\ \textit{strongly in}\ L^2(Q)\ \ \textit{as}\ \varepsilon\to 0.$$

Proof. It is clear that

$$L_\varepsilon(y_\varepsilon,u_\varepsilon)\leq L_\varepsilon(y_1^*,u_1^*)=\int_0^T[g^\varepsilon(t,y_1^*)+h_\varepsilon(u_1^*)]dt+\frac{\varepsilon}{2}.$$

By a standard argument as in [2], this implies that

$$\overline{\lim}_{\varepsilon\to 0}L_\varepsilon(y_\varepsilon,u_\varepsilon)\leq\int_0^T[g(t,y_1^*)+h(u_1^*)]dt=L(y_1^*,u_1^*). \tag{2.12}$$

By virtue of (2.1) and by (H_1), $\{y_\varepsilon\}$ is bounded in $L^{2\tilde{r}}(Q)$, $\{u_\varepsilon\}$ is bounded in $L^2(Q)$, and

$$\int_\Omega|y_\varepsilon(x,0)-y_0(x)|^2dx\leq C\varepsilon, \tag{2.13}$$

$$\int_Q\left|\frac{\partial y_\varepsilon}{\partial t}+Ay_\varepsilon+f(x,t,y_\varepsilon)-u_\varepsilon\right|^2dxdt\leq C\varepsilon \tag{2.14}$$

for some constant C independent of ε.

By the same argument as in the proof of Lemma 2.1, there exists a generalized subsequence of ε, still denoted by itself, such that

$$y_\varepsilon \to \tilde{y} \text{ weakly in } Y \text{ and strongly in } L^2(Q) \text{ as } \varepsilon \to 0, \tag{2.15}$$

$$y_\varepsilon(x,0) \to \tilde{y}(x,0) \text{ weakly in } L^2(\Omega) \text{ as } \varepsilon \to 0, \tag{2.16}$$

$$u_\varepsilon \to \tilde{u} \text{ weakly in } L^2(Q) \text{ as } \varepsilon \to 0, \tag{2.17}$$

and

$$\frac{\partial y_\varepsilon}{\partial t} + Ay_\varepsilon + f(x,t,y_\varepsilon) - u_\varepsilon \to \frac{\partial \tilde{y}}{\partial t} + A\tilde{y} + f(x,t,\tilde{y}) - \tilde{u} \text{ weakly in } L^2(Q). \tag{2.18}$$

It follows from (2.13), (2.14), (2.16), and (2.18) that

$$\begin{cases} \frac{\partial \tilde{y}}{\partial t} + A\tilde{y} + f(x,t,\tilde{y}) - \tilde{u} = 0, & \text{in } Q, \\ \tilde{y}(x,t) = 0, & \text{on } \sum, \\ \tilde{y}(x,0) = y_0(x), & \text{in } \Omega. \end{cases} \tag{2.19}$$

On the other hand, by (2.1) and (2.12), we know that $\frac{1}{2\varepsilon}[\varepsilon + d_W(F(y_\varepsilon))]^2 \le C$, which shows that $d_W(F(y_\varepsilon)) \to 0$ as $\varepsilon \to 0$. This together with (2.15) and (H_3) yields that

$$F(\tilde{y}) \in W. \tag{2.20}$$

Since (y_1^*, u_1^*) is an optimal pair of problem (P_1), it follows from (2.19) and (2.20) that

$$L(y_1^*, u_1^*) \le L(\tilde{y}, \tilde{u}). \tag{2.21}$$

By the same argument as in [2], we get that

$$\underline{\lim}_{\varepsilon \to 0} \int_0^T [g^\varepsilon(t, y_\varepsilon) + h_\varepsilon(u_\varepsilon)]dt \ge \int_0^T [g(t,\tilde{y}) + h(\tilde{u})]dt. \tag{2.22}$$

By (2.1),(2.21), and (2.22), we deduce that

$$\underline{\lim}_{\varepsilon \to 0} L_\varepsilon(y_\varepsilon, u_\varepsilon) \ge L(y_1^*, u_1^*). \tag{2.23}$$

Then by (2.1), (2.12), and (2.23), there exists a generalized subsequence of ε, still denoted by itself, such that

$$y_\varepsilon \to y_1^* \text{ strongly in } L^{2\tilde{r}}(Q), \text{ weakly in } Y \text{ as } \varepsilon \to 0, \tag{2.24}$$

$$y_\varepsilon(x,0) \to y_1^*(x,0) \text{ strongly in } L^2(\Omega) \text{ as } \varepsilon \to 0, \tag{2.25}$$

$$u_\varepsilon \to u_1^* \text{ strongly in } L^2(Q) \text{ as } \varepsilon \to 0. \tag{2.26}$$

Now we claim that

$$f(x,t,y_\varepsilon) \to f(x,t,y_1^*) \text{ strongly in } L^2(Q) \text{ as } \varepsilon \to 0. \tag{2.27}$$

Here is the argument. We observe first that

$$|f(x,t,y_\varepsilon) - f(x,t,y_1^*)| = |y_\varepsilon - y_1^*| \cdot |a_\varepsilon(x,t)|,$$

where $a_\varepsilon(x,t) = \int_0^1 f_y'(x,t,y_1^* + \theta(y_\varepsilon - y_1^*))d\theta$.

By (H_2), we yield that $a_\varepsilon^2(x,t) \le \{\tilde{a}_1(x,t) + \tilde{b}_1[|y_1^*| + |y_\varepsilon|]^{r_1 - 1}\}^2$, which, combined with Sobolev's imbedding theorem, indicates that $\{a_\varepsilon^2(x,t)\}$ is bounded in $L^{\frac{n}{2}}(Q)$. Then by Holder's inequality, we infer that

$$\int_Q |f(x,t,y_\varepsilon) - f(x,t,y_1^*)|^2 dxdt \le \left[\int_Q |y_\varepsilon - y_1^*|^{2\tilde{r}} dxdt\right]^{\frac{n-2}{n}} \cdot \left[\int_Q |a_\varepsilon|^n dxdt\right]^{\frac{2}{n}},$$

which immediately implies (2.27).

Now by (2.14), (2.26), and (2.27), we infer that

$$\frac{\partial(y_\varepsilon - y_1^*)}{\partial t} + A(y_\varepsilon - y_1^*) \to 0 \text{ strongly in } L^2(Q) \text{ as } \varepsilon \to 0.$$

This together with (2.25) shows that (cf. [15]) $y_\varepsilon \to y_1^*$ strongly in Y as $\varepsilon \to 0$, which completes the proof. □

Now we turn to proving Theorem 1.1.

Proof of Theorem 1.1. Let $Z = \{z \in Y \mid z(x,0) = 0\}$. As we know (cf. [15]), the space Z is a Hilbert space endowed with the norm of Y. Let $(z,v) \in Z \times L^2(Q)$ be arbitrary but fixed, and set $y_\varepsilon^\rho = y_\varepsilon + \rho z$, $u_\varepsilon^\rho = u_\varepsilon + \rho v$, where $\rho > 0$. It is clear that $(y_\varepsilon^\rho, u_\varepsilon^\rho) \in Y \times L^2(Q)$, and so

$$\frac{L_\varepsilon(y_\varepsilon^\rho, u_\varepsilon^\rho) - L_\varepsilon(y_\varepsilon, u_\varepsilon)}{\rho} \ge 0 \text{ for all } \rho > 0. \tag{2.28}$$

After some simple calculations, we obtain that

$$\begin{aligned} &\lim_{\rho\to 0} \int_0^T \frac{g^\varepsilon(t,y_\varepsilon^\rho) - g^\varepsilon(t,y_\varepsilon)}{\rho} dt = \int_Q \nabla g^\varepsilon(t,y_\varepsilon) z dxdt, \\ &\lim_{\rho\to 0} \int_0^T \frac{h_\varepsilon(u_\varepsilon^\rho) - h_\varepsilon(u_\varepsilon)}{\rho} dt = \int_Q \nabla h_\varepsilon(u_\varepsilon) v dxdt, \end{aligned} \tag{2.29}$$

$$\begin{aligned} &\lim_{\rho\to 0} \tfrac{1}{2\rho} \int_Q \left[|u_\varepsilon^\rho - u_1^*|^2 - |u_\varepsilon - u_1^*|^2\right] dxdt = \int_Q (u_\varepsilon - u_1^*) v dxdt, \\ &\lim_{\rho\to 0} \tfrac{1}{2\tilde{r}\rho} \int_Q \left[|y_\varepsilon^\rho - y_1^*|^{2\tilde{r}} - |y_\varepsilon - y_1^*|^{2\tilde{r}}\right] dxdt = \int_Q (y_\varepsilon - y_1^*)^{2\tilde{r}-1} z dxdt. \end{aligned} \tag{2.30}$$

Since $y_\varepsilon^\rho(x,0) = y_\varepsilon(x,0)$, we have

$$\frac{1}{2\varepsilon\rho} \int_\Omega \{[y_\varepsilon^\rho(x,0) - y_0(x)]^2 - [y_\varepsilon(x,0) - y_0(x)]^2\} dx = 0 \text{ for all } \rho > 0. \tag{2.31}$$

Now we claim that there is a generalized subsequence of ρ, denoted by itself again, such that

(2.32)
$$\lim_{\rho\to 0}\frac{1}{2\varepsilon\rho}\int_Q\left[\left|\frac{\partial y_\varepsilon^\rho}{\partial t}+Ay_\varepsilon^\rho+f(x,t,y_\varepsilon^\rho)-u_\varepsilon^\rho\right|^2-\left|\frac{\partial y_\varepsilon}{\partial t}+Ay_\varepsilon+f(x,t,y_\varepsilon)-u_\varepsilon\right|^2\right]dxdt$$
$$=\frac{1}{\varepsilon}\int_Q\left[\frac{\partial y_\varepsilon}{\partial t}+Ay_\varepsilon+f(x,t,y_\varepsilon)-u_\varepsilon\right]\cdot\left[\frac{\partial z}{\partial t}+Az+f_y'(x,t,y_\varepsilon)z-v\right]dxdt.$$

Here is the argument. We observe first that

$$\frac{f(x,t,y_\varepsilon^\rho)-f(x,t,y_\varepsilon)}{\rho}=a_\varepsilon^\rho(x,t)z(x,t),$$

where $a_\varepsilon^\rho(x,t)=\int_0^1 f_y'(x,t,y_\varepsilon(x,t)+\theta\rho z(x,t))d\theta$. Since $f_y'(x,t,\cdot)$ is continuous and $(y_\varepsilon^\rho,u_\varepsilon^\rho)\to(y_\varepsilon,u_\varepsilon)$ strongly in $Y\times L^2(Q)$ as $\rho\to 0$, there exists a generalized subsequence of ρ, still denoted by itself, such that

$$[a_\varepsilon^\rho(x,t)z(x,t)-f_y'(x,t,y_\varepsilon(x,t))z(x,t)]^2\to 0\ \text{ a.e. in } Q\ \text{ as } \rho\to 0.$$

It follows from (H_2) that

$$[a_\varepsilon^\rho(x,t)z-f_y'(x,t,y_\varepsilon(x,t))z]^2\le 4\{\tilde a_1(x,t)+\tilde b_1[|y_\varepsilon|+|z|]^{r_1-1}\}^2z^2\in L^1(Q);$$

here we have used Sobolev's imbedding theorem and Holder's inequality. Then by the Lebesgue dominated convergence theorem, we obtain that

$$a_\varepsilon^\rho(x,t)z\to f_y'(x,t,y_\varepsilon)z\ \text{ strongly in } L^2(Q)\ \text{ as } \rho\to 0, \tag{2.33}$$

which implies that

$$f(x,t,y_\varepsilon^\rho)\to f(x,t,y_\varepsilon)\ \text{ strongly in } L^2(Q)\ \text{ as } \rho\to 0. \tag{2.34}$$

Thus (2.32) follows immediately from (2.33) and (2.34).

By the same argument as in [18], we get that

$$\begin{aligned}&\lim_{\rho\to 0}\frac{1}{2\varepsilon\rho}\{[\varepsilon+d_W(F(y_\varepsilon^\rho))]^2-[\varepsilon+d_W(F(y_\varepsilon))]^2\}\\&=\frac{\varepsilon+d_W(F(y_\varepsilon))}{\varepsilon}\langle\xi_\varepsilon,F'(y_\varepsilon)z\rangle_{X^*,X},\end{aligned} \tag{2.35}$$

where

$$\xi_\varepsilon\in\partial d_W(F(y_\varepsilon))=\begin{cases}\nabla d_W(F(y_\varepsilon)), & \text{if } F(y_\varepsilon)\notin W,\\ 0, & \text{if } F(y_\varepsilon)\in W\end{cases}$$

and

$$\|\xi_\varepsilon\|_{X^*}=\begin{cases}1, & \text{if } F(y_\varepsilon)\notin W,\\ 0, & \text{if } F(y_\varepsilon)\in W.\end{cases} \tag{2.36}$$

Let

$$\lambda_\varepsilon=\frac{\varepsilon}{\varepsilon+d_W(F(y_\varepsilon))}\ \text{ and }\ \mu_\varepsilon=\frac{1}{\varepsilon+d_W(F(y_\varepsilon))}. \tag{2.37}$$

It is obvious that

$$1 \le \lambda_\varepsilon^2 + \|\xi_\varepsilon\|_{X^*}^2 \le 2. \tag{2.38}$$

Now it follows from (2.28)–(2.37) that

$$\begin{aligned} &\lambda_\varepsilon \left\{ \int_Q \nabla g^\varepsilon(t, y_\varepsilon) z dx dt + \int_Q \nabla h_\varepsilon(u_\varepsilon) v dx dt + \int_Q (u_\varepsilon - u_1^*) v dx dt \right. \\ &\left. + \int_Q (y_\varepsilon - y_1^*)^{2\tilde{r}-1} z dx dt \right\} + \int_Q [F'(y_\varepsilon)]^* \xi_\varepsilon z dx dt \\ &+ \mu_\varepsilon \int_Q \left(\frac{\partial y_\varepsilon}{\partial t} + A y_\varepsilon + f(x,t,y_\varepsilon) - u_\varepsilon \right) \left(\frac{\partial z}{\partial t} + Az + f_y'(x,t,y_\varepsilon) z - v \right) dx dt \ge 0 \end{aligned} \tag{2.39}$$

for all $(z, v) \in Z \times L^2(Q)$.

Let

$$p_\varepsilon = \mu_\varepsilon \left(\frac{\partial y_\varepsilon}{\partial t} + A y_\varepsilon + f(x,t,y_\varepsilon) - u_\varepsilon \right). \tag{2.40}$$

It is clear that $p_\varepsilon \in L^2(Q)$. By taking $z = 0$ in (2.39), we obtain that

$$\lambda_\varepsilon \left\{ \int_Q \nabla h_\varepsilon(u_\varepsilon) v dx dt + \int_Q (u_\varepsilon - u_1^*) v dx dt \right\} - \int_Q p_\varepsilon v dx dt \ge 0 \tag{2.41}$$

for all $v \in L^2(Q)$. This implies that

$$p_\varepsilon = \lambda_\varepsilon [\, \nabla h_\varepsilon(u_\varepsilon) + u_\varepsilon - u_1^* \,] \text{ a.e. in } Q. \tag{2.42}$$

By Lemma 2.2, $u_\varepsilon \to u_1^*$ strongly in $L^2(Q)$ as $\varepsilon \to 0$. Then by the same argument as in [2], $\{\nabla h_\varepsilon(u_\varepsilon)\}$ is bounded in $L^2(Q)$. Thus it follows from (2.42) that $\{p_\varepsilon\}$ is bounded in $L^2(Q)$.

By taking $v = 0$ in (2.39), we obtain that

$$\begin{aligned} &\int_Q \left\{ \lambda_\varepsilon [\, \nabla g^\varepsilon(t, y_\varepsilon) + (y_\varepsilon - y_1^*)^{2\tilde{r}-1} \,] + [F'(y_\varepsilon)]^* \xi_\varepsilon \right\} z dx dt \\ &+ \int_Q p_\varepsilon \left(\frac{\partial z}{\partial t} + Az + f_y'(x,t,y_\varepsilon) \right) z dx dt = 0 \text{ for all } z \in Z. \end{aligned} \tag{2.43}$$

This shows that (cf. [14])

$$\begin{cases} \frac{\partial p_\varepsilon}{\partial t} - A p_\varepsilon - f_y'(x,t,y_\varepsilon) p_\varepsilon = \lambda_\varepsilon [\nabla g^\varepsilon(t, y_\varepsilon) + (y_\varepsilon - y_1^*)^{2\tilde{r}-1}] + [F'(y_\varepsilon)]^* \xi_\varepsilon, & \text{in } Q, \\ p_\varepsilon(x,t) = 0, & \text{on } \sum, \\ p_\varepsilon(x,T) = 0, & \text{in } \Omega. \end{cases} \tag{2.44}$$

Note that (2.42) and (2.44) can be regarded as necessary conditions for $(y_\varepsilon, u_\varepsilon)$ to be optimal for problem (P_1^ε).

Now we are going to pass to the limit for $\varepsilon \to 0$ in (2.42) and (2.44) (or (2.43)) and derive the necessary conditions for (y_1^*, u_1^*) to be optimal for problem (P_1).

First we deal with (2.42). By (2.38), there exists a generalized subsequence of $\{\lambda_\varepsilon\}$, still denoted by itself, such that

$$\lambda_\varepsilon \to \lambda_0 \text{ as } \varepsilon \to 0. \tag{2.45}$$

By Lemma 2.2 and by the same argument as in [2], there exist $\alpha \in \partial g(t, y_1^*)$, $\beta \in \partial h(u_1^*)$ a.e. in Q such that on a generalized subsequence of ε, still denoted by itself,

$$\nabla g^{\varepsilon}(t, y_{\varepsilon}) \to \alpha \text{ weakly in } L^2(Q) \text{ as } \varepsilon \to 0 \tag{2.46}$$

and

$$\nabla h_{\varepsilon}(u_{\varepsilon}) \to \beta \text{ weakly in } L^2(Q) \text{ as } \varepsilon \to 0. \tag{2.47}$$

Since $\{p_{\varepsilon}\}$ is bounded in $L^2(Q)$, there exists a generalized subsequence of ε, still denoted by itself, such that

$$p_{\varepsilon} \to p \text{ weakly in } L^2(Q) \text{ as } \varepsilon \to 0. \tag{2.48}$$

By (2.45), (2.47), and (2.48), we may pass to the limit for $\varepsilon \to 0$ in (2.42) and obtain (1.7).

Next we deal with (2.44). We claim the following inequality:

$$\|p_{\varepsilon} f_y'(x, t, y_{\varepsilon})\|_{L^{\frac{2n}{n+2}}(Q)} \le C \text{ for some positive constant } C \text{ independent of } \varepsilon. \tag{2.49}$$

Here is the argument. By Lemma 2.2 and by Sobolev's imbedding theorem, $\{|y_{\varepsilon}|^{r_1 - 1}\}$ is bounded in $L^n(Q)$. Thus it follows from (H_2) that $\{f_y'(x, t, y_{\varepsilon})\}$ is bounded in $L^n(Q)$. Then by Holder's inequality, we obtain that

$$\int_Q |p_{\varepsilon} f_y'(x, t, y_{\varepsilon})|^{\frac{2n}{n+2}} dx dt \le \left[\int_Q |p_{\varepsilon}|^2 dx dt\right]^{\frac{n}{n+2}} \left[\int_Q |f_y'(x, t, y_{\varepsilon})|^n dx dt\right]^{\frac{2}{n+2}},$$

which implies (2.49), because $\{p_{\varepsilon}\}$ is bounded in $L^2(Q)$.

On the other hand, by (2.38), Lemma 2.2, and by Sobolev's imbedding theorem, we get that there exists a generalized subsequence of ε, still denoted by itself, such that

$$\lambda_{\varepsilon}(y_{\varepsilon} - y_1^*)^{2\tilde{r} - 1} \to 0 \text{ strongly in } L^{\frac{2n}{n+2}}(Q) \text{ as } \varepsilon \to 0 \tag{2.50}$$

and

$$\xi_{\varepsilon} \to \xi_0 \text{ weakly star in } X^* \text{ as } \varepsilon \to 0,$$

which, combined with (H_3) and Lemma 2.2, indicate that

$$[F'(y_{\varepsilon})]^* \xi_{\varepsilon} \to [F'(y_1^*)]^* \xi_0 \text{ weakly in } L^2(Q) \text{ as } \varepsilon \to 0. \tag{2.51}$$

Now it follows from $(2.44)_1$ (the first equality of (2.44)), (2.49), (2.50), and (2.51) that $\{-\frac{\partial p_{\varepsilon}}{\partial t} + A p_{\varepsilon}\}$ is bounded in $L^{\frac{2n}{n+2}}(Q)$. Then by $(2.44)_2$ and $(2.44)_3$, $\{p_{\varepsilon}\}$ is bounded in $H^{2,1}_{\frac{2n}{n+2}}(Q)$ (cf. [14]). So there exist $p \in H^{2,1}_{\frac{2n}{n+2}}(Q)$ and a generalized subsequence of $\{p_{\varepsilon}\}$, still denoted by itself, such that

$$p_{\varepsilon} \to p \text{ weakly in } H^{2,1}_{\frac{2n}{n+2}}(Q) \text{ as } \varepsilon \to 0 \tag{2.52}$$

and

$$p_{\varepsilon}(x, t) \to p(x, t) \text{ a.e. in } Q \text{ as } \varepsilon \to 0. \tag{2.53}$$

Since $f'_y(x,t,\cdot)$ is continuous, by Lemma 2.2 and by (2.53), there exists a generalized subsequence of ε, still denoted by itself, such that

$$p_\varepsilon(x,t)f'_y(x,t,y_\varepsilon(x,t)) \to p(x,t)f'_y(x,t,y_1^*(x,t)) \text{ a.e. in } Q \text{ as } \varepsilon \to 0. \tag{2.54}$$

By (2.49) and (2.54), we obtain that

$$p_\varepsilon f'_y(x,t,y_\varepsilon) \to p f'_y(x,t,y_1^*) \text{ weakly in } L^{\frac{2n}{n+2}}(Q) \text{ as } \varepsilon \to 0. \tag{2.55}$$

From (2.45), (2.46), (2.50), (2.51), (2.52), and (2.55), we may pass to the limit for $\varepsilon \to 0$ in (2.44) to yield (1.6) (cf. [14]).

Now we turn to proving (1.8). By the definition of the subdifferential of the distance function $d_W(\cdot)$, we have

$$\langle \xi_\varepsilon, \psi - F(y_\varepsilon)\rangle_{X^*,X} \le 0 \text{ for all } \psi \in W.$$

It follows from (H_3) that $F(y_\varepsilon) \to F(y_1^*)$ strongly in X as $\varepsilon \to 0$. Thus we deduce that

$$\langle \xi_\varepsilon, \psi - F(y_1^*)\rangle_{X^*,X} \le \langle \xi_\varepsilon, F(y_\varepsilon) - F(y_1^*)\rangle_{X^*,X} \text{ for all } \psi \in W. \tag{2.56}$$

By taking the limit for $\varepsilon \to 0$ in (2.56), we get (1.8).

It remains to show that $(\lambda_0, \xi_0) \neq 0$. If $\lambda_0 = 0$, then it follows from (2.38) that there exist constants $\delta > 0$ and $\varepsilon_1 > 0$ such that

$$\|\xi_\varepsilon\|_{X^*} \ge \delta > 0 \text{ for all } \varepsilon < \varepsilon_1. \tag{2.57}$$

By (2.39) and (2.56), we obtain that

(2.58)

$$\langle \xi_\varepsilon, F'(y_1^*)z - \psi + F(y_1^*)\rangle_{X^*,X} + \int_Q p_\varepsilon \left[\frac{\partial z}{\partial t} + Az + f'_y(x,t,y_\varepsilon)z - v\right] dxdt \ge -\eta_\varepsilon(z,v)$$

for all $(z,v) \in Z \times L^2(Q)$, where

$$\begin{aligned}\eta_\varepsilon(z,v) = \lambda_\varepsilon \Big\{ &\int_Q \nabla g^\varepsilon(t,y_\varepsilon) z dxdt + \int_Q \nabla h_\varepsilon(u_\varepsilon) v dxdt + \int_Q (u_\varepsilon - u_1^*) v dxdt \\ &+ \int_Q (y_\varepsilon - y_1^*)^{2\tilde{r}-1} z dxdt \Big\} + \langle \xi_\varepsilon, [F'(y_\varepsilon) - F'(y_1^*)]z + F(y_\varepsilon) - F(y_1^*)\rangle_{X^*,X}.\end{aligned}$$

For any $z \in D_r$, which was defined in section 1, and $\varepsilon > 0$, by taking $v = v_\varepsilon(z) \equiv \frac{\partial z}{\partial t} + Az + f'_y(x,t,y_\varepsilon)z$ in (2.58), we obtain that

$$\langle \xi_\varepsilon, F'(y_1^*)z - \psi + F(y_1^*)\rangle_{X^*,X} \ge -\eta_\varepsilon(z, v_\varepsilon(z)) \text{ for all } z \in D_r \text{ and } \varepsilon > 0. \tag{2.59}$$

On the other hand, by (H_2) and Lemma 2.2, there exists a positive constant, denoted by ε_1 again, such that $\|f'_y(x,t,y_\varepsilon)\|_{L^n(Q)} \le C$ for all $\varepsilon < \varepsilon_1$, where C is a constant independent of ε. Then by Holder's inequality, we infer that

$$\begin{aligned}&\int_Q |f'_y(x,t,y_\varepsilon)z|^2 dxdt \\ &\le \left[\int_Q |z|^{\frac{2n}{n-2}} dxdt\right]^{\frac{n-2}{n}} \cdot \left[\int_Q |f'_y(x,t,y_\varepsilon)|^n dxdt\right]^{\frac{2}{n}} \\ &\le Cr^2\end{aligned}$$

for all $z \in D_r$ and $\varepsilon < \varepsilon_1$, where C is a constant independent of ε and z. This shows that

$$\|v_\varepsilon(z)\|_{L^2(Q)} \le C \ \text{ for all } z \in D_r \ \text{ and } \varepsilon < \varepsilon_1. \tag{2.60}$$

By (H_3) and by (2.38), we infer that

$$\langle \xi_\varepsilon, [F'(y_\varepsilon) - F'(y_1^*)]z\rangle_{X^*,X} \to 0 \ \text{ as } \varepsilon \to 0, \ \text{ uniformly in } z \in D_r. \tag{2.61}$$

It follows from (2.60) and (2.61) that

$$\eta_\varepsilon(z, v_\varepsilon(z)) \to 0 \ \text{ as } \varepsilon \to 0, \ \text{ uniformly in } z \in D_r. \tag{2.62}$$

By (H_4), $F'(y_1^*)D_r - W + \{F(y_1^*)\}$ has finite codimensionality in X. Thanks to Lemma 3.6 of Chapter 4 of [13], we conclude from (2.57), (2.59), and (2.62) that $\xi_0 \neq 0$. Hence

$$(\lambda_0, \xi_0) \neq 0. \tag{2.63}$$

Finally, in the case in which $[F'(y_1^*)]$ is injective, if $\lambda_0 = 0$, then by (1.7) we obtain that $p = 0$. Hence, by (1.6), $[F'(y_1^*)]^*\xi_0 = 0$, which shows that $\xi_0 = 0$. This contradicts (2.63). So $\lambda_0 \neq 0$ in this case. This completes the proof. ∎

3. Maximum principle for problem (P_2). In this section, we shall prove Theorem 1.2. The main steps here are similar to those in section 2. However, the penalty functional is different from that in section 2 because we consider a two-point boundary constraint (time variable) here. For this reason we shall prove all results in detail.

First, for each $\varepsilon > 0$, we define a penalty functional L_ε on $Y \times L^2(Q)$ by

$$\begin{aligned} L_\varepsilon(y,u) = &\int_0^T [g^\varepsilon(t,y) + h_\varepsilon(u)]dt + \frac{1}{2}\int_Q |u - u_2^*|^2 dxdt + \frac{1}{2\tilde{r}}\int_Q |y - y_2^*|^{2\tilde{r}} dxdt \\ &+ \tfrac{1}{2}\int_\Omega [\ |y(x,0) - y_2^*(x,0)|^2 + |y(x,T) - y_2^*(x,T)|^2\ ]dx \\ &+ \tfrac{1}{2\varepsilon}[d_S(y(x,0), y(x,T)) + \varepsilon]^2 + \tfrac{1}{2\varepsilon}\int_Q \left| \frac{\partial y}{\partial t} + Ay + f(x,t,y) - u \right|^2 dxdt, \end{aligned} \tag{3.1}$$

where $\tilde{r} = \frac{n}{n-2}$.

Because $y \in Y$, we have that $y \in L^{2\tilde{r}}(Q)$ and $y(x,0), y(x,T) \in L^2(\Omega)$ (cf. [15]). Thus L_ε is well defined. So we may consider an approximate problem (P_2^ε) as follows.

(P_2^ε) Inf $L_\varepsilon(y,u)$ over all $(y,u) \in Y \times L^2(Q)$.

The following two lemmas provide the existence of optimal solutions of approximate problem (P_2^ε) and the convergence of such optimal solutions.

LEMMA 3.1. *For each $\varepsilon > 0$, problem (P_2^ε) has at least one solution.*

Proof. Let $(y_m, u_m) \in Y \times L^2(Q)$ be such that

$$d \le L_\varepsilon(y,u) \le d + \frac{1}{m}, \tag{3.2}$$

where $d = \mathrm{Inf}_{(y,u)\in Y\times L^2(Q)}\ L_\varepsilon(y,u)$. It is clear that $d > -\infty$.

By virtue of (3.1), using the same argument as in the proof of Lemma 2.1, one can show that there exist subsequences of $\{y_m\}$ and $\{u_m\}$, still denoted by themselves, such that

$$u_m \to \tilde{u} \ \text{ weakly in } L^2(Q) \text{ as } m \to \infty, \tag{3.3}$$

$$y_m \to \tilde{y} \ \text{ weakly in } Y, \text{ strongly in } L^2(Q) \text{ as } m \to \infty, \tag{3.4}$$

$$y_m(x,t) \to \tilde{y}(x,t) \ \text{ a.e. in } Q \ \text{ as } m \to \infty, \tag{3.5}$$

$$(y_m(x,0), y_m(x,T)) \to (\tilde{y}(x,0), \tilde{y}(x,T)) \ \text{ weakly in } L^2(\Omega) \times L^2(\Omega) \ \text{ as } m \to \infty. \tag{3.6}$$

By (3.6), we obtain that

$$\begin{aligned} &\varliminf_{m\to\infty} [\, \|y_m(x,0) - y_2^*(x,0)\|^2_{L^2(\Omega)} + \|y_m(x,T) - y_2^*(x,T)\|^2_{L^2(\Omega)} \,] \\ &\geq \|\tilde{y}(x,0) - y_2^*(x,0)\|^2_{L^2(\Omega)} + \|\tilde{y}(x,T) - y_2^*(x,T)\|^2_{L^2(\Omega)}. \end{aligned} \tag{3.7}$$

Since S is convex and closed in $L^2(\Omega) \times L^2(\Omega)$, $d_S(\cdot,\cdot)$ is weakly lower semicontinuous. Thus it follows from (3.6) that

$$\varliminf_{m\to\infty} d_S(y_m(x,0), y_m(x,T)) \geq d_S(\tilde{y}(x,0), \tilde{y}(x,T)). \tag{3.8}$$

By (3.7) and (3.8), using the same argument as in the proof of Lemma 2.1, we find that

$$\varliminf_{m\to\infty} L_\varepsilon(y_m, u_m) \geq L_\varepsilon(\tilde{y}, \tilde{u}),$$

which together with (3.2) shows that $L_\varepsilon(\tilde{y}, \tilde{u}) = d$. This completes the proof. □

LEMMA 3.2. *Let $(y_\varepsilon, u_\varepsilon)$ be optimal for problem (P_2^ε). Then there exists a generalized subsequence of ε, still denoted by itself, such that*

$$y_\varepsilon \to y_2^* \ \textit{strongly in } Y, \ \ u_\varepsilon \to u_2^* \ \textit{strongly in } L^2(Q) \ \textit{ as } \varepsilon \to 0.$$

Proof. It is clear that

$$L_\varepsilon(y_\varepsilon, u_\varepsilon) \leq L_\varepsilon(y_2^*, u_2^*) = \int_0^T [g^\varepsilon(t, y_2^*) + h_\varepsilon(u_2^*)]dt + \frac{\varepsilon}{2},$$

which implies that

$$\overline{\varlimsup_{\varepsilon\to 0}} L_\varepsilon(y_\varepsilon, u_\varepsilon) \leq L(y_2^*, u_2^*). \tag{3.9}$$

On the other hand, by virtue of (3.1) and by the same argument as in the proof of Lemma 2.2, we obtain that there exist $\tilde{y} \in Y$ and a generalized subsequence of ε, still denoted by itself, such that

$$y_\varepsilon \to \tilde{y} \ \text{ weakly in } Y, \text{ strongly in } L^2(Q) \text{ as } \varepsilon \to 0, \tag{3.10}$$

$$(y_\varepsilon(x,0), y_\varepsilon(x,T)) \to (\tilde{y}(x,0), \tilde{y}(x,T)) \ \text{ weakly in } L^2(\Omega) \times L^2(\Omega) \text{ as } \varepsilon \to 0, \tag{3.11}$$

$$u_\varepsilon \to \tilde{u} \ \text{ weakly in } L^2(Q) \text{ as } \varepsilon \to 0, \tag{3.12}$$

and

$$\frac{\partial y_\varepsilon}{\partial t} + Ay_\varepsilon + f(x,t,y_\varepsilon) - u_\varepsilon \to \frac{\partial \tilde{y}}{\partial t} + A\tilde{y} + f(x,t,\tilde{y}) - \tilde{u} \ \text{ weakly in } L^2(Q). \tag{3.13}$$

Moreover, $\tilde{y}$ satisfies the following equation:

$$\begin{cases} \frac{\partial \tilde{y}}{\partial t} + A\tilde{y} + f(x,t,\tilde{y}) = \tilde{u}, & \text{in } Q, \\ \tilde{y}(x,t) = 0, & \text{on } \sum. \end{cases} \tag{3.14}$$

It follows from (3.1) and (3.9) that

$$d_S(y_\varepsilon(x,0), y_\varepsilon(x,T)) \le C\sqrt{\varepsilon}, \tag{3.15}$$

where C is a positive constant independent of ε. Since S is convex and closed, it follows from (3.11) and (3.15) that

$$d_S(\tilde{y}(x,0), \tilde{y}(x,T)) \le \varliminf_{\varepsilon\to 0} d_S(y_\varepsilon(x,0), y_\varepsilon(x,T)) = 0,$$

which implies that

$$(\tilde{y}(x,0), \tilde{y}(x,T)) \in S. \tag{3.16}$$

By (3.14) and (3.16), we deduce that

$$L(\tilde{y}, \tilde{u}) \ge L(y_2^*, u_2^*). \tag{3.17}$$

Then by (3.10), (3.11), (3.12), (3.13), and (3.17), using the same argument as in the proof of Lemma 2.2, we obtain that

$$\varliminf_{\varepsilon\to 0} L_\varepsilon(y_\varepsilon, u_\varepsilon) \ge L(y_2^*, u_2^*). \tag{3.18}$$

Now by (3.1), (3.9), and (3.18), there exists a generalized subsequence of ε, still denoted by itself, such that

$$y_\varepsilon \to y_2^* \text{ strongly in } L^{2\tilde{r}}(Q) \text{ as } \varepsilon \to 0, \tag{3.19}$$

$$(y_\varepsilon(x,0), y_\varepsilon(x,T)) \to (y_2^*(x,0), y_2^*(x,T)) \text{ strongly in } L^2(\Omega) \text{ as } \varepsilon \to 0, \tag{3.20}$$

$$u_\varepsilon \to u_2^* \text{ strongly in } L^2(Q) \text{ as } \varepsilon \to 0. \tag{3.21}$$

From (3.19), (3.20), and (3.21), using the same argument as in the proof of Lemma 2.2, we infer that $y_\varepsilon \to y_2^*$ strongly in Y as $\varepsilon \to 0$. This completes the proof. □

Now we are ready to prove Theorem 1.2.

Proof of Theorem 1.2. Let $(z,v) \in Y \times L^2(Q)$ be arbitrary but fixed. For each $\rho > 0$, set $y_\varepsilon^\rho = y_\varepsilon + \rho z$, $u_\varepsilon^\rho = u_\varepsilon + \rho v$. It is clear that $(y_\varepsilon^\rho, u_\varepsilon^\rho) \in Y \times L^2(Q)$ and $y_\varepsilon^\rho \to y_\varepsilon$ strongly in Y, $u_\varepsilon^\rho \to u_\varepsilon$ strongly in $L^2(Q)$ as $\rho \to 0$. Moreover, we have that

$$\frac{L_\varepsilon(y_\varepsilon^\rho, u_\varepsilon^\rho) - L_\varepsilon(y_\varepsilon, u_\varepsilon)}{\rho} \ge 0 \text{ for all } \rho > 0. \tag{3.22}$$

By (H_5) and by the same argument as in [16], we obtain that

$$\begin{aligned} &\lim_{\rho\to 0} \tfrac{1}{2\varepsilon\rho}\{[\varepsilon + d_S(y_\varepsilon^\rho(x,0), y_\varepsilon^\rho(x,T))]^2 - [\varepsilon + d_S(y_\varepsilon(x,0), y_\varepsilon(x,T))]^2\} \\ &= \frac{\varepsilon + d_S(y_\varepsilon(x,0), y_\varepsilon(x,T))}{\varepsilon} \left[\int_\Omega a_\varepsilon z(x,0)dx + \int_\Omega b_\varepsilon z(x,T)dx\right], \end{aligned} \tag{3.23}$$

where $(a_\varepsilon, b_\varepsilon) \in d_S(y_\varepsilon(x,0), y_\varepsilon(x,T))$ satisfying

$$\|a_\varepsilon\|^2_{L^2(\Omega)} + \|b_\varepsilon\|^2_{L^2(\Omega)} = \begin{cases} 1 & \text{if } (y_\varepsilon(x,0), y_\varepsilon(x,T)) \notin S, \\ 0 & \text{if } (y_\varepsilon(x,0), y_\varepsilon(x,T)) \in S. \end{cases} \tag{3.24}$$

By (3.22) and (3.23), using the same argument as in the proof of Theorem 1.1, we yield that for all $(z,v) \in Y \times L^2(Q)$ and $\varepsilon > 0$,

$$\begin{aligned} 0 \le \lambda_\varepsilon \Big\{ & \int_Q \nabla g^\varepsilon(t, y_\varepsilon) z dxdt + \int_Q \nabla h_\varepsilon(u_\varepsilon) v dxdt + \int_Q (u_\varepsilon - u_2^*) v dxdt \\ & + \int_Q (y_\varepsilon - y_2^*)^{2\tilde{r}-1} z dxdt + \int_\Omega [y_\varepsilon(x,0) - y_2^*(x,0)] z(x,0) dx \\ & + \int_\Omega [y_\varepsilon(x,T) - y_2^*(x,T)] z(x,T) dx \Big\} + \int_\Omega a_\varepsilon z(x,0) dx + \int_\Omega b_\varepsilon z(x,T) dx \\ & + \int_Q p_\varepsilon \left(\frac{\partial z}{\partial t} + Az + f_y'(x,t,y_\varepsilon) z - v \right) dxdt, \end{aligned} \tag{3.25}$$

where

$$\lambda_\varepsilon = \frac{\varepsilon}{\varepsilon + d_S(y_\varepsilon(x,0), y_\varepsilon(x,T))}, \qquad \mu_\varepsilon = \frac{1}{\varepsilon + d_S(y_\varepsilon(x,0), y_\varepsilon(x,T))},$$

and

$$p_\varepsilon = \mu_\varepsilon \left(\frac{\partial y_\varepsilon}{\partial t} + Ay_\varepsilon + f(x,t,y_\varepsilon) - u_\varepsilon \right).$$

It is clear that $p_\varepsilon \in L^2(Q)$ and

$$1 \le \lambda_\varepsilon^2 + \|a_\varepsilon\|^2_{L^2(\Omega)} + \|b_\varepsilon\|^2_{L^2(\Omega)} \le 2. \tag{3.26}$$

By taking $z = 0$ in (3.25), we yield that

$$\lambda_\varepsilon \left\{ \int_Q \nabla h_\varepsilon(u_\varepsilon) v dxdt + \int_Q (u_\varepsilon - u_2^*) v dxdt \right\} - \int_Q p_\varepsilon v dxdt \le 0 \text{ for all } v \in L^2(Q),$$

which implies that

$$p_\varepsilon = \lambda_\varepsilon \nabla h_\varepsilon(u_\varepsilon) + \lambda_\varepsilon (u_\varepsilon - u_2^*) \text{ a.e. in } Q. \tag{3.27}$$

By (3.27) and by the same argument as in the proof of Theorem 1.1, we infer that $\{p_\varepsilon\}$ is bounded in $L^2(Q)$.

By taking $v = 0$ in (3.25), we obtain that

$$\begin{aligned} 0 \le & \int_Q \lambda_\varepsilon \nabla g^\varepsilon(t, y_\varepsilon) z dxdt + \int_\Omega a_\varepsilon z(x,0) dx + \int_\Omega b_\varepsilon z(x,T) dx \\ & + \int_Q p_\varepsilon \left[\frac{\partial z}{\partial t} + Az + f_y'(x,t,y_\varepsilon) z \right] dxdt + \lambda_\varepsilon \Big\{ \int_\Omega [y_\varepsilon(x,0) - y_2^*(x,0)] z(x,0) dx \\ & + \int_\Omega [y_\varepsilon(x,T) - y_2^*(x,T)] z(x,T) dx + \int_Q (y_\varepsilon - y_2^*)^{2\tilde{r}-1} z dxdt \Big\} \end{aligned} \tag{3.28}$$

for all $z \in Y$.

By (3.28) and by the same argument as in [14], we obtain the following:

(3.29)
$$\begin{cases} -\frac{\partial p_\varepsilon}{\partial t} + Ap_\varepsilon + f_y'(x,t,y_\varepsilon)p_\varepsilon + \lambda_\varepsilon \nabla g^\varepsilon(t,y_\varepsilon) + \lambda_\varepsilon (y_\varepsilon - y_2^*)^{2\tilde{r}-1} = 0, & \text{in } Q, \\ p_\varepsilon(x,t) = 0, & \text{on } \sum, \\ p_\varepsilon(x,T) = -b_\varepsilon - \lambda_\varepsilon[y_\varepsilon(x,T) - y_2^*(x,T)], & \text{in } \Omega, \\ p_\varepsilon(x,0) = a_\varepsilon + \lambda_\varepsilon[y_\varepsilon(x,0) - y_2^*(x,0)], & \text{in } \Omega. \end{cases}$$

Next we are going to pass to the limit for $\varepsilon \to 0$ in (3.27) and (3.28). To this end, we observe first that, by (3.26), there exists a generalized subsequence of ε, still denoted by itself, such that

$$(a_\varepsilon, b_\varepsilon) \to (a_0, b_0) \text{ weakly in } L^2(\Omega) \times L^2(\Omega) \text{ and } \lambda_\varepsilon \to \lambda_0 \text{ as } \varepsilon \to 0. \tag{3.30}$$

Thus, by (3.30), $(3.29)_3$, and $(3.29)_4$ and by Lemma 3.2, we find that

$$p_\varepsilon(x,T) \to -b_0,\ p_\varepsilon(x,0) \to a_0 \text{ weakly in } L^2(\Omega) \text{ as } \varepsilon \to 0. \tag{3.31}$$

On the other hand, by the same argument as in the proof of Theorem 1.1, we infer that

$$\|f_y'(x,t,y_\varepsilon)p_\varepsilon\|_{L^{\frac{2n}{n+2}}(Q)} \le C, \tag{3.32}$$

$$\lambda_\varepsilon (y_\varepsilon - y_2^*)^{2\tilde{r}-1} \to 0 \text{ strongly in } L^{\frac{2n}{n+2}}(Q) \text{ as } \varepsilon \to 0, \tag{3.33}$$

and

$$\lambda_\varepsilon \nabla g^\varepsilon(t,y_\varepsilon) \to \lambda_0 \alpha \text{ weakly in } L^2(0,T;L^2(\Omega)) \text{ as } \varepsilon \to 0, \tag{3.34}$$

where $\alpha \in \partial g(t, y_2^*)$ a.e. in Q.

By $(3.29)_1$, (3.32), (3.33), (3.34) and by Lemma 3.2, we infer that

$$\left\{ -\frac{\partial p_\varepsilon}{\partial t} + Ap_\varepsilon \right\} \text{ is bounded in } L^{\frac{2n}{n+2}}(Q). \tag{3.35}$$

By $(3.29)_2$, (3.31), and (3.35), using argument similar to those in [15], we obtain that $\{p_\varepsilon\}$ is bounded in $L^{\frac{2n}{n+2}}(0,T;W_0^{1,\frac{2n}{n+2}}(\Omega))$.

Then by the same argument as in [2], we find that there exists a generalized subsequence of ε, still denoted by itself, such that

$$\begin{aligned} p_\varepsilon \to p \quad & \text{weakly in } L^{\frac{2n}{n+2}}(0,T;W_0^{1,\frac{2n}{n+2}}(\Omega)) \cap L^2(Q), \\ & \text{strongly in } L^{\frac{2n}{n+2}}(Q) \text{ as } \varepsilon \to 0, \end{aligned} \tag{3.36}$$

$$p_\varepsilon(x,t) \to p(x,t) \text{ a.e. in } Q \text{ as } \varepsilon \to 0. \tag{3.37}$$

Here we have used the fact that $\{p_\varepsilon\}$ is bounded in $L^2(Q)$. Since f_y' is continuous, by Lemma 3.2 and (3.37), we obtain that

$$f_y'(x,t,y_\varepsilon(x,t))p_\varepsilon(x,t) \to f_y'(x,t,y_2^*(x,t))p(x,t) \text{ a.e. in } Q \text{ as } \varepsilon \to 0. \tag{3.38}$$

This together with (3.32) implies that

$$p_\varepsilon f_y'(x,t,y_\varepsilon) \to p f_y'(x,t,y_2^*) \text{ weakly in } L^{\frac{2n}{n+2}}(Q) \text{ as } \varepsilon \to 0,$$

and so we have that

$$\int_Q p_\varepsilon f_y'(x,t,y_\varepsilon)z\,dxdt \to \int_Q p f_y'(x,t,y_2^*)z\,dxdt \ \text{ as } \varepsilon \to 0, \tag{3.39}$$

because $z \in Y \subset L^{\frac{2n}{n-2}}(Q)$. Thus by (3.31), (3.33), (3.34), (3.36), and (3.39), we may take the limit for $\varepsilon \to 0$ in (3.28) to obtain that

$$\begin{aligned} 0 = &\int_Q \lambda_0 \alpha z\,dxdt + \int_\Omega a_0 z(x,0)dx + \int_\Omega b_0 z(x,T)dx \\ &+ \int_Q p\left(\frac{\partial z}{\partial t} + Az + f_y'(x,t,y_2^*)z\right)dxdt \ \text{ for all } z \in Y. \end{aligned} \tag{3.40}$$

By (3.40) and by the same argument as in [14], we infer that $p \in L^{\frac{2n}{n+2}}(0,T; W_0^{1,\frac{2n}{n+2}}(\Omega)) \cap L^2(Q)$ and satisfies (1.9) and (1.10). By (3.30), (3.36), and Lemma 3.2, we may pass to the limit for $\varepsilon \to 0$ in (3.27) to obtain (1.12).

On the other hand, since $(a_\varepsilon, b_\varepsilon) \in \partial d_S(y_\varepsilon(x,0), y_\varepsilon(x,T))$, we have that

$$\langle a_\varepsilon, x_0 - y_\varepsilon(x,0)\rangle + \langle b_\varepsilon, x_1 - y_\varepsilon(x,T)\rangle \le 0 \ \text{ for all } (x_0,x_1) \in S. \tag{3.41}$$

By (3.30) and by Lemma 3.2 again, we may take the limit for $\varepsilon \to 0$ in (3.41) to obtain (1.11).

It remains to show that $\lambda_0 \neq 0$. As a contradiction, we assume that $\lambda_0 = 0$. Then by (1.12), we get that $p = 0$. Because $\lambda_\varepsilon \to \lambda_0 = 0$, it follows from (3.26) that there exist $\delta > 0$ and $\varepsilon_1 > 0$ such that

$$2 \ge \|a_\varepsilon\|^2_{L^2(\Omega)} + \|b_\varepsilon\|^2_{L^2(\Omega)} \ge \delta > 0 \qquad \text{for all } \varepsilon < \varepsilon_1. \tag{3.42}$$

By (3.25) and (3.41), we deduce that

$$\begin{aligned} &\int_Q p_\varepsilon\left(\frac{\partial z}{\partial t} + Az + f_y'(x,t,y_\varepsilon)z - v\right)dxdt \\ &+ \int_\Omega a_\varepsilon[z(x,0) - x_0 + y_2^*(x,0)]dx + \int_\Omega b_\varepsilon[z(x,T) - x_1 + y_2^*(x,T)]dx \ge -\zeta_\varepsilon(z,v) \end{aligned} \tag{3.43}$$

for all $(z,v) \in Y \times L^2(Q)$, where

$$\begin{aligned} \zeta_\varepsilon(z,v) = \lambda_\varepsilon \Big\{ &\int_Q \nabla g^\varepsilon(t,y_\varepsilon)z\,dxdt + \int_Q \nabla h_\varepsilon(u_\varepsilon)v\,dxdt \\ &+ \int_Q (u_\varepsilon - u_2^*)v\,dxdt + \int_Q (y_\varepsilon - y_2^*)^{2\tilde{r}-1}z\,dxdt \\ &+ \int_\Omega [y_\varepsilon(x,0) - y_2^*(x,0)]z(x,0)dx + \int_\Omega [y_\varepsilon(x,T) - y_2^*(x,T)]z(x,T)dx \Big\} \\ &+ \int_\Omega a_\varepsilon[y_\varepsilon(x,0) - y_2^*(x,0)]dx + \int_\Omega b_\varepsilon[y_\varepsilon(x,T) - y_2^*(x,T)]dx. \end{aligned}$$

Observe that $\zeta_\varepsilon(z,v) \to 0$ as $\varepsilon \to 0$ uniformly in $(z,v) \in \{(z,v) \in Y \times L^2(Q) : \|z\|_Y \le r_2, \|v\|_{L^2(Q)} \le r_3\}$. By Lemma 3.2, there exists a positive constant, denoted by ε_1 again, such that $\|y_\varepsilon - y_2^*\|_Y \le r_1$ for all $\varepsilon < \varepsilon_1$. Then by (H_6), for any $(z_0, z_T) \in B_{r_1,r_2,r_3}$ and $\varepsilon < \varepsilon_1$, there exists $(z_\varepsilon, v_\varepsilon) \in Y \times L^2(Q)$ with $\|z_\varepsilon\|_Y \le r_2$, $\|v_\varepsilon\|_{L^2(Q)} \le r_3$ such that $z_\varepsilon(x,0) = z_0(0)$, $z_\varepsilon(x,0) = z_1(x)$, and

$$\frac{\partial z_\varepsilon}{\partial t} + Az_\varepsilon + f_y'(x,t,y_\varepsilon)z_\varepsilon = v_\varepsilon \ \text{ in } Q.$$

By taking $z = z_\varepsilon$ and $v = v_\varepsilon$ for $\varepsilon < \varepsilon_1$ in (3.43), we obtain that

$$\langle a_\varepsilon, z_0 - x_0 + y_2^*(x,0)\rangle + \langle b_\varepsilon, z_1 - x_1 + y_2^*(x,T)\rangle \geq -\zeta_\varepsilon(z_\varepsilon, v_\varepsilon) \tag{3.44}$$

and

$$\zeta_\varepsilon(z_\varepsilon, v_\varepsilon) \to 0 \ \text{ as } \varepsilon \to 0, \ \text{ uniformly in } (z_0, z_T) \in B_{r_1,r_2,r_3}. \tag{3.45}$$

Thanks to Lemma 3.6 of Chapter 4 of [13], we conclude by (3.42), (3.44), and (3.45) that $(a_0, b_0) \neq 0$, which yields that $p \neq 0$. This contradiction shows that $\lambda_0 \neq 0$ and completes the proof. □

4. Existence of optimal pairs for (P_1) and (P_2). In this section we shall prove Theorem 1.3 and Theorem 1.4.

Proof of Theorem 1.3. Since $D_{ad} \neq \emptyset$, we may set $d = \mathrm{Inf}_{(y,u)\in D_{ad}} L(y,u)$. It is clear that $d > -\infty$. We assume that $(y_m, u_m) \in D_{ad}$ satisfies

$$d \leq L(y_m, u_m) < d + \frac{1}{m}. \tag{4.1}$$

This, together with (H_1) and (H_7), implies that $\{u_m\}$ is bounded in $L^2(Q)$ and that $\{y_m\}$ is bounded in $L^{2\tilde{r}}(Q)$. By (H_2), one can easily check that $\{f(x,t,y_m)\}$ is bounded in $L^2(Q)$. Hence

$$\left\{\frac{\partial y_m}{\partial t} + Ay_m\right\} \ \text{ is bounded in } \ L^2(Q). \tag{4.2}$$

Since $y_m(x,t) = 0$ on $\sum$ and $y_m(x,0) = y_0(x)$ in Ω, it follows from (4.2) that $\{y_m\}$ is bounded in Y (cf. [15]). Thus we may extract a subsequence of $\{y_m\}$, denoted by itself again, such that

$$\begin{array}{ll} y_m \to y^* & \text{weakly in } Y, \ \text{strongly in } L^2(Q) \ \text{ as } m \to \infty, \\ u_m \to u^* & \text{weakly in } L^2(Q) \ \text{ as } m \to \infty. \end{array} \tag{4.3}$$

By the same argument as in the proof of Lemma 2.1, we have that

$$f(x,t,y_m) \to f(x,t,y^*) \ \text{ weakly in } L^2(Q) \ \text{ as } m \to \infty. \tag{4.4}$$

It follows from (4.3) and (4.4) that (y^*, u^*) satisfies (1.1). By (4.3) and by (H_3), we obtain that

$$F(y_m) \to F(y^*) \ \text{ strongly in } X \ \text{ as } m \to \infty,$$

which implies that $F(y^*) \in W$, because W is closed. Thus we have

$$(y^*, u^*) \in D_{ad}. \tag{4.5}$$

On the other hand, by (4.3) and by the same argument as in [2], we get that

$$\varliminf_{m\to\infty} \int_0^T [g(t,y_m) + h(u_m)]dt \geq \int_0^T [g(t,y^*) + h(u^*)]dt,$$

which, combined with (4.1), indicates that

$$L(y^*, u^*) = d. \tag{4.6}$$

By (4.5) and (4.6), we obtain that (y^*, u^*) is optimal for problem (P_1). This completes the proof.

Proof of Theorem 1.4. We may set $d = \mathrm{Inf}_{(y,u)\in\tilde{D}_{ad}} L(y,u)$ because $\tilde{D}_{ad} \neq \emptyset$. It is clear that $d > -\infty$. Let $(y_m, u_m) \in \tilde{D}_{ad}$ be such that

$$d \leq L(y_m, u_m) < d + \frac{1}{m}. \tag{4.7}$$

By (H_1), (H_7), and (H_{10}), we have that

$$\begin{array}{l} \{u_m\} \text{ is bounded in } L^2(Q), \\ \{y_m\} \text{ is bounded in } L^{2\tilde{r}}(Q), \\ \{y_m(x,0)\} \text{ is bounded in } L^2(\Omega). \end{array} \tag{4.8}$$

By (4.8) and by the same argument as in the proof of Theorem 1.3, we infer that $\{\frac{\partial y_m}{\partial t} + Ay_m\}$ is bounded in $L^2(Q)$, which together with (4.8) implies that $\{y_m\}$ is bounded in Y (cf. [15]).

Thus there exist a pair $(y^*, u^*) \in Y \times L^2(Q)$ and subsequences of $\{y_m\}$ and $\{u_m\}$, still denoted by themselves, such that

$$y_m \to y^* \text{ weakly in } Y, \text{ strongly in } L^2(Q) \text{ as } m \to \infty, \tag{4.9}$$

$$u_m \to u^* \text{ weakly in } L^2(Q) \text{ as } m \to \infty, \tag{4.10}$$

$$(y_m(x,0), y_m(x,T)) \to (y^*(x,0), y^*(x,T)) \text{ weakly in } L^2(\Omega) \times L^2(\Omega) \text{ as } m \to \infty. \tag{4.11}$$

By (4.9), (4.10), and (4.11), one can easily check that (y^*, u^*) satisfies (1.3).

On the other hand, since S is convex and closed, d_S is lower semicontinuous in the weak topology of $L^2(\Omega) \times L^2(\Omega)$. Thus it follows from (4.11) that

$$0 = \varliminf_{m\to\infty} d_S(y_m(x,0), y_m(x,T)) \geq d_S(y^*(x,0), y^*(x,T)),$$

which yields that $(y^*(x,0), y^*(x,T)) \in S$. Thus we get that

$$(y^*, u^*) \in \tilde{D}_{ad}. \tag{4.12}$$

Now by (4.12) and by the same argument as in the proof of Theorem 1.3, we infer that (y^*, u^*) is optimal for problem (P_2). This completes the proof. □

DYNAMIC MEAN-VARIANCE PORTFOLIO SELECTION WITH NO-SHORTING CONSTRAINTS*

XUN LI†, XUN YU ZHOU†, AND ANDREW E. B. LIM‡

Abstract. This paper is concerned with mean-variance portfolio selection problems in continuous-time under the constraint that short-selling of stocks is prohibited. The problem is formulated as a stochastic optimal linear-quadratic (LQ) control problem. However, this LQ problem is *not* a conventional one in that the control (portfolio) is constrained to take nonnegative values due to the no-shorting restriction, and thereby the usual Riccati equation approach (involving a "completion of squares") does not apply directly. In addition, the corresponding Hamilton–Jacobi–Bellman (HJB) equation inherently has no smooth solution. To tackle these difficulties, a continuous function is constructed via two Riccati equations, and then it is shown that this function is a viscosity solution to the HJB equation. Solving these Riccati equations enables one to explicitly obtain the efficient frontier and efficient investment strategies for the original mean-variance problem. An example illustrating these results is also presented.

Key words. continuous-time, mean-variance portfolio selection, short-selling prohibition, efficient frontier, stochastic LQ control, HJB equation, viscosity solution

1. Introduction.

Research on portfolio selection dates back to the 1950s with Markowitz's pioneering work [24] on mean-variance efficient portfolios for a single-period investment. The most important contribution of Markowitz's work is the introduction of quantitative and scientific approaches to risk management and analysis. When short-selling of stocks is not allowed, efficient portfolios are obtained computationally via solving a quadratic programming problem. Later, Merton [26] derived an analytical solution to the single-period mean-variance problem under the assumption that the covariance matrix is positive definite and short-selling is allowed.

While it is natural to extend Markowitz's work to multiperiod and continuous-time portfolio selections, these extensions have, by and large, taken a somewhat different tack to Markowitz's original formulation; see, e.g., [1, 10, 14, 27, 28] for the multiperiod case and [4, 7, 8, 13, 17, 25] for the continuous-time case. Specifically, rather than treating the Var $X(T)$ and $EX(T)$ of a portfolio as separate quantities and finding the relationship between them, a single quantity, the expected utility of terminal wealth $EU(X(T))$, is considered instead. The utility function U commonly has a power, log, exponential, or quadratic form. One disadvantage of this approach is that the relationship between risk and return is contained only implicitly in the utility function. Hence, it is less clear in general what relationship exists between the risk and the return of the derived policy. It should be noted that mean-variance analysis and expected utility formulation are two *different* tools for dealing with portfolio selections. As a consequence, optimal portfolios determined by utility functions

are usually not mean-variance efficient. One exception is the case of the quadratic utility function; see Duffie and Richardson [7], where this relationship is shown in the setting of the related mean-variance hedging problem. For comparisons of the performance of the mean-variance versus utility approaches, the reader is referred to [11, 12, 14, 31, 36].

One difficulty in extending Markowitz's idea to the multiperiod or continuous-time settings is that the variance Var $X(T)$ involves a term $[EX(T)]^2$ that is hard to analyze due to its nonseparability in the sense of dynamic programming; see [37, p. 20] for a more detailed discussion on this point. Only recently have Li and Ng [20] faithfully extended Markowitz's mean-variance model to the multiperiod setting by using the idea of embedding the problem in a tractable auxiliary problem.

In the paper by Zhou and Li [37], the continuous-time mean-variance problem in which short-selling of stocks is allowed is studied by incorporating the embedding technique used in Li and Ng [20]. However, the main contribution of [37] is not the explicit mean-variance efficient frontier it obtained per se; rather it is the unifying framework, namely, that of the stochastic linear-quadratic (LQ) optimal control, that it introduced in order to solve certain finance problems including mean-variance portfolio selection. The so-called indefinite stochastic LQ control theory has been developed extensively in recent years (see, e.g., [2, 3, 21, 34]), and this in turn provides a powerful tool for solving some finance problems that are linear-quadratic in nature [19, 22, 37].

The objective of this paper is to investigate continuous-time mean-variance portfolio selection in the case where short-selling of stocks is not allowed. (However, shorting the riskless asset—the bond—is still allowed.) This belongs to the realm of so-called constrained portfolio selection, which essentially renders the market incomplete. In the past decade, the constrained portfolio selection problem has been extensively studied (see, e.g., [6, 16, 30, 32, 33]). However, again the expected utility model has been mainly adopted. In particular, Xu and Shreve in their two-part paper [32, 33] investigated a utility maximization problem with a no-shorting constraint using a duality analysis. In [6, 18], the duality results of [32, 33] are extended to a general class of portfolio selection problems in incomplete markets, including those with constraints. The main results in [6, 18] establish the existence of a solution to the dual problem and show how it can be used to construct a solution of the original portfolio optimization problem. One important difference between the approach we adopt and the duality methods in [6, 18] is that existence and optimality of the candidate portfolio in this paper are established using the theory of *viscosity solutions* and the viscosity verification theorem in [38]. This enables us to sidestep the considerable technicalities encountered in [6, 18] when studying existence through convex duality.

In this paper we continue to use stochastic LQ control as the framework for studying the constrained mean-variance portfolio problem. Compared with [22, 37], the distinctive feature of this paper is that shorting is prohibited. As a consequence, a major difficulty in the present case is that the control (portfolio) is constrained, while the LQ theory typically requires the control to be unconstrained (the reason is that the optimal control constructed through the Riccati equation may not satisfy the control constraint). This means that the elegant Riccati approach does not apply directly. We sidestep this problem by studying the Hamilton–Jacobi–Bellman (HJB) equation. (Recall that the Riccati equation *is* essentially the HJB equation after separating the time and spatial variables.) However, the HJB equation has no classical (i.e., smooth) solutions in our case due to the presence of the control constraint. To cope

with this difficulty, we first conjecture a continuous solution to the HJB equation via *two* Riccati equations, and then show that it is indeed the *viscosity solution* to the equation. Further, using the viscosity verification theorem established in [38], we explicitly obtain the optimal strategy along with the efficient frontier.

The outline of this paper is as follows. In section 2, we formulate the mean-variance portfolio problem under a short-selling prohibition. In section 3, we study a stochastic LQ control problem of which portfolio selection is a special case, and we obtain the viscosity solution to the corresponding HJB equation along with the optimal feedback control. Section 4 is devoted to the derivation of the efficient investment strategies and efficient frontier for the portfolio selection problem. In section 5, we present a numerical example to illustrate the results obtained. Finally, section 6 concludes the paper.

2. Problem formulation and preliminaries.

2.1. Notation.

We make use of the following notation:

M'	:	the transpose of any matrix or vector M;
$\|M\|$	:	$\sqrt{\sum_{i,j} m_{ij}^2}$ for any matrix or vector $M = (m_{ij})$;
$\mathbb{R}^n$	:	n-dimensional real Euclidean space;
$\mathbb{R}^n_+$	:	the subset of $\mathbb{R}^n$ consisting of elements with nonnegative components.

The underlying uncertainty is generated by a fixed filtered complete probability space $(\Omega, \mathcal{F}, \mathbf{P}, \{\mathcal{F}_t\}_{t\geq 0})$ on which is defined a standard $\{\mathcal{F}_t\}_{t\geq 0}$-adapted m-dimensional Brownian motion $W(t) \equiv (W^1(t), \ldots, W^m(t))'$. Given a probability space $(\Omega, \mathcal{F}, \mathbf{P})$ with a filtration $\{\mathcal{F}_t | a \leq t \leq b\}(-\infty \leq a < b \leq +\infty)$, and a Hilbert space $\mathcal{H}$ with the norm $\|\cdot\|_{\mathcal{H}}$, define the Banach space

$$L^2_{\mathcal{F}}(0,T;\mathcal{H}) = \left\{ \varphi(\cdot) \,\middle|\, \begin{array}{l} \varphi(\cdot) \text{ is an } \mathcal{F}_t\text{-adapted, } \mathcal{H}\text{-valued measurable process on } [a,b] \\ \text{and } E\int_a^b \|\varphi(t,\omega)\|^2_{\mathcal{H}} dt < +\infty \end{array} \right\}$$

with the norm

$$\|\varphi(\cdot)\|_{\mathcal{F},2} = \left(E\int_a^b \|\varphi(t,\omega)\|^2_{\mathcal{H}} dt \right)^{\frac{1}{2}} < +\infty.$$

2.2. Problem formulation.

We consider a financial market where $m+1$ assets are traded continuously on a finite horizon $[0,T]$. One asset is a bond, whose price $\mathbb{P}_0(t)$, $t \geq 0$, evolves according to the differential equation

$$\left\{ \begin{array}{rcl} d\mathbb{P}_0(t) &=& r(t)\mathbb{P}_0(t)dt, \quad t \in [0,T], \\ \mathbb{P}_0(0) &=& p_0 > 0, \end{array} \right. \tag{2.1}$$

where $r(t)$ (> 0) is the interest rate of the bond. The remaining m assets are stocks, and their prices are modeled by the stochastic differential equations

$$\left\{ \begin{array}{rcl} d\mathbb{P}_i(t) &=& \mathbb{P}_i(t)\{b_i(t)dt + \sum_{j=1}^m \sigma_{ij}(t)W^j(t)\}, \quad t \in [0,T], \\ \mathbb{P}_i(0) &=& p_i > 0, \end{array} \right. \tag{2.2}$$

where $b_i(t)(> r(t))$ is the appreciation rate and $\sigma_{ij}(t)$ is the volatility coefficient. Denote $b(t) := (b_1(t), \ldots, b_m(t))'$ and $\sigma(t) := (\sigma_{ij}(t))$. We assume throughout that $r(t)$, $b(t)$, and $\sigma(t)$ are deterministic, Borel-measurable, and bounded on $[0,T]$. In addition, we assume that the nondegeneracy condition

$$\sigma(t)\sigma(t)' \geq \delta I \quad \forall t \in [0,T], \tag{2.3}$$

where $\delta > 0$ is a given constant, is satisfied. Also, we define the relative risk coefficient

$$\theta(t) \triangleq \sigma^{-1}(t)(b(t) - r(t)\mathbf{1}), \tag{2.4}$$

where $\mathbf{1}$ is the m-dimensional column vector with each component equal to 1.

Suppose an agent has an initial wealth $X_0 > 0$, and the total wealth of his position at time $t \geq 0$ is $X(t)$. Then it is well-known that $X(t),\ t \geq 0$, follows (see, e.g., [37])

$$\begin{cases} dX(t) = \{r(t)X(t) + \sum_{i=1}^{m}(b_i(t) - r(t))u_i(t)\}dt + \sum_{j=1}^{m}\sum_{i=1}^{m}\sigma_{ij}(t)u_i(t)dW^j(t), \\ X(0) = X_0, \end{cases} \tag{2.5}$$

where $u_i(t),\ i = 0, 1, \ldots, m$, denotes the total market value of the agent's wealth in the ith bond/stock. We call $u(t) := (u_1(t), \ldots, u_m(t))$ the portfolio (which changes over time t). An important restriction considered in this paper is the prohibition of short-selling the stocks, i.e., it must be satisfied that $u_i(t) \geq 0,\ i = 1, \ldots, m$. On the other hand, borrowing from the money market (at the interest rate $r(t)$) is still allowed; that is, $u_0(t)$ is not explicitly constrained.

Mean-variance portfolio selection refers to the problem of finding an allowable investment policy (i.e., a dynamic portfolio satisfying all the constraints) such that the expected terminal wealth satisfies $EX(T) = d$ while the risk measured by the variance of the terminal wealth

$$\text{Var } X(T) = E[X(T) - EX(T)]^2 = E[X(T) - d]^2$$

is minimized.

We impose throughout this paper the following assumption.

Assumption 2.1. The value of the expected terminal wealth d satisfies $d \geq X_0 e^{\int_0^T r(s)ds}$.

Remark 2.1. Assumption 2.1 states that the investor's expected terminal wealth d cannot be less than $X_0 e^{\int_0^T r(s)ds}$, which coincides with the amount that he/she would earn if all of the initial wealth were invested in the bond for the entire investment period. Clearly, this is a reasonable assumption, for the solution of the problem under $d < X_0 e^{\int_0^T r(s)ds}$ is foolish for rational investors.

DEFINITION 2.1. *A portfolio $u(\cdot)$ is said to be admissible if $u(\cdot) \in L^2_{\mathcal{F}}(0, T; \mathbb{R}^m_+)$.*

DEFINITION 2.2. *The mean-variance portfolio selection problem is formulated as the following optimization problem parameterized by $d \geq X_0 e^{\int_0^T r(s)ds}$:*

$$\begin{array}{ll} \min & \text{Var } X(T) \equiv E[X(T) - d]^2, \\ \text{subject to} & \begin{cases} EX(T) = d, \\ u(\cdot) \in L^2_{\mathcal{F}}(0, T; \mathbb{R}^m_+), \\ (X(\cdot), u(\cdot)) \text{ satisfy (2.5)}. \end{cases} \end{array} \tag{2.6}$$

Moreover, the optimal control of (2.6) *is called an efficient strategy, and* $(\text{Var } X(T), d)$, *where* Var $X(T)$ *is the optimal value of* (2.6) *corresponding to d, is called an efficient point. The set of all efficient points, when the parameter d runs over $[X_0 e^{\int_0^T r(s)ds}, +\infty)$, is called the efficient frontier.*

Since (2.6) is a convex optimization problem, the equality constraint $EX(T) = d$ can be dealt with by introducing a Lagrange multiplier $\mu \in \mathbb{R}$. In this way the portfolio

problem (2.6) can be solved via the following optimal stochastic control problem (for every fixed μ):

$$\begin{array}{ll} \min & E\Big\{[X(T)-d]^2+2\mu[EX(T)-d]\Big\}, \\ \text{subject to} & \left\{\begin{array}{l} u(\cdot)\in L^2_{\mathcal{F}}(0,T;\mathbb{R}^m_+), \\ (X(\cdot),u(\cdot)) \text{ satisfy (2.5)}, \end{array}\right. \end{array} \tag{2.7}$$

where the factor 2 in front of the multiplier μ is introduced in the objective function just for convenience. Clearly, this problem is equivalent to

$$(A(\mu)): \quad \begin{array}{ll} \min & E\Big\{\frac{1}{2}[X(T)-(d-\mu)]^2\Big\}, \\ \text{subject to} & \left\{\begin{array}{l} u(\cdot)\in L^2_{\mathcal{F}}(0,T;\mathbb{R}^m_+), \\ (X(\cdot),u(\cdot)) \text{ satisfy (2.5)}, \end{array}\right. \end{array}$$

in the sense that the two problems have exactly the same optimal control.

3. A general constrained stochastic LQ problem. The problem $A(\mu)$ formulated in the previous section is a stochastic optimal LQ control problem. This problem has two features which distinguish it from conventional LQ problems. One is that the running cost of this problem is identically zero; that is, it is an *indefinite* stochastic LQ control problem, the theory of which has been developed extensively in recent years (see, for example, [2, 3, 21, 34, 35]). The other feature, which also gives rise to the main difficulty of the problem, is that the control is constrained. Therefore, the conventional "completion of squares" approach to the unconstrained LQ problem, which involves the Riccati equation, will no longer apply. In this section, we solve a class of constrained, indefinite stochastic LQ problems of which $A(\mu)$ is a special case.

Consider the controlled linear stochastic differential equation

$$\left\{\begin{array}{rcl} dx(t) &=& [A(t)x(t)+B(t)u(t)+f(t)]ds+\sum_{j=1}^m D_j(t)u(t)dW^j(t), \quad t\in[s,T], \\ x(s) &=& y\in\mathbb{R}, \end{array}\right. \tag{3.1}$$

where $A(t)$ and $f(t)\in\mathbb{R}$ are scalars, $B(t)'\in\mathbb{R}^m_+$ and $D_j(t)'\in\mathbb{R}^m$ $(j=1,\dots,m)$ are column vectors. In addition, we assume that the matrix $\sum_{j=1}^m D_j(t)'D_j(t)$ is nonsingular.

The class of admissible controls associated with (3.1) is the set $\mathcal{U}[s,T]=L^2_{\mathcal{F}}(s,T;\mathbb{R}^m_+)$. Given $u(\cdot)\in\mathcal{U}[s,T]$, the pair $(x(\cdot),u(\cdot))$ is referred to as an admissible pair if $x(\cdot)\in L^2_{\mathcal{F}}(s,T;\mathbb{R})$ is a solution of the stochastic differential equation (3.1) associated with $u(\cdot)\in\mathcal{U}[s,T]$. Our objective is to find an optimal $u(\cdot)$ that minimizes the quadratic (terminal) cost function

$$J(s,y;u(\cdot))=E\left\{\tfrac{1}{2}x(T)^2\right\}. \tag{3.2}$$

The value function associated with the LQ problem (3.1)–(3.2) is defined by

$$V(s,y)=\inf_{u(\cdot)\in\mathcal{U}[s,T]} J(s,y;u(\cdot)). \tag{3.3}$$

3.1. HJB equation. Since the Riccati equation approach is not applicable in this case, we study the corresponding HJB equation instead, which is the following partial differential equation:

$$\left\{\begin{array}{l} v_t(t,x)+\inf_{u\geq 0}\left\{v_x(t,x)[A(t)x+B(t)u+f(t)]+\frac{1}{2}v_{xx}(t,x)u'D(t)'D(t)u\right\}=0, \\ v(T,x)=\frac{1}{2}x^2, \end{array}\right. \tag{3.4}$$

where $D(t)' = (D_1(t)', \ldots, D_m(t)')$. Unfortunately, owing essentially to the nonnegativity constraint of the control, the HJB equation does not have a smooth solution, as opposed to the unconstrained case in which the solution to the HJB equation is a quadratic function which can be constructed via the Riccati equation. The idea here is to construct a function, show that it is a *viscosity* solution (see the appendix for the definition) to the HJB equation, and then employ the verification theorem to construct the optimal control.

Before we start, we recall some results from convex analysis.

LEMMA 3.1. *Let s be a continuous, strictly convex quadratic function*

$$s(z) \triangleq \tfrac{1}{2}\|(\mathcal{D}')^{-1}z + (\mathcal{D}')^{-1}\mathcal{B}'\|^2 \tag{3.5}$$

over $z \in [0,\infty)^m$, where $\mathcal{B}' \in \mathbb{R}^m_+$, $\mathcal{D} \in \mathbb{R}^{m\times m}$, and $\mathcal{D}'\mathcal{D} > 0$. Then s has a unique minimizer $\bar{z} \in [0,\infty)^m$, i.e.,

$$\|(\mathcal{D}')^{-1}\bar{z} + (\mathcal{D}')^{-1}\mathcal{B}'\|^2 \le \|(\mathcal{D}')^{-1}z + (\mathcal{D}')^{-1}\mathcal{B}'\|^2 \quad \forall z \in [0,\infty)^m. \tag{3.6}$$

The Kuhn–Tucker conditions for the minimization of s in (3.5) over $[0,\infty)^m$ lead to the Lagrange multiplier vector $\bar{\nu} \in [0,\infty)^m$ such that $\bar{\nu} = \nabla s(\bar{z}) = (\mathcal{D}'\mathcal{D})^{-1}\bar{z} + (\mathcal{D}'\mathcal{D})^{-1}\mathcal{B}'$ and $\bar{\nu}'\bar{z} = 0$.

LEMMA 3.2. *Let h be a continuous, strictly convex quadratic function*

$$h(z) \triangleq \tfrac{1}{2}z'\mathcal{D}'\mathcal{D}z - \alpha\mathcal{B}z \tag{3.7}$$

over $z \in [0,\infty)^m$, where $\mathcal{B}' \in \mathbb{R}^m_+$, $\mathcal{D} \in \mathbb{R}^{m\times m}$, and $\mathcal{D}'\mathcal{D} > 0$.

(i) *For every $\alpha \ge 0$, h has the unique minimizer $\alpha D^{-1}\bar{\xi} \in [0,\infty)^m$, where $\bar{\xi} = (\mathcal{D}')^{-1}\bar{z} + (\mathcal{D}')^{-1}\mathcal{B}'$. Here $\bar{z}$ is the minimizer of $s(z)$ specified in Lemma* 3.1. *Furthermore, $\bar{z}'\mathcal{D}^{-1}\bar{\xi} = 0$ and*

$$h(\alpha\bar{\nu}) = h(\alpha\mathcal{D}^{-1}\bar{\xi}) = -\tfrac{1}{2}\alpha^2\|\bar{\xi}\|^2. \tag{3.8}$$

(ii) *For every $\alpha < 0$, h has the unique minimizer* 0.

Lemma 3.1 and Lemma 3.2(i) are proved in section 5.2 and Lemma 3.2 of [33], while Lemma 3.2(ii) is obvious.

Remark 3.1. It should be noted that the vector $\bar{\xi}$ is independent of the parameter α.

Now let us come back to the LQ problem (3.1)–(3.2). Let

$$\bar{z}(t) := \arg\min_{z(t)\in[0,\infty)^m} \tfrac{1}{2}\|(D(t)')^{-1}z(t) + (D(t)')^{-1}B(t)'\|^2 \tag{3.9}$$

and

$$\bar{\xi}(t) := (D(t)')^{-1}\bar{z}(t) + (D(t)')^{-1}B(t)'. \tag{3.10}$$

Note that $\bar{\xi}(t)$ is a column vector *independent* of x. Let $\overline{P}(t)$, $\overline{g}(t)$, and $\overline{c}(t)$, respectively, denote the solutions of the following differential equations (the first being a special Riccati equation)

$$\begin{cases} \dot{\overline{P}}(t) = [-2A(t) + \|\bar{\xi}(t)\|^2]\overline{P}(t), \\ \overline{P}(T) = 1, \\ \overline{P}(t) > 0 \qquad \forall t \in [0,T], \end{cases} \tag{3.11}$$

$$\begin{cases} \dot{\overline{g}}(t) = [-A(t) + \|\bar{\xi}(t)\|^2]\overline{g}(t) - f(t)\overline{P}(t), \\ \overline{g}(T) = 0, \end{cases} \tag{3.12}$$

$$\begin{cases} \dot{\overline{c}}(t) = -f(t)\overline{g}(t) + \tfrac{1}{2}\|\bar{\xi}(t)\|^2\overline{P}(t)^{-1}\overline{g}(t)^2, \\ \overline{c}(T) = 0, \end{cases} \tag{3.13}$$

and $\widetilde{P}(t)$, $\widetilde{g}(t)$, and $\widetilde{c}(t)$, respectively, denote the solutions of the following differential equations (the first being *another* special Riccati equation)

$$\begin{cases} \dot{\widetilde{P}}(t) = -2A(t)\widetilde{P}(t), \\ \widetilde{P}(T) = 1, \\ \widetilde{P}(t) > 0 \qquad \forall t \in [0,T], \end{cases} \tag{3.14}$$

$$\begin{cases} \dot{\widetilde{g}}(t) = -A(t)\widetilde{g}(t) - f(t)\widetilde{P}(t), \\ \widetilde{g}(T) = 0, \end{cases} \tag{3.15}$$

$$\begin{cases} \dot{\widetilde{c}}(t) = -f(t)\widetilde{g}(t), \\ \widetilde{c}(T) = 0. \end{cases} \tag{3.16}$$

In the next subsection, we shall show that

$$V(t,x) = \begin{cases} \frac{1}{2}\overline{P}(t)x^2 + \overline{g}(t)x + \overline{c}(t) & \text{if } x + e^{-\int_t^T A(s)ds}\displaystyle\int_t^T f(z)e^{\int_z^T A(s)ds}dz \le 0, \\ \frac{1}{2}\widetilde{P}(t)x^2 + \widetilde{g}(t)x + \widetilde{c}(t) & \text{if } x + e^{-\int_t^T A(s)ds}\displaystyle\int_t^T f(z)e^{\int_z^T A(s)ds}dz > 0 \end{cases} \tag{3.17}$$

is a viscosity solution of the HJB equation (3.4), and

$$u^*(t,x) = \begin{cases} -D(t)^{-1}\bar{\xi}(t)\left(x + e^{-\int_t^T A(s)ds}\displaystyle\int_t^T f(z)e^{\int_z^T A(s)ds}dz\right) \\ \qquad\qquad \text{if } x + e^{-\int_t^T A(s)ds}\displaystyle\int_t^T f(z)e^{\int_z^T A(s)ds}dz \le 0, \\ 0 \qquad\qquad \text{if } x + e^{-\int_t^T A(s)ds}\displaystyle\int_t^T f(z)e^{\int_z^T A(s)ds}dz > 0 \end{cases} \tag{3.18}$$

is the associated optimal feedback control.

Remark 3.2. Equations (3.11)–(3.13) appear naturally in stochastic LQ problems with nonhomogeneous terms in the dynamics. They can be derived by conjecturing the value function to be a quadratic function (as in (3.17)), plugging in the HJB equation (3.4), and then comparing the terms of x^2, x, and the constant, respectively. See [35, pp. 317–318] for a detailed derivation.

3.2. Value function and optimal control. This subsection is devoted to verifying the aforementioned results. First we show that V constructed in (3.17) is a viscosity solution to the HJB equation (3.4).

We start with (3.11). Clearly

$$\overline{P}(t) = e^{\int_t^T (2A(s) - \|\bar{\xi}(s)\|^2)ds} \tag{3.19}$$

is the solution of (3.11). Note, in particular, that the constraint $\overline{P}(t) > 0$ is automatically satisfied. Defining $\overline{\eta}(t) := \frac{\overline{g}(t)}{\overline{P}(t)}$, it follows from (3.11) and (3.12) that

$$\dot{\overline{\eta}}(t) = \frac{\overline{P}(t)\dot{\overline{g}}(t) - \dot{\overline{P}}(t)\overline{g}(t)}{\overline{P}(t)^2} = \frac{A(t)\overline{P}(t)\overline{g}(t) - f(t)\overline{P}(t)^2}{\overline{P}(t)^2} = A(t)\overline{\eta}(t) - f(t).$$

Solving this equation with $\overline{\eta}(T) = 0$ yields

$$\overline{\eta}(t) = e^{-\int_t^T A(s)ds}\int_t^T f(z)e^{\int_z^T A(s)ds}dz. \tag{3.20}$$

Hence,

$$\overline{g}(t) = \overline{P}(t)\overline{\eta}(t) = e^{\int_t^T (A(s) - \|\bar{\xi}(s)\|^2) ds} \int_t^T f(z) e^{\int_z^T A(s) ds} dz.$$

Substituting these expressions into (3.13), we obtain

$$\begin{aligned} \dot{\bar{c}}(t) &= -f(t)\overline{g}(t) + \tfrac{1}{2}\|\bar{\xi}(t)\|^2 \overline{P}(t)^{-1}\overline{g}(t)^2 \\ &= \left[-f(t) + \tfrac{1}{2}\|\bar{\xi}(t)\|^2 e^{-\int_t^T A(s) ds} \int_t^T f(z) e^{\int_z^T A(s) ds} dz \right] \\ &\quad \cdot e^{\int_t^T (A(s) - \|\bar{\xi}(s)\|^2) ds} \int_t^T f(z) e^{\int_z^T A(s) ds} dz. \end{aligned}$$

Therefore,

$$\begin{aligned} \bar{c}(t) &= \int_t^T \left[f(v) - \tfrac{1}{2}\|\bar{\xi}(v)\|^2 e^{-\int_v^T A(s) ds} \int_v^T f(z) e^{\int_z^T A(s) ds} dz \right] \\ &\quad \cdot e^{\int_v^T (A(s) - \|\bar{\xi}(s)\|^2) ds} \int_v^T f(z) e^{\int_z^T A(s) ds} dz dv. \end{aligned}$$

Now we define the region Γ_1 in the (t, x)-plane as

$$\Gamma_1 := \left\{ (t, x) \in [0, T] \times \mathbb{R} \;\middle|\; x + e^{-\int_t^T A(s) ds} \int_t^T f(z) e^{\int_z^T A(s) ds} dz < 0 \right\}.$$

In Γ_1, V as given by (3.17) is sufficiently smooth for the terms in (3.4) to be well-defined, with

$$V_t(t, x) = \tfrac{1}{2}\dot{\overline{P}}(t)x^2 + \dot{\overline{g}}(t)x + \dot{\bar{c}}(t), \quad V_x(t, x) = \overline{P}(t)x + \overline{g}(t), \quad V_{xx}(t, x) = \overline{P}(t).$$

Substituting these into the left-hand side (LHS) of (3.4), we obtain

$$\begin{aligned} \text{LHS} &= V_t(t, x) + V_x(t, x)[A(t)x + f(t)] + \inf_{u \geq 0} \left[\tfrac{1}{2} V_{xx}(t, x) u' D(t)' D(t) u + V_x(t, x) B(t) u \right] \\ &= \left[\tfrac{1}{2}\dot{\overline{P}}(t)x^2 + \dot{\overline{g}}(t)x + \dot{\bar{c}}(t) \right] + [\overline{P}(t)x + \overline{g}(t)][A(t)x + f(t)] \\ &\quad + \inf_{u \geq 0} \left\{ \tfrac{1}{2}\overline{P}(t) u' D(t)' D(t) u + [\overline{P}(t)x + \overline{g}(t)] B(t) u \right\} \\ &= \left[\tfrac{1}{2}\dot{\overline{P}}(t) + A(t)\overline{P}(t) \right] x^2 + \left[\dot{\overline{g}}(t) + A(t)\overline{g}(t) + f(t)\overline{P}(t) \right] x + \left[\dot{\bar{c}}(t) + f(t)\overline{g}(t) \right] \\ &\quad + \overline{P}(t) \inf_{u \geq 0} \left\{ \tfrac{1}{2} u' D(t)' D(t) u + [x + \overline{\eta}(t)] B(t) u \right\}. \end{aligned} \tag{3.21}$$

By using Lemma 3.2 with $\alpha = -[x + \overline{\eta}(t)] > 0$, it follows that the minimizer of (3.21) is achieved by

$$\begin{aligned} u^*(t, x) &= -D(t)^{-1}\bar{\xi}(t)[x + \overline{\eta}(t)] \\ &= -D(t)^{-1}\bar{\xi}(t) \left[x + e^{-\int_t^T A(s) ds} \int_t^T f(z) e^{\int_z^T A(s) ds} dz \right]. \end{aligned} \tag{3.22}$$

Substituting $u^*(t,x)$ back into (3.21) and noting (3.11), (3.12), and (3.13), it immediately follows that the LHS $= 0$. This implies that V satisfies the HJB equation (3.4) in Γ_1.

Remark 3.3. Although the minimizer (3.22) of (3.21) involves the parameter $\bar{\xi}(t)$, as defined by (3.9) and (3.10), it is important to recognize that $\bar{\xi}(t)$ does not depend on x. In particular, this means that $\overline{P}(t)$, $\overline{g}(t)$, and $\overline{c}(t)$, which also depend on $\bar{\xi}(t)$, do not depend on x. Hence, the expressions for $V_t(t,x)$, $V_x(t,x)$, and $V_{xx}(t,x)$ do not involve terms of the form $\overline{P}_x(t)$, $\overline{g}_x(t)$, and $\overline{c}_x(t)$, etc. It is precisely for this reason that closed form expressions for the value function can still be obtained.

Remark 3.4. Although the expression of $\bar{\xi}(\cdot)$ is not explicitly analytical as it involves $\bar{z}(\cdot)$, it can easily be obtained numerically via solving the quadratic program in (3.9) off line.

Next we proceed to the region Γ_2 defined by

$$\Gamma_2 := \left\{ (t,x) \in [0,T] \times \mathbb{R} \;\middle|\; x + e^{-\int_t^T A(s)ds} \int_t^T f(z) e^{\int_z^T A(s)ds} dz > 0 \right\}.$$

Similar to the derivations for the previous case, we obtain

$$\begin{cases} \widetilde{P}(t) &= e^{2\int_t^T A(s)ds}, \\ \widetilde{g}(t) &= e^{\int_t^T A(s)ds} \displaystyle\int_t^T f(z) e^{\int_z^T A(s)ds} dz, \\ \widetilde{c}(t) &= \displaystyle\int_t^T f(v) e^{\int_v^T A(s)ds} \int_v^T f(z) e^{\int_z^T A(s)ds} dz dv, \\ \widetilde{\eta}(t) &= \frac{\widetilde{g}(t)}{\widetilde{P}(t)} = e^{-\int_t^T A(s)ds} \displaystyle\int_t^T f(z) e^{\int_z^T A(s)ds} dz. \end{cases}$$

In Γ_2, V is once again sufficiently smooth for the derivatives in (3.4) to be well-defined, and

$$V_t(t,x) = \tfrac{1}{2}\dot{\widetilde{P}}(t)x^2 + \dot{\widetilde{g}}(t)x + \dot{\widetilde{c}}(t), \quad V_x(t,x) = \widetilde{P}(t)x + \widetilde{g}(t), \quad V_{xx}(t,x) = \widetilde{P}(t).$$

Substituting into the LHS of (3.4), we obtain

$$\begin{aligned} \text{LHS} &= V_t(t,x) + V_x(t,x)[A(t)x + f(t)] + \inf_{u \geq 0}\left[\tfrac{1}{2} V_{xx}(t,x) u' D(t)' D(t) u + V_x(t,x) B(t) u\right] \\ &= \left[\tfrac{1}{2}\dot{\widetilde{P}}(t)x^2 + \dot{\widetilde{g}}(t)x + \dot{\widetilde{c}}(t)\right] + [\widetilde{P}(t)x + \widetilde{g}(t)][A(t)x + f(t)] \\ &\quad + \inf_{u \geq 0}\left\{\tfrac{1}{2}\widetilde{P}(t) u' D(t)' D(t) u + [\widetilde{P}(t)x + \widetilde{g}(t)] B(t) u\right\} \\ &= \left[\tfrac{1}{2}\dot{\widetilde{P}}(t) + A(t)\widetilde{P}(t)\right]x^2 + \left[\dot{\widetilde{g}}(t) + A(t)\widetilde{g}(t) + f(t)\widetilde{P}(t)\right]x + \left[\dot{\widetilde{c}}(t) + f(t)\widetilde{g}(t)\right] \\ &\quad + \widetilde{P}(t) \inf_{u \geq 0}\left\{\tfrac{1}{2} u' D(t)' D(t) u + [x + \widetilde{\eta}(t)] B(t) u\right\}. \end{aligned} \tag{3.23}$$

Since $x + \widetilde{\eta}(t) > 0$, the minimizer of (3.23) is

$$u^*(t,x) = 0. \tag{3.24}$$

Substituting $u^*(t,x)$ into (3.23), it is easy to show that V satisfies the HJB equation (3.4) in Γ_2.

Finally, the switching curve Γ_3 defined by

$$\Gamma_3 := \left\{ (t,x) \in [0,T] \times \mathbb{R} \;\middle|\; x + e^{-\int_t^T A(s)ds} \int_t^T f(z) e^{\int_z^T A(s)ds} dz = 0 \right\}$$

is where the nonsmoothness of V occurs. First, a direct calculation shows that $V(t,x) = \frac{1}{2}\overline{P}(t)x^2 + \overline{g}(t)x + \overline{c}(t) = \frac{1}{2}\widetilde{P}(t)x^2 + \widetilde{g}(t)x + \widetilde{c}(t) = 0$ on Γ_3. Therefore, $V(t,x)$ is continuous at $(t,x) \in \Gamma_3$. In addition, we also easily obtain

$$\begin{cases} V_t(t,x) = \frac{1}{2}\dot{\overline{P}}(t)x^2 + \dot{\overline{g}}(t)x + \dot{\overline{c}}(t) = \frac{1}{2}\dot{\widetilde{P}}(t)x^2 + \dot{\widetilde{g}}(t)x + \dot{\widetilde{c}}(t) = 0, \\ V_x(t,x) = \overline{P}(t)x + \overline{g}(t) = \widetilde{P}(t)x + \widetilde{g}(t) = 0. \end{cases}$$

That is, $V(t,x)$ is also continuously differentiable at points on Γ_3. However, V_{xx} does not exist on Γ_3, since $\overline{P}(t) \not\equiv \widetilde{P}(t)$. This means that V does not possess the necessary smoothness properties to qualify as a classical solution of the HJB equation (3.4). For this reason, we are required to work within the framework of viscosity solutions. From Definition 6.1 in the appendix, it can be shown that for any $(t,x) \in \Gamma_3$,

$$\begin{cases} D^{1,2,+}_{t,x} V(t,x) = \{0\} \times \{0\} \times [\widetilde{P}(t), +\infty), \\ D^{1,2,-}_{t,x} V(t,x) = \{0\} \times \{0\} \times (-\infty, \overline{P}(t)]. \end{cases} \tag{3.25}$$

For the HJB equation (3.4), we define $G(t,x,u,p,P) = p[A(t)x + B(t)u + f(t)] + \frac{1}{2}Pu'D(t)'D(t)u$. For any $(q,p,P) \in D^{1,2,+}_{t,x} V(t,x)$, where $(t,x) \in \Gamma_3$, we have

$$q + \inf_{u \geq 0} G(t,x,u,p,P) = \inf_{u \geq 0} \left\{ \tfrac{1}{2} Pu'D(t)'D(t)u \right\} \geq \inf_{u \geq 0} \left\{ \tfrac{1}{2} \widetilde{P}(t)u'D(t)'D(t)u \right\} = 0.$$

Therefore, V is a viscosity subsolution of the HJB equation (3.4). On the other hand, for $(q,p,P) \in D^{1,2,-}_{t,x} V(t,x)$, where $(t,x) \in \Gamma_3$, we have

$$q + \inf_{u \geq 0} G(t,x,u,p,P) = \inf_{u \geq 0} \left\{ \tfrac{1}{2} Pu'D(t)'D(t)u \right\} \leq \inf_{u \geq 0} \left\{ \tfrac{1}{2} \overline{P}(t)u'D(t)'D(t)u \right\} = 0.$$

Therefore, V is also a viscosity supersolution of the HJB equation (3.4). Finally, it is easy to see that the terminal condition $V(T,x) = \frac{1}{2}x^2$ is satisfied. Hence, it follows from Definition 6.1 that $V(t,x)$ is a viscosity solution of the HJB equation (3.4). Moreover, for any $(t,x) \in \Gamma_3$, take $(q^*(t,x), p^*(t,x), P^*(t,x), u^*(t,x)) := (0, 0, \widetilde{P}(t), 0) \in D^{1,2,+}_{t,x} V(t,x) \times \mathcal{U}[s,T]$; then

$$q^*(t,x) + G(t,x,u^*(t,x), p^*(t,x), P^*(t,x)) = 0.$$

It then follows from the *verification theorem* in [38, Theorem 3.1] that $u^*(t,x)$ defined by (3.18) is the optimal feedback control.

Remark 3.5. We mention, once again, that our proof that the control (3.18) is optimal for the problem (3.1)–(3.2) is based on the viscosity verification theorem from [38, Theorem 3.1]. This enables us to solve the constrained LQ problem (3.1)–(3.2) without the technicalities of the duality analysis in [6, 18].

4. Efficient strategies and efficient frontier. In this section we apply the general results established in the previous section to the problem $A(\mu)$ formulated in section 2. Set

$$x(t) = X(t) - (d - \mu).$$

Problem $A(\mu)$ is equivalent to the following problem:

$$\min E\Big\{\tfrac{1}{2}x(T)^2\Big\}, \tag{4.1}$$

subject to

$$\begin{cases} dx(t) = [A(t)x(t) + B(t)u(t) + f(t)]dt + \sum_{j=1}^{m} D_j(t)u(t)dW^j(t), \\ x(0) = X_0 - (d-\mu), \end{cases} \tag{4.2}$$

where $u(\cdot) \in L^2_{\mathcal{F}}(0,T;\mathbb{R}^m_+)$ and

$$\begin{cases} A(t) = r(t), & B(t) = (b_1(t) - r(t), \dots, b_m(t) - r(t)), \\ f(t) = (d-\mu)r(t), & D_j(t) = (\sigma_{1j}(t), \dots, \sigma_{mj}(t)). \end{cases} \tag{4.3}$$

Now, corresponding to (3.9) and (3.10), set

$$\bar{\pi}(t) := \arg \min_{\pi(t)\in[0,\infty)^m} \tfrac{1}{2}\|\sigma(t)^{-1}\pi(t) + \sigma(t)^{-1}(b(t) - r(t)\mathbf{1})\|^2 \tag{4.4}$$

and

$$\bar{\theta}(t) := \sigma(t)^{-1}\bar{\pi}(t) + \sigma(t)^{-1}(b(t) - r(t)\mathbf{1}). \tag{4.5}$$

4.1. An optimal strategy. Before analyzing the efficient frontier of the original portfolio selection problem (2.6), we first present the optimal investment strategy for the problem $A(\mu)$. The optimal control obtained in (3.18) translates into the following strategy:

$$\begin{aligned} & u^*(t,X) \equiv (u_1^*(t,X), \dots, u_m^*(t,X))' \\ = & \begin{cases} -(\sigma(t)')^{-1}\bar{\theta}(t)\Big[x + (d-\mu)(1 - e^{-\int_t^T r(s)ds})\Big] \\ \qquad\qquad \text{if } x + (d-\mu)(1 - e^{-\int_t^T r(s)ds}) \le 0 \\ 0 \qquad\qquad \text{if } x + (d-\mu)(1 - e^{-\int_t^T r(s)ds}) > 0, \end{cases} \\ = & \begin{cases} -(\sigma(t)\sigma(t)')^{-1}[\bar{\pi}(t) + (b(t) - r(t)\mathbf{1})]\Big[X - (d-\mu)e^{-\int_t^T r(s)ds}\Big] \\ \qquad\qquad \text{if } X - (d-\mu)e^{-\int_t^T r(s)ds} \le 0, \\ 0 \qquad\qquad \text{if } X - (d-\mu)e^{-\int_t^T r(s)ds} > 0. \end{cases} \end{aligned} \tag{4.6}$$

THEOREM 4.1. *An optimal investment strategy to the problem $A(\mu)$ is given by* (4.6).

4.2. Efficient frontier. In this subsection, we derive the efficient frontier for the portfolio selection problem (2.6), i.e., we specify the relation between the variance and the expected value of the terminal wealth for every efficient strategy. First of all, note that

$$\begin{aligned} E\Big\{\tfrac{1}{2}x(T)^2\Big\} &= E\Big\{\tfrac{1}{2}[X(T) - (d-\mu)]^2\Big\} \\ &= E\Big\{\tfrac{1}{2}[X(T) - d]^2\Big\} + \mu[EX(T) - d] + \tfrac{1}{2}\mu^2. \end{aligned}$$

Hence, for every fixed μ, we have

$$\begin{aligned}
&\min_{u(\cdot)\in\mathcal{U}[0,T]} E\Big\{\tfrac{1}{2}[X(T)-d]^2+\mu[EX(T)-d]\Big\}\\
&=\min_{u(\cdot)\in\mathcal{U}[0,T]} E\Big\{\tfrac{1}{2}x(T)^2\Big\}-\tfrac{1}{2}\mu^2\\
&=V(0,x(0))-\tfrac{1}{2}\mu^2\\
&=\tfrac{1}{2}P(0)x(0)^2+g(0)x(0)+c(0)-\tfrac{1}{2}\mu^2\\
&=\tfrac{1}{2}P(0)[X_0-(d-\mu)]^2+g(0)[X_0-(d-\mu)]+c(0)-\tfrac{1}{2}\mu^2,
\end{aligned}$$

where $P(\cdot), g(\cdot)$, and $c(\cdot)$ are either $\bar{P}(\cdot), \bar{g}(\cdot)$, and $\bar{c}(\cdot)$ or $\tilde{P}(\cdot), \tilde{g}(\cdot)$, and $\tilde{c}(\cdot)$, respectively, depending on whether or not $X_0-(d-\mu)e^{-\int_0^T r(s)ds}\le 0$ (see (3.17)). Now, if $X_0-(d-\mu)e^{-\int_0^T r(s)ds}\le 0$, we have a concave quadratic function in μ

$$\begin{aligned}
&\min_{u(\cdot)\in\mathcal{U}[0,T]} E\Big\{\tfrac{1}{2}[X(T)-d]^2+\mu[EX(T)-d]\Big\}\\
&=\tfrac{1}{2}\overline{P}(0)[X_0-(d-\mu)]^2+\overline{g}(0)[X_0-(d-\mu)]+\overline{c}(0)-\tfrac{1}{2}\mu^2\\
&=\tfrac{1}{2}e^{-\int_0^T\|\bar{\theta}(s)\|^2ds}\Big[X_0e^{\int_0^T r(s)ds}-(d-\mu)\Big]^2-\tfrac{1}{2}\mu^2.
\end{aligned}$$

If $X_0-(d-\mu)e^{-\int_0^T r(s)ds}>0$, we have a linear function in μ

$$\begin{aligned}
&\min_{u(\cdot)\in\mathcal{U}[0,T]} E\Big\{\tfrac{1}{2}[X(T)-d]^2+\mu[EX(T)-d]\Big\}\\
&=\tfrac{1}{2}\widetilde{P}(0)[X_0-(d-\mu)]^2+\widetilde{g}(0)[X_0-(d-\mu)]+\widetilde{c}(0)-\tfrac{1}{2}\mu^2\\
&=\tfrac{1}{2}\Big[X_0e^{\int_0^T r(s)ds}-(d-\mu)\Big]^2-\tfrac{1}{2}\mu^2\\
&=\tfrac{1}{2}\Big(X_0e^{\int_0^T r(s)ds}-d\Big)^2+\Big(X_0e^{\int_0^T r(s)ds}-d\Big)\mu.
\end{aligned}$$

Therefore we conclude that under the optimal investment strategy (4.6) the optimal cost for problem (2.7) is

(4.7)

$$\begin{aligned}
&\min_{u(\cdot)\in\mathcal{U}[0,T]} E\Big\{[X(T)-d]^2+2\mu[EX(T)-d]\Big\}\\
&=\begin{cases}
e^{-\int_0^T\|\bar{\theta}(s)\|^2ds}\Big[X_0e^{\int_0^T r(s)ds}-(d-\mu)\Big]^2-\mu^2 & \text{if } X_0-(d-\mu)e^{-\int_0^T r(s)ds}\le 0,\\
\Big[X_0e^{\int_0^T r(s)ds}-(d-\mu)\Big]^2-\mu^2 & \text{if } X_0-(d-\mu)e^{-\int_0^T r(s)ds}>0.
\end{cases}
\end{aligned}$$

Note that the above value still depends on the Lagrange multiplier μ. To obtain the optimal value (i.e., the minimum variance Var $X(T)$) and optimal strategy for the original portfolio selection problem (2.6) one needs to maximize the value in (4.7) over $\mu\in\mathbb{R}$ according to the Lagrange duality theorem [23]. A simple calculation shows that (4.7) attains its maximum value

$$\frac{\Big(d-X_0e^{\int_0^T r(s)ds}\Big)^2}{e^{\int_0^T\|\bar{\theta}(s)\|^2ds}-1}\quad\text{at}\quad\mu^*=\frac{d-X_0e^{\int_0^T r(s)ds}}{1-e^{\int_0^T\|\bar{\theta}(s)\|^2ds}}.$$

(Note that in the calculation we made use of the fact that

$$X_0-(d-\mu^*)e^{-\int_0^T r(s)ds}=\frac{de^{-\int_0^T r(s)ds}-X_0}{e^{-\int_0^T\|\bar{\theta}(s)\|^2ds}-1}\le 0,$$

due to Assumption 2.1.)

The above discussion leads to the following theorem.

THEOREM 4.2. *The efficient strategy of portfolio selection problem* (2.6) *corresponding to the expected terminal wealth* $EX(T) = d$*, as a function of time* t *and wealth* X*, is*

$$u^*(t,X) \equiv (u_1^*(t,X), \ldots, u_m^*(t,X))' = \begin{cases} -(\sigma(t)\sigma(t)')^{-1}[\bar{\pi}(t) + (b(t) - r(t)\mathbf{1})]\Big[X - (d-\mu^*)e^{-\int_t^T r(s)ds}\Big] \\ \qquad\qquad \text{if } X - (d-\mu^*)e^{-\int_t^T r(s)ds} \le 0, \\ 0 \qquad\qquad \text{if } X - (d-\mu^*)e^{-\int_t^T r(s)ds} > 0, \end{cases} \tag{4.8}$$

where $\mu^* = \frac{d - X_0 e^{\int_0^T r(s)ds}}{1 - e^{\int_0^T \|\bar{\theta}(s)\|^2 ds}}$*, and* $\bar{\pi}(\cdot)$ *and* $\bar{\theta}(\cdot)$ *are defined in* (4.4) *and* (4.5)*, respectively. Moreover, the efficient frontier is*

$$\text{Var } X(T) = \frac{(d - X_0 e^{\int_0^T r(s)ds})^2}{e^{\int_0^T \|\bar{\theta}(s)\|^2 ds} - 1} \equiv \frac{(EX(T) - X_0 e^{\int_0^T r(s)ds})^2}{e^{\int_0^T \|\bar{\theta}(s)\|^2 ds} - 1}. \tag{4.9}$$

Remark 4.1. The form of the efficient strategy (4.8) suggests that it should put all the money in the bond if the current wealth is large enough.

Remark 4.2. The so-called *mutual fund theorem*, due originally to Tobin [31] for single-period investment, is a natural consequence of the mean-variance theory and is the foundation of the CAPM (*Capital Asset Pricing Model*; Sharpe [29]). It basically asserts that any mean-variance efficient portfolio is a convex combination of the riskless asset and a prescribed portfolio containing only the risky assets. (The latter is called the *tangent fund*.) As an immediate consequence, in all the efficient portfolios the allocations among the risky assets have constant proportions—the same as those in the tangent fund. In particular, it implies that those proportions should not depend on the total wealth of the investor. It then follows from (4.8) that the mutual fund theorem does not hold under the short-selling prohibition, because the fraction of wealth in stocks in an efficient portfolio does depend on the wealth of the agent. However, we see that a modified form of the mutual fund theorem still holds true in the present case. Specifically, we now have two modes depending on whether $X - (d-\mu^*)e^{-\int_t^T r(s)ds} \le 0$. In each mode the allocations among the stocks keep constant proportions.

Remark 4.3. The efficient frontier in the mean-standard deviation diagram is still a straight line, as with the single-period mean-variance setting (see, e.g., [24]). To be specific, let $\sigma_{X(T)}$ be the standard deviation of the terminal wealth; then (4.9) gives

$$EX(T) = X_0 e^{\int_0^T r(s)ds} + \sigma_{X(T)} \sqrt{e^{\int_0^T \|\bar{\theta}(s)\|^2 ds} - 1}, \tag{4.10}$$

which is also called the capital market line.

5. An example. In this section, a numerical example is presented to demonstrate the results in the previous section. Let $m = 3$. The interest rate of the bond and the appreciation rate of the m stocks are $r = \frac{2}{100}$ and $(b_1, b_2, b_3)' = (\frac{4}{100}, \frac{5}{100}, \frac{6}{100})'$, respectively, and the volatility matrix is

$$\sigma = \begin{bmatrix} 1 & 0 & \frac{2}{3} \\ 0 & 1 & 0 \\ 0 & 0 & \frac{2}{3} \end{bmatrix}.$$

Then we have

$$\sigma^{-1} = \begin{bmatrix} 1 & 0 & -1 \\ 0 & 1 & 0 \\ 0 & 0 & \frac{3}{2} \end{bmatrix}$$

and $(b_1 - r, b_2 - r, b_3 - r)' = (\frac{2}{100}, \frac{3}{100}, \frac{4}{100})'$. Hence, $\theta := \sigma^{-1}(b - r\mathbf{1}) = (\frac{-2}{100}, \frac{3}{100}, \frac{6}{100})'$. Obviously, $s(\pi) \triangleq \frac{1}{2}\|\sigma^{-1}\pi + \theta\|^2$ over $[0,\infty)^m$ has a unique minimizer $\bar{\pi} = \left(\frac{2}{100}, 0, 0\right)'$ with the minimum value $s(\bar{\pi}) = \frac{1}{2}\|\sigma^{-1}\bar{\pi} + \theta\|^2 = \frac{9}{4000}$. Then we have

$$\|\bar{\theta}\|^2 = \|\sigma^{-1}\bar{\pi} + \theta\|^2 = \frac{9}{2000}$$

and

$$(\sigma\sigma')^{-1}[\bar{\pi} + (b - r\mathbf{1})] = \left(\ 0, \quad \frac{3}{100}, \quad \frac{9}{100} \ \right)'.$$

Therefore, Theorem 4.2 implies that an efficient strategy is

$$\begin{aligned} u^*(t,X) &\equiv (u_1^*(t,X), u_2^*(t,X), u_3^*(t,X))' \\ &= \begin{cases} \begin{bmatrix} 0 \\ 3/100 \\ 9/100 \end{bmatrix} [(d - \mu^*)e^{\frac{2}{100}(t-T)} - X] & \text{if } X - (d-\mu^*)e^{\frac{2}{100}(t-T)} \le 0, \\ 0 & \text{if } X - (d-\mu^*)e^{\frac{2}{100}(t-T)} > 0, \end{cases} \end{aligned}$$

where $\mu^* = \frac{d - X_0 e^{rT}}{1 - e^{\|\bar{\theta}\|^2 T}} = \frac{d - X_0 e^{\frac{2}{100}T}}{1 - e^{\frac{9}{2000}T}}$. The efficient frontier is

$$\text{Var } X(T) = \frac{(d - X_0 e^{rT})^2}{e^{\|\bar{\theta}\|^2 T} - 1} = \frac{\left[EX(T) - X_0 e^{\frac{2}{100}T}\right]^2}{e^{\frac{9}{2000}} - 1}.$$

6. Conclusion. This paper investigates a continuous-time mean-variance portfolio selection problem where short-selling is not allowed. The efficient strategies and efficient frontier are derived explicitly based on stochastic LQ control technique and viscosity solution theory. This also demonstrates that stochastic LQ control is a powerful framework to treat some finance problems.

An immediate open problem is to extend the results in this paper to the case in which all the market coefficients are random processes. This is a challenging problem because the HJB equation becomes a backward stochastic partial differential equation due to the randomness of coefficients for which viscosity solution theory is still largely unexplored.

Appendix: Viscosity solutions. We list here some basic terminologies from the theory of viscosity solutions which are referred to in the paper.

Let

$$G(t,x,u,p,P) = \tfrac{1}{2}\sigma(t,x,u)'P\sigma(t,x,u) + p'h(t,x,u) - L(t,x,u),$$

where $\sigma : [0,T) \times \mathbb{R}^n \times \mathbb{R}^{n_u} \to \mathbb{R}^n$, $h : [0,T) \times \mathbb{R}^n \times \mathbb{R}^{n_u} \to \mathbb{R}^n$, and $L : [0,T) \times \mathbb{R}^n \times \mathbb{R}^{n_u} \to \mathbb{R}$. Consider the second-order PDE

$$\begin{cases} v_t + \inf\limits_{u \ge 0} G(t,x,u,v_x,v_{xx}) = 0, \quad (t,x) \in [0,T) \times \mathbb{R}^n, \\ v(T,x) = g(x), \end{cases} \tag{6.1}$$

where $g : \mathbb{R}^n \to \mathbb{R}$.

Clearly the HJB equation (3.4) is a special case of (6.1). It is well-known that (6.1) does not in general have classical (smooth) solutions. A generalized concept of solution, called a viscosity solution, is introduced in [5]. The main result in [35] is that under certain mild conditions there exists a unique viscosity solution in the first-order case. In the second-order case, uniqueness is proven in [15]. See also [9, 35] for more details about the viscosity solution and its application in stochastic control.

DEFINITION 6.1. *Let $v \in C([0,T] \times \mathbb{R}^n)$ and $(t_0, x_0) \in (0,T) \times \mathbb{R}^n$. Then the second-order superdifferential of v at (t_0, x_0) is defined by*

$$D^{1,2,+}_{t,x} v(t_0,x_0) = \Big\{ (\varphi_t(t_0,x_0),\, \varphi_x(t_0,x_0), \varphi_{xx}(t_0,x_0)) \;\Big|\; \varphi \in C^\infty((0,T)\times\mathbb{R}^n) \text{ and } v-\varphi \text{ has a local maximum at } (t_0,x_0) \Big\}, \tag{6.2}$$

and the second order subdifferential of v is defined by

$$D^{1,2,-}_{t,x} v(t_0,x_0) = \Big\{ (\varphi_t(t_0,x_0),\, \varphi_x(t_0,x_0), \varphi_{xx}(t_0,x_0)) \;\Big|\; \varphi \in C^\infty((0,T)\times\mathbb{R}^n) \text{ and } v-\varphi \text{ has a local minimum at } (t_0,x_0) \Big\}. \tag{6.3}$$

Moreover, v is a viscosity solution of (6.1) *if*

$$v(T,x) = g(x) \quad \forall\, x \in \mathbb{R}^n, \tag{6.4}$$

and

$$q + \inf_{u\in U} G(t,x,u,p,P) \geq 0 \quad \forall (q,p,P) \in D^{1,2,+}_{t,x} v(t,x), \tag{6.5}$$

$$q + \inf_{u\in U} G(t,x,u,p,P) \leq 0 \quad \forall (q,p,P) \in D^{1,2,-}_{t,x} v(t,x), \tag{6.6}$$

for all $(t,x) \in [0,T) \times \mathbb{R}^n$.

In particular, v is called a *viscosity subsolution* if it satisfies (6.4)–(6.5), and a *viscosity supersolution* if it satisfies (6.4) and (6.6).

SAFE COOPERATIVE ROBOT DYNAMICS ON GRAPHS*

ROBERT W. GHRIST† AND DANIEL E. KODITSCHEK‡

Abstract. This paper introduces the use of vector fields to design, optimize, and implement reactive schedules for safe cooperative robot patterns on planar graphs. We consider automated guided vehicles (AGVs) operating upon a predefined network of pathways. In contrast to the case of locally Euclidean configuration spaces, regularization of collisions is no longer a local procedure, and issues concerning the global topology of configuration spaces must be addressed. The focus of the present inquiry is the definition, design, and algorithmic construction of controllers for achievement of safe, efficient, cooperative patterns in the simplest nontrivial example (a pair of robots on a Y-network) by means of a hierarchical event-driven state feedback law.

Key words. configuration spaces, AGV, graph network, hierarchical control

1. Introduction.

Recent literature suggests the growing awareness of a need for "reactive" scheduling wherein one desires not merely a single deployment of resources but a plan for successive redeployments against a changing environment [19]. However, scheduling problems have been traditionally solved by appeal to a discrete representation of the domain at hand. Thus the need for "tracking" changing goals introduces a conceptual dilemma: there is no obvious topology by which proximity to the target of a given deployment can be measured. In contrast to problems entailing the management of information alone, problems in many robotics and automation settings involve the management of *work*—the exchange of energy in the presence of geometric constraints. In these settings, it may be desirable to postpone the imposition of a discrete representation long enough to gain the benefit of the natural topology that accompanies the original domain.

This paper explores the use of vector fields for reactive scheduling of safe cooperative robot patterns on graphs. The word "safe" means that obstacles—designated illegal portions of the configuration space—are avoided. The word "cooperative" connotes situations wherein physically distributed agents are collectively responsible for executing the schedule. The word "pattern" refers to tasks that cannot be encoded simply in terms of a point goal in the configuration space. The word "reactive" will be interpreted as requiring feedback so that the desired pattern rejects perturbations: conditions close but slightly removed from those desired remain close and, indeed, converge toward the exactly desired pattern.

1.1. Setting: AGVs on a guidepath network of wires.

An automated guided vehicle (AGV) is an unmanned powered cart "capable of following an external guidance signal to deliver a unit load from destination to destination," where, in most

common applications, the guidepath signal is buried in the floor [6]. Thus the AGV's work space is a network of wires—a graph. The motivation to choose AGV-based materials handling systems over more conventional fixed conveyors rests not simply in their ease of reconfigurability but in the potential they offer for graceful response to perturbations in normal plant operation. In real production facilities, the flow of work in process fluctuates constantly in the face of unanticipated work station downtime, variations in process rate, and, indeed, variations in materials transport and delivery rates [8]. Of course, realizing their potential robustness against these fluctuations in work flow remains an only partially fulfilled goal of contemporary AGV systems.

Choreographing the interacting routes of multiple AGVs in a nonconflicting manner presents a novel, complicated, and necessarily online planning problem. Nominal routes might be designed offline, but they can never truly be traversed with the nominal timing for all the reasons described above. Even under normal operating conditions, no single nominal schedule can suffice to coordinate the work flow as the production volume or product mix changes over time: new vehicles need to be added or deleted, and the routing scheme needs to be adapted. In any case, abnormal conditions—unscheduled process down times, blocked work stations, failed vehicles—continually arise, demanding altered routes.

The traffic control schemes deployed in contemporary AGV systems are designed to simplify the real-time route planning and adaptation process by "blocking zone control" strategies. The work space is partitioned into a small number of cells, and, regardless of the details of their source and destination tasks, no two AGVs are ever allowed into the same cell at the same time [6]. Clearly, this simplification results in significant loss of a network's traffic capacity.

In this paper, we will consider a centralized approach that employs dynamical systems theory to focus on real-time responsiveness and efficiency as opposed to computational complexity or average throughput. Without a doubt, beyond a certain maximum number of vehicles, the necessity to compute in the high dimensional configuration space will limit the applicability of any algorithms that arise. However, this point of view seems not to have been carefully explored in the literature. Indeed, we will sketch some ideas about how an approach that starts from the coupled version of the problem may lend sufficient insight to move back and forth between the individuals' and the group's configuration spaces even in real time. For the sake of concreteness we will work in the so-called pickup and delivery (i.e., where loads are picked up at certain points and dropped off at others, as opposed to "stop and go," where an AGV network stands in for an assembly line [3]) paradigm of assembly or fabrication (where a desired steady state "pattern"—a scheduled series of visits to specific work stations by specific AGVs—is dispatched ahead of time), and we will not be concerned with warehousing-style AGV applications.

1.2. Organization of the paper.

Section 2. We introduce the salient properties of a feedback controlled dynamical system on a graph by addressing the closed loop motion planning problem of a single AGV on its wire network. In this setting, configuration spaces are not required, although the nonmanifold structure of the work space necessitates a mild adaptation of the dynamical systems machinery, specified in Appendix A. We describe a simple hybrid controller built from *edge point fields*—locally defined dynamics that realize single letter patterns—which generalize the scheme Burridge, Rizzi, and Koditschek have proposed in [5].

Section 3. Turning to the central topic, we address the case of multiple AGVs in

the simplest possible setting—two AGVs on a Y-graph—as a local exemplar of the general problem. The contributions of this section include

1. an intrinsic coordinate system for the configuration space;
2. a detailed analysis of the topology of the configuration space, affording immediate recourse to previously developed methods of safe controller design [12];
3. the construction of a "circulating flow" on this space that executes a stable safe periodic pattern as a canonical example of dynamically controlled collision-free behavior suitable to more general settings of the problem.

Section 4. Because limit cycles are likely too rigid a means of arbitrary pattern specification in the more generalized settings of the problem, we return to the notion of building a palette of control laws that realize safe "letters" along with a hybrid (logical level) scheme for concatenating them to produce arbitrary patterns in the form of periodic attracting orbits whose limit set is any desired "word," within a "monotone cycle" grammar as formalized in Theorem 3. Section 4 ends with a constructive procedure for incorporating performance guarantees in the construction of these grammars, concluding with a more speculative view of potential extensions of this work.

Appendix A is included to place on a rigorous foundation the use of vector fields on graphs and configuration spaces thereof.

2. Notation and background.

2.1. Graph topology. A *graph*, Γ, consists of a finite collection of 0-dimensional vertices $\mathcal{V}:=\{v_i\}_1^N$, and 1-dimensional edges $\mathcal{E}:=\{e_j\}_1^M$ assembled as follows. Each edge is homeomorphic to the closed interval $[0,1]$ attached to $\mathcal{V}$ along its boundary points $\{0\}$ and $\{1\}$.[1] We place upon Γ the quotient topology given by the endpoint identifications: neighborhoods of a point in the interior of e_j are homeomorphic images of interval neighborhoods of the corresponding point in $[0,1]$, and neighborhoods of a vertex v_i consist of the union of homeomorphic images of half-open neighborhoods of the endpoints for all incident edges.

The configuration spaces we consider in section 3 and throughout are subsets of self-products of graphs. The topology of $\Gamma \times \Gamma$ is easily understood in terms of the topology of Γ as follows [17]. Let $(x,y) \in \Gamma \times \Gamma$ denote an ordered pair in the product. Then any small neighborhood of (x,y) within $\Gamma \times \Gamma$ is the union of neighborhoods of the form $\mathcal{N}(u) \times \mathcal{N}(v)$, where $\mathcal{N}(\cdot)$ denotes the neighborhood within Γ. In other words, the products of neighborhoods form a *basis* of neighborhoods in the product space.

Given a graph, Γ, outfitted with a finite number N of noncolliding AGVs constrained to move on Γ, the (labeled) configuration space of safe motions is defined as

$$\mathcal{C}:= (\Gamma \times \cdots \times \Gamma) - \mathcal{N}(\Delta), \tag{2.1}$$

where $\Delta:=\{(x_i) \in \Gamma \times \cdots \times \Gamma : x_j = x_k \text{ for some } j \neq k\}$ denotes the pairwise diagonal and $\mathcal{N}(\cdot)$ denotes the (small) neighborhood.

[1] In our model, we will disallow "homoclinic" edges whose boundary points are attached to the same vertex. With respect to the application setting, this is very natural since vertices correspond to work stations along a path. It is hard to imagine networks designed with loops that do not service any work stations. In the worst case, there is established precedent in the AGV technology literature for introducing additional "transfer point" technology to a factory setting solely for purposes of traffic control [3].

For general graphs, the topological features of $\mathcal{C}$ can be extremely complicated, as measured by, say, the rank of the fundamental group (see [17] for definitions). Even in the case where the work space, Γ, is contractible (and thus, the product of its n copies is contractible), removal of this collision diagonal often creates spaces with a large fundamental group. For example, given a graph Γ_K with K edges all connected at a single point (forming a K-pronged "star"), it follows from the more general results in [9] that the fundamental group of the configuration space $\Gamma_K \times \Gamma_K - \mathcal{N}(\Delta)$ is a free group on $K^2 - 3K + 1$ generators; i.e., the number of "independent" closed paths in this space (with respect to continuous deformation) grows quadratically with K.

Mathematically, it is usually most interesting to pass to the quotient of $\mathcal{C}$ by the action of the permutation group on N elements, thus forgetting the identities of the AGV elements; however, as such spaces are almost completely divorced from any applications involving coordinated transport, we work on the "full" configuration space $\mathcal{C}$. We do not treat the general aspects of this problem comprehensively in this paper; rather, we restrict our attention to the simplest nontrivial example, which illustrates nicely the relevant features present in the more general situation.

In order to proceed, it is necessary to clarify what we mean by a vector field on a simplicial complex that fails to be a manifold. This is a nontrivial issue: for example, in the case of a graph, the tangent space to a vertex with incidence number greater than two is not well defined. We defer a more detailed discussion of these statements to Appendix A. The essential difference is that we construct *semiflows*—flows which possess unique forward orbits.

2.2. Edge point fields for single AGV control. In the context of describing and executing *patterns* or periodic motions on a graph, one desires a set of building blocks for moving from one goal to the next. We introduce the terminology and philosophy for constructing patterns by way of the simplest possible examples: a single AGV on a graph. This avoids the additional topological complications present in the context of cooperative motion.

To this end, we introduce the class of *edge point fields* as a dynamical toolbox for a hybrid controller. Given a specified goal point $g \in e_j$ within an edge of Γ, an *edge point field* is a locally defined vector field X_g on Γ with the following properties:

Locally defined. X_g is defined on a neighborhood $\mathcal{N}(e_j)$ of the goal edge e_j within the graph topology, and forward orbits under X_g are uniquely defined.

Point attractor. Every forward orbit of X_g asymptotically approaches the unique fixed point $g \in e_j$.[2]

Navigation-like. X_g admits a C^0 Lyapunov function, $\Phi_g : \Gamma \to R$.

The following existence lemma (whose trivial proof we omit) holds.

LEMMA 1. *Given any edge $e_j \subset \Gamma$ which is contractible within Γ, there exists an edge point field X_g for any desired goal $g \in e_j$.*

As a remark, we note that, as is usual in the traditional dynamical systems settings, the orbits of an edge point field may take an infinite amount of time to reach their destination. We can always rectify this situation by modifying the flow in a neighborhood of the goal via a sublinear term, e.g., $\dot{x} = -x^{1/3}$. This comment applies to vector fields used throughout the remainder of this work.

2.3. Discrete regulation of patterns. By an excursion on a graph, we mean a (possibly infinite) sequence of edges from the graph, $E = e_{i_1} \dots e_{i_N} \dots \in \mathcal{E}^Z$, having

[2] When it is not clear from the context, we shall denote the goal point achieved by an edge point flow as $\mathbf{g}(X_g) = \{g\}$.

the property that each pair of contiguous edges e_{i_j} and $e_{i_{j+1}}$ share a vertex in common. The set of excursions forms a language, $\mathcal{L}$, the so-called *subshift* on the alphabet defined by the named edges (we assume each name is unique) [13]. Given a legal block, $B = e_{i_1} \dots e_{i_M} \in \mathcal{L}$, we say that an excursion realizes that pattern if its periodic extension eventually reaches the "goal" $BBBBB\dots$ under the iterates of the block shift. In other words, after some transient behavior, the excursion consists of repetitions of the block B (terminating possibly with the empty edge).

In a previous paper [5], Burridge, Rizzi, and Koditschek introduced a very simple but effective discrete event controller for regulating patterns on abstract graphs representing a "prepares" relation imposed on families of controllers over general smooth manifolds. We introduce this prepares relation below and prune it as in [5]. The resulting ordering on the controllers yields a controller transition logic that enlarges the basin of any one member of the family to include the union of all "higher" controllers. This simple idea has a much longer history. It was in introduced in robotics as "preimage backchaining" [14], pursued in [15] as a method for building verifiable hardened automation via the metaphor of a family of funnels, and pursued in [7] as a means of prescribing sensor specifications from goals and action sets. In the discrete event systems literature, an optimal version of this procedure has been introduced in [4], and a generalization has recently been proposed in [18].

Let $\mathcal{E}^0{:=}B \subset \mathcal{E}$ denote the edges of Γ that appear in the block of letters specifying the desired pattern. Denote by

$$\mathcal{E}^{n+1} \subset \mathcal{E} - \bigcup_{k \le n} \mathcal{E}^k$$

those edges that share a vertex with an edge in $\mathcal{E}^n$ but are not in any of the previously defined subsets. This yields a finite partition of $\mathcal{E}$ into "levels," $\{\mathcal{E}^p\}_{p=0}^{P}$, such that for each edge, $e_i^p \in \mathcal{E}^p$, there can be found a legal successor edge, $e_j^{p-1} \in \mathcal{E}^{p-1}$, such that $e_i^p e_j^{p-1} \in \mathcal{L}$ is a legal block in the language. Note that we have implicitly assumed that $\mathcal{E}^0$ is reachable from the entire graph—otherwise, there will be some "leftover" component of $\mathcal{E}$ forming the last cell in the partition starting within which it is not possible to achieve the pattern. Note as well that we impose some ordering of each cell $\mathcal{E}^p = \{e_i^p\}_{i=1}^{M_p}$: the edges of $\mathcal{E}^0 = B$ are ordered by their appearance in the block; the ordering of edges in higher level cells is arbitrary.

We may now define a "graph control" law $G{:}\mathcal{E} \to \mathcal{E}$ as follows. From the nature of the partition $\{\mathcal{E}^p\}$ above, it is clear that the least legal successor function,

$$L(p,i){:=}\begin{cases} i+1 \bmod M & : p = 0, \\ \min\{j \le M_p : e_i^p e_j^{p-1} \in \mathcal{L}\} & : p > 0 \end{cases} \tag{2.2}$$

is well defined. From this, we construct the graph controller:

$$G(e_i^p){:=}e_{L(p,i)}^{p-1}. \tag{2.3}$$

It follows almost directly from the definition of this function that its successive application to any edge leads eventually to a repetition of the desired pattern.

PROPOSITION 2. *The iterates of G on $\mathcal{E}$ achieve the pattern B.*

2.4. Hybrid edge point fields. A semiflow, $(X)^t$, on the graph induces excursions in $\mathcal{L}$ parametrized by an initial condition as follows. The first letter corresponds to the edge in which the initial condition is located. (Initial conditions at vertices

are assigned to the incident edge along which the semiflow points.) The next letter is added to the sequence by motion through a vertex from one edge to the next.

We will say of two edge point fields X_1, X_2 on a graph, Γ, that X_1 *prepares* X_2, denoted $X_1 \succ X_2$, if the goal of the first is in the domain of attraction of the second, $\mathsf{g}(X_1) \subset \mathcal{N}(X_2)$. Given any finite collection of edge point fields on Γ, we will choose some $0 < \alpha < 1$ and assume that their associated Lyapunov functions have been scaled in such a fashion that $X_1 \succ X_2$, implies $(\Phi_1)^{-1}[0, \alpha] \subset \mathcal{N}(X_2)$. In other words, an α crossing of the trajectory $\Phi_1 \circ (X_1)^t$ signals arrival in $\mathcal{N}(X_2)$.

Suppose now that for every edge in some pattern block, $e_i^0 \in \mathcal{E}^0$, there has been designated a goal point g_i^0 along with an edge point field X_i^0 taking that goal: $\mathsf{g}(X_i^0) = g_i^0$. Assume as well that the edge point field associated with each previous edge in the pattern prepares the flow associated with the next edge; in other words, using the successor function (2.2), we have

$$\mathsf{g}\left(X_j^0\right) \subset \mathcal{N}\left(X_{L(p,j)}^0\right).$$

Now construct edge point fields on all the edges of Γ such that the tree representation of their $\succ$ relations is exactly the tree pruned from the original graph above:

$$\mathsf{g}\left(X_j^p\right) \subset \mathcal{N}\left(X_{L(p,j)}^{p-1}\right).$$

We are finally in a position to construct a hybrid semiflow on Γ. This feedback controller will run the piecewise smooth vector field, $\dot{x} = X$, as follows:

$$X := \begin{cases} X_j^p & : x \in e_j^p \text{ and } \Phi_j^p > \alpha, \\ X_{L(p,j)}^{p-1} & : x \in e_{L(p,j)}^{p-1} \text{ or } \Phi_j^p \leq \alpha. \end{cases} \tag{2.4}$$

It is clear from the construction that progress from edge to edge of the state of this flow echoes the graph transition rule G constructed above.

PROPOSITION 3. *The edge transitions induced by the hybrid controller* (2.4) *are precisely the iterates of the graph map* G (2.3) *in the language* $\mathcal{L}$.

3. The Y-graph. We now turn our attention to the safe control of multiple AGVs on a graph work space via vector fields. Whereas the case of a single AGV on a graph could be controlled by vector fields on the graph itself, the safe coordination of multiple agents necessitates vector field controls on the appropriate configuration space—a space whose topological features are by no means obvious.

For the remainder of this work, we consider the simplest example of a nontrivial configuration space: that associated with the *Y-graph*, Υ, having four vertices $\{v_i\}_0^3$ and three edges $\{e_i\}_1^3$. Each edge e_i attaches a vertex v_i to the central vertex v_0. Although this is a simple scenario compared to what one finds in a typical setting, there are several reasons why this example is in many respects canonical.

1. *Simplicity.* Any graph may be constructed by gluing index-K radial graphs together for various K. The $K = 3$ model we consider is the simplest nontrivial case and is instructive for understanding the richness and challenges of local cooperative dynamics on graphs.
2. *Genericity with respect to graphs.* Graphs which consist of copies of Υ glued together, the *trivalent graphs*, are generic: any nontrivial graph may be perturbed in a neighborhood of the vertex set so as to be trivalent. For example, the 4-valent graph resembling the letter "X" may be perturbed slightly to

resemble the letter "H"—a trivalent graph. An induction argument shows that this is true for all graphs. Hence the dynamics on an arbitrary graph are approximated by patching together dynamics on copies of Υ.

3. *Genericity with respect to local dynamics.* Finally, pairwise local AGV interactions on an arbitrary graph restrict themselves precisely to the dynamics of two agents on Υ as follows. Given a vertex v of a graph Γ, assume that two AGVs x and y are on different edges e_1 and e_2 incident to v and moving toward v with the goal of switching positions. A collision is imminent unless one AGV "moves out of the way" onto some other edge e_3 incident to v. The local interactions thus restrict themselves to dynamics of a pair of AGVs on the subgraph defined by $\{v; e_1, e_2, e_3\}$. Hence the case we treat in this paper is the generic scenario for the local resolution of collision singularities in cooperative dynamics on graphs and forms a basis for decentralized control of large numbers of independent agents.

3.1. Intrinsic coordinates. The configuration space $\mathcal{C}$ of two points on Υ is a subset of the cartesian product $\Upsilon \times \Upsilon$. Since Υ (and indeed any graph which is physically relevant to the setting of this paper) is embedded in a factory floor or ceiling and thus planar, the configuration space $\mathcal{C}$ embeds naturally in R^4. We wish to modify this embedding to facilitate both analysis on and visualization of the configuration space. We will present alternate embeddings in both higher and lower dimensional Euclidean spaces for these purposes.

We begin by representing the configuration space within a higher dimensional Euclidean space via *intrinsic* coordinates—coordinates independent of the graphs embedded in space. We illustrate this coordinate system with the Y-graph Υ, noting that a few simple modifications yield coordinate schemes for general graphs.

Let $\{e_i\}_1^3$ denote the three edges in Υ, parametrized so that the closure of each edge e_i is identified with $[0,1]$ oriented so that $[0,1]$ is mapped to $[v_0, v_i]$. Any point in Υ is thus given by a vector x in the $\{e_i\}$ basis whose magnitude $|x| \in [0,1]$ determines the position of the point in the e_i direction. For $|x| > 0$, denote by $\iota(x)$ the value of i so that $x = |x| e_{\iota(x)}$. This parameterization embeds Υ as the positive unit axis frame in R^3. Likewise, a point in $\mathcal{C}$ is given as a pair of distinct vectors (x, y), i.e., as the positive unit axis frame in R^3 cross itself sitting inside of $R^3 \times R^3 \cong R^6$. We have thus embedded the configuration space of two distinct points on Υ in the positive orthant of R^6. It is clear that one can embed the more general configuration space of N points on Υ in R^{3N} in this manner.

This coordinate system is particularly well suited to describing vector fields on $\mathcal{C}$ and implementing numerical simulations of dynamics, as the coordinates explicitly track the physical position of each point on the graph.

3.2. A topological analysis. Visualizing $\mathcal{C}$ as a subset of R^4 or R^6 is unenlightening. More useful for visualization purposes is the following construction which embeds $\mathcal{C}$ within R^3.

THEOREM 1. *The configuration space $\mathcal{C}$ associated with a pair of AGVs restricted to the Y-graph Υ is homeomorphic to a punctured disc with six 2-simplices attached as per Figure* 3.1.

Proof. Recall that $\mathcal{C}$ consists of pairs of distinct vectors (x, y) in intrinsic coordinates. Restrict attention to the subspace $\mathcal{D} \subset \mathcal{C}$ defined by

$$\mathcal{D} := \{(x, y) \in \mathcal{C} : \iota(x) \neq \iota(y)\}, \tag{3.1}$$

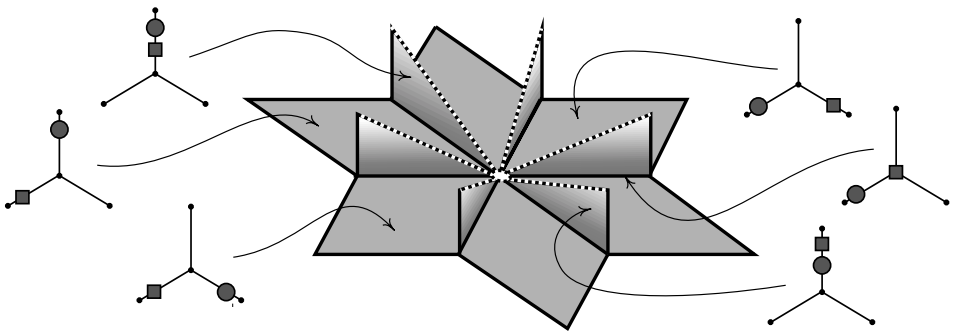

FIG. 3.1. *The configuration space $\mathcal{C}$ embedded in R^3. Dashed lines refer to open boundaries; sample configurations for representative 2-cells are illustrated to the sides.*

where an undefined index is considered to be not equal to one which is defined. Thus $\mathcal{D}$ consists of configurations for which both AGVs do not occupy the same edge interior.

The set $\mathcal{D}$ has a cellular decomposition as follows. There are 2 AGVs and 3 edges in Υ; hence there are $3 \cdot 2 = 6$ cells $\mathcal{D}_{i,j} \subset \mathcal{D}$, where $i := \iota(x) \neq \iota(y) =: j$. Since (the closure of) each edge in Υ is homeomorphic to $[0,1]$ (determined by $|\cdot|$), the cell $\mathcal{D}_{i,j}$ is homeomorphic to $([0,1] \times [0,1]) - \{(0,0)\}$, where, of course, the origin $(0,0)$ is removed as it belongs to the diagonal Δ. A path in $\mathcal{D}$ can move from cell to cell only along the subsets where the index of one AGV changes, e.g., $|x| = 0$ or $|y| = 0$. Thus the edges $\{0\} \times (0,1]$ and $(0,1] \times \{0\}$ of the punctured square $\mathcal{D}_{i,j}$ are attached, respectively, to $\mathcal{D}_{k,j}$ and $\mathcal{D}_{i,k}$, where k is the unique index not equal to i or j.

Furthermore, each 2-cell $\mathcal{D}_{i,j}$ has a product structure as follows: decompose $\mathcal{D}_{i,j}$ along the lines of constant $\theta := \tan^{-1}(\frac{|y|}{|x|})$. It is clear that θ is the angle in the unit's first quadrant in which $\mathcal{D}_{i,j}$ sits. Hence each $\mathcal{D}_{i,j}$ is decomposed into a product of a closed interval $S_{i,j} := \theta \in [0, \pi/2]$ (an "angular" coordinate) with the half-open interval $(0,1]$ (a "radial" coordinate). As this product decomposition is respected along the gluing edges, we have a decomposition of all of $\mathcal{D}$ into the product of $(0,1] \times S$, where S is a cellular complex given by gluing the six segments $S_{i,j}$ end-to-end cyclically along their endpoints. The set S is a 1-manifold without boundary since each $S_{i,j}$ is a closed interval, each of whose endpoints is glued to precisely one other $S_{i,j}$. Hence, by the classification of 1-manifolds, S is homeomorphic to a circle. We have thus decomposed $\mathcal{D}$ as the cross product of a circle with $(0,1]$—a punctured unit disc.

The complement of $\mathcal{D}$ in $\mathcal{C}$ consists of those regions where $\iota(x) = \iota(y)$. For each $i = 1 \ldots 3$, the subset of $\mathcal{C}$ where $\iota(x) = \iota(y) = i$ is homeomorphic to $((0,1] \times (0,1]) - \{|x| = |y|\}$: this consists of two disjoint triangular "fins." A total of six such fins are thus attached to $\mathcal{D}$ along the six edges where $|x|$ or $|y| = 0$. In the coordinates of the product decomposition for $\mathcal{D}$, these fins emanate along the radial lines where θ equals zero or $\pi/2$, yielding the topological space illustrated in Figure 3.1. □

COROLLARY 4. *Given any point goal $g \in \mathcal{D} \subset \mathcal{C}$, there exists an explicit navigation function (of class piecewise real-analytic) generating a semiflow which sends all but a measure-zero set of initial conditions to g under the gradient semiflow.*

Proof. The subset $\mathcal{D} \subset \mathcal{C}$ is homeomorphic to a punctured disc $S \times (0,1]$ and may easily be compactified to an annulus with boundary $S \times [\epsilon, 1]$ by removing an open neighborhood of the diagonal. Then the conditions for the theorems of Koditschek and Rimon [12] are met since an annulus is a *sphereworld*. Hence not only does a

navigation function Φ on this subspace exist, but an explicit procedure for determining Φ is given [12]. One may then extend Φ to the remainder of $\mathcal{C}$ as follows: choose a point (x, y) on the fin, and define

$$\Phi(x,y) := \begin{cases} \frac{1}{1-|x|}\Phi(0,y), & |x| < |y|, \\ \frac{1}{1-|y|}\Phi(x,0), & |y| < |x|, \end{cases} \tag{3.2}$$

so that Φ increases sharply along the fins.[3] This directs the gradient flow to monotonically "descend" away from the diagonal and onto $\mathcal{D}$. Note that $\mathcal{D}$ is forward-invariant under the dynamics and that, upon prescribing the vector field on the fins to point into $\mathcal{D}$, we have defined a semiflow and hence a well-defined navigational procedure. □

This result is very satisfying in the sense that it guarantees a navigation function by applying existing theory to a situation which, from the definition alone, would not appear to be remotely related to a sphereworld. However, a deeper analysis of configuration spaces of graphs [9] reveals that, for more than two AGVs, the configuration space of a graph is never a sphereworld.[4]

We thus consider alternate methods for realizing compatible goals by means of a vector field on the configuration space, focusing, in particular, on the use of attracting periodic orbits as a controller component in the "toolbox" for building up the sort of hybrid feedback laws to be considered carefully in section 4.

3.3. Example: A circulating flow. We begin with a simple example of a vector field on $\mathcal{C}$ which possesses an attracting limit cycle as a goal. This "circulating field," which cycles a pair of AGVs through states on the boundary of $\mathcal{D} \subset \mathcal{C}$, is a canonical example of (1) a meaningful semiflow with limit cycle and (2) a practical field for implementing collision avoidance in a hybrid controller (cf. item 3 in the preface to section 3). Figure 3.2 (right) illustrates the flow restricted to $\mathcal{D}$.

THEOREM 2. *There exists a piecewise-smooth vector field X on $\mathcal{C}$ which has the following properties:*

1. *X defines a nonsingular semiflow on $\mathcal{C}$.*
2. *The diagonal Δ is repelling with respect to X.*
3. *Every orbit of X approaches a unique attracting limit cycle on $\mathcal{C}$ which cycles through all possible ordered pairs of distinct edge states.*

Proof. Recall that $\mathcal{D}$ denotes that portion of the configuration space corresponding to a placement of the AGVs on distinct edges of the graph; from the proof of Theorem 1, $\mathcal{D}$ is homeomorphic to a punctured disc. The intrinsic coordinates on the configuration space $\mathcal{C}$ are illustrated in Figure 3.2 (left), where only $\mathcal{D}$ is shown for simplicity. The reader should think of this as a collection of six square coordinate planes, attached together pairwise along axes with the origin removed.[5] The six triangular fins are then attached as per Figure 3.1.

Recall that any point in the graph is represented as a vector $x = |x|e_i$ for some i. Denote by $\hat{e}_i$ the unit tangent vector in each tangent space $T_x e_i$ pointing in the

[3] This construction does not satisfy the formal requirements for a "navigation function" since it is not bounded on the closure of the configuration space. There is a straightforward procedure detailed in [12] that can be used to complete the construction.

[4] Any configuration space of any graph is *aspherical*; there are no essential closed spheres of dimension larger than one, in contrast to a sphereworld. Thus, although a navigation is guaranteed to result in any case, the explicit constructions [12] are inapplicable.

[5] In the natural product metric on $\mathcal{C}$, these six 2-cells are flat Euclidean squares.

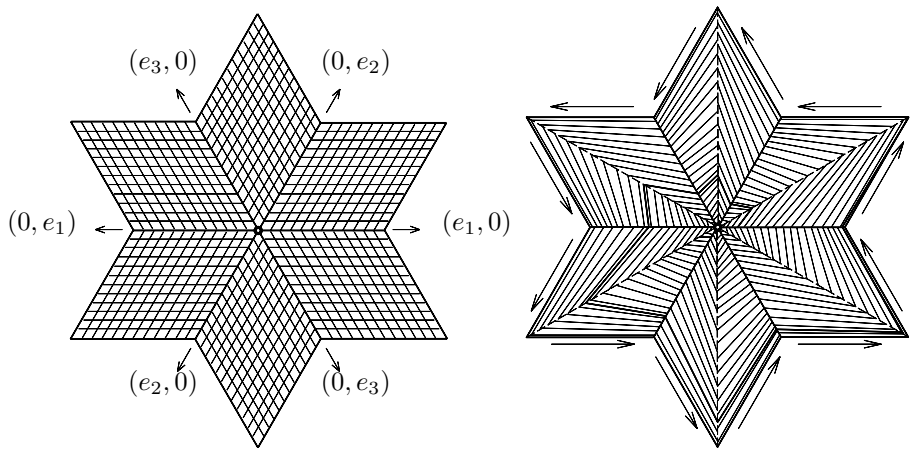

FIG. 3.2. *Left: The coordinate system on the unfinned region $\mathcal{D}$ of $\mathcal{C}$. Right: The circulating flow with a typical orbit.*

positive (outward) direction toward the endpoint v_i. The vector field we propose is the following. Given $(x, y) \in \mathcal{C}$,

1. if $\iota(x) = \iota(y)$, then

$$\left.\begin{array}{l} \dot{x} = -|y|\hat{e}_{\iota(x)}, \\ \dot{y} = |y|(1-|y|)\hat{e}_{\iota(y)}, \end{array}\right\} \quad 0 < |x| < |y|,$$
$$\left.\begin{array}{l} \dot{x} = |x|(1-|x|)\hat{e}_{\iota(x)}, \\ \dot{y} = -|x|\hat{e}_{\iota(y)}, \end{array}\right\} \quad 0 < |y| < |x|; \tag{3.3}$$

2. if $\iota(x) = \iota(y) + 1$ or $|x| = 0$, then

$$\left.\begin{array}{l} \dot{x} = |y|\hat{e}_{(\iota(y)+1)}, \\ \dot{y} = |y|(1-|y|)\hat{e}_{\iota(y)}, \end{array}\right\} \quad 0 \le |x| < |y|,$$
$$\left.\begin{array}{l} \dot{x} = |x|(1-|x|)\hat{e}_{\iota(x)}, \\ \dot{y} = -|x|\hat{e}_{\iota(y)}, \end{array}\right\} \quad 0 < |y| \le |x|; \tag{3.4}$$

3. if $\iota(y) = \iota(x) + 1$ or $|y| = 0$, then

$$\left.\begin{array}{l} \dot{x} = -|y|\hat{e}_{\iota(x)}, \\ \dot{y} = |y|(1-|y|)\hat{e}_{\iota(y)}, \end{array}\right\} \quad 0 < |x| \le |y|,$$
$$\left.\begin{array}{l} \dot{x} = |x|(1-|x|)\hat{e}_{\iota(x)}, \\ \dot{y} = |x|\hat{e}_{(\iota(x)+1)}, \end{array}\right\} \quad 0 \le |y| < |x|. \tag{3.5}$$

Note that all addition operations on $\iota(x)$ and $\iota(y)$ are performed mod three.

The vector field is nonsingular as follows: if $|x||y| \neq 0$, then the vector field is by inspection nonsingular. If $|x| = 0$, then $|y| > 0$ since the points are distinct. It then follows from (3.4) that the vector field on this region has $d|x|/dt = |y| \neq 0$. A similar argument holds for the case where $|y| = 0$.

The vector field defines a semiflow as follows: on those regions where $0 \neq |x| \neq |y| \neq 0$, the vector field is smooth and hence defines a true flow. Along the lines where $|x| = |y|$, the vector field is not smooth but nevertheless is constructed so as to define unique solution curves; hence the region $\mathcal{D}$, where $\iota(x) \neq \iota(y)$, is invariant under the flow. Finally, along the branch line curves where $|x| = 0$ or $|y| = 0$, the vector field

points into the branch lines from the fins, implying that the dynamics is a semiflow (see the remarks in Appendix A).

This vector field admits a C^0 Lyapunov function $\Phi : \mathcal{C} \to [0, 1)$ of the form

$$\Phi(x,y) := \begin{cases} 1 - |(|x| - |y|)| & : \iota(x) = \iota(y), \\ 1 - \max\{|x|, |y|\} & : \iota(x) \neq \iota(y). \end{cases} \tag{3.6}$$

From (3.3), one computes that on the fins (where $\iota(x) = \iota(y)$),

$$\frac{d\Phi}{dt} = -\left|\left(\frac{d|x|}{dt} - \frac{d|y|}{dt}\right)\right| < 0 \tag{3.7}$$

since here $|x| \neq |y|$. Furthermore, on the disc $\mathcal{D}$ ($\iota(x) \neq \iota(y)$), Φ changes as $\frac{d\Phi}{dt} = \Phi(\Phi - 1)$. Hence Φ strictly decreases off of the boundary of the disc

$$\partial\mathcal{D} := \{(x,y) : |x| = 1 \text{ or } |y| = 1\} = \Phi^{-1}(0). \tag{3.8}$$

It follows from the computation of $d\Phi/dt$ that the diagonal set Δ of $\Upsilon \times \Upsilon$ is repelling and that the boundary cycle $\partial\mathcal{D}$ is an attracting limit cycle. □

This example illustrates how one can use a relatively simple vector field on the configuration space to construct a pattern which is free from collisions. Indeed, as part of a hybrid control scheme, one could use this circulating flow to resolve potential collisions between AGVs in a general setting by localizing the dynamics near a pairwise collision to those on a trivalent subgraph. In practice, the fact that the outer vertices of the Y-graph are never quite reached by an interior orbit is irrelevant: a near-approach suffices for any practical application.

4. Patterns and vector fields for monotone cycles. In this section, we consider the problem of constructing vector fields which are tuned to trace out specific collision-free patterns—scheduled series of visits to specific work stations by the pair of AGVs whose regularity we wish to achieve at steady state, and return back to from any temporary perturbation or disruption. We begin with a specification of a suitable language for describing patterns.

4.1. A grammar for patterns. The setting we envisage is as follows: the three ends of the graph Υ are stations at which an AGV can perform some function. The AGV pair is required to execute an ordered sequence of functions, requiring an interleaved sequence of visitations. In order to proceed with vector field controls for cooperative patterns, it is helpful to construct the appropriate symbolic language, as introduced in section 2 for single AGV systems. Denote the pair of AGV states as x and y, respectively. Also, denote the three docking stations as vertices v_1 through v_3 as in Figure 3.1. The grammar $\mathcal{G}$ we use is defined as follows:

- (**xi**): These represent configurations for which the AGV x is docked at the vertex v_i, $i = 1 \ldots 3$. The AGV y is at an unspecified undocked position.
- (**yi**): These represent configurations for which the AGV y is docked at the vertex v_i, $i = 1 \ldots 3$. The AGV x is at an unspecified undocked position.
- (**xiyj**): These represent configurations for which the AGV x is docked at vertex v_i, while the AGV y is simultaneously docked at the vertex v_j, $j \neq i$.

For example, the word (**x1**)(**y2**)(**x3y2**) executes a sequence in which the first AGV docks at Station v_1 and then undocks while the second AGV docks at Station v_2. Finally, the AGVs simultaneously dock at Stations v_3 and v_2, respectively.

As we have assumed from the beginning, the one-dimensional nature of the graph-constraints precludes the presence of multiple agents at a single docking station; hence there are exactly twelve symbols in the grammar $\mathcal{G}$. From this assumption, it follows that particular attention is to be paid to those trajectories which do not make excursions onto the "fins" of the configuration space. It is obvious from the physical nature of the problem that planning paths which involve traveling on the fins is not a locally optimal trajectory with respect to minimizing distance or elapsed time. It suffices to say that we restrict our attention for the moment to trajectories and limit cycles for patterns, in particular, which are constrained to the region $\mathcal{D} \subset \mathcal{C}$.

We identify each symbol with a region of the boundary of the unbranched portion of $\mathcal{C}$; namely, $\partial\mathcal{D}$ is partitioned into twelve *docking zones* as in Figure 4.1. Note further that there is a cyclic ordering, $\prec$, on $\mathcal{G}$ induced by the orientation on the boundary of the disc along which the zones lie. By a cyclic ordering, we mean a way of determining whether a point q lies between any ordered pair of points (p_1, p_2).

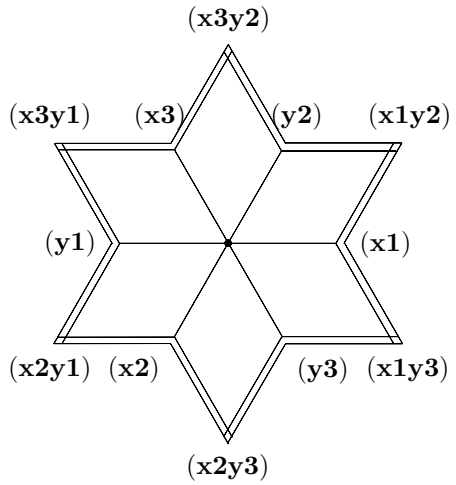

FIG. 4.1. *Labels for the cyclically ordered grammar* $\mathcal{G}$.

We proceed with the analysis of limit cycles on $\mathcal{C}$. Consider the class of *pattern vector fields*, $\mathcal{X}_P$, on $\mathcal{C}$ defined as follows. For every $X \in \mathcal{X}_P$,

1. X defines a semiflow on $\mathcal{C}$ and a true flow off the nonmanifold set of $\mathcal{C}$;
2. there is a unique limit cycle γ which is attracting and which traces out a nonempty word in the grammar $\mathcal{G}$;
3. the diagonal set Δ is a repeller with respect to X;
4. there are no fixed invariant sets of X which attract a subset of positive measure save γ.

Denote by $\mathcal{X}_M$ the subset of $\mathcal{X}_P$ for which the limit cycle, γ, lies in $\mathcal{D}$. The question of which words in the grammar $\mathcal{G}$ are admissible for the class $\mathcal{X}_P$ has a simple answer in terms of the cyclic ordering $\prec$. A word $\mathbf{w}$ composed of elements $\mathbf{w} = w_1 w_2 \dots w_n$ in the grammar $\mathcal{G}$ said to be *monotone* with respect to the cyclic ordering $\prec$ if $w_{i-1} \prec w_i \prec w_{i+1}$ for every i (index operations all mod n).

THEOREM 3. *Within the class of vector fields* $\mathcal{X}_M$*, the limit cycles trace out monotone words in the cyclically ordered grammar* $(\mathcal{G}, \prec)$.

Proof. The idea of the proof is simple and follows from the observation that any limit cycle of the flow must be embedded (the curve does not intersect itself). After a small perturbation, one may assume that the boundary zone $\partial\mathcal{D}$ is visited by γ in

a finite number of points, $Q := \gamma \cap \partial\mathcal{D}$. Consider two points $p, q \in Q$, which are consecutive in the limit cycle: that is, there is an embedded subarc $\alpha \subset \gamma$ which connects p to q within the interior of $\mathcal{D}$. The arc α separates $\mathcal{D}$ into two topological discs (this is the Jordan curve theorem [17]); hence γ must lie entirely within the closure of one of these discs. This implies that the limit cycle cannot visit any point $x \in \partial\mathcal{D}$ satisfying $p \prec x \prec q$. Repeating this argument for all pairs of consecutive points yields the monotonicity property. □

Although the only admissible words in the grammar $\mathcal{G}$ are those which are monotone, it is possible to realize many if not all of the nonmonotone cycles as limit cycles for a semiflow on the *full* configuration space $\mathcal{C}$; one must design the semiflow so as to utilize the fins for "jumping" over regions of $\mathcal{D}$ cut off by the limit cycle. Such vector fields quickly become very convoluted, even for relatively simple nonmonotone limit cycles, and a more explicit constructive procedure would need stronger motivation from the application domain than we are presently aware of.

4.2. Isotopy classes of limit cycles. Given a limit cycle γ which traces out a pattern by visiting the boundary zone $\partial\mathcal{D}$ in the ordered set $Q \subset \partial\mathcal{D}$, one wants to know which other limit cycles minimize a given performance functional while still visiting Q in the proper sequence. The mathematical framework for dealing with this problem is the notion of *isotopy classes* of curves.

Two subsets A_0 and A_1 of a set B are said to be (ambiently) *isotopic rel* C (where $C \subset B$) if there exists a continuous 1-parameter family of homeomorphisms $f_t : B \to B$ such that

1. f_0 is the identity map on B,
2. $f_1(A_0) = A_1$, and
3. $f_t|_C$ is the identity map on C for all t.

As t increases, f_t deforms B, pushing A_0 to A_1 without cutting or tearing the spaces and without disturbing C.

There are two ways in which optimization questions relate to isotopy classes of limit cycles: (1) Given an element of the grammar $\mathcal{G}$, in which isotopy class (rel the docking zones) of curves does an optimal limit cycle reside? (2) Within a given isotopy class of cycles rel Q, which particular cycle is optimal?

For a monotone limit cycle on $\mathcal{D}$, question (1) focuses on the location of the cycle with respect to the central point $(0, 0)$, which is deleted from the disc $\mathcal{D}$. It is a standard fact from planar topology that every curve in the punctured disc has a well-defined *winding number*, which measures how many times the cycle goes about the origin, and, furthermore, that this number is -1, 0, or 1 if the cycle is an embedded curve. This winding number determines the isotopy class of the curve in $\mathcal{D}$. Hence the problem presents itself as follows: given an element of the grammar $\mathcal{G}$, which isotopy class rel the docking zones is optimal (with respect to any or all of the functionals defined)? Is the winding number zero or nonzero?[6]

To address this question, we define the *gap angles* associated to a limit cycle. For the remainder of this section, we will place standard polar coordinates on the region $\mathcal{D}$ (given as a subset of the plane as per Figures 3.2 and 4.1) with the central puncture corresponding to the origin. Given a set of "docked states"—or points $Q = \{q_1, q_2, \ldots, q_J\}$ ordered with respect to time—we define the gap angles to be the successive differences in the angular coordinates of the q_j: thus $\angle_j := P(q_{j+1}) - P(q_j)$, where P denotes projection of points in $\mathcal{D}$ onto their angular coordinates, and

[6]The difference between $+1$ and -1 is the orientation of time.

subtraction is performed with respect to the orientation on $\partial\mathcal{D}$.

For simplicity, we consider the optimization-isotopy problem in the case of a discrete cost functional $\mathbf{W}_d$, defined to be the intersection number of the path with the branch locus of $\mathcal{C}$, i.e., the number of times an AGV occupies the central vertex (the shared resource in the problem). Similar arguments are possible for other natural performance metrics.

PROPOSITION 5. *Given a cyclically ordered set of points $Q = \{q_j\}_1^J$ on the boundary of $\mathcal{D}$, consider the class of embedded monotone cycles on $\mathcal{D}$ which trace out the points of Q.*

1. *There is a $\mathbf{W}_d$-minimizing embedded monotone cycle on $\mathcal{D}$ having winding number zero with respect to the origin if there is a gap angle greater than π.*
2. *Conversely, if there are no gap angles greater than π, then there is a $\mathbf{W}_d$-minimizing embedded cycle of index ± 1.*

Proof. Define the gap angles $\{\angle_j\}_1^J$ to be the differences of the angles between the points q_j and q_{j+1} (in standard planar polar coordinates with all indices mod J). Since $\sum_j \angle_j = 2\pi$, there can be at most one gap angle greater than π. To simplify the problem, use a 1-parameter family P_t of maps from the identity P_0 to the projection $P = P_1$, which deforms $\mathcal{D}$ to the boundary circle $S := \partial\mathcal{D}$ by projecting along radial lines. The index of a curve on $\mathcal{D}$ is invariant under this deformation as is the functional $\mathbf{W}_d$.

Denote by γ_j the subarc of γ between points q_j and q_{j+1} (all indices mod J). Denote by α_j the subarc of the boundary S between points q_j and q_{j+1}, where the arc is chosen to subtend the gap angle $\angle_j$. Since the boundary curve $S = \cup_j \alpha_j$ is a curve of index ± 1, the arcs γ_j and α_j are isotopic in $\mathcal{D}$ rel their endpoints for all j if and only if γ is a curve of index ± 1.

Assume first that there is a gap angle $\angle_j > \pi$ with γ an index ± 1 curve on S which intersects the branch angles $\Theta = \{n\pi/3 : n \in Z\}$ in a minimal number of points among all other closed curves on S which visit the points Q in the specified order. It follows that the arc $P(\gamma_j)$ subtends an angle greater than π and thus increments $\mathbf{W}_d$ by at least three. One may replace γ_j by a curve γ_j', which substitutes for the arc γ_j, one which wraps around "the other way" monotonically. This changes the index of γ from nonzero to zero since the arc γ_j' is no longer isotopic to α_j. Also, it is clear that this either decreases the number of intersections with Θ or leaves this number unchanged.

We must show that the replacement arc γ_j' can be chosen in such a way that it does not intersect the remainder of γ. However, since γ is a curve of index ± 1, we may isotope each arc γ_i to the boundary curve α_i without changing the value of $\mathbf{W}_d$. Thus we may remove γ_j and replace it with the curve which is, say, a geodesic (in the natural metric geometry) from q_j to q_{j+1}. As this curve does not approach the boundary S apart from its ends, the new curve γ' is an embedded curve of index zero without an increase in $\mathbf{W}_d$.

Now assume, on the contrary, that γ is a $\mathbf{W}_d$ minimizer of index zero which has all gap angles strictly less than π. Then each arc from γ_i must intersect the branch set Θ in at most three components since, otherwise, the subtended arc would be in excess of $4\pi/3$. In the case where there exists an arc with exactly three intersections with the branch set, this arc may be replaced by an arc which goes around the singularity in the other direction without changing the number of intersections with the branch set (since there are a total of six branch lines); however, the index of the curve is toggled between zero and nonzero.

The final case is that in which each arc intersects the branch set in at most two places. However, since γ is a curve of index zero, some arc γ_j must not be isotopic to α_j. Hence the projection deformations P_t must push γ_j to a curve in the boundary S whose subtended gap angle is $2\pi - \angle_j > \pi$. Thus γ_j intersects the branch set in at least three places, yielding a contradiction. Replacing γ_j by the appropriate arc which is isotopic to α_j yields a $\mathbf{W}_d$-minimal cycle of nonzero index. □

4.3. Tuning cycles. Designing a customized "pattern" of two AGVs on the Y-graph is as simple as drawing a vector field on $\mathcal{C}$ with a stable limit cycle tracing out the desired motion. The problem then is how to specify such a vector field in coordinates. Since we focus on those limit cycles which are contained within $\mathcal{D}$, we can exploit the fact that $\mathcal{D}$ is topologically a punctured disc. We thus give an explicit coordinate-change between the natural polar coordinates on a disc and the intrinsic coordinates of section 3. Once we possess an explicit coordinate change (and its inverse), we can design a vector field in polar coordinates (an easy task to do in these coordinates) and then take the push-forward of the vector field under the coordinate change.

It will be convenient to keep track of which "wedge" of the annular region a point (r, θ) is. To do so, we introduce a parity function

$$P(\theta) := (-1)^{\{\lfloor 3\theta/\pi \rfloor + \lfloor 6\theta/\pi \rfloor\}}, \tag{4.1}$$

where $\lfloor t \rfloor$ is the integer-valued floor function. Recall the notation for the intrinsic coordinates for a point x on the graph Υ: $x = |x|\hat{e}_{\iota(x)}$, where $|x| \in [0, 1]$ is the distance from x to the central vertex, and $\hat{e}_{\iota(x)}$ is the unit tangent vector pointing along the direction of the $\iota(x)$-edge. Here the index $\iota(x)$ is an integer (defined modulo 3) and will be undefined in the case when $|x| = 0$, i.e., x is at the central vertex.

LEMMA 6. *The following is a piecewise-linear homeomorphism from the punctured unit disc in R^2 to the subset $\mathcal{D}$. Define $F(r, \theta) = (x, y)$, where*

$$\begin{aligned} \iota(x) &= \left\lfloor -\tfrac{3}{2\pi}(\theta - \pi) \right\rfloor \quad , \quad |x| = \begin{cases} r & \mathcal{P}(\theta) = +1, \\ r\left|\cot \tfrac{3}{2}\theta\right| & \mathcal{P}(\theta) = -1, \end{cases} \\ \iota(y) &= \left\lfloor -\tfrac{3}{2\pi}\theta \right\rfloor \quad , \quad |y| = \begin{cases} r\left|\tan \tfrac{3}{2}\theta\right| & \mathcal{P}(\theta) = +1, \\ r & \mathcal{P}(\theta) = -1. \end{cases} \end{aligned} \tag{4.2}$$

The inverse of this homeomorphism is given by $F^{-1}(x, y) = (r, \theta)$, where

$$\begin{aligned} \theta &= \begin{cases} \tfrac{2}{3}\tan^{-1}\tfrac{|y|}{|x|} - \tfrac{2\pi}{3}(\iota(y) + 1), & \iota(y) = \iota(x) + 1, \\ & \quad or\ |x| = 0, \\ -\tfrac{2}{3}\tan^{-1}\tfrac{|y|}{|x|} - \tfrac{2\pi}{3}(\iota(x) - 1), & \iota(x) = \iota(y) + 1, \\ & \quad or\ |y| = 0, \end{cases} \\ r &= \begin{cases} |x| & \mathcal{P}(\theta) = +1, \\ |y| & \mathcal{P}(\theta) = -1. \end{cases} \end{aligned} \tag{4.3}$$

Note that all θ values are defined modulo 2π, and all index values are integers defined modulo 3.

Proof. Begin by working on the region $\mathcal{D}_{1,2} \subset \mathcal{D}$, where $\iota(x) = 1$ and $\iota(y) = 2$. As noted earlier, this subspace is isometric to the positive unit square in R^2 with the origin removed. We need to map this to the subset $\{(r, \theta) : r \in (0, 1], \theta \in [0, \pi/3]\}$. The simplest such homeomorphism is to first shrink along radial lines, leaving the

angle invariant; hence

$$r = \begin{cases} |x| & : |x| \le |y|, \\ |y| & : |y| \le |x|. \end{cases} \tag{4.4}$$

Next, we squeeze the quarter-circle into a sixth of a circle by multiplying the angle by 2/3, leaving the radial coordinate invariant:

$$\theta = \frac{2}{3} \tan^{-1} \frac{|y|}{|x|}. \tag{4.5}$$

This gives the basic form of F^{-1} as per (4.3). To extend this to the remainder of $\mathcal{D}$, it is necessary to carefully keep track of $\iota(x)$ and $\iota(y)$ and subtract the appropriate angle from the computation of θ. Also, the condition of $|x| \le |y|$, etc., in (4.4) is incorrect on other domains of $\mathcal{D}$ since the inequalities flip as one traverses from square to square: the parity function $\mathcal{P}(\theta)$ keeps track of which "wedge" one is working on.

To determine F from F^{-1} is a tedious but unenlightening calculation, made more unpleasant by the various indices to be kept track of. Briefly, given r and θ on the first sixth of the unit disc, one knows from (4.4) that either $|x| = r$ or $|y| = r$, depending on whether θ is above or below $\pi/4$. To solve for the other magnitude, one inverts (4.5) to obtain $|y| = r\left|\tan \frac{3}{2}\theta\right|$ or $|x| = r\left|\cot \frac{3}{2}\theta\right|$, respectively. To generalize this to the other $\mathcal{D}_{i,j}$ domains of $\mathcal{D}$, it is necessary to take absolute values and to use the parity function $\mathcal{P}(\theta)$ as before. Finally, the computation of the index is obtainable from the combinatorics of the coordinate system as illustrated in Figure 3.2. □

For the design of limit cycles, it is easier to work on the polar disc and write out an explicit vector field $X = (\dot{r}, \dot{\theta})$ with a limit cycle. To transform this into intrinsic coordinates, one takes the push-forward of X with respect to F, obtaining the piecewise-smooth vector field

$$\begin{cases} \begin{pmatrix} |\dot{x}| = \dot{r}, \\ |\dot{y}| = \dot{r}\left|\tan(\frac{3}{2}\theta)\right| + \frac{3}{2} r\dot{\theta} \sec^2(\frac{3}{2}\theta) \end{pmatrix} & \mathcal{P}(\theta) = +1, \\ \begin{pmatrix} |\dot{x}| = \dot{r}\left|\cot(\frac{3}{2}\theta)\right| + \frac{3}{2} r\dot{\theta} \csc^2(\frac{3}{2}\theta), \\ |\dot{y}| = \dot{r} \end{pmatrix} & \mathcal{P}(\theta) = -1, \end{cases} \tag{4.6}$$

which simplifies to

$$\begin{cases} \begin{pmatrix} |\dot{x}| = \dot{r}, \\ |\dot{y}| = \dot{r}\dfrac{|y|}{|x|} + \dfrac{3}{2}\dot{\theta}\dfrac{|x|}{1 + \left(\frac{|y|}{|x|}\right)^2} \end{pmatrix} & \mathcal{P}(\theta) = +1, \\ \begin{pmatrix} |\dot{x}| = \dot{r}\dfrac{|x|}{|y|} + \dfrac{3}{2}\dot{\theta}\dfrac{|y|}{1 + \left(\frac{|x|}{|y|}\right)^2}, \\ |\dot{y}| = \dot{r} \end{pmatrix} & \mathcal{P}(\theta) = -1. \end{cases} \tag{4.7}$$

We present a more explicit example. Given a simple closed curve γ in R^2 which has nonzero winding number with respect to the origin, γ may be parametrized as $\{(r, \theta) : r = f(\theta)\}$ for some periodic positive function f. To construct a vector field on R^2 whose limit sets consist of the origin as a source and γ as an attracting limit cycle, it suffices to take the push-forward of the vector field $\dot{r} = r(1 - r),\ \dot{\theta} = \omega$ under the

planar homeomorphism $\phi : (r, \theta) \mapsto (f(\theta)r, \theta)$, which rescales linearly in the angular component. The calculations follow:

$$\begin{aligned} \phi_* \begin{pmatrix} \dot{r} \\ \dot{\theta} \end{pmatrix} &= D\phi \begin{pmatrix} \dot{r} \\ \dot{\theta} \end{pmatrix} \Big|_{r \mapsto \frac{r}{f}} = \begin{bmatrix} f & rf' \\ 0 & 1 \end{bmatrix} \begin{pmatrix} r(1-r) \\ \omega \end{pmatrix} \Big|_{r \mapsto \frac{r}{f}} \\ &= \begin{pmatrix} r\left(1 - \frac{r - f'\omega}{f}\right) \\ \omega \end{pmatrix}. \end{aligned} \tag{4.8}$$

Hence, given $f(\theta)$, we may tune a vector field to trace out the desired limit cycle and then use (4.2) and (4.3) to map it into intrinsic coordinates.

4.4. Optimal chords within a hybrid controller. To design optimal cycles with winding number zero, then we turn to constructing customized portions of limit cycles, or *chords* which can be pieced together via a state-actuated hybrid controller, much as in section 2. In other words, instead of building a simple fixed vector field with a limit cycle, we will use a set of vector fields which vary discretely in time and which may be pieced together so as to tune a limit cycle to the desired specifications. There is nothing in this construction which relies on the index-zero property, and thus these chords can be used to generate all monotone limit cycles on $\mathcal{C}$.

Let G denote a word representing a desired monotone limit cycle on the configurations space $\mathcal{C}$. Choose points $\{q_i\}$ on the boundary of $\mathcal{D}$ which correspond to the docking zones for the cycle given by G. Choose arcs α_i on $\mathcal{D}$ which connect q_i to q_{i+1} (using cyclic index notation). The arcs α_i are assumed given in the intrinsic coordinates on $\mathcal{D}$, as would be the case if one were determining a length-minimizing curve.

In the case where the limit cycle $\alpha := \cup_i \alpha_i$ is an embedded curve of nonzero index, the procedure of the previous subsection determines a vector field X_α on $\mathcal{C}$ which realizes α as an attracting limit cycle with the appropriate dynamics on the complementary region. Recall that one translates α to a curve on the disc model via the homeomorphism of (4.3). Then, representing the limit cycle α as a function $f_\alpha(\theta)$, one takes the vector field of (4.8) and, if desired, takes the image of this vector field under (4.7).

If, however, this is not the case, consider the arc α_j for a fixed j, and construct an index ± 1 cycle $\beta^j = \cup_i \beta^j_i$ which has docking zones $\{q_i\}$ such that $\beta^j_j = \alpha_j$. Then the vector field X^j as constructed above has β as an attracting limit cycle. Denote by Φ^j the Lyapunov function which measures proximity to β: $\Phi^j(p) := \left\| p - \beta^j \right\|$ (with distance measured in say the product metric on $\mathcal{C}$). Then consider the modified Lyapunov function $\Psi^j(p) := \Phi^j(p) + \|p - q_{j+1}\|$, which measures the distance to the endpoint of the arc β^j_j in addition to the proximity to β^j.

Repeat this procedure for each j, yielding the vector fields $\{X^j\}$ which attract, respectively, to limit cycles β^j. It follows that X^j prepares X^{j+1} since the goal point of X^j, q_{j+1} lies on the attracting set of X^{j+1}. The Lyapunov functions $\{\Psi^j\}$ serve as a set of funnels which channel the orbit into the sequence of arcs α_j, forming α. One scales the Ψ^j so that a $\Psi^j < \epsilon$ event triggers the switching in the hybrid controller from X^j to X^{j+1}:

$$X := \begin{cases} X^1 & : \quad \Phi^j > \epsilon \quad \forall\, j, \\ X^j & : \quad \Phi^j < \epsilon \text{ and } \Psi^j > \epsilon. \end{cases} \tag{4.9}$$

By construction, the hybrid controller (4.9) realizes a limit cycle within ϵ of α as the attracting set.

5. Future directions. A point of primary concern is the adaptability of the global topological approach to systems which increase in complexity, either through more intricate graphs or through increased numbers of AGVs. The latter is of greater difficulty than the former since the dimension of the resulting configuration space is equal to the number of AGVs. Hence, no matter how simple the underlying graph is, a system with ten independent AGVs will require a dynamical controller on a (topologically complicated) ten-dimensional space—a formidable problem both from the topological, dynamical, and computational viewpoints.

However, there are some approaches which may facilitate working with such spaces. Consider the model space $\mathcal{C}$ with which this paper is concerned: although a two-dimensional space $\mathcal{C}$ is homeomorphic to the product of a graph (a circle with six radial edges attached) with the interval $(0, 1]$. In fact, if we consider the circulating flow of (3.3)–(3.5), one can view this as a product field of a semiflow on the graph (which "circulates") with a vector field on the factor $(0, 1]$ (which "pushes out" to the boundary).

A similar approach is feasible for arbitrary graphs [9].

THEOREM 4. *Given any graph* Γ *(except the graph homeomorphic to a circle), the configuration space of* N *distinct points on* Γ *can be deformation retracted to a subcomplex whose dimension is bounded above by the number of vertices of* Γ *of valency greater than two.*[7]

This theorem implies the existence of low dimensional *spines* which carry all of the topology of the configuration space. For example, the configuration space of N points on the Y-graph can be continuously deformed to a one-dimensional graph, regardless of the size of N. Since the full space can be deformation retracted onto the spine, a vector field defined on the spine can be pulled back continuously to the full configuration space, thus opening up the possibility of reducing the control problem to that on a much "smaller" space. Additional results about the topology of configuration spaces on graphs may yield computationally tractable means of dealing with complex path planning: for example, having a presentation for the fundamental group of a configuration space of a graph in terms of a suitably simple set of cycles would be extremely well-suited to a hybrid control algorithm based on "localized" vector fields supported on small portions of the full configuration space.

Results connected with computational issues for configuration spaces of graphs are also being developed. Abrams has developed a "discretization" algorithm for converting the configuration space of a graph into a cubical complex [1]. This is then perfectly suited to the recent algorithms in computational homology [11] which prefer cube complex structures and can quickly determine geodesic paths.

The optimization problem is another avenue for inquiry. The fact that a dynamical approach allows for increased density of AGVs on a graph (as compared with blocking-zone strategies) would indicate an increased efficiency with respect to, say, elapsed time of flight. However, a more careful investigation of the tuning of optimal cycles is warranted. A careful treatment of the geometry of configuration spaces of graphs is essential to the optimization problem: it follows from the recent thesis of Abrams [1] that these spaces always possess a remarkable geometric property (*NPC* or *nonpositively curved*) which implies, among other things, that geodesics are unique

[7] Added in proof: A similar result has been shown in [16].

within their homotopy class. Such properties, though rare in the world of topological spaces, appear to be not at all uncommon among real-world robotic systems [2].

We believe that the benefits associated with using the full configuration space to tune optimal dynamical cycles justifies a careful exploration of these challenging spaces.

Appendix A. The topology and dynamics of graphs.

In this appendix, we provide a careful basis for the use of vector fields on configuration spaces of graphs. In the setting of manifolds, all of the constructions used in this paper are entirely natural and well defined. However, on spaces like $\mathcal{C}$, the most fundamental of notions (like the existence and uniqueness theorems for ODEs) are not in general valid.

We begin by defining vector fields on graphs. For present purposes, it is convenient to work with an intrinsic formulation (i.e., directly in the graph rather than via an embedding) of these objects. To this end, denote by v a vertex with K incident edges $\{e_i\}_1^K$ and by $\{X_i\}_1^K$ a collection of nonsingular vector fields locally defined on a neighborhood of the endpoint of each e_i (homeomorphic to $[0,1)$).

LEMMA 7. *A set of nonsingular vector fields $\{X_i\}$ on the local edge set of a graph Γ generates a well-defined semiflow on Γ if the following hold:*

1. *Each edge field X_i generates a well-defined local semiflow on $(0,1)$.*
2. *The magnitude of the endpoint vectors $\|X_i(0)\|$ (taken with respect to the attaching homeomorphisms) are all identical.*
3. *Among the* signs *of the endpoint vectors $X_i(0)$ (either positive if pointing into $[0,\epsilon)$ or negative if pointing out) there is a single positive sign.*

Proof. Since the vector field is well defined away from the vertex, it is only necessary to have the magnitudes $\|X_i(0)\|$ agree in order to have a well-defined function $\|X\|$ on Γ. In order to make this a well-defined field of directions, we must also consider in which direction the vector is pointing. Again, this is determined off of the vertex by (1). Condition (3) means that at the vertex there is a unique direction along which the vector field is pointing out: all other edges point in. Hence the direction field, as well as the magnitude field, is well defined.

The semiflow property follows naturally from this. Assume that the Nth edge of Γ has the positive sign. Then, given an initial point $x \in \Gamma$, if $x \in e_N$, then the orbit of x under the local field X_N remains in e_N and is well defined. If $x \in e_j$ for some $j \neq N$, then the union of the edges $e_j \cup e_N$ is a manifold homeomorphic to R on which the vector fields X_j and X_N combine to yield a well-defined vector field, since the directions are "opposite." As we are now on a manifold, the standard existence theorem implies that x has a forward orbit (which passes through the vertex and continues into e_N). Thus every point on Γ has a well-defined forward orbit. □

In the case where the vector fields have singularities, it is a simpler matter. If the singularities are not at the vertex, then there is no difference. If there is a singularity at the vertex, then condition (3) in Lemma 7 is void—all such vector fields are well defined.

In order to extend these results to the configuration space of this paper, consider the space $\mathcal{C} = \Upsilon \times \Upsilon - \Delta$, and let $(x,y) \in \mathcal{C}$ denote a point on the branch set of $\mathcal{C}$. Because of the structure of Υ and the fact that the diagonal points are deleted, it follows that at most one AGV may occupy a nonmanifold point of Υ. Hence a neighborhood of (x,y) in $\mathcal{C}$ has a natural product structure $N \cong \Upsilon \times R$. Let $P : N \to \Upsilon$ denote projection onto the first factor.

LEMMA 8. *A nonsingular vector field X on the individual cells of $\mathcal{C}$ generates*

a well-defined semiflow if (1) *the projection of the local vector fields onto the graph factor,* $P_*(X|_{\{x\}\times\Upsilon})$*, satisfies Lemma* 7 *for each point* x *in the branch set of* $\mathcal{C}$ *and* (2) *the projections of the vector fields on the branch set to the* R*-factor are equal up to the attaching maps.*

Proof. Off of the branch set, the space is a manifold, and hence the vector field gives a well defined flow. If p is a point on the branch line, condition (2) implies that the vector field is well defined with respect to the attaching maps and the net effect in the R-factor is a drift in this direction. In the graph factor, condition (1) and the proof of Lemma 7 imply that there is a unique forward orbit through p. □

Intuitively, this condition means that, as in the case of a graph, the vector field must point "in" on all but one sheet of the configuration space in order to have well-defined orbits. We may thus lift the criteria of Lemma 7 to the product configuration space. All of the vector fields in this paper are so constructed.

FILTERING OF NONLINEAR STOCHASTIC FEEDBACK SYSTEMS*

F. CARRAVETTA†, A. GERMANI‡, R. LIPTSER§, AND C. MANES‡

Abstract. This paper concerns the filtering problem for a class of stochastic nonlinear systems where the drift term may depend either on some external function (*open-loop system*) or on the system output (*closed-loop system*), through a *controller*. Such systems are denoted *feedback systems*. The following result is proven: for feedback systems, the optimal filter in the open-loop case remains optimal when the feedback is closed. The proof is obtained by showing equivalence of suitable expressions for the estimators of the open-loop and closed-loop systems, obtained using the Kallianpur–Striebel formula [G. Kallianpur and C. Striebel, *Ann. Math. Statist.*, 39 (1968), pp. 785–801].

1. Introduction.

Consider the class of nonlinear stochastic systems described by the equations

$$\begin{aligned} dX_t^\phi &= f(t, X_t^\phi, u(t, \phi_{[0,t]}))dt + b(t, X_t^\phi)dW_t', \\ dY_t^\phi &= h(t, X_t^\phi)dt + B(t)dW_t'', \end{aligned} \tag{1.1}$$

where $X_t^\phi \in \mathbb{R}^n$ is the system state, $Y_t^\phi \in \mathbb{R}^m$ is the observation process, and $u(t, \phi_{[0,t]}) \in \mathbb{R}^p$ is the input function, generated by some driving function ϕ. f, h are vector functions of suitable dimensions. $W_t' \in \mathbb{R}^n$ and $W_t'' \in \mathbb{R}^m$ are independent Wiener processes. (Without loss of generality, we consider square diffusion matrices b and B.)

If in system (1.1) the driving function ϕ is *replaced* by the system output Y, we obtain the following system:

$$\begin{aligned} dX_t &= f(t, X_t, u(t, Y_{[0,t]}))dt + b(t, X_t)dW_t', \\ dY_t &= h(t, X_t)dt + B(t)dW_t''. \end{aligned} \tag{1.2}$$

So the term $u(t, Y_{[0,t]})$ represents a causal map of the observation process into the input, describing a behavior of some feedback control device (*the controller*). We will refer to system (1.1) as the *open-loop* system, and to system (1.2) as the *closed-loop* system.

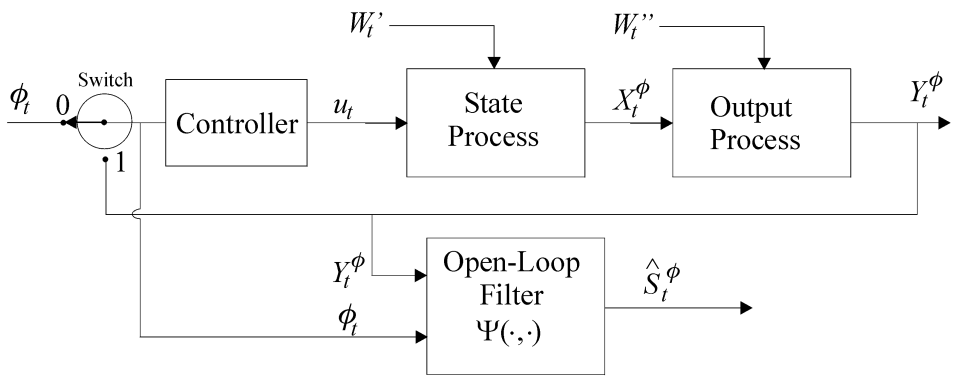

FIG. 1.1. *The optimal filter for the open-loop system.*

Let $F : \mathbb{R}^n \mapsto \mathbb{R}^{n'}$ be a function of the system state that defines a signal to be estimated for the open- and closed-loop systems:

$$S_t^\phi = F\big(X_t^\phi\big), \tag{1.3}$$

$$S_t = F\big(X_t\big). \tag{1.4}$$

Assume for every fixed t there is a function $\Psi_t(y_{[0,t]}; \phi_{[0,t]})$, $(y_t, \phi(t),\ t \geq 0$, are continuous vector functions valued in $\mathbb{R}^p)$ such that

$$\Psi_t(Y_{[0,t]}^\phi; \phi_{[0,t]}) = E\big(S_t^\phi / Y_{[0,t]}^\phi\big). \tag{1.5}$$

This is the *open-loop filter*, i.e., the optimal filter for the open-loop system (1.1), forced by the system output and by the forcing term ϕ. For every t, also assume that there exists a function $\Phi_t(y_{[0,t]})$ such that

$$\Phi_t(Y_{[0,t]}) = E\big(S_t / Y_{[0,t]}\big),\ P\text{-a.s.} \tag{1.6}$$

This is the *closed-loop filter*, i.e., the optimal filter for the closed-loop system (1.2) that is forced by the system output only.

The following question arises:

$$\Psi_t(Y_{[0,t]}; Y_{[0,t]}) \stackrel{?}{=} \Phi_t(Y_{[0,t]}),\ P\text{-a.s.} \tag{1.7}$$

Stated in other words, if we apply the *open-loop filter to the closed-loop system*, then does the estimate agree with the optimal state-estimate for the closed-loop system?

This problem is also depicted in Figures 1.1 and 1.2, where a switch can commute from position 0 (open-loop system) to position 1 (closed-loop system). For each position of the switch there is a different optimal filter. An affirmative answer to question (1.7) means that the filter of Figure 1.1 remains optimal when the switch commutes from position 0 to position 1.

The question if (1.7) holds or not is not only interesting by itself but is important in many applications. For instance, in all cases in which a finite-dimensional filter exists for the open-loop system (see [4]), identity (1.7) proves that the filter remains optimal and finite-dimensional also when the feedback is closed. Another

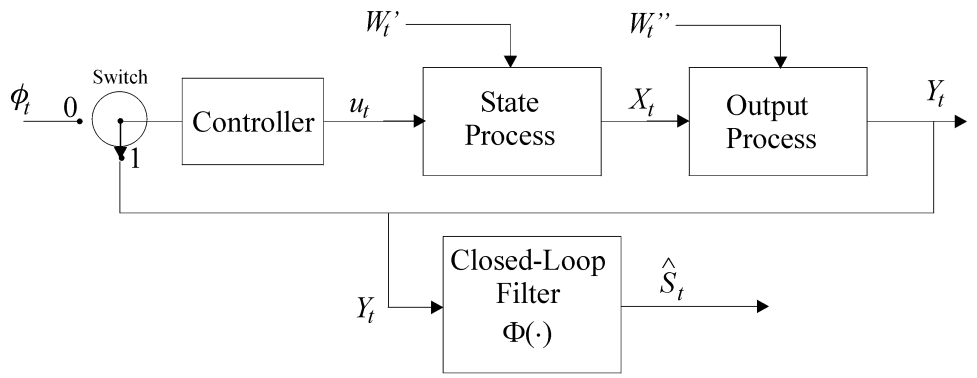

FIG. 1.2. *The optimal filter for the closed-loop system.*

interesting application is when $\Phi_t(Y_{[0,t]})$ is computed by the Monte Carlo method via $\Psi_t(Y^{\phi}_{[0,t]}; \phi_{[0,t]})$.

Up to now, the correctness of (1.7) has been proved only for particular cases of the problem, such as in the case of the linear-Gaussian system under nonlinear feedback [6], [10], [11] of the type

$$\begin{aligned} dX_t &= (A(t, Y_{[0,t]})X_t + u(t, Y_{[0,t]}))dt + F(t, Y_{[0,t]})dW_t', \\ dY_t &= C(t, Y_{[0,t]})X_t dt + G(t, Y_{[0,t]})dW_t'', \end{aligned}$$

which is important from an application point of view.

In this paper, we give an affirmative answer to question (1.7) for the nonlinear models (1.1), (1.2), under some not very restrictive assumptions.

The paper is organized as follows: section 2 reports the rigorous statement of the problem, and section 3 presents the main theorem. Conclusions follow.

2. Problem statement. On a probability space $\{\Omega, \mathcal{F}, P\}$, consider two independent Wiener processes W_t' and W_t'', $t \in [0, \infty)$, of dimension n and m, respectively, and a random vector $\mathcal{X} \in \mathbb{R}^n$. Let $\mathcal{F}^t$ be the nondecreasing family of σ-algebras generated by $\{(\mathcal{X}, W_s', W_s''),\ 0 \le s \le t\}$. Throughout the paper, $\mathcal{C}_{[0,\infty)}(\mathbb{R}^q)$ shall denote the space of $\mathbb{R}^q$-valued continuous functions over the interval $[0, \infty)$. On this space, let $\mathcal{B}_t^q$, $t \ge 0$, be the σ-algebra generated by cylinder sets of the form

$$\big\{\varphi \in \mathcal{C}_{[0,\infty)}(\mathbb{R}^q) :\ \phi(t_k) \in B_k;\ t_k \le t;\ k{=}1,\ldots,\bar{k};\ \bar{k} \in \mathbb{N};\ B_k \in \mathcal{B}(\mathbb{R}^q)\big\}, \tag{2.1}$$

where $\mathcal{B}(\mathbb{R}^q)$ is the Borel σ-algebra of $\mathbb{R}^q$. Moreover, let $\mathcal{B}_\infty^q = \vee_{t\ge 0}\mathcal{B}_t^q$. Let $\mathcal{R}_+$ be the Borel σ-algebra on $\mathbb{R}_+$.

Given a process ξ_t, let $\sigma_t(\xi)$ be the σ-algebra generated by $\{\xi_s,\ 0 \le s \le t\}$.

For a given $\phi \in \mathcal{C}_{[0,\infty)}(\mathbb{R}^m)$, consider the *open-loop* model:

$$\begin{aligned} dX_t^\phi &= f(t, X_t^\phi, u(t,\phi))dt + b(t, X_t^\phi)dW_t', \quad & X_0^\phi &= \mathcal{X}, \\ dY_t^\phi &= h(t, X_t^\phi)dt + B(t)dW_t'', & Y_0^\phi &= 0, \\ S_t^\phi &= F\big(X_t^\phi\big). \end{aligned} \tag{2.2}$$

Consider also the *closed-loop* model:

$$
\begin{aligned}
dX_t &= f(t, X_t, u(t,Y))dt + b(t, X_t)dW'_t, \quad X_0 = \mathcal{X},\\
dY_t &= h(t, X_t)dt + B(t)dW''_t, \qquad\qquad\quad Y_0 = 0,\\
S_t &= F\big(X_t\big).
\end{aligned} \tag{2.3}
$$

In both models the state space is $\mathbb{R}^n$, the observation space is $\mathbb{R}^m$, and the signal space is $\mathbb{R}^{n'}$.

For models (2.2) and (2.3), we make the following assumptions:

(i) The function $u:\ \mathbb{R}_+ \times \mathcal{C}_{[0,\infty]}(\mathbb{R}^m) \mapsto \mathbb{R}^p$ is $\mathbb{R}_+ \otimes \mathcal{B}^m_\infty$-measurable and $\{\mathcal{B}^m_t\}_{t\geq 0}$-adapted.

(ii) For any $t \in \mathbb{R}_+$, the functions $f(t,\cdot,\cdot)$, $h(t,\cdot)$, $F(\cdot)$ have bounded components.

(iii) There exist an increasing function $L(t)$ and a measure $\mu(dt)$ on $\mathbb{R}_+$, with $\int_0^t \mu(ds) < \infty$, $t > 0$, so that (here $\|\cdot\|$ is the Euclidean norm)

$$
\begin{aligned}
&\big\|f(t,x',u(t,y')) - f(t,x'',u(t,y''))\big\|\\
&\qquad\qquad \leq L(t)\left(\|x'-x''\| + \int_0^t \|y'_s - y''_s\|\mu(ds)\right),\\
&\big\|h(t,x') - h(t,x''))\big\| \leq L(t)(\|x'-x''\|),\\
&\big\|b(t,x') - b(t,x''))\big\| \leq L(t)(\|x'-x''\|).
\end{aligned} \tag{2.4}
$$

(iv) Matrices $\mathfrak{D}_t := BB^*(t)$ and $\mathfrak{d}_t := bb^*(t,x)$ (* is the transposition symbol) are uniformly nonsingular, respectively, in $\mathbb{R}_+$ and in $\mathbb{R}_+ \times \mathbb{R}^n$, with bounded inverse.

(v) (*Open-loop filter.*) There exists a function $\Psi : \mathbb{R}_+ \times \mathcal{C}_{[0,\infty]}(\mathbb{R}^m) \times \mathcal{C}_{[0,\infty]}(\mathbb{R}^m) \mapsto \mathbb{R}^{n'}$, $\mathcal{R}_+ \otimes \mathcal{B}^m_\infty \otimes \mathcal{B}^m_\infty$-measurable and $\{\mathcal{B}^m_t \otimes \mathcal{B}^m_t\}_{t\geq 0}$-adapted, such that

$$
\Psi_t(Y^\phi;\phi) = E\big(S^\phi_t/\sigma_t(Y^\phi)\big),\ P\text{-a.s.},\ \forall t \in \mathbb{R}_+. \tag{2.5}
$$

(vi) (*Closed-loop filter.*) There exists a function $\Phi : \mathbb{R}_+ \times \mathcal{C}_{[0,\infty]}(\mathbb{R}^m) \mapsto \mathbb{R}^{n'}$, $\mathcal{R}_+ \otimes \mathcal{B}^m_\infty$-measurable and $\{\mathcal{B}^m_t\}_{t\geq 0}$-adapted, such that

$$
\Phi_t(Y) = E\big(S_t/\sigma_t(Y)\big),\ P\text{-a.s.},\ \forall t \in \mathbb{R}_+. \tag{2.6}
$$

Note that thanks to the assumption of $\{\mathcal{B}_t\}_{t\geq 0}$-measurability of the function u, the term $u(t,Y)$ performs a causal mapping of the observation process into the input. Moreover, note that condition (iii) guarantees existence and uniqueness of strong solutions of (2.2) and of (2.3), adapted to $\mathcal{F}^t$.

3. Main result. The main result of this paper is given by the following theorem, which answers question (1.7).

THEOREM 3.1. *Consider the open-loop and the closed-loop nonlinear stochastic models* (2.2) *and* (2.3). *Let the assumptions* (i)–(vi) *be satisfied. Then the functions* Ψ_t *and* Φ_t *defined in* (2.5) *and* (2.6) *are such that*

$$
\Psi_t(Y;Y) = \Phi_t(Y),\ P\text{-a.s.},\ \forall\ t \in \mathbb{R}_+. \tag{3.1}
$$

Before proving this theorem, we have to state some preliminary results. Throughout the paper we will use the following notation:

$$
\big\|h(t,x)\big\|^2_{\mathfrak{D}_t^{-1}} = h^*(t,x)\left(BB^*\right)^{-1}(t)h(t,x). \tag{3.2}
$$

Moreover, for a given process ξ taking values on $\mathcal{C}_{[0,\infty)}(\mathbb{R}^q)$, we shall denote by μ_ξ^t the measure induced by the process on $\{\mathcal{C}_{[0,\infty)}(\mathbb{R}^q), \mathcal{B}_t^q\}$.

Let $F_t : \mathcal{C}_{[0,\infty]}(\mathbb{R}^n) \mapsto \mathbb{R}^{n'}$ be the bounded function defined by the equality $F_t(z) = F(z(t))$, where F is the function defining the signals for systems (2.2), (2.3).

LEMMA 3.2 (Kallianpur–Striebel formula for $\Psi_t(Y^\phi;\phi)$). *For any $t \geq 0$, the open-loop filter can be written as*

$$\Psi_t(Y^\phi;\phi) = \frac{\int_{\mathcal{C}_{[0,\infty)}(\mathbb{R}^n)} F_t(z)\Lambda_t(z,Y^\phi)\mu^t_{X^\phi}(dz)}{\int_{\mathcal{C}_{[0,\infty)}(\mathbb{R}^n)} \Lambda_t(z,Y^\phi)\mu^t_{X^\phi}(dz)}, \tag{3.3}$$

where

$$\Lambda_t(X^\phi,Y^\phi) = \exp\left(\int_0^t h^*(s,X_s^\phi)\mathfrak{D}_s^{-1}dY_s^\phi - \frac{1}{2}\int_0^t \left\|h(s,X_s^\phi)\right\|^2_{\mathfrak{D}_s^{-1}}ds\right). \tag{3.4}$$

Proof. Consider the process

$$d\zeta_t = B(t)dW_t'', \quad \zeta_0 = 0. \tag{3.5}$$

By Theorem 7.20 of [5] and comments from subsection 7.6.4 after this theorem in [5], for any $t \geq 0$ the distributions of processes $(X_s^\phi, Y_s^\phi)_{s\leq t}$, $(X_s^\phi, \zeta_s)_{s\leq t}$ are equivalent. Moreover, we have

$$\begin{gathered}\Lambda_t(z,y) = \frac{d\mu^t_{X^\phi,Y^\phi}}{d\mu^t_{X^\phi,\zeta}}(z,y),\\ (z,y) \in \mathcal{C}_{[0,\infty)}(\mathbb{R}^n) \times \mathcal{C}_{[0,\infty)}(\mathbb{R}^m).\end{gathered} \tag{3.6}$$

From this, the following equation is obtained:

$$\int_{\mathcal{C}_{[0,\infty)}(\mathbb{R}^n)} \Lambda_t(z,y)\mu^t_{X^\phi}(dz) = \frac{d\mu^t_{Y^\phi}}{d\mu^t_\zeta}(y), \qquad y \in \mathcal{C}_{[0,\infty)}(\mathbb{R}^m). \tag{3.7}$$

From Theorem 7.23 in [5] and its multidimensional analogue Lemma 2.3 in [12], it is

$$\Psi_t(Y^\phi;\phi) = \int_{\mathcal{C}_{[0,\infty)}(\mathbb{R}^n)} F_t(z)\rho_t(z,Y^\phi)\mu^t_{X^\phi}(dz), \tag{3.8}$$

with

$$\rho_t(z,y) = \frac{d\mu^t_{X^\phi,Y^\phi}}{d\mu^t_{X^\phi,\zeta}}(z,y) \Big/ \frac{d\mu^t_{Y^\phi}}{d\mu^t_\zeta}(y). \tag{3.9}$$

From the expressions of the Radon–Nikodym derivatives, it follows that

$$\begin{gathered}\rho_t(z,y) = \frac{\Lambda_t(z,y)}{\int_{\mathcal{C}_{[0,\infty)}(\mathbb{R}^n)} \Lambda_t(z,y)\mu^t_{X^\phi}(dz)},\\ (z,y) \in \mathcal{C}_{[0,\infty)}(\mathbb{R}^n) \times \mathcal{C}_{[0,\infty)}(\mathbb{R}^m),\end{gathered} \tag{3.10}$$

and from this (3.3) follows. ∎

From assumptions (i)–(iii), there exists a $Q : \mathbb{R}_+ \times \mathbb{R}^n \times \mathcal{C}_{[0,\infty)}(\mathbb{R}^n) \times \mathcal{C}_{[0,\infty)}(\mathbb{R}^m) \mapsto \mathbb{R}^n$, measurable and $\{\mathcal{B}(\mathbb{R}^n) \otimes \mathcal{B}_t^n \otimes \mathcal{B}_t^m\}$-adapted, such that the closed-loop state process can be written as

$$X_t = Q_t(\mathcal{X}, W', Y). \tag{3.11}$$

$Q(\mathcal{X}, W', Y)$ will denote the process $\{Q_s(\mathcal{X}, W', Y), s \in \mathbb{R}_+\}$.

LEMMA 3.3 (Kallianpur–Striebel formula for $\Phi_t(Y)$). *For any $t \geq 0$, the closed-loop filter can be written as*

$$\Phi_t(Y) = \frac{\int_{\mathbb{R}^n \times \mathcal{C}_{[0,t]}(\mathbb{R}^n)} F\big(Q(x,w,Y)\big)\mathfrak{A}_t(x,w,Y)\mu_{\mathcal{X}}(dx)\mu_{W'}^t(dw)}{\int_{\mathbb{R}^n \times \mathcal{C}_{[0,t]}(\mathbb{R}^n)} \mathfrak{A}_t(x,w,Y)\mu_{\mathcal{X}}(dx)\mu_{W'}^t(dw)}, \tag{3.12}$$

where

$$\begin{aligned}\mathfrak{A}_t(x,w,Y) = \exp\Bigg\{ &\int_0^t h^*\ \big(\ s, Q_s(x,w,Y)\big)\mathfrak{D}_s^{-1} dY_s \\ &- \frac{1}{2}\int_0^t \big\|h\big(s, Q_s(x,w,Y)\big)\big\|^2_{\mathfrak{D}_s^{-1}} ds\Bigg\}.\end{aligned} \tag{3.13}$$

Proof. As in the proof of Lemma 3.2, apply Theorem 7.20 of [5] to the processes $\big(\mathcal{X}, W', Y\big)$ and $\big(\mathcal{X}, W', \zeta\big)$: for all $t \geq 0$ the distributions $\mu^t_{\mathcal{X},W',Y}$ and $\mu^t_{\mathcal{X},W',\zeta}$ are equivalent, and the Radon–Nikodym derivative is

$$\begin{aligned}&\frac{d\mu^t_{\mathcal{X},W',Y}}{d\mu^t_{\mathcal{X},W',\zeta}}(x,w,y) = \mathfrak{A}_t(x,w,y), \\ &(x,w,y) \in \mathbb{R}^n \times \mathcal{C}_{[0,\infty)}(\mathbb{R}^n) \times \mathcal{C}_{[0,\infty)}(\mathbb{R}^m),\end{aligned} \tag{3.14}$$

where $\mathfrak{A}_t$ is defined in (3.13). The following equation can be verified:

$$\int_{\mathcal{C}_{[0,\infty)}(\mathbb{R}^n)} \mathfrak{A}_t(x,w,y)\mu_{\mathcal{X}}(dx)\mu_{W'}^t(dw) = \frac{d\mu_Y^t}{d\mu_\zeta^t}(y), \qquad y \in \mathcal{C}_{[0,\infty)}(\mathbb{R}^m). \tag{3.15}$$

Again, using Theorem 7.23 in [5] and its multidimensional analogue Lemma 2.3 in [12], we have

$$\Phi_t(Y) = \int_{\mathbb{R}^n \times \mathcal{C}_{[0,\infty)}(\mathbb{R}^n)} F\big(Q_s(x,w,Y)\big)\gamma_s(x,w,Y)\mu_{\mathcal{X}}(dx)\mu_{W'}^t(dw), \tag{3.16}$$

with

$$\gamma_t(x,w,y) = \frac{d\mu^t_{\mathcal{X},W',Y}}{d\mu^t_{\mathcal{X},,W',\zeta}}(x,w,y) \Big/ \frac{d\mu_Y^t}{d\mu_\zeta^t}(y). \tag{3.17}$$

From these one has

$$\begin{aligned}&\gamma_t(x,w,y) = \frac{\mathfrak{A}_t(x,w,y)}{\int_{\mathbb{R}^n \times \mathcal{C}_{[0,\infty)}(\mathbb{R}^n)} \mathfrak{A}_t(x,w,y)\mu_{\mathcal{X}}(dx)\mu_{W'}^t(dw)}, \\ &(x,w,y) \in \mathbb{R}^n \times \mathcal{C}_{[0,\infty)}(\mathbb{R}^n) \times \mathcal{C}_{[0,\infty)}(\mathbb{R}^m).\end{aligned} \tag{3.18}$$

Equation (3.12) follows. □

Let us define the process Γ as follows:

$$\Gamma_t(X,Y) = \exp\left\{ \int_0^t h^*(s,X_s)\mathfrak{D}_s^{-1} dY_s - \frac{1}{2}\int_0^t \big\|h(s,X_s)\big\|^2_{\mathfrak{D}_s^{-1}} ds \right\}. \tag{3.19}$$

Note that from (3.11) and (3.13) we have

$$\Gamma_t\big(Q(\mathcal{X},W',Y),Y\big) = \mathfrak{A}_t(\mathcal{X},W',Y). \tag{3.20}$$

In the following, we have to rewrite the expressions of the open- and closed-loop filters, given by (3.3) and (3.12), respectively, in a more convenient form related to the underlying probability space. For this purpose, we introduce a copy $(\widetilde{\Omega},\widetilde{\mathcal{F}},\widetilde{P})$ of the original probability space so that all of the processes defined on it are independent copies of the original ones. We also introduce random variables and processes on the product probability space $\big(\Omega\times\widetilde{\Omega},\mathcal{F}\otimes\widetilde{\mathcal{F}},P\times\widetilde{P}\big)$.

