$$+[C_1 - D_{12}R_{02}^{-1}(D_{02}^T C_0 + B_2^T P_2(t))]^T[C_1 - D_{12}R_{02}^{-1}(D_{02}^T C_0 + B_2^T P_2(t))],$$

$$-\dot{P}_2(t) = (A_s + \gamma^{-2}B_1B_1^T P_1)^T P_2(t) + P_2(t)(A_s + \gamma^{-2}B_1B_1^T P_1(t)) - P_2(t)B_2R_{02}^{-1}B_2^T P_2(t) + Q,$$

$$\dot{P}_3(t) = (A_f + \gamma^{-2}B_1B_1^T P_1(t))P_3(t) + P_3(t)(A_f + \gamma^{-2}B_1B_1^T P_1(t))^T - P_3(t)C_2^T R_{20}^{-1}C_2P_3(t) + P$$

have solutions $P_1(t) \geq 0$, $P_2(t) \geq 0$, *and* $P_3(t) \geq 0$ *on* $[0,T]$ *with* $P_1(T) = 0$, $P_2(T) = 0$, *and* $P_3(0) = 0$.

If the solutions exist, then

$$w_* = \gamma^{-2}B_1^T P_1(t)x, \quad F_*(t) = -R_{02}^{-1}(D_{02}^T C_0 + B_2^T P_2(t)), \quad L_*(t) = -(B_0D_{20}^T + P_3(t)C_2^T)R_{20}^{-1}.$$

Proof. Suppose there exist solutions $P_1(t) \geq 0$, $P_2(t) \geq 0$, and $P_3(t) \geq 0$, $t \in [0,T]$, with $P_1(T) = 0$, $P_2(T) = 0$, and $P_3(0) = 0$ for the three differential Riccati equations. We have

$$J_1(u, w, w_0) = \gamma^2\|w\|_{[0,T]}^2 - \|z\|_{[0,T]}^2 = E\left\{\int_0^T (\gamma^2\|w\|^2 - \|z\|^2)dt\right\}$$

$$= E\left\{\int_0^T [\gamma^2\|w\|^2 - \|z\|^2 - \frac{d}{dt}(x^T P_1(t)x)]dt\right\}$$

$$= E\left\{\int_0^T [\gamma^2\|w\|^2 - \|z\|^2 - \dot{x}^T P_1(t)x - x^T\dot{P}_1(t)x - x^T P_1(t)\dot{x}]dt\right\}.$$

Using the equation for $\dot{P}_1(t)$, we get

$$J_1(u,w,w_0) = E\left\{\int_0^T [\gamma^2 \|w-w_*\|^2 - u^T R_1 u + \bar{u}_*^T R_1 \bar{u}_*\right.$$

$$\left. -2x^T(P_1(t)B_2 + C_1^T D_{12})(u-\bar{u}_*) - 2x^T P_1(t) B_0 w_0]dt\right\},$$

where $w_* = \gamma^{-2} B_1^T P_1(t) x$ and $\bar{u}_* = -R_{02}^{-1}(D_{02}^T C_0 + B_2^T P_2(t))x$, i.e., the optimal strategies for state feedback case. Clearly, if we take $w = w_*$, then for any u, hence for the optimally designed output feedback control law u_*, we have $J_1(u_*, w_*, w_0) \le J_1(u_*, w, w_0)$.

Now we design u_* to minimize $J_2(u, w_*, w_0)$. By substituting the w_* into the system equation, we get

$$\begin{aligned}
&\dot{x} = (A + \gamma^{-2} B_1 B_1^T P_1(t))x + B_0 w_0 + B_2 u, \quad x(0) = 0,\\
&y = C_2 x + D_{20} w_0, \quad R_0 := D_{20} D_{20}^T > 0,\\
&z_0 = C_0 x + D_{02} u, \quad R_{02} := D_{02}^T D_{02} > 0.
\end{aligned}$$

This is a standard LQG problem [1, 16]. Thus the optimal control law is given by

$$\begin{aligned}
&\dot{\hat{x}} = (A + \gamma^{-2} B_1 B_1^T P_1(t))\hat{x} + B_2 u_* + L_*(t)(C_2\hat{x} - y),\\
&u_* = F_*(t)\hat{x},
\end{aligned}$$

where $F_*(t) = -R_{02}^{-1}(D_{02}^T C_0 + B_2^T P_2(t))$, $L_*(t) = -(B_0 D_{20}^T + P_3(t) C_2^T) R_{20}^{-1}$, $P_2(t) > 0$, and $P_3(t) > 0$ solve

$$-\dot{P}_2(t) = (A_s + \gamma^{-2} B_1 B_1^T P_1(t))^T P_2(t) + P_2(t)(A_s + \gamma^{-2} B_1 B_1^T P_1(t))$$

$$-P_2(t) B_2 R_{02}^{-1} B_2^T P_2(t) + Q,$$

$$\dot{P}_3(t) = (A_f + \gamma^{-2} B_1 B_1^T P_1(t)) P_3(t) + P_3(t)(A_f + \gamma^{-2} B_1 B_1^T P_1(t))^T$$

$$-P_3(t) C_2^T R_{20}^{-1} C_2 P_3(t) + P,$$

with $P_2(T) = 0$ and $P_3(0) = 0$, and u_* achieves $J_2(u_*, w_*, w_0) \le J_2(u, w_*, w_0)$. □

THEOREM 10. *Suppose the state feedback control problem is solvable, i.e., there are $P_1(t) \ge 0$ and $P_2(t) \ge 0$ with $P_1(T) = 0$ and $P_2(T) = 0$ solving*

$$-\dot{P}_1(t) = (A_s - B_2 R_{02}^{-1} B_2^T P_2(t))^T P_1(t) + P_1(t)(A_s - B_2 R_{02}^{-1} B_2^T P_2(t)) + \gamma^{-2} P_1(t) B_1 B_1^T P_1(t)$$

$$+[C_1 - D_{12} R_{02}^{-1}(D_{02}^T C_0 + B_2^T P_2(t))]^T [C_1 - D_{12} R_{02}^{-1}(D_{02}^T C_0 + B_2^T P_2(t))],$$

$$-\dot{P}_2(t) = (A_s + \gamma^{-2} B_1 B_1^T P_1(t))^T P_2(t) + P_2(t)(A_s + \gamma^{-2} B_1 B_1^T P_1(t))$$

$$-P_2(t) B_2 R_{02}^{-1} B_2^T P_2(t) + Q,$$

and there is a w_* and an output feedback control u_* (hence an $L_*(t)$) in the given form of

$$\begin{aligned}\dot{\hat{x}} &= (A+\gamma^{-2}B_1B_1^TP_1(t)+B_2F_*(t))\hat{x}+L_*(t)(C_2\hat{x}-y),\\ u_* &= F_*(t)\hat{x},\end{aligned}$$

where $F_*(t)=-R_{02}^{-1}(D_{02}^TC_0+B_2^TP_2(t))$, such that

$$J_1(u_*,w_*,w_0)\le J_1(u_*,w,w_0),\quad J_2(u_*,w_*,w_0)\le J_2(u,w_*,w_0);$$

then there is a $P_3(t)\ge 0$ with $P_3(0)=0$ solving

$$\begin{aligned}\dot{P}_3(t) = (A_f+\gamma^{-2}B_1B_1^TP_1(t))P_3(t)+P_3(t)(A_f+\gamma^{-2}B_1B_1^TP_1(t))^T\\ -P_3(t)C_2^TR_{20}^{-1}C_2P_3(t)+P,\end{aligned}$$

and $L_*(t)$ can be chosen as $L_*(t)=-(B_0D_{20}^T+P_3(t)C_2^T)R_{20}^{-1}$.

Proof. Let $P_1(t)\ge 0$ and $P_2(t)\ge 0$ with $P_1(T)=0$ and $P_2(T)=0$ solve

$$\begin{aligned}-\dot{P}_1(t) &= (A_s-B_2R_{02}^{-1}B_2^TP_2(t))^TP_1(t)\\ &\quad +P_1(t)(A_s-B_2R_{02}^{-1}B_2^TP_2(t))+\gamma^{-2}P_1(t)B_1B_1^TP_1(t)\\ &\quad +[C_1-D_{12}R_{02}^{-1}(D_{02}^TC_0+B_2^TP_2(t))]^T[C_1-D_{12}R_{02}^{-1}(D_{02}^TC_0+B_2^TP_2(t))],\\ -\dot{P}_2(t) &= (A_s+\gamma^{-2}B_1B_1^TP_1(t))^TP_2(t)+P_2(t)(A_s+\gamma^{-2}B_1B_1^TP_1(t))\\ &\quad -P_2(t)B_2R_{02}^{-1}B_2^TP_2(t)+Q.\end{aligned}$$

Since

$$\begin{aligned}J_1(u_*,w,w_0) &= E\left\{\int_0^T(\gamma^2\|w\|^2-\|z\|^2)dt\right\}\\ &= E\left\{\int_0^T\left[\gamma^2\|w\|^2-\|z\|^2-\frac{d}{dt}(x^TP_1(t)x)\right]dt\right\}\\ &= E\left\{\int_0^T[\gamma^2\|w\|^2-\|z\|^2-\dot{x}^TP_1(t)x-x^T\dot{P}_1(t)x-x^TP_1(t)\dot{x}]dt\right\},\end{aligned}$$

using the equation for $\dot{P}_1(t)$, we get

$$\begin{aligned}E\left\{\int_0^T(\gamma^2\|w\|^2-\|z\|^2)dt\right\} = E\left\{\int_0^T[\gamma^2\|w-w_*\|^2-u^TR_1u+\bar{u}_*^TR_1\bar{u}_*\right.\\ \left.-2x^T(P_1(t)B_2+C_1^TD_{12})(u-\bar{u}_*)-2x^TP_1(t)B_0w_0]dt\right\},\end{aligned}$$

where $w_*=\gamma^{-2}B_1^TP_1(t)x$, $\bar{u}_*=-R_{02}^{-1}(D_{02}^TC_0+B_2^TP_2(t))x=F_*(t)x$. Hence u_* and w_* achieve $J_1(u_*,w_*,w_0)\le J_1(u_*,w,w_0)$.

Substituting w_* into the system equation, we get

$$\begin{aligned}\dot{x} &= (A+\gamma^{-2}B_1B_1^TP_1(t))x+B_0w_0+B_2u_*,\\ y &= C_2x+D_{20}w_0,\\ z_0 &= C_0x+D_{02}u_*.\end{aligned}$$

Thus

$$J_2(u_*, w_*, w_0) = E\int_0^T \|z_0\|^2 dt$$
$$= E\int_0^T \left[x^T C_0^T C_0 x + 2x^T C_0^T D_{02} u_* + u_*^T R_{02} u_* + \frac{d}{dt}(x^T P_2(t) x)\right] dt$$

$$= E\int_0^T [x^T C_0^T C_0 x + 2x^T C_0^T D_{02} u_* + u_*^T R_{02} u_* + \dot{x}^T P_2(t) x + x^T \dot{P}_2(t) x + x^T P_2(t) \dot{x}] dt.$$

Using the equation about $P_2(t)$, we get

$$J_2(u_*, w_*, w_0) = E\int_0^T (u_* - \bar{u}_*)^T R_{02}(u_* - \bar{u}_*) dt + 2E\int_0^T x^T P_2(t) B_0 w_0 dt$$

$$= E\int_0^T (u_* - \bar{u}_*)^T R_{02}(u_* - \bar{u}_*) dt + 2\mathrm{trace}\int_0^T P_2(t) B_0 E\{w_0 x^T\} dt.$$

By Lemma 5, we have $E\{x w_0^T\} = B_0/2$. Hence

$$J_2(u_*, w_*, w_0) = E\int_0^T (u_* - \bar{u}_*)^T R_{02}(u_* - \bar{u}_*) dt + \mathrm{trace}\int_0^T P_2(t) B_0 B_0^T dt$$
$$= E\int_0^T (u_* - \bar{u}_*)^T R_{02}(u_* - \bar{u}_*) dt + \mathrm{trace}\int_0^T B_0^T P_2(t) B_0 dt.$$

We need only to consider the first term. Define $e_x = x - \hat{x}$; then

$$E\int_0^T (u_* - \bar{u}_*)^T R_{02}(u_* - \bar{u}_*) dt = E\int_0^T e_x^T F_*^T(t) R_{02} F_*(t) e_x dt.$$

Since we have

$$\dot{\hat{x}} = (A + \gamma^{-2} B_1 B_1^T P_1(t) + B_2 F_*(t))\hat{x} + L_*(t)(C_2 \hat{x} - y),$$
$$u_* = F_*(t)\hat{x},$$

clearly, e_x satisfies

$$\dot{e}_x = \dot{x} - \dot{\hat{x}} = (A + \gamma^{-2} B_1 B_1^T P_1(t) + L_*(t) C_2) e_x + (B_0 + L_*(t) D_{20}) w_0 := A_{L_*} e_x + B_{L_*} w_0.$$

Let $\Phi(t, \tau)$ be the transition matrix of $A + \gamma^{-2} B_1 B_1^T P_1(t) + L_*(t) C_2$; then

$$e_x = \int_0^t \Phi(t, \tau)(B_0 + L_*(t) D_{20}) w_0 d\tau.$$

This gives

$$
\begin{aligned}
&E\int_0^T e_x^T F_*^T(t)R_{02}F_*(t)e_x dt\\
&\quad = E\left\{\int_0^T\int_0^t\int_0^t w^T(\tau)B_{L_*}^T\Phi^T(t,\tau)F_*^T(t)R_{02}F_*(t)\Phi(t,\tau)B_{L_*}w(s)d\tau\, ds\, dt\right\}\\
&\quad = \operatorname{trace}\left\{\int_0^T\int_0^t\int_0^t F_*^T(t)R_{02}F_*(t)\Phi(t,\tau)B_{L_*}E\{w(s)w(\tau)\}B_{L_*}^T\Phi^T(t,\tau)d\tau\, ds\, dt\right\}\\
&\quad = \operatorname{trace}\left\{\int_0^T\int_0^t\int_0^t F_*^T(t)R_{02}F_*(t)\Phi(t,\tau)B_{L_*}\delta(\tau-s)B_{L_*}^T\Phi^T(t,\tau)d\tau\, ds\, dt\right\}\\
&\quad = \operatorname{trace}\left\{\int_0^T D_{02}F_*(t)Y(t)F_*^T(t)D_{02}^T dt\right\},
\end{aligned}
$$

where $Y(t)=\int_0^t\Phi(t,s)B_{L_*}B_{L_*}^T\Phi^T(t,s)ds\geq 0$ satisfies

$$\dot{Y}(t)=A_{L_*}Y(t)+Y(t)A_{L_*}^T+B_{L_*}B_{L_*}^T,\quad Y(0)=0.$$

Since

$$J_2(u_*,w_*,w_0)=\operatorname{trace}\left\{\int_0^T D_{02}F_*(t)Y(t)F_*^T(t)D_{02}^T dt\right\}+\operatorname{trace}\int_0^T B_0^T P_2(t)B_0 dt$$

is the minimum value by assumption, by Theorem 6 there is a $P_3(t)\geq 0,\ P_3(t)\leq Y(t),\ \ \forall t\in[0,T]$, with $P_3(0)=0$ solving

$$\dot{P}_3(t)=(A_f+\gamma^{-2}B_1B_1^TP_1(t))P_3(t)+P_3(t)(A_f+\gamma^{-2}B_1B_1^TP_1(t))^T$$

$$-P_3(t)C_2^TR_{20}^{-1}C_2P_3(t)+P,$$

and, besides, $L_*(t)$ can be chosen as $L_*(t)=-(B_0D_{20}^T+P_3(t)C_2^T)R_{20}^{-1}$ since

$$J_2(u_*,w_*,w_0)=\operatorname{trace}\left\{\int_0^T D_{02}F_*(t)P_3(t)F_*^T(t)D_{02}^T dt\right\}+\operatorname{trace}\int_0^T B_0^TP_2(t)B_0dt.$$

This concludes the proof. □

4.2. Multiobjective control design—infinite time horizon. For multiobjective control design in infinite time horizon, we need to add the following standard assumptions:

(A1) (A,B_2) is stabilizable and (C_2,A) is detectable,

(A2) $\begin{bmatrix} A-j\omega I & B_2\\ C_0 & D_{02}\end{bmatrix}$ has full column rank for all ω,

(A3) $\begin{bmatrix} A-j\omega I & B_0\\ C_2 & D_{20}\end{bmatrix}$ has full row rank for all ω.

The state feedback design result [22] is presented in the next theorem.

THEOREM 11. *There exist linear memoryless state feedback strategies (Nash equilibrium strategies) u_* and w_* such that*

$$0\leq J_3(u_*,w_*,0)\leq J_3(u_*,w,0),\ \ J_4(u_*,w_*,0)\leq J_4(u,w_*,0)$$

if and only if the coupled Riccati equations

$$(A_s - B_2R_{02}^{-1}B_2^TP_2)^TP_1 + P_1(A_s - B_2R_{02}^{-1}B_2^TP_2) + \gamma^{-2}P_1B_1B_1^TP_1$$

$$+[C_1 - D_{12}R_{02}^{-1}(D_{02}^TC_0 + B_2^TP_2)]^T[C_1 - D_{12}R_{02}^{-1}(D_{02}^TC_0 + B_2^TP_2)] = 0$$

and

$$(A_s + \gamma^{-2}B_1B_1^TP_1)^TP_2 + P_2(A_s + \gamma^{-2}B_1B_1^TP_1) - P_2B_2R_{02}^{-1}B_2^TP_2 + Q = 0$$

have stabilizing solutions $P_1 \geq 0$ and $P_2 \geq 0$, i.e., $A_s + \gamma^{-2}B_1B_1^TP_1 - B_2R_{02}^{-1}B_2^TP_2$ is stable.

Furthermore, if the solutions exist, we have $w_* = \gamma^{-2}B_1^TP_1x$ and $u_* = F_*x$ with $F_* := -R_{02}^{-1}(D_{02}^TC_0 + B_2^TP_2)$.

Now we prove the results of output feedback design.

THEOREM 12. *There exist a w_* and an output feedback control law u_* such that*

$$J_3(u_*, w_*, w_0) \leq J_3(u_*, w, w_0), \quad J_4(u_*, w_*, w_0) \leq J_4(u, w_*, w_0)$$

if the coupled Riccati algebraic equations

$$(A_s - B_2R_{02}^{-1}B_2^TP_2)^TP_1 + P_1(A_s - B_2R_{02}^{-1}B_2^TP_2) + \gamma^{-2}P_1B_1B_1^TP_1$$

$$+[C_1 - D_{12}R_{02}^{-1}(D_{02}^TC_0 + B_2^TP_2)]^T[C_1 - D_{12}R_{02}^{-1}(D_{02}^TC_0 + B_2^TP_2)] = 0,$$

$$(A_s + \gamma^{-2}B_1B_1^TP_1)^TP_2 + P_2(A_s + \gamma^{-2}B_1B_1^TP_1) - P_2B_2R_{02}^{-1}B_2^TP_2 + Q = 0$$

and

$$(A_f + \gamma^{-2}B_1B_1^TP_1)P_3 + P_3(A_f + \gamma^{-2}B_1B_1^TP_1)^T - P_3C_2^TR_{20}^{-1}C_2P_3 + P = 0$$

have stabilizing solutions $P_1 \geq 0$, $P_2 \geq 0$, and $P_3 \geq 0$, i.e., both $A_s + \gamma^{-2}B_1B_1^TP_1 - B_2R_{02}^{-1}B_2^TP_2$ and $A_f + \gamma^{-2}B_1B_1^TP_1 - P_3C_2^TR_{20}^{-1}C_2$ are stable.

If the solutions exist, we have $w_* = \gamma^{-2}B_1^TP_1x$, and u_* is of the form

$$\begin{aligned}\dot{\hat{x}} &= (A + \gamma^{-2}B_1B_1^TP_1 + B_2F_*)\hat{x} + L_*(C_2\hat{x} - y),\\ u_* &= F_*\hat{x},\end{aligned}$$

where $F_* = -R_{02}^{-1}(D_{02}^TC_0 + B_2^TP_2)$ and $L_* = -(B_0D_{20}^T + P_3C_2^T)R_0^{-1}$.

Conversely, if the state feedback control problem is solvable, i.e., there are stabilizing solutions $P_1 \geq 0$ and $P_2 \geq 0$ for

$$(A_s - B_2R_{02}^{-1}B_2^TP_2)^TP_1 + P_1(A_s - B_2R_{02}^{-1}B_2^TP_2) + \gamma^{-2}P_1B_1B_1^TP_1$$

$$+[C_1 - D_{12}R_{02}^{-1}(D_{02}^TC_0 + B_2^TP_2)]^T[C_1 - D_{12}R_{02}^{-1}(D_{02}^TC_0 + B_2^TP_2)] = 0,$$

$$(A_s + \gamma^{-2}B_1B_1^TP_1)^TP_2 + P_2(A_s + \gamma^{-2}B_1B_1^TP_1) - P_2B_2R_{02}^{-1}B_2^TP_2 + Q = 0,$$

and there is a w_* and an optimal control u_* in the form of

$$\begin{aligned}\dot{\hat{x}} &= (A + \gamma^{-2}B_1B_1^TP_1 + B_2F_*)\hat{x} + L_*(C_2\hat{x} - y),\\ u_* &= F_*\hat{x},\end{aligned}$$

where $F_* = -R_{02}^{-1}(D_{02}^T C_0 + B_2^T P_2)$ *such that*

$$J_3(u_*, w_*, w_0) \le J_3(u_*, w, w_0), \quad J_4(u_*, w_*, w_0) \le J_4(u, w_*, w_0),$$

then there is a $P_3 \ge 0$ *solving*

$$(A_f + \gamma^{-2} B_1 B_1^T P_1) P_3 + P_3 (A_f + \gamma^{-2} B_1 B_1^T P_1)^T - P_3 C_2^T R_0^{-1} C_2 P_3 + P = 0.$$

Moreover, if $A + \gamma^{-2} B_1 B_1^T P_1 - (B_0 D_{20}^T + P_3 C_2^T) R_0^{-1} C_2$ *is stable, then* $L_* = -(B_0 D_{20}^T + P_3 C_2^T) R_0^{-1}$.

Proof. Suppose there exist stabilizing solutions $P_1 \ge 0$, $P_2 \ge 0$, and $P_3 \ge 0$ to the following Riccati equations:

$$(A_s - B_2 R_{02}^{-1} B_2^T P_2)^T P_1 + P_1 (A_s - B_2 R_{02}^{-1} B_2^T P_2) + \gamma^{-2} P_1 B_1 B_1^T P_1$$

$$+ [C_1 - D_{12} R_{02}^{-1} (D_{02}^T C_0 + B_2^T P_2)]^T [C_1 - D_{12} R_{02}^{-1} (D_{02}^T C_0 + B_2^T P_2)] = 0,$$

$$(A_s + \gamma^{-2} B_1 B_1^T P_1)^T P_2 + P_2 (A_s + \gamma^{-2} B_1 B_1^T P_1) - P_2 B_2 R_{02}^{-1} B_2^T P_2 + Q = 0,$$

and

$$(A_f + \gamma^{-2} B_1 B_1^T P_1) P_3 + P_3 (A_f + \gamma^{-2} B_1 B_1^T P_1)^T - P_3 C_2^T R_0^{-1} C_2 P_3 + P = 0.$$

Let u be any stabilizing control law. Since

$$\begin{aligned} J_3(u, w, w_0) &= \gamma^2 \|w\|_{\mathcal{P}}^2 - \|z\|_{\mathcal{P}}^2 \\ &= \lim_{T \to \infty} E \left\{ \frac{1}{T} \int_0^T (\gamma^2 \|w\|^2 - \|z\|^2) dt \right\} \\ &= \lim_{T \to \infty} E \left\{ \frac{1}{T} \int_0^T (\gamma^2 \|w\|^2 - x^T C_1^T C_1 x - 2 x^T C_1^T D_{12} u - u^T R_{12} u) dt \right\}, \end{aligned}$$

using the equation for P_1, we get

$$J_3(u, w, w_0) = E \left\{ \lim_{T \to \infty} \int_0^T [\gamma^2 \|w - w_*\|^2 - u^T R_{12} u + \bar{u}_*^T R_1 \bar{u}_* \right.$$

$$\left. - 2 x^T (P_1 B_2 + C_1^T D_{12})(u - \bar{u}_*) - 2 x^T P_1 B_0 w_0] dt \right\},$$

where $R_1 := D_{12}^T D_{12}$, $w_* = \gamma^{-2} B_1^T P_1 x$, and $\bar{u}_* = -R_{02}^{-1}(D_{02}^T C_0 + B_2^T P_2) x$, i.e., the optimal strategies for state feedback case. Clearly, if we take $w = w_*$, then for any u, and hence for the optimally designed output feedback control law u_*, we have $J_3(u_*, w_*, w_0) \le J_3(u_*, w, w_0)$. Now we design u_* to minimize J_4. By substituting the w_* into the system equation, we get

$$\begin{aligned} \dot{x} &= (A + \gamma^{-2} B_1 B_1^T P_1) x + B_0 w_0 + B_2 u, \\ y &= C_2 x + D_{20} w_0, \\ z_0 &= C_0 x + D_{02} u. \end{aligned}$$

Clearly, for the index functional J_4, it is a standard LQG problem [1, 16]. Thus the optimal control law is given by

$$\begin{aligned}\dot{\hat{x}} &= (A+\gamma^{-2}B_1B_1^TP_1)\hat{x}+B_2u_*+L_*(C_2\hat{x}-y),\\ u_* &= F_*\hat{x},\end{aligned}$$

where $F_* = -R_{02}^{-1}(D_{02}^TC_0+B_2^TP_2)$, $L_* = -(B_0D_{20}^T+P_3C_2^T)R_0^{-1}$, and u_* achieves $J_4(u_*,w_*,w_0)\le J_4(u,w_*,w_0)$. Note that $J_4(u_*,w_*,w_0)$ can be calculated as

$$J_4(u_*,w_*,w_0) = \operatorname{trace}\left\{B_0B_0^TP_2\right\}+\operatorname{trace}\left\{F_*^TR_{02}F_*P_3\right\}.$$

Conversely, suppose the state feedback control problem is solvable, i.e., there are stabilizing solutions to

$$(A_s-B_2R_{02}^{-1}B_2^TP_2)^TP_1+P_1(A_s-B_2R_{02}^{-1}B_2^TP_2)+\gamma^{-2}P_1B_1B_1^TP_1$$

$$+[C_1-D_{12}R_{02}^{-1}(D_{02}^TC_0+B_2^TP_2)]^T[C_1-D_{12}R_{02}^{-1}(D_{02}^TC_0+B_2^TP_2)]=0,$$

$$(A_s+\gamma^{-2}B_1B_1^TP_1)^TP_2+P_2(A_s+\gamma^{-2}B_1B_1^TP_1)-P_2B_2R_{02}^{-1}B_2^TP_2+Q=0.$$

Let u_* be in the form of

$$\begin{aligned}\dot{\hat{x}} &= (A+\gamma^{-2}B_1B_1^TP_1+B_2F_*)\hat{x}+L_*(C_2\hat{x}-y),\\ u_* &= F_*\hat{x},\end{aligned}$$

where $F_* = -R_{02}^{-1}(D_{02}^TC_0+B_2^TP_2)$ and u_* and w_* achieve

$$J_3(u_*,w_*,w_0)\le J_3(u_*,w,w_0),\quad J_4(u_*,w_*,w_0)\le J_4(u,w_*,w_0).$$

From the proof of the sufficiency, we get $w_* = \gamma^{-2}B_1^TP_1x$. Substituting w_* and u_* into the system equations, we have

$$\begin{aligned}\dot{x} &= (A+\gamma^{-2}B_1B_1^TP_1)x+B_0w_0+B_2u_*,\\ y &= C_2x+D_{20}w_0,\\ z_0 &= C_0x+D_{02}u_*.\end{aligned}$$

Since

$$J_4(u_*,w_*,w_0) = \|z_0\|_{\mathcal{P}}^2 = \lim_{T\to\infty}E\left\{\frac{1}{T}\int_0^T\|z_0\|^2dt\right\}$$

$$=\lim_{T\to\infty}E\left\{\frac{1}{T}\int_0^T[x^TC_0^TC_0x+2x^TC_0^TD_{02}u_*+u_*^TR_{02}u_*]dt\right\},$$

using the equation about P_2, we get

$$J_4(u_*,w_*,w_0) = \lim_{T\to\infty}E\left\{\frac{1}{T}\int_0^T(u_*-\bar{u}_*)^TR_{02}(u_*-\bar{u}_*)dt\right\}$$

$$
\begin{aligned}
&+2\lim_{T\to\infty} E\left\{\frac{1}{T}\int_0^T x^T P_2 B_0 w_0 dt\right\}\\
&=\lim_{T\to\infty} E\left\{\frac{1}{T}\int_0^T (u_*-\bar{u}_*)^T R_{02}(u_*-\bar{u}_*)dt\right\}\\
&\quad+2\mathrm{trace}\left\{\lim_{T\to\infty}\frac{1}{T}\int_0^T P_2 B_0 E\{w_0 x^T\}dt\right\}\\
&=\lim_{T\to\infty} E\left\{\frac{1}{T}\int_0^T (u_*-\bar{u}_*)^T R_{02}(u_*-\bar{u}_*)dt\right\}\\
&\quad+\mathrm{trace}(B_0^T P_2 B_0),
\end{aligned}
$$

where $\bar{u}_* = -R_{02}^{-1}(D_{02}^T C_0 + B_2^T P_2)x$. We need only to consider the first term. Define $e_x = x - \hat{x}$; then

$$
\lim_{T\to\infty} E\left\{\frac{1}{T}\int_0^T (u_*-\bar{u}_*)^T R_{02}(u_*-\bar{u}_*)dt\right\} = \lim_{T\to\infty} E\left\{\frac{1}{T}\int_0^T e_x^T F_*^T R_{02} F_* e_x dt\right\},
$$

where e_x satisfies

$$
\dot{e}_x = \dot{x} - \dot{\hat{x}} = (A + \gamma^{-2} B_1 B_1^T P_1 + L_* C_2) e_x + (B_0 + L_* D_{20}) w_0 = A_{L_*} e_x + B_{L_*} w_0.
$$

Hence $e_x = \int_0^t e^{A_{L_*}(t-\tau)} B_{L_*} w_0 \ d\tau$. This gives

$$
\lim_{T\to\infty} E\left\{\frac{1}{T}\int_0^T e_x^T F_*^T R_{02} F_* e_x dt\right\} = \mathrm{trace}(D_{02} F_* Y F_*^T D_{02}^T),
$$

where $Y = \int_0^\infty \exp(A_{L_*} s) B_{L_*} B_{L_*}^T \exp(A_{L_*}^T s) ds \geq 0$ satisfies $A_{L_*} Y + Y A_{L_*}^T + B_{L_*} B_{L_*}^T = 0$. Since

$$
J_4(u_*, w_*, w_0) = \mathrm{trace}(D_{02} F_* Y F_*^T D_{02}^T) + \mathrm{trace}(B_0^T P_2 B_0)
$$

is the minimum value, by Theorem 7, there is a $P_3 \geq 0,\ P_3 \leq Y$ solving

$$
(A_f + \gamma^{-2} B_1 B_1^T P_1) P_3 + P_3 (A_f + \gamma^{-2} B_1 B_1^T P_1)^T - P_3 C_2^T R_0^{-1} C_2 P_3 + P = 0.
$$

If $A + \gamma^{-2} B_1 B_1^T P_1 - (B_0 D_{20}^T + P_3 C_2^T) R_0^{-1} C_2$ is stable, then L_* can be chosen as $L_* = -(B_0 D_{20}^T + P_3 C_2^T) R_0^{-1}$ because $J_4(u_*, w_*, w_0) = \mathrm{trace}(D_{02} F_* P_3 F_*^T D_{02}^T) + \mathrm{trace}(B_0^T P_2 B_0)$. This concludes the proof. □

5. $\mathcal{H}_\infty$ Gaussian control design. In this section, we give the solution to the problem formulated in section 2.3. To simplify the notations, we shall introduce the following abbreviations:

$$
A_x := A - B_2 R_1^{-1} D_{12}^T C_1, \quad A_y := A - B_0 D_{20}^T R_0^{-1} C_2,
$$

$$
P := B_0 (I - D_{20}^T R_0^{-1} D_{20}) B_0^T, \quad Q := C_1^T (I - D_{12} R_1^{-1} D_{12}^T) C_1.
$$

5.1. $\mathcal{H}_\infty$ Gaussian control design—finite time horizon. The design results for $\mathcal{H}_\infty$ Gaussian control in the finite time horizon are summarized in the next theorem.

THEOREM 13. *Let the dynamical system G be described by* (5)–(7). *If there are solutions $P_1(t) \geq 0$, $P_2(t) \geq 0$, and $P_3(t) \geq 0$ with $P_1(T) = 0$, $P_2(T) = 0$, and $P_3(0) = 0$ solving the differential Riccati equations*

$$A_x^T P_1(t) + P_1(t)A_x + P_1(t)(B_1 B_1^T/\gamma^2 - B_2 R_1^{-1} B_2^T)P_1(t) + Q = -\dot{P}_1(t),$$

$$P_2(t)(A_y+\gamma^{-2}B_1B_1^TP_1(t)-P_3(t)C_2^TR_0^{-1}C_2)+(A_y+\gamma^{-2}B_1B_1^TP_1(t)-P_3(t)C_2^TR_0^{-1}C_2)^TP_2(t)$$

$$+\gamma^{-2}P_2(t)B_1B_1^TP_2(t) + (D_{12}^TC_1 + B_2^TP_1(t))^TR_1^{-1}(D_{12}^TC_1 + B_2^TP_1(t)) = -\dot{P}_2(t),$$

$$[A_y + \gamma^{-2}B_1B_1^T(P_1(t) + P_2(t))]P_3(t) + P_3(t)[A_y + \gamma^{-2}B_1B_1^T(P_1(t) + P_2(t))]^T$$

$$-P_3(t)C_2^TR_0^{-1}C_2P_3(t) + P = \dot{P}_3(t),$$

then there exist an optimal control law u_* and a worst disturbance signal w_* such that

$$J_1(u_*, w_*, w_0) \leq J_1(u_*, w, w_0), \quad J_2(u_*, w_*, w_0) \leq J_2(u, w_*, w_0).$$

If the solutions exist, we have the optimal controller

$$\begin{aligned}\dot{\hat{x}} &= (A + \gamma^{-2}B_1B_1^TP_1(t) + L_*(t)C_2 + B_2F_*(t))\hat{x} - L_*(t)y, \quad \hat{x}(0) = 0,\\ u_* &= F_*(t)\hat{x},\end{aligned}$$

where $F_*(t) := -R_1^{-1}(D_{12}^TC_1 + B_2^TP_1(t))$, $L_*(t) = -(B_0D_{20}^T + P_3(t)C_2^T)R_0^{-1}$, and $w_* = \gamma^{-2}B_1^T(P_1(t)x + P_2(t)e_x)$, $e_x = x - \hat{x}$.

Conversely, let $P_1(t) \geq 0$ with $P_1(T) = 0$ solve

$$A_x^T P_1(t) + P_1(t)A_x + P_1(t)(B_1 B_1^T/\gamma^2 - B_2 R_1^{-1} B_2^T)P_1(t) + Q = -\dot{P}_1(t).$$

Suppose there exist a w_*' and an optimal control u_* (hence an $L_*(t)$) in the form

$$\begin{aligned}\dot{\hat{x}} &= (A + \gamma^{-2}B_1B_1^TP_1(t) + L_*(t)C_2 + B_2F_*(t))\hat{x} - L_*(t)y, \quad \hat{x}(0) = 0,\\ u_* &= F_*(t)\hat{x},\end{aligned}$$

where $F_*(t) = -R_1^{-1}(D_{12}^TC_1 + B_2^TP_1(t))$ such that $0 < J_1(u_*, w_*', 0) \leq J_1(u_*, w, 0)$. Then, there is a w_* plus the same u_* achieving $J_1(u_*, w_*, w_0) \leq J_1(u_*, w, w_0)$.

If, furthermore, u_* and w_* also achieve $J_2(u_*, w_*, w_0) \leq J_2(u, w_*, w_0)$, then there exist $P_2(t) \geq 0$, $P_3(t) \geq 0$ with $P_2(T) = 0$ and $P_3(0) = 0$ solving

$$P_2(t)(A_y+\gamma^{-2}B_1B_1^TP_1(t)-P_3(t)C_2^TR_0^{-1}C_2)+(A_y+\gamma^{-2}B_1B_1^TP_1(t)-P_3(t)C_2^TR_0^{-1}C_2)^TP_2(t)$$

$$+\gamma^{-2}P_2(t)B_1B_1^TP_2(t) + (D_{12}^TC_1 + B_2^TP_1(t))^TR_1^{-1}(D_{12}^TC_1 + B_2^TP_1(t)) = -\dot{P}_2(t),$$

$$[A_y + \gamma^{-2}B_1B_1^T(P_1(t) + P_2(t))]P_3(t) + P_3(t)[A_y + \gamma^{-2}B_1B_1^T(P_1(t) + P_2(t))]^T$$

$$-P_3(t)C_2^T R_0^{-1} C_2 P_3(t) + P = \dot{P}_3(t),$$

and $J_2(L(t))$ *is minimized by* $L_*(t) = -(B_0 D_{20}^T + P_3(t)C_2^T)R_0^{-1}$.

Proof (sufficiency). Suppose there exist solutions $P_1(t) \geq 0$, $P_2(t) \geq 0$, and $P_3(t) \geq 0$ $\forall t \in [0,T]$ with $P_1(T) = 0$, $P_2(T) = 0$, and $P_3(0) = 0$ solving those three differential Riccati equations.

Using the first Riccati equation and Lemma 5 to complete square for $J_1(u, w, w_0)$, we get

$$\begin{aligned} J_1(u,w,w_0) &= \gamma^2 \|w\|_{[0,T]}^2 - \|z\|_{[0,T]}^2 \\ &= \gamma^2 \|w - \tilde{w}_*\|_{[0,T]}^2 - \|D_{12}(u - \tilde{u}_*)\|_{[0,T]}^2 - \int_0^T \operatorname{trace}\{B_0^T P_1(t) B_0\} dt, \end{aligned}$$

where $\tilde{w}_* = \gamma^{-2} B_1^T P_1(t) x$ and $\tilde{u}_* = -R_1^{-1}(D_{12}^T C_1 + B_2^T P_1(t))x$. Define

$$r := w - \gamma^{-2} B_1^T P_1(t) x, \quad v := D_{12}\left\{u + R_1^{-1}(D_{12}^T C_1 + B_2^T P_1(t))x\right\}.$$

Then the system equations can be rewritten as

$$\begin{aligned} \dot{x} &= (A + \gamma^{-2} B_1 B_1^T P_1(t))x + B_0 w_0 + B_1 r + B_2 u, \quad x(0) = 0, \\ v &= D_{12}\left\{R_1^{-1}(D_{12}^T C_1 + B_2^T P_1(t))x + u\right\}, \\ y &= C_2 x + D_{20} w_0, \end{aligned}$$

and the performance index $J_1(u, w, w_0)$ becomes

$$J_1(u,w,w_0) = \gamma^2 \|r\|_{[0,T]}^2 - \|v\|_{[0,T]}^2 - \int_0^T \operatorname{trace}\{B_0^T P_1(t) B_0\} dt.$$

Using $L_* = -R_1^{-1}(D_{12}^T C_1 + B_2^T P_1(t))$ to construct a state estimator,

$$\dot{\hat{x}} = (A + \gamma^{-2} B_1 B_1^T P_1(t))\hat{x} + B_2 u + L_*(t)(C_2 \hat{x} - y), \quad \hat{x}(0) = 0,$$

a natural choice of the optimal control law $u = u_*$ would be $u_* = -R_1^{-1}(D_{12}^T C_1 + B_2^T P_1(t))\hat{x}$. Denote $e_x = x - \hat{x}$. Accordingly, the system can be further simplified into

$$\begin{aligned} \dot{e}_x &= (A + \gamma^{-2} B_1 B_1^T P_1(t) + L_*(t) C_2) e_x + (B_0 + L_*(t) D_{20}) w_0 + B_1 r, \quad e_x(0) = 0, \\ v &= D_{12} R_1^{-1}(D_{12}^T C_1 + B_2^T P_1(t)) e_x. \end{aligned}$$

Now we can complete square for $J_1(u, w, w_0)$ again by using the second Riccati equation and Lemma 5 to get

$$\begin{aligned} J_1(u_*, w, w_0) = \gamma^2 \|r - \gamma^{-2} B_1^T P_2(t) e_x\|_{[0,T]}^2 &- \int_0^T \operatorname{trace}\{B_0^T P_1(t) B_0\} dt \\ &- \int_0^T trace\{(B_0 + L_*(t) D_{20})^T P_2(t)(B_0 + L_*(t) D_{20})\} dt. \end{aligned}$$

We claim that the worst signal w_* can be taken as

$$w_* = \gamma^{-2} B_1^T (P_1(t) x + P_2(t) e_x) \quad \text{or} \quad r_* = \gamma^{-2} B_1^T P_2(t) e_x.$$

Indeed, substituting $w_* = \gamma^{-2}B_1^T(P_1(t)x+P_2(t)e_x)$ and $u_* = -R_1^{-1}(D_{12}^TC_1+B_2^TP_1(t))(x-e_x)$ into the system equation (5)–(7), we get

$$\dot{\bar{x}} = \bar{A}\bar{x} + \bar{B}w_0, \quad z = \bar{C}\bar{x},$$

where $\bar{x} = [\ x^T \quad e_x^T\ ]^T$,

$$\bar{A} = \begin{bmatrix} A+\gamma^{-2}B_1B_1^TP_1(t) - B_2R_1^{-1}(D_{12}^TC_1+B_2^TP_1(t)) & \gamma^{-2}B_1B_1^TP_2(t) + B_2R_1^{-1}(D_{12}^TC_1+B_2^TP_1(t)) \\ 0 & A+\gamma^{-2}B_1B_1^T(P_1(t)+P_2(t))+L_*(t)C_2 \end{bmatrix},$$

$$\bar{B} = [\ B_0^T \quad (B_0+L_*(t)D_{20})^T\ ]^T,$$
$$\bar{C} = [\ C_1 - D_{12}R_1^{-1}(D_{12}^TC_1+B_2^TP_1(t)) \quad D_{12}R_1^{-1}(D_{12}^TC_1+B_2^TP_1(t))\ ].$$

Hence $\bar{x} = \int_0^t e^{\bar{A}(t-\tau)}\bar{B}w_0 d\tau$. By Lemma 5, we have

$$E\{x(t)w_0^T(t)\} = \frac{1}{2}B_0, \quad E\{e_x(t)w_0^T(t)\} = \frac{1}{2}(B_0+L_*(t)D_{20}).$$

The first completed square gives

$$\begin{aligned} J_1(u_*,w_*,w_0) &= \gamma^2\|w_*\|_{[0,T]}^2 - \|z\|_{[0,T]}^2 \\ &= \gamma^2\|\gamma^{-2}B_1^TP_2(t)e_x\|_{[0,T]}^2 - \|D_{12}R_1^{-1}(D_{12}^TC_1+B_2^TP_1(t))e_x\|_{[0,T]}^2 \\ &\qquad -2\int_0^T \operatorname{trace}\{B_0^TP_1(t)E(xw_0^T)\}dt \\ &= \gamma^2\|\gamma^{-2}B_1^TP_2(t)e_x\|_{[0,T]}^2 - \|D_{12}R_1^{-1}(D_{12}^TC_1+B_2^TP_1(t))e_x\|_{[0,T]}^2 \\ &\qquad -\int_0^T \operatorname{trace}\{B_0^TP_1(t)B_0\}dt. \end{aligned}$$

Note that the second Riccati equation can be written as

$$P_2(t)(A+\gamma^{-2}B_1B_1^T(P_1(t)+P_2(t))+L_*(t)C_2)+(A+\gamma^{-2}B_1B_1^T(P_1(t)+P_2(t))+L_*(t)C_2)^TP_2(t)$$

$$-\gamma^{-2}P_2(t)B_1B_1^TP_2(t) + (D_{12}^TC_1+B_2^TP_1(t))^TR_1^{-1}(D_{12}^TC_1+B_2^TP_1(t)) = -\dot{P}_2(t).$$

Hence

$$\gamma^2\|\gamma^{-2}B_1^TP_2(t)e_x\|_{[0,T]}^2 - \|D_{12}R_1^{-1}(D_{12}^TC_1+B_2^TP_1(t))e_x\|_{[0,T]}^2$$

$$= E\int_0^T e_x^T[\gamma^{-2}P_2(t)B_1B_1^TP_2(t) - (D_{12}^TC_1+B_2^TP_1(t))^TR_1^{-1}(D_{12}^TC_1+B_2^TP_1(t))]e_x dt$$

$$= E\int_0^T e_x^T[P_2(t)(A+\gamma^{-2}B_1B_1^T(P_1(t)+P_2(t))+L_*(t)C_2)$$

$$+(A+\gamma^{-2}B_1B_1^T(P_1(t)+P_2(t))+L_*(t)C_2)^TP_2(t)+\dot{P}_2(t)]e_x dt$$

$$= E\int_0^T [e_x^T P_2(t)\dot{e}_x + \dot{e}_x^T P_2(t)e_x + e_x^T \dot{P}_2(t)e_x - 2e_x P_2(t)(B_0 + L_*(t)C_2)w_0]dt$$

$$= -2\int_0^T \text{trace}\{(B_0 + L_*(t)C_2)^T P_2(t)E(e_x w_0^T)\}dt$$

$$= -\int_0^T \text{trace}\{(B_0 + L_*(t)C_2)^T P_2(t)(B_0 + L_*(t)C_2)\}dt.$$

Therefore,

$$J_1(u_*, w_*, w_0) = -\int_0^T \{\text{trace}\{(B_0 + L_*(t)C_2)^T P_2(t)(B_0 + L_* C_2(t))\} + \text{trace}\{B_0^T P_1(t)B_0\}\}dt.$$

Clearly, $J_1(u_*, w_*, w_0) \le J_1(u_*, w, w_0)$ for all w which is independent from w_0. Hence w_* is the worst signal.

Next, it is shown that u_* does minimize the index $J_2(u, w_*, w_0)$ under the worst disturbance w_*. Let $L(t)$ be any filter gain. Substituting w_* (or r_*) into the system equations, we get

$$\dot{e}_x = (A + \gamma^{-2}B_1B_1^T P_1(t) + L(t)C_2 + \gamma^{-2}B_1B_1^T P_2(t))e_x + (B_0 + L(t)D_{20})w_0, \quad e_x(0) = 0,$$
$$:= A_L e_x + B_L w_0.$$

Let $\Phi(t,\tau)$ be the transition matrix for A_L; then $e_x = \int_0^t \Phi(t,\tau)B_L w_0(\tau)d\tau$ and

$$J_2(u, w_*, w_0) = \|e_x\|^2_{[0,T]} = E\left\{\int_0^T \int_0^t \int_0^t w_0^T(\tau)B_L^T\Phi^T(t,\tau)\Phi(t,s)B_L w_0(s)d\tau\, ds\, dt\right\}$$

$$= \text{trace}\left\{\int_0^T \int_0^t \int_0^t \Phi(t,s)B_L E\{w_0(s)w_0^T(\tau)\}B_L^T\Phi^T(t,\tau)d\tau\, ds\, dt\right\}$$

$$= \text{trace}\left\{\int_0^T \int_0^t \int_0^t \Phi(t,s)B_L\delta(\tau - s)B_L^T\Phi^T(t,\tau)d\tau\, ds\, dt\right\}$$

$$= \text{trace}\left\{\int_0^T \int_0^t \Phi(t,s)B_L B_L^T\Phi^T(t,s)ds\, dt\right\} = \text{trace}\{\int_0^T Y(t)dt\},$$

where $Y(t) = \int_0^t \Phi(t,s)B_L B_L^T\Phi^T(t,s)ds \ge 0$ satisfies $A_L Y(t) + Y(t)A_L^T + B_L B_L^T = \dot{Y}(t)$. By Theorem 6 and applying the third Riccati equation, $J_2(u, w*, w_0)$ achieves the minimum value at $L(t) = L_*(t)$, which means that u_* is the desired optimal control. Thus u_* and w_* achieve

$$J_1(u_*, w_*, w_0) \le J_1(u_*, w, w_0), \quad J_2(u_*, w_*, w_0) \le J_2(u, w_*, w_0).$$

Proof (necessity). Let $P_1(t) \ge 0\ \forall t \in [0,T]$ with $P_1(T) = 0$ solve

$$A_x^T P_1(t) + P_1(t)A_x + P_1(t)(B_1B_1^T/\gamma^2 - B_2R_1^{-1}B_2^T)P_1(t) + Q = -\dot{P}_1(t).$$

Suppose there are a w_*' and an optimal control u_* in the form of

$$\dot{\hat{x}} = (A + \gamma^{-2}B_1B_1^T P_1(t) + L_*(t)C_2 + B_2F_*(t))\hat{x} - L_*(t)y, \quad \hat{x}(0) = 0,$$
$$u_* = F_*(t)\hat{x},$$

where $F_*(t) = -R_1^{-1}(D_{12}^T C_1 + B_2^T P_1(t))$, achieving $0 < J_1(u_*, w'_*, 0) \le J_1(u_*, w, 0)$. This suggests that the system without the white noise,

$$\begin{aligned}
&\dot{x} = Ax + B_1 w + B_2 u_*, \quad x(0) = 0,\\
&z = C_1 x + D_{12} u_*,\\
&y = C_2 x + D_{20} w_0,
\end{aligned}$$

achieves the $\mathcal{H}_\infty$ performance on finite support $[0, T]$. Now define

$$e_x := x - \hat{x}, \quad r := w - \gamma^{-2} B_1^T P_1(t) x, \quad v_* := D_{12}\left\{u_* + R_1^{-1}(D_{12}^T C_1 + B_2^T P_1(t))x\right\}.$$

The system without the white noise can be converted into

$$\begin{aligned}
&\dot{e}_x = (A + \gamma^{-2} B_1 B_1^T P_1(t) + L_*(t) C_2) e_x + B_1 r, \quad e_x(0) = 0,\\
&v_* = D_{12}\left\{R_1^{-1}(D_{12}^T C_1 + B_2^T P_1(t)) e_x\right\},
\end{aligned}$$

and $J_1(u_*, w, 0)$ can be converted into

$$J_1(u_*, w, 0) = \gamma^2 \|w - \tilde{w}_*\|_{[0,T]}^2 - \|D_{12}(u_* - \tilde{u}_*)\|_{[0,T]}^2 = \gamma^2 \|r\|_{[0,T]}^2 - \|v_*\|_{[0,T]}^2,$$

where $\tilde{w}_* = \gamma^{-2} B_1^T P_1(t) x$ and $\tilde{u}_* = -R_1^{-1}(D_{12}^T C_1 + B_2^T P_1(t))x$. Hence, by Lemma 3, there is a $P_2(t) \ge 0\ \forall t \in [0, T]$ with $P_2(T) = 0$ solving

$$P_2(t)(A + \gamma^{-2} B_1 B_1^T P_1(t) + L_*(t) C_2) + (A_y + \gamma^{-2} B_1 B_1^T P_1(t) + L_*(t) C_2)^T P_2(t)$$

$$+\gamma^{-2} P_2(t) B_1 B_1^T P_2(t) + (D_{12}^T C_1 + B_2^T P_1(t))^T R_1^{-1}(D_{12}^T C_1 + B_2^T P_1(t)) = -\dot{P}_2(t),$$

and, clearly, w'_* can be obtained as

$$w'_* = r'_* + \gamma^{-2} B_1^T P_1(t) x = \gamma^{-2} B_1^T (P_1(t) x + P_2(t) e_x), \quad r'_* = \gamma^{-2} B_1^T P_2(t) e_x.$$

Consider the system with white noise

$$\begin{aligned}
&\dot{x} = Ax + B_0 w_0 + B_1 w + B_2 u_*, \quad x(0) = 0,\\
&z = C_1 x + D_{12} u_*,\\
&y = C_2 x + D_{20} w_0.
\end{aligned}$$

Under the same transformation, we have

$$\begin{aligned}
&\dot{e}_x = (A + \gamma^{-2} B_1 B_1^T P_1(t) + L_*(t) C_2) e_x + (B_0 + L_*(t) D_{20}) w_0 + B_1 r, \quad e_x(0) = 0,\\
&v_* = D_{12}\left\{R_1^{-1}(D_{12}^T C_1 + B_2^T P_1(t)) e_x\right\}.
\end{aligned}$$

$J_1(u_*, w, w_0)$ becomes (see the proof for the sufficiency)

$$J_1(u_*, w, w_0) = \gamma^2 \|w - \tilde{w}_*\|_{[0,T]}^2 - \|D_{12}(u_* - \tilde{u}_*)\|_{[0,T]}^2 - \int_0^T \operatorname{trace}\{B_0^T P_1(t) B_0\} dt$$

$$= \gamma^2 \|r - \gamma^{-2} B_1^T P_2(t) e_x\|_{[0,T]}^2 - \int_0^T \operatorname{trace}\{B_0^T P_1(t) B_0\} dt$$

$$-\int_0^T \text{trace}\{(B_0 + L_*(t)D_{20})^T P_2(t)(B_0 + L_*(t)D_{20})\}dt.$$

Choosing

$$r_* = \gamma^{-2}B_1^T P_2(t)e_x \quad \text{or} \quad w_* = r_* + \gamma^{-2}B_1^T P_1(t)x = \gamma^{-2}B_1^T(P_1(t)x + P_2(t)e_x),$$

it is easy to see that $J_1(u_*, w_*, w_0) \le J_1(u_*, w, w_0)$. If, furthermore, this w_* together with u_* achieves $J_2(u_*, w_*, w_0) \le J_2(u, w_*, w_0)$, by substituting w_* into the system equations, we get

$$\begin{aligned}\dot{e}_x &= (A + \gamma^{-2}B_1B_1^T P_1(t) + L_*(t)C_2 + \gamma^{-2}B_1B_1^T P_2(t))e_x + (B_0 + L_*(t)D_{20})w_0,\\ &:= A_{L_*}e_x + B_{L_*}w_0.\end{aligned}$$

Let $\Phi(t,\tau)$ be the transition matrix of A_{L_*}; then $e_x = \int_0^t \Phi^T(t,\tau)B_{L_*}w_0(\tau)d\tau$, and

$$J_2(u_*, w_*, w_0) = \|e_x\|_{[0,T]} = \text{trace}\left\{\int_0^T Y(t)dt\right\}$$

is the minimum value, where $Y(t) = \int_0^t \Phi(t,s)B_{L_*}B_{L_*}^T\Phi^T(t,s)ds \ge 0$, $Y(0) = 0$, satisfies $A_{L_*}Y(t) + Y(t)A_{L_*}^T + B_{L_*}B_{L_*}^T = \dot{Y}(t)$. Thus, by Theorem 6, there is a $P_3(t) \ge 0\ \forall t \in [0,T]$ with $P_3(0) = 0$ solving

$$[A_y + \gamma^{-2}B_1B_1^T(P_1(t) + P_2(t))]P_3(t) + P_3(t)[A_y + \gamma^{-2}B_1B_1^T(P_1(t) + P_2(t))]^T$$

$$-P_3(t)C_2^T R_0^{-1}C_2P_3(t) + P = \dot{P}_3(t),$$

and $L_*(t)$ can be chosen as $L_*(t) = -(B_0D_{20}^T + P_3(t)C_2^T)R_0^{-1}$. Substituting L_* back into the Riccati equation about $P_2(t)$, clearly, $P_2(t) \ge 0\ \forall t \in [0,T]$ with $P_2(T) = 0$ solves

$$P_2(t)(A_y+\gamma^{-2}B_1B_1^T P_1(t)-P_3(t)C_2^T R_0^{-1}C_2)+(A_y+\gamma^{-2}B_1B_1^T P_1(t)-P_3(t)C_2^T R_0^{-1}C_2)^T P_2(t)$$

$$+\gamma^{-2}P_2(t)B_1B_1^T P_2(t) + (D_{12}^TC_1 + B_2^T P_1(t))^T R_1^{-1}(D_{12}^TC_1 + B_2^T P_1(t)) = -\dot{P}_2(t). \qquad \square$$

5.2. $\mathcal{H}_\infty$ Gaussian control design—infinite time horizon. For $\mathcal{H}_\infty$ Gaussian design on infinite time horizon, we need to add the following standard assumptions:

(A1) (A, B_2) is stabilizable and (C_2, A) is detectable;

(A2) $\begin{bmatrix} A - j\omega I & B_2 \\ C_1 & D_{12} \end{bmatrix}$ has full column rank for all ω;

(A3) $\begin{bmatrix} A - j\omega I & B_0 \\ C_2 & D_{20} \end{bmatrix}$ has full row rank for all ω.

The infinite time $\mathcal{H}_\infty$ Gaussian control design is presented in the next theorem.

THEOREM 14. *Let the dynamical system G be described by* (5)–(7). *Suppose that w and w_0 are independent. If there are stabilizing solutions $P_1 \ge 0$, $P_2 \ge 0$, and $P_3 \ge 0$ solving the Riccati equations*

$$A_x^T P_1 + P_1A_x + P_1(B_1B_1^T/\gamma^2 - B_2R_1^{-1}B_2^T)P_1 + Q = 0,$$

$$P_2(A_y + \gamma^{-2}B_1B_1^T P_1 - P_3C_2^T R_0^{-1}C_2) + (A_y + \gamma^{-2}B_1B_1^T P_1 - P_3C_2^T R_0^{-1}C_2)^T P_2$$

$$+\gamma^{-2}P_2B_1B_1^TP_2+(D_{12}^TC_1+B_2^TP_1)^TR_1^{-1}(D_{12}^TC_1+B_2^TP_1)=0,$$

$$[A_y+\gamma^{-2}B_1B_1^T(P_1+P_2)]P_3+P_3[A_y+\gamma^{-2}B_1B_1^T(P_1+P_2)]^T$$

$$-P_3C_2^TR_0^{-1}C_2P_3+P=0,$$

i.e., if $A_x+(B_1B_1^T/\gamma^2-B_2R_1^{-1}B_2^T)P_1$ *and* $A_y+\gamma^{-2}B_1B_1^T(P_1+P_2)-P_3C_2^TR_0^{-1}C_2$ *are both stable, then there exist an optimal control law* u_* *and a worst disturbance signal* w_* *such that*

$$J_3(u_*,w_*,w_0)\le J_3(u_*,w,w_0),\quad J_4(u_*,w_*,w_0)\le J_4(u,w_*,w_0).$$

If the solutions exist, then $w_*=\gamma^{-2}B_1^T(P_1x+P_2e)$*, and an optimal controller is given by*

$$\begin{aligned}\dot{\hat{x}}&=(A+\gamma^{-2}B_1B_1^TP_1+L_*C_2+B_2F_*)\hat{x}-L_*y,\\ u_*&=F_*\hat{x},\quad \hat{x}(0)=0,\end{aligned}$$

where $F_*:=-R_1^{-1}(D_{12}^TC_1+B_2^TP_1)$ *and* $L_*=-(B_0D_{20}^T+P_3C_2^T)R_0^{-1}$.

Conversely, let $P_1\ge 0$ *be a stabilizing solution to*

$$A_x^TP_1+P_1A_x+P_1(B_1B_1^T/\gamma^2-B_2R_1^{-1}B_2^T)P_1+Q=0.$$

Suppose there exist a w_*' *and a controller* u_* *(hence, an* L_**)*

$$\begin{aligned}\dot{\hat{x}}&=(A+\gamma^{-2}B_1B_1^TP_1+L_*C_2+B_2F_*)\hat{x}-L_*y,\\ u_*&=F_*\hat{x},\quad F_*=-R_1^{-1}(D_{12}^TC_1+B_2^TP_1),\end{aligned}$$

achieving $0<J_3(u_*,w_*',0)\le J_3(u_*,w,0)$*. Then there exists a* w_* *achieving* $J_3(u_*,w_*,w_0)\le J_3(u_*,w,w_0)$*. If, furthermore, this* w_* *also achieves* $J_4(u_*,w_*,w_0)\le J_4(u,w_*,w_0)$*, then there exist* $P_2\ge 0$ *and* $P_3\ge 0$ *solving*

$$P_2(A_y+\gamma^{-2}B_1B_1^TP_1-P_3C_2^TR_0^{-1}C_2)+(A_y+\gamma^{-2}B_1B_1^TP_1-P_3C_2^TR_0^{-1}C_2)^TP_2$$

$$+\gamma^{-2}P_2B_1B_1^TP_2+(D_{12}^TC_1+B_2^TP_1)^TR_1^{-1}(D_{12}^TC_1+B_2^TP_1)=0,$$

$$[A_y+\gamma^{-2}B_1B_1^T(P_1+P_2)]P_3+P_3[A_y+\gamma^{-2}B_1B_1^T(P_1+P_2)]^T-P_3C_2^TR_0^{-1}C_2P_3+P=0.$$

Moreover, if $A+\gamma^{-2}B_1B_1^T(P_1+P_2)-(B_0D_{20}^T+P_3C_2^T)R_0^{-1}C_2$ *is stable, then* $L_*=-(B_0D_{20}^T+P_3C_2^T)R_0^{-1}$.

Proof (sufficiency). Suppose that there are $P_1\ge 0$, $P_2\ge 0$, and $P_3\ge 0$ solving

$$A_x^TP_1+P_1A_x+P_1(B_1B_1^T/\gamma^2-B_2R_1^{-1}B_2^T)P_1+Q=0,$$

$$P_2(A_y+\gamma^{-2}B_1B_1^TP_1-P_3C_2^TR_0^{-1}C_2)+(A_y+\gamma^{-2}B_1B_1^TP_1-P_3C_2^TR_0^{-1}C_2)^TP_2$$

$$+\gamma^{-2}P_2B_1B_1^TP_2+(D_{12}^TC_1+B_2^TP_1)^TR_1^{-1}(D_{12}^TC_1+B_2^TP_1)=0,$$

$$[A_y+\gamma^{-2}B_1B_1^T(P_1+P_2)]P_3+P_3[A_y+\gamma^{-2}B_1B_1^T(P_1+P_2)]^T-P_3C_2^TR_0^{-1}C_2P_3+P=0.$$

First, it is claimed that $A_y+\gamma^{-2}B_1B_1^TP_1-P_3C_2^TR_0^{-1}C_2=A+\gamma^{-2}B_1B_1^TP_1+L_*C_2$ is stable, where $L_*=-(B_0D_{20}^T+P_3C_2^T)R_0^{-1}$. The reason is as follows: if $A+\gamma^{-2}B_1B_1^TP_1+L_*C_2$ is not stable, then at least one of its eigenvalues λ is on the closed right-half plane, i.e., $\mathrm{Re}(\lambda)\geq 0$. Let x be the eigenvector corresponding to λ; then

$$x^TP_2(A_y+\gamma^{-2}B_1B_1^TP_1-P_3C_2^TR_0^{-1}C_2)x+x^T(A_y+\gamma^{-2}B_1B_1^TP_1-P_3C_2^TR_0^{-1}C_2)^TP_2x$$

$$\gamma^{-2}x^TP_2B_1B_1^TP_2x+x^T(D_{12}^TC_1+B_2^TP_1)^TR_1^{-1}(D_{12}^TC_1+B_2^TP_1)x=0$$

or

$$2\mathrm{Re}(\lambda)x^TP_2x+x^T(D_{12}^TC_1+B_2^TP_1)^TR_1^{-1}(D_{12}^TC_1+B_2^TP_1)x+\gamma^{-2}x^TP_2B_1B_1^TP_2x=0,$$

which gives $B_1^TP_2x=0$ and $(D_{12}^TC_1+B_2^TP_1)x=0$. Thus

$$[A_y+\gamma^{-2}B_1B_1^T(P_1+P_2)-P_3C_2^TR_0^{-1}C_2]x=[A+\gamma^{-2}B_1B_1^TP_1+L_*C_2]x=\lambda x,$$

which means that $A_y+\gamma^{-2}B_1B_1^T(P_1+P_2)-P_3C_2^TR_0^{-1}C_2$ is not stable, which is a contradiction.

Now consider the index $J_3(u,w,w_0)$. Let u be any stabilizing control law. Define $r:=w-\gamma^{-2}B_1^TP_1x$ and $v:=D_{12}\left\{u+R_1^{-1}(D_{12}^TC_1+B_2^TP_1)x\right\}$. Then the system equations can be rewritten as

$$\begin{aligned}\dot{x}&=(A+\gamma^{-2}B_1B_1^TP_1)x+B_0w_0+B_1r+B_2u,\\ v&=D_{12}\left\{R_1^{-1}(D_{12}^TC_1+B_2^TP_1)x+u\right\},\\ y&=C_2x+D_{20}w_0,\end{aligned}$$

and the performance index $J_3(u,w,w_0)$ becomes

$$J_3(u,w,w_0)=\gamma^2\|w\|_{\mathcal{P}}^2-\|z\|_{\mathcal{P}}^2=\gamma^2\|r\|_{\mathcal{P}}^2-\|v\|_{\mathcal{P}}^2-\mathrm{trace}\{B_0^TP_1B_0\}.$$

Note that the first Riccati equation and Lemma 4 are used to derive this equation.

We can use L_* to construct a state estimator:

$$\dot{\hat{x}}=(A+\gamma^{-2}B_1B_1^TP_1)\hat{x}+B_2u+L_*(C_2\hat{x}-y),\quad \hat{x}(0)=0.$$

It is pointed out that the control law $u_*=-R_1^{-1}(D_{12}^TC_1+B_2^TP_1)\hat{x}$ comes naturally when the state information is not available. Let $e_x=x-\hat{x}$. The system can be further simplified into

$$\begin{aligned}\dot{e}_x&=(A+\gamma^{-2}B_1B_1^TP_1+L_*C_2)e_x+(B_0+L_*D_{20})w_0+B_1r,\\ v&=D_{12}R_1^{-1}(D_{12}^TC_1+B_2^TP_1)e_x.\end{aligned}$$

Now $J_3(u,w,w_0)$ becomes (by using the second Riccati equation and Lemma 5)

$$\begin{aligned}J_3(u_*,w,w_0)=\gamma^2\|r-\gamma^{-2}B_1^TP_2e_x\|_{\mathcal{P}}^2&-\mathrm{trace}\{B_0^TP_1B_0\}\\ &-\mathrm{trace}\{(B_0+L_*D_{20})^TP_2(B_0+L_*D_{20})\}.\end{aligned}$$

Similar to finite time horizon case, we can take

$$r_* = \gamma^{-2} B_1^T P_2 e_x \quad \text{or} \quad w_* = r_* + \gamma^{-2} B_1^T P_1 x = \gamma^{-2} B_1^T (P_1 x + P_2 e_x).$$

Then we have $J_3(u_*, w_*, w_0) \le J_3(u_*, w, w_0)$.

Next, it is shown that u_* does minimize the index $J_4(u, w_*, w_0)$. Let L be any filter gain such that both $A + \gamma^{-2} B_1 B_1^T P_1 + LC_2$ and $A + \gamma^{-2} B_1 B_1^T P_1 + LC_2 + \gamma^{-2} B_1 B_1^T P_2$ are stable. Substituting w_* (or r_*) into the system equations, we get $\dot{e}_x = A_L e_x + B_L w_0$, where

$$A_L = A + \gamma^{-2} B_1 B_1^T P_1 + LC_2 + \gamma^{-2} B_1 B_1^T P_2, \quad B_L = B_0 + LD_{20}.$$

Note that $e_x = \int_0^t e^{A_L(t-\tau)} B_L w_0(\tau) d\tau$ and

$$\begin{aligned} J_4(u, w_*, w_0) &= \|e_x\|_{\mathcal{P}}^2 \\ &= \lim_{T\to\infty} E \left\{ \frac{1}{T} \int_0^T \int_0^t \int_0^t w_0^T(\tau) B_L^T e^{A_L^T(t-\tau)} e^{A_L(t-s)} B_L w_0(s) d\tau \, ds \, dt \right\} \\ &= \operatorname{trace} \left\{ \lim_{T\to\infty} \frac{1}{T} \int_0^T \int_0^t \int_0^t e^{A_L(t-s)} B_L \delta(\tau - s) B_L^T e^{A_L^T(t-\tau)} d\tau \, ds \, dt \right\} \\ &= \operatorname{trace} \left\{ \lim_{T\to\infty} \frac{1}{T} \int_0^T \int_0^t e^{A_L(t-s)} B_L B_L^T e^{A_L^T(t-s)} ds \, dt \right\} = \operatorname{trace}\{Y\}, \end{aligned}$$

where $Y = \int_0^\infty e^{A_L s} B_L B_L^T e^{A_L^T s} ds \ge 0$ satisfies $A_L Y + Y A_L^T + B_L B_L^T = 0$. By Theorem 7 and using the third Riccati equation, it can be seen that $J_4(u, w_*, w_0)$ achieves the minimum value at $L = L_*$, where $L_* = -(B_0 D_{20}^T + P_3 C_2^T) R_0^{-1}$, which means that u_* is indeed the desired optimal control. Thus u_* and w_* achieve

$$J_3(u_*, w_*, w_0) \le J_3(u_*, w, w_0), \quad J_4(u_*, w_*, w_0) \le J_4(u, w_*, w_0).$$

Proof (necessity). Let $P_1 \ge 0$ solve

$$A_x^T P_1 + P_1 A_x + P_1 (B_1 B_1^T / \gamma^2 - B_2 R_1^{-1} B_2^T) P_1 + Q = 0.$$

Suppose the controller u_*,

$$\begin{aligned} \dot{\hat{x}} &= (A + \gamma^{-2} B_1 B_1^T P_1 + L_* C_2 + B_2 F_*) \hat{x} - L_* y, \\ u_* &= F_* \hat{x}, \quad F_* = -R_1^{-1} (D_{12}^T C_1 + B_2^T P_1), \end{aligned}$$

and a w_*' achieve $0 < J_3(u_*, w_*', 0) \le J_3(u_*, w, 0)$. This suggests that the system without the white noise

$$\begin{aligned} \dot{x} &= Ax + B_1 w + B_2 u_*, \quad x(0) = 0, \\ z &= C_1 x + D_{12} u_*, \\ y &= C_2 x + D_{20} w_0, \end{aligned}$$

achieves the $\mathcal{H}_\infty$ performance. Define

$$e_x := x - \hat{x}, \quad r := w - \gamma^{-2} B_1^T P_1 x, \quad v_* := D_{12} \left\{ u_* + R_1^{-1} (D_{12}^T C_1 + B_2^T P_1) x \right\}.$$

The system without the white noise can be converted into

$$\begin{aligned}\dot{e}_x &= (A+\gamma^{-2}B_1B_1^TP_1+L_*C_2)e_x+B_1r, \quad e_x(0)=0,\\ v_* &= D_{12}\left\{R_1^{-1}(D_{12}^TC_1+B_2^TP_1)e_x\right\},\end{aligned}$$

and $J_3(u_*,w,0)$ can be converted into

$$J_3(u_*,w,0)=\gamma^2\|w-\tilde{w}_*\|_{\mathcal{P}}^2-\|D_{12}(u_*-\tilde{u}_*)\|_{\mathcal{P}}^2=\gamma^2\|r\|_{\mathcal{P}}^2-\|v_*\|_{\mathcal{P}}^2,$$

where $\tilde{w}_*=\gamma^{-2}B_1^TP_1x$ and $\tilde{u}_*=-R_1^{-1}(D_{12}^TC_1+B_2^TP_1)x$. Hence, by the bounded real lemma, there is a $P_2\geq 0$ solving

$$P_2(A+\gamma^{-2}B_1B_1^TP_1+L_*C_2)+(A_y+\gamma^{-2}B_1B_1^TP_1+L_*C_2)^TP_2$$

$$+\gamma^{-2}P_2B_1B_1^TP_2+(D_{12}^TC_1+B_2^TP_1)^TR_1^{-1}(D_{12}^TC_1+B_2^TP_1)=0,$$

and, accordingly, w_*' can be obtained as

$$w_*'=r_*'+\gamma^{-2}B_1^TP_1x=\gamma^{-2}B_1^T(P_1x+P_2e_x), \quad r_*'=\gamma^{-2}B_1^TP_2e_x.$$

Now consider the system with white noise

$$\begin{aligned}\dot{x} &= Ax+B_0w_0+B_1w+B_2u_*, \quad x(0)=0,\\ z &= C_1x+D_{12}u_*,\\ y &= C_2x+D_{20}w_0.\end{aligned}$$

Under the same transformation, we have

$$\begin{aligned}\dot{e}_x &= (A+\gamma^{-2}B_1B_1^TP_1+L_*C_2)e_x+(B_0+L_*D_{20})w_0+B_1r, \quad e_x(0)=0,\\ v_* &= D_{12}\left\{R_1^{-1}(D_{12}^TC_1+B_2^TP_1)e_x\right\},\end{aligned}$$

and $J_3(u_*,w,w_0)$ becomes (see the proof for the sufficiency)

$$J_3(u_*,w,w_0)=\gamma^2\|w-\tilde{w}_*\|_{\mathcal{P}}^2-\|D_{12}(u_*-\tilde{u}_*)\|_{\mathcal{P}}^2-\operatorname{trace}\{B_0^TP_1B_0\}$$

$$=\gamma^2\|r-\gamma^{-2}B_1^TP_2e_x\|_{\mathcal{P}}^2-\operatorname{trace}\{B_0^TP_1B_0\}-\operatorname{trace}\{(B_0+L_*D_{20})^TP_2(B_0+L_*D_{20})\}.$$

Therefore, if we choose

$$w_*=r_*+\gamma^{-2}B_1^TP_1x=\gamma^{-2}B_1^T(P_1x+P_2e_x), \quad r_*=\gamma^{-2}B_1^TP_2e_x,$$

then we have $J_3(u_*,w_*,w_0)\leq J_3(u_*,w,w_0)$.

If, furthermore, this w_* together with u_* achieves $J_4(u_*,w_*,w_0)\leq J_4(u,w_*,w_0)$, by substituting w_* into the system equations, we get

$$\begin{aligned}\dot{e}_x &= (A+\gamma^{-2}B_1B_1^TP_1+L_*C_2+\gamma^{-2}B_1B_1^TP_2)e_x+(B_0+L_*D_{20})w_0,\\ &:= A_{L_*}e_x+B_{L_*}w_0,\end{aligned}$$

where $A_{L_*}=A+\gamma^{-2}B_1B_1^TP_1+L_*C_2+\gamma^{-2}B_1B_1^TP_2$ and $B_{L_*}=B_0+L_*D_{20}$. So $e_x=\int_0^t e^{A_{L_*}(t-\tau)}B_{L_*}w_0(\tau)d\tau$ and $J_4(u_*,w_*,w_0)=\operatorname{trace}\{Y\}$ is the minimum value,

where $Y = \int_0^\infty e^{A_{L_*}s} B_{L_*} B_{L_*}^T e^{A_{L_*}^T s} ds \geq 0$ satisfies $A_{L_*} Y + Y A_{L_*}^T + B_{L_*} B_{L_*}^T = 0$. Thus, by Theorem 7, there are $P_3 \geq 0$ and $P_3 \leq Y$ solving

$$[A_y + \gamma^{-2} B_1 B_1^T (P_1 + P_2)] P_3 + P_3 [A_y + \gamma^{-2} B_1 B_1^T (P_1 + P_2)]^T - P_3 C_2^T R_0^{-1} C_2 P_3 + P = 0.$$

In the case in which $A + \gamma^{-2} B_1 B_1^T (P_1 + P_2) - (B_0 D_{20}^T + P_3 C_2^T) R_0^{-1} C_2$ is stable, L_* can be chosen as $L_* = -(B_0 D_{20}^T + P_3 C_2^T) R_0^{-1}$. Substituting L_* back into the Riccati equation about P_2, clearly, P_2 solves

$$P_2 (A_y + \gamma^{-2} B_1 B_1^T P_1 - P_3 C_2^T R_0^{-1} C_2) + (A_y + \gamma^{-2} B_1 B_1^T P_1 - P_3 C_2^T R_0^{-1} C_2)^T P_2$$

$$+ \gamma^{-2} P_2 B_1 B_1^T P_2 + (D_{12}^T C_1 + B_2^T P_1)^T R_1^{-1} (D_{12}^T C_1 + B_2^T P_1) = 0.$$

This concludes the proof. □

6. Comments. We have the following comments on the results in this paper.

1. It must be pointed out that, in either of our developments, while we can achieve quadratic optimization ($\mathcal{H}_2$ performance) under the worst disturbance, the optimal γ may or may not be achievable. As seen from the results, we can only show that the $\mathcal{H}_\infty$ performance index has a lower bound, but this bound may or may not be the optimal γ as achieved by a pure $\mathcal{H}_\infty$ control. This means that, naturally and reasonably, we should not expect a multiobjective control law to be as robust as an $\mathcal{H}_\infty$ control law. Similarly, we can only expect that a multiobjective control law achieves the quadratic optimal performance when the disturbance signal is in its "worst" form. And all of these facts exactly reflect the design trade-off.

2. For the solvability of the solutions in this paper, we point out that, although our results are characterized by three Riccati equations, only two of them are really coupled, while the third one can be solved independently. Hence the computation of our results should be no more difficult than that of the state feedback case, where two coupled Riccati equations can be solved by standard numerical integration, as pointed out in [22].

7. Conclusion. In this paper, we have generalized the state feedback results of mixed $\mathcal{H}_2/\mathcal{H}_\infty$ control [22] to the output feedback case. We have also solved a newly formulated $\mathcal{H}_\infty$ Gaussian control problem which provides a natural design trade-off between the LQG performance and the robust performance. Both sufficient and necessary conditions were given for the existence of the control law in both the finite time horizon and the infinite time horizon. Since these conditions are in the form of coupled Riccati equations, differential or algebraic, which are deemed as solvable by standard algorithm, the design procedures developed in this paper provide computable solutions, which strongly enhances the possibility of potential engineering applications.

Appendix: Proof for necessary conditions in Theorems 6 and 7. Note that we shall only give the proof in detail for necessary conditions in Theorem 6 because the proof for Theorem 7 can be done in very similar way.

We shall first establish some preliminary results for the proof.

Let $\{P_i(t), \quad i = 1, 2, \ldots, P_i(t) = P_i^T(t), t \geq 0\}$ be a sequence in $\mathbf{R^{n \times n}}$. Correspondingly, we define a sequence $\{L_i(t),\ i = 2, 3 \ldots, t \geq 0\}$ in $\mathbf{R^{n \times p}}$ with $L_{i+1}(t) = -(P_i(t) C^T + B D^T) R^{-1}\ \forall t \geq 0$, for some $R > 0$. The limits of $\{P_i(t)\}$ and $\{L_i(t)\}$ are defined as follows.

DEFINITION 15. *We say that $P_*(t)$ and $L_*(t)$ are the limits of sequences $\{P_i(t)\}$ and $\{L_i(t)\}$ if*

$$x^T P_*(t)x = \lim_{i\to\infty} x^T P_i(t)x, \quad L_*(t) = -(P_*(t)C^T + BD^T)R^{-1} \ \ \forall x \in \mathbf{R}^n, \forall t \geq 0.$$

If these limits exist, we denote

$$P_*(t) = \lim_{i\to\infty} P_i(t), \quad L_*(t) = \lim_{i\to\infty} L_{i+1}(t) = -\lim_{i\to\infty}(P_i(t)C^T + BD^T)R^{-1}.$$

It is easy to see that $L_i(t)$ has a limit if $P_i(t)$ does.

PROPOSITION 16. *A sequence $\{P_i(t)\}$ converges to some $P_*(t)$ if and only if the convergence is entrywise, i.e., if $p^i_{kj}(t)$ and $p_{kj*}(t)$ are entries of $P_i(t)$ and $P_*(t)$, then*

$$p_{kj*}(t) = \lim_{i\to\infty} p^i_{kj}(t), \qquad k, j = 1, 2, \ldots, n \qquad \forall t \geq 0.$$

Proof. If the convergence is entrywise, i.e.,

$$p_{kj*}(t) = \lim_{i\to\infty} p^i_{kj}(t), \quad k, j = 1, 2, \ldots, n,$$

then we have $\forall x \in \mathbf{R}^n$ and $\forall t \geq 0$

$$\lim_{i\to\infty} x^T P_i(t)x = \lim_{i\to\infty} \sum_{k,j} p^i_{kj}(t)x_k x_j = \sum_{k,j} \lim_{i\to\infty} p^i_{kj}(t)x_k x_j = \sum_{k,j} p_{kj*}(t)x_k x_j = x^T P_*(t)x.$$

So $P_*(t) = \lim_{i\to\infty} P_i(t)$. Conversely, if $P_i(t)$ converges to $P_*(t)$ for any $t \geq 0$, i.e., $x^T P_*(t)x = \lim_{i\to\infty} x^T P_i(t)x \ \forall x \in \mathbf{R}^n, \ \forall t \geq 0$, or

$$\sum_{j,q} p_{jq*}(t)x_j x_q = \lim_{i\to\infty} \sum_{j,q} p^i_{jq}(t)x_j x_q = \sum_{j,q} \lim_{i\to\infty} p^i_{jq}(t)x_j x_q.$$

Comparing coefficients on both sides (considering x is arbitrary), we obtain

$$p_{jq*}(t) = \lim_{i\to\infty} p^i_{jq}(t).$$

That is, $P_i(t)$ converges to $P_*(t)$ entrywise. □

We are interested in a pair of special sequences $\{P_i(t)\}$ and $\{L_i(t)\}$, which are generated by the following procedures.

Procedures.

1. Choose $L_1(t) \in \mathbf{R}^{n\times p}$ for any $t \geq 0$.
2. Solve $P_i(t), i = 1, 2, \ldots, \ P_i(0) = 0$ from

$$(A + L_i(t)C)P_i(t) + P_i(t)(A + L_i(t)C)^T + (B + L_i(t)D)(B + L_i(t)D)^T = \dot{P}_i(t).$$

3. Set $L_{i+1}(t) = -(P_i(t)C^T + BD^T)R^{-1}$, $i = 1, 2, \ldots$, for some $R > 0$.

PROPOSITION 17. *Sequences $P_i(t)$ and $L_i(t)$ generated by the above procedures* 1–3 *always have limits $P_*(t)$ and $L_*(t)$.*

Proof. We need only to prove that $P_i(t)$ has a limit $P_*(t)$. Note that we have, for $i = 1, 2, \ldots,$

$$(A + L_i(t)C)P_i(t) + P_i(t)(A + L_i(t)C)^T + (B + L_i(t)D)(B + L_i(t)D)^T = \dot{P}_i(t),$$

$$(A+L_{i+1}(t)C)P_{i+1}+P_{i+1}(A+L_{i+1}(t)C)^T+(B+L_{i+1}(t)D)(B+L_{i+1}(t)D)^T=\dot{P}_{i+1}(t).$$

Define $\Delta P_i(t)=P_{i+1}-P_i(t)$ and $\Delta L_i(t)=L_{i+1}(t)-L_i(t)$; then

$$(A+L_{i+1}(t)C)\Delta P_i(t)+\Delta P_i(t)(A+L_{i+1}(t)C)^T-\Delta L_i(t)R\Delta L_i^T(t)=\Delta\dot{P}_i(t).$$

Let $\Phi(t,\tau)$ be the transition matrix of $A+L_{i+1}(t)C$; then we have

$$\Delta P_i(t)=-\int_0^t \Phi(t,s)\Delta L_i(s)R\Delta L_i^T(s)\Phi^T(t,s)ds,$$

which gives that $\Delta P_i(t)\le 0\ \forall t\ge 0$. This means that for any $x\in\mathbf{R}^n$

$$0\le\cdots\le x^TP_{i+1}(t)x\le x^TP_i(t)x\le\cdots\le x^TP_1(t)x\ \ \forall t\ge 0.$$

Hence $\lim_{i\to\infty}x^TP_i(t)x$ exists and

$$\begin{aligned}\lim_{i\to\infty}x^TP_i(t)x&=\lim_{i\to\infty}\sum_{k,j}p_{kj}^i(t)(t)x_kx_j=\sum_{k,j}\lim_{i\to\infty}p_{kj}^i(t)x_kx_j\\&=\sum_{k,j}p_{kj*}(t)x_kx_j=x^TP_*(t)x,\end{aligned}$$

where $p_{kj*}(t)=\lim_{i\to\infty}p_{kj}^i(t)\ \forall t\ge 0$ and $P_*(t)=[p_{kj*}(t)]$. Therefore, $P_i(t)$ has a limit and so does $L_i(t)$ with

$$L_*(t)=\lim_{i\to\infty}L_{i+1}(t)=-\lim_{i\to\infty}(P_i(t)C^T+BD^T)R^{-1}=-(P_*(t)C^T+BD^T)R^{-1}.\qquad\square$$

LEMMA 18. *For sequences $P_i(t)$ and $L_i(t)$ generated by the procedures* 1–3, *if $P_*(t)$ and $L_*(t)$ are the limit points of these sequences, then $P_*(t)\ge 0$ solves*

$$(A+L_*(t)C)P_*(t)+P_*(t)(A+L_*(t)C)^T+(B+L_*(t)D)(B+L_*(t)D)^T=\dot{P}_*(t),$$

where $L_*(t)=-(P_*(t)C^T+BD^T)R^{-1}$.

Proof. Suppose $P_*(t)$ and $L_*(t)$ are the limit points of sequences $P_i(t)$ and $L_i(t)$. Let $p_{kj}^i(t)$ and $p_{kj*}(t)$ be entries of $P_i(t)$ and $P_*(t)$. Let $l_{mq}^i(t)$ and $l_{mq*}(t)$ be entries of $L_i(t)$ and $L_*(t)$. By Proposition 16, we have entrywise convergence $p_{kj*}(t)=\lim_{i\to\infty}p_{kj}^i(t),\ k,j=1,2,\dots,n$, and, consequently, for any $m=1,\dots,n$, and $q=1,\dots,p$,

$$l_{mq*}(t)=\lim_{i\to\infty}l_{mq}^i(t)(p_{kj}^i(t),\ k,j=1,2,\dots,n)=l_{mq}^i(t)(\lim_{i\to\infty}p_{kj}^i(t),\ k,j=1,2,\dots,n)$$

since $l_{mq}^i(t)$ is a continuous function of $p_{kj}^i(t),\ k,j=1,2,\dots,n$.

Next we define

$$F(P_i(t),L_i(t))=\dot{P}_i(t)-(A+L_i(t)C)P_i(t)+P_i(t)(A+L_i(t)C)^T+(B+L_i(t)D)(B+L_i(t)D)^T.$$

Obviously, $F(P_i(t),L_i(t))=0\ \forall i=1,2,\dots,\forall t\ge 0$. Let $f_{kj}^i(t),\ k,j=1,\dots,n$ be entries of $F(P_i(t),L_i(t))$; then they are continuous about all $p_{kj}^i(t)$, $\dot{p}_{kj}^i(t)$, and $l_{mq}^i(t)$. Therefore,

$$f_{kj*}(t)=\lim_{i\to\infty}f_{kj}^i(t)(p_{kj}^i(t),l_{mq}^i(t))=0,\quad k,j=1,\dots,n,\ \ \forall t\ge 0.$$

This shows that $F(P_*(t), L_*(t)) = 0$ or

$$(A + L_*(t)C)P_*(t) + P_*(t)(A + L_*(t)C)^T + (B + L_*(t)D)(B + L_*(t)D)^T = \dot{P}_*(t),$$

where $L_*(t) = -(P_*(t)C^T + BD^T)R^{-1}$. □

Now we are in the position to prove the necessity of Theorem 6.

Proof. If there are $L(t)$ and a $P(t), P(0) = 0$, such that

$$(A + L(t)C)P(t) + P(t)(A + L(t)C)^T + (B + L(t)D)(B + L(t)D)^T = \dot{P}(t),$$

and J_1 achieves the minimum value at $L(t)$, take $L_1(t) = L(t)$ as the initial value and generate the sequences $P_i(t)$ and $L_i(t)$ using the procedures 1–3. Then the following claims can be made (see Proposition 17):

1. $0 \leq \cdots \leq P_{i+1}(t) \leq P_i(t) \leq \cdots \leq P_1(t)$.
2. $\{P_i(t),\ i = 1, 2, \ldots,\}$ and $\{L_i(t),\ i = 1, 2, \ldots,\}$ have limit points $P_*(t)$ and $L_*(t)$ and $P_*(t) \leq P_1(t)\ \forall t \geq 0$.

Hence, by Lemma 18, $P_*(t)$ and $L_*(t) = -(P_*(t)C^T + BD^T)R^{-1}$ solve

$$(A + L_*(t)C)P_*(t) + P_*(t)(A + L_*(t)C)^T + (B + L_*(t)D)(B + L_*(t)D)^T = \dot{P}_*(t),$$

and, clearly, $J_1(L)$ achieves the minimum value at $L_*(t) = -(P_*(t)C^T + BD^T)R^{-1}$. □

STABILITY OF PERTURBED DELAY DIFFERENTIAL EQUATIONS AND STABILIZATION OF NONLINEAR CASCADE SYSTEMS*

W. MICHIELS†, R. SEPULCHRE‡, AND D. ROOSE†

Abstract. In this paper the effect of bounded input perturbations on the stability of nonlinear globally asymptotically stable delay differential equations is analyzed. We investigate under which conditions global stability is preserved and if not, whether semiglobal stabilization is possible by controlling the size or shape of the perturbation. These results are used to study the stabilization of partially linear cascade systems with partial state feedback.

Key words. cascade systems, delay equations, nonlinear control

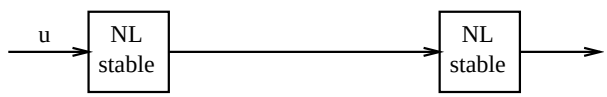
1. Introduction.

The stability analysis of the series (cascade) interconnection of two stable nonlinear systems described by ODEs is a classical subject in system theory [8, 9, 11].



Contrary to the linear case, the zero-input global asymptotic stability of each subsystem does not imply the zero-input global asymptotic stability of the interconnection. The output of the first subsystem acts as a transient input disturbance which can be sufficient to destabilize the second subsystem. In the ODE case, such destabilizing mechanisms are well understood since the seminal work by Sussmann and Kokotovic [10]. They can be subtle but are almost invariably associated to a finite escape time in the second subsystem. (Some states blow up to infinity in a finite time.) The present paper explores similar instability mechanisms generated by the series interconnection of nonlinear delay differential equations (DDEs). In particular, we consider the situation where the destabilizing effect of the interconnection is delayed and examine the difference from the ODE situation.

Instrumental to the stability analysis of cascades, we first study the effect of external (affine) perturbations w on the stability of nonlinear time delay systems

$$\dot{z} = f(z, z(t-\tau)) + \Psi(z, z(t-\tau))w, \quad z \in \mathbb{R}^n, \ w \in \mathbb{R}, \tag{1.1}$$

where we assume that the equilibrum $z = 0$ of $\dot{z} = f(z, z(t-\tau))$ is globally asymptotically stable (GAS). We consider perturbations $w = \eta(t)$ which belong to both L_1 and L_∞ and investigate the region in the space of initial conditions which give rise to bounded solutions under various assumptions on the system and the perturbation.

These results are strengthened to asymptotic stability results when the perturbation is generated by a GAS DDE.

We consider both global and semiglobal results. In the ODE-case, an obstruction to global stability is formed by the fact that arbitrarily small input perturbations can cause the state to escape to infinity in a finite time, for instance, when the interconnection term $\Psi(z)$ is nonlinear in z. This is studied extensively in the literature in the context of the stability of cascades, see, e.g., [10, 8] and the references therein. Even though delayed perturbations do not cause a finite escape time, we explain a similar mechanism giving rise to unbounded solutions, caused by nonlinear delayed interconnection terms.

In situations where unbounded solutions are inevitable for large initial conditions, we investigate under which conditions trajectories can be bounded semiglobally in the space of initial conditions, in case the perturbation is parametrized, i.e., $\eta = \eta(t, a)$. Hereby we let the parameter a control the L_1 or L_∞ norm of the perturbation. We also consider the effect of concentrating the perturbation in an arbitrarily small time-interval. The study of controlled perturbations is motivated by the situation where the perturbation is the output of a controlled system; see Figure 1.1.

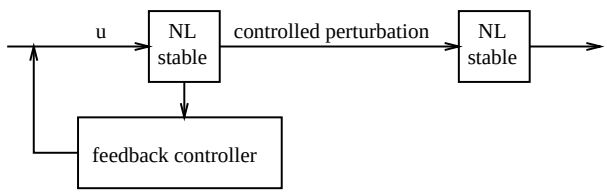

FIG. 1.1. *Partial state feedback as a way of controlling the input perturbation to the second subsystem.*

In particular, we will be interested in the stabilization of the cascade

$$\left\{ \begin{array}{l} \dot{z} = f(z, z(t-\tau)) + \Psi(z, z(t-\tau))y, \\ \dot{\xi} = A\xi + Bu, \\ y = C\xi, \qquad \xi \in \mathbb{R}^\mu, \quad u, y \in \mathbb{R}, \end{array} \right. \tag{1.2}$$

where the perturbation w in (1.1) is now the output of a linear system. We assume that the pair (A, B) is controllable and will control the "perturbation" y with linear state feedback

$$u = F\xi. \tag{1.3}$$

In the ODE-case this stabilization problem has been extensively studied in the literature, for instance, in [12, 1, 10, 6]. Because the output of the linear subsystem, which acts as a destabilizing disturbance to the nonlinear subsystem, can cause trajectories to escape to infinity in a finite time, one typically tries to drive the "perturbation" y quickly to zero. However, a high-gain control, placing all observable eigenvalues far into the left half plane, will not necessarily result in large stability regions because of the fast peaking phenomenon [10, 8]. Peaking is a structural property of the ξ-subsystem whereby achieving faster convergence implies larger overshoots which can in turn destabilize the cascade. Semiglobal stability results are obtained when imposing structural assumptions on the ξ-subsystem (a nonpeaking system) or by imposing

conditions on the z-subsystem and the growth of the interconnection term Ψ: for instance, in [8, Theorem 4.41] one requires a nonpeaking linear subsystem, and the conditions of [10, Theorem 9.1] are a trade-off between peaking and growth.

The structure of the paper is as follows. After some preliminaries (section 2), we study the effect of bounded input perturbations in sections 3 and 4 and use the obtained results to study the stabilization of partially linear cascades with partial state feedback in section 5.

2. Preliminaries. The state of the delay equation (1.1) at time t can be described as a vector $z(t) \in \mathbb{R}^n$ or as a function segment z_t defined by

$$z_t(\theta) = z(t+\theta),\ \theta \in [-\tau,\ 0].$$

Therefore, delay equations form a special class of functional differential equations [2, 4, 5].

We assume that the right-hand side of (1.1) is continuous in all of its arguments and Lipschitz in z and $z(t-\tau)$. Then a solution is uniquely defined by specifying as an initial condition a function segment z_0 whereby $z_0 \in \mathcal{C}([-\tau,\ 0],\ \mathbb{R}^n)$, the Banach space of continuous functions mapping the delay-interval $[-\tau,\ 0]$ into $\mathbb{R}^n$ and equipped with the supremum-norm $\|.\|_s$.

Sufficient conditions for stability of a functional differential equation are provided by the theory of Lyapunov functionals [2, 5], a generalization of the classical Lyapunov theory for ODEs. For functional differential equations of the form

$$\dot{z} = F(z_t), \tag{2.1}$$

according to [2, Definition V.5.3], a mapping $V : \mathcal{C}([-\tau,\ 0],\ \mathbb{R}^n) \to \mathbb{R}$ is called a Lyapunov functional on a set G if V is continuous on $\overline{G}$ and $\dot{V} \leq 0$ on G. Here $\dot{V}$ is the upper-right-hand derivative of V along the solutions of (2.1), i.e.,

$$\dot{V}(z_t) = \limsup_{h \to 0+} \frac{1}{h} \left[V(z_{t+h}) - V(z_t) \right].$$

The following theorem, taken from [2, Corollary V.3.1], provides sufficient conditions for global asymptotic stability.

THEOREM 2.1. *Suppose $z = 0$ is a solution of (2.1) and $V : \mathcal{C}([-\tau,\ 0],\ \mathbb{R}^n) \to \mathbb{R}$ is continuous with $V(0) = 0$. When there exist nonnegative functions $a(r)$ and $b(r)$ with $a(r) > 0$ as $r > 0$ and $a(r) \to \infty$ as $r \to \infty$ such that*

$$a(\|z(t)\|) \leq V(z_t), \quad \dot{V}(z_t) \leq -b(\|z(t)\|),$$

then the zero solution is stable, and every solution is bounded. If, in addition, $b(r)$ is positive definite, then every solution approaches zero as $t \to \infty$.

Instead of working with functionals, it is also possible to use classical Lyapunov functions when relaxing the condition $\dot{V} \leq 0$. This approach, leading to the so-called Lyapunov–Razumikhin theorems [5], is not considered in this paper.

In most of the theorems of the paper, the condition of global asymptotic stability for the unperturbed system ((1.1) with $\eta = 0$) is not sufficient. When the dimension of the system is higher than one, we sometimes need precise information about the interaction of different components of the state $z(t)$. This information is captured in the Lyapunov functional, associated with the unperturbed system. Therefore, when necessary, we will restrict ourselves to the class of DDEs, satisfying the following assumption.

ASSUMPTION 2.2. *The unperturbed system* $\dot{z} = f(z, z(t-\tau))$ *is* delay-independent *globally asymptotically stable (i.e., GAS for all values of the delay) with a Lyapunov functional of the form*

$$V(z_t) = k(z) + \int_{t-\tau}^{t} l(z(\theta))d\theta \tag{2.2}$$

with $k(z) > 0$, $l(z) \geq 0$, *and* $k(z)$ *radially unbounded, such that the conditions of Theorem* 2.1 *(with* $b(r)$ *positive definite) are satisfied.*

This particular choice is motivated by the fact that such functionals are used for a class of linear time-delay systems [2, 5]. Furthermore, choosing a delay-independent stable unperturbed system also allows us to investigate whether the results obtained in the presence of perturbations are still global in the delay. Note that in the ODE-case (2.2) reduces to $V = k(z)$ and hardly forms any restriction because under mild conditions its existence is guaranteed by converse theorems.

The perturbation $\eta(t) \in L_p([0,\ \infty))$ when $\exists M$ such that $\|\eta\|_p = \left[\int_0^\infty |\eta(s)|^p ds\right]^{\frac{1}{p}} = M < \infty$, $\eta(t) \in L_\infty$, when $\|\eta\|_\infty = \sup_{t\geq 0} |\eta(t)| < \infty$.

We assume η in (1.1) to be continuous and to belong to both L_1 and L_∞. When the perturbation is generated by an autonomous DDE, $\dot{\xi} = a(\xi, \xi(t-\tau))$, $\eta = b(\xi, \xi(t-\tau))$ with a and b continuous, locally Lipschitz and $b(0,0) = 0$, which is GAS and locally exponentially stable (LES), these assumptions are satisfied.

In the paper we show that when the unperturbed system is delay-independent stable and the initial conditions are bounded (i.e., $\|z_0\|_s \leq R < \infty$), arbitrarily small perturbations may cause unbounded trajectories provided the delay is large enough; hence arbitrarily small perturbations may destroy the delay-independent stability property. For such cases it is instructive to investigate whether semiglobal stabilization in the delay is possible: with a parametrized perturbation $\eta(t, a)$, we say that the trajectories of (1.1) can be bounded semiglobally in z and semiglobally in the delay if for each compact region $\Omega \subset \mathbb{R}^n$ and $\forall \bar{\tau} \in \mathbb{R}^+$ there exists a positive number $\bar{a}$ such that for every delay value $\tau \leq \bar{\tau}$, all initial conditions $z_0 \in \mathcal{C}([-\tau,\ 0],\ \mathbb{R}^n)$, with $z_0(\theta) \in \Omega,\ \theta \in [-\tau,\ 0]$, give rise to bounded trajectories when $a \geq \bar{a}$.

A C^0 function $\gamma : \mathbb{R} \to \mathbb{R}$ belongs to class κ if it is strictly increasing and $\gamma(0) = 0$. The symbol $\|.\|$ is used for the Euclidean norm in $\mathbb{R}^n$, and by $\|x, y\|$ we mean $\left(\|x\|^2 + \|y\|^2\right)^{\frac{1}{2}}$.

3. The mechanism of destabilizing perturbations. In contrast to linear systems, small perturbations (in the L_1 or L_∞ sense) are sufficient to destabilize nonlinear differential equations. In the ODE-case, the nonlinear mechanism for instability is well known: small perturbations suffice to make solutions escape to infinity in a finite time, for instance, when the interconnection term Ψ is nonlinear in z. This is illustrated with the following example:

$$\begin{aligned} \dot{z} &= -z + z^2\eta, \\ \dot{\eta} &= -a\eta, \end{aligned} \tag{3.1}$$

which can be solved analytically for z to give

$$z(t) = \frac{e^{-t}}{\frac{1}{z(0)} - \int_0^t e^{-s}\eta(s)ds} = \frac{e^{-t}}{\frac{1}{z(0)} - \eta(0)\int_0^t e^{-(1+a)s}ds}. \tag{3.2}$$

If $z(0)\eta(0) > 1 + a$, z escapes to infinity in a finite time t_e, which is given by

$$t_e = \frac{1}{1+a} \log \left(\frac{z(0)\eta(0)}{z(0)\eta(0) - (1+a)} \right). \tag{3.3}$$

This last expression shows that the escape time becomes smaller as the initial conditions are chosen larger, and, as a consequence, however fast $\eta(t)$ would be driven to zero in the first equation of (3.1), $z(0)$ could always be chosen large enough for the solution to escape to infinity in finite time.

In the simple example (3.1), the perturbation is the output of a stable linear system. Its initial condition $\eta(0)$ dictates the L_∞ norm of the perturbation, while the parameter a controls its L_1 norm. Making these norms arbitrarily small does not result in global stability. This is due to the nonlinear growth of the interconnection term.

One may wonder whether the instability mechanism encountered in the ODE situation (3.1) will persist in the DDE situation

$$\begin{cases} \dot{z} = -bz + z(t-\tau)^2\eta, \\ \dot{\eta} = -a\eta. \end{cases} \tag{3.4}$$

In contrast to (3.1), system (3.4) exhibits no finite escape time. This can be proven by application of the method of steps, i.e., from the boundedness of $z(\theta)$, $\theta \in [(k-1)\tau, k\tau]$, we conclude boundedness in $[k\tau, (k+1)\tau]$ of $\dot{z}(\theta)$ and thus of $z(\theta)$. Nevertheless the exponentially decaying input η still causes unbounded solutions in (3.4): this particular system is easily seen to have an exponential solution $z_e(t) = \frac{a+b}{\eta(0)} e^{2a\tau} e^{at}$. The instability mechanism can be explained by the superlinear divergence of the solutions of $\dot{z} = z^\alpha(t-\tau)$ for $\alpha > 1$.

PROPOSITION 3.1.

$$\dot{z} = z(t-\tau)^\alpha, \quad \alpha > 1,$$

has solutions which diverge faster than any exponential function.

Proof. Take as an initial condition a strictly positive solution segment z_0 over $[-\tau,\ 0]$ with $z(0) > 1$. For $t \geq 0$, the trajectory is monotonically increasing. This means that in the interval $[k\tau,\ (k+1)\tau]$ for $k \geq 1$,

$$z((k-1)\tau)^\alpha \leq \dot{z} \leq z(k\tau)^\alpha.$$

The solution at point $k\tau, k \geq 1$ is bounded below by the sequence satisfying

$$z_{k+1} = z_k + \tau z_{k-1}^\alpha, \quad z_0 = z(0),\ z_1 = z(\tau),$$

which has limit $+\infty$. The ratio $R_k = \frac{z_k}{z_{k-1}}$ satisfies

$$R_{k+1}R_k = R_k + \tau z_{k-1}^{\alpha-1},$$

and, consequently, $(R_{k+1} - 1)R_k$ tends to infinity. However, for an exponential function e^{at}, $R = e^{a\tau}$ and $(R-1)R$ is constant. ∎

Because of the faster than exponential growth of z in (3.4), the arbitrarily fast exponential decay of η cannot counter the blow-up caused by the nonlinearity in $z(t-\tau)$, and hence the system is not GAS.

The instability mechanism illustrated by (3.1) and (3.4) can be avoided by imposing suitable growth restrictions on the interconnection term Ψ. When the unperturbed system is scalar, it is sufficient to restrict the interconnection term to have linear growth in both of its arguments, i.e.,

$$\exists c_1, c_2 > 0 \text{ such that } \|\Psi(z, z(t-\tau))\| \leq c_1 + c_2\|z, z(t-\tau)\|. \tag{3.5}$$

This linear growth condition is by itself not sufficient, however, if the unperturbed system has dimension greater than one. In that case, the interaction of the different components of the state $z(t)$ can still cause "nonlinear" effects leading to unbounded solutions. An illustration of this phenomenon is given by the system

$$\left\{ \begin{array}{rcl} \dot{z}_1 &=& -z_1 + z_2\eta(t), \\ \dot{z}_2 &=& -z_2 + z_1^2 z_2, \\ \dot{\eta} &=& -\eta, \end{array} \right. \tag{3.6}$$

which was shown in [8] to have unbounded solutions, despite the linearity of the interconnection. The instability is caused by the mutual interaction between z_1 and z_2 when $\eta \neq 0$.

The following theorem, inspired by Theorem 4.7 in [8], provides sufficient conditions for bounded solutions. To prevent the instability mechanism due to interacting states, conditions are put on the Lyapunov functional of the unperturbed system.

THEOREM 3.2. *Assume that the system $\dot{z} = f(z, z(t-\tau)) + \Psi(z, z(t-\tau))\eta$ satisfies Assumption* 2.2 *and that the interconnection term $\Psi(z, z(t-\tau))$ grows linearly in its arguments, i.e., satisfies* (3.5)*. Furthermore, if the perturbation $\eta(t) \in L_1([0, \infty))$ and $k(z)$ satisfies*

(i) $\alpha_1\|z\|^\gamma \leq k(z) \leq \alpha_2\|z\|^\gamma, \quad 0 < \alpha_1 < \alpha_2 < \infty, \quad 1 \leq \gamma < \infty,$

(ii) $||\frac{dk}{dz}||\ ||z|| \leq ck(z),$

then all trajectories of the perturbed system are bounded for all values of the time delay.

Condition (ii) is sometimes called a *polynomial growth condition* because it is satisfied if $k(z)$ is polynomial in z but not satisfied if $k(z)$ is exponential in z.

Proof. Along a trajectory $z(t)$ we have

$$\begin{aligned} \dot{V} &\leq \left\| \frac{dk}{dz} \right\| \|\Psi(z, z(t-\tau))\||\eta| \\ &\leq c\frac{k(z)}{\|z\|}(c_1 + c_2\sqrt{\|z\|^2 + \|z(t-\tau)\|^2})|\eta| \\ &\leq c\alpha_2^{1/\gamma}k(z)^{1-1/\gamma}\left(c_1 + c_2\sqrt{\tfrac{k(z)^{2/\gamma}}{\alpha_1^{2/\gamma}} + \tfrac{k(z(t-\tau))^{2/\gamma}}{\alpha_1^{2/\gamma}}}\right)|\eta| \\ &\leq c\alpha_2^{1/\gamma}(c_1 k(z)^{1-1/\gamma} + c_2\alpha_1^{-1/\gamma}\sqrt{k(z)^2 + k(z)^{2-2/\gamma}k(z(t-\tau))^{2/\gamma}})|\eta| \\ &\leq c\alpha_2^{1/\gamma}(c_1 V^{1-1/\gamma} + c_2\alpha_1^{-1/\gamma}\sqrt{V^2 + V^{2-2/\gamma}k(z(t-\tau))^{2/\gamma}})|\eta|. \end{aligned} \tag{3.7}$$

For $t \in [0,\ \tau]$, $z(t)$ cannot escape to infinity because $k(z(t-\tau))$ is bounded (calculated from the initial condition), and the above estimate can be integrated over the interval since the right-hand side is linear in V and $\eta \in L_1$.

For $t \geq \tau$ we can use the estimate $k(z(t-\tau)) \leq V(z(t-\tau))$:

$$\dot{V} \leq c\alpha_2^{1/\gamma}\left(c_1 V^{1-1/\gamma} + c_2\alpha_1^{-1/\gamma}\sqrt{V^2 + V^{2-2/\gamma}V(t-\tau)^{2/\gamma}}\right)|\eta|.$$

Because this estimate for $\dot{V}$ is increasing in both of its arguments, an upper bound for V along the trajectory is described by

$$\dot{W} = c\alpha_2^{1/\gamma}\left(c_1 W^{1-1/\gamma} + c_2\alpha_1^{-1/\gamma}\sqrt{W^2 + W^{2-2/\gamma}W(t-\tau)^{2/\gamma}}\right)|\eta|$$

with $W(z_\tau) = V(z_\tau)$ as the initial condition. Via the method of steps, it is clear that W cannot escape to infinity in a finite time. From $t = \tau$ on, W is monotonically increasing. As a consequence, for $t \geq 2\tau$, $W(t) \geq W(t-\tau)$ and

$$\dot{W} \quad \leq c\alpha_2^{1/\gamma}\left(c_1 W^{1-1/\gamma} + c_2\alpha_1^{-1/\gamma}\sqrt{2}W\right)|\eta(t)|,$$

and this estimate can be integrated leading to uniform boundedness of $W(t)$ and $V(t)$ in $[0,\ \infty)$ since $\eta(t) \in L_1$. Hence the trajectory $z(t)$ is bounded. ∎

Remark 3.3. When the interconnection term is undelayed, i.e., Ψ depends only on the argument z, condition (i) in Theorem 3.2 can be dropped, and as a special case (f also undelayed), Theorem 4.7 of [8] is recovered. The presence of a delay in the unperturbed system does not provide additional complications compared to the ODE-case, and the proof is analogous to the proof of Theorem 4.7 of [8].

Along a trajectory, we now have

$$\dot{V} \leq \left\|\frac{dk}{dz}\right\|(c_1 + c_2\|z\|)|\eta|.$$

When $\|z\| \geq 1$ it follows from $\|\frac{dk}{dz}\| \leq \frac{ck(z)}{\|z\|}$ that $\dot{V} \leq c(c_1 + c_2)V|\eta|$. When $\|z\| \leq 1$, we have $\dot{V} \leq M|\eta|$ with $M = \sup_{\|z\|\leq 1}\|\frac{dk}{dz}\|(c_1 + c_2\|z\|)$, and when, in addition, $V \geq 1$, we have $\dot{V} \leq MV|\eta|$.

Hence the following estimate holds whenever $V \geq 1$:

$$\dot{V} \leq \max\left(c(c_1 + c_2), M\right)V|\eta|.$$

From the explicit integration of this estimate the boundedness of V and the trajectory are proven. ∎

4. Semiglobal results for controlled perturbations. Although no global results can be guaranteed in the absence of growth conditions, the examples in the previous section suggest that one should be able to bound the solutions semiglobally in the space of initial conditions by decreasing the size of the perturbation. Therefore, we assume that the perturbation is parametrized:

$$\eta = \eta(t, a).$$

We will consider two cases: (a) parameter a controls the L_1 or the L_∞ norm of η, and (b) a regulates the shape of a perturbation with fixed L_1 norm.

4.1. Controlling the L_1 norm and the L_∞ norm of the perturbation. We first assume that the L_1 norm of η is controlled. We have the following result.

THEOREM 4.1. *Consider the system*

$$\dot{z} = f(z, z(t-\tau)) + \Psi(z, z(t-\tau))\eta(t, a),$$

and suppose that the unperturbed system is GAS with the Lyapunov functional $V(z_t)$ satisfying Assumption 2.2. *If, furthermore, $\|\eta(t,a)\|_1 \to 0$ as $a \to \infty$, then the trajectories can be bounded semiglobally both in z and the delay τ by increasing a.*

Proof. Let $\tau \geq 0$ be fixed, and denote by Ω the desired stability domain in $\mathbb{R}^n$, i.e., such that all trajectories $z(t)$ with initial condition $z_0(\theta) \in \Omega$ for all $\theta \in [-\tau,\ 0]$ are bounded. Let $V_c = \sup_{z_0 \in \Omega} V(z_0)$. Along a trajectory starting in Ω, we have

$$\begin{aligned}\dot{V} &= \frac{dk}{dz} f(z, z(t-\tau)) + l(z(t)) - l(z(t-\tau)) + \frac{dk}{dz}\Psi(z, z(t-\tau))\eta(t,a) \\ &\leq |\frac{dk}{dz}\Psi(z, z(t-\tau))|.|\eta(t,a)|.\end{aligned}$$

As long as $V(t) \leq 2V_c$, both $z(t)$ and $z(t-\tau)$ belong to a compact set. Hence $\exists M > 0$ such that $|\frac{dk}{dz}\Psi(z, z(t-\tau)| \leq M$ and

$$V(t) - V(0) \leq M \int_0^\infty |\eta(s,a)| ds = M\|\eta(t,a)\|_1.$$

When $a \to \infty$, the maximal increase of V tends to zero. Hence there exists a number $\bar{a} >$ such that for $a \geq \bar{a}$, the assumption $V(t) \leq 2V_c$ is valid for all $t \geq 0$ and the trajectories with initial condition in Ω are bounded.