Let $Z(\omega,\tilde{\omega})$ be a random variable defined on the product space. Let us define the operator $\widetilde{E}$ as follows:

$$\widetilde{E}(Z)(\omega) = \int_{\widetilde{\Omega}} Z(\omega,\tilde{\omega})P(d\tilde{\omega}). \tag{3.21}$$

For a given process ξ defined on the original space, we shall denote by $\tilde{\xi}$ a process defined on the product space as $\tilde{\xi}(\omega,\tilde{\omega}) = \xi(\tilde{\omega})$. Whenever it does not cause confusion, we shall use the same symbol ξ to denote both the original process and its extension to the product space: $\xi(\omega,\tilde{\omega}) = \xi(\omega)$.

On the product space it is possible to define the process $\widetilde{X}^Y$ as follows:

$$\widetilde{X}^Y_t = Q_t(\widetilde{\mathcal{X}},\widetilde{W}',Y). \tag{3.22}$$

With these positions, recalling also the definition of Γ given in (3.19), we can rewrite expressions (3.3) and (3.12) as follows:

$$\Psi_t(Y^\phi;\phi) = \frac{\widetilde{E}\big\{F_t(\widetilde{X}^\phi)\Lambda_t(\widetilde{X}^\phi,Y^\phi)\big\}}{\widetilde{E}\big\{\Lambda_t(\widetilde{X}^\phi,Y^\phi)\big\}}, \quad P\text{-a.s.}, \tag{3.23}$$

$$\Phi_t(Y) = \frac{\widetilde{E}\big\{F_t(\widetilde{X}^Y)\Gamma_t(\widetilde{X}^Y,Y)\big\}}{\widetilde{E}\big\{\Gamma_t(\widetilde{X}^Y,Y)\big\}}, \quad P\text{-a.s.} \tag{3.24}$$

Now we are in a position to give the proof of Theorem 3.1.

Proof of Theorem 3.1. From expressions (3.23) and (3.24), Theorem 3.1 is proved as soon as it is shown that

$$\Lambda_t(\widetilde{X}^\phi,Y^\phi)\big|_{\phi=Y} = \Gamma_t(\widetilde{X}^Y,Y), \qquad P\times\widetilde{P}\text{-a.s.} \tag{3.25}$$

From definitions (3.4) and (3.19) we have

$$\Lambda_t(\widetilde{X}^\phi,Y^\phi) = \exp\left(\int_0^t h^*(s,\widetilde{X}^\phi_s)\mathfrak{D}_s^{-1} dY^\phi_s - \frac{1}{2}\int_0^t \big\|h(s,\widetilde{X}^\phi_s)\big\|^2_{\mathfrak{D}_s^{-1}} ds \right), \tag{3.26}$$

$$\Gamma_t(\widetilde{X}^Y, Y) = \exp\left(\int_0^t h^*(s, \widetilde{X}_s^Y)\mathfrak{D}_s^{-1} dY_s - \frac{1}{2}\int_0^t \left\| h\big(s, \widetilde{X}_s^Y\big)\right\|^2_{\mathfrak{D}_s^{-1}} ds \right). \tag{3.27}$$

Since the integrals in (3.26) are $\sigma_t(\widetilde{X}^\phi, Y^\phi)$-adapted processes, there exist functions H and $L : \mathcal{C}_{[0,\infty)}(\mathbb{R}^n) \times \mathcal{C}_{[0,\infty)}(\mathbb{R}^m) \mapsto \mathcal{C}_{[0,\infty)}(\mathbb{R})$ that are $\mathcal{B}_t^n \otimes \mathcal{B}_t^m$-adapted and that are such that their values at time t are

$$\begin{aligned} H_t(\widetilde{X}^\phi, Y^\phi) &= \int_0^t h^*(s, \widetilde{X}_s^\phi)\mathfrak{D}_s^{-1} dY_s^\phi, \qquad P \times \widetilde{P}\text{-a.s.}, \\ L_t(\widetilde{X}^\phi, Y^\phi) &= \int_0^t \left\| h(s, \widetilde{X}_s^\phi)\right\|^2_{\mathfrak{D}_s^{-1}} ds, \qquad P \times \widetilde{P}\text{-a.s.} \end{aligned} \tag{3.28}$$

Similarly, the integrals in (3.27) can be written as

$$\begin{aligned} H'_t(\widetilde{X}^Y, Y) &= \int_0^t h^*(s, \widetilde{X}_s^Y)\mathfrak{D}_s^{-1} dY_s, \qquad P \times \widetilde{P}\text{-a.s.}, \\ L'_t(\widetilde{X}^Y, Y) &= \int_0^t \left\| h\big(s, \widetilde{X}_s^Y\big)\right\|^2_{\mathfrak{D}_s^{-1}} ds, \qquad P \times \widetilde{P}\text{-a.s.}, \end{aligned} \tag{3.29}$$

where H' and L' are functions with the same properties of H and L. We can use Lemma 4.10 of [5] to prove that[1]

$$\begin{aligned} H_t(\widetilde{X}^Y, Y) &= H'_t(\widetilde{X}^Y, Y), \\ L_t(\widetilde{X}^Y, Y) &= L'_t(\widetilde{X}^Y, Y), \end{aligned} \qquad P \times \widetilde{P}\text{-a.s.}, \tag{3.30}$$

by showing that the measures $\mu^t_{\widetilde{X}^\phi, Y^\phi}$ and $\mu^t_{\widetilde{X}^Y, Y}$ are equivalent.

As a matter of fact, Theorem 7.19 of [5] guarantees the equivalence of the measures induced by the processes $(\widetilde{X}^\phi, X^\phi, Y^\phi)$ and $(\widetilde{X}^Y, X, Y)$, which are defined on $\big(\Omega \times \widetilde{\Omega}, \mathcal{F} \otimes \widetilde{\mathcal{F}}, P \times \widetilde{P}\big)$ as follows:

$$\begin{aligned} d\widetilde{X}_t^\phi &= f(t, \widetilde{X}_t^\phi, u(t,\phi))dt + b(t, \widetilde{X}_t^\phi)d\widetilde{W}'_t, \quad \widetilde{X}_0^\phi = \widetilde{\mathcal{X}}, \\ dX_t^\phi &= f(t, X_t^\phi, u(t,\phi))dt + b(t, X_t^\phi)dW'_t, \quad X_0^\phi = \mathcal{X}, \\ dY_t^\phi &= h(t, X_t^\phi)dt + B(t)dW''_t, \qquad\qquad\quad Y_0^\phi = 0, \end{aligned} \tag{3.31}$$

$$\begin{aligned} d\widetilde{X}_t^Y &= f(t, \widetilde{X}_t^Y, u(t,Y))dt + b(t, \widetilde{X}_t^Y)d\widetilde{W}'_t, \qquad \widetilde{X}_0^Y = \widetilde{\mathcal{X}}, \\ dX_t &= f(t, X_t, u(t,Y))dt + b(t, X_t)dW'_t, \qquad X_0 = \mathcal{X}, \\ dY_t &= h(t, X_t)dt + B(t)dW''_t, \qquad\qquad Y_0 = 0. \end{aligned} \tag{3.32}$$

Since $\mu^t_{\widetilde{X}^\phi, Y^\phi}$ and $\mu^t_{\widetilde{X}^Y, Y}$ are marginal distributions of $\mu^t_{\widetilde{X}^\phi, X^\phi, Y^\phi}$ and $\mu^t_{\widetilde{X}^Y, X, Y}$, respectively, their equivalence follows as well. □

4. Conclusion. The contribution of this paper is Theorem 3.1, which represents a general property of stochastic systems that can be informally expressed in these words: whenever the optimal filter is available for a given open-loop system, the *same filter* will work optimally on the closed-loop system. One important implication of Theorem 3.1 is that any system admitting a finite-dimensional filter when in open-loop also admits a finite-dimensional filter when in closed-loop.

[1] It may seem that an alternative way of proving (3.30) and, by consequence, (3.25) could be provided by the Karandikar method [9], [3] dealing with the "pathwise definition" of the Itô integral. Our proof of (3.30) permits the traditional definition of the Itô integral and heavily uses only the equivalence of probability measures.

Acknowledgment. The authors gratefully acknowledge the careful review of an anonymous referee, who also pointed out a mistake in the original version. Due to his comments, the paper has been significantly improved.

ASYMPTOTIC PROPERTIES OF RECEDING HORIZON OPTIMAL CONTROL PROBLEMS*

KAZUFUMI ITO† AND KARL KUNISCH‡

Abstract. The asymptotic behavior of receding horizon optimal control problems with terminal cost chosen as a control Liapunov function is analyzed for regulator as well as disturbance attenuation problems. Both the continuous as well as the discrete time cases are treated. Further, the approximation of the continuous time optimal control problem by the discrete time receding horizon problems is studied.

Key words. receding horizon control, model prediction control, control Liapunov function, stabilizability, Liapunov equation

1. Introduction.

This research is devoted to the analysis of certain aspects of a receding horizon formulation to optimal control problems. To motivate the approach we consider

$$\inf \int_0^{T_\infty} f^0(x(t), u(t))\, dt \tag{1.1}$$

subject to

$$\begin{cases} \frac{d}{dt}x(t) = f(x(t), u(t)) \ \text{ for } \ t > 0, \\ x(0) = x_0, \quad u(t) \in U. \end{cases} \tag{1.2}$$

We refer to $x(\cdot)$ and $u(\cdot)$ as state and control variables and assume that $x(t) \in R^n$ and $U \subset R^m$. Under appropriate conditions, (1.1)–(1.2) admit a solution which satisfies the minimum principle (e.g., [FR, IK]):

$$\begin{cases} \frac{d}{dt}x(t) = H_p(x(t), u(t), p(t)), \quad x(0) = x_0, \\ \frac{d}{dt}p(t) = -H_x(x(t), u(t), p(t)), \quad p(T_\infty) = 0, \\ u(t) = \arg\min_{u \in U} H(x(t), u, p(t)), \end{cases} \tag{1.3}$$

where $H(x, u, p) = f^0(x, u) + f(x, u) \cdot p$. The coupled system of two-point boundary value problems with initial condition for the primal equation and terminal condition for the adjoint equation represents a significant numerical challenge in the case when T_∞ is large, and it has therefore been the focus of many research efforts. If (1.1)–(1.2) arises as the discretization of an optimal control problem governed by partial differential equations, e.g., from fluid mechanics, then the numerical realization of (1.3) may become infeasible. Alternatively, if the optimal control task is for a smaller

problem but requires a fast, possibly real-time, computation, then again it may be inadequate to aim for a solution of (1.3).

Difficulties similar to those explained above occur as well for infinite horizon problems, where $T_\infty = \infty$. Moreover, when expressing the optimality condition by means of the minimum principle (1.3), we focused on open loop solutions. Closed loop solutions for (1.1)–(1.2) are given by the Hamilton–Jacobi–Bellman equation, which is even less tractable numerically.

In view of the difficulties explained above, the question of obtaining suboptimal controls arises. One of the possibilities is given by receding horizon formulations. To briefly explain the concept, let $\{T_i\}_{i\in I}$, with $T_{i-1} < T_i$ and I an index set, be sampling points, and let T stand for the control horizon, satisfying $\max_{i\in I} |T_i - T_{i-1}| \le T \ll T_\infty$. Receding horizon suboptimal solutions to (1.1)–(1.2) are obtained by solving a sequence of auxiliary optimal control problems on the subintervals $[T_i, T_i + T]$ and utilizing the informations obtained on $[T_{i-1}, T_{i-1} + T]$ to initialize the problem on the new horizon $[T_i, T_i + T]$. If $T > T_i - T_{i-1}$, then we have overlapping horizons. If $x(T_i)$ is observed, then the receding horizon control is a state feedback. In fact, the receding horizon optimal control on $[T_i, T_{i+1}]$ is determined as a function of the state $x(T_i)$. It is obtained by solving the two-point boundary value problem (1.3) on the interval $[0, T]$, with x_0 replaced by $x(T_i)$ and an appropriately modified terminal condition for p. If $T > 0$ is small, then the optimality system on the short time interval is better conditioned and easier to solve numerically than (1.3). For surveys of this general concept for continuous as well as for discrete systems, we refer, e.g., to [ABQRW, GPM, SMR].

Receding horizon formulations have proved to be effective numerically both for optimal control problems governed by ordinary (e.g., [CA, JYH, PND]) and for partial differential equations, e.g., in the form of the instantaneous control technique for problems in fluid mechanics [CHK, CTMC, HV] and heat conduction [TU]. For discrete time systems we refer to [NP], for example. The theoretical justification of receding horizon control techniques is commonly addressed by means of the stabilization problem [ABQRW, GPM, SMR]. Assuming that $x = 0$ is a steady state for (1.2) with $u = 0$ which can be stabilized by means of an optimal control formulation (1.1) with $T_\infty = \infty$, the question of whether stabilization can also be achieved by means of a receding horizon technique is addressed. To guarantee that this is the case, different variations of receding horizon formulations were utilized. An important aspect of the analysis in each of the approaches is the monotonicity of the cost functional with respect to the time horizon. In earlier versions of the formulation of receding horizon problems, the terminal condition $x(T_i + T) = 0$ was added to the auxiliary problems; see [KG, K, MM] and the references given there. Later this condition was relaxed to requiring $x(t_i + T)$ to be contained in an appropriate neighborhood of the origin; see, e.g., [ABQRW, SMR].

In this paper, we address the stabilization problem by terminal penalty terms rather than terminal constraints; i.e., we consider a sequence of auxiliary problems of the type

$$\min \int_{T_i}^{T_i+T} f^0(x(t), u(t))\, dt + G(x(T_i + T)) \tag{1.4}$$

subject to

$$\frac{d}{dt}x(t) = f(x(t), u(t)), \quad t \geq T_i$$
$$x(T_i) = \bar{x}(T_i),$$

where $\bar{x}$ is the solution to the auxiliary problem on $[T_{i-1}, T_{i-1} + T]$. The optimal pair for (1.4) has the property that $(\bar{x}(t - T_i), \bar{u}(t - T_i))$, $t \in [T_i, T_{i+1}]$, satisfies the two-point boundary value problem (1.3) on the interval $[0, T]$, with the terminal condition $p(T) = G_x(x(T))$ and the initial condition $x(0) = \bar{x}$. The functional $G\colon R^n \to R$ will be chosen as an appropriately defined control Liapunov function (see Definition 2.1). It will be shown that the addition of the terminal cost G to the cost functional provides asymptotic stability, and hence the receding horizon strategy is a suboptimal synthesis for the optimal control problem (1.1).

Control Liapunov functions received considerable attention as a means of analyzing the stability of the control system (1.1)–(1.2), regardless of issues related to optimal control. We refer to the monograph [FK] and the references given there. The use of control Liapunov functions within the context of receding horizon control is a recent one. In [PND], control Liapunov functions were utilized as explicit constraints in the auxiliary problems to guarantee that the final state $x(T_i + T)$ lies within the level curve of the control Liapunov function that is determined by the trajectory controlled by a minimum norm control. The analysis in [JYH] utilizes control Liapunov functions as a terminal penalty as in (1.4). The stabilizing properties of the resulting receding horizon optimal control strategy are analyzed under the assumption that f possesses an exponentially stabilizable critical point.

Let us now outline the contributions of this paper. Throughout, we use only a penalty term as opposed to terminal constraints to analyze and justify the receding horizon technique. We assume that the sampling points are equidistant and that the sampling rate coincides with the time horizon so that $T = T_i - T_{i-1}$ and $T_i = i\,T$, $i = 0, 1, \ldots$. If G is a control Liapunov function (see Definition 2.1 and Theorem 2.2), then we first establish the monotonicity of the value function $V_T(x_0)$:

$$V_T(x_0) = \inf \left\{ \int_0^T f^0(x(t), u(t))\, dt + G(x(T)) \text{ subject to (1.2)} \right\}$$

with respect to T; i.e., $V_T(x_0) \leq V_{\hat{T}}(x_0) \leq G(x_0)$ for $0 \leq \hat{T} \leq T$ and $x_0 \in R^n$. Thus we have (see Theorems 2.3–2.5)

$$G(x_{i+1}) + \int_{T_i}^{T_{i+1}} f^0(\bar{x}(t), \bar{u}(t))\, dt \leq G(x_i),$$

where $x_i = \bar{x}(T_i)$, $i = 1, 2, \ldots$. This implies that the values x_i are confined to the level set $S_\alpha = \{x \in R^n : G(x) \leq G(x_0) = \alpha\}$. Assume that $f(0, 0) = 0$, $G(0) = 0$, and that $f^0(x, u) > 0$ and $G(x) > 0$ except at $(0, 0)$. Then, we have $G(x_{i+1}) < V_T(x_i) \leq G(x_i)$. Assuming further that S_α is compact, we have the existence of $\rho < 1$ such that $G(x_{i+1}) \leq \rho\, G(x_i)$ for all $x \in S_\alpha$. Hence $G(x_k) \leq \rho^k\, G(x_0) \to 0$ as $k \to \infty$, which implies asymptotic stability. Moreover, if $f^0(x, u) \geq \omega G(x)$ for some $\omega > 0$, then $G(x_{i+1}) \leq e^{-\omega T} G(x_i)$ (see Theorem 2.13). We prove that the quadratic functional $G(x) = \frac{\alpha}{2}\,|x|^2$, $\alpha > 0$, can be chosen as a control Liapunov function if the control system (1.2) is closed loop dissipative (Definition 2.6), and we argue that this is

satisfied for certain classes of dissipative equations. In general, the quadratic terminal penalty is not a Liapunov function. However, we have $V_T(x) \leq \rho_T\, G(x)$ with $\rho_T < 1$ for T sufficiently large (see Theorem 2.7) provided that the value function $V(x)$ of the infinite time horizon problem satisfies $V(x) \leq \frac{\beta}{2}\,|x|^2$ and the corresponding optimal trajectory satisfies $|x^*(t)| \leq M\, e^{-\omega\, t}|x_0|,\ \omega > 0$.

In our discussion above, it is implicitly assumed that the infinite time horizon optimal control problem admits solutions, as, for example, in the case of stabilizable steady states. We refer to this situation as the regulator case, which is discussed in sections 2.1 and 2.2, and distinguish it from the general case, which is analyzed in section 2.3. The latter applies to disturbance attenuation problems and to problems with cost functionals of tracking type. We introduce control λ-Liapunov functions (see Definition 2.8) and extend the previously described analysis to the general case (Theorems 2.10–2.12). Here the positive constant λ represents the attenuation or tracking rate given by $\lim_{T\to\infty} \frac{1}{T} \int_0^T f^0(\bar{x}(t), \bar{u}(t))\, dt$.

While section 2 treats continuous time systems, section 3 is devoted to discrete time problems. Our interest is the case when the discrete time problems arise from a finite difference approximation of (1.1)–(1.2) as, for example, the explicit Euler approximation $x_j = x_{j-1} + \Delta t\, f(x_{j-1}, u_j)$ and general one-step methods. Concepts as well as results paralleling those of the continuous time case are established. In section 4 we investigate the asymptotic behavior of continuous time systems (1.2) if the controls are determined by means of a discrete time synthesis, specifically, the one-step receding horizon formulation. This analysis is of practical importance since numerical methods for solutions of (1.3) commonly use a finite difference approximation of (1.1)–(1.2), and thus the control synthesis $\bar{u}(t)$ is computed in terms of discrete time control systems.

The final section contains examples illustrating the applicability of the concepts and results of this paper.

2. Receding horizon control problems: Continuous case. We consider the control system in R^n

$$\begin{cases} \frac{d}{dt}x(t) = f(x(t), u(t)), & t > 0, \\ x(0) = x_0, \end{cases} \tag{2.1}$$

where $f\colon R^n \times U \to R^n$ is C^2, $f(0,0) = 0$, and U is a closed subset of R^m. It is assumed that for every $x_0 \in R^n$ and $T > 0$ there exists an admissible control $u \in U_{ad} = \{u \in L^1(0,T;R^m)\colon u(t) \in U \text{ a.e.}\}$ such that (2.1) admits a solution $x \in W^{1,1}(0,T;R^n)$. In our notation, we do not indicate the dependence of U_{ad} on T. If $T = \infty$, then $U_{ad} = \{u \in L^1_{loc}(0,\infty;R^n)\colon u(t) \in U \text{ a.e.}\}$. Consider the infinite time horizon optimal control problem

$$\inf_{u\in U_{ad}} \int_0^\infty f^0(x(t), u(t))\, dt \tag{2.2}$$

subject to (2.1). Here $f^0\colon R^n \times U \to R^+$ is assumed to be C^2. We suppose further that for each $(x,p) \in R^n \times R^n$ the functional

$$u \to f^0(x,u) + p \cdot f(x,u)$$

admits a unique minimizer over U denoted by $\Psi(x,p)$ and that Ψ is continuous. A sufficient condition for the continuity of Ψ is that $f(x,u)$ is linear in u and $f^0(x,u)$

is strictly convex in u. Together with (2.2), we consider the finite horizon optimal control problems on $[0,T]$, $T>0$:

$$\inf_{u\in U_{ad}} \int_0^T f^0(x(t),u(t))\,dt + G(x(T))$$

subject to (2.1). Here $G\colon R^n \to R^+$ is a continuous function.

We shall discuss and analyze the receding horizon control strategy: it consists in successively solving the finite horizon optimal control problems on $[(k-1)T, kT]$:

$$\min_{u\in U_{ad}} \int_{(k-1)T}^{kT} f^0(x(t),u(t))\,dt + G(x(kT)) \tag{2.3}$$

subject to

$$\frac{d}{dt}x(t) = f(x(t),\ u(t)),\ x((k-1)T) = x_{k-1}, \tag{2.4}$$

where $(\bar{x}_k, \bar{u}_k)$ is an optimal pair for the kth horizon $[(k-1)T, kT]$ and $x_k = \bar{x}_k(kT)$ for $k = 1, 2, \ldots$.

2.1. Regulator case.

DEFINITION 2.1. *A nonnegative continuous function G with $G(0)=0$ is a control Liapunov function for* (2.1)–(2.2) *if for all $x_0 \in R^n$ and $T>0$ there exists a control $u = u(\cdot; x_0, T) \in U_{ad}$ such that*

$$\int_0^T f^0(x(t),u(t))\,dt + G(x(T)) \le G(x_0), \tag{2.5}$$

where $x(t)$ is a solution to (2.1).

Our definition of a control Liapunov function is adapted to (1.1)–(1.2), and it therefore involves f^0 as well as f, as opposed to the one for control systems (1.2), which only involves f [S]. The following relationship between control Liapunov functions and a certain differential inequality will be useful for providing concrete examples for control Liapunov functions.

THEOREM 2.2. *Assume that G is C^1 with $G(0)=0$ and $\{x\in R^n\colon G(x)\le\alpha\}$ is bounded for every $\alpha \ge 0$.*

(a) *If there exists a locally Lipschitz continuous function $u = \Phi(x) \in U$ such that*

$$f(x,u)\cdot G_x(x) + f^0(x,u) \le 0 \tag{2.6}$$

for all $x\in R^n$, then G is a control Liapunov function for (2.1)–(2.2).

(b) *If U is compact and if for all $x_0 \in R^n$ and $\delta>0$ there exists $\tau>0$ (which may depend on x_0 and $\delta>0$) such that*

$$|x(t)-x_0| \le \delta \ \text{ for all } t\in[0,\tau] \text{ and } u\in\mathcal{U}, \tag{2.7}$$

where $u\in\mathcal{U} = \{u\in U_{ad}\colon \int_0^\tau f^0(x(t),u(t))\,dt \le G(x_0)\}$, then (2.5) *implies that for each $x\in R^n$ there exists $u\in U$ such that* (2.6) *holds.*

Proof. (a) Choose $x\in R^n$, and let $\alpha = 2G(x)$. By assumption, the set $S = \{y\colon G(y)\le\alpha\}$ is compact, and, therefore, Φ is uniformly Lipschitz continuous on S. Hence there exists $\tau = \tau(\alpha)$ such that the closed loop system

$$\frac{d}{dt}x(t) = f(x(t),\Phi(x(t))), \quad x(0)=x_0, \tag{2.8}$$

admits a unique solution on $[0,\tau]$. Thus

$$\frac{d}{dt}G(x(t)) = f(x(t),\Phi(x(t)))\cdot G_x(x(t)) \le -f^0(x(t),u(t))$$

on $[0,\tau]$. Integrating with respect to t, we have

$$G(x(\tau)) + \int_0^\tau f^0(x(t),u(t))\,dt \le G(x_0),$$

and thus $G(x(\tau)) \le G(x_0)$ and $x(\tau)\in S$. By the continuation method, there exists a unique global solution to (2.8), and (2.5) holds.

(b) If the conclusion was false, then, by compactness of U and continuity of f, f^0, and G_x, there exist $x_0 \in R^n$ and $\delta > 0$ such that, for $|x - x_0| \le \delta$,

$$f(x,u)\cdot G_x(x) + f^0(x,u) \ge \delta \tag{2.9}$$

for all $u \in U$. Let $x(0) = x_0$, choose $\tau > 0$ such that (2.7) holds, and let u denote any control satisfying (2.5). Then, in particular, $u \in \mathcal{U}$, and consequently $|x(t) - x_0| \le \delta$ by (2.7). Thus (2.9) implies

$$G(x(\tau)) + \int_0^\tau f^0(x(t),u(t))dt \ge G(x_0) + \delta\,\tau,$$

which contradicts (2.5). □

Remark 2.1. Consider the optimal control problem

$$\begin{cases} \inf \int_0^\infty (\ell(x(t)) + \frac{1}{2}|u(t)|^2)dt, \\ \dot{x}(t) = a(x(t)) + B(x(t))u(t), \quad x(0) = x_0, \end{cases} \tag{2.10}$$

with $u(t) \in R^m$, $x(t) \in R^n$, and $\ell(0) = 0$. The Hamilton–Jacobi–Bellman equation associated to (2.10) is given by

$$a(x)\cdot V_x(x) - \frac{1}{2}|b^T(x)V_x(x)|^2 + \ell(x) = 0, \tag{2.11}$$

with $V(0) = 0$. Assuming that (2.11) admits a solution in C^1, the feedback solution to (2.10) is given by $u(x) = -B^T(x)V_x(x)$. In particular, (2.6) holds as an equality if G is chosen as the minimal value function V associated to (2.10) and $\Phi(x) = -B^T(x)V_x(x)$. In [Lu], the existence of a C^1-solution to (2.11) is proved in a neighborhood N of an equilibrium point $(x_0, 0)$ of (2.10), assuming that the linearized control system of (2.10) at $(x_0, 0)$ is stabilizable and observable. In this case, N is an invariant neighborhood of the closed loop system. In general, a global C^1-solution may not exit. However, consider the special case of system (2.10) with $a(x) = Ax - B\,B^tU_x(x)$, $B(x) = B$, where U is a convex C^1-function satisfying $U_x(0) = 0$. Setting $W = V + U$, we can write the Hamilton–Jacobi–Bellman equation (2.11) as

$$Ax\cdot W_x(x) - \frac{1}{2}\,|b^TW_x(x)|^2 + \ell(x) - Ax\cdot U_x + \frac{1}{2}\,|b^TU_x|^2 = 0.$$

Thus if (A,b) is controllable and the function $x \to \ell(x) - Ax\cdot U_x + \frac{1}{2}\,|b^TU_x|^2$ with $\ell(0) = 0$ is convex, then it can be proved [FS] that W is convex and C^1, and thus $V = W - U$ is C^1. □

For the following discussion, we introduce the value function $V_T(x_0)$ of the finite horizon optimal control problem

$$V_T(x_0) = \inf_{u \in U_{ad}} \int_0^T (f^0(x(t), u(t))\, dt + G(x(T))$$

subject to (2.1) and the value function $V(x_0)$ of the infinite horizon optimal control problem

$$V(x_0) = \inf_{u \in U_{ad}} \int_0^\infty f^0(x(t), u(t))\, dt$$

subject to (2.1).

THEOREM 2.3. *Assume that G is a control Liapunov function. Then $V(x_0) \le V_T(x_0) \le G(x_0)$ for every $T \ge 0$ and $x_0 \in R^n$.*

Proof. The assertion $V_T(x_0) \le G(x_0)$ follows directly from Definition 2.1. By repeated application of (2.5) for some $T > 0$ we construct a control $u \in L^1_{loc}(0, \infty; R^n)$ with $u(t) \in U$ for a.e. $t \in [0, \infty)$ and an associated trajectory $x \in W^{1,1}_{loc}(0, \infty; R^n)$ such that for $k \ge 1$

$$G(x(kT)) + \int_{(k-1)T}^{kT} f^0(x(t), u(t))\, dt \le G((x(k-1)T)).$$

Summation of these inequalities implies for every $k \ge 1$

$$G(x(kT)) + \int_0^{kT} f^0(x(t), u(t))\, dt \le G(x_0).$$

Thus, by the Lebesgue–Fatou lemma,

$$\lim_{k \to \infty} \int_0^{kT} f^0(x(t), u(t))\, dt = \int_0^\infty f^0(x(t), u(t))\, dt \le G(x_0),$$

and hence $V(x_0)$ is finite and $V(x_0) \le G(x_0)$. Next we note that

$$\begin{aligned} &\int_0^T f^0(x(t), u(t))\, dt + G(x(T)) \\ &= \int_0^T f^0(x(t), u(t))\, dt + V(x(T)) + G(x(T)) - V(x(T)) \end{aligned} \tag{2.12}$$

and recall the optimality principle

$$V(x_0) = \inf_{u \in U_{ad}} \left\{ \int_0^T f^0(x(t), u(t))\, dt + V(x(T)) \right\}. \tag{2.13}$$

Since $G(x(T)) \ge V(x(T))$, we have $V(x_0) \le V_T(x_0)$ by (2.12)–(2.13). ∎

THEOREM 2.4 (monotonicity). *Assume that G is a control Liapunov function for (2.1)–(2.2). If $V_T(x_0)$ is the value function of the finite horizon optimal control problem, then $V_{\hat{T}}(x_0) \ge V_T(x_0)$ for $0 \le \hat{T} \le T$.*

Proof. For every $\epsilon > 0$ there exists a pair (x, u) such that (2.1) is satisfied, $u \in U_{ad}$, and

$$V_{\hat{T}}(x_0) + \epsilon \ge \int_0^{\hat{T}} f^0(x(t), u(t))\, dt + G(x(\hat{T})).$$

From (2.5) it follows that there exists $u(t+\hat{T}) = u(t; x(\hat{T}), T-\hat{T})$ for $t \in [0, T-\hat{T}]$ such that

$$\int_{\hat{T}}^{T} f^0(x(t), u(t))\, dt + G(x(T)) \leq G(x(\hat{T})).$$

Concatenation of the solutions on $[0, \hat{T}]$ and $[\hat{T}, T]$ implies that

$$\int_0^{\hat{T}} f^0(x(t), u(t))\, dt + G(x(\hat{T})) \geq \int_0^{T} f^0(x(t), u(t))\, dt + G(x(T)) \geq V_T(x_0),$$

and hence $V_{\hat{T}}(x_0) + \epsilon \geq V_T(x_0)$. Since $\epsilon > 0$ is arbitrary, $V_{\hat{T}}(x_0) \geq V_T(x_0)$ for $0 \leq \hat{T} \leq T$. □

A result related to Theorem 2.4 is contained in [JYH].

Remark 2.2. Theorem 2.4 asserts that a sufficient condition for monotonic decay of $T \to V_T(x)$ is the control Liapunov function property of G. As will be illustrated in section 2.2, this property requires, in some sense, that G be sufficiently large. Note also that αV, with V the value function of the infinite horizon problem, is a control Liapunov function if $\alpha \geq 1$. On the other hand, if $\alpha < 1$, then αV will not be a control Liapunov function in general, as can already be seen for linear-quadratic optimal control problems in dimension one.

For this purpose, consider

$$\text{(2.14)} \qquad \begin{cases} \min \frac{1}{2} \int_0^\infty q\, x^2(t)\, dt + \int_0^\infty u^2(t)\, dt \\ \text{subject to} \\ \dot{x}(t) = ax(t) + u(t), \quad x(0) = x_0, \end{cases}$$

where $q \geq 0$. The associated Riccati equation is given by

$$\text{(2.15)} \qquad 2ap_\infty - p_\infty^2 + q = 0,$$

with solutions $p_\infty^{\pm} = a \pm \sqrt{a^2+q}$. The optimal control in feedback form is given by $u^*(t) = -p_\infty^+ x^*(t)$, where $p_\infty^+ = a + \sqrt{a^2+q}$, and the optimal value function is $V(x) = \frac{1}{2} p_\infty^+ x^2$. Consider also the finite horizon problems

$$\text{(2.16)} \qquad \begin{cases} \min \frac{1}{2} \int_0^T q\, x^2(t)\, dt + \frac{1}{2} \int_0^T u^2(t)\, dt + \frac{1}{2} g x^2(T) \\ \text{subject to} \\ \dot{x}(t) = ax(t) + u(t), \quad x(0) = x_0. \end{cases}$$

The associated Liapunov differential equation is given by

$$\text{(2.17)} \qquad \frac{d}{dt} p(t) + 2ap(t) - p^2(t) + q = 0, \quad p(T) = g.$$

If p_T is a nonnegative solution to (2.17), then $u^*(t) = -p_T(t) x^*(t)$, $t \in [0, T]$, defines a feedback solution to (2.16) and the optimal value is given by $V_T(x) = \frac{1}{2} p_T(0) x^2$. Note that the two solutions to the algebraic equation (2.15) are steady states for (2.17) with p_∞^+ unstable and p_∞^- stable. All trajectories of (2.17) are monotone and nonintersecting. In particular, if $g \geq p_\infty^+$, then $p_\infty^+ \leq p_T(0) < p_{\hat{T}}(0)$ if $0 \leq \hat{T} < T$. If, on the other hand, $g \in (-p_\infty^-, p_\infty^+)$, then $p_{\hat{T}}(0) < p_T(0)$ for $0 \leq \hat{T} < T$. □

The following main result for receding horizon problems can be obtained from the definition of a control Liapunov function and Theorems 2.3–2.4.

THEOREM 2.5. *Assume that G is a control Liapunov function and that $(\bar{x}, \bar{u})$ is a solution to the receding horizon problem* (2.3)–(2.4) *on* $[0, \infty)$. *Then we have*

$$G(x_k) + \int_{T_{k-1}}^{T_k} f^0(\bar{x}(t), \bar{u}(t))\, dt \le G(x_{k-1})$$

and $V_T(\bar{x}(t)) \le V_T(x_{k-1})$ *for* $t \in [T_{k-1}, T_k]$ *and* $k = 1, 2, \ldots$. *Thus*

$$G(x_k) + \int_0^{kT} f^0(\bar{x}(t), \bar{u}(t))\, dt \le G(x_0)$$

for all $k \ge 1$. *Moreover, if we assume that* $V_T(x) \le \rho_T\, G(x)$ *for some* $\rho_T \le 1$ *and* $T \ge 0$ *independently of* $x \in R^n$, *then* $G(x_k) \le \rho_T^k\, G(x_0)$ *for all* $k \ge 1$.

Proof. The second assertion follows from the optimality principle

$$\int_{T_{k-1}}^{t} f^0(t, \bar{x}(t), \bar{u}(t))\, dt + V_{T_k - t}(x(t)) = V_T(x_{k-1}), \quad t \in [T_{k-1}, T_k],$$

and the monotonicity of V_T. If $V_T(x) \le \rho_T\, G(x)$, then $G(x_1) \le V_T(x_0) \le \rho_T\, G(x_0)$ since $f^0 \ge 0$. The final claim then follows by iteration. □

Note that if, in addition to the assumptions of Theorem 2.5, the level-set $S_{x_0} = \{x : g(x) \le G(x_0)\}$ is bounded, $G(x) \ne 0$ for $x \ne 0$, and $\rho_T < 1$, then $\lim_{k\to\infty} x_k = 0$.

From Theorem 2.5 we conclude that the receding horizon trajectory $\bar{x}(t)$ is confined in the set $\{x \in R^n : V_T(x) \le V(x_0)\}$. Concerning the assumption that $\rho_T \le 1$ in Theorem 2.5, note that ρ_T is nonincreasing with respect to T by Theorem 2.4. We refer to the following remark and section 2.2 for a discussion of cases which allow $\rho_T < 1$.

Remark 2.3. Let us briefly comment on a localization of the concept of a control Liapunov function. For $\alpha > 0$, we define the level-set $S_\alpha = \{x\colon G(x) \le \alpha\}$. A nonnegative function G with $G(0) = 0$ is called a local (by α)-control Liapunov function for (2.1)–(2.2) if for all $x \in S_\alpha$ and $T > 0$ there exists a control $u(\cdot; x, T) \in U_{ad}$ such that (2.5) holds. Theorems 2.3–2.5 can be appropriately modified to hold for local-control Liapunov functions if x, respectively, x_0 are chosen in S_α. If S is a compact subset of S_α not containing 0, and $f^0(x, u) > 0$ and $G(x) > 0$ for $x \ne 0$, then there exists $\rho_T < 1$ such that $G(x(T)) \le \rho_T\, G(x_0)$ for every $x_0 \in S$. In fact, if $x_0 \ne 0$, we have $f^0(\bar{x}(t), \bar{u}(t)) \ne 0$ for t in a subinterval of $[0, T]$, and hence $G(x(T)) < G(x_0)$. Compactness of S implies the existence of $\rho_T < 1$ such that $G(x(T)) \le \rho_T\ G(x_0)$ for all $x_0 \in S$.

2.2. Quadratic terminal penalty. In this section, we discuss the case when $G(x) = \frac{\alpha}{2}\,|x|^2,\ \alpha > 0$, serves as a control Liapunov function.

DEFINITION 2.6. *The control system* (2.1)–(2.2) *is called closed loop dissipative if there exists a locally Lipschitzian feedback law* $u = -K(x) \in U$ *such that*

$$f(x, -K(x)) \cdot (\alpha\, x) + f^0(x, -K(x)) \le 0$$

for some $\alpha > 0$ *and all* $x \in R^n$.

If (2.1)–(2.2) is closed loop dissipative, then $\frac{\alpha}{2}|x|^2$ is a control Liapunov function for (2.1)–(2.2) by Theorem 2.2. In the case when (2.1)–(2.2) is not closed loop dissipative, we have the following result, which allows us to use $\frac{\alpha}{2}\,|x|^2$ as a control Liapunov function.

THEOREM 2.7. *Let $G(x) = \frac{\alpha}{2}|x|^2$, and let $V(x)$ and $V_T(x)$ be the infinite and the finite horizon value functionals, respectively. We assume that for every $x \in R^n$ there exists an admissible control $u^*(t) = u^*(t;x)$ such that*

$$V(x^*(T)) + \int_0^T f^0(x^*(t), u^*(t))\, dt = V(x)$$

for all $T \geq 0$ and that the corresponding trajectory $x^*(t)$ satisfies $|x^*(t)| \leq M\, e^{-\omega t}|x|$, with $M \geq 0$, $\omega > 0$, independently of $t \geq 0$ and $x \in R^n$. Then

$$V_T(x) \leq V(x) + \frac{M^2\alpha}{2} e^{-2\omega T}|x|^2.$$

Moreover, if $V(x) \leq \frac{\beta}{2}\,|x|^2$, then

$$V_T(x) \leq \left(\frac{\beta}{2} + \frac{M^2\alpha}{2} e^{-2\omega T}\right)|x|^2 \leq \left(\frac{\beta}{\alpha} + M^2 e^{-2\omega T}\right) G(x).$$

Proof. Note that

$$V_T(x) \leq \int_0^T f^0(x^*(t), u^*(t))\, dt + V(x^*(T)) + G(x^*(T)) - V(x^*(T)) \leq V(x) + G(x^*(T)),$$

which implies the first assertion. The second assertion simply follows from the first one. ∎

Theorem 2.5 implies that for every $\alpha > \beta$ there exists $\bar{T} > 0$ such that for $T \geq \bar{T}$ we have $V_T(x) \leq \rho_T\, G(x)$ with $\rho_T < 1$, and thus Theorem 2.5 applies for $T \geq \bar{T}$.

2.3. General case. In this section, we discuss the case when the value functional $V(x)$ of the infinite horizon optimal control problem (2.1)–(2.2) does not exist for every $x \in X$. This includes, for example, the disturbance attenuation problem: consider the problem (2.1)–(2.2) with the linear control system $f = Ax + Bu + d$ and quadratic performance $f^0 = |x|^2 + |u|^2$, where a nonzero constant vector d denotes the disturbance. In order to deal with this case, the following two approaches suggest themselves. One of them is the introduction of a discounted cost functional

$$\min_{u \in U_{ad}} \quad \int_0^\infty e^{-\rho t}\, f^0(x(t), u(t))\, dt, \quad \rho > 0.$$

The other is the ergodic cost functional

$$\min_{u \in U_{ad}} \quad \lim_{T \to \infty} \frac{1}{T} \int_0^T f^0(x(t), u(t))\, dt.$$

We discuss the ergodic cost functional and return to the discounted cost functional at the end of this subsection.

DEFINITION 2.8. *A nonnegative continuous function G is called a control λ-Liapunov function for (2.1)–(2.2) if for every $x_0 \in R^n$ and $T > 0$ there exists a control $u = u(\cdot; x, T) \in U_{ad}$ satisfying*

$$\int_0^T f^0(x(t), u(t))\, dt + G(x(T)) \leq G(x_0) + \lambda T, \tag{2.18}$$

where $x(\cdot)$ is a solution to (2.1).

We have the following relationship of control λ-Liapunov functions to a differential inequality.

THEOREM 2.9. *Assume that G is a nonnegative C^1-function and that $\{x \in R^n : G(x) \le \alpha\}$ is bounded for every $\alpha > 0$.*

(a) *If there exists a locally Lipschitzian function $u = \Phi(x) \in U$ such that for all $x \in R^n$*

$$f(x,u) \cdot G_x(x) + f^0(x,u) \le \lambda, \tag{2.19}$$

then G is a control λ-Liapunov function for (2.1)–(2.2).

(b) *If U is compact and for all $x_0 \in R^n$ and $\delta > 0$ there exists a $\tau = \tau_{\delta,x_0} > 0$ such that*

$$|x(t) - x_0| \le \delta \quad \text{for all } t \in [0,T] \text{ and } u \in \mathcal{U},$$

where $\mathcal{U} = \{u \in U_{ad} : \int_0^\tau f^0(x(t),u(t))\,dt \le G(x) + \lambda T\}$, then (2.18) *implies that for each $x \in R^n$ there exists $u \in U$ such that* (2.19) *holds.*

The proof is analogous to that for Theorem 2.2, and it is therefore omitted.

THEOREM 2.10 (monotonicity). *Assume that G is a control λ-Liapunov function for* (2.1)–(2.2). *Then $V_{\hat{T}}(x_0) - \lambda T \ge V_T(x_0) - \lambda \hat{T}$ for $0 \le \hat{T} \le T$.*

The proof is analogous to that of Theorem 2.3.

THEOREM 2.11. *Assume that G is a control λ-Liapunov function and $f^0(x,u) \ge \omega G(x)$ for some $\omega > 0$ and all $x \in R^n$ and $u \in U$. Then if $(u(t),x(t))$ minimizes $\int_0^T f^0(x(t),u(t))\,dt + G(x(T))$ over $u \in U_{ad}$ subject to* (2.1), *we have*

$$G(x(T)) \le e^{-\omega T}(G(x_0) + \lambda T) + \lambda\left(\frac{1}{\omega} - e^{-\omega T}\left(T + \frac{1}{\omega}\right)\right).$$

Proof. By the optimality principle,

$$\int_t^\tau f^0(x(s),u(s))\,ds + V_{T-\tau}(x(\tau)) = V_{T-t}(x(t)) \tag{2.20}$$

for every $0 \le t \le \tau \le T$. From (2.20) it follows that $t \to g(t) = V_{T-t}(x(t))$ is a $W^{1,1}$-function. By Definition 2.8 and the lower bound on f^0 it follows that

$$\omega \int_t^\tau V_{T-s}(x(s))\,ds + V_{T-\tau}(x(\tau)) \le V_{T-t}(x(t)) + \omega\lambda \int_t^\tau (T-s)\,ds,$$

and, consequently,

$$\omega g(t) + \frac{d}{dt}\,g(t) \le \omega\lambda(T-t) \text{ for a.e. } t \in [0,T].$$

Multiplying by $e^{\omega t}$ and integrating on $[0,T]$ imply

$$e^{\omega T} g(T) - g(0) \le \lambda\left(\frac{1}{\omega}e^{\omega T} - T - \frac{1}{\omega}\right).$$

We conclude that

$$G(x(T)) \le e^{-\omega T} V_T(x_0) + \lambda\left(\frac{1}{\omega} - e^{-\omega T}\left(T + \frac{1}{\omega}\right)\right),$$

and the claim follows since $V_T(x_0) \le G(x_0) + \lambda T$. □

THEOREM 2.12 (stability). *Assume that $(\bar{x}, \bar{u})$ is a solution to the receding horizon problem* (2.3)–(2.4). *If G is a control λ-Liapunov function, then*

$$G(x_k) + \int_0^{kT} f^0(\bar{x}(t), \bar{u}(t))\, dt - \lambda k T \le G(x_0) \tag{2.21}$$

for all $k = 1, 2, \ldots$. Moreover, if the assumption of Theorem 2.11 *holds, then*

$$\begin{aligned} G(x_k) &\le e^{-k\omega T} G(x_0) \\ &+ \left(\lambda T e^{-\omega T} + \lambda \left(\frac{1}{\omega} - e^{-\omega T} \left(T + \frac{1}{\omega} \right) \right) \right) \frac{1 - e^{-k\omega T}}{1 - e^{-\omega T}}. \end{aligned} \tag{2.22}$$

Note that Theorem 2.12 implies that

$$\lim_{\tau \to \infty} \frac{1}{\tau} \int_0^{\tau} f^0(\bar{x}(t), \bar{u}(t))\, dt \le \lambda$$

and that $\{G(x_k)\}$ is uniformly bounded in k.

Proof of Theorem 2.12. Inequality (2.21) follows by repeated application of Definition 2.8. An induction argument and Theorem 2.11 imply (2.22). □

For the particular case when $\lambda = 0$, we obtain the following theorem as a corollary to Theorems 2.11 and 2.12.

THEOREM 2.13. *Under the assumptions of Theorem* 2.11 *with $\lambda = 0$, we have*

$$G(x(T)) \le e^{-\omega T} V_T(x) \le e^{-\omega T} G(x_0).$$

Moreover, if $(\bar{x}, \bar{u})$ denotes a solution to the receding horizon problem (2.3)–(2.4), *then*

$$G(x_k) \le e^{-k\omega T} G(x_0).$$

Remark 2.4. We discuss the particular case when the control λ-Liapunov function can be taken as a quadratic penalty function $G(x) = \frac{\alpha}{2}|x|^2$, $\alpha > 0$.

Consider (2.1) with right-hand side

$$f(x, u) = \tilde{f}(x, u) + d, \tag{2.23}$$

where $d \in R^n$. Assume that (2.1)–(2.2) with f replaced by $\tilde{f}$ is uniformly closed loop dissipative; i.e., there exist $\alpha > 0$, $\kappa > 0$, and a locally Lipschitz continuous feedback law $u = -K(x) \in U$ such that

$$\tilde{f}(x, -K(x)) \cdot (\alpha x) + f^0(x, -K(x)) \le -\kappa |x|^2$$

for all $x \in R^n$. Then

$$f(x, -K(x)) \cdot (\alpha x) + f^0(x, -K(x)) \le -\kappa |x|^2 + \alpha\, dx \le \frac{\alpha^2}{4\kappa} d^2,$$

and hence $G(x) = \frac{\alpha}{2}|x|^2$ is a control λ-Liapunov function with $\lambda = \frac{\alpha^2}{4\kappa} d^2$ for (2.1), (2.2) with f given by (2.23).

Right-hand sides of the type (2.23) occur in disturbance attenuation and in tracking-type problems. As for the latter, assume that A is exponentially stable, and consider for $z \in R^n$

$$\begin{cases} \inf \frac{1}{2} \int_0^T |y(t) - z|^2 dt + \frac{\gamma}{2} \int_0^T |u(t)|^2 dt, \\ \frac{d}{dt} y(t) = Ay(t) + Bu(t), \quad y(0) = y_0. \end{cases}$$

Then, setting $x = y - z$, we find the equivalent problem

$$\begin{cases} \inf \frac{1}{2}\int_0^T |x(t)|^2 dt + \frac{\gamma}{2}\int_0^T |u(t)|^2 dt, \\ \frac{d}{dt}x(t) = Ax(t) + Bu(t) + Az, \quad x(0) = y_0 + z, \end{cases}$$

where the right-hand side is of the form (2.23).

Remark 2.5. Let us briefly return to the discounted cost functional formulation. In this case, a nonnegative functional G is called a d-control λ-Liapunov function if there exists $\lambda > 0$ such that for every $x \in R^n$ and $T > 0$ there exists a control $u = u(\cdot; x, T) \in U_{ad}$ satisfying

$$\int_0^T e^{-\lambda t} f^0(x(t), u(t))\, dt + e^{-\lambda T} G(x(T)) \leq G(x_0), \tag{2.24}$$

where $x(\cdot)$ is a solution to (2.1). For d-control λ-Liapunov functionals, the analogues of Theorems 2.2–2.4 can readily be derived. The receding horizon control strategy based on the discounted cost functional requires us to successively solve

$$\min_{u \in U_{ad}} \int_{(k-1)T}^{kT} e^{\lambda t} f^0(x(t), u(t))\, dt + e^{-\lambda T} G(x(kT)) \tag{2.25}$$

subject to $\frac{d}{dt}x(t) = f(x(t), u(t)), x((k-1)T) = x_{k-1}$, where $(\bar{x}_k, \bar{u}_k)$ is the optimal pair for the kth horizon $[(k-1)T, kT]$, and $x_k = \bar{x}_k(kT)$. Assuming existence of solutions $(\bar{x}_k, \bar{u}_k)$ to (2.25) it follows from (2.25) that $\int_0^\infty e^{-\lambda t} f^0(\bar{x}(t), \bar{u}(t))\, dt \leq G(x_0)$, provided that G is a d-control λ-Liapunov functional. Here $(\bar{x}, \bar{u})$ arises from concatenation of the solutions $(\bar{x}_k, \bar{u}_k)$ on $[(k-1)T, kT]$. Comparing the estimate $\int_0^\infty e^{-\lambda t} f^0(\bar{x}(t), \bar{u}(t))\, dt \leq G(x_0)$ to the asymptotic properties that were obtained in Theorem 2.12 for the ergodic formulation, the discounted cost formulation gives weaker properties.

3. Receding horizon control problems: Discrete time. In this section, we consider the discrete infinite time horizon problem

$$\inf_{u_j \in U} \sum_{j=1}^{\infty} \Delta t\, f^0(x_{j-1}, u_j) \tag{3.1}$$

subject to

$$x_j = x_{j-1} + \Delta t\, F(x_{j-1}, u_j), \quad x_0 \text{ given}, \tag{3.2}$$

with $\Delta t > 0$. Here (3.2) represents a finite difference discretization to (2.1), where the continuous function $F\colon R^n \times U \to R^n$ may also depend on Δt. For example, in the case of the explicit Euler rule,

$$F(x, u) = f(x, u),$$

and in the case of the implicit midpoint rule,

$$F(x, u) = f(\hat{x}, u),$$

where $\hat{x} \in R^n$ satisfies

$$\hat{x} - x = \frac{\Delta t}{2} f(\hat{x}, u).$$

The minimal value functional associated to (3.1)–(3.2) will be denoted by $V(x)$. Together with (3.1)–(3.2) we consider the finite time problem

$$\inf_{u_j \in U} \sum_{j=1}^{N} \Delta t\ f^0(x_{j-1}, u_j) + G(x_N) \tag{3.3}$$

subject to (3.2). Here $N \in \mathbb{N}$, and $G\colon R^n \to R^+$ is a continuous function. The value function associated to (3.3) is denoted by $V_N(x)$. The receding horizon control approach to (3.1)–(3.2) consists in iteratively solving problem (3.3):

$$\min_{u_j \in U} \sum_{j=(k-1)N+1}^{kN} \Delta t\ f^0(x_{j-1}, u_j) + G(x_{kN}) \tag{3.4}$$

subject to

$$x_j = x_{j-1} + \Delta t\ F(x_{j-1}, u_j),\ x_{(k-1)N} = \bar{x}_{(k-1)N}, \tag{3.5}$$

where $(\bar{x}_{(k-1)N+j}, \bar{u}_{(k-1)N+j})$, $1 \le j \le N$, is the sequence of optimal pairs for the kth optimal control problem, where $k \in \mathbb{N}$.

3.1. Regulator case.

DEFINITION 3.1. *A nonnegative continuous functional G with $G(0) = 0$ is called a discrete control Liapunov functional if for all $x_0 \in R^n$ there exists $u \in U$ such that*

$$\Delta t\ f^0(x_0, u) + G(x_0 + \Delta t\, F(x_0, u)) \le G(x_0). \tag{3.6}$$

If G is a discrete control Liapunov functional, then for every $x_0 \in R^n$ and $N \in \mathbb{N}$ there exists a sequence $\{u_j\}_{j=1}^N$ in U such that

$$\sum_{j=1}^{N} \Delta t\ f^0(x_{j-1}, u_j) + G(x_N) \le G(x_0), \tag{3.7}$$

where $\{x_j\}_{j=1}^N$ satisfies (3.2). In fact, (3.6) implies for each x_{j-1} the existence of $u_j \in U$, $j = 1, \dots, N$, such that

$$\Delta t\ f^0(x_{j-1}, u_j) + G(x_{j-1} + \Delta t\ F(x_{j-1}, u_j)) \le G(x_{j-1}).$$

Summation with respect to j and (3.2) imply (3.7).

The following result is the analogue to Theorem 2.2 for discrete control Liapunov functions.

THEOREM 3.2. *Assume that G is a nonnegative C^1-function with $G(0) = 0$.*

(a) *If G is a convex discrete control Liapunov function, then for each $x \in R^n$ there exists $u \in U$ such that*

$$F(x, u) \cdot G_x(x) + f^0(x, u) \le 0.$$

(b) *Assume that G_x and F are Lipschitz continuous, with $F(0, 0) = 0$, and that there exists a Lipschitz continuous function $u = \phi(x) \in U$, with $\phi(0) = 0$, such that*

$$F(x, \phi(x)) \cdot G_x(x) + f^0(x, \phi(x)) \le -\kappa |x|^2$$

for some $\kappa > 0$ independent of $x \in R^n$. Then there exists $\bar{\Delta} > 0$ such that G is a discrete control Liapunov function for $\Delta t \le \bar{\Delta}$.

Proof. (a) follows directly from (3.6) and the convexity of G. To verify (b), choose $x \in R^n$ and $u = \phi(x)$. Let $K_i, i = 1, 2, 3$, denote the Lipschitz constants of F, ϕ, and G_x. By the Lagrange form of the mean value theorem we find

$$\begin{aligned}
&\Delta t\ f^0 c(x,u) + G(x + \Delta t\ F(x,u)) - G(x) \\
&= \Delta t\ f^0(x,u) + \Delta t\, G_x(x) \cdot F(x,u) \\
&\qquad + \Delta t \int_0^1 (G_x(x + s\Delta t\, F(x,u)) - G_x(x)) F(x,u) ds,
\end{aligned}$$

and, therefore,

$$\begin{aligned}
&\Delta t\ f^0(x,u) + G(x + \Delta t\, F(x,u)) - G(x) \\
&\le -\kappa \Delta t |x|^2 + \frac{(\Delta t)^2}{2} K_1^2 K_3 (|x|^2 + |\phi(x)|^2) \le \Delta t \left(\frac{\Delta t}{2} K_1^2 K_3 (1 + K_2^2) - \kappa \right) |x|^2,
\end{aligned}$$

and the claim follows. ∎

THEOREM 3.3. *Assume that G is a discrete control Liapunov function. Then $V(x_0) \le V_N(x_0) \le V_{\hat{N}}(x_0) \le G(x_0)$ for all $x_0 \in R^n$ and $0 \le \hat{N} \le N$.*

The proof is similar to that of Theorems 2.3 and 2.4, and it is therefore omitted. For the discrete receding horizon problem, we find the following theorem by the argument implying (3.7).

THEOREM 3.4. *Assume that G is a discrete Liapunov function and that $\{(\bar{x}_{j-1}, \bar{u}_j)\}_{j=1}^{kN}$ is a solution to the discrete receding horizon problem. Then we have*

$$\sum_{j=1}^{kN} \Delta t\ f^0(\bar{x}_{j-1}, \bar{u}_j) + G(\bar{x}_{kN}) \le G(x_0).$$

3.2. Quadratic terminal penalty. We discuss situations in which $G(x) = \frac{\alpha}{2}|x|^2, \alpha > 0$, can serve as a discrete control Liapunov functional.

DEFINITION 3.5. *The discrete infinite time horizon problem* (3.1)–(3.2) *is closed loop dissipative if there exist a Lipschitz continuous feedback law $u = -K(x) \in U$, for $x \in R^n$, and $\kappa > 0$, $\alpha > 0$ such that*

$$F(x, -K(x)) \cdot (\alpha x) + f^0(x, -K(x)) \le -\kappa |x|^2$$

for all $x \in R^n$.

If (3.1)–(3.2) is closed loop dissipative, F is Lipschitz continuous, $F(0,0) = 0$, and $K(0) = 0$, then $G(x) = \frac{\alpha}{2}|x|^2$ is a discrete Liapunov functional whenever Δt is sufficiently small. This follows immediately from Theorem 3.2 (b). In the case when (3.1)–(3.2) is not closed loop dissipative, the following result gives sufficient conditions which imply that $\frac{\alpha}{2}|x|^2$ is a discrete control Liapunov function.

THEOREM 3.6. *Let $G(x) = \frac{\alpha}{2}|x|^2$, and assume that there exist $M \ge 1$ and $\rho > 0$ such that for every $x_0 \in R^n$ there is an optimal control $\{u_j^*\}_{j=1}^{\infty}$ with associated states $\{x_j^*\}_{j=1}^{\infty}$ satisfying $|x_j^*| \le M\, e^{-\rho j} |x_0|$ for $j = 1, 2, \ldots$. If, moreover, $V(x) \le \frac{\beta}{2}|x|^2$ for some $\beta > 0$, then $V_N(x_0) \le (\frac{\beta}{2} + M^2 e^{-2\rho N}) G(x_0)$ for every $x_0 \in R^n$ and $N \ge 1$. Further, there exists $\bar{N} > 0$ such that for all $N \ge \bar{N}$*

$$V_N(x_0) \le \rho_N G(x_0)$$

for some $\rho_N < 1$ independent of $x \in R^n$.

Proof. For every N we have

$$\begin{aligned} V_N(x_0) &= \Delta t \sum_{j=1}^{N} f^0(x^*_{j-1}, u^*_j) + G(x^*_N) - V(x^*_N) + V(x^*_N) \\ &\le V(x_0) + G(x^*_N) = V(x_0) + \frac{\alpha}{2} M^2 e^{-2\rho N} |x_0|^2 \le \left(\frac{\beta}{2\alpha} + M^2 e^{-2\rho N} \right) G(x_0). \end{aligned}$$

The first assertion is a consequence of this estimate. The second one follows directly from the first. ∎

3.3. General case. Here we discuss the ergodic case for the discrete receding horizon problem.

DEFINITION 3.7. *A nonnegative continuous function G is called a discrete control λ-Liapunov functional for* (3.1)–(3.2) *if for every $x \in R^n$ there exists $u \in U$ satisfying*

$$\Delta t\, f^0(x,u) + G(x + \Delta t\, F(x,u)) \le G(x) + \lambda\, \Delta t. \tag{3.8}$$

If G is a discrete control λ-Liapunov functional for (3.1)–(3.2), then for every $x \in R^n$ and $N \in \mathbb{N}$ there exists a sequence $\{u_j\}_{j=1}^N$ in U such that

$$\sum_{j=1}^{N} \Delta t\, f^0(x_{j-1}, u_j) + G(x_N) \le G(x_0) + \lambda\, N \Delta t, \tag{3.9}$$

where $\{x_j\}_{j=1}^N$ satisfies (3.2). Moreover, we have

$$V_N(x_0) - \lambda\, \hat{N} \Delta t \le V_{\hat{N}}(x_0) - \lambda\, N \Delta t \tag{3.10}$$

for $0 \le \hat{N} \le N$. Under appropriate conditions, one also obtains the analogue of Theorem 3.2 relating (3.8) to $F(x,u) \cdot G_x(x) + f^0(x,u) \le \lambda$. We shall not pursue this aspect and shall rather turn to the asymptotic behavior of the discrete receding horizon problem. We require the following result.

THEOREM 3.8. *Assume that G is a discrete control λ-Liapunov functional and that $f^0(x,u) \ge \omega G(x)$ for some $\omega \in (0,1]$ independently of $x \in R^n$ and $u \in U$. Then if $\{(x_{j-1}, u_j)\}_{j=1}^N$ is a solution to* (3.3)*, we have*

$$G(x_N) \le e^{-\omega N \Delta t}(G(x_0) + \lambda N \Delta t) + \lambda^{\omega \Delta t} \left[\frac{1}{\omega} - e^{-\omega N \Delta t} \left(N \Delta t + \frac{1}{\omega} \right) \right].$$

Proof. For every $0 < N_1 \le N_2 \le N$ we have

$$\sum_{J=N_1}^{N_2} \Delta t\, f^0(x_{j-1}, u_j) + \sum_{j=N_2+1}^{N} \Delta t\, f^0(x_{j-1}, u_j) + G(x_N) = V_N(x_0),$$

and hence by the optimality principle

$$\sum_{j=N_1}^{N_2} \Delta t\, f^0(x_{j-1}, u_j) + V_{N-N_2}(x_{N_2}) = V_{N-N_1+1}(x_{N_1-1}),$$

and by assumption

$$\omega \sum_{j=N_1}^{N_2} \Delta t\, G(x_{j-1}) + V_{N-N_2}(x_{N_2}) \le V_{N-N_1+1}(x_{N_1-1}).$$

Using (3.9) with $x = x_{j-1}$, we find

$$\omega \sum_{j=N_1}^{N_2} \Delta t\, V_{N-j+1}(x_{j-1}) + V_{N-N_2}(x_{N_2}) \le V_{N-N_1+1}(x_{N_1-1}) + \omega\lambda(\Delta t)^2 \sum_{j=N_1}^{N_2} (N-j+1).$$

Setting $r_j = V_{N-j}(x_j)$ and $N_1 = N_2$ implies that

$$\omega\Delta t\, r_{j-1} + r_j - r_{j-1} \le \omega\lambda(\Delta t)^2(N-j+1).$$

Multiplying with $e^{\omega j\Delta t}$, summing with respect to j, and rearranging terms give

$$\begin{aligned} e^{\omega\Delta t N} r_N \quad &+ \quad (\omega\Delta t - 1)e^{\omega\Delta t} r_0 + (\omega\Delta t + e^{-\omega\Delta t} - 1)\sum_{j=2}^{N} e^{\omega j\Delta t} r_{j-1} \\ &\le \quad \omega\lambda(\Delta t)^2 \sum_{j=1}^{N} e^{\omega j\Delta t}(N-j+1), \end{aligned}$$

and, consequently,

$$\begin{aligned} r_N \quad &\le e^{-\omega(N-1)\Delta t}(1-\omega\Delta t) r_0 + \omega\lambda(\Delta t)^2 e^{-\omega N\Delta t} \sum_{j=1}^{N} e^{\omega j\Delta t}(N-j+1) \\ &\le e^{-\omega N\Delta t} r_0 + \lambda e^{\omega\Delta t}\left[\frac{1}{\omega} - e^{-\omega N\Delta t}\left(N\Delta t + \frac{1}{\omega}\right)\right]. \end{aligned}$$

By the definition of r_j and (3.9), the last inequality implies

$$G(x_N) \le e^{-\omega N\Delta t}(G(x_0) + \lambda N\Delta t) + \lambda e^{\omega\Delta t}\left[\frac{1}{\omega} - e^{-\omega N\Delta t}\left(N\Delta t + \frac{1}{\omega}\right)\right]. \qquad \square$$

THEOREM 3.9. *Let $\{\bar{x}_{j-1}, \bar{u}_j\}_{j=1}^{\infty}$ denote a solution to the discrete receding horizon problem* (3.4)–(3.5)*. Then, under the assumptions of Theorem* 3.8*, we have*

$$G(x_{kN}) + \sum_{j=1}^{kN} \Delta t\; f^0(x_{j-1}, u_j) \le G(x_0) + \lambda kN\Delta t \tag{3.11}$$

and

$$G(x_{kN}) \le e^{-\omega kN\Delta t} G(x_0) + \mu\, \frac{1 - e^{-k\omega N\Delta t}}{1 - e^{-\omega N\Delta t}} \tag{3.12}$$

for all $k = 1, 2, \dots$, where $\mu = \lambda N\Delta t\, e^{-\omega N\Delta t} + \lambda\, e^{\omega N\Delta t}[\frac{1}{\omega} - e^{-\omega N\Delta t}(N\Delta t + \frac{1}{\omega})]$.

Theorem 3.9 implies that

$$\lim_{k\to\infty} \frac{1}{kN} \sum_{j=1}^{kN} f^0(x_{j-1}, u_j) \le G(x) + \lambda$$

and that $\{G(x_{kN})\}_{k=1}^{\infty}$ is bounded.

Proof of Theorem 3.9. Inequality (3.11) follows from (3.9). An induction argument over k utilizing the estimate given in Theorem 3.8 implies (3.12). $\square$

4. Approximation and stabilization by the discrete receding horizon problem. In this section, we therefore analyze some aspects of controlling (2.1) by means of the one-step discrete receding horizon problems

$$\min_{u\in U} \{\Delta t\ f^0(x_0,u) + G(x_0 + \Delta t\, F(x_0,u))\}. \tag{4.1}$$

Here $x_1 = x_0 + \Delta t\, F(x_0,u)$ is a one-step approximation to $\frac{d}{dt}x(t) = f(x(t),u(t))$, $x(0) = x_0$, with step-size Δt. In the notation of section 3, we have $N = 1$. One of the motivations for considering this case is given by large scale optimal control problems; see, e.g., [CHK, CTMC] and the references given there. Computing the solutions to (2.3) or (3.3) can still be very expensive, and one therefore resorts to the extreme case consisting of the one-step receding horizon strategy.

We first consider the case when the full state $x(t)$ of (2.1) can be observed. Let G be a locally Lipschitz continuous control Liapunov function for (2.1)–(2.2) such that level-sets $\{x\colon G(x) \le \alpha\}, \alpha > 0$, are bounded in R^n. We assume that for every $\alpha > 0$ there exists a continuous nondecreasing function ϵ with $\epsilon(0) = 0$ such that for each x_0 with $G(x_0) \le \alpha$

$$|\bar u(t) - u| + |\bar x(t) - x_0| \le \epsilon(\Delta t) \ \text{ for all } \ t \in [0,\Delta t]. \tag{4.2}$$

Here u minimizes (4.1), and $(\bar x, \bar u)$ is an optimal pair for the finite horizon problem

$$\min \int_0^{\Delta t} f^0(x(t),u(t))\,dt + G(x(\Delta t)) \tag{4.3}$$

subject to $\frac{d}{dt}\,x(t) = f(x(t),u(t)), x(0) = x_0$. It is further assumed that there exists $\omega > 0$ such that

$$V_{\Delta t}(x_0) \le (1 - \omega\Delta t)G(x_0) \ \text{ for all } \ x_0 \in R^n \tag{4.4}$$

and all sufficiently small $\Delta t > 0$. Finally, we shall assume that $U \subset R^m$ is bounded. In the two theorems below, this requirement can be replaced by assuming that

$$\big\{u = \arg\min\,[\Delta t f^0(x_0,u) + G(x_0 + \Delta t F(x_0,u))]\colon \Delta t \in [0,1], x_0 \in S\big\} \tag{4.5}$$

is a bounded subset of R^m whenever S is bounded in R^n. Note that (4.5) can be verified, for example, if f^0 is quadratic in x and u, G is quadratic, and F is affine in u.

We are now prepared to analyze the following strategy: given x_{k-1}, solve (4.1) with initial condition $x_0 = x_{k-1}$ for u_k, then advance (2.1) on $[(k-1)\Delta t, k\Delta t]$ by means of

$$\frac{d}{dt}\,x(t) = f(x(t),u_k), \quad x((k-1)\Delta t) = x_{k-1}, \tag{4.6}$$

and set $x_k = x(k\Delta t)$. Henceforth we put $t_k = k\Delta t$.

THEOREM 4.1. *Assume that G is a locally Lipschitz continuous control Liapunov function with bounded level-sets, that* (4.2) *and* (4.4) *hold, and that U is bounded. Then for every $r > 0$ there exists $C > 0$ such that, for all sufficiently small Δt and all k,*

$$G(x_k) \le (1 - \omega\Delta t)^k G(x_0) + \frac{C}{\omega}\epsilon(\Delta t)$$

and

$$\int_0^{k\Delta t} f^0(x(t),u(t))\,dt \le (1-\omega\Delta t)G(x_0) + \frac{C\,\epsilon(\Delta t)}{\omega(1-\omega\Delta t)^{k-1}}$$

whenever $|x_0| \le r$. *Here* $x(\cdot)$ *is the concatenation of the solutions to* (4.6), $u(t) = u_k$ *on* $[t_{k-1}, t_k]$, *and* $u_k \in U$ *minimizes* $[\Delta t\, f^0(x_{k-1},u) + G(x_{k-1} + F(x_{k-1},u))]$.

Proof. Throughout, we assume that Δt is sufficiently small so that $\Delta t < 1$ and $\epsilon(\Delta t) < 1$. Let $r > 0$, and set $\alpha = \max\{G(x)\colon |x| \le r\}$. Then the level-set $\{x\colon G(x) \le \alpha\}$ is contained in a closed ball $B(0,\rho)$ with radius $\rho \ge r$ centered at the origin. Let $\|f\|, \|f^0\|$, and $\|G\|$ denote the Lipschitz constants of f, f^0, and G on $B(0,\rho+1)\times U$ and $B(0,\rho+1)$, respectively. Let $x_0 \in R^n$ be such that $|x_0| \le r$.

First we argue that for x_{k-1} with $G(x_{k-1}) \le \alpha$, $k = 1,\dots,$ (4.6) admits a solution. Let $(\hat{x},\hat{u})$ be a solution to the finite horizon problem (4.3) with initial condition $x_0 = x_{k-1}$, and denote by $(\bar{x},\bar{u})$ its translation from $[0,\Delta t]$ to $[t_{k-1},t_k]$. By Gronwall's lemma we have the a priori estimate

$$|x(t) - \bar{x}(t)| \le \|f\|\Delta t\,\epsilon(\Delta t)\,e^{\|f\|\Delta t} \quad \text{for} \quad t \in [t_{k-1},t_k], \tag{4.7}$$

and, therefore, by (4.2)

$$\begin{aligned} |x(t)| &\le |x_{k-1}| + |x_{k-1} - \bar{x}(t)| + |x(t) - \bar{x}(t)| \\ &\le \rho + \epsilon(\Delta t) + \|f\|\,\Delta t\,\epsilon(\Delta t)\,e^{\|f\|\Delta t} \le \rho + 1 \end{aligned}$$

for all $t \in [t_{k-1},t_k]$, provided that Δt is sufficiently small. In particular, this implies the existence of a solution to (4.6) on $[t_{k-1},t_k]$. To estimate $G(x_k)$, we utilize (4.2), (4.4), and (4.7):

$$\begin{aligned} G(x_k) &+ \int_{t_{k-1}}^{t_k} f^0(x(t),u(t))\,dt = G(x_k) - G(\bar{x}(t_k)) + G(\bar{x}(t_k)) \\ &+ \int_{t_{k-1}}^{t_k} (f^0(x(t),u(t)) - f^0(\bar{x}(t),\bar{u}(t)))\,dt + \int_{t_{k-1}}^{t_k} f^0(\bar{x}(t),\bar{u}(t))\,dt \\ &\le V_{\Delta t}(x_{k-1}) + (\|G\| + \|f^0\|\Delta t)\,\|x - \bar{x}\|_{C([t_{k-1},t_k])} \\ &+ \Delta t\,\|f^0\|\,\|u - \bar{u}\|_{C([t_{k-1},t_k])} \\ &\le (1-\omega\Delta t)G(x_{k-1}) + C\,\Delta t\,\epsilon(\Delta t), \end{aligned}$$

where $C = (\|G\| + \|f^0\|)\|f\|\,e^{\|f\|} + \|f^0\|$. In the above estimate, we used the facts that $|x(t)| \le \rho+1, |\bar{x}(t))| \le \rho+1$, $u_k \in U$, and $u(t) \in U$ for all $t \in [t_{k-1},t_k]$ and the assumption that $\epsilon(\Delta t) \le 1$. Hence

$$G(x_k) + \int_{t_{k-1}}^{t_k} f^0(x(t),u(t))\,dt \le (1-\omega\Delta t)G(x_{k-1}) + C\,\Delta t\,\epsilon(\Delta t), \tag{4.8}$$

and, therefore, $G(x_k) \le \alpha$ for all Δt sufficiently small. Repeated application of (4.8) implies

$$G(x_k) + \sum_{i=0}^{k-1}(1-\omega\Delta t)^i \int_{t_{k-i-1}}^{t_{k-i}} f^0(x(t),u(t))\,dt \le (1-\omega\Delta t)^k G(x_0) + \frac{C\epsilon(\Delta t)}{\omega},$$

and the desired estimates follow. □

Next we consider the case when $x(t)$ is not observed. We assume that $G(x)$ is a discrete control Liapunov function satisfying

$$V_1(x) \leq (1 - \omega\,\Delta t)\, G(x), \tag{4.9}$$

where $\omega > 0$ and V_1 is the optimal value function for (4.1). We analyze the strategy of solving the discrete time optimal control problem (3.4) for $k = 1, \dots$ (and $N = 1$) to obtain a sequence of optimal controls $\{\bar{u}_k\}$ with corresponding states $\{\bar{x}_k\}$ and to utilize these controls in (2.1) with $u(t) = \bar{u}_k$ on (t_{k-1}, t_k). We assume that

$$(f(x_1, u) - f(x_2, u), x_1 - x_2) \leq \beta\, |x_1 - x_2|^2 \tag{4.10}$$

for some $\beta \in R$ and all $x_1, x_2 \in R^n$, and $u \in U$, and we define the linear interpolation

$$\xi(t) = \bar{x}_{k-1} + (t - t_{k-1}) \frac{\bar{x}_k - \bar{x}_{k-1}}{\Delta t} \quad \text{on} \quad (t_{k-1}, t_k). \tag{4.11}$$

Note that

$$\frac{d}{dt}\xi(t) = f(\xi(t), u(t)) + d(t),$$

where

$$d(t) = F(\bar{x}_{k-1}, \bar{u}_k) - f(\xi(t), \bar{u}_k) \quad \text{on} \quad (t_{k-1}, t_k). \tag{4.12}$$

THEOREM 4.2. *Assume that G is a locally Lipschitz continuous discrete control Liapunov function with bounded level-sets, that* (4.9) *and* (4.10) *are satisfied, that U is bounded, and that there exist some $x \in R^n$ and $\hat{u} \in L^1(0, T; R^m)$ with $T = k\,\Delta t$ such that* (2.1) *admits a solution $\hat{x}$ on $[0, T]$. Then for every $r > 0$ there exists a constant $C = C(r, k\Delta t)$ such that*

$$G(x(k\Delta t)) \leq (1 - \omega\Delta t)^k G(x_0) + C\,\tilde{\epsilon}(\Delta t) \tag{4.13}$$

and

$$\int_0^{k\Delta t} f^0(x(t), u(t))\, dt \leq (1 - \omega\Delta t) G(x_0) + C(\tilde{\epsilon}(\Delta t) + k(\Delta t)^2)$$

for every x_0 with $|x_0| \leq r$. Here $x(t)$ is the solution to (2.1) *with $x = x_0$,*

$$u = \bar{u}_j \quad \text{on} \quad (t_{j-1}, t_j), \tag{4.14}$$

with $\bar{u}_j$ the solution of the discrete receding horizon problem (3.4) *with $N = 1$, and $\tilde{\epsilon}(\Delta t) = \int_0^{k\Delta t} d(s)\, ds$.*

Proof. Choose $r > 0$. Since level-sets of G are bounded, there exists $\rho > 0$ such that the set $\{x\colon G(x) \leq r\}$ as well as the trajectory $\{\hat{x}(t)\colon t \in [0, T]\}$ are contained in $B(0, \rho) \subset R^n$. Due to (4.10), the existence of a reference solution $\hat{x}$ on $[0, k, \Delta t]$, and the assumption that U is bounded, there exists, for every $u \in U_{ad}$ and $x_0 \in R^n$ with $|x_0| \leq r$, a solution $x(\cdot; u, x_o)$ to (2.1), and the set $\{x(t; u, x_0)\colon t \in [0, k\Delta t], u \in U_{ad}, |x_0| \leq r\}$ is contained in a ball $B(0, \bar{\rho})$ with $\bar{\rho} \geq \rho$. Let $\|f^0\|$ and $\|G\|$ denote the Lipschitz constants of f^0 and G on $B(0, \bar{\rho}) \times U$ and $B(0, \bar{\rho})$, respectively.

Now fix $x_0 \in R$ with $|x_0| \le r$, and determine the discrete receding horizon sequence $\{(\bar{x}_{j-1}, \bar{u}_j)\}_{j=1}^k$ according to (3.4) with $N = 1$. Due to (4.9), we have $G(\bar{x}_j) \le G(x_0)$ for all $j = 1, \dots, k$ (in fact all $j \ge 1$), and hence $\{(\bar{x}_{j-1}, \bar{u}_j)\}_{j=1}^k \subset B(0, \bar{\rho}) \times U$. Let x denote the solution to (2.1) with $x(0) = x_0$ and $u = \bar{u}_j$ on $[t_{j-1}, t_j], j = 1, \dots, r$, and note that $x(t) \in B(0, \bar{\rho})$ for $t \in [0, k\Delta t]$. For the interpolation ξ, according to (4.11) we find

$$\frac{d}{dt}(\xi(t) - x(t)) = f(\xi(t), u(t)) - f(x(t), u(t)) + d(t),$$

with d given in (4.12). It thus follows from (4.10) that

$$|\xi(t) - x(t)| \le \int_0^t (\beta|\xi(s) - x(s)| + d(s))\, ds,$$

and by Gronwall's inequality

$$|\xi(t) - x(t)| \le e^{\beta t} \int_0^t |d(s)| ds \quad \text{for} \quad t \in [0, k\Delta t]. \tag{4.15}$$

From (4.9) we deduce that

$$G(\bar{x}_k) + \Delta t \sum_{j=0}^{k-1} \gamma^{k-j} f^0(\bar{x}_{j-1}, \bar{u}_j) \le \gamma^k G(x_0), \tag{4.16}$$

where we put $\gamma = 1 - \omega\Delta t$. This implies

$$\begin{aligned} &G(x(k\Delta t)) \le \gamma^k G(x_0) + \|G\|\, |x(k\Delta t) - \bar{x}_k| \\ &\le \gamma^k G(x_0) + \|G\|\, |x(k\Delta t) - \xi(k\Delta t)| \le \gamma^k G(x_0) + \|G\| \exp(\beta k\Delta t)\, \tilde{\epsilon}(\Delta t), \end{aligned}$$

and (4.13) follows with $C = \|G\| \exp(\beta k\Delta t)$. We utilize (4.16) once again to obtain

$$\begin{aligned} &\int_0^{t_k} f^0(x(s), u(s))\, ds \le \gamma G(x_0) + \sum_{j=0}^{k-1} \int_{t_{j-1}}^{t_j} |f^0(x(s), u(s)) - f^0(\bar{x}_{j-1}, \bar{u}_j)|\, ds \\ &\le \gamma G(x_0) + \|f^0\| \int_0^{t_k} |x(s) - \xi(x)|\, ds + \|f^0\| \sum_{j=0}^{k-1} \int_0^{\Delta t} s \frac{|\bar{x}_j - \bar{x}_{j-1}|}{\Delta t}\, ds. \end{aligned}$$

By the continuity of F and the boundedness of $\{(\bar{x}_{j-1}, \bar{u}_j)\}_{j=1}^k$, it follows that $\{\frac{1}{\Delta t}(\bar{x}_j - \bar{x}_{j-1})\}_{j=1}^k$ is bounded by a constant c; hence

$$\int_0^{t_k} f^0(x(x), u(s))\, ds \le \gamma G(x_0) + \|f^0\| \left(\tilde{\epsilon}(\Delta t) + \frac{k(\Delta t)^2 c}{2}\right),$$

and (4.14) follows.

5. Applications. In this section, we demonstrate the applicability of the concepts of this paper to certain classes of control systems. Most of the examples that we consider are motivated by nonlinear dissipative control systems with finite or infinite dimensional dynamics (e.g., [T]). In the case of infinite dimensional systems, we assume that an appropriate discretization has been carried out. A full account of infinite dimensional systems will be given independently.

We consider control systems of the general form

$$\frac{d}{dt}x(t) = A_0x(t) + F(x(t)) + B(x(t))u(t) + d, \tag{5.1}$$

where $A_0 \in R^{n\times n}$, $F : R^n \to R^n$, with $F(0) = 0$, $d \in \mathbb{R}^n$, and $B : R^n \to R^{n\times m}$ are given. Many physical processes modeled by (5.1) have a natural dissipative mechanism when $u = 0$, and thus it can be shown that a certain quadratic form can serve as a control Liapunov function.

5.1. Gradient dynamics. Consider control systems of the form

$$\frac{d}{dt}x(t) = A_0x(t) - \Psi_x(x(t)) + Bu(t), \tag{5.2}$$

where $A_0 \in R^{n\times n}$ and $B \in R^{n\times m}$. Further, Ψ is a convex C^1-functional on R^n with $\Psi_x(0) = 0$ and the property that there exists a positive definite symmetric matrix $P \in R^{n\times n}$ such that

$$\Psi_x(x) \cdot (Px) \geq 0 \text{ for all } x \in R^n. \tag{5.3}$$

We assume that there exist positive constants β and c_1 such that with $u = -\beta\, B^TPx$

$$(A_0x - \Psi_x(x) + Bu) \cdot (\,Px) \leq -c_1\, x^TPx \text{ for all } x \in R^n. \tag{5.4}$$

Let $f^0(x,u) = \frac{1}{2}|x|^2 + \frac{\gamma}{2}|u|^2$, and let $\gamma > 0$ be given. Then by Theorem 2.2 the quadratic functional $G(x) = \frac{\alpha}{2}x^TPx$ is a control Liapunov function for all α sufficiently large.

If $P = I$, then the uncontrolled dynamics ($u = 0$) consists of linear as well as gradient dynamics. Due to the convexity of Ψ and $\Psi_x(0) = 0$, we have $\Psi_x(x) \cdot x \geq 0$, and hence (5.3) holds. In this case, condition (5.4) is equivalent to assuming that

$$W(x) = -(A_0x, x) + (\Psi_x(x), x) + \beta\,|B^Tx|^2$$

is positive for $x \neq 0$.

Example. As a specific case for (5.2), consider the control system (motivated by the Schrödinger equation):

$$\frac{d}{dt}z(t) = i\,Az(t) - |z(t)|^{p-2}z(t) + B_0v(t),$$

where $z(t) \in C^n$, $v \in C^m$, and A is a symmetric nonnegative definite matrix on R^n. For $z = x_1 + i\,x_2$ with $x = (x_1, x_2) \in R^{2n}$ and $v = u_1 + i\,u_2$ with $u = (u_1, u_2) \in R^{2m}$, the above equation can be written as (5.2) with

$$A_0 = \begin{pmatrix} 0 & A \\ -A & 0 \end{pmatrix}, \quad B = \begin{pmatrix} B_0 & 0 \\ 0 & B_0 \end{pmatrix}, \text{ and } \Psi(x) = \frac{1}{p}\,|x|^p.$$

Example (damped vibration dynamics). System (5.2) is also motivated by the damped wave equation. We consider the second order system

$$\frac{d^2}{dt^2}z(t) + \psi_z\left(\frac{d}{dt}z(t)\right) + \Lambda z(t) = B_0u(t),$$

where $z(t) \in R^n, B_0 \in R^{n\times m}$, and $\Lambda \in R^{n\times n}$ is positive definite. Further, ψ is a convex functional on R^n with $\psi_x(0) = 0$ and $|\psi_x(z)| \le c_1|z|$ for a constant c_1 independent of $z \in R^n$. In the case of Coulomb-like friction $\psi(z) = \sum_{i=1}^n \gamma_i \,|\sqrt{|z_i|^2 + \epsilon}|$ with constants $\gamma_i \ge 0$ and $\epsilon > 0$. If we define $x_1(t) = z(t)$ and $x_2(t) = \frac{d}{dt}z(t)$, then $x = col(x_1, x_2)$ satisfies (5.2) with

$$A_0 = \begin{pmatrix} 0 & I \\ -\Lambda & 0 \end{pmatrix}, \quad B = \begin{pmatrix} 0 \\ B_0 \end{pmatrix}, \quad \text{and} \quad \Psi(x) = \begin{pmatrix} 0 \\ \psi(x_2) \end{pmatrix}.$$

Setting

$$P = \begin{pmatrix} \Lambda & 0 \\ 0 & I \end{pmatrix},$$

we find

$$(A_0x - \Psi_x(x)) \cdot (Px) = -(\psi_x(x_2), x_2) \le 0.$$

Also note that

$$(A_0x - \Psi_x(x)) \cdot Q_x = |x_2|^2 - x_1^T\Lambda x_1 - x_1^T\psi_x(x_2),$$

where $Q(x) = x_1^Tx_2$. Let us define

$$G(x) = \frac{\alpha}{2}x^TPx + x_1^Tx_2.$$

Then for $u = -B_0^Tx_2$ we find

$$(A_0x - \Psi_x(x) + Bu) \cdot G_x = -x_1^T\Lambda x_1 - \alpha\,(|B_0^Tx_2|^2 + (\psi_x(x_2), x_2)) + |x_2|^2 - x_1^T\psi_x(x_2).$$

Thus if $|B_0^Tx_2|^2 + (\psi_z(x_2), x_2) \ge c_2\,|x_2|^2$ for some $c_2 > 0$ and α is sufficiently large, then $G(x)$ is a control Liapunov function for $f^0(x,u) = \frac{c_3}{2}\,(x^TPx + |u|^2)$ for $0 \le c_3 \le 2$.

We return to the general discussion at the beginning of this subsection and replace condition (5.4) by the following assumptions:

$$A_0x \cdot Px \le 0 \ \text{ for all } \ x \in \mathbb{R}^n, \ \text{ and } \ (A_0 - BB^TP) \ \text{ is exponentially stable.}$$

Let Π denote the solution to the Liapunov equation

$$(A_0 - BB^TP)^T\Pi + \Pi(A_0 - BB^TP) + P = 0.$$

We choose the control Liapunov function $G(x) = \frac{1}{2}x^T\Pi x + \alpha x^TPx$, with $\alpha \ge 0$ and the feedback control law $u = -B^TPx$. Then we have with $G_x(x) = \Pi x + \alpha Px$

$$\begin{aligned}
&(A_0x - \Psi_x(x) - BB^TPx) \cdot (\Pi x + \alpha Px) = (A_0x - BB^TPx) \cdot \Pi x \\
&-\Psi_x(x) \cdot \Pi x + \alpha A_0x \cdot Px - \alpha\Psi_x(x) \cdot Px - \alpha|P^TPx|^2 \\
&\le -\frac{1}{2}\,x^TPx - \Psi_x(x) \cdot \Pi x - \alpha|B^TPx|^2 - \alpha\Psi_x(x) \cdot Px,
\end{aligned}$$

where we recall that $\Psi_x(x) \cdot Px \ge 0$. Assume that there exists $\bar\alpha$ such that

$$\Psi_x(x) \cdot \Pi x \le \bar\alpha\,\Psi_x(x) \cdot Px + \frac{1}{4}\,x^TPx + \frac{\bar\alpha}{2}\,|B^TPx|^2.$$

With this choice of $\bar\alpha$, the functional $G(x)$ is a control Liapunov function for the control system (5.2) with cost given by $f^\circ(x,u) = \frac{1}{4}\,x^TPx + \frac{\bar\alpha}{2}\,|B^TPx|^2$.

5.2. Dissipative systems. The second class of dissipative nonlinear systems that we consider here is motivated by the incompressible Navier–Stokes equations (e.g., with homogeneous Dirichlet boundary conditions),

$$\frac{d}{dt}x(t) = A_0x(t) + F(x(t)) + Bu(t) + d, \tag{5.5}$$

where $F : R^n \to R^n$ is a locally Lipschitz function satisfying $(F(x), x)_{R^n} = 0$, A_0 is a nonpositive definite symmetric matrix on R^n, $B \in R^{n\times m}$, and $d \in R^n$. Then for $u \in L^2_{loc}(0,\infty, R^m)$ there exists a globally defined unique solution to (5.5). In fact, suppose x is a solution defined on $[0,\tau)$. Then

$$\frac{1}{2}\frac{d}{dt}|x(t)|^2 = (A_0x(t) + F(x(t)) + Bu(t) + d)\cdot x(t) \le \frac{1}{2}|x(t)|^2 + |B|^2|u(t)|^2 + |d|^2$$

for $t \in [0,\tau)$. Thus we have the a priori bound

$$|x(t)|^2 \le e^t\,|x_0|^2 + 2\int_0^t e^{t-s}(|B|^2|u(t)|^2 + |d|^2)\,ds$$

for $t \in [0,\tau)$. By the continuation method there exists a unique global solution to (5.5). Let us assume that

$$\ker(A_0) \subset \text{range}(B).$$

Further, let $G(x) = \frac{\alpha}{2}|x|^2$, $\alpha > 0$, and set $u = -B^Tx$. Then there exists $\omega_1 > 0$ such that

$$(A_0x + F(x) + Bu)\cdot(\alpha x) = x^TA_0x - |B^Tx|^2 \le -\alpha\,\omega_1\,|x|^2$$

for all $x \in R^n$. Consequently, G is a control Liapunov function for $f^0(x,u) = \frac{1}{2}|x|^2 + \frac{\gamma}{2}|u|^2$, $\gamma > 0$, and $\alpha = 0$, whenever α is sufficiently large. Moreover, if $(F(x), A_0x) \ge 0$ (for example, in the case of the incompressible Navier–Stokes equation with periodic boundary condition $(F(x), A_0x) = 0$ [T]), then $G(x) = -\frac{\alpha}{2}x^TA_0x$ is a control Liapunov function for all α sufficiently large and f^0 as above. In fact, for $u = B^TA_0x$, we have

$$(A_0x + F(x) + Bu)\cdot(-A_0x) = -|A_0x|^2 - |B^TA_0x|^2 \le -\omega_2\,|x|^2$$

for some $\omega_2 > 0$, independently of $x \in R^n$, and the claim follows.

Example (Lorenz system). The following system, proposed by Lorenz as an evidence of the limits of predictability in weather prediction, is also of the form (5.5). It is a three-mode Galerkin approximation of the Boussinesq equations for fluid convection in a two-dimensional layer heated from below and is given by

$$\frac{d}{dt}\begin{pmatrix} x_1\\ x_2\\ x_3\end{pmatrix} = \begin{pmatrix} -\sigma & 0 & 0\\ 0 & -1 & 0\\ 0 & 0 & -b\end{pmatrix}x(t) + \begin{pmatrix} \sigma x_2\\ -\sigma x_1 - x_1x_3\\ x_1x_2\end{pmatrix} - \begin{pmatrix} 0\\ 0\\ b(r+\sigma)\end{pmatrix} + \begin{pmatrix} 0\\ 0\\ 1\end{pmatrix}u(t).$$

5.3. Localized control Liapunov function. We discuss the local control Liapunov function in the sense of Remarks 2.3 and 2.5 for systems of the form

$$\frac{d}{dt}x(t) = Ax(t) + F(x(t)) + Bu(t) + d, \tag{5.6}$$

where $F(0) = 0$. Suppose that (A, B) is controllable. Then there exists a unique positive definite symmetric matrix solution Π to the Riccati equation $A^T\Pi + \Pi A - \Pi BB^T\Pi + I = 0$. We shall argue that $G(x) = \frac{1}{2}\, x^T\Pi x$ is a local λ-control Liapunov function for the feedback law $u = -B^T\Pi x$ provided that there exist $\alpha > 0$ and $\omega > 0$ such that

$$-\frac{1}{2}\left(|B^T\Pi x|^2 + |x|^2\right) + f^0(x, -B^T\Pi x) + (F(x), \Pi x) \le -\frac{\omega}{2}\,|x|^2 \tag{5.7}$$

for all $x \in S_\alpha = \{x : G(x) \le \alpha\}$. In fact,

$$f(x, -B^T\Pi)\cdot(\Pi x) + f^0(x, -B^T\Pi x) \le -\frac{\omega}{2}\,|x|^2 + (d, x) \le \frac{|d|^2}{2\omega},$$

and hence $G(x) = \frac{1}{2}\, x^T\Pi x$ is a local λ-control Liapunov function with $\lambda = \frac{|d|^2}{2\omega}$. For example, consider system (5.6) with

$$A = \begin{pmatrix} 0 & 1 \\ \\ 1 & 0 \end{pmatrix}, \quad B = \begin{pmatrix} 0 \\ \\ 1 \end{pmatrix}, \quad F(x) = \begin{pmatrix} 0 \\ \\ -U_{x_1}(x_1) \end{pmatrix},$$

where U is a potential function on R and satisfies $U_{x_1}(0) = 0$. In the case of the inverted pendulum, $U_{x_1}(x_1) = x_1 - \sin(x_1)$. Then $\Pi = \begin{pmatrix} 1+\gamma & \gamma \\ \gamma & \gamma \end{pmatrix}$ with $\gamma = 1 + \sqrt{2}$ solves the Riccati equation. Condition (5.7) is equivalent to

$$-\frac{1}{2}\left(\gamma^2\,|x_1 + x_2|^2 + |x|^2\right) - \gamma\,(U_{x_1}(x_1), x_1 + x_2) + f^0(x, -\gamma\,(x_1 + x_2)) \le -\frac{\omega}{2}\,|x|^2.$$

In the case of the inverted pendulum, it can be proved that this holds for all $x \in R^2$, where $f^\circ(x, u) = \frac{c_1}{2}\,|x|^2 + \frac{c_2}{2}\,|u|^2$ for appropriate choice of $c_1 > 0$, $c_2 > 0$.

OVERLAPPING QUADRATIC OPTIMAL CONTROL OF LINEAR TIME-VARYING COMMUTATIVE SYSTEMS*

LUBOMÍR BAKULE†, JOSÉ RODELLAR‡, AND JOSEP M. ROSSELL§

Abstract. Overlapping quadratic optimal control of linear time-invariant continuous-time systems by using *generalized selection of complementary matrices* has been recently developed as a powerful and effective means of decentralized control design of linear time-invariant systems. In this paper, it is shown that similar generalizations exist for linear time-varying systems. The results presented here concern implicit conditions for a general form of the transition matrices and explicit conditions for a commutative class of linear time-varying systems. Several important large classes of complementary matrices are selected to offer computationally attractive results. The effectiveness of this generalized selection scheme is illustrated by a numerical example of overlapping decentralized control design.

Key words. linear time-varying continuous-time systems, large scale systems, commutative systems, inclusion principle, overlapping decomposition, optimal control, decentralization, suboptimality

1. Introduction.

In a large variety of physical, natural, and man-made systems, subsystems share common parts. It is useful to recognize this reality, which is usually determined by either system structure or computational requirements, in proposing decentralized control schemes that use overlapping information sets. In certain control problems appearing in areas such as traffic systems, large space structures, power systems, or data communication networks, this approach is the only effective way to proceed. Decentralized control strategies offer satisfactory performance at minimum communication cost. The designer of overlapping decentralized control first expands the system into a larger space where the subsystems are disjoint, then designs decentralized controllers in the expanded space by using standard weak coupling disjoint control design methods, and finally contracts the system and local control laws into the original space to implement such controllers.

This paper addresses the problem of overlapping decentralized control design via state linear quadratic (LQ) optimal control for a commutative class of continuous-time linear time-varying (LTV) systems.

1.1. Relevant references.

The mathematical framework for expansion-contraction relations and conditions became known as the inclusion principle [11], [12], [13], [22]. This principle defines a framework for two dynamic systems with different dimensions, in which solutions of the system with larger dimension include solutions of

the system with smaller dimension. The relation between both systems is usually constructed on the basis of appropriate linear transformations between the corresponding systems in the original and expanded spaces, where a key role in the selection of appropriate structure of all matrices in the expanded space is played by the so-called *complementary matrices* [11], [22]. The conditions given in these works on the complementary matrices have a fundamental, implicit nature, in the sense that it is not easy to select specific values for these matrices. In fact, only two particular forms of aggregations and restrictions have been commonly adopted in the literature for numerical computations [2], [15], [22], [24]. A new characterization of the complementary matrices for linear time-invariant (LTI) systems has been recently presented in [3], [19], which gives a more explicit method for their selection and includes aggregations and restrictions as particular cases. It relies on a new constructive way of approaching the concept of canonical form within the inclusion principle previously proposed in [13], [22]. This structural characterization has been used to develop the strategy of *generalized selection of complementary matrices* in [4] to find both their structure and the optimal values of their free elements with respect to suboptimality when considering the problem of overlapping decentralized state LQ control design for LTI systems. The importance of the inclusion principle is underlined by promising applications in such diverse areas as applied mathematics [5], [6], [21], [26], automated highway systems [10], [23], flexible structures [2], data communication networks [9], and electric power systems [12], [22], [24].

One of the open research issues surrounding the inclusion principle is the extension of the results available for LTI systems to LTV systems. To the authors' knowledge, the only available results in this direction are in [14], where overlapping decentralized state LQ control of LTV systems is considered. However, the results in [14] are restricted to the use of standard forms of complementary matrices, i.e., aggregations and restrictions.

The present paper differs from all the cited references in the application of the strategy of *generalized selection of complementary matrices* to LTV systems. It extends both the results in [14] as well as those in [3], [4], [19].

1.2. Outline of the paper. When abstracting the problem of quadratic optimal control, the influence of complementary matrices on suboptimality is an important issue. The strategy of *generalized selection of complementary matrices* has been developed as an effective tool to find both structure and optimal values of free elements of complementary matrices for LTI systems. We devote the main part of this paper to an extension of this strategy for overlapping state LQ optimal control from LTI systems to a class of LTV systems possessing the commutativity property, including contractibility conditions.

The paper is organized as follows. The problem is formulated in section 2. The main results are presented in section 3, identifying a new block structure of the complementary matrices that generalizes well-known results for expansion-contraction of pairs of systems and optimal control criteria. Subsection 3.1 presents the general conditions on the complementary matrices in the LQ control of LTV systems. Because of their implicit dependence on the transition matrix, they cannot be used to derive explicit conditions. The explicit conditions are derived for LTV systems possessing the commutativity property in subsection 3.2. Subsection 3.3 presents the derivation of structural properties of the complementary matrices. From this structure, subsection 3.4 outlines a selection procedure for these matrices. In section 4, this procedure is used in an overlapping state LQ optimal control problem, which is illustrated by a

numerical example.

2. Problem formulation.

2.1. Preliminaries. Consider the optimal control problems

(2.1)
$$\min_{u(t)} \quad J(x_0,u) = x^T(t_f)\Pi\, x(t_f) + \int_{t_0}^{t_f} \left[x^T(t)Q^*(t)x(t) + u^T(t)R^*(t)u(t)\right]\, dt,$$
$$\text{subject to (s.t.) } \mathbf{S}: \quad \dot{x}(t) = A(t)x(t) + B(t)u(t),$$

(2.2)
$$\min_{\tilde{u}(t)} \quad \tilde{J}(\tilde{x}_0,\tilde{u}) = \tilde{x}^T(t_f)\tilde{\Pi}\,\tilde{x}(t_f) + \int_{t_0}^{t_f} \left[\tilde{x}^T(t)\tilde{Q}^*(t)\tilde{x}(t) + \tilde{u}^T(t)\tilde{R}^*(t)\tilde{u}(t)\right]\, dt,$$
$$\text{s.t. } \tilde{\mathbf{S}}: \quad \dot{\tilde{x}}(t) = \tilde{A}(t)\tilde{x}(t) + \tilde{B}(t)\tilde{u}(t),$$

where $x(t) \in \mathbb{R}^{\mathbf{n}}$, $u(t) \in \mathbb{R}^{\mathbf{m}}$ are the state and input of $\mathbf{S}$ at time t for $t \in [t_0, t_f]$; t_0 and t_f are the initial and the terminal time, respectively; $\tilde{x}(t) \in \mathbb{R}^{\tilde{\mathbf{n}}}$ and $\tilde{u}(t) \in \mathbb{R}^{\tilde{\mathbf{m}}}$ are the state and input of $\tilde{\mathbf{S}}$. The matrices $A(t)$, $B(t)$ and $\tilde{A}(t)$, $\tilde{B}(t)$ are continuous in t of dimensions $n \times n$, $n \times m$ and $\tilde{n} \times \tilde{n}$, $\tilde{n} \times \tilde{m}$, respectively. $Q^*(t)$, $\tilde{Q}^*(t)$ are symmetric, nonnegative definite matrices, continuous in t, of dimensions $n \times n$, $\tilde{n} \times \tilde{n}$, respectively. $R^*(t)$, $\tilde{R}^*(t)$ are symmetric, positive definite matrices, continuous in t, of dimensions $m \times m$, $\tilde{m} \times \tilde{m}$, respectively. Π, $\tilde{\Pi}$ are constant, symmetric, nonnegative definite matrices of dimensions $n \times n$, $\tilde{n} \times \tilde{n}$, respectively. In problems (2.1) and (2.2), the final time t_f is fixed, and $x(t_f)$ is free. The minimization of $J(x_0,u)$ searches for a control $u(t)$ able without an excessive effort to maintain the state vector $x(t)$ close to the zero required state at any time $t \in [t_0, t_f]$, with particular emphasis at the terminal time t_f as weighted by matrix Π. It is well known that the solution of (2.1) exists, is unique, and is given in the form $u(t) = -K(t)x(t) = -(R^*)^{-1}(t)B^T(t)P(t)x(t)$, where $P(t)$ is the nonnegative definite symmetric solution of the corresponding Riccati equation [1]. If t_f is finite, this control law ensures a bounded state, and the stability issues are absent. If t_f is infinite (with $\Pi = 0$), the question of stability becomes important. It has been shown that this control guarantees that the closed-loop system is exponentially stable under certain conditions related to controllability and observability [14], [18]. We assume that the system $\mathbf{S}$ satisfies such conditions. Similar comments hold for (2.2). Suppose that the dimensions of the state and input vectors $x(t)$, $u(t)$ of $\mathbf{S}$ are smaller than (or at most equal to) those of $\tilde{x}(t)$, $\tilde{u}(t)$ of $\tilde{\mathbf{S}}$. Denote by $x(t; x_0, u)$ the solution of $\mathbf{S}$ for a fixed input $u(t)$ and an initial state $x(0) = x_0$. Analogously, $\tilde{x}(t; \tilde{x}_0, \tilde{u})$ is used for the system $\tilde{\mathbf{S}}$. In order to simplify the notation, define $x(t; x_0, u) = x(t)$ and $\tilde{x}(t; \tilde{x}_0, \tilde{u}) = \tilde{x}(t)$. It is well known that

(2.3)
$$x(t) = \Phi(t, t_0)\, x_0 + \int_{t_0}^{t} \Phi(t,\tau)B(\tau)u(\tau)\, d\tau,$$

(2.4)
$$\tilde{x}(t) = \tilde{\Phi}(t, t_0)\, \tilde{x}_0 + \int_{t_0}^{t} \tilde{\Phi}(t,\tau)\tilde{B}(\tau)\tilde{u}(\tau)\, d\tau$$

are the unique, continuously differentiable solutions of the systems in (2.1) and (2.2), respectively. The *transition matrices* $\Phi(t, t_0)$, $\tilde{\Phi}(t, t_0)$ are given by the Peano–Baker series [20].

The systems $\mathbf{S}$ and $\tilde{\mathbf{S}}$ are related by the following transformations:

(2.5)
$$\tilde{x}(t) = Vx(t), \quad x(t) = U\tilde{x}(t), \quad \tilde{u}(t) = Ru(t), \quad u(t) = Q\tilde{u}(t),$$

where V, U, R, and Q are constant matrices of appropriate dimensions and full ranks.

DEFINITION 2.1. *Consider* $\mathbf{S}$ *and* $\tilde{\mathbf{S}}$ *given in* (2.1) *and* (2.2)*, respectively. We say that a system* $\tilde{\mathbf{S}}$ *includes the system* $\mathbf{S}$*—that is,* $\tilde{\mathbf{S}} \supset \mathbf{S}$*—if there exists a quadruplet of constant matrices* (U, V, Q, R) *such that* $UV = I_n$*,* $QR = I_m$*, and for any initial state* x_0 *and any fixed input* $u(t)$ *of* $\mathbf{S}$*,* $x(t; x_0, u) = U\tilde{x}(t; Vx_0, Ru)$ *for all* $t \in [t_0, t_f]$*.*

DEFINITION 2.2. *A pair* $(\tilde{\mathbf{S}}, \tilde{J})$ *includes a pair* $(\mathbf{S}, J)$ *if* $\tilde{\mathbf{S}} \supset \mathbf{S}$ *and* $J(x_0, u) = \tilde{J}(Vx_0, Ru)$*.*

DEFINITION 2.3. *If* $(\tilde{\mathbf{S}}, \tilde{J}) \supset (\mathbf{S}, J)$*, then* $(\tilde{\mathbf{S}}, \tilde{J})$ *is said to be an* expansion *of* $(\mathbf{S}, J)$*, and* $(\mathbf{S}, J)$ *is called a* contraction *of* $(\tilde{\mathbf{S}}, \tilde{J})$*.*

In other words, this inclusion means that the problem $(\mathbf{S}, J)$ can be solved by solving the problem $(\tilde{\mathbf{S}}, \tilde{J})$.

DEFINITION 2.4. *Consider* $\mathbf{S}$ *and* $\tilde{\mathbf{S}}$ *given in* (2.1) *and* (2.2)*, respectively, such that* $\tilde{\mathbf{S}} \supset \mathbf{S}$*. Then a control law* $\tilde{u}(t) = -\tilde{K}(t)\,\tilde{x}(t)$ *for* $\tilde{\mathbf{S}}$ *is contractible to the control law* $u(t) = -K(t)\,x(t)$ *for* $\mathbf{S}$ *if the choice* $\tilde{x}_0 = Vx_0$ *and* $\tilde{u}(t) = Ru(t)$ *implies* $K(t)x(t; x_0, u) = Q\tilde{K}(t)\tilde{x}(t; Vx_0, Ru)$ *for all* $t \in [t_0, t_f]$*, for any initial state* x_0 *and any fixed input* $u(t)$ *of* $\mathbf{S}$*.*

We may also say that the gain matrix $\tilde{K}(t)$ is contractible to the gain matrix $K(t)$. Contractibility implies that the expanded closed-loop system $\dot{\tilde{x}}(t) = [\tilde{A}(t) - \tilde{B}(t)\tilde{K}(t)]\tilde{x}(t)$ includes the closed-loop system $\dot{x}(t) = [A(t) - B(t)K(t)]x(t)$.

In order to obtain conditions for expansions and contractions between problems (2.1) and (2.2) as well as conditions for contractibility of control laws, the following matrix relations are introduced:

$$
\begin{aligned}
\tilde{A}(t) &= VA(t)U + M(t), & \tilde{B}(t) &= VB(t)Q + N(t),\\
\tilde{\Pi} &= U^T \Pi U + M_\Pi, & \tilde{Q}^*(t) &= U^T Q^*(t) U + M_{Q^*}(t),\\
\tilde{R}^*(t) &= Q^T R^*(t) Q + N_{R^*}(t), & \tilde{K}(t) &= RK(t)U + F(t),
\end{aligned}
\tag{2.6}
$$

where $M(t)$, $N(t)$, M_Π, $M_{Q^*}(t)$, $N_{R^*}(t)$, and $F(t)$ are called *complementary matrices*.

Usually, the transformations (U, V) and (Q, R) are selected a priori to define structural relations between the state and control variables in both systems $\mathbf{S}$ and $\tilde{\mathbf{S}}$. Given these transformations, the choice of the complementary matrices gives degrees of freedom to complete the definition of the expansion/contraction framework involving problems $(\mathbf{S}, J)$ and $(\tilde{\mathbf{S}}, \tilde{J})$ to meet some design requirements.

2.2. The problem. The motivation of this work is to systematically extend the strategy of *generalized selection of complementary matrices* for overlapping state linear quadratic optimal control from LTI systems to LTV systems. The specific objectives are the following:

- To give implicit conditions on the complementary matrices for the inclusion $(\tilde{\mathbf{S}}, \tilde{J}) \supset (\mathbf{S}, J)$ and the contractibility of the gain matrix for general LTV systems.
- To give explicit conditions on the complementary matrices for the inclusion $(\tilde{\mathbf{S}}, \tilde{J}) \supset (\mathbf{S}, J)$ and the contractibility of the gain matrix for LTV commutative systems and to derive a systematic procedure for their selection, involving overlapping decentralized state LQ optimal control design.
- To illustrate the derived results on a numerical example.

3. Main results. This section gives the results covering mainly the expansion-contraction process for continuous-time LTV systems. Subsection 3.1 includes the general results. Subsection 3.2 presents the results for LTV systems possessing the commutativity property. Subsection 3.3 characterizes the expansion-contraction process presented at a general level by using a new basis and including contractibility

conditions. Subsection 3.4 offers the results of this process for selecting particular transformation matrices.

3.1. General LTV systems. For $(\tilde{\mathbf{S}}, \tilde{J})$ to be an expansion of $(\mathbf{S}, J)$ and to ensure contractibility, we must impose some conditions on the complementary matrices given in (2.6). This is provided by the following theorems.

THEOREM 3.1. *Consider the problems given in* (2.1) *and* (2.2). $(\tilde{\mathbf{S}}, \tilde{J}) \supset (\mathbf{S}, J)$ *if and only if*

$$\begin{aligned} &U\tilde{\Phi}(t,t_0)V = \Phi(t,t_0), \qquad U\tilde{\Phi}(t,\tau)N(\tau)R = 0, \qquad V^T M_\Pi V = 0, \\ &V^T M_{Q^*}(t)V = 0, \qquad\qquad R^T N_{R^*}(t)R = 0 \end{aligned} \tag{3.1}$$

for all $t \in [t_0, t_f]$ *and all* $\tau \in [t_0, t]$.

Proof. By Definition 2.2, suppose $x(t) = U\tilde{x}(t)$. Substituting (2.3) and (2.4) into this relation and comparing both sides, we obtain (1) $U\tilde{\Phi}(t,t_0)V = \Phi(t,t_0)$ and (2) $\int_{t_0}^{t} U\tilde{\Phi}(t,\tau)\tilde{B}(\tau)\tilde{u}(\tau)\,d\tau = \int_{t_0}^{t} \Phi(t,\tau)B(\tau)u(\tau)\,d\tau$ for all $t \in [t_0, t_f]$. From (2.6), relation (2) is equivalent to $\int_{t_0}^{t} U\tilde{\Phi}(t,\tau)N(\tau)Ru(\tau)\,d\tau = 0$ for all $t \in [t_0, t_f]$, and consequently to $U\tilde{\Phi}(t,\tau)N(\tau)R = 0$ for all $t \in [t_0, t_f]$ and all $\tau \in [t_0, t]$. The remaining conditions can be obtained easily from $J(x_0, u) = \tilde{J}(Vx_0, Ru)$ and by using (2.6). ∎

THEOREM 3.2. *Consider the problems given in* (2.1) *and* (2.2). $(\tilde{\mathbf{S}}, \tilde{J}) \supset (\mathbf{S}, J)$ *if* $V^T M_\Pi V = 0$, $V^T M_{Q^*}(t)V = 0$, $R^T N_{Q^*}(t)R = 0$, *and either*

$$\begin{aligned} &\text{(a)} \quad M(t)V = 0, \qquad N(t)R = 0 \ \textit{or} \\ &\text{(b)} \quad UM(t) = 0, \quad UN(t)R = 0 \end{aligned} \tag{3.2}$$

for all $t \in [t_0, t_f]$.

Proof. We can view the transition matrix $\tilde{\Phi}(t,t_0)$ as a function of two variables defined by the Peano–Baker series

$$\begin{aligned} \tilde{\Phi}(t,t_0) = I &+ \int_{t_0}^{t} \tilde{A}(\sigma_1)\,d\sigma_1 + \int_{t_0}^{t} \tilde{A}(\sigma_1) \int_{t_0}^{\sigma_1} \tilde{A}(\sigma_2)\,d\sigma_2 d\sigma_1 \\ &+ \int_{t_0}^{t} \tilde{A}(\sigma_1) \int_{t_0}^{\sigma_1} \tilde{A}(\sigma_2) \int_{t_0}^{\sigma_2} \tilde{A}(\sigma_3)\,d\sigma_3 d\sigma_2 d\sigma_1 + \cdots, \end{aligned} \tag{3.3}$$

where $\tilde{A}(\sigma_i) = VA(\sigma_i)U + M(\sigma_i)$, $i = 1, 2, \ldots$. Multiplying both sides of $\tilde{\Phi}(t,t_0)$ by U and V, respectively, and comparing to $\Phi(t,t_0)$, the condition $M(t)V = 0$ implies $U\tilde{\Phi}(t,t_0)V = \Phi(t,t_0)$. Obviously, $N(t)R = 0$ implies $U\tilde{\Phi}(t,\tau)N(\tau)R = 0$ for all $t \in [t_0, t_f]$ and all $\tau \in [t_0, t]$. This proves part (a). Following a similar process for part (b), $UM(t) = 0$ and $UN(t)R = 0$ are sufficient conditions in order for $U\tilde{\Phi}(t,t_0)V = \Phi(t,t_0)$ and $U\tilde{\Phi}(t,\tau)N(\tau)R = 0$ to hold, respectively. ∎

The conditions (a) and (b) are two independent sets of sufficient conditions for $(\tilde{\mathbf{S}}, \tilde{J})$ to be an expansion of $(\mathbf{S}, J)$. Condition (a) corresponds to a restriction, whereas condition (b) corresponds to an aggregation [14].

THEOREM 3.3. *Consider* $\mathbf{S}$ *and* $\tilde{\mathbf{S}}$ *given in* (2.1) *and* (2.2), *respectively, such that* $\tilde{\mathbf{S}} \supset \mathbf{S}$. *A control law* $\tilde{u}(t) = -\tilde{K}(t)\,\tilde{x}(t)$ *for* $\tilde{\mathbf{S}}$ *is contractible to the control law* $u(t) = -K(t)\,x(t)$ *for* $\mathbf{S}$ *if and only if*

$$QF(t)\left[\tilde{\Phi}(t,t_0)Vx_0 + \int_{t_0}^{t} \tilde{\Phi}(t,\tau)\tilde{B}(\tau)\tilde{u}(\tau)\,d\tau\right] = 0 \tag{3.4}$$

for all $t \in [t_0, t_f]$.

Proof. By Definition 2.4, a control law $\tilde{u}(t)$ is contractible to the control law $u(t)$ when $K(t)x(t; x_0, u) = Q\tilde{K}(t)\tilde{x}(t; Vx_0, Ru)$. Then, substituting $\tilde{K}(t)$ given in (2.6) and $\tilde{x}(t)$ given in (2.4) into the above equation and comparing both sides, the proof is straightforward. □

THEOREM 3.4. *Consider* $\mathbf{S}$ *and* $\tilde{\mathbf{S}}$ *given in* (2.1) *and* (2.2)*, respectively, such that* $\tilde{\mathbf{S}} \supset \mathbf{S}$. *A control law* $\tilde{u}(t) = -\tilde{K}(t)\,\tilde{x}(t)$ *for* $\tilde{\mathbf{S}}$ *is contractible to the control law* $u(t) = -K(t)\,x(t)$ *for* $\mathbf{S}$ *if either*

$$\begin{aligned} &\text{(a)} \quad M(t)V = 0, \qquad N(t)R = 0, \quad QF(t)V = 0 \ \text{ or} \\ &\text{(b)} \quad UM(t) = 0, \quad UN(t)R = 0, \quad QF(t) = 0 \end{aligned} \tag{3.5}$$

for all $t \in [t_0, t_f]$.

Proof. Substituting the transition matrix $\tilde{\Phi}(t, t_0)$ given in (3.3) into (3.4) and using (2.6), the sufficient conditions (a) and (b) independently imply Theorem 3.3. □

Theorems 3.2 and 3.4 do not require that we know the transition matrices. However, the selections of $M(t)$, $N(t)$, $F(t)$ are constrained only to restrictions and aggregations.

The transition matrix $\tilde{\Phi}(t, t_0)$ appears in the conditions given by Theorems 3.1 and 3.3. Since it depends on the system matrix $\tilde{A}(t)$, $\tilde{\Phi}(t, t_0)$ implicitly depends on the complementary matrix $M(t)$ as given in (2.6). On the other hand, it is very difficult, if not impossible, to obtain expressions for the transition matrices except for some particular classes of systems. The computation of the solutions via the Peano–Baker series can be a complicated task excluding trivial cases. Thus the task of obtaining explicit conditions for complementary matrices satisfying Theorems 3.1 and 3.3 is practically unsolvable for general time-varying systems. Therefore, we focus our attention on a particular but sufficiently large and important class of time-varying systems characterized by possessing the commutativity property.

3.2. Commutative systems. Let us start the presentation for this class of systems.

DEFINITION 3.5. *An LTV system* $\mathbf{S}$ *such as* (2.1) *is a commutative system if and only if* $A(t)$ *satisfies* $A(t)(\int_{t_0}^{t} A(\tau)\,d\tau) = (\int_{t_0}^{t} A(\tau)\,d\tau)A(t)$ *for all* $t \in [t_0, t_f]$. *In such a case, the matrix* $\Phi(t, t_0)$ *is given by*

$$\Phi(t, t_0) = e^{\int_{t_0}^{t} A(\tau)\,d\tau} = \sum_{k=0}^{\infty} \frac{1}{k!} \left(\int_{t_0}^{t} A(\tau)\,d\tau \right)^k .$$

In particular, this is the case for any $A(t)$ given by $A(t) = \sum_{i=1}^{r} f_i(t)A_i$, where $f_i(t)$ are arbitrary real-valued functions of t and A_i are arbitrary constant $n \times n$ matrices which satisfy the commutativity conditions $A_iA_j = A_jA_i$ for all integers $1 \le i,\ j \le r$. A linear system is called *exponential* when its state-transition matrix can be written in the matrix exponential form $\Phi(t, t_0) = e^{\Gamma(t, t_0)}$, where $\Gamma(t, t_0)$ is an $n \times n$ matrix function of t and t_0. Any commutative system is exponential. In such a case, $\Gamma(t, t_0) = \int_{t_0}^{t} A(\tau)\,d\tau$. If $A(t)$ is a triangular matrix, then the solution can be reduced to a readily solvable set of scalar differential equations. When $A(t)$ is a diagonal or a constant matrix, then it meets the commutative property and the results are well known. Summarizing, the class of systems for which $A(t)$ commutes with its integral is actually fairly large [16], [20], [25].

We need to know the conditions ensuring the commutativity property of an expanded system $\tilde{\mathbf{S}}$ when assuming the commutativity of the initial system $\mathbf{S}$. This result is given by the following proposition.

PROPOSITION 3.6. *Consider* $\mathbf{S}$ *and* $\tilde{\mathbf{S}}$ *given in* (2.1) *and* (2.2)*, respectively, such that* $\tilde{\mathbf{S}} \supset \mathbf{S}$*. Suppose* $\mathbf{S}$ *a commutative system. Then* $\tilde{\mathbf{S}}$ *is a commutative system if and only if*

$$\begin{aligned} &VA(t)U\left(\int_{t_0}^{t} M(\tau)\,d\tau\right) + M(t)V\left(\int_{t_0}^{t} A(\tau)\,d\tau\right)U + M(t)\left(\int_{t_0}^{t} M(\tau)\,d\tau\right) \\ &= V\left(\int_{t_0}^{t} A(\tau)\,d\tau\right)UM(t) + \left(\int_{t_0}^{t} M(\tau)\,d\tau\right)VA(t)U + \left(\int_{t_0}^{t} M(\tau)\,d\tau\right)M(t) \end{aligned} \tag{3.6}$$

for all $t \in [t_0, t_f]$.

Proof. The relation $\tilde{A}(t)(\int_{t_0}^{t} \tilde{A}(\tau)\,d\tau) = (\int_{t_0}^{t} \tilde{A}(\tau)\,d\tau)\tilde{A}(t)$ for all $t \in [t_0, t_f]$ holds when considering $\tilde{A}(t) = VA(t)U + M(t)$ given in (2.6) together with (3.6). ∎

The remainder of this subsection specifies Theorems 3.1 and 3.3 for the class of commutative systems.

THEOREM 3.7. *Consider that* $\mathbf{S}$ *and* $\tilde{\mathbf{S}}$ *given in* (2.1) *and* (2.2)*, respectively, are commutative systems.* $(\tilde{\mathbf{S}}, \tilde{J}) \supset (\mathbf{S}, J)$ *if and only if*

$$\begin{aligned} &U\left(\int_{t_0}^{t} M(\tau)\,d\tau\right)^{i} V = 0, \quad U\left(\int_{\tau}^{t} M(\beta)\,d\beta\right)^{i-1} N(\tau)R = 0, \quad V^T M_{\Pi} V = 0, \\ &V^T M_{Q^*}(t)V = 0, \qquad\qquad R^T N_{R^*}(t)R = 0 \end{aligned} \tag{3.7}$$

for $i = 1, \ldots, \tilde{n}$*, all* $t \in [t_0, t_f]$*, and all* $\tau \in [t_0, t]$.

Proof. Since $\tilde{\mathbf{S}}$ is a commutative system, the expanded transition matrix is given by $\tilde{\Phi}(t, t_0) = \sum_{k=0}^{\infty} \frac{1}{k!}(\int_{t_0}^{t} \tilde{A}(\tau)\,d\tau)^k$. Substituting $\tilde{\Phi}(t, t_0)$ into the corresponding requirements given in Theorem 3.1, the proof is concluded. ∎

THEOREM 3.8. *Consider that* $\mathbf{S}$ *and* $\tilde{\mathbf{S}}$ *given in* (2.1) *and* (2.2)*, respectively, are commutative systems such that* $\tilde{\mathbf{S}} \supset \mathbf{S}$*. A control law* $\tilde{u}(t) = -\tilde{K}(t)\,\tilde{x}(t)$ *for* $\tilde{\mathbf{S}}$ *is contractible to the control law* $u(t) = -K(t)\,x(t)$ *for* $\mathbf{S}$ *if and only if*

$$QF(t)\left(\int_{t_0}^{t} M(\tau)\,d\tau\right)^{i-1} V = 0, \qquad QF(t)\left(\int_{\tau}^{t} M(\beta)\,d\beta\right)^{i-1} N(\tau)R = 0 \tag{3.8}$$

for $i = 1, \ldots, \tilde{n}$*, all* $t \in [t_0, t_f]$*, and all* $\tau \in [t_0, t]$.

Proof. By Theorem 3.3 with $\tilde{\Phi}(t, t_0) = \sum_{k=0}^{\infty} \frac{1}{k!}(\int_{t_0}^{t} \tilde{A}(\tau)\,d\tau)^k$ and by using relations (2.6), the theorem is proved. ∎

3.3. Expansion-contraction process.

Change of basis. Since the inclusion principle does not depend on the specific basis used in the state, input, and output spaces, we may introduce convenient changes of basis in $\tilde{\mathbf{S}}$ [3], [4], [19]. Thus the expansion-contraction process between systems $\mathbf{S}$ and $\tilde{\mathbf{S}}$ can be illustrated in the form

$$\begin{array}{ccccccccc} \mathbf{S} & \longrightarrow & \tilde{\mathbf{S}} & \longrightarrow & \bar{\tilde{\mathbf{S}}} & \longrightarrow & \tilde{\mathbf{S}} & \longrightarrow & \mathbf{S}, \\ \mathbb{R}^{\mathbf{n}} & \xrightarrow{V} & \mathbb{R}^{\tilde{\mathbf{n}}} & \xrightarrow{T_A^{-1}} & \bar{\mathbb{R}}^{\tilde{\mathbf{n}}} & \xrightarrow{T_A} & \mathbb{R}^{\tilde{\mathbf{n}}} & \xrightarrow{U} & \mathbb{R}^{\mathbf{n}}, \\ \mathbb{R}^{\mathbf{m}} & \xrightarrow{R} & \mathbb{R}^{\tilde{\mathbf{m}}} & \xrightarrow{T_B^{-1}} & \bar{\mathbb{R}}^{\tilde{\mathbf{m}}} & \xrightarrow{T_B} & \mathbb{R}^{\tilde{\mathbf{m}}} & \xrightarrow{Q} & \mathbb{R}^{\mathbf{m}}, \end{array} \tag{3.9}$$

where $\tilde{\tilde{\mathbf{S}}}$ denotes the expanded system with the new basis. The idea of using changes of basis in the expansion-contraction process was already introduced by Ikeda, Šiljak, and White [13] to represent $\tilde{\mathbf{S}}$ in a canonical form. Given V and R, we define their pseudoinverses as $U = (V^TV)^{-1}V^T$ and $Q = (R^TR)^{-1}R^T$, respectively. Let us consider the changes of basis

$$T_A = (V \;\; W_A), \qquad T_B = (R \;\; W_B), \tag{3.10}$$

where W_A, W_B are chosen such that $Im\, W_A = Ker\, U$, $Im\, W_B = Ker\, Q$. Using these transformations, it is easy to verify the conditions $\bar{U}\bar{V} = I_n$, $\bar{V}\bar{U} = \left(\begin{smallmatrix} I_n & 0 \\ 0 & 0 \end{smallmatrix}\right)$, and $\bar{Q}\bar{R} = I_m$, $\bar{R}\bar{Q} = \left(\begin{smallmatrix} I_m & 0 \\ 0 & 0 \end{smallmatrix}\right)$, where $\bar{V} = T_A^{-1}V = \left(\begin{smallmatrix} I_n \\ 0 \end{smallmatrix}\right)$, $\bar{U} = UT_A = (I_n \; 0)$ and $\bar{R} = T_B^{-1}R = \left(\begin{smallmatrix} I_m \\ 0 \end{smallmatrix}\right)$, $\bar{Q} = QT_B = (I_m \; 0)$. In fact, obtaining these conditions is the motivating factor for defining T_A and T_B in (3.10). These conditions will be crucial to obtaining explicit block structures (with zero blocks) of the complementary matrices and, further, to giving a general strategy for their selection.

Expansion-contraction in the new basis. For simplicity, we will consider the system $\mathbf{S}$ having the following structure:

(3.11)

$$\begin{pmatrix} \dot{x}_1(t) \\ \dot{x}_2(t) \\ \dot{x}_3(t) \end{pmatrix} = \left(\begin{array}{c|c|c} A_{11}(t) & A_{12}(t) & A_{13}(t) \\ \hline & --- & --- \\ A_{21}(t) & A_{22}(t) & A_{23}(t) \\ --- & --- & \\ \hline A_{31}(t) & A_{32}(t) & A_{33}(t) \end{array}\right) \begin{pmatrix} x_1(t) \\ x_2(t) \\ x_3(t) \end{pmatrix} + \left(\begin{array}{c|c|c} B_{11}(t) & B_{12}(t) & B_{13}(t) \\ \hline & --- & --- \\ B_{21}(t) & B_{22}(t) & B_{23}(t) \\ --- & --- & \\ \hline B_{31}(t) & B_{32}(t) & B_{33}(t) \end{array}\right) \begin{pmatrix} u_1(t) \\ u_2(t) \\ u_3(t) \end{pmatrix},$$

where $A_{ii}(t)$, $B_{ii}(t)$, $i = 1, 2, 3$, are $n_i \times n_i$, $n_i \times m_i$ matrices, respectively. This system is composed of two subsystems with one overlapped part, but it is well known that it can be easily generalized for any number of interconnected overlapped subsystems. This structure has been extensively adopted as a prototype structure in the literature [12], [14], [22].

Consider $(\tilde{\tilde{\mathbf{S}}}, \tilde{\tilde{J}})$ defined by the problem

(3.12)

$$\min_{\tilde{\tilde{u}}(t)} \; \tilde{\tilde{J}}\big(\tilde{\tilde{x}}_0, \tilde{\tilde{u}}(t)\big) = \tilde{\tilde{x}}^T(t_f)\tilde{\tilde{\Pi}}\,\tilde{\tilde{x}}(t_f) + \int_{t_0}^{t_f} \left[\tilde{\tilde{x}}^T(t)\tilde{\tilde{Q}}^*(t)\tilde{\tilde{x}}(t) + \tilde{\tilde{u}}^T(t)\tilde{\tilde{R}}^*(t)\tilde{\tilde{u}}(t)\right] dt$$
$$\text{s.t. } \tilde{\tilde{\mathbf{S}}}: \quad \dot{\tilde{\tilde{x}}}(t) = \tilde{\tilde{A}}(t)\,\tilde{\tilde{x}}(t) + \tilde{\tilde{B}}(t)\,\tilde{\tilde{u}}(t),$$

where $\tilde{\tilde{A}}(t)$, $\tilde{\tilde{B}}(t)$, $\tilde{\tilde{\Pi}}$, $\tilde{\tilde{Q}}^*(t)$, and $\tilde{\tilde{R}}^*(t)$ denote the matrices in the system $\tilde{\tilde{\mathbf{S}}}$ of appropriate dimensions. The vectors $\tilde{\tilde{x}}(t)$ and $\tilde{\tilde{u}}(t)$ are defined as $\tilde{\tilde{x}}(t) = T_A^{-1}Vx(t) = \bar{V}x(t)$, $\tilde{\tilde{u}}(t) = T_B^{-1}Ru(t) = \bar{R}u(t)$. Now, analogously to $\tilde{\mathbf{S}}$, denote the relations for the system $\tilde{\tilde{\mathbf{S}}}$ as

$$\begin{aligned} \tilde{\tilde{A}}(t) &= \bar{V}A(t)\bar{U} + \bar{M}(t), & \tilde{\tilde{B}}(t) &= \bar{V}B(t)\bar{Q} + \bar{N}(t), \\ \tilde{\tilde{\Pi}} &= \bar{U}^T\Pi\bar{U} + \bar{M}_\Pi, & \tilde{\tilde{Q}}^*(t) &= \bar{U}^TQ^*(t)\bar{U} + \bar{M}_{Q^*}(t), \\ \tilde{\tilde{R}}^*(t) &= \bar{Q}^TR^*(t)\bar{Q} + \bar{N}_{R^*}(t), \end{aligned} \tag{3.13}$$

where the new complementary matrices are

$$\begin{aligned} \bar{M}(t) &= T_A^{-1}M(t)T_A, & \bar{N}(t) &= T_A^{-1}N(t)T_B, & \bar{M}_\Pi &= T_A^TM_\Pi T_A, \\ \bar{M}_{Q^*}(t) &= T_A^TM_{Q^*}(t)T_A, & \bar{N}_{R^*}(t) &= T_B^TN_{R^*}(t)T_B. \end{aligned} \tag{3.14}$$

Note. Since changes of basis do not affect the commutativity property, the system $\tilde{\tilde{\mathbf{S}}}$ is commutative if $\tilde{\mathbf{S}}$ is commutative.

First, we analyze the structure of the matrices $\bar{M}(t)$, $\bar{N}(t)$, $\bar{M}_{\Pi}$, $\bar{M}_{Q^*}(t)$, and $\bar{N}_{R^*}(t)$ in the expanded system. Consider the complementary matrices of $\tilde{\mathbf{S}}$ having the form $M(t) = (M_{ij}(t))$, $N(t) = (N_{ij}(t))$, $M_{\Pi} = (M_{\Pi_{ij}})$, $M_{Q^*}(t) = (M_{Q^*_{ij}}(t))$, $N_{R^*}(t) = (N_{R^*_{ij}}(t))$ for $i, j = 1, \ldots, 4$, with $M_{\Pi_{ij}} = M^T_{\Pi_{ji}}$, $M_{Q^*_{ij}}(t) = M^T_{Q^*_{ji}}(t)$, $N_{R^*_{ij}}(t) = N^T_{R^*_{ji}}(t)$, where each matrix has appropriate dimensions corresponding to the initial structure given in (3.11). It is convenient to deal with matrix blocks when using the matrices T_A, T_B, T_A^{-1}, T_B^{-1}. Suppose the matrices

$$\bar{M}(t) = \begin{pmatrix} \bar{M}_{11}(t) & \bar{M}_{12}(t) \\ \bar{M}_{21}(t) & \bar{M}_{22}(t) \end{pmatrix}, \quad \bar{N}(t) = \begin{pmatrix} \bar{N}_{11}(t) & \bar{N}_{12}(t) \\ \bar{N}_{21}(t) & \bar{N}_{22}(t) \end{pmatrix}, \quad \bar{M}_{\Pi} = \begin{pmatrix} \bar{M}_{\Pi_{11}} & \bar{M}_{\Pi_{12}} \\ \bar{M}^T_{\Pi_{12}} & \bar{M}_{\Pi_{22}} \end{pmatrix},$$

$$\bar{M}_{Q^*}(t) = \begin{pmatrix} \bar{M}_{Q^*_{11}}(t) & \bar{M}_{Q^*_{12}}(t) \\ \bar{M}^T_{Q^*_{12}}(t) & \bar{M}_{Q^*_{22}}(t) \end{pmatrix}, \quad \bar{N}_{R^*}(t) = \begin{pmatrix} \bar{N}_{R^*_{11}}(t) & \bar{N}_{R^*_{12}}(t) \\ \bar{N}^T_{R^*_{12}}(t) & \bar{N}_{R^*_{22}}(t) \end{pmatrix},$$

where $\bar{M}_{11}(t)$, $\bar{M}_{22}(t)$ are $n \times n$, $(\tilde{n} - n) \times (\tilde{n} - n)$ matrices, respectively. $\bar{N}_{11}(t)$, $\bar{N}_{22}(t)$ are $n \times m$, $(\tilde{n} - n) \times (\tilde{m} - m)$ matrices, respectively. $\bar{M}_{\Pi_{11}}$, $\bar{M}_{\Pi_{22}}$ are $n \times n$, $(\tilde{n} - n) \times (\tilde{n} - n)$ matrices, respectively. $\bar{M}_{Q^*_{11}}(t)$, $\bar{M}_{Q^*_{22}}(t)$ are $n \times n$, $(\tilde{n} - n) \times (\tilde{n} - n)$ matrices, respectively. $\bar{N}_{R^*_{11}}(t)$, $\bar{N}_{R^*_{22}}(t)$ are $m \times m$, $(\tilde{m} - m) \times (\tilde{m} - m)$ matrices, respectively. We need to know the form of the submatrices $\bar{M}_{ij}(t)$, $\bar{N}_{ij}(t)$, $\bar{M}_{\Pi_{ij}}$, $\bar{M}_{Q^*_{ij}}(t)$, and $\bar{N}_{R^*_{ij}}(t)$ for $i, j = 1, 2$. This is given in the following propositions.

PROPOSITION 3.9. *Consider that* $\mathbf{S}$ *and* $\tilde{\tilde{\mathbf{S}}}$ *given in* (2.1) *and* (3.12)*, respectively, are commutative systems such that* $\tilde{\tilde{\mathbf{S}}} \supset \mathbf{S}$*. Then* $\bar{M}(t) = \left(\begin{smallmatrix} 0 & \bar{M}_{12}(t) \\ \bar{M}_{21}(t) & \bar{M}_{22}(t) \end{smallmatrix}\right)$*, where* (0) *denotes a matrix of order* n*, and the other blocks satisfy* $\int_{t_0}^t \bar{M}_{12}(\tau)\, d\tau (\int_{t_0}^t \bar{M}_{22}(\tau)\, d\tau)^{i-2} \int_{t_0}^t \bar{M}_{21}(\tau)\, d\tau = 0$ *for* $i = 2, \ldots, \tilde{n}$ *and all* $t \in [t_0, t_f]$*.*

Proof. Imposing the first condition given in Theorem 3.7, $\bar{U}(\int_{t_0}^t \bar{M}(\tau)\, d\tau)^i \bar{V} = 0$ for $i = 1$, we get $\bar{U}(\int_{t_0}^t \bar{M}(\tau)\, d\tau)\bar{V} = 0$ and consequently $\int_{t_0}^t \bar{M}_{11}(\tau)\, d\tau = 0$ for all $t \in [t_0, t_f]$. Then $\bar{M}_{11}(t) = 0$ for all $t \in [t_0, t_f]$. For $\mu = 2, \ldots, \tilde{n}$ we obtain

$$\left(\int_{t_0}^t \bar{M}(\tau)\, d\tau\right)^{\mu} = \begin{pmatrix} \int_{t_0}^t \bar{M}_{12}(\tau)\, d\tau \Big(\int_{t_0}^t \bar{M}_{22}(\tau)\, d\tau\Big)^{\mu-2} \int_{t_0}^t \bar{M}_{21}(\tau)\, d\tau & | \\ & | \\ \Big(\int_{t_0}^t \bar{M}_{22}(\tau)\, d\tau\Big)^{\mu-1} \int_{t_0}^t \bar{M}_{21}(\tau)\, d\tau & | \end{pmatrix}$$

$$\begin{pmatrix} | & \int_{t_0}^t \bar{M}_{12}(\tau)\, d\tau \Big(\int_{t_0}^t \bar{M}_{22}(\tau)\, d\tau\Big)^{\mu-1} \\ | & \\ | & \Big(\int_{t_0}^t \bar{M}_{22}(\tau)\, d\tau\Big)^{\mu} + \sum_{j=0}^{j=\mu-2} \Big(\int_{t_0}^t \bar{M}_{22}(\tau)\, d\tau\Big)^j \int_{t_0}^t \bar{M}_{21}(\tau)\, d\tau \int_{t_0}^t \bar{M}_{12}(\tau)\, d\tau \Big(\int_{t_0}^t \bar{M}_{22}(\tau)\, d\tau\Big)^{\mu-2-j} \end{pmatrix}. \tag{3.15}$$

Then, for $i = k \geq 2$, $\bar{U}(\int_{t_0}^t \bar{M}(\tau)\, d\tau)^k \bar{V} = 0$ implies $\int_{t_0}^t \bar{M}_{12}(\tau)\, d\tau\, (\int_{t_0}^t \bar{M}_{22}(\tau)\, d\tau)^{k-2} \int_{t_0}^t \bar{M}_{21}(\tau)\, d\tau = 0$. Repeating this process for $i = \tilde{n}$, $\bar{U}(\int_{t_0}^t \bar{M}(\tau)\, d\tau)^{\tilde{n}} \bar{V} = 0$ leads to $\int_{t_0}^t \bar{M}_{12}(\tau)\, d\tau (\int_{t_0}^t \bar{M}_{22}(\tau)\, d\tau)^{\tilde{n}-2} \int_{t_0}^t \bar{M}_{21}(\tau)\, d\tau = 0$ for all $t \in [t_0, t_f]$. ∎

PROPOSITION 3.10. *Consider that* $\mathbf{S}$ *and* $\tilde{\tilde{\mathbf{S}}}$*, given in* (2.1) *and* (3.12)*, respectively, are commutative systems such that* $\tilde{\tilde{\mathbf{S}}} \supset \mathbf{S}$*. Then* $\bar{N}(t) = \left(\begin{smallmatrix} 0 & \bar{N}_{12}(t) \\ \bar{N}_{21}(t) & \bar{N}_{22}(t) \end{smallmatrix}\right)$*, where* (0) *is an* $n \times m$ *matrix and the other blocks satisfy* $\int_{t_0}^t \bar{M}_{12}(\tau)\, d\tau \, (\int_{\tau}^t \bar{M}_{22}(\beta)\, d\beta)^{i-2} \, \bar{N}_{21}(\tau) = 0$ *for* $i = 2, \ldots, \tilde{n}$*, all* $t \in [t_0, t_f]$*, and all* $\tau \in [t_0, t]$*.*

Proof. This proof is similar to Proposition 3.9 from the condition $\bar{U}\left(\int_\tau^t \bar{M}(\beta)\,d\beta\right)^{i-1}\bar{N}(\tau)\bar{R}=0$, $i=1,\dots,\tilde{n}$, given in Theorem 3.7 and using Proposition 3.9. ∎

Note. The conditions imposed by Theorem 3.7 on matrices $M(t)$ and $N(t)$ in order to verify $\tilde{\bar{\mathbf{S}}}\supset\mathbf{S}$ have been reduced to conditions on submatrices, that is, $\int_{t_0}^t \bar{M}_{12}(\tau)\,d\tau\left(\int_{t_0}^t \bar{M}_{22}(\tau)\,d\tau\right)^{i-2}\int_{t_0}^t \bar{M}_{21}(\tau)\,d\tau=0$ and $\int_{t_0}^t \bar{M}_{12}(\tau)\,d\tau\left(\int_\tau^t \bar{M}_{22}(\beta)\,d\beta\right)^{i-2}\bar{N}_{21}(\tau)=0$ for $i=2,\dots,\tilde{n}$, all $t\in[t_0,t_f]$, and all $\tau\in[t_0,t]$, where $\bar{M}(t)=\left(\begin{smallmatrix}0 & \bar{M}_{12}(t)\\ \bar{M}_{21}(t) & \bar{M}_{22}(t)\end{smallmatrix}\right)$ and $\bar{N}(t)=\left(\begin{smallmatrix}0 & \bar{N}_{12}(t)\\ \bar{N}_{21}(t) & \bar{N}_{22}(t)\end{smallmatrix}\right)$.

THEOREM 3.11. *Consider that* $\mathbf{S}$ *and* $\tilde{\bar{\mathbf{S}}}$, *given in* (2.1) *and* (3.12), *respectively, are commutative systems.* $(\tilde{\bar{\mathbf{S}}},\tilde{\bar{J}})\supset(\mathbf{S},J)$ *if* $\bar{M}_\Pi=\left(\begin{smallmatrix}0 & \bar{M}_{\Pi_{12}}\\ \bar{M}_{\Pi_{12}}^T & \bar{M}_{\Pi_{22}}\end{smallmatrix}\right)$, $\bar{M}_{Q^*}(t)=\left(\begin{smallmatrix}0 & \bar{M}_{Q_{12}^*}(t)\\ \bar{M}_{Q_{12}^*}^T(t) & \bar{M}_{Q_{22}^*}(t)\end{smallmatrix}\right)$, $\bar{N}_{R^*}(t)=\left(\begin{smallmatrix}0 & \bar{N}_{R_{12}^*}(t)\\ \bar{N}_{R_{12}^*}^T(t) & \bar{N}_{R_{22}^*}(t)\end{smallmatrix}\right)$, *and either*

$$\begin{aligned}&\text{(a)}\quad \bar{M}(t)=\begin{pmatrix}0 & \bar{M}_{12}(t)\\ 0 & \bar{M}_{22}(t)\end{pmatrix},\quad \bar{N}(t)=\begin{pmatrix}0 & \bar{N}_{12}(t)\\ 0 & \bar{N}_{22}(t)\end{pmatrix}\quad \textit{or}\\ &\text{(b)}\quad \bar{M}(t)=\begin{pmatrix}0 & 0\\ \bar{M}_{21}(t) & \bar{M}_{22}(t)\end{pmatrix},\quad \bar{N}(t)=\begin{pmatrix}0 & \bar{N}_{12}(t)\\ \bar{N}_{21}(t) & \bar{N}_{22}(t)\end{pmatrix}\end{aligned}\tag{3.16}$$

for all $t\in[t_0,t_f]$.

Proof. Considering the conditions (a) and (b) given by Theorem 3.2, respectively, in the new expanded system $\tilde{\bar{\mathbf{S}}}$, the proof is straightforward. ∎

Contractibility. The idea is to design control laws in the expanded system $\tilde{\mathbf{S}}$ so that we can contract and implement them into the original system $\mathbf{S}$. Now, we want to determine the conditions under which a control law designed in $\tilde{\bar{\mathbf{S}}}$ can be contracted into the system $\mathbf{S}$ in terms of the complementary matrices.

Suppose that the complementary matrix $F(t)$ has the form $F(t)=(F_{ij}(t))$, $i,j=1,\dots,4$, where $F_{11}(t)$, $F_{22}(t)$, $F_{33}(t)$, and $F_{44}(t)$ are $m_1\times n_1$, $m_2\times n_2$, $m_2\times n_2$, and $m_3\times n_3$ matrices, respectively. Define $\bar{F}(t)=\left(\begin{smallmatrix}\bar{F}_{11}(t) & \bar{F}_{12}(t)\\ \bar{F}_{21}(t) & \bar{F}_{22}(t)\end{smallmatrix}\right)$, where $\bar{F}_{11}(t)$ and $\bar{F}_{22}(t)$ are $m\times n$ and $(\tilde{m}-m)\times(\tilde{n}-n)$ matrices, respectively. Similarly, denote $K(t)=(K_{ij}(t))$, $i,j=1,\dots,3$, where $K_{11}(t)$, $K_{22}(t)$, $K_{33}(t)$ are $m_i\times n_i$ matrices, $i=1,\dots,3$, respectively. The gain matrix $\tilde{\bar{K}}(t)$ for the system $\tilde{\bar{\mathbf{S}}}$ has the form $\tilde{\bar{K}}(t)=\bar{R}K(t)\bar{U}+\bar{F}(t)$, where $\tilde{\bar{K}}(t)=T_{_B}^{-1}\tilde{K}(t)T_{_A}$ and $\bar{F}(t)=T_{_B}^{-1}F(t)T_{_A}$. By Definition 2.4, $\tilde{\bar{u}}(t)=-\tilde{\bar{K}}(t)\tilde{\bar{x}}(t)$ of $\tilde{\bar{\mathbf{S}}}$ is contractible to the control law $u(t)=-K(t)x(t)$ of $\mathbf{S}$ whenever $K(t)x(t;x_0,u)=\bar{Q}\tilde{\bar{K}}(t)\tilde{\bar{x}}(t;\bar{V}x_0,\bar{R}u)$ for all $t\in[t_0,t_f]$.

So far we do not know the form of the complementary matrix $F(t)$ and the conditions which must be satisfied in order to get a contractible control law. The following theorem answers this question.

THEOREM 3.12. *Consider that* $\mathbf{S}$ *and* $\tilde{\bar{\mathbf{S}}}$ *given in* (2.1) *and* (3.12), *respectively, are commutative systems such that* $\tilde{\bar{\mathbf{S}}}\supset\mathbf{S}$. *A control law* $\tilde{\bar{u}}(t)=-\tilde{\bar{K}}(t)\tilde{\bar{x}}(t)$ *in the expanded system* $\tilde{\bar{\mathbf{S}}}$ *is contractible to the control law* $u(t)=-K(t)x(t)$ *of* $\mathbf{S}$ *if and only if* $\bar{F}=\left(\begin{smallmatrix}0 & \bar{F}_{12}(t)\\ \bar{F}_{21}(t) & \bar{F}_{22}(t)\end{smallmatrix}\right)$ *and satisfies*

$$\begin{aligned}\bar{F}_{12}(t)\left(\int_{t_0}^t \bar{M}_{22}(\tau)\,d\tau\right)^{i-1}\int_{t_0}^t \bar{M}_{21}(\tau)\,d\tau=0,\\ \bar{F}_{12}(t)\left(\int_\tau^t \bar{M}_{22}(\beta)\,d\beta\right)^{j-1}\bar{N}_{21}(\tau)=0\end{aligned}\tag{3.17}$$

for $i = 1, \dots, \tilde{n}-1$, $j = 1, \dots, \tilde{n}$, *all* $t \in [t_0, t_f]$, *and all* $\tau \in [t_0, t]$.

Proof. Let $\bar{F}(t)$ be $\bar{F}(t) = \left(\begin{smallmatrix} \bar{F}_{11}(t) & \bar{F}_{12}(t) \\ \bar{F}_{21}(t) & \bar{F}_{22}(t) \end{smallmatrix}\right)$. Imposing the first condition given in Theorem 3.8, that is, $\bar{Q}\bar{F}(t)\left(\int_{t_0}^{t} \bar{M}(\tau)\,d\tau\right)^{i-1}\bar{V} = 0$ for $i = 1$, we obtain $\bar{Q}\bar{F}(t)\bar{V} = 0$ and thus that $\bar{F}_{11}(t) = 0$. For $i = k \geq 2$, $\bar{Q}\bar{F}(t)\left(\int_{t_0}^{t} \bar{M}(\tau)\,d\tau\right)^{k-1}\bar{V} = 0$ implies $\bar{F}_{12}(t)\left(\int_{t_0}^{t} \bar{M}_{22}(\tau)\,d\tau\right)^{k-2}\int_{t_0}^{t} \bar{M}_{21}(\tau)\,d\tau = 0$. For $i = \tilde{n}$, $\bar{Q}\bar{F}(t)\left(\int_{t_0}^{t} \bar{M}(\tau)\,d\tau\right)^{\tilde{n}-1}\bar{V} = 0$ implies that $\bar{F}_{12}(t)\left(\int_{t_0}^{t} \bar{M}_{22}(\tau)\,d\tau\right)^{\tilde{n}-2}\int_{t_0}^{t} \bar{M}_{21}(\tau)\,d\tau = 0$ holds for all $t \in [t_0, t_f]$. This proves the first equation in (3.17). Similarly, $\bar{Q}\bar{F}(t)\left(\int_{\tau}^{t} \bar{M}(\beta)\,d\beta\right)^{i-1}\bar{N}(\tau)\bar{R} = 0$ for $i = 1, \dots, \tilde{n}$, all $t \in [t_0, t_f]$, and all $\tau \in [t_0, t]$; this equality leads to $\bar{F}_{12}(t)\left(\int_{\tau}^{t} \bar{M}_{22}(\beta)\,d\beta\right)^{j-1}\cdot \bar{N}_{21}(\tau) = 0$ for $j = 1, \dots, \tilde{n}$, all $t \in [t_0, t_f]$, and all $\tau \in [t_0, t]$. ∎

3.4. Selection of complementary matrices. The above results do not depend on the selection of the matrices V and R, and thus they can be applied to any expansion-contraction process. To use these results in a practical scheme, we start by defining specific transformations V and R to expand a given problem (2.1). Here we consider the following expansion transformation matrices:

$$V = \begin{pmatrix} I_{n_1} & 0 & 0 \\ 0 & I_{n_2} & 0 \\ 0 & I_{n_2} & 0 \\ 0 & 0 & I_{n_3} \end{pmatrix}, \qquad R = \begin{pmatrix} I_{m_1} & 0 & 0 \\ 0 & I_{m_2} & 0 \\ 0 & I_{m_2} & 0 \\ 0 & 0 & I_{m_3} \end{pmatrix}. \tag{3.18}$$

These usual transformations are chosen to lead, in a simple natural way, to an expanded system where the state vector $x_2(t)$ and the control vector $u_2(t)$ appear repeated in $\tilde{x}(t) = (x_1^T(t), x_2^T(t), x_2^T(t), x_3^T(t))^T$ and $\tilde{u}(t) = (u_1^T(t), u_2^T(t), u_2^T(t), u_3^T(t))^T$, respectively. According to (3.10), the changes of basis to define the system $\tilde{\bar{\mathbf{S}}}$ for matrices (3.18) are given by

$$T_A = \begin{pmatrix} I_{n_1} & 0 & 0 & 0 \\ 0 & I_{n_2} & 0 & I_{n_2} \\ 0 & I_{n_2} & 0 & -I_{n_2} \\ 0 & 0 & I_{n_3} & 0 \end{pmatrix}, \qquad T_A^{-1} = \begin{pmatrix} I_{n_1} & 0 & 0 & 0 \\ 0 & \frac{1}{2}I_{n_2} & \frac{1}{2}I_{n_2} & 0 \\ 0 & 0 & 0 & I_{n_3} \\ 0 & \frac{1}{2}I_{n_2} & -\frac{1}{2}I_{n_2} & 0 \end{pmatrix}. \tag{3.19}$$

Analogously, they are given by T_B, T_B^{-1}. The following theorems express the structure of the complementary matrices $M(t)$, $N(t)$, M_Π, $M_{Q^*}(t)$, $N_{R^*}(t)$, and $F(t)$ in the initial basis.

THEOREM 3.13. *Consider that* $\mathbf{S}$ *and* $\tilde{\mathbf{S}}$, *given in* (2.1) *and* (2.2), *respectively, are commutative systems.* $\tilde{\mathbf{S}} \supset \mathbf{S}$ *if and only if*

(3.20)

$$\begin{pmatrix} \int_{t_0}^{t} M_{12}(\tau)\,d\tau \\ \int_{t_0}^{t} (M_{23}(\tau)+M_{33}(\tau))\,d\tau \\ \int_{t_0}^{t} M_{42}(\tau)\,d\tau \end{pmatrix}\left(\int_{t_0}^{t} \left(M_{22}(\tau)+M_{33}(\tau) \right) d\tau\right)^{i-2}\int_{t_0}^{t} \left(M_{21}(\tau)M_{22}(\tau)+M_{23}(\tau)M_{24}(\tau) \right) d\tau = 0,$$

$$\begin{pmatrix} \int_{t_0}^{t} M_{12}(\tau)\,d\tau \\ \int_{t_0}^{t} (M_{23}(\tau)+M_{33}(\tau))\,d\tau \\ \int_{t_0}^{t} M_{42}(\tau)\,d\tau \end{pmatrix}\left(\int_{\tau}^{t} \left(M_{22}(\beta)+M_{33}(\beta) \right) d\beta\right)^{i-2}\begin{pmatrix} N_{21}(\tau)N_{22}(\tau)+N_{23}(\tau)N_{24}(\tau) \end{pmatrix} = 0$$

for $i = 2, \dots, \tilde{n}$, *all* $t \in [t_0, t_f]$, *and all* $\tau \in [t_0, t]$, *where*

$$M(t) = \begin{pmatrix} 0 & M_{12}(t) & -M_{12}(t) & 0 \\ M_{21}(t) & M_{22}(t) & M_{23}(t) & M_{24}(t) \\ -M_{21}(t) & -(M_{22}(t)+M_{23}(t)+M_{33}(t)) & M_{33}(t) & -M_{24}(t) \\ 0 & M_{42}(t) & -M_{42}(t) & 0 \end{pmatrix}. \tag{3.21}$$

The matrix $N(t)$ has the same structure as $M(t)$.

Proof. Consider $\bar{M}(t) = T_A^{-1} M(t) T_A$, given in (3.14), where T_A and T_A^{-1} are given in (3.19). From Proposition 3.9, $\bar{M}_{11}(t) = 0$ and the matrix blocks $\bar{M}_{ij}(t)$, $i, j = 1, 2$, can be identified. Consequently, we obtain the structure of the complementary matrix $M(t)$ given in (3.21). We proceed analogously for the matrix $N(t)$ by using $\bar{N}(t) = T_A^{-1} N(t) T_B$ given in (3.14) and Proposition 3.10. Now, imposing $\int_{t_0}^{t} \bar{M}_{12}(\tau)\, d\tau$ $(\int_{t_0}^{t} \bar{M}_{22}(\tau)\, d\tau)^{i-2}$ $\int_{t_0}^{t} \bar{M}_{21}(\tau)\, d\tau = 0$ and $\int_{t_0}^{t} \bar{M}_{12}(\tau)\, d\tau$ $(\int_{\tau}^{t} \bar{M}_{22}(\beta)\, d\beta)^{i-2}$ $\bar{N}_{21}(\tau) = 0$ for $i = 2, \ldots, \tilde{n}$, given by Propositions 3.9 and 3.10, respectively, we get (3.20). ∎

PROPOSITION 3.14. *Consider that* $\mathbf{S}$ *and* $\tilde{\mathbf{S}}$*, given in* (2.1) *and* (2.2)*, respectively, are commutative systems such that* $\tilde{\mathbf{S}} \supset \mathbf{S}$*. Then the corresponding expanded matrix* $\tilde{A}(t)$ *has the form*

$$\tilde{A}(t) = \begin{pmatrix} A_{11}(t) & \frac{1}{2}A_{12}(t)+M_{12}(t) & \frac{1}{2}A_{12}(t)-M_{12}(t) & A_{13}(t) \\ A_{21}(t)+M_{21}(t) & \frac{1}{2}A_{22}(t)+M_{22}(t) & \frac{1}{2}A_{22}(t)+M_{23}(t) & A_{23}(t)+M_{24}(t) \\ A_{21}(t)-M_{21}(t) & \frac{1}{2}A_{22}(t)-(M_{22}(t)+M_{23}(t)+M_{33}(t)) & \frac{1}{2}A_{22}(t)+M_{33}(t) & A_{23}(t)-M_{24}(t) \\ A_{31}(t) & \frac{1}{2}A_{32}(t)+M_{42}(t) & \frac{1}{2}A_{32}(t)-M_{42}(t) & A_{33}(t) \end{pmatrix}.$$

A similar structure can be presented for the expanded control matrix $\tilde{B}(t)$*.*

Proof. The proof is straightforward by substituting the matrix $M(t)$ given in (3.21) into $\tilde{A}(t) = VA(t)U + M(t)$. The same holds for $\tilde{B}(t) = VB(t)Q + N(t)$. ∎

THEOREM 3.15. *Consider that* $\mathbf{S}$ *and* $\tilde{\mathbf{S}}$*, given in* (2.1) *and* (2.2)*, respectively, are commutative systems.* $(\tilde{\mathbf{S}}, \tilde{J}) \supset (\mathbf{S}, J)$ *if*

(3.22)

$$M_\Pi = \begin{pmatrix} 0 & M_{\Pi_{12}} & -M_{\Pi_{12}} & 0 \\ M_{\Pi_{12}}^T & -M_{\Pi_{23}} - M_{\Pi_{23}}^T - M_{\Pi_{33}} & M_{\Pi_{23}} & M_{\Pi_{24}} \\ -M_{\Pi_{12}}^T & M_{\Pi_{23}}^T & M_{\Pi_{33}} & -M_{\Pi_{24}} \\ 0 & M_{\Pi_{24}}^T & -M_{\Pi_{24}}^T & 0 \end{pmatrix},$$

$$M_{Q^*}(t) = \begin{pmatrix} 0 & M_{Q_{12}^*}(t) & -M_{Q_{12}^*}(t) & 0 \\ M_{Q_{12}^*}^T(t) & -M_{Q_{23}^*}(t) - M_{Q_{23}^*}^T(t) - M_{Q_{33}^*}(t) & M_{Q_{23}^*}(t) & M_{Q_{24}^*}(t) \\ -M_{Q_{12}^*}^T(t) & M_{Q_{23}^*}^T(t) & M_{Q_{33}^*}(t) & -M_{Q_{24}^*}(t) \\ 0 & M_{Q_{24}^*}^T(t) & -M_{Q_{24}^*}^T(t) & 0 \end{pmatrix},$$

$$N_{R^*}(t) = \begin{pmatrix} 0 & N_{R_{12}^*}(t) & -N_{R_{12}^*}(t) & 0 \\ N_{R_{12}^*}^T(t) & -N_{R_{23}^*}(t) - N_{R_{23}^*}^T(t) - N_{R_{33}^*}(t) & N_{R_{23}^*}(t) & N_{R_{24}^*}(t) \\ -N_{R_{12}^*}^T(t) & N_{R_{23}^*}^T(t) & N_{R_{33}^*}(t) & -N_{R_{24}^*}(t) \\ 0 & N_{R_{24}^*}^T(t) & -N_{R_{24}^*}^T(t) & 0 \end{pmatrix}$$ *and either*

(a) $$M(t) = \begin{pmatrix} 0 & M_{12}(t) & -M_{12}(t) & 0 \\ 0 & M_{22}(t) & -M_{22}(t) & 0 \\ 0 & M_{32}(t) & -M_{32}(t) & 0 \\ 0 & M_{42}(t) & -M_{42}(t) & 0 \end{pmatrix}, \quad N(t) = \begin{pmatrix} 0 & N_{12}(t) & -N_{12}(t) & 0 \\ 0 & N_{22}(t) & -N_{22}(t) & 0 \\ 0 & N_{32}(t) & -N_{32}(t) & 0 \\ 0 & N_{42}(t) & -N_{42}(t) & 0 \end{pmatrix}$$ *or*

(b) $$M(t) = \begin{pmatrix} 0 & 0 & 0 & 0 \\ M_{21}(t) & M_{22}(t) & M_{23}(t) & M_{24}(t) \\ -M_{21}(t) & -M_{22}(t) & -M_{23}(t) & -M_{24}(t) \\ 0 & 0 & 0 & 0 \end{pmatrix},$$

$$N(t) = \begin{pmatrix} 0 & N_{12}(t) & -N_{12}(t) & 0 \\ N_{21}(t) & N_{22}(t) & N_{23}(t) & N_{24}(t) \\ -N_{21}(t) & -(N_{22}(t)+N_{23}(t)+N_{33}(t)) & N_{33}(t) & -N_{24}(t) \\ 0 & N_{42}(t) & -N_{42}(t) & 0 \end{pmatrix}$$

for all $t \in [t_0, t_f]$*.*

Proof. By using the equations (3.14) together with Theorem 3.11, the proof is concluded. ∎

THEOREM 3.16. *Consider that* $\mathbf{S}$ *and* $\tilde{\mathbf{S}}$*, given in* (2.1) *and* (2.2)*, respectively, are commutative systems such that* $\tilde{\mathbf{S}} \supset \mathbf{S}$*. A control law* $\tilde{u}(t) = -\tilde{K}(t)\tilde{x}(t)$ *in the expanded system* $\tilde{\mathbf{S}}$ *is contractible to the control law* $u(t) = -K(t)x(t)$ *of the system* $\mathbf{S}$ *if and only if*

(3.23)
$$\begin{pmatrix} F_{12}(t) \\ F_{23}(t)+F_{33}(t) \\ F_{42}(t) \end{pmatrix} \left(\int_{t_0}^{t} \left(M_{22}(\tau)+M_{33}(\tau) \right) d\tau \right)^{i-1} \int_{t_0}^{t} \left(M_{21}(\tau) \;\; M_{22}(\tau)+M_{23}(\tau) \;\; M_{24}(\tau) \right) d\tau = 0,$$
$$\begin{pmatrix} F_{12}(t) \\ F_{23}(t)+F_{33}(t) \\ F_{42}(t) \end{pmatrix} \left(\int_{\tau}^{t} \left(M_{22}(\beta)+M_{33}(\beta) \right) d\beta \right)^{j-1} \begin{pmatrix} N_{21}(\tau) \;\; N_{22}(\tau)+N_{23}(\tau) \;\; N_{24}(\tau) \end{pmatrix} = 0$$

for $i = 1, \ldots, \tilde{n}-1$*,* $j = 1, \ldots, \tilde{n}$*, all* $t \in [t_0, t_f]$*, and all* $\tau \in [t_0, t]$*, where the matrix* $F(t)$ *has the form*

$$F(t) = \begin{pmatrix} 0 & F_{12}(t) & -F_{12}(t) & 0 \\ F_{21}(t) & F_{22}(t) & F_{23}(t) & F_{24}(t) \\ -F_{21}(t) & -(F_{22}(t)+F_{23}(t)+F_{33}(t)) & F_{33}(t) & -F_{24}(t) \\ 0 & F_{42}(t) & -F_{42}(t) & 0 \end{pmatrix}. \tag{3.24}$$

Proof. Consider $\bar{F}(t) = T_B^{-1} F(t) T_A$ with T_B^{-1}, T_A given by (3.19). From Theorem 3.12, $\bar{F}_{11}(t) = 0$ and the other matrix blocks $\bar{F}_{ij}(t)$, $i, j = 1, 2$, can be identified. Thus we obtain the structure of the complementary matrix $F(t)$ given in (3.24). We get (3.23) by imposing (3.17). □

Note. From (3.20), we may identify some important cases in order to obtain possible structures of the complementary matrices $M(t)$ and $N(t)$. They are

$$\begin{aligned} &(a) \quad M_{12}(t) = 0, \quad M_{23}(t) + M_{33}(t) = 0, \quad M_{42}(t) = 0, \\ &(b) \quad M_{21}(t) = 0, \quad M_{22}(t) + M_{23}(t) = 0, \quad M_{24}(t) = 0, \quad N_{21}(t) = 0, \\ &\qquad N_{22}(t) + N_{23}(t) = 0, \quad N_{24}(t) = 0, \\ &(c) \quad \text{others} \end{aligned} \tag{3.25}$$

for all $t \in [t_0, t_f]$.

We focus our attention on the case (c) because it offers more freedom to select the corresponding complementary matrices than do cases (a) and (b). Now we assume that $M_{22}(t)+M_{33}(t) = 0$. Then (3.20) holds for $i > 2$, all $t \in [t_0, t_f]$, and all $\tau \in [t_0, t]$. If $i = 2$, choosing $M_{23}(t)+M_{33}(t) = 0$ or $M_{22}(t)+M_{23}(t) = 0$ in (3.20), two subcases of case (c) are obtained.

Subcase (c_1): $M_{23}(t) + M_{33}(t) = 0$. Then, relations (3.20) become

$$\begin{aligned} &\begin{pmatrix} M_{12}(t) \\ 0 \\ M_{42}(t) \end{pmatrix} \begin{pmatrix} \int_{t_0}^{t} M_{21}(\tau)\, d\tau & \int_{t_0}^{t} M_{22}(\tau)\, d\tau & \int_{t_0}^{t} M_{24}(\tau)\, d\tau \end{pmatrix} = 0, \\ &\begin{pmatrix} M_{12}(t) \\ 0 \\ M_{42}(t) \end{pmatrix} \begin{pmatrix} N_{21}(\tau) & N_{22}(\tau)+N_{23}(\tau) & N_{24}(\tau) \end{pmatrix} = 0. \end{aligned} \tag{3.26}$$

Subcase (c_2): $M_{22}(t) + M_{23}(t) = 0$. Then (3.20) becomes

$$\begin{aligned} &\begin{pmatrix} M_{12}(t) \\ M_{22}(t) \\ M_{42}(t) \end{pmatrix} \begin{pmatrix} \int_{t_0}^{t} M_{21}(\tau)\, d\tau & 0 & \int_{t_0}^{t} M_{24}(\tau)\, d\tau \end{pmatrix} = 0, \\ &\begin{pmatrix} M_{12}(t) \\ M_{22}(t) \\ M_{42}(t) \end{pmatrix} \begin{pmatrix} N_{21}(\tau) & N_{22}(\tau)+N_{23}(\tau) & N_{24}(\tau) \end{pmatrix} = 0 \end{aligned} \tag{3.27}$$

for all $t \in [t_0, t_f]$ and all $\tau \in [t_0, t]$.

The above cases give possible structures for choosing $M(t)$ and $N(t)$. A similar track should be followed to obtain structures for the other complementary matrices [3], [4], [19]. Finally, the designer can select specific values of free elements of the block complementary matrices in (3.26) or (3.27) according to given design requirements. Simultaneously, it should be checked that the matrix $M(t)$ satisfies condition (3.6) in Proposition 3.6. In the next section, this procedure is illustrated in the context of the design of overlapping decentralized controllers.

Note. It is important to recognize that it is not necessary to know the transition matrices explicitly in order to select the complementary matrices satisfying the required conditions.

4. Example.

Objective. Consider problem (2.1) for system (3.11) with the specific matrices

$$A(t) = \left(\begin{array}{ccc:c} -t & 0 & 0 & 0 \\ \hdashline 0 & 0 & 0 & -t \\ 0 & 0 & 0 & 0 \\ \hdashline 0 & 0 & 0 & -t \end{array}\right), \qquad B(t) = \left(\begin{array}{ccc:c} e^{-t} & 0 & 0 & 0 \\ \hdashline 0 & 0 & 0 & -0.5 \\ -1 & 0 & 0 & e^{-t} \\ \hdashline -3 & 0 & 0 & 0 \end{array}\right), \tag{4.1}$$

$\Pi = Q^* = diag(1,1,1,1)$, and $R^* = diag(1,1,1)$. The overlapping decomposition is determined by dashed lines. Consider the initial and the terminal time as $t_0 = 0$ and $t_f = 3$, respectively. System (4.1) is a commutative system by Definition 3.5.

The objective is to show the potential advantages offered by the characterization of the presented complementary matrices for an overlapping decentralized state LQ optimal control design.

We consider the following scheme as in [14].

(1) The pair $(\mathbf{S}, J)$ in (2.1) is expanded to $(\tilde{\mathbf{S}}, \tilde{J})$. The system $\tilde{\mathbf{S}}$ can be represented as

$$\tilde{\mathbf{S}}: \quad \dot{\tilde{x}}(t) = \tilde{A}_{D}(t)\,\tilde{x}(t) + \tilde{B}_{D}(t)\,\tilde{u}(t) + \tilde{A}_{C}(t)\,\tilde{x}(t) + \tilde{B}_{C}(t)\,\tilde{u}(t), \tag{4.2}$$

where $\tilde{A}_{D}(t)$, $\tilde{B}_{D}(t)$ are the block diagonal matrices and $\tilde{A}_{C}(t)$, $\tilde{B}_{C}(t)$ the corresponding interconnection matrices. Check the controllability of the pair $(\tilde{A}_{D}(t), \tilde{B}_{D}(t))$.

(2) A decentralized control law $\tilde{u}_{D}(t)$ is designed for the decoupled expanded system

$$\tilde{\mathbf{S}}_{\mathbf{D}}: \quad \dot{\tilde{x}}(t) = \tilde{A}_{D}(t)\,\tilde{x}(t) + \tilde{B}_{D}(t)\,\tilde{u}(t), \tag{4.3}$$

where $\tilde{u}_{D}(t) = -\tilde{K}_{D}(t)\,\tilde{x}(t)$ and $\tilde{K}_{D}(t) = (\tilde{R}^*)^{-1}(t)\tilde{B}_{D}^{T}(t)\tilde{P}_{D}(t)$. The matrix $\tilde{P}_{D}(t)$ is the symmetric, nonnegative definite solution of the Riccati equation

$$\dot{\tilde{P}}_{D}(t) = -\tilde{A}_{D}^{T}(t)\tilde{P}_{D}(t) - \tilde{P}_{D}(t)\tilde{A}_{D}(t) + \tilde{P}_{D}(t)\tilde{B}_{D}(t)(\tilde{R}^*)^{-1}(t)\tilde{B}_{D}^{T}(t)\tilde{P}_{D}(t) - \tilde{Q}^*(t) \tag{4.4}$$

with the boundary condition $\tilde{P}_{D}(t_f) = \tilde{\Pi}_{D}$.

(3) This control is contracted to $u_{D}(t) = -Q\tilde{K}_{D}(t)Vx(t) = -K_{D}(t)x(t)$, to be implemented into the original system $\mathbf{S}$. The evaluation of this control law is made

by means of the concept of suboptimality, which is determined by the value of the cost function in (2.1) for this controller. It is known that this value is given by

$$J^{\oplus}(x_0) = x_0^T H(t_0)\, x_0, \tag{4.5}$$

where $H(t)$ is the nonnegative definite solution of the differential Lyapunov equation

$$\begin{aligned} \dot{H}(t) = &- \left[A(t) - B(t)K_{D}(t)\right]^T H(t) - H(t)\left[A(t) - B(t)K_{D}(t)\right] \\ &- \left[Q^*(t) + K_{D}^T(t)R^*(t)K_{D}(t)\right] \end{aligned} \tag{4.6}$$

satisfying the boundary condition $H(t_f) = \Pi$.

In order to eliminate the dependence of $J^{\oplus}$ on the initial state, it is possible to assume x_0 as a random variable uniformly distributed over a dimensional unit sphere. Then the expected value of the performance criterion can be evaluated as $J^{\oplus} = \mathrm{tr}\{H(t_0)\}$, where $\mathrm{tr}\{\cdot\}$ denotes the trace operator [7], [17].

Consider the complementary matrices $N(t) = 0$, $M_{\Pi} = 0$, $M_{Q^*}(t) = 0$, $N_{R^*}(t) = 0$, and $F(t) = 0$, which are particular simple cases that verify Theorems 3.15 and 3.16. The complementary matrix $M(t)$ is selected within the cases described in the previous section, and $J^{\oplus}$ is computed. To evaluate and compare the results obtained by the proposed method, we will also consider the selection of $M(t)$ corresponding to the cases of aggregations and restrictions.

Results. *Overlapping decomposition using an aggregation.* Choosing a typical matrix M used in the literature [22], we obtain

$$M(t) = \begin{pmatrix} 0 & 0 & 0 & 0 \\ A_{21} & \frac{1}{2}A_{22} & -\frac{1}{2}A_{22} & -A_{23} \\ -A_{21} & -\frac{1}{2}A_{22} & \frac{1}{2}A_{22} & A_{23} \\ 0 & 0 & 0 & 0 \end{pmatrix} = \begin{pmatrix} 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & t \\ 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & -t \\ 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \end{pmatrix} \tag{4.7}$$

with the corresponding expanded system matrix

$$\tilde{A}(t) = \begin{pmatrix} A_{11} & \frac{1}{2}A_{12} & \frac{1}{2}A_{12} & A_{13} \\ 2A_{21} & A_{22} & 0 & 0 \\ 0 & 0 & A_{22} & 2A_{23} \\ A_{31} & \frac{1}{2}A_{32} & \frac{1}{2}A_{32} & A_{33} \end{pmatrix} = \begin{pmatrix} -t & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & -2t \\ 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & -t \end{pmatrix}. \tag{4.8}$$

Overlapping decomposition using a restriction. Another frequent choice of the matrix $M(t)$ [8], [12], [14], [22] is given by

$$M(t) = \begin{pmatrix} 0 & \frac{1}{2}A_{12} & -\frac{1}{2}A_{12} & 0 \\ 0 & \frac{1}{2}A_{22} & -\frac{1}{2}A_{22} & 0 \\ 0 & -\frac{1}{2}A_{22} & \frac{1}{2}A_{22} & 0 \\ 0 & -\frac{1}{2}A_{32} & \frac{1}{2}A_{32} & 0 \end{pmatrix} = \begin{pmatrix} 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \end{pmatrix} \tag{4.9}$$

with the corresponding expanded system matrix

$$\tilde{A}(t) = \begin{pmatrix} A_{11} & A_{12} & 0 & A_{13} \\ A_{21} & A_{22} & 0 & A_{23} \\ A_{21} & 0 & A_{22} & A_{23} \\ A_{31} & 0 & A_{32} & A_{33} \end{pmatrix} = \begin{pmatrix} -t & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & -t \\ 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & -t \\ 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & -t \end{pmatrix}. \tag{4.10}$$

Overlapping decomposition using the proposed method. Considering subcase (c_1) with the purpose of maximizing the number of zeros in the off-diagonal blocks of

the expanded matrix $\tilde{A}(t)$, we select the submatrices of $M(t)$ as follows: $M_{12}(t) = \frac{1}{2}A_{12}(t) = \begin{pmatrix} 0 & 0 \end{pmatrix}$, $M_{21}(t) = A_{21}(t) = \begin{pmatrix} 0 \\ 0 \end{pmatrix}$, $M_{24}(t) = -A_{23}(t) = \begin{pmatrix} t \\ 0 \end{pmatrix}$. We also select $M_{42}(t) = \begin{pmatrix} 0 & t \end{pmatrix}$. From (3.26), if $M_{42}(t)M_{22}(t) = 0$, then the conditions for subcase (c_1) are satisfied. Consider $M_{22}(t) = \begin{pmatrix} 0 & m_{23} \\ 0 & 0 \end{pmatrix}$. Then the complementary matrix $M(t)$ has the form

$$M(t) = \begin{pmatrix} 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & m_{23} & 0 & m_{23} & t \\ 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & -m_{23} & 0 & -m_{23} & -t \\ 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & t & 0 & -t & 0 \end{pmatrix} \tag{4.11}$$

with the degree of freedom to select the value of m_{23}. Notice that $M(t)$ satisfies condition (3.6), ensuring that $\tilde{\mathbf{S}}$ is a commutative system.

Following the steps given above and using an algorithm to minimize $\mathrm{tr}\{H(t_0)\}$ with respect to m_{23}, we can summarize the obtained results as follows.

Proposed method	Aggregation	Restriction	Centralized case
$J^{\oplus} = 7.95$ $m_{23} = -0.67$	$J^{\oplus} = 15.30$	$J^{\oplus} = 14.80$	$J^{\circ} = 5.39$

Note that J° is the cost for the centralized optimal control solving (2.1). Since a goal of a decentralized control is to drive the system as close as possible to the (ideal) centralized control, we may observe the best performance when using the proposed method for the selection of the complementary matrices. This method represents a reduction of 48% and 46.3% in the $J^{\oplus}$ with respect to the aggregations and restrictions, respectively. These results illustrate the freedom introduced by this approach in selecting the complementary matrices to minimize the cost function in overlapping decentralized control design. The minimization can be considered for more elements of $M(t)$ and also for other complementary matrices.

5. Conclusion. The inclusion principle has been specialized for a quadratic optimal control design for both general and commutative continuous-time LTV systems. The strategy of *generalized selection of complementary matrices* has been developed for commutative continuous-time LTV systems. It includes the presentation of a general structure of complementary matrices, including explicit conditions on them as well as optimization of their free elements. This structure offers flexibility in selection of complementary matrices, resulting in more appropriate costs when designing quadratic optimal control via overlapping decompositions for this class of systems. The efficiency of the proposed method has been demonstrated on an illustrative example.

FINITE TIME–HORIZON RISK-SENSITIVE CONTROL AND THE ROBUST LIMIT UNDER A QUADRATIC GROWTH ASSUMPTION*

FRANCESCA DA LIO† AND WILLIAM M. MCENEANEY‡

Abstract. The finite time–horizon risk-sensitive limit problem for continuous nonlinear systems is considered. Previous results are extended to cover more typical examples. In particular, the cost may grow quadratically, and the diffusion coefficient may depend on the state. It is shown that the risk-sensitive value function is the solution of the corresponding dynamic programming equation. It is also shown that this value converges to the value of the robust control problem as the cost becomes infinitely risk averse, with corresponding scaling of the diffusion coefficient.

Key words. risk-sensitive control, robust, H_∞, viscosity solutions, nonlinear HJB equations, nonlinear Isaacs equations

1. Introduction.

The nonlinear, finite time–horizon risk-sensitive limit problem is considered. It is, by now, well known that the value functions of risk-sensitive stochastic control problems tend to converge to the value functions of the corresponding robust/H_∞ control problems as one approaches infinite risk aversion. This was addressed first in the LEQG (linear-exponential-quadratic-Gaussian) case in which, in fact, one does not need to take the risk averse limit [28], [51], [6], [12]. In the nonlinear case, results were first developed for finite time–horizon control problems [52], [29], [17], [42], [43]. Further studies considered nonlinear, infinite time–horizon problems (in which case one gets the H_∞ limit) [18], [43], [19], [16], [44], [23], [47], [38], [31], [5] and nonlinear escape problems [37], [9]. Other studies have involved discrete systems [48], [13], [15] and the partial observations case [7], [30].

The results for both the finite time–horizon problem and the infinite time–horizon problem have mainly been obtained under assumptions which preclude quadratic cost criteria. In other words, the LEQG results were not subsumed by the nonlinear results. Since control systems for nonlinear systems are often designed by analogy with the linear-quadratic theory, it would be most desirable for the nonlinear theory to subsume the LEQG theory. For the infinite time–horizon problem, this is addressed in a preliminary fashion in [27] and [38] (with some results taken from [39], [40] in this latter case). The infinite time–horizon case presents certain technical difficulties which are not present in the finite time–horizon case. In particular, there is a certain lack of uniqueness of solutions to the dynamic programming equation (DPE) in the infinite time–horizon case which is not a problem in the finite time–horizon case. That is, there may be an infinite number of viscosity solutions and multiple classical solutions (when they exist) to the DPE. (This is in addition to the multiplicity incurred by scaling with an additive constant.) This question is addressed in [39], [40].

One approach to the finite time–horizon problem is to prove that the value function is a viscosity (or classical) solution to the associated DPE for the risk-sensitive problem. This is the approach taken by most of the work to date, and is the approach taken here as well. More specifically, let the parameter associated with risk-sensitivity be ε (described more accurately below). This parameter will also be used to scale the diffusion term. One wishes to show that as $\varepsilon \downarrow 0$ (i.e., as the problem becomes infinitely risk averse), the value function of the risk-sensitive problem converges to that of a robust (H_∞) control problem. It is easily seen that the DPE for the risk-sensitive problem formally converges to the DPE for the robust control problem as $\varepsilon \downarrow 0$. One may also show that the value of the robust control problem is a viscosity solution of this limit DPE. If one proves uniform boundedness and equicontinuity results for the prelimit value functions, then by the stability of viscosity solutions these converge (subsequentially) to viscosity solutions of the limit DPE. A key step is to prove a uniqueness result for viscosity solutions of this limit DPE. Then, one can assert that the solutions of the prelimit DPE (the risk-sensitive values) converge to the unique solution of the limit DPE, which must also then be the value of the limit robust control problem.

One of the key difficulties encountered in earlier attempts (cf. [17], [43]) employing the plan outlined in the previous paragraph was that the viscosity solution uniqueness results did not cover the limit DPEs except under rather strict conditions such as globally Lipschitz conditions on the cost and dynamics. In [42], viscosity solution uniqueness results were extended to cover certain cases in which the cost could grow quadratically. However, it was still required that one prove a certain Lipschitz condition with Lipschitz constant growing linearly with the norm of the state, uniformly for the prelimit solutions as well as the limit. Some recent results (obtained independently and concurrently; [3], [26]) have extended the uniqueness results in ways that do not require this Lipschitz condition. These results allow one to extend the previous risk-sensitive limit results to a larger class which subsumes a large variety of LEQG problems. (However, it does not subsume all, and in particular, the control set must be bounded.) Such extension is the subject of this paper. Consequently, the uniqueness result of Theorem 4.1 is a central topic of the paper. Note that the uniqueness results in [3], [26] do not cover the particular limit PDE encountered here. In section 4 of the present paper, the results of [3] are extended to yield the uniqueness result needed here.

Some other technical difficulties arise in this case as well. In particular, there is some difficulty with a Novikov condition that was not present previously (see the discussion prior to Lemma 2.2). Some difficulties also arise in the proof of the equicontinuity of the value functions. These last technical difficulties were overcome in this paper by consideration of the risk-sensitive value function as the value function for a stochastic game, and the use of known results showing that this game value is the limit of the value of a discrete game as the time-step size goes to zero. The delicateness of the required estimates is not surprising given the possible finite time blow-up property of the Riccati equations associated with linear-quadratic problems.

In sections 2 and 3, a representation result will be obtained that states that any classical solution of the risk-sensitive DPE must be the value function of the risk-sensitive problem. The assumptions will also be listed in that section. Further, in section 3, the existence of the above classical solution will be proved, and the uniform boundedness and equicontinuity results will be obtained along the way. Section 4 contains the limit result. Of course these results require the uniqueness result dis-

cussed above. This uniqueness result is stated and proved there. At the same time, it is shown that this unique solution is the value of the robust control problem, thus making the connection between the risk averse limit of the risk-sensitive problem and the robust control problem.

2. Risk-sensitive representation result. In the stochastic (prelimit) risk-sensitive problem, we consider a system of the form

$$\begin{aligned} dy_t^\varepsilon &= f(y_t^\varepsilon, u_t)\,dt + \sqrt{\frac{\varepsilon}{\gamma^2}}\sigma(y_t^\varepsilon)\,dB_t, \\ y_s^\varepsilon &= x, \end{aligned} \tag{1}$$

where y_t^ε is the state at time t taking values in $\Re^n$, x is the (known) initial state at time $s \geq 0$, f represents the nominal dynamics with control u taking values in $U \in \Re^l$, and $\{B_\cdot, \mathcal{F}_\cdot\}$ is an m-dimensional Brownian motion on the probability space $(\Omega, \mathcal{F}, P)$, where $\mathcal{F}_0$ contains all the P-negligible elements of $\mathcal{F}$ and σ is an $n \times m$-valued diffusion coefficient. The role of the parameters $\varepsilon, \gamma > 0$ will become more clear subsequently. However, perhaps it should be remarked here that ε will be a measure of the risk-sensitivity and scales the diffusion term in (1) above so that the cost below will remain bounded (for each x, as a function of ε).

We consider a cost criterion of the form

$$J^\varepsilon(s, x, u_\cdot) = \mathrm{E} \exp\left\{ \frac{1}{\varepsilon} \left[\int_s^T \ell(y_t^\varepsilon, u_t)\,dt + \psi(y_T^\varepsilon) \right] \right\}, \tag{2}$$

where $0 \leq s \leq T < \infty$, T is a fixed terminal time, ℓ is the running cost, and ψ is the terminal cost. The value function is

$$\begin{aligned} V^\varepsilon(s, x) &= \inf_{u \in \mathcal{U}_s} \varepsilon \log J^\varepsilon(s, x, u_\cdot) \\ &= \varepsilon \log \inf_{u \in \mathcal{U}_s} J^\varepsilon(s, x, u_\cdot), \end{aligned} \tag{3}$$

where $\mathcal{U}_s$ is the set of U-valued, $\mathcal{F}_t$-progressively measurable controls such that there exists a strong solution to (1).

We make the following assumptions throughout the paper.

(A0) U is a compact subset of $\Re^l$,

(A1)
$$\begin{cases} \text{i)} & f \in C^2(\Re^n \times U, \Re^n), & \\ \text{ii)} & |f_x(x,u)| \leq K & \forall x \in \Re^n,\ u \in U, \\ \text{iii)} & |f(x,u)| \leq K(1+|x|) & \forall x \in \Re^n,\ u \in U, \\ \text{iv)} & |f_{xx}(x,u)| \leq K/(1+|x|) & \forall x \in \Re^n,\ u \in U, \end{cases}$$

(A2)
$$\begin{cases} \text{i)} & \sigma \in C^2(\Re^n, \mathcal{L}(\Re^m, \Re^n)), & \\ \text{ii)} & |\sigma(x)| \leq M & \forall x \in \Re^n, \\ \text{iii)} & \xi^T \sigma(x) \sigma^T(x) \xi \geq \eta |\xi|^2 & \forall \xi, x \in \Re^n, \\ \text{iv)} & |\sigma_x(x)| \leq L_\sigma/(1+|x|) & \forall x \in \Re^n, \\ \text{v)} & |\sigma_{xx}(x)| \leq L_\sigma/(1+|x|^2) & \forall x \in \Re^n, \end{cases}$$

(A3)
$$\begin{cases} \text{i)} & \ell \in C^\infty(\Re^n \times U, \Re), \quad |\ell_{xx}(x,u)| \leq \overline{C} & \forall (x,u) \in \Re^n \times U, \\ \text{ii)} & \ell(x,u) \geq 0 & \forall (x,u) \in \Re^n \times U, \\ \text{iii)} & |\ell(x,u)| \leq C(1+|x|^2) & \forall (x,u) \in \Re^n \times U, \\ \text{iv)} & |\ell(x,u) - \ell(y,u)| \leq C(1+|x|+|y|)|x-y| & \forall x, y \in \Re^n, \forall u \in U, \end{cases}$$

(A4)

$$\begin{cases} \text{i)} & \psi \in C^\infty(\Re^n, \Re), \qquad |\psi_{xx}(x)| \le \overline{C} & \forall x \in \Re^n, \\ \text{ii)} & \psi(x) \ge 0 & \forall x \in \Re^n, \\ \text{iii)} & |\psi(x)| \le C(1+|x|^2) & \forall x \in \Re^n, \\ \text{iv)} & |\psi(x)-\psi(y)| \le C(1+|x|+|y|)|x-y| & \forall x, y \in \Re^n, \\ \text{v)} & \text{higher (above second) derivatives of } \psi \text{ uniformly bounded,} & \end{cases}$$

where $L_\sigma, C, K, M, \eta \in (0,\infty)$, and $\mathcal{L}(\Re^m, \Re^n)$ appearing in (A2.i) represents the space of $n \times m$ matrices. There is some intended redundancy in the above assumptions; for instance, (A1.iii) is included to indicate that the same constant, K, will be used as in (A1.ii), even though the existence of some constant for which (A1.iii) holds follows from (A0), (A1.i), (A1.ii). Note that many of the assumptions are needed only for the results of section 3, and in particular, are not needed for the uniqueness result of section 4. Specifically in section 4 we use (A1.iii), (A2.ii), (A3.ii)–(A3.iv), (A4.ii)–(A4.iv), while (A1.iv), (A2.v), and (A4.v) are used only to obtain the results in section 3. This is also true of the requirement of continuous, bounded second-derivatives in (A3.i) and (A4.i). It seems that many of the above smoothness assumptions, which are required in the prelimit analysis but not in the limit uniqueness result, might be removable; however, the prelimit analysis is already quite technical, and so no attempt is made to reduce the assumptions further. There will be one additional assumption in section 3.

In section 3, it will be shown that there exists a classical solution $\widetilde{V}^\varepsilon \in C^{1,2}$ to the PDE

$$\begin{aligned} 0 = {} & V_s + \frac{\varepsilon}{2\gamma^2} \sum_{i,j=1}^n a_{i,j}(x) V_{x_i x_j} + \frac{1}{2\gamma^2} \nabla V^T a(x) \nabla V \\ & + \min_{u \in U} [f(x,u) \cdot \nabla V + \ell(x,u)], \qquad 0 \le s \le T, \\ & V(T,x) = \psi(x), \end{aligned} \tag{4}$$

where $a \doteq \sigma\sigma^T$. For the purposes of this section, assume that the classical solution exists; we postpone the proof of this fact to the next section. Note that

$$\frac{1}{2\gamma^2} \nabla V^T a \nabla V = \max_{w \in \Re^m} \left[(\sigma w) \cdot \nabla V - \frac{\gamma^2}{2} \|w\|^2 \right]. \tag{5}$$

Define a measurable (see, for instance, [21]) feedback control

$$\overline{u}(t,x) \in \operatorname{argmin}[f(x,u) \cdot \nabla \widetilde{V}^\varepsilon(t,x) + \ell(x,u)]. \tag{6}$$

Using [50], one proves the existence of a strong solution, $\overline{y}^\varepsilon$, to (1) with feedback $\overline{u}$ (see [43]; also see [4] for a quicker proof of a weak solution). Then define the $\mathcal{F}_t$-progressively measurable control $\widetilde{u}_\cdot$ given by $\widetilde{u}_t(\omega) \doteq \overline{u}(t, \overline{y}^\varepsilon_t(\omega))$ for all $\omega \in \Omega$.

The first lemma is rather easily proved.

LEMMA 2.1.

$$\varepsilon \log J^\varepsilon(s,x,\widetilde{u}) \le \widetilde{V}^\varepsilon(s,x) \qquad \forall\, s \in [0,T], x \in \Re^n.$$

Proof. By Ito's rule and (1),

$$\widetilde{V}^\varepsilon(T,y_T^\varepsilon)-\widetilde{V}^\varepsilon(s,x)=\int_s^T\left[f(\overline{y}_t^\varepsilon,\widetilde{u}_t)\cdot\nabla\widetilde{V}^\varepsilon+\widetilde{V}_t^\varepsilon+\frac{\varepsilon}{2\gamma^2}\sum_{i,j=1}^n a_{i,j}(\overline{y}_t^\varepsilon)\widetilde{V}^\varepsilon_{x_ix_j}\right]dt$$
$$+\int_s^T\sqrt{\frac{\varepsilon}{\gamma^2}}(\nabla\widetilde{V}^\varepsilon)^T\sigma\cdot dB_t.$$

Using (4) and (6), one finds

$$\int_s^T\ell(\overline{y}_t^\varepsilon,\widetilde{u}_t)\,dt+\psi(\overline{y}_T^\varepsilon)=\widetilde{V}^\varepsilon(s,x)+\sqrt{\frac{\varepsilon}{\gamma^2}}\int_s^T(\nabla\widetilde{V}^\varepsilon)^T\sigma\,dB_t-\frac{1}{2\gamma^2}\int_s^T(\nabla\widetilde{V}^\varepsilon)^Ta\nabla\widetilde{V}^\varepsilon\,dt,$$

which yields

$$\mathrm{E}\exp\frac{1}{\varepsilon}\left[\int_s^T\ell(\overline{y}_t^\varepsilon,\widetilde{u}_t)\,dt+\psi(\overline{y}_T^\varepsilon)\right]$$
$$=e^{\frac{1}{\varepsilon}\widetilde{V}^\varepsilon(s,x)}\cdot\mathrm{E}\exp\left[\frac{1}{\sqrt{\gamma^2\varepsilon}}\int_s^T(\nabla\widetilde{V}^\varepsilon)^T\sigma\,dB_t-\frac{1}{2\gamma^2\varepsilon}\int_s^T(\nabla\widetilde{V}^\varepsilon)^Ta\nabla\widetilde{V}^\varepsilon\,dt\right].$$

By [25] (see also [46]), this last term is a supermartingale, and thus one has

$$\mathrm{E}\exp\frac{1}{\varepsilon}\left[\int_s^T\ell(\overline{y}_t^\varepsilon,\widetilde{u}_t)\,dt+\psi(\overline{y}_T^\varepsilon)\right]\le e^{\frac{1}{\varepsilon}\widetilde{V}^\varepsilon(s,x)}.\qquad\square$$

For the approach that we will use to prove a reverse inequality for (not necessarily optimal) controls, one needs to use Girsanov's theorem. Consequently, one is interested in controls for which a weak form of the Novikov condition holds. More specifically, we will be interested in controls for which there exists $\tau>0$, $m<\infty$ such that

$$\mathrm{E}\exp\frac{1}{2\gamma^2\varepsilon}\left[\int_t^{t+\tau}(\nabla\widetilde{V}^\varepsilon(t,y_t^\varepsilon))^Ta(y_t^\varepsilon)\nabla\widetilde{V}^\varepsilon(t,y_t^\varepsilon)\,dt\right]\le m\qquad\forall\,0\le s\le t\le t+\tau\le T. \tag{7}$$

The following lemma applies only to controls satisfying (7), but this lemma will also be useful in a generalization to appear at a later point in the paper.

LEMMA 2.2. *Let $0\le s\le T$ and $x\in\Re^n$. Let $u\in\mathcal{U}_s$ be a control such that* (7) *holds. Then*

$$\varepsilon\log J^\varepsilon(s,x,u)\ge\widetilde{V}^\varepsilon(s,x).$$

Proof. Let y^ε be the solution to (1) corresponding to the initial conditions and control in the lemma statement. Consider the change of drift given by

$$y_t^\varepsilon=x+\int_s^t f(y_r^\varepsilon,u_r)\,dr+\sqrt{\frac{\varepsilon}{\gamma^2}}\int_s^t\sigma(y_r^\varepsilon)\,dB_r \tag{8}$$
$$=x+\int_s^t[f(y_r^\varepsilon,u_r)+\sigma(y_r^\varepsilon)w_r]\,dr+\sqrt{\frac{\varepsilon}{\gamma^2}}\int_s^t\sigma(y_r^\varepsilon)\,d\widehat{B}_r,$$

where w is an adapted process to be given below. By (7) (see, for instance, [32]), $\widehat{B}$ is a Brownian motion under new probability measure, $\widehat{P}$, where

$$P(d\omega)=\exp\Bigg[-\frac{1}{\sqrt{\gamma^2\varepsilon}}\int_s^t(\nabla\widetilde{V}^\varepsilon(r,y_r^\varepsilon))^T\sigma(y_r^\varepsilon)\,d\widehat{B}_r$$
$$-\frac{1}{2\gamma^2\varepsilon}\int_s^t(\nabla\widetilde{V}^\varepsilon(r,y_r^\varepsilon))^Ta(y_r^\varepsilon)\nabla\widetilde{V}^\varepsilon(r,y_r^\varepsilon)\,dr\Bigg]\widehat{P}(d\omega).$$

Consequently,

$$\begin{aligned}
&\mathrm{E}\exp\frac{1}{\varepsilon}\left[\int_s^T \ell(y_t^\varepsilon,u_t)\,dt+\psi(y_T^\varepsilon)\right]\\
&\quad=\widehat{\mathrm{E}}\exp\frac{1}{\varepsilon}\Bigg[\int_s^T\left(\ell(y_t^\varepsilon,u_t)-\frac{1}{2\gamma^2}(\nabla\widetilde{V}^\varepsilon(t,y_t^\varepsilon))^T a(y_t^\varepsilon)\nabla\widetilde{V}^\varepsilon(t,y_t^\varepsilon)\right)dt\\
&\qquad\qquad-\sqrt{\frac{\varepsilon}{\gamma^2}}\int_s^T(\nabla\widetilde{V}^\varepsilon(t,y_t^\varepsilon))^T\sigma(y_t^\varepsilon)\,d\widehat{B}_t+\psi(y_T^\varepsilon)\Bigg].
\end{aligned}\tag{9}$$

By Ito's rule with dynamics (8),

$$\begin{aligned}
\widetilde{V}^\varepsilon(T,y_T^\varepsilon)-\widetilde{V}^\varepsilon(s,x)=\int_s^T\Bigg[&\widetilde{V}_t^\varepsilon+(f(y_t^\varepsilon,u_t)+\sigma(y_t^\varepsilon)w_t)\cdot\nabla\widetilde{V}^\varepsilon+\frac{\varepsilon}{2\gamma^2}\sum_{i,j=1}^n a_{i,j}(y_t^\varepsilon)\widetilde{V}^\varepsilon_{x_ix_j}\Bigg]dt\\
&+\sqrt{\frac{\varepsilon}{\gamma^2}}\int_s^T(\nabla\widetilde{V}^\varepsilon)^T\sigma(y_t^\varepsilon)\,d\widehat{B}_t.
\end{aligned}$$

Taking $w_t\doteq\frac{1}{\gamma^2}\sigma^T(y_t^\varepsilon)\nabla\widetilde{V}^\varepsilon(y_t^\varepsilon)$ yields

$$\begin{aligned}
\psi(y_T^\varepsilon)-\widetilde{V}^\varepsilon(s,x)=\int_s^T\Bigg[&\widetilde{V}_t^\varepsilon+f(y_t^\varepsilon,u_t)\cdot\nabla\widetilde{V}^\varepsilon+\frac{1}{2\gamma^2}(\nabla\widetilde{V}^\varepsilon)^T a(y_t^\varepsilon)\nabla\widetilde{V}^\varepsilon\\
&+\frac{\varepsilon}{2\gamma^2}\sum_{i,j=1}^n a_{i,j}(y_t^\varepsilon)\widetilde{V}^\varepsilon_{x_ix_j}\Bigg]dt\\
&+\frac{1}{2\gamma^2}\int_s^T(\nabla\widetilde{V}^\varepsilon)^T a(y_t^\varepsilon)\nabla\widetilde{V}^\varepsilon\,dt+\sqrt{\frac{\varepsilon}{\gamma^2}}\int_s^T(\nabla\widetilde{V}^\varepsilon)^T\sigma(y_t^\varepsilon)\,d\widehat{B}.
\end{aligned}\tag{10}$$

Now, since this choice of u is not necessarily optimal in (4), one has at any time

$$0\le\widetilde{V}_t^\varepsilon+\frac{\varepsilon}{2\gamma^2}\sum_{i,j=1}^n a_{i,j}(y_t^\varepsilon)\widetilde{V}^\varepsilon_{x_ix_j}+\frac{1}{2\gamma^2}(\nabla\widetilde{V}^\varepsilon)^T a(y_t^\varepsilon)\nabla\widetilde{V}^\varepsilon+f(y_t^\varepsilon,u_t)\nabla\widetilde{V}^\varepsilon+\ell(y_t^\varepsilon,u_t).\tag{11}$$

Combining (10) and (11) yields

$$\begin{aligned}
\exp\frac{1}{\varepsilon}\widetilde{V}^\varepsilon(s,x)\le\exp\frac{1}{\varepsilon}\Bigg[&\int_s^T\ell(y_t^\varepsilon,u_t)\,dt+\psi(y_T^\varepsilon)-\sqrt{\frac{\varepsilon}{\gamma^2}}\int_s^T(\nabla\widetilde{V}^\varepsilon)^T\sigma(y_t^\varepsilon)\,d\widehat{B}\\
&-\frac{1}{2\gamma^2}\int_s^T(\nabla\widetilde{V}^\varepsilon)^T a(y_t^\varepsilon)\nabla\widetilde{V}^\varepsilon\,dt,\Bigg],
\end{aligned}$$

which, by (9), implies

$$\exp\frac{1}{\varepsilon}\widetilde{V}^\varepsilon(s,x)\le\mathrm{E}\exp\frac{1}{\varepsilon}\left[\int_s^T\ell(y_t^\varepsilon,u_t)\,dt+\psi(y_T^\varepsilon)\right].\qquad\square$$

Summarizing the results in this section, we have the following.

LEMMA 2.3. *Let $0 \le s \le T$ and $x \in \Re^n$. For any $u \in \mathcal{U}_s$ such that (7) holds, one has*

$$\varepsilon \log J^\varepsilon(s,x,u) \ge \widetilde{V}^\varepsilon(s,x),$$

while with optimal $\widetilde{u}$ given by (6) one has

$$\varepsilon \log J^\varepsilon(s,x,\widetilde{u}) \le \widetilde{V}^\varepsilon(s,x).$$

Lemma 2.3 is not quite what we will obtain for the risk-sensitive prelimit result. The lemma is deficient, due to the requirement that (7) hold in order to obtain the first assertion. Without that condition, the lemma would show that $\widetilde{V}^\varepsilon$ is the value of the risk-sensitive control problem. In the next section, while proving the existence of a classical solution to (4), we will obtain results that allow one to improve Lemma 2.3 in this way; specifically, that the value, V^ε, given by (3) is this classical solution. The improved result will be Theorem 3.11.