Note that for a fixed region $\Omega \subset \mathbb{R}^n$, V_c increases with τ and this influences both the value of M in the estimation of $|\frac{dk}{dz}\Psi(z, z(t-\tau)|$ and the critical value $\bar{a}$ of a. However, for any delay value τ in a compact interval $[0,\ \bar{\tau}]$, the trajectories starting in Ω are bounded when taking $a \geq \sup_{\tau \in [0,\ \bar{\tau}]} \bar{a}(\tau)$. Hence the trajectories can be bounded semiglobally in both the state and the delay. ∎

This result above is natural because for a given initial condition, a certain amount of energy is needed for destabilization, expressed mathematically by $\|\eta\|_1$. However, global stability in the state is not possible because the required energy can become arbitrarily small for large initial conditions; see, for instance, example (3.1). Later we will discuss why the trajectories cannot be bounded globally in the delay.

Now we consider the case whereby the L_∞ norm of the perturbation is controlled.

THEOREM 4.2. *Consider the system*

$$\dot{z} = f(z, z(t-\tau)) + \Psi(z, z(t-\tau))\eta(t,a).$$

Suppose that the unperturbed system is GAS with the Lyapunov functional $V(z_t)$ satisfying Assumption 2.2. *If $\|\eta(t,a)\|_\infty \to 0$ as $a \to \infty$, the trajectories of the perturbed system can be bounded semiglobally in both z and the delay τ.*

Proof. As in the proof of Theorem 4.1, it is sufficient to prove semiglobal boundedness in the state for a fixed $\tau \geq 0$. Let Ω and V_c be defined as in the proof of Theorem 4.1. Define $\Omega_2 = \{z \in \mathbb{R}^n : k(z) \leq 4V_c\}$, and for some (small) $\epsilon > 0$, $\Omega_\epsilon = \{z \in \mathbb{R}^n :\ \|z\| \leq \epsilon\} \subset \Omega$.

Because of Assumption 2.2, the time derivative of V along a trajectory satisfies

$$\begin{aligned}\dot{V} &= \frac{dk}{dz} f(z, z(t-\tau)) + l(z(t)) - l(z(t-\tau)) + \frac{dk}{dz}\Psi(z, z(t-\tau))\eta(t,a) \\ &\leq -b(\|z\|) + \left|\frac{dk}{dz}\Psi(z, z(t-\tau))\right| \eta(t,a).\end{aligned} \tag{4.1}$$

Let $M = \sup_{z,y \in \Omega_2} |\frac{dk}{dz}\Psi(z,y)|$.

When $z(t) \in \Omega_2 \backslash \Omega_\epsilon$ we have, since b is positive definite, $\dot{V} \leq -b(\|z\|) + M\|\eta\|_\infty \leq -N$ for some number $N > 0$, provided $\|\eta\|_\infty$ is small. For $z(t) \in \Omega_\epsilon$, we have the estimate $\dot{V} \leq M\|\eta\|_\infty$.

Now we prove by contradiction that all trajectories with initial condition in Ω are bounded for small $\|\eta\|_\infty$. Suppose that a solution starting in Ω (hence $V(z_0) \leq V_c$) is unbounded. Then it has to cross the "level set" $2V_c$. Assume that this happens for the first time at t^*. Note that for small $\|\eta\|_\infty$, t^* is large. During the interval $[t^* - \tau,\ t^*]$, V can both increase and decrease. When V increases in this time-interval, $z(t) \in \Omega_\epsilon$, and the increase ΔV is limited: $\Delta V \leq M\|\eta\|_\infty \tau$. When $z(t)$ is outside Ω_ϵ during a time-interval $\Delta t \subset [t^* - \tau,\ t^*]$, V always decreases because $\dot{V} \leq -N$. Since $V(t^*) > V(t^* - \tau)$, we have

$$N\Delta t \leq M\tau\|\eta\|_\infty. \tag{4.2}$$

Hence by reducing $\|\eta(t,a)\|_\infty$ we can make the time-interval Δt arbitrarily small. On the other hand, there exists a constant L, independently of a, such that

$$\left\| \frac{dz}{dt} \right\| \leq \|f(z, z(t-\tau)) + \Psi(z, z(t-\tau))\eta(t,a)\| \leq L < \infty$$

when z_t is inside Ω_2, because f and Ψ map bounded sets into bounded sets. Hence with $|t_2 - t_1| \leq \Delta t$ we have $\|z(t_1) - z(t_2)\| \leq L\Delta t$. Because of (4.2) we can increase a (reduce $\|\eta(t,a)\|_\infty$) such that $L\Delta t \leq \epsilon$, and consequently we have

$$\|z(t)\| \leq 2\epsilon, \quad t \in [t^* - \tau,\ t^*].$$

If ϵ was chosen such that $\Omega_{2\epsilon} = \{z \in \mathbb{R}^n :\ \|z\| \leq 2\epsilon\}$ lies inside Ω, we have a contradiction because this implies $V(t^*) \leq V_c$. Hence a trajectory can never cross the level set $2V_c$ and is bounded. ∎

The results of Theorems 4.1 and 4.2 are not global in the delay, even though the unperturbed system is delay-independent stable. Global results in the delay are generally not possible. We illustrate this fact with the following example, where it is impossible to bound the trajectories semiglobally in the state and globally in the delay, even if we make the size of the perturbation arbitrarily small with respect to the L_1 and L_∞ norms.

Example 4.3. Consider the following system:

$$\begin{cases} \dot{z_1} = -2z_1 + z_1(t-\tau), \\ \dot{z_2} = -\frac{(z_1-2)^2-1}{z_2^2+1} z_2 + z_2^3 \eta(t,a). \end{cases} \tag{4.3}$$

The unperturbed system, i.e., (4.3) with $\eta = 0$, is delay-independent stable. This is proven with the Lyapunov functional

$$V = z_1^2 + \int_{t-\tau}^{t} z_1^2 d\theta + \frac{1}{2} z_2^2.$$

Its time derivative,

$$\begin{aligned} \dot{V} &= [z_1\ z_1(t-\tau)] \begin{bmatrix} -3 & 1 \\ 1 & -1 \end{bmatrix} \begin{bmatrix} z_1 \\ z_1(t-\tau) \end{bmatrix} \\ &\quad -z_2^2 \tfrac{(z_1-2)^2-1}{z_2^2+1} \\ &\leq -2z_1^2 - z_2^2 \tfrac{(z_1-2)^2-1}{z_2^2+1}, \end{aligned}$$

is negative definite: when $z_1 \notin [1,\ 3]$, both terms are negative, and in the other case the second term is dominated, because it saturates in z_2. From this it follows that the conditions of Assumption 2.2 are satisfied.

With the perturbation

$$\eta(t,a) \begin{array}{ll} = (t-t_0)^2 e^{-a(t-t_0)} & t \geq t_0 = a^3 \\ = 0, & t \leq t_0, \end{array} \tag{4.4}$$

whereby increasing a leads to a reduction of both $\|\eta\|_1$ and $\|\eta\|_\infty$, we cannot bound the trajectories semiglobally in the state and globally in τ: for each value of a we can find a bounded initial condition (upper bound independent of a), leading to a diverging solution, provided τ is large enough. The first equation of (4.3) has a solution $z_1(t) = 2.5e^{-\alpha t}$, where $-\alpha$ is the real solution of

$$\lambda = -2 + e^{-\lambda\tau}.$$

Clearly, $\alpha \to 0$ as $\tau \to \infty$. Since $z_1(-\tau) = 2.5e^{\alpha\tau} \to 5$ as $\tau \to \infty$, uniform boundedness in τ of this solution over the interval $[-\tau,\ 0]$ (initial condition) is guaranteed. Furthermore, we have

$$z_1(t) \in [1.5,\ 2.5]$$

when $t \in [0,\ \frac{1}{\alpha}\log\frac{5}{3}]$, and thus

$$\dot{z_2} \geq \frac{z_2}{2(1+z_2^2)} + z_2^3\eta(t,a) \tag{4.5}$$

for any positive initial condition $z_2(0)$. A rather lengthy calculation shows that with $z_2(0) = 1$ and the perturbation (4.4), the solution of (4.5) always escapes to infinity in a finite time $t_f(a)$. Hence this also holds for the solution of the system (4.3)–(4.4) when the delay is large enough such that

$$\frac{1}{\alpha(\tau)}\log\frac{5}{3} > t_f(a).$$

This result is not in contradiction with the intuition that a perturbation with small L_1 norm can only cause a finite escape time when the initial condition is far away from the origin, as illustrated with example (3.1). In the system (4.3) with $\eta = 0$, z_2 is driven away from the origin as long as $z_1 \in [1,\ 3]$. By increasing the delay in the first equation, we can keep z_1 in this interval as long as desired. Thus the diverging transient of the *unperturbed* system is used to drive the state away from the origin, far enough to make the perturbation cause escape.

4.2. Controlling the shape of the perturbation. We now assume that the shape of a perturbation with a fixed L_1 norm can be controlled and consider the influence of a concentration of the perturbation in arbitrarily small time-intervals near $t = 0$. In the ODE-case this does not allow improvement of stability properties. This is illustrated with the first equation of example (3.1): instability occurs when $z(0) \geq \frac{1}{\int_0^t e^{-s}\eta(s)ds}$, and by concentrating the perturbation the stability domain may even shrink, because the beneficial influence of damping is reduced. In the DDE-case however, when the interconnection term is linear in the undelayed argument, it behaves linearly during one delay interval, preventing escape. Moreover, starting from a compact region of initial conditions, the reachable set after one delay interval can be bounded independently of the shape of the perturbation (because of the fixed L_1 norm). After one delay interval we are in the situation treated in Theorem 4.1. This

is expressed in the following theorem. As in Theorem 3.2, the polynomial growth condition prevents a destabilizing interaction between different components of the state vector $z(t)$.

THEOREM 4.4. *Consider*

$$\dot{z}(t) = f(z(t), z(t-\tau)) + \Psi(z(t), z(t-\tau))\eta(t,a), \tag{4.6}$$

and suppose that the unperturbed system is GAS with the Lyapunov functional $V(z_t) = k(z) + \int_{t-\tau}^{t} l(z(\theta))d\theta$ *satisfying Assumption* 2.2. *Let* $k(z)$ *satisfy the polynomial growth condition* $\|\frac{dk}{dz}\|\|z\| \le ck(z)$, *and assume that* Ψ *has linear growth in* $z(t)$, *i.e., there exist two class-*κ *functions* γ_1 *and* γ_2 *such that*

$$\|\Psi(z, z(t-\tau))\| \le \gamma_1(\|z(t-\tau)\|) + \gamma_2(\|z(t-\tau)\|)\|z\|.$$

Assume further that $\|\eta(t,a)\|_1 < M$ *for some constant* M *independent of* a, *and that* $\lim_{a\to\infty} \int_t^\infty |\eta(s,a)|ds = 0$ *for all* $t > 0$. *Then the solutions of* (4.6) *can be bounded semiglobally in* z *and for all* $\tau \in [\tau_1,\ \tau_2]$ *with* $0 < \tau_1 \le \tau_2 < \infty$.

Proof. Consider first a fixed value of $\tau \in [\tau_1,\ \tau_2]$. Let Ω be the desired stability domain in $\mathbb{R}^n$. Let $V_{\max} = \max\left(\sup_{z_t\in\Omega} V(z_t), 1\right)$. The time-derivative of the functional V along a trajectory starting in Ω satisfies

$$\begin{aligned}\dot{V} &\le \left\|\frac{dk}{dz}\right\| .\|\Psi(z, z(t-\tau))\|.|\eta(t,a)| \\ &\le \left\|\frac{dk}{dz}\right\| .\left(\gamma_1(\|z(t-\tau)\|) + \gamma_2(\|z(t-\tau)\|)\|z\|\right).|\eta(t,a)|.\end{aligned}$$

Consider the interval $[0, \tau]$. Then $z(t-\tau)$ belongs to the compact set Ω. When $\|z\| \ge 1$, there exists a constant c_1 such that

$$\begin{aligned}\dot{V} &\le ck(z).\left(\frac{\gamma_1(\|z(t-\tau)\|)}{\|z\|} + \gamma_2(\|z(t-\tau)\|)\right)|\eta(t,a)| \\ &\le cV|\eta(t,a)|\left(\frac{\gamma_1(\|z(t-\tau)\|)}{\|z\|} + \gamma_2(\|z(t-\tau)\|)\right) \\ &\le cc_1V|\eta(t,a)|.\end{aligned} \tag{4.7}$$

When $\|z\| \le 1$ and $V \ge 1$, we have

$$\dot{V} \le c_2|\eta(t,a)| \le c_2V|\eta(t,a)| \tag{4.8}$$

with $c_2 = \sup\left\{\|\frac{dk}{dz}\|\|\Psi(z, z(t-\tau))\| :\ \|z\| \le 1, z(t-\tau) \in \Omega\right\}$. From (4.7) and (4.8) we have, whenever $V \ge 1$ in $[0,\ \tau]$, $\dot{V} \le c_3V|\eta(t,a)|$ with $c_3 = \max(cc_1, c_2)$. Hence for all $t \in [0,\ \tau]$,

$$V \le V_{\max}e^{c_3\int_0^t |\eta(s,a)|ds} \le V_{\max}e^{c_3\|\eta(t,a)\|_1} \le V_{\max}e^{c_3M}.$$

As a consequence, $k(z)$ and $\|z(t)\|$ can also be uniformly bounded over the interval $[0,\ \tau]$, independently of a. Hence there exists a compact set $\Omega_2 \subset \mathbb{R}^n$ such that $z_\tau \in \Omega_2$, whatever the value of a and $z_0 \in \Omega$.

Now we can translate the original problem over one delay interval: at time τ the "initial conditions" belong to the compact set Ω_2, and with $t' = t - \tau$ we have

$$\|\eta(t', a)\|_1 = \int_\tau^\infty |\eta(s,a)|ds \to 0 \text{ as } a \to \infty.$$

Because of Theorem 4.1, we can increase a such that all solutions starting in Ω_2 are bounded.

Until now we assumed a fixed τ. But because $[\tau_1,\ \tau_2]$ is compact, we can take the largest threshold of a for bounded solutions over this delay interval. ∎

Remark 4.5. Whenever the perturbation in (1.1) is generated by a GAS and LES DDE, the boundedness results are strengthened to asymptotic stability results. This can be shown following the lines of the proof of Proposition 4.1 in [8]. Stability follows from a local version of Theorem 4.1, and attractivity follows from the application of a generalization to the time-delay case of the classical theorem proposed by LaSalle [2, Theorem V.3.1].

5. Stabilization of partially linear cascades. In the rest of the paper we consider the stabilization of the cascade (1.2) with the control law (1.3).

From the previous sections it is clear that the input y of the z-subsystem can act as a destabilizing disturbance. However, the control can drive the output of the linear system fast to zero. We will investigate under which conditions this is sufficient to stabilize the whole cascade. An important issue in this context is the so-called *fast peaking* phenomenon [10]. This is a structural property of the ξ-system whereby imposing faster convergence of the output to zero implies larger overshoots which can in turn destabilize the cascade and may form an obstacle to both global and semiglobal stabilizability. We start with a short description of the peaking phenomenon and then apply the results of previous sections to the stabilization of the cascade system (1.2).

Our presentation of the peaking phenomenon is inspired by [10], but, following [8], we place the phenomenon in an input-output framework rather than an input-state framework. We also emphasize the relation between a peaking system and the L_1 norm of its output.

5.1. The peaking phenomenon. When in the system

$$\begin{aligned} \dot{\xi} &= A\xi + Bu, \\ y &= C\xi, \end{aligned} \tag{5.1}$$

the pair (A, B) is controllable, one can always find state feedback laws $u = F\xi$ resulting in an exponential decay rate with exponent $-a$. Then the output of the closed loop system satisfies

$$\|y(t)\| \leq \gamma \|\xi(0)\| e^{-at}, \tag{5.2}$$

where γ depends on the choice of the feedback gain. We are interested in the lowest achievable value of γ among different feedback laws and its dependence upon a. This will be determined by the so-called peaking exponent, which we now define.

Denote by $\mathcal{F}(a)$ the collection of all stabilizing feedback laws $u : \xi \to F\xi$ with the additional property that all *observable*[1] eigenvalues λ of (C, A_F), with $A_F = A + BF$, satisfy $\mathrm{Re}(\lambda) < -a$. For a given a and $F \in \mathcal{F}(a)$, define the smallest value of γ in (5.2) as

$$\kappa_F(a) = \sup \left\{ \|y(t)\| e^{at} \right\},$$

where the supremum is taken over all $t \geq 0$ and all initial conditions satisfy $\|\xi(0)\| \leq 1$. Now denote $\kappa(a) = \inf_{F \in \mathcal{F}(a)} \kappa_F$. The output of system (5.1) is said to have peaking

[1] In [10], where the peaking phenomenon is rather studied in an input-state framework, one places all eigenvalues to the left of the line $\lambda = -a$.

exponent s when there exist constants α_1, α_2 such that

$$\alpha_1 a^s < \kappa(a) < \alpha_2 a^s \tag{5.3}$$

for large a. When $s = 0$ the output is said to be *nonpeaking*.

The peaking exponent s is a structural property related to the zero dynamics. When the system has relative degree r, it can be transformed (including a preliminary feedback transformation) into the normal form [3, 1]:

$$\begin{cases} \dot{\xi}_0 = A_0\xi_0 + B_0 y, \\ y^{(r)} = u, \end{cases} \tag{5.4}$$

which can be interpreted as an integrator chain linearly coupled with the zero-dynamics subsystem $\dot{\xi}_0 = A_0\xi_0$. Using state feedback the output of an integrator chain can be forced to zero rapidly without peaking [8]. Because of the linear interconnection term, asymptotic stability of the zero-dynamics subsystem then implies asymptotic stability of the whole cascade. On the contrary, when the zero dynamics are unstable, some amount of energy, expressed by $\int_0^\infty \|y(t)\|dt$, is needed for its stabilization, and therefore the output must peak. More precisely, we have the following theorem, proven in the appendix.

THEOREM 5.1. *The peaking exponent s equals the number of eigenvalues in the closed right half plane (RHP) of the zero-dynamics subsystem.*

The definition of the peaking exponent (5.3) is based on an upper bound of the exponentially weighted output, while its L_1 norm is important in most of the theorems of section 4. But because the overshoots related to peaking occur in a fast time-scale ($\sim at$), there is a connection. For instance, we have the following theorem, based on a result of Braslavsky and Middleton [7].

THEOREM 5.2. *When the output y of system* (5.1) *is peaking* ($s \geq 1$), *$\|y(t)\|_1$ cannot be reduced arbitrarily.*

Proof. Denote by z_0 an unstable eigenvalue of the zero dynamics of (5.1). When a feedback $u = F\xi$ asymptotically stabilizes the system, the relation between y and $w = u + F\xi$ in the Laplace domain is given by

$$\begin{aligned} Y(s) &= C(sI - \bar{A})^{-1}BW(s) + C(sI - \bar{A})^{-1}\xi(0) \\ &= H(s)W(s) + C(sI - \bar{A})^{-1}\xi(0) \end{aligned}$$

with $\bar{A} = A + BF$. The first term vanishes at z_0 because the eigenvalues of the zero dynamics appear as zeros in the corresponding transfer function $H(s)$, and since the feedback F is stabilizing, no unstable pole-zero cancellation occurs at z_0. Hence

$$\begin{aligned} \|y\|_1 &\geq \int_0^\infty |y(t)e^{-z_0 t}|dt \\ &\geq \left| \int_0^\infty y(t)e^{-z_0 t}dt \right| \\ &= |C(z_0 I - \bar{A})^{-1}\xi(0)|. \end{aligned} \tag{5.5}$$

∎

5.2. Nonpeaking cascades. When the ξ-subsystem is minimum-phase and thus nonpeaking, one can find state feedback laws $u = F_a\xi$ resulting in

$$|y(t)| \leq \alpha_2 e^{-at},$$

and the L_1 norm of the output can be made arbitrarily small. So by Theorem 4.1, the cascade (1.2) can be semiglobally asymptotically stabilized in both the state and the delay.

5.3. Peaking cascades. When the ξ-subsystem is nonminimum-phase, the peaking phenomenon forms an obstacle to semiglobal stabilizability because the L_1 norm of the output cannot be reduced (Theorem 5.2).

For ODE-cascades, we illustrate the peaking obstruction with the following example.

Example 5.3. In the cascade,

$$\begin{aligned}\dot{z} &= -z + z^2 y,\\ \dot{\xi}_1 &= \xi_1 + \xi_2,\\ \dot{\xi}_2 &= u, \quad y = -\xi_2.\end{aligned}$$

The peaking exponent of the ξ-subsystem is 1 (zero dynamics $\dot{\xi}_1 = \xi_1$). The cascade cannot be stabilized semiglobally since the explicit solution of the first equation is given by

$$z(t) = \frac{e^{-t}}{\frac{1}{z(0)} - \int_0^t e^{-s} y(s) ds},$$

whereby $\int_0^\infty e^{-s} y(s) ds = \xi_1(0)$. Hence the solution reaches infinity in a finite time when $0 < \frac{1}{\xi_1(0)} < z(0)$.

For DDE-cascades, we consider two cases.

Case 1. Peaking exponent=1. We can apply Theorem 4.4 and obtain semiglobal stabilizability in the state and in the delay when the interconnection term has linear growth in the undelayed argument: besides (5.5) the L_1 norm of y can also be bounded from above since there exist feedback laws $u = F_a \xi$ and a constant α_2 such that

$$\|y(t)\|_1 \leq \int_0^\infty \alpha_2 a e^{-as} ds = \alpha_2,$$

and because of the fast time-scale property, the energy can be concentrated since for all $t > 0$

$$\int_t^\infty |y(s)| ds \leq \int_t^\infty \alpha_2 a e^{-as} ds \to 0 \text{ as } a \to \infty.$$

Case 2. Peaking exponent > 1. In this case, we expect the L_1 norm of y to grow unbounded with a, as suggested by the following example.

Example 5.4. When ξ_k is considered as the output of the integrator chain,

$$\dot{\xi}_1 = \xi_2, \ \dot{\xi}_2 = \xi_3, \ldots, \dot{\xi}_n = u,$$

the peaking exponent is $k-1$ (Theorem 5.1), and $\|\xi_k(t)\|_1, \ k = 2, n$ cannot be reduced arbitrarily by achieving a faster exponential decay rate. In Proposition 4.32 of [8], it is shown that with the feedback law $u = K(a)\xi = -\sum_{k=1}^n a^{n-k+1} q_{k-1} \xi_k$, where all solutions of $\sum_{k=0}^{n-1} q_k \lambda^k + \lambda^n = 0$ satisfy $\mathrm{Re}(\lambda) < -1$, there exists a constant c independent of a such that

$$|\xi_k(t)| \leq c a^{k-1} e^{-at} \|\xi(0)\|;$$

hence the particular feedback $u = K(a)\xi$ is able to achieve an upper bound which corresponds to definition (5.3) for each choice of the output $y = \xi_k$. It is also shown in [8] that with the same feedback and with as initial condition $\xi_1(0) = 1, \ \xi_k(0) =$

$0,\ k = 2, n$, there exists a constant d such that $s_k = \sup_{t\geq 0} |\xi_k(t)| \geq da^{k-1}$. Define $t_k,\ k = 2, n$ such that $|\xi_k(t_k)| = s_k$. As a consequence,

$$\|\xi_k(t)\|_1 \geq \left| \int_0^{t_{k-1}} \xi_k(s)ds \right| = |\xi_{k-1}(t_{k-1})| \geq da^{k-2}, \quad k = 3, n,$$

while the peaking exponent of output $y = \xi_k$ is $k - 1$.

With the two following examples, we show that when the energy of an exponentially decaying input perturbation ($\sim e^{-at}$) grows unbounded with a, an interconnection term which is linear in the undelayed argument is not sufficient to bound the solutions semiglobally in the state. Because it is hard to deal in general with outputs generated by a linear system with peaking exponent $s > 1$, we use an artificial perturbation $a^s e^{-at}$, which has both the fast time-scale property and the suitable growth rate of the energy (a^{s-1}) with respect to a.

Example 5.5. The solutions of equation

$$\dot{z} = -bz + zz(t-\tau)^\alpha a^s e^{-at}, \quad \alpha > 0, \tag{5.6}$$

cannot be bounded semiglobally in z by increasing a for any $\tau > 0$ if the "peaking exponent" s is larger than one.

Proof. Equation (5.6) has an exponential solution $z_e(t)$:

$$z_e(t) = \left[\frac{(\frac{a}{\alpha} + b)e^{a\tau}}{a^s} \right]^{\frac{1}{\alpha}} e^{\frac{a}{\alpha}t}.$$

Consider the solution $z(t)$ with initial condition $z_0 \equiv L > 0$ on $[-\tau,\ 0]$. For $t \in [0,\ \tau]$, $z(t)$ satisfies

$$\dot{z} = -bz + zL^\alpha a^s e^{-at}$$

and consequently coincides on $[o,\ \tau]$ with

$$y(t) = Le^{L^\alpha a^{s-1}(1-e^{-at})-bt}. \tag{5.7}$$

For large a, expression (5.7) describes a lower bound for $z(t)$ on $[\tau,\ 2\tau]$. Furthermore, $y(t)$ decreases on this interval since it reaches its maximum in $t^*(a)$ with $t^* \to 0$ as $a \to \infty$. Thus imposing $y(2\tau) > z_e(2\tau)$ implies that $z(t) > z_e(t), t \in [\tau,\ 2\tau]$, and from this one can argue[2] that $z(t) \geq z_e(t),\ t \geq \tau$. Thus the trajectory starting with initial condition L on $[-\tau,\ 0]$ is unbounded when

$$Le^{L^\alpha a^{s-1}(1-e^{-2a\tau})-2b\tau} > x_e(2\tau) = \left[\frac{\frac{a}{\alpha} + b}{a^s} \right]^{\frac{1}{\alpha}} e^{\frac{3a}{\alpha}\tau}.$$

When $s > 2$, for each value of L, the solution is unstable for large a, and thus the attraction domain of the stable zero solution shrinks to zero. When $s = 2$, a solution with initial condition $L > \left[\frac{3\tau}{\alpha}\right]^{\frac{1}{\alpha}}$ is unstable for large a. ∎

Even when the interconnection term contains no terms in $z(t)$ but only delayed terms of z, semiglobal results are still not possible in general, as shown with the following example.

[2]From (5.6), intersection at t^* would imply $\dot{z}(t^*) > \dot{z_e}(t^*)$ and we have a contradiction.

Example 5.6. The solutions of the system

$$\dot{z} = -\mathrm{sat}(z) + e^{z(t-\tau)} a^s e^{-at} \tag{5.8}$$

with $\mathrm{sat}(z) = z$ when $|z| \leq 1$ and $\mathrm{sat}(z) = \mathrm{sign}(z)$ otherwise cannot be bounded semiglobally in z by increasing a for any $\tau > 0$ when the "peaking exponent" s is greater than one.

Proof. When $z \geq 1$, (5.8) reduces to

$$\dot{z} = -1 + e^{z(t-\tau)} a^s e^{-at},$$

which has the following explicit solution:

$$z_l(t) = at + b, \quad b = a\tau - \log\left(\frac{a^s}{a+1}\right).$$

When a is large enough such that $b \geq 1$, $z_l(t)$ is a solution of (5.8) for all $t \geq 0$.

When the initial condition of (5.8) is L on $[-\tau,\ 0]$ one can find a lower bound for the corresponding solution $z(t)$ on $[0,\ \tau]$ by integrating

$$\dot{z} = -z + e^L a^s e^{-at},\ z(0) = L,$$

yielding

$$z_u(t) = Le^{-t} + e^{-t} e^L \frac{a^s}{a-1}(1 - e^{-(a-1)t}).$$

Furthermore, for large a, $z_u(t)$ describes a lower bound for this solution in the interval $[0,\ 2\tau]$. When imposing $z_u(2\tau) > z_l(2\tau)$, we have for large a, $z_u(t) > z_l(t)$ for all $t \in [\tau,\ 2\tau]$. ($z_u(t)$ reaches its maximum in $t^*(a) \to 0$ as $a \to \infty$.) Hence $z(t) > z_l(t)$ for all $t \in [\tau,\ 2\tau]$ and consequently for all $t \geq \tau$. Thus the trajectory with initial condition L on $[-\tau,\ 0]$ is unbounded when

$$Le^{-2\tau} + e^{-2\tau} e^L \frac{a^s}{a-1}(1 - e^{-(a-1)2\tau}) > 3a\tau - \log\left(\frac{a^s}{a+1}\right). \qquad \square$$

5.4. Zero dynamics with eigenvalues on the imaginary axis. The situation where the zero dynamics possess eigenvalues on the imaginary axis but no eigenvalues in the open RHP deserves special attention. According to Theorem 5.1, the system is peaking; that is, the L_1 norm of the output cannot be reduced arbitrarily. However, this energy can be "spread out" over a long time-interval. It is indeed well known that a system with all its eigenvalues in the closed left half plane (LHP) can be stabilized with a low-gain feedback, as expressed by the following theorem taken from [8].

THEOREM 5.7. *If a system $\dot{\xi}_0 = A_0\xi_0 + B_0 y$ is stabilizable and the eigenvalues of A_0 are in the closed left half plane, then it can be stabilized with a low-gain control law $y = K_0(a)\xi_0$ which for large a satisfies*

$$|y(t)| \leq \frac{\gamma}{a}\|\xi_0(0)\|.$$

The infinity norm of such a low-gain control signal can be arbitrarily reduced, which results, by Theorem 4.2, in satisfactory stabilizability results when it also acts as an input disturbance of a nonlinear system. This suggests not to force the output

of (5.1) exponentially fast ($\sim e^{-at}$) to zero, which results in peaking, but to drive it rapidly without peaking to the manifold $y = K_0(a)\xi_0$, on which the dynamics are controlled by the low-gain control action. Mathematically, with $e = y - K_0(a)\xi_0$ and a feedback transformation $v = u + M\xi$, the normal form of the ξ-subsystem is transformed into

$$\begin{aligned}\dot{\xi}_0 &= A_0\xi_0 + B_0K_0(a)\xi + B_0e,\\ e^r &= v.\end{aligned}$$

Using a high-gain feedback driving $e(t)$ to zero without peaking, as proven in [8, Proposition 4.37], one can always force the output to satisfy the constraint

$$|y(t)| \le \gamma\left(e^{-at} + \frac{1}{a}\right)\|\xi(0)\| \tag{5.9}$$

with γ independent of a. A systematic treatment of such high-low-gain control laws can be found in [6].

For instance, the system

$$\begin{cases}\dot{\xi}_1 = \xi_2,\\ \dot{\xi}_2 = u, \quad y = \xi_2\end{cases} \tag{5.10}$$

is weakly minimum-phase (zero dynamics $\dot{\xi}_1 = 0$). With the high-low gain feedback $u = -\xi_1 - a\xi_2$ the explicit solution of (5.10) for large a can be approximated by

$$\begin{bmatrix}\xi_1\\ \xi_2 = y\end{bmatrix} \approx c_1e^{-at}\begin{bmatrix}\frac{1}{a}\\ -1\end{bmatrix} + c_2e^{-\frac{1}{a}t}\begin{bmatrix}1\\ -\frac{1}{a}\end{bmatrix}. \tag{5.11}$$

Perturbations satisfying constraint (5.9) can be decomposed in signals with vanishing L_1 or L_∞ norm. This suggests the combination of Theorems 4.1 and 4.2 as follows.

THEOREM 5.8. *Consider the interconnected system*

$$\begin{aligned}\dot{z} &= f(z, z(t-\tau)) + \Psi(z, z(t-\tau))y,\\ \dot{\xi} &= A\xi + Bu,\\ y &= C\xi.\end{aligned}$$

Suppose that the z-subsystem is GAS with the Lyapunov functional $V(z_t)$ satisfying Assumption 2.2 and the zeros of the ξ-subsystem are in the closed LHP. Then the interconnected system can be made semiglobally asymptotically stable in both $[z,\ \xi]$ and the delay, using only partial-state feedback.

Proof. As explained in Remark 4.5, the origin $(z, \xi) = (0, 0)$ is stable. Let Ω be the desired region of attraction in the $(z,\ \xi)$-space and choose R such that for all $(z_0, \xi) \in \Omega,\ \|\xi\| < R$. Because of the assumption on the ξ-subsystem, there exist partial-state feedback laws such that

$$\|y(t)\| \le \gamma\|\xi(0)\|\left(e^{-at} + \frac{1}{a}\right) \le \gamma R\left(e^{-at} + \frac{1}{a}\right)$$

with γ independent of a.

Consider the time-interval $[0,\ 1]$. Because

$$\int_0^1 \gamma R\left(e^{-at} + \frac{1}{a}\right) \to 0, \quad a \to \infty,$$

one can show, as in the proof of Theorem 4.1, that by taking a large, the increase of V can be limited arbitrarily. Hence for $t \leq 1$, the trajectories can be bounded inside a compact region Ω_2. We can now translate the original problem over one time-unit, and since

$$\sup_{t \geq 1} \gamma R \left(e^{-at} + \frac{1}{a} \right) \to 0$$

as $a \to \infty$, we can, by Theorem 4.2, increase a until the stability domain contains Ω_2. Then all trajectories starting in Ω are bounded and hence converge to the origin (Remark 4.5). □

6. Conclusions. In this paper, we first studied the effect of bounded input perturbations on the stability of nonlinear delay equations of the form (1.1).

Global stability results are generally not possible without structural assumptions on the unperturbed system and the interconnection term, because arbitrarily small perturbations can lead to unbounded trajectories, even when they are exponentially decaying. In the ODE-case this is caused by the fact that superlinear destabilizing terms can drive the state to infinity in a finite time. Superlinear delayed terms cannot cause a finite escape-time but can still make trajectories diverge faster than any exponential function.

We also considered semiglobal results when the size or shape of the perturbation can be controlled. We assumed that the unperturbed system is delay-independent stable. When the L_1 or the L_∞ norm of the perturbations is brought to zero, trajectories can be bounded semiglobally in both the state and the delay. By means of an example we explained why global results in the delay are generally not possible. Next we considered the effect of concentrating a perturbation with a fixed L_1 norm in arbitrarily small time-intervals. This leads to semiglobal stabilizability in both the state and the delay (compact delay-intervals not containing $\tau = 0$), when the interconnection term is linear in its undelayed arguments.

Using these boundedness results, we studied the stabilizability of the partially linear cascade (1.2) using partial state feedback. When the interconnection term is nonlinear, output peaking of the linear system can form an obstruction to semiglobal stabilizability because the L_1 norm of the output cannot be reduced by achieving a faster exponential decay rate. If we assume that the interconnection term has linear growth in the undelayed argument and the peaking exponent is one, we have semiglobal stabilizability results, because the L_1 norm of the output can be bounded from above while concentrating its energy. Even with this assumption on the interconnection term, higher peaking exponents may form an obstruction. When the zeros of the linear subsystem are in the closed left half plane, satisfactory stability results are obtained when using a high-low-gain feedback, whereby the output of the linear subsystem can be decomposed in two signals with vanishing L_1 and L_∞ norm, respectively.

The main contribution of this paper lies in generalizing classical cascade results to a class of functional differential equations. Instrumental to this generalization is the observation that the way a bounded input perturbation affects a nonlinear system mainly lies in the way its L_1 and L_∞ norm can be controlled.

Appendix. Proof of Theorem 5.1. We transform the system (5.1) into the normal form

$$\begin{aligned} \dot{\xi}_0 &= A_0\xi_0 + B_0 y, \\ \dot{y} &= y_2, \\ &\vdots \\ \dot{y_r} &= u, \end{aligned} \tag{A.1}$$

where $y = C[\xi_0^T\ Y^T]^T,\ Y = [y\ y_1 \cdots y_r]^T$, is the output, and $\dot{\xi}_0 = A_o\xi_0,\ A_0 \in \mathbb{R}^{m\times m}$, describes the zero dynamics. We consider two cases.

Case 1. All eigenvalues of A_0 lie in the closed RHP.

For the stabilization of the system (A.1), we use a state feedback

$$u = F_0\xi_0 + F_1 Y.$$

The closed loop matrix is

$$A_{cl} = \left[\begin{array}{c|cccc} A_0 & B_0 & & & \\ \hline & 0 & 1 & & \\ & \vdots & & \ddots & \\ & 0 & & \cdots\ 0 & 1 \\ F_0 & & & F_1 & \end{array}\right].$$

For asymptotic stability, the observability of (F_0, A_0) is required. In the other case (unstable) eigenvalues of A_0 will still be present in the closed loop system. Mathematically, when (F_0, A_0) would not be observable, one can perform a similarity transformation on ξ_0 leading to

$$\left[\begin{array}{c|c} A_0 & B_0 \\ \hline F_0 & \end{array}\right] \to \left[\begin{array}{cc|c} A_{\bar{o}} & A_{12} & B_{\bar{o}} \\ 0 & A_o & B_o \\ \hline 0 & F_o & \end{array}\right],$$

whereby $A_{\bar{o}}$ contains the unobservable modes of A_0. These unstable eigenvalues are still present in the closed loop matrix A_{cl}, which contradicts the stability assumption.

As a consequence, the whole system is observable since the observability matrix of (C, A_{cl}) is given by

$$\mathcal{O}_{cl} = \left[\begin{array}{c|c} 0 & \mathcal{O}_{1,2} \\ \hline \mathcal{O}_{2,1} & \mathcal{O}_{2,2} \end{array}\right],$$

whereby $\mathcal{O}_{1,2}$ is the unity matrix in $\mathbb{R}^r$ and

$$\mathcal{O}_{2,1} = \left[\begin{array}{cccc} 1 & & & \\ f_n & 1 & & \\ \vdots & & \ddots & \\ f_n^{m-1} & \cdots & f_n & 1 \end{array}\right] \cdot \left[\begin{array}{c} F_0 \\ F_0A_0 \\ \vdots \\ F_0A_0^{m-1} \end{array}\right]$$

with f_n the last component of F_1. From this it follows that the observability of (C, A_{cl}) is implied by the observability of (F_0, A_0).

Consequently, in order to achieve an exponential decay of the output ($\sim e^{-at}$), we need to place *all* eigenvalues to the left of the line $\lambda = -a$. But now we are in the situation considered by Sussmann and Kokotovic [10]. From Theorem 8.1 in [10], it follows that in this case the peaking exponent equals the dimension of the zero dynamics.

Case 2. A_0 has eigenvalues λ with $\mathrm{Re}(\lambda) < 0$.

With another similarity transformation we split off the asymptotically stable part A_{0s} of A_0. Equation (A.1) becomes

$$\begin{cases} \dot{\xi}_{0s} = A_{0s}\xi_{0s} + A_{0su}\xi_{0u} + B_{0s}y, \\ \dot{\xi}_{0u} = A_{0u}\xi_{0u} + B_{0u}y, \\ y^{(r)} = u. \end{cases}$$

Because ξ_{0s} is linearly coupled with the other states, it is sufficient to consider state-feedback laws for the (ξ_{0u}, Y) subsystem (which render the eigenvalues of A_{0s} unobservable). □

Acknowledgments. The authors thank W. Aernouts for fruitful discussions on the results presented in the paper. This paper presents research results of the Belgian program on Interuniversity Poles of Attraction, initiated by the Belgian State, Prime Minister's Office for Science, Technology, and Culture (IUAP P4/02). LEARNING ALGORITHMS FOR MARKOV DECISION PROCESSES WITH AVERAGE COST*

J. ABOUNADI†, D. BERTSEKAS†, AND V. S. BORKAR‡

Abstract. This paper gives the first rigorous convergence analysis of analogues of Watkins's Q-learning algorithm, applied to average cost control of finite-state Markov chains. We discuss two algorithms which may be viewed as stochastic approximation counterparts of two existing algorithms for recursively computing the value function of the average cost problem—the traditional relative value iteration (RVI) algorithm and a recent algorithm of Bertsekas based on the stochastic shortest path (SSP) formulation of the problem. Both synchronous and asynchronous implementations are considered and analyzed using the ODE method. This involves establishing asymptotic stability of associated ODE limits. The SSP algorithm also uses ideas from two-time-scale stochastic approximation.

Key words. simulation-based algorithms, Q-learning, controlled Markov chains, average cost control, stochastic approximation, dynamic programming

1. Introduction.

Q-learning algorithms are simulation-based reinforcement learning algorithms for learning the value function arising in the dynamic programming approach to Markov decision processes. They were first introduced for the discounted cost problem by Watkins [27] and analyzed partially in Watkins [27] and then in Watkins and Dayan [28]. A more comprehensive analysis was given by Tsitsiklis [25] (also reproduced in Bertsekas and Tsitsiklis [7]), which made the connection between Q-learning and stochastic approximation. (See also Jaakola, Jordan, and Singh [15] for a parallel treatment, which made the connection between TD(λ) and stochastic approximation.) In particular, Q-learning algorithms for discounted cost problems or stochastic shortest path (SSP) problems were viewed as stochastic approximation variants of well-known value iteration algorithms in dynamic programming.

These techniques, however, do not extend automatically to the average cost problem, which is harder to analyze even when the model (i.e., controlled transition probabilities) is readily available. Not surprisingly, the corresponding developments for the average cost problem have been slower. One of the first was the "R-learning" algorithm proposed by Schwartz [22]. This is a two-time-scale algorithm that carries out a value iteration-type step to update values of state-action pairs and updates concurrently an estimate of the optimal average cost using the immediate reward along with an adjustment factor. The idea is to obtain a good estimate for the average cost while searching for the optimal policy using a value iteration-type update. Although Schwartz presents some intuitive arguments to justify his algorithm along with some

numerical results, he does not provide any convergence analysis. Singh [23] presents two Q-learning algorithms for the average cost problem: one is a slight modification of Schwartz's algorithm which updates the estimate of optimal cost at every step. The other one updates the estimate of average cost in a fashion similar to Jalali and Ferguson's deterministic asynchronous algorithm for average cost problems [16]. He provides simulation results for medium-sized problems but no convergence analysis. Finally, Mahadevan [20] discusses average cost problems and the need to consider the average cost criterion, with an emphasis on the difference between gain-optimal and bias-optimal policies. He presents extensive numerical experiments, highlighting the problems the algorithm can run into. He does not, however, provide any convergence analysis. It is also noteworthy that none of these algorithms use the relative value iteration (RVI) algorithm for average cost problems (see, e.g., [4], [21], [24]) as a basis for the learning algorithms because the latter may not converge asynchronously, as shown in [3]. Nevertheless, a diminishing stepsize does work around this problem, as we show in this paper.

We propose and give for the first time a complete convergence analysis of two Q-learning algorithms for average cost. The first is a stochastic approximation analogue of (RVI). The second is a stochastic approximation analogue of a recent value iteration algorithm of Bertsekas based on the SSP formulation of the average cost problem. We consider both synchronous and asynchronous implementations. The analysis relies on the ODE method, based on establishing first the boundedness of iterates and then the asymptotic stability of limiting ODEs. The rest then follows as in the Kushner–Clark approach [18] (see also Kushner and Yin [19]) in the synchronous case and by Borkar's theorem [10] in the asynchronous case.

The paper is organized as follows. The next section describes the two algorithms in both synchronous and asynchronous modes and states the assumptions required in each case. Section 3 provides the convergence analysis of the RVI-based Q-learning algorithm. Section 4 does likewise for the SSP Q-learning algorithm. Section 5 concludes with some general remarks. An Appendix collects some key facts from the literature that we used here.

2. Average cost Q-learning algorithms.

2.1. Preliminaries. We consider a controlled Markov chain $\{X_n\}$ on a finite state space $S = \{1, 2, \ldots, d\}$ with a finite action space $A = \{a_1, \ldots, a_r\}$ and transition probabilities $p(i, a, j) =$ the probability of transition from i to j under action a for $i, j \in S, a \in A$. Associated with this transition is a "cost" $g(i, a, j)$ and the aim is to choose actions $\{Z_n\}$ nonanticipatively (i.e., conditionally independent of the future state trajectory given past states and actions) so as to minimize the "average cost"

$$\limsup_{n\to\infty} \frac{1}{n} \sum_{m=0}^{n-1} E[g(X_m, Z_m, X_{m+1})]. \tag{2.1}$$

This problem is extensively treated in [4], [21], and [24] among others, to which we refer the reader for details. We recall here the minimal necessary background material required to motivate our algorithms.

We shall be interested in "stationary policies" wherein $Z_n = v(X_n)$ for a map $v : S \to A$. It is known that an optimal one exists under the following "unichain" condition which we assume throughout.

ASSUMPTION 2.1. *Under any stationary policy, the chain has a single communicating class and a common state (say, s) that is recurrent.*

In particular, this implies that "limsup" in (2.1) is a limit under any stationary policy. It is known that one can then associate a "value function" $V : S \to R$ with the problem, given as the solution to the dynamic programming equations

$$V(i) = \min_a \left[\sum_j p(i,a,j)(g(i,a,j) + V(j)) - \beta \right], \qquad i \in S, \tag{2.2}$$

where β is the optimal cost. $V(\cdot)$ is the unique solution to (2.2) modulo an additive constant. Let $Q(i,a)$ denote the expression inside the square brackets on the right-hand-side (r.h.s.) of (2.2). Equation (2.2) is useful because of the following fact: A stationary policy $v : S \to A$ is optimal if and only if $v(i) \in \text{Argmin}\,(Q(i,\cdot))$ for all i that are recurrent under v. $Q(\cdot,\cdot)$ is called the "Q-factor," also defined uniquely only up to an additive constant. Thus $V(i) = \min_a Q(i,a)$ for all i, and $Q(\cdot,\cdot)$ satisfies

$$Q(i,a) = \sum_j p(i,a,j) \left(g(i,a,j) + \min_b Q(j,b) \right) - \beta, \qquad i \in S, \quad a \in A. \tag{2.3}$$

The aim of any Q-learning algorithm is to "learn" the Q-factors when $p(\cdot,\cdot,\cdot)$ is not known, but one has access to a simulation device that can generate an independent S-valued random variable (i.e., independent of other random variables that might have been generated up to that point in time) ξ_{ia} whose probability law is $p(i,a,\cdot), i \in S, a \in A$. Let $\xi = [\xi_{ia}]$.

2.2. RVI Q-learning. The RVI algorithm is given by (see, e.g., [4], [21], [24])

$$V^{n+1}(i) = \min_a \left[\sum_j p(i,a,j)(g(i,a,j) + V^n(j)) - V^n(i_0) \right], \qquad i \in S, \tag{2.4}$$

where $i_0 \in S$ is an arbitrary but fixed state. This can be shown, under some additional aperiodicity conditions (see [4, Chap. 4]), to converge to the unique $V(\cdot)$ that satisfies (2.2) with $V(i_0) = \beta$. The purpose of subtracting the scalar "offset" $V^n(i_0)$ from each component on the r.h.s. of (2.4) is to keep the iterations stable—recall that $V(\cdot)$ is specified anyway only up to an additive constant. It turns out that $V^n(i_0) \to \beta$. However, $V^n(i_0)$ is not the unique choice of an offset term that makes the algorithm work. More generally, one can replace it by $f(V)$ for an $f : R^d \to R$ satisfying suitable hypotheses. (See below.)

Algorithm (2.4) suggests the "relative Q-factor iteration"

$$Q^{n+1}(i,a) = \sum_j p(i,\alpha,j) \left(g(i,a,j) + \min_b Q^n(j,b) \right) - Q^n(i_0,a_0), \qquad i \in S, \qquad a \in A,$$

with $i_0 \in S, a_0 \in A$ prescribed. The idea behind RVI Q-learning is to replace the conditional average with respect to the transition probability $p(i,a,\cdot)$ by an actual evaluation at a random variable ξ_{ia} with law $p(i,a,\cdot)$ and then "see" the conditional average by means of the well-known averaging effect of the stochastic approximation algorithm. Thus the synchronous RVI Q-learning algorithm is

$$Q^{n+1}(i,a) = Q^n(i,a) + \gamma(n)\left(g(i,a,\xi^n_{ia}) + \min_b Q^n(\xi^n_{ia},b) - f(Q^n) - Q^n(i,a)\right), \qquad i \in S, \qquad a \in A, \tag{2.5}$$

where ξ^n_{ia} are independent with the law of ξ^n_{ia} being $p(i,a,\cdot)$ for all n. $\{\gamma(k)\} \in (0,\infty)$ is the usual diminishing stepsize schedule of stochastic approximation satisfying

$$\sum_k \gamma(k) = \infty, \quad \sum_k \gamma^2(k) < \infty. \tag{2.6}$$

The function $f : R^{d\times r} \to R$ satisfies the following assumption.

ASSUMPTION 2.2. *f is Lipschitz, and, furthermore, for e equal to the constant vector of all 1's in $R^{d\times r}$, $f(e) = 1$ and $f(x + ce) = f(x) + c$ for $c \in R$.*

Examples are $f(Q) = Q(i_0,b_0)$ for prescribed $i_0,b_0, f(Q) = \min_u Q(i_0,u)$ for prescribed $i_0, f(Q) = \frac{1}{dr}\sum_{i,a} Q(i,a)$, and so on.

For the asynchronous algorithm, we hypothesize a set-valued process $\{Y^n\}$ taking values in the set of nonempty subsets of $S \times A$ with the interpretation: $Y^n = \{(i,a) :$ (i,a)th component of Q was updated at time $n\}$. (Thus $Y^n \equiv S\times A$ is the synchronous case.)

Remarks. As argued in [10], we may take $Y^n = \{\phi^n\}$ for some $\phi^n \in S \times A$, i.e., a singleton. This can be achieved by unfolding a single iteration that updates k components into k iterations that update one component each. While this introduces "delays" in the formulation of the algorithm below, that does not affect the results of [10] that we use here. Alternatively, we may use the results of [17, section 4], which work with the Y^n's directly. The only difference is that the resultant ODE is a time-scaled version of the one arising in the former approach with a nonautonomous time-scaling which, however, does not affect its qualitative behavior.

Define

$$\nu(n,i,a) = \sum_{k=0}^{n} I\{(i,a) \in Y^k\},$$

where $I\{\ldots\}$ is the indicator function. Thus $\nu(n,i,a) =$ the number of times $Q^m(i,a)$ was updated up to time n.

The asynchronous RVI Q-learning algorithm then is

$$Q^{n+1}(i,a) = Q^n(i,a) + \gamma(\nu(n,i,a))\left(g(i,a,\xi^n_{ia}) + \min_u Q^n(\xi^n_{ia},u) - f(Q^n) - Q^n(i,a)\right) I\{(i,a) \in Y^n\} \tag{2.7}$$

for $(i,a) \in S \times A$. For the asynchronous case, we need the following additional assumptions.

ASSUMPTION 2.3. *In addition to* (2.6), *$\{\gamma(n)\}$ satisfy the following: If $[\ldots]$ stands for "the integer part of ...," then for $x \in (0,1)$,*

$$\sup_k \gamma([xk])/\gamma(k) < \infty,$$

and

$$\frac{\sum_{m=0}^{[yk]} \gamma(m)}{\sum_{m=0}^{k} \gamma(m)} \to 1 \quad \textit{uniformly in } y \in [x,1].$$

Examples of stepsizes satisfying Assumption 2.3 are $\gamma(n) = \frac{1}{n}, \frac{1}{n \log n}, \frac{\log n}{n}$, etc., for $n \geq 2$.

ASSUMPTION 2.4. *There exists* $\Delta > 0$ *such that*

$$\liminf_{n \to \infty} \frac{\nu(n,i,a)}{n+1} \geq \Delta \text{ a.s.}, \qquad (i,a) \in S \times A.$$

Furthermore, for all $x > 0$ *and*

$$N(n,x) = \min \left\{ m \geq n : \sum_{k=n}^{m} \gamma(k) \geq x \right\},$$

the limit

$$\lim_{n \to \infty} \frac{\sum_{k=\nu(n,i,a)}^{\nu(N(n,x),i,a)} \gamma(k)}{\sum_{k=\nu(n,j,u)}^{\nu(N(n,x),j,u)} \gamma(k)}$$

exists a.s. for all i, j, a, u.

That is, all components are updated comparably often in an evenly distributed manner.

2.3. SSP Q-learning. SSP Q-learning is based on the observation that the average cost under any stationary policy is simply the ratio of expected total cost and expected time between two successive visits to the reference state s. This connection was exploited by Bertsekas in [5] to give a new algorithm for computing $V(\cdot)$, which we describe below.

Define a parametrized family of SSP problems parametrized by a scalar λ as follows.

(i) The state space is $S' = S \cup \{s'\}$, where s' is an artificially added terminal state (i.e., zero-cost and absorbing).

(ii) The action set is A for all states.

(iii) The transition probabilities are

$$p'(i,a,j) = \begin{cases} p(i,a,j) & \text{if} \quad j \neq s, s', \\ 0 & \text{if} \quad j = s, \\ p(i,a,s) & \text{if} \quad j = s'. \end{cases}$$

(iv) The costs are defined by

$$g'(i,a,j) = \begin{cases} g(i,a,j) - \lambda & \text{if} \quad j \neq s, s', \\ 0 & \text{if} \quad j = s, \\ g(i,a,s) - \lambda & \text{if} \quad j = s'. \end{cases}$$

By Assumption 2.1, s' is reached from every state with probability 1. Thus all policies are proper (as defined in [4]). Let $V_\lambda(\cdot)$ denote the value function given as the unique solution to the dynamic programming equations

$$V_\lambda(i) = \min_a \left[\sum_{j=1}^{d} p(i,a,j) \left(g(i,a,j) + \sum_{j \neq s} p(i,a,j) V_\lambda(j) \right) - \lambda \right], \quad 1 \leq i \leq d,$$

$$V_\lambda(s') = 0.$$

For each fixed policy, the cost is linear in λ with negative slope. Thus $V_\lambda(\cdot)$, which by standard dynamic programming arguments is the lower envelope thereof, is piecewise linear with finitely many linear pieces and concave decreasing in λ for each component. If $\lambda = \beta$, we "recover" (2.2), which can be shown to happen when $V_\lambda(s) = 0$. This suggests the coupled iterations

$$V^{k+1}(i) = \min_a \left[\sum_{j=1}^{d} p(i,a,j) \left(g(i,a,j) + \sum_{j \neq s} p(i,a,j) V^k(j) \right) - \lambda^k \right], \qquad i \in S,$$
$$\lambda^{k+1} = \lambda^k + b(k) V^k(s),$$

where $\{b(k)\} \subset (0,\infty)$ with $\sum_k b(k) = \infty$ and $\sum_k b^2(k) < \infty$. This is the algorithm of [5], wherein the first "fast" iteration sees λ^k as quasi-static ($b(k)$'s are "small") and thus tracks $V_{\lambda^k}(\cdot)$, while the second "slow" iteration gradually guides λ^k to the desired value.

This suggests the SSP Q-learning algorithm (synchronous) as

(2.8a)
$$Q^{n+1}(i,a) = Q^n(i,a) + \gamma(n) \left[(g(i,a,\xi^n_{ia}) + \min_u Q^n(\xi^n_{ia},u)) I\{\xi^n_{ia} \neq s\} - \lambda^n - Q^n(i,a) \right],$$

(2.8b)
$$\lambda^{n+1} = \lambda^n + b(n) \min_u Q^n(s,u),$$

where $b(n) = o(\gamma(n))$. Unfortunately, it appears hard to ensure boundedness of $\{\lambda^n\}$. So we propose replacing (2.8b) by

(2.8b′)
$$\lambda^{n+1} = \Gamma \left(\lambda^n + b(n) \min_u Q^n(s,u) \right),$$

where $\Gamma(\cdot)$ is the projection onto an interval $[-K,K]$ with K chosen so that $\beta \in (-K,K)$. (This assumes prior knowledge of a bound on β, but this can be obtained from a bound on $g(\cdot,\cdot,\cdot)$.)

As in the case of RVI Q-learning, we impose Assumptions 2.3 and 2.4 for the asynchronous SSP Q-learning, which is

$$Q^{n+1}(i,a) = Q^n(i,a) + \gamma(\nu(n,i,a)) \left[\left(g(i,a,\xi^n_{ia}) + \min_u Q^n(\xi^n_{ia},u) I\{\xi^n_{ia} \neq s\} \right) \right.$$

(2.9a)
$$\left. - \lambda^n - Q^n(i,a) \right] I\{(i,a) \in Y^n\},$$

(2.9b)
$$\lambda^{n+1} = \Gamma \left(\lambda^n + b(n) \min_u Q^n(s,u) \right).$$

3. Convergence of RVI Q-learning.

3.1. ODE analysis. We can rewrite the synchronous RVI Q-learning algorithm (2.5) as

(3.1)
$$Q^{n+1} = Q^n + \gamma(n)(T(Q^n) - f(Q^n)e - Q^n + M^{n+1}),$$

where Q^n stands for $Q^n(i,a)$, $T : R^{d \times r} \to R^{d \times r}$ is the map defined by

$$(TQ)(i,a) = \sum_j p(i,a,j) \left(g(i,a,j) + \min_u Q(j,u) \right),$$

and, for $n \geq 0$,

$$M^{n+1}(i,a) = g(i,a,\xi_{ia}^n) + \min_u Q^n(\xi_{ia}^n, u) - (TQ^n)(i,a).$$

Letting $\mathcal{F}_n = \sigma(Q^m, M^m, m \leq n), n \geq 0$, we note that, for all n,

$$E[M^{n+1} \mid \mathcal{F}_n] = 0, \tag{3.2}$$

$$E[||M^{n+1}||^2 \mid \mathcal{F}_n] \leq C_1(1 + ||Q^n||^2) \tag{3.3}$$

for a suitable constant $C_1 > 0$.

Define $\hat{T} : R^{d\times r} \to R^{d\times r}, T' : R^{d\times r} \to R^{d\times r}$ by

$$\hat{T}(Q) = T(Q) - \beta e,$$
$$T'(Q) = T(Q) - f(Q)e = \hat{T}(Q) + (\beta - f(Q))e,$$

where, as before, $e \in R^{d\times r}$ is the constant vector of all 1's.

Let $||x||_\infty = \max_{i,a} |x_{ia}|, ||x||_s = \max_{i,a} x_{ia} - \min_{i,a} x_{ia}$ for $x \in R^{d\times r}$. These are, respectively, the max-norm and the span seminorm, the latter having the property that $||x||_s = 0$ if and only if x is a scalar multiple of e. The following "nonexpansivity" properties are then easily verified:

$$||T(Q) - T(Q')||_\infty \leq ||Q - Q'||_\infty,$$

and likewise for $\hat{T}(\cdot)$. Also,

$$||T(Q) - T(Q')||_s \leq ||Q - Q'||_s,$$

and likewise for $\hat{T}(\cdot), T'(\cdot)$. In fact, $||T(Q)||_s = ||T'(Q)||_s = ||\hat{T}(Q)||_s$ since $||e||_s = 0$.

Algorithm (3.1) is in the form of a standard stochastic approximation algorithm with the martingale difference sequence $\{M^{n+1}\}$ serving as the "noise." The ODE approach to analyzing the convergence of such algorithms (described in [2], [13], [18], and [19], among others) is based on the stability of the associated ODE

$$\dot{Q}(t) = T'(Q(t)) - Q(t). \tag{3.4}$$

This subsection is devoted to studying the stability properties of this ODE. We do so through a succession of lemmas. The analysis is inspired by a similar analysis in [9] in the context of value iteration. (See also [17].)

We shall also consider the related ODE

$$\dot{Q}(t) = \hat{T}(Q(t)) - Q(t). \tag{3.5}$$

Note that by the properties of $T(\cdot), f(\cdot)$, both (3.4) and (3.5) have Lipschitz r.h.s.'s and thus are well-posed.

The set G of equilibrium points of (3.5) is precisely the set of fixed points of $\hat{T}(\cdot)$, i.e., the solutions of (2.3) which are unique up to an additive constant. Thus $G = \{Q : Q = Q^* + ce, c \in R\}$, where Q^* is the solution to (2.3) satisfying $f(Q^*) = \beta$. (That there will indeed be one such solution follows from the fact that $f(x + ce) = f(x) + c$ for $c \in R$.)

The next lemma is a special case of Theorem 4.1 of [14] (see the appendix).

LEMMA 3.1. *Let $y(\cdot)$ and z be a solution and an equilibrium point of* (3.5)*, respectively. Then $||y(t) - z||_\infty$ is nonincreasing, and $y(t) \to y^*$ for some equilibrium point y^* of* (3.5) *that may depend on $y(0)$.*

We use this to analyze (3.4). But first note the following.

LEMMA 3.2. *Equation* (3.4) *has a unique equilibrium point at Q^*.*

Proof. Since $f(Q^*) = \beta$, it follows that $T'(Q^*) = \hat{T}(Q^*) = Q^*$; thus Q^* is an equilibrium point for (3.4). Conversely, if $T'(Q) = Q$, then $Q = \hat{T}(Q) + (\beta - f(Q))e$. But the Bellman equation

$$Q = \hat{T}(Q) + ce$$

has a solution if and only if $c = 0$. (This can be deduced from the corresponding statement for (2.2), which is well known, and the relation $V(i) = \min_u Q(i, u)$ modulo an additive constant.) Thus $f(Q) = \beta$, implying $Q = Q^*$. □

LEMMA 3.3. *Let $x(\cdot), y(\cdot)$ satisfy* (3.4) *and* (3.5)*, respectively, with $x(0) = y(0) = x_0$. Then $x(t) = y(t) + r(t)e$, where $r(\cdot)$ satisfies the ODE*

$$\dot{r}(t) = -r(t) + (\beta - f(y(t))).$$

Proof. By the variation of constants formula,

$$x(t) = x_0 e^{-t} + \int_0^t e^{-(t-s)} \hat{T}(x(s)) ds + \left[\int_0^t e^{-(t-s)} (\beta - f(x(s))) ds \right] e,$$
$$y(t) = x_0 e^{-t} + \int_0^t e^{-(t-s)} \hat{T}(y(s)).$$

Therefore, with $\hat{T}_i(\cdot)$ denoting the ith component of $\hat{T}(\cdot)$,

$$\max_i (x_i(t) - y_i(t)) \leq \int_0^t e^{-(t-s)} \max_i (\hat{T}_i(x(s)) - \hat{T}_i(y(s))) ds + \int_0^t e^{-(t-s)} (\beta - f(x(s))) ds,$$
$$\min_i (x_i(t) - y_i(t)) \geq \int_0^t e^{-(t-s)} \min_i (\hat{T}_i(x(s)) - \hat{T}_i(y(s))) ds + \int_0^t e^{-(t-s)} (\beta - f(x(s))) ds.$$

Subtracting, we have

$$\begin{aligned} ||x(t) - y(t)||_s &\leq \int_0^t e^{-(t-s)} ||\hat{T}(x(s)) - \hat{T}(y(s))||_s ds \\ &\leq \int_0^t e^{-(t-s)} ||x(s) - y(s)||_s ds. \end{aligned}$$

By Gronwall's inequality, $||x(t) - y(t)||_s = 0$ for all $t \geq 0$. Since $||x||_s = 0$ if and only if $x = ce$ for some $c \in R$, we have $x(t) = y(t) + r(t)e, t \geq 0$. Since $x(0) = y(0), r(0) = 0$. Since

$$\hat{T}(x + ce) = \hat{T}(x) + ce,$$
$$f(x + ce) = f(x) + c,$$

for $r \in R$ we have

$$\begin{aligned} \dot{r}(t)e &= \dot{x}(t) - \dot{y}(t) \\ &= (\hat{T}(x(t)) - x(t) + \beta - f(x(t))e) - (\hat{T}(y(t)) - y(t)) \\ &= (-r(t) + \beta - f(y(t)))e. \end{aligned}$$ □

THEOREM 3.4. *Q^* is the globally asymptotically stable equilibrium point for* (3.4).

Proof. By the variation of constants formula, in the foregoing,

$$r(t) = \int_0^t e^{-(t-s)}(\beta - f(y(s)))ds. \tag{3.6}$$

Let $y(t) \to y^* \in G$. Then $r(t) \to \beta - f(y^*)$ so that $x(t) \to y^* + (\beta - f(y^*))e$, which must coincide with Q^*, since that is the only equilibrium point for (3.4). To claim asymptotic stability, we also need to prove Liapunov stability. (That is, we need to show that given any $\epsilon > 0$, we can find a $\delta > 0$ such that $\|x(0) - Q^*\|_\infty < \delta$ implies $\|x(t) - Q^*\|_\infty < \epsilon$ for $t \geq 0$.) Now

$$\begin{aligned} ||x(t) - Q^*||_\infty &\leq ||y(t) - Q^*||_\infty + |r(t)| \\ &\leq ||y(0) - Q^*||_\infty + \int_0^t e^{-(t-s)}|\beta - f(y(s))|ds \\ &\leq ||x(0) - Q^*||_\infty + \int_0^t e^{-(t-s)}|f(Q^*) - f(y(s))|ds. \end{aligned} \tag{3.7}$$

Since $f(\cdot)$ is Lipschitz,

$$\begin{aligned} |f(Q^*) - f(y(s))| &\leq L||y(s) - Q^*||_\infty \\ &\leq L||y(0) - Q^*||_\infty \\ &= L||x(0) - Q^*||_\infty \end{aligned} \tag{3.8}$$

for a suitable $L > 0$. Thus

$$||x(t) - Q^*||_\infty \leq (1 + L)||x(0) - Q^*||_\infty.$$

Liapunov stability follows, completing the proof. □

3.2. Boundedness and convergence. The ODE method described variously in [2], [13], [18], [19], etc. immediately yields the following.

THEOREM 3.5. *In both the synchronous and the asynchronous Q-learning iterations (cf.* (2.5), (2.7)*), if $\{Q^n\}$ remain bounded a.s., then $Q^n \to Q^*$ a.s.*

Proof. The synchronous case follows from the standard ODE approach in view of Theorem 3.4. The asynchronous case follows likewise from the results of [10]. (In either case, given our prior assumptions, the only things left to verify are the a.s. boundedness of the iterates, which we simply *assumed* for the time being, and the global asymptotic stability of the associated ODE, which we just proved in the previous subsection.) □

The problem of proving a.s. boundedness remains. We shall indicate two proof approaches. The first, which works only for the synchronous case, is based on Lemma 2.2 of [1] (see Appendix). Note that by Theorem 3.4 and the converse Liapunov theorem [29], there exists a C^1 Liapunov function $V : R^{d\times r} \to R^+$ with $\lim_{||x||\to\infty} V(x) = \infty$ and

$$\langle \nabla V(x), T'(x) - x\rangle < 0, \quad x \neq Q^*.$$

Let B be an open neighborhood of Q^*, and let $C = \{x : V(x) \leq c\}$, where $c > 0$ is chosen sufficiently large so as to ensure that $B \subset$ interior (C). Note that C is compact. Define $\pi : R^{d\times r} \to C$ by

$$\pi(x) = x \qquad \text{if} \quad x \in C,$$

$$= Q^* + \eta(x)(x - Q^*) \quad \text{if} \quad x \notin C,$$

where $\eta(x) = \max\{a > 0 : Q^* + a(x - Q^*) \in B\}$. Consider the "scaled" version of (2.5) given by

$$\begin{aligned} \overline{Q}^{n+1}(i,a) = \tilde{Q}^n(i,a) + \gamma(n) \Big(& g(i,a,\xi^n_{ia}) + \min_u \tilde{Q}^n(\xi^n_{ia},u) \\ & -f(\tilde{Q}^n) - \tilde{Q}^n(i,a) \Big), \qquad i \in S, \quad a \in A, \end{aligned} \tag{3.9}$$

where $\tilde{Q}^n = \pi(\overline{Q}^n)$. The iterates (3.9) remain bounded a.s. by construction. To use Lemma 2.2 of [1], we need the following:

(i) The maps $x \to (1-\gamma(n))x + \gamma(n)T'(x)$ are nonexpansive with respect to $||\cdot||_s$ (where without any loss of generality we take $\gamma(n) < 1$). Note that they are so if $T'(\cdot)$ is, which it indeed is, as already observed.

(ii) The iterates $\{\overline{Q}^n\}$ converge to Q^* a.s., which, in view of Theorem 3.4, is proved exactly as in [1, section 3].

We shall also need the following additional assumption on $f(\cdot)$.

ASSUMPTION 3.6. $|f(Q)| \leq ||Q||_\infty$ for all $Q \in R^{d\times r}$.

Note that this is satisfied by the examples of $f(\cdot)$ that follow Assumption 2.2.

LEMMA 3.7. *Under the additional Assumption* 3.6, $\{Q^n\}$ *given by the synchronous Q-learning iteration* 2.5 *is bounded a.s.*

Proof. In view of above remarks and Lemma 2.2 of [1], $||\overline{Q}^n - Q^n||_s$ remains bounded a.s. Note that

$$\sup_n ||Q^n||_s \leq \sup_n ||\overline{Q}^n||_s + \sup_n ||Q^n - \overline{Q}^n||_s \triangleq K < \infty.$$

Let $D = \max(||Q^0||, \max_{i,a,j} |g(i,a,j)| + K)$. Then by Assumptions 2.2 and 3.6,

$$\begin{aligned} \left|\min_u Q^n(\xi^n_{ia},u) - f(Q^n)\right| &= \left|f\left(Q^n - \left(\min_u Q^n(\xi^n_{ia},u)\right)e\right)\right| \\ &\leq \left|\left|Q^n - \left(\min_u Q^n(\xi^n_{ia},u)\right)e\right|\right|_\infty \\ &\leq ||Q^n||_s \leq K. \end{aligned}$$

Then

$$\begin{aligned} |Q^{n+1}(i,a)| &\leq (1-\gamma(n))||Q^n||_\infty + \gamma(n)\left(\max_{i,a,j} g(i,a,j) + K\right) \\ &\leq (1-\gamma(n))||Q^n||_\infty + \gamma(n)D. \end{aligned}$$

A simple induction shows that $||Q^n||_\infty \leq D$ for all n. ∎

The boundedness argument above does not work for the asynchronous iteration (2.7). The reason is as follows: The term $f(Q^n)e$ (resp., $f(\overline{Q}^n)e$) being subtracted from the r.h.s. of (2.5) (resp., (3.7)) implies that exactly the same "offset" is being subtracted from all the components. These terms, being scalar multiples of e, contribute nothing to the span seminorm, a fact that is crucial in the analysis of [1] used above. In the asynchronous case, there is no way of achieving this without artificial restrictions.

The second technique is that of [13], which applies to both synchronous and asynchronous cases. We need the following assumption.

ASSUMPTION 3.6′. $f(cQ) = cf(Q)$ for all $c \in R, Q \in R^{d\times r}$.

Once again, this is satisfied by all the examples of $f(\cdot)$ given in the preceding section. Define $T_0 : R^{d\times r} \to R^{d\times r}$ by

$$(T_0(x))_{ia} = \sum_j p(i,a,j) \min_b x_{jb}, \quad x = [[x_{ia}]] \in R^{d\times r}.$$

The technique of [13] requires that we look at

$$\begin{aligned} h(x) &\stackrel{\Delta}{=} \lim_{c\to\infty} (T'(cx) - cx)/c \\ &= T_0(x) - x - f(x)e \end{aligned}$$

(in view of Assumption 3.6′) and requires that the origin be the globally asymptotically stable equilibrium point of the ODE $\dot{x}(t) = h(x(t))$. But this is merely a special case of Theorem 3.4, corresponding to $g(\cdot,\cdot,\cdot)$ being identically zero. Thus Theorem 2.2 of [13] applies, implying that $\{Q^n\}$ remains bounded a.s. for both the synchronous iteration (2.5), and its asynchronous version (2.7). (For the latter, see section 4 of [13].) We state this conclusion as a lemma.

LEMMA 3.8. *Under the additional Assumption* 3.6′, $\{Q^n\}$ *given by the synchronous Q-learning iteration* (2.5) *and its asynchronous version* (2.7) *is bounded a.s.*

4. Convergence of SSP Q-learning.

4.1. ODE analysis. Redefine T, T', f as follows. $T : R^{d\times r} \to R^{d\times r}, T' : R^{d\times r\times 1} \to R^{d\times r}, f : R^{d\times r} \to R$ are given by

$$\begin{aligned} (TQ)(i,a) &= \sum_{j=1}^{d} p(i,a,j) \left(g(i,a,j) + \sum_{j\neq s} p(i,a,j) \min_u Q(j,u) \right), \\ (T'(Q,\lambda))(i,a) &= (TQ)(i,a) - \lambda, \\ f(Q) &= \min_u Q(s,u). \end{aligned}$$

Then the synchronous iteration (2.8a)–(2.8b′) can be rewritten as

$$Q^{n+1} = Q^n + \gamma(n)[T'(Q^n,\lambda^n) - Q^n + M^{n+1}], \tag{4.1}$$

$$\lambda^{n+1} = \Gamma(\lambda^n + b(n) f(Q^n)), \tag{4.2}$$

where $M^{n+1} = [M^{n+1}(i,a)]$ with

$$\begin{aligned} M^{n+1}(i,a) = &\left[g(i,a,\xi_{ia}^n) + \min_u Q^n(\xi_{ia}^n, u) \right] I\{\xi_{ia}^n \neq s\} \\ &- \lambda^n - T'(Q^n,\lambda^n). \end{aligned}$$

In this new setup one verifies (3.2), (3.3) as before. Note that (4.2) can be rewritten as

$$\lambda^{n+1} = \lambda^n + e(n),$$

where $e(n) = O(b(n)) = o(\gamma(n))$. Thus the limiting ODE associated with (4.1)–(4.2) is

$$\dot{Q}(t) = T'(Q(t),\lambda(t)) - Q(t),$$

$$\dot{\lambda}(t) = 0.$$

Thus it suffices to consider

$$\dot{Q}(t) = T'(Q(t), \lambda) - Q(t) \tag{4.3}$$

for a fixed λ. As observed in [25], the map $T(\cdot)$, and therefore the map $T'(\cdot, \lambda)$ for fixed λ, is a contraction on $R^{d\times r}$ with respect to a certain weighted max-norm

$$||x||_w \stackrel{\Delta}{=} \max |w_i x_i|, \quad x \in R^{d\times r},$$

for an appropriate weight vector $w = [w_1, \ldots, w_{rd}], w_i > 0$ for all i. In particular, $T'(\cdot, \lambda)$ has a unique fixed point $Q(\lambda)$. A straightforward adaptation of the arguments of [14] then shows the following.

LEMMA 4.1. *$Q(\lambda)$ is the globally asymptotically stable equilibrium for* (4.1). *In fact, $||Q(t) - Q(\lambda)||_w$ decreases monotonically to zero.*

4.2. Boundedness and convergence. Once again we present two alternative schemes for proving the a.s. boundedness of $\{Q^n\}$. (Note that $\{\lambda^n\}$ are bounded anyway, as they are constrained to remain in $[-K, K]$.) The first approach is based on [25].

LEMMA 4.2. *For both synchronous and asynchronous SSP Q-learning algorithms, $\{Q^n\}$ remain bounded a.s.*

Proof. Since $T(\cdot)$ is a contraction with respect to $||\cdot||_w$, we have

$$||T(Q)||_w \leq \alpha||Q||_w + D$$

for some $\alpha \in (0, 1), D > 0$. Thus

$$||T'(Q, \lambda)||_w \leq \alpha||Q||_w + D'$$

with $D' = D + K$. Since the r.h.s. does not involve λ, one can mimick the arguments of [25] to conclude. □

An alternative proof of Lemma 4.2 is to directly quote the results of [13]. For this, consider $T^0 : R^{d\times r} \to R^{d\times r}$ defined by

$$(T^0 Q)(i, a) = \sum_{j\neq s} p(i, a, j) \min_u Q(j, u).$$

Then

$$\lim_{a\to\infty} \frac{T'(cQ, \lambda)}{c} = T^0(Q),$$

and the ODE

$$\dot{Q}(t) = T^0(Q) - Q$$

has the origin as the globally asymptotically stable equilibrium. (This is just a special case of Lemma 4.1 with $g(\cdot) \equiv 0$.) Thus the results of [13] apply, allowing us to conclude Lemma 4.2.

Given the a.s. boundedness of iterates, one proves a.s. convergence for the synchronous case as follows.

LEMMA 4.3. *$||Q^n - Q(\lambda^n)|| \to 0$ a.s.*

Proof. Note that $Q(\lambda)$ is simply the Q-factor associated with the SSP problem described in section 2.3 with the prescribed λ, that is,

$$(Q(\lambda))(i,a) = \sum_{j=1}^{d} p(i,a,j)\left(g(i,a,j) + \sum_{j\neq s} p(i,a,j)V_\lambda(j) - \lambda\right), \qquad i \in S, \qquad a \in A.$$

Since the map $\lambda \to V_\lambda$ is concave, it is continuous, and therefore so is the map $\lambda \to Q(\lambda)$. In view of Lemmas 4.1 and 4.2, the claim now follows as in Corollary 2.1 of [8]. □

We shall also need the following lemma.

LEMMA 4.4.

$$\Pi_{i=0}^{n}(1-b(i)) \to 0, \quad \limsup_{n\to\infty} \sum_{i=0}^{n} \Pi_{j=i+1}^{n}(1-b(j))b(i) < \infty,$$

and for any sequence $\{a_n\}$ *with* $a_n \to 0$,

$$\sum_{i=0}^{n}\left(\prod_{j=i+1}^{n}(1-b(j))\right)b(i)a_i \to 0.$$

Proof. Since $\sum_i b(i) = \infty$ and $1 - x \le e^{-x}$ for all x,

$$\prod_{i=0}^{n}(1-b(i)) \le e^{-\sum_{i=0}^{n} b(i)} \to 0$$

as $n \to \infty$. Let $t(0) = 0, t(n) = \sum_{i=0}^{n-1} b(i), n \ge 1$. Then

$$\begin{aligned}\sum_{i=0}^{n}\prod_{j=i+1}^{n}(1-b(j))b(i) &\le \sum_{i=0}^{n} b(i)\exp\left(-\sum_{j=i+1}^{n} b(j)\right)\\ &= \sum_{i=0}^{n} e^{-(t(n+1)-t(i))}(t(i+1)-t(i))\\ &\le \int_0^{t(n+1)} e^{-(t(n+1)-s)}ds \to 1\end{aligned}$$

as $n \to \infty$. Define $h(t), t \ge 0$, by $h(t) = a_n$ for $t \in [t(n), t(n+1)), n \ge 0$. Then a similar argument shows that

$$\sum_{i=0}^{n}\prod_{j=i+1}^{n}(1-b(j))b(i)a_i \le \int_0^{t(n+1)} e^{-(t(n+1)-s)}h(s)ds.$$

Since $h(t) \to 0$ as $t \to \infty$, the r.h.s. $\to 0$ as $n \to \infty$. □

THEOREM 4.5. *For the synchronous SSP Q-learning algorithm* (2.8a)–(2.8b′), $(Q^n, \lambda^n) \to (Q^*, \beta)$ *a.s.*

Proof. Define $\Delta^n = \lambda^n - \beta, r_n = f(Q^n) - f(Q(\lambda^n)), n \ge 0$. By Lemma 4.3, $r_n \to 0$. Also,

$$\begin{aligned}\Delta^{n+1} &= \Gamma(\Delta^n + \beta + b(n)f(Q^n)) - \beta \\ &= \Gamma(\Delta^n + \beta + b(n)f(Q(\lambda^n)) + b(n)r_n) - \beta. \end{aligned} \tag{4.4}$$

Since the map $\lambda \to V_\lambda$, and therefore also the map $\lambda \to f(Q(\lambda)) = \min_u(Q(\lambda))(s,u)$, is concave and piecewise linear with finitely many linear pieces, it follows that there exist $0 < L_1 \le L_2$ such that

$$-L_2(\lambda_1 - \lambda_2) \le f(Q(\lambda_1)) - f(Q(\lambda_2)) \le -L_1(\lambda_1 - \lambda_2)$$

for all $\lambda_1, \lambda_2 \in R$. (Basically, these are upper and lower bounds on the slope of the map $\lambda \to f(Q(\lambda))$.) With $\lambda_1 = \lambda^n, \lambda_2 = \beta$, and using the fact that $f(Q(\beta)) = f(Q^*) = 0$, this reduces to

$$-L_2\Delta^n \le f(Q(\lambda^n)) \le -L_1\Delta^n.$$

Using this, (4.4), and the fact that $\Gamma(\cdot)$ is nondecreasing, we have

$$\begin{aligned}&\Gamma((1 - L_2 b(n))\Delta^n + b(n)r_n + \beta) - \beta \le \Delta^{n+1} \\ &\quad \le \Gamma((1 - L_1 b(n))\Delta^n + b(n)r_n + \beta) - \beta.\end{aligned}$$

Note that for $i = 1, 2$,

$$\begin{aligned}(1 - L_i b(n))\Delta^n + b(n)r_n + \beta &= \lambda^n + b(n)(r_n - L_i\Delta^n) \\ &= \lambda^n + O(b(n)).\end{aligned}$$

Since $\lambda^n \in [-K, K]$ for all n and $b(n) \to 0$, it follows from the definition of $\Gamma(\cdot)$ that for any $\epsilon > 0$, there is an $N \ge 1$ sufficiently large so that for $n \ge N$,

$$\begin{aligned}&(1 - L_2 b(n))\Delta^n + (b(n)r_n - \epsilon) + \beta \\ &\quad \le \Gamma((1 - L_2 b(n))\Delta^n + b(n)r_n + \beta) \\ &\quad \le \Gamma((1 - L_1 b(n))\Delta^n + b(n)r_n + \beta) \\ &\quad \le (1 - L_i b(n))\Delta^n + (b(n)r_n + \epsilon) + \beta.\end{aligned}$$

Therefore,

$$(1 - L_2 b(n))\Delta^n + b(n)r_n - \epsilon \le \Delta^{n+1} \le (1 - L_1 b(n))\Delta^n + b(n)r_n + \epsilon.$$

Iterating the inequalities, we have for $n > N$

$$\begin{aligned}&\prod_{i=N}^{n+1}(1 - L_2 b(i))\Delta^N + \sum_{i=N}^{n}\prod_{j=i+1}^{n}(1 - L_2 b(j))(b(i)r_i - \epsilon) \le \Delta^{n+1} \\ &\qquad \le \prod_{i=N}^{n+1}(1 - L_1 b(i))\Delta^N + \sum_{i=N}^{n}\prod_{j=i+1}^{n}(1 - L_1 b(j))b(i)(r_i - \epsilon).\end{aligned}$$

Letting $n \to \infty$ and using Lemma 4.4, we have $\Delta^n \to [-C\epsilon, C\epsilon]$ for a suitable constant $C > 0$. Since $\epsilon > 0$ was arbitrary, $\Delta^n \to 0$, i.e., $\lambda^n \to \beta$. Since $\lambda \to Q(\lambda)$ is continuous, $Q(\lambda^n) \to Q(\beta) = Q^*$, and, by Lemma 4.3, $Q^n \to Q^*$. ∎

Remark. If we consider instead the SSP Q-learning algorithm (2.8a)–(2.8b) that does not use the projection $\Gamma(\cdot)$, it is possible to argue as above to conclude that *if* the iterates $\{\lambda^n\}$ remain bounded a.s., then Theorem 4.5 holds.

Finally, we have the following theorem.

THEOREM 4.6. *For the asynchronous SSP Q-learning algorithm* (2.9a)–(2.9b), $(Q^n, \lambda^n) \to (Q^*, \lambda^*)$ *a.s.*

Proof. The analysis of [10], [17] applies, implying, in particular, that Lemma 4.3 holds exactly as before. The only difference is that now the interpolated algorithm would track a time-scaled version of (4.1). The rest is as before because the iteration scheme for $\{\lambda^n\}$ is unchanged. ∎

5. Conclusions. We have presented two Q-learning algorithms for average cost control of finite Markov chains—one based on RVI and another on an SSP formulation of the average cost problem. We have rigorously established their stability and convergence to the desired limits with probability one. As already remarked in the introduction, this is the first rigorous analysis of any Q-learning algorithms for average cost problems. Nevertheless, this is only a first step toward a better understanding of these algorithms. In conclusion, we mention three important directions for future work in this area:

(i) Typically, the state space can be very large. This calls for approximations, such as state aggregation or considering a parametrized family of candidate Q-factor functions with a low dimensional parameter space. (See, e.g., [7], [26].) The algorithms presented need to be interlaced with such approximation architectures and analyzed as such. A popular architecture is a linear combination of suitable basis functions, the weights in question being the parameters that are tuned [7], [26]. A good choice of basis functions is crucial, and it has been suggested that they be based upon sample simulation runs [6]. Yet another technique for reducing computation is to update not at every sample but at an appropriately chosen subsequence of samples. This can be combined with "kernel" methods, where one updates in a neighborhood of the sample in a weighted fashion. While there is an enormous amount of empirical work on such ideas in recent years, the theory has been lacking. Finally, it is worthwhile exploring the use of acceleration techniques in traditional Monte Carlo methods (such as importance sampling) to reinforcement learning.

(ii) Simulation-based algorithms are slow. An analysis of rate of convergence and good speed-up procedures are needed. To some extent, the rate of convergence statements for general stochastic approximation algorithms, based on associated limit theorems or asymptotics for moments, will also bear upon these algorithms. However, they have enough special structure that one should be able to say more. A recent work [12] takes a step in this direction by estimating the number of steps required by Q-learning for discounted cost problems to attain a prescribed level of accuracy with a prescribed probability.

(iii) Extension to the case where the state space is not finite is an open issue. See, however, [11] for the discounted cost problem.

Appendix. We briefly recall the key results from the literature that have been used here in a crucial manner. To begin with, let $F(\cdot,\cdot) = [F_1(\cdot,\cdot),\ldots,F_d(\cdot,\cdot)]^T : R^d \times R^m \to R^d$ be Lipschitz in the first argument uniformly with respect to the second, i.e., for some scalar K, we have

$$\|F(x,y) - F(y,u)\| \le K\|x-y\| \qquad \forall\ x,y,u.$$

Consider the stochastic approximation algorithm of the form

$$x^{k=1} = x^k + \gamma(k)F(x^k,\xi^k), \qquad k \ge 0,$$

for $x^k = [x_1^k,\ldots,x_d^k]$, with $\{\xi^k\}$ i.i.d., R^n-valued random variables. Let $h(x) = E[F(x,\xi)]$. The ODE approach views the above recursion as

$$x^{k=1} = x^k + \gamma(k)[h(x^k) + M^{k+1}]$$

with

$$M^{k+1} = F(x^k,\xi^k) - h(x^k), \qquad k \ge 0,$$

a "martingale difference" sequence. The term in square brackets is viewed as a noisy measurement of $h(x^k)$ with M^{k+1} as the "noise." The iteration can then be viewed as a noisy discretization of the ODE $\dot{x}(t) = h(x(t))$ with diminishing time steps. We assume that this ODE has a globally asymptotically stable equilibrium x^*. If $\{x^k\}$ remains bounded and the martingale $\sum \gamma(k) M^{k+1}$ converges with probability one, both the discretization error and the error due to noise in the above "approximation" of the ODE become asymptotically negligible, and therefore the iterates track the ODE. In particular, $x^k \to x^*$ a.s.

The asynchronous version of this algorithm is

$$x_i^{k+1} = x_i^k + \nu(k,i) I(i \in Y^k) F_i(x_1^{k-\tau_{1i}}(k), \ldots, x_d^{k-\tau_{di}}(k), \xi^k), \qquad 1 \le i \le d,$$

for $k \ge 0$, where (1) $\{Y^k\}$ is a set-valued random process taking values in the subsets of $\{1, \ldots, d\}$, representing the components that do get updated at time k, (2) $\{\tau_{ij}(k)\}$, $1 \le i, j \le d$, $k \ge 0\}$, are bounded random delays, and (3) $\nu(k,i) = \sum_{m=0}^{k} I(i \in Y^m)$ denotes the number of times component i gets updated up to time k. Under the kind of assumptions on $\{\gamma(k)\}$ and $\{\nu(k,i)\}$ we have used here, Borkar [10] shows that the asynchronous iterations track the ODE $\dot{x}(t) = \frac{1}{d} h(x(t))$, which is a time-scaled version of $\dot{x}(t) = h(x(t))$ and has the same trajectories.

The two-time-scale stochastic approximation algorithm of Borkar [8] considers the following iteration:

$$x^{k+1} = x^k + \gamma(k) F(x^k, y^k, \xi^k),$$

$$y^{k=1} = y^k + \beta(k) G(x^k, y^k, \zeta^k),$$

where $\{\xi^k\}$, $\{\zeta^k\}$ are i.i.d., and $\{\beta(k)\}$ satisfy

$$\sum_{k=0}^{\infty} \beta(k) = \infty, \qquad \sum_{k=0}^{\infty} \beta(k)^2 < \infty, \qquad \beta(k) = o(\gamma(k)).$$

Thus $\{y^k\}$ (resp., $\{x^k\}$) is the slow (resp., fast) component of the iteration. One can analyze $\{x^k\}$ viewing $\{y^k\}$ as quasi-static, and then analyze $\{y^k\}$, viewing $\{x^k\}$ as essentially equilibrated. In other words, consider the ODE $\dot{x}(t) = h(x(t), \overline{y})$, where $h(x,y) = E[F(x,y,\xi)]$ and $\overline{y}$ is treated as a fixed parameter. Suppose it has a globally asymptotically stable equilibrium $\lambda(\overline{y})$, where $\lambda(\cdot)$ is a Lipschitz function. Then $\{x^k\}$ tracks $\{\lambda(y^k)\}$. In turn, $\{y^k\}$ tracks the ODE $\dot{y}(t) = g(\lambda(y(t)), y(t))$, where $g(x,y) = E[G(x,y,\zeta)]$. If the latter ODE has a globally asymptotically stable equilibrium y^*, one can show that $(x^k, y^k) \to (\lambda(y^*), y^*)$ a.s.

In dynamic programming applications, an important special class of ODEs arises, wherein $h(x) = f(x) - x$ for an $f : R^d \to R^d$ satisfying the "nonexpansivity property"

$$\|f(x) - f(y)\|_\infty \le \|x - y\|_\infty.$$

The set $B = \{x : f(x) = x\}$ of fixed points of $f(\cdot)$, assumed to be nonempty, is precisely the set of equilibria for the ODE $\dot{x}(t) = f(x(t)) - x(t)$. It is shown in Borkar and Soumyanath [14] that $x(\cdot)$ converges to a point in B and, furthermore, for any $x^* \in B$, $\|x(t) - x^*\|_\infty$ is nonincreasing in t.

Finally, we recall Lemma 2.2 of [1], which has been used here. Let $D \subset R^d$ be an open bounded set, and let $C \subset R^d$ be a set containing D. Define $\Pi_{D,C} : R^d \to \overline{D}$ by

$$\prod_{D,C}(x) = \alpha_{D,C}(x) \cdot x,$$

where

$$\alpha_{D,C}(x) = \begin{cases} 1 & \text{if } x \in C, \\ \max\{\beta > 0 \,:\, \beta x \in \overline{D}\} & \text{if } x \notin C. \end{cases}$$

Let $\|x\|_s = \max_i x_i - \min_i x_i$ define the span seminorm on R^d. Consider an iteration

$$x^{k+1} = G^k(x^k, \xi^k),$$

where $\{\xi^k\}$ is a random process and $\{G^k\}$ satisfy

$$\|G^k(x,\xi) - G^k(y,\xi)\|_s \le \|x - y\|_s \qquad \forall\, x, y, \xi.$$

Suppose the sequence $\{\tilde{x}^k\}$ generated by the "scaled" iteration

$$\tilde{x}^{k+1} = G^k\left(\prod_{D,C}(\tilde{x}^k), \xi^k\right)$$

converges a.s. Lemma 2.1 of [1] then says that $\{\|x^k\|_s\}$ remains bounded with probability one.

SENSITIVITY ANALYSIS OF THE VALUE FUNCTION FOR OPTIMIZATION PROBLEMS WITH VARIATIONAL INEQUALITY CONSTRAINTS*

YVES LUCET† AND JANE J. YE‡

Abstract. In this paper we perform sensitivity analysis for optimization problems with variational inequality constraints (OPVICs). We provide upper estimates for the limiting subdifferential (singular limiting subdifferential) of the value function in terms of the set of normal (abnormal) coderivative (CD) multipliers for OPVICs. For the case of optimization problems with complementarity constraints (OPCCs), we provide upper estimates for the limiting subdifferentials in terms of various multipliers. An example shows that the other multipliers may not provide useful information on the subdifferentials of the value function, while the CD multipliers may provide tighter bounds. Applications to sensitivity analysis of bilevel programming problems are also given.

Key words. sensitivity analysis, optimization problems, variational inequality constraints, complementarity constraints, limiting subdifferentials, value functions, bilevel programming problems

1. Introduction.

In this paper, we consider the sensitivity analysis for the following optimization problem with variational inequality constraints (OPVIC):

$$\begin{aligned} \text{(OPVIC)} \qquad & \text{minimize} && f(x,y) \\ & \text{subject to} && \Psi(x,y) \le 0, H(x,y) = 0, (x,y) \in C, \\ & && y \in \Omega, \langle F(x,y), y - z\rangle \le 0 \quad \forall z \in \Omega, \end{aligned} \tag{1}$$

where the following basic assumptions are satisfied:

(BA) The functions $f : R^{n+m} \to R$, $\Psi : R^{n+m} \to R^d$, $H : R^{n+m} \to R^l$, and $F : R^{n+m} \to R^m$ are Lipschitz near any given point of C; C is a closed subset of R^{n+m}, and Ω is a closed convex subset of R^m. Note that the OPVIC is also called the mathematical program with equilibrium constraints (MPEC).

By definition of a normal cone in the sense of convex analysis, the variational inequality (1) is equivalent to saying that $y \in \Omega$ and the vector $-F(x,y)$ is in the normal cone of the convex set Ω at y. Hence the OPVIC can be rewritten as an optimization problem with a generalized equation constraint:

$$\begin{aligned} \text{(GP)} \qquad & \text{minimize } f(x,y) \\ & \text{subject to } \Psi(x,y) \le 0, H(x,y) = 0, (x,y) \in C, \\ & 0 \in F(x,y) + N_\Omega(y), \end{aligned} \tag{2}$$

where

$$N_\Omega(y) := \begin{cases} \text{the normal cone of } \Omega \text{ if } y \in \Omega, \\ \emptyset \text{ otherwise} \end{cases}$$

‡Department of Mathematics and Statistics, University of Victoria, Victoria, BC, Canada V8W 3P4 (janeye@Math.UVic.CA).

is the normal cone operator.

Let $(\bar{x}, \bar{y})$ be an optimal solution of the OPVIC. If $N_\Omega(y)$ is single-valued and smooth, then the generalized equation constraint (2) would reduce to an ordinary equation $0 = F(x, y) + N_\Omega(y)$. Moreover, if all problem data are smooth and there is no abstract constraint, then the Fritz John necessary optimality condition can be stated as follows. There exist scalar $\lambda \geq 0$ and the vectors (γ, β, η) not all zero such that

$$\begin{cases} 0 = \lambda \nabla f(\bar{x}, \bar{y}) + \nabla \Psi(\bar{x}, \bar{y})^\top \gamma + \nabla H(\bar{x}, \bar{y})^\top \beta + \nabla F(\bar{x}, \bar{y})^\top \eta + \{0\} \times \nabla N_\Omega(\bar{y})^\top \eta, \\ \gamma \geq 0, \text{ and } \langle \Psi(\bar{x}, \bar{y}), \gamma \rangle = 0, \end{cases}$$

where ∇ denotes the usual gradient and $A^\top$ denotes the transpose of a matrix A. In general, however, the map $y \rightrightarrows N_\Omega(y)$ is a set-valued map. Naturally, the usual gradient $\nabla N_\Omega(\bar{y})$ has to be replaced by some kinds of derivatives of set-valued maps.

The Kuhn–Tucker-type necessary conditions with the transpose of the usual gradient ∇N_Ω replaced by the Mordukhovich coderivative $D^* N_\Omega$ were first derived in Ye and Ye [24] under the so-called pseudo-upper-Lipschitz condition for the case of no inequality, no equality constraints, and an abstract constraint in x only. They were further studied under the strong regularity condition in the sense of Robinson and the generalized Mangasarian–Fromovitz constraint qualifications by Outrata in [14] in the case of complementarity constraints and constraints in x only. The first order theory including the necessary optimality conditions involving the Mordukhovich coderivative, various constraint qualifications and their relationships for the general setting of this paper was given in Ye [23]. (Although the equality constraint $H(x, y) = 0$ was not considered explicitly there, the general results under the presence of an equality constraint still hold without any difficulty.) In Ye [22] the Kuhn–Tucker-type necessary conditions with the proximal coderivative for the case of optimization problems with complementarity constraints (OPCCs) were also studied . For recent developments and references on other optimality conditions and computational algorithms, the reader is referred to recent monographs of Luo, Pang, and Ralph [8] and Outrata, Kočvara, and Zowe [15].

In this paper we continue the study by considering the value function $V(p, q, r)$ associated with the right-hand side perturbations

$$\begin{array}{lll} \mathrm{GP}(p,q,r) & \text{minimize} & f(x,y) \\ & \text{subject to} & \Psi(x,y) \leq p, H(x,y) = q, (x,y) \in C, \\ & & r \in F(x,y) + N_\Omega(y), \end{array} \tag{3}$$

i.e.,

$$\begin{aligned} V(p,q,r) := \inf\{ f(x,y) : \quad & \Psi(x,y) \leq p, H(x,y) = q, (x,y) \in C \\ & r \in F(x,y) + N_\Omega(y)\}, \end{aligned}$$

where by convention $\inf \emptyset := +\infty$.

Our main result shows that as in sensitivity analysis for ordinary nonlinear programming (NLP) problems, under certain growth hypotheses, the value function V is lower semicontinuous near 0, and the limiting subdifferentials of the value functions are contained in the negative of the multiplier sets, i.e.,

$$\partial V(0) \subseteq -M^1(\Sigma), \tag{4}$$

$$\partial^\infty V(0) \subseteq -M^0(\Sigma), \tag{5}$$

where Σ is the set of solutions of GP and $M^\lambda(\Sigma)$ is the set of index λ CD multipliers for problem GP, which is the set of vectors (γ, β, η) satisfying the Fritz John necessary condition stated above with the transpose of the usual gradient ∇N_Ω replaced by the Mordukhovich coderivative $D^* N_\Omega$ in the case of smooth problem data and no abstract constraints.

In the case of $M^0(\Sigma) = \{0\}$, (5) implies that the singular limiting subgradient $\partial^\infty V(0)$ contains only the zero vector, and hence the value function is Lipschitz continuous near 0. Moreover, if the optimal solution is unique, if the set of abnormal multipliers $M^0(\Sigma)$ contains only the zero vector, and if the set of Kuhn–Tucker multipliers $M^1(\Sigma)$ is a singleton ζ, then inclusion (4) implies that the value function is smooth and $\nabla V(0) = -\zeta$.

In the case where $\Omega = R^m_+, C = R^{n+m}$, OPVIC reduces to the following OPCC.

$$\begin{array}{lll} \text{(OPCC)} & \text{minimize} & f(x,y), \\ & \text{subject to} & \Psi(x,y) \le 0, H(x,y) = 0, \\ & & y \ge 0,\ F(x,y) \ge 0, \langle y, F(x,y)\rangle = 0. \end{array}$$

In this case (when all functions involved are smooth), an index λ CD multiplier set corresponding to a feasible solution $(\bar{x}, \bar{y})$ denoted by $M^\lambda_{CD}(\bar{x}, \bar{y})$ consists of $(\gamma, \beta, \eta) \in R^d \times R^l \times R^m$ such that

$$0 = \lambda \nabla f(\bar{x}, \bar{y}) + \nabla \Psi(\bar{x}, \bar{y})^\top \gamma + \nabla H(\bar{x}, \bar{y})^\top \beta + \nabla F(\bar{x}, \bar{y})^\top \eta + (0, \xi), \tag{6}$$

$$\gamma \ge 0 \text{ and } \langle \Psi(\bar{x}, \bar{y}), \gamma \rangle = 0, \tag{7}$$

$$\xi_i = 0 \qquad \text{if } \bar{y}_i > 0 \text{ and } F_i(\bar{x}, \bar{y}) = 0, \tag{8}$$

$$\eta_i = 0 \qquad \text{if } \bar{y}_i = 0 \text{ and } F_i(\bar{x}, \bar{y}) > 0, \tag{9}$$

and

$$\text{either } \xi_i < 0,\ \eta_i < 0, \text{or } \xi_i \eta_i = 0 \qquad \text{if } \bar{y}_i = 0 \text{ and } F_i(\bar{x}, \bar{y}) = 0.$$

We call vectors $(\gamma, \beta, \eta) \in R^d \times R^l \times R^m$ satisfying (6)–(9) and

$$\xi_i \eta_i \ge 0 \qquad \text{if } \bar{y}_i = 0 \text{ and } F_i(\bar{x}, \bar{y}) = 0$$

an index λ C-multiplier set and denote it by $M^\lambda_C(\bar{x}, \bar{y})$, and we call those satisfying (6)–(9) and

$$\xi_i \le 0, \eta_i \le 0 \qquad \text{if } \bar{y}_i = 0 \text{ and } F_i(\bar{x}, \bar{y}) = 0$$

an index λ S-multiplier set and denote it by $M^\lambda_S(\bar{x}, \bar{y})$.

Under certain growth hypotheses, we show that the value function

$$\begin{aligned} V(p,q,r) := \{ f(x,y) : & \Psi(x,y) \le p, H(x,y) = q, \\ & y \ge 0, F(x,y) - r \ge 0, \langle y, F(x,y) - r \rangle = 0 \} \end{aligned}$$

is lower semicontinuous near 0 and

$$\partial V(0) \subseteq -M^1 \quad \partial^\infty V(0) \subseteq -M^0,$$

where

$$\begin{aligned} M^1 &= M^1_{CD}(\Sigma), M^1_C(\Sigma), M^1_S(\Sigma), \text{ or } \{(\gamma, \beta, \mu\bar{y} - r^F) : (\gamma, \beta, r^F, r^y, \mu) \in M^1_{NLP}(\Sigma)\}, \\ M^0 &= M^0_{CD}(\Sigma), M^0_C(\Sigma), M^0_S(\Sigma), \text{ or } \{(\gamma, \beta, \mu\bar{y} - r^F) : (\gamma, \beta, r^F, r^y, \mu) \in M^0_{NLP}(\Sigma)\}, \end{aligned}$$

where $M^{\lambda}_{NLP}(\bar{x},\bar{y})$ is the set of index λ ordinary NLP multipliers when the OPCC is treated as an ordinary NLP problem.

Moreover, we show that the above multiplier sets can be ordered as follows:

$$\{(\gamma,\beta,\mu\bar{y}-r^F) : (\gamma,\beta,r^F,r^y,\mu)\in M^{\lambda}_{NLP}(\Sigma)\}\subseteq M^{\lambda}_{S}(\Sigma)\subseteq M^{\lambda}_{CD}(\Sigma)\subseteq M^{\lambda}_{C}(\Sigma).$$

It is obvious that one should use the smallest multiplier sets as possible. However, the smaller multiplier sets may be empty and hence may not provide any information on the properties of the value function. We show that under reasonable constraint qualifications such as the generalized Mangasarian–Fromovitz constraint qualification and the strongly regular constraint qualification, the abnormal CD multiplier set contains only the zero vector, and the set of normal CD multipliers is nonempty. An example is given to show that in sensitivity analysis the CD multipliers may provide more useful information than the other multipliers. In this example, the value function is Lipschitz, and the limiting subdifferentials of the value function coincide with the set of negative CD multipliers, while the limiting subdifferentials are contained strictly in the set of negative C multipliers and the set of P multipliers, NLP multipliers, and S multipliers are empty. Applications to the bilevel programming problem are also given.

In this paper we deal only with the sensitivity analysis of the optimal values. For the sensitivity analysis of the optimal solutions, the reader is referred to Scheel and Scholtes [19].

The following notations are used throughout the paper: B denotes the open unit ball; $B(\bar{z};\delta)$ denotes the open ball centered at $\bar{z}$ with radius $\delta>0$. For a set E, co$E$ denotes the convex hull of E, and int$E$ and cl$E$ denote the interior and the closure of E, respectively. The notation $\langle a,b\rangle$ denotes the inner products of vectors a and b. For a differentiable function f, $\nabla f(\bar{x})$ denotes the gradient of f at $\bar{x}$. For a vector $a\in R^n$, a_i denotes the ith component of a. For an m by n matrix A and index sets $I\subseteq\{1,2,\dots,m\}, J\subseteq\{1,2,\dots,n\}$, A_I and $A_{I,J}$ denote the submatrix of A with rows specified by I and the submatrix of A with rows and columns specified by I and J, respectively. $A^{\top}$ denotes the transpose of a matrix A. For a vector $d\in R^m$, d_I is the subvector composed from the components $d_i, i\in I$.

2. Preliminaries. The purpose of this section is to provide the background material on nonsmooth analysis which will be used later. We give only concise definitions and facts that will be needed in the paper. For more detailed information on the subject, our references are Clarke [3], Loewen [7], Rockafellar and Wets [18], and Mordukhovich [10, 12, 13].

First we give some definitions for various subdifferentials and normal cones.

DEFINITION 2.1. *Let $f: R^n\to R\cup\{+\infty\}$ be lower semicontinuous and finite at $\bar{x}\in R^n$. The proximal subdifferential of f at $\bar{x}$ is the set defined by*

$$\begin{aligned}\partial^{\pi} f(\bar{x}) = \{v\in R^n :&\exists M>0,\delta>0 \text{ s.t.}\\ &f(x)\ge f(\bar{x})+\langle v,x-\bar{x}\rangle + M\|x-\bar{x}\|^2 \ \ \forall x\in\bar{x}+\delta B\},\end{aligned}$$

the limiting subdifferential of f at $\bar{x}$ is the set defined by

$$\partial f(\bar{x}) := \left\{v\in R^n : v=\lim_{\nu\to\infty} v^{\nu} \text{ with } v^{\nu}\in\partial^{\pi} f(x^{\nu}) \text{ and } x^{\nu}\to\bar{x}\right\},$$

the singular limiting subdifferential of f at $\bar{x}$ is the set defined by

$$\partial^{\infty} f(\bar{x}) := \left\{v\in R^n : v=\lim_{\nu\to\infty} \lambda^{\nu}v^{\nu} \text{ with } v^{\nu}\in\partial^{\pi} f(x^{\nu}) \text{ and } \lambda^{\nu}\downarrow 0, x^{\nu}\to\bar{x}\right\}.$$

Let $f : R^n \to R$ be Lipschitz near $\bar{x} \in R^n$. The Clarke generalized gradient of f at $\bar{x}$ is the set

$$\partial_C f(\bar{x}) := clco\partial f(\bar{x}).$$

For set-valued maps, the definition for a limiting normal cone leads to the definition of the coderivative of a set-valued map introduced by Mordukhovich in [9].

DEFINITION 2.2. *For a closed set $C \subset R^n$ and $\bar{x} \in C$, the proximal normal cone to C at $\bar{x}$ is defined by*

$$N_C^\pi(\bar{x}) := \{v \in R^n : \exists M > 0 \text{ s.t. } \langle v, x - \bar{x}\rangle \le M\|x - \bar{x}\|^2 \quad \forall x \in C\},$$

and the limiting normal cone to C at $\bar{x}$ is defined by

$$N_C(\bar{x}) := \left\{ \lim_{\nu\to\infty} v^\nu : v^\nu \in N_C^\pi(x^\nu), x^\nu \to \bar{x} \right\}.$$

DEFINITION 2.3. *Let $\Phi : R^n \Rightarrow R^q$ be a set-valued map. Let $(\bar{x}, \bar{p}) \in clGph\Phi$, where $Gph\Phi := \{(x, p) \ : \ p \in \Phi(x)\}$ is the graph of the set-valued map Φ. The set-valued map $D^*\Phi(\bar{x}, \bar{p})$ from R^q into R^n, defined by*

$$D^*\Phi(\bar{x}, \bar{p})(\eta) := \{\xi \in R^n \ : \ (\xi, -\eta) \in N_{Gph\Phi}(\bar{x}, \bar{p})\},$$

is called the Mordukhovich coderivative of Φ at $(\bar{x}, \bar{p})$.

In general, we have the following inclusions, which may be strict:

$$\partial^\pi f(\bar{x}) \subseteq \partial f(\bar{x}) \subseteq \partial_C f(\bar{x}).$$

In the case where f is a convex function, all subdifferentials coincide with the subdifferentials in the sense of convex analysis, i.e.,

$$\partial^\pi f(\bar{x}) = \partial f(\bar{x}) = \partial_C f(\bar{x}) = \{\zeta : f(x) - f(\bar{x}) \ge \langle\, \zeta, x - \bar{x}\rangle \quad \forall x\}.$$

In the case where f is strictly differentiable (see the definition, e.g., in Clarke [2]), we have

$$\partial f(\bar{x}) = \partial_C f(\bar{x}) = \{\nabla f(\bar{x})\}.$$

The following facts about the subdifferentials are well known.

PROPOSITION 2.4.

(i) *A function $f : R^n \to R$ is Lipschitz near $\bar{x}$ and $\partial f(\bar{x}) = \{\zeta\}$ if and only if f is strictly differentiable at $\bar{x}$ and the gradient of f at $\bar{x}$ equals ζ.*

(ii) *A function $f : R^n \to R$ is Lipschitz near $\bar{x}$ if and only if $\partial^\infty f(\bar{x}) = \{0\}$.*

(iii) *If a function $f : R^n \to R$ is Lipschitz near $\bar{x}$ with positive constant L_f, then $\partial f(\bar{x}) \subseteq L_f clB$.*

The following calculus rules will be useful and can be found in the references given in the beginning of this section.

PROPOSITION 2.5 (see, e.g., [7, Proposition 5A.4]). *Let $f : R^n \to R$ be Lipschitz near $\bar{x}$, and let $g : R^n \to R \cup \{+\infty\}$ be lower semicontinuous and finite at $\bar{x}$. Then*

$$\partial(f + g)(\bar{x}) \subseteq \partial f(\bar{x}) + \partial g(\bar{x}),$$
$$\partial^\infty(f + g)(\bar{x}) \subseteq \partial^\infty g(\bar{x}).$$

PROPOSITION 2.6 (see, e.g., [7, Lemma 5A.3]). *Let $f : R^n \times R^m \to R \cup \{+\infty\}$ be lower semicontinuous and finite at $(\bar{x}, \bar{y})$. If $(\zeta, 0) \in \partial^\infty f(\bar{x}, \bar{y})$ implies that $\zeta = 0$, then*

$$\partial_y f(\bar{x}, \bar{y}) \subseteq \{\eta : (\zeta, \eta) \in \partial f(\bar{x}, \bar{y}) \quad \text{for some } \zeta\},$$
$$\partial_y^\infty f(\bar{x}, \bar{y}) \subseteq \{\eta : (\zeta, \eta) \in \partial^\infty f(\bar{x}, \bar{y}) \quad \text{for some } \zeta\}.$$

PROPOSITION 2.7 (see, e.g., [13, Theorem 7.6]). *Let the minimum function be*

$$(\wedge f_j)(x) := \min\{f_j(x) | j = 1, 2, \ldots, m\},$$

where $f_j : R^n \to R \cup \{+\infty\}$. Assume that f_j are lower semicontinuous around $\bar{x}$ for $j \in J(\bar{x})$ and lower semicontinuous at $\bar{x}$ for $j \notin J(\bar{x})$, where

$$J(x) := \{j | f_j(x) = \wedge f_j(x)\}.$$

Then the minimum function $\wedge f_j(x)$ is lower semicontinuous around $\bar{x}$ and

$$\partial(\wedge f_j)(\bar{x}) \subseteq \bigcup\{\partial f_j(\bar{x}) | j \in J(\bar{x})\},$$
$$\partial^\infty(\wedge f_j)(\bar{x}) \subseteq \bigcup\{\partial^\infty f_j(\bar{x}) | j \in J(\bar{x})\}.$$

Classical results on the value function can be found in [2, 4, 7, 11, 18], while the results we quote are from [7].

PROPOSITION 2.8 (see [7, (b) and (d) of Theorem 5A.2]). *Let $g : R^n \times R^m \to R \cup \{+\infty\}$ be lower semicontinuous everywhere and finite at $(\bar{z}, \bar{\alpha})$. Suppose g is bounded below on some set $E \times O$, where E is a compact neighborhood of $\bar{z}$ and O is an open set containing $\bar{\alpha}$. Define the value function $V : R^m \to R \cup \{+\infty\}$ and the set of minimizers Σ as follows:*

$$V(\alpha) := \inf\{g(z, \alpha) : z \in E\},$$
$$\Sigma(\alpha) := \{z \in E : g(z, \alpha) = V(\alpha)\}.$$

If $\Sigma(\bar{\alpha}) \subseteq \text{int}E$, then the value function V is lower semicontinuous on O, and the subdifferentials of V satisfy these estimates:

$$\partial V(\bar{\alpha}) \subseteq \{\eta \in R^m : (0, \eta) \in \partial g(z, \bar{\alpha}) \quad \text{for some } z \in \Sigma(\bar{\alpha})\},$$
$$\partial^\infty V(\bar{\alpha}) \subseteq \{\eta \in R^m : (0, \eta) \in \partial^\infty g(z, \bar{\alpha}) \quad \text{for some } z \in \Sigma(\bar{\alpha})\}.$$

Our results are stated using the limiting subdifferentials. Alternatively, they could be derived by using the Fréchet subdifferentials instead of the proximal subdifferentials. (Both lead to the same limiting subdifferentials in finite dimensional spaces.) In [18] arguments are given in favor of the former (called there the regular subdifferentials). In the present paper we use the proximal subdifferentials to provide the same framework as in [23].

3. Main results. Let $(\bar{x}, \bar{y})$ be a feasible solution of the OPVIC and let λ be a nonnegative number. We define $M^\lambda(\bar{x}, \bar{y})$, the index λ CD multiplier set corresponding to $(\bar{x}, \bar{y})$, to be the set of vectors (γ, β, η) in $R^d \times R^l \times R^m$ satisfying the Fritz John-type necessary optimality condition involving the Mordukhovich coderivatives for GP, that is, the vectors (γ, β, η) such that

$$\begin{cases} 0 \in \lambda \partial f(\bar{x}, \bar{y}) + \partial\langle \Psi, \gamma\rangle(\bar{x}, \bar{y}) + \partial\langle H, \beta\rangle(\bar{x}, \bar{y}) + \partial\langle F, \eta\rangle(\bar{x}, \bar{y}) \\ \qquad + \{0\} \times D^* N_\Omega(\bar{y}, -F(\bar{x}, \bar{y}))(\eta) + N_C(\bar{x}, \bar{y}), \\ \gamma \geq 0, \text{ and } \langle \Psi(\bar{x}, \bar{y}), \gamma\rangle = 0. \end{cases}$$

Then by Ye [23, Theorem 3.1], the Fritz John-type necessary optimality condition involving the Mordukhovich coderivatives can be rephrased as follows.

PROPOSITION 3.1. *Under the basic assumption* (BA), *if* $(\bar{x}, \bar{y})$ *is a local solution of* OPVIC, *then either the set of normal* CD *multipliers is nonempty or there is a nonzero abnormal* CD *multiplier, i.e.,*

$$M^1(\bar{x}, \bar{y}) \cup (M^0(\bar{x}, \bar{y}) \setminus \{0\}) \neq \emptyset.$$

Note that by the definition of the Mordukhovich coderivative,

$$\xi \in D^* N_\Omega(\bar{y}, -F(\bar{x}, \bar{y}))(\eta) \text{ if and only if } (\xi, -\eta) \in N_{GphN_\Omega}(\bar{y}, -F(\bar{x}, \bar{y})).$$

In the case where $\Omega = \{0\}$, OPVIC reduces to an ordinary mathematical programming problem with equality, inequality, and abstract constraints. The term $D^* N_\Omega(\bar{y}, -F(\bar{x}, \bar{y}))(\eta)$ vanishes, and the above Fritz John condition can be considered as a limiting subdifferential version of the generalized Lagrange multiplier rule as found in Clarke [2, Theorem 6.1.1] and was obtained by Mordukhovich [9, Theorem 1(b)].

In the case where $\Omega = R^m_+$, (1) reduces to a complementarity constraint,

$$y \geq 0,\ F(x, y) \geq 0,\ \langle F(x, y), y \rangle = 0,$$

and the coderivative of the normal cone to the set R^m_+ can be calculated using the following lemma whose proof follows from [22, Proposition 2.7] and the definition of the limiting normal cones.

LEMMA 3.2. *For any* $(\bar{u}, -\bar{v}) \in GphN_{R^m_+}$,

$$\begin{aligned} N_{GphN_{R^m_+}}(\bar{u}, -\bar{v}) = \{(\xi, -\eta) \in R^{2m} :& \xi_i = 0 \text{ if } \bar{u}_i > 0, \bar{v}_i = 0, \\ & \eta_i = 0 \text{ if } \bar{u}_i = 0, \bar{v}_i > 0, \\ & \text{either } \xi_i \eta_i = 0 \text{ or } \xi_i < 0 \text{ and } \eta_i < 0 \text{ if } \bar{u}_i = 0, \bar{v}_i = 0\}. \end{aligned}$$

In the case where Ω is a polyhedral convex set, one can calculate the Mordukhovich coderivative of the normal cone to the set Ω by using the formula of the limiting normal cone to the graph of the normal cone to the set Ω, which was first given in the proof of Dontchev and Rockafellar [5, Theorem 2] and stated in Poliquin and Rockafellar [16, Proposition 4.4].

We first consider the following additively (right-hand side) perturbed GP:

$$\begin{array}{lll} \text{GP}(p, q, r) & \text{minimize} & f(x, y) \\ & \text{subject to} & \Psi(x, y) \leq p, H(x, y) = q, (x, y) \in C, \\ & & r \in F(x, y) + N_\Omega(y), \end{array}$$

with the solution set denoted by $\Sigma(p, q, r)$.

In order to obtain useful information on the subdifferentials of the value function at $(\bar{p}, \bar{q}, \bar{r})$, some hypotheses are usually made for $\text{GP}(p, q, r)$, where (p, q, r) are sufficiently close to the point of interest $(\bar{p}, \bar{q}, \bar{r})$ (see, for example, [4, Growth Hypothesis 3.1.1], [2, Hypothesis 6.5.1], [18, Definition 1.8]). In this paper, we make the following growth hypothesis [7, Theorem 5A.2]:

(GH) at $(\bar{p}, \bar{q}, \bar{r})$: There exists $\delta > 0$ such that the set

$$\begin{aligned} \{(x, y) \in C\ :\ & \Psi(x, y) \leq p, H(x, y) = q, r \in F(x, y) + N_\Omega(y), f(x, y) \leq M, \\ & (p, q, r) \in B(\bar{p}, \bar{q}, \bar{r}; \delta)\} \end{aligned}$$

is bounded for each M.

In order to apply Proposition 2.8, we rewrite the value function in the following form:

$$V(p,q,r) = \inf g(x,y,p,q,r),$$

where g is the extended-value function defined by

$$g(x,y,p,q,r) := f(x,y) + I_{(Gph\Phi)\cap(C\times R^{d+l+m})}(x,y,p,q,r)$$

with I_E being the indicator function of a set E defined by

$$I_E(x) := \begin{cases} 0 \text{ if } x \in E, \\ \infty \text{ if } x \notin E \end{cases}$$

and Φ being the set-valued map defined by

$$\Phi(x,y) = (\Psi(x,y), H(x,y), F(x,y)) + R^d_+ \times \{0\} \times N_\Omega(y).$$

The growth hypothesis (GH) amounts to saying the function g is level-bounded in (x,y) uniformly for any $(p,q,r) \in B(\bar p,\bar q,\bar r;\delta)$. Hence by virtue of [18, Theorem 1.9], $\bigcup_{(p,q,r)\in B(\bar p,\bar q,\bar r;\delta)} \Sigma(p,q,r)$ is a compact set and for all $(p,q,r) \in B(\bar p,\bar q,\bar r;\delta)$,

$$V(p,q,r) = \inf\{g(x,y,p,q,r) : (x,y) \in E\},$$

where E is a compact set with interior containing $\bigcup_{(p,q,r)\in B(\bar p,\bar q,\bar r;\delta)} \Sigma(p,q,r)$. It is clear that g is lower semicontinuous everywhere and finite at any $(x,y,p,q,r) \in (Gph\Phi) \cap (C \times R^{d+l+m})$. Since f is Lipschitz on E, g is bounded below on $E \times B(\bar x,\bar y;\epsilon)$. The following result then follows immediately by applying Proposition 2.8.

PROPOSITION 3.3. *Under the basic assumption* (BA) *and the growth hypothesis* (GH) *at* $(\bar p,\bar q,\bar r)$ *the value function* V *is lower semicontinuous on* $B(\bar p,\bar q,\bar r;\delta)$ *and*

$$\partial V(\bar p,\bar q,\bar r) \subseteq \bigcup_{(\bar x,\bar y)\ \in\Sigma(\bar p,\bar q,\bar r)} \{(u,v,w)\ :\ (0,0,u,v,w) \in \partial g(\bar x,\bar y,\bar p,\bar q,\bar r)\}, \tag{10}$$

$$\partial^\infty V(\bar p,\bar q,\bar r) \subseteq \bigcup_{(\bar x,\bar y)\in\Sigma(\bar p,\bar q,\bar r)} \{(u,v,w)\ :\ (0,0,u,v,w) \in \partial^\infty g(\bar x,\bar y,\bar p,\bar q,\bar r)\}. \tag{11}$$

We now prove that the set in the right-hand side of (10) (respectively, (11)) is included in the normal multiplier set M^1 (respectively, the abnormal multiplier set M^0).

By the sum rule (see Proposition 2.5) and the fact that for any closed set E with $\bar z \in E$

$$\partial I_E(\bar z) = \partial^\infty I_E(\bar z) = N_E(\bar z),$$

we have

$$\begin{aligned} \partial g(\bar x,\bar y,\bar p,\bar q,\bar r) &\subset \partial f(\bar x,\bar y) \times \{(0,0)\} + N_{(Gph\Phi)\cap(C\times R^{d+l+m})}(\bar x,\bar y,\bar p,\bar q,\bar r), \\ \partial^\infty g(\bar x,\bar y,\bar p,\bar q,\bar r) &\subset N_{(Gph\Phi)\cap(C\times R^{d+l+m})}(\bar x,\bar y,\bar p,\bar q,\bar r). \end{aligned}$$

Hence we need only to compute the normal cone.

LEMMA 3.4. *If* $(s_x,s_y,s_p,s_q,s_r) \in N_{(Gph\Phi)\cap(C\times R^{d+l+m})}(\bar x,\bar y,\bar p,\bar q,\bar r)$, *then*

$$\begin{cases} (s_x,s_y) \in \partial\langle\Psi,-s_p\rangle(\bar x,\bar y) + \partial\langle H,-s_q\rangle(\bar x,\bar y) + \partial\langle F,-s_r\rangle(\bar x,\bar y) + N_C(\bar x,\bar y) \\ \qquad\qquad +\{0\} \times D^*N_\Omega(\bar y,\bar r - F(\bar x,\bar y))(-s_r), \\ s_p \ge 0, \ \textit{and}\ \langle\Psi(\bar x,\bar y) - \bar p, s_p\rangle = 0. \end{cases}$$

Proof. Step 1. Let $(\tilde{x},\tilde{y},\tilde{p},\tilde{q},\tilde{r})$ be any point in a neighborhood of $(\bar{x},\bar{y},\bar{p},\bar{q},\bar{r})$ on which Ψ, H, and F are Lipschitz continuous and

$$(s_x,s_y,s_p,s_q,s_r)\in N^{\pi}_{(Gph\Phi)\cap(C\times R^{d+l+m})}(\tilde{x},\tilde{y},\tilde{p},\tilde{q},\tilde{r}).$$

By definition of the proximal normal cone, there is $M>0$ such that for all $(x,y,p,q,r)\in (Gph\Phi)\cap(C\times R^{d+l+m})$,

$$\langle (s_x,s_y,s_p,s_q,s_r),(x,y,p,q,r)-(\tilde{x},\tilde{y},\tilde{p},\tilde{q},\tilde{r})\rangle \le M\|(x,y,p,q,r)-(\tilde{x},\tilde{y},\tilde{p},\tilde{q},\tilde{r})\|^2.$$

In other words, $(\tilde{x},\tilde{y},\tilde{p},\tilde{q},\tilde{r})$ is a solution to the optimization problem

$$\begin{array}{ll}\text{minimize} & \langle -(s_x,s_y,s_p,s_q,s_r),(x,y,p,q,r)\rangle + M\|(x,y,p,q,r)-(\tilde{x},\tilde{y},\tilde{p},\tilde{q},\tilde{r})\|^2\\ \text{subject to} & \Psi(x,y)\le p, H(x,y)=q,(x,y)\in C,\\ & r\in F(x,y)+N_\Omega(y).\end{array}$$

We now prove that the only abnormal CD multiplier for the above problem is the zero vector. Indeed, the set of abnormal CD multipliers at $(\tilde{x},\tilde{y},\tilde{p},\tilde{q},\tilde{r})$ for the above problem are the vectors (γ,β,η) satisfying

$$\begin{cases}0\in \partial\langle\Psi,\gamma\rangle(\tilde{x},\tilde{y})\times\{(-\gamma,0,0)\}+\partial\langle H,\beta\rangle(\tilde{x},\tilde{y})\times\{(0,-\beta,0)\}+\partial\langle F,\eta\rangle(\tilde{x},\tilde{y})\\ \times\{(0,0,-\eta)\}+\{0\}\times D^*N_\Omega(\tilde{y},\tilde{r}-F(\tilde{x},\tilde{y}))(\eta)\times\{(0,0,0)\}+N_C(\tilde{x},\tilde{y})\\ \times\{(0,0,0)\},\ \gamma\ge 0,\ \text{and}\ \langle\Psi(\tilde{x},\tilde{y})-\tilde{p},\gamma\rangle=0,\end{cases}$$

which obviously coincides with the set $\{(0,0,0)\}$. Applying Proposition 3.1, we conclude that the set of normal CD multipliers for the above problem must be nonempty. That is, there are vectors $\eta\in R^m,\beta\in R^l$, and $\gamma\in R^d$ such that

$$\begin{cases}0\in -\{(s_x,s_y,s_p,s_q,s_r)\}+\partial\langle\Psi,\gamma\rangle(\tilde{x},\tilde{y})\times\{(-\gamma,0,0)\}+\partial\langle H,\beta\rangle(\tilde{x},\tilde{y})\times\{(0,-\beta,0)\}\\ \quad+\partial\langle F,\eta\rangle(\tilde{x},\tilde{y})\times\{(0,0,-\eta)\}+\{0\}\times D^*N_\Omega(\tilde{y},\tilde{r}-F(\tilde{x},\tilde{y}))(\eta)\times\{(0,0,0)\}\\ \qquad\qquad +N_C(\tilde{x},\tilde{y})\times\{(0,0)\},\\ \gamma\ge 0,\ \text{and}\ \langle\Psi(\tilde{x},\tilde{y})-\tilde{p},\gamma\rangle=0.\end{cases}$$

That is,

$$\begin{cases}(s_x,s_y)\in \partial\langle\Psi,-s_p\rangle(\tilde{x},\tilde{y})+\partial\langle H,-s_q\rangle(\tilde{x},\tilde{y})\\ \qquad +\partial\langle F,-s_r\rangle(\tilde{x},\tilde{y})+\{0\}\times D^*N_\Omega(\tilde{y},\tilde{r}-F(\tilde{x},\tilde{y}))(-s_q)+N_C(\tilde{x},\tilde{y}),\\ s_p\ge 0,\ \text{and}\ \langle\Psi(\tilde{x},\tilde{y})-\tilde{p},s_p\rangle=0.\end{cases}$$

Step 2. Now take any $(s_x,s_y,s_p,s_q,s_r)\in N_{(Gph\Phi)\cap(C\times R^{d+l+m})}(\bar{x},\bar{y},\bar{p},\bar{q},\bar{r})$. Then by definition of limiting normal cones, there are sequences $(x^\nu,y^\nu,p^\nu,q^\nu,r^\nu)\to(\bar{x},\bar{y},\bar{p},\bar{q},\bar{r})$ and $(s_x^\nu,s_y^\nu,s_p^\nu,s_q^\nu,s_r^\nu)\to(s_x,s_y,s_p,s_q,s_r)$ with

$$(s_x^\nu,s_y^\nu,s_p^\nu,s_q^\nu,s_r^\nu)\in N^{\pi}_{(Gph\Phi)\cap(C\times R^{d+l+m})}(x^\nu,y^\nu,p^\nu,q^\nu,r^\nu).$$

By virtue of step 1,

$$\begin{cases}(s_x^\nu,s_y^\nu)\in \partial\langle\Psi,-s_p^\nu\rangle(x^\nu,y^\nu)+\partial\langle H,-s_q^\nu\rangle(x^\nu,y^\nu)+\partial\langle F,-s_r^\nu\rangle(x^\nu,y^\nu)\\ \qquad +\{0\}\times D^*N_\Omega(y^\nu,r^\nu-F(x^\nu,y^\nu))(-s_r^\nu)+N_C(x^\nu,y^\nu),\\ s_p^\nu\ge 0,\ \text{and}\ \langle\Psi(x^\nu,y^\nu)-p^\nu,s_p^\nu\rangle=0.\end{cases}$$

Since Ψ is Lipschitz near $(\bar{x}, \bar{y})$, we have

$$\begin{aligned}\partial\langle\Psi, -s_p^\nu\rangle(x^\nu, y^\nu) &\subseteq \partial\langle\Psi, -s_p\rangle(x^\nu, y^\nu) + \partial\langle\Psi, s_p - s_p^\nu\rangle(x^\nu, y^\nu) \text{ by Proposition 2.5}\\ &\subseteq \partial\langle\Psi, -s_p\rangle(x^\nu, y^\nu) + \|s_p^\nu - s_p\| L_\Psi clB \text{ by Proposition 2.4,}\end{aligned}$$

where L_Ψ is the Lipschitz constant of Ψ. Similarly,

$$\begin{aligned}\partial\langle H, -s_q^\nu\rangle(x^\nu, y^\nu) &\subseteq \partial\langle H, -s_q\rangle(x^\nu, y^\nu) + \|s_q^\nu - s_q\| L_H clB,\\ \partial\langle F, -s_r^\nu\rangle(x^\nu, y^\nu) &\subseteq \partial\langle F, -s_r\rangle(x^\nu, y^\nu) + \|s_r^\nu - s_r\| L_F clB,\end{aligned}$$

where L_H, L_F are the Lipschitz constants of F and H. Hence we have

$$\begin{cases}(s_x^\nu, s_y^\nu) \in \partial\langle\Psi, -s_p\rangle(x^\nu, y^\nu) + \partial\langle H, -s_q\rangle(x^\nu, y^\nu) + \partial\langle F, -s_r\rangle(x^\nu, y^\nu)\\ \qquad + (\|s_p^\nu - s_p\| + \|s_q^\nu - s_q\| + \|s_r^\nu - s_r\|)(L_\Psi + L_H + L_F) clB\\ \qquad + \{0\} \times D^* N_\Omega(y^\nu, r^\nu - F(x^\nu, y^\nu))(-s_r^\nu) + N_C(x^\nu, y^\nu),\\ s_p^\nu \geq 0, \text{ and } \langle\Psi(x^\nu, y^\nu) - p^\nu, s_p^\nu\rangle = 0.\end{cases}$$

Taking limits as $\nu \to \infty$ and using the definitions of the limiting normal cone and the limiting subdifferentials completes the proof. □

Remark. As is pointed out by referee 1, alternatively, Lemma 3.4 can also be proved by formulating the constraints in the form of [12, equation (6.19)] and applying [12, Theorem 6.10].

All in all, we proved the following result.

THEOREM 3.5. *Assume* (GH) *and* (BA) *hold. Then the value function V is lower semicontinuous on $B(\bar{p}, \bar{q}, \bar{r}; \delta)$ and*

$$\partial V(\bar{p}, \bar{q}, \bar{r}) \subset \bigcup_{(\bar{x}, \bar{y}) \in \Sigma(\bar{p}, \bar{q}, \bar{r})} -M^1(\bar{x}, \bar{y}) \text{ and } \partial^\infty V(\bar{p}, \bar{q}, \bar{r}) \subset \bigcup_{(\bar{x}, \bar{y}) \in \Sigma(\bar{p}, \bar{q}, \bar{r})} -M^0(\bar{x}, \bar{y}).$$

We now consider the value function $V(\alpha)$ associated with the following perturbed GP:

$$\begin{array}{lll}\text{GP}(\alpha) & \text{minimize} & f(x, y, \alpha)\\ & \text{subject to} & \Psi(x, y, \alpha) \leq 0, H(x, y, \alpha) = 0, (x, y) \in C,\\ & & 0 \in F(x, y, \alpha) + N_\Omega(y),\end{array}$$

i.e.,

$$\begin{aligned}V(\alpha) := \inf\{f(x, y, \alpha) : \quad &\Psi(x, y, \alpha) \leq 0, H(x, y, \alpha) = 0, (x, y) \in C,\\ &0 \in F(x, y, \alpha) + N_\Omega(y)\},\end{aligned}$$

where the following basic assumptions are satisfied:

(BH) The functions $f : R^{n+m+c} \to R, \Psi : R^{n+m+c} \to R^d, H : R^{n+m+c} \to R^l$, and $F : R^{n+m+c} \to R^m$ are locally Lipschitz near any points in $C \times R^c$; C is a closed subset of R^{n+m}; and Ω is a closed convex subset of R^m.

It is easy to see that we can turn the nonadditive perturbations into additive perturbations by adding an auxiliary variable:

$$\begin{array}{lll}\text{GP}(\alpha) & \text{minimize} & f(x, y, z)\\ & \text{subject to} & \Psi(x, y, z) \leq 0, H(x, y, z) = 0, (x, y, z) \in C \times R^c,\\ & & 0 \in F(x, y, z) + N_\Omega(y),\\ & & z = \alpha,\end{array}$$

which is the partially perturbed problem of the fully perturbed problem

$$\begin{array}{lll} \mathrm{GP}(p,q,r,\alpha) & \text{minimize} & f(x,y,z) \\ & \text{subject to} & \Psi(x,y,z)\le p, H(x,y,z)=q, (x,y,z)\in C\times R^c, \\ & & r\in F(x,y,z)+N_\Omega(y), \\ & & z=\alpha. \end{array}$$

By Theorem 3.5, if the fully perturbed problem $\mathrm{GP}(p,q,r,\alpha)$ satisfies the growth hypothesis (GH) at $(0,0,0,\bar\alpha)$, then the value function $\widetilde V(p,q,r,\alpha)$ defined by

$$\begin{aligned}\widetilde V(p,q,r,\alpha) := \inf\{f(x,y,z) :&\Psi(x,y,z)\le p, H(x,y,z)=q, (x,y,z)\in C\times R^c,\\ &r\in F(x,y,z)+N_\Omega(y), z=\alpha\}\end{aligned}$$

is lower semicontinuous on $B(0,0,0,\bar\alpha;\delta)$ and

$$\begin{aligned}\partial\widetilde V(0,0,0,\bar\alpha)&\subseteq \bigcup_{(\bar x,\bar y,\bar\alpha)\in\Sigma(0,0,0,\bar\alpha)} -M^1(\bar x,\bar y,\bar\alpha),\\ \partial^\infty\widetilde V(0,0,0,\bar\alpha)&\subseteq \bigcup_{(\bar x,\bar y,\bar\alpha)\in\Sigma(0,0,0,\bar\alpha)} -M^0(\bar x,\bar y,\bar\alpha).\end{aligned}$$

For any $(0,0,0,\zeta)\in\partial^\infty\widetilde V(0,0,0,\bar\alpha)$, we have $(0,0,0,\zeta)\in -M^0(\bar x,\bar y,\bar\alpha)$ for some point $(\bar x,\bar y,\bar\alpha)\in\Sigma(0,0,0,\bar\alpha)$. Therefore,

$$(0,0,\zeta)\in N_C(\bar x,\bar y)\times\{0\},$$

which implies that $\zeta=0$. By Proposition 2.6, we have

$$\begin{aligned}\partial_\alpha\widetilde V(0,0,0,\bar\alpha)&\subseteq\{-\zeta : -(\gamma,\beta,\eta,\zeta)\in\partial\widetilde V(0,0,0,\bar\alpha)\text{ for some }(\gamma,\beta,\eta)\},\\ \partial^\infty_\alpha\widetilde V(0,0,0,\bar\alpha)&\subseteq\{-\zeta : -(\gamma,\beta,\eta,\zeta)\in\partial^\infty\widetilde V(0,0,0,\bar\alpha)\text{ for some }(\gamma,\beta,\eta)\}.\end{aligned}$$

Moreover, since all functions involved are continuous, it suffices to fix α at $\bar\alpha$ in the growth hypothesis (GH) at $(0,0,0,\bar\alpha)$ for the fully perturbed problem $\mathrm{GP}(p,q,r,\alpha)$. Consequently, noticing that $V(\alpha)=\widetilde V(0,0,0,\alpha)$, we have proved the following theorem.

THEOREM 3.6. *In addition to the basic assumption* (BH)*, assume that there exists $\delta>0$ such that the set*

$$\begin{aligned}\{(x,y)\in C\ :\ &\Psi(x,y,\bar\alpha)\le p, H(x,y,\bar\alpha)=q, r\in F(x,y,\bar\alpha)+N_\Omega(y), f(x,y,\bar\alpha)\le M,\\ &(p,q,r)\in B(0;\delta)\}\end{aligned}$$

is bounded for each M. Then the value function $V(\alpha)$ is lower semicontinuous near $\bar\alpha$ and

$$\begin{aligned}\partial V(\bar\alpha)&\subseteq \bigcup_{(\bar x,\bar y)\in\Sigma(\bar\alpha)}\{-\zeta : (\gamma,\beta,\eta,\zeta)\in M^1(\bar x,\bar y,\bar\alpha)\},\\ \partial^\infty V(\bar\alpha)&\subseteq \bigcup_{(\bar x,\bar y)\in\Sigma(\bar\alpha)}\{-\zeta : (\gamma,\beta,\eta,\zeta)\in M^0(\bar x,\bar y,\bar\alpha)\},\end{aligned}$$

where $M^\lambda(\bar x,\bar y,\bar\alpha)$ is the set of index λ multipliers for problem $\mathrm{GP}(p,q,r,\alpha)$ *at $(0,0,0,\bar\alpha)$, i.e., vectors $(\gamma,\beta,\eta,\zeta)$ in $R^d\times R^l\times R^m\times R$ satisfying*

$$\begin{cases} 0\in\lambda\partial f(\bar x,\bar y,\bar\alpha)+\partial\langle\Psi,\gamma\rangle(\bar x,\bar y,\bar\alpha)+\partial\langle H,\beta\rangle(\bar x,\bar y,\bar\alpha)+\partial\langle F,\eta\rangle(\bar x,\bar y,\bar\alpha)\\ \qquad +\{0\}\times D^*N_\Omega(\bar y,-F(\bar x,\bar y,\bar\alpha))(\eta)\times\{0\}+\{(0,0,\zeta)\}+N_C(\bar x,\bar y)\times\{0\},\\ \gamma\ge 0,\ \text{and}\ \langle\Psi(\bar x,\bar y,\bar\alpha),\gamma\rangle=0,\end{cases}$$

and $\Sigma(\bar{\alpha})$ is the set of solutions of problem GP($\bar{\alpha}$).

The above estimates may not be useful in the case where $\partial V(\bar{\alpha})$ is empty. The following consequence of Theorem 3.6 and Proposition 2.4 provides conditions which rule out this possibility.

COROLLARY 3.7. *Under the assumption of Theorem* 3.6*, if the set of ζ components of the abnormal* CD *multiplier set contains only the zero vector, i.e.,*

$$\bigcup_{(\bar{x},\bar{y})\in\Sigma(\bar{\alpha})} \{-\zeta : (\gamma,\beta,\eta,\zeta) \in M^0(\bar{x},\bar{y},\bar{\alpha})\} = \{0\},$$

then $V(\bar{\alpha})$ is finite and Lipschitz near $\bar{\alpha}$ with

$$\emptyset \neq \partial V(\bar{\alpha}) \subset \bigcup_{(\bar{x},\bar{y})\in\Sigma(\bar{\alpha})} \{-\zeta : (\gamma,\beta,\eta,\zeta) \in M^1(\bar{x},\bar{y},\bar{\alpha})\}.$$

In addition to the above assumptions, if the ζ components of the normal CD multiplier set are unique, i.e.,

$$\bigcup_{(\bar{x},\bar{y})\in\Sigma(\bar{\alpha})} \{-\zeta : (\gamma,\beta,\eta,\zeta) \in M^1(\bar{x},\bar{y},\bar{\alpha})\} = \{-\zeta\},$$

then V is strictly differentiable at $\bar{\alpha}$ and $\nabla V(\bar{\alpha}) = -\zeta$.

In the case where all functions are smooth, the estimates have the following simple expression.

COROLLARY 3.8. *In addition to the assumptions in Theorem* 3.6*, assume that f, Ψ, H, F are C^1 at each $(\bar{x},\bar{y},\bar{\alpha})$, where $(\bar{x},\bar{y}) \in \Sigma(\bar{\alpha})$; then the value function V is lower semicontinuous near $\bar{\alpha}$, and*

$$\begin{aligned}
\partial V(\bar{\alpha}) \subseteq \bigcup_{(\bar{x},\bar{y})\in\Sigma(\bar{\alpha})} \{&\nabla_\alpha f(\bar{x},\bar{y},\bar{\alpha}) + \nabla_\alpha \Psi(\bar{x},\bar{y},\bar{\alpha})^\top \gamma + \nabla_\alpha H(\bar{x},\bar{y},\bar{\alpha})^\top \beta \\
&+\nabla_\alpha F(\bar{x},\bar{y},\bar{\alpha})^\top \eta : \quad (\gamma,\beta,\eta) \in M^1(\bar{x},\bar{y})\}, \\
\partial^\infty V(\bar{\alpha}) \subseteq \bigcup_{(\bar{x},\bar{y},\bar{z})\in\Sigma(\bar{\alpha})} \{&\nabla_\alpha \Psi(\bar{x},\bar{y},\bar{\alpha})^\top \gamma + \nabla_\alpha H(\bar{x},\bar{y},\bar{\alpha})^\top \beta \\
&+\nabla_\alpha F(\bar{x},\bar{y},\bar{\alpha})^\top \eta : \quad (\gamma,\beta,\eta) \in M^0(\bar{x},\bar{y})\},
\end{aligned}$$

where $M^\lambda(\bar{x},\bar{y})$ is the set of index λ CD *multipliers for problem* GP($\bar{\alpha}$).

Note that in the case where there are no variational inequality constraints, the CD multipliers are the ordinary NLP multipliers, and the above results recover the well-known results in the sensitivity analysis of NLP.

4. Applications to OPCCs. In this section, we apply our main results to the following perturbed OPCC:

$$\begin{array}{lll}
\text{(OPCC)}(\alpha) & \text{minimize} & f(x,y,\alpha), \\
& \text{subject to} & \Psi(x,y,\alpha) \le 0, H(x,y,\alpha) = 0, (x,y) \in C, \\
& & y \ge 0,\ F(x,y,\alpha) \ge 0, \\
& & \langle y, F(x,y,\alpha)\rangle = 0,
\end{array}$$

which is GP(α) with $\Omega = R^m_+$.

For easier exposition, we assume in this section that all problem data f, Ψ, H, F are C^1. We denote by $\nabla f(x,y,\alpha)$ the gradient of function f with respect to (x,y).

For $(\bar{x},\bar{y})$, a feasible solution of (OPCC)$(\bar{\alpha})$, we define the index sets

$$\begin{aligned} L := L(\bar{x},\bar{y}) &:= \{1 \le i \le m : \bar{y}_i > 0, F_i(\bar{x},\bar{y},\bar{\alpha}) = 0\},\\ I_+ := I_+(\bar{x},\bar{y}) &:= \{1 \le i \le m : \bar{y}_i = 0, F_i(\bar{x},\bar{y},\bar{\alpha}) > 0\},\\ I_0 := I_0(\bar{x},\bar{y}) &:= \{1 \le i \le m : \bar{y}_i = 0, F_i(\bar{x},\bar{y},\bar{\alpha}) = 0\}. \end{aligned}$$

4.1. Sensitivity analysis of the value function via NLP multipliers. Let $(\bar{x},\bar{y})$ be a local optimal solution for (OPCC)$(\bar{\alpha})$. Treating (OPCC)$(\bar{\alpha})$ as an ordinary NLP problem with inequality constraints

$$\Psi(x,y,\bar{\alpha}) \le 0, y \ge 0, F(x,y,\bar{\alpha}) \ge 0,$$

equality constraints

$$H(x,y,\bar{\alpha}) = 0, \langle y, F(x,y,\bar{\alpha}\rangle = 0,$$

and the abstract constraint $(x,y) \in C$, it is easy to see that the Fritz John optimality condition implies the existence of $\lambda \ge 0, \gamma \in R^d, \beta \in R^l, r^F \in R^m, r^y \in R^m, \mu \in R$, not all zero, such that

$$\begin{aligned} &0 \in \lambda\nabla f(\bar{x},\bar{y},\bar{\alpha}) + \nabla\Psi(\bar{x},\bar{y},\bar{\alpha})^\top\gamma + \nabla H(\bar{x},\bar{y},\bar{\alpha})^\top\beta\\ &\quad -\nabla F(\bar{x},\bar{y},\bar{\alpha})^\top r^F - \{(0,r^y)\} + \mu\nabla\langle y,F\rangle(\bar{x},\bar{y},\bar{\alpha}) + N_C(\bar{x},\bar{y}),\\ &\gamma \ge 0, \langle\gamma, \Psi(\bar{x},\bar{y},\bar{\alpha})\rangle = 0,\\ &r^F \ge 0, r^y \ge 0, \langle r^F, F(\bar{x},\bar{y},\bar{\alpha})\rangle = 0, \langle r^y,\bar{y}\rangle = 0. \end{aligned}$$

Using the sum and product rules, we have

$$\nabla\langle y,F\rangle(\bar{x},\bar{y},\bar{\alpha}) = \{(0,F(\bar{x},\bar{y},\bar{\alpha}))\} + \nabla F(\bar{x},\bar{y},\bar{\alpha})^\top\bar{y}.$$

Therefore, the Fritz John necessary condition becomes

$$\begin{aligned} &0 \in \lambda\nabla f(\bar{x},\bar{y},\bar{\alpha}) + \nabla\Psi(\bar{x},\bar{y},\bar{\alpha})^\top\gamma + \nabla H(\bar{x},\bar{y},\bar{\alpha})^\top\beta\\ &\quad +\nabla F(\bar{x},\bar{y},\bar{\alpha})^\top(\mu\bar{y} - r^F) + \{(0,\mu F(\bar{x},\bar{y},\bar{\alpha}) - r^y)\} + N_C(\bar{x},\bar{y}),\\ &\gamma \ge 0, \langle\gamma,\Psi(\bar{x},\bar{y},\bar{\alpha})\rangle = 0,\\ &r^F \ge 0, r^y \ge 0, \text{ and } \langle r^F, F(\bar{x},\bar{y},\bar{\alpha})\rangle = 0, \langle r^y,\bar{y}\rangle = 0. \end{aligned}$$

Definition 4.1 (NLP multipliers). *We call all vectors $(\gamma,\beta,r^F,r^y,\mu) \in R^d \times R^l \times R^m \times R^m \times R$ satisfying the above Fritz John necessary condition for any $\lambda \ge 0$ the index λ NLP multipliers for OPCC$(\bar{\alpha})$ and denote the set by $M^\lambda_{NLP}(\bar{x},\bar{y})$.*

Since we treat OPCC(α) as an ordinary NLP problem, $\Omega = \{0\}$ in the corresponding problem GP(α). Hence the CD multipliers for the corresponding $GP(\alpha)$ are the NLP multipliers defined above. Applying Corollary 3.8 and Proposition 2.4, we derive the following upper estimates of the limiting subdifferentials of the value function in terms of the NLP multipliers.

Theorem 4.2. *Assume that there exists $\delta > 0$ such that the set*

$$\begin{aligned} \{(x,y) \in C :&(p,q,p_y,p_F,q_\mu) \in B(0;\delta), \Psi(x,y,\bar{\alpha}) \le p, H(x,y,\bar{\alpha}) = q,\\ &y \ge p_y,\ F(x,y,\bar{\alpha}) \le p_F, \langle y, F(x,y,\bar{\alpha})\rangle = q_\mu, f(x,y,\bar{\alpha}) \le M\} \end{aligned}$$

is bounded for each M. Then the value function V is lower semicontinuous near $\bar{\alpha}$ and

$$\partial V(\bar{\alpha}) \subseteq \bigcup_{(\bar{x},\bar{y})\in\Sigma(\bar{\alpha})} \{\nabla_\alpha f(\bar{x},\bar{y},\bar{\alpha}) + \nabla_\alpha \Psi(\bar{x},\bar{y},\bar{\alpha})^\top \gamma + \nabla_\alpha H(\bar{x},\bar{y},\bar{\alpha})^\top \beta$$

$$+\nabla_\alpha F(\bar{x},\bar{y},\bar{\alpha})^\top(\mu\bar{y} - r^F) : (\gamma,\beta,r^F,r^y,\mu) \in M^1_{NLP}(\bar{x},\bar{y})\}, \tag{12}$$

$$\partial^\infty V(\bar{\alpha}) \subseteq \bigcup_{(\bar{x},\bar{y})\in\Sigma(\bar{\alpha})} \{\nabla_\alpha \Psi(\bar{x},\bar{y},\bar{\alpha})^\top \gamma + \nabla_\alpha H(\bar{x},\bar{y},\bar{\alpha})^\top \beta$$

$$+\nabla_\alpha F(\bar{x},\bar{y},\bar{\alpha})^\top(\mu\bar{y} - r^F) : (\gamma,\beta,r^F,r^y,\mu) \in M^0_{NLP}(\bar{x},\bar{y})\}. \tag{13}$$

If the set in the right-hand side of inclusion (13) *contains only the zero vector, then the value function V is Lipschitz near $\bar{\alpha}$. If the set in the right-hand side of inclusion* (13) *contains only the zero vector and the set in the right-hand side of inclusion* (12) *is a singleton, then the value function is strictly differentiable at $\bar{\alpha}$.*

4.2. Sensitivity analysis of the value function via CD multipliers. Since OPCC($\bar{\alpha}$) is OPVIC($\bar{\alpha}$) with $\Omega = R^m_+$, the following expression of CD multiplers follows immediately from Lemma 3.2.

PROPOSITION 4.3. *For* OPCC($\bar{\alpha}$)*, an index* λ CD *multiplier corresponding to a feasible solution $(\bar{x},\bar{y})$ is a vector $(\gamma,\beta,\eta) \in R^d \times R^l \times R^m$ such that*

$$0 \in \lambda\nabla f(\bar{x},\bar{y},\bar{\alpha}) + \nabla\Psi(\bar{x},\bar{y},\bar{\alpha})^\top\gamma + \nabla H(\bar{x},\bar{y},\bar{\alpha})^\top\beta$$

$$+\nabla F(\bar{x},\bar{y},\bar{\alpha})^\top\eta + (0,0,\xi) + N_C(\bar{x},\bar{y}), \tag{14}$$

$$\gamma \geq 0 \text{ and } \langle\Psi(\bar{x},\bar{y},\bar{\alpha}),\gamma\rangle = 0, \tag{15}$$

$$\xi_i = 0 \qquad \text{if } \bar{y}_i > 0 \text{ and } F_i(\bar{x},\bar{y},\bar{\alpha}) = 0, \tag{16}$$

$$\eta_i = 0 \qquad \text{if } \bar{y}_i = 0 \text{ and } F_i(\bar{x},\bar{y},\bar{\alpha}) > 0, \tag{17}$$

$$\text{either } \xi_i < 0,\ \eta_i < 0,\ \text{or } \xi_i\eta_i = 0 \qquad \text{if } \bar{y}_i = 0 \text{ and } F_i(\bar{x},\bar{y}) = 0. \tag{18}$$

Corollary 3.8 and Proposition 2.4 now lead to the following result.

THEOREM 4.4. *Assume that there exists $\delta > 0$ such that the set*

$$\{(x,y) \in C : (p,q,r) \in B(0;\delta), \Psi(x,y,\bar{\alpha}) \leq p, H(x,y,\bar{\alpha}) = q,$$
$$y \geq 0,\ F(x,y,\bar{\alpha}) \geq r, \langle y, F(x,y,\bar{\alpha}) - r\rangle = 0, f(x,y,\bar{\alpha}) \leq M\}$$

is bounded for each M. Then the value function V is lower semicontinuous near $\bar{\alpha}$ and

$$\partial V(\bar{\alpha}) \subseteq \bigcup_{(\bar{x},\bar{y})\in\Sigma(\bar{\alpha})} \{\nabla_\alpha f(\bar{x},\bar{y},\bar{\alpha}) + \nabla_\alpha \Psi(\bar{x},\bar{y},\bar{\alpha})^\top \gamma + \nabla_\alpha H(\bar{x},\bar{y},\bar{\alpha})^\top \beta$$

$$+\nabla_\alpha F(\bar{x},\bar{y},\bar{\alpha})^\top\eta : (\gamma,\beta,\eta) \in M^1_{CD}(\bar{x},\bar{y})\}, \tag{19}$$

$$\partial^\infty V(\bar{\alpha}) \subseteq \bigcup_{(\bar{x},\bar{y})\in\Sigma(\bar{\alpha})} \{\nabla_\alpha \Psi(\bar{x},\bar{y},\bar{\alpha})^\top \gamma + \nabla_\alpha H(\bar{x},\bar{y},\bar{\alpha})^\top \beta$$

$$+\nabla F(\bar{x},\bar{y},\bar{\alpha})^\top\eta : (\gamma,\beta,\eta) \in M^0_{CD}(\bar{x},\bar{y})\}. \tag{20}$$

If the set in the right-hand side of inclusion (20) *contains only the zero vector, then the value function V is Lipschitz near $\bar{\alpha}$. If the set in the right-hand side of inclusion* (20) *contains only the zero vector and the set in the right-hand side of inclusion* (19) *is a singleton, then the value function is strictly differentiable at $\bar{\alpha}$.*

We say that the generalized Mangasarian–Fromovitz constraint qualification for OPCC($\bar{\alpha}$) is satisfied at $(\bar{x},\bar{y})$ if $C = D \times R^m$ and

(i) for every partition of I_0 into sets P, Q, R with $R \neq \emptyset$, there exist vectors $k \in \text{int}T_C(\bar{x}, D), h \in R^m$ such that $h_{I_+} = 0, h_Q = 0, h_R \geq 0$,

$$\begin{aligned}
&\nabla_x \Psi_{I(\Psi)}(\bar{x}, \bar{y}, \bar{\alpha})k + \nabla_y \Psi_{I(\Psi)}(\bar{x}, \bar{y}, \bar{\alpha})h \leq 0,\\
&\nabla_x H(\bar{x}, \bar{y}, \bar{\alpha})k + \nabla_y H(\bar{x}, \bar{y}, \bar{\alpha})h = 0,\\
&\nabla_x F_{L\cup P}(\bar{x}, \bar{y}, \bar{\alpha})k + \nabla_y F_{L\cup P}(\bar{x}, \bar{y}, \bar{\alpha})h = 0,\\
&\nabla_x F_R(\bar{x}, \bar{y}, \bar{\alpha})k + \nabla_y F_R(\bar{x}, \bar{y}, \bar{\alpha})h \geq 0,
\end{aligned}$$

and either $h_i > 0$ or

$$\nabla_x F_i(\bar{x}, \bar{y}, \bar{\alpha})k + \nabla_y F_i(\bar{x}, \bar{y}, \bar{\alpha})h > 0 \text{ for some } i \in R;$$

(ii) for every partition of I_0 into the sets P, Q, the matrix

$$\begin{bmatrix} \nabla_x H(\bar{x}, \bar{y}, \bar{\alpha}) & \nabla_y H_{A,L\cup P}(\bar{x}, \bar{y}, \bar{\alpha}) \\ \nabla_x F_{L\cup P}(\bar{x}, \bar{y}, \bar{\alpha}) & \nabla_y F_{L\cup P, L\cup P}(\bar{x}, \bar{y}, \bar{\alpha}) \end{bmatrix}$$

has full row rank and there exist vectors $k \in \text{int}T_C(\bar{x}, D), h \in R^m$ such that

$$\begin{aligned}
&h_{I_+} = 0, h_Q = 0,\\
&\nabla_x \Psi_{I(\Psi)}(\bar{x}, \bar{y}, \bar{\alpha})k + \nabla_y \Psi_{I(\Psi)}(\bar{x}, \bar{y}, \bar{\alpha})h < 0,\\
&\nabla_x H(\bar{x}, \bar{y}, \bar{\alpha})k + \nabla_y H(\bar{x}, \bar{y}, \bar{\alpha})h = 0,\\
&\nabla_x F_{L\cup P}(\bar{x}, \bar{y}, \bar{\alpha})k + \nabla_y F_{L\cup P}(\bar{x}, \bar{y}, \bar{\alpha})h = 0,
\end{aligned}$$

where $A := \{1, \ldots, l\}$, $T_C(\bar{x}, D)$ denotes the Clarke tangent cone of D at $\bar{x}$, and $I(\Psi) := \{i : \Psi_i(\bar{x}, \bar{y}) = 0\}$ is the index set of the binding inequality constraints.

In [23, Proposition 4.5] it was proved that the generalized Mangasarian–Fromovitz constraint qualification implies that the only abnormal CD multiplier is the zero vector. Hence Theorem 4.4 has the following consequence.

COROLLARY 4.5. *In addition to the assumptions of Theorem* 4.4*, if the generalized Mangasarian–Fromovitz constraint qualification as defined above is satisfied for* OPCC($\bar{\alpha}$)*, then $V(\alpha)$ is finite and Lipschitz near $\bar{\alpha}$.*

Another sufficient condition for $M^0_{CD}(\Sigma(\bar{\alpha})) = \{0\}$ is the strong regularity condition in the sense of Robinson [17]. For OPCC ($\bar{\alpha}$), the strong regularity condition has the following form according to [17, Theorem 3.1].

COROLLARY 4.6. *In addition to the assumptions of Theorem* 4.4*, assume that $C = D \times R^m$ for some $D \subseteq R^n$, that there are no inequality constraints, and that the following conditions are satisfied:*

(i) *the matrix*

$$\begin{bmatrix} \nabla_y H_{A,L}(\bar{x}, \bar{y}, \bar{\alpha}) \\ \nabla_y F_{L,L}(\bar{x}, \bar{y}, \bar{\alpha}) \end{bmatrix}$$

is nonsingular, where $A := \{1, \ldots, l\}$;

(ii) *the Schur complement of the above matrix in the matrix*

$$\begin{bmatrix} \nabla_y H_{A,L}(\bar{x}, \bar{y}, \bar{\alpha}) & \nabla_y H_{A,I_0}(\bar{x}, \bar{y}, \bar{\alpha}) \\ \nabla_y F_{L,L}(\bar{x}, \bar{y}, \bar{\alpha}) & \nabla_y F_{L,I_0}(\bar{x}, \bar{y}, \bar{\alpha}) \\ \nabla_y F_{I_0,L}(\bar{x}, \bar{y}, \bar{\alpha}) & \nabla_y F_{I_0,I_0}(\bar{x}, \bar{y}, \bar{\alpha}) \end{bmatrix}$$

has positive principle minors;

then $V(\alpha)$ is finite and Lipschitz near $\bar{\alpha}$.

4.3. Sensitivity analysis of the value function via C multipliers. It is easy to see that OPCC $(\bar{\alpha})$ can be formulated as the following optimization problem with a nonsmooth equation:

$$\begin{array}{lll} \text{OPCC}(\bar{\alpha}) & \text{minimize} & f(x,y,\alpha) \\ & \text{subject to} & \Psi(x,y,\alpha) \le 0, H(x,y,\alpha) = 0, (x,y) \in C, \\ & & \min\{y_i, F_i\}(x,y,\alpha) = 0, \qquad i = 1,2,\ldots,m. \end{array} \tag{21}$$

It can be shown as in Scheel and Scholtes [19, Lemma 1] that a solution of the OPCC is C stationary defined as follows.

DEFINITION 4.7 (C multipliers). *Let $(\bar{x},\bar{y})$ be a feasible point of the* OPCC. *The point $(\bar{x},\bar{y})$ is C stationary if there exist vectors $(\gamma,\beta,\eta,\xi) \in R^d \times R^l \times R^m \times R^m$ satisfying* (14)–(17) *and*

$$\xi_i \eta_i \ge 0 \qquad \text{if } \bar{y}_i = 0 \text{ and } F_i(\bar{x},\bar{y},\bar{\alpha}) = 0.$$

The set of vectors (γ,β,η) satisfying the above condition for some ξ is called the index λ C multiplier set and is denoted by $M_C^{\lambda}(\bar{x},\bar{y})$.

THEOREM 4.8. *Assume that there exists $\delta > 0$ such that the set*

$$\begin{aligned} \{(x,y) \in C :& (p,q,q^m) \in B(0;\delta), \Psi(x,y,\bar{\alpha}) \le p, H(x,y,\bar{\alpha}) = q, \\ & \min\{y_i, F_i(x,y,\bar{\alpha})\} = q_i^m, i = 1,\ldots,m, f(x,y,\bar{\alpha}) \le M\} \end{aligned}$$

is bounded for each M. Then the value function V is lower semicontinuous near $\bar{\alpha}$ and

$$\begin{aligned} \partial V(\bar{\alpha}) \subseteq \bigcup_{(\bar{x},\bar{y}) \in \Sigma(\bar{\alpha})} & \{\nabla_\alpha f(\bar{x},\bar{y},\bar{\alpha}) + \nabla_\alpha \Psi(\bar{x},\bar{y},\bar{\alpha})^\top \gamma + \nabla_\alpha H(\bar{x},\bar{y},\bar{\alpha})^\top \beta \\ & + \nabla_\alpha F(\bar{x},\bar{y},\bar{\alpha})^\top \eta : (\gamma,\beta,\eta) \in M_C^1(\bar{x},\bar{y})\}, \end{aligned} \tag{22}$$

$$\begin{aligned} \partial^\infty V(\bar{\alpha}) \subseteq \bigcup_{(\bar{x},\bar{y}) \in \Sigma(\bar{\alpha})} & \{\nabla_\alpha \Psi(\bar{x},\bar{y},\bar{\alpha})^\top \gamma + \nabla_\alpha H(\bar{x},\bar{y},\bar{\alpha})^\top \beta \\ & + F(\bar{x},\bar{y},\bar{\alpha})^\top \eta : (\gamma,\beta,\eta) \in M_C^0(\bar{x},\bar{y})\}. \end{aligned} \tag{23}$$

If the set in the right-hand side of inclusion (23) *contains only the zero vector, then the value function V is Lipschitz near $\bar{\alpha}$. If the set in the right-hand side of inclusion* (23) *contains only the zero vector and the set in the right-hand side of inclusion* (22) *is a singleton, then the value function is strictly differentiable at $\bar{\alpha}$.*

Proof. By Theorem 3.6, since the growth assumption is satisfied, the value function is lower semicontinuous near $\bar{\alpha}$ and

$$\begin{aligned} \partial V(\bar{\alpha}) &\subseteq \bigcup_{(\bar{x},\bar{y}) \in \Sigma(\bar{\alpha})} \{-\zeta : (\gamma,\eta,\zeta) \in M^1(\bar{x},\bar{y},\bar{\alpha})\}, \\ \partial^\infty V(\bar{\alpha}) &\subseteq \bigcup_{(\bar{x},\bar{y}) \in \Sigma(\bar{\alpha})} \{-\zeta : (\gamma,\eta,\zeta) \in M^0(\bar{x},\bar{y},\bar{\alpha})\}, \end{aligned}$$

where $M^\lambda(\bar{x},\bar{y},\bar{\alpha})$ is the set of vectors $(\gamma,\beta,r,\zeta) \in R^{d+l+m+c}$ such that

$$\begin{aligned} 0 \in{}& \lambda \nabla f(\bar{x},\bar{y},\bar{\alpha}) + \nabla \Psi(\bar{x},\bar{y},\bar{\alpha})^\top \gamma + \nabla H(\bar{x},\bar{y},\bar{\alpha})^\top \beta \\ & + \partial \sum_{i=1}^m r_i \min\{y_i, F_i\}(\bar{x},\bar{y},\bar{\alpha}) + \{(0,0,\zeta)\} + N_C(\bar{x},\bar{y}) \times \{0\}, \\ \gamma \ge 0, & \langle \gamma, \Psi \rangle (\bar{x},\bar{y},\bar{\alpha}) = 0. \end{aligned}$$

Note that, in the above, ∇f denotes the gradient of a function f with respect to (x, y, α). Since

$$\partial \sum_{i=1}^{m} r_i \min\{y_i, F_i\}(\bar{x}, \bar{y}, \bar{\alpha}) \subseteq \sum_{i=1}^{m} r_i \partial_C \min\{y_i, F_i\}(\bar{x}, \bar{y}, \bar{\alpha})$$

and

$$\partial_C \min\{y_i, F_i\}(\bar{x}, \bar{y}, \bar{\alpha}) = \begin{cases} (0, e_i, 0) & \forall i \in I_+, \\ \nabla F_i(\bar{x}, \bar{y}, \bar{\alpha}) & \forall i \in L, \\ \{t(0, , e_i, 0) + (1-t)\nabla F_i(\bar{x}, \bar{y}, \bar{\alpha}) : t \in [0,1]\} & \forall i \in I_0, \end{cases}$$

where e_i is the unit vector whose ith component is 1 and those other components are zero, there exist γ, β, η such that

$$\zeta = \lambda \nabla_\alpha f(\bar{x}, \bar{y}, \bar{\alpha}) + \nabla_\alpha \Psi(\bar{x}, \bar{y}, \bar{\alpha})^\top \gamma + \nabla_\alpha H(\bar{x}, \bar{y}, \bar{\alpha})^\top \beta + \nabla_\alpha F(\bar{x}, \bar{y}, \bar{\alpha})^\top \eta$$

and

$$\begin{aligned} 0 \in\ & \lambda \nabla f(\bar{x}, \bar{y}, \bar{\alpha}) + \nabla \Psi(\bar{x}, \bar{y}, \bar{\alpha})^\top \gamma + \nabla H(\bar{x}, \bar{y}, \bar{\alpha})^\top \beta + \nabla F(\bar{x}, \bar{y}, \bar{\alpha})^\top \eta \\ & + (0, \xi) + N_C(\bar{x}, \bar{y}), \\ & \gamma \geq 0, \langle \Psi, \gamma \rangle (\bar{x}, \bar{y}, \bar{\alpha}) = 0, \end{aligned}$$

where

$$\begin{array}{ll} \eta_i = 0 & \forall i \in I_+, \\ \xi_i = 0 & \forall i \in L, \\ \eta_i = r_i(1 - \bar{t}_i), \xi_i = r_i \bar{t}_i \text{ for some } \bar{t}_i \in [0,1], & \forall i \in I_0. \end{array}$$

It is then easy to see that

$$\forall i \in I_0, \eta_i \xi_i \geq 0.$$

Hence (γ, β, η) is a C multiplier, and the proof of the theorem is complete. □

4.4. Sensitivity analysis via P multipliers and S multipliers. Taking the "piecewise programming" approach, for any given index set $\nu \subseteq I := \{1, \ldots, m\}$, we consider the subproblem associated with ν:

$$\begin{array}{lll} \text{OPCC}(\alpha)_\nu & \text{minimize} & f(x, y, \alpha) \\ & \text{subject to} & \Psi(x, y, \alpha) \leq 0, H(x, y, \alpha) = 0, (x, y) \in C, \\ & & y_i \geq 0,\ F_i(x, y, \alpha) = 0 \quad \forall i \in \nu \\ & & y_i = 0,\ F_i(x, y, \alpha) \geq 0 \quad \forall i \in I \backslash \nu. \end{array}$$

As suggested by referee 2, since the value function is the minimum of the value functions for the subproblems, i.e.,

$$V(\alpha) = \min_{\nu \subset I} V_\nu(\alpha)$$

and

$$V(\bar{\alpha}) = V_\nu(\bar{\alpha})\ \forall \nu = L(\bar{x}, \bar{y}) \cup \sigma, \sigma \subseteq I_0(\bar{x}, \bar{y}), (\bar{x}, \bar{y}) \in \Sigma(\bar{\alpha}),$$

applying the calculus for the minimum functions in Proposition 2.7, we conclude that the value function V is lower semicontinuous if each $V_\nu(\alpha), \nu = L(\bar{x},\bar{y}) \cup \sigma, \sigma \subseteq I_0(\bar{x},\bar{y}), (\bar{x},\bar{y}) \in \Sigma(\bar{\alpha})$, is lower semicontinuous and the following inclusion holds:

$$\partial^\infty V(\bar{\alpha}) \subseteq \{\partial^\infty V_\nu(\bar{\alpha}) : \nu = L(\bar{x},\bar{y}) \cup \sigma, \sigma \subseteq I_0(\bar{x},\bar{y}), (\bar{x},\bar{y}) \in \Sigma(\bar{\alpha})\}, \tag{24}$$

$$\partial V(\bar{\alpha}) \subseteq \{\partial V_\nu(\bar{\alpha}) : \nu = L(\bar{x},\bar{y}) \cup \sigma, \sigma \subseteq I_0(\bar{x},\bar{y}), (\bar{x},\bar{y}) \in \Sigma(\bar{\alpha})\}. \tag{25}$$

The Fritz John condition for the subproblem $\mathrm{OPCC}(\bar{\alpha})_\nu$ with

$$\nu = L(\bar{x},\bar{y}) \cup \sigma, \sigma \subseteq I_0(\bar{x},\bar{y}), (\bar{x},\bar{y}) \in \Sigma(\bar{\alpha})$$

implies the existence of vectors $(\gamma,\beta,\eta,\xi) \in R^d \times R^a \times R^b \times R^b$ satisfying (14)–(17) and

$$\xi_\sigma \le 0, \eta_{I_0\setminus\sigma} \le 0. \tag{26}$$

Definition 4.9 (P multipliers). *The set of all vectors (γ,β,η) satisfying the above Fritz John condition at $(\bar{x},\bar{y})$ is denoted by $M^\lambda_\sigma(\bar{x},\bar{y})$, and $\bigcup_{\sigma\subseteq I_0} M^\lambda_\sigma(\bar{x},\bar{y})$ is called the set of P multipliers.*

Applying Corollary 3.8, we have the following result.

Proposition 4.10. *For any $(\bar{x},\bar{y}) \in \Sigma(\bar{\alpha})$ and any given index set $\sigma \subseteq I_0(\bar{x},\bar{y})$, assume that there exists $\delta > 0$ such that the set*

$$\begin{aligned}\{(x,y) \in C :&(p,q,q^y,q^F,) \in B(0;\delta), \Psi(x,y,\bar{\alpha}) \le p, H(x,y,\bar{\alpha}) = q,\\ &y_i \ge q^y_i,\ F_i(x,y,\bar{\alpha}) = q^F_i \quad \forall i \in \nu := \sigma \cup L(\bar{x},\bar{y}),\\ &y_i = q^y_i,\ F_i(x,y,\bar{\alpha}) \ge q^F_i \quad \forall i \in I\setminus\nu, f(x,y,\bar{\alpha}) \le M\}\end{aligned}$$

is bounded for each M. Then the value function for subproblem $\mathrm{OPCC}(\bar{\alpha})_\nu$ with $\nu = L(\bar{x},\bar{y}) \cup \sigma$ is lower semicontinuous near $\bar{\alpha}$ and

$$\begin{aligned}\partial V_\nu(\bar{\alpha}) \subseteq \bigcup_{(\bar{x},\bar{y})\in\Sigma_\nu(\bar{\alpha})} &\{\nabla_\alpha f(\bar{x},\bar{y},\bar{\alpha}) + \nabla_\alpha \Psi(\bar{x},\bar{y},\bar{\alpha})^\top \gamma + \nabla_\alpha H(\bar{x},\bar{y},\bar{\alpha})^\top \beta\\ &+\nabla_\alpha F(\bar{x},\bar{y},\bar{\alpha})^\top \eta : (\gamma,\beta,\eta) \in M^1_\sigma(\bar{x},\bar{y})\},\\ \partial^\infty V_\nu(\bar{\alpha}) \subseteq \bigcup_{(\bar{x},\bar{y})\in\Sigma_\nu(\bar{\alpha})} &\{\nabla_\alpha \Psi(\bar{x},\bar{y},\bar{\alpha})^\top \gamma + \nabla_\alpha H(\bar{x},\bar{y},\bar{\alpha})^\top \beta\\ &+\nabla_\alpha F(\bar{x},\bar{y},\bar{\alpha})^\top \eta : (\gamma,\beta,\eta) \in M^0_\sigma(\bar{x},\bar{y})\},\end{aligned}$$

where $\Sigma_\nu(\bar{\alpha})$ denotes the set of solutions for the subproblem $\mathrm{OPCC}\ (\alpha)_\nu$.

We have the following estimates for the value function in terms of P multipliers.

Theorem 4.11. *Assume that there exists $\delta > 0$ such that for $(\bar{x},\bar{y}) \in \Sigma(\bar{\alpha})$ and each index set $\sigma \subseteq I_0(\bar{x},\bar{y})$, the set in Proposition 4.10 is bounded for each M. Then the value function V is lower semicontinuous near $\bar{\alpha}$ and*

$$\begin{aligned}\partial V(\bar{\alpha}) \subseteq \bigcup_{(\bar{x},\bar{y})\in\Sigma(\bar{\alpha})} &\{\nabla_\alpha f(\bar{x},\bar{y},\bar{\alpha}) + \nabla_\alpha \Psi(\bar{x},\bar{y},\bar{\alpha})^\top \gamma + \nabla_\alpha H(\bar{x},\bar{y},\bar{\alpha})^\top \beta\\ &+\nabla_\alpha F(\bar{x},\bar{y},\bar{\alpha})^\top \eta : (\gamma,\beta,\eta) \in \cup_{\sigma\subseteq I_0} M^1_\sigma(\bar{x},\bar{y})\},\end{aligned} \tag{27}$$

$$\begin{aligned}\partial^\infty V(\bar{\alpha}) \subseteq \bigcup_{(\bar{x},\bar{y})\in\Sigma(\bar{\alpha})} &\{\nabla_\alpha \Psi(\bar{x},\bar{y},\bar{\alpha})^\top \gamma + \nabla_\alpha H(\bar{x},\bar{y},\bar{\alpha})^\top \beta\\ &+\nabla_\alpha F(\bar{x},\bar{y},\bar{\alpha})^\top \eta : (\gamma,\beta,\eta) \in \cup_{\sigma\subseteq I_0} M^0_\sigma(\bar{x},\bar{y})\}.\end{aligned} \tag{28}$$

If the set in the right-hand side of inclusion (28) *contains only the zero vector, then the value function V is Lipschitz near $\bar{\alpha}$. If the set in the right-hand side of inclusion* (28) *contains only the zero vector and the set in the right-hand side of inclusion* (27) *is a singleton, then the value function is strictly differentiable at $\bar{\alpha}$.*

DEFINITION 4.12 (S multipliers). *The set of index λ S multipliers, denoted by $M_S^{\lambda}(\bar{x},\bar{y})$, is the set of all vectors $(\gamma,\beta,\eta) \in R^d \times R^a \times R^b$ satisfying* (14)–(17) *and*

$$\xi_i \le 0, \eta_i \le 0 \qquad \text{if } \bar{y}_i = 0 \text{ and } F_i(\bar{x},\bar{y},\bar{\alpha}) = 0.$$

In the following theorem, we give a condition under which the set of P multipliers and S multipliers coincide, and so we have the estimates in terms of the S multipliers.

THEOREM 4.13. *In addition to the assumptions of Theorem* 4.11*, assume that $C = R^n \times R^a \times R^b$ and for all $(\bar{x},\bar{z},\bar{u}) \in \Sigma(\bar{\alpha})$, the partial MPEC linear independence constraint qualification is satisfied, i.e.,*

$$\begin{cases} 0 = \nabla\Psi(\bar{x},\bar{y},\bar{\alpha})^{\top}\gamma + \nabla H(\bar{x},\bar{y},\bar{\alpha})^{\top}\beta + \nabla F(\bar{x},\bar{y},\bar{\alpha})^{\top}\eta + (0,0,\xi), \\ \gamma_{J(\Psi)} = 0,\ \eta_{I_+} = 0,\ \xi_L = 0, \end{cases}$$

implies that $\eta_{I_0} = 0, \xi_{I_0} = 0$, where $J(\Psi) := \{i : \Psi_i(\bar{x},\bar{y},\bar{\alpha}) < 0\}$. Then the value function V is lower semicontinuous near $\bar{\alpha}$ and

$$\begin{aligned} \partial V(\bar{\alpha}) \subseteq \bigcup_{(\bar{x},\bar{y})\in\Sigma(\bar{\alpha})} & \{\nabla_\alpha f(\bar{x},\bar{y},\bar{\alpha}) + \nabla_\alpha\Psi(\bar{x},\bar{y},\bar{\alpha})^{\top}\gamma + \nabla_\alpha H(\bar{x},\bar{y},\bar{\alpha})^{\top}\beta \\ & + \nabla_\alpha F(\bar{x},\bar{y},\bar{\alpha})^{\top}\eta : (\gamma,\beta,\eta) \in M_S^1(\bar{x},\bar{y})\}, \\ \partial^\infty V(\bar{\alpha}) \subseteq \bigcup_{(\bar{x},\bar{y})\in\Sigma(\bar{\alpha})} & \{\nabla_\alpha\Psi(\bar{x},\bar{y},\bar{\alpha})^{\top}\gamma + \nabla_\alpha H(\bar{x},\bar{y},\bar{\alpha})^{\top}\beta \\ & + \nabla_\alpha F(\bar{x},\bar{y},\bar{\alpha})^{\top}\eta : (\gamma,\beta,\eta) \in M_S^0(\bar{x},\bar{y})\}. \end{aligned}$$

Remark. As in the proof of [22, Theorem 3.2], it is easy to see that under the partial MPEC linear independence constraint qualification, all multipliers including the S multiplier, the CD multiplier, the C multiplier, and the P multiplier coincide.

Recently, the MPEC linear independence constraint qualifications have received a lot of attention. It is known that under the MPEC linear independence constraint qualification, the computation of the OPCC is much easier and more efficient (see, e.g., Scholtes [20]). Furthermore, it was shown in Scholtes [21] that the MPEC linear independence constraint qualification is a generic condition for the OPCC. Here we prove the importance of the MPEC linearly independence constraint qualification from the aspect of the sensitivity analysis: the value function is Lipschitz continuous, and it is even strictly differentiable in the case where the optimal solution set is unique. Note that the MPEC linear independence constraint qualification is stronger than the partial MPEC linear independence constraint qualification.

COROLLARY 4.14. *In addition to the assumptions of Theorem* 4.11*, assume that the MPEC linear independence constraint qualifications are satisfied at all $(\bar{x},\bar{y}) \in \Sigma(\bar{\alpha})$, i.e.,*

$$\begin{cases} 0 = \nabla\Psi(\bar{x},\bar{y},\bar{\alpha})^{\top}\gamma + \nabla H(\bar{x},\bar{y},\bar{\alpha})^{\top}\beta + \nabla F(\bar{x},\bar{y},\bar{\alpha})^{\top}\eta + (0,0,\xi), \\ \gamma_{J(\Psi)} = 0, \eta_{I_+} = 0, \xi_L = 0, \end{cases}$$

implies that $\gamma = 0, \beta = 0, \eta = 0, \xi = 0$. Then the value function is Lipschitz continuous near $\bar{\alpha}$. Furthermore, if the set of optimal solutions $\Sigma(\bar{\alpha})$ is a singleton, then the value function V is strictly differentiable at $\bar{\alpha}$.

Proof. The MPEC linear independence constraint qualification obviously implies that $M_S^0(\bar{x},\bar{y}) = \{0\}$ and $M_S^1(\bar{x},\bar{y})$ is a singleton. Hence the conclusion follows from Theorem 4.13 and Proposition 2.4. □

4.5. Relationships between the multipliers for the OPCC. Applying the definitions, it is clear that

$$M_S^\lambda(\bar{x},\bar{y}) \subseteq M_{CD}^\lambda(\bar{x},\bar{y}) \subseteq M_C^\lambda(\bar{x},\bar{y}), \qquad M_S^\lambda(\bar{x},\bar{y}) \subseteq M_P^\lambda(\bar{x},\bar{y}). \tag{29}$$

It is not possible to compare the set of NLP multipliers directly with the other multipliers since the spaces they belong to have different dimensions. However, the following interesting relationships can be obtained.

PROPOSITION 4.15 (relationship between an NLP multiplier and an S multiplier).

$$\{(\gamma,\beta,\mu\bar{y}-r^F) : (\gamma,\beta,r^F,r^y,\mu) \in M_{NLP}^\lambda(\bar{x},\bar{y})\} \subseteq M_S^\lambda(\bar{x},\bar{y})$$

for all $\lambda \geq 0$.

Proof. Let $(\gamma,\beta,r^F,r^y,\mu) \in M_{NLP}^\lambda(\bar{x},\bar{y})$. We consider the following cases.

Case $\bar{y}_i > 0, F_i(\bar{x},\bar{y}) = 0$. Then $r_i^y = 0$. So $\xi_i := \mu F_i - r_i^y = 0$.

Case $\bar{y}_i = 0, F_i(\bar{x},\bar{y}) > 0$. Then $r_i^F = 0$. So $\eta_i = \mu\bar{y}_i - r_i^F = 0$.

Case $\bar{y}_i = 0, F_i(\bar{x},\bar{y}) = 0]$. Then $\xi_i = \mu F_i(\bar{x},\bar{y}) - r_i^y = -r_i^y$ and $\eta_i = \mu\bar{y}_i - r_i^F = -r_i^F$. So $\xi_i = -r_i^y \leq 0$ and $\eta_i = -r_i^F \leq 0$.

Hence (γ,β,η), where $\eta := \mu\bar{y} - r^F$, is an S multiplier, and the proof of the proposition is complete. □

The above relationship indicates that one can arrange the upper estimates of the limiting subdifferentials in Theorems 4.2, 4.13, 4.4, and 4.8 from the smallest to the largest in the order of NLP multipliers, S multipliers, CD multipliers, and C multipliers.

One may try to use the smallest multiplier set in sensitivity analysis. However, the smaller multipler sets tend to require stronger constraint qualifications and hence may be empty. In such a case, where the smaller multipler set is empty, one may have to use the larger multiplier set.

We now use the following example to show that in some cases the smaller multiplier sets such as the NLP and the S multiplier sets may be empty while the CD multiplier provides the tightest bound.

Example. Consider the OPCC

$$(P) \qquad \begin{aligned} \text{minimize} \quad & -y \\ \text{subject to} \quad & x - y = 0, \\ & x \geq 0, y \geq 0, xy = 0, \end{aligned}$$

where $x \in R$ and $y \in R$, and its perturbed problem

$$P(q,r) \qquad \begin{aligned} \text{minimize} \quad & -y \\ \text{subject to} \quad & x - y = q, \\ & x - r \geq 0, y \geq 0, (x-r)y = 0, \end{aligned}$$

which is OPCC (α) with $\alpha = (q,r), f = -y, H = x - y - q, F = x - r$. Let $\bar{\alpha} = (0,0)$. It is clear that the only feasible solution for problem $(P) = P(0,0)$ is $(0,0)$. Hence the only optimal solution for *(P)* is $(0,0)$. The set of index λ NLP multipliers (β, r^y, r^F, μ)

at $(0,0)$ satisfy

$$\begin{cases} 0 = \lambda(0,-1) + \beta(1,-1) - (r^F, 0) - (0, r^y) + \mu(0,0), \\ r^F, r^y \geq 0. \end{cases}$$

It is clear that any $(\beta, r^y, r^F, \mu) = (0,0,0,\mu)$ with $\mu \neq 0$ is a nonzero NLP abnormal multiplier and there is no NLP normal multiplier. Hence $M^0_{NLP}(0,0) = \{(0,0,0)\} \times (-\infty, +\infty) \neq \{(0,0,0,0)\}$ and $M^1_{NLP}(0,0) = \emptyset$.

Since $\bar{y} = 0$ and $F(\bar{x}, \bar{y}, 0) = \bar{x} = 0$, the index λ CD multipliers (β, η) at $(0,0)$ satisfy

$$\begin{aligned} &0 = \lambda(0,-1) + \beta(1,-1) + \eta(1,0) + (0,\xi), \\ &\text{either } \xi < 0, \eta < 0, \text{ or } \xi\eta = 0. \end{aligned}$$

When $\lambda = 0$, the above condition implies that $\beta = \eta = \xi = 0$, while when $\lambda = 1$, either $\eta = 1, \beta = -1, \xi = 0$, or $\beta = \eta = 0, \xi = 1$. So $M^1_{CD}(0,0) = \{(0,0)\} \cup \{(-1,1)\}$ and $M^0_{CD}(0,0) = \{(0,0)\}$.

The set of index λ C multipliers (β, η) at $(0,0)$ satisfy

$$\begin{aligned} &0 = \lambda(0,-1) + \beta(1,-1) + \eta(1,0) + (0,\xi), \\ &\xi\eta \geq 0. \end{aligned}$$

When $\lambda = 0$, the above condition implies that $\beta = \eta = \xi = 0$, while for $\lambda = 1$, $-\beta = \eta \in [0,1]$. So $M^1_C(0,0) = \{(\beta, \eta) : \eta = -\beta \in [0,1]\}$ and $M^0_C(0,0) = \{(0,0)\}$.

Since the optimal solution for (P) is $(\bar{x}, \bar{y}) = (0,0)$, $(0,0)$ is also optimal for the subproblem associated with $\nu = \{1\}$,

$$\begin{aligned} (P_1) \qquad & \text{minimize} && -y \\ & \text{subject to} && x - y = 0, \\ & && y \geq 0, x = 0, \end{aligned}$$

and the subproblem associated with $\nu = \emptyset$,

$$\begin{aligned} (P_2) \qquad & \text{minimize} && -y \\ & \text{subject to} && x - y = 0, \\ & && y = 0, x \geq 0. \end{aligned}$$

The index λ multiplier set for (P_1) consists of vectors (β, η) satisfying

$$\begin{cases} 0 = \lambda(0,-1) + \beta(1,-1) + \eta(1,0) + (0,\xi), \\ \xi \leq 0, \end{cases}$$

and the index λ multiplier set for (P_2) consist of vectors (β, η) satisfying

$$\begin{cases} 0 = \lambda(0,-1) + \beta(1,-1) + \eta(1,0) + (0,\xi), \\ \eta \leq 0. \end{cases}$$

Therefore, the abnormal P multiplier set is

$$\begin{aligned} M^0_P(0,0) = M^0_1(0,0) \cup M^0_2(0,0) &= \{(\beta,\eta) : \beta = -\eta \leq 0\} \cup \{(\beta,\eta) : \beta = -\eta \geq 0\} \\ &= \{(\beta,\eta) : \beta = -\eta\}, \end{aligned}$$

and the normal P multiplier set is

$$\begin{aligned} M_P^1(0,0) = M_1^1(0,0) \cup M_2^1(0,0) &= \{(\beta,\eta) : \beta = -\eta \le -1\} \cup \{(\beta,\eta) : \beta = -\eta \ge 0\} \\ &= \{(\beta,\eta) : \beta = -\eta \in (-\infty,-1] \cup [0,\infty)\}. \end{aligned}$$

The index λ S multiplier set consists of vectors (β,η) satisfying

$$\begin{cases} 0 = \lambda(0,-1) + \beta(1,-1) + \eta(1,0) + (0,\xi), \\ \xi \le 0, \eta \le 0, \end{cases}$$

i.e.,

$$\begin{aligned} &\beta = -\eta,\ \beta = -\lambda + \xi, \\ &\xi \le 0,\ \eta \le 0. \end{aligned}$$

That is, $M_S^0(0,0) = \{0\}$, and $M_S^1(0,0) = \emptyset$.

Consider the value function

$$V(q,r) := \inf\{-y : x - r \ge 0, y \ge 0, (x-r)y = 0, x - y = q\}.$$

Then by Theorem 4.4, since the only abnormal CD multiplier is the zero vector, we conclude that the value function is Lipschitz near $(0,0)$, and

$$\begin{aligned} \emptyset \ne \partial V(0,0) &\subseteq \{\beta(-1,0) + \eta(0,-1) : (\beta,\eta) \in M_{CD}^1(0,0)\} \\ &= -M_{CD}^1(0,0) = \{(0,0)\} \cup \{(1,-1)\}. \end{aligned}$$

In fact, we can easily find the expression for the value function for this simple example since the feasible set of the perturbed problem $P(q,r)$ still reduces to one point. Indeed, we have

$$\begin{cases} \Sigma(q,r) = \{(r, r-q)\} \text{ and } V(q,r) = q - r & \text{if } q < r, \\ \Sigma(q,r) = \{(q,0)\} \text{ and } V(q,r) = 0 & \text{if } q \ge r. \end{cases}$$

So $V(q,r) = \min(0, q-r)$, which is Lipschitz continuous everywhere. By definition of the limiting subdifferentials, it is easy to see that

$$\begin{aligned} \partial V(0,0) &= \{(0,0)\} \cup \{(1,-1)\}, \\ \partial^\infty V(0,0) &= \{(0,0)\}. \end{aligned}$$

Therefore, the inclusions in Theorem 4.4 are actually equalities here, i.e.,

$$\begin{aligned} \partial V(0,0) &= \{(0,0)\} \cup \{(1,-1)\} = -M_{CD}^1(0,0), \\ \partial^\infty V(0,0) &= \{(0,0)\} = -M_{CD}^0(0,0). \end{aligned}$$

Using Theorem 4.8, since the only abnormal C multiplier is the zero vector, one also concludes that the value function is Lipschitz. However, the upper estimate for the limiting subdifferentials of the value function in terms of the C multiplier set is a strict inclusion here:

$$\begin{aligned} \partial V(0,0) &= \{(0,0)\} \cup \{(1,-1)\} \subset \{(\beta,\eta) : \beta = -\eta \in [0,1]\} = -M_C^1(0,0), \\ \partial^\infty V(0,0) &= \{(0,0)\} = -M_{CD}^0(0,0). \end{aligned}$$

The upper estimate for both the limiting and the singular limiting subdifferentials of the value function in Theorem 4.11 are both strict:

$$\begin{aligned}\partial V(0,0) &= \{(0,0)\} \cup \{(1,-1)\} \\ &\subset \{(\beta,\eta) : \beta = -\eta \in (-\infty, 0] \cup (1,\infty)\} = -M_P^1(0,0), \\ \partial^\infty V(0,0) &= \{(0,0)\} \\ &\subset \{(\beta,\eta) : \beta = -\eta\} = -M_P^0(0,0).\end{aligned}$$

These inclusions are not very helpful since the Lipschitz continuity of the value function cannot be detected and the upper estimate is unbounded.

Since there is no S multiplier for this problem, the limiting subdifferential of the value function cannot be estimated in terms of the S multiplier. In fact, the assumptions in Theorem 4.13 are not satisfied for this problem. Indeed,

$$(0,0) = \beta(1,-1) + \eta(1,0) + (0,\xi)$$

does not imply that $\eta = 0, \xi = 0$.

Note that by Theorem 4.2, if the growth hypotheses were satisfied, then

$$\begin{aligned}\partial V(0,0) &\subseteq \{\beta(-1,0) - r^F(0,-1) : (\beta, r^F, r^y, \mu) \in M_{NLP}^1(\Sigma)\}, \\ \partial^\infty V(0,0) &\subseteq \{\beta(-1,0) - r^F(0,-1) : (\beta, r^F, r^y, \mu) \in M_{NLP}^0(\Sigma)\}.\end{aligned}$$

But this is not possible since $M_{NLP}^1(\Sigma) = \emptyset$. Indeed, (GH) is not satisfied for this example.

In the above example, $M_{NLP}^0(\Sigma) \neq \{0\}$, while $M_{CD}^0(\Sigma) = \{0\}$. In fact, it is not just a coincidence that $M_{NLP}^0(\Sigma) \neq \{0\}$. In general, the Mangasarian–Fromovitz constraint qualification satisfying at a feasible solution $(\bar{x}, \bar{z}, \bar{u})$ implies that $M_{NLP}^0((\bar{x}, \bar{z}, \bar{u})) = \{0\}$, and in the case of no abstract constraint, the two conditions are equivalent (see, e.g., [6] and [25, Proposition 4.5] for details). It is well known that in the case of no abstract constraint, the Mangasarian–Fromovitz constraint qualification fails to hold at every feasible point of the OPCCs. (The proof for the case where the complementarity constraint comes from the KKT condition of a lower level quadratic programming problem was given in Chen and Florian [1, Lemma 3.1], and the proof for the general case was given in [25, Proposition 1.1].) We now prove that even for the case when the abstract constraint set C is present, there always exist nonzero abnormal NLP multipliers for the OPCC.

PROPOSITION 4.16. *Let $(\bar{x}, \bar{y}) \in R^{n+m}$ be any feasible solution of the* OPCC. *Then $M_{NLP}^0(\bar{x}, \bar{y}) \backslash \{0\} \neq \emptyset$.*

Proof. The point $(\bar{x}, \bar{y})$ is obviously a solution to the following optimization problem:

$$\begin{aligned}\text{minimize} \quad & \langle y, F(x,y)\rangle \\ \text{subject to} \quad & y \geq 0, F(x,y) \geq 0.\end{aligned}$$

By the multiplier rule, there exists $\mu \geq 0, r^y \in R_+^m, r^F \in R_+^m$ not all zero such that

$$\begin{aligned}&0 = \mu \nabla \langle y, F\rangle(\bar{x}, \bar{y}) - (0, r^y) - \nabla F(\bar{x}, \bar{y})^\top r^F, \\ &\langle \bar{y}, r^y\rangle = 0, \langle r^F, F(\bar{x}, \bar{y}) = 0.\end{aligned}$$

Therefore, taking $\gamma = 0, \beta = 0$ $(\gamma = 0, \beta = 0, r^F, r^y, \mu)$ is a nonzero NLP abnormal multiplier of the OPCC. □

4.6. Applications to the bilevel programming problem. One of the motivations to consider OPCCs is to solve the following bilevel programming problem:

$$\text{(BLPP)} \qquad \begin{array}{ll} \text{minimize} & f(x,z) \\ \text{subject to} & z \in S(x), \Psi(x,z) \le 0, (x,z) \in C, \end{array} \tag{30}$$

where $S(x)$ is the solution of the lower-level problem

$$P_x \qquad \begin{array}{ll} \text{minimize} & g(x,z) \\ \text{subject to} & \psi(x,z) \le 0, \end{array} \tag{31}$$

where $f : R^{n+a} \to R, g : R^{n+a} \to R, \psi : R^{n+a} \to R^b, \Psi : R^{n+a} \to R^d$. Under suitable convexity assumptions, we can replace the lower problem by its KKT conditions. As in [24], we find that any (x,z) is solution of (BLPP) if and only if there is u such that (x,z,u) is solution of the problem

$$\begin{array}{ll} \text{minimize} & f(x,z) \\ \text{subject to} & \psi(x,z) \le 0 \text{ and } u \ge 0, \\ & \langle \psi(x,z), u \rangle = 0, \\ & \nabla_z g(x,z) + \nabla_z \psi(x,z)^\top u = 0, \\ & \Psi(x,z) \le 0, (x,z) \in C, \end{array} \tag{32}$$

which is an OPCC.

Consider the perturbed bilevel programming problem

$$\text{BLPP}(\alpha) \quad \begin{array}{ll} \text{minimize} & f(x,z,\alpha) \\ \text{subject to} & z \in S(x,\alpha), \Psi(x,z,\alpha) \le 0, (x,z) \in C, \end{array} \tag{33}$$

where $S(x,\alpha)$ is the solution of the lower-level problem

$$\begin{array}{ll} \text{minimize} & g(x,z,\alpha) \\ \text{subject to} & \psi(x,z,\alpha) \le 0. \end{array} \tag{34}$$

Under suitable assumptions, BLPP(α) is equivalent to

$$\begin{array}{ll} \text{minimize} & f(x,z,\alpha) \\ \text{subject to} & \psi(x,z,\alpha) \le 0 \text{ and } u \ge 0, \\ & \langle \psi(x,z,\alpha), u \rangle = 0, \\ & \nabla_z g(x,z,\alpha) + \nabla_z \psi(x,z,\alpha)^T u = 0, \\ & \Psi(x,z,\alpha) \le 0, (x,z) \in C. \end{array} \tag{35}$$

Hence the results in this section allow us to derive the properties of the value function and compute the upper estimates of the limiting subdifferentials of V by the various kinds of multipliers for the above problem. For example, we can conclude that the value function is Lipschitz continuous when the strong second order sufficient condition and the linear independence of the binding constraints hold for the lower level problem. Indeed, in this case the corresponding generalized equation is strongly regular; hence the set of abnormal CD multipliers contains only the zero vector (see Ye [23, Theorem 5.1]).

Acknowledgments. The authors would like to thank the anonymous referees whose constructive suggestions led to the better presentation of the results and the consideration of the upper estimates in terms of various multipliers other than the CD multipliers in the last section.

A STATE-SPACE CALCULUS FOR RATIONAL PROBABILITY DENSITY FUNCTIONS AND APPLICATIONS TO NON-GAUSSIAN FILTERING*

BERNARD HANZON† AND RAIMUND J. OBER‡

Abstract. We propose what we believe to be a novel approach to performing calculations for rational density functions using state-space representations of the densities. By standard results from realization theory, a rational probability density function is considered to be the transfer function of a linear system with generally complex entries. The stable part of this system is positive-real, which we call the density summand. The existence of moments is investigated using the Markov parameters of the density summand. Moreover, explicit formulae are given for the existing moments in terms of these Markov parameters. Some of the main contributions of the paper are explicit state-space descriptions for products and convolutions of rational densities.

As an application which is of interest in its own right, the filtering problem is investigated for a linear time-varying system whose noise inputs have rational probability density functions. In particular, state-space formulations are derived for the calculation of the prediction and update equations. The case of Cauchy noise is treated as an illustrative example.

Key words. probability theory, realization theory for linear systems, non-Gaussian filtering, rational functions, linear algebra

1. Introduction.

We are going to consider the filtering problem for the first order system

$$x_{t+1} = f_t x_t + \eta_t,$$
$$y_t = h_t x_t + \epsilon_t,$$

$t = 0, 1, 2, \ldots$, where f_t, h_t are assumed to be known real numbers and, for ease of exposition, are assumed to be such that $f_t \neq 0$ and $h_t > 0$, $t \geq 0$. The noise sequences $\{\eta_t\}_{t\geq 0}$ and $\{\epsilon_t\}_{t\geq 0}$ are assumed to be mutually independent sequences of independent random variables whose probability density functions are rational. The initial state x_0 is also assumed to be a random variable which is independent of the noise sequences and also has a rational density. No assumption is made that any of the random variables are identically distributed.

This filtering problem with non-Gaussian noise has applications in econometrics, for example in the analysis of financial time series. Studies have shown that the quantities that are encountered there often do not admit a Gaussian distribution ([7], [5], and see also [12]), since these distributions have "heavy tails." As one of the consequences, higher order moments may not exist. It has therefore been proposed (see, e.g., [11]) that these distributions be modelled by rational densities, both because

they do have "heavy tails" and because of the richness of the class of distributions. Examples of rational probability densities which have been used in the literature are Cauchy densities and Student densities with odd number of degrees of freedom.

The state filtering problem is defined as the problem of finding the best estimate $\hat{x}_t$ of x_t for the quadratic loss function given knowledge of the distribution of x_0 and the values of $y_0, y_1, \ldots, y_t$. Since

$$\hat{x}_t = \int_{-\infty}^{\infty} xp(x)_{x_t|y_t,y_{t-1},\ldots,y_0} dx,$$

this estimate can be found if the conditional density $p_{x_t|y_t,y_{t-1},\ldots,y_0}$ of x_t is known and the first moment exists, given the measured values of $y_t, y_{t-1}, \ldots, y_0$ and knowledge of the distribution of x_0.

In principle, the calculation of the conditional densities is not difficult. The unnormalized conditional densities, denoted by ρ instead of p, are given by the following.

Update step. For $t = 0$,

$$\rho_{x_0|\mathcal{Y}_0}(x) = \rho_{x_0|y_0}(x) = \rho_{y_0|x}(y_0)\rho_{x_0}(x) = \rho_{\epsilon_0}(y_0 - h_0 x)\rho_{x_0}(x);$$

for $t \geq 1$,

$$\rho_{x_t|\mathcal{Y}_t}(x) = \rho_{y_t|x}(y_t)\rho_{x_t|\mathcal{Y}_{t-1}}(x) = \rho_{\epsilon_t}(y_t - h_t x)\rho_{x_t|\mathcal{Y}_{t-1}}(x),$$

$x \in \Re$.

Prediction step. For $t \geq 0$,

$$\rho_{x_{t+1}|\mathcal{Y}_t}(x) = (\rho_{f_t x_t|\mathcal{Y}_t} * \rho_{\eta_t})(x) = \int_{-\infty}^{\infty} \rho_{x_t|\mathcal{Y}_t}\left(\frac{\xi}{f_t}\right) \rho_{\eta_t}(x - \xi)\, d\xi, \quad x \in \Re.$$

Here we have set $\mathcal{Y}_t$ to be the collection of observations $y_t, y_{t-1}, \ldots, y_0$.

In [11] it was noted that the various probability densities occurring in the filtering problem are all rational functions if the noise variables and the initial state have rational probability densities and if explicit formulas are given. The practical problem in doing these calculations for large numbers of observations is that the conditional densities are fairly complicated to calculate. To alleviate this problem we propose the use of state-space techniques for these calculations. Since by assumption the initial state and the noise sequences have rational densities, this is indeed possible. For this purpose we are going to develop a "state-space calculus" for rational probability density functions. We believe that the use of linear system theory to analyze rational probability densities is novel and may be of relevance beyond the application to non-Gaussian filtering as discussed here. Since the approach is valid in general, we develop the state-space approach for general probability density functions as well as for conditional probability density functions.

Let ρ be a not necessarily normalized rational probability density, i.e., $\rho(x)$ is a rational function in the independent variable x, such that $\rho(x) \geq 0$, $x \in \Re$, and $0 < \int_{-\infty}^{\infty} \rho(x)dx < \infty$. This implies that ρ is *strictly proper*, i.e., $\lim_{|x|\to\infty} \rho(x) = 0$. To speak of a not necessarily normalized or unnormalized probability density function is an abuse of the standard notion of a probability density function, since this term implies that its integral is 1. For ease of notation we use the notion of a not necessarily normalized or unnormalized density function to imply that all properties of a density function are given, with the possible exception of the normalization of its integral.

By standard realization theory there exists a minimal state-space realization such that

$$\rho(x) = c(ixI - A)^{-1}b, \qquad x \in \Re.$$

In particular, we will present here state-space formulae for the translation, scaling, product, and convolution of rational probability density functions. Most of our results will be formulated in terms of state-space realizations for the density summand, which is defined to be the "stable" part of the probability density function. One reason for doing this is that in this way the dimensions of the realizations are typically half of what they would be otherwise. For actual implementations of our results, this could lead to significant computational advantages, in particular when repeated applications are necessary such as can be expected for the filtering case. Moreover, we will investigate the existence of moments from the state-space point of view and give state-space formulae for the existing moments in terms of the Markov parameters of the density summand. A major part of the investigation will be built on a careful analysis of the connections between impulse responses, transfer functions, and characteristic functions of the various objects. In a result that may be of independent interest, a state-space formula is given for the system whose impulse response is the product of impulse responses of two systems.

2. Notation and preliminaries. The symbol $\mathcal{C}$ stands for the complex field, and the symbol $\Re$ stands for the real field. If (A, b, c) is a linear state-space system, we also often use the notation $(\frac{A\,|\,b}{c\,|\,0})$. If M is a complex matrix, M^* denotes the adjoint matrix. If G is a rational function, G^* is defined by $G^*(s) = \overline{(G(-\bar{s}))}$, $s \in \mathcal{C}$. If G has the realization (A, b, c) (i.e., $G(s) = c(sI - A)^{-1}b$ for $s \in \mathcal{C}\backslash\sigma(A)$, where $\sigma(A)$ is the spectrum of A), then G^* has the realization $(-A^*, c^*, -b^*)$. We call a system (A, b, c) *stable* if all eigenvalues of A are in the open left half plane. Note that such systems are often also called asymptotically stable. A rational function G is called strictly proper if $\lim_{|s|\to\infty} G(s) = 0$. An unnormalized probability density function ρ is a nonnegative integrable function on $\Re$ such that $\int_{-\infty}^{\infty} \rho(x)dx > 0$, but not necessarily 1. Then $p = \rho/\int_{-\infty}^{\infty} \rho(x)dx$ is a normalized density function. The set of functions $\mathcal{P}$ is defined in section 3.

3. State-space representations of rational densities. If ρ is not a necessarily normalized rational probability density function, then ρ is strictly proper, i.e., $\lim_{|x|\to\infty} \rho(x) = 0$. Therefore, by standard realization theory (see, e.g., [4, Section 2.1], [10, Sections 10–11]), there exists a minimal linear state-space system (A, b, c) such that

$$\rho(x) = c(ixI - A)^{-1}b, \qquad x \in \Re.$$

It should be noted that the system matrices A, b, c will be, in general, complex matrices. A rational probability density function which is symmetric with respect to 0, however, could be realized with real system matrices.

Note also that we have set up the realization in such a way that we consider the rational function to be defined on the imaginary axis. While in principle the choice of axis is arbitrary, it is convenient to choose the imaginary axis since then standard realization theoretic methods can be adopted without having to change the axis. In particular, we will be using the formal analogy of methods developed for spectral densities which are most naturally considered to be defined on the imaginary axis. To

make this convention clear, set

$$\Phi(ix) := \rho(x), \qquad x \in \Re.$$

Since Φ is a rational function defined on the imaginary axis, it can be extended as a rational function to the whole complex plane. This rational function has the following properties.

1. $\Phi(s) = \Phi^*(s), s \in \mathcal{C}$.
2. Φ has no poles on the imaginary axis.
3. $\Phi(ix) \geq 0$, $x \in \Re$.
4. $\lim_{|s|\to\infty} \Phi(x) = 0$.

The set of rational functions that satisfies properties 1, 2, 3, and 4 is denoted by $\mathcal{P}$. Many of our calculations are going to be based on the following well-known additive decomposition (see Lemma 3.1) of Φ:

$$\Phi(s) = Z(s) + Z^*(s), \qquad s \in \mathcal{C},$$

where Z is a stable rational function, i.e., all poles of Z are in the open left half plane. This decomposition is unique if we assume that $Z(\infty) = 0$, which can be done since $\Phi(\infty) = 0$. The function Z is called the *spectral summand* or Φ. We will also call Z the *density summand* of ρ.

In the following lemma some elementary and standard state-space properties are collected concerning this additive decomposition of Φ. For the sake of completeness, a short proof is added for this standard result.

LEMMA 3.1. *Let $\Phi \in \mathcal{P}$. Then there exists a stable rational function Z such that*

$$\Phi = Z + Z^*.$$

Let (A, b, c) be a minimal realization of Φ, i.e., $\Phi(s) = c(sI - A)^{-1}b$, and (A, b, c) is minimal. There exists an equivalent realization

$$\left(\begin{array}{cc|c} A_1 & 0 & b_1 \\ 0 & A_2 & b_2 \\ \hline c_1 & c_2 & 0 \end{array}\right)$$

of (A, b, c) such that all eigenvalues of A_1 are in the open left half plane and all eigenvalues of A_2 are in the open right half plane. The state-space system (A_1, b_1, c_1) is a minimal realization of Z, and (A_2, b_2, c_2) is a minimal realization of Z^*.

Moreover, (A_2, b_2, c_2) is equivalent to $(-A_1^*, c_1^*, -b_1^*)$. In particular, there exists a minimal realization of Φ such that

$$\left(\begin{array}{cc|c} A_1 & 0 & b_1 \\ 0 & -A_1^* & c_1^* \\ \hline c_1 & -b_1^* & 0 \end{array}\right).$$

Proof. Let $\Phi = Z_s + Z_u$ be a stable-unstable partial fraction decomposition of Φ, i.e., the partial fraction decomposition of Φ such that Z_s is stable, meaning that all its poles are in the open left half plane, and Z_u is unstable, meaning that all its poles are in the open right half plane. Note that this decomposition is unique. Let

(A_1, b_1, c_1) be a minimal realization of Z_s, and let (A_2, b_2, c_2) be a minimal realization of Z_u. Then

$$\left(\begin{array}{cc|c} A_1 & 0 & b_1 \\ 0 & A_2 & b_2 \\ \hline c_1 & c_2 & 0 \end{array}\right)$$

is a minimal realization of Φ and hence equivalent to (A, b, c). Set $Z := Z_s$. We need to show that $Z_u = Z^*$. Now consider $Z_s + Z_u = \Phi = \Phi^* = (Z_s + Z_u)^* = Z_s^* + Z_s^*$. Note that Z_s^* has all its roots in the open right half plane, and Z_u^* has all its roots in the open left half plane. By the above-mentioned uniqueness of the stable-unstable partial fraction decomposition, we have that $Z_u = Z_s^* = Z^*$. The remaining parts of the lemma follow immediately. □

Example. As a special case we are going to consider the Cauchy density, which was suggested, for example in [7], as a suitable density to study financial time series. The normalized Cauchy density is defined as

$$p(x) = \frac{1}{\pi} \frac{k}{(x - x_0)^2 + k^2}, \quad x \in \Re,$$

where $x_0 \in \Re$ and $k > 0$. A state-space realization of $\Phi(ix) := p(x)$, $x \in \Re$, is given by

$$\left[\begin{array}{c|c} A_\Phi & b_\Phi \\ \hline c_\Phi & 0 \end{array}\right] := \left[\begin{array}{cc|c} -k + ix_0 & 0 & \frac{1}{2\pi} \\ 0 & k + ix_0 & 1 \\ \hline 1 & -\frac{1}{2\pi} & 0 \end{array}\right].$$

The density summand of p is

$$Z(s) = \frac{1}{2\pi} \frac{1}{s - (-k + ix_0)},$$

which has one pole at $-k + ix_0$. A state-space realization of Z is given by

$$\left[\begin{array}{c|c} A & b \\ \hline c & 0 \end{array}\right] := \left[\begin{array}{c|c} -k + ix_0 & \frac{1}{2\pi} \\ \hline 1 & 0 \end{array}\right].$$

4. Fourier transforms, moments, and Markov parameters. In order to obtain state space formulae for the moments of probability density functions and for the convolution of such densities, we need to employ the Fourier transform. The main tool will be to interpret the density summand as the Fourier transform of the impulse response of a stable linear state-space system. Actually, we introduce the Fourier transform as the Laplace transform evaluated on the imaginary axis. For a general reference on Fourier transforms see, e.g., [9], [6]. This way of proceeding is of course closely related to the use of the characteristic function in statistics, but there are a few more minor technical differences.

For an integrable function f on $\Re$ define the Fourier transform as usual by

$$(\mathcal{F}(f))(iw) = \int_{-\infty}^{\infty} f(t) e^{-iwt} dt, \qquad iw \in i\Re.$$

If (A, b, c) is a stable system, let $m^+(t) := ce^{tA}b$ for $t \geq 0$, and $m^+(t) := 0$ for $t < 0$. Then the Fourier transform of m^+ is given by

$$(\mathcal{F}m^+)(iw) = \int_0^\infty ce^{tA}be^{-itw}dt = c(-iwI + A)^{-1}e^{(-iwI+A)t}|_0^\infty b = c(iwI - A)^{-1}b$$
$$=: G(iw), \qquad iw \in i\Re.$$

If we set $m^-(t) := b^*e^{-tA^*}c^*$ for $t < 0$ and $m^-(t) := 0$ for $t \geq 0$, then the Fourier transform of m^- is given by

$$(\mathcal{F}m^-)(iw) = \int_{-\infty}^0 b^*e^{-tA^*}c^*e^{-itw}dt = b^*(-iwI - A^*)^{-1}e^{(-iwI-A^*)t}|_{-\infty}^0 c^*$$
$$= -b^*(iwI - (-A)^*)^{-1}c^* = G^*(iw), \quad iw \in i\Re.$$

The lth derivative of m^+ at $t > 0$ is given by $(m^+)^{(l)}(t) = cA^le^{tA}b$. Hence the right-hand side limit of the lth derivative at 0 is given by $(m^+)^{(l)}(0+) = cA^lb$. The lth derivative of m^- at $t < 0$ is given by $(m^-)^{(l)}(t) = b^*(-A^*)^le^{-tA^*}c^*$. Hence the left-hand side limit of the lth derivative at 0 is given by $(m^-)^{(l)}(0-) := b^*(-A^*)^lc^* = (-1)^l(cA^lb)^* = (-1)^l((m^+)^{(l)}(0+))^*$, $l \geq 0$.

Assume now that (A, b, c) is a realization of the spectral summand Z of the function $\Phi \in \mathcal{P}$. Then $(\mathcal{F}m^+)(iw) = Z(iw)$, $(\mathcal{F}m^-)(iw) = Z^*(iw)$, and for $m := m^+ + m^-$ we have that $(\mathcal{F}m)(iw) = \Phi(iw)$, $iw \in i\Re$. Hence m is the inverse Fourier transform of Φ. Note that m is l times continuously differentiable at $t = 0$, $l \geq 0$, if and only if $cA^kb = (-1)^k(cA^kb)^*$, $k = 0, 1, \ldots, l$.

If G is a strictly proper rational function on $\mathcal{C}$, then G admits a Laurent expansion around ∞ such that

$$G(s) = \sum_{n=1}^\infty M(n)\frac{1}{s^n}$$

for $s \in \mathcal{C}$ with $|s|$ large enough. The parameters $M(n)$, $n = 1, 2, \ldots$, are the *Markov parameters* of G (see, e.g., [10, p. 194]). If (A, b, c) is a realization of G, then

$$G(s) = c(sI - A)^{-1}b = \frac{1}{s}c\left(I - \frac{A}{s}\right)^{-1}b = \frac{1}{s}c\sum_{k=0}^\infty\left(\frac{1}{s}A\right)^k b = \sum_{n=1}^\infty \frac{1}{s^n}cA^{n-1}b.$$

Hence the Markov parameters of G are given by

$$M(n) = cA^{n-1}b, \quad n = 1, 2, 3, \ldots.$$

The Markov parameters of a rational strictly proper function of $\mathcal{P}$ and its spectral summand are easily determined.

LEMMA 4.1. *Let Φ be a strictly proper rational function in $\mathcal{P}$ with spectral summand Z. If (A, b, c) is a realization of Z, then*

1. *the Markov parameters of Z are given by*

$$cA^{n-1}b, \qquad n = 1, 2, 3, \ldots,$$

2. *the Markov parameters of Z^* are given by*

$$(-1)^nb^*(A^*)^{n-1}c^* = (-1)^n(cA^{n-1}b)^*, \qquad n = 1, 2, 3, \ldots, \text{ and}$$

3. *the Markov parameters of* Φ *are given by*

$$cA^{n-1}b - (-1)^{n-1}(cA^{n-1}b)^*, \qquad n = 1, 2, 3, \ldots.$$

In the following lemma, a basic result on the integrability of rational functions is summarized.

LEMMA 4.2. *Let* $G = \frac{n}{d}$ *with* n *and* d *as a pair of coprime polynomials. Then*

$$\int_{-\infty}^{\infty} |G(x)|dx < \infty$$

if and only if degree$(n) \leq$ *degree*$(d) - 2$ *and* $d(x) \neq 0$ *for all* $x \in \Re$.

If G is as defined in the lemma, then *degree*(d) − *degree*(n) is called the *codegree* of the rational function G. Therefore, G is integrable if and only if the codegree of G is greater than or equal to 2. This lemma also implies that if the random variable X has the rational probability density function $p = \frac{n}{d}$, then the moments EX^k exist for $k = 0, 1, 2, \ldots$, codegree$(p) - 2$.

Let k be such that $M(n) = 0$ for $n = 1, 2, \ldots, k-1$ and $M(k) \neq 0$. Then the codegree of G is k [10, p. 254].

Summarizing the previous remarks, we obtain the following proposition.

PROPOSITION 4.1. *Let* Φ *be a strictly proper rational function in* $\mathcal{P}$ *with spectral summand* Z. *Let* (A, b, c) *be a minimal realization of* Z. *Let* $m(t) := ce^{tA}b$ *for* $t \geq 0$ *and* $m(t) := b^*e^{-tA^*}c^*$ *for* $t < 0$. *Then the following hold.*

1. *The codegree of* Φ *is* k *if and only if* $M(n) = 0$ *for all* $n \in \{1, \ldots, k-1\}$ *and* $M(k) \neq 0$, *where* $M(n)$ *is the* nth *Markov parameter of* Φ.

2. *The codegree of* Φ *is* k *if and only if*

$$cA^{n-1}b = (-1)^{n-1}(cA^{n-1}b)^*$$

for all $n \in \{1, \ldots, k-1\}$ *and*

$$cA^{k-1}b \neq (-1)^{k-1}(cA^{k-1}b)^*.$$

3. m *is* $k-1$ *times continuously differentiable at* 0 *if and only if the first* k *Markov parameters of* Φ *are zero.*

4. Φ *has codegree* k *if and only if* m *is* $k-2$ *times continuously differentiable but not* $k-1$ *times continuously differentiable at* 0.

The following theorem provides important results concerning moments of a random variable with rational probability density.

THEOREM 4.1. *Let* X *be a random variable with unnormalized rational probability density function* ρ. *Let* (A, b, c) *be a realization of the density summand* Z *of* ρ. *Then the following hold.*

1. *The codegree of* ρ *is* k *if and only if*

$$cA^{n-1}b = (-1)^{n-1}(cA^{n-1}b)^*$$

for all $n \in \{1, \ldots, k-1\}$ *and* $cA^{k-1}b \neq (-1)^{k-1}(cA^{k-1}b)^*$.

2. *The* lth *moment* EX^l *of* X *with* l *a nonnegative integer exists if and only if* $l \in \{0, 1, \ldots, k-2\}$.

3. $EX^l = (-i)^l \frac{cA^lb}{cb}$ *for all* $l \in \{0, 1, \ldots, k-2\}$.

Proof. (1) The proof follows immediately from Proposition 4.1.

(2) Recall that the lth moment of X is given by

$$EX^l = \frac{1}{R}\int_{-\infty}^{\infty} x^l \rho(x)\,dx,$$

where $R := \int_{-\infty}^{\infty} \rho(x)\,dx$. The codegree of the integrand is $k-l$. By Lemma 4.2 the integrand is integrable if and only if its codegree is greater than or equal to 2. Hence the claim.

(3) Let $0 \le l \le k-2$. Set $\Phi(ix) := \rho(x)$, $x \in \Re$, and use the notation of Proposition 4.1. Then m is $k-2$ times continuously differentiable at 0 and therefore on $\Re$. Since the codegree of ρ is greater than or equal to 2, m is continuous on $\Re$. Since ρ and m are continuous and integrable, we have by the inversion theorem for Fourier transforms (see, e.g., [6, Theorem 60.1, p. 296]) that

$$m(t) = \frac{1}{2\pi}\int_{-\infty}^{\infty} \Phi(iw)e^{iwt}dw, \qquad t \in \Re.$$

Note that differentiation up to order $k-2$ under this integral is justified by the usual argument (see, e.g. [6, Theorem 53.5, p. 268]) as $|\omega^l \Phi(i\omega)e^{i\omega t}| = |\omega^l \Phi(i\omega)|$ is integrable for each $t \in \Re$ and $0 \le l \le k-2$. Hence for $t \in \Re$,

$$\frac{d^l}{dt^l}m(t) = \frac{1}{2\pi}\int_{-\infty}^{\infty} \Phi(iw)\frac{d^l}{dt^l}e^{iwt}dw = (i)^l \frac{1}{2\pi}\int_{-\infty}^{\infty} w^l \Phi(iw)e^{iwt}\,dw.$$

Evaluating at $t=0$, we have

$$\frac{d^l}{dt^l}m(t)|_{t=0} = \frac{1}{2\pi}(i)^l \int_{-\infty}^{\infty} w^l \Phi(iw)e^{iwt}dw|_{t=0} = R(i)^l \frac{1}{2\pi}EX^l.$$

Since $\frac{d^l}{dt^l}m(t)|_{t=0} = cA^l b$, $l = 0, \ldots, k-2$, we have that

$$EX^l = \frac{2\pi}{R}(-i)^l cA^l b.$$

The constant R is determined by considering this equation for $l=0$. Since $EX^0 = 1$, we have that $R = 2\pi cb$. Hence $EX^l = (-i)^l \frac{cA^l b}{cb}$. □

In most of this paper we will be dealing with unnormalized rational probability densities ρ. If (A,b,c) is a state-space realization of the density summand of ρ, the normalized probability density function is given by $p := \rho / \int_{-\infty}^{\infty} \rho(x)dx$. By the above proposition $\int_{-\infty}^{\infty} \rho(x)dx = 2\pi cb$, which provides a state-space formula for the normalization constant.

If X is a random variable with rational probability density function ρ whose density summand has the state-space realization (A,b,c), then the first moment exists if the codegree of ρ is at least 3. This is the case if and only if

$$cb = (cb)^*$$

and

$$cAb = -(cAb)^*.$$

If the first moment, i.e., the mean, exists, then by the theorem it is given by

$$EX = -i\frac{cAb}{cb}.$$

In the above discussion we gave a state-space construction for the inverse Fourier transform m of a not necessarily normalized rational probability density function ρ, i.e.,

$$m(t) = \frac{1}{2\pi}\int_{-\infty}^{\infty} \rho(\omega)e^{i\omega t}d\omega, \qquad \omega \in \Re.$$

In the statistical literature an important object is the characteristic function of a random variable X which is defined by $E(e^{itX})$, $t \in \Re$. If X has the unnormalized probability density function ρ, then

$$E(e^{itX}) = \frac{1}{\int_{-\infty}^{\infty}\rho(x)dx}\int_{-\infty}^{\infty} e^{itx}\rho(x)dx = \frac{2\pi}{\int_{-\infty}^{\infty}\rho(x)dx}m(t), \qquad t \in \Re.$$

Hence up to a (known) scaling factor the function m is identical to the characteristic function.

Example continued. We continue the discussion of the Cauchy density from section 3. Note that for all $x_0 \in \Re$ and $k > 0$

$$cAb = \frac{1}{2\pi}(-k + ix_0) \neq -\frac{1}{2}(-k - ix_0) = -(cAb)^*.$$

Hence by the theorem the mean EX does not exist. This is of course also directly evident by consideration of the integral $\int_{-\infty}^{\infty} xp(x)dx$.

If $m^+(\tau) := \frac{1}{2\pi}e^{\tau(-k+ix_0)}$ for $t \geq 0$ and $m^+(\tau) := 0$ for $t < 0$, then $\mathcal{F}(m^+)(iw) = \frac{1}{2\pi}\frac{1}{iw-(-k+ix_0)}$, $iw \in i\Re$. If $m^-(\tau) := \frac{1}{2\pi}e^{-\tau(-k-ix_0)}$ for $t < 0$ and $m^-(\tau) := 0$ for $t \geq 0$, then $\mathcal{F}(m^-)(iw) = \frac{1}{2\pi}\frac{1}{iw+(k-ix_0)}$, $iw \in i\Re$. With $m := m^+ + m^-$, we have that m is continuous at 0. The derivative is given by

$$\frac{d}{dt}m(t) = \frac{1}{2\pi}(-k + ix_0)e^{\tau(-k+ix_0)}, \qquad \tau > 0,$$
$$\frac{d}{dt}m(t) = \frac{1}{2\pi}(k + ix_0)e^{-\tau(-k-ix_0)}, \qquad \tau < 0.$$

Note that the left-hand side limit and the right-hand side limit do not agree at 0. Hence m is not differentiable at 0. As the codegree of p is 2, this is in agreement with Proposition 4.1. The first two Markov parameters of Φ are

$$c_\Phi b_\Phi = 0, \qquad c_\Phi A_\Phi b_\Phi = \frac{-k}{\pi}.$$

Hence the second Markov parameter is nonzero, which is also in agreement with Proposition 4.1. □

5. Operations on probability densities. In this section we are going to discuss state-space formulations of operations on rational probability densities. Given state-space realizations for the density summands of two probability densities, we will give state-space realizations for the density summand of the translation, scaling, product, and convolution of the densities.

5.1. Translation and scaling of a probability density. In the next straightforward lemma the effect of translation and scaling of a random variable on the state-space realization of the density is considered.

LEMMA 5.1. *Let X be a random variable with unnormalized rational density ρ. Let (A, b, c) be a minimal realization such that $\rho(x) = c(ixI - A)^{-1}b$, $x \in \Re$.*

Let $x_0 \in \Re$. Then the random variable $X + x_0$ has an unnormalized probability density function $q(x) = \rho(x - x_0)$, which has a realization $(A + ix_0 I, b, c)$, so

$$q(x) = c(ixI - (A + ix_0 I))^{-1}b, \qquad x \in \Re.$$

Let $a \in \Re$, $a \neq 0$; then the random variable aX has the unnormalized probability density function $q(x) = \frac{1}{a}\rho(\frac{x}{|a|})$ which has a realization $(aA, b, \frac{a}{|a|}c)$, so

$$q(x) = \frac{a}{|a|}c(ixI - aA)^{-1}b, \qquad x \in \Re.$$

In the following lemma, we are going to write down the analogous results for the case when a state-space realization is given for the density summand of the probability density. The proof is elementary.

LEMMA 5.2. *Let X be a random variable with unnormalized rational density ρ. Let (A, b, c) be a realization of the density summand Z of ρ.*

Let $x_0 \in \Re$; then the random variable $X + x_0$ has the unnormalized probability density function $q(x) = \rho(x - x_0)$, $x \in \Re$, whose density summand has a realization

$$\left(\begin{array}{c|c} A + ix_0 I & b \\ \hline c & 0 \end{array}\right).$$

Let $a \in \Re$, $a \neq 0$; then the random variable aX has the unnormalized probability density function $q(x) = \frac{1}{|a|}\rho(\frac{x}{a})$, whose density summand has a realization

$$\left(\begin{array}{c|c} aA & b \\ \hline c & 0 \end{array}\right)$$

if $a > 0$ and

$$\left(\begin{array}{c|c} -aA^* & c^* \\ \hline b^* & 0 \end{array}\right)$$

if $a < 0$.