3. Existence and uniformity. The representation results of the previous section required the existence of a $C^{1,2}$ solution to (4). That will be obtained in this section. Also, in order to prove the risk averse limit result to follow, we will need continuity and local boundedness estimates on $\widetilde{V}^\varepsilon$ independent of $\varepsilon > 0$. These will be obtained at the same time as the existence result. Finally, we will obtain the promised improvement over Lemma 2.3. These results will all be obtained through the stochastic game representation.

Before proceeding with the technical details, we give some formal indications of the general concepts.

Using convex duality, one may rewrite DPE (4) as

$$0 = V_s + \frac{\varepsilon}{2\gamma^2}\sum_{i,j=1}^n a_{i,j}(x)V_{x_ix_j} + \min_{u\in U}\max_{w\in\Re^m}\left\{[f(x,u)+\sigma(x)w]\nabla V + \ell(x,u) - \frac{\gamma^2}{2}|w|^2\right\},$$

$$V(T,x) = \psi(x). \tag{12}$$

In this form, it is intuitive that this PDE might be associated with the stochastic differential game with dynamics

$$dy_t^\varepsilon = [f(y_t^\varepsilon,u_t) + \sigma(y_t^\varepsilon)w_t]\,dt + \sqrt{\frac{\varepsilon}{\gamma^2}}\sigma(y_t^\varepsilon)\,dB_t,$$

$$y_s^\varepsilon = x \tag{13}$$

and payoff

$$J_g^\varepsilon(s,x;u,w) = \mathrm{E}\left[\int_s^T \ell(y_t^\varepsilon,u_t) - \frac{\gamma^2}{2}|w_t|^2\,dt + \psi(y_T^\varepsilon)\right].$$

In this game, $w.$ is the control for the opposing (disturbance) player who is trying to maximize this payoff which we are trying to minimize. The definitions of value for such a game [24] are discussed further below. The connections between such games and their corresponding DPEs (now second-order Isaacs equations) are not known for the class of systems considered here, so it will be necessary to consider some more restrictive assumptions and then to relax these assumptions to obtain the above game and DPE.

One technique that is sometimes useful for games associated with H_∞ control is to obtain an L_2-bound on ε-optimal controls, w, for the disturbance player [41], [39], [40]. This is then used to obtain continuity estimates on the value function. The simplest analogue is to prove a bound of the form $\|w\|_{L_2([s,T]\times\Omega)} \le M < \infty$ for ε-optimal w. Such a bound is not difficult to obtain in this case, but it does not yield the equicontinuity estimates for the value needed for the proofs to follow. Instead, one would ideally obtain an almost sure bound of some form. This bound is rather technical due to the presence of the Brownian motion with its unbounded variation. Instead, a discrete game is analyzed here in order to obtain an analogous bound and consequent continuity estimates. A limit is then taken to obtain the continuity estimates for the original game. We now proceed with the analysis.

We first work with a system where the dynamics and cost functions are all bounded. Let

$$\widetilde{\ell}^R(x,u) = \begin{cases} \ell(x,u) & \text{if } \ell(x,u) \le R, \\ R & \text{otherwise,} \end{cases} \tag{14}$$

$$\widetilde{\psi}^R(x) = \begin{cases} \psi(x) & \text{if } \psi(x) \le R, \\ R & \text{otherwise,} \end{cases} \tag{15}$$

$$\widetilde{f}^b(x,u) = \begin{cases} f(x,u) & \text{if } |f(x,u)| \le b, \\ b\frac{f(x,u)}{|f(x,u)|} & \text{otherwise.} \end{cases} \tag{16}$$

The final assumption in the paper is that for all R sufficiently large one can mollify $\widetilde{\ell}^R, \widetilde{\psi}^R, \widetilde{f}^b$ yielding ℓ^R, ψ^R, f^b such that

$$\left\{ \begin{array}{ll} \ell^R \in C^2(\Re^n \times U) & \\ \ell^R(x,u) = \widetilde{\ell}^R(x,u) & \forall |x| \le D_R^\ell \\ \ell^R(x,u) \le R & \forall x \in \Re^n \\ |\nabla \ell^R(x,u)| \le 2C'|x| & \forall x \in \Re^n \\ |\ell^R_{xx}(x,u)| \le \overline{C}' & \forall x \in \Re^n \end{array} \right\}, \quad \left\{ \begin{array}{ll} \psi^R \in C^2(\Re^n) & \\ \psi^R(x) = \widetilde{\psi}^R(x) & \forall |x| \le D_R^\psi \\ \psi^R(x) \le R & \forall x \in \Re^n \\ |\nabla \psi^R(x)| \le 2C'|x| & \forall x \in \Re^n \\ |\psi^R_{xx}(x)| \le \overline{C}' & \forall x \in \Re^n \end{array} \right\},$$

$$\left\{ \begin{array}{ll} f^b \in C^2(\Re^n \times U) & \\ f^b(x,u) = \widetilde{f}^b(x,u) & \forall |x| \le D_b^f, u \in U \\ |f^b(x,u)| \le b & \forall x \in \Re^n, u \in U \\ |f^b_x(x,u)| \le K' & \forall x \in \Re^n, u \in U \\ |f^b_{xx}(x,u)| \le K'/(1+|x|) & \forall x \in \Re^n, u \in U \end{array} \right\}, \tag{A5}$$

where $D_R^\ell, D_R^\psi \to \infty$ as $R \to \infty$, $D_b^f \to \infty$ as $b \to \infty$. We claim that this can be achieved by a relatively standard mollification, but as we do not want to take up space with the technical details, we make it an assumption. In particular, for the ψ case we claim that one would use the following convolution for $R > C$: $\psi^R(x) = \int J_\varepsilon(x-y)\widetilde{\psi}^R(y)\,dy$, where $J_1(z) = k\exp\{-1/(1-|z|^2)\}$ on $|z| \le 1$ and 0 elsewhere, where k is such that $\int_{\Re^n} J_1 = 1$, $J_\varepsilon(z) = \varepsilon^{-n} J_1(z/\varepsilon)$, $D_R^\psi = \frac{1}{2}\sqrt{R/C-1}$, $\varepsilon = 0$ for $|x| \le D_R^\psi$, $\varepsilon = \frac{1}{2}D_R^\psi \exp\{1 - 1/[1 - |(|x| - 3D_R^\psi/2)/(D_R^\psi/2)|]\}$ for $D_R^\psi < |x| \le 3D_R^\psi/2$, and $\varepsilon = D_R^\psi/2$ for $3D_R^\psi/2 < |x|$. The bounds on the derivatives use the smoothness of ψ itself (as well as $\max_{x,R}|\varepsilon_x|$, $\max_{x,R}|\varepsilon_{xx}|$ bounded for sufficiently large R) on $|x| \le 3D_R^\psi/2$ and then rely on the fact that the derivatives can be translated onto J_ε itself in the convolution for $|x| > 3D_R^\psi/2$ (cf. [1],[53]). Again, by making (A5) an assumption, we avoid the details and leave them only to an interested reader.

Also, let

$$\mathcal{W}_s \doteq \{\mathcal{F}_t\text{-adapted, right-continuous } w. \text{ such that } \|w\|_{L_2([s,T]\times\Omega)} < \infty\}, \tag{17}$$

$$\mathcal{W}_s^m \doteq \{w \in \mathcal{W}_s : |w_t(\omega)| \le m \quad \forall t \in [s,T], \omega \in \Omega\}. \tag{18}$$

Note that condition (17) implies that any $w \in \mathcal{W}_s$ is $\mathcal{F}_t$-progressively measurable; see [22], [10]. Let the dynamics of the modified game be

$$\begin{aligned} dy_t^{\varepsilon,b} &= [f^b(y_t^{\varepsilon,b}, u_t) + \sigma(y_t^{\varepsilon,b})w_t]\,dt + \sqrt{\frac{\varepsilon}{\gamma^2}}\sigma(y_t^{\varepsilon,b})\,dB_t, \\ y_s^{\varepsilon,b} &= x, \end{aligned} \tag{19}$$

and define the payoff by

$$J_g^{\varepsilon,b,R}(s,x;u,w) = \mathrm{E}\left\{\int_s^T \left[\ell^R(y_t^{\varepsilon,b}, u_t) - \frac{\gamma^2}{2}|w_t|^2\right] dt + \psi^R(y_T^{\varepsilon,b})\right\}. \tag{20}$$

An admissible strategy for the player with control u is a mapping $\theta : \mathcal{W}_s \to \mathcal{U}_s$ (alternatively, $\theta : \mathcal{W}_s^m \to \mathcal{U}_s$ when the disturbance set is $\mathcal{W}_s^m$) such that if, almost surely, $w_r = \widetilde{w}_r$ for almost every $r \in [s,t]$, then, almost surely, $\theta[w]_r = \theta[\widetilde{w}]_r$ for almost every $r \in [s,t]$, for any $t \in [s,T]$; see [24]. The set of all admissible strategies will be denoted by Θ_s. Define the set of admissible strategies for the player with control w analogously, and denote them by Λ_s in the case in which the disturbance set is $\mathcal{W}_s$. (In the case in which the disturbance set is $\mathcal{W}_s^m$, denote it by Λ_s^m.) Then (see [24]), the upper and lower values are

$$\underline{V}^{\varepsilon,b,R,m}(s,x) = \inf_{\theta\in\Theta_s}\sup_{w\in\mathcal{W}_s^m} J_g^{\varepsilon,b,R}(s,x,\theta[w],w), \tag{21}$$

$$\overline{V}^{\varepsilon,b,Rm}(s,x) = \sup_{\lambda\in\Lambda_s^m}\inf_{u\in\mathcal{U}_s} J_g^{\varepsilon,b,R}(s,x,u,\lambda[u]), \tag{22}$$

and we note that, by (20), these are bounded. Then, by [24], $\underline{V}^{\varepsilon,b,R,m} = \overline{V}^{\varepsilon,b,R,m}$ is the unique, bounded, continuous viscosity solution to the Isaacs equation

$$\begin{aligned} 0 = V_s + \frac{\varepsilon}{2\gamma^2}\sum_{i,j=1}^n a_{i,j}(x)V_{x_ix_j} + \min_{u\in U}\max_{|w|\le m}\Big\{&[f^b(x,u)+\sigma(x)w]\cdot\nabla V + \ell^R(x,u) \\ &- \frac{\gamma^2}{2}|w|^2\Big\}, \\ V(T,x) = \psi^R(x). \end{aligned} \tag{23}$$

LEMMA 3.1. *$\underline{V}^{\varepsilon,b,R,m} = \overline{V}^{\varepsilon,b,R,m}$ is the unique, bounded, $C^{1,2}$ solution to* (23).

Proof. From the above, we know that the equality in Lemma 3.1 is the unique, bounded, continuous viscosity solution. Additionally, [24] tells us that it is Lipschitz in x and Holder continuous in s. (We will be interested in specific bounds independent of ε, b, R, m further below, but for simplicity we do not look for these here.) Under our assumptions, it is not difficult to show that it is also Lipschitz in s, and we do so now.

Fix $s, s+\delta \in [0,T]$, $\delta > 0$. We will bound $|\underline{V}^{\varepsilon,b,R,m}(s,x) - \underline{V}^{\varepsilon,b,R,m}(s+\delta,x)|$. Fix any $x \in \Re^n$, $u \in \mathcal{U}_s$, and $w \in \mathcal{W}_s^m$. Let the corresponding solution of (19) be denoted

by $y_\cdot^{0,\varepsilon,b}$. Recall that the probability space is $(\Omega, \{\mathcal{F}_t\}, P)$. Define a new Brownian motion $B_\cdot^\delta$ by $B_t^\delta = B_{t-\delta}$ on a new probability space with filtration $\mathcal{F}_t^0 = \mathcal{F}_{t-\delta}$. Let $u_t^\delta = u_{t-\delta}$ and $w_t^\delta = w_{t-\delta}$. Let the solution of (19) corresponding to this new Brownian motion, controls u^δ, w^δ, and initial condition x at time $s+\delta$ be denoted by $y_\cdot^{\delta,\varepsilon,b}$. Then

$$y_t^{\delta,\varepsilon,b} = y_{t-\delta}^{0,\varepsilon,b} \qquad \forall\, t \in [\delta, T+\delta].$$

Consequently, one has

$$J_g^{\varepsilon,b,R}(s+\delta, x; u^\delta, w^\delta) = \mathrm{E}\left[\int_s^{T-\delta} \ell^R(y_t^{0,\varepsilon,b}, u_t) - \frac{\gamma^2}{2}\|w_t\|^2\, dt + \psi^R(y_{T-\delta}^{0,\varepsilon,b})\right].$$

Therefore,

$$\begin{aligned} &J_g^{\varepsilon,b,R}(s+\delta, x; u^\delta, w^\delta) - J_g^{\varepsilon,b,R}(s, x; u, w) \\ &\quad = \mathrm{E}\left[\psi^R(y_{T-\delta}^{0,\varepsilon,b}) - \int_{T-\delta}^{T}\left(\ell^R(y_t^{0,\varepsilon,b}, u_t) - \frac{\gamma^2}{2}\|w_t\|^2\right) dt - \psi^R(y_T^{0,\varepsilon,b})\right] \\ &\quad \le \left(R + \frac{\gamma^2}{2}m^2\right)\delta + \mathrm{E}\left[\psi^R(y_{T-\delta}^{0,\varepsilon,b}) - \psi^R(y_T^{0,\varepsilon,b})\right] \end{aligned}$$

which by Ito's rule

$$\begin{aligned} &= \left(R + \frac{\gamma^2}{2}m^2\right)\delta + \mathrm{E}\Bigg\{\int_{T-\delta}^{T} \nabla\psi^R(y_t^{0,\varepsilon,b}) \cdot \left[f^b(y_t^{0,\varepsilon,b}, u_t) + \sigma(y_t^{0,\varepsilon,b}) w_t\right] dt \\ &\qquad\qquad + \frac{\varepsilon}{2\gamma^2}\int_{T-\delta}^{T} \sum_{i=1,j=1}^{n} \psi_{x_i x_j}^R(y_t^{0,\varepsilon,b}) a_{ij}(y_t^{0,\varepsilon,b})\, dt\Bigg\} \\ &\le \left[R + \frac{\gamma^2}{2}m^2 + 2M_R(b+Mm) + \frac{\varepsilon \overline{C} M^2}{2\gamma^2}\right]\delta. \end{aligned}$$

From this (and an analogous bound on the other side using approximately optimal w), one easily finds that $\underline{V}^{\varepsilon,b,R,m}$ is Lipschitz in s.

On the other hand, (23) has a $C^{1,2}$ solution which is globally Lipschitz and bounded ([45]; see also [35], [21]). Since classical solutions are viscosity solutions, the uniqueness of viscosity solutions for (23) implies that $\underline{V}^{\varepsilon,b,R,m}$ is, in fact, this $C^{1,2}$ solution. □

Lipschitz bounds dependent on ε, b, R, m were sufficient to obtain the above result. Below, however, we will need bounds independent of these parameters. These bounds require more technical arguments, which we now present. The first bound is actually quite straightforward.

LEMMA 3.2. *There exists $\widetilde{\gamma} < \infty$ such that for all $\gamma > \widetilde{\gamma}$,*

$$\underline{V}^{\varepsilon,b,R,m}(s,x) \le M_T(1+|x|^2) \qquad \forall\, s \in [0,T], \quad x \in \Re^n,$$

and further, for $\delta \le 1$, any δ-optimal $w_\delta \in \mathcal{W}_s$ with respect to any $\theta \in \Theta_s$ (i.e., $J_g^{\varepsilon,b,R}(s,x;\theta[w_\delta], w_\delta) \ge \sup_{w\in\mathcal{W}_s} J_g^{\varepsilon,b,R}(s,x;\theta[w],w) - \delta$) satisfies

$$\|w_\delta\|^2_{L_2(\Omega\times[0,T])} \le M_T'(1+|x|^2). \tag{24}$$

We note that M_T, M_T' depend on T but are independent of ε, b, R, m.

Remark 3.3. A value for $\widetilde{\gamma}$ is easily obtained from the proof below. Since this $\widetilde{\gamma}$ is general for all systems satisfying the assumptions, it is quite conservative. If one has additional structure such as contractivity of f, a much smaller value for $\widetilde{\gamma}$ can be obtained [39], [40].

Proof. Suppressing certain arguments for notational simplicity, one has

$$|y_t^{\varepsilon,b}|^2 \le |x|^2 + 2\int_s^t (y_r^{\varepsilon,b})^T[f^b + \sigma w_r]\,dr + 2\sqrt{\frac{\varepsilon}{\gamma^2}}\int_s^t (y_r^{\varepsilon,b})^T\sigma\,dB_r + \frac{\varepsilon}{\gamma^2}\int_s^t \sum a_{ii}\,dr,$$

where (see [36], for example) the stochastic integral is a square-integrable martingale. Then, using (A1.iii), (A2.ii),

$$\begin{aligned}\mathrm{E}|y_t^{\varepsilon,b}|^2 &\le |x|^2 + 2K\mathrm{E}\int_s^t (|y_r^{\varepsilon,b}| + |y_r^{\varepsilon,b}|^2)\,dr + 2M\mathrm{E}\int_s^t |y_r^{\varepsilon,b}||w_r|\,dr + \frac{\varepsilon}{\gamma^2}M^2(t-s)\\ &\le |x|^2 + (3K+M)\int_s^t \mathrm{E}|y_r^{\varepsilon,b}|^2\,dr + \Big(\frac{\varepsilon}{\gamma^2}M^2 + K\Big)(t-s) + M\int_s^t \mathrm{E}|w_r|^2\,dr.\end{aligned}$$

By Gronwall's inequality, there exists $C_t < \infty$ such that

$$\mathrm{E}|y_t^{\varepsilon,b}|^2 \le C_t(1 + |x|^2 + \|w\|^2_{L_2(\Omega\times[0,T])}).$$

Consequently,

$$J_g^{\varepsilon,b,R}(s,x;u,w) \le C_T'(1+|x|^2) + (\widetilde{\gamma}^2 - \gamma^2)\|w\|^2_{L_2(\Omega\times[0,T])}$$

for proper choice of $C_T', \widetilde{\gamma}$ which depend on T but not b, R, and $\varepsilon \le 1$. This yields the first assertion. The second then follows by comparison with $\overline{w} \equiv 0$. □

The proof of continuity estimates uniform over b, R, m, and $\varepsilon \le 1$ is considerably more technical than the above results. In the deterministic setting, an L_2-bound on δ-optimal w is sufficient to yield equicontinuity estimates. However, in the stochastic case, the type of L_2-bound obtained in the previous lemma is not sufficient. This is due to the fact that L_2-bounds over the sample space as well as the state space do not imply bounds on the expectation of the exponentiation of the state space L_2-norm of w, and this is exactly what appears when using Gronwall-type estimates. (Recall that we are only assuming Lipschitz conditions on the dynamics, not stability.) However, one expects that if a set of Brownian paths does not diverge much from the origin, then the near-optimal disturbance paths over that portion of the sample space should not have "too large" L_2-norms. Measurability conditions make it difficult to refine that idea into a proof in the continuous-time case, so we work first with discrete-time approximations and then use well-known limit results to obtain the continuity estimate.

LEMMA 3.4. *For γ sufficiently large (i.e., $\gamma \ge \overline{\gamma}$), there exists $\overline{C}_{T,D} < \infty$ (depending on $T, D \in [0,\infty)$ but independent of b, R, m, ε) such that*

$$|\underline{V}^{\varepsilon,b,R,m}(s,x) - \underline{V}^{\varepsilon,b,R,m}(\hat{s},\hat{x})| \le \overline{C}_{T,D}[|x-\hat{x}| + |s-\hat{s}|] \qquad \forall\, s,\hat{s} \in [0,T],\ x,\hat{x} \in B_D(0).$$

Actually, $C_{T,D}$ is linear in D for the space estimate.

Proof. We first obtain the Lipschitz estimate in the space variable. This requires the discrete game approximation. Once one has this, the estimate in the time variable follows without having to use discrete approximations. The proof is very technical, and a significant portion of it is moved to Appendix A.

Define the discrete approximation as follows. Let the number of time-steps be N, and the step size is then $\Delta \doteq T/N$. We assume $\Delta \leq 1$ freely throughout the proof. Let B_n be a sequence of independent identically distributed m-dimensional random variables with $\mathrm{E}[B_n] = 0$, $\mathrm{E}[B_n B_n^T] = I_m$, and finite range. In particular, we will actually take the B_n such that the components always consist entirely of the terms -1 and 1 in order to simplify the proof. Let the B_n be adapted to the sequence of σ-algebras $\mathcal{F}_n$, where $\mathcal{F}_0$ is trivial. Let the control and disturbance at step n be u_n and w_n, which are measurable with respect to $\mathcal{F}_{n-1}$. We suppress the b and R superscripts on f, ℓ, ψ and also use the original bounds (without the $'$ superscripts) of assumption (A5) to simplify matters—we note that these coefficients were independent of b, R. The dynamics for the discrete game are then

$$\overline{y}_n = \overline{y}_{n-1} + [f(\overline{y}_{n-1}, u_n) + \sigma(\overline{y}_{n-1})w_n]\Delta + \sqrt{\frac{\varepsilon\Delta}{\gamma^2}}\sigma(\overline{y}_{n-1})B_n. \tag{25}$$

Let $\mathcal{W}^N$ be the set of sequences of L_2 disturbances, $\{w_n\}_{n=1}^N$, of length N, where each w_n is $\mathcal{F}_{n-1}$-measurable. Let Θ^N be the set of admissible strategies for the player with control u, where admissibility is defined analogously to that in the continuous-time case above; we do not repeat it here. For any $\theta \in \Theta^N$, $w \in \mathcal{W}^N$, and initial state $y_0 = x$, define the payoff

$$J^N(x, \theta, w) = \mathrm{E}\left[\sum_{i=1}^{N}\left[\ell(\overline{y}_{n-1}, u_n) - \frac{\gamma^2}{2}|w_n|^2\right]\Delta + \psi(\overline{y}_N)\right]$$

and value

$$V^N(x) = \inf_{\theta\in\Theta^N} \overline{V}^N(x, \theta),$$
$$\overline{V}^N(x, \theta) = \sup_{w\in\mathcal{W}^N} J^N(x, \theta, w).$$

Note that if one obtains a Lipschitz bound in x on $\overline{V}^N(x, \theta)$ that is uniform over $\theta \in \Theta^N$, then one automatically obtains the desired Lipschitz bound in x on $V^N(x)$. Consequently, we will work only with $\overline{V}^N(x, \theta)$ and, again to simplify the notation, drop the θ argument, simply referring to $\overline{V}^N(x)$.

We will use dynamic programming to work back from our assumed Lipschitz continuity estimate on ψ to obtain the estimate on V^N. Let

$$\overline{V}_N^N(x_N) = \psi(x_N),$$
$$\overline{J}_{n-1}^N(x_{n-1}, v_n) = \mathrm{E}\left[\left(\ell(x_{n-1}) - \frac{\gamma^2}{2}|v_n|^2\right)\Delta + \overline{V}_n^N(y_n)\right],$$
$$\overline{V}_{n-1}^N(x_{n-1}) = \sup_{v_n\in\Re^m} \overline{J}_{n-1}^N(x_{n-1}, v_n) \qquad \forall\, n = 1, 2, \ldots, N,$$

where we again drop θ, and let y_n be given by

$$y_n = x_{n-1} + [f(x_{n-1}) + \sigma(x_{n-1})w_n]\Delta + \sqrt{\frac{\varepsilon\Delta}{\gamma^2}}\sigma(x_{n-1})B_n$$

and $w_n = v_n$, where x_{n-1}, v_n are deterministic. Then, of course,

$$\overline{V}^N(x) = \overline{V}_0^N(x). \tag{26}$$

We now proceed to obtain the Lipschitz bound in x on near-optimal $\overline{V}_0^N(x)$. First we obtain a bound on $|v_N|$ depending on $|x_{N-1}|$. Given v_N, let

$$y_N = x_{N-1} + [f(x_{N-1}) + \sigma(x_{N-1})v_N]\Delta + \sqrt{\frac{\varepsilon\Delta}{\gamma^2}}\sigma(x_{N-1})B_N, \tag{27}$$

$$y_N^0 = x_{N-1} + [f(x_{N-1})]\Delta + \sqrt{\frac{\varepsilon\Delta}{\gamma^2}}\sigma(x_{N-1})B_N. \tag{28}$$

Then by assumption (A4),

$$\begin{aligned}
&\psi(y_N) - \psi(y_N^0)\\
&\quad\le C(3/2 + 2|y_N| + 2|y_N^0|)|\sigma(x_{N-1})v_N\Delta|\\
&\quad\le C\left[(3/2 + 4K\Delta) + 2(1 + 2K\Delta)|x_{N-1}| + 2M|v_N|\Delta + 4\sqrt{\frac{\varepsilon\Delta}{\gamma^2}}M|B_N|\right]M|v_N|\Delta\\
&\quad\le C\Big[(3/2 + 4K\Delta) + 2(1 + 2K\Delta)|x_{N-1}|\Big]M|v_N|\Delta + \ 3CM^2|v_N|^2\Delta^2\\
&\qquad + 2CM^2\varepsilon\Delta|B_N|^2/\gamma^2.
\end{aligned}$$

(The weaker constants $3/2$ and 2 appearing in the first term above are being used here in place of 1 merely for reasons of consistency with later estimates; this will become clear upon a reading of Appendix A.) This implies that for $\delta\Delta$-optimal v_N,

$$\begin{aligned}
-\delta\Delta\le\ &\overline{J}_{N-1}^N(x_{N-1}, v_n) - \overline{J}_{N-1}^N(x_{N-1}, 0)\\
&\le -\left(\frac{\gamma^2}{2} - 3CM^2\Delta\right)|v_N|^2\Delta + CM\Big[(3/2 + 4K\Delta) + 2(1 + 2K\Delta)|x_{N-1}|\Big]|v_N|\Delta\\
&\quad + 2CM^2\varepsilon\Delta/\gamma^2
\end{aligned}$$

or

$$\begin{aligned}
0 \le\ &-\left(\frac{\gamma^2}{2} - 3CM^2\Delta\right)|v_N|^2 + CM\Big[(3/2 + 4K\Delta) + 2(1 + 2K\Delta)|x_{N-1}|\Big]|v_N|\\
&\quad + 2CM^2\varepsilon/\gamma^2 + \delta.
\end{aligned}$$

(One can use $a^2 + b^2 \ge 2ab$ to eliminate the cross-terms in $|v_N|, |x_{N-1}|$, leading to an additional term in the coefficient in the quadratic term, and thus leading to a stricter requirement below on γ, but that is avoidable in this proof.) Consequently, with Δ sufficiently small so that the coefficient on the quadratic term is negative, one obtains

$$|v_N| \le \frac{C}{\gamma}\left[C_1 + C_2|x_{N-1}|\right] \tag{29}$$

for proper choice of C_1, C_2, which may be chosen independently of Δ for sufficiently small Δ.

Next we propagate the Lipschitz property back one step. This is a rather technical step, and consequently we have moved the estimates to Appendix A. The resulting Lipschitz bound is

$$\begin{aligned}
&\left|\overline{V}_{N-1}^N(x_{N-1}) - \overline{V}_{N-1}^N(\hat{x}_{N-1})\right|\\
&\qquad\le b(|\hat{x}_{N-1}|)\left[1 + c_1\Delta + c_2\frac{K_4}{\gamma}\Delta + c_3\frac{K_4^2}{\gamma^2}\Delta^2\right]|x_{N-1} - \hat{x}_{N-1}|\\
&\qquad\quad + \overline{C}\sqrt{\frac{\varepsilon}{\gamma^2}}\left[K_3\Delta + M\frac{K_4}{\gamma}\Delta\right]|x_{N-1} - \hat{x}_{N-1}|,
\end{aligned} \tag{30}$$

provided that $\Delta \le \min\{1, d_1\}$, where the constants and restrictions are given in the appendix. Also, the function b is given in the appendix as

$$b(x) = \begin{cases} C(\frac{3}{2} + 2|x|^2) & \text{if } |x| \le 1, \\ C(\frac{3}{2} + 2|x|) & \text{if } |x| > 1. \end{cases} \tag{31}$$

This bound requires a one-sided bound on ψ_{xx}. In fact, the semiconvexity of ψ is sufficient to obtain this step. Consequently, the next step is to propagate the semiconvexity of ψ backward one step to obtain a semiconvexity bound on $\overline{V}^N_{N-1}$. This step also appears in Appendix A.

Next one works backwards with minor variants of (29), (30), and the semiconvexity bound. This appears in Appendix A and leads of course to a Lipschitz bound on $\overline{V}^N_0(x)$. One must then let $N \to \infty$ and show that this bound does not blow up. The corresponding sequences are given in the appendix, and the limit bound is denoted simply as $M_\infty b(|x|)$. Since there are well-known results demonstrating the convergence of such discrete-time games to their continuous-time counterparts (see, for instance, [14], [24]), one obtains a Lipschitz bound on the limit continuous-time game. In other words (reinstating the superscripts), one has obtained the Lipschitz bound

$$|\underline{V}^{\varepsilon,b,R,m}(s,x) - \underline{V}^{\varepsilon,b,R,m}(s,\hat{x})| \le M_\infty b(|x|)|x - \hat{x}| \qquad \forall\, s \in [0,T],\ |\hat{x}| \le |x| < \infty.$$

Once one obtains the above Lipschitz bound in the space variable, one may obtain the bound in the time variable without resorting to the discrete-time setting. The details are relatively long and technical, but rather standard. Consequently, they will only be sketched. Perhaps it should be noted that they rely on the bounds on the second derivatives of ℓ and ψ, of course. As a first step, let us note a result which is a slightly more specific bound on near-optimal disturbances than that of Lemma 3.2 and which is particularly oriented toward small time–horizons. It also allows for a random initial state. It is stated as a lemma below, and the proof is sketched. Following the sketched proof of the lemma, the remaining steps in the proof of the Lipschitz bound in the time variable are presented.

LEMMA 3.5. *Consider the above stochastic game, but now let the terminal time be denoted by τ, so as to differentiate this from the main problem of the section (with terminal time denoted by T), let $\tau \le 1$, and let $s \in [0,\tau]$. Also, now let the initial state, $y^\varepsilon_s = x$, be random and independent of B_t for $t \ge s$. Then there exists $\widetilde{\gamma} < \infty$ such that for all $\gamma > \widetilde{\gamma}$, for $\delta \le \tau - s$, any δ-optimal $w_\delta \in \mathcal{W}_s$ with respect to any $\theta \in \Theta_s$ satisfies*

$$\|w_\delta\|_{L_2(\Omega\times[s,\tau])} \le \overline{M}' \sqrt{1 + \mathrm{E}\big[|x|^2\big]}\sqrt{\tau - s} \tag{32}$$

for properly chosen $\overline{M}'$ (independent of x, s, τ).

Proof. The proof relies again on comparison of the near-optimal disturbance with the use of the disturbance process $w \equiv 0$. To simplify notation, we will work directly with f, ℓ, ψ, rather than with their cut-offs (f^b, ℓ^R, ψ^R); the structure of the proof is unchanged. Let $\theta \in \Theta_s$. Let y^ε satisfy (13) with disturbance w^δ, which is δ-optimal with respect to θ (for the problem over $[s,\tau]$). Using standard techniques, one shows that there exists $\widehat{C}_1 < \infty$ such that

$$\mathrm{E}\left[|y^\varepsilon_t - x|^2\right] \le \widehat{C}_1 \left[\Big(1 + \mathrm{E}\big[|x|^2\big]\Big)(t-s) + \int_s^t \mathrm{E}|w^\delta_r|^2\, dr\right] \qquad \forall\, t \in [s,\tau]. \tag{33}$$

Similarly,

$$\mathrm{E}|y_t^\varepsilon - x| \le \widehat{C}_2 \left[\Big(1 + \mathrm{E}|x|\Big)(t-s) + \int_s^t \mathrm{E}|w_r^\delta|\, dr \right] \qquad \forall\, t \in [s,\tau]. \tag{34}$$

Denote the payoff (with $u = \theta[w^\delta]$) as

$$\begin{aligned} J^\varepsilon_{g,\tau,\delta}(s,x;u,w^\delta) &\doteq \mathrm{E}\left[\int_s^\tau \ell(y_t^\varepsilon, u_t) - \frac{\gamma^2}{2}|w_t^\delta|^2\, dt + \psi(y_\tau^\varepsilon) \right] \\ &\le \mathrm{E}[\psi(x)] + \mathrm{E}[\ell(x)](\tau - s) \\ &\quad + \mathrm{E}\Bigg\{ \int_s^\tau \left[|\ell_x(x)||y_t^\varepsilon - x| + \frac{1}{2}|\ell_{xx}(\xi_t')||y_t^\varepsilon - x|^2 - \frac{\gamma^2}{2}|w_t^\delta|^2 \right] dt \\ &\qquad + |\psi_x(x)||y_\tau^\varepsilon - x| + \frac{1}{2}|\psi_{xx}(\xi_\tau')||y_\tau^\varepsilon - x|^2 \Bigg\}, \end{aligned}$$

where ξ_t' is on the line from x to y_t^ε for each t. Then, using (33), (34), (A3), and (A4) yields

$$\begin{aligned} J^\varepsilon_{g,\tau,\delta}(s,x;u,w^\delta) \le{}& \mathrm{E}[\psi(x)] + \mathrm{E}[\ell(x)](\tau - s) \\ &+ \widehat{C}_3 \left[\big(1 + \mathrm{E}\big[|x|^2\big]\big)\,(\tau - s) + \int_s^\tau \mathrm{E}\big[(1+|x|)|w_t^\delta|\big]\, dt \right] \\ &+ \widehat{C}_4 \left[\big(1 + \mathrm{E}\big[|x|^2\big]\big)\,(\tau - s) + \int_s^\tau \mathrm{E}|w_t^\delta|^2\, dt \right] - \frac{\gamma^2}{2}\int_s^\tau \mathrm{E}|w_t^\delta|^2\, dt \end{aligned} \tag{35}$$

for proper choice of $\widehat{C}_3, \widehat{C}_4$.

On the other hand, let y^0 be the solution of (13) with the same θ but with $w_0 \equiv 0$. Let the corresponding payoff be denoted by $J^\varepsilon_{g,\tau,0}(s,x;u_0,w_0)$. By similar techniques, one has

$$\mathrm{E}|y_t^0 - x|^2 \le \widehat{C}_5\big(1 + \mathrm{E}\big[|x|^2\big]\big)(t-s) \quad \text{and} \quad \mathrm{E}|y_t^0 - x| \le \widehat{C}_6\big(1 + \mathrm{E}|x|\big)(t-s)$$

for proper choice of $\widehat{C}_5, \widehat{C}_6$. This leads to

$$J^\varepsilon_{g,\tau,0}(s,x;u_0,w_0) \ge \mathrm{E}[\psi(x)] + \mathrm{E}[\ell(x)](\tau - s) - \widehat{C}_7\big(1 + \mathrm{E}\big[|x|^2\big]\big)(\tau - s) \tag{36}$$

for proper choice of $\widehat{C}_7$.

Now, using the δ-optimality of w^δ and combining (35) and (36) yields

$$\begin{aligned} 0 \le{}& \delta + \widehat{C}_8\big(1 + \mathrm{E}\big[|x|^2\big]\big)(\tau - s) + \widehat{C}_3 \int_s^\tau \mathrm{E}\big[(1+|x|)|w_t^\delta|\big]\, dt - \left(\frac{\gamma^2}{2} - \frac{\widetilde{\gamma}^2}{2}\right)\int_s^\tau \mathrm{E}|w_t^\delta|^2\, dt \\ \le{}& \delta + \widehat{C}_8\big(1 + \mathrm{E}\big[|x|^2\big]\big)(\tau - s) + \widehat{C}_3\sqrt{2(1+\mathrm{E}|x|^2)}\sqrt{\tau - s}\left[\int_s^\tau \mathrm{E}|w_t^\delta|^2\, dt\right]^{\frac{1}{2}} \\ &- \left(\frac{\gamma^2}{2} - \frac{\widetilde{\gamma}^2}{2}\right)\int_s^\tau \mathrm{E}|w_t^\delta|^2\, dt, \end{aligned}$$

where $\widehat{C}_8 \doteq \widehat{C}_3 + \widehat{C}_4 + \widehat{C}_7$ and $\frac{\widetilde{\gamma}^2}{2} \doteq \widehat{C}_4$. Letting $\delta \le \tau - s$, solving this last quadratic equation yields the desired result. ∎

Now we return to the sketch of the proof of the Lipschitz condition in the time variable. Again, to simplify matters, we work directly with f, ℓ, ψ, rather than with their cut-offs (f^b, ℓ^R, ψ^R). Consider $\underline{V}^\varepsilon(s,x)$ and $\overline{V}^\varepsilon(\hat{s},x)$ (where we are suppressing the cut-off superscripts), where $0 \le s \le \hat{s} \le T$ and $\tau \doteq \hat{s} - s$. Note that, under the given conditions, one has strong solutions of (13). Let the probability triple under which $\underline{V}^\varepsilon(s,x)$ is computed be $(\Omega, P, \mathcal{F}_\cdot)$. As in the proof of Lemma 3.1, for the computation of $\underline{V}^\varepsilon(\hat{s},x)$, one may use instead $(\Omega, P, \widehat{\mathcal{F}}_\cdot)$, where $\widehat{\mathcal{F}}_t \doteq \mathcal{F}_{t-\tau}$ for all $t \ge \hat{s} = s + \tau$; the corresponding Brownian motion is $\widehat{B}_t = B_{t-\tau}$ for all $t \ge \hat{s}$.

Let $\mathcal{U}_{[r_1,r_2]}$ ($\widehat{\mathcal{U}}_{[r_1,r_2]}$) be the set of $\mathcal{F}_t$- ($\widehat{\mathcal{F}}_t$-)progressively measurable controls over time interval $[r_1, r_2]$. Let $\widetilde{\theta}$ be $\frac{\varepsilon}{2}$-optimal for problem $\underline{V}^\varepsilon(\hat{s},x)$, and let $\widehat{\theta}$ be any extension of $\widetilde{\theta}$ to time $T+\tau$. Noting that $\widehat{\theta} : L_2[s+\tau, T+\tau] \to \widehat{\mathcal{U}}_{[s+\tau,T+\tau]}$, let $\overline{\theta} : L_2[s,T] \to \mathcal{U}_{[s,T]}$ be given by $\overline{\theta}_t[w] = \widehat{\theta}_{t+\tau}[\widetilde{w}]$, where $\widetilde{w}_{t+\tau} = w_t$. Then let w be $\frac{\varepsilon}{2}$-optimal for $\underline{V}^\varepsilon(s,x)$ corresponding to $\overline{\theta}$. Let $\widehat{w}$ be given by $\widehat{w}_t = w_{t-\tau}$ for all $t \ge \hat{s}$. Let y^ε be the solution to (13) with the above w and $\overline{u} \doteq \overline{\theta}[w]$. Let $\widehat{y}^\varepsilon$ be the solution to (13) with new initial condition $\widehat{y}^\varepsilon_{\hat{s}} = x$ and the above $\widehat{w}$ and $\widehat{u} \doteq \widehat{\theta}[\widehat{w}]$. Then

$$\widehat{y}^\varepsilon_t = y^\varepsilon_{t-\tau} \qquad \forall\, t \in [\hat{s}, T].$$

Note that

$$\underline{V}^\varepsilon(s,x) - \underline{V}^\varepsilon(\hat{s},x) \le J^\varepsilon_g(s,x,u,w) - J^\varepsilon_g(\hat{s},x,\widehat{u},\widehat{w}) + \varepsilon,$$

and, by the time shift, this is equal to

$$\mathrm{E}\left[\int_{T-\tau}^{T} \ell(y^\varepsilon_t, \overline{u}_t) - \frac{\gamma^2}{2}|w_t|^2\, dt + \psi(y^\varepsilon_T) - \psi(\widehat{y}^\varepsilon_{T-\tau})\right] + \varepsilon.$$

Letting $\varepsilon \downarrow 0$, one must show that this is bounded above by $\overline{C}_{T,D}\tau$ for any $|x| \le D < \infty$ (for proper choice of $\overline{C}_{T,D}$). The bound from below is similar, and thus is not discussed here. Also, since the bound on the integral term is somewhat simpler than the bound on the terminal cost difference, we consider only a bound on $\mathrm{E}[\psi(y^\varepsilon_T) - \psi(\widehat{y}^\varepsilon_{T-\tau})]$ of the desired form here. Note that by (A4),

$$\mathrm{E}\left[\psi(y^\varepsilon_T)\right] - \mathrm{E}\left[\psi(\widehat{y}^\varepsilon_{T-\tau})\right] \le \mathrm{E}\left[\psi_x(y^\varepsilon_{T-\tau})[y^\varepsilon_T - y^\varepsilon_{T-\tau}]\right] + \frac{1}{2}\overline{C}\mathrm{E}\left[|y^\varepsilon_T - y^\varepsilon_{T-\tau}|^2\right]. \tag{37}$$

Also, from Lemma 3.5 and the choice of w,

$$\|w\|_{L_2(\Omega\times[T-\tau,T])} \le \overline{M}'\sqrt{1 + \mathrm{E}\left[|y^\varepsilon_{T-\tau}|^2\right]}\sqrt{\tau} \tag{38}$$

for ε sufficiently small. Using (37), using techniques similar to those in the proof of Lemma 3.5, and employing (38) yields the desired bound. This completes the sketch of the proof of the Lipschitz bound in the time variable. □

LEMMA 3.6. *Given any sequences $\{b_n\}, \{m_n\}$ such that $b_n, m_n \to \infty$, there exists a subsequence which we also subscript by n (to reduce notational complexity) such that*

$$\underline{V}^{\varepsilon, b_n, R, m_n} \to \widetilde{V}^{\varepsilon, R}$$

uniformly on compact sets, where $\widetilde{V}^{\varepsilon,R} \in C^{1,2}$ (and the derivatives converge uniformly on compact sets as well). Further, $\widetilde{V}^{\varepsilon,R}$ is a solution to

$$0 = V_s + \frac{\varepsilon}{2\gamma^2}\sum_{i,j=1}^{n} a_{i,j}(x)V_{x_ix_j} + \min_{u\in U}\max_{w\in\Re^m}\left\{[f(x,u)+\sigma(x)w]\nabla V + \ell^R(x,u) - \frac{\gamma^2}{2}|w|^2\right\},$$

$$V(T,x) = \psi^R(x). \tag{39}$$

Proof. By Lemmas 3.1, 3.2, and 3.4, we have that $\underline{V}^{\varepsilon,b,R,m}, \underline{V}_s^{\varepsilon,b_n,R,m_n}, \nabla\underline{V}^{\varepsilon,b_n,R,m_n}$ are all uniformly bounded on compact sets. Combining this with (23) implies that $\sum_{i,j=1}^n a_{i,j}\cdot\underline{V}_{x_i,x_j}^{\varepsilon,b_n,R,m_n}$ are also bounded uniformly on compact sets. Then following the method in [21, Appendix E] (see also [43]), one obtains the result. □

Recall process (1) of section 2. Define the modified risk-sensitive cost and value,

$$J^{\varepsilon,R}(s,x,u.) = \mathrm{E}\exp\left\{\frac{1}{\varepsilon}\left[\int_s^T \ell^R(y_t^\varepsilon,u_t)\,dt + \psi^R(y_T^\varepsilon)\right]\right\} \tag{40}$$

and

$$V^{\varepsilon,R}(s,x) = \inf_{u\in\mathcal{U}_s}\varepsilon\log J^{\varepsilon,R}(s,x,u.). \tag{41}$$

THEOREM 3.7. *Let $0\le s\le T$ and $x\in\Re^n$. For any $u\in\mathcal{U}_s$, one has*

$$\varepsilon\log J^{\varepsilon,R}(s,x,u) \ge \widetilde{V}^{\varepsilon,R}(s,x),$$

while with optimal $\widetilde{u}^R$ given by (6), with $\widetilde{V}^{\varepsilon,R}, \ell^R$ replacing $\widetilde{V}^\varepsilon, \ell$, one has

$$\varepsilon\log J^{\varepsilon,R}(s,x,\widetilde{u}^R) = \widetilde{V}^{\varepsilon,R}(s,x).$$

Proof. By $\widetilde{V}^{\varepsilon,R}\in C^{1,2}$, assumptions (A3.iv), (A4.iv), and (40), one easily shows that there exists $C_R<\infty$ such that

$$|\nabla\widetilde{V}^{\varepsilon,R}(s,x)|\le C_R \qquad \forall\, s\in[0,T], x\in\Re^n.$$

In this case, (7) holds for any $u\in\mathcal{U}_s$. Consequently, the proof of Lemma 2.2 holds for $\widetilde{V}^{\varepsilon,R}$ for any control $u\in\mathcal{U}_s$, and so

$$\varepsilon\log J^{\varepsilon,R}(s,x,u) \ge \widetilde{V}^{\varepsilon,R}(s,x)$$

for any $u\in\mathcal{U}_s$. Lemma 2.1 also holds with $\widetilde{V}^{\varepsilon,R}, J^{\varepsilon,R}$ replacing $\widetilde{V}^\varepsilon, J^\varepsilon$. □

COROLLARY 3.8.

$$\underline{V}^{\varepsilon,b,R,m} \to \widetilde{V}^{\varepsilon,R}$$

uniformly on compact sets (not just sequentially).

Proof. Combine the uniqueness implied by Theorem 3.7 with the subsequential convergence of Lemma 3.6. □

COROLLARY 3.9. *$\widetilde{V}^{\varepsilon,R}$ is monotonically increasing as a function of R and is bounded above by*

$$\varepsilon\log J^\varepsilon(s,x,\widetilde{u}) \le \widetilde{V}^\varepsilon(s,x).$$

Proof. The first assertion follows by the definitions of ℓ^R, ψ^R. For the second assertion, note that by Theorem 3.7

$$\begin{aligned}\widetilde{V}^{\varepsilon,R}(s,x) &\le \varepsilon\log J^{\varepsilon,R}(s,x,\widetilde{u})\\ &\le \varepsilon\log J^\varepsilon(s,x,\widetilde{u}),\end{aligned}$$

which by Lemma 2.1

$$\leq \widetilde{V}^{\varepsilon}(s,x). \qquad \square$$

We now obtain the promised existence result for (4).

THEOREM 3.10. *$\widetilde{V}^{\varepsilon,R}(s,x) \uparrow \widetilde{V}^{\varepsilon}(s,x) \in C^{1,2}$ as $R \to \infty$, where $\widetilde{V}^{\varepsilon}$ is a solution to (4).*

Proof. The result follows exactly as in Lemma 3.6, with the added monotonicity from Corollary 3.9. $\square$

As an added bonus, we obtain the promised improvement over Lemma 2.3.

THEOREM 3.11. *There exists a solution $\widetilde{V}^{\varepsilon} \in C^{1,2}$ of (4). Further, for any $0 \leq s \leq T$, $x \in \Re^n$, and $u \in \mathcal{U}_s$, one has*

$$\varepsilon \log J^{\varepsilon}(s,x,u) \geq \widetilde{V}^{\varepsilon}(s,x),$$

while with optimal $\widetilde{u}$ given by (6) one has

$$\varepsilon \log J^{\varepsilon}(s,x,\widetilde{u}) = \widetilde{V}^{\varepsilon}(s,x).$$

Proof. Note that for any $u \in \mathcal{U}_s$,

$$\varepsilon \log J^{\varepsilon}(s,x,u) \geq \varepsilon \log J^{\varepsilon,R}(s,x,u),$$

which by Theorem 3.7

$$\geq \widetilde{V}^{\varepsilon,R}(s,x).$$

Combining this with Theorem 3.10 yields the first assertion. The second assertion follows by combining the first assertion with Lemma 2.1. $\square$

4. Uniqueness and risk-sensitive limit results. In this section we consider the following terminal value problem:

$$\begin{cases} -W_t(t,x) + H(x, D_x W(t,x)) = 0 & \text{in } (0,T) \times \Re^n, \\ W(T,x) = \psi(x) & \text{in } \Re^n, \end{cases} \tag{42}$$

where the Hamiltonian H is

$$\begin{aligned} H(x,p) &:= \max_{u \in U} \min_{\omega \in \Re^m} \left\{ -(f(x,u) + \sigma(x)\omega) \cdot p - \ell(x,u) + \frac{\gamma^2}{2}|\omega|^2 \right\} \\ &= \min_{\omega \in \Re^m} \left\{ \frac{\gamma^2}{2}|\omega|^2 - \sigma(x)\omega \cdot p \right\} + \max_{u \in U} \{ -f(x,u) \cdot p - \ell(x,u) \}. \end{aligned} \tag{43}$$

This is the DPE corresponding to a robust/H_∞ control problem. This problem can be considered a *differential game* with the following cost functional:

$$J(s,x,u,\omega) := \int_s^T \ell(y_x(t),u(t)) - \frac{\gamma^2}{2}|\omega(t)|^2 dt + \psi(y_x(T)), \tag{44}$$

where $u(\cdot) \in \mathcal{U} := \{\text{measurable functions } [0,T] \to U\}$ is the control of the minimizing player, $\omega(\cdot) \in \mathcal{B} := L^2([0,T], \Re^m)$ is the control of the maximizing player, and $y_x(\cdot)$ is the unique solution of the following dynamical system:

$$\begin{cases} y'(t) = f(y(t),u(t)) + \sigma(y(t))\omega(t), \\ y(s) = x. \end{cases} \tag{S}$$

Note that we switch notation for the time argument here from y_t to $y(t)$, to emphasize that the y paths are now (deterministic) solutions of ODEs rather than (stochastic) solutions of SDEs.

We define the set of nonanticipating strategies for the minimizing player to be

$$\Theta := \{\theta : \mathcal{B} \to \mathcal{U} : \text{ given any } \tau \in [0,T],\ \omega(t) = \overline{\omega}(t) \\ \text{for all } t \in [0,\tau] \text{ implies } \theta[\omega](t) = \theta[\overline{\omega}](t) \text{ for all } t \in [0,\tau]\},$$

and the set of nonanticipating strategies of the maximizing player to be

$$\Lambda := \{\lambda : \mathcal{U} \to \mathcal{B} : \text{ given any } \tau \in [0,T],\ u(t) = \overline{u}(t) \\ \text{for all } t \in [0,\tau] \text{ implies } \lambda[u](t) = \lambda[\overline{u}](t) \text{ for all } t \in [0,\tau]\}.$$

The *lower value* and the *upper value* of the game are given by (see, for instance, [11])

$$V(s,x) := \inf_{\theta \in \Theta} \sup_{\omega \in \mathcal{B}} J(s,x,\theta[\omega],\omega), \tag{45}$$

$$W(s,x) := \sup_{\lambda \in \Lambda} \inf_{u \in \mathcal{U}} J(s,x,u,\lambda[u]). \tag{46}$$

This section will be concerned with the *lower value*; analogous results hold for the *upper value* as well.

In the following theorem we prove a uniqueness result for (42) in the set of nonnegative continuous functions with locally bounded superdifferential in the x variable and growing at most quadratically. More precisely, given $U : [0,T] \times \Re^n \to \Re$, we define

$$D_x^+ U(t,x) = \left\{ p \in \Re^n : \ \limsup_{|x-y| \to 0} \frac{U(t,y) - U(t,x) - (y-x)\cdot p}{|x-y|} \le 0 \right\},$$

$$||U||_R := \sup\{|U(t,x)| + |p|,\ (t,x) \in [0,T] \times \overline{B}_R(0)\,,\ p \in D_x^+ U(t,x)\},$$

and

$$\mathcal{K} := \Bigg\{ U \in C([0,T] \times \Re^n) : \ U(t,x) \ge 0,\ ||U||_R < +\infty \qquad \forall\, R > 0 \\ \text{and} \quad \sup_{(t,x) \in [0,T] \times \Re^n} \frac{|U(t,x)|}{1+|x|^2} < +\infty \Bigg\}.$$

For the uniqueness result, we use, besides some hypotheses stated in section 2, the following less restrictive assumptions:

(H1) $f \in C(\Re^n \times U, \Re^n)$, $\sigma \in C(\Re^n, \mathcal{L}(\Re^m, \Re^n))$, $\ell \in C(\Re^n \times U, \Re)$, $\psi \in C(\Re^n, \Re)$;

(H2) there exists $M > 0$ such that

$$|\sigma(x)| \le M(1+|x|) \quad \forall x \in \Re; \tag{47}$$

(H3) for any $R > 0$ there exists $L_R > 0$ such that

$$|f(x,u) - f(y,u)| \le L_R |x-y| \quad \forall x,y \in \overline{B}_R(0),\ u \in U,$$
$$|\sigma(x) - \sigma(y)| \le L_R |x-y| \quad \forall x,y \in \overline{B}_R(0).$$

THEOREM 4.1. *Assume* (A0), (A1.iii), (A3.ii)–(A3.iv), (A4.ii)–(A4.iv), *and* (H1)–(H3). *If* $W_1, W_2 \in \mathcal{K}$ *are viscosity solutions of* (42), *then* $W_1 = W_2$ *in* $[0,T] \times \Re^n$.

Proof. We follow some arguments used in the proof of Theorem 3.1 in [3] for convex Hamiltonians. Let $W_1, W_2 \in \mathcal{K}$ be viscosity solutions of (42). We first note that if (x,p) belongs to a compact $K \subseteq \Re^{2n}$, then there exists $\widetilde{R} > 0$, depending on K, such that

$$H(x,p) = H_{\widetilde{R}}(x,p) := \min_{|\omega| \le \widetilde{R}} \left\{ \frac{\gamma^2}{2}|\omega|^2 - \sigma(x)\omega \cdot p \right\} + \max_{u \in U} \{-f(x,u) \cdot p - \ell(x,u)\}. \tag{48}$$

In fact, it can be easily verified that

$$\lim_{|\omega| \to \infty} \inf_{(x,p) \in K} \left\{ \frac{\gamma^2}{2}|\omega|^2 - \sigma(x)\omega \cdot p \right\} = +\infty.$$

Thus, since $\gamma^2|0|^2 - \sigma(x)0 \cdot p = 0$, the min in (43) can be computed in a compact subset of $\Re^m$. Now fix $r > 0$ and choose $R > r$. First we suppose that

$$T \le \delta(\gamma, r, R) := \min\left(1, \frac{R-r}{K(1+R)}, \frac{\gamma^2(R-r)^2}{2M^2(1+R)^2\overline{C}(1+R^2) + 2\gamma^2 K(R-r)(1+R)}\right), \tag{49}$$

where $\overline{C} = \max(C, \sup_{(t,x)\in[0,T]\times\Re^n} \frac{|W_1(t,x)|}{1+|x|^2}, \sup_{(t,x)\in[0,T]\times\Re^n} \frac{|W_2(t,x)|}{1+|x|^2})$ and C is the growth constant of ℓ and ψ.

Since W_1, $W_2 \in \mathcal{K}$ and (48) holds, there exists $\widetilde{R} > 0$ such that

$$H(x,p) = H_{\widetilde{R}}(x,p) \qquad \forall\, p \in D_x^+ W_1(t,x) \cup D_x^+ W_2(t,x),\ (t,x) \in [0,T] \times \overline{B}_R(0).$$

Thus W_i $(i = 1,2)$ is a viscosity solution also of

$$\begin{cases} -W_t(t,x) + H_{\widetilde{R}}(x, D_x W(t,x)) = 0 & \text{in } (0,T) \times B_R(0), \\ W(x,T) = \psi(x) & \text{in } B_R(0). \end{cases} \tag{50}$$

Under the current assumptions, the continuous viscosity solutions W of (50) satisfy the so-called *optimality principle* (see, e.g., Propositions 2.1 and 2.2 in [34]); namely, for all $s \in [0,T]$ and $0 \le \rho \le T - s$, the following estimate holds:

$$W(s,x) = \inf_{\theta \in \Theta} \sup_{\substack{\omega \in \mathcal{B} \\ |\omega| \le \widetilde{R}}} \Big\{ \mathcal{I}(s, (s+\rho) \wedge t_x^R(\theta[\omega], \omega)) + W((s+\rho) \wedge t_x^R(\theta[\omega],\omega), y_x((s+\rho) \wedge t_x^R(\theta[\omega],\omega))) \Big\}, \tag{51}$$

where for all $s, t \in [0,T]$, $\mathcal{I}(s,t) := \int_s^t \ell(y(\tau), \theta[\omega](\tau)) - \frac{\gamma^2}{2}|\omega(\tau)|^2 d\tau$, $y_x(t) = y_x(t, \theta[\omega], \omega)$ is the unique solution of (S) corresponding to $\theta[\omega]$, ω (we drop the dependence on $\theta[\omega]$, ω for simplicity of notations), and $t_x^R(\theta[\omega],\omega)$ is the first exit time from $B_R(0)$, i.e.,

$$t_x^R(\theta[\omega],\omega) := \inf\{t \ge s : |y_x(t)| \ge R\}.$$

In particular, (51) is satisfied by W_i $(i = 1,2)$. We observe that, since $W_i \ge 0$, for any strategy θ the sup in (51), corresponding to $\rho = T - s$, may be confined to the controls

ω such that $\mathcal{I}(s, T \wedge t_x^R(\theta[\omega], \omega)) + W_i((T \wedge t_x^R(\theta[\omega], \omega)), y(T \wedge t_x^R(\theta[\omega], \omega))) \geq 0$. For any strategy θ, we define the set

$$\mathcal{A}_\theta := \left\{\omega \in \mathcal{B} :\ \mathcal{I}(s, T \wedge t_x^R(\theta[\omega], \omega)) + W_i((T \wedge t_x^R(\theta[\omega], \omega)), y_x(T \wedge t_x^R(\theta[\omega], \omega))) \geq 0\right\}.$$

We observe that $\mathcal{A}_\theta \neq \emptyset$, since it contains the control $\omega \equiv 0$. We claim that if $t_x^R(\theta[\omega], \omega)) < T$, then $\omega \notin \mathcal{A}_\theta$. In fact, suppose that $y_x(\bar{t}) \in \partial B_R(0)$, for some $\bar{t} \in [s, T)$, and $y_x(t) \in B_R(0)$ for all $t \in [s, \bar{t})$. Then we have the following estimate:

$$\begin{aligned} R - |x| = |y_x(\bar{t})| - |x| &\leq \int_s^{\bar{t}} K(1 + |y_x(\tau)|)d\tau + \int_s^{\bar{t}} M(1 + |y_x(\tau)|)\omega(\tau)|d\tau \\ &\leq K(1 + R)(\bar{t} - s) + M(1 + R)||\omega||_{L^2(s,\bar{t})}(\bar{t} - s)^{1/2}. \end{aligned}$$

Thus $||\omega||_{L^2(s,\bar{t})} \geq \chi[r, R](\bar{t})$, where

$$\chi[r, R](\bar{t}) := \frac{R - r - K(1 + R)(\bar{t} - s)}{M(1 + R)(\bar{t} - s)^{1/2}}.$$

We observe that, by the assumption of (49), $\chi[r, R](t)$ is positive for all $t \in [s, T]$. Hence we have

$$\begin{aligned} \mathcal{I}(s, \bar{t}) + W_i(\bar{t}, y_x(\bar{t})) &\leq \int_s^{\bar{t}} C(1 + |y_x(t)|^2) - \frac{\gamma^2}{2}|\omega(t)|^2\ dt + \widetilde{C}(1 + |y_x(\bar{t})|^2) \\ &\leq C(1 + R^2)(\bar{t} - s) - \frac{\gamma^2}{2}|\chi[r, R](\bar{t})|^2 + \widetilde{C}(1 + R^2) \\ &\leq \overline{C}(1 + R^2) + \gamma^2 \frac{K(R - r)(1 + R)}{M^2(1 + R)^2} - \frac{\gamma^2}{2}\frac{(R - r)^2}{M^2(1 + R)^2(\bar{t} - s)} \\ &\quad - \frac{\gamma^2}{2}\frac{K^2(\bar{t} - s)}{M^2} \\ &\leq \overline{C}(1 + R^2) + \gamma^2 \frac{K(R - r)}{M^2(1 + R)} - \frac{\gamma^2}{2}\frac{(R - r)^2}{M^2(1 + R)^2(T - s)}, \end{aligned}$$

where $\widetilde{C} := (\sup_{(t,x)\in[0,T]\times\Re^n} \frac{|W_1(t,x)|}{1+|x|^2}, \sup_{(t,x)\in[0,T]\times\Re^n} \frac{|W_2(t,x)|}{1+|x|^2})$.

By the condition (49), we have $\mathcal{I}(s, \bar{t}) + W(\bar{t}, y_x(\bar{t})) < 0$, and this proves the claim. Therefore for all $(s, x) \in [0, T] \times \overline{B}_r(0)$, each W_i $(i = 1, 2)$ satisfies

$$W_i(s, x) = \inf_{\theta\in\Theta} \sup_{\substack{\omega\in\mathcal{A}_\theta \\ |\omega|\leq\widetilde{R}}} \left\{\mathcal{I}(s, T) + \psi(y_x(T))\right\}, \tag{52}$$

and we can conclude that $W_1 = W_2$ in $[0, T] \times \overline{B}_r(0)$. In the case of $T > \delta(\gamma, r, R)$, we can divide the interval $[0, T]$ into subintervals whose length is less than $\delta(\gamma, r, R)$. Let $0 = t_0, t_1, \ldots, t_n = T$ be the points of such a division, and for any $k = 1, \ldots, n$ let us consider the following Cauchy problem:

$$\begin{cases} -W_t(t, x) + H_{\widetilde{R}}(x, D_x W(t, x)) = 0 & \text{in } (t_{k-1}, t_k) \times B_R(0), \\ W(x, t_k) = \psi_k(x) & \text{in } B_R(0), \end{cases} \tag{53}$$

where the terminal value $\psi_k(x)$ can coincide either with $W_1(t_k, x)$ or with $W_2(t_k, x)$. We start with $k = n$. Since $|t_n - t_{n-1}| < \delta(\gamma, r, R)$, we can argue as above and obtain

that the W_i's coincide in $[t_{n-1}, t_n] \times \overline{B}_r(0)$. Then, by proceeding backward in the time variable, we obtain that for all $k \in \{0, \dots, n\}$, $W_1 = W_2$ in $[t_{k-1}, t_k] \times \overline{B}_r(0)$, and this completes the proof. □

In [41] it is proved that, under the hypotheses of Theorem 4.1 (with (A2.ii) instead of (H2)), for sufficiently large γ the *lower value* V is a locally Lipschitz continuous function growing at most quadratically in the state variable (thus $V \in \mathcal{K}$), and it is a viscosity solution of (42). Thus we have the following corollary.

COROLLARY 4.2. *Assume the hypotheses of Theorem* 4.1*, with* (H2) *replaced by* (A2.ii). *Then for γ large enough the value V is the unique viscosity solution of* (42) *in $\mathcal{K}$.*

As a consequence of the uniqueness Theorem 4.1 we get the convergence of the value function $\widetilde{V}^\varepsilon$ of the risk-sensitive problem to the value V of the robust/H_∞ control problem as $\varepsilon \to 0$. The proof of this result is standard (see, e.g., [2]), and it follows directly from the stability of the viscosity solutions with respect to the locally uniform convergence of the DPE for the risk-sensitive problem to the DPE for the corresponding robust control problem and the local uniform boundedness and equicontinuity estimates obtained in section 3.

THEOREM 4.3. *Assume* (A0)–(A5). *Then, for γ large enough, $\widetilde{V}^\varepsilon \to V$ uniformly on the compact subsets of $[0, T] \times \Re^n$.*

Proof. From Lemmas 3.2, 3.4, 3.6 and Theorem 3.10 it follows that, for γ large enough and for any $D > 0$, there exist $C_{T,D}$, $M_{T,D} > 0$ (independent of ε) such that

$$|\widetilde{V}^\varepsilon(s_1, x) - \widetilde{V}^\varepsilon(s_2, z)| \le C_{T,D}[|x - z| + |s_1 - s_2|] \quad \forall\, s_1, s_2 \in [0, T],\ x, z \in \overline{B}_D(0) \tag{54}$$

and

$$|\widetilde{V}^\varepsilon(t, x)| \le M_{T,D} \qquad \forall\, t \in [0, T],\ x \in \overline{B}_D(0). \tag{55}$$

By using the Ascoli–Arzelà theorem and a standard *diagonal procedure* (see, e.g., [2]), we get the existence of a subsequence of $\widetilde{V}^\varepsilon$ converging uniformly on the compact subsets of $[0, T] \times \Re^n$ to a function $U \in \mathcal{K}$. From the stability of viscosity solutions with respect to the locally uniform convergence of the DPE (4) for the risk-sensitive problem to the DPE (42) for the robust control problem as $\varepsilon \to 0$, it follows that U is a viscosity solution of (42), and the uniqueness Theorem 4.1 implies that $U = V$. Thus we can conclude that the entire sequence $\widetilde{V}^\varepsilon$ converges to V as $\varepsilon \to 0$, uniformly on compact subsets of $[0, T] \times \Re^n$. □

Appendix A. In this appendix, we first propagate the Lipschitz bound for $\overline{V}^N$ back one step from the terminal time; that is, we obtain the Lipschitz bound for $\overline{V}^N_{N-1}$, given the corresponding bound for $\overline{V}^N_N = \psi$. We will then continue this procedure back to the initial time.

Let v^δ_N be δ-optimal at x_{N-1}. Then

$$\overline{V}^N_{N-1}(x_{N-1}) - \overline{V}^N_{N-1}(\hat{x}_{N-1}) \le \mathrm{E}\big[\psi(y_N) - \psi(\hat{y}_N)\big] + C(1 + |x_{N-1}| + |\hat{x}_{N-1}|) \cdot |x_{N-1} - \hat{x}_{N-1}|\Delta + \delta, \tag{56}$$

where y_N is given by (27) with disturbance v^δ_N, and

$$\hat{y}_N = \hat{x}_{N-1} + [f(\hat{x}_{N-1}) + \sigma(\hat{x}_{N-1})v^\delta_N]\Delta + \sqrt{\frac{\varepsilon\Delta}{\gamma^2}}\sigma(\hat{x}_{N-1})B_N. \tag{57}$$

The following rather technical estimates will lead to a Lipschitz bound on the $\mathrm{E}[\psi(y_N) - \psi(\hat{y}_N)]$ term in (56). In particular, a one-sided Lipschitz bound is obtained using a one-sided bound on ψ_{xx}. Symmetry then leads to the usual (two-sided) Lipschitz bound. This approach is employed due to the semiconvexity-preserving nature of the maximizing control problem, which has previously been applied, for instance, in [20].

First, we will replace the bound on ψ_x so as to smooth it near the origin. Note that by Assumption (A4), $|\psi_x(x)| \leq C(1+2|x|)$ for all x. A quick computation shows that $C(1+2|x|) \leq C(\frac{3}{2} + 2|x|^2)$ for all x. Consequently, we have

$$\psi_x(x) \leq b(x) \qquad \forall\, x \in \Re^n,$$

where

$$b(x) = \begin{cases} C(\frac{3}{2} + 2|x|^2) & \text{if } |x| \leq 1, \\ C(\frac{3}{2} + 2|x|) & \text{if } |x| > 1. \end{cases} \tag{58}$$

Now note that, by the mean value theorem,

$$\psi(y_N) - \psi(\hat{y}_N) = \psi_x(\xi)(y_N - \hat{y}_N),$$

where

$$\xi \doteq \lambda y_N + (1-\lambda)\hat{y}_N$$

and λ is a random variable with range $[0,1]$. Use the notation $(\delta f) \doteq f(x_{N-1}) - f(\hat{x}_{N-1})$ and $(\delta\sigma) \doteq \sigma(x_{N-1}) - \sigma(\hat{x}_{N-1})$, so that

$$y_N - \hat{y}_N = (x_{N-1} - \hat{x}_{N-1}) + \big((\delta f) + (\delta\sigma)v_N^\delta\big)\,\Delta + \sqrt{\frac{\varepsilon\Delta}{\gamma^2}}(\delta\sigma)B_N.$$

(The δ in the notation (δf) is not intended to be confused with the δ superscript in v_N^δ; it is merely intended as a shorthand to reduce the size of the displayed equations.) Consequently, we have

$$\begin{aligned} \mathrm{E}[\psi(y_N) - \psi(\hat{y}_N)] = {} & \mathrm{E}[\psi_x(\xi)]\left[(x_{N-1} - \hat{x}_{N-1}) + ((\delta f) + (\delta\sigma)v_N^\delta)\Delta\right] \\ & + \sqrt{\frac{\varepsilon\Delta}{\gamma^2}}\mathrm{E}[\psi_x(\xi)(\delta\sigma)B_N]. \end{aligned} \tag{59}$$

We will work with each of the two terms on the right-hand side of (59) separately. The second is easier, and we begin with that.

As mentioned in section 3, we let each component of B_N, B_{Nj} be independent, with

$$P\Big(B_{Nj} = 1\Big) = \frac{1}{2}, \qquad P\Big(B_{Nj} = -1\Big) = \frac{1}{2} \qquad \text{for } j = 1, \ldots, m.$$

Then, by the definition of y_N, (A1), (A2), and (29), there exists $K_1 < \infty$ such that

$$|y_N - x_{N-1}| \leq K(1 + |x_{N-1}|)\Delta + K_1\sqrt{\Delta} + MD_v(x_{N-1})\Delta \qquad \forall\, \omega \in \Omega, \tag{60}$$

where

$$K_1 = \sqrt{\frac{\varepsilon m}{\gamma^2}}M$$

and, as a shorthand,

$$D_v(x_{N-1}) = \frac{C}{\gamma}\left[C_1 + C_2|x_{N-1}|\right].$$

Similarly,

$$|\hat{y}_N - \hat{x}_{N-1}| \le K(1+|\hat{x}_{N-1}|)\Delta + K_1\sqrt{\Delta} + MD_v(\hat{x}_{N-1})\Delta \qquad \forall\,\omega\in\Omega. \tag{61}$$

Let us take

$$|x_{N-1} - \hat{x}_{N-1}| \le \Delta \le 1, \tag{62}$$

in order to simplify matters below. (The bound on $|x_{N-1} - \hat{x}_{N-1}|$ is irrelevant to the Lipschitz bound; the bound on Δ is also not important, since we will be taking $\Delta = T/N$ to zero.) Also, without loss of generality, let us suppose $|\hat{x}_{N-1}| \le |x_{N-1}|$. By the definition of ξ,

$$|\xi - x_{N-1}| \le \max\left\{|y_N - x_{N-1}|,\, |\hat{y}_N - \hat{x}_{N-1}| + |\hat{x}_{N-1} - x_{N-1}|\right\},$$

which by (62)

$$\le \max\left\{|y_N - x_{N-1}|,\, |\hat{y}_N - \hat{x}_{N-1}| + \Delta\right\}. \tag{63}$$

Then by (60), (61), and (63),

$$|\xi - x_{N-1}| \le [K(2+|x_{N-1}|) + K_1]\sqrt{\Delta} + MD_v(x_{N-1})\Delta \qquad \forall\,\omega\in\Omega. \tag{64}$$

Now,

$$\begin{aligned}
&\mathrm{E}\left[\psi_x(\xi)(\delta\sigma)B_N\right]\\
&\quad= \mathrm{E}\left[\psi_x(x_{N-1})(\delta\sigma)B_N\right] + \mathrm{E}\left[(\psi_x(\xi) - \psi_x(x_{N-1}))(\delta\sigma)B_N\right]\\
&\quad= \mathrm{E}\left[(\psi_x(\xi) - \psi_x(x_{N-1}))(\delta\sigma)B_N\right],
\end{aligned}$$

which for proper choice of ζ on the line from x_{N-1} to ξ

$$= \mathrm{E}\left[\psi_{xx}(\zeta)(\xi - x_{N-1})(\delta\sigma)B_N\right],$$

which by (A2) and (A4)

$$\ge -\overline{C}L_\sigma \mathrm{E}\left\{|\xi - x_{N-1}|\frac{|x_{N-1} - \hat{x}_{N-1}|}{1+|\hat{x}_{N-1}|}|B_N|\right\},$$

which by (64) and (62)

$$\ge -\overline{C}\left[K_3 + M\frac{K_4}{\gamma}\right]|x_{N-1} - \hat{x}_{N-1}|\sqrt{\Delta} \qquad \forall\,\omega\in\Omega, \tag{65}$$

where

$$K_3 \doteq L_\sigma \max_{z\in\Re^n}\left\{\frac{K(3+|z|)+K_1}{1+|z|}\right\} \quad \text{and} \quad K_4 \doteq CL_\sigma \max_{z\in\Re^n}\left\{\frac{C_1 + C_2(|z|+1)}{1+|z|}\right\}.$$

Employing (65) in (59) yields

$$\begin{aligned}\mathrm{E}[\psi(y_N)-\psi(\hat{y}_N)] \geq\ & \mathrm{E}[\psi_x(\xi)]\left[(x_{N-1}-\hat{x}_{N-1})+((\delta f)+(\delta\sigma)v_N^\delta)\Delta\right] \\ & -\overline{C}\sqrt{\frac{\varepsilon}{\gamma^2}}\left[K_3+M\frac{K_4}{\gamma}\right]\Delta|x_{N-1}-\hat{x}_{N-1}|. \end{aligned} \tag{66}$$

We now turn to the first term. Employing (A1), (A2), and (29) in (66) yields

$$\begin{aligned}\mathrm{E}[\psi(y_N)-\psi(\hat{y}_N)] \geq\ & -\ |\mathrm{E}[\psi_x(\xi)]|\left[1+\left(K+L_\sigma M\frac{K_4}{\gamma}\right)\Delta\right]|x_{N-1}-\hat{x}_{N-1}| \\ & -\overline{C}\sqrt{\frac{\varepsilon}{\gamma^2}}\left[K_3+M\frac{K_4}{\gamma}\right]\Delta|x_{N-1}-\hat{x}_{N-1}|. \end{aligned} \tag{67}$$

A rather long argument will now be used to obtain a bound on

$$|\mathrm{E}[\psi_x(\xi)]|\,.$$

This will involve the use of the bound b from (58). Recalling the form of b, we see that this will involve bounds on $\mathrm{E}|y_N|$, $\mathrm{E}|\hat{y}_N|$, $\mathrm{E}|y_N|^2$, and $\mathrm{E}|\hat{y}_N|^2$.

We work first with $\mathrm{E}|y_N|$ (and $\mathrm{E}|\hat{y}_N|$). As a shorthand, let

$$z_{x_{N-1}} \doteq x_{N-1}+(f(x_{N-1})+\sigma(x_{N-1})v_N^\delta)\Delta.$$

Then

$$\begin{aligned}\mathrm{E}|y_N| &= \mathrm{E}\left|z_{x_{N-1}}+\sqrt{\frac{\varepsilon}{\gamma^2}}\sigma(x)\sqrt{\Delta}B_N\right| \\ &= \frac{1}{2^m}\sum_{j_1=1}^{2}\sum_{j_2=1}^{2}\cdots\sum_{j_m=1}^{2}\left|z_{x_{N-1}}+\sqrt{\frac{\varepsilon}{\gamma^2}}\sqrt{\Delta}\sigma(x)\left(-1^{j_1},-1^{j_2},\ldots,-1^{j_m}\right)^T\right|. \end{aligned} \tag{68}$$

Define G, $\overline{G}$ by

$$\begin{aligned} G(z_{x_{N-1}},\Delta) &\doteq \max_{u\in\Re^m,\,|u|=1}\frac{1}{2}\left[\left|z_{x_{N-1}}+\sqrt{\frac{\varepsilon}{\gamma^2}}\sqrt{\Delta}\sigma(x)u\right|+\left|z_{x_{N-1}}-\sqrt{\frac{\varepsilon}{\gamma^2}}\sqrt{\Delta}\sigma(x)u\right|\right] \\ &\leq \max_{|v|\leq M}\frac{1}{2}\left[\left|z_{x_{N-1}}+\sqrt{\frac{\varepsilon}{\gamma^2}}\sqrt{\Delta}v\right|+\left|z_{x_{N-1}}-\sqrt{\frac{\varepsilon}{\gamma^2}}\sqrt{\Delta}v\right|\right] \\ &\doteq \overline{G}(z_{x_{N-1}},\Delta), \end{aligned} \tag{69}$$

and note that $\mathrm{E}|y_N| \leq G(z_{x_{N-1}},\Delta)$. It is an exercise in Lagrange multipliers (which we do not include, since it is quite standard) to show that the maximum occurs when v is perpendicular to $z_{x_{N-1}}$. Consequently (using the Pythagorean theorem),

$$G(z_{x_{N-1}},\Delta) \leq \overline{G}(z_{x_{N-1}},\Delta) = \left[|z_{x_{N-1}}|^2+\frac{\varepsilon}{\gamma^2}M^2\Delta\right]^{\frac{1}{2}}. \tag{70}$$

Note that

$$\overline{G}(z_{x_{N-1}},0) = |z_{x_{N-1}}|,$$

$$\frac{d}{d\Delta}\overline{G}(z_{x_{N-1}},0) = \frac{\varepsilon}{2\gamma^2|z_{x_{N-1}}|}M^2,$$

and

$$\frac{d^2}{d\Delta^2}\overline{G}(z_{x_{N-1}},\Delta)=\left(\frac{-1}{4\left[|z_{x_{N-1}}|^2+\frac{\varepsilon}{\gamma^2}M^2\Delta\right]^{\frac{3}{2}}}\right)\frac{\varepsilon^2}{\gamma^4}M^4<0.$$

Consequently,

$$\overline{G}(z_{x_{N-1}},\Delta)\le|z_{x_{N-1}}|+\frac{\varepsilon}{2\gamma^2|z_{x_{N-1}}|}M^2\Delta. \tag{71}$$

Combining (68), (69), and (71), one finds

$$\mathrm{E}|y_N|\le|z_{x_{N-1}}|+\frac{\varepsilon}{4\gamma^2|z_{x_{N-1}}|}M^2\Delta. \tag{72}$$

Further, from the definition of $z_{x_{N-1}}$, (A1), (A2), and (29), $z_{x_{N-1}}\ge 1/4$ for $x_{N-1}\ge 1/2$ if

$$\Delta\le\frac{5}{4(2K+M(C_1+C_2))}\doteq d_1.$$

Consequently, if $\Delta\le\min\{1,d_1\}$, then

$$\mathrm{E}|y_N|\le|z_{x_{N-1}}|+\frac{\varepsilon}{\gamma^2}M^2\Delta \tag{73}$$

for any $x_{N-1}\ge 1/2$. Again using the definition of $z_{x_{N-1}}$, (A1), (A2), and (29), this implies

$$\mathrm{E}|y_N|\le|x_{N-1}|+\left[K(1+|x_{N-1}|)+MD_v(x_{N-1})+\frac{\varepsilon M^2}{\gamma^2}\right]\Delta\quad\forall|x_{N-1}|\ge\frac{1}{2}, \tag{74}$$

provided $\Delta\le\min\{1,d_1\}$. A similar statement holds for $\hat{y}_N$.

Noting that $\psi_x(x)\le b(x)\le C(\frac{3}{2}+2|x|)$ for all x, one finds using (74) and (A4) that

$$|\mathrm{E}\psi_x(\xi)|\le C\left\{\frac{3}{2}+2|x_{N-1}|+\left[2K_6(1+|x_{N-1}|)+2MD_v(x_{N-1})\right]\Delta\right\}$$
$$\forall\,|x_{N-1}|,|\hat{x}_{N-1}|\ge\frac{1}{2}, \tag{75}$$

where $K_6=\max\{K,\varepsilon M^2/(\gamma^2)\}$, provided $\Delta\le\min\{1,d_1\}$.

We now turn to the quadratic portion of $b(x)$, which occurs for $|x|\le 1$. Using the fact that B_N has zero mean,

$$\begin{aligned}\mathrm{E}|y_N|^2&=\mathrm{E}\left|z_{x_{N-1}}+\sqrt{\frac{\varepsilon\Delta}{\gamma^2}}\sigma(x_{N-1})B_N\right|^2\\&=|z_{x_{N-1}}|^2+\frac{\varepsilon}{\gamma^2}\Delta\mathrm{E}\left[B_N^T\sigma^T\sigma B_N\right]\\&\le|z_{x_{N-1}}|^2+\frac{\varepsilon}{\gamma^2}M^2\Delta,\end{aligned}$$

which by the definition of $z_{x_{N-1}}$, (A1), (A2), and (29) again,

$$\leq |x_{N-1}|^2 + K_7(1+|x_{N-1}|)^2\Delta + 2M^2 D_v^2(x_{N-1})\Delta^2,$$

where $K_7 = 2[K + K^2 + M(K_4/\gamma) + (\varepsilon/(2\gamma^2))M^2]$. In a similar manner to that above, this implies that

$$|\mathrm{E}\psi_x(\xi)| \leq C\left[\frac{3}{2} + 2|x_{N-1}|^2 + 2K_7(1+|x_{N-1}|)^2\Delta + \ 4M^2 D_v^2(x_{N-1})\Delta^2\right] \tag{76}$$

$$\forall\, x_{N-1}, \hat{x}_{N-1} \in \Re^n.$$

Combining (75) and (76), one finds

$$|\mathrm{E}\psi_x(\xi)| \leq b(|x_{N-1}|)\left[1 + K_8\Delta + 2M\frac{K_4}{\gamma}\Delta + 8M^2\frac{K_4^2}{\gamma^2}\Delta^2\right] \qquad \forall\, |x_{N-1} - \hat{x}_{N-1}| \leq \frac{1}{2}, \tag{77}$$

where $K_8 = \max\{2K_6, 4K_7\}$, provided $\Delta \leq \min\{1, d_1\}$, which is the inequality indicated earlier.

Combining (67) and (77), one finds

$$\begin{aligned}\mathrm{E}[\psi(y_N) - \psi(\hat{y}_N)] \geq\ & -b(|\hat{x}_{N-1}|)\left[1 + c_1\Delta + c_2\frac{K_4}{\gamma}\Delta + c_3\frac{K_4^2}{\gamma^2}\Delta^2\right]|x_{N-1} - \hat{x}_{N-1}| \\ & - \overline{C}\sqrt{\frac{\varepsilon}{\gamma^2}}\left[K_3\Delta + M\frac{K_4}{\gamma}\Delta\right]|x_{N-1} - \hat{x}_{N-1}|,\end{aligned} \tag{78}$$

where

$$\begin{aligned}\overline{c}_1 &= K + K_8 + KK_8, \\ c_2 &= 2MK + K_8 M L_\sigma, \\ c_3 &= M^2[2L_\sigma + 8(1+K)],\end{aligned}$$

provided $\Delta \leq \min\{1, d_1\}$ and $|x_{N-1} - \hat{x}_{N-1}| \leq \frac{1}{2}$. By symmetry, and by taking intermediary steps (to remove the $|x_{N-1} - \hat{x}_{N-1}| \leq \frac{1}{2}$ bound), this implies

$$\begin{aligned}\left|\mathrm{E}[\psi(y_N) - \psi(\hat{y}_N)]\right| \leq\ & b(|\hat{x}_{N-1}|)\left[1 + c_1\Delta + c_2\frac{K_4}{\gamma}\Delta + c_3\frac{K_4^2}{\gamma^2}\Delta^2\right]|x_{N-1} - \hat{x}_{N-1}| \\ & + \overline{C}\sqrt{\frac{\varepsilon}{\gamma^2}}\left[K_3\Delta + M\frac{K_4}{\gamma}\Delta\right]|x_{N-1} - \hat{x}_{N-1}|,\end{aligned} \tag{79}$$

provided $\Delta \leq \min\{1, d_1\}$.

Finally, combining (79) with (56) (and letting $\delta \downarrow 0$) yields

$$\begin{aligned}&\left|\overline{V}_{N-1}^N(x_{N-1}) - \overline{V}_{N-1}^N(\hat{x}_{N-1})\right| \\ &\quad \leq b(|\hat{x}_{N-1}|)\left[1 + c_1\Delta + c_2\frac{K_4}{\gamma}\Delta + c_3\frac{K_4^2}{\gamma^2}\Delta^2\right]\cdot|x_{N-1} - \hat{x}_{N-1}| \\ &\quad + \overline{C}\sqrt{\frac{\varepsilon}{\gamma^2}}\left[K_3\Delta + M\frac{K_4}{\gamma}\Delta\right]\cdot|x_{N-1} - \hat{x}_{N-1}|,\end{aligned} \tag{80}$$

provided $\Delta \leq \min\{1, d_1\}$, where $c_1 = \overline{c}_1 + 1$.

LEMMA A.1. *$\overline{V}^N_{N-1}$ is semiconvex with uniform constant $C[2K\Delta + 4L_\sigma \frac{K_4}{\gamma}\Delta] + \overline{C}\{1 + c_4\Delta + c_5\frac{K_4}{\gamma}\Delta + c_6\frac{K_4^2}{\gamma^2}\Delta^2\}$, where c_4, c_5, c_6 are given in the proof.*

Proof. Recall that

$$\overline{V}^N_{N-1}(x_{N-1}) = \sup_{|v_N| \le C_1 + C_2|x_{N-1}|} \overline{J}^N_{N-1}(x_{N-1}, v_N),$$

where

$$\overline{J}^N_{N-1}(x_{N-1}, v_N) = \mathrm{E}\left[\left(\ell(x_{N-1}) - \frac{\gamma^2}{2}|v_N|^2\right)\Delta + \psi(y_N)\right].$$

Fix a v_N satisfying $|v_N| \le C_1 + C_2|x_{N-1}|$. First, a lower bound on

$$\frac{d^2}{dh^2}\overline{J}^N_{N-1}(x_{N-1} + h\eta, v_N)\Big|_{h=0} \tag{81}$$

will be obtained for any $\eta \in \Re^n$ with $|\eta| = 1$.

One has

$$\frac{d^2}{dh^2}\overline{J}^N_{N-1}(x_{N-1}+h\eta, v_N)|_{h=0} = \eta^T l_{xx}(x_{N-1})\eta\Delta + \mathrm{E}\{{\zeta^1}^T\psi_{xx}(y_N)\zeta^1\} + \mathrm{E}\{\psi_x(y_N)\zeta^2\},$$

where

$$\zeta^1 \doteq \frac{d}{dh}y^h_N\big|_{h=0},$$

$$\zeta^2 \doteq \frac{d^2}{dh^2}y^h_N\big|_{h=0},$$

$$y^h_N = (x_{N-1} + h\eta) + [f(x_{N-1} + h\eta) + \sigma(x_{N-1} + h\eta)v_N]\Delta + \sqrt{\frac{\varepsilon\Delta}{\gamma^2}}\sigma(x_{N-1} + h\eta)B_N.$$

Consequently, by Assumption (A4),

$$\frac{d^2}{dh^2}\overline{J}^N_{N-1}(x_{N-1} + h\eta, v_N)|_{h=0} \ge -\overline{C}\Delta + \mathrm{E}\{{\zeta^1}^T\psi_{xx}(y_N)\zeta^1\} + \mathrm{E}\{\psi_x(y_N)\zeta^2\}. \tag{82}$$

Note that

$$\zeta^1 = \eta + [f_x(x_{N-1})\eta + \sigma_x(x_{N-1})\eta v_N]\,\Delta + \sqrt{\frac{\varepsilon\Delta}{\gamma^2}}\sigma_x(x_{N-1})\eta B_N.$$

Using the facts that $\mathrm{E}(B_N) = 0$ and $\mathrm{E}(B_N^2) = 1$, this yields

$$\begin{aligned}\mathrm{E}\left\{{\zeta^1}^T\psi_{xx}(y_N)\zeta^1\right\} \ge& -\overline{C}\mathrm{E}\left|\eta + [f_x(x_{N-1})\eta + \sigma_x(x_{N-1})\eta v_N]\,\Delta + \sqrt{\frac{\varepsilon\Delta}{\gamma^2}}\sigma_x(x_{N-1})\eta B_N\right|^2 \\ \ge& -\overline{C}\left[1 + \left(2|f_x(x_{N-1})| + 2|\sigma_x(x_{N-1})v_N| + \frac{\varepsilon}{\gamma^2}|\sigma_x(x_{N-1})|^2\right)\Delta \right. \\ & \left. + \left(|f_x(x_{N-1})| + |\sigma_x(x_{N-1})v_N|\right)^2\Delta^2\right],\end{aligned}$$

which by Assumptions (A1) and (A2), and by (29),

$$\geq -\overline{C}\left[1 + K_9\Delta + 2\frac{K_4}{\gamma}\Delta + 2\frac{K_4^2}{\gamma^2}\Delta^2\right], \tag{83}$$

where $K_9 = 2K + 2K^2 + \varepsilon L_\sigma^2/\gamma^2$.

Next, one finds

$$\zeta^2 = \left[\eta^T f_{xx}(x_{N-1})\eta + \eta^T \sigma_{xx}(x_{N-1})\eta v_N\right]\Delta + \sqrt{\frac{\varepsilon\Delta}{\gamma^2}}\eta^T\sigma_{xx}(x_{N-1})\eta B_N.$$

Then using (componentwise)

$$(\psi_x)_i(y_N) = (\psi_x)_i(x_{N-1}) + [(\psi_{xx})_i(\xi_i)](y_N - x_{N-1})$$

for the proper choice of ξ_i on the line segment from x_{N-1} to y_N (leaving out the x_{N-1} argument where it is clear), and letting $H(\{\xi_i\})$ be the matrix composed of the rows $(\psi_{xx})_i(\xi_i)$, one finds

$$\begin{aligned}
\mathrm{E}\{\psi_x(y_N)\zeta^2\} &= \psi_x(x_{N-1})\left[\eta^T f_{xx}(x_{N-1})\eta + \eta^T\sigma_{xx}(x_{N-1})\eta v_N\right]\Delta \\
&\quad + \mathrm{E}\Bigg\{H(\{\xi\}_i)\Bigg[\eta^T(f_{xx} + \sigma_{xx}v_N)\eta(f + \sigma v_N)\Delta^2 \\
&\qquad + \left[(f + \sigma v_N)\eta^T\sigma_{xx}\eta\sqrt{\frac{\varepsilon}{\gamma^2}} + \eta^T(f_{xx} + \sigma_{xx}v_N)\eta\sigma\sqrt{\frac{\varepsilon}{\gamma^2}}\right]B_N\Delta^{3/2} \\
&\qquad + \eta^T\sigma_{xx}\eta\sigma\frac{\varepsilon}{\gamma^2}B_N^2\Delta\Bigg]\Bigg\} \\
&\geq -|\psi_x(x_{N-1})|\left[|f_{xx}(x_{N-1})| + |\sigma_{xx}(x_{N-1})v_N|\right]\Delta \\
&\quad - \overline{C}\Bigg[\big(|f_{xx}| + |\sigma_{xx}v_N|\big)\big(|f| + |\sigma v_N|\big)\Delta^2 \\
&\quad + \Big(\big(|f| + |\sigma v_N|\big)|\sigma_{xx}| + \big(|f_{xx}| + |\sigma_{xx}v_N|\big)|\sigma|\Big)\sqrt{\frac{\varepsilon}{\gamma^2}}\Delta^{3/2} + |\sigma_{xx}|\,|\sigma|\frac{\varepsilon}{\gamma^2}\Delta\Bigg],
\end{aligned}$$

from which with a few bounds on rational functions of $|x|$ (such as $(3/2 + 2|x|)/(1 + |x|) \leq 2$) one has

$$\begin{aligned}
&\geq -C\left[2K + 4L_\sigma\frac{K_4}{\gamma}\right]\Delta \\
&\quad - \overline{C}\Bigg\{\left[K^2 + ML_\sigma\frac{K_4^2}{\gamma^2} + KM\frac{K_4}{\gamma} + 2KL_\sigma\frac{K_4}{\gamma}\right]\Delta^2 \\
&\qquad + \left[K(L_\sigma + M) + 2ML_\sigma\frac{K_4}{\gamma}\right]\sqrt{\frac{\varepsilon}{\gamma^2}}\Delta^{3/2} + ML_\sigma\frac{\varepsilon}{\gamma^2}\Delta\Bigg\} \\
&\geq -C\left[2K\Delta + 4L_\sigma\frac{K_4}{\gamma}\Delta\right] - \overline{C}\left\{K_{11}\Delta + K_{12}\frac{K_4}{\gamma}\Delta + K_{13}\frac{K_4^2}{\gamma^2}\Delta^2\right\},
\end{aligned} \tag{84}$$

where

$$K_{11} = K^2\Delta + K(L_\sigma + M)\sqrt{\frac{\varepsilon}{\gamma^2}}\sqrt{\Delta} + ML_\sigma\frac{\varepsilon}{\gamma^2},$$

$$K_{12} = (KM + 2KL_\sigma)\Delta + 2ML_\sigma\sqrt{\frac{\varepsilon}{\gamma^2}}\sqrt{\Delta},$$
$$K_{13} = ML_\sigma.$$

Combining (82), (83), and (84) yields

$$\frac{d^2}{dh^2}\overline{J}^N_{N-1}(x_{N-1}+h\eta, v_N)|_{h=0} \geq -C\left[2K\Delta + 4L_\sigma\frac{K_4}{\gamma}\Delta\right] - \overline{C}\left\{1 + c_4\Delta + c_5\frac{K_4}{\gamma}\Delta + c_6\frac{K_4^2}{\gamma^2}\Delta^2\right\}, \tag{85}$$

where $c_4 = 1 + K_9 + K_{11}$, $c_5 = 2 + K_{12}$, and $c_6 = 2 + K_{13}$.

This implies that $\overline{J}^N_{N-1}(x, v_N)$ is semiconvex, with uniform constant given by the right-hand side of (85) over all of $\Re^n$ if $|v_N| \leq (C/\gamma)[C_1 + C_2|x|]$. By the definition of $\overline{V}^N_{N-1}$ as a supremum of these, $\overline{V}^N_{N-1}$ is semiconvex with this same constant. This completes the proof of the lemma. □

We now proceed to step backwards. Note that we used the derivatives of ψ in the above argument. One can first smooth $\overline{V}^N$ via convolution with approximations to the identity, before proceeding backwards; since this is an obvious, but time-consuming, technicality, we do not include it. Instead, simply assuming differentiability, we now have from (29), (80), and the above lemma,

$$|v_N(x)| \leq \frac{C}{\gamma}\left[C_1 + C_2|x|\right], \tag{86}$$

$$\left|\overline{V}^N_{N-1_x}(x)\right| \leq b(|x|)\left[1 + c_1\Delta + c_2\frac{K_4}{\gamma}\Delta + c_3\frac{K_4^2}{\gamma^2}\Delta^2\right] + \overline{C}\sqrt{\frac{\varepsilon}{\gamma^2}}\left[K_3\Delta + M\frac{K_4}{\gamma}\Delta\right], \tag{87}$$

and that $\overline{V}^N_{N-1}$ is semiconvex with constant

$$\overline{C}_1 = C\left[2K\Delta + 4L_\sigma\frac{K_4}{\gamma}\Delta\right] + \overline{C}_0\left\{1 + c_4\Delta + c_5\frac{K_4}{\gamma}\Delta + c_6\frac{K_4^2}{\gamma^2}\Delta^2\right\}, \tag{88}$$

where $\overline{C}_0 \doteq \overline{C}$.

Define

$$K_4^{(0)} = K_4,$$
$$M_0 = 1,$$
$$M_1 = \left\{\left[1 + c_1\Delta + c_2\frac{K_4^{(0)}}{\gamma}\Delta + c_3\frac{{K_4^{(0)}}^2}{\gamma^2}\Delta^2\right] + \frac{\overline{C}_0}{b(0)}\sqrt{\frac{\varepsilon}{\gamma^2}}\left[K_3\Delta + M\frac{K_4^{(0)}}{\gamma}\Delta\right]\right\}M_0.$$

Note then that the above Lipschitz and semiconvexity bounds become

$$\left|\overline{V}^N_{N-1_x}(x)\right| \leq b(|x|)M_1,$$
$$\overline{C}_1 = \overline{C}_0\left\{1 + c_4\Delta + c_5\frac{K_4^{(0)}}{\gamma}\Delta + c_6\frac{{K_4^{(0)}}^2}{\gamma^2}\Delta^2\right\} + CM_0\left[2K\Delta + 4L_\sigma\frac{K_4^{(0)}}{\gamma}\Delta\right].$$

Stepping backward, one finds

$$
\begin{aligned}
&|v_{N-1}(x)| \le \frac{C}{\gamma}\left[C_1 + C_2|x|\right] M_1,\\
&\left|\overline{V}^N_{N-2_x}(x)\right| \le b(|x|)M_2,\\
&\overline{C}_2 \doteq \overline{C}_1\left\{1 + c_4\Delta + c_5\frac{K_4^{(1)}}{\gamma}\Delta + c_6\frac{K_4^{(1)^2}}{\gamma^2}\Delta^2\right\} + CM_1\left[2K\Delta + 4L_\sigma\frac{K_4^{(1)}}{\gamma}\Delta\right],
\end{aligned}
$$

where

$$
\begin{aligned}
&K_4^1 = M_1K_4^{(0)},\\
&M_2 = \left\{\left[1 + c_1\Delta + c_2\frac{K_4^{(1)}}{\gamma}\Delta + c_3\frac{K_4^{(1)^2}}{\gamma^2}\Delta^2\right] + \frac{\overline{C}_1}{b(0)}\sqrt{\frac{\varepsilon}{\gamma^2}}\left[K_3\Delta + M\frac{K_4^{(1)}}{\gamma}\Delta\right]\right\}M_1.
\end{aligned}
$$

Continuing this process, one has

$$
\begin{aligned}
&|v_{N-n}(x)| \le \frac{C}{\gamma}\left[C_1 + C_2|x|\right] M_n,\\
&\left|\overline{V}^N_{N-(n+1)_x}(x)\right| \le b(|x|)M_{n+1},\\
&\overline{C}_{n+1} \doteq \overline{C}_n\left\{1 + c_4\Delta + c_5\frac{K_4^{(n)}}{\gamma}\Delta + c_6\frac{K_4^{(n)^2}}{\gamma^2}\Delta^2\right\} + CM_n\left[2K\Delta + 4L_\sigma\frac{K_4^{(n)}}{\gamma}\Delta\right],
\end{aligned}
$$

where

$$
\begin{aligned}
&K_4^{(n)} = M_nK_4^{(0)},\\
&M_{n+1} = \left\{\left[1 + c_1\Delta + c_2\frac{K_4^{(n)}}{\gamma}\Delta + c_3\frac{K_4^{(n)^2}}{\gamma^2}\Delta^2\right] + \frac{\overline{C}_n}{b(0)}\sqrt{\frac{\varepsilon}{\gamma^2}}\left[K_3\Delta + M\frac{K_4^{(n)}}{\gamma}\Delta\right]\right\}M_n.
\end{aligned}
$$

Now, we note that one is interested here in the Lipschitz constant for $\overline{V}^N_0$, and in particular, in whether this stays bounded as $N \to \infty$. Noting in the above that $\Delta = T/N$, we see that this question reduces to consideration of the sequence

$$
\begin{aligned}
M_{N,0} &= 1,\\
\overline{C}_{N,0} &= \overline{C},\\
M_{N,n+1} &= \left\{\left[1 + c_1\frac{T}{N} + c_2\frac{K_4^{(N,n)}}{\gamma}\frac{T}{N} + c_3\frac{K_4^{(N,n)^2}}{\gamma^2}\frac{T^2}{N^2}\right]\right.\\
&\qquad \left. + \frac{\overline{C}_{N,n}}{b(0)}\sqrt{\frac{\varepsilon}{\gamma^2}}\left[K_3\frac{T}{N} + M\frac{K_4^{(N,n)}}{\gamma}\frac{T}{N}\right]\right\}M_{N,n},\\
\overline{C}_{N,n+1} &\doteq \overline{C}_{N,n}\left\{1 + c_4\frac{T}{N} + c_5\frac{K_4^{(N,n)}}{\gamma}\frac{T}{N} + c_6\frac{K_4^{(N,n)^2}}{\gamma^2}\frac{T^2}{N^2}\right\}\\
&\qquad + CM_{N,n}\left[2K\frac{T}{N} + 4L_\sigma\frac{K_4^{(N,n)}}{\gamma}\frac{T}{N}\right],
\end{aligned}
$$

where

$$K_4^{(N,n)} = M_{N,n}K_4.$$

Note that $|\overline{V}^N_{0\ x}(x)| \le b(|x|)M_{N,N}$.

Showing that $M_{N,N}$ stays bounded for sufficiently large γ can be done with some rather crude estimates. Again, we are not interested here in the minimal possible γ, but mainly in developing the machinery to handle risk-sensitive control limit problems under quadratic growth assumptions. In that spirit, one may define

$$R_{N,n} \doteq \max\{M_{N,n}, \overline{C}_{N,n}\}.$$

Then, for $N > K_4T$ one has

$$M_{N,n+1} \le R_{N,n}\left\{1 + c_1\frac{T}{N} + \frac{\overline{c}_2}{\gamma}R_{N,n}\frac{T}{N} + \frac{\overline{c}_3}{\gamma^2}R^2_{N,n}\frac{T}{N}\right\},$$

$$\overline{C}_{N,n+1} \le R_{N,n}\left\{1 + c_4\frac{T}{N} + \frac{\overline{c}_5}{\gamma}R_{N,n}\frac{T}{N} + \frac{\overline{c}_6}{\gamma^2}R^2_{N,n}\frac{T}{N}\right\},$$

where $\overline{c}_2 = c_2 + \sqrt{\varepsilon}K_3/b(0)$, $\overline{c}_3 = c_3 + \sqrt{\varepsilon}MK_4/b(0)$, $\overline{c}_4 = c_4 + 2CK$, $\overline{c}_5 = c_5K_4 + 4L_\sigma CK_4$, and $\overline{c}_6 = c_6K_4$. This implies

$$R_{N,n+1} \le R_{N,n}\left\{1 + c_7\frac{T}{N} + \frac{c_8}{\gamma}R_{N,n}\frac{T}{N} + \frac{c_9}{\gamma^2}R^2_{N,n}\frac{T}{N}\right\},$$

where $c_7 = c_1 + \overline{c}_4$, $c_8 = c_2 + \overline{c}_5$, and $c_7 = \overline{c}_3 + \overline{c}_6$. Letting $\overline{\rho}_{N,n} \doteq \ln(R_{N,n})$, one has

$$\overline{\rho}_{N,n+1} \le \overline{\rho}_{N,n} + \left[c_7 + \frac{c_8}{\gamma}e^{\overline{\rho}_{N,n}} + \frac{c_9}{\gamma^2}e^{2\overline{\rho}_{N,n}}\right]\frac{T}{N},$$

and perhaps one should note $\overline{\rho}_{N,0} = \max\{0, \ln(\overline{C})\}$. Then $\overline{\rho}_{N,n} \le \rho_{N,n}$ for all N, n, where $\rho_{N,n}$ satisfies

$$\rho_{N,n+1} = \rho_{N,n} + \left[c_7 + \frac{c_{10}}{\gamma}e^{2\rho_{N,n}}\right]\frac{T}{N}, \tag{89}$$

$$\rho_{N,0} = \max\{0, \ln(\overline{C})\}, \tag{90}$$

and $c_{10} = c_8 + (c_9/\gamma)$. Note that then

$$M_{N,N} \le e^{\rho_{N,N}} \qquad \forall\, N.$$

Also, note that (89), (90) is simply the Euler numerical method (with N time-steps) for the ODE problem over $[0, T]$ given by

$$\dot{\widehat{\rho}} = c_7 + \frac{c_{10}}{\gamma}e^{2\rho},$$

$$\widehat{\rho}(0) = \max\{0, \ln(\overline{C})\}.$$

By elementary calculus, one can show that, given $T < \infty$, there is $\widetilde{\gamma} < \infty$ such that this ODE has a solution over $[0, T]$. Letting the maximum of this solution be ρ_M, one sees that $M_{N,N} \le e^{\rho_M + 1}$ for sufficiently large N. This behavior (increasingly large γ required for increasingly large T) is expected, since the Riccati equation for the linear-quadratic case displays the finite-time blow-up property. (A reader curious about this point might note that letting $\widehat{\mathcal{M}} \doteq \exp(\widehat{\rho})$, one finds that $\widehat{\mathcal{M}}$ satisfies the ODE $\dot{\widehat{\mathcal{M}}} = c_7\widehat{\mathcal{M}} + (c_{10}/\gamma)\widehat{\mathcal{M}}^3$, which is somewhat worse than the Riccati equation which has a squared term only on the right-hand side; thus we have lost a bit in all the bounding estimates.)

Acknowledgments. The authors wish to thank M. Bardi, W. H. Fleming, S.-J. Sheu, the referee, and the associate editor for helpful discussions and/or comments.

PERPETUAL AMERICAN OPTIONS UNDER LÉVY PROCESSES*

S. I. BOYARCHENKO† AND S. Z. LEVENDORSKIĬ‡

Abstract. We consider perpetual American options, assuming that under a chosen equivalent martingale measure the stock returns follow a Lévy process. For put and call options, their analogues for more general payoffs, and a wide class of Lévy processes that contains Brownian motion, normal inverse Gaussian processes, hyperbolic processes, truncated Lévy processes, and their mixtures, we obtain formulas for the optimal exercise price and the fair price of the option in terms of the factors in the Wiener–Hopf factorization formula, i.e., in terms of the resolvents of the supremum and infimum processes, and derive explicit formulas for these factors. For calls, puts, and some other options, the results are valid for any Lévy process.

We use Dynkin's formula and the Wiener–Hopf factorization to find the explicit formula for the price of the option for any candidate for the exercise boundary, and by using this explicit representation, we select the optimal solution.

We show that in some cases the principle of the smooth fit fails and suggest a generalization of this principle.

Key words. Lévy processes, perpetual American options, Wiener–Hopf factorization

1. Introduction.

Consider the market of a riskless bond and a stock whose returns follow a Lévy process. If the Lévy process is neither a Brownian motion nor a Poisson process, then the market is incomplete. According to the modern martingale approach to option pricing [16], arbitrage-free prices can be obtained as expectations under any equivalent martingale measure (EMM), which is absolutely continuous w.r.t. the historic measure.

Let the riskless rate $r > 0$ and the dividend rate $\lambda \geq 0$ be fixed, let $S = \{S_t\}_{t\geq 0}$, $S_t = \exp X_t$, be the price process of the stock, and let $\mathbf{Q}$ be an EMM chosen by the market. Let $\{X_t\}$ be a Lévy process under $\mathbf{Q}$, and $(\Omega, \mathcal{F}, \mathbf{Q})$ the corresponding probability space. (For general definitions of the theory of Lévy processes, see, e.g., [32], [5], and [33].)

Let $g(X_t)$ be the payoff function for a perpetual American option on the stock (e.g., for a put, $g(x) = K - e^x$, and for a call, $g(x) = e^x - K$, where K is the strike price; for the formulation of our results, it is more convenient to use $g(X_t)$ rather than $\max\{g(X_t), 0\}$). Set $q = r + \lambda$, and denote by $V_*(x)$, where $x = \ln S$, the rational price of the perpetual American option. It is given by

$$V_*(x) = \sup E^x[e^{-q\tau} g(X_\tau)], \tag{1.1}$$

where E^x denotes the expectation under $\mathbf{Q}$, and the supremum is taken over a set $\mathcal{M}$ of all stopping times $\tau = \tau(\omega)$ satisfying $0 \leq \tau(\omega) < \infty$, $\omega \in \Omega$ (see, e.g., [34, Chapter XVIII, section 2]).

‡Rostov State University of Economics, 69, B. Sadovaya, Rostov-on-Don, 344007, Russia (leven@ns.rnd.runnet.ru).

Suppose that the optimal stopping time is the hitting time of the exterior of an open set $\mathcal{C} \subset \mathbf{R}$:

$$\tau_* = \inf\{t \geq 0 \mid X_t \notin \mathcal{C}\}. \tag{1.2}$$

In the pure diffusion case, one finds a candidate for the optimal stopping time (1.2) or, equivalently, a boundary of $\mathcal{C}$, by using the smooth fit principle as in [21] and in [27]; see also [34]. When jumps are present, this principle may fail. This effect was demonstrated in [30] for sequential testing problems for the Poisson process, and in [7], [8] and [10], [11], [12] for a discrete-time model of the investment under uncertainty, the perpetual American put in discrete time, and the perpetual American put in continuous time, respectively. (In [7], [8] and [10], [11], [12], only the free boundary value problem was considered.)

We use a direct reduction of the problems for puts and calls to the free boundary problem based on Dynkin's formula, and we solve this problem directly by using the Wiener–Hopf factorization method in the form which is standard in the theory of pseudodifferential operators (PDO) (see, e.g., [20]).[1] A similar but less direct approach was used in [28] for pure jumps and jump-diffusion mixtures of special forms; only puts and calls were considered. In [15], the perpetual call for random walks was considered, and the answer in terms of the supremum process was obtained. In [29], the paper [15] was used to derive results in the same nonexplicit form for calls and puts and any Lévy process.

We do not use the smooth pasting principle but make the direct comparison of expected payoffs for different choices of candidates for the exercise price. We formulate the optimality conditions for a relatively general payoff, and verify them for puts, calls, and other options with payoffs of the form

$$g(x) = \sum_{j=1}^{m} c_j \exp(\gamma_j x); \tag{1.3}$$

the list of examples can be extended. An example of (1.3) is an option which gives its owner the right to sell the stock for $K + a\sqrt{S_t}$.

We obtain the optimal solution in the class $\mathcal{M}_0$ of hitting times of semi-infinite intervals; the verification in the class $\mathcal{M}$ is made for Brownian motions (BM), normal inverse Gaussian processes (NIG) and their generalizations, hyperbolic processes (HP), truncated Lévy processes (TLP), and any finite mixture of independent BM, NIG, HP, and TLP.

The results are formulated in terms of the infinitesimal generator and the factors in the Wiener–Hopf factorization formula (equivalently, in terms of the resolvents of the supremum and infimum processes); in this form, they make sense for any Lévy process. We prove the results by using explicit analytic expressions for the factors, obtained in the paper for a wide class of Lévy processes. This class can be loosely characterized as a class of Lévy processes with the Lévy measures exponentially decaying at infinity and having polynomial singularity at the origin; we call these processes regular Lévy processes of exponential type (RLPE).[2] Notice that BM, NIG, HP, and TLP and any finite mixture of independent BM, NIG, HP, and TLP are RLPE.

[1] Notice that the stochastic version of the Wiener–Hopf method was used to solve boundary value problems for stochastic processes in queuing theory and insurance (see [13] and [31]).

[2] In [9], [10], [11], [12], a misleading name generalized truncated Lévy processes was used. Here we use the name suggested in [4].

We exclude variance gamma processes (VGP), since they need special treatment at many places; in particular, the explicit formulas for the factors in the Wiener–Hopf factorization formula, which we use, need regularization in the case of VGP.

Not only BM, but also the other mentioned processes have been widely used to describe the behavior of stock prices in real financial markets: VGPs have been used by Madan and coauthors in a series of papers during the 90s (see [23] and the bibliography there); HP were constructed and used by Eberlein and coauthors [17], [18], [19]; hyperbolic distributions were constructed in [1]; NIG were constructed in [2] and used to model German stocks in [3]; TLP constructed in [22] were used for modeling in real financial markets in [6], [14], [26]; a generalization of this family was constructed in [9], [11], [12]. As A. N. Shiryaev and O. E. Barndorff-Nielsen remarked, the name TLP was misleading, and thus from now on we will call this family of processes the KoBoL family.

Earlier, noninfinitely divisible truncations of stable Lévy distributions were constructed and used to model the behavior of the Standard & Poor 500 Index by Mantegna and Stanley [24], [25].

Notice that the Lévy measure of any Lévy process can be approximated by a sequence of Lévy measures of RLPE so that the factors in the Wiener–Hopf factorization formula also converge, and in the case of payoffs of the form (1.3), the answers and conditions are formulated in terms of these factors. Hence, for these payoffs, our results are valid for any Lévy process. Whether they are valid for any Lévy process when payoffs are more general than (1.3) remains an open question.

As is well known, simple formulas for the factors in the Wiener–Hopf factorization formula can be obtained in few cases only. Here we obtain them (in two versions) by using only one integration, and for model classes HP, NIG, and the KoBoL family we derive really simple approximate formulas, with small errors if the rate of decay of the tails is large. As empirical studies in [3] and [26] suggest, this is usually the case, and so these approximate formulas may be of some interest.

The plan of the paper is as follows. In section 2, we introduce the class RLPE, give examples, and prove several properties of the characteristic exponents of RLPE. In section 3, we derive two sets of explicit formulas for factors in the Wiener–Hopf factorization formula and necessary bounds for these factors; for model classes of RLPE, we also obtain approximate effective formulas for the factors.

In section 4 (resp., section 5), we solve the problem for the perpetual American put (resp., call) and similar more general payoffs, in the class $\mathcal{M}_0$. In section 6, we formulate the free boundary value problem, prove that its solution solves the optimal stopping problem in the class $\mathcal{M}$, and for model classes of RLPE and mixtures of independent processes of the model classes, verify that the explicit solutions found in sections 4–5 for puts, calls, and some other options with the payoffs of the form (1.3) solve the free boundary value problem and, hence, solve problem (1.1).

In section 7 we show that in some cases the smooth pasting condition fails, and we offer its generalization, which is valid for RLPE; in the appendix, we prove the most technical statements of sections 2–6.

2. RLPEs.

2.1. Some basic facts about Lévy processes (See, e.g., [32, section I.4], [5, pp. 3, 13], and [33, p. 3]). We assume as given a filtered probability space $(\Omega, \mathcal{F}, (\mathcal{F}_t)_{0\le t<+\infty}, \mathbf{P})$ satisfying the usual hypotheses.

DEFINITION 2.1. *An adapted process $X = (X_t)_{0\le t<+\infty}$ with $X_0 = 0$ a.s. is a Lévy process if and only if*

(i) *X has increments independent of the past, i.e., $X_t - X_s$ is independent of $\mathcal{F}_s, 0 \le s < t < +\infty$;*

(ii) *X has stationary increments, i.e., $X_t - X_s$ has the same distribution as $X_{t-s}, 0 \le s < t < +\infty$;*

(iii) *X is continuous in probability.*

There exists a nice formula (the Lévy–Khintchine formula) which explicitly describes a Lévy process in terms of its characteristic exponent, ψ, defined by $E[e^{i\xi X_t}] = e^{-t\psi(\xi)}$. Since we consider only one-dimensional Lévy processes here, we formulate the corresponding theorem in the one-dimensional case only.

THEOREM 2.2. (a) *Let X be a Lévy process on $\mathbf{R}$. Then its characteristic exponent admits the representation*

$$\psi(\xi) = \frac{\sigma^2}{2}\xi^2 - i\gamma\xi - \int_{\mathbf{R}^n} \Big(e^{ix\xi} - 1 - ix\xi\mathbf{1}_{[-1,1]}(x)\Big)\Pi(dx), \tag{2.1}$$

where $\sigma \ge 0$, $\gamma \in \mathbf{R}$, and Π is a measure supported on $\mathbf{R}\setminus\{0\}$ that satisfies

$$\Pi(\{0\}) = 0, \qquad \int_{-\infty}^{+\infty} (|x|^2 \wedge 1)\Pi(dx) < \infty. \tag{2.2}$$

(b) *The representation* (2.1) *is unique.*

(c) *Conversely, if $\sigma \ge 0$, $\gamma \in \mathbf{R}$, and Π is a measure supported on $\mathbf{R}\setminus\{0\}$ that satisfies* (2.2)*, then there exists a Lévy process X with the characteristic exponent defined by* (2.1)*; X is uniquely defined in law.*

The triple (σ^2, Π, γ) is called the *generating triplet* of X. The σ^2 and Π are called the *Gaussian coefficient* and *Lévy measure* of X. When $\Pi = 0$, X is Gaussian, and if $\sigma = 0$, then X is called purely non-Gaussian.

The infinitesimal generator, L, of a Lévy process X acts as follows:

$$Lf(x) = \frac{\sigma^2}{2}f''(x) + \gamma f'(x) + \int_{-\infty}^{+\infty} (f(x+y) - f(x) - yf'(x)\mathbf{1}_{[-1,1]}(y))\Pi(dy). \tag{2.3}$$

Apply $-L$ to an oscillating exponent $f(x) = e^{ix\xi}$ and use (2.3):

$$(-L)e^{ix\xi} = \left[\frac{\sigma^2}{2}\xi^2 - i\gamma\xi - \int_{-\infty}^{+\infty} \Big(e^{iy\xi} - 1 - iy\xi\mathbf{1}_{(-1,1)}(y)\Big)\Pi(dy)\right] e^{ix\xi} = \psi(\xi)e^{ix\xi}. \tag{2.4}$$

By decomposing a sufficiently regular function u into the Fourier integral

$$u(x) = (2\pi)^{-1}\int_{-\infty}^{+\infty} e^{ix\xi}\hat{u}(\xi)d\xi,$$

where

$$\hat{u}(\xi) = \int_{-\infty}^{+\infty} e^{-ix\xi}u(x)dx \tag{2.5}$$

is the Fourier transform of a function u (this is the standard definition in the literature on PDOs), and using (2.4), we conclude that $-L$ is a pseudodifferential operator with the symbol $\psi(\xi)$:

$$-L = \psi(D).$$

Recall that a pseudodifferential operator with the (constant) symbol a is defined by

$$a(D)u(x) = (2\pi)^{-1} \int_{-\infty}^{+\infty} e^{ix\xi} a(\xi)\hat{u}(\xi)d\xi.$$

For an introduction to the general theory of PDOs, see [20].

2.2. Lévy processes of exponential type.

DEFINITION 2.3. *Let $\lambda_- < 0 < \lambda_+$. We call X a Lévy process of exponential type $[\lambda_-, \lambda_+]$ if its Lévy measure satisfies*

$$\int_{-\infty}^{-1} e^{-\lambda_+ x}\Pi(dx) + \int_{1}^{+\infty} e^{-\lambda_- x}\Pi(dx) < \infty. \tag{2.6}$$

LEMMA 2.4. *Let X be a Lévy process of exponential type $[\lambda_-, \lambda_+]$. Then*

(a) *the characteristic exponent ψ is holomorphic in the strip $\Im\xi \in (\lambda_-, \lambda_+)$ and continuous up to the boundary of the strip;*

(b) *there exist C and $\nu > 0$ such that for all ξ in the strip $\Im\xi \in [\lambda_-, \lambda_+]$*

$$|\psi(\xi)| \le C(1 + |\xi|)^\nu; \tag{2.7}$$

(c) *for any $q > 0$ there exist $\delta > 0$ and $\sigma_- < 0 < \sigma_+$ such that for any $[\omega_-, \omega_+] \subset (\sigma_-, \sigma_+)$ and all ξ in the strip $\Im\xi \in [\omega_-, \omega_+]$*

$$q + \Re\psi(\xi) \ge \delta, \tag{2.8}$$

where $\delta = \delta(\omega_-, \omega_+) > 0$;

(d) *if*

$$q + \psi(i(\sigma_- + 0)) \ge 0, \quad \text{and} \quad q + \psi(i(\sigma_+ - 0)) \ge 0, \tag{2.9}$$

then (2.8) holds;

(e) *for any $q > 0$, the equation*

$$q + \psi(\xi) = 0 \tag{2.10}$$

has at most one purely imaginary root in the lower half-plane (call it $-i\beta_+$) and at most one, $-i\beta_-$, in the upper half-plane;

(f) *the root $-i\beta_\mp$ exists if and only if*

$$q + \psi(i\lambda_\pm \mp 0) < 0, \tag{2.11}$$

and if it exists, it is a simple root.

Proof. (a) is immediate from (2.6), and (b) can be easily deduced from the Lévy–Khintchine formula, by considering separately the integral over $|x| \le |\xi|^{-1}$ and $|x| \ge |\xi|^{-1}$.

(c)–(d) Set $M_1(\sigma) = \int_{-\infty}^{+\infty} e^{-\sigma x}\mu^1(dx)$, where $\mu^1(dx)$ is the probability distribution of X_1. By differentiating twice, we conclude that M_1 is convex and, clearly,

$M_1(0) = 1 < e^q$. Hence, there exist $\omega_- < 0 < \omega_+$ and $\delta > 0$ such that for all $\sigma \in [\omega_-, \omega_+]$, $M_1(\sigma) \le e^{q-\delta}$.

Now, for any $\xi \in \mathbf{R}$ and these σ,

$$\begin{aligned}\exp(-\Re\psi(\xi + i\sigma)) &= |\exp(-\psi(\xi + i\sigma))| \\ &= \left|\int_{-\infty}^{+\infty} e^{i\xi x - \sigma x}\mu^1(dx)\right| \le \int_{-\infty}^{+\infty} e^{-\sigma x}\mu^1(dx);\end{aligned}$$

therefore (2.8) holds with $\sigma_- = \inf\omega_-, \sigma_+ = \sup\omega_+$, and (2.9) implies (2.8).

(e)–(f) Notice that by the proof of (c), $\sigma \mapsto q + \psi(i\sigma)$ is concave and equal to $q > 0$ at 0. □

2.3. Two definitions of RLPEs. For the sake of brevity, we consider processes with Lévy measures (almost) symmetric in a neighborhood of the origin.

DEFINITION 2.5. *Let $\lambda_- < 0 < \lambda_+$ and $\nu \in [0, 2)$. A purely non-Gaussian Lévy process is called an RLPE of type $[\lambda_-, \lambda_+]$ and order ν if its Lévy measure satisfies* (2.6) *and, in a neighborhood of zero, admits a representation $\Pi(dx) = f(x)dx$, where f satisfies the following condition: There exist $\nu' < \nu$, $c > 0$, and $C > 0$ such that*

$$\left|f(x) - c|x|^{-\nu-1}\right| \le C|x|^{-\nu'-1} \qquad \forall\ |x| \le 1. \tag{2.12}$$

If the sample paths of a Lévy process have bounded variation on every compact time interval a.s., one says that the Lévy process has bounded variation. A regular Lévy process of exponential type has bounded variation if and only if $\nu < 1$, since this is equivalent to $\int_{-\infty}^{+\infty}(|x| \wedge 1)\Pi(dx) < +\infty$ (see, e.g., [5], p. 15).

Straightforward calculation (see [9]) shows that an RLPE of order $\nu > 0$ in the sense of Definition 2.5 is an RLPE in the sense of the following definition.

DEFINITION 2.6. *Let $\lambda_- < 0 < \lambda_+$ and $\nu \in (0, 2]$. A Lévy process is called an RLPE of type $[\lambda_-, \lambda_+]$ and order $\nu > 0$ if the following two conditions are satisfied:*

(i) *the characteristic exponent admits a representation*

$$\psi(\xi) = -i\mu\xi + \phi(\xi), \tag{2.13}$$

where ϕ is holomorphic in the strip $\Im\xi \in (\lambda_-, \lambda_+)$, is continuous up to the boundary of the strip, and admits a representation

$$\phi(\xi) = c|\xi|^\nu + O(|\xi|^{\nu_1}) \tag{2.14}$$

as $\xi \to \infty$ in the strip $\Im\xi \in [\lambda_-, \lambda_+]$, where $\nu_1 < \nu$;

(ii) *there exist $\nu_2 < \nu$ and C such that the derivative of ϕ in* (2.13) *admits a bound*

$$|\phi'(\xi)| \le C(1 + |\xi|)^{\nu_2}, \qquad \Im\xi \in [\lambda_-, \lambda_+]. \tag{2.15}$$

One can easily generalize both definitions by using $c_\pm \ge 0$ in (2.12) on the half-axis $\pm x > 0$, and in (2.14) as $\Re\xi \to \pm\infty$.

2.4. Model classes of RLPEs. All model classes listed in the introduction except for VGP are RLPE:

- BM are RLPE of order 2 and any exponential type;

- a KoBoL process of order $\nu \in (0,2)$, with steepness parameters $\lambda_- < 0$ and $\lambda_+ > 0$, is an RLPE of order ν and exponential type $[\lambda_-, \lambda_+]$. An (asymmetric) version can be defined as a purely non-Gaussian Lévy process with the Lévy measure

$$\Pi(dx) = c_+ x_+^{-\nu-1} e^{\lambda_- x} dx + c_- x_-^{-\nu-1} e^{\lambda_+ x} dx, \tag{2.16}$$

where $x_+ = \max\{x, 0\}$ and $c_\pm > 0$. An RLPE in the sense of Definitions 2.5–2.6 holds with $c_+ = c_-$. Direct calculation shows that if $\nu \in (0,2)$, $\nu \neq 1$, and $c_+ = c_- = c$, then the characteristic exponent of a KoBoL process is of the form

$$\psi(\xi) = -i\mu\xi + c\Gamma(-\nu)[\lambda_+^\nu - (\lambda_+ + i\xi)^\nu + (-\lambda_-)^\nu - (-\lambda_- - i\xi)^\nu]. \tag{2.17}$$

In the case $\nu = 1$, the formula differs from (2.17) (see [9], [12]).

- a normal tempered stable Lévy process of order $\nu \in (0,2)$, with parameters $\delta > 0$, $\alpha > \beta > -\alpha$, is an RLPE of order ν and exponential type $[-\alpha+\beta, \alpha+\beta]$; in particular, NIG processes are RLPE of order 1. The characteristic exponent is of the form

$$\psi(\xi) = -i\mu\xi + \delta[(\alpha^2 - (\beta + i\xi)^2)^{\nu/2} - (\alpha^2 - \beta^2)^{\nu/2}]; \tag{2.18}$$

- an HP with parameters $\delta > 0$, $\alpha > \beta > -\alpha$, is an RLPE of order 1 and exponential type $[\lambda_-, \lambda_+]$ for any $[\lambda_-, \lambda_+] \subset (-\alpha+\beta, \alpha+\beta)$. Its characteristic exponent is equal to

$$\psi(\xi) = -i\mu\xi - \ln\left[\left(\frac{\alpha\delta}{K_1(\alpha\delta)}\right)\frac{K_1(\delta\sqrt{\alpha^2 - (\beta+i\xi)^2})}{\delta\sqrt{\alpha^2-\beta^2}}\right]. \tag{2.19}$$

2.5. Properties of the characteristic exponent of an RLPE.

2.5.1. General properties. Clearly, an RLPE is a Lévy process of exponential type; therefore the properties listed in Lemma 2.4 hold for any RLPE.

2.5.2. Additional properties of the characteristic exponents from model classes. In order to derive simple approximate formulas for the factors in the Wiener–Hopf factorization formula, we need the following lemma, which we managed to prove only for model classes on a case-by-case basis. We conjecture that this lemma holds for a much wider variety of RLPE, if not for all RLPE.

LEMMA 2.7. *Let X be one of the model processes, of order $\nu > 0$ and exponential type $[\lambda_-, \lambda_+]$. Then*

(a) *the ϕ in* (2.13) *admits the analytic continuation into the complex plane with two cuts, $(-i\infty, i\lambda_-]$ and $[i\lambda_+, +i\infty)$, and outside any neighborhood of $i\lambda_-$ and $i\lambda_+$ it satisfies the following estimate:*

$$|\phi(\xi)| \le C(1 + |\xi|)^\nu; \tag{2.20}$$

(b) *all the roots in the plane with the cuts are purely imaginary.*

For the proof, see the appendix. □

3. The Wiener–Hopf factorization.

3.1. General Lévy processes. Let $(\Omega, \mathcal{F}, \mathbf{P})$ be a probability space on which a one-dimensional Lévy process X is defined, and let Ω_0 be a subset of Ω such that for each $\omega \in \Omega_0$ the trajectory $X_\cdot(\omega)$ is right-continuous with left limits. Define, on Ω_0, $M_t = \sup_{0\le s\le t} X_s$ and $N_t = \inf_{0\le s\le t} X_s$. On $\Omega \setminus \Omega_0$, both M_t and N_t are set to be 0. $M = \{M_t\}$ and $N = \{N_t\}$ are called the supremum process and the infimum process, respectively. The Laplace transform (in t) of the distribution of X_t, or more precisely,

$$qE^x\left[\int_0^\infty e^{-qt}e^{i\xi X_t}dt\right] = q(q+\psi(\xi))^{-1},$$

can be factorized by using the Laplace transforms (in t) of the distributions of the supremum and infimum processes. Among many factorization identities, we will use only the simplest one ([33, Theorems 45.2 and 45.5]; for more detailed exposition, see [33, section 45]).

Let μ^t be the law of X.

THEOREM 3.1. (a) *Let $q > 0$. There exists a unique pair of infinitely divisible distributions μ_q^+ and μ_q^- supported on $(-\infty, 0]$ and $[0, +\infty)$, respectively, such that their Fourier transforms ϕ_q^+ and ϕ_q^- satisfy*

$$q(q+\psi(\xi))^{-1} = \phi_q^+(\xi)\phi_q^-(\xi), \quad \xi \in \mathbf{R}. \tag{3.1}$$

(b) *The functions ϕ_q^+ and ϕ_q^- admit the following representations:*

$$\phi_q^+(\xi) = q\int_0^{+\infty} e^{-qt}E[e^{i\xi M_t}]dt = q\int_0^{+\infty} e^{-qt}E[e^{i\xi(X_t-N_t)}]dt, \tag{3.2}$$

$$\phi_q^-(\xi) = q\int_0^{+\infty} e^{-qt}E[e^{i\xi N_t}]dt = q\int_0^{+\infty} e^{-qt}E[e^{i\xi(X_t-M_t)}]dt \tag{3.3}$$

and

$$\phi_q^+(\xi) = \exp\left[\int_0^{+\infty} t^{-1}e^{-qt}dt\int_0^{+\infty}(e^{ix\xi}-1)\mu^t(dx)\right], \tag{3.4}$$

$$\phi_q^-(\xi) = \exp\left[\int_0^{+\infty} t^{-1}e^{-qt}dt\int_{-\infty}^{0}(e^{ix\xi}-1)\mu^t(dx)\right]. \tag{3.5}$$

Notice that $\phi_q^+(\xi)$ (resp., $\phi_q^-(\xi)$) admits the analytic continuation into the upper half-plane $\Im\xi > 0$ (resp., lower half-plane $\Im\xi < 0$) and does not vanish there. Thus, (3.1) is a special case of the *Wiener–Hopf factorization* introduced in solving integral equations by Wiener and Hopf in 1931 [35], and widely used in the theory of boundary value problems for PDE and PDO.

The formulas (3.2)–(3.3) are by no means explicit, though very convenient for theoretical considerations, and (3.4)–(3.5) are rather involved. Simple explicit analytical formulas can be obtained for special cases only.

Example 3.1. Let X be a BM with the drift γ and variance σ^2. Then the characteristic exponent is $\psi(\xi) = \frac{\sigma^2}{2}\xi^2 - i\gamma\xi$. It is clear that for $q > 0$ the equation $q+\psi(\xi) = 0$ has two roots $-i\beta_-$ and $-i\beta_+$ in the upper and lower half-planes, respectively, and therefore, $q(q+\psi(\xi))^{-1}$ admits the factorization (3.1) with

$$\phi_q^+(\xi) = \frac{\beta_+}{\beta_+ - i\xi}, \qquad \phi_q^-(\xi) = \frac{-\beta_-}{-\beta_- + i\xi}. \tag{3.6}$$

Clearly, ϕ_q^- is the Fourier transform of the exponential distribution with parameter $-\beta_-$, and ϕ_q^+ is the Fourier transform of the dual to the exponential distribution with parameter β_+.

3.2. Lévy processes of exponential type. We fix a branch of ln by the requirement $\ln a \in \mathbf{R}$ for $a > 0$. We also fix $\omega_- < 0 < \omega_+$, for which (2.8) holds.

THEOREM 3.2. *Let X be a Lévy process of exponential type, let there exist $C, c, \nu > 0$ such that*

$$\Re\psi(\xi) \geq c(1+|\xi|)^\nu, \qquad \Im\xi \in [\omega_-, \omega_+], \tag{3.7}$$

and let there exist $q > 0$ such that for $\omega = \omega_\pm$

$$\int_{-\infty+i\omega}^{+\infty+i\omega} \frac{|\psi'(\eta)|}{(1+|\eta|)(q+\Re\psi(\eta))} d\eta < +\infty. \tag{3.8}$$

Then (a) *$\phi_q^+(\xi)$ admits the analytic continuation into a half-plane $\Im\xi > \omega_-$ and can be calculated as follows:*

$$\phi_q^+(\xi) = \exp\left[(2\pi i)^{-1} \int_{-\infty+i\omega_-}^{+\infty+i\omega_-} \frac{\psi'(\eta)}{q+\psi(\eta)} \ln\frac{\eta-\xi}{\eta} d\eta\right] \tag{3.9}$$

$$= \exp\left[(2\pi i)^{-1} \int_{-\infty+i\omega_-}^{+\infty+i\omega_-} \frac{\xi \ln(q+\psi(\eta))}{\eta(\xi-\eta)} d\eta\right]; \tag{3.10}$$

(b) *$\phi_q^-(\xi)$ admits the analytic continuation into a half-plane $\Im\xi < \omega_+$ and can be calculated as follows:*

$$\phi_q^-(\xi) = \exp\left[-(2\pi i)^{-1} \int_{-\infty+i\omega_+}^{+\infty+i\omega_+} \frac{\psi'(\eta)}{q+\psi(\eta)} \ln\frac{\eta-\xi}{\eta} d\eta\right] \tag{3.11}$$

$$= \exp\left[-(2\pi i)^{-1} \int_{-\infty+i\omega_+}^{+\infty+i\omega_+} \frac{\xi \ln(q+\psi(\eta))}{\eta(\xi-\eta)} d\eta\right]; \tag{3.12}$$

(c) *$\phi_q^+(\xi)^{-1}$ (resp., $\phi_q^-(\xi)^{-1}$) admits the analytic continuation into a wider half-plane $\Im\xi > \lambda_-$ (resp., $\Im\xi < \lambda_+$) by*

$$\phi_q^+(\xi)^{-1} = q^{-1}(q+\psi(\xi))\phi_q^-(\xi), \quad \Im\xi \in (\lambda_-, \omega_-] \tag{3.13}$$

$$\phi_q^-(\xi)^{-1} = q^{-1}(q+\psi(\xi))\phi_q^+(\xi), \quad \Im\xi \in [\omega_+, \lambda_+). \tag{3.14}$$

Proof. (a) Consider the expression under the exponent sign in (3.4):

$$\begin{aligned} f(\xi) :&= \int_0^{+\infty} \frac{e^{-qt}}{t} \int_0^{+\infty} (e^{ix\xi} - 1)\mu^t(dx)dt \\ &= \int_0^{+\infty} \frac{e^{-qt}}{t} \int_0^{+\infty} (e^{ix\xi} - 1)(2\pi)^{-1} \int_{-\infty}^{+\infty} e^{-ix\eta - t\psi(\eta)} d\eta dx dt. \end{aligned}$$

On the strength of (3.7), we may apply the Cauchy theorem and shift the line of integration:

$$f(\xi) = \int_0^{+\infty} \frac{e^{-qt}}{t} \int_0^{+\infty} (e^{ix\xi} - 1)(2\pi)^{-1} \int_{-\infty+i\omega_-}^{+\infty+i\omega_-} e^{-ix\eta - t\psi(\eta)} d\eta dx dt.$$

Now the inner double integral converges absolutely; hence we can apply the Fubini theorem and integrate w.r.t. x first:

$$f(\xi)=\int_0^{+\infty}\frac{e^{-qt}}{t}(2\pi i)^{-1}\int_{-\infty+i\omega_-}^{+\infty+i\omega_-}e^{-t\psi(\eta)}((\eta-\xi)^{-1}-\eta^{-1})d\eta dt.$$

Integrate by parts:

$$\begin{aligned}f(\xi)&=\int_0^{+\infty}\frac{e^{-qt}}{t}(2\pi i)^{-1}\int_{-\infty+i\omega_-}^{+\infty+i\omega_-}\ln\frac{\eta-\xi}{\eta}t\psi'(\eta)e^{-t\psi(\eta)}d\eta dt\\&=(2\pi i)^{-1}\int_0^{+\infty}\int_{-\infty+i\omega_-}^{+\infty+i\omega_-}\ln\frac{\eta-\xi}{\eta}\psi'(\eta)e^{-t(q+\psi(\eta))}d\eta dt.\end{aligned}$$

From (3.8), the integral above, calculated in the reverse order $dtd\eta$, converges absolutely. Hence we can apply the Fubini theorem once again and obtain (3.9); integrating in (3.9) by parts, we arrive at (3.10).

(b) The dual process $\tilde X$ is of exponential type $[-\lambda_+,-\lambda_-]$, its characteristic exponent is $\bar\psi$, and $[-\omega_+,-\omega_-]$ plays the part of $[\omega_-,\omega_+]$ in Lemma 2.4. Write down the Wiener–Hopf factorization for $\tilde X$ and apply the complex conjugation; then the "+"-factor for $\tilde X$ becomes the "−"-factor for X, and (3.9) for $\tilde X$ becomes (3.11) for X.

(c) This part follows from (3.1) and Lemma 2.4(a). □

Remark 3.1. If X is an RLPE in the sense of Definition 2.6, then (3.8) and (3.7) hold; hence, Theorem 3.2 holds as well.

LEMMA 3.3. *Let ω_- and ω_+ be as in Theorem* 3.2. *Then there exists $C>0$ such that in the half-plane $\pm\Im\xi\ge\pm\omega_\mp$, $\phi_q^\pm$ admits estimates*

$$(1+|\xi|)^{-C}\le|\phi_q^\pm(\xi)|\le(1+|\xi|)^C. \tag{3.15}$$

Proof. In (3.9) and (3.11), make the change of variables $\eta\mapsto|\xi|\eta$ and use (2.7) to notice that the expressions under the exponential sign admit an estimate via $C\ln(2+|\xi|)$. □

Equation (3.15) is insufficient for the proofs in sections 4–6. More information about properties of the factors is obtained below.

3.3. RLPE. Let $\sigma_-<0<\sigma_+$ be from (2.8). Fix $\lambda>\max\{-\sigma_-,\sigma_+\}$, and set $\Lambda_\pm(\xi)^s=(\lambda\mp i\xi)^s=\exp[s\ln(\lambda\mp i\xi)]$. Next, choose $d>0$ and $\kappa_-,\kappa_+\in\mathbf{R}$ so that

$$B(\xi):=d^{-1}\Lambda_+(\xi)^{-\kappa_+}\Lambda_-(\xi)^{-\kappa_-}(q+\psi(\xi)) \tag{3.16}$$

satisfies

$$\lim_{\xi\to\pm\infty}B(\xi)=1. \tag{3.17}$$

Choices of d, κ_+, and κ_- depend on the properties of ψ, and hence on ν,μ, and c in (2.13)–(2.14). We have to consider four cases.

1. If $\nu\in(1,2)$ or $\nu\in(0,1]$ and $\mu=0$, we set $d=c$, $\kappa_+=\kappa_-=\nu/2$.
2. If $\nu\in(0,1)$ and $\mu>0$, we set $d=\mu$, $\kappa_+=1$, $\kappa_-=0$.
3. If $\nu\in(0,1)$ and $\mu<0$, we set $d=|\mu|$, $\kappa_+=0$, $\kappa_-=1$.
4. If $\nu=1$, we set $d=(c^2+\mu^2)^{1/2}$, $\kappa_\pm=1/2\pm\pi^{-1}\arctan(\mu/c)$.

In all cases, (3.17) follows from (2.13)–(2.14). In the first three cases, (3.17) is immediate, and in the last case, the simplest way is to check that $\ln B(\xi) \to 0$ as $\xi \to \pm\infty$:

$$\lim_{\xi\to\pm\infty} \ln B(\xi) = \pm\frac{\pi i}{2}\kappa_+ \mp \frac{\pi i}{2}\kappa_- + \ln\frac{c \mp i\mu}{(c^2+\mu^2)^{1/2}} + (-\kappa_+ - \kappa_- + 1)\ln|k|$$
$$= \pm(\kappa_+ - \kappa_-)\frac{\pi i}{2} \mp i \arctan\frac{\mu}{c} = 0$$

by our choice of κ_+ and κ_-.

The last factor in (3.16) assumes values in a half-plane $\Re z > 0$ by (2.8), and the same is true of the product of the first three factors, since the first one is positive, $\Lambda_-(\xi)$ and $\Lambda_+(\xi)$ assume values in the half-plane but in different quadrants, and $0 \le \kappa_\pm \le 1$. Hence, for all $\xi \in \mathbf{R}$, $-\pi < \arg B(\xi) < \pi$, and therefore $b = \ln B$ is well-defined on $\mathbf{R}$. Fix $\omega_- < 0 < \omega_+$ such that $\sigma_- < \omega_-, \omega_+ < \sigma_+$, where $\sigma_\pm$ are from (2.8), and notice that all the arguments above are valid on any line $\Im\xi = \sigma \in [\omega_-, \omega_+]$.

Next, for $\tau > \omega_-$, $\tau_1 \in [\omega_-, \tau)$ and real ξ, set

$$b_+(\xi + i\tau) = \frac{i}{2\pi}\int_{-\infty+i\tau_1}^{+\infty+i\tau_1} \frac{b(\eta)}{\xi + i\tau - \eta}d\eta \tag{3.18}$$

(by the Cauchy theorem, $b_+(\eta + i\tau)$ is independent of a choice of τ_1), and for $\tau < \omega_+$, $\tau_2 \in (\tau, \omega_+]$, and real ξ, set

$$b_-(\xi + i\tau) = -\frac{i}{2\pi}\int_{-\infty+i\tau_2}^{+\infty+i\tau_2} \frac{b(\eta)}{\xi + i\tau - \eta}d\eta. \tag{3.19}$$

It follows from (2.13), (2.14), (3.16), and (3.17) that there exist $C_1, \rho > 0$ such that for any η in a strip $\Im\eta \in [\omega_-, \omega_+]$

$$|b(\eta)| \le C_1(1 + |\eta|)^{-\rho}. \tag{3.20}$$

Hence, the integrals in (3.18)–(3.19) converge, and $b_+(\xi)$ (resp., $b_-(\xi)$) is well-defined in a half-plane $\Im\xi\ \omega_-$ (resp., $\Im\xi < \omega_+$). We set $a_\pm(\xi) = \Lambda_\pm(\xi)^{\kappa_\pm}\exp b_\pm(\xi)$.

THEOREM 3.4. (a) *a_+ (resp., a_-) is holomorphic in a half-plane $\Im\xi > \omega_-$ (resp., $\Im\xi < \omega_+$). It admits the analytic continuation into a wider half-plane $\Im\xi > \lambda_-$ (resp., $\Im\xi < \lambda_+$) and the continuous extension up to the boundary, by*

$$a_+(\xi) = a(\xi)/a_-(\xi), \quad \Im\xi \in [\lambda_-, \omega_-],$$

$$a_-(\xi) = a(\xi)/a_+(\xi), \quad \Im\xi \in [\omega_+, \lambda_+],$$

where $a(\xi) = d^{-1}(q + \psi(\xi))$;

(b) *on a strip $\Im\xi \in [\lambda_-, \lambda_+]$,*

$$q + \psi(\xi) = da_+(\xi)a_-(\xi); \tag{3.21}$$

(c) *there exist C, $c > 0$, and $\rho_1 > 0$ such that in a half-plane $\Im\xi \ge \omega_-$,*

$$c(1 + |\xi|)^{\kappa_+} \le |a_+(\xi)| \le C(1 + |\xi|)^{\kappa_+}, \tag{3.22}$$

$$|a_+(\xi)^{\pm 1} - \Lambda_+(\xi)^{\pm\kappa_+}| \le C(1 + |\xi|)^{\pm\kappa_+ - \rho_1}, \tag{3.23}$$

and in a half-plane $\Im\xi \le \omega_+$,

$$c(1+|\xi|)^{\kappa_-} \le |a_-(\xi)| \le C(1+|\xi|)^{\kappa_-}, \tag{3.24}$$

$$|a_-(\xi)^{\pm 1} - \Lambda_-(\xi)^{\pm\kappa_-}| \le C(1+|\xi|)^{\pm\kappa_- - \rho_1}; \tag{3.25}$$

(d) *factors in* (3.1) *and* (3.21) *are related by*

$$\phi_q^{\pm}(\xi)^{-1} = a_\pm(\xi)/a_\pm(0). \tag{3.26}$$

Proof. (a) The first statement is straightforward from (3.20), and once (c) is proven, the second one follows, since $a(\xi)$ is holomorphic on a strip $\Im\xi \in (\lambda_-, \lambda_+)$ and admits the continuous extension up to the boundary of the strip.

(b) By the residue theorem, we have for $\tau_1 \in (\omega_-, \Im\xi)$ and $\tau_2 \in (\Im\xi, \omega_+)$

$$b_+(\xi) = \frac{i}{2\pi}\left(\int_{-\infty+i\tau_1}^{+\infty+i\tau_1} - \int_{-\infty+i\tau_2}^{+\infty+i\tau_2}\right)\frac{b(\eta)}{\xi-\eta}d\eta + \frac{i}{2\pi}\int_{-\infty+i\tau_2}^{+\infty+i\tau_2}\frac{b(\eta)}{\xi-\eta}d\eta = b(\xi) - b_-(\xi).$$

Hence, $\exp b_+(\xi)\exp b_-(\xi) = B(\xi)$, and (3.21) is immediate on a narrow strip $\omega_- < \Im\xi < \omega_+$; on a wider strip $\Im\xi \in [\lambda_-, \lambda_+]$, it holds by construction.

(c) By using (3.20), we obtain

$$|(\xi + i\tau - \eta)^{-1} b(\eta)| \le C(1+|\xi-\eta|)^{-1}(1+|\eta|)^{-\rho}.$$

By separately considering a region, where $|\xi-\eta| \ge |\xi|/2$, and its complement, it is easy to show that the right-hand side (RHS) admits an upper bound via

$$C_1(1+|\xi|)^{-\rho_1}(1+|\eta|)^{-1-\rho_1} + C_1(1+|\xi|)^{-\rho_1}(1+|\xi-\eta|)^{-1-\rho_1},$$

where $\rho_1 = \min\{1,\rho\}/2 > 0$. By integrating, we obtain for ξ in a half-plane $\pm\Im\xi \ge \omega_\mp$ (see (3.18)–(3.19))

$$|b_\pm(\xi)| \le C_3(1+|\xi|)^{-\rho_1}, \tag{3.27}$$

and (3.22)–(3.25) follow from (3.27) and the definition of $a_\pm$.

(d) Notice that $a_\pm$, $1/a_\pm$, $\phi_q^\pm$, and $1/\phi_q^\pm$ are bounded by a polynomial in the half-plane $\pm\Im\xi \ge \pm\omega_\mp$; therefore, by comparing (3.1) and (3.21), we conclude that $a_\pm\phi_q^\pm$ is holomorphic, polynomially bounded, and nonvanishing on the complex plane. By the Liouville theorem, this is constant, and taking into account that $\phi_q^\pm(0) = 1$, we obtain (3.26). □

3.4. Approximate formulas for the factors in the case of NIG, HP, and KoBoL. We can write these formulas down for both representations (in (3.1) and (3.21)). In the case of the former, the argument and formulas are shorter. We use (3.9) and Lemma 2.7 to transform the line of integration into the contour along the banks of the cut $(-i\infty, i\lambda_-]$. In empirical studies (see, e.g., [3] and [26]), the λ_+ and $-\lambda_-$ are usually large, of order 40–50, and then for typical values of other parameters both roots $-i\beta_\pm$ in Lemma 2.7 exist. Therefore, in the process of transformation, the contour crosses the simple pole at $\eta = -i\beta_+$. By the residue theorem we obtain, for ξ in the upper half-plane,

$$\phi_q^+(\xi) = \exp\left[\ln\frac{-i\beta_+}{-i\beta_+ - \xi} + \Phi_q^+(\xi)\right],$$

where

$$\Phi_q^+(\xi) = (2\pi)^{-1} \int_{-\infty}^{\lambda_-} \left[\frac{\psi'(iz-0)}{q+\psi(iz-0)} - \frac{\psi'(iz+0)}{q+\psi(iz+0)} \right] \ln \frac{-z-i\xi}{-z} dz. \tag{3.28}$$

Thus,

$$\phi_q^+(\xi) = \frac{\beta_+}{\beta_+ - i\xi} \exp \Phi_q^+(\xi). \tag{3.29}$$

Similarly, from (3.11) we deduce, for ξ in the lower half-plane,

$$\phi_q^-(\xi) = \frac{-\beta_-}{-\beta_- + i\xi} \exp \Phi_q^-(\xi), \tag{3.30}$$

where

$$\Phi_q^-(\xi) = (2\pi)^{-1} \int_{\lambda_+}^{+\infty} \left[\frac{\psi'(iz-0)}{q+\psi(iz-0)} - \frac{\psi'(iz+0)}{q+\psi(iz+0)} \right] \ln \frac{z+i\xi}{z} dz. \tag{3.31}$$

If $-\lambda_-$ (resp., λ_+) is large, then $|\Phi_q^+(\xi)|$ (resp., $|\Phi_q^+(\xi)|$) is small uniformly in ξ in the upper (resp., lower) half-plane, which can be easily seen from the explicit formulas for the characteristic exponents and (3.28) (resp., (3.31)). Hence, we may calculate the integrals in (3.28) and (3.31) with large relative error and still obtain $\phi_q^+(\xi)$ from (3.29) and $\phi_q^-(\xi)$ from (3.30) with good accuracy. This observation can be used to develop effective numerical procedures. In fact, even the simple approximations

$$\phi_q^+(\xi) \sim \frac{\beta_+}{\beta_+ - i\xi}, \qquad \phi_q^-(\xi) \sim \frac{-\beta_-}{-\beta_- + i\xi} \tag{3.32}$$

produce errors of only several percent for many typical parameters values.

The comparison of (3.6) and (3.32) provides an analytical explanation of why a simple adjustment of parameters of the Gaussian model can give fairly good fit even in a very non-Gaussian situation.

4. Pricing of the perpetual American put and similar perpetual options.

4.1. Sufficient conditions for the solution for the perpetual put-like options, in the class $\mathcal{M}_0$ of hitting times $\tau(a)$ of segments $(-\infty, a]$. Let $\mathbf{Q}$ be an EMM chosen by the market, and assume that X under $\mathbf{Q}$ is an RLPE with the characteristic exponent ψ and the infinitesimal generator L. For $g(X_t)$ the payoff, set

$$V(h,x) := E^x[e^{-q\tau(h)} g(X_{\tau(h)})], \tag{4.1}$$

where E^x is the expectation operator of the process X started at x, under $\mathbf{Q}$.

LEMMA 4.1. *Let there exist h_* with the following properties:*

(a) *if $h < h_*$, then there exists x such that*

$$V(h,x) < g(x); \tag{4.2}$$

(b) *for any $x \geq h_*$,*

$$V(h^*,x) \geq g(x); \tag{4.3}$$

(c) *if $h > h^*$, then for any $x \geq h$,*

$$V(h^*, x) \geq V(h, x). \tag{4.4}$$

Then $\tau(h_*)$ is an optimal stopping time of the class $\mathcal{M}_0$.

Proof. Clearly, the rational price of the option must satisfy (4.3); hence (4.2) excludes $h < h_*$. Due to (4.3), h_* is an admissible choice, and (4.3)–(4.4) ensure that a choice $h > h_*$ is no better than h_*. □

To apply Lemma 4.1, we need an explicit formula for $V(h, x)$. We derive it by using Dynkin's formula and the solution to the Wiener–Hopf equation. Let $U^q = U^q_X$ be the potential operator (the resolvent) of the process X:

$$U^q W(x) = E^x \left[\int_0^{+\infty} e^{-qt} W(X_t) dt \right].$$

If $V \in C_0$ is sufficiently regular, for instance, $(q - L)V \in C_0$, then

$$U^q (q - L)V = V \tag{4.5}$$

(see, e.g., [33, Theorem 31.3]). We will need (4.5) for not-so-regular V.

LEMMA 4.2. *Let $W := (q - L)V := (q + \psi(D))V$ belong to L_1 and*

$$(q + \Re\psi)^{-1} \hat{W} \in L_1. \tag{4.6}$$

Then (4.5) *holds.*

Proof. Since $W \in L_1$, we have

$$\begin{aligned}(U^q W)(x) &= \int_0^{+\infty} e^{-qt} (P_t W)(x) dt \\ &= \int_0^{+\infty} e^{-qt} (2\pi)^{-n} \int_{\mathbf{R}^n} e^{-i\langle x, \xi\rangle - t\psi(\xi)} \hat{f}(\xi) d\xi dt.\end{aligned}$$

Due to (4.6), the last integral, computed in the reverse order $dtd\xi$, converges absolutely, and hence we can apply the Fubini theorem and obtain $U^q W = (q+\psi(D))^{-1} W$; (4.5) follows. □

If W is universally measurable, then for any stopping time τ, Dynkin's formula is valid (see, e.g., [33, equation (41.3)]):

$$U^q W(x) = E^x \left[\int_0^{\tau} e^{-qt} W(X_t) dt \right] + E^x \left[e^{-q\tau} U^q W(X_\tau) \right]. \tag{4.7}$$

It follows that (4.7) holds for $g \in L_1 := L_1(\mathbf{R}^n)$, which admits a representation $g = g_1 + g_2$, where $g_1 \in C_0$ and g_2 is a nonnegative (or nonpositive) function of the class L_1. Denote the class of such sums by $UL := UL(\mathbf{R}^n)$. This class is sufficiently wide for all the applications that we will need in the paper.

LEMMA 4.3. *Let $W := (q - L)V := (q + \psi(D))V \in UL$ satisfy* (4.6). *Then*

$$W(x) = E^x \left[\int_0^{\tau} e^{-qt} (q - L) W(X_t) dt \right] + E^x \left[e^{-q\tau} W(X_\tau) \right]. \tag{4.8}$$

Proof. Apply (4.7) to W. Due to (4.6), (4.5) holds, and hence, (4.7) becomes (4.8). □

Let $\sigma_+ > 0$ be from Lemma 2.4. Let $g^{(s)} = D^s g$, $s = 0, \dots, m$, be measurable, and let

$$\sum_{0 \le s \le m} |g^{(s)}(x)| \le C e^{-\omega'_+ x}, \quad x \le 0, \tag{4.9}$$

$$\sum_{0 \le s \le m} |g^{(s)}(x)| \le C e^{-\omega'_- x}, \quad x \ge 0, \tag{4.10}$$

In subsection 4.3, we will prove the following theorem.

THEOREM 4.4. *Let g satisfy (4.9)–(4.10) with $\omega'_- < \omega'_+ < \sigma_+$ and $m = 2$. Then*

(a) *for any $h \in \mathbf{R}$, a solution of the problem*

$$(q - L)V(x) = 0, \qquad x > h, \tag{4.11}$$

$$V(x) = g(x), \qquad x \le h, \tag{4.12}$$

in the class of measurable functions, bounded on $[h, +\infty)$, exists.

(b) (1) *If $\kappa_- = 1$, then a continuous bounded solution is unique. It is given by*

$$V = \phi_q^-(D)\mathbf{1}_{(-\infty,h)}\phi_q^-(D)^{-1}g. \tag{4.13}$$

(2) *If $\kappa_- \in (0,1)$, then a bounded solution is unique. It is given by (4.13), and it is continuous.*

(3) *If $\kappa_- = 0$, then a bounded solution is unique. It is given by (4.13), and it is continuous if and only if $(\phi_q^-(D)^{-1}g)(h) = 0$.*

(4) *If $\kappa_- \in (0,1]$, then $V'(h-0) = V'(h+0)$ if and only if $(\phi_q^-(D)^{-1}g)(h) = 0$.*

Remark 4.1. (a) The condition $\kappa_- = 0$ is equivalent to $\nu \in (0,1)$ and $\mu > 0$. This is the case of the process of bounded variation, with positive drift.

(b) The regularity condition on g can be relaxed: For some $s > \kappa_- + 1/2$ and $\omega'_- < \omega'_+ < \sigma_+$,

$$(e^{-\omega'_- x} + e^{-\omega'_+ x})^{-1} g \in H^s(\mathbf{R}).$$

(c) Equation (4.13) can be written as

$$V(h, \cdot) := V(\cdot) = q U_N^q \mathbf{1}_{(-\infty,h)} w(\cdot), \tag{4.14}$$

where

$$w := \phi_q^-(D)^{-1} g = U_M^q (q - L) g \tag{4.15}$$

and U_M^q and U_N^q are the resolvents of the supremum and infimum processes, respectively.

We continue to study the optimal stopping problem. If $\kappa_- > 0$ or $\kappa_- = 0$ and $w(h) = 0$, then the next lemma provides the representation of $W := (q - L)V$, which implies that $W \in UL$ and (4.6) holds. The lemma is formulated and proven under simplifying assumptions, which hold for model classes. We also require more regularity of g.

Thus, in these cases, we may use (4.8) due to Lemma 4.2. If $\kappa_- = 0$, the condition $w(h) = 0$ can be used formally to find the optimal exercise boundary as the only boundary for which the solution is continuous, and in section 6 we will show that this is really the optimal boundary (for model classes, at least). Otherwise, we cannot

justify the usage of Dynkin's formula for discontinuous V. This is the reason why we exclude the case $\nu \in (0,1)$ and $\mu > 0$ below.

LEMMA 4.5. *Assume that* $\nu_1 = \nu - 1$ *in* (2.15)*, and that* (4.9)–(4.10) *hold with* $m = 3$*. Then the following hold:*

(a) *If* $\kappa_+ < 1$*, then* W *is continuous on* $(h, +\infty)$*, exponentially decays as* $x \to +\infty$*, and admits the following representation in the right neighborhood of* h*:*

$$W(x) = a_+(0)^{-1} w(h) \Gamma(1-\kappa_+)^{-1} (x-h)^{-\kappa_+} (1 + O((x-h)^{\gamma_1}) + O((x-h)^{\gamma_2}) \tag{4.16}$$

for some $\gamma_1, \gamma_2 > 0$.

(b) *If* $\kappa_+ = 1$ *and* $w(h) = 0$*, then* W *is continuous on* $(h, +\infty)$ *and exponentially decays as* $x \to +\infty$*; in addition,* $W(h+0)$ *exists.*

(c) *If* $\kappa_+ = 1$ *and* (2.14) *holds with* $\nu = 2$ *and* $\nu_1 < 1$ *(that is, the process* X *is a mixture of a BM with independent RLPE of order less than* 1*), then the statement in* (b) *holds.*

(d) *In all cases,* W *satisfies* (4.6).

Proof of this lemma will be given in subsection 4.4.

Thus, our further considerations in this section do not apply in the case of the mixture of a BM with RLPE of order ≥ 1. Notice that we will not use the additional conditions when we verify the sufficient optimality conditions in section 6 for all mixtures of processes from model classes and put options.

Under the conditions of Lemma 4.5, we can use (4.8); from (4.11)–(4.12), we conclude that V is nothing else but $V(h,x)$ given by (4.1). Hence, (4.13) is the formula for $V(h,x)$ that we need, and we can formulate a simple sufficient optimality condition in the class $\mathcal{M}_0$.

THEOREM 4.6. *Let* p_q^-*, the (generalized) density of the distribution* μ_q^- *in* Theorem 3.1*, be continuous; let* (4.9)–(4.10) *hold with* $\omega'_- < \omega'_+ < \sigma_+$ *and* $m = 3$*; and let there exist* $\tilde{h}_1 \leq \tilde{h}_2$ *such that the following conditions are satisfied:*

$$w(x) > 0 \qquad \forall\ x < \tilde{h}_1, \tag{4.17}$$

$$w(x) = 0 \qquad \forall\ \tilde{h}_1 \leq x \leq \tilde{h}_2, \tag{4.18}$$

$$w(x) < 0 \qquad \forall\ x > \tilde{h}_2. \tag{4.19}$$

Then for any $\tilde{h} \in [\tilde{h}_1, \tilde{h}_2]$*,* $\tau(\tilde{h})$ *is an optimal stopping time in the class* $\mathcal{M}_0$.

Proof. Write (4.13), for $x > h$, as

$$V(h,x) = \int_{-\infty}^{h} p_q^-(x-y) w(y) dy \tag{4.20}$$

and as

$$V(h,x) = g(x) - \int_{h}^{+\infty} p_q^-(x-y) w(y) dy. \tag{4.21}$$

If $h < \tilde{h}_1$, we notice that $\operatorname{supp} p_q^- \subset [0, +\infty)$, and therefore from (4.17) and (4.21) we conclude that there exist x such that $V(h,x) < g(x)$, which violates the necessary optimality conditions. Now consider h on the half-axis $(\tilde{h}_2, +\infty)$, and $x > h$. By differentiating (4.20) w.r.t. h and using (4.19), we find

$$V'_h(h,x) = p_q^-(x-h) w(h) < 0;$$

hence for these h, x, we have $V(h,x) < V(\tilde{h}_2, x)$. Finally, for $\tilde{h}_1 \le h \le \tilde{h}_2$ and $x > h$, we have from (4.18)

$$V'_h(h,x) = p_q^-(x-h)w(h) = 0;$$

hence

$$V(h,x) = V(\tilde{h}_1, x) \qquad \forall\ h \in [\tilde{h}_1, \tilde{h}_2] \text{ and } x > h.$$

We conclude that any $h \in [\tilde{h}_1, \tilde{h}_2]$ is an optimal exercise boundary. □

Let us show that if (2.15) holds with any $\nu_1 \in (\nu - 1, \nu)$ (this condition is satisfied for model processes), then p_q^- is continuous on $(0, +\infty)$. For $x > 0$,

$$p_q^-(x) = (2\pi)^{-1} \int_{-\infty}^{+\infty} e^{ix\xi} \phi_q^-(\xi) d\xi. \tag{4.22}$$

By choosing ν_1 sufficiently closely to $\nu - 1$, it is possible to refine the proof of (3.25) and obtain (3.25) with any $\rho_1 \in (0,1)$ (and C depending on ρ_1). Then from (3.25) and (3.26), we deduce

$$\phi_q^-(\xi) = a_-(0)(\lambda + i\xi)^{-\kappa_-} + \hat{f}(\xi), \tag{4.23}$$

where $\hat{f}(\xi) = O((1+|\xi|)^{-s})$ as $\xi \to \infty$, with some $s > 1$. Hence, f, the inverse Fourier transform of $\hat{f}$, is a continuous function, and since for $\nu < 1$

$$\int_0^{+\infty} e^{-ix\xi} x^{-\nu-1} e^{-\lambda x} dx = \Gamma(-\nu)(\lambda + i\xi)^{\nu}, \tag{4.24}$$

we deduce from (4.22)–(4.23) that

$$p_q^-(x) = a_-(0)\Gamma(\kappa_-)^{-1} \mathbf{1}_{(0,+\infty)}(x) x^{\kappa_- - 1} e^{-\lambda x} + f(x) \tag{4.25}$$

is continuous on $(0, +\infty)$.

Example 4.1. Let g be given by (1.3). Then

$$w(x) = \sum_{j=1}^{l} c_j \phi_q^-(-i\gamma_j)^{-1} e^{\gamma_j x}, \tag{4.26}$$

and it is easy to verify the sufficient conditions of Theorem 4.6 in concrete cases. In particular, if they are satisfied, then $\tilde{h}_1 = \tilde{h}_2$; call it $\tilde{h}$.

For instance, if the option owner has the right to sell a share of the stock for $K + a\sqrt{S}$, where S is the spot price, then $g(x) = K + ae^{x/2} - e^x$, $w(x) = K + a\phi_q^-(-i/2)^{-1} e^{x/2} - \phi_q^-(-i)^{-1} e^x$, and the optimal exercise price is $\sqrt{Y}$, where Y is the only positive root of

$$K + a\phi_q^-(-i/2)^{-1} Y - \phi_q^-(-i)^{-1} Y^2 = 0.$$

When an optimal $\tilde{h}$ is found, we can calculate the rational price by using the explicit formulas for ϕ_q^-:

$$V(\tilde{h}, x) = (2\pi)^{-1} \int_{-\infty+i\sigma}^{+\infty+i\sigma} \phi_q^-(\xi) \hat{u}(\tilde{h}, \xi) d\xi, \tag{4.27}$$

where $\sigma \in (\omega'_+, \lambda_+)$ is arbitrary and $\hat{u}$ is the Fourier transform of

$$u(\tilde{h}, x) := \mathbf{1}_{(-\infty,\tilde{h})}(x)w(x)$$

w.r.t. x. If $\hat{u}(\xi)$ and ψ are holomorphic in the upper half-plane with pole(s) and/or cut(s), then we can reduce the calculation of the integral in (4.27) to the sum of terms corresponding to poles, and integrals over these cuts. This procedure allows one to derive more effective formulas. We illustrate this procedure for puts.

4.2. Perpetual American put. For puts, $g(x) = K - e^x$; (4.9) and (4.10) hold with $\omega'_+ = 0$ and $\omega'_- = -1$, respectively, and any m; and $\tilde{h}$ is defined as the solution to the equation $K - \phi_q^-(-i)^{-1}e^x = 0$, that is,

$$e^{\tilde{h}} = K\phi_q^-(-i) = KqE\left[\int_0^\infty e^{-qt+N_t}dt \mid N_0 = 0\right]. \tag{4.28}$$

Take $\sigma \in (0, \lambda_+)$ and calculate for $\Im\xi = \sigma$

$$\begin{aligned}\hat{u}(\tilde{h}, \xi) &= \int_{-\infty}^{\tilde{h}} e^{-ix\xi}(K - \phi_q^-(-i)^{-1}e^x)dx \\ &= \frac{Ke^{-i\tilde{h}\xi}}{(-i\xi)(1-i\xi)} = \frac{-Ke^{-i\tilde{h}\xi}}{\xi(\xi+i)}.\end{aligned}$$

By substituting into (4.27), we obtain the formula for the rational perpetual put price

$$V(\tilde{h}, x) = -\frac{K}{2\pi}\int_{-\infty+i\sigma}^{+\infty+i\sigma} \frac{\exp[i(x-\tilde{h})\xi]\phi_q^-(\xi)}{\xi(\xi+i)}d\xi, \tag{4.29}$$

where $\sigma \in (0, \lambda_+)$ is arbitrary.

Assume that ϕ in (2.13) admits the analytic continuation into the upper half-plane $\Im\xi > 0$ with the cut $[i\lambda_+, +i\infty)$ and satisfies (2.20) there. (If $\phi(\xi) = a\xi^2 + \phi_1(\xi)$, we assume that ϕ_1 satisfies (2.20) with $\nu_1 < 2$, in the upper half-plane with the cut.) Assume also that $q+\psi$ has the only zero $-i\beta_-$ in the upper half-plane, $0 < -\beta_- < \lambda_+$; by Lemma 2.7, these conditions are satisfied for model processes. Then ϕ_q^- admits the analytic continuation into the upper half-plane with one simple pole at $-i\beta_-$, and the cut $[i\lambda_+, +i\infty)$, by

$$\phi_q^-(\xi) = q(q + \psi(\xi))^{-1}\phi_q^+(\xi)^{-1}. \tag{4.30}$$

For $z \in (\lambda_+, +\infty)$, set

$$\Phi_q^-(z) = iq[(q + \psi(iz + 0))^{-1} - (q + \psi(iz - 0))^{-1}]\phi_q^+(iz)^{-1}. \tag{4.31}$$

By transforming the contour in (4.29) into the integral over the banks of the cut $[i\lambda_+, +i\infty)$, we meet the simple pole, which gives the first term in (4.32) below; in the integral over the banks of the contour, we make the change of variables $\xi = iz$, and, finally, obtain for $x > \tilde{h}$

$$V(\tilde{h}, x) = \frac{iqK\exp[\beta_-(x-\tilde{h})]}{\psi'(-i\beta_-)\phi_q^+(-i\beta_-)(-\beta_-)(1-\beta_-)} + (2\pi)^{-1}\int_{\lambda_+}^{+\infty} \frac{K\Phi_q^-(z)\exp[-(x-\tilde{h})z]}{z(1+z)}dz. \tag{4.32}$$

As the empirical studies of financial markets reveal, λ_+ is usually large; hence, the second term in (4.32) is small. Therefore, one may calculate it with a large relative error. This observation facilitates the numerical implementation of (4.32). The leading term is a decaying exponential function, as in the Gaussian case, when there is no cut at all, and the second term in (4.32) is zero.

In particular, in the Gaussian case,

$$(q+\psi(\xi))/q = ((-\beta_- + i\xi)/(-\beta_-))\,((\beta_+ - i\xi)/\beta_+) = \phi_q^-(\xi)^{-1}\phi_q^+(\xi)^{-1}, \tag{4.33}$$

and hence $q^{-1}\psi'(-i\beta_-) = i(-\beta_-)^{-1}\phi_q^+(-i\beta_-)^{-1}$. By substituting into (4.28) and (4.32), we obtain the optimal exercise price

$$e^{\tilde{h}} = \frac{K\beta_-}{\beta_- - 1} \tag{4.34}$$

and the rational put price, for $x > \tilde{h}$,

$$V(\tilde{h}, x) = \frac{K\exp[\beta_-(x-\tilde{h})]}{1-\beta_-} = \left(\frac{K}{1-\beta_-}\right)^{1-\beta_-}(-\beta_-)^{-\beta_-}e^{\beta_- x}. \tag{4.35}$$

This is Merton's result. One can easily calculate $\hat{u}$ for payoffs of the form (1.3), and obtain the analogues of (4.29) and (4.32) and, in the Gaussian case, of (4.34) and (4.35) as well.

4.3. Proof of Theorem 4.4. We need several basic definitions and facts of the theory of PDO. For the sake of completeness, and in order to demonstrate the role of the conditions that we impose, we give the proof of two crucial facts (for more details, see [20]).

$H^s(\mathbf{R}^n)$ is the space of generalized functions on $\mathbf{R}^n$ with the finite norm

$$||u||_s = \left(\int_{\mathbf{R}^n}(1+|\xi|^2)^s|\hat{u}(\xi)|^2 d\xi\right)^{1/2}. \tag{4.36}$$

Denote by $\overset{o}{H}{}^s(\mathbf{R}_+)$ (resp., by $\overset{o}{H}{}^s(\mathbf{R}_-)$) the subspace of $H^s(\mathbf{R})$ consisting of generalized functions supported on $[0,+\infty)$ (resp., on $(-\infty,0]$).

THEOREM 4.7. *Let $s, m \in \mathbf{R}$, and let ϕ be a measurable function which admits the following estimate, for $\xi \in \mathbf{R}$:*

$$|\phi(\xi)| \le C(1+|\xi|)^m. \tag{4.37}$$

Then

$$\phi(D) : H^s(\mathbf{R}) \to H^{s-m}(\mathbf{R}) \quad \textit{is bounded.} \tag{4.38}$$

Proof. Apply the Fourier transform and the definition of the norm (4.36) to obtain the conclusion. □

We call ϕ a symbol of order m, and $\phi(D)$ is called a PDO of order m.

THEOREM 4.8. *Let $s, m \in \mathbf{R}$. Let $\phi_\pm$ be holomorphic in the half-plane $\pm\Im\xi > 0$, continuous up to the boundary, and admitting of the estimate* (4.37) *in the closed half-plane. Then*

(a) *for any $v \in C_0^\infty((-\infty,0))$ (resp., $v \in C_0^\infty((0,+\infty))$), the function $\phi_+(D)v$ (resp., $\phi_-(D)v$) is supported on $(-\infty,0)$ (resp., on $(0,+\infty)$);*

(b) *for any* $s \in \mathbf{R}$, $\phi_{\mp}(D) : \overset{o}{H}{}^{s}(\mathbf{R}_{\pm}) \to \overset{o}{H}{}^{s-m}(\mathbf{R}_{\pm})$ *is bounded.*

We call ϕ_+ (resp., ϕ_-) a positive (resp., negative) symbol of order m.

Proof. Consider $\phi^-(D)$ and $v \in C_0^\infty((0,+\infty))$. (a) Let $x_0 := \inf \operatorname{supp} v (> 0)$. We will prove that $\phi_-(D)v(x) = 0$ for all $x \le x_0$. By changing the variable, we may assume $x_0 = 0$. Take $x \le 0$ and calculate

$$\phi_-(D)v(x) = (2\pi)^{-1} \int_{-\infty}^{+\infty} e^{ix\xi} \phi_-(\xi) \hat{u}(\xi) d\xi. \tag{4.39}$$

Change the line of integration in (4.39):

$$\phi_-(D)v(x) = (2\pi)^{-1} \int_{-\infty+i\sigma}^{+\infty+i\sigma} e^{ix\xi} \phi_-(\xi) \hat{u}(\xi) d\xi, \tag{4.40}$$

where $\sigma < 0$. Since $u \in C_0^\infty((0,+\infty))$, its Fourier transform admits the following estimate in the half-plane $\Im\xi \le 0$:

$$|\hat{u}(\xi)| \le C_N (1 + |\xi|)^{-N} \tag{4.41}$$

for any N. From (4.37) and (4.41), we conclude that the integrand admits the bound via

$$C_N e^{-\sigma x} (1 + |\xi|)^{m-N}$$

for any N. By choosing $N > m + 1$ and passing to the limit $\sigma \to -\infty$ in (4.40), we obtain 0.

(b) Since $C_0^\infty((0,+\infty))$ is dense in $\overset{o}{H}{}^{s}(\mathbf{R}_+)$, we deduce (b) from Theorem 4.7 and from (a). □

By the change of the variable $x \mapsto h + x$, we reduce the proof of Theorem 4.4 to the case $h = 0$. Next, for $\omega'_+ < \sigma_+$ in (4.9), take any $\gamma \in (\omega'_+, \sigma_+)$ and set $V_\gamma(x) = e^{\gamma x} V(x)$. Denote

$$a(D) := q + \psi(D) = q - L,$$

insert $V(x) = e^{-\gamma x} V_\gamma(x)$ into (4.11), after that multiply (4.11) and (4.12) by $e^{\gamma x}$ and use the equality

$$e^{\gamma x} a(D) e^{-\gamma x} = a(D + i\gamma). \tag{4.42}$$

We obtain

$$a(D + i\gamma) V_\gamma(x) = 0, \qquad x > 0, \tag{4.43}$$

$$V_\gamma(x) = g_\gamma(x), \qquad x \le 0. \tag{4.44}$$

Notice that g_γ decays exponentially as $x \to -\infty$: From (4.9), on $(-\infty, 0]$,

$$\sum_{0 \le s \le 2} |g_\gamma^{(s)}(x)| \le C e^{-\epsilon|x|}, \tag{4.45}$$

where $\epsilon = \gamma - \omega'_+ > 0$. Construct G_γ, which coincides with g_γ on $\mathbf{R}_-$ and admits a bound (4.45) on $\mathbf{R}$, and set $u_\gamma = V_\gamma - G_\gamma$, $F_\gamma = -a(D + i\gamma) G_\gamma$. Then u_γ solves the problem

$$a(D + i\gamma) u_\gamma(x) = F_\gamma(x), \qquad x > 0, \tag{4.46}$$

$$u_\gamma(x) = 0 \qquad x \le 0. \tag{4.47}$$

Now (4.45) implies that $G_\gamma \in H^2(\mathbf{R})$, and from (2.13)–(2.14) we conclude that $F_\gamma \in H^{2-\bar\nu}(\mathbf{R})$, where $\bar\nu = \nu$ if $\nu \geq 1$ or $\mu = 0$, and $\bar\nu = \max\{\nu, 1\}$, otherwise. Recall that we are looking for V, which is measurable and bounded on $(0, +\infty)$. Hence, u_γ is measurable and admits a bound via $Ce^{\gamma x}$. We want to reduce to the case of an unknown function of the class $L_2(\mathbf{R}_+)$. Since $\sigma_- < 0$, we can choose $\gamma' \in (\sigma_- - \gamma, -\gamma)$. Set $u_{\gamma,\gamma'}(x) = e^{\gamma' x} u_\gamma(x)$, insert $u_\gamma(x) = e^{-\gamma' x} u_{\gamma,\gamma'}(x)$ into (4.46) and (4.47), and after that multiply (4.46) by $e^{\gamma' x}$. By using (4.42), we obtain

$$a(D + i(\gamma + \gamma'))u_{\gamma,\gamma'}(x) = F_{\gamma,\gamma'}(x), \qquad x > 0, \tag{4.48}$$

$$u_{\gamma,\gamma'}(x) = 0, \qquad x \leq 0. \tag{4.49}$$

Now $u_{\gamma,\gamma'} \in L_2(\mathbf{R}_+)$, and on the strength of (2.13)–(2.14), Theorem 4.7 gives $a(D + i(\gamma + \gamma'))u_{\gamma,\gamma'} \in H^{-\bar\nu}(\mathbf{R})$. Hence, we can write the Wiener–Hopf equation (4.48) in the form

$$a(D + i(\gamma + \gamma'))u_{\gamma,\gamma'} = F_{\gamma,\gamma'} + F_-, \tag{4.50}$$

where $F_- \in \overset{o}{H}{}^{-\bar\nu}(\mathbf{R}_-)$. Multiply by q^{-1}, and then apply $\phi_q^+(D + i(\gamma + \gamma'))$. Since in the strip $\Im\xi \in (\lambda_-, \lambda_+)(\supset (\sigma_-, \sigma_+) \supset (\sigma_-, 0))$

$$q^{-1}a(\xi) = \phi_q^+(\xi)^{-1}\phi_q^-(\xi)^{-1},$$

and by our choice, $\gamma + \gamma' \in (\sigma_-, 0)$, we obtain

$$\phi_q^-(D + i(\gamma + \gamma'))^{-1}u_{\gamma,\gamma'} = K + K_-, \tag{4.51}$$

where

$$\begin{aligned} K :&= q^{-1}\phi_q^+(D + i(\gamma + \gamma'))F_{\gamma,\gamma'} \\ &= q^{-1}\phi_q^+(D + i(\gamma + \gamma'))e^{\gamma' x}(-a(D + i\gamma))G_\gamma \\ &= -\phi_q^-(D + i(\gamma + \gamma'))^{-1}e^{\gamma' x}G_\gamma \end{aligned}$$

and

$$K_- := q^{-1}\phi_q^+(D + i(\gamma + \gamma'))F_-.$$

By construction, $G_\gamma \in H^2(\mathbf{R})$, and $u_{\gamma,\gamma'} \in L_2(\mathbf{R}_+) = \overset{o}{H}{}^0(\mathbf{R}_+)$, $F_- \in \overset{o}{H}{}^{-\bar\nu}(\mathbf{R}_-)$. From Theorem 3.4, we know that for any $\sigma \in (\sigma_-, \sigma_+)$,

$$c(1 + |\xi|)^{\kappa_\pm} \leq |\phi_q^\pm(\xi)| \leq C(1 + |\xi|)^{\kappa_\pm}, \qquad \pm\Im\xi \geq \sigma;$$

therefore, by applying Theorem 4.7 and Theorem 4.8, we conclude that

$$\phi_q^-(D + i(\gamma + \gamma'))^{-1}u_{\gamma,\gamma'} \in \overset{o}{H}{}^{-\kappa_-}(\mathbf{R}_+), \qquad K_- \in \overset{o}{H}{}^{-\kappa_-}(\mathbf{R}_-), \quad K \in H^{-\kappa_-}(\mathbf{R}_+).$$

Notice that $\kappa_- \in [0, 1]$, and consider two cases: (i) $\kappa_- \in [0, 0.5)$ and (ii) $\kappa_- \in [0.5, 1]$.

In case (i), $H^{-\kappa_-}(\mathbf{R})$ is the direct sum of the subspaces $\overset{o}{H}{}^{-\kappa_-}(\mathbf{R}_\pm)$, the projections being $\theta_\pm$, the closures of the multiplication-by-$\mathbf{1}_{\mathbf{R}_\pm}$ operators defined on a dense subset $L_2(\mathbf{R}) \subset H^{-\kappa_-}(\mathbf{R})$ (see [20, Theorem 5.1 and Lemma 5.4]). Hence, from (4.51), we deduce

$$\phi_q^-(D + i(\gamma + \gamma'))^{-1}u_{\gamma,\gamma'} = -\theta_+\phi_q^-(D + i(\gamma + \gamma'))^{-1}e^{\gamma' x}G_\gamma. \tag{4.52}$$

Next, we multiply (4.52) by $\phi_q^-(D+i(\gamma+\gamma'))$, which establishes an isomorphism between $\overset{o}{H}{}^{-\kappa_-}(\mathbf{R}_+)$ and $L_2(\mathbf{R}_+)$:

$$u_{\gamma,\gamma'} = -\phi_q^-(D+i(\gamma+\gamma'))\theta_+\phi_q^-(D+i(\gamma+\gamma'))^{-1}e^{\gamma' x}G_\gamma. \tag{4.53}$$

Then we multiply (4.53) by $e^{-\gamma' x}$ and use (4.42):

$$u_\gamma = -\phi_q^-(D+i\gamma)\theta_+\phi_q^-(D+i\gamma)^{-1}G_\gamma.$$

After that, we return to

$$\begin{aligned} V_\gamma &= G_\gamma + u_\gamma \\ &= G_\gamma - \phi_q^-(D+i\gamma)\theta_+\phi_q^-(D+i\gamma)^{-1}G_\gamma \\ &= \phi_q^-(D+i\gamma)\theta_-\phi_q^-(D+i\gamma)^{-1}G_\gamma \end{aligned}$$

and notice that, since G_γ coincides with g_γ on $\mathbf{R}_-$, Theorem 4.8 ensures that $\operatorname{supp}\phi_q^-(D+i\gamma)^{-1}(G_\gamma - g_\gamma) \subset [0,+\infty)$. Thus,

$$\theta_-\phi_q^-(D+i\gamma)^{-1}G_\gamma = \theta_-\phi_q^-(D+i\gamma)^{-1}g_\gamma,$$

and in the formula for V_γ, we may replace G_γ with g_γ. By using (4.42), we finally arrive at

$$V = \phi_q^-(D)\theta_-\phi_q^-(D)^{-1}g. \tag{4.54}$$

Due to (4.9)–(4.10) and Theorem 4.7, $w := \phi_q^-(D)^{-1}g \in H^{2-\kappa_-}(\mathbf{R})$. Since $2-\kappa_- > 1/2$, we can apply Lemma 5.5 of [20] and obtain

$$\theta_-\phi_q^-(D)^{-1}g = w(0)(1-iD)^{-1}\delta + (1-iD)^{-1}\theta_-(1-iD)\phi_q^-(D)^{-1}g, \tag{4.55}$$

where δ is the Dirac delta-function. Notice that for any $\epsilon > 0$, $\delta \in H^{-1/2-\epsilon}(\mathbf{R})$ and $\theta_-(1-iD)\phi_q^-(D)^{-1}g \in H^0(\mathbf{R})$. Hence, if $\kappa_- > 0$, we obtain $V \in H^{1/2+\rho}(\mathbf{R})$ for any $\rho \in (0,\kappa_-)$. But for $s > 1/2$, $H^s(\mathbf{R}) \subset C(\mathbf{R})$, and therefore, V is continuous. By using (4.42) and (4.9), it is easy to show that the RHS in (4.54) decays exponentially.

If $\kappa_- = 0$, we have from (3.25) and (3.26)

$$\phi_q^-(D) = a_-(0) + T(D), \tag{4.56}$$

where $T(\xi)$ admits an estimate (4.37) with $m < 0$; therefore from (4.54) and (4.55) we conclude that

$$V = a_-(0)w(0)(1-iD)^{-1}\delta + V_1, \tag{4.57}$$

where $V_1 \in C(\mathbf{R})$. It is straightforward to check that the Fourier transform of $\mathbf{1}_{(-\infty,0]}(x)e^x$ is $(1-i\xi)^{-1}$; therefore $(1-iD)^{-1}\delta = \mathbf{1}_{(-\infty,0]}e^x$, and we conclude from (4.57) that V is continuous if and only if $w(0) = 0$.

In case (ii), we notice that for $s \in (-3/2,-1/2)$, the decomposition of $H^s(\mathbf{R})$ into the sum of the subspaces $\overset{o}{H}{}^s(\mathbf{R}_\pm)$ is not direct, the intersection of the latter couple being $\mathbf{C}\cdot\delta$, where δ is the Dirac delta-function. It follows that in (4.52), an additional term $C\delta$ may appear, and in (4.54), the term $C\phi_q^-(D)\delta$, where C is a constant.

If $\kappa_- = 0$, we use (3.25) and (3.26) and conclude from (4.55) that $V = C\delta + V_1$, where $V_1 \in H^s(\mathbf{R})$ for some $s > -1/2$. Since $\delta \notin H^s(\mathbf{R})$, for $s > -1/2$, and V is bounded, we conclude that C must be 0.

If $\kappa_- \in (0,1)$, we can show with the help of (3.25) and (3.26) that

$$\phi_q^-(D)\delta(x) = (2\pi)^{-1}\int_{-\infty}^{+\infty} e^{ix\xi}\phi_q^-(\xi)d\xi$$

is unbounded as $x \to +0$. Further, for $\kappa_- > 0$, V in (4.54) belongs to $H^s(\mathbf{R})$ for some $s > 1/2$ and hence is continuous. We conclude that $C\phi_q^-(D)\delta + V$ is bounded only in the case $C = 0$, and so we are left with the same (4.54). Finally, if $\kappa_- = 1$, then the argument in part (i) shows that V in (4.54) is continuous, and the same argument shows that $\phi_q^-(D)\delta(x)$ is discontinuous at 0. Hence, in order to get a continuous solution, we need $C = 0$. This finishes the proof of part (a) and part (b) (1)–(3). The last part (b) (4) can be proven by the same argument, after differentiating in (4.54).

Theorem 4.4 has thus been proven. □

4.4. Proof of Lemma 4.5. As in the proof of Theorem 4.4, we change the variable so that $h = 0$, and the usage of (4.42) establishes the exponential decay at infinity. The main difficulty is the regularity at 0. We have

$$(q - L)V = a(D)V = \phi_q^+(D)^{-1}\theta_-\phi_q^-(D)^{-1}g.$$

Under our regularity assumption on g, we can use Lemma 5.5 in [20] with one more term than in (4.55) and obtain

$$(q - L)V = W_1 + W_2 + W_3, \tag{4.58}$$

where

$$\begin{aligned} W_1 &= \phi_q^+(D)^{-1}(1 - iD)^{-1}(\phi_q^-(D)^{-1}g)(0)\delta, \\ W_2 &= \phi_q^+(D)^{-1}(1 - iD)^{-2}(\phi_q^-(D)^{-1}(1 - iD)g)(0)\delta, \\ W_3 &= \phi_q^+(D)^{-1}(1 - iD)^{-2}\theta_+(1 - iD)^2\phi_q^-(D)^{-1}g. \end{aligned}$$

Equality (4.58) holds, provided that for some $s > 5/2$, $\phi_q^-(D)^{-1}g \in H^s(\mathbf{R})$ (locally). By using (4.9)–(4.10), we conclude that, locally, $g \in H^3(\mathbf{R})$, and by Theorem 4.7, $\phi_q^-(D)^{-1}g \in H^{3-\kappa_-}(\mathbf{R})$. Since $\kappa_- \in [0,1]$, (4.58) holds.

For $|s| < 1/2$, $\theta_- : H^s(\mathbf{R}) \to \overset{o}{H}{}^s(\mathbf{R}_-)$ is bounded, and since $\kappa_+ \le 1$, we conclude that $W_3 \in \overset{o}{H}{}^s(\mathbf{R})$ for some $s > 1/2$. For such s, $H^s(\mathbf{R}) \subset C^0(\mathbf{R})$; hence W_3 is continuous and vanishes on $[0, +\infty)$. Since $\delta \in \overset{o}{H}{}^{-s}(\mathbf{R})$ for any $s > 1/2$ and since $\kappa_+ \le 1$, we obtain $W_2 \in \overset{o}{H}{}^{2-\kappa_+-s}(\mathbf{R}_-)$. If $\kappa_+ < 1$, we conclude that $W_2 \in \overset{o}{H}{}^s(\mathbf{R}_-)$. If $\kappa_+ = 1$, we use (3.23) and represent $\phi_q^+(D)^{-1}(1 - iD)^{-2}$ in the form

$$\phi_q^+(D)^{-1}(1 - iD)^{-2} = a_+(0)^{-1}(1 - iD)^{-1} + T(D), \tag{4.59}$$

where $T(\xi)$ is a positive symbol of order less than one. Hence, $f := T(D)\delta$ is continuous and vanishes on $[0, +\infty)$, and

$$(\phi_q^+(D)^{-1}(1 - iD)^{-2}\delta)(x) = a_+(0)^{-1}\mathbf{1}_{(-\infty,0]}(x)e^x + f(x). \tag{4.60}$$

It remains to consider W_1. Since in part (b), $w(h) = 0$ and hence $W_1 = 0$, the application of (4.60) finishes the proof of part (a). Let $\kappa_+ < 1$. By using (2.14) with $\nu_1 = \nu - 1$ and the same sort of argument as in the proof of (4.25), we obtain

$$\phi_q^+(D)^{-1}(1 - iD)^{-1}\delta = \Gamma(\kappa_+ - 1)^{-1}a_+(0)^{-1}\mathbf{1}_{(-\infty,0]}(x)(-x)^{-\kappa_+}e^x + f_1(x), \tag{4.61}$$

where f_1 is continuous and vanishes on $[0, +\infty)$, and (4.16) follows from (4.61).

The proof of part (c) differs from the one above. We represent $q - L$ in the form $q - L = a_2(D) + a_{\nu'}(D)$, where $a_2(D)$ is a differential operator of order 2 and $a_{\nu'}(D)$ is a PDO of order $\nu' < 1$, and consider separately $a_2(D)V$ and $a_{\nu'}(D)V$ on $(-\infty, 0)$. Since $a_2(D)$ is local, we obtain, for $x < 0$,

$$a_2(D)V(x) = \phi_q^-(D)\theta_+\phi_q^-(D)^{-1}a_2(D)g(x).$$

By Theorem 4.7, $\phi_q^-(D)^{-1}a_2(D)g \in H^{3-\kappa_- -2}(\mathbf{R}) = L_2(\mathbf{R})$, since $\kappa_- = 2 - \kappa_+ = 1$, and hence, by the same theorem, $\phi_q^-(D)\theta_+\phi_q^-(D)^{-1}a_2(D)g \in H^1(\mathbf{R})$. Hence, this is a continuous function. Since $\nu' < 1$ and the order of $\phi_q^-(D)$ is $-\kappa_- = -1$, the continuity of $a_{\nu'}(D)V = a_{\nu'}(D)\phi_q^-(D)\theta_-\phi_q^-(D)^{-1}g$ is established as in the proof of part (a) above.

It remains to verify (d). In the course of the proof of (a)–(c), we have shown that

$$|\hat{V}(\xi)| \le C(1 + |\xi|)^{-1-\kappa_-};$$

therefore, from (2.13)–(2.14),

$$(q + \Re\psi(\xi))^{-1}|\hat{W}(\xi)| = (q + \Re\psi(\xi))^{-1}|(q + \psi(\xi))\hat{V}(\xi)| \le C(1 + |\xi|)^{-1+\kappa_+-\nu}.$$

If $\kappa_- > 0$, then $\nu - \kappa_+ > 0$ and (4.6) holds.

Lemma 4.5 has thus been proven. □

5. Pricing of the perpetual American call and similar perpetual options.

5.1. Sufficient conditions for the solution for the perpetual call-like options, in the class $\mathcal{M}_0$ of hitting times $\tau(a)$ of segments $[a, +\infty)$. The substitutions $-x$ for x and the dual process $\tilde{X}$ for X transform a problem for an RLPE X on $(h, +\infty)$ into a problem for an RLPE $\tilde{X}$ on $(-\infty, -h)$. Therefore, all the statements and proofs for call-like options are obtained from the corresponding statements for put-like options by changing the direction on the real axis and the reflection of the complex plane w.r.t. the real axis. The boundedness conditions (4.9) and (4.10) allow for the growth of the payoff in the direction to $-\infty$, so the growth of the payoff for the call option is not a problem, insofar as the main considerations in the proof of the analogue of Theorem 4.4 can be restricted to a strip $\Im\xi \in (\sigma_-, \sigma_+)$, where the real part of $a(\xi) = q + \psi(\xi)$ is positive. In the case of calls, the payoff is $g(x) = e^x - K$; hence we need $a(-i) = q + \psi(-i)$ to be positive. If there is no dividend, $q = r$, and the EMM condition for the measure means that $q + \psi(-i) = 0$. This provides the formal explanation of why we need the condition $q > r$ in the case of calls; standard considerations can be used to show that in the no-dividend case, it is nonoptimal to exercise the call option ever.

The analogue of Lemma 4.1 is obtained by inverting signs in all the inequalities there, and we will not state it explicitly. The reformulation of Theorem 4.4 is also straightforward; in addition to changing the signs of inequalities and reflections, the condition $\omega'_- < \omega'_+ < \sigma_+$ must be replaced with $\sigma_- < \omega'_- < \omega'_+$.

Notice only that we consider a problem

$$(q - L)V(x) = 0, \qquad x < h, \tag{5.1}$$

$$V(x) = g(x), \qquad x \geq h, \tag{5.2}$$

in the class of measurable functions bounded on $(-\infty, h]$, and its solution is

$$V = \phi_q^+(D)\mathbf{1}_{(h,+\infty)}\phi_q^+(D)^{-1}g. \tag{5.3}$$

The solution can be written as

$$V(h,\cdot) := V(\cdot) = qU_M^q\mathbf{1}_{(h,+\infty)}w(\cdot), \tag{5.4}$$

where

$$w = U_N^q(q - L)g \tag{5.5}$$

and U_M^q and U_N^q are the resolvents of the supremum and infimum processes, respectively.

THEOREM 5.1. *Assume that $\nu_1 = \nu - 1$ in (2.15), and that (4.9)–(4.10) hold with $\sigma_- < \omega'_- < \omega'_+$ and $m = 2$, and let there exist $\tilde{h}_1 \leq \tilde{h}_2$ such that the following conditions are satisfied:*

$$w(x) < 0 \qquad \forall\ x < \tilde{h}_1, \tag{5.6}$$

$$w(x) = 0 \qquad \forall\ \tilde{h}_1 \leq x \leq \tilde{h}_2, \tag{5.7}$$

$$w(x) > 0 \qquad \forall\ x > \tilde{h}_2. \tag{5.8}$$

Then for any $\tilde{h} \in [\tilde{h}_1, \tilde{h}_2]$, $\tau(\tilde{h})$ is an optimal stopping time in the class $\mathcal{M}_0$.

5.2. Perpetual American call. For calls $g(x) = e^x - K$, (4.9) and (4.10) hold with $\omega'_+ = 0$ and $\omega'_- = -1$, respectively, and any m. So, we have to assume that $\sigma_- < -1$, which is equivalent to $q > r$.

Here $\tilde{h}$ is defined as the solution to the equation $\phi_q^+(-i)^{-1}e^x - K = 0$, that is,

$$e^{\tilde{h}} = K\phi_q^+(-i) = KqE\left[\int_0^\infty e^{-qt+M_t}dt \mid M_0 = 0\right]. \tag{5.9}$$

When an optimal $\tilde{h}$ is found, we can calculate the rational price by using the explicit formulas for ϕ_q^+:

$$V(\tilde{h}, x) = (2\pi)^{-1}\int_{-\infty+i\sigma}^{+\infty+i\sigma}\phi_q^+(\xi)\hat{u}(\tilde{h},\xi)d\xi, \tag{5.10}$$

where $\sigma \in (\lambda_-, -1)$ is arbitrary and $\hat{u}(\tilde{h},\xi)$ is the Fourier transform of $u(\tilde{h}, x) := \mathbf{1}_{(\tilde{h},+\infty)}(x)w(x)$:

$$\hat{u}(\tilde{h},\xi) = \int_{\tilde{h}}^{+\infty} e^{-ix\xi}(\phi_q^+(-i)^{-1}e^x - K)dx = \frac{Ke^{-i\tilde{h}\xi}}{(-i\xi)(1 - i\xi)} = \frac{-Ke^{-i\tilde{h}\xi}}{\xi(\xi + i)}.$$

By substituting into (5.10), we obtain the formula for the rational perpetual call price

$$V(\tilde{h}, x) = -\frac{K}{2\pi}\int_{-\infty+i\sigma}^{+\infty+i\sigma}\frac{\exp[i(x - \tilde{h})\xi]\phi_q^+(\xi)}{\xi(\xi + i)}d\xi, \tag{5.11}$$

where $\sigma \in (\lambda_-, -1)$ is arbitrary. One can easily calculate $\hat{u}$ for payoffs of the form (1.3) and obtain the analogue of (5.11).

Assume that ϕ in (2.13) admits the analytic continuation into the lower half-plane $\Im\xi < 0$ with the cut $(-i\infty, i\lambda_-]$ and satisfies (2.20) there. (If $\phi(\xi) = a\xi^2 + \phi_1(\xi)$, then we require that ϕ_1 satisfies (2.20) with $\nu_1 < 2$, in the lower half-plane with the cut.) Assume also that $q+\psi$ has the only zero $-i\beta_+$ in the lower half-plane, $\lambda_- < -\beta_+ < 0$; by Lemma 2.7, these conditions are satisfied for model processes. Then ϕ_q^+ admits the analytic continuation into the lower half-plane with one simple pole at $-i\beta_+$, and the cut $(-i\infty, i\lambda_-]$, by

$$\phi_q^+(\xi) = q(q + \psi(\xi))^{-1}\phi_q^-(\xi)^{-1}. \tag{5.12}$$

For $z \in (\lambda_+, +\infty)$, set

$$\Phi_q^+(z) = iq[(q + \psi(iz - 0))^{-1} - (q + \psi(iz + 0))^{-1}]\phi_q^-(iz)^{-1}. \tag{5.13}$$

By transforming the contour in (5.11) into the integral over the banks of the cut $(-i\infty, i\lambda_-]$, we meet the simple pole, which gives the first term in (5.14) below; in the integral over the banks of the contour, we make the change of variables $\xi = iz$, and, finally, obtain for $x < \tilde{h}$

$$V(\tilde{h}, x) = \frac{iqK\exp[\beta_+(x - \tilde{h})]}{\psi'(-i\beta_+)\phi_q^-(-i\beta_+)\beta_+(\beta_+ - 1)} + (2\pi)^{-1}\int_{-\infty}^{\lambda_-} \frac{K\Phi_q^+(z)\exp[-(x - \tilde{h})z]}{z(1 + z)}dz. \tag{5.14}$$

As the empirical studies of financial markets reveal, $-\lambda_-$ is usually large; hence, the second term in (5.14) is small. Therefore, one may calculate it with a large relative error. This observation facilitates the numerical implementation of (5.14). The leading term is a decaying exponential function, as in the Gaussian case, when there is no cut at all, and the second term in (5.14) is zero.

6. Reduction to the free boundary value problem and verification of optimality in the class $\mathcal{M}$.

6.1. Main lemma. Consider the following free boundary value problem: Given a nonnegative continuous function g, find an open set $\mathcal{C}$ and a function V such that

$$(q - L)V(x) = 0, \qquad x \in \mathcal{C}, \tag{6.1}$$

$$V(x) = g(x), \qquad x \notin \mathcal{C}, \tag{6.2}$$

$$V(x) \geq g(x), \qquad x \in \mathcal{C}, \tag{6.3}$$

$$(q - L)V(x) \geq 0, \qquad x \notin \overline{\mathcal{C}}. \tag{6.4}$$

LEMMA 6.1. *Let $(\tilde{\mathcal{C}}, \tilde{V})$ be a solution of* (6.1)–(6.4)*, let τ_* be the hitting time of $\mathcal{C}$, and let*

$$\tilde{W} := (q - L)\tilde{V} \quad \textit{be universally measurable}; \tag{6.5}$$

$$U^q\tilde{W} = \tilde{V}. \tag{6.6}$$

Then τ_* and $V_* = \tilde{V}$ solve the optimization problem (1.1).

Proof. Due to (6.1) and (6.4), $\tilde{W}$ is nonnegative, and by (6.5), it is universally measurable; therefore, for any stopping time τ, (4.7) holds, and by substituting from

(6.6), we obtain (4.8). From (4.8), (6.4), and (6.1), we conclude that for any stopping time τ,

$$\tilde{V}(x) \geq E^x \left[e^{-q\tau} \tilde{V}(X_\tau) \right], \tag{6.7}$$

and from (4.8) and (6.1), for a chosen stopping time τ_*,

$$\tilde{V}(x) = E^x \left[e^{-q\tau_*} \tilde{V}(X_{\tau_*}) \right]. \tag{6.8}$$

By using (6.3) and (6.2), we deduce from (6.7) and (6.8)

$$\tilde{V}(x) \geq E^x[e^{-q\tau} g(X_\tau)],$$

$$\tilde{V}(x) = E^x[e^{-q\tau_*} g(X_{\tau_*})].$$

But this means that a pair (τ_*, V_*), where $V_* = \tilde{V}$, is the optimal stopping time and the rational price. □

6.2. Verification of conditions of Lemma 6.1 for puts and options with payoffs (1.3). Assume that the conditions of Theorem 4.4 hold. Let $\tilde{h}$ be defined by conditions (4.17)–(4.19), and set $\mathcal{C} = (\tilde{h}, +\infty)$. Define $\tilde{V}(x) = V(h, x)$ by (4.11). Then (6.1)–(6.2) hold by Theorem 4.4, and by repeating a part of the proof of Theorem 4.6, we see that (6.3) holds. It remains to verify (6.4)–(6.6). We formulate sufficient conditions, which hold for puts and many other payoffs of the form (1.3).

Of the process, we require the following:

A. The function ϕ in (2.14) admits the analytic continuation into the lower half-plane with the cut $(-i\infty, i\lambda_-]$, and admits the bound (2.20) in this half-plane, outside a vicinity of $i\lambda_-$. If $\nu = 2$, there exist c and $\nu_1 < 2$ such that $\phi(\xi) - c\xi^2$ satisfy (2.20) with ν_1 instead of ν.

B. In a neighborhood of $i\lambda_-$, ϕ may have a weak singularity:

$$|\phi(\xi)| \leq C|\xi - i\lambda_-|^{-\alpha} \tag{6.9}$$

for some $\alpha < 1$.

C. For any $z \in (-\infty, \lambda_-)$, the limit

$$\Psi_-(z) = i[\psi(iz - 0) - \psi(iz + 0)] \tag{6.10}$$

exists and is nonpositive.