5.2. Product of two rational probability densities. In the update step of the filtering problem, it is necessary to calculate the product of two density functions. We are going to do this also by state-space techniques using the decomposition into density summands. The following lemmas will be useful.

LEMMA 5.3. *Let G_1 and G_2 be two stable strictly proper rational functions with minimal state-space realizations (A_1, b_1, c_1) and (A_2, b_2, c_2). Then the product $G_1^* G_2$ can be decomposed as*

$$G_1^* G_2 = F + H^*,$$

where F, H are stable strictly proper rational functions such that F has the realizations given by

$$\left(\begin{array}{c|c} A_2 & b_2 \\ \hline b_1^* T_1 & 0 \end{array}\right), \qquad \left(\begin{array}{c|c} A_2 & T_2 c_1^* \\ \hline c_2 & 0 \end{array}\right),$$

and H^* has the realizations given by

$$\left(\begin{array}{c|c} -A_1^* & T_1 b_2 \\ \hline -b_1^* & 0 \end{array}\right), \qquad \left(\begin{array}{c|c} -A_1^* & -c_1^* \\ \hline c_2 T_2 & 0 \end{array}\right),$$

where T_1 is the unique solution to the Sylvester equation

$$A_1^* T_1 + T_1 A_2 + c_1^* c_2 = 0$$

and T_2 is the unique solution to the Sylvester equation

$$A_2 T_2 + T_2 A_1^* + b_2 b_1^* = 0.$$

Proof. Note that a realization of G_1^* is given by

$$(-A_1^*, c_1^*, -b_1^*),$$

and a realization of $G_1^* G_2$ is given by

$$\left(\begin{array}{cc|c} -A_1^* & c_1^* c_2 & 0 \\ 0 & A_2 & b_2 \\ \hline -b_1^* & 0 & 0 \end{array}\right).$$

Performing a state-space basis transformation with transformation matrix $\left(\begin{smallmatrix} I & T_1 \\ 0 & I \end{smallmatrix}\right)$, we obtain the equivalent realization

$$\left(\begin{array}{cc|c} -A_1^* & A_1^* T_1 + T_1 A_2 + c_1^* c_2 & T_1 b_2 \\ 0 & A_2 & b_2 \\ \hline -b_1^* & b_1^* T_1 & 0 \end{array}\right) = \left(\begin{array}{cc|c} -A_1^* & 0 & T_1 b_2 \\ 0 & A_2 & b_2 \\ \hline -b_1^* & b_1^* T_1 & 0 \end{array}\right)$$

since T_1 is such that $A_1^* T_1 + T_1 A_2 + c_1^* c_2 = 0$. Note that such a T_1 exists and is unique since both A_1^* and A_2 have all their eigenvalues in the open left half plane (see, e.g., [1, Vol. I, p. 225]). This representation implies the first set of realizations. The other set of realizations follows analogously by considering the state-space formula which corresponds to $G_2 G_1^*$. ∎

Remark. A method to generate explicit formulas for the solutions of Sylvester equations is presented in [3].

We can now derive the desired representation for the density summand of the product of two rational probability density functions.

PROPOSITION 5.1. *Let ρ_1 and ρ_2 be two unnormalized rational probability density functions with density summands Z_1 and Z_2. Let (A_i, b_i, c_i) be a minimal realization of Z_i, $i = 1, 2$. Then the density summand Z of the unnormalized rational probability density function $\rho = \rho_1 \rho_2$ has a realization given by*

$$\left(\begin{array}{cc|c} A_1 & b_1 c_2 & T_2^* c_2^* \\ 0 & A_2 & b_2 \\ \hline c_1 & b_1^* T_1 & 0 \end{array}\right),$$

where T_1, T_2 are the unique solutions to the Sylvester equations

$$A_1^* T_1 + T_1 A_2 + c_1^* c_2 = 0,$$
$$A_2 T_2 + T_2 A_1^* + b_2 b_1^* = 0.$$

Proof. We have that

$$\rho = \rho_1\rho_2 = (Z_1 + Z_1^*)(Z_2 + Z_2^*) = Z_1Z_2 + Z_1Z_2^* + (Z_1Z_2^*)^* + (Z_1Z_2)^*.$$

By Lemma 5.3 a state-space realization for the stable part of this expression is given by

$$\left(\begin{array}{cccc|c} A_1 & b_1c_2 & 0 & 0 & 0 \\ 0 & A_2 & 0 & 0 & b_2 \\ 0 & 0 & A_1 & 0 & T_2^*c_2^* \\ 0 & 0 & 0 & A_2 & b_2 \\ \hline c_1 & 0 & c_1 & b_1^*T_1 & 0 \end{array}\right),$$

where T_1 is the unique solution of the equation

$$A_1^*T_1 + T_1A_2 + c_1^*c_2 = 0$$

and T_2 is the unique solution of the equation

$$A_2T_2 + T_2A_1^* + b_2b_1^* = 0.$$

Performing a state-space basis transformation with transformation matrix

$$T = \left(\begin{array}{cccc} I & 0 & 0 & 0 \\ 0 & I & 0 & 0 \\ 0 & 0 & I & 0 \\ 0 & -I & 0 & I \end{array}\right),$$

we obtain the equivalent realization

$$\left(\begin{array}{cccc|c} A_1 & b_1c_2 & 0 & 0 & 0 \\ 0 & A_2 & 0 & 0 & b_2 \\ 0 & 0 & A_1 & 0 & T_2^*c_2^* \\ 0 & 0 & 0 & A_2 & 0 \\ \hline c_1 & b_1^*T_1 & c_1 & b_1^*T_1 & 0 \end{array}\right),$$

which is equivalent to

$$\left(\begin{array}{ccc|c} A_1 & b_1c_2 & 0 & 0 \\ 0 & A_2 & 0 & b_2 \\ 0 & 0 & A_1 & T_2^*c_2^* \\ \hline c_1 & b_1^*T_1 & c_1 & 0 \end{array}\right).$$

On this realization perform another state-space basis transformation with transformation matrix

$$T = \left(\begin{array}{ccc} I & 0 & I \\ 0 & I & 0 \\ 0 & 0 & I \end{array}\right)$$

to obtain

$$\left(\begin{array}{ccc|c} A_1 & b_1c_2 & 0 & T_2^*c_2^* \\ 0 & A_2 & 0 & b_2 \\ 0 & 0 & A_1 & T_2^*c_2^* \\ \hline c_1 & b_1^*T_1 & 0 & 0 \end{array}\right),$$

which is equivalent to

$$\left(\begin{array}{cc|c} A_1 & b_1c_2 & T_2^*c_2^* \\ 0 & A_2 & b_2 \\ \hline c_1 & b_1^*T_1 & 0 \end{array}\right). \qquad \square$$

It was noted before that the codegree of a rational probability density function is at least 2. Therefore, the product of two such probability density functions has codegree at least 4. Hence for a random variable whose density is given by such a product, at least the first and second moments exist. This will be used in the next section to show the existence of a conditional mean and variance.

5.3. Convolution of probability densities. We now come to determine a state-space formulation for the convolution of two probability densities. Recall that if X and Y are two random variables with rational probability densities ρ_X and ρ_Y, then the probability density of $X+Y$ is given by the convolution $\rho_X * \rho_Y$.

Let ρ_1 and ρ_2 be two unnormalized rational probability functions with corresponding spectral summands Z_1 and Z_2. Let (A_i, b_i, c_i) be a realization of Z_i, $i = 1, 2$. Let, for $i = 1, 2$,

$$m_i^+(\tau) := \begin{cases} c_i e^{\tau A_i} b_i, & \tau \geq 0, \\ 0, & \tau < 0, \end{cases}$$

$$m_i^-(\tau) := \begin{cases} b_i^* e^{-\tau A_i^*} c_i^*, & \tau < 0, \\ 0, & \tau \geq 0. \end{cases}$$

Then $(\mathcal{F}m_i^+)(iw) = Z_i(iw)$, $(\mathcal{F}m_i^-)(iw) = Z_i^*(iw)$, $iw \in i\Re$, and

$$\begin{aligned}(\rho_1 * \rho_2)(w) &= \int_{-\infty}^{\infty} \Phi_1(iw - i\nu)\Phi_2(i\nu)d\nu = \mathcal{F}\left(\mathcal{F}^{-1}\int_{-\infty}^{\infty} \Phi_1(iw - i\nu)\Phi_2(i\nu)d\nu\right) \\ &= \mathcal{F}((\mathcal{F}^{-1}\Phi_1)(\mathcal{F}^{-1}\Phi_2))(iw) = \mathcal{F}((\mathcal{F}^{-1}(Z_1 + Z_1^*))(\mathcal{F}^{-1}(Z_2 + Z_2^*)))(iw) \\ &= \mathcal{F}((m_1^+ + m_1^-)(m_2^+ + m_2^-))(iw) = \mathcal{F}(m_1^+ m_2^+ + m_1^- m_2^-)(iw) \\ &= \mathcal{F}(m_1^+ m_2^+)(iw) + \mathcal{F}(m_1^- m_2^-)(iw).\end{aligned}$$

It follows that the spectral summand Z of $\rho_1 * \rho_2$ is given by $Z(iw) = \mathcal{F}(m_1^+ m_2^+)(iw)$.

In the following proposition we are going to give the state-space formulae for the product of the impulse responses of two single-input single-output state-space systems. This will be the key step to determine a state-space realization for the convolution of two rational probability density functions.

PROPOSITION 5.2. *Let $m_i^+(\tau) := c_i e^{\tau A_i} b_i$ for $\tau \geq 0$, and $m_i^+(\tau) := 0$ for $\tau < 0$, where (A_i, b_i, c_i) is an n_i-dimensional single-input single-output system, $i = 1, 2$. Then*

$$m^+(\tau) := m_1^+(\tau) m_2^+(\tau), \quad \tau \geq 0,$$

has a realization $m^+(\tau) = ce^{\tau A}b$ *for* $\tau \geq 0$ *and* $m^+(\tau) = 0$ *for* $\tau < 0$, *where*

$$A = A_1 \otimes I_{n_2} + I_{n_1} \otimes A_2,$$
$$b = b_1 \otimes b_2,$$
$$c = c_1 \otimes c_2.$$

(Here $\otimes$ *denotes the Kronecker product.)*

Proof. This follows immediately from basic rules on the Kronecker product (see, e.g., [8]), since for $\tau \geq 0$

$$\begin{aligned} m^+(\tau) &= ce^{\tau A}b = (c_1 \otimes c_2)e^{\tau(A_1 \otimes I_{n_2} + I_{n_1} \otimes A_2)}(b_1 \otimes b_2) \\ &= (c_1 \otimes c_2)(e^{\tau A_1} \otimes e^{\tau A_2})(b_1 \otimes b_2) = c_1 e^{\tau A_1} b_1 \otimes c_2 e^{\tau A_2} b_2 = c_1 e^{\tau A_1} b_1 c_2 e^{\tau A_2} b_2 \\ &= m_1^+(\tau) m_2^+(\tau). \qquad \square \end{aligned}$$

The proposition is of interest in its own right, as it allows one to find state-space formulas for products of impulse response functions.

Summarizing, we have the following result.

PROPOSITION 5.3. *Let* ρ_1 *and* ρ_2 *be unnormalized rational probability densities whose spectral summands* Z_1 *and* Z_2 *have the* n_1*-dimensional and* n_2*-dimensional state-space realizations* (A_1, b_1, c_1) *and* (A_2, b_2, c_2). *Then the density summand* Z *of the convolution* $\rho = \rho_1 * \rho_2$ *has the state-space realization*

$$\left(\begin{array}{c|c} A_1 \otimes I_{n_2} + I_{n_1} \otimes A_2 & b_1 \otimes b_2 \\ \hline c_1 \otimes c_2 & 0 \end{array} \right). \tag{1}$$

Proof. Suppose Z has the realization (1). Then the inverse Fourier transform of Z is $m_1^+ m_2^+$, showing that Z is the spectral summand of ρ. $\square$

Note that the state-space dimension of this realization is $n_1 n_2$, which implies that the McMillan degree of Z is at most $n_1 n_2$.

6. State-space expressions for the filtering equations. We are now in a position to derive state-space expressions for the unnormalized conditional densities in the filter equations which were discussed in the introduction.

THEOREM 6.1. *Assume the notation and assumptions for the filtering problem as presented in the introduction.*

Let $t \geq 0$, *and let* $(A_{x_{t|t-1}}, b_{x_{t|t-1}}, c_{x_{t|t-1}})$ *be a minimal* n_{x_t}*-dimensional state-space realization of the density summand of the unnormalized conditional density* $\rho_{x_t|\mathcal{Y}_{t-1}}$. *For* $t = 0$, *set* $\rho_{x_t|\mathcal{Y}_{t-1}} := \rho_{x_0}$, *the density of the initial state* x_0. *Let* $(A_{\eta_t}, b_{\eta_t}, c_{\eta_t})$ *be a minimal* n_{η_t}*-dimensional state-space realization of the density summand of the unnormalized rational density* ρ_{η_t} *of the noise random variable* η_t, *and let* $(A_{\epsilon_t}, b_{\epsilon_t}, c_{\epsilon_t})$ *be a minimal* η_{ϵ_t}*-dimensional state-space realization of the density summand of the unnormalized rational density* ρ_{ϵ_t} *of the noise random variable* ϵ_t, $t \geq 0$.

Let T_1 *be the unique solution to the equation*

$$\left(\frac{1}{h_t} A_{\epsilon_t} + iy_t I \right) T_1 + T_1 A_{x_{t|t-1}} + b_{\epsilon_t} c_{x_{t|t-1}} = 0,$$

and let T_2 *be the unique solution to the equation*

$$A_{x_{t|t-1}} T_2 + T_2 \left(\frac{1}{h_t} A_{\epsilon_t} + iy_t \right) + b_{x_{t|t-1}} c_{\epsilon_t} = 0.$$

Then the density summand of the unnormalized density $\rho_{x_t|\mathcal{Y}_t}$ has state-space realization

$$\left(\begin{array}{c|c} A_{x_{t|t}} & b_{x_{t|t}} \\ \hline c_{x_{t|t}} & 0 \end{array}\right) = \left(\begin{array}{cc|c} \frac{1}{h_t}A^*_{\epsilon_t} - iy_tI & c^*_{\epsilon_t}c_{x_{t|t}} & T_2^*c^*_{x_{t|t}} \\ 0 & A_{x_{t|t}} & t_{x_{t|t}} \\ \hline b^*_{\epsilon_t} & c_{\epsilon_t}T_1 & 0 \end{array}\right).$$

The density summand of $\rho_{x_{t+1}|\mathcal{Y}_t}$ has state-space realization

$$\begin{aligned} &\left(\begin{array}{c|c} A_{x_{t+1|t}} & b_{x_{t+1|t}} \\ \hline c_{x_{t+1|t}} & 0 \end{array}\right) \\ &= \left(\begin{array}{c|c} f_tA_{x_{t|t}} \otimes I_{n_{\eta_t}} + I_{n_{\epsilon_t}+n_{x_t}} \otimes A_{\eta_t} & b_{x_{t|t}} \otimes b_{n_{\eta_t}} \\ \hline c_{x_{t|t}} \otimes c_{\eta_t} & 0 \end{array}\right) \quad \textit{if } f_t > 0, \\ &= \left(\begin{array}{c|c} -f_tA^*_{x_{t|t}} \otimes I_{n_{\eta_t}} + I_{n_{\epsilon_t}+n_{x_t}} \otimes A_{\eta_t} & c^*_{x_{t|t}} \otimes b_{n_{\eta_t}} \\ \hline b^*_{x_{t|t}} \otimes c_{\eta_t} & 0 \end{array}\right) \quad \textit{if } f_t < 0. \end{aligned}$$

Proof. Since by assumption $h_t > 0$, the density summand of the density $q(x) = \rho_{\epsilon_t}(y_t - h_tx)$, $x \in \Re$, has the realization

$$\left(\begin{array}{c|c} \frac{1}{h_t}A^*_{\epsilon_t} - iy_tI & c^*_{\epsilon_t} \\ \hline b^*_{\epsilon_t} & 0 \end{array}\right).$$

As

$$\rho_{x_t|\mathcal{Y}_t}(x) = \rho_{\epsilon_t}(y_t - h_tx)\rho_{x_t|\mathcal{Y}_{t-1}}(x), \quad x \in \Re,$$

by Proposition 5.1 the density summand of ρ has the realization

$$\left(\begin{array}{cc|c} \frac{1}{h_t}A^*_{\epsilon_t} - iy_tI & c^*_{\epsilon_t}c_{x_{t|t-1}} & T_2^*c^*_{x_{t|t-1}} \\ 0 & A_{x_{t|t-1}} & b_{x_{t|t-1}} \\ \hline b^*_{\epsilon_t} & c_{\epsilon_t}T_1 & 0 \end{array}\right),$$

where T_1 is the unique solution to the equation

$$\begin{aligned} &\left(\frac{1}{h_t}A^*_{\epsilon_t} - iy_tI\right)^* T_1 + T_1A_{x_{t|t-1}} + b_{\epsilon_t}c_{x_{t|t-1}} \\ &\quad = \left(\frac{1}{h_t}A_{\epsilon_t} + iy_tI\right)T_1 + T_1A_{x_{t|t-1}} + b_{\epsilon_t}c_{x_{t|t-1}} = 0, \end{aligned}$$

and T_2 is the unique solution to the equation

$$\begin{aligned} &A_{x_{t|t-1}}T_2 + T_2\left(\frac{1}{h_t}A^*_{\epsilon_t} - iy_tI\right)^* + b_{x_{t|t-1}}c_{\epsilon_t} \\ &\quad = A_{x_{t|t-1}}T_2 + T_2\left(\frac{1}{h_t}A_{\epsilon_t} + iy_tI\right) + b_{x_{t|t-1}}c_{\epsilon_t} = 0. \end{aligned}$$

To obtain a state-space formula for the prediction step

$$\rho_{x_{t+1}|\mathcal{Y}_t} = \rho_{f_tx_t|\mathcal{Y}_t} * \rho_{\eta_t},$$

we use Proposition 5.3. We need to introduce two cases depending on the sign of f_t. If $f_t > 0$, the density summand of $\rho_{f_t x_t|\mathcal{Y}_t}$ has the realization

$$\left(\begin{array}{c|c} f_t A_{x_{t|t}} & b_{x_{t|t}} \\ \hline c_{x_{t|t}} & 0 \end{array}\right).$$

If $f_t < 0$, the density summand of $\rho_{f_t x_t|\mathcal{Y}_t}$ has the realization

$$\left(\begin{array}{c|c} -f_t A^*_{x_{t|t}} & c^*_{x_{t|t}} \\ \hline b^*_{x_{t|t}} & 0 \end{array}\right).$$

The remaining parts of the result now follow by Proposition 5.3. □

It should be noted that the presented state-space realizations are data dependent and, in particular, dependent on $\mathcal{Y}_t$. As the formulae that use Kronecker products show, the dimensions of the state-space representation can potentially grow very quickly as the number of data points increases. It should be pointed out, however, that the growth in complexity is inherent in the use of random variables with rational densities (see also [11]). If, however, the density summand corresponding to η_t has only McMillan degree 1, i.e., η_t has Cauchy distribution, then the Kronecker products reduce to standard multiplication and the prediction step does not lead to an increase in dimension. Also, if the density summand corresponding to ϵ_t has McMillan degree 1, i.e., ϵ_t has Cauchy distribution, then the matrix equations can be solved explicitly to give

$$T_1 = -b_{\epsilon_t} c_{x_{t|t-1}} \left(\left(\frac{1}{h_t} A_{\epsilon_t} + i y_t \right) I + A_{x_{t|t-1}} \right)^{-1},$$

$$T_2 = -\left(\left(\frac{1}{h_t} A_{\epsilon_t} + i y_t \right) I + A_{x_{t|t-1}} \right)^{-1} b_{x_{t|t-1}} c_{\epsilon_t}.$$

Note that the inverse exists, since $A_{x_{t|t-1}}$ has all eigenvalues in the open left half plane and $\frac{1}{h_t} A_{\epsilon_t} + i y_t$ has negative real part, because of the stability of A_{ϵ_t} and since $h_t > 0$. From the remark after Proposition 5.1, it follows that the conditional mean $E(x_t|\mathcal{Y}_t)$ and the corresponding conditional variance $E(x_t - E(x_t|\mathcal{Y}_t)^2|\mathcal{Y}_t)$ exist and can be calculated from the density summand realization $(A_{x_{t|t}}, b_{x_{t|t}}, c_{x_{t|t}})$ using the formulas given in Theorem 4.1.

Note that prediction is also possible using the formulas presented here. For example, the unnormalized rational conditional probability density of the output variable at time $t+1$, given the observations of the output until time t, is equal to $\rho_{y_{t+1|t}}(y) = \rho_{h_{t+1} x_{t+1|t}} * \rho_{\epsilon_{t+1}}$, and the spectral summand of this density can be calculated using the formulas of section 5.

7. Conclusions. State-space formulae have been developed for various operations on rational density functions, and it is shown how this can be used to treat the filtering problem in the case of a first order linear stochastic model with stochastically independent noise variables with rational probability densities and stochastically independent initial state with rational probability density. This makes such filters easy to program on present-day computers, using, e.g., a linear algebra package. If the number of observations is not very small, however, the order of the conditional rational densities will tend to grow quickly. Therefore, various schemes of order reduction for positive real functions may be of relevance in practical applications (see, e.g.,

[2]). The formulae presented can also be used for further theoretical research in the behavior of the optimal filter. It follows, for example, that the conditional mean of the present state, given present and past observations, is a rational function of the present and past observations, which could be further investigated. The formula that is presented for the realization of the product of impulse response functions appears to be important in its own right.

SEQUENCING AND ROUTING IN MULTICLASS QUEUEING NETWORKS PART I: FEEDBACK REGULATION*

SEAN P. MEYN†

Abstract. This paper establishes new criteria for stability and for instability of multiclass network models under a given stationary policy. It also extends previous results on the approximation of the solution to the average cost optimality equations through an associated fluid model: It is shown that an optimized network possesses a fluid limit model which is itself optimal with respect to a total cost criterion.

A general framework for constructing control algorithms for multiclass queueing networks is proposed based on these general results. Network sequencing and routing problems are considered as special cases. The following aspects of the resulting *feedback regulation policies* are developed in the paper:

(i) The policies are stabilizing and are, in fact, geometrically ergodic for a Markovian model.

(ii) Numerical examples are given. In each case it is shown that the feedback regulation policy closely resembles the average-cost optimal policy.

(iii) A method is proposed for reducing variance in simulation for a network controlled using a feedback regulation policy.

Key words. queueing networks, routing, scheduling, optimal control

1. Introduction.

This paper concerns the effective management of large networks through scheduling and routing.

Specific applications of interest include cellular and internet communication systems, large scale manufacturing processes, and computer systems (see, e.g., [5, 55, 22]). In spite of the diversity of these applications, one can find many common goals:

(i) Controlling delay, throughput, inventory, and loss. The crudest issue is *stability*: do queue lengths remain bounded for all time?

(ii) Estimating performance, or comparing the performance of one policy over another one. *Performance* is context-dependent, but common metrics are average delay and loss probabilities.

(iii) Prescriptive approaches to policy synthesis which are intuitive, flexible, robust, and reasonable in complexity. *Robustness* means that the policy will be effective even under significant modeling error. By *flexibility* we mean that the policies will react appropriately to changes in network topology or other gross structural changes.

(iv) In applications to telecommunications or power systems one may have limited information. Routing or sequencing decisions must then be determined using only that information which can be made available. This issue is becoming less critical with ever-increasing information processing power. In the future internet it may be possible to assume essentially complete information at every node in the network through current flooding algorithms and proposed *explicit congestion notification algorithms* [21].

There are currently several popular classes of models which describe in various

levels of detail the dynamics of a queueing network to address the range of issues in (i)–(iv). The utility of a particular model depends upon one's particular goals.

A traditional academic approach to policy synthesis is to construct a Markov decision process (MDP) model for the network. This involves constructing a controlled transition operator $P_a(x, y)$, which gives the probability of moving from state x to state y when the control decision $a \in \mathcal{A}(x)$ is applied. The state space X (where x and y live) is typically taken as the set of all possible buffer levels at the various stations in the network; $\mathcal{A}(x)$ is then the set of feasible control actions when the state takes the value $x \in \mathsf{X}$. Given an MDP model and a one step cost function $c\colon \mathsf{X} \to \mathbb{R}_+$, a solution to the average cost optimal control problem is found by solving the resulting dynamic programming equations,

$$\eta^* + h^*(x) = \min_{a \in \mathcal{A}(x)} [c(x) + P_a h^*(x)], \tag{1.1}$$

$$F^*(x) = \arg\min_{a \in \mathcal{A}(x)} P_a h^*(x), \qquad x \in \mathsf{X}. \tag{1.2}$$

The function F^* on X then defines an optimal stationary policy.

The difficulty with this approach is very well known: When buffers are infinite, this becomes an infinite dimensional optimization problem. Even when considering finite buffers, the complexity grows exponentially with the dimension of the state space. Some form of aggregation is necessary—the Markovian model is simply too detailed to be useful in optimization.

An elegant approach is to consider the model in heavy traffic where a reflected Brownian motion model is appropriate. The papers [24, 28] develop these ideas for the network scheduling or sequencing problems, and [32] considers routing and other control problems. One is then faced with optimizing a controlled stochastic differential equation (SDE) model. In many examples considered in the literature this control problem has a simple intuitive solution. This is just one example of a fluid model for the physical network. Another popular model is the "σ-ρ" constrained fluid model [11, 51] and the linear fluid model considered here (see, e.g., [8, 7, 56, 41, 42, 2]). Any one of these models is valuable in network design because unimportant details are stripped away.

Justification for considering these various idealizations comes from theory that establishes solidarity between idealized fluid models and more accurate discrete models, when the load is close to capacity [32, 4], or the state of the system is large (e.g., the network is congested [45], or a "large deviation" occurs [54]). Stability theory for networks, as in (i), has essentially reached maturation over the past decade, following counterexamples introduced in [35, 52]. This theory is based on the close ties between a stochastic network model and its linear fluid counterpart [14, 15, 16].

There are, however, several difficulties with these approaches:

- The Brownian motion approximation is based on a model in heavy traffic. If the stations are not balanced then one loses some information at the stations which are not heavily loaded.
- Although the optimal control problem for a Brownian motion or σ-ρ constrained fluid model often has a simple intuitive solution, frequently this is not the case. There is currently no general practical method for generating policies.
- It is not always obvious how to translate an optimal policy for an abstract model to a feasible and efficient policy for the original discrete model.

In this paper, we consider exclusively the linear fluid model (2.2) in design. Theorem 3, an extension of the main result of [45], establishes a strong form of solidarity between the discrete optimization problem (1.1) (1.2) and a related total-cost optimal control problem for the linear fluid model. These results can be generalized to show that an optimized SDE model possesses a fluid limit model which is itself optimal with respect to the total-cost criterion. Hence to optimize the Brownian motion model one must also solve the linear fluid model optimization problem.

A translation of a policy from the fluid model to the original discrete model of interest is again not obvious. This issue is addressed in [42, 2], where it is shown that virtually any "fluid trajectory" can be approximately tracked using a discrete policy for the discrete-stochastic network. In [13, 45] the results from several numerical studies are described. It is found that the optimal discrete policy resembles the optimal fluid policy, but with the origin θ for the model (2.2) shifted to some value $\bar{x} \in \mathbb{R}_+^\ell$. From these results it is argued that one should use the fluid model to attempt to regulate the state to some deterministic value $\bar{x}$. In the numerical studies considered, it was found that the average cost was nearly optimal and that the variance at each buffer was *lower* than that obtained using an optimal policy. The computation of optimal policies for the linear fluid model appears to be feasible for network models of moderate complexity [56, 41, 49].

A final motivation for considering the simplest network model follows on considering our main goal: robust policy synthesis. As described in (iii) above, any policy that we construct should be sufficiently robust so that it will tolerate modeling errors resulting from uncertain variability in service or arrival rates.

The main results of the present paper builds upon those of [45, 44]:

(i) The class of models is extended to include routing and processor sharing models as well as the scheduling models considered earlier. This requires that we introduce a notion of stabilizability for networks, which is a generalization of the usual capacity conditions.

(ii) The underlying theory is improved. It is shown that optimal policies have optimal fluid limits with respect to the total cost criterion. This improves upon the main result of [45, 44], which required specialization to a class of "fluid limit models" obtained via weak convergence. Moreover, the stability theory relating networks and their fluid models is improved to give criteria for geometric ergodicity and simpler conditions implying transience of the controlled network.

(iii) The practical usefulness of the approach is improved by borrowing from the BIGSTEP approach of [28] and by exploring reduced complexity control approaches for the fluid model.

(iv) Numerical examples are given. In each case it is shown that the feedback regulation policy closely resembles the average-cost optimal policy.

(v) Consideration of the fluid model leads to an approach to estimating steady state performance indicators, such as mean delay, through simulation. This requires care since standard Monte Carlo simulation is known to have high variance for highly loaded networks.

The viewpoint arrived at in this paper leads to policies which are similar to those found through a heavy traffic analysis using a Brownian motion approximation. Consider, for example, the models treated in [32]. In each case one could perform designs on the fluid model, translate these policies as in (4.1), and arrive at the same policy that was obtained using a Brownian motion approximation. Given the greater complexity of the Brownian motion model, we conclude that while diffusion

approximations are tremendously useful for analysis and performance approximation, presently they appear to be less useful for the purposes of control design. This will change if more efficient numerical methods can be devised for control synthesis in SDE models [38].

One of the most important benefits of a heavy traffic assumption is that the resulting "state space collapse" can result in a model of reduced complexity. In the models considered in the aforementioned references, in each case one is left with a one dimensional state process which captures all relevant information. This model reduction is obtained for *either* model, fluid or SDE, when the system load approaches a critical value. The aim of Part II, the sequel to the present paper, is to exploit this observation to prove that, under certain geometric conditions, an optimal policy for the fluid model may be translated to form a policy which is approximately optimal for the stochastic model [43].

The remainder of the paper is organized as follows. Section 2 describes the class of models considered and their associated fluid limit model. Here some general stability theory for networks and their fluid models is presented, including criteria for geometric ergodicity. In section 3 this solidarity between the fluid model and the discrete network is extended. It is shown that, provided the fluid model is stabilizable, there exists an average cost optimal policy whose fluid model is optimal with respect to the total-cost criterion. Several examples are given to illustrate the relationship between the two optimization problems for specific models. The *feedback regulation* policies are introduced in section 4. Several classes of stabilizing fluid policies are described, and a stability proof is provided in this section. Conclusions are postponed to Part II.

2. Networks and their fluid limit models. The networks envisioned here consist of a finite set of resources, a finite set of buffers, and various customers classes which arrive to the network for processing. Resources perform various activities, which transform parts or customers at the various buffers. On completion of service, a customer either leaves the network or visits another resource for further processing. This is the intuitive definition of a multiclass queueing network. A popular continuous-time model is given by

$$Q(t;x) = x - S(Z(t;x)) + R(Z(t;x)) + A(t), \qquad t \geq 0. \tag{2.1}$$

The vector-valued stochastic process $Q(t;x)$ denotes the buffer levels at time t with initial condition $Q(0;x) = x \in \mathbb{R}^{\ell}$. Some of these buffers may be *virtual*. In a manufacturing model, such as that shown in Figure 1, virtual buffers may correspond to backlog or excess inventory.

The vector-valued stochastic process $Z(t;x)$ is the *allocation* (or *control*). The ith component $Z_i(t;x)$ gives the cumulative time that the activity i has run up to time t.

The vector-valued process $\boldsymbol{A}$ may denote a combination of exogenous arrivals to the network and exogenous demands for materials *from* the network. The vector-valued functions $S(\,\cdot\,), R(\,\cdot\,)$ represent, respectively, the effects of random service rates and the effects of a combination of possibly uncontrolled, possibly random routing, and random service rates.

The *fluid limit model* is obtained on considering a congested network. When $Q(t;x)$ is large in magnitude, variations in the arrival and service processes appear small when compared with the state. The behavior of $\boldsymbol{Q}$ when viewed on this large spatial scale will appear deterministic and can be approximated by the *mean field*

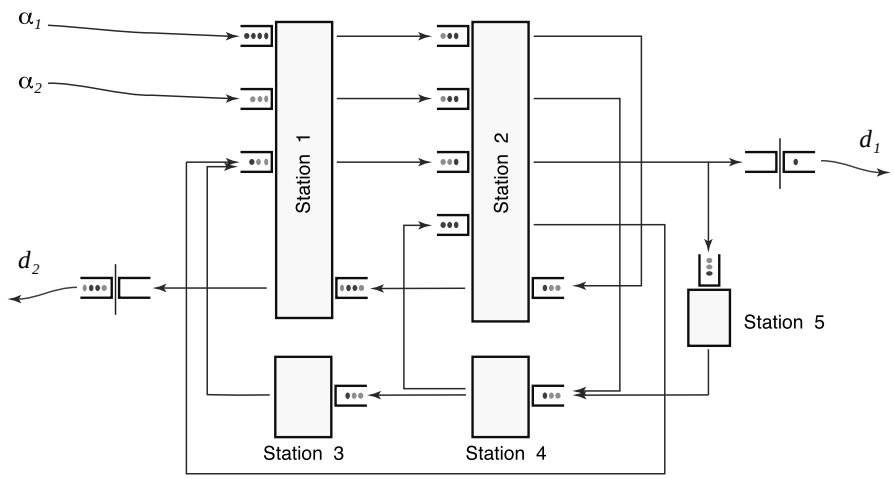

FIG. 1. *A network with many buffers, controlled routing, uncontrolled routing, multiple demands, and virtual buffers.*

equations, or *(linear) fluid model*,

$$q(t;x) = x + Bz(t;x) + \alpha t, \qquad t \geq 0. \tag{2.2}$$

Here B is a matrix of appropriate dimension, interpreted as a long-run average of $\boldsymbol{R} - \boldsymbol{S}$, and α is a long-run average of $\boldsymbol{A}$.

There are several ways of making this precise, and very few assumptions are required to ensure the existence of a well-defined fluid limit model. A construction is provided in section 2.1, and section 2.2 describes a stability theory for (2.1) based on the simpler model (2.2).

Section 2.1 introduces a discrete-time countable state space MDP model. In the special case where all of the driving processes $(\boldsymbol{A}, \boldsymbol{R}, \boldsymbol{S})$ are multidimensional Poisson processes, the discrete-time model is obtained from (2.1) via *uniformization* [40]. The MDP model is convenient for the purposes of optimization and also provides the simplest setting for constructing the fluid limit model through scaling $\boldsymbol{Q}$ and $\boldsymbol{Z}$.

2.1. A Markovian network model and its fluid limit. Consider the M/M/1 queue, described in continuous time by

$$Q(t;x) = x - S(Z(t;x)) + A(t), \qquad t \geq 0,$$

where the *cumulative busy time* $\boldsymbol{Z}$ satisfies $\frac{d}{dt} Z(t;x) = 1$ whenever $Q(t;x) \neq 0$. The stochastic processes $(\boldsymbol{A}, \boldsymbol{S})$ are one dimensional Poisson processes with rates α, μ, respectively. The fluid model is given by the analogous equation,

$$q(t;x) = -\mu z(t) + \alpha t, \qquad t \geq 0. \tag{2.3}$$

To obtain a discrete-time process, one might sample at successive jump times of $\boldsymbol{Q}$, but this would introduce bias. When $Q(t;x) = 0$, only upward jumps are possible; hence sampling is less frequent in this situation, and the overall sampling rate is *nonuniform*. Consequently, the steady-state queue length for the sampled process is strictly larger than that of the unsampled queue.

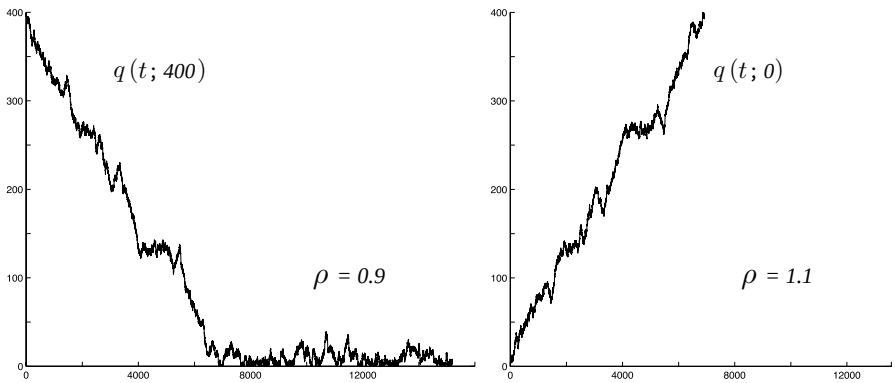

FIG. 2. *The M/M/1 queue: In the stable case on the left we see that the process $Q(t;x)$ appears piecewise linear with a relatively small high frequency "disturbance." The process explodes linearly in the unstable case shown at right.*

Uniformization corrects this by introducing *virtual service times* and by sampling $\boldsymbol{Q}$ at times of arrivals, service completions, or virtual service completions. For example, the first sampling time is of the form $\tau_1 = \min(S_1, T_1)$, where S_1 and T_1 are exponentially distributed random variables with mean $1/\mu$ and $1/\alpha$, respectively. If $Q(0;x) = x > 0$, then S_1 is the remaining service time for the customer currently in service. If $x = 0$, then S_1 is again exponential with mean $1/\mu$, but it is now a random variable which is independent of the original queue length process. Sampling results in a discrete-time Markov chain with transition probabilities:

$$P(x, x+1) = \alpha, \qquad P(x, (x-1)_+) = \mu, \qquad x = 0, 1, 2, 3, \ldots .$$

When $\rho = \alpha/\mu$ is less than one, then the queue is *positive recurrent*, as shown in the left-hand side of Figure 2.

The discrete-time M/M/1 queue model may be viewed as a random linear system,

$$Q(k+1) = Q(k) + \widetilde{B}(k+1)U(k) + \widetilde{\alpha}(k+1), \tag{2.4}$$

where the sequence $\boldsymbol{U}$ is defined again by the nonidling policy $U(k) = \mathbb{I}(Q(k) > 0)$, $k \geq 0$, and $\{\widetilde{B}(k), \widetilde{\alpha}(k) : k \geq 1\}$ is an indendent and identically distributed (i.i.d.) sequence satisfying,

$$\begin{pmatrix} \widetilde{B}(k) \\ \widetilde{\alpha}(k) \end{pmatrix} = \begin{cases} -e^1 & \text{with prob } \mu, \\ e^2 & \text{with prob } \alpha, \end{cases}$$

with e^i equal to the standard basis element in $\mathbb{R}^2$, $i = 1, 2$. The general network model may be sampled in the same way to obtain a similar, multidimensional model whenever $(\boldsymbol{A}, \boldsymbol{R}, \boldsymbol{S})$ are Poisson.

Since we will not consider again the continuous-time model, we will denote by $(\boldsymbol{Q}, \boldsymbol{U}) = \{(Q(k;x), U(k;x)) : k \geq 0\}$ the state-allocation process for a discrete-time model with initial condition x. (This dependency will be suppressed when the particular initial condition is not relevant.) We assume that there are ℓ buffers and ℓ_u activities so that $(\boldsymbol{Q}, \boldsymbol{U})$ evolves on $\mathbb{Z}_+^{\ell} \times \mathbb{Z}_+^{\ell_u}$. As in the continuous-time case, each $U_i(k)$, $1 \leq i \leq \ell_u$, takes binary values. The discrete-time Markovian model is then *defined* as the random linear system (2.4).

We assume that the sequence $\{\widetilde{B}(k), \widetilde{\alpha}(k) : k \geq 1\}$ is i.i.d.. For each k, the matrix $\widetilde{B}(k)$ has dimension $\ell \times \ell_u$, the vector $\widetilde{\alpha}(k)$ has dimension ℓ, and the components of both take on integer values, again strictly bounded. We assume, moreover, that the components of $\widetilde{\alpha}(k)$ are nonnegative.

This is a generalization of the sampled model, in which the entries of $(\widetilde{B}(k), \widetilde{\alpha}(k))$ take on the values $(-1, 0, 1)$ only. However, this discrete-time model covers only a very narrow set of stochastic network models. For example, it is not possible to convert the natural continuous time model into a countable-state, discrete-time MDP if service times are uniformly distributed. We restrict ourselves to the simple discrete-time model for the sake of exposition only. General distributions are considered in [14, 15], where it is shown that stability theory goes through without change. To generalize the results of the present paper, e.g., Theorem 4, one must assume a bounded hazard rate as in [46] to ensure that the mean forward recurrence time is bounded. Part II, which does not require a Markovian description, develops the general model (2.1) [43].

We assume that there is an integer $\ell_m \geq 1$ and an $\ell_m \times \ell_u$ *constituency matrix* C, such that

$$CU(k) \leq \mathbf{1}, \qquad k \geq 0,$$

where $\mathbf{1}$ denotes a vector of ones. The entries of C take on binary values, and each row defines a *resource*: The ith resource $\mathcal{R}_i$ is defined to be the set of activities j such that $C_{ij} = 1$.

There may also be auxiliary constraints on the control sequence $\boldsymbol{U}$ and further constraints on $\boldsymbol{Q}$. For example, buffers may require synchronous processing, or strict limits on buffer levels may be imposed. We assume that these may be expressed through linear constraints,

$$C_a U(k) \leq b_a, \qquad C_s Q(k) \leq b_s, \qquad k \geq 0,$$

for matrices C_a, C_s and vectors b_a, b_s of appropriate dimension.

We have thus restricted $(\boldsymbol{Q}, \boldsymbol{U})$ to lie in the countable sets

$$Q(k) \in \mathsf{X} \cap \mathbb{Z}^{\ell} \quad U(k) \in \mathsf{U} \cap \mathbb{Z}^{\ell_u}, \qquad k \geq 0,$$

where

$$\mathsf{U} := \{\zeta \in \mathbb{R}_+^{\ell_u} : \zeta \geq \theta,\ C\zeta \leq \mathbf{1},\ C_a\zeta \leq b_a\}, \tag{2.5}$$

$$\mathsf{X} := \{x \in \mathbb{R}_+^{\ell} : x \geq \theta,\ C_s x \leq b_s\}. \tag{2.6}$$

We assume throughout the paper that U is bounded. Unless noted otherwise, we assume that C_a and C_s are null.

The sequence $\boldsymbol{U}$ is an adapted (history-dependent) stochastic process. We say that $\boldsymbol{U}$ is defined by a *stationary policy* if there is a feedback function $F\colon \mathsf{X} \to \mathsf{U}$ satisfying

$$\mathsf{P}(U_i(k) = 1 \mid Q(0), \ldots, Q(k)) = F_i(Q(k)), \qquad k \geq 0.$$

The policies we consider are primarily stationary or are based on such policies.

In the classical *scheduling model*, the ℓ_m resources $\{\mathcal{R}_i : 1 \leq i \leq \ell_m\}$ are called *stations*. There is one activity for each customer class, giving $\ell_u = \ell$. Class i customers wait in the ith queue, if necessary, and then receive service via the ith activity. Upon

completion of service, a class i customer becomes a class j customer with probability R_{ij} and exits the system with probability $R_{i0}:=1-\sum_j R_{ij}$. The constraint $CU(k) \le \mathbf{1}$ is the usual condition that no two customers receive service simultaneously at a single station.

To construct the fluid limit model, first consider the time-invariant means, given by

$$B = \mathsf{E}[\widetilde{B}(k)], \quad \alpha = \mathsf{E}[\widetilde{\alpha}(k)], \qquad k \ge 1.$$

We may then write

$$Q(k+1) = Q(k) + BU(k) + \alpha + D(k+1), \tag{2.7}$$

where the process $\boldsymbol{D}$ is bounded, and it is a martingale difference sequence with respect to the natural filtration. In this way, the model (2.4) may be viewed as a deterministic "fluid model" with a bounded "disturbance" $\boldsymbol{D}$. When the initial condition $Q(0)$ is large, then the state dominates this disturbance, and the network behavior appears deterministic.

The fluid limit model considered in this paper is obtained by scaling the process, both temporally and spatially, through a scaling parameter $n \in \mathbb{Z}_+$. For any $x \in \mathbb{R}_+^\ell$, $n \ge 1$, we define

$$q^n(t;x) = \frac{1}{n} Q(nt; nx), \tag{2.8}$$

$$z^n(t;x) = \frac{1}{n} \sum_{i \le nt} U(i;x), \qquad t = \frac{0}{n}, \frac{1}{n}, \frac{2}{n}, \dots, \tag{2.9}$$

where we are taking the integer part of nx whenever necessary so that the initial condition nx lies in $\mathbb{Z}_+^\ell$. We then extend the definition of $\{q^n(t;x), z^n(t;x)\}$ to arbitrary $t \in \mathbb{R}_+$ so that these processes are linear on each time segment $[i/n, (i+1)/n]$ and continuous on $\mathbb{R}_+$.

We have $q^n(0;x) = x$ and $z^n(0;x) = \theta$, and $\{q^n(\,\cdot\,;x), z^n(\,\cdot\,;x)\}$ are Lipschitz continuous for any n and x. Typically, we find that $\{\boldsymbol{q}^n, \boldsymbol{z}^n\}$ converges to a limiting, deterministic function of time $\{\boldsymbol{q}, \boldsymbol{z}\}$ as $n \to \infty$. The limits $\boldsymbol{q}$ and $\boldsymbol{z}$ are piecewise linear functions of t in all of the examples considered below. Figure 2 illustrates the nature of this convergence for the M/M/1 queue, where the limiting process satisfies (2.3).

For each x, the set $\mathcal{L}_x$ denotes all weak limits of $\{(q^n(\,\cdot\,;x), z^n(\,\cdot\,;x)) : n \ge 1\}$ as $n \to \infty$. The *fluid limit model*, denoted $\mathcal{L}$, is the union of $\mathcal{L}_x$ over all initial conditions. Any $(q,z) \in \mathcal{L}$ satisfies (2.2), together with the rate constraints

$$C[z(t) - z(s)] \le (t-s)\mathbf{1}, \quad z(t) - z(s) \ge \theta, \qquad t \ge s \ge 0. \tag{2.10}$$

That is, $\frac{z(t)-z(s)}{t-s} \in \mathsf{U}$ for any $t \ne s$.

2.2. Stability of the models. Stability of the network under some policy requires some assumptions on the model. We say that $\boldsymbol{z}$ is a *feasible allocation* for the fluid model if the resulting state trajectory $\boldsymbol{q}$ satisfying (2.2), (2.10) remains in X for all $t \ge 0$. The fluid model is said to be

- *stabilizable* if, from any initial condition $x \in \mathsf{X}$, there exist $T_\theta < \infty$ and a feasible allocation $\boldsymbol{z}$ such that

$$q(t;x) = x + \alpha t + Bz(t) = \theta, \qquad t \ge T_\theta;$$

- *controllable* if for any pair $x, y \in \mathsf{X}$, there is a feasible allocation $\boldsymbol{z}$ and a time T such that $q(T; x) = y$.

Note that one can assume without loss of generality that an allocation $\boldsymbol{z}$ driving x to y is *linear*.

PROPOSITION 1. *Suppose that $x, y \in \mathsf{X}$, $T > 0$, and $\boldsymbol{z}$ is an allocation satisfying*

$$q(T; x) = x + \alpha T + Bz(T) = y.$$

Then the linear allocation $z^1(t) = \bar{z}t$, $0 \le t \le T$, also brings $\boldsymbol{q}$ to y from x at time T and satisfies (2.10) *on* $[0, T]$.

A necessary condition for stabilizability is that there must exist some solution to the equilibrium equation

$$B\zeta^{\text{ss}} + \alpha = \theta, \qquad \zeta^{\text{ss}} \in \mathsf{U}. \tag{2.11}$$

In the special case of network scheduling, the $\ell \times \ell$ matrix B has the form

$$B = -(I - R^{\text{T}})M, \tag{2.12}$$

where M is the diagonal matrix with diagonal entries $\mu^{\text{T}} = (\mu_1, \dots, \mu_\ell)$. There is a unique solution to the equilibrium equation (2.11), given by $\zeta^{\text{ss}} = -B^{-1}\alpha$, and the standard load condition may be written as

$$\vec{\rho} = -C\zeta^{\text{ss}} = M^{-1}(I - R^{\text{T}})^{-1}\alpha < \mathbf{1}. \tag{2.13}$$

It is readily seen that the load condition implies stabilizability. In routing models and many other examples, the "load" at a station is policy-dependent [32].

To obtain sufficient conditions for stabilizability, it is convenient to envision (2.2) as a differential inclusion,

$$\dot{q} \in \mathsf{V} := \{B\zeta + \alpha : \zeta \in \mathsf{U}\} \subset \mathbb{R}^\ell.$$

The set V is equal is the set of possible velocity vectors for the fluid model. We let $-\mathsf{V}$ denote its reflection. The proof of the following result is obvious and will be omitted. In Proposition 2 the set $B(\theta, \varepsilon)$ denotes the open ball of radius ε, centered at the origin.

PROPOSITION 2. *The fluid model* (2.2) *is*

(i) *stabilizable if and only if there exists $\varepsilon > 0$ such that*

$$B(\theta, \varepsilon) \cap \mathbb{R}^\ell_+ \subset \{-\mathsf{V}\} \cap \mathbb{R}^\ell_+,$$

(ii) *controllable if and only if there exists $\varepsilon > 0$ such that $B(\theta, \varepsilon) \subset \mathsf{V}$.*

Either of the conditions (i) or (ii) can be formulated as a finite linear program. For example, the following set of constraints summarizes the condition that V contains each of the vectors $\{-\varepsilon e^i : 1 \le i \le \ell\}$.

$$\begin{aligned} B\zeta^i + \alpha &= -\varepsilon_i e^i, \\ C\zeta^i &\le \mathbf{1}, \\ \zeta^i &\ge \theta, \qquad 1 \le i \le \ell. \end{aligned}$$

A related linear program is devised to define the system load in [26, 25].

We now turn to the discrete-stochastic network.

When controlled by a randomized stationary policy with feedback law F, the state process becomes a time-homogeneous Markov chain. The state transition matrix is denoted $P_{\scriptscriptstyle F}$—the subscript is supressed when there is no risk of ambiguity. *Stability* of the controlled process is defined as positive recurrence of the resulting Markov chain. Under stability, there exists a unique invariant probability $\pi = \pi_{\scriptscriptstyle F}$, and steady-state performance measures such as mean delay or average total congestion can be described in terms of the invariant probability.

We assume that, under the transition law P, the state process possesses a single communicating class $\mathcal{C}$ which contains the origin θ. We assume, moreover, that the controlled system is ψ-irreducible and aperiodic, as defined in [47]. Defining the first return time to a set $A \subseteq \mathsf{X}$ by

$$\tau_A = \min(k \geq 1 : Q(k) \in A),$$

the ψ-irreducibility condition can be expressed as $\mathsf{P}_x(\tau_\theta < \infty) > 0$ for any $x \in \mathsf{X}$. This is typically a minor constraint on the policy. For the network scheduling problem these conditions hold when the policy is nonidling.

Throughout the paper we use $c\colon \mathbb{R}_+^\ell \to \mathbb{R}_+$ to denote a norm, i.e., it is continuous, convex, vanishes only at θ, and it is radially homogeneous. The function c will be interpreted as a one step cost function for the model. For a particular stationary policy, the controlled chain is called *c-regular* if, for any initial condition x,

$$\mathsf{E}_x \left[\sum_{i=0}^{\tau_\theta - 1} c(Q(i)) \right] < \infty.$$

A c-regular chain always possesses a unique invariant probability π such that

$$\pi(c) := \sum_{x \in \mathsf{X}} c(x)\, \pi(x) < \infty.$$

A stationary Markov policy (and its associated feedback function F) is called *regular* if the controlled chain is c-regular. In this case it follows from the f-norm ergodic theorem of [47, Chapter 14] that the following average cost exists and is independent of the initial condition x:

$$\begin{aligned} &\text{(i)} \qquad J(x,w) = \lim_{k\to\infty} \mathsf{E}_x[c(Q(k))] \;\; = \;\; \pi(c), \\ &\text{(ii)} \qquad\quad \lim_{n\to\infty} \frac{1}{n} \sum_{k=1}^{n} c(Q(k)) \;\; = \;\; \pi(c), \qquad \text{almost surely (a.s.).} \end{aligned}$$

The fluid limit model is said to be *stable* if there exist $\varepsilon > 0$ and $T < \infty$ such that $q(T;x) = \theta$ for any $q \in \mathcal{L}_x$ with $\|x\| \leq \varepsilon$. It will be called *L_p-stable* if, for some $\varepsilon > 0$,

$$\lim_{t\to\infty} \sup_{q \in \mathcal{L}_x : \|x\| \leq \varepsilon} \mathsf{E}[\|q(t)\|^p] = 0.$$

The following result is a minor generalization of [45, Theorem 5.2]. Related results are found in [20, 52, 14, 15].

THEOREM 3. *The following stability criteria are equivalent for the network under any nonidling, stationary Markov policy.*

(i) *There exist $b_0 < \infty$ and a function $V\colon \mathbb{R}^\ell \to \mathbb{R}_+$ such that the following drift condition holds:*

$$PV(x) := \mathsf{E}_x[V(Q(k+1)) \mid Q(k) = x] \le V(x) - c(x) + b_0, \qquad x \in \mathsf{X}. \tag{2.14}$$

The function V is equivalent to a quadratic in the sense that, for some $\varepsilon > 0$,

$$1 + \varepsilon\|x\|^2 \le V(x) \le 1 + \varepsilon^{-1}\|x\|^2, \qquad x \in \mathsf{X}.$$

(ii) *For some quadratic function V and some $b_0 < \infty$,*

$$\mathsf{E}_x\left[\sum_{n=0}^{\tau_\theta} c(Q(n))\right] \le V(x) + b_0, \qquad x \in \mathsf{X}.$$

(iii) *For some quadratic function V and some $b_0 < \infty$,*

$$\sum_{n=1}^{N} \mathsf{E}_x[c(Q(n))] \le V(x) + b_0 N \quad \text{for all } x \text{ and } N \ge 1.$$

(iv) *The fluid limit model is L_2-stable.*

(v) *The total cost for the fluid limit is uniformly bounded in the sense that, for some quadratic function V,*

$$\mathsf{E}\left[\int_0^\infty \|q(\tau; x)\|\, d\tau\right] \le V(x), \qquad x \in \mathbb{R}_+^\ell,\ q \in \mathcal{L}_x.$$

If any of these equivalent conditions, hold then the stationary policy is regular.

For a well-designed policy the controlled chain will be stable in a far stronger sense. A Markov chain $\boldsymbol{Q}$ is called *V-uniform ergodic*, with $V\colon \mathbb{R}^\ell \to [1, \infty)$ a given function, if there exist $\gamma < 1$ and $b < \infty$ such that

$$|\mathsf{E}[g(Q(k)) \mid Q(0) = x] - \pi(g)| \le b\gamma^k V(x), \qquad k \in \mathbb{Z}_+,\ x \in \mathsf{X},$$

where g is any function satisfying $|g(x)| \le V(x)$, $x \in \mathsf{X}$ (see [47, Chapter 17]). A Markov chain satisfying this strong form of ergodicity is similar to an i.i.d. process. In particular, a V-uniform Markov chain satisfies a strong form of the large deviations principle [3, 33].

This stronger form of stability holds under uniform convergence to the fluid limit. The following two forms of uniform convergence will be assumed on a given set $S \subset \mathsf{X}$ of initial conditions. For a set $Y \subseteq \mathbb{R}^\ell$ and a point $x \in \mathbb{R}^\ell$, we define

$$d\{x, Y\} = \inf(\|x - y\| : y \in Y).$$

Similarly, if $\mathcal{F} \subseteq C([0,T], \mathbb{R}^{\ell+\ell_u})$ is a set of functions and $q \in C([0,T], \mathbb{R}^{\ell+\ell_u})$ is another function, then we define

$$d\{q, \mathcal{F}\} = \inf_{\psi \in \mathcal{F}} \sup_{0 \le t \le T} \|q(t) - \psi(t)\|.$$

(U1) For any given T, ε there is a sequence $\{\Theta(\varepsilon, T, n)\}$ such that for any $x \in S$,

$$\mathsf{P}\Big(d\{q^n(T; x), Y_x(T)\} > \varepsilon\Big) \le \Theta(\varepsilon, T, n) \to 0, \qquad n \to \infty,$$

where $Y_x(T) = \{q(T; x) : q \in \mathcal{L}_x\} \subseteq \mathbb{R}_+^\ell$.

(U2) For any given T, ε there is a sequence $\{\Theta(\varepsilon, T, n)\}$ such that for any $x \in S$,

$$\mathsf{P}\Big(d\{q^n(\,\cdot\,;x), \mathcal{L}_x\} > \varepsilon\Big) \le \Theta(\varepsilon, T, n) \to 0, \qquad n \to \infty.$$

These conditions are frequently automatic since the functions $\big\{q^n(\,\cdot\,;x) - q(\,\cdot\,;x), z^n(\,\cdot\,,x) : n \ge 1, x \ne \theta\big\}$ are uniformly bounded and uniformly Lipschitz continuous.

A stable fluid limit model always admits a *Lyapunov function* $V\colon \mathbb{R}_+^\ell \to \mathbb{R}_+$ satisfying

$$V(q(t;x)) \le V(x) - t \qquad \text{for } t < \tau_\theta = \min(t : q(t;x) = \theta). \tag{2.15}$$

One can take the maximal emptying time itself and, moreover, this Lyapunov function is radially homogeneous. Conversely, the existence of a Lyapunov function satisfying (2.15) is known to imply stability.

If there exists a *Lipschitz continuous* Lyapunov function, then one can deduce not just stability but robustness with respect to parametric perturbations. It is not surprising then that the existence of a Lipschitz Lyapunov function implies a form of exponential stability.

THEOREM 4. *Suppose that the network is controlled using a stationary policy, and that there exists $b_0 < \infty$ such that, with $S = \{x : \|x\| \ge b_0\}$,*

(i) *assumption* (U1) *holds on S;*

(ii) *there exists a Lipschitz continuous function $V\colon \mathbb{R}_+^\ell \to \mathbb{R}_+$ satisfying* (2.15) *for $x \in S$.*

Then the network is V_ε-uniformly ergodic, where $V_\varepsilon(x) = \exp(\varepsilon V(x))$ for some $\varepsilon > 0$ sufficiently small.

Proof. Note first that V can be taken as radially homogeneous without loss of generality: $V(bx) = bV(x)$ for $b \ge 0$. If this is not the case, we can replace V by $V^1(x) = \inf_{b>0} \frac{1}{b} V(bx)$.

Given the uniform convergence of $\{q^n\}$ and the inequality (2.15) for the limit, we can find an $n_0 > 0$ such that

$$\mathsf{E}[V(Q(n;nx))] = n\mathsf{E}[V(q^n(1;x))] \le n(x - 1/2), \qquad \|x\| \ge b_0,\ n \ge n_0.$$

Hence we can assume that (V1) of [47] is satisfied for the n-step chain:

$$P^n V\,(x) \le V(x) - 1, \qquad \|x\| \ge nb_0.$$

The result then follows from [47, Theorem 16.3.1]. □

A strengthened form of convergence to the fluid limit model also provides a basis for establishing transience of a network model. Note that a large deviations bound would provide a rate of convergence far stronger than assumed in (i).

THEOREM 5. *Suppose that the network is controlled using a stationary policy and that the following hold for the set $S = \mathcal{O}$, where $\mathcal{O}$ is bounded and open as a subset of $\mathbb{R}_+^\ell$.*

(i) *The uniform limit* (U2) *holds, where, for some finite $b(\,\cdot\,)$,*

$$\Theta(\varepsilon, T, n) \le b(\varepsilon, T)/n, \qquad n \ge 1.$$

(ii) *There is an open set $\mathcal{V}$ with $\bar{\mathcal{V}} \subset \mathcal{O}$, and there are an $r > 1$, $T < \infty$, such that*

$$q(T;x) \in r\mathcal{V}, \qquad x \in \mathcal{O},\ q \in \mathcal{L}_x.$$

(iii) *For some $\varepsilon_1 > 0$ we have the uniform lower bound*

$$\|q(t;x)\| \ge \varepsilon_1, \qquad 0 \le t \le T, x \in \mathcal{O},\ q \in \mathcal{L}_x.$$

Then there is a constant b_2 such that for $x \in \mathcal{O}$

$$\mathsf{P}(\boldsymbol{Q} \to \infty \mid Q(0) = nx) \ge 1 - \frac{b_2}{n}.$$

Hence if $\{n\mathcal{O}\} \cap \mathcal{C} \neq \emptyset$ for some $n > b_2$, then the state process $\boldsymbol{Q}$ is a transient Markov chain.

Proof. By (U2) we have, for some $0 < \varepsilon_2 < \varepsilon_1$, some $b_1 < \infty$, and any $x \in \mathcal{O}$,

$$\begin{aligned}
&\mathsf{P}\Big(\|Q(nt;nx)\| \ge \varepsilon_2 n,\ 0 \le t \le T,\ \text{and } Q(nT;nx) \in nr\mathcal{O}\Big) \\
&= \mathsf{P}\Big(\|q^n(t;x)\| \ge \varepsilon_2,\ 0 \le t \le T,\ \text{and } q^n(T;x) \in r\mathcal{O}\Big) \\
&\ge 1 - \frac{b_1}{n}.
\end{aligned}$$

Here we are also using the assumption that $\bar{\mathcal{V}} \subset \mathcal{O}$.

The above bound can be generalized by replacing the integer n with $r^i n$, where $r > 1$ is given in (ii) (again taking integer parts whenever necessary). For any $x \in \mathbb{R}_+^\ell$ and any $i \ge 1, n \ge 1$, define the event $\mathcal{A}(x,i,n) =$

$$\Big\{\|Q(r^i nt;nx)\| \ge \varepsilon_2 r^i n,\ 0 \le t \le T,\ \text{and } Q(r^i nT;nx) \in r^{i+1} n\mathcal{O}\Big\}$$

so that by the previous bound, whenever $x \in r^i\mathcal{O}$,

$$\mathsf{P}(\mathcal{A}(x,i,n)) \ge 1 - \frac{b_1}{n} r^{-i}.$$

By stopping the process at the successive times, $N_0 = 0$, $N_k = N_{k-1} + nr^{k-1}T$, $k \ge 1$, and, using the Markov property, we find that for $x \in \mathcal{O}$ and with $\beta = \varepsilon_2 T^{-1}(1 - r^{-1})$,

$$\begin{aligned}
\mathsf{P}(\|Q(k;nx)\| \ge \beta t,\ 0 \le t \le nN_k) &\ge \sum_{i=0}^{k-1} \inf_{y \in \{r^i\mathcal{O}\}} \mathsf{P}(\mathcal{A}(y,i,n)) \\
&\ge 1 - \frac{b_1}{n}(1 + r^{-1} + \cdots + r^{-k+1}).
\end{aligned}$$

This proves the theorem with $b_2 = \frac{b_1}{1 - r^{-1}}$ since the integer k is arbitrary. ∎

We consider the example illustrated in Figure 10 to show how Theorems 4 and 5 can be applied. This example was introduced in [52, 35] to show how instability can arise in networks even when the traffic conditions are satisfied.

To give one example of a stabilizing policy, suppose that at each time k we choose $U^\circ(k)$ to minimize the conditional mean,

$$U^\circ(k) = \arg\min_a \mathsf{E}[\|Q(k+1)\|^2 \mid Q(k), U(k) = a],$$

where the minimum is over all $a \in \mathsf{U}$, subject to the constraint that $a_i = 0$ if $Q_i(k) = 0$. The minimization can be selected so that $\mathbf{U}^\circ$ is defined by a nonidling, stationary Markov policy defined by a feedback law F°.

The feedback law can be written as

$$F^\circ(x) = \arg\min P_a V_2\,(x), \qquad x \in \mathsf{X},$$

where $V_2(\,\cdot\,) := \|\,\cdot\,\|^2$. The function $F^\circ\colon \mathsf{X} \to \mathsf{U}$ is radially constant and vanishes on the boundaries $F_i^\circ(x) = 0$ when $x_i = 0$. The uniform condition (U2) is readily verified in this case since, for large x, the controlled chain resembles an unreflected random walk (see [6] and also Proposition 8 below).

To evaluate F° note that for any action a, the drift $P_a V_2 - V_2$ is the sum of a linear term $\langle v_a, x\rangle$ and a bounded term. The vector v_a can be expressed as

$$v_a = 2(Ba + \alpha) = 2(\alpha_1 - \mu_1 a_1, \mu_1 a_1 - \mu_2 a_2, \alpha_3 - \mu_3 a_3, \mu_3 a_3 - \mu_4 a_4)^{\scriptscriptstyle T}.$$

The choice $a^{\scriptscriptstyle \rm ss} = (\alpha_1\mu_1^{-1}, \alpha_1\mu_2^{-1}, \alpha_3\mu_3^{-1}, \alpha_3\mu_4^{-1})^{\scriptscriptstyle T}$ makes $v_{a^{\rm ss}} = 0$ and is in the interior of the control space provided that the capacity conditions hold. This gives $P_{a^{\rm ss}} V_2 - V_2 \le b_0$ for some constant b_0. This is a randomized action, which is feasible provided $x_i \neq 0$, $1 \le i \le 4$. If some $x_i = 0$, then the corresponding value $a_i^{\rm ss}$ must also be set to 0, but we still obtain an upper bound of the form $P_{a^{\rm ss}} V_2 - V_2 \le b_0$.

One can conclude that the feedback law

$$F^\varepsilon(x) = \mathbb{I}_+(x)\left(a^{\rm ss} - \varepsilon B^{-1}\frac{x}{\|x\|}\right) \tag{2.16}$$

with B given in (2.12) and $\mathbb{I}_+(x) = \operatorname{diag}(\mathbb{I}(x_1 > 0), \ldots, \mathbb{I}(x_4 > 0))$ is feasible for $\varepsilon > 0$ sufficiently small. For some possibly larger b_0, it satisfies

$$P_{F^\varepsilon} V_2 \le V_2 - 2\varepsilon\|x\| + b_0.$$

By minimality, the feedback law F° exhibits an even larger negative drift,

$$P_{F^\circ} V_2 \le P_{F^\varepsilon} V_2 \le V_2 - 2\varepsilon\|x\| + b_0.$$

Using Jensen's inequality, we find that the function $V(x) = \sqrt{V_2(x)} = \|x\|$ is a Lyapunov function for the network, and it is also a Lyapunov function for the fluid limit model. Applying Theorem 4, we see that F° is a regular policy, and that the controlled network is V_ε-uniformly ergodic.

Suppose that we replace the ℓ_2-norm by the ℓ_1-norm. Letting $c(x) = \sum x_i$, we minimize over all a the conditional mean $P_a c\,(x)$. The resulting policy is the last-buffer-first-served (LBFS) policy (where buffers 2 and 4 have strict priority). This is also one version of the $c\mu$-rule.

This policy is known to lead to a *transient* model for certain parameters, even when (2.13) holds. Specifically, suppose that

$$\frac{\alpha_1}{\mu_2} + \frac{\alpha_2}{\mu_4} > 1.$$

Under the LBFS policy the resulting fluid limit model satisfies, for some T, r,

$$q(T; x_0) = r x_0, \qquad x_0 = (0, 0, 0, 1)^{\scriptscriptstyle T}.$$

This was first shown in [35]. We also have $\|q(t; x_\varepsilon) - q(t; x_0)\| \le \varepsilon$, $0 \le t \le T$, for all $\varepsilon > 0$ sufficiently small and all $x_\varepsilon \in \mathbb{R}_+^\ell$ satisfying $\|x_\varepsilon - x_0\| \le \varepsilon$. Hence the assumptions of Theorem 5 are satisfied with $\mathcal{O} = \{x \in \mathbb{R}_+ : \|x - x_0\| < \varepsilon\}$ and $\mathcal{V} = \{x \in \mathbb{R}_+ : \|x - x_0\| < r^{-1}\varepsilon\}$. Condition (U2) holds with $S = \mathcal{O}$, again using the fact that between emptying times at buffers 2 and 4 the process $\boldsymbol{Q}$ is a simple random walk. We conclude that the network model is transient under the LBFS policy.

3. Optimization.

3.1. The average-cost optimization problem. In this paper we restrict our attention to the average cost problem. For any allocation sequence $\boldsymbol{U}$ and any initial condition x we set

$$J(x,\boldsymbol{U}) = \limsup_{N\to\infty} \frac{1}{N} \sum_{0}^{N-1} \mathsf{E}_x[c(Q(k))].$$

The most common choice is $c(x) = |x|$, where we let $|\cdot|$ denote the ℓ_1-norm. In this case the optimization of J amounts to delay minimization by Little's theorem. We have already seen that the cost $J(x,\boldsymbol{U})$ is finite and independent of x when $\boldsymbol{U}$ is a regular policy.

An optimal policy, if it exists, can be taken to be stationary, where the associated average cost optimality equations are given in (1.1),(1.2). We show below that a solution does exist when the fluid model is stabilizable, and that h^* can be approximated by the value function for a fluid model optimal control problem. For any T and any $x \in \mathbb{R}^\ell_+$, consider the problem of minimizing

$$\int_0^T c(q(t;x))\,dt$$

subject to the constraint that $q\colon [0,T] \to \mathbb{R}^\ell_+$ must satisfy (2.2) for some feasible allocation $\boldsymbol{z}$. The infimum is denoted $V^*(x,T)$.

The following proposition shows that the fluid optimal policy is in some sense *greedy*. That is, the cost as a function of the state $c(q(t))$ is never increasing, and its rate of decrease is maximal when $t \sim 0$. Such behavior is rarely found in dynamic optimization problems. For example, even a second order linear system controlled using optimal linear quadratic regulator (LQR) linear feedback can be expected to exhibit overshoot. An illustration is shown in Figure 3 for the network shown in Figure 12.

The proof of (ii) follows from the aforementioned fact that a state can be reached by following a straight line, provided it is reachable through some control. The result (i) easily follows, and (iii) is well known (see [56, 50]).

PROPOSITION 6. *For any time horizon T,*

(i) *the value function $V^*(\cdot\,,T)$ is convex;*

(ii) *for any $x \in \mathbb{R}^\ell_+$ and any optimal allocation $z^*(\cdot\,;x)$, the function $c(z^*(t;x))$ is decreasing and convex as a function of t;*

(iii) *if the cost c is linear, then $V^*(\cdot\,,T)$ is piecewise quadratic. Moreover, for any $x \in \mathbb{R}^\ell_+$ there exists an optimal state trajectory $q^*(\cdot\,;x)$ and an optimal allocation $z^*(\cdot\,;x)$ which are piecewise linear.*

For any fixed x we evidently have that $V^*(x,T)$ is increasing with T. Moreover, there exists some T_θ such that the optimal trajectories vanish by time T_θ when the time horizon T is at least T_θ, whenever the initial condition satisfies $\|x\| \le 1$. It follows that $V^*(x,T) = V^*(x,T_\theta)$ for any such T and x (see the proof of Theorem 7 (ii) below). Hence for such x and T we have

$$V^*(x,T) = V^*(x) = \min \int_0^\infty c(q(t))\,dt, \tag{3.1}$$

where the minimum is subject to the same constraints on q over the entire positive time axis.

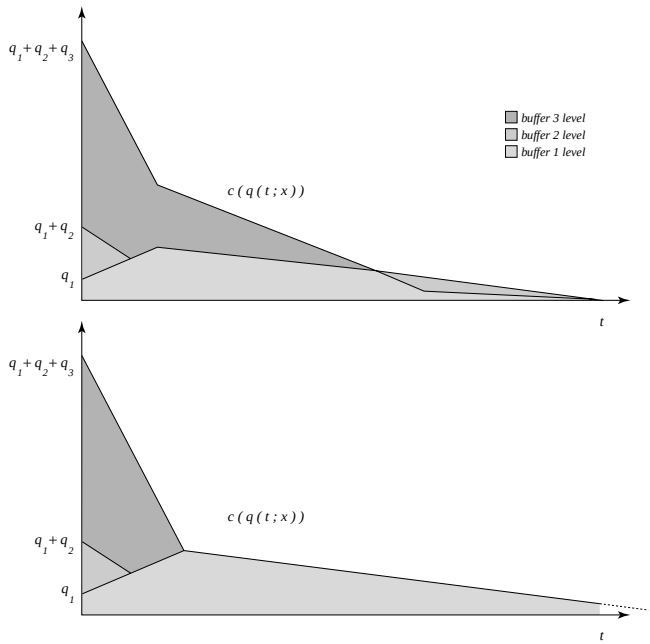

FIG. 3. *The trajectory of buffer levels and evolution of the cost $c(q(t)) = |q(t)|$ for the model of Figure* 12 *for a given set of initial conditions. The first figure illustrates the optimal policy, and the second shows the LBFS priority policy.*

THEOREM 7. *If the fluid model is stabilizable, then for the network* (2.7) *there is a stationary, nonrandomized feedback law F^* with the following properties:*

(i) *It is regular, and hence the average cost $\eta^* = J(x, F^*)$ is finite and independent of x.*

(ii) *The fluid limit model $\mathcal{L}^*$ is stable.*

(iii) *The fluid limit model is optimal with respect to the total cost: With probability one, for any $x \in \mathbb{R}_+^\ell$ and any fluid limit $q^* \in \mathcal{L}_x^*$,*

$$\int_0^\infty c(q^*(t;x))\,dt = V^*(x).$$

(iv) *There exists a solution h^* to the average cost optimality equation* (1.1), (1.2) *which satisfies*

$$\limsup_{\|x\|\to\infty} \left| \frac{h^*(x)}{\|x\|^2} - \frac{V^*(x)}{\|x\|^2} \right| = 0.$$

Proof. Result (i) is a minor generalization of [45, Theorem 5.2]. The existence of a stabilizing policy, as required in this result, is guaranteed by the stabilizability of the fluid model (see Theorem 13 below).

To prove (ii), assume that (iii) holds. We then have for all t, with probability one,

$$V^*(q^*(t;x)) = V^*(x) - \int_0^t c(q^*(s;x))\,ds.$$

From the Lipschitz continuity of the model one can show that V^* is equivalent to a quadratic, in the sense that $V^*(x)/\|x\|^2$ is bounded from above and below for $x \neq \theta$

[45]. It then follows that for some $l_0 < \infty$,

$$\sqrt{V^*(q^*(t;x))} \le \sqrt{V^*(x)} - l_0 t, \qquad t \le \tau_\theta,$$

where τ_θ is the emptying time for $q^*(t;x)$. Thus we have the bound $\tau_\theta \le \sqrt{V^*(x)}/l_0 < \infty$

To prove (iii) we use the following previous results.

(a) It is shown in [45, Theorem 5.2 (i)] that the policy F^* can be chosen so that for any other policy F,

$$\lim_{T\to\infty} \inf \lim_{n\to\infty} \inf \left(\mathsf{E}\left[\int_0^T c(q_F^n(t;x))\,ds\right] - \mathsf{E}\left[\int_0^T c(q_{F^*}^n(s;x))\,ds\right]\right) \ge 0. \tag{3.2}$$

(b) In [42, 2] it is shown that for any T there is a policy F^∞ which attains the optimal cost for the fluid control problem:

$$\lim_{n\to\infty} \mathsf{E}\left[\int_0^T c(q_{F^\infty}^n(s;x))\,ds\right] = V^*(x,T), \qquad \|x\| = 1.$$

Taking $T > T_\theta$, we see that, for any $m \ge 1$,

$$\lim_{n\to\infty} \mathsf{E}\left[\int_0^{mT} c(q_{F^\infty}^n(s;x))\,ds\right] = V^*(x), \qquad \|x\| = m.$$

The point of (b) is that the optimal cost $V^*(x)$ is attainable, and hence the bound given in (a) can be strengthened: For any weak limit $q_{F^*}(\,\cdot\,;x)$ and any T we have by weak convergence

$$\mathsf{E}\left[\int_0^T c(q_{F^*}(s;x))\,ds\right] \le V^*(x), \qquad x \in \mathbb{R}_+^\ell.$$

But for $T \ge T_\theta \|x\|$ we have, with probability one,

$$\int_0^T c(q_{F^*}(s;x))\,ds \ge V^*(x).$$

Combining these two inequalities completes the proof of (iii).

Result (iv) then follows as in the proof of [45, Theorem 5.2 (iii)]. □

From these results we can obtain much insight into the structure of optimal policies for the discrete network when the state is large, i.e., the network is congested. We illustrate this now with several examples.

3.2. Examples. At this stage in the theory there are no general results which are as striking as those that can be found in numerical examples. The general principle appears to be that an optimal policy for the discrete network is equal to the fluid policy, suitably modified along the boundary of the state space. In fact, in several special cases it has been shown that an approximately optimal policy can be constructed in this manner [32, 26, 4], and a general approach is developed in [43].

In computing optimal policies for the examples below, we are forced to truncate the state space to obtain a finite MDP model. Optimization is still difficult due to the large state spaces involved. For example, for a network with four buffers of size

twenty each, the state space contains $m = 160,000$ elements, and computing the optimal policy involves inverting an $m \times m$ matrix.

However, one can use successive approximation to obtain a sequence of approximations $\{h_n : n \geq 0\}$. This is also known as the value iteration algorithm. Theorem 7 (iv) suggests an initialization for the algorithm: $h_0 = V^* \approx h^*$. Numerical results obtained in [9] show that this choice can speed convergence by orders of magnitude. We have used this approach in all of the examples below.

Boundary effects for a truncated model can be severe. For instance, for a loss model, if a buffer is full, then it may be desirable to serve an upstream buffer: the resulting overflow will reduce the steady-state cost. The policies are shown in a truncated region since this behavior has nothing to do with real network dynamics. For example, Figure 5 shows the optimal policy $F^*(x)$ for all x satisfying $\|x\|_\infty < 25$. In this example the value iteration algorithm was used with a network model allowing 39 customers at each buffer. The dimension of the resulting average-cost optimality equations (1.1), (1.2) was 40^3 since there are three buffers in this example.

The $M/M/1$ queue. Recall that the fluid limit model satisfies $q(t;x) = x - \mu z(t) + \alpha t$, $t \geq 0$, where $\alpha + \mu = 1$. Using the notation defined in section 2, we have

$$B = -\mu,\ C = 1, \quad \text{and} \quad \mathbf{1} = 1.$$

The nonidling policy is given by $\zeta(t) = \frac{d}{dt} z(t) = 1$ when $q(t;x) > 0$. It is optimal for any monotone cost function.

For the discrete-stochastic model with cost $c(x) = x$, the relative value function h^* is given by

$$h^*(x) = \frac{1}{2} \frac{x^2 + x}{\mu - \alpha}.$$

The fluid value function is given by

$$\begin{aligned} V^*(x) &= \int_0^\infty q(t;x)\, dt \\ &= \frac{1}{2} \frac{x^2}{\mu - \alpha}. \end{aligned} \tag{3.3}$$

We see that the error in the approximation $h^*(x) \approx V^*(x)$ is linear in this special case.

The "criss-cross" network. Figure 4 shows a model introduced in [27] to illustrate the use of Brownian motion approximation for networks. The system parameters are

$$B = \begin{bmatrix} -\mu_1 & 0 & 0 \\ \mu_1 & -\mu_2 & 0 \\ 0 & 0 & -\mu_3 \end{bmatrix}, \qquad C = \begin{bmatrix} 1 & 0 & 1 \\ 0 & 1 & 0 \end{bmatrix},$$

and in this model we take $\alpha_2 = 0$. This model has become a standard example.

Optimal policies for the fluid model are easily computed. Take c equal to the ℓ_1-norm, and suppose that $\mu_2, < \mu_3 < \mu_1$. In this case strict priority is given to buffer 3 whenever buffer 2 is nonempty. When this buffer does empty, then the optimal policy sets

$$z_1(t) = \mu_2/\mu_1, \qquad z_3(t) = 1 - z_1(t),$$

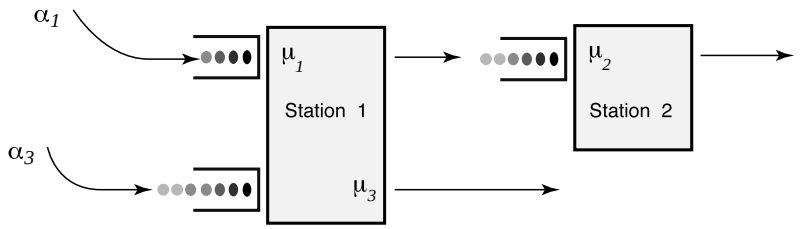

FIG. 4. *A simple two station network with* $\ell_m = 2$ *and* $\ell = \ell_u = 3$.

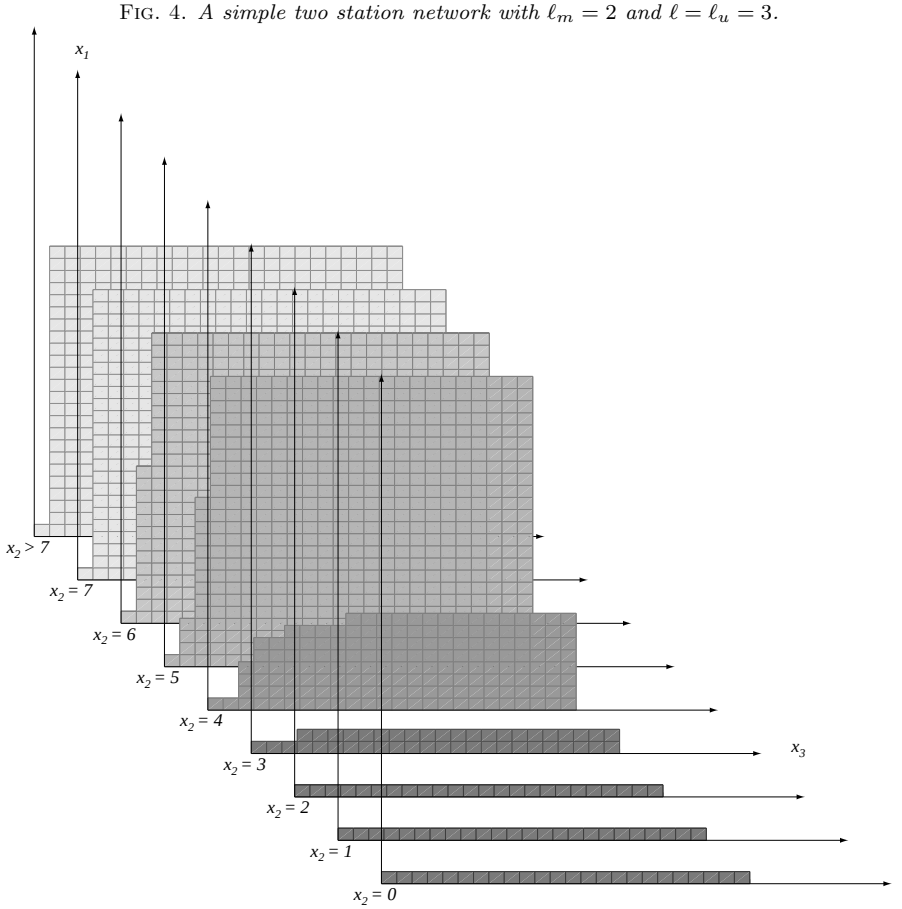

FIG. 5. *The optimal policy for the network above with* $\alpha^T = (9, 0, 9)$ *and* $\mu^T = (25, 10, 20)$. *The grey areas indicate states at which buffer* 3 *is given strict priority.*

provided both buffers 1 and 3 are nonempty. This is a pathwise optimal policy in the sense that it minimizes $c(q(t; x))$, for each $t \geq 0$, over all policies.

The optimal policy for the discrete model with particular parameter values satisfying these constraints is given in Figure 5. As always, the fluid limit of this optimal policy is the optimal policy for the fluid model. The discrete optimal policy is similar to the optimal fluid policy: The critical value $q_2(t) = 0$ has been shifted upward to $Q_2(t) \approx 4$.

A routing model. We now show how the theory applies to a routing problem. The model illustrated in Figure 6 has been considered in several papers; see, in particular,

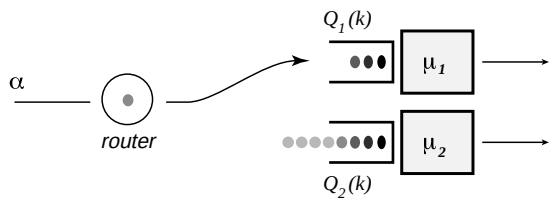

FIG. 6. *A network with controlled routing:* $\ell_m = 3$, $\ell = 2$, *and* $\ell_u = 4$.

[23, 32]. Customers that arrive to the system are routed to one of the two servers. In this example, $\ell = 2$, $\ell_u = 4$, and

$$B = \begin{bmatrix} \alpha & 0 & -\mu_1 & 0 \\ 0 & \alpha & 0 & -\mu_2 \end{bmatrix}, \quad C = \begin{bmatrix} 1 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix}.$$

The router is nonidling in this model; $\zeta_1 + \zeta_2 = 1$. This requirement can be expressed as the additional linear constraint, $C_a\zeta \le b_a$, where $C_a = [-1, -1, 0, 0]$ and $b_a = -1$. Alternatively, one can enlarge the state space to include a buffer at the router but impose the linear constraint that $Q_3(t) \equiv 0$.

Note that in the routing model the arrival stream is absorbed into the random matrix $\widetilde{B}$. Hence in this model we take the two dimensional vector α to be zero. Assume that $\mu_1 = \mu_2 = \mu$ and that $\mu < \alpha < 2\mu$. The fluid model is then stabilizable.

To minimize the total cost for the fluid model

$$\int_0^\infty c(q(t;x))\,dt,$$

one obviously takes z_3 and z_4 to be nonidling. Consider the case where c is linear with $c(x) = (c_1, c_2) \cdot x$ and $c_1 > c_2$. Then the priority policy is optimal, where fluid is routed to buffer 2 as long as buffer 1 is nonempty. As soon as it does empty, then fluid is routed to buffer 1 at rate $\zeta_1(t) = \frac{d}{dt} z_1(t) = \mu_1/\alpha$ so that buffer 1 is nonidling, but empty. The remaining fluid is sent to buffer 2 so that $\zeta_2(t) = 1 - \mu_1/\alpha$. This policy is again pathwise optimal, and it enforces nonidleness so that $\zeta_3(t) = \zeta_4(t) = 1$ for $t < \tau_\theta$.

The discrete-stochastic model is considered in [23] for a general linear cost function. It is shown that an optimal policy exists, and that it is of a nonlinear threshold form: There is a nondecreasing function $\gamma\colon \mathbb{Z}_+ \to \mathbb{Z}_+$ such that when a job arrives, when the queue lengths are x_1 and x_2, then buffer 1 receives the job if and only if $\gamma(x_1) \ge x_2$. The analysis of [58] implies that the function γ is unbounded, but in general no analytic formula is available for the computation of γ.

We see in Figure 7 that the optimal policy for the discrete network is closely approximated by the optimal fluid policy, modified along the boundary. The "thickened boundary" ensures that, with high probability, neither buffer will idle when the network is congested.

A processor-sharing model. Another simple example where the optimal allocation for the fluid model is explicitly computable is the processor-sharing network considered in [4, 26] and illustrated in Figure 8. In this example, $\ell = 2$, $\ell_u = 3$, and the system parameters are

$$B = \begin{bmatrix} -\mu_A & -\mu_B & 0 \\ 0 & 0 & -\mu_C \end{bmatrix}, \quad C = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 1 \end{bmatrix}, \quad \alpha = \begin{bmatrix} \alpha_A \\ \alpha_B \end{bmatrix}.$$

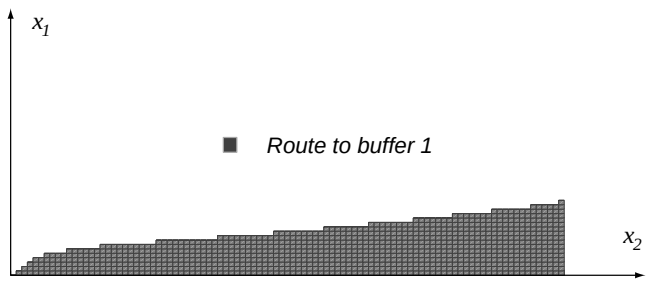

FIG. 7. *Optimal discrete policy for the simple routing model with* $\alpha = 9$ *and* $\mu^T = (5, 5)$. *The one step cost is* $c(x) = 3x_1 + 2x_2$.

As in the previous example, for any cost c we can assume that the optimal policy is nonidling at station 1. The fluid limit model illustrated on the right in Figure 8 is based on this assumption.

We assume that $\alpha_A > \mu_A$. In this case, it is critical that station 1 receive outside assistance. Under this condition and the nonidling assumption at station 1, we arrive at a reduced order model with $\ell = \ell_u = 2$ and

$$B = \begin{bmatrix} -\mu_B & 0 \\ 0 & -\mu_C \end{bmatrix}, \quad C = \begin{bmatrix} 1 & 1 \end{bmatrix}, \quad \alpha = \begin{bmatrix} \alpha_A - \mu_A \\ \alpha_B \end{bmatrix}.$$

For any linear cost the optimal allocation is the $c\mu$-rule priority policy, which is again pathwise optimal in this example. It is shown in [4] that a modification of this policy is nearly optimal in heavy traffic. Figure 9 shows the optimal policy for the discrete model. It is similar to the $c\mu$ priority policy, with priority given to processor B at station 2. However, the boundary $\{x_2 = 0\}$ has been shifted to form the concave region shown in the figure.

A generalized $c\mu$*-rule in scheduling.* We return now to the example illustrated in Figure 10, whose fluid model is defined by the parameters

$$B = \begin{bmatrix} -\mu_1 & 0 & 0 & 0 \\ \mu_1 & -\mu_2 & 0 & 0 \\ 0 & 0 & -\mu_3 & 0 \\ 0 & 0 & \mu_3 & -\mu_4 \end{bmatrix}, \quad C = \begin{bmatrix} 1 & 0 & 0 & 1 \\ 0 & 1 & 1 & 0 \end{bmatrix},$$

with $\alpha_2 = \alpha_4 = 0$. Consider for simplicity the symmetric case where $\mu_1 = \mu_3$ and $\mu_2 = \mu_4$. We also assume that $\mu_1 = 2\mu_2$ so that the exit buffers are slow.

It is pointed out in [42] that the optimal policy for the fluid model when c is the ℓ_1-norm is given as follows: The exit buffers have strict priority when $q_2(t) > 0$ and $q_4(t) > 0$. As soon as one of these buffers empties, say, buffer 2, then one sets $\zeta_1(t) = \mu_2/\mu_1$ and $\zeta_4(t) = 1 - \mu_1$ and continues to set $\zeta_2(t) = 1$. This policy maximizes the overall draining rate at each time t, it is pathwise optimal, and it achieves the total cost V^* for the fluid model. Recall that the analogous greedy policy, defined through the discrete model, is destabilizing!

We have computed an optimal policy for the discrete network numerically for this special case. However, noting that the optimal fluid policy is independent of the arrival rates $\alpha^T = (\alpha_1, 0, \alpha_3, 0)$, we have taken an extreme case with $\alpha = 0$ and have considered the total cost problem,

$$V(x) = \min \sum_0^\infty \mathsf{E}_x[c(Q(k))],$$

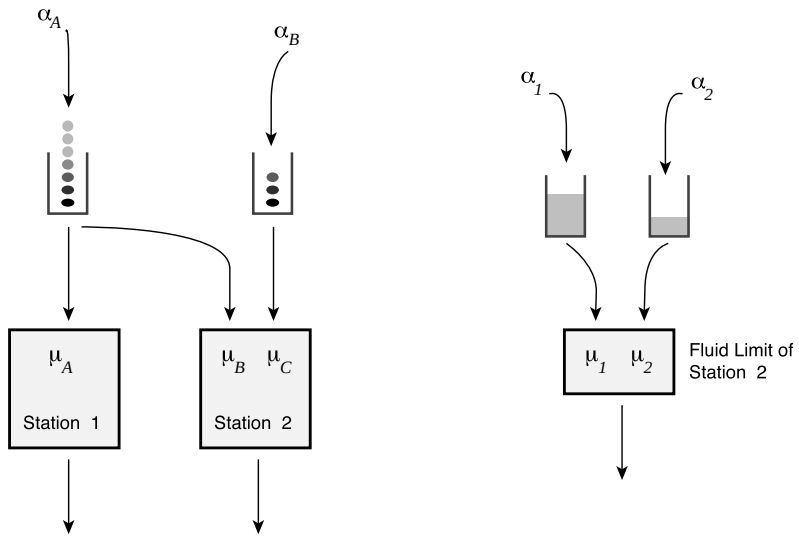

FIG. 8. *On the left is the processor-sharing network of* [27]. *On the right is its fluid limit model.*

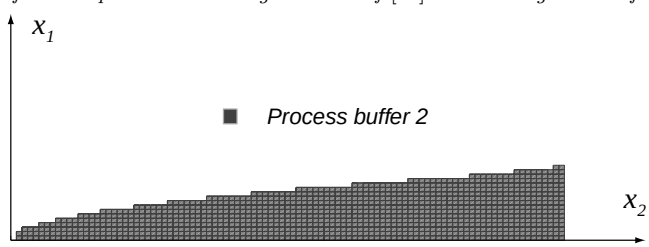

FIG. 9. *Optimal policy for the processor sharing model with ℓ_1 cost, $\alpha = (1, 1)$, and $\mu = (1, 3, 2)$. This closely resembles the optimal fluid policy which gives strict priority to the first server at station two since $\mu_B > \mu_C$.*

where the minimum is with respect to all policies. This gives rise to a finite dimensional optimization problem which can be solved exactly for each x.

The results shown in Figure 11 indicate that the optimal discrete policy is again similar to the optimal fluid policy.

A scheduling-model with no pathwise optimal solution. Consider the network given in Figure 12 with c taken to be the ℓ_1-norm. One policy that minimizes the total cost for the fluid model is defined as follows, where γ is a positive constant defined by the parameters of the network.

(i) Serve $q_3(t)$ exclusively ($\zeta_3(t) = 1$) whenever $q_2(t) > 0$ and $q_3(t) > 0$.
(ii) Serve $q_3(t)$ exclusively whenever $q_2(t) = 0$ and $q_3(t)/q_1(t) > \gamma$.
(iii) Give $q_1(t)$ partial service with $\zeta_1(t) = \mu_2/\mu_1$ whenever $q_2(t) = 0$, and

$$0 < q_3(t)/q_1(t) \le \gamma.$$

This model is most interesting when station 2 is the bottleneck, since one must then make a tradeoff between draining the system and avoiding starvation at the bottleneck. Taking $\rho_2 = \alpha/\mu_2 = 9/10$ and $\rho_1 = \alpha/\mu_1 + \alpha/\mu_3 = 9/11$, the constant γ is equal to one, and hence the optimal policy is of the form illustrated in Figure 13.

Optimal policies are computed numerically in [45] for versions of this model with truncated buffers. Results from one experiment are shown in Figure 14. As in the

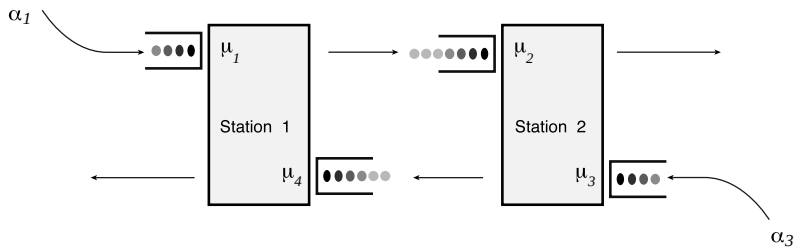

FIG. 10. *A multiclass network with* $\ell_m = 2$ *and* $\ell = \ell_u = 4$.

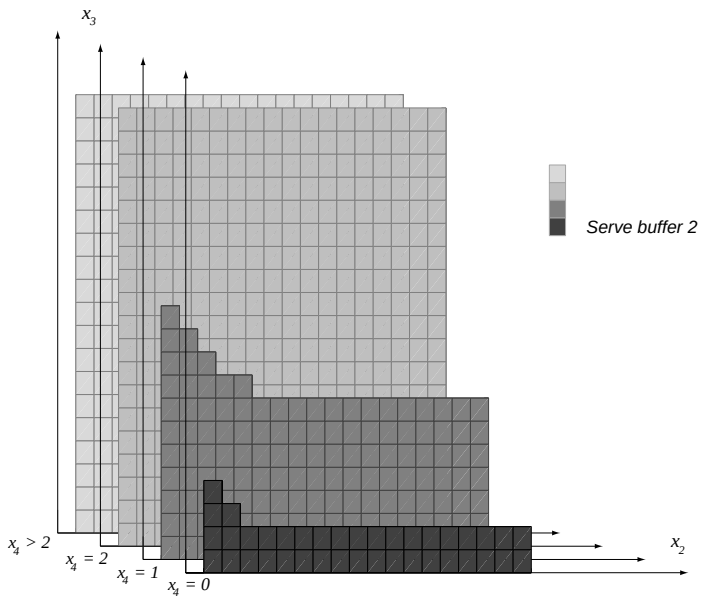

FIG. 11. *Optimal policy for the four-buffer scheduling model shown in Figure* 10 *under the total cost criterion with c equal to the* ℓ_1*-norm. The arrival streams are null, and* $\mu = (2, 1, 2, 1)$. *The figure shows the policy when* $x_1 = 3$, $x_4 = 0, 1, 2, 3$, *with* x_2 *and* x_3 *arbitrary. This optimal policy is of the same form as the fluid policy: It gives strict priority to the exit buffer at station* 2, *unless buffer* 4 *is starved of work, in which case buffer* 3 *releases parts to feed buffer* 4.

previous examples we see that the discrete optimal policy is easily interpreted. It regulates the work waiting at buffer 2, and does so in such a way that buffer 2 is rarely starved of work when the network is congested.

The policy shown in Figure 14 is also very similar to the fluid policy. Performing some curve fitting, we can approximate this discrete policy as follows: serve buffer one at time t if and only if either buffer three is equal to zero or

$$Q_1(k) - \bar{x}_1 > Q_3(k) - \bar{x}_3 \qquad \text{and} \qquad Q_2(k) \le \bar{x}_2, \tag{3.4}$$

where the translation $\bar{x}$ positive. The most accurate approximation is obtained when $\bar{x}$ depends upon the current state $Q(k) = x$, say,

$$\bar{x} = \bar{x}_0 \log(\|x\| + 1), \qquad x \in \mathsf{X}, \tag{3.5}$$

with $\bar{x}_0 > 0$ and constant. Moreover, with this choice, the fluid limit obtained using the policy (3.4) is precisely the optimal policy minimizing the total fluid cost, which is illustrated in Figure 13.

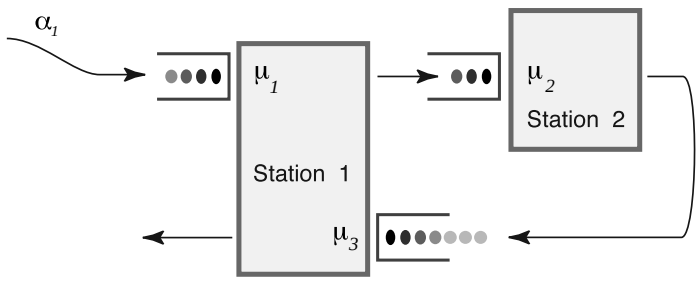

FIG. 12. *A multiclass network with* $\ell_m = 2$ *and* $\ell = \ell_u = 3$.

4. Feedback regulation. The results and examples of the previous section all suggest that the fluid model should play a useful role in control synthesis for network models. Theorem 7 establishes a connection between two optimization problems: one is deterministic and relatively transparent, and the other is stochastic, discrete, and apparently hopeless.

Even if one can find a feedback law $\frac{d}{dt}z(t) = \zeta(t) = f^*(q(t))$ which is optimal for the fluid model, it is not obvious how to use this information. A direct translation such as $F(x) = f^*(x)$ is not appropriate. It is shown in [45] that this policy may have a fluid limit model which differs grossly from the desirable optimal fluid process. However, the numerical results given above all show that, at least for simple models, an optimal policy for a discrete network is approximated by an affine shift of the form

$$F(x) = f^*((x - \bar{x})^+), \qquad x \in \mathsf{X}. \tag{4.1}$$

Moreover, one can show that a properly defined shift of this form ensures that the resulting fluid limit model for the network controlled using F approximates the optimized fluid model (see [42, 2, 43] and Proposition 8 below).

One might arrive at the policy (4.1) without any consideration of optimization. When the feedback law f^* is chosen appropriately, this policy will attempt to regulate the state $Q(k)$ about the value $\bar{x}$. If this regulation is accomplished successfully, then

- provided $\bar{x}$ is not too big, the cost $c(Q(k))$ will not be too large;
- if the target $\bar{x}$ is not too small then this policy will avoid starvation of any resource; and
- regulation to a constant should provide reduced variance at each station, as has been argued for the class of fluctuation smoothing policies [37].

4.1. Discrete review structure. In this section we adapt the approach of [28] to define policies for the physical network based on an idealized allocation derived from the fluid model. Related approaches are described in [22].

In practice one will rarely use a stationary policy F since one is forced to make scheduling decisions at every discrete sampling instance. This is undesirable since it results in high computational overhead and, more importantly, excessive switch-overs. The proposed policies consist of three components:

(a) For each initial condition x, a well-designed fluid trajectory $q(t; x)$ satisfying (2.2) for some allocation process $\boldsymbol{U}$. This will typically be defined through a feedback law f so that

$$q(t; x) = x + \alpha t + B \int_0^t f(q(s; x))\, ds, \qquad t \in \mathbb{R}_+,\ x \in \mathbb{R}_+^\ell.$$

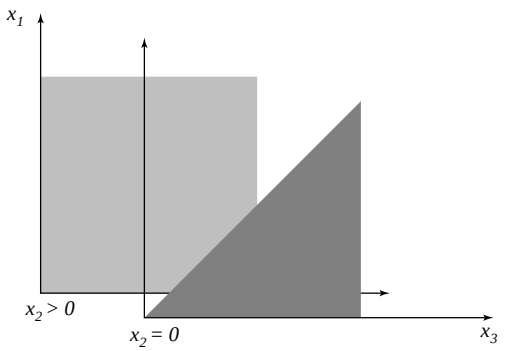

FIG. 13. *The optimal fluid policy for the three buffer re-entrant line with* $\rho_2 = 9/10$ *and* $\rho_1 = 9/11$. *In this illustration, the grey regions indicate those states for which buffer three is given exclusive service.*

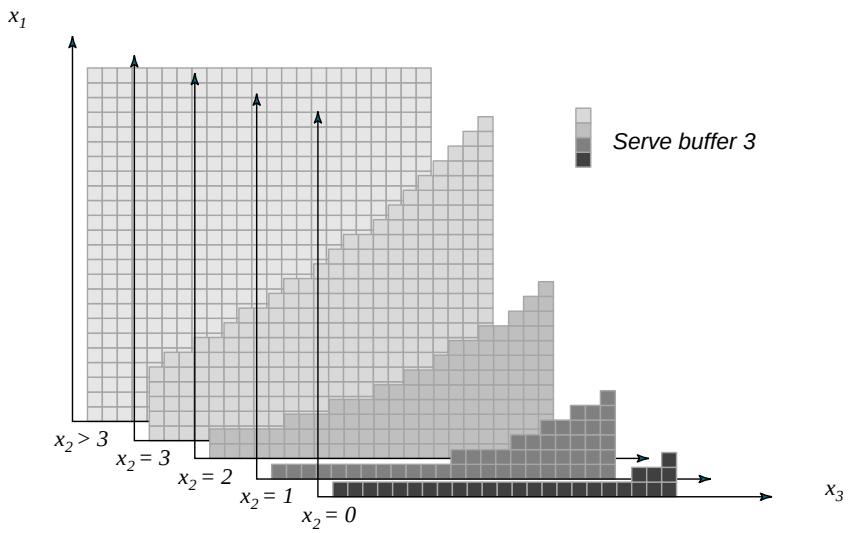

FIG. 14. *Optimal discrete policy for three buffer re-entrant line in the balanced case:* $\alpha/\mu_1 = \alpha/\mu_3 = \frac{1}{2}\rho_1$.

(b) A target vector $\bar{x}$;

(c) A time horizon N over which the policy is fixed.

The target $\bar{x}$ may be a "moving target," in which case it is assumed to be a function of the state. In general, we may also take N as a function of the state, but we will always assume that N and $\bar{x}$ are "roughly constant" for large x.

Given these, we set $N_0 = 0$, and, given $Q(N_0) = x$, we determine the time horizon $N_1 = N(x)$. The values $U(k)$, $N_0 \le t < N_1$ are chosen so that

$$\mathsf{E}[Q(N_1 - N_0; x)] - x \approx \delta(N_1 - N_0; (x - \bar{x})^+), \tag{4.2}$$

where $\delta(T; y) = q(T; y) - y$ for any $y \in \mathbb{R}_+^\ell$, $T \ge 0$.

This final choice is far from unique but will be dictated by considerations such as minimizing switch-over times and avoiding starvation at any station. Once one arrives at time N_1, the choice of $U(k)$ on the time interval $[N_1, N_2)$ proceeds exactly as before, where $N_2 = N_1 + N(Q(N_1))$. Successive review times $\{N_i : i \ge 0\}$ and

actions $\{U(k) : k \geq 0\}$ can then be found by induction.

We shall call any policy of this form a *feedback regulation policy* since it is similar to a state feedback approach to regulation as covered in a second-year control systems course. Below we list some of the issues in design:

- The most basic question is the design of the fluid state trajectories $\{q(\,\cdot\,;x) : x \in \mathbb{R}_+^\ell\}$. A first requirement is stability, and the theory suggests that good performance for the fluid model with respect to the total cost is highly desirable. These design issues will be discussed in depth in section 4.2.
- How do we choose $\bar{x}$?
- How do we choose the time horizon N? This will be dictated by such issues as batch or packet sizes and switch-over costs.
- How do we choose a sequence of actions on $[N_k, N_{k+1})$ so that (4.2) holds? Again, one must consider switch-over costs—two approaches are described below.
- In many models one must also consider idleness avoidance. For routing models this can be treated as in [32] by enforcing routing to a buffer whenever its level falls below a threshold. Scheduling models can be treated similarly.
- Machine failures and maintenance: How should the policy change during a failure? One can again address this problem by considering a fluid model, but one should consider the *delayed* fluid model which includes the residual-life of each service process.

Much has been written on the choice of safety-stock levels. In some simple examples a constant threshold is optimal (see, e.g., [18, 39]). A value of zero is optimal in the single-machine scheduling problem with linear cost since the $c\mu$-rule is optimal for both the fluid and stochastic models.

A general approach is suggested by a rich literature on networks in heavy traffic. In [32] and many other references one considers the case where the system load ρ is close to unity, and

$$(1-\rho)\sqrt{n} \to L, \qquad n \to \infty,$$

where n is a parameter which is sent to ∞ for the purpose of analysis, $\rho = \rho(n)$, and L is a nonzero, finite number. The steady-state number of customers in the system is typically of order $(1-\rho)^{-1}$. (Consider a $G/G/1$ queue or the functional bounds obtained in [31].) Hence the assumptions commonly used in the literature imply that

$$\sqrt{n} = O\left(\frac{1}{1-\rho}\right) = O(\mathsf{E}_\pi[\|Q(k)\|]),$$

where $\mathsf{E}_\pi[\|Q(k)\|]$ denotes the steady-state mean. The thresholds $\bar{x}$ determined in [4, 32] are of order $\log(n)$, so that $\|\bar{x}\| = O\big(\log(\mathsf{E}_\pi[\|Q(k)\|])\big)$. By replacing the steady-state mean with the current value $Q(k) = x$, we arrive at $\|\bar{x}(x)\| = O(\log(\|x\|))$.

However, the results of [43] show that such a small offset may be overly optimistic in general. We are currently exploring parameterizations of the form (3.5), where $\bar{x}_0$ can be tuned, perhaps on-line.

Two major issues are stability and performance of the network under a feedback regulation policy. A stability proof and some approaches to estimating performance through simulation are given in section 4.4. Stability requires some assumptions.

(A1) There exists a function $V\colon \mathbb{R}_+^\ell \to \mathbb{R}_+$ which is Lipschitz continuous and satisfies

$$V(q(t;x)) - V(x) \leq -t, \qquad x \in \mathbb{R}_+^\ell, \qquad t \leq \tau_\theta.$$

(A2) There exist an i.i.d. process $\{\Gamma(k) : k \geq 0\}$ evolving $\mathbb{R}^\ell$ and a family of functions $\{\boldsymbol{F}(\cdot, k, N) : 0 \leq k < N < \infty\}$ such that for each $k < N$,

$$\boldsymbol{F}(\cdot, k, N) \colon \mathsf{X}^{k+1} \times \mathbb{R}^{\ell(k+1)} \to \{0,1\}^{\ell_u},$$

and when $N(Q(0)) = N$,

$$U(k) = \boldsymbol{F}(Q(0), \ldots, Q(k), \Gamma(0), \ldots, \Gamma(k), k, N).$$

(A3) The convergence to the fluid model is uniform in the sense of (U1): For any fixed N, there are a $\Theta(N) > 0$ and a $b_0(N) < \infty$ such that when $U(k) = \boldsymbol{F}(Q(0), \ldots, Q(k), \Gamma(0), \ldots, \Gamma(k), k, N)$ for $k < N$,

$$\frac{1}{N}\mathsf{E}_x\Big[\|Q(N;x) - q(N, (x-\bar{x})^+)\|\Big] \leq \Theta(N), \qquad \|x\| \geq b_0(N),$$

where $\Theta(N) \to 0$ as $N \to \infty$.

Assumption (A1) ensures that the fluid process $q(t;x)$ is stable. The Lipschitz assumption is an important aspect of these policies since it is what allows us to establish robustness with respect to perturbations in system parameters such as arrival and service rates.

The proof of Theorem 13 below is based on a Markovian description of the controlled network, which is possible by assumption (A2). Under this assumption, we can define the Markov state process,

$$\Phi(k)^{\scriptscriptstyle T} = [Q(k), \ldots, Q(n(k))], \qquad t \in \mathbb{Z}_+,$$

where $n(k)$ is the last switch-over time: $n(k) = \min(s \leq t : s = N_k \text{ for some } k)$.

Assumption (A3) requires that one faithfully follow the fluid model. Consider for simplicity the network scheduling problem where $\ell = \ell_u$. Perhaps the most natural approach is to define a processing plan on $[N(k), N(k+1))$ in a generalized round-robin fashion: Take $k = 0$, without loss of generality, and, given $Q(0) = x$, set

$$y = q(T; (x-\bar{x})^+) = (x-\bar{x})^+ + Bz(T; (x-\bar{x})^+) + T\alpha.$$

The vector $a = z(T; (x-\bar{x})^+)/T$ satisfies $a \geq 0$, $Ca \leq \mathbf{1}$, and since $y = (x-\bar{x})^+ + T(Ba+\alpha)$, we obviously have

$$(Ba+\alpha)_i \geq 0 \text{ whenever } x_i \leq \bar{x}_i. \tag{4.3}$$

At machine s suppose we have ℓ_s buffers $i_1, \ldots, i_{\ell_s}$. Given this value of a and given a constant $m > 0$, we perform $a_{i_1} m$ consecutive services at buffer i_1 and then $a_{i_2} m$ consecutive services at buffer i_2, continuing until buffer i_{ℓ_s} has received $a_{i_{\ell_s}} m$ services and then returning to buffer i_1. This cycle repeats itself until time $N(1)$. We again must take the integer parts of $a_k m$, and this will lead to some error. This is insignificant for large N.

An approach based on randomization is particularly straightforward. Suppose that the function $\boldsymbol{F}$ is formed in a stationary, randomized fashion as follows:

$$\begin{aligned} &\mathsf{P}(U_i(k) = 1 \mid Q(0), \ldots, Q(k), \Gamma(0), \ldots, \Gamma(k-1)) \\ &= \mathsf{P}(U_i(t) = 1 \mid Q(k)) \\ &= a_i \mathbb{I}(Q_i(k) > 0). \end{aligned} \tag{4.4}$$

This construction of $U(k)$ for $t < N$ can be equivalently expressed through a feedback function of the form required in (A2), where, for some fixed function $F\colon \mathsf{X}\times\mathbb{R}^{\ell} \to \mathbb{R}^{\ell}_{+}$,

$$\boldsymbol{F}(Q(0),\dots,Q(k),\Gamma(0),\dots,\Gamma(k),t,N) = F(Q(k),\Gamma(k)).$$

PROPOSITION 8. *Consider the network scheduling problem. The randomized policy given in* (4.4) *defines a function* $\boldsymbol{F}$ *satisfying* (A2) *and* (A3).

Proof. We have already seen that (A2) holds.

For any $a \in \mathbb{R}^{\ell}_{+}$ we let $\boldsymbol{Q}^a = \{Q(k;x,a) : k \ge 0\}$ denote the state process for a Jackson network with arrival and service rates given, respectively, by $(\alpha_i, a_i\mu_i)$, $1 \le i \le \ell$. We always assume that $a \in \mathsf{U}$ ($a \in \mathbb{R}^{\ell}_{+}$ with $Ca \le \mathbf{1}$). We can construct all of the processes $\{Q(\,\cdot\,;x,a) : x \in \mathsf{X}, a \in \mathsf{U}\}$ on the same probability space as follows: We are given two mutually independent ℓ-dimensional Poisson processes $M(t), N(t)$ of rate one. The length of the service times, either real or virtual, at buffer i are defined as the interjump times of $N_i(\mu_i a_i t)$; the exogenous arrivals to buffer i occur at the jump times of $M_i(\alpha_i t)$, $t \in \mathbb{R}_{+}$. The kth component of $\boldsymbol{U}^a$ is given by $U_k(k;x,a) = \mathbb{I}(Q_k(k;x,a) > 0)$.

For each n, we let $\{q^n(t;x,a), z^n(t;x,a)\}$ denote the nth scaled queue length and cummulative allocation process. We then set

$$\mathcal{L}_n = \overline{\overline{\bigcup_{k=n}^{\infty} \Big\{(q^k(\,\cdot\,;x,a), z^k(\,\cdot\,;x,a)) : \|x\| = b_0; a \in \mathsf{U}\Big\}}}.$$

The double bar indicates *strong closure* in the function space $C([0,T],\mathbb{R}^{\ell+\ell_v})$, in the uniform norm. The set $\mathcal{L}_n \subset C([0,T],\mathbb{R}^{\ell+\ell_v})$ is compact for any n, and so is its intersection over all n: $\mathcal{L} = \bigcap_n \mathcal{L}_n$.

The set $\mathcal{L}$ is defined for almost every (a.e.) sample path of (M,N). If $(q,u) \in \mathcal{L}$, then there exist $x^i \to x$, $a^i \to a$, and a subsequence $\{n^i\}$ of $\mathbb{Z}_{+}$ such that

$$q^{n^i}(\,\cdot\,;x^i,a^i) \Longrightarrow q, \quad z^{n^i}(\,\cdot\,;x^i,a^i) \Longrightarrow z, \qquad i \to \infty,$$

where the convergence is in $C([0,T],\mathbb{R}^{\ell+\ell_v})$. We then have $q(0) = x$, and for any time t at which q and $\boldsymbol{U}$ are differentiable,

$$\begin{aligned} &\frac{d}{dt}q_i(t) = 0 \qquad \text{if } q_i(t) = 0,\\ &\frac{d}{dt}z_i(t) = 1 \qquad \text{if } q_i(t) > 0, \qquad 1 \le i \le \ell. \end{aligned}$$

This is enough to completely determine the limit set: For any (x,a) there is a unique $q(\,\cdot\,;x,a) \in \mathcal{L}$.

It follows that we have uniformity in the sense of (U2): For any $\varepsilon > 0$,

$$\sup_{\substack{\|x\|=b_0\\ a\in\mathsf{U}}} \mathsf{P}\left(\sup_{0\le t\le T} \|z^n(t;x,a) - z(t;x,a)\| > \varepsilon\right) \to 0, \qquad n \to \infty, \tag{4.5}$$

and the analogous limit holds for $\{q^n\}$.

For $x \in \mathbb{R}^{\ell}_{+}$, $T > 0$, we denote

$$\mathcal{A}(x,T) = \{a \in \mathbb{R}^{\ell}_{+} : Ca \le \mathbf{1}, \quad x + T(Ba + \alpha) \in \mathbb{R}^{\ell}_{+}\}.$$

For the randomized policies considered in Proposition 8 we always have $a \in \mathcal{A}(x,T)$ (see the discussion surrounding (4.3)). Note also that for such a we have $z_i(t) = t$ for any i, and any $0 \le t \le T$. Hence, from (4.5),

$$\sup_{\substack{\|x\|=b_0 \\ a\in\mathcal{A}(x,T)}} \mathsf{P}\left(\sup_{0\le t\le T} \|z_i^n(t;x,a) - t\| > \varepsilon\right) \to 0, \qquad n \to \infty.$$

It is well known that Jackson networks are *monotone* in the sense that if $y \ge x$, then $U_i(k;y,a) \ge U_i(k;x,a)$ for any i,t, and a (see [53]). Hence the above bound can be improved:

$$\sup_{\substack{\|x\|\ge b_0 \\ a\in\mathcal{A}(x,T)}} \mathsf{P}\left(\sup_{0\le t\le T} \|z_i^n(t;x,a) - t\| > \varepsilon\right) \to 0, \qquad n \to \infty, \tag{4.6}$$

and this easily implies that (A3) holds. □

4.2. Design of the fluid trajectory. There are many control strategies for a fluid model which have desirable stability characteristics. Here we describe four approaches which always lead to a stabilizing solution: In each case we construct a Lipschitz continuous Lyapunov function. We have already seen in Theorem 4 that this can imply a strong form of stochastic stability for the network. These results will be generalized to feedback regulation policies in Theorem 13.

The first three classes of policies considered below are based on optimal control: the optimal fluid policies, time-optimal fluid policies, and constrained complexity optimal fluid policies. The latter have fixed complexity which can be chosen in advance by the user. The fourth class that we consider consists of greedy policies. Such policies can be computed easily for large networks by solving an ℓ-dimensional linear program.

Optimal fluid policies. The policy f^* which optimizes the fluid model under the total cost criterion is a natural candidate for application in a feedback regulation policy. The computation of f^* may be posed as an infinite dimensional linear program. Because of the specific structure of the linear program, it is frequently feasible to compute f^* numerically, even though such problems are, in general, intractable (see [41, 49]).

Time-optimal allocations can be computed with only trivial calculation: Proposition 1 implies that a linear time-optimal policy can be constructed for any stabilizable network, which is the basis of the main result of [17]. Time-optimality is used as a *constraint* in the construction of the policies described in [43].

Optimal fluid policies are stabilizing for the fluid model. Moreover, they satisfy assumption (A1) and are hence guaranteed to be stabilizing for the stochastic model when used in a feedback regulation policy.

PROPOSITION 9. *Suppose that the fluid model is stabilizable.*

(i) *Suppose that $q(\,\cdot\,;x)$ is optimal with respect to the total cost* (3.1) *for each x. Then there exists a Lipschitz Lyapunov function so that* (A1) *holds.*

(ii) *Suppose that $q(\,\cdot\,;x)$ is time-optimal in the sense that $\tau_\theta(x)$ is minimized over all fluid policies. Then $V(x) = \tau_\theta(x)$, $x \in \mathbb{R}_+^\ell$, is a Lipschitz Lyapunov function so that* (A1) *holds.*

Proof. Let $V = \beta\sqrt{V^*}$, where $\beta > 0$. From Proposition 6 we can conclude that V is radially homogeneous, and each sublevel set $S_\eta = \{x : V(x) \le \eta\}$ is a convex subset of $\mathbb{R}_+^\ell$ for any $\eta > 0$. It follows that V itself is convex and continuous, which implies Lipschitz continuity. The negative drift required in (A1) holds for β sufficiently large, which establishes (i).

Another Lyapunov function is $V = \beta c$. This satisfies the required drift for sufficiently large β since, as we have already observed, $c(q(t))$ is a convex, decreasing function of t under an optimal policy.

The proof of (ii) is identical since the function $V(x) = \tau_\theta(x)$ is radially homogeneous and convex. □

Although Proposition 9 shows that optimal fluid policies are stabilizing, these policies can be highly complex, even when they are computable (see [41, 49]). We turn next to a simpler class of policies.

The constrained-complexity optimal fluid policy. The difficulty with using an optimal state trajectory $q^*(\,\cdot\,;\,\cdot\,)$ is that complexity, as measured by the number of discontinuities in $\frac{d}{dt}q^*(t;x)$, i.e., the number of switches in the control $z^*(t;x)$, can grow exponentially with ℓ.

To bound complexity, suppose that we take a number κ and demand that q be piecewise linear, with at most κ pieces, so that the control can change no more than κ times. Any $q(\,\cdot\,;\,\cdot\,)$ which is optimal with respect to the total cost (3.1) subject to this constraint will be called a κ-constrained optimal fluid process.

Any such policy can be computed by solving a $\kappa\cdot(\ell+1)$-dimensional quadratic program when the cost is linear [41]. The variables can be taken as the switch-over times $\{0 = T_0, T_1, \ldots, T_\kappa\}$ and the control increments $\{z(T_{i+1}) - z(T_i) : 0 \le i < \kappa\}$.

PROPOSITION 10. *Suppose that the fluid model is stabilizable. Then any κ-constrained optimal fluid process possesses a Lipschitz continuous Lyapunov function so that* (A1) *holds.*

Proof. One can again show that $c(q(t))$ is a convex, decreasing function of t for any κ-constrained optimal fluid process. Hence one can take $V = \beta c$ for $\beta > 0$ sufficiently large. □

The greedy fluid policy. The greedy policy determines the allocation rate $\zeta(t)$ that minimizes $\frac{d}{dt}c(q(t))$ at each t. One motivation for this class of policies comes from considering the dynamic programing equations for the infinite-horizon optimal control problem. The optimal policy is the solution to (4.7) with c replaced by the value function V^*. Greedy heuristics are the most popular in queueing theory. The papers [8, 28] consider greedy policies for state-based cost functions as developed here. The shortest expected delay policy [32] and the least slack policy [37] are based on greedy heuristics for delay minimization.

Suppose that the cost function c is continuously differentiable (C^1). The greedy feedback law $f(x)$ is computed by solving the following ℓ-dimensional linear program: For any x, let ∇c denote the gradient of c evaluated at x, and solve

$$
\begin{aligned}
&\min \langle \nabla c, B\zeta \rangle \\
&\text{subject to} \qquad (B\zeta + \alpha)_i \;\ge\; 0 \quad \text{for all } i \text{ such that } x_i = 0, \\
&\qquad\qquad\qquad\quad \zeta \;\in\; \mathsf{U}.
\end{aligned} \tag{4.7}
$$

Then $f(x)$ is defined to be any ζ which optimizes this linear program. The linear program depends only upon $\operatorname{sign}(x)$ when the cost is linear. Given the feedback law f, we then set $\frac{d}{dt}z(t;x) = f(q(t;x))$. As was seen in the previous examples, in many cases the greedy policy leads to a pathwise optimal solution—geometric conditions ensuring this are developed in [43].

The following is a generalization of a result of [10].

PROPOSITION 11. *Suppose that the fluid model is stabilizable, and the cost function c is C^1. In this case any greedy fluid policy f is stabilizing for the fluid model, and it is pathwise optimal if a unique pathwise optimal solution exists.*

Moreover, assumption (A1) *holds with the Lyapunov function* $V(x) = \beta c(x)$ *for* $\beta > 0$ *sufficiently large.*

Proof. As in the construction of a solution to (2.16), we can use stabilizability to ensure the existence of an $\varepsilon > 0$ such that the equation

$$B\zeta + \alpha = -\varepsilon \frac{x}{\|x\|}$$

has a solution $\zeta^x \in \mathsf{U}$ for any $x \neq \theta$. Hence, under the greedy policy we have, when $q(t) = x \neq \theta$,

$$\begin{aligned} \frac{d}{dt} c(q(t)) &\leq \langle \nabla c, B\zeta^x + \alpha \rangle \\ &\leq -\frac{\varepsilon}{\|x\|} \langle \nabla c, x \rangle = -\varepsilon \frac{c(x)}{\|x\|}. \end{aligned}$$

The last equality follows from radial homogeneity of the norm c. This implies the result with $\beta = \varepsilon^{-1} \max_{x \neq \theta} \{\|x\|/c(x)\}$. ∎

For the first four models shown above in Figures 4, 6, 8, and 10, the greedy fluid policy is pathwise optimal. Hence it attains the minimal cost $V^*(x, T)$ for any x and any $T > 0$. The model shown in Figure 12 is a re-entrant line for which the greedy policy is the LBFS priority policy. In this example the LBFS policy is *not* optimal for the fluid model since it results in excessive starvation at the second machine whenever the second machine is the bottleneck (see Figure 3).

Note that the greedy policy for a *discrete network* is typically defined to be the policy which, at time t, minimizes over all admissible actions a the value $\mathsf{E}[c(Q(k+1)) \mid Q(k), a]$. For any network scheduling problem this policy gives strict priority to exit buffers when $c(\,\cdot\,) = |\,\cdot\,|$. In general, such a policy may perform extremely poorly: For the example given in Figure 10 the greedy fluid policy is pathwise optimal, but we saw in section 2 that the priority policy is destabilizing for some parameter values even under (2.13).

4.3. Information. The policies considered thus far require the following information for successful design:

- the arrival rates α,
- service rates and routing information as coded in the matrix B,
- bounds on variability of $(\boldsymbol{A}, \boldsymbol{R}, \boldsymbol{S})$ so that appropriate safety-stocks can be defined,
- global state information $q(t; x)$ for each time t.

Relaxing this information structure is of interest in various applications.

We consider here only the first issue: In telecommunications applications we may know little about arrival rates to the system, and in a manufacturing application *demand* may be uncertain. Sensitivity with respect to service and arrival rates may be large when the load is close to unity (see [19]).

To obtain a design without knowledge of arrival rates we define a set of *generalized Klimov indices* which assign priorities to buffers, subject to positivity constraints, and buffer level constraints. In this way one can define the policy in terms of observed buffer levels without knowledge of the value of α. One can address (ii) in a similar manner.

Define the permutation $(i_1, \ldots, i_\ell)$ of $\{1, \ldots, \ell\}$ so that for any resource j

$$\langle \nabla c, Be^{i_n} \rangle \leq \langle \nabla c, Be^{i_m} \rangle \qquad \text{if } n < m \text{ and } i_n, i_m \in \mathcal{R}_j.$$

An allocation rate $\zeta = f(x)$ can then be defined as follows: for any $n \ge 1$,

$$\sum\{\zeta_{i_k} : k \le n, i_k \in \mathcal{R}_j\} = 1 \qquad \text{whenever} \quad \sum\{q_{i_k} : k \le n, i_k \in \mathcal{R}_j\} > 0. \tag{4.8}$$

Proposition 12 follows from Proposition 11 since (4.8) may be viewed as an alternative representation of the greedy allocation.

PROPOSITION 12. *Suppose that the network is stabilizable. Then the policy* (4.8) *is stabilizing for the fluid model. It is pathwise optimal if a unique pathwise optimal solution exists.*

4.4. Stability and performance. We are assured of stability under assumptions (A1)–(A3).

THEOREM 13. *Suppose that assumptions* (A1) – (A3) *hold, and suppose that for some* $\varepsilon_1 \ge 0$, $\underline{N} > 0$,

(a) $\limsup_{\|x\|\to\infty} \frac{N(x)}{\|x\|} \le \varepsilon_1$,

(b) $\limsup_{\|x\|\to\infty} \frac{\|\bar{x}(x)\|}{N(x)} \le \varepsilon_1$,

(c) $\liminf_{\|x\|\to\infty} N(x) \ge \underline{N}$.

Then, for all $\underline{N}$ *sufficiently large, the following hold.*

(i) *The state process* $\boldsymbol{Q}$ *is ergodic in the sense that for any initial condition* $Q(0) = x$ *and any function* g *which is bounded by some polynomial function of* x, *there exists a finite* $\nu(g)$ *such that as* $T \to \infty$,

$$\frac{1}{T}\sum_{0}^{T-1} g(Q(k)) \to \nu(g) \qquad a.s.,$$
$$\mathsf{E}_x[g(Q(T))] \to \nu(g).$$

(ii) *There exists* $\Delta > 0$ *such that if* $\boldsymbol{Q}^\Delta$ *is the state process for a new network satisfying* $\|B^\Delta - B\| \le \Delta$, $\|\alpha^\Delta - \alpha\| \le \Delta$, *then the policy will continue to stabilize the perturbed system in the sense of* (i).

Proof. The idea of the proof is to construct a constant b and $\varepsilon > 0$ such that

$$P^{N(x)}V(x) = \mathsf{E}[V(Q(N(x);x))] \le V(x) - \varepsilon N(x), \qquad \|x\| \ge b. \tag{4.9}$$

From the Lipschitz continuity of the model we can then find for each p a $b_p < \infty$ and $\varepsilon_p > 0$ such that

$$P^{N(x)}V^p(x) \le V^p(x) - \varepsilon_p N(x) V^{p-1}(x), \qquad \|x\| \ge b_p.$$

Since V is equivalent to a norm on $\mathbb{R}^\ell$, we can argue as in [15] that

$$P^{N(x)}V^p(x) \le V^p(x) - \varepsilon_p \mathsf{E}_x\left[\sum_{0}^{N(x)-1} \|Q(k)\|^{p-2}\right], \qquad \|x\| \ge b_p,$$

where the constants b_p, ε_p may have to be adjusted but remain finite and nonzero. It follows that the process $\boldsymbol{\Phi}$ is g-regular, with $g(x) = \|x\|^q$, for any $q \ge 1$. The ergodic theorems then follow, and, in fact, the ergodic limit in (i) converges faster than any polynomial function of time (see [15]).

How then do we establish (4.9)? For $x \in \mathsf{X}$ let $T = N(x)$, and write

$$\begin{aligned} V(Q(T;x)) &= V\Big(q(T;(x-\bar{x})^+) + (Q(T;x) - q(T;(x-\bar{x})^+)\Big) \\ &\le V(q(T;(x-\bar{x})^+) + b_0\|Q(T;x) - q(T;(x-\bar{x})^+)\|, \end{aligned}$$

where the inequality follows from Lipschitz continuity. The desired bound easily follows since $V(q(T;(x-\bar{x})^+) \le V((x-\bar{x})^+) - T$ for all x sufficiently large.

This proves (i), and (ii) follows since the drift inequality is preserved under perturbations in the model when V is Lipschitz.

Note that if N and $\bar{x}$ are bounded, then, by following the proof of Theorem 4 and the arguments here, one can show that the state process $\mathbf{\Phi}$ is V_ε-uniformly ergodic. □

Given this large class of policies, how can we compare one to another? If our goal is to estimate η, the steady-state mean of $c(Q(k))$ under a given policy, and if the one step cost c is linear, then bounds on η can be obtained by solving certain linear programs [36, 12, 34] or through comparison methods with a simpler model for which performance is readily computed [48]. If these bounds are not useful, then one can resort to simulation.

The standard estimator of η is given by $\widehat{\eta}(k) := k^{-1}\sum_0^{k-1} c(Q(i))$, and this estimator is strongly consistent for the policies considered here. From g-regularity with $g(\,\cdot\,) = \|\,\cdot\,\|^4$ we can also establish a central limit theorem of the form $\sqrt{t}(\widehat{\eta}(k)-\eta) \Rightarrow \sigma N(0,1)$, where $\Rightarrow$ denotes weak convergence, and $N(0,1)$ is a standard normal random variable [47]. The constant σ^2 is known as the *time-average variance constant* (TAVC) and provides a measure of the effectiveness of $\widehat{\eta}(k)$.

The problem with simulation is that the TAVC is large in heavy traffic. It is known that the TAVC is of order $(1-\rho)^{-4}$ for the M/M/1 queue [1, 57], and similar bounds hold for other network control problems [30]. With such a large variance, long run-lengths will be required to estimate η effectively.

One method of reducing variance is through control variates: For any function $h\colon \mathsf{X} \to \mathbb{R}$ let $\Delta_h = h - Ph$. Here the transition function P may define the statistics of the process $\mathbf{\Phi}$, in which case h is interpreted as a function of the first component of $\mathbf{\Phi}$ only. If the function h is π-integrable, then $\pi(\Delta_h) = 0$, and so one might use the consistent estimator

$$\widehat{\eta}_c(n) = \widehat{\eta}(n) + \frac{1}{n}\sum_{i=0}^{n-1} \Delta_h(Q(i)). \tag{4.10}$$

This approach can lead to substantial variance reductions, especially in heavy traffic, when applied to the GI/G/1 queue [29].

In [30] these ideas are extended to network models. First note that the estimator (4.10) will have a variance of *zero* when h solves the Poisson equation $\Delta_h = -c + \eta$. While this choice is not computable in general, we can approximate h by the fluid value function

$$V(y) := \int_0^\infty c(q(t;x))\,dt.$$

The *fluid estimator* of η is then given by (4.10) with $h = V$,

$$\widehat{\eta}_f(n) = \widehat{\eta}(n) + \frac{1}{n}\sum_{k=0}^{n-1} \Delta_V(\Phi(k)). \tag{4.11}$$

Why should V provide an approximation to the solution of Poisson's equation? This actually follows from the construction of the feedback regulation policy which requires that the increments of $\boldsymbol{Q}$ approximate the increments of the fluid trajectories. See [30] for details.

A ROTATED MULTIPLIER APPLIED TO THE CONTROLLABILITY OF WAVES, ELASTICITY, AND TANGENTIAL STOKES CONTROL*

AXEL OSSES†

Abstract. A new family of multipliers with rotated direction is introduced. This technique is applied to obtain new results concerning controllability of waves, elasticity, and Stokes equations. The boundary exact controllability for the wave equation and the dynamic elasticity system is reviewed generalizing the classical exit condition in the case of explicit observability constants. Approximate controllability for the Stokes system is also studied using a boundary control acting only on the tangential component of the velocity. A geometric sufficient condition of exit generalized type is deduced.

Key words. multiplier method, exact controllability, approximate controllability, unique continuation, wave equation, elasticity, Stokes system

1. Introduction.

In 1940, Rellich [41] introduced a multiplier technique in order to obtain direct a priori estimates in linear partial differential equations (PDEs). This method was called multiplier method since it consists in multiplying the equation by the gradient of the solution following some convenient vector field and then integrating by parts in the domain. This technique was widely used in the classical PDE development [32], [11]. Later on, in the 70s and 80s, this technique was used to derive inverse estimates: the asymptotic estimates in scattering theory for unbounded domains [30], [31] and the direct study of uniform stabilization in bounded domains [5], [6], [17], [21].

In 1986, Ho [10] used this multiplier technique to prove an inverse inequality for the linear wave equation implying its exact controllability. Ho arrived to a geometrical condition called *exit condition*: The control region must contain a subset of the boundary where the scalar product between the outward normal and the vector pointing from some origin towards the normal is positive. By varying the origin, a family of control boundaries satisfying the condition is found. In a square, for instance, the condition gives control boundaries consisting of four, three, or two adjacent sides. Ho's result was improved [25], [24] and adapted to other systems like vibrating plates and the elasticity system [24], [19]. Afterwards, the method also gave similar results for Maxwell [18], [16] and Schrödinger [29] equations.

Several authors have used multiplier techniques for control or stabilization of mathematical models: viscoelastic or thermoelastic beams [23], [12]; semilinear wave equations [44]; wave equation with mixed boundary conditions [8], [7] or in domains with corners or cracks [9], [33], [34]; Euler–Bernoulli equations [13]; hybrid systems in elasticity [40]; networks of membranes or beams with discontinuous coefficients [24], [20]; coupled Schrödinger equations [14]; Korteweg–de Vries equations [42]. [15] for other references.

In recent years, microlocal techniques and geometric optics analysis allow us to find geometrical characterization of control location and minimal control time in the exact controllability of waves. After eventual reflection, diffraction, or sliding on the boundary, every optic ray issue from the observation domain has to reach the control zone. This is a necessary and sufficient condition [4] called the *Bardos–Lebeau–Rauch (BLR) condition* [1]. This technique has also been applied to vibrating plates [22], the elasticity system [2], and Maxwell equations [39].

Exit condition turns to be a particular case of the BLR condition. But there is a certain balance: In the BLR condition, control time is optimal but the observability constants are not explicit. In the exit condition, time is not optimal, but observability, constants can be explicit and this fact is very useful in theoretical and numerical estimations. In general [3], the BLR condition assumes more regularity on coefficients and boundaries than exit condition.

In this article we introduce a family of multipliers with rotated direction as a new approach in the multiplier method. More precisely, we propose to multiply the equation by the gradient of the solution following not only a radial but also a rotated direction. This takes advantage of invariances under rotations for the differential operators considered here and leads to derive a *generalized exit condition*. For instance, in two dimensions, the condition is that the control region must contain a subset of the boundary where the scalar product between the outward normal rotated in an angle and the vector pointing from some origin towards the normal is positive. A family of control boundaries is obtained by varying the origin and the angle. The minimal time of control results to be proportional to the inverse of the cosine of the angle of the rotation.

To show the particularities of this method we have chosen some controllability problems, but the technique could be a useful tool in other areas. We revisit the exact or approximate controllability of some linear classical models in PDEs: the wave equation, the elasticity system, and the Stokes system.

The paper is organized as follows. In section 2, rotated multipliers are used to derive a generalization of classical inverse inequality for the linear wave equation conserving explicit observability constants (see Theorem 2.2 and Theorem 2.3). New boundary control geometries are found (Figures 2.1 and 2.2) which are particular cases of the BLR condition and satisfy a generalized exit condition. In section 3, the method is extended to the study of the exact controllability of the elasticity system. Beside the choice of a rotated direction in a natural manner, a second multiplier formula is needed in this case. The classical inverse inequality with explicit constants is also generalized (see Theorem 3.3 and Theorem 3.4). The same geometrical conditions as for the wave equation are found. In section 4, a different application in fluid control is developed: the study of the approximate controllability of the Stokes system with a boundary control acting only on the tangential part of the velocity. As far as we know, this is an almost untreated topic (except for references [35] and [36]). A sufficient geometric condition is found similar to one deduced for the wave equation and the elasticity system. The final results are presented in two and three dimensions, but the technique is actually not limited by dimension.

In the case of controlling all the velocity trace on an arbitrarily small nonempty open part of the boundary, approximate controllability is easily obtained by using a unique continuation property of Holmgren's type. Second, approximate controllability using the normal component of the velocity is studied in [27] and [28], where the result

is proved in a real analytic connected domain with a simple spectrum for the Laplacian with a control acting on an arbitrary small nonempty open part of the boundary and a counterexample in a ball is given. It is amazing to observe that the normal boundary approximate controllability also holds if the boundary has at least a rectangular corner [38]. In the tangential case that we treat in this paper, we begin by following the idea of [27] introducing a spectral decomposition to characterize the unique continuation property of the time dependent system as a unique continuation property on each frequency. Then we use rotated multipliers to obtain an inverse inequality for each eigenfrequency and a sufficient geometrical condition to have the unique continuation (see Theorem 4.3). We prove that this condition is not necessary for two dimensional connected domains with analytic boundary (see Theorem 4.4). But, as far as all the other cases are concerned, there is a lack of counterexamples for which tangential boundary approximate controllability could not hold.

In summary, multipliers with rotated direction generalize the standard multipliers in a natural way. For second order hyperbolic systems, the application of this technique provides a wider class of geometric examples with explicit observability constants which are particular cases of the BLR condition. For partially controlled Petrovskii systems, the technique reveals to be useful to find results of approximate controllability.

2. Wave equation.[1]

2.1. Control problem. Let Ω be a bounded domain of $\mathbb{R}^N$ $(N \geq 2)$ with a regular[2] boundary Γ of class C^2. Let ν be the unit exterior normal to Ω. Let $T > 0$ be given, and define $Q = \Omega \times (0,T)$ and $\Sigma = \Gamma \times (0,T)$. We consider the following classical control problem. Let $\Gamma_0 \subseteq \Gamma$ and $\Sigma_0 = \Gamma_0 \times (0,T)$. Our problem consists of finding T_0 such that for each $T > T_0$ and for every $(y_0, y_1) \in L^2(\Omega)^N \times H^{-1}(\Omega)^N$, there exists $v \in L^2(\Sigma_0)^N$ in such a way that the solution of the wave equation

$$y'' - \Delta y = 0 \quad \text{in} \quad Q, \tag{2.1a}$$

$$y = v \quad \text{on} \quad \Sigma_0, \tag{2.1b}$$

$$y = 0 \quad \text{on} \quad \Sigma \setminus \Sigma_0, \tag{2.1c}$$

$$y(0) = y_0,\ y'(0) = y_1 \quad \text{in} \quad \Omega \tag{2.1d}$$

satisfies

$$y(T) = 0,\ y'(T) = 0 \quad \text{in} \quad \Omega, \tag{2.2}$$

where the prime symbol $'$ stands for derivation with respect to time.

Following the Hilbert uniqueness method (HUM) [24], the solution to this problem is equivalent to studying the observability properties of the adjoint problem. For each pair of initial conditions $(\varphi_0, \varphi_1) \in H_0^1(\Omega)^N \times L^2(\Omega)^N$, let us consider the solution φ of the wave equation as follows:

$$\varphi'' - \Delta \varphi = 0 \quad \text{in} \quad Q, \tag{2.3a}$$

$$\varphi = 0 \quad \text{on} \quad \Sigma, \tag{2.3b}$$

$$\varphi(0) = \varphi_0,\ \varphi'(0) = \varphi_1 \quad \text{in} \quad \Omega. \tag{2.3c}$$

[1] A note about the results of this section was published in [37].

[2] The results of this section are also valid if we suppose that Ω is either a bounded polygonal of $\mathbb{R}^2$ or a bounded polyhedral of $\mathbb{R}^3$. (It suffices to apply the methods of Grisvard [8].)

More precisely, exact controllability is equivalent to demonstrate that for $T > T_0$, the inverse inequality

$$E_0 \leq C(\Omega, T) \int_{\Sigma_0} \left| \frac{\partial \varphi}{\partial \nu} \right|^2 \, d\sigma dt$$

holds, where

$$E_0 = \frac{1}{2} \left(\int_\Omega |\nabla \varphi_0|^2 \, dx + \int_\Omega |\varphi_1|^2 \, dx \right) \tag{2.4}$$

is the initial energy of system (2.3), and $C(\Omega, T)$ is a constant depending only on geometry and final time. Multiplier methods [24] can give explicit constants, but only for large Γ_0 and T. Microlocal techniques [1], [4] characterize all Γ_0 and T for which we obtain such a result, but in this case the constant is not explicit.

Using a new choice in the classical multiplier method, we will enlarge the set of geometric examples with explicit knowledge of constants.

2.2. Inverse inequality and exact controllability.

DEFINITION 2.1. *Let $A \in \mathbb{R}^{N\times N}$ be such that $A = -A^t$ (skew-symmetric). Let $d > 0$ be a positive real number and I the identity matrix in $\mathbb{R}^{N\times N}$. We define for each $x^0 \in \mathbb{R}^N$ the set*

$$\Gamma(x^0, d, A) = \{x \in \Gamma \text{ such that } (x - x^0) \cdot (dI + A)\nu > 0\}. \tag{2.5}$$

Without loss of generality we introduce the following normalizing condition:

$$d^2 + \|A\|_2^2 = 1, \tag{2.6}$$

where $\|A\|_2 = \sup\{|Ax|\,,\ |x| = 1\}$ and $|\cdot|$ is the Euclidean norm in $\mathbb{R}^N$. We also define

$$r(x^0, d, A) = \max\{(x - x^0) \cdot (dI + A)\nu \text{ with } x \in \Gamma(x^0, d, A)\}, \tag{2.7a}$$

$$R(x^0) = \max\{\left|x - x^0\right| \text{ with } x \in \overline{\Omega}\}. \tag{2.7b}$$

THEOREM 2.2 (inverse inequality). *Given $x^0 \in \mathbb{R}^N$, $d > 0$, and a skew-symmetric matrix A normalized as in* (2.6)*, for each $T > 2d^{-1}R(x^0)$ and for each weak solution φ of* (2.3) *the following inequality holds:*

$$E_0 \leq \frac{r(x^0, d, A)}{2\,(dT - 2R(x^0))} \int_0^T \int_{\Gamma(x^0,d,A)} \left| \frac{\partial \varphi}{\partial \nu} \right|^2 \, d\sigma dt. \tag{2.8}$$

THEOREM 2.3 (exact controllability). *Suppose that we can find $x^0 \in \mathbb{R}^N$, $d > 0$, and a skew-symmetric matrix A normalized as in* (2.6) *such that $\Gamma(x^0, d, A)$ is not empty and $\Gamma(x^0, d, A) \subset \Gamma_0$; then for each $T > 2d^{-1}R(x^0)$ there exists a control $v \in L^2(\Sigma_0)^N$ such that the corresponding solution of* (2.1) *satisfies the final condition* (2.2).

Remark 1. In the case $d = 1$ and $A = 0$ we recover classical results (see [24]).

Remark 2. For $N = 2$, introducing $\theta \in]-\pi/2, \pi/2[$, taking $d = \cos\theta$ and $A_{21} = A_{12} = \sin\theta$, definition (2.5) can be replaced by

$$\Gamma(x^0, \theta) = \{x \in \Gamma \text{ such that } (x - x^0) \cdot M(\theta)\nu > 0\}, \tag{2.9}$$

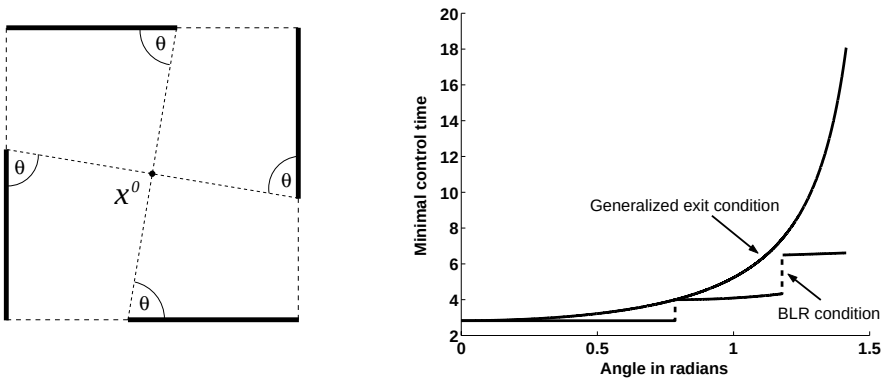

FIG. 2.1. *Left: Control region* $\Gamma(x^0, \theta)$ *(bold line) in the square* $]-1,1[^2$ *for* x^0 *centered and* $\theta < \pi/2$. *Theorem* 2.3 *gives a control time* $T > 2\sqrt{2}/\cos\theta$. *Right: Comparison between BLR minimal control time and the minimal time given by Theorem* 2.3 *for this example.*

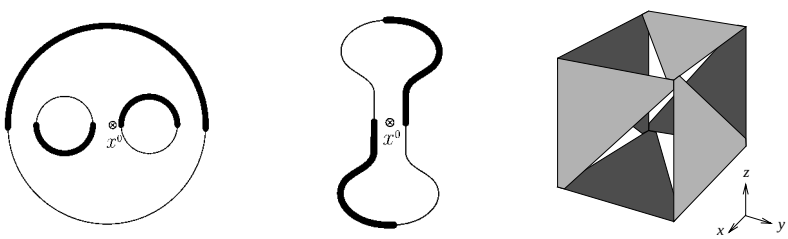

FIG. 2.2. *Other regions of control obtained by applying a rotated multiplier technique. Left: Control region (bold line) for the Ikawa's bowling ball and a bone-shape region for* θ *near* $\pi/2$. *Right: Control region* $\Gamma(x^0, d, \alpha)$ *(in gray) in the cube* $]-1,1[^3$ *for a centered* x^0, $d = 0.1$ *and* α *in the direction* $-(1,1,1)$.

where $M(\theta)$ is a rotation matrix of angle θ anticlockwise (see Figures 2.1 and 2.2).

Remark 3. For $N = 3$, if $\alpha \in \mathbb{R}^3$ and $d^2 + |\alpha|^2 = 1$ we take $A_{12} = -\alpha_3$, $A_{13} = \alpha_2$, and $A_{23} = -\alpha_1$, and the definition (2.5) can be written using the exterior product in $\mathbb{R}^3$ as (see Figure 2.2, right)

$$\Gamma(x^0, d, \alpha) = \{x \in \Gamma \text{ such that } (x - x^0) \cdot (d\nu + \alpha \times \nu) > 0\}. \tag{2.10}$$

2.3. Rotated multiplier: Proof of Theorems 2.2 and 2.3. Let φ be a weak solution of (2.3). Multiplying (2.3) by $\nabla\varphi \cdot q$, where $q \in W^{1,\infty}(\overline{\Omega})^N$, and by φ and integrating by parts, the following classical formulas [24, Chapter I], are deduced:

$$\begin{aligned}(\varphi'(t)\,,\, q \cdot \nabla\varphi)_{0,\Omega}\Big|_{t=0}^{T} + \frac{1}{2}\int_Q \operatorname{div} q(|\varphi'|^2 - |\nabla\varphi|^2)\,dxdt \\ + \int_Q (\nabla q)\nabla\varphi \cdot \nabla\varphi\,dxdt = \frac{1}{2}\int_\Sigma q \cdot \nu \left|\frac{\partial\varphi}{\partial\nu}\right|^2 d\sigma dt\end{aligned} \tag{2.11}$$

and

$$(\varphi'(t)\,,\, \varphi(t))_{0,\Omega}\Big|_{t=0}^{T} = \int_Q (|\varphi'|^2 - |\nabla\varphi|^2)\,dxdt, \tag{2.12}$$

where $(\cdot\,,\,\cdot)_{0,\Omega}$ and $\|\cdot\|_{0,\Omega}$ denote the usual inner product and norm in $L^2(\Omega)^N$, respectively.

We consider now in (2.11) a direction of type

$$q = (dI - A)(x - x^0), \tag{2.13}$$

where $d > 0$ and $A = -A^t$ verify the normalizing condition (2.6). Note that $\operatorname{div} q = dN$, $\nabla q = dI - A$, and $(A\nabla\varphi\,,\,\nabla\varphi)_{0,\Omega} = 0$. With this choice (2.11) becomes

$$\begin{aligned}(\varphi'\,,\,q\cdot\nabla\varphi)_{0,\Omega}\Big|_{t=0}^{T} + \frac{dN}{2}\int_Q (|\varphi'|^2 - |\nabla\varphi|^2)\,dxdt \\ + d\int_Q |\nabla\varphi|^2\,dxdt = \frac{1}{2}\int_\Sigma q\cdot\nu\left|\frac{\partial\varphi}{\partial\nu}\right|^2 d\sigma dt.\end{aligned} \tag{2.14}$$

If we add up this last identity to (2.12) multiplied by $d(N-1)/2$, we obtain

$$\left(\varphi'\,,\,q\cdot\nabla\varphi + \frac{d(N-1)}{2}\varphi\right)_{0,\Omega}\Big|_{t=0}^{T} + \frac{d}{2}\int_Q (|\varphi'|^2 + |\nabla\varphi|^2)\,dxdt = \frac{1}{2}\int_\Sigma q\cdot\nu\left|\frac{\partial\varphi}{\partial\nu}\right|^2 d\sigma dt.$$

In virtue of the energy conservation principle it follows that

$$\left(\varphi'\,,\,q\cdot\nabla\varphi + \frac{d(N-1)}{2}\varphi\right)_{0,\Omega}\Big|_{t=0}^{T} + dTE_0 = \frac{1}{2}\int_\Sigma q\cdot\nu\left|\frac{\partial\varphi}{\partial\nu}\right|^2 d\sigma dt. \tag{2.15}$$

Now, from

$$(q\cdot\nabla\varphi\,,\,\varphi)_{0,\Omega} = -\frac{1}{2}\int_\Omega \operatorname{div} q\,|\varphi|^2\,dx = -\frac{dN}{2}\,\|\varphi\|_{0,\Omega}^2\,,$$

we can see that

$$\begin{aligned}\left\|q\cdot\nabla\varphi + \frac{d(N-1)}{2}\varphi\right\|_{0,\Omega}^2 &= \|q\cdot\nabla\varphi\|_{0,\Omega}^2 - \frac{d^2N(N-1)}{2}\,\|\varphi\|_{0,\Omega}^2 + \frac{d^2(N-1)^2}{4}\,\|\varphi\|_{0,\Omega}^2 \\ &\le \|q\cdot\nabla\varphi\|_{0,\Omega}^2 + \frac{d^2(1-N^2)}{4}\,\|\varphi\|_{0,\Omega}^2 \\ &\le \|q\cdot\nabla\varphi\|_{0,\Omega}^2\,.\end{aligned}$$

The above inequality implies that the first term in the left hand side of (2.15) is bounded by

$$2\left(\frac{R(x^0)}{2}\,\|\varphi'\|_{0,\Omega}^2 + \frac{1}{2R(x^0)}\,\|q\cdot\nabla\varphi\|_{0,\Omega}^2\right),$$

where $R(x^0)$ was defined in (2.7). Using the normalization condition (2.6), we obtain

$$\|q\cdot\nabla\varphi\|_{0,\Omega} \le (d^2 + \|A\|_2^2)^{1/2} R(x^0)\,\|\nabla\varphi\|_{0,\Omega} = R(x^0)\,\|\nabla\varphi\|_{0,\Omega}\,.$$

Therefore, from (2.15) we deduce that

$$-2R(x^0)E_0 + dTE_0 \le \frac{1}{2}\int_\Sigma (dI - A)(x - x^0)\cdot\nu\left|\frac{\partial\varphi}{\partial\nu}\right|^2 d\sigma dt.$$

If we note that $(dI-A)(x-x^0)\cdot\nu = (x-x^0)\cdot(dI+A)\nu$, we have only to use definitions (2.5) of $\Gamma(x^0,d,A)$ and (2.7a) of $r(x^0,d,A)$ in order to conclude the inverse inequality (2.8) and Theorem 2.2.

The exact controllability result of Theorem 2.3 follows directly from Theorem 2.2 applying HUM method (see [24, Chapter IV]). □

3. Elasticity system.

3.1. Control problem. We consider an isotropic homogeneous elastic body occupying a bounded open subset Ω of $\mathbb{R}^N$. We keep the same regularity assumptions and notations of section 2. We introduce the boundary Γ of Ω, the control boundary Γ_0, and given a final time $T > 0$, the associated cilinders $Q = \Omega \times (0,T)$, $\Sigma = \Gamma \times (0,T)$, and $\Sigma_0 = \Gamma_0 \times (0,T)$. We study the exact controllability of the system of linear elasticity with a control acting on a part of the boundary. More precisely, given $\mathbf{f} \in L^2(Q)^N$, a control $\mathbf{v} \in L^2(\Sigma_0)^N$, and initial conditions $\mathbf{u}^0 \in L^2(\Omega)^N$ and $\mathbf{u}^1 \in H^{-1}(\Omega)^N$, let $\mathbf{u}$ be the solution of

$$\mathbf{u}'' - \mu\Delta\mathbf{u} - (\lambda+\mu)\nabla\operatorname{div}\mathbf{u} = \mathbf{f} \quad \text{in} \quad Q, \tag{3.1a}$$

$$\mathbf{u} = \mathbf{v} \quad \text{on} \quad \Sigma_0, \tag{3.1b}$$

$$\mathbf{u} = \mathbf{0} \quad \text{on} \quad \Sigma \setminus \Sigma_0, \tag{3.1c}$$

$$\mathbf{u}(0) = \mathbf{u}^0,\ \mathbf{u}'(0) = \mathbf{u}^1 \quad \text{in} \quad \Omega, \tag{3.1d}$$

where μ and λ are Lamé's constants with $\lambda + 2\mu > 0$. The symbol $'$ (prime) means derivation with respect to time. We take the notation $(\Delta\mathbf{u})_i = \partial^2 u_i/\partial x_j \partial x_j$ and the convention that a repeated index in some expression means implicit sum on this index.

Under the conditions described above, system (3.1) has a solution in a transposition sense. It can be shown that $\mathbf{u} \in C([0,T]; L^2(\Omega)^N)$ and also that $\mathbf{u}' \in C([0,T]; H^{-1}(\Omega)^N)$; hence the conditions (3.1d) have a sense.

We seek for a control function $\mathbf{v}$ such that

$$\mathbf{u}(T) = \mathbf{0} \ \text{ and } \ \mathbf{u}'(T) = \mathbf{0}. \tag{3.2}$$

Now, let us consider the solution φ of the adjoint system:

$$\varphi'' - \mu\Delta\varphi - (\lambda+\mu)\nabla\operatorname{div}\varphi = \mathbf{0} \quad \text{in} \quad Q, \tag{3.3a}$$

$$\varphi = \mathbf{0} \quad \text{on} \quad \Sigma, \tag{3.3b}$$

$$\varphi(0) = \varphi^0,\ \varphi'(0) = \varphi^1 \quad \text{in} \quad \Omega \tag{3.3c}$$

for each $\varphi^0 \in H_0^1(\Omega)^N$ and $\varphi^1 \in L^2(\Omega)^N$. From classical regularity results, we know that $\varphi \in C([0,T]; H_0^1(\Omega)^N)$ and $\varphi' \in C([0,T]; L^2(\Omega)^N)$.

If we define the initial energy by

$$E_0 = \frac{1}{2}\int_\Omega \left(\left|\varphi^1\right|^2 + \mu \left|\nabla\varphi^0\right|^2 + (\lambda+\mu)\left|\operatorname{div}\varphi^0\right|^2 \right) dx, \tag{3.4}$$

multiplying (3.3) by φ' we obtain the conservation of energy

$$E(t) = \frac{1}{2}\int_\Omega \left(|\varphi'(t)|^2 + \mu\,|\nabla\varphi(t)|^2 + (\lambda+\mu)\,|\operatorname{div}\varphi(t)|^2 \right) dx = E_0 \text{ for all } t \in [0,T]. \tag{3.5}$$

3.2. Two multiplier formulas. The following geometric property will be useful in this section and in the next section.

PROPOSITION 3.1. *Let Γ_0 be a subset of Γ with positive measure. Let $\varphi \in H^2(\Omega)^N$ be such that the trace of φ on Γ_0 is a constant vector of $\mathbb{R}^N$. Then*

$$\frac{\partial\varphi_i}{\partial x_j}\nu_k = \frac{\partial\varphi_i}{\partial x_k}\nu_j \quad \text{on} \quad \Gamma_0 \quad \forall \text{ different} \quad i,j,k \in \{1,\dots,N\}. \tag{3.6}$$

Proof. We assume that $\varphi \in C^1(\overline{\Omega})^N$ and we can deduce the general case thanks to a density argument. If the symbol $\times$ stands for the exterior product in $\mathbb{R}^N$, the condition imposed to φ on Γ_0 is equivalent to $\nabla\varphi_i \times \nu = 0$ on Γ_0 for each $i = 1, \dots, N$, and this corresponds exactly to (3.6). ∎

We introduce the well-known tensorial product

$$e : f = e_{ij}\, f_{ij},$$

where $e = \{e_{ij}\}_{j=1}^N$ and $f = \{f_{ij}\}_{j=1}^N$ are tensorial fields defined in $\overline{\Omega}$ onto $\mathbb{R}^{N\times N}$. We suppose that this tensorial product has lower precedence than the usual matrix product in $\mathbb{R}^{N\times N}$.

Let q be a vector field defined in $\overline{\Omega}$ with $q \in W^{2,\infty}(\overline{\Omega})$.

Taking the multiplier $(\nabla\varphi)q$ for each term of the left-hand side in (3.3a) the following identities are deduced:

$$\int_\Omega \nabla \operatorname{div}\varphi \cdot (\nabla\varphi)q\, dx = \int_\Omega \frac{\partial^2\varphi_i}{\partial x_i \partial x_j}\frac{\partial\varphi_j}{\partial x_k} q_k\, dx \tag{3.7}$$
$$= -\int_\Omega \frac{\partial\varphi_i}{\partial x_i}\frac{\partial^2\varphi_j}{\partial x_j \partial x_k} q_k\, dx - \int_\Omega \frac{\partial\varphi_i}{\partial x_i}\frac{\partial\varphi_j}{\partial x_k}\frac{\partial q_k}{\partial x_j}\, dx + \int_\Gamma \frac{\partial\varphi_i}{\partial x_i}\frac{\partial\varphi_j}{\partial x_k}\, q_k\nu_j\, d\sigma,$$

but

$$-\int_\Omega \frac{\partial\varphi_i}{\partial x_i}\frac{\partial^2\varphi_j}{\partial x_j \partial x_k} q_k\, dx = \frac{1}{2}\int_\Omega \frac{\partial\varphi_i}{\partial x_i}\frac{\partial\varphi_j}{\partial x_j}\frac{\partial q_k}{\partial x_k}\, dx - \frac{1}{2}\int_\Gamma \frac{\partial\varphi_i}{\partial x_i}\frac{\partial\varphi_j}{\partial x_j}\, q_k\nu_k\, d\sigma$$

and, taking into account Proposition 3.1,

$$\int_\Gamma \frac{\partial\varphi_i}{\partial x_i}\frac{\partial\varphi_j}{\partial x_k}\, q_k\nu_j\, d\sigma = \int_\Gamma \frac{\partial\varphi_i}{\partial x_i}\frac{\partial\varphi_j}{\partial x_j}\, q_k\nu_k\, d\sigma.$$

Hence it follows that

$$\int_\Omega \nabla\operatorname{div}\varphi\cdot(\nabla\varphi)q\, dx = \frac{1}{2}\int_\Omega |\operatorname{div}\varphi|^2 \operatorname{div} q\, dx - \int_\Omega \operatorname{div}\varphi\, \nabla\varphi : \nabla^t q\, dx + \frac{1}{2}\int_\Gamma |\operatorname{div}\varphi|^2\, q\cdot\nu\, d\sigma.$$

The other term gives

$$\int_\Omega \Delta\varphi \cdot (\nabla\varphi)q\, dx = \int_\Omega \frac{\partial^2\varphi_i}{\partial x_j \partial x_j}\frac{\partial\varphi_i}{\partial x_k} q_k\, dx \tag{3.8}$$
$$= -\int_\Omega \frac{\partial\varphi_i}{\partial x_j}\frac{\partial^2\varphi_i}{\partial x_j \partial x_k} q_k\, dx - \int_\Omega \frac{\partial\varphi_i}{\partial x_j}\frac{\partial\varphi_i}{\partial x_k}\frac{\partial q_k}{\partial x_j}\, dx + \int_\Gamma \frac{\partial\varphi_i}{\partial x_j}\frac{\partial\varphi_i}{\partial x_k}\, q_k\nu_j\, d\sigma,$$

but

$$-\int_\Omega \frac{\partial\varphi_i}{\partial x_j}\frac{\partial^2\varphi_i}{\partial x_j \partial x_k} q_k\, dx = \frac{1}{2}\int_\Omega \frac{\partial\varphi_i}{\partial x_j}\frac{\partial\varphi_i}{\partial x_j}\frac{\partial q_k}{\partial x_k}\, dx - \frac{1}{2}\int_\Gamma \frac{\partial\varphi_i}{\partial x_j}\frac{\partial\varphi_i}{\partial x_j}\, q_k\nu_k\, d\sigma,$$

and, from Proposition 3.1,

$$\int_\Gamma \frac{\partial\varphi_i}{\partial x_j}\frac{\partial\varphi_i}{\partial x_k}\, q_k\nu_j\, d\sigma = \int_\Gamma \frac{\partial\varphi_i}{\partial x_j}\frac{\partial\varphi_i}{\partial x_j}\, q_k\nu_k\, d\sigma;$$

then

$$\int_\Omega \Delta\varphi \cdot (\nabla\varphi)q\, dx = \frac{1}{2}\int_\Omega |\nabla\varphi|^2 \operatorname{div} q\, dx - \int_\Omega \nabla\varphi : \nabla\varphi\nabla q\, dx + \frac{1}{2}\int_\Gamma |\nabla\varphi|^2\, q\cdot\nu\, d\sigma.$$

Always with the multiplier $(\nabla\varphi)q$ the last term in (3.3a) gives in a classical manner

$$\int_Q \varphi'' \cdot (\nabla\varphi)q\,dxdt = \frac{1}{2}\int_Q |\varphi'|^2 \operatorname{div} q\,dxdt - \frac{1}{2}\int_\Sigma |\varphi'|^2\, q\cdot\nu\,d\sigma dt + (\varphi'\,,\,(\nabla\varphi)q)_{0,\Omega}\Big|_{t=0}^{T}.$$

Using the other multiplier $(\nabla^t q)\varphi$ for each term of the left-hand side in (3.3a) it follows that

$$\int_\Omega \nabla\operatorname{div}\varphi\cdot(\nabla^t q)\varphi\,dx = \int_\Omega \frac{\partial^2\varphi_i}{\partial x_i\partial x_j}\frac{\partial q_k}{\partial x_j}\varphi_k\,dx \tag{3.9}$$

$$= -\int_\Omega \frac{\partial\varphi_i}{\partial x_i}\frac{\partial^2 q_k}{\partial x_j\partial x_j}\varphi_k\,dx - \int_\Omega \frac{\partial\varphi_i}{\partial x_i}\frac{\partial q_k}{\partial x_j}\frac{\partial\varphi_k}{\partial x_j}\,dx + \int_\Omega \frac{\partial\varphi_i}{\partial x_i}\frac{\partial q_k}{\partial x_j}\,\varphi_k\nu_j\,dx$$

$$= -\int_\Omega \operatorname{div}\varphi\Delta q\cdot\varphi\,dx - \int_\Omega \operatorname{div}\varphi\nabla\varphi : \nabla q\,dx,$$

since $\varphi = 0$ on Γ. For the second term,

$$\int_\Omega \Delta\varphi\cdot(\nabla^t q)\varphi\,dx = \int_\Omega \frac{\partial^2\varphi_i}{\partial x_j\partial x_j}\frac{\partial q_k}{\partial x_i}\varphi_k\,dx \tag{3.10}$$

$$= -\int_\Omega \frac{\partial\varphi_i}{\partial x_j}\frac{\partial^2 q_k}{\partial x_i\partial x_j}\varphi_k\,dx - \int_\Omega \frac{\partial\varphi_i}{\partial x_j}\frac{\partial q_k}{\partial x_i}\frac{\partial\varphi_k}{\partial x_j}\,dx + \int_\Gamma \frac{\partial\varphi_i}{\partial x_j}\frac{\partial q_k}{\partial x_i}\,\varphi_k\nu_j\,d\sigma$$

$$= -\int_\Omega \frac{\partial\varphi_i}{\partial x_j}\frac{\partial^2 q_k}{\partial x_i\partial x_j}\varphi_k\,dx - \int_\Omega \nabla\varphi : (\nabla^t q)\nabla\varphi\,dx.$$

For the last term, always with the second multiplier$(\nabla^t q)\varphi$, integration by parts in Q gives

$$\int_Q \varphi''\cdot(\nabla^t q)\varphi\,dxdt = -\int_Q (\nabla q)\varphi'\cdot\varphi'\,dxdt + \big(\varphi'\,,\,(\nabla^t q)\varphi\big)_{0,\Omega}\Big|_{t=0}^{T}.$$

Combining the identities above, a multiplier formula appears for each multiplier $(\nabla\varphi)q$ and $(\nabla^t q)\varphi$.

LEMMA 3.2. *Let φ be the solution of* (3.3). *For all $q\in W^{2,\infty}(\overline{\Omega})^N$ we have*

$$(\varphi'\,,\,(\nabla\varphi)q)_{0,\Omega}\Big|_{t=0}^{T} + \frac{1}{2}\int_Q \operatorname{div} q(|\varphi'|^2 - \mu\,|\nabla\varphi|^2 - (\lambda{+}\mu)\,|\operatorname{div}\varphi|^2)\,dxdt \tag{3.11}$$

$$+\mu\int_Q \nabla\varphi : \nabla\varphi\nabla q\,dxdt + (\lambda{+}\mu)\int_Q \operatorname{div}\varphi\,\nabla\varphi : \nabla^t q\;dxdt$$

$$= \frac{1}{2}\int_\Sigma q\cdot\nu(\mu\,|\nabla\varphi|^2 + (\lambda{+}\mu)\,|\operatorname{div}\varphi|^2)\,d\sigma dt,$$

$$\big(\varphi'\,,\,(\nabla^t q)\varphi\big)_{0,\Omega}\Big|_{t=0}^{T} = \int_Q (\nabla q)\varphi'\cdot\varphi'\,dxdt - \mu\int_Q \nabla\varphi : \nabla^t q\nabla\varphi\,dxdt \tag{3.12}$$

$$-(\lambda{+}\mu)\int_Q \operatorname{div}\varphi\,\nabla\varphi : \nabla q\,dxdt - \mu\int_Q \frac{\partial\varphi_i}{\partial x_j}\frac{\partial^2 q_k}{\partial x_i\partial x_j}\varphi_k\,dxdt$$

$$-(\lambda{+}\mu)\int_Q \operatorname{div}\varphi\,\Delta q\cdot\varphi\,dxdt.$$

3.3. Choice of the rotated direction. The classical choice $q = x - x^0$, $x^0 \in \mathbb{R}^N$, in (3.11) and (3.12) gives (see [24])

$$(3.13)\quad \big(\varphi'\,,\,\nabla\varphi(x-x^0)\big)_{0,\Omega}\Big|_{t=0}^{T} + \frac{N}{2}\int_Q (|\varphi'|^2 - \mu\,|\nabla\varphi|^2 - (\lambda+\mu)\,|\operatorname{div}\varphi|^2)\,dxdt$$
$$+ \int_Q (\mu\,|\nabla\varphi|^2 + (\lambda+\mu)\,|\operatorname{div}\varphi|^2)\,dxdt = \frac{1}{2}\int_\Sigma (\mu\,|\nabla\varphi|^2 + (\lambda+\mu)\,|\operatorname{div}\varphi|^2)(x-x^0)\cdot\nu\,d\sigma dt$$

and

$$(3.14)\qquad (\varphi'\,,\,\varphi)_{0,\Omega}\Big|_{t=0}^{T} = \int_Q (|\varphi'|^2 - \mu\,|\nabla\varphi|^2 - (\lambda+\mu)\,|\operatorname{div}\varphi|^2)\,dxdt.$$

Now, a rotated direction $q = A(x-x^0)$, $A = -A^t$ (skew-symmetric) in (3.11) and (3.12) gives the following new identities:

$$(3.15)\big(\varphi'\,,\,\nabla\varphi A(x-x^0)\big)_{0,\Omega}\Big|_{t=0}^{T} - (\lambda+\mu)\int_Q \operatorname{div}\varphi\nabla\varphi : A\,dxdt$$
$$= \frac{1}{2}\int_\Sigma (\mu\,|\nabla\varphi|^2 + (\lambda+\mu)\,|\operatorname{div}\varphi|^2)A(x-x^0)\cdot\nu\,d\sigma dt,$$

$$(3.16)\qquad (\varphi'\,,\,A\varphi)_{0,\Omega}\Big|_{t=0}^{T} = (\lambda+\mu)\int_Q \operatorname{div}\varphi\,\nabla\varphi : A\;dxdt.$$

Remark 4. For $N = 2$ or $N = 3$, the tensorial product $\nabla\varphi : A$ in (3.15) and (3.16) can be written in terms of the curl and **curl** operators, respectively. Indeed, let $\mathbf{e}_{ij} = \mathbf{e}_i \otimes \mathbf{e}_j = \mathbf{e}_j\,\mathbf{e}_i^t$, where $\{\mathbf{e}_i\}_{i=1}^N$ is the canonical basis in $\mathbb{R}^N$. If $N = 2$ and $A = \alpha(\mathbf{e}_{21} - \mathbf{e}_{12})$, where $\alpha \in \mathbb{R}$, then

$$\nabla\varphi : A = \alpha\left(\frac{\partial\varphi_2}{\partial x_1} - \frac{\partial\varphi_1}{\partial x_2}\right) = \alpha\operatorname{curl}\varphi.$$

In $N = 3$ and $A = \alpha_1(\mathbf{e}_{32}-\mathbf{e}_{23})+\alpha_2(\mathbf{e}_{13}-\mathbf{e}_{31})+\alpha_3(\mathbf{e}_{21}-\mathbf{e}_{12})$ where $\alpha = (\alpha_1,\alpha_2,\alpha_3) \in \mathbb{R}^3$, then

$$\nabla\varphi : A = \alpha_1\left(\frac{\partial\varphi_3}{\partial x_2} - \frac{\partial\varphi_2}{\partial x_3}\right) + \alpha_2\left(\frac{\partial\varphi_1}{\partial x_3} - \frac{\partial\varphi_3}{\partial x_1}\right) + \alpha_3\left(\frac{\partial\varphi_2}{\partial x_1} - \frac{\partial\varphi_1}{\partial x_2}\right) = \alpha\cdot\mathbf{curl}\,\varphi.$$

One can compare with the analogous properties of Corollary 4.12 in section 4.

3.4. Inverse inequality and exact controllability. Given the same notations as in section 2, if we introduce the subset $\Gamma(x^0,d,A)$ of Γ as in (2.5) and the quantities $r(x^0,d,A)$ and $R(x^0)$ as in (2.7), we obtain the following observability inequality and exact controllability result.

THEOREM 3.3 (inverse inequality). *Given $x^0 \in \mathbb{R}^N$, $d > 0$, and a skew-symmetric matrix A normalized as in* (2.6)*, if $\lambda_0^2 = \inf\{\|\nabla\varphi\|_{0,\Omega}^2 \,/\, \|\varphi\|_{0,\Omega}^2; \varphi \in H_0^1(\Omega)^N\}$ and if we define*

$$(3.17)\qquad T(x^0,d,A) = \frac{2}{\sqrt{\mu}}\left(R(x^0) + \frac{\|A\|_2}{\lambda_0}\right),$$

then for each $T > d^{-1}T(x^0, d, A)$ and for each weak solution φ of (3.3) *the following inequality holds:*

$$E_0 \le \frac{r(x^0,d,A)}{2(dT - T(x^0,d,A))} \int_0^T \int_{\Gamma(x^0,d,A)} (\mu\,|\nabla\varphi|^2 + (\lambda{+}\mu)\,|\operatorname{div}\varphi|^2)\,d\sigma dt, \tag{3.18}$$

where the initial energy E_0 was defined in (3.4).

THEOREM 3.4 (exact controllability). *Suppose that there exist $x^0 \in \mathbb{R}^N$, $d > 0$, and a skew-symmetric matrix A normalized as in* (2.6) *such that $\Gamma(x^0, d, A)$ is not empty and $\Gamma(x^0, d, A) \subset \Gamma_0$, then for each $T > d^{-1}T(x^0, d, A)$ there exists a control $v \in L^2(\Sigma_0)^N$ such that the corresponding solution of* (3.1) *satisfies the final time condition* (3.2).

Proof. Adding up the classical formulas (3.13) multiplied by b with (3.14) multiplied by $d(N-1)/2$ let us to obtain

$$\left(\varphi'\,,\,\nabla\varphi(x{-}x^0) + \frac{d(N-1)}{2}\varphi\right)_{0,\Omega}\Bigg|_{t=0}^{T} + \frac{d}{2}\int_Q (|\varphi'|^2 - \mu\,|\nabla\varphi|^2 - (\lambda{+}\mu)\,|\operatorname{div}\varphi|^2)\,dxdt$$
$$+ d\int_Q (\mu\,|\nabla\varphi|^2 + (\lambda{+}\mu)\,|\operatorname{div}\varphi|^2)\,dxdt = \frac{d}{2}\int_\Sigma (\mu\,|\nabla\varphi|^2 + (\lambda{+}\mu)\,|\operatorname{div}\varphi|^2)(x{-}x^0)\cdot\nu\,d\sigma dt.$$

Now, the new formula (3.16) replaced into the new identity (3.15) gives

$$\left(\varphi'\,,\,\nabla\varphi A(x{-}x^0) - A\varphi\right)_{0,\Omega}\Big|_{t=0}^{T} = \frac{1}{2}\int_\Sigma (\mu\,|\nabla\varphi|^2 + (\lambda{+}\mu)\,|\operatorname{div}\varphi|^2)A(x{-}x^0)\cdot\nu\,d\sigma dt.$$

By subtracting the last two identities we establish that

$$\begin{aligned}&(X_1(t) + X_2(t))\big|_{t=0}^{T} + dTE_0\\ &= \frac{1}{2}\int_\Sigma (\mu\,|\nabla\varphi|^2 + (\lambda{+}\mu)\,|\operatorname{div}\varphi|^2)(x - x^0)\cdot(dI + A)\nu\,d\sigma dt,\end{aligned} \tag{3.19}$$

where we have defined the quantities

$$X_1(t) = (\varphi'\,,\,A\varphi)_{0,\Omega} \quad\text{and}\quad X_2(t) = \left(\varphi'\,,\,\nabla\varphi(dI - A)(x{-}x^0) + d\frac{N-1}{2}\varphi\right)_{0,\Omega}.$$

We will prove the inverse inequality (3.18). On one hand, we deduce, from the Cauchy–Schwarz inequality, the inequality $ab \le a^2/(4\varepsilon) + \varepsilon b^2$ with $\varepsilon = \lambda_0\sqrt{\mu}/(2\,\|A\|_2)$ and from the definition of λ_0 and E_0 that

$$\left|X_1(t)\big|_{t=0}^{T}\right| \le 2\frac{\|A\|_2}{2\lambda_0\sqrt{\mu}}\,\|\varphi'\|_{0,\Omega}^2 + 2\frac{\lambda_0\sqrt{\mu}}{2\,\|A\|_2}\,\|A\|_2^2\,\frac{1}{\lambda_0^2}\,\|\nabla\varphi\|_{0,\Omega}^2 \le 2\frac{\|A\|_2}{\lambda_0\sqrt{\mu}}E_0. \tag{3.20}$$

Note that if $\|A\|_2 = 0$ then $X_1 = 0$. On the other hand, using the Cauchy–Schwarz inequality and the same inequality as before with $\varepsilon = \sqrt{\mu}/(2R(x^0))$ we obtain

$$\begin{aligned}|X_2(t)| \quad &\le \frac{R(x^0)}{2\sqrt{\mu}}\,\|\varphi'\|_{0,\Omega}^2 + \frac{\mu}{2R(x^0)\sqrt{\mu}}\left(\left\|\nabla\varphi(dI - A)(x{-}x^0)\right\|_{0,\Omega}^2\right.\\ &\left. + d^2\frac{(N-1)^2}{4}\,\|\varphi\|_{0,\Omega}^2 + d(N-1)\left(\nabla\varphi(dI - A)(x{-}x^0)\,,\,\varphi\right)_{0,\Omega}\right),\end{aligned} \tag{3.21}$$

where $R(x^0) = \max_{x\in\overline{\Omega}} \left|x - x^0\right| > 0$ was introduced in (2.7). We note that

$$\left(\nabla\varphi(dI - A)(x-x^0)\,,\,\varphi\right)_{0,\Omega} = -\frac{Nd}{2}\,\|\varphi\|^2_{0,\Omega}\,,$$

hence the last two terms in (3.21) have a negative sum $-d^2(N^2-1)\,\|\varphi\|^2_{0,\Omega}/4$. One also remarks that

$$\left\|\nabla\varphi(dI - A)(x-x^0)\right\|^2_{0,\Omega} \le (d^2 + \|A\|_2^2)R(x^0)^2\,\|\nabla\varphi\|^2_{0,\Omega} \le R(x^0)^2\,\|\nabla\varphi\|^2_{0,\Omega}\,,$$

since it has been assumed that $d^2 + \|A\|_2^2 = 1$. Finally we obtain

$$\left|X_2(t)|_{t=0}^T\right| \le 2\frac{R(x^0)}{2\sqrt{\mu}}\,\|\varphi'\|^2_{0,\Omega} + 2\frac{1}{2R(x^0)\sqrt{\mu}}R(x^0)^2\mu\,\|\nabla\varphi\|^2_{0,\Omega} \le 2\frac{R(x^0)}{\sqrt{\mu}}E_0. \tag{3.22}$$

The inequality (3.18) follows from (3.19), (3.20), (3.22), and definitions (2.5) and (2.7).

Theorem 3.4 follows immediately from Theorem 3.3 applying the HUM method (see [24, Chapter IV]). □

4. Stokes system.

4.1. Control problem. Let Ω be an open bounded subset of $\mathbb{R}^N$ ($N = 2$ or 3) with boundary Γ of class C^2. Let ν be the unit exterior normal to Ω. If $N = 2$ we refer to the tangent vector on Γ as $\tau = (-\nu_2, \nu_1)$.

DEFINITION 4.1. *For a vector field* $\mathbf{z}$ *defined on the boundary* Γ*, we introduce the operators* γ_n *and* γ_τ *defined by*

$$\gamma_n\mathbf{z} = \mathbf{z}\cdot\nu, \tag{4.1}$$

$$\gamma_\tau\mathbf{z} = \begin{cases} \mathbf{z}\cdot\tau & \text{if } N = 2,\\ \nu\times\mathbf{z} & \text{if } N = 3. \end{cases} \tag{4.2}$$

Remark 5. It should be noticed that on Γ

$$\mathbf{z} = \gamma_n(\mathbf{z})\nu + \gamma_\tau(\mathbf{z})\tau \quad \text{if} \quad N = 2, \tag{4.3a}$$

$$\mathbf{z} = \gamma_n(\mathbf{z})\nu + \gamma_\tau(\mathbf{z})\times\nu \quad \text{if} \quad N = 3. \tag{4.3b}$$

Therefore, γ_n corresponds to the normal trace for $N = 2$ and $N = 3$ and γ_τ corresponds to the tangential trace for $N = 2$. In case $N = 3$, $\gamma_\tau\times\nu$ corresponds to the tangential components.

Now, let us introduce the following classical functional spaces (see [43]) with their usual topologies:

$$H = \{\mathbf{v}\in L^2(\Omega)^N \mid \operatorname{div}\mathbf{v} = 0\ ,\gamma_n\mathbf{v} = 0 \text{ on } \Gamma\},\ V = \{\mathbf{v}\in H_0^1(\Omega)^N \mid \operatorname{div}\mathbf{v} = 0\}$$

in the standard embedding scheme $V'\subset H'\equiv H\subset V$.

The following control problem is considered. Let $T > 0$ and let Γ_0 be a subset of Γ with positive measure. Given $\mathbf{y}_0\in H$ and $\mathbf{f}\in L^2(0,T;V')$, for each control v scalar field if $N = 2$ or $\mathbf{v}$ vector field in $\mathbb{R}^3$ if $N = 3$, we consider (formally at the moment) the solution $(\mathbf{y}, p)$ of the following evolution Stokes problem:

$$\mathbf{y}' - \Delta\mathbf{y} + \nabla p = \mathbf{f} \quad \text{in} \quad \Omega\times(0,T), \tag{4.4a}$$

$$\operatorname{div} \mathbf{y} = 0 \quad \text{in} \quad \Omega \times (0,T), \tag{4.4b}$$

$$\gamma_n \mathbf{y} = 0 \quad \text{on} \quad \Gamma_0 \times (0,T), \tag{4.4c}$$

$$\gamma_\tau \mathbf{y} = \begin{cases} v & \text{if } N = 2 \\ \mathbf{v} & \text{if } N = 3 \end{cases} \quad \text{on} \quad \Gamma_0 \times (0,T), \tag{4.4d}$$

$$\mathbf{y} = 0 \quad \text{on} \quad (\Gamma \setminus \Gamma_0) \times (0,T), \tag{4.4e}$$

$$\mathbf{y}(0) = \mathbf{y}_0 \quad \text{in} \quad \Omega. \tag{4.4f}$$

Here $\mathbf{y}$ is the vector velocity field in $\mathbb{R}^N$ and p is the pressure, defined up to an additive constant. The symbol $'$ (prime) means derivation with respect to time and we use the usual notation $(\Delta \mathbf{y})_i = \partial^2 y_i / \partial x_j \partial x_j$ here (where repeated index means sum). In case $N = 3$, the control $\mathbf{v}$ must satisfy the following compatibility condition:

$$\gamma_n \mathbf{v} = 0 \quad \text{on} \quad \Gamma_0 \quad \text{if} \quad N = 3. \tag{4.5}$$

Our main goal is to find geometric conditions over Γ_0 in such a way that the space $\{\mathbf{y}(T)\}$ is dense in a suitable space when the control function v or $\mathbf{v}$ varies in a space also to be determined. In other words, we seek for conditions to have the tangential boundary approximate controllability.

Without loss of generality, for the approximate control problem, the initial datum $\mathbf{y}_0$ and $\mathbf{f}$ may be taken to be zero.

4.2. Tangential boundary approximate controllability. In Theorem 4.3 we obtain approximate controllability by using a rotated direction multiplier technique, with a geometric condition similar to that required in sections 2 and 3. In Theorem 4.4 we state the result for analytic boundaries and, in this particular case, the geometric condition of Theorem 4.3 is not necessary.

In order to describe the condition appearing in Theorem 4.3, we set down an analogous to Definition 2.1 in two and three dimensions including the case $d = 0$ and other signs of the inner product appearing in the main condition.

DEFINITION 4.2. *Let x^0 be a vector in $\mathbb{R}^N$, $d \geq 0$, and $\alpha \in \mathbb{R}$ when $N = 2$ or $\alpha \in \mathbb{R}^3$ when $N = 3$. We define the following subset of Γ:*

$$\Gamma^+(x^0, d, \alpha) = \begin{cases} \{x \in \Gamma \text{ such that } (x - x^0) \cdot (d\nu + \alpha\tau) > 0\} & \text{if } N = 2, \\ \{x \in \Gamma \text{ such that } (x - x^0) \cdot (d\nu + \alpha \times \nu) > 0\} & \text{if } N = 3, \end{cases} \tag{4.6}$$

and analogously we define $\Gamma^-(x^0, d, \alpha)$ and $\Gamma^0(x^0, d, \alpha)$ if the sign of the inner product in (4.6) is negative or zero, respectively.

In order to shorten notations let us define

$$\Sigma_0 = \Gamma_0 \times (0,T).$$

THEOREM 4.3 (approximate controllability). *We suppose that there exist $x^0 \in \mathbb{R}^N$, $d \geq 0$, and $\alpha \in \mathbb{R}$ when $N = 2$ or $\alpha \in \mathbb{R}^3$ when $N = 3$ such that Γ_0 satisfies the conditions*

$$\Gamma_0 \supseteq \Gamma^+(x^0, d, \alpha) \quad \text{if} \quad d > 0, \tag{4.7a}$$

$$\Gamma_0 \supseteq \Gamma^+(x^0, 0, \alpha) \cup \Gamma^0(x^0, 0, \alpha) \quad \text{if} \quad d = 0. \tag{4.7b}$$

For each $T > 0$ and for each $v \in L^2(\Sigma_0)$ when $N = 2$ or $\mathbf{v} \in L^2(\Sigma_0)^3$ satisfying (4.5) when $N = 3$, let us consider a solution $(\mathbf{y}, \mathbf{y}^T)$ of (4.4) in the weak sense of Definition 4.6. Then for all $T > 0$ the following sets are dense in V':

$$\begin{array}{ll} \{\mathbf{y}^T \text{ such that } v \in L^2(\Sigma_0)\} & \text{if} \quad N = 2, \\ \{\mathbf{y}^T \text{ such that } \mathbf{v} \in L^2(\Sigma_0)^3 \text{ satisfying (4.5)}\} & \text{if} \quad N = 3. \end{array} \tag{4.8}$$

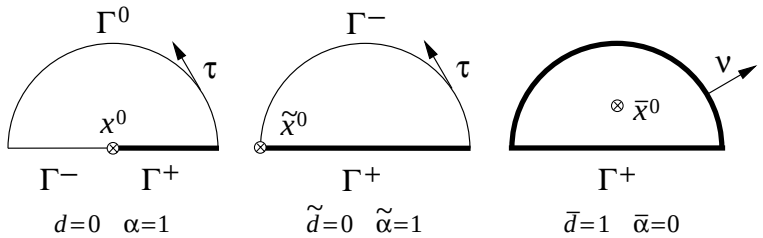

FIG. 4.1. *Example for Remark* 7 *in a half circle. Left: Take* $\Gamma_0 = \Gamma^+(x^0, 0, 1)$ *(bold line).* Γ_0 *can be extended to the whole diameter* $\Gamma_0 = \Gamma^+(x^0, 0, 1) \cup \Gamma^-(x^0, 0, 1)$. *Center: For a new* $\tilde{x}^0$, Γ_0 *can be extended to the whole boundary* $\Gamma_0 = \Gamma^+(\tilde{x}^0, 0, 1) \cup \Gamma^-(\tilde{x}^0, 0, 1)$. *Right: Another choice of parameters e.g.,* $\overline{x}^0$, $\overline{d} = 1$, $\overline{\alpha} = 0$ *leads to apply Theorem* 4.3 *to conclude the approximate controllability.*

Remark 6. With a boundary control in $L^2(\Sigma_0)$, we will give a sense to $\mathbf{y}(T)$ only in V'. More precisely, if $(\mathbf{y}, \mathbf{y}^T)$ is a weak solution of (4.4) in the sense of Definition 4.6, we will show that $\mathbf{y} \in C^0([0,T]; V')$.

Remark 7. If Γ_0 verifies $\Gamma_0 \supseteq \Gamma^+(x^0, 0, \alpha)$ for a choice of the parameters x^0, $d = 0$ and α, but the condition (4.7b) is not fulfilled, then it is showed that Γ_0 can be replaced by $\Gamma_0 \cup \Gamma^-(x^0, 0, \alpha)$ and Theorem 4.3 can be applied again with a new choice $\overline{x}^0$, $\overline{d}$, $\overline{\alpha}$ of the parameters (see the example provided by Figure 4.1).

The following result shows that condition (4.7) of Theorem 4.3 is not necessary for analytic boundaries if $N = 2$.

THEOREM 4.4 (approximate controllability for analytic boundaries). *Assume that* $N = 2$ *and* Ω *connected. Let* $\{\Gamma^i\}_{i=1}^K$ *be the connected components of* Γ *and define* $\Gamma_0^i = \Gamma_0 \cap \Gamma^i$. *If for each* $i = 1, \ldots, K$ *we have* $\Gamma_0^i = \Gamma^i$ *or* Γ^i *analytic and* Γ_0^i *an arbitrary nonempty open subset of* Γ^i, *then for each* $T > 0$ *the sets* (4.8) *are dense in* V'.

Remark 8. Condition (4.7) is not necessary in a generic sense: For all N and for a regular boundary Γ, if Γ_0 is an arbitrary nonempty subset of Γ, we could always slightly modify Γ_0 in order to have the result of Theorem 4.3 (see [36]).

Remark 9. There is no counterexample in order to decide if condition (4.7) is too restrictive, for instance, in the case of nonanalytic boundaries for $N = 2$.

4.3. A trace property. Here, we recall the definitions

$$(\nabla \mathbf{z})_{ij} = \frac{\partial z_i}{\partial x_j} \quad \text{and} \quad \operatorname{curl} \mathbf{z} = \frac{\partial z_2}{\partial x_1} - \frac{\partial z_1}{\partial x_2} \quad \text{if} \quad N = 2, \tag{4.9a}$$

$$\mathbf{curl}\, \mathbf{z} = \left(\frac{\partial z_3}{\partial x_2} - \frac{\partial z_2}{\partial x_3}, \frac{\partial z_1}{\partial x_3} - \frac{\partial z_3}{\partial x_1}, \frac{\partial z_2}{\partial x_1} - \frac{\partial z_1}{\partial x_2} \right) \quad \text{if} \quad N = 3. \tag{4.9b}$$

PROPOSITION 4.5. *Let* $\mathbf{z} \in H^2(\Omega)^N$ *with* $\mathbf{z} = \mathbf{c}$ *on* Γ_0, *where* $\mathbf{c}$ *is a constant vector of* $\mathbb{R}^N$ *and* Γ_0 *is a subset of* Γ *of positive measure. Then, on* Γ_0, *we have*

$$\gamma_n((\nabla \mathbf{z})\nu) = \operatorname{div} \mathbf{z}, \tag{4.10a}$$

$$\gamma_\tau((\nabla \mathbf{z})\nu) = \begin{cases} \operatorname{curl} \mathbf{z} & \text{if } N = 2, \\ \mathbf{curl}\, \mathbf{z} & \text{if } N = 3. \end{cases} \tag{4.10b}$$

Proof. We will prove the result for $\mathbf{z} \in C^1(\overline{\Omega})$. The condition $\mathbf{z} = \mathbf{c}$ on Γ_0 allows us to use Proposition 3.1, that is to say, that the derivative and normal indexes can

be permuted on Γ_0. Thanks to this property we easily see that

$$(\nabla \mathbf{z})\nu \cdot \nu = \frac{\partial z_i}{\partial x_j}\nu_j\nu_i = \frac{\partial z_i}{\partial x_i}\nu_j\nu_j = \operatorname{div} \mathbf{z}.$$

We recall the condensed formulas:

$$\operatorname{curl} \mathbf{z} = \varepsilon_{ij}\frac{\partial z_j}{\partial x_i} \text{ if } N = 2 \quad \text{and} \quad (\mathbf{curl}\, \mathbf{z})_i = \varepsilon_{ijk}\frac{\partial z_k}{\partial x_j} \text{ if } N = 3,$$

where ε_{ij} and ε_{ijk} are the signs of index permutations, i.e., if $\mathbf{e}_i$ is the ith canonical base vector of $\mathbb{R}^N$, we have $\varepsilon_{ij} = \det(\mathbf{e}_i\, \mathbf{e}_j)$ and $\varepsilon_{ijk} = \det(\mathbf{e}_i\, \mathbf{e}_j\, \mathbf{e}_k)$. In case $N = 2$, if we remember that $\tau_i = -\varepsilon_{ik}\nu_k$ and $\varepsilon_{ik} = -\varepsilon_{ki}$, then

$$(\nabla \mathbf{z})\nu \cdot \tau = -\frac{\partial z_i}{\partial x_j}\nu_j\varepsilon_{ik}\nu_k = \varepsilon_{ki}\frac{\partial z_i}{\partial x_k}\nu_j\nu_j = \operatorname{curl} \mathbf{z}.$$

For $N = 3$, if we use the fact that $(\mathbf{a} \times \mathbf{b})_i = \varepsilon_{ijk}a_j\, b_k$, we obtain

$$(\nu \times (\nabla \mathbf{z})\nu)_i = \varepsilon_{ijk}\nu_j\frac{\partial z_k}{\partial x_l}\nu_l = \varepsilon_{ijk}\frac{\partial z_k}{\partial x_j}\nu_l\nu_l = (\mathbf{curl}\, \mathbf{z})_i.$$

The general case $\mathbf{z} \in H^2(\Omega)$ can be deduced by a density argument from the regular case. □

4.4. Weak formulation of the nonsmooth data problem (4.4). Without loss of generality, we consider the case $\mathbf{f} = \mathbf{0}$ and $\mathbf{y}_0 = \mathbf{0}$. We can always do this by choosing new variables $\mathbf{y} - \overline{\mathbf{y}}$ and $p - \overline{p}$ where $(\overline{\mathbf{y}}, \overline{p})$ is the solution of (4.4) for $v = 0$ (or $\mathbf{v} = \mathbf{0}$). We recall that [43, Theorem 1.1, p. 254],

$$\overline{\mathbf{y}} \in L^2(0,T;V) \cap C([0,T];H),\ \overline{\mathbf{y}}' \in L^2(0,T;V'),$$
$$\overline{p} = \overline{P}' \text{ with } \overline{P} \in C([0,T];L^2(\Omega)).$$

DEFINITION 4.6. *For each $v \in L^2(\Sigma_0)$ if $N = 2$ or $\mathbf{v} \in L^2(\Sigma_0)^3$ verifying* (4.5) *if $N = 3$, we say that $(\mathbf{y}, \mathbf{y}^T)$ is a weak solution to Problem* (4.4) *if $\mathbf{y} \in L^2(0,T;H)$, $\mathbf{y}^T \in V'$, and*

$$\int_Q \mathbf{y} \cdot \mathbf{h}\, dxdt + \langle \mathbf{y}^T, \mathbf{z}^T \rangle_{V',V} = \begin{cases} -\int_{\Sigma_0} v \operatorname{curl} \mathbf{z}\, d\sigma dt & \text{if } N = 2, \\ -\int_{\Sigma_0} \mathbf{v} \cdot \mathbf{curl}\, \mathbf{z}\, d\sigma dt & \text{if } N = 3 \end{cases} \tag{4.11}$$

for each $\mathbf{h} \in L^2(0,T;H)$ and $\mathbf{z}^T \in V$, where $\mathbf{z}$ is the solution of

$$-\mathbf{z}' - \Delta \mathbf{z} + \nabla q = \mathbf{h} \quad \text{in} \quad \Omega \times (0,T), \tag{4.12a}$$
$$\operatorname{div} \mathbf{z} = 0 \quad \text{in} \quad \Omega \times (0,T), \tag{4.12b}$$
$$\mathbf{z} = \mathbf{0} \quad \text{on} \quad \Gamma \times (0,T), \tag{4.12c}$$
$$\mathbf{z}(T) = \mathbf{z}^T \quad \text{on} \quad \Omega. \tag{4.12d}$$

We know [43, Proposition 1.2, p. 267], that problem (4.12) has a unique solution

$$\mathbf{z} \in L^2(0,T;H^2(\Omega)^N \cap V) \text{ and } q \in L^2(0,T;H^1(\Omega)/\mathbb{R}),$$

with continuous dependence with respect to the data. From (4.12a) we also see that $\mathbf{z}' \in L^2(0,T;H)$ hence $\mathbf{z} \in C([0,T];V)$ (see [43, Chapter 1, Proposition 2.1] or [26, Chapter 3, Lemma 1.1]), and then (4.12d) is meaningful.

LEMMA 4.7. *For each $v \in L^2(\Sigma_0)$ when $N = 2$ or $\mathbf{v} \in L^2(\Sigma_0)^3$ verifying (4.5) when $N = 3$, there exists a unique solution $(\mathbf{y}, \mathbf{y}^T)$ of (4.11) – (4.12) in $L^2(0,T;H) \times V'$. Moreover, $\mathbf{y} \in C([0,T];V')$ and $\mathbf{y}(T) = \mathbf{y}^T$ in V'.*

Proof. The hardest part is to show that $\mathbf{y} \in C([0,T];V')$. Let $\mathcal{A}$ be the Stokes operator and let $D(\mathcal{A})$ be its domain,

$$D(\mathcal{A}) = \{\mathbf{v} \in V \text{ such that } \mathcal{A}\mathbf{v} \in H\} = H^2(\Omega)^N \cap V.$$

If $\mathbf{h} \in L^2(0,T;D(\mathcal{A}))$ and $\mathbf{z}^T = \mathbf{0}$, it can be shown that the solution of (4.12) satisfies $\mathbf{z}' \in L^2(0,T;D(\mathcal{A}))$ with a continuous dependence. Note that for each $\mathbf{h} \in \mathcal{D}((0,T);D(\mathcal{A}))$ we have in the sense of distributions

$$\langle \mathbf{y}', \mathbf{h} \rangle = -\langle \mathbf{y}, \mathbf{h}' \rangle = -\int_Q \mathbf{y} \cdot \mathbf{h}' \, dxdt,$$

and then using problem (4.11)–(4.12) with $\mathbf{z}^T = \mathbf{0}$, it follows that

$$|\langle \mathbf{y}', \mathbf{h} \rangle| = \left| \int_Q \mathbf{y} \cdot \mathbf{h}' \, dxdt \right| \leq \|v\|_{L^2(\Sigma_0)} \|\operatorname{curl} \mathbf{z}'\|_{L^2(\Sigma_0)} \leq C \|\mathbf{h}\|_{L^2(0,T;D(\mathcal{A}))},$$

and then by density $\mathbf{y}' \in L^2(0,T;D(\mathcal{A})')$. Since $\mathbf{y} \in L^2(0,T;H)$ we have $\mathbf{y} \in C([0,T];X)$ (see [26]) with

$$X = [H, D(\mathcal{A})']_{\frac{1}{2}} = [D(\mathcal{A}), H]'_{\frac{1}{2}} = V',$$

where $[X_1, X_2]_{\frac{1}{2}}$ denotes the interpolated space between X_1 and X_2 (see [26, Chapter 1, Proposition 2.1]). Once we know that $\mathbf{y} \in C([0,T];V')$ a density argument can be used to prove $\mathbf{y}(T) = \mathbf{y}^T$. Indeed, by taking $\mathbf{z} \in D((0,T);\mathcal{V})$, where $\mathcal{V} = \{\phi \in D(\Omega) \mid \operatorname{div} \phi = 0 \text{ in } \Omega\}$ in (4.11)–(4.12) we obtain the weak solution $\mathbf{y}$ satisfying (4.4a) in the sense of distributions. Then taking a test function $\mathbf{z} \in L^2(0,T;\mathcal{V})$ in this equation and observing that the Green formula

$$\int_0^T \langle \mathbf{y}', \mathbf{z} \rangle_{D(\mathcal{A})', D(\mathcal{A})} \, dt = -\int_0^T \langle \mathbf{y}, \mathbf{z}' \rangle_H \, dt + \langle \mathbf{y}(T), \mathbf{y}^T \rangle_{V',V}$$

is valid, after comparing with (4.11) we obtain that

$$\langle \mathbf{y}(T) - \mathbf{y}^T, \mathbf{z}^T \rangle_{V',V} = 0 \quad \forall \, \mathbf{z}^T \in \mathcal{V},$$

that is, for all $\mathbf{z}^T \in V$ and this implies that $\mathbf{y}(T) = \mathbf{y}^T$ in V'. ∎

LEMMA 4.8. *If v (or $\mathbf{v}$) is a regular function, then problem (4.4) is equivalent to problems (4.11)–(4.12).*

Proof. If we multiply (4.4) by the solution of (4.12) and if we integrate by parts, we obtain

$$\int_Q \mathbf{y} \cdot \mathbf{h} \, dxdt + \int_\Omega \mathbf{y}(T) \cdot \mathbf{z}^T \, dx = -\int_{\Sigma_0} (\nabla \mathbf{z})\nu \cdot \mathbf{y} \, d\sigma dt.$$

But we know that $\mathbf{z}$ satisfies (4.12c), thus it is constant on Γ_0. By using Proposition 4.5, conditions (4.12b), (4.4c), and (4.4d), we infer that on Σ_0

$$(\nabla \mathbf{z})\nu \cdot \mathbf{y} = \begin{cases} \gamma_n((\nabla \mathbf{z})\nu)\gamma_n \mathbf{y} + \gamma_\tau((\nabla \mathbf{z})\nu)\gamma_\tau \mathbf{y} = v \operatorname{curl} \mathbf{z} & \text{if } N = 2, \\ \gamma_n((\nabla \mathbf{z})\nu)\gamma_n \mathbf{y} + \gamma_\tau((\nabla \mathbf{z})\nu) \cdot \gamma_\tau \mathbf{y} = \mathbf{v} \cdot \mathbf{curl}\, \mathbf{z} & \text{if } N = 3. \end{cases}$$

Conversely, in the previous lemma we have proved that the solution of Problems (4.11)–(4.12) satisfies (4.4) except for (4.4d). But this can be easily shown in the regular case by comparison. □

4.5. Spectral decomposition. We want to prove that, under the hypothesis of Theorem 4.3 or Theorem 4.4, the set $\{\mathbf{y}^T\}$ of solutions to problems (4.11)–(4.12) is dense in V' as v (or $\mathbf{v}$) varies in the control set. Given $\mathbf{z}^T \in V$, we suppose that for each $v \in L^2(\Sigma_0)$ if $N = 2$ or $\mathbf{v} \in L^2(\Sigma_0)^3$ verifying (4.5) if $N = 3$, we have

$$\langle \mathbf{y}^T, \mathbf{z}^T \rangle_{V',V} = 0.$$

We will show that $\mathbf{z}^T = 0$. We take $\mathbf{h} = 0$ in Problem (4.11)–(4.12); therefore we have

$$\begin{cases} \int_{\Sigma_0} v \operatorname{curl} \mathbf{z}\, d\sigma dt = 0 & \text{if } N = 2, \\ \int_{\Sigma_0} \mathbf{v} \cdot \mathbf{curl}\, \mathbf{z}\, d\sigma dt = 0 & \text{if } N = 3 \end{cases}$$

for each $v \in L^2(\Sigma_0)$ when $N = 2$ or $\mathbf{v} \in L^2(\Sigma_0)^3$ verifying (4.5) when $N = 3$. Thus we have $\operatorname{curl} \mathbf{z} = 0$ on Σ_0 when $N = 2$. In case $N = 3$, Proposition 4.5 implies that $\mathbf{curl}\, \mathbf{z} \cdot \nu = 0$ on Σ_0 and then we also have $\mathbf{curl}\, \mathbf{z} = \mathbf{0}$ on Σ_0.

After reversing time and changing notations by $\mathbf{z}^0 = \mathbf{z}^T$, we see that in order to prove Theorem 4.3 or Theorem 4.4 we need to show the following unique continuation property: Let $(\mathbf{z}, q)$ be a solution of

$$\mathbf{z}' - \Delta \mathbf{z} + \nabla q = \mathbf{0} \quad \text{in} \quad \Omega \times (0,T), \tag{4.13a}$$

$$\operatorname{div} \mathbf{z} = 0 \quad \text{in} \quad \Omega \times (0,T), \tag{4.13b}$$

$$\mathbf{z} = \mathbf{0} \quad \text{on} \quad \Gamma \times (0,T), \tag{4.13c}$$

$$\mathbf{z}(0) = \mathbf{z}^0 \quad \text{in} \quad \Omega \tag{4.13d}$$

under the condition

$$\begin{cases} \operatorname{curl} \mathbf{z} = 0 & \text{if } N = 2 \\ \mathbf{curl}\, \mathbf{z} = \mathbf{0} & \text{if } N = 3 \end{cases} \quad \text{on} \quad \Sigma_0; \tag{4.14a}$$

then necessarily

$$\mathbf{z} = \mathbf{0} \ \text{ and } \ q = \textit{constant } (ct) \quad \text{in} \quad \Omega \times (0,T).$$

In order to study this property, we use an spectral decomposition method as in [27]. In this way, we first extend the solutions of (4.13) analytically for $t > 0$ and we introduce the spectrum of the Stokes operator ordered as

$$0 < \lambda_1 < \lambda_2 < \cdots \to \infty.$$

For each eigenvalue λ_i, $i \geq 1$, with multiplicity l_i, the associated eigenfunctions are designated by (φ_i^j, π_i^j), $j = 1, \ldots, l_i$, and they form an orthonormal basis. Thus we have

$$-\Delta \varphi_i^j + \nabla \pi_i^j = \lambda_i \varphi_i^j \quad \text{in} \quad \Omega, \tag{4.15a}$$

$$\operatorname{div} \varphi_i^j = 0 \quad \text{in} \quad \Omega, \tag{4.15b}$$

$$\varphi_i^j = \mathbf{0} \quad \text{on} \quad \Gamma. \tag{4.15c}$$

If we decompose $\mathbf{z}^0 = \sum_{i\geq 1}\sum_{j=1,\dots,l_i} a_i^j\varphi_i^j$, the solution of (4.13) can be written as follows: for every $t>0$:

$$\mathbf{z} = \sum_{i\geq 1}\sum_{j=1}^{l_i} a_i^j \exp(-\lambda_i t)\varphi_i^j.$$

Then, from condition (4.14), we have on Γ_0 for each $t>0$

$$\operatorname{curl}\mathbf{z} = 0 = \sum_{i\geq 1}\sum_{j=1}^{l_i} a_i^j \exp(-\lambda_i t)\operatorname{curl}\varphi_i^j.$$

Finally, instead of condition (4.14), from the strictly increasing ordering of the eigenvalues, we have the following condition for every $i\geq 1$:

$$\sum_{j=1}^{l_i} a_i^j \operatorname{curl}\varphi_i^j = 0 \quad \text{on} \quad \Sigma_0.$$

If now, for a fixed $i\geq 1$, we define

$$\varphi = \sum_{j=1}^{l_i} a_i^j\varphi_i^j \quad \text{and} \quad \nabla\pi = \sum_{j=1}^{l_i} a_i^j\nabla\pi_i^j,$$

we deduce that, for proving Theorem 4.3 or Theorem 4.4, we only have to show that the following unique continuation property on each frequency holds.

LEMMA 4.9. *Under the hypothesis of Theorem* 4.3 *or Theorem* 4.4, *if* (φ,π,λ) *is the solution of*

$$-\Delta\varphi + \nabla\pi = \lambda\varphi \quad \textit{in} \quad \Omega, \tag{4.16a}$$

$$\operatorname{div}\varphi = 0 \quad \textit{in} \quad \Omega, \tag{4.16b}$$

$$\varphi = \mathbf{0} \quad \textit{on} \quad \Gamma, \tag{4.16c}$$

with the additional condition that

$$\begin{cases} \operatorname{curl}\varphi = 0 & \textit{if } N=2 \\ \mathbf{curl}\,\varphi = \mathbf{0} & \textit{if } N=3 \end{cases} \quad \textit{on} \quad \Gamma_0, \tag{4.17}$$

then

$$\varphi = \mathbf{0} \quad \textit{and} \quad \pi = ct \quad \textit{in} \quad \Omega. \tag{4.18}$$

4.6. Proof of Lemma 4.9 under the hypothesis of Theorem 4.4. We take $\varphi = \mathbf{curl}\, w$. Then $-\Delta^2 w = \lambda\Delta w$ in Ω, $w=0$ on Γ^1, w constant on Γ^i, $i=2,\dots,K$, and $\frac{\partial w}{\partial\nu}=0$ on $\Gamma=\Gamma^1\cup\cdots\cup\Gamma^K$. From (4.16a) we also see that on Γ

$$\frac{\partial\pi}{\partial\nu} = \frac{\partial(\Delta w+\lambda w)}{\partial\tau} \quad \text{and} \quad \frac{\partial\pi}{\partial\tau} = -\frac{\partial(\Delta w+\lambda w)}{\partial\nu}. \tag{4.19}$$

Thanks to the assumed hypothesis we have $\Delta w = 0$ on Γ; then (4.19) implies that $\frac{\partial\pi}{\partial\nu}=0$ on Γ. Since $\Delta\pi=0$ in Ω then $\pi = ct$ in Ω. Using again (4.19) we obtain that $\frac{\partial\Delta w}{\partial\nu}=0$ on Γ and then

$$w = \frac{\partial w}{\partial\nu} = \Delta w = \frac{\partial\Delta w}{\partial\nu} = 0 \quad \text{on} \quad \Gamma^1,$$

and this implies that $w=0$, then $\varphi=\mathbf{0}$ by Holmgren's uniqueness property. This concludes the proof of Theorem 4.4.

4.7. Proof of Lemma 4.9 under the hypothesis of Theorem 4.3.

4.7.1. Step 1. Two multiplier formulas. In order to prove Lemma 4.9 under the hypothesis of Theorem 4.3, we have to introduce two new multiplier identities for the eigenvalue problem (4.16). We state the results in a more general manner than is required in this paper, since the results have an independent interest. We recall the notation $e : f = e_{ij} f_{ij}$ for e, f tensorial fields.

LEMMA 4.10. *Let (φ, π) and (ϕ, ρ) be solutions to the eigenvalue problem* (4.16) *for the same λ. Then for all $m \in W^{1,\infty}(\overline{\Omega})^N$ we have the following two formulas:*

$$\begin{aligned}(4.20)\quad \int_\Gamma (\nabla\varphi)\nu \cdot (\nabla\phi)\nu \ (m\cdot\nu)\, d\sigma &= \lambda \int_\Omega \varphi\cdot\phi \ \operatorname{div} m\, dx - \int_\Omega \nabla\varphi : \nabla\phi \ \operatorname{div} m\, dx \\ &+ \int_\Omega \nabla\varphi : \nabla\phi(\nabla m + \nabla m^t)\, dx - \int_\Omega \pi\, \nabla\phi : \nabla m^t\, dx - \int_\Omega \rho\, \nabla\varphi : \nabla m^t\, dx,\end{aligned}$$

$$\begin{aligned}(4.21)\quad &\int_\Omega \nabla\pi\cdot(\nabla m)^t\phi\, dx + \int_\Omega \nabla\rho\cdot(\nabla m)^t\varphi\, dx = \lambda\int_\Omega \varphi\cdot(\nabla m + \nabla m^t)\phi\, dx \\ &- \int_\Omega \nabla\varphi : (\nabla m + \nabla m^t)\nabla\phi\, dx + \int_\Omega \nabla\varphi : (\nabla\phi^t\nabla m + \nabla m\nabla\phi^t)\, dx.\end{aligned}$$

Proof. Briefly, we deduce the identities by using the multipliers $(\nabla\phi)m$ and $(\nabla\varphi)m$ in (4.16) in order to obtain (4.20) and the multipliers $(\nabla m)^t\phi$ and $(\nabla m)^t\varphi$ again in (4.16) to deduce (4.21). We now give the details. We multiply the pressure term in (4.16a) by $(\nabla\phi)m$ and we integrate the result by parts in Ω to obtain

$$\begin{aligned}(4.22)\quad \int_\Omega \nabla\pi\cdot(\nabla\phi)m\, dx &= \int_\Omega \frac{\partial\pi}{\partial x_i}\frac{\partial\phi_i}{\partial x_j} m_j\, dx \\ &= -\int_\Omega \pi\frac{\partial^2\phi_i}{\partial x_i\partial x_j} m_j\, dx - \int_\Omega \pi\frac{\partial\phi_i}{\partial x_j}\frac{\partial m_j}{\partial x_i}\, dx + \int_\Gamma \pi\frac{\partial\phi_i}{\partial x_j} m_j\,\nu_i\, d\sigma \\ &= -\int_\Omega \pi\nabla\phi : \nabla m^t\, dx + \int_\Gamma \pi\nu\cdot(\nabla\phi)m\, d\sigma = -\int_\Omega \pi\nabla\phi : \nabla m^t\, dx,\end{aligned}$$

since $\operatorname{div}\phi = 0$ and thanks to index change property (3.1)

$$(4.23)\qquad (\nabla\phi)m = \frac{\partial\phi_i}{\partial x_j} m_j = \frac{\partial\phi_i}{\partial x_j}\,\nu_k\,\nu_k\, m_j = \frac{\partial\phi_i}{\partial x_k}\,\nu_j\,\nu_k\, m_j = (\nabla\phi)\nu\,(m\cdot\nu)$$

and then from Proposition 4.5

$$(\nabla\phi)m\cdot\nu = (\nabla\phi)\nu\cdot\nu\,(m\cdot\nu) = \operatorname{div}\phi\,(m\cdot\nu) = 0.$$

Now, if we multiply the diffusion term in (4.16a) by $(\nabla\phi)m$ we have

$$\begin{aligned}(4.24)\quad \int_\Omega \Delta\varphi\cdot(\nabla\phi)m\, dx &= \int_\Omega \frac{\partial^2\varphi_i}{\partial x_j\partial x_j}\frac{\partial\phi_i}{\partial x_k} m_k\, dx \\ &= -\int_\Omega \frac{\partial\varphi_i}{\partial x_j}\frac{\partial^2\phi_i}{\partial x_k\partial x_j} m_k\, dx - \int_\Omega \frac{\partial\varphi_i}{\partial x_j}\frac{\partial\phi_i}{\partial x_k}\frac{\partial m_k}{\partial x_j}\, dx + \int_\Gamma \frac{\partial\varphi_i}{\partial x_j}\frac{\partial\phi_i}{\partial x_k} m_k\,\nu_j\, d\sigma \\ &= -\int_\Omega \nabla\varphi : (m\cdot\nabla)\nabla\phi\, dx - \int_\Omega \nabla\varphi : \nabla\phi\nabla m\, dx + \int_\Gamma (\nabla\varphi)\nu\cdot(\nabla\phi)m\, d\sigma,\end{aligned}$$

with the notation $(m\cdot\nabla)\nabla\phi \equiv m_k \frac{\partial}{\partial x_k}\nabla\phi$. To sum up, (4.16a) multiplied by $(\nabla\phi)m$ gives

$$\int_\Omega \nabla\varphi : (m\cdot\nabla)\nabla\phi\,dx + \int_\Omega \nabla\varphi : \nabla\phi\nabla m\,dx \tag{4.25}$$
$$-\int_\Gamma (\nabla\varphi)\nu\cdot(\nabla\phi)\nu\,(m\cdot\nu)\,d\sigma - \int_\Omega \pi\nabla\phi : \nabla m^t\,dx = \lambda\int_\Omega \varphi\cdot(\nabla\phi)m\,dx.$$

If we add the identity (4.25) to the same one obtained by interchanging the roles of φ and ϕ we obtain the identity (4.20). We have only to remark that

$$\nabla\phi : \nabla\varphi\nabla m = \nabla\varphi : \nabla\phi\nabla m^t$$

to observe that

$$\int_\Omega \varphi\cdot(\nabla\phi)m\,dx + \int_\Omega (\nabla\varphi)m\cdot\phi\,dx = -\int_\Omega \varphi\cdot\phi\ \operatorname{div} m\,dx,$$
$$\int_\Omega \nabla\varphi : (m\cdot\nabla)\nabla\phi\,dx + \int_\Omega (m\cdot\nabla)\nabla\varphi : \nabla\phi\,dx$$
$$= -\int_\Omega \nabla\varphi : \nabla\phi\ \operatorname{div} m\,dx + \int_\Gamma \nabla\varphi : \nabla\phi\,(m\cdot\nu)\,d\sigma$$

and to transform the last boundary integral by proving the following relation on Γ

$$\nabla\varphi : \nabla\phi = \frac{\partial\varphi_i}{\partial x_j}\frac{\partial\phi_i}{\partial x_j} = \frac{\partial\varphi_i}{\partial x_j}\,\nu_k\,\nu_k\,\frac{\partial\phi_i}{\partial x_j} = \frac{\partial\varphi_i}{\partial x_k}\,\nu_j\,\nu_k\,\frac{\partial\phi_i}{\partial x_j} = (\nabla\varphi)\nu\cdot(\nabla\phi)\nu,$$

valid thanks to the Proposition 3.1.

To prove (4.21), we notice that if we multiply the diffusion term in (4.16a) by $(\nabla m)^t\phi$ and if we integrate by parts, then we obtain

$$\int_\Omega \Delta\varphi\cdot(\nabla m)^t\phi\,dx = \int_\Omega \frac{\partial^2\varphi_i}{\partial x_k\partial x_k}\frac{\partial m_j}{\partial x_i}\phi_j\,dx \tag{4.26}$$
$$= -\int_\Omega \frac{\partial\varphi_i}{\partial x_k}\frac{\partial^2 m_j}{\partial x_k\partial x_i}\phi_j\,dx - \int_\Omega \frac{\partial\varphi_i}{\partial x_k}\frac{\partial m_j}{\partial x_i}\frac{\partial\phi_j}{\partial x_k}\,dx$$
$$= \int_\Omega \frac{\partial^2\varphi_i}{\partial x_k\partial x_i}\frac{\partial m_j}{\partial x_k}\phi_j\,dx + \int_\Omega \frac{\partial\varphi_i}{\partial x_k}\frac{\partial m_j}{\partial x_k}\frac{\partial\phi_j}{\partial x_i}\,dx - \int_\Omega \frac{\partial\varphi_i}{\partial x_k}\frac{\partial m_j}{\partial x_i}\frac{\partial\phi_j}{\partial x_k}\,dx$$
$$= \int_\Omega \nabla\varphi : \nabla\phi^t\nabla m\,dx - \int_\Omega \nabla\varphi : \nabla m^t\nabla\phi\,dx.$$

Therefore, the multiplier $(\nabla m)^t\phi$ in (4.16) gives

$$-\int_\Omega \nabla\varphi : \nabla\phi^t\nabla m\,dx + \int_\Omega \nabla\varphi : \nabla m^t\nabla\phi\,dx$$
$$+\int_\Omega \nabla\pi\cdot(\nabla m)^t\phi\,dx = \lambda\int_\Omega \varphi\cdot(\nabla m)^t\phi\,dx. \tag{4.27}$$

By interchanging the roles of φ and ϕ we obtain an analogous formula to (4.27). If we add up these two formulas, by using that (note the easy rules $F : GH = H : G^tF = G : FH^t$ and that $F : G = F^t : G^t$)

$$\nabla\varphi : \nabla\phi^t\nabla m = \nabla\phi : \nabla m\nabla\varphi^t,$$
$$\nabla\phi : \nabla m^t\nabla\varphi = \nabla\varphi : \nabla m\nabla\phi,$$

we obtain the identity (4.21). □

4.7.2. Step 2. A particular case in the formulas. A particular case of formulas (4.20) and (4.21) in which we are interested is the choice $m = B(x - x^0)$, where B is a constant matrix in $\mathbb{R}^{N\times N}$ and x^0 is a constant vector in $\mathbb{R}^N$.

COROLLARY 4.11. *Let (φ, π) and (ϕ, ρ) be solutions to the eigenvalue problem (4.16) for the same λ. For each matrix $B \in \mathbb{R}^{N\times N}$ and for each $x^0 \in \mathbb{R}^N$ we have*

$$\int_\Gamma (\nabla\varphi)\nu \cdot (\nabla\phi)\nu\,((x - x^0) \cdot B\nu)\,d\sigma = \int_\Omega \nabla\varphi : \nabla\phi(B + B^t)\,dx + \lambda \int_\Omega \varphi \cdot (B + B^t)\phi\,dx - \int_\Omega \nabla\varphi : (B + B^t)\nabla\phi\,dx, \tag{4.28}$$

$$\int_\Omega \pi\nabla\phi : B\,dx + \int_\Omega \rho\nabla\varphi : B\,dx = -\lambda \int_\Omega \varphi \cdot (B + B^t)\phi\,dx + \int_\Omega \nabla\varphi : (B + B^t)\nabla\phi\,dx. \tag{4.29}$$

Proof. We take $m = B(x - x^0)$ in (4.21). Since $\nabla m = B$ and

$$\int_\Omega \nabla\varphi : \nabla\phi^t B\,dx = \int_\Omega \frac{\partial\varphi_i}{\partial x_j}\frac{\partial\phi_k}{\partial x_i}b_{kj}\,dx = -\int_\Omega \frac{\partial\varphi_i}{\partial x_j}\phi_k\frac{\partial b_{kj}}{\partial x_i}\,dx = 0,$$
$$\int_\Omega \nabla\varphi : B\nabla\phi^t\,dx = \int_\Omega \frac{\partial\varphi_i}{\partial x_j}b_{ik}\frac{\partial\phi_j}{\partial x_k}\,dx = -\int_\Omega \varphi_i\frac{\partial b_{ik}}{\partial x_j}\frac{\partial\phi_j}{\partial x_k}\,dx = 0,$$

we directly obtain (4.29), after noticing that

$$\int_\Omega \nabla\pi \cdot B^t\phi\,dx + \int_\Omega \nabla\rho \cdot B^t\varphi\,dx = -\int_\Omega \pi\nabla\phi : B\,dx - \int_\Omega \rho\nabla\varphi : B\,dx. \tag{4.30}$$

On the other hand, if we multiply (4.16a) by ϕ and if we integrate by parts, we obtain

$$\int_\Omega \nabla\varphi : \nabla\phi\,dx = \lambda \int_\Omega \varphi \cdot \phi\,dx. \tag{4.31}$$

By taking $m = B^t(x - x^0)$ in (4.20) and using (4.30) and (4.31) we deduce (4.28). □

Remark 10. There are two cases where formulas (4.28) and (4.29) are simpler. The case $B = B^t$ (skew-symmetric) and the case $B = dI$, $d \in \mathbb{R}$, I the identity matrix in $\mathbb{R}^{N\times N}$. The case $B = I$ in (4.28) was also treated in [36] to study the generic simplicity of the Stokes' spectrum.

Now, we will restrict ourselves to the two and three dimensional cases. First we choose $B = A$ where A is a skew-symmetric matrix of the form

$$A = \begin{pmatrix} 0 & -\alpha \\ \alpha & 0 \end{pmatrix} \text{ if } N = 2 \quad \text{and} \quad A = \begin{pmatrix} 0 & -\alpha_3 & \alpha_2 \\ \alpha_3 & 0 & -\alpha_1 \\ -\alpha_2 & \alpha_1 & 0 \end{pmatrix} \text{ if } N = 3, \tag{4.32}$$

where $\alpha \in \mathbb{R}$ if $N = 2$ or $\alpha \in \mathbb{R}^3$ if $N = 3$.

From (4.29), we obtain the following orthogonality property.

COROLLARY 4.12. *Let* (φ,π) *and* (ϕ,ρ) *be solutions to the eigenvalue problem* (4.16) *for the same* λ. *Then*

$$\int_\Omega \pi \operatorname{curl}\phi\,dx + \int_\Omega \rho\operatorname{curl}\varphi\,dx = 0 \quad \textit{if} \quad N=2, \tag{4.33a}$$

$$\int_\Omega \pi\,\mathbf{curl}\,\phi\,dx + \int_\Omega \rho\,\mathbf{curl}\,\varphi\,dx = \mathbf{0} \quad \textit{if} \quad N=3. \tag{4.33b}$$

Now, we choose $B = dI + A$ in (4.28) with $d \geq 0$, I the identity matrix in $\mathbb{R}^{N\times N}$ and A always a skew-symmetric matrix in the form (4.32). The following result is obtained.