LEMMA 6.2. *Let X be a mixture of independent BM, HP, NIG, normal tempered stable (NTS) Lévy, and KoBoL. Then* A–C *hold.*

Proof. For the proof, see the appendix. □

THEOREM 6.3. *Let X be an RLPE of exponential type $[\lambda_-, \lambda_+]$, let* A–C *hold, and let*

$$g(x) = K - \sum_{j=1}^{l} c_j e^{\gamma_j x}, \tag{6.11}$$

where $K > 0$, $c_j > 0$, and $-i\gamma_j \in [i\sigma_-, 0)$, $j = 1, \ldots, l$. Then

(a) *the solution of the optimal stopping problem* (1.1) *in the class $\mathcal{M}$ exists and belongs to $\mathcal{M}_0$;*

(b) *the optimal exercise price, $\tilde{h}$, is the solution to the equation*

$$K = \sum_{j=1}^{l} c_j \phi_q^-(-i\gamma_j)^{-1} e^{\gamma_j h}; \tag{6.12}$$

(c) *the price of the option can be calculated from* (4.27) *with any $\sigma \in (0, \sigma_+)$ and*

$$\hat{u}(\xi) = K(-i\xi)^{-1} - \sum_{j=1}^{l} c_j \phi_q^-(-i\gamma_j)^{-1}(\gamma_j - i\xi)^{-1}. \tag{6.13}$$

Proof. Notice that $\hat{u}$ admits the meromorphic continuation into the complex plane with a finite number of simple poles at points $\{0, -i\gamma_1, \dots, -i\gamma_l\} \subset (i\lambda_-, i\sigma)$, and it has the following asymptotics, as $\xi \to \infty$:

$$\hat{u}(\xi) = c_1\xi^{-1} + c_2\xi^{-2} + O(|\xi|^{-3}). \tag{6.14}$$

Under condition (6.12), $c_1 = 0$, which means that the candidate for the optimal solution is more smooth than a solution for a generic h. Hence, much simpler considerations than in the proof of Lemma 4.5 for a generic h, and without additional conditions, show that $(q - L)V \in UL$ (in fact, it turns out to be even bounded), and therefore, (6.5) and (6.6) hold. It remains to verify (6.4). The conditions (6.4) and (6.12) are evidently "additive" w.r.t. g in the sense that if g_1 and g_2 satisfy (6.4) (resp., (6.12)), then $g_1 + g_2$ satisfies (6.4) (resp., (6.12)) as well. Hence, it suffices to prove that if g is a payoff of the form

$$g(x) = A - Be^{\gamma x}, \tag{6.15}$$

where $A, B > 0$, $\sigma_- \le \gamma < 0$, and

$$A - B\phi_q^-(-i\gamma)^{-1} e^{\gamma h} = 0, \tag{6.16}$$

then $V = \phi_q^-(D)\mathbf{1}_{(-\infty,h)}\phi_q^-(D)^{-1}g$ satisfies $(q - L)V \ge 0$. The payoff (6.15) being essentially the same as the one for puts, the calculations leading to (4.29) give

$$V(x) = \frac{A}{2\pi} \int_{-\infty+i\sigma}^{+\infty+i\sigma} \frac{\exp[i(x-h)\xi]\phi_q^-(\xi)}{(-i\xi)(\gamma - i\xi)} d\xi, \tag{6.17}$$

where $\sigma \in (0, \lambda_+)$ is arbitrary. By applying $(q - L) = q + \psi(D)$ to (6.17), we see that it suffices to prove that the following function is nonnegative on $(0, +\infty)$:

$$W(x) = (2\pi)^{-1} \int_{-\infty+i\sigma}^{+\infty+i\sigma} \frac{\exp[ix\xi](q + \psi(\xi))\phi_q^-(\xi)}{(-i\xi)(\gamma - i\xi)} d\xi.$$

By using A–C, we can transform the contour of integration and reduce to the integral over the banks of the cut $(-i\infty, i\lambda_-]$. In the process of the transformation, the contour crosses two simple poles at $\xi = 0$ and $\xi = -i\gamma$ (if $-i\gamma$ is a root of $q + \psi(\xi)$, as in the case of puts on a nondividend-paying stock, there is no second pole, but there is no need to consider this case separately: The corresponding term below will automatically be 0), which gives the first two terms; in the integral over the banks of the cut, we make the change of the variable $\xi = iz$. The result is

$$W(x) = q/\gamma - (1/\gamma)(q + \psi(-i\gamma))\phi^-(-i\gamma)e^{\gamma x} + (2\pi)^{-1} \int_{-\infty}^{\lambda_-} \frac{\Psi_-(z)\phi_q^-(iz)\exp[-zx]}{z(z+\gamma)} dz. \tag{6.18}$$

For $z \le 0$, $\phi_q^-(iz) > 0$, and since $\lambda_- < -\gamma$, the denominator of the integrand is positive. From (6.10), the integrand is negative; hence it is a decreasing function of x on $(-\infty, 0)$. Since $0 < \gamma \le -\sigma_-$, $(1/\gamma)(q + \psi(-i\gamma))\phi^-(-i\gamma) \ge 0$. It follows that W is decreasing on $(-\infty, 0)$, and hence it suffices to show that $W(+0) \ge 0$.

If $\kappa_+ < 1$, the integrand is absolutely integrable uniformly in $x \in (-\infty, 0]$, and therefore

$$W(+0) = W(0) = (q/\gamma) - (1/\gamma)(q + \psi(-i\gamma))\phi^-(-i\gamma) + (2\pi)^{-1} \int_{-\infty}^{\lambda_-} \frac{\Psi_-(z)\phi_q^-(iz)}{z(z+\gamma)} dz.$$

By transforming the contour of integration back, and taking into account that $(q + \psi(\xi))\phi_q^-(\xi) = q\phi_q^+(\xi)^{-1}$, we arrive at

$$W(+0) = W(0) = q(2\pi)^{-1} \int_{-\infty+i\sigma}^{+\infty+i\sigma} \frac{d\xi}{\phi_q^+(\xi)(-i\xi)(\gamma - i\xi)}.$$

The integrand is holomorphic in the upper half-plane $\Im\xi > 0$ and admits an estimate via $C(1 + |\xi|)^{-2+\kappa_+}$ for $\Im\xi \ge \sigma > 0$. Hence, we can push the line of integration up, and in the limit $\sigma \to +\infty$ obtain zero. This finishes the proof in the case $\kappa_+ < 1$.

If $\kappa_+ = 1$, we can represent $(q + \psi(\xi))\phi_q^-(\xi) = q\phi_q^+(\xi)^{-1}$ in the form

$$(q + \psi(\xi))\phi_q^-(\xi) = qa_+(0)^{-1}(-i\xi) + \chi(\xi),$$

where $a_+(0) > 0$ and χ enjoys all the properties of $(q + \psi(\xi))\phi_q^-(\xi)$ in the case $\kappa_+ < 1$ that have been used above. Hence, if we use χ instead of $(q + \psi(\xi))\phi_q^-(\xi)$ in the constructions above, we obtain a nonnegative function. To finish the proof, it remains to notice that

$$\begin{aligned} W_1(x) &:= (2\pi)^{-1} \int_{-\infty+i\sigma}^{+\infty+i\sigma} \frac{\exp[ix\xi] qa_+(0)^{-1}(-i\xi)}{(-i\xi)(\gamma - i\xi)} d\xi \\ &= qa_+(0)^{-1} \mathbf{1}_{(-\infty,0]}(x) e^{\gamma x} \ge 0. \qquad \square \end{aligned}$$

Now we consider the general case of payoffs of the form (1.3).

THEOREM 6.4. *Let the following conditions be satisfied:*

(1) *the equation*

$$\sum_{j=1}^{m} c_j \phi_q^-(-i\gamma_j)^{-1} e^{\gamma_j h} = 0 \tag{6.19}$$

has the unique solution, call it $\tilde{h}$*;*

(2) g *can be represented in the form*

$$g(x) = \sum_{k=1}^{l} c_k^+ \exp[\gamma_k^+ x] - \sum_{k=1}^{l} c_k^- \exp[\gamma_k^- x], \tag{6.20}$$

where $c_k^\pm$ *are positive,* $\gamma_k^\pm \in (-\sigma_+, -\sigma_-]$ *are not necessarily different and satisfy*

$$\gamma_k^+ < \gamma_k^- \qquad \forall\, k, \tag{6.21}$$

$$c_k^+ \phi_q^-(-i\gamma_k^+)^{-1} e^{\gamma_k^+ h} = c_k^- \phi_q^-(-i\gamma_k^-)^{-1} e^{\gamma_k^- h} \qquad \forall\, k. \tag{6.22}$$

Then

(a) *the solution of the optimal stopping problem* (1.1) *in the class* $\mathcal{M}$ *exists and belongs to* $\mathcal{M}_0$*, the* $\tilde{h}$ *being the optimal exercise price;*
(b) *the price of the option can be calculated from* (4.27) *with any* $\sigma \in (\max_j(-\gamma_j), \sigma_+)$*, and*

$$\hat{u}(\xi) = \sum_{j=1}^{l} c_j \phi_q^-(-i\gamma_j)^{-1}(\gamma_j - i\xi)^{-1}. \tag{6.23}$$

Proof. First, notice that for payoffs (6.11), (2) follows from (1).

Second, the conditions (1) and (6.4) are evidently "additive" w.r.t. g in the sense that if g_1 and g_2 satisfy (1) (resp., (6.4)), then $g_1 + g_2$ also satisfies (1) (resp., (6.4)). Condition (2) allows one to reduce to the case of the payoff of the form

$$g(x) = Ae^{\gamma^+ x} - Be^{\gamma^- x},$$

where $A, B > 0$ and $\sigma_- \le -\gamma^+ < -\gamma^- < \sigma_+$. Further, by using (4.42), we can reduce the verification to the case of the payoff (6.15), where $\gamma = \gamma^- - \gamma^+ > 0$, and $\psi(\cdot - i\gamma^+)$ instead of ψ. Since the conditions A–C are invariant under such a shift in the argument of the characteristic exponent, we can repeat the end of the proof of Theorem 6.3. □

6.3. Verification of conditions of Lemma 6.1 for calls and options with payoffs (1.3). In all formulations and proofs above, change the signs and make the reflection w.r.t. the origin.

7. The smooth fit principle. Consider the case of put options.

THEOREM 7.1. *Let* ϕ_q^- *satisfy*

$$\int_{-\infty+i\sigma}^{+\infty+i\sigma} |\phi_q^-(\xi)(1 - i\xi)^{-1}| d\xi < +\infty \tag{7.1}$$

for some $\sigma \in (0, \sigma_+)$*. Then the price of the perpetual American put satisfies the smooth fit principle.*

Proof. By differentiating under the integral sign in (4.27), we obtain $V' = v$, where

$$v(x) := -\frac{K}{2\pi} \int_{-\infty+i\sigma}^{+\infty+i\sigma} e^{i(x-\tilde{h})\xi} \phi_q^-(\xi)(1 - i\xi)^{-1} d\xi < +\infty.$$

Hence, V is smooth if and if only v is continuous. Under condition (7.1), the Fourier transform of v is of the class $L_1(\mathbf{R})$; hence v is continuous, and the smooth fit principle holds. □

THEOREM 7.2. *Let* ϕ_q^- *admit a representation* $\phi_q^-(\xi) = c + \chi(\xi)$*, where* $c \ne 0$ *and* χ *satisfies* (7.1)*. Then the smooth fit principle fails.*

Proof. This time we obtain that $v = v_1 + v_2$, where v_1 is continuous, and

$$v_2(x) = -\frac{cK}{2\pi} \int_{-\infty+i\sigma}^{+\infty+i\sigma} \frac{\exp[i(x - \tilde{h})\xi] d\xi}{1 - i\xi} = -cK\mathbf{1}_{(-\infty,\tilde{h})}(x) e^{x-\tilde{h}},$$

which is discontinuous. □

Notice that for RLPE, condition (7.1) fails if and only if $\mu > 0$ and $\nu \in (0, 1)$.

As our results in sections 4 and 6 show, the natural candidate is determined from the equation $w(x) := \phi_q^-(D)^{-1}g(x) = 0$, and it can be singled out formally in one of the following forms:

I. *If there is a unique h such that $V(h;\cdot)$ is continuous, this h is the candidate; if $V(h;\cdot)$ is continuous for all h, then the candidate is chosen by the standard smooth fit principle.* (This observation was used in [30] for a jump process with the drift.)

II. *If there is an h such that $V'_x(h; H\pm 0)$ are finite, then h is the optimal boundary.*

The second principle works for purely non-Gaussian RLPE, i.e., for RLPE of order $\nu < 2$.

In all cases, one may say that the optimal choice of h makes $V(h,\cdot)$ "more smooth" at h than generically.

8. Appendix.

8.1. Proof of Lemma 6.2. The verification of A for NIG (and more generally, normal tempered stable Lévy processes (NTSLP)) and KoBoL is trivial due to the simplicity of the analytic expressions (2.18) and (2.17). In both cases, the characteristic exponents are continuous at the ends of the cuts, and there is no singularity mentioned in B.

Verification of C for NTSLP: Here $\lambda_- = -\alpha+\beta$, and for $z < -\alpha+\beta$,

$$\begin{aligned}
\Psi_-(z) &= i\delta[(\alpha^2-(\beta+i(iz-0)^2)^{\nu/2}-(\alpha^2-(\beta+i(iz+0)^2)^{\nu/2}]\\
&= i\delta[((\alpha+\beta-z-i0)(\alpha-\beta+z+i0))^{\nu/2}-((\alpha+\beta-z+i0)(\alpha-\beta+z-i0))^{\nu/2}]\\
&= i\delta(\alpha+\beta-z)^{\nu/2}[(\alpha-\beta+z+i0)^{\nu/2}-(\alpha-\beta+z+i0)^{\nu/2}]\\
&= i\delta(\alpha+\beta-z)^{\nu/2}(-\alpha+\beta-z)^{\nu/2}[e^{i\pi\nu/2}-e^{-i\pi\nu/2}]\\
&= -\delta(\alpha+\beta-z)^{\nu/2}(-\alpha+\beta-z)^{\nu/2}2\sin[\pi\nu/2]<0.
\end{aligned}$$

Verification for KoBoL: For $z<\lambda_-$,

$$\begin{aligned}
\Psi_-(z) &= ic\Gamma(-\nu)[-(-\lambda_- - i(iz-0))^\nu+(-\lambda_- - i(iz+0))^\nu]\\
&= -ic\Gamma(-\nu)[(-\lambda_-+z+i0)^\nu-(-\lambda_-+z-i0)^\nu]\\
&= -ic\Gamma(-\nu)(-z+\lambda_-)^\nu[e^{i\pi\nu}-e^{-i\pi\nu}]\\
&= c\Gamma(-\nu)(-z+\lambda_-)^\nu 2\sin(\pi\nu)<0,
\end{aligned}$$

since $\Gamma(-\nu)\sin(\pi\nu)<0$.

Equation (2.19) being more involved, the verification of A–C for HP is rather long, and we omit it here to save space.

8.2. Proof of Lemma 2.7. Part (a) for the lower half-plane is a part of the statement A of Lemma 6.2 proven above, so it remains to prove that there are no roots of $q+\psi(\xi)$ outside the imaginary axis. Take a large R and small $\epsilon>0$ so that all roots of $q+\psi(\xi)$ on $(i\lambda_-, i\lambda_+)$ lie on $(i(\lambda_-+2\epsilon), i(\lambda_+-2\epsilon))$, and construct a contour

$$\mathcal{L}_{\epsilon,R} = \mathcal{L}^+_{\epsilon,R}\cup\mathcal{L}^l_{\epsilon,R}\cup\mathcal{L}^-_{\epsilon,R}\cup\mathcal{L}^r_{\epsilon,R},$$

where

$$\begin{aligned}
\mathcal{L}^+_{\epsilon,R} &= \{\xi \mid |\xi|\le R,\ \Im\xi\ge\lambda_+-\epsilon,\ \operatorname{dist}(\xi,[i\lambda_+,+i\infty))=\epsilon\},\\
\mathcal{L}^-_{\epsilon,R} &= \{\xi \mid |\xi|\le R,\ \Im\xi\le\lambda_-+\epsilon,\ \operatorname{dist}(\xi,(-i\infty,i\lambda_-])=\epsilon\},\\
\mathcal{L}^l_{\epsilon,R} &= \{\xi \mid |\xi|= R,\ \Re\xi<0,\ \operatorname{dist}(\xi,[i\lambda_+,+i\infty)\cup(-i\infty,i\lambda_-])\ge\epsilon\},\\
\mathcal{L}^r_{\epsilon,R} &= \{\xi \mid |\xi|= R,\ \Re\xi>0,\ \operatorname{dist}(\xi,(-i\infty,i\lambda_-]\cup[i\lambda_+,+i\infty))\ge\epsilon\}.
\end{aligned}$$

Let $U_{\epsilon,R}$ be a part of the complex plane, bounded by $\mathcal{L}_{\epsilon,R}$, and $N \in \{0,1,2\}$ (resp., $N_{\epsilon,R}$) the number of roots of $q+\psi(\xi)$ on $(i(\lambda_- + 2\epsilon), i(\lambda_+ - 2\epsilon))$ (resp., on $U_{\epsilon,R}$). Since the complex plane with cuts $(-i\infty, i\lambda_-]$ and $[i\lambda_+, +i\infty)$ is a union of all $U_{\epsilon,R}$, and since $U_{\epsilon,R} \subset U_{\epsilon',R'}$ whenever $\epsilon \geq \epsilon'$ and $R \leq R'$, it suffices to show that for sufficiently large R and small $\epsilon > 0$, $N = N_{\epsilon,R}$.

We will do this for KoBoL; the other cases can be considered similarly. First we check that

$$q + \psi(\xi) \neq 0 \tag{8.1}$$

for any $\xi \in \mathcal{L}_{\epsilon,R}$, provided that $\epsilon > 0$ is sufficiently small and R is sufficiently large:

(1) For $\xi \in \mathcal{L}_{\epsilon,R}$ such that $\Im\xi \in [\lambda_-, \lambda_+]$, (8.1) holds by continuity of ψ for all $\epsilon \in (0, \epsilon_0)$ and $R \geq R_0$, provided that $\epsilon_0 > 0$ is sufficiently small and R_0 large.

(2) As $R \to +\infty$ and $|\xi| = R$,

$$q + \psi(\xi) \sim -i\mu\xi + o(|\xi|), \quad \nu \in (0,1), \tag{8.2}$$

and if $\nu \in (1,2)$ or $\mu = 0$ and $\nu \in (0,1)$,

$$q + \psi(\xi) \sim c\Gamma(-\nu)[(-i\xi)^\nu + (i\xi)^\nu] + o(|\xi|^\nu); \tag{8.3}$$

hence (8.1) holds for these R and ξ.

(3) Fix such R; then on parts of $\mathcal{L}_{\epsilon,R}$ near the cuts, (8.1) holds since the limits of the imaginary part of $q+\psi(\xi)$ are nonzero, namely, for $z > \lambda_+$,

$$\Im(q + \psi(iz \mp 0)) = -c\Gamma(-\nu)(z - \lambda_+)^\nu \sin(\mp\pi\nu), \tag{8.4}$$

and for $z < \lambda_-$,

$$\Im(q + \psi(iz \mp 0)) = -c\Gamma(-\nu)(-z + \lambda_-)^\nu \sin(\pm\pi\nu). \tag{8.5}$$

Thus, (8.1) has been proven, and now, to show that $N = N_{\epsilon,R}$, it suffices to verify an equality

$$\frac{1}{2\pi} \int_{\partial U_{\epsilon,R}} d\arg(q + \psi(\xi)) = N. \tag{8.6}$$

One can check (8.6) by considering various N and $\nu \in (0,1)$, $\nu \in (1,2)$; if $N = 1$, one has to distinguish cases $q + \psi(i\lambda_-) > 0$, $q + \psi(i\lambda_-) < 0$, and if $\nu \in (0,1)$, cases $\mu = 0$, $\mu > 0$, and $\mu < 0$.

We write down the argument for two cases; the other cases can be considered similarly.

1. If $\nu \in (1,2)$ or $\nu \in (0,1)$ and $\mu = 0$, and $N = 2$, then at $\xi = i(\lambda_- + \epsilon)$ and $\xi = i(\lambda_+ - \epsilon)$, $q + \psi(\xi)$ is negative and (8.3) holds. When ξ moves from $i(\lambda_+ - \epsilon)$ along $\mathcal{L}_{\epsilon,R}$ counterclockwise till an intersection point with a circle $|\xi| = R$, and $\epsilon > 0$ is small enough, $q + \psi(\xi)$ moves to the right half-plane due to (8.3), passing below the origin in the complex plane due to (8.4) and an inequality $-\Gamma(-\nu)\sin(-\pi\nu) < 0$. At the intersection point, it is (approximately) equal to $2c\Gamma(-\nu)\cos(\pi\nu)R^\nu$, due to (8.3). When ξ moves along $\mathcal{L}^l_{\epsilon,R}$ till the intersection with a line $\Re\xi = -\epsilon$, $q + \psi(\xi)$ remains in an angle of less than 2π and arrives at approximately the starting point $2c\Gamma(-\nu)\cos(\pi\nu)R^\nu$, due to (8.3). After that, ξ moves to $i(\lambda_- + \epsilon)$; due to (8.5),

$q + \psi(\xi)$ passes above the origin till a point on the negative real axis. In the result, we obtain

$$\frac{1}{2\pi} \int_{\xi \in \mathcal{L}_{\epsilon,R}, \Re\xi \le 0} d \arg(q + \psi(\xi)) = 1. \tag{8.7}$$

Similarly, we obtain (8.7) with $\Re\xi \ge 0$, and by adding the two integrals, we finish the proof of (8.6).

2. Let $N = 1$, $q + \psi(i\lambda_-) < 0$, and $\nu \in (0,1)$, $\mu > 0$. Then $q + \psi(i\lambda_+) > 0$, and therefore the first part of the journey described above is in the right half-plane $\Re\xi > 0$, due to (8.2) and an assumption $\mu > 0$. During the second part of the journey, $q + \psi(\xi)$ moves above the origin and arrives at (approximately) $-\mu R$, and after that moves to $i(i\lambda_- + \epsilon)$, remaining in the left half-plane. Thus, this time we obtain (8.7) with 1/2 in the RHS, and after completing the full circle, we obtain (8.6) with $N = 1$.

Acknowledgments. The second author thanks A.N. Shiryaev, A. Melnikov, O.E. Barndorff-Nielsen, Ken-Iti Sato, G. Peskir, participants of the Europhysics conference in Dublin (July 1999), the Probability Theory seminar at MGU (December 1999), and the Workshop on Lévy processes at the University of Aarhus (January 2000), for useful discussions. The first part of the work was done at the University of Aarhus, and the second author is grateful to O.E. Barndorff-Nielsen and the University of Aarhus for the hospitality.

We are also thankful to the anonymous referee for valuable remarks on the first version of the paper.

NORMAL FORMS AND BIFURCATIONS OF DISCRETE TIME NONLINEAR CONTROL SYSTEMS*

ARTHUR J. KRENER† AND LONG LI†

Abstract. The quadratic and cubic normal forms of discrete time nonlinear control systems are presented. These are the normal forms with respect to the group of state coordinate changes and invertible state feedbacks. We introduce the concept of a control bifurcation for such systems. A control bifurcation takes place at an equilibrium where there is a loss of linear stabilizability in contrast to a classical bifurcation, which typically takes place at an equilibrium where there is a loss of linear stability. We present the analogous control bifurcations to the well-known classical bifurcations; the fold, the transcritical, the flip, and the Neimark–Sacker bifurcations. When the loop is closed, a control bifurcation can lead to a classical bifurcation.

Key words. discrete time nonlinear control system, normal forms, bifurcations, control bifurcations

1. Introduction.

The theory of normal forms and bifurcations of nonlinear difference equations is well known [1], [5], [9], [13]. Briefly, it is as follows. Consider two smooth (C^4) n dimensional difference equations with equilibrium points

$$\begin{aligned} x^+ &= f(x), \\ 0 &= f(0) \end{aligned} \tag{1.1}$$

and

$$\begin{aligned} z^+ &= g(z), \\ 0 &= g(0), \end{aligned} \tag{1.2}$$

where $x^+(t) = x(t+1)$. These are *locally diffeomorphic* if there exists a local diffeomorphism

$$\begin{aligned} z &= \phi(x), \\ 0 &= \phi(0) \end{aligned} \tag{1.3}$$

which carries (1.1) to (1.2),

$$g(\phi(x)) = \phi(f(x)).$$

Such a local diffeomorphism carries trajectories $x(t)$ in its domain onto trajectories $z(t)$ in its range,

$$z(t) = \phi(x(t));$$

hence the two dynamics are locally smoothly equivalent.

There is a weaker notion of equivalence; (1.1) is *locally topologically conjugate* to (1.2) if there is a local homeomorphism (1.3) which carries trajectories $x(s)$ in its domain onto trajectories $z(t)$ in its range while preserving the orientation of time, but not the exact time.

The *linear approximation* of (1.1) around the fixed point $x = 0$ is

$$\delta x^+ = \frac{\partial f}{\partial x}(0)\ \delta x, \tag{1.4}$$

and this is a *hyperbolic fixed point* if $\frac{\partial f}{\partial x}(0)$ has no eigenvalues on the unit circle. The discrete time *Grobman–Hartman* theorem states that if the equilibrium $x = 0$ of (1.1) is hyperbolic, then it is locally topologically conjugate to its linear approximation (1.4). A related theorem is that two hyperbolic equilibria are locally topologically conjugate if their linear approximations have the same number of eigenvalues strictly inside the unit circle, the signs of their products are the same, and the same number of eigenavalues strictly outside and the signs of their products are the same [9].

A parametrized system

$$x^+ = f(x, \mu) \tag{1.5}$$

can have a locus of equilibria

$$x_e = f(x_e, \mu_e).$$

It undergoes a *local bifurcation* at an equilibrium $x_e,\ \mu_e$ that is not locally topologically conjugate to every nearby equilibrium. In light of the above, such a bifurcation can happen only if one or more eigenvalues of the linearized system cross the unit circle, or the sign of the product of the strictly stable eigenvalues changes, or the sign of the product of the strictly unstable eigenvalues changes.

A standard approach to analyzing the behavior of the parametrized system (1.5) around a bifurcation point is to add the parameter as an additional state with trivial dynamics

$$\mu^+ = \mu \tag{1.6}$$

and then compute the center manifold through the bifurcation point and the dynamics restricted to this manifold [3], [9]. The center manifold is an invariant manifold of the extended difference equation (1.5)–(1.6), which is tangent at the bifurcation point to the eigenspace of the eigenvalues on the unit circle. In practice, one does not compute the center manifold and its dynamics exactly; in most cases of interest, an approximation of degree two or three suffices. If the other eigenvalues are off the unit circle, then this part of the dynamics cannot affect the local topological conjugacy around the bifurcation point. If at the bifurcation point all of the eigenvalues of the linear approximation are inside or on the unit circle, then the bifurcation point will be locally asymptotically stable for the complete dynamics iff the dynamics on the center manifold is locally asymptotically stable. Of course, at some nearby equilibria the dynamics may be unstable.

The next step is to compute the Poincaré normal form of the center manifold dynamics. This is a normal form under smooth changes of coordinates

$$z = \phi(x) = Tx - \phi^{[2]}(x) - \phi^{[3]}(x) - \cdots, \tag{1.7}$$

where $\phi^{[d]}(x)$ denotes a vector field that is a homogeneous polynomial of degree d in x. The linear part of the change of coordinates T puts the linear part of the center manifold dynamics in Jordan form. The quadratic, cubic, and higher parts of the change of coordinates $\phi^{[2]}$ and $\phi^{[3]}$ simplify the quadratic, cubic, and higher parts of the center manifold dynamics by putting them in Poincaré normal form. From its normal form the bifurcation is recognized and understood. Examples are the fold (or saddle-node), the flip, and the Neimark–Sacker bifurcations. The first depends on the normal form of degree two, and the last two depend on the normal form of degree three. These are the only ones that are generic and of codimension 1, i.e., depend on a single parameter, so these are the most important.

Kang and Krener [6] developed a quadratic normal form for continuous time nonlinear systems whose linear part is controllable. This was extended to discrete time systems by Barbot, Monaco, and Normand-Cyrot [2]. These authors considered a larger group of transformations to bring the system to normal form, including invertible state feedback as well as change of state coordinates. Kang [7], [8] also developed a quadratic normal form for continuous time nonlinear systems whose linear part may have uncontrollable modes. Krener, Kang, and Chang [10], [4] described the quadratic and cubic normal forms of continuous time nonlinear control systems and also their bifurcations.

In this paper, we will develop quadratic and cubic normal forms for discrete time nonlinear control systems of the form

$$\begin{aligned} x^+ = f(x,u) = Ax + Bu + f^{[2]}(x,u) \\ +f^{[3]}(x,u) + O(x,u)^4, \end{aligned} \tag{1.8}$$

where x, u are of dimensions $n, 1$ and $f^{[d]}(x,u)$ denotes a vector field that is a homogeneous polynomial of degree d in x, u. We do not assume that the linear part of the system is controllable. Moreover, our linear and quadratic normal forms differ from that of [2] for linearly controllable systems.

We also describe some of the simplest bifurcations of discrete time nonlinear control systems. A control system does not need a parameter to bifurcate; the control can play the same role. The equilibria of a controlled difference equation,

$$x^+ = f(x,u), \tag{1.9}$$

are those values of x_e, u_e such that $f(x_e, u_e) = x_e$. The equilibria are conveniently parametrized by u or one of the state variables. Two key facts differentiate bifurcations of a control system (1.8) from that of a parametrized system (1.5). The first is that for the latter the structural stability of the equilibria is the crucial issue, but for the former the stabilizability by state feedback is the crucial issue. A control system (1.8) is linearly controllable (linearly stabilizable) at x_e, u_e if the local linear approximation

$$\delta x^+ = \frac{\partial f}{\partial x}(x_e, u_e)\ \delta x + \frac{\partial f}{\partial u}(x_e, u_e)\ \delta u$$

is controllable (stabilizable). If the linear approximation is stabilizable, then the nonlinear system is locally stabilizable. If the linear approximation is not stabilizable, then the nonlinear system may or may not be locally stabilizable, depending on higher degree terms. A *control bifurcation* of (1.8) takes place at an equilibrium where the linear approximation loses stabilizability. Notice that this is different from the bifurcation of a parametrized system (1.5), which takes place at an equilibrium where there

is a loss of structural stability with respect to parameter variations. To emphasize this distinction, we shall refer to the latter as a *classical bifurcation*.

The other difference between control and classical bifurcations is that when bringing the control system into normal form, a different group of transformations is used. For classical bifurcations, we use parameter dependent change of state coordinates and change of parameter coordinates, but for control bifurcations we use change of state coordinates and state dependent change of control coordinates (invertible state feedback) to simplify the dynamics.

2. Quadratic normal form. Consider a smooth (C^3) system of the form (1.8) under the action of linear and quadratic change of state coordinates and state feedback

$$z = \phi(x) = Tx - \phi^{[2]}(x), \tag{2.1}$$

$$v = \alpha(x,u) = Kx + Lu - \alpha^{[2]}(x,u), \tag{2.2}$$

where $T,\ L$ are invertible.

It is well known that there exist a linear change of coordinates T and a linear feedback $K,\ L$ that transform the system into the linear normal form

$$\begin{aligned}\begin{bmatrix} x_1^+ \\ x_2^+ \end{bmatrix} &= \begin{bmatrix} f_1(x_1,x_2,u) \\ f_2(x_1,x_2,u) \end{bmatrix} \\ &= \begin{bmatrix} A_1 & 0 \\ 0 & A_2 \end{bmatrix}\begin{bmatrix} x_1 \\ x_2 \end{bmatrix} + \begin{bmatrix} 0 \\ B_2 \end{bmatrix} u \\ &\quad + \begin{bmatrix} f_1^{[2]}(x_1,x_2,u) \\ f_2^{[2]}(x_1,x_2,u) \end{bmatrix} + O(x_1,x_2,u)^3,\end{aligned} \tag{2.3}$$

where $x_1,\ x_2$ are $n_1,\ n_2$ dimensional, $n_1 + n_2 = n$, A_1 is in Jordan form, and A_2, B_2 are in controller (Brunovsky) form:

$$A_2 = \begin{bmatrix} 0 & 1 & \dots & 0 \\ & \ddots & \ddots & \\ 0 & 0 & \dots & 1 \\ 0 & 0 & \dots & 0 \end{bmatrix}, \qquad B_2 = \begin{bmatrix} 0 \\ \vdots \\ 0 \\ 1 \end{bmatrix}.$$

The following result generalizes [11].

THEOREM 2.1. *Consider the system* (2.3)*, where A_1 is diagonal and A_2, B_2 are in Brunovsky form. There exist a quadratic change of coordinates and a quadratic feedback*

$$\begin{bmatrix} z_1 \\ z_2 \end{bmatrix} = \begin{bmatrix} x_1 \\ x_2 \end{bmatrix} - \begin{bmatrix} \phi_1^{[2]}(x_1,x_2) \\ \phi_2^{[2]}(x_1,x_2) \end{bmatrix},$$

$$v = u - \alpha^{[2]}(x_1,x_2,u)$$

which transform the system (2.3) *into the quadratic normal form*

$$\begin{aligned}\begin{bmatrix} z_1^+ \\ z_2^+ \end{bmatrix} &= \begin{bmatrix} A_1 & 0 \\ 0 & A_2 \end{bmatrix}\begin{bmatrix} z_1 \\ z_2 \end{bmatrix} + \begin{bmatrix} 0 \\ B_2 \end{bmatrix} v \\ &\quad + \begin{bmatrix} \tilde f_1^{[2;0]}(z_1;z_2,v) & + & \tilde f_1^{[1;1]}(z_1;z_2,v) & + & \tilde f_1^{[0;2]}(z_1;z_2,v) \\ 0 & + & 0 & + & \tilde f_2^{[0;2]}(z_1;z_2,v) \end{bmatrix} \\ &\quad + O(z_1,z_2,v)^3,\end{aligned} \tag{2.4}$$

where $\tilde{f}_i^{[d_1;d_2]}(z_1; z_2, v)$ *is a polynomial vector field homogeneous of degree* d_1 *in* z_1 *and homogeneous of degree* d_2 *in* z_2, v. *For notational convenience, we define* $z_{2,n_2+1} = v$.

The vector field $\tilde{f}_1^{[2;0]}$ *is in the quadratic normal form of Poincaré,*

$$\tilde{f}_1^{[2;0]} = \sum_{\lambda_i=\lambda_j\lambda_k} \beta_i^{jk}\ \mathbf{e}_1^i\ z_{1,j}\ z_{1,k}, \tag{2.5}$$

where $\lambda_1, \ldots, \lambda_{n_1}$ *are the eigenvalues of* A_1, $\mathbf{e}_r^i$ *is the* ith *unit vector in* z_r *space, and* $z_{r,i}$ *is the* ith *component of* z_r. *The other vector fields are as follows:*

$$\begin{aligned}\tilde{f}_1^{[1;1]} = &\sum_{\lambda_i=0}\sum_{\lambda_j=0}\sum_{k=1}^{n_2+1} \gamma_i^{jk}\ \mathbf{e}_1^i\ z_{1,j}\ z_{2,k} \\ &+ \sum_{\lambda_i\neq 0}\sum_{\lambda_j\neq 0} \gamma_i^{j1}\ \mathbf{e}_1^i\ z_{1,j}\ z_{2,1},\end{aligned} \tag{2.6}$$

$$\tilde{f}_1^{[0;2]} = \sum_{\lambda_i\neq 0}\sum_{k=1}^{n_2+1} \delta_i^{1k}\ \mathbf{e}_1^i\ z_{2,1}\ z_{2,k}, \tag{2.7}$$

$$\tilde{f}_2^{[0;2]} = \sum_{i=1}^{n_2-1}\sum_{k=i+2}^{n_2+1} \epsilon_i^{1k}\ \mathbf{e}_2^i\ z_{2,1}\ z_{2,k}. \tag{2.8}$$

The normal form is unique; that is, each system (2.3) *can be transformed into only one such normal form* (2.4)–(2.8) *by a quadratic change of coordinates* (2.1) *and quadratic feedback* (2.2). *This follows from the fact that the numbers in the above,* $\beta_i^{jk}, \gamma_i^{jk}, \delta_i^{1k}, \epsilon_i^{1k}$ *for the indicated indices, are moduli, i.e., continuous invariants of the system* (2.3) *under a quadratic change of coordinates and quadratic feedback. Let* $\sigma_{jk} = 2$ *if* $j = k$ *and* $\sigma_{jk} = 1$ *otherwise. The moduli are defined as follows:*

$$\begin{aligned}\beta_i^{jk} = &\frac{1}{\sigma_{jk}}\ \frac{\partial^2 f_{1,i}}{\partial x_{1,j}\partial x_{1,k}}(0,0,0) \\ &\text{for } 1 \le i,\ j,k \le n_1,\ \text{and } \lambda_i = \lambda_j\lambda_k,\end{aligned} \tag{2.9}$$

$$\begin{aligned}\gamma_i^{jk} = &\frac{\partial^2 f_{1,i}}{\partial x_{1,j}\partial x_{2,k}}(0,0,0) \\ &\text{for } 1 \le i,\ j \le n_1,\ 1 \le k \le n_2+1,\ \text{and } \lambda_i = \lambda_j = 0,\end{aligned} \tag{2.10}$$

$$\begin{aligned}\gamma_i^{j1} = &\sum_{l=0}^{n_2} \left(\frac{\lambda_i}{\lambda_j}\right)^l \frac{\partial^2 f_{1,i}}{\partial x_{1,j}\partial x_{2,l+1}}(0,0,0) \\ &\text{for } 1 \le i,\ j \le n_1,\ \text{and } \lambda_i\lambda_j \neq 0,\end{aligned} \tag{2.11}$$

$$\begin{aligned}\delta_i^{1k} = &\frac{1}{\sigma_{1k}} \sum_{l=0}^{n_2-k+1} \lambda_i^l \frac{\partial^2 f_{1,i}}{\partial x_{2,1+l}\partial x_{2,k+l}}(0,0,0) \\ &\text{for } 1 \le i \le n_1,\ 1 \le k \le n_2+1,\ \text{and } \lambda_i \neq 0,\end{aligned} \tag{2.12}$$

$$\begin{aligned}\epsilon_i^{1k} = &\sum_{l=0}^{n_2-k+1} \frac{\partial^2 f_{2,i+l}}{\partial x_{2,1+l}\partial x_{2,k+l}}(0,0,0) \\ &\text{for } 1 \le i \le n_2-1 \text{ and } i+2 \le k \le n_2+1.\end{aligned} \tag{2.13}$$

Remarks. If some of the eigenvalues of A_1 are complex, then a linear complex change of coordinates is required to bring it to Jordan form. In this case, some of

the coordinates of z_1 are complex conjugate pairs, and some of the coefficients in the normal form are complex. These complex coefficients occur in conjugate pairs so that the real dimension of the coefficient space of the normal form is unchanged.

In the normal form of Poincaré (2.5), the eigenvalues satisfying $\lambda_i = \lambda_j \lambda_k$ are said to be in quadratic resonance.

We defer the proof to a later section as it is quite lengthy.

3. Cubic normal form. We present the cubic normal form of a system that is already in linear and quadratic normal form.

THEOREM 3.1. *Consider a smooth* (C^4) *system*

$$\begin{aligned}\begin{bmatrix} x_1^+ \\ x_2^+ \end{bmatrix} &= \begin{bmatrix} f_1(x_1, x_2, u) \\ f_2(x_1, x_2, u) \end{bmatrix} \\ &= \begin{bmatrix} A_1 & 0 \\ 0 & A_2 \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \end{bmatrix} + \begin{bmatrix} 0 \\ B_2 \end{bmatrix} u \\ &\quad + \begin{bmatrix} f_1^{[2;0]}(x_1; x_2, u) \\ 0 \end{bmatrix} + \begin{bmatrix} f_1^{[1;1]}(x_1; x_2, u) \\ 0 \end{bmatrix} + \begin{bmatrix} f_1^{[0;2]}(x_1; x_2, u) \\ f_2^{[0;2]}(x_1; x_2, u) \end{bmatrix} \\ &\quad + \begin{bmatrix} f_1^{[3]}(x_1; x_2, u) \\ f_2^{[3]}(x_1; x_2, u) \end{bmatrix} + O(x_1, x_2, u)^4, \end{aligned} \tag{3.1}$$

where A_1 *is diagonal,* A_2, B_2 *are in Brunovsky form, and the quadratic terms are in the normal form of Theorem* 2.1. *There exist a cubic change of coordinates and a cubic feedback*

$$\begin{bmatrix} z_1 \\ z_2 \end{bmatrix} = \begin{bmatrix} x_1 \\ x_2 \end{bmatrix} - \begin{bmatrix} \phi_1^{[3]}(x_1, x_2) \\ \phi_2^{[3]}(x_1, x_2) \end{bmatrix},$$

$$v = u - \alpha^{[3]}(x_1, x_2, u)$$

which transform the system (3.1) *into the cubic normal form*

$$\begin{aligned}\begin{bmatrix} z_1^+ \\ z_2^+ \end{bmatrix} &= \begin{bmatrix} A_1 & 0 \\ 0 & A_2 \end{bmatrix} \begin{bmatrix} z_1 \\ z_2 \end{bmatrix} + \begin{bmatrix} 0 \\ B_2 \end{bmatrix} v \\ &\quad + \begin{bmatrix} f_1^{[2;0]}(z_1; z_2, v) \\ 0 \end{bmatrix} + \begin{bmatrix} f_1^{[1;1]}(z_1; z_2, v) \\ 0 \end{bmatrix} + \begin{bmatrix} f_1^{[0;2]}(z_1; z_2, v) \\ f_2^{[0;2]}(z_1; z_2, v) \end{bmatrix} \\ &\quad + \begin{bmatrix} \tilde{f}_1^{[3;0]}(z_1; z_2, v) \\ 0 \end{bmatrix} + \begin{bmatrix} \tilde{f}_1^{[2;1]}(z_1; z_2, v) \\ 0 \end{bmatrix} \\ &\quad + \begin{bmatrix} \tilde{f}_1^{[1;2]}(z_1; z_2, v) \\ \tilde{f}_2^{[1;2]}(z_1; z_2, v) \end{bmatrix} + \begin{bmatrix} \tilde{f}_1^{[0;3]}(z_1; z_2, v) \\ \tilde{f}_2^{[0;3]}(z_1; z_2, v) \end{bmatrix} + O(z_1, z_2, v)^4. \end{aligned} \tag{3.2}$$

The vector field $\tilde{f}_1^{[3;0]}$ *is in the cubic normal form of Poincaré,*

$$\tilde{f}_1^{[3;0]} = \sum_{\lambda_i = \lambda_j \lambda_k \lambda_l} \beta_i^{jkl} \, \mathbf{e}_1^i \; z_{1,j} \; z_{1,k} \; z_{1,l}, \tag{3.3}$$

and the other vector fields are as follows:

$$\tilde{f}_1^{[2;1]} = \sum_{\lambda_i=0} \sum_{\lambda_j\lambda_k=0} \sum_{l=1}^{n_2+1} \gamma_i^{jkl}\ \mathbf{e}_1^i\ z_{1,j}\ z_{1,k}\ z_{2,l}$$

$$+ \sum_{\lambda_i\neq 0} \sum_{\lambda_j\lambda_k\neq 0} \gamma_i^{jk1}\ \mathbf{e}_1^i\ z_{1,j}\ z_{1,k}\ z_{2,1}, \tag{3.4}$$

$$\tilde{f}_1^{[1;2]} = \sum_{\lambda_i=0} \sum_{\lambda_j=0} \sum_{k=1}^{n_2+1} \sum_{l=k}^{n_2+1} \delta_i^{jkl}\ \mathbf{e}_1^i\ z_{1,j}\ z_{2,k}\ z_{2,l}$$

$$+ \sum_{\lambda_i\neq 0} \sum_{\lambda_j\neq 0} \sum_{l=1}^{n_2+1} \delta_i^{j1l}\ \mathbf{e}_1^i\ z_{1,j}\ z_{2,1}\ z_{2,l}, \tag{3.5}$$

$$\tilde{f}_1^{[0;3]} = \sum_{\lambda_i\neq 0} \sum_{k=1}^{n_2+1} \sum_{l=k}^{n_2+1} \epsilon_i^{1kl}\ \mathbf{e}_1^i\ z_{2,1}\ z_{2,k}\ z_{2,l}, \tag{3.6}$$

$$\tilde{f}_2^{[1;2]} = \sum_{i=1}^{n_2-1} \sum_{\lambda_j\neq 0} \sum_{l=i+2}^{n_2+1} \zeta_i^{j1l}\ \mathbf{e}_2^i\ z_{1,j}\ z_{2,1}\ z_{2,l}, \tag{3.7}$$

$$\tilde{f}_2^{[0;3]} = \sum_{i=1}^{n_2-1} \sum_{l=i+2}^{n_2+1} \sum_{k=1}^{l} \eta_i^{1kl}\ \mathbf{e}_2^i\ z_{2,1}\ z_{2,k}\ z_{2,l}. \tag{3.8}$$

The normal form is unique; that is, each system (3.1) *can be transformed into only one such normal form* (3.2)–(3.8). *This follows from the fact that the numbers in the above,* $\beta_i^{jkl}, \gamma_i^{jkl}, \delta_i^{1kl}, \epsilon_i^{1kl}, \zeta_i^{j1l}, \eta_i^{1kl}$ *for the indicated indices, are moduli of the system* (2.3) *under a cubic change of coordinates and cubic feedback. Let* $\sigma_{jkl} = 6$ *if* $j = k = l$ *and* $\sigma_{jkl} = \sigma_{jk}\sigma_{kl}\sigma_{jl}$ *otherwise. These moduli are defined as follows:*

$$\beta_i^{jkl} = \frac{1}{\sigma_{jkl}}\ \frac{\partial^3 f_{1,i}}{\partial x_{1,j}\partial x_{1,k}\partial x_{1,l}}(0,0,0) \tag{3.9}$$

for $1 \le i,\ j,k,l \le n_1$, *and* $\lambda_i = \lambda_j\lambda_k\lambda_l$,

$$\gamma_i^{jkl} = \frac{1}{\sigma_{jk}}\ \frac{\partial^3 f_{1,i}}{\partial x_{1,j}\partial x_{1,k}\partial x_{2,l}}(0,0,0) \tag{3.10}$$

for $1 \le i \le n_1,\ 1 \le j \le k \le n_1,\ 1 \le l \le n_2+1$,
and $\lambda_i = \lambda_j\lambda_k = 0$,

$$\gamma_i^{jk1} = \frac{1}{\sigma_{jk}} \sum_{r=0}^{n_2-k+1} \left(\frac{\lambda_i}{\lambda_j\lambda_k}\right)^r \frac{\partial^3 f_{1,i}}{\partial x_{1,j}\partial x_{1,k}\partial x_{2,r+1}}(0,0,0) \tag{3.11}$$

for $1 \le i \le n_1,\ 1 \le j \le k \le n_1$, *and* $\lambda_i\lambda_j\lambda_k \neq 0$,

$$\delta_i^{jkl} = \frac{1}{\sigma_{kl}}\ \frac{\partial^3 f_{1,i}}{\partial x_{1,j}\partial x_{2,k}\partial x_{2,l}}(0,0,0) \tag{3.12}$$

for $1 \le i,\ j \le n_1,\ 1 \le k \le l \le n_2+1$, *and* $\lambda_i = \lambda_j = 0$,

$$\delta_i^{j1l} = \frac{1}{\sigma_{1l}} \sum_{r=0}^{n_2-l+1} \left(\frac{\lambda_i}{\lambda_j}\right)^l \frac{\partial^3 f_{1,i}}{\partial x_{1,j}\partial x_{2,1+r}\partial x_{2,l+r}}(0,0,0) \tag{3.13}$$

for $1 \le i,\ j \le n_1,\ 1 \le k \le n_2+1$, *and* $\lambda_i\lambda_j\lambda_k \neq 0$,

$$\epsilon_i^{1kl} = \frac{1}{\sigma_{1kl}} \sum_{r=0}^{n_2-l+1} \lambda_i^r \frac{\partial^3 f_{1,i}}{\partial x_{2,1+r}\partial x_{2,k+r}\partial x_{2,l+r}}(0,0,0) \tag{3.14}$$

$$\text{for } 1 \le i \le n_1,\ 1 \le k \le l,\ i+2 \le l \le n_2+1,\ \text{and } \lambda_i \neq 0,$$

$$\zeta_i^{j1l} = \frac{1}{\sigma_{1l}} \sum_{r=0}^{n_2-l+1} \lambda_j^{-r} \frac{\partial^3 f_{2,i+r}}{\partial x_{1,j} \partial x_{2,1+r} \partial x_{2,l+r}}(0,0,0) \tag{3.15}$$

$$\text{for } 1 \le i \le n_2-1,\ i+2 \le l \le n_2+1,\ \text{and } \lambda_j \neq 0,$$

$$\eta_i^{1kl} = \frac{1}{\sigma_{1kl}} \sum_{r=0}^{n_2-l+1} \frac{\partial^3 f_{2,i+r}}{\partial x_{2,1+r} \partial x_{2,k+r} \partial x_{2,l+r}}(0,0,0) \tag{3.16}$$

$$\text{for } 1 \le i \le n_2-1,\ 1 \le k \le l,\ \text{and } i+2 \le l \le n_2+1.$$

Remarks. Once again, if some of the eigenvalues of A_1 are complex, then a linear complex change of coordinates is required to bring it to Jordan form. In this case, some of the coordinates of z_1 are complex conjugate pairs, and some of the coefficients in the normal form are complex. These complex coefficients occur in conjugate pairs so that the real dimension of the coefficient space of the normal form is unchanged.

In the normal form of Poincaré (3.3), the eigenvalues satisfying $\lambda_i = \lambda_j \lambda_k \lambda_l$ are said to be in cubic resonance.

We defer the proof to a later section as it is quite lengthy.

4. Control bifurcations. In the above theorems, there are many more details than are necessary to understand the types of bifurcations that are possible. Recall that, in the bifurcation theory of a parametrized system of difference equations, the interesting part of the dynamics is that restricted to the center manifold. This leads to a great reduction in the dimension of space that must be explored. A similar fact holds true when studying control bifurcations. In most applications, one will ultimately use state feedback in an attempt to stabilize the system so the coordinates that are linearly stabilizable can be ignored to a large extent. If there are modes which are neutrally stable and are not linearly stabilizable, then the particular choice of feedback will influence the shape of the center manifold of the closed loop system and the dynamics thereon. It might be possible to achieve asymptotically stable center manifold dynamics by the proper choice of feedback although it will not be exponentially stable. We now discuss some important bifurcations of control systems.

4.1. Fold control bifurcation. Just as with classical bifurcations of discrete time dynamical systems, the simplest control bifurcation is the fold. The uncontrollable part is one dimensional and unstable with $A_1 > 1$. Because the linearly controllable part of the quadratic normal form (2.4) is in Brunovsky form, the equilibria z_e, v_e are conveniently parametrized by $\mu = v_e$. The equilibria $z_e(\mu), v_e(\mu)$ are given by

$$z_{e1} = \mu^2 (1 - A_1)^{-1} \tilde{\delta} + O(\mu)^3, \tag{4.1}$$

$$z_{e2,i} = \mu + O(\mu)^2, \qquad i = 1, \ldots, n_2, \tag{4.2}$$

$$v_e = \mu, \tag{4.3}$$

where

$$\tilde{\delta} = \sum_{k=1}^{n_2+1} \delta_1^{1k}.$$

The local linearization around z_e, v_e is

$$\begin{aligned}\begin{bmatrix} \tilde{z}_1^+ \\ \tilde{z}_2^+ \end{bmatrix} &= \left(\begin{bmatrix} A_1 + \mu\gamma_1^{11} & \mu\Delta \\ 0 & A_2 \end{bmatrix} + O(\mu)^2 \right) \begin{bmatrix} \tilde{z}_1 \\ \tilde{z}_2 \end{bmatrix} \\ &\quad + \left(\begin{bmatrix} \mu B_1 \\ B_2 \end{bmatrix} + O(\mu)^2 \right) \tilde{v}, \end{aligned} \tag{4.4}$$

where $\tilde{z} = z - z_e(\mu)$, $\tilde{v} = v - v_e(\mu)$, and

$$\begin{aligned}\Delta &= \begin{bmatrix} \tilde{\delta} + \delta_1^{11} & \delta_1^{12} & \dots & \delta_1^{1n_2} \end{bmatrix}, \\ B_1 &= \delta_1^{1,n_2+1}. \end{aligned}$$

If the transversality condition

$$\tilde{\delta} + \delta_1^{11} + A_1\delta_1^{12} + \cdots + A_1^{n_2}\delta_1^{1,n_2+1} \neq 0 \tag{4.5}$$

is satisfied, then the system is linearly controllable and hence stabilizable about any equilibrium except $\mu = 0$. Consider a parametrized family of feedbacks

$$\begin{aligned} v &= \kappa(z, \mu), \\ \tilde{v} &= K_1(\mu)\tilde{z_1} + K_2(\mu)\tilde{z_2}. \end{aligned} \tag{4.6}$$

Ideally one would like to find a smooth family of feedbacks that makes the family of equilibria asymptotically stable, i.e., for each small μ, the closed loop system

$$z^+ = \tilde{f}(z, \kappa(z, \mu))$$

is asymptotically stable to $z_e(\mu)$. Notice that the lowest degree terms of more general smooth feedbacks will be like (4.6). We restrict our attention to smooth feedbacks for practical and mathematical reasons. Smooth feedbacks are easy to implement, and they allow an analysis of the closed loop system based on the low degree terms.

Clearly the z_2 subsystem is stabilizable for all μ by the proper choice of K_2, and this feedback gain can be chosen independent of μ. The question is: Can we find $K_1(\mu)$ which stabilizes the z_1 coordinate?

Since the linear approximations are stabilizable for $\mu \neq 0$, it is certainly possible to find a stabilizing feedback at each such μ. The linear approximation at $\mu = 0$ has an uncontrollable, unstable mode, so it is not possible to stabilize it. But is it possible to stabilize the approximations for $\mu \neq 0$ with a feedback that is bounded through $\mu = 0$? The answer is no for systems with a fold control bifurcation. For any bounded feedback, the closed loop system will be unstable in some neighborhood of $\mu = 0$.

To see this, note that the closed loop linear approximation

$$\begin{bmatrix} \tilde{z}_1^+ \\ \tilde{z}_2^+ \end{bmatrix} = \left(\begin{bmatrix} A_1 + \mu\left(\gamma_1^{11} + B_1K_1\right) & \mu\left(\Delta + B_1K_2\right) \\ B_2K_1 & A_2 + B_2K_2 \end{bmatrix} + O(\mu)^2 \right) \begin{bmatrix} \tilde{z}_1 \\ \tilde{z}_2 \end{bmatrix} \tag{4.7}$$

is clearly unstable at $\mu = 0$ since it has an eigenvalue $A_1 > 1$. Furthermore, if the feedback $v = K_2(\mu)z_2$ stabilizes the z_2 subsystem, then A_1 is a simple root of the characteristic polynomial of the closed loop system when $\mu = 0$. Hence there is a simple root near A_1 of the characteristic polynomial for all small $|\mu|$.

By using larger and larger gain, it is possible to stabilize the system closer and closer to $\mu = 0$. But if the feedback gain is continuous, at best it will stabilize the closed loop system for only some small but not too small $\mu > 0$ or only some small

but not too small $\mu < 0$. The controllability of z_1 reverses direction (folds) at $\mu = 0$, so a continuous choice of feedback gain cannot stabilize on both sides of $\mu = 0$. If a smooth family of feedbacks (4.6) does stabilize the system for some small $\mu > 0$, the parametrized closed loop system generically undergoes a classical fold bifurcation at some smaller $\mu > 0$. A classical fold bifurcation is also called a limit point bifurcation, a saddle-node bifurcation, or a turning point bifurcation.

We illustrate this with a simple example in normal form:

$$\begin{aligned} z_1^+ &= 2z_1 - z_2^2, \\ z_2^+ &= v. \end{aligned}$$

The equilibria are $z_{e,1} = \mu^2,\ z_{e,2} = \mu,\ v_e = \mu$. Under the feedback $v = K_1(\mu)\tilde{z}_1 + K_2(\mu)\tilde{z}_2$, the closed loop linear approximation is

$$\begin{bmatrix} \tilde{z}_1^+ \\ \tilde{z}_2^+ \end{bmatrix} = \begin{bmatrix} 2 & -2\mu \\ K_1(\mu) & K_2(\mu) \end{bmatrix} \begin{bmatrix} \tilde{z}_1 \\ \tilde{z}_2 \end{bmatrix},$$

where $\tilde{z} = z - z_e(\mu),\ \tilde{v} = v - v_e(\mu)$. If $K(\mu)$ is bounded, then as $\mu \to 0$ one eigenvalue converges to 2, so the system is unstable for small $|\mu|$. If we choose $K_1 = 15/2$ and $K_2 = -1/2$, then the closed loop linear approximation is stable for $|\mu| > 0.1$ and unstable for $|\mu| < 0.1$. It undergoes a fold bifurcation at $\mu = 0.1$.

To see this, consider the closed loop nonlinear system under this feedback in coordinates centered at the bifurcation $\bar{z}_1 = z_1 - 0.01,\ \bar{z}_2 = z_2 - 0.1,\ \bar{\mu} = \mu - 0.1$,

$$\begin{aligned} \bar{z}_1^+ &= 2\bar{z}_1 - 0.2\bar{z}_2 - \bar{z}_2^2, \\ \bar{z}_2^+ &= 7.5\bar{z}_1 - 0.5\bar{z}_2 - 7.5\bar{\mu}^2. \end{aligned}$$

It is convenient to reparametrize by $\nu = 7.5\bar{\mu}^2 \geq 0$. The center manifold is given by

$$\bar{z}_2 = -2\nu + 5\bar{z}_1 + 440\nu^2 - 600\nu\bar{z}_1 + 250\bar{z}_1^2 + O(\bar{z}_1, \nu)^3,$$

and the center manifold dynamics is

$$\bar{z}_1^+ = 0.4\nu + \bar{z}_1 - 92\nu^2 + 140\nu\bar{z}_1 - 75\bar{z}_1^2 + O(\bar{z}_1, \nu)^3$$

or, in the variables $\hat{z}_1 = \sqrt{75}(\bar{z}_1 - 0.9333\nu),\ \hat{\nu} = 0.4\nu - 26.667\nu^2$,

$$\hat{z}_1^+ = \hat{\nu} + \hat{z}_1 - \hat{z}_1^2 + O(\hat{z}_1, \hat{\nu})^3,$$

the familiar form of a discrete time fold bifurcation [9].

4.2. Transcritical control bifurcation. A degenerate form of the above bifurcation occurs when the uncontrollable part is one dimensional and neutrally stable, $A_1 = 1$. The equilibria z_e, v_e depend on roots z_1, μ of the quadratic form

$$0 = \beta_1^{11} z_1^2 + \gamma_1^{11} z_1 \mu + \tilde{\delta}\mu^2.$$

If this form is positive or negative definite, then there is only an isolated equilibrium $z_1 = z_{2,1} = \cdots z_{2,n_2} = v = 0$.

If this form is indefinite but not degenerate, i.e., if it has a positive and a negative eigenvalue, then there are two curves of equilibria that cross at $z_1 = z_{2,1} = \cdots z_{2,n_2} =$

$v = 0$. Suppose that $z_1 = c_k\mu,\ k = 1, 2$, are the two lines of roots of the quadratic form; then the equilibria z_e, v_e are given by

$$\begin{aligned} z_1 &= c_k\mu + O(\mu)^2, && k = 1, 2, \\ z_{e2,i} &= \mu + O(\mu)^2, && i = 1, \ldots, n_2, \\ v_e &= \mu. \end{aligned}$$

Suppose $z_e(\mu),\ v_e(\mu)$ is one curve of equilibria, and one chooses a parametrized family of smooth feedbacks (4.6), where $\tilde{z} = z - z_e(\mu),\ \tilde{v} = v - v_e(\mu)$. Notice that the closed loop system has a single curve of equilibria. The closed loop approximation (4.7) has $\lambda = A_1 = 1$ as an eigenvalue at $\mu = 0$. This eigenvalue is a function $\lambda = \lambda(\mu)$ and

$$\frac{d\lambda}{d\mu}(0) = \gamma_1^{11} + B_1K_1(0),$$

so generically the eigenvalues pass through the unit circle at $\mu = 0$, and the closed loop system goes from stable to unstable through a classical fold bifurcation.

Suppose one chooses a parametrized family of smooth feedbacks that preserves both curves of equilibria,

$$\begin{aligned} &v = \kappa(z, \mu), \\ &\tilde{v} = K_1(\mu)(z_1 - c_1\mu + O(\mu)^2)(z_1 - c_2\mu + O(\mu)^2) + K_2(\mu)\tilde{z}_2. \end{aligned}$$

Then generically the closed loop system undergoes a classical transcritical bifurcation.

If the quadratic form is degenerate, then the locus or loci of equilibria may depend on cubic and higher terms.

4.3. Flip control bifurcation. The next simplest control bifurcation of a discrete time system is the flip. The uncontrollable part is again one dimensional and unstable, but now $A_1 \leq -1$. The equilibria z_e, v_e are conveniently parametrized by $\mu = v_e$. The equilibria $z_e(\mu), v_e(\mu)$ are given by (4.1), and the local linearizations are given by (4.4). If the transversality condition (4.5) is satisfied, then these are controllable when $\mu \neq 0$ but unstabilizable when $\mu = 0$.

One can find a parametrized family of smooth feedbacks (4.6) which will stabilize the z_2 modes for all μ and the z_1 mode for some range of $\mu \neq 0$. If $A_1 < -1$, then as $\mu \to 0$ it requires larger and larger gain to stabilize the latter. To see this, note that the closed loop linear approximation (4.7) is clearly unstable at $\mu = 0$ since $A_1 < -1$. Furthermore, if the feedback $v = K_2(\mu)z_2$ stabilizes the z_2 subsystem, then A_1 is a simple root of the characteristic polynomial of the closed loop system when $\mu = 0$. Hence there is a simple root near A_1 of the characteristic polynomial for all small $|\mu|$.

By using larger and larger gain, it is possible to stabilize the system closer and closer to $\mu = 0$. But if the feedback gain is bounded, at best it will stabilize the closed loop system only for some small but not too small $\mu > 0$ and/or only some small but not too small $\mu < 0$. If a smooth family of feedbacks (4.6) does stabilize the system for some small $\mu > 0$, the parametrized closed loop system generically undergoes a classical flip bifurcation at some smaller $\mu > 0$.

We illustrate this with an example:

$$\begin{aligned} z_1^+ &= -2z_1 + z_2^2, \\ z_2^+ &= v. \end{aligned}$$

The equilibria are $z_{e,1} = \frac{1}{3}\mu^2,\ z_{e,2} = \mu,\ v_e = \mu$. Under the feedback $v = K_1(\mu)\tilde{z}_1 + K_2(\mu)\tilde{z}_2$, the closed loop linear approximation is

$$\begin{bmatrix} \tilde{z}_1^+ \\ \tilde{z}_2^+ \end{bmatrix} = \begin{bmatrix} -2 & 2\mu \\ K_1(\mu) & K_2(\mu) \end{bmatrix} \begin{bmatrix} \tilde{z}_1 \\ \tilde{z}_2 \end{bmatrix},$$

where $\tilde{z} = z - z_e(\mu),\ \tilde{v} = v - v_e(\mu)$. If $K(\mu)$ is bounded, then as $\mu \to 0$ one eigenvalue converges to -2, so the system is unstable for small $|\mu|$. If we choose $K_1 = -15/2$ and $K_2 = 1/2$, then the closed loop linear approximation is stable for $|\mu| > 0.1$ and unstable for $|\mu| < 0.1$. It undergoes a classical flip bifurcation at $\mu = 0.1$.

To see this, consider the closed loop nonlinear system under this feedback in coordinates centered at the the bifurcation $\bar{z}_1 = z_1 - 1/300,\ \bar{z}_2 = z_2 - 1/10,\ \bar{\mu} = \mu - 1/10$,

$$\begin{aligned} \bar{z}_1^+ &= -2\bar{z}_1 + 0.2\bar{z}_2 + \bar{z}_2^2, \\ \bar{z}_2^+ &= -7.5\bar{z}_1 + 0.5\bar{z}_2 + \bar{\mu} + 2.5\bar{\mu}^2. \end{aligned}$$

It is convenient to reparametrize by $\nu = \bar{\mu} + 2.5\bar{\mu}^2$. The center manifold is given by

$$\bar{z}_2 = 0.67\nu + 5\bar{z}_1 - 10.37\nu^2 + 111.11\nu\bar{z}_1 - 83.33\bar{z}_1^2 + O(\bar{z}_1, \nu)^3,$$

and the center manifold dynamics is

$$\begin{aligned} \bar{z}_1^+ = {} & 0.13\nu - \bar{z}_1 - 1.63\nu^2 + 2.89\nu\bar{z}_1 + 8.33\bar{z}_1^2 \\ & -123.12\nu^3 + 1763.0\nu^2\bar{z}_1 - 111.11\nu\bar{z}_1^2 - 1944.4\bar{z}_1^3 + O(\bar{z}_1, \nu)^4, \end{aligned}$$

or, in the variables

$$\begin{aligned} \hat{\nu} &= 3\nu + 172.50\nu^2, \\ \hat{z}_1 &= -2.87\nu + 43.30\bar{z}_1 - 8.02\nu^2 + 24.06\nu\bar{z}_1 - 180.42\bar{z}_1^2 \\ &\quad +48.11\nu^3 - 360.84\nu^2\bar{z}_1 + 2706.3\nu\bar{z}_1, \end{aligned}$$

the parametrized closed loop system is

$$\begin{aligned} \hat{\nu}^+ &= \hat{\nu}, \\ \hat{z}_1^+ &= -\hat{z}_1 + \hat{\nu}\hat{z}_1 - \hat{z}_1^3 + O(\hat{\nu}, \hat{z}_1)^4, \end{aligned}$$

a familiar form of a discrete time flip bifurcation [9].

4.4. Neimark–Sacker control bifurcation. The discrete time analogue of a classical Hopf bifurcation is called a Neimark–Sacker bifurcation. We present the control analogue of this bifurcation. The uncontrollable modes are a nonzero complex conjugate pair,

$$A_1 = \begin{bmatrix} \lambda & 0 \\ 0 & \bar{\lambda} \end{bmatrix},$$

where $\lambda = \rho e^{i\theta},\ \bar{\lambda} = \rho e^{-i\theta},\ \theta \neq 0, \pi/2, \pi, 3\pi/2$. The equilibria $z_e(\mu), v_e(\mu)$ are given by

$$\begin{bmatrix} z_{e1,1} \\ z_{e1,2} \end{bmatrix} = \mu^2(I - A_1)^{-1} \begin{bmatrix} \tilde{\delta}_1 \\ \tilde{\delta}_2 \end{bmatrix} + O(\mu)^3, \tag{4.8}$$

$$z_{e2,i} = \mu + O(\mu)^2, \qquad i = 1, \ldots, n_2, \tag{4.9}$$

$$v_e = \mu, \tag{4.10}$$

where

$$\tilde{\delta}_i = \sum_{k=1}^{n_2+1} \delta_i^{1k}.$$

The local linearization around z_e, v_e is

$$\begin{aligned}\begin{bmatrix} \tilde{z}_1^+ \\ \tilde{z}_2^+ \end{bmatrix} &= \left(\begin{bmatrix} A_1 + \mu\Gamma & \mu\Delta \\ 0 & A_2 \end{bmatrix} + O(\mu)^2 \right) \begin{bmatrix} \tilde{z}_1 \\ \tilde{z}_2 \end{bmatrix} \\ &\quad + \left(\begin{bmatrix} \mu B_1 \\ B_2 \end{bmatrix} + O(\mu)^2 \right) \tilde{v}, \end{aligned} \tag{4.11}$$

where $\tilde{z} = z - z_e(\mu)$, $\tilde{v} = v - v_e(\mu)$, and

$$\Gamma = \begin{bmatrix} \gamma_1^{11} & \gamma_1^{21} \\ \gamma_2^{11} & \gamma_2^{21} \end{bmatrix},$$

$$\Delta = \begin{bmatrix} \tilde{\delta}_1 + \delta_1^{11} & \delta_1^{12} & \dots & \delta_1^{1n_2} \\ \tilde{\delta}_2 + \delta_2^{11} & \delta_2^{12} & \dots & \delta_2^{1n_2} \end{bmatrix},$$

$$B_1 = \begin{bmatrix} \delta_1^{1,n_2+1} \\ \delta_2^{1,n_2+1} \end{bmatrix}.$$

If the transversality condition

$$\begin{bmatrix} \tilde{\delta}_1 + \delta_1^{11} \\ \tilde{\delta}_2 + \delta_2^{11} \end{bmatrix} + A_1 \begin{bmatrix} \delta_1^{12} \\ \delta_2^{12} \end{bmatrix} + \cdots + A_1^{n_2} \begin{bmatrix} \delta_1^{1,n_2+1} \\ \delta_2^{1,n_2+1} \end{bmatrix} \neq 0 \tag{4.12}$$

is satisfied, then the system is linearly controllable and hence stabilizable about any equilibrium except $\mu = 0$. Consider a parametrized family of feedbacks (4.6).

If $\rho < 1$, then the system is stabilizable about any equilibrium, but if $\rho \geq 1$, then the system is not stabilizable when $\mu = 0$. The case $\rho \geq 1$ is called a Neimark–Sacker control bifurcation. We distinguish two subcases, $\rho > 1$ and $\rho = 1$.

If $\rho > 1$, then it requires larger and larger gain to stabilize the system closer and closer to $\mu = 0$. Since the feedback (4.6) is smooth, it will stabilize only for some small $\mu > 0$ or for some small $\mu < 0$ but not both. At $\mu = 0$, the poles of the closed loop system are $\lambda, \bar{\lambda}$ and the poles of $A_2 + B_2 K_2(0)$. The latter can be made stable, but the former are unstable. Since the feedback is bounded, as $\mu \to 0$ the poles converge to these. The system is controllable for $\mu \neq 0$, so the poles can be placed arbitrarily by feedback. The poles associated primarily with the z_2 subsystem can be kept stable, but the two poles associated primarily with the z_1 subsystem will leave the unit disk at some small value(s) of μ. Depending on the choice of feedback, they will leave one at a time as real poles, leave together through ± 1, or leave together as a nonzero complex conjugate pair. If they leave separately as real poles, then generically the closed loop system undergoes a fold or flip bifurcation as the first pole leaves through ± 1. If they leave together as a complex conjugate pair that is neither real nor imaginary, then generically the system undergoes a Neimark–Sacker bifurcation. If they leave together through ± 1, the situation can be quite complicated and will not be discussed here.

If $\rho = 1$ and the feedback (4.6) is continuous, then generically the system undergoes a Neimark–Sacker bifurcation at $\mu = 0$ provided that $e^{ik\theta} \neq 1$ for $k = 1, 2, 3, 4$. We illustrate this with an example:

$$z_{1,1}^+ = e^{i\pi/4} z_{1,1} + z_2^2,$$

$$\begin{aligned} z_{1,2}^+ &= e^{-i\pi/4} z_{1,2} + z_2^2, \\ x_2 &= u. \end{aligned}$$

The equilibria are

$$\begin{aligned} z_{e1,1} &= c\mu^2, \\ z_{e1,2} &= \bar{c}\mu^2, \\ x_{e2} &= \mu, \\ u_e &= \mu, \end{aligned}$$

where $c = \left(1 - e^{i\pi/4}\right)^{-1}$. The linear approximations are

$$\begin{aligned} \tilde{z}_{1,1}^+ &= e^{i\pi/4} \tilde{z}_{1,1} + 2\mu \tilde{z}_2, \\ \tilde{z}_{1,2}^+ &= e^{-i\pi/4} \tilde{z}_{1,2} + 2\mu \tilde{z}_2, \\ \tilde{x}_2^+ &= \tilde{u}, \end{aligned}$$

where $\tilde{z}_{1,1} = z_{1,1} - c\mu^2$, $\tilde{z}_{1,2} = z_{1,2} - \bar{c}\mu^2$, $\tilde{x}_z = z_2 - \mu$, $\tilde{u} = u - \mu$. The linear approximations are controllable except at $\mu = 0$.

The feedback

$$u = \mu + 0.5(z_{1,1} - c\mu^2) + 0.5(z_{1,2} - \bar{c}\mu^2) + 0.5(x_2 - \mu)$$

places the poles of the closed loop system inside the open unit disk at $0.7953 \pm 0.5743i$, 0.3957 at $\mu = 0.1$. A pair of poles leaves the unit disk at $e^{\pm i\pi/4}$ when $\mu = 0$.

The closed loop dynamics undergoes a Neimark–Sacker classical bifurcation at $\mu = 0$. The discrete time analogue of the first Lyapunov coefficient is found in Kuznetsov [9, p. 186, formula (5.74)]. For this example, its value is 46.8, which indicates that the system undergoes a subcritical Neimark–Sacker bifurcation at $\mu = 0$. For small $\mu > 0$, the equilibrium is exponentially stable, but there is an unstable invariant closed curve nearby. For small $\mu < 0$, the equilibrium is unstable as is the bifurcation equilibrium $\mu = 0$.

5. Proof of the quadratic normal form. We can expand the change of coordinates and feedback as follows:

$$\begin{aligned} \begin{bmatrix} z_1 \\ z_2 \end{bmatrix} = \begin{bmatrix} x_1 \\ x_2 \end{bmatrix} &- \begin{bmatrix} \phi_1^{[2;0]}(x_1; x_2) \\ \phi_2^{[2;0]}(x_1; x_2) \end{bmatrix} \\ &- \begin{bmatrix} \phi_1^{[1;1]}(x_1; x_2) \\ \phi_2^{[1;1]}(x_1; x_2) \end{bmatrix} - \begin{bmatrix} \phi_1^{[0;2]}(x_1; x_2) \\ \phi_2^{[0;2]}(x_1; x_2) \end{bmatrix}, \end{aligned}$$

$$\begin{aligned} v = u &- \alpha^{[2;0]}(x_1; x_2, u) \\ &- \alpha^{[1;1]}(x_1; x_2, u) - \alpha^{[0;2]}(x_1; x_2, u). \end{aligned}$$

These do not change the linear part of the dynamics. The quadratic part of the dynamics is changed to

$$\begin{aligned} \tilde{f}_i^{[d_1;d_2]}(z_1; z_2, v) = f_i^{[d_1;d_2]}(z_1; z_2, v) \\ - \phi_i^{[d_1;d_2]}(A_1 z_1; A_2 z_2) \\ + A_i \phi_i^{[d_1;d_2]}(z_1; z_2) \\ - B_i \alpha^{[d_1;d_2]}(z_1; z_2, v), \end{aligned}$$

where $B_1 = 0$, so the proof splits into six cases, $i = 1, 2$; $d_1 = 0, 1, 2$; $d_2 = 2 - d_1$.

The normal form of $\tilde{f}_2^{[0;2]}(z_1; z_2, v)$. We start by showing that $\tilde{f}_2^{[0;2]}(z_1; z_2, v)$ can be brought into the above form. There are two basic operations, *pull up* and *push down*, which are used to achieve this. Consider a part of the dynamics

$$\begin{aligned} z_{2,i-1}^+ &= z_{2,i} + \cdots, \\ z_{2,i}^+ &= z_{2,i+1} + cz_{2,j}z_{2,k} + \cdots, \\ z_{2,i+1}^+ &= z_{2,i+2} + \cdots, \end{aligned}$$

where $1 < i \le n_2$, $1 \le j \le k \le n_2 + 1$; recall that $z_{2,n+1} = v$.

If $1 < j$, we can *pull up* the quadratic term by defining

$$\bar{z}_{2,i} = z_{2,i} - cz_{2,j-1}z_{2,k-1},$$

and then the dynamics becomes

$$\begin{aligned} z_{2,i-1}^+ &= \bar{z}_{2,i} + cz_{2,j-1}z_{2,k-1} + \cdots, \\ \bar{z}_{2,i}^+ &= z_{2,i+1} + \cdots, \\ z_{2,i+1}^+ &= z_{2,i+2} + \cdots, \end{aligned}$$

and all the other quadratic terms remain the same. Notice that if $i = 1$, we can still pull up, and the term disappears. By pulling up all the quadratic terms until $j = 1$, we obtain

$$z_{2,i}^+ = z_{2,i+1} + cz_{2,1}z_{2,k} + \cdots. \tag{5.1}$$

The other operation on the dynamics is *push down*. If $k \le n_2$, define

$$\bar{z}_{2,i+1} = z_{2,i+1} + cz_{2,j}z_{2,k}$$

yielding

$$\begin{aligned} z_{2,i-1}^+ &= z_{2,i} + \cdots, \\ z_{2,i}^+ &= \bar{z}_{2,i+1} + \cdots, \\ \bar{z}_{2,i+1}^+ &= z_{2,i+2} + cz_{2,j+1}z_{2,k+1} + \cdots, \end{aligned}$$

and all the other quadratic terms remain unchanged. Notice that if $i + 1 = n_2$, then we can absorb the quadratic term into the control using feedback. From (5.1) we push down every term where $k \le i + 1$. These terms can be pushed all the way down and absorbed in the control. The result is (2.8).

Next we show that the number ϵ_i^{1k} (2.13) is an invariant. Clearly ϵ_i^{1k} is potentially changed only by $\phi_2^{[0;2]}(x_1; x_2)$ and $\alpha_2^{[0;2]}(x_1; x_2, u)$. Therefore, we need only consider coordinate changes of the form

$$\bar{x}_{2,\rho} = x_{2,\rho} + cx_{2,\sigma}x_{2,\tau},$$

where $1 \le \rho \le n_2$, $1 \le \sigma \le \tau \le n_2$, and feedbacks of the form

$$\bar{u} = u + cx_{2,\sigma}x_{2,\tau},$$

where $1 \le \sigma \le \tau \le n_2 + 1$ with $x_{2,n+1} = u$. More general coordinate changes and feedbacks are just compositions of these. The coordinate change affects only a piece of the dynamics (2.3),

$$\begin{aligned} x^+_{2,\rho-1} &= x_{2,\rho} + f^{[2]}_{2,\rho-1}(x_1, x_2, u) + O(x_1, x_2, u)^3, \\ x^+_{2,\rho} &= x_{2,\rho+1} + f^{[2]}_{2,\rho}(x_1, x_2, u) + O(x_1, x_2, u)^3 \end{aligned}$$

is transformed to

$$\begin{aligned} x^+_{2,\rho-1} &= \bar{x}_{2,\rho} + f^{[2]}_{2,\rho-1}(x_1, x_2, u) - c x_{2,\sigma} x_{2,\tau} + O(x_1, x_2, u)^3, \\ \bar{x}^+_{2,\rho} &= x_{2,\rho+1} + f^{[2]}_{2,\rho}(x_1, x_2, u) + c x_{2,\sigma+1} x_{2,\tau+1} + O(x_1, x_2, u)^3, \end{aligned}$$

and ϵ^{1k}_i is unchanged. The feedback affects only

$$x^+_{2,n_2} = u + f^{[2]}_{2,n_2}(x_1, x_2, u) + O(x_1, x_2, u)^3,$$

transforming it into

$$x^+_{2,n_2} = \bar{u} + f^{[2]}_{2,n_2}(x_1, x_2, u) - c x_{2,\sigma} x_{2,\tau} + O(x_1, x_2, u)^3,$$

and again ϵ^{1k}_i is unchanged because $i + l \le n_2 - 1$.

The normal form of $\tilde{f}^{[1;1]}_2(z_1; z_2, v)$. The two basic operations, pull up and push down, are slightly different. Consider a part of the dynamics

$$\begin{aligned} z^+_{2,i-1} &= z_{2,i} + \cdots, \\ z^+_{2,i} &= z_{2,i+1} + c z_{1,j} z_{2,k} + \cdots, \\ z^+_{2,i+1} &= z_{2,i+2} + \cdots, \end{aligned}$$

where $1 < i \le n_2$, $1 \le j \le n_1$, $1 \le k \le n_2 + 1$.

If $\lambda_j \ne 0$ and $1 < k$, we can pull up the quadratic term by defining

$$\bar{z}_{2,i} = z_{2,i} - \frac{c}{\lambda_j} z_{1,j} z_{2,k-1};$$

then the dynamics becomes

$$\begin{aligned} z^+_{2,i-1} &= \bar{z}_{2,i} + \frac{c}{\lambda_j} z_{1,j} z_{2,k-1} + \cdots, \\ \bar{z}^+_{2,i} &= z_{2,i+1} + \cdots, \\ z^+_{2,i+1} &= z_{2,i+2} + \cdots, \end{aligned}$$

and all the other quadratic terms remain the same. Again, if $i = 1$, we can still pull up, and the term disappears. So by pulling up all quadratic terms where $\lambda_j \ne 0$ until $k = 1$, we obtain

$$z^+_{2,i} = z_{2,i+1} + c z_{1,j} z_{2,1} + \cdots.$$

Repeated pushing down eliminates this term. Define

$$\bar{z}_{2,i+1} = z_{2,i+1} + c z_{1,j} z_{2,1},$$

yielding

$$\begin{aligned} z^+_{2,i-1} &= z_{2,i} + \cdots, \\ z^+_{2,i} &= \bar{z}_{2,i+1} + \cdots, \\ \bar{z}^+_{2,i+1} &= z_{2,i+2} + c\lambda_j z_{1,j} z_{2,2} + \cdots, \end{aligned}$$

and all the other quadratic terms remain unchanged. If $\lambda_j = 0$, then the term drops out. If $\lambda_j \neq 0$, then we can continue to push down until $i+1 = n_2$ and the quadratic term can be absorbed into the control using feedback. The result is $\tilde{f}_2^{[1;1]}(z_1; z_2, v) = 0$.

The normal form of $\tilde{f}_2^{[2;0]}(z_1; z_2, v)$. Consider a part of the dynamics

$$\begin{aligned} z^+_{2,i} &= z_{2,i+1} + c z_{1,j} z_{1,k} + \cdots, \\ z^+_{2,i+1} &= z_{2,i+2} + \cdots, \end{aligned}$$

where $1 \leq i \leq n_2$, $1 \leq j \leq k \leq n_1$.

Pushing down one or more times eliminates this term. Define

$$\bar{z}_{2,i+1} = z_{2,i+1} + c z_{1,j} z_{1,k},$$

yielding

$$\begin{aligned} z^+_{2,i-1} &= z_{2,i} + \cdots, \\ z^+_{2,i} &= \bar{z}_{2,i+1} + \cdots, \\ \bar{z}^+_{2,i+1} &= z_{2,i+2} + c\lambda_j\lambda_k z_{1,j} z_{1,k} + \cdots, \end{aligned}$$

and all the other quadratic terms remain unchanged. If $\lambda_j \lambda_k = 0$, then the term drops out. Otherwise, the quadratic term can be pushed down repeatedly until it is absorbed in the control. The result is $\tilde{f}_2^{[2;0]}(z_1; z_2, v) = 0$.

The normal form of $\tilde{f}_1^{[2;0]}(z_1; z_2, v)$. This is just the quadratic normal form of Poincaré as described in the introduction, and β_i^{jk} are the invariants. See [1], [5], [9], or [13]. Consider a part of the dynamics

$$z^+_{1,i} = \lambda_i z_{1,i} + c z_{1,j} z_{1,k} + \cdots,$$

where $1 \leq i \leq n_1$, $1 \leq j \leq k \leq n_1$.

If $\lambda_i \neq \lambda_j \lambda_k$, then define

$$\bar{z}_{1,i} = z_{1,i} - \frac{c}{(\lambda_j \lambda_k - \lambda_i)} z_{1,j} z_{1,k}$$

so that

$$\bar{z}^+_{1,i} = \lambda_i \bar{z}_{1,i} + \cdots.$$

Next we show that the numbers β_i^{jk} (2.9) are invariants. Clearly β_i^{jk} is potentially changed only by $\phi_1^{[2;0]}(x_1; x_2)$. Therefore, we need only consider coordinate changes of the form

$$\bar{x}_{1,\rho} = x_{1,\rho} + c x_{1,\sigma} x_{1,\tau},$$

where $1 \le \rho \le n_1$, $1 \le \sigma \le \tau \le n_1$, because more general ones are just compositions of these. This coordinate change affects only a piece of the dynamics (2.3), and

$$x^+_{1,\rho} = \lambda_\rho x_{1,\rho} + f^{[2]}_{1,\rho}(x_1, x_2, u) + O(x_1, x_2, u)^3$$

is transformed to

$$\bar{x}^+_{1,\rho} = \lambda_\rho \bar{x}_{1,\rho} + f^{[2]}_{1,\rho}(x_1, x_2, u) + c(\lambda_\sigma \lambda_\tau - \lambda_\rho) x_{1,\sigma} x_{1,\tau} + O(x_1, x_2, u)^3.$$

Clearly, if $\lambda_\rho = \lambda_\sigma \lambda_\tau$, then β^{jk}_i (2.9) is unchanged.

The normal form of $\tilde{f}^{[1;1]}_1(z_1; z_2, v)$. Consider a part of the dynamics

$$z^+_{1,i} = \lambda_i z_{1,i} + c z_{1,j} z_{2,k} + \cdots,$$

where $1 \le i \le n_1$, $1 \le j \le n_1$, $1 \le k \le n_2 + 1$.

If $\lambda_j \neq 0$ and $k > 1$, then we can pull up by defining

$$\bar{z}_{1,i} = z_{1,i} - \frac{c}{\lambda_j} z_{1,j} z_{2,k-1}$$

so that

$$\bar{z}^+_{1,i} = \lambda_i \bar{z}_{1,i} + \frac{c\lambda_i}{\lambda_j} z_{1,j} z_{2,k-1} + \cdots.$$

If $\lambda_i = 0$, then the term disappears; otherwise, we can continue to pull up until $k = 1$.

If $\lambda_i \neq 0$, then we can push down by defining

$$\bar{z}_{1,i} = z_{1,i} + \frac{c}{\lambda_i} z_{1,j} z_{2,k};$$

then

$$\bar{z}^+_{1,i} = \lambda_i \bar{z}_{1,i} + \frac{c\lambda_j}{\lambda_i} z_{1,j} z^+_{2,k} + \cdots.$$

If $\lambda_j = 0$, then the term disappears.

If $\lambda_i = \lambda_j = 0$, then we cannot pull up or push down. The result is (2.7).

Next we show that the numbers γ^{jk}_i (2.10)–(2.11) are invariants. Clearly γ^{jk}_i is potentially changed only by $\phi^{[1;1]}_1(x_1; x_2)$. Therefore, we need only consider coordinate changes of the form

$$\bar{x}_{1,\rho} = x_{1,\rho} + c x_{1,\sigma} x_{2,\tau},$$

where $1 \le \rho, \sigma \le n_1$, $1 \le \tau \le n_2$, because more general ones are just compositions of these. This coordinate change affects only a piece of the dynamics (2.3), and

$$x^+_{1,\rho} = \lambda_\rho x_{1,\rho} + f^{[2]}_{1,\rho}(x_1, x_2, u) + O(x_1, x_2, u)^3$$

is transformed to

$$\bar{x}^+_{1,\rho} = \lambda_\rho \bar{x}_{1,\rho} + f^{[2]}_{1,\rho}(x_1, x_2, u) + c\lambda_\sigma x_{1,\sigma} x_{2,\tau+1} - c\lambda_\rho x_{1,\sigma} x_{2,\tau} + O(x_1, x_2, u)^3.$$

Clearly, if $\lambda_\rho = \lambda_\sigma = 0$, then γ^{jk}_i (2.10) is unchanged. A simple calculation shows that if $\lambda_\rho \lambda_\sigma \neq 0$, then γ^{j1}_i (2.11) is unchanged.

The normal form of $\tilde{f}_1^{[0;2]}(z_1; z_2, v)$. Consider a part of the dynamics

$$z_{1,i}^+ = \lambda_i z_{1,i} + c z_{2,j} z_{2,k} + \cdots,$$

where $1 \le i \le n_1$, $1 \le j \le k \le n_2$.

If $j > 1$, then we can pull up by defining

$$\bar{z}_{1,i} = z_{1,i} - c z_{2,j-1} z_{2,k-1};$$

then

$$\bar{z}_{1,i}^+ = \lambda_i \bar{z}_{1,i} + c\lambda_i z_{2,j-1} z_{2,k-1} + \cdots.$$

If $\lambda_i = 0$, then the term disappears; otherwise, we can continue to pull up until $j = 1$. The result is (2.7).

Finally, we show that the numbers δ_i^{1k} (2.12) are invariants. Clearly, δ_i^{1k} is potentially changed only by $\phi_1^{[0;2]}(x_1; x_2)$. Therefore, we need only consider coordinate changes of the form

$$\bar{x}_{1,\rho} = x_{1,\rho} + c x_{2,\sigma} x_{2,\tau},$$

where $1 \le \rho \le n_1$, $1 \le \sigma \le \tau \le n_2$, because more general ones are just compositions of these. This change of coordinates affects only a piece of the dynamics (2.3), and

$$x_{1,\rho}^+ = \lambda_\rho x_{1,\rho} + f_{1,\rho}^{[2]}(x_1, x_2, u) + O(x_1, x_2, u)^3$$

is transformed to

$$\bar{x}_{1,\rho}^+ = \lambda_\rho \bar{x}_{1,\rho} + f_{1,\rho}^{[2]}(x_1, x_2, u) + c x_{2,\sigma+1} x_{2,\tau+1} - c\lambda_\rho x_{2,\sigma} x_{2,\tau} + O(x_1, x_2, u)^3.$$

Clearly, if $\lambda_\rho \ne 0$, then δ_i^{1k} (2.12) is unchanged.

6. Proof of the cubic normal form. Cubic changes of coordinates and cubic feedbacks do not change the linear and quadratic parts of the system. Their effect on the cubic part of the system splits into cases, this time eight cases, $i = 1, 2$; $d_1 = 0, 1, 2, 3$; $d_2 = 3 - d_1$.

The normal form of $\tilde{f}_2^{[0;3]}(z_1; z_2, v)$. We again use the two basic operations pull up and push down. Consider a part of the dynamics

$$\begin{aligned} z_{2,i-1}^+ &= z_{2,i} + f_{2,i-1}^{[2]}(z_1, z_2, v) + \cdots, \\ z_{2,i}^+ &= z_{2,i+1} + f_{2,i}^{[2]}(z_1, z_2, v) + c z_{2,j} z_{2,k} z_{2,l} + \cdots, \\ z_{2,i+1}^+ &= z_{2,i+2} + f_{2,i+1}^{[2]}(z_1, z_2, v) + \cdots, \end{aligned}$$

where $1 < i \le n_2$, $1 \le j \le k \le l \le n_2 + 1$; recall that $z_{2,n+1} = v$.

If $1 < j$, we can *pull up* the cubic term by defining

$$\bar{z}_{2,i} = z_{2,i} - c z_{2,j-1} z_{2,k-1} z_{2,l-1};$$

then the dynamics becomes

$$\begin{aligned} z_{2,i-1}^+ &= \bar{z}_{2,i} + f_{2,i-1}^{[2]}(z_1, z_2, v) + c z_{2,j-1} z_{2,k-1} z_{2,l-1} + \cdots, \\ \bar{z}_{2,i}^+ &= z_{2,i+1} + f_{2,i}^{[2]}(z_1, z_2, v) + \cdots, \\ z_{2,i+1}^+ &= z_{2,i+2} + f_{2,i+1}^{[2]}(z_1, z_2, v) + \cdots, \end{aligned}$$

and all the other cubic terms remain the same. Notice that if $i = 1$, we can still pull up, and the term disappears. By pulling up all cubic terms until $j = 1$, we obtain that

$$z^+_{2,i} = z_{2,i+1} + f^{[2]}_{2,i}(z_1, z_2, v) + cz_{2,1}z_{2,k}z_{2,l} + \cdots. \tag{6.1}$$

The other operation on the dynamics is *push down*. If $l \le n_2$, define

$$\bar{z}_{2,i+1} = z_{2,i+1} + cz_{2,j}z_{2,k}z_{2,l},$$

yielding

$$\begin{aligned} z^+_{2,i-1} &= z_{2,i} + f^{[2]}_{2,i-1}(z_1, z_2, v) + \cdots, \\ z^+_{2,i} &= \bar{z}_{2,i+1} + f^{[2]}_{2,i}(z_1, z_2, v) + \cdots, \\ \bar{z}^+_{2,i+1} &= z_{2,i+2} + f^{[2]}_{2,i+1}(z_1, z_2, v) + cz_{2,j+1}z_{2,k+1}z_{2,l+1} + \cdots, \end{aligned}$$

and all the other cubic terms remain unchanged. Notice that if $i + 1 = n_2$, then we can absorb the cubic term into the control. From (6.1) we push down every term where $l \le i + 1$. These terms can be pushed all the way down and absorbed in the control. The result is (3.8).

Next we show that the number η^{1kl}_i (3.16) is an invariant. Clearly η^{1kl}_i is potentially changed only by $\phi^{[0;3]}_2(x_1; x_2)$ and $\alpha^{[0;3]}_2(x_1; x_2, u)$. Therefore, we need only consider coordinate changes of the form

$$\bar{x}_{2,\rho} = x_{2,\rho} + cx_{2,\sigma}x_{2,\tau}x_{2,\upsilon},$$

where $1 \le \rho \le n_2$, $1 \le \sigma \le \tau \le \upsilon \le n_2$, and feedbacks of the form

$$\bar{u} = u + cx_{2,\sigma}x_{2,\tau}x_{2,\upsilon},$$

where $1 \le \rho \le n_2, 1 \le \sigma \le \tau \le \upsilon \le n_2 + 1$ with $x_{2,n+1} = u$ because more general ones are just compositions of these. The coordinate change affects only a piece of the dynamics (3.1),

$$\begin{aligned} x^+_{2,\rho-1} &= x_{2,\rho} + f^{[2]}_{2,\rho-1}(x_1, x_2, u) + f^{[3]}_{2,\rho-1}(x_1, x_2, u), \\ x^+_{2,\rho} &= x_{2,\rho+1} + f^{[2]}_{2,\rho}(x_1, x_2, u) + f^{[3]}_{2,\rho}(x_1, x_2, u) \end{aligned}$$

is transformed to

$$\begin{aligned} x^+_{2,\rho-1} &= \bar{x}_{2,\rho} + f^{[2]}_{2,\rho-1}(x_1, x_2, u) + f^{[3]}_{2,\rho-1}(x_1, x_2, u) - cx_{2,\sigma}x_{2,\tau}x_{2,\upsilon}, \\ \bar{x}^+_{2,\rho} &= x_{2,\rho+1} + f^{[2]}_{2,\rho}(x_1, x_2, u) + f^{[3]}_{2,\rho}(x_1, x_2, u) + cx_{2,\sigma+1}x_{2,\tau+1}x_{2,\upsilon+1}, \end{aligned}$$

and η^{1kl}_i is unchanged. The feedback affects only

$$x^+_{2,n_2} = u + f^{[2]}_{2,n_2}(x_1, x_2, u) + f^{[3]}_{2,n_2}(x_1, x_2, u),$$

transforming it into

$$x^+_{2,n_2} = \bar{u} + f^{[2]}_{2,n_2}(x_1, x_2, u) + f^{[3]}_{2,n_2}(x_1, x_2, u) - cx_{2,\sigma}x_{2,\tau}x_{2,\upsilon},$$

and again η^{1kl}_i is unchanged because $i + r \le n_2 - 1$.

The normal form of $\tilde{f}_2^{[1;2]}(z_1; z_2, v)$. The two basic operations, pull up and push down, are slightly different. Consider a part of the dynamics

$$\begin{aligned} z_{2,i-1}^+ &= z_{2,i} + f_{2,i-1}^{[2]}(z_1, z_2, v) + \cdots, \\ z_{2,i}^+ &= z_{2,i+1} + f_{2,i}^{[2]}(z_1, z_2, v) + cz_{1,j}z_{2,k}z_{2,l} + \cdots, \\ z_{2,i+1}^+ &= z_{2,i+2} + f_{2,i}^{[2]}(z_1, z_2, v) + \cdots, \end{aligned}$$

where $1 < i \le n_2$, $1 \le j \le n_1$, $1 \le k \le l \le n_2 + 1$.

If $\lambda_j \neq 0$ and $1 < k$, we can pull up the cubic term by defining

$$\bar{z}_{2,i} = z_{2,i} - \frac{c}{\lambda_j} z_{1,j} z_{2,k-1} z_{2,l-1};$$

then the dynamics becomes

$$\begin{aligned} z_{2,i-1}^+ &= \bar{z}_{2,i} + \frac{c}{\lambda_j} z_{1,j} z_{2,k-1} z_{2,l-1} + \cdots, \\ \bar{z}_{2,i}^+ &= z_{2,i+1} + \cdots, \\ z_{2,i+1}^+ &= z_{2,i+2} + \cdots, \end{aligned}$$

and all the other cubic terms remain the same. Again, if $i = 1$, we can still pull up, and the term disappears. So by pulling up all cubic terms where $\lambda_j \neq 0$ until $k = 1$, we obtain

$$z_{2,i}^+ = z_{2,i+1} + f_{2,i}^{[2]}(z_1, z_2, v) + cz_{1,j}z_{2,1}z_{2,l} + \cdots.$$

If $l \le n_2$, we can also push down by defining

$$\bar{z}_{2,i+1} = z_{2,i+1} + cz_{1,j}z_{2,1}z_{2,l},$$

yielding

$$\begin{aligned} z_{2,i-1}^+ &= z_{2,i} + f_{2,i-1}^{[2]}(z_1, z_2, v) + \cdots, \\ z_{2,i}^+ &= \bar{z}_{2,i+1} + f_{2,i}^{[2]}(z_1, z_2, v) + \cdots, \\ \bar{z}_{2,i+1}^+ &= z_{2,i+2} + f_{2,i+1}^{[2]}(z_1, z_2, v) + c\lambda_j z_{1,j} z_{2,2} z_{2,l+1} + \cdots, \end{aligned}$$

and all the other cubic terms remain unchanged. If $\lambda_j = 0$, then the term drops out. If $\lambda_j \neq 0$ and $l \le i + 1$, then the cubic term can be pushed down repeatedly and absorbed in the control. The result is (3.7).

Next we show that the number ζ_i^{j1l} (3.15) is an invariant. Clearly ζ_i^{j1l} is potentially changed only by $\phi_2^{[1;2]}(x_1; x_2)$ and $\alpha_2^{[1;2]}(x_1; x_2, u)$. Therefore, we need only consider coordinate changes of the form

$$\bar{x}_{2,\rho} = x_{2,\rho} + cx_{1,\sigma}x_{2,\tau}x_{2,\upsilon},$$

where $1 \le \rho \le n_2$, $1 \le \sigma \le n_1$, $1 \le \tau \le \upsilon \le n_2$ and feedbacks of the form

$$\bar{u} = u + cx_{1,\sigma}x_{2,\tau}x_{2,\upsilon},$$

where $1 \le \sigma \le n_1$, $1 \le \tau \le \upsilon \le n_2 + 1$ with $x_{2,n+1} = u$ because more general ones are just compositions of these. The coordinate change affects only a piece of the dynamics (3.1),

$$\begin{aligned} x^+_{2,\rho-1} &= x_{2,\rho} + f^{[2]}_{2,\rho-1}(x_1, x_2, u) + f^{[3]}_{2,\rho-1}(x_1, x_2, u), \\ x^+_{2,\rho} &= x_{2,\rho+1} + f^{[2]}_{2,\rho}(x_1, x_2, u) + f^{[3]}_{2,\rho}(x_1, x_2, u) \end{aligned}$$

is transformed to

$$\begin{aligned} x^+_{2,\rho-1} &= \bar{x}_{2,\rho} + f^{[2]}_{2,\rho-1}(x_1, x_2, u) + f^{[3]}_{2,\rho-1}(x_1, x_2, u) - c x_{1,\sigma} x_{2,\tau} x_{2,\upsilon}, \\ \bar{x}^+_{2,\rho} &= x_{2,\rho+1} + f^{[2]}_{2,\rho}(x_1, x_2, u) + f^{[3]}_{2,\rho}(x_1, x_2, u) + c\lambda_\sigma x_{1,\sigma} x_{2,\tau+1} x_{2,\upsilon+1}, \end{aligned}$$

and ζ_i^{j1l} is unchanged. The feedback affects only

$$x^+_{2,n_2} = u + f^{[2]}_{2,n_2}(x_1, x_2, u) + f^{[3]}_{2,n_2}(x_1, x_2, u),$$

transforming it into

$$x^+_{2,n_2} = \bar{u} + f^{[2]}_{2,n_2}(x_1, x_2, u) + f^{[3]}_{2,n_2}(x_1, x_2, u) - c x_{1,\sigma} x_{2,\tau} x_{2,\upsilon},$$

and again ζ_i^{j1l} is unchanged.

The normal form of $\tilde{f}_2^{[2;1]}(z_1; z_2, v)$. Consider a part of the dynamics

$$\begin{aligned} z^+_{2,i-1} &= z_{2,i} + f^{[2]}_{2,i-1}(z_1, z_2, v) + \cdots, \\ z^+_{2,i} &= z_{2,i+1} + f^{[2]}_{2,i}(z_1, z_2, v) + c z_{1,j} z_{1,k} z_{2,l} + \cdots, \\ z^+_{2,i+1} &= z_{2,i+2} + f^{[2]}_{2,i+1}(z_1, z_2, v) + \cdots, \end{aligned}$$

where $1 < i \le n_2$, $1 \le j \le k \le n_1$, $1 \le l \le n_2 + 1$.

If $\lambda_j \lambda_k \neq 0$ and $1 < l$, we can pull up the cubic term by defining

$$\bar{z}_{2,i} = z_{2,i} - \frac{c}{\lambda_j \lambda_k} z_{1,j} z_{1,k} z_{2,l-1};$$

then the dynamics becomes

$$\begin{aligned} z^+_{2,i-1} &= \bar{z}_{2,i} + f^{[2]}_{2,i-1}(z_1, z_2, v) + \frac{c}{\lambda_j \lambda_k} z_{1,j} z_{1,k} z_{2,l-1} + f^{[2]}_{2,i}(z_1, z_2, v) + \cdots, \\ \bar{z}^+_{2,i} &= z_{2,i+1} + f^{[2]}_{2,i}(z_1, z_2, v) + \cdots, \\ z^+_{2,i+1} &= z_{2,i+2} + f^{[2]}_{2,i+1}(z_1, z_2, v) + \cdots, \end{aligned}$$

and all the other cubic terms remain the same. Again, if $i = 1$, we can still pull up, and the term disappears. So by pulling up all cubic terms where $\lambda_j \lambda_k \neq 0$ until $l = 1$, we obtain

$$z^+_{2,i} = z_{2,i+1} + c z_{1,j} z_{1,k} z_{2,1} + \cdots.$$

Pushing down eliminates this term and any term with $\lambda_j \lambda_k = 0$. Define

$$\bar{z}_{2,i+1} = z_{2,i+1} + c z_{1,j} z_{1,k} z_{2,1},$$

yielding

$$\begin{aligned} z^+_{2,i-1} &= z_{2,i} + f^{[2]}_{2,i-1}(z_1, z_2, v) + \cdots, \\ z^+_{2,i} &= \bar{z}_{2,i+1} + f^{[2]}_{2,i}(z_1, z_2, v) + \cdots, \\ \bar{z}^+_{2,i+1} &= z_{2,i+2} + f^{[2]}_{2,i+1}(z_1, z_2, v) + c\lambda_j\lambda_k z_{1,j} z_{1,k} z_{2,2} + \cdots, \end{aligned}$$

and all the other cubic terms remain unchanged. If $\lambda_j\lambda_k = 0$, then the term drops out. If $\lambda_j\lambda_k \neq 0$, then we can push down repeatedly until the cubic term is absorbed in the control. The result is $\tilde{f}^{[2;1]}_2(z_1; z_2, v) = 0$.

The normal form of $\tilde{f}^{[3;0]}_2(z_1; z_2, v)$. Consider a part of the dynamics

$$\begin{aligned} z^+_{2,i} &= z_{2,i+1} + f^{[2]}_{2,i}(z_1, z_2, v) + c z_{1,j} z_{1,k} z_{1,l} + \cdots, \\ z^+_{2,i+1} &= z_{2,i+2} + f^{[2]}_{2,i+1}(z_1, z_2, v) + \cdots, \end{aligned}$$

where $1 \le i \le n_2$, $1 \le j \le k \le l \le n_1$.

Pushing down one or more times eliminates this term. Define

$$\bar{z}_{2,i+1} = z_{2,i+1} + c z_{1,j} z_{1,k} z_{1,l},$$

yielding

$$\begin{aligned} z^+_{2,i} &= \bar{z}_{2,i+1} + f^{[2]}_{2,i}(z_1, z_2, v) + \cdots, \\ \bar{z}^+_{2,i+1} &= z_{2,i+2} + f^{[2]}_{2,i+1}(z_1, z_2, v) + c\lambda_j\lambda_k\lambda_l z_{1,j} z_{1,k} z_{1,l} + \cdots, \end{aligned}$$

and all the other cubic terms remain unchanged. If $\lambda_j\lambda_k\lambda_l = 0$, then the term drops out. Otherwise, the term can be pushed down repeatedly until it is absorbed in the control. The result is $\tilde{f}^{[3;0]}_2(z_1; z_2, v) = 0$.

The normal form of $\tilde{f}^{[3;0]}_1(z_1; z_2, v)$. This is just the cubic normal form and invariants of Poincaré (see [1], [5], [9], and [13]). Consider a part of the dynamics

$$z^+_{1,i} = \lambda_i z_{1,i} + f^{[2]}_{1,i}(z_1, z_2, v) + c z_{1,j} z_{1,k} z_{1,l} + \cdots,$$

where $1 \le i \le n_1$, $1 \le j \le k \le l \le n_1$.

If $\lambda_i \neq \lambda_j\lambda_k\lambda_l$, then define

$$\bar{z}_{1,i} = z_{1,i} - \frac{c}{(\lambda_j\lambda_k\lambda_l - \lambda_i)} z_{1,j} z_{1,k} z_{1,l}$$

so that

$$\bar{z}^+_{1,i} = \lambda_i \bar{z}_{1,i} + f^{[2]}_{1,i}(z_1, z_2, v) + \cdots.$$

Next we show that the numbers β^{jkl}_i (3.9) are invariants. Clearly, β^{jkl}_i is potentially changed only by $\phi^{[3;0]}_1(x_1; x_2)$. Therefore, we need only consider coordinate changes of the form

$$\bar{x}_{1,\rho} = x_{1,\rho} + c x_{1,\sigma} x_{1,\tau} x_{1,\upsilon},$$

where $1 \le \rho \le n_1$, $1 \le \sigma \le \tau \le \upsilon \le n_1$ because more general ones are just compositions of these. This coordinate change affects only a piece of the dynamics (3.1), and

$$x^+_{1,\rho} = \lambda_\rho x_{1,\rho} + f^{[2]}_{1,\rho}(x_1, x_2, u) + f^{[3]}_{1,\rho}(x_1, x_2, u) + O(x_1, x_2, u)^3$$

is transformed to

$$\bar{x}^+_{1,\rho} = \lambda_\rho \bar{x}_{1,\rho} + f^{[2]}_{1,\rho}(x_1, x_2, u) + f^{[3]}_{1,\rho}(x_1, x_2, u) + c(\lambda_\sigma\lambda_\tau\lambda_\upsilon - \lambda_\rho)x_{1,\sigma}x_{1,\tau} + O(x_1, x_2, u)^3.$$

Clearly, if $\lambda_\rho = \lambda_\sigma\lambda_\tau\lambda_\upsilon$, then β^{jkl}_i (3.9) is unchanged.

The normal form of $\tilde{f}^{[2;1]}_1(z_1; z_2, v)$. Consider a part of the dynamics

$$z^+_{1,i} = \lambda_i z_{1,i} + f^{[2]}_{1,i}(z_1, z_2, v) + cz_{1,j}z_{1,k}z_{2,l} + \cdots,$$

where $1 \le i \le n_1$, $1 \le j \le k \le n_1$, $1 \le l \le n_2$.

If $\lambda_j\lambda_k \neq 0$ and $l > 1$, we can pull up by defining

$$\bar{z}_{1,i} = z_{1,i} - \frac{c}{\lambda_j\lambda_k} z_{1,j}z_{1,k}z_{2,l-1}$$

so that

$$\bar{z}^+_{1,i} = \lambda_i \bar{z}_{1,i} + f^{[2]}_{1,i}(z_1, z_2, v) + \frac{c\lambda_i}{\lambda_j\lambda_k} z_{1,j}z_{1,k}z_{2,l-1} + \cdots.$$

If $\lambda_i = 0$, then the term disappears; otherwise, we can continue to pull up until $l = 1$.

If $\lambda_i \neq 0$ and $\lambda_j\lambda_k = 0$, then the term disappears by pushing down

$$\bar{z}_{1,i} = z_{1,i} + \frac{c}{\lambda_i} z_{1,j}z_{1,k}z_{2,l}$$

so that

$$\begin{aligned}\bar{z}^+_{1,i} &= \lambda_i \bar{z}_{1,i} + f^{[2]}_{1,i}(z_1, z_2, v) + \frac{c\lambda_j\lambda_k}{\lambda_i} z_{1,j}z_{1,k}z^+_{2,l} + \cdots, \\ &= \lambda_i \bar{z}_{1,i} + f^{[2]}_{1,i}(z_1, z_2, v) + \cdots.\end{aligned}$$

If $\lambda_i = \lambda_j\lambda_k = 0$, then we cannot pull up or push down. The result is (3.4).

Next we show that the numbers γ^{jkl}_i (3.10)–(3.11) are invariants. Clearly, γ^{jkl}_i is potentially changed only by $\phi^{[2;1]}_1(x_1; x_2)$. Therefore, we need only consider coordinate changes of the form

$$\bar{x}_{1,\rho} = x_{1,\rho} + cx_{1,\sigma}x_{1,\tau}x_{2,\upsilon},$$

where $1 \le \rho \le n_1$, $1 \le \sigma \le \tau \le n_1$, $1 \le \upsilon \le n_2$ because more general ones are just compositions of these. This coordinate change affects only a piece of the dynamics (3.1), and

$$x^+_{1,\rho} = \lambda_\rho x_{1,\rho} + f^{[2]}_{1,\rho}(x_1, x_2, u) + f^{[3]}_{1,\rho}(x_1, x_2, u) + O(x_1, x_2, u)^4$$

is transformed to

$$\begin{aligned}\bar{x}^+_{1,\rho} = \lambda_\rho \bar{x}_{1,\rho} &+ f^{[2]}_{1,\rho}(x_1, x_2, u) + f^{[3]}_{1,\rho}(x_1, x_2, u) \\ &+ c\lambda_\sigma\lambda_\tau x_{1,\sigma}x_{1,\tau}x_{2,\upsilon+1} - c\lambda_\rho x_{1,\sigma}x_{1,\tau}x_{2,\upsilon} + O(x_1, x_2, u)^4.\end{aligned}$$

Clearly, if $\lambda_\rho = \lambda_\sigma\lambda_\tau = 0$, then γ^{jkl}_i (3.10) is unchanged. A simple calculation shows that if $\lambda_\rho\lambda_\sigma\lambda_\tau \neq 0$, then γ^{jk1}_i (3.11) is unchanged.

The normal form of $\tilde{f}_1^{[1;2]}(z_1; z_2, v)$. Consider a part of the dynamics

$$z_{1,i}^+ = \lambda_i z_{1,i} + f_{1,i}^{[2]}(z_1, z_2, v) + c z_{1,j} z_{2,k} z_{2,l} + \cdots,$$

where $1 \le i \le n_1$, $1 \le j \le n_1$, $1 \le k \le l \le n_2$.

If $\lambda_j \neq 0$ and $k > 1$, then we can pull up by defining

$$\bar{z}_{1,i} = z_{1,i} - \frac{c}{\lambda_j} z_{1.j} z_{2,k-1} z_{2,l-1};$$

then

$$\bar{z}_{1,i}^+ = \lambda_i \bar{z}_{1,i} + f_{1,i}^{[2]}(z_1, z_2, v) + \frac{c\lambda_i}{\lambda_j} z_{1,j} z_{2,k-1} z_{2,l-1} + \cdots.$$

If $\lambda_i = 0$, then the term disappears; otherwise, we can continue to pull up until $k = 1$.

If $\lambda_i \neq 0$ and $\lambda_j = 0$, then the term disappears by pushing down

$$\bar{z}_{1,i} = z_{1,i} + \frac{c}{\lambda_i} z_{1,j} z_{2,k} z_{2,l};$$

then

$$\begin{aligned} \bar{z}_{1,i}^+ &= \lambda_i \bar{z}_{1,i} + f_{1,i}^{[2]}(z_1, z_2, v) + \frac{c\lambda_j}{\lambda_i} z_{1,j} z_{1,k}^+ z_{2,l}^+ + \cdots, \\ &= \lambda_i \bar{z}_{1,i} + f_{1,i}^{[2]}(z_1, z_2, v) + \cdots. \end{aligned}$$

If $\lambda_i = \lambda_j = 0$, then we cannot pull up or push down. The result is (3.5).

Next we show that the numbers δ_i^{jkl} (3.12)–(3.13) are invariants. Clearly, δ_i^{jkl} is potentially changed only by $\phi_1^{[1;2]}(x_1; x_2)$. Therefore, we need only consider coordinate changes of the form

$$\bar{x}_{1,\rho} = x_{1,\rho} + c x_{1,\sigma} x_{2,\tau} x_{2,\upsilon},$$

where $1 \le \rho, \sigma \le n_1$, $1 \le \tau \le \upsilon \le n_2$ because more general ones are just compositions of these. This coordinate change affects only a piece of the dynamics (3.1), and

$$x_{1,\rho}^+ = \lambda_\rho x_{1,\rho} + f_{1,\rho}^{[2]}(x_1, x_2, u) + f_{1,\rho}^{[3]}(x_1, x_2, u) + O(x_1, x_2, u)^4$$

is transformed to

$$\begin{aligned} \bar{x}_{1,\rho}^+ = \lambda_\rho \bar{x}_{1,\rho} &+ f_{1,\rho}^{[2]}(x_1, x_2, u) + f_{1,\rho}^{[3]}(x_1, x_2, u) \\ &+ c\lambda_\sigma \lambda_\tau x_{1,\sigma} x_{1,\tau} x_{2,\upsilon+1} - c\lambda_\rho x_{1,\sigma} x_{1,\tau} x_{2,\upsilon} + O(x_1, x_2, u)^4. \end{aligned}$$

Clearly, if $\lambda_\rho = \lambda_\sigma \lambda_\tau = 0$, then δ_i^{jkl} (3.12) is unchanged. A simple calculation shows that if $\lambda_\rho \lambda_\sigma \lambda_\tau \neq 0$, then δ_i^{j1l} (3.13) is unchanged.

The normal form of $\tilde{f}_1^{[0;3]}(z_1; z_2, v)$. Consider a part of the dynamics

$$z_{1,i}^+ = \lambda_i z_{1,i} + f_{1,i}^{[2]}(z_1, z_2, v) + c z_{2,j} z_{2,k} z_{2,l} + \cdots,$$

where $1 \le i \le n_1$, $1 \le j \le k \le l \le n_2$.

If $j > 1$, we can pull up by defining

$$\bar{z}_{1,i} = z_{1,i} - c z_{2,j-1} z_{2,k-1} z_{2,l-1};$$

then

$$\bar{z}^+_{1,i} = \lambda_i \bar{z}_{1,i} + f^{[2]}_{1,i}(z_1, z_2, v) + c\lambda_i z_{2,j-1} z_{2,k-1} z_{2,l-1} + \cdots .$$

If $\lambda_i = 0$, then the term disappears; otherwise, we can continue to pull up until $j = 1$. The result is (3.6).

Finally, we show that the numbers ϵ^{1kl}_i (3.14) are invariants. Clearly, ϵ^{1kl}_i is potentially changed only by $\phi^{[0;3]}_1(x_1; x_2)$. Therefore, we need only consider coordinate changes of the form

$$\bar{x}_{1,\rho} = x_{1,\rho} + c x_{2,\sigma} x_{2,\tau} x_{2,\upsilon},$$

where $1 \le \rho \le n_1$, $1 \le \sigma \le \tau \le \upsilon \le n_2$ because more general ones are just compositions of these. This change of coordinates affects only a piece of the dynamics (2.3), and

$$x^+_{1,\rho} = \lambda_\rho x_{1,\rho} + f^{[2]}_{1,\rho}(x_1, x_2, u) + f^{[3]}_{1,\rho}(x_1, x_2, u)$$

is transformed to

$$\begin{aligned} \bar{x}^+_{1,\rho} = \lambda_\rho \bar{x}_{1,\rho} &+ f^{[2]}_{1,\rho}(x_1, x_2, u) + f^{[3]}_{1,\rho}(x_1, x_2, u) \\ &+ c x_{2,\sigma+1} x_{2,\tau+1} x_{2,\upsilon+1} - c\lambda_\rho x_{2,\sigma} x_{2,\tau} x_{2,\upsilon}. \end{aligned}$$

Clearly, if $\lambda_\rho \neq 0$, then ϵ^{1kl}_i (3.14) is unchanged.

7. Conclusion. We have developed a theory of quadratic and cubic normal forms for discrete time control systems. To avoid notational difficulties, we have restricted our attention to scalar input systems whose uncontrollable part is diagonalizable. But the basic operations of pull up and push down extend to more general systems. We have also shown the uniqueness of the normal forms.

We have introduced the concept of control bifurcation and have exhibited some simple examples.

GENERALIZED SOLUTIONS IN NONLINEAR STOCHASTIC CONTROL PROBLEMS*

F. DUFOUR† AND BORIS M. MILLER‡

Abstract. An optimal stochastic control problem is considered for systems with unbounded controls satisfying an integral constraint. It is shown that there exists an optimal control within the class of generalized controls leading to impulse actions. Applying an approach of time transformation, developed recently for deterministic systems, the original control problem is shown to be equivalent to an optimal stopping problem. Moreover, the description of generalized solutions is given in terms of stochastic differential equations governed by a measure.

Key words. nonlinear stochastic systems, impulse control, generalized solutions, discontinuous time-change

1. Introduction.

In this paper, the existence of an optimal control is discussed for the nonlinear stochastic system defined by the following equation:

$$x_t \doteq \zeta + \int_0^t A(s, x_s)ds + \int_0^t B(s, x_s)u_s ds + \int_0^t D(s, x_s)dW_s, \tag{1}$$

where the functions A, B, and D are deterministic, $\{W_t\}$ is a Brownian motion, and $\{u_t\}$ is the control. All the processes are assumed to be defined on a probability space $(\Omega, \mathcal{F}, P, \{\mathcal{F}_t\})$. Let K be a closed convex cone. The class of admissible controls, labeled $\mathfrak{C}^a$, is defined by the class of K-valued, $\{\mathcal{F}_t\}$-predictable processes subject to the following constraint:

$$\int_0^T |u_s|ds \le M. \tag{2}$$

For an admissible control u, the cost is given by

$$J[u] = E[g(x_T)], \tag{3}$$

where g is a deterministic function and T is the terminal time.

When the control satisfies condition (2), it is easy to see that the optimal solution may not exist within the class of admissible control (see the example in section 3). Indeed, this constraint (2) implies that the admissible control can be chosen as close as desired to a control of impulsive type. An approach to solve this problem in a deterministic context, based on a time transformation, was originally suggested by Warga [21] and has been actively developed recently (see, for example, the survey [15]).

In the stochastic context, this approach was introduced by Miller and Runggaldier in [17] to solve a special case of the problem studied in the present work. In this context, it appears necessary to introduce a new concept to describe the limit of a sequence of control processes subject to the constraint (2); this is the so-called *generalized* control. (For a more precise exposition, see Definition 3.1.) Similarly, the limit of a sequence of solutions of (1) is defined as a *generalized* solution. These definitions of generalized control and generalized solution are taken from the deterministic context (see, for example, [1, 16, 18]).

Our aim is to characterize the value of $\inf_{u\in\mathfrak{C}^a} J[u]$. By introducing the class of admissible generalized controls, labeled $\overline{\mathfrak{C}}^a$, it is shown that $\inf_{u\in\mathfrak{C}^a} J[u] = \inf_{u\in\overline{\mathfrak{C}}^a} J[u]$. The characterization of $\inf_{u\in\mathfrak{C}^a} J[u]$ will be completed when it is shown that the there exists an optimal generalized control $u^* \in \overline{\mathfrak{C}}^a$ such that $\inf_{u\in\overline{\mathfrak{C}}^a} J[u] = J[u^*]$. It proves that there exists an optimal generalized control for the original control problem, justifying, therefore, the introduction of this class of process, $\overline{\mathfrak{C}}^a$. This existence result is obtained by using a time transformation to convert the original control problem into an optimal stopping problem. Moreover, the representation of the generalized solution is given in terms of a stochastic differential equation governed by a measure. This important property enhances the link existing between this control problem and the class of singular control problems.

Singular stochastic control problems have recently received considerable attention in the literature (see [9, 10, 22] and the references therein). However, until now the theoretical basis for this kind of stochastic control problem was restricted to the class of systems where the gain of the singular control does not depend on the state process (see, for example, [9, 10] and the references therein). Therefore, our work can be considered as a first attempt to extend these results in the case where the gain of the singular control may depend on the state process. Other extensions of our approach are already planned, and in [4] it will be shown how this method can be applied to re-examine the singular problem studied in [9]. It must be pointed out that the control problem defined in (1)–(3) cannot be solved directly by using the results in [8, Theorem 4.7]. Our work can be generalized in several directions by adding soft constraints and considering the optimal stopping problem.

The paper is organized as follows. In section 2, we formulate the original control problem. The concept of *generalized* control is introduced in section 3 by analogy with the deterministic case. It is shown that the infimum of the expected cost over the class of admissible controls and the infimum over the class of admissible generalized controls are the same (see Proposition 3.2). Section 4 contains the description of the time transformation and introduces an auxiliary control problem that will be shown to be equivalent to the original one. On the basis of known results [8], the existence theorem is proved for the auxiliary problem. A consequence of this result is derived in section 5 and shows that there exists an optimal generalized control for the original control problem. Its representation is given in terms of a stochastic differential equation governed by a measure. In the appendix, some technical results are derived.

We introduce the following notation and terminology.

Notation. $\mathbb{N}_N$ is the set of the first N integers, that is, $\mathbb{N}_N = \{1, \dots, i, \dots, N\}$. $\mathbb{R}_+ \doteq \{x \in \mathbb{R} : x \geq 0\}$. The ith component of a vector M is denoted by M^i. The symbol $|.|$ is used to denote the norm of vectors and matrices. If X is a normed space, then for $R > 0$ the set $B_R(X)$ is defined by $\{x \in X : |x| < R\}$ and $\overline{B}_R(X) \doteq \{x \in X : |x| \leq R\}$. $(')$ denotes the transpose operation. $0_n \in \mathbb{R}^n$ is the zero vector. The indicator function of a set A is defined as $I_A(x)$. On a probability space $(\Omega, \mathcal{F}, P)$,

the mathematical expectation will be denoted by $E_P[.]$.

In order to define the state processes, let us introduce the following data:

- K is a subset of $\mathbb{R}^p$.
- $A : \mathbb{R}_+ \times \mathbb{R}^n \to \mathbb{R}^n$.
- $B : \mathbb{R}_+ \times \mathbb{R}^n \to \mathbb{R}^{n\times p}$.
- $D : \mathbb{R}_+ \times \mathbb{R}^n \to \mathbb{R}^{n\times m}$.
- $g : \mathbb{R}^n \to \mathbb{R}_+$.
- ζ is a fixed vector in $\mathbb{R}^n$.
- T and M are fixed real numbers.
- $G : \mathbb{R}_+ \to \overline{\mathbb{R}}_+$ such that $G(T) = 0$ and $G(t) = \infty$ for $t \neq T$.

The following assumptions will be used in the paper.

(A.1) There are constants L_1 and L_2 such that for all $t, s \in \mathbb{R}_+$ and $x, y \in \mathbb{R}^n$

$$|A(t,x)| + |B(t,x)| + |D(t,x)| \leq L_1(1 + |x|),$$
$$|A(t,x) - A(s,y)| + |B(t,x) - B(s,y)| + |D(t,x) - D(s,y)| \leq L_2(|x-y| + |t-s|).$$

(A.2) The function g is continuous, and there exist a constant L_3 and a positive integer q such that

$$|g(x)|^2 \leq L_3(1 + |x|^q).$$

(A.3) K is a closed cone which is convex.

(A.4) For all $(t,x) \in [0,T) \times \mathbb{R}^n$, the set $K(t,x)$ defined by

$$K(t,x) \doteq \big\{((1-|\theta|)A(t,x) + B(t,x)\theta, (1-|\theta|)D(t,x)D(t,x)', |\theta|) \ : \ \theta \in \overline{B}_1(K)\big\}$$

is convex.

2. Problem statement. In this section, we formulate the stochastic control problem presented in the introduction using the formulation described in Haussmann and Lepeltier [8] and El Karoui, Nguyen, and Jeanblanc-Picqué [5].

Definition 2.1. *A control is defined by the term*

$$C \doteq (\Omega, \mathcal{F}, P, \{\mathcal{F}_t\}, \{u_t\}, \{W_t\}, \{x_t\}),$$

where the following hold:

(i) $(\Omega, \mathcal{F}, P)$ *is a complete probability space with a right continuous complete filtration* $\{\mathcal{F}_t\}$.

(ii) $\{u_t\}$ *is a* K*-valued,* $\{\mathcal{F}_t\}$*-predictable process such that*

$$\int_0^T |u_s| ds \leq M. \tag{4}$$

(iii) $\{W_t\}$ *is an* $\{\mathcal{F}_t\}$ *standard* m*-dimensional Brownian motion.*

(iv) $\{x_t\}$ *is an* $\mathbb{R}^n$*-valued,* $\{\mathcal{F}_t\}$ *progressively measurable process such that*

$$(\forall t \in [0,T]), \ x_t \doteq \zeta + \int_0^t A(s,x_s)ds + \int_0^t B(s,x_s)u_s ds + \int_0^t D(s,x_s)dW_s. \tag{5}$$

We write $\mathfrak{C}$ *for the set of controls satisfying the previous conditions.*

The cost is given by

$$J[C] \doteq E_P[g(x_T)]. \tag{6}$$

The set $\mathfrak{C}^a$ *of admissible controls is defined by*

$$\mathfrak{C}^a \doteq \{C \in \mathfrak{C} : J[C] < \infty\}. \tag{7}$$

We shall consider as a control objective the minimization of $J[C]$ on $\mathfrak{C}^a$.

As already pointed out in the introduction, since we do not assume any conditions such as the coercivity condition (see (3.5) in [8]), the existence of an optimal control for the previous problem cannot be claimed using the approach described in [8]. Before presenting the concept of generalized control, let us derive the following technical lemma.

LEMMA 2.2. *The stochastic differential equation* (5)*, where* $\{u_t\}$ *satisfies item* (ii) *of Definition* 2.1*, has a unique solution such that*

$$(\forall q \in \mathbb{N}) \qquad E_P\left[\sup_{t\in[0,T]} |x_t|^{2q}\right] < D, \tag{8}$$

where D *is a constant.*

Proof. Using (A.1) and Theorem 7, page 197 in [19], the existence and the uniqueness of the solution are straightforward. The proof of (8) is given in the appendix. We cannot use standard arguments to derive it since the process $\{u_t\}$ may not be bounded but satisfies the inequality (4). □

3. Generalized controls. An optimal control may not exist within the class of ordinary admissible controls $\mathfrak{C}^a$. An example is now presented in order to illustrate this assertion. A deterministic problem is considered where $T = 1$, $M = 1$, the control $u_t \in K \doteq \mathbb{R}_+$, and the state satisfies the following equation:

$$(\forall t \in [0,1]) \quad x_t \doteq \int_0^t (u_s - x_s)ds.$$

The aim is to minimize the cost $J[C] = (1 - x_1)^2$. It is easy to show that $x_1 = \int_0^1 e^{(s-1)}u_s ds$, and, by using the fact that $\int_0^1 u_s ds \leq 1$, it follows that for any admissible control $J[C] > 0$.

Now let us introduce the sequence of admissible controls

$$u_t^n = \begin{cases} 0 & \text{for } 0 \leq t \leq 1 - \frac{1}{n}, \\ n & \text{for } 1 - \frac{1}{n} < t \leq 1. \end{cases}$$

Clearly, $\int_0^1 u_s^n ds = 1$, and the cost $J[C^n]$ associated to u^n is equal to $[1 - n(1 - e^{-\frac{1}{n}})]^2$. Consequently, $\lim_{n\to\infty} J[C^n] = 0$, showing that an optimal control does not exist within the class of ordinary admissible controls $\mathfrak{C}^a$. This is a consequence of the discontinuous behavior of the minimizing sequence $\{u_t^n\}$ at $t = 1$.

In order to characterize $\inf_{C\in\mathfrak{C}^a} J[C]$, we introduce the concept of generalized control, labeled C^g, and its associated class of admissible controls $\overline{\mathfrak{C}}^a$. Moreover, the correspondence between $\inf_{C\in\mathfrak{C}^a} J[C]$ and $\inf_{C^g\in\overline{\mathfrak{C}}^a} J[C^g]$ is given in Proposition 3.2, justifying the introduction of this new class of controls $\overline{\mathfrak{C}}^a$.

DEFINITION 3.1. *A generalized control is defined by the term*

$$C^g \doteq (\Omega, \mathcal{F}, P, \{\mathcal{F}_t\}, \{U_t\}, \{W_t\}, \{X_t\}),$$

where the following hold:

(i) $(\Omega, \mathcal{F}, P)$ *is a complete probability space with a right continuous complete filtration* $\{\mathcal{F}_t\}$.

(ii) $\{U_t\}$ *is a* K*-valued, corlol,* $\{\mathcal{F}_t\}$ *progressively measurable process satisfying*

$$\operatorname*{Var}_{[0,T]}[U_t] \leq M, \qquad U_t - U_s \in K \quad \text{for } t \geq s. \tag{9}$$

(iii) $\{W_t\}$ *is an* $\{\mathcal{F}_t\}$ *standard* m*-dimensional Brownian motion.*

(iv) $\{X_t\}$ *is an* $\mathbb{R}^n$*-valued, corlol,* $\{\mathcal{F}_t\}$ *progressively measurable semimartingale such that the continuous part of* $\{X_t\}$ *satisfies*

$$\begin{aligned}(\forall t \in [0,T]) \quad X_t^c \doteq \zeta &+ \int_0^t A(s, X_s)ds + \int_0^t B(s, X_s)dU_s^c \\ &+ \int_0^t D(s, X_s)dW_s.\end{aligned} \tag{10}$$

(v) *There exists a sequence* $\{C^n\}_{n\in\mathbb{N}}$ *defined by*

$$C^n \doteq (\Omega, \mathcal{F}, P, \{\mathcal{F}_t^n\}, \{u_t^n\}, \{W_t^n\}, \{x_t^n\})$$

such that

$$(\forall n \in \mathbb{N}) \qquad C^n \in \mathfrak{C}^a$$

and

$$\begin{aligned}(\forall t \in [0,T)) \qquad X_t &= \limsup_{\substack{s\to t \\ s>t}} \lim_{n\to\infty} x_s^n, \quad P-a.s., \\ \text{and} \quad X_T &= \lim_{n\to\infty} x_T^n, \quad P-a.s.\end{aligned} \tag{11}$$

We write $\overline{\mathfrak{C}}$ *for the set of controls satisfying the previous conditions.*

The cost is given by

$$J[C^g] \doteq E_P[g(X_T)]. \tag{12}$$

The set $\overline{\mathfrak{C}}^a$ *of admissible controls is defined by*

$$\overline{\mathfrak{C}}^a \doteq \{C^g \in \overline{\mathfrak{C}} : J[C^g] < \infty\}. \tag{13}$$

Note that the discontinuous part of $\{X_t\}$ is generated by the discontinuous part of $\{U_t\}$.

The following result provides a correspondence between the sets of control $\mathfrak{C}^a$ and $\overline{\mathfrak{C}}^a$. Its proof is an immediate consequence of the definitions of $\mathfrak{C}^a$ and $\overline{\mathfrak{C}}^a$ and assumption (A.2).

PROPOSITION 3.2. *The set of control* $\mathfrak{C}^a$ *is a subset of* $\overline{\mathfrak{C}}^a$*, and*

$$\inf_{C\in\mathfrak{C}^a} J[C] = \inf_{C^g\in\overline{\mathfrak{C}}^a} J[C^g]. \tag{14}$$

4. Time transformation and the auxiliary control problem. In this section, we introduce an auxiliary control problem which is given in terms of an optimal stopping problem (see Definition 4.1). It is shown in Corollary 4.16 that this problem is equivalent to the initial one. A key property of the auxiliary control problem is that the controls take their values in a compact set.

DEFINITION 4.1. *An auxiliary control is defined by the term*

$$\Psi \doteq (\Omega, \mathcal{F}, P, \{\mathcal{G}_t\}, \{\theta_t\}, \{V_t\}, \{\Lambda_t\}, \gamma),$$

where the following hold:

(i) $(\Omega, \mathcal{F}, P)$ *is a complete probability space with a right continuous complete filtration* $\{\mathcal{G}_t\}$.

(ii) $\{\theta_t\}$ *is a* $\overline{B}_1(K)$*-valued,* $\{\mathcal{G}_t\}$*-predictable process.*

(iii) $\{V_t\}$ *is a* $\{\mathcal{G}_t\}$ *standard* m*-dimensional Brownian motion.*

(iv) γ *is a* $\{\mathcal{G}_t\}$ *stopping time such that*

$$\gamma \le T + M. \tag{15}$$

(v) $\{\Lambda_t \doteq (\eta_t, \xi_t')'\}$ *is an* $\mathbb{R}^{n+1}$*-valued,* $\{\mathcal{G}_t\}$ *progressively measurable process such that*

$$\eta_t \doteq t - \int_0^t |\theta_s| ds, \tag{16}$$

$$\xi_t \doteq \zeta + \int_0^t (1 - |\theta_s|) A(\eta_s, \xi_s) ds + \int_0^t B(\eta_s, \xi_s)\theta_s ds + \int_0^t \sqrt{1 - |\theta_s|}\, D(\eta_s, \xi_s) dV_s \tag{17}$$

for $t \in [0, \gamma]$.

We write $\overline{\Upsilon}$ *for the set of controls satisfying the previous conditions.*

The cost is given by

$$\mathcal{M}[\Psi] \doteq E_P[g(\xi_\gamma) + G(\eta_\gamma)]. \tag{18}$$

The set $\overline{\Upsilon}^a$ *of admissible auxiliary controls is defined by*

$$\overline{\Upsilon}^a \doteq \{\Psi \in \overline{\Upsilon} : \mathcal{M}[\Psi] < \infty\}. \tag{19}$$

Our aim is to show the equivalence between the auxiliary and the initial control problems. However, we first show the existence of an optimal control for the auxiliary problem.

THEOREM 4.2. *For the auxiliary control problem there exists an optimal control* Θ^**:*

$$\inf_{\Psi \in \overline{\Upsilon}^a} \mathcal{M}[\Psi] = \mathcal{M}[\Theta^*] \qquad \text{and} \qquad \Theta^* \in \overline{\Upsilon}^a. \tag{20}$$

Proof. Applying Corollary 4.8 in [8], it follows that there exist a probability space $(\Omega, \widetilde{\mathcal{F}}, \widetilde{P})$ and a filtration $\{\widetilde{\mathcal{G}}_t\}$ such that

- $\{\widetilde{\theta}_t\}$ is a $\overline{B}_1(K)$-valued, $\{\widetilde{\mathcal{G}}_t\}$ progressively measurable process,
- $\{V_t\}$ is a $\{\widetilde{\mathcal{G}}_t\}$ standard m-dimensional Brownian motion,

and

$$E_{\widetilde{P}}[g(\xi_\gamma)] \leq \inf_{\Psi\in\overline{\Upsilon}^a} \mathcal{M}[\Psi], \tag{21}$$

where γ is a $\{\widetilde{\mathcal{G}}_t\}$ stopping time and

$$\eta_t = t - \int_0^t |\widetilde{\theta}_s| ds,$$
$$\xi_t = \zeta + \int_0^t (1-|\widetilde{\theta}_s|)A(\eta_s,\xi_s)ds + \int_0^t B(\eta_s,\xi_s)\widetilde{\theta}_s ds + \int_0^t \sqrt{1-|\widetilde{\theta}_s|}D(\eta_s,\xi_s)dV_s.$$

In (21), we do not have an equality because in the control problem studied by Haussmann and Lepeltier [8] the set of admissible controls is defined on the set of progressively measurable processes and for an arbitrary probability space. In our case, the admissible controls are defined in the smaller set of predictable processes and on a probability space that must satisfy the usual hypotheses (completion and right continuity). However, using Lemmas A.1 and A.2, it can be shown that there exists a new probability space $(\Omega,\mathcal{F},P,\{\mathcal{G}_t\})$ satisfying the usual hypotheses based on a modification of $(\Omega,\widetilde{\mathcal{F}},\widetilde{P},\{\widetilde{\mathcal{G}}_t\})$. Moreover, the existence of a $\overline{B}_1(K)$-valued, $\{\mathcal{G}_t\}$-predictable process $\{\theta_t\}$ such that

$$\Theta^* \doteq (\Omega,\mathcal{F},P,\{\mathcal{G}_t\},\{\theta_t\},\{V_t\},\{(\eta_t,\xi_t')'\},\gamma) \in \overline{\Upsilon}^a \quad \text{and} \quad \mathcal{M}[\Theta^*] \leq \inf_{\Psi\in\overline{\Upsilon}^a} \mathcal{M}[\Psi]$$

is guaranteed by Lemma A.3.

Consequently, we have $\mathcal{M}[\Theta^*] = \inf_{\Psi\in\overline{\Upsilon}^a} \mathcal{M}[\Psi]$, which gives the result. □

In order to establish the correspondence between the auxiliary control problem and the initial one, we need to introduce the following subset of $\overline{\Upsilon}^a$, labeled Υ^a (see Definition 4.3). We prove in Theorem 4.9 that

$$\begin{aligned} \inf_{\Psi\in\Upsilon^a} \mathcal{M}[\Psi] &= \min_{\Psi\in\overline{\Upsilon}^a} \mathcal{M}[\Psi] \\ &= \mathcal{M}[\Theta^*]. \end{aligned} \tag{22}$$

Then it is shown in Theorem 4.15 that

$$\inf_{C\in\mathfrak{C}^a} J[C] = \inf_{\Psi\in\Upsilon^a} \mathcal{M}[\Psi]. \tag{23}$$

Therefore, combining (22) and (23), the main result of this section (see Corollary 4.16) will follow; that is,

$$\inf_{C\in\mathfrak{C}^a} J[C] = \mathcal{M}[\Theta^*].$$

The rest of this section is devoted to the proofs of relations (22) and (23).

First, in order to show that (22) holds, we prove that for any control $\Psi \in \overline{\Upsilon}^a$ there exists a sequence of controls $\{\Psi^n\}$ in Υ^a such that $\lim_{n\to\infty} \mathcal{M}[\Psi^n] = \mathcal{M}[\Psi]$. This is not a trivial consequence of the closure of Υ^a by $\overline{\Upsilon}^a$ since it is necessary to approximate the stopping time γ. Now we need the following definitions and technical results.

Definition 4.3. *Let us introduce the set* $\Upsilon \subset \overline{\Upsilon}$*:*

$$\Psi \doteq (\Omega,\mathcal{F},P,\{\mathcal{G}_t\},\{\theta_t\},\{V_t\},\{\Lambda_t\},\gamma) \in \Upsilon \Longleftrightarrow \begin{cases} \Psi \in \overline{\Upsilon} \\ \textit{and} \\ \{\theta_t\} \textit{ is a } B_1(K)\textit{-valued process} \end{cases}$$

and the corresponding set of admissible controls

$$\Upsilon^a = \Upsilon \cap \overline{\Upsilon}^a. \tag{24}$$

DEFINITION 4.4. *For* $\Psi \doteq (\Omega, \mathcal{F}, P, \{\mathcal{G}_t\}, \{\theta_t\}, \{V_t\}, \{\Lambda_t = (\eta_t, \xi_t')'\}, \gamma) \in \overline{\Upsilon}^a$, *define on* $(\Omega, \mathcal{F}, P)$

$$\nu^n \doteq \inf\left\{t \geq 0 : t - \int_0^t \frac{n}{n+1}|\theta_s|ds \geq \frac{nT}{n+1}\right\}, \tag{25}$$

$$\nu \doteq \inf\{t \geq 0 : \eta_t \geq T\}, \tag{26}$$

$$\alpha^n \doteq \frac{T + M - \nu^n - \frac{T}{n+1}}{T + M - \nu^n}. \tag{27}$$

LEMMA 4.5. *If* $\Psi \doteq (\Omega, \mathcal{F}, P, \{\mathcal{G}_t\}, \{\theta_t\}, \{V_t\}, \{\Lambda_t = (\eta_t, \xi_t')'\}, \gamma)$ *is an element of* $\overline{\Upsilon}^a$, *then* ν *and* ν^n *are* $\{\mathcal{G}_t\}$ *stopping times (for all* $n \in \mathbb{N}$*) and*

$$\lim_{n\to\infty} \nu^n = \nu, \quad P- \textit{a.s.}, \tag{28}$$

and

$$0 \leq \alpha^n < 1. \tag{29}$$

Proof. See the appendix. □

Using Lemma 4.5, we can now show that a sequence of control $\{\Psi^n\}$ in Υ^a can be constructed from any element Ψ in $\overline{\Upsilon}^a$ as described below.

PROPOSITION 4.6. *Assume that* $\Psi \doteq (\Omega, \mathcal{F}, P, \{\mathcal{G}_t\}, \{\theta_t\}, \{V_t\}, \{\Lambda_t = (\eta_t, \xi_t')'\}, \gamma)$ *is an element of* $\overline{\Upsilon}^a$. *Define the sequence* $\{\Psi^n\}_{n\in\mathbb{N}}$ *by*

$$\Psi^n \doteq \big(\Omega, \mathcal{F}, P, \{\mathcal{G}_t\}, \{\theta_t^n\}, \{V_t\}, \{\Lambda_t^n = (\eta_t^n, \xi_t^{n\prime})'\}, \gamma^n\big), \tag{30}$$

where

$$\theta_t^n \doteq \frac{n}{n+1}\theta_t I_{[\![0,\nu^n]\!]} + \alpha^n e_1 I_{]\!]\nu^n,\nu]\!]} + \alpha^n \theta_t I_{]\!]\nu,\gamma]\!]} \quad (\, e_1 \doteq (1, 0, \ldots, 0)' \in \mathbb{R}^p\,), \tag{31}$$

$$\eta_t^n \doteq t - \int_0^t |\theta_s^n|ds, \tag{32}$$

$$\begin{aligned}\xi_t^n \doteq \zeta &+ \int_0^t (1 - |\theta_s^n|)A(\eta_s^n, \xi_s^n)I_{\{s\leq\gamma^n\}}ds + \int_0^t B(\eta_s^n, \xi_s^n)\theta_s^n I_{\{s\leq\gamma^n\}}ds \\ &+ \int_0^t \sqrt{1 - |\theta_s^n|}D(\eta_s^n, \xi_s^n)I_{\{s\leq\gamma^n\}}dV_s,\end{aligned} \tag{33}$$

$$\gamma^n \doteq \inf\{t \geq 0 : \eta_t^n > T\}. \tag{34}$$

Then $\Psi^n \in \Upsilon^a$ *for all* $n \in \mathbb{N}$.

Proof. From Lemma 4.5 and assumption (A.2), it follows that for all $n \in \mathbb{N}$, $\{\theta_t^n\}$ is a $B_1(K)$-valued process. Moreover, using the fact that α^n is measurable with respect to $\mathcal{G}_{\nu^n}$, $\mathcal{G}_{\nu^n} \subset \mathcal{G}_\nu$, and Corollary 6.34 in [6], it follows easily that for all $n \in \mathbb{N}$, the process $\{\theta_t^n\}$ is $\{\mathcal{G}_t\}$-predictable. From the definitions of $\{\eta_t^n\}$ and γ^n, we obtain that $\eta_{T+M}^n \geq \eta_{\gamma^n}^n$. Therefore, we have that

$$\gamma^n \leq T + M \tag{35}$$

because $\{\eta_t^n\}$ is a strictly increasing process.

Now, applying Theorem 7, page 197 in [19], it is easy to see that (33) has a unique solution. Therefore, for all $n \in \mathbb{N}$ the control Ψ^n satisfies all of the conditions of Definition 4.3.

Clearly, we have $E_P[G(\eta^n_{\gamma^n})] = 0$ and

$$E_P\left[\sup_{s\leq T+M}|\xi_s^n|^p\right] \leq C \tag{36}$$

for a constant C depending on p but independent of n.

Combining hypothesis (A.2), the previous inequalities, and (35), we obtain that

$$\mathcal{M}[\Psi^n] = E_P[g(\xi^n_{\gamma^n})] \quad < \quad \infty, \tag{37}$$

and so $\Psi^n \in \Upsilon^a$ for all $n \in \mathbb{N}$. □

In order to derive the convergence of $\mathcal{M}[\Psi^n]$ to the cost function $\mathcal{M}[\Psi]$, we need the following technical lemma.

LEMMA 4.7. *Assume that* $\Psi \doteq (\Omega, \mathcal{F}, P, \{\mathcal{G}_t\}, \{\theta_t\}, \{V_t\}, \{\Lambda_t = (\eta_t, \xi_t')'\}, \gamma)$ *is an element of* $\overline{\Upsilon}^a$. *Then*

$$0 \leq \gamma^n - \gamma \leq \frac{T}{n+1} \tag{38}$$

and

$$E_P\left[\left|\int_0^\gamma |\theta_s - \theta_s^n|^2 ds\right|^2 + \int_0^\gamma |\eta_s - \eta_s^n|^2 ds\right] \leq C\left\{\frac{1}{(n+1)^2} + E_P[|\nu - \nu^n|^2]\right\} \tag{39}$$

for a constant C *independent of* n.

Proof. See the appendix. □

Finally, based on the previous lemma, we can prove that the sequence $\{\Psi^n\}$ satisfies the desired property.

PROPOSITION 4.8. *Assume that* $\Psi \doteq (\Omega, \mathcal{F}, P, \{\mathcal{G}_t\}, \{\theta_t\}, \{V_t\}, \{\Lambda_t = (\eta_t, \xi_t')'\}, \gamma)$ *is an element of* $\overline{\Upsilon}^a$. *Then the sequence* $\{\Psi^n\}$ *in* Υ^a *satisfies*

$$\lim_{n\to\infty} \mathcal{M}[\Psi^n] = \mathcal{M}[\Psi]. \tag{40}$$

Proof. Let us introduce the following equation:

$$\begin{aligned}\chi_t = \zeta &+ \int_0^t (1 - |\theta_s|)A(\eta_s, \chi_s)I_{\{s\leq\gamma\}}ds + \int_0^t B(\eta_s, \chi_s)\theta_s I_{\{s\leq\gamma\}}ds \\ &+ \int_0^t \sqrt{1 - |\theta_s|}D(\eta_s, \chi_s)I_{\{s\leq\gamma\}}dV_s.\end{aligned} \tag{41}$$

Applying Theorem 7, page 197 in [19], it is easy to see that this equation has a unique solution.

By using Doob's inequality and Gronwall's lemma, it is easy to show that there exists a constant $\overline{C}$ such that

$$(\forall t \in [0, T+M]) \qquad E_P\left[\sup_{s\leq t}|\chi_s - \xi_s^n|^2\right] \leq \overline{C}\left[\frac{1}{n+1} + \sqrt{E_P[|\nu^n - \nu|^2]}\right]. \tag{42}$$

Moreover, we clearly have $\chi_{T+M} = \xi_\gamma$ and $\xi^n_{T+M} = \xi^n_{\gamma^n}$, and so

$$E_P[|\xi_\gamma - \xi^n_{\gamma^n}|^2] \le \overline{C}\ \left[\frac{1}{n+1} + \sqrt{E_P[|\nu^n - \nu|^2]}\right]. \tag{43}$$

The sequence ν^n is bounded by $T + M$, and so it is uniformly integrable. Therefore, using Lemma 4.5, we have that $\lim_{n\to\infty} E_P[|\nu^n - \nu|^2]$. With (43), we obtain that $g(\xi^n_{\gamma^n}) \longrightarrow^P_{n\to\infty} g(\xi_\gamma)$ since the function g is continuous. Clearly, the sequence $\{g(\xi^n_{\gamma^n})\}$ is uniformly integrable, and so

$$\lim_{n\to\infty} E_P[g(\xi^n_{\gamma^n})] = E_P[g(\xi_\gamma)], \tag{44}$$

giving the result. □

In conclusion, we obtain the following result.

THEOREM 4.9. *Let $\Theta^* \in \overline{\Upsilon}^a$ be the optimal control for the auxiliary control problem. Then*

$$\inf_{\Psi\in\Upsilon^a} \mathcal{M}[\Psi] = \mathcal{M}[\Theta^*]. \tag{45}$$

Proof. The existence of Θ^* has been shown in Theorem 4.2. Since $\Upsilon^a \subset \overline{\Upsilon}^a$, we clearly have

$$\inf_{\Psi\in\Upsilon^a} \mathcal{M}[\Psi] \ge \mathcal{M}[\Theta^*].$$

However, using Proposition 4.8, the result follows. □

Now let us show that (23) holds. Its proof is given in Theorem 4.15 and is based on Propositions 4.12 and 4.14. Here we use two time transformations which establish the correspondence between $\mathfrak{C}^a$ and Υ^a.

Let us introduce the following time-change.

LEMMA 4.10. *Let $(\Omega, \mathcal{F}, P, \{\mathcal{F}_t\}, \{u_t\}, \{W_t\}, \{z_t = (y_t, x_t')'\})$ be an element of $\mathfrak{C}$, and let $\{\Gamma_t\}$ be the process defined by*

$$\Gamma_t \doteq t + \int_0^t |u_{s\wedge T}| ds. \tag{46}$$

Denote by $\{\Phi_t\}$ the right inverse of Γ:

$$\Phi_t \doteq \inf\{s \ge 0 : \Gamma_s > t\}. \tag{47}$$

Then $\{\Phi_t\}$ is a continuous time-change satisfying the following properties:

(i) $(\forall\ t \in \mathbb{R}_+)\quad \Phi_{\Gamma_t} = t \quad$ *and* $\quad \Gamma_{\Phi_t} = t.$

(ii) $(\forall\ t \in \mathbb{R}_+)\quad \Phi_t = \int_0^t \frac{1}{1+|u_{\Phi_s\wedge T}|} ds.$

Proof. Item (i) is obvious. Differentiating the second equality in (i) and using (46), item (ii) follows easily. □

REMARK 4.11. *An immediate consequence of the previous lemma is the following assertion:*

$$(\forall t \in [0, \Gamma_T]) \qquad \Phi_t = \int_0^t \frac{1}{1 + |u_{\Phi_s}|} ds, \tag{48}$$

which will be used repeatedly in what follows.

The following proposition shows that for any control $C \in \mathfrak{C}^a$, there exists a control $\Theta \in \Upsilon^a$ having the same cost.

PROPOSITION 4.12. *Assume that* $C \doteq (\Omega, \mathcal{F}, P, \{\mathcal{F}_t\}, \{u_t\}, \{W_t\}, \{x_t\})$ *is an element of* $\mathfrak{C}^a$. *Write* Θ *for* $(\Omega, \mathcal{F}, P, \{\mathcal{F}_{\Phi_t}\}, \{\theta_t\}, \{V_t\}, \{\Delta_t\}, \Gamma_T)$, *where*

$$\theta_t \doteq \frac{u_{\Phi_t}}{1+|u_{\Phi_t}|}, \quad V_t \doteq \int_0^{\Phi_t} \sqrt{1+|u_s|}dW_s, \quad \Delta_t \doteq \begin{pmatrix} \Phi_t \\ x_{\Phi_t} \end{pmatrix}, \tag{49}$$

and Φ_t *(respectively,* Γ_t*) is defined by* (47) *(respectively,* (46)*). Then* Θ *belongs to* Υ^a *and*

$$\mathcal{M}[\Theta] = J[C]. \tag{50}$$

Proof. From Proposition 1.1 in [20, Chapter V], $\{\mathcal{F}_{\Phi_t}\}$ defines an increasing and right continuous filtration which is complete. Then assertion (i) of Definition 4.1 is satisfied. Now, using Theorem 3.52 in [11], it follows that $\{\frac{u_{\Phi_t}}{1+|u_{\Phi_t}|}\}$ is an $\{\mathcal{F}_{\Phi_t}\}$-predictable process. Moreover, for all $t \in \mathbb{R}_+$, $\frac{u_{\Phi_t}}{1+|u_{\Phi_t}|} \in B_1(K)$.

The process $\{N_t \doteq \int_0^t \sqrt{1+|u_s|}dW_s\}$ is an $\{\mathcal{F}_t\}$ continuous local martingale such that

$$(\forall t \in [0,T],\ \forall (i,j) \in \mathbb{N}_n^2) \quad \langle N^i, N^i\rangle_t = \Gamma_t,\ \langle N^i, N^j\rangle_t = 0 \quad (i \neq j). \tag{51}$$

Therefore, according to Theorem 4.13 in [12], $\{V_t = N_{\Phi_t}\}$ is an $\{\mathcal{F}_{\Phi_t}\}$ standard m-dimensional Brownian motion which gives item (iii) of Definition 4.1.

By Remark 2.9 and Theorem 2.33 in [6], the process $\{\Delta_t\}$ is adapted to $\{\mathcal{F}_{\Phi_t}\}$. Clearly, the process $\{\Delta_t\}$ is *corlol*. Consequently, $\{\Delta_t\}$ is progressively measurable with respect to $\{\mathcal{F}_{\Phi_t}\}$.

Using Proposition 1.1 in [20, Chapter V], Γ_T is an $\{\mathcal{F}_{\Phi_t}\}$ stopping time. With (4), we have that $\Gamma_T = T + \int_0^T |u_s|ds \leq T + M$. Therefore, item (iv) of Definition 4.1 is satisfied.

Now let us show that the components of $\{\Delta_t\}$ satisfy (16) and (17) on $[0, \Gamma_T]$. Using (48) and the definition of $\{\theta\}$, we have

$$(\forall t \in [0,\Gamma_T]) \qquad \Phi_t = t - \int_0^t |\theta_s|ds. \tag{52}$$

Therefore, the first component of the process $\{\Delta_t\}$ satisfies (16).

Now the process $\{x_{\Phi_t}\}$ satisfies (for all $t \in [0,\Gamma_T]$)

$$x_{\Phi_t} \doteq \zeta + \int_0^{\Phi_t} A(s,x_s)ds + \int_0^{\Phi_t} B(s,x_s)u_s ds + \int_0^{\Phi_t} D(s,x_s)dW_s. \tag{53}$$

Since $\{\Gamma_t\}$ is continuous, we can use Proposition 1.4 in [20, Chapter V] and Lemma 4.10 in order to obtain that

$$\begin{aligned} (\forall t \in [0,\Gamma_T]) \qquad \int_0^{\Phi_t} A(s,x_s)ds &= \int_0^t A(\Phi_s, x_{\Phi_s})d\Phi_s \\ &= \int_0^t A(\Phi_s, x_{\Phi_s})(1-|\theta_s|)ds. \end{aligned} \tag{54}$$

We can repeat the same argument to show that

$$(\forall t \in [0,\Gamma_T]) \qquad \int_0^{\Phi_t} B(s,x_s)u_s ds = \int_0^t B(\Phi_s, x_{\Phi_s})\theta_s ds. \tag{55}$$

Moreover,

$$(\forall t \in [0,\Gamma_T]) \qquad \int_0^{\Phi_t} D(s,x_s)dW_s = \int_0^{\Phi_t} D(s,x_s)\frac{1}{\sqrt{1+|u_s|}}dN_s$$

$$= \int_0^t D(\Phi_s, x_{\Phi_s})\sqrt{1-|\theta_s|}dV_s, \tag{56}$$

where the last equality is obtained by using Proposition 4.8 in [12].

Combining (53)–(56), we obtain that the process $\{x_{\Phi_t}\}$ satisfies

$$(\forall t \in [0,\Gamma_T]) \qquad x_{\Phi_t} = \zeta + \int_0^t (1-|\theta_s|)A(\Phi_s, x_{\Phi_s})ds + \int_0^t B(\Phi_s, x_{\Phi_s})\theta_s ds$$

$$+ \int_0^t \sqrt{1-|\theta_s|}D(\Phi_s, x_{\Phi_s})dV_s. \tag{57}$$

Therefore, assertion (iv) of Definition 4.1 is satisfied for the process $\{\Delta_t\}$ (see (49) for its definition). Finally, it follows that $\Theta \in \overline{\Upsilon}$. However, we have shown that $\{\theta_t\}$ is a $B_1(K)$-valued process. Consequently, $\Theta \in \Upsilon$.

Now the cost corresponding to Θ is given by $\mathcal{M}(\Theta) = E_P[g(x_{\Phi_{\Gamma_T}}) + G(\Phi_{\Gamma_T})]$.

However, $\Phi_{\Gamma_T} = T$ (see item (i) of Lemma 4.10). Therefore, we have $\mathcal{M}[\Theta] = E_P[g(x_T)] = J[C] < \infty$, implying that $\Theta \in \Upsilon^a$. □

The proof of the following lemma is similar to that of Lemma 4.10. Therefore, it is omitted.

LEMMA 4.13. *Let $(\Omega, \mathcal{F}, P, \{\mathcal{G}_t\}, \{\theta_t\}, \{V_t\}, \{\Lambda_t = (\eta_t, \xi_t')'\}, \gamma)$ be an element of Υ, and let $\{\psi_t\}$ be the right inverse of η:*

$$\psi_t \doteq \inf\{s \geq 0 : \eta_s > t\}. \tag{58}$$

The process $\{\psi_t\}$ is a continuous time-change satisfying the following properties:

(i) $(\forall\ t \in \mathbb{R}_+)$ $\psi_{\eta_t} = t$ *and* $\eta_{\psi_t} = t$.

(ii) $(\forall\ t \in \mathbb{R}_+)$ $\psi_t = \int_0^t \frac{1}{1-|\theta_{\psi_s}|}ds$.

Conversely to Proposition 4.12, we show that, for any control $\Psi \in \Upsilon^a$, there exists a control $S \in \mathfrak{C}^a$ having the same cost. The ideas to show this result are the same as the one used in the proof of Proposition 4.12. Consequently, this result is quoted without proof.

PROPOSITION 4.14. *Let $\Psi \doteq (\Omega, \mathcal{F}, P, \{\mathcal{G}_t\}, \{\theta_t\}, \{V_t\}, \{\Lambda_t = (\eta_t, \xi_t')'\}, \gamma)$ be an element of Υ^a. Write S for $(\Omega, \mathcal{F}, P, \{\mathcal{G}_{\psi_t}\}, \{u_t\}, \{W_t\}, \{\xi_{\psi_t}\})$, where*

$$u_t \doteq \frac{\theta_{\psi_t}}{1-|\theta_{\psi_t}|}, \qquad W_t \doteq \int_0^{\psi_t} \sqrt{1-|\theta_s|}dV_s, \tag{59}$$

and $\{\Psi_t\}$ is defined in (58).

Then S belongs to $\mathfrak{C}^a$, and

$$J[S] = \mathcal{M}[\Psi]. \tag{60}$$

Now we obtain the following result.

THEOREM 4.15. *The following property holds:*

$$\inf_{C \in \mathfrak{C}^a} J[C] = \inf_{\Psi \in \Upsilon^a} \mathcal{M}[\Psi]. \tag{61}$$

Proof. The result is an immediate consequence of Propositions 4.12 and 4.14. ∎

Finally, we derive an important characterization of $\inf_{C\in\mathfrak{C}^a} J[C]$.

COROLLARY 4.16. *Let $\Theta^* \in \overline{\Upsilon}^a$ be the optimal control for the auxiliary control problem. Then*

$$\inf_{C\in\mathfrak{C}^a} J[C] = \mathcal{M}[\Theta^*]. \tag{62}$$

Proof. It is a straightforward combination of Theorems 4.9 and 4.15. ∎

REMARK 4.17. *Let us denote by $\Theta^* \doteq (\Omega, \mathcal{F}, P, \{\mathcal{G}_t\}, \{\theta_t\}, \{V_t\}, \{(\eta_t, \xi_t')'\}, \gamma)$ the optimal control in $\overline{\Upsilon}^a$. There is no loss of generality to assume that*

$$\inf\{s : \eta_s > T\} = \gamma.$$

Indeed, if this is not the case, let $\widetilde{\Theta}$ be the control defined by

$$\begin{aligned}
\widetilde{\Theta} &\doteq (\Omega, \mathcal{F}, P, \{\mathcal{G}_t\}, \{\widetilde{\theta}_t\}, \{V_t\}, \{(\widetilde{\eta}_t, \widetilde{\xi}_t')'\}, \gamma),\\
\widetilde{\theta}_t &\doteq \theta_t I_{[0,\gamma]},\\
\widetilde{\eta}_t &\doteq t - \int_0^t |\widetilde{\theta}_s| ds,\\
\widetilde{\xi}_t &\doteq \zeta + \int_0^t (1 - |\widetilde{\theta}_s|) A(\widetilde{\eta}_s, \widetilde{\xi}_s) ds + \int_0^t B(\widetilde{\eta}_s, \widetilde{\xi}_s)\widetilde{\theta}_s ds\\
&\quad + \int_0^t \sqrt{1 - |\widetilde{\theta}_s|} D(\widetilde{\eta}_s, \widetilde{\xi}_s) dV_s.
\end{aligned}$$

Clearly, $\widetilde{\Theta} \in \Upsilon^a$ and $\inf\{s : \widetilde{\eta}_s > T\} = \gamma$. Moreover, it is easy to check that (for all $t \in [0, \gamma]$) $\widetilde{\theta}_t = \theta_t$, $\widetilde{\eta}_t = \eta_t$, and $\widetilde{\xi}_t = \xi_t$. Therefore,

$$\mathcal{M}(\widetilde{\Theta}) = \mathcal{M}(\Theta^*) = \min_{\Psi\in\overline{\Upsilon}^a} \mathcal{M}[\Psi].$$

5. Existence of an optimal generalized control. In this section, we obtain the last characterization of $\inf_{C\in\mathfrak{C}^a} J[C]$ in terms of an optimal generalized control.

THEOREM 5.1. *There exists a generalized control $C^{g*} \in \overline{\mathfrak{C}}^a$ such that*

$$\begin{aligned}
\inf_{C\in\mathfrak{C}^a} J[C] &= J[C^{g*}]\\
&= \min_{C^g\in\overline{\mathfrak{C}}^a} J[C^g].
\end{aligned}$$

Proof. Let us denote by

$$\Theta^* \doteq (\Omega, \mathcal{F}, P, \{\mathcal{G}_t\}, \{\theta_t\}, \{V_t\}, \{(\eta_t, \xi_t')'\}, \gamma)$$

the optimal control in $\overline{\Upsilon}^a$.

Define

$$\psi_t \doteq \inf\{s : \eta_s > t\}, \tag{63}$$

$$X_t \doteq \xi_{\psi_t}, \tag{64}$$

$$U_t \doteq \int_0^{\psi_t} \theta_s ds, \tag{65}$$

$$W_t \doteq \int_0^{\psi_t} \sqrt{1 - |\theta_s|} dV_s. \tag{66}$$

On the probability space $(\Omega, \mathcal{F}, P)$, $\{\psi_t\}$ is a time-change (see Proposition 1.1 in [20, Chapter V]). Moreover, $\{\mathcal{G}_{\psi_t}\}$ defines a right continuous complete filtration. Therefore, the processes $\{X_t\}$, $\{Y_t\}$, and $\{U_t\}$ are $\{\mathcal{G}_{\psi_t}\}$ progressively measurable (see Theorem T57, page 105 in [14]). Since $\{\xi_t\}$ is a continuous process, $\{X_t\}$, $\{Y_t\}$, and $\{U_t\}$ are *corlol*. Moreover, since K is a separable metric space satisfying assumption (A.3), it is easy to obtain that $\{U_t\}$ is a K-valued process and $U_t - U_s \in K$ for $t \geq s$.

According to Theorem 4.13 in [12], $\{W_t\}$ is a $\{\mathcal{G}_{\psi_t}\}$ standard m-dimensional Brownian motion.

Now, using Theorem 6.46 in [6], there exists a sequence $\{\tau_n\}$ of stopping times which exhausts the jumps of $\{\psi_t\}$. Clearly, we have

$$\overset{\infty}{\underset{n=1}{\cup}} [\![\psi_{\tau_n -}, \psi_{\tau_n}]\!] \subset \{(t,\omega) \in \mathbb{R}_+ \times \Omega : |\theta_t| = 1\}.$$

Define

$$\mathcal{D} \doteq \{(t,\omega) \in \mathbb{R}_+ \times \Omega : |\theta_t| = 1\} - \overset{\infty}{\underset{n=1}{\cup}} [\![\psi_{\tau_n -}, \psi_{\tau_n}]\!].$$

Consequently,

$$\begin{aligned}(\forall t \in [0,T]) \quad U_t &= \int_0^{\psi_t} I_{\{|\theta_s|<1\}} \theta_s ds + \int_0^{\psi_t} I_{\{|\theta_s|=1\}} \theta_s ds \\ &= \int_0^{\psi_t} [I_{\{|\theta_s|<1\}} + I_{\mathcal{D}}] \theta_s ds + \sum_{n \in \mathbb{N}} \int_{\psi_{\tau_n -}}^{\psi_{\tau_n}} \theta_s ds \, I_{[\![\tau_n, \infty[\![}.\end{aligned}$$

For $(t,\omega) \in \cup_{n=1}^{\infty} [\![\psi_{\tau_n -}, \psi_{\tau_n}]\!]$, we have $I_{\{|\theta_t|<1\}}(\omega) + I_{\mathcal{D}}(t,\omega) = 0$.

Therefore, $\{\int_0^t [I_{\{|\theta_s|<1\}} + I_{\mathcal{D}}] \theta_s ds\}$ is a $\{\psi_t\}$ continuous process. Consequently, the decomposition of the process $\{U_t\}$ is given by

$$\begin{aligned} U_t^c &= \int_0^{\psi_t} [I_{\{|\theta_s|<1\}} + I_{\mathcal{D}}] \theta_s ds, \\ U_t^d &= \sum_{n \in \mathbb{N}} \int_{\psi_{\tau_n -}}^{\psi_{\tau_n}} \theta_s ds \, I_{[\![\tau_n, \infty[\![}. \end{aligned}$$

From Lemma 1.37 in [11], we have

$$(\forall t \in \mathbb{R}_+) \qquad \eta_{\psi_t} = t. \tag{67}$$

Moreover, using Proposition 4.8 in [12], it follows that

$$(\forall t \in [0,T]) \quad \int_0^{\psi_t} \sqrt{1 - |\theta_s|} D(\eta_s, \xi_s) dV_s = \int_0^t D(s, \xi_{\psi_s}) dW_s.$$

Note that $\{\eta_t\}$ is a $\{\psi_t\}$ continuous process. Moreover, $\{\eta_t\}$ is a process of finite variation because it is absolutely continuous. Therefore, using Proposition 1.4 in [20, Chapter V] and (67), we obtain that

$$\begin{aligned}(\forall t \in [0,T)) \quad \int_0^{\psi_t} (1 - |\theta_s|) A(\eta_s, \xi_s) ds &= \int_0^{\psi_t} A(\eta_s, \xi_s) d\eta_s \\ &= \int_0^t A(s, \xi_{\psi_s}) ds.\end{aligned}$$

Again, using the fact that $\{\int_0^t [I_{\{|\theta_s|<1\}} + I_{\mathcal{D}}]\theta_s ds\}$ is a $\{\psi_t\}$ continuous process and Proposition 1.4 in [20, Chapter V], we have

$$\begin{aligned}\int_0^{\psi_t} B(\eta_s,\xi_s)\theta_s ds &= \int_0^{\psi_t} B(\eta_s,\xi_s)\left[I_{\{|\theta_s|<1\}} + I_{\mathcal{D}}\right]\theta_s ds \\ &\quad + \sum_{n\in\mathbb{N}} \int_{\psi_{\tau_n-}}^{\psi_{\tau_n}} B(\eta_s,\xi_s)\theta_s ds\, I_{[\![\tau_n,\infty[\![} \\ &= \int_0^t B(s,\xi_{\psi_s}) dU_s^c + \sum_{n\in\mathbb{N}} \int_{\psi_{\tau_n-}}^{\psi_{\tau_n}} B(\eta_s,\xi_s)\theta_s ds\, I_{[\![\tau_n,\infty[\![}.\end{aligned}$$

It follows that the process $\{X_t\}$ satisfies the following equation:

$$\begin{aligned}(\forall t\in[0,T]) \quad X_t &= \zeta + \int_0^t A(s,X_s)ds + \int_0^t B(s,X_s)dU_s^c + \int_0^t D(s,X_s)dW_s \\ &\quad + \sum_{n\in\mathbb{N}} \Delta X_{\tau_n}\ I_{[\![\tau_n,\infty[\![},\end{aligned} \tag{68}$$

where

$$\Delta X_{\tau_n} \doteq \int_{\psi_{\tau_n-}}^{\psi_{\tau_n}} B(\eta_s,\xi_s)\theta_s ds. \tag{69}$$

According to Proposition 4.8, there exists a sequence $\{\Psi^n\}$ such that $\Psi^n \in \Upsilon^a$ for all $n\in\mathbb{N}$. Write

$$\psi_t^n \doteq \inf\{s : \eta_s^n > t\}.$$

From Proposition 4.6, it follows that $\{\psi_t^n\}$ is a continuous, strictly increasing process and such that

$$\left(\forall t\in\left[0,\frac{nT}{n+1}\right)\right) \qquad \psi_t^n \le \psi_t^{n+1} \le \psi_t. \tag{70}$$

Therefore, for t in $[0,T))$, $\overline{\psi}_t \doteq \lim_{n\to\infty}\psi_t^n$ exists. Again, using (70), this limit is lower semicontinuous and increasing on $[0,T)$.

Using similar arguments as in the proof of Lemma 4.5, it can be shown easily that

$$(\forall t\in[0,T)) \qquad \eta_{\overline{\psi}_t} = t. \tag{71}$$

Combining (67) with (71), we obtain that

$$(\forall t\in\mathbb{R}_+) \qquad \sum_n I_{]\tau_n\wedge T,\tau_{n+1}\wedge T[\![}\psi_t = \sum_n I_{]\tau_n\wedge T,\tau_{n+1}\wedge T[\![}\overline{\psi}_t.$$

However, recalling that $\{\overline{\psi}_t\}$ is a lower semicontinuous, increasing process and $\{\psi_t\}$ is *corlol*, it follows that $\{\overline{\psi}_t\}$ is *collor* and

$$(\forall t\in[0,T)) \qquad \psi_t = \overline{\psi}_{t+}. \tag{72}$$

There is no loss of generality to assume that $\lim_{t\to 0 t<0}\psi_t = 0$, and so

$$(\forall t\in[0,T)) \qquad \overline{\psi}_t = \psi_{t-}. \tag{73}$$

Moreover, since $\psi^n \in \Upsilon^a$, we have that $\eta^n_{\gamma^n} = T$. Recalling that $\{\eta^n_t\}$ is strictly increasing and continuous, we obtain that $\psi^n_T = \gamma^n$. Note that $\psi_T = \gamma$ (see Remark 4.17). Using Lemma 4.7, it follows that

$$\overline{\psi}_T \doteq \lim_{n\to\infty} \psi^n_T = \psi_T = \gamma, \quad P-\text{a.s.} \tag{74}$$

Using (73) and the fact that $\{\psi_t\}$ is an increasing process, we have that, for all $t \in [0,T)$, $\overline{\psi}_t \le \psi_{T-} \le \psi_T = \overline{\psi}_T$. Consequently, $\{\overline{\psi}_t\}$ is increasing.

However, using similar arguments as in the proof of Proposition 4.8 (see (42)), it can be shown easily that there exists a subsequence, still denoted by n, such that (for all $t \in [0,T]$)

$$\lim_{n\to\infty} \xi^n_{\psi^n_t} = \xi_{\overline{\psi}_t}, \quad P-\text{a.s., and } \lim_{n\to\infty} \int_0^{\psi^n_t} |\theta^n_s| ds = \int_0^{\overline{\psi}_t} |\theta_s| ds, \quad P-\text{a.s.} \tag{75}$$

Define

$$C^n = \left(\Omega, \mathcal{F}, P, \{\mathcal{G}_{\psi^n_t}\}, \left\{\frac{\theta^n_{\psi^n_t}}{1-|\theta^n_{\psi^n_t}|}\right\}, \left\{\int_0^{\psi^n_t} \sqrt{1-|\theta^n_s|} dV_s\right\}, \{(\psi^n_t - t, \xi^{n\prime}_{\psi^n_t})'\}\right).$$

Since $\Psi^n \in \Upsilon^a$ for all $n \in \mathbb{N}$ and using Proposition 4.14, it follows that $C^n \in \mathfrak{C}^a$ for all $n \in \mathbb{N}$.

Using the fact that $\{\xi_t\}$ is continuous, (72), and (75), we obtain that

$$(\forall t \in [0,T)) \qquad X_t = \lim_{\substack{s\to t \\ s>t}} \lim_{n\to\infty} \xi^n_{\psi^n_s}, \quad P-\text{a.s.}$$

Moreover, using (74) and (75),

$$X_T = \xi_{\psi_T} = \xi_{\overline{\psi}_T} = \lim_{n\to\infty} \xi^n_{\psi^n_T}, \quad P-\text{a.s.} \tag{76}$$

From the definition of $\{\psi^n_t\}$ and since $\Psi^n \in \Upsilon^a$, we can use Lemma 4.13 in order to obtain

$$\begin{aligned}(\forall t \in [0,T]) \qquad \psi^n_t - t &= \int_0^t \frac{|\theta^n_{\psi^n_s}|}{1-|\theta^n_{\psi^n_s}|} ds \\ &= \int_0^t |\theta^n_{\psi^n_s}| d\psi^n_s.\end{aligned}$$

Using Proposition 1.4 in [20, Chapter V] and the fact that $\{\psi^n_t\}$ is a continuous process, we have

$$(\forall t \in [0,T]) \qquad \psi^n_t - t = \int_0^{\psi^n_t} |\theta^n_s| ds. \tag{77}$$

Therefore, combining (74), (75), and (77) yields

$$\int_0^{\psi_T} |\theta_s| ds = \gamma - T.$$

However,

$$\operatorname*{Var}_{[0,T]}[U_t] \le \operatorname*{Var}_{[0,T]}\left[\int_0^{\psi_t} |\theta_s| ds\right] = \int_0^{\psi_T} |\theta_s| ds.$$

Consequently, using (15), it follows that

$$\operatorname*{Var}_{[0,T]}[U_t] \leq M.$$

Finally, the generalized control C^{g*} defined by

$$C^{g*} \doteq (\Omega, \mathcal{F}, P, \{\mathcal{F}_t\}, \{U_t\}, \{W_t\}, \{X_t\})$$

is an element of $\overline{\mathfrak{C}}^a$.

However, by hypothesis, $\inf_{C\in\mathfrak{C}^a} J[C] = E_P[g(\xi_\gamma)]$, and so we obtain with (76)

$$\inf_{C\in\mathfrak{C}^a} J[C] = E_P[g(X_T)] = J[C^{g*}].$$

Now, using Proposition 3.2, we obtain the result. □

Appendix. In this section, we prove some technical results.

Proof of Lemma 2.2. Let us consider $R > |\zeta|$ and define $\tau_R \doteq \inf\{t : |x_t| \geq R\}$. Clearly, the process $\{x_{t\wedge\tau_R}\}$ is solution of the following equation:

$$\begin{aligned} x_{t\wedge\tau_R} \doteq \zeta &+ \int_0^t A(s, x_{s\wedge\tau_R}) I_{\{s\leq\tau_R\}} ds + \int_0^t B(s, x_{s\wedge\tau_R}) u_s I_{\{s\leq\tau_R\}} ds \\ &+ \int_0^t D(s, x_{s\wedge\tau_R}) I_{\{s\leq\tau_R\}} dW_s. \end{aligned}$$

Using (A.1) and (4), it follows that

$$\begin{aligned} |x_{t\wedge\tau_R}| \leq |\zeta| + L_1(T+M) &+ \left| \int_0^t D(s, x_{s\wedge\tau_R}) I_{\{s\leq\tau_R\}} dW_s \right| \\ &+ \int_0^t |x_{s\wedge\tau_R}| L_1(1+|u_t|) ds. \end{aligned}$$

Using Gronwall's lemma, we obtain that

$$|x_{t\wedge\tau_R}| \leq M_1 + M_2 \sup_{s\leq t} \left| \int_0^s D(s, x_{s\wedge\tau_R}) I_{\{s\leq\tau_R\}} dW_s \right|,$$

where M_1 and M_2 are two constants. Using Theorem 6.5, page 87 in [7], assumption (A.1), and Gronwall's lemma, we finally have that

$$E_P\left[\sup_{t\leq T} |x_{t\wedge\tau_R}|^{2q}\right] \leq M$$

for a constant M.

Due to the continuity of $\{x_t\}$, $\tau_R \to \infty$ as $R \to \infty$. Therefore, using Fatou's lemma and the previous equation, the result follows. □

LEMMA A.1. *Suppose $(\Omega, \mathcal{F}, P)$ is a probability space with a filtration $\{\mathcal{G}_t\}$ and $\{V_t\}$ is a $\{\mathcal{G}_t\}$ standard Brownian motion. Then $\{V_t\}$ is a $\{\mathcal{G}_t^q\}$ standard Brownian motion on the probability space $\left(\Omega, \mathcal{F}^q, \overline{P}\right)$, where*

$$\begin{aligned} \mathcal{F}^q &\doteq \{A \subset \Omega : (\exists B \in \mathcal{F}) \text{ such that } A \triangle B \in \mathcal{N}\}, \\ \mathcal{G}_t^q &\doteq \{A \subset \Omega : (\exists B \in \mathcal{G}_t) \text{ such that } A \triangle B \in \mathcal{N}\}, \\ \mathcal{N} &\doteq \{A \subset \Omega : (\exists B \in \mathcal{F}) \text{ such that } A \subset B \text{ and } P(B) = 0\}, \end{aligned}$$

and the probability $\overline{P}$ *is defined by (for all* $A \in \mathcal{F}^q$*)* $\overline{P}(A) = P(B)$*, where* $B \in \mathcal{F}$ *and* $A \triangle B \in \mathcal{N}$.

Proof. From the definition of $\mathcal{G}_s^q$ and $\mathcal{N}$, it follows that

$$(\forall s > 0, \quad \forall A \in \mathcal{G}_s^q) \quad (\exists (B, N) \in \mathcal{G}_s \times \mathcal{N}) \qquad \text{such that} \qquad A = B + N.$$

Therefore, for all $t > s \geq 0$ and for all $A \in \mathcal{G}_s^q$ we have

$$\int_A \exp[iu'(V_t - V_s)]\, d\overline{P} = \exp -\frac{|u|^2(t-s)}{2}\, P(B). \tag{78}$$

Moreover, $P(B) = \overline{P}(A)$, and, using (78), we obtain

$$E_{\overline{P}}[\exp[iu'(V_t - V_s)]\, |\mathcal{G}_s^q] = \exp -\frac{|u|^2(t-s)}{2},$$

which gives the result. □

LEMMA A.2. *Suppose* $(\Omega, \mathcal{F}, P)$ *is a complete probability space with a complete filtration* $\{\mathcal{G}_t\}$ *and* $\{V_t\}$ *is a* $\{\mathcal{G}_t\}$ *standard Brownian motion. Then* $\{V_t\}$ *is a* $\{\mathcal{G}_{t+}\}$ *standard Brownian motion.*

Proof. For all $t > s \geq 0$ and $0 < \epsilon < t - s$ we have

$$E_P[\exp[iu'(V_t - V_{s+\epsilon})]\, |\mathcal{G}_{s+\epsilon}] = \exp -\frac{|u|^2(t-s-\epsilon)}{2}.$$

Since $\mathcal{G}_{s+} = \bigcap_{\epsilon>0} \mathcal{G}_{s+\epsilon}$, we obtain that

$$(\forall A \in \mathcal{G}_{s+}) \qquad \lim_{\substack{\epsilon \to 0 \\ \epsilon > 0}} \int_A \exp[iu'(V_t - V_{s+\epsilon})]\, dP = \exp -\frac{|u|^2(t-s)}{2}\, P(A).$$

By using the bounded convergence theorem and the fact that the $\{V_t\}$ is a continuous process, we have

$$E_P[\exp[iu'(V_t - V_s)]\, |\mathcal{G}_{s+}] = \exp -\frac{|u|^2(t-s)}{2},$$

and the result follows. □

LEMMA A.3. *Assume that* $\{\theta_t\}$ *is a* $\overline{B}_1(K)$*-valued,* $\{\mathcal{G}_t\}$ *progressively measurable process. Then* (16) *and* (17) *have a unique solution such that*

$$(\forall q \in \mathbb{N}) \qquad E_P\left[\sup_{t \in [0,\gamma]} |\xi_t|^{2q}\right] < \infty. \tag{79}$$

Moreover, there exist a $\overline{B}_1(K)$*-valued,* $\{\mathcal{G}_t\}$*-predictable process* $\{\overline{\theta}_t\}$ *such that*

$$\overline{\theta} = \theta, \quad \lambda \otimes P - a.e., \tag{80}$$

and the process $\{\overline{\xi}_t\}$ *solution of the following stochastic differential equation:*

$$\overline{\xi}_t \doteq \zeta + \int_0^t (1 - |\overline{\theta}_s|) A(\overline{\eta}_s, \overline{\xi}_s) ds + \int_0^t B(\overline{\eta}_s, \overline{\xi}_s) \overline{\theta}_s ds + \int_0^t \sqrt{1 - |\overline{\theta}_s|}\, D(\overline{\eta}_s, \overline{\xi}_s) dV_s,$$

where $\overline{\eta}_t = t - \int_0^t |\overline{\theta}_s| ds$ *is indistinguishable from* $\{\xi_t\}$.

Proof. Using (A.1) and Theorem 7, page 197 in [19], the existence and the uniqueness of the solution are straightforward. The conditions of Corollary 10, page 85 in [13] are satisfied, and the inequality (79) follows.

By hypothesis, the process θ is progressively measurable with respect to $\{\mathcal{G}_t\}$. Using Theorem 3.7 in [3], it follows that the function $\theta : \mathbb{R}_+ \times \Omega \to K$ is $\mathcal{P}^*$ measurable, where

$$\mathcal{P}^* \doteq \{A \in \mathcal{B}(\mathbb{R}_+) \otimes \mathcal{F} : A \triangle B \in \mathcal{N} \text{ for some } B \in \mathcal{P}\},$$

$\mathcal{P}$ denoting the predictable σ-field and $\mathcal{N} \doteq \{N \in \mathcal{B}(\mathbb{R}_+) \otimes \mathcal{F} : \lambda \otimes P(N) = 0\}$. Since $\overline{B}_1(K)$ is a locally compact separable metric space, we can use the lemma and its associated remark [2, pp. 59–60] to obtain the existence of a $\overline{B}_1(K)$-valued, $\{\mathcal{G}_t\}$-predictable process $\{\overline{\theta}_t\}$ satisfying (80).

Consequently,

$$\eta_t = t - \int_0^t |\overline{\theta}_s| ds. \tag{81}$$

Moreover, since $\{\overline{\eta}_t\}$ and $\{\eta_t\}$ are continuous, they are indistinguishable processes. Combining (81), (8), and (A.1), we obtain that $\int_{[0,T+M]\times\Omega} |B(.,\overline{x}_.)u_.| \, \lambda \otimes P < \infty$, so

$$(\forall t \in [0,\gamma]) \quad \int_0^t B(\overline{\eta}_s, \overline{\xi}_s)\overline{\theta}_s ds = \int_0^t B(\eta_s, \overline{\xi}_s)\theta_s ds$$

by using Fubini's theorem.

Similarly, we have that

$$(\forall t \in [0,\gamma]) \quad \int_0^t (1 - |\overline{\theta}_s|) A(\overline{\eta}_s, \overline{\xi}_s) ds = \int_0^t (1 - |\theta_s|) A(\eta_s, \overline{\xi}_s) ds$$

and

$$(\forall t \in [0,\gamma]) \quad \int_0^t (1 - |\overline{\theta}_s|) |D(\overline{\eta}_s, \overline{\xi}_s)|^2 ds = \int_0^t (1 - |\theta_s|) |D(\eta_s, \overline{\xi}_s)|^2 ds.$$

Consequently, we obtain that

$$(\forall t \in [0,\gamma]) \quad \int_0^t \sqrt{1 - |\overline{\theta}_s|} D(\overline{\eta}_s, \overline{\xi}_s) ds = \int_0^t \sqrt{1 - |\theta_s|} D(\eta_s, \overline{\xi}_s) ds,$$

which implies that $\{\overline{\xi}_t\}$ satisfies (17).

By the uniqueness of the solution of (17), $\xi_t = \overline{\xi}_t$, $P-$ a.s., for all t in $[0,\gamma]$. However, $\{\xi_t\}$ and $\{\overline{\xi}_t\}$ are continuous processes, so they are indistinguishable. ∎

Proof of Lemma 4.5. Clearly, ν and ν^n are $\{\mathcal{G}_t\}$ stopping times (for all $n \in \mathbb{N}$). Since $\Psi \in \overline{\Upsilon}^a$, we have that $E_P[G(\eta_\gamma)] < \infty$, implying that $\eta_\gamma = T$. With (15) and the definition of ν, we obtain that

$$\nu \leq \gamma \leq T + M. \tag{82}$$

Note that

$$\nu^n \leq \inf\left\{t \geq 0 : t - \int_0^t \frac{n+1}{n+2} |\theta_s| ds \geq \frac{nT}{n+1}\right\}.$$

Since the process $\{t - \int_0^t \frac{n}{n+1}|\theta_s|ds\}$ is continuous and strictly increasing, we have $\nu^n < \nu^{n+1}$. Similarly, it can be shown that

$$\nu^n < \nu. \tag{83}$$

Therefore, the sequence $\{\nu^n\}$ converges almost surely to a limit labeled $\overline{\nu}$ such that

$$\overline{\nu} \leq \nu. \tag{84}$$

By definition of ν^n, we have

$$\nu^n - \int_0^{\nu^n} \frac{n}{n+1}|\theta_s|ds = \frac{nT}{n+1}, \tag{85}$$

and letting $n \to \infty$, we obtain

$$\eta_{\overline{\nu}} = T.$$

From the definition of ν, we have $\overline{\nu} \geq \nu$. However, with (84) we obtain that $\overline{\nu} = \nu$, and so $\lim_{n\to\infty} \nu^n = \nu$.

From the definition of ν and (85), we obtain that

$$\nu - \nu^n - \frac{T}{n+1} \geq 0.$$

With (84), we have $T + M - \nu^n - \frac{T}{n+1} \geq 0$. Moreover, using (82) and (83), we obtain that $T + M - \nu^n > 0$. Finally, $0 \leq \alpha^n < 1$, which gives the result. □

Proof of Lemma 4.7. Since the process $\{\eta_t^n\}$ is strictly increasing, it follows that γ^n is the unique solution of the following equation:

$$\eta_{\gamma^n}^n = T. \tag{86}$$

However,

$$\begin{aligned} \eta_\gamma^n &= \eta_{\nu^n}^n + \gamma - \nu^n - \int_{\nu^n}^{\gamma} |\theta_s^n|ds \\ &= \frac{nT}{n+1} + \frac{T(\gamma - \nu^n)}{(n+1)(T + M - \nu^n)}. \end{aligned} \tag{87}$$

Using (15), it follows that

$$\eta_\gamma^n \leq T. \tag{88}$$

From (86), we have

$$\eta_\gamma^n + \gamma^n - \gamma = T. \tag{89}$$

Combining (87)–(89), we obtain (38).

By using the definition of $\{\theta_t^n\}$, (15), and the fact that $|\theta_t| \leq 1$, we have

$$\begin{aligned} \int_0^\gamma |\theta_s - \theta_s^n|^2 ds &\leq 2\left[\int_0^{\nu^n} |\theta_s - \theta_s^n|ds + \int_{\nu^n}^{\nu} |\theta_s - \theta_s^n|ds + \int_\nu^\gamma |\theta_s - \theta_s^n|ds\right] \\ &\leq 2\left[\frac{T+M}{n+1} + \nu - \nu^n + \frac{T}{n+1}\frac{\gamma - \nu}{T + M - \nu^n}\right]. \end{aligned}$$

From (15), (82), and (83), it follows that

$$\frac{\gamma-\nu}{T+M-\nu^n} \leq \frac{T+M-\nu}{T+M-\nu^n} \leq 1.$$

Consequently, there exists a constant C_1 such that

$$E_P\left[\left|\int_0^\gamma |\theta_s-\theta_s^n|^2 ds\right|^2\right] \leq C_1\left\{\frac{1}{(n+1)^2}+E_P[|\nu-\nu^n|^2]\right\}.$$

Similarly, it is easy to deduce the same bound for $E_P[\int_0^\gamma |\eta_s-\eta_s^n|^2 ds]$, which gives the result. □

Acknowledgments. The authors are grateful to anonymous referees for many suggestions which have greatly improved the presentation of the paper.

The authors would like to thank P. Bertrand (L2S-CNRS) and F. Lamnhabi (NCN, L2S-CNRS) for their support.

SYSTEMS OF CONTROLLED FUNCTIONAL DIFFERENTIAL EQUATIONS AND ADAPTIVE TRACKING*

A. ILCHMANN†, E. P. RYAN‡, AND C. J. SANGWIN§

Abstract. An adaptive servomechanism is developed in the context of the problem of approximate or practical tracking (with prescribed asymptotic accuracy), by the system output, of any admissible reference signal (absolutely continuous and bounded with essentially bounded derivative) for every member of a class of controlled dynamical systems modelled by functional differential equations.

Key words. adaptive control, nonlinear systems, functional differential equations, practical tracking, universal servomechanism

PII. S0363012900379704

1. Introduction.

A servomechanism problem is addressed in the context of a class of controlled dynamical systems having the interconnected structure shown in the dashed box in Figure 1. In particular, the aim is the development of an adaptive servomechanism which, for every system of the underlying class, ensures practical tracking (in the sense that prespecified asymptotic tracking accuracy, quantified by $\lambda > 0$, is assured), by the system output, of an arbitrary reference signal assumed to be locally absolutely continuous and bounded with essentially bounded derivative. (We denote by $\mathcal{R}$ the class of such functions and remark that bounded globally Lipschitz functions form an easily recognized subclass.) The system consists of the interconnection of two blocks: The dynamic block Σ_1, which can be influenced directly by the system input/control u (an $\mathbb{R}^M$-valued function), is also driven by the output w from the dynamic block Σ_2. Viewed abstractly, the block Σ_2 can be considered as a causal operator which maps the system output y (an $\mathbb{R}^M$-valued function) to w (an internal quantity, unavailable for feedback purposes).

In essence, the underlying system class $\mathcal{S}$ consists of infinite-dimensional nonlinear M-input u, M-output y systems (p, f, g, T), given by a controlled nonlinear functional differential equation of the form

(1.1)
$$\dot{y}(t) = f(p(t), (Ty)(t)) + g(p(t), (Ty)(t), u(t)), \quad y|_{[-h,0]} = y^0 \in C([-h, 0]; \mathbb{R}^M),$$

where, loosely speaking, $h \geq 0$ quantifies the "memory" of the system, p may be thought of as a (bounded) disturbance term, and T is a nonlinear causal operator. While a full description of the system class $\mathcal{S}$ is postponed to section 3, we remark here that diverse phenomena are incorporated within the class including, for example, diffusion processes, delays (both point and distributed), and hysteretic effects.

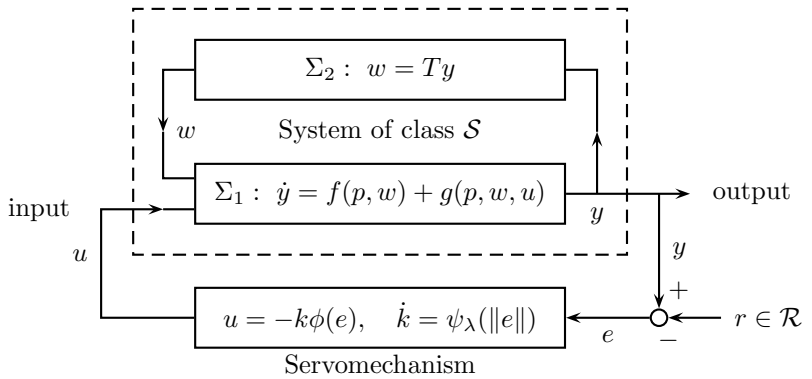

FIG. 1. $(\mathcal{R},\mathcal{S})$-*universal* λ-*servomechanism.*

Furthermore, we remark that results pertaining to adaptive control of functional differential equations are also contained in [3], wherein both the underlying class of systems and the analytic framework differs in an essential manner from those of the present paper; restricted to a problem of adaptive *stabilization*, related results are also reported in [19], with the fundamental distinction that, in [19], *discontinuous* stabilizing feedback strategies are developed within an analytic framework of differential inclusions.

The control objective is to determine an $(\mathcal{R},\mathcal{S})$-universal λ-servomechanism: specifically, to determine continuous functions $\phi : \mathbb{R}^M \to \mathbb{R}^M$ and $\psi_\lambda : \mathbb{R}_+ \to \mathbb{R}_+$ (parameterized by $\lambda > 0$) such that, for each system of class $\mathcal{S}$ and every reference signal $r \in \mathcal{R}$, the control

$$u(t) = -k(t)\phi(y(t) - r(t)), \quad \dot{k}(t) = \psi_\lambda(\|y(t) - r(t)\|), \quad k|_{[-h,0]} = k^0 \tag{1.2}$$

applied to (1.1) ensures (i) convergence of the controller gain, and (ii) tracking of $r(\cdot)$ with asymptotic accuracy quantified by $\lambda > 0$, in the sense that $\max\{\|y(t) - r(t)\| - \lambda, 0\} \to 0$ as $t \to \infty$. See Figure 1.

Given $\lambda > 0$, $r \in \mathcal{R}$ and writing

$$F : (t,w,y,k) \mapsto (f(p(t),w) + g(p(t),w,-k\phi(y - r(t))),\ \psi_\lambda(\|y - r(t)\|)), \tag{1.3}$$

we see that analysis of the behavior of a system $(p,f,g,T) \in \mathcal{S}$ under control (1.2) constitutes a study of an initial-value problem of the form

$$\dot{x}(t) = F(t,(\widehat{T}x)(t)), \quad x|_{[-h,0]} = x^0 := (y^0,k^0) \in C([-h,0];\mathbb{R}^N), \tag{1.4}$$

where $N = M+1$, $x(t) = (y(t),k(t))$, and $\widehat{T}$ is an operator defined on $C([-h,\infty);\mathbb{R}^N)$ by

$$(\widehat{T}x)(t) = (\widehat{T}(y,k))(t) := ((Ty)(t),y(t),k(t)). \tag{1.5}$$

The contribution of this paper is threefold in theme: First, we provide an existence theory for initial-value problems of the general form (1.4) under relatively mild hypotheses on F and $\widehat{T}$; second, and within the framework of the first theme,

we develop a universal servomechanism[1] for a class of nonlinear, infinite-dimensional systems; third, we elucidate the hypotheses on the right-hand side ψ_λ of the gain adaptation equation in (1.2) under which the tracking objective is achievable. In the very specific context of the linear systems of section 2.2 below we will show that $\psi_\lambda : [0,\infty) \to [0,\infty)$ may be chosen as any continuous function with the properties $\psi_\lambda^{-1}(0) = [0,\lambda]$ and $\liminf_{s\to\infty} \psi_\lambda(s) \neq 0$. (In particular, ψ_λ may be chosen to be a bounded function; one such choice is given by $\psi_\lambda(s) = \max\{s-\lambda, 0\}/s$ for $s > 0$ with $\psi_\lambda(0) := 0$.) This ensures that the gain k can exhibit at most linear growth, a feature with attendant practical advantages.

We close this section with some remarks on notation. For $I \subset \mathbb{R}$ an interval $C(I;\mathbb{R}^N)$ (respectively, $AC_{\mathrm{loc}}(I;\mathbb{R}^N)$) denotes the set of continuous (respectively, locally absolutely continuous) functions $I \to \mathbb{R}^N$; $L^\infty_{\mathrm{loc}}(I;\mathbb{R}^N)$ denotes the space of measurable locally essentially bounded functions $I \to \mathbb{R}^N$. For $x : I \to \mathbb{R}^N$, the restriction of x to $J \subset I$ is denoted by $x|_J$. The open ball of radius $r > 0$, centered at $c \in \mathbb{R}^N$, is written as $\mathbb{B}_r(c)$. For $\lambda > 0$, d_λ denotes the Euclidean distance function for $[-\lambda,\lambda]$ given by

$$d_\lambda(\xi) := \max\{0, |\xi| - \lambda\}. \tag{1.6}$$

$\mathcal{R}$ denotes the space of bounded functions in $AC_{\mathrm{loc}}(\mathbb{R};\mathbb{R}^M)$ with essentially bounded derivative; when equipped with the norm $\|\cdot\|_{1,\infty}$ given by $\|r\|_{1,\infty} = \sup_{t\in\mathbb{R}} \|r(t)\| + \text{ess-sup}_{t\in\mathbb{R}} \|\dot{r}(t)\|$, $\mathcal{R}$ can be identified as the Sobolev space $W^{1,\infty}(\mathbb{R};\mathbb{R}^M)$. We write $\mathbb{R}_+ := [0,\infty)$. $\mathcal{K}$ denotes the class of continuous, strictly increasing functions $\alpha : \mathbb{R}_+ \to \mathbb{R}_+$ with $\alpha(0) = 0$; the subclass of *unbounded* class $\mathcal{K}$ functions is denoted $\mathcal{K}_\infty$. $\mathcal{KL}$ is the class of functions $\gamma : \mathbb{R}_+^2 \to \mathbb{R}_+$ such that for each $t \in \mathbb{R}_+$, $\gamma(\cdot,t)$ is of class $\mathcal{K}$ and for each $s \in \mathbb{R}_+$, $\gamma(s,\cdot)$ is decreasing with $\gamma(s,t) \to 0$ as $t \to \infty$.

2. Functional differential equations. The focus of this section is the development of an existence theory, for initial-value problems of the form (1.4), of sufficient generality to accommodate the analysis of dynamic behavior of the adaptively controlled systems of later sections. While the literature is rich in existence results for functional differential equations (see, for example, [4]), we are unaware of a result directly applicable to the particular class of equations which form the focus of the present paper. For this reason, and to make the present paper self-contained, we provide an appropriate result in Theorem 2.3 below (with proof in the appendix). First, we make precise the class of admissible operators $\widehat{T}$ in (1.4).

DEFINITION 2.1 (the operator class $\mathcal{T}_h^{N,K}$). *For $h \geq 0$ and $N, K \in \mathbb{N}$, let $\mathcal{T}_h^{N,K}$ denote the space of operators $T : C([-h,\infty);\mathbb{R}^N) \to L^\infty_{\mathrm{loc}}(\mathbb{R}_+;\mathbb{R}^K)$ with the following properties.*

1. *For every $\delta > 0$ and every bounded interval $I \subset \mathbb{R}_+$, there exists $\Delta > 0$ such that, for all $x \in C([-h,\infty);\mathbb{R}^N)$,*

$$\sup_{t\in[-h,\infty)} \|x(t)\| < \delta \quad \Longrightarrow \quad \|(Tx)(t)\| < \Delta \quad \textit{for almost all (a.a.) } t \in I\,.$$

2. *For all $t \in \mathbb{R}_+$, the following hold:*
   (a) *for all $x, \xi \in C([-h,\infty);\mathbb{R}^N)$,*

$$x(\cdot) \equiv \xi(\cdot) \text{ on } [-h,t] \quad \Longrightarrow \quad (Tx)(s) = (T\xi)(s) \ \textit{ for a.a. } s \in [0,t];$$

[1] The servomechanism can also tolerate disturbances on the output measurement in a sense to be described in section 3.

(b) *for all continuous* $\zeta : [-h, t] \to \mathbb{R}^N$*, there exist* $\tau, \delta, c > 0$ *such that, for all* $x, \xi \in C([-h, \infty); \mathbb{R}^N)$ *with* $x|_{[-h,t]} = \zeta = \xi|_{[-h,t]}$ *and* $x(s), \xi(s) \in \mathbb{B}_\delta(\zeta(t))$ *for all* $s \in [t, t + \tau]$*,*

$$\operatorname*{ess\,sup}_{s\in[t,t+\tau]} \|(Tx)(s) - (T\xi)(s)\| \;\le\; c \sup_{s\in[t,t+\tau]} \|x(s) - \xi(s)\|.$$

Remark 2.2. (i) The essence of property 1 of Definition 2.1 is a "bounded-input, *locally* bounded-output" assumption.

(ii) Property 2(a) is an assumption of causality.

(iii) Property 2(b) is a technical assumption on T of a "locally Lipschitz" nature.

(iv) Let $T \in \mathcal{T}_h^{N,K}$ and $t \ge 0$. Given $x \in C([-h, t); \mathbb{R}^N)$, let x^e denote an arbitrary extension of x to $C([-h, \infty); \mathbb{R}^N)$. By virtue of property 2(a), $Tx^e|_{[0,t)}$ is uniquely determined by the function x, in the sense that the former is independent of the extension x^e chosen for the latter. Expanding on this observation, we will adopt the following notational convention: For $s \in [0, t)$, we simply write $(Tx)(s)$ in place of $(Tx^e)(s)$, where $x^e \in C([-h, \infty); \mathbb{R}^N)$ is any continuous extension of x.

(v) For $\omega \in \mathbb{R}$, let S_ω denote the shift operator on functions $\mathbb{R} \to \mathbb{R}^M$ given by $(S_\omega x)(t) := x(t + \omega)$ for all $t \in \mathbb{R}$. Then

$$T \in \mathcal{T}_h^{N,K} \quad \Longrightarrow \quad TS_{-\omega} \in \mathcal{T}_{h+\omega}^{N,K} \quad \text{for all } \omega \ge 0. \tag{2.1}$$

(vi) Let $T_1, T_2 \in \mathcal{T}_h^{N,K}$ and $\tau_1, \tau_2 \in \mathbb{R}$. Then the operator $\tau_1 T_1 + \tau_2 T_2$, defined by $(\tau_1 T_1 + \tau_2 T_2)(y)(t) := \tau_1 (T_1 y)(t) + \tau_2 (T_2 y)(t)$, is also of class $\mathcal{T}_h^{N,K}$.

(vii) The class $\mathcal{T}_h^{N,N}$ differs from class $\mathcal{T}_h^N$ of [19, Definition 4] only insofar as operators of the former class have range $C([-h, \infty); \mathbb{R}^N)$ while operators of the latter class have domain $L^\infty_{\mathrm{loc}}(\mathbb{R}; \mathbb{R}^N)$.

2.1. An existence theorem. Consider the initial-value problem

$$\dot{x}(t) = F(t, (\widehat{T}x)(t)), \quad x|_{[-h,0]} = x^0 \in C([-h, 0]; \mathbb{R}^N), \tag{2.2}$$

where $\widehat{T}$ is a causal operator of class $\mathcal{T}_h^{N,K}$ and $F : [-h, \infty) \times \mathbb{R}^K \to \mathbb{R}^N$ is a Carathéodory function. (Specifically, (i) for almost all $t \in \mathbb{R}$, $F(t, \cdot)$ is continuous; (ii) for each fixed $w \in \mathbb{R}^K$, $F(\cdot, w)$ is measurable; (iii) for each compact $C \subset \mathbb{R}^K$ there exists $\kappa \in L^1_{\mathrm{loc}}([-h, \infty); \mathbb{R}_+)$ such that

$$\|F(t, w)\| \le \kappa(t) \quad \text{for almost all } t \in [-h, \infty) \text{ and all } w \in C.)$$

By a solution of (2.2) on $[-h, \omega)$, we mean a function $x \in C([-h, \omega); \mathbb{R}^N)$, with $\omega \in (0, \infty]$ and $x|_{[-h,0]} = x^0$, such that $x|_{[0,\omega)}$ is absolutely continuous and satisfies the differential equation in (2.2) for almost all $t \in [0, \omega)$; x is maximal if it has no right extension that is also a solution.

THEOREM 2.3. *Let* $N, K \in \mathbb{N}$*,* $\widehat{T} \in \mathcal{T}_h^{N,K}$*, and* $x^0 \in C([-h, 0]; \mathbb{R}^N)$*. Assume* $F : [-h, \infty) \times \mathbb{R}^K \to \mathbb{R}^N$ *is a Carathéodory function.*

There exists a solution $x : [-h, \omega) \to \mathbb{R}^N$ *of the initial-value problem* (2.2)*, and every solution can be extended to a maximal solution; moreover, if* $F \in L^\infty_{\mathrm{loc}}([-h, \infty) \times \mathbb{R}^K; \mathbb{R}^N)$ *and* $x : [-h, \omega) \to \mathbb{R}^N$ *is a bounded maximal solution, then* $\omega = \infty$*.*

Proof. For proof, see the appendix.