COROLLARY 4.13. *Let* (φ,π) *and* (ϕ,ρ) *solutions of* (4.16) *for the same* λ. *Then for each* $x^0\in\mathbb{R}^N$, $d\geq 0$, *and* $\alpha\in\mathbb{R}$ *if* $N=2$ *or* $\alpha\in\mathbb{R}^3$ *if* $N=3$ *we have*

$$\int_\Gamma \operatorname{curl}\varphi\operatorname{curl}\phi\,(x-x^0)\cdot(d\nu+\alpha\tau)\,d\sigma = 2d\int_\Omega \nabla\varphi:\nabla\phi\,dx \ \textit{if}\ N=2, \tag{4.34a}$$

$$\int_\Gamma \mathbf{curl}\,\varphi\cdot\mathbf{curl}\,\phi\,(x-x^0)\cdot(d\nu+\alpha\times\nu)\,d\sigma = 2d\int_\Omega \nabla\varphi:\nabla\phi\,dx \ \textit{if}\ N=3. \tag{4.34b}$$

4.7.3. Step 3. Splitting the boundary. By taking $\varphi=\phi$ in (4.34), we obtain

$$\int_\Gamma |\operatorname{curl}\varphi|^2\,(x-x^0)\cdot(d\nu+\alpha\tau)\,d\sigma = 2d\int_\Omega |\nabla\varphi|^2\,dx \quad \text{if} \quad N=2, \tag{4.35a}$$

$$\int_\Gamma |\mathbf{curl}\,\varphi|^2\,(x-x^0)\cdot(d\nu+\alpha\times\nu)\,d\sigma = 2d\int_\Omega |\nabla\varphi|^2\,dx \quad \text{if} \quad N=3. \tag{4.35b}$$

Now, we split Γ as follows:

$$\Gamma = \Gamma^+(x^0,d,\alpha)\cup\Gamma^0(x^0,d,\alpha)\cup\Gamma^-(x^0,d,\alpha). \tag{4.36}$$

Since Γ_0 satisfies the geometric condition (4.7a) of Theorem 4.3, then

$$\operatorname{curl}\mathbf{z}=0 \ \text{ or } \ \mathbf{curl}\,\mathbf{z}=\mathbf{0} \quad \text{on} \quad \Gamma^+(x^0,d,\alpha). \tag{4.37}$$

If we consider decomposition (4.36) and condition (4.37) in identity (4.35), it follows that $d\int_\Omega|\nabla\varphi|^2\,dx\leq 0$ and therefore we directly obtain $\varphi=0$ if $d>0$.

The case $d=0$ is more complicated. Using decomposition (4.36) and condition (4.37) in (4.35) with $d=0$ let us deduce only that

$$\operatorname{curl}\mathbf{z}=0 \ \text{ or } \ \mathbf{curl}\,\mathbf{z}=\mathbf{0} \quad \text{on} \quad \Gamma^-(x^0,d,\alpha). \tag{4.38}$$

Nevertheless, thanks to the geometric condition (4.7b) of Theorem 4.3, we obtain that $\operatorname{curl}\mathbf{z}=0$ or $\mathbf{curl}\,\mathbf{z}=\mathbf{0}$ on the whole Γ. Since $\Gamma\supseteq\Gamma^+(\overline{x}^0,1,0)$ for some $\overline{x}^0$ we deduce from the previous case ($d>0$) that $\varphi=0$ in all Ω. This concludes the proof of Theorem 4.3. □

Remark 11. Condition (4.37) implies (4.38) if $d=0$. This justifies Remark 7.

STOCHASTIC LINEAR-QUADRATIC CONTROL VIA SEMIDEFINITE PROGRAMMING*

DAVID D. YAO†, SHUZHONG ZHANG‡, AND XUN YU ZHOU‡

Abstract. We study stochastic linear-quadratic (LQ) optimal control problems over an infinite time horizon, allowing the cost matrices to be indefinite. We develop a systematic approach based on semidefinite programming (SDP). A central issue is the stability of the feedback control; and we show this can be effectively examined through the complementary duality of the SDP. Furthermore, we establish several implication relations among the SDP complementary duality, the (generalized) Riccati equation, and the optimality of the LQ control problem. Based on these relations, we propose a numerical procedure that provides a thorough treatment of the LQ control problem via primal-dual SDP: it identifies a stabilizing feedback control that is optimal or determines that the problem possesses no optimal solution. For the latter case, we develop an ϵ-approximation scheme that is asymptotically optimal.

Key words. stochastic LQ control, semidefinite programming, complementary duality, mean-square stability, generalized Riccati equation

1. Introduction.

Consider the following stochastic linear-quadratic (LQ) optimal control problem:

$$\text{(LQ)} \qquad \min \quad J(x_0, u(\cdot)) := \mathsf{E}\int_0^{+\infty} [x(t)^T Q x(t) + u(t)^T R u(t)]dt \tag{1.1}$$

$$\text{s.t. (subject to)} \quad dx(t) = [Ax(t) + Bu(t)]dt + [Cx(t) + Du(t)]dW(t) \tag{1.2}$$
$$x(0) = x_0 \in \Re^n.$$

Here and throughout the paper, A, B, C, D and Q, R are constant matrices, with Q and R being symmetric matrices; the superscript T denotes the transpose of matrices and vectors; $W(\cdot)$ is a one-dimensional standard Brownian motion (with $t \in [0, +\infty)$ and $W(0) = 0$), defined on a filtered probability space $(\Omega, \mathcal{F}, \mathcal{F}_t, P)$; and $u(\cdot)$ denotes the (open-loop) control, which belongs to $L^2_{\mathcal{F}}(\Re^m)$, the space of all $\Re^m$-valued, $\mathcal{F}_t$-adapted measurable processes satisfying

$$\mathsf{E}\int_0^{+\infty} \|u(t)\|^2 dt < +\infty.$$

Note that allowing multidimensional Brownian motion will render no additional difficulty to the results below. Also note that the dynamics in (1.2) involve multiplicative

noise in both the state and the control. A motivating application is given below in section 2.1, where the control of a portfolio affects not only the average return of the portfolio but also its volatility.

Studies on LQ control problems have a long history that can be traced back to the pioneering works of Kalman [12] and Wonham [22] (also refer to [5, 6, 9] and the references therein). A primary tool in solving LQ control problems is the following (stochastic algebraic) Riccati equation, with the symmetric matrix P being the unknown:

$$A^TP+PA+Q+C^TPC-(PB+C^TPD)(R+D^TPD)^{-1}(B^TP+D^TPC)=0. \tag{1.3}$$

Suppose P^* is a solution to the above equation with $R+D^TP^*D \succ 0$ (positive definite). Then, following the classical LQ theory, we know that

$$u^*(t)=-(R+D^TP^*D)^{-1}(B^TP^*+D^TP^*C)x^*(t), \tag{1.4}$$

assuming that it is mean-square stabilizing, is an optimal state feedback control for (LQ).

The limitation of the classical theory, however, lies in the difficulty involved in solving the Riccati equation (1.3), in particular since the matrix inverse term also involves the unknown P. In fact, there is no guarantee for $R+D^TP^*D \succ 0$, except when $Q \succeq 0$ (positive semidefinite) and $R \succ 0$, in which case $P^* \succeq 0$ follows as a solution to (1.3); see [1, Corollary 5.1].

In the deterministic case, $R \succeq 0$ is in fact necessary for the LQ problem to be well-posed (cf. [25, Chapter 6, Proposition 2.4]), whereas the Riccati approach further requires the nonsingularity of R. The positive definiteness of R has been a starting point of most of the stochastic LQ literature; see [5, 6, 9, 22] and the references therein. Recent studies (e.g., [8]) have, however, made a case for studying LQ problems in which R is singular or even indefinite in the stochastic case, with relevant applications ranging from portfolio selection to pollution control [8, 13, 26]. In particular, a singular or indefinite R may naturally arise in a class of problems in which the control affects the diffusion part of the system dynamics (i.e., $D \neq 0$ in (1.2)).

A traditional method for solving the Riccati equation (in the case of $D=0$) is to consider the so-called associated Hamiltonian matrix [7]. In this case it is known that the Riccati equation has a solution if and only if the associated Hamiltonian matrix admits no pure imaginary eigenvalues, a condition that can be verified using a Routh–Hurwitz-type test on a set of polynomial inequalities involving the given matrices. If the associated Hamiltonian matrix passes this test, then the solution to the Riccati equation can be constructed using the eigenvectors of the associated Hamiltonian matrix. This procedure, however, does not apply when R is indefinite, as the matrix inverse in (1.3), and hence the Riccati equation and the associated Hamiltonian matrix themselves, may not be well defined.

To overcome this difficulty, our idea here is to use semidefinite programming (SDP) as a unifying approach to solve the stochastic LQ control problem, generally in the absence of the positive definiteness/semidefiniteness of the cost matrices R and Q. SDP is a newly developed tool in optimization (see [16, 3]). It relates intimately to the so-called linear matrix inequalities (LMI) (see [23]). Pioneered by Yakubovich [24] and Willems [21], a vast literature has since appeared, applying the LMI approach to both deterministic and stochastic systems; refer to [7] for a systematic exposition and detailed literature review. However, the definiteness of R has remained a predominant

assumption in the research literature. In a recent work, [1], the relationship between the Riccati equation in (1.3) and the associated LMI has been examined under the assumption that $R + D^T P D \succ 0$ for some solution P of the Riccati equation (while R itself is allowed to be indefinite). This assumption, however, is hard to verify a priori as P is unknown; and even when this assumption is not satisfied, the corresponding LQ problem may still possess a meaningful optimal control; see Example 6.1 below.

In contrast, our focus here is to develop a direct connection between the LQ control problem and the duality theory of SDP. In particular, we demonstrate that to extend beyond the confines of the classical LQ theory (with positive definite cost matrices) the central issue is *stability*; and stability is intimately related to the *complementary duality* of the SDP associated with the LQ problem. We establish several equivalence relations between the stability/optimality of the LQ problem and the duality of the SDP, and demonstrate that a new class of optimal controls can be constructed based on the dual SDP. Furthermore, exploiting the primal-dual structure of the SDP also leads to powerful and efficient computational means, based on the newly developed primal-dual interior-point technologies (refer to, e.g., [18]), to solving the LQ problem. In short, while the LMI approach is a primal-only method, our primal-dual SDP approach applies to a more general class of problems, generates new theoretical results, and leads to practical computational algorithms.

Briefly, the rest of the paper is organized as follows. In section 2, we start with an application example that motivates the general LQ problem formulated above, introduce several regularity conditions relating to stability, and present the preliminaries of SDP. The main results of the paper are presented in the next two sections: We establish first in section 3, the connection between stability and the dual SDP; and then in section 4, we establish several implication relations among the optimality of LQ control problem, the complementary duality of the SDP, and a generalized version of the Riccati equation (1.3) involving a matrix pseudoinverse. A synthesis of these results is presented in section 5, along with a computational procedure that provides a systematic treatment of the LQ control problem via SDP. Several examples are collected in section 6 to illustrate some of the key technical issues involved in the SDP approach. For problems that do not possess an attainable optimal control, an ϵ-approximation scheme is developed in section 7, which achieves asymptotic optimality. Brief concluding remarks are summarized in section 8.

2. Preliminaries.

2.1. An application example. To motivate the general LQ problem formulated in the last section, consider a market where there is one bond and one stock, with price dynamics governed, respectively, by

$$dP_0(t) = rP_0(t)dt, \quad P_0(0) = p_0,$$

and

$$dP_1(t) = P_1(t)\big[bdt + \sigma dW(t)\big], \quad P_1(0) = p_1,$$

where $W(\cdot)$ denotes the one-dimensional standard Brownian motion. Suppose an agent, with an initial endowment z_0, wants to track a (stochastic) wealth trajectory (e.g., that of an index fund) $I(t)$ determined by the following equation:

$$dI(t) = I(t)[b_I dt + \sigma_I(t)dW(t)], \quad I(0) = i_0.$$

At any time $t \geq 0$ the total wealth of the agent is denoted by $z(t)$, of which the market value of the stock is denoted by $\pi(t)$. If we assume that the stock is traded continuously, and that there is no transaction cost, dividend payment, and withdrawal for consumption, then $z(t)$ must satisfy the following (see, e.g., [25, Chapter 2, section 3.2]):

$$dz(t) = [rz(t) + (b-r)\pi(t)]dt + \sigma\pi(t)dW(t), \quad z(0) = z_0.$$

The objective of the agent is to choose $\pi(\cdot)$ so as to minimize the following objective:

$$J(z(0), \pi(\cdot)) = \mathsf{E}\int_0^{+\infty} e^{-\rho t}|z(t) - I(t)|^2 dt,$$

where ρ is the discount rate.

To transform the above into the formulation in (1.1) and (1.2), define the state and control variables as follows:

$$(x(t), y(t)) = e^{-\frac{1}{2}\rho t}(z(t), I(t)), \qquad u(t) = e^{-\frac{1}{2}\rho t}\pi(t).$$

Then, the state dynamics become

$$\begin{aligned} dx(t) &= \left[\left(r - \frac{1}{2}\rho\right)x(t) + (b-r)u(t)\right]dt + \sigma u(t)dW(t), \quad x(0) = z_0, \\ dy(t) &= \left(b_I - \frac{1}{2}\rho\right)y(t) + \sigma_I y(t)dW(t), \quad y(0) = i_0, \end{aligned}$$

and the objective function can be rewritten as follows:

$$\begin{aligned} J(x(0), y(0), u(\cdot)) &= \mathsf{E}\int_0^{+\infty} |x(t) - y(t)|^2 dt \\ &= \mathsf{E}\int_0^{+\infty} \begin{bmatrix} x(t), & y(t) \end{bmatrix} \begin{bmatrix} 1, & -1 \\ -1, & 1 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix} dt. \end{aligned}$$

This way, we are in the framework of (1.1) and (1.2), with the control cost $R \equiv 0$, and the state cost $Q = \begin{bmatrix} 1, & -1 \\ -1, & 1 \end{bmatrix}$ being singular.

2.2. Regularity conditions.

DEFINITION 2.1.

(i) *An open-loop control $u(\cdot)$ is called (mean-square) stabilizing at x_0, if the corresponding state $x(\cdot)$ of (1.2) with the initial state x_0 satisfies* $\lim_{t\to+\infty} \mathsf{E}[x(t)^T x(t)] = 0$.

(ii) *A feedback control $u(t) = Kx(t)$, where K is a constant matrix, is called stabilizing if for every initial state x_0, the solution to the equation*

$$\begin{cases} dx(t) = (A + BK)x(t)dt + (C + DK)x(t)dW(t), \\ x(0) = x_0, \end{cases}$$

satisfies $\lim_{t\to+\infty} \mathsf{E}[x(t)^T x(t)] = 0$.

(iii) *The system in (1.2) is called (mean-square) stabilizable if there exists a stabilizing feedback control of the form $u(t) = Kx(t)$ where K is a constant matrix.*

DEFINITION 2.2.

(i) *An open-loop control* $u(\cdot) \in L^2_{\mathcal{F}}(\Re^m)$ *is called admissible (at* x_0*) if it is stabilizing at* x_0*. The set of all admissible controls at* x_0 *is denoted as* $U_{ad}^{x_0}$*.*

(ii) *An admissible pair* $(x^*(\cdot), u^*(\cdot))$ *is called* optimal *(at* x_0*) if* $u^*(\cdot)$ *achieves the infimum of* $J(x_0, u(\cdot))$ *over* $u(\cdot) \in U_{ad}^{x_0}$*.*

(iii) *The control problem* (LQ) *is called well-posed (at* x_0*) if*

$$-\infty < \inf_{u(\cdot)\in U_{ad}^{x_0}} J(x_0, u(\cdot)) < +\infty;$$

(LQ) *is called attainable (at* x_0*) if it is well-posed (at* x_0*) and there exists an optimal admissible control.*

Unless explicitly stated otherwise, we shall assume throughout the paper that the system under consideration, (1.2), is mean-square stabilizable. Note that this is a very mild regularity condition; in particular, it is implied by the well-posedness of (LQ) when $Q \succ 0$ and $R \succeq 0$. Indeed, the well-posedness of (LQ) yields that there is at least one control whose cost is finite. As a result, under that control, $\lim_{t\to+\infty} \mathsf{E}[x(t)^T Q x(t)] = 0$. Thus the control must be stabilizing due to the nonsingularity of Q.

On the other hand, to appreciate why the admissible controls have to be stabilizing, consider the case when $Q \succ 0$ and $R \succeq 0$. In order for the cost objective in (1.1) to be finite it is necessary (as shown above) that the corresponding control must be stabilizing. In general, a nonstabilizing control is ill behaved and hence should be excluded.

Attainability of an optimal admissible control is another issue, even when the problem is well-posed. Consider the following simple (deterministic) LQ problem:

$$\begin{array}{ll} \min & \displaystyle\int_0^\infty x(t)^2 dt \\ \text{s.t.} & dx(t) = [-x(t) + u(t)]dt, \\ & x(0) = 1. \end{array}$$

Clearly, this problem has an infimum value zero. However, there is no control that attains the zero cost. In general, deciding whether or not a problem has an attainable optimal control is as hard as solving the (LQ) problem, especially for large problems.

2.3. Semidefinite programming. SDP is a special form of the so-called *conic optimization problem*, which is in essence to optimize a linear function over the intersection of two closed convex sets: one being an affine subspace and the other a cone. In SDP, the cone is formed by positive semidefinite matrices in the linear space of symmetric matrices. Similar to linear programming, an SDP problem can be cast in various ways. In standard form, an SDP is the following convex optimization problem:

$$\begin{array}{lll} (SDP)_p & \min & \langle C, X\rangle \\ & \text{s.t.} & \langle A_i, X\rangle = b_i \text{ for } i = 1, \ldots, m, \\ & & X \succeq 0, \end{array}$$

where C and A_i are $n \times n$ symmetric matrices, $b_i \in \Re^m$ is a vector, $i = 1, \ldots, m$, and $\langle X, Y\rangle := \sum_{i,j} X_{ij} Y_{ij}$ denotes the matrix inner-product.

The above has an associated dual, which is also an SDP problem:

$$\begin{array}{lll} (SDP)_d & \max & b^T y \\ & \text{s.t.} & \sum_{i=1}^m y_i A_i + Z = C, \\ & & Z \succeq 0. \end{array}$$

A conic optimization problem is said to satisfy the *Slater condition* if its feasible region has a nonempty intersection with the interior of the cone. In our standard primal-dual SDP problems stated above, the Slater condition has the following characterization. For the primal problem $(SDP)_p$, the Slater condition is equivalent to the existence of a primal feasible solution X^0 such that $X^0 \succ 0$. Similarly, for the dual problem $(SDP)_d$, the Slater condition is the existence of a dual feasible solution (y^0, Z^0) with $Z^0 \succ 0$.

For conic optimization problems, a well-developed duality theory exists; see e.g., [23, 14, 16]. Key points of the theory can be highlighted as follows:

- The *weak duality* always holds, i.e., any feasible solution to the primal (minimization) problem always possesses an objective value that is no less than the (dual) objective value of any dual feasible solution (the dual being a maximization problem).
- In contrast, the *strong duality*—that the optimal values of the primal and dual problems coincide—holds if there exists a pair of *complementary optimal solutions* X^* and (y^*, Z^*), namely, they satisfy $X^*Z^* = 0$. If, furthermore, it holds that $X^* + Z^* \succ 0$, then this pair of optimal solutions is called *strictly complementary*.
- Unlike linear programming, SDP may fail to satisfy the strong duality, let alone strict complementarity. It is known, however, that if the primal problem is feasible and the dual satisfies the Slater condition, then the primal problem must have a nonempty and compact optimal solution set. Moreover, if both the primal and the dual satisfy the Slater condition, then both must have nonempty and compact optimal solution sets, and the strong duality holds.

In the SDP literature, the Slater type regularity conditions are mostly assumed in order to avoid pathological cases. In Luo, Sturm, and Zhang [14, 15], extensive analysis can be found addressing the issue of regularity in the context of duality theory, and the related issue of how to detect the duality status numerically.

The linkage between the LQ control problem and the SDP is best understood in the deterministic setting. Consider the deterministic version of (LQ) as follows:

$$\begin{aligned} \min & \int_0^\infty [x(t)^T Q x(t) + u(t)^T R u(t)] dt \\ \text{s.t. } & \dot{x}(t) = Ax(t) + Bu(t), \\ & x(0) = x_0 \in \Re^n. \end{aligned}$$

Assume $Q \succeq 0$ and $R \succ 0$. Then, the optimal solution to the above problem is

$$u^*(t) = -R^{-1}B^T P^* x^*(t),$$

where P^* is a nonnegative definite solution to the Riccati equation

$$Q + A^T P + PA - PBR^{-1}B^T P = 0.$$

It turns out that solutions to the Riccati equation can be found through solving the following SDP:

$$\begin{aligned} \max & \langle I, P \rangle \\ \text{s.t. } & \begin{bmatrix} R, & B^T P \\ PB, & Q + A^T P + PA \end{bmatrix} \succeq 0, \\ & P \in \mathcal{S}^{n \times n}, \end{aligned}$$

where $\mathcal{S}^{n\times n}$ denotes the space of n by n symmetric matrices. Note that the above is an SDP problem because the constraint set can be viewed as an intersection between a linear subspace and the cone of positive semidefinite matrices. The dual problem is

$$\begin{aligned}&\min \langle R, Z_b\rangle + \langle Q, Z_n\rangle\\ &\text{s.t. } I + Z_u^T B^T + BZ_u + Z_n A^T + AZ_n = 0,\\ &\qquad Z := \begin{bmatrix} Z_b, & Z_u \\ Z_u^T, & Z_n \end{bmatrix} \succeq 0.\end{aligned}$$

It is interesting to note that both the primal and dual SDPs above are well defined even in the presence of the singularity of R and Q. In particular, there is no matrix inverse involved. Similarly, the primal and dual SDPs for the stochastic problem in (LQ) can be written as follows:

$$\begin{aligned}\text{(P)}\quad &\max \langle I, P\rangle\\ &\text{s.t.}\quad \mathcal{L}(P) \succeq 0,\\ &\qquad P \in \mathcal{S}^{n\times n},\end{aligned}$$

where

$$\mathcal{L}(P) := \begin{bmatrix} R + D^T PD, & B^T P + D^T PC \\ PB + C^T PD, & Q + C^T PC + A^T P + PA \end{bmatrix}; \tag{2.1}$$

and

$$\begin{aligned}\text{(D)}\quad &\min \langle R, Z_B\rangle + \langle Q, Z_N\rangle\\ &\text{s.t.}\quad I + Z_U^T B^T + BZ_U + Z_N A^T + AZ_N\\ &\qquad +CZ_N C^T + DZ_U C^T + CZ_U^T D^T + DZ_B D^T = 0,\\ &\qquad Z := \begin{bmatrix} Z_B, & Z_U \\ Z_U^T, & Z_N \end{bmatrix} \succeq 0.\end{aligned}$$

In the above forms, (P) and (D) are said to satisfy the Slater condition, if there exist primal and dual feasible solutions, P^0 and Z^0, such that $\mathcal{L}(P^0) \succ 0$ and $Z^0 \succ 0$, respectively. On the other hand, a primal optimal solution P^* and a dual optimal solution Z^* are called complementary optimal solutions if $\mathcal{L}(P^*)Z^* = 0$. Furthermore, they are called strictly complementary if $\mathcal{L}(P^*) + Z^* \succ 0$.

As a least condition in order to apply the SDP approach, we assume throughout the paper that the feasible set of (P) is nonempty. This assumption is satisfied automatically if the Riccati equation (1.3) has a solution P^* with $R + D^T P^* D \succ 0$ (which is the key assumption in [1]) by virtue of the well-known Schur lemma. It is also satisfied when $Q \succeq 0$ and $R \succeq 0$. Therefore, without this assumption, the original LQ problem cannot be solved by either the Riccati or the SDP approach.

3. Stability. Since we require admissible controls to be stabilizing, we need first to address the issue of stability, which, as it will become evident below, relates closely to the dual SDP.

The following results from [1, Theorems 2.1, 5.2] will be used later.

PROPOSITION 3.1. *The following conditions are equivalent.*

(i) *System* (1.2) *is mean-square stabilizable.*

(ii) *Problem (D) satisfies the Slater condition.*

(iii) *There exists a matrix K and a symmetric matrix Y such that*

$$(A+BK)Y+Y(A+BK)^T+(C+DK)Y(C+DK)^T \prec 0, Y \succ 0. \tag{3.1}$$

In this case the feedback $u(t)=Kx(t)$ is a stabilizing control.

(iv) *There exists a matrix K such that for any X there exists a unique solution Y to the following equation:*

$$(A+BK)Y+Y(A+BK)^T+(C+DK)Y(C+DK)^T+X=0. \tag{3.2}$$

Moreover, if $X \succ 0$ (resp., $X \succeq 0$) then $Y \succ 0$ (resp., $Y \succeq 0$). Furthermore, in this case the feedback $u(t)=Kx(t)$ is a stabilizing control.

(v) *There exist a matrix X and a positive definite matrix $Y \succ 0$ such that*

$$\begin{bmatrix} AY+YA^T+BX+X^TB^T & CY+DX \\ YC^T+X^TD^T & -Y \end{bmatrix} \prec 0. \tag{3.3}$$

In this case, the feedback $u(t)=XY^{-1}x(t)$ is a stabilizing control.

Note that the last equivalent condition above is an LMI condition, based on which the mean-square stabilizability can be verified numerically (cf. [7, 10]). Moreover, to check whether or not a given feedback control $u(t)=Kx(t)$ is stabilizing, it suffices to check if the LMIs in (3.1) have a feasible solution, which again can be carried out numerically.

Define

$$F(P) := A^TP+PA+Q+C^TPC-(PB+C^TPD)(R+D^TPD)^+(B^TP+D^TPC). \tag{3.4}$$

Here, M^+ stands for the pseudoinverse of a matrix M (refer to [17]). Note that when M is a positive semidefinite matrix, M^+ satisfies the following properties:

$$M^+ \succeq 0, \quad (M^+)^T = M^+, \quad M^+M = MM^+;$$

$$MM^+M = M, \qquad M^+MM^+ = M^+.$$

Clearly, the equation $F(P)=0$ generalizes the classical Riccati equation (1.3). Hence, we shall refer to it below as the *generalized Riccati equation.*

The following extended Schur's lemma [2] plays an important technical role.

LEMMA 3.2. *Let matrices $M=M^T, N$ and $S=S^T$ be given with appropriate dimensions. Then the following three conditions are equivalent:*

(i) $M-NS^+N^T \succeq 0$, $S \succeq 0$, *and* $N(I-SS^+)=0$.

(ii) $\begin{bmatrix} M & N \\ N^T & S \end{bmatrix} \succeq 0$.

(iii) $\begin{bmatrix} S & N^T \\ N & M \end{bmatrix} \succeq 0$.

THEOREM 3.3. *If a feasible solution of* (P), *P^*, is such that $F(P^*)=0$, and the feedback control*

$$u(t) = -(R+D^TP^*D)^+(B^TP^*+D^TP^*C)x(t) \tag{3.5}$$

is stabilizing, then there exist complementary optimal solutions of (P) *and* (D). *In particular, P^* is optimal to* (P); *and there exists a complementary dual optimal solution Z^*, such that $Z_N^* \succ 0$.*

Proof. Denote $K := -(R + D^T P^* D)^+ (B^T P^* + D^T P^* C)$. By the stability assumption of the control (3.5) and Proposition 3.1(iv), the equation

$$(A + BK)Y + Y(A + BK)^T + (C + DK)Y(C + DK)^T + I = 0$$

has a positive solution. Let it be $Y^* \succ 0$. Furthermore, let

$$Z_N^* = Y^*,\ Z_U^* = KZ_N^*, \text{ and } Z_B^* = K(Z_U^*)^T. \tag{3.6}$$

By this construction, we can easily verify that

$$\begin{bmatrix} Z_B^*, & Z_U^* \\ (Z_U^*)^T, & Z_N^* \end{bmatrix} = \begin{bmatrix} I, & K \\ 0, & I \end{bmatrix} \begin{bmatrix} 0, & 0 \\ 0, & Z_N^* \end{bmatrix} \begin{bmatrix} I, & 0 \\ K^T, & I \end{bmatrix} \succeq 0.$$

Moreover, by direct verification, we know

$$I + (Z_U^*)^T B^T + BZ_U^* + Z_N^* A^T + AZ_N^* + CZ_N C^T + DZ_U^* C^T + C(Z_U^*)^T D^T + DZ_B^* D^T = 0.$$

Therefore, Z^* is a feasible solution of (D). Moreover, using extended Schur's lemma (Lemma 3.2), we have

$$\begin{aligned}
&\mathcal{L}(P^*) \begin{bmatrix} Z_B^*, & Z_U^* \\ (Z_U^*)^T, & Z_N^* \end{bmatrix} \\
&= \begin{bmatrix} I, & 0 \\ -K^T, & I \end{bmatrix} \begin{bmatrix} R + D^T P^* D, & 0 \\ 0, & F(P^*) \end{bmatrix} \begin{bmatrix} I, & -K \\ 0, & I \end{bmatrix} \begin{bmatrix} Z_B^*, & Z_U^* \\ (Z_U^*)^T, & Z_N^* \end{bmatrix} \\
&= \begin{bmatrix} I, & 0 \\ -K^T, & I \end{bmatrix} \begin{bmatrix} (R + D^T P^* D)(Z_B^* - K(Z_U^*)^T), & R(Z_U^* - KZ_N^*) \\ F(P^*)(Z_U^*)^T, & F(P^*)Z_N^* \end{bmatrix} \\
&= \begin{bmatrix} 0, & 0 \\ 0, & 0 \end{bmatrix},
\end{aligned}$$

where in the first equation the decomposition of $\mathcal{L}(P^*)$ into the product of three matrices (the Schur decomposition) is possible because $\mathcal{L}(P^*) \succeq 0$, since P^* is a feasible solution to (P); hence, Lemma 3.2 can be invoked.

Therefore, the above establishes that P^* and Z^* are complementary solutions; in particular, P^* is optimal to (P), and Z^* is optimal to (D). The last statement of the theorem follows from the fact that $Z_N^* = Y^* \succ 0$. □

Note that the assumption in the above theorem, that the control in (3.5) is stabilizing, is not automatically satisfied even in the case when $R + D^T P^* D \succ 0$; see Example 6.2. The following result shows, however, that we can possibly obtain a stabilizing feedback control via the *dual* SDP.

THEOREM 3.4. *Let* $Z = \begin{bmatrix} Z_B, & Z_U \\ Z_U^T, & Z_N \end{bmatrix}$ *be a feasible solution of* (D) *with* $Z_N \succ 0$, *then the feedback control* $u(t) = Z_U Z_N^{-1} x(t)$ *is stabilizing.*

Proof. First of all, by feasibility of Z to (D) along with Schur's lemma we have

$$Z_B \succeq Z_U Z_N^{-1} Z_U^T.$$

Then,

$$\begin{aligned}
0 = \ & I + Z_U^T B^T + BZ_U + Z_N A^T + AZ_N + CZ_N C^T + DZ_U C^T + CZ_U^T D^T + DZ_B D^T \\
\succeq \ & I + Z_U^T B^T + BZ_U + Z_N A^T + AZ_N + CZ_N C^T \\
+ \ & DZ_U C^T + CZ_U^T D^T + DZ_U Z_N^{-1} Z_U^T D^T \\
\succ \ & Z_U^T B^T + BZ_U + Z_N A^T + AZ_N + (CZ_N + DZ_U) Z_N^{-1} (Z_N C^T + Z_U^T D^T).
\end{aligned}$$

Applying Schur's lemma again, we conclude that Proposition 3.1(v) holds with $X = Z_U$ and $Y = Z_N \succ 0$. Hence $u(t) = Z_U Z_N^{-1} x(t)$ is stabilizing. □

4. Optimality. Here we establish the relationship among the optimality of the original LQ problem, the primal/dual SDP problems, and the generalized Riccati equation.

THEOREM 4.1. *If* (LQ) *is attainable at any* $x_0 \in \Re^n$, *then* (P) *must have an optimal solution* P^* *satisfying* $F(P^*) = 0$.

Proof. First, note that since (LQ) has a finite optimal value with respect to any initial value, it must have a quadratic representation

$$\inf_{u(\cdot)\in U_{ad}^{x_0}} J(x_0, u(\cdot)) = x_0^T M x_0 \ \ \forall x_0 \in \Re^n;$$

see [4, p. 21]. (Note that the proof there, which is for the deterministic case, readily extends to the stochastic case.)

Suppose for the time being that the matrix M is a feasible solution of (P), the validity of which will be proved later. Let $u^*(\cdot)$ be the optimal control and $x^*(\cdot)$ be the corresponding state from the initial x_0. Then for any feasible solution P of (P), applying Itô's formula (see, e.g., [25, p. 36]) yields

$$\begin{aligned}
&d(x^*(t)^T P x^*(t)) \\
&= \Big[(Ax^*(t) + Bu^*(t))^T P x^*(t) + x^*(t)^T P(Ax^*(t) + Bu^*(t)) \\
&\quad +(Cx^*(t) + Du^*(t))^T P(Cx^*(t) + Du^*(t))\Big] dt + \{\ldots\} dW(t) \\
&= \big[x^*(t)^T (A^T P + PA + C^T PC) x^*(t) \\
&\quad +2u^*(t)^T (B^T P + D^T PC) x^*(t) + u^*(t)^T D^T PD u^*(t)\ \big] dt \\
&\quad +\{\ldots\} dW(t).
\end{aligned}$$

If we integrate the above over $[0, \infty)$, take expectations, and use that $\mathsf{E}[x^*(t)^T P x^*(t)] \to 0$ (as $u^*(\cdot)$ is stabilizing), we obtain

$$\begin{aligned}
0 = \quad & x_0^T P x_0 + \mathsf{E} \int_0^\infty [x^*(t)^T (A^T P + PA + C^T PC) x^*(t) \\
& +2u^*(t)^T (B^T P + D^T PC) x^*(t) \\
& +u^*(t)^T D^T PD u^*(t)] dt.
\end{aligned} \tag{4.1}$$

Completion of square yields

$$\begin{aligned}
&J(x_0, u^*(\cdot)) \\
&= \mathsf{E} \int_0^\infty [x^*(t)^T Q x^*(t) + u^*(t)^T R u^*(t)] dt \\
&= x_0^T P x_0 + \\
&\mathsf{E} \int_0^\infty \left\{ [u^*(t) - Kx^*(t)]^T (R + D^T PD)[u^*(t) - Kx^*(t)] + x^*(t)^T F(P) x^*(t) \right\} dt,
\end{aligned} \tag{4.2}$$

where $K := -(R + D^T PD)^+ (B^T P + D^T PC)$. Since P is feasible to (P), we have $R + D^T PD \succeq 0$ and $F(P) \succeq 0$ by extended Schur's lemma. This means that

$$x_0^T M x_0 \equiv J(x_0, u^*(\cdot)) \geq x_0^T P x_0 \tag{4.3}$$

for any P feasible to (P). Hence M must be optimal to (P). On the other hand, taking $P = M$ in (4.2) and noting $J(x_0, u^*(\cdot)) = x_0^T M x_0$, we conclude that $x(t)^T F(M) x(t) =$

0 for all $t \in [0, \infty)$. Since x_0 can be chosen arbitrarily it follows that $F(M) = 0$. The desired result thus follows.

What remains is to show the primal feasibility of M. To this end we consider a perturbation on the problem (LQ). That is, we keep all the data A, B, C, and D unchanged, and let $R_\epsilon = R + \epsilon I$ and $Q_\epsilon = Q + \epsilon I$ where $\epsilon > 0$ is a small positive number.

Under the perturbation ($\epsilon > 0$), the corresponding SDPs,

$$\begin{aligned}(P_\epsilon)\quad & \max \langle I, P\rangle \\ & \text{s.t.} \begin{bmatrix} R+\epsilon I + D^T P D, & B^T P + D^T P C \\ PB + C^T P D, & Q + \epsilon I + C^T P C + A^T P + PA \end{bmatrix} \succeq 0, \\ & P \in \mathcal{S}^{n\times n},\end{aligned}$$

and

$$\begin{aligned}(D_\epsilon)\quad & \min \langle R+\epsilon I, Z_B\rangle + \langle Q + \epsilon I, Z_N\rangle \\ & \text{s.t. } I + Z_U^T B^T + B Z_U + Z_N A^T + A Z_N \\ & \qquad + C Z_N C^T + D Z_U C^T + C Z_U^T D^T + D Z_B D^T = 0, \\ & \begin{bmatrix} Z_B, & Z_U \\ Z_U^T, & Z_N \end{bmatrix} \succeq 0,\end{aligned}$$

both satisfy the Slater condition (the former does because the feasible set of (P) is assumed to be nonempty, and the latter because of the mean-square stabilizability assumption and Proposition 3.1(ii)), and therefore complementary optimal solutions exist [23]. Observe that the feasible set of (D_ϵ) is independent of ϵ. Take any dual feasible solution Z^0. By weak duality, we have

$$\text{tr } P = \langle I, P\rangle \le \langle R + \epsilon I, Z_B^0\rangle + \langle Q + \epsilon I, Z_N^0\rangle. \tag{4.4}$$

Let $\hat{P}$ be a feasible solution of (P), which exists by our assumption. Certainly, $\hat{P}$ is feasible to (P_ϵ) for all $\epsilon \ge 0$. Theorem 5.5 in [1] asserts that for $\epsilon > 0$, the unique optimal solution for (P_ϵ), denoted by P_ϵ^*, dominates any other feasible solutions. Hence, $\hat{P} \preceq P_\epsilon^*$ for all $\epsilon > 0$.

This, together with (4.4), implies in particular that P_ϵ^* are contained in a compact set, with $0 \le \epsilon \le \epsilon_0$ ($\epsilon_0 > 0$ is a predetermined constant.) Now, take a convergent subsequence such that

$$\lim_{i\to\infty} P_{\epsilon_i}^* = P_0^*$$

with $\epsilon_i \to 0$ as $i \to \infty$.

Clearly, P_0^* is a feasible solution of (P) since the feasible region of (P_ϵ) monotonically shrinks as $\epsilon \downarrow 0$. We now show that $P_0^* = M$. Define the perturbed cost function

$$J_\epsilon(x_0, u(\cdot)) = \mathsf{E}\int_0^\infty [x(t)^T Q_\epsilon x(t) + u(t)^T R_\epsilon u(t)]dt.$$

Similar to (4.2), we can show

$$\begin{aligned}J_\epsilon(x_0, u(\cdot)) = x_0^T P_\epsilon^* x_0 + \mathsf{E}\int_0^\infty \big\{&[u(t) - K_\epsilon x(t)]^T (R_\epsilon + D^T P_\epsilon^* D)[u(t) - K_\epsilon x(t)] \\ &+ x(t)^T F_\epsilon(P_\epsilon^*) x(t)\big\} dt\end{aligned}$$

for any $u(\cdot) \in U_{ad}^{x_0}$, where $K_\epsilon := -(R_\epsilon + D^T P_\epsilon^* D)^+ (B^T P_\epsilon^* + D^T P_\epsilon C)$, and F_ϵ is the "perturbed" Riccati operator with Q and R in (3.4) replaced by Q_ϵ and R_ϵ, respectively. In [1, Theorems 5.4 and 5.5] it is stated that if the problem (P_ϵ) is strictly feasible (which is the case here) with an optimal solution P_ϵ^*, then the corresponding feedback control $u(t) = K_\epsilon x(t)$ must be stabilizing (and hence admissible), and P_ϵ^* must be the unique optimal solution to (P_ϵ) satisfying the corresponding Riccati equation $F_\epsilon(P) = 0$. Thus $u(t) = K_\epsilon x(t)$ must be optimal, and

$$\inf_{u(\cdot)\in U_{ad}^{x_0}} J_\epsilon(x_0, u(\cdot)) = x_0^T P_\epsilon^* x_0,$$

which further yields

$$x_0^T P_{\epsilon_i}^* x_0 = \inf_{u(\cdot)\in U_{ad}^{x_0}} J_{\epsilon_i}(x_0, u(\cdot)) \geq \inf_{u(\cdot)\in U_{ad}^{x_0}} J(x_0, u(\cdot)) = x_0^T M x_0.$$

Letting $\epsilon_i \to 0$, we obtain

$$x_0^T P_0^* x_0 \geq x_0^T M x_0.$$

On the other hand, (4.3) gives rise to the opposite inequality since P_0^* is feasible to (P). Thus we have $M = P_0^*$. This establishes that M is indeed a primal feasible solution. □

An important implication, which is the contrapositive of the above theorem, is this: If (P) has no optimal solution, or if (P) has optimal solutions but none of them satisfies the generalized Riccati equation $F(P) = 0$, then (LQ) has no attainable optimal control; in particular, it does not have any optimal feedback control.

A natural question to ask at this point is whether or not the converse of the above statement is true. Namely, if (P) admits an optimal solution P^* satisfying $F(P^*) = 0$, then does (LQ) have an attainable optimal control? Recall that in the finite horizon case an optimal feedback control is represented as $u^*(t) = -(R+D^T P^* D)^{-1}(B^T P^* + D^T P^* C)x^*(t)$ (cf. [8, Theorem 3.2]). However in the present case $R + D^T P^* D$ may be singular, therefore we naturally expect that an optimal feedback control should be

$$u^*(t) = -(R + D^T P^* D)^+ (B^T P^* + D^T P^* C)x^*(t). \tag{4.5}$$

The following result establishes that this control is indeed optimal if it is stabilizing. (Recall that in the infinite horizon case, stability is essential.)

THEOREM 4.2. *If a feasible solution of* (P)*, P^*, is such that $F(P^*) = 0$, and the feedback control $u^*(t)$ in* (4.5) *is stabilizing, then it must be optimal for* (LQ).

Proof. For any admissible control $u(\cdot) \in U_{ad}^{x_0}$, an argument similar to that in proving (4.2) leads to

$$\begin{aligned}
&J(x_0, u(\cdot)) \\
&= \mathsf{E}\int_0^\infty [x(t)^T Q x(t) + u(t)^T R u(t)]dt \\
&= x_0^T P^* x_0 \\
&\quad + \mathsf{E}\int_0^\infty \left\{[u(t) - Kx(t)]^T (R + D^T P^* D)[u(t) - Kx(t)] + x(t)^T F(P^*) x(t)\right\} dt \\
&= x_0^T P^* x_0 \\
&\quad + \mathsf{E}\int_0^\infty [u(t) - Kx(t)]^T (R + D^T P^* D)[u(t) - Kx(t)]dt,
\end{aligned} \tag{4.6}$$

where $K := -(R + D^T P^* D)^+ (B^T P^* + D^T P^* C)$. Since $u^*(t) = Kx^*(t)$ is stabilizing, the above shows that $u^*(\cdot)$ must be optimal. □

As mentioned earlier, the stability of the control in (4.5) can be examined numerically via the LMIs as stipulated in Proposition 3.1(iii). On the other hand, by Theorem 3.3, in order for this control to be stabilizing, it is *necessary* that there exist complementary solutions P^* and Z^* of (P) and (D), respectively, with $Z_N^* \succ 0$. It is interesting that under these (weaker) conditions, one can prove the existence of an explicitly representable optimal feedback control of (LQ) in (4.9) below (which is not necessarily in the same form as the control in (4.5)).

First we need a lemma.

LEMMA 4.3. *Suppose* (P) *and* (D) *have complementary optimal solutions,* P^* *and* Z^**, respectively. Then,* $F(P^*) = 0$.

Proof. We have the following decomposition:

$$\mathcal{L}(P^*) = \begin{bmatrix} I, & 0 \\ -K^T, & I \end{bmatrix} \begin{bmatrix} R + D^T P^* D, & 0 \\ 0, & F(P^*) \end{bmatrix} \begin{bmatrix} I, & -K \\ 0, & I \end{bmatrix}, \tag{4.7}$$

where $K := -(R + D^T P^* D)^+ (B^T P^* + D^T P^* C)$. From the relation $\mathcal{L}(P^*) Z^* = 0$, it follows that

$$\begin{aligned} &\begin{bmatrix} R + D^T P^* D, & 0 \\ 0, & F(P^*) \end{bmatrix} \begin{bmatrix} I, & -K \\ 0, & I \end{bmatrix} \begin{bmatrix} Z_B^*, & Z_U^* \\ (Z_U^*)^T, & Z_N^* \end{bmatrix} \\ &= \begin{bmatrix} (R + D^T P^* D)(Z_B^* - K(Z_U^*)^T), & (R + D^T P^* D)(Z_U^* - K Z_N^*) \\ F(P^*)(Z_U^*)^T, & F(P^*) Z_N^* \end{bmatrix} \\ &= \begin{bmatrix} 0, & 0 \\ 0, & 0 \end{bmatrix}. \end{aligned} \tag{4.8}$$

Therefore,

$$F(P^*)(Z_U^*)^T = 0, \qquad F(P^*) Z_N^* = 0$$

and

$$Z_U^* F(P^*) = 0, \qquad Z_N^* F(P^*) = 0.$$

On the other hand, the dual nonnegativity constraint, together with the extended Schur's lemma, yields

$$Z_B^* - Z_U^* (Z_N^*)^+ (Z_U^*)^T \succeq 0,$$

and

$$Z_U^* (I - Z_N^* (Z_N^*)^+) = 0.$$

Multiplying $F(P^*)$ on both sides of the dual equality constraint and making use of the above relations, we obtain

$$\begin{aligned} 0 &= F(P^*)(I + C Z_N^* C^T + D Z_U^* C^T + C^T Z_U^* D + D Z_B^* D^T) F(P^*) \\ &\succeq F(P^*)(I + C Z_N^* C^T + D Z_U^* C^T + C^T Z_U^* D + D Z_U^* (Z_N^*)^+ (Z_U^*)^T D^T) F(P^*) \\ &= F(P^*)^2 + F(P^*)[C Z_N^* + D Z_U^*](Z_N^*)^+ [Z_N^* C^T + (Z_U^*)^T D^T] F(P^*) \\ &\succeq F(P^*)^2. \end{aligned}$$

This means, $F(P^*) = 0$. □

THEOREM 4.4. *Assume that solving* (P) *and* (D) *yields complementary optimal solutions* P^* *and* Z^*, *with* $Z_N^* \succ 0$. *Then* $F(P^*) = 0$, *and* (LQ) *has an attainable optimal feedback control given by*

$$u^*(t) = Z_U^*(Z_N^*)^{-1}x^*(t). \tag{4.9}$$

Proof. First, that $F(P^*) = 0$ is seen from Lemma 4.3 (even without the assumption $Z_N^* \succ 0$).

Next, for any feasible solution P of (P) and any (stabilizing) control $u(\cdot) \in U_{ad}^{x_0}$, along with the corresponding state $x(\cdot)$, an argument similar to the one that proved (4.2) leads to

$$\begin{aligned} & J(x_0, u(\cdot)) \\ &= \mathsf{E}\int_0^\infty [x(t)^T Q x(t) + u(t)^T R u(t)]dt \\ &= x_0^T P x_0 \\ &+\mathsf{E}\int_0^\infty \left\{[u(t) - Kx(t)]^T (R + D^T P D)[u(t) - Kx(t)] + x(t)^T F(P) x(t)\right\} dt, \end{aligned} \tag{4.10}$$

where $K := -(R + D^T P D)^+ (B^T P + D^T P C)$. Since P is feasible to (P), we have $F(P) \succeq 0$. This means that

$$J(x_0, u(\cdot)) \geq x_0^T P x_0 \ \forall u(\cdot) \in U_{ad}^{x_0}$$

for any P feasible to (P).

Note that as yet we cannot conclude that the control in (4.5) is optimal, since we do not know whether or not the control is stabilizing, whereas (4.10) holds only for stabilizing controls. To get around, let us define a feedback control $u^*(t) = Z_U^*(Z_N^*)^{-1}x^*(t)$, which, following Theorem 3.4, is stabilizing. Hence (4.10) with $u(\cdot) = u^*(\cdot)$ and $P = P^*$ yields

$$J(x_0, u^*(\cdot)) = x_0^T P^* x_0 + \mathsf{E}\int_0^\infty [u^*(t) - K^* x^*(t)]^T (R + D^T P^* D)[u^*(t) - K^* x^*(t)]dt, \tag{4.11}$$

with $K^* := -(R + D^T P^* D)^+ (B^T P^* + D^T P^* C)$. Next, we show that

$$\begin{aligned} & [u^*(t) - K^* x^*(t)]^T (R + D^T P^* D)[u^*(t) - K^* x^*(t)] \\ \equiv\ & [u^*(t) - Z_U^*(Z_N^*)^{-1} x^*(t)]^T (R + D^T P^* D)[u^*(t) - Z_U^*(Z_N^*)^{-1} x^*(t)] \\ =\ & 0. \end{aligned} \tag{4.12}$$

To this end, apply the complementary duality. From the relation $\mathcal{L}(P^*)Z^* = 0$, it follows that

$$\begin{aligned} & \begin{bmatrix} R + D^T P^* D, & 0 \\ 0, & F(P^*) \end{bmatrix} \begin{bmatrix} I, & -K^* \\ 0, & I \end{bmatrix} \begin{bmatrix} Z_B^*, & Z_U^* \\ (Z_U^*)^T, & Z_N^* \end{bmatrix} \\ &= \begin{bmatrix} (R + D^T P^* D)(Z_B^* - K^*(Z_U^*)^T), & (R + D^T P^* D)(Z_U^* - K^* Z_N^*) \\ F(P^*)(Z_U^*)^T, & F(P^*) Z_N^* \end{bmatrix} \\ &= \begin{bmatrix} (R + D^T P^* D) Z_B^* + (B^T P^* + D^T P^* C)(Z_U^*)^T, & (R + D^T P^* D) Z_U^* + (B^T P^* + D^T P^* C) Z_N^* \\ F(P^*)(Z_U^*)^T, & F(P^*) Z_N^* \end{bmatrix} \\ &= \begin{bmatrix} 0, & 0 \\ 0, & 0 \end{bmatrix}. \end{aligned}$$

Therefore,

$$(R + D^T P^* D) Z_U^* = -(B^T P^* + D^T P^* C) Z_N^*. \tag{4.13}$$

Repeatedly using the above identity, we get

$$\begin{aligned}
0 &= [u^*(t) - Z_U^*(Z_N^*)^{-1}x^*(t)]^T (R + D^T P^* D)[u^*(t) - Z_U^*(Z_N^*)^{-1}x^*(t)] \\
&= u^*(t)^T (R + D^T P^* D) u^*(t) - 2u^*(t)^T (R + D^T P^* D) Z_U^*(Z_N^*)^{-1} x^*(t) \\
&\quad + x^*(t)^T (Z_N^*)^{-1} (Z_U^*)^T (R + D^T P^* D) Z_U^* (Z_N^*)^{-1} x^*(t) \\
&= u^*(t)^T (R + D^T P^* D) u^*(t) + 2u^*(t)^T (B^T P^* + D^T P^* C) x^*(t) \\
&\quad + x^*(t)^T (Z_N^*)^{-1} (Z_U^*)^T (R + D^T P^* D)(R + D^T P^* D)^+ (R + D^T P^* D) Z_U^* (Z_N^*)^{-1} x^*(t) \\
&= u^*(t)^T (R + D^T P^* D) u^*(t) + 2u^*(t)^T (B^T P^* + D^T P^* C) x^*(t) \\
&\quad + x^*(t)^T (P^* B + C^T P^* D)(R + D^T P^* D)^+ (B^T P^* + D^T P^* C) x^*(t) \\
&= [u^*(t) - K^* x^*(t)]^T (R + D^T P^* D)[u^*(t) - K^* x^*(t)].
\end{aligned}$$

This proves (4.12). It then follows from (4.10) and (4.11) that

$$J(x_0, u^*(\cdot)) = x_0^T P^* x_0 \le J(x_0, u(\cdot)) \qquad \forall u(\cdot) \in U_{ad}^{x_0}.$$

Hence, $u^*(\cdot)$ is optimal. □

A sufficient condition for Theorem 4.4 to hold is the *strict complementarity* of the SDPs (P) and (D), as the following proposition asserts.

PROPOSITION 4.5. *Suppose that* (P) *and* (D) *have strictly complementary optimal solutions* P^* *and* Z^**, respectively, i.e.,* $\mathcal{L}(P^*)Z^* = 0$ *and* $\mathcal{L}(P^*) + Z^* \succ 0$*. Then,* $Z_N^* \succ 0$*.*

Proof. Following Lemma 4.3 and (4.7) we have

$$\mathcal{L}(P^*) = (H^{-1})^T \mathrm{diag}(R + D^T P^* D, 0) H^{-1},$$

where

$$H = \begin{bmatrix} I, & K \\ 0, & I \end{bmatrix} \text{ and } K = -(R + D^T P^* D)^+ (B^T P^* + D^T P^* C).$$

Let $\bar{Z}^* := H^{-1} Z^* (H^{-1})^T$.

It is readily seen that $\bar{Z}_N^* = Z_N^*$. Moreover, diag $(R + D^T P^* D, 0) = H^T \mathcal{L}(P^*) H$ and $\bar{Z}^* = H^{-1} Z^* (H^{-1})^T$ are positive semidefinite and they are complementary to each other. We shall further show that they stay strictly complementary. To see this we first note that the range space of $\mathcal{L}(P^*)$, range$(\mathcal{L}(P^*))$, and the range space of Z^*, range(Z^*), form an orthogonal decomposition of the whole space. Clearly, range$(H^T \mathcal{L}(P^*) H)$ has the same dimension as that of range$(\mathcal{L}(P^*))$; and range$(\bar{Z}^*)$ has the same dimension as that of range(Z^*). Finally, range$(H^T \mathcal{L}(P^*) H)$ and range$(\bar{Z}^*)$ remain orthogonal to each other. Hence they span the whole space too. Therefore,

$$H^T \mathcal{L}(P^*) H + \bar{Z}^* \succ 0.$$

As we noted before, the last diagonal block of the above matrix is Z_N^*. Hence, $Z_N^* \succ 0$, as the proposition stipulates. □

If P^* and Z^* are strictly complementary optimal solutions with

$$R + D^T P^* D \succ 0, \tag{4.14}$$

and $Z_N^* \succ 0$, then by (4.13), the feedback control in (4.9) coincides with the one in (3.5). But if $R + D^T P^* D$ is singular, then these two controls can indeed be *different*; see Example 6.1.

5. Synthesis. To summarize the results we have so far obtained, consider the following statements:

(a) (LQ) is attainable at any $x_0 \in \Re^n$.

(b) (P) has an optimal solution P^* that satisfies:

(i) the generalized stochastic Riccati equation $F(P) = 0$;

(ii) the corresponding feedback control $u^*(t)$ of (4.5) is stabilizing.

(c) (P) and (D) have complementary optimal solutions P^* and Z^*, with $Z_N^* \succ 0$.

The following theorem is a summary of our main results.

THEOREM 5.1. *The following implications hold:*

- (a) $\Rightarrow$ (b(i))*: Theorem* 4.1.
- (b) $\Rightarrow$ (a)*, with the control in* (4.5) *being optimal: Theorem* 4.2.
- (b) $\Rightarrow$ (c)*: Theorem* 3.3.
- (c) $\Rightarrow$ (a)*, with the control in* (4.9) *being optimal: Theorem* 4.4.

Some remarks are in order. Among the above statements, (a) is a direct statement about the solution of the original problem (LQ); (b) and (c), on the other hand, provide two computational approaches to (LQ) via SDP — note that they both imply (a) with the respective optimal feedback controls explicitly given. There are differences, however, between the two; in particular, they have different requirements, and lead to different controls. Computationally, (c) appears to have an edge over (b), as most SDP solvers are based on primal-dual interior point methods. This implies that the iterative solutions produced by such a solver will likely converge to the analytic centers of the primal and dual optimal sets, respectively, which are known to be "maximally complementary" to each other. Therefore, if there is indeed any dual optimal solution with $Z_N^* \succ 0$, then the solver will return such a solution. In this respect, checking $Z_N^* \succ 0$ is much easier than verifying the stabilizing condition in (b(ii)).

Furthermore, Theorem 5.1 also reveals the relationship between (b) and (c): (b) implies (c), whereas (c) implies (b(i)) via (a). That (c) cannot imply the stabilizing condition in (b(ii)) is in itself an interesting fact, which suggests that the two controls in (4.5) and (4.9) are in general intrinsically different. Even when the former is stabilizing, and hence both controls are optimal—since we then have (b) $\Rightarrow$ (c) $\Rightarrow$ (a)—they can still be different (except for the special case of (4.14), where (b) and (c) become equivalent); see Example 6.1.

If (b(ii)) is satisfied, then (b) is reduced to (b(i)). Consequently, (a), (b), and (c) are equivalent. Hence we have the following result.

COROLLARY 5.2. *Suppose that the control in* (4.5) *is stabilizing, Then,* (a), (b), *and* (c) *are equivalent.*

An important special case is when

$$Q \succ 0, \qquad R \succ 0. \tag{5.1}$$

In this case, (P) satisfies the Slater condition because $P = 0$ is a strictly feasible solution, and so does (D) because of the mean-square stabilizability assumption of the original LQ problem. Therefore, (c) holds. On the other hand, by [1, Corollary 5.1] the control in (4.5) must be stabilizing. Hence Corollary 5.2 stipulates that (a) and (b) must hold true as well.

COROLLARY 5.3. *Suppose* (5.1) *holds. Then, the three statements* (a), (b), *and* (c) *hold true.*

Based on the results obtained earlier, it is possible to develop a computational procedure as follows to provide a complete treatment of the stochastic LQ control

problem, and in particular to answer if the problem has an optimal feedback control representable as in (4.5) or in (4.9). The procedure involves only solving some LMIs, an SDP and its dual, for which numerical algorithms have been extensively developed (among others see [11, 19, 20]). Insofar as the complementary primal SDP solution satisfies the generalized Riccati equation (see Lemma 4.3), the procedure can also be viewed as a numerical approach to solving the Riccati equation.

Step 1. Check if the feasible set of (P) is nonempty (which is an LMI condition). If not, then stop: the LQ problem cannot be solved by either the SDP approach or by the Riccati equation; else continue.

Step 2. Check if (D) satisfies the Slater condition, which amounts to solving a system of strict LMIs. If not, then stop: the LQ problem is not mean-square stablizable according to Proposition 3.1(ii) and hence ill-posed; else continue.

Step 3. At this point we know that (P) is feasible and (D) satisfies the Slater condition, and hence (P) has an optimal solution (see, e.g., [14, Theorem 5]). Check if there is any optimal solution of (P) that satisfies $F(P) = 0$. If not, then stop: the LQ problem has no attainable optimal feedback control according to Theorem 4.1; else continue.

Step 4. Check if the control in (4.5) is stabilizing (which can be checked by LMIs according to Proposition 3.1(iii)). If yes, then stop: the control is optimal; else continue.

Step 5. Check if (P) and (D) have complementary optimal solutions P^* and Z^* with $Z_N^* \succ 0$. If yes, then stop: the control $u^*(t) = Z_U^*(Z_N^*)^{-1}x^*(t)$ is optimal; otherwise (LQ) cannot be solved by our SDP approach, nor can it be solved by any other existing method.

Notice that in practical implementation one might as well starts solving (P) and (D) by means of a primal-dual interior point code (e.g., that of using the homogeneous self-dual embedding technique; see [19]), i.e., running Step 5 first. If the result turns out to be positive, then Steps 1–4 are not necessary. On the other hand, even if the result is negative, the algorithm will still tell the feasibility of (P) and (D). This makes it easier to carry out Step 1, followed by subsequent steps.

6. Examples. The first example below demonstrates how the LQ control problem can be solved by the SDP approach developed here, even in the presence of the singularity of $R + D^T P^* D$. It also shows that optimal stabilizing controls can be obtained by both SDP approaches in (b) and (c) of Theorem 5.1, leading to different optimal controls in (4.5) and (4.9), respectively.

Example 6.1. Let $m = n = 1$; $A = C = -1$, $B = D = 1$; $Q = 1$ and $R = -1$. Namely, the problem is this:

$$\begin{array}{ll} \min & \mathsf{E}\int_0^\infty [x(t)^2 - u(t)^2]dt \\ \text{s.t.} & dx(t) = [-x(t) + u(t)]dt + [-x(t) + u(t)]dW(t), \\ & x(0) = x_0. \end{array}$$

This system is mean-square stabilizable, as $u(t) = \alpha x(t)$ is stabilizing for any α with $|\alpha| < 1$. To see this, applying Itô's formula to the system (1) under the above feedback control, we obtain

$$d\mathsf{E}[x(t)^2] = (\alpha^2 - 1)\mathsf{E}[x(t)^2]dt, \;\; \mathsf{E}[x(0)^2] = x_0^2.$$

Hence

$$\mathsf{E}[x(t)^2] = e^{(\alpha^2-1)t}x_0^2, \tag{6.1}$$

which converges to 0 as $t \to +\infty$.

Now, the primal SDP is

$$\begin{array}{ll} \max & p \\ \text{s.t.} & \left[\begin{array}{cc} -1+p, & 0 \\ 0, & 1-p \end{array} \right] \succeq 0. \end{array}$$

The above has an optimal solution $p^* = 1$ (the only feasible solution), which also satisfies the generalized Riccati equation $F(p) = 1 - p = 0$. (Note that singularity occurs in this solution). The feedback control given by (4.5) reduces to $u^*(t) = 0$, which is stabilizing as shown above ($\alpha = 0 < 1$). Therefore, all the tests in Steps 1–4 of the computational procedure presented in section 5 are passed. Consequently, $u^*(t) = 0$ is *one* optimal control of the LQ problem. Moreover, the corresponding objective value is

$$\mathsf{E} \int_0^\infty [x^*(t)]^2 dt = x_0^2 \int_0^\infty e^{-t} dt = x_0^2, \tag{6.2}$$

where the first equality is due to (6.1) with $\alpha = 0$.

Next, we can obtain additional — in fact, infinitely many more — optimal controls by virtue of (c). Indeed, the dual SDP in this case is

$$\begin{array}{ll} \min & -z_b + z_n \\ \text{s.t.} & 1 + z_b - z_n = 0, \\ & z := \left[\begin{array}{cc} z_b, & z_u \\ z_u, & z_n \end{array} \right] \succeq 0. \end{array}$$

It can be directly verified that the above has multiple optimal solutions:

$$(z_b, z_u, z_n) = (z_b, z_u, 1 + z_b),$$

parameterized by (z_u, z_b) with

$$z_b \geq 0, \;\; z_u^2 \leq z_b(1 + z_b). \tag{6.3}$$

In particular, note that the above ensures $z_n = 1 + z_b > 0$. Furthermore, these (parameterized) solutions are all complementary to the primal optimal solution $p^* = 0$. Hence, the test in Step 5 of the numerical procedure is passed, which gives rise to (multiple) optimal controls

$$u^*(t) = z_u z_n^{-1} x^*(t) \equiv \alpha x^*(t).$$

Notice that the feedback gain α satisfies

$$|\alpha| = \frac{z_u}{1 + z_b} \leq \frac{\sqrt{z_b(1 + z_b)}}{1 + z_b} = \sqrt{\frac{z_b}{1 + z_b}} < 1,$$

where the first inequality follows from (6.3). Therefore, these controls are indeed stabilizing by (6.1). Finally, the optimal cost corresponding to these controls is

$$\begin{array}{rcl} J = & \mathsf{E} \int_0^\infty (1 - \alpha^2)[x(t)]^2 dt \\ = & x_0^2 (1 - \alpha^2) \int_0^\infty e^{(\alpha^2 - 1)t} dt \\ = & x_0^2, \end{array}$$

which coincides with (6.2).

The next example illustrates two points: First, when the primal SDP solution satisfies the Riccati equation (i.e., (b(i)) holds), and moreover (4.14) holds, the resulting feedback control may still not be stabilizing (i.e., (b(ii)) fails). When this does happen, the complementarity condition in (c) fails. Second, there indeed exist well-posed stochastic control problems which, however, do not have any attainable optimal control. This calls for approximation methods, which will be presented in the next section.

Example 6.2. Suppose $m = n = 1$; $A = C = 0$, $B = D = 1$; $Q = 4$ and $R = -1$. The control system is as follows:

$$\begin{array}{ll} \min & \mathsf{E}\int_0^\infty [4x(t)^2 - u(t)^2]dt \\ \text{s.t.} & dx(t) = u(t)dt + u(t)dW(t), \\ & x(0) = x_0. \end{array}$$

Consider a feedback control $u(t) = -kx(t)$. Applying Itô's lemma yields

$$d[x(t)]^2 = (k^2 - 2k)[x(t)]^2 - 2k[x(t)]^2 dW(t).$$

Clearly, such a feedback control is stabilizing if and only if $k^2 - 2k < 0$ or $0 < k < 2$. In particular, this implies that $u(t) = -x(t)$ is stabilizing while $u(t) = -2x(t)$ is not.

For any $0 < k < 2$, it follows that $\mathsf{E}\int_0^\infty [x(t)]^2 dt = x_0^2/(2k - k^2)$. Therefore, the control $u(t) = -kx(t)$ has a cost

$$(4 - k^2)\mathsf{E}\int_0^\infty [x(t)]^2 dt = \left(1 + \frac{2}{k}\right) x_0^2.$$

As $k \uparrow 2$ we see that the cost can be arbitrarily close to $2x_0^2$. Nevertheless, this optimum is not attainable when $x_0 \neq 0$.

In terms of the corresponding SDPs, the primal reads

$$\begin{array}{ll} \max & p \\ \text{s.t.} & \left[\begin{array}{cc} -1 + p, & p \\ p, & 4 \end{array} \right] \succeq 0. \end{array}$$

This problem has only one feasible solution $p^* = 2$, which is necessarily the optimal solution. It clearly satisfies the Riccati equation:

$$4 + \frac{p^2}{1 - p} = 0.$$

Hence the control in (4.5) is

$$u^*(t) = -\frac{p^*}{-1 + p^*} x^*(t) = -2x^*(t),$$

which is *not* stabilizing as we discussed before.

Since (b(ii)) does not hold, we expect (c) to fail as well, as (b) and (c) are equivalent under (4.14). So, let us now examine the dual:

$$\begin{array}{ll} \min & 4z_n - z_b \\ \text{s.t.} & 1 + 2z_u + z_b = 0, \\ & z := \left[\begin{array}{cc} z_b, & z_u \\ z_u, & z_n \end{array} \right] \succeq 0. \end{array}$$

This problem is strictly feasible, since the original LQ problem is stabilizable. For instance, $(z_b, z_u, z_n) = (1, -1, 2)$ is a strictly feasible solution. Hence ([23, Theorem 3.1]), the infimum of the dual objective value must coincide with the supremum of the primal objective value, which is 2. This means, should the dual optimal solution z^* exist, it must satisfy $4z_n^* - z_b^* = 2$, or $z_n^* = (2 + z_b^*)/4$. This, along with $z_u^* = -(1 + z_b^*)/2$, leads to

$$z_b^* z_n^* = z_b^* \cdot \frac{2 + z_b^*}{4} < \frac{(1 + z_b^*)^2}{4} = (z_u^*)^2,$$

which violates $z \succeq 0$. Consequently, the dual does not have an attainable optimal solution, and the complementary duality fails.

The third example below illustrates a situation opposite to Example 6.2: (b(i)) fails while (b(ii)) holds. Namely, when $R + D^T P^* D = 0$, the optimal primal solution P^* may *not* satisfy the generalized Riccati equation $F(P) = 0$ (and *vice versa*), even when the corresponding control is stabilizing. In this case, Theorem 4.1 shows that the LQ problem has no attainable optimal control.

Example 6.3. Let $m = n = 1$; $A = -1$, $B = 1$, $C = D = 0$; $Q = 1$ and $R = 0$. This is actually a deterministic system that is mean-square stabilizable, as $u(t) = 0$ is stabilizing. The corresponding SDP reads:

$$\begin{array}{ll} \max & p \\ \text{s.t.} & \left[\begin{array}{cc} 0, & p \\ p, & 1 - 2p \end{array} \right] \succeq 0. \end{array}$$

The above has a unique feasible solution $p^* = 0$, which is hence optimal too. However, the generalized Riccati equation in this case is $F(p) = 1 - 2p = 0$, which has a unique solution $p = \frac{1}{2}$. Therefore, the two solutions are completely different.

Moreover, notice that while (b(i)) fails in this case, (b(ii)) does hold: $u^*(t) = 0$ is indeed stabilizing. On the other hand, in view of Theorem 5.1, (c) $\Rightarrow$ (a) $\Rightarrow$ (b(i)), we expect (c) to fail. Indeed, the dual SDP is

$$\begin{array}{ll} \min & z_n \\ \text{s.t.} & 1 + 2z_u - 2z_n = 0, \\ & z := \left[\begin{array}{cc} z_b, & z_u \\ z_u, & z_n \end{array} \right] \succeq 0. \end{array}$$

This dual problem is strictly feasible, and it has an infimum equal to 0, which is the supremum of the primal. However, the dual optimal solution is not attainable, because whenever $z_n = 0$ we must have $z_u = 1/2$, and hence it is impossible to have $z \succeq 0$.

7. ϵ-Approximation. Examples 6.2 and 6.3 have illustrated that the LQ control problem could be well-posed, but still there exists no attainable optimal control. When this happens we propose to consider (LQ$_\epsilon$), obtained by keeping all the data A, B, C, and D in (LQ) unchanged, and letting $R_\epsilon = R + \epsilon I$ and $Q_\epsilon = Q + \epsilon I$ with $\epsilon > 0$; such a perturbation was already considered in the proof of Theorem 4.1. Recall that the associated SDPs for (LQ$_\epsilon$) are

$$\begin{array}{lll} (\mathrm{P}_\epsilon) & \max & \langle I, P \rangle \\ & \text{s.t.} & \left[\begin{array}{cc} R + \epsilon I + D^T P D, & B^T P + D^T P C \\ P B + C^T P D, & Q + \epsilon I + C^T P C + A^T P + P A \end{array} \right] \succeq 0, \\ & & P \in \mathcal{S}^{n \times n}, \end{array}$$

and

$$\begin{array}{lll}(\mathrm{D}_\epsilon) & \min & \langle R+\epsilon I, Z_B\rangle + \langle Q+\epsilon I, Z_N\rangle \\ & \text{s.t.} & I + Z_U^T B^T + BZ_U + Z_N A^T + AZ_N \\ & & \quad + CZ_N C^T + DZ_U C^T + CZ_U^T D^T + DZ_B D^T = 0, \\ & & \left[\begin{array}{ll} Z_B, & Z_U \\ Z_U^T, & Z_N \end{array}\right] \succeq 0. \end{array}$$

Assuming that the LQ is stablizable and (P) is feasible, both (P_ϵ) and (D_ϵ) satisfy the Slater condition.

THEOREM 7.1. *Suppose* (LQ) *is well-posed. Let* $J_\epsilon^*(x_0)$ *and* $J^*(x_0)$ *be the optimal values of* (LQ_ϵ) *and* (LQ)*, respectively. Then,*

$$\lim_{\epsilon \downarrow 0} J_\epsilon^*(x_0) = J^*(x_0).$$

Proof. Let the optimal solution of (P_ϵ) be P_ϵ^*. In the proof of Theorem 4.1, we proved that

$$u^\epsilon(t) = -(R_\epsilon + D^T P_\epsilon^* D)^+ (B^T P_\epsilon^* + D^T P_\epsilon C) x^\epsilon(t) \tag{7.1}$$

is optimal for (LQ_ϵ), with the corresponding optimal objective value equal to $J_\epsilon^*(x_0) = x_0^T P_\epsilon^* x_0$.

Following the same argument as in the proof of Theorem 4.1, we know that P_ϵ^* is contained in a compact set, with $0 < \epsilon \le \epsilon_0$. Moreover, since by definition $J_\epsilon^*(x_0)$ decreases monotonically as $\epsilon \downarrow 0$, so does P_ϵ^*. Therefore, P_ϵ^* itself also converges as $\epsilon \downarrow 0$.

What remains is to show that $x_0^T P_0^* x_0$ is equal to the true infimum of (LQ), now denoted as $J^*(x_0)$. To this end, first note that

$$x_0^T P_\epsilon^* x_0 = J_\epsilon^*(x_0) \ge J^*(x_0),$$

where the inequality is due to the positive perturbation in (P_ϵ). Letting $\epsilon \to 0$, we obtain

$$x_0^T P_0^* x_0 \ge J^*(x_0).$$

On the other hand, since P_0^* is feasible to (P) (see the proof of Theorem 4.1), it follows from (4.10) that

$$J^*(x_0) \equiv \inf_{u(\cdot) \in U_{ad}^{x_0}} J(x_0, u(\cdot)) \ge x_0^T P_0^* x_0.$$

This completes the proof. □

The above theorem says that the objective value achieved by the perturbed problem is asymptotically optimal. The next result is concerned with the asymptotic optimality of the feedback control.

THEOREM 7.2. *The feedback control* $u^\epsilon(\cdot)$ *constructed by* (7.1) *is asymptotically optimal for* (LQ)*, namely,*

$$\lim_{\epsilon \downarrow 0} J(x_0, u^\epsilon(\cdot)) = J^*(x_0).$$

Proof. Denote by $J_\epsilon(x_0, u(\cdot))$ the cost of the perturbed problem (LQ_ϵ) under an admissible control $u(\cdot) \in U_{ad}^{x_0}$ w.r.t. the initial state x_0. Then for any $\eta > 0$, there is an ϵ_0 such that when $0 < \epsilon < \epsilon_0$,

$$\begin{aligned} J^*(x_0) &\le J(x_0, u^\epsilon(\cdot)) \\ &\le J_\epsilon(x_0, u^\epsilon(\cdot)) \\ &= J_\epsilon^*(x_0) \\ &\le J^*(x_0) + \eta, \end{aligned}$$

where the last inequality is due to Theorem 7.1. This proves our claim. □

Consider Example 6.2. With perturbation, the corresponding primal SDP becomes

$$\begin{array}{ll} \max & p \\ \text{s.t.} & \left[\begin{array}{cc} -1+\epsilon+p, & p \\ p, & 4+\epsilon \end{array} \right] \succeq 0. \end{array}$$

Solving this problem yields

$$p_\epsilon^* = \frac{4+\epsilon+\sqrt{(4+\epsilon)^2+4(4+\epsilon)(-1+\epsilon)}}{2}.$$

Clearly, $p_\epsilon^* = 2 + O(\sqrt{\epsilon})$, and hence the optimal value of (P_ϵ), $p_\epsilon^* x_0^2$, converges to $2x_0^2$ as $\epsilon \downarrow 0$.

8. Concluding remarks. We have developed a systematic approach to the stochastic LQ control problem based on primal-dual SDP, allowing indefinite cost matrices. We have shown that, in addition to its obvious computational advantage, the SDP duality theory provides critical qualitative information about the LQ control problem, in particular, regarding issues such as stability and optimality.

Among the three statements presented in section 5, the strongest is (b), which consists of two parts: (i) the optimal solution to the primal SDP satisfies the generalized Riccati equation, and (ii) the corresponding feedback control is stabilizing. It implies (c), the SDP complementary duality, which, in turn, implies (a): the existence of an optimal control to the LQ problem. Both (b) and (c) hence provide useful computational approaches to solving the LQ problem.

Conversely, our results also provide new insight as to when the LQ problem does *not* possess an optimal solution: Since (b(i)) is implied by (a), if no primal SDP solution satisfies the generalized Riccati equation, then the LQ problem has no attainable optimal control. (For such problems we have developed an ϵ-approximation scheme that yields asymptotic optimal solutions.) However, as the SDP in general possesses multiple optimal solutions, and most SDP solvers usually return a single optimal solution, this result is of more theoretical, as opposed to computational, interest. This limitation is reflected in Step 3 of the procedure outlined in section 5: it requires checking if there is *any* optimal solution of (P) satisfying $F(P) = 0$.

Finally, the gap alluded to in the last step of the same procedure points to an open problem: whether our SDP approach might fail to find an optimal control (a counter-example), or this is simply impossible (a proof).

Acknowledgment. We thank the Associate Editor and the two reviewers for their careful reading of an earlier version of the paper and for their insightful comments.

STATIONARY HAMILTON–JACOBI EQUATIONS IN HILBERT SPACES AND APPLICATIONS TO A STOCHASTIC OPTIMAL CONTROL PROBLEM*

SANDRA CERRAI†

Abstract. We study an infinite horizon stochastic control problem associated with a class of stochastic reaction-diffusion systems with coefficients having polynomial growth. The hamiltonian is assumed to be only locally Lipschitz continuous so that the quadratic case can be covered. We prove that the value function V corresponding to the control problem is given by the solution of the stationary Hamilton–Jacobi equation associated with the state system. To this purpose we write the Hamilton–Jacobi equation in integral form, and, by using the smoothing properties of the transition semigroup relative to the state system and the theory of m-dissipative operators, we show that it admits a unique solution. Moreover, the value function V is obtained as the limit of minima for some approximating control problems which admit unique optimal controls and states.

Key words. stochastic reaction-diffusion systems, stationary Hamilton–Jacobi–Bellman equations in infinite dimension, infinite horizon stochastic control problems

1. Introduction.

In the present paper we are concerned with an infinite horizon stochastic control problem associated with the following reaction-diffusion system perturbed by a random term:

(1.1)
$$\begin{cases} \dfrac{\partial y_k}{\partial t}(t,\xi) = \mathcal{A}_k\, y_k(t,\xi) + f_k(\xi, y_1(t,\xi), \dots, y_r(t,\xi)) + z_k(t,\xi) + Q_k \dfrac{\partial^2 w_k}{\partial t \partial \xi}(t,\xi), \\ y_k(0,\xi) = x_k(\xi), \qquad t \geq 0, \quad \xi \in \overline{\mathcal{O}}, \\ \mathcal{B}_k\, y_k(s,\xi) = 0, \qquad \xi \in \partial\mathcal{O}, \qquad k = 1, \dots, r. \end{cases}$$

Here $\mathcal{O}$ is a bounded open set in $\mathbb{R}^d$, $d \leq 3$, with regular boundary. The second order differential operators $\mathcal{A}_k$ are strictly elliptic, have regular coefficients, and are endowed with some boundary conditions $\mathcal{B}_k$. The function $f = (f_1, \dots, f_r) : \overline{\mathcal{O}} \times \mathbb{R}^r \to \mathbb{R}^r$ is twice differentiable, has polynomial growth together with its derivatives, and verifies suitable dissipativity conditions. The linear operators Q_k are bounded and self-adjoint from $L^2(\mathcal{O})$ into itself and are not assumed to be Hilbert–Schmidt in general. Finally, the random fields $\partial^2 w_k / \partial t \partial \xi$ are mutually independent white noises in space and in time, defined on the same stochastic basis $(\Omega, \mathcal{F}, \mathcal{F}_t, \mathbb{P})$, and z_k are square integrable processes adapted to the filtration $\mathcal{F}_t$.

Such a class of systems are of interest in applications and, especially in chemistry and in the present setting, have been widely studied by several authors (see, for example, Friedlin in [18] and Da Prato and Zabczyk in [14]). We recall that in [14] it

†Dipartimento di Matematica per le Decisioni, Università di Firenze, Via C. Lombroso 6/17, I-50134 Firenze, Italy (cerrai@cce.unifi.it).

is proved that for any initial datum x in the Hilbert space $H = L^2(\mathcal{O}; \mathbb{R}^r)$ and for any adapted control $z \in L^2(\Omega; L^2(0, +\infty; H))$ the system (1.1) admits a unique solution $y(t; x, z)$ in a *generalized* sense that we will specify later. Moreover, if $x \in C(\overline{\mathcal{O}}; \mathbb{R}^r)$ and $z \in L^2(\Omega; L^p(0, +\infty; H))$ with $p > 4/(4 - d)$, such a solution is a *mild* solution.

In correspondence with the system (1.1) we study the following stochastic control problem: *minimizing* the cost functional

$$J(x, z) = \mathbb{E} \int_0^{+\infty} e^{-\lambda t} \left[g(y(t; x, z)) + k(z(t)) \right] dt, \tag{1.2}$$

among all controls $z \in L^2(\Omega; L^2(0, +\infty; H))$ adapted to the filtration $\mathcal{F}_t$. Here $y(t; x, z)$ is the unique solution of (1.1), and $g : H \to \mathbb{R}$ is Lipschitz continuous and bounded. Moreover, $k : H \to (-\infty, +\infty]$ is a measurable mapping such that its Legendre transform K, which is defined by

$$K(x) = \sup_{y \in H} \left\{ - \langle x, y \rangle_H - k(y) \right\}, \qquad x \in H,$$

is Fréchet differentiable and *locally* Lipschitz continuous together with its derivative.

Our aim here is to study the *value function* corresponding to the functional (1.2)

$$V(x) = \inf \left\{ J(x, z) ;\ z \in L^2(\Omega; L^2(0, +\infty; H)),\ \text{adapted} \right\}.$$

Namely, we show that, if A is the realization in H of the differential operator $\mathcal{A} = (\mathcal{A}_1, \dots, \mathcal{A}_r)$, endowed with the boundary conditions $\mathcal{B} = (\mathcal{B}_1, \dots, \mathcal{B}_r)$, and if F is the Nemytskii operator associated with the function $f = (f_1, \dots, f_r)$, then, under the assumption of Lipschitz continuity for K, for any $\lambda > 0$ and $g \in C_b(H)$[1] the infinite dimensional second order nonlinear elliptic problem

$$\lambda \varphi(x) - \frac{1}{2} \mathrm{Tr} \left[Q^2 D^2 \varphi(x) \right] - \langle Ax + F(x), D\varphi(x) \rangle_H + K(D\varphi(x)) = g(x) \tag{1.3}$$

admits a unique differentiable *mild* solution φ. This means that there exists a unique solution $\varphi \in C_b^1(H)$ to the integral problem

$$\varphi(x) = \mathbb{E} \int_0^{+\infty} e^{-\lambda t} \left[g(y(t; x)) - K(D\varphi(y(t; x))) \right] dt,$$

where $y(t; x)$ is the solution of the system (1.1), corresponding to $z = 0$. Moreover, for any $x \in H$ the solution $\varphi(x)$ coincides with the function $V(x)$. When K is only locally Lipschitz continuous, there exists $\mu_0 > 0$ such that the same result holds for any $\lambda > \mu_0$ and $g \in C_b^1(H)$.

It is important to remark that even if we assume $f(\xi, \cdot)$ to be more than once differentiable, nevertheless we are able to prove only C^1-regularity in H for the transition semigroup P_t associated with the system (1.1) (see [8]). Then the solution φ of the problem (1.3) is only C^1, and we can not prove the existence of an optimal state and an optimal control for our control problem. Actually, by following a dynamic

[1] We shall denote by $B_b(H)$ the Banach space of all bounded Borel functions $\varphi : H \to \mathbb{R}$ and by $C_b(H)$ the subspace of uniformly continuous functions. Moreover, we denote by $C_b^k(H)$, $k \in \mathbb{N}$, the subspace of all k-times Fréchet differentiable functions, having uniformly continuous and bounded derivatives, up to the kth order.

programming approach, the optimal state and the optimal control would be given, respectively, by the solution $y^\star(t)$ of the so-called *closed loop equation*

$$dy(t) = [Ay(t) + F(y(t)) - DK(D\varphi(y(t)))]\,dt + Q\,dw(t), \qquad y(0) = x, \tag{1.4}$$

and by

$$z^\star(t) = -DK(D\varphi(y^\star(t))).$$

On the other hand, as $D\varphi$ is only continuous, the mapping $x \mapsto -DK(D\varphi(x))$ is only continuous. Thus we are able only to prove the existence of martingale solutions for the problem (1.4), which are not defined in general in the original stochastic basis $(\Omega, \mathcal{F}, \mathcal{F}_t, \mathbb{P})$, so that the control $z^\star(t)$ is not admissible for our original problem. However, in the case of space dimension $d = 1$ it is possible to prove the existence and uniqueness of solutions for the closed loop equation and then the existence and uniqueness of an optimal control. In what follows, it could be interesting to see if, by introducing the notion of *relaxed controls* (see [17] for the definition and some interesting results in finite dimension), it is possible to prove the existence of an optimal control.

Nevertheless, even if we are not able to prove in general the existence of an optimal control, we can show that the value function V is obtained as the limit of minima of suitable approximating cost functionals J_α, $\alpha \geq 0$, which admit unique optimal controls and unique optimal states and whose value functions coincide with the solutions of suitable approximating Hamilton–Jacobi problems.

Several authors have studied second order Hamilton–Jacobi equations by the approach of viscosity solutions. For the finite dimensional case we refer to the paper by Crandall, Ishii, and Lions [11] and to the book by Fleming and Soner [17], and for the infinite dimensional case we refer to the papers by Lions [25, 26] and to the thesis of Swiech [28]. Other authors have studied regular solutions of second order Hamilton–Jacobi equations, and as far as the infinite dimension is concerned we refer to the works by Barbu and Da Prato [1], Cannarsa and Da Prato [2, 3], Gozzi [20, 21], Haverneau [23] for the evolution case, and by Gozzi and Rouy [22] and Chow and Menaldi [10] for the stationary case. More recently, infinite dimensional Hamilton–Jacobi equations have been studied in connection with some ergodic control problems (see, for example, [19] and [16]).

The main novelty here lies in the fact that we can prove the existence and uniqueness of regular solutions for (1.3) when the nonlinear coefficient F in the state equation has polynomial growth and is not even well defined in the Hilbert space H. Moreover, we can treat both the case of a Lipschitz continuous hamiltonian and the case of a locally Lipschitz hamiltonian so that the quadratic case can be covered.

Due to the difficulties arising from coefficients which are not Lipschitz continuous, the study of mild solutions for the problem (1.3) is quite delicate, and we have to proceed in several steps. We first consider the case of a Lipschitz hamiltonian K, and we prove the existence and uniqueness result for λ large enough. To this purpose, we apply a fixed point argument in the space $C_b^1(H)$, and we use the regularizing properties of the semigroup P_t which have been studied in detail in [7] and [8]. Namely, it has been proved that

$$\varphi \in B_b(H) \Longrightarrow P_t\varphi \in C_b^1(H), \qquad t > 0,$$

and

$$\sup_{x\in H} |D(P_t\varphi)(x)|_H \leq c\,(t \wedge 1)^{-\frac{1+\epsilon}{2}} \sup_{x\in H} |\varphi(x)|$$

for some constant $\epsilon < 1$ depending on Q. Then, if we denote by L the weak generator of P_t (see [4] for the definition and main properties) by proceeding with suitable approximations, we show that the operator

$$N(\varphi) = L\varphi - K(D\varphi)$$

is m-dissipative. This yields the existence and uniqueness of solutions for any $\lambda > 0$. Then we consider a locally Lipschitz hamiltonian K. We approximate it by a sequence of Lipschitz functions, we consider the problems associated with the approximating hamiltonians, and, by a suitable a priori estimate, we get our result, even if in a less general case.

We remark that throughout the paper we have to proceed by several approximations because of the intrinsic difficulties in the study of the system (1.1) and because of the corresponding transition semigroup P_t. Actually, first we have to approximate the reaction term F by Lipschitz continuous functionals F_α in order to get C^2 regularity for the semigroup P_t^α associated with the system

$$dy(t) = [Ay(t) + F_\alpha(y(t))]\, dt + Q\, dw(t), \qquad y(0) = x, \tag{1.5}$$

and then we have to approximate P_t^α by the semigroups $P_t^{\alpha,n}$ associated with the finite dimensional version of (1.5) in order to apply the usual Itô calculus. Unfortunately, the direct approximation of the semigroup P_t by the semigroups $P_t^{\alpha,n}$ does not work.

2. Assumptions. We denote by H the Hilbert space $L^2(\mathcal{O}; \mathbb{R}^r)$, where $\mathcal{O}$ is a bounded open set of $\mathbb{R}^d$, $d \le 3$, having the boundary sufficiently regular. The norm and the scalar product in H are, respectively, denoted by $|\cdot|_H$ and $\langle \cdot, \cdot \rangle_H$. Moreover, we denote by E the Banach space $C(\overline{\mathcal{O}}; \mathbb{R}^r)$, endowed with the usual *sup-norm* $|\cdot|_E$.

$B_b(H)$ is the Banach space of bounded Borel functions $\varphi : H \to \mathbb{R}$, endowed with the *sup-norm*

$$\|\varphi\|_0 = \sup_{x \in H} |\varphi(x)|.$$

$C_b(H)$ is the subspace of uniformly continuous functions. Moreover, $\mathrm{Lip}_b(H)$ denotes the subspace of functions φ such that

$$[\varphi]_{\mathrm{Lip}} = \sup_{\substack{x,y \in H \\ x \neq y}} \frac{|\varphi(x) - \varphi(y)|}{|x - y|_H} < \infty.$$

$\mathrm{Lip}_b(H)$ is a Banach space endowed with the norm

$$\|\varphi\|_{\mathrm{Lip}} = \|\varphi\|_0 + [\varphi]_{\mathrm{Lip}}.$$

For each $k \in \mathbb{N}$, we denote by $C_b^k(H)$ the Banach space of k-times Fréchet differentiable functions, endowed with the norm

$$\|\varphi\|_k = \|\varphi\|_0 + \sum_{h=1}^{k} \sup_{x \in H} |D^h \varphi(x)|_{\mathcal{L}^h(H)}.$$

(Here and in what follows $\mathcal{L}^h(H) = \mathcal{L}(H; \mathcal{L}^{h-1}(H))$, $h \ge 1$, and $\mathcal{L}^0(H) = \mathbb{R}$.) Finally, for any $k \in \mathbb{N}$ and $\theta \in (0,1)$, we denote by $C_b^{k+\theta}(H)$ the subspace of all functions $\varphi \in C_b^k(H)$ such that

$$[\varphi]_{k+\theta} = \sup_{\substack{x,y \in H \\ x \neq y}} \frac{\left|D^k \varphi(x) - D^k \varphi(y)\right|_{\mathcal{L}^k(H)}}{|x - y|_H^\theta} < \infty.$$

$C_b^{k+\theta}(H)$ is a Banach space endowed with the norm

$$\|\varphi\|_{k+\theta} = \|\varphi\|_k + [\varphi]_{k+\theta}.$$

In what follows we shall assume that for any $\xi \in \overline{\mathcal{O}}$ and $\sigma = (\sigma_1, \dots, \sigma_r) \in \mathbb{R}^r$

$$f_k(\xi, \sigma_1, \dots, \sigma_r) = g_k(\xi, \sigma_k) + h_k(\xi, \sigma_1, \dots, \sigma_r), \qquad k = 1, \dots, r.$$

The functions $g_k : \overline{\mathcal{O}} \times \mathbb{R} \to \mathbb{R}$ and $h_k : \overline{\mathcal{O}} \times \mathbb{R}^r \to \mathbb{R}$ are continuous. Moreover, they are assumed to fulfill the following conditions.

Hypothesis 1.

1. *For any $\xi \in \overline{\mathcal{O}}$, the function $h_k(\xi, \cdot)$ is of class C^2 and has bounded derivatives, uniformly with respect to $\xi \in \overline{\mathcal{O}}$. Moreover, the mappings $D_\sigma^j h_k : \overline{\mathcal{O}} \times \mathbb{R}^r \to \mathbb{R}$ are continuous for $j = 1, 2$.*
2. *For any $\xi \in \overline{\mathcal{O}}$, the function $g_k(\xi, \cdot)$ is of class C^2, and there exists $m \geq 0$ such that*

$$\sup_{\xi \in \overline{\mathcal{O}}} \sup_{t \in \mathbb{R}} \frac{|D_t^j g_k(\xi, t)|}{1 + |t|^{2m+1-j}} < \infty.$$

   Moreover, the mappings $D_t^j g_k : \overline{\mathcal{O}} \times \mathbb{R} \to \mathbb{R}$ are continuous for $j = 1, 2$.
3. *If $m \geq 1$, there exist $a > 0$ and $c \in \mathbb{R}$ such that*

$$\sup_{\xi \in \overline{\mathcal{O}}} D_t g_k(\xi, t) \leq -a\, t^{2m} + c, \qquad t \in \mathbb{R}. \tag{2.1}$$

Notice that if c_k and c_{kj} are continuous functions from $\overline{\mathcal{O}}$ into $\mathbb{R}$ for $k = 1, \dots, r$ and $j = 1, \dots, 2m$, and

$$\inf_{\xi \in \overline{\mathcal{O}}} c_k(\xi) > 0,$$

then, for any $k = 1, \dots, r$, the function

$$g_k(\xi, t) = c_k(\xi)\, t^{2m+1} + \sum_{j=1}^{2m} c_{kj}(\xi)\, t^j$$

fulfills the conditions of the Hypothesis 1.

Now we define the operator F by setting for any function $x : \overline{\mathcal{O}} \to \mathbb{R}^r$

$$F(x)(\xi) = f(\xi, x(\xi)), \qquad \xi \in \overline{\mathcal{O}}.$$

If we set $p_\star = 2m+2$ and $q_\star = (2m+2)/(2m+1)$, then F is continuous from $L^{p_\star}(\mathcal{O}; \mathbb{R}^r)$ into $L^{q_\star}(\mathcal{O}; \mathbb{R}^r)$, and if $m \geq 1$, it is twice Fréchet differentiable. In particular, from (2.1) and the mean-value theorem for $x, y \in L^{p_\star}(\mathcal{O}; \mathbb{R}^r)$, it holds that

$$\langle F(x) - F(y), x - y \rangle_H \leq c\, |x - y|_H^2. \tag{2.2}$$

In the same way, we have that the functional F is twice differentiable and dissipative from E into itself. (For more details on the properties of F we refer to [7] and [9].) Notice that due to the growth conditions on f, the functional F is not even well defined in H.

As in [9], we can construct a sequence of functionals $\{F_\alpha\}_\alpha$ which are Lipschitz continuous both in H and in E and such that for any $x, y \in H$

$$\langle F_\alpha(x) - F_\alpha(y), x - y\rangle_H \le c\,|x-y|_H^2 \tag{2.3}$$

for a suitable constant c independent of $\alpha > 0$. Moreover, they are twice Fréchet differentiable in E and for each $j \le 2$ and $R > 0$

$$\lim_{\alpha\to 0} \sup_{|x|_E \le R} |D^j F_\alpha(x) - D^j F(x)|_{\mathcal{L}^j(E)} = 0.$$

Concerning the differential operator $\mathcal{A} = (\mathcal{A}_1, \dots, \mathcal{A}_r)$, we assume that for any $k = 1, \dots, r$

$$\mathcal{A}_k(\xi, D) = \sum_{i,j=1}^d a_{ij}^k(\xi)\frac{\partial^2}{\partial\xi_i\partial\xi_j} + \sum_{i=1}^d b_i^k(\xi)\frac{\partial}{\partial\xi_i}, \qquad \xi \in \overline{\mathcal{O}}.$$

The coefficients a_{ij}^k and b_i^k are of class $C^1(\overline{\mathcal{O}})$, and for any $\xi \in \overline{\mathcal{O}}$ the matrix $[a_{ij}^k(\xi)]$ is symmetric and strictly positive, uniformly with respect to $\xi \in \overline{\mathcal{O}}$. The boundary operators $\mathcal{B}_k$ are given by

$$\mathcal{B}_k(\xi, D) = I \quad \text{or} \quad \mathcal{B}_k(\xi, D) = \sum_{i,j=1}^d a_{ij}^k(\xi)\nu_j(\xi)\frac{\partial}{\partial\xi_i}, \quad \xi \in \overline{\mathcal{O}},$$

where ν is the exterior normal to the boundary of $\mathcal{O}$.

We denote by A the realization in H of the differential operator $\mathcal{A}$ equipped with the boundary conditions $\mathcal{B}$. The unbounded operator $A : D(A) \subset H \to H$ generates an analytic semigroup $e^{t\,A}$, which is not restrictive to assume of negative type. Thus we have

$$\langle Ax, x\rangle_H \le 0, \qquad x \in D(A). \tag{2.4}$$

Notice that each $L^p(\mathcal{O}; \mathbb{R}^r)$, $p \in [1, +\infty]$, is invariant for the semigroup $e^{t\,A}$, and if $p > 1$, then $e^{t\,A}$ is analytic in $L^p(\mathcal{O}; \mathbb{R}^r)$. Moreover, E is invariant for $e^{t\,A}$ as well, and $e^{t\,A}$ generates an analytic semigroup in E which is not strongly continuous. (For the proofs of these facts we refer to [15] and [27].)

Now, for any $k = 1, \dots, r$ we define

$$\mathcal{G}_k(\xi, D) = \sum_{i=1}^d \left(b_i^k(\xi) - \sum_{j=1}^d \frac{\partial a_{ij}^k}{\partial\xi_j}(\xi) \right) \frac{\partial}{\partial\xi_i}, \qquad \xi \in \overline{\mathcal{O}},$$

and by difference we set $\mathcal{C}_k = \mathcal{A}_k - \mathcal{G}_k$. The realization C of the operator $\mathcal{C} = (\mathcal{C}_1, \dots, \mathcal{C}_r)$ with the boundary conditions $\mathcal{B}$ generates in H a self-adjoint analytic semigroup $e^{t\,C}$. In what follows we denote by Q the bounded linear operator of components $Q_1, \dots, Q_r$.

Hypothesis 2.

1. *There exists a complete orthonormal basis* $\{e_k\}$ *in* H *which diagonalizes* C *such that* $\sup_{k\in\mathbb{N}} |e_k|_E < \infty$. *The corresponding set of eigenvalues is denoted by* $\{-\alpha_k\}$.

2. *The bounded linear operator $Q : H \to H$ is nonnegative and diagonal with respect to the complete orthonormal basis $\{e_k\}$ which diagonalizes C. Moreover, if $\{\lambda_k\}$ is the corresponding set of eigenvalues, we have*

$$\sum_{k=1}^{\infty} \frac{\lambda_k^2}{\alpha_k^{1-\gamma}} < +\infty$$

for some $\gamma > 0$.

3. *There exists $\epsilon < 1$ such that*

$$D((-C)^{\frac{\epsilon}{2}}) \subset D(Q^{-1}).$$

If the operator $\mathcal{A}$ with the boundary conditions $\mathcal{B}$ is smooth enough, then $\alpha_k \asymp k^{2/d}$. Thus, if we assume that $\lambda_k \asymp \alpha_k^{-\rho}$, when $d \leq 3$ it is possible to find some ρ such that the conditions of Hypothesis 2 are verified. (For more details see [7] and [8].)

In what follows we shall denote by P_n the projection operator of H onto H_n, the subspace generated by the eigenfunctions $\{e_1, \dots, e_n\}$. Then for any $x \in H$ we define $A_n x = P_n A P_n x$ and $F_{\alpha,n}(x) = P_n(F_\alpha(P_n x))$. It is immediate to check that there exists a constant c independent of $\alpha > 0$ and $n \in \mathbb{N}$ such that

$$\langle F_{\alpha,n}(x) - F_{\alpha,n}(y), x - y \rangle_H \leq c\,|x - y|_H^2. \tag{2.5}$$

Next, let $\{w_k(t)\}$ be a sequence of mutually independent real-valued Brownian motions defined on a stochastic basis $(\Omega, \mathcal{F}, \mathcal{F}_t, \mathbb{P})$. The cylindrical Wiener process $w(t)$ is formally defined as

$$\sum_{k=1}^{\infty} e_k w_k(t),$$

where $\{e_k\}$ is the orthonormal basis of H introduced in Hypothesis 2(1). Under the Hypotheses 2(1) and 2(2) it is possible to show that the linear problem associated with the system (1.1),

$$dz(t) = Az(t)\,dt + Q\,dw(t), \qquad z(0) = 0, \tag{2.6}$$

admits a unique solution $w^A(t)$ which is the mean-square Gaussian process with values in H given by

$$w^A(t) = \int_0^t e^{(t-s)\,A} Q\,dw(s).$$

As shown, for example, in [14], the process w^A belongs to $C([0, +\infty) \times \overline{\mathcal{O}})$, $\mathbb{P}$ almost surely (a.s), and for any $p \geq 1$ and $T > 0$ it holds that

$$\mathbb{E} \sup_{t \in [0,T]} |w^A|_E^p < \infty. \tag{2.7}$$

3. The transition semigroup. By using the notations introduced in the previous section, the system (1.1) can be rewritten as

$$dy(t) = [Ay(t) + F(y(t)) + z(t)]\,dt + Q\,dw(t), \qquad y(0) = x. \tag{3.1}$$

The following theorem is proved in [14] in the uncontrolled case. The proof in the controlled case is analogous; thus we omit it. (For more details we refer also to [7] and [8].)

THEOREM 3.1. *Assume Hypotheses* 1 *and* 2.

1. *For any* $x \in E$ *and for any adapted process* $z \in L^2(\Omega; L^p(0,+\infty;H))$ *with* $p > 4/(4-d)$, *there exists a unique* mild *solution* $y(\cdot;x,z)$ *for the problem* (3.1) *which belongs to* $L^2(\Omega; C((0,T];E) \cap L^\infty(0,T;E))$, *for any* $T > 0$. *This means that*

$$y(t;x,z) = e^{t\,A}x + \int_0^t e^{(t-s)\,A} F(y(s;x,z))\,ds + w^A(t), \tag{3.2}$$

where $w^A(t)$ *is the solution of the linear system* (2.6). *Moreover, it holds that*

$$|y(t;x,z)|_E \le c(t)\left(|x|_E + |z|^{2m+1}_{L^p(0,+\infty;H)} + \sup_{s\in[0,t]} |w^A(s)|^{2m+1}_E\right), \tag{3.3}$$

$\mathbb{P}$-*a.s. for a suitable continuous increasing function* $c(t)$.

2. *For any* $x \in H$ *and for any adapted process* $z \in L^2(\Omega; L^2(0,+\infty;H))$, *there exists a unique* generalized *solution* $y(\cdot;x,z) \in L^2(\Omega; C([0,+\infty);H))$ *for the problem* (3.1). *This means that for any sequence* $\{z_n\} \subset L^2(\Omega; L^p(0,+\infty;H))$ *converging to* z *in* $L^2(\Omega; L^2(0,+\infty;H))$ *and for any sequence* $\{x_n\} \subset E$ *converging to* x *in* H, *the corresponding sequence of mild solutions* $\{y(\cdot;x_n,z_n)\}$ *converges to the process* $y(\cdot;x,z)$ *in* $C([0,T];H)$, $\mathbb{P}$-*a.s., for any fixed* $T > 0$. *Moreover, it holds that*

$$|y(t;x,z)|_H \le c(t)\left(|x|_H + |z|^{2m+1}_{L^2(0,+\infty;H)} + \sup_{s\in[0,t]} |w^A(s)|^{2m+1}_E\right),$$

$\mathbb{P}$-*a.s., for a suitable continuous increasing function* $c(t)$.

3. *The generalized solution* $y(\cdot;x,z)$ *belongs to* $L^{2m+2}(0,+\infty; L^{2m+2}(\mathcal{O};\mathbb{R}^r))$, $\mathbb{P}$-*a.s., and fulfills the integral equation* (3.2).

4. *For any* $x_1, x_2 \in H$ *and* $z_1, z_2 \in L^2(\Omega; L^2(0,+\infty;H))$ *it holds that*

$$|y(t;x_1,z_1) - y(t;x_2,z_2)|_H \le c(t)\left(|x_1 - x_2|_H + |z_1 - z_2|_{L^2(0,t;H)}\right), \tag{3.4}$$

$\mathbb{P}$-*a.s., for a suitable continuous increasing function* $c(t)$.

Next, for any $\alpha > 0$, we introduce the approximating problem

$$dy(t) = (Ay(t) + F_\alpha(y(t)) + z(t))\,dt + Q\,dw(t), \qquad y(0) = x. \tag{3.5}$$

If $x \in H$ and $z \in L^2(\Omega; L^2(0,+\infty;H))$, the system (3.5) admits a unique mild solution $y_\alpha(\cdot;x,z) \in L^2(\Omega; C([0,+\infty);H))$. If $x \in E$ and $z \in L^2(\Omega; L^p(0,+\infty;H))$ with $p > 4/(4-d)$, then $y_\alpha(\cdot;x,z) \in L^2(\Omega; C((0,T];E) \cap L^\infty(0,T;E))$ for any $T > 0$. Moreover, an estimate analogous to (3.3) holds, uniformly with respect to $\alpha > 0$. Namely, there exists an increasing continuous function $c(t)$ independent of α such that

$$|y_\alpha(t;x,z)|_E \le c(t)\left(|x|_E + |z|^{2m+1}_{L^p(0,+\infty;H)} + \sup_{s\in[0,t]} |w^A(s)|^{2m+1}_E\right), \tag{3.6}$$

$\mathbb{P}$-a.s. The following approximation result has been proved already in [9].

PROPOSITION 3.2. *Under the Hypotheses* 1 *and* 2, *for any* $q \ge 1$ *there exists* $p \ge 1$ *such that if* $x \in E$ *and* $z \in L^p(\Omega; L^\infty(0,+\infty;H))$, *then it holds that*

$$\lim_{\alpha\to 0} \mathbb{E}\,|y(t;x,z) - y_\alpha(t;x,z)|^q_E = 0, \qquad \mathbb{P}\text{-}a.s., \tag{3.7}$$

uniformly with respect to (t,x) *in bounded sets of* $[0,+\infty)\times E$ *and* z *in the set*

$$\mathcal{M}_R^2=\left\{ z\in L^2(\Omega;L^2(0,+\infty;H)) \ : \ \sup_{t\geq 0}|z(t)|_H\leq R, \quad \mathbb{P}\text{-}a.s. \right\} \tag{3.8}$$

for any $R\geq 0$.

For any $\alpha>0$ and $n\in\mathbb{N}$, we denote by $y_{\alpha,n}(\cdot;x,z)$ the unique strong solution in $L^2(\Omega;C([0,+\infty);H))$ of the approximating problem

$$dy(t)=(A_ny(t)+F_{\alpha,n}(y(t))+P_nz(t))\,dt+Q_ndw(t), \qquad y(0)=P_nx, \tag{3.9}$$

with $x\in H$ and $z\in L^2(\Omega;L^2(0,+\infty;H))$ adapted. In [9, Lemma 3.4] we have shown that for any fixed $R,T>0$

$$\lim_{n\to+\infty}\sup_{|x|_H\leq R}|y_{\alpha,n}(\cdot;x,z)-y_\alpha(\cdot;x,z)|_{L^2(\Omega;C([0,T];H))}=0. \tag{3.10}$$

Moreover, we have

$$|y_{\alpha,n}(t;x,z)|_H\leq c(t)\left(|x|_H+|z|^{2m+1}_{L^2(0,+\infty;H)}+\sup_{s\in[0,t]}|w^A(s)|^{2m+1}_E\right), \qquad \mathbb{P}\text{-a.s.} \tag{3.11}$$

In what follows we shall denote by $y(t;x)$ the solution of (3.1) with $z=0$. In [7, Theorem 7.4] we have shown that if $f(\xi,\cdot)$ is k-times differentiable, then for any $t\geq 0$ the mapping

$$E\to L^2(\Omega;E), \qquad x\mapsto y(t;x)$$

is k-times Fréchet differentiable. In particular, the first derivative $Dy(t;x)h$ is the unique solution of the linearized problem

$$\frac{dv}{dt}(t)=Av(t)+DF(y(t;x))v(t), \qquad v(0)=h,$$

and it holds that

$$\sup_{x\in E}|Dy(t;x)h|_H\leq e^{c\,t}|h|_H, \qquad \mathbb{P}\text{-a.s.}$$

If $x,h\in H$, then, as shown in [8], the problem above admits a unique generalized solution $v(t;x,h)$ which is not intended to be the mean-square derivative of $y(t;x)$ in general.

In [6] we have proved that, since F_α and $F_{\alpha,n}$ are Lipschitz continuous, $y_\alpha(t;x)$ and $y_{\alpha,n}(t;x)$ are twice mean-square differentiable with respect to $x\in H$ along any direction $h\in H$. In addition, their derivatives belong to $D(A^{1/2})\subset D(Q^{-1})$ and for any $T>0$

$$\begin{aligned}
&\sup_{x\in H}|Dy_\alpha(\cdot;x)h|_{L^\infty(0,T;H)\cap L^2(0,T;D(A^{1/2}))}\leq c_T|h|_H, \qquad \mathbb{P}\text{-a.s.},\\
&\sup_{x\in H}|Dy_{\alpha,n}(t;x)h|_{L^\infty(0,T;H)\cap L^2(0,T;D(A^{1/2}))}\leq c_T|h|_H, \qquad \mathbb{P}\text{-a.s.},
\end{aligned} \tag{3.12}$$

for a constant c_T which is independent of $\alpha > 0$ and $n \in \mathbb{N}$. In [9, Lemma 4.1] we have also proved that

$$\lim_{\alpha\to 0} \mathbb{E} \sup_{|h|_H\le 1} |Dy(\cdot;x)h - Dy_\alpha(\cdot;x)h|^2_{L^\infty(0,T;H)\cap L^2(0,T;D((-A)^{1/2}))} = 0,$$

uniformly with respect to x in bounded sets of E, and in [9, Lemma 4.2] we have proved that

$$\lim_{n\to+\infty} \mathbb{E} \sup_{|h|_H\le 1} |Dy_\alpha(\cdot;x)h - Dy_{\alpha,n}(\cdot;x)h|^2_{L^\infty(0,T;H)\cap L^2(0,T;D((-A)^{1/2}))} = 0,$$

uniformly with respect to x in bounded sets of H.

Next we define the transition semigroup P_t corresponding to the system (3.1) by setting for any $\varphi \in B_b(H)$ and $x \in H$

$$P_t\varphi(x) = \mathbb{E}\,\varphi(y(t;x)), \qquad t \ge 0.$$

In an analogous way, we define the semigroups P_t^α and $P_t^{\alpha,n}$ associated, respectively, to the systems (3.5) and (3.9). Due to (3.7), for any $\varphi \in C_b(H)$ and $R > 0$

$$\lim_{\alpha\to 0} \sup_{|x|_E\le R} |P_t^\alpha\varphi(x) - P_t\varphi(x)| = 0, \tag{3.13}$$

uniformly for t in bounded sets of $[0,+\infty)$. Moreover, due to (3.10) we have that

$$\lim_{n\to+\infty} \sup_{|x|_H\le R} |P_t^{\alpha,n}\varphi(x) - P_t^\alpha\varphi(x)| = 0, \tag{3.14}$$

uniformly for t in bounded sets of $[0,+\infty)$. It is important to notice that all the properties of the semigroup P_t which we are going to describe are fulfilled by the semigroups P_t^α and $P_t^{\alpha,n}$ as well.

From (3.4) it easily follows that P_t maps $C_b(H)$ into itself as a contraction. In general P_t is not strongly continuous in $C_b(H)$. (See [4] for a counter example even in finite dimension.) Nevertheless, as $y(\cdot;x) \in L^2(\Omega; C([0,+\infty);H))$ for any fixed $x \in H$, by the dominated convergence theorem, we have that if $\varphi \in C_b(H)$, then the mapping

$$[0,+\infty) \to \mathbb{R}, \qquad t \mapsto P_t\varphi(x)$$

is continuous. Thus, by proceeding as in [4], we define the generator L of P_t as the unique closed operator $L : D(L) \subset C_b(H) \to C_b(H)$ such that

$$R(\lambda,L)\varphi(x) = \int_0^{+\infty} e^{-\lambda t} P_t\varphi(x)\,dt, \qquad \lambda > 0,$$

for any fixed $\varphi \in C_b(H)$ and $x \in H$. In a similar way we define the generators L_α and $L_{\alpha,n}$ corresponding, respectively, to the semigroups P_t^α and $P_t^{\alpha,n}$.

In [4] it is shown that for any $\varphi \in D(L)$ and $x \in H$ the mapping

$$[0,+\infty) \to \mathbb{R}, \qquad t \mapsto P_t\varphi(x)$$

is differentiable and

$$\frac{d}{dt}P_t\varphi(x) = L(P_t\varphi)(x) = P_t(L\varphi)(x).$$

The same holds for L_α and $L_{\alpha,n}$. In particular, if $\varphi \in C_b^2(H)$, we have that $P_s^{\alpha,n}\varphi \in D(L_{\alpha,n})$, for any $\alpha > 0$, $n \in \mathbb{N}$, and $s \geq 0$, and

$$L_{\alpha,n}(P_s^{\alpha,n}\varphi) = \mathcal{L}_{\alpha,n}(P_s^{\alpha,n}\varphi), \tag{3.15}$$

where the differential operator $\mathcal{L}_{\alpha,n}$ is defined by

$$\mathcal{L}_{\alpha,n}\varphi(x) = \frac{1}{2}\mathrm{Tr}\left[Q_n^2 D^2\varphi(x)\right] + \langle A_n x + F_{\alpha,n}(x), D\varphi(x)\rangle_H, \qquad x \in H. \tag{3.16}$$

Actually, if we define $\psi = \lambda P_s^{\alpha,n}\varphi - \mathcal{L}_{\alpha,n}(P_s^{\alpha,n}\varphi)$ for some $\lambda > 0$, we have that

$$R(\lambda, L_{\alpha,n})\psi(x) = \int_0^{+\infty} e^{-\lambda t}\left[\lambda P_{t+s}^{\alpha,n}\varphi(x) - P_t^{\alpha,n}\mathcal{L}_{\alpha,n}(P_s^{\alpha,n}\varphi)(x)\right] dt.$$

It is not difficult to prove that, in general, if φ is twice differentiable, then

$$P_t^{\alpha,n}(\mathcal{L}_{\alpha,n}\varphi)(x) = \mathcal{L}_{\alpha,n}(P_t^{\alpha,n}\varphi)(x).$$

Thus, as $P_s^{\alpha,n}\varphi \in C_b^2(H)$, from the Itô formula we have

$$P_t^{\alpha,n}\mathcal{L}_{\alpha,n}(P_s^{\alpha,n}\varphi)(x) = \mathcal{L}_{\alpha,n}\left(P_{t+s}^{\alpha,n}\varphi\right)(x) = \frac{d}{dt}(P_{t+s}^{\alpha,n}\varphi(x)).$$

This allows us to conclude that

$$R(\lambda, L_{\alpha,n})\psi(x) = -\int_0^{+\infty} \frac{d}{dt}(e^{-\lambda t}P_{t+s}^{\alpha,n}\varphi(x))\, dt = P_s^{\alpha,n}\varphi(x),$$

so that $P_s^{\alpha,n}\varphi \in D(L_{\alpha,n})$ and (3.15) holds.

In [8] we have proved that the semigroup P_t has a smoothing effect. Namely, it maps $B_b(H)$ into $C_b^1(H)$ for any $t > 0$, and for $i \leq j = 0, 1$ it holds that

$$\|P_t\varphi\|_j \leq c\,(t \wedge 1)^{-\frac{(j-i)(1+\epsilon)}{2}}\|\varphi\|_i, \tag{3.17}$$

where ϵ is the constant introduced in Hypothesis 2(3). As far as the semigroups P_t^α and $P_t^{\alpha,n}$ are concerned, in [6] it is proved that they map $B_b(H)$ into $C_b^2(H)$ for any $t > 0$, and

$$\|P_t^\alpha\varphi\|_j + \|P_t^{\alpha,n}\varphi\|_j \leq c_\alpha\,(t \wedge 1)^{-\frac{(j-i)(1+\epsilon)}{2}}\|\varphi\|_i \tag{3.18}$$

for any $i \leq j \leq 2$, for some constant c_α independent of n. Moreover, if $i \leq j \leq 1$, the constant c_α is independent of α as well.

We conclude, recalling that in [9] it has been proved that if $\varphi \in C_b(H)$, then for any $R > 0$

$$\lim_{\alpha\to 0}\sup_{|x|_E \leq R}|D(P_t^\alpha\varphi)(x) - D(P_t\varphi)(x)|_H = 0, \tag{3.19}$$

uniformly for t in bounded sets of $[\delta, +\infty)$ with $\delta > 0$. Moreover, it has been proved that

$$\lim_{n\to+\infty}\sup_{|x|_H \leq R}|D(P_t^{\alpha,n}\varphi)(x) - D(P_t^\alpha\varphi)(x)|_H = 0, \tag{3.20}$$

uniformly for t in bounded sets of $[\delta, +\infty)$ with $\delta > 0$.

4. The Hamilton–Jacobi equation. We are here concerned with the stationary Hamilton–Jacobi equation

$$\lambda\varphi(x) - L\varphi(x) + K(D\varphi(x)) = g(x), \qquad x \in H. \tag{4.1}$$

Our aim is to show that such an equation admits a unique solution $\varphi(\lambda, g)$ for any $\lambda > 0$ and $g \in C_b(H)$. To this purpose we first prove a regularity result for the elements of $D(L)$.

LEMMA 4.1. *Assume Hypotheses* 1 *and* 2. *Then* $D(L) \subset C_b^1(H)$, *and for any* $\lambda > 0$ *and* $g \in C_b(H)$ *it holds that*

$$\|R(\lambda, L)g\|_1 \le \rho(\lambda)\|g\|_0, \tag{4.2}$$

where $\rho(\lambda) = c(\lambda^{\frac{\epsilon-1}{2}} + \lambda^{-1})$.

Proof. We recall that if $\varphi \in C_b(H)$, then $P_t\varphi \in C_b^1(H)$ for any $t > 0$. Thus for any $x, h \in H$ and $\lambda > 0$ we have

$$R(\lambda, L)g(x+h) - R(\lambda, L)g(x) = \int_0^{+\infty} e^{-\lambda t}(P_t g(x+h) - P_t g(x))\, dt$$

$$= \int_0^{+\infty} e^{-\lambda t} \langle D(P_t g)(x), h\rangle_H \, dt + E(x, h),$$

where

$$E(x, h) = \int_0^{+\infty} e^{-\lambda t} \int_0^1 \langle D(P_t g)(x + \theta h) - D(P_t g)(x), h\rangle_H \, d\theta \, dt.$$

Due to (3.17) we have

$$\left| \int_0^{+\infty} e^{-\lambda t} \langle D(P_t g)(x), h\rangle_H \, dt \right|$$

$$\le c \int_0^{+\infty} e^{-\lambda t}(t \wedge 1)^{-\frac{1+\epsilon}{2}} \, dt \, |h|_H \, \|g\|_0 = c \left(\lambda^{\frac{\epsilon-1}{2}} + \lambda^{-1}\right) |h|_H \, \|g\|_0.$$

Moreover, as $D(P_t g)$ is continuous in H, by the dominated convergence theorem we easily have that

$$\lim_{|h|_H \to 0} \frac{|E(x, h)|}{|h|_H} = 0.$$

This implies that $R(\lambda, L)g \in C_b^1(H)$, and for any $x, h \in H$

$$\langle D(R(\lambda, L)g)(x), h\rangle_H = \int_0^{+\infty} e^{-\lambda t} \langle D(P_t g)(x), h\rangle_H \, dt \tag{4.3}$$

so that the estimate (4.2) holds true. □

Remark 4.2. Notice that due to (3.18) we can repeat the arguments used above, and we can show that both $D(L_\alpha)$ and $D(L_{\alpha,n})$ are contained in $C_b^1(H)$, and a formula analogous to (4.3) holds for the derivatives of $R(\lambda, L_\alpha)g$ and $R(\lambda, L_{\alpha,n})g$ when $g \in C_b(H)$. In particular, it holds that

$$\|R(\lambda, L_\alpha)g\|_1 + \|R(\lambda, L_{\alpha,n})g\|_1 \le \rho(\lambda)\|g\|_0. \tag{4.4}$$

Moreover, as

$$\|P_t^\alpha\varphi\|_i + \|P_t^{\alpha,n}\varphi\|_i \le c_\alpha\,(t\wedge 1)^{-\frac{(i-j)(1+\epsilon)}{2}}\|\varphi\|_j, \qquad j\le i\le 2,$$

for a constant c_α independent of $n\in\mathbb{N}$, by interpolation we have that for any $\theta_1,\theta_2\in[0,1]$

$$\|P_t^\alpha\varphi\|_{1+\theta_1} + \|P_t^{\alpha,n}\varphi\|_{1+\theta_1} \le c_\alpha\,(t\wedge 1)^{-\frac{(\theta_1-\theta_2+1)(1+\epsilon)}{2}}\|\varphi\|_{\theta_2}.$$

By proceeding as in the proof of the previous lemma, this implies that if $\varphi\in C_b^{\theta_2}(H)$, then $R(\lambda,L_\alpha)\varphi$ and $R(\lambda,L_{\alpha,n})\varphi$ are in $C_b^{1+\theta_1}(H)$ for any $\theta_1<\theta_2+(1-\epsilon)/(1+\epsilon)$ and

$$\|R(\lambda,L_\alpha)\varphi\|_{1+\theta_1} + \|R(\lambda,L_{\alpha,n})\varphi\|_{1+\theta_1} \le c_\alpha\left(\lambda^{\frac{(\theta_1-\theta_2+1)(\epsilon+1)}{2}-1}+\lambda^{-1}\right)\|g\|_{\theta_2}. \tag{4.5}$$

In particular, we have that $D(L_\alpha)$ and $D(L_{\alpha,n})$ are contained in $C_b^{1+\theta}(H)$ for any $\theta<(1-\epsilon)/(\epsilon+1)$.

4.1. Lipschitz hamiltonian K. In the proof of the existence and uniqueness of solutions for the problem (4.1) we proceed in several steps. First we assume the Lipschitz continuity of the hamiltonian K.

Hypothesis 3. *The mapping $K:H\to\mathbb{R}$ is Fréchet differentiable and Lipschitz continuous together with its derivative. Moreover, $K(0)=0$.*

Notice that the condition $K(0)=0$ is not restrictive, as we can substitute g by $g-K(0)$.

By using the Lemma 4.1 we get the following result.

PROPOSITION 4.3. *Under Hypotheses* 1, 2, *and* 3, *there exists $\lambda_0>0$ such that* (4.1) *admits a unique solution $\varphi(\lambda,g)\in C_b^1(H)$ for any $\lambda>\lambda_0$ and for any $g\in C_b(H)$.*

Proof. The equation (4.1) is equivalent to the equation

$$\varphi = R(\lambda,L)\,(g-K(D\varphi)) = \Gamma(\lambda,g)(\varphi).$$

Due to Lemma 4.1, if $\varphi\in C_b^1(H)$ and $g\in C_b(H)$, then $\Gamma(\lambda,g)(\varphi)\in C_b^1(H)$. Thus if we show that for some $\lambda_0>0$ the mapping $\Gamma(\lambda,g)$ is a contraction in $C_b^1(H)$ for any $\lambda>\lambda_0$, our thesis follows.

As K is Lipschitz continuous for any $\varphi_1,\varphi_2\in C_b^1(H)$, we have

$$\|R(\lambda,L)(K(D\varphi_1)-K(D\varphi_2))\|_1 \le c\,\rho(\lambda)\|\varphi_1-\varphi_2\|_1.$$

Thus, if we choose λ_0 such that $c\rho(\lambda_0)=1$, we have that $\Gamma(\lambda,g)$ is a contraction in $C_b^1(H)$ for any $\lambda>\lambda_0$. This implies that it admits a unique fixed point $\varphi\in C_b^1(H)$, which is the unique solution of (4.1) in $C_b^1(H)$. □

Remark 4.4. By using (4.4) it is possible to prove that there exists $\lambda_0>0$ sufficiently large such that the mappings

$$\Gamma_\alpha(\lambda,g)(\varphi) = R(\lambda,L_\alpha)(g-K(D\varphi)), \qquad \alpha>0,$$

are contractions in $C_b^1(H)$ for any $\lambda>\lambda_0$ and for any $g\in C_b(H)$, and the approximating Hamilton–Jacobi equations

$$\lambda\varphi - L_\alpha\varphi + K(D\varphi) = g \tag{4.6}$$

admit a unique solution $\varphi_\alpha(\lambda, g) \in C_b^1(H)$. Moreover, as the function $\rho(\lambda)$ in (4.4) does not depend on $\alpha > 0$, the constant λ_0 does not depend on α either.

LEMMA 4.5. *Under Hypotheses* 1, 2, *and* 3, *for any* $\lambda > 0$ *and* $g \in C_b(H)$ *we have*

$$\lim_{\alpha\to 0} \sup_{|x|_E \le R} \left| D^j \left(\Gamma_\alpha^k(\lambda, g)(0) - \Gamma^k(\lambda, g)(0) \right)(x) \right|_{\mathcal{L}^j(H)} = 0, \qquad j = 0, 1, \tag{4.7}$$

for any $k \in \mathbb{N}$ *and* $R > 0$.

Proof. We proceed by induction. For $k = 1$ the limit (4.7) is trivially verified. Assume that (4.7) holds for some $k \ge 1$. We show that this implies that (4.7) holds for $k + 1$. We have

$$\begin{aligned} &D^j \left(\Gamma_\alpha^{k+1}(\lambda, g)(0) - \Gamma^{k+1}(\lambda, g)(0) \right) \\ &= D^j \left(R(\lambda, L_\alpha) \left[g - K \left(D(\Gamma_\alpha^k(\lambda, g)(0)) \right) \right] - R(\lambda, L) \left[g - K \left(D(\Gamma^k(\lambda, g)(0)) \right) \right] \right). \end{aligned}$$

In general, if $f \in C_b(H)$ and $\{f_\alpha\}$ is any bounded generalized sequence of $C_b(H)$ such that for any $R > 0$

$$\lim_{\alpha\to 0} \sup_{|x|_E \le R} |f_\alpha(x) - f(x)| = 0, \tag{4.8}$$

then for any $R > 0$ and $j = 0, 1$ we have

$$\lim_{\alpha\to 0} \sup_{|x|_E \le R} |D^j (R(\lambda, L_\alpha)(f_\alpha - f))(x)|_H = 0. \tag{4.9}$$

Indeed, as the formula (4.3) holds for the derivative of $R(\lambda, L_\alpha)$, as well, for any $x \in H$ we have

$$D^j (R(\lambda, L_\alpha)(f_\alpha - f))(x) = \int_0^{+\infty} e^{-\lambda t} D^j \left(P_t^\alpha (f_\alpha - f) \right)(x)\, dt.$$

If x lies in a bounded set of E, due to (2.7) and (3.6) the solution $y_\alpha(t; x)(\omega)$ lies in a bounded set of E for $\mathbb{P}$-almost all $\omega \in \Omega$. Therefore, by (4.8) for any $R > 0$ this yields

$$\lim_{\alpha\to 0} \sup_{|x|_E \le R} |(f_\alpha - f)(y_\alpha(t; x))| = 0, \qquad \mathbb{P}\text{-a.s.}, \tag{4.10}$$

and by applying the dominated convergence theorem we get (4.9) for $j = 0$. As proved in [5], for any $t > 0$ we have

$$\langle D(P_t^\alpha (f_\alpha - f))(x), h \rangle_H = \frac{1}{t} \mathbb{E} \left(f_\alpha - f \right)(y_\alpha(t; x)) \int_0^t \left\langle Q^{-1} D y_\alpha(s; x) h, dw(s) \right\rangle_H,$$

where $D y_\alpha(t; x) h$ is the mean-square derivative of $y_\alpha(t; x)$ along the direction $h \in H$. Hence, thanks to (3.12), by interpolation we easily get

$$|D(P_t^\alpha (f_\alpha - f))(x)|_H \le c\, (t \wedge 1)^{-\frac{1+\epsilon}{2}} \left(\mathbb{E} \left| (f_\alpha - f)(y_\alpha(t; x)) \right|^2 \right)^{1/2},$$

and, thanks to (4.10), this implies (4.9) for $j = 1$.

Thus, since from the inductive hypothesis and the Lipschitz continuity of K the sequence $\{K(D[\Gamma^k_\alpha(\lambda,g)(0)])\}$ and $K(D[\Gamma^k(\lambda,g)(0)])$ fulfill (4.8), we can conclude that for any $R>0$

(4.11)
$$\lim_{\alpha\to0}\sup_{|x|_E\le R}\left|D^j\left(R(\lambda,L_\alpha)\left[K(D[\Gamma^{k+1}_\alpha(\lambda,g)(0)]))-K(D[\Gamma^{k+1}_\alpha(\lambda,g)(0)])\right]\right)(x)\right|=0.$$

Now, if $f\in C^1_b(H)$, for any $x\in H$ we have

$$D^j\left[(R(\lambda,L_\alpha)-R(\lambda,L))\,(g-K(Df))\right](x)$$

$$=\int_0^{+\infty}e^{-\lambda\,t}D^j\left[(P^\alpha_t-P_t)(g-K(Df))\right](x)\,dt.$$

Then, by using the estimates (3.17) and (3.18) and the limits (3.13) and (3.19), we get that

$$\lim_{\alpha\to0}\sup_{|x|_E\le R}\left|D^j\left[(R(\lambda,L_\alpha)-R(\lambda,L))\,(g-K(Df))\right](x)\right|_H=0$$

for any $R>0$. As $\Gamma^k(\lambda,L)(0)\in C^1_b(H)$, this implies that

$$\lim_{\alpha\to0}\sup_{|x|_E\le R}\left|D^j\left[(R(\lambda,L_\alpha)-R(\lambda,L))\,(g-\Gamma^k(\lambda,g)(0))\right](x)\right|_H=0,$$

and recalling (4.11) we can conclude that

$$\lim_{\alpha\to0}\sup_{|x|_E\le R}\left|D^j\left(\Gamma^{k+1}_\alpha(\lambda,g)(0)-\Gamma^{k+1}(\lambda,g)(0)\right)(x)\right|=0.$$

By induction this yields (4.7). □

In the next proposition we show that the solution $\varphi(\lambda,g)$ of the problem (4.1) can be approximated by the solutions $\varphi_\alpha(\lambda,g)$ of the problems (4.6).

PROPOSITION 4.6. *Assume Hypotheses* 1, 2, *and* 3. *Then, if* λ_0 *is the constant introduced in the Proposition* 4.3, *for any* $\lambda>\lambda_0$ *and* $g\in C_b(H)$ *it holds that*

$$\lim_{\alpha\to0}\sup_{|x|_E\le R}\left|D^j\left(\varphi(\lambda,g)-\varphi_\alpha(\lambda,g)\right)(x)\right|_{\mathcal{L}^j(H)}=0,\qquad j=0,1,\tag{4.12}$$

for any $R>0$. *In particular, for any* $\lambda>0$ *we have*

(4.13)
$$\lim_{\alpha\to0}\sup_{|x|_E\le R}\left|D^j\left[\varphi(\lambda,g)-\varphi_\alpha(\lambda+\lambda_0,g+\lambda_0\,\varphi(\lambda,g))\right](x)\right|_{\mathcal{L}^j(H)}=0,\qquad j=0,1.$$

Proof. Let us fix λ_0 as in Proposition 4.3. We have seen that $\varphi=\varphi(\lambda,g)$ and $\varphi_\alpha=\varphi_\alpha(\lambda,g)$ are, respectively, the unique fixed points of the mappings $\Gamma(\lambda,g)$ and $\Gamma_\alpha(\lambda,g)$. Since for any $\lambda>\lambda_0$ and $g\in C_b(H)$ the contraction constants of $\Gamma_\alpha(\lambda,g)$ are the same for all $\alpha>0$, for any $\epsilon>0$ there exists $k_\epsilon\in\mathbb{N}$ such that

$$\|\Gamma^{k_\epsilon}(\lambda,g)(0)-\varphi\|_1+\sup_{\alpha>0}\|\Gamma^{k_\epsilon}_\alpha(\lambda,g)(0)-\varphi_\alpha\|_1\le\epsilon.$$

Thus for $j=0,1$ and $x\in H$ we have

$$\left|D^j\left(\varphi-\varphi_\alpha\right)(x)\right|\le\epsilon+\left|D^j\left(\Gamma^{k_\epsilon}(\lambda,g)(0)-\Gamma^{k_\epsilon}_\alpha(\lambda,g)(0)\right)(x)\right|,$$

and due to (4.7) this implies (4.12). Now, since $\varphi(\lambda, g) = \varphi(\lambda + \lambda_0, g + \lambda_0\, \varphi(\lambda, g))$, by using (4.12) we can conclude that (4.13) holds true. □

Remark 4.7. For any $\alpha > 0$ and $n \in \mathbb{N}$, consider the problem

$$\lambda\varphi - L_{\alpha,n}\varphi + K_n(D\varphi) = g_n, \tag{4.14}$$

where $K_n(x) = K(P_n x)$ and $g_n(x) = g(P_n x)$ for each $n \in \mathbb{N}$ and $x \in H$. By proceeding as for the problems (4.1) and (4.6), it is possible to show that there exists λ_0 large enough such that for any $g \in C_b(H)$ and $\lambda > \lambda_0$ there exists a unique solution $\varphi_{\alpha,n}(\lambda, g) \in C_b^1(H)$. Such a solution is given by the unique fixed point of the mapping

$$\Gamma_{\alpha,n}(\lambda, g)(\varphi) = R(\lambda, L_{\alpha,n})(g_n - K_n(D\varphi)).$$

By using arguments analogous to those used in the Lemma 4.5, due to the estimates (3.11) and (3.18), and due to the limits (3.14) and (3.20), there exists $\lambda_0 > 0$ such that for $\lambda > \lambda_0$ and $g \in C_b(H)$ it holds that

$$\lim_{n\to+\infty} \sup_{|x|_H \le R} \left| D^j \left(\Gamma_{\alpha,n}^k(\lambda, g)(0) - \Gamma_\alpha^k(\lambda, g)(0) \right)(x) \right|_{\mathcal{L}^j(H)} = 0, \qquad j = 0, 1,$$

for any $\alpha > 0$, $k \in \mathbb{N}$, and $R > 0$. Thus, by proceeding as in the proof of Proposition 4.6, due to (3.14) and (3.20) it is possible to verify that there exists $\lambda_0 > 0$ such that if $\lambda > \lambda_0$, then for any $\alpha > 0$, and $R > 0$ it holds that

$$\lim_{n\to+\infty} \sup_{|x|_H \le R} \left| D^j \left[\varphi_\alpha(\lambda, g) - \varphi_{\alpha,n}(\lambda, g) \right](x) \right|_{\mathcal{L}^j(H)} = 0. \tag{4.15}$$

In the next proposition we show that if the datum g belongs to $C_b^1(H)$, then the approximating problems (4.6) and (4.14) have a solution of class C^2.

LEMMA 4.8. *Under Hypotheses* 1, 2, *and* 3, *if* $g \in C_b^1(H)$ *and* $\lambda > 0$, *then the solutions* $\varphi_\alpha(\lambda, g)$ *and* $\varphi_{\alpha,n}(\lambda, g)$ *of the problems* (4.6) *and* (4.14) *belong to* $C_b^2(H)$. *Moreover, for any* $R > 0$ *and* $\lambda > 0$

$$\sup_{\|g\|_1 \le R} \|\varphi_\alpha(\lambda, g)\|_2 < \infty. \tag{4.16}$$

Proof. We prove the lemma only for the problem (4.6), as the proof for the problem (4.14) is identical.

As shown in Remark 4.2, $D(L_\alpha) \subset C_b^{1+\theta}(H)$ for any $\theta < (1-\epsilon)/(1+\epsilon)$. Thus, if $\varphi_\alpha(\lambda, g)$ is the solution of the problem (4.6), we have that $\varphi_\alpha(\lambda, g) \in C_b^{1+\theta_0}(H)$ for some $0 < \theta_0 < (1-\epsilon)/(1+\epsilon)$. As we have

$$\varphi_\alpha(\lambda, g) = R(\lambda, L_\alpha)\left(g - K(D\varphi_\alpha(\lambda, g))\right),$$

by using again Remark 4.2 it follows that $\varphi_\alpha(\lambda, g) \in C_b^{1+2\,\theta_0}(H)$. Therefore, by repeating this argument a finite number of steps we get that $\varphi_\alpha(\lambda, g) \in C_b^2(H)$.

The estimate (4.16) follows as above by applying (4.5) a finite number of times. □

Due to (3.15), the previous lemma implies that if $g \in C_b^1(H)$, then $\varphi_{\alpha,n} = \varphi_{\alpha,n}(\lambda, g)$ is a strict solution of the problem (4.14); that is,

$$\lambda\varphi_{\alpha,n} - \mathcal{L}_{\alpha,n}\varphi_{\alpha,n} + K_n(D\varphi) = g_n,$$

where $\mathcal{L}_{\alpha,n}$ is the differential operator introduced in (3.16).

Now, for any $\varphi \in D(L)$ we define

$$N(\varphi) = L\varphi - K(D\varphi). \tag{4.17}$$

In the same way, for any $\alpha > 0$ and $n \in \mathbb{N}$ we define $N_\alpha(\varphi) = L_\alpha\varphi - K(D\varphi)$ and $N_{\alpha,n}(\varphi) = L_{\alpha,n}\varphi - K_n(D\varphi)$.

THEOREM 4.9. *Under Hypotheses* 1, 2, *and* 3, *the operator* N *defined by* (4.17) *is m-dissipative. Thus for any* $\lambda > 0$ *and for any* $g \in C_b(H)$ *there exists a unique solution* $\varphi(\lambda, g) \in D(L)$ *for the problem* (4.1).

Thanks to Proposition 4.3, in order to show that N is m-dissipative, it suffices to show that N is dissipative. To this purpose, we first give the following preliminary result.

LEMMA 4.10. *Assume that Hypotheses* 1, 2, *and* 3 *hold. Then there exists* $\lambda_0 > 0$ *such that for any* $\lambda > \lambda_0$ *and* $\varphi_1, \varphi_2 \in D(L_\alpha)$

$$\|\varphi_1 - \varphi_2\|_0 \le \frac{1}{\lambda}\,\|\lambda(\varphi_1 - \varphi_2) - (N_\alpha(\varphi_1) - N_\alpha(\varphi_2))\|_0\,.$$

Proof. We set $g_1 = \lambda\varphi_1 - N_\alpha(\varphi_1)$ and $g_2 = \lambda\varphi_2 - N_\alpha(\varphi_2)$, and for any $n \in \mathbb{N}$ we set $g_{1,n}(x) = g_1(P_n x)$ and $g_{2,n}(x) = g_2(P_n x)$, $x \in H$. Then for λ large enough there exist $\varphi_{1,n}$ and $\varphi_{2,n}$ in $D(L_{\alpha,n})$ such that

$$\lambda\varphi_{1,n} - N_{\alpha,n}(\varphi_{1,n}) = g_{1,n}, \qquad \lambda\varphi_{2,n} - N_{\alpha,n}(\varphi_{2,n}) = g_{2,n}.$$

If we show that

$$\|\varphi_{1,n} - \varphi_{2,n}\|_0 \le \frac{1}{\lambda}\|g_{1,n} - g_{2,n}\|_0, \tag{4.18}$$

we are done. Actually, for any $x \in H$ this implies that

$$|\varphi_{1,n}(x) - \varphi_{2,n}(x)| \le \frac{1}{\lambda}\|g_{1,n} - g_{2,n}\|_0 \le \frac{1}{\lambda}\|g_1 - g_2\|_0,$$

and due to (4.15) we can take the limit as $n \to +\infty$, and we get

$$|\varphi_1(x) - \varphi_2(x)| \le \frac{1}{\lambda}\|g_1 - g_2\|_0.$$

By taking the supremum for $x \in H$, we can conclude.

Thus in order to conclude the proof we have to show that the operator $N_{\alpha,n}$ fulfills (4.18). The operator $L_{\alpha,n}$ satisfies the same conditions of the operator $\mathcal{L}$ studied in [5]; thus, thanks to [5, Proposition 7.5],

$$D(L_{\alpha,n}) = \left\{ \varphi \in \bigcap_{p\ge 1} W^{2,p}_{\rm loc}(\mathbb{R}^n) \cap C_b(\mathbb{R}^n)\,;\, \mathcal{L}_{\alpha,n}\varphi \in C_b(\mathbb{R}^n) \right\},$$

$$L_{\alpha,n}\varphi = \mathcal{L}_{\alpha,n}\varphi.$$

Now we remark that

$$K_n(D\varphi_{1,n}(x)) - K_n(D\varphi_{2,n}(x))$$

$$= \left\langle \int_0^1 DK_n(\lambda D\varphi_{1,n}(x) + (1-\lambda)D\varphi_{2,n}(x))\,d\lambda, D\varphi_{1,n}(x) - D\varphi_{2,n}(x) \right\rangle;$$

thus, if we set

$$U_{\alpha,n}(x) = \int_0^1 DK_n(\lambda D\varphi_{1,n}(x) + (1-\lambda)D\varphi_{2,n}(x))\,d\lambda,$$

we have

$$\lambda(\varphi_{1,n} - \varphi_{2,n})(x) - \mathcal{L}_{\alpha,n}(\varphi_{1,n} - \varphi_{2,n})(x)$$

$$+ \langle U_{\alpha,n}(x), D(\varphi_{1,n} - \varphi_{2,n})(x)\rangle = g_{1,n}(x) - g_{2,n}(x).$$

Since the function $U_{\alpha,n}$ is uniformly continuous, as $\varphi_{1,n}$ and $\varphi_{2,n}$ belong to $C_b^1(H)$, the operator $\mathcal{N}_{\alpha,n}$ defined by

$$\mathcal{N}_{\alpha,n}\psi(x) = \mathcal{L}_{\alpha,n}\psi(x) - \langle U_{\alpha,n}(x), D\psi(x)\rangle$$

is of the same type as the operator $\mathcal{L}$ studied in [5]. Therefore, we can adapt the proof of [5, Lemma 7.4] to the present situation, and we obtain

$$\|\varphi_{1,n} - \varphi_{2,n}\|_0 \le \frac{1}{\lambda}\|\lambda(\varphi_{1,n} - \varphi_{2,n}) - \mathcal{N}_{\alpha,n}(\varphi_{1,n} - \varphi_{2,n})\|_0 = \frac{1}{\lambda}\|g_{1,n} - g_{2,n}\|_0. \qquad \square$$

Proof of Theorem 4.9. Let us fix $\lambda > 0$ and $\varphi_1, \varphi_2 \in D(L)$, and let us define $g_1 = \lambda\varphi_1 - N(\varphi_1)$ and $g_2 = \lambda\varphi_2 - N(\varphi_2)$. If λ_0 is the maximum between the constant introduced in Remark 4.4 and the constant introduced in Lemma 4.10, for any $\alpha > 0$ there exist $\varphi_{1,\alpha}, \varphi_{2,\alpha} \in D(L_\alpha)$ such that

$$(\lambda + \lambda_0)\,\varphi_{1,\alpha} - N_\alpha\varphi_{1,\alpha} = g_1 + \lambda_0\,\varphi_1, \qquad (\lambda + \lambda_0)\,\varphi_{2,\alpha} - N_\alpha\varphi_{2,\alpha} = g_2 + \lambda_0\,\varphi_2,$$

and

$$\|\varphi_{1,\alpha} - \varphi_{2,\alpha}\|_0 \le \frac{1}{\lambda + \lambda_0}\|(g_1 - g_2) + \lambda_0\,(\varphi_1 - \varphi_2)\|_0.$$

Thus for any $x \in H$ we have

$$|\varphi_{1,\alpha}(x) - \varphi_{2,\alpha}(x)| \le \frac{1}{\lambda + \lambda_0}\|g_1 - g_2\|_0 + \frac{\lambda_0}{\lambda + \lambda_0}\|\varphi_1 - \varphi_2\|_0.$$

Now, if $x \in E$, due to (4.13) we can take the limit in the left-hand side as α goes to zero, and we get

$$|\varphi_1(x) - \varphi_2(x)| \le \frac{1}{\lambda + \lambda_0}\|g_1 - g_2\|_0 + \frac{\lambda_0}{\lambda + \lambda_0}\|\varphi_1 - \varphi_2\|_0.$$

As φ_1 and φ_2 are continuous in H, the estimate above holds also for $x \in H$, and by taking the supremum for $x \in H$ it follows that

$$\|\varphi_1 - \varphi_2\|_0 - \frac{\lambda_0}{\lambda + \lambda_0}\|\varphi_1 - \varphi_2\|_0 \le \frac{1}{\lambda + \lambda_0}\|g_1 - g_2\|_0,$$

so that

$$\|\varphi_1 - \varphi_2\|_0 \le \frac{1}{\lambda}\|g_1 - g_2\|_0. \qquad \square$$

4.2. Locally Lipschitz hamiltonian K. We first prove an a priori estimate which is crucial in order to prove the m-dissipativity of the operator N in the case of a locally Lipschitz hamiltonian K.

PROPOSITION 4.11. *Assume that Hypotheses* 1, 2, *and* 3 *hold. Then there exists some $\mu_0 > 0$, which does not depend on K, such that if $g \in C_b^1(H)$ and $\lambda > \mu_0$, then*

$$\|D\varphi(\lambda, g)\|_0 \le \|Dg\|_0. \tag{4.19}$$

Proof. Let us fix $\lambda, \mu > 0$ and $g \in C_b^1(H)$, and let us consider $\varphi_\alpha = \varphi_\alpha(\lambda + \mu, g + \mu\,\varphi(\lambda, g))$ and $\varphi_{\alpha,n} = \varphi_{\alpha,n}(\lambda + \mu, g + \mu\,\varphi(\lambda, g))$. Since $g \in C_b^1(H)$, then $\varphi_{\alpha,n}$ belongs to $C_b^2(H)$, and it is a strict solution of the problem

$$(\lambda + \mu)\,\varphi - N_{\alpha,n}(\varphi) = g_n + \mu\,\varphi_n(\lambda, g),$$

where $\varphi_n(\lambda, g)(x) = \varphi(\lambda, g)(P_n x)$. The problem above can be rewritten as

$$(\lambda + \mu)\,\varphi(x) - \frac{1}{2}\sum_{h=1}^{n} \lambda_h^2 D_h^2\varphi(x) - \sum_{h,k=1}^{n} a_{hk}x_k D_h\varphi(x)$$

$$- \langle F_\alpha(P_n x), D\varphi(x)\rangle_H + K(P_n D\varphi(x)) = g(P_n x) + \mu\,\varphi(\lambda, g)(P_n x),$$

where $D_h\varphi(x) = \langle D\varphi(x), e_h\rangle_H$ and $a_{hk} = \langle Ae_k, e_h\rangle_H$. By differentiating with respect to x_j, by setting $\psi_h = D_h\varphi$, for $h = 1, \dots, n$, and by multiplying each side by ψ_j, we get

$$(\lambda + \mu)\,\psi_j^2 - \frac{1}{2}\sum_{h=1}^{n} \lambda_h^2 \psi_j D_h^2\psi_j - \sum_{h,k=1}^{n} a_{hk}x_k\psi_j D_h\psi_j - \sum_{h=1}^{n} a_{hj}\psi_h\psi_j$$

$$- \sum_{h=1}^{n} \langle F_{\alpha,n}, e_h\rangle\,\langle \psi_j D\psi_j, e_h\rangle - \sum_{h=1}^{n} \langle DF_{\alpha,n}e_j\psi_j, e_h\rangle\,\psi_h$$

$$+ \sum_{h=1}^{n} D_h K(P_n D\varphi_{\alpha,n})\psi_j D_h\psi_j = \langle Dg_n, e_j\psi_j\rangle + \mu\,\langle D\varphi_n(\lambda, g), e_j\psi_j\rangle\,.$$

Then we sum up over j and by setting $z(x) = |D\varphi_{\alpha,n}(x)|_H^2$ and by taking into account that

$$\left(D_h^2\psi_j\right)\psi_j = \frac{1}{2}D_h^2(\psi_j^2) - (D_h\psi_j)^2,$$

we have

$$2(\lambda + \mu)\,z(x) - \frac{1}{2}\mathrm{Tr}\,\left[Q_n^2 D^2 z(x)\right] + \sum_{h,j=1}^{n} \lambda_h^2 (D_h\psi_j)^2(x) - \langle A_n x, Dz(x)\rangle$$

$$-2\,\langle A_n D\varphi_{\alpha,n}(x), D\varphi_{\alpha,n}(x)\rangle + \langle DK(D\varphi_{\alpha,n}(x)), Dz(x)\rangle - \langle F_\alpha(P_n x), Dz(x)\rangle$$

$$-2\,\langle DF_\alpha(P_n x)D\varphi_{\alpha,n}(x), D\varphi_{\alpha,n}(x)\rangle = 2\,\langle Dg(P_n x) + \mu\,D\varphi(\lambda, g)(P_n x), D\varphi_{\alpha,n}(x)\rangle\,.$$

Therefore, by using (2.3) and (2.4) it follows that

$$2(\lambda+\mu)\,z(x)-\frac{1}{2}\mathrm{Tr}\,\left[Q_n^2D^2z(x)\right]-\langle A_nx,Dz(x)\rangle-\langle F_\alpha(P_nx),Dz(x)\rangle$$

$$+\langle DK(D\varphi_{\alpha,n}(x)),Dz(x)\rangle\le 2\,\langle Dg(x)+\mu\,D\varphi(\lambda,g)(P_nx),D\varphi_{\alpha,n}(P_nx)\rangle+\gamma\,z(x)$$

$$\le 2\,(\|Dg\|_0+\mu\,\|D\varphi(\lambda,g)\|_0)\,|D\varphi_{\alpha,n}(x)|_H+\gamma\,z(x)$$

for a suitable constant $\gamma\in\mathbb{R}$ depending only on F and A.

Now let us consider the equation

$$dy(t)=[A_ny(t)+F_{\alpha,n}(y(t))+U_{\alpha,n}(y(t))]\,dt+Q_n\,dw(t),\qquad y(0)=P_nx, \tag{4.20}$$

where $U_{\alpha,n}(x)=-DK(D\varphi_{\alpha,n}(x))$ for any $x\in H$. If $g\in C_b^1(H)$, then $\varphi_{\alpha,n}\in C_b^2(H)$, and then the mapping $U_{\alpha,n}:H\to H$ is Lipschitz continuous. This implies that there exists a unique strong solution $y_{\alpha,n}(\cdot;x)\in L^2(\Omega;C([0,+\infty);H))$ for (4.20). If we denote by $R_t^{\alpha,n}$ the corresponding transition semigroup, it is possible to show that the solution of the problem

$$(2(\lambda+\mu)-\gamma)\psi(x)-\frac{1}{2}\mathrm{Tr}\,\left[Q_n^2D^2\psi(x)\right]-\langle A_nx,D\psi(x)\rangle-\langle F_\alpha(P_nx),D\psi(x)\rangle$$

$$+\langle DK(D\varphi_{\alpha,n}(x)),D\psi(x)\rangle=2\,(\|Dg\|_0+\mu\,\|D\varphi(\lambda,g)\|_0)\;|D\varphi_{\alpha,n}(x)|_H$$

for any $\lambda>\gamma$ is given by

$$\psi(x)=2\,(\|Dg\|_0+\mu\,\|D\varphi(\lambda,g)\|_0)\int_0^{+\infty}e^{-(2(\lambda+\mu)-\gamma)\,t}R_t^{\alpha,n}\,(|D\varphi_{\alpha,n}|_H)\,(x)\,dt.$$

(See [5] for a proof.) Thus by a comparison argument we have that

$$|D\varphi_{\alpha,n}(x)|_H^2\le\frac{2}{2(\lambda+\mu)-\gamma}\;(\|Dg\|_0+\mu\,\|D\varphi(\lambda,g)\|_0)\,|D\varphi_{\alpha,n}(x)|_H,$$

and if we take $\lambda>1+\gamma/2=\mu_0$, it follows that

$$|D\varphi_{\alpha,n}(\lambda+\mu,g+\mu\,\varphi(\lambda,g))(x)|_H\le\frac{1}{1+\mu}\,(\|Dg\|_0+\mu\,\|D\varphi(\lambda,g)\|_0)\,.$$

Due to (4.13) and (4.15), if μ is large enough, we can take first the limit as n goes to infinity and then the limit as α goes to zero, and for any $x\in E$ we get

$$|D\varphi(x)|_H\le\frac{1}{1+\mu}\,(\|Dg\|_0+\mu\,\|D\varphi(\lambda,g)\|_0)\,.$$

As $\varphi(\lambda,g)\in C_b^1(H)$, the same estimate holds for $x\in H$, and then, by taking the supremum for $x\in H$, we get

$$\|D\varphi(\lambda,g)\|_0\le\frac{1}{1+\mu}\,(\|Dg\|_0+\mu\,\|D\varphi(\lambda,g)\|_0)\,,$$

which immediately yields (4.19). □

Remark 4.12. It is immediate to check that the proof of the previous proposition adapts to the problem (4.6). Thus there exists $\lambda_0 > 0$, which is clearly independent of $\alpha > 0$, such that for any $\lambda > \lambda_0$ and $g \in C_b^1(H)$

$$\|D\varphi_\alpha(\lambda, g)\|_0 \le \|Dg\|_0.$$

From now on we shall assume that K fulfills the following assumption.

Hypothesis 4. *The hamiltonian $K : H \to \mathbb{R}$ is Fréchet differentiable and is locally Lipschitz continuous, together with its derivative. Moreover, $K(0) = 0$.*

We want to show that under the hypotheses above the problem (4.1) admits a unique solution for any $\lambda > \mu_0$ and $g \in C_b^1(H)$. To this purpose, for any $r > 0$ let K_r be a Fréchet differentiable function such that

$$K_r(x) = \begin{cases} K(x) & \text{if } |x|_H \le r, \\ K\left(\dfrac{(r+1)x}{|x|_H}\right) & \text{if } |x|_H > r+1. \end{cases} \tag{4.21}$$

It is immediate to check that K_r is Lipschitz continuous, together with its derivative, for each $r > 0$, and $K_r(x) = K(x)$ if $|x|_H \le r$.

THEOREM 4.13. *Under Hypotheses* 1, 2, *and* 4 *there exists $\mu_0 > 0$ such that for any $\lambda > \mu_0$ and $g \in C_b^1(H)$ there exists a unique solution $\varphi(\lambda, g) \in D(L)$ for the problem* (4.1).

Proof. For any $r > 0$ and $g \in C_b^1(H)$ we define $\varphi_r(\lambda, g)$ as the solution of the problem $\lambda\varphi - L\varphi + K_r(D\varphi) = g$. Due to Proposition 4.11 there exists $\mu_0 > 0$ such that for any $\lambda > \mu_0$

$$\sup_{r>0} \|D\varphi_r(\lambda, g)\|_0 \le \|Dg\|_0.$$

Thus, if we fix $r > \|g\|_1$, we have that $K_r(D\varphi_r(\lambda, g)) = K(D\varphi_r(\lambda, g))$, and then

$$\lambda\varphi_r(\lambda, g) - L\varphi_r(\lambda, g) + K(D\varphi_r(\lambda, g)) = g. \qquad \square$$

Remark 4.14. The operator N is dissipative. Actually, fix $\lambda > 0$ and $\varphi_1, \varphi_2 \in D(L)$, and define $g_i = \lambda\varphi_i - N(\varphi_i)$ for $i = 1, 2$. If we take $r \ge \max(\|\varphi_1\|_1, \|\varphi_2\|_1)$, we have

$$g_i = \lambda\varphi_i - L\varphi_i + K_r(D\varphi_i), \qquad i = 1, 2.$$

Thus we can apply Theorem 4.9 to the hamiltonian K_r, and we get

$$\|\varphi_1 - \varphi_2\|_0 \le \frac{1}{\lambda}\|g_1 - g_2\|_0,$$

so that N is dissipative. In particular, N is closable, and its closure $\bar{N}$ is m-dissipative, so that for any $\lambda > 0$ and $g \in C_b(H)$ there exists a unique solution to the problem

$$\lambda\varphi - \bar{N}(\varphi) = g.$$

5. Application to the control problem. Let $k : H \to (-\infty, +\infty]$ be a measurable mapping such that its Legendre transform

$$K(x) = \sup \{ -\langle x, y\rangle_H - k(y) ;\ y \in H \}, \qquad x \in H,$$

fulfills Hypothesis 4. It is possible to show that if k is strictly convex and continuously Fréchet differentiable, if

$$\lim_{|y|_H \to +\infty} \frac{k(y)}{|y|_H} = 0,$$

and if $Dk : H \to \mathcal{L}(H)$ has a continuous inverse which is Lipschitz continuous on bounded subsets of H, then Hypothesis 4 is verified. An easy example is given by $k(y) = |y|_H^2$.

For any $\lambda > 0$ and $g \in C_b(H)$ we consider the *cost functional*

$$J(x; z) = \mathbb{E} \int_0^{+\infty} e^{-\lambda t} \left[g(y(t)) + k(z(t)) \right] dt, \tag{5.1}$$

where $y(t) = y(t; x, z)$ is the unique solution of the system (3.1). The corresponding value function is defined as

$$V(x) = \inf \left\{ J(x; z) ;\ z \in L^2(\Omega; L^2(0, +\infty; H)) \text{ adapted} \right\}.$$

Our aim is to prove that if φ is the unique solution of the Hamilton–Jacobi equation (4.1), then $V(x) = \varphi(x)$ for any $x \in H$. To this purpose we first prove the following preliminary result.

LEMMA 5.1. *Assume Hypotheses* 1, 2, *and* 4. *If $\varphi = \varphi(\lambda, g)$ is the solution of the problem* (4.1) *in $C_b^1(H)$ and if $y(t) = y(t; x, z)$ is the solution of the controlled system* (3.1), *we have*

$$J(x; z) = \varphi(x) + \mathbb{E} \int_0^{+\infty} e^{-\lambda t} \left[K(D\varphi(y(t))) + \langle z(t), D\varphi(y(t))\rangle_H + k(z(t)) \right] dt. \tag{5.2}$$

Proof. If $r \geq \|D\varphi(\lambda, g)\|_0$ and if K_r is defined as in (4.21), then we have $K(D\varphi(x)) = K_r(D\varphi(x))$ for any $x \in H$, and the problem (4.1) can be rewritten as

$$\lambda\varphi - L\varphi + K_r(D\varphi) = g.$$

Now we fix a sequence $\{g_k\} \subset C_b^1(H)$ converging to g in $C_b(H)$ and for any $k, n \in \mathbb{N}$ and $\alpha > 0$ we denote by $\varphi_{\alpha,n}^k = \varphi_{\alpha,n}^k(\lambda + \mu, g_k + \mu\,\varphi(\lambda, g))$ the solution of the problem

$$(\lambda + \mu)\,\varphi - L_{\alpha,n}\varphi + K_{r,n}(D\varphi) = g_{k,n} + \mu\,\varphi_n(\lambda, g), \tag{5.3}$$

where $K_{r,n}(x) = K_r(P_n x)$, $g_{k,n}(x) = g_k(P_n x)$, and $\varphi_n(\lambda, g)(x) = \varphi(\lambda, g)(P_n x)$, and μ is some positive constant to be determined later. Since g_k and $\varphi(\lambda, g)$ are continuously differentiable, due to Lemma 4.8 we have that $\varphi_{\alpha,n}^k$ belongs to $C_b^2(H)$. Then, since $y_{\alpha,n}(t; x, z)$ is a strong solution of the problem (3.9), we can apply the Itô formula to the mapping $t \mapsto e^{-\lambda t}\varphi_{\alpha,n}^k(y_{\alpha,n}(t))$, and we get

$$d\left(e^{-\lambda t}\varphi_{\alpha,n}^k(y_{\alpha,n}(t))\right) = e^{-\lambda t}\left\langle D\varphi_{\alpha,n}^k(y_{\alpha,n}(t)), Q_n\, dw(t)\right\rangle_H$$

$$+e^{-\lambda t}\left((\mathcal{L}_{\alpha,n} - \lambda)\varphi_{\alpha,n}^k(y_{\alpha,n}(t)) + \left\langle P_n z(t), D\varphi_{\alpha,n}^k(y_{\alpha,n}(t))\right\rangle_H\right).$$

Recalling that $\varphi^k_{\alpha,n}$ is the solution of (5.3) and that (3.15) holds, we have

$$(\mathcal{L}_{\alpha,n}-\lambda)\varphi^k_{\alpha,n}=\mu\,\varphi^k_{\alpha,n}+K_{r,n}(D\varphi^k_{\alpha,n})-g_{k,n}-\mu\,\varphi_n(\lambda,g).$$

Then, by integrating with respect to $t\in[0,T]$ and by taking the expectation, we get

$$e^{-\lambda\,T}P^{\alpha,n}_T\varphi^k_{\alpha,n}-\varphi^k_{\alpha,n}=\mu\,\mathbb{E}\int_0^T e^{-\lambda\,t}\left(\varphi^k_{\alpha,n}-\varphi(\lambda,g)\right)(y_{\alpha,n}(t))\,dt$$

$$+\mathbb{E}\int_0^T e^{-\lambda\,t}\left(K_r(D\varphi^k_{\alpha,n}(y_{\alpha,n}(t)))-g_k(y_{\alpha,n}(t))+\left\langle z(t),D\varphi^k_{\alpha,n}(y_{\alpha,n}(t))\right\rangle_H\right)dt.$$

Due to (3.10) and (4.15), if μ is large enough, we can take the limit as n goes to infinity, and we get

$$e^{-\lambda\,T}P^{\alpha}_T\varphi^k_{\alpha}(x)-\varphi^k_{\alpha}(x)=\mu\,\mathbb{E}\int_0^T e^{-\lambda\,t}\left(\varphi^k_{\alpha}-\varphi(\lambda,g)\right)(y_{\alpha}(t))\,dt$$

$$=\mathbb{E}\int_0^T e^{-\lambda\,t}\left[K_r(D\varphi^k_{\alpha}(y_{\alpha}(t)))-g_k(y_{\alpha}(t))+\left\langle z(t),D\varphi^k_{\alpha}(y_{\alpha}(t))\right\rangle_H\right]dt,$$

where $\varphi^k_\alpha=\varphi^k_\alpha(\lambda+\mu,g_k+\mu\,\varphi(\lambda,g))$ is the solution of the problem

$$(\lambda+\mu)\varphi-L_\alpha\varphi+K_r(D\varphi)=g_k+\mu\,\varphi(\lambda,g).$$

By taking the limit as T goes to infinity, this yields

$$\begin{aligned}-\varphi^k_\alpha&=\mu\,\mathbb{E}\int_0^{+\infty} e^{-\lambda\,t}\left(\varphi^k_{\alpha}-\varphi(\lambda,g)\right)(y_{\alpha}(t))\,dt\\&+\mathbb{E}\int_0^{+\infty} e^{-\lambda\,t}\left[K_r(D\varphi^k_{\alpha}(y_{\alpha}(t)))-g_k(y_{\alpha}(t))+\left\langle z(t),D\varphi^k_{\alpha}(y_{\alpha}(t))\right\rangle_H\right]dt.\end{aligned}\tag{5.4}$$

We remark that for any $h,k\in\mathbb{N}$ and $\alpha>0$ we have

$$\varphi^k_\alpha-\varphi^h_\alpha=R(\lambda+\mu,L_\alpha)\left[g_k-g_h-\left(K_r(D\varphi^k_\alpha)-K_r(D\varphi^h_\alpha)\right)\right],$$

and then, due to (4.2),

$$\|\varphi^k_\alpha-\varphi^h_\alpha\|_1\le\rho(\lambda+\mu)\left(\|g_k-g_h\|_0+c_r\|D\varphi^k_\alpha-D\varphi^h_\alpha\|_0\right),$$

where c_r is the Lipschitz constant of K_r. Therefore, if μ is sufficiently large, we have $\rho(\lambda+\mu)c_r<1$, so that

$$\|\varphi^k_\alpha-\varphi^h_\alpha\|_1\le\frac{\rho(\lambda+\mu)}{1-\rho(\lambda+\mu)c_r}\|g_k-g_h\|_0.\tag{5.5}$$

This means that the sequence $\{\varphi^k_\alpha\}$ converges to some φ_α in $C^1_b(H)$. It is immediate to check that φ_α coincides with $\varphi_\alpha(\lambda+\mu,g+\mu\,\varphi(\lambda,g))$, and then, by taking the limit as k goes to infinity in (5.4), due to the dominated convergence theorem we can conclude that

$$\begin{aligned}-\varphi_\alpha&=\mu\,\mathbb{E}\int_0^{+\infty} e^{-\lambda\,t}\left(\varphi_{\alpha}-\varphi(\lambda,g)\right)(y_{\alpha}(t))\,dt\\&+\mathbb{E}\int_0^{+\infty} e^{-\lambda\,t}\left[K_r(D\varphi_{\alpha}(y_{\alpha}(t)))-g(y_{\alpha}(t))+\left\langle z(t),D\varphi_{\alpha}(y_{\alpha}(t))\right\rangle_H\right]dt.\end{aligned}\tag{5.6}$$

If $x \in E$ and $z \in L^p(\Omega; L^\infty(0,+\infty;H))$ with p as in the Proposition 3.2, we can use (3.7) and (4.13), and by taking the limit as α goes to zero we have

$$\varphi(x) + \mathbb{E}\int_0^{+\infty} e^{-\lambda t}\left[K(D\varphi(y(t))) - g(y(t)) + \langle z(t), D\varphi(y(t))\rangle_H\right] dt = 0.$$

Notice that here we have replaced K_r by K, as we fixed $r \geq \|D\varphi(\lambda,g)\|_0$. Since $\varphi \in C_b^1(H)$ and $y(t;x,z)$ depends continuously on $x \in H$ and $z \in L^2(\Omega; L^2(0,+\infty;H))$, the same identity holds for $x \in H$ and $z \in L^2(\Omega; L^2(0,+\infty;H))$. Then, recalling how $J(x;z)$ is defined, if we rearrange all terms, we get (5.2). □

THEOREM 5.2. *Assume that Hypotheses* 1, 2, *and* 4 *hold. Then there exists* μ_0 *such that for any* $\lambda > \mu_0$ *and* $g \in C_b^1(H)$ *the value function* V *corresponding to the cost functional* (5.1) *coincides with the solution* $\varphi(\lambda,g)$ *of the Hamilton–Jacobi equation* (4.1).

Moreover, for any $x \in E$ *we have*

$$V(x) = \lim_{\alpha\to 0} \min\left\{ J_\alpha(x;z)\,;\ z \in L^2(\Omega; L^2(0,+\infty;H)) \text{ adapted}\right\},$$

where $\{J_\alpha(x,z)\}$ *is a sequence of cost functionals which admit unique optimal controls and states and whose value functions* V_α *coincide with the solution of the problems*

$$(\lambda+\lambda_0)\varphi - L_\alpha\varphi + K_r(D\varphi) = g + \lambda_0\,\varphi(\lambda,g)$$

for some $\lambda_0 > 0$ *large enough and* $r \geq \|D\varphi(\lambda,g)\|_0$.

Proof. In Theorem 4.13 we have seen that, if $\lambda > \mu_0$ and $g \in C_b^1(H)$, there exists a unique solution $\varphi(\lambda,g) \in C_b^1(H)$ for (4.1). Due to (5.2) and to the definition of K, we have that $V(x) \geq \varphi(\lambda,g)(x)$ for any $x \in H$. Now we try to prove the opposite inequality. To this purpose we proceed by approximation.

We fix $r \geq \|D\varphi(\lambda,g)\|_0$, and for any $\alpha > 0$ we define the cost functional

$$J_\alpha(x;z) = \mathbb{E}\int_0^{+\infty} e^{-\lambda t}\left[g(y_\alpha(t;x,z)) + k(z(t))\right] dt$$

$$+\lambda_0\,\mathbb{E}\int_0^{+\infty} e^{-\lambda t}\left[(\varphi(\lambda,g) - \varphi_\alpha)\,(y_\alpha(t;x,z))\right] dt$$

$$+\mathbb{E}\int_0^{+\infty} e^{-\lambda t}\left[K(D\varphi_\alpha(y_\alpha(t;x,z))) - K_r(D\varphi_\alpha(y_\alpha(t;x,z)))\right] dt,$$

where $\varphi_\alpha = \varphi_\alpha(\lambda+\lambda_0, g+\lambda_0\,\varphi(\lambda,g))$ is the solution of the problem

$$(\lambda+\lambda_0)\varphi - L_\alpha\varphi + K_r(D\varphi) = g + \lambda_0\,\varphi(\lambda,g),$$

and λ_0 is the constant introduced in Proposition 4.3 corresponding to the hamiltonian K_r. We denote by $V_\alpha(x)$ the corresponding value function. Thanks to (5.6) we easily have that $V_\alpha(x) \geq \varphi_\alpha(x)$ for any $x \in H$. In fact, it is possible to show that $V_\alpha(x) = \varphi_\alpha(x)$. Indeed, for each $x \in H$ the function

$$H \to \mathbb{R}, \qquad z \mapsto -\langle z, D\varphi_\alpha(x)\rangle_H - k(z)$$

attains its maximum at $z = -DK(D\varphi_\alpha(x))$. Then, if we show that the *closed loop equation*

$$dy(t) = \left[Ay(t) + F_\alpha(y(t)) - DK(D\varphi_\alpha(y(t)))\right] dt + Q\,dw(t), \qquad y(0) = x, \tag{5.7}$$

has a unique adapted solution $y^\star_\alpha(t)$, we have that for the control

$$z^\star_\alpha(t) = -DK(D\varphi_\alpha(y^\star_\alpha(t)))$$

it holds that $J_\alpha(x, z^\star_\alpha) = \varphi_\alpha(x)$. This means that $V_\alpha(x) = \varphi_\alpha(x)$, and there exists a unique optimal control and a unique optimal state for the minimizing problem corresponding to the cost functional $J_\alpha(x; z)$.

If $g \in C^1_b(H)$, then due to Lemma 4.8 $\varphi_\alpha \in C^2_b(H)$, so that the mapping

$$U_\alpha : H \to H, \qquad x \mapsto -DK(D\varphi_\alpha(x))$$

is Lipschitz continuous. This implies that the closed loop equation admits a unique solution.

For any $\alpha > 0$ the optimal control relative to the functional $J_\alpha(x; z)$ is $z^\star_\alpha(t) = -DK(D\varphi_\alpha(y^\star_\alpha(t)))$. According to Proposition 4.11 we have

$$\|D\varphi_\alpha\|_0 \le \|Dg\|_0 + \lambda_0 \|D\varphi(\lambda, g)\|_0,$$

and then, since DK is bounded on bounded sets, there exists $R > 0$ such that

$$\sup_{\alpha>0} \sup_{t\ge 0} |z^\star_\alpha(t)|_H = R, \qquad \mathbb{P}\text{-a.s.}$$

This implies that

$$V_\alpha(x) = \inf \left\{ J_\alpha(x; z) \,:\, z \in \mathcal{M}^2_R \right\},$$

where $\mathcal{M}^2_R$ is the subset of admissible controls introduced in (3.8).

Now, recalling Proposition 4.6, we have that for any $x \in E$

$$\lim_{\alpha\to 0} V_\alpha(x) = \lim_{\alpha\to 0} \varphi_\alpha(\lambda + \lambda_0, g + \lambda_0\varphi(\lambda, g))(x) = \varphi(\lambda, g)(x).$$

Thus, if we show that

$$\lim_{\alpha\to 0} \sup_{z\in \mathcal{M}^2_R} |J_\alpha(x; z) - J(x; z)| = 0, \tag{5.8}$$

it immediately follows that $V(x) = \varphi(\lambda, g)(x)$ for $x \in E$.

Due to Proposition 3.2, we have that

$$\lim_{\alpha\to 0} \mathbb{E}\, |g(y_\alpha(t; x, z)) - g(y(t; x, z))| = 0,$$

uniformly for (t, x) in bounded sets of $[0, +\infty) \times E$ and $z \in \mathcal{M}^2_R$. Hence, if we fix $\epsilon > 0$ and $M > 0$ such that

$$\int_M^{+\infty} e^{-\lambda\, t}\, dt \le \frac{\epsilon}{2\, \|g\|_0},$$

we have

$$\mathbb{E} \int_0^{+\infty} e^{-\lambda\, t}\, [g(y_\alpha(t; x, z)) - g(y(t; x, z))]\, dt$$

$$\le \epsilon + \int_0^M e^{-\lambda\, t} \mathbb{E}\, |g(y_\alpha(t; x, z)) - g(y(t; x, z))|\, dt,$$

so that, due to the arbitrariness of $\epsilon > 0$,

$$\lim_{\alpha\to 0} \sup_{z\in \mathcal{M}_R^2} \mathbb{E}\int_0^{+\infty} e^{-\lambda t}\left[g(y_\alpha(t;x,z)) - g(y(t;x,z))\right]\,dt = 0.$$

Thanks to Lemma 4.8, we have that for $j = 0, 1$

$$\lim_{\alpha\to 0} \sup_{|x|_E\le R} \left|D^j\left(\varphi_\alpha - \varphi\right)(x)\right|_{\mathcal{L}^j(H)} = 0. \tag{5.9}$$

Moreover, thanks to (3.6),

$$\sup_{z\in \mathcal{M}_R^2} \sup_{t\in[0,T]} |y_\alpha(t;x,z)|_E < +\infty, \qquad \mathbb{P}\text{-a.s.}$$

for any $T > 0$. Thus, by using the same arguments as above, we have

$$\lim_{\alpha\to 0} \sup_{z\in \mathcal{M}_R^2} \mathbb{E}\int_0^{+\infty} e^{-\lambda t}\left[(\varphi_\alpha - \varphi)(y_\alpha(t;x,z))\right]\,dt = 0.$$

Finally, since the sequence $\{\varphi_\alpha\}$ is bounded in $C_b^1(H)$, recalling that K and K_r are bounded on bounded sets and $K(D\varphi(x)) = K_r(D\varphi(x))$ for any $x \in H$, by using (5.9) and by arguing as above, we have

$$\lim_{\alpha\to 0} \sup_{z\in \mathcal{M}_R^2} \mathbb{E}\int_0^{+\infty} e^{-\lambda t}\left[K(D\varphi_\alpha(y_\alpha(t;x,z))) - K_r(D\varphi_\alpha(y_\alpha(t;x,z)))\right]\,dt = 0.$$

Therefore, we can conclude that (5.8) holds for any $x \in E$, and then $V(x) = \varphi(x)$ for $x \in E$.

Now assume that $x \in H$. We fix a sequence $\{x_n\} \subset E$ converging to x in H. For each $n \in \mathbb{N}$ we have $V(x_n) = \varphi(x_n)$ and

$$J(x_n;z) - J(x;z) = \mathbb{E}\int_0^{+\infty} e^{-\lambda t}\left[g(y(t;x_n,z)) - g(y(t;x,z))\right]\,dt.$$

Then, due to (3.4), if $\varphi \in C_b^1(H)$, we easily get

$$\lim_{n\to+\infty} \sup_{z\in \mathcal{M}_R^2} J(x_n;z) = J(x;z),$$

so that we can conclude that $V(x) = \varphi(x)$ for any $x \in H$. □

We have seen that if we assume the hamiltonian K to be Lipschitz continuous, then for any $\lambda > 0$ and $g \in C_b(H)$ there exists a unique solution $\varphi(\lambda, g)$ in $D(L) \subset C_b^1(H)$ to the problem (4.1). This allows us to have a stronger version of the previous theorem in the case of Lipschitz K.

THEOREM 5.3. *Assume that Hypotheses* 1, 2, *and* 3 *hold. Then for any* $\lambda > 0$ *and* $g \in \mathrm{Lip}_b(H)$ *the value function* V *corresponding to the cost functional* (5.1) *coincides with the solution* $\varphi(\lambda, g)$ *of the Hamilton–Jacobi equation* (4.1).

Moreover, for any $x \in E$ *we have*

$$V(x) = \lim_{\alpha\to 0} \min\left\{ J_\alpha(x;z)\,;\ z \in L^2(\Omega; L^2(0,+\infty;H)) \text{ adapted}\right\},$$

where $\{J_\alpha(x,z)\}$ is a sequence of cost functionals which admit unique optimal controls and states and whose value functions V_α coincide with the solution of the problems

$$(\lambda+\lambda_0)\varphi - L_\alpha\varphi + K(D\varphi) = g + \lambda_0\,\varphi(\lambda,g)$$

for some $\lambda_0 > 0$.

Proof. By arguing as in the proof of the previous theorem, we have the thesis for any $g \in C_b^1(H)$ and $\lambda > 0$. Thus, in order to conclude, we have to show that for any $g \in \mathrm{Lip}_b(H)$ the approximating closed loop equation

$$du(t) = [Au(t) + F_\alpha(u(t)) - DK(D\varphi_\alpha(u(t)))]\,dt + Q\,dw(t), \qquad u(0) = x,$$

admits a unique adapted solution $u_\alpha^\star(t)$.

If $g \in \mathrm{Lip}_b(H)$, we can find a bounded sequence $\{g_k\} \subset C_b^1(H)$ converging to g in $C_b(H)$. For each $k \in \mathbb{N}$ there exists a unique solution $\varphi_{\alpha,k}$ for the Hamilton–Jacobi problem

$$(\lambda+\lambda_0)\,\varphi - L_\alpha\varphi + K_r(D\varphi) = g_k + \lambda_0\varphi(\lambda,g).$$

Then, since $g_k + \lambda_0\varphi(\lambda,g) \in C_b^1(H)$, as proved above, the corresponding closed loop equation has a unique solution $y^\star_{\alpha,k}(t)$. If we show that for any $T > 0$ the sequence $\{y^\star_{\alpha,k}\}$ converges to some $y^\star_\alpha$ in $C([0,T];H)$, $\mathbb{P}$-a.s. and in mean-square, then we easily have that $y^\star_\alpha$ is the solution of the closed loop equation (5.7).

For $k,h \in \mathbb{N}$ we define $v_\alpha^{k,h}(t) = y^\star_{\alpha,k}(t) - y^\star_{\alpha,h}(t)$. We have that $v_\alpha^{k,h}$ is the solution of the problem

$$\begin{aligned}\frac{dv}{dt}(t) = \quad & Av(t) + F_\alpha(y^\star_{\alpha,k}(t)) - F_\alpha(y^\star_{\alpha,h}(t)) - DK(D\varphi_{\alpha,k}(y^\star_{\alpha,k}(t))) \\ & + DK(D\varphi_{\alpha,h}(y^\star_{\alpha,h}(t))), \qquad v(0) = 0.\end{aligned}$$

By multiplying each side by $v_\alpha^{k,h}(t)$ and recalling (2.3) and (2.4), we have

$$\begin{aligned}&\frac{1}{2}\frac{d}{dt}|v_\alpha^{k,h}(t)|_H^2 \le c\,|v_\alpha^{k,h}(t)|_H^2 \\ &+|DK(D\varphi_{\alpha,k}(y^\star_{\alpha,k}(t))) - DK(D\varphi_{\alpha,h}(y^\star_{\alpha,h}(t)))|_H|v_\alpha^{k,h}(t)|_H.\end{aligned}$$

Since DK is locally Lipschitz continuous and according to Lemma 4.11 we have

$$\sup_{k\in\mathbb{N}}\|D\varphi_{\alpha,k}\|_0 \le \sup_{k\in\mathbb{N}}(\|Dg_k\|_0 + \lambda_0\,\|D\varphi\|_0) < \infty,$$

we obtain

$$\begin{aligned}&|DK(D\varphi_{\alpha,k}(y^\star_{\alpha,k}(t))) - DK(D\varphi_{\alpha,h}(y^\star_{\alpha,h}(t)))|_H \\ &\le c\,\left|D\varphi_{\alpha,k}(y^\star_{\alpha,k}(t)) - D\varphi_{\alpha,h}(y^\star_{\alpha,h}(t))\right|_H.\end{aligned}$$

For each $x,y \in H$ we have

$$|D\varphi_{\alpha,k}(x) - D\varphi_{\alpha,k}(y)|_H \le c\,\|\varphi_{\alpha,k}\|_2|x-y|_H,$$

and then, since the sequence $\{g_k\}$ is bounded in $C_b^1(H)$, from (4.16) it follows that

$$|D\varphi_{\alpha,k}(y^\star_{\alpha,k}(t)) - D\varphi_{\alpha,k}(y^\star_{\alpha,h}(t))|_H \le c_\alpha\,|v_\alpha^{k,h}(t)|_H.$$

Moreover, if λ_0 is large enough, due to (5.5) we have

$$\|D\varphi_{\alpha,k} - D\varphi_{\alpha,h}\|_0 \le c_\alpha \, \|g_k - g_h\|_0.$$

Therefore, we can conclude that

$$|DK(D\varphi_{\alpha,k}(y^\star_{\alpha,k}(t))) - DK(D\varphi_{\alpha,h}(y^\star_{\alpha,h}(t)))|_H \le c_\alpha \, |v^{k,h}_\alpha(t)|_H + c_\alpha \, \|g_k - g_h\|_0,$$

so that from the Young inequality we have

$$\frac{1}{2}\frac{d}{dt}|v^{k,h}_\alpha(t)|^2_H \le c_\alpha \, |v^{k,h}_\alpha(t)|^2_H + c_\alpha \, \|g_k - g_h\|^2_0.$$

By the Gronwall lemma this yields

$$\sup_{t\in[0,T]} |y^\star_{\alpha,k}(t) - y^\star_{\alpha,h}(t)|_H \le c_T \|g_k - g_h\|_0, \qquad \mathbb{P}\text{-a.s.},$$

for some constant C_T. Thus $y^\star_{\alpha,k}$ converges to some $y^\star_\alpha$ in $C([0,T];H)$, $\mathbb{P}$-a.s and in mean-square, and it is not difficult to check that $y^\star_\alpha$ is the solution of the closed loop equation corresponding to the datum g. □

By proceeding as in [9, Theorem 7.3] it is possible to show that when the space dimension d equals 1, under suitable assumptions there exist an optimal control and the corresponding optimal state.

THEOREM 5.4. *Assume that the space dimension d equals* 1.

1. *If the constant m in Hypothesis* 1 *is less than or equal to* 1, *then there exists a unique optimal control for the minimizing problem associated with the functional J. Furthermore, the optimal control $z^\star$ is related to the corresponding optimal state $y^\star$ by the feedback formula*

$$z^\star(t) = -DK[DV(y^\star(t))], \qquad t \in [0,T].$$

2. *If DK can be extended as a Lipschitz continuous mapping from $E^\star$ into itself, then the same conclusion holds for any $x \in E$.*

VIABILITY KERNELS AND CAPTURE BASINS OF SETS UNDER DIFFERENTIAL INCLUSIONS*

JEAN-PIERRE AUBIN†

Abstract. This paper provides a characterization of viability kernels and capture basins of a target viable in a constrained subset as a *unique* closed subset between the target and the constrained subset satisfying tangential conditions or, by duality, normal conditions. It is based on a method devised by Hélène Frankowska for characterizing the value function of an optimal control problem as generalized (contingent or viscosity) solutions to Hamilton–Jacobi equations. These abstract results, interesting by themselves, can be applied to epigraphs of functions or graphs of maps and happen to be very efficient for solving other problems, such as stopping time problems, dynamical games, boundary-value problems for systems of partial differential equations, and impulse and hybrid control systems, which are the topics of other companion papers.

Key words. differential inclusion, control system, viability kernel, capture basin, Hamilton–Jacobi equations, local viability, backward invariance

1. Introduction.

We consider in this paper a differential inclusion $x' \in F(x)$ (summarizing the dynamics of a control system) and two subsets C and K of a finite dimensional vector space X such that $C \subset K$. Here, K is regarded as a *constrained subset* in which the solution must evolve until possibly reaching the subset C regarded as a *target*.

DEFINITION 1.1.

1. *The subset* $\mathrm{Viab}_F(K)$ *of initial states* $x_0 \in K$ *such that at least one solution* $x(\cdot)$ *to differential inclusion* $x' \in F(x)$ *starting at* x_0 *is viable in* K *for all* $t \geq 0$ *is called the* viability kernel *of* K *under* F. *A subset* K *is a* repeller *under* F *if its viability kernel is empty.*
2. *The subset* $\mathrm{Capt}_F^K(C)$ *of initial states* $x_0 \in K$ *such that* C *is reached in finite time before possibly leaving* K *by at least one solution* $x(\cdot)$ *to differential inclusion* $x' \in F(x)$ *starting at* x_0 *is called the* viable-capture basin *of* C *in* K, *and* $\mathrm{Capt}_F(C) := \mathrm{Capt}_F^X(C)$ *is said to be the* capture basin *of* C.
3. *The subset*

$$\mathrm{Viab}_F(K, C) \ := \ \mathrm{Viab}_F(K \backslash C) \cup \mathrm{Capt}_F^K(C)$$

of initial states $x_0 \in K$ *such that at least one solution* $x(\cdot)$ *to differential inclusion* $x' \in F(x)$ *starting at* x_0 *is viable in* K *for all* $t \geq 0$ *or viable in* K *until it reaches* C *in finite time is called the* viability kernel of K with target C *under* F.

A subset $C \subset K$ *is said to be* isolated in K by F *if it coincides with its viability kernel* K *with target* C*:*

$$\mathrm{Viab}_F(K, C) \ = \ C.$$

†Université Paris-Dauphine, Centre de Recherche Viabilité, Jeux, Contrôle, F-75775 Paris Cedex 16, France (J.P.Aubin@wanadoo.fr, aubin@viab.dauphine.fr).

The subset $\mathrm{Env}_F(C) := \mathrm{Capt}_{-F}(C)$ is known under various names such as *invariance envelope* or *accessibility map* or *controlled map* of C. (See [45] for properties of invariance envelopes under Lipschitz maps and [6, 8, 9] for Marchaud maps.) Henri Poincaré introduced the concept of *shadow* (in French, *ombre*) of K, which is the set of initial points of K from which (all) solutions leave K in finite time. It is thus equal to the complement $K\backslash\mathrm{Viab}_F(K)$ of the viability kernel of K, which has been introduced in the context of differential inclusions in [1]. The concept of *viability kernel with a target* by a Lipschitz set-valued map has been introduced and studied in [48], where the viability kernel algorithm designed in [50] (see also the survey [31]) has been extended for approximating the viability kernel with a target.

One could regard the viability kernel $\mathrm{Viab}(K)$ of K as the viability kernel $\mathrm{Viab}(K, \emptyset)$ of K with the empty set as a target:

$$\mathrm{Viab}(K) \;=\; \mathrm{Viab}(K, \emptyset) \;\text{ and }\; \mathrm{Capt}^K(\emptyset) \;=\; \emptyset.$$

Therefore, the viability kernel $\mathrm{Viab}(K, C)$ of K with target C coincides with the capture basin $\mathrm{Capt}^K(C)$ of C viable in K whenever the viability kernel $\mathrm{Viab}(K\backslash C)$ is empty, i.e., whenever $K\backslash C$ is a repeller:

$$\mathrm{Viab}(K\backslash C) \;=\; \emptyset \;\Rightarrow\; \mathrm{Viab}(K, C) \;=\; \mathrm{Capt}^K(C).$$

This happens, in particular, when K is a repeller, or when the viability kernel $\mathrm{Viab}(K)$ of K is contained in the target C.

Consequently, the concept of viability kernel with a target allows us to study *both the viability kernel of a closed subset and the viable-capture basin of a target.*

These subsets can be characterized in diverse ways through tangential conditions. We recall that the contingent cone $T_L(x)$ to $L \subset X$ at $x \in L$ is the set of directions $v \in X$ such that there exist sequences $h_n > 0$ converging to 0 and v_n converging to v satisfying $x + h_n v_n \in K$ for every n.

One of our objectives is to prove the following characterizations of the viability kernels and capture basins.

THEOREM 1.2. *Let us assume that F is Marchaud and that the target $C \subset K$ and K are closed. The viability kernel* $\mathrm{Viab}_F(K, C)$ *of the subset K with target C is*

1. *the* largest *closed subset D satisfying $C \subset D \subset K$ and*

$$D\backslash C \text{ is locally viable under } F \;(\forall\, x \in D\backslash C,\; F(x) \cap T_D(x) \neq \emptyset).$$

2. *If, furthermore, K is assumed to be backward invariant under F and F to be Lipschitz, the viability kernel* $\mathrm{Viab}_F(K, C)$ *is the* unique *closed subset $D \subset K$ satisfying the following.*

$$(1.1)\quad \begin{cases} \text{(i)} & D\backslash C \text{ is locally viable under } F \;(\forall\, x \in D\backslash C,\; F(x) \cap T_D(x) \neq \emptyset), \\ \text{(ii)} & D \text{ is backward invariant under } F \;(\forall\, x \in D,\; F(x) \subset -T_D(x)), \\ \text{(iii)} & K\backslash D \text{ is a repeller.} \end{cases}$$

The uniqueness properties of the viability kernel and the viable-capture basins are obtained thanks to the *Frankowska method*, consisting in introducing (local) backward invariance together with (local) forward viability of subsets. Indeed, Hélène Frankowska did point out in [39, 40] the backward invariance and local forward viability properties of the epigraph of the value function of an optimal control problem. She proved that the epigraph of the value function of an optimal control problem—assumed to be only lower semicontinuous—is backward invariant and viable under a

(natural) auxiliary system. It allowed her to characterize the value functions as unique solutions of contingent inequalities and, by duality, to obtain lower semicontinuous (or bilateral) solutions to Hamilton–Jacobi partial differential equations, obtained by other methods in [19]. (See also [18] for more details on this point of view.) Furthermore, when the value function is continuous, she proved that its epigraph is viable and its hypograph invariant [35, 36, 37, 38]. By duality, she proved that the latter property is equivalent to the fact that the value function is a viscosity solution of the associated Hamilton–Jacobi equation in the sense of Crandall and Lions in [32]. This *epigraphical approach* in the field of Hamilton–Jacobi equations has since been taken up by other authors.

Actually, we can spare the assumption that K is backward invariant in the above theorem if we are ready to trade the property that D is backward invariant with the weaker property that D satisfies $\mathrm{Capt}_F^K(D) = D$. Indeed, we shall derive this theorem from Theorem 4.4 below, which does not assume that K is backward viable.

Not only is the concept of the viability kernel naturally important in the framework of economic models and biological problems having motivated viability theory in the first place, but it happens that the notions of equilibria, of absorbing sets, of basins of absorption, of attractors, of "permanence," of "fluctuation," of "Lyapunov stability," of optimal Lyapunov functions, and of value function of an intertemporal optimization problem as well as other dynamical features can be studied by using the concept of the *viability kernel* as a mathematical tool (see [2, 3, 4, 5] for applications and further references).

The concept of the viable-capture basin also plays a fundamental role for solving first-order partial differential equations (see [12, 13, 14, 15, 16], chapter 8 of [2], [11] without boundary conditions, and [6, 7, 8, 9] for the Dirichlet boundary-value problems for such systems). Finally, the viability kernel algorithm allows us to compute the viability kernel (see [31, 47, 50]). Nonemptiness of the viability kernel is studied in [22, 23, 24]. Extension of this concept to impulse and hybrid control systems can be found in [17].

We shall conclude this paper by describing (without proofs that will be given in a forthcoming companion paper) an application of these results to optimal discounted intertemporal control. Consider the evolution of a control system with (multivalued) feedbacks:

$$\begin{cases} \text{(i)} & x'(t) = f(x(t), u(t)), \\ \text{(ii)} & u(t) \in P(x(t)), \end{cases}$$

where the state $x(\cdot)$ ranges over a finite dimensional vector-space X and the control $u(\cdot)$ ranges over another finite dimensional vector-space $\mathcal{M}$. The problem is to minimize a functional of the form

$$\begin{cases} J(t, x; (x(\cdot), u(\cdot))) \\ \\ := \; e^{\int_0^t \mathbf{m}(x(s),u(s))ds}\mathbf{c}(T-t, x(t)) + \displaystyle\int_0^t e^{\int_0^\tau \mathbf{m}(x(s),u(s))ds}\mathbf{l}(x(\tau), u(\tau))d\tau \end{cases}$$

over the set $\mathcal{S}(x)$ of solutions $(x(\cdot), u(\cdot))$ to a control system

$$V(T, x) \; := \inf_{(x(\cdot),u(\cdot))\in\mathcal{S}(x)} \inf_{t\in[0,T]} J(t, x; (x(\cdot), u(\cdot)))$$

or,

$$W(T, x) \; := \inf_{(x(\cdot),u(\cdot))\in\mathcal{S}(x)} \sup_{t\in[0,T]} J(t, x; (x(\cdot), u(\cdot))).$$

The connection between these problems and the basic viability theorems is simple. For instance, the epigraph of the value function is the capture basin of the epigraph of the cost function $\mathbf{c}$ under the auxiliary control system governed by the dynamics

$$g(x,y,u) \;=\; (f(x,u), -\mathbf{m}(x,y)y - \mathbf{l}(x,u)),$$

viable in the epigraph of an adequate function. This being checked, it will be sufficient to translate the properties of capture basins stated in Theorem 1.2 in terms of value functions, the tangential conditions characterizing capture basins becoming the Hamilton–Jacobi–Bellman variational inequalities of which the value function is an (adequately generalized) solution. It is enough to observe that the contingent cone to the epigraph of a function is, by definition, the epigraph of the contingent epiderivative of this function.

When we are studying the viability kernels with targets under differential inclusions, we observe that they are not specific to differential inclusions. They involve only few properties[1] of the solution map $\mathcal{S}$ associating with any initial state x the set $\mathcal{S}(x)$ of pairs $t \mapsto (x(t), u(t))$ that are solutions to the above control system starting at x at initial time 0. These properties of the solution map are common to other control problems, such as

1. control problems with memory (see the contributions of [42, 43], some of them being presented in [2])—previously known under the name of functional control problems, the new fashion calling them "path dependent control systems,"
2. parabolic type partial differential inclusions (see the contributions of [51, 52, 53, 54, 55], some of them being presented in [2])—also known as distributed control systems;
3. "mutational equations" governing the evolution in metric spaces, including "morphological equations" governing the evolution of sets (see [4], for instance).

Although these problems are not covered in this paper by lack of place, we shall make another step in abstraction by gathering these common properties of the solution map under the name of *evolutionary systems* and study the properties of viability kernels with targets in this general framework. In the case of differential inclusions, we shall use the viability and invariance theorems for characterizing them in terms of tangential conditions.

The paper is organized as follows. Section 2 introduces evolutionary systems. The third section defines hitting and exit functions. Viability kernels and capture basins are defined and characterized in section 4 for general evolutionary systems. Their characterizations in terms of tangential conditions or, by duality, in terms of normal conditions, are provided in the fifth section. The sixth provides useful stability results. The last section summarizes the applications of the above theorems to optimal control and stopping time problems.

2. Evolutionary systems.

2.1. Definition of evolutionary systems. The following results dealing with viability kernel and capture basins are valid for any *evolutionary system* described by a set-valued map $\mathcal{S}$ mapping some topological space X (most often, a topological

[1] These are the translation and concatenation properties of the set-valued map $x \rightsquigarrow \mathcal{S}(x)$, as well as continuity properties of this set-valued map.

vector-space) to the space $\mathcal{C}(0,\infty;X)$ of continuous functions $x(\cdot)$ from $\mathbf{R}_+$ to X, supplied with the topology of uniform convergence on compact intervals.

It can be the solution map associated with a differential inclusion $x' \in F(x)$ on a finite dimensional vector space X, with a differential inclusion with memory $x'(t) \in F(T(t)x)$ or with a mutational equation $\overset{\circ}{x} \ni f(x)$ on metric spaces.

DEFINITION 2.1. *An evolutionary system is a set-valued map* $\mathcal{S} : X \rightsquigarrow \mathcal{C}(0,\infty;X)$ *satisfying the following.*

1. *The* translation property. *Let* $x(\cdot) \in \mathcal{S}(x)$. *Then for all* $T \geq 0$, *the function* $y(\cdot)$ *defined by* $y(t) := x(t+T)$ *is a solution* $y(\cdot) \in \mathcal{S}(x(T))$ *starting at* $x(T)$.
2. *The* concatenation property. *Let* $x(\cdot) \in \mathcal{S}(x)$ *and* $T \geq 0$. *Then for every* $y(\cdot) \in \mathcal{S}(x(T))$, *the function* $z(\cdot)$, *defined by*

$$z(t) := \begin{cases} x(t) & \text{if} \quad t \in [0,T], \\ y(t-T) & \text{if} \quad t \geq T, \end{cases}$$

belongs to $\mathcal{S}(x)$.

We shall associate with $\mathcal{S}$ *its* backward evolutionary system $\mathcal{S}_- : X \rightsquigarrow \mathcal{C}(0,\infty;X)$ *defined by* $y(\cdot) \in \mathcal{S}_-(x)$ *if and only if there exists a solution* $z(\cdot) \in \mathcal{S}(x)$ *such that for every* $T \geq 0$, *the function* $x(\cdot)$, *defined by*

$$x(t) := \begin{cases} y(T-t) & \text{if} \quad t \in [0,T], \\ z(t-T) & \text{if} \quad t \geq T, \end{cases}$$

belongs to $\mathcal{S}(x)$.

We observe that $\mathcal{S}_{-\,-} = \mathcal{S}$.

The viability and capturability issues use the notion of evolutions viable in a subset.

DEFINITION 2.2. *Let* $K \subset X$ *be a subset of* X. *A function* $t \in [0,T] \mapsto x(t) \in X$ *is said to be* viable *in* K *on* $[0,T]$ *if*

$$\forall\, t \in [0,T], \;\; x(t) \;\in\; K,$$

and viable in K *if* $T = +\infty$.

The following results dealing with these issues shall use only the translation and concatenation properties and topological properties such that the upper semicompactness[2] and/or lower semicontinuity of the evolutionary system $\mathcal{S} : x \in X \rightsquigarrow \mathcal{S}(x) \subset \mathcal{C}(0,\infty;X)$.

Before proceeding further, let us recall that differential inclusions provide examples of evolutionary systems.

2.2. Evolutionary systems associated with differential inclusions. Let $X := \mathbf{R}^n$ be a finite dimensional vector space, and let $F : X \rightsquigarrow X$ be a strict[3]

[2]A set-valued map $F : X \rightsquigarrow Y$ is said to be *upper semicompact* at x if for every sequence x_n converging to x and for every sequence $y_n \in F(x_n)$, there exists a subsequence y_{n_p} converging to some $y \in F(x)$. It is said to be lower semicontinuous at x if and only if for any $y \in F(x)$ and for any sequence of elements $x_n \in \mathrm{Dom}(F)$ converging to x, there exists a sequence of elements $y_n \in F(x_n)$ converging to y.

[3]This means that for every $x \in X$, $F(x) \neq \emptyset$. We denote by

$$\mathrm{Graph}(F) := \{(x,y) \in X \in Y \mid y \in F(x)\}$$

the *graph* of a set-valued map $F : X \rightsquigarrow Y$ and by $\mathrm{Dom}(F) := \{x \in X | F(x) \neq \emptyset\}$ its *domain*.

set-valued map. We denote by $\mathcal{S}_F(x) \subset \mathcal{C}(0,\infty;X)$ the set of *absolutely continuous functions* $t \mapsto x(t) \in X$ satisfying

$$\text{for almost all } t \geq 0, \quad x'(t) \in F(x(t)),$$

starting at time 0 at x: $x(0) = x$. The set-valued map $\mathcal{S}_F : X \rightsquigarrow \mathcal{C}(0,\infty;X)$ is called the *solution map* (or the set-valued flow) associated with F.

Without assumptions, the solution map $\mathcal{S}_F$ may have empty values. However, whenever the solution map $\mathcal{S}_F : X \rightsquigarrow \mathcal{C}(0,\infty;X)$ associated with the differential inclusion $x' \in F(x)$ is strict, it obviously satisfies the *translation property* and the *concatenation property*.

One can also observe that the backward evolutionary system $\mathcal{S}_{F_-}$ is the solution map $\mathcal{S}_{-F}$ associated with $-F$.

2.2.1. Marchaud differential inclusions.

DEFINITION 2.3 (Marchaud map). *We shall say that F is a* Marchaud map *if*

$$\begin{cases} \text{(i)} & \text{the graph and the domain of } F \text{ are nonempty and closed,} \\ \text{(ii)} & \text{the values } F(x) \text{ of } F \text{ are convex,} \\ \text{(iii)} & \text{the growth of } F \text{ is linear:} \\ & \exists\, c > 0 \mid \forall\, x \in X, \quad \|F(x)\| := \sup_{v \in F(x)} \|v\| \leq c(\|x\| + 1). \end{cases}$$

We recall the following version of the important Theorem 3.5.2 of [2] stating that the solution map is strict and upper semicompact.

STATEMENT 1. *Assume that $F : X \rightsquigarrow X$ is Marchaud. Then the solution map $\mathcal{S}_F$ is an upper semicompact evolutionary system from X into the space of continuous functions supplied with the topology of uniform convergence on compact intervals.*

2.2.2. Lipschitz differential inclusions.

DEFINITION 2.4. *The set-valued map F is said to be Lipschitz if there exists a constant $\lambda > 0$ such that*

$$\forall\, x, y \in X, \quad F(x) \subset F(y) + B(0, \lambda\|x - y\|).$$

The Filippov theorem (see Theorem 5.3.1 of [2]) implies that whenever F is Lipschitz, the associated evolutionary system is lower semicontinuous.

STATEMENT 2. *Assume that $F : X \rightsquigarrow X$ is Lipschitz. Then the solution map $\mathcal{S}_F$ is a lower semicontinuous evolutionary system from X into the space of continuous functions supplied with the topology of uniform convergence on compact intervals.*

3. Exit and hitting time functions. We shall associate with an evolutionary system $\mathcal{S} : X \rightsquigarrow \mathcal{C}(0,\infty;X)$ the concepts of upper exit time function of a subset K and the lower hitting function (or minimal time function) of a target and study their continuity (actually, semicontinuity) properties.

DEFINITION 3.1. *Let $K \subset X$ be a subset. The functional $\tau_K : \mathcal{C}(0,\infty;X) \mapsto \mathbf{R}_+ \cup \{+\infty\}$ associating with $x(\cdot)$ its* exit time *$\tau_K(x(\cdot))$ defined by*

$$\tau_K(x(\cdot)) := \inf\{t \in [0,\infty[\mid x(t) \notin K\}$$

is called the exit functional.

Let $C \subset K$ be a target. We introduce the (constrained) hitting functional *$\varpi_{(K,C)}$ defined by*

$$\varpi_{(K,C)}(x(\cdot)) := \inf\{t \geq 0 \mid x(t) \in C \text{ and } \forall s \in [0,t],\ x(s) \in K\}$$

associating with $x(\cdot)$ *its* hitting time*, introduced in* [29]*). When* $K := X$*, we set*

$$\varpi_C(x(\cdot)) \;=\; \varpi_{(X,C)}(x(\cdot)) : \mathcal{C}(0,\infty;X) \mapsto \mathbf{R}_+ \cup \{+\infty\}$$

and call it the hitting functional *(or* minimal time functional*).*

We use the convention $\inf\{\emptyset\} := +\infty$, and we observe that

$$\text{if } \varpi_{(X,C)}(x(\cdot)) < +\infty, \text{ then } \varpi_C(x(\cdot)) \;=\; \varpi_{(X,C)}(x(\cdot)) \;\leq\; \tau_C(x(\cdot)).$$

We also note that

$$\forall\, s \in [0, \varpi_C(x(\cdot))],\;\; \varpi_C(x(\cdot + s)) \;=\; \varpi_C(x(\cdot)) - s \tag{3.1}$$

and that if $K_1 \subset K_2$ and $D_1 \supset D_2$, then $\varpi_{(K_1,D_1)}(x(\cdot)) \leq \varpi_{(K_2,D_2)}(x(\cdot))$. Let us point out that

$$\varpi_{\bigcup_{i=1}^{n} D_i}(x(\cdot)) \;=\; \min_{i=1,\ldots,n} \varpi_{D_i}(x(\cdot)).$$

Therefore,

$$\forall\, x \in K\backslash C,\;\; \tau_{K\backslash C}(x(\cdot)) = \min(\varpi_C(x(\cdot), \tau_K(x(\cdot)))$$

since

$$\tau_{K\backslash C}(x) \;=\; \varpi_{X\backslash(K\backslash C)}(x(\cdot)) \;=\; \varpi_{C\cup(X\backslash K)} \;=\; \min(\varpi_C(x(\cdot)), \varpi_{X\backslash K}(x(\cdot))).$$

Definition 3.2. *Consider an evolutionary system* $\mathcal{S} : X \rightsquigarrow \mathcal{C}(0,+\infty;X)$*. Let* $C \subset K$ *and* K *be two subsets.*

The function $\tau_K^\sharp : K \mapsto \mathbf{R}_+ \cup \{+\infty\}$ *defined by*

$$\tau_K^\sharp(x) \;:=\; \sup_{x(\cdot)\in\mathcal{S}(x)} \tau_K(x(\cdot))$$

is called the upper exit function*.*

The function $\varpi^\flat_{(K,C)} : K \mapsto \mathbf{R}_+ \cup \{+\infty\}$ *defined by*

$$\varpi^\flat_{(K,C)}(x) \;:=\; \inf_{x(\cdot)\in\mathcal{S}(x)} \varpi_{(K,C)}(x(\cdot))$$

is called the lower constrained hitting function*, and the function*

$$\varpi^\flat_C(x) \;:=\; \inf_{x(\cdot)\in\mathcal{S}(x)} \varpi_C(x(\cdot))$$

is called the lower hitting function*.*

Statement 3. *Let* $\mathcal{S} : X \rightsquigarrow \mathcal{C}(0,+\infty;X)$ *be a strict upper semicompact map, and let* C *and* K *be two closed subsets such that* $C \subset K$*. Then the hitting function* $\varpi^\flat_{(K,C)}$ *is lower semicontinuous and the exit function* $\tau_K^\sharp$ *is upper semicontinuous. Furthermore, for any* $x \in \mathrm{Dom}(\varpi^\flat_{(K,C)})$*, there exists at least one solution* $x^\flat(\cdot) \in \mathcal{S}(x)$ *which hits* C *as soon as possible before possibly leaving* K*,*

$$\varpi^\flat_{(K,C)}(x) \;=\; \varpi_{(K,C)}(x^\flat(\cdot)),$$

and for any $x \in \mathrm{Dom}(\tau_K^\sharp)$*, there exists at least one solution* $x^\sharp(\cdot) \in \mathcal{S}(x)$ *which remains viable in* K *as long as possible:*

$$\tau_K^\sharp(x) \;=\; \tau_K(x^\sharp(\cdot)).$$

This statement is a consequence of the more general Theorem 6.2 dealing with upper hypolimits of upper exit functions and epilimits of lower constrained epifunctions of subsets that is proved below. See also [29, 30].

4. Viability kernels and capture basins. We shall answer in this section questions such as the following.

- Starting from K, is it possible to remain viable in K (as long as possible)?
- Starting outside of a target $C \subset K$, is it possible to reach it (as fast as possible) while being viable in the subset K?

These two very natural questions lead to the introduction of the following concepts.

4.1. Viability kernels with targets. We now define the viability kernels, the capture basins, and the viable-capture basins of a subset under a set-valued map.

DEFINITION 4.1. *Let $\mathcal{S} : X \rightsquigarrow \mathcal{C}(0, +\infty; X)$ be a set-valued evolutionary system, and let $C \subset K \subset X$ be two subsets, C being regarded as a target and K as a constrained set.*

1. *The subset K is said to be* locally viable *under $\mathcal{S}$ if from any initial state $x \in K$ starts at least one solution viable in K on a nonempty interval and* viable *if this solution is viable on $[0, +\infty[$. We shall say that K* captures *the target C if from any initial state $x \in K$ starts at least one solution viable in K until it may reach the target C, and we say that K* finitely captures *the target C if it reaches it in finite time.*
2. *The subset $\mathrm{Viab}(K, C)$ of initial states $x_0 \in K$ such that at least one solution $x(\cdot) \in \mathcal{S}(x_0)$ starting at x_0 is viable in K for all $t \geq 0$ or viable in K until it reaches C in finite time is called the* viability kernel of K with target C *under $\mathcal{S}$. A subset $C \subset K$ is said to be* isolated in K by $\mathcal{S}$ *if it coincides with its viability kernel:*

$$\mathrm{Viab}(K, C) \;=\; C.$$

3. *The subset $\mathrm{Capt}^K(C)$ of initial states $x_0 \in K$ such that C is reached in finite time before possibly leaving K by at least one solution $x(\cdot) \in \mathcal{S}(x_0)$ starting at x_0 is called the* viable-capture basin *of C in K, and*

$$\mathrm{Capt}(C) \;:=\; \mathrm{Capt}^X(C)$$

is said to be the capture basin *of C.*
4. *When the target $C = \emptyset$ is the empty set, we set*

$$\mathrm{Viab}(K) \;:=\; \mathrm{Viab}(K, \emptyset) \;\; \textit{and} \;\; \mathrm{Capt}^K(\emptyset) \;=\; \emptyset,$$

and we say that $\mathrm{Viab}(K)$ is the viability kernel of K. A subset K is a repeller *under $\mathcal{S}$ if its viability kernel is empty, or, equivalently, if the empty set is isolated in K.*

In other words, the viability kernel $\mathrm{Viab}(K)$ is the subset of initial states $x_0 \in K$ such that at least one solution $x(\cdot) \in \mathcal{S}(x_0)$ starting at x_0 is viable in K for all $t \geq 0$. Furthermore, we observe that

$$\mathrm{Viab}(K, C) \;=\; \mathrm{Viab}(K \backslash C) \cup \mathrm{Capt}^K(C). \tag{4.1}$$

Therefore, the viability kernel $\mathrm{Viab}(K, C)$ of K with target C coincides with the capture basin $\mathrm{Capt}^K(C)$ of C viable in K whenever the viability kernel $\mathrm{Viab}(K \backslash C)$ is empty, i.e., whenever $K \backslash C$ is a repeller:

$$\mathrm{Viab}(K \backslash C) \;=\; \emptyset \;\Rightarrow\; \mathrm{Viab}(K, C) \;=\; \mathrm{Capt}^K(C). \tag{4.2}$$

Consequently, the concept of the viability kernel with a target allows us to study both the viability kernel of a closed subset and the viable-capture basin of a target.

Remark. If subsets K_i capture a given target $C \subset K_i$ for all $i \in I$, so does their union $\bigcup_{i\in I} K_i$. However, the intersection of two subsets K_1 and K_2 capturing a same target C does not necessarily capture C, since starting from a state of $K_1 \cap K_2$, there may exist two different solutions that are viable in K_1 or in K_2 but no solution viable in $K_1 \cap K_2$. □

We observe that the *viability kernel* is characterized by

$$\mathrm{Viab}(K) \;:=\; \{x \in K \mid \tau^\sharp_K(x) \;=\; +\infty\}$$

and that the *viable-capture basin*

$$\mathrm{Capt}^K(C) \;:=\; \{x \in K \mid \varpi^\flat_{(K,C)}(x) \;<\; +\infty\}$$

is the domain of the constrained hitting function $\varpi^\flat_{(K,C)}$.

To say that K is a repeller under $\mathcal{S}$ amounts to saying that the exit function $\tau^\sharp_K$ is finite on K, and to say that $K\backslash C$ is a repeller amounts to saying that all solutions $x(\cdot) \in \mathcal{S}(x)$ starting from $x \in K\backslash C$ reach C or leave K in finite time, i.e., satisfy $\tau_{K\backslash C}(x(\cdot)) = \min(\varpi_C(x(\cdot), \tau_K(x(\cdot)))) < +\infty$.

The viability kernel $\mathrm{Viab}(K, C)$ of K with target C captures C.

PROPOSITION 4.2. *The viability kernel* $\mathrm{Viab}(K, C)$ *of* K *with target* C *is the largest subset of* K *capturing* C*, and the viability kernel* $\mathrm{Viab}(K)$ *of* K *is the largest viable subset of* K*.*

Proof. First, any subset D such that $C \subset D \subset K$ capturing C is obviously contained in the viability kernel $\mathrm{Viab}(K, C)$ with target C.

For proving that the viability kernel $\mathrm{Viab}(K, C)$ with target C captures the target C, take $x_0 \in \mathrm{Viab}(K, C)$, and prove that there exists a solution $x(\cdot) \in \mathcal{S}(x_0)$ starting at x_0 viable in $\mathrm{Viab}(K, C)$ until it possibly reaches C. Indeed, there exists a solution $x(\cdot) \in \mathcal{S}(x_0)$ viable in K until some time $T \geq 0$, either finite when it reaches C or infinite. Then for all $t \in [0, T[$, the function $y(\cdot)$ defined by $y(\tau) := x(t + \tau)$ is a solution $y(\cdot) \in \mathcal{S}(x(t))$ starting at $x(t)$ and viable in K until it reaches C at time $T - t$. Hence $x(t)$ does belong to $\mathrm{Viab}(K, C)$ for every $t \in [0, T[$. □

Furthermore, we derive from Proposition 4.2 and Theorem 6.4 below the following proposition.

PROPOSITION 4.3. *Let us assume that the map* $\mathcal{S}$ *is upper semicompact and that* $C \subset K$ *and* K *are closed. Then the viability kernel* $\mathrm{Viab}(K, C)$ *with a target is the largest closed subset of* K *capturing* C*, and the viability kernel* $\mathrm{Viab}(K)$ *is the largest viable closed subset of* K*.*

4.2. Characterization of the viability kernel with a target. The first characterization is stated in the following theorem.

THEOREM 4.4. *Let us assume that* $\mathcal{S}$ *is upper semicompact and that the subsets* $C \subset K$ *and* K *are closed. The viability kernel* $\mathrm{Viab}(K, C)$ *of a subset* K *with target* C *under* $\mathcal{S}$ *is the* unique *closed subset satisfying* $C \subset D \subset K$*, and*

$$\text{(4.3)} \qquad \begin{cases} \text{(i)} & D\backslash C \textit{ is} \text{ locally viable } \textit{under } \mathcal{S}, \\ \text{(ii)} & D \textit{ is} \text{ isolated } \textit{in } K \textit{ by } \mathcal{S} \ (\mathrm{Viab}(K, D) \;=\; D). \end{cases}$$

It follows from Theorem 4.6 characterizing the viability kernel as the largest closed subset $D \subset K$ such that $D\backslash C$ is locally viable and from Theorem 4.7 characterizing the viability kernel as the smallest subset D isolated in K.

We begin with necessary conditions.

PROPOSITION 4.5. *Let us consider a closed subset C of K. Then the following hold.*

1. *If $D \supset C$ captures C, then $D\backslash C$ is locally viable under $\mathcal{S}$.*
2. *If $D_1 \supset C$ captures C and $D_2 \supset D_1$ captures D_1, then D_2 captures C (transitivity of the capturability property).*

Consequently, the viability kernel $\mathrm{Viab}(K, C)$ *of a subset K with target C under $\mathcal{S}$ satisfies the following properties:*

$$\begin{cases} \text{(i)} & \mathrm{Viab}(K,C)\backslash C \text{ is locally viable and } \mathrm{Viab}(K) \text{ is viable under } \mathcal{S}, \\ \text{(ii)} & \mathrm{Viab}(K,C) \text{ is isolated in } K \text{ by } \mathcal{S} \ (\mathrm{Viab}(K, \mathrm{Viab}(K,C)) = \mathrm{Viab}(K,C)). \end{cases}$$

Proof. For proving the first statement, take $x_0 \in D\backslash C$, and prove that there exists a solution $x(\cdot) \in \mathcal{S}(x_0)$ starting at x_0 viable in $D\backslash C$ on a nonempty interval. Indeed, since C is closed, there exists $\eta > 0$ such that $B(x_0, \eta) \cap C = \emptyset$, so that $x(t) \in B(x_0, \eta) \cap D \subset D\backslash C$ on some nonempty interval.

For proving that D_2 captures C, take any $x_0 \in D_2$. There exists a solution $x(\cdot) \in \mathcal{S}(x_0)$ viable in D_2 forever or else, until it possibly reaches the subset D_1 of D_2 at some *finite time* $T > 0$ at $x(T) \in D_1$. In this case, for any $t \geq T$, $x(t)$ remains in D_1, and thus, in D_2, until it possibly reaches C. Hence D_2 captures C.

In particular, if we take $D_1 := \mathrm{Viab}(K, C)$ and $D_2 := \mathrm{Viab}(K, \mathrm{Viab}(K, C))$, we infer that $D_1 = D_2$ since D_1 is the largest subset of K capturing the target C. □

We now proceed with the proof of the sufficiency.

THEOREM 4.6. *Assume that $\mathcal{S}$ is upper semicompact. Let $C \subset K$ be closed subsets.*

Then the viability kernel $\mathrm{Viab}(K, C)$ *of K with target C under $\mathcal{S}$ is the* largest closed subset $D \subset K$ *containing C such that $D\backslash C$ is locally viable.*

In particular, K captures C if and only if $K\backslash C$ is locally viable.

Proof. When $C = \emptyset$, this is Proposition 4.3. Otherwise, Theorem 6.4 and Proposition 4.5 imply that the viability kernel $\mathrm{Viab}(K, C)$ of K with target C under $\mathcal{S}$ is a closed subset such that $\mathrm{Viab}(K, C)\backslash C$ is locally viable.

Let $D \subset K$ containing C such that $D\backslash C$ is locally viable. Since $C \subset \mathrm{Viab}(K, C)$, let us take x in $D\backslash C$ and show that it belongs to $\mathrm{Viab}(K, C)$. Either there exists a solution $x(\cdot) \in \mathcal{S}(x)$ viable in $D \subset K$ forever or, if not, by Statement 3, there exists a solution $x^\sharp(\cdot) \in \mathcal{S}(x)$ that maximizes $\tau_D(x(\cdot))$,

$$\tau_D^\sharp(x) := \sup_{x(\cdot) \in \mathcal{S}(x)} \tau_D(x(\cdot)) = \tau_D(x^\sharp(\cdot)),$$

and thus that leaves D at $x^\sharp := x^\sharp(\tau_D^\sharp(x)) \in D$. Actually, this point belongs to C.

Otherwise, since $D\backslash C$ is locally viable, one could associate with $x^\sharp \in D\backslash C$ a solution $y(\cdot) \in \mathcal{S}(x^\sharp)$ and $T > 0$ such that $y(\tau) \in D\backslash C$ for all $\tau \in [0, T]$. Concatenating this solution to $x^\sharp(\cdot)$, we obtain a solution viable in D on an interval $[0, \tau_D^\sharp(x) + T]$, which contradicts the definition of $x^\sharp(\cdot)$. □

THEOREM 4.7. *Let $C \subset K$. Then the viability kernel* $\mathrm{Viab}(K, C)$ *is the* smallest *subset D between C and K isolated in K by $\mathcal{S}$.*

Proof. Proposition 4.5 implies that the viability kernel $\mathrm{Viab}(K, C)$ is isolated in K by $\mathcal{S}$. Conversely, since D is isolated in K by $\mathcal{S}$, we infer that $\mathrm{Viab}(K, C) \subset \mathrm{Viab}(K, D) = D$. □

4.3. Isolated subsets. We need to characterize further isolated subsets for enriching the above characterization theorem.

First, we point out the following.

PROPOSITION 4.8. *Let C and K be two subsets such that $C \subset K$. Then the following properties are equivalent.*

1. *C is isolated in K by $\mathcal{S}$:* $\mathrm{Viab}(K, C) = C$.
2. *For all $x \in K\backslash C$, all solutions reach $X\backslash K$ in finite time before (possibly) hitting C.*
3. $\mathrm{Viab}(K) = \mathrm{Viab}(C)$, *and* $\mathrm{Capt}^K(C) = C$.
4. *$K\backslash C$ is a repeller and* $\mathrm{Capt}^K(C) = C$.

Isolated subsets enjoy local backward invariance properties discovered by Hélène Frankowska in her studies of Hamilton–Jacobi equations associated with value functions of optimal control problems under state constraints that play a crucial role in the characterization of viability kernels with a target. Indeed, there is a close connection between isolation in K and local backward invariance relatively to K.

DEFINITION 4.9. *We shall say that a subset $C \subset K$ is* locally backward invariant relatively to K *under $\mathcal{S}$ if for every $x \in C$, all backward solutions starting from x and viable in K on an interval $[0, T]$ are viable in C on $[0, T]$, i.e., if for every $x \in C$, for every $t_0 \in]0, +\infty[$, and for all solutions $x(\cdot)$ arriving at x at time t_0 such that there exists $s \in [0, t_0[$ such that $x(\cdot)$ is viable in K on the interval $[s, t_0]$, then $x(\cdot)$ is viable in C on the same interval.*

Naturally, if $C \subset K$ is locally backward invariant, it remains locally backward invariant relatively to K. If K is itself locally backward invariant, any subset locally backward invariant relatively to K is locally backward invariant.

If $C \subset K$ is locally backward invariant relatively to K, then $C \cap \mathrm{Int}(K)$ is locally backward invariant, and from any $x \in C \cap \partial K$, all backward solutions $y(\cdot) \in \mathcal{S}_-(x)$ satisfy

$$\begin{cases} \text{either } \exists\, T > 0 \quad \text{such that } \forall\, t \in [0, T], \quad x(t) \in C, \\ \text{or } \exists\ t_n \to 0+ \mid y(t_n) \in X\backslash K. \end{cases}$$

THEOREM 4.10. *A closed subset $C \subset K$ is locally backward invariant relatively to K if and only if* $\mathrm{Capt}^K(C) = C$.

Proof. Assume that C is locally backward invariant relatively to K, and consider $x \in \mathrm{Capt}^K(C)\backslash C$. There exists a solution $x(\cdot) \in \mathcal{S}(x)$ viable in K until it reaches C at time $T := \varpi_C(x(\cdot)) \geq 0$ at $c = x(\varpi_C(x(\cdot)))$. Since C is closed, then $T > 0$ is positive. Let $z(\cdot) \in \mathcal{S}_-(x)$, and let $y(\cdot)$ be the function defined by

$$y(t) := \begin{cases} x(T - t) & \text{if} \quad t \in [0, T], \\ z(t - T) & \text{if} \quad t \geq T. \end{cases}$$

Then $y(\cdot) \in \mathcal{S}_-(c)$ and is viable in K on the interval $[0, \varpi_C(x(\cdot))]$. Since C is assumed to be locally backward invariant relatively to K, then $y(t) \in C$ for all $t \in [0, \varpi_C(x(\cdot))]$, and, in particular, $y(T) = x$ belongs to C. We have obtained a contradiction.

The converse statement follows from the next theorem.

PROPOSITION 4.11. *The viability kernel* $\mathrm{Viab}(K, C)$ *of K with a target $C \subset K$ and the viable-capture basin* $\mathrm{Capt}^K(C)$ *are locally backward invariant relatively to K. Consequently, every subset $C \subset K$ isolated in K is locally backward invariant relatively to K.*

Proof. Let us consider $x \in \mathrm{Viab}(K, C)$ and $z(\cdot) \in \mathcal{S}(x)$ viable in K until it possibly reaches C. Let us consider a backward solution $y(\cdot) \in \mathcal{S}_-(x)$ viable in K

such that $\tau_K(y(\cdot)) > 0$. (This is always the case whenever $x \in \mathrm{Int}(K)$.) For every $T \in [0, \tau_K(y(\cdot))[$, we associate with it the solution $x(\cdot) \in \mathcal{S}(x(T))$ defined by

$$x(t) := \begin{cases} y(T-t) & \text{if} \quad t \in [0,T], \\ z(t-T) & \text{if} \quad t \geq T, \end{cases}$$

starting at $y(T) \in K$ viable in K until it possibly reaches C. This means that $y(T) \in \mathrm{Viab}(K,C)$ for every $T \in [0, \tau_K(y(\cdot))[$, i.e., that the backward solution $y(\cdot) \in \mathcal{S}_-(x)$ is viable in $\mathrm{Viab}(K,C)$ on the interval $[0, \tau_K(y(\cdot))]$.

In other words, for every $x \in \mathrm{Viab}(K,C)$, every backward solution viable in K on some time interval is actually viable in $x \in \mathrm{Viab}(K,C)$ on the same interval. □

We derive the following characterization.

PROPOSITION 4.12. *Let us consider a closed subset $C \subset K$. Then C is isolated in K by $\mathcal{S}$ if and only if*

1. *C is locally backward invariant relatively to K, and*
2. *$K \backslash C$ is a repeller.*

Putting together these results, we obtain Theorem 4.13, characterizing viability kernels with targets, and Theorem 4.14, characterizing capture basins.

THEOREM 4.13. *Let us assume that $\mathcal{S}$ is upper semicompact and that the subsets $C \subset K$ and K are closed. The viability kernel* $\mathrm{Viab}(K,C)$ *of a subset K with target C under $\mathcal{S}$ is the* unique *closed subset satisfying $C \subset D \subset K$ and*

$$(4.4) \qquad \begin{cases} \text{(i)} & D \backslash C \text{ is locally viable under } \mathcal{S}, \\ \text{(ii)} & D \text{ is locally backward invariant relatively to } K \text{ under } \mathcal{S}, \\ \text{(iii)} & K \backslash D \text{ is a repeller under } \mathcal{S}. \end{cases}$$

Therefore, Theorem 4.13 and (4.2) imply that when $K \backslash C$ is a repeller, the above theorem implies a characterization of the viable-capture basins.

THEOREM 4.14. *Let us assume that $\mathcal{S}$ is upper semicompact and that a closed subset $C \subset K$ satisfies the property*

$$(4.5) \qquad \mathrm{Viab}(K \backslash C) = \emptyset.$$

Then the viable-capture basin $\mathrm{Capt}^K(C)$ *is the* unique *closed subset D satisfying $C \subset D \subset K$ and*

$$(4.6) \qquad \begin{cases} \text{(i)} & D \backslash C \text{ is locally viable under } \mathcal{S}, \\ \text{(ii)} & D \text{ is locally backward invariant relatively to } K \text{ under } \mathcal{S}. \end{cases}$$

4.4. Viability kernels of backward invariant sets. We obtain further properties when K is backward invariant under $\mathcal{S}$. To begin with, *the capture basin* $\mathrm{Capt}(C) := \mathrm{Capt}^X(C)$ *is contained in K and equal to* $\mathrm{Capt}^K(C)$, *so that*

$$\mathrm{Viab}(K,C) = \mathrm{Viab}(K \backslash C) \cup \mathrm{Capt}(C).$$

THEOREM 4.15. *A subset K is invariant under a set-valued map $\mathcal{S}$ if and only if its complement $X \backslash K$ is backward invariant under $\mathcal{S}$.*

Proof. To say that K is not invariant under $\mathcal{S}$ amounts to saying that there exists a solution $x(\cdot) \in \mathcal{S}(x_0)$ and $T > 0$ such that

$$x(0) \in K \ \& \ x(T) \in X \backslash K.$$

Let $z(\cdot) \in \mathcal{S}_-(x_0)$ be a backward solution, and define the function $y(\cdot)$ by

$$y(t) = \begin{cases} x(T-t) & \text{if} \quad t \in [0,T], \\ z(t-T) & \text{if} \quad t \geq T. \end{cases}$$

It is a backward solution starting at $y(0) = x(T) \in X\backslash K$ and satisfying $y(T) = x_0 \in K$. This amounts to saying that the complement $X\backslash K$ of K is not backward invariant. □

We then derive the following theorem.