Next, we show that the operators of the class $\mathcal{T}_h^{N,K}$ encompass the input-output behavior of a diverse range of subsystems Σ_2 (see Figure 1).

2.2. Linear systems. *The finite-dimensional prototype.* Consider the well-studied class $\mathcal{L}$ of finite-dimensional, real, linear, minimum-phase, M-input ($u(t)$), M-output ($y(t)$) systems having high-frequency gain $B \in \mathbb{R}^{M\times M}$ with spectrum in the open right half complex plane. Under a suitable coordinate transformation (see, for example, [5, Proposition 2.1.2]), every system in $\mathcal{L}$ can be expressed in the form of two coupled subsystems

$$\left.\begin{aligned} \dot{y}(t) &= A_1 y(t) + A_2 z(t) + Bu(t), \quad y(0) = y^0 \\ \dot{z}(t) &= A_3 y(t) + A_4 z(t), \qquad\qquad z(0) = z^0 \end{aligned}\right\} \tag{2.3}$$

with $y(t), u(t) \in \mathbb{R}^M$, $z(t) \in \mathbb{R}^{N-M}$, and where A_4 has spectrum in the open left half complex plane. Introducing the linear operator T given by

$$(Ty)(t) := A_1 y(t) + A_2 \int_0^t \exp(A_4(t-s))A_3 y(s)ds \tag{2.4}$$

and the function p given by $p(t) := A_2 \exp(A_4 t)z^0$, then, with respect to an operator theoretic viewpoint, system (2.3) can be interpreted as

$$\dot{y}(t) = p(t) + (Ty)(t) + Bu(t), \quad y(0) = y^0. \tag{2.5}$$

With reference to Figure 1, (2.4) and (2.5) correspond to components Σ_2 and Σ_1 of the interconnected system.

Regular linear systems with bounded observation operator. The following example is adapted from [19] and extends the prototype linear class $\mathcal{L}$ to an infinite-dimensional setting by replacing the second of the differential equations (2.3) by an infinite-dimensional analogue on a Hilbert space X. Let $\mathbf{G}$ denote the transfer function of a regular (in the sense of [22]) linear system with state space X, with generating operators (A, B, C, D), and with $\mathbb{R}^M$-valued input and $\mathbb{R}^Q$-valued output. This means, in particular, that (i) A generates a strongly continuous semigroup $\mathbf{S} = (\mathbf{S}_t)_{t\geq 0}$ of bounded linear operators on X, (ii) the control operator B is a bounded linear operator from $\mathbb{R}^M$ to X_{-1}, (iii) the observation operator C is a bounded linear operator from X_1 to $\mathbb{R}^Q$, and (iv) the feedthrough operator D is a linear operator from $\mathbb{R}^M$ to $\mathbb{R}^Q$. Here X_1 denotes the space $\mathrm{dom}(A)$ (the domain of A) endowed with the graph norm, and X_{-1} denotes the completion of X with respect to the norm $\|z\|_{-1} = \|(s_0 I - A)^{-1} z\|$, where s_0 is any fixed element of the resolvent set of A and $\|\cdot\|$ denotes the norm on X. As a regular linear system, the transfer function $\mathbf{G}$ is holomorphic and bounded on every half-plane $\mathbb{C}_\alpha$ with $\alpha > \omega(\mathbf{S}) := \lim_{t\to\infty} t^{-1} \ln \|\mathbf{S}_t\|$. Moreover,

$$\lim_{s\to\infty,\ s\in\mathbb{R}} \mathbf{G}(s) = D.$$

The system is said to be exponentially stable if the semigroup $\mathbf{S}$ is exponentially stable—that is, if $\omega(\mathbf{S}) < 0$. Henceforth, we assume that the system is exponentially stable and, moreover, we assume that the observation operator C can be extended to a bounded linear operator from X to $\mathbb{R}^Q$; this extended operator is again denoted by C.

In terms of the generating operators (A, B, C, D), the transfer function $\mathbf{G}$ is given by

$$\mathbf{G}(s) = C(sI - A)^{-1}B + D.$$

For any $z^0 \in X$ and input $y \in L^\infty_{\rm loc}(\mathbb{R}_+;\mathbb{R}^M)$, the state $z(\cdot)$ and the output $w(\cdot)$ of the regular system (with bounded observation operator) satisfy the equations

$$\dot z(t) = Az(t) + By(t)\,, \quad z(0) = z^0, \tag{2.6}$$

$$w(t) = Cz(t) + Dy(t) \tag{2.7}$$

for almost all $t \geq 0$. The derivative on the left-hand side of (2.6) has, of course, to be understood in X_{-1}. In other words, if we consider the initial-value problem (2.6) in the space X_{-1}, then for any $z^0 \in X$ and $y \in L^\infty_{\rm loc}(\mathbb{R}_+;\mathbb{R}^M)$, (2.6) has a unique strong solution given by the variation of parameters formula (see [16, Chapter 4, Theorem 2.9])

$$z(t) = \mathbf{S}_t z^0 + \int_0^t \mathbf{S}_{t-s} By(s)\, ds. \tag{2.8}$$

Restricting to continuous inputs, define the operator $T : C(\mathbb{R}_+;\mathbb{R}^M) \to L^\infty_{\rm loc}(\mathbb{R}_+;\mathbb{R}^Q)$ by

$$(Ty)(t) := C\int_0^t \mathbf{S}_{t-s} By(s)\ ds + Dy(t), \quad t \geq 0. \tag{2.9}$$

(We remark that the above operator is the infinite-dimensional counterpart of the operator (2.4) in the case of the finite-dimensional prototype.) By exponential stability of the semigroup $\mathbf{S}$, there then exist constants $c_1 > 0$ such that

$$\|z\|_{L^\infty(\mathbb{R}_+;X)} \leq c_1\left[\|z^0\| + \|y\|_{L^\infty(\mathbb{R}_+;\mathbb{R}^M)}\right] \quad \text{for all } \ (z^0, y) \in X \times L^\infty(\mathbb{R}_+;\mathbb{R}^M). \tag{2.10}$$

Setting $h = 0$, we see that property 2(a) of Definition 2.1 holds and property 2(b) is a consequence of the linearity of T and (2.10), in view of (2.10), and causality property 1 of Definition 2.1 also holds. Therefore, the operator T is of class $\mathcal{T}_0^{M,Q}$.

2.3. Nonlinear systems. *Input-to-state stable (ISS) systems.* Let $Z : \mathbb{R}^L \times \mathbb{R}^M \to \mathbb{R}^L$ be locally Lipschitz with $Z(0,0) = 0$. For $y \in L^\infty_{\rm loc}(\mathbb{R}_+;\mathbb{R}^M)$, let $z(\cdot, z^0, y)$ denote the maximal solution of the initial-value problem

$$\dot z(t) = Z(z(t), y(t)), \quad z(0) = z^0 \in \mathbb{R}^L. \tag{2.11}$$

Assume that the system is input-to-state stable (ISS) [20]; that is, there exist functions $\theta \in \mathcal{KL}$ and $\gamma \in \mathcal{K}$ such that, for all $(z^0, y) \in \mathbb{R}^L \times L^\infty_{\rm loc}(\mathbb{R}_+;\mathbb{R}^M)$,

$$\|z(t, z^0, y)\| \leq \theta(\|z^0\|, t) + \operatorname*{ess\,sup}_{s\in[0,t]} \gamma(\|y(s)\|) \quad \text{for all } \ t \geq 0. \tag{2.12}$$

Let $W : \mathbb{R}^L \to \mathbb{R}^Q$ be locally Lipschitz and such that there exists $c > 0$ such that $\|W(z)\| \leq c\|z\|$ for all $z \in \mathbb{R}^L$. Now consider system (2.11) with output w given by

$$w(t) = W(z(t, z^0, y)).$$

Fix $z^0 \in \mathbb{R}^L$ arbitrarily. Again, restricting to continuous inputs, define the operator $T : C(\mathbb{R}_+;\mathbb{R}^M) \to L^\infty_{\rm loc}(\mathbb{R}_+;\mathbb{R}^Q)$ by

$$(Ty)(t) := W(z(t, z^0, y)), \quad t \geq 0. \tag{2.13}$$

In view of (2.12), property 1 of Definition 2.1 evidently holds; setting $h = 0$, we see that property 2(a) also holds. Arguing as in [19, section 3.2.3], via an application of Gronwall's lemma, it can be shown that property 2(b) holds. Therefore, the operator T is of class $\mathcal{T}_0^{M,Q}$. We note that, strictly speaking, the above construction yields a family of operators T_{z^0} parameterized by the initial data z^0.

Systems in input affine form. A particular generalization of the prototype class $\mathcal{L}$ of linear, finite-dimensional, minimum-phase systems is the class of nonlinear systems in input affine form

$$\left.\begin{array}{ll} \dot{y}(t) = a(t, y(t), z(t)) + b(t, y(t), z(t))u(t), & y(0) = y^0 \\ \dot{z}(t) = c(t, y(t), z(t)), & z(0) = z^0 \end{array}\right\} \tag{2.14}$$

where $a : \mathbb{R}_+ \times \mathbb{R}^M \times \mathbb{R}^L \to \mathbb{R}^M$, $b : \mathbb{R}_+ \times \mathbb{R}^M \times \mathbb{R}^L \to \mathbb{R}^{M\times M}$, and $c : \mathbb{R}_+ \times \mathbb{R}^M \times \mathbb{R}^L \to \mathbb{R}^L$ are Carathéodory functions and (y_e, z_e, u_e) is an equilibrium ($(y_e, z_e, u_e) = (0, 0, 0)$ in the linear prototype) in the sense that

$$a(t, y_e, z_e) = 0, \quad b(t, y_e, z_e)u_e = 0, \quad c(t, y_e, z_e) = 0 \quad \text{for all } t \geq 0.$$

The problem of construction of a λ-servomechanism for such systems has been investigated in [1, 6]. There, the minimum-phase property of the linear prototype in (2.3) is replaced by the assumptions that z_e is a global, uniformly exponentially stable equilibrium of

$$\dot{\eta}(t) = c(t, y_e, \eta(t)). \tag{2.15}$$

We assume that (i) for each compact set $C \subset \mathbb{R}^M \times \mathbb{R}^L$, there exists $\kappa \in L^1_{\mathrm{loc}}(\mathbb{R}_+)$ such that $\|c(t, y, z) - c(t, \xi, \zeta)\| \leq \kappa(t)\|(y, z) - (\xi, \zeta)\|$ for almost all $t \in \mathbb{R}_+$ and all $(y, z), (\xi, \zeta) \in C$, and (ii) for some constant $c_0 > 0$,

$$\|c(t, y, z) - c(t, y_e, z)\| \leq c_0\ [1 + \|y - y_e\|] \quad \text{for all } (t, y, z) \in \mathbb{R}_+ \times \mathbb{R}^M \times \mathbb{R}^L.$$

Considering the second equations of (2.14) in isolation, for $y \in L^\infty_{\mathrm{loc}}(\mathbb{R}_+, \mathbb{R}^M)$ we denote by $z(\cdot, z^0, y)$ the unique solution of

$$\dot{z}(t) = c(t, y(t), z(t)) = c(t, y_e, z(t)) + [c(t, y(t), z(t)) - c(t, y_e, z(t))], \quad z(0) = z^0.$$

Invoking exponential stability of the equilibrium of (2.15) in conjunction with converse Lyapunov theory (details omitted here), we may conclude the existence of a constant $c_1 > 0$ such that, for each $(z^0, y) \in \mathbb{R}^L \times L^\infty_{\mathrm{loc}}(\mathbb{R}_+; \mathbb{R}^M)$,

$$\|z(t, z^0, y)\| \leq c_1[\|z^0\| + 1 + \operatorname*{ess\,sup}_{s\in[0,t]} \|y(s)\|] \quad \text{for all } t \geq 0. \tag{2.16}$$

Fix $z^0 \in \mathbb{R}^L$ arbitrarily. Define the operator $T : C(\mathbb{R}_+; \mathbb{R}^M) \to L^\infty_{\mathrm{loc}}(\mathbb{R}_+; \mathbb{R}^L)$ by

$$(Ty)(t) := z(t, z^0, y), \quad t \geq 0. \tag{2.17}$$

In view of (2.16), property 1 of Definition 2.1 evidently holds; setting $h = 0$, we see that property 2(a) also holds. An application of Gronwall's lemma (analogous to that adopted in [19, section 3.2.3] in the context of ISS systems) yields property 2(b). Therefore, the operator T is of class $\mathcal{T}_0^{M,L}$. As in the case of ISS systems, we remark that, strictly speaking, the above construction yields a family of operators T_{z^0} parameterized by the initial data z^0.

The general case. Elaborating on the above two cases, consider the system

$$\dot{z}(t) = Z(t, z(t), y(t)), \quad z(0) = z^0 \in \mathbb{R}^L, \tag{2.18}$$

with input $y \in L^\infty_{\mathrm{loc}}(\mathbb{R}_+; \mathbb{R}^M)$ and output

$$w(t) = W(t, z(t)) \in \mathbb{R}^Q.$$

Assume that $W : \mathbb{R}_+ \times \mathbb{R}^L \to \mathbb{R}^Q$ and $Z : \mathbb{R}_+ \times \mathbb{R}^L \times \mathbb{R}^M \to \mathbb{R}^L$ are Carathéodory functions and such that the following hold: (i) for some constant $c > 0$, $\|W(t, z)\| \le c\|z\|$ for almost all $t \ge 0$ and all $z \in \mathbb{R}^L$; (ii) for each compact set $C \subset \mathbb{R}^L \times \mathbb{R}^M$, there exists $\kappa \in L^1_{\mathrm{loc}}(\mathbb{R}_+)$ such that $\|Z(t, z, y) - Z(t, \zeta, \xi)\| \le \kappa(t)\|(z, y) - (\zeta, \xi)\|$ for almost all $t \in \mathbb{R}_+$ and all $(z, y), (\zeta, \xi) \in C$; and (iii) for each $(z^0, y) \in \mathbb{R}^L \times L^\infty_{\mathrm{loc}}(\mathbb{R}_+; \mathbb{R}^M)$, the unique maximal solution of initial-value problem (2.18) has interval of existence $\mathbb{R}_+$. (We denote the solution by $z(\cdot, z^0, y)$.) Furthermore, we assume the existence of a function $\gamma \in \mathcal{K}$ such that, for each $z^0 \in \mathbb{R}^L$, there exists a constant $c > 0$ such that, for all $y \in L^\infty_{\mathrm{loc}}(\mathbb{R}_+; \mathbb{R}^M)$,

$$\|z(t, z^0, y)\| \le c[1 + \text{ess-sup}_{s \in [0,t]} \gamma(\|y(s)\|)] \quad \text{for all } t \ge 0 \tag{2.19}$$

(a weaker condition than the ISS inequality (2.12)). Fix $z^0 \in \mathbb{R}^L$ arbitrarily. Define the operator $T : C(\mathbb{R}_+; \mathbb{R}^M) \to L^\infty_{\mathrm{loc}}(\mathbb{R}_+; \mathbb{R}^Q)$ by

$$(Ty)(t) = W(t, z(t, z^0, y)), \quad t \ge 0.$$

Then this construction yields a family (parameterized by the initial data z^0) of operators T of class $\mathcal{T}_0^{M,Q}$: This family subsumes the operators discussed in sections 2.2 and 2.3 above.

2.4. Nonlinear delay elements. Let $\mathcal{D}^{M,Q}$ denote the class of functions $\mathbb{R} \times \mathbb{R}^M \to \mathbb{R}^Q : (t, y) \mapsto \Psi(t, y)$ that are measurable in t and locally Lipschitz in y uniformly with respect to t. Precisely, (i) for each fixed y, $\Psi(\cdot, y)$ is measurable, and (ii) for every compact $C \subset \mathbb{R}^M$ there exists a constant c such that

$$\text{for a.a. } t, \quad \|\Psi(t, y) - \Psi(t, z)\| \le c\|y - z\| \quad \text{for all } y, z \in C.$$

For $i = 0, \dots, n$, let $\Psi_i \in \mathcal{D}^{M,Q}$ and $h_i \in \mathbb{R}_+$. Define $h := \max_i h_i$. For $y \in C([-h, \infty); \mathbb{R}^M)$, let

$$(Ty)(t) := \int_{-h_0}^{0} \Psi_0(s, y(t + s))\, ds + \sum_{i=1}^{n} \Psi_i(t, y(t - h_i)), \quad t \ge 0. \tag{2.20}$$

The operator T, so defined, is of class $\mathcal{T}_h^{M,Q}$; for details, see [19].

2.5. Hysteresis. A general class of nonlinear operators $C(\mathbb{R}_+; \mathbb{R}) \to C(\mathbb{R}_+; \mathbb{R})$, which includes many physically motivated hysteretic effects, is defined via assumptions (N1)–(N8) of [11, section 3]. Assumption (N1) implies that property 2(a) of Definition 2.1 holds with $h = 0$. Assumption (N5) implies that property 2(b) of Definition 2.1 holds. Finally, (N8) implies that property 1 of Definition 2.1 holds. Therefore, the nonlinear operators considered in [11] are of class $\mathcal{T}_0^{1,1}$. Examples of such operators, including relay hysteresis, backlash hysteresis, elastic-plastic hysteresis, and Preisach operators, are detailed in [11, section 5]. By way of illustration, we briefly describe the first two of these examples.

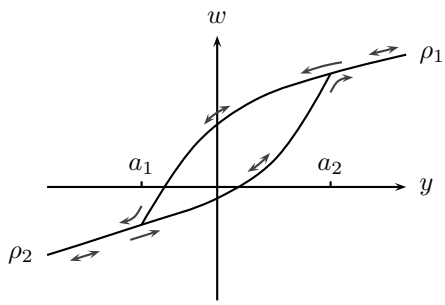

FIG. 2. *Relay hysteresis.*

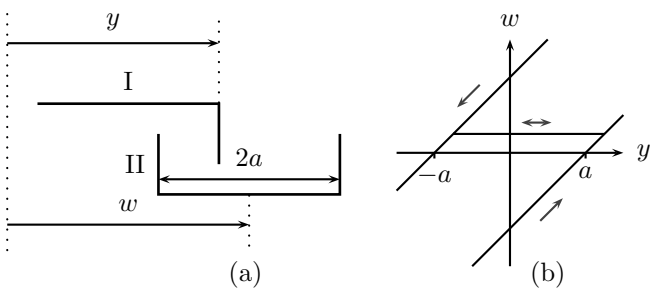

FIG. 3. *Backlash hysteresis.*

Relay hysteresis. Let $a_1 < a_2$ and let $\rho_1 : [a_1, \infty) \to \mathbb{R}$, $\rho_2 : (-\infty, a_2] \to \mathbb{R}$ be continuous, globally Lipschitz, and satisfying $\rho_1(a_1) = \rho_2(a_1)$ and $\rho_1(a_2) = \rho_2(a_2)$. For a given input $y \in C(\mathbb{R}_+; \mathbb{R})$ to the hysteresis element, the output w is such that $(y(t), w(t)) \in \operatorname{graph}(\rho_1) \cup \operatorname{graph}(\rho_2)$ for all $t \in \mathbb{R}_+$: The value $w(t)$ of the output at $t \in \mathbb{R}_+$ is either $\rho_1(y(t))$ or $\rho_2(y(t))$, depending on which of the threshold values a_2 or a_1 was "last" attained by the input y. This situation is illustrated by Figure 2.

When suitably initialized, such a hysteresis element has the property that, to each input $y \in C(\mathbb{R}_+; \mathbb{R})$ there corresponds a unique output $w = Ty \in C(\mathbb{R}_+; \mathbb{R})$; the operator T, so defined, is of class $\mathcal{T}_0^{1,1}$. Full details may be found in [11, section 5]. (See also [12, 10].)

Backlash hysteresis. Next consider a one-dimensional mechanical link consisting of the two solid parts I and II, as shown in Figure 3(a), the displacements of which (with respect to some fixed datum) at time $t \geq 0$ are given by $y(t)$ and $w(t)$ with $|y(t) - w(t)| \leq a$ for all t, and $w(0) := y(0) + \xi$ for some prespecified $-a \leq \xi \leq a$.

Within the link there is mechanical play; that is to say, the position $w(t)$ of II remains constant as long as the position $y(t)$ of I remains within the interior of II. Thus, assuming the continuity of y, we have $\dot{w}(t) = 0$ whenever $|y(t) - w(t)| < a$. Given a continuous input $y \in C(\mathbb{R}_+; \mathbb{R})$, describing the evolution of the position of I, denote the corresponding position of II by $w = Ty$. The operator T so defined (in effect we define a family T_ξ of operators parameterized by the initial offset ξ) is known as *backlash* or *play* and is of class $\mathcal{T}_0^{1,1}$. Full details may be found in [11, section 5].

3. Adaptive control. We now focus on the adaptive control problem. The following subclass $\mathcal{J}$ of $\mathcal{K}$ functions will play an important role:

$$\mathcal{J} := \{\alpha \in \mathcal{K} |\ \text{ for each } \ \delta \in \mathbb{R}_+ \text{ there exists } \Delta \in \mathbb{R}_+ :\ \alpha(\delta\tau) \le \Delta\alpha(\tau) \ \text{ for all } \ \tau \ge 0\}.$$

Furthermore, we define $\mathcal{J}_\infty := \mathcal{J} \cap \mathcal{K}_\infty$. For example, (a) for each $s > 0$, the function $\tau \mapsto \tau^s$ is of class $\mathcal{J}_\infty$, and (b) the function $\tau \mapsto \ln(1+\tau)$ is of class $\mathcal{J}_\infty$; its inverse $\tau \mapsto \exp(\tau) - 1$ is of class $\mathcal{K}_\infty$ but is *not* of class $\mathcal{J}$. In addition to their defining property, the ensuing properties of class $\mathcal{J}$ functions are readily established and will be freely invoked later in the analysis:

1. $\alpha, \beta \in \mathcal{J} \quad \Longrightarrow \quad \alpha \circ \beta \in \mathcal{J}$ and $\alpha + \beta \in \mathcal{J}$;
2. $\alpha \in \mathcal{J} \quad \Longrightarrow \quad \exists \Delta > 0 :\ \alpha(a+b) \le \Delta[\alpha(a) + \alpha(b)] \quad$ for all $\ a, b \in \mathbb{R}_+$.

We also record a property of $\mathcal{K}$ functions (and, a fortiori, a property of $\mathcal{J}$ functions):

3. Let $t > 0$, $I = [0,t]$, $\xi \in C(I;\mathbb{R}_+)$, and $\alpha \in \mathcal{K}$; then $\alpha(\max_{s\in I} \xi(s)) = \max_{s\in I} \alpha(\xi(s))$.

DEFINITION 3.1 (the system class). *Let $\alpha_f, \alpha_T \in \mathcal{J}$; then $\mathcal{S} = \mathcal{S}(\alpha_f, \alpha_T)$ denotes the class of M-input, M-output systems of the form* (1.1) *with the following properties (wherein $P, Q \in \mathbb{N}$ are arbitrary):*

1. $p \in L^\infty([-h,\infty);\mathbb{R}^P)$;
2. $f : \mathbb{R}^P \times \mathbb{R}^Q \to \mathbb{R}^M$ *is continuous and, for every compact set $C \subset \mathbb{R}^P$, there exists a constant $c_f \ge 0$ such that*

$$\|f(p,w)\| \le c_f\,[1 + \alpha_f(\|w\|)] \quad \text{for all } \ (p,w) \in C \times \mathbb{R}^Q\,;$$

3. $g : \mathbb{R}^P \times \mathbb{R}^Q \times \mathbb{R}^M \to \mathbb{R}^M$ *is continuous and, for every compact set $C \subset \mathbb{R}^P$, there exists a positive definite, symmetric $G \in \mathbb{R}^{M\times M}$ such that*

$$\langle Gu, g(p,w,u)\rangle \ge \|u\|^2 \quad \text{for all } (p,w,u) \in C \times \mathbb{R}^Q \times \mathbb{R}^M\,;$$

4. $T : C([-h,\infty);\mathbb{R}^M) \to L^\infty_{\mathrm{loc}}(\mathbb{R}_+;\mathbb{R}^Q)$ *is of class $\mathcal{T}_h^{M,Q}$, and there exist $\alpha_T \in \mathcal{J}$ and constant $c_T \ge 0$ such that, for all $y \in C([-h,\infty);\mathbb{R}^M)$,*

$$\|(Ty)(t)\| \le c_T \left[1 + \max_{s\in[0,t]} \alpha_T(\|y(s)\|)\right] \quad \text{for almost all } \ t \in \mathbb{R}_+\,. \tag{3.1}$$

For convenience, we denote a system of class $\mathcal{S}(\alpha_f, \alpha_T)$ by $(p, f, g, T) \in \mathcal{S}(\alpha_f, \alpha_T)$ and, whenever the functions α_f and α_T are contextually evident, we simply write $\mathcal{S}$ in place of $\mathcal{S}(\alpha_f, \alpha_T)$. We emphasize that, in the construction of an $(\mathcal{R}, \mathcal{S})$-universal control strategy, only the (instantaneous) tracking error $e(t) = y(t) - r(t)$ is assumed to be available for feedback, and the only a priori structural information assumed is knowledge of the functions α_f, $\alpha_T \in \mathcal{J}$. Some examples follow.

Assume f has the polynomial form given by $f(p,w) := \sum_{i=0}^{l} p_i w^i$. Then property 2 of Definition 3.1 holds with $\alpha_f : s \mapsto s^m$ for $m \ge l$; if an upper bound for the degree l of the polynomial is unknown, then the map $\alpha_f : s \mapsto \exp(s) - 1$ suffices.

If $g(p,w,u) = Bu$, as in the linear prototype (2.3), and $B \in \mathbb{R}^{M\times M}$ has spectrum in the open right half complex plane, then there exists a positive definite $G \in \mathbb{R}^{M\times M}$ satisfying $GB + B^TG = 2I$, whence property 3 of Definition 3.1.

Consider again the examples of operators in sections 2.2–2.5.

Let $T \in \mathcal{T}_h^{M,Q}$, given by (2.9), be the input-output operator of an exponentially stable regular linear system with $\mathbb{R}^M$-valued input and $\mathbb{R}^Q$-valued output. Then (2.10) and causality imply that (3.1) holds with the $\alpha_T \in \mathcal{J}$ given by $\alpha_T(s) = s$.

Let $T \in \mathcal{T}_h^{M,Q}$, given by (2.13), be the input-output operator of an ISS system with $\mathbb{R}^M$-valued input and $\mathbb{R}^Q$-valued output. If (2.12) holds for some function γ of class $\mathcal{J}$, then (3.1) holds with $\alpha_T := \gamma$.

Let $\beta \in \mathcal{J}$, $h \in \mathbb{R}_+$, and $\Psi \in \mathcal{D}^{M,Q}$ (recall section 2.4), and assume that

$$\|\Psi(t,y)\| < \mu\,[1 + \beta(\|y\|)] \quad \text{for all } (t,y) \in \mathbb{R}_+ \times \mathbb{R}^M$$

for some $\mu \in \mathbb{R}_+$. Both the point delay given by $(Ty)(t) = \Psi(t, y(t-h))$ and the distributed delay given by $(Ty)(t) = \int_{-h}^{0} \Psi(s, y(t+s))\, ds$ are of class $\mathcal{T}_h^{M,Q}$, and (3.1) holds with $\alpha_T := \beta$.

Last, for the nonlinear operators of section 2.5, assumption (N8) of [11, section 3] asserts that such operators satisfy (3.1) with the $\alpha_T \in \mathcal{J}$ given by $\alpha_T(s) = s$.

3.1. The servomechanism. The servomechanism is designed as follows. Let $\alpha_f, \alpha_T \in \mathcal{J}$. Choose $\alpha \in \mathcal{J}_\infty$ with the property

$$\liminf_{s\to\infty} \frac{\alpha(s)}{s + \alpha_f(\alpha_T(s))} \neq 0. \tag{3.2}$$

For example, the choice $\alpha : s \mapsto s + \alpha_f(\alpha_T(s))$ suffices. For $\lambda > 0$, choose $\psi_\lambda : \mathbb{R}_+ \to \mathbb{R}_+$ to be a continuous function with the properties

$$\text{(i)} \quad \liminf_{s\to\infty} \frac{s\psi_\lambda(s)}{\alpha(s)} \neq 0 \quad \text{and} \quad \text{(ii)} \quad \psi_\lambda^{-1}(0) := \{s \mid \psi_\lambda(s) = 0\} = [0, \lambda]. \tag{3.3}$$

For example, the choice ψ_λ given by $\psi_\lambda(s) := d_{\alpha(\lambda)}(\alpha(s))/s$ for $s > 0$, with $\psi_\lambda(0) := 0$, suffices.

Define the continuous function

$$\phi : \mathbb{R}^M \to \mathbb{R}^M, \quad e \mapsto \begin{cases} \alpha(\|e\|)\|e\|^{-1}e, & e \neq 0, \\ 0, & e = 0. \end{cases} \tag{3.4}$$

Writing $\mathcal{S} = \mathcal{S}(\alpha_f, \alpha_T)$, the next objective is to show that the strategy

$$u(t) = -k(t)\phi(e(t)), \quad \dot{k}(t) = \psi_\lambda(\|e(t)\|), \quad e(t) := y(t) - r(t) \tag{3.5}$$

is an $(\mathcal{R}, \mathcal{S})$-universal λ-servomechanism.

THEOREM 3.2. *Let $\alpha_f, \alpha_T \in \mathcal{J}$. Choose $\alpha \in \mathcal{J}_\infty$ so that* (3.2) *holds and define the continuous $\phi : \mathbb{R}^M \to \mathbb{R}^M$ by* (3.4). *Let $\lambda > 0$ and let $\psi_\lambda : \mathbb{R}_+ \to \mathbb{R}_+$ be continuous with properties* (3.3). *Then feedback strategy* (3.5) *is an $(\mathcal{R}, \mathcal{S})$-universal λ-servomechanism in the sense that for all $(p, f, g, T) \in \mathcal{S}(\alpha_f, \alpha_T)$, $r \in \mathcal{R}$, and $(y^0, k^0) \in C([-h, 0]; \mathbb{R}^{M+1})$ the feedback controlled initial-value problem*

$$\left.\begin{aligned} \dot{y}(t) &= f(p(t), (Ty)(t)) + g(p(t), (Ty)(t), -k(t)\phi(y(t) - r(t))) \\ \dot{k}(t) &= \psi_\lambda(\|y(t) - r(t)\|) \\ (y,k)|_{[-h,0]} &= (y^0, k^0) \end{aligned}\right\} \tag{3.6}$$

has a solution. Every solution can be extended to a maximal solution and every maximal solution $(y,k) : [0,\omega) \to \mathbb{R}^{M+1}$ has the following properties:

(i) *(y,k) is bounded;*

(ii) *$\omega = \infty$;*

(iii) $\lim_{t\to\infty} k(t)$ *exists and is finite;*
(iv) $\lim_{t\to\infty} d_\lambda(\|y(t)-r(t)\|)=0$, *with* d_λ *as in* (1.6).

We preface the proof of Theorem 3.2 by a proposition. (Proof of the latter is straightforward and omitted here.)

PROPOSITION 3.3. *Let* $\xi \in AC_{loc}(\mathbb{R}_+;\mathbb{R}_+)$, $k \in C(\mathbb{R}_+;\mathbb{R}_+)$, $\beta \in \mathcal{K}$, *and* $c \geq 0$. *If* k *is monotonically nondecreasing and unbounded, and* $\dot{\xi}(t) \leq c - k(t)\beta(\xi(t))$ *for almost all* $t \in \mathbb{R}_+$, *then* $\xi(t) \to 0$ *as* $t \to \infty$.

Proof of Theorem 3.2. Write $N := M+1$ and $K := Q+M+1$. Define $F : [-h,\infty)\times\mathbb{R}^K \to \mathbb{R}^N$ by (1.3) and define $\widehat{T} : C([-h,\infty);\mathbb{R}^N) \to L^\infty_{\mathrm{loc}}(\mathbb{R}_+;\mathbb{R}^K)$ by (1.5). Thus, the initial-value problem (3.6) is equivalent to (2.2). By the continuity of f, g, ϕ, ψ_λ and (essential) boundedness of p, it follows that F is a Carathéodory function with the property that, for each $w \in \mathbb{R}^K$, $F(\cdot,w) \in L^\infty_{\mathrm{loc}}([-h,\infty);\mathbb{R}^N)$. By assumption, $T \in \mathcal{T}_h^{M,Q}$ and so $\widehat{T} \in \mathcal{T}_h^{N,K}$. Therefore, by Theorem 2.3, (3.6) has a solution and every solution can be maximally extended. Moreover, every *bounded* maximal solution has interval of existence $[-h,\infty)$.

Let $(y,k) : [-h,\omega) \to \mathbb{R}^N$ be a maximal solution of (3.6). Writing $e := y - r$, we have

(3.7)
$$\left.\begin{aligned} \dot{e}(t) &= f(p(t),(T(e+r))(t)) \\ &\quad + g(p(t),(T(e+r))(t)),-k(t)\phi(e(t))) - \dot{r}(t) \\ \dot{k}(t) &= \psi_\lambda(\|e(t)\|) \end{aligned}\right\} \quad \text{for a.a. } t \in [0,\omega).$$

By (essential) boundedness of p and property 3 of Definition 3.1 of g, there exists a positive definite, symmetric G such that

(3.8)
$$\langle Ge(t), g(p(t),(T(e+r))(t)),-k(t)\phi(e(t)))\rangle \leq -k(t)\alpha(\|e(t)\|)\|e(t)\| \quad \text{for a.a. } t \in [0,\omega).$$

Define $c_0 := \sqrt{2\|G^{-1}\|}$ and $c_1 := \sqrt{2/\|G\|}$. For notational convenience, we introduce functions $V, W \in AC_{\mathrm{loc}}([0,\omega);\mathbb{R}_+)$ given by

$$V(t) := \frac{1}{2}\langle Ge(t), e(t)\rangle \quad \text{and} \quad W(t) := \sqrt{V(t)}$$

with

$$c_0^{-1}\|e(t)\| \leq W(t) \leq c_1^{-1}\|e(t)\| \quad \text{for all } t \in [0,\omega). \tag{3.9}$$

By (3.7), (3.8) and properties of f, g, and T, together with (essential) boundedness of p, r, and $\dot{r}$, there exist constants $c_f, c_T > 0$ such that

(3.10)
$$\begin{aligned} \dot{V}(t) = \langle Ge(t), \dot{e}(t)\rangle &\leq c_f\|G\|\left[1+\alpha_f\left(c_T + c_T \max_{s\in[0,t]} \alpha_T(\|e(s)+r(s)\|)\right)\right]\|e(t)\| \\ &\quad - k(t)\alpha(\|e(t)\|)\|e(t)\| + \|G\|\|r\|_{1,\infty}\|e(t)\| \quad \text{for a.a. } t \in [0,\omega). \end{aligned}$$

Invoking properties of $\mathcal{J}$ functions, we may conclude that, for some constant $c_2 > 0$,

(3.11)
$$\dot{V}(t) \leq c_2\left[1 + \max_{s\in[0,t]} \alpha_f(\alpha_T(\|e(s)\|))\right]\|e(t)\| - k(t)\alpha(\|e(t)\|)\|e(t)\| \quad \text{a.a. } t \in [0,\omega).$$

By (3.2) and the first of properties (3.3), there exist constants $\gamma > \|e(0)\|$, c_γ, $\tilde{c}_\gamma > 0$ such that

(3.12)
$$\alpha_f(\alpha_T(s)) \le c_\gamma \alpha(s) \quad \text{for all } s \ge \gamma \qquad \text{and} \qquad \psi_\lambda(s) \ge \frac{c_\gamma \alpha(s)}{\tilde{c}_\gamma s} \quad \text{for all } s \ge \gamma.$$

With a view to proving Theorem 3.2(i), we first show that e is bounded. Seeking a contradiction, suppose that e (equivalently, W) is unbounded. For each $n \in \mathbb{N}$, define

$$\tau_n := \inf\{t \in [0,\omega) \mid c_1 W(t) = n + 1 + \gamma\}, \quad \sigma_n := \sup\{t \in [0,\tau_n] \mid c_1 W(t) = n + \gamma\}.$$

Recalling that $\gamma > \|e(0)\| \ge c_1 W(0)$, this construction yields a sequence of disjoint intervals (σ_n, τ_n) such that

$$\left.\begin{aligned} &\max_{t\in[0,\tau_n]} c_1 W(t) = c_1 W(\tau_n) = n + 1 + \gamma \\ &c_1 W(\sigma_n) = n + \gamma \\ &c_1 W(t) \in (n + \gamma, n + 1 + \gamma) \ \text{ for all } \ t \in (\sigma_n, \tau_n) \end{aligned}\right\} \quad \text{for all } \ n \in \mathbb{N}.$$

Moreover, for all $n \in \mathbb{N}$,

$$\max_{s\in[0,t]} c_1 W(s) = \max_{s\in[\sigma_n,t]} c_1 W(s) \le n + 1 + \gamma < 2n + 2\gamma \le 2c_1 W(t) \quad \text{for all } \ t \in [\sigma_n, \tau_n],$$

which, together with (3.9) and properties of $\mathcal{J}$ functions, implies the existence of constants $c_3, c_4 > 0$ such that

$$\begin{aligned} (3.13)\quad \max_{s\in[0,t]} \alpha(\|e(s)\|) &\le \max_{s\in[0,t]} \alpha(c_0 W(s)) \le \alpha(2c_0 W(t)) \le \alpha(2c_0 c^{-1} \|e(t)\|) \\ &\le c_3 \alpha(\|e(t)\|) \le c_3 \alpha(c_0 W(t)) \le c_4 \alpha(c_1 W(t)) \quad \text{for all } \ t \in \cup_{n\in\mathbb{N}} [\sigma_n, \tau_n]. \end{aligned}$$

Noting that, for all $n \in \mathbb{N}$, $\alpha(\|e(t)\|) \ge \alpha(\gamma)$ for all $t \in [\sigma_n, \tau_n]$ and invoking (3.13) together with (3.9), (3.11), and (3.12), we may conclude the existence of constants $c_5, c_6 > 0$ such that

(3.14)
$$\dot{V}(t) \le [c_5 - k(t)]\alpha(\|e(t)\|)\|e(t)\| \le c_6 \alpha(c_1 W(t)) W(t) \quad \text{for all } \ t \in \cup_{n\in\mathbb{N}} [\sigma_n, \tau_n].$$

Our next task is to show that supposition of the unboundedness of e implies the unboundedness of k. Invoking (3.12), (3.14), and (3.9) yields

$$\begin{aligned} 2\ln\left(\frac{n+1+\gamma}{1+\gamma}\right) &= \ln V(\tau_n) - \ln V(\sigma_1) = \sum_{j=1}^{n} [\ln V(\tau_j) - \ln V(\sigma_j)] = \sum_{j=1}^{n} \int_{\sigma_j}^{\tau_j} \frac{\dot{V}(t)}{V(t)}\, dt \\ &\le c_6 \sum_{j=1}^{n} \int_{\sigma_j}^{\tau_j} \frac{\alpha(c_1 W(t))}{W(t)}\, dt \le c_6 c_0 \sum_{j=1}^{n} \int_{\sigma_j}^{\tau_j} \frac{\alpha(\|e(t)\|)}{\|e(t)\|}\, dt. \end{aligned} \tag{3.15}$$

By construction of (σ_n, τ_n) we have

$$\gamma < \|e(t)\| \qquad \text{if } t \in (\sigma_j, \tau_j).$$

Hence substituting the second inequality of (3.12) into (3.15) yields

$$2\ln\left(\frac{n+1+\gamma}{1+\gamma}\right) \le c_6 c_0 \frac{\tilde{c}_\gamma}{c_\gamma} \sum_{j=1}^{n} \int_{\sigma_j}^{\tau_j} \psi_\lambda(\|e(t)\|)\, dt \le c_6 c_0 \frac{\tilde{c}_\gamma}{c_\gamma} k(\tau_n) \quad \text{for all } n \in \mathbb{N},$$

and so $k(t) \to \infty$ as $t \uparrow \omega$. Let $n^* \in \mathbb{N}$ be such that $k(\sigma_{n^*}) \ge 2c_5$. By the first inequality in (3.14),

$$\dot{V}(t) \le -c_5 \alpha(\|e(t)\|)\|e(t)\| < 0 \quad \text{for a.a. } t \in [\sigma_{n^*}, \tau_{n^*}]\,,$$

which contradicts the fact that $V(\tau_{n^*}) = W^2(\tau_{n^*}) > W^2(\sigma_{n^*}) = V(\sigma_{n^*})$. Therefore, e is bounded.

By the boundedness of e and continuity of ψ_λ, it follows that $\dot{k}$ is bounded, and so k is bounded on every compact subinterval of $[0, \omega)$. Therefore $\omega = \infty$.

Next, we prove the boundedness of k. By the boundedness of e and (3.11), there exists a constant $c_9 > 0$ such that

$$\dot{V}(t) \le c_9 - k(t)\beta(V(t)) \quad \text{for a.a. } t \in [0, \infty),$$

where $\beta \in \mathcal{K}$ is given by $\beta(s) = \alpha\,(c_1\sqrt{s})\, c_1\sqrt{s}$. Seeking a contradiction, suppose k is unbounded. Then $k(t) \uparrow \infty$ as $t \to \infty$ and so, by Proposition 3.3, $V(t) \to 0$ as $t \to \infty$. Therefore, there exists $\tau \in [0, \infty)$ such that $\|e(t)\| < \lambda$ for all $t \in [\tau, \infty)$ and so $\dot{k}(t) = 0$ for all $t \in [\tau, \infty)$, which again contradicts the supposition of the unboundedness of k.

We have now established Theorem 3.2(i) and (ii). Assertion (iii) follows by the boundedness and monotonicity of k. By the boundedness of e and $\dot{e}$ (see (3.6)), it follows that $t \mapsto e(t)$ is uniformly continuous. By the continuity of $\psi_\lambda(\|\cdot\|)$, we see that $\psi_\lambda(\|e(\cdot)\|)$ is also uniformly continuous. By the boundedness of k, $\int_0^\infty \psi_\lambda(\|e(t)\|)dt < \infty$. By Barbălat's lemma [2], we conclude that $\psi_\lambda(\|e(t)\|) \to 0$ as $t \to \infty$, whence, recalling that $\psi_\lambda^{-1}(0) = [0, \lambda]$, we have assertion (iv). □

3.2. Discussion. Theorem 3.2 also holds in the situation wherein the output measurement is subject to an additive disturbance term η, in which case the control and gain adaptation become

$$u(t) = -k(t)\phi(y(t) - r(t) + \eta(t)), \quad \dot{k}(t) = \psi_\lambda(\|y(t) - r(t) + \eta(t)\|), \quad k|_{[-h,0]} = k^0.$$

If the disturbance η is of class $\mathcal{R}$, then, by Theorem 3.2, $\lim_{t\to\infty} d_\lambda(\|y(t) + \eta(t) - r(t)\|) = 0$. Thus, from a strictly analytical viewpoint, in the presence of output disturbances of class $\mathcal{R}$, the disturbance-free analysis is immediately applicable to replacing the reference signal r by the signal $r - \eta =: \hat{r} \in \mathcal{R}$. Even though the reference signal r and disturbance signal η are assumed to be of the same class $\mathcal{R}$, in practice these signals might be distinguished by their respective spectra (η typically having "high-frequency" content). Moreover, from a practical viewpoint, one might reasonably expect that the disturbance η is "small"; if an a priori bound on the magnitude of the disturbance is available, then λ should be chosen to be commensurate with such a bound.

We remark on the flexibility of choice in the controller functions $\alpha \in \mathcal{J}_\infty$ and ψ_λ (continuous), which are required only to satisfy (3.2) and (3.3). In essence, (3.2) reflects the reasonable requirement that the "strength" of the controller nonlinearity α should be capable of counteracting the potentially destabilizing effects of the

(unknown) system nonlinearities; condition (3.3)(i) translates to a requirement that the gain adaptation function ψ_λ should be commensurate (in the sense of (3.3)(i)) with the strength of the function α. Next, we illustrate by example that the latter condition is also reasonable.

Consider the scalar nonlinear system

$$\dot{y}(t) = a|y(t)|^\epsilon y(t) + u(t), \quad y(0) = y^0 \in \mathbb{R}, \tag{3.16}$$

with $a \in \mathbb{R}$ and $\epsilon > 0$. The choice $\alpha : s \mapsto s^{1+\epsilon}$ implies that (3.2) holds. For $\lambda > 0$, the choice

$$\psi_\lambda : s \mapsto s^\epsilon \min\{d_\lambda(s), 1\} \tag{3.17}$$

implies that (3.3) holds. Therefore, by Theorem 3.2, the control

$$\begin{aligned} u(t) &= -k(t)|y(t) - r(t)|^\epsilon (y(t) - r(t)), \\ \dot{k}(t) &= |y(t) - r(t)|^\epsilon \min\{d_\lambda(|y(t) - r(t)|), 1\}, \quad k(0) = k^0, \end{aligned}$$

ensures that, for every $r \in \mathcal{R}$, the tracking objective is achieved with asymptotic accuracy quantified by $\lambda > 0$.

Now assume that $\epsilon > 0$ is "small." We will investigate the consequences of replacing the above choice of ψ_λ (for which (3.3)(i) holds) by the simpler function $s \mapsto \min\{d_\lambda(s), 1\}$ (equivalent to setting $\epsilon = 0$ in (3.17) and for which (3.3)(i) fails to hold). Taking $r = 0$, $a = 1$, $y^0 > 0$, and (for simplicity) $k^0 = 0$, a straightforward calculation reveals that the control objective is not achievable by the control

$$u(t) = -k(t)|y(t)|^\epsilon y(t), \quad \dot{k}(t) = \min\{d_\lambda(s), 1\}, \quad k(0) = 0.$$

In particular, the feedback-controlled initial-value problem can exhibit finite-time "blow-up" of its solution: Specifically, for each $y^0 > (2/\epsilon)^{1/\epsilon}$, the solution of the feedback-controlled system is such that $y(t) \uparrow \infty$ as $t \uparrow T$ with $T \in (0, T^*)$, where $T^* := 1 - \sqrt{1 - (2/\epsilon)(y^0)^{-\epsilon}} < 1$.

Now consider again linear systems, such as the motivating class $\mathcal{L}$ of finite-dimensional, linear, minimum-phase systems described in section 2.2, and let $\mathcal{R}$ be the space of bounded absolutely continuous functions $\mathbb{R} \to \mathbb{R}^M$ with essentially bounded derivative. As is well known (see, for example, [7]), the following output feedback strategy (a variant of the seminal results in [23, 15, 13, 14]) is an $(\mathcal{R}, \mathcal{L})$-universal λ-servomechanism in the sense that, for each system of class $\mathcal{L}$ and reference signal $r \in \mathcal{R}$, the strategy ensures (i) boundedness of the state, (ii) convergence of the controller gain, and (iii) output tracking with prescribed accuracy λ (in the sense that $d_\lambda(\|e(t)\|) \to 0$ as $t \to \infty$, where $e(t) := y(t) - r(t)$ is the tracking error):

$$u(t) = -k(t)e(t), \qquad \dot{k}(t) = d_\lambda^2(\|e(t)\|), \quad k(0) = k^0. \tag{3.18}$$

Generalizations of this strategy to nonlinear finite-dimensional settings are reported in, for example, [7, 17, 6, 18, 24]; applications to biotechnological processes are contained in [8, 9].

Each of α_f and α_T can be taken to be the identity map $id : s \mapsto s$, and so $\mathcal{L} \subset \mathcal{S}(id, id)$. In this context, $\alpha : s \mapsto s$ and $\psi_\lambda : s \mapsto d_\lambda^2(s)$ are allowable choices, in which case we recover (3.18). Note that the latter choice for ψ_λ, being quadratic in nature, implies that the controller gain $k(\cdot)$ can exhibit rapid growth whenever the tracking error is large. Such behavior may be undesirable from a practical viewpoint.

A very simple but admissible alternative choice of a *bounded* function ψ_λ is $s \mapsto \min\{d_\lambda(s), 1\}$. This choice ensures that k exhibits at most linear growth and the overall control strategy (3.5) reduces to

(3.19)
$$u(t) = -k(t)(y(t) - r(t)), \qquad \dot{k}(t) = \min\{d_\lambda(\|y(t) - r(t)\|), 1\}, \qquad k|_{[-h,0]} = k^0.$$

Theorem 3.2 ensures that this control achieves the tracking objective, with prespecified asymptotic error bound $\lambda > 0$, not only for the motivating finite-dimensional class $\mathcal{L}$, but also for general interconnections of linear systems of the form in Figure 1, encompassing those cases where Σ_2 corresponds to linear delay elements (both pointwise and distributed) or to an exponentially stable infinite-dimensional regular linear system (such as a diffusion process), or linear combinations of these.

Appendix. Proof of Theorem 2.3. (i) By property 2(b) of Definition 2.1 there exist $\tau > 0$, $\delta > 0$, and $c > 0$ such that, for all $x, \xi \in C([-h, \infty); \mathbb{R}^N)$ with $x|_{[-h,0]} = x^0 = \xi|_{[-h,0]}$ and $x(t), \xi(t) \in \mathbb{B}_\delta(x^0(0))$ for all $t \in [0, \tau]$,

$$\operatorname*{ess\,sup}_{t\in[0,\tau]} \|(\widehat{T}x)(t) - (\widehat{T}\xi)(t)\| \le c \sup_{t\in[0,\tau]} \|x(t) - \xi(t)\|.$$

By property 1 of Definition 2.1 of $\widehat{T}$, there exists $\Delta > 0$ such that for all $x \in C([-h, \infty); \mathbb{R}^N)$,

$$\sup_{t\in[-h,\infty)} \|x(t)\| < \delta^* := \delta + \|x^0\|_\infty \quad \Longrightarrow \quad \|(\widehat{T}x)(t)\| < \Delta \quad \text{for almost all} \quad t \in [0, \tau].$$

Since F is a Carathéodory function, there exists integrable $\gamma : [0, \tau] \to \mathbb{R}$ such that

$$\|F(t, w)\| \le \gamma(t) \quad \text{for all} \quad (t, w) \in [0, \tau] \times \mathbb{B}_\Delta(0). \tag{A.1}$$

Define $\Gamma : [-h, \tau] \to \mathbb{R}_+$ by

$$\Gamma(t) := \begin{cases} 0, & t \in [-h, 0), \\ \int_0^t \gamma(s)ds, & t \in [0, \tau], \end{cases}$$

and let $0 < \beta < \tau$ be such that $\Gamma(\beta) < \delta$.

Next, we construct a sequence $\{x_n\}_{n\in\mathbb{N}}$ of continuous functions $[-h, \beta] \to \mathbb{R}^N$ as follows. Let $n \in \mathbb{N}$. For $i = 1, \dots, n$, define $x_n^i : [-h, i\beta/n] \to \mathbb{R}^N$ by the recursive formula:

$$i = 1: \quad x_n^1(t) := \begin{cases} x^0(t), & t \in [-h, 0], \\ x^0(0), & t \in (0, \beta/n], \end{cases}$$

$$i > 1: \quad x_n^i(t) := \begin{cases} x_n^{i-1}(t), & t \in [-h, (i-1)\beta/n], \\ x^0(0) + \int_0^{t-(\beta/n)} F(s, (\widehat{T}x_n^{i-1})(s))ds, & t \in ((i-1)\beta/n, i\beta/n]. \end{cases}$$

Observe that if $i \in \{1, \dots, n-1\}$ and $\|x_n^i(t)\| < \delta^*$ for all $t \in [-h, (i\beta)/n]$, then (a) $\|x_n^{i+1}(t)\| < \delta^*$ for all $t \in [-h, (i\beta)/n]$, and (b) $\|(\widehat{T}x_n^i)(t)\| < \Delta$ for all $t \in [0, (i\beta)/n]$, which, in turn, implies for all $t \in (i\beta/n, (i+1)\beta/n]$

$$\|x_n^{i+1}(t) - x^0(0)\| \le \int_0^{t-\beta/n} \|F(s, (\widehat{T}x_n^i)(s))\|ds \le \int_0^{t-\beta/n} \gamma(s)ds = \Gamma(t - \beta/n) < \delta.$$

Noting that $\|x_n^1(t)\| \le \|x^0\|_\infty < \delta^*$ for all $t \in [-h, \beta/n]$, we may now infer (by induction on i) that

$$\|x_n^i(t)\| < \delta^* \quad \text{for all } \ i \in \{1, \dots, n\}, \quad t \in [-h, i\beta/n].$$

For notational convenience, we write $x_n := x_n^n$. By causality of $\widehat{T}$, the sequence $\{x_n\}_{n\in\mathbb{N}}$ so constructed has the property that, for each $n \in \mathbb{N}$,

$$x_n(t) = \begin{cases} x^0(t), & t \in [-h, 0], \\ x^0(0), & t \in (0, \beta/n], \\ x^0(0) + \int_0^{t-(\beta/n)} F(s, (\widehat{T}x_n)(s))ds, & t \in (\beta/n, \beta]. \end{cases} \tag{A.2}$$

Moreover, for all $n \in \mathbb{N}$, $\|x_n(t)\| < \delta^*$ for all $t \in [-h, \beta]$, and so the sequence $\{x_n\}_{n\in\mathbb{N}}$ is uniformly bounded.

Next we prove that the sequence $\{x_n\}_{n\in\mathbb{N}}$ is equicontinuous. Let $\epsilon > 0$. On the closed interval $[0, \beta]$, Γ is uniformly continuous, and so there exists some $\bar{\delta} > 0$ such that

$$t, s \in [0, \beta] \quad \text{with} \quad |t - s| < \bar{\delta} \implies |\Gamma(t) - \Gamma(s)| < \epsilon. \tag{A.3}$$

Let $n \in \mathbb{N}$, $s, t \in [0, \beta]$ with $|t - s| < \bar{\delta}$. Without loss of generality, we assume that $s \le t$. We consider three exhaustive cases.

First, if $0 \le s \le t \le \beta/n$, then $\|x_n(t) - x_n(s)\| = 0$. Second, if $0 < s \le \beta/n \le t \le \beta$, then $t - \beta/n < \bar{\delta}$, and so

$$\|x_n(t) - x_n(s)\| = \|x_n(t) - x^0(0)\| \le \Gamma(t - \beta/n) < \epsilon.$$

Third, if $\beta/n \le s \le t \le \beta$, then

$$\|x_n(t) - x_n(s)\| \le |\Gamma(t - \beta/n) - \Gamma(s - \beta/n)| < \epsilon.$$

Recalling that $x_n|_{[-h,0]} = x^0$ for all n, we conclude that the sequence $\{x_n\}_{n\in\mathbb{N}}$ is equicontinuous. By the Arzelà–Ascoli theorem and extracting a subsequence if necessary, we may assume that the sequence $\{x_n\}_{n\in\mathbb{N}}$ converges uniformly on $[-h, \beta]$ to a continuous limit which we denote by x. Clearly $x|_{[-h,0]} = x^0$.

By property 2(b) of Definition 2.1, $\lim_{n\to\infty}(\widehat{T}x_n)(t) = (\widehat{T}x)(t)$ for almost all $t \in [0, \beta]$ and so, by the continuity of the function $F(t, \cdot)$,

$$\lim_{n\to\infty} F(t, (\widehat{T}x_n)(t)) = F(t, (\widehat{T}x)(t)) \quad \text{for a.a.} \quad t \in [0, \beta].$$

Noting that $\|(\widehat{T}x_n)(s)\| < \Delta$ for all $s \in [0, \beta]$, and also invoking (A.1), we next have $\|F(s, (\widehat{T}x)(s))\| \le \gamma(s)$ for all $s \in [0, \beta]$ and all $n \in \mathbb{N}$. Therefore,

$$\lim_{n\to\infty} \int_{t-\beta/n}^{t} F(s, (\widehat{T}x_n)(s))ds = 0 \quad \text{for all } t \in (0, \beta] \tag{A.4}$$

and, by the Lebesgue dominated convergence theorem,

$$\lim_{n\to\infty} \int_0^t F(s, (\widehat{T}x_n)(s))ds = \int_0^t F(s, (\widehat{T}x)(s))ds \quad \text{for all } t \in [0, \beta]. \tag{A.5}$$

By (A.2), (A.4), and (A.5), it follows that

$$x(t) = \begin{cases} x^0(t), & t \in [-h, 0], \\ x^0(0) + \int_0^t F(s, (\widehat{T}x)(s))ds, & t \in (0, \beta], \end{cases}$$

and so x is a solution of the initial-value problem.

(ii) Let $x : [-h, \omega) \to \mathbb{R}^N$ be a solution of (2.2). Define

$$\mathcal{A} := \left\{(\rho, \xi) |\ \omega \le \rho \le \infty,\ \xi : [-h, \rho) \to \mathbb{R}^N \text{ is a solution of (2.2) with } \xi|_{[-h,\omega)} = x\right\}.$$

On this nonempty set define a partial order $\preceq$ by

$$(\rho_1, \xi_1) \preceq (\rho_2, \xi_2) \quad \Longleftrightarrow \quad \rho_1 \le \rho_2 \text{ and } \xi_1(t) = \xi_2(t) \text{ for all } t \in [-h, \rho_1).$$

Let $\mathcal{O}$ be a totally ordered subset of $\mathcal{A}$. Let $P := \sup\{\rho | (\rho, \xi) \in \mathcal{O}\}$ and let $\Xi : [-h, P) \to \mathbb{R}^M$ be defined by the property that, for every $(\rho, \xi) \in \mathcal{O}$, $\Xi|_{[0,\rho)} = \xi$. Then (P, Ξ) is in $\mathcal{A}$ and is an upper bound for $\mathcal{O}$. By Zorn's lemma, it follows that $\mathcal{A}$ contains at least one maximal element.

(iii) Assume that $x \in C([-h, \omega); \mathbb{R}^N)$ is a bounded maximal solution of (2.2) and that $F \in L^\infty_{\text{loc}}([-h, \infty) \times \mathbb{R}^K; \mathbb{R}^N)$. Seeking a contradiction, suppose $\omega < \infty$. By the boundedness of x, together with property 1 of Definition 2.1 of $\widehat{T}$, it follows that $\dot{x}(\cdot)$ is essentially bounded. Therefore, x is uniformly continuous and so extends to a continuous function $x : [-h, \omega] \to \mathbb{R}^N$. Now consider the initial-value problem

$$\dot{v}(t) = S_\omega F\big(t, (\widehat{T} S_{-\omega} v)(t)\big), \qquad v|_{[-(h+\omega),0]} = S_\omega x. \tag{A.6}$$

By (2.1) and the above existence result, the initial-value problem (A.6) has a solution $\tilde{v} : [-(h + \omega), \tau) \to \mathbb{R}^N$, $\tau > 0$. It follows that $\tilde{x} = S_{-\omega}\tilde{v} : [-h, \omega + \tau) \to \mathbb{R}^N$ is a solution of the original initial-value problem (2.2) and is a proper right extension of the solution x. This contradicts the maximality of x. Therefore, $\omega = \infty$. □

OPTIMAL CONSUMPTION AND PORTFOLIO WITH BOTH FIXED AND PROPORTIONAL TRANSACTION COSTS*

BERNT ØKSENDAL† AND AGNÈS SULEM‡

Abstract. We consider a market model with one risk-free and one risky asset, in which the dynamics of the risky asset are governed by a geometric Brownian motion. In this market we consider an investor who consumes from the bank account and who has the opportunity at any time to transfer funds between the two assets. We suppose that these transfers involve a fixed transaction cost $k > 0$, independent of the size of the transaction, plus a cost proportional to the size of the transaction.

The objective is to maximize the cumulative expected utility of consumption over a planning horizon. We formulate this problem as a combined stochastic control/impulse control problem, which in turn leads to a (nonlinear) quasi-variational Hamilton–Jacobi–Bellman inequality (QVHJBI). We prove that the value function is the unique viscosity solution of this QVHJBI. Finally, numerical results are presented.

Key words. portfolio selection, transaction cost, impulse control, quasi-variational inequalities, viscosity solutions

1. Introduction.

Let $(\Omega, \mathcal{F}, P)$ be a probability space with a given filtration $\{\mathcal{F}_t\}_{t\geq 0}$. We denote by $X(t)$ the amount of money the investor has in the bank at time t and by $Y(t)$ the amount of money invested in the risky asset at time t. We assume that in the absence of consumption and transactions the process $X(t)$ grows deterministically at exponential rate r, while $Y(t)$ is a geometric Brownian motion; i.e.,

$$dX(t) = rX(t)dt, \qquad X(0) = x, \tag{1.1}$$

$$dY(t) = \alpha Y(t)dt + \sigma Y(t)dW(t), \qquad Y(0) = y, \tag{1.2}$$

where $W(t)$ is one-dimensional $\mathcal{F}_t$-Brownian motion and $\alpha > r > 0$ and $\sigma \neq 0$ are constants.

Suppose that at any time t the investor is free to choose a *consumption rate* $c(t) \geq 0$. This consumption is automatically drawn from the bank account holding with no extra costs. Moreover, at any time the investor can decide to transfer money from the bank account to the stock and conversely. Assume that a purchase of size ℓ of stocks incurs a transaction cost consisting of a sum of a fixed cost $k > 0$ (independent of the size of the transaction) plus a cost $\lambda\ell$ proportional to the transaction ($\lambda \geq 0$). These costs are drawn from the bank account. Similarly a sale of size m of stocks incurs the fixed cost $K > 0$ plus the proportional cost μm ($\mu \geq 0$). For simplicity we will assume that $K = k$ and $\mu = \lambda$. In this context the investor will only change his

portfolio finitely many times in any finite time interval. The control of the investor will consist of a combination of a regular *stochastic control* $c(t)$ and an *impulse control* $v = (\tau_1, \tau_2, \ldots; \xi_1, \xi_2, \ldots)$. Here $0 \leq \tau_1 < \tau_2 < \cdots$ are $\mathcal{F}_t$-stopping times giving the times when the investor decides to change his portfolio, and $\{\xi_j \in \mathbf{R};\ j = 1, 2, \ldots\}$ are $\mathcal{F}_{\tau_j}$-measurable random variables giving the sizes of the transactions at these times. We assume that

$$c(t) \text{ is } \mathcal{F}_t\text{-adapted}, \quad c(t, \omega) \geq 0, \quad \text{and } \lim_{j \to \infty} \tau_j = \infty \quad \text{a.s.} \tag{1.3}$$

(possibly $\tau_n = \infty$ a.s. for some $n < \infty$).

If such a control $w = (c, v)$ is applied to the system $(X(t), Y(t))$, it gets the form

$$dX(t) = (rX(t) - c(t))dt, \qquad \tau_i \leq t < \tau_{i+1}, \tag{1.4}$$

$$dY(t) = \alpha Y(t)dt + \sigma Y(t)dW(t), \qquad \tau_i \leq t < \tau_{i+1}, \tag{1.5}$$

$$X(\tau_{i+1}) = X(\tau_{i+1}^-) - k - \xi_{i+1} - \lambda|\xi_{i+1}|, \tag{1.6}$$

$$Y(\tau_{i+1}) = Y(\tau_{i+1}^-) + \xi_{i+1}. \tag{1.7}$$

Thus a positive value of ξ_{i+1} indicates that money is being taken from the bank account at time τ_{i+1} to buy stocks, and conversely if ξ_{i+1} is negative.

If our agent has the amounts x in the bank account and y in stocks, his *net wealth* is given by

$$H(x, y) = \max\{x + y - \lambda|y| - k, \min\{x, y\}\}. \tag{1.8}$$

Therefore it is natural to define the *solvency region* $\mathcal{S}$ by

$$\mathcal{S} = \{(x, y) \in \mathbf{R}^2; H(x, y) \geq 0\}, \tag{1.9}$$

and we set

$$\widetilde{\mathcal{S}} = \mathbf{R}^+ \times \mathcal{S}. \tag{1.10}$$

Define the line segments ℓ_1, ℓ_2 by

$$\ell_1 = \{(x, y);\ x + (1 - \lambda)y = k,\ x < 0\}, \tag{1.11}$$

$$\ell_2 = \{(x, y);\ x + (1 + \lambda)y = k,\ y < 0\}, \tag{1.12}$$

and let the points P, Q be the end points of these segments, i.e.,

$$P = \left(0, \frac{k}{1 - \lambda}\right), \qquad Q = (k, 0). \tag{1.13}$$

(See Figure 1.1 and also Remark 2.4.) The investor's objective is to maximize over all combined controls $w = (c, v)$ the expression

$$J^w(s, x, y) = E^{s,x,y}\left[\int_0^\infty e^{-\delta(s+t)} \frac{c^\gamma(t)}{\gamma} dt\right] = e^{-\delta s} E^{x,y}\left[\int_0^\infty e^{-\delta t} \frac{c^\gamma(t)}{\gamma} dt\right], \tag{1.14}$$

where $\delta > 0$, $0 < \gamma < 1$ are constants ($1 - \gamma$ is the relative risk aversion coefficient) and $E^{s,x,y}$ denotes the expectation with respect to the probability law $P^{s,x,y}$ of

$$Z(t) = Z^w(t) := (s + t, X(t), Y(t)), \qquad t \geq 0, \tag{1.15}$$

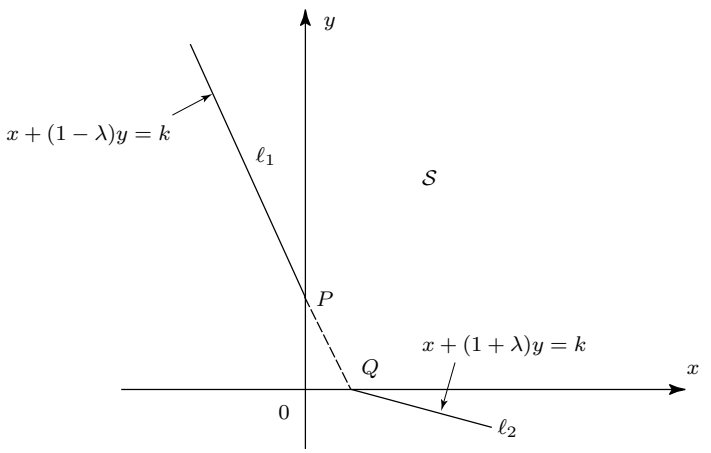

FIG. 1.1. *The solvency region.*

starting at $z = (s, x, y)$.

We seek the value function(s)

$$\Phi(s,x,y) = \sup_{w \in \mathcal{W}} J^w(s,x,y), \qquad \Psi(x,y) = \Phi(0,x,y), \tag{1.16}$$

where $\mathcal{W} = \mathcal{W}(x,y)$ is the set of all *admissible* controls, i.e., all combined controls which satisfy (1.3) and which do not cause the process $Z(t)$ to exit from $\mathcal{S}$. Note that

$$J^w(s,x,y) = e^{-\delta s} J^w(0,x,y) \quad \text{and} \quad \Phi(s,x,y) = e^{-\delta s}\Phi(0,x,y) = e^{-\delta s}\Psi(x,y), \tag{1.17}$$

so the introduction of the s-variable is not really necessary. However, it turns out to be convenient in order to simplify the notation and the arguments in some of the later proofs.

We also seek a corresponding *optimal* control, i.e., a combined control w^* such that

$$\Phi(s,x,y) = J^{w^*}(s,x,y) = e^{-\delta s}\Psi(x,y). \tag{1.18}$$

This problem may be regarded as a generalization of the optimal consumption and portfolio problems studied by Merton [M] and Davis and Norman [DN]. See also Shreve and Soner [SS]. [M] considers the case with no transaction costs ($\lambda = k = 0$), in which case the problem is no longer a combined control problem but a pure stochastic control problem. In this case it is proved in [M] that it is optimal to choose the portfolio such that

$$\frac{Y(t)}{X(t)} = \frac{\pi^*}{1-\pi^*} \qquad \text{for all } t \tag{1.19}$$

(the Merton line), where

$$\pi^* = \frac{\alpha - r}{(1-\gamma)\sigma^2}\ . \tag{1.20}$$

Moreover, the corresponding value function in the Merton case $\lambda = k = 0$ is given by

$$\Psi_0(x,y) = C_1(x+y)^\gamma, \tag{1.21}$$

where

$$C_1 = \frac{1}{\gamma} C_0^{\gamma-1} \qquad \text{with} \qquad C_0 = \frac{1}{1-\gamma}\left[\delta - \gamma r - \frac{\gamma(\alpha - r)^2}{2\sigma^2(1-\gamma)}\right], \tag{1.22}$$

provided that

$$\delta > \gamma\left[r + \frac{(\alpha - r)^2}{2\sigma^2(1-\gamma)}\right]. \tag{1.23}$$

See, e.g., [DN, section 2].

From now on we assume that (1.23) holds.

It is easy to see that

$$\Psi(x, y) \leq \Psi_0(x, y). \tag{1.24}$$

This is also pointed out in Corollary 2.2, to be proved later.

[DN] and [SS] consider the case with proportional transaction costs only ($k = 0$), in which case the problem can be formulated as a singular stochastic control problem. It is proved in [DN] and [SS] that under some conditions there exist two straight lines Γ_1, Γ_2 through the origin, bounding a cone NT, such that it is optimal to make no transactions if $(X(t), Y(t)) \in NT$ and make transactions corresponding to local time at $\partial(NT)$, resulting in reflections back to NT every time $(X(t), Y(t)) \in \partial(NT)$. Depending on the parameters, the Merton line may or may not go between the lines Γ_1, Γ_2 (see Figure 1.2 and the discussion in [AMS, section 7.2]). For an extension of these results to markets with jumps, see [FØS1] and [FØS2].

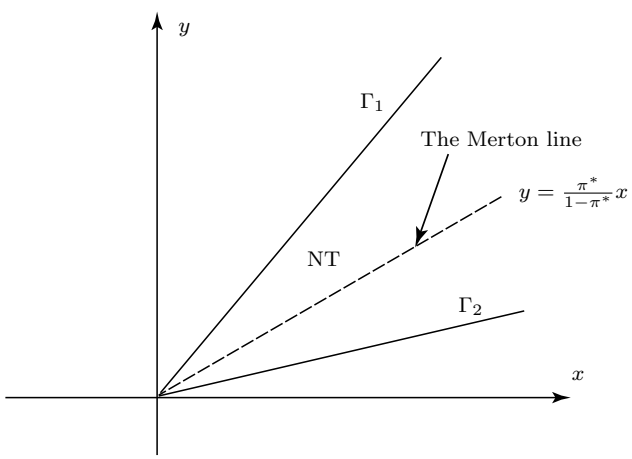

FIG. 1.2. *The no-transaction cone when* $k = 0$.

The first paper to model markets with fixed transaction costs $k > 0$ by impulse control theory seems to be [EH], but they do not consider optimal consumption.

Perhaps the paper which is closest to ours is [K]. Here optimal consumption in markets with fixed transaction costs is considered, but consumption is allowed only at the discrete times of the transactions. This makes it possible to put the problem within the framework of impulse control and quasi-variational inequalities.

In our paper we allow consumption to take place at any time, independent of the (discrete) times chosen for the transactions. As explained above, we model this

as a combined stochastic control and impulse control problem, or a *combined control* problem, for short.

In section 2 we introduce quasi-variational Hamilton–Jacobi–Bellman inequalities (QVHJBI) associated with this combined control problem. We point out that if a function $\psi(x,y)$ satisfies these QVHJBI (and some additional smoothness conditions), then ψ coincides with the value function Ψ, defined by (1.16). (See Theorem 2.1).

In section 3 we prove that the value function Ψ is the unique viscosity solution of the QVHJBI formulated in section 2.

Finally in section 4 we present some numerical estimates for Ψ and the optimal consumption-investment policy $w^* = (c^*, v^*)$.

For other recent papers on impulse control and combined control see, e.g., [BØ], [MØ], [CZ1], [CZ2], and [BP] and the references therein. We refer to [BL] and [ØS] for a comprehensive treatment of the general theory of impulse control and its quasi-variational inequalities.

Remark 1.1. Another natural choice of solvency region would be the set

$$\mathcal{S}_+ := [0,\infty) \times [0,\infty). \tag{1.25}$$

This choice models a situation in which no borrowing or short-selling is allowed. We will mostly use the choice $\mathcal{S}$ given by (1.9) in this paper, but we point out that the proofs carry over to the $\mathcal{S}_+$ case with only minor modifications. (Usually the $\mathcal{S}_+$ case is simpler.)

2. Quasi-variational Hamilton–Jacobi–Bellman inequalities (QVHJBI). Let A^c be the generator of the process $Z^c(t) = (s+t, X^c(t), Y^c(t))$ when there are no transactions; i.e., A^c is the partial differential operator given by

$$(A^c f)(s,x,y) = \frac{\partial f}{\partial s} + (rx - c)\frac{\partial f}{\partial x} + \alpha y \frac{\partial f}{\partial y} + \tfrac{1}{2}\sigma^2 y^2 \frac{\partial^2 f}{\partial y^2} \tag{2.1}$$

for any $f : \mathbf{R}^3 \to \mathbf{R}$ and (s,x,y) such that the derivatives exist. In particular, if $f(s,x,y) = e^{-\delta s} g(x,y)$, then

$$(A^c f)(s,x,y) = e^{-\delta s} L^c g(x,y),$$

where

$$L^c g(x,y) = -\delta g + (rx - c)\frac{\partial g}{\partial x} + \alpha y \frac{\partial g}{\partial y} + \tfrac{1}{2}\sigma^2 y^2 \frac{\partial^2 g}{\partial y^2}. \tag{2.2}$$

For $(x,y) \in \mathcal{S}$ and $\xi \neq 0$ set

$$x' = x'(\xi) = x - k - \xi - \lambda|\xi|, \qquad y' = y'(\xi) = y + \xi. \tag{2.3}$$

We define the *intervention operator* $\mathcal{M}$ by

$$\mathcal{M}h(x,y) = \sup\{h(x',y'); \xi \in \mathbf{R} \setminus \{0\}, (x',y') \in \mathcal{S}\} \tag{2.4}$$

for all locally bounded $h : \mathcal{S} \to \mathbf{R}^+$, $(x,y) \in \mathcal{S}$.

If $(x',y') \notin \mathcal{S}$ for all $\xi \in \mathbf{R} \setminus \{0\}$, we set $\mathcal{M}h(x,y) = 0$. If for all $(x,y) \in \mathcal{S}$ there exists $(x',y') = (x'(\xi), y'(\xi)) \in \mathcal{S}$ such that

$$\mathcal{M}h(x,y) = h(x',y'),$$

then we set

$$\widehat{\xi}(x,y) = \widehat{\xi}_h(x,y) = (x',y'). \tag{2.5}$$

(More precisely, we let $\widehat{\xi}(x,y)$ denote a measurable selection of the map $(x,y) \to (x',y')$.)

If Φ is the value function for our problem, then for each s we can interpret $\mathcal{M}\Phi(s,x,y)$ as the maximal value we can obtain by making an admissible transaction at (s,x,y).

Following [BØ] we call a locally bounded function $h : \widetilde{\mathcal{S}} \to \mathbf{R}^+$ *stochastically* C^2 with respect to Z^c if $(A^c h)(z)$ exists for almost all $z = (s,x,y)$ with respect to *the Green measure* (expected occupation time measure) $G(z_0,\cdot)$, and the generalized Dynkin formula holds for h, i.e.,

$$E^{z_0}[h(Z^c(\tau'))] = E^{z_0}[h(Z^c(\tau))] + E^{z_0}\left[\int_\tau^{\tau'} (A^c h)(Z^c(t))dt\right]$$

for all stopping times τ, τ' such that

$$\tau \le \tau' \le T_R := \inf\{t > 0, |Z^c(t)| \ge R\} \wedge R \qquad \text{for some } R < \infty. \tag{2.6}$$

Recall (see, e.g., [Ø]) that for each $z_0 \in \widetilde{\mathcal{S}}$ the *Green measure* $G(z_0,\cdot)$ of the process Z^c in $\widetilde{\mathcal{S}}$ is defined by

$$G(z_0,H) = E^{z_0}\left[\int_0^\tau \mathcal{X}_H(Z^c(t))dt\right] \qquad \text{for all Borel sets } H \subset \widetilde{\mathcal{S}},$$

where $\tau = \inf\{t > 0; Z^c(t) \notin \widetilde{\mathcal{S}}\}$ and $\mathcal{X}_H(z) = 1$ if $z \in H$, $\mathcal{X}_H(z) = 0$ if $z \notin H$.

If h is a function on $\mathcal{S}$, we define

$$\mathcal{L}h(x,y) = \sup_{c \ge 0}\left\{L^c h(x,y) + \frac{c^\gamma}{\gamma}\right\}, \qquad (x,y) \in \mathcal{S}, \tag{2.7}$$

and

$$\mathcal{L}_0 h(x,y) = L^0 h(0,y) = -\delta h + \alpha y\frac{\partial h}{\partial y} + \tfrac{1}{2}\sigma^2 y^2 \frac{\partial^2 h}{\partial y^2} \tag{2.8}$$

for all points (x,y) where the partial derivatives of h involved in $L^c h$ exist.

We then set (see (1.11)–(1.13) for definitions of ℓ_1, ℓ_2, and P)

$$\mathcal{L}_1 h(x,y) = \begin{cases} \mathcal{L}h(x,y) & \text{for} \quad (x,y) \in \mathcal{S} \setminus (\ell_1 \cup \ell_2) \setminus [0,P], \\ \mathcal{L}_0 h(x,y) & \text{for} \quad (x,y) \in [0,P]. \end{cases} \tag{2.9}$$

Note that at $[0,P]$ the only admissible consumption is $c = 0$.

By adapting Theorem 3.1 in [BØ] to our situation, we get the following sufficient QVHJBI.

THEOREM 2.1. *Let $\mathcal{S}$ and $\widetilde{\mathcal{S}}$ be as defined in* (1.9) *and put $U = \mathcal{S} \setminus (\ell_1 \cup \ell_2)$, $\widetilde{U} = [0,\infty) \times U$.*

(i) *Suppose we can find a locally bounded function* $\psi : \mathcal{S} \to \mathbf{R}^+$ *such that* $\psi \in C^1(U)$ *and*

$$\phi(s,x,y) := e^{-\delta s}\psi(x,y) \quad \text{is stochastically } C^2 \text{ with respect to } Z^c(t) \tag{2.10}$$
$$\text{for all Markov controls } c = c(x,y);$$

$$\mathcal{L}_1\psi \le 0 \qquad \text{a.e. with respect to } G(z_0,\cdot) \text{ on } \widetilde{U} \text{ for all } z_0 \in \widetilde{U}; \tag{2.11}$$

$$\psi(x,y) \ge \mathcal{M}\psi(x,y) \qquad \text{for all } (x,y) \in U. \tag{2.12}$$

Then

$$\psi(x,y) \ge \Psi(x,y) \qquad \text{for all } (s,x,y) \in \widetilde{U}.$$

(ii) *Define the continuation region*

$$D = \{(x,y) \in U; \psi(x,y) > \mathcal{M}\psi(x,y)\}.$$

Suppose

$$\mathcal{L}_1\psi(x,y) = 0 \qquad \text{on } D \tag{2.13}$$

and that $\widehat{\xi}(x,y) = \widehat{\xi}_\psi(x,y)$ *(defined in* (2.5)*) exists for all* $(x,y) \in \mathcal{S}$. *Define*

$$c^*(x,y) = \begin{cases} (\frac{\partial\psi}{\partial x})^{\frac{1}{\gamma-1}} & \text{for} \quad (x,y) \in U \setminus [0,P], \\ 0 & \text{for} \quad (x,y) \in [0,P], \end{cases}$$

and define the impulse control

$$v^* := (\tau_1^*, \tau_2^*, \ldots; \xi_1^*, \xi_2^*, \ldots)$$

as follows.

Put $\tau_0^* = 0$ *and inductively*

$$\tau_{k+1}^* = \inf\{t > \tau_k^*; (X^{(k)}(t), Y^{(k)}(t)) \notin D\}, \tag{2.14}$$

$$\xi_{k+1}^* = \widehat{\xi}(X^{(k)}(\tau_{k+1}^{*-}), Y^{(k)}(\tau_{k+1}^{*-})), \tag{2.15}$$

where $\widehat{\xi}$ *is as defined in* (2.5) *and* $(X^{(k)}, Y^{(k)})$ *is the process obtained by applying the combined control*

$$w^{(k)} := (c^*, (\tau_1^*, \ldots, \tau_k^*; \xi_1^*, \ldots, \xi_k^*)), \qquad k = 1, 2, \ldots.$$

Suppose $w^* := (c^*, v^*) \in \mathcal{W}$ *and that*

$$e^{-\delta t}\psi(X^{(w^*)}(t), Y^{(w^*)}(t)) \to 0 \qquad \text{as } t \to \infty \text{ a.s.} \tag{2.16}$$

and that the family

$$\{e^{-\delta\tau}\psi(X^{(w^*)}(\tau), Y^{(w^*)}(\tau));\ \tau \ \text{ stopping time}\} \tag{2.17}$$

is uniformly integrable. Then

$$\psi(x,y) = \Psi(x,y) \tag{2.18}$$

and w^* is optimal.

Proof. This follows by the proof of Theorem 3.1 in [BØ] with only minor modifications. Note that the Hamilton–Jacobi–Bellman inequality (HJBI) (3.7) in [BØ] has the following form in our case, if $(x,y) \in U \setminus [0,P]$:

$$\mathcal{L}\psi(x,y) = \sup_{c\geq 0}\left\{ -\delta\psi + (rx-c)\frac{\partial\psi}{\partial x} + \alpha y\frac{\partial\psi}{\partial y} + \frac{1}{2}\sigma^2 y^2\frac{\partial^2\psi}{\partial y^2} + \frac{c^\gamma}{\gamma}\right\} \leq 0.$$

This can only hold if $\frac{\partial\psi}{\partial x} > 0$, and then the supremum of this expression is obtained when

$$c = c^* = \left(\frac{\partial\psi}{\partial x}\right)^{\frac{1}{\gamma-1}}. \tag{2.19}$$

If $(x,y) \in [0,P]$, then only the zero consumption $c = c^* = 0$ is admissible, so again by the HJBI we get $L^0\psi(0,y) = 0$. □

We can use this to prove the claim (1.24), as follows.

Corollary 2.2.

(i) *As in* (1.21)–(1.22) *let*

$$\Psi_0(x,y) = C_1(x+y)^\gamma \tag{2.20}$$

be the value function for the Merton problem ($k = \lambda = 0$). *Then*

$$\Psi(x,y) \leq \Psi_0(x,y) \qquad \text{for all } (x,y) \in \mathcal{S}. \tag{2.21}$$

(ii) *Let b be a constant such that*

$$1-\lambda \leq b \leq 1+\lambda. \tag{2.22}$$

Suppose

$$\delta > \gamma\alpha. \tag{2.23}$$

Then there exists $K < \infty$ such that

$$\Psi(x,y) \leq K(x+by)^\gamma \qquad \text{for all } (x,y) \in \mathcal{S}. \tag{2.24}$$

Proof. (i) We verify that $\psi := \Psi_0$ satisfies the conditions of Theorem 2.1(i). First, $\phi(s,x,y) = e^{-\delta s}\psi(x,y)$ is C^2 and therefore trivially stochastically C^2. Hence (2.10) holds. Second, ψ satisfies (2.11), because Ψ_0 satisfies the Hamilton–Jacobi–Bellman (HJB) equation. Third, if we put, as in (2.3),

$$x' = x'(\xi) = x - \xi - k - \lambda|\xi| \qquad \text{and} \qquad y' = y'(\xi) = y + \xi,$$

then $x' + y' \leq x + y$ for all x, y, ξ and therefore

$$\begin{aligned}\mathcal{M}\Psi_0(x,y) &= \sup_{\xi\neq 0}\Psi_0(x',y') = \sup_{\xi\neq 0}\{C_1(x'+y')^\gamma\}\\ &\leq C_1(x+y)^\gamma = \Psi_0(x,y),\end{aligned} \tag{2.25}$$

where C_1 is defined in (1.22). Therefore (2.12) also holds. Hence (2.21) follows.

(ii) We proceed as in (i), except that now we choose $K < \infty$ and define

$$u(x,y) = K(x+by)^\gamma. \tag{2.26}$$

Then we get

$$x' + by' = \begin{cases} x + by - k - \xi(1+\lambda-b) & \text{for } \xi > 0, \\ x + by - k - \xi(1-\lambda-b) & \text{for } \xi < 0. \end{cases}$$

Thus in any case we have, by (2.22),

$$x' + by' \le x + by,$$

and this proves that

$$u(x,y) \ge \mathcal{M}u(x,y).$$

It remains to verify that $\psi := u$ satisfies (2.11). By (2.26) we get

$$\mathcal{L}u(x,y) = (x+by)^{\gamma-2}\left[\left(\frac{1-\gamma}{\gamma}(K\gamma)^{\frac{\gamma}{\gamma-1}} - \delta K\right)(x+by)^2 + K\gamma(rx+\alpha by)(x+by) - \tfrac{1}{2}\sigma^2 K\gamma(1-\gamma)b^2y^2\right].$$

Hence $\mathcal{L}u(x,y) \le 0$ for all $(x,y) \in \mathcal{S}$ if and only if

$$\left[\frac{1-\gamma}{\gamma}(K\gamma)^{\frac{\gamma}{\gamma-1}} - \delta K + K\gamma\alpha\right](x+by)^2 \le \tfrac{1}{2}\sigma^2 K\gamma(1-\gamma)b^2y^2$$

for all $(x,y) \in \mathcal{S}$. This holds if and only if

$$\delta > \gamma\alpha + (1-\gamma)(K\gamma)^{\frac{1}{\gamma-1}}. \tag{2.27}$$

If (2.23) holds, then (2.27) holds for K large enough. Thus (2.24) follows from Theorem 2.1(i). □

Remark 2.3. Corollary 2.2 proves in particular that the value function Ψ is *finite*. Moreover, $\Psi(x,y)$ is *bounded* on every straight line in $\mathcal{S}$ of the form

$$x + by = \text{constant}$$

for every constant $b \in [1-\lambda, 1+\lambda]$.

Remark 2.4 (Some comments on the boundary behavior). Suppose the current position of the investor is a point $(x,y) \in \mathcal{S}$. If we make a transaction of size ξ at that instant, then after the transaction the new position is given by

$$\begin{cases} x' = x - \xi - \lambda|\xi| - k, \\ y' = y + \xi. \end{cases} \tag{2.28}$$

Hence

$$x' + (1-\lambda)y' = x + (1-\lambda)y - k - \lambda(|\xi| + \xi) \tag{2.29}$$

and

$$x' + (1+\lambda)y' = x + (1+\lambda)y - k - \lambda(|\xi| - \xi). \tag{2.30}$$

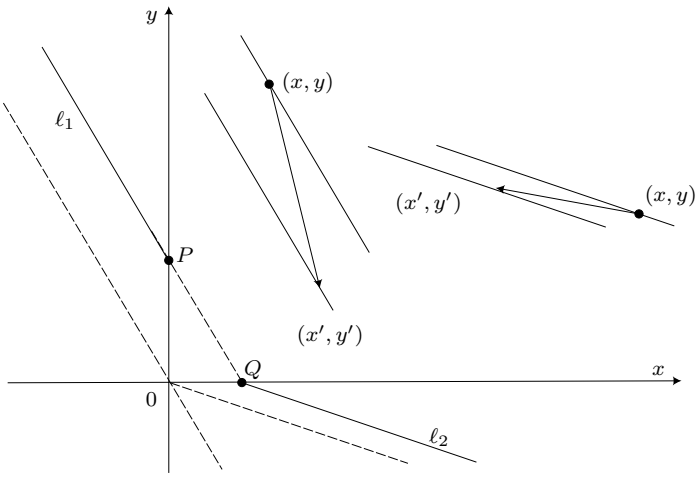

FIG. 2.1. *Examples of transactions (buying and selling).*

In particular, if we *sell* stocks ($\xi < 0$), then $x' + (1-\lambda)y' = x + (1-\lambda)y - k$, so (x, y) will move to a point (x', y') on the line parallel to ℓ_1 lying $\frac{k}{1-\lambda}$ units below the parallel of ℓ_1 through (x, y). See Figure 2.1. Similarly, if we *buy* stocks ($\xi > 0$), then $x' + (1+\lambda)y' = x + (1+\lambda)y - k$, so (x, y) will move to a point (x', y') on the line parallel to ℓ_2 lying $\frac{k}{1+\lambda}$ units below the parallel of ℓ_2 through (x, y).

We now use this to deduce the boundary behavior of the value function Ψ on $\partial\mathcal{S}$.

(a) If $(x, y) \in \ell_1$, then we have to make an immediate transaction to avoid the diffusion $Y(t)$ taking us out of $\mathcal{S}$. By the above we see that the only possibility is to *sell* stocks of such an amount that $(x', y') = (0, 0)$. We conclude that

$$\Psi(x, y) = \mathcal{M}\Psi(x, y) = 0 \qquad \text{for } (x, y) \in \ell_1. \tag{2.31}$$

(b) If $(x, y) \in \ell_2$, we argue similarly: The only admissible action is to *buy* stocks immediately of such an amount that $(x', y') = (0, 0)$. Hence

$$\Psi(x, y) = \mathcal{M}\Psi(x, y) = 0 \qquad \text{for } (x, y) \in \ell_2. \tag{2.32}$$

(c) On the segment $0 < x < k$, $y = 0$, we are not allowed to make any transaction. There is no diffusion and all we can do is consume optimally. Hence the HJB equation indicates that, with $\mathcal{L}$ as in (2.7), we should have

$$\mathcal{L}\Psi = -\delta\Psi + rx\frac{\partial\Psi}{\partial x} + \frac{1-\gamma}{\gamma}\left(\frac{\partial\Psi}{\partial x}\right)^{\frac{\gamma}{\gamma-1}} = 0 \qquad \text{for } x \in (0, k), \tag{2.33}$$

provided that Ψ is smooth enough (see section 4).

(d) On the segment $x = 0$, $0 < y < \frac{k}{1-\lambda}$, we cannot consume because this would bring us outside $\mathcal{S}$. Hence the HJB equation indicates that

$$\mathcal{L}\Psi(0, y) = c^* = 0 \qquad \text{for } 0 < y < \frac{k}{1-\lambda}, \tag{2.34}$$

and hence that

$$\mathcal{L}_0\Psi := -\delta\Psi + \alpha y\frac{\partial\Psi}{\partial y} + \tfrac{1}{2}\sigma^2 y^2\frac{\partial^2\Psi}{\partial y^2} = 0 \qquad \text{for } 0 < y < \frac{k}{1-\lambda}, \tag{2.35}$$

provided that Ψ is smooth enough (see section 4).

Summarizing, we see that the boundary behavior of Ψ on $\partial\mathcal{S}$ can be described by

$$(2.36)\quad \begin{cases} \Psi(x,y) = \mathcal{M}\Psi(x,y) = 0 & \text{for } (x,y) \in \ell_1 \cup \ell_2, \\ \mathcal{L}\Psi(x,y) = 0 & \text{for } 0 \le x \le k,\ y = 0, \text{ i.e., } (x,y) \in [0,Q], \\ \mathcal{L}_0\Psi(x,y) = 0 & \text{for } x = 0,\ 0 \le y \le y_1 = \frac{k}{1-\lambda}, \text{ i.e., } (x,y) \in [0,P]. \end{cases}$$

Note that Ψ is not continuous on ∂S: The points $(0, \frac{k}{1-\lambda})$ and $(k,0)$ are points of discontinuity. However, Ψ is upper semicontinuous.

3. Viscosity solutions. Theorem 2.1 is a *verification theorem*, stating that if we can find a smooth enough function satisfying the required (quasi-) variational inequalities, then we have also found the value function of the problem. It is natural to ask if the converse is also true: Is the value function always a solution of the corresponding (quasi-) variational inequalities? The problem is that the value function need not be smooth enough for these inequalities to be well defined in the strong sense. In fact, the value function is not even continuous at the points P and Q (see (2.36) and below). However, we shall see that the inequalities are satisfied in a weak sense: The value function is a *viscosity solution* of the (quasi-) variational inequalities.

We first recall the following concepts, which will be useful for us.

DEFINITION 3.1. *If C is a topological space and $u\colon C \to \mathbf{R}$ is a function, then the* upper semi-continuous *(usc)* envelope $\overline{u}\colon C \to \mathbf{R}$ *and the* lower semi-continuous *(lsc)* envelope $\underline{u}\colon C \to \mathbf{R}$ *of u are defined by*

$$\overline{u}(x) = \limsup_{\substack{y \to x \\ y \in C}} u(y), \qquad \underline{u}(x) = \liminf_{\substack{y \to x \\ y \in C}} u(y), \quad \textit{respectively.}$$

We let $\mathrm{USC}(C)$ and $\mathrm{LSC}(C)$ denote the set of usc functions and lsc functions on C, respectively.

Note that in general we have

$$\underline{u} \le u \le \overline{u},$$

and that u is usc if and only if $u = \overline{u}$, u is lsc if and only if $u = \underline{u}$. In particular, u is continuous if and only if

$$\underline{u} = u = \overline{u}.$$

We establish some auxiliary results about the operator $\mathcal{M}$, as follows.

LEMMA 3.2.

(i) *If $u : \mathcal{S} \to \mathbf{R}$ is* usc*, then $\mathcal{M}u$ is* usc*.*

(ii) *If $u : \mathcal{S} \to \mathbf{R}$ is continuous, then $\mathcal{M}u$ is continuous.*

Proof. (i) Suppose that $u : \mathcal{S} \to \mathbf{R}$ is usc. For $\zeta = (x,y) \in \mathcal{S}$ define

$$\ell(\zeta) = \ell(x,y) = \{(x'(\xi), y'(\xi)) \in \mathcal{S};\quad \xi \in \mathbf{R} \setminus \{0\}\},$$

where x', y' are as in (2.3). Then $\ell(\zeta)$ is a union of two *closed finite* line segments, and since u is usc there exists $\zeta^* \in \ell(\zeta)$ such that

$$\mathcal{M}u(\zeta) = \sup\{u(\zeta'); \zeta' \in \ell(\zeta)\} = u(\zeta^*).$$

Fix $\zeta_0 \in \mathcal{S}$ and let $\{\zeta_n\}_{n=1}^{\infty}$ be a sequence in $\mathcal{S}$ such that $\zeta_n \to \zeta_0$ as $n \to \infty$. We must show that

$$\mathcal{M}u(\zeta_0) \ge \limsup_{n \to \infty} \mathcal{M}u(\zeta_n).$$

Let $\hat{\zeta}$ be a cluster point of $\{\zeta_n^*\}_{n=1}^{\infty}$, i.e., $\hat{\zeta}$ is the limit of some convergent subsequence $\{\zeta_{n_k}^*\}_{k=1}^{\infty}$ of $\{\zeta_n^*\}_{n=1}^{\infty}$. Since $\zeta_n \to \zeta_0$, we see that $\ell(\zeta_n) \to \ell(\zeta_0)$, in the natural sense. Hence, since $\zeta_{n_k}^* \in \ell(\zeta_{n_k})$ for all k, we conclude that $\hat{\zeta} = \lim_{k\to\infty} \zeta_{n_k}^* \in \ell(\zeta_0)$. Therefore

$$\mathcal{M}u(\zeta_0) \geq u(\hat{\zeta}) \geq \limsup_{n\to\infty} u(\zeta_n^*) = \limsup_{n\to\infty} \mathcal{M}u(\zeta_n).$$

(ii) Suppose that $u : \mathcal{S} \to \mathbf{R}$ is continuous. Fix $\zeta_0 \in \mathcal{S}$ and let $\zeta_n \to \zeta_0$ as in (i). By (i) it suffices to show that

$$(*) \qquad \mathcal{M}u(\zeta_0) \leq \liminf_{n\to\infty} \mathcal{M}u(\zeta_n).$$

Suppose not. Then $u(\zeta_0^*) = \mathcal{M}u(\zeta_0) > \liminf_{n\to\infty} \mathcal{M}u(\zeta_n) + \varepsilon = \liminf_{n\to\infty} u(\zeta_n^*) + \varepsilon$ for some $\varepsilon > 0$.

Since u is continuous, there is a neighborhood G of ζ_0^* such that

$$u(\zeta') \geq \liminf u(\zeta_n^*) + \varepsilon \qquad \text{for all } \zeta' \in G.$$

But if n is big enough we have $\ell(\zeta_n) \cap G \neq \emptyset$, so since ζ_n^* is a maximum point of u on $\ell(\zeta_n)$ we have

$$u(\zeta_n^*) \geq u(\zeta') \qquad \text{for } n \text{ big enough.}$$

This contradiction shows that $(*)$ holds, and the proof is complete. □

LEMMA 3.3.

(i) *Let $u : \mathcal{S} \to \mathbf{R}$. Then $\overline{\mathcal{M}u} \leq \mathcal{M}\bar{u}$.*

(ii) *Let $\psi : \mathcal{S} \to \mathbf{R}$ be such that $\psi \geq \mathcal{M}\psi$. Then $\underline{\psi} \geq \mathcal{M}\underline{\psi}$.*

Proof. (i) Choose $\zeta_0, \zeta_n \in \mathcal{S}$, $n = 1, 2, \ldots$, such that $\zeta_n \to \zeta_0$ and $\mathcal{M}u(\zeta_n) \to \overline{\mathcal{M}u}(\zeta_0)$ as $n \to \infty$. Then by Lemma 3.2(i) applied to the usc function $\bar{u}$,

$$\overline{\mathcal{M}u}(\zeta_0) = \lim_{n\to\infty} \mathcal{M}u(\zeta_n) \leq \limsup_{n\to\infty} \mathcal{M}\bar{u}(\zeta_n) \leq \mathcal{M}\bar{u}(\zeta_0).$$

(ii) Choose $\zeta_0, \zeta_n \in \mathcal{S}$, $n = 1, 2, \ldots$, such that $\zeta_n \to \zeta_0$ and $\mathcal{M}\psi(\zeta_n) \to \underline{\mathcal{M}\psi}(\zeta_0)$ as $n \to \infty$. Then

$$\underline{\psi}(\zeta_0) \geq \underline{\mathcal{M}\psi}(\zeta_0) = \lim_{n\to\infty} \mathcal{M}\psi(\zeta_n) \geq \liminf_{n\to\infty} \mathcal{M}\underline{\psi}(\zeta_n) \geq \mathcal{M}\underline{\psi}(\zeta_0). \qquad \square$$

COROLLARY 3.4. *Suppose $u : \mathcal{S} \to \mathbf{R}$ is* usc *and $u(\zeta_0) > \mathcal{M}u(\zeta_0) + \eta$ for some $\zeta_0 \in \mathcal{S}$, $\eta > 0$. Then $u(\zeta_0) > \overline{\mathcal{M}u}(\zeta_0) + \eta$.*

Proof. $u(\zeta_0) > \mathcal{M}u(\zeta_0) + \eta = \mathcal{M}\bar{u}(\zeta_0) \geq \overline{\mathcal{M}u}(\zeta_0) + \eta$ by Lemma 3.3(i). □

As in (2.7) we let $\mathcal{L}$ be the differential operator

$$(3.1) \qquad \mathcal{L}h(x,y) = \sup_{c\geq 0} \left\{ -\delta h + (rx - c)\frac{\partial h}{\partial x} + \alpha y \frac{\partial h}{\partial y} + \frac{1}{2}\sigma^2 y^2 \frac{\partial^2 h}{\partial y^2} + \frac{c^\gamma}{\gamma} \right\},$$

and as in (2.2) we set

$$(3.2) \qquad \mathcal{M}h(x,y) = \sup_{\xi\neq 0} \{h(x',y'); (x',y') \in \mathcal{S}\} \qquad \text{for } (x,y) \in \mathcal{S},$$

where

$$(3.3) \qquad x' = x - k - \xi - \lambda|\xi|, \qquad y' = y + \xi.$$

The inequalities (2.11), (2.12), and (2.13) of Theorem 2.1 together with the boundary behavior (2.36) can be combined into one equation as follows:

$$F(D^2\Psi(\zeta), D\Psi(\zeta), \Psi, \zeta) = 0 \qquad \text{for all } \zeta = (x, y) \in \mathcal{S}, \tag{3.4}$$

where

$$F\colon \mathbf{R}^{2\times 2} \times \mathbf{R}^2 \times \mathbf{R}^{\mathcal{S}} \times \mathbf{R}^2 \to \mathbf{R}$$

is defined by

$$F(A, p, g, \zeta) = \begin{cases} \max\{\Lambda(A, p, g, \zeta), (\mathcal{M}g - g)(\zeta)\}, & \zeta \in \mathcal{S}^0, \\ \Lambda(A, p, g, \zeta), & \zeta \in [0, Q], \\ \Lambda_0(A, p, g, \zeta), & \zeta \in [0, P], \\ (\mathcal{M}g - g)(\zeta), & \zeta \in \ell_1 \cup \ell_2, \end{cases} \tag{3.5}$$

where

$$\Lambda(A, p, g, \zeta) = -\delta g + r\zeta_1 p_1 + \alpha\zeta_2 p_2 + \tfrac{1}{2}\sigma^2\zeta_2^2 A_{22} + \max_{c\geq 0}\left(-cp_1 + \frac{c^\gamma}{\gamma}\right) \tag{3.6}$$

and

$$\Lambda_0(A, p, g, \zeta) = -\delta g + \alpha\zeta_2 p_2 + \tfrac{1}{2}\sigma^2\zeta_2^2 A_{22}, \qquad A = \left[A_{ij}\right]_{1\leq i,j\leq 2}. \tag{3.7}$$

Note that F is not a local operator: The value of F at (A, p, g, ζ) depends on the value of g on the whole space $\mathcal{S}$.

Also note that

$$\overline{F}(A, p, g, \zeta) = \max\{\Lambda(A, p, g, \zeta), (\mathcal{M}g - g)(\zeta)\} \text{ for } \textit{all } \zeta \in \mathcal{S} \tag{3.8}$$

and that

$$\underline{F}(A, p, g, \zeta) = F(A, p, g, \zeta) \qquad \text{(i.e., } F \text{ is lsc)}. \tag{3.9}$$

Following Barles [B], we now give the definition of the viscosity solution of elliptic equations of type (3.4).

DEFINITION 3.5.

(i) *A function* $u \in \mathrm{USC}(\mathcal{S})$ *is a* viscosity subsolution *of*

$$F(D^2u(\zeta), Du(\zeta), u, \zeta) = 0 \qquad \textit{for all } \zeta = (x, y) \in \mathcal{S} \tag{3.10}$$

if for every function f *which is* C^2 *in a neighbourhood of* $\mathcal{S}$ *and for every point* $\zeta_0 \in \mathcal{S}$ *such that* $f \geq u$ *on* $\mathcal{S}$ *and* $f(\zeta_0) = u(\zeta_0)$ *we have*

$$\overline{F}(D^2 f(\zeta_0), Df(\zeta_0), u, \zeta_0) \geq 0. \tag{3.11}$$

(ii) *A function* $u \in \mathrm{LSC}(\mathcal{S})$ *is a* viscosity supersolution *of* (3.10) *if for every function* f *which is* C^2 *in a neighbourhood of* $\mathcal{S}$ *and for every point* $\zeta_0 \in \mathcal{S}$ *such that* $f \leq u$ *on* $\mathcal{S}$ *and* $f(\zeta_0) = u(\zeta_0)$ *we have*

$$\underline{F}(D^2 f(\zeta_0), Df(\zeta_0), u, \zeta_0) \leq 0. \tag{3.12}$$

(iii) *We say that a function* $u: \mathcal{S} \to \mathbf{R}$ *is a* viscosity solution *of* (3.10) *if* u *is locally bounded and* $\overline{u}$ *is a viscosity subsolution and* $\underline{u}$ *is a viscosity supersolution of* (3.10).

An equivalent definition of viscosity solutions which is useful for proving uniqueness results is the following (see [CIL, section 2]).

DEFINITION 3.6.

(i) *A function* $u \in \mathrm{USC}(\mathcal{S})$ *is a* viscosity subsolution *of* (3.4) *if*

$$\overline{F}(A,p,u,\zeta) \geq 0 \qquad \text{for all } (p,A) \in \bar{J}^{2,+}_{\mathcal{S}} u(\zeta),\ \zeta \in \mathcal{S}. \tag{3.13}$$

(ii) *A function* $u \in \mathrm{LSC}(\mathcal{S})$ *is a* viscosity supersolution *of* (3.4) *if*

$$\underline{F}(A,p,u,\zeta) \leq 0 \qquad \text{for all } (p,A) \in \bar{J}^{2,-}_{\mathcal{S}} u(\zeta),\ \zeta \in \mathcal{S}.$$

Here the second order "superjets" $J^{2,+}_{\mathcal{S}}$, $J^{2,-}_{\mathcal{S}}$ *and their "closures"* $\bar{J}^{2,+}_{\mathcal{S}}$, $\bar{J}^{2,-}_{\mathcal{S}}$ *are defined by*

$$J^{2,+}_{\mathcal{S}} u(\zeta) = \Bigg\{ (p,A) \in \mathbf{R}^2 \times \mathbf{R}^{2\times 2};$$

$$\limsup_{\substack{\eta \to \zeta \\ \eta \in \mathcal{S}}} \big\{ [u(\eta) - u(\zeta) - p \cdot (\eta - \zeta) - \tfrac{1}{2}(\eta-\zeta)^T A (\eta - \zeta)] |\eta - \zeta|^{-2} \big\} \leq 0 \Bigg\} \tag{3.14}$$

(where $(\ )^T$ *denotes matrix transposed),*

$$\begin{aligned} \bar{J}^{2,+}_{\mathcal{S}} u(\zeta) = \{ (p,A) \in \mathbf{R}^2 \times \mathbf{R}^{2\times 2}\ ;\ & \exists (\zeta_n, p_n, A_n) \in \mathcal{S} \times \mathbf{R}^2 \times \mathbf{R}^{2\times 2}, \\ & \text{with } (p_n, A_n) \in J^{2,+}_{\mathcal{S}} u(\zeta_n) \text{ and } (\zeta_n, u(\zeta_n), p_n, A_n) \\ & \to (\zeta, u(\zeta), p, A), \quad \text{when } n \to \infty \}, \end{aligned} \tag{3.15}$$

and

$$J^{2,-}_{\mathcal{S}} u = -J^{2,+}_{\mathcal{S}}(-u), \qquad \bar{J}^{2,-}_{\mathcal{S}} u = -\bar{J}^{2,+}_{\mathcal{S}}(-u). \tag{3.16}$$

We are now ready for the first main result of this section.

THEOREM 3.7. *Suppose that* (2.23) *holds. Then the value function* Ψ *is a viscosity solution of* (3.4).

Proof. We first make some useful observations. Suppose $w = (c, v) \in \mathcal{W}$ is an admissible control with $v = (\tau_1, \tau_2, \ldots; \xi_1, \xi_2, \ldots)$, where $\tau_1 > 0$ a.s. Then by the *Markov property* we have, with J^w as in (1.14),

$$J^w(z) = E^z \Big[\int_0^\tau e^{-\delta(s+t)} \frac{c^\gamma(t)}{\gamma} dt + J^w(Z^{(w)}(\tau)) \Big] \tag{3.17}$$

for all stopping times $\tau \leq \tau_1$.

Note that

$$\Psi(\zeta) \geq \mathcal{M}\Psi(\zeta) \qquad \text{for all } \zeta \in \mathcal{S}. \tag{3.18}$$

To see this, suppose on the contrary that there exists ζ_1 such that

$$\Psi(\zeta_1) < \mathcal{M}\Psi(\zeta_1).$$

This would mean that we could improve the performance at ζ_1 by making a transaction immediately. This contradicts that $\Psi(\zeta_1)$ is the optimal performance value at ζ_1.

Also note that since τ_1 is a stopping time, we know that $\{\omega; \tau_1(\omega) = 0\}$ is $\mathcal{F}_0$-measurable and hence this event has probability either 1 or 0. So we either have

$$\tau_1(\omega) = 0 \quad \text{a.s.} \quad \text{or} \qquad \tau_1(\omega) > 0 \quad \text{a.s.}$$

(A) We prove that $\bar{\Psi}$ is a viscosity subsolution. To this end, let f be a C^2 function in a neighborhood of $\mathcal{S}$ and let $\zeta_0 \in \mathcal{S}$ be such that $f \geq \bar{\Psi}$ on $\mathcal{S}$ and $f(\zeta_0) = \bar{\Psi}(\zeta_0)$. We consider the following two cases separately.

Case 1. $\bar{\Psi}(\zeta_0) \leq \mathcal{M}\bar{\Psi}(\zeta_0)$.
Then by (3.8) $\bar{F}(D^2 f(\zeta_0), Df(\zeta_0), f(\zeta_0), \bar{\Psi}, \zeta_0) \geq (\mathcal{M}\bar{\Psi} - \bar{\Psi})(\zeta_0) = 0$, and hence (3.11) holds at ζ_0 for $u = \bar{\Psi}$.

Case 2. $\bar{\Psi}(\zeta_0) > \mathcal{M}\bar{\Psi}(\zeta_0)$.
It suffices to prove that $\mathcal{L}f(\zeta_0) \geq 0$. We argue by contradiction: *Suppose* $\zeta_0 = (x_0, y_0) \in \mathcal{S}$ *and* $\mathcal{L}f(\zeta_0) < 0$. Then from the definition (3.1) of $\mathcal{L}$ we deduce that $\frac{\partial f}{\partial x}(\zeta_0) > 0$. Hence by continuity, $\frac{\partial f}{\partial x}(\zeta) > 0$ in a neighborhood G of ζ_0. But then, with $\zeta = (x, y)$,

$$\mathcal{L}f(\zeta) = -\delta f(\zeta) + (rx - \widehat{c})\frac{\partial f}{\partial x} + \alpha y \frac{\partial f}{\partial y} + \tfrac{1}{2}\sigma^2 y^2 \frac{\partial^2 f}{\partial y^2} + \frac{\widehat{c}^{\gamma}}{\gamma}$$

with $\widehat{c} = \widehat{c}(\zeta) = (\frac{\partial f}{\partial x})^{\frac{1}{\gamma - 1}}$ for all $\zeta \in G \cap \mathcal{S}$.

Hence $\mathcal{L}f(\zeta)$ is continuous on $G \cap \mathcal{S}$ and so there exists a (bounded) neighborhood G_ρ of ζ_0 such that $G_\rho = \{(x, y); |x - x_0| < \rho \text{ and } |y - y_0| < \rho\}$ for some $\rho > 0$ and

$$\mathcal{L}f(\zeta) < \tfrac{1}{2}\mathcal{L}f(\zeta_0) < 0 \qquad \text{for all } \zeta \in G_\rho \cap \mathcal{S}. \tag{3.19}$$

Now let η be any number such that

$$0 < \eta < (\bar{\Psi} - \mathcal{M}\bar{\Psi})(\zeta_0). \tag{3.20}$$

Since $\bar{\Psi}(\zeta_0) > \mathcal{M}\bar{\Psi}(\zeta_0) + \eta$, we can by Corollary 3.4 find a sequence $\{\zeta_n\}_{n=1}^{\infty} \subset G_\rho \cap \mathcal{S}$ such that $\zeta_n \to \zeta_0$ and $\Psi(\zeta_n) \to \bar{\Psi}(\zeta_0)$ as $n \to \infty$ and

$$\mathcal{M}\Psi(\zeta_n) < \Psi(\zeta_n) - \eta \qquad \text{for all } n \geq 1. \tag{3.21}$$

Choose $\varepsilon \in (0, \eta)$. Since $\bar{\Psi}(\zeta_0) = f(\zeta_0)$, we can choose n_0 such that

$$|\Psi(\zeta_n) - f(\zeta_n)| < \varepsilon \qquad \text{for all } n \geq n_0. \tag{3.22}$$

In the following we fix $n \geq n_0$ and put $\zeta = \zeta_n$.

Let $\widetilde{w} = (\widetilde{c}, \widetilde{v})$ with $\widetilde{v} = (\widetilde{\tau}_1, \widetilde{\tau}_2, \ldots; \widetilde{\xi}_1, \widetilde{\xi}_2, \ldots)$ be an ε-optimal control for ζ, in the sense that

$$\Psi(\zeta) \leq J^{\widetilde{w}}(0, \zeta) + \varepsilon.$$

If $\widetilde{\tau}_1 = 0$ a.s., then $(X^{(\widetilde{w})}, Y^{(\widetilde{w})})$ makes an immediate jump from ζ to some point $\zeta' \in \mathcal{S}$, and hence by (3.17)

$$J^{\widetilde{w}}(0, \zeta) = E^{0,\zeta_0}[J^{\widetilde{w}}(0, \zeta')].$$

But then

$$\Psi(\zeta) \le J^{\tilde{w}}(0,\zeta) + \varepsilon = E^{0,\zeta}[J^{\tilde{w}}(0,\zeta')] + \varepsilon \le E^{0,\zeta}[\Psi(\zeta')] + \varepsilon \le \mathcal{M}\Psi(\zeta) + \varepsilon,$$

which contradicts (3.21). We conclude that $\widetilde{\tau}_1 > 0$ a.s.

Fix $R < \infty$ and define τ to be the stopping time

$$\tau = \tau(\varepsilon) = \widetilde{\tau}_1 \wedge R \wedge \inf\{t > 0; (X^{(\tilde{w})}(t), Y^{(\tilde{w})}(t)) \notin G_\rho\}.$$

Then by the Dynkin formula we have

$$E^{0,\zeta}[e^{-\delta\tau} f(X^{(\tilde{w})}(\tau), Y^{(\tilde{w})}(\tau))] = f(\zeta) + E^{0,\zeta}\bigg[\int_0^\tau e^{-\delta t} L^{\tilde{c}} f(X^{(\tilde{w})}(t), Y^{(\tilde{w})}(t))dt\bigg]$$
$$+ E^{0,\zeta}[e^{-\delta\tau}[f(X^{(\tilde{w})}(\tau), Y^{(\tilde{w})}(\tau)) - f(X^{(\tilde{w})}(\tau^-), Y^{(\tilde{w})}(\tau^-))]]$$

or

$$E^{0,\zeta}[e^{-\delta\tau} f(X^{(\tilde{w})}(\tau^-), Y^{(\tilde{w})}(\tau^-))] = f(\zeta) + E^{0,\zeta}\bigg[\int_0^\tau e^{-\delta t} L^{\tilde{c}} f(X^{(\tilde{w})}(t), Y^{(\tilde{w})}(t))dt\bigg].$$

Combining this with (3.17) we get, since $\Psi \ge \mathcal{M}\Psi$,

$$\begin{aligned}
\Psi(\zeta) &\le J^{(\tilde{w})}(0,\zeta) + \varepsilon \\
&= E^{0,\zeta}\bigg[\int_0^\tau e^{-\delta t}\frac{\tilde{c}^\gamma(t)}{\gamma}dt + J^{\tilde{w}}(Z^{(\tilde{w})}(\tau))\bigg] + \varepsilon \\
&\le E^{0,\zeta}\bigg[\int_0^\tau e^{-\delta t}\frac{\tilde{c}^\gamma(t)}{\gamma}dt + e^{-\delta\tau}\Psi(X^{(\tilde{w})}(\tau), Y^{(\tilde{w})}(\tau))\bigg] + \varepsilon \\
&\le E^{0,\zeta}\bigg[\int_0^\tau e^{-\delta t}\frac{\tilde{c}^\gamma(t)}{\gamma}dt + e^{-\delta\tau}\{\Psi(X^{(\tilde{w})}(\tau^-), Y^{(\tilde{w})}(\tau^-)) \cdot \chi_{\tau<\tilde{\tau}_1} \\
&\qquad + \mathcal{M}\Psi(X^{(\tilde{w})}(\tau^-), Y^{(\tilde{w})}(\tau^-)) \cdot \chi_{\tau=\tilde{\tau}_1}\}\bigg] + \varepsilon \\
&\le E^{0,\zeta}\bigg[\int_0^\tau e^{-\delta t}\frac{\tilde{c}^\gamma(t)}{\gamma}dt + e^{-\delta\tau}\Psi(X^{(\tilde{w})}(\tau^-), Y^{(\tilde{w})}(\tau^-))\bigg] + \varepsilon \\
&\le E^{0,\zeta}\bigg[\int_0^\tau e^{-\delta t}\frac{\tilde{c}^\gamma(t)}{\gamma}dt + e^{-\delta\tau} f(X^{(\tilde{w})}(\tau^-), Y^{(\tilde{w})}(\tau^-))\bigg] + \varepsilon \\
&= f(\zeta) + E^{0,\zeta}\bigg[\int_0^\tau e^{-\delta t}\bigg(L^{\tilde{c}} f(X^{(\tilde{w})}(t), Y^{(\tilde{w})}(t)) + \frac{\tilde{c}^\gamma(t)}{\gamma}\bigg)dt\bigg] + \varepsilon \\
&\le \Psi(\zeta) + E^{0,\zeta}\bigg[\int_0^\tau e^{-\delta t}\mathcal{L} f(X^{(\tilde{w})}(t), Y^{(\tilde{w})}(t))dt\bigg] + 2\varepsilon.
\end{aligned}$$

We conclude from this that

$$E^{0,\zeta}\Big[\int_0^\tau e^{-\delta t}\mathcal{L}f(X^{(\tilde{w})}(t),Y^{(\tilde{w})}(t))dt\Big] \geq -2\varepsilon. \tag{3.23}$$

On the other hand, from (3.19) we deduce that

$$E^{0,\zeta}\Big[\int_0^\tau e^{-\delta t}\mathcal{L}f(X^{(\tilde{w})}(t),Y^{(\tilde{w})}(t))dt\Big] \leq \frac{1}{2\delta}\mathcal{L}f(\zeta)(1-E^{0,\zeta}[e^{-\delta\tau}]). \tag{3.24}$$

We claim that

$$E^{0,\zeta_n}[e^{-\delta\tau(\varepsilon)}] \quad \text{is bounded away from 1} \tag{3.25}$$

when $n\to\infty$ and $\varepsilon\to 0$.

If this claim is proved, then we see that (3.23) contradicts (3.24) if ε is small enough. This contradiction proves that $\mathcal{L}f(\zeta_0)\leq 0$ and hence (3.11) holds. Therefore, to complete the proof we must verify the claim (3.25).

First note that for $t<\tau$ we have by (1.4)

$$X^{(\tilde{w})}(t) = X(0)e^{rt} - e^{rt}\int_0^t e^{-rs}\,\tilde{c}(s)ds \geq X(0)-\rho,$$

and hence, with some constant $C_2<\infty$,

$$\begin{aligned}
&\int_0^\tau e^{-\delta t}\,\frac{\tilde{c}^\gamma(t)}{\gamma}dt \leq \frac{1}{\gamma}\Big[\int_0^\tau e^{-rt}\tilde{c}(t)dt\Big]^\gamma\Big[\int_0^\tau e^{\frac{r\gamma-\delta}{1-\gamma}t}dt\Big]^{1-\gamma}\\
&\leq C_2\left(X(0)(1-e^{-r\tau})+\rho e^{-r\tau}\right)^\gamma, \qquad \text{since } r\gamma-\delta<0 \text{ by (1.2) and (2.23).}
\end{aligned}$$

Combining this with (3.17), we get

$$\begin{aligned}
&\Psi(\zeta)-\varepsilon \leq J^{(\tilde{w})}(0,\zeta)\\
&\leq E^{0,\zeta}\Big[\int_0^\tau e^{-\delta t}\,\frac{\tilde{c}^\gamma(t)}{\gamma}dt + e^{-\delta\tau}\Psi(X^{(\tilde{w})}(\tau),Y^{(\tilde{w})}(\tau))\Big]\\
&\leq E^{0,\zeta}[C_2(x-(x-\rho)e^{-r\tau})^\gamma] + E^{0,\zeta}[e^{-\delta\tau}\Psi(X^{(\tilde{w})}(\tau^-),Y^{(\tilde{w})}(\tau^-))\cdot\mathcal{X}_{\tilde{\tau}_1>\tau}]\\
&\quad + E^{0,\zeta}[e^{-\delta\tau}\{\Psi(X^{(\tilde{w})}(\tau),Y^{(\tilde{w})}(\tau)) - \Psi(X^{(\tilde{w})}(\tau^-),Y^{(\tilde{w})}(\tau^-))\}\cdot\mathcal{X}_{\tilde{\tau}_1\leq\tau}]\\
&\leq E^{0,\zeta}[C_2(x-(x-\rho)e^{-r\tau})^\gamma] + E^{0,\zeta}[e^{-\delta\tau}\Psi(X^{(\tilde{w})}(\tau^-),Y^{(\tilde{w})}(\tau^-))\cdot\mathcal{X}_{\tilde{\tau}_1>\tau}]\\
&\quad + E^{0,\zeta}[e^{-\delta\tau}\mathcal{M}\Psi(X^{(\tilde{w})}(\tau^-),Y^{(\tilde{w})}(\tau^-))\cdot\mathcal{X}_{\tilde{\tau}_1\leq\tau}]\\
&\leq E^{0,\zeta}[C_2(x-(x-\rho)e^{-r\tau})^\gamma] + E^{0,\zeta}[e^{-\delta\tau}\mathcal{X}_{\tilde{\tau}_1>\tau}]\cdot\sup\{\Psi(\tilde{\zeta});\tilde{\zeta}\in G_\rho\}\\
&\quad + E^{0,\zeta}[e^{-\delta\tau}\mathcal{X}_{\tilde{\tau}_1\leq\tau}]\cdot\sup\{\mathcal{M}\Psi(\tilde{\zeta});\tilde{\zeta}\in G_\rho\}.
\end{aligned} \tag{3.26}$$

Now if there exists a sequence $\varepsilon_k\to 0$ and a subsequence $\{\zeta_{n_k}\}$ of $\{\zeta_n\}$ such that

$$E^{0,\zeta_{n_k}}[e^{-\delta\tau(\varepsilon_k)}]\to 1 \qquad \text{when } k\to\infty,$$

then

$$E^{0,\zeta_{n_k}}[e^{-\delta\tau(\varepsilon_k)}\mathcal{X}_{\tilde{\tau}_1>\tau}] \to 0 \qquad \text{when } \ k \to \infty,$$

so by choosing $\zeta = \zeta_{n_k}$, $\tau = \tau(\varepsilon_k)$ in (3.26) and letting $k \to \infty$, we obtain

$$\bar{\Psi}(\zeta_0) \le C_2\rho^\gamma + \sup\{\mathcal{M}\Psi(\tilde{\zeta}); \tilde{\zeta} \in G_\rho\}.$$

Hence by Lemma 3.3 and (3.20)

$$\begin{aligned}\bar{\Psi}(\zeta_0) &\le \lim_{\rho\to 0}(C_2\rho^\gamma + \sup\{\mathcal{M}\Psi(\tilde{\zeta}); \tilde{\zeta} \in G_\rho\}) \\ &= \overline{\mathcal{M}\Psi}(\zeta_0) \le \mathcal{M}\bar{\Psi}(\zeta_0) < \Psi(\zeta_0) - \eta.\end{aligned}$$

This contradiction proves claim (3.25) and completes the proof that $\bar{\Psi}$ is a viscosity subsolution.

(B) Next we prove that $\underline{\Psi}$ is a viscosity supersolution. So we let f be a C^2 function in a neighborhood of $\mathcal{S}$ and we let $\zeta_0 \in \mathcal{S}$ be such that $f \le \underline{\Psi}$ on $\mathcal{S}$ and $f(\zeta_0) = \underline{\Psi}(\zeta_0)$. We want to show that

$$F(D^2 f(\zeta_0), Df(\zeta_0), f(\zeta_0), \underline{\Psi}, \zeta_0) \le 0.$$

Since by Lemma 3.3(ii) $\mathcal{M}\underline{\Psi} - \underline{\Psi} \le 0$ everywhere, we see from (3.5) that this holds for $\zeta_0 \in \ell_1 \cup \ell_2$ and it suffices to show that

$$\mathcal{L}f(\zeta_0) \le 0 \qquad \text{for } \ \zeta_0 \in \mathcal{S}^0 \cup [0, Q]$$

and

$$\mathcal{L}_0 f(\zeta_0) \le 0 \qquad \text{for } \ \zeta_0 \in [0, P].$$

For $\varepsilon > 0$ let $\widehat{w} = \widehat{w}_{\varepsilon,c}$ be an admissible control beginning with a constant consumption rate $c \ge 0$ and no transactions up to the first time τ_ε at which the process $Z^c(t)$ exits from

$$K_\varepsilon = \{(s,x,y); |(s,x,y) - (0,x_0,y_0)| < \varepsilon\} \cap \widetilde{\mathcal{S}},$$

where $\zeta_0 = (x_0, y_0)$. Choose $\zeta_n \in K_\varepsilon$ such that $\zeta_n \to \zeta_0$ and $\Psi(\zeta_n) \to \underline{\Psi}(\zeta_0)$ as $n \to \infty$.

Then by combining Dynkin's formula with the *dynamic programming principle* ([Kr, Theorem 6, p. 150]) we get for all n

$$\begin{aligned}\Psi(\zeta_n) &\ge E^{0,\zeta_n}\left[\int_0^\tau e^{-\delta t}\frac{c^\gamma}{\gamma}dt + e^{-\delta\tau}\Psi(X^{(\hat{w})}(\tau), Y^{(\hat{w})}(\tau))\right] \\ &\ge E^{0,\zeta_n}\left[\int_0^\tau e^{-\delta t}\frac{c^\gamma}{\gamma}dt + e^{-\delta\tau} f(X^{(\hat{w})}(\tau), Y^{(\hat{w})}(\tau))\right] \\ &= f(\zeta_n) + E^{0,\zeta_n}\left[\int_0^\tau e^{-\delta t}\left(L^c f(X^{(\hat{w})}(t), Y^{(\hat{w})}(t)) + \frac{c^\gamma}{\gamma}\right)dt\right].\end{aligned}$$

We conclude that

$$E^{0,\zeta_n}\left[\int_0^{\tau_\varepsilon} e^{-\delta t}\left\{L^c f(X^{(\hat{w})}(t), Y^{(\hat{w})}(t)) + \frac{c^\gamma}{\gamma}\right\} dt\right] \le \Psi(\zeta_n) - f(\zeta_n) \qquad \text{for all } n.$$

Taking the limit as $n \to \infty$, we obtain

$$E^{0,\zeta_0}\left[\int_0^{\tau_\varepsilon} h(t)dt\right] \le 0,$$

where

$$h(t) = e^{-\delta t}\left(L^c f(X^{(\hat{w})}(t), Y^{(\hat{w})}(t)) + \frac{c^\gamma}{\gamma}\right).$$

By dividing the left-hand side by $E^{0,\zeta_0}[\tau_\varepsilon]$ we get

$$\frac{E^{0,\zeta_0}\left[\int_0^{\tau_\varepsilon} h(t)dt\right]}{E^{0,\zeta_0}[\tau_\varepsilon]} = \frac{E^{0,\zeta_0}\left[\int_0^{\tau_\varepsilon}(h(t)-h(0))dt\right] + h(0)E^{0,\zeta_0}[\tau_\varepsilon]}{E^{0,\zeta_0}[\tau_\varepsilon]}$$
$$\longrightarrow h(0) \qquad \text{as } \varepsilon \to 0, \text{ since } h(t) \text{ is continuous at } t = 0.$$

We conclude that

$$h(0) = L^c f(\zeta_0) + \frac{c^\gamma}{\gamma} \le 0 \tag{3.27}$$

for all $c \ge 0$ such that $\widehat{w}_{\varepsilon,c}$ is admissible for ε small enough. If $\zeta_0 \in \mathcal{S}^0 \cup [0, Q]$, then this is clearly the case for all $c \ge 0$, and therefore (3.27) implies that $\mathcal{L}f(\zeta_0) \le 0$. If $\zeta_0 \in [0, P]$, then the only such admissible c is $c = 0$. Therefore we get $\mathcal{L}_0 f(\zeta_0) \le 0$ in this case, as required. □

Next we turn to the question of uniqueness. Our second main result in the section is the following theorem.

THEOREM 3.8 (Comparison theorem).

(i) *Suppose that u is a viscosity subsolution and v is a viscosity supersolution of* (3.4) *and that u and v satisfy the estimates*

$$-C|x+y|^\gamma \le u(x,y) \qquad \textit{for all} \quad (x,y) \in \mathcal{S}, \tag{3.28}$$

$$v(x,y) \le C|x+y|^\gamma \qquad \textit{for all} \quad (x,y) \in \mathcal{S}, \tag{3.29}$$

for some constant $C < \infty$. Then

$$u \le v \qquad \textit{in } \mathcal{S}^0.$$

(ii) *Moreover, if in addition*

$$v(x,y) = \liminf_{\substack{(\xi,\eta)\to(x,y)\\(\xi,\eta)\in\mathcal{S}^0}} v(\xi,\eta) \qquad \textit{for all } (x,y) \in \partial\mathcal{S}, \tag{3.30}$$

then

$$u \le v \qquad \textit{in } \mathcal{S}.$$

COROLLARY 3.9. *Suppose that u and v are two viscosity solutions of* (3.4) *satisfying* (3.28) *and* (3.29). *Then*

$$u = v \qquad \text{in } \mathcal{S}^0,$$

and u is continuous in $\mathcal{S}^0$. In particular, if (2.23) *holds, then the value function Ψ is continuous on $\mathcal{S}^0$.*

Proof of Corollary 3.9. Since u is a viscosity solution, it follows that $\overline{u}$ is a viscosity subsolution and $\underline{u}$ is a viscosity supersolution, and similarly for v. Hence, by Theorem 3.8,

$$\overline{u} \le \underline{v} \le \overline{v} \le \underline{u} \le \overline{u} \qquad \text{in } \mathcal{S}^0.$$

This implies that

$$\underline{u} = \overline{u} = \underline{v} = \overline{v} \qquad \text{in } \mathcal{S}^0.$$

The last statement of Corollary 3.9 now follows from Theorem 3.7 and Corollary 2.2. □

Proof of Theorem 3.8. The proof is based on the technique of Ishii (see [B], [CIL], and [IL]) and on the proofs of Lemma 3.12 in [AMS] and Theorem 5.7 in [AST]. Consequently we shall not give a detailed proof here but rather point out the special treatment required to handle the nonlocal intervention operator $\mathcal{M}$.

Let u and v be as in Theorem 3.8. We first construct a strict supersolution of (3.4) by making a perturbation of v. Choose $\gamma' \in (\gamma, 1)$ such that (see (1.23))

$$\delta > \gamma' \left[r + \frac{(\alpha - r)^2}{2\sigma^2(1-\gamma')} \right]. \tag{3.31}$$

Set

$$g(x,y) = (x+y)^{\gamma'} \tag{3.32}$$

and choose $\varepsilon > 0$. Then

$$\mathcal{M}(v + \varepsilon g) \le \mathcal{M}v + \varepsilon \mathcal{M}g \tag{3.33}$$

and hence

$$\mathcal{M}(v+\varepsilon g) - (v + \varepsilon g) \le (\mathcal{M}v - v) + \varepsilon(\mathcal{M}g - g). \tag{3.34}$$

Since v is a supersolution, we have

$$\mathcal{M}v - v \le 0. \tag{3.35}$$

Moreover, with $\zeta = (x,y)$,

$$\begin{aligned}(\mathcal{M}g - g)(\zeta) &= \sup_{\xi \ne 0}\{g(x - k - \xi - \lambda|\xi|, y + \xi)\} - g(x,y) \\ &= \sup_{\xi \ne 0}\{(x + y - k - \lambda|\xi|)^{\gamma'}\} - (x+y)^{\gamma'} \\ &\le (x+y)^{\gamma'} \left[\left(1 - \frac{k}{x+y}\right)^{\gamma'} - 1 \right]. \end{aligned} \tag{3.36}$$

Therefore, for each compact subset C of $\mathcal{S} \setminus \{0\}$ there exists $\rho_1 > 0$ such that $(\mathcal{M}g - g)(\zeta) \le -\rho_1$ for all $\zeta \in C$. So from (3.34) and (3.35) we get

$$\mathcal{M}(v + \varepsilon g) - (v + \varepsilon g) \le -\varepsilon\rho_1 \qquad \text{in } C. \tag{3.37}$$

Now if we define the operator L^0 by (see (2.2))

$$L^0 = -\delta I + rx\frac{\partial}{\partial x} + \alpha y\frac{\partial}{\partial y} + \tfrac{1}{2}\sigma^2 y^2\frac{\partial^2}{\partial y^2}, \tag{3.38}$$

where I is the identity operator, then

$$\begin{aligned} L^0 g(x,y) &= -\delta(x+y)^{\gamma'} + (rx + \alpha y)\gamma'(x+y)^{\gamma'-1} \\ &\quad + \tfrac{1}{2}\sigma^2 y^2\gamma'(\gamma'-1)(x+y)^{\gamma'-2} \\ &= (x+y)^{\gamma'}\left[-\delta + \gamma'\frac{rx+\alpha y}{x+y} + \tfrac{1}{2}\sigma^2\gamma'(\gamma'-1)\frac{y^2}{(x+y)^2}\right]. \end{aligned} \tag{3.39}$$

If we put

$$\eta = \frac{y}{x+y} \qquad \text{so that} \qquad \frac{x}{x+y} = 1 - \eta,$$

then we get

$$L^0 g(x,y) = (x+y)^{\gamma'}[-\delta + \gamma' r + \gamma'(\alpha - r)\eta + \tfrac{1}{2}\sigma^2\gamma'(\gamma'-1)\eta^2].$$

By (3.31) it follows that

$$L^0 g(x,y) < 0 \qquad \text{for all } (x,y) \ne (0,0).$$

Consequently, on every compact C of $\mathcal{S} \setminus \{0\}$ there exists $\rho_2 > 0$ such that

$$L^0 g(x,y) + \max_{c \ge 0}\left(-c\frac{\partial g}{\partial x}\right) \le -\rho_2 \qquad \text{on } C.$$

Therefore, since v is a supersolution of (3.4), we conclude that on every compact C of $\mathcal{S} \setminus \{0\}$ there exists $\rho > 0$ such that

$$v_\varepsilon := v + \varepsilon g$$

is a viscosity supersolution of

$$F(D^2 v_\varepsilon(\zeta), Dv_\varepsilon(\zeta), v_\varepsilon(\zeta), v_\varepsilon, \zeta) = -\varepsilon\rho \qquad \text{for } \zeta \in C.$$

Let us now prove the theorem by contradiction. Assume that

$$\sup_{\zeta \in \mathcal{S}}\{u(\zeta) - v(\zeta)\} > 0. \tag{3.40}$$

Choose $\varepsilon > 0$ such that

$$\sup_{\zeta \in \mathcal{S}}\{u(\zeta) - v_\varepsilon(\zeta)\} > 0. \tag{3.41}$$

Define

$$h(\zeta) := u(\zeta) - v_\varepsilon(\zeta). \tag{3.42}$$

Since h is usc and tends to $-\infty$ when $|\zeta| \to \infty$, the set

$$\text{Argmax } h := \{\overline{\zeta}; h(\overline{\zeta}) = \sup\{h(\zeta); \zeta \in \mathcal{S}\}\}$$

is nonempty and compact in $\mathcal{S} \setminus \{0\}$. Choose an open set $G \subset \mathcal{S} \setminus \{0\}$ containing this compact (G open relative to $\mathcal{S}$) and with $\overline{G}$ compact. In order to get a contradition it suffices to prove that

$$u \leq v_\varepsilon \qquad \text{in } G.$$

Thus we have reduced the problem to proving a comparison theorem for a strict supersolution v_ε and a subsolution u of (3.4) in an open subset G of $\mathcal{S} \setminus \{0\}$ with compact closure $\overline{G}$, when the supremum of $u - v_\varepsilon$ is attained in G only. This is proved by using Ishii's technique, adapted as in [B, Theorem 4.6] and in [AMS, Theorem 5.7] for the boundary conditions. We now explain this in more detail, as follows.

For $j = 1, 2, \ldots$, define, for $(\zeta, \eta) \in \mathcal{S} \times \mathcal{S}$,

$$H_j(\zeta, \eta) = u(\zeta) - v_\varepsilon(\eta) - \frac{j}{2}|\zeta - \eta|^2 \tag{3.43}$$

and set

$$m_j = \sup\{H_j(\zeta, \eta); (\zeta, \eta) \in \mathcal{S} \times \mathcal{S}\} \tag{3.44}$$

and

$$m = \sup\{h(\zeta); \zeta \in \mathcal{S}\}. \tag{3.45}$$

Proceeding exactly as in [AMS], we obtain that there exist ζ_j, η_j in $\mathcal{S}$ such that

$$m_j = H_j(\zeta_j, \eta_j) < \infty. \tag{3.46}$$

Moreover,

$$j|\zeta_j - \eta_j|^2 \to 0 \qquad \text{as } j \to \infty \tag{3.47}$$

and

$$m_j \to m \qquad \text{as } j \to \infty. \tag{3.48}$$

Suppose

$$\text{Argmax } h \text{ is contained in } \mathcal{S}^0 \tag{3.49}$$

and choose $\hat{\zeta} \in \mathcal{S}^0$ such that

$$m = h(\hat{\zeta}).$$

Then we get that

$$(\zeta_j, \eta_j) \in \mathcal{S}^0 \times \mathcal{S}^0 \qquad \text{for } j \text{ large enough.} \tag{3.50}$$

By applying [CIL, Theorem 3.2] we now obtain that there exist 2×2 matrices P_j, Q_j such that

$$(p_j, P_j) \in \bar{J}^{2,+} u(\zeta_j) \qquad \text{and} \qquad (q_j, Q_j) \in \bar{J}^{2,-} v_\varepsilon(\eta_j)$$

and

$$\begin{bmatrix} P_j & 0 \\ 0 & -Q_j \end{bmatrix} \leq 3j \begin{bmatrix} I & -I \\ -I & I \end{bmatrix}, \tag{3.51}$$

where

$$p_j = j(\zeta_j - \eta_j) \qquad \text{and} \qquad q_j = p_j.$$

Since u is a subsolution and v_ε is a strict supersolution, we obtain

$$\overline{F}(P_j, p_j, u, \zeta_j) \geq 0 \tag{3.52}$$

and

$$\underline{F}(Q_j, q_j, v_\varepsilon, \eta_j) \leq -\varepsilon\rho. \tag{3.53}$$

From (3.53) it follows that

$$\Lambda(Q_j, q_j, v_\varepsilon, \eta_j) < 0,$$

and proceeding as in [AMS], we obtain

$$\Lambda(P_j, p_j, u, \zeta_j) - \Lambda(Q_j, q_j, v_\varepsilon, \eta_j) < 0. \tag{3.54}$$

Consequently $\Lambda(P_j, p_j, u, \zeta_j) < 0$, and from (3.52) we obtain that

$$(\mathcal{M}u - u)(\zeta_j) \geq 0. \tag{3.55}$$

From (3.53) we have

$$(\mathcal{M}v_\varepsilon - v_\varepsilon)(\eta_j) \leq -\varepsilon\rho < 0. \tag{3.56}$$

Therefore, combining (3.55) and (3.56), we get

$$m_j < u(\zeta_j) - v_\varepsilon(\eta_j) < \mathcal{M}u(\zeta_j) - \mathcal{M}v_\varepsilon(\eta_j) - \varepsilon\rho. \tag{3.57}$$

Since $\zeta_j, \eta_j \to \hat{\zeta}$ and u is usc, we obtain

$$m < \liminf_{j\to\infty} [\mathcal{M}u(\zeta_j) - \mathcal{M}v_\varepsilon(\eta_j)]. \tag{3.58}$$

Since u is usc and v_ε is lsc we see, after some reflections, that

$$\limsup_{j\to\infty} \mathcal{M}u(\zeta_j) \leq \mathcal{M}u(\hat{\zeta}) \tag{3.59}$$

and

$$\limsup_{j\to\infty} (-\mathcal{M}v_\varepsilon(\eta_j)) \leq -\mathcal{M}v_\varepsilon(\hat{\zeta}). \tag{3.60}$$

Hence we get the desired contradiction:

$$\begin{aligned} m &< \mathcal{M}u(\hat{\zeta}) - \mathcal{M}v_\varepsilon(\hat{\zeta}) \\ &= \sup_{\xi_1 \neq 0} \{u(\hat{x}'(\xi_1), \hat{y}'(\xi_1))\} - \sup_{\xi_2 \neq 0} \{v_\varepsilon(\hat{x}'(\xi_2), \hat{y}'(\xi_2))\} \\ &\leq \sup_{\xi \neq 0} \{(u - v_\varepsilon)(\hat{x}'(\xi), \hat{y}'(\xi))\} \\ &\leq \sup\{(u - v_\varepsilon)(\zeta); \zeta \in \mathcal{S}\} = m, \end{aligned}$$

where $\hat{\zeta} = (\hat{x}, \hat{y})$ and (see (2.3))

$$\hat{x}'(\xi) = \hat{x} - \xi - \lambda|\xi| - k, \qquad \hat{y}'(\xi) = \hat{y} + \xi.$$

This contradiction shows that assumption (3.49) cannot hold. Therefore we must have

$$\hat{\zeta} \in \text{Argmax } h \cap \partial\mathcal{S}. \tag{3.61}$$

To treat the boundary points we proceed exactly as in the proof of Theorem 5.7 of [AST], which itself is based on the proof of Theorem 4.6 in [B] (see the appendix there, p. 166).

From (3.30) there exists a sequence $\{\zeta_j\} \subset \mathcal{S}^0 \cap G$ converging to $\hat{\zeta}$ such that $v_\varepsilon(\zeta_j) \to v_\varepsilon(\hat{\zeta})$ when $j \to \infty$. Let $\varepsilon_j = |\zeta_j - \hat{\zeta}|$. The idea is now to introduce the test function

$$w_j(\zeta, \eta) = u(\zeta) - v_\varepsilon(\eta) - \theta_j(\zeta, \eta), \qquad (\zeta, \eta) \in \mathcal{S} \times \mathcal{S},$$

where

$$\theta_j(\zeta, \eta) = \frac{|\zeta - \eta|^2}{2\varepsilon_j} + \frac{1}{4}\left(\frac{d(\eta) - d(\zeta)}{d(\zeta_j)} - 1\right)^4 + \frac{1}{4}|\zeta - \hat{\zeta}|^4.$$

Here $d(\eta)$ denotes the distance from η to $\partial\mathcal{S}$, and similarly for $d(\zeta), d(\zeta_j)$.

Following exactly the same steps as in [AST] and treating the term $\mathcal{M}u - u$ as we did before, we obtain a contradiction also in the case (3.61). This shows that (3.40) cannot hold and this completes the proof of Theorem 3.8. □

We summarize the results of this section in the following.

THEOREM 3.10. *Let $\Psi(x, y)$ be the value function given by* (1.17). *Suppose* (2.23) *holds, i.e.,*

$$\delta > \gamma\alpha. \tag{3.62}$$

Then Ψ is continuous on $\mathcal{S}^0$, and Ψ is the unique viscosity solution of (3.4) *with the property that there exists $C < \infty$ such that*

$$|\Psi(x, y)| \le C|x + y|^\gamma \qquad \textit{for all } (x, y) \in \mathcal{S}. \tag{3.63}$$

4. Numerical results. In this section we present the result of a numerical method used to approximate the viscosity solution of (3.4) in the case when the solvency region is $\mathcal{S}_+ = [0, \infty) \times [0, \infty)$. (See Remark 1.1.) This method is detailed in [CØS].

The problem is first localized on $D := (0, L) \times (0, L)$, assuming zero Neumann boundary conditions on the localized boundary. The localized problem is then solved by using an iterative method, which permits us to obtain the QVHJBI as a limit of variational HJBIs. Each variational inequality is approximated by a finite difference scheme and then solved by a Howard algorithm.

Figure 4.1 represents the optimal transaction policy for the following values of the parameters: $k = 0.05, \lambda = 0.1, \sigma = 0.3, r = 0.07, \delta = 0.1, \gamma = 0.3, \alpha = 0.11, L = 100$.

The results are relevant only in a smaller domain, for example $[0, 50] \times [0, 50]$, because of the side effects of the truncature and the artificial boundary conditions set for $x = 100$ and $y = 100$.

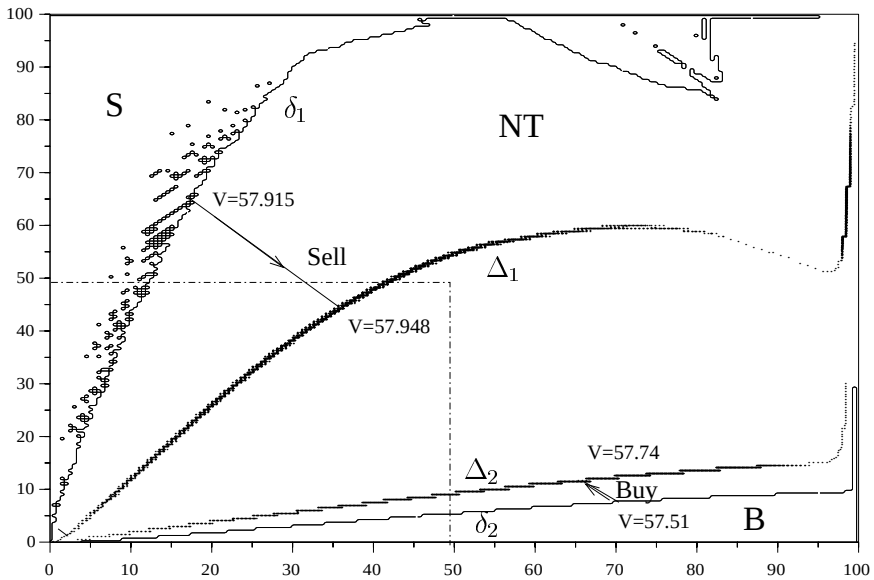

FIG. 4.1. *Optimal transaction policy (see text for parameter values).*

The domain consists of 3 regions: buy (B), sell (S), and no transaction (NT).

The set of states Δ_1 and Δ_2 reached after a purchase or a sale of stock are plotted. They are situated inside the continuation set NT. Unlike the case of no fixed costs, these lines do not coincide with the boundaries δ_1 and δ_2 of NT.

After a transaction, the position of the investor evolves as a pure diffusion process inside NT until it reaches the boundary. Then, a jump occurs back to the closest of the two lines Δ_1, Δ_2 in the transaction directions.

It is natural to ask whether it is possible to obtain more information about the shape of the no-transaction region NT, both for this choice $\mathcal{S}_+$ of solvency region and for the choice $\mathcal{S}$ given by (1.9). As mentioned in the introduction, we know that if $k = 0$, then NT is bounded by two straight lines from the origin [DN] (see Figure 1.2). If $k > 0$, is NT still bounded by two curves? If so, what can be said about the form of these curves? Can they be given an explicit description?

Remark 4.1. For results on the viscosity solutions of QVIs corresponding to impulse control problems (which, however, do not apply to our situation), see [I], [P], and [TY].

ROBUST CONTROL VIA SEQUENTIAL SEMIDEFINITE PROGRAMMING*

B. FARES†, D. NOLL†, AND P. APKARIAN‡

Abstract. This paper discusses nonlinear optimization techniques in robust control synthesis, with special emphasis on design problems which may be cast as minimizing a linear objective function under linear matrix inequality (LMI) constraints in tandem with nonlinear matrix equality constraints. The latter type of constraints renders the design numerically and algorithmically difficult. We solve the optimization problem via *sequential semidefinite programming* (SSDP), a technique which expands on sequential quadratic programming (SQP) known in nonlinear optimization. Global and fast local convergence properties of SSDP are similar to those of SQP, and SSDP is conveniently implemented with available semidefinite programming (SDP) solvers. Using two test examples, we compare SSDP to the augmented Lagrangian method, another classical scheme in nonlinear optimization, and to an approach using concave optimization.

Key words. nonlinear programming, sequential semidefinite programming, robust gain-scheduling control design, linear matrix inequalities, nonlinear matrix equalities

1. Introduction.

A variety of problems in robust control design can be cast as minimizing a linear objective subject to linear matrix inequality (LMI) constraints and additional nonlinear matrix equality constraints:

$$(D)\quad \begin{array}{ll} \text{minimize} & d^T x \\ \text{subject to} & \mathcal{A}(x) \le 0, \\ & \mathcal{B}(x) = 0, \end{array}$$

where d is a given vector, x denotes the vector of decision variables, $\mathcal{A}(x)$ is an affine symmetric matrix function, ≤ 0 means negative semidefinite, and $\mathcal{B}(x)$ is a nonlinear matrix valued function, which in many cases is bilinear in x. In the present paper, we are primarily interested in robust gain-scheduling control design, but a variety of other design problems may be cast in the form (D). Without aiming at completeness, let us just mention examples like fixed or reduced-order $\mathcal{H}_2$ and $\mathcal{H}_\infty$ synthesis, robust control synthesis with different classes of scalings, robust control design with parameter-dependent Lyapunov functions, robust control of nonlinear systems with integral-quadratic-constraints (IQC)-defined components, and, more generally, minimization or feasibility problems with bilinear matrix inequality (BMI) constraints. We discuss some of these applications of (D) at more detail.

Example 1. Observe that the reduced-order $\mathcal{H}_\infty$ synthesis problem may be cast

as

$$(H_\infty)\quad \begin{array}{ll} \text{minimize} & d^T x \\ \text{subject to} & \mathcal{A}(x) \le 0, \\ & \text{rank } \mathcal{Q}(x) \le r, \end{array}$$

where $\mathcal{A}(x)$ and $\mathcal{Q}(x)$ are symmetric affine. One way to transform (H_∞) into the form (D) is to introduce a slack matrix variable W of size $q \times r$, q the dimension of $\mathcal{Q}(x)$, let $\tilde{x} = (x, W)$ be the new decision vector, and introduce the quadratic equality constraint

$$\mathcal{B}(\tilde{x}) = \mathcal{Q}(x) - W^T W = 0.$$

In special situations, there may be better suited ways to obtain the form (D).

Example 2. The BMI-feasibility problem is a near at hand application of our method. If the BMI appears in standard form

$$\mathcal{B}(x) = \mathcal{A}(x) + \sum_{1 \le i < j \le n} B_{ij} x_i x_j$$

for an affine symmetric matrix valued function $\mathcal{A}$ and symmetric matrices B_{ij}, we are readily led to introduce a slack variable $z_{ij} = x_i x_j$, and replace the BMI with a new LMI in tandem with the nonlinear constraints $z_{ij} - x_i x_j = 0$. In practice, we are more likely to encounter BMIs or even multilinear matrix inequalities, featuring terms of the form $X_i A X_j$ with X_i, X_j parts of the decision vector. In this event, introducing an auxiliary decision matrix variable $Z_{ij} = X_i A X_j$ will have the same effect and transform the constraint set into the form of LMIs plus algebraic equalities.

Example 3. As a special case of a BMI problem, consider static output feedback control design, where we have to find a Lyapunov matrix variable $X > 0$ and a controller K such that for given matrices A, B, C the BMI

$$(A + BKC)X + X(A + BKC)^T < 0$$

is satisfied. Introducing a new variable $W = KCX$, we could readily transform this into an LMI plus a nonlinear matrix equality, $KCX - W = 0$, to obtain the program (D).

An alternative way to obtain the form (D) is to open the BMI via the projection lemma [18]. This leads to two LMIs,

$$\mathcal{N}_{B^T}^T (AX + XA^T)\mathcal{N}_{B^T} < 0, \qquad \mathcal{N}_C^T (YA + A^T Y)\mathcal{N}_C < 0,$$

in tandem with $X = Y^{-1}$. Here $\mathcal{N}_{B^T}$, $\mathcal{N}_C$ are bases for the null spaces of B^T, C. With the nonlinear equality constraint rearranged as $XY - I = 0$, we obtain a second version of (D).

It seems appealing to include the LMI

$$\begin{pmatrix} X & I \\ I & Y \end{pmatrix} \ge 0$$

among the above; as with $Y > 0$, and via Schur complement, it is equivalent to $X - Y^{-1} \ge 0$. While becoming redundant near the optimum, the new LMI will

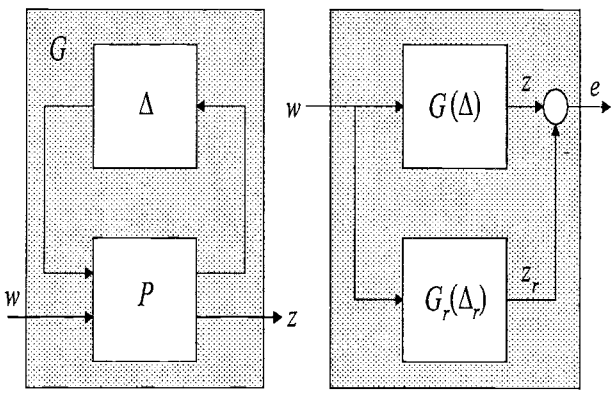

FIG. 1. *Designing reduced LFT model.*

help to stabilize the problem. Notice, however, that this idea, which has even been used to relax the static output feedback problem into an LMI problem, is no longer applicable in the more complicated robust design problem we shall present in more detail in section 2.

Example 4. Yet another important case is robust control design via generalized Popov multipliers (cf. [33, 28]), also known as k_m or μ synthesis. Here we encounter a BMI of the form

$$(P + UKV)^T S^T + S(P + UKV) \leq 0$$

to be solved for S and K for given P, U, V. By introducing a slack matrix variable $G = SUKV + (SUKV)^T$, the design problem may be cast in the form (D) as

$$\begin{aligned} \text{minimize} \quad & d^T x, x = (S, C, G) \\ \text{subject to} \quad & P^T S^T + SP + G \leq 0, \\ & SUKV + (SUKV)^T - G = 0. \end{aligned}$$

A similar situation occurs in mixed $\mathcal{H}_2/\mathcal{H}_\infty$-control design, where a BMI of the more general form

$$\Psi + (P + UKV)^T S^T \Phi + \Phi S(P + UKV) \leq 0$$

with fixed Ψ, Φ, P, U, V, to be solved for S, K, arises. This could now be handled using $G = \Phi SUKV + (\Phi SUKV)^T$.

Example 5. For many robust control problems, linear fractional transformations (LFT) are used to model plants with uncertain components or to represent nonlinear systems as uncertain linear systems. The corresponding LFTs are often highly complex and difficult to handle numerically, and techniques for reducing the order of LFT representations are required. One way to compute a reduced-order LFT approximation of the nominal LFT is by minimizing the worst-case energy discrepancy between outputs of the nominal and the reduced plant in response to arbitrary finite-energy input signals (see Figure 1). This approach admits a formulation of the form (D). See, e.g., [21] for more details.

The nonlinear constraint $\mathcal{B}(x) = 0$ renders problem (D) highly complex and difficult to solve in practice (cf. [13]). Nonetheless, due to its importance, various

heuristics and ad hoc methods have been developed over recent years to obtain suboptimal solutions to (D). Methods currently employed are usually *coordinate descent schemes*, which alternatively and iteratively fix parts of the coordinates of the decision vector, x, trying to optimize the remaining indices. The D-K (scaling-controller) iteration procedure is an example of this type [6, 37], whose popularity may be attributed to the fact that it is conceptually simple and easily implemented as long as the intermediate steps are convex LMI programs. The latter may often be guaranteed through an appropriate choice of the decision variables held fixed at each step. However, a major drawback of coordinate descent schemes is that they almost always fail to converge, even for starting points close to a local solution (see [22]). As a result, controllers obtained via such methods are highly questionable and bear the risk of unnecessary conservatism.

A new optimization approach to robust control design was initiated in [5], where the authors showed that reduced-order $\mathcal{H}_\infty$ control could be cast as a concave minimization problem. It was observed, however, that in a number of cases local concave minimization, which is known to be numerically difficult, produced unsatisfactory results. This occurs, in particular, when iterations get stalled, which is probably due to the lack of second-order information.

In [16], we therefore proposed a different approach to (D), again based on nonlinear optimization techniques. The *augmented Lagrangian method* from nonlinear optimization was successfully extended to program (D). The difficult nonlinear constraints were incorporated into an augmented Lagrangian function, while the LMI constraints, due to their linear structure, were kept explicitly during optimization. A Newton-type method including a line search, or, alternatively, a trust-region strategy, was shown to work if the penalty parameters were appropriately increased at each step, and if the so-called first-order update rule for the Lagrange multiplier estimates (cf. [9]) was used.

The disadvantage of the augmented Lagrangian method is that its convergence is at best linear if the penalty parameter c is held fixed. Superlinear convergence is guaranteed if $c \to \infty$, but the use of large c, due to the inevitable ill-conditioning, is prohibitive in practice. The present investigation therefore aims at adapting methods with better convergence properties, like sequential quadratic programming (SQP), to the case of LMI constrained problems. Minimizing at each step the second-order Taylor expansion of the Lagrangian of (D) about the current iterate defines the *tangent subproblem*, (T), whose solution will provide the next iterate. Due to the constraints $\mathcal{A}(x) \leq 0$, (T) is not a quadratic program, as in the case of SQP, but requires minimizing a quadratic objective function under LMI constraints. After convexification of the objective, (T) may be turned into a semidefinite program, conveniently solved with current LMI tools (cf., for instance, [20, 36]). We refer to this approach as *sequential semidefinite programming* (SSDP). It will be discussed in section 4, and a local convergence analysis will be presented in section 5. Although more complex than most coordinate descent schemes, the advantages of the new approach are at hand:

- The entire vector x of decision variables is updated at each step, so, for instance, we do not have to separate Lyapunov and scaling variables from controller variables.
- Like SQP, SSDP is guaranteed to converge globally, which means, for an arbitrary and possibly remote initial guess, if an appropriate line search or trust region strategy is applied.
- Being of second-order type, the rate of convergence of SSDP is superlinear in

a neighborhood of attraction of a local optimum.

The present paper discusses and compares three nonlinear optimization techniques suited for the design problem (D) with special emphasis on SSDP since it performed best. The reader might be missing an approach via interior-point techniques—perhaps more in the spirit of the age. In fact, in a different context, Jarre [24] proposes such a method based on the log-barrier function known from the interior-point approach to the semidefinite programming (SDP) problem but does not present any numerical evidence as to the practicality of the approach. Theoretical *and* practical results are presented by Leibfritz and Mostafa [25, 26], who consider static output feedback control and mixed $\mathcal{H}_2/\mathcal{H}_\infty$-control. Our own numerical experiments [3] with interior-point methods for robust control design seem to indicate that those are generally less robust and that the different parameters may be difficult to tune. We emphasize that the method proposed for robust control design is modulable in the sense that the optimization procedure featuring SSDP may be replaced by any other tool based on the user's favorite optimizer. Future investigations will show which methods work best in a given situation, and the present contribution does not claim to present the ultimate tool.

The paper is organized as follows. Section 2 presents and develops the setting of the robust gain-scheduling control, a particularly important application of (D). Even though the full robust gain-scheduling case has never been presented, let alone attacked algorithmically, we keep this part rather cursory, as the individual steps of the method are essentially known. We rely on a recent excellent exposition of the material by Scherer [35] and related texts [29, 1, 21]. We have chosen this problem as our main motivating case study, as it seems to be among the most difficult and numerically demanding cases of the scheme (D).

Section 3 aims at practical aspects. We offer more specific choices of parameter uncertainties and scaling variables which help to reduce the algorithmic complexity of the problem and, as far as our own experiments go, work well in practice.

Section 4 gives a description of the SSDP method as it naturally emerges from the classical SQP method. Local superlinear and quadratic convergence of SSDP is shown in section 5. While several convergence proofs for the SQP method are known in the literature, (cf. [11, 12]), they all seem to depend heavily on the polyhedrality of the classical-order cone, and no extension addressing the semidefinite cone seems available. The proof we present here is fairly general and includes nonlinear programming with more general order cones.

Numerical aspects of the SSDP method are discussed in section 7. Using two typical test examples, we compare it to the augmented Lagrangian method and to concave programming. While apparently of moderate size, these examples represent cases where classical approaches like the D-K iteration perform poorly or are even at complete loss.

2. Robust gain-scheduling control design. We wish to design a robust gain-scheduling controller for a plant which depends rationally on the uncertain and scheduled parameters. Consider an LFT plant in standard form described by the state-space equations

$$\left(\begin{array}{c} \dot{x} \\ \hline z_\theta \\ z \\ y \end{array}\right) = \left(\begin{array}{c|ccc} A & B_\theta & B_1 & B_2 \\ \hline C_\theta & D_{\theta\theta} & D_{\theta 1} & D_{\theta 2} \\ C_1 & D_{1\theta} & D_{11} & D_{12} \\ C_2 & D_{2\theta} & D_{21} & 0 \end{array}\right) \left(\begin{array}{c} x \\ \hline w_\theta \\ w \\ u \end{array}\right), \qquad w_\theta = \Theta z_\theta, \tag{1}$$

where $\Theta(t)$ is a time-varying matrix valued parameter assumed to have a two-block diagonal structure

$$\Theta = \begin{pmatrix} \Theta_m & \\ & \Theta_u \end{pmatrix}. \tag{2}$$

Here $\Theta_m(t)$ represents the scheduled parameters, measured on-line, and $\Theta_u(t)$ represents the time-varying parametric uncertainties, which we allow to vary in a known compact set $\mathcal{K}$ of matrices. We call parameters Θ of this form *admissible*, and the set of admissible (scheduled and bounded uncertain) parameters is denoted Θ.

We recall that the limiting case, no Θ_u (all parameters measured), is called the linear parameter-varying (LPV) or gain-scheduling control problem, while the case no Θ_m (all parameters uncertain) is referred to as the robust control problem.

The state-space entries of the plant (1) with inputs w, u and outputs z, y are rational functions of the parameters Θ_m and Θ_u. The meaning of the signals is as follows: u is the control input, y is the measurement signal, w stands for the vector of exogenous signals, and z stands for regulated variables.

The robust gain-scheduling control design requires finding a linear controller K of the form

$$\left(\begin{array}{c} \dot{\bar{x}} \\ \hline \bar{z}_\theta \\ u \end{array}\right) = \left(\begin{array}{c|cc} A_K & B_{K\theta} & B_{K1} \\ \hline C_{K\theta} & D_{K\theta\theta} & D_{K\theta 1} \\ C_{K2} & D_{K2\theta} & D_{K21} \end{array}\right) \left(\begin{array}{c} \bar{x} \\ \hline \bar{w}_\theta \\ y \end{array}\right), \quad \bar{w}_\theta = \phi(\Theta_m)\bar{z}_\theta, \tag{3}$$

where ϕ is called the *scheduling function*, to be determined as part of the design, such that (3) fulfills the following requirements:

- The closed-loop system, obtained by substituting (3) into (1), is internally stable.
- The L_2-gain of the closed-loop operator mapping w to z is bounded by γ.
- The above specifications hold for *all* admissible parameter trajectories $\Theta \in \Theta$.

In order to continue our analysis, we apply a convenient procedure first used in [29, 1]. We gather all parameter-dependent components into a single block, which leads to an augmented plant $\bar{P}(s)$ described in the frequency domain as

$$\left(\begin{array}{c} \bar{z}_\theta \\ \hline z_\theta \\ z \\ y \\ \hline \bar{w}_\theta \end{array}\right) = \overbrace{\left(\begin{array}{c|c|c} 0 & 0 & I \\ \hline 0 & P(s) & 0 \\ \hline I & 0 & 0 \end{array}\right)}^{\bar{P}(s)} \left(\begin{array}{c} \bar{w}_\theta \\ \hline w_\theta \\ w \\ u \\ \hline \bar{z}_\theta \end{array}\right). \tag{4}$$

It is easy to verify pictorially that the original scheme shown on the left-hand side of Figure 2 is equivalent to the one shown on the right-hand side using the augmented system $\bar{P}(s)$. After closing the loop, i.e., substituting (3) into (1), respectively, (4), the closed-loop systems mapping exogenous inputs w to regulated outputs z are the same on both sides.

By inspecting the left-hand diagram in Figure 2, we see that the original robust gain-scheduling control problem can now be viewed as a standard robust control problem for the time-invariant plant $\bar{P}$ facing the augmented uncertain parameter matrix $\tilde{\Theta}$, where

$$\tilde{\Theta} = \begin{pmatrix} \phi(\Theta_m) & \\ & \Theta \end{pmatrix}, \quad \Theta = \begin{pmatrix} \Theta_m & \\ & \Theta_u \end{pmatrix}.$$

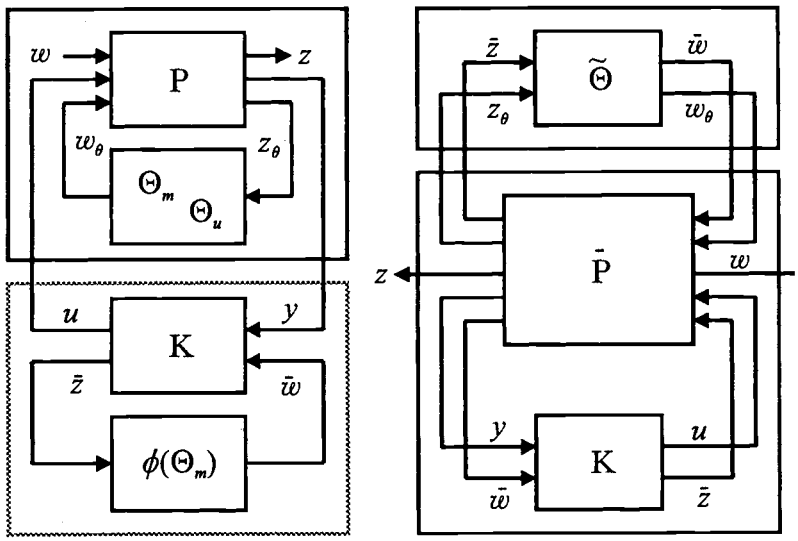

FIG. 2. *Gain-scheduling robust control.*

Based on this reformulation, sufficient conditions for the existence of a robust gain-scheduling linear time-invariant (LTI) controller (3) are consequently obtained by a suitable extension of the usual procedure in robust control design: Apply the bounded real lemma and the generalized S-procedure with a suitable choice of scalings to obtain sufficient conditions for robust stability of the closed-loop system (Lemma 1). Then use the projection theorem [18, 35] to eliminate the state-space variables of the controller K. The sufficient conditions for solvability are now again formulated in terms of the state-space entries (1) in conjunction with the Lyapunov and scaling variables (Theorem 2). They form, as we shall see, a mix of LMIs and nonlinear algebraic equalities. Now, at the core of the procedure, calculate the optimal gain using the proposed optimization techniques. As a final step, extract the robust controller K from the decision parameters used during optimization using, e.g., the method in [1].

We proceed to present the details of this scheme for the robust gain-scheduling control case. At the present stage, we aim at a fairly general approach, but the next section will focus on the practical aspects, where some of the theoretically possible steps will have to be reconsidered regarding their numerical performance. This concerns, in particular, the choice of the Lyapunov test matrix used in the bounded real lemma, the S-procedure, and the choice of the scalings (structured or general).

In this section, we allow for a fairly general class of scalings $\mathcal{Q}$ of the form

$$\mathcal{Q} = \begin{pmatrix} \mathcal{Q}_m & \\ & Q_u \end{pmatrix}, \quad \mathcal{Q}_m = \begin{pmatrix} Q_1 & Q_2 \\ Q_2^T & Q_m \end{pmatrix} \tag{5}$$

compatible with the block structure of $\tilde{\Theta}$. Later on we shall, at the cost of some conservatism, consider more special classes of scalings in order to reduce the numerical burden in the design.

Remark. Let us address the question of choosing the Lyapunov test function. Although parameter-dependent Lyapunov functions can be used (see [7, 17] for discussions), in the present paper, we shall restrict our attention to the more traditional

single quadratic Lyapunov approach based on a parameter-independent Lyapunov matrix $\mathcal{P}_0$. This choice is at the cost of some conservatism but keeps the theoretical descriptions simple and practically useful.

For the notation, observe that we use script matrix symbols $\mathcal{A}$, $\mathcal{B}_1$, $\mathcal{B}_\theta$, etc., for the state-space data of the closed-loop system obtained by substituting (3) into (4); see Figure 2. We have the following lemma.

LEMMA 1. *Suppose there exists a Lyapunov matrix $\mathcal{P}_0 > 0$ and scalings $\mathcal{Q}$, $\mathcal{R}$, and $\mathcal{S}$ of the above form* (5) *such that the nonlinear matrix inequality*

$$\star \left(\begin{array}{cc|cc|cc} 0 & I & & & & \\ I & 0 & & & & \\ \hline & & \mathcal{Q} & \mathcal{S} & & \\ & & \mathcal{S}^T & \mathcal{R} & & \\ \hline & & & & -\gamma & 0 \\ & & & & 0 & \frac{1}{\gamma} \end{array}\right) \left(\begin{array}{ccc} \mathcal{P}_0 & 0 & 0 \\ \mathcal{A} & \mathcal{B}_\theta & \mathcal{B}_1 \\ \hline 0 & I & 0 \\ \mathcal{C}_\theta & \mathcal{D}_{\theta\theta} & \mathcal{D}_{\theta 1} \\ \hline 0 & 0 & I \\ \mathcal{C}_1 & \mathcal{D}_{1\theta} & \mathcal{D}_{11} \end{array}\right) < 0 \tag{6}$$

is satisfied. Further suppose that the scalings satisfy the condition

$$\left(\begin{array}{c} \tilde{\Theta} \\ I \end{array}\right)^T \left(\begin{array}{cc} \mathcal{Q} & \mathcal{S} \\ \mathcal{S}^T & \mathcal{R} \end{array}\right) \left(\begin{array}{c} \tilde{\Theta} \\ I \end{array}\right) \geq 0 \tag{7}$$

for each admissible $\tilde{\Theta}$. Then the closed-loop system is robustly stable over the uncertain set Θ. Moreover, for every admissible $\tilde{\Theta} \in \Theta$, the operator mapping the exogenous signal w into the regulated variables z has an L_2-gain bounded above by γ.

Proof. The result is essentially the same as that of Theorem 10.4 in [35]. It consists of applying the bounded real lemma in tandem with the full block S-procedure. ∎

Remark. The derived sufficient conditions for robust gain-scheduling control are not suited for practice as they stand. This is mainly due to the infinite constraint (7), which involves an infinity of test matrices $\tilde{\Theta}$. In the following section, we shall indicate in which way (7) may, at the cost of some conservatism, be turned into a finite condition.

A second aspect of the derived criteria is that (6) is not jointly convex in the decision variables $\mathcal{P}_0$, $\mathcal{Q}$, $\mathcal{R}$, $\mathcal{S}$, and K. As a consequence, using these variables in the design is a difficult problem not suited for the usual convexity techniques in control.

As we shall see in our next step, the nonconvexity of the design problem may to some extent be reduced through the projection lemma [18]. As a result, the solvability conditions are stated back in terms of the original state-space entries in tandem with the Lyapunov and scaling variables, whereas the controller variable K has been eliminated. The mild inconvenience of this is that the actual controller has to be obtained in an extra step using the decision variables in Theorem 2 below. This step may itself be numerically demanding if the scheduling function ϕ has some undesirable properties.

THEOREM 2. *Consider the LFT plant* (1) *with scheduled and uncertain parameters $\Theta \in \Theta$ as in* (2). *Let $\mathcal{N}_X$ and $\mathcal{N}_Y$ be bases of the null spaces of $(C_2, D_{\theta 2}, D_{12}, 0, 0)$ and $(B_2^T, D_{2\theta}^T, D_{21}^T, 0, 0)$, respectively. Suppose there exist scalings Q, R, S, $\tilde{Q}$, $\tilde{R}$, $\tilde{S}$ of the form*

$$Q = \left(\begin{array}{cc} Q_m & \\ & Q_u \end{array}\right), \quad R = \left(\begin{array}{cc} R_m & \\ & R_u \end{array}\right), \text{etc.} \tag{8}$$

compatible with the block structure of Θ *in* (2) *and a pair of symmetric matrices* (X, Y) *satisfying the matrix completion conditions*

$$\begin{pmatrix} X & I \\ I & Y \end{pmatrix} > 0, \tag{9}$$

such that the linear matrix inequalities (10)–(12)

$$\mathcal{N}_X^T \begin{pmatrix} A^TX + XA & XB_\theta + C_\theta^T S^T & XB_1 & C_\theta^T R & C_1^T \\ B_\theta^T X + SC_\theta & Q + SD_{\theta\theta} + D_{\theta\theta}^T S^T & SD_{\theta 1} & D_{\theta\theta}^T R & D_{1\theta}^T \\ B_1^T X & D_{\theta 1}^T S^T & -\gamma I & D_{\theta 1}^T R & D_{11}^T \\ RC_\theta & RD_{\theta\theta} & RD_{\theta 1} & -R & 0 \\ C_1 & D_{1\theta} & D_{11} & 0 & -\gamma I \end{pmatrix} \mathcal{N}_X < 0, \tag{10}$$

$$\mathcal{N}_Y^T \begin{pmatrix} AY + YA^T & YC_\theta^T + B_\theta \tilde{S} & YC_1^T & B_\theta \tilde{Q} & B_1 \\ C_\theta Y + \tilde{S}^T B_\theta^T & D_{\theta\theta}\tilde{S} + \tilde{S}^T D_{\theta\theta} - \tilde{R} & \tilde{S}^T D_{1\theta}^T & D_{\theta\theta}\tilde{Q} & D_{\theta 1} \\ C_1 Y & D_{1\theta}\tilde{S} & -\gamma I & D_{1\theta}\tilde{Q} & D_{11} \\ \tilde{Q}B_\theta^T & \tilde{Q}D_{\theta\theta}^T & \tilde{Q}D_{1\theta}^T & \tilde{Q} & 0 \\ B_1^T & D_{\theta 1}^T & D_{11}^T & 0 & -\gamma I \end{pmatrix} \mathcal{N}_Y < 0, \tag{11}$$

$$\begin{pmatrix} \Theta \\ I \end{pmatrix}^T \begin{pmatrix} Q & S \\ S^T & R \end{pmatrix} \begin{pmatrix} \Theta \\ I \end{pmatrix} \geq 0 \text{ for every } \Theta \in \boldsymbol{\Theta} \tag{12}$$

in tandem with the nonlinear algebraic equality

$$\begin{pmatrix} Q_u & S_u \\ S_u^T & R_u \end{pmatrix}^{-1} = \begin{pmatrix} \tilde{Q}_u & \tilde{S}_u \\ \tilde{S}_u^T & \tilde{R}_u \end{pmatrix} \tag{13}$$

are satisfied. Then there exists an nth order gain-scheduling controller K *(*n *the order of the plant* (1)*), and a choice of the scheduling function* ϕ *such that the closed-loop system is internally and robustly stable, and the operator mapping* w *into* z *has* L_2*-gain bounded by* γ *for all admissible parameter trajectories* $\Theta \in \boldsymbol{\Theta}$*.*

Proof. The argument is based on a solvability test for quadratic inequalities developed in [34, 1, 2]. The most recent reference is Lemma 10.2 in [35]. This result is used to eliminate the controller variable K from the solvability conditions (6) in Lemma 1.

When applying the solvability test, due to the special structure of $\bar{P}(s)$, the solvability conditions obtained simplify to (9)–(12), (13). The question which remains is how the scheduled part of the coupling condition (13) is avoided. Following Theorem 10.11 of [35], one may show that the variables Q_1, Q_2, R_1, R_2, S_1, S_2 in the scheduled part of the multipliers are not called for by the matrix inequalities (9)–(12) and are therefore free to be chosen to satisfy the scheduled part of (13). This also requires a special choice of the scheduling function ϕ given in [35]. □

As already mentioned, condition (12) needs to be worked on in order to become numerically tractable. This aspect is treated in the next section.

3. Choices suited for practice. In this section, we address the practical aspects of the control design part and indicate that, at the cost of some conservatism, the difficulty of the design may be greatly reduced by accepting some restrictions in the general outline.

To begin with, let us assume that the uncertain matrix function $\Theta_u(t)$ varies in a polyhedral convex and compact set $\mathcal{K}$ of matrices, i.e., $\Theta_u(t) \in \mathcal{K} = \mathrm{co}\{\Theta_{u1}, \ldots, \Theta_{uN}\}$ at all times t. We refer to the Θ_{ui} as the vertices of the value set. Let us examine the consequence of this choice. Observe that due to the block structure of $\tilde{\Theta}$, the infinite dimensional scaling condition (12) already decouples into a scheduled part and an uncertain part. Concerning the uncertain part, we have the following lemma.

LEMMA 3. *Suppose the value set of $\Theta_u(t)$ is polyhedral and the scaling satisfies $Q_u < 0$. Then the uncertain part of condition* (12) *is equivalent to the finite condition*

$$\begin{pmatrix} \Theta_{ui} \\ I \end{pmatrix}^T \begin{pmatrix} Q_u & S_u \\ S_u^T & R_u \end{pmatrix} \begin{pmatrix} \Theta_{ui} \\ I \end{pmatrix} \geq 0 \qquad \text{for every } i = 1, \ldots, N. \tag{14}$$

The proof is in fact a straightforward convexity argument based on $Q_u < 0$ and may be found, e.g., in [19, 35]. This settles the question of finiteness for the uncertain part of (12) at the slight cost of conservatism introduced by assuming $Q_u < 0$.

Remark. We mention that in practice it is sufficient to let Θ_u have a block diagonal structure of the form

$$\Theta_u(t) = \mathrm{diag}(\theta_{u1}(t) I_{p_1}, \ldots, \theta_{ur}(t) I_{p_r}), \tag{15}$$

where we may without loss assume that $|\theta_{uj}| \leq 1$, so the set $\mathcal{K}$ will be a cube with the 2^r vertices $\theta_{uj}(t) = \pm 1$.

The conservatism introduced to obtain the finite condition (14) is minor and acceptable in practice. Notice that the number N may become inconveniently large if the number of parameters θ_{ui} grows. We therefore mention another strategy to avoid the infinite scaling condition. Assuming that the uncertain parameters have the block diagonal structure (15), we consider what we call *structured scalings* satisfying the following conditions: (i) Q_u and S_u commute with $\Theta_u(t)$; (ii) $R_u = -Q_u$ and $R_u > 0$; (iii) $S_u^T = -S_u$. We check that the scheduled part of condition (7) is satisfied. Developing the term gives

$$\Theta_u^2 Q_u + \Theta_u S_u + S_u^T \Theta_u + R_u = (I - \Theta_u^2) R_u \geq 0$$

as required. This choice of the scaling appears rather special and therefore bears the risk of unnecessary conservatism, but its merit is that it greatly reduces the number of decision variables and LMI constraints.

Let us now consider the corresponding questions for the scheduled part of (12). We start with the following technical lemma, which was already used in the proof of Theorem 2; cf. [35].

LEMMA 4. *Suppose the scalings Q_m, S_m, and R_m have been found such that*

$$\begin{pmatrix} \Theta_m \\ I \end{pmatrix}^T \begin{pmatrix} Q_m & S_m \\ S_m^T & R_m \end{pmatrix} \begin{pmatrix} \Theta_m \\ I \end{pmatrix} \geq 0 \quad \text{for every } \Theta \in \boldsymbol{\Theta}. \tag{16}$$

Then there is a choice of the scheduling function ϕ along with appropriate choices of

Q_1, Q_2, R_1, R_2, and S_1, S_2 such that the scheduled part of (7) *is satisfied, i.e.,*

$$\begin{pmatrix} \tilde{\Theta}_m \\ I \end{pmatrix}^T \begin{pmatrix} \mathcal{Q}_m & \mathcal{S}_m \\ \mathcal{S}_m^T & \mathcal{R}_m \end{pmatrix} \begin{pmatrix} \tilde{\Theta}_m \\ I \end{pmatrix} \geq 0 \quad \textit{for every } \Theta \in \mathbf{\Theta}. \tag{17}$$

Proof. As shown in [35], if $\Phi_m := [Q_m S_m; S_m^T R_m]$ satisfies (16), it is always possible to adjust the extended scalings $\mathcal{Q}_m = [Q_1 Q_2; Q_2^T Q_m]$, $\mathcal{R}_m = [R_1 R_2; R_2^T R_m]$, $\mathcal{S}_m = [S_1 S_2; S_2^T S_m]$ in such a way that, with an appropriate choice of the scheduling function ϕ, the scheduled part (17) of condition (12) holds true. An explicit formula for ϕ is given in [35]. ∎

This means that we are left to define a class of scalings Q_m, R_m S_m, which allows the reduction of the infinite set of LMIs (16) to a finite set. If Θ_m has a block diagonal structure

$$\Theta_m = \operatorname{diag}(\theta_{m1} I_{\ell_1}, \ldots, \theta_{ms} I_{\ell_s}) \tag{18}$$

and if prior bounds $|\theta_{mj}(t)| \leq 1$ like for the uncertain parameters are available, this may be done in exactly the same way as for the uncertain part.

Assuming block diagonal structures (15), (18) for both types of parameters, we find it useful in practice to pursue different strategies for the two types of parameters. We use the vertex idea to render the uncertain part of (7) finite, and we use structured scalings for the scheduled parameters. This avoids numerical difficulties which may arise when constructing K if a complicated scheduling function ϕ is required. The use of structured scalings allows the choice $\phi(x) = x$. Notice that for the scheduled parameters, due to conditions (i) above, choosing structured scalings implies that each of the subblocks Q_1, Q_2, Q_m of $\mathcal{Q}_m$ has the block diagonal structure with diagonal blocks of sizes $\ell_1, \ldots, \ell_s$ in (18). This option finally was a good compromise in our numerical tests, and we recommend its use for the type of problem under investigation.

4. Sequential semidefinite programming. In this section, we cast the robust gain-scheduling control design problem as an optimization problem and present an algorithmic approach to its solution.

Recall from Theorem 2 that the complete vector of decision variables for design is $x = (\gamma, Q, R, S, \tilde{Q}, \tilde{R}, \tilde{S}, X, Y)$. We find it notationally useful to point to parts of the vector x by introducing the notation

$$\Phi_u = \begin{pmatrix} Q_u & S_u \\ S_u^T & R_u \end{pmatrix}, \qquad \tilde{\Phi}_u = \begin{pmatrix} \tilde{Q}_u & \tilde{S}_u \\ \tilde{S}_u^T & \tilde{R}_u \end{pmatrix},$$

involving the uncertain blocks of the scaling variables. Similarly, Φ_m, $\tilde{\Phi}_m$ regroup the scheduled parts of Q, R, S, $\tilde{Q}$, $\tilde{R}$, $\tilde{S}$.

Let $\mathcal{A}(x) \leq 0$ represent the LMI constraints (9)–(12), where (12), using one of the techniques from the previous section, has been replaced with a finite set of LMIs, along with $Q \leq 0$ and $\tilde{Q} \leq 0$ required for these procedures. Finally, let $\mathcal{B}(x) = \Phi_u \tilde{\Phi}_u - I = 0$ represent the nonlinear algebraic constraint (13). Then the robust gain-scheduling control problem may be cast in the form (D). More generally, we consider an augmented version (D_c) of (D) for a penalty parameter $c \geq 0$:

$$(D_c) \quad \begin{array}{ll} \text{minimize} & f_c(x) = \gamma + \frac{c}{2} \|\Phi_u \tilde{\Phi}_u - I\|^2 \\ \text{subject to} & \mathcal{A}(x) \leq 0, \\ & \mathcal{B}(x) = \Phi_u \tilde{\Phi}_u - I = 0. \end{array}$$

Remark. Notice that problems (D) and (D_c) are equivalent since the penalty term $\frac{c}{2}\|\Phi_u\tilde{\Phi}_u - I\|^2$ added in (D_c) will vanish at the optimal x. Using (D_c) instead of (D), as we shall see, may add some numerical stability.

Remark. We observe that the variables Q_m, R_m, S_m, $\tilde{Q}_m$, $\tilde{R}_m$, $\tilde{S}_m$, and X, Y occur only in the LMI constraint, which strongly indicates that we expect redundancies in the decision parameters. In fact, our experiments indicate that this is a strong point for using structured scalings in the Θ_m block, as this tends to limit these redundancies. In general, we propose to put bounds $\|\cdot\|_\infty \le M$ on the free variables in order to avoid degeneracy or failure of the successive LMI subproblems. As these additional constraints may be included among the LMIs, $\mathcal{A}(x) \le 0$, we do not change the notation here.

Remark. Notice that the trick used in Examples 1 and 2 of the introductory section does not apply in the robust synthesis case, as the matrices Φ_u, $\tilde{\Phi}_u$ are indefinite. This shows that the problem is as a rule numerically harder than, e.g., static output feedback design or reduced order design.

Let us now extend the idea of SQP to the augmented program (D_c). As we aim at a *primal-dual* method, this requires maintaining estimates for the decision *and* Lagrange multiplier variables. Consider the Lagrangian associated with (D_c):

$$L_c(x;\Lambda,\lambda) = f_c(x) + \operatorname{trace}(\Lambda\cdot\mathcal{A}(x)) + \lambda^T \operatorname{vec}(\Phi_u\tilde{\Phi}_u - I), \tag{19}$$

where $\Lambda \ge 0$ is a positive semidefinite dual matrix variable, λ is a traditional Lagrange multiplier variable whose dimension is m^2, and m is the size of the matrices Φ_u, $\tilde{\Phi}_u$. Given the current iterate x and the current Lagrange multiplier estimates λ, $\Lambda \ge 0$, we define the *tangent problem*

$$(T)\quad \begin{array}{ll} \text{minimize} & \nabla f_c(x)^T\Delta x + \frac{1}{2}\Delta x^T\nabla^2 L_c(x;\Lambda,\lambda)\Delta x \\ \text{subject to} & \mathcal{A}(x+\Delta x) \le 0, \\ & \Phi_u\tilde{\Phi}_u + \Phi_u\Delta\tilde{\Phi}_u + \Delta\Phi_u\tilde{\Phi}_u - I = 0, \end{array}$$

which consists of minimizing the second-order Taylor polynomial of $L_c(x+\Delta x;\Lambda,\lambda)$ about the current x for possible steps Δx, subject to the LMI constraints $\mathcal{A} \le 0$ and the equality constraint $\mathcal{B} = 0$ linearized about the current Φ_u, $\tilde{\Phi}_u$. Notice that the equality constraint above is given in matrix notation. The equivalent expression in long vector notation using the Kronecker product $\otimes$ is

$$(\tilde{\Phi}_u \otimes I)\ \operatorname{vec}(\Delta\Phi) + (I\otimes\Phi_u)\ \operatorname{vec}(\Delta\tilde{\Phi}_u) - \operatorname{vec}(I - \Phi_u\tilde{\Phi}_u) = 0. \tag{20}$$

Here $\tilde{\Phi}_u \otimes I$ is invertible as soon as $\tilde{\Phi}_u$ has maximal rank, while $I\otimes\Phi_u$ is invertible as soon as Φ_u has maximal rank.

Remark. If either Φ_u or $\tilde{\Phi}_u$ is positive definite, we may symmetrize the equality constraint, as considered, e.g., in [15]. As mentioned before, this is typically not possible in the robust synthesis case but may help in different cases.

The choice of (T) is understood by inspecting the necessary optimality conditions, which show that the solution Δx of (T) may be considered as the Newton step from the current point x to the new iterate $x^+ = x+\Delta x$. The Lagrange multipliers $\Lambda^+ \ge 0$ and λ^+ belonging to the linear constraints in (T) are the updates for Λ and λ. Notice that $\Lambda^+ \ge 0$ as a consequence of the Kuhn–Tucker conditions for (T). Further notice that, despite the notation, Λ does not explicitly appear in the Hessian $\nabla^2 L_c(x;\Lambda,\lambda)$ of the Lagrangian, a fact which is due to the linearity of $\mathcal{A} \le 0$. On the other hand,

due to nonlinearity of the equality constraint, λ appears explicitly in the Hessian of the Lagrangian. Updating Λ is then still mandatory to obtain the update λ^+.

Remark. At this stage, we observe that due to the linearity of the LMI constraints, the iterates produced by the SSDP scheme will always satisfy the LMIs, while the nonlinear equality constraint will of course be only approximately satisfied. The fact that we iterate on decision variables satisfying the LMIs is an advantage of our method since it may render even suboptimal solutions of the optimization problem (D_c) useful for the design (cf. the termination phase in the robust control design algorithm presented at the end of this section).

The special structure and the moderate size of the variable $(\Phi_u, \tilde{\Phi}_u)$ occurring in the equality constraint $\mathcal{B} = 0$ suggest using a reduced Hessian technique. For fixed x, respectively, Φ_u, $\tilde{\Phi}_u$, we can eliminate either $\Delta\Phi_u$ or $\Delta\tilde{\Phi}_u$ from the linearized equality constraint in (T) as long as we maintain iterates x with full rank Φ_u, $\tilde{\Phi}_u$. In that event, the matrix $B = [\tilde{\Phi}_u \otimes I \; I \otimes \Phi_u]$ has full row rank m^2, m the size of the matrix Φ_u, and eliminating the equality constraint therefore reduces the problem size by m^2.

Following the standard notation in SQP, let Z be a matrix whose columns form a basis (preferably orthogonal) of the null space of the matrix B belonging to (20), and let the columns of Y form a basis for the range of B^T. Then we may write the displacement Δx as $\Delta x = Z\Delta\tilde{x} + Yw_0 = Z\Delta\tilde{x} + p_0$ for the fixed vector $p_0 = Y(BY)^{-1}\mathrm{vec}(I - \Phi_u\tilde{\Phi}_u)$, where $\Delta\tilde{x}$ is now the reduced decision vector.

With this notation, the reduced tangent problem is

$$(\tilde{T}) \qquad \begin{array}{ll} \text{minimize} & (\nabla f_c(x)^T Z + p_0^T \nabla^2 L_c Z)\Delta\tilde{x} + \frac{1}{2}\Delta\tilde{x} Z^T \nabla^2 L_c Z \Delta\tilde{x} \\ \text{subject to} & \mathcal{A}_* \circ Z(\Delta\tilde{x}) \leq -\mathcal{A}(x + p_0), \end{array}$$

where $\mathcal{A}_*$ is the linear part of $\mathcal{A}$. Notice that in general $(\tilde{T})$ is not yet an SDP since the reduced Hessian $Z^T\nabla^2 L_c Z$ may be indefinite. In order to obtain a convex program, we have to convexify the reduced Hessian, which may be done in several ways. We comment on these at the end of the section.

When the correction is done, the subproblem is convex and may easily be transformed into an SDP problem. Ideally, the solution $\Delta\tilde{x}$ gives rise to a step Δx in the original tangent problem, and the new iterate x^+ is obtained as $x + \Delta x$, but in practice a line search using an appropriate merit function is required. For appropriate choices avoiding the Maratos effect, we refer to the vast literature on the subject (see, e.g., [10], [12]).

In order to obtain the Lagrange multiplier updates, we have to inspect the necessary optimality conditions for $(\tilde{T})$. Let $\tilde{\Lambda}^+ \geq 0$ be the Lagrange multiplier matrix variable in $(\tilde{T})$ associated with the constraint $\mathcal{A} \leq 0$, and let $\Delta\tilde{x}$ be the optimal solution of $(\tilde{T})$. Then the optimal Δx is readily obtained via (20), Λ^+ is chosen as $\tilde{\Lambda}^+$, while λ^+ is found through

$$Y^T\nabla f_c(x) + Y^T\nabla^2 L_c(Z\Delta\tilde{x} + p_0) + Y^T\mathcal{A}_*^T\Lambda^+ + Y^T B^T\lambda^+ = 0, \tag{21}$$

which determines λ^+ uniquely if B has full rank. Conceptually, the SSDP algorithm proposed to solve (D) may be described as follows.

SSDP Algorithm.

1. Find an initial point x^0, such that $\mathcal{A}(x^0) \leq 0$ and such that Φ_u^0, $\tilde{\Phi}_u^0$ are full rank. Select Lagrange multiplier estimates λ^0 and $\Lambda^0 \geq 0$ using formula (21).
2. Given the iterate x^k with Φ_u^k and $\tilde{\Phi}_u^k$ nonsingular and multiplier estimates $\Lambda^k \geq 0$, λ^k, form the reduced tangent problem $(\tilde{T}_k)$ about the current data.

Render the reduced Hessian positive definite if required. Obtain the reduced step $\Delta\tilde{x}^k$ as a solution to the SDP problem, and let $\Delta x^k = Z_k\Delta\tilde{x}^k + p_0^k$. Obtain Lagrange multipliers $\Lambda^\sharp \geq 0$ and $\lambda^\sharp$ from $(\tilde{T}_k)$ using (21).

3. Do a line search in direction Δx^k using an appropriate merit function, and determine the new iterate $x^{k+1} = x^k + \alpha_k\Delta x^k$. Set $\Lambda^{k+1} = \Lambda^k + \alpha_k(\Lambda^\sharp - \Lambda^k)$ and $\lambda^{k+1} = \lambda^k + \alpha_k(\lambda^\sharp - \lambda^k)$. Choose α_k so that Φ_u^{k+1} and $\tilde{\Phi}_u^{k+1}$ are nonsingular.
4. Check the stopping criteria. Either halt or replace k by $k+1$, and go back to step 2.

In order to compute the Hessian $\nabla^2 L(x;\Lambda,\lambda)$ of the Lagrangian in step 2, only second-order derivatives with respect to Φ_u and $\tilde{\Phi}_u$ are required, as $f_c(x)$ is linear in γ and does not depend on the other decision variables. Using the Kronecker product $\otimes$, we have the following formulae (cf. also [16]).

LEMMA 5.

$$\nabla^2_{\tilde{\Phi}_u\Phi_u} L_c = c(\tilde{\Phi}_u \otimes I)^T(\tilde{\Phi}_u \otimes I),\ \nabla^2_{\tilde{\Phi}_u\tilde{\Phi}_u} L_c = c(I \otimes \Phi_u)^T(I \otimes \Phi_u),$$
$$\nabla^2_{\tilde{\Phi}_u\Phi_u} L_c = (I \otimes \mathrm{mat}(\lambda))^T + c((\Phi_u\tilde{\Phi}_u - I)^T \otimes I + (I \otimes \Phi_u)^T(\tilde{\Phi}_u \otimes I)).$$

Remark. Let us comment on the convexification of the reduced tangent problem $(\tilde{T})$ required to obtain an SDP problem. Recent trends in optimization indicate that one should dispense with this procedure. It is considered important to take the directions of negative curvature of the (reduced) Hessian into account, e.g., by using a trust region strategy or by doing sophisticated line searches which combine the Newton direction and the dominant direction of negative curvature. While the second idea could be at least partially realized, a trust region approach is not feasible as yet in the presence of LMI constraints as optimizing a nonconvex quadratic function subject to LMIs is presently too difficult numerically to become a functional scheme. We therefore have to use the well-known convexification methods used in nonlinear optimization over many years, and we refer to [9, 23] for several such strategies.

In our numerical experiments, we tested Powell's idea of doing a Cholesky factorization, and adding correction terms as soon as negative square roots appear, and a direct method which used the QR-factorization to correct negative eigenvalues of the reduced Hessian. A third method adapted to the structure of the problem which we found even more efficient consisted of a Gauss–Newton-type idea. We neglect the term $\Phi_u\tilde{\Phi}_u - I$ in the Hessian matrix (22), performing the modified Cholesky factorization on the remaining term. This is motivated by the fact that dropping this term leaves a positive semidefinite matrix, which is still close to the correct Hessian as long as the neglected term $\Phi_u\tilde{\Phi}_u - I$ is small. This is the case when the nonlinear constraint (13) is approximately satisfied, and the matrix is therefore asymptotically close to the correct (reduced) Hessian. As a consequence, and in contrast with the true Gauss–Newton method, this procedure therefore does not destroy the superlinear quadratic convergence of the scheme.

Observe that in all these procedures, the augmented form (D_c) of the program helps. In fact, the penalty term renders the Hessian more convex than in the original form (D), and so the corrections are often very mild in practice and, according to the theory in polyhedral programming, are not even required asymptotically (cf. [8, 10, 12]. This observation is corroborated in our experiments with LMI constraints.

We summarize the result of this section by presenting the following algorithmic approach to the robust gain-scheduling design problem.

Algorithm for robust gain-scheduling control design.

- *Step* 1. *Initialization.* Locate a strictly feasible decision vector x^0 for the LMI constraints: For fixed large enough $\gamma = \gamma_0$, render the LMIs (9)–(12) maximally negative by solving the SDP problem

$$\min\{t : \text{LMIs (9)–(12)} < tI\}.$$

  Then determine X_0, Y_0, Φ_u^0, and $\tilde{\Phi}_u^0$ so that $\Phi_u^0\tilde{\Phi}_u^0 - I$ is as close as possible to zero. Then initialize the Lagrange multiplier estimates λ_0 and $\Lambda_0 \geq 0$.
- *Step* 2. *Optimization.* Solve the optimization problem (D_c) via SSDP, using $(x^0, \Lambda^0, \lambda^0)$ as a primal-dual starting point. The primal solution is x.
- *Step* 3. *Terminating phase.* Due to nonlinearity, the algebraic constraint (13) is never exactly satisfied at the solution x. It is, however, possible to terminate the program without strict satisfaction of the nonlinear constraints by a simple *perturbation technique* [5], which is applicable as long as the LMIs (9)–(12) are strictly satisfied. One can then replace Φ_u with $\tilde{\Phi}_u^{-1}$ and check whether the LMI constraints (9)–(12) hold, possibly with new X and Y. In this case, a controller is readily obtained. Dually, we can replace $\tilde{\Phi}_u$ with Φ_u^{-1} and check the LMI constraints (9)–(11), with (7), respectively, (17) suitably replaced with its dual form

$$\begin{pmatrix} I \\ -\Theta_i^T \end{pmatrix}^T \tilde{\Phi}_u \begin{pmatrix} I \\ -\Theta_i^T \end{pmatrix} < 0 \quad \forall i = 1, \ldots, N.$$

  If the test fails, the numerical solution to (D_c) is unsatisfactory and has to be improved, e.g., by changing the stopping criteria or by increasing the penalty constant c and rerunning step 2.

Remark. Notice that strict feasibility < 0 is a priori not guaranteed by SSDP but may easily be forced if we replace ≤ 0 in the corresponding LMIs by the stronger $\leq -\varepsilon I$ for a small $\varepsilon > 0$. Moreover, if the SDP subproblem is solved by the notorious interior point techniques, the LMIs are automatically strictly satisfied, and the above perturbation argument is applicable.

5. Fast local convergence of SSDP. In this section, we prove local superlinear and quadratic convergence of the SSDP method under mild regularity hypotheses. It is interesting to recall the history of the SQP method, which was already popular during the late 1970s, even though the first proof of superlinear and quadratic convergence under realistic assumptions was published as late as 1994 by Bonnans [11]. A more compact version of that proof is published in [12]. Both versions are based on techniques introduced by Robinson in the 1980s.

The time interval is the more remarkable, as the equality constrained case was settled much earlier, apparently first by Boggs and Tolle around 1982. See [10] and the references given there. Early proofs of the general case existed but always reduced the situation to the equality constrained case under the (unrealistic) assumption of strict complementarity at the optimal pair.

Inspecting the convergence proofs for Newton's method in [11, 12] shows that they heavily depend on the polyhedrality of the order cone in classical nonlinear programming, so a natural extension to the present case of SSDP does not seem near at hand. Our present approach is nevertheless inspired by Bonnans's paper [11]. It turns out that our method of proof applies even to more general situations, and we present the method in a fairly general context.

We consider the nonlinear programming problem of the form

$$(P)\quad \begin{array}{ll} \text{minimize} & f(x) \\ \text{subject to} & g_E(x) = 0, \\ & g_I(x) \in K^0, \end{array}$$

where $f : \mathbb{R}^n \to \mathbb{R}$, $g_E : \mathbb{R}^n \to \mathbb{R}^m$, and $g_I : \mathbb{R}^n \to \mathbb{R}^p$ are $\mathcal{C}^2$-functions, K is a cone in $\mathbb{R}^p$, and K^0 is its polar cone defined as

$$K^0 = \{y \in \mathbb{R}^p : \langle x, y\rangle \le 0 \text{ for each } x \in K\}.$$

In the classical nonlinear programming case, $K = \mathbb{R}^p_+$, $K^0 = \mathbb{R}^p_-$, and the constraint $g_I(x) \in K^0$ becomes $g_i(x) \le 0$ componentwise, while in the semidefinite case, $\mathbb{R}^p \cong \mathbb{S}^r$ (with $p = r(r+1)/2$), the space of symmetric $r \times r$-matrices, $K = \mathbb{S}^r_+$ (with $K^0 = \mathbb{S}^r_-$), the cone of positive semidefinite matrices, and the constraint $g_i(x) \in K^0$ means that the matrix $g_i(x)$ is negative semidefinite. We use the notation $\langle \cdot, \cdot \rangle$ for the scalar product employed, since this may include the classical case $\langle x, y\rangle = \sum_i x_i y_i$ as well as $\langle x, y\rangle = \operatorname{trace}(x \cdot y)$ in the semidefinite case. The adjoint of an operator A with respect to this scalar product is denoted A^*; derivatives with respect to $\langle \cdot, \cdot \rangle$ in the x-variable are indicated by primes. Notice also that $g_I(x)$ was an affine matrix valued function in our applications, but we prefer to include the general nonlinear case as applications of this type are eminent.

We suppose that $\bar{x}$ is a local minimum of (P) and that there exists a Lagrange multiplier $\bar{\lambda} = (\bar{\lambda}_E, \bar{\lambda}_I)$ satisfying the necessary optimality condition

$$(KT)\quad \begin{array}{ll} (1) & f'(\bar{x}) + g'(\bar{x})^* \bar{\lambda} = 0, \\ (2) & g_E(\bar{x}) = 0, \\ (3) & g_I(\bar{x}) \in K^0, \lambda_I \in K, \langle g_I(x), \bar{\lambda}_I\rangle = 0. \end{array}$$

Observe that the existence of $\bar{\lambda}$ is guaranteed under a weak regularity assumption like, for instance, Robinson's constraint qualification hypothesis (cf. [32]). The Lagrangian associated with (P) is

$$L(x; \lambda) = f(x) + \langle g(x), \lambda\rangle = f(x) + \langle g_E(x), \lambda_E\rangle + \langle g_I(x), \lambda_I\rangle. \tag{22}$$

We consider Newton's method for solving the Kuhn–Tucker system (KT), which generates a sequence (x^k, λ^k) approximating the optimal pair $(\bar{x}, \bar{\lambda})$. Given the kth iterate (x^k, λ^k), the $(k+1)$st iterate is obtained by solving the tangent problem

$$(T_k)\quad \begin{array}{ll} \text{minimize} & \langle f'(x^k), \Delta x\rangle + \frac{1}{2}\langle \Delta x, L''(x^k; \lambda^k)\Delta x\rangle \\ \text{subject to} & g_E(x^k) + g'_E(x^k)\Delta x = 0, \\ & g_I(x^k) + g'_I(x^k)\Delta x \in K^0. \end{array}$$

If Δx is the solution to (T_k), then $x^{k+1} = x^k + \Delta x$. The Lagrange multiplier update $\lambda^{k+1} = (\lambda_E^{k+1}, \lambda_I^{k+1})$ is just the Lagrange multiplier belonging to the linearized constraints in (T_k). The Kuhn–Tucker conditions for (T_k) are the following:

$$(KT_k)\quad \begin{array}{l} L'(x^k; \lambda^{k+1}) + L''(x^k; \lambda^k)(x^{k+1} - x^k) = 0, \\ g_E(x^k) + g'_E(x^k)(x^{k+1} - x^k) = 0, \\ g_I(x^k) + g'_I(x^k)(x^{k+1} - x^k) \in K^0, \lambda_I^{k+1} \in K, \\ \qquad \langle g_I(x^k) + g'_I(x^k)(x^{k+1} - x^k), \lambda_I^{k+1}\rangle = 0. \end{array}$$

The aim of the following analysis is to give sufficient conditions for local quadratic or superlinear convergence of the sequence (x^k, λ^k).

Remark. The usual choice of quasi-Newton methods is easily obtained from our scheme by approximating the Hessian $L''(x^k; \lambda^k)$ of the Lagrangian of (P) by a matrix M^k. In order to account for modifications of $L''(x^k; \lambda^k)$ like convexifications as proposed in our experimental section, we include the quasi-Newton approach into our convergence analysis. We shall use the notation $(T_k(M^k))$ for the modified tangent problem with M^k replacing the Hessian of the Lagrangian.

Inspecting classical approaches for the usual polyhedral cone in nonlinear programming shows that local convergence of Newton's method usually requires two types of hypothesis: (a) the second-order sufficient optimality condition and (b) a constraint qualification. As we mentioned before, a third type of condition, strict complementarity, is often used but should be avoided since it is artificial as a rule. At the core is the second-order sufficient optimality condition, saying that the Hessian of the Lagrangian $L''(\bar{x}, \bar{\lambda})$ is positive definite along critical directions. We adopt the definition of critical directions from [32, 11], which in the presence of a multiplier leads to the following.

Definition. The direction $h \neq 0$ is critical at $\bar{x}$ with respect to the Lagrange multiplier $\bar{\lambda}$ if the following hold:

1. $g'_E(\bar{x})h = 0$.
2. There exist $h^k \to h$, $x^k = \bar{x} + t_k h^k$ with $t_k \to 0^+$ in tandem with $\lambda_I^k \to \bar{\lambda}_I$, $\lambda_I^k \in K$ such that for some v^k with $v^k = \mathrm{o}(t_k)$, $g_I(x^k) - v^k \in K^0$ and $\langle g_I(x^k) - v^k, \lambda_I^k \rangle = 0$.

Remark. Recall that in the case of the polyhedral cone $K = \mathbb{R}^p_+$ in nonlinear programming, a critical direction h satisfies conditions (1) for the equality constraints along with the following condition $(2')$ for inequalities: $g'_i(\bar{x})h = 0$ for active constraints $i \in I$ having multiplier $\bar{\lambda}_i > 0$, and $g'_i(\bar{x})h \leq 0$ for active constraints $i \in I$, where $\bar{\lambda}_i = 0$. It is an easy exercise to show that, in this case, (2) is equivalent to this classical definition of criticality $(2')$.

Let us now start analyzing the Newton step for (P) via the following perturbation result.

LEMMA 6. *Suppose there exist sequences $x^k \to \bar{x}$, $\lambda^k \to \bar{\lambda}$, $\delta_k \to 0^+$, and u^k, $v^k = (v_E^k, v_I^k)$ satisfying $u^k = \mathcal{O}(\delta_k)$, $v^k = \mathcal{O}(\delta_k)$ such that*

1. *$L'(x^k; \lambda^k) = u^k$;*
2. *$g_E(x^k) = v_E^k$;*
3. *$g_I(x^k) - v_I^k \in K^0$, $\langle g_I(x^k) - v_I^k, \lambda_I^k \rangle = 0$, $\lambda_I^k \in K$.*

Further suppose that the second-order sufficient optimality condition is satisfied at $(\bar{x}, \bar{\lambda})$, i.e., $\langle h, L''(\bar{x}; \bar{\lambda})h \rangle > 0$ for every critical direction $h \neq 0$, and that $g'(\bar{x})$ has maximal rank. Then $x^k - \bar{x} = \mathcal{O}(\delta_k)$ and $\lambda^k - \bar{\lambda} = \mathcal{O}(\delta_k)$.

Proof. Subtracting equation (1) in the Kuhn–Tucker equations from the perturbed equation (1) above gives

$$L'(x^k; \bar{\lambda}) - L'(\bar{x}; \bar{\lambda}) + g'(x^k)^*(\lambda^k - \bar{\lambda}) = u^k. \tag{23}$$

Now it suffices to show $x^k - \bar{x} = \mathcal{O}(\delta_k)$, for then the first term $L'(x^k; \bar{\lambda}) - L'(\bar{x}; \bar{\lambda})$ on the left-hand side of (23) is $\mathcal{O}(\delta_k)$, and hence so is the second term. Since $g'(x^k) = g'(\bar{x}) + \mathcal{O}(x^k - \bar{x})$, this implies $g'(\bar{x})^*(\lambda^k - \bar{\lambda}) = \mathcal{O}(x^k - \bar{x})$, and since $g'(\bar{x})$ has maximal rank, we conclude $\lambda^k - \bar{\lambda} = \mathcal{O}(x^k - \bar{x}) = \mathcal{O}(\delta_k)$.

Suppose now that the result is incorrect, so $u^k / \|x^k - \bar{x}\| \to 0$, $v^k / \|x^k - \bar{x}\| \to 0$. Picking a subsequence if necessary, we may assume that $(x^k - \bar{x})/\|x^k - \bar{x}\| \to h$ with

$\|h\| = 1$. We show that h is a critical direction.

Notice first that subtracting the perturbed condition (2) from condition (2) in the Kuhn–Tucker ensemble gives

$$\frac{g_E(x^k) - g_E(\bar{x})}{\|x^k - \bar{x}\|} = \frac{v_E^k}{\|x^k - \bar{x}\|} \to 0;$$

hence the equality part (1) of criticality is satisfied. As for the inequality part, observe that the perturbed conditions (1)–(3) just match the second part of the definition of criticality if we use the standing hypothesis that $x^k \to \bar{x}$ slower than $\delta_k \to 0$. Hence h is critical.

To conclude the proof, let us multiply (23) by $x^k - \bar{x}$ and divide by $\|x^k - \bar{x}\|^2$. The right-hand term of the modified equation is then

$$\frac{\langle u^k, x^k - \bar{x}\rangle}{\|x^k - \bar{x}\|^2} \to 0$$

by our standing hypothesis, so the left-hand side of the modified equation also has to converge to 0. The first term on the left-hand side of the modified equation is

$$\frac{\langle L'(x^k; \bar{\lambda}) - L'(\bar{x}; \bar{\lambda}), x^k - \bar{x}\rangle}{\|x^k - \bar{x}\|^2},$$

which converges to $\langle L''(\bar{x}; \bar{\lambda})h, h\rangle$. Since the direction h was seen to be critical, this term is strictly positive. We shall now obtain the sought for contradiction by showing that the remaining term on the left-hand side of the modified equation is asymptotically nonnegative. This is verified by splitting this term into its equality and inequality parts.

The equality part of the term in question is

$$\frac{\langle g_E'(x^k)(x^k - \bar{x}), \lambda_E^k - \bar{\lambda}_E\rangle}{\|x^k - \bar{x}\|^2},$$

which, due to $g_E'(\bar{x})h = 0$, tends to 0. This argument uses the fact that $\lambda_E^k - \bar{\lambda}_E = \mathcal{O}(x^k - \bar{x})$, which itself is a consequence of the standing hypothesis (23) and the constraint qualification.

Inspecting the inequality term remains. Via Taylor expansion, the latter is

$$\frac{\langle g_I(x^k) - g_I(\bar{x}), \lambda_I^k - \bar{\lambda}_I\rangle}{\|x^k - \bar{x}\|^2} + \mathrm{o}(1), \tag{24}$$

again using $\lambda^k - \bar{\lambda} = \mathcal{O}(x^k - \bar{x})$. The left-hand term of (24) is recast as

$$\frac{\langle g_I(x^k) - v_I^k - g_I(\bar{x}), \lambda_I^k - \bar{\lambda}_I\rangle}{\|x^k - \bar{x}\|^2} + \frac{\langle v_I^k, \lambda_I^k - \bar{\lambda}_I\rangle}{\|x^k - \bar{x}\|^2}, \tag{25}$$

and the second term in (25) tends to 0 due to the standing hypothesis. The first term in (25) is nonnegative, for expanding its nominator gives

$$\langle g_I(x^k) - v_I^k, \lambda_I^k\rangle - \langle g_I(x^k) - v_I^k, \bar{\lambda}_I\rangle - \langle g_I(\bar{x}), \lambda_I^k\rangle + \langle g_I(\bar{x}), \bar{\lambda}_I\rangle.$$

Here the first and the last terms vanish as a consequence of the complementarity condition (3) in the Kuhn–Tucker ensemble (KT) and the perturbed condition (3)

above, while the two terms with the negative signs are themselves negative, again due to the conditions (3) above and in (KT). Indeed, λ_I^k, $\bar{\lambda}_I \in K$ and $g_I(\bar{x}) \in K^0$, $g_I(x^k) - v_I^k \in K^0$ imply $\langle g_I(x^k) - v_I^k, \bar{\lambda}\rangle \leq 0$ and $\langle g_i(\bar{x}), \lambda_I^k\rangle \leq 0$. This settles the case by providing the desired contradiction. ∎

With this observation, we are now ready to state our first result.

LEMMA 7. *Suppose Newton's method for solving (P) via a successive solution of $(T_k(M^k))$ with a choice of matrices M^k generates a sequence of iterates (x^k, λ^k) which converges to the Kuhn–Tucker pair $(\bar{x}, \bar{\lambda})$. Further suppose that $g'(\bar{x})$ has maximal rank and that the second-order sufficient optimality condition is satisfied at $(\bar{x}, \bar{\lambda})$.*

1. *If $M^k \to L''(\bar{x}; \bar{\lambda})$, convergence $(x^k, \lambda^k) \to (\bar{x}, \bar{\lambda})$ is superlinear.*
2. *If $M^k - L''(\bar{x}; \bar{\lambda}) = \mathcal{O}(x^k - \bar{x})$, then convergence $(x^k, \lambda^k) \to (\bar{x}, \bar{\lambda})$ is even quadratic.*

Proof. We observe that with $x^{k+1} = x^k + \Delta x$, and λ^{k+1} the Lagrange multiplier in $(T_k(M^k))$, the quasi-Newton step about the current iterate (x^k, λ^k) may be represented as

(i) $L'(x^{k+1}; \lambda^{k+1}) = u^k$,
(ii) $g_E(x^{k+1}) = v_E^k$,
(iii) $g_I(x^{k+1}) - v_I^k \in K^0$, $\lambda_I^{k+1} \in K$, $\langle g_I(x^{k+1}) - v_I^k, \lambda_I^{k+1}\rangle = 0$,

where the perturbation terms u^k and $v^k = (v_E^k, v_I^k)$ are as follows:

$$\begin{aligned} u^k &= L'(x^{k+1}; \bar{\lambda}) - L'(x^k; \bar{\lambda}) - L''(x^k; \bar{\lambda})(x^{k+1} - x^k) + (L''(\bar{x}; \bar{\lambda}) - M^k)(x^{k+1} - x^k) \\ &\quad + (L''(x^k; \bar{\lambda}) - L''(\bar{x}; \bar{\lambda}))(x^{k+1} - x^k) + (g'(x^{k+1}) - g'(x^k))^*(\lambda^{k+1} - \bar{\lambda}), \\ v^k &= -g(x^{k+1}) + g(x^k) + g'(x^k)(x^{k+1} - x^k). \end{aligned}$$

As we wish to bring in the perturbation Lemma 6 above, we let $\delta_k \to 0$ be the speed of convergence of $(u^k, v^k) \to (0, 0)$; then $(x^k, \lambda^k) - (\bar{x}, \bar{\lambda}) = \mathcal{O}(\delta_k)$ as a consequence of that lemma.

Now observe that $v^k = \mathrm{o}(x^{k+1} - x^k)$ and, similarly, $u^k = \mathrm{o}(x^{k+1} - x^k)$ if we use the hypothesis $M^k - L''(\bar{x}; \bar{\lambda}) = \mathrm{o}(1)$. Altogether, $\delta_k = \mathrm{o}(x^{k+1} - x^k)$. The perturbation lemma therefore implies

$$x^{k+1} - \bar{x} = \mathcal{O}(\delta_k) = \mathrm{o}(x^{k+1} - x^k) = \mathrm{o}(\|x^{k+1} - \bar{x}\| + \|x^k - \bar{x}\|).$$

Similarly, as $g'(\bar{x})$ has maximal rank,

$$\lambda^{k+1} - \bar{\lambda} = \mathcal{O}(\delta_k) = \mathrm{o}(\|x^{k+1} - \bar{x}\| + \|x^k - \bar{x}\|).$$

These estimates prove superlinear convergence.

The argument giving quadratic convergence under the stronger hypothesis in (2) is standard and left to the reader (see, for instance, [11]). ∎

As a consequence of Lemma 7, what remains to be checked is mere convergence of Newton's method under the same regularity hypotheses. Here we shall be able to follow a known line of argument already present in Robinson's approach [32]. Let us consider the *limiting tangent problem*

$$(T_\infty) \qquad \begin{aligned} &\text{minimize} && \langle f'(\bar{x}), d\rangle + \tfrac{1}{2}\langle d, L''(\bar{x}; \bar{\lambda})d\rangle \\ &\text{subject to} && g_E(\bar{x}) + \langle g_E'(\bar{x}), d\rangle = 0, \\ & && g_I(\bar{x}) + \langle g_I'(\bar{x}), d\rangle \in K^0, \end{aligned}$$

whose optimal solution is $\bar{d} = 0$, and for which $\bar{\lambda}$ is a Lagrange multiplier. Observe that the second-order optimality conditions for (T_∞) are identical with those of (P),

so if we adopt the constraint qualification from before and the second-order sufficient optimality condition for (P), they also hold for (T_∞). Using a result obtained by Robinson [32, Theorems 2.3, 3.1], we have the following lemma.

LEMMA 8. *Suppose the second-order sufficient optimality condition for (P) is satisfied at the optimal pair $(\bar{x}, \bar{\lambda})$. Further suppose that $g'(\bar{x})$ has maximal rank. Then, given $\varepsilon > 0$, there exists $\delta > 0$ such that if $\|x^k - \bar{x}\| < \delta$, $\|\lambda^k - \bar{\lambda}\| < \delta$, and $\|M^k - L''(\bar{x}; \bar{\lambda})\| < \delta$, then the tangent problem $(T_k(M^k))$ has a local minimum x^{k+1} and an associated Lagrange multiplier λ^{k+1} satisfying $\|x^{k+1} - \bar{x}\| < \varepsilon$ and $\|\lambda^{k+1} - \bar{\lambda}\| < \varepsilon$.*

Proof. Notice that the tangent subproblem $(T_k(M^k))$ may be considered a perturbed version of the ideal tangent problem (T_∞) in the sense of [32, (2.7)]. Now by assumption $g'(\bar{x})$ has maximal rank, and hence (T_∞) is regular in the sense of [32]. Second, since (P) satisfies the second-order sufficient optimality condition at $(\bar{x}, \bar{\lambda})$, so does (T_∞) at the optimal pair $(0, \bar{\lambda})$. Using [32, Theorem 3.1], there exist neighborhoods N_1 of $\bar{x}$, N_2 of $\bar{\lambda}$, and N_3 of $L''(\bar{x}; \bar{\lambda})$ such that for $x^k \in N_1$, $\lambda^k \in N_2$, and $M^k \in N_3$ the tangent problem $(T_k(M^k))$ has a solution x^{k+1}. We may, in addition, choose N_1 small enough to guarantee that $g'(x^k)$ has maximal rank, and therefore $(T_k(M^k))$ also admits Lagrange multipliers λ^{k+1}.

Now using Theorem 2.3 of the same paper, the set valued operator mapping the datum (x^k, λ^k, M^k) of $(T_k(M^k))$ into the set of possible optimal pairs (x^{k+1}, λ^{k+1}) is upper semicontinuous. By second-order sufficient optimality, $(\bar{x}, \bar{\lambda})$ is locally unique. Therefore, upper semicontinuity translates into the following statement: Given $\varepsilon > 0$, there exists $\delta > 0$ such that if (x^k, λ^k, M^k) is in the δ-neighborhood of $(\bar{x}, \bar{\lambda}, L''(\bar{x}; \bar{\lambda}))$, then any (x^{k+1}, λ^{k+1}) lies in the ε-neighborhood of $(\bar{x}, \bar{\lambda})$. This is just what we claimed. ∎

With these auxiliary results, we are now ready to state our local convergence theorem for Newton's method.

THEOREM 9. *Let $(\bar{x}, \bar{\lambda})$ be a Kuhn–Tucker pair for (P) satisfying the second-order sufficient optimality condition, and suppose $g'(\bar{x})$ has maximal rank. Then there exists $\delta > 0$ such that if $\|x^0 - \bar{x}\| < \delta$, $\|\lambda^0 - \bar{\lambda}\| < \delta$, $\|M^k - L''(\bar{x}; \bar{\lambda})\| < \delta$ for every k, and $M^k \to L''(\bar{x}; \bar{\lambda})$, then the sequence (x^k, λ^k) obtained by successive solution of the tangent subproblems $(T_k(M^k))$ is well defined and converges superlinearly to $(\bar{x}, \bar{\lambda})$. Convergence is even quadratic if $M^k - L''(\bar{x}; \bar{\lambda}) = \mathcal{O}(\|x^k - \bar{x}\| + \|\lambda^k - \bar{\lambda}\|)$.*

Proof. (1) Observe that the perturbation Lemma 6 tells that, due to second-order sufficient optimality, the Kuhn–Tucker conditions for (P) follow a Lipschitz-type behavior with respect to specific perturbations u^k, v^k. Let us quantify this: There exist $\delta_1 > 0$ and $\alpha > 0$, $\beta > 0$ such that if u^k, v^k are sufficiently small in the sense that $\|v^k\|$, $\|u^k\| < \delta_1$ and if x^k, λ^k along with u^k, v^k satisfy (1)–(3) in the perturbation Lemma 6, then $\|x^k - \bar{x}\| + \|\lambda^k - \bar{\lambda}\| < \alpha$, and $\|x^k - \bar{x}\| + \|\lambda^k - \bar{\lambda}\| < \beta(\|u^k\| + \|v^k\|)$.

(2) Let $\delta_3 \leq \min(\alpha, \frac{1}{3\beta})$. According to Lemma 8, there exists $\delta_2 > 0$ such that whenever $\|\hat{x} - \bar{x}\| < \delta_2$, $\|\hat{\lambda} - \bar{\lambda}\| < \delta_2$, and $\|\hat{M} - L''(\bar{x}; \bar{\lambda})\| < \delta_2$, the result (x, λ) of the Newton step with datum $(\hat{x}, \hat{\lambda}, \hat{M})$ satisfies $\|(x, \lambda) - (\bar{x}, \bar{\lambda})\| < \delta_3$.

(3) Choose $\delta_4 > 0$ such that the following five conditions are satisfied. First,

$$\|g(x^1) - g(x^2) - g'(x^2)(x^1 - x^2)\| \leq \frac{1}{24\beta}\|x^1 - x^2\|$$

whenever x^1, $x^2 \in B(\bar{x}, \delta_4)$. Second,

$$\|L'(x^1; \bar{\lambda}) - L'(x^2; \bar{\lambda}) - L''(x^2; \bar{\lambda})(x^1 - x^2)\| \leq \frac{1}{24\beta}\|x^1 - x^2\|$$

whenever x^1, $x^2 \in B(\bar{x}, \delta_4)$. Third, $\delta_4 < 1/24\beta$, and fourth

$$\|L''(x^1; \bar{\lambda}) - L''(\bar{x}, \bar{\lambda})\| \leq \frac{1}{24\beta}$$

whenever $x^1 \in B(\bar{x}, \delta_4)$. Finally,

$$\|(g'(x^2) - g'(x^1))(\lambda^1 - \lambda^2)\| \leq \frac{1}{24\beta}\|\lambda^1 - \lambda^2\|$$

whenever λ^1, $\lambda^2 \in B(\bar{\lambda}, \delta_4)$ and x^1, $x^2 \in B(\bar{x}, \delta_4)$.

(4) Now choose $\delta = \min(\delta_1, \delta_2, \delta_3, \delta_4)$; then the conclusion of the theorem holds. In fact, let (x^k, λ^k, M^k) be the datum of the kth Newton step. As $\delta \leq \delta_1$, an optimal pair (x^{k+1}, λ^{k+1}) exists and satisfies $\|(x^{k+1}, \lambda^{k+1}) - (\bar{x}, \bar{\lambda})\| < \delta_3$.

As in the proof of Lemma 7, let us write the Newton step in the form

(i) $L(x^{k+1}; \lambda^{k+1}) = u^k$,

(ii) $g_E(x^{k+1}) = v_E^k$,

(iii) $g_I(x^{k+1}) - v_I^k \in K^0$, $\lambda_I^{k+1} \in K$, $\langle g_I(x^{k+1}) - v_I^k, \lambda_I^{k+1} \rangle = 0$,

where u^k, v^k have the meaning given there. Then $\delta \leq \delta_2$ and $\delta \leq \delta_1$ and step (1) imply $\|u^k\| \leq \frac{1}{6\beta}\|x^{k+1} - x^k\|$ and $\|v^k\| \leq \frac{1}{6\beta}(\|x^{k+1} - x^k\| + \|\lambda^{k+1} - \lambda^k\|)$. Therefore, step (1) implies

$$\|x^{k+1} - \bar{x}\| \leq \beta\frac{1}{6\beta}(\|x^{k+1} - x^k\| + \|\lambda^{k+1} - \lambda^k\|)$$
$$\leq \frac{1}{6}(\|x^k - \bar{x}\| + \|x^{k+1} - \bar{x}\| + \|\lambda^k - \bar{\lambda}\| + \|\lambda^{k+1} - \bar{\lambda}\|),$$

and similarly for $\|\lambda^{k+1} - \bar{\lambda}\|$. Adding both estimates gives

$$\|(x^{k+1}, \lambda^{k+1}) - (\bar{x}, \bar{\lambda})\| \leq \frac{1}{3}(\|(x^k, \lambda^k) - (\bar{x}, \bar{\lambda})\| + \|(x^{k+1}, \lambda^{k+1}) - (\bar{x}, \bar{\lambda})\|).$$

Therefore,

$$\|(x^{k+1}, \lambda^{k+1}) - (\bar{x}, \bar{\lambda})\| \leq \frac{1}{2}\|(x^k, \lambda^k) - (\bar{x}, \bar{\lambda})\|,$$

and this proves linear convergence of the sequence. This settles the case, since it proves, in particular, that the situation needed to start this argument is reproduced at each step. □

Remarks. (1) Notice that Newton's method $M^k = L(x^k; \lambda^k)$ satisfies hypothesis (2) and therefore converges quadratically.

(2) As is well known, superlinear and quadratic convergence of the primal-dual pair (x^k, λ^k) does not imply superlinear or quadratic convergence of the primal sequence x^k. In order to establish primal superlinear convergence, an extra argument is needed, and this leads to a result in the style of the classical Dennis–Moré characterization of superlinear convergence for unconstrained optimization. The result is similar to [12, Theorem 11.5], and we do not present the details here.

In the same vein, a more thorough analysis of the SSDP method will have to address the following elements not considered here due to the lack of space: a global convergence analysis based on an appropriate merit function and an extension of the known result in polyhedral programming saying that the Hessian of the augmented Lagrangian is positive definite at the optimal pair if the penalty parameter c is properly chosen (cf., for instance, [12, Proposition 12.2]). In particular, in our numerical

tests, we observed this effect, and it should be proven rigorously in order to fully justify our approach via SSDP.

(3) Let us point to the main difference of our approach to the setting [11]. Following Robinson's methods, Bonnans embeds the Newton step for (P) into the Newton step of a suitably formulated variational inequality and then establishes a perturbation Lemma in the style of Lemma 6 but with perturbations based on the variational formulation. Consequently, more (and in fact, too many) perturbations are allowed, and the Lipschitz-type behavior is then established only under polyhedrality.

6. Existing techniques and comparison. In principle, the optimization step in our control design algorithm may be replaced with any optimization technique adapted to deal with LMI constraints. Here we shall compare SSDP to two other methods which we have previously used in robust control design: the augmented Lagrangian method and an approach via concave programming. Numerical experiments based on interior-point methods have been reported by Leibfritz and Mostafa [25, 26] for a different but related type of application. Our own experiments with the interior-point approach will be presented in [3].

A thorough investigation of nonlinear optimization techniques in robust control synthesis should include comparison with existing techniques like the D-K iteration scheme. This has already been addressed in [16], where test examples similar to the ones here were used to compare these approaches. As a result, we observed that the D-K iteration scheme was not at ease with these seemingly innocent cases and very often could not even be started due to the lack of a useful initial controller.

A partially augmented Lagrangian scheme for solving (D) was discussed in [16], and we reproduce it here for the convenience of the reader.

Augmented Lagrangian method.

1. Select an initial penalty parameter $c_0 > 0$, a Lagrange multiplier estimate λ^0, and an initial decision vector x^0 satisfying the LMIs, $\mathcal{A}(x^0) \le 0$.
2. For given c_k, λ^k, and x^k, solve

$$\begin{aligned} &\text{minimize} && L_{c_k}(x; 0, \lambda^k) \\ &\text{subject to} && \mathcal{A}(x) \le 0, \end{aligned} \tag{26}$$

   and let x^{k+1} be the solution to (26).
3. Update the Lagrange multiplier using the first-order update formula

$$\lambda^{k+1} = \lambda^k + c_k \mathcal{B}(x^{k+1}). \tag{27}$$

4. Update the penalty parameter such that $c_{k+1} \ge c_k$, increase k, and go back to step 2.

This scheme is often called the *first-order method of multipliers*. It takes the constraint set $\{x : \mathcal{A}(x) \le 0\}$ as an unstructured set and does not attempt to exploit its special LMI structure, which would require attaching a matrix Lagrange multiplier variable $\Lambda \ge 0$ to the LMI. As a consequence, its rate of convergence is only linear if the penalty parameter $c_k = c$ is held fixed, while superlinear convergence is guaranteed if $c_k \to \infty$. The latter is of minor practical importance due to the inevitable ill-conditioning for large c.

Remark. Aiming at good theoretical local convergence properties, we should certainly avoid the augmented Lagrangian method. To ensure superlinear convergence with fixed large enough c, we have to use second-order methods like the proposed SSDP method. Nevertheless, the augmented Lagrangian method has some merits as

it is robust in practice and, similar to the case of SSDP, may be tackled by a series of SDP subproblems if the Newton step called for to solve (26) is suitably convexified. In contrast with the tangent subproblem (T) in SSDP, these SDP subproblems may be solved by primal methods, as Lagrange multipliers Λ are not required. This may be an advantage of the augmented Lagrangian approach since, for instance, in our experiments, a well-implemented primal SDP solver like [20] often outperformed existing primal-dual software, even though the latter is preferred by theory.

Let us finally recall an approach to (D) discussed in [4]. Primarily, this scheme is suited for the feasibility problem (find x such that $\mathcal{B}(x) = 0$, $\mathcal{A}(x) \leq 0$) but may be modified to apply to (D).

Consider (D) with a nonlinear equality constraint of the form $\mathcal{B}(x) = P\tilde{P} - I = 0$ as encountered in our applications. Introducing a slack matrix variable Z, problem (D) may be replaced by the concave program (cf. [4] for a proof)

$$(C)\qquad \begin{aligned} &\text{minimize} && f_c(x) = \gamma + c\ \operatorname{trace}(Z_1 - Z_3^T Z_2^{-1} Z_3) \\ &\text{subject to} && \mathcal{A}(x) \leq 0, \\ & && \mathcal{L}(x) = \begin{pmatrix} Z_1 & Z_3^T & P & I \\ Z_3 & Z_2 & I & \tilde{P} \\ * & * & I & 0 \\ * & * & 0 & I \end{pmatrix} \geq 0. \end{aligned}$$

We may solve (C) by a sequence of subproblems, each of which minimizes the first-order Taylor polynomial of $f_c(x)$ about the inner current iterate x and over the convex set $\{\mathcal{A} \leq 0, \mathcal{L} \geq 0\}$. This procedure is known as the conditional gradient or Frank and Wolfe method. In order to improve its performance, second-order information is at least partially included by approximating the concave second-order term of the objective $f_c(x)$ by a linear underestimate (see [30]). This modification improves convergence but still has the inconvenience of a high CPU cost. Altogether, concave methods cannot compete with the SSDP or augmented Lagrangian techniques, as they are very slow and, due to the slack variable Z, lead to large size problems. We use the concave programming approach in order to check on the quality of our local optimal solutions. In a reasonable number of tests, SSDP did, in fact, terminate with values of γ close to the global optimum. Yet another way to test the quality of the gain γ is to establish a lower bound γ_ℓ for the optimal γ_{opt} by solving (D) without the nonlinear constraint $\mathcal{B} = 0$.

7. Numerical experiments. In this section, two typical test examples are used to compare the SSDP method to the augmented Lagrangian method proposed in [16] for a related situation and a concave programming approach.

7.1. Robust control of a flexible actuator. Consider the unbalanced oscillator described in Figure 3. The plant is built with a cart of weight M, fixed to a vertical plane by a linear spring k and constrained to move only along the z axis. An embedded pendulum with mass m and moment of inertia I is attached to the cart's center of mass and can be rotated in the vertical plane. The cart is submitted to an external disturbance F, and a control torque N is applied to the pendulum to stabilize its movement. The nonlinear equations of motion are

$$(M+m)\ddot{Z} + me\ddot{\vartheta}\cos\vartheta = me\dot{\vartheta}^2\sin\vartheta - kZ + F, \qquad me\ddot{Z}\cos\vartheta + (I+me^2)\ddot{\vartheta} = N,$$

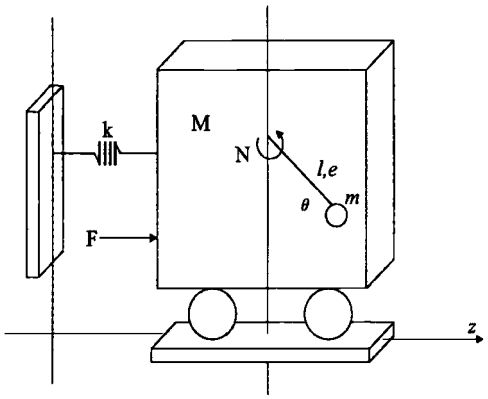

FIG. 3. *Flexible actuator.*

where ϑ and $\dot{\vartheta}$ denote the angular position and velocity of the pendulum and Z, $\dot{Z}$ denote the position and velocity of the cart. We normalize these equations as in [14]:

$$\ddot{\zeta} + \varepsilon\ddot{\vartheta}\cos\vartheta = \varepsilon\dot{\vartheta}^2\sin\vartheta - \zeta + w, \qquad \varepsilon\ddot{\zeta}\cos\vartheta + \ddot{\vartheta} = u,$$

where $[\zeta\dot{\zeta}\vartheta\dot{\vartheta}]^T$ is the new state vector. We assume $\theta_m = \cos\vartheta$ is measured, and we express the remaining nonlinear term in the left-hand equation through the uncertain parameter $\theta_u = \dot{\vartheta}\sin\vartheta$. The parameter block becomes $\Theta = \mathrm{diag}(\theta_m, \theta_u I_3)$. The LFT model of the plant is then derived, and numerical data are given below in order to allow testing of our results with different approaches. Table 1 displays the behavior of the SSDP algorithm. We can see that SSDP achieves good values of γ already after a few iterations. The nonlinear constraints decrease with an approximately linear rate. In practice, one may stop the algorithm whenever γ is no longer reduced over a certain number of iterations and the nonlinear constraint norm is sufficiently small, say, smaller than 10^{-6} or 10^{-7}. The final steps in the table are only for illustration of the asymptotic behavior of the method. Note that the number of decision variables in

TABLE 2

this example was 94. The gain $\gamma_{\text{opt}} = 1.262$ obtained by SSDP was close to the lower estimate $\gamma_\ell = 1.18$ obtained by solving (D) without the constraint $\mathcal{B} = 0$. Note that these results improve on those of the modified conditional gradient which is slower and leads to higher cost values in Table 2.

The numerical data for the flexible actuator LFT plant are

$$P(s) \cong \left(\begin{array}{cccc|cccc|cc} 0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ -1 & 0 & 0 & 0 & 5\varepsilon & \varepsilon & -\varepsilon & -\varepsilon & 1 & -0.2 \\ 0 & 0 & 0 & 1.02 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0.2 & 0 & 0 & 0 & -\varepsilon & \varepsilon & \varepsilon & 0 & -0.2 & 1 \\ \hline 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0.84 & 0 & 0 & 0 & -4\varepsilon & -\varepsilon & 0 & \varepsilon & -0.84 & 0.16 \\ 1.23 & 0 & 0 & 0 & -6\varepsilon & 0 & 2\varepsilon & 2\varepsilon & -1.23 & 0.23 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 \\ \hline 0.1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0.1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0.2 \\ \hline 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \end{array}\right),$$

where ε, a coupling parameter, is chosen in this problem to equal 0.01. The vector of regulated variables z consists of three components: z_ζ, z_θ are the damping specifications on ζ, θ; and z_u serves to limit the control activity. The exogenous input w is the external force F.

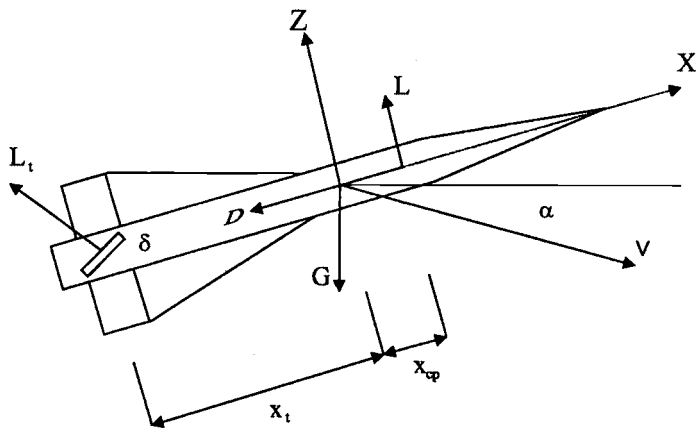

FIG. 4. *Aerodynamic model for air-to-air missile.*

7.2. Robust autopilot of a missile. Consider the missile-airframe control problem illustrated in Figure 4, where the missile is flying with an angle of attack α. The control problem requires that the autopilot generate the elevator deflection δ to maintain the angle of attack α_c called for by the guidance law. The tail-fin actuator is modeled as a first-order system

$$\dot{\delta} = \tau(u - \delta)$$

with time constant $\tau = 1/150$ seconds, so δ itself becomes a state of the system. The nonlinear dynamics of the missile are adopted from [31]:

$$\dot{\alpha} = f\frac{\cos(\alpha/f)}{mV}Z + q, \qquad \dot{q} = fM_\ell/I_y,$$

where m is the mass, $V = M/V_s$ is the speed, I_y is the pitch moment of inertia, $Z = C_Z(\alpha, \delta, M)QS$ is the normal force, $M_\ell = C_m(\alpha, \delta, M)QSd$ is the pitch moment, Q is the dynamic pressure, and S, d reference area and diameter. The normal force and pitch moment aerodynamic coefficients are approximated by third-order polynomials in α and first-order polynomials in δ and M.

Sensor measurements y for feedback include the pitch rate q and α, while the state of the actuator deflection δ is unmeasured. The robust control scheme for the missile autopilot is shown in Figure 5. The time-varying matrix valued parameter is $\Theta = \mathrm{diag}(\theta_m I_4, \theta_u)$, where θ_u is used to translate the nonlinearity in α in the left-hand equation into an LFT with uncertainty. The scheduled parameter θ_m is the variation in Mach number M about nominal flight conditions, $M_0 = 3$. The Mach number is slowly time-varying and is easily measured on-line.

The vector of regulated variables z consists of two components (see Figure 5). The first, z_1, corresponds to a frequency-weighted sensitivity design goal, for tracking error accuracy, while $z_2 = c_\delta\dot{\delta} = c_\delta\tau(u - \delta)$ serves to limit the tail-fin actuator rate $\dot{\delta}$ and indirectly to bound the controller bandwidth in order to avoid trouble with unmodeled flexible modes. The vector of exogenous inputs w includes the command α_c and the pitch rate sensor noise n.

For the problem considered, it is desired to track the step input command $\alpha_c = 20^0$ with a steady state accuracy of 2%, to achieve a rise time of less than 0.3 seconds,

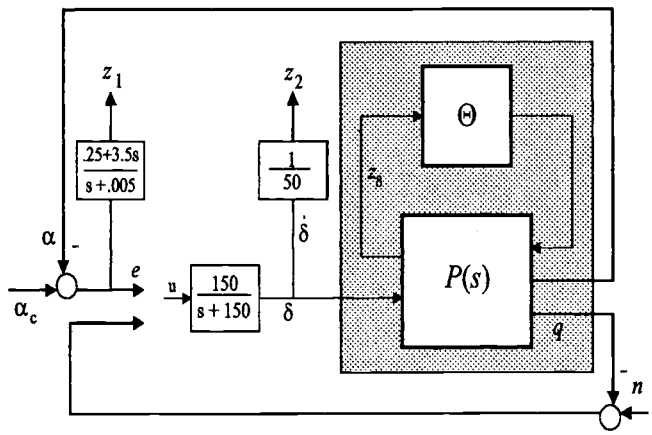

FIG. 5. *Configuration for synthesis.*

and to limit overshoot to 5% for a wide range of angles of attach ±20 deg and under variations in Mach number ranging from 2 to 4.

For comparison, the numerical data for this LFT model of the missile are reproduced below. Our optimization techniques are then readily applicable, and the results are shown in Table 3. SSDP achieves good values of γ after a few iterations with a similar rate of decrease for the nonlinear constraints. The autopilot example involved 132 decision variables. Again the gain $\gamma_{\text{opt}} = 0.597$ observed at the optimum was close to the lower estimate $\gamma_\ell = 0.57$. The optimal controller obtained by SSDP was then tested in a time domain simulation based on the nonlinear model. The results are shown in Figure 6. The upper curve shows the tracking in α, and the lower curve

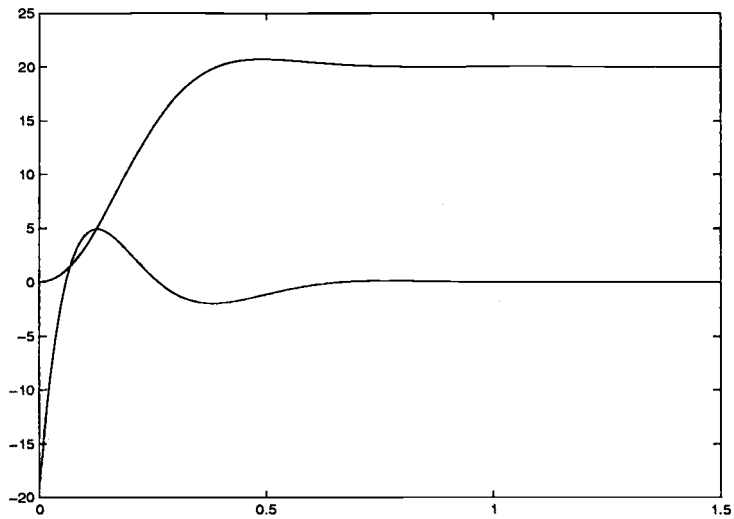

FIG. 6. *Nonlinear simulation for missile autopilot example.*

shows the corresponding elevator deflection δ.

\end{array}\right).$$

Remark. Computational experience with a larger set of typical design examples indicates that the number of iterations (in terms of semidefinite programs) required by SSDP is almost independent of the problem dimension, whereas the CPU of course strongly depends on the efficiency of the SDP solver. As it turns out, in its actual state, the bottleneck of SSDP *is* the SDP solver. The public domain software for SDP we tested could be reliably used to problem sizes of up to 500–1000 decision variables. For larger sizes, the method may fail due to failure of the SDP solver, often already at the stage of finding feasible starting values, or while trying to solve one of the LMI subproblems. Solvers exploiting at best the structure of the problem under consideration may then be required.

Remark. A special type of LMI solver which replaces the SDP by an eigenvalue optimization and uses the bundle method from nonsmooth optimization was presented by Lemaréchal and Oustry [27] and was reported to work well for certain large-size

LMI problems. On the other hand, for large-size problems where most SDP solvers are at ill, the direct approach via interior-point methods may be preferable.

8. Concluding remarks. In this paper, we have developed SSDP, a technique for finding local solutions to robust control design problems. SSDP is an extension of (and is inspired by) SQP, a method in nonlinear optimization known since the late 1970s. Expanding on SQP, SSDP comprises LMI constraints, which are handled explicitly in the course of the algorithm. The method is comfortably implemented with available SDP codes if the Hessian or reduced Hessian is suitably convexified. We found the approach highly reliable (as we demonstrated on a set of test examples), exhibiting local superlinear convergence properties, and applicable to a rich list of problems in robust control theory.

ε-EQUILIBRIA FOR STOCHASTIC GAMES WITH UNCOUNTABLE STATE SPACE AND UNBOUNDED COSTS*

ANDRZEJ S. NOWAK† AND EITAN ALTMAN‡

Abstract. We study a class of noncooperative stochastic games with unbounded cost functions and an uncountable state space. It is assumed that the transition law is absolutely continuous with respect to some probability measure on the state space. Undiscounted stochastic games with expected average costs are considered first. It is shown under a uniform geometric ergodicity assumption that there exists a stationary ε-equilibrium for each $\varepsilon > 0$. The proof is based on recent results on uniform bounds for convergence rates of Markov chains [S. P. Meyn and R. L. Tweedie, *Ann. Appl. Probab.*, 4 (1994), pp. 981–1011] and on an approximation method similar to that used in [A. S. Nowak, *J. Optim. Theory Appl.*, 45 (1985), pp. 591–602], where an ε-equilibrium in stationary policies was shown to exist for the bounded discounted costs. The stochastic game is approximated by one with a countable state space for which a stationary Nash equilibrium exists (see [E. Altman, A. Hordijk, and F. M. Spieksma, *Math. Oper. Res.*, 22 (1997), pp. 588–618]); this equilibrium determines an ϵ-equilibrium for the original game. Finally, new results for the existence of stationary ε-equilibrium for discounted stochastic games are given.

1. Introduction.

This paper treats nonzero-sum stochastic games with general state space and unbounded cost functions. Our motivation for studying unbounded costs comes from applications of stochastic games to queuing theory and telecommunication networks (see [2, 3, 4, 38]). We assume that the transition law is absolutely continuous with respect to some probability measure on the state space. For the expected average cost case, we impose some stochastic stability conditions, considered often in the theory of Markov chains in general state space [25, 26]. These assumptions imply the so-called ν-geometric ergodicity condition for Markov chains governed by stationary multipolicies of players. Using an approximation technique similar to that in [29], we prove the existence of stationary ε-equilibria in m-person average cost games satisfying the mentioned stability conditions and some standard regularity assumptions. A similar result is stated for discounted stochastic games, but then we do not impose any ergodicity assumptions. To obtain an ε-equilibrium, we apply a recent result by Altman, Hordijk, and Spieksma [4] given for nonzero-sum stochastic games with countably many states. Completely different approximation schemes for stochastic games with a separable metric state space were given by Rieder [39] and Whitt [48]. As in [29], they considered only (bounded) discounted stochastic games.

The passage from finite (or even countably infinite) state space with possibly unbounded cost turns out to be quite a tough problem. In fact, the question of the existence of stationary Nash equilibria in nonzero-sum stochastic games with uncountable state space remains open even in the discounted case. Only some special

classes of games are known to possess a stationary Nash equilibrium. For example, Parthasarathy and Sinha [37] proved the existence of stationary Nash equilibria in discounted stochastic games with finitely many actions for the players and state independent nonatomic transition probabilities. Their result was extended by Nowak [30] to a class of uniformly ergodic average cost games. There are papers on certain economic games in which a stationary equilibrium is shown to exist by exploiting a very special transition and payoff structure; see, for example, [5, 7]. Mertens and Parthasarathy [24] reported the existence of nonstationary subgame-perfect Nash equilibria in a class of discounted stochastic games with norm continuous transition probabilities. Some results for nonzero-sum stochastic games with additive reward and transition structure (and, in particular, games with complete information) are given by Küenle [19, 20]. Finally, Harris, Reny, and Robson [13] proved the existence of correlated subgame-perfect equilibria in a class of stochastic games with weakly continuous transition probabilities. We would like to point out that the only papers which deal with nonzero-sum average cost stochastic games with uncountable state space are [20] and [30]. In the zero-sum case, the theory of stochastic games with uncountable state spaces is much more complete. Mertens and Neyman [23] provided some conditions for the existence of value, and Maitra and Sudderth [21, 22] developed a general theory of zero-sum stochastic games with limsup payoffs. Stationary optimal strategies exist in the average cost zero-sum games only if some ergodicity conditions are imposed in the model; see, for example, [31, 34, 15, 17, 18].

In this paper, we make use of an extension of Federgruen's work [11] given by Altman, Hordijk, and Spieksma [4]. Other approaches (based on different assumptions) to nonzero-sum stochastic games with countably many states can be found in [6, 40] and [33]. Some results on sensitive equilibria in a class of ergodic stochastic games are discussed in [33, 16, 35]. To close this brief overview of the existing literature, we note that the theory of stochastic games is much more complete in the case of finite state and action spaces. On one hand, many deep existence theorems are available at the moment; see [23, 22, 44, 45] and some references therein. On the other hand, a theory of algorithms for solving special classes of stochastic games with finitely many states and actions is also well developed [12].

In order to study the uncountable state space, we make use of Lyapunov-type techniques [25] (which also allows us to treat unbounded costs) and of approximations based on discretization. Unfortunately, the discretization to a countable state space does not directly yield a setting for which we can apply the existing theory for stochastic games with a countable state [4]. For example, the Foster (or Lyapunov)-type conditions that have been used for countable Markov chains always involved the requirement of a negative drift outside a finite set, whereas our discretization provides a negative drift outside a countable set. Also, ensuring that the approximating game maintains the same type of ergodic structure as the initial game turned out to be a highly complex problem. The fact that our model allows us to handle unbounded costs is very useful in stochastic games occurring in queueing and in networking applications; see [2, 3, 4, 38], in which bounded costs turn out to be unnatural.

The involved process of discretization given in our paper, which requires assumptions that may be restrictive in some applications, may suggest that, when possible, other equilibrium concepts might be sought instead of the Nash equilibrium. Indeed, some results on the existence of stationary *correlated* equilibria are available at the moment [36, 30, 10]. This type of equilibrium allows for some coordination between players, and the proof of existence is considerably simpler.

This paper is organized as follows. In section 2, we describe our game model. Section 3 is devoted to studying the average cost games. In section 4, we examine discounted stochastic games. An appendix is given in section 5, which contains some auxiliary results on piecewise constant policies in controlled Markov chains.

2. The model and notation. Before presenting the model, we collect some basic definitions and notation. Let $(\Omega, \mathcal{F})$ be a measurable space, where $\mathcal{F}$ is the σ-field of subsets in Ω. By $\mathbb{P}(\Omega)$ we denote the space of all probability measures on $(\Omega, \mathcal{F})$. If Ω is a metric space, then $\mathcal{F}$ is assumed to be the Borel σ-field in Ω. Let $(S, \mathcal{G})$ be another measurable space. We write $P(\cdot|\omega)$ to denote a transition probability from Ω into S. Recall that $P(\cdot|\omega) \in \mathbb{P}(S)$ for each $\omega \in \Omega$, and $P(D|\cdot)$ is a measurable function for each $D \in \mathcal{G}$.

We now describe the game model:

(i) S—the *state space*, endowed with a *countably generated* σ-field $\mathcal{G}$.

(ii) X^i—a *compact metric action space* for player i, $i = 1, 2, \ldots, m$. Let $X = X^1 \times X^2 \times \cdots \times X^m$. We assume that X is given the Borel σ-field.

(iii) $c^i : S \times X \to \mathbb{R}$—a product measurable *cost (payoff) function* for player i.

(iv) $Q(\cdot|s, x)$—a (product measurable) transition probability from $S \times X$ into S, called the *law of motion among states*.

We assume that actions are chosen by the players at discrete times $k = 1, 2, \ldots$. At each time k, the players observe the current state s_k and choose their actions independently of one another. In other words, they select a vector $x_k = (x_k^1, \ldots, x_k^m)$ of actions, which results in a cost $c^i(s_k, x_k)$ at time k incurred by player i, and in a transition to a new state, whose distribution is given by $Q(\cdot|s_k, x_k)$. Let $H_1 = S$ and let $H_n = S \times X \times S \times X \times \cdots \times S$ ($2n - 1$ factors) be the space of all n-stage histories of the game, endowed with the product σ-field. A randomized *policy* γ^i for player i is a sequence $\gamma^i = (\gamma_1^i, \gamma_2^i, \ldots)$, where each γ_n^i is a (product measurable) transition probability $\gamma_n^i(\cdot|h_n)$ from H_n into X^i. The *class of all policies* for player i will be denoted by Γ^i. Let U^i be the set of all transition probabilities u^i from S into X^i. A *Markov policy* for player i is a sequence $\gamma^i = (u_1^i, u_2^i, \ldots)$, where $u_k^i \in U^i$ for every k. A Markov policy γ^i for player i is called *stationary* if it is of the form $\gamma^i = (u^i, u^i, \ldots)$ for some $u^i \in U^i$. Every stationary policy $(u^i, u^i, \ldots)$ for player i can thus be identified with $u^i \in U^i$. Denote by $\Gamma = \prod_{i=1}^m \Gamma^i$ the *set of all multipolicies*, and by U the *subset of stationary multipolicies*. Let $H = S \times X \times S \times X \times \cdots$ be the space of all infinite histories of the game, endowed with the product σ-field. For any $\gamma \in \Gamma$ and every initial state $s_1 = s \in S$, a probability measure P_s^γ and a stochastic process $\{S_k, X_k\}$ are defined on H in a canonical way, where the random variables S_k and X_k describe the state and the action, respectively, chosen by the players on the kth stage of the game (see Proposition V.1.1 in [28]). Thus, for each initial state $s \in S$, any multipolicy $\gamma \in \Gamma$, and any finite horizon n, the *expected n-stage cost* of player i is

$$J_n^i(s, \gamma) = E_s^\gamma \left(\sum_{k=1}^n c^i(S_k, X_k) \right),$$

where E_s^γ means the expectation operator with respect to the probability measure P_s^γ. (Later on we make an assumption on the functions c^i that assures that all the expectations considered in this paper are well defined.)

The *average cost per unit time* to player i is defined as

$$J^i(s, \gamma) = \limsup_{n \to \infty} J_n^i(s, \gamma)/n.$$

If β is a fixed real number in $(0,1)$, called the *discount factor*, then the *expected discounted cost* to player i is

$$D^i(s,\gamma) = E_s^\gamma \left(\sum_{k=1}^{\infty} \beta^{k-1} c^i(S_k, X_k) \right).$$

For any multipolicy $\gamma = (\gamma^1, \ldots, \gamma^m) \in \Gamma$ and a policy σ^i for player i, we define (γ^{-i}, σ^i) to be the multipolicy obtained from γ by replacing γ^i with σ^i.

Let $\varepsilon \geq 0$. A multipolicy γ is called an ε-equilibrium for the average cost stochastic game if for every player i and any policy $\sigma^i \in \Gamma^i$,

$$J^i(s,\gamma) \leq J^i(s,(\gamma^{-i},\sigma^i)) + \varepsilon.$$

We similarly define ε-equilibria for the expected discounted cost games. Of course, a 0-equilibrium will be called a Nash equilibrium.

To ensure the existence of ε-equilibrium strategies for the players in the stochastic game, we will accept some regularity conditions on the primitive data, and in the average expected cost case we will also impose some general Lyapunov stability assumptions on the transition structure.

In both the discounted and average cost cases, we make the following assumptions.

C1: For each player i and $s \in S$, $c^i(s,\cdot)$ is continuous on X. Moreover, there exists a measurable function $\nu : S \to [1,\infty)$ such that

$$L \stackrel{\text{def}}{=} \sup_{s\in S, x\in X, i=1,\ldots,m} \frac{|c^i(s,x)|}{\nu(s)} < \infty. \tag{2.1}$$

C2: There exists a probability measure $\varphi \in \mathbb{P}(S)$ such that

$$Q(B|s,x) = \int_B z(s,t,x)\varphi(dt)$$

for each $B \in \mathcal{G}$ and $(s,x) \in S \times X$. Moreover, we assume that if $x_n \to x_0$ in X, then

$$\lim_{n\to\infty} \int_S |z(s,t,x_n) - z(s,t,x_0)|\nu(t)\varphi(dt) = 0,$$

where ν was defined above (2.1).

Remark 2.1. Let w be a measurable function such that $1 \leq w(s) \leq \nu(s) + \delta$ for all $s \in S$ and for some $\delta > 0$. If $x_n \to x_0$ in X as $n \to \infty$, then

$$\int_S |z(s,t,x_n) - z(s,t,x_0)|w(s)\varphi(dt) \to 0.$$

This follows from **C2**, since $\nu \geq 1$ implies that

$$\int_S |z(s,t,x_n) - z(s,t,x_0)|\varphi(dt) \to 0.$$

3. The undiscounted stochastic game. To formulate our further assumptions, we introduce some helpful notation. Let $s \in S$, $u = (u^1, \dots, u^m) \in U$. We set

$$c^i(s,u) = \int_{X^1} \cdots \int_{X^m} c^i(s, x^1, \dots, x^m) u^1(dx^1|s) \cdots u^m(dx^m|s),$$

and, for any set $D \in \mathcal{G}$, we set

$$Q(D|s,u) = \int_{X^1} \cdots \int_{X^m} Q(D|s, x^1, \dots, x^m) u^1(dx^1|s) \cdots u^m(dx^m|s).$$

By $Q^n(\cdot|s,u)$, we denote the n-step transition probability induced by Q and the multipolicy $u \in U$.

C3 (Drift inequality): Let $\nu : S \to [1, \infty)$ be some given measurable function. There exists a set $C \in \mathcal{G}$ such that ν is bounded on C and for some $\xi \in (0,1)$ and $\eta > 0$ we have

$$\int_S \nu(t) Q(dt|s,x) \le \xi \nu(s) + \eta 1_C(s)$$

for each $(s,x) \in S \times X$. Here 1_C is the characteristic function of the set C.

C4: There exist a $\lambda \in (0,1)$ and a probability measure ζ concentrated on the set C such that

$$Q(D|s,x) \ge \lambda \zeta(D)$$

for any $s \in C$, $x \in X$ and for each measurable set $D \subset C$.

For any measurable function $w : S \to R$, we define the ν-weighted norm as

$$\|w\|_\nu = \sup_{s \in S} \frac{|w(s)|}{\nu(s)}.$$

We write L_ν^∞ to denote the Banach space of all measurable functions w for which $\|w\|_\nu$ is finite.

Condition **C3** implies that, outside a set C, the function ν decreases under any stationary multipolicy u; i.e.,

$$E_s^u \left(\nu(S_{k+1}) - \nu(S_k)|S_k\right) \le -(1-\xi)\nu(S_k) \le -(1-\xi). \tag{3.1}$$

This is known as a drift condition. If (i) the state space is countable, (ii) the set C is finite, and (iii) the state space is communicating under a stationary policy u, then (3.1) implies that the Markov chain (when using u) is ergodic. (This is the well known Foster criterion for ergodicity; see, e.g., [27].)

In the uncountable infinite state space, the same drift condition should be used to obtain the ergodicity condition. However, the finiteness of the set C is replaced by a weaker assumption. Namely, C has to be a *small* set or a *petite set* [25]; condition **C4** is a simple sufficient condition for the set C to be small.

Beyond the ergodicity of the Markov chain $\{S_k\}$ under a stationary multipolicy, Foster-type criteria (i.e., conditions **C3**–**C4**) also ensure the finiteness of the expectation $E_s^u \nu(S_k)$ in steady state, as well the finiteness of the expected cost $E_s^u w(S_k)$

for every potential cost function $w \in L_\nu^\infty$; moreover, they provide a geometric rate of convergence of the expected costs at time k to the steady state cost for $w \in L_\nu^\infty$. These statements will be made precise below.

Note that **C3**–**C4** provide uniform conditions for ergodicity; i.e., ξ, ζ, C, and λ do not depend on the actions (or on the policies). This will be needed in order for approximating games (with countable state space) to have stationary Nash equilibria [4].

LEMMA 3.1. *Assume* **C3**–**C4**. *Then the following properties hold.*

C5: *For every $u \in U$, the corresponding Markov chain is aperiodic and ψ_u-irreducible for some σ-finite measure ψ_u on $\mathcal{G}$. (The latter condition means that if $\psi_u(D) > 0$ for some set $D \in \mathcal{G}$, then the chance that the Markov chain (starting at any $s \in S$ and induced by u) ever enters D is positive.) Thus the state process $\{S_n\}$ is a positive recurrent Markov chain with the unique invariant probability measure denoted by π_u.*

C6: *For every stationary multipolicy u,*

(a)

$$\int_S \nu(s)\pi_u(ds) < \infty.$$

(b) *$\{S_n\}$ is ν-uniformly ergodic; that is, there exist $\theta > 0$ and $\alpha \in (0,1)$ such that*

$$\left| \int_S w(t)Q^n(dt|s,u) - \int_S w(t)\pi_u(dt) \right| \le \nu(s)\|w\|_\nu \theta\alpha^n$$

for every $w \in L_\nu^\infty$ and $s \in S$, $n \ge 1$.

Proof. **C3**–**C4** imply that for any stationary u, the chain is positive Harris recurrent (see Theorem 11.3.4 in [25]). It is thus ψ_u-irreducible (see Chapter 9 of [25]). The aperiodicity (and, in fact, strong aperiodicity) follows from condition **C4** (see [25, p. 116]). This establishes **C5**. **C6** follows from Theorem 2.3 in [26]. □

Remark 3.1. From Lemma 3.1 it follows that for any player i and $u \in U$ we have

$$J^i(u) := \int_S c^i(s,u)\pi_u(ds) = J^i(s,u);$$

that is, the expected average cost of player i is independent of the initial state. Theorem 2.3 in [26] implies that the constants α and θ in Lemma 3.1 depend only on ξ, η, λ, and $\nu_C = \sup_{s\in C} \nu(s)$ (and, in particular, they do not depend on u). **C1**, **C3**, and **C4** imply that the expected costs considered in this section are well defined for any multipolicy $\gamma \in \Gamma$; see [34] or [14].

In what follows, whenever we assume **C1**–**C4**, we shall take the same function ν in **C1** as in **C3**. We are now ready to state our first main result.

THEOREM 3.1. *Consider an undiscounted stochastic game satisfying* **C1**–**C4**. *Then for any $\varepsilon > 0$ there exists a stationary ε-equilibrium.*

The proof of this result is based on an approximation technique and consists of several steps which will be described later on. Before proving the result, we briefly mention the approach and the steps we are using, the difficulties, and the way we overcome these difficulties.

Basic idea behind the proof. Our basic goal is to approximate our game by a sequence of m-person games with countable state spaces and compact action spaces

and which have equilibria in stationary policies; based on such approximating games, we shall construct a stationary policy which is an ϵ-equilibrium for the original game. The basic idea here is similar to the one already used in [29] for the problem with discounted cost. However, the situation here is much more involved; indeed, in the discounted case one does not need to bother about the ergodic structure of the approximating games in order to show that they possess equilibrium in stationary policies. Here, in contrast, we need to carefully construct the approximating games so as to ensure that they not only have the required ergodic property but also are uniform ergodic and have some additional "good" properties for the cost. Our first step in the proof will be to construct such approximating games, which will also satisfy conditions **C1**–**C4**. The function ν, as well as the other objects that appear in these assumptions, will be approximated as well. (We will have to show, for example, that the approximation of ξ is indeed within $(0, 1)$, etc.) The approximation of the game in a way that allows conditions similar to **C1**–**C4** to hold is done in the next two subsections.

Properties similar to **C2**–**C4** were used in [4] to establish the existence of equilibria in stationary policies for games with countable state space; the properties imply, for example, that the costs are continuous in the policies. Unfortunately, the counterpart of property **C4** that is used to establish ergodicity in the literature of countable state Markov chains (or for Markov decision processes, or for Markov games) requires that the set C that appears in conditions **C3**–**C4** be finite. Unfortunately, we *were not able to* come up with a direct approximation scheme for which C is finite. To overcome this problem, we first use some results from [26] to obtain uniform ergodicity results for the approximating chains. Using a key theorem from [41], this will be shown to imply that there exist some function (instead of the original approximation of ν) and constants for which properties **C3**–**C4** hold and for which C is a singleton. This is done in subsection 3.3.

3.1. Transition operators and their ν-weighted norms. If $f \in L_\nu^\infty$ and σ is a finite signed measure on $(S, \mathcal{G})$, then for convenience we set

$$\sigma(f) = \int_S f(s)\sigma(ds),$$

provided that this integral exists. Let P_1 and P_2 be transition subprobabilities from S into S. Define

$$\|P_1 - P_2\|_\nu = \sup_{s\in S} \sup_{|f|\le\nu} \frac{|P_1(f|s) - P_2(f|s)|}{\nu(s)}. \tag{3.2}$$

We will also use the definition (3.2) in the case in which P_1 and P_2 are probability measures on $(S, \mathcal{G})$, or when one of them is zero. Note that if $P_2 = 0$ and P_1 is a transition probability, then it follows from (3.2) that

$$\|P_1\|_\nu = \sup_{s\in S} \frac{P_1(\nu|s)}{\nu(s)}.$$

If P_1 and P_2 are transition probabilities and $\|P_1 - P_2\| < \infty$, then $P_1 - P_2$ induces a bounded linear operator from L_ν^∞ into itself, and $\|P_1 - P_2\|_\nu$ is its operator norm (see Lemma 16.1.1 in [25]).

We now come back to our game model and accept the following notation. For any $u \in U$, we use $Q(u)$ to denote the operator on L_ν^∞ defined by $Q(u)f(s) = Q(f|s, u)$,

$s \in S$, and $f \in L^\infty_\nu$. By **C3**, we have

$$\|Q(u)\|_\nu \le \xi + \eta. \tag{3.3}$$

Clearly, (3.3) implies that $Q(u)$ is (under condition **C3**) a bounded linear operator from L^∞_ν into itself. By $\Pi(u)$ we denote the invariant probability measure operator given by

$$\Pi(u)f = \pi_u(f),$$

where π_u is the invariant probability measure for $Q(\cdot|s,u)$, $u \in U$, and $f \in L^\infty_\nu$.

3.2. Approximating games. We define Γ_A to be the class of stochastic games that "resemble" stochastic games with countably many states and can be used to approximate the original game. The games in Γ_A will depend on some parameter $\delta > 0$. The transition probability in a game belonging to Γ_A is denoted by Q_δ, and the cost function of player i is denoted by c^i_δ.

We introduce some notation:

- $\mathbb{N}$—the set of positive integers,
- $C(X)$—the Banach space of all continuous functions on X, endowed with the supremum norm $\|\cdot\|$,
- $L^1_\nu = L^1_\nu(S, \mathcal{G}, \varphi)$—the Banach space of measurable functions $f : S \to \mathbb{R}$ such that $\int_S |f(s)|\nu(s)\varphi(ds) < \infty$.

We assume that each game $G_\delta \in \Gamma_A$ corresponds to some sequences $\{Y_n\}$, $\{c^i_n\}$, $\{z_n\}$, and $\{\nu_n\}$, where n belongs to some subset $\mathbb{N}_1 \subset \mathbb{N}$ and $\{Y_n\}$ is a measurable partition of the state space such that $Y_n \subset C$ or $Y_n \subset S \setminus C$ for each $n \in \mathbb{N}_1$ (the set C is introduced in assumption **C3**),

$$c^i_\delta(s,x) = c^i_n(x), \quad \text{and} \quad Q_\delta(B|s,x) = \int_B z_n(t,x)\varphi(dt)$$

for all $s \in Y_n$, $x \in X$, and $n \in \mathbb{N}_1$. Moreover, ν_n are rational numbers and $\nu_n \ge 1$ for all $n \in \mathbb{N}_1$. Define $\nu_\delta(s) \stackrel{\text{def}}{=} \nu_n$ if $s \in Y_n$.

We will show that for each $\delta > 0$ it is possible to construct a game G_δ such that $c^i_n \in C(X)$ and $z_n(\cdot,x) \in L^1_\nu$ while $z_n(s,\cdot) \in C(X)$ for all $n \in \mathbb{N}_1$, $x \in X$, and $s \in S$.

Because in our approximation we need to preserve (in some sense) condition **C4**, we consider the following subset $\Delta \subset L^1_\nu$: $\phi \in \Delta$ if and only if ϕ is a density function such that

$$\int_D \phi(s)\varphi(ds) \ge \lambda\zeta(D) \tag{3.4}$$

for each $D \in \mathcal{G}$ such that $D \subset C$. Our assumption **C4** implies that $\Delta \ne \emptyset$. It is obvious that Δ is *convex*. Suppose that $\phi_n \in \Delta$ and $\phi_n \to \phi \in L^1_\nu$. Since $\nu \ge 1$, then $\phi_n \to \phi$ in L^1. By Scheffe's theorem, ϕ is a density function. Moreover, ϕ satisfies (3.4). Thus, we have shown that Δ is a *closed* and *convex* subset of L^1_ν.

Let V be the space of all continuous mappings from X into Δ with the metric ρ defined by

$$\rho(\phi_1,\phi_2) = \max_{x\in X} \int_S |\phi_1(x)(s) - \phi_2(x)(s)|\nu(s)\varphi(ds). \tag{3.5}$$

Since $\mathcal{G}$ is countably generated, L_1 is separable. As in [47, Theorem I.5.1], we can prove the following.

LEMMA 3.2. *V is a complete separable metric space.*

Note that the proof of Theorem I.5.1 in [47] makes use of the convexity of the range space of the continuous mappings involved. In our case, the range space Δ is also convex.

For each $s \in \mathbf{S}$, the transition probability density z of the original game induces elements $\phi(s,\cdot)$ of V by

$$\phi(s,x) = z(s,\cdot,x).$$

From the product measurability of z on $S \times S \times X$, it follows that $s \to \phi(s,\cdot)$ is a measurable mapping from S into V.

We introduce the following notation:

- $\{\phi_k\}$—a countable dense subset of V (see Lemma 3.2),
- $\{c_k\}$—a countable dense set in $C(X)$,
- $\{r_k\}$, $r_k \geq 1$, where $\{r_k\}$ is the set of all rational numbers satisfying $r_k \geq 1$.

Let $0 < \delta < 1$ be fixed. Define for any $k, k_1, \ldots, k_m, l$

$$B(k,k_1,\ldots,k_m,l) = \left\{ s \in S : \rho(\phi(s,\cdot),\phi_k) + \sum_{i=1}^{m} \left\| c^i(s,\cdot) - c_{k_i} \right\| + |\nu(s) - r_l| < \delta \right\}.$$

Let τ be a (fixed) one-to-one correspondence between $\mathbb{N}$ and $\mathbb{N} \times \cdots \times \mathbb{N} = \mathbb{N}^{m+2}$. Define $T_n \overset{\text{def}}{=} B(\tau(n))$, $n \in \mathbb{N}$. Next, set $\bar{Y}_1 \overset{\text{def}}{=} T_1$ and $\bar{Y}_k \overset{\text{def}}{=} T_k - \cup_{j<k} \bar{Y}_j$ for $k \geq 2$.

Let $\{Y_n\}$ be the enumeration of all nonempty sets $\bar{Y}_k$. Clearly, $\{Y_n\}$ is a measurable countable partition of the state space, and n belongs to some $\mathbb{N}_1 \subset \mathbb{N}$.

If necessary, we can modify (trivially) this partition in such a way that $Y_n \subset C$ or $Y_n \subset S \setminus C$ for each n. Note that for each $n \in \mathbb{N}_1$ and each set Y_n there correspond some $z_n \in V$ and $c_n^i \in C(X)$, so that we obtain a game $G_\delta \in \Gamma_A$. Moreover, we have

$$\rho(\phi(s,\cdot), z_n) < \delta$$

($\phi(s,x) = z(s,\cdot,x)$, by definition) for each $n \in \mathbb{N}_1$ and $s \in Y_n$. This implies that

$$\|Q(u) - Q_\delta(u)\|_\nu < \delta \tag{3.6}$$

for every $u \in U$. Next, we have

$$\left\| c^i(s,\cdot) - c_n^i \right\| < \delta$$

for each $n \in \mathbb{N}_1$ and $s \in Y_n$. If we set $c_\delta^i(s,x) = c_n^i(x)$ for $s \in Y_n, x \in X$, we obtain

$$\sup_{s \in S} \sup_{x \in X} |c^i(s,x) - c_\delta^i(s,x)| \leq \delta. \tag{3.7}$$

We also have

$$|\nu(s) - \nu_\delta(s)| < \delta \tag{3.8}$$

for every $s \in S$.

3.3. Equivalence with a game with a countable state space. Next, we shall show that the G_δ game has an equilibrium in the class of stationary multipolicies. This will be done in the proof of the following lemma.

LEMMA 3.3. *Assume that the stochastic game satisfies* **C1**–**C4** *and* $\xi_\delta \stackrel{\text{def}}{=} 3\delta+\xi < 1$. *Then*

(i) *the game* G_δ *satisfies* **C3** *with* ξ *and* ν *replaced by* ξ_δ *and* ν_δ, *respectively, and it satisfies* **C4**; *moreover,*

(ii) *it has a Nash equilibrium in the class of stationary multipolicies.*

Proof. (i) From (3.6), it follows that

$$Q_\delta(\nu|s,x) \le Q(\nu|s,x) + \delta\nu(s)$$

for every $s \in S$ and $x \in X$. Since **C3** holds for the original game, this implies that

$$Q_\delta(\nu|s,x) \le (\delta+\xi)\nu(s) + \eta 1_C(s). \tag{3.9}$$

From (3.8) and (3.9), we conclude that

$$Q_\delta(\nu_\delta|s,x) \le \delta + (\delta+\xi)\delta + (\delta+\xi)\nu_\delta(s) + \eta 1_C(s).$$

Hence

$$Q_\delta(\nu_\delta|s,x) \le \xi_\delta\nu_\delta(s) + \eta 1_C(s) \tag{3.10}$$

for every $s \in S$ and $x \in X$; i.e., a condition of the type **C3** holds. Condition **C4** follows from the construction of Δ (above (3.4)).

(ii) Consider the approximating games under the further assumption that every player i restricts to the class U_0^i of policies that are piecewise constant: u^i belongs to U_0^i if and only if $s \to u^i(\cdot|s)$ is constant on each set Y_n of the partition $\{Y_n\}$ of S. Denote by U_0 the set of all stationary piecewise constant multipolicies. Every game G_δ with the above restriction is equivalent to a stochastic game denoted by $\bar{G}$ with the countable state space $\mathbb{N}_1$ (defined in our approximation procedure). Because every stationary multipolicy in $\bar{G}$ corresponds to a multipolicy in U_0, we will use U_0 also to denote the set of *all stationary multipolicies* in $\bar{G}$. The cost functions in $\bar{G}$ are $c_n^i \in C(X)$, where $n \in \mathbb{N}_1$. The transition probabilities in $\bar{G}$ are given by

$$P_{mn}(u) = Q_\delta(Y_n|s,u)$$

for all $s \in Y_m$, $u \in U_0$, and $m,n \in \mathbb{N}_1$. Let $P(u)$ denote the transition probability matrix corresponding to any $u \in U_0$. Finally, the piecewise constant function ν_δ induces a function $\mu : \mathbb{N}_1 \to [1,\infty)$ by $\mu(n) = \nu_\delta(s), s \in Y_n, n \in \mathbb{N}_1$. (Sometimes we will identify μ with the column vector, and $\mu(n)$ with its nth coordinate.)

Fix δ such that $\xi_\delta < 1$. Applying Lemma 3.1 to the game G_δ, we conclude that it satisfies **C5**. By part (i) and Theorem 2.3 in [26], this game also satisfies **C6** (with possibly different constants θ_1 and α_1). A simple translation of **C5** to the game $\bar{G}$ with countably many states says that for any $u \in U_0$ the Markov chain with the transition probability matrix $P(u)$ has a single ergodic class and is aperiodic. On the other hand, a translation of **C6** and the fact that $\|Q_\delta(u)\|_{\nu_\delta} \le \xi_\delta + \eta$ (which follows from (3.10)) mean that the Markov chain is μ-uniform geometric ergodic; see [9, 41]. By Key Theorem II and Lemma 5.3(ii) in [41], there exist a nonempty finite set $M \subset \mathbb{N}_1$, a function $\tilde{\mu} : \mathbb{N}_1 \to [1,\infty)$, and some $b \in (0,1)$ such that

$$\sum_{n \notin M} P_{kn}(u)\tilde{\mu}(n) \le b\tilde{\mu}(k) \tag{3.11}$$

for every $k \in \mathbb{N}_1$ and $u \in U_0$. This property is called the $\tilde{\mu}$-uniform geometric recurrence (see [8, 9, 41]) and is Assumption A2(1) in [4]. The function $\tilde{\mu}$ is given by

$$\tilde{\mu}(k) = \mu(k) + \sup_{u \in U_0} \left(\sum_{n=1}^{\infty} {}_M P^n(u) \mu \right)(k),$$

where $k \in \mathbb{N}_1$ (${}_M P(u)$ is the matrix $P(u)$ in which we replace the columns corresponding to states $m \in M$ by zeros); see [4, pp. 99–100]. Note that this new function $\tilde{\mu}$ is μ-bounded (i.e., $\sup_{n \in \mathbb{N}_1} \tilde{\mu}(n)/\mu(n) < \infty$) and vice versa. Indeed, $\mu(k) \le \tilde{\mu}(k)$ for each k. On the other hand, by (3.11), we have $({}_M P(u)\tilde{\mu})(k) \le b\tilde{\mu}(k)$ for any $k \in \mathbb{N}_1$ and $u \in U_0$. Hence

$$\tilde{\mu}(k) = \mu(k) + \sup_{u \in U_0} \left(\sum_{n=1}^{\infty} {}_M P^n(u) \mu \right)(k) \le \mu(k) + \sup_{u \in U_0} ({}_M P(u)\tilde{\mu})(k) \le \mu(k) + b\tilde{\mu}(k).$$

Thus, $\tilde{\mu}(k) \le \mu(k)/(1-b)$ for every $k \in \mathbb{N}_1$. Since $\tilde{\mu}$ is μ-bounded and vice versa, this implies the $\tilde{\mu}$-continuity of the immediate costs (recall **C1**) and of the transition probabilities (recall **C2** and Remark 2.1). This is Assumption 1^* in [4]. Since both assumptions 1^* as well as 2(1) in [4] hold, it follows that the game $\bar{G}$ has a stationary Nash equilibrium $u^* \in U_0$, and consequently G_δ has a stationary equilibrium (also denoted by u^*) in the class U_0 of all stationary piecewise constant multipolicies. It now follows from Lemma 5.1 in the appendix that u^* is a Nash equilibrium for the game G_δ in the class U of all stationary multipolicies. □

3.4. Uniform convergence of the steady state probabilities and costs, and proof of the main result. Let $J^i_\delta(u)$ be the expected average cost for player i in the game G_δ when a stationary multipolicy u is used (see Remark 3.1 and Lemma 3.3(i)).

Let $Q_\delta(u)$ and $\Pi_\delta(u)$ denote the transition probability and the invariant probability measure operators under any stationary multipolicy $u \in U$ in the approximating game.

LEMMA 3.4. *Under* **C1**–**C4**,

(i)

$$\lim_{\delta \to 0} \|\Pi_\delta(u) - \Pi(u)\|_\nu = 0$$

uniformly in $u \in U$.

(ii)

$$\lim_{\delta \to 0} \left| J^i_\delta(u) - J^i(u) \right| = 0$$

uniformly in $u \in U$.

Proof. (i) If $\xi_\delta = 3\delta + \xi < 1$, then (by Lemma 3.3) the games G_δ satisfy **C4** and **C3**, with ξ replaced by ξ_δ. By (3.10), we have $\|Q_\delta(u)\|_{\nu_\delta} \le \xi_\delta + \eta$ for all $u \in U$. This and Theorem 2.3 in [26] (applied to the games G_δ) imply that there exists a δ_0 such that

$$\sup_{\delta \le \delta_0} \sup_{u \in U} \|\Pi_\delta(u)\|_{\nu_\delta} < \infty.$$

Hence

$$K_0 \stackrel{\text{def}}{=} \sup_{\delta \le \delta_0} \sup_{u \in U} \|\Pi_\delta(u)\|_\nu < \infty. \tag{3.12}$$

The rest of the proof is an adaptation of the proof of Proposition 1 in [42]. By Lemma 3.1 and Remark 3.1, there exist some $\theta > 0$ and $\alpha \in (0,1)$ such that

$$\sup_{u\in U} \|Q^n(u) - \Pi(u)\|_\nu \le \theta\alpha^n$$

for every n. Hence, there exists an n_0 such that

$$\sup_{n\ge n_0}\sup_{u\in U}\left\|\frac{1}{n}\sum_{i=0}^{n-1} Q^i(u) - \frac{1}{n}(I - Q(u)) - \Pi(u)\right\|_\nu < 1;$$

$Q^0 = I$ is the identity operator. Therefore for each $n \ge n_0$ there exists a ν-bounded transition operator

$$\Phi_n(u) \stackrel{\text{def}}{=} \left(I + \Pi(u) - \frac{1}{n}\sum_{i=0}^{n-1} Q^i(u) + \frac{1}{n}(I - Q(u))\right)^{-1}$$

and

$$K_1 \stackrel{\text{def}}{=} \sup_{n\ge n_0}\sup_{u\in U}\|\Phi_n(u)\|_\nu < \infty. \tag{3.13}$$

Define

$$Z_n(u) \stackrel{\text{def}}{=} I + \frac{1}{n}\sum_{i=1}^{n-1}\sum_{j=1}^{i-1}(Q^j(u) - \Pi(u)).$$

We have

$$K_2 \stackrel{\text{def}}{=} \sup_{n\ge n_0}\sup_{u\in U}\|Z_n(u)\|_\nu < \infty. \tag{3.14}$$

A direct calculation yields

$$(I - Q(u) + \Pi(u))Z_n(u)\Phi_n(u) = I. \tag{3.15}$$

Clearly, (3.15) implies that

$$\Pi_\delta(u)(I - Q(u) + \Pi(u))Z_n(u)\Phi_n(u) = \Pi_\delta(u),$$

so that

$$\Pi_\delta(u)(I - Q(u))Z_n(u)\Phi_n(u) + \Pi(u)Z_n(u)\Phi_n(u) = \Pi_\delta(u). \tag{3.16}$$

From (3.15), we infer that

$$\Pi(u)(I - Q(u) + \Pi(u))Z_n(u)\Phi_n(u) = \Pi(u).$$

Therefore

$$\Pi(u)Z_n(u)\Phi_n(u) = \Pi(u).$$

Substituting into (3.16), we obtain

$$\Pi_\delta(u)(I - Q(u))Z_n(u)\Phi_n(u) = \Pi_\delta(u) - \Pi(u),$$

and consequently

$$\|\Pi_\delta(u) - \Pi(u)\|_\nu = \|\Pi_\delta(u)(Q_\delta(u) - Q(u))Z_n(u)\Phi_n(u)\|_\nu .$$

Combining this with (3.6) and (3.12)–(3.14), we obtain

$$\|\Pi_\delta(u) - \Pi(u)\|_\nu \le \|Q_\delta(u) - Q(u)\|_\nu K_0K_1K_2 < \delta K_0K_1K_2.$$

The proof of statement (i) is finished.

(ii) Using L defined in (2.1) and (3.7), we obtain

$$\begin{aligned}
|J^i(u) - J^i_\delta(u)| &= |\Pi(u)c^i(\cdot,u) - \Pi_\delta(u)c^i_\delta(\cdot,u)| \\
&\le |\Pi(u)c^i(\cdot,u) - \Pi_\delta(u)c^i(\cdot,u)| + |\Pi_\delta(u)(c^i(\cdot,u) - c^i_\delta(\cdot,u))| \\
&\le L\nu(s_0) \sup_{|w|\le\nu} \frac{|\Pi(u)w - \Pi_\delta(u)w|}{\nu(s_0)} + \delta \\
&\le L\nu(s_0) \sup_{s\in S} \sup_{|w|\le\nu} \frac{|\Pi(u)w - \Pi_\delta(u)w|}{\nu(s)} + \delta \\
&= L\nu(s_0)\, \|\Pi(u) - \Pi_\delta(u)\|_\nu + \delta,
\end{aligned}$$

where s_0 is an arbitrary state. Now (ii) follows from (i). □

A version of Lemma 3.4 corresponding with a *bounded* function ν was established by Stettner [42]. When ν is bounded, an elementary proof of Lemma 3.4 (stated as an extension of Ueno's lemma [46]) is possible [32].

Proof of Theorem 3.1. Choose some $\epsilon > 0$. According to Lemma 3.4 there exists some δ such that for all $u \in U$,

$$\left|J^i(u) - J^i_\delta(u)\right| \le \epsilon. \tag{3.17}$$

Let $u^* \in U$ be a Nash equilibrium for the game G_δ in the class U of multipolicies (its existence follows from Lemma 3.3). It then follows from (3.17) that u^* is an ϵ-equilibrium (in the class U) for the original game. The fact that u^* is an ϵ-equilibrium in the class Γ of all multipolicies follows from Theorem 3 and Remark 1 in [34] (or [18, 14] in the Borel state space framework). □

4. The discounted stochastic game. In this section, we drop conditions **C3** and **C4**. However, in the unbounded cost case, we make the following assumption.

C7: There exists $\alpha \in [\beta, 1)$ such that

$$\beta Q(\nu|s,x) \le \alpha\nu(s)$$

for each $s \in S$ and $x \in X$.

Using **C7**, we can easily prove that, for any $s \in S$, any multipolicy $\gamma \in \Gamma$, and any number of stages k, we have

$$|\beta^{k-1}E^\gamma_s(c^i(S_k,X_k))| \le \beta^{k-1}E^\gamma_s(|c^i(S_k,X_k)|) \le L\beta^{k-1}E^\gamma_s(\nu(S_k)) \le L\alpha^{k-1}\nu(s),$$

where L is the constant defined in **C1**. This gives us the following lemma.

LEMMA 4.1. *Assume* **C1** *and* **C7**. *Then for every player i the expected discounted cost $D^i(s,\gamma)$ is well defined (absolutely convergent) for each $s \in S$ and $\gamma \in \Gamma$.*

We are ready to formulate our main result in this section.

THEOREM 4.1. *Any discounted stochastic game satisfying conditions* **C1**, **C2**, *and* **C7** *has a stationary ε-equilibrium for any $\varepsilon > 0$.*

Before we give the proof of this theorem, we state some auxiliary results. Let Δ_1 be the set of *all density functions* in L^1_ν. Clearly, Lemma 3.2 holds true if Δ is replaced by Δ_1. Applying the approximation scheme from section 3 to the present situation, we construct a game G_δ for any $\delta > 0$ such that (3.7) holds and, moreover, we have

$$\sup_{|f|\le\nu} |Q(f|s,u) - Q_\delta(f|s,u)| \le \delta \tag{4.1}$$

for each $s \in S$ and any stationary multipolicy $u \in U$.

Fix player i and set

$$K^n(s,u) = E^u_s(c^i(S_n, X_n)) \quad \text{and} \quad K^n_\delta(s,u) = E^u_s(c^i_\delta(S_n, X_n)),$$

where $s \in S$ and $u \in U$. Clearly, $K^n(s,u)$ is the nth stage cost for player i under stationary multipolicy u when the game starts at an initial state $s \in S$.

LEMMA 4.2. *Assume* **C1** *and* **C7**. *Then, for each* $s \in S$ *and* $u \in U$, *we have*

$$|K^n(s,u) - K^n_\delta(s,u)| \le \delta(1 + (n-1)L)\left(\frac{\alpha}{\beta}\right)^{n-1}.$$

Proof. The proof proceeds by induction. For $n = 1$ the inequality follows immediately from (3.7). We now give the induction step. Note that

$$\begin{aligned} |K^{n+1}(s,u) - K^{n+1}_\delta(s,u)| &= |Q(K^n(\cdot,u)|s,u) - Q_\delta(K^n_\delta(\cdot,u)|s,u)| \\ &\le |Q(K^n(\cdot,u)|s,u) - Q_\delta(K^n(\cdot,u)|s,u)| \\ &\quad + |Q_\delta(K^n(\cdot,u)|s,u) - Q_\delta(K^n_\delta(\cdot,u)|s,u)|. \end{aligned}$$

Using (4.1), our induction hypothesis, and the obvious inequality

$$K^n(s,u) \le L\left(\frac{\alpha}{\beta}\right)^{n-1}\nu(s),$$

which holds for every $s \in S$ and $u \in U$, we obtain

$$\begin{aligned} |K^{n+1}(s,u) - K^{n+1}_\delta(s,u)| &\le \delta L\left(\frac{\alpha}{\beta}\right)^{n-1} + \delta(1 + (n-1)L)\left(\frac{\alpha}{\beta}\right)^{n-1} \\ &= \delta(1+nL)\left(\frac{\alpha}{\beta}\right)^{n-1} \le \delta(1+nL)\left(\frac{\alpha}{\beta}\right)^{n}, \end{aligned}$$

which ends the proof. □

From Lemmas 4.1 and 4.2, we infer the following result.

LEMMA 4.3. *Assume* **C1** *and* **C7**. *If* $D^i_\delta(s,u)$ *is the expected* β*-discounted cost for player* i *in the game* G_δ, *then*

$$|D^i(s,u) - D^i_\delta(s,u)| \le \delta(1 + \alpha(L-1))(1-\alpha)^{-2}$$

for each $s \in S$ *and* $u \in U$.

The game G_δ is characterized by the cost functions c^i_δ, transition probability Q_δ, and the function ν_δ. Note that if δ is sufficiently small, then the game G_δ satisfies condition **C1** with L replaced by $2L$. From our approximation scheme (the new

definition of the space V) and Remark 2.1, it follows also that **C2** is satisfied in our game G_δ. Since $|\nu(s) - \nu_\delta(s)| < \delta$ for all $s \in S$, we have (by (4.1))

$$\beta \int_S \nu_\delta(t) Q_\delta(dt|s,x) \le \alpha \nu_\delta(s) + \alpha\delta + 2\beta\delta < \alpha_0 \nu_\delta(s),$$

where $\alpha_0 = \alpha + \alpha\delta + 2\delta$ and $s \in S$, $x \in X$. Note that $\beta < \alpha_0$, and if δ is sufficiently small, then $\alpha_0 < 1$, and thus G_δ satisfies condition **C7** with α replaced by α_0. Let δ_0 be a positive number such that for every $\delta < \delta_0$ the game G_δ satisfies conditions of type **C1**, **C2**, and **C7**. In particular, we have $\beta < \alpha_0 < 1$.

LEMMA 4.4. *If $\delta < \delta_0$, then the game G_δ has a Nash equilibrium in the class U of all stationary multipolicies.*

Proof. We use a transformation to bounded cost games similar to that of [43, p. 101]. One may define the new discount factor $\tilde\beta \stackrel{\text{def}}{=} \alpha_0$ and the functions

$$\tilde c^i(s,x) = \frac{c^i_n(x)}{\nu_\delta(s)}, \qquad \tilde z(s,t,x) = \frac{\beta z_n(t,x)\nu_\delta(t)}{\alpha_0 \nu_\delta(s)},$$

where $s \in Y_n$, $t \in S$, and $x \in X$. This transformation ensures that the new costs $\tilde c^i$ are bounded and that

$$q(\cdot|s,x) \stackrel{\text{def}}{=} \int_S \tilde z(s,t,x)\varphi(dt)$$

is a transition subprobability such that $q(Y_n|s,x)$ is continuous in x for each n and $s \in S$. Moreover, it implies that

$$\tilde D^i(s,u) = \frac{D^i_\delta(s,u)}{\nu_\delta(s)}, \tag{4.2}$$

where $\tilde D^i(s,u)$ is the expected discounted cost for player i under any $u \in U$ in the transformed (bounded) game. Similarly, as in section 3 we can recognize the game G_δ as a game with countably many states. By [11], such a game has a stationary Nash equilibrium. In other words, our bounded game has an equilibrium $u^\star$ in the class U_0 of all piecewise constant multipolicies. It now follows from Lemma 5.2 in the appendix that $u^\star$ is an equilibrium for the bounded game in the class U. By (4.2), we infer that $u^\star$ is also an equilibrium (in the class U of all stationary multipolicies) for the game G_δ. □

Proof of Theorem 4.1. Fix $\varepsilon > 0$. By Lemma 4.3, there exists $\delta < \delta_0$ such that

$$|D^i(s,u) - D^i_\delta(s,u)| \le \varepsilon/2$$

for each $s \in S$ and $u \in U$. It follows from Lemma 4.4 that the game G_δ has an equilibrium $u^\star$ in the class U. Clearly, $u^\star$ is an ε-equilibrium in the class U for the original game. The fact that $u^\star$ is also an ε-equilibrium in Γ follows from Theorem 2 and Remark 1 in [34] (or [14] in the case of Borel state space games). □

5. Appendix. In this section we restrict our attention to the approximating games and state some auxiliary results on sufficiency of piecewise constant policies in the sense that they can be used to dominate any other policy. Related statements are proven in [1] for countable state space models. Their extension to the present situation would require new notation and some additional measure theoretic work.

Therefore, in this section we restrict ourselves to stationary policies, and in such a case we can use different methods which are based on some standard arguments from the dynamic programming literature [14].

Let G_δ be an approximating game corresponding to a partition of the state space. Fix player i and a stationary *piecewise constant* multipolicy u^{-i} for the other players. For any $s \in S$ and $f \in U^i$ set

$$c(s,f) = c^i_\delta(s,(u^{-i},f)) \quad \text{and} \quad q(\cdot|s,f) = Q_\delta(\cdot|s,(u^{-i},f)).$$

Recall that U^i_0 denotes the set of all piecewise constant stationary policies for player i.

Consider the Markov decision process (MDP) with the state space S, the action space X^i, the cost function c, and the transition probability q.

The average cost case. We assume that δ is sufficiently small so that the MDP satisfies conditions **C1**–**C4** (restricted to the one-player case). Let $J_n(s,f)$ ($J(f)$) denote the expected n-stage (expected average) cost (in the MDP) under stationary policy f.

LEMMA 5.1. *Assume* **C1**–**C4**, *and consider the average cost MDP described above. Then for each $f \in U^i$ there exists some $f_0 \in U^i_0$ such that*

$$J(f_0) \le J(f).$$

Proof. Let $f \in U^i$ and $g = J(f)$. By Lemma 3.1, our MDP satisfies condition **C6** with ν replaced by ν_δ and possibly different constants. It is well known that in such a case the function

$$h(s) \stackrel{\text{def}}{=} E^f_s \left[\sum_{n=1}^{\infty} (c(S_n, X^i_n) - g) \right]$$

is well defined and $h \in L^\infty_{\nu_\delta}$. Moreover, we have

$$g + h(s) = c(s,f) + q(h|s,f) \quad \text{for each} \quad s \in S.$$

For the details, see [14] and [25]. Our approximating game (and thus the MDP) satisfies continuity conditions **C1**–**C2**. Because the cost function c and the transition probability correspond to a partition of the state space (and, in addition, the other players use stationary piecewise constant multipolicy u^{-i}), this implies that one can find some $f_0 \in U^i_0$ such that

$$c(s,f_0) + q(h|s,f_0) \le c(s,f) + q(h|s,f) = g + h(s)$$

for all $s \in S$. Iterating this inequality, we obtain

$$J_n(s,f_0) + q^n(h|s,f_0) \le ng + h(s)$$

for all $s \in S$. Hence

$$\frac{J_n(s,f_0)}{n} + \frac{q^n(h|s,f_0)}{n} \le g + \frac{h(s)}{n}$$

for each n, and consequently

$$J(f_0) \le g = J(f).$$

For a detailed discussion of the fact that **C3** implies that $q^n(h|s, f_0)/n \to 0$ as $n \to \infty$, consult [14] or [34]. □

The discounted cost case. We now assume that the stochastic game satisfies **C1**, **C2**, and **C7**. If δ is sufficiently small, then both G_δ and the aforementioned MDP satisfy **C1**, **C2**, and **C7**, but with different constants (see section 4). Let $f \in U^i$. By $D_n(s, f)$ ($D(s, f)$) we denote the expected n-stage discounted (total discounted) cost in the MDP under policy f.

LEMMA 5.2. *Assume* **C1**, **C2**, *and* **C7**, *and consider the discounted MDP described above. Then for each $f \in U^i$ there exists some $f_0 \in U_0^i$ such that*

$$D(s, f_0) \le D(s, f) \quad \textit{for every} \quad s \in S.$$

Proof. Set $d(s) = D(s, f)$, $s \in S$. Under our assumptions, we have

$$d(s) = c(s, f) + \beta q(d|s, f)$$

for all $s \in S$ (see Lemma 4.1). From our compactness and continuity conditions, **C7**, and the construction of the approximating game, it follows that there exists some $f_0 \in U_0^i$ such that

$$c(s, f_0) + \beta q(d|s, f_0) \le c(s, f) + \beta q(d|s, f) = d(s)$$

for each $s \in S$. Hence

$$D_n(s, f_0) + \beta^n q^n(d|s, f_0) \le d(s)$$

for each n and $s \in S$, and consequently

$$D(s, f_0) \le D(s, f) \quad \text{for each} \quad s \in S.$$

The fact that $\beta^n q^n(d|s, f_0) \to 0$ as $n \to \infty$ follows easily from **C7**. □

EXISTENCE, MULTIPLICITY, AND REGULARITY FOR SUB-RIEMANNIAN GEODESICS BY VARIATIONAL METHODS*

ROBERTO GIAMBÒ†, FABIO GIANNONI†, AND PAOLO PICCIONE‡

Abstract. We develop a variational theory for geodesics joining a point and a one dimensional submanifold of a sub-Riemannian manifold. Given a Riemannian manifold (M, g), a smooth distribution $\Delta \subset TM$ of codimension one in M, a point $p \in M$, and a smooth immersion $\gamma : \mathbb{R} \to M$ with closed image in M and which is everywhere transversal to Δ, we look for curves in M that are stationary with respect to the Riemannian energy functional among all of the absolutely continuous curves *horizontal* with respect to Δ and that join p and γ. If (M, g) is complete, such extremizers exist, and they are curves of class C^2 characterized as the solutions of an integro-differential equation or by a system of ordinary differential equations. We present some results concerning a sort of *exponential map* relative to the integro-differential equation and some applications. In particular, we obtain that if p and γ are sufficiently close in M, then there exists a unique length minimizer. We obtain existence and multiplicity results by means of the Ljusternik–Schnirelman theory.

1. Introduction.

The goal of this paper is to develop a variational theory for sub-Riemannian geodesics in a general context and to obtain existence and multiplicity results, in analogy with the corresponding theory for Riemannian geodesics.

The interest in the existence of (local) length minimizers in a sub-Riemannian manifold comes essentially from control theory, where such minimizers represent optimal solutions of a system with linear constraints on the first derivatives of the admissible paths.

A sub-Riemannian manifold consists of a triple (M, Δ, g), where M is a smooth manifold, $\Delta \subset TM$ is a smooth distribution in M, and g is a positive definite metric tensor on Δ. The kind of sub-Riemannian geodesics that we are interested in are the so-called *normal* geodesics, which are curves obtained as solutions of the sub-Riemannian Hamiltonian $H = \frac{1}{2}g\big(p|_\Delta, p|_\Delta\big)$ on TM^*. It is well known that normal sub-Riemannian geodesics are horizontal with respect to Δ, i.e., $\dot{x} \in \Delta$, and that they locally minimize their length (see [7]); such curves will be studied in this paper as solutions of a Lagrangian variational problem. There is a class of geodesic curves, called *abnormal*, which satisfies Hamiltonian equations with abnormal Hamiltonians. These equations are determined by the distribution Δ and not by the metric g. The first example of an abnormal sub-Riemannian length minimizer has been constructed by Montgomery in [9]. Wide classes of abnormal minimizers for 2-distributions have been described in [7]. Good references for the basics of sub-Riemannian geodesics are [8, 10]. A wide study of abnormal geodesics can be found in [1].

An approach to multiplicity results in optimal control theory by means of global analysis techniques (Morse theory and Ljusternik–Schnirelman theory) has been developed in a different context by the Russian school (see Vakhrameev [13] and its extensive bibliography). The main assumption of [13] is that the control system is of *constant rank*, i.e., that the *endpoint mapping* defined on the space of horizontal paths is of constant rank. This assumption is satisfied, for instance, when Δ is strongly bracket-generating (or when Δ is integrable in the sense of Frobenius).

The main obstruction for developing a variational theory for sub-Riemannian geodesics between two points is that, in general, the set of horizontal curves joining two fixed points does not have a differentiable structure unless one poses strong nonintegrability conditions on the distribution Δ, or, for instance, when the system is of constant rank in the sense of Vakhrameev [13]. In this paper, we do not make such assumptions on Δ, but rather we allow that the final endpoint of a trial path for our variational problem is free to move on a submanifold of M which is *transversal* to Δ. With such a choice we overcome the *rigidity* problem of the fixed endpoint case, and we obtain a smooth manifold structure for the set of horizontal curves satisfying suitable regularity conditions (see Proposition 2.1 and Remark 2.2).

As a first approach to this technique, we will initially consider the case of a distribution Δ of codimension one in TM, and we will assume that Δ is *transversally oriented* in TM, i.e., that the quotient bundle TM/Δ is orientable. One can extend the sub-Riemannian metric defined on Δ to a Riemannian metric in M; such an extension is of course noncanonical. By the transversal orientation, it is not restrictive to assume that Δ is the orthogonal distribution to a unit vector field on M. Moreover, if the original sub-Riemannian structure is complete, one can assume that the Riemannian extension is also complete. We will therefore consider the following geometric setup.

Let (M, g) be a complete Riemannian manifold, let Y be a never vanishing smooth vector field on M, and let $\Delta = Y^{\perp}$ denote the orthogonal distribution to Y. For all $q \in M$, we set $\Delta_q = \Delta \cap T_q M$; moreover, we will denote by $\langle \cdot, \cdot \rangle$ the positive definite inner product on each tangent space $T_q M$ given by $g(q)$ and by $|\cdot|$ the corresponding length. We will assume without loss of generality that Y is normalized on M:

$$\langle Y, Y \rangle = 1. \tag{1}$$

Let $\gamma : \mathbb{R} \to M$ be a smooth curve in M which is a closed immersion of $\mathbb{R}$ in M (i.e., $\gamma'(t) \neq 0$ for all t and γ has closed image $\mathrm{Im}(\gamma)$ in M) and which is everywhere *transversal* to Δ, i.e., $\dot\gamma(t) \notin \Delta_{\gamma(t)}$ for all t.

Let ∇ denote the covariant derivative relative to the Levi–Civita connection of g; given a smooth function α on M, we denote by $\nabla\alpha$ the gradient of α with respect to the metric g.

Let p be a fixed point in M, set $\mathrm{Im}(\gamma) = \gamma(\mathbb{R})$, and let $\mathcal{C}^1_{p,\gamma}$ denote the set of all curves of class C^1 in M parameterized on $[0, 1]$ joining p and γ:

$$\mathcal{C}^1_{p,\gamma} = \{z \in C^1([0,1], M) : z(0) = p,\ z(1) \in \mathrm{Im}(\gamma)\};$$

by $\mathcal{C}^1_{p,\gamma}(\Delta)$ we will denote the subset of $\mathcal{C}^1_{p,\gamma}$ consisting of *horizontal* curves:

$$\mathcal{C}^1_{p,\gamma}(\Delta) = \{z \in \mathcal{C}^1_{p,\gamma} : \dot z(t) \in \Delta_{z(t)} \text{ for all } t\}. \tag{2}$$

The set $\mathcal{C}^1_{p,\gamma}$ has a natural structure of an infinite dimensional Banach differentiable manifold; the differentiable structure of (a suitable completion of) $\mathcal{C}^1_{p,\gamma}(\Delta)$ will be discussed in section 2. We denote by L and E, respectively, the Riemannian *length* and *energy* functionals on $\mathcal{C}^1_{p,\gamma}$ defined by

$$L(z) = \int_0^1 \sqrt{\langle \dot z, \dot z\rangle}\, \mathrm{d}t, \quad E(z) = \frac{1}{2}\int_0^1 \langle \dot z, \dot z\rangle\, \mathrm{d}t. \tag{3}$$

In this paper, we will be interested in studying the curves in $\mathcal{C}^1_{p,\gamma}(\Delta)$ that are local length minimizers, i.e., in those horizontal curves z between p and γ such that, for $a, b \in [0,1]$ sufficiently close, the restriction $z|_{[a,b]}$ is a horizontal curve of minimal length between $z(a)$ and $z(b)$. Such curves will be called local *sub-Riemannian length minimizers* between p and γ. More in particular, we will consider the stationary points of the functional E in $\mathcal{C}^1_{p,\gamma}(\Delta)$: they are geodesics in the sub-Riemannian manifold $(\mathcal{M}, \Delta, g)$. Namely, the critical points of E in $\mathcal{C}^1_{p,\gamma}(\Delta)$ are normal sub-Riemannian geodesics, and therefore they locally minimize their length (see, for instance, [7, Appendix C]). Moreover, the minima in $\mathcal{C}^1_{p,\gamma}(\Delta)$ of the functionals E and of L coincide up to parameterization.

PROPOSITION 1.1. *A curve $x \in \mathcal{C}^1_{p,\gamma}(\Delta)$ is a minimal point for E on $\mathcal{C}^1_{p,\gamma}(\Delta)$ if and only if it is a sub-Riemannian length minimizer between p and γ satisfying $|\dot x(t)| = \text{const.}$ on $[0,1]$.*

We have a first existence result concerning the minima of the length functional.

THEOREM 1.2. *Let (M, g) be a complete Riemannian manifold, let Y be a never vanishing smooth vector field on M, let $\Delta = Y^\perp$ be its orthogonal distribution, and let $\gamma : \mathbb{R} \to M$ be a closed immersion which is transversal to Δ. Then there exists at least one minimizer x for L in $\mathcal{C}^1_{p,\gamma}(\Delta)$, with $|\dot x(t)|$ constant on $[0,1]$.*

Some results concerning the characterization of the normal geodesics in a sub-Riemannian manifold, connecting submanifolds $\mathcal{P}$ and $\mathcal{Q}$ of any codimension, as critical points of the action functional can be found, for instance, in [12]. Existence and multiplicity results can be obtained if $\mathcal{P}$ and $\mathcal{Q}$ are closed submanifolds of $\mathcal{M}$ and one of them is compact. The proof is essentially the same as that of Theorem 1.8 (thanks to the results proved in [12]).

As will be observed in section 2, for the proof of Theorem 1.2 it is not restrictive to assume that γ is an integral line of the vector field Y. For the other results of the paper, we will explicitly make such assumption.

Given a smooth vector field W on M, we denote by $(\nabla W)^*$ the transpose of the covariant derivative of W, which is the $(1,1)$ tensor field on M whose value at a point $q \in M$ is the linear map on T_qM defined by

$$\big\langle (\nabla W)^*[v_1], v_2\big\rangle = \big\langle \nabla_{v_2} W, v_1\big\rangle \quad \text{for all } v_1, v_2 \in T_qM. \tag{4}$$

For all x in $\mathcal{C}^1_{p,\gamma}(\Delta)$, let $\lambda_x : [0,1] \to \mathbb{R}$ be the map of class C^2 given by

$$\lambda_x(t) = e^{\int_0^t \langle \dot x, \nabla_Y Y\rangle\, \mathrm{d}s} \cdot \left[\int_t^1 \big\langle \dot x, \nabla_{\dot x} Y\big\rangle e^{-\int_0^s \langle \dot x, \nabla_Y Y\rangle\, \mathrm{d}r}\, \mathrm{d}s\right]. \tag{5}$$

THEOREM 1.3. *Suppose that γ is an integral line of Y. If x is a critical point of E in $\mathcal{C}^1_{p,\gamma}(\Delta)$, then x is a curve of class C^2, and it satisfies the equation*

$$\nabla_{\dot x}\dot x - \nabla_{\dot x}\left(\lambda_x \cdot Y\right) + \lambda_x \cdot (\nabla Y)^*[\dot x] = 0. \tag{6}$$

Remark 1.4. Observe that the integro-differential equation (5)–(6) is not *local*, in the following sense. Given any subinterval $[a,b] \subseteq [0,1]$, one can consider an alternative integro-differential problem given by (6) and λ_x given by

$$\lambda_x = e^{\int_a^t \langle \dot{x}, \nabla_Y Y\rangle \, \mathrm{d}s} \cdot \left[\int_t^b \left\langle \dot{x}, \nabla_{\dot{x}} Y \right\rangle e^{-\int_0^s \langle \dot{x}, \nabla_Y Y\rangle \, \mathrm{d}r} \, \mathrm{d}s \right]. \tag{7}$$

Given a solution x of (5)–(6), the restriction of x to the interval $[a,b]$ is not, in general, a solution of (6)–(7). The interpretation of this fact is that, even though the critical points of E in $\mathcal{C}^1_{p,\gamma}(\Delta)$ locally minimize their length, in general they do *not* minimize locally the distance between a point and an integral line of Y. The fact that sufficiently small portions of solutions of (6)–(7) minimize their length can be deduced from the fact that (6)–(7) are equivalent to the Hamilton equations satisfied by the normal sub-Riemannian geodesics (see Appendix B); for normal sub-Riemannian geodesics the local minimality is proven, for instance, in [7, Appendix C]. However, a direct proof of the local minimality for solutions of (6)–(7) can also be given without the use of Hamiltonian formalism.

Note that if the pair (x, λ_x) satisfies (6)–(7), clearly it satisfies the system of ordinary differential equations

$$\begin{cases} \nabla_{\dot{x}} \dot{x} - \nabla_{\dot{x}} (\lambda Y) + \lambda \, (\nabla Y)^* [\dot{x}] = 0, \\ \lambda' - \lambda \left\langle \nabla_Y Y, \dot{x} \right\rangle + \left\langle \dot{x}, \nabla_{\dot{x}} Y \right\rangle = 0. \end{cases} \tag{8}$$

At the end of section 2, we point out that, if $(x(t), \lambda_x(t))$ is a solution of the above system, then $\langle \dot{x}(t), \dot{x}(t) \rangle$ and $\langle \dot{x}(t), Y(x(t)) \rangle$ are constant. From this point of view (in analogy with Riemannian geodesics), we could say that the sub-Riemannian geodesics are the solution of (8) with the initial condition $\langle \dot{x}(0), Y(x(0)) \rangle = 0$. Observe also that the pair (x, λ) plays the role of the *Hamiltonian lift* of the sub-Riemannian geodesic x.

Remark 1.5. Suppose that Y is a conformal Killing vector field. Then, for all $v \in Y^\perp$, it is $\langle \nabla_v Y, v \rangle = 0$. Hence, for all $x \in \mathcal{C}^1_{p,\gamma}(\Delta)$, it is $\langle \nabla_{\dot{x}} Y, \dot{x} \rangle \equiv 0$, and so $\lambda_x \equiv 0$. From (6), this implies that if x is a critical point of E in $\mathcal{C}^1_{p,\gamma}(\Delta)$, then it is a Riemannian geodesic.

Remark 1.6. Changing the point of view, the stationary paths x for the functional E in $\mathcal{C}^1_{p,\gamma}(\Delta)$ can be thought of as *constrained* critical points of E in $\mathcal{C}^1_{p,\gamma}$ subject to the linear constraint on the first derivative $\dot{x} \in \Delta$. From this viewpoint, given such a constrained critical point x, the map λ_x of formula (5) can be interpreted as the corresponding *Lagrange multiplier* (see Appendix A).

Remark 1.7. It is well known (see for instance, [7]) that, as a consequence of the Pontryagin maximum principle, the sub-Riemannian extremals are either abnormal or they satisfy the Hamilton equations corresponding to the Hamiltonian function $H : TM^* \to \mathbb{R}$ given by

$$H(q,p) = \frac{1}{2} g^{-1}\big(p|_\Delta, p|_\Delta\big),$$

where $g^{-1} : \Delta^* \times \Delta^* \to \mathbb{R}$ is the inverse of the metric $g|_\Delta$. We will prove in Appendix B that (5) and (6) (or, equivalently, system (8)) are equivalent to the Hamilton equations of H.

Let us recall the following definition: let $\mathcal{X}$ be a topological space, and let $\mathcal{Y} \subset \mathcal{X}$ be a subspace. The *Ljusternik–Schnirelman category* $\mathrm{cat}_{\mathcal{X}}(\mathcal{Y})$ of $\mathcal{Y}$ in $\mathcal{X}$ is the possibly

infinite minimal number of closed contractible subsets of $\mathcal{X}$ that form a covering of $\mathcal{Y}$. We set $\operatorname{cat}(\mathcal{X}) = \operatorname{cat}_{\mathcal{X}}(\mathcal{X})$.

We have a multiplicity result for sub-Riemannian geodesics between p and γ given in terms of the Ljusternik–Schnirelman category of the Hilbert manifold $\Omega_{p,\gamma}(\Delta)$ defined in (10) as follows.

THEOREM 1.8. *Under the assumptions of Theorem* 1.2, *if* γ *is an integral line of* Y, *there are at least* $\operatorname{cat}(\Omega_{p,\gamma}(\Delta))$ *normal geodesics between* p *and* γ. *Moreover, if* $\operatorname{cat}(\Omega_{p,\gamma}(\Delta))$ *is infinite, then there exists a sequence* $\{x_n\}_{n\in\mathbb{N}}$ *of normal geodesics between* p *and* γ *such that*

$$\lim_{n\to\infty} E(x_n) = +\infty.$$

Under suitable assumptions on the flow of Y, one proves that the inclusion map $\Omega_{p,\gamma}(\Delta)$ into $\Omega_{p,\gamma}$ (defined in (9)) is a homotopy equivalence; it follows, in particular, that $\operatorname{cat}(\Omega_{p,\gamma}(\Delta))$ is equal to $\operatorname{cat}(\Omega_{p,\gamma})$ (see Proposition 3.3). If M is not contractible, by a well known result of Fadell and Husseini (see [3]), it is $\operatorname{cat}(\Omega_{p,\gamma}) = +\infty$, and we have a class of examples where Theorem 1.8 gives the existence of infinite normal geodesics between p and γ.

Let us now look abstractly at the integro-differential equation (6). Observe that it makes perfect sense to consider solutions of (6) that are not horizontal curves. We will prove in section 2 that a solution x of (6) is a horizontal curve if and only if $\dot{x}(0) \in \Delta$ (Theorem 2.3). Moreover, we will see that a solution of (6) satisfying $x(0) = v \in T_pM$ exists and is unique, provided that v is small enough (Proposition 4.1). This fact allows us to introduce a *sub-Riemannian* point-to-line exponential map $\mathfrak{exp}_p$, defined in a neighborhood of $0 \in T_pM$ by $\mathfrak{exp}_p(v) = x_v(1)$, where x_v is the unique solution of (6) satisfying the initial condition $\dot{x}_v(0) = v$.

In perfect analogy with the well-known properties of the Riemannian exponential map, the map $\mathfrak{exp}_p$ is a diffeomorphism between a neighborhood of $0 \in T_pM$ and a neighborhood of $p \in M$. As a first important (and trivial) consequence of this fact, we obtain the following local uniqueness result for sub-Riemannian length minimizers between a point and an integral line of Y.

THEOREM 1.9. *Under the hypotheses of Theorem* 1.2, *if* γ *is sufficiently close to* p, *then there is a unique minimizer* x *for* L *in* $\mathcal{C}^1_{p,\gamma}(\Delta)$ *with* $|\dot{x}(t)|$ *constant on* $[0,1]$.

We conclude with a remark that sub-Riemannian geodesics of the kind considered in this paper have appeared recently in a general relativistic context (see [4, 5]). Given a *stationary Lorentzian manifold*, which represents the model for a relativistic spacetime with gravitational field stationary with respect to a distinguished observer field Y, one has a natural sub-Riemannian metric defined on the orthogonal distribution to Y by taking the restriction of the spacetime metric tensor. In this situation, the sub-Riemannian geodesics (in a suitable conformal perturbation of the metric) joining an event p of M and an integral line of Y represent the *travel time* brachistochrones between a source and an observer in the spacetime.

We briefly outline the structure of the paper. In order to be able to apply techniques from critical point theory and global analysis on manifolds, our variational problem has to be cast in a Hilbert manifold setting. In section 2, we define the variational framework by proving the existence of a Hilbert manifold structure on the set $\Omega_{p,\gamma}(\Delta)$ of horizontal curves from p to γ of Sobolev class H^1; then we study the first variation of the sub-Riemannian energy functional E defined on $\Omega_{p,\gamma}(\Delta)$.

In section 3 we prove that $E : \Omega_{p,\gamma}(\Delta) \to \mathbb{R}$ satisfies a certain compactness property, called the Palais–Smale condition, which is the key property for all of the

results of existence and multiplicity of critical points for functions on noncompact manifolds. By standard arguments of critical point theory we will then obtain the proof of Proposition 1.1, Theorem 1.2, Theorem 1.3, and Theorem 1.8.

In section 4 we look at the flow on M defined by the integro-differential equation (6), and we study the sub-Riemannian exponential map.

Finally, the paper has two short appendices. In Appendix A, we show that the map λ_x of formula (5) and the integro-differential equation (6) appear naturally also when one uses the method of Lagrange multipliers. In Appendix B we prove that the integro-differential equation (5)–(6) is equivalent to the normal extremal equations coming from the maximum principle of Pontryagin.

2. The variational framework. First variation and the critical points of E. We assume hereafter that (M, g) is a complete Riemannian manifold and that Y is a normalized smooth vector field on M; we set $\Delta = Y^{\perp}$. For each $q \in M$, we set $\Delta_q = \Delta \cap T_q M$.

Let $I \subset \mathbb{R}$ be any interval, and suppose that $\gamma : I \to M$ is a smooth curve having values in a compact subset of M. Suppose that γ is everywhere transversal to Δ. By the transversality of γ and a partition of unity argument, it is easy to prove that we can find a complete Riemannian metric $\tilde{g}$ and a smooth vector field $\tilde{Y}$ on M such that

- the orthogonal distribution $\tilde{Y}^{\perp}$ with respect to $\tilde{g}$ coincides with Δ;
- g and $\tilde{g}$ coincide on Δ;
- $\dot{\gamma}(t) = \tilde{Y}(\gamma(t))$ for all $t \in I$.

Now, since (M, g) is complete, all curves starting at the fixed point p whose length is bounded above by a given constant remain inside a compact subset of M. Then, to prove the results announced in the introduction, it suffices to treat the case that γ is a maximal integral line of the vector field Y.

We will assume hereafter that $\gamma : \mathbb{R} \to M$ is an integral curve of Y.

As is customary, if $I \subseteq \mathbb{R}$ is any interval, we will denote by $H^1(I, \mathbb{R}^n)$ the Sobolev space of absolutely continuous curves $z : I \longmapsto \mathbb{R}^n$ such that the integral $\int_I |\dot{z}|^2 \, \mathrm{d}t$ is finite, where $|\cdot|$ denotes the Euclidean norm in $\mathbb{R}^n$.

Given *any* differentiable manifold N, the set $H^1([0,1], N)$ is defined as the set of all absolutely continuous curves $z : [0,1] \longmapsto N$ such that, for every local chart (V, φ) on N, with $\varphi : U \longmapsto \mathbb{R}^n$ a diffeomorphism, and for every closed subinterval $I \subseteq [0,1]$ such that $z(I) \subset V$, it is $\varphi \circ z \in H^1(I, \mathbb{R}^n)$. For all differentiable manifold N, with $\dim(N) = n$, the set $H^1([0,1], N)$ has the structure of an infinite dimensional manifold, modeled on the Hilbert space $H^1([0,1], \mathbb{R}^n)$. We will denote by TN the tangent bundle of N and by $\pi : TN \to N$ the canonical projection; for $p \in N$, $T_pN = \pi^{-1}(p)$ denotes the tangent space of N at p. A vector field along a curve $z : [0,1] \to N$ is a map $\zeta : [0,1] \to TN$ with $\pi(\zeta(t)) = z(t)$ for all t. Given any $z \in H^1([0,1], N)$, the tangent space $T_z H^1([0,1], N)$ is identified with the set

$$T_z H^1([0,1], N) = \{\zeta \in H^1([0,1], TN) : \zeta \text{ vector field along } z\},$$

which is an infinite dimensional vector space with a topology that makes it into a *Hilbertable* space.

We introduce the sets

$$\Omega_{p,\gamma} = \{z \in H^1([0,1], M) : z(0) = p, \ z(1) \in \mathrm{Im}(\gamma)\}, \tag{9}$$

and

$$\Omega_{p,\gamma}(\Delta) = \{z \in \Omega_{p,\gamma} : \langle \dot{z}, Y \rangle = 0 \text{ a.e. in } [0,1]\}. \tag{10}$$

It is well known that $\Omega_{p,\gamma}$ is a smooth Hilbert submanifold of $H^1([0,1],M)$; for all $z \in \Omega_{p,\gamma}$ the tangent space $T_z\Omega_{p,\gamma}$ is given by

$$T_z\Omega_{p,\gamma} = \{V \in T_zH^1([0,1],M) : V(0) = 0,\ V(1) \parallel Y(z(1))\}.$$

We endow $T_z\Omega_{p,\gamma}$ with the Hilbert space structure induced by the inner product:

$$\langle\!\langle V, V \rangle\!\rangle = \int_0^1 \langle \nabla_{\dot z} V, \nabla_{\dot z} V \rangle \, \mathrm{d}t; \tag{11}$$

then $\Omega_{p,\gamma}$ becomes an infinite dimensional Riemannian manifold with the metric defined by (11).

The functionals E and L defined in formula (3) have a continuous extension to the space $H^1([0,1],M)$. The energy functional E is smooth, and so is its restriction to $\Omega_{p,\gamma}$; the length functional L is only Lipschitz continuous. For $z \in H^1([0,1],M)$, the Gateaux derivative $\mathrm{d}E(z)$ is given by the bounded linear map on $T_zH^1([0,1],M)$:

$$\mathrm{d}E(z)[V] = \int_0^1 \langle \nabla_{\dot z} V, \dot z \rangle \, \mathrm{d}t. \tag{12}$$

PROPOSITION 2.1. *$\Omega_{p,\gamma}(\Delta)$ is a smooth Hilbert submanifold of $\Omega_{p,\gamma}$. For all $z \in \Omega_{p,\gamma}(\Delta)$, the tangent space $T_z\Omega_{p,\gamma}(\Delta)$ is given by the Hilbert subspace of $T_z\Omega_{p,\gamma}$:*

$$T_z\Omega_{p,\gamma}(\Delta) = \{V \in T_z\Omega_{p,\gamma} : \langle \nabla_{\dot z} V, Y \rangle + \langle \dot z, \nabla_V Y \rangle = 0\}. \tag{13}$$

The restriction of E to $\Omega_{p,\gamma}(\Delta)$ is smooth.

Proof. We consider the map $F : \Omega_{p,\gamma} \to L^2([0,1],\mathbb{R})$ defined by

$$F(z) = \langle \dot z, Y \rangle. \tag{14}$$

It is easy to see that F is smooth, that $\Omega_{p,\gamma}(\Delta) = F^{-1}(0)$, and that the Gateaux derivative $\mathrm{d}F(z)$ of F at z is given by

$$\mathrm{d}F(z)[V] = \langle \nabla_{\dot z} V, Y \rangle + \langle \dot z, \nabla_V Y \rangle. \tag{15}$$

By the implicit function theorem (see [6]), to prove the proposition we need to show that, for all $z \in \Omega_{p,\gamma}(\Delta)$, the differential $\mathrm{d}F(z) : T_z\Omega_{p,\gamma} \to L^2([0,1],\mathbb{R})$ is surjective. To this aim, let $h \in L^2([0,1],M)$ be fixed; consider the vector field $V_h = \phi_h \cdot Y$ along z, where ϕ_h is the function

$$\phi_h(t) = e^{-\int_0^t \langle \nabla_Y Y, \dot z \rangle \, \mathrm{d}s} \cdot \left[\int_0^t h(s) \cdot e^{\int_0^s \langle \nabla_Y Y, \dot z \rangle \, \mathrm{d}r} \, \mathrm{d}s \right]. \tag{16}$$

It is easily checked that $\phi_h \in H^1([0,1],\mathbb{R})$ and $\phi_h(0) = 0$, which implies that $V_h \in T_z\Omega_{p,\gamma}$. Moreover, $\mathrm{d}F(z)[V_h] = h$, which proves that $\mathrm{d}F(z)$ is surjective. Finally, for $z \in \Omega_{p,\gamma}(\Delta)$, the tangent space $T_z\Omega_{p,\gamma}(\Delta)$ is given by the kernel of $\mathrm{d}F(z)$, and (13) is proven. □

Remark 2.2. The regularity of the set of horizontal curves joining a fixed point p and a curve γ can be studied alternatively considering the *endpoint mapping* $\Omega_p(\Delta) \ni z \mapsto z(1) \in M$ defined on the set of horizontal curves starting at p. It is well known that $\Omega_p(\Delta)$ has the structure of a smooth Hilbert manifold and that the image of the differential of the endpoint map at the point z contains the distribution $\Delta_{z(1)}$.

By the inverse mapping theorem $\Omega_{p,\gamma}(\Delta)$ is a smooth submanifold of $\Omega_p(\Delta)$ provided that γ is transversal to Δ. Using the same argument, one proves (see [12]) that for distributions Δ of arbitrary rank, the set $\Omega_{P_1,P_2}(\Delta)$ of horizontal paths joining two given submanifolds $P_1, P_2 \subset M$ has the structure of an infinite dimensional Hilbert manifold provided that either P_1 or P_2 is everywhere transversal to Δ.

THEOREM 2.3. *The critical points of E in $\Omega_{p,\gamma}(\Delta)$ are curves of class C^2. They are characterized as the solutions on the interval $[0,1]$ of the following integro-differential equation:*

$$\nabla_{\dot{x}}\dot{x} - \nabla_{\dot{x}}\left(\lambda_x \cdot Y\right) + \lambda_x \cdot (\nabla Y)^*[\dot{x}] = 0, \tag{17}$$

where

$$\lambda_x(t) = e^{\int_0^t \langle \nabla_Y Y, \dot{x}\rangle \,\mathrm{d}s} \cdot \left[\int_t^1 \left\langle \dot{x}, \nabla_{\dot{x}} Y\right\rangle e^{-\int_0^s \langle \nabla_Y Y, \dot{x}\rangle \,\mathrm{d}r}\,\mathrm{d}s\right], \tag{18}$$

and $\dot{x}(0) \in \Delta_p$.

Proof. To determine the integro-differential equation (17)–(18), we argue as follows. Let x be any point in $\Omega_{p,\gamma}(\Delta)$; for all $W \in T_x\Omega_{p,\gamma}$, we define a *projection* V_W of W onto $T_x\Omega_{p,\gamma}(\Delta)$ by setting

$$V_W = W - \psi_W \cdot Y, \tag{19}$$

where

$$\psi_W(t) = e^{-\int_0^t \langle \nabla_Y Y, \dot{x}\rangle \,\mathrm{d}s} \cdot \left[\int_0^t C_W(s) \cdot e^{\int_0^s \langle \nabla_Y Y, \dot{x}\rangle \,\mathrm{d}r}\,\mathrm{d}s\right], \tag{20}$$

and

$$C_W = \left\langle \dot{x}, \nabla_W Y\right\rangle + \left\langle \nabla_{\dot{x}} W, Y\right\rangle = \left\langle W, (\nabla Y)^*[\dot{x}]\right\rangle + \left\langle \nabla_{\dot{x}} W, Y\right\rangle. \tag{21}$$

Observe that, since $\left\langle Y, Y\right\rangle = 1$, then $\left\langle \nabla_{\dot{x}} Y, Y\right\rangle = 0$, and

$$C_Y = \left\langle \dot{x}, \nabla_Y Y\right\rangle.$$

Checking, with the above definitions, that V_W is in $T_x\Omega_{p,\gamma}(\Delta)$ is straightforward, and the details are omitted.

Now, if x is a critical point of E in $\Omega_{p,\gamma}(\Delta)$, it is $\mathrm{d}E(x)[V_W] = 0$ for all $W \in T_x\Omega_{p,\gamma}$, and, since $\left\langle \dot{x}, Y\right\rangle = 0$, (12) gives

$$\begin{aligned} 0 = \mathrm{d}E(x)[W - \psi_W \cdot Y] &= \int_0^1 \left[\left\langle \nabla_{\dot{x}}\left(W - \psi_W \cdot Y\right), \dot{x}\right\rangle\right]\,\mathrm{d}t \\ &= \int_0^1 \left[\langle \nabla_{\dot{x}} W, \dot{x}\rangle - \dot{\psi}_W \cdot \langle Y, \dot{x}\rangle - \psi_W \cdot \langle \nabla_{\dot{x}} Y, \dot{x}\rangle\right]\mathrm{d}t \\ &= \int_0^1 \left[\left\langle \nabla_{\dot{x}} W, \dot{x}\right\rangle - \psi_W \cdot \left\langle \nabla_{\dot{x}} Y, \dot{x}\right\rangle\right]\,\mathrm{d}t. \end{aligned} \tag{22}$$

Now let λ_x be given by (18). Reversing the order of integration with Fubini's theorem and recalling (20) and (21), we get

$$\begin{aligned}
&\int_0^1 \psi_W \cdot \langle \nabla_{\dot x} Y, \dot x\rangle \,\mathrm{d}t \\
&\quad= \int_0^1 \langle \nabla_{\dot x} Y, \dot x\rangle e^{-\int_0^t \langle \nabla_Y Y, \dot x\rangle \,\mathrm{d}r} \cdot \left[\int_0^t C_W(s) e^{\int_0^s \langle \nabla_Y Y, \dot x\rangle \,\mathrm{d}r}\,\mathrm{d}s\right] \mathrm{d}t \\
&\quad= \int_0^1 C_W(s) e^{\int_0^s \langle \nabla_Y Y, \dot x\rangle \,\mathrm{d}r} \cdot \left[\int_s^1 \langle \nabla_{\dot x} Y, \dot x\rangle e^{-\int_0^t \langle \nabla_Y Y, \dot x\rangle \,\mathrm{d}r}\,\mathrm{d}t\right] \mathrm{d}s \\
&\quad= \int_0^1 C_W(s)\cdot \lambda_x(s)\,\mathrm{d}s = \int_0^1 \left[\langle W, (\nabla Y)^*[\dot x]\rangle + \langle \nabla_{\dot x} W, Y\rangle\right]\cdot \lambda_x(s)\,\mathrm{d}s.
\end{aligned} \tag{23}$$

Then (22) becomes

$$\int_0^1 \left[\langle \nabla_{\dot x} W, \dot x\rangle - \lambda_x(s)\cdot \langle \nabla_{\dot x} W, Y\rangle - \lambda_x(s)\cdot \langle W, (\nabla Y)^*[\dot x]\rangle\right]\,\mathrm{d}s = 0. \tag{24}$$

Suppose that x is of class C^2; integrating by parts the terms in (24) containing the covariant derivative $\nabla_{\dot x} W$, we obtain

$$\int_0^1 \langle W, \nabla_{\dot x}(\dot x - \lambda_x \cdot Y) + \lambda_x \cdot (\nabla Y)^*[\dot x]\rangle \,\mathrm{d}t = 0 \tag{25}$$

for all $W \in T_x\Omega_{p,\gamma}$. Observe that there is no boundary term arising from the integration by parts because $W(0) = 0$, $\lambda_x(1) = 0$, and $\langle W(1), \dot x(1)\rangle = 0$. This last equality follows from the fact that $W(1)$ is parallel to $\dot\gamma$, hence to Y, and $\langle \dot x, Y\rangle = 0$.

Since W is arbitrary in (25), the fundamental lemma of calculus of variations tells us that x satisfies (17), and we have proven that the critical points of E in $\Omega_{p,\gamma}(\Delta)$ satisfy the integro-differential problem (17)–(18).

The C^2-regularity of the critical points of E is obtained by a bootstrap argument. If $x \in \Omega_{p,\gamma}(\Delta)$ is a critical point of E, then (24) holds for any C^∞ vector field W along x such that $W(0) = W(1) = 0$. If Z is a vector field of class L^2, let us denote by $\int_0^s Z\,\mathrm{d}s$ the vector field U solving

$$\begin{cases} \nabla_{\dot x} U = Z, \\ U(0) = 0. \end{cases} \tag{26}$$

From now on, all the integrals of vector fields along curves will be understood in this sense. Using a local coordinate system and Gronwall's lemma, it is easily seen that $U \in H^1$ and, therefore, $U \in C^0$.

Note that $\dot x \in L^2$ and $\lambda_x \in C^0$. Integrating by parts the last term inside the integral in (24) (and recalling that W vanishes at both endpoints of x), we get

$$\begin{aligned}
0 &= \int_0^1 \langle \nabla_{\dot x} W, \dot x - \lambda_x(s) Y\rangle - \langle W, \lambda_x(s)(\nabla Y)^*[\dot x]\rangle \mathrm{d}s \\
&= \int_0^1 \left\langle \nabla_{\dot x} W, \dot x - \lambda_x(s) Y + \left[\int_0^s \lambda_x(t)(\nabla Y)^*[\dot x]\,\mathrm{d}t\right]\right\rangle \,\mathrm{d}s.
\end{aligned} \tag{27}$$

Set

$$\chi(s) = \dot x(s) - \lambda_x(s) Y(x(s)) + \int_0^s \lambda_x(t)(\nabla Y)^*[\dot x(t)]\,\mathrm{d}t.$$

Using local coordinates and Christoffel symbols, we obtain by (27) $\chi \in H^1$ and, in particular, $\chi \in C^0$. Since λ_x and Y are C^0, we deduce $\dot{x} \in C^0$. Then λ_x, Y, $\int_0^s \lambda_x(t)(\nabla Y)^*[\dot{x}]\ \mathrm{d}t$ are C^1, while, by (27), $\chi \in C^1$. Hence $\dot{x}$ is C^1, obtaining the desired regularity.

Conversely, if x is a solution of (17)–(18) such that $\dot{x}(0) \in \Delta$, then x is a horizontal curve. Namely, using (17), we compute

$$\begin{aligned} \frac{\mathrm{d}}{\mathrm{d}t}\langle \dot{x}, Y\rangle &= \langle \nabla_{\dot{x}}\dot{x}, Y\rangle + \langle \dot{x}, \nabla_{\dot{x}} Y\rangle \\ &= \lambda_x' - \lambda_x\langle \nabla_Y Y, \dot{x}\rangle + \langle \dot{x}, \nabla_{\dot{x}} Y\rangle = 0, \end{aligned} \tag{28}$$

where the last equality is due to (18). Hence, if $\langle \dot{x}(0), Y\rangle = 0$, then $\langle \dot{x}, Y\rangle \equiv 0$. Moreover, it is easy to see that all elements $V \in T_x\Omega_{p,\gamma}(\Delta)$ are of the form V_W given in formula (19). Indeed, since $C_V = 0$, we can choose $W = V$ and $\psi_W = 0$. So every solution x of (17)–(18) such that $x(0) = p$ and $\dot{x}(0) \in \Delta_p$ is a critical point of E in $\Omega_{p,\gamma}(\Delta)$. This concludes the proof. ∎

Remark 2.4. Observe that, by (28), a solution $(x(t), \lambda_x(t))$ of the system (8) satisfies the conservation law $\langle \dot{x}(t), Y(x(t))\rangle = 0$.

We remark that the map λ_x in Theorem 2.3 can be interpreted as the *Lagrangian multiplier* of the constrained critical point x in $\Omega_{p,\gamma}(\Delta)$ (see Lemma A.1).

COROLLARY 2.5. *If x is a critical point of E in $\Omega_{p,\gamma}(\Delta)$, then it satisfies the conservation law:*

$$|\dot{x}| \equiv \text{const}. \tag{29}$$

Proof. Taking the product of (17) by $\dot{x}$, we obtain

$$\begin{aligned} 0 &= \langle \nabla_{\dot{x}}\dot{x}, \dot{x}\rangle - \lambda_x' \cdot \langle Y, \dot{x}\rangle - \lambda_x \cdot \langle \nabla_{\dot{x}} Y, \dot{x}\rangle + \lambda_x \cdot \langle \nabla_{\dot{x}} Y, \dot{x}\rangle \\ &= \langle \nabla_{\dot{x}}\dot{x}, \dot{x}\rangle = \frac{1}{2}\frac{\mathrm{d}}{\mathrm{d}t}\langle \dot{x}, \dot{x}\rangle, \end{aligned} \tag{30}$$

which proves the claim. ∎

3. Minimal curves for L. In this section, we show the existence of a minimum for the energy functional E in $\Omega_{p,\gamma}(\Delta)$, whose regularity has already been proven in Theorem 2.3. To this aim, we show that E satisfies a good enough compactness property, namely the Palais–Smale condition. Proposition 1.1, which establishes the relation between minimal points for E and sub-Riemannian length minimizers can be obtained easily by standard arguments.

We recall, given a C^1 functional $\mathfrak{f} : \mathfrak{X} \to \mathbb{R}$ on a Hilbert manifold $\mathfrak{X}$, that $\mathfrak{f}$ is said to satisfy the *Palais–Smale condition* at level $c \in \mathbb{R}$ if every sequence $\{x_n\}_{n\in\mathbb{N}} \subset \mathfrak{X}$ such that

$$\begin{aligned} &\lim_{n\to\infty} \mathfrak{f}(x_n) = c, \\ &\lim_{n\to\infty} \|\mathrm{d}\mathfrak{f}(x_n)\| = 0 \end{aligned} \tag{31}$$

(where $\|\cdot\|$ denotes the norm of bounded linear functionals on the Hilbert space $T_{x_n}\mathfrak{X}$) has a subsequence converging in $\mathfrak{X}$. We will use throughout the paper some well-known results concerning functionals satisfying the Palais–Smale condition (see, for instance, the proofs of Corollary 3.2 and Theorem 1.8); for the reader's convenience, we will briefly give a formal statement of these properties when they are used.

PROPOSITION 3.1. *The functional E satisfies the Palais–Smale condition at every level $c \in \mathbb{R}$.*

Proof. Let $\{x_n\}_{n\in\mathbb{N}}$ be a sequence in $\Omega_{p,\gamma}(\Delta)$ satisfying (31). Since M is complete and $\int_0^1 \langle \dot{x}_n, \dot{x}_n\rangle \mathrm{d}t \leq \text{const.}$, up to subsequences we can assume that x_n is convergent to some curve x uniformly and $\dot{x}_n$ is weakly convergent to $\dot{x}$ in L^2. Observe that $x \in \Omega_{p,\gamma}(\Delta)$; the fact that $x(1) \in \mathrm{I}m(\gamma)$ follows from our assumption that $\mathrm{I}m(\gamma)$ is closed in M.

Then (31) yields

$$\int_0^1 \left\langle \dot{x}_n, \nabla_{\dot{x}_n}\zeta \right\rangle \mathrm{d}t = \int_0^1 \left\langle a_n, \nabla_{\dot{x}_n}\zeta \right\rangle \mathrm{d}t \tag{32}$$

for every admissible variation ζ and for some sequence a_n converging to 0 in L^2. Then, with a similar argument as in Theorem 2.3, (32) gives the existence of a sequence b_n converging to 0 in L^2 such that

$$\dot{x}_n - b_n - \varphi_{x_n} Y(x_n) + \int_0^s \varphi_{x_n} \cdot (\nabla Y)^*[\dot{x}_n]\,\mathrm{d}t = z_n, \tag{33}$$

where

$$\varphi_{x_n}(\tau) = \int_\tau^1 \left\langle \dot{x}_n, \nabla_{\dot{x}_n} Y(x_n)\right\rangle e^{\int_\sigma^\tau \langle \dot{x}_n, \nabla_{Y(x_n)}Y(x_n)\rangle\,\mathrm{d}\rho}\,\mathrm{d}\sigma, \tag{34}$$

and z_n is a sequence in L^2 such that $\nabla_{\dot{x}_n} z_n = 0$. From (34), φ_{x_n} is uniformly bounded in L^∞, and it has uniformly bounded derivative in L^1. Moreover, the covariant integral V_n,

$$V_n = \int_0^s A_n\,\mathrm{d}t, \quad A_n = \varphi_{x_n} \cdot (\nabla Y)^*[\dot{x}_n], \tag{35}$$

solves the equation

$$\begin{cases} \nabla_{\dot{x}_n} V_n = A_n, \\ V_n(0) = 0; \end{cases} \tag{36}$$

since $\dot{x}_n$ is uniformly bounded in L^2, using the coordinate expression of (36), we have that V_n is uniformly bounded in L^∞, and $\dot{V}_n$ is uniformly bounded in L^2; then V_n is uniformly bounded in H^1.

The uniform boundedness of z_n in L^2 implies the existence of a sequence $s_n \in [0,1]$ such that $z_n(s_n)$ is bounded. Using again the coordinate expression for the equation

$$\begin{cases} \nabla_{\dot{x}_n} z_n = 0, \\ z_n(s_n) = B_n, \end{cases} \tag{37}$$

with B_n bounded, we obtain that z_n is uniformly bounded in H^1.

In conclusion, (33) yields the existence of a sequence c_n which is uniformly bounded in L^∞ and has uniformly bounded derivative in L^1 such that

$$\dot{x}_n - b_n = c_n. \tag{38}$$

But c_n has a converging subsequence in L^2 (see [2]), and b_n converges to 0 in L^2; these two facts imply that $\dot{x}_n$ has a converging subsequence in L^2, and then E satisfies the Palais–Smale condition at every level $c \in \mathbb{R}$. ∎

We are now ready to prove the existence of a minimizer for E:

COROLLARY 3.2. *The functional E attains its minimum in $\Omega_{p,\gamma}(\Delta)$.*

Proof. This is a classical argument of calculus of variations, repeated here for the reader's convenience. Suppose that we are given a (possibly infinite dimensional) complete Hilbert manifold $\mathfrak{X}$ and a smooth functional $\mathfrak{f} : \mathfrak{X} \to \mathbb{R}$ satisfying the Palais–Smale condition at every level $c \in \mathbb{R}$. For $c \in \mathbb{R}$, let $\mathfrak{f}^c = \{x \in \mathfrak{X} : \mathfrak{f}(x) \leq c\}$ denote the closed c-sublevel of $\mathfrak{f}$. If $c_0 \in \mathbb{R}$ is *not* a critical value of $\mathfrak{f}$, then there exists $\eta > 0$ such that $\mathfrak{f}^{c_0-\eta}$ is homeomorphic to $\mathfrak{f}^{c_0+\eta}$ (see, e.g., [11]); such a homeomorphism can be given explicitly using the flow of the gradient of $\mathfrak{f}$. It follows that $\mathfrak{f}$ attains its minimum if $\mathfrak{f}$ is bounded from below; namely, if $c_0 = \inf \mathfrak{f}$ were not a critical value, then $\mathfrak{f}^{c_0-\eta} = \emptyset$ would be homeomorphic to $\mathfrak{f}^{c_0+\eta} \neq \emptyset$.

In our situation, we have that the Hilbert manifold $\mathfrak{X} = \Omega_{p,\gamma}(\Delta)$ is complete because (M, g) is complete and because $\mathrm{Im}(\gamma)$ is closed in M; the functional $\mathfrak{f} = E$ satisfies the Palais–Smale condition by Proposition 3.1, and it is clearly bounded from below. The conclusion follows. □

Proof of Proposition 1.1. It follows easily from the existence of a minimizer of E and a reparameterization argument. □

Also, the proof of Theorems 1.2 and 1.3 is a straightforward consequence of Proposition 1.1, Theorem 2.3 and Corollary 2.5.

Proof of Theorem 1.8. It is a classical argument of the theory of Ljusternik and Schnirelman (see [11] for details). We recall briefly the main ideas of the theory; assume that $\mathfrak{X}$ is a complete Hilbert manifold and that $\mathfrak{f} : \mathfrak{X} \to \mathbb{R}$ is a smooth functional satisfying the Palais–Smale condition at every level $c \in \mathbb{R}$ which is bounded from below. Then one proves the following facts:

1. for every $c \in \mathbb{R}$, the Ljusternik–Schnirelman category $\mathrm{cat}_{\mathfrak{X}}(\mathfrak{f}^c)$ of the sublevel $\mathfrak{f}^c$ is finite;
2. if there exists $c \in \mathbb{R}$ such that $\sup\{\mathfrak{f}(z) : \mathfrak{f}'(z) = 0\} < c$, then $\mathrm{cat}_{\mathfrak{X}}(\mathfrak{f}^c) = \mathrm{cat}(\mathfrak{X})$;
3. if $c \in \mathbb{R}$ as in (2) does not exist, then there exists a sequence $\{x_n\}$ of critical points such that $\mathfrak{f}(x_n) \to +\infty = \sup \mathfrak{f}$;
4. if, on the contrary, such a c exists, let Γ_k denote the collection of closed subsets A of $\mathfrak{X}$ whose Ljusternik–Schnirelman category $\mathrm{cat}_{\mathfrak{X}}(A)$ is greater than or equal to k. Then there exists $c \in \mathbb{R}$ such that $\mathfrak{f}^c \in \Gamma_k$ for all $k = 1, \ldots, \mathrm{cat}(\mathfrak{X})$. Since $\sup \mathfrak{f} > -\infty$, one can define the following (possibly finite) sequence of real numbers:
$$c_k = \inf_{A \in \Gamma_k} \left[\sup_{x \in A} \mathfrak{f}(x) \right], \qquad k = 1, 2, \ldots, \mathrm{cat}(\mathfrak{X}); \tag{39}$$
5. each c_k is a critical value of $\mathfrak{f}$; moreover, if for some k and $r > 0$ one has $c_k = c_{k+1} = \cdots = c_r$, then there are at least $r + 1$ critical points in $\mathfrak{f}^{-1}(c_k)$.

By the facts above, one concludes easily that $\mathfrak{f}$ has at least $\mathrm{cat}(\mathfrak{X})$ critical points.

Now, the proof of Theorem 1.8 is an application of the above theory in the case that $\mathfrak{X} = \Omega_{p,\gamma}(\Delta)$ and $\mathfrak{f} = E$, keeping in mind the results of Theorem 2.3 and of Proposition 3.1. □

Finally, we conclude the section with a result that relates the topology of the spaces $\Omega_{p,\gamma}(\Delta)$ and $\Omega_{p,\gamma}$; the latter space is in general an easier object to deal with.

PROPOSITION 3.3. *Assume that the vector field Y is complete on M, and denote by $\psi : M \times \mathbb{R} \to \mathcal{M}$ its flow, i.e., for all $q \in M$, $t \mapsto \psi(q, t)$ is the maximal integral line of Y passing through q at the instant $t = 0$; let $\mathrm{d}_x\psi(q, t)$ denote the differential of the map $m \mapsto \psi(m, t)$ at the point q.*

Assume that there exist continuous maps $A, B : M \to \mathbb{R}^+$ such that the following estimate holds for the norm of $\mathrm{d}_x\psi$:

$$\|\mathrm{d}_x\psi(q,r)\| \le A(q)\cdot|r| + B(q) \quad \textit{for all } (q,r)\in M\times\mathbb{R}. \tag{40}$$

Then there exists a strong deformation retract[1] *from $\Omega_{p,\gamma}$ to $\Omega_{p,\gamma}(\Delta)$; in particular, $\Omega_{p,\gamma}$ and $\Omega_{p,\gamma}(\Delta)$ have the same homotopy type and the same Ljusternik–Schnirelman category.*

Proof. Given an H^1 map $\mu : [0,1] \to \mathbb{R}$ with $\mu(0) = 0$ and a curve $z \in \Omega_{p,\gamma}$, denote by $\mathfrak{c}(z,\mu) \in \Omega_{p,\gamma}$ the curve $t \mapsto \psi\big(z(t),\mu(t)\big)$; clearly, if $\mu \equiv 0$ on $[0,1]$, then $\mathfrak{c}(z,\mu) = z$.

For $z \in \Omega_{p,\gamma}$, denote by $\mu_z : [0,1] \to \mathbb{R}$ the solution of the initial value problem:

$$\mu_z'(t) = -\langle \mathrm{d}_x\psi\big(z(t),\mu_z(t)\big)[\dot z(t)], Y\big(\psi\big(z(t),\mu_z(t)\big)\big)\rangle, \quad \mu_z(0) = 0. \tag{41}$$

The existence of a global solution on the interval $[0,1]$ of (41) follows easily using the estimate (40), observing that z and $\langle Y, Y\rangle$ are bounded and $\dot z \in L^2$.

By standard continuous dependence arguments for ordinary differential equations, the map $\Omega_{p,\gamma} \ni z \mapsto \mu_z \in \mathcal{H}^1([0,1],\mathbb{R})$ is continuous; therefore, we get a continuous map $\Omega_{p,\gamma} \ni z \mapsto \mathfrak{c}(z,\mu_z) \in \Omega_{p,\gamma}$.

Now, using (41), it is easily seen that $\mathfrak{c}(z,\mu_z)$ is almost everywhere orthogonal to Y, and hence $\mathfrak{c}(z,\mu_z) \in \Omega_{p,\gamma}(\Delta)$ for all $z \in \Omega_{p,\gamma}$. A strong deformation retract $h : \Omega_{p,\gamma}\times[0,1] \to \Omega_{p,\gamma}$ from $\Omega_{p,\gamma}$ to $\Omega_{p,\gamma}(\Delta)$ is then obtained by setting

$$h(z,s) = \mathfrak{c}(z, s\cdot\mu_z). \qquad \square$$

For instance, the assumptions of Proposition 3.3 hold if Y is a complete Killing vector field in (M,g), in which case $\mathrm{d}_x\psi$ is an isometry. More generally, if Y is of the form $Y = \langle W,W\rangle^{-\frac{1}{2}}W$ for some *conformal* vector field, then the inequality (40) is satisfied when $\langle W,W\rangle$ is bounded on each integral line of W. Recall that a smooth vector field W on M is conformal if its flow consists of conformal (i.e., angle preserving) maps; equivalently, W is conformal if the Lie derivative $\mathcal{L}_W(g)$ of the metric g is conformally equivalent to g, i.e., of the form $\phi\cdot g$ for some smooth map $\phi : M \to \mathbb{R}^+$.

4. Local theory: The exponential map. In this section, we study the flow on M defined by the integro-differential equation (6), with the aim of proving the local uniqueness of sub-Riemannian length minimizers between a point and an integral line of y.

We start by proving an existence and uniqueness result for local solutions of (6).

PROPOSITION 4.1. *Let $p \in M$ and $v_0 \in T_pM$; suppose that $|v_0|$ is sufficiently small. Then there exists a unique solution of the integro-differential equation* (17)–(18) *satisfying the initial conditions $x(0) = p$ and $\dot x(0) = v_0$.*

Proof. As we have observed in Corollary 2.5, the solutions of the integro-differential problem satisfy $|\dot x| = \text{const.}$, and hence all the solutions of our initial value problem remain inside a ball of radius b around the point p. Using local coordinates, we may therefore assume that $M = \mathbb{R}^n$, $p = 0$.

[1]Recall that, given a topological space $\mathcal{X}$ and a subspace $\mathcal{Y} \subset \mathcal{X}$, a strong deformation retract from $\mathcal{X}$ to $\mathcal{Y}$ is a continuous map $h : \mathcal{X}\times[0,1] \to \mathcal{X}$ such that $h(x,0) = x$ for all $x \in \mathcal{X}$, $h(y,s) = y$ for all $(y,s) \in \mathcal{Y}\times[0,1]$, and $h(x,1) \in \mathcal{Y}$ for all $x \in \mathcal{X}$.

For all $v_1, v_2, v_3 \in \mathbb{R}^n$, we set

$$A(v_1)[v_2] = (\nabla_{v_2} Y)(v_1) - (\nabla Y)^*[v_2](v_1) + \big\langle v_2, \nabla_{Y(v_1)} Y \big\rangle\, Y \tag{42}$$

and

$$B(v_1)[v_2, v_3] = -\Gamma(v_1)[v_2, v_3] - \big\langle v_2, \nabla_{v_3} Y \big\rangle_{v_1}, \tag{43}$$

where $\Gamma(q)[\cdot,\cdot] : \mathbb{R}^n \times \mathbb{R}^n \to \mathbb{R}^n$ is the bilinear map given by the Christoffel symbols at the point q of the metric g in local coordinates. Observe that $B(x)[z,z]$ is continuous in x and bilinear in z, while $A(x)[z]$ is continuous in x and linear in z. We now consider the map

$$G : C^0([0,1],\mathbb{R}^n) \times C^0([0,1],\mathbb{R}^n) \times \mathbb{R}^n \to C^0([0,1],\mathbb{R}^n) \times C^0([0,1],\mathbb{R}^n) \tag{44}$$

given by $G = (G_1, G_2)$, where

$$G_1(z,x,v)(t) = z(t) - v - \int_0^t [B(x)[z,z] + \Lambda(z,x)\, A(x)[z]]\, \mathrm{d}t, \tag{45}$$

$$G_2(z,x,v)(t) = x(t) - \int_0^t z\, \mathrm{d}s, \tag{46}$$

the maps A and B are defined in (42) and (43), and, finally,

$$\Lambda(z,x)(t) = e^{\int_0^t \langle \nabla_Y Y, z\rangle\, \mathrm{d}s} \cdot \left[\int_t^1 \big\langle z, \nabla_z Y \big\rangle e^{-\int_0^s \langle \nabla_Y Y, z\rangle\, \mathrm{d}r}\, \mathrm{d}s \right]. \tag{47}$$

Clearly, G is of class C^1, and $G(0,0,0) = 0$.

An elementary calculation shows that $(z, x, w_0) \in G^{-1}(0)$ if and only if x is of class C^2, $z = \dot{x}$, and x is a solution for the integro-differential problem (17)–(18) satisfying $x(0) = p$ and $\dot{x}(0) = z(0) = w_0$. Once we prove that the Jacobian

$$\frac{\partial G}{\partial (z,x)}(0,0,0) : C^0([0,1],\mathbb{R}^{2n}) \to C^0([0,1],\mathbb{R}^{2n}) \tag{48}$$

is invertible, there exists, for v sufficiently small, a C^1 map

$$v \mapsto (z_v, x_v) \tag{49}$$

such that

$$G(z_v, x_v, v) = 0. \tag{50}$$

To prove this, we differentiate formally the maps (45) and (46) at a generic point (z,x,v) in the direction (ω,ξ), obtaining

$$\begin{aligned} &\frac{\partial G_1}{\partial z}(z,x,v)[\omega] + \frac{\partial G_1}{\partial x}(z,x,v)[\xi] \\ &= \omega(t) - \int_0^t \left[\frac{\mathrm{d}B}{\mathrm{d}x}[\xi][z,z] + B(x)[\omega,z] + B(x)[z,\omega] + \frac{\partial \Lambda}{\partial z}[\omega]\, A(x)[z] \right] \mathrm{d}s \\ &\qquad - \int_0^t \left[\frac{\partial \Lambda}{\partial x}[\xi]\, A(x)[z] + \Lambda(z,x)\, \frac{\mathrm{d}A}{\mathrm{d}x}[\xi][z] + \Lambda(z,x)\, A(x)[\omega] \right] \mathrm{d}s \end{aligned} \tag{51}$$

and

$$\frac{\partial G_2}{\partial z}(z,x,v)[\omega] + \frac{\partial G_2}{\partial x}(z,x,v)[\xi] = \xi(t) - \int_0^t \omega \, \mathrm{d}s. \tag{52}$$

When we evaluate (51) and (52) at $(z,x,v) = (0,0,0)$, considering the linearity of the above functions in the variables between brackets and the fact that $\Lambda(0,0) = 0$, we obtain the following simple expression for the Jacobian (48):

$$\frac{\partial G}{\partial(z,x)}(0,0,0)[\omega,\xi] = \left(\omega, \xi - \int_0^t \omega \, \mathrm{d}s\right). \tag{53}$$

Clearly, this is an invertible map, whose inverse is easily computed as

$$\left(\frac{\partial G}{\partial(z,x)}(0,0,0)\right)^{-1}[\omega,\xi] = \left(\omega, \xi + \int_0^t \omega \, \mathrm{d}s\right). \tag{54}$$

This proves that the pair (z_v, x_v) and, in particular, the curve x_v depend regularly on v for v small enough such that (49) is well defined. □

By Proposition 4.1, for all $p \in M$ there exists a neighborhood $\mathcal{U}_p$ of 0 in T_pM such that for all $v \in \mathcal{U}_p$ the integro-differential equation (17)–(18) admits a unique solution x_v satisfying $x_v(0) = p$ and $\dot{x}_v(0) = v$. We can therefore define the following *exponential map* $\mathfrak{exp}_p : \mathcal{U}_p \to M$ by

$$\mathfrak{exp}_p(v) = x_v(1). \tag{55}$$

PROPOSITION 4.2. *For all $p \in M$, $\mathfrak{exp}_p$ is a local diffeomorphism between an open neighborhood of 0 in T_pM and an open neighborhood of p in M. In particular, $\mathfrak{exp}_p$ gives a local diffeomorphism between a neighborhood of 0 in Δ_p and a hypersurface Σ_p of M through p, with $T_p\Sigma_p = \Delta_p$, which is transversal to Y.*

Proof. From Proposition 4.1 we know that $\mathfrak{exp}_p$ is a map of class C^1 around $v = 0$; we now show that its differential $\mathrm{d}\mathfrak{exp}_p(0)$ is the *identity map* on T_pM.

From the implicit function theorem, the differential at $v = 0$ of the map $v \mapsto (z_v, x_v)$ is given by

$$-\left(\frac{\partial G}{\partial(z,x)}(0,0,0)\right)^{-1} \circ \frac{\partial G}{\partial v}(0,0,0),$$

which is easily computed from (45), (46), and (54) as

$$-\left(\frac{\partial G}{\partial(z,x)}(0,0,0)\right)^{-1}\left[\frac{\partial G}{\partial v}(0,0,0)[w]\right] = (w, w\cdot t) \quad \text{for all } w \in \mathbb{R}^n. \tag{56}$$

The derivative of $\mathfrak{exp}_p$ at $v = 0$ in the direction w is given by the evaluation at $t = 1$ of the second component of (56). Hence $\mathrm{d}\mathfrak{exp}_p(0)[w] = w$ and $\mathfrak{exp}_p$ is a local diffeomorphism in a neighborhood $\mathcal{U}_p$ of $0 \in T_pM$, which proves the first part of the statement.

Since Δ_p is a vector subspace of codimension one in T_pM, it follows that the image Σ_p of $\Delta_p \cap \mathcal{U}_p$ through $\mathfrak{exp}_p$ is a codimension one submanifold of M. Since $\mathrm{d}\mathfrak{exp}_p(0)$ is the identity map, it follows that $T_p\Sigma_p = \Delta_p$; moreover, since γ is transversal to Δ_p, by continuity every flow line of Y will be a transversal to Σ_p around the point p, and this concludes the proof. □

Proof of Theorem 1.9. If γ is sufficiently close to p, then, by the transversality, γ intercepts exactly once the hypersurface Σ_p of Proposition 4.2. The conclusion follows immediately from Propositions 1.1 and 4.1. ∎

Appendix A. The method of Lagrange multipliers. In this short appendix, we use the method of Lagrange multipliers to study the solutions of our variational problem, and we show that the map λ_x of formula equation (5) and the integro-differential equation (6) appear naturally also in this context.

We recall that $x \in \Omega_{p,\gamma}(\Delta)$ is a *constrained* critical point of E if and only if there exists a function $\lambda_x \in L^2([0,1],\mathbb{R})$ such that x is a *free* critical point in $\Omega_{p,\gamma}$ for the functional E_{λ_x} defined by

$$E_{\lambda_x}(z) = E(z) - \int_0^1 \lambda_x \cdot \langle \dot{z}, Y \rangle \, \mathrm{d}t. \tag{57}$$

In this case, the function λ_x is necessarily unique, and it is called the *Lagrange multiplier* associated to x.

We have the following.

LEMMA A.1. *Let $x \in \Omega_{p,\gamma}(\Delta)$ be a critical point for E. Then the corresponding Lagrange multiplier λ_x is a C^2-function given by*

$$\lambda_x(t) = e^{\int_0^t \langle \dot{x}, \nabla_Y Y \rangle \, \mathrm{d}s} \cdot \left[\int_t^1 \langle \dot{x}, \nabla_{\dot{x}} Y \rangle e^{-\int_0^s \langle \dot{x}, \nabla_Y Y \rangle \, \mathrm{d}r} \, \mathrm{d}s \right]. \tag{58}$$

Proof. The condition that x is a constrained critical point for E is that the following equation is satisfied for all $V \in T_x\Omega_{p,\gamma}$:

$$\int_0^1 \left[\langle \dot{x}, \nabla_{\dot{x}} V \rangle - \lambda_x \left(\langle \nabla_{\dot{x}} V, Y \rangle + \langle \dot{x}, \nabla_V Y \rangle \right) \right] \, \mathrm{d}t = 0. \tag{59}$$

Taking the covariant integral of $\lambda_x (\nabla Y)^*[\dot{x}]$ vanishing at $s = 1$, we see that $\dot{x} - \lambda_x Y$ is of class C^0. Taking its scalar product with Y, we obtain that λ_x is of class C^0, and therefore $\dot{x}$ is C^0. Repeating the above argument, we have also that $\dot{x}$ is C^1.

At this point, integration by parts in (59) of the terms containing the covariant derivative $\nabla_{\dot{x}} V$ gives

$$\int_0^1 \langle -\nabla_{\dot{x}} \dot{x} + \nabla_{\dot{x}} (\lambda_x \cdot Y) - \lambda_x (\nabla Y)^*[\dot{x}], V \rangle \, \mathrm{d}t - \lambda_x(1) \langle V(1), Y(x(1)) \rangle = 0. \tag{60}$$

Since $V(1)$ is arbitrary, it is easy to see that (60) is satisfied for all $V \in T_x\Omega_{p,\gamma}$ if and only if the following two equations are satisfied:

$$-\nabla_{\dot{x}} \dot{x} + \nabla_{\dot{x}} (\lambda_x \cdot Y) - \lambda_x \cdot (\nabla Y)^*[\dot{x}] = 0, \quad \lambda_x(1) = 0. \tag{61}$$

Taking the product of the differential equation in (61) by Y and considering that, since $\langle \dot{x}, Y \rangle \equiv 0$, it is

$$-\langle \nabla_{\dot{x}} \dot{x}, Y \rangle = \langle \dot{x}, \nabla_{\dot{x}} Y \rangle,$$

we obtain the following Cauchy problem for λ_x (recall that $\langle Y, Y \rangle = 1$):

$$\begin{cases} \lambda_x' - \lambda_x \cdot \langle \dot{x}, \nabla_Y Y \rangle + \langle \dot{x}, \nabla_{\dot{x}} Y \rangle = 0, \\ \lambda_x(1) = 0. \end{cases} \tag{62}$$

The unique solution of (62) is (58), and this concludes the proof. ∎

Appendix B. The system (8) is equivalent to Hamilton's equations of normal geodesics. Using the Pontryagin maximum principle, one proves (see, for instance, [7, Appendix B]) that a sub-Riemannian extremizer either is abnormal or satisfies the Hamilton equations of the Hamiltonian $H : TM^* \to \mathbb{R}$ given by

$$H(q,p) = \frac{1}{2} g^{-1}\big(p|_\Delta, p|_\Delta\big), \tag{63}$$

where $g^{-1} : \Delta^* \times \Delta^* \to \mathbb{R}$ is the metric induced by $g|_\Delta$ on Δ^*. In this appendix, we will show that (5) and (6) (or, equivalently, system (8)) are, in fact, equivalent to the Hamilton equations of H.

A convenient setup for this calculation is obtained by identifying the tangent bundle TM with the cotangent bundle TM^* using the metric g and considering the pull-back of the canonical symplectic form ω of TM^*. If $\pi_\Delta : TM \to \Delta$ denotes the orthogonal projection, the sub-Riemannian Hamiltonian (63) is given as a map $H : TM \to \mathbb{R}$ by

$$H = \frac{1}{2} \left\langle \pi_\Delta(u), \pi_\Delta(u) \right\rangle, \quad u \in TM;$$

since $\Delta = Y^\perp$ and $g(Y,Y) = 1$,

$$\pi_\Delta(u) = u - \langle u, Y \rangle\, Y$$

for all $u \in TM$.

Let us consider the horizontal subspace $T_{\mathrm{hor}}\big(TM\big)$ of $T(TM)$ determined by the Levi–Civita connection of g, and let us write

$$T(TM) = T_{\mathrm{hor}}\big(TM\big) \oplus T_{\mathrm{ver}}\big(TM\big),$$

where $T_{\mathrm{ver}}\big(TM\big)$ is the vertical subspace of $T(TM)$, i.e., the subspace tangent to the fibers of TM. For $v_1, v_2 \in T_{\mathrm{hor}}\big(TM\big)$ and $w_1, w_2 \in T_{\mathrm{ver}}\big(TM\big)$, the canonical symplectic form is given by

$$\omega\big((v_1,w_1),(v_2,w_2)\big) = \langle v_1, w_2 \rangle - \langle w_1, v_2 \rangle.$$

Given a smooth curve $(x,u) : [0,1] \to TM$, the Hamilton equations are then written as

$$\begin{cases} \dot{x} = \vec{H}_{\mathrm{hor}}, \\ \\ \nabla_{\dot{x}} u = \vec{H}_{\mathrm{ver}}, \end{cases} \tag{64}$$

where $\vec{H}$ is the Hamiltonian vector field defined by $\mathrm{d}H = \omega\big(\vec{H}, \cdot\big)$ and $\vec{H}_{\mathrm{hor}}$ and $\vec{H}_{\mathrm{ver}}$ are, respectively, its horizontal and vertical components in $T(TM)$. Moreover, a sub-Riemannian minimizer between a point $p \in M$ and an integral curve of γ must satisfy the boundary conditions

$$x(0) = p, \qquad u(1) \perp Y(x(1)). \tag{65}$$

In order to obtain an explicit expression for the components of $\vec{H}$, we compute as follows. For $u \in TM$, let $t \mapsto z(t)$ be a parallel vector field along a curve in M with velocity v at $t = 0$ and such that $z(0) = u$; then

$$\mathrm{d}H_u(v,0) = \frac{\mathrm{d}}{\mathrm{d}t} \left[\frac{1}{2} \big\langle z - \langle z, Y \rangle Y, z - \langle z, Y \rangle Y \big\rangle \right] = -\langle u, Y \rangle \, \langle u, \nabla_v Y \rangle;$$

moreover,

$$\mathrm{d}H(0,w) = \mathrm{d}\big(H|_{T_{\mathrm{ver}}(TM)}\big)(w) = \big\langle u - g(u,Y)\,Y, w\big\rangle.$$

Hence we get

$$\vec{H}_{\mathrm{ver}} = \langle u, Y\rangle\,(\nabla Y)^*[u], \quad \vec{H}_{\mathrm{hor}} = u - \langle u, Y\rangle\,Y,$$

and (64) becomes

$$\begin{cases} \dot{x} = u - \langle u, Y\rangle\,Y, \\ \\ \nabla_{\dot{x}} u = \langle u, Y\rangle\,(\nabla Y)^*[u]. \end{cases} \tag{66}$$

Setting $\lambda = -\langle u, Y\rangle$, we get from (66)

$$\nabla_{\dot{x}}\dot{x} - \lambda' Y - \lambda\nabla_{\dot{x}} Y = -\lambda\big((\nabla Y)^*[\dot{x}] + \lambda(\nabla Y)^*[Y]\big). \tag{67}$$

Now, since $g(Y,Y) \equiv 1$, we have $(\nabla Y)^*[Y] = 0$, and hence we get

$$\nabla_{\dot{x}}\dot{x} - \lambda' Y - \lambda\nabla_{\dot{x}} Y = -\lambda\,(\nabla Y)^*[\dot{x}]. \tag{68}$$

Multiplying (68) by Y and using the relation $\big\langle \nabla_{\dot{x}}\dot{x}, Y\big\rangle = -\big\langle \dot{x}, \nabla_{\dot{x}} Y\big\rangle$, we get

$$-\big\langle \dot{x}, \nabla_{\dot{x}} Y\big\rangle - \lambda' = -\lambda\big\langle \nabla_Y Y, \dot{x}\big\rangle. \tag{69}$$

Moreover, the boundary condition $\langle u(1), Y(x(1))\rangle = 0$ in (65) gives

$$\lambda(1) = 0; \tag{70}$$

now (68), (69), and (70) are clearly the same as (5) and (6).

Acknowledgments. We wish to thank the referees for their very useful comments and suggestions.

A CONSTRAINT ON THE MAXIMUM REFLECTANCE OF RAPIDLY OSCILLATING DIELECTRIC GRATINGS*

GANG BAO†, DAVID C. DOBSON‡, AND KARIM RAMDANI†

Abstract. When considering optimal design problems involving diffraction gratings, it is useful to have some a priori characterization of the range of possible reflectances one can achieve for given material parameters. Here we consider the limiting case of a rapidly oscillating dielectric grating and show that such gratings can have reflectance no greater than that of a flat interface, regardless of the shape of the grating interface.

Key words. diffraction grating, optimal design, maximum reflectance

1. Introduction.

A diffraction grating is formed by a periodic interface separating two homogeneous materials. In practical applications, one wishes to design the shape of the interface so that time-harmonic waves incident on the interface have a desired reflection and transmission pattern. Such design problems can be solved, for example, by optimization techniques [7] and homogenization [2]. An important question arising in this context is as follows: Given a particular class of admissible designs (interface shapes), which reflection and transmission patterns are attainable? In this paper we provide an answer in the case of *blazed* gratings (i.e., interfaces which can be represented by the graph of a function), which are rapidly oscillating with respect to the incident wavelength. The gratings are required to be dielectric. The basic result is a constraint on the reflectance, which says that in the limit as the grating period goes to zero the grating reflectance can be no greater than the reflectance obtained for a flat interface. This constraint holds regardless of the depth of the grating and the shape of the interface.

While rapidly oscillating gratings may seem to be of limited practical interest, they are, in fact, widely used. Optical engineers have been aware of homogenization effects in gratings for many years and often use high spatial frequency gratings to approximate corresponding multilayered structures (and vice-versa) [12]. The primary practical advantage of this approach is that material "layers" with intermediate refractive indices can be approximated by a grating composed of only two materials. In this way, the use of expensive, unstable, or nonexistent materials can often

be avoided. One of the primary uses for rapidly oscillating gratings is in so-called *moth-eye* antireflective structures (see, e.g., [1, 8] and references therein), which are widely used to reduce glare on display devices and are commercially available.

Any optical engineer engaged in designing or optimizing a rapidly oscillating grating is faced with the question of whether or not a desired reflectance profile is attainable with given materials. This paper is aimed exactly at that question, showing that high reflectivity designs are generally *not* attainable with simple blazed high spatial frequency gratings. We consider the approach taken here as a first step toward solving the more difficult problem of characterizing attainable reflection/transmission patterns in more general diffraction gratings.

The plan of the paper is as follows. In the next section, we begin by analyzing the case of reflection from a "layered medium," i.e., a medium which has spatial dependence in only one direction. Under the condition that the refractive index of the medium is monotone in that direction, we establish the desired reflectance constraint. We conclude in section 3 by using homogenization theory to reduce the limiting case of a rapidly oscillating grating to the monotone layered medium. We prove that in the limit as the grating period goes to zero, the reflectance constraint is satisfied.

2. Layered medium case. We first consider a layered medium in $\mathbb{R}^2$, characterized by the real dielectric coefficient $k(x_2)$, where $x = (x_1, x_2) \in \mathbb{R}^2$. It is assumed that $k(x_2) \equiv k_a$ for $x_2 \geq 0$ (i.e., in the "air"), and $k(x_2) \equiv k_s$ for $x_2 \leq -b$, (i.e., in the "substrate"), where $0 < b < \infty$ is an arbitrary depth. Consider an incoming plane wave $u_i = e^{i\alpha x_1 + i\beta_a x_2}$, where

$$\alpha = k_a \sin\theta, \quad \beta_a = k_a \cos\theta, \tag{1}$$

and $|\theta| < \pi/2$ is the angle of incidence with respect to the x_2-axis. We wish to find solutions w satisfying the Helmholtz equation $\triangle w + k^2 w = 0$ in $\mathbb{R}^2$, plus appropriate outgoing wave conditions.

To make the problem independent of x_1, one can consider the functions $u = we^{-i\alpha x_1}$. Defining $\beta(x_2) = \sqrt{k(x_2)^2 - \alpha^2}$ and setting $\beta_s = \beta(-b)$, we specify the reflection and transmission conditions

$$\begin{aligned} u(x_2) &= e^{i\beta_a x_2} + re^{-i\beta_a x_2} \quad \text{for } x_2 \geq 0, \\ u(x_2) &= te^{i\beta_s x_2} \qquad\qquad\quad \text{for } x_2 \leq -b, \end{aligned} \tag{2}$$

where the coefficients r and t are to be determined. This leads to the following boundary value problem in x_2:

$$u'' + \beta^2 u = 0 \quad \text{in } (0, -b), \tag{3}$$

$$u'(0) = -i\beta_a u(0) + 2i\beta_a, \tag{4}$$

$$u'(-b) = i\beta_s u(-b). \tag{5}$$

In weak form, we have

$$\int_{-b}^{0} u'\overline{v}' - \int_{-b}^{0} \beta^2 u\overline{v} + i\beta_a u(0)\overline{v}(0) + i\beta_s u(-b)\overline{v}(-b) = 2i\beta_a \overline{v}(0). \tag{6}$$

LEMMA 2.1. *Let $\beta \in L^\infty(-b, 0)$ be real-valued. Then problem* (3)–(5) *admits a unique weak solution $u \in H^1(-b, 0)$.*

Proof. We seek $u \in H^1(-b, 0)$ such that (6) is satisfied for all $v \in H^1(-b, 0)$. It is easy to rewrite this problem as a linear operator equation $u - Au = f$, where A

is compact (see, e.g., [7]). Applying the Fredholm alternative, existence then follows from uniqueness for the homogeneous problem $w - Aw = 0$.

Thus it suffices to prove uniqueness for the homogeneous problem

$$w'' + \beta^2 w = 0 \quad \text{in } (0, -b), \tag{7}$$

$$w'(0) = -i\beta_a w(0), \tag{8}$$

$$w'(-b) = i\beta_s w(-b), \tag{9}$$

with associated weak form

$$\int_{-b}^{0} w'\overline{v}' - \int_{-b}^{0} \beta^2 w\overline{v} + i\beta_a w(0)\overline{v}(0) + i\beta_s w(-b)\overline{v}(-b) = 0. \tag{10}$$

Note that any solution $w \in H^1(-b, 0)$ of (10) is also in $H^2(-b, 0)$ since $w'' = -\beta^2 w$ a.e., and the right-hand side is in L^2. By Sobolev imbedding, $w \in C^1$. Setting $v = w$ in (10) and taking the imaginary part, we find that $w(-b) = w(0) = 0$. From (8), (9) we also have $w'(-b) = w'(0) = 0$. Uniqueness now follows by classical results for the Cauchy problem (see Hörmander [9, section 8.9] or Nirenberg [10]). □

We can now investigate the properties of the reflectance of a given structure defined by $\beta(x_2)$. First, given the solution u to (3)–(5), we define the reflection coefficient $r = u(0) - 1$, and the *reflectance* $\mathcal{R} = |r|^2$. The reflectance represents the proportion of incident energy reflected from the structure. Similarly, we define the transmission coefficient $t = u(-b)$, and the *transmittance* $\mathcal{T} = (\beta_s/\beta_a)|t|^2$. Setting $v = u$ and taking the imaginary part of the resulting equality in (6) yield *conservation of energy*:

$$\mathcal{R} + \mathcal{T} = 1. \tag{11}$$

Now taking $v = u'$ and applying the identities (3)–(5), one finds from (6) that

$$\beta_s^2|u(-b)|^2 - \beta_a^2\{|u(0)|^2 - 4\text{Re } u(0) - 4\} = \int_{-b}^{0} \beta^2(u'\overline{u} + u\overline{u}'). \tag{12}$$

Integrating the last term in (12) by parts, we have

$$\int_{-b}^{0} \beta^2(u'\overline{u} + u\overline{u}') = -\int_{-b}^{0} (\beta^2)'|u|^2 + \beta_a^2|u(0)|^2 - \beta_s^2|u(-b)|^2.$$

Then (12) becomes

$$2\beta_s^2|u(-b)|^2 - 2\beta_a^2|u(0) - 1|^2 - 2\beta_a^2 = -\int (\beta^2)'|u|^2. \tag{13}$$

Applying conservation of energy (11), $|t|^2 = (\beta_a/\beta_s)(1 - |r|^2)$ so that (13) yields

$$\mathcal{R} = \frac{\beta_s - \beta_a}{\beta_s + \beta_a} + \frac{1}{2\beta_a(\beta_a + \beta_s)} \int_{-b}^{0} (\beta^2)'|u|^2. \tag{14}$$

Since β^2 is nonincreasing, we immediately obtain that

$$\mathcal{R} \leq \frac{\beta_s - \beta_a}{\beta_s + \beta_a}.$$

The term on the right is the *square root* of the reflectance in the case of a flat profile (see, e.g., Born and Wolf [4] for a complete discussion of reflectance from flat interfaces). To improve this estimate, we need a lower bound on $|u|^2$.

LEMMA 2.2. *Suppose $\beta(x_2)$ is nonincreasing. Then the solution u of* (3)–(5) *satisfies*

$$|u|^2 \geq |t|^2,$$

where $t = u(-b)$ is the transmission coefficient.

Proof. First suppose that $k(x_2)$ is composed of a finite number of homogeneous layers, with refractive indices $k_a \leq k_1 \leq k_2 \leq \cdots \leq k_n \leq k_s$, with depths $h_1, \ldots, h_n$; i.e., setting $b_j = \sum_{k=1}^{j} h_k$, we have $k(x_2) = k_j$ for $-b_j \leq x_2 \leq -b_{j-1}$. Set $b = b_n$.

Letting $u(-b) = t$, the boundary condition (5) is $u'(-b) = i\beta_s t$. Solving for u in the nth layer, $-b_n \leq x \leq -b_{n-1}$, one obtains

$$u(x) = t(\cos\beta_n(x + b_n) + i(\beta_s/\beta_n)\sin\beta_n(x + b_n))e^{-i\beta_s b_n}.$$

Note that since $\beta_s/\beta_n \geq 1$, we have $|u(x)|^2 \geq |t|^2$. Having obtained u in terms of t the nth layer, one can now continue propagating the solution upward layer by layer, each time obtaining a solution in the form

$$u(x) = \tilde{t}_j(q_1 \cos\theta + iq_2(\beta_j/\beta_{j-1})\sin\theta),$$

where $\tilde{t}_j$ is a complex constant with $|\tilde{t}_j|^2 \geq |t|^2$, and q_1 and q_2 are complex constants in the form

$$\begin{aligned} q_1 &= \cos\phi + i(\beta_{j+1}/\beta_j)\sin\phi, \\ q_2 &= i\sin\phi + (\beta_{j+1}/\beta_j)\cos\phi. \end{aligned}$$

The result follows from the fact that the complex number $Z = q_1\cos\theta + iq_2(\beta_j/\beta_{j-1})\sin\theta$ satisfies $|Z| \geq 1$. Indeed, setting $\gamma_j = \beta_j/\beta_{j-1}$, we have

$$\begin{aligned} |Z|^2 &= (\cos\theta\cos\phi - \gamma_j\sin\theta\sin\phi)^2 + \gamma_{j+1}^2(\cos\theta\sin\phi + \gamma_j\sin\theta\cos\phi)^2 \\ &= \cos^2\theta(\cos^2\phi + \gamma_{j+1}^2\sin^2\phi) + \gamma_j^2\sin^2\theta(\sin^2\phi + \gamma_{j+1}^2\cos^2\phi) \\ &\quad + 2\gamma_j(\gamma_{j+1}^2 - 1)\cos\theta\cos\phi\sin\theta\sin\phi \\ &= \cos^2\theta(1 + (\gamma_{j+1}^2 - 1)\sin^2\phi) + \gamma_j^2\sin^2\theta(1 + (\gamma_{j+1}^2 - 1)\cos^2\phi) \\ &\quad + 2\gamma_j(\gamma_{j+1}^2 - 1)\cos\theta\cos\phi\sin\theta\sin\phi. \end{aligned}$$

Thus $|Z|^2$ can be written as

$$|Z|^2 = \cos^2\theta + \gamma_j^2\sin^2\theta + (\gamma_{j+1}^2 - 1)(\cos\theta\sin\phi + \gamma_j\sin\theta\cos\phi)^2.$$

Since β is a nonincreasing function, we have $\gamma_j = \beta_j/\beta_{j-1} \geq 1$, and thus $|Z| \geq 1$. Consequently, $|u(x)| \geq |t|^2$ in each layer.

In a manner exactly analogous to the procedure above, one can also obtain the estimate

$$|u(x)|^2 \leq |u(0)|^2 + |2 - u(0)|^2 \quad \text{for } x \leq 0. \tag{15}$$

Since $|u(0)-1|^2 = \mathcal{R} \le 1$, it follows that $\int_{-b}^{0} |u|^2 \le C$, where C is independent of the piecewise constant function β, provided only that β is nonincreasing. Taking the real part of the bilinear form (6) with $v = u$, we then find immediately that

$$\|u\|_{H^1} \le C, \tag{16}$$

where C now depends only on b, β_a, β_s.

The general case of nonincreasing $\beta \in L^\infty$ is now handled easily by approximation. Specifically, let $\{\beta^k\}$ be a sequence of nondecreasing, piecewise constant functions converging to a given β in the weak $*$ L^∞ sense. Let u_k be the corresponding sequence of solutions to (3)–(5). By (16), $\|u_k\|_{H^1} \le C$; hence there exists a subsequence (still denoted u_k) converging weakly in H^1 and strongly in L^2 to some $\tilde{u}$. It follows that, for every fixed $v \in H^1$,

$$\begin{aligned} 2i\beta_a \overline{v}(0) &= \int_{-b}^{0} u_k' \overline{v}' - \int_{-b}^{0} (\beta^k)^2 u_k \overline{v} + i\beta_a u_k(0)\overline{v}(0) + i\beta_s u_k(-b)\overline{v}(-b) \\ &\to \int_{-b}^{0} \tilde{u}' \overline{v}' - \int_{-b}^{0} \beta^2 \tilde{u}\overline{v} + i\beta_a \tilde{u}(0)\overline{v}(0) + i\beta_s \tilde{u}(-b)\overline{v}(-b) \end{aligned}$$

so that by Lemma 2.1, $\tilde{u} = u$, the unique solution to (3)–(5). Finally, since u_k, $k = 1, 2, \ldots$, along with u are uniformly bounded in H^2 and hence in C^1, we see that the convergence $u_k \to u$ is actually pointwise. Since the estimate $|u_k(x)|^2 \ge |t_k|^2$ holds for each k, it must also hold for u, t. ∎

LEMMA 2.3. *Suppose $\beta(x_2)$ is nonincreasing. Then*

$$\mathcal{R} \le \left(\frac{\beta_s - \beta_a}{\beta_s + \beta_a} \right)^2. \tag{17}$$

Proof. Using the previous lemma, we find that

$$\int_{-b}^{0} (\beta^2)' |u|^2 \le |t|^2 (\beta_a^2 - \beta_s^2).$$

Noting that $|t|^2 = (\beta_a/\beta_s)(1 - \mathcal{R})$, the identity (14) then yields the desired estimate with a simple manipulation. ∎

The estimate in Lemma 2.3 is sharp. Equality is attained for a sharp interface between two media with refractive indices k_a and k_s. Thus *the reflectance produced by any nonincreasing refractive index $k(x_2)$ with $k(-b) = k_s$ and $k(0) = k_a$ can be no more than the reflectance produced by the piecewise constant $k_c(x_2)$ with $k_c(x_2) = k_s$ for $x_2 < a$ and $k_c(x_2) = k_a$ for $x_2 > a$, $a \in (-b, 0)$.* Incidentally, it is well known in engineering that for a fixed incidence angle one can create a layered structure with $\mathcal{R}$ lying anywhere in the interval $[0, R_{max}]$, with $R_{max} = ((\beta_s - \beta_a)/(\beta_s + \beta_a))^2$. The key point here is that $\mathcal{R}$ cannot exceed R_{max} with nonincreasing β.

3. Rapidly oscillating case. We now consider the case of a rapidly oscillating dielectric grating. Specifically, suppose that we are given a grating structure with period L. By rescaling the problem, it suffices to consider the case $L = 2\pi$. Let $f \in L^\infty(\mathbb{R})$ be 2π-periodic; i.e., let

$$f(x_1) = f(x_1 + 2\pi n) \quad \text{a.e. in } x_1, \text{ for all integers } n$$

and satisfy

$$-b < \inf f \le \sup f < 0. \tag{18}$$

The function f represents an interface between two homogeneous materials with refractive indices k_a and k_s. Define a corresponding refractive index function on $\mathbb{R}^2$:

$$\rho_f(x) = \begin{cases} k_a^2 & \text{if } x_2 > f(x_1), \\ k_s^2 & \text{otherwise.} \end{cases} \tag{19}$$

As in the previous section, given an incoming plane wave from above $u_i = e^{i\alpha x_1 + i\beta_a(x_2)}$ (where α and β_a are as defined in (1)), we seek solutions of the Helmholtz equation $\triangle w + \rho_f w = 0$, where w is a sum of the incoming and scattered fields and satisfies appropriate outgoing wave conditions. The standard approach to solving this problem is to search for "quasi-periodic" solutions, that is, solutions w such that $u = we^{-i\alpha x_1}$ is 2π-periodic in x_1. A well-known procedure exists for formulating the problem variationally. This is outlined, for example, in [2, 7]. The basic idea is to expand the periodic functions u in a Fourier series in x_1 and match the solutions with the fundamental solution in the homogeneous regions $x_2 > 0$ and $x_2 < -b$. This leads naturally to a Fourier series expansion for the Dirichlet-to-Neumann operators on the boundaries $\{x_2 = 0\}$ and $\{x_2 = -b\}$. Defining the cylindrical domain $\Omega = (\mathbb{R} \times (-b, 0))/(2\pi Z \times \{0\})$ and the periodic boundaries Γ_a corresponding to $\{x_2 = 0\}$ and Γ_s corresponding to $\{x_2 = -b\}$, the problem can then be formulated as

$$\begin{aligned} \triangle_\alpha u + \rho_f u &= 0 \qquad \text{in } \Omega, \\ T_a u - \frac{\partial u}{\partial x_2} &= 2i\beta_a \quad \text{on } \Gamma_a, \\ T_s u + \frac{\partial u}{\partial x_2} &= 0 \qquad \text{on } \Gamma_s, \end{aligned}$$

where $\triangle_\alpha = \triangle + 2i\alpha\partial_1 - \alpha^2$. The Dirichlet-to-Neumann operators T_j are defined by

$$(T_j\phi)(x_1) = \sum_{n\in Z} i\beta_j^n \phi_n e^{inx_1}, \quad j = a, s,$$

where

$$\beta_j^n = \begin{cases} \sqrt{k_j^2 - (n+\alpha)^2} & \text{if } k_j^2 \ge (n+\alpha)^2, \\ i\sqrt{k_j^2 - (n+\alpha)^2} & \text{if } k_j^2 < (n+\alpha)^2, \end{cases}$$

and ϕ_n denote the Fourier coefficients of ϕ. To obtain the weak form, we define for $u, v \in H^1(\Omega)$

$$B_{\rho_f}(u, v) \equiv \int_\Omega (\nabla + i\underline{\alpha})u \cdot \overline{(\nabla + i\underline{\alpha})v} - \int_\Omega \rho_f\, u\overline{v} - \int_{\Gamma_a} (T_a u)\overline{v} + \int_{\Gamma_s} (T_s u)\overline{v},$$

where $\underline{\alpha} = (\alpha, 0)$ and

$$g(v) = -2i\beta_a \int_{\Gamma_a} \overline{v}.$$

We then wish to find $u \in H^1(\Omega)$ such that

$$B_{\rho_f}(u, v) = g(v) \quad \text{for all } v \in H^1(\Omega). \tag{20}$$

It is well known that a unique solution $u \in H^1(\Omega)$ of problem (20) exists for all but possibly a discrete set of parameters k_a, k_s (see [3]). In addition, using a perturbation argument, the following lemma is proved in [6].

LEMMA 3.1. *Provided that the incoming wave is sufficiently low-frequency (k_a, k_s are sufficiently small), problem* (20) *admits a unique weak solution for all f satisfying* (18). *Furthermore, the solutions u are bounded in $H^1(\Omega)$ independently of f.*

Remark. Under the conditions of Lemma 3.1, solutions are actually uniformly bounded in H^2, independent of f. This follows immediately from the equation

$$\triangle u = -2i\alpha\partial_1 u + (\alpha^2 - \rho_f)u.$$

The H^1 bound on u and the L^∞ bound on ρ_f guarantee that $\|\triangle u\|_{L^2} \leq C$, giving the H^2 estimate.

Once the solution to problem (20) has been determined, one can easily find the scattered far-field. The *Rayleigh expansion* [11] dictates that the field above $\{x_2 = 0\}$ must be in the form

$$u(x_1, x_2) = \sum_{n=-\infty}^{\infty} r_n e^{i(nx_1 - \beta_a^n x_2)},$$

where the r_n are unknown scalars. Matching this expansion with the boundary conditions for the variational solution, one finds that r_0, which corresponds to the "zero order" reflected mode, must be given by

$$r_0 = \frac{1}{2\pi}\int_0^{2\pi} u(x_1, 0)\, dx_1 - 1. \tag{21}$$

By rescaling the problem, one can see easily that for a sufficiently small grating period L the coefficients β_a^n are real only for $n = 0$. This means that only the zero order mode propagates. Similarly, using the Rayleigh expansion in the region $x_2 < -b$ and the fact that the grating period L is small, one finds the lone transmitted mode $t_0 = \frac{1}{2\pi}\int_0^{2\pi} u(x_1, -b)\, dx_1$.

As in the layered medium case, setting the reflectance $\mathcal{R}_0 = |r_0|^2$ and the transmittance $\mathcal{T}_0 = |t_0|^2$, one can easily verify conservation of energy $\mathcal{R}_0 + \mathcal{T}_0 = 1$ [7]. We would like to show that a reflectance bound similar to (17) holds in the grating case.

For $n = 1, 2, \ldots$, define $\rho_n(x_1, x_2) = \rho_f(nx_1, x_2)$. Thus ρ_n represents a 2π-periodic grating oscillating more and more rapidly as n increases. It is easily verified that $\rho_n \rightharpoonup \tilde{\rho}$ in the weak $*$ $L^\infty(\Omega)$ sense, where

$$\tilde{\rho}(x_1, x_2) = \frac{1}{2\pi}\int_0^{2\pi} \rho_f(x_1, x_2)\, dx_1.$$

Note that $\tilde{\rho}$ is independent of x_1. Furthermore, due to the form of ρ_f (19) and the fact that $k_a^2 \leq k_s^2$, it is easy to see that $\tilde{\rho}$ is nonincreasing in x_2.

We can now state the main result of this paper.

THEOREM 3.2. *Assume the conditions of Lemma* 3.1. *Given an arbitrary grating profile f and any $\epsilon > 0$, there exists a grating period L such that when the profile f is produced with period L or less, the reflectance $\mathcal{R}_0$ resulting from f satisfies*

$$\mathcal{R}_0 \leq \left(\frac{\beta_s^0 - \beta_a^0}{\beta_s^0 + \beta_a^0}\right)^2 + \epsilon. \tag{22}$$

Thus, analogous to the layered medium case, for rapidly oscillating gratings the reflectance can be no more than the reflectance of a sharp interface between materials k_a and k_b plus a small error, regardless of the grating shape.

Proof. Since the bound (17) holds for $\tilde{\rho}$, inequality (22) is simply a statement of the continuity of $\mathcal{R}_0(\rho)$ with respect to weak $*$ L^∞ convergence $\rho_n \rightharpoonup \tilde{\rho}$. This is easy to prove. Let u_n denote the sequence of solutions to problem (20) corresponding to the coefficients ρ_n. By Lemma 3.1, $\|u_n\|_{H^1}$ is uniformly bounded; hence each subsequence of $\{u_n\}$ has a further subsequence $\{u_{n'}\}$ which converges weakly in H^1 to some $u \in H^1$. We show that the weak limit u of each such subsequence is the same, thus proving that the original sequence $\{u_n\}$ converges weakly to u.

Holding $v \in H^1$ fixed, observe that

$$B_{\rho_{n'}}(u,v) - B_{\rho_{n'}}(u_{n'},v) = \int_\Omega (\nabla + i\underline{\alpha})(u-u_{n'}) \cdot \overline{(\nabla + i\underline{\alpha})v} - \int_\Omega \rho_{n'}(u-u_{n'})\overline{v} - \int_{\Gamma_a} (T_a(u-u_{n'}))\overline{v} + \int_{\Gamma_s} (T_s(u-u_{n'}))\overline{v}.$$

Since $u_{n'} \rightharpoonup u$ in H^1 and the operators T_j are bounded maps from $H^{1/2}(\Gamma_j)$ into $H^{-1/2}(\Gamma_j)$, the first integral and the last two integrals vanish as $n' \to \infty$. Further, the weak convergence of $u_{n'}$ in H^1 implies strong convergence in L^2 so that

$$\left| \int_\Omega \rho_{n'}(u-u_{n'})\overline{v} \right| \le \|\rho_{n'}\|_{L^\infty} \|u-u_{n'}\|_{L^2} \|v\|_{L^2} \to 0.$$

Thus $B_{\rho_{n'}}(u,v) \to B_{\rho_{n'}}(u_{n'},v) = g(v)$. The convergence $\rho_{n'} \overset{*}{\rightharpoonup} \tilde{\rho}$ implies $B_{\rho_{n'}}(u,v) \to B_{\tilde{\rho}}(u,v)$. Hence $B_{\tilde{\rho}}(u,v) = g(v)$ for all v; i.e., u solves (20) for $\tilde{\rho}$. Since the solution u is unique by Lemma 3.1, we conclude that the original sequence $u_n \rightharpoonup u$ weakly in H^1.

Since the traces $u_n|_{\Gamma_a} \rightharpoonup u|_{\Gamma_a}$ weakly in $H^{1/2}$, it follows by the definition (21) that the corresponding reflection coefficients, and hence the reflectances, converge. ∎

Acknowledgments. The authors wish to thank Jeff Rauch for raising the question which led to this work. They are also very grateful to the referees and the associate editor for their helpful comments, which improved the paper greatly.

EXISTENCE CONDITIONS AND PROPERTIES OF THE FREQUENCY RESPONSE OPERATORS OF CONTINUOUS-TIME PERIODIC SYSTEMS*

JUN ZHOU† AND TOMOMICHI HAGIWARA†

Abstract. The definition of the frequency response operator via the steady-state analysis in finite-dimensional linear continuous-time periodic (FDLCP) systems is revisited. It is shown that the frequency response operator is guaranteed to be well defined only densely on the linear space l_2, which is different from the usual understanding. Fortunately, however, it turns out that this frequency response operator can have an extension onto l_2 so that the equivalence between the time-domain H_2 norm (respectively, the L_2-induced norm) and the frequency-domain H_2 norm (respectively, the H_∞ norm of the frequency response operator) is recovered. Under some stronger assumptions, it is also shown that the frequency response operator can be viewed as a bounded operator from l_1 to l_1, which can also be established via the steady-state analysis.

Key words. continuous-time periodic system, frequency response operator, existence conditions, H_2 and H_∞ norms

1. Introduction.

In general there are two ways to establish the frequency response relations in finite-dimensional linear continuous-time periodic (FDLCP) systems: the lifting technique [2] and the steady-state input-output analysis [26], [27]. The former technique [3], [30] has been widely used in the sampled-data systems analysis [5], [15], [28], while the latter is the standard technique of the frequency response analysis in linear continuous-time systems, and there are also works in which the latter is utilized in establishing the frequency response operator, or FR-operator, in sampled-data systems [1], [8], [9], [11], [14], [16]. There are also some works [29], [32] in which these two approaches are compared and/or combined.

In this paper, we reconsider the problem of establishing the frequency response relation of FDLCP systems through the steady-state input-output analysis. The general idea of such a treatment has been discussed in [27], but the rigorous existence conditions of the frequency response operators are not given explicitly. To clarify these conditions, we concentrate our attention on the validity of the Fourier series expansions and the Toeplitz transformation employed in the arguments. Our study reveals that the frequency response operator defined with the steady-state input-output analysis is guaranteed to be well defined only on the subset l_1 of the linear space l_2 rather than on the whole l_2 even though the latter is an implicit assumption in [26], [27]. This subtle deviation of the domains of the frequency response operator leads us to put up such a question: if it still makes sense to define the H_2 and H_∞ norms on such a "deficient" frequency response operator for FDLCP systems. Fortunately, our study shows that the domain of the frequency response operator can actually be extended to l_2 apart from the steady-state analysis interpretation, and hence the existing definitions

of these norms suffer no problems. In fact, the equivalence between the time-domain and frequency-domain H_2 norms and that between the L_2-induced norm and the H_∞ norm (i.e., the maximum of the l_2-induced norm over a certain frequency interval) of the frequency response operator are proved under some stronger assumptions on the system matrices. Another important point of our study is to show that the frequency response operator can also be regarded as a bounded mapping defined on the linear space l_1 (with its range also contained in l_1) under some stronger assumptions.

The paper is organized as follows. Section 2 gives some mathematical preliminaries about FDLCP systems, the Fourier series expansions, and the Toeplitz transformation of h-periodic time-varying matrix functions. The definition of the frequency response operator of FDLCP systems is reconsidered in section 3. In section 4, we prove that the frequency response operator via the steady-state analysis is also a bounded mapping on l_1 under some strengthened conditions. The equivalences of the various norms are dealt with in section 5.

The notation of this paper is standard. The Euclidean norm of a vector and the norm of a matrix induced by this vector norm are denoted by $||\cdot||$. l_1 is the set of all infinite-dimensional vectors $\underline{x}$ such that $||\underline{x}||_{l_1} := \sum_{m=-\infty}^{+\infty} ||[\underline{x}]_m|| < \infty$, where $[\underline{x}]_m$ is the mth (block) entry of $\underline{x}$. l_2 is the set of all infinite-dimensional vectors $\underline{x}$ such that $||\underline{x}||_{l_2} := (\underline{x}^*\underline{x})^{1/2} < \infty$, where $*$ denotes the complex conjugate transpose. $L_2[0,h]$ is the linear space of all vector measurable functions x defined on the interval $[0,h]$ such that $||x(\cdot)||_{L_2[0,h]} := [\int_0^h ||x(t)||^2 dt]^{1/2} < \infty$. L_1 is the set of all vector measurable functions x defined on $[0,\infty)$ such that $||x(\cdot)||_{L_1} := \int_0^\infty ||x(t)||dt < \infty$, while L_2 is the set of all such defined vector functions x satisfying $||x(\cdot)||_{L_2} := [\int_0^\infty ||x(t)||^2 dt]^{1/2} < \infty$. $||\cdot||_{Y/X}$ denotes the induced norm from X to Y. In particular, $||\cdot||_{l_2/l_2}$ is the l_2-induced norm. With a little abuse of notation, we say $F(t) \in L_2[0,h]$ means that F is a matrix function, each element of which is h-periodic and belongs to $L_2[0,h]$ when its domain is restricted to the interval $[0,h]$. The same is true for other function sets defined over $[0,h]$. $\mathcal{Z}$ is the set of all integers.

2. Preliminaries. Consider the FDLCP system

$$G : \begin{cases} \dot{x} = A(t)x + B(t)u, \\ y = C(t)x + D(t)u, \end{cases} \tag{1}$$

where $A(t), B(t), C(t)$, and $D(t)$ are h-periodic time-varying matrix functions belonging to $L_2[0,h]$. The transition matrix of the system (1) is denoted by $\Phi(t,t_0)$ when the initial time is t_0. The system is said to be strictly proper if $D(t) \equiv 0$ for all $t \in [0,h]$.

PROPOSITION 2.1 (Floquet theorem [10], [20], [22], [23]). *Let $A(t)$ be defined as in the system* (1). *Then the transition matrix $\Phi(t,t_0)$ is continuous with respect to t and can be expressed as $\Phi(t,t_0) = P(t,t_0)e^{Q(t-t_0)}$, where $P(t,t_0)$ is a nonsingular h-periodic matrix and Q is a constant matrix. Moreover, the system is asymptotically stable if and only if the eigenvalues of the monodromy matrix, $\Phi(h+t_0,t_0)$, are in the open unit disk or, equivalently, the eigenvalues of Q lie in the open left-half plane.*

Now expand $A(t)$ to its Fourier series $A(t) = \sum_{m=-\infty}^{+\infty} A_m e^{jm\omega_h t}$ with $\omega_h = \frac{2\pi}{h}$, which is well defined in the sense that $||A(\cdot) - \sum_{m=-\infty}^{+\infty} A_m e^{jm\omega_h(\cdot)}||_{L_2[0,h]} = 0$. The Toeplitz transformation on $A(t)$ [27], denoted by $\mathcal{T}\{A(t)\}$, maps $A(t)$ into a doubly infinite-dimensional block Toeplitz operator [26] (or to be more precise, block Laurent operator [13]) of the form

$$\mathcal{T}\{A(t)\} := \begin{bmatrix} \ddots & \vdots & \vdots & \vdots & \iddots \\ \cdots & A_0 & A_{-1} & A_{-2} & \cdots \\ \cdots & A_1 & A_0 & A_{-1} & \cdots \\ \cdots & A_2 & A_1 & A_0 & \cdots \\ \iddots & \vdots & \vdots & \vdots & \ddots \end{bmatrix} =: \underline{A}. \tag{2}$$

It is straightforward to show that $\mathcal{T}\{X(t)+Y(t)\} = \mathcal{T}\{X(t)\} + \mathcal{T}\{Y(t)\}$ when $X(t)$ and $Y(t)$ are h-periodic and belong to $L_2[0,h]$. However, the situation is different for the Toeplitz transformation of the product of two matrix functions. Now consider the two conformable h-periodic matrix functions $X(t)$ and $Y(t)$ with the Fourier series expansions $X(t) = \sum_{m=-\infty}^{+\infty} X_m e^{jm\omega_h t}$ and $Y(t) = \sum_{m=-\infty}^{+\infty} Y_m e^{jm\omega_h t}$, respectively. To facilitate our statements, we introduce the sets of h-periodic functions, each of which is a subset of $L_2[0,h]$.

$$L_{\mathrm{PCD}}[0,h] := \left\{ f(t) : \begin{array}{l} f(t) \text{ is piecewise continuous and} \\ \text{differentiable at a.e. } t \in [0,h] \end{array} \right\},$$

$$L_{\mathrm{PCC}}[0,h] := \left\{ f(t) : \begin{array}{l} f(t) \text{ is piecewise continuous and the Fourier series} \\ \text{expansion of } f(t) \text{ is convergent to } f(t_0) \text{ for a.e. } t_0 \in [0,h] \end{array} \right\},$$

$$L_{\mathrm{CAC}}[0,h] := \left\{ f(t) : \begin{array}{l} f(t) \text{ is continuous and the Fourier series} \\ \text{expansion of } f(t) \text{ is absolutely convergent} \end{array} \right\} \subset L_{\mathrm{PCC}}[0,h],$$

$$L_{\mathrm{CPCD}}[0,h] := \left\{ f(t) : \begin{array}{l} f(t) \text{ is continuous and the derivative of} \\ f(t) \text{ is piecewise continuous in } [0,h] \end{array} \right\} \subset L_{\mathrm{PCD}}[0,h],$$

where PCD stands for piecewise continuous and differentiable and PCC is short for piecewise continuous and convergent, while CAC and CPCD are abbreviated from continuous and absolute convergent and continuous and piecewise continuously (first-order) differentiable, respectively. By Theorem 10′ of [18, p. 173], $L_{\mathrm{CPCD}}[0,h] \subset L_{\mathrm{PCD}}[0,h] \subset L_{\mathrm{PCC}}[0,h]$. It is also clear that $L_{\mathrm{CAC}}[0,h] \subset L_{\mathrm{PCC}}[0,h]$. The following results are helpful in our subsequent arguments. The proofs for these lemmas are given in Appendix B.

LEMMA 2.1. *Suppose that the Fourier series expansion of $X(t)$ converges to $X(t_0)$ for almost every (a.e.) $t_0 \in [0,h]$. Also suppose that $Y(t) \in L_{\mathrm{CAC}}[0,h]$. Then $\mathcal{T}\{X(t)Y(t)\} = \mathcal{T}\{X(t)\}\mathcal{T}\{Y(t)\}$ and $\mathcal{T}\{Y(t)X(t)\} = \mathcal{T}\{Y(t)\}\mathcal{T}\{X(t)\}$.*

Remark 2.1. In [27, p. 36], the absolute convergence of the Fourier series expansions of both $X(t)$ and $Y(t)$ is required to ensure the validity of the relations of Lemma 2.1. However, for some reasons unknown from this thesis [27], this constraint was not taken into consideration when the frequency response relation is established with the Toeplitz operator expressions. Hence, the frequency response operator has been introduced to a larger class of FDLCP systems than a precise class for which it can be introduced in a rigorous manner. Our study in the following will pay attention to such a precise class while trying to make the class as large as possible, which leads us to a little different but rigorous interpretation about the frequency response operator of an FDLCP system. In the development of such an argument, it is quite important to note that the conditions of Lemma 2.1 are much weaker than the absolute convergence condition of both $X(t)$ and $Y(t)$.

LEMMA 2.2. *$L_{\mathrm{CAC}}[0,h]$ is dense in $L_2[0,h]$.*

LEMMA 2.3. *If $X(t) \in L_{\mathrm{PCC}}[0,h]$, then $||\underline{X}||_{l_2/l_2} = \sup_{t\in[0,h]} ||X(t)||$ and $\underline{X}$ is bounded on l_2.*

Now we are in a position to derive Propositions 2.2 and 2.3, which describe the basic properties of the FDLCP system (1) in the Toeplitz operator sense and guarantee the existence of the frequency response operator we will introduce.

PROPOSITION 2.2. *Assume that in the system* (1) *the state matrix* $A(t)$ *is piecewise continuous in* $[0,h]$*, and let* $\mathcal{T}\{P(t,0)\} =: \underline{P}$*. Then the Fourier series expansions of* $P(t,0)$ *and* $P^{-1}(t,0)$ *are absolutely convergent, and* $\mathcal{T}\{P^{-1}(t,0)\} = \underline{P}^{-1}$*.*

Proof. By Theorem 6.3.2 of [20] and the Floquet theorem, it follows that

$$(3)\quad \begin{cases} P(t,0) = \Phi(t,0)e^{-Qt}, & \dfrac{d}{dt}P(t,0) = [A(t)\Phi(t,0) - \Phi(t,0)Q]e^{-Qt} \ \text{(a.e.)}, \\ P^{-1}(t,0) = e^{Qt}\Phi(0,t), & \dfrac{d}{dt}P^{-1}(t,0) = e^{Qt}[Q\Phi(0,t) - \Phi(0,t)A(t)] \ \text{(a.e.)}, \end{cases}$$

which clearly says that $P(t,0)$ and $P^{-1}(t,0)$ are continuous and their first-order derivatives are piecewise continuous by the assumption on $A(t)$. Hence, by Theorem 2 of [6, p. 104], the Fourier series expansions of $P(t,0)$ and $P^{-1}(t,0)$ are absolutely convergent. On the other hand,

$$P(t,0)P^{-1}(t,0) = I \quad \forall t \in [0,h].$$

Hence, from Lemma 2.1, applying the Toeplitz transformation on the above equation gives

$$\underline{I} = \mathcal{T}\{P(t,0)P^{-1}(t,0)\} = \mathcal{T}\{P(t,0)\}\mathcal{T}\{P^{-1}(t,0)\}.$$

Similarly, $\underline{I} = \mathcal{T}\{P^{-1}(t,0)\}\mathcal{T}\{P(t,0)\}$. Hence we have $\mathcal{T}\{P^{-1}(t,0)\} = \underline{P}^{-1}$ by the uniqueness of the inverse operator [7]. □

Next let us define $l_E := \{\underline{x} \in l_2 : \underline{E}(j0)\underline{x} \in l_2\} \subset l_2$ with

$$\underline{E}(j0) = \mathrm{diag}[\ldots, -j2\omega_h I, -j\omega_h I, 0, j\omega_h I, j2\omega_h I, \ldots]$$

and establish the following results.

PROPOSITION 2.3. *Assume that in* (1) $A(t) \in L_{\mathrm{PCD}}[0,h]$ *and* $B(t), C(t) \in L_{\mathrm{PCC}}[0,h]$*. Then* l_E *is* $\underline{P}$*-,* $\underline{P}^{-1}$*-,* $\underline{P}^*$*-, and* $\underline{P}^{-*}$*-invariant, where* $\underline{P}^{-*} := [\underline{P}^{-1}]^*$*.* $\underline{P}$ *is invertible on* l_E*, and the unique inverse of* $\underline{P}$ *on* l_E *is* $\underline{P}^{-1}$ *restricted to* l_E*. It holds on* $l_E \subset l_2$ *that*

$$(4)\qquad \underline{P}(\underline{E}(j0) - \underline{Q})\underline{P}^{-1} = \underline{E}(j0) - \underline{A},$$

where $\underline{Q} = \mathcal{T}\{Q\}$*. Moreover, let* $\hat{\underline{B}} := \mathcal{T}\{P^{-1}(t,0)B(t)\}$ *and* $\hat{\underline{C}} := \mathcal{T}\{C(t)P(t,0)\}$*. Then it holds on the whole* l_2 *that* $\hat{\underline{B}} = \underline{P}^{-1}\underline{B}$ *and* $\hat{\underline{C}} = \underline{C}\,\underline{P}$*.*

Proof. By the Floquet theorem and Theorem 6.3.2 of [20], we obtain

$$(5)\qquad P(t,0)Q = A(t)P(t,0) - \dot{P}(t,0) \quad \text{(a.e.)}.$$

By Proposition 2.2, the Fourier series expansion of $P(t,0)$ is absolutely convergent. Note also that by Theorem $10'$ of [18, p. 173], the Fourier series expansion of $A(t)$ converges to $A(t_0)$ for a.e. $t_0 \in [0,h]$ from the assumption. Hence, by Lemma 2.1, we have

$$(6)\qquad \mathcal{T}\{A(t)P(t,0)\} = \mathcal{T}\{A(t)\}\mathcal{T}\{P(t,0)\}.$$

Again by (3) and the assumption about $A(t)$, the first-order derivative of $P(t,0)$ is piecewise continuous, and its second-order derivative exists a.e. in $[0,h]$. Thus, by Theorem 3 of [6, p. 106],

$$\dot{P}(t,0) = \sum_{m=-\infty}^{+\infty} jm\omega_h P_m e^{jm\omega_h t} \quad \text{(a.e.)} \tag{7}$$

through the termwise differentiation, where $\{P_m\}_{m=-\infty}^{+\infty}$ is the Fourier coefficients sequence of $P(t,0)$. In other words, $\{jm\omega_h P_m\}_{m=-\infty}^{+\infty}$ is the Fourier coefficients sequence of $\dot{P}(t,0)$ so that by some trivial algebra [27] we are led to

$$\mathcal{T}\{\dot{P}(t,0)\} = \underline{E}(j0)\underline{P} - \underline{P}\,\underline{E}(j0). \tag{8}$$

Note that $\mathcal{T}\{\dot{P}(t,0)\}$ is bounded on l_2 (which follows from Lemma 2.3 since $\dot{P}(t,0)$ belongs to $L_{\mathrm{PCC}}[0,h]$ by the assumption on $A(t)$, again from Theorem 10′ of [18, p. 173]) but that the two operators on the right-hand side of the above equation are unbounded since $\underline{E}(j0)$ is. This means that we are not allowed to use the operators $\underline{E}(j0)\underline{P}$ and $\underline{P}\,\underline{E}(j0)$ separately if the underlying space is l_2. To get around the problem, we have to restrict the domain of these operators to $l_E \subset l_2$. Now take $\underline{x} \in l_E \subset l_2$. Then $\mathcal{T}\{\dot{P}(t,0)\}\underline{x} \in l_2$. Also, $\underline{P}\,\underline{E}(j0)\underline{x} \in l_2$ since $\underline{E}(j0)\underline{x} \in l_2$ and $\underline{P}$ is bounded on l_2 (which follows again from Lemma 2.3 by the fact that the Fourier series expansion of $P(t,0)$ is absolutely convergent). It follows that $\underline{E}(j0)\underline{P}\,\underline{x} \in l_2$, which clearly says that l_E is $\underline{P}$-invariant.

Similarly, by repeating the arguments about $\dot{P}(t,0)$ on $\dot{P}^{-1}(t,0)$, it readily follows that l_E is also $\underline{P}^{-1}$-invariant. Hence $\underline{P}$ and $\underline{P}^{-1}$ are mappings on l_E. From this, it can be asserted that $\underline{P}$ is invertible on l_E, and the unique inverse of $\underline{P}$ on l_E is nothing but $\underline{P}^{-1}$ restricted to $l_E \subset l_2$.

On the other hand, (6) and (8) actually say that the Toeplitz transformation applies to each term of (5) under the given assumptions so that we obtain

$$\underline{P}\,\underline{Q} = \underline{A}\,\underline{P} - \underline{E}(j0)\underline{P} + \underline{P}\,\underline{E}(j0).$$

Therefore, if we work on l_E instead of l_2, the operators involved are well defined from l_E to l_2; i.e., the above equation can be rewritten as

$$\underline{P}(\underline{E}(j0) - \underline{Q}) = (\underline{E}(j0) - \underline{A})\underline{P}, \tag{9}$$

which, together with the fact that $\underline{P}$ is invertible on l_E, gives (4).

To see that l_E is $\underline{P}^*$-invariant, we note that $\underline{P}^* = \mathcal{T}\{P^*(t,0)\}$. It is evident from the assumption about $A(t)$ that the first-order derivative of $P^*(t,0)$ is piecewise continuous in $[0,h]$ and the second-order derivation of $P^*(t,0)$ exists a.e. in $[0,h]$. Then from Theorem 3 of [6, p. 106], it is true that

$$\mathcal{T}\{\dot{P}^*(t,0)\} = \underline{E}(j0)\underline{P}^* - \underline{P}^*\underline{E}(j0),$$

which gives the assertion immediately. Similarly, one can show that l_E is $\underline{P}^{-*}$-invariant.

Recall that the Fourier series expansion of $P^{-1}(t,0)$ is absolutely convergent. This, by the assumption on $B(t)$ and Lemma 2.1, implies that $\mathcal{T}\{P^{-1}(t,0)B(t)\} = \mathcal{T}\{P^{-1}(t,0)\}\mathcal{T}\{B(t)\}$. Combining this with Proposition 2.2, the last assertion follows. □

Now we answer the question that asks under what conditions the operator $\underline{E}(j0)-\underline{A}$ is invertible. This is another problem remaining unsolved in the works of [26], [27]. It is evident that $\underline{E}(j0)-\underline{A}$ is invertible if and only if $\underline{E}(j0)-\underline{Q}$ is and that if such an inverse exists, the inverse operator is a mapping from l_2 to l_E. The following proposition gives the answer to this question.

PROPOSITION 2.4. *Assume that $A(t) \in L_{\mathrm{PCD}}[0,h]$ and that the system (1) is asymptotically stable in the Floquet theorem sense. Then $\underline{E}(j\varphi)-\underline{A}$ is invertible for all $\varphi \in [-\frac{\omega_h}{2}, \frac{\omega_h}{2}) =: \mathcal{I}_0$ and*

$$(\underline{E}(j\varphi)-\underline{A})^{-1} = \underline{P}(\underline{E}(j\varphi)-\underline{Q})^{-1}\underline{P}^{-1}, \tag{10}$$

where $\underline{E}(j\varphi) = \underline{E}(j0) + j\varphi\underline{I}$ and

$$\begin{aligned}&(\underline{E}(j\varphi)-\underline{Q})^{-1}\\ &= \mathrm{diag}[\ldots,(j\varphi_{-1}I-Q)^{-1},(j\varphi_0 I-Q)^{-1},(j\varphi_1 I-Q)^{-1},\ldots]\end{aligned} \tag{11}$$

with $\varphi_m := \varphi + m\omega_h, m \in \mathcal{Z}$. Moreover, $(\underline{E}(j\varphi)-\underline{A})^{-1}$ is compact and uniformly bounded on l_2 over $\varphi \in \mathcal{I}_0$.

Proof. By the assumption on $A(t)$, we have (4) so that for any $\varphi \in \mathcal{I}_0$

$$\underline{P}(\underline{E}(j\varphi)-\underline{Q})\underline{P}^{-1} = \underline{E}(j\varphi)-\underline{A}.$$

Also, by the stability assumption, all of the eigenvalues of $Q - j\varphi_m I$ for all $m \in \mathcal{Z}$ have negative real parts. Thus the operator on the right-hand side of (11), which is denoted by $\underline{D}(Q,\varphi)$, is well defined and bounded on l_2. To see this, we note that there exists $K > 0$ such that

$$||(j\varphi_m I - Q)^{-1}|| \le Kf(m) \quad (m \in \mathcal{Z}), \tag{12}$$

where f is defined in Appendix A. Noting that $\underline{D}(Q,\varphi)$ is block-diagonal, it follows that

$$||\underline{D}(Q,\varphi)||_{l_2/l_2} = \sup_{m\in\mathcal{Z}} ||(j\varphi_m I - Q)^{-1}|| \le K. \tag{13}$$

Some simple computations show that $\underline{D}(Q,\varphi)(\underline{E}(j\varphi)-\underline{Q}) = (\underline{E}(j\varphi)-\underline{Q})\underline{D}(Q,\varphi) = \underline{I}$. This, together with the fact that $\underline{P}$ and $\underline{P}^{-1}$ are invertible on l_2 and l_E, respectively, establishes (10). Noting that $(\underline{E}(j\varphi)-\underline{Q})^{-1}$ is uniformly bounded on l_2 by (13) and that $\underline{P}$ and $\underline{P}^{-1}$ are bound on l_2, then the uniform boundedness of $(\underline{E}(j\varphi)-\underline{A})^{-1}$ on l_2 over $\varphi \in \mathcal{I}_0$ follows from (10).

To see the compactness of $(\underline{E}(j\varphi)-\underline{Q})^{-1}$, we define

$$\begin{aligned}&[(\underline{E}(j\varphi)-\underline{Q})^{-1}]_N\\ &= \mathrm{diag}[\ldots,0,(j\varphi_{-N}I-Q)^{-1},\ldots,(j\varphi_0 I-Q)^{-1},\ldots,(j\varphi_N I-Q)^{-1},0,\ldots].\end{aligned}$$

It is clear that for any fixed N, the operator $[(\underline{E}(j\varphi)-\underline{Q})^{-1}]_N$ is bounded on l_2 by (12) and is a compact operator. Furthermore, it is easy to see from (12) that for any $\varphi \in \mathcal{I}_0$, $\lim_{N\to\infty}[(\underline{E}(j\varphi)-\underline{Q})^{-1}]_N = (\underline{E}(j\varphi)-\underline{Q})^{-1}$ in the l_2-induced norm sense, which implies that $(\underline{E}(j\varphi)-\underline{Q})^{-1}$ is a compact mapping on l_2. Noting that $\underline{P}$ and $\underline{P}^{-1}$ are bounded on l_2, it follows by (10) that $(\underline{E}(j\varphi)-\underline{A})^{-1}$ are also compact. ∎

The following result describes basic properties of the set l_E (see Appendix B for the proof).

LEMMA 2.4. *l_E is dense in l_2. Also, l_E is a proper and dense subset of l_1 in the l_2-norm sense.*

Lemma 2.4 reveals that (4) can be seen as an operator-valued relation densely defined on l_2 (i.e., from the dense subset $l_E \subset l_2$ to l_2).

Finally, for our later use, we denote the Fourier series expansion operator from $L_2[0,h]$ to l_2 by $\mathcal{F}$. Then, it is easy to see that if $\mathcal{F}\{x(\cdot)\} \in l_1$ for $x(t) \in L_2[0,h]$, then the Fourier series expansion of $x(t)$ is absolutely convergent.

3. Frequency response operators viewed on l_2. In this section, we construct the frequency response relation of the FDLCP system (1) by the steady-state input-output analysis. This is first proposed in [26], [27]. The basic idea can be described as follows. First, impose an l_2-EMP signal u (where EMP stands for exponentially modulated periodic) to the system of (1), that is,

$$u(t) = \sum_{m=-\infty}^{+\infty} u_m e^{j(\varphi+m\omega_h)t} = \sum_{m=-\infty}^{+\infty} u_m e^{j\varphi_m t} \quad (t \geq 0, \varphi \in \mathcal{I}_0),$$

where the infinite-dimensional vector $\underline{u} := [\ldots, u_{-1}^T, u_0^T, u_1^T, \ldots]^T$ belongs to l_2. Second, measure the steady-state output y of the system, which is (assumed to be) also an l_2-EMP signal under the asymptotic stability assumption of the system and represent the signal y by the infinite-dimensional vector $\underline{y} := [\ldots, y_{-1}^T, y_0^T, y_1^T, \ldots]^T \in l_2$ according to the definition of l_2-EMP signals. Finally, the input-output response relation observed in the above is expressed as a mapping $\underline{G}(j\varphi) : \underline{u} \mapsto \underline{y}$.

In the above arguments, the Fourier series expansions of $A(t), B(t), C(t)$, and $D(t)$ as well as the Toeplitz operators expressions of these h-periodic matrix functions are used repeatedly. It should be pointed out that the validity of such use has not been verified rigorously in [26], [27]. In the following, we will reconsider the above-mentioned arguments and concentrate our attention on the convergence problems of the Fourier series expansions and the Toeplitz transformations involved. To this purpose, we note from the Floquet theorem that

$$\begin{aligned} y(t) &= C(t)P(t,0)e^{Q(t-t_0)}P^{-1}(t_0,0)x_0 \\ &\quad + C(t)P(t,0)\int_{t_0}^{t} e^{Q(t-\tau)}P^{-1}(\tau,0)B(\tau)u(\tau)d\tau + D(t)u(t) \\ &= \hat{C}(t)\left[e^{Q(t-t_0)}q_0 + \int_{t_0}^{t} e^{Q(t-\tau)}\hat{B}(\tau)u(\tau)d\tau\right] + D(t)u(t) \end{aligned} \tag{14}$$

with $\hat{B}(t) := P^{-1}(t,0)B(t), \hat{C}(t) := P(t,0)C(t)$, and $q_0 := P^{-1}(t_0,0)x_0$. The second relation of (14) says that if we introduce the initial value transformation $q_0 = P^{-1}(t_0,0)x_0$, the system (1) can be represented equivalently in the input-output sense by the system configuration shown in Figure 1.

Now we are in a position to establish the frequency response relation in the system of Figure 1 by imposing an l_2-EMP sinusoid input u to the system and measuring the steady-state output y. From Figure 1, this can be completed by showing that under certain assumptions given below, the steady-state responses at the points p, q, and y are also l_2-EMP signals so that the input-output response relation $u \mapsto y$ can be written as a mapping of $\underline{u} \mapsto \underline{y}$. We complete this in three steps.

Step 1. Take an h-periodic continuous signal $\hat{u}(t) \in L_2[0,h]$ such that $\mathcal{F}\{\hat{u}(\cdot)\} =: \underline{\hat{u}} \in l_1 \subset l_2$. Then the Fourier series expansion of $\hat{u}(t)$ is absolutely convergent.

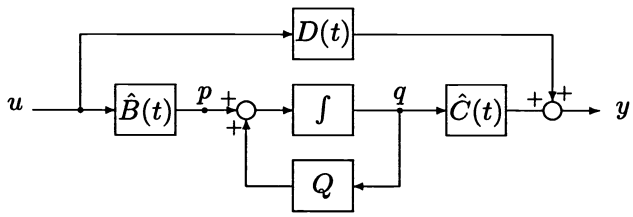

FIG. 1. *Equivalent system configuration.*

Constructing the input l_2-EMP signal as $u(t) = \hat{u}(t)e^{j\varphi t}, \varphi \in \mathcal{I}_0$ (where $\mathcal{I}_0$ is defined in Proposition 2.4), it follows that the corresponding output of $\hat{B}(t)$ to this l_2-EMP signal is

$$p(t) = \hat{p}(t)e^{j\varphi t} \quad (t \geq 0, \varphi \in \mathcal{I}_0),$$

where $\hat{p}(t) = \hat{B}(t)\hat{u}(t) = P^{-1}(t,0)B(t)\hat{u}(t)$.

Now assume that $B(t) \in L_{\mathrm{PCC}}[0,h]$. Then, from the choice of $\hat{u}$ and Lemma 2.1 (the assertion is expressed in terms of the operator $\mathcal{F}$ by taking the central column), we obtain

$$\mathcal{F}\{B(\cdot)\hat{u}(\cdot)\} = \underline{B}\,\mathcal{F}\{\hat{u}(\cdot)\} = \underline{B}\,\underline{\hat{u}},$$

and the Fourier series expansion of $B(t)\hat{u}(t)$ is convergent to $B(t_0)\hat{u}(t_0)$ for a.e. $t_0 \in [0,h]$.

Furthermore, let us assume that $A(t) \in L_{\mathrm{PCD}}[0,h]$. Then, from Proposition 2.2, $P^{-1}(t,0)$ is continuous, and the Fourier series expansion of $P^{-1}(t,0)$ is absolutely convergent. Again by Lemma 2.1 and Proposition 2.2, we obtain

$$\mathcal{F}\{P^{-1}(\cdot,0)B(\cdot)\hat{u}(\cdot)\} = \mathcal{T}\{P^{-1}(\cdot,0)\}\mathcal{F}\{B(\cdot)\hat{u}(\cdot)\} = \underline{P}^{-1}\underline{B}\,\underline{\hat{u}},$$

which can be interpreted as

$$\mathcal{F}\{\hat{p}(\cdot)\} =: \underline{\hat{p}} = \underline{P}^{-1}\underline{B}\,\underline{\hat{u}} \in l_2. \tag{15}$$

The assertion that $\underline{\hat{p}} \in l_2$ follows from the facts that $\underline{P}^{-1}$ and $\underline{B}$ are bounded on l_2 under the given assumptions on $A(t)$ and $B(t)$. From the above arguments, it follows that $\hat{p}(t)e^{j\varphi t} = p(t)$ is also l_2-EMP. In other words, one can conclude that $p(t) = \sum_{m=-\infty}^{+\infty} p_m e^{j(\varphi + m\omega_h)t}$ with $p_m := [\underline{\hat{p}}]_m$.

Remark 3.1. The reason we constrain the domain of $\hat{u}$ is that if we work on a general $\hat{u}(t) \in L_2[0,h]$, we may not arrive at the above conclusions for some $\underline{\hat{u}} \in l_2$ because of the convergence problems in the Fourier series expansions and the Toeplitz transformations.

Step 2. Now impose the signal p to the linear time-invariant (LTI) subsystem of Figure 1. We suppose that this subsystem is asymptotically stable (i.e., all the eigenvalues of Q have negative real parts). Then, by the superposition principle of linear systems [21, Theorem 5.6.2, p. 237], the output q of the LTI subsystem to p is

$$
\begin{aligned}
q(t) &= e^{Qt}q_0 + \int_0^t e^{Q(t-\tau)} \sum_{m=-\infty}^{+\infty} p_m e^{j(\varphi+m\omega_h)\tau} d\tau \\
&= e^{Qt}\left(q_0 + \sum_{m=-\infty}^{+\infty} \int_0^t e^{(j\varphi_m I - Q)\tau} d\tau p_m\right) \\
&= e^{Qt}\left(q_0 + \sum_{m=-\infty}^{+\infty} (Q - j\varphi_m I)^{-1} p_m\right) + \sum_{m=-\infty}^{+\infty} (j\varphi_m I - Q)^{-1} p_m e^{j\varphi_m t}. \qquad (16)
\end{aligned}
$$

On the other hand, by the stability assumption of Q, (12) is true for all $\varphi \in \mathcal{I}_0$. Therefore, we observe by the Cauchy–Schwarz inequality and Appendix A that

$$
\begin{aligned}
\sum_{m=-\infty}^{+\infty} ||(Q - j\varphi_m I)^{-1} p_m|| &\le \sum_{m=-\infty}^{+\infty} ||(Q - j\varphi_m I)^{-1}|| \cdot ||p_m|| \\
&\le \left(\sum_{m=-\infty}^{+\infty} ||(Q - j\varphi_m I)^{-1}||^2\right)^{\frac{1}{2}} \left(\sum_{m=-\infty}^{+\infty} ||p_m||^2\right)^{\frac{1}{2}} \\
&\le K\left(\sum_{m=-\infty}^{+\infty} f(m)^2\right)^{\frac{1}{2}} ||\underline{p}||_{l_2} \le \sqrt{5}K\,||\underline{p}||_{l_2}, \qquad (17)
\end{aligned}
$$

where $\underline{p} := [\ldots, p_{-1}^T, p_0^T, p_1^T, \ldots] = \underline{\hat{p}} \in l_2$. The above inequality implies that the summation $\sum_{m=-\infty}^{+\infty}(Q - j\varphi_m I)^{-1} p_m$ is absolutely convergent for any $\varphi \in \mathcal{I}_0$. Combining this fact with (16), it follows that as $t \to \infty$, the steady-state response is

$$\left(\sum_{m=-\infty}^{+\infty} (j\varphi_m I - Q)^{-1} p_m e^{jm\omega_h t}\right) e^{j\varphi t}$$

since $e^{Qt} \to 0$. This steady-state output q of the LTI subsystem can be expressed as

$$q(t) := \hat{q}(t) e^{j\varphi t} \quad (t \ge 0),$$

where $\hat{q}(t) = \sum_{m=-\infty}^{+\infty} \hat{q}_m e^{jm\omega_h t}$ with $\hat{q}_m := (j\varphi_m I - Q)^{-1} p_m$. The arguments in (17) also indicate that $\mathcal{F}\{\hat{q}(\cdot)\} =: \underline{\hat{q}} \in l_1 \subset l_2$. More precisely, since $(\underline{E}(j\varphi) - \underline{Q})^{-1}$ is a mapping from l_2 to $l_E \subset l_1$ by Proposition 2.4 and Lemma 2.4, it also follows that $\underline{\hat{q}} \in l_E \subset l_1$. Consequently, $\hat{q}(t) \in L_2[0, h]$ and the Fourier series expansion of $\hat{q}(t)$ is absolutely convergent. Obviously, $q(t)$ is an l_2-EMP signal.

Step 3. Since the Fourier series expansion of $P(t, 0)$ is absolutely convergent, the assertion in the last paragraph of Step 2 actually says that the Fourier series expansion of $P(t, 0)\hat{q}(t)$ is also absolutely convergent by the fact [19] that the Fourier series expansion of the product of two matrix functions is absolutely convergent if the Fourier series expansions of these two matrix functions are absolutely convergent. Now, repeating the arguments in Step 1 on the matrix function $C(t)P(t, 0)\hat{q}(t)$, the relation

$$\mathcal{F}\{\hat{y}(\cdot)\} =: \underline{\hat{y}} = \underline{C}\,\underline{P}\,\underline{\hat{q}} \qquad (18)$$

can be asserted if $C(t) \in L_{\mathrm{PCC}}[0, h]$, where $\hat{y}$ is the output of $C(t)P(t, 0)$ to the input $\hat{q}(t)$. It is clear that $\underline{\hat{y}} \in l_2$, and thus the output y of $C(t)P(t, 0)$ to the input $q(t) = \hat{q}(t)e^{j\varphi t}$ is l_2-EMP.

Finally, from (15) and (18) and by Proposition 2.4, we obtain

$$\underline{\hat{y}} = \underline{C}\,\underline{P}(\underline{E}(j\varphi) - \underline{Q})^{-1}\underline{P}^{-1}\underline{B}\,\underline{u} = \underline{C}(\underline{E}(j\varphi) - \underline{A})^{-1}\underline{B}\,\underline{u}$$

by setting $\underline{u} := \underline{\hat{u}}$. Summarizing the above discussions and taking $D(t)$ into consideration, we can state the following main result about the existence conditions of the frequency response operator.

THEOREM 3.1. *Assume that in the system* (1) $A(t)$ *belongs to* $L_{\mathrm{PCD}}[0,h]$, $B(t)$, $C(t)$, *and* $D(t)$ *belong to* $L_{\mathrm{PCC}}[0,h]$, *and that the system* (1) *is asymptotically stable in the Floquet theorem sense. Then the steady-state response of the system* (1) *to the* l_2-EMP *input* $u(t) = \sum_{m=-\infty}^{+\infty} u_m e^{j\varphi_m t}$ *with* $\underline{u} = [\ldots, u_{-1}^T, u_0^T, u_1^T, \ldots]^T \in l_1 \subset l_2$ *is also an* l_2-EMP *signal* $y(t) = \sum_{m=-\infty}^{+\infty} y_m e^{j\varphi_m t}$ *with* $\underline{y} = [\ldots, y_{-1}^T, y_0^T, y_1^T, \ldots]^T = \underline{G}(j\varphi)\underline{u} \in l_2$, *where*

$$\underline{G}(j\varphi) := \underline{C}(\underline{E}(j\varphi) - \underline{A})^{-1}\underline{B} + \underline{D}. \tag{19}$$

Hence the frequency response operator $\underline{G}(j\varphi)$ *is a densely defined mapping on* l_2 *for each* $\varphi \in \mathcal{I}_0$. *Furthermore, it is uniformly bounded over* $\varphi \in \mathcal{I}_0$ *in the sense that* $||\underline{G}(j\varphi)||_{l_2/l_1(l_2)} \le K < \infty$ *for all* $\varphi \in \mathcal{I}_0$ *for some* $K > 0$, *where*

$$||\underline{G}(j\varphi)||_{l_2/l_1(l_2)} := \sup_{0 \neq \underline{x} \in l_1} \left\{ \frac{||\underline{G}(j\varphi)\underline{x}||_{l_2}}{||\underline{x}||_{l_2}} \right\}.$$

Proof. The first assertion follows directly from the preceding arguments. It is clear from the above arguments that $\underline{G}(j\varphi)$ is a mapping from l_1 into l_2. However, l_1 is dense in l_2 so that the frequency response operator established via the steady-state input-output analysis is a densely defined operator on l_2 [21, p. 486]. To see the uniform boundedness of $\underline{G}(j\varphi)$ over the interval $\mathcal{I}_0$, we note that $\underline{B}, \underline{C}$, and $\underline{D}$ are bounded on l_2 by the assumptions on $B(t), C(t)$, and $D(t)$ from Lemma 2.3. Then the uniform boundedness assertion of $\underline{G}(j\varphi)$ follows from Proposition 2.4. ∎

Remark 3.2. Note that we have used the l_2 norm on l_1 in Theorem 3.1. Accordingly, $||\underline{G}(j\varphi)||_{l_2/l_1(l_2)}$ is the l_2-induced norm of $\underline{G}(j\varphi)$ on the subset l_1 of l_2.

By the mathematical expression of the frequency response operator, this operator can have two interpretations. The first one is to view it as a mapping from l_1 into l_2, which has a clear steady-state analysis interpretation as we discussed above; the second is to treat it as a mapping on l_2. The second viewpoint makes sense because it can be seen as a mapping with the extended domain l_2 instead of the original domain l_1, and this mapping itself is bounded on l_2 (since all the operators in $\underline{G}(j\varphi)$ are bounded on l_2, and this fact is used in the uniform boundedness proof of $\underline{G}(j\varphi)$ in Theorem 3.1). Here, to distinguish these two operators, the frequency response operator in the first interpretation is given a new notation $\underline{\tilde{G}}(j\varphi)$, while the original notation $\underline{G}(j\varphi)$ is taken over by the second interpretation. Note that $\underline{\tilde{G}}(j\varphi)$ and $\underline{G}(j\varphi)$ have the same mathematical expression but are defined on different domains.

Compared with $\underline{G}(j\varphi)$, the frequency response operator $\underline{\tilde{G}}(j\varphi)$ defined via the steady-state analysis is "deficient" in the sense that the domain of $\underline{\tilde{G}}(j\varphi)$ is a dense subset of l_2. However, it is straightforward to establish the following corollary, which shows that the l_2-induced norm of $\underline{\tilde{G}}(j\varphi)$ from l_1 to l_2 coincides with the l_2-induced norm of $\underline{G}(j\varphi)$ on l_2. This validates the existing studies on the definition and computation of the H_∞ norm of the FDLCP system (1) based on the frequency response operator $\underline{G}(j\varphi)$.

COROLLARY 3.1. *Suppose that in the system* (1) $A(t)$ *belongs to* $L_{\mathrm{PCD}}[0,h]$, $B(t), C(t)$, *and* $D(t)$ *belong to* $L_{\mathrm{PCC}}[0,h]$, *and that the system* (1) *is asymptotically stable. Then for all* $\varphi \in \mathcal{I}_0$

$$||\tilde{\underline{G}}(j\varphi)||_{l_2/l_1(l_2)} = ||\underline{G}(j\varphi)||_{l_2/l_2}.$$

Hence $\underline{G}(j\varphi)$ *is bounded on* l_2 *uniformly over* $\varphi \in \mathcal{I}_0$.

As final words of this section, we make a few remarks about the H_2 norm of FDLCP systems. In [27], the H_2 norm of FDLCP systems has been defined by

$$||\mathcal{G}||_2 := \left\{ \frac{1}{2\pi} \int_{-\frac{\omega_h}{2}}^{\frac{\omega_h}{2}} \mathrm{trace}(\underline{G}(j\varphi)^* \underline{G}(j\varphi)) d\varphi \right\}^{\frac{1}{2}}. \tag{20}$$

In (20), we have implicitly assumed that the system (1) is strictly proper. Thus $\underline{G}(j\varphi)$ is compact by Proposition 2.4 and the fact that $\underline{B}$ and $\underline{C}$ are bounded on l_2. Even though, rigorously speaking, the steady-state input-output analysis of [27] leads only to $\tilde{\underline{G}}(j\varphi)$ rather than $\underline{G}(j\varphi)$ as mentioned above, it is indeed reasonable to adopt the above definition in terms of $\underline{G}(j\varphi)$ rather than $\tilde{\underline{G}}(j\varphi)$. This is because, as is well known (see, e.g., [12, p. 105], [21, p. 389], [31, p. 347]), trace is defined only for trace class operators, which are a class of (compact) operators defined on Hilbert spaces. Since the domain of $\tilde{\underline{G}}(j\varphi)$ is only a subset of the Hilbert space l_2, it is not adequate to define trace on $\tilde{\underline{G}}(j\varphi)^* \tilde{\underline{G}}(j\varphi)$. On the other hand, it is not hard to show that $\underline{G}(j\varphi)^* \underline{G}(j\varphi)$ is indeed a trace class operator on l_2, which follows from (12). Some further discussions are given in section 5.

4. Frequency response operators viewed on l_1. In this section, we show that under certain conditions, the frequency response operator can also be established via the steady-state analysis of l_1-EMP input signals as a bounded mapping on l_1 (i.e., from l_1 into l_1). Now let us define the set $l_e = \{\underline{x} \in l_1 : \underline{E}(j0)\underline{x} \in l_1\}$ and state the following lemma, which can be shown in a similar way to Lemma 2.4.

LEMMA 4.1. l_e *is a proper dense subset of* l_1 *and* $l_e \subset l_E$.

Lemma 4.1 says that the role of the subset l_e of l_1 is similar to that of the subset l_E of l_2 so that the inverse of $\underline{E}(j0) - \underline{A}$ can be derived as a mapping from l_1 to l_e from (9). For brevity, the details are omitted, but the assertions are stated in the following proposition, which is helpful in establishing the frequency response relation of the FDLCP system in terms of a mapping on l_1.

PROPOSITION 4.1. *Suppose that in* (1) $A(t) \in L_{\mathrm{CPCD}}[0,h], B(t), C(t) \in L_{\mathrm{CAC}}[0,h]$. *Then* $\underline{P}$ *and* $\underline{P}^{-1}$ *are bounded on* l_1. *In particular,* l_e *is* $\underline{P}$- *and* $\underline{P}^{-1}$-*invariant, and hence* $\underline{P}$ *is invertible on* l_e. *The unique inverse of* $\underline{P}$ *on* l_e *is* $\underline{P}^{-1}$ *restricted to* l_e. *It is also true that on* $l_e \subset l_1$

$$\underline{P}(\underline{E}(j0) - \underline{Q})\underline{P}^{-1} = \underline{E}(j0) - \underline{A}. \tag{21}$$

Also, it holds on the whole l_1 *that* $\hat{\underline{B}} = \underline{P}^{-1}\underline{B}$ *and* $\hat{\underline{C}} = \underline{C}\,\underline{P}$. *Furthermore, if the system* (1) *is asymptotically stable in the Floquet theorem sense, then* $\underline{E}(j\varphi) - \underline{A}$ *is invertible for all* $\varphi \in \mathcal{I}_0$, *and*

$$\underline{P}(\underline{E}(j\varphi) - \underline{Q})^{-1}\underline{P}^{-1} = (\underline{E}(j\varphi) - \underline{A})^{-1}, \tag{22}$$

which is a mapping from l_1 *to* l_e. *Also,* $(\underline{E}(j\varphi) - \underline{A})^{-1}$ *is compact and uniformly bounded on* l_1 *over* $\varphi \in \mathcal{I}_0$.

Proof. The proof can be given by some similar steps to those in Propositions 2.3 and 2.4. Here it remains only to show that the operators $\mathcal{T}\{\dot{P}(t,0)\}$, $\underline{P}, \underline{P}^{-1}, \underline{B}$, and $\underline{C}$ are bounded on l_1 and that $(\underline{E}(j\varphi) - \underline{Q})^{-1}$ is uniformly bounded on l_1 over $\varphi \in \mathcal{I}_0$. By (3) and the assumption on $A(t)$, $\dot{P}(t,0)$ is continuous and the first-order derivative of $\dot{P}(t,0)$ is piecewise continuous in $[0,h]$. Hence, by Theorem 2 of [6, p. 104], the Fourier series expansion of $\dot{P}(t,0)$ is absolutely convergent. Now we denote the Fourier coefficients sequence of $\dot{P}(t,0)$ by $\{\hat{P}_m\}_{m=-\infty}^{+\infty}$. Obviously, if $\underline{x} \in l_1$, then

$$\begin{aligned} ||\mathcal{T}\{\dot{P}(t,0)\}\underline{x}||_{l_1} &= \sum_{m=-\infty}^{+\infty} \left|\left| \sum_{k=-\infty}^{+\infty} \hat{P}_{m-k} x_k \right|\right| \\ &\le \sum_{m=-\infty}^{+\infty} \sum_{k=-\infty}^{+\infty} ||\hat{P}_{m-k}|| \cdot ||x_k|| = \left(\sum_{m=-\infty}^{+\infty} ||\hat{P}_m|| \right) ||\underline{x}||_{l_1}, \end{aligned}$$

where $\sum_{m=-\infty}^{+\infty} ||\hat{P}_m|| < \infty$ by the absolute convergence mentioned above. From this, it follows readily that the operator $\mathcal{T}\{\dot{P}(t,0)\}$ is bounded on l_1. Similarly, since the Fourier series expansions of $P(t,0)$ and $P^{-1}(t,0)$ are absolutely convergent, $\underline{P}$ and $\underline{P}^{-1}$ are bounded on l_1. The boundedness of $\underline{B}$ and $\underline{C}$ on l_1 follows directly from the assumption that $B(t)$ and $C(t)$ belong to $L_{\mathrm{CAC}}[0,h]$. The last assertion follows from the above discussions, (12), and (22). ∎

By Proposition 4.1, one can establish the frequency response operator on l_1 by the steady-state analysis but with the l_1-EMP signals. That is, the l_1-EMP input is $u(t) = \sum_{m=-\infty}^{+\infty} u_m e^{j\varphi_m t}, \varphi \in \mathcal{I}_0$, with $\underline{u} := [\ldots, u_{-1}^T, u_0^T, u_1^T, \ldots]^T \in l_1$. The following theorem summarizes such discussions.

THEOREM 4.1. *Assume that in the system* (1) $A(t) \in L_{\mathrm{CPCD}}[0,h]$, $B(t), C(t)$, *and* $D(t)$ *belong to* $L_{\mathrm{CAC}}[0,h]$, *and that the system* (1) *is asymptotically stable. Then the steady-state response of* (1) *to the* l_1-EMP *input* $u(t) = \sum_{m=-\infty}^{+\infty} u_m e^{j\varphi_m t}$ *with* $\underline{u} = [\ldots, u_{-1}^T, u_0^T, u_1^T, \ldots]^T \in l_1$ *is also an* l_1-EMP *signal* $y(t) = \sum_{m=-\infty}^{+\infty} y_m e^{j\varphi_m t}$ *with* $\underline{y} = [\ldots, y_{-1}^T, y_0^T, y_1^T, \ldots]^T = \underline{G}(j\varphi)\underline{u} \in l_1$, *where* $\underline{G}(j\varphi)$ *is given in* (19). *Hence the frequency response operator* $\underline{G}(j\varphi)$ *is well defined on* l_1 *for each* $\varphi \in \mathcal{I}_0$. *Also, it is uniformly bounded over* $\varphi \in \mathcal{I}_0$ *in the sense that* $||\underline{G}(j\varphi)||_{l_1/l_1} \le K < \infty$ *for all* $\varphi \in \mathcal{I}_0$ *for some* $K > 0$.

Remark 4.1. We mention that Theorem 4.1 is not a special case of Theorem 3.1. To see this, the following facts are mentioned. (i) In Theorem 3.1, the EMP signal $u(t)$ is viewed as an l_2-EMP signal even though $u(t)$ itself is l_1-EMP; (ii) Theorems 3.1 and 4.1 are proved by using Propositions 2.4 and 4.1, respectively, which hold on different linear spaces; (iii) The uniform boundedness of the frequency response operator $\underline{G}(j\varphi)$ in Theorem 3.1 is stated in the l_2-induced norm sense from $l_1 \subset l_2$ to l_2, while that of Theorem 4.1 is in the l_1-induced norm sense.

5. Relations to the time-domain definitions of H_2 and H_∞ norms. In this section, we show that the H_2 and H_∞ norms of FDLCP systems defined via the frequency response operator are equal to the time-domain counterparts under some conditions. To this end, let us first define the formal frequency response operator of the system in Figure 1 by

$$\hat{\underline{G}}(j\varphi) = \hat{\underline{C}}(\underline{E}(j\varphi) - \underline{Q})^{-1}\hat{\underline{B}} + \underline{D},$$

where $\hat{\underline{B}} = \mathcal{T}\{\hat{B}(t)\}$ and $\hat{\underline{C}} = \mathcal{T}\{\hat{C}(t)\}$. For $\hat{\underline{G}}(j\varphi)$ to make sense, we assume that $A(t) \in L_2[0,h]$ and the system is asymptotically stable so that $\underline{E}(j\varphi) - \underline{Q}$ is invertible

for all $\varphi \in \mathcal{I}_0$. We also assume that $\underline{\hat{B}}, \underline{\hat{C}}$, and $\underline{D}$ are bounded on l_2. The purpose of introducing this frequency response operator is that the time-domain H_2 norm and the L_2-induced norm are more naturally connected with $\underline{\hat{G}}(j\varphi)$ rather than $\underline{G}(j\varphi)$, although, under stronger assumptions, the matrix representations of these two operators eventually coincide with each other. This coincidence will help to recover the equivalences between these two norms and the counterparts in terms of the frequency response operator.

First, we consider the H_2 norm of FDLCP systems. In what follows, we assume that the FDLCP system (1) is strictly proper when the H_2 norm problem is considered. Denoting the impulse response of the system (1) by $g(\cdot,\cdot)$, the time-domain H_2 norm [5], [27], [32] of the FDLCP system (1) is

$$||\mathcal{G}||_2 = \left\{ \frac{1}{h} \int_0^h \int_{-\infty}^{+\infty} \mathrm{trace}(g(t,\tau)^* g(t,\tau)) dt d\tau \right\}^{\frac{1}{2}}.$$

PROPOSITION 5.1. *Suppose that in the system* (1) $A(t) \in L_2[0,h]$*, and the system is asymptotically stable. Also assume that* $\hat{B}(t)$ *and* $\hat{C}(t)$ *belong to* $L_{\mathrm{CAC}}[0,h]$*. Then it holds that*

$$||\mathcal{G}||_2 = \left\{ \frac{1}{2\pi} \int_{-\frac{\omega_h}{2}}^{\frac{\omega_h}{2}} \mathrm{trace}(\underline{\hat{G}}(j\varphi)^* \underline{\hat{G}}(j\varphi)) d\varphi \right\}^{\frac{1}{2}}.$$

Proof. See Appendix B. □

We are in a position to show the following result, which says that the time-domain definition of the H_2 norm is equivalent to the frequency-domain definition given in [27]. Even though this fact seems to be regarded as well known, we stress here that no direct and explicit proof via the frequency response operator is available in the literature to the best of the knowledge of the authors.

THEOREM 5.1. *Suppose that in the system* (1) $A(t)$ *belongs to* $L_{\mathrm{PCD}}[0,h]$*,* $B(t)$ *and* $C(t)$ *belong to* $L_{\mathrm{CAC}}[0,h]$*, and that the system is asymptotically stable. Then*

$$||\mathcal{G}||_2 = \left\{ \frac{1}{2\pi} \int_{-\frac{\omega_h}{2}}^{\frac{\omega_h}{2}} \mathrm{trace}(\underline{G}(j\varphi)^* \underline{G}(j\varphi)) d\varphi \right\}^{\frac{1}{2}}.$$

Proof. Under the given conditions, it is clear from Propositions 2.3 and 2.4 that $\underline{\hat{G}}(j\varphi) = \underline{G}(j\varphi)$. Hence, by the result in Proposition 5.1, it remains to show that the Fourier series expansions of $\hat{B}(t) = P^{-1}(t,0)B(t)$ and $\hat{C}(t) = C(t)P(t,0)$ are absolutely convergent. To see this, it is enough to note that the Fourier series expansions of $P^{-1}(t,0)$ and $P(t,0)$ are absolutely convergent from Proposition 2.2 by the assumption on $A(t)$. □

Now we discuss the relation between the L_2-induced norm and the H_∞ norm of FDLCP systems. The L_2-induced norm of the FDLCP system (1) is

$$||\mathcal{G}||_{L_2/L_2} = \sup_{0 \neq u \in L_2} \frac{||y(\cdot)||_{L_2}}{||u(\cdot)||_{L_2}}.$$

To establish the relation between the L_2-induced norm and the H_∞ norm of FDLCP systems, we first prove the following proposition. To this purpose, we introduce the so-called SD-Fourier transform [1]. For a signal $x \in L_2$, its SD-Fourier

transform is defined as

$$\underline{X}_{\mathrm{SD}}(j\varphi) := [\ldots, X(j\varphi_{-1})^T, X(j\varphi_0)^T, X(j\varphi_1)^T, \ldots]^T, \tag{23}$$

where $X(j\omega)$ is the Fourier transform of x, and $X(j\varphi_n) = X(j(\varphi + n\omega_h)), n \in \mathcal{Z}, \varphi \in \mathcal{I}_0$. It can also be said that $\underline{X}_{\mathrm{SD}}(j\varphi)$ is the lifted version of $X(j\omega)$ in the frequency domain. This kind of frequency-domain lifting technique has been frequently used in sampled-data system sensitivity analysis [4] and signal processing [24].

PROPOSITION 5.2. *Suppose that in the system* (1) $A(t)$ *belongs to* $L_2[0,h]$, $\hat{B}(t), \hat{C}(t)$, *and* $D(t)$ *belong to* $L_{\mathrm{CAC}}[0,h]$, *and that the system is asymptotically stable in the Floquet theorem sense. Then the system* (1) *is* L_2*-stable and*

(1) $\underline{Y}_{\mathrm{SD}}(j\varphi) = \underline{\hat{G}}(j\varphi)\underline{U}_{\mathrm{SD}}(j\varphi)$ *for all* $\varphi \in \mathcal{I}_0$ *for any* $u(t) \in C_0^1$, *where* C_0^1 *denotes the space of continuously differentiable functions with compact support;*

(2) $||y(\cdot)||_{L_2}^2 = \frac{1}{2\pi}\int_{\mathcal{I}_0} \underline{U}_{\mathrm{SD}}^*(j\varphi)\underline{\hat{G}}^*(j\varphi)\underline{\hat{G}}(j\varphi)\underline{U}_{\mathrm{SD}}(j\varphi)d\varphi$ *for any* $u(t) \in C_0^1$;

where $\underline{U}_{\mathrm{SD}}(j\varphi)$ *and* $\underline{Y}_{\mathrm{SD}}(j\varphi)$ *are the* SD*-Fourier transforms of* $u(t)$ *and* $y(t)$, *respectively.*

Proof. See Appendix B. ∎

Based on Proposition 5.2, we establish the equivalence between the L_2-induced norm of the system (1) and the maximum of the l_2-induced norm of $\underline{G}(j\varphi)$ over $\varphi \in \mathcal{I}_0$, which is called the H_∞ norm of the frequency response operator $\underline{G}(j\varphi)$ of the FDLCP system (1) [17], [27]. Again, no direct and explicit proof for this equivalence is available in the literature.

THEOREM 5.2. *Suppose that in the system* (1) $A(t)$ *belongs to* $L_{\mathrm{PCD}}[0,h]$, $B(t)$, $C(t)$, *and* $D(t)$ *belong to* $L_{\mathrm{CAC}}[0,h]$, *and that the system is asymptotically stable. Then*

$$||\mathcal{G}||_{L_2/L_2} = \max_{\varphi\in\mathcal{I}_0} ||\underline{G}(j\varphi)||_{l_2/l_2}.$$

Proof. By the assumptions on $A(t), B(t)$, and $C(t)$, together with Proposition 2.2, it follows that the Fourier series expansions of $\hat{B}(t)$ and $\hat{C}(t)$ are also absolutely convergent. This implies that Proposition 5.2 applies to the system of Figure 1. In view of this, we show that

$$||\mathcal{G}||_{L_2/C_0^1(L_2)} := \sup_{u\in C_0^1} \frac{||y(\cdot)||_{L_2}}{||u(\cdot)||_{L_2}} = \max_{\varphi\in\mathcal{I}_0} ||\underline{\hat{G}}(j\varphi)||_{l_2/l_2}. \tag{24}$$

This can be accomplished by some similar arguments to those in the proof of Theorem 5 of [1]. On the other hand, since C_0^1 is dense in L_2, it follows that $||\mathcal{G}||_{L_2/C_0^1(L_2)} = ||\mathcal{G}||_{L_2/L_2}$. Furthermore, under the given assumptions, it is obvious that $\underline{\hat{G}}(j\varphi) = \underline{G}(j\varphi)$ by Propositions 2.3 and 2.4. This, together with (24), completes the proof. ∎

6. Conclusion. The frequency response relation of FDLCP systems via the steady-state input-output analysis is reconsidered in this paper. We found that because of the various convergence problems related to the Fourier analysis and the Toeplitz transformation, the frequency response operator defined in [27] via such an analysis is actually guaranteed to be defined only densely on l_2 but that the frequency response operator can be extended to have the whole l_2 as its domain so that we still can define and compute the H_2 and H_∞ norms of FDLCP systems based on the frequency response operator [33]. It is also proved that, under some strengthened conditions, the time-domain H_2 norm (respectively, the L_2-induced norm) is equal to

the frequency-domain H_2 norm (respectively, the H_∞ norm of the frequency response operator). Thus the well-known equivalences about the H_2 and H_∞ norms in LTI continuous-time systems are recovered in a class of FDLCP systems. As another contribution of this study, it is verified that the frequency response operator defined by the steady-state input-output analysis can also be established as a mapping on l_1 under some strengthened assumptions on the system matrices $\{A(t), B(t), C(t), D(t)\}$. How to exploit this frequency response operator on l_1 remains one of our future research topics. The implication of this work is that the frequency response operator defined via the steady-state input-output analysis is well defined in most practical FDLCP systems, and the mathematical expression of these operators are similar to the well-known results in LTI systems. In addition, it is worth mentioning that this study reveals that the frequency response operators via the steady-state analysis may contain much more system structural information of FDLCP systems than we have understood in the usual ways before. For example, we believe that through the steady-state input-output analysis to l_p-EMP signals, $2 < p < \infty$, the frequency response operators of FDLCP systems can be introduced as a mapping (densely defined) on l_p under possibly weaker assumptions than those in the l_2 case. This is left for our further study.

Appendix A.

LEMMA A.1 (see [1]). *If the function $f(n)$ of an integer n is defined by*

$$f(n) = \begin{cases} 1, & n = 0, \\ |n|^{-1}, & n \neq 0, \end{cases}$$

then we have $\sum_{n=N+1}^{\infty} f(n)^2 < \frac{1}{N}$ $(N \geq 1)$ and $\sum_{n=-\infty}^{\infty} f(n)^2 < 5$.

Appendix B.

Proof of Lemma 2.1. Since $Y(t) \in L_{\mathrm{CAC}}[0, h]$, it follows that its Fourier series expansion is uniformly convergent with respect to t over $[0, h]$. Thus the Fourier series expansion of $Y(t)$ defines a continuous function over $[0, h]$, which is nothing but $Y(t)$ by the continuity of $Y(t)$. In other words, for every $t_0 \in [0, h]$, the Fourier series expansion of $Y(t)$ converges to $Y(t_0)$. Hence, for each $t_0 \in [0, h]$ at which the Fourier series expansion of $X(t)$ converges to $X(t_0)$, we have

$$\begin{aligned} X(t_0)Y(t_0) &= \left(\sum_{m=-\infty}^{+\infty} X_m e^{jm\omega_h t_0} \right) \left(\sum_{m=-\infty}^{+\infty} Y_m e^{jm\omega_h t_0} \right) \\ &= \sum_{m=-\infty}^{+\infty} \left(\sum_{k=-\infty}^{+\infty} X_{m-k} Y_k \right) e^{jm\omega_h t_0}, \end{aligned} \tag{25}$$

where we used the Mertens theorem to compute the product of two infinite sums, which also ensures that the right-hand side of (25) is convergent at t_0. Noting that it is in the form of the Fourier series expansion, it immediately follows that $\{\sum_{k=-\infty}^{+\infty} X_{m-k} Y_k\}_{m=-\infty}^{+\infty}$ is indeed the Fourier coefficients sequence of $X(t)Y(t)$ because we readily have

$$\left\| X(t)Y(t) - \sum_{m=-\infty}^{+\infty} \left(\sum_{k=-\infty}^{+\infty} X_{m-k} Y_k \right) e^{jm\omega_h t} \right\|_{L_2[0,h]} = 0 \tag{26}$$

(since (25) holds for a.e. $t_0 \in [0, h]$ by the assumption), and the Fourier series expansion is unique. This gives $\mathcal{T}\{X(t)Y(t)\} = \mathcal{T}\{X(t)\}\mathcal{T}\{Y(t)\}$. The same is true for $\mathcal{T}\{Y(t)X(t)\} = \mathcal{T}\{Y(t)\}\mathcal{T}\{X(t)\}$. ∎

Proof of Lemma 2.2. Take an arbitrary $f(t) \in L_2[0,h]$, and expand it into the Fourier series expansion $f(t) = \sum_{n=-\infty}^{+\infty} f_n e^{jn\omega_h t}$ with $\underline{f} := [\ldots, f_{-1}^T, f_0^T, f_1^T, \ldots]^T \in l_2$. Note that, for any $\epsilon > 0$, we can find $\underline{d} \in l_1$ such that $||\underline{f} - \underline{d}||_{l_2} < \epsilon$ since l_1 is dense in l_2. Now construct $d(t) := \sum_{n=-\infty}^{+\infty} d_n e^{jn\omega_h t}$. It is easy to see that $d(t) \in L_{\mathrm{CAC}}[0,h]$ and

$$||f(\cdot) - d(\cdot)||_{L_2[0,h]} = \left|\left| \sum_{n=-\infty}^{+\infty} (f_n - d_n) e^{jn\omega_h t} \right|\right|_{L_2[0,h]} = ||\underline{f} - \underline{d}||_{l_2} < \epsilon$$

by the Parseval theorem. This completes the proof. □

Proof of Lemma 2.3. Taking $f(t) \in L_{\mathrm{CAC}}[0,h]$ and expanding it into the Fourier series expansion $f(t) = \sum_{n=-\infty}^{+\infty} f_n e^{jn\omega_h t}$, it follows that $\underline{f} := [\ldots, f_{-1}^T, f_0^T, f_1^T, \ldots]^T \in l_1$. The converse is also true. On the other hand, by the assumption on $X(t)$, it follows from Lemma 2.1 that $\underline{X}\,\underline{f} = \underline{y}$, where $\underline{y}$ is similarly defined to $\underline{f}$ but in terms of the Fourier coefficients of $X(t)f(t)$. Thus it follows that

$$||\underline{X}||_{l_2/l_1(l_2)} := \sup_{\underline{f} \in l_1} \left\{ \frac{||\underline{X}\,\underline{f}||_{l_2}}{||\underline{f}||_{l_2}} \right\} = \sup_{f(t) \in L_{\mathrm{CAC}}[0,h]} \left\{ \frac{||X(\cdot)f(\cdot)||_{L_2[0,h]}}{||f(\cdot)||_{L_2[0,h]}} \right\} =: ||X(\cdot)||_*.$$

Obviously, $||\underline{X}||_{l_2/l_1(l_2)} = ||\underline{X}||_{l_2/l_2}$ since l_1 is dense in l_2. Similarly, from Lemma 2.2, $||X(\cdot)||_* = ||X(\cdot)||_{L_2[0,h]/L_2[0,h]}$. Hence we obtain $||\underline{X}||_{l_2/l_2} = ||X(\cdot)||_{L_2[0,h]/L_2[0,h]} = \sup_{t \in [0,h]} ||X(t)||$. Since $X(t) \in L_{\mathrm{PCC}}[0,h]$ by the assumption, the boundedness assertion follows. □

Proof of Lemma 2.4. Let $\underline{x} \in l_2$. For any $\epsilon > 0$, there exists $\underline{x}' \in l_2$ with only finite nonzero entries such that $||\underline{x} - \underline{x}'||_{l_2} < \epsilon$. It is obvious that $\underline{E}(j0)\underline{x}' \in l_2$. Hence $\underline{x}' \in l_E$, which implies that l_E is dense in l_2.

Furthermore, it is clear that $\underline{x} \in l_E$ if and only if $\sum_{\substack{m=-\infty \\ m \neq 0}}^{+\infty} m^2 \omega_h^2 ||[\underline{x}]_m||^2 < \infty$. It follows from the Cauchy–Schwarz inequality that if $\underline{x} \in l_E$, then

$$\sum_{\substack{m=-\infty \\ m \neq 0}}^{+\infty} ||[\underline{x}]_m|| = \sum_{\substack{m=-\infty \\ m \neq 0}}^{+\infty} m \cdot \frac{1}{m} ||[\underline{x}]_m|| \leq \left(\sum_{\substack{m=-\infty \\ m \neq 0}}^{+\infty} m^2 ||[\underline{x}]_m||^2 \right)^{\frac{1}{2}} \left(\sum_{\substack{m=-\infty \\ m \neq 0}}^{+\infty} \frac{1}{m^2} \right)^{\frac{1}{2}} \leq M < \infty$$

for some $M > 0$. This implies that if $\underline{x} \in l_E$, then $\underline{x} \in l_1$. The fact that l_E is dense in l_1 can be shown in exactly the same way as in the proof for the first assertion (i.e., via truncation). Now take

$$[\underline{x}]_m = \begin{cases} \frac{1}{|m|^{\frac{5}{4}}} [1, 0, \ldots, 0]^T & (m \neq 0), \\ 0 & (m = 0). \end{cases}$$

Then it can be shown that $\underline{x} \in l_1$ but $\underline{E}(j0)\underline{x} \notin l_2$, which says that l_E is a proper subset of l_1. □

Proof of Proposition 5.1. A complete proof can be found in [34]. Here we give only an outline of the proof. By the Floquet theorem, the transition matrix of (1) can be written as $\Phi(t,0) = P(t,0)e^{Qt}$ when the initial time $t_0 = 0$. Thus the impulse response of the system to the input $e_i \delta(t-\tau)$ ($\delta(t-\tau)$ is the delta function imposed at $t = \tau \geq 0$, e_i is the ith natural basis of $\mathbf{R}^m$) is given by

$$(Ge_i\delta_\tau)(t) = \begin{cases} C(t)P(t,0)e^{Q(t-\tau)}P^{-1}(\tau,0)B(\tau)e_i & (t \geq \tau), \\ 0 & (t < \tau). \end{cases} \tag{27}$$

Here we further define $\tilde{B}^T := [\ldots, \hat{B}_{-1}^T, \hat{B}_0^T, \hat{B}_1^T, \ldots]^T$, $\tilde{C} := [\ldots, \hat{C}_1, \hat{C}_0, \hat{C}_{-1}, \ldots]$, and $\Lambda(t) := [\ldots, e^{j\omega_h t} I, I, e^{-j\omega_h t} I, \ldots]^T$ with $\{\hat{B}\}_{m=-\infty}^{+\infty}$ and $\{\hat{C}\}_{m=-\infty}^{+\infty}$ being the Fourier coefficients sequence of $\hat{B}(t)$ and $\hat{C}(t)$, respectively. Then, by the assumptions on $\hat{B}(t)$ and $\hat{C}(t)$, $\hat{B}(t) = \Lambda(\tau)^* \tilde{B}$ and $\hat{C}(t) = \tilde{C}\Lambda(t)$ hold. Therefore, taking the Fourier transformation on (27) about t, we obtain

$$\begin{aligned} F[(Ge_i\delta_\tau)(t)](j\omega) &= \tilde{C} \int_\tau^{+\infty} \Lambda(t) e^{Q(t-\tau)} e^{-j\omega t} dt \Lambda(\tau)^* \tilde{B} e_i \\ &= \tilde{C}(\underline{E}(j\omega) - \underline{Q})^{-1} \Lambda(\tau)\Lambda(\tau)^* \tilde{B} e_i e^{-j\omega\tau}. \end{aligned} \tag{28}$$

In (28), the order of the integral and the infinite summation caused by $\hat{C}(t)\Lambda(t)$ is interchanged. This is validated by the stability assumption, $\hat{C}(t) \in L_{CAC}[0, h]$, and by the Levi theorem [21, p. 577].

Hence, by the time-domain definition of the H_2 norm, we have

$$\begin{aligned} ||\mathcal{G}||_2^2 &= \frac{1}{h} \int_0^h \sum_{i=1}^m \operatorname{trace} \left(\int_0^{+\infty} (Ge_i\delta_\tau)(t)(Ge_i\delta_\tau)^*(t) dt \right) d\tau \\ &= \frac{1}{2\pi h} \int_0^h \sum_{i=1}^m \operatorname{trace} \left(\int_{-\infty}^{+\infty} \tilde{C}(\underline{E}(j\omega) - \underline{Q})^{-1} \Lambda(\tau)\Lambda(\tau)^* \tilde{B} e_i \right. \\ &\qquad \left. \cdot e_i^* \tilde{B}^* \Lambda(\tau)\Lambda(\tau)^* (\underline{E}(j\omega) - \underline{Q})^{-*} \tilde{C}^* d\omega \right) d\tau \\ &= \frac{1}{2\pi h} \int_0^h \operatorname{trace} \left(\int_{-\infty}^{+\infty} \tilde{C}(\underline{E}(j\omega) - \underline{Q})^{-1} \Lambda(\tau)\Lambda(\tau)^* \tilde{B} \right. \\ &\qquad \left. \cdot \tilde{B}^* \Lambda(\tau)\Lambda(\tau)^* (\underline{E}(j\omega) - \underline{Q})^{-*} \tilde{C}^* d\omega \right) d\tau \\ &= \frac{1}{2\pi h} \int_{-\infty}^{+\infty} \operatorname{trace} \left(\tilde{C}(\underline{E}(j\omega) - \underline{Q})^{-1} \right. \\ &\qquad \left. \cdot \left[\int_0^h \Lambda(\tau)\Lambda(\tau)^* \tilde{B} \tilde{B}^* \Lambda(\tau)\Lambda(\tau)^* d\tau \right] (\underline{E}(j\omega) - \underline{Q})^{-*} \tilde{C}^* \right) d\omega \end{aligned} \tag{29}$$

by the Parseval theorem and (28). In (29), the orders of the integrals and the infinite summations are interchanged repeatedly. These can be validated by the Fubini theorem [21, p. 598] and the Levi theorem. Noting also that the trace computations are done on finite-dimensional matrices, the trace computations here are actually only finite summations.

Furthermore, it is easy to see that

$$\Lambda(\tau)\Lambda(\tau)^* \tilde{B}\, \tilde{B}^* \Lambda(\tau)\Lambda(\tau)^* = R(\tau)\Lambda(\tau)\Lambda(\tau)^* R(\tau)^*, \tag{30}$$

where $R(\tau) := \operatorname{diag}[\ldots, \hat{B}(\tau), \hat{B}(\tau), \hat{B}(\tau), \ldots]$. By the assumption, $\hat{B}(\tau)$ has the absolutely convergent Fourier series expansion $\hat{B}(\tau) = \sum_{q=-\infty}^{+\infty} \hat{B}_q e^{jq\omega_h\tau}$. Hence, it follows from Cauchy's rule that $\hat{B}(\tau)\hat{B}(\tau)^* = \sum_{m=-\infty}^{+\infty} (\sum_{n=-\infty}^{+\infty} \hat{B}_{m-n} \hat{B}_n^*) e^{jm\omega_h\tau}$, which implies that

$$\frac{1}{h} \int_0^h R(\tau)\Lambda(\tau)\Lambda(\tau)^* R(\tau)^* d\tau = \underline{\hat{B}}\, \underline{\hat{B}}^* \tag{31}$$

with $\hat{\underline{B}}$ similarly defined to $\underline{A}$ but in terms of $\{\hat{B}_q\}_{q=-\infty}^{+\infty}$. Finally, using (31) in (29) yields

$$\begin{aligned}
||\mathcal{G}||_2^2 &= \frac{1}{2\pi}\int_{-\infty}^{+\infty} \mathrm{trace}(\tilde{C}(\underline{E}(j\omega)-\underline{Q})^{-1}\hat{\underline{B}}\,\hat{\underline{B}}^*(\underline{E}(j\omega)-\underline{Q})^{-*}\tilde{C}^*)d\omega \\
&= \frac{1}{2\pi}\sum_{m=-\infty}^{+\infty}\int_{-\frac{\omega_h}{2}}^{\frac{\omega_h}{2}} \mathrm{trace}(\tilde{C}(\underline{E}(j\varphi_m)-\underline{Q})^{-1}\hat{\underline{B}}\,\hat{\underline{B}}^*(\underline{E}(j\varphi_m)-\underline{Q})^{-*}\tilde{C}^*)d\varphi \\
&= \frac{1}{2\pi}\int_{-\frac{\omega_h}{2}}^{\frac{\omega_h}{2}}\sum_{m=-\infty}^{+\infty} \mathrm{trace}(\tilde{C}(\underline{E}(j\varphi_m)-\underline{Q})^{-1}\hat{\underline{B}}\,\hat{\underline{B}}^*(\underline{E}(j\varphi_m)-\underline{Q})^{-*}\tilde{C}^*)d\varphi \\
&= \frac{1}{2\pi}\int_{-\frac{\omega_h}{2}}^{\frac{\omega_h}{2}} \mathrm{trace}(\hat{\underline{C}}(\underline{E}(j\varphi)-\underline{Q})^{-1}\hat{\underline{B}}\,\hat{\underline{B}}^*(\underline{E}(j\varphi)-\underline{Q})^{-*}\hat{\underline{C}}^*)d\varphi
\end{aligned}$$

as claimed. In the above, we have interchanged the order of the integral and the summation. To validate this, it suffices to show that the convergence of

$$\sum_{|m|\le M} \mathrm{trace}(\tilde{C}(\underline{E}(j\varphi_m)-\underline{Q})^{-1}\hat{\underline{B}}\,\hat{\underline{B}}^*(\underline{E}(j\varphi_m)-\underline{Q})^{-*}\tilde{C}^*) \to \mathrm{trace}(\hat{\underline{G}}(j\varphi)^*\hat{\underline{G}}(j\varphi))$$

is uniform over $\varphi \in \mathcal{I}_0$ as $M \to \infty$. This can be completed by using the trace formula on an orthonormal basis of l_2 [21]. A full explanation is given in [34]. □

Proof of Proposition 5.2. By the Floquet theorem, the L_2-stability is obvious. Then, for any $u(t) \in L_2$, the output $y(t)$ belongs to L_2. Also, C_0^1 is a dense subset of L_2 [21, Exercise D.13.3, p. 593]. Therefore, it makes sense to define the Fourier transforms $U(j\omega)$ and $Y(j\omega)$ for the input $u(t) \in C_0^1$ and the output $y(t)$. We compute $Y(j\omega)$ in four steps.

Step 1. The Fourier transform of the signal p (see Figure 1) is given by

$$P(j\omega) = \int_{-\infty}^{+\infty}\left(\sum_{m=-\infty}^{+\infty}\hat{B}_m e^{jm\omega_h t}\right)u(t)e^{-j\omega t}dt = \sum_{m=-\infty}^{+\infty}\hat{B}_m U(j(\omega - m\omega_h)), \tag{32}$$

which is well defined since $\hat{B}(t)$ is L_2-stable (by the boundedness of $\hat{B}(t)$ on $[0,h]$). Here, the order of infinite integral and infinite summation is interchanged. This is valid by the absolute convergence of the Fourier series expansion of $\hat{B}(t)$ and the fact that $u(t)$ has compact support.

Step 2. Imposing the signal p to the LTI subsystem of Figure 1, the Fourier transform of q is

$$Q(j\omega) = (j\omega I - Q)^{-1}\sum_{m=-\infty}^{+\infty}\hat{B}_m U(j(\omega - m\omega_h)). \tag{33}$$

Since $u(t) \in C_0^1$, it is clear that $\hat{B}(t)u(t) \in L_1$. Also, by the stability assumption, the LTI subsystem of Figure 1 is L_1-stable [25]. Hence $q(t) \in L_1$. Now truncate $q(t)$ as follows. Obviously, $q_{_T}(t) \in L_1$.

$$q_{_T}(t) = \begin{cases} q(t) & (0 \le t \le T), \\ 0 & (t > T). \end{cases}$$

Based on the facts that $q(t)$ and $q_{_T}(t)$ belong to L_1 for all $T > 0$, we have

$$\lim_{T\to\infty} Q_T(j\omega) = Q(j\omega) \tag{34}$$

uniformly over $\omega \in (-\infty, +\infty)$, where $Q_T(j\omega)$ is the Fourier transform of the signal $q_{_T}(t)$ since

$$||Q_T(j\omega) - Q(j\omega)|| = \left|\left|\int_0^\infty (q_{_T}(t) - q(t))e^{-j\omega t}dt\right|\right| \le \int_0^\infty ||q_{_T}(t) - q(t)||dt \to 0 \quad (T \to \infty).$$

Step 3. Let $\hat{y}(t)$ be the output of $\hat{C}(t)$ to the input $q(t)$, and let $\hat{y}_{_T}(t)$ be that corresponding to the truncated signal $q_{_T}(t)$, which has compact support. Then we clearly have $\hat{y}_{_T}(t) = \hat{C}(t)q_{_T}(t)$ so that by repeating the arguments about (32) on $\hat{C}(t)$, the Fourier transform of $y_{_T}(t)$ is given by

$$\hat{Y}_T(j\omega) = \sum_{n=-\infty}^{+\infty} \hat{C}_n Q_T(j(\omega - n\omega_h)). \tag{35}$$

It is obvious that $\hat{y}(t)$ and $\hat{y}_{_T}(t)$ belong to L_1 since $\hat{C}(t)$ is bounded on $t \ge 0$. Based on this fact, repeating the arguments about $q(t)$ and $q_{_T}(t)$ on $y(t)$ and $y_{_T}(t)$, it follows that $\lim_{T\to\infty} Y_T(j\omega) = Y(j\omega)$ uniformly over $\omega \in (-\infty, +\infty)$. This further gives the relation

$$\hat{Y}(j\omega) = \sum_{n=-\infty}^{+\infty} \hat{C}_n Q(j(\omega - n\omega_h)) \tag{36}$$

since it is evident that

$$\left|\left| \sum_{n=-\infty}^{+\infty} \hat{C}_n Q_T(j(\omega - n\omega_h)) - \sum_{n=-\infty}^{+\infty} \hat{C}_n Q(j(\omega - n\omega_h)) \right|\right| \le \sum_{n=-\infty}^{+\infty} ||\hat{C}_n|| \cdot ||Q_T(j(\omega - n\omega_h)) - Q(j(\omega - n\omega_h))|| \to 0 \quad (T \to \infty)$$

uniformly over $\omega \in (-\infty, +\infty)$ by (34) and $\sum_{n=-\infty}^{+\infty} ||\hat{C}_n|| < \infty$, which follows from the absolute convergence of the Fourier series expansion of $\hat{C}(t)$.

Step 4. Taking the feedforward term $D(t)$ into consideration and lifting the Fourier transform $Y(j\omega)$ of the whole output to its SD-Fourier transform $\underline{Y}_{\rm SD}(j\varphi)$ leads to the assertion (1).

To show the assertion (2), by the well-known Parseval theorem, we note that

$$||y(\cdot)||_{L_2}^2 = \frac{1}{2\pi}\int_{-\infty}^{+\infty} Y(j\omega)^* Y(j\omega)d\omega = \frac{1}{2\pi}\sum_{m=-\infty}^{+\infty}\int_{\mathcal{I}_0} Y(j\varphi_m)^* Y(j\varphi_m)d\varphi$$
$$= \frac{1}{2\pi}\int_{\mathcal{I}_0} \underline{Y}_{\rm SD}(j\varphi)^* \underline{Y}_{\rm SD}(j\varphi)d\varphi = \frac{1}{2\pi}\int_{\mathcal{I}_0} \underline{U}_{\rm SD}(j\varphi)^* \underline{\hat{G}}(j\varphi)^* \underline{\hat{G}}(j\varphi)\underline{U}_{\rm SD}(j\varphi)d\varphi.$$

To complete the proof, it remains to show that the interchange of the integral and summation is valid. To this end, it is enough to show that the convergence of $\sum_{m=-M}^{M} Y(j\varphi_m)^* Y(j\varphi_m) \to \underline{Y}_{\rm SD}(j\varphi)^* \underline{Y}_{\rm SD}(j\varphi)$ as $M \to \infty$ is uniform over $\varphi \in \mathcal{I}_0$. A complete proof can be found in [34]. □

A UNIFYING INTEGRAL ISS FRAMEWORK FOR STABILITY OF NONLINEAR CASCADES*

MURAT ARCAK†, DAVID ANGELI‡, AND EDUARDO SONTAG§

Abstract. We analyze nonlinear cascades in which the driven subsystem is integral input-to-state stable (ISS), and we characterize the admissible integral ISS gains for stability. This characterization makes use of the convergence speed of the driving subsystem and allows a larger class of gain functions when the convergence is faster. We show that our integral ISS gain characterization unifies different approaches in the literature which restrict the nonlinear growth of the driven subsystem and the convergence speed of the driving subsystem. The result is used to develop a new observer-based backstepping design in which the growth of the nonlinear damping terms is reduced.

Key words. nonlinear cascades, stabilization, integral input-to-state stability

1. Introduction.

Studies on the stabilization of cascade systems have paved the road to major advances in nonlinear control theory. Among these advances are several constructive design methods such as *backstepping* and *forwarding*, which are based on recursive applications of cascade designs (see, e.g., Sepulchre, Janković, and Kokotović [17]), and the discovery of structural obstacles to stabilization such as the *peaking phenomenon* (see Sussmann and Kokotović [23]).

One of the main motivations for the stabilization of cascades came from the linear-nonlinear cascade

$$\dot{x} = f(x, z), \tag{1}$$

$$\dot{z} = Az + Bu \tag{2}$$

resulting from input-output linearization. Because global asymptotic stability (GAS) of the x-subsystem $\dot{x} = f(x, 0)$ is not sufficient to achieve GAS of the whole cascade with z-feedback $u = Kz$, alternative designs which employ x-feedback were developed, such as the *feedback passivation* design of Kokotović and Sussmann [8]. To achieve GAS by z-feedback, Sontag [18], Seibert and Suarez [16], Mazenc and Praly [11], Janković, Sepulchre, and Kokotović [6], and Panteley and Loría [12, 13] studied general cascades in the which the z-subsystem is nonlinear and derived conditions for the x- and z-subsystems that ensure stability of the cascade. Among these results, a particularly useful one is the input-to-state stability (ISS) condition in [19], which states that if the x-subsystem is ISS with input z and the z-subsystem is GAS, then the cascade is GAS. This result has been widely used for nonlinear designs based on the *normal form* (1)–(2), in which the *zero dynamics* (1) is ISS. Other results, such

as [11] and [6], make less restrictive assumptions than ISS for the x-subsystem but restrict the z-subsystem to be locally exponentially stable (LES).

The integral version of ISS (iISS), recently introduced in [20], requires that an energy norm of the input be bounded to ensure boundedness of the states. As shown in [20], iISS is less restrictive than ISS because, in an iISS system, a bounded input may lead to unbounded solutions if its energy norm is infinite.

In this paper, we analyze the stability of nonlinear cascades in which the x-subsystem is iISS and the z-subsystem is GAS. The admissible iISS gains for stability are characterized from the speed of convergence of the z-subsystem. When the convergence is fast, the iISS gain function of the x-subsystem is allowed to be "steep" at zero. We show that this trade-off between slower convergence and steeper iISS gain encompasses and unifies several results in the literature. In particular, if the x-subsystem is ISS, then the slope of its iISS gain function is very gentle at zero and tolerates every GAS z-subsystem no matter how slow its convergence is. On the other hand, if the convergence is exponential, that is, if the z-subsystem is LES, then the cascade is stable for a large class of iISS gains. This class includes all iISS x-subsystems that are affine in the input z. Thus, for systems like (1)–(2), where a control law can be designed to render the z-subsystem GAS and LES, the iISS of the x-subsystem ensures GAS of the cascade.

In section 2, we define the new concepts used in the paper and present lemmas which are preliminary to our main results. In section 3, we present our main result, Theorem 1, which characterizes the admissible iISS gains from the speed of convergence of the z-subsystem. We show that several results in the literature are special cases of Theorem 1, including those that restrict the x-subsystem to be ISS (Corollary 1) and those that restrict the z-subsystem to be LES (Corollary 2). In section 4, we show that Corollary 2 restricts the nonlinear growth of the interconnection term and illustrate with an example that violating this growth condition leads to instability of the cascade.

The second main contribution of the paper is an output-feedback application of our cascade result. Due to the absence of a separation principle, it is necessary to design control laws that guarantee robustness against the observer error. We present a design which renders the system iISS with respect to the observer error and hence ensures robustness when the error is exponentially decaying. The advantage of our design over the observer-based backstepping scheme of Kanellakopoulos, Kokotović, and Morse [7] is that we employ "weak" nonlinear damping terms which grow slower than those in [7] and result in a "softer" control law. The main features of the design are discussed and illustrated in an example in section 5. The general design procedure and its stability proof are given in section 6.

2. Definitions and preliminary lemmas. In this section, we give definitions and present lemmas that will be used in the rest of the paper. The proofs are given in section 7.

We first recall standard definitions: $\mathcal{K}$ is the class of functions $\mathbb{R}_{\geq 0} \to \mathbb{R}_{\geq 0}$ which are zero at zero, strictly increasing, and continuous. $\mathcal{K}_\infty$ is the subset of class-$\mathcal{K}$ functions that are unbounded. $\mathcal{L}$ is the set of functions $\mathbb{R}_{\geq 0} \to \mathbb{R}_{\geq 0}$ which are continuous, decreasing, and converging to zero as their argument tends to $+\infty$. $\mathcal{KL}$ is the class of functions $\mathbb{R}_{\geq 0} \times \mathbb{R}_{\geq 0} \to \mathbb{R}_{\geq 0}$ which are class-$\mathcal{K}$ in the first argument and class-$\mathcal{L}$ in the second argument.

DEFINITION 1. *We say that the function $\mu(\cdot) : \mathbb{R}_{\geq 0} \to \mathbb{R}_{\geq 0}$ is class-$\mathcal{K}_o$ if it is class-$\mathcal{K}$ and $\mathcal{O}(s)$ near $s = 0$; that is, for all $s \in [0, 1]$, $\mu(s) \leq ks$ for some $k > 0$.*

DEFINITION 2 (see [20]). *The system*

$$\dot{x} = f(x, z) \tag{3}$$

is said to be iISS with input z if there exist a class-$\mathcal{K}_\infty$ function $\omega(\cdot)$, a class-$\mathcal{KL}$ function $\beta(\cdot,\cdot)$, and a class-$\mathcal{K}$ iISS gain $\mu(\cdot)$ such that, for all $t \geq 0$,

$$\omega(|x(t)|) \leq \beta(|x(0)|, t) + \int_0^t \mu(|z(\tau)|)d\tau. \tag{4}$$

Lemma 1 computes an iISS gain $\mu(\cdot)$ from the derivative of an *iISS Lyapunov function.*

LEMMA 1.

(i) *If there exists a C^1, positive definite, radially unbounded function $V(x)$ satisfying*

$$\frac{\partial V}{\partial x} f(x, z) \leq -\rho(|x|) + \mu(|z|) \tag{5}$$

for some positive definite function $\rho(\cdot)$, then the system (3) *with input z is iISS with gain $\mu(\cdot)$.*

(ii) *If there exists a C^1, positive definite, radially unbounded function $V(x)$ satisfying*

$$\frac{\partial V}{\partial x} f(x, z) \leq \sigma(|z|) \tag{6}$$

for some class-$\mathcal{K}$ function $\sigma(\cdot)$, and if the system (3) *is GAS when $z \equiv 0$, then there exists a class-$\mathcal{K}_o$ function $\theta_o(\cdot)$ such that* (3) *is iISS with gain $\mu(\cdot) = \sigma(\cdot) + \theta_o(\cdot)$.*

The following lemma proves that if (3) is affine in the input z, then $\sigma(\cdot)$ in (6) is class-$\mathcal{K}_o$, which means that the iISS gain $\mu(\cdot) = \sigma(\cdot) + \theta_o(\cdot)$ is also class-$\mathcal{K}_o$.

LEMMA 2. *If the input-affine system*

$$\dot{x} = f(x) + g(x)z \tag{7}$$

is iISS, then it is also iISS with a class-$\mathcal{K}_o$ gain $\mu(\cdot)$.

It is known [20] that ISS implies iISS. We further show that ISS allows us to select the iISS gain $\mu(\cdot)$ in (4) to match any desired class-$\mathcal{K}$ function $\tilde{\mu}(\cdot)$ locally.

LEMMA 3. *Suppose the system* (3) *is ISS. Then, for any class-$\mathcal{K}$ function $\tilde{\mu}(\cdot)$, it is iISS with a gain $\mu(\cdot)$ satisfying $\mu(s) = \tilde{\mu}(s)$ for all $s \in [0, 1]$.*

It is proved in [20, Proposition 7] that, for a GAS system $\dot{z} = q(z)$, the solutions $z(t)$ satisfy

$$|z(t)| \leq \alpha(e^{-kt}\gamma(|z(0)|)) \tag{8}$$

for some constant $k > 0$ and class-$\mathcal{K}_\infty$ functions $\alpha(\cdot)$ and $\gamma(\cdot)$. The following definition classifies GAS systems using the function $\alpha(\cdot)$ as an index of their speed of convergence to zero.

DEFINITION 3. *Given a class-$\mathcal{K}_\infty$ function $\alpha(\cdot)$, we say that the system $\dot{z} = q(z)$ is GAS(α) if there exist a class-$\mathcal{K}_\infty$ function $\gamma(\cdot)$ and a positive constant $k > 0$ such that* (8) *holds for all $z(0)$.*

Thus, for the identity function $\alpha(\cdot) = I(\cdot)$, GAS(I) consists of systems in which the convergence is exponential. We next show that $\alpha(\cdot)$ is determined by the local speed of convergence.

LEMMA 4. *If the equilibrium $z = 0$ of $\dot{z} = q(z)$ is GAS and if there exist a constant $\epsilon > 0$ and a $\mathcal{K}_\infty$ function $\tilde{\gamma}(\cdot)$ such that*

$$|z(0)| \le \epsilon \quad \Rightarrow \quad |z(t)| \le \alpha(e^{-kt}\tilde{\gamma}(|z(0)|)), \tag{9}$$

then there exists a class-$\mathcal{K}_\infty$ function $\gamma(s) = \mathcal{O}(\tilde{\gamma}(s))$ near $s = 0$ such that (8) holds for all $z(0)$; that is, $\dot{z} = q(z)$ is GAS(α).

The following definition will be used in our cascade result to characterize the admissible iISS gains from the speed of convergence $\alpha(\cdot)$ of the GAS(α) driving subsystem.

DEFINITION 4. *Given a class-$\mathcal{K}$ $\alpha(\cdot)$, we say that the function $\mu(\cdot)$ is class-$\mathcal{H}_\alpha$ if it is class-$\mathcal{K}$ and satisfies*

$$\int_0^1 \frac{(\mu \circ \alpha)(s)}{s} ds < \infty. \tag{10}$$

In particular, for the identity function $\alpha(\cdot) = I(\cdot)$, class-$\mathcal{H}_I$ is defined by

$$\int_0^1 \frac{\mu(s)}{s} ds < \infty. \tag{11}$$

Thus $\mu(s)$ is class-$\mathcal{H}_I$ if it is class-$\mathcal{K}_o$ or if $\mu(s) \le s^p$ for some $p > 0$, such as $\mu(s) = \sqrt{s}$.

3. Main results. We consider the cascade

$$\dot{x} = f(x, z), \tag{12}$$

$$\dot{z} = q(z), \tag{13}$$

where $x \in \mathbb{R}^{n_x}$, $z \in \mathbb{R}^{n_z}$, and $f(\cdot,\cdot)$ and $q(\cdot)$ are locally Lipschitz and satisfy $f(0,0) = 0$, $q(0) = 0$. The stability properties to be analyzed are with respect to the origin $(x, z) = (0, 0)$, which is an equilibrium for (12)–(13).

Our main stability result characterizes the admissible iISS gains for the x-subsystem from the speed of convergence of the z-subsystem.

THEOREM 1. *If the z-subsystem (13) is GAS(α) as in (8) and the x-subsystem with input z is iISS with a class-$\mathcal{H}_\alpha$ iISS gain $\mu(\cdot)$ as in (10), then the cascade (12)–(13) is GAS.*

Proof. We note from (8) that

$$\int_0^\infty \mu(|z(\tau)|)d\tau \le \int_0^\infty (\mu \circ \alpha)(\gamma(|z(0)|)e^{-k\tau})d\tau = \frac{1}{k}\int_0^{\gamma(|z(0)|)} \frac{(\mu \circ \alpha)(s)}{s} ds, \tag{14}$$

where $s := \gamma(|z(0)|)e^{-k\tau}$. From (10),

$$\lambda(s') := \frac{1}{k}\int_0^{s'} \frac{(\mu \circ \alpha)(s)}{s} ds \tag{15}$$

exists for all $s' \ge 0$, and it is class-$\mathcal{K}$ because $\lambda(0) = 0$ and $\frac{(\mu\circ\alpha)(s)}{s} > 0$ for all $s > 0$. Thus, from (4),

$$\omega(|x(t)|) \le \beta(|x(0)|, 0) + \lambda(\gamma(|z(0)|)), \tag{16}$$

which proves stability of the cascade (12)–(13). Because $\int_0^\infty \mu(|z(\tau)|)d\tau$ is bounded, (4) implies that $x(t) \to 0$ as $t \to \infty$, as proved in [20, Proposition 6]. ∎

If the x-subsystem with input z is ISS as in [19], then, from Lemma 3, it is also iISS with a class-$\mathcal{H}_\alpha$ gain. This means that no matter what the speed of convergence $\alpha(\cdot)$ is for the z-subsystem, the ISS x-subsystem satisfies the corresponding $\mathcal{H}_\alpha$ iISS gain condition of Theorem 1. Thus Theorem 1 encompasses the following well-known result.

COROLLARY 1. *If the z-subsystem* (13) *is GAS and the x-subsystem is ISS, then the cascade* (12)–(13) *is GAS.*

Another particular case of interest is when the z-subsystem is LES, that is, when (9) holds with $\alpha(\cdot) = I(\cdot)$ and $\tilde{\gamma}(s) = cs$ for some $c \geq 1$. From Lemma 4, there exist a class-$\mathcal{K}_o$ function $\gamma(\cdot)$ and a constant $k > 0$ such that, for all $z(0)$,

$$|z(t)| \leq e^{-kt}\gamma(|z(0)|)\,. \tag{17}$$

This means that the z-subsystem is GAS(I), and hence Theorem 1 requires that the iISS gain be class-$\mathcal{H}_I$.

COROLLARY 2. *If the z-subsystem* (13) *is GAS and LES and the x-subsystem is iISS with a class-$\mathcal{H}_I$ gain $\mu(\cdot)$ as in* (11)*, then the cascade* (12)–(13) *is GAS.*

We note from Lemma 2 that the class-$\mathcal{H}_I$ restriction of Corollary 2 is satisfied when the iISS x-subsystem is affine in z.

COROLLARY 3. *If the z-subsystem* (13) *is GAS and LES and the x-subsystem is iISS and affine in z, then the cascade* (12)–(13) *is GAS.*

Examples 1 and 2 illustrate that the LES and the class-$\mathcal{H}_I$ gain restrictions cannot be removed from Corollary 2.

Example 1. For the cascade system

$$\dot{x} = -\mathrm{sat}(x) + xz, \tag{18}$$

$$\dot{z} = -z^3\,, \tag{19}$$

where $\mathrm{sat}(x) := \mathrm{sgn}(x)\min\{1, |x|\}$, the x-subsystem with input z is iISS with a class-$\mathcal{K}_o$ (hence class-$\mathcal{H}_I$) gain, as verified from $V(x) = \frac{1}{2}\ln(1+x^2)$, which satisfies $\dot{V} \leq |z|$ as in Lemma 1. However, the cascade (18)–(19) has unbounded solutions because the z-subsystem is not LES. To prove this, we let $z(0) = 1$ so that $z(t) = \frac{1}{\sqrt{1+2t}}$, and we let $x(0) > 1$ so that, as long as $x(t) \geq 1$,

$$\dot{x} = \frac{1}{\sqrt{1+2t}}\,x - 1 \quad \Rightarrow \quad x(t) = e^{(\sqrt{1+2t}-1)}\left[x(0) - \int_0^t e^{(1-\sqrt{1+2\tau})}d\tau\right]. \tag{20}$$

Using the change of variables $s = -1 + \sqrt{1+2\tau}$, we obtain

$$\int_0^t e^{(1-\sqrt{1+2\tau})}d\tau \leq \int_0^\infty e^{(1-\sqrt{1+2\tau})}d\tau = \int_0^\infty e^{-s}(s+1)\,ds = 2; \tag{21}$$

thus, if $x(0) \geq 3$, then (20) implies $x(t) \geq e^{(\sqrt{1+2t}-1)}$. This means that $x(t) \geq 1$ for all $t \geq 0$ and $x(t) \to \infty$ as $t \to \infty$.

Example 2. In this example, we show that the class-$\mathcal{H}_I$ gain restriction cannot be removed from Corollary 2. Consider the locally Lipschitz system

$$\dot{x} = -m(x) + g^{-1}\left(g\left(e^{e^{\frac{x-1}{b}}-a}z^2\right)\mathrm{sat}(z^2)/2\right), \tag{22}$$

$$\dot{z} = -z/2, \tag{23}$$

where $g : [0, +\infty) \to [0, 1]$ is defined as $g(x) := e^{-\frac{1}{x}}$ for $x > 0$ and $g(0) = 0$, $m(x)$ is a locally Lipschitz function satisfying $m(x)x > 0$ for all $x \neq 0$,

$$m(x) = \frac{1}{2e^{\frac{|x|-1}{b}}} \qquad \forall\, x \geq 1 + b\ln(a)\,, \tag{24}$$

and $a, b > 0$ are constants to be specified. Using $V(x) = \ln(1 + x^2)$ and $|g(r)| \leq 1$ for all $r \in \mathbb{R}_{\geq 0}$, we obtain

$$\begin{aligned} \dot{V} &= -\frac{2m(x)x}{1+x^2} + \frac{2x}{1+x^2} g^{-1}\left(g\left(e^{e^{\frac{x-1}{b}} - a z^2}\right)\mathrm{sat}(z^2)/2\right) \\ &\leq -\frac{2m(x)x}{1+x^2} + g^{-1}(\mathrm{sat}(z^2)/2)\,, \end{aligned} \tag{25}$$

which, from Lemma 1, proves that the x-subsystem is iISS with input z. Moreover, the z-subsystem is exponentially stable as in Corollary 2. However, because the iISS gain is not class-$\mathcal{H}_I$, the cascade (22)–(23) admits the unbounded solution

$$x(t) = 1 + b\ln(a + t) \tag{26}$$

when $z(0) \in (0, 1)$, $a = \ln(2/z^2(0)g(z^2(0)))$, and $b = 1/2$. To see that (26) satisfies (22), note that the time derivative of $x(t)$ is $\dot{x}(t) = b/(t+a)$ and that the substitution in (22) of

$$m(x(t)) = \frac{1}{2(a+t)} = \frac{b}{a+t}, \tag{27}$$

$$\begin{aligned} g^{-1}\left(g\left(e^{e^{\frac{x(t)-1}{b}} - a z^2(t)}\right)\mathrm{sat}(z^2(t))/2\right) &= g^{-1}(g(e^t z^2(0)e^{-t})z^2(0)e^{-t}/2) \\ = g^{-1}(g(z^2(0))z^2(0)e^{-t}/2) &= \frac{1}{t + \ln(2/z^2(0)g(z^2(0)))} = \frac{2b}{a+t} \end{aligned} \tag{28}$$

indeed yields $\dot{x}(t) = b/(t + a)$.

Theorem 1 characterized the class of admissible iISS gains from the speed of convergence of the z-subsystem. It may appear that this class can be enlarged by a change of coordinates in which the z-subsystem converges faster as in Grüne, Sontag, and Wirth [5]. The following example illustrates that such an attempt fails because in the new coordinates the iISS gain of the x-subsystem becomes steeper.

Example 3. For the system (18)–(19), the change of coordinates

$$\tilde{z} = \Phi(z) := z e^{-\frac{1}{2z^2}} \tag{29}$$

ensures exponential convergence for the $\tilde{z}$-subsystem:

$$\dot{x} = -\mathrm{sat}(x) + x\Phi^{-1}(\tilde{z}), \tag{30}$$

$$\dot{\tilde{z}} = -(1 + [\Phi^{-1}(z)]^2)\tilde{z}\,. \tag{31}$$

Using $V(x) = \frac{1}{2}\ln(1 + x^2)$, we obtain

$$\dot{V} \leq -\frac{x\mathrm{sat}(x)}{1+x^2} + \Phi^{-1}(|\tilde{z}|)\,,$$

which, from Lemma 1, implies that the x-subsystem with input $\tilde{z}$ is iISS with gain $\Phi^{-1}(\cdot)$. The cascade (30)–(31) has unbounded solutions as proved in Example 1 because all derivatives of $\Phi(z)$ vanish at $z = 0$, and hence the inverse function $\Phi^{-1}(\cdot)$ is too steep at zero to satisfy the class-$\mathcal{H}_I$ condition of Corollary 2.

4. Growth restrictions on the interconnection term. It is well known that the nonlinear growth of the interconnection term $h(x,z) := f(x,z) - f(x,0)$ plays an important role for the stability of the cascade (12)–(13), rewritten here as

$$\dot{x} = f(x,0) + h(x,z), \tag{32}$$

$$\dot{z} = q(z)\,. \tag{33}$$

In this section, we show that the class-$\mathcal{H}_I$ gain condition of Corollary 2 imposes a restriction on the nonlinear growth of $h(x,z)$ in x. To this end, we consider the cascade (32)–(33) with $x \in \mathbb{R}$ and with $h(x,z)$ bounded by

$$|h(x,z)| \le \gamma_1(|z|) + \gamma_2(|z|)\varphi(|x|). \tag{34}$$

We characterize the class-$\mathcal{K}$ functions $\varphi(\cdot)$ for which the x-subsystem satisfies the class-$\mathcal{H}_I$ gain condition of Corollary 2.

PROPOSITION 1. *Consider the cascade* (32)–(33)*, where* $x \in \mathbb{R}$*. If* $\dot{x} = f(x,0)$ *is GAS,* $\dot{z} = q(z)$ *is GAS and LES, and* $h(x,z)$ *satisfies* (34) *for some class-*$\mathcal{H}_I$ *functions* $\gamma_1(\cdot)$*,* $\gamma_2(\cdot)$*, and a class-*$\mathcal{K}$ *function* $\varphi(\cdot)$ *satisfying*

$$\int_1^\infty \frac{1}{\varphi(s)} ds = \infty\,, \tag{35}$$

then the origin is GAS.

Proof. To prove that the x-subsystem is iISS with a class-$\mathcal{H}_I$ gain, we let $V(x)$ be a smooth, positive definite function such that $V(x) = V(-x)$, and

$$x \ge 1 \quad \Rightarrow \quad V(x) = V(1) + \int_1^x \frac{1}{\varphi(s)} ds\,. \tag{36}$$

Because of (35), $V(x)$ is radially unbounded and satisfies

$$|x| \ge 1 \quad \Rightarrow \quad \left|\frac{\partial V}{\partial x}\right| = \frac{1}{\varphi(|x|)}\,. \tag{37}$$

Thus, if $|x| \ge 1$, (34) and (37) yield

$$\frac{\partial V}{\partial x}[f(x,0) + h(x,z)] \le \frac{1}{\varphi(1)}\gamma_1(|z|) + \gamma_2(|z|) =: \gamma_5(|z|)\,. \tag{38}$$

If $|x| \le 1$, then $\left|\frac{\partial V}{\partial x}\right| \le b$ for some positive constant b, and

$$\frac{\partial V}{\partial x}[f(x,0) + h(x,z)] \le b\gamma_1(|z|) + b\gamma_2(|z|)\varphi(1) := \gamma_6(|z|)\,. \tag{39}$$

Because $\dot{V} \le \max\{\gamma_5(|z|), \gamma_6(|z|)\}$, the x-subsystem is iISS with a class-$\mathcal{H}_I$ gain as in Corollary 2, and hence the cascade (32)–(33) is GAS. ∎

It is important to note that the growth condition (35) encompasses functions that grow faster than linear, such as $\varphi(|x|) = |x|\ln(|x|)$. On the other hand, (35) disallows $\varphi(|x|) = |x|^2$, $\varphi(|x|) = |x|^3$, etc. Growth conditions similar to (35) have been derived by Mazenc and Praly [11] and, more recently, by Panteley and Loría [13]. Proposition 1 gives a simple iISS interpretation of their more involved Lyapunov arguments. We finally show that (35) is tight and cannot be relaxed.

Example 4. The cascade

$$\dot{x} = -\mathrm{sat}(x) + \varphi(x)z, \tag{40}$$

$$\dot{z} = -z \tag{41}$$

exhibits finite escape time when the class-$\mathcal{K}$ function $\varphi(x)$ fails to satisfy (35), that is,

$$\int_1^\infty \frac{1}{\varphi(s)} ds < \infty\,. \tag{42}$$

To prove this, we let $V(x)$ be as in (36) and note from (42) that there exists a constant $V_\infty > 0$ such that $V(x) < V_\infty$ for all $x \in \mathbb{R}$, and $V(x) \to V_\infty$ as $x \to \infty$. Moreover, from (36),

$$x(t) \geq 1 \quad \Rightarrow \quad \dot{V} = -\frac{1}{\varphi(x(t))} + z(t) \geq -\frac{1}{\varphi(1)} + z(0)e^{-t}\,. \tag{43}$$

If $z(0) > 1/\varphi(1)$, then we can find $T > 0$ such that

$$\phi(t) := \int_0^t \left(-\frac{1}{\varphi(1)} + z(0)e^{-t}\right) dt = -\frac{t}{\varphi(1)} + z(0)(1 - e^{-t}) \tag{44}$$

satisfies $\phi(t) > 0$ for all $t \in (0, T]$. Thus, if $x(0)$ is such that $x(0) \geq 1$ and $V_\infty - \phi(T) \leq V(x(0)) < V_\infty$, then it follows from (43) that

$$V(x(T)) \geq V(x(0)) + \phi(T) \geq V_\infty\,,$$

which proves that $x(T)$ is not defined.

5. Application to output-feedback design. One of the major difficulties in nonlinear output-feedback design is the absence of a separation principle. Even when a nonlinear observer is available, it may be necessary to redesign the control law to make it robust against the observer error. One such design is the observer-based backstepping scheme of Kanellakopoulos, Kokotović, and Morse [7], further extended by Praly and Jiang [14], which makes use of *nonlinear damping* terms to render the system ISS with respect to the observer error. A shortcoming of this design, pointed out by several authors, is the rapid growth of the nonlinearities in the control law due to nonlinear damping terms. Such nonlinearities in the control law make the implementation difficult and are harmful in the presence of unmodeled actuator dynamics, saturation, etc. Efforts to reduce the growth of nonlinear damping terms are restricted to a result for Euler–Lagrange systems, Aamo et al. [1], and an adaptive backstepping design in Krstić, Kanellakopoulos, and Kokotović [10, section 5.8], where stability is achieved with the help of a strengthened parameter identifier.

We now give a systematic procedure to reduce the growth of nonlinear damping terms. Our main idea is to render the system iISS against the observer error. Because iISS is less restrictive than ISS, it is achieved with a "weak" form of nonlinear damping. Closed-loop stability is then established using Corollary 2 because the observer error is exponentially decaying. This exponential decay condition is satisfied by most observers used in backstepping, including Krener and Isidori [9], Arcak and Kokotović [4, 3], and Praly and Kanellakopoulos [15]. We wish to emphasize that our iISS design is not of "certainty-equivalence" type because, as in the ISS design of [7], the design of the controller makes use of the observer equations.

To make the main features of our design more apparent, we first illustrate it in an example. The general design procedure and its stability proof are given in the next section.

Example 5. For the system

$$\begin{aligned} \dot{x}_1 &= x_2 + x_1^3, \\ \dot{x}_2 &= u + x_2 - x_2^3, \\ y &= x_1, \end{aligned} \tag{45}$$

the problem is to stabilize the origin $x = 0$ by output-feedback. The following observer, designed as in [3], ensures exponential convergence of the estimates $\hat{x}_1$ and $\hat{x}_2$ to the true states:

$$\begin{aligned} \dot{\hat{x}}_1 &= \hat{x}_2 + G_1(y, \hat{x}_1) := \hat{x}_2 + y^3 - 2(\hat{x}_1 - y), \\ \dot{\hat{x}}_2 &= u + G_2(y, \hat{x}_1, \hat{x}_2) := u + \hat{x}_2 - (\hat{x}_2 - 1.5(\hat{x}_1 - y))^3 - 3(\hat{x}_1 - y). \end{aligned} \tag{46}$$

To incorporate this observer in feedback control we employ the observer-based backstepping procedure of Kanellakopoulos, Kokotović, and Morse [7]. Defining the observer error $z_2 := x_2 - \hat{x}_2$ and letting $\chi_1 := x_1$, we rewrite the first equation of (45) as

$$\dot{\chi}_1 = \hat{x}_2 + \chi_1^3 + z_2\,. \tag{47}$$

For $\hat{x}_2$ we design the virtual control law

$$\alpha_1(\chi_1) = -c_1\chi_1 - \chi_1^3\,, \quad c_1 > 0, \tag{48}$$

which results in

$$\dot{\chi}_1 = -c_1\chi_1 + \chi_2 + z_2\,, \tag{49}$$

where $\chi_2 = \hat{x}_2 - \alpha_1(\chi_1)$. Differentiating χ_2 with respect to time, we obtain

$$\dot{\chi}_2 = u + G_2(y, \hat{x}_1, \hat{x}_2) - \frac{\partial \alpha_1}{\partial \chi_1}(\chi_1^3 + \hat{x}_2) - \frac{\partial \alpha_1}{\partial \chi_1} z_2 \tag{50}$$

and note that the control law

$$u = -(c_2 + \delta(\chi_1))\chi_2 - \chi_1 - G_2(y, \hat{x}_1, \hat{x}_2) + \frac{\partial \alpha_1}{\partial \chi_1}(\chi_1^3 + \hat{x}_2) \tag{51}$$

yields

$$\dot{\chi}_2 = -(c_2 + \delta(\chi_1))\chi_2 - \chi_1 - \frac{\partial \alpha_1}{\partial \chi_1} z_2\,. \tag{52}$$

In the ISS design of Kanellakopoulos, Kokotović, and Morse [7], the *nonlinear damping* term is

$$\delta(\chi_1) = \delta_{\text{ISS}}(\chi_1) = \left(\frac{\partial \alpha_1}{\partial \chi_1}\right)^2 = (c_1 + 3\chi_1^2)^2, \tag{53}$$

whose growth in χ_1 is quartic.

To design a "softer" $\delta(\chi_1)$, let us pursue an iISS design with the help of the Lyapunov function $U(\chi_1,\chi_2)=\frac{1}{2}\chi_1^2+\frac{1}{2}\chi_2^2$. From (47) and (50),

$$\dot U=-c_1\chi_1^2+\chi_1z_2-c_2\chi_2^2-\delta(\chi_1)\chi_2^2+\chi_2(c_1+3\chi_1^2)z_2, \tag{54}$$

and hence, using the inequalities

$$3\chi_2\chi_1^2z_2\le\chi_2^2\chi_1^2+\frac{9}{4}\chi_1^2z_2^2,\quad \chi_1z_2\le\frac{c_1}{2}\chi_1^2+\frac{1}{2c_1}z_2^2,\quad c_1\chi_2z_2\le\frac{c_2}{2}\chi_2^2+\frac{c_1^2}{2c_2}z_2^2\,, \tag{55}$$

we can find positive constants k_1, k_2, k_3 such that

$$\dot U\le-k_1U-\delta(\chi_1)\chi_2^2+\chi_1^2\chi_2^2+k_2Uz_2^2+k_3z_2^2\,. \tag{56}$$

Unlike the iISS Lyapunov function (5) in Lemma 1, the inequality (56) contains the product of U and the disturbance z_2^2, which means that $U(\chi)$ cannot be an iISS Lyapunov function. However, the new C^1 function $V(\chi):=\ln(1+U(\chi))$ results in

$$\dot V=\frac{\dot U}{1+U}\,, \tag{57}$$

which means that the product $k_2Uz_2^2$ in (56) is now

$$k_2\frac{U}{1+U}z_2^2\le k_2z_2^2, \tag{58}$$

and hence

$$\dot V\le-k_1\frac{U}{1+U}+(k_2+k_3)z_2^2+(\chi_1^2-\delta(\chi_1))\frac{\chi_2^2}{1+U}\,. \tag{59}$$

Because the first two terms on the right-hand side are as in the iISS Lyapunov function (5), the choice

$$\delta(\chi_1)=\delta_{\mathrm{iISS}}(\chi_1)=\chi_1^2 \tag{60}$$

eliminates the third term and ensures iISS as in Lemma 1. It follows from Corollary 3 that our iISS design ensures GAS of the closed-loop system (45)–(46) because the observer error z is exponentially decaying and the χ-subsystem is affine in z_2.

Unlike the quartic $\delta_{\mathrm{ISS}}(\chi_1)$, the "weak" nonlinear damping term $\delta_{\mathrm{iISS}}(\chi_1)$ is only quadratic. This reduction in the nonlinear growth is more pronounced for higher relative degree systems studied in the next section, which require several steps of observer-based backstepping.

6. Observer-based backstepping with weak nonlinear damping. We now generalize the above design to the system

$$\begin{aligned}
y&=x_1,\\
\dot x_1&=x_2+g_1(x_1),\\
\dot x_2&=x_3+g_2(x_1,x_2),\\
&\cdots\\
\dot x_r&=p(\xi,u)+g_r(x),\\
\dot\xi&=q(\xi,x,u)\,,
\end{aligned} \tag{61}$$

where $x := (x_1, \ldots, x_r)^T$ and the functions $g_1, \ldots, g_r, p$ and q are smooth and vanish when their arguments are zero; that is, the origin $(x, \xi) = (0, 0)$ is an equilibrium when $u = 0$.

We assume the availability of a global observer of the form

$$\begin{aligned} \dot{\hat{x}}_1 &= \hat{x}_2 + G_1(y, \hat{x}_1), \\ \dot{\hat{x}}_2 &= \hat{x}_3 + G_2(y, \hat{x}_1, \hat{x}_2), \\ &\cdots \\ \dot{\hat{x}}_r &= p(\hat{\xi}, u) + G_r(y, \hat{x}), \\ \dot{\hat{\xi}} &= Q(\hat{\xi}, \hat{x}, u, y)\,. \end{aligned} \tag{62}$$

Assumption 1. *The observer* (62) *guarantees exponential convergence of the state estimates to the true states; that is, there exist a constant $k > 0$ and a class-$\mathcal{K}$ function $\gamma(\cdot)$ such that, for every input u and for every initial condition $x(0)$, $\xi(0)$, $\hat{x}(0)$, $\hat{\xi}(0)$, the observer error $z = (x^T, \xi^T)^T - (\hat{x}^T, \hat{\xi}^T)^T$ satisfies*

$$|z(t)| \leq e^{-kt}\gamma(|z(0)|) \tag{63}$$

for all t in the maximal interval of existence $[0, t_f)$ of (61)–(62).

Observer designs satisfying Assumption 1 are being reported at an increasing rate [15, 4, 3]. Our next assumption is that the function $p(\xi, u)$ is invertible in u.

Assumption 2. *There exists a function $\pi(\cdot, \cdot)$ satisfying*

$$v = p(\xi, u) \quad \Leftrightarrow \quad u = \pi(\xi, v). \tag{64}$$

Finally, the zero dynamics of the system (61),

$$\dot{\xi} = q(\xi, 0, \pi(\xi, 0)), \tag{65}$$

satisfy the following robust stability assumption.

Assumption 3. *The zero dynamics* (65)*, perturbed by v_0, v_1, and v_2,*

$$\dot{\xi} = q(\xi, v_0, \pi(\xi - v_1, v_2)), \tag{66}$$

are ISS with input (v_0, v_1, v_2).

The class of systems defined by (61) and Assumptions 1–3 encompasses the one studied in [7] and [10] for observer-based backstepping. We now present our new design, which renders the system (61) iISS with respect to the observer error z.

Step 1. Defining

$$\chi_1 := y \tag{67}$$

and using $x_2 = \hat{x}_2 + z_2$, we rewrite the first equation of (61) as

$$\dot{\chi}_1 = \hat{x}_2 + g_1(\chi_1) + z_2\,. \tag{68}$$

For $\hat{x}_2$, we design the *virtual* control law

$$\alpha_1(\chi_1) = -c_1\chi_1 - g_1(\chi_1), \quad c_1 > 0\,, \tag{69}$$

and obtain

$$\dot{\chi}_1 = -c_1\chi_1 + \chi_2 + z_2, \tag{70}$$

where

$$\chi_2 := \hat{x}_2 - \alpha_1(\chi_1)\,. \tag{71}$$

Step 2. From (62) and (68), χ_2 is governed by

$$\dot{\chi}_2 = \hat{x}_3 + G_2(\chi_1, \hat{x}_1, \hat{x}_2) - \phi_1(\chi_1)(\hat{x}_2 + g_1(\chi_1)) - \phi_1(\chi_1)z_2\,, \tag{72}$$

where

$$\phi_1(\chi_1) := \frac{\partial \alpha_1}{\partial \chi_1}\,. \tag{73}$$

Because $\phi_1(\chi_1)$ is a smooth function, we can rewrite it as

$$\phi_1(\chi_1) = \phi_{10} + \chi_1\Phi_1(\chi_1), \tag{74}$$

where

$$\phi_{10} = \phi_1(0)\,, \quad \Phi_1(\chi_1) = \int_0^1 \left.\frac{\partial \phi_1(X_1)}{\partial X_1}\right|_{X_1 = s\chi_1} ds\,. \tag{75}$$

For $\hat{x}_3$, we design the virtual control law

$$\alpha_2(\chi_1, \hat{x}_1, \hat{x}_2) = -[c_2 + d_2\Phi_1^2(\chi_1)]\chi_2 - \chi_1 - G_2(\chi_1, \hat{x}_1, \hat{x}_2) + \phi_1(\chi_1)(\hat{x}_2 + g_1(\chi_1)), \tag{76}$$

which results in

$$\dot{\chi}_2 = -\chi_1 - [c_2 + d_2\Phi_1^2(\chi_1)]\chi_2 + \chi_3 - [\phi_{10} + \chi_1\Phi_1(\chi_1)]z_2\,, \tag{77}$$

where

$$\chi_3 := \hat{x}_3 - \alpha_2(\chi_1, \hat{x}_1, \hat{x}_2)\,. \tag{78}$$

Step i ($3 \le i \le r$). For

$$\chi_i := \hat{x}_i - \alpha_{i-1}(\chi_1, \hat{x}_1, \ldots, \hat{x}_{i-1})\,, \tag{79}$$

we obtain

$$\begin{aligned}\dot{\chi}_i = {} & \hat{x}_{i+1} + G_i(\chi_1, \hat{x}_1, \ldots, \hat{x}_i) - \phi_{i-1}(\chi_1, \hat{x}_1, \ldots, \hat{x}_{i-1})[\hat{x}_2 + g_1(\chi_1) + z_2] \\ & - \frac{\partial \alpha_{i-1}}{\partial \hat{x}_1}(\hat{x}_2 + G_1(y, \hat{x}_1)) - \cdots - \frac{\partial \alpha_{i-1}}{\partial \hat{x}_{i-1}}(\hat{x}_i + G_{i-1}(y, \ldots, \hat{x}_{i-1})),\end{aligned} \tag{80}$$

where $\hat{x}_{r+1} := p(\hat{\xi}, u)$ and

$$\phi_{i-1}(\chi_1, \hat{x}_1, \ldots, \hat{x}_{i-1}) := \frac{\partial \alpha_{i-1}}{\partial \chi_1}\,. \tag{81}$$

To factor ϕ_{i-1} as in (74) in Step 2, we first rewrite it as a function of $(\chi_1, \ldots, \chi_{i-1}, z_1)$, where $z_1 = x_1 - \hat{x}_1$:

$$\phi_{i-1}(\chi_1, \hat{x}_1, \ldots, \hat{x}_{i-1}) = \tilde{\phi}_{i-1}(\chi_1, \ldots, \chi_{i-1}, z_1)\,. \tag{82}$$

Next, defining $\phi_{i-1,\,0}(z_1) = \tilde{\phi}_{i-1}(0,\ldots,0,z_1)$ and

$$\Phi_{i-1}(\chi_1,\ldots,\chi_{i-1},z_1) = \int_0^1 \left(\frac{\partial\tilde{\phi}_{i-1}(X_1,\ldots,X_{i-1},z_1)}{\partial(X_1,\ldots,X_{i-1})}\right)^T\Bigg|_{(X_1,\ldots,X_{i-1})=s(\chi_1,\ldots,\chi_{i-1})} ds\,, \tag{83}$$

we get

$$\phi_{i-1}(\chi_1,\hat{x}_1,\ldots,\hat{x}_{i-1}) = \phi_{i-1,\,0}(z_1) + [\chi_1\cdots\chi_{i-1}]\,\Phi_{i-1}(\chi_1,\ldots,\chi_{i-1},z_1)\,. \tag{84}$$

The virtual control law for $\hat{x}_{i+1}$ is

$$\begin{aligned}\alpha_i(\chi_1,\hat{x}_1,\ldots,\hat{x}_i) = {}& -\chi_{i-1} - [c_i + d_i\Phi_{i-1}^T\Phi_{i-1}]\chi_i - G_i(\chi_1,\hat{x}_1,\ldots,\hat{x}_i)\\ & + \frac{\partial\alpha_{i-1}}{\partial\hat{x}_1}(\hat{x}_2 + G_1(y,\hat{x}_1)) + \cdots + \frac{\partial\alpha_{i-1}}{\partial\hat{x}_{i-1}}(\hat{x}_i + G_{i-1}(y,\ldots,\hat{x}_{i-1}))\\ & + \phi_{i-1}(\chi_1,\hat{x}_1,\ldots,\hat{x}_{i-1})[\hat{x}_2 + g_1(\chi_1)]\,.\end{aligned} \tag{85}$$

If $i < r$, we define

$$\chi_{i+1} = \hat{x}_{i+1} - \alpha_i(\chi_1,\hat{x}_1,\ldots,\hat{x}_i) \tag{86}$$

and proceed with step $i+1$. The control law obtained by r steps of backstepping is

$$u = \pi(\hat{\xi},\alpha_r(\chi_1,\hat{x}_1,\ldots,\hat{x}_r))\,, \tag{87}$$

where the function $\pi(\cdot,\cdot)$ is as in (64).

The resulting closed-loop system consists of the exponentially converging observer error z driving the (χ,ξ)-subsystem

$$\begin{aligned}\dot{\xi} &= q(\xi, v_0(\chi,z), \pi(\xi - v_1(z), v_2(\chi,z))),\\ \dot{\chi}_1 &= -c_1\chi_1 + \chi_2 + z_2,\\ &\cdots\\ \dot{\chi}_i &= -\chi_{i-1} - [c_i + d_i\Phi_{i-1}^T\Phi_{i-1}]\chi_i + \chi_{i+1} - (\phi_{i-1,0}(z_1) + [\chi_1\cdots\chi_{i-1}]\Phi_{i-1})z_2,\\ &\cdots\\ \dot{\chi}_r &= -\chi_{r-1} - [c_r + d_r\Phi_{r-1}^T\Phi_{r-1}]\chi_r - (\phi_{r-1,0}(z_1) + [\chi_1\cdots\chi_{r-1}]\Phi_{r-1})z_2\,,\end{aligned} \tag{88, 89}$$

where the functions $v_0(\chi,z) = x$, $v_2(\chi,z) = \alpha_r(\chi_1,\hat{x}_1,\ldots,\hat{x}_r)$, and $v_1(z) = \xi - \hat{\xi}$ vanish at $(\chi,z) = (0,0)$.

THEOREM 2. *If Assumptions* 1–3 *hold, then the control law* (87) *guarantees GAS of the closed-loop system* (61)–(62).

Proof. We first prove that the χ-subsystem (89) is iISS with input z. To this end, we note that the function $U = \frac{1}{2}\sum_{i=1}^r \chi_i^2$ satisfies

$$\dot{U} = \left(\sum_{i=1}^r -c_i\chi_i^2 - \chi_i\phi_{i-1,0}(z_1)z_2\right) + \left(\sum_{i=2}^r -d_i\Phi_{i-1}^T\Phi_{i-1}\chi_i^2 - z_2[\chi_1\cdots\chi_{i-1}]\Phi_{i-1}\chi_i\right)\,, \tag{90}$$

where $\phi_{00}(z_1) = -1$ and $\phi_{10}(z_1) = \phi_{10}$ as in (74). Using the inequalities

$$-\chi_i\phi_{i-1,0}(z_1)z_2 \le \frac{c_i}{2}\chi_i^2 + \frac{1}{2c_i}\phi_{i-1,0}^2(z_1)z_2^2, \tag{91}$$

$$-z_2[\chi_1\cdots\chi_{i-1}]\Phi_{i-1}\chi_i \le d_i\Phi_{i-1}^T\Phi_{i-1}\chi_i^2 + \frac{1}{4d_i}[\chi_1\cdots\chi_{i-1}]\,[\chi_1\cdots\chi_{i-1}]^T z_2^2\,, \tag{92}$$

we obtain

$$\dot{U} \le -\sum_{i=1}^{r} \frac{c_i}{2}\chi_i^2 + \sum_{i=1}^{r} \frac{1}{2c_i}\phi_{i-1,0}^2(z_1)z_2^2 + \sum_{i=2}^{r} \frac{1}{4d_i}(\chi_1^2 + \cdots + \chi_{i-1}^2)z_2^2 \tag{93}$$

$$\le -cU + \frac{1}{2c}\left(\sum_{i=1}^{r} \phi_{i-1,0}^2(z_1)\right) z_2^2 + \frac{r}{2d} U z_2^2\,, \tag{94}$$

where $c := \min_{1\le i\le r} c_i$, $d := \min_{2\le i\le r} d_i$. Thus

$$V(\chi) := \ln(1 + U(\chi)) \tag{95}$$

satisfies

$$\dot{V} \le -c\frac{U}{1+U} + \left(\frac{r}{2d} + \frac{1}{2c}\sum_{i=1}^{r} \phi_{i-1,0}^2(z_1)\right) z_2^2\,, \tag{96}$$

which, from Lemma 1, proves that the χ-subsystem (89) with input z is iISS with a class-$\mathcal{K}_o$ gain. Moreover, the observer error z satisfies the exponential decay condition (63) for all $t \in [0, t_f)$. Thus, letting $T < t_f$, we can show from Corollary 2 that there exists a class-$\mathcal{KL}$ function $\beta_1(\cdot,\cdot)$ such that, for all $t \in [0, T]$,

$$|(\chi(t), z(t))| \le \beta_2(|(\chi(0), z(0))|, t)\,. \tag{97}$$

Next, we note from Assumption 3 that the ξ-subsystem (88) is ISS with input (χ, z). In view of Corollary 1, this means that a class-$\mathcal{KL}$ function $\beta_3(\cdot,\cdot)$ exists such that, for all $t \in [0, T]$,

$$|(\xi(t), \chi(t), z(t))| \le \beta_3(|(\xi(0), \chi(0), z(0))|, t)\,. \tag{98}$$

Finally, we note that $|(\xi(T), \chi(T), z(T))|$ is bounded by $\beta_3(|(\xi(0), \chi(0), z(0))|, 0)$, which is independent of T. This means that $t_f = \infty$, and hence (98) holds for all $t \ge 0$, which proves GAS of the closed-loop system (61)–(62). □

7. Proofs of lemmas.

Proof of Lemma 1. Part (i) is proved in [2]. To prove part (ii), we modify [2, Proposition II.5], which is proved for a class-$\mathcal{K}$ function $\theta(\cdot)$, and show that it actually holds with a class-$\mathcal{K}_o$ function $\theta_o(\cdot)$.

LEMMA 5. *The system $\dot{x} = f(x, 0)$ is GAS iff there exist a smooth semiproper*[1] *function $W(x)$, a class-$\mathcal{K}_o$ function $\theta_o(\cdot)$, and a continuous positive definite function $\rho : \mathbb{R}_{\ge 0} \to \mathbb{R}_{\ge 0}$ such that*

$$\frac{\partial W}{\partial x} f(x, z) \le -\rho(|x|) + \theta_o(|z|). \tag{99}$$

The proof is given at the end of this section. In passing we emphasize that, in general, Lemma 5 does not hold with a *proper* (radially unbounded) $W(x)$.

To complete the proof of Lemma 1, we define $V_1(x) = V(x) + W(x)$, where $V(x)$ and $W(x)$ are as in (6) and (99), respectively, and obtain

$$\dot{V}_1 \le -\rho(|x|) + \sigma(|z|) + \theta_o(|z|)\,, \tag{100}$$

which is (5) with $\mu(|z|) := \sigma(|z|) + \theta_o(|z|)$. □

[1] A positive definite function $W(x)$ is called *semiproper* if there exist a class-$\mathcal{K}$ function $\pi(\cdot)$ and a radially unbounded positive definite function $W_0(x)$ such that $W(x) = \pi(W_0(x))$. Thus $W(x)$ may not be radially unbounded.

Proof of Lemma 2. Because (7) is iISS with input z, it follows from [2] that there exists an *iISS Lyapunov function* $V(x)$ satisfying

$$L_fV(x) + L_gV(x)z := \frac{\partial V}{\partial x}f(x) + \frac{\partial V}{\partial x}g(x)z \leq -\rho(|x|) + \tilde{\sigma}(|z|) \tag{101}$$

for some positive definite function $\rho(\cdot)$ and some class-$\mathcal{K}$ function $\tilde{\sigma}(\cdot)$. To prove that $\mu(\cdot)$ in (4) is class-$\mathcal{K}_o$, we first show that

$$L_fV(x) + |L_gV(x)| \leq \tilde{\sigma}(1)\,. \tag{102}$$

If $L_gV(x) \neq 0$, then (102) follows by evaluating (101) at $z = \frac{1}{|L_gV(x)|}L_gV(x)^T$. If $L_gV(x) = 0$, then (102) holds because $L_fV(x) \leq -\rho(|x|)$ from (101). Next, we note that $L_fV(x) \leq L_fV(x)|z|$ when $|z| \leq 1$ and obtain

$$|z| \leq 1 \quad \Rightarrow \quad L_fV(x)+L_gV(x)z \leq L_fV(x)|z|+|L_gV|\,|z| = (L_fV+|L_gV|)|z| \leq \tilde{\sigma}(1)|z|\,. \tag{103}$$

Inequalities (101) and (103) imply

$$L_fV(x) + L_gV(x)z \leq \sigma(|z|), \tag{104}$$

where

$$\sigma(|z|) := \begin{cases} \tilde{\sigma}(1)|z| & \text{if} \quad |z| \leq 1, \\ \tilde{\sigma}(|z|) & \text{if} \quad |z| > 1\,. \end{cases} \tag{105}$$

Because $\sigma(\cdot)$ is class-$\mathcal{K}_o$, it follows from Lemma 1 that the system (7) is iISS with a class-$\mathcal{K}_o$ gain $\mu(\cdot)$. □

Proof of Lemma 3. Because of ISS, it follows from [22] that there exists an *ISS Lyapunov function* $V(x)$ satisfying

$$\dot{V} \leq -\rho(|x|) + \sigma(|z|) \tag{106}$$

for some class-$\mathcal{K}_\infty$ functions $\rho(\cdot)$ and $\sigma(\cdot)$. Letting $\mu(\cdot)$ be a class-$\mathcal{K}$ function such that $\mu(s) = \tilde{\mu}(s)$ when $s \in [0,1]$ and $\mu(s) = \sigma(s)$ when $s \geq 2$ and applying the *changing supply functions lemma* [21], we can find another ISS Lyapunov function $\tilde{V}(x)$ satisfying

$$\dot{\tilde{V}} \leq -\tilde{\rho}(|x|) + \mu(|z|) \tag{107}$$

for some class-$\mathcal{K}$ function $\tilde{\rho}(\cdot)$. From Lemma 1, this implies iISS with gain $\mu(\cdot)$. □

Proof of Lemma 4. Because of GAS, there exists a $T^* > 0$ such that $|z(T^*)| \leq \epsilon$, and hence, for all $t \geq T^*$,

$$|z(t)| \leq \alpha\left(e^{-k(t-T^*)}\tilde{\gamma}(\epsilon)\right) = \alpha\left(e^{kT^*}e^{-kt}\tilde{\gamma}(\epsilon)\right). \tag{108}$$

Again, from GAS, there exists a class-$\mathcal{KL}$ function $\beta(\cdot,\cdot)$ such that

$$|z(t)| \leq \alpha(\beta(|z(0)|,t)); \tag{109}$$

thus, for all $t \in [0, T^*]$,

$$|z(t)| \leq \alpha\left((\beta(|z(0)|,t)e^{kt})e^{-kt}\right) \leq \alpha((\beta(|z(0)|,0)e^{kT^*})e^{-kt})\,. \tag{110}$$

Choosing $T^* = T(|z(0)|)$ such that $T(|z(0)|) = 0$ for $|z(0)| \in [0, \epsilon]$ and $T(|z(0)|)$ is a continuous, strictly increasing function for $|z(0)| \geq \epsilon$, we conclude from (9), (108), and (110) that (8) holds with

$$\gamma(s) = \begin{cases} \max\left\{1, \frac{\beta(\epsilon,0)}{\tilde{\gamma}(\epsilon)}\right\} \tilde{\gamma}(s) & \text{if} \quad s \leq \epsilon, \\ \max\{\tilde{\gamma}(\epsilon), \beta(s,0)\} e^{kT(s)} & \text{if} \quad s > \epsilon\,. \end{cases} \tag{111}$$

□

Proof of Lemma 5. The result follows by using Lemma 6 instead of [2, Corollary IV.5] and modifying the proof of [2, Proposition II.5] accordingly. For Lemma 6, we define a function $\sigma_- : \mathbb{R}_{\geq 0} \to \mathbb{R}_{\geq 0}$ to be class-$\mathcal{K}_-$ if it is continuous and strictly increasing but, unlike a class-$\mathcal{K}$ function, not necessarily zero at zero.

LEMMA 6. *If $\gamma : \mathbb{R}^2_{\geq 0} \to \mathbb{R}$ is such that $\gamma(\cdot, s)$ is class-$\mathcal{K}$ for each $s \in \mathbb{R}_{\geq 0}$ and $\gamma(r, \cdot)$ is class-$\mathcal{K}_o$ for each $r \in \mathbb{R}_{\geq 0}$, then there exist a class-$\mathcal{K}_-$ function $\sigma_-(\cdot)$ and a class-$\mathcal{K}_o$ function $\sigma_o(\cdot)$, such that*

$$\gamma(r, s) \leq \sigma_-(r)\sigma_o(s)\,. \tag{112}$$

Proof. Because both $\gamma(\cdot, s)$ and $\gamma(r, \cdot)$ are class-$\mathcal{K}$, it follows from [2, Corollary IV.5] that there exists a class-$\mathcal{K}$ function $\sigma_1(\cdot)$ such that

$$\gamma(r, s) \leq \sigma_1(r)\sigma_1(s)\,. \tag{113}$$

Because $\gamma(r, s) = \mathcal{O}(s)$ for all $r \geq 0$, we can find a class-$\mathcal{K}_-$ function $\sigma_2(\cdot)$ such that, for all $s \leq 1$,

$$\gamma(r, s) \leq \sigma_2(r)s\,. \tag{114}$$

The inequalities (113) and (114) imply $\gamma(r, s) \leq \sigma_-(r)\tilde{\sigma}_o(s)$, where $\sigma_-(r) := \max\{\sigma_1(r), \sigma_2(r)\}$ and

$$\tilde{\sigma}_o(s) := \begin{cases} s, & s \leq 1, \\ \sigma_1(s), & s > 1\,. \end{cases} \tag{115}$$

Thus (112) follows by finding a continuous upper-bound $\sigma_o(\cdot)$ on $\tilde{\sigma}_o(\cdot)$. □

8. Conclusion. We have studied the stability of nonlinear cascades and showed that a trade-off exists between slower convergence for the driving subsystem and steeper iISS gain for the driven subsystem. This approach unifies several results in the literature, obtained by restricting the speed of convergence of the driving subsystem and the nonlinear growth of the driven subsystem. We have studied the connection between these growth conditions and the iISS gain and have proved that our iISS gain restriction leads to a less restrictive condition than the linear growth assumption common in the literature. The cascade result has been used to develop a new observer-based backstepping design which reduces the growth of nonlinear damping terms. It would be of interest to extend our cascade result to feedback interconnections, where small-gain formulations of iISS can be pursued.

RIESZ BASIS PROPERTY AND EXPONENTIAL STABILITY OF CONTROLLED EULER–BERNOULLI BEAM EQUATIONS WITH VARIABLE COEFFICIENTS*

BAO-ZHU GUO†

Abstract. This paper studies the basis property and the stability of a distributed system described by a nonuniform Euler–Bernoulli beam equation under linear boundary feedback control. It is shown that there is a sequence of generalized eigenfunctions of the system, which forms a Riesz basis for the state Hilbert space. The asymptotic distribution of eigenvalues, the spectrum-determined growth condition, and the exponential stability are concluded. The results are applied to a nonuniform beam equation with viscous damping of variable coefficient as a generalization of existing results for the uniform beam.

Key words. beam equation, variable coefficients, asymptotic analysis, Riesz basis, stability

1. Introduction.

The Riesz basis property, meaning that the generalized eigenvectors of the system form an unconditional basis for the state Hilbert space, is one of the fundamental properties of a linear vibrating system. The establishment of the basis property will naturally lead to solutions to such problems as the spectrum-determined growth condition and the exponential stability for infinite dimensional systems. Unfortunately, verification of the Riesz basis generation is challenging even for extensively studied systems such as Euler–Bernoulli beam equations. Recently, a new approach has been suggested [1] to obtain a complete solution to the basis property of the following uniform Euler–Bernoulli beam equation under linear boundary feedback control:

$$\begin{cases} y_{tt}(x,t) + y_{xxxx}(x,t) = 0, & 0 < x < 1, t > 0, \\ y(0,t) = y_x(0,t) = 0, & \\ y_{xx}(1,t) = -k_1 y_{xt}(1,t), & k_1 \geq 0, \\ y_{xxx}(1,t) = k_2 y_t(1,t), & k_2 \geq 0. \end{cases} \tag{1}$$

In this paper, we shall develop parallel results for the same system with variable coefficients. What makes it unique compared to the case of constant coefficients is that with variable coefficients both the characteristic equation and the analytic expression of the eigenfunctions have no explicit formulae. The asymptotic technique appears to be essential for the study.

There are two steps usually found in the study of linear systems with variable coefficients. The first is to transform the "dominant term" of the system under study into a uniform "dominant equation" by space scaling and state transformation where no variable coefficient is involved any longer, while the second is to approximate the eigenfunctions of the system by those of the uniform "dominant equation." This

fundamental idea comes essentially from Birkhoff's works on asymptotic estimation of the eigenpairs of the linear differential operators with generalized homogeneous boundary conditions done in the beginning of the last century [5]. A comprehensive review can be found in [4]. This approach has been used in dealing with the beam equations with low order perturbation of variable coefficients (see [6], [7], and [8]). A similar adoption can also be found in the study of the string equations with variable coefficients, for which we refer to [9], [10], and [11] as well as the references therein.

By considering a sequence of eigenfunctions rather than whole sequences in the state Hilbert space, the author recently presented a corollary of Bari's theorem on the Riesz basis property [1]. The result greatly simplifies the procedure in establishing the Riesz basis property for systems described by discrete operators in a Hilbert space since the result eliminates the requirement of estimation of low eigenfunctions, which is rather difficult by other methods found in all previous papers [10], [11], [12].

Following the approach used in [1], together with the asymptotic analysis, this paper presents the Riesz basis property for the Euler–Bernoulli beam equation with variable coefficients. Other major contributions include the exponential stability and asymptotic behavior of the systems under boundary feedback control.

In the next section, we shall present the main results of the paper. The proof of the results and some remarks are given in section 3.

2. Main results. Consider the following nonuniform Euler–Bernoulli beam equation with linear boundary feedback control:

$$\begin{cases} \rho(x)y_{tt}(x,t) + (EI(x)y_{xx}(x,t))_{xx} = 0, & 0 < x < 1, t > 0, \\ y(0,t) = y_x(0,t) = y_{xx}(1,t) = 0, \\ (EI(x)y_{xx})_x(1,t) = ky_t(1,t), \end{cases} \tag{2}$$

where x stands for the position and t the time. $EI(x)$ is the flexural rigidity of the beam, and $\rho(x)$ is the mass density at x. $k \geq 0$ is a constant feedback gain. Unlike system (1), here we impose only one end feedback control for simplicity of computation because, from Theorem 2.5 below, it is sufficient for the exponential stabilization of the system. Moreover, it does not make much difference from the methodology point of view. Actually, the analysis in this paper can be used to similarly treat the boundary conditions of (1) along the same lines as the analysis in [1].

The total energy of system (2) is

$$E(t) = \frac{1}{2}\int_0^1 [\rho(x)y_t^2(x,t) + EI(x)y_{xx}^2(x,t)]dx.$$

Formally,

$$\frac{dE(t)}{dt} = -ky_t^2(x,t) \leq 0.$$

That is, system (2) is dissipative. Throughout this paper, we always assume that

$$\rho(x), EI(x) \in C^4[0,1], EI, \quad \rho > 0. \tag{3}$$

System (2) will be considered in the energy Hilbert space $\mathbf{H} = H_E^2(0,1) \times L^2(0,1)$, $H_E^2(0,1) = \{f \in H^2(0,1) | f(0) = f'(0) = 0\}$, in which the inner product induced norm is defined by

$$\|(f,g)\|_{\mathbf{H}}^2 = \int_0^1 [\rho(x)|g(x)|^2 + EI(x)|f''(x)|^2]dx \qquad \forall (f,g) \in \mathbf{H}. \tag{4}$$

Define operator $\mathcal{A} : D(\mathcal{A})(\subset \mathbf{H}) \to \mathbf{H}$ as

$$\begin{cases} \mathcal{A}(f,g) = (g, -\frac{1}{\rho(x)}(EI(x)f''(x))''), \\ D(\mathcal{A}) = \{(f,g) \in (H_E^2 \cap H^4) \times H_E^2 | f''(1) = 0, (EIf'')'(1) = kg(1)\}. \end{cases} \tag{5}$$

With the operator $\mathcal{A}$ at hand, we can write (2) into an evolutionary equation in $\mathbf{H}$:

$$\frac{d}{dt}Y(t) = \mathcal{A}Y(t), Y(t) = (y(\cdot,t), y_t(\cdot,t)). \tag{6}$$

When we talk about system (2) later, we mean its abstract formulation (6). We are concerned with the Riesz basis property of (6) in $\mathbf{H}$; that is, we want to know whether the generalized eigenfunctions of $\mathcal{A}$ form an unconditional basis for $\mathbf{H}$. To do this, we need the following spectral property of $\mathcal{A}$.

LEMMA 2.1. *Let $\mathcal{A}$ be defined by (5). Then $\mathcal{A}^{-1}$ exists and is compact on $\mathbf{H}$. Hence $\sigma(\mathcal{A})$, the spectrum of $\mathcal{A}$, consists only of isolated eigenvalues, which distribute in conjugate pairs on the complex plane. Moreover, the eigenfunction corresponding to $\lambda \in \sigma(\mathcal{A})$ is of the form $(\lambda^{-1}\phi, \phi)$, where $\phi \neq 0$ satisfies*

$$\begin{cases} \lambda^2\rho(x)\phi(x) + (EI(x)\phi''(x))'' = 0, \qquad 0 < x < 1, \\ \phi(0) = \phi'(0) = \phi''(1) = 0, \\ (EI(x)\phi'')'(1) = \lambda k\phi(1). \end{cases} \tag{7}$$

To verify the basis property, we need the asymptotic properties of both eigenvalues and eigenfunctions, which are stated as the following propositions.

PROPOSITION 2.2. *Let $\mathcal{A}$ be defined by (5). Then the eigenvalues $\{\lambda_n, \overline{\lambda_n}\}$ of $\mathcal{A}$ have the following asymptotic property:*

$$\lambda_n = \frac{\rho_n^2}{h^2}, h = \int_0^1 \left(\frac{\rho(\tau)}{EI(\tau)}\right)^{1/4} d\tau, \rho_n = \frac{1}{\sqrt{2}}\left(n + \frac{1}{2}\right)\pi(1+i) + \mathcal{O}(n^{-1}) \text{ as } n \to \infty, \tag{8}$$

where n is a large positive integer and $\overline{\lambda_n}$ denotes the complex conjugate of λ_n. Moreover, λ_n is geometrically simple when n is large enough.

PROPOSITION 2.3. *Let λ_n be defined as in Proposition 2.2. Then there is a solution ϕ_n to (7) corresponding to λ_n having the following asymptotic expansion:*

$$\begin{aligned} &-\frac{\sqrt{2}}{4}(1+i)e^{\frac{1}{4}\int_0^z a(\tau)d\tau}\phi_n(x) = \sin(n+\pi/2)z - \cos(n+\pi/2)z \\ &+e^{-(n+1/2)\pi z} + (-1)^n e^{-(n+1/2)\pi(1-z)} + \mathcal{O}(n^{-1}), \end{aligned} \tag{9}$$

$$\begin{aligned} &-\frac{\sqrt{2}}{4}(1+i)e^{\frac{1}{4}\int_0^z a(\tau)d\tau}\lambda_n^{-1}\phi_n''(x) = i\left(\frac{\rho(x)}{EI(x)}\right)^{1/2}[\cos(n+\pi/2)z - \sin(n+\pi/2)z \\ &+e^{-(n+1/2)\pi z} + (-1)^n e^{-(n+1/2)\pi(1-z)}] + \mathcal{O}(n^{-1}), \end{aligned} \tag{10}$$

where $z = z(x)$ and $a(z)$ are defined by

$$\begin{cases} z = z(x) = \dfrac{1}{h}\displaystyle\int_0^x \left(\frac{\rho(\tau)}{EI(\tau)}\right)^{1/4} d\tau, h = \int_0^1 \left(\frac{\rho(\tau)}{EI(\tau)}\right)^{1/4} d\tau, \\ a(z) = \dfrac{3h}{2}\left(\dfrac{\rho(x)}{EI(x)}\right)^{-5/4} \dfrac{d}{dx}\left(\dfrac{\rho(x)}{EI(x)}\right) + h\dfrac{2EI'(x)}{EI(x)}\left(\dfrac{\rho(x)}{EI(x)}\right)^{-1/4}. \end{cases} \tag{11}$$

The main result is the following basis property for system (2).

THEOREM 2.4. *Let $\mathcal{A}$ be defined by* (5). *Then the following hold.*

(i) *There is a sequence of generalized eigenfunctions of $\mathcal{A}$ which forms a Riesz basis for the state space* $\mathbf{H}$.

(ii) *The eigenvalues $\{\lambda_n, \overline{\lambda_n}\}$ of $\mathcal{A}$ have the asymptotic expansion* (8).

(iii) *All $\lambda \in \sigma(\mathcal{A})$ with sufficiently large modulus are algebraically simple.*

Therefore, $\mathcal{A}$ generates a C_0-group, and, for the semigroup $e^{\mathcal{A}t}$ generated by $\mathcal{A}$, the spectrum-determined growth condition holds: $\omega(\mathcal{A}) = S(\mathcal{A})$, where $\omega(\mathcal{A}) = \lim_{t\to\infty} \frac{1}{t}\|e^{\mathcal{A}t}\|$ is the growth order of $e^{\mathcal{A}t}$ and $S(\mathcal{A}) = \sup\{\mathrm{Re}\lambda | \lambda \in \sigma(\mathcal{A})\}$ is the spectral bound of $\mathcal{A}$.

Remark 1. From Theorem 2.4 (iii), (9) and (10) are asymptotic expansions for all generalized eigenfunctions of $\mathcal{A}$.

Theorem 2.4 is the fundamental property of system (2). Many other important properties of system (2) can be concluded from Theorem 2.4. The exponential stability stated below is one such important property that has been studied extensively in the past two decades.

THEOREM 2.5. *System* (2) *is exponentially stable for any $k > 0$. That is, there are constants $M, \omega > 0$ such that the energy $E(t)$ of system* (2) *satisfies*

$$E(t) = \frac{1}{2}\int_0^1 [\rho(x)y_t^2(x,t) + EI(x)y_{xx}^2(x,t)]dx \le Me^{-\omega t}E(0) \qquad \forall t \ge 0,$$

for any initial condition $(y(x,0), y_t(x,0)) \in \mathbf{H}$.

Theorem 2.4 will also be applied to the following beam equation with variable viscous damping:

$$\begin{cases} \rho(x)y_{tt}(x,t) + b(x)y_t(x,t) + (EI(x)y_{xx}(x,t))_{xx} = 0, & 0 < x < 1, t > 0, \\ y(0,t) = y_x(0,t) = y_{xx}(1,t) = 0, \\ (EI(x)y_{xx})_x(1,t) = ky_t(1,t). \end{cases} \tag{12}$$

The uniform case of $EI = \rho = \text{const}, b \in C[0,1], k = 0$ was discussed in [8]. System (12) can be written as

$$\frac{d}{dt}Y(t) = (\mathcal{A} + \mathcal{B})Y(t), Y(t) = (y(\cdot,t), y_t(\cdot,t)), \tag{13}$$

where $\mathcal{A}$ is defined by (5) and $\mathcal{B}$ is a linear bounded operator on $\mathbf{H}$:

$$\mathcal{B}(f,g) = (0, -b\cdot g). \tag{14}$$

Equation (13) can be put into the generic framework of discrete-type operators perturbed by the linear bounded operator in the Hilbert spaces. First, we introduce the following definition.

DEFINITION 2.6. *A linear operator A in a Hilbert space H is called discrete-type, or $[D]$-class for short, if there are Riesz basis $\{\phi_n\}_1^\infty$ of H, complex series $\{\lambda_n\}_1^\infty$, and an integer $N > 0$ such that*

(i) $\lim_{n\to\infty} |\lambda_n| = \infty, \lambda_n \ne \lambda_m$ *as* $n, m > N$;

(ii) $A\phi_n = \lambda_n\phi_n,\ n > N$;

(iii) $A[\phi_1, \phi_2, \ldots, \phi_N] \subset [\phi_1, \phi_2, \ldots, \phi_N]$, *and A has spectrum $\{\lambda_i\}_1^N$ in $[\phi_1, \phi_2, \ldots, \phi_N]$, where $[\phi_1, \phi_2, \ldots, \phi_N]$ is the linear subspace spanned by $\{\phi_i\}_1^N$.*

Remark 2. Theorem 2.4 shows that $\mathcal{A}$ is of $[D]$-class.

It is known that any $[D]$-class operator A must be a discrete operator [14], and for the C_0-semigroup e^{At} generated by A, the spectrum-determined growth condition holds. The following basic result can be concluded from the proof of a more general result in [14] (see also [15], [16, section V.4]). A short proof will be given in the next section.

THEOREM 2.7. *Suppose that A is of $[D]$-class satisfying conditions of Definition* 2.6 *in a Hilbert space H. Let $d_n = \min_{n\neq m} |\lambda_n - \lambda_m|$. If*

$$\sum_{n>N}^{\infty} d_n^{-2} < \infty, \tag{15}$$

then, for any linear bounded operator B on H, there are constants $C, L > 0$, an integer $M > 0$, and eigenpairs $\{\mu_n, \psi_n\}_M^\infty$ of $A + B$ such that

(i) $|\mu_n - \lambda_n| \leq C$ *for all* $n \geq M$.

(ii) $\|\psi_n - \phi_n\| \leq L d_n^{-1}, n \geq M$. *Hence* $\sum_{n=M}^{\infty} \|\psi_n - \phi_n\|^2 < \infty$.

We can now consider (12). By Remark 1, $\mathcal{A}$ is of $[D]$-class. And the spectral separation of $\mathcal{A}$ satisfies $d_n^{-1} = \mathcal{O}(n^{-1})$. In Remark 4 of the next section, we shall show that d_n is never vanishing. Hence Theorem 2.7 can be applied to $(A, B) = (\mathcal{A}, \mathcal{B})$ to get the following parallel result of Theorem 2.4 for system (12).

THEOREM 2.8. *Suppose $EI, \rho \in C^4[0,1], EI, \rho > 0, b \in C[0,1]$. Then the following hold.*

(i) $\mathcal{A} + \mathcal{B}$ *is of $[D]$-class.*

(ii) *The eigenvalues $\{\mu_n, \overline{\mu_n}\}$ of $\mathcal{A} + \mathcal{B}$ have the asymptotic expansion*

$$\mu_n = \lambda_n + \mathcal{O}(1) \text{ as } n \to \infty, \tag{16}$$

where λ_n is defined by (8).

(iii) *The corresponding eigenfunctions $\{(\mu_n^{-1}\psi_n, \psi_n)\} \cup \{$ their conjugates $\}$ of $\mathcal{A}+\mathcal{B}$ have the asymptotic expansion*

$$(\mu_n^{-1}\psi_n, \psi_n) = (\lambda_n^{-1}\phi_n, \phi_n) + \epsilon_n \text{ as } n \to \infty, \tag{17}$$

where ϕ_n is defined by (9) *and*

$$\|\epsilon_n\|_{\mathbf{H}} = \mathcal{O}(n^{-1}). \tag{18}$$

The following result can be viewed as a consequence of Theorem 2.8.

COROLLARY 2.9. *Let $\{\mu_n\}$ be the eigenvalues of $\mathcal{A}+\mathcal{B}$ determined in Theorem* 2.8. *Then*

$$\lim_{n\to\infty} \mathrm{Re}\mu_n = -\frac{1}{2} \frac{\int_0^1 b(x) e^{-\frac{1}{2}\int_0^z a(\tau)d\tau} dx + 4k e^{-\frac{1}{2}\int_0^1 a(\tau)d\tau}}{\int_0^1 \rho(x) e^{-\frac{1}{2}\int_0^z a(\tau)d\tau} dx}, \tag{19}$$

where $z = z(x), a(z)$ are defined in (11).

Corollary 2.9 concludes some existing results for system (12). We give several examples below.

Example 1. Suppose that $\rho = 1, k = 0$, and EI is a constant. Then $a = 0$. Equation (19) becomes

$$\lim_{n\to\infty} \mathrm{Re}\mu_n = -\frac{1}{2}\int_0^1 b(x)dx, \tag{20}$$

which is a strengthened conjecture

$$\lim_{n\to\infty}\frac{\sum_{j\le n}\mathrm{Re}\mu_j}{n}=-\frac{1}{2}\int_0^1 b(x)dx \tag{21}$$

made in [13] for the same system with hinged boundary conditions and resolved later in [6] under the assumption that $b(x)\ge 0$. However, we do not impose any assumption on the symbol of b.

Example 2. Suppose that $\rho = EI = 1, k = 0$. Then (12) becomes

$$\begin{cases} y_{tt}(x,t)+b(x)y_t(x,t)+y_{xxxx}(x,t)=0, & 0<x<1, t>0,\\ y(0,t)=y_x(0,t)=y_{xx}(1,t)=y_{xxx}(1,t)=0, \end{cases} \tag{22}$$

which is just the system studied in [8]. Equation (20) holds for this system. However, our result shows that the main hypothesis (1.3) of [8] is nothing but $\int_0^1 b(x)dx>0$. Moreover, from our discussion, Theorem 2.8 is sufficient to derive (20). This is because spectral analysis for system (22) with $b=0$ is quite simple and does not necessarily need to rely on Theorem 2.4 [1].

Example 3. Suppose that $b(x)\ge 0$ for $x\in[0,1]$, and $b(x)>b_0>0$ for all x in some subset $(a,b)\subset[0,1]$ in (22). The system is then exponentially stable. When $k=0, b(x)\ge 0$ for $x\in[0,1]$ and $b(x)>b_0>0$ for all x in some subset $(a,b)\subset[0,1]$, system (12) is also exponentially stable. However, the method used in [18] appears to be unavailable for this case. We will give a short interpretation for Example 3 in section 3.

Finally, we present a high order approximation of the eigenvalues of system (12).

PROPOSITION 2.10. *Suppose* (3) *and*

$$b(x)\in C^1[0,1],\quad \int_0^1 b(x)e^{-\frac{1}{2}\int_0^z a(\tau)d\tau}dx+4ke^{-\frac{1}{2}\int_0^1 a(\tau)d\tau}>0. \tag{23}$$

Then the eigenvalues $\{\mu_n,\overline{\mu_n}\}$ *of* $\mathcal{A}+\mathcal{B}$ *have the asymptotic expansion*

$$\mu_n=-\frac{2\tilde{k}}{h^2}+i\left[(n+1/2)\frac{\pi}{h}\right]^2-\frac{i}{2h^2}\int_0^1 a_1(\tau)d\tau-\frac{1}{2h^2}\int_0^1\tilde{b}(\tau)d\tau+\mathcal{O}(n^{-1}), \tag{24}$$

where $\tilde{b}(z), a_1(z)$, *and* $\tilde{k}$ *are given by*

$$\tilde{k}=\frac{kh}{EI(1)}\left(\frac{\rho(1)}{EI(1)}\right)^{-3/4}, \tag{25}$$

$$\tilde{b}(z)=\frac{b(x)}{\rho(x)}, z=\frac{1}{h}\int_0^x\left(\frac{\rho(\tau)}{EI(\tau)}\right)^{1/4}d\tau, \tag{26}$$

$$a_1(z)=-\frac{3}{2}a'(z)-\frac{9}{16}a^2(z)-\frac{1}{4}a(z). \tag{27}$$

3. Proof of main results.

Proof of Lemma 2.1. A direct calculation shows that

$$\mathcal{A}^{-1}(f,g)=(\phi,\psi)\text{ for any }(f,g)\in \mathrm{H},$$

where

$$\begin{cases} \psi & = f, \\ \phi(x) & = kf(1)\displaystyle\int_0^x (x-\tau)\frac{\tau-1}{EI(\tau)}d\tau + \int_0^x \rho(\tau)g(\tau)d\tau \int_\tau^x d\vartheta \int_\tau^\vartheta \frac{s-\tau}{EI(s)}ds. \end{cases}$$

The compactness follows from the Sobolev embedding theorem. Other conclusions are obvious, and the details are omitted. □

In order to study the asymptotic behavior of the solution of (7), we rewrite (7) in a standard form of the eigenproblem of a linear differential operator with generalized homogeneous boundary conditions:

$$\begin{cases} \phi^{(4)}(x) + \dfrac{2EI'(x)}{EI(x)}\phi'''(x) + \dfrac{EI''(x)}{EI(x)}\phi''(x) + \lambda^2\dfrac{\rho(x)}{EI(x)}\phi(x) = 0, \\ \phi(0) = \phi'(0) = \phi''(1) = 0, \\ \phi'''(1) = \lambda\dfrac{k}{EI(1)}\phi(1). \end{cases} \tag{28}$$

Two basic transformations are essential. First, the "dominant term," $\phi^{(4)}(x) + \lambda^2\rho(x)/EI(x)\phi(x)$ of (28), is transformed to become a uniform form by space scaling. In fact, set

$$\phi(x) = f(z), z = z(x) = \frac{1}{h}\int_0^x \left(\frac{\rho(\tau)}{EI(\tau)}\right)^{1/4} d\tau, h = \int_0^1 \left(\frac{\rho(\tau)}{EI(\tau)}\right)^{1/4} d\tau. \tag{29}$$

Then f satisfies

$$\begin{cases} f^{(4)}(z) + a(z)f'''(z) + b_f(z)f''(z) + c(z)f'(z) + \lambda^2h^4f(z) = 0, \\ f(0) = f'(0) = 0, \\ f''(1) + a_0f'(1) = 0, \\ f'''(1) = b_0f'(1) + \lambda\dfrac{kh^3}{EI(1)}\left(\dfrac{\rho(1)}{EI(1)}\right)^{-3/4} f(1), \end{cases} \tag{30}$$

where a_0 and b_0 are constants depending on $h, \rho^{(i)}(1), EI^{(i)}(1), i = 0, 1, 2, b_f(z)$ and $c(z)$ are the smooth functions of $h, \rho^{(i)}(x), EI^{(i)}(x), i = 0, 1, 2, 3$ through $z = z(x)$ defined by (11), and $a(z)$ is the function given by (11).

Second, in order to cancel the term $a(z)f'''$ in (30) as was done in [4], we make the invertible state transformation

$$f(z) = e^{-\frac{1}{4}\int_0^z a(\tau)d\tau}g(z). \tag{31}$$

Then g satisfies

$$\begin{cases} g^{(4)}(z) + a_1(z)g''(z) + a_2(z)g'(z) + a_3(z)g(z) + \lambda^2h^4g(z) = 0, \\ g(0) = g'(0) = 0, \\ g''(1) = a_{11}g'(1) + a_{12}g(1), \\ g'''(1) = a_{21}g'(1) + \left[\lambda\dfrac{kh^3}{EI(1)}\left(\dfrac{\rho(1)}{EI(1)}\right)^{-3/4} + a_{22}\right] g(1), \end{cases} \tag{32}$$

where $a_{ij}, i, j = 1, 2$ are some real constants depending on $h, \rho^{(i)}(1), EI^{(i)}(1), i = 0, 1, 2, a_2(z)$ and $a_3(z)$ are the smooth functions of $h, \rho^{(i)}(x), EI^{(i)}(x), i = 0, 1, 2, 3$ through $z = z(x)$ defined by (29), and $a_1(z)$ is given by (27).

It can be seen that (7) and (32) are equivalent. Our next task is to use the eigenpairs of the uniform "dominant term," $g^{(4)}(z)+\lambda^2 h^4 g(z)=0$ of (32), to approximate those of the whole system. Note that when $k=0$, (32) is in the standard form of a linear differential operator with generalized homogeneous boundary conditions, which was studied in [4] in greater detail.

Now we proceed as in section 4, Chapter 2 of [4] to estimate asymptotically the solutions to (32). Since system (2) is dissipative, all eigenvalues are located on the left half complex plane. Due to the conjugate property of the eigenvalues, we may consider only those λ with $\pi/2 \le \arg\lambda \le \pi$.

Let $\lambda=\rho^2/h^2$. Then, as $\pi/2 \le \arg\lambda \le \pi$,

$$\pi/4 \le \arg\rho \le \pi/2. \tag{33}$$

Now set

$$\begin{cases} \omega_1 = e^{3/4\pi i}, \omega_2 = e^{\pi/4 i}, \omega_3 = -\omega_2, \omega_4 = -\omega_1, \\ S = \left\{\rho | \frac{\pi}{4} \le \arg\rho \le \frac{\pi}{2}\right\}. \end{cases} \tag{34}$$

In what follows, ρ is always assumed to be in S. Note that

$$\mathrm{Re}(\rho\omega_1) \le \mathrm{Re}(\rho\omega_2) \le \mathrm{Re}(\rho\omega_3) \le \mathrm{Re}(\rho\omega_4) \qquad \forall \rho \in S. \tag{35}$$

The following important facts are used frequently in what follows.

$$\begin{cases} \mathrm{Re}(\rho\omega_1) = -|\rho|\sin(\arg\rho + \frac{\pi}{4}) \le -\sqrt{2}/2|\rho| < 0, \\ \mathrm{Re}(\rho\omega_2) = |\rho|\cos(\arg\rho + \frac{\pi}{4}) \le 0. \end{cases} \tag{36}$$

Lemma 3.1 comes from Theorem 2.4 in section 4, Chapter 2 of [4].

LEMMA 3.1. *For $|\rho|$ large enough, $\rho \in S$, there are four linearly independent solutions $g_k(z), k=1,2,3,4$ to*

$$g^{(4)}(z)+a_1(z)g''(z)+a_2(z)g'(z)+a_3(z)g(z)+\rho^4 g(z)=0,$$

such that

$$\begin{cases} g_k(z) = e^{\rho\omega_k z}[1+\mathcal{O}(\frac{1}{\rho})], \\ g_k'(z) = \rho\omega_k e^{\rho\omega_k z}[1+\mathcal{O}(\frac{1}{\rho})], \\ g_k''(z) = (\rho\omega_k)^2 e^{\rho\omega_k z}[1+\mathcal{O}(\frac{1}{\rho})], \\ g_k'''(z) = (\rho\omega_k)^3 e^{\rho\omega_k z}[1+\mathcal{O}(\frac{1}{\rho})]. \end{cases} \tag{37}$$

With these preparations, we come to the proof of Proposition 2.2.

Proof of Proposition 2.2. Let $g(z)$ be a solution of (32). There are constants $c_i, i=1,2,3,4$, such that

$$g(z) = c_1 g_1(z) + c_2 g_2(z) + c_3 g_3(z) + c_4 g_4(z), \tag{38}$$

where $g_k(z), k=1,2,3,4$ are defined by (37). By boundary conditions, $c_i, i=1,2,3,4$ are solutions to the following system of linear algebraic equations:

$$\begin{cases} c_1 g_1(0) + c_2 g_2(0) + c_3 g_3(0) + c_4 g_4(0) = 0, \\ c_1 g_1'(0) + c_2 g_2'(0) + c_3 g_3'(0) + c_4 g_4'(0) = 0, \\ \left[g_1''(1) - a_{11}g_1'(1) - a_{12}g_1(1)\right]c_1 + \left[g_2''(1) - a_{11}g_2'(1) - a_{12}g_2(1)\right]c_2 \\ +[g_3''(1) - a_{11}g_3'(1) - a_{12}g_3(1)]c_3 + [g_4''(1) - a_{11}g_4'(1) - a_{12}g_4(1)]c_4 = 0, \\ \left[g_1'''(1) - a_{21}g_1'(1) - a_{22}g_1(1) - \tilde{k}\rho^2 g_1(1)\right] c_1 + [g_2'''(1) - a_{21}g_2'(1) - a_{22}g_2(1) - \tilde{k}\rho^2 g_2(1)]c_2 \\ +[g_3'''(1) - a_{21}g_3'(1) - a_{22}g_3(1) - \tilde{k}\rho^2 g_3(1)]c_3 + [g_4'''(1) - a_{21}g_4'(1) - a_{22}g_4(1) - \tilde{k}\rho^2 g_4(1)]c_4 = 0, \end{cases} \tag{39}$$

where $\tilde{k}$ is defined by (25).

From (36) and (37), for any $k, 1 \le k \le 4$,

$$\begin{cases} g_k(0) = 1 + \mathcal{O}(\frac{1}{\rho}), g_k'(0) = \rho\omega_k[1 + \mathcal{O}(\frac{1}{\rho})], \\ [g_k''(1) - a_{11}g_k'(1) - a_{12}g_k(1)] = (\rho\omega_k)^2 e^{\rho\omega_k}[1 + \mathcal{O}(\frac{1}{\rho})], \\ g_k'''(1) - a_{21}g_k'(1) - a_{22}g_k(1) - \tilde{k}\rho^2 g_k(1) \\ = (\rho\omega_k)^3 e^{\rho\omega_k}[1 + \mathcal{O}(\frac{1}{\rho})] - \tilde{k}\rho^2 e^{\rho\omega_k}[1 + \mathcal{O}(\frac{1}{\rho})], \end{cases} \tag{40}$$

and

$$|e^{\rho\omega_2}| \le 1, |e^{\rho\omega_1}| = \mathcal{O}(e^{-c|\rho|}) \text{ as } |\rho| \to \infty, \tag{41}$$

for some constant $c > 0$. Then we know that $g(z)$ is nonzero if and only if ρ satisfies the characteristic equation

$$\det \begin{pmatrix} [1] & [1] & [1] & [1] \\ \rho\omega_1[1] & \rho\omega_2[1] & \rho\omega_3[1] & \rho\omega_4[1] \\ (\rho\omega_1)^2 e^{\rho\omega_1}[1] & (\rho\omega_2)^2 e^{\rho\omega_2}[1] & (\rho\omega_3)^2 e^{\rho\omega_3}[1] & (\rho\omega_4)^2 e^{\rho\omega_4}[1] \\ (\rho\omega_1)^3 e^{\rho\omega_1}[1] & (\rho\omega_2)^3 e^{\rho\omega_2}[1] & (\rho\omega_3)^3 e^{\rho\omega_3}[1] & (\rho\omega_4)^3 e^{\rho\omega_4}[1] \end{pmatrix} = 0,$$

where $[1] = 1 + \mathcal{O}(\frac{1}{\rho})$. Since $\omega_4 = -\omega_1, \omega_3 = -\omega_2$, the above equation is equivalent to

$$\det \begin{pmatrix} [1] & [1] & e^{\rho\omega_2}[1] & e^{\rho\omega_1}[1] \\ \omega_1[1] & \omega_2[1] & -\omega_2 e^{\rho\omega_2}[1] & -\omega_1 e^{\rho\omega_1}[1] \\ \omega_1^2 e^{\rho\omega_1}[1] & \omega_2^2 e^{\rho\omega_2}[1] & \omega_2^2[1] & \omega_1^2[1] \\ \omega_1^3 e^{\rho\omega_1}[1] & \omega_2^3 e^{\rho\omega_2}[1] & -\omega_2^3[1] & -\omega_1^3[1] \end{pmatrix} = 0. \tag{42}$$

Noting that each element of the matrix in (42) is bounded, we may rewrite (42) as

$$\det \begin{pmatrix} 1 & 1 & e^{\rho\omega_2} & 0 \\ \omega_1 & \omega_2 & -\omega_2 e^{\rho\omega_2} & 0 \\ 0 & \omega_2^2 e^{\rho\omega_2} & \omega_2^2 & \omega_1^2 \\ 0 & \omega_2^3 e^{\rho\omega_2} & -\omega_2^3 & -\omega_1^3 \end{pmatrix} + \mathcal{O}\left(\frac{1}{\rho}\right) = 0, \tag{43}$$

which results in

$$e^{2\rho\omega_2} = \left(\frac{\omega_2 - \omega_1}{\omega_2 + \omega_1}\right)^2 + \mathcal{O}\left(\frac{1}{\rho}\right) = -1 + \mathcal{O}\left(\frac{1}{\rho}\right). \tag{44}$$

By solving (44), we obtain (8) by the same arguments as those of section 4, Chapter 2 of [4]. Since the matrix in (43) has rank 3 for each sufficiently large ρ_n, there is only one linearly independent solution g to (32) for $\rho = \rho_n$. Hence each λ_n is geometrically simple for n sufficiently large. □

In Remark 4, we will indicate that each eigenvalue of $\mathcal{A}$ must be geometrically simple. Noting (37), (38), and (42), we can write g, g'' as

$$g(z) = \det \begin{pmatrix} [1] & [1] & e^{\rho\omega_2}[1] & e^{\rho\omega_1}[1] \\ e^{\rho\omega_1 z}[1] & e^{\rho\omega_2 z}[1] & e^{\rho\omega_2(1-z)}[1] & e^{\rho\omega_1(1-z)}[1] \\ \omega_1^2 e^{\rho\omega_1}[1] & \omega_2^2 e^{\rho\omega_2}[1] & \omega_2^2[1] & \omega_1^2[1] \\ \omega_1^3 e^{\rho\omega_1}[1] & \omega_2^3 e^{\rho\omega_2}[1] & -\omega_2^3[1] & -\omega_1^3[1] \end{pmatrix}, \tag{45}$$

$$g''(z) = \rho^2 \det \begin{pmatrix} [1] & [1] & e^{\rho\omega_2}[1] & e^{\rho\omega_1}[1] \\ \omega_1^2 e^{\rho\omega_1 z}[1] & \omega_2^2 e^{\rho\omega_2 z}[1] & \omega_2^2 e^{\rho\omega_2(1-z)}[1] & \omega_1^2 e^{\rho\omega_1(1-z)}[1] \\ \omega_1^2 e^{\rho\omega_1}[1] & \omega_2^2 e^{\rho\omega_2}[1] & \omega_2^2[1] & \omega_1^2[1] \\ \omega_1^3 e^{\rho\omega_1}[1] & \omega_2^3 e^{\rho\omega_2}[1]] & -\omega_2^3[1] & -\omega_1^3[1] \end{pmatrix}. \tag{46}$$

LEMMA 3.2. *Let λ_n, ρ_n be defined as in Proposition* 2.2. *Then the unique (up to a scalar) associated solution g_n to* (32) *has the following asymptotic expansion:*

$$-\frac{\sqrt{2}}{4}(1+i)g_n(z) = \sin(n+\pi/2)z - \cos(n+\pi/2)z + e^{-(n+1/2)\pi z} + (-1)^n e^{-(n+1/2)\pi(1-z)} + \mathcal{O}(n^{-1}), \tag{47}$$

$$-\frac{\sqrt{2}}{4}(1+i)\rho_n^{-2}g_n''(z) = i[\cos(n+\pi/2)z - \sin(n+\pi/2)z + e^{-(n+1/2)\pi z} + (-1)^n e^{-(n+1/2)\pi(1-z)}] + \mathcal{O}(n^{-1}). \tag{48}$$

Moreover, it follows directly from (37) *and* (45) *that*

$$\rho_n^{-2}g_n'(z) = \mathcal{O}(n^{-1}). \tag{49}$$

Proof. It follows from (45) that

$$g_n(z) = \det\begin{pmatrix} 1 & 1 & e^{\rho_n\omega_2} & 0 \\ e^{\rho_n\omega_1 z} & e^{\rho_n\omega_2 z} & e^{\rho_n\omega_2(1-z)} & e^{\rho_n\omega_1(1-z)} \\ 0 & \omega_2^2 e^{\rho_n\omega_2} & \omega_2^2 & \omega_1^2 \\ 0 & \omega_2^3 e^{\rho_n\omega_2} & -\omega_2^3 & -\omega_1^3 \end{pmatrix} + \mathcal{O}\left(\frac{1}{\rho_n}\right).$$

After a simple calculation, we find that

$$\begin{aligned} g_n(z) &= \omega_1^2\omega_2^2[2\omega_1 e^{\rho_n\omega_1 z} + 2\omega_2 e^{\rho_n\omega_2} e^{\rho_n\omega_1(1-z)} \\ &\quad + (\omega_2+\omega_1)e^{\rho_n\omega_2} e^{\rho_n\omega_2(1-z)} + (\omega_2-\omega_1)e^{\rho_n\omega_2 z}] + \mathcal{O}(\tfrac{1}{\rho_n}) \\ &= \sqrt{2}(i-1)[\sin(n+\pi/2)z - \cos(n+\pi/2)z \\ &\quad + e^{-(n+1/2)\pi z} + (-1)^n e^{-(n+1/2)\pi(1-z)}] + \mathcal{O}(\tfrac{1}{n}). \end{aligned}$$

This is (47). Equation (48) can be proved similarly. □

Note that the asymptotic expansions (47) and (48) are exactly the same as those obtained in [1] for the eigenfunctions of system (2) with constant coefficients; i.e., $EI = \rho = \text{const}$. However, it should be pointed out that the estimates in [1] and [2] rely on the analytic expression of the eigenfunctions.

Proof of Proposition 2.3. The result follows directly from the following facts that are deduced from transformations (29), (31), and (49):

$$\begin{cases} -\frac{\sqrt{2}}{4}(1+i)e^{\frac{1}{4}\int_0^z a(\tau)d\tau} f_n(z) = -\frac{\sqrt{2}}{4}(1+i)g_n(z), \\ -\frac{\sqrt{2}}{4}(1+i)e^{\frac{1}{4}\int_0^z a(\tau)d\tau}\rho_n^{-2}f_n''(z) = -\frac{\sqrt{2}}{4}(1+i)\rho_n^{-2}g_n''(z) + \mathcal{O}\left(\frac{1}{n}\right), \\ \phi_n(x) = f_n(z), \rho_n^{-2}\phi_n''(x) = \frac{1}{h^2}\left(\frac{\rho(x)}{EI(x)}\right)^{1/2}\rho_n^{-2}f_n''(z) + \mathcal{O}\left(\frac{1}{n}\right). \end{cases} \tag{50}$$

□

Before proving Theorem 2.4, let us recall that for a closed linear operator A in a Hilbert space H, a nonzero $x \in H$ is called a generalized eigenvector of A, corresponding to an eigenvalue λ of A which has finite algebraic multiplicity, if there is a positive integer n such that $(\lambda - \mathrm{A})^n x = 0$. A sequence $\{x_n\}_1^\infty$ in H is called a

Riesz basis for H if there is an orthonormal basis $\{e_n\}_1^\infty$ in H and a linear bounded invertible operator T such that

$$\mathrm{T}e_n = x_n, n = 1, 2, \ldots.$$

It is seen that each Riesz basis sequence must be approximately normalized:

$$C_1 \le \|x_n\| \le C_2, C_1, C_2 > 0, n = 1, 2, \ldots.$$

Suppose that $\{\lambda_n\}_1^\infty \subset \sigma(\mathrm{A})$ and lie in some left half complex plane. If each λ_n has finite algebraic multiplicity m_n and $m_n = 1$ as $n > N$ for some integer $N > 1$, then there is a sequence of linearly independent generalized eigenvectors $\{x_{n_i}\}_{i=1}^{m_n}$ corresponding to λ_n. If $\{\{x_{n_i}\}_{i=1}^{m_n}\}_{n=1}^\infty$ forms a Riesz basis for H, then A generates a C_0-semigroup $e^{\mathrm{A}t}$ which can be represented as

$$e^{\mathrm{A}t}x = \sum_{n=1}^{\infty} e^{\lambda_n t} \sum_{i=1}^{m_n} a_{ni} \sum_{j=1}^{m_n} f_{nj}(t)x_{n_j} \text{ for any } x = \sum_{n=1}^{\infty}\sum_{i=1}^{m_n} a_{ni}x_{n_i} \in H,$$

where $f_{nj}(t)$ is a polynomial of t with order less than m_n. In particular, if $a < \mathrm{Re}\lambda < b$ for some real numbers a and b, then A generates a C_0-group on H. Moreover, the spectrum-determined growth condition holds for $e^{\mathrm{A}t}$.

In order to remove the requirement of the estimation of the low eigenpairs of the system, a corollary of Bari's theorem is recently reported in [1] (a simplified proof can be found in [2]), which provides a much less demanding approach in generating a Riesz basis for general discrete operators in the Hilbert spaces. The result is cited here.

THEOREM 3.3. *Let* A *be a densely defined discrete operator (that is,* $(\lambda - \mathrm{A})^{-1}$ *is compact for some* λ*) in a Hilbert space* H*. Let* $\{z_n\}_1^\infty$ *be a Riesz basis for* H*. If there are an* $N \ge 0$ *and a sequence of generalized eigenvectors* $\{x_n\}_{N+1}^\infty$ *of* A *such that*

$$\sum_{N+1}^{\infty} \|x_n - z_n\|^2 < \infty,$$

then

(i) *There are an* $M > N$ *and generalized eigenvectors* $\{x_{n0}\}_1^M$ *of* A *such that* $\{x_{n0}\}_1^M \cup \{x_n\}_{M+1}^\infty$ *forms a Riesz basis for* H*.*

(ii) *Consequently, let* $\{x_{n0}\}_1^M \cup \{x_n\}_{M+1}^\infty$ *correspond to eigenvalues* $\{\sigma_n\}_1^\infty$ *of* A*. Then* $\sigma(\mathrm{A}) = \{\sigma_n\}_1^\infty$*, where* σ_n *is counted according to its algebraic multiplicity.*

(iii) *If there is an* $M_0 > 0$ *such that* $\sigma_n \ne \sigma_m$ *for all* $m, n > M_0$*, then there is an* $N_0 > M_0$ *such that all* $\sigma_n, n > N_0$ *are algebraically simple.*

Remark 3. It follows from Theorem 3.3 that when A and B satisfy the conditions (i) and (ii) of Theorem 2.7, $A + B$ is of $[D]$-class.

In order to apply Theorem 3.3 to the operator $\mathcal{A}$ when we consider $\{x_n\}$ in Theorem 3.3 as the eigenfunctions of $\mathcal{A}$, we need a referring Riesz basis $\{z_n\}_1^\infty$ as well. For the system (2), this is accomplished by collecting (approximately) normalized eigenfunctions of the following free conservative system:

$$\begin{cases} \rho(x)y_{tt}(x,t) + (EI(x)y_{xx}(x,t))_{xx} = 0, & 0 < x < 1, t > 0, \\ y(0,t) = y_x(0,t) = y_{xx}(1,t) = (EIy_{xx})_x(1,t) = 0. \end{cases} \tag{51}$$

The system operator $\mathcal{A}_0 : D(\mathcal{A}_0)(\subset \mathrm{H}) \to \mathrm{H}$ associated with (51) is nothing but the operator $\mathcal{A}$ with $k = 0$:

$$\begin{cases} \mathcal{A}_0(f,g) = (g, -\frac{1}{\rho(x)}(EI(x)f''(x))''), \\ D(\mathcal{A}_0) = \{(f,g) \in (H_E^2 \cap H^4) \times H_E^2 | f''(0) = f'''(1) = 0\}. \end{cases} \tag{52}$$

$\mathcal{A}_0$ is skew-adjoint with compact resolvent in H. Since Propositions 2.2 and 2.3 still keep valid when $k = 0$, we have the following counterpart for the operator $\mathcal{A}_0$.

LEMMA 3.4. *Each $\mu \in \sigma(\mathcal{A}_0)$, with sufficiently large modulus, is geometrically simple and hence algebraically simple. The eigenvalues $\{\lambda_{n0}, \overline{\lambda_{n0}}\}$ and the corresponding eigenfunctions $\{(\lambda_{n0}^{-1}\phi_{n0}, \phi_{n0})\} \cup \{$their conjugates$\}$ of $\mathcal{A}_0$ have the following asymptotic expressions:*

$$\lambda_{n0} = \frac{\rho_n^2}{h^2}, h = \int_0^1 \left(\frac{\rho(\tau)}{EI(\tau)}\right)^{1/4} d\tau, \rho_n = \frac{1}{\sqrt{2}}\left(n + \frac{1}{2}\right)\pi(1+i) + \mathcal{O}(n^{-1}) \text{ as } n \to \infty, \tag{53}$$

where n is a large positive integer, and

$$\begin{cases} -\frac{\sqrt{2}}{4}(1+i)e^{\frac{1}{4}\int_0^z a(\tau)d\tau}\phi_{n0}(x) = \sin(n+\pi/2)z - \cos(n+\pi/2)z \\ +e^{-(n+1/2)\pi z} + (-1)^n e^{-(n+1/2)\pi(1-z)} + \mathcal{O}(n^{-1}), \\ -\frac{\sqrt{2}}{4}(1+i)e^{\frac{1}{4}\int_0^z a(\tau)d\tau}\lambda_{n0}^{-1}\phi_{n0}''(x) = i\left(\frac{\rho(x)}{EI(x)}\right)^{1/2}[\cos(n+\pi/2)z - \sin(n+\pi/2)z \\ +e^{-(n+1/2)\pi z} + (-1)^n e^{-(n+1/2)\pi(1-z)}] + \mathcal{O}(n^{-1}). \end{cases} \tag{54}$$

Proof of Theorem 2.4. Since $\mathcal{A}_0$ is a skew-adjoint discrete operator in H, from a well-known result in functional analysis, the set of all ω-linearly independent eigenfunctions of $\mathcal{A}_0$ forms an orthogonal basis for H. Since $(\phi_{n0}, \lambda_{n0}\phi_{n0})$ defined by (54) are approximately normalized, $\{(\phi_{n0}, \lambda_{n0}\phi_{n0})\} \cup \{$their conjugates$\}$ form a (orthogonal) Riesz basis for H. Combining (9), (10), (53), and (54), we see that there is an $N > 0$ such that

$$\sum_{n>N}^{\infty} \|(\lambda_n^{-1}\phi_n, \phi_n) - (\lambda_{n0}^{-1}\phi_{n0}, \phi_{n0})\|_{\mathrm{H}}^2 = \sum_{n>N}^{\infty} \mathcal{O}(n^{-2}) < \infty. \tag{55}$$

The same is true for their conjugates. Hence the conditions of Theorem 2.5 are satisfied with correspondence $\mathcal{A} = A, x_n = (\lambda_n^{-1}\phi_n, \phi_n), z_n = (\lambda_{n0}^{-1}\phi_{n0}, \phi_{n0})$. The proof is complete. □

Now we are in a position to show the exponential stability confirmed by Theorem 2.7. Since the spectrum-determined growth condition holds, which is claimed by Theorem 2.4, system (2) is exponentially stable if and only if there is an $\omega > 0$ such that

$$\mathrm{Re}\lambda < -\omega \quad \forall\ \lambda \in \sigma(\mathcal{A}).$$

LEMMA 3.5. *Let λ_n be defined by* (8). *Then there is an $\omega_0 > 0$ such that*

$$\lim_{n\to\infty} \mathrm{Re}\lambda_n = -\omega_0 < 0. \tag{56}$$

Proof. Let $(\lambda, \phi) = (\lambda_n, \phi_n)$ in (7), where ϕ_n is defined by (9). Multiplying $\overline{\phi_n}$ on both sides of the first equation in (7) and integrating from 0 to 1 with respect to x, we obtain

$$\lambda_n^2 \int_0^1 \rho(x)|\phi_n(x)|^2 dx + \int_0^1 EI(x)|\phi_n''(x)|^2 dx + k\lambda_n|\phi_n(1)|^2 = 0.$$

Since $\mathrm{Im}\lambda_n \neq 0$ for sufficiently large n, we have, from the above equation, that

$$2\mathrm{Re}\lambda_n \int_0^1 \rho(x)|\phi_n(x)|^2 dx = -k|\phi_n(1)|^2 \text{ as } n \to \infty.$$

Then by (9) and the Riemann–Lebesgue lemma, we have

$$\lim_{n\to\infty} |\phi_n(1)|^2 = 16e^{-\frac{1}{2}\int_0^1 a(\tau)d\tau}, \lim_{n\to\infty} \int_0^1 \rho(x)|\phi_n(x)|^2 dx = 4\int_0^1 \rho(x)e^{-\frac{1}{2}\int_0^z a(\tau)d\tau} dx,$$

where $z = z(x)$ is specified by (29). Hence

$$\lim_{n\to\infty} \mathrm{Re}\lambda_n = -2k \frac{e^{-\frac{1}{2}\int_0^1 a(\tau)d\tau}}{\int_0^1 \rho(x)e^{-\frac{1}{2}\int_0^z a(\tau)d\tau} dx} < 0.$$

The result follows. □

Proof of Theorem 2.5. By Lemma 3.5 and the spectrum-determined growth condition, we need only show that

$$\mathrm{Re}\lambda < 0 \text{ for any } \lambda \in \sigma(\mathcal{A}). \tag{57}$$

Since the system is dissipative, $\mathrm{Re}\lambda \leq 0$ for any $\lambda \in \sigma(\mathcal{A})$. Suppose that $\mathrm{Re}\lambda = 0$. Then from $\mathrm{Re}\langle \mathcal{A}Y, Y\rangle = -k|\phi(1)|^2$ for each $Y = (\phi, \lambda\phi)$, we have $\phi(1) = 0$. In this case, (7) becomes

$$\begin{cases} \lambda^2\rho(x)\phi(x) + (EI(x)\phi''(x))'' = 0, & 0 < x < 1, \\ \phi(0) = \phi'(0) = \phi''(1) = \phi'''(1) = \phi(1) = 0. \end{cases} \tag{58}$$

The proof is complete if we can show that there is only zero solution to (58). To this end, we follow the idea used in [17].

First, we claim that there is at least one zero of ϕ in (0,1). In fact, by $\phi(0) = \phi(1) = 0$, it follows from Rolle's theorem that there is a $\xi_1 \in (0,1)$ such that $\phi'(\xi_1) = 0$, which, together with $\phi'(0) = 0$, claims that $(EI\phi'')(\xi_2) = 0$ for some $\xi_2 \in (0, \xi_1)$, and so $(EI\phi'')'(\xi_3) = 0$ for some $\xi_3 \in (\xi_2, 1)$ by the condition $(EI\phi'')(1) = 0$. Hence there is a $\xi_4 \in (\xi_3, 1)$ such that $(EI\phi'')''(\xi_4) = 0$ by the condition $(EI\phi'')'(1) = 0$. However, $(EI\phi'')''(\xi_4) = -\lambda^2\rho(\xi)\phi(\xi_4)$; we conclude that $\phi(\xi_4) = 0$.

Next, we show that if there are n different zeros of ϕ in (0,1), then there are at least $n+1$ number of different zeros of ϕ in (0,1).

Indeed, suppose that

$$0 < \xi_1 < \xi_2 < \cdots < \xi_n < 1, \phi(\xi_i) = 0, i = 1, 2, \ldots, n.$$

Since $\phi(0) = \phi(1) = 0$, it follows from Rolle's theorem that there are $\eta_i, i = 1, 2, \ldots, n+1$,

$$0 < \eta_1 < \xi_1 < \eta_2 < \xi_2 < \cdots < \xi_n < \eta_{n+1} < 1$$

such that $\phi'(\eta_i) = 0$. Noting that $\phi'(0) = 0$, there are $\alpha_i, i = 1, 2, \ldots, n+1$,

$$0 < \alpha_1 < \eta_1 < \alpha_2 < \eta_2 < \cdots < \alpha_{n+1} < \eta_{n+1} < 1$$

such that $(EI\phi'')(\alpha_i) = 0$. Since $(EI\phi'')(1) = 0$, using Rolle's theorem again, we have $\beta_i, i = 1, 2, \ldots, n+1$,

$$0 < \alpha_1 < \beta_1 < \alpha_2 < \cdots < \alpha_{n+1} < \beta_{n+1} < 1$$

such that $(EI\phi'')'(\beta_i) = 0$. Finally, by the condition $(EI\phi'')'(1) = 0$, we have $\vartheta_i, i = 1, 2, \ldots, n+1$,

$$0 < \beta_1 < \vartheta_1 < \beta_2 < \cdots < \beta_{n+1} < \vartheta_{n+1} < 1$$

such that $(EI\phi'')''(\vartheta_i) = 0$. Therefore,

$$\phi(\vartheta_i) = 0, i = 1, 2, \ldots, n+1.$$

Third, by mathematical induction, there is an infinite number of different zeros $\{x_i\}_1^\infty$ of ϕ in (0,1). Let $x_0 \in [0, 1]$ be an accumulation point of $\{x_i\}_1^\infty$. It is obvious that

$$\phi^{(i)}(x_0) = 0, \qquad i = 0, 1, 2, 3.$$

Note that ϕ satisfies the linear differential equation $(EI(x)\phi''(x))'' + \lambda^2\rho(x)\phi(x) = 0$. Therefore, $\phi \equiv 0$ by the uniqueness of the solution of linear ordinary different equations. □

Remark 4. The proof of Theorem 2.5 shows that each eigenvalue of $\mathcal{A}$ must be geometrically simple. In fact, suppose that $(\phi_1, \lambda\phi_1), (\phi_2, \lambda\phi_2)$ are any two eigenfunctions of $\mathcal{A}$ corresponding to λ. Then one can choose constants c_1, c_2 not identical to zero simultaneously such that $\phi = c_1\phi_1 + c_2\phi_2$ satisfies $\phi(1) = 0$. Now ϕ satisfies (58), and so $\phi \equiv 0$. Hence ϕ_1 and ϕ_2 are linearly independent.

From previous discussions, we see that our method can be easily used to get the Riesz basis property for the following beam equation under boundary moment feedback control:

$$\begin{cases} \rho(x)y_{tt}(x,t) + (EI(x)y_{xx}(x,t))_{xx} = 0, & 0 < x < 1, t > 0, \\ y(0,t) = y_x(0,t) = y_{xxx}(1,t) = 0, \\ y_{xx}(1,t) = -ky_{xt}(1,t), & k > 0. \end{cases} \tag{59}$$

It should be noted that the referring Riesz basis applied with Theorem 3.3 is accomplished by collecting all eigenfunctions of the following conservative free system:

$$\begin{cases} \rho(x)y_{tt}(x,t) + (EI(x)y_{xx}(x,t))_{xx} = 0, & 0 < x < 1, t > 0, \\ y(0,t) = y_x(0,t) = y_{xxx}(1,t) = y_{xt}(1,t) = 0. \end{cases} \tag{60}$$

This is the same as that of the uniform case [1]. Moreover, the analysis in this paper shows that the low order perturbations do not affect the basis property. For example, if we assume $b(x) \in C^3[0, 1]$, then Theorem 2.7 is still valid for the following system:

$$\begin{cases} \rho(x)y_{tt}(x,t) + b(x)y_{xxx}(x,t) + (EI(x)y_{xx}(x,t))_{xx} = 0, & 0 < x < 1, t > 0, \\ y(0,t) = y_x(0,t) = y_{xx}(1,t) = 0, (EI(x)y_{xx})_x(1,t) = ky_t(1,t). \end{cases} \tag{61}$$

Let us turn to system (12). First, we give a short proof of Theorem 2.7 by virtue of Theorem 3.3.

Proof of Theorem 2.7. Obviously, $A+B$ is a discrete operator in H. Write $A+B=A_s+T$, where $A_s\phi_n=\lambda_n\phi_n$ for all $n\geq 1$ and T is a linear bounded operator on H. We may assume without loss of generality that $\|\phi_n\|=1$ for all $n\geq 1$. Since $\{\phi_n\}_1^\infty$ is a Riesz basis, there is a $K>0$ such that for any $\phi=\sum_{n=1}^\infty a_n\phi_n$ and any complex series $\{\beta_n\}, |\beta_n|\leq 1$,

$$\left\|\sum_{n=1}^{\infty}\beta_n a_n\phi_n\right\|\leq K\|\phi\|. \tag{62}$$

By (15), we have $d_n\to\infty$ as $n\to\infty$. Hence for any $C>K\|T\|$, there is an integer $M>N$ such that $2\|T\|K/d_n<1$ for all $n\geq M$ and

$$|\lambda-\lambda_m|\geq C \text{ for any } \lambda \text{ satisfying } |\lambda-\lambda_n|=C, n\geq M.$$

First, for any $\phi=\sum_{n=1}^\infty a_n\phi_n$ and λ satisfying $|\lambda-\lambda_n|=C, n\geq M$,

$$\|CR(\lambda,A_s)\phi\|=\left\|\sum_{n=1}^{\infty}\frac{C}{\lambda-\lambda_n}a_n\phi_n\right\|\leq K\|\phi\|,$$

and so $\|R(\lambda,A_s)\|\leq K/C$. Hence $\|R(\lambda,A_s)T\|\leq K\|T\|/C<1$. This shows that $\{\lambda||\lambda-\lambda_n|=C, n\geq M\}\subset\rho(A_s+T)$ since $\lambda\in\sigma(A_s+T)$ if and only if $1\in\rho(R(\lambda,A_s)T)$. Let $\Gamma_n=\{\lambda||\lambda-\lambda_n|=C\}, n\geq$M. Consider eigenprojectors

$$\begin{aligned}Q_n-P_n&=\frac{1}{2\pi i}\int_{\Gamma_n}R(\lambda,A_s+T)d\lambda-\frac{1}{2\pi i}\int_{\Gamma_n}R(\lambda,A_s)d\lambda\\&=\frac{1}{2\pi i}\sum_{m=1}^{\infty}\int_{\Gamma_n}[R(\lambda,A_s)T]^mR(\lambda,A_s)d\lambda.\end{aligned}$$

One can choose $C>0$ large enough such that

$$\|Q_n-P_n\|\leq C\sum_{m=1}^{\infty}(K\|T\|/C)^mK/C=K\frac{K\|T\|/C}{1-K\|T\|/C}<1. \tag{63}$$

Therefore, $\dim(Q_n)=\dim(P_n)$. Hence there exists a unique $\mu_n, |\mu_n-\lambda_n|<C$ such that $\mu_n\in\sigma(A_s+T)=\sigma(A+B)$. This is (i). Moreover, since $\|P_n\phi_n\|=\|\phi_n\|=1$, we see that $Q_n\phi_n\neq 0$ and

$$Q_n\phi_n=\phi_n+\frac{1}{2\pi i}\sum_{m=1}^{\infty}\int_{\Gamma_n}[R(\lambda,A_s)T]^mR(\lambda,A_s)d\lambda d\lambda\phi_n. \tag{64}$$

Next, take $\Lambda_n=\{\lambda||\lambda-\lambda_n|=d_n/2\}, n\geq M$. Then for any $\phi=\sum_{n=1}^\infty a_n\phi_n$ and $\lambda\in\Lambda_n, \|d_n/2R(\lambda,A_s)\phi\|=\|\sum_{m=1}^\infty\frac{d_n}{2}\frac{1}{\lambda-\lambda_m}a_m\phi_m\|\leq K\|\phi\|$, and thus $\|R(\lambda,A_s)\|\leq\frac{2}{d_n}K$. Since $\|R(\lambda,A_s)T\|\leq\frac{2}{d_n}\|T\|K<1$, we see that $\{\Lambda_n, n\geq M\}\subset\rho(A_s+T)=\rho(A+B)$. Now consider

$$\begin{aligned}\tilde{Q}_n-P_n&=\frac{1}{2\pi i}\int_{\Lambda_n}R(\lambda,A_s+T)d\lambda-\frac{1}{2\pi i}\int_{\Lambda_n}R(\lambda,A_s)d\lambda\\&=\frac{1}{2\pi i}\sum_{m=1}^{\infty}\int_{\Lambda_n}[R(\lambda,A_s)T]^mR(\lambda,A_s)d\lambda.\end{aligned}$$

We have

$$\|\tilde{Q}_n - P_n\| \le \frac{\frac{2}{d_n}\|T\|K}{1-\frac{2}{d_n}\|T\|K}\|T\|K \le \frac{L}{d_n}, \qquad n \ge M,$$

for some constant $L > 0$. We may consider

$$\|\tilde{Q}_n - P_n\| \le \frac{L}{d_n} < 1, \qquad n \ge M. \tag{65}$$

Hence $\dim(\tilde{Q}_n) = \dim(P_n) = 1$, and $Q_n = \tilde{Q}_n$ as $n \ge M$. Therefore, $\psi_n = Q_n\phi_n$ satisfies

$$\|\psi_n - \phi_n\|^2 \le L^2 d_n^{-2} \text{ as } n \ge M, \tag{66}$$

proving the theorem. □

Note that the eigenproblem of (12) is to find the nonzero solution ψ such that

$$\begin{cases} \mu^2\rho(x)\psi(x) + \mu b(x)\psi(x) + (EI(x)\psi''(x))'' = 0, & 0 < x < 1, \\ \psi(0) = \psi'(0) = \psi''(1) = 0, \\ (EI(x)\psi'')'(1) = \mu k\psi(1), \end{cases} \tag{67}$$

and the eigenfunction of $\mathcal{A} + \mathcal{B}$ is of the form $(\psi, \mu\psi)$.

Proof of Corollary 2.9. Let $(\mu, \psi) = (\mu_n, \psi_n)$ in (67), where ψ_n is determined by (17). Multiplying $\overline{\psi_n}$ on both sides of the first equation in (67) and integrating from 0 to 1 with respect to x, we obtain

$$\mu_n^2 \int_0^1 \rho(x)|\psi_n(x)|^2dx + \mu_n \int_0^1 b(x)|\psi_n(x)|^2dx + \int_0^1 EI(x)|\psi_n''(x)|^2dx + k\lambda_n|\psi_n(1)|^2 = 0.$$

Since Im $\mu_n \ne 0$ for sufficiently large n, we have, from the above equation, the following:

$$\mathrm{Re}\mu_n = -\frac{1}{2}\frac{\int_0^1 b(x)|\psi_n(x)|^2dx + k|\psi_n(1)|^2}{\int_0^1 \rho(x)|\psi_n(x)|^2dx} \text{ as } n \to \infty. \tag{68}$$

It follows from (17) and (18) that $\|\psi_n - \phi_n\|_{L^2(0,1)} \to 0, \|\psi_n' - \phi_n'\|_{L^2(0,1)} \to 0$ as $n \to \infty$. By the trace theorem $|\psi_n(1) - \phi_n(1)| \to 0$. Therefore,

$$\mathrm{Re}\mu_n \to -\frac{1}{2}\frac{\int_0^1 b(x)|\phi_n(x)|^2dx + k|\phi_n(1)|^2}{\int_0^1 \rho(x)|\phi_n(x)|^2dx} \text{ as } n \to \infty. \tag{69}$$

Similar to the proof of Lemma 3.5, we obtain (19). □

Proof of Example 3. It follows from the proof of Corollary 2.9 that for any eigenfunction $(\psi, \mu\psi)$ of $\mathcal{A} + \mathcal{B}$

$$\mu^2 \int_0^1 |\psi(x)|^2dx + \mu \int_0^1 b(x)|\psi(x)|^2dx + \int_0^1 |\psi''(x)|^2dx = 0.$$

If Im $\mu = 0$, then from the above equation

$$(\mathrm{Re}\mu)^2 \int_0^1 |\psi(x)|^2dx + \mathrm{Re}\mu \int_0^1 b(x)|\psi(x)|^2dx + \int_0^1 |\psi''(x)|^2dx = 0.$$

Hence $\mathrm{Re}\mu < 0$. If $\mathrm{Im}\ \mu \neq 0$,

$$\mathrm{Re}\mu = -\frac{1}{2}\frac{\int_0^1 b(x)|\psi(x)|^2dx}{\int_0^1 |\psi(x)|^2dx} \leq -\frac{1}{2}\frac{b_0\int_a^b |\psi(x)|^2dx}{\int_0^1 |\psi(x)|^2dx} < 0.$$

Therefore, for any $\mu \in \sigma(\mathcal{A}+\mathcal{B})$, $\mathrm{Re}\mu < 0$. This, together with (20), gives the exponential stability of system (22), which is indicated in [18]. By similar reasoning, when $k = 0, b(x) \geq 0$ for $x \in [0,1]$ and $b(x) > b_0 > 0$ for all x in some subset $(a,b) \subset [0,1]$, system (12) is also exponential stable. □

Finally, we give the proof of Proposition 2.10. The validity of Proposition 2.10 deduces Lemma 3.5 automatically.

Proof of Proposition 2.10. Like the transformation from (7) to (32), (67) can be transformed into

$$\begin{cases} g^{(4)}(z) + a_1(z)g''(z) + a_2(z)g'(z) + a_3(z)g(z) + \lambda h^4\tilde{b}(z)g(z) + \lambda^2 h^4 g(z) = 0, \\ g(0) = g'(0) = 0, \\ g''(1) = a_{11}g'(1) + a_{12}g(1), \\ g'''(1) = a_{21}g'(1) + \left[\lambda\dfrac{kh^3}{EI(1)}\left(\dfrac{\rho(1)}{EI(1)}\right)^{-3/4} + a_{22}\right]g(1), \end{cases} \tag{70}$$

where the functions are the same as those in (32). By Theorem 2.8 and Corollary 2.9, all eigenvalues of $\mathcal{A}+\mathcal{B}$ with sufficiently large modulus must be located on the left complex plane under the assumption (23). Following [4], by noticing the smooth assumption (3) and (23), we know that for $\lambda = \rho^2/h^2$, $|\rho|$ sufficiently large,

$$g^{(4)}(z) + a_1(z)g''(z) + a_2(z)g'(z) + a_3(z)g(z) + \lambda h^4\tilde{b}(z) + \lambda^2 h^4 g(z) = 0$$

admits four linearly independent solutions $g_k, k = 1,2,3,4$ for any $\rho \in S$, which satisfy

$$\begin{cases} g_k(z) = e^{\rho\omega_k z}[1 + \frac{L_k(z)}{\rho} + \mathcal{O}(\frac{1}{\rho^2})], \\ g_k'(z) = \rho\omega_k e^{\rho\omega_k z}[1 + \frac{L_k(z)}{\rho} + \mathcal{O}(\frac{1}{\rho^2})], \\ g_k''(z) = (\rho\omega_k)^2 e^{\rho\omega_k z}[1 + \frac{L_k(z)}{\rho} + \mathcal{O}(\frac{1}{\rho^2})], \\ g_k'''(z) = (\rho\omega_k)^3 e^{\rho\omega_k z}[1 + \frac{L_k(z)}{\rho} + \mathcal{O}(\frac{1}{\rho^2})], \qquad k = 1,2,3,4, \end{cases} \tag{71}$$

where

$$L_k(z) = -\frac{1}{4\omega_k}\int_0^z a_1(\tau)d\tau + \frac{h^2}{4}\omega_k\int_0^z \tilde{b}(\tau)d\tau. \tag{72}$$

Similar to (37)–(40), by noting (71), we can write the characteristic equation (42) as

$$\det\begin{pmatrix} 1 & 1 & e^{\rho\omega_2} & 0 \\ \omega_1 & \omega_2 & -\omega_2 e^{\rho\omega_2} & 0 \\ 0 & \omega_2^2 e^{\rho\omega_2}\left[1+\dfrac{\ell_2}{\rho}\right] & \omega_2^2\left[1+\dfrac{\ell_3}{\rho}\right] & \omega_1^2\left[1+\dfrac{\ell_4}{\rho}\right] \\ 0 & \omega_2^3 e^{\rho\omega_2}\left[1+\dfrac{\ell_2}{\rho}\right] - \dfrac{\tilde{k}}{\rho}e^{\rho\omega_2} & -\omega_2^3\left[1+\dfrac{\ell_3}{\rho}\right] - \dfrac{\tilde{k}}{\rho} & -\omega_1^3\left[1+\dfrac{\ell_4}{\rho}\right] - \dfrac{\tilde{k}}{\rho} \end{pmatrix} = \mathcal{O}\left(\frac{1}{\rho^2}\right), \tag{73}$$

where $\ell_k = L_k(1)$. A direct computation yields

$$e^{2\rho\omega_2} = -1 + 2\frac{\tilde{k}}{\rho}\omega_2 + \frac{2\ell_2}{\rho} + \mathcal{O}\left(\frac{1}{\rho^2}\right). \tag{74}$$

Substituting $\rho = -(n+1/2)\pi\omega_2 + \mathcal{O}(n^{-1})$ into (74), the term $\mathcal{O}(n^{-1})$ satisfies

$$-2\omega_2\mathcal{O}(n^{-1}) = \frac{2\tilde{k}}{(n+1/2)\pi} - \frac{2\ell_2}{(n+1/2)\pi\omega_2} + \mathcal{O}(n^{-2});$$

hence

$$\mathcal{O}(n^{-1}) = \frac{\tilde{k}}{(n+1/2)\pi\omega_2} - \frac{2\ell_2}{(n+1/2)\pi\omega_2}\frac{1}{2\omega_2} + \mathcal{O}(n^{-2}).$$

Therefore,

$$\rho = -(n+1/2)\pi\omega_2 + \frac{2\tilde{k}}{2(n+1/2)\pi\omega_2} + \frac{2\ell_2}{(n+1/2)\pi\omega_2}\frac{1}{2\omega_2} + \mathcal{O}(n^{-2}),$$

which produces

$$\lambda h^2 = \rho^2 = -2\tilde{k} + i[(n+1/2)\pi]^2 - \frac{2\ell_2}{\omega_2} + \mathcal{O}(n^{-1}).$$

The required result then follows. □

It is seen that Proposition 2.10 coincides with the estimates in [1] for the uniform system (1) with $k_1 = 0, b = 0$.

Thus, from (24), condition (23) can be replaced by

$$\int_0^1 \tilde{b}(z)dz = \frac{1}{h}\int_0^1 \frac{b(x)}{\rho(x)}\left(\frac{\rho(x)}{EI(x)}\right)^{1/4} dx > 0. \tag{75}$$

For the case of $EI = \rho = 1$, the result can be found in [6].

ANALYSIS OF THE HAMILTON–JACOBI EQUATION IN NONLINEAR CONTROL THEORY BY SYMPLECTIC GEOMETRY*

NOBORU SAKAMOTO†

Abstract. In this paper, the geometric property and structure of the Hamilton–Jacobi equation arising from nonlinear control theory are investigated using symplectic geometry. The generating function of symplectic transforms plays an important role in revealing the structure of the Hamilton–Jacobi equation. It is seen that many fundamental properties of the Riccati equation can be generalized in the Hamilton–Jacobi equation, and, therefore, the theory of the Hamilton–Jacobi equation naturally contains that of the Riccati equation.

Key words. Hamilton–Jacobi equation, nonlinear control theory, symplectic geometry

1. Introduction.

The Hamilton–Jacobi equation plays a fundamental role in nonlinear control theory. The solvability of many important problems, such as optimal regulation [15], the H^∞ control problem [3, 11, 12, 21, 22], dissipative system theory [10, 26], and factorization theory [4] is represented by that of the Hamilton–Jacobi equation, and feedback functions depend on the solution of the Hamilton–Jacobi equation. When the system under consideration is linear and time-invariant, the Hamilton–Jacobi equation reduces to the Riccati equation. The most successful theory in linear control theory is H^∞ robust control. It naturally extends to nonlinear control systems. However, there are very few applications of nonlinear H^∞ control that have been reported, while linear H^∞ theory is now commonly used by industrial engineers. One of the biggest reasons for this is that little is known about the solution method, structure, and property of the Hamilton–Jacobi equation.

Only a few research papers have reported on the study of exact solutions of the Hamilton–Jacobi equation. In [21, 22], it is proved that if the Riccati equation constructed from the linear approximation of the Hamilton–Jacobi equation can be solved, then there exists, locally, a solution of the Hamilton–Jacobi equation, and nonlinear L^2 gain is also discussed by the linearization argument. After [21, 22], attention in nonlinear H^∞ theory has been paid not to the Hamilton–Jacobi equation itself, which represents the essential difficulty of nonlinearity, but to the derivation of the Hamilton–Jacobi equation, which is rather similar to that of the Riccati equation in linear H^∞ theory. For approximation methods of the solution of the Hamilton–Jacobi equation, we refer to [15] for the method by Taylor series expansion, [6, 7] for the Galerkin approximation, and [18] for the method by the state-dependent Riccati equation. One may also find extensive surveys on the research of the approximation of the Hamilton–Jacobi equation in [6, 7]. For the use of the theory of viscosity solutions in nonlinear H^∞ control when the system is not necessarily in the control-affine form, we refer to [5, 24, 25].

In this paper, we investigate the geometric property and structure of the Hamilton–Jacobi equation by using symplectic geometry. Symplectic geometry also plays a cen-

tral role in [21, 22], but the linearization argument is not employed in the present paper. Without linear approximation, it will be shown that major properties of the Riccati equation can be generalized and similar structures can be found in the Hamilton–Jacobi equation. In other words, the theory of the Riccati equation can be naturally embedded in that of the Hamilton–Jacobi equation. There exists a precise geometric theory in the Riccati equation developed in the course of the research from linear quadratic regulator theory to modern H^∞ robust control theory. Symplectic geometry provides a geometric framework in which we can investigate the Hamilton–Jacobi equation almost as well as we can for the Riccati equation.

The organization of the paper is as follows. In section 2, the theory of partial differential equations of the first order [8, 19] is outlined in the context of the Hamilton–Jacobi equation. According to the theory, to solve the Hamilton–Jacobi equation, all one has to do is solve a system of ordinary differential equations and/or integrate a completely integrable Pfaffian system. In section 3, attention is paid to a special kind of solution, a stabilizing solution, which plays an important role in control theory. The well-known theory [2, 20] by Arimoto and Potter, that is, a necessary and sufficient condition of the existence of a stabilizing solution, is reviewed as a part of the theory of the Hamilton–Jacobi equation. In control theory, we are interested in obtaining as many solutions as possible. To do this, more information on the structure of the Hamilton–Jacobi equation will be necessary, which is indicated by Example 1 of section 4. In section 4.1, the theory of the generating function for symplectic transforms is introduced; this will play a central role in a later subsection. Given a solution to the Hamilton–Jacobi equation, an auxiliary equation is derived that determines the other solutions using the generating function of symplectic transforms. It will also be seen that the auxiliary equation even characterizes the whole structure of the Hamilton–Jacobi equation. The linear control theoretic explanation of this structure will also be provided.

2. Overview of the theory of partial differential equations of the first order. In this section, we outline, by using a symplectic geometry machinery, the essential parts of the theory of partial differential equations of the first order that will be necessary for the analysis of the Hamilton–Jacobi equation.

Let us consider a partial differential equation of the form

$$\text{(PD)} \qquad F(x_1, \dots, x_n, p_1, \dots, p_n) = 0,$$

where F is a C^∞ function of $2n$ variables, $x_1, \dots, x_n$ are independent variables, z is an unknown function, and $p_1 = \partial z/\partial x_1, \dots, p_n = \partial z/\partial x_n$. Let M be an n dimensional space for $(x_1, \dots, x_n)$. We regard the $2n$ dimensional space for $(x, p) = (x_1, \dots, x_n, p_1, \dots, p_n)$ as the cotangent bundle T^*M of M. T^*M is a symplectic manifold with $\theta = \sum_{i=1}^n dx_i \wedge dp_i$.

Let $\pi : T^*M \to M$ be a natural projection, and let $V \subset T^*M$ be a hypersurface defined by $F = 0$. Define a submanifold

$$\Lambda_Z = \{(x, p) \in T^*M \mid p_i = \partial z/\partial x_i(x), i = 1, \dots, n\}$$

for a smooth function $z(x)$. Then, $z(x)$ is a solution of (PD) if and only if $\Lambda_Z \subset V$. Furthermore, $\pi|_{\Lambda_Z} : \Lambda_Z \to M$ is a diffeomorphism, and Λ_Z is a Lagrangian submanifold because $\dim \Lambda_Z = n$ and

$$\theta|_{\Lambda_Z} = \sum_{1 \leqslant i < j \leqslant n} \left(\frac{\partial^2 z}{\partial x_j \partial x_i} - \frac{\partial^2 z}{\partial x_i \partial x_j} \right) dx_i \wedge dx_j = 0.$$

Conversely, it is well known (see, e.g., [1, 19]) that for a Lagrangian submanifold Λ passing through $q \in T^*M$ on which $\pi|_\Lambda : \Lambda \to M$ is a diffeomorphism, there exists a neighborhood U of q and a function $z(x)$ defined on $\pi(U)$ such that

$$\Lambda \cap U = \{(x,p) \in U \mid p_i = \partial z/\partial x_i(x), i = 1, \dots, n\}.$$

Therefore, finding a solution of (PD) is equivalent to finding a Lagrangian submanifold $\Lambda \subset V$ on which $\pi|_\Lambda : \Lambda \to M$ is a diffeomorphism.

Let $f_1 = F$. To construct such a Langrangian submanifold passing through $q \in T^*M$, and hence to obtain a solution defined on a neighborhood of $\pi(q)$, it suffices to find functions $f_2, \dots, f_n \in \mathsf{F}(T^*M)$ with $df_1(q) \wedge \cdots \wedge df_n(q) \neq 0$ such that $\{f_i, f_j\} = 0$ $(i, j = 1, \dots, n)$, where $\{\cdot, \cdot\}$ is the Poisson bracket, and

$$\left| \frac{\partial(f_1, \cdots, f_n)}{\partial(p_1, \cdots, p_n)} \right| (q) \neq 0. \tag{2.1}$$

For if functions $\varphi, \psi \in \mathsf{F}(T^*M)$ satisfy $\varphi|_\Lambda = \psi|_\Lambda = 0$ for $\Lambda = \{f_1 = \cdots = f_n = 0\}$, then there exist functions $a_i, b_j \in \mathsf{F}(T^*M)$ $(i, j = 1, \dots, n)$ such that $\varphi = \sum_{i=1}^n a_i f_i$ and $\psi = \sum_{j=1}^n b_j f_j$, and, therefore, we have $\{\varphi, \psi\}|_\Lambda = 0$ from

$$\{\varphi, \psi\} = \sum_{i,j=1}^n a_i f_j \{f_i, b_j\} + b_j f_i \{a_i, f_j\} + f_i f_j \{a_i, b_j\},$$

where we used the fact that an n dimensional submanifold Λ is Lagrangian if and only if $\{f, g\}|_\Lambda = 0$ for all $f, g \in \mathsf{F}(T^*M)$ satisfying $f|_\Lambda = g|_\Lambda = 0$. Note that the condition (2.1) implies, by the implicit function theorem, that $\pi|_\Lambda$ is a diffeomorphism of some neighborhood of q.

Since $\{F, \cdot\}$ is the Hamiltonian vector field X_F with Hamiltonian F, the functions $f_2, \dots, f_n$ above are integrals of X_F. The ordinary differential equation that gives the integral curve of X_F is

$$\begin{cases} \dfrac{dx_i}{dt} = \dfrac{\partial F}{\partial p_i}, \\ \dfrac{dp_i}{dt} = -\dfrac{\partial F}{\partial x_i} \end{cases} \qquad (i = 1, \dots, n). \tag{2.2}$$

An integral of X_F is a function that is constant along solutions of (2.2), and, therefore, we seek integrals of the following Pfaffian equations together with the condition (2.1):

$$\frac{dp_1}{-\partial F/\partial x_1} = \cdots = \frac{dp_n}{-\partial F/\partial x_n} = \frac{dx_1}{\partial F/\partial p_1} = \cdots = \frac{dx_n}{\partial F/\partial p_n},$$

which is called the Lagrange–Charpit system.

The theory for general partial differential equations is developed as contact geometry, and the complete treatment of them, that is, how the solvability of them can be reduced to the existence theory of solutions for ordinary differential equations, can be found in [19]. [14] also contains the geometric theory of first order partial differential equations.

3. Stabilizing solutions of the Hamilton–Jacobi equation. In what follows, we consider the Hamilton–Jacobi equation in nonlinear control theory

$$\text{(HJ)} \qquad H(x,p) = p^T f(x) - \frac{1}{2} p^T R(x) p + q(x) = 0,$$

where $f : M \to \mathbb{R}^n$, $R : M \to \mathbb{R}^{n\times n}$, $q : M \to \mathbb{R}$ are all C^∞ and $R(x)$ are symmetric for all $x \in M$. We also assume that f and q satisfy $f(0) = 0$, $q(0) = 0$, and $\frac{\partial q}{\partial x}(0) = 0$.

A stabilizing solution of (HJ) is defined as follows.

DEFINITION 3.1. *A solution $z(x)$ of* (HJ) *is said to be a stabilizing solution if $p(0) = 0$, and 0 is an asymptotically stable equilibrium of the vector field $f(x) - R(x)p(x)$, where $p(x) = (\partial z/\partial x)^T(x)$. A solution $z(x)$ is called an antistabilizing solution if $p(0) = 0$ and $-f(x) + R(x)p(x)$ has an asymptotically stable equilibrium at 0.*

For example, let us consider a classical nonlinear optimal regulator problem (see, e.g., [15]),

$$\dot{x} = f(x) + g(x)u, \quad x(0) = x_0,$$
$$J(x_0) = \int_0^\infty q(x(t)) + u(t)^T u(t)\, dt,$$

where $f(0) = 0$ and $q(x)$ is positive definite. The optimal feedback is

$$u = -\frac{1}{2} g(x)^T \left(\frac{\partial V}{\partial x}\right)^T (x),$$

where $V(x)$ is a stabilizing solution of the following Hamilton–Jacobi equation:

$$\frac{\partial V}{\partial x} f(x) - \frac{1}{4} \frac{\partial V}{\partial x} g(x) g(x)^T \left(\frac{\partial V}{\partial x}\right)^T + q(x) = 0, \quad V(0) = 0.$$

When the system is linear, the above equation reduces to a Riccati equation, which will be discussed in the next subsection. See also [4, 11, 12, 21, 22, 23] for details of the role of the stabilizing solution in nonlinear control theory.

Let V be the hypersurface in T^*M defined by (HJ). According to the theory of partial differential equations of the first order described in the previous section, a solution of (HJ) can be considered as a Lagrangian submanifold contained in V such that $\pi|_\Lambda$ is a diffeomorphism. However, (HJ) reduces to the Riccati equation when systems are linear time-invariant, and a precise theory is established for the Riccati equation. So the natural question would be how the theory of partial differential equations for (HJ) reduces to the theory of the Riccati equation. We clarify the relation between them in sections 3.1 and 3.2.

3.1. The Riccati equation. The algebraic Riccati equation

$$\text{(RIC)} \qquad PA + A^T P - PRP + Q = 0$$

plays a fundamental role in linear control theory such as linear quadratic regulator, H^∞ control, factorization theory, etc. In (RIC), A is a real square matrix of dimension n and R and Q are symmetric matrices of dimension n. A symmetric matrix P is said to be a stabilizing solution of (RIC) if it is a solution of (RIC) and $A - RP$ is stable.

The $2n \times 2n$ matrix

$$\mathrm{Ham} = \begin{pmatrix} A & -R \\ -Q & -A^T \end{pmatrix}$$

is called the Hamiltonian matrix of (RIC). A necessary and sufficient condition for the existence of a stabilizing solution [2, 20, 9, 13] is that (i) Ham has no eigenvalues on the imaginary axis, and (ii) the generalized eigenspace $\mathbb{E}_-$ for n stable eigenvalues satisfies the following complementary condition:

$$\mathbb{E}_- \oplus \mathrm{Im} \begin{pmatrix} 0 \\ I \end{pmatrix} = \mathbb{R}^{2n}.$$

The Hamilton–Jacobi equation corresponding to (RIC) is

$$(\mathrm{HJ})' \qquad H'(x,p) = p^T A x - \frac{1}{2} p^T R p + \frac{1}{2} x^T Q x = 0.$$

Let $V' := \{(x,p) \in T^*M \mid H'(x,p) = 0\}$. In this case, we look for a Lagrangian subspace, regarding T^*M as a linear space of $2n$ dimension, with the properties in section 2. A Lagrangian subspace is an n dimensional subspace of T^*M on which θ vanishes. Note that V' is a quadric surface in T^*M such as an ellipsoid or a hyperboloid.

By using the properties of Ham, if Ham has no eigenvalues on the imaginary axis, it is shown that there exist an $n \times n$ stable matrix E_1, an unstable matrix E_2, and $n \times n$ matrices T_1, T_2, T_3, and T_4 satisfying

$$\mathrm{Ham} \begin{pmatrix} T_1 & T_3 \\ T_2 & T_4 \end{pmatrix} = \begin{pmatrix} T_1 & T_3 \\ T_2 & T_4 \end{pmatrix} \begin{pmatrix} E_1 & 0 \\ 0 & E_2 \end{pmatrix}, \tag{3.1}$$

$$T^T J T = J, \tag{3.2}$$

where $J = \left(\begin{smallmatrix} 0 & I \\ -I & 0 \end{smallmatrix} \right)$. Thus it is seen that V' contains Lagrangian subspaces. If, in addition, $\mathbb{E}_-$ satisfies the complementary condition, there exists a Lagrangian subspace $\Lambda \subset V'$ such that $\pi|_\Lambda$ is an isomorphism. See [16, 23] for details.

3.2. Lagrangian submanifold for stabilizing solutions. The observation on Lagrangian subspace for (RIC) is naturally generalized for (HJ) using symplectic geometry (see also [12, 23]).

Equation (3.1) takes the form

$$X_H \circ g = Dg \cdot X_A \tag{3.3}$$

with an immersion g from a neighborhood of 0 in $\mathbb{R}^n$ into T^*M with $g(0) = (0,0)$ and a vector field X_A on $\mathbb{R}^n$. Write $g(u) = (g_1(u), g_2(u)) = (g_{11}(u), \ldots, g_{1n}(u), g_{21}(u), \ldots, g_{2n}(u))$. If $g_1 : \mathbb{R}^n \to M$ is a local diffeomorphism and X_A has an asymptotically stable equilibrium at the origin, the Lagrange submanifold described by g as its image yields a stabilizing solution.

Indeed, from (3.3), we have

$$F_t \circ g = g \circ \tilde{F}_t, \quad t \geqslant 0, \tag{3.4}$$

in a neighborhood of $0 \in \mathbb{R}^n$, where $F_t(x,p)$ and $\tilde{F}_t(u)$ are integral curves of X_H and X_A, respectively. Taking the derivative of (3.4) and using the fact that F_t is a symplectic transform yield

$$Dg(u)^T J\, Dg(u) = D\tilde{F}_t(u)^T Dg(\tilde{F}_t(u))^T J\, Dg(\tilde{F}_t(u))\, D\tilde{F}_t(u).$$

Thus, for a neighborhood U' of $0 \in \mathbb{R}^n$, it follows that

$$Dg(u)^T J\, Dg(u) = Dg_1(u)^T Dg_2(u) - Dg_2(u)^T Dg_1(u) = 0, \quad u \in U', \tag{3.5}$$

since X_A is asymptotically stable. Equation (3.5) corresponds to (3.2). Taking the derivative of (3.4) with respect to t and setting $t = 0$ and $x = g_1(u)$ give

$$X_H(x, g_2 \circ g_1^{-1}(x)) = \begin{pmatrix} I \\ Dg_2(u)Dg_1^{-1}(x) \end{pmatrix} \cdot Dg_1(u) X_A(u). \tag{3.6}$$

Define $p(x) = g_2 \circ g_1^{-1}(x)$ for $x \in U = g_1(U') \subset M$. Then, premultiplying (3.6) by $[Dp(x) \quad -I]$, we have

$$\begin{aligned} &Dp(x)f(x) - Dp(x)R(x)p(x) + \left(\frac{\partial f}{\partial x}\right)^T (x)p(x) \\ &\qquad - \frac{1}{2}\left(\frac{\partial R(x)p}{\partial x}\right)^T (x)p(x) + \left(\frac{\partial q}{\partial x}\right)^T (x) \\ &= \frac{\partial^T}{\partial x}\left\{p(x)^T f(x) - \frac{1}{2}p(x)^T R(x)p(x) + q(x)\right\} = 0, \end{aligned} \tag{3.7}$$

where $\frac{\partial R(x)p}{\partial x}$ denotes the Jacobian matrix of $R(x)p(x)$ for fixed $p(x)$. Therefore, we obtain (HJ) from $f(0) = 0$, $q(0) = 0$, $p(0) = g_2 \circ g_1^{-1}(0) = g_2(0) = 0$. The solution is obtained from

$$dz = g_{21} \circ g_1^{-1}(x)dx_1 + \cdots + g_{2n} \circ g_1^{-1}(x)dx_n,$$

the integrability of which follows from $Dp(x)^T = Dp(x)$. The solution is a stabilizing one since $f(x) - R(x)p(x) = ((g_1)_* X_A)(x)$, the push-forward (see, e.g., [1]) of X_A.

Comparing this to [9], one can see a parallel structure to the Riccati equation.

4. The structure of the Hamilton–Jacobi equation. Let us begin this section with the following example.

Example 1. Consider the equation

$$H' = -p_1 x_1 + p_2(x_1 + x_2) - \frac{1}{2}p_2^2 + \frac{1}{2}x_1^2 = 0. \tag{4.1}$$

This can be seen as a Riccati equation for

$$A = \begin{pmatrix} -1 & 0 \\ 1 & 1 \end{pmatrix}, \quad R = \begin{pmatrix} 0 & 0 \\ 0 & 1 \end{pmatrix}, \quad Q = \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}.$$

The corresponding Hamiltonian vector field is $X_{H'} = (-x_1, x_1 + x_2, p_1 - p_2 - x_1, -p_2)$, and the Lagrange–Charpit system is

$$\frac{dx_1}{-x_1} = \frac{dx_2}{x_1 + x_2 - p_2} = \frac{dp_1}{p_1 - p_2 - x_1} = \frac{dp_2}{-p_2}.$$

The integrals H' and p_2/x_1 are readily obtained. The integral p_2/x_1 satisfies (2.1), and with a nonzero constant c we get a solution

$$P = \begin{pmatrix} 1/2 + c - c^2/2 & c \\ c & 0 \end{pmatrix}.$$

However, this solution is not a stabilizing one because $A-RP$ is not stable. To find a stabilizing solution, we need to find another integral. It is a simple task to state but not an easy one to handle to find out that $(-2x_1+2p_1-p_2)dx_1+2x_1dp_1-x_1dp_2=0$, $(-2x_1+2p_1-p_2)dx_1+2x_1dp_1-x_1dp_2=d(2x_1p_1-x_1^2-x_1p_2)$, and, therefore, $2x_1p_1-x_1^2-x_1p_2$ is an integral of the Lagrange–Charpit system. From this integral (with zero constant) and (4.1), we get

$$P=\begin{pmatrix}1&1\\1&2\end{pmatrix},\quad \begin{pmatrix}1/2&0\\0&0\end{pmatrix}.$$

The former is a stabilizing solution.

This example illustrates the difficulty of finding all solutions even for the Riccati equation by means of the method in section 2. Some solutions are obtained rather easily, and some are not. It would be, then, a natural desire to want to find another solution by using information from the solution on hand. We try that by using the generating function of symplectic transforms.

4.1. The generating function of symplectic transforms. In this subsection, we give a brief introduction to the theory of the generating function of symplectic transforms.

Let $x'_1(x,\,p),\dots,x'_n(x,\,p)$ be n independent functions defined on a neighborhood of $(0,\,0)\in T^*M$ satisfying $\{x'_k,\,x'_{k'}\}=0$ for $1\leqslant k,\,k'\leqslant n$ and

$$\left|\frac{\partial(x'_1,\dots,x'_n)}{\partial(x_{j_1},\dots,x_{j_{n-l}},p_{i_1},\dots,p_{i_l})}\right|(0,\,0)\neq 0 \tag{4.2}$$

for subsets $I=\{i_1,\dots,i_l\}$ and $J=\{j_1,\dots,j_{n-l}\}$ of $\{1,\dots,n\}$ with $I\cap J=\phi$. By the implicit function theorem,

$$\begin{cases} p_i=h_i(x',\,x_I,\,p_J) & (i\in I),\\ x_j=h_j(x',\,x_I,\,p_J) & (j\in J)\end{cases}$$

where $x_I=(x_{i_1},\dots,x_{i_l})$ and $p_J=(p_{j_1},\dots,p_{j_{n-l}})$. Since $\Lambda=\{(x,\,p)\,|\,x'_1=\cdots=x'_n=0\}$ is a Lagrangian submanifold, it follows that

$$0=\sum_{k=1}^{n}dx_k\wedge dp_k\bigg|_\Lambda=\left(\sum_{i\in I}dx_i\wedge dh_i+\sum_{j\in J}dh_j\wedge dp_j\right)\bigg|_\Lambda,$$

which implies

$$\frac{\partial h_i}{\partial x_\mu}=\frac{\partial h_\mu}{\partial x_i},\quad \frac{\partial h_i}{\partial p_j}=-\frac{\partial h_j}{\partial x_i},\quad \frac{\partial h_j}{\partial p_\nu}=\frac{\partial h_\nu}{\partial p_j}\quad (i,\,\mu\in I;\,j,\,\nu\in J). \tag{4.3}$$

These guarantee the existence of a function $\Phi(x',\,x_I,\,p_J)$ that satisfies

$$\begin{cases}\dfrac{\partial\Phi}{\partial x_i}=h_i & (i\in I),\\[2ex] \dfrac{\partial\Phi}{\partial p_j}=-h_j & (j\in J)\end{cases}$$

(see [19] for a proof).

Now define a function

$$\Omega(x',\, x_I,\, p_J) = \Phi(x',\, x_I,\, p_J) + \psi(x') + \sum_{j\in J} x_j p_j,$$

with an arbitrary function $\psi(x')$. Then

$$\begin{aligned}\sum_{k=1}^{n} p_k dx_k - d\Omega &= \sum_{k=1}^{n} p_k dx_k - \sum_{i\in I} h_i dx_i + \sum_{j\in J} h_j dp_j \\ &\quad - \sum_{k=1}^{n} \frac{\partial(\Phi+\psi)}{\partial x'_k} dx'_k - d\left(\sum_{j\in J} x_j p_j\right) \\ &= -\sum_{k=1}^{n} \frac{\partial(\Phi+\psi)}{\partial x'_k} dx'_k\end{aligned}$$

shows that the transformation defined by

$$\begin{cases} x'_k = x'_k(x,\, p), \\ p'_k = -\dfrac{\partial(\Phi+\psi)}{\partial x'_k}(x'(x,\, p)) \end{cases} \qquad (1 \leqslant k \leqslant n)$$

is a symplectic transform because $\sum_{k=1}^{n} dp_k \wedge dx_k = \sum_{k=1}^{n} p'_k \wedge dx'_k$.

Conversely, if a transformation $x' = x'(x,\, p)$, $p' = p'(x,\, p)$ is symplectic, then $\{x'_k,\, x'_{k'}\} = 0$ for $1 \leqslant k,\, k' \leqslant n$. Also, it can be shown that there exist subsets $I = \{i_1, \ldots, i_l\}$ and $J = \{j_1, \ldots, j_{n-l}\}$ with $I \cap J = \phi$ such that (4.2) holds. Therefore, there exists a function $\Phi(x',\, x_I,\, p_J)$ such that

$$\left|\frac{\partial^2 \Phi}{\partial(x_I,\, p_J)\partial x'}\right| \neq 0, \quad \begin{cases} p_i = \dfrac{\partial \Phi}{\partial x_i}, \quad x_j = -\dfrac{\partial \Phi}{\partial p_j} & (i \in I;\, j \in J), \\ p'_k = -\dfrac{\partial \Phi}{\partial x'_k} & (k = 1, \ldots, n). \end{cases}$$

See [17, 19] for details of the generating function of symplectic transforms.

4.2. Realization of the entire structure of (HJ) using the generating function of symplectic transforms. Motivated by Example 1, we propose the method of obtaining other solutions from one solution. This is done by clarifying the whole structure of the Hamilton–Jacobi equation that determines the rest of the solutions. The role of the generating function of symplectic transforms is significant.

THEOREM 4.1. *Let $z(x)$ be a solution of* (HJ) *defined on a neighborhood of $0 \in M$ and $x'_k = p_k - p_k(x)$ for $1 \leqslant k \leqslant n$. Suppose there exists a solution $z''(x')$ around $x' = 0$ to the auxiliary equation*

$$x'^T f^*(p'') - \frac{1}{2} x'^T R(p'') x' = 0, \tag{4.4}$$

where $p''_k = \partial z''/\partial x'_k$ $(1 \leqslant k \leqslant n)$ and $f^*(x) = f(x) - R(x)p(x)$. Then, together with $x'_k(x,\, p)$ $(1 \leqslant k \leqslant n)$, the functions $p'_1(x,\, p), \ldots, p'_n(x,\, p)$ defined by

$$p'_k(x,\, p) = -x_k + p''_k(x'(x,\, p)) = -x_k + \frac{\partial z''}{\partial x'_k}(x'(x,\, p)), \quad 1 \leqslant k \leqslant n,$$

form a symplectic transform

$$\alpha : \begin{cases} x'_k = p_k - p_k(x), \\ p'_k = -x_k + \dfrac{\partial z''}{\partial x'_k}(x'(x,\, p)) \end{cases} \qquad (1 \leqslant k \leqslant n), \tag{4.5}$$

and the Hamiltonian vector field X_H leaves the submanifold $\Lambda_+ = \{(x,\, p) \,|\, p'_1 = \cdots = p'_n = 0\}$ invariant.

Proof. We note that (4.2) holds for $I = \{1, \ldots, n\}$. Define a function $\Phi(x',\, x) = \sum_{k=1}^n x'_k x_k + z(x)$. Then it satisfies

$$\frac{\partial \Phi}{\partial x_k} = x'_k + p_k(x), \quad 1 \leqslant k \leqslant n.$$

Therefore, from the theory of the generating function of symplectic transforms, (4.5) is a symplectic transform for an arbitrary function $z''(x')$. Next we determine z'' so that Λ_+ is invariant for X_H; in other words, $X_H \cdot p'_k|_{p'_1 = \cdots = p'_n = 0} = 0$ for $1 \leqslant k \leqslant n$. This is equivalent to

$$\{H,\, p'_k\}|_{p'_1 = \cdots = p'_n = 0} = 0 \quad (1 \leqslant k \leqslant n).$$

Rewrite $H(x,\, p)$ in $(x',\, p')$ coordinates as

$$\begin{aligned} H(x,\, p) &= (x' + p(x))^T f(x) - \frac{1}{2}(x' + p(x))^T R(x)(x' + p(x)) + q(x) \\ &= p(x)^T f(x) - \frac{1}{2} p(x)^T R(x) p(x) p(x) + q(x) \\ &\quad + x'^T f(x) - x'^T R(x) p(x) - \frac{1}{2} x'^T R(x) x' \\ &= x'^T f^*(-p' + p''(x')) - \frac{1}{2} x'^T R(-p' + p''(x')) x', \end{aligned}$$

where we used the relation (HJ). Denote $\{\, ,\, \}'$ the Poisson bracket with respect to $(x',\, p')$ coordinates. Then $\{\cdot, \cdot\} = \{\cdot, \cdot\}'$ because $\alpha : (x,\, p) \mapsto (x',\, p')$ is a symplectic transform. Therefore,

$$\begin{aligned} &\{H,\, p'_k\}|_{p'_1 = \cdots = p'_n = 0} = 0 \qquad (1 \leqslant k \leqslant n) \\ &\Leftrightarrow \{H,\, p'_k\}'|_{p'_1 = \cdots = p'_n = 0} = 0 \quad (1 \leqslant k \leqslant n) \\ &\Leftrightarrow \left.\frac{\partial H}{\partial x'_k}\right|_{p'_1 = \cdots = p'_n = 0} = 0 \qquad (1 \leqslant k \leqslant n) \\ &\Leftrightarrow \frac{\partial}{\partial x'} \left\{ x'^T f^*(p''(x')) - \frac{1}{2} x'^T R(p''(x')) x' \right\} = 0 \\ &\Leftrightarrow x'^T f^*(p''(x')) - \frac{1}{2} x'^T R(p''(x')) x' = \text{const}\,. \end{aligned}$$

Substituting $x' = 0$ into the last equation yields (4.4). □

Remark. Let us interpret Theorem 4.1 in the linear case. Let P be a symmetric solution of (RIC). Then

$$\text{Ham} \begin{pmatrix} I \\ P \end{pmatrix} = \begin{pmatrix} I \\ P \end{pmatrix} E_1$$

for $E_1 = A - RP$. It can be verified that

$$\begin{pmatrix} x' \\ p' \end{pmatrix} = \begin{pmatrix} p - Px \\ -x + Sx' \end{pmatrix} = \begin{pmatrix} p - Px \\ Sp - (SP + I)x \end{pmatrix}$$

is a symplectic transform for any symmetric S. Also, a direct computation shows that $T = \left(\begin{smallmatrix} I & S \\ P & PS+I \end{smallmatrix}\right)$ satisfies $T^T J T = J$. (That is, T is symplectic.) If S is a solution of the Lyapunov equation

$$E_1 S + S E_1^T = R, \tag{4.6}$$

which corresponds to (4.4), then it follows that

$$\mathrm{Ham}\begin{pmatrix} S \\ PS + I \end{pmatrix} = -\begin{pmatrix} S \\ PS + I \end{pmatrix} (A - RP)^T$$

from (RIC) and (4.6). This means that (3.1) holds for

$$T = \begin{pmatrix} I & S \\ P & PS + I \end{pmatrix}, \quad E_1 = A - RP, \quad E_2 = -(A - RP)^T = -E_1^T.$$

What we did here was to obtain T_3 and T_4 (that is, to establish the second half of (3.1)) from a solution (the first half of (3.1)) by means of solving (4.6).

Example 1 (continued). The stabilizing solution of (4.1) can be obtained more easily by following the method in Theorem 4.1. The solution $P = \left(\begin{smallmatrix} 1/2+c-c^2/2 & c \\ c & 0 \end{smallmatrix}\right)$ was not a stabilizing solution. Let $c = 1$ for the sake of simplicity. Then $f^*(x) = (-x_1, x_2)$, $x_1' = p_1 - x_1 - x_2$, and $x_2' = p_2 - x_1$. The auxiliary equation (4.4) is

$$-x_1' p_1'' + x_2' p_2'' - \frac{1}{2} {x_2'}^2 = 0,$$

and the Lagrange–Charpit system is

$$\frac{dx_1'}{-x_1'} = \frac{dx_2'}{x_2'} = \frac{dp_1''}{p_1''} = \frac{dp_2''}{x_2' - p_2''}.$$

From the equation for the first and third parts, the integral $x_1' p_1''$ is found, and we have $p_1'' = 0$ and $p_2'' = \frac{1}{2} x_2'$. Thus, from (4.5),

$$\begin{aligned} p_1' &= -x_1 + 0 = -x_1, \\ p_2' &= -x_2 + \frac{1}{2} x_2' = \frac{1}{2} p_2 - \frac{1}{2} x_1 - x_2. \end{aligned}$$

Note that

$$\begin{aligned} &dx_1' \wedge dp_1' + dx_2' \wedge dp_2' \\ &= (dp_1 - dx_1 - dx_2) \wedge (-dx_1) + (dp_2 - dx_1) \wedge \left(\frac{1}{2} dp_2 - \frac{1}{2} dx_1 - dx_2\right) \\ &= dx_1 \wedge dp_1 + dx_2 \wedge dp_2, \end{aligned}$$

and the submanifolds $\{x_1' = 0\}$, $\{x_2' = 0\}$, $\{p_1' = 0\}$, and $\{p_2' = 0\}$ are invariant for $X_{H'}$. The stabilizing solution is obtained from $\{x_1' = p_2' = 0\}$.

Equation (3.1) suggests that Ham can be decomposed into two parts E_1 and E_2 by a similarity transformation. Also, in the remark after Theorem 4.1, if P is a stabilizing solution, then E_1 is a stable matrix, and, therefore, so is $-E_2$. This is a consequence from the well-known property of Ham that if λ is an eigenvalue of Ham, then so is $-\lambda$, which can be verified from $\mathrm{Ham}J + J\mathrm{Ham} = 0$. Are these properties of the Riccati equation carried over to the Hamilton–Jacobi equation? More specifically, is it possible to find a coordinate system in which X_H is decomposed into two noninteracting subsystems? And if $z(x)$ is a stabilizing solution and the conditions in Theorem 4.1 are fulfilled, is one of the subsystems of X_H in the new coordinates asymptotically stable and the other asymptotically unstable? The following example says that the first property may be partially true, but the second is not.

Example 2. The equation

$$-2p_1x_1^3 + 2p_2x_2 - p_2^2 + x_1^4 = 0$$

is of Hamilton–Jacobi type with a nonhyperbolic equilibrium. One still can obtain a stabilizing solution $z(x) = \frac{1}{4}x_1^2 + x_2^2$ using the method in section 2. The auxiliary equation (4.4) associated with this solution is

$$x_1' {p_1''}^3 + x_2' p_2'' + \frac{1}{2} {x_2'}^2 = 0.$$

The Lagrange–Charpit system is

$$\frac{dx_1'}{3x_1' {p_1''}^2} = \frac{dx_2'}{x_2'} = \frac{dp_1''}{-{p_1''}^3} = \frac{dp_2''}{-p_2'' - x_2'};$$

hence $p_1'' = 0$ and $p_2'' = -\frac{1}{2}x_2'$ are readily obtained from the equation for the second and fourth parts. The symplectic transform (4.5) is

$$\alpha : \begin{cases} x_1' = p_1 - \dfrac{1}{2}x_1, \\ x_2' = p_2 - 2x_2, \\ p_1' = -x_1, \\ p_2' = -\dfrac{1}{2}p_2. \end{cases}$$

The push-forward $\alpha_* X_H$ of X_H by α is

$$(\alpha_* X_H)(x',\, p') = D\alpha(\alpha^{-1}(x',\, p'))X_H(\alpha^{-1}(x',\, p')) = \begin{pmatrix} 3x_1' {p_2'}^2 \\ x_2' \\ -{p_1'}^3 \\ -p_2' \end{pmatrix}.$$

It can be seen that $(\alpha_* X_H)(0,\, p') = (0,\, 0,\, -x_1^3,\, -x_2)$, so the second half is an asymptotically stable vector field. However, the first half of $-(\alpha_* X_H)(x',\, 0) = (0,\, -x_2',\, 0,\, 0)$ is not asymptotically stable.

THEOREM 4.2. *Assume that the conditions of Theorem* 4.1 *are satisfied and* $p''(0) = 0$. *Then the following hold.*

(i) $(\alpha_* X_H)(0,\, p') = \begin{pmatrix} 0 \\ -f^*(-p') \end{pmatrix}$, *which equals* $\begin{pmatrix} 0 \\ f^*(x) \end{pmatrix}$ *in* x *coordinates.*

(ii) $(\alpha_* X_H)(x',\, 0) = \begin{pmatrix} f^{**}(x') \\ 0 \end{pmatrix}$, *where*

$$f^{**}(x') = -\left(\frac{\partial f^*}{\partial x}\right)^T (p''(x'))x' + \frac{1}{2}\left(\frac{\partial R(x)x'}{\partial x}\right)^T (p''(x'))x'.$$

Proof. We first claim that the inverse transformation α^{-1} of

$$\alpha : \begin{cases} x' = p - p(x), \\ p' = -x + p''(x'(x,\, p)) = -x + p''(p - p(x)) \end{cases}$$

is given by

$$\alpha^{-1} : \begin{cases} x = p''(x') - p', \\ p = p(p''(x') - p') + x'. \end{cases}$$

To see this, one can check that $\alpha \circ \alpha^{-1} = id_{(x',\, p')}$ and $\alpha^{-1} \circ \alpha = id_{(x,\, p)}$ by direct computations. The derivative of α is

$$D\alpha(x,\, p) = \begin{pmatrix} -\dfrac{\partial p}{\partial x}(x) & I \\ -I - \dfrac{\partial p''}{\partial x'}(p - p(x))\dfrac{\partial p}{\partial x}(x) & \dfrac{\partial p''}{\partial x'}(p - p(x)) \end{pmatrix}.$$

Since $z(x)$ is a solution of (HJ),

$$\begin{aligned} &\frac{\partial p}{\partial x}(x)f(x) - \frac{\partial p}{\partial x}(x)R(x)p(x) + \left(\frac{\partial f}{\partial x}\right)^T(x)p(x) \\ &\qquad - \frac{1}{2}\left(\frac{\partial R(x)p}{\partial x}\right)^T(x)p(x) + \left(\frac{\partial q}{\partial x}\right)^T(x) = 0 \end{aligned} \tag{4.7}$$

for all x in a neighborhood of $0 \in \mathbb{R}^n$. Premultiplying

$$X_H(\alpha^{-1}(0,\, p')) = \begin{pmatrix} f(-p') - R(-p')p(-p') \\ -\left(\dfrac{\partial f}{\partial x}\right)^T(-p')p + \dfrac{1}{2}\left(\dfrac{\partial R(x)p}{\partial x}\right)^T(-p')p(-p') - \left(\dfrac{\partial q}{\partial x}\right)^T(-p') \end{pmatrix}$$

by $D\alpha(\alpha^{-1}(0,\, p'))$ and using (4.7), the first part of the theorem follows.

The second part of the theorem is proved by premultiplying

$$\begin{aligned} &X_H(\alpha^{-1}(x',\, 0)) \\ &= X_H(p''(x'),\, p(p''(x')) + x') \\ &= \begin{pmatrix} f(p''(x')) - R(p''(x'))p(p''(x')) - R(p''(x'))x' \\ -\left(\dfrac{\partial f}{\partial x}\right)^T(p''(x'))\cdot(p(p''(x')) + x') \\ +\dfrac{1}{2}\left(\dfrac{\partial R(x)\cdot(p(p''(x')) + x')}{\partial x}\right)^T(p''(x'))\cdot(p(p''(x')) + x') - \left(\dfrac{\partial q}{\partial x}\right)^T(p''(x')) \end{pmatrix}, \end{aligned}$$

by

$$D\alpha(\alpha^{-1}(x',\, 0)) = \begin{pmatrix} -\dfrac{\partial p}{\partial x}(p''(x')) & I \\ -I - \dfrac{\partial p''}{\partial x'}(x')\dfrac{\partial p}{\partial x}(p''(x')) & \dfrac{\partial p''}{\partial x'}(x') \end{pmatrix},$$

where we use

$$\left(\frac{\partial R(x)p(p''(x'))}{\partial x}\right)^T(p''(x'))x' = \left(\frac{\partial R(x)x'}{\partial x}\right)^T(p''(x'))p(p''(x'))$$

and

$$f^*(p'(x')) - R(p''(x'))x' + \frac{\partial p''}{\partial x'}\left\{\left(\frac{\partial f^*}{\partial x}\right)^T (p''(x'))x' - \frac{1}{2}\left(\frac{\partial R(x)x'}{\partial x}\right)^T (p''(x'))x'\right\} = 0,$$

which is derived by taking the derivative of (4.4) with respect to x'. □

COROLLARY 4.3. *Under the assumptions in Theorem* 4.2,

$$Df^{**}(0) = -Df^*(0)^T.$$

Proof. This follows immediately from Theorem 4.2. □

Remark. Theorem 4.2 generalizes the eigenequation (3.1) and the result $E_2 = -E_1^T$ in the theory of the Riccati equation (see the remark after Theorem 4.1). It should also be noted that one can answer the question raised before Example 2 by the expression of f^{**} in Theorem 4.2.

5. Concluding remarks. In this paper, the geometric property and structure of the Hamilton–Jacobi equation have been investigated using symplectic geometry. Many fundamental properties of the Riccati equation can be generalized in the Hamilton–Jacobi equation, and, therefore, the theory of the Hamilton–Jacobi equation naturally contains that of the Riccati equation.

It should be noted that before the modern linear robust control such as H^∞ theory became a key technology in industry, there was a tremendous amount of research undertaken on the Riccati equation from an analytical viewpoint as well as a numerical viewpoint. The lack of applicability of nonlinear control theory up to this time, such as nonlinear H^∞ theory, is mainly due to the lack of understanding of the Hamilton–Jacobi equation. More research of the Hamilton–Jacobi equation needs to be done for the development of applicable nonlinear control theory.

STABILIZATION IN PROBABILITY OF NONLINEAR STOCHASTIC SYSTEMS WITH GUARANTEED COST*

S. BATTILOTTI† AND A. DE SANTIS†

Abstract. We deal with nonlinear dynamical systems, consisting of a linear nominal part plus model uncertainties, nonlinearities, and both additive and multiplicative random noise, modeled as a Wiener process. In particular, we study the problem of finding suitable measurement feedback control laws such that the resulting closed-loop system is stable in some probabilistic sense and a given cost functional is minimized. We give a Lyapunov-based separation result which splits the control design into a *state feedback* problem and a *filtering problem*. Finally, we point out constructive algorithms for solving the state feedback and filtering problems with arbitrarily large region of attraction for a wide class of nonlinear systems, which at least include *feedback linearizable systems*.

Key words. stochastic nonlinear systems, optimal control, robust stabilization, filtering

1. Introduction.

In modeling dynamical systems, the stochastic framework is suitable for taking into account either randomly varying system parameters or stochastic exogenous inputs. It is important in many practical situations to require, besides stability in some sense, some optimal and robustness performances, which can be usually described through a suitable cost functional. These performances may include tracking errors and physical constraints, due, for example, to control actuators or sensors with limited range.

According to the existing literature (see [20], [21], [16], [17], [18]; see also the textbooks [13] and [19]), by stability it is usually meant that

- the probability that the trajectory, stemming from x_0, leaves an ϵ-ball around the origin goes to zero as x_0 tends to the origin;
- the trajectory, stemming from x_0, goes asymptotically to zero almost surely.

This stability, known as *stability in probability*, is either *local* or *global* according to whether x_0 is in some (small) neighborhood of the origin or, respectively, it is *any point of the state space*. In [13] Lyapunov-based conditions are given for guaranteeing stability in probability, and they require the solution of partial differential inequalities (PDIs). In [15] and [17] it has been proved that a step-by-step algorithm (*backstepping*) can be successfully implemented for globally solving these PDIs whenever the state is available for feedback and the uncertainties have an upper triangular structure; by using the same backstepping design, in [16] the problem of global output feedback stabilization in probability is solved for the following class of nonlinear systems with triangular structure:

$$\begin{aligned} dx_i(t) &= x_{i+1}(t)dt + \varphi_i^T(y(t))dw(t), \quad i = 1, \dots, n-1, \\ dx_n(t) &= u(t)dt + \varphi_n^T(y(t))dw(t), \\ y(t) &= x_1(t), \end{aligned} \tag{1}$$

†Dipartimento di Informatica e Sistemistica, Via Eudossiana 18, 00184 Roma, Italy (battilotti@dis.uniroma1.it, desantis@dis.uniroma1.it).

where $w(t)$ is a Wiener process. Even in a deterministic framework, as shown through some counterexamples in [11], the class of systems for which global stabilization can be achieved using output feedback can be only slightly enlarged with respect to (1). Indeed, as shown in [11], the system

$$\begin{aligned} \dot{x}_1(t) &= x_2(t), \\ \dot{x}_2(t) &= x_2^j(t) + u(t), \quad j \geq 3, \\ y(t) &= x_1(t) \end{aligned} \tag{2}$$

cannot be globally stabilized by any C^0 finite-dimensional output feedback dynamic controller. On the other hand, the earlier works of Esfandiari and Khalil [8], [9] have shown that feedback linearizable systems, such as, for example, (2), are instead *semiglobally* stabilizable via output feedback. *Semiglobal stabilization* was introduced in [4] and requires a local asymptotic stability of the closed-loop system plus a region of attraction containing any a priori given compact set of the state space. The basic ingredients for achieving semiglobal stability via output feedback are *control saturations* and *high-gain observers* [8], [9], [12]: large values of the observer gain guarantee that the error between the state and its estimate, generated by the observer itself, goes to zero "sufficiently fast," while input saturations rule out destabilizing effects such as *peaking* [6], which is a phenomenon occurring when one is trying to force some state variables to zero as fast as possible, causing an impulsive-like behavior of some others.

A first objective of our paper is to extend the notion of semiglobal stabilization to the following class of nonlinear stochastic systems:

$$\begin{aligned} dx(t) &= (Ax(t) + B_2u(t) + B_1\Phi(t, u(t), x(t)))dt + H(t, x(t))dw(t), \\ dy(t) &= (C_2x(t) + C_1\Phi(t, u(t), x(t)))dt + K(t, x(t))dw(t), \end{aligned} \tag{3}$$

where $w(t) \in \mathbb{R}^s$ is a Wiener process, $u(t) \in \mathbb{R}^m$ is the control, $x(t) \in \mathbb{R}^n$ is the state, $y(t) \in \mathbb{R}^p$ are the measurements, and $\Phi(t, u(t), x(t)) \in \mathbb{R}^r$ are model uncertainties and nonlinearities. The system

$$\begin{aligned} \dot{x}(t) &= Ax(t) + B_2u(t), \\ y(t) &= C_2x(t) \end{aligned} \tag{4}$$

can be understood as a *nominal system*, i.e., a system under nominal conditions, and Φ, Kdw, and Hdw are model nonlinearities and parameter uncertainties. We will not assume any *global growth condition* on Φ, H, and K as in [1]. Moreover, we will consider families of admissible controllers

$$\begin{aligned} u(t) &= \eta(F(k)\sigma(t)), \\ d\sigma(t) &= (L(k)\sigma(t) + B_2u(t))dt + G(k)dy(t), \quad \sigma \in \mathbb{R}^n, \end{aligned} \tag{5}$$

for $k \in \mathbb{R}^+$ and for some matrices $F(k)$, $L(k)$, and $G(k)$ and C^0 function $\eta : \mathbb{R}^m \to \mathbb{R}^m$, *linear* near the origin. This is a reasonable structure for the controller since near the origin (3) behaves as its own linearization.

Given numbers $\alpha, \beta \in [0, 1)$ and a pair of compact sets $\mathcal{B}^e \subset \Omega^e$ containing the origin, we use the same notion of stabilization in probability ($(\Omega^e, \mathcal{B}^e, \alpha, \beta)$-*SP* given in [3]. This notion requires that for sufficiently large k the trajectories of the closed-loop system, resulting from (3), with initial condition in Ω^e, remain inside some compact

set $\Omega^e(k) \supseteq \Omega^e$ of the state space, eventually enter any given neighborhood of the target set $\mathcal{B}^e$ in finite time, and remain therein with probability at least $(1-\alpha)(1-\beta)$. The numbers α and β are given *risk margins*: the first one quantifies the risk of leaving $\Omega^e(k)$ with initial condition in Ω^e rather than getting close to the target, while the second one gives a risk margin for remaining close to the target. If $\mathcal{B}^e = \{0\}$ and Ω^e can be taken to be any a priori given compact set of the state space and α and β any numbers in $[0, 1)$, our definition extends to a stochastic setting the notion of *semiglobal stabilization* as introduced in [4], and in what follows we will refer to this property as *semiglobal stabilization in probability*. If $\Omega^e = \mathbb{R}^{2n}$ and $\mathcal{B}^e$ can be taken any a priori given compact subset of Ω^e and α and β any a priori given numbers in $[0, 1)$, our definition gives a stochastic analogue of the concept of *practical stabilization*, which will be referred to as *practical stabilization in probability*.

As a second step, we define our optimality and robustness criteria. First, we give a set of admissibility constraints which impose precise characteristics to Φ, H, K, and η, generally satisfied under mild assumptions. As will be clear, these constraints lead to an optimal controller (5) in which

$$\begin{aligned} u(t) &= F(k)\sigma(t), \\ d\sigma(t) &= (L(k)\sigma(k) + B_2 u(t))dt + G(k)dy(t), \quad \sigma \in \mathbb{R}^n, \end{aligned} \tag{6}$$

is a *worst-case linear controller for the nominal system with disturbance* Φ.

The optimality criteria are formulated in terms of achieving either a guaranteed value or the minimum value of some cost functionals, according to whether multiplicative or additive noise is taken into account. These functionals penalize the "distance" from a reference situation for which the worst-case linear controller (6) is designed, and in the linear case they reduce to a standard quadratic cost (see [18] and [19] for comparisons with other inverse optimal schemes for deterministic and stochastic nonlinear systems).

We show that the problem of finding a stabilizing optimal controller can be split into two lower dimensional problems: one is related to the case in which the *state x is available for feedback* and the other to the possibility of *constructing an observer for estimating the state x*. Furthermore, we show that the conditions of our theorems can be actually met with an arbitrarily large region of attraction for a wide class of nonlinear stochastic systems with noiseless outputs, which include at least *feedback linearizable systems*, and we show that *control saturations* and *high gain observers* are instrumental in accomplishing this task exactly as in the case of deterministic systems. We do this into two steps. First, we give a semiglobal in probability backstepping design procedure for solving the state feedback problem, which stands as a *practical semiglobal* version of the corresponding *global* result proved in [15] and [17]. On the other hand, our step-by-step procedure is computationally simpler for the choice at each step of both the Lyapunov functions and the change of coordinates. Finally, we give some constructive tools for the observer design.

2. Notation and basic notions. First, we give some notation extensively used throughout the paper.

- If $\|v\|$ denotes the 2-norm of any given vector v, by $\|A\|$ we denote the induced 2-norm of any given matrix A; by $\|v\|_A$ we denote the A-norm of v, i.e., $\|v\|_A = \sqrt{v^T A v}$; let col $(v_1, \ldots, v_n)$ be the column vector with the ith entry equal to v_i.
- By $\mathcal{SP}^n$ (resp., $\mathcal{SN}^n$) we denote the set of $n \times n$ positive (resp., negative) definite symmetric matrices; by $\mathcal{SSP}^n$ we denote the set of $n \times n$ positive

semidefinite symmetric matrices; $\mathbb{R}^+$ denotes the set of positive real numbers and $\mathbb{R}^{\geq}$ the set of nonnegative real numbers.

- For any vector-valued function $\eta : \mathbb{R}^s \to \mathbb{R}^r$, we denote by η_i (or $[\eta]_i$) its ith component.
- For any given set $\mathcal{S}$, we denote by $\overline{\mathcal{S}}$ its closure and by $\partial\mathcal{S}$ its boundary; moreover, given $\delta > 0$ and a set $\mathcal{S}$, by *δ-neighborhood* of $\mathcal{S}$ we denote the set $\mathcal{S}_\delta = \{z : \inf_{y\in\mathcal{S}} \|z - y\| < \delta\}$.
- For any sequence of sets $\{\mathcal{S}_k\}$, $\liminf_{k\to\infty} \mathcal{S}_k = \cup_{k=1}^{\infty} \cap_{i\geq k} \mathcal{S}_i$ and $\limsup_{k\to\infty} \mathcal{S}_k = \cap_{k=1}^{\infty} \cup_{i\geq k} \mathcal{S}_i$. It is easy to see that if $\liminf_{k\to\infty} \mathcal{S}_k \supset \mathcal{V}$, then there exists k° such that $\mathcal{S}_k \supseteq \mathcal{V}$ for all $k \geq k^\circ$. Similarly, if $\limsup_{k\to\infty} \mathcal{S}_k \subset \mathcal{V}$, then there exists k° such that $\mathcal{S}_k \subseteq \mathcal{V}$ for all $k \geq k^\circ$.

In the remaining part of this section, we briefly recall some notions of stochastic processes, referring the reader to standard textbooks for the basic concepts [23], [24]. We assume that the reader is familiar with the basic notions of probability theory and stochastic processes $\{x(t), t \in \mathbb{R}\}$ on a given probability space $(\Omega, \mathcal{F}, \mathbf{P})$. (We assume that the probability space and all the σ-algebras we consider are completed with all the subsets of sets having null measure.) We denote by $\mathbf{E}\{\cdot\}$ the expectation and by $\mathbf{P}\{\cdot|\cdot\}$ ($\mathbf{E}\{\cdot|\cdot\}$) the conditional probability (expectation).

An important definition regards the notion of *Markov time*. Let $\{\mathcal{F}_t, t \in \mathbb{R}\}$ be an increasing family of right continuous σ-algebras contained in $\mathcal{F}$ (*filtration*).

DEFINITION 2.1. *A nonnegative random variable τ, $\tau \leq +\infty$, is called an $\mathcal{F}_t$ Markov time if for all $t \geq 0$ $\{\omega : \tau(\omega) \leq t\} \in \mathcal{F}_t$ (i.e., it is $\mathcal{F}_t$ adapted). If $\mathbf{P}\{\tau < \infty\} = 1$, then τ is called a stopping time.*

A stochastic process $\{x(t), t \in \mathbb{R}\}$ is a *Wiener process* (with respect to $\{\mathcal{F}_t, t \in \mathbb{R}\}$) if $\mathbf{E}\{x(t)|\mathcal{F}_s\} = x(s)$ and $\mathbf{E}\{(x(t) - x(s))^2|\mathcal{F}_s\} = t - s$ for $t \geq s$. A stochastic process $\{x(t), t \in \mathbb{R}\}$ is a *Markov process* if for any collections $t_1 < \cdots < t_N$ and $r_1, \ldots, r_N$,

$$\mathbf{P}\{x_{t_N} < r_N | x_{t_1} = r_1, \ldots, x_{t_{N-1}} = r_{N-1}\} = \mathbf{P}\{x_{t_N} < r_N | x_{t_{N-1}} = r_{N-1}\}. \tag{7}$$

For the corresponding definitions in the multidimensional case, we refer to [25].

By a *stochastic differential equation*, we mean the following equation:

$$dx(t) = f(x(t), t)dt + g(x(t), t)dw(t) \tag{8}$$

with initial condition $x(t_0) = \overline{x}$, where $\{w(t), t \in \mathbb{R}\}$ is a Wiener process (with respect to $\{\mathcal{F}_t, t \in \mathbb{R}\}$). The solution $x(t, t_0, \overline{x})$ of (8), whenever it exists, is a Markov process satisfying

$$x(t, t_0, \overline{x}) = \overline{x} + \int_{t_0}^{t} f(x(s, t_0, \overline{x}), s)ds + \int_{t_0}^{t} g(x(s, t_0, \overline{x}), s)dw(s) \tag{9}$$

almost surely (a.s.). The last integral is called the *Itô integral*. It is well known [13] that if

$$\begin{aligned} \|f(t, x_1) - f(x_2, t)\| + \|g(t, x_1) - g(t, x_2)\| &\leq K\|x_1 - x_2\|, \\ \|f(t, x)\| + \|g(t, x)\| &\leq H(1 + \|x\|) \end{aligned} \tag{10}$$

for all (x_1, t), (x_2, t), and (x, t) in $\mathcal{Z} \times [t_0, T]$, with $\mathcal{Z}$ a compact set containing $\overline{x}$, then there exists an a.s. unique stochastic process $x(t)$, sample continuous and satisfying (9) on $[t_0, \tau_{\mathcal{Z},T}(t)]$, where $\tau_{\mathcal{Z},T}(t) = \min(t, \tau_{\mathcal{Z}}, T)$ and $\tau_{\mathcal{Z}}$ is the Markov time (relative to the σ-algebra generated by $\{x(s), s \leq t\}$) defined as the first time at which $x(t)$ reaches the boundary of $\mathcal{Z}$ [13].

An important property of solutions of stochastic differential equations is *regularity*. Consider a sequence of increasing bounded domains $\{\mathcal{Z}(n)\}$, containing the origin, such that the distance of the boundary from the origin goes to infinity as n tends to infinity, and let $\{\tau_{\mathcal{Z}(n)}\}$ be the corresponding sequence of Markov times. Since $\{\tau_{\mathcal{Z}(n)}\}$ is nondecreasing, its limit exists. We will say that the solution is *regular* if $\lim_{n\to\infty} \tau_{\mathcal{Z}(n)} = \infty$ a.s. Any regular solution can be uniquely (a.s.) extended for all $t \geq t_0$.

Any solution $x(t)$ of (8) satisfies the following *strong Markov property* [24]:

$$\begin{aligned}&\mathbf{P}\{x(t+\tau, t_0, \overline{x}) \in A\}\\ &\quad = \int \mathbf{P}\{\tau \in ds;\ x(\tau, t_0, \overline{x}) \in dz\}\mathbf{P}\{x(t+\tau, s, z) \in A\},\end{aligned} \tag{11}$$

where τ is any given Markov time (relative to the σ-algebra generated by $\{x(s), s \leq t\}$). In (11) we can substitute $\mathbf{P}\{\cdot\}$ with its conditioned version $\mathbf{P}\{\cdot|\cdot\}$ as long as $\mathbf{P}\{\cdot|\cdot\}$ is regular, i.e., it is a function $p(\omega, A)$, measurable for each fixed A and a probability for each fixed ω [24].

From now on, we will denote $x(t, t_0, \overline{x})$, if not otherwise stated, simply by $x(t)$. Given a C^2 (measurable) function $V : \mathbb{R}^n \to \mathbb{R}$, define

$$\mathcal{L}V(x) = \frac{\partial V}{\partial x}(x) f(x,t) + \frac{1}{2}\mathbf{Tr}\left\{g^T(x,t)\frac{\partial^2 V}{\partial x^2}(x) g(x,t)\right\}. \tag{12}$$

Proposition 2.1 (Dynkin's formula). *Let $\overline{x} \in \mathcal{Z}$ a.s. The solution $x(t)$ of (8) satisfies on $[t_0, \tau_{\mathcal{Z},T}(t)]$ the following equation:*

$$\mathbf{E}\{V(x(\tau_{\mathcal{Z},T}(t)))\} - V(\overline{x}) = \mathbf{E}\left\{\int_{t_0}^{\tau_{\mathcal{B},T}(t)} \mathcal{L}V(x(s))ds\right\}. \tag{13}$$

The integral appearing in the right-hand side of (13) is meant in the sense that

$$\int_{t_0}^{\tau_{\mathcal{Z},T}(t)} \mathcal{L}V(x(s))ds = \int_{t_0}^{t} \xi_{\tau_{\mathcal{Z},T} > t}\mathcal{L}V(x(s))ds,$$

where $\xi_{\tau_{\mathcal{Z},T}>t}$ is the indicator function corresponding to the event $\{\tau_{\mathcal{Z},T} > t\}$.

Also, we will use extensively the following (generalized) *Čebyšev inequality*:

$$\mathbf{P}\{\eta \notin \mathcal{S}\} \leq \frac{\mathbf{E}\{V(\eta)\}}{\inf_{s\in\mathbb{R}^n\setminus\mathcal{S}}\{V(s)\}}, \tag{14}$$

where $\mathcal{S} \subset \mathbb{R}^n$, $V(\cdot)$ is real nonnegative, and η is a given random variable such that $\mathbf{E}\{V(\eta)\}$ exists. Finally, we recall the following fundamental formula of the differential calculus.

Proposition 2.2 (Itô's rule). *Given a C^2 function $\varphi : \mathbb{R}^n \to \mathbb{R}$ and if $x(t)$ is a solution of (8), then*

$$d\varphi(x(t)) = \frac{\partial \varphi}{\partial x}(x(t))dx(t) + \frac{1}{2}\mathbf{Tr}\left\{g^T(x(t),t)\frac{\partial^2\varphi}{\partial x^2}(x(t))g(x(t),t)\right\}dt. \tag{15}$$

3. Main motivations. To understand some key points of the forthcoming results, we illustrate some known facts under the assumptions that Φ, H, and K are bounded by a linear function. In particular, we consider the problem of stabilizing (3) under the assumption that $H = \sum_{j=1}^{s} H_j x$ and

$$\|\Phi(t,u,x)\|^2 \le \frac{\|x\|_E^2 + \|u\|_{R_1}^2}{\gamma^2} \tag{16}$$

for all x, u, and t and for some $E \in \mathcal{SSP}^n$, $R_1 \in \mathcal{SP}^m$, and $\gamma > 0$.

First, assume that the state vector x is available for feedback. Assume also the existence of $P_{SF}, Q_{SF} \in \mathcal{SP}^n$ such that

$$A^T P_{SF} + P_{SF} A + P_{SF}\left(\frac{1}{\gamma^2} B_1 B_1^T - B_2 R_1^{-1} B_2^T\right) P_{SF} + E + \sum_{j=1}^{s} H_j^T P_{SF} H_j = -Q_{SF}. \tag{17}$$

Let $V_{SF}(x) = \|x\|_{P_{SF}}^2$ and $F = -R^{-1} B_2^T P_{SF}$. Let us pretend that Φ is an "external" disturbance such that $\int_0^\infty \mathbf{E}\{\|\Phi\|^2\} dt < \infty$. Along the trajectories of the system

$$dx = (Ax + B_2 u + B_1 \Phi)dt + H dw \tag{18}$$

by (17)

$$\begin{aligned} &\mathcal{L}V_{SF} + \|x\|_E^2 + \|u\|_{R_1}^2 - \gamma^2 \|\Phi\|^2 \\ &\qquad = \|u - Fx\|_{R_1}^2 - \gamma^2 \|\Phi - \Phi_*\|^2 - \|x\|_{Q_{SF}}^2, \end{aligned} \tag{19}$$

where $\Phi_* = \frac{1}{\gamma^2} B_1^T P_{SF} x$ is the *worst-case disturbance* [14], since it maximizes the left-hand part of (19).

By taking the expectations in (19) and integrating between $[0, \infty)$, it follows that the $\mathcal{L}_2$ gain of the closed-loop system (18), with $u = Fx$, from any Φ to

$$z = \sqrt{\|x\|_E^2 + \|u\|_{R_1}^2}, \tag{20}$$

is *less than or equal to* γ [14] or, in other words, the admissible controller $u = Fx$ attains for (18) a *guaranteed level of attenuation* γ (in terms of the *expectation of energy*) of the effect of Φ over the "cost" z. On the other hand, since $\|x\|_E^2 + \|u\|_{R_1}^2 \ge \gamma^2 \|\Phi(t,u,x)\|^2$ *for all* t, u, x by (16), it follows from (19) that the trajectories of (3), with $u = Fx$, tend to zero as $t \to \infty$ in the quadratic mean and, therefore, in probability.

When the state vector x is not available for feedback, we should replace x by some estimate. To this aim, assume $B_1 C_1^T = 0$, $K = \sum_{j=1}^{s} K_j x$ the existence of $R_2 \in \mathcal{SP}^p$, with $R_2 \ge C_1 C_1^T$, and $P_m, Q_m \in \mathcal{SP}^n$ such that

$$\begin{aligned} &\left(A + \frac{1}{\gamma^2} B_1 B_1^T P_{SF}\right)^T P_m + P_m \left(A + \frac{1}{\gamma^2} B_1 B_1^T P_{SF}\right) + \frac{1}{\gamma^2} P_m B_1 B_1^T P_m \\ &\qquad + F^T R_1 F - \gamma^2 C_2^T R_2^{-1} C_2 = -Q_m \end{aligned} \tag{21}$$

and

$$Q_{SF} - \sum_{j=1}^{s} (H_j - GK_j)^T P_m (H_j - GK_j) > 0, \tag{22}$$

where $G = \gamma^2 P_m^{-1} C_2^T R_2^{-1}$.

Along the trajectories of

$$\begin{aligned} dx &= (Ax + B_2 u + B_1 \Phi)dt + H dw, \\ d\sigma &= \left(\left(A + \frac{1}{\gamma^2} B_1 B_1^T P_{SF} - G C_2 \right) \sigma + B_2 u \right) dt + G dy, \\ dy &= (C_2 x + C_1 \Phi)dt + K dw, \end{aligned} \tag{23}$$

with $G = \gamma^2 P_m^{-1} C_2^T R_2^{-1}$ and $e = x - \sigma$, we obtain

$$\begin{aligned} \mathcal{L}V_m + \|Fe\|_{R_1}^2 - \gamma^2 \|\Phi - \Phi_*\|^2 = &- \|e\|_{Q_m}^2 + \sum_{j=1}^{s} x^T (H_j - GK_j)^T P_m (H_j - GK_j) x \\ &- \gamma^2 \|\Phi - \Phi_*^e\|^2, \end{aligned} \tag{24}$$

where $\Phi_*^e = \frac{1}{\gamma^2}(B_1 - GC_1)^T P_m e + \frac{1}{\gamma^2} B_1^T P_{SF} x$. Summing up (19) and (24),

$$\begin{aligned} &\mathcal{L}V_{SF} + \mathcal{L}V_m + \|x\|_E^2 + \|u\|_{R_1}^2 - \gamma^2 \|\Phi\|^2 \\ &\quad = \|u - Fx\|_{R_1}^2 - \|Fe\|_{R_1}^2 - \|x\|^2_{Q_{SF} - \sum_{j=1}^{s} (H_j - GK_j)^T P_m (H_j - GK_j)} - \|e\|_{Q_m}^2 \\ &\qquad - \gamma^2 \|\Phi - \Phi_*^e\|^2. \end{aligned} \tag{25}$$

Note that Φ_*^e is the *worst-case disturbance* for (23) since it maximizes the left-hand part of (25).

By taking the expectations in (25) and integrating between $[0, \infty)$, it follows that the $\mathcal{L}_2$ gain of (23), with $u = F\sigma$, from any Φ such that $\int_0^\infty \mathbf{E}\{\|\Phi\|^2\} dt < \infty$ to (20) is *less than or equal to* γ [14]. Since $\|x\|_E^2 + \|u\|_{R_1}^2 \geq \gamma^2 \|\Phi(t,u,x)\|^2$ *for all* t, u, x by (16), it follows from (25) that the trajectories of (3) together with the admissible controller

$$\begin{aligned} u &= F\sigma, \\ d\sigma &= \left(\left(A + \frac{1}{\gamma^2} B_1 B_1^T P_{SF} - G C_2 \right) \sigma + B_2 u \right) dt + G dy \end{aligned} \tag{26}$$

tend to zero as $t \to \infty$ in the quadratic mean and, therefore, in probability [1], [14].

Besides asymptotic stability in the quadratic mean, it is possible to require some optimal performances. In particular, assume that $K = 0$ and that $C_1^T C_1$ is nonsingular, and define the following cost functional:

$$J = \lim_{T \to \infty} \int_{t_0}^{T} \sum_{j=1}^{2} \mathbf{E}\{\mathcal{W}_j(t, u(t), x(t), e(t))\} dt, \tag{27}$$

where

$$\begin{aligned} \mathcal{W}_1(t,u,x,e) &= \widetilde{\mathcal{W}}_1(t,u,x,e) + \gamma^2 \|\Phi(t,u,x) - \Phi_*^e\|^2, \\ \widetilde{\mathcal{W}}_1(t,u,x,e) &= -\gamma^2 \|\Phi(t,u,x)\|^2 + \|x\|_E^2 + \|u\|_{R_1}^2, \\ \mathcal{W}_2(t,u,x,e) &= \|e\|_{Q_m(k)}^2 + \|x\|^2_{Q_{SF} - \sum_{j=1}^{s} (H_j - GK_j)^T P_m (H_j - GK_j)}. \end{aligned} \tag{28}$$

Note that the term $\mathcal{W}_1(t,x,e)$ penalizes the distance of Φ from a *worst-case situation*, with respect to which the $\mathcal{H}_\infty$ controller is designed, and the term $\mathcal{W}_2(t,x,e)$ represents a *parametric quadratic cost*. By using standard arguments, it is possible to prove

that $F = -R_1^{-1}B_2^T P_{SF}$ and $G = \gamma^2 P_m^{-1} C_2^T R_2^{-1}$ characterize the optimal controller within the class (26). Indeed, from (25) and with $V^e = V_{SF} + V_m$ and $x^e = (x, \sigma)$

$$\mathcal{L}V^e(x^e) + \sum_{j=1}^{2} \mathcal{W}_j(t, u, x, e) = 0. \tag{29}$$

From Dynkin's formula and (29)

$$\mathbf{E}\{V^e(x^e(t))\} - V^e(x_0^e) = -\int_{t_0}^{t} \mathbf{E}\left\{\sum_{j=1}^{2} \mathcal{W}_j(t, u(t), x(t), e(t))\right\} ds. \tag{30}$$

Differentiating both sides of (30), since V^e is a quadratic function of x and e and by (22) and (28) $\sum_{j=1}^{2} \mathcal{W}_j(t, u, x, e)$ is lower bounded by a quadratic function of x and e, we obtain for some $\widetilde{\lambda}, \widetilde{\nu} > 0$

$$\mathbf{E}\{V^e(x^e(t))\} \leq \widetilde{\lambda} V^e(x_0^e) e^{-\widetilde{\nu}(t-t_0)}. \tag{31}$$

We conclude that $\mathbf{E}\{V^e(x^e(t))\} \to 0$ as $t \to \infty$ and from (30), with $t \to \infty$, $J = V^e(x_0)$.

Since

$$\mathcal{L}V^e + \sum_{j=1}^{2} \mathbf{E}\{\mathcal{W}_j(t, u, x, e)\} \geq 0 \tag{32}$$

for any other F and G, we conclude that J achieves its minimum with $F = -R_1^{-1}B_2^T P_{SF}$ and $G = \gamma^2 P_m^{-1} C_2^T R_2^{-1}$ [1], [14].

In the case that Φ, H, and K contain some *nonlinear term* as, for example, in

$$\begin{aligned} dx_1(t) &= x_2(t)dt, \\ dx_2(t) &= (x_2^3(t) + u(t))dt + x_1^2(t)dw, \\ y(t) &= x_1(t), \end{aligned} \tag{33}$$

(16) cannot be satisfied for all t, u, and x by some *constant* E, and known results in the literature do not apply. However, (16) can be still satisfied on some compact set of the state space for some E, provided the trajectories are ensured to stay in this compact set (and eventually approach a given target set) at least with some guaranteed probability. These requirements are well represented by the notion of semiglobal stability in probability, introduced in [3]. Moreover, since in (33) both *additive and multiplicative noise* affects the system, the cost functional J is no longer suitable, and a *time average* version of that functional should be considered (for the state feedback case, see the work of [15]). All of these facts will be discussed in detail in the next section.

4. Problem formulation. Let us consider nonlinear stochastic systems Σ of the form (3), where $x(t) \in \mathbb{R}^n$, $u(t) \in \mathbb{R}^m$, $y(t) \in \mathbb{R}^p$, $w(t)$ is an s-dimensional Wiener process, and $\Phi(t, u(t), x(t)) \in \mathbb{R}^r$ represents model uncertainties and nonlinearities. The discussion in section 3 suggests considering as the class of *candidate controllers* $\{\mathcal{C}(k)\}$

$$\begin{aligned} u &= \eta(F(k)\sigma), \\ d\sigma &= (L(k)\sigma + B_2 u)dt + G(k)dy, \quad \sigma \in \mathbb{R}^n, \end{aligned} \tag{34}$$

with

$$L(k) = A + \frac{1}{\gamma^2(k)} B_1 B_1^T P_{SF}(k) - G(k) C_2 \tag{35}$$

for some sequence of real positive extended numbers $\{\Delta(k)\}$, $k \in \mathbb{R}^+$, matrices $\{F(k)\}$ and $\{G(k)\}$, positive numbers $\{\gamma(k)\}$, and symmetric positive definite matrices$\{P_{SF}(k)\}$ and $\eta : \mathbb{R}^m \to \mathbb{R}^m$ any C^0 function such that

$$\|\eta(s)\| \le \Delta(k) \quad \forall s, \tag{36}$$

$$\eta(s) = s, \qquad \|s\| \le s_0, \tag{37}$$

for some $s_0 > 0$. In other words, any candidate controller is the composition of a *linear controller* with a *static nonlinearity* η, which is *bounded by* $\Delta(k)$ (unbounded if $\Delta(k) = \infty$) and *it is the identity function near the origin*. While $\eta(s)$ is designed in such a way to counteract the destabilizing effects due to large values of $G(k)$ (peaking), $\Delta(k)$ accounts for possible limitations on the control u (as an example, saturations of the control actuators).

For the stability analysis of the closed-loop system (3)–(34), we also define a class of *candidate Lyapunov functions* $\{V_k^e\}$

$$V_k^e(x, \sigma) = \|x\|^2_{P_{SF}(k)} + \varphi(\|x - \sigma\|^2_{P_m(k)}), \tag{38}$$

where $\{P_m(k)\}$ is a sequence in $\mathcal{SP}^n$ and $\varphi : \mathbb{R}^{\ge} \to \mathbb{R}$ is any (at least) C^2, positive definite and proper function such that

$$\frac{\partial^2 \varphi}{\partial s^2}(s) \le 0 < \frac{\partial \varphi}{\partial s}(s) \le 1 \tag{39}$$

for all $s \ge 0$. Conditions (39) imply that over any compact set containing the origin any *candidate Lyapunov function is bounded from below and above by a quadratic function*, and, as will be clear in the next sections, the function φ is instrumental in enlarging the region of attraction of the closed-loop system.

Next we define some *admissibility constraints* for the noise coefficients H and K and for the uncertainty term Φ. To this aim, define the following compact sets:

$$\begin{aligned} \Omega(k) &= \{x \in \mathbb{R}^n : \|x\|^2_{P_{SF}(k)} \le k\}, \\ \mathcal{U}_{\Delta(k)} &= \{u \in \mathbb{R}^m : \|u\| \le \Delta(k)\}. \end{aligned} \tag{40}$$

Let $\{E(k)\}$, $\{R_1(k)\}$, and $\{c_1(k)\}$ be sequences in $\mathcal{SSP}^n$, $\mathcal{SP}^m$, and $\mathbb{R}^{\ge}$, respectively. Define

$$\begin{aligned} \Phi_*^e &= \frac{1}{\gamma^2(k)} \left[B_1^T P_{SF}(k) x + \frac{\partial \varphi}{\partial s}\Big|_{s=\|e\|^2_{P_m(k)}} (B_1 - G(k) C_1)^T P_m(k) e \right], \\ \widetilde{\mathcal{P}}_1(t, u, x, e, k) &= -\gamma^2(k) \|\Phi(t, u, x)\|^2 + \|x\|^2_{E(k)} + \|u\|^2_{R_1(k)} + c_1(k), \\ \mathcal{P}_1(t, u, x, e, k) &= \widetilde{\mathcal{P}}_1(t, u, x, e, k) + \gamma^2 \|\Phi(t, u, x) - \Phi_*^e\|^2, \end{aligned} \tag{41}$$

and let $\mathcal{F}(k)$ be the class of C^0 functions $\Phi : \mathbb{R} \times \mathbb{R}^m \times \mathbb{R}^n \to \mathbb{R}^r$ such that $\widetilde{\mathcal{P}}_1(t, u, x, e, k) \ge 0$ for all t, $u \in \mathcal{U}_{\Delta(k)}$, $x \in \Omega(k)$, and $e \in \mathbb{R}^n$. Note that Φ_*^e is the uncertainty Φ which maximizes $\mathcal{L}V_k^e - \gamma^2 \|\Phi\|^2$ along the trajectories of

$$\begin{aligned} dx &= (Ax + B_2 \eta(F(k)\sigma) + B_1 \Phi) dt + H dw, \\ d\sigma &= (L(k)\sigma(k) + B_2 \eta(F(k)\sigma)) dt + G(k) dy, \end{aligned} \tag{42}$$

or, in other words, it is the *worst-case uncertainty* for the closed-loop system (see section 3). Note also that $\mathcal{P}_1$ penalizes the distance of Φ from being the worst-case uncertainty Φ_*^e and, at the same time, from being a linear (parametrized by k) function of x and u over the sets $\Omega(k)$ and $\mathcal{U}_{\Delta(k)}$, which represent a worst-case situation with respect to which the matrices $F(k)$ and $G(k)$ are designed according to an $\mathcal{H}_\infty$ strategy.

Let $\{\widehat{H}_j(k)\}$, $j = 1, \dots, s$, be a sequence in $\mathbb{R}^{n\times n}$, and let $\{c_2(k)\}$ be a sequence in $\mathbb{R}^{\geq}$. Define

$$\begin{aligned}\mathcal{P}_2(t,u,x,e,k) = &-\mathbf{Tr}\{H^T(t,x)P_{SF}(k)H(t,x))\}\\ &+\sum_{j=1}^{s} x^T\widehat{H}_j^T(k)P_{SF}(k)\widehat{H}_j(k)x + c_2(k).\end{aligned} \tag{43}$$

Let $\mathcal{H}(k)$ be the class of C^0 functions $H : \mathbb{R}\times\mathbb{R}^n \to \mathbb{R}^{n\times s}$ such that $\mathcal{P}_2(t,u,x,e,k) \geq 0$ for all $t \geq 0$, $u \in \mathcal{U}_{\Delta(k)}$, $x \in \Omega(k)$, and $e \in \mathbb{R}^n$. Note that $\mathcal{P}_2$ penalizes the distance of $\mathbf{Tr}\{H^T(t,x)P_{SF}(k)H(t,x))\}$ from a sum of quadratic functions over the sets $\Omega(k)$ and $\mathcal{U}_{\Delta(k)}$. Since $\Omega(k)$ and $\mathcal{U}_{\Delta(k)}$ are compact sets, the admissibility constraints on $\widetilde{\mathcal{P}}_1$ and $\mathcal{P}_2$ can be always met whenever Φ and H are *locally Lipschitz*, uniformly with respect to t (compare with [1]).

Let $\{Q_m(k)\}$ and $\{c_3(k)\}$ be sequences in $\mathcal{SP}^n$ and $\mathbb{R}^{\geq}$, respectively, and let

$$M(t,x,k) = H(t,x) - G(k)K(t,x). \tag{44}$$

Define $\mathcal{K}(k)$ and $\mathcal{D}(k)$ as the class of C^0 functions $K : \mathbb{R}\times\mathbb{R}^n \to \mathbb{R}^{p\times s}$ and, respectively, the class of pairs of C^0 functions $\eta : \mathbb{R}^m \to \mathbb{R}^m$ and $\varphi : \mathbb{R}^{\geq} \to \mathbb{R}$ satisfying (36), (37), and (39) and such that

$$\begin{aligned}\mathcal{P}_3(t,u,x,e,k) = &-\|\eta(F(k)(x-e)) - F(k)x\|^2_{R_1(k)} + \|x\|^2_{Q_{SF}(k)} + c_3(k)\\ &+\frac{\partial\varphi}{\partial s}\Big|_{s=\|e\|^2_{P_m(k)}}[\|F(k)e\|^2_{R_1(k)} + \|e\|^2_{Q_m(k)}\\ &-\mathbf{Tr}\{M^T(t,x,k)P_m(k)M(t,x,k))\}] > 0\end{aligned} \tag{45}$$

for all $(x,e) \in (\Omega(k)\times\mathbb{R}^n)\backslash(0,0)$. Note that $c_1(k)$, $c_2(k)$, and $c_3(k)$ take into account additive noise and nonzero equilibrium points.

Finally, let

$$\begin{aligned}&\mathcal{P}_4(t,u,x,e,k)\\ &\quad= \frac{1}{\gamma^2(k)}\frac{\partial\varphi}{\partial s}\Big|_{s=\|e\|^2_{P_m(k)}}\Bigg[\left(1-\frac{\partial\varphi}{\partial s}\Big|_{s=\|e\|^2_{P_m(k)}}\right)\\ &\qquad\qquad\times e^TP_m(k)(B_1-G(k)C_1)(B_1-G(k)C_1)^TP_m(k)e\\ &\qquad\qquad+e^TP_m(k)G(k)(R_2(k)-C_1C_1^T)G^T(k)P_m(k)e\Bigg]\\ &\qquad-\frac{\partial^2\varphi}{\partial s^2}\Big|_{s=\|e\|^2_{P_m(k)}} e^TP_m(k)M(t,x,k)M^T(t,x,k)P_m(k)e\end{aligned} \tag{46}$$

for some sequence $\{R_2(k)\}$ in $\mathcal{SP}^p$ such that $R_2(k) \geq C_1C_1^T$. Note that, by (39), (46) is nonnegative for all $e \in \mathbb{R}^n$, and if $C_1C_1^T$ is nonsingular, then we can take directly

$R_2(k) = C_1 C_1^T$. Note also that $\mathcal{P}_4$ penalizes the distance from the situation for which φ is *linear* (i.e., quadratic Lyapunov functions) and $R_2(k) = C_1 C_1^T$.

In what follows, we will refer to $\Phi \in \mathcal{F}(k)$, $H \in \mathcal{H}(k)$, $K \in \mathcal{K}(k)$, and $(\eta, \varphi) \in \mathcal{D}(k)$ as *admissible functions*. Moreover, any choice of $\{P_{SF}(k)\}$, $\{P_m(k)\}$, $\{Q_{SF}(k)\}$, $\{Q_m(k)\}$, $\{R_1(k)\}$, $\{R_2(k)\}$, $\{\gamma(k)\}$, $\{\Delta(k)\}$, $\{E(k)\}$, $\{c_j(k)\}$, $j = 1, 2, 3$, $\{\widehat{H}_j(k)\}$, $j = 1, \ldots, s$, for which $\Phi \in \mathcal{F}(k)$, $H \in \mathcal{H}(k)$, and $K \in \mathcal{K}(k)$ will be referred to as *admissible parametrization*.

Denote by $x_k^e(t, t_0, x_0^e) = col(x_k(t, t_0, x_0^e), \sigma_k(t, t_0, x_0^e))$ the trajectory of the closed-loop system $\Sigma \circ \mathcal{C}(k)$ at time $t \geq t_0$ stemming from $x_0^e = col(x_0, \sigma_0)$. With some abuse of notation, wherever there is no ambiguity, we will use $x_k^e(t)$ instead of $x_k^e(t, t_0, x_0^e)$. Moreover, let $e_k(t) = x_k(t) - \sigma_k(t)$.

Our goal is to find an admissible parametrization which minimizes the expectation of the sum of the $\mathcal{P}_j$'s: this corresponds to achieving *semiglobal inverse optimality* with respect to a "reference" system for which a worst-case linear controller can be designed. At the same time, local optimality is guaranteed since the closed-loop system behaves locally as its reference system. To this aim, we introduce two sequences of cost functionals $\{J_h(k)\}$, $h = 1, 2$, defined as follows:

$$J_1(k) = \lim_{T \to \infty} \frac{1}{T - t_0} \int_{t_0}^{T} \mathbf{E} \left\{ \sum_{j=1}^{4} \mathcal{P}_j(t, u(t), x_k(t), e_k(t), k) \right\} dt \tag{47}$$

and

$$J_2(k) = \lim_{T \to \infty} \int_{t_0}^{T} \mathbf{E} \left\{ \sum_{j=1}^{4} \mathcal{P}_j(t, u(t), x_k(t), e_k(t), k) \right\} dt. \tag{48}$$

Note that $J_h(k) \geq 0$, $h = 1, 2$, for any $\Phi \in \mathcal{F}(k)$, $H \in \mathcal{H}(k)$, $K \in \mathcal{K}(k)$, and $(\eta, \varphi) \in \mathcal{D}(k)$. While $J_1(k)$ is more suitable in the case of both *additive and multiplicative noise*, $J_2(k)$ is not suitable for the case of *additive noise*, since the constant $c_j(k) \neq 0$ for at least one j would cause $J_2(k)$ to diverge.

The aim of this paper is to study under which conditions it is possible to modify the behavior of (3) in such a way that $J_1(k)$ achieves a guaranteed value (resp., $J_2(k)$ achieves its minimum) and to obtain stability in some "stochastic" sense. To make the last point precise, let us give the following definition.

DEFINITION 4.1. *Let $\alpha, \beta \in [0, 1)$ and $\Omega^e, \mathcal{B}^e \subset \mathbb{R}^{2n}$ be compact sets. The system (3) is said to be $(\Omega^e, \mathcal{B}^e, \alpha, \beta)$-stabilizable in probability (or $(\Omega^e, \mathcal{B}^e, \alpha, \beta)$-SP) if there exist a sequence of admissible control laws $\{\mathcal{C}(k)\}$, a sequence of compact sets $\{\Omega^e(k)\}$, and open sets $\{\mathcal{B}^e(k)\}$ of $\mathbb{R}^{2n}$ such that*

(i) $\liminf_{k \to \infty} \Omega^e(k) \supset \Omega^e \supset \mathcal{B}^e \supseteq \limsup_{k \to \infty} \mathcal{B}^e(k)$;

(ii) *for each $\delta > 0$ and $\Phi \in \mathcal{F}(k)$,*

$$\liminf_{k \to \infty} \inf_{x_0^e \in \overline{\mathcal{B}}^e(k)} \mathbf{P}\{x_k^e(t) \in \overline{\mathcal{B}}_\delta^e \ \forall t \geq t_0\} \geq 1 - \beta; \tag{49}$$

(iii) *for each $\delta > 0$ and $\Phi \in \mathcal{F}(k)$,*

$$\begin{aligned} \liminf_{k \to \infty} \inf_{x_0^e \in \Omega^e \setminus \mathcal{B}^e(k)} \mathbf{P}\{ & x_k^e(t) \in \Omega^e(k) \ \forall t \geq t_0 \\ & \text{and } x_k^e(t + \tau_{\mathbb{R}^{2n} \setminus \mathcal{B}^e(k)}) \in \mathcal{B}_\delta^e \ \forall t \geq 0 \\ & \text{and } \tau_{\mathbb{R}^{2n} \setminus \mathcal{B}^e(k)} < \infty\} \geq (1 - \alpha)(1 - \beta). \end{aligned} \tag{50}$$

Note that the events in (49) and (50) are measurable by separability and measurability (on the product σ-algebra $\mathcal{F} \times \mathcal{I}$, where $\mathcal{I}$ is the Borel σ-algebra on the line) of the process $x_k^e(t)$ and by being $\{\tau_{\mathbb{R}^{2n} \setminus \mathcal{B}^e(k)} \leq t\}$ adapted to the σ-algebra generated by $\{x_k^e(s),\ s \leq t\}$.

The set Ω^e gives the *guaranteed region of attraction* of the closed-loop system $\Sigma \circ \mathcal{C}(k)$, while $\mathcal{B}^e$ represents the *target set*. From (i) it follows that there exists k° such that $\Omega^e(k) \supset \Omega^e \supset \mathcal{B}^e \supset \mathcal{B}^e(k) \subset \mathcal{B}_\delta^e$ for all $k \geq k^\circ$. Property (ii) is a *local* property with respect to $\mathcal{B}^e$: for each δ-neighborhood of $\mathcal{B}^e$, there exists sufficiently large k° for which the probability that the trajectories $x_k^e(t)$ of the closed-loop system $\Sigma \circ \mathcal{C}(k)$, starting from $\overline{\mathcal{B}}^e(k)$, stay forever in $\overline{\mathcal{B}}_\delta^e$ is at least $1-\beta$ for all $k \geq k^\circ$. Property (iii) is a property *in the large* with respect to Ω^e: there exists sufficiently large k° for which the trajectories of $\Sigma \circ \mathcal{C}(k)$ starting inside Ω^e remain inside $\Omega^e(k)$, eventually enter any given δ-neighborhood of the target set $\mathcal{B}^e$ in finite time, and remain therein with probability at least $(1-\alpha)(1-\beta)$ for all $k \geq k^\circ$. The numbers α and β are given *risk margins: the first one quantifies the risk of leaving the compact set $\Omega^e(k)$ with initial condition in Ω^e rather than getting close to the target, while the second one gives a risk margin for remaining close to the target*. Note also that (iii) requires that $\tau_{\mathbb{R}^{2n} \setminus \mathcal{B}^e(k)} < \infty$. As will be clear in the next section, under the standard assumptions of local existence and uniqueness a.s. of trajectories, each Markov time $\tau_{\mathbb{R}^{2n} \setminus \mathcal{B}^e(k)}$, conditioned to $x_k(t) \in \Omega^e(k)$ for all $t \geq t_0$, is always finite and $\tau_{\mathbb{R}^{2n} \setminus \mathcal{B}^e(k)} \to \infty$ as $k \to \infty$ as long as $\limsup_{k \to \infty} \mathcal{B}^e(k) = \{0\}$. In particular, this implies that, if $\mathcal{B}^e = \{0\}$, the trajectory approaches the origin as $t \to \infty$.

The roles of the risk margins, region of attraction, and target set are peculiar of our setup and become unessential in the classical definitions given in [13]. If $\mathcal{B}^e = \{0\}$, $\alpha = \beta = 0$, and $\{\mathcal{C}(k)\} = \mathcal{C}$ for all k, Definition 4.1 recovers the classical definition of *asymptotic stability in probability* [13]. If in addition $\Omega^e = \mathbb{R}^{2n}$, Definition 4.1 gives the notion of *asymptotic stability in probability in the large* [13]. On the other hand, if $\mathcal{B}^e = \{0\}$ and Ω^e can be taken to be any a priori given compact set of $\mathbb{R}^{2n}$ and α and β any a priori given numbers in $[0, 1)$, our definition gives a stochastic analogue of the concept of *semiglobal stabilization*, as introduced in [4]. If $\Omega^e = \mathbb{R}^{2n}$ and $\mathcal{B}^e$ can be taken to be any a priori given compact set of $\mathbb{R}^{2n}$ and α and β any a priori given number in $[0, 1)$, Definition 4.1 extends to a stochastic setting the concept of *practical stabilization*.

All of the above remarks can be straightforwardly extended to the definition of stability in the quadratic mean.

We are ready to formulate our problems.

Problem I: Nonlinear stabilization in probability with guaranteed cost. Let $\Phi \in \mathcal{F}(k)$, $H \in \mathcal{H}(k)$, $K \in \mathcal{K}(k)$, $\mathcal{B}^e \subset \Omega^e$ be compact sets of $\mathbb{R}^{2n}$, $\alpha, \beta \in [0, 1)$, $x_0^e \in \Omega^e$ and $\{\overline{\omega}(k)\}$ a given sequence in $\mathbb{R}^{\geq}$. Find an admissible parametrization and $(\eta, \varphi) \in \mathcal{D}(k)$ such that

- (*guaranteed cost*) along the trajectories of the closed-loop systems $\Sigma \circ \mathcal{C}(k)$,

$$\liminf_{k \to \infty} \mathbf{Pr}\{J_1(k) \leq \overline{\omega}(k)\} \geq (1 - \alpha); \tag{51}$$

- (*stability*) $\Sigma \circ \mathcal{C}(k)$ is $(\Omega^e, \mathcal{B}^e, \alpha, \beta)$-stable in probability.

Problem II: Nonlinear stabilization in quadratic mean with optimality. Let $\Phi \in \mathcal{F}(k)$, $H \in \mathcal{H}(k)$, $K \in \mathcal{K}(k)$, $\mathcal{B}^e \subset \Omega^e$ be compact sets of $\mathbb{R}^{2n}$, $\alpha, \beta \in [0, 1)$, $x_0^e \in \Omega^e$. Find an admissible parametrization and $(\eta, \varphi) \in \mathcal{D}(k)$ such that

- (*optimality*) along the trajectories of the closed-loop systems $\Sigma \circ \mathcal{C}(k)$,

$$\liminf_{k\to\infty} \mathbf{Pr}\{J_2(k) \le \widetilde{J}_2(k)\} \ge (1-\alpha), \tag{52}$$

  where $\widetilde{J}_2(k)$ is the value of $J_2(k)$ corresponding to any other admissible parametrization;
- (*stability*) $\Sigma \circ \mathcal{C}(k)$ is $(\Omega, \{0\}, \alpha, 0)$-stable in the quadratic mean.

5. Main results. Let

$$\begin{aligned} H(t,x) &= (\, H_1(t,x) \cdots H_s(t,x)\,), \\ K(t,x) &= (\, K_1(t,x) \cdots K_s(t,x)\,), \end{aligned} \tag{53}$$

and, without loss of generality, assume that $B_1 C_1^T = 0$ and $H(t,x)K^T(t,x) = 0$ for all x and t.

THEOREM 5.1. *Assume that there exist an admissible parametrization and* $(\eta, \varphi) \in \mathcal{D}(k)$ *such that*

- (state feedback (SF))

$$\begin{aligned} A^T P_{SF}(k) + P_{SF}(k)A + \frac{1}{\gamma^2(k)} P_{SF}(k) B_1 B_1^T P_{SF}(k) + E(k) \\ - F^T(k) R_1(k) F(k) \\ + \sum_{j=1}^{s} \widehat{H}_j^T(k) P_{SF}(k) \widehat{H}_j(k) = -Q_{SF}(k), \end{aligned} \tag{54}$$

  where

$$F(k) = -R_1^{-1}(k) B_2^T P_{SF}(k); \tag{55}$$

- (output injection (OI))

$$\begin{aligned} P_m(k) \left(A + \frac{1}{\gamma^2(k)} B_1 B_1^T P_{SF}(k) \right) \\ + \left(A + \frac{1}{\gamma^2(k)} B_1 B_1^T P_{SF}(k) \right)^T P_m(k) + F^T(k) R_1 F(k) \\ + \frac{1}{\gamma^2(k)} P_m(k) B_1 B_1^T P_m(k) - \gamma^2(k) C_2^T R_2^{-1}(k) C_2 = -Q_m(k); \end{aligned} \tag{56}$$

- (risk margins (RM)) *if*

$$\Omega^e(k) = \{(x,\sigma) \in \mathbb{R}^n \times \mathbb{R}^n : V_k^e(x,\sigma) \le k\} \tag{57}$$

  and $\{\mathcal{B}^e(k)\}$, *a sequence of open sets of* $\mathbb{R}^{2n}$, *are such that*

$$\limsup_{k\to\infty} \mathcal{B}^e(k) \subseteq \mathcal{B}^e \subset \Omega^e \subset \liminf_{k\to\infty} \Omega^e(k), \tag{58}$$

  then for each $\delta > 0$,

$$\limsup_{k\to\infty} \sup_{(x,\sigma)\in\Omega^e \setminus \mathcal{B}^e(k)} \frac{V_k^e(x,\sigma)}{k} \le \alpha, \tag{59}$$

$$\limsup_{k\to\infty} \sup_{(x,\sigma)\in\partial\mathcal{B}^e(k)} \frac{V_k^e(x,\sigma)}{\inf_{(s_1,s_2)\in\mathbb{R}^{2n}\setminus\overline{\mathcal{B}}_\delta^e} V_k^e(s_1,s_2)} \le \beta, \tag{60}$$

and

$$\sum_{j=1}^{4} \mathcal{P}_j(t, \eta(F(k)\sigma), x, x-\sigma, k) - \sum_{j=1}^{3} c_j(k) \geq Q_k^e(x,\sigma) \tag{61}$$

for all t *and* $(x,\sigma) \in \Omega^e(k)$ *and for some sequence of quadratic* C^0 *positive definite functions* $\{Q_k^e\}$.

Under the above assumptions, the controller (34) *with* $F(k)$ *as in* (55) *and*

$$G(k) = \gamma^2(k) P_m^{-1}(k) C_2^T R_2^{-1}(k) \tag{62}$$

solves problem I *with* $\overline{\omega}(k) = \sum_{j=1}^{3} c_j(k)$. *If, in addition,* $c_j(k) = 0$ *for all* $j = 1,2,3$, *and* $K(t,x) = 0$ *for all* t, x, *and* $j = 1, \ldots, r$, *the same controller* (34) *solves problem* II.

Proof. Throughout the proof, unless otherwise stated, we will omit k and the arguments of Φ, K, and H. Moreover, we can assume $k \geq k^*$, where k^* is such that $\Omega^e(k) \supseteq \Omega^e \supset \mathcal{B}^e(k)$ for all $k \geq k^*$. (This is always possible by (58).)

Let $V_{SF}(x) = \|x\|^2_{P_{SF}}$ and V_k^e, M and e as in section 4. The closed-loop system is

$$\begin{aligned} dx &= \left(\left(A + \frac{1}{\gamma^2} B_1 B_1^T P_{SF} \right) x + B_2 u + B_1 \widetilde{\Phi} \right) dt + H dw, \\ de &= (Le + (B_1 - GC_1)\widetilde{\Phi}) dt + M dw, \end{aligned} \tag{63}$$

where $\widetilde{\Phi} = \Phi - \frac{1}{\gamma^2} B_1^T P_{SF} x$ and $u = \eta(F\sigma)$.

By (12)

$$\begin{aligned} \mathcal{L}\varphi &= \frac{\partial \varphi}{\partial e} \left[Le + (B_1 - GC_1)\widetilde{\Phi} \right] + \frac{1}{2} \mathbf{Tr} \left\{ M^T \frac{\partial^2 \varphi}{\partial e^2} M \right\}, \\ \mathcal{L}V_{SF} &= 2x^T P_{SF} \left[\left(A + \frac{1}{\gamma^2} B_1 B_1^T P_{SF} \right) x + B_2 u + B_1 \widetilde{\Phi} \right] + \mathbf{Tr}\{H^T P_{SF} H\}. \end{aligned} \tag{64}$$

Moreover,

$$\frac{\partial^2 \varphi}{\partial e^2} = 2 \frac{\partial^2 \varphi}{\partial s^2}\Big|_{s=\|e\|^2_{P_m}} P_m e e^T P_m + 2 \frac{\partial \varphi}{\partial s}\Big|_{s=\|e\|^2_{P_m}} P_m. \tag{65}$$

Since $HK^T = 0$ and $\mathbf{Tr}(AB) = \mathbf{Tr}(BA)$, by (65) one has

$$\begin{aligned} &\frac{1}{2} \mathbf{Tr} \left\{ M^T \frac{\partial^2 \varphi}{\partial e^2} M \right\} \\ &\quad = \frac{\partial \varphi}{\partial s}\Big|_{s=\|e\|^2_{P_m}} \mathbf{Tr}\{M^T P_m M\} + \frac{\partial^2 \varphi}{\partial s^2}\Big|_{s=\|e\|^2_{P_m}} e^T P_m M M^T P_m e. \end{aligned} \tag{66}$$

Since $B_1 C_1^T = 0$ and $HK^T = 0$, using (56) and (66), we have

$$
\begin{aligned}
&\mathcal{L}\varphi + \frac{\partial\varphi}{\partial s}\Big|_{s=\|e\|^2_{P_m}} \|Fe\|^2_{R_1} - \gamma^2\|\widetilde{\Phi}\|^2 \\
&\quad = \frac{\partial\varphi}{\partial s}\Big|_{s=\|e\|^2_{P_m}} [2e^T P_m(Le + (B_1 - GC_1)\widetilde{\Phi}) + \|Fe\|^2_{R_1}] - \gamma^2\|\widetilde{\Phi}\|^2 \\
&\qquad + \frac{\partial\varphi}{\partial s}\Big|_{s=\|e\|^2_{P_m}} \mathbf{Tr}\{M^T P_m M\} + \frac{\partial^2\varphi}{\partial s^2}\Big|_{s=\|e\|^2_{P_m}} e^T P_m M M^T P_m e \\
&\quad = \frac{\partial\varphi}{\partial s}\Big|_{s=\|e\|^2_{P_m}} e^T[P_m L + L^T P_m + F^T R_1 F]e - \gamma^2\|\Phi - \Phi^e_*\|^2 \\
&\qquad + \frac{1}{\gamma^2} e^T P_m \left(\frac{\partial\varphi}{\partial s}\Big|_{s=\|e\|^2_{P_m}}\right)^2 (B_1 B_1^T + GC_1 C_1^T G^T) P_m e \\
&\qquad + \frac{\partial^2\varphi}{\partial s^2}\Big|_{s=\|e\|^2_{P_m}} e^T P_m M M^T P_m e + \frac{\partial\varphi}{\partial s}\Big|_{s=\|e\|^2_{P_m}} \mathbf{Tr}\{M^T P_m M\} \\
&\quad = \frac{\partial\varphi}{\partial s}\Big|_{s=\|e\|^2_{P_m}} \Bigg[e^T \left(P_m L + L^T P_m + F^T R_1 F + \frac{1}{\gamma^2} P_m (B_1 B_1^T + G R_2 G^T) P_m \right) e \\
&\qquad\qquad + \mathbf{Tr}\{M^T P_m M\} \Bigg] - \gamma^2\|\Phi - \Phi^e_*\|^2 - \mathcal{P}_4 \\
&\quad = -\|u - Fx\|^2_{R_1} + \|x\|^2_{P_{SF}} + \frac{\partial\varphi}{\partial s}\Big|_{s=\|e\|^2_{P_m}} \|Fe\|^2_{R_1} - \mathcal{P}_1 + \widetilde{\mathcal{P}}_1 - \mathcal{P}_3 - \mathcal{P}_4 + c_3. \qquad (67)
\end{aligned}
$$

Moreover, for all u, by completing the square and using (54)

$$
\mathcal{L}V_{SF} = \|u - Fx\|^2_{R_1} - \gamma^2\|\widetilde{\Phi}\|^2 - \|x\|^2_{Q_{SF}} - \widetilde{\mathcal{P}}_1 - \mathcal{P}_2 + c_1 + c_2. \qquad (68)
$$

Summing up together (67) and (68), we conclude that

$$
\mathcal{L}V^e_k + \sum_{j=1}^{4} \mathcal{P}_j = \overline{\omega} = \sum_{j=1}^{3} c_j. \qquad (69)
$$

To prove our theorem, we are left with proving the following facts:

- $J_1(k) \le \overline{\omega}(k)$ (resp., $J_2(k)$ achieves its minimum), conditionally to the event $\{x^e_k(t) \in \Omega^e(k),\ t \ge t_0\}$;
- $\liminf_{k\to\infty} \mathbf{Pr}\{(x^e_k(t) \in \Omega^e(k),\ t \ge t_0\} \ge 1 - \alpha$, i.e., the event $\{x^e_k(t) \in \Omega^e(k),\ t \ge t_0\}$ has a guaranteed probability $1 - \alpha$ for sufficiently large k;
- $\Sigma \circ \mathcal{C}(k)$ is $(\Omega^e, \mathcal{B}^e, \alpha, \beta)$-stable in probability ($\Sigma \circ \mathcal{C}(k)$ is $(\Omega^e, \{0\}, \alpha, 0)$-stable in quadratic mean, respectively).

First, we prove that $J_1(k) = \overline{\omega}(k)$ (resp., $J_2(k)$ achieves its minimum), conditionally to the event $\{x^e_k(t) \in \Omega^e(k),\ t \ge t_0\}$. By (69) and Dynkin's formula, for each $T > t_0$

$$
\begin{aligned}
&\frac{1}{T - t_0} \int_{t_0}^{T} \mathbf{E}\left\{ \sum_{j=1}^{4} \mathcal{P}_j(s, u, x^e_k(s), k) \right\} ds \\
&\qquad = \frac{1}{T - t_0}(V^e_k(x^e_0) - \mathbf{E}\{V^e_k(x^e_k(T))\}) + \overline{\omega}(k) \qquad (70)
\end{aligned}
$$

for all $x^e_0 \in \Omega^e(k)$. From (70), letting $T \to \infty$ and since $\sum_{j=1}^{4} \mathcal{P}_j \ge 0$ by admissibility and $V^e_k \ge 0$, we obtain $0 \le J_1(k) = \overline{\omega}(k)$. If, in addition, $c_j(k) = 0$ for all $j = 1, 2, 3$ and $K(t, x) = 0$ for all t, x, it is easy to see that (70) holds with $\overline{\omega}(k) = 0$.

As a consequence of the above facts, $x_k^e(t)$ being defined for all $t \geq t_0$ a.s., by Dynkin's formula

$$\mathbf{E}\{V_k^e(x_k^e(t))\} - V_k^e(x_0^e) = \int_{t_0}^{t} \mathbf{E}\{\mathcal{L}V_k^e(x_k^e(s))\}ds. \tag{71}$$

Differentiating both sides of (71), taking into account that V_k^e is lower bounded by a quadratic function of x and e, from (61) and (69) we obtain for some sequences $\{\widetilde{\lambda}(k)\}, \{\widetilde{\nu}(k)\}$ of positive numbers

$$\mathbf{E}\{V_k^e(x_k^e(t))\} \leq \widetilde{\lambda}(k)V_k^e(x_0^e)e^{-\widetilde{\nu}(k)(t-t_0)} \tag{72}$$

conditionally to the event $\{x_k^e(t) \in \Omega^e(k),\ t \geq t_0\}$. We conclude that $\mathbf{E}\{V_k^e(x_k^e(t))\} \to 0$ as $t \to \infty$ and $J_2(k) = V_k^e(x_0)$.

Since

$$\mathcal{L}V_k^e + \sum_{j=1}^{4} \mathcal{P}_j \geq 0 \tag{73}$$

for any other $F(k)$ and $G(k)$, we conclude that $J_2(k)$ achieves its minimum with $F(k)$ and $G(k)$ as in (55) and (62), respectively.

Using (69) and (RM), the $(\Omega^e, \mathcal{B}^e, \alpha, \beta)$ stability of $\Sigma \circ \mathcal{C}(k)$ is a consequence of the following lemma, which is proved in the appendix. If, in addition, $c_j = 0$ for all j and $K(t,x) = 0$ for all t and x, from (72) we conclude also the $(\Omega^e, \{0\}, \alpha, 0)$ stability in quadratic mean of $\Sigma \circ \mathcal{C}(k)$. From (124) (see the appendix), we also infer that $\liminf_{k\to\infty} \mathbf{Pr}\{x_k^e(t) \in \Omega^e(k),\ t \geq t_0\} \geq 1 - \alpha$. □

LEMMA 5.1. *The system* (3) *is* $(\Omega^e, \mathcal{B}^e, \alpha, \beta)$*-SP if there exist a sequence of admissible control laws* $\{\mathcal{C}(k)\}$*, a sequence of (at least)* C^2*, positive definite and proper functions* $\{V_k^e(x^e)\}$*, a sequence of* C^0*, positive definite functions* $\{Q_k^e(x^e)\}$*, and open sets* $\{\mathcal{B}^e(k)\}$*,* $\mathcal{B}^e(k) \subset \mathbb{R}^{2n}$*, containing the origin, such that*

(iv) $\liminf_{k\to\infty} \Omega^e(k) \supset \Omega^e \supset \mathcal{B}^e \supseteq \limsup_{k\to\infty} \mathcal{B}^e(k)$ *and* $\Omega^e(k) \supset \mathcal{B}^e(k)$ *for all* k*, where*

$$\Omega^e(k) = \{z \in \mathbb{R}^{2n} : V_k^e(z) \leq k\};$$

(v) $\mathcal{L}V_k^e(x^e) \leq -Q_k^e(x^e)$ *for all* k*,* t*,* $\Phi \in \mathcal{F}(k)$*, and* $x^e \in \Omega^e(k) \backslash \mathcal{B}^e(k)$;

(vi) $\limsup_{k\to\infty} \sup_{x^e \in \Omega^e \backslash \mathcal{B}^e(k)} \frac{V_k^e(x^e)}{k} \leq \alpha$ *and*

$$\limsup_{k\to\infty} \sup_{x^e \in \partial\mathcal{B}^e(k)} \frac{V_k^e(x^e)}{\inf_{z \in \mathbb{R}^{2n} \backslash \overline{\mathcal{B}}_\delta^e} V_k^e(z)} \leq \beta$$

for each $\delta > 0$.

Remark 5.1. We note that, as a consequence of (59), if

$$\limsup_{k\to\infty} \frac{V_k^e(x^e)}{k} = 0 \tag{74}$$

for each x^e, then the risk margin α can be taken to be *any* number in $[0, 1)$ and any a priori given compact set can be included in Ω^e. Thus, condition (74), together with (iv)–(vi) of Lemma 5.1, guarantee *semiglobal stabilization in probability.*

On the other hand, if $\limsup_{k\to\infty} \mathcal{B}^e(k) = \{0\}$, then for each $\delta > 0$

$$\limsup_{k\to\infty} \sup_{x^e \in \partial\mathcal{B}^e(k)} \frac{V_k^e(x^e)}{\inf_{z\in\mathbb{R}^{2n}\setminus\overline{\mathcal{B}}_\delta^e} V_k^e(z)} = 0 \tag{75}$$

and the risk margin β can be taken to be *any* number in $[0, 1)$. Moreover, any a priori given compact set can be chosen as target set, and condition (75) together with (iv)–(vi) of Lemma 5.1 guarantee *practical stabilization in probability*.

Remark 5.2. The proof of Lemma 5.1 is based on a *probabilistic invariance property* which extends to a stochastic setup the following well-known property: if there exists a C^1 proper and positive definite function $V_k^e : \mathbb{R}^{2n} \to \mathbb{R}$ such that, along the trajectories $x_k^e(t, t_0, x_0^e)$ of $\Sigma \circ \mathcal{C}(k)$, $\dot{V}_k^e$ is definite negative on $\Omega^e(k)\backslash\mathcal{B}^e(k)$ and (iv) and (vi) hold, then any trajectory $x_k^e(t, t_0, x_0^e)$ starting from $\Omega^e \subseteq \Omega^e(k)$ stays forever in $\Omega^e(k)$, eventually enters any given δ-neighborhood of $\mathcal{B}^e$ in finite time, and remains therein. In our setting, this invariance property corresponds to an event which occurs with probability at least $(1-\alpha)(1-\beta)$. For the above reasons, α and β can be thought of as *risk margins*. In the deterministic case, (vi) corresponds to a precise geometric property of the level sets of V_k^e for sufficiently large k: one is that Ω^e is contained in $\Omega^e(k)$, and the other is that $\overline{\mathcal{B}}^e(k)$ is contained in some level set of V_k^e which is, in turn, contained in $\overline{\mathcal{B}}_\delta^e$.

Remark 5.3. On the other hand, conditions of Theorem 5.1 ensure that stability in probability in the sense of Definition 4.1 is achieved together with *robust performances* with respect to parameter variations and model uncertainties. Moreover, it is easily seen from the proof that the conditions of Theorem 5.1 guarantee properties (ii) and (iii) of Definition 4.1 to hold *uniformly with respect to* $\Phi \in \mathcal{F}(k)$.

Remark 5.4 (linear case). Consider the class of systems (3) with $H_j(t, x) = H_j x$ and $K_j(t, x) = K_j x$ for all $j = 1, \ldots, s$, x, and t and, in addition, with $\Phi(t, u, x)$ satisfying $\widetilde{\mathcal{P}}_1 \geq 0$ *for all* x, u, and t. Pick admissible $\eta(s) = s$ (i.e., *linear controllers*) and $\varphi(s) = s$ (i.e., *quadratic* Lyapunov functions). With our positions the admissibility constraint $\mathcal{P}_3 > 0$ boils down to the following *matrix inequality*:

$$Q_{SF}(k) > \sum_{j=1}^{s} (H_j - GK_j)^T P_m(k)(H_j - GK_j) \tag{76}$$

(see (22)). This recovers the stabilization results with the optimality of [14] and [1]. Moreover, if $H_j = 0$ and $K_j = 0$ for all j (i.e., deterministic case), then the constraint on $\mathcal{P}_3$ is trivially satisfied (see [2]).

6. Stochastic stabilization with guaranteed cost for feedback linearizable systems. The conditions of Theorem 5.1 do not provide any constructive procedure to find an admissible parametrization with the functions η and φ. In the next two sections, we want to outline algorithms for accomplishing this task for the following class of nonlinear stochastic systems:

$$\begin{aligned} dx &= (Ax + B(u + \Phi(t, u, x)))dt + Bh(t, x)dw, \\ y &= Cx \end{aligned} \tag{77}$$

with (A, B, C) invertible with no invariant zeros and $\Phi(t, u, x)$ and $h(t, x)$ norm-bounded from above by a locally Lipschitz function of x and u, uniformly with respect to t. Moreover, we will assume that $\Phi(t, 0, 0) = 0$ and $h(t, 0) = 0$ for all t. (The cases $\Phi(t, 0, 0) \neq 0$ or $h(t, 0) \neq 0$ can be treated in a similar way with heavier calculations.)

First, we give a *semiglobal in probability backstepping* design procedure for solving the state feedback problem (SF); then we give a recursive procedure to satisfy (OI) and (RM). We remark that Theorem 5.1 still holds if one replaces (54) with

$$\begin{aligned}\mathcal{L}V_{SF} &= \|u - F(k)x\|^2_{R_1(k)} - \gamma^2(k)\|\widetilde{\Phi}\|^2 - \|x\|^2_{Q_{SF}(k)} \\ &\quad - \widetilde{\mathcal{P}}_1(t,u,x,e,k) - \mathcal{P}_2(t,u,x,e,k) + c_1(k) + c_2(k)\end{aligned} \tag{78}$$

and

$$\widetilde{\mathcal{P}}_1(t,u,x,e,k) = -\gamma^2(k)\|\Phi(t,u,x)\|^2 + \|x\|^2_{E(k)} + \|u - \Gamma(k)x\|^2_{R_1(k)} + c_1(k) \tag{79}$$

for some sequence of matrices $\Gamma(k)$ and with $F(k) = -R_1^{-1}(k)B_2^T P_{SF}(k) + \Gamma(k)$. In order to keep the backstepping algorithm as simple as possible, it is convenient to satisfy (78) rather than (54). Moreover, the choice of $\Gamma(k)$ gives an additional flexibility in the optimal control design.

Preliminarly, by [10] there exists a change of coordinates $z = Zx$ such that (77) reads out in the new coordinates

$$\begin{aligned} dz &= [\widehat{A}z + \widehat{B}(u + \Phi(t,u,Z^{-1}z))]dt + Bh(t,Z^{-1}z)dw, \\ y &= \widehat{C}z, \end{aligned} \tag{80}$$

where

$$\widehat{A} = \begin{pmatrix} a_{11} & 1 & 0 & \cdots & 0 & 0 \\ a_{12} & 0 & 1 & \cdots & 0 & 0 \\ \vdots & \vdots & \vdots & \cdots & \vdots & \vdots \\ a_{n-1,1} & 0 & 0 & \cdots & 0 & 1 \\ a_{n1} & a_{n2} & a_{n3} & \cdots & a_{n,n-1} & a_{nn} \end{pmatrix},$$

$$\widehat{B} = \begin{pmatrix} 0 \\ 0 \\ 0 \\ \vdots \\ 0 \\ 1 \end{pmatrix},$$

$$\widehat{C} = (\,1 \quad 0 \quad 0 \quad \cdots \quad 0 \quad 0\,).$$

To simplify notation, we will omit the hats and denote z by x.

6.1. Backstepping design. The main result of the section is the following.

THEOREM 6.1. *The system* (80) *is semiglobally stabilizable in quadratic mean with optimality through a linear state feedback controller.*

As a first step toward the proof of Theorem 6.1, rewrite (80) as

$$d\pi_0 = (A_0\pi_0 + B_0 x_n)dt, \tag{81}$$

$$dx_n = (\widetilde{f}_n(t,u,x) + u)dt + \widetilde{h}_n(t,x)dw \tag{82}$$

with $\pi_0 = \mathrm{col}(x_1,\ldots,x_{n-1})$. We will prove (78) directly on (81)–(82), and this amounts to introducing the following definition.

DEFINITION 6.1. *We will say that*

$$d\pi = (A(k)\pi + B_1(k)\Phi(t,u,\pi) + B_2(k)u)dt + H(t,\pi)dw \tag{83}$$

satisfies the property DI if there exist C^0 *functions* $P_{SF}, Q_{SF} : \mathbb{R}^+ \to \mathcal{SP}^n$, $R_1, \gamma : \mathbb{R}^+ \to \mathbb{R}^+$, $E : \mathbb{R}^+ \to \mathcal{SSP}^n$, *and* $\Gamma : \mathbb{R}^m \times \mathbb{R}^n$ *such that* $\Phi \in \mathcal{F}(k)$, $H \in \mathcal{H}(k)$, *and for all* $\pi \in \Omega(k) = \{\pi \in \mathbb{R}^n : V_{SF}(\pi) \le k\}$, u, *and* t *one has*

$$\|\Phi(t,u,\pi)\|^2 \le \frac{\|\pi\|^2_{E(k)} + \|u - \Gamma(k)\pi\|^2_{R_1(k)}}{\gamma^2(k)} \tag{84}$$

and

$$\begin{aligned} &\mathcal{L}V_{SF} + \|\pi\|^2_{E(k)} + \|u - \Gamma(k)\pi\|^2_{R_1(k)} - \gamma^2(k)\|\Phi(t,u,\pi)\|^2 \\ &- \mathbf{Tr}\{H^T(t,\pi)P_{SF}H(t,\pi)\} + \sum_{j=1}^{r} \pi^T \widehat{H}_j(k) P_{SF} \widehat{H}_j(k)\pi \\ &= -\|\pi\|^2_{Q_{SF}(k)} + \|u - F(k)\pi\|^2_{R_1(k)} - \gamma^2(k)\|\Phi(t,u,\pi) - \frac{1}{\gamma^2(k)} B_1^T(k) P_{SF}(k)\pi\|^2, \end{aligned} \tag{85}$$

where

$$V_{SF}(\pi) = \|\pi\|^2_{P_{SF}(k)}, \tag{86}$$

$$F(k) = -R_1^{-1}(k)B_2^T(k)P_{SF}(k) + \Gamma(k). \tag{87}$$

We have the following result, which roughly states that (81)–(82) satisfies the DI property in some new coordinates π.

LEMMA 6.1. *There exists a* C^0 *function* $\lambda : \mathbb{R}^+ \to (0,1)$ *and a change of coordinates*

$$\begin{aligned} \pi &= \begin{pmatrix} \pi_0 \\ \zeta \end{pmatrix}, \\ \zeta &= \lambda(k)(x_n - F_0\pi_0), \end{aligned} \tag{88}$$

such that (81)–(82) *reads out as*

$$d\pi = (A(k)\pi + B_1(k)\Phi(t,u,\pi) + B_2(k)u)dt + H(t,\pi)dw \tag{89}$$

and satisfies DI, with

$$\begin{aligned} \pi &= \begin{pmatrix} \pi_0 \\ \zeta \end{pmatrix}, \\ \zeta &= \lambda(k)(x_n - F_0\pi_0), \\ F_0 &= -R_0^{-1}B_0^T P_0, \\ A(k) &= \begin{pmatrix} A_0 + B_0F_0 & \dfrac{B_0}{\lambda(k)} \\ -\lambda(k)F_0(A_0 + B_0F_0) & -F_0B_0 \end{pmatrix}, \\ B_1(k) &= \begin{pmatrix} 0 & 0 \\ 0 & 1 \end{pmatrix}, \\ B_2(k) &= \lambda(k)\begin{pmatrix} 0 \\ 1 \end{pmatrix}, \\ H(t,\pi) &= \lambda(k)\begin{pmatrix} 0 \\ \widetilde{h}_n(t, \frac{\zeta}{\lambda(k)} + F_0\pi_0) \end{pmatrix}, \\ \Phi(t,u,\pi) &= \lambda(k)\begin{pmatrix} 0 \\ \widetilde{f}_n(t,u, \frac{\zeta}{\lambda(k)} + F_0\pi_0) \end{pmatrix} \end{aligned} \tag{90}$$

and $R_0 > 0$ *and* $P_0 \in \mathcal{SP}^{n-1}$ *such that*

$$A_0P_0 + P_0A_0^T - P_0B_0R_0^{-1}B_0^TP_0 + I = 0. \tag{91}$$

Proof. For simplicity, throughout the proof and whenever there is no ambiguity, we omit the arguments of the functions involved.

Pick a C^0 function $\widetilde{P} : \mathbb{R}^+ \to (0,1)$ such that $\lim_{k\to\infty} \widetilde{P}(k) = 0$, and define

$$\Omega(k) = \{(v_1, v_2) \in \mathbb{R}^{n-1} \times \mathbb{R} : \|v_1\|^2_{P_0} + \widetilde{P}(k)v_2^2 \le k\}. \tag{92}$$

We have by our assumptions on $\widetilde{h}_n$

$$\|\widetilde{h}_n\|^2 \le 2\left[\|\widetilde{h}_n - \widetilde{h}_n\Big|_{\zeta=0}\|^2 + \|\widetilde{h}_n\Big|_{\zeta=0}\|^2\right] \le \|\pi_0\|^2_{\widetilde{M}(k)} + \widetilde{N}(k)\zeta^2 \tag{93}$$

for all t, π, and u such that $\pi \in \Omega(k)$, where $\widetilde{h}_n|_{\zeta=0}$ denotes $\widetilde{h}_n$ evaluated for $\zeta = 0$ and for some C^0 functions $\widetilde{M} : \mathbb{R}^+ \to \mathcal{SSP}^{n-1}$ and $\widetilde{N} : \mathbb{R}^+ \to \mathbb{R}^{\ge}$. We remark that $\widetilde{M}$ can be chosen as function of P_0 only. Pick $\lambda : \mathbb{R}^+ \to (0,1)$ such that

$$\lambda^2(k)\widetilde{M}(k) < \frac{I}{2}. \tag{94}$$

By the Îto rule

$$d\zeta = (\lambda(k)(\widetilde{f}_n + u - \mathit{\Gamma}(k)\pi)dt + \widetilde{h}d\widetilde{w}), \tag{95}$$

where

$$\mathit{\Gamma}(k) = F_0\left(A_0 + B_0F_0 \qquad \frac{B_0}{\lambda(k)}\right).$$

Find C^0 functions $\widetilde{Q} : \mathbb{R}^+ \to \mathbb{R}^+$, $\gamma : \mathbb{R}^+ \to \mathbb{R}^+$, $\widetilde{R} : \mathbb{R}^+ \to \mathbb{R}^+$, $\widetilde{E}_1 : \mathbb{R}^+ \to \mathbb{R}^{\ge}$, and $\widetilde{E}_2 : \mathbb{R}^+ \to \mathcal{SSP}^{n-1}$ such that

- for all t, π, u such that $\pi \in \Omega(k)$, one has

$$\lambda^2(k)\widetilde{f}_n^2 \le \frac{\zeta^2\widetilde{E}_1(k) + \|\pi_0\|^2_{\widetilde{E}_2(k)} + |u - \mathit{\Gamma}(k)\pi|^2\widetilde{R}(k)}{\gamma^2(k)} \tag{96}$$

and

$$\widetilde{E}_2(k) < \frac{I}{2}; \tag{97}$$

- the following equality holds:

$$\frac{\widetilde{P}^2(k)}{\gamma^2(k)} - \frac{\lambda^2(k)\widetilde{P}^2(k)}{\widetilde{R}(k)} + \widetilde{E}_1(k) + \lambda^2(k)\widetilde{P}(k)\widetilde{N}(k) = -\widetilde{Q}(k) \tag{98}$$

with

$$\widetilde{Q}(k) > \frac{R_0}{\lambda^2(k)}. \tag{99}$$

Let $\widetilde{V}_k(\zeta) = \widetilde{P}(k)\zeta^2$, $\widetilde{F}(k) = -\lambda(k)\widetilde{R}^{-1}(k)\widetilde{P}(k)$. From (98)

$$\begin{aligned}
&\mathcal{L}\widetilde{V}_k + \|\pi_0\|^2_{\widetilde{E}_2(k)} + \zeta^2\widetilde{E}_1(k) + |u - \Gamma(k)\pi|^2\widetilde{R}(k) - \gamma^2(k)\lambda^2(k)\widetilde{f}_n^2 \\
&\quad + \lambda^2\widetilde{P}\left(-\|\widetilde{h}_n\Big|_{x_n=\frac{\zeta}{\lambda(k)}+F_0(k)\pi_0}\|^2 + \|\pi_0\|^2_{\widetilde{M}(k)} + \zeta^2\widetilde{N}(k)\right) \\
&= -\zeta^2\widetilde{Q}(k) + \|\pi_0\|^2_{\widetilde{E}_2(k)+\lambda^2(k)\widetilde{P}(k)\widetilde{M}(k)} + |u - \widetilde{F}(k)\zeta - \Gamma(k)\pi|^2_{\widetilde{R}(k)} \\
&\quad - \gamma^2(k)\left|\lambda(k)\widetilde{f}_n - \frac{1}{\gamma^2(k)}\widetilde{P}(k)\zeta\right|^2. \qquad (100)
\end{aligned}$$

Define

$$P_{SF}(k) = \begin{pmatrix} P_0 & 0 \\ 0 & \widetilde{P}(k) \end{pmatrix}. \qquad (101)$$

With our definitions

$$\mathbf{Tr}\{H^T P_{SF}(k) H\} = \lambda^2(k)\widetilde{P}(k)\|\widetilde{h}_n\Big|_{x_n=\frac{\zeta}{\lambda(k)}+F_0(k)\pi_0}\|^2. \qquad (102)$$

From (91), (94), (97), (99), (100), and (102), with $V_0(\pi_0) = \|\pi_0\|^2_{P_0}$ and $V_{SF}(\pi) = V_0(\pi_0) + \widetilde{P}(k)\zeta^2$, it follows that

$$\begin{aligned}
&\mathcal{L}V_0 + x_n^2 R_0 + \mathcal{L}\widetilde{V}_k + \|\pi_0\|^2_{\widetilde{E}_2(k)} + \zeta^2\widetilde{E}_1(k) + |u - \Gamma(k)\pi|^2\widetilde{R}(k) - \lambda^2(k)\gamma^2(k)\widetilde{f}_n^2 \\
&\quad + \lambda^2\widetilde{P}(-\|\widetilde{h}_n|_{x_n=\frac{\zeta}{\lambda(k)}+F_0(k)\pi_0}\|^2 + \|\pi_0\|^2_{\widetilde{M}(k)} + \zeta^2\widetilde{N}(k)) \\
&= \mathcal{L}V_{SF} + \|\pi\|^2_{E(k)} + |u - \Gamma(k)\pi|^2 R_1(k) - \gamma^2(k)\|\Phi\|^2 \\
&\quad - \mathbf{Tr}\{H^T(t,\pi)P_{SF}H(t,\pi)\} + \sum_{j=1}^{s}\pi^T\widehat{H}_j(k)P_{SF}\widehat{H}_j(k)\pi \\
&= -\|\pi\|^2_{Q_{SF}(k)} + |u - F(k)\pi|^2 R_1(k) - \gamma^2(k)\|\Phi - \frac{1}{\gamma^2(k)}B_1^T(k)P_{SF}(k)\pi\|^2 \qquad (103)
\end{aligned}$$

for a suitably defined $E(k)$, with $R_1(k) = \widetilde{R}(k)$ and

$$\widehat{H}_j(k) = \lambda(k)\begin{pmatrix} P_0^{-\frac{1}{2}}\sqrt{\widetilde{M}(k)\widetilde{P}(k)} & 0 \\ 0 & \sqrt{\widetilde{N}(k)} \end{pmatrix},$$

$$Q_{SF}(k) = \begin{pmatrix} I - \widetilde{E}_2(k) - \lambda^2(k)\widetilde{M}(k)\widetilde{P}(k) & 0 \\ 0 & \widetilde{Q}(k) - \dfrac{R_0}{\lambda^2(k)} \end{pmatrix}. \qquad (104)$$

This proves (85).

Finally, from (93), (96), and (102) it follows that $\widetilde{\mathcal{P}}_1 \geq 0$ and $\mathcal{P}_2 \geq 0$ for all $\pi \in \Omega(k)$. This proves the admissibility of Φ and H. □

We are ready to obtain Theorem 6.1. Note that each $\widetilde{P}(k)$ can be chosen in such a way that

$$\lim_{k\to\infty}\frac{\widetilde{P}(k)}{k} = 0, \qquad (105)$$

which implies

$$\lim_{k\to\infty} \frac{V_{SF}(\pi)}{k} = 0 \tag{106}$$

for each $\pi \in \mathbb{R}^n$. From (103), (106), and Theorem 5.1, with (54) replaced by (78), since $c_j(k) = 0$ for all j so that the sequence $\{\mathcal{B}^e(k)\}$ can be chosen arbitrarily, we conclude that (89) is *semiglobally stabilizable in quadratic mean* with $u = F(k)\pi$. Moreover, by the same arguments used in the proof of Theorem 5.1, it is easy to see that $J_2(k)$, with $u = F(k)\pi$, achieves its minimum (i.e., $J_2(k) = 0$).

Since F_0 is independent of k, (105) is sufficient to conclude also that the original system (80) is *semiglobally stabilizable in quadratic mean with optimality*, which proves Theorem 6.1.

If either $\Phi(t,0,0) \neq 0$ or $h(t,0) \neq 0$, we have the following result, which can be proved as Theorem 6.1.

THEOREM 6.2. *The system* (80) *is semiglobally practically stabilizable in quadratic mean with optimality through a linear state feedback controller.*

6.2. Filter design. In this section, we want to show that, for some admissible parametrization and $(\eta,\varphi) \in \mathcal{D}(k)$, (OI) and (RM) can also be met for (89), i.e., (81)–(82) in the new coordinates π. First, let us prove (OI).

Define

$$\begin{aligned} Q_m(k) &= 2\epsilon^2(k)P_m(k), \\ P_m(k) &= \widetilde{P}_m(\epsilon(k)) \\ &= \operatorname{diag}\{\epsilon^{2(n-1)}(k), \epsilon^{2(n-2)}(k), \dots, 1\} P_1(\epsilon(k)) \operatorname{diag}\{\epsilon^{2(n-1)}(k), \epsilon^{2(n-2)}(k), \dots, 1\}, \end{aligned} \tag{107}$$

where $\epsilon : \mathbb{R}^+ \to \mathbb{R}^+$ is a C^0 function (to be specified later) such that $\lim_{k\to\infty} \epsilon(k) = \infty$.

In what follows, for the sake of simplicity we will omit the argument k when there is no ambiguity. We claim that there exists a C^0 function $\epsilon_1^* : \mathbb{R}^+ \to \mathbb{R}^+$ such that Q_m and P_m, defined in (107), solve (OI) with $R_2 = \frac{\gamma^2}{\epsilon^{2(2n-1)}}$ for all C^0 functions $\epsilon \geq \epsilon_1^*$. Indeed, substituting in (OI), left- and right-multiplying by $\operatorname{diag}\{\epsilon^{-2(n-1)}, \epsilon^{-2(n-2)}, \dots, 1\}$ and dividing both members by ϵ^2, we find out that solving (OI) amounts to satisfying

$$\begin{aligned} &P_1(\epsilon)(J + I + S_1(\epsilon)) + (J + I + S_1(\epsilon))^T P_1(\epsilon) \\ &\qquad - C^T C + \frac{1}{\gamma^2\epsilon^2} P_1(\epsilon) B B^T P_1(\epsilon) + S_2(\epsilon) = 0, \end{aligned} \tag{108}$$

where $S_1, S_2 : \mathbb{R}^+ \to \mathbb{R}^{n\times n}$ are C^0 functions such that $\lim_{\epsilon\to\infty} S_j(\epsilon) = 0$, $j = 1,2$, $S_2(\epsilon)$ is symmetric and positive semidefinite, and

$$J = \begin{pmatrix} 0 & 1 & 0 & \cdots & 0 & 0 \\ 0 & 0 & 1 & \cdots & 0 & 0 \\ \vdots & \vdots & \vdots & \cdots & \vdots & \vdots \\ 0 & 0 & 0 & \cdots & 0 & 1 \\ 0 & 0 & 0 & \cdots & 0 & 0 \end{pmatrix}.$$

It can be shown that there exists $\epsilon_1^* : \mathbb{R}^+ \to \mathbb{R}^+$ such that (108) (and thus (OI)) holds for each $\epsilon \geq \epsilon_1^*$ and for some $P_1(\epsilon) \in \mathcal{SP}^n$. Indeed, since by continuity and for

sufficiently large ϵ $(J+I+S_1(\epsilon), B)$ is controllable and $(C, J+I+S_1(\epsilon))$ is observable, for each sufficiently large ϵ and for some $P_1^0(\epsilon) \in \mathcal{SP}^n$

$$P_1^0(\epsilon)(J+I+S_1(\epsilon))+(J+I+S_1(\epsilon))^T P_1^0(\epsilon)-C^TC+\frac{1}{\gamma^2\epsilon^2}P_1^0(\epsilon)BB^TP_1^0(\epsilon)=0. \tag{109}$$

Moreover, if $\epsilon \to \infty$, then $P_1^0(\epsilon) \to P_1^0(\infty)$. Finally, by standard arguments, for ϵ large enough the existence of some $P_1(\epsilon) \in \mathcal{SP}^n$ satisfying (108) and such that $P_1(\epsilon) > P_1^0(\epsilon)$ and $P_1(\epsilon) \to P_1^0(\infty)$ as $\epsilon \to \infty$ can be shown. This proves (OI).

Next we define an admissible pair (φ, η). Choose $\varphi(s) = \frac{1}{\epsilon}\ln(1+s)$ if $s \geq 0$,

$$\eta(s) = \begin{cases} s & \text{if } |s| \leq M, \\ \dfrac{s}{|s|}M & \text{otherwise,} \end{cases} \tag{110}$$

where $M = \max_{\pi\in\Omega}|F\pi|$, and F and Ω are as in (87) and (92). Note that $\frac{\partial^2\varphi}{\partial s^2} \leq 0 < \frac{\partial\varphi}{\partial s} \leq 1$ for all $s \geq 0$ and the function η is a bounded function, linear near the origin. Moreover, the pair (φ, η) is admissible if there exists a C^0 function $\epsilon_2^* : \mathbb{R}^+ \to \mathbb{R}^+$ such that

$$\mathcal{P}_3 = \frac{2\epsilon^2\|e\|^2_{\widetilde{P}_{m(\epsilon)}} + \|Fe\|^2_{R_1} - \|\widetilde{h}_n\|^2 P_{nn}}{\epsilon(1+\|e\|^2_{\widetilde{P}_{m(\epsilon)}})} - \|\eta(F(\pi-e))+F\pi\|^2_{R_1}+\|\pi\|^2_{Q_{SF}} > 0 \tag{111}$$

for all C^0 functions $\epsilon \geq \epsilon_2^*$ and $(\pi, e) \in (\Omega \times \mathbb{R}^n)\backslash(0,0)$, with P_{nn} being the (n,n) entry (independent of k) of P_m.

In order to prove (111), find a covering $\cup_{j=1}^3 \mathcal{M}_j$ of $\{(\pi, e) \in \Omega \times \mathbb{R}^n\}$, with

$$\begin{aligned} \mathcal{M}_1 &= \left\{(\pi, e) \in \Omega \times \mathbb{R}^n : \|\pi - e\| \leq \vartheta_1;\ \|e\| \leq \frac{\vartheta_1}{2}\right\}, \quad \vartheta_1 > 0, \\ \mathcal{M}_2 &= \{(\pi, e) \in \Omega \times \mathbb{R}^n : \|\pi - e\| \geq \vartheta_1;\ \|e\| \leq \vartheta_2\}, \qquad \vartheta_2 \leq \frac{\vartheta_1}{2}, \\ \mathcal{M}_3 &= \{(\pi, e) \in \Omega \times \mathbb{R}^n : \|e\| \geq \vartheta_2\}, \end{aligned} \tag{112}$$

Pick $\vartheta_1 > 0$ such that $\eta(F(\pi - e)) = F(\pi - e)$ for all $\|\pi - e\| \leq \vartheta_1$.

Note that, since $P_1(\epsilon) \to P_1^0(\infty)$ as $\epsilon \to \infty$, the term $-\frac{\|\widetilde{h}_n\|^2 P_{nn}}{\epsilon(1+\|e\|^2_{\widetilde{P}_{m(\epsilon)}})} + \|\pi\|^2_{Q_{SF}}$ can be rendered positive over the set Ω by choosing ϵ large enough.

First, it is easy to see that there exists a C^0 function $\epsilon_3^* : \mathbb{R}^+ \to \mathbb{R}^+$ such that (111) holds for all C^0 functions $\epsilon \geq \epsilon_3^*$ and $(\pi, e) \in \mathcal{M}_1$.

Moreover, (111) holds for all $(\pi, e) \in \mathcal{M}_2$ for some $\vartheta_2 \leq \frac{\vartheta_1}{2}$ and for all $k > 0$. Indeed, $(0, e) \notin \mathcal{M}_2$ since $\vartheta_1 > \vartheta_2$. Thus we have $\|\pi\|^2_{Q_{SF}} > 0$ on $\mathcal{M}_2$. It follows that for any such π by continuity there exists $e_\pi > 0$ such that (111) holds for all $\|e\| \leq e_\pi$ and for all C^0 functions $\epsilon \geq \epsilon_3^*$. Since $\mathcal{O} = \{\pi \in \Omega : \|\pi\| \geq \frac{\vartheta_1}{2}\}$ is compact and $\vartheta_1 > 0$, one can take $\vartheta_2 = \min\{\frac{\vartheta_1}{2}, \min_{\pi\in\mathcal{O}} e_\pi\}$.

We are left with proving that there exists $\epsilon_4^* : \mathbb{R}^+ \to \mathbb{R}^+$ such that (111) holds for all $(\pi, e) \in \mathcal{M}_3$ and for all C^0 functions $\epsilon \geq \epsilon_4^*$. On the other hand, this readily follows by the boundedness of η and since

$$\lim_{\epsilon\to\infty} \inf_{\|e\|\geq\vartheta_2} \frac{\epsilon\|e\|^2_{\widetilde{P}_{m(\epsilon)}}}{1+\|e\|^2_{\widetilde{P}_{m(\epsilon)}}} = \infty. \tag{113}$$

Pick $\epsilon_2^* \geq \max\{\epsilon_3^*, \epsilon_4^*\}$.

By similar arguments (111) can be satisfied in such a way that its left-hand part of (111) is lower bounded by a quadratic function of π and e.

Finally, we will show how to satisfy (RM). Since

$$\lim_{s\to 0} s \ln s^{-r} = 0 \quad \forall r \geq 0$$

by (106) and the definition of $P_m(k)$, there exists a C^0 function $\epsilon_5^* : \mathbb{R}^+ \to \mathbb{R}^+$ such that for all C^0 functions $\epsilon \geq \epsilon_5^*$

$$\lim_{k\to\infty} \frac{\|\pi\|^2_{P_{SF}(k)} + \dfrac{1}{\epsilon(k)} \ln(1 + \|e\|^2_{\widetilde{P}_m(\epsilon(k))})}{k} = 0 \tag{114}$$

for each $(\pi, e) \in \mathbb{R}^{2n}$, which proves (59). On the other hand, by properly choosing the sequence $\{\mathcal{B}^e(k)\}$, we can also satisfy (60). Moreover, since $\mathcal{P}_3$ is lower bounded by a quadratic function of π and e, (61) also holds true.

We conclude that (OI)–(RM) hold as long as $\epsilon : \mathbb{R}^+ \to \mathbb{R}^+$ is any C^0 function such that $\epsilon \geq \max\{\epsilon_1^*, \epsilon_2^*, \epsilon_5^*\}$. By using Theorem 6.1, with (54) replaced by (78), and the above results and since (77) can be put in the form of (80) after a linear change of coordinates, we obtain the following theorem.

THEOREM 6.3. *Any system* (77) *is semiglobally stabilizable in quadratic mean with optimality.*

If either $\Phi(t, 0, 0) \neq 0$ or $h(t, 0) \neq 0$, we have the following result, which can be proved as Theorem 6.3.

THEOREM 6.4. *Any system* (77) *is semiglobally practically stabilizable in quadratic mean with optimality.*

To conclude we will perform the main calculations for obtaining a stabilizing controller for the system (33). Pick $0 < P_0, \widetilde{P}(k) < 1$, $\lim_{k\to\infty} \frac{\widetilde{P}(k)}{k} = 0$, and $R_0 = P_0^2$, and define $\Omega(k) = \{(x_1, \zeta_2) : P_0 x_1^2 + \widetilde{P}(k)\zeta_2^2 \leq k\}$. Let $\widetilde{N}(k) = 0$, $\widetilde{M}(k) = \frac{k^2}{P_0^2}$, and choose $\lambda(k)$ such that $\frac{\lambda^2(k)k^2}{P_0^2} < \frac{1}{2}$. Define $\Gamma(k) = -\frac{P_0}{R_0}(-\frac{P_0}{R_0} \ \ \frac{1}{\lambda(k)})$. Moreover, let

$$\begin{aligned} \widetilde{E}_1(k) &= 8\gamma^2(k)k^2 \left(\frac{1}{\lambda^2(k)\widetilde{P}(k)} + \frac{P_0}{R_0^2}\right)^2, \\ \widetilde{E}_2(k) &= \frac{8\gamma^2(k)k^2 P_0^2 \lambda^2(k)}{R_0^2} \left(\frac{1}{\lambda^2(k)\widetilde{P}(k)} + \frac{P_0}{R_0^2}\right)^2, \end{aligned} \tag{115}$$

and $\gamma(k) > 0$ be such that $\widetilde{E}_2(k) < \frac{1}{2}$. Also, let $\widetilde{Q}(k), \widetilde{R}(k) > 0$ such that

$$\begin{aligned} \frac{\widetilde{P}^2}{\gamma^2(k)} - \frac{\lambda^2(k)\widetilde{P}^2(k)}{\widetilde{R}(k)} + \widetilde{E}_1(k) &= -\widetilde{Q}(k), \\ \widetilde{Q}(k) &> \frac{R_0}{\lambda^2(k)}. \end{aligned} \tag{116}$$

Moreover, both P_0 and $\widetilde{P}$ can be chosen in such a way that $\Omega(k)$ (and the region of attraction of the system in the original coordinates) contains an a priori given compact set. This concludes the backstepping design. As to the filter design, let $\epsilon(k) > 0$ be

such that $(J+S_1(\epsilon(k))+I, \binom{0}{1})$ is controllable, $((1 \quad 0), J+S_1(\epsilon(k))+I)$ is observable, $-\left(\begin{smallmatrix}1 & 0\\ 0 & 1\end{smallmatrix}\right) + S_2(\epsilon(k)) < 0$, and, correspondingly, find $P_1 \in \mathcal{SP}^2$ such that

$$\begin{aligned} &P_1(J + S_1(\epsilon(k)) + I) + (J + S_1(\epsilon(k)) + I)^T P_1 \\ &\qquad - \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} + \frac{1}{\gamma^2(k)\epsilon^2(k)} P_1 \begin{pmatrix} 0 & 0 \\ 0 & 1 \end{pmatrix} P_1 + S_2(\epsilon(k)) = 0, \end{aligned} \tag{117}$$

where

$$S_1(\epsilon(k)) = \frac{1}{\epsilon^2(k)} \left[\begin{pmatrix} F^2(k) & 0 \\ -\dfrac{\lambda(k)F^2(k)}{\epsilon^2(k)} & -\dfrac{F(k)}{\lambda^2(k)} \end{pmatrix} + \frac{1}{\gamma^2(k)} \begin{pmatrix} 0 & 0 \\ 0 & \widetilde{P}(k) \end{pmatrix} \right],$$

$$S_2(\epsilon(k)) = \frac{1}{\epsilon^2(k)} \begin{pmatrix} \dfrac{1}{\epsilon^2(k)} & 0 \\ 0 & 1 \end{pmatrix} F^T(k) \widetilde{R}(k) F(k) \begin{pmatrix} \dfrac{1}{\epsilon^2(k)} & 0 \\ 0 & 1 \end{pmatrix}, \tag{118}$$

and $F(k) = -\frac{P_0}{R_0} + \Gamma(k)$. Finally, $\epsilon(k)$ can be chosen at the same time in such a way to satisfy (111), as pointed out above.

Appendix.

Proof of Lemma 5.1. Throughout the proof, $\tau_{\mathcal{S}}(t) = \min\{t, \tau_{\mathcal{S}}\}$, where $\tau_{\mathcal{S}}$ is the Markov time (relative to the σ-algebra generated by $\{x_k^e(s), s \le t\}$) defined as the first time at which the trajectory of (3) reaches the boundary of $\mathcal{S}$. By (iv) we can assume $k \ge k^*$, with k^* such that $\Omega^e(k) \supseteq \Omega^e$ for all $k \ge k^*$, and we fix any $\Phi \in \mathcal{D}_\Xi$.

We have to show only (ii) and (iii) of Definition 4.1. As a consequence of Dynkin's formula (with $\mathcal{Z} = \Omega^e(k) \backslash \mathcal{B}^e(k)$ and $T = \infty$), since $\mathcal{L}V_k^e$ is negative definite on $\Omega^e(k) \backslash \mathcal{B}^e(k)$,

$$\mathbf{E}\{V_k^e(x_k^e(\tau_{\Omega^e(k)\backslash\mathcal{B}^e(k)}(t), t_0, x_0^e))\} \le V_k^e(x_0^e) \tag{119}$$

for all $x_0^e \in \partial\mathcal{B}^e(k)$. By (iv) for each $\delta > 0$ there exists k° such that $\mathcal{B}_\delta^e \supset \mathcal{B}^e(k)$. By the Čebyšev inequality (with $\mathcal{S} = \overline{\mathcal{B}}_\delta^e$, $\eta = x_k^e(\tau_{\Omega^e(k)\backslash\mathcal{B}^e(k)}(r), t_0, x_0^e)$, $r \ge t_0$ ranging over the rationals, and $V = V_k^e$), (119), and (v) we have

$$\mathbf{P}\{x_k^e(r, t_0, x_0^e) \notin \overline{\mathcal{B}}_\delta^e \text{ for some rational } r \ge t_0\} \le \frac{V_k^e(x_0^e)}{\inf_{z \in \mathbb{R}^{2n} \backslash \overline{\mathcal{B}}_\delta^e} V_k^e(z)} \tag{120}$$

for all $k \ge k^\circ$ and $x_0^e \in \partial\mathcal{B}^e(k)$. Since, by $\mathcal{B}^e(k) \subset \mathcal{B}_\delta^e$ for all $k \ge k^\circ$,

$$\mathbf{P}\{x_k^e(r, t_0, x_0^e) \notin \overline{\mathcal{B}}_\delta^e \text{ for some rational } r \in [t_0, \tau_{\mathcal{B}^e(k)})\} = 0$$

for all $k \ge k^\circ$ and $x_0^e \in \mathcal{B}^e(k)$, by (vi) and the continuity of $x_k^e(t, \cdot, \cdot)$, we conclude (ii) of Definition 4.1.

To prove (iii) we implicitly assume that $x_0^e \in \Omega^e \backslash \mathcal{B}^e(k)$. First, we prove

$$\mathbf{P}\{\tau_{\Omega^e(k)\backslash\mathcal{B}^e(k)} < \infty\} = 1 \tag{121}$$

in the case that $x_k^e(t, t_0, x_0^e)$ is regular since otherwise it is trivially true. Since $Q_k^e(x^e)$ is continuous on its domain, we have $\mathcal{L}V_k^e \le -\nu(k) < 0$ for all $x^e \in \Omega^e(k) \backslash \mathcal{B}^e(k)$ and for some $\nu(k) > 0$. Directly from Dynkin's formula (with $\mathcal{Z} = \Omega^e(k) \backslash \mathcal{B}^e(k)$ and $T = \infty$) we obtain

$$\nu(k)\mathbf{E}\{\tau_{\Omega^e(k)\backslash\mathcal{B}^e(k)}(t) - t_0\} \le V_k^e(x_0^e). \tag{122}$$

Thus, by the Čebyšev inequality (with $\mathcal{S} = \mathbb{R}^{2n}\backslash(\Omega^e(k)\backslash\mathcal{B}^e(k))$, $\eta = x_k^e(\tau_{\Omega^e(k)\backslash\mathcal{B}^e(k)}(r), t_0, x_0^e)$, with $r \geq t_0$ ranging over the rationals, and $V(\eta) = \tau_{\Omega^e(k)\backslash\mathcal{B}^e(k)} - t_0$),

$$\mathbf{P}\{\tau_{\Omega^e(k)\backslash\mathcal{B}^e(k)} \geq r\} \leq \frac{V_k^e(x_0^e)}{\nu(k)(r-t_0)}. \tag{123}$$

Since $\frac{V_k^e(x_0^e)}{\nu(k)(r-t_0)} \to 0$ as $r \to \infty$, from (123) and the (sequential) continuity of $\mathbf{Pr}\{\cdot\}$, we obtain (121).

Next we show that

$$\liminf_{k\to\infty} \inf_{x_0^e \in \Omega^e\backslash\mathcal{B}^e(k)} \mathbf{P}\{\tau_{\mathbb{R}^{2n}\backslash\mathcal{B}^e(k)} < \tau_{\Omega^e(k)}\} \geq 1-\alpha. \tag{124}$$

From Dynkin's formula (with $\mathcal{Z}$ and T as above) and since $\mathcal{L}V_k^e$ is negative definite on $\Omega^e(k)\backslash\mathcal{B}^e(k)$, it follows that

$$\mathbf{E}\{V_k^e(x_k^e(\tau_{\Omega^e(k)\backslash\mathcal{B}^e(k)}(t), t_0, x_0^e))\} \leq V_k^e(x_0^e). \tag{125}$$

By (121)

$$\tau_{\Omega^e(k)\backslash\mathcal{B}^e(k)}(t) = \tau_{\Omega^e(k)\backslash\mathcal{B}^e(k)} \quad \text{a.s.} \tag{126}$$

From (14) and (125)

$$\mathbf{P}\{\tau_{\mathbb{R}^{2n}\backslash\mathcal{B}^e(k)} > \tau_{\Omega^e(k)}\} \leq \mathbf{P}\left\{\frac{V_k^e(x_k^e(\tau_{\Omega^e(k)\backslash\mathcal{B}^e(k)}, t_0, x_0^e))}{k} \geq 1\right\} \leq \frac{V_k^e(x_0^e)}{k}. \tag{127}$$

By (127) and since $\limsup_{k\to\infty} \sup_{x_0^e\in\Omega^e\backslash\mathcal{B}^e(k)} \frac{V_k^e(x_0^e)}{k} \leq \alpha$ by (vi), we get

$$\limsup_{k\to\infty} \sup_{x_0^e \in \Omega^e\backslash\mathcal{B}^e(k)} \mathbf{P}\{\tau_{\mathbb{R}^{2n}\backslash\mathcal{B}^e(k)} > \tau_{\Omega^e(k)}\} \leq \alpha. \tag{128}$$

By the continuity of $x_k^e(t,\cdot,\cdot)$ and since $\mathcal{B}^e(k) \subset \Omega^e(k)$, $\mathbf{P}\{\tau_{\mathbb{R}^{2n}\backslash\mathcal{B}^e(k)} = \tau_{\Omega^e(k)}\} = 0$, which along with (128) implies (124).

By (120) and (vi) and using the continuity of $x_k^e(t,\cdot,\cdot)$, for each $\epsilon, \delta > 0$ there exists k° such that $\mathcal{B}_\delta^e \supset \mathcal{B}^e(k)$ and

$$\mathbf{P}\{x_k^e(t,s,z) \notin \overline{\mathcal{B}}_\delta^e \text{ for some } t \geq s\} < \beta + \epsilon \tag{129}$$

for all $k \geq k^\circ$ and $z \in \partial\mathcal{B}^e(k)$.

Finally, let $\mathcal{F}(\Omega^e(k), \mathcal{B}^e(k))$ denote the σ-algebra generated by the events $\{x_k^e(r, t_0, x_0^e) \in \Omega^e(k), r \leq \tau_{\mathbb{R}^{2n}\backslash\mathcal{B}^e(k)}\}$. Since $\mathcal{F}(\Omega^e(k), \mathcal{B}^e(k))$ is a sub-σ-algebra of the one generated by $\{x_k^e(r, t_0, x_0^e), r \leq \tau_{\mathbb{R}^{2n}\backslash\mathcal{B}^e(k)}\}$ and by the strong Markov property, for each $\epsilon, \delta > 0$ and for all $k \geq k^\circ$

$$\begin{aligned}
&\mathbf{P}\{x_k^e(t + \tau_{\mathbb{R}^{2n}\backslash\mathcal{B}^e(k)}, t_0, x_0^e) \notin \overline{\mathcal{B}}_\delta^e \text{ for some } t \geq 0 | \mathcal{F}(\Omega^e(k), \mathcal{B}^e(k))\} \\
&\quad = \int_{t_0}^{\infty} \int_{z\in\partial\mathcal{B}^e(k)} (\mathbf{P}\{\tau_{\mathbb{R}^{2n}\backslash\mathcal{B}^e(k)} \in ds;\ x_k^e(\tau_{\mathbb{R}^{2n}\backslash\mathcal{B}^e(k)}, t_0, x_0^e) \in dz | \mathcal{F}(\Omega^e(k), \mathcal{B}^e(k))\} \\
&\quad \cdot \mathbf{P}\{x_k^e(t,s,z) \notin \overline{\mathcal{B}}_\delta^e \text{ for some } t \in [s,\infty) | \mathcal{F}(\Omega^e(k), \mathcal{B}^e(k))\}) < \beta + \epsilon,
\end{aligned} \tag{130}$$

which implies for each $\delta > 0$

$$\liminf_{k\to\infty} \inf_{x_0^e\in\Omega^e\backslash\mathcal{B}^e(k)} \mathbf{P}\{x_k^e(t+\tau_{\mathbb{R}^{2n}\backslash\mathcal{B}^e(k)}, t_0, x_0^e) \in \overline{\mathcal{B}}_\delta^e\ \forall t \geq 0 | \mathcal{F}(\Omega^e(k), \mathcal{B}^e(k))\} \geq 1-\beta. \tag{131}$$

Property (iii) of Definition 4.1 follows directly from (121), (131), (124), and the Bayes formula. □

LINEAR PROGRAMMING FORMULATION FOR OPTIMAL STOPPING PROBLEMS*

MOON JUNG CHO† AND RICHARD H. STOCKBRIDGE†

Abstract. Optimal stopping problems for continuous time Markov processes are shown to be equivalent to infinite-dimensional linear programs over a space of pairs of measures under very general conditions. The measures involved represent the joint distribution of the stopping time and stopping location and the occupation measure of the process until it is stopped. These measures satisfy an identity for each function in the domain of the generator which is sufficient to characterize the stochastic process. Finite-dimensional linear programs obtained using Markov chain approximations are solved in two examples to illustrate the numerical accuracy of the linear programming formulation.

Key words. linear programming, optimal stopping, occupation measures

1. Introduction.

This paper establishes an infinite-dimensional linear programming formulation for problems in optimal stopping. In general terms, a decision maker observes a process X and decides the time τ at which to stop it. The person receives a reward $R(x)$ when the process is stopped in state x, i.e., when $X(\tau) = x$. The goal of the decision maker is to select a stopping rule which maximizes the expected reward $E[R(X(\tau))]$.

American options provide one set of examples of optimal stopping problems. For an American option, the person has the right to exercise the option at any time during the contract period, that is, up until its time of expiration. Thus the owner of the option must decide when to exercise his or her option.

Another example of optimal stopping in the area of finance is the decision about when to sell stock. Suppose a person must liquidate his or her holdings by a certain date. This person must then choose the time to sell. Of course, the goal in this setting is to try to choose the time when the stock is at its highest level for the entire period. A formulation of this problem has been studied by Shiryaev [13].

Optimal stopping has been well studied, and the value function has been characterized in terms of the minimal excessive function lying above the reward function (see, e.g., the text by Shiryaev [12]). This paper adopts a linear programming formulation for optimal stopping problems. This approach has the benefit that numerical solution is often easy to obtain since there are excellent linear programming software packages available.

The main contribution is that the paper establishes an equivalence between the stochastic process formulation and the linear programming formulation. It also indicates an equivalence between optimal stopping and control problems. In addition, this paper presents two examples to illustrate the effectiveness of linear programming as a numerical solution technique. The optimal stopping linear programs are

infinite-dimensional. It is thus necessary to approximate these by finite-dimensional linear programs. In this paper, we adopt a discretization approach to the general state space processes and approximate the continuous time stochastic processes by continuous time Markov chains (see Kushner and Dupuis [9]).

This work extends to optimal stopping problems similar types of infinite-dimensional linear programming formulations for stochastic control and Markov decision problems (see, e.g., Bhatt and Borkar [1], Hernández-Lerma and Lasserre [6], Helmes and Stockbridge [4], Helmes, Röhl, and Stockbridge [5], Kurtz and Stockbridge [8], and Mendiondo and Stockbridge [11]). In particular, the papers [4, 5, 11] demonstrate the accuracy of the linear programming approach for the numerical analysis of controlled and uncontrolled processes.

The paper is organized as follows. We give the stochastic process formulation in section 2 and identify the linear programming form of the problem in section 2.1. Section 3 proves equivalence between these forms, section 4 discusses convergence of finite-dimensional approximation schemes, and the linear programming method is illustrated in examples in section 5.

2. Formulation. We formulate the optimal stopping problem in a very general setting by assuming the state space E is a complete, separable metric space. We will augment the state space with extra components for time and control processes. Note that the augmented spaces will still be complete, separable metric spaces. We therefore define the notation used in this paper for a complete, separable metric space S. Let $M(S)$ denote the space of Borel measurable functions on S, let $C(S)$ denote the space of continuous functions on S, let $\overline{C}(S)$ denote the space of bounded, continuous functions on S, let $\mathcal{M}(S)$ denote the space of finite Borel measures on S, and let $\mathcal{P}(S) \subset \mathcal{M}(S)$ denote the collection of probability measures on S. For a Borel set $\Gamma \subset S$, we define $I_\Gamma \in M(S)$ to be the indicator function of the set Γ, and, for a point $s \in S$, we define $\delta_{\{s\}}(\cdot) \in \mathcal{M}(S)$ to be the Borel measure which places a unit point mass at $\{s\}$.

The processes under consideration are characterized as solutions to a martingale problem for their generator; that is, suppose A is the generator for a Markov process X with state space E, where X is related to A by the requirement that

$$f(X(t)) - f(X(0)) - \int_0^t Af(X(s))ds \tag{1}$$

be a martingale for each $f \in \mathcal{D}$, the domain of A. This characterization was developed by Stroock and Varadhan [14, 15, 16] for multidimensional diffusion processes and has been studied by many authors. Ethier and Kurtz [3] provide an excellent reference for general Markov processes.

We assume that the generator A has the following properties.

Condition 1.

(i) $A : \mathcal{D} \subset \overline{C}(E) \to C(E)$, $1 \in \mathcal{D}$, and $A1 = 0$.

(ii) $\mathcal{D}$ is closed under multiplication and separates points.

(iii) The graph of A is *separable* in the sense that there exists a countable collection $\{g_k\} \subset \mathcal{D}$ such that $\{(f, Af) : f \in \mathcal{D}\}$ is contained in the bounded, pointwise closure of the linear span of $\{(g_k, Ag_k) : k \geq 1\}$.

Let $\nu_0 \in \mathcal{P}(E)$ denote the initial distribution of the desired processes. We say a process $X = \{X(t) : t \geq 0\}$ is a solution of the martingale problem for (A, ν_0) if there

exists a filtration $\{\mathcal{F}_t\}$ such that $X(0)$ has distribution ν_0, X is $\{\mathcal{F}_t\}$-progressively measurable, and (1) is an $\{\mathcal{F}_t\}$-martingale for every $f \in \mathcal{D}$.

The reward obtained when the process stops is given by the function $R : E \to \mathbb{R}$. We assume that R is upper-semicontinuous and bounded above. The objective of the decision maker is to maximize

$$E[R(X(\tau))] \tag{2}$$

over all $\{\mathcal{F}_t\}$-stopping times τ. We require

$$E[\tau] < \infty, \tag{3}$$

which implies $\tau < \infty$ a.s.

2.1. Linear programming formulation. Let X be a solution of the martingale problem for (A, ν_0). It then follows that, for each $\gamma \in \widehat{C}^1(\mathbb{R}^+)$, $\widehat{C}^1(\mathbb{R}^+)$ being the space of continuously differentiable functions which vanish at ∞, and each test function $f \in \mathcal{D}$,

$$\gamma(t)f(X(t)) - \int_0^t [\gamma(s)Af(X(s)) + \gamma'(s)f(X(s))]ds \tag{4}$$

is an $\{\mathcal{F}_t\}$-martingale (see [3, Theorem 4.7.1]). To simplify notation, define

$$\widehat{A}(\gamma f)(t,x) = \gamma(t)Af(x) + \gamma'(t)f(x),$$

and let $\widehat{\mathcal{D}} = \{\gamma f : \gamma \in \widehat{C}^1(\mathbb{R}^+), f \in \mathcal{D}\}$.

Now let τ be any stopping time satisfying (3). Since (4) is an $\{\mathcal{F}_t\}$-martingale, the optional sampling theorem (see [3]) implies that

$$E\left[\gamma(\tau)f(X(\tau)) - \int_0^\tau \widehat{A}(\gamma f)(s, X(s))ds \,\middle|\, \mathcal{F}_0\right] = \gamma(0)f(X(0)), \tag{5}$$

and hence

$$E\left[\gamma(\tau)f(X(\tau)) - \int_0^\tau \widehat{A}(\gamma f)(s, X(s))ds\right] = \gamma(0)E[f(X(0))] \tag{6}$$

for each $\gamma f \in \widehat{\mathcal{D}}$.

Now let the measure $\mu_\tau \in \mathcal{P}(\mathbb{R}^+ \times E)$ be the joint distribution of $(\tau, X(\tau))$, and define the occupation measure $\mu_0 \in \mathcal{M}(\mathbb{R}^+ \times E)$ by

$$\mu_0(\Gamma) = E\left[\int_0^\tau I_\Gamma(s, X(s))ds\right] \quad \forall\, \Gamma \in \mathcal{B}(\mathbb{R}^+ \times E). \tag{7}$$

Note that $\mu_0(\mathbb{R}^+ \times E) = E[\tau] < \infty$. Then (6) can be rewritten, for each $\gamma f \in \widehat{\mathcal{D}}$, as

$$\int \gamma(t)f(x)\mu_\tau(dt \times dx) - \int \widehat{A}(\gamma f)(t,x)\mu_0(dt \times dx) = \gamma(0)\int f(x)\nu_0(dx). \tag{8}$$

Thus for each X and τ there are measures μ_τ and μ_0 satisfying (8) for all $\gamma f \in \widehat{\mathcal{D}}$.

We will show that for each pair of measures (μ_τ, μ_0) satisfying the conditions (8) there are a corresponding process X and a stopping time τ for which X is a solution of the martingale problem for (A, ν_0) up to time τ, and μ_τ and μ_0 are the joint distribution and occupation measures, respectively. The optimal stopping problem can thus be reformulated as the following infinite-dimensional linear programming problem over the space of pairs of measures:

$$
\begin{aligned}
&\text{Max} \int R(x)\mu_\tau(dt \times dx) \\
&\text{S.t.} \int \gamma f d\mu_\tau - \int \widehat{A}(\gamma f) d\mu_0 = \gamma(0) \int f d\nu_0 \qquad \forall\, \gamma f \in \widehat{\mathcal{D}}, \\
&\mu_\tau \in \mathcal{P}(\mathbb{R}^+ \times E),\ \mu_0 \in \mathcal{M}(\mathbb{R}^+ \times E).
\end{aligned} \tag{9}
$$

3. Existence result. Section 2.1 showed that to each solution X of the martingale problem for (A, ν_0) and stopping time τ satisfying (3) there corresponds a pair of measures (μ_τ, μ_0) satisfying (8). We now establish the reverse correspondence.

The approach taken to establish this existence result is to define a new generator $\overline{A}$ for a *controlled* process having two time components, one spatial component, and one control component (u). The generator $\overline{A}$ involves the choice between the spatial dynamics specified by A and a process in which the spatial component is fixed until a random time at which the process is "restarted." One time component tracks the time in which the process having generator A runs, and the other measures the time in which the process is fixed until it restarts. We then define a stationary measure for the generator $\overline{A}$ and use an existence result of Bhatt and Borkar [1] to obtain a stationary (three-dimensional) process having generator $\overline{A}$. A new process is defined by (pathwise) starting the stationary process at a time that the process restarts (thus losing stationarity). The stopping time τ is then the time at which the control switches away from the generator A, and a change of measure ensures that the process restricted to one "cycle" has the desired dynamics.

For completeness, we state the existence result of Bhatt and Borkar using our notation (see [1, Theorem 2.1 and Corollary 2.1]). We refer the reader to the reference for the necessary modification of Condition 1 to incorporate controls in the formulation. We also restate a technical lemma of Kurtz and Stockbridge (see [8, Lemma 4.4]) which is used to establish the behavior of the stationary process.

THEOREM 3.1. *Let S be a complete, separable metric space, and let U be a compact metric space. Suppose the generator $A : \mathcal{D}(A) \subset \overline{C}(S) \to C(S \times U)$. Suppose $\mu \in \mathcal{P}(S \times U)$ is such that*

$$\int_{S \times U} Af(y,u)\, \mu(dy \times du) = 0 \qquad \forall f \in \mathcal{D}(A).$$

Let η be the regular conditional distribution of u given y under μ, so η satisfies $\mu(dy \times du) = \eta(y, du)\mu(dy \times U)$. Then there exists a stationary process Y such that

$$f(Y(t)) - \int_0^t \int_U Af(Y(s), u)\eta(Y(s), du)ds$$

is an $\{\mathcal{F}_t^Y\}$*-martingale for each* $f \in \mathcal{D}(A)$*, and*

$$E\left[\int_U I_\Gamma(Y(s),u)\eta(Y(s),du)\right] = \mu(\Gamma) \qquad \forall\, \Gamma \in \mathcal{B}(E\times U).$$

LEMMA 3.2. *Let* Q *be a nonnegative,* $\{\mathcal{F}_t\}$*-adapted cadlag process, let* V_1 *and* V_2 *be bounded, nonnegative, measurable,* $\{\mathcal{F}_t\}$*-adapted processes, and suppose that*

$$g(Q(t)) - \int_0^t (V_1(s)g'(Q(s)) + V_2(s)(g(0) - g(Q(s)))) \, ds$$

is an $\{\mathcal{F}_t\}$*-martingale for every* C^1 *function* g *with* g *and* g' *bounded. Let* τ *be a stopping time, and define* $\sigma_0^\tau = \inf\{t > \tau : Q(t) > 0\}$ *and* $\sigma_1^\tau = \int\{t > \sigma_0^\tau : Q(t) = 0\}$*. Then, for* $\tau \le t < \sigma_1^\tau$*,* $Q(t) - Q(\tau) = \int_\tau^t V_1(s)\, ds$*, and if* $\sigma_1^\tau < \infty$ *a.s.,*

$$P\left\{\int_{\sigma_0^\tau}^{\sigma_1^\tau} V_2(s)\, ds > x | \mathcal{F}_{\sigma_0^\tau}\right\} = e^{-x}, \qquad x \ge 0.$$

The main result is given in the next theorem. The proof of this result follows the proof of a similar result in Kurtz and Stockbridge (see [8, Theorem 4.5]).

THEOREM 3.3. *Suppose* $\mu_\tau \in \mathcal{P}(\mathbb{R}^+ \times E)$ *and* $\mu_0 \in \mathcal{M}(\mathbb{R}^+ \times E)$ *satisfy* (8)*. Then there exist a filtration* $\{\mathcal{F}_t\}$*, a process* X*, and an* $\{\mathcal{F}_t\}$*-stopping time* τ *such that* X *is a solution of the martingale problem for* (A, ν_0) *up to time* τ*,* $(\tau, X(\tau))$ *has distribution* μ_τ*, and the occupation measure of* X *up to time* τ*, defined in* (7)*, is* μ_0*.*

Proof. Augment the state space with an extra time dimension and the space $U = \{0,1\}$, which we refer to as the ("bang-bang") control space. Define a new generator $\overline{A}$ by

(10)
$$\begin{aligned}\overline{A}(\beta\gamma f)(r,s,x,u) &= u\beta(r)\widehat{A}(\gamma f)(s,x)\\ &\quad + (1-u)\left[\beta(0)\gamma(0)\int f d\nu_0 - \beta(r)\gamma(s)f(x) + \beta'(r)\gamma(s)f(x)\right]\end{aligned}$$

for each $\beta, \gamma \in \widehat{C}^1(\mathbb{R}^+)$ and $f \in \mathcal{D}$.

Define the measure $\overline{\mu} \in \mathcal{P}(\mathbb{R}^+ \times \mathbb{R}^+ \times E \times \{0,1\})$, which satisfies

(11)
$$\begin{aligned}\int h(r,s,x,u)\overline{\mu}(dr\times ds\times dx\times du) &= K^{-1}\left(\int_{\mathbb{R}^+\times E} h(0,s,x,1)\mu_0(ds\times dx)\right.\\ &\quad \left. + \int_{\mathbb{R}^+\times E}\int_0^\infty e^{-r}h(r,s,x,0)dr\mu_\tau(ds\times dx)\right)\end{aligned}$$

for each bounded, continuous h, where $K = \mu_0(\mathbb{R}^+\times E)+1$. Note that the conditional distribution of u given (r,s,x) under $\overline{\mu}$ is

$$\overline{\eta}(r,s,x,du) = \delta_{\{1\}}(du)I_{\{0\}}(r)\frac{d\mu_0}{d\overline{\mu}}(s,x) + \delta_{\{0\}}(du)e^{-r}I_{(0,\infty)}(r)\frac{d\mu_\tau}{d\overline{\mu}}(s,x). \tag{12}$$

The following computation shows that $\int \overline{A}(\beta\gamma f)d\overline{\mu} = 0$ for all $\beta, \gamma \in \widehat{C}^1(\mathbb{R}^+)$, and $f \in \mathcal{D}$.

$$\begin{aligned}
&\int \overline{A}(\beta\gamma f)(r,s,x,u)\overline{\mu}(dr \times ds \times dx \times du)\\
&\quad = K^{-1}\left(\int 1\cdot\beta(0)\widehat{A}(\gamma f)(s,x)\mu_0(ds\times dx)\right.\\
&\qquad\quad + \int_{\mathbb{R}^+\times E}\int_0^\infty e^{-r}(-\beta(r)+\beta'(r))\gamma(s)f(x)\,dr\mu_\tau(ds\times dx)\\
&\qquad\quad \left. + \beta(0)\gamma(0)\int f d\nu_0\right)\\
&\quad = K^{-1}\left(\int \beta(0)\widehat{A}(\gamma f)(s,x)\mu_0(ds\times dx)\right.\\
&\qquad\quad + \int_{\mathbb{R}^+\times E}\int_0^\infty \frac{d}{dr}\left(e^{-r}\beta(r)\right)dr\gamma(s)f(x)\mu_\tau(ds\times dx) + \beta(0)\gamma(0)\left.\int f d\nu_0\right)\\
&\quad = K^{-1}\beta(0)\left(\int \widehat{A}(\gamma f)(s,x)\mu_0(ds\times dx)\right.\\
&\qquad\quad \left. - \int_{\mathbb{R}^+\times E}\gamma(s)f(x)\mu_\tau(ds\times dx) + \gamma(0)\int f d\nu_0\right)\\
&\quad = 0.
\end{aligned}$$

The conditions of Theorem 3.1 on the state and control spaces and the generator are also satisfied, which therefore implies the existence of a stationary $\mathbb{R}^+\times\mathbb{R}^+\times E$-valued process (R,S,Y) (which we may assume is defined for all $t\in\mathbb{R}$) such that

(13)
$$\beta(R(t))\gamma(S(t))f(Y(t)) - \int_0^t\int_U \overline{A}(\beta\gamma f)(R(s),S(s),Y(s),u)\,\overline{\eta}(R(s),S(s),Y(s),du)\,ds$$

is an $\{\mathcal{F}_t^{R,S,Y}\}$-martingale for all $\beta,\gamma\in\widehat{C}^1(\mathbb{R}^+)$, and $f\in\mathcal{D}$, where $\overline{\eta}$ is given by (12).

For each $t\geq 0$, define the following random variables: $\sigma_{-1}^t = \sup\{r<t : S(r)=0, R(r)=0\}$, $\sigma_1^t = \inf\{r\geq t : S(r)=0, R(r)=0\}$, $\tau_1^t = \inf\{r>\sigma_1^t : R(r)>0\}$, and $\sigma_2^t = \inf\{r>\tau_1^t : R(r)=0\}$. For $s\in[\sigma_1^t,\tau_1^t)$, by definition $R(s)=0$ and by Lemma 3.2 $S(s) = \int_{\sigma_1^t}^s I_{\{0\}}(R(r))dr = (s-\sigma_1^t)$. For $s\in[\tau_1^t,\sigma_2^t)$, by Lemma 3.2 $R(s) = \int_{\tau_1^t}^s I_{(0,\infty)}(R(r))dr = s-\tau_1^t$ a.s. and conditional on $\mathcal{F}_{\tau_1^t}$, $\sigma_2^t-\tau_1^t$ is exponentially distributed with mean 1, and again by Lemma 3.2 $S(s) = S(\tau_1^t) + \int_{\tau_1^t}^s I_{\{0\}}(R(r))dr = S(\tau_1^t) = \tau_1^t - \sigma_1^t$. Starting with $g(r+s) = e^{-\alpha(r+s)}$ and approximating more general g by linear combinations of these exponentials, we see that

$$\begin{aligned}
g(S(t)+R(t)) - \int_0^t (g'(S(r)+R(r)) + (1-\overline{u}(R(r),S(r),Y(r)))(g(0)\\
- g(S(r)+R(r))))dr
\end{aligned}$$

is a martingale for C^1 functions with g and g' bounded, where

$$\overline{u}(R(r),S(r),Y(r)) = \int u\overline{\eta}(R(r),S(r),Y(r),du).$$

Letting $\tilde{\sigma}_2^t = \inf\{r > \tau_1^t : S(r) + R(r) = 0\}$, Lemma 3.2 implies

$$P\left\{\int_{\tau_1^t}^{\sigma_2^t}(1-\overline{u}(R(r),S(r),Y(r)))dr > x\big|\mathcal{F}_{\tau_1^t}^{R,S,Y}\right\}$$
$$= e^{-x} = P\left\{\int_{\tau_1^t}^{\tilde{\sigma}_2^t}(1-\overline{u}(R(r),S(r),Y(r)))dr > x\big|\mathcal{F}_{\tau_1^t}^{R,S,Y}\right\},$$

and since $\sigma_2^t \le \tilde{\sigma}_2^t$, we must have $\sigma_2^t = \tilde{\sigma}_2^t$ a.s. In particular, $S(\sigma_2^t) = 0$ a.s. Finally, defining $Z(r) = (R(\tau_1^t + r), S(\tau_1^t + r), Y(\tau_1^t + r))$ for $r \le \sigma_2^t - \tau_1^t$, we can extend Z to be a solution of the martingale problem for the generator C defined by

$$Cg(r,s,x) = \int g(0,0,y)\nu_0(dy) - g(r,s,x) + \frac{\partial}{\partial r}g(r,s,x).$$

Since any solution of this martingale problem has the property that the final component is constant except for jumps that occur when the first two components jump to zero, it follows that $Y(r) = Y(\tau_1^t)$ for $\tau_1^t \le r < \sigma_2^t$.

Let h be a fixed, bounded, continuous function and, for $\epsilon > 0$, define

$$H_\epsilon(r) = \int_U e^{-\epsilon(R(r)+S(r))}h(R(r),S(r),Y(r),u)\,\overline{\eta}(R(r),S(r),Y(r),du).$$

Then, as a process in t,

$$(\sigma_1^t - \sigma_{-1}^t)^{-1}\int_{\sigma_1^t}^{\sigma_2^t} H_\epsilon(r)\,dr \tag{14}$$

is stationary, and for each t and $s \in [\sigma_{-1}^t, \sigma_1^t)$

$$(\sigma_1^s - \sigma_{-1}^s)^{-1}\int_{\sigma_1^s}^{\sigma_2^s} H_\epsilon(r)\,dr = (\sigma_1^t - \sigma_{-1}^t)^{-1}\int_{\sigma_1^t}^{\sigma_2^t} H_\epsilon(r)\,dr.$$

These expressions are set equal to 0 whenever $\sigma_{-1}^t = -\infty$ or $\sigma_1^t = +\infty$.

Using stationarity,

$$E\left[(\sigma_1^t - \sigma_{-1}^t)^{-1}\int_{\sigma_1^t}^{\sigma_2^t} H_\epsilon(r)\,dr\right] = T^{-1}\int_0^T E\left[(\sigma_1^t - \sigma_{-1}^t)^{-1}\int_{\sigma_1^t}^{\sigma_2^t} H_\epsilon(r)dr\right]\,dt, \tag{15}$$

in which both sides may be infinite due to the $(\sigma_1^t - \sigma_{-1}^t)^{-1}$ term. The following argument, in fact, shows that both terms are finite and identifies their common value.

Let $N(T)$ denote the number of jumps of the process (R,S,Y) in the interval $[0,T]$, let $\{\sigma_k : k = 1,\ldots,N(T)\}$ denote these jump times, and let $\sigma_{N(T)+1}$ and σ_{-1} ($= \sigma_0$ in the summation) denote the first jump time after time T and the last jump

time before time 0, respectively. Then the right-hand side of (15) equals

$$
\begin{aligned}
T^{-1}E\left[\sum_{k=1}^{N(T)+1}\frac{T\wedge\sigma_k-\sigma_{k-1}\vee 0}{\sigma_k-\sigma_{k-1}}\int_{\sigma_{k+1}}^{\sigma_{k+2}}H_\epsilon(r)\,dr\right]
&= T^{-1}E\left[\int_0^T H_\epsilon(r)\,dr\right]\\
&\quad -T^{-1}E\left[\int_0^{\sigma_1\wedge T}\left(1-\frac{T\wedge\sigma_1}{\sigma_1-\sigma_{-1}}\right)H_\epsilon(r)\,dr\right]\\
&\quad +T^{-1}E\left[I_{\{N(T)=1\}}\frac{\sigma_1}{\sigma_1-\sigma_{-1}}\int_T^{\sigma_2}H_\epsilon(r)\,dr\right]\\
&\quad +T^{-1}E\left[I_{\{N(T)>1\}}\int_T^{\sigma_{N(T)+1}}H_\epsilon(r)\,dr\right]\\
&\quad +T^{-1}E\left[I_{\{N(T)>0\}}\frac{T-\sigma_{N(T)}}{\sigma_{N(T)+1}-\sigma_{N(T)}}\int_{\sigma_{N(T)+1}}^{\sigma_{N(T)+2}}H_\epsilon(r)\,dr\right].
\end{aligned}
$$

Observe that the first term is

$$
\int e^{-\epsilon(r+s)}h(r,s,x,u)\,\overline{\mu}(dr\times ds\times dx\times du) \tag{16}
$$

and that the last four terms are bounded above by $4||h||/(\epsilon T)$. Thus all terms are finite, implying the terms in (15) are finite, and, moreover, as $T\to\infty$, these converge to (16).

Letting $\epsilon\to 0$ gives, for each bounded, continuous h (and hence for each bounded, measurable h),

$$
\begin{aligned}
&E\left[(\sigma_1^t-\sigma_{-1}^t)^{-1}\int_{\sigma_1^t}^{\sigma_2^t}\int_U h(R(r),S(r),Y(r),u)\,\overline{\eta}(R(r),S(r),Y(r),du)dr\right]\\
&\qquad=\int h(r,s,x,u)\,\overline{\mu}(dr\times ds\times dx\times du).
\end{aligned} \tag{17}
$$

Then considering $h(r,s,x,u)=I_{\{0\}}(u)$ in (17) yields

$$
\begin{aligned}
K^{-1}&=E[(\sigma_1^t-\sigma_{-1}^t)^{-1}(\sigma_2^t-\tau_1^t)]\\
&=E[(\sigma_1^t-\sigma_{-1}^t)^{-1}],
\end{aligned}
$$

in which the last equality follows from the fact that, conditional on $\mathcal{F}^{R,S,Y}_{\tau_1^t}$, $\sigma_2^t-\tau_1^t$ is exponentially distributed with mean 1.

Now specify σ_{-1}^t and σ_1^t when $t=0$. Define the process $\tilde{X}$ by $\tilde{X}(r)=Y(\sigma_1^0+r)$, $\tilde{R}(r)=R(\sigma_1^0+r)$, $\tilde{S}(r)=S(\sigma_1^0+r)$, and the filtration $\{\mathcal{F}_r\}=\{\mathcal{F}^{R,S,Y}_{\sigma_1^0+r}\}$. Let $\tilde{\tau}=\inf\{r\ge 0:\tilde{R}(r)>0\}$ and $\tilde{\sigma}=\inf\{r>\tilde{\tau}:\tilde{R}(r)=0\}$, and note that $\tilde{X}(r)=\tilde{X}(\tilde{\tau})$ for $\tilde{\tau}\le r<\tilde{\sigma}$. Observe that both σ_1^0 and σ_{-1}^0 are $\mathcal{F}_0$-measurable. Define a new

probability measure $\hat{P}$ to have Radon–Nikodym derivative $K(\sigma_1^0 - \sigma_{-1}^0)^{-1}$. It then follows from (17) that for each bounded, measurable h

$$
\begin{aligned}
&E^{\hat{P}}\left[\int_0^{\tilde{\sigma}} \int_U h(\tilde{R}(r), \tilde{S}(r), \tilde{X}(r), u)\, \overline{\eta}(\tilde{R}(r), \tilde{S}(r), \tilde{X}(r), du)dr\right] \\
&\qquad = \int h(r, s, x, u)\, \overline{\mu}(dr \times ds \times dx \times du)/E[(\sigma_1^0 - \sigma_{-1}^0)^{-1}] \qquad (18) \\
&\qquad = \int h(0, s, x, 1)\mu_0(ds \times dx) \\
&\qquad\qquad + \int_0^{\infty} \int e^{-r} h(r, s, x, 0)\ \mu_\tau(ds \times dx)dr.
\end{aligned}
$$

Taking $h(r, s, x, u) = I_{\{0\}}(r)I_{\{0\}}(u)$ in (18) shows that $\overline{\eta}(\tilde{R}(r), \tilde{S}(r), \tilde{X}(r), \cdot)$ places unit mass at $\{1\}$ a.s. for $0 \le r \le \tilde{\tau}$, and, similarly, $h(r, s, x, u) = I_{(0,\infty)}(r)I_{\{1\}}(u)$ establishes that $\overline{\eta}(\tilde{R}(r), \tilde{S}(r), \tilde{X}(r), \cdot)$ places unit mass at $\{0\}$ a.s. for $\tilde{\tau} \le r \le \tilde{\sigma}$. Furthermore, for $\Gamma \in \mathcal{B}(\mathbb{R}^+ \times E)$ and $h(r, s, x, u) = I_{(0,\infty)\times\Gamma\times\{0\}}(r, s, x, u)$, (18) implies

$$
\begin{aligned}
\mu_\tau(\Gamma) &= E\left[\int_{\tilde{\tau}}^{\tilde{\sigma}} I_\Gamma(\tilde{S}(r), \tilde{X}(r))\, dr\right] \\
&= E[I_\Gamma(\tilde{\tau}, \tilde{X}(\tilde{\tau}))(\tilde{\sigma} - \tilde{\tau})] \\
&= E[I_\Gamma(\tilde{\tau}, \tilde{X}(\tilde{\tau}))],
\end{aligned}
$$

where the last equality follows from the fact that $\tilde{\sigma} - \tilde{\tau}$ is a mean 1 exponential time conditional on $\mathcal{F}_{\tilde{\tau}}$. Similarly, for $\Gamma \in \mathcal{B}(\mathbb{R}^+ \times E)$ and $h(r, s, x, u) = I_{\{0\}\times\Gamma\times\{1\}}(r, s, x, u)$, (18) implies

$$
E\left[\int_0^{\tilde{\tau}} I_\Gamma(r, \tilde{X}(r))\, dr\right] = \mu_0(\Gamma).
$$

Finally, by compactifying the time components to $[0, \infty]$, extending the generator $\overline{A}$ to allow $\beta, \gamma \in C[0, \infty]$ (see [3, Theorem 4.5.4]), taking $\beta \equiv 1$ and $\gamma \equiv 1$ in (13), and recalling that $\overline{\eta}(\tilde{R}(r), S(\tilde{r}), \tilde{X}(r), \cdot) = \delta_{\{0\}}(\cdot)$ for $r \in (0, \tilde{\tau})$, the optional sampling theorem implies that under $\hat{P}$

$$
f(\tilde{X}(t \wedge \tilde{\tau})) - \int_0^{t\wedge\tilde{\tau}} Af(\tilde{X}(s))\, ds
$$

is a martingale with respect to the filtration $\{\mathcal{F}_t\}$.

4. Finite-dimensional approximation. The linear program (9) is typically infinite-dimensional since the variables are measures on $\mathbb{R}^+ \times E$. To obtain numerical results, it is therefore necessary to reduce the linear program to a finite-dimensional linear program. In this section, we give conditions under which the solutions to a sequence of approximating linear programs converge to the solution of (9). We provide two approaches toward this result.

4.1. Convergence of approximating linear programs. The equivalence of optimal stopping problems with the linear program (9) has been established in sections 2 and 3 under very general conditions. The convergence results, however, are

shown under more restricted conditions and are based on the results of Mendiondo and Stockbridge [10]. An alternate approach to the approximation of the infinite-dimensional linear program is possible using the numerical scheme of Hernández-Lerma and Lasserre [7]. It should be noted that the issue of obtaining approxmiate control policies that converge to the optimal control policy for the original problem remains an open problem.

We assume that E is a compact, metric space and that the reward function R is continuous. We also compactify $\mathbb{R}^+$ with the point at ∞ and extend the generator $\widehat{A}$ to functions γf with $\gamma \in C(\overline{\mathbb{R}^+})$ and $f \in \mathcal{D}$ as in [3, Theorem 4.5.4]. The extension of the generator and domain are still denoted $\widehat{A}$ and $\widehat{\mathcal{D}}$, respectively.

The approximating linear programming problems. In our application of the convergence results, the approximations will be obtained by discretizing the space. The convergence results apply to other approximation schemes as well, so we establish the results in the more general setting.

For $n \geq 0$, let E_n be a metric space, and denote the distance between points in E_n by $|\cdot - \cdot|$. We assume for each n there exist measurable functions $\psi_n : E_n \to E$ and $\phi_n : E \to E_n$ such that

(C1) $|x - \psi_n(\phi_n(x))| \to 0$ as $n \to \infty$ for all $x \in E$.

Note that, in our application, E_n will be a discretization of E, ψ_n will be the natural imbedding of E_n in E, and ϕ_n will map rectangles to the (single) point in the discretization contained in the rectangles.

For each n, we transfer the reward function R to E_n by defining $R_n = R \circ \psi_n$.

Let $A_n : \mathcal{D}_n \subset C(E_n) \to C(E_n)$ be such that, for each $f \in \mathcal{D}$, there exists $f_n \in \mathcal{D}(A_n)$ satisfying the following:

(C2) $\sup_{y \in E_n} |f_n(y) - f(\psi_n(y))| \to 0$ as $n \to \infty$;

(C3) $\sup_{y \in E_n} |A_n f_n(y) - Af(\psi_n(y))| \to 0$ as $n \to \infty$.

Note that conditions (C2) and (C3) are satisfied by $\widehat{A}$. We denote the approximations of $\widehat{A}$ by $\widehat{A}_n$ and the approximations of the initial distribution ν_0 by ν_0^n.

The approximating linear programs are

$$\begin{aligned} &\text{Max} \int R_n(y)\mu_\tau^n(dt \times dy) \\ &\text{S.t.} \int \gamma_n f_n d\mu_\tau^n - \int \widehat{A}_n(\gamma_n f_n) d\mu_0^n = \gamma_n(0) \int f_n d\nu_0^n \qquad \forall \gamma_n f_n \in \widehat{\mathcal{D}}(A_n), \\ &\mu_\tau^n \in \mathcal{P}(\overline{\mathbb{R}_n^+} \times E_n),\ \mu_0^n \in \mathcal{M}(\overline{\mathbb{R}_n^+} \times E_n). \end{aligned} \tag{19}$$

To apply the results in [10], the constraints of (9) and (19) will be rephrased to fit the formulation of that paper. Let $U = \{u_1, u_2\}$ be a control space consisting of two distinct points. Define a new generator $\tilde{A} : \widehat{\mathcal{D}} \to C(\overline{\mathbb{R}^+} \times E \times U)$ by

$$\tilde{A}(\gamma f)(t,x,u) = \begin{cases} \widehat{A}(\gamma f)(t,x) & \text{if } u = u_1, \\ \gamma(0) \int f d\nu_0 - \gamma(t) f(x) & \text{if } u = u_2, \end{cases}$$

and note that conditions (C2)–(C3) apply to $\tilde{A}$. We denote the approximations of $\tilde{A}$ by $\tilde{A}_n$.

We further assume the following.

(C4) For each n, for each conditional distribution $\widehat{\eta}^n$ on $\{u_1, u_2\}$ given E_n, there exist measures $\mu_\tau^n \in \mathcal{M}(\overline{\mathbb{R}_n^+} \times E_n)$ and $\mu_0^n \in \mathcal{P}(\overline{\mathbb{R}_n^+} \times E_n)$ such that for each $\gamma_n f_n \in \widehat{\mathcal{D}}(A_n)$

$$\int \gamma_n f_n(t,y)\mu_\tau^n(dt \times dy) - \int\int \widehat{A}_n(\gamma_n f_n)(t,y,u)\widehat{\eta}^n(y,du)\mu_0^n(dt \times dy) = \gamma_n(0)\int f_n d\nu_0^n.$$

Condition (C4) essentially assumes the existence of a stationary distribution for the approximating process.

Define the measure $\tilde{\mu} \in \mathcal{P}(\overline{\mathbb{R}^+} \times E \times U)$ by

$$\tilde{\mu}(\cdot \times \{u_1\}) = K^{-1}\mu_0(\cdot), \qquad \tilde{\mu}(\cdot \times \{u_2\}) = K^{-1}\mu_\tau(\cdot),$$

where $K = \mu_0(\overline{\mathbb{R}^+} \times E) + 1$. Then the constraints of (9) become

$$\int_{\mathbb{R}^+ \times E \times U} \tilde{A}(\gamma f)d\tilde{\mu} = 0 \qquad \forall\, \gamma f \in \widehat{\mathcal{D}},$$
$$\mu \in \mathcal{P}(\overline{\mathbb{R}^+} \times E \times U).$$

A similar reformulation of the constraints of (19) gives the form which is analyzed in [10], and thus the optimal values of (19) converge to that of (9) (see Theorem 4 of [10]).

4.2. Markov chain approximations. The second approach to the issue of finite-dimensional approximations and convergence of the optimal values is to employ Kushner's Markov chain approximation scheme. To apply the convergence results in Kushner and Dupuis [9], we establish the equivalence between the optimal stopping problem and an associated absolutely continuous stochastic control problem. This control problem is then approximated by the corresponding problem of controlling a continuous time Markov chain which approximates the original Markov process. Convergence of the value function then follows.

Let $U = \{0, 1\}$, and this time define the controlled generator $\tilde{A} : \mathcal{D} \to \overline{C}(E \times U)$ by

$$\tilde{A}f(x,u) = u\,Af(x). \tag{20}$$

A paired process $(\tilde{X}, u)$ is a solution of the controlled martingale problem for $(\tilde{A}, \nu_0)$ if $\tilde{X}(0)$ has distribution ν_0, and there is a filtration $\{\mathcal{F}_t\}$ such that $(\tilde{X}, u)$ is $\{\mathcal{F}_t\}$-progressively measurable and

$$f(\tilde{X}(t)) - \int_0^t \tilde{A}f(\tilde{X}(s), u(s))ds$$

is an $\{\mathcal{F}_t\}$-martingale. For the optimal stopping problem, we further require

$$\lim_{t\to\infty} \tilde{X}(t) =: \tilde{X}(\infty) \text{ exists a.s.} \tag{21}$$

The first theorem shows that to each pair (X, τ), in which X is a solution of the martingale problem for (A, ν_0) and τ is a stopping time, there exists a pair $(\tilde{X}, u)$, which is a solution of the controlled martingale problem for $(\tilde{A}, \nu_0)$ satisfying (21).

THEOREM 4.1. *Let X be a solution of the martingale problem for (A, ν_0), and let τ be a stopping time having finite expectation. Let μ_τ denote the distribution of $X(\tau)$, and let μ_0 be defined by (7). Then there exists a solution $(\tilde{X}, u)$ of the controlled martingale problem for $(\tilde{A}, \nu_0)$ such that $\lim_{t\to\infty} \tilde{X}(t)$ exists a.s., $\tilde{X}(\infty)$ has distribution μ_τ, and*

$$E\left[\int_0^\infty u(s) I_\Gamma(\tilde{X}(s)) ds\right] = \mu_0(\Gamma)$$

for every $\Gamma \in \mathcal{B}(E)$.

Proof. Define $\tilde{X}(t) = X(t \wedge \tau)$ and $u(t) = I_{[0,\tau)}(t)$. The conclusion now follows.

The next theorem shows the reverse correspondence.

THEOREM 4.2. *Let $(\tilde{X}, u)$ be a solution of the controlled martingale problem for $(\tilde{A}, \nu_0)$ with*

$$E\left[\int_0^\infty u(s) ds\right] < \infty$$

and such that $\lim_{t\to\infty} \tilde{X}(t)$ exists a.s. Then there exist a process X and a stopping time τ, with $E[\tau] < \infty$, such that X is a solution of the martingale problem for (A, ν_0) up to time τ.

Proof. We sketch the proof. Define $\tau = \int_0^\infty u(s)\, ds$, and note that $\tau < \infty$ a.s. Now we restrict our attention to the times that $u = 1$ by defining, for $r \in \mathbb{R}^+$,

$$\sigma(r) = \inf\left\{t : \int_0^t u(s)\, ds = r\right\},$$

where $\sigma(r) = \infty$ for $r \geq \tau$. It then follows that

$$f(\tilde{X}(\sigma(r))) - \int_0^{\sigma(r)} u(s) A f(\tilde{X}(s))\, ds \tag{22}$$

is an $\{\mathcal{F}_{\sigma(r)}\}$-martingale. Define $X(r) = \tilde{X}(\sigma(r))$ and $\mathcal{G}_r = \mathcal{F}_{\sigma(r)}$ for $r \in \mathbb{R}^+$, and observe that (22) is

$$f(X(r \wedge \tau)) - \int_0^{r\wedge\tau} A f(X(s))\, ds.$$

Theorems 4.1 and 4.2 establish the equivalence of stopped solutions (X, τ) of the martingale problem for (A, ν_0) with controlled solutions $(\tilde{X}, u)$ of the martingale problem for $(\tilde{A}, \nu_0)$. The formulation of the objective (2) of the stopping problem in terms of the controlled process is

$$E[R(\tilde{X}(\infty))], \tag{23}$$

and the control problem is to maximize (23) over all solutions of the controlled martingale problem for $(\tilde{A}, \nu_0)$ satisfying (21).

Kushner's numerical method approximates the process $(\tilde{X}, u)$ by a continuous time controlled Markov chain $(\tilde{X}^{(n)}, u^{(n)})$, which satisfies local consistency conditions and then optimizes the corresponding objective involving $\tilde{X}^{(n)}$.

5. Numerical examples. We illustrate the accuracy of the linear programming formulation for optimal stopping problems in this section.

Example 5.1. Let X be a one-dimensional Brownian motion with $X(0) = x_0$, where $0 < x_0 < 1$, so the generator of the Brownian motion process is

$$Af(x) = \frac{1}{2}f''(x), \qquad 0 < x < 1.$$

The process stops automatically when it reaches 0 or 1. Note that this implies that if the decision maker allows the process to run without intervention, it will still stop at some random time τ having finite expectation. The reward obtained when the process stops is given by the function

$$R(x) = 1 - 9x + 59x^2 - 100x^3 + 50x^4.$$

Since the reward function is not time-dependent, we can simplify the problem by taking $\gamma \equiv 1$ in (9) and letting μ_τ and μ_0 be the marginal measures on $[0,1]$ defined by $\mu_\tau(\mathbb{R}^+ \times \cdot)$ and $\mu_0(\mathbb{R}^+ \times \cdot)$, respectively. The linear program for the optimal stopping problem becomes

$$\begin{aligned} &\text{Max} \int [1 - 9x + 59x^2 - 100x^3 + 50x^4]\mu_\tau(dx) \\ &\text{S.t.} \int f(x)\mu_\tau(dx) - \int \frac{1}{2}f''(x)\mu_0(dx) = f(x_0), \\ &\quad \mu_\tau \in \mathcal{P}([0,1]),\ \mu_0 \in \mathcal{M}([0,1]). \end{aligned} \tag{24}$$

This optimal solution for this example can be readily computed using the methods of [12]. The continuation region for this problem consists of $(0, 0.440589) \cup (0.55941, 1)$ with the stopping region being its complement. The value function is the smallest concave function lying above R and is displayed on the graph of the numerical results in Figure 1.

To approximate this infinite-dimensional linear program, discretize $[0,1]$ by setting

$$E_n = \left\{ \frac{k}{n} : k = 1, \ldots, n-1 \right\}$$

and $\overline{E}_n = E_n \cup \{0\} \cup \{1\}$ and using the central finite difference approximation

$$f''(y_k) \approx n^2[f(y_k + 1/n) + f(y_k - 1/n) - 2f(y_k)]$$

for $y_k \in E_n$. The linear program which results is

$$\begin{aligned} &\text{Max} \sum [1 - 9y_k + 59y_k^2 - 100y_k^3 + 50y_k^4]\mu_\tau^{(n)}(y_k) \\ &\text{S.t.} \sum f(y_k)\mu_\tau^{(n)}(y_k) - \sum A_n f(y_k)\mu_0^{(n)}(y_k) = f(x_0), \\ &\quad \mu_\tau^{(n)} \in \mathcal{P}(\overline{E}_n),\ \mu_0^{(n)} \in \mathcal{M}(\overline{E}_n). \end{aligned} \tag{25}$$

Notice that it is only necessary to use a finite number of functions f since there are only a finite number of states in the discretization.

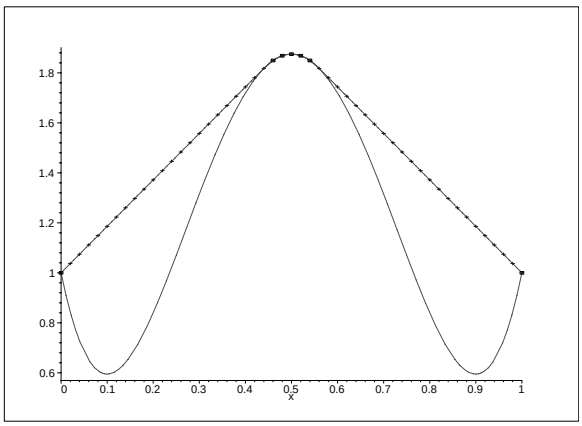

FIG. 1. *The value function.*

This numerical scheme approximates the Brownian motion process by a continuous time Markov chain (a simple random walk with absorption at $\{0, 1\}$) having generator

$$A_n f(y_k) = \frac{n^2}{2}[f(y_k + 1/n) + f(y_k - 1/n) - 2f(y_k)]$$

for $y_k \in E_n$. When the process jumps, it moves to the right or left one point in the discretization with equal probability. It is necessary to approximate f'' by the central difference approximation in order to satisfy condition (C4). Note that the stationarity condition in the constraints of (24) translates into the stationarity condition in the constraints of (25). Thus the stationary distributions of the Brownian motion are approximated by the stationary distributions of the random walk.

We illustrate the results of (25) by setting $n = 50$. The value function is approximated by solving the linear program (25) with each discretized state as the initial state of the process (thus solving 51 linear program problems) and recording the optimal values. We used AMPL as a user interface with the linear program solver CPLEX. The optimal values are plotted along with the value function V in Figure 1. Observe that the linear program gives excellent results.

To better illustrate the results of solving the linear program, we plot the two measures $\mu_\tau^{(n)}$ and $\mu_0^{(n)}$ for the case $x_0 = 0.7$ in Figures 2 and 3, respectively. Note that the occupation measure puts its mass entirely on $\{0.58, \ldots, 0.98\}$, and the distribution at τ consists of two masses at 0.56 and 1, respectively.

The masses of $\mu_\tau^{(n)}$ give the probability that when the process stops, it does so at each of these locations. Thus the optimal stopping rule is to decide to stop the process when it first hits 0.56 or 1.

The masses of $\mu_0^{(n)}$ give the expected length of time the Markov chain occupies each state in the continuation region. Note that only the right half of the continuation region is obtained from this solution of the linear program. This is due to the fact that the initial position of X is $x_0 = 0.7$, so the process, when optimally stopped, will reach only points in $\{0.56, \ldots .1\}$. Solving the linear program with $x_0 = 0.2$ will identify the lower continuation region and stopping region.

An additional comment is needed due to the numerical results of $\mu_0^{(n)}$. It can be shown that the optimal μ_0 has a piecewise linear density g consisting of two seg-

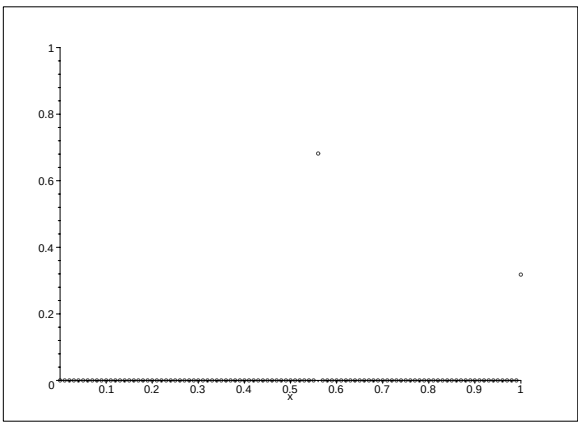

FIG. 2. $\mu_\tau^{(n)}$: *The probability of stopping in each state.*

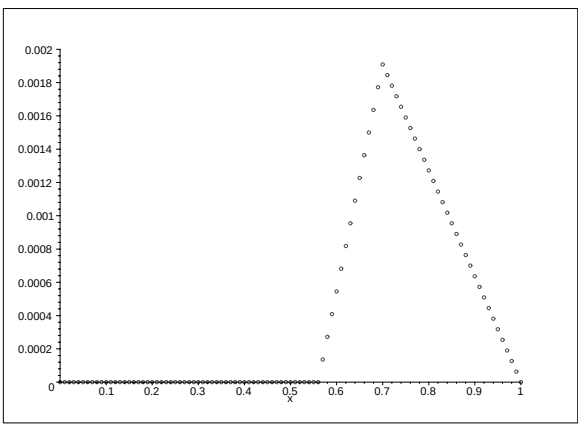

FIG. 3. $\mu_0^{(n)}$: *The expected length of time in each state.*

ments where the density is positive. The density g is 0 at the stopping locations. It is also continuous with its maximum at the initial state. Figure 3 displays these characteristics.

We also ran the linear program at various discretization levels with $x_0 = 0.7$ and recorded the lower stopping location from $\mu_\tau^{(n)}$. These values are listed in Table 1.

In each case, the stopping rule chooses the point in the discretization closest to the stopping location for the Brownian motion process.

The previous example involving one-dimensional Brownian motion was simple enough to solve analytically and thereby allowed for comparison of the numerical solution using linear programming with the analytical solution. We now present a two-dimensional example involving Brownian motion in the unit square which is an extension of the one-dimensional example with quartic reward.

Example 5.2. Let (X, Y) be a two-dimensional Brownian motion process with $X(0) = X_0$ and $Y(0) = Y_0$, where $0 < X_0, Y_0 < 1$, so the generator of the two-dimensional process is

$$Af(x,y) = \frac{1}{2}\frac{\partial^2 f}{\partial x^2}(x,y) + \frac{1}{2}\frac{\partial^2 f}{\partial y^2}(x,y).$$

TABLE 1

Discretization size h	Stopping location	Exact value
0.1	0.6	0.55941
0.05	0.55	0.55941
0.02	0.56	0.55941
0.01	0.56	0.55941
0.001	0.559	0.55941

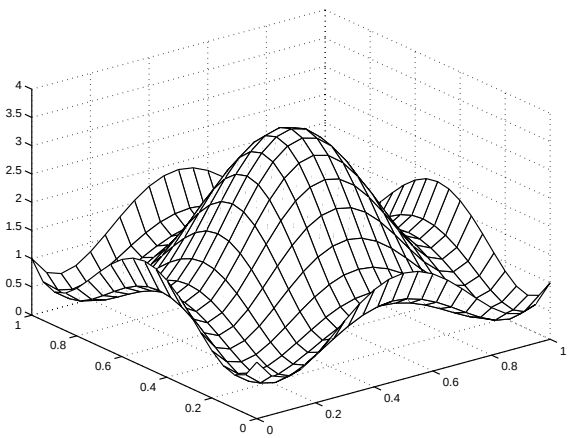

FIG. 4. *The reward function.*

The process automatically stops when it hits the boundary of the unit square. A reward of

$$R(x,y) = (1 - 9x + 59x^2 - 100x^3 + 50x^4)(1 - 9y + 59y^2 - 100y^3 + 50y^4)$$

is earned when the process stops in location (x, y). Thus the decision maker's goal is to maximize

$$E[R(X(\tau), Y(\tau))]$$

over all stopping times τ. Note every stopping rule satisfies (3) (see Figure 4).

The linear program for this optimal stopping problem is

$$\text{Max} \int R(x,y)\mu_\tau(dx \times dy)$$

(26)

$$\text{S.t.} \int f(x)\mu_\tau(dx \times dy) - \int \left[\frac{1}{2}\frac{\partial^2 f}{\partial x^2}(x,y) + \frac{1}{2}\frac{\partial^2 f}{\partial y^2}(x,y)\right] \mu_0(dx \times dy) = f(X_0, Y_0)$$

$$\forall f \in C^2([0,1] \times [0,1]),$$

$$\mu_\tau \in \mathcal{P}([0,1] \times [0,1]),$$

$$\mu_0 \in \mathcal{M}([0,1] \times [0,1]).$$

As in the one-dimensional case, we discretize the unit interval and approximate the Brownian motion process by a random walk. For example, we approximate

$$\frac{\partial^2 f}{\partial x^2}(x_k, y_k) \approx \frac{f(x_{k+1}, y_k) + f(x_{k-1}, y_k) - 2f(x_k, y_k)}{h^2},$$

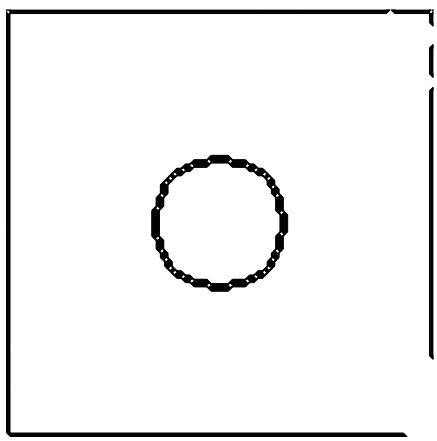

FIG. 5. *The stopping locations.*

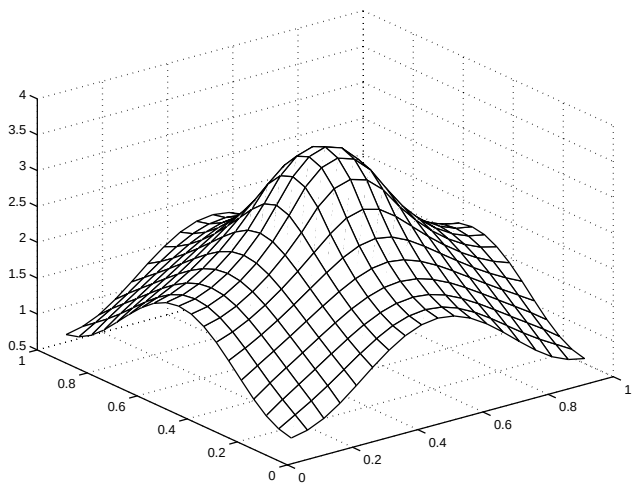

FIG. 6. *The value function.*

where h denotes the mesh size. This linear program was run using AMPL as an interface for the linear program solver CPLEX with initial state $(X_0, Y_0) = (0.2, 0.6)$ and taking $h = 0.01$. Figure 5 shows the locations where the measure $\mu_\tau^{(n)}$ puts positive mass. Recall that the measure $\mu_\tau^{(n)}$ identifies the boundary of the stopping region as those states which have positive mass and hence a positive probability of the process being in those states when the decision is made to stop the process. The stopping locations in the center of the square are clearly identified. There are a few states on the boundary, however, which are assigned no $\mu_\tau^{(n)}$ mass by the linear program. The reason appears to be that since the initial state of the process is at $(0.2, 0.6)$, the probability of the process stopping in those states is small enough to be numerically equal to zero.

The value function is approximated by solving the approximating linear program with each point in the discretization as the initial value and recording the optimal values. This approximation of V using the points in the interior of the unit square is given in Figure 6 when $h = 0.02$.