THEOREM 4.16. *Assume that $\mathcal{S}$ is upper semicompact, that $C \subset K$ and K are closed, and that K is backward invariant under $\mathcal{S}$. Then the viability kernel* $\mathrm{Viab}(K,C)$ *of K with target C under $\mathcal{S}$ is the* unique *closed subset D satisfying $C \subset D \subset K$ and*

$$\begin{cases} \text{(i)} & D\backslash C \text{ is locally viable under } \mathcal{S}, \\ \text{(ii)} & D \text{ is backward invariant under } \mathcal{S} \text{ (or, equivalently, } X\backslash D \text{ is invariant under } \mathcal{S}), \\ \text{(iii)} & K\backslash D \text{ is a repeller under } \mathcal{S}. \end{cases}$$

Proof. To say that K is backward invariant amounts to saying that the complement of K is invariant thanks to Theorem 4.15. Therefore, $\mathrm{Viab}(K,C)$ being isolated, all solutions starting from $K\backslash\mathrm{Viab}(K,C)$ leave K in finite time before possibly hitting C. Actually, they never reach C because the complement $X\backslash K$ is invariant. Hence we have checked that the complement $X\backslash\mathrm{Viab}(K,C)$ of the viability kernel of K with target C is invariant. Theorem 4.15 implies that the viability kernel $\mathrm{Viab}(K,C)$ of K with target C is backward invariant. □

4.5. The barrier property. The boundary of the viability kernel satisfies the barrier property.

DEFINITION 4.17. *If $D \subset K$, the* boundary $\partial_K(D)$ of D relative to K *is the subset*

$$\partial_K(D) := \overline{D} \cap \overline{(K\backslash D)},$$

and the subset $\partial D := \partial_X(D)$ is called the boundary *of D. We shall say that a subset $D \subset K$ enjoys the* barrier property relative to K under $\mathcal{S}$ *if its boundary $\partial_K(D)$ of D relative to K is locally invariant with respect to D: For every $x \in \partial_K(D)$, all solutions starting from x viable in D are actually viable in the boundary $\partial_K(D)$ of D relative to K until they reach the boundary of K.*

We see at once that

$$\partial_K(D) \cap \mathrm{Int}(K) = \partial D \cap \mathrm{Int}(K)$$

and that

$$\text{if } D \subset \mathrm{Int}(K), \text{ then } \partial_K(D) = \partial D.$$

Remark on the barrier property. The "barrier property" of the viability kernel of a closed subset has been discovered by Marc Quincampoix in [46] and generalized by Pierre Cardaliaguet in [25, 26, 27, 28] for differential games. It plays an important role in control theory and the theory of differential games, because every solution starting from the boundary of the viability kernel can either remain in the boundary or leave the viability kernel, or, equivalently, no solution starting from outside the viability

kernel can cross its boundary. Such solutions can remain only on the boundary of the viability kernel, or leave it.

This is a semipermeability property of the viability kernel, which is very important in terms of interpretation. Viability is indeed a very fragile property, which cannot be reestablished from the outside. *In other words, love it or leave it.* □

THEOREM 4.18. *If $\mathcal{S}$ is upper semicompact and lower semicontinuous, then the viability kernel* $\mathrm{Viab}(K,C)$ *of a closed subset K with a closed target $C \subset K$ under $\mathcal{S}$ enjoys the barrier property relative to K.*

Proof. Let x belong to $\partial_K(\mathrm{Viab}(K,C))$, and let $x(\cdot) \in \mathcal{S}(x)$ be a solution viable in K forever ($\varpi^\sharp_{(K,C)}(x(\cdot)) = +\infty$) or until it reaches C at finite time $\varpi^\sharp_{(K,C)}(x(\cdot)) < +\infty$. Let $x_n \in K\backslash\mathrm{Viab}(K,C)$ converge to x. Since $\mathcal{S}$ is lower semicontinuous by Statement 3, there exists a solution $x_n(\cdot) \in \mathcal{S}(x_n)$ converging to $x(\cdot)$ uniformly over compact intervals. Since $\mathrm{Viab}(K,C)$ is isolated, we know that for every n,

$$\forall\, t \leq \tau_K(x_n(\cdot)),\ \ x_n(t) \in K\backslash\mathrm{Viab}(K,C).$$

Since $\varpi_{\partial K}(x_n(\cdot)) \ \leq\ \tau_K(x_n(\cdot))$ and since the functional $x(\cdot) \mapsto \varpi_{\partial K}(x(\cdot))$ is lower semicontinuous, we infer that for every $t < \varpi_{\partial K}(x(\cdot))$ there exists $N > 0$ such that for any $n \geq N$,

$$t < \varpi_{\partial K}(x_n(\cdot)) \ \leq\ \tau_K(x_n(\cdot)),$$

and thus that $x_n(t)$ belongs to $K\backslash\mathrm{Viab}(K,C)$. Taking the limit, we infer that $x(t)$ belongs to $\overline{K\backslash\mathrm{Viab}(K,C)}$. Hence $x(t)$ belongs to the boundary $\partial_K(\mathrm{Viab}(K,C))$ of the viability kernel relative to K whenever $t < \varpi_{\partial K}(x(\cdot))$. □

5. Frankowska's and viscosity property of viability kernels. We restrict now our study to the case of viability kernels with targets under evolutionary systems defined by the solution maps of differential inclusions $x' \in F(x)$. In this case, the viability and invariance theorems characterize the viability and invariance properties by tangential conditions, as it was mentioned in the introduction, or, equivalently,[4] by normal conditions. We recall that the (regular) *normal cone*[5] $N_L(x) := T_L(x)^-$ to a subset L at $x \in L$ is the polar cone to the contingent cone $T_L(x)$ (see, for instance, [10] or [49] for more details). We denote by

$$\forall\, p \in X^\star,\ \ \sigma(K,p) \ :=\ \sup_{x\in K}\langle p,x\rangle$$

the *support function* of K.

$$\forall\, x \in K\backslash R^{-1}(K),\ \ F(x) \cap T_K(x) \neq \emptyset.$$

5.1. The basic viability and invariance theorems.

STATEMENT 4. *Assume that F is Marchaud. The two following statements hold true.*

1. *If K is closed, then K is (globally) viable under F if and only if*

$$\forall\, x \in K,\ \ F(x) \cap T_K(x) \neq \emptyset,$$

[4]The equivalence between tangential and normal conditions was first noticed in a different context in [41]. A simpler proof of this fact was given by Hélène Frankowska and appeared in [14] and in Theorem 3.2.4 of [2]. Other proofs were provided later in [24] and [57].

[5]One can replace if wished this normal cone $N_L(x)$ by the smaller subset $x - \Pi_L(x)$ of *normal proximals* to L at x, where $\Pi_L(x)$ denotes the set of best approximations of x by elements of L.

or, equivalently, in dual form, if and only if

$$\forall\, x \in K,\ \forall\, p \in N_K(x),\ \ \sigma(F(x), -p)\ \geq\ 0.$$

2. *If $C \subset K$ is closed, then K captures C by F if and only if*

$$\forall\, x \in K\backslash C,\ \ F(x) \cap T_K(x) \neq \emptyset,$$

or, equivalently, in dual form, if and only if

$$\forall\, x \in K\backslash C,\ \forall\, p \in N_K(x),\ \ \sigma(F(x), -p)\ \geq\ 0.$$

STATEMENT 5. *Assume that F is Lipschitz. The two following statements hold true.*

1. *If K is closed, then K is (globally) invariant under F if and only if*

$$\forall\, x \in K,\ \ F(x)\ \subset\ T_K(x),$$

or, equivalently, in dual form, if and only if

$$\forall\, x \in K,\ \forall\, p \in N_K(x),\ \sigma(F(x), p)\ \leq\ 0.$$

2. *If $C \subset K$ is closed, then K absorbs C by F if and only if*

$$\forall\, x \in K\backslash C,\ \ F(x)\ \subset\ T_K(x),$$

or, equivalently, in dual form, if and only if

$$\forall\, x \in K\backslash C,\ \forall\, p \in N_K(x),\ \sigma(F(x), p)\ \leq\ 0.$$

3. *If $C \subset K$ is closed, then C is backward invariant under F relatively to K if and only if*

$$(5.1)\qquad \begin{cases} \text{(i)} & \forall\, x \in C \cap \mathrm{Int}(K),\ \ -F(x)\ \subset\ T_C(x), \\ \text{(ii)} & \forall\, x \in C \cap \partial K,\ \ -F(x)\ \subset\ T_C(x) \cup T_{X\backslash K}(x), \end{cases}$$

or, equivalently, in normal form, if and only if

$$(5.2)\begin{cases} \text{(i)} & \forall\, x \in C \cap \mathrm{Int}(K),\ \ \forall\, p \in N_C(x),\ \ \sigma(F(x), -p)\ \leq\ 0, \\ \text{(ii)} & \forall\, x \in C \cap \partial K,\ \ \forall\, p \in N_C(x) \cap N_{\overline{X\backslash K}}(x),\ \ \sigma(F(x), -p)\ \leq\ 0. \end{cases}$$

5.2. Tangential and normal characterizations of viability kernels with targets. Using the viability theorem, Statement 1, and the invariance theorem, Statement 5, we deduce that the viability kernels and the viable-capture basins enjoy tangential and normal characterizations.

For that purpose, we introduce the following Frankowska property.

DEFINITION 5.1. *Let us consider a set-valued map $F : X \rightsquigarrow X$ and two subsets $C \subset K$ and K. We shall say that a subset D between C and K satisfies the* Frankowska property *with respect to F if*

$$(5.3)\qquad \begin{cases} \text{(i)} & \forall\, x \in D\backslash C,\ \ F(x) \cap T_D(x)\ \neq\ \emptyset, \\ \text{(ii)} & \forall\, x \in D \cap \mathrm{Int}(K),\ \ -F(x)\ \subset\ T_D(x), \\ \text{(iii)} & \forall\, x \in D \cap \partial K,\ \ -F(x)\ \subset\ T_D(x) \cup T_{X\backslash K}(x), \end{cases}$$

or, equivalently, by duality, satisfying the "normal conditions"

$$(5.4)\quad \begin{cases} \text{(i)} & \forall\, x \in D\backslash C,\ \forall\, p \in N_D(x),\ \ \sigma(F(x), -p) \geq 0, \\ \text{(i)} & \forall\, x \in D \cap \mathrm{Int}(K),\ \forall\, p \in N_D(x),\ \ \sigma(F(x), -p) \leq 0, \\ \text{(ii)} & \forall\, x \in D \cap \partial K,\ \forall\, p \in N_D(x) \cap N_{\overline{X\backslash K}}(x),\ \ \sigma(F(x), -p) \leq 0. \end{cases}$$

When K is assumed further to be backward locally invariant, the above conditions (5.3) *and* (5.4) *boil down to*

$$(5.5)\quad \begin{cases} \text{(i)} & \forall\, x \in D\backslash C,\ \ F(x) \cap T_D(x) \neq \emptyset, \\ \text{(ii)} & \forall\, x \in D,\ \ -F(x) \subset T_D(x), \end{cases}$$

and

$$(5.6)\quad \begin{cases} \text{(i)} & \forall\, x \in D\backslash C,\ \forall\, p \in N_D(x),\ \ \sigma(F(x), -p) = 0, \\ \text{(ii)} & \forall\, x \in D,\ \forall\, p \in N_D(x),\ \ \sigma(F(x), -p) \leq 0, \end{cases}$$

respectively.

We deduce from the characterization theorem, Theorem 4.13, its tangential and normal formulations.

THEOREM 5.2. *Let us assume that F is Marchaud and that $C \subset K$ and K are closed. The viability kernel* $\mathrm{Viab}_F(K, C)$ *of the subset K with target C under F is*

1. *the* largest *closed subset D of K satisfying*

$$\forall\, x \in D\backslash C,\ \ F(x) \cap T_D(x) \neq \emptyset.$$

2. *When F is assumed to be also Lipschitz, the viability kernel* $\mathrm{Viab}_F(K, C)$ *is the* unique *closed subset $D \subset K$ satisfying*
   (a) *the Frankowska property* (5.3) *(or its dual formulation* (5.4)*);*
   (b) *$K\backslash D$ is a repeller.*

As a consequence, we obtain the following tangential characterization of viable-capture basins.

THEOREM 5.3. *Let us assume that F is Marchaud, that K is closed, and that a closed subset C satisfies* $\mathrm{Viab}_F(K\backslash C) = \emptyset$. *Then the viable-capture basin* $\mathrm{Capt}_F^K(C)$ *is*

1. *the* largest *closed subset D satisfying $C \subset D \subset K$ and*

$$(5.7)\qquad \forall\, x \in D\backslash C,\ \ F(x) \cap T_D(x) \neq \emptyset.$$

2. *If F is Lipschitz, the viable-capture basin* $\mathrm{Capt}_F^K(C)$ *is the* unique *closed subset D satisfying the Frankowska property* (5.3) *(or its dual formulation* (5.4)*).*

We now define the following "viscosity property."

DEFINITION 5.4. *Let us consider a set-valued map $F : X \rightsquigarrow X$ and two subsets $C \subset K$ and K. We shall say that a subset D between C and K satisfies the* viscosity property *with respect to F if*

$$(5.8)\quad \begin{cases} \text{(i)} & \forall\, x \in \underline{D\backslash C},\ \ F(x) \cap T_D(x) \neq \emptyset, \\ \text{(ii)} & \forall\, x \in \overline{X\backslash D},\ \ F(x) \subset T_{\overline{X\backslash D}}(x), \end{cases}$$

and, in normal form,

$$(5.9)\quad \begin{cases} \text{(i)} & \forall\, x \in \underline{D\backslash C},\ \forall\, p \in N_D(x),\ \ \sigma(F(x), -p) \geq 0, \\ \text{(ii)} & \forall\, x \in \overline{X\backslash D},\ \forall\, p \in N_{\overline{X\backslash D}}(x),\ \ \sigma(F(x), p) \leq 0, \end{cases}$$

respectively.

When $C = \emptyset$, we recognize the definition of a discriminating kernel of K of the Hamiltonian $H(x,p) := \sigma(F(x), -p)$ given in [26], for instance.

THEOREM 5.5. *Let us assume that F is Marchaud and Lipschitz, that $C \subset K$ and K are closed, and that K is backward invariant. The viability kernel* $\mathrm{Viab}_F(K,C)$ *of the subset K with the target C under F is the* unique *closed subset $D \subset K$ satisfying the following:*

1. *the viscosity property* (5.8) *(or its dual formulation* (5.9)*);*
2. *$K \backslash D$ is a repeller.*

6. Stability properties. Consider two sequences of subsets $C_n \subset C$ and $K_n \subset X$ and their Painlevé–Kuratowski upper limits

$$C^\sharp := \mathrm{Limsup}_{n\to+\infty} C_n \;\&\; K^\sharp := \mathrm{Limsup}_{n\to+\infty} K_n.$$

Recall that the upper limit of a sequence of constant subsets C is the closure of C.

DEFINITION 6.1. *We define the hypolimit* $\lim^\sharp_{\downarrow n\to\infty} \tau^\sharp_{K_n}$ *of upper exit functions* $\tau^\sharp_{K_n}$ *whose hypograph is the upper limit of the hypographs of the functions* $\tau^\sharp_{K_n}$

$$\mathcal{H}p\left(\lim^\sharp_{\downarrow n\to\infty}\left(\tau^\sharp_{K_n}\right)\right) := \mathrm{Limsup}_{n\to\infty} \mathcal{H}p(\tau^\sharp_{K_n}).$$

It is the upper hypolimit *of the functions $\tau^\sharp_{K_n}$, equal to*

$$\left(\lim^\sharp_{\downarrow n\to\infty} \tau^\sharp_{K_n}\right)(x_0) = \limsup_{n\to\infty,\, x_n \to_{K_n} x_0} \tau^\sharp_{K_n}(x_n).$$

In the same way, we define the upper epilimit $\lim^\sharp_{\uparrow n\to\infty} \varpi^\flat_{(K_n,C_n)}$ *whose epigraph is the upper limit of the epigraphs of the functions* $\varpi^\flat_{(K_n,C_n)}$

$$\mathcal{E}p\left(\lim^\sharp_{\uparrow n\to\infty} \varpi^\flat_{(K_n,C_n)}\right) := \mathrm{Limsup}_{n\to\infty} \mathcal{E}p\left(\varpi^\flat_{(K_n,C_n)}\right).$$

It is the upper epilimit *of the functions $\varpi^\flat_{(K_n,C_n)}$, equal to*

$$\left(\lim^\sharp_{\uparrow n\to\infty} \varpi^\flat_{(K_n,C_n)}\right)(x_0) = \liminf_{n\to\infty,\, x_n \to_{K_n} x_0} \varpi^\flat_{(K_n,C_n)}(x_n).$$

We have to prove this very useful stability result.

THEOREM 6.2. *Let $\mathcal{S} : X \rightsquigarrow \mathcal{C}(0,+\infty;X)$ be a strict upper semicompact map. Consider two sequences of subsets $C_n \subset C$ and $K_n \subset X$ and their Painlevé–Kuratowski upper limits*

$$C^\sharp := \mathrm{Limsup}_{n\to+\infty} C_n \;\&\; K^\sharp := \mathrm{Limsup}_{n\to+\infty} K_n.$$

Then

1. *the upper hypolimit of the upper exit functions of a sequence of subsets K_n is smaller than or equal to the upper exit function of their upper limit:*

$$\left(\lim^\sharp_{\downarrow n\to\infty} \tau^\sharp_{K_n}\right)(x) \le \tau^\sharp_{K^\sharp}(x);$$

2. *the upper epilimit of the lower constrained hitting functions of a sequence of subsets $C_n \subset K_n$ is larger than or equal to the lower constrained hitting function of their upper limit:*

$$\left(\liminf^{\sharp}_{\uparrow n\to\infty} \varpi^{\flat}_{(K_n,C_n)}\right)(x) \;\geq\; \varpi^{\flat}_{(K^\sharp,C^\sharp)}(x).$$

Proof. Let us begin by proving the first inequality, which can be translated in the form of the inclusion

$$\mathrm{Limsup}_{n\to\infty} \mathcal{H}p\left(\tau^{\sharp}_{K_n}\right) \;\subset\; \mathcal{H}p\left(\tau^{\sharp}_{K^\sharp}\right).$$

For that purpose, let us take a sequence $(T_n, x_n) \in \mathcal{H}p(\tau^{\sharp}_{K_n})$ converging to (T, x) and check that this limit belongs to the hypograph of $\tau^{\sharp}_{K^\sharp}$. By definition, there exists a solution $x_n(\cdot) \in \mathcal{S}(x_n)$ starting at x_n such that, for every $t \in [0, T_n[$, $x_n(t)$ belongs to K_n. Since $\mathcal{S}$ is upper semicompact, a subsequence (again denoted by) $x_n(\cdot)$ converges uniformly on compact intervals to some solution $x(\cdot) \in \mathcal{S}(x)$ starting at x. Take $t < T$ and n large enough for having $t < T_n$. In this case, $x_n(t)$ belongs to K_n and, passing to the limit, $x(t)$ belongs to $K^\sharp$. This implies that

$$T \;\leq\; \tau_K(x(\cdot)) \;\leq\; \tau^{\sharp}_{K^\sharp}(x).$$

Taking $K_n := K$, $x_n := x \in K$, and $T_n < \tau^{\sharp}_K(x)$ converging to $\tau^{\sharp}_K(x)$, we infer that the solution $x(\cdot)$ obtained above achieves the supremum.

Let us prove now the second inequality, which can be translated in the form of the inclusion

$$\mathrm{Limsup}_{n\to\infty} \mathcal{E}p\left(\varpi^{\flat}_{(K_n,C_n)}\right) \;\subset\; \mathcal{E}p\left(\varpi^{\flat}_{(K_n,C_n)}\right).$$

For that purpose, let us take sequences $(T_n, x_n) \in \mathcal{E}p(\varpi^{\flat}_{(K_n,C_n)})$ converging to (T, x) and check that this limit belongs to the epigraph of $\varpi_{(K^\sharp,C^\sharp)}$.

For every $\varepsilon > 0$, there exist N such that for $n \geq N$, there exists a solution $x_n(\cdot) \in \mathcal{S}(x_n)$ and $t_n \leq T_n + \frac{\varepsilon}{2} \leq T + \varepsilon$ such that $x_n(t_n) \in C_n$, and for every $s < t_n$, $x_n(s) \in K_n$. Since $\mathcal{S}$ is upper semicompact, a subsequence (again denoted by) $x_n(\cdot)$ converges uniformly on compact intervals to some solution $x(\cdot) \in \mathcal{S}(x)$. Let us consider also a subsequence (again denoted by) t_n converging to some $T^\star \leq T + \varepsilon$. By passing to the limit, we infer that $x(T^\star)$ belongs to $C^\sharp$ and that, for any $s < T^\star$, $x(s)$ belongs to $K^\sharp$. This implies that

$$\varpi^{\flat}_{(K^\sharp,C^\sharp)}(x) \;\leq\; \varpi_{(K^\sharp,C^\sharp)}(x(\cdot)) \;\leq\; T^\star \;\leq\; T + \varepsilon.$$

We conclude by letting ε converge to 0. Taking $K_n := K$, $x_n := x \in K$, and $T_n < \tau^{\sharp}_K(x)$ converging to $\tau^{\sharp}_K(x)$, we infer that the solution $x(\cdot)$ obtained above achieves the supremum.

Taking $K_n := K$, $C_n := C$, $x_n := x \in K$, and $T_n \geq \varpi^{\flat}_{(K,C)}(x)$ converging to $\varpi^{\flat}_{(K,C)}(x)$, we infer that the solution $x(\cdot)$ obtained above achieves the infimum. □

We derive stability properties of the viability kernels with targets.

THEOREM 6.3. *Let us assume that the map $\mathcal{S}$ is upper semicompact.*

If a subset K captures a subset $C \subset K$ under $\mathcal{S}$, then its closure $\overline{K}$ also captures the closure $\overline{C}$ of the target C.

More generally, let us consider a sequence of subsets K_n and of targets $C_n \subset K_n$. If K_n captures C_n for every $n \geq 0$, then the upper limit $\mathrm{Limsup}_{n\to+\infty} K_n$ *captures the upper limit* $\mathrm{Limsup}_{n\to+\infty} C_n$ *of the targets C_n.*

Proof. Let us set

$$C^\sharp := \mathrm{Limsup}_{n\to+\infty} C_n \text{ and } K^\sharp := \mathrm{Limsup}_{n\to+\infty} K_n.$$

Let us consider the limit $x := \lim_{n\to+\infty} x_n \in K^\sharp$ of elements $x_n \in K_n$. Since C_n captures K_n, there exists a solution $x_n(\cdot) \in \mathcal{S}(x_n)$ viable in K_n until it possibly reaches C_n at time $t_n := \varpi_{C_n}(x_n(\cdot))$, finite or infinite.

Since $\mathcal{S}$ is upper semicompact, a subsequence (again denoted by) $x_n(\cdot)$ converges to some $x(\cdot) \in \mathcal{S}(x)$ uniformly on compact intervals.

Since $x_n(\cdot)$ is viable in K_n until it reaches C_n, we know that

$$\varpi_{C_n}(x_n(\cdot)) \leq \tau_{K_n}(x_n(\cdot)).$$

Either the limit x belongs to the viability kernel $\mathrm{Viab}(K^\sharp)$ of the upper limit $K^\sharp$, or else this limit x does not belong to the viability kernel $\mathrm{Viab}(K^\sharp)$ and we have to check that it belongs to the viable-capture basin $\mathrm{Capt}_{K^\sharp}(C^\sharp)$. This means that $\tau^\sharp_{K^\sharp}(x)$ is finite. Since $\mathcal{S}$ is upper semicompact, Theorem 6.2 implies that

$$\limsup_{n\to+\infty, x_n \to_{K_n} x} \tau^\sharp_{K_n}(x_n) \leq \tau^\sharp_{K^\sharp}(x).$$

For n large enough, there exists $T_n < +\infty$ satisfying

$$\varpi_{C_n}(x_n(\cdot)) \leq T_n \leq \tau_{K_n}(x_n(\cdot)) \leq \tau^\sharp_{K_n}(x_n) \leq \tau^\sharp_{K^\sharp}(x) + 1 < +\infty.$$

Therefore, a subsequence (again denoted by) T_n converges to some $T^\star \leq \tau^\sharp_{K^\sharp}(x) + 1$. Theorem 6.2 implies that

$$\varpi^\flat_{(K^\sharp, C^\sharp)}(x) \leq \varpi_{(K^\sharp, C^\sharp)}(x(\cdot)) \leq T^\star \leq \tau_{K^\sharp}(x(\cdot)) \leq \tau_{K^\sharp}(x).$$

Hence from every $x \in K^\sharp$ starts a solution viable in $K^\sharp$ until it possibly reaches C, so that $K^\sharp$ captures $C^\sharp$. □

As a consequence, we obtain the following theorem.

THEOREM 6.4. *Let us assume that the map $\mathcal{S}$ is upper semicompact. Then*

$$\overline{\mathrm{Viab}(K, C)} \subset \mathrm{Viab}(\overline{K}, \overline{C}),$$

and thus, if $C \subset K$ and K are closed, so is the viability kernel $\mathrm{Viab}(K, C)$ *of K with target C.*

More generally, let us consider a sequence of subsets K_n and of targets $C_n \subset K_n$ and their upper limits $K^\sharp$ and $C^\sharp$. Then

$$\mathrm{Limsup}_{n\to+\infty} \mathrm{Viab}(K_n, C_n) \subset \mathrm{Viab}(\mathrm{Limsup}_{n\to+\infty} K_n, \mathrm{Limsup}_{n\to+\infty} C_n). \tag{6.1}$$

THEOREM 6.5. *If the set-valued map $\mathcal{S}_-$ is lower semicontinuous, then for any sequence of closed subsets C_n,*

$$\mathrm{Capt}(\mathrm{Liminf}_{n\to+\infty} C_n) \subset \mathrm{Liminf}_{n\to+\infty} \mathrm{Capt}(C_n). \tag{6.2}$$

Proof. For proving that

$$\mathrm{Capt}(\mathrm{Liminf}_{n\to+\infty} C_n) \subset \mathrm{Liminf}_{n\to+\infty} \mathrm{Capt}(C_n),$$

let $C^\flat$ denote the lower limit of the subsets C_n. Let us take $x \in \mathrm{Capt}(C^\flat)$ and a solution $x(\cdot) \in \mathcal{S}(x)$ viable in K until it reaches the target $C^\flat$ at time $T < +\infty$ at $c := x(T) \in C^\flat$. Hence the function $t \mapsto y(t) := x(T-t)$ is a solution $y(\cdot) \in \mathcal{S}_-(c)$. Let us consider a sequence of elements $c_n \in C_n$ converging to c.

Since $\mathcal{S}_-$ is lower semicontinuous, there exist solutions $y_n(\cdot) \in \mathcal{S}_-(c_n)$ converging uniformly over compact intervals to $x(\cdot)$. Therefore, $x_n := y_n(T)$ converges to x. It is enough to observe that x_n belongs to $\mathrm{Capt}(C_n)$ to conclude. □

As a consequence, we obtain the following theorem.

THEOREM 6.6. *Let us consider a sequence of closed subsets C_n satisfying* $\mathrm{Viab}(K) \subset C_n \subset K$ *and*

$$\mathrm{Lim}_{n\to+\infty} C_n \;:=\; \mathrm{Limsup}_{n\to+\infty} C_n \;=\; \mathrm{Liminf}_{n\to+\infty} C_n.$$

If the set-valued map $\mathcal{S}$ is upper semicompact, if $\mathcal{S}_-$ is lower semicontinuous, and if K is closed and backward invariant under $\mathcal{S}$, then

$$\mathrm{Lim}_{n\to+\infty} \mathrm{Capt}^K(C_n) \;=\; \mathrm{Capt}^K(\mathrm{Lim}_{n\to+\infty} C_n). \tag{6.3}$$

7. Optimal evolutionary control system. We devote this section to statements of applications to optimal control and stopping time problems. We refer to [8, 9] for applications to systems of first-order partial differential equations and inclusions.

7.1. Control evolutionary systems. We denote by $L^1(0,\infty;\mathcal{U})$ the space of measurable integrable functions from $[0,+\infty[$ to a finite dimensional vector-space $\mathcal{U}$, the *control space*. We shall supply it with the weakened topology.

DEFINITION 7.1. *Let us consider topological vector spaces X (the* state space*) and $\mathcal{U}$ (the control space). A control evolutionary system is a set-valued map $\mathcal{C} : X \rightsquigarrow \mathcal{C}(0,\infty;X) \times L^1(0,\infty;\mathcal{U})$ associating with any x a set of state-control pairs $(x(\cdot),u(\cdot))$ satisfying the following.*

1. *The* translation property. *Let $(x(\cdot),u(\cdot)) \in \mathcal{C}(x)$. Then for all $T \geq 0$, the function $(y(\cdot),v(\cdot))$ defined by $y(t) := x(t+T)$ and $v(t) := u(t+T)$ is a solution $(y(\cdot),v(\cdot)) \in \mathcal{C}(x(T))$ starting at $x(T)$.*
2. *The* concatenation property. *Let $(x(\cdot),u(\cdot)) \in \mathcal{C}(x)$, and $T \geq 0$. Then for every $(y(\cdot),v(\cdot)) \in \mathcal{C}(x(T))$, the pair $(z(\cdot),w(\cdot))$ of functions defined by*

$$z(t) \;:=\; \begin{cases} x(t) & \text{if} \quad t \in [0,T], \\ y(t-T) & \text{if} \quad t \geq T \end{cases}$$

and

$$w(t) \;:=\; \begin{cases} u(t) & \text{if} \quad t \in [0,T], \\ v(t-T) & \text{if} \quad t \geq T \end{cases}$$

belongs to $\mathcal{C}(x)$.

We shall say that the control evolutionary system $\mathcal{C}$ is upper semicompact if the set-valued map $x \rightsquigarrow \mathcal{C}(x)$ is upper semicompact from X to $\mathcal{C}(0,\infty;X) \times L_1(0,\infty;X)$.

Control evolutionary systems provide examples of evolutionary systems by setting

$$\mathcal{S}(x) \;:=\; \bigcup_{\{u(\cdot)\;|\;(x(\cdot),u(\cdot))\in\mathcal{C}(x)\}} \{x(\cdot)\}.$$

Usual control problems provide examples of control evolutionary systems.

7.2. Control systems. Let us consider a control problem (P, f) with a priori feedback map $P : X \rightsquigarrow \mathcal{U}$ from X to some finite dimensional vector space $\mathcal{U}$ governing the evolution of $(x(\cdot), u(\cdot))$ according the system

$$\left\{ \begin{array}{ll} \text{(i)} & x'(t) \ = \ f(x(t), u(t)), \\ \text{(ii)} & u(t) \ \in \ P(x(t)). \end{array} \right. \tag{7.1}$$

Starting from x, we define $\mathcal{C}_{(P,F)}(x)$ as the set of pairs $(x(\cdot), u(\cdot)) \in \mathcal{C}(0, \infty; X) \times L^1(0, \infty; \mathcal{U})$ satisfying (7.1) for almost all $t \geq 0$ such that $x(0) = 0$.

DEFINITION 7.2. *We shall say that the* control system (P, f) *is*

1. Marchaud *if the set-valued map $P : X \rightsquigarrow \mathcal{U}$ is Marchaud, if $f : X \times \mathcal{U} \mapsto X$ is continuous and affine with respect to the control, and if f satisfies the growth condition*

$$\forall\ (x, u) \in \text{Graph}(P), \ \ \|f(x, u)\| \ \leq \ c(\|x\| + \|u\| + 1);$$

2. Lipschitz *if the set-valued map $P : X \rightsquigarrow \mathcal{U}$ is Lipschitz and if $f : X \times \mathcal{U} \mapsto X$ is Lipschitz.*

Therefore, a control system (P, f) provides an example of upper semicompact evolutionary systems $\mathcal{S}$ if the control system (P, f) is Marchaud and an example of a lower semicontinuous evolutionary systems $\mathcal{S}$ if the control system (P, f) is Lipschitz.

7.3. Optimal evolutionary control. Let us introduce the following two features:

1. a discount factor

$$\mathbf{m} : (x, u) \in X \times \mathcal{U} \mapsto \mathbf{m}(x, u) \in \mathbf{R},$$

2. an extended "Lagrangian"

$$\mathbf{l} : (x, u) \in X \times \mathcal{U} \mapsto \mathbf{l}(x, u) \in \mathbf{R},$$

used to measure a cumulated cost over time.

We associate with them the auxiliary evolutionary control system $\mathcal{R}$ defined by

$$\mathcal{R}(T, x, y) \ = \ \{(T - \cdot, x(\cdot), u(\cdot), y(\cdot))\}_{(x(\cdot),u(\cdot))\in\mathcal{C}(x)},$$

where

$$y(t) \ \leq \ e^{-\int_0^t \mathbf{m}(x(s),u(s))ds} \left(y - \int_0^t e^{\int_0^\tau \mathbf{m}(x(s),u(s))ds} \mathbf{l}(x(\tau), u(\tau))d\tau \right). \tag{7.2}$$

7.4. Objective and constraints. Let us consider two nonnegative extended cost functions $\mathbf{b}$ (constraint function) and $\mathbf{c}$ (objective function) satisfying

$$\forall\ (t, x) \in \mathbf{R}_+ \times \mathbf{R}_+^{n+1}, \ \ 0 \ \leq \ \mathbf{b}(t, x) \ \leq \ \mathbf{c}(t, x) \ \leq \ +\infty,$$

allowed to take infinite values in order to describe state constraints. We extend them as functions from $\mathbf{R} \times \mathbf{R}^{n+1}$ to $\mathbf{R}_+ \cup \{+\infty\}$ by setting

$$\forall\ (t, x) \notin \mathbf{R}_+ \times \mathbf{R}_+^{n+1}, \ \ \mathbf{b}(t, x) \ = \ \mathbf{c}(t, x) \ = \ +\infty,$$

so that nonnegativity constraints on time and on the state variables are automatically taken into account. In particular, we shall denote by $\mathbf{0}$ the function defined by

$$\mathbf{0}(t, x) \ = \left\{ \begin{array}{ll} 0 & \text{if} \qquad t \geq 0, \ x \in \mathbf{R}_+^{n+1}, \\ +\infty & \text{if not.} \end{array} \right.$$

Several control problems, in particular, financial problems such as the valuation of options, are stated in the following fashion.

DEFINITION 7.3. *The two nonnegative extended constraint and objective functions being given, and given also a horizon time $T > 0$, the problem is to*

1. *find the* valuation subset $\mathcal{V} \subset \mathbf{R}_+ \times \mathbf{R}^{n+1} \times \mathbf{R}$ *of triples* (T, x, y) *made of the horizon time* T*, the initial state* x*, and the cost* y *such that there exists a control* $t \in [0, T] \mapsto u(t) \in P(x(t))$ *and a time* $\varpi(T) \in [0, T]$ *such that the solution to the system* (7.3) *satisfying* $x(0) = x$*,* $y(0) = y$ *and*

$$\left\{ \begin{array}{ll} \text{(i)} & \forall\, t \in [0, \varpi(T)],\ \ y(t) \geq \mathbf{b}(T - t, x(t)), \\ \text{(ii)} & y(\varpi(T) \geq \mathbf{c}(T - \varpi(T), x(\varpi(T))); \end{array} \right. \tag{7.3}$$

2. *associate with any initial price* x *the smallest cost*

$$V(T, x) \ := \ \inf_{(T,x,y) \in \mathcal{V}} y. \tag{7.4}$$

The function $(T, x) \mapsto V(T, x)$ *is called the* value function of the problem*, i.e., the minimal initial cost* y *satisfying the two above constraints* (7.3)*.*

We observe at once the following property. *The value function satisfies the initial condition*

$$\forall\, x \in \mathbf{R}^n,\ \ V(0, x) \ = \ \mathbf{c}(0, x).$$

We observe that *the valuation subset* $\mathcal{V}$ *is the viable-capture basin of the epigraph of* $\mathbf{c}$ *viable in the epigraph of* $\mathbf{b}$ *under the auxiliary evolutionary control system* (7.3) because dynamical constraints (7.3) can be reformulated in the form

$$\left\{ \begin{array}{ll} \text{(i)} & \forall\, t \in [0, \varpi(T)],\ \ (T - t, x(t), y(t)) \ \in \ \mathcal{E}p(\mathbf{b}), \\ \text{(ii)} & (T - \varpi(T), x(\varpi(T)), y(\varpi(T))) \ \in \ \mathcal{E}p(\mathbf{c}). \end{array} \right. \tag{7.5}$$

Therefore, we can reformulate the definition of the valuation subset $\mathcal{V}$ and of the value function $(T, x) \mapsto V(T, x)$ in the following way.

PROPOSITION 7.4. *The valuation subset*

$$\mathcal{V} \ = \ \mathrm{Capt}_{\mathcal{R}}^{\mathcal{E}p(\mathbf{b})}(\mathcal{E}p(\mathbf{c}))$$

is the viable-basin capture of the epigraph of the cost function $\mathbf{c}$ *under the auxiliary evolutionary control system* (7.3) *viable in the epigraph of the cost function* $\mathbf{b}$*.*

We can prove that V is the concealed value function of an optimal evolutionary control system that we have to unearth. For that purpose, we associate with the function $\mathbf{c}$ the *cost functional*

$$\left\{ \begin{array}{l} J_{\mathbf{c}}(t, x; (x(\cdot), u(\cdot))) \\ \\ := \ e^{\int_0^t \mathbf{m}(x(s), u(s))ds} \mathbf{c}(T - t, x(t)) + \displaystyle\int_0^t e^{\int_0^\tau \mathbf{m}(x(s), u(s))ds} \mathbf{l}(x(\tau), u(\tau))d\tau \end{array} \right.$$

(where t ranges over $[0, T]$), constituted by the sum of the discounted spot cost and the cumulated costs at time t of a solution to the control problem starting at x at the initial time. The controls—most often prices or other regulees in economics, portfolio in finance—appear *both* in the discount factor $\mathbf{m}$ and the Lagrangian $\mathbf{l}$. In

the same way, we associate with the function $\mathbf{b}$ the *cost functional* $J_{\mathbf{b}}$ and the maximal cumulated cost up to the current time t:

$$K_{\mathbf{b}}(t,x;(x(\cdot),u(\cdot))) := \sup_{s\in[0,t]} J_{\mathbf{b}}(s,x;(x(\cdot),u(\cdot))).$$

We next integrate this cumulated cost together with the former cost $J_{\mathbf{c}}(t,x;(x(s),u(s)))$ by introducing the new cost function

$$L^{\mathbf{c}}_{\mathbf{b}}(t,x;(x(\cdot),u(\cdot))) := \max(K_{\mathbf{b}}(t,x;(x(\cdot),u(\cdot))), J_{\mathbf{c}}(t,x;(x(\cdot),u(\cdot)))).$$

The problem is now to minimize over all $t\in[0,T]$ and over all the solutions to the evolutionary control problem:

$$V_{\mathbf{b}}(\mathbf{c})(T,x) := \inf_{(x(\cdot),u(\cdot))\in\mathcal{C}(x)} \inf_{t\in[0,T]} L^{\mathbf{c}}_{\mathbf{b}}(t,x;(x(\cdot),u(\cdot))).$$

STATEMENT 6. *Let us assume that the extended functions* $\mathbf{b}$ *and* $\mathbf{c}$ *are nontrivial and nonnegative. The constrained discounted intertemporal value function* $V_{\mathbf{b}}(\mathbf{c})$ *is equal to the function* V *associated with the viable-capture basin* $\mathrm{Capt}^{\mathcal{E}p(\mathbf{b})}_{\mathcal{R}}(\mathcal{E}p(\mathbf{c}))$ *of* $\mathcal{E}p(\mathbf{c})$ *under* $\mathcal{R}$. *Furthermore, any solution* $(x(\cdot),u(\cdot))\in\mathcal{C}(x)$ *starting from* $x\in \mathrm{Dom}(V_{\mathbf{b}}(\mathbf{c}))$ *satisfying the inequality for every* $t\in[0,\varpi(T,x(\cdot))]$

$$(7.6)\quad \begin{cases} V_{\mathbf{b}}(\mathbf{c})(T,x) \\ \geq\ e^{\int_0^t \mathbf{m}(x(s),u(s))ds} V_{\mathbf{b}}(\mathbf{c})(T-t,x(t)) + \displaystyle\int_0^t e^{\int_0^\tau \mathbf{m}(x(s),u(s))ds}\mathbf{l}(x(\tau),u(\tau))d\tau \end{cases}$$

until the first time $\varpi(T,x(\cdot))$ *when*

$$V_{\mathbf{b}}(\mathbf{c})(T-\varpi(T,x(\cdot))),x(\varpi(T,x(\cdot))) = \mathbf{b}(T-\varpi(T,x(\cdot))),x(\varpi(T,x(\cdot)))$$

is an optimal solution for the optimal time $\varpi(T,x(\cdot))$ *and actually satisfies the equality*

$$(7.7)\quad \begin{cases} \forall\, t\in[0,\varpi(T,x(\cdot))],\ V_{\mathbf{b}}(\mathbf{c})(T,x) \\ \\ =\ e^{\int_0^t \mathbf{m}(x(s),u(s))ds} V_{\mathbf{b}}(\mathbf{c})(T-t,x(t)) + \displaystyle\int_0^t e^{\int_0^\tau \mathbf{m}(x(s),u(s))ds}\mathbf{l}(x(\tau),u(\tau))d\tau. \end{cases}$$

Finally, the value function is a solution $\mathbf{v}$ *to the two following functional equations stating that the functions* $L^{\mathbf{v}}_{\mathbf{b}}$ *and* $L^{\mathbf{c}}_{\mathbf{v}}$ *have the same infimum as* $L^{\mathbf{c}}_{\mathbf{b}}$:

$$(7.8)\quad \begin{cases} \inf_{(x(\cdot),u(\cdot))\in\mathcal{C}(x)} \inf_{t\in[0,T]} L^{\mathbf{c}}_{\mathbf{v}}(t,x;(x(\cdot),u(\cdot))) \\ =\ \mathbf{v}(T,x) \\ =\ \inf_{(x(\cdot),u(\cdot))\in\mathcal{C}(x)} \inf_{t\in[0,T]} L^{\mathbf{v}}_{\mathbf{b}}(t,x;(x(\cdot),u(\cdot))). \end{cases}$$

We list a manifold of examples in classical optimal control (in the case when $\mathbf{m}=0$), recalling that financial problems[6] (in the case when $\mathbf{l}=0$) also fit the above framework. Playing with the choice of the spot cost $\mathbf{c}$, we shall cover several examples.

[6]See [44] for a treatment of dynamical valuation of portfolios in the framework of dynamical games.

1. Taking $\mathbf{b} = 0$ and $\mathbf{c}$ defined by

$$\mathbf{c}(t,x) := \begin{cases} \mathbf{u}(x) & \text{if} \quad t = 0, \\ +\infty & \text{if} \quad t > 0, \end{cases}$$

the above problem boils down to

$$V(\mathbf{c})(T,x) := \inf_{(x(\cdot),u(\cdot))\in\mathcal{C}(x)} J_{\mathbf{c}}(T,x;(x(\cdot),u(\cdot))),$$

which is the *Bolza problem*

$$\inf_{(x(\cdot),u(\cdot))\in\mathcal{C}(x)} \left(\mathbf{u}(x(T)) + \int_0^T \mathbf{l}(x(\tau),u(\tau))d\tau\right)$$

and the *Mayer problem*

$$\inf_{(x(\cdot),u(\cdot))\in\mathcal{C}(x)} \mathbf{u}(x(T))$$

when, furthermore, $\mathbf{l} = 0$.

2. Taking $\mathbf{b} = 0$ and $\mathbf{c}(t,x) := \mathbf{u}(x)$, we find the classical *stopping time problem*

$$\mathbf{F}(u)(T,x) := \inf_{(x(\cdot),u(\cdot))\in\mathcal{C}(x)} \inf_{t\in[0,T]} \left(\mathbf{u}(x(t)) + \int_0^t \mathbf{l}(x(\tau),u(\tau))d\tau\right)$$

associated with $\mathbf{u}$ in control theory. The cost function $\mathbf{l}$ can be regarded as a density of Maslov measures, $\mathbf{F}(\mathbf{u})$ being then the *mathematical faith* of $\mathbf{u}$ introduced by Pierre Bernhard (with the minus sign, under the name of *mathematical fear*). They correspond to the *mathematical expectation* $\mathbf{E}(f)$ of densities f of probability measures.

3. Let us consider an extended function $\mathbf{b} : \mathbf{R}_+ \times X \mapsto \mathbf{R} \cup \{+\infty\}$ with which we associate the problem

$$W(\mathbf{b})(T,x) := \inf_{(x(\cdot),u(\cdot))\in\mathcal{C}(x)} \sup_{t\in[0,T]} J_{\mathbf{b}}(t,x;(x(\cdot),u(\cdot))).$$

$\mathbf{b} : \mathbf{R}_+ \times X \mapsto \mathbf{R} \cup \{+\infty\}$ is an extended cost function. We observe that $W(\mathbf{b}) = V_{\mathbf{b}}(\mathbf{c})$, where

$$\mathbf{c}(t,x) := \begin{cases} \mathbf{b}(0,x) & \text{if} \quad t = 0, \\ +\infty & \text{if} \quad t > 0. \end{cases}$$

Indeed, we see that $J_{\mathbf{c}}(t,x;(x(\cdot),u(\cdot))) = +\infty$ if $t < T$ and $J_{\mathbf{c}}(T,x;(x(\cdot),u(\cdot))) = J_{\mathbf{b}}(T,x;(x(\cdot),u(\cdot)))$. Therefore,

$$L^{\mathbf{c}}_{\mathbf{b}}(t,x;(x(\cdot),u(\cdot))) := \begin{cases} K_{\mathbf{b}}(T,x;(x(\cdot),u(\cdot))) & \text{if} \quad t = T, \\ +\infty & \text{if} \quad t < T, \end{cases}$$

and thus, $W(\mathbf{b}) = V_{\mathbf{b}}(\mathbf{c})$.

7.5. Episolutions to Hamilton–Jacobi–Bellman inequalities. Let us consider the case when the evolutionary control system is associated with the control system (7.1) and apply Theorem 5.3 characterizing capture basins in terms of the tangential conditions. This allows us to relate the value function with generalized solutions to Hamilton–Jacobi–Bellman partial differential variational inequalities

$$\left\{ \begin{array}{l} \forall\ (t,x) \in \Omega(\mathbf{v}), \\ -\dfrac{\partial \mathbf{v}(t,x)}{\partial t} + \inf\limits_{u \in P(x)} \left(\left\langle \dfrac{\partial \mathbf{v}(t,x)}{\partial x}, f(x,u) \right\rangle + \mathbf{l}(x,u) + \mathbf{m}(x,u)\mathbf{v}(t,x) \right) = 0 \end{array} \right.$$

on the subset

$$\Omega(\mathbf{v}) \ := \ \{(t,x) \in \mathbf{R}_+ \times X \mid \mathbf{b}(t,x) \ \leq \ \mathbf{v}(t,x) \ < \ \mathbf{c}(t,x)\}.$$

Let us recall that the *contingent epiderivative* $D_\uparrow \mathbf{v}(t,x)$ of $\mathbf{v}$ at (t,x) is defined by

$$D_\uparrow \mathbf{v}(t,x)(\lambda,v) \ := \ \liminf_{h \to 0+,\ u \to v} \frac{\mathbf{v}(t+h\lambda, x+hu)}{h}$$

and that

$$\mathcal{E}p(D_\uparrow \mathbf{v}(t,x)) \ = \ T_{\mathcal{E}p(\mathbf{v})}(t,x,\mathbf{v}(t,x)).$$

The first part of Theorem 5.3 implies a characterization of the value function as a solution of Hamilton–Jacobi variational inequalities.

STATEMENT 7 (Frankowska). *Let us assume that the control system* $(P,f,\mathbf{l},\mathbf{m})$ *is Marchaud and that the functions* $\mathbf{b}$ *and* $\mathbf{c}$ *are nontrivial, nonnegative, and lower semicontinuous.*

Then the value function $V_{\mathbf{b}}(\mathbf{c})$ *is characterized as the smallest of the nonnegative lower semicontinuous functions* $\mathbf{v} : \mathbf{R}_+ \times X \mapsto \mathbf{R}_+ \cup \{+\infty\}$ *satisfying for every* $(t,x) \in]0,\infty[\times X$

$$\left\{ \begin{array}{ll} \text{(i)} & \mathbf{b}(t,x) \ \leq \ \mathbf{v}(t,x) \ \leq \ \mathbf{c}(t,x), \\ \text{(ii)} & \text{if } (t,x) \in \Omega(\mathbf{v}), \\ & \inf_{u \in P(x)} \left(D_\uparrow \mathbf{v}(t,x)(-1, f(x,u)) + \mathbf{l}(x,u) + \mathbf{m}(x,u)\mathbf{v}(t,x) \right) \ \leq \ 0. \end{array} \right.$$

Let us set

$$\mathbf{R}(t,x) \ := \ \{u \in P(x) \mid D_\uparrow V_{\mathbf{b}}(\mathbf{c})(t,x)(-1,f(x,u)) + \mathbf{l}(x,u) + \mathbf{m}(x,u) V_{\mathbf{b}}(\mathbf{c})(t,x) \leq 0\}.$$

Knowing the value function, an optimal solution is obtained in the following way. Starting from x_0 *such that* $V_{\mathbf{b}}(\mathbf{c})(T,x_0) \ < \ \mathbf{c}(T,x_0)$*, any solution* $(x(\cdot),u(\cdot))$ *to the control system*

$$\left\{ \begin{array}{ll} \text{(i)} & x'(t) \ = \ f(x(t),u(t)), \\ \text{(ii)} & u(t) \ \in \ \mathbf{R}(t,x(t)), \end{array} \right. \tag{7.9}$$

is an optimal solution, and the first time $\varpi(T,x(\cdot)) \geq 0$ *when*

$$V_{\mathbf{b}}(\mathbf{c})(T - \varpi(T,x(\cdot)), x(\varpi(T,x(\cdot)))) \ = \ \mathbf{c}(T - \varpi(T,x(\cdot)), x(\varpi(T,x(\cdot))))$$

is the optimal time.

The second part of Theorem 5.3 implies the characterization of the value function $V_{\mathbf{b}}(\mathbf{c})$ as a unique Frankowska *episolution* to the Hamilton–Jacobi–Bellman variational inequality.

STATEMENT 8 (Frankowska). *Let us assume that the control system (P, f) is Marchaud and Lipschitz and that* $\mathbf{b}$ *and* $\mathbf{c}$ *are nontrivial, nonnegative, and lower semicontinuous.*

Then the value function $V_{\mathbf{b}}(\mathbf{c})$ is the unique lower semicontinuous episolution $\mathbf{v}$ *to the system of differential inequalities: for every $(t, x) \in \mathrm{Dom}(\mathbf{v})$,*

$$
(7.10)\quad \left\{ \begin{array}{ll}
\text{(i)} & \mathbf{b}(t,x) \le \mathbf{v}(t,x) \le \mathbf{c}(t,x), \\
\text{(ii)} & \text{if } \mathbf{v}(t,x) < \mathbf{c}(t,x), \\
 & \inf_{u \in P(x)} (D_\uparrow \mathbf{v}(t,x)(-1, f(x,u)) + \mathbf{l}(x,u) + \mathbf{m}(x,u)\mathbf{v}(t,x)) \le 0, \\
\text{(iii)} & \text{if } \mathbf{v}(t,x) > \mathbf{b}(t,x), \\
 & \sup_{u \in P(x)} (D_\uparrow \mathbf{v}(t,x)(1, -f(x,u)) - \mathbf{l}(x,u) - \mathbf{m}(x,u)\mathbf{v}(t,x)) \le 0, \\
\text{(iv)} & \text{if } \mathbf{v}(t,x) = \mathbf{b}(t,x), \\
 & \sup_{u \in P(x)} [\min(D_\uparrow \mathbf{v}(t,x)(1, -f(x,u)), D_\downarrow \mathbf{b}(t,x)(1, -f(x,u))) \\
 & -\mathbf{l}(x,u)) - \mathbf{m}(x,u)\mathbf{v}(t,x)))] \le 0.
\end{array} \right.
$$

Remark. Condition (7.10)(iv) is automatically satisfied whenever

$$
\sup_{u \in P(x)} (D_\downarrow \mathbf{b}(t,x)(1, -f(x,u)) - \mathbf{l}(x,u)) - \mathbf{m}(x,u)\mathbf{v}(t,x) \le 0,
$$

i.e., whenever the epigraph of $\mathbf{b}$ is locally backward invariant under the auxiliary system. □

7.6. Bilateral and viscosity solutions to Hamilton–Jacobi–Bellman variational inequalities. We obtain by duality equivalent statements involving subdifferential and/or superdifferentials, involving the Hamiltonian $H : X \times \mathbf{R}_+ \times X^\star \mapsto \mathbf{R} \cup \{+\infty\}$ associated with the control problem and the Lagrangian by

$$
H(x, y, p) := \inf_{u \in P(x)} (\langle p, f(x,u) \rangle + \mathbf{l}(x,u) + \mathbf{m}(x,u)y)
$$

and the horizon Hamiltonian $H^\infty : X \times X^\star \mapsto \mathbf{R} \cup \{+\infty\}$, by

$$
H^\infty(x, p) := \inf_{u \in P(x)} \langle p, f(x,u) \rangle.
$$

We recall the definition of the subdifferential $\partial_- \mathbf{v}(t,x)$ and the horizon subdifferential $\partial_-^\infty \mathbf{v}(t,x)$ of the function $\mathbf{v}$ at (t,x):

$$
\left\{ \begin{array}{ll}
\text{(i)} & (p_t, p_x) \in \partial_- \mathbf{v}(t,x) \text{ if } (p_t, p_x, -1) \in N_{\mathcal{E}p(\mathbf{v})}(t, x, \mathbf{v}(t,x)), \\
\text{(ii)} & (p_t, p_x) \in \partial_-^\infty \mathbf{v}(t,x) \text{ if } (p_t, p_x, 0) \in N_{\mathcal{E}p(\mathbf{v})}(t, x, \mathbf{v}(t,x)).
\end{array} \right.
$$

Let us recall that *the horizon subdifferential $\partial_-^\infty \mathbf{v}(t,x) = (0,0)$ whenever the domain of the contingent epiderivative $D_\uparrow \mathbf{v}(t,x)$ is dense in $\mathbf{R}_+ \times X$. This happens whenever* $\mathbf{v}$ *is Lipschitz in a neighborhood of* (t,x).

STATEMENT 9 (Frankowska). *Under the assumptions of Statement* 7*, the value function $V_{\mathbf{b}}(\mathbf{c})$ is the smallest lower semicontinuous nonnegative function $\mathbf{v} : X \mapsto \mathbf{R} \cup \{+\infty\}$ satisfying for every $(t,x) \in]0, \infty[\times X$*

$$
\left\{ \begin{array}{ll}
\text{(i)} & \mathbf{b}(t,x) \le \mathbf{v}(t,x) \le \mathbf{c}(t,x), \\
\text{(ii)} & \text{if } \mathbf{v}(t,x) < \mathbf{c}(t,x), \\
 & \forall\, (p_t, p_x) \in \partial_- \mathbf{v}(t,x), \quad -p_t + H(x, \mathbf{v}(t,x), p_x) \le 0, \\
 & \forall\, (p_t, p_x) \in \partial_-^\infty \mathbf{v}(t,x), \quad -p_t + H^\infty(x, p_x) \le 0.
\end{array} \right.
$$

Statement 8 can be stated in terms of subdifferentials, providing the existence and uniqueness of bilateral solutions proved independently by Barron and Jensen and Frankowska.

STATEMENT 10 (Barron–Jensen and Frankowska). *We posit the assumptions of Statement* 8. *Then the value function* $V_{\mathbf{b}}(\mathbf{c})$ *is the* unique lower semicontinuous solution $\mathbf{v}$—*also called* bilateral solution—*to the system of differential inequalities: for every* $(t,x) \in \mathrm{Dom}(\mathbf{v})$,

$$
(7.11)\quad \left\{\begin{array}{ll}
\text{(i)} & \mathbf{b}(t,x) \le \mathbf{v}(t,x) \le \mathbf{c}(t,x), \\
\text{(ii)} & \textit{if } \mathbf{b}(t,x) < \mathbf{v}(t,x) < \mathbf{c}(t,x), \textit{ the equations} \\
& \quad \forall\, (p_t,p_x) \in \partial_- \mathbf{v}(t,x), \quad -p_t + H(x,\mathbf{v}(t,x),p_x) = 0, \\

ON PERSISTENT EXCITATION FOR LINEAR SYSTEMS WITH STOCHASTIC COEFFICIENTS*

DAVID LEVANONY† AND PETER E. CAINES‡

Abstract. A Wiener input process is shown to be persistently exciting (PE) for linear stochastic systems with time-varying, convergent, random coefficients, provided asymptotic noise controllability holds a.s. The PE result is in the sense that the minimum eigenvalue of the integrated outer product of the state process is of $O(t)$ (t being the upper time limit of the integral).

Key words. persistent excitation, linear stochastic systems, convergent coefficients, noise controllability

1. Introduction.

A central issue in the identification of stochastic systems by such methods as maximum likelihood estimation, recursive least squares, and, more generally, prediction error methods (see, e.g., Caines (1988) and the references therein) is whether the control input and the system disturbance input will excite the system state process sufficiently for consistent parameter estimation to occur. More specifically, many strong consistency results for the estimation of system parameters depend upon the satisfaction of some form of asymptotic condition on the minimum and, in some cases, the maximum and the minimum eigenvalues of the matrix process $\{P_t\}$ given by the integrated outer product of the system state process (or an equivalent observed regression process) with itself. Such a condition is called a *persistent excitation condition* on the state (respectively, regression) process with respect to the given system inputs.

The use of various forms of persistent excitation conditions is ubiquitous in the system identification field (see, e.g., Caines (1988) and the bibliography therein). To cite just a few examples, applications of such conditions appear in Duncan and Pasik-Duncan (1986), where an assumption implying that $\lambda_{max}(P_t)/\lambda_{min}(P_t) = O(1)$ is employed, and in Caines (1992), where a condition of the type $\lambda_{min}(P_t)/t = O(1)$ is assumed. The well-known persistent excitation condition developed by Lai and Wei (1982), which involves the ratio of the logarithm of the maximum eigenvalue to the value of the minimum eigenvalue, is discussed in the remark at the end of this paper. In this context, we note the persistent excitation results for linear, time-invariant, systems presented by Moore (1987), which show the value of stochastic excitation signals in the identification and adaptive control of otherwise deterministic systems.

In this paper we analyze time-varying stochastic linear systems that are driven solely by a Wiener process, and whose stochastic system matrix converges a.s. in such a way that the resulting system pair $[A_\infty, C]$ is a.s. controllable from the disturbance

input. We show that the state process of such a system satisfies the persistent excitation condition that the minimum eigenvalue of P_t is of $O(t)$ a.s. as $t \to \infty$. Apart from its general applicability, this result plays a key role in the theory of stochastic adaptive control developed in Caines and Levanony (1993) and Levanony and Caines (1994, 1996).

2. Main result.

THEOREM 2.1. *Let $\{x_t\}$ be an $\mathbf{R}^n$ valued process, evolving according to*

$$dx_t = A_t x_t dt + C dw_t, \quad t \geq 0, \quad x_0 \text{ given,} \tag{2.1}$$

where $\{w_t\}$ is an $\mathbf{R}^m$ valued standard Brownian motion, and $\{A_t\}$ an $\mathbf{R}^{n\times n}$ valued $\{\mathbf{F}_t^x\}$ adapted process. Suppose that $\{A_t\}$ is a.s. continuous and that there exists an a.s. finite A_∞ such that

$$A_t \to A_\infty, \quad \text{a.s., as } t \to \infty. \tag{2.2}$$

Then if the pair $[A_\infty, C]$ is a.s. controllable, it follows that

$$\liminf_{t\to\infty} \frac{1}{t} \lambda_{min} \left\{ \int_0^t x_r x_r^T dr \right\} > 0, \quad \text{a.s.} \tag{2.3}$$

Proof. The proof consists of several steps, some of which are constructed to overcome a key problem, namely, how to handle the possibility of trajectories $\{x_t\}$ diverging to infinity.

2.1. A truncation mechanism. First, note that continuity and convergence imply that

$$\sup_{t\geq 0} \|A_t\| < \infty, \qquad \text{a.s.} \tag{2.4}$$

Hence it suffices to prove (2.3) for stopped versions $\{A_t^N\}$ of $\{A_t\}$ which satisfy

$$\sup_{t\geq 0} \|A_t^N\| \leq N, \qquad \text{a.s.} \tag{2.5}$$

for a deterministic arbitrary large $N < \infty$. This is proved by the following (standard) argument. Fix $\varepsilon > 0$ and let N be such that

$$\sup_{t\geq 0} \|A_t\| \leq N, \quad \text{with probability greater than } 1-\varepsilon.$$

Let $T_N = \inf\{t \geq 0 : \|A_t\| > N\}$ and define $\{x_t^N\}$ so as to satisfy

$$\begin{aligned} x_t^N &= x_t, \quad 0 \leq t < T_N, \\ dx_t^N &= A_{T_N} x_t^N dt + C dw_t, \quad T_N \leq t < \infty, \ x_{T_N}^N = x_{T_N}. \end{aligned}$$

Suppose now that (2.3) holds for $\{x_t^N\}$. Let $\Gamma_N \underline{\Delta} \{x_t = x_t^N, t \geq 0\}$, where, by the choice of N, $P(\Gamma_N) > 1-\varepsilon$, it then follows that (2.3) holds for $\{x_t\}$, with probability greater than $1-\varepsilon$. The arbitrary nature of $\varepsilon > 0$ then implies that if (2.4) holds and (2.3) holds for $\{x_t^N\}$ for all $N > 0$, then (2.3) holds for $\{x_t\}$.

At this point it is worth emphasizing that $A_t^N \to A_\infty^N$ a.s. (where $\{A_t^N\}$ denotes the dynamic matrix process for the truncated process $\{x_t^N\}$), where

$$A_\infty^N = \begin{cases} A_\infty & \text{a.e. on } \Gamma_N, \\ A_{T_N} & \text{otherwise.} \end{cases}$$

Therefore, while the pair $[A_\infty^N, C]$ is a.e. controllable on Γ_N, $[A_\infty^N, C]$ might be uncontrollable on Γ_N^c. (This point will reappear at the end of the proof.)

Henceforth we continue our investigation for the truncated process x^N. To avoid cumbersome notation, the superscript N will be omitted throughout, unless specifically required.

2.2. A consequence of the contradiction to the theorem. Assume that (2.3) does not hold. Then there exists an event $\widetilde{\Omega} \in \mathbf{F}_\infty^x$ with $P(\widetilde{\Omega}) > 0$ such that $\liminf_{t\to\infty} \frac{1}{t}\lambda_{min}\{\int_0^t x_r x_r^T dr\} = 0$ a.e. on $\widetilde{\Omega}$. Hence there exists an $\mathbf{R}^n$ vector process $\alpha_t \in \mathbf{F}_\infty^x, t \geq 0$, with

$$\|\alpha_t\| = \begin{cases} 1 & \text{a.e. on } \widetilde{\Omega}, \\ 0 & \text{a.e. on } \widetilde{\Omega}^c, \end{cases} \tag{2.6}$$

such that

$$\liminf_{t\to\infty} \frac{1}{t}\int_0^t (\alpha_t^T x_r)^2 dr = 0, \quad \text{a.s.} \tag{2.7}$$

The equality (2.7) in turn implies that

$$\liminf_{t\to\infty} \int_t^{t+1} (\alpha_{t+1}^T x_r)^2 dr = \liminf_{t\to\infty} \int_0^1 (\alpha_{t+1}^T x_{t+s})^2 ds = 0, \quad \text{a.s.} \tag{2.8}$$

2.3. Construction of a convergent subsequence. Equation (2.8) implies the existence of a subsequence $\{t_n\}_{n\geq 1}$ and an associated subsequential limit $\alpha \in \mathbf{R}^n$, $\|\alpha\| \leq 1$, such that $\alpha_{t_n+1} \to \alpha$ a.s. and

$$\lim_{n\to\infty} \int_0^1 (\alpha_{t_n+1}^T x_{t_n+s})^2 ds = 0, \quad \text{a.s.} \tag{2.9}$$

With $\{x_t\}$ being a strong solution of the linear SDE (2.1) (for which no finite explosion time exists), and due to (2.9), one may conclude that

$$\sup_{n\geq 1} \int_0^1 (\alpha_{t_n+1}^T x_{t_n+s})^2 ds < \infty, \quad \text{a.s.} \tag{2.10}$$

One now may assume that $E[\sup_{n\geq 1} \int_0^1 (\alpha_{t_n+1}^T x_{t_n+s})^2 ds] < \infty$, because if not, then by a truncation mechanism identical to the one described by (2.23)–(2.26) below, one can redefine the vector process $\{\alpha_{t_n+1}\}$ so as to make the left-hand side of (2.10) integrable (see below for details, omitted here to avoid repetition).

It now follows from the integrability above, (2.9), the a.s. convergence of $\{\alpha_{t_n+1}\}$, and Corollary II-2.4 in Revuz and Yor (1991) that

$$\lim_{n\to\infty} E\left[\int_0^1 (\alpha_{t_n+1}^T x_{t_n+s})^2 ds + \|\alpha_{t_n+1} - \alpha\| | \mathbf{F}_{t_n}^x\right] = 0, \quad \text{a.s.}, \tag{2.11}$$

which enables us to define a sequence of stopping times in the form:

$$\tau_n = \inf\left\{t > 0 : E\left[\int_0^1 (\alpha_{t+1}^T x_{t+s})^2 ds + \|\alpha_{t+1} - \alpha\| | \mathbf{F}_t^x\right] < 1/n\right\}. \tag{2.12}$$

Then, obviously, $\{\tau_n\}$ is an $\{\mathbf{F}_t^x\}$-adapted subsequence which satisfies

$$\lim_{n\to\infty} E\left[\int_0^1 (\alpha_n^T x_{\tau_n+s})^2 ds | \mathbf{F}_{\tau_n}^x\right] = 0, \quad \text{a.s.}, \tag{2.13}$$

where $\alpha_n \underline{\Delta} \alpha_{\tau_n+1}$. Note that

$$0 \le E\left[\lim_{n\to\infty}\int_0^1 (\alpha_n^T x_{\tau_n+s})^2 ds\right] = \lim_{n\to\infty} E\left[\int_0^1 (\alpha_n^T x_{\tau_n+s})^2 ds\right]$$
$$= \lim_{n\to\infty} E\left\{E\left[\int_0^1 (\alpha_n^T x_{\tau_n+s})^2 ds | \mathbf{F}_{\tau_n}^x\right]\right\} = E\left\{\lim_{n\to\infty} E\left[\int_0^1 (\alpha_n^T x_{\tau_n+s})^2 ds | \mathbf{F}_{\tau_n}^x\right]\right\} = 0.$$

The first equality is due to (2.9), (2.10) (together with its assumed integrability), and dominated convergence. The second equality is based on smoothing, while the third rests on (2.12) and dominated convergence. Finally, the last equality results from (2.13). This chain of calculations therefore leads one to conclude that

$$\lim_{n\to\infty}\int_0^1 (\alpha_n^T x_{\tau_n+s})^2 ds = 0, \quad \text{a.s.} \tag{2.14}$$

Similarly, (2.11) and (2.12) imply $\alpha_n \to \alpha$, a.s. (The replacement of the sequence $\{t_n\}$ with the *adapted* subsequence $\{\tau_n\}$ is made to enable the future use of conditional expectations, which, being $\mathbf{F}_{\tau_n}^x$-measurable approximations, will allow relatively simple calculations.)

We shall show that, under the hypotheses of the theorem, (2.14) yields a contradiction.

2.4. Calculation of bounds. Let $\phi_n(s,u)$ be the transition matrix generated by $\{A_{\tau_n+r}, u \le r \le s\}$, where $\dot{\phi}_n(r,u) = A_{\tau_n+r}\phi_n(r,u)$ and $\phi_n(r,r) = I, u \le r \le s$. Define

$$z_n(s) = \phi_n^T(s,0)\alpha_n,$$
$$m_n(s) = \int_0^s \phi_n(0,r) C dw_{\tau_n+r}.$$

Then the integrand in (2.14) can be rewritten as

$$(\alpha_n^T x_{\tau_n+s})^2 = [z_n^T(s)(x_{\tau_n} + m_n(s))]^2, \qquad 0 \le s \le 1. \tag{2.15}$$

Note now that the boundedness of $\{A_t\}$ given in (2.5) implies that

$$\|\phi_n(s,u)\| \le e^N \quad \forall n \ge 0,\ u,s \in [0,1], \quad \text{a.s.} \tag{2.16}$$

For the martingale $\{m_n(s), \mathbf{F}_{\tau_n+s}^x\}$ one therefore has

$$E \sup_{0\le s\le 1} \|m_n(s)\|^2 = E \sup_{0\le s\le 1} \left\|\int_0^s \phi_n(0,r) C dw_{\tau_n+r}\right\|^2$$
$$\le 4E\left\|\int_0^1 \phi_n(0,r) C dw_{\tau_n+r}\right\|^2$$
$$= 4Tr\left\{E\int_0^1 \phi_n(0,r) CC^T \phi_n^T(0,r) dr\right\}$$
$$\le 4e^{2N} TrCC^T \qquad \forall n \ge 0, \tag{2.17}$$

where the first inequality is Doob's inequality and the last inequality is due to (2.16).

It follows that

$$\sup_{n\geq 0}\int_0^1 \|m_n(s)\|^2 ds < \infty, \quad \text{a.s.} \tag{2.18}$$

Furthermore, (2.16) and the definition of α_n imply that

$$\sup_{n\geq 0}\sup_{0\leq s\leq 1} \|z_n(s)\| \leq e^N, \quad \text{a.s.}, \tag{2.19}$$

and hence, via (2.18),

$$\sup_{n\geq 0}\int_0^1 (z_n^T(s)m_n(s))^2 ds < \infty, \quad \text{a.s.} \tag{2.20}$$

Now, we rewrite (2.14) using (2.15) to obtain

$$\lim_{n\to 0}\int_0^1 (z_n^T(s)(x_{\tau_n}+m_n(s)))^2 ds = 0, \quad \text{a.s.} \tag{2.21}$$

Hence we conclude (by writing $x_{\tau_n} = (x_{\tau_n}+m_n)-m_n$, using (2.20), (2.21), and the Cauchy–Schwarz (C–S) inequality) that

$$\sup_{n\geq 0}\int_0^1 (z_n^T(s)x_{\tau_n})^2 ds < \infty, \quad \text{a.s.} \tag{2.22}$$

At this stage in the proof we have replaced the initial hypothesized contradiction (2.14) by the study of the consequences of (2.21) and (2.22), where the processes $\{x_{\tau_n+s}\ 0\leq s\leq 1\}, n\geq 0$, are generated by an A_t process with a.s. bounded trajectories. The next stage is to replace the integrals in (2.21) with integrals with past measurable integrands, and hence to approximate the basic controllability covariance (or Grammian) calculation, which will give a contradiction by virtue of the controllability of $[A_\infty, C]$.

2.5. A truncation to obtain uniform integrability. As will be seen below, the technique of the proof uses uniform integrability of the integral in (2.22). Since this is not guaranteed here, we resort to another truncation mechanism.

Let $\varepsilon > 0$ be such that $P(\widetilde{\Omega}) > 2\varepsilon$. Next let $\Omega_N \in \mathbf{F}_\infty^x$ be the set such that, by (2.22),

$$\sup_{n\geq 0}\int_0^1 (z_n^T(s)x_{\tau_n})^2 ds \leq N \quad \text{a.e. on } \Omega_N, \tag{2.23}$$

with $P(\Omega_N) > 1-\varepsilon$ for all sufficiently large N. Further, by (2.4) and (2.22), $P(\Gamma_N \cap \Omega_N) > 1-2\varepsilon$ for sufficiently large N, and hence $P(\widetilde{\Omega}\cap\Gamma_N\cap\Omega_N) > 0$. (Recall that $\Gamma_N = \{x_t = x_t^N, t\geq 0\}$.)

Define the $\mathbf{R}^n$ valued process $\{\alpha_n^N\}$ by

$$\alpha_n^N = \begin{cases} \alpha_n & \text{a.e. on } \Omega_N\cap\Gamma_N, \\ 0 & \text{a.e. on } \Omega_N^c\cup\Gamma_N^c \end{cases} \tag{2.24}$$

(with an associated limit α^N) and accordingly

$$z_n^N(s) = \phi_n^T(s,0)\alpha_n^N. \tag{2.25}$$

Then, by definition,

$$\sup_{n\geq 0}\int_0^1 (x_{\tau_n}^T z_n^N(s))^2 ds \leq N, \quad \text{a.s.} \tag{2.26}$$

Hence, with (2.26), the basic limiting relation (2.14) (or equivalently (2.21)) implies

$$\lim_{n\to\infty}\int_0^1 ((x_{\tau_n}+m_n(s))^T z_n^N(s))^2 ds = 0, \quad \text{a.s.} \tag{2.27}$$

Recall that z and hence z^N are uniformly bounded by e^N. Hence z^N is square integrable, and this enables us to define

$$\widehat{z}_n^N(s) = E[z_n^N(s)|\mathbf{F}_{\tau_n}^x], \quad s\in[0,1]. \tag{2.28}$$

2.6. The uniform consistency of $\widehat{z}^N$. Our objective now is to show that, in the formula (2.27), z^N can be replaced by $\widehat{z}^N$. Towards this end, we observe that the ODE for $z_n^N(s)$ (as defined in (2.25)) is

$$\frac{d}{ds}z_n^N(s) = A_{\tau_n+s}^T z_n^N(s), \quad z_n^N(0)=\alpha_n^N, \quad 0\leq s\leq 1. \tag{2.29}$$

In order to derive an ODE for $\widehat{z}_n^N$, note that

$$\begin{aligned}\|z_n(s+h)-z_n(s)\|/h &\leq \|\phi_n^T(s,0+h)-\phi_n^T(s,0)\|/h\\ &\leq 2\sup_{0\leq s\leq 1}\|A_{\tau_n+s}^T\phi_n(s,0)\|\leq 2Ne^N\end{aligned}$$

for any $n\geq 0, s\in[0,1]$, and small enough h.

Hence, by letting $h\to 0$, dominated convergence leads to

$$\begin{aligned}\frac{d}{ds}\widehat{z}_n^N(s) &= \lim_{h\to 0}E[z_n^N(s+h)-z_n^N(s)|\mathbf{F}_{\tau_n}^x]/h = E\left[\lim_{h\to 0}(z_n^N(s+h)-z_n^N(s))/h|\mathbf{F}_{\tau_n}^x\right]\\ &= E[A_{\tau_n+s}^T z_n^N(s)|\mathbf{F}_{\tau_n}^x], \qquad \widehat{z}_n^N(0)=\widehat{\alpha}_n^N \underline{\Delta} E[\alpha_n^N|\mathbf{F}_{\tau_n}^x].\end{aligned} \tag{2.30}$$

Let $e_n(s)=z_n^N(s)-\widehat{z}_n^N(s)$. Then, from (2.29) and (2.30),

$$\begin{aligned}\frac{d}{ds}e_n(s) &= A_{\tau_n+s}^T z_n^N(s) - E[A_{\tau_n+s}^T z_n^N(s)|\mathbf{F}_{\tau_n}^x]\\ &= A_{\tau_n+s}^T(z_n^N(s)-\widehat{z}_n^N(s)) + A_{\tau_n+s}^T\widehat{z}_n^N(s) - E[A_{\tau_n+s}^T z_n^N(s)|\mathbf{F}_{\tau_n}^x]\\ &= A_{\tau_n+s}^T e_n(s) + (A_{\tau_n+s}-A_{\tau_n})^T\widehat{z}_n^N(s) + A_{\tau_n}^T\widehat{z}_n^N(s) - E[A_{\tau_n+s}^T z_n^N(s)|\mathbf{F}_{\tau_n}^x]\\ &= A_{\tau_n+s}^T e_n(s) + (A_{\tau_n+s}-A_{\tau_n})^T\widehat{z}_n^N(s) + E[(A_{\tau_n}-A_{\tau_n+s})^T z_n^N(s)|\mathbf{F}_{\tau_n}^x],\end{aligned} \tag{2.31}$$

with the initial condition $e_n(0)=\alpha_n^N-\widehat{\alpha}_n^N$. (Note that in introducing $A_{\tau_n}^T\widehat{z}_n^N(s)$ into the conditional expectation, we have used the definition of $\widehat{z}^N$ and the measurability of A_{τ_n} w.r.t. $\mathbf{F}_{\tau_n}^x$.)

The solution of (2.31) is then

$$e_n(s) = \phi_n^T(s,0)(\alpha_n^N - \widehat{\alpha}_n^N) + \int_0^s \phi_n^T(r,s)[A_{\tau_n+r} - A_{\tau_n}]^T \widehat{z}_n^N(r)dr$$
$$+ \int_0^s \phi_n^T(r,s)E[(A_{\tau_n} - A_{\tau_n+r})^T z_n^N(r)|\mathbf{F}^x_{\tau_n}]dr. \tag{2.32}$$

Using the uniform bounds which hold on ϕ, z^N, and $\widehat{z}^N$, it can be deduced from (2.32) that

$$\sup_{0\le s\le 1}\|z_n^N(s) - \widehat{z}_n^N(s)\| = \sup_{0\le s\le 1}\|e_n(s)\| \le e^N\|\alpha_n^N - \widehat{\alpha}_n^N\| + e^{2N}\sup_{0\le s\le 1}\|A_{\tau_n+s} - A_{\tau_n}\|$$
$$+ e^{2N}\left(E\left[\sup_{0\le s\le 1}\|A_{\tau_n+s} - A_{\tau_n}\|^2|\mathbf{F}^x_{\tau_n}\right]\right)^{1/2}.$$

Let $u_n = \sup_{0\le s\le 1}\|A_{\tau_n+s} - A_{\tau_n}\|^2$ and note that, due to (2.2) and the definition of the stopped A_t process, $u_n \to 0$ a.s. as $n \to \infty$; hence the second term on the right-hand side (RHS) goes to zero as $n \to \infty$, a.s. Furthermore, since by (2.5) $0 \le u_n \le 2N$, the dominated convergence theorem implies that $Eu_n \to 0$, which makes the third term on the RHS decay to zero as $n \to \infty$. Finally, observing that $\widehat{\alpha}_n^N = E[\alpha_n^N|\mathbf{F}^x_{\tau_n}] \to E[\alpha^N|\mathbf{F}^x_\infty] = \alpha^N$ (as $\alpha^N \in \mathbf{F}^x_\infty$), one has

$$\limsup_{n\to\infty 0\le s\le 1}\|z_n^N(s) - \widehat{z}_n^N(s)\| = 0, \quad \text{a.s.} \tag{2.33}$$

Furthermore, using the same method with which (2.33) was obtained, we see that, with probability 1 (w.p.1)

$$\limsup_{n\to\infty 0\le s\le 1}\|\phi_n(s,0) - \exp A_{\tau_n}s\| = \limsup_{n\to\infty 0\le s\le 1}\sup_{\|y\|=1}\|\phi_n(s,0)y - [\exp A_{\tau_n}s]y\| = 0, \tag{2.34}$$

a fact used in what follows.

2.7. Main argument to obtain a contradiction. Returning to our main problem, it can be verified that the integrand in (2.27) may be rewritten as

$$\begin{aligned}[(x_{\tau_n} + m_n(s))^T z_n^N(s)]^2 &= [(x_{\tau_n} + m_n(s))^T \widehat{z}_n^N(s)]^2 + [(x_{\tau_n} + m_n(s))^T(\widehat{z}_n^N(s) - z_n^N(s))]^2\\ &- 2(\widehat{z}_n^N(s) - z_n^N(s))^T m_n(s)m_n^T(s)\widehat{z}_n^N(s)\\ &- 2(\widehat{z}_n^N(s) - z_n^N(s))^T m_n(s)x_{\tau_n}^T\widehat{z}_n^N(s)\\ &- 2(\widehat{z}_n^N(s) - z_n^N(s))^T x_{\tau_n}x_{\tau_n}^T\widehat{z}_n^N(s)\\ &- 2(\widehat{z}_n^N(s) - z_n^N(s))^T x_{\tau_n}m_n^T(s)\widehat{z}_n^N(s).\end{aligned} \tag{2.35}$$

Using (2.33), our next step is to show that the integrals over $[0,1]$ of the third and fourth terms on the RHS of (2.35) decay to zero as $n \to \infty$. Consider first the third term on the RHS of (2.35): Equipped with (2.18), (2.33), and the uniform bound on $\widehat{z}^N$, a C–S inequality leads to

$$\lim_{n\to\infty}\int_0^1 (\widehat{z}_n^N(s) - z_n^N(s))^T m_n(s)m_n^T(s)\widehat{z}_n^N(s)ds = 0, \quad \text{a.s.} \tag{2.36}$$

As for the fourth term on the RHS of (2.35), first note that (2.26), the fact that $x_{\tau_n} \in \mathbf{F}^x_{\tau_n}$, $n \geq 0$, and Jensen's inequality guarantee that $\sup_{n\geq 0} \int_0^1 (x_{\tau_n} \widehat{z}_n^N(s))^2 ds \leq N$, a.s. Hence, at this point, (2.18), (2.26), and a C–S inequality imply that

$$\lim_{n\to\infty} \int_0^1 (\widehat{z}_n^N(s) - z_n^N(s))^T m_n(s) x_{\tau_n}^T \widehat{z}_n^N(s) ds = 0, \quad \text{a.s.} \tag{2.37}$$

Let us consider the two last terms on the RHS of (2.35).

First, by the Burkholder–Davis–Gundy (B-D-G) inequality (e.g., Theorem IV-4.1, Revuz and Yor (1991)), together with the uniform bounds (2.16), (2.19), on ϕ_n and z_n (respectively), it follows that

$$\begin{aligned} E \sup_{s\in[0,1]} (m_n^T(s) z_n^N(s))^4 &\leq e^{4N} E \sup_{s\in[0,1]} \|m_n(s)\|^4 && \text{(due to (2.19))} \\ &\leq c_4 e^{4N} \left(Tr E \int_0^1 \phi_n(s,0) C C^T \phi_n^T(s,0) ds \right)^2 && \text{(due to the B-D-G inequality)} \\ &\leq c_4 e^{8N} (Tr C C^T)^2 && \text{(due to (2.16))} \end{aligned}$$

(where c_4 is the universal constant in the 4th moment, B-D-G inequality), and, by Theorem 2, section 3-VII of Shiryayev (1984) (for which use of the bound on the 4th moment above is required),

$$E \sup_{n\geq 0} \sup_{s\in[0,1]} (m_n^T(s) z_n^N(s))^2 \leq 9\sqrt{c_4} e^{4N} Tr C C^T.$$

This, together with (2.26), enables us to apply the dominated convergence theorem to (2.27). Recall that (2.35) is the integrand $((x_{\tau_n} + m_n(s))^T z_n^N(s))^2$ in (2.27), broken into the sum of six terms. After the elimination of the third and fourth terms (by (2.36) and (2.37), respectively) and the use of the dominated convergence theorem (justified above), (2.27) results in

$$\begin{aligned} 0 &= \lim_{n\to\infty} E \left[\int_0^1 \left((x_{\tau_n} + m_n(s))^T z_n^N(s) \right)^2 ds \right] \\ &\geq \liminf_{n\to\infty} E \left[\int_0^1 ((x_{\tau_n} + m_n(s))^T \widehat{z}_n^N(s))^2 ds \right] \\ &\quad - 2 \limsup_{n\to\infty} E \left[\int_0^1 \left(\widehat{z}_n^N(s) - z_n^N(s) \right)^T x_{\tau_n} \left(x_{\tau_n} + m_n(s) \right)^T \widehat{z}_n^N(s) ds \right]. \end{aligned} \tag{2.38}$$

On our way to obtaining a contradiction, the next step involves the elimination of the second term on the RHS of (2.38). First, note that the measurability of x_{τ_n} and $\widehat{z}_n^N$ w.r.t. $\mathbf{F}^x_{\tau_n}$, the definition of $\widehat{z}_n^N(s)$, and (2.26) together lead to

$$\begin{aligned} & E \left[\int_0^1 \left(\widehat{z}_n^N(s) - z_n^N(s) \right)^T x_{\tau_n} x_{\tau_n}^T \widehat{z}_n^N(s) ds \right] \\ &= E \left\{ E \left[\int_0^1 \left(\widehat{z}_n^N(s) - z_n^N(s) \right)^T x_{\tau_n} x_{\tau_n}^T \widehat{z}_n^N(s) ds | \mathbf{F}^x_{\tau_n} \right] \right\} \\ &= E \left\{ \int_0^1 E \left[\left(\widehat{z}_n^N(s) - z_n^N(s) \right)^T | \mathbf{F}^x_{\tau_n} \right] x_{\tau_n} x_{\tau_n}^T \widehat{z}_n^N(s) ds \right\} = 0 \quad \forall n \geq 0. \end{aligned} \tag{2.39}$$

To complete the elimination of the second term in the right-most expression in the chain (2.38), we claim that

$$\lim_{n\to\infty} E\left[\int_0^1 \left(\widehat{z}_n^N(s) - z_n^N(s)\right)^T x_{\tau_n} m_n^T(s)\widehat{z}_n^N(s)ds\right] = 0. \tag{2.40}$$

To see this, first note that, (i) since x_{τ_n} and $\widehat{z}_n^N(s)$ are $\mathbf{F}^x_{\tau_n}$-measurable and (ii) because $\{m_n(s), \mathbf{F}^x_{\tau_n+s}, s \in [0,1]\}$ is a zero mean martingale satisfying $E[m_n(s)|\mathbf{F}^x_{\tau_n}] = 0$, it follows that

$$\begin{aligned}
&E\left[\int_0^1 \left(\widehat{z}_n^N(s) - z_n^N(s)\right)^T x_{\tau_n} m_n^T(s)\widehat{z}_n^N(s)ds\right] \\
&= \int_0^1 E\left[\left(\widehat{z}_n^N(s) - z_n^N(s)\right)^T x_{\tau_n} m_n^T(s)\widehat{z}_n^N(s)\right] ds \\
&= \int_0^1 E\left\{\left(\widehat{z}_n^N(s)\right)^T x_{\tau_n} E\left[m_n(s)|\mathbf{F}^x_{\tau_n}\right]\widehat{z}_n^N(s)\right\} ds - \int_0^1 E\left[\left(z_n^N(s)\right)^T x_{\tau_n} m_n^T(s)\widehat{z}_n(s)\right] ds \\
&= \int_0^1 E\left[x_{\tau_n}^T z_n^N(s) m_n^T(s)\widehat{z}_n(s)\right] ds.
\end{aligned}$$

(A Fubini-type argument justifies the interchange between integration (over $[0,1]$) and expectation.)

Hence the claim (2.40) is equivalent to the following statement, for which a proof is given in the appendix.

PROPOSITION 2.2.

$$\lim_{n\to\infty} \int_0^1 E\left[x_{\tau_n}^T z_n^N(s) m_n^T(s)\widehat{z}_n^N(s)\right] ds = 0. \tag{2.41}$$

We now proceed assuming the validity of (2.41). Having shown that the second term on the RHS of (2.38) is equal to zero, it is clear that a contradiction to (2.38) will be established if it is shown that

$$\liminf_{n\to\infty} E\left[\int_0^1 \left((x_{\tau_n} + m_n(s))^T \widehat{z}_n^N(s)\right)^2 ds\right] > 0, \tag{2.42}$$

which in turn is implied by

$$\liminf_{n\to\infty} E\left[\int_0^1 \left((x_{\tau_n} + m_n(s))^T \widehat{z}_n^N(s)\right)^2 ds|\mathbf{F}^x_{\tau_n}\right] > 0, \tag{2.43}$$

with positive probability.

2.8. Approximations to the transition matrix. It remains to prove (2.43). To simplify the presentation, we first show that $m_n^T(s)\widehat{z}_n^N(s)$ may be replaced (in the formula (2.43)) by a conditionally Gaussian process. Let

$$\widetilde{m}_n(s) = \int_0^s [\exp -A_{\tau_n} r] C dw_{\tau_n+r}, \tag{2.44}$$

$$\widetilde{z}_n^N(s) = [\exp A_{\tau_n} s]^T \widehat{\alpha}_n^N. \tag{2.45}$$

Then, using the convergence of $\{A_{\tau_n}\}$ to A_∞, we follow an argument closely analogous to that which led to (2.34) (the difference being that the corresponding second term

on the RHS of (2.31), (2.32), etc., is zero in the current case) to obtain

$$\limsup_{n\to\infty 0\le s\le 1} \|\widehat{z}_n^N(s) - \widetilde{z}_n^N\| = 0, \quad \text{a.s.} \tag{2.46}$$

Hence, by dominated convergence,

$$\lim_{n\to\infty} E \sup_{0\le s\le 1} \|\widehat{z}_n^N(s) - \widetilde{z}_n^N(s)\|^2 = 0.$$

Furthermore, using calculations similar to (2.17),

$$\begin{aligned}
&\lim_{n\to\infty} E \sup_{0\le s\le 1} \|m_n(s) - \widetilde{m}_n(s)\|^2 \\
&\quad \le \lim_{n\to\infty} 4TrE \int_0^1 [\phi_n(0,r) - \exp(-A_{\tau_n} r)]CC^T[\phi_n(0,r) - \exp(-A_{\tau_n} r)]^T dr = 0,
\end{aligned} \tag{2.47}$$

which is obtained due to the uniform convergence of the integrand (see (2.34)) and dominated convergence.

Therefore, since $\|\widetilde{z}_n^N(s)\|^2 \le e^{2N}$ and (see (2.17))

$$E\left[\sup_{0\le s\le 1} \|m_n(s)\|^2 |\mathbf{F}^x_{\tau_n}\right] \le 4e^{2N} Tr\ CC^T,$$

one has

$$\begin{aligned}
&E \sup_{0\le s\le 1} |m_n^T(s)\widehat{z}_n^N(s) - \widetilde{m}_n^T(s)\widetilde{z}_n^N(s)|^2 \\
&\le 2E \sup_{0\le s\le 1} \|\widetilde{z}_n^N(s)\|^2 \sup_{0\le s\le 1} \|m_n(s) - \widetilde{m}_n(s)\|^2 \\
&\quad + 2E \sup_{0\le s\le 1} \|\widetilde{z}_n^N(s) - \widehat{z}_n^N(s)\|^2 E\left[\sup_{0\le s\le 1} \|m_n(s)\|^2 |\mathbf{F}^x_{\tau_n}\right] \to 0, \quad \text{a.s., } n\to\infty.
\end{aligned} \tag{2.48}$$

Proof of (2.43). Equipped with (2.48), it is obvious that proving (2.43) is equivalent to showing that

$$\liminf_{n\to\infty} E\left[\int_0^1 (x_{\tau_n}^T \widehat{z}_n^N(s) + \widetilde{m}_n^T(s)\widetilde{z}_n^N(s))^2 ds |\mathbf{F}^x_{\tau_n}\right] > 0, \quad \text{with positive probability.} \tag{2.49}$$

Towards this end we use standard (Gaussian) calculations. Let

$$\gamma_{n+1} = \int_0^1 (x_{\tau_n}^T \widehat{z}_n^N(s) + \widetilde{m}_n(s)\widetilde{z}_n^N(s))^2 \wedge 1 ds. \tag{2.50}$$

To establish (2.49), it suffices to show that

$$\liminf_{n\to\infty} E[\gamma_{n+1} |\mathbf{F}^x_{\tau_n}] > 0, \quad \text{a.e. on } \widetilde{\Omega}_N, \tag{2.51}$$

where $\widetilde{\Omega}_N \underline{\Delta} \widetilde{\Omega} \cap \Gamma_N \cap \Omega_N$, and, by the choice of N, $P(\widetilde{\Omega}_N) > 0$.

To simplify notation, we define

$$\mu_n(s) = x^T_{\tau_n} \widehat{z}^N_n(s), \tag{2.52}$$

$$\zeta_n(s) = \widetilde{m}^T_n(s)\widetilde{z}^N_n(s) = (\widehat{\alpha}^N_n)^T \int_0^s [\exp A_{\tau_n}(s-r)]C dw_{\tau_n+r}. \tag{2.53}$$

Note that $\mu_n(s) \in \mathbf{F}^x_{\tau_n}$, and that $\zeta_n(s)$, for any fixed s, is a conditionally centered Gaussian random variable (w.r.t. $\mathbf{F}^x_{\tau_n}$).

Define the conditional variance by

$$\begin{aligned}\sigma^2_n(s) &= E[\zeta^2_n(s)|\mathbf{F}^x_{\tau_n}] \\ &= (\widehat{\alpha}^N_n)^T \int_0^s [\exp A_{\tau_n}(s-r)]CC^T[\exp A_{\tau_n}(s-r)^T]dr\widehat{\alpha}^N_n. \end{aligned} \tag{2.54}$$

With these definitions and observations we turn to the calculation of $E[\gamma_{n+1}|\mathbf{F}^x_{\tau_n}]$:

$$\begin{aligned} E[\gamma_{n+1}|\mathbf{F}^x_{\tau_n}] &= E\left\{\int_0^1 (\zeta_n(s)+\mu_n(s))^2 \wedge 1 ds|\mathbf{F}^x_{\tau_n}\right\} \\ &= \int_0^1 E[(\zeta_n(s)+\mu_n(s))^2 \wedge 1|\mathbf{F}^x_{\tau_n}]ds \\ &\geq \int_0^1 P[(\zeta_n(s)+\mu_n(s))^2 \geq 1|\mathbf{F}^x_{\tau_n}]ds \\ &\geq \frac{1}{2}\inf_{\frac{1}{2}\leq s\leq 1}\left\{P\left(\zeta_n(s)\geq 1-\mu_n(s)|\mathbf{F}^x_{\tau_n}\right)+P\left(\zeta_n(s)\leq -1-\mu_n(s)|\mathbf{F}^x_{\tau_n}\right)\right\} \\ &\geq \inf_{\frac{1}{2}\leq s\leq 1} P(\zeta_n(s)\geq 1|\mathbf{F}^x_{\tau_n}) = \inf_{\frac{1}{2}\leq s\leq 1}\frac{1}{\sqrt{2\pi}}\int_{1/\sigma_n(s)}^{\infty}\exp\left(\frac{-u^2}{2}\right)du \\ &= \frac{1}{\sqrt{2\pi}}\int_{1/\sigma_n(\frac{1}{2})}^{\infty}\exp\left(\frac{-u^2}{2}\right)du \\ &\geq \frac{1}{\sqrt{2\pi}}\frac{\sigma_n(\frac{1}{2})}{1+\sigma^2_n(\frac{1}{2})}\exp\left(\frac{-1}{2\sigma^2_n(\frac{1}{2})}\right), \end{aligned} \tag{2.55}$$

where the last equality is due to the fact that $\sigma_n(\cdot)$ is nondecreasing, and the last inequality is a simple lower bound for the Gaussian integral.

Recall that

$$\widehat{\alpha}^N_n = E[\alpha^N_n|\mathbf{F}^x_{\tau_n}] \to E[\alpha^N|\mathbf{F}^x_{\infty}] = \alpha^N, \quad \text{a.s. as } n\to\infty.$$

Furthermore, the integrand in (2.54) converges uniformly. This leads to

$$\sigma^2_{\infty} \underline{\Delta} \lim_{n\to\infty}\sigma^2_n\left(\frac{1}{2}\right) = (\alpha^N)^T \int_0^{1/2}\left[\exp A_{\infty}\left(\frac{1}{2}-r\right)\right]CC^T\left[\exp A_{\infty}\left(\frac{1}{2}-r\right)\right]^T dr\alpha^N, \tag{2.56}$$

and, with the continuity of the last expression on the RHS of (2.55) (as a function of σ), one has

$$\liminf_{n\to\infty} E[\gamma_{n+1}|\mathbf{F}^x_{\tau_n}] \geq \frac{1}{\sqrt{2\pi}}\frac{\sigma_{\infty}}{1+\sigma^2_{\infty}}\exp\left(\frac{-1}{2\sigma^2_{\infty}}\right), \quad \text{a.s.} \tag{2.57}$$

Finally, recall that, by definition, $\|\alpha^N\| = 1$ a.e. on $\widetilde{\Omega}_N$. Hence, with the fact that the pair $[A_\infty, C]$ is controllable (a.s.), it follows that

$$\sigma_\infty^2 > 0 \quad \text{a.e. on } \widetilde{\Omega}_N, \tag{2.58}$$

which immediately leads to (2.51). (Note that for the truncated process x^N and its limiting dynamic matrix A_∞^N, the pair $[A_\infty^N, C]$ is a.e. controllable on Γ_N, while $[A_\infty^N, C]$ might be uncontrollable on Γ_N^C, for which $A_\infty^N = A_{T_N}, T_N < \infty$.)

Since N was chosen such that $P(\widetilde{\Omega}_N) > 0$, the required contradiction is finally established. □

3. Examples and conclusion. We conclude the paper with a discussion of potential applications of the main result. Let $\lambda_m(t) = \lambda_m\{\int_0^t x_r x_r^T dr\}, m = \min, \max$. Then it follows from (2.3) that at one extreme $\lambda_{min}(t) = O(t)$, a.s. On the other hand, it is known that with unstable dynamics $\lambda_{max}(t) = O(te^{\beta t})$, a.s., for some $\beta > 0$, as $t \to \infty$. It turns out, then, that in the context of parameter estimation, an input signal $\{x_t\}$ (satisfying the above growth rates for its $\lambda_m(t)$, m = min, max), lacks adequate excitation for a recursive least squares (RLS)-type algorithm, as it fails to satisfy the condition (from Lai and Wei (1982)) that $\log \lambda_{max}(t)/\lambda_{min}(t) \to 0$ as $t \to \infty$, a.s. (In the absence of the convergence of this ratio to zero, Lai and Wei provide a counterexample to consistency.) On the other hand, in a Bayesian setting, (2.3) is sufficient to ensure consistency, where only $\lim_{t\to\infty} \lambda_{min}(t) = \infty$ is required.

Example 1. As an application of the main result of the paper, consider the system (2.1), where $\{A_t\}$ is a random, time-varying, convergent matrix process, i.e., a process satisfying (2.2). In this case, the consistency of the Bayesian estimate $E[A_t|\mathbf{F}_t^x]$ is ensured by the condition $\lambda_{min}(t) = O(t)$, a.s., a property implied by (2.3) (see Levanony (2001)). For the system described by (2.1), one then has $E[A_t|\mathbf{F}_t^x] \to A_\infty$, a.s. Furthermore, suppose that instead of the Bayesian estimate $E[A_t|\mathbf{F}_t^x]$ one uses a least squares (LS) estimate, denoted here by $\widehat{A}_t$; and finally, suppose that the system (2.1) can be parameterized by a *deterministic* parameter, say $\theta \in \mathbf{R}^p$. Then, by applying the idea of Bayesian embedding (Kumar (1989); see also the discussion in Caines (1988, pp. 294–295)), we may identify $\widehat{A}_t$ with $E[A_t|\mathbf{F}_t^x]$ for almost all $\theta \in \mathbf{R}^p$, and so it follows that under (2.3),

$$\widehat{A}_t \to A_\infty, \quad \text{a.s., for almost all} \quad \theta \in \mathbf{R}^p. \tag{3.1}$$

Hence, we conclude that, subject to the a.s. convergence condition (2.2), both the Bayesian and the LS consistency properties hold.

Example 2. As a control-related example of the above, consider an adaptive linear quadratic Gaussian (LQG) control problem of the form described in Duncan, Guo, and Pasik-Duncan (1999), where the system

$$dx_t = Ax_t dt + Bu_t + Cdw_t, \quad t \geq 0, \tag{3.2}$$

is to be controlled by an input function $u = \{u_t\}$, which is chosen so as to minimize a (standard) long-term averaged linear quadratic (LQ) cost. It is well known that the optimal control u^0 takes the form $u_t^0 = -K(A, B)x_t$. With *unknown* system matrices (A, B), one can use a CE (certainty equivalence) approach by which $\theta = (A, B)$ is estimated by $\widehat{\theta}_t = \widehat{\theta}_t(x_s, 0 \leq s \leq t)$, generated by some specified parameter estimation algorithm. The resulting control input would then assume the form $u_t = -K(\widehat{\theta}_t)x_t$

and, under this scheme, (3.1) is rewritten as (2.1) with $A_t = A - BK(\widehat{\theta}_t)$. (See Kumar (1983) for the discrete time, finite parameter set case.)

Suppose that the chosen parameter estimation algorithm is self-convergent (not necessarily consistent) (Duncan, Guo, and Pasik-Duncan (1999)); that is, for almost all parameters $\theta \in \mathbf{R}^p$ there exists an a.s. finite random vector $\widehat{\theta}_\infty$ such that $\widehat{\theta}_t \to \widehat{\theta}_\infty$ (w.p.1). Then, the continuity of $K(\cdot)$ clearly leads to $A_t \to A_\infty = A - BK(\widehat{\theta}_\infty)$, which is the basic assumption (2.2) above. Hence, given (2.2), the main result implies the persistent excitation (PE) property (2.3).

Now consider a separate procedure to estimate the time varying, *closed-loop* system matrix A_t by a Bayesian or an LS estimate, depending, respectively, on whether $\theta = (A, B)$ is random and Gaussian, or deterministic. By Example 1 above, both procedures yield a strongly consistent limit, where, in the LS case, this property is obtained in terms of Bayesian embedding.

Although the estimation of $\theta = (A, B)$ and the estimation of the closed-loop matrix $A_t = A - BK(\widehat{\theta}_t)$ were conceptually taken as two separate procedures, the two can be combined within one estimation scheme, as is easily seen in the Bayesian setting. Suppose that $\theta = (A, B)$ is Gaussian and independent of x_0, $\{w_t\}$. Then the Bayesian estimate of A_t takes the form

$$E[A_t|\mathbf{F}_t^x] = E[A - BK(\widehat{\theta}_t)|\mathbf{F}_t^x] = E[A|\mathbf{F}_t^x] - E[B|\mathbf{F}_t^x]K(\widehat{\theta}_t), \tag{3.3}$$

where the last equality follows from the fact that $K(\widehat{\theta}_t) \in \mathbf{F}_t^x$. Now take $\widehat{\theta}_t = E[\theta|\mathbf{F}_t^x]$; then the closed-loop estimate (3.3) is immediately obtained without any further calculation. In the deterministic (A, B) setting, the same applies for the LS estimate by virtue of Bayesian embedding (BE). Further, note that the Bayesian estimate of θ converges to a finite limit and, due to BE, so does the LS estimate (the self-convergence property, leading to (2.2)).

As far as adaptive control is concerned, it is interesting to note that the strong consistency of the *closed-loop* Bayesian (equivalently, LS) estimates implies that the corresponding generated limits $\widehat{\theta}_\infty = \theta' = (A', B')$ are characterized by the property that they form closed-loop dynamics which are *indistinguishable* from the actual (closed-loop) dynamics, that is to say, $A' - B'K(\theta') = A - BK(\theta')$ (Caines and Levanony (1993); Levanony and Caines (1996)).

This property, obtained from (2.3), may form the foundation of modifications to the (original) adaptive schemes, which would lead to the desired property of long-run, optimal performance (Caines and Levanony (1993)).

Appendix: Proof of Proposition 2.2. Recall (2.53), i.e., that $\zeta_n(s) = \widetilde{m}_n^T(s)\widetilde{z}_n^N(s)$ (where $\widetilde{m}$ and $\widetilde{z}$ are defined in (2.44) and (2.45), respectively), and let

$$\zeta(s) = (\alpha^N)^T \int_0^s \big[\exp A_\infty(s-r)\big] C d\beta_r, \tag{A.1}$$

where $A_\infty \in \mathbf{F}_\infty^x (= \sigma\{\bigcup_{n\geq 0} \mathbf{F}_{\tau_n}^x\})$ is the a.s. limit of $\{A_{\tau_n} \in \mathbf{F}_{\tau_n}^x\}$ and β is a (vector-valued) Brownian motion, *independent of* $\mathbf{F}_\infty^x$. (It is assumed that the probability space has been properly extended to support this Brownian motion.) Note that this definition makes $\zeta(s)$ conditionally Gaussian w.r.t. $\mathbf{F}_\infty^x$ (as is ζ_n, w.r.t. $\mathbf{F}_{\tau_n}^x$).

We now show that ζ induces a unique measure on $\mathbf{R}$ such that

$$\zeta_n(s) \longrightarrow \zeta(s) \quad \forall s \in [0, 1] \tag{A.2}$$

in distribution. For (A.2) to hold, it suffices that (i) all moments of ζ_n converge to those of ζ and that (ii) the set of moments form a separating function class, a fact which guarantees uniqueness; see, e.g., Billingsley (1979) and Breiman (1968).

The $2k$th moment of $\zeta_n(s)$ is calculated by utilizing its conditionally Gaussian distribution (note that odd moments of ζ_n and ζ are identically zero):

(A.3)
$$E|\zeta_n(s)|^{2k} = E\big\{E\big[|\zeta_n(s)|^{2k}|\mathbf{F}^x_{\tau_n}\big]\big\} = 1\cdot 3\cdot 5\cdots(2k-1)E\left\{E\big[|\zeta_n(s)|^2|\mathbf{F}^x_{\tau_n}\big]^k\right\},$$

where, w.p.1,

$$E\big[|\zeta_n(s)|^2|\mathbf{F}^x_{\tau_n}\big] = E\big[|\widetilde{m}^T_n(s)\widetilde{z}^N_n(s)|^2|\mathbf{F}^x_{\tau_n}\big]$$

$$= (\widehat{\alpha}^N_n)^T\int_0^s \big[\exp A_{\tau_n}(s-r)\big]CC^T\big[\exp A_{\tau_n}(s-r)\big]^T dr\widehat{\alpha}^N_n \le ||C||^2e^{2N}. \tag{A.4}$$

A similar calculation leads to

$$E|\zeta(s)|^{2k} = 1\cdot 3\cdot 5\cdots(2k-1)E\left\{E\big[|\zeta(s)|^2|\mathbf{F}^x_\infty\big]^k\right\}, \tag{A.5}$$

where

$$E\big[|\zeta(s)|^2|\mathbf{F}^x_\infty\big] = (\alpha^N)^T\int_0^s \big[\exp A_\infty(s-r)\big]CC^T\big[\exp A_\infty(s-r)\big]^T dr\alpha^N. \tag{A.6}$$

Now as $\widehat{\alpha}^N_n \to \alpha^N$, $A_{\tau_n}\to A_\infty$ (a.s.) with α^N and A_∞ being $\mathbf{F}^x_\infty$-measurable, it follows (with the aid of dominated convergence) that

$$E|\zeta_n(s)|^{2k} \to E|\zeta(s)|^{2k} \tag{A.7}$$

as $n\to\infty$, $k=1,2,\ldots$, $s\in[0,1]$, which in turn implies (A.2) (Breiman (1968), Theorem 8.48). Uniqueness follows from the fact that

$$\limsup_{k\to\infty}\frac{(E|\zeta(s)|^{2k})^{1/2k}}{2k} \le \limsup_{k\to\infty}\frac{(1\cdot 3\cdot 5\cdots(2k-1))^{1/2k}}{2k}||C||^2e^N \le ||C||^2e^N < \infty,$$

which makes the set of moments a separating function class (Breiman (1968), Proposition 8.49). (Another uniqueness condition, namely that $\sum_{k=1}^\infty E|\zeta(s)|^{2k}r^{2k}/(2k)! < \infty$ for some $r>0$, is satisfied here with $0<r<(||C||^2e^N)^{-1}$ (Billingsley (1979, Theorem 30.1)).)

Now, combining (2.27) with (2.33), (2.46), and (2.47) leads to

$$\lim_{n\to\infty}\int_0^1 (x^T_{\tau_n}z^N_n(s)+\zeta_n(s))^2ds = 0, \quad \text{a.s.}, \tag{A.8}$$

and integrability and dominated convergence imply that

$$\lim_{n\to\infty}\int_0^1 E(x^T_{\tau_n}z^N_n(s)+\zeta_n(s))^2ds = 0. \tag{A.9}$$

Define $\eta_n(s)\underline{\Delta}x^T_{\tau_n}z^N_n(s)$, fix $s\in[0,1]$, and write

$$\delta_n(s) = \zeta_n(s)+\eta_n(s). \tag{A.10}$$

Then by (A.9) one obviously has

$$\delta_n(s) \longrightarrow 0 \tag{A.11}$$

in L_2, a.e. on [0,1]. We now claim the following.

LEMMA A.1.

$$(\zeta_n(s), \delta_n(s)) \longrightarrow (\zeta(s), 0), \tag{A.12}$$

in distribution, a.e. on [0,1].

Proof. Based on (A.2) and (A.11),

$$\begin{aligned} P(\zeta_n(s) \le a, \delta_n(s) \le b) &= P(\zeta_n(s) \le a) - P(\zeta_n(s) \le a, \delta_n(s) > b) \\ &\to \begin{cases} P(\zeta(s) \le a), & b \ge 0, \\ 0, & b < 0. \end{cases} \end{aligned}$$

This is due to the fact that

$$P(\zeta_n(s) \le a, \delta_n(s) > b) \le \begin{cases} P(\delta_n(s) > b) \to 0, & b \ge 0, \\ P(\zeta_n(s) \le a) \to P(\zeta(s) \le a), & b < 0, \end{cases}$$

while on the other hand,

$$P(\zeta_n(s) \le a, \delta_n(s) > b) \ge \begin{cases} 0, & b \ge 0, \\ P(\zeta_n(s) \le a) - P(\delta_n(s) \le b) \to P(\zeta(s) \le a), & b < 0. \end{cases}$$

Thus the claim is proved. □

It follows from (A.10) and (A.12) that there exists a random process $\{\eta(s), s \in [0,1]\}$, defined on the *underlying probability space* $(\Omega, \mathbf{F}, P)$, such that

$$(\zeta_n(s), \eta_n(s)) \longrightarrow (\zeta(s), \eta(s)), \tag{A.13}$$

in distribution, a.e. on [0, 1], where $\zeta(s)$ has been previously constructed as a random variable on the underlying probability space $(\Omega, \mathbf{F}, P)$, and, by (A.10) and (A.12), the aforementioned limit $\eta(s)$ is also defined on $(\Omega, \mathbf{F}, P)$. Furthermore, recall that $\eta_n(s) = x_{\tau_n}^T z_n^N(s) = x_{\tau_n}^T \phi_n(s,0)\alpha_n^N$, where $\alpha_n^N \in \mathbf{F}_\infty^x$, $x_{\tau_n} \in \mathbf{F}_{\tau_n}^x \subset \mathbf{F}_\infty^x$, and $\phi_n \in \mathbf{F}_{\tau_n+1}^x \subset \mathbf{F}_\infty^x$. Next recall that, by (2.34),

$$z_n^N(s) \longrightarrow z^N(s) = [\exp A_\infty^T s]\alpha^N, \tag{A.14}$$

uniformly over $[0,1]$, a.s. Since (i) $z^N(s)$ is $\mathbf{F}_\infty^x$-measurable (by definition) and (ii) $\{x_{\tau_n}\} \in \mathbf{F}_\infty^x$, it follows from (A.14) and Skorohod's theorem (Billigsley (1979, Theorem 25.6)) that $\{\eta(s), s \in [0,1]\}$, being the limit in distribution of $\eta_n(s) = x_{\tau_n}^T z_n^N(s) \in \mathbf{F}_\infty^x$, $s \in [0,1]$, is also $\mathbf{F}_\infty^x$-measurable (recall that η is defined on $(\Omega, \mathbf{F}, P)$).

In light of the definition of ζ (see (A.1)), this fact therefore implies that η and ζ are conditionally independent w.r.t. $\mathbf{F}_\infty^x$; i.e., the limit joint distribution of $\eta_n(s)$ and $\zeta_n(s)$ is that of two $\mathbf{F}_\infty^x$-conditionally independent random processes. This, together with the fact that ζ is conditionally centered, yields

$$\begin{aligned} \lim_{n\to\infty} E\big[x_{\tau_n}^T z_n^N(s) \widetilde{m}_n^T(s) \widetilde{z}_n(s)\big] &= \lim_{n\to\infty} E\big[\eta_n(s)\zeta_n(s)\big] = E\big[\eta(s)\zeta(s)\big] \\ &= E\big\{\eta(s) E\big[\zeta(s) | \mathbf{F}_\infty^x\big]\big\} = 0, \end{aligned} \tag{A.15}$$

a.e. on [0, 1]. Hence, utilizing dominated convergence yields

$$\lim_{n\to\infty}\int_0^1 E\big[x_{\tau_n}^T z_n^N(s)\widetilde{m}_n^T(s)\widetilde{z}_n(s)\big]\,ds = 0,$$

and, with (2.26) and (2.48), equation (2.41) is finally obtained. □

Remarks. 1. Recall that the construction of the limit measure for ζ_n (namely, that of ζ) has been carried out by the use of a Brownian motion β, assumed to be *independent* of $\mathbf{F}_\infty^x$. While the uniqueness of the resulting limit law has already been proved, it is worth noting that this independence, which plays a key role in the proof (see (A.15)), is crucial. This is due to the fact that if β were not independent of $\mathbf{F}_\infty^x$, then (A.5) and (A.6) would no longer hold, thus ruling out the validity of (A.7) and hence that of the claim (A.2). By introducing this particular Brownian motion β, we have (implicitly) constructed the conditional orthogonality between ζ and η (as part of their joint distribution), which, in turn, enabled the calculation made in (A.15).

2. We note the following additional contradiction, which was generated in the proof of the contradiction to (2.27): while (A.10) and (A.12) imply that $E[\eta(s)\zeta(s)] = -E[\zeta^2(s)] < 0$, this is not the case, since η and ζ were found to be mutually orthogonal.

Acknowledgments. The authors gratefully acknowledge the constructive comments of Ofer Zeitouni and those of the anonymous reviewers.

EXISTENCE AND LIMITING BEHAVIOR OF A NON–INTERIOR-POINT TRAJECTORY FOR NONLINEAR COMPLEMENTARITY PROBLEMS WITHOUT STRICT FEASIBILITY CONDITION*

YUN-BIN ZHAO† AND DUAN LI‡

Abstract. For P_0-complementarity problems, most existing non–interior-point path-following methods require the existence of a strictly feasible point. (For a P_*-complementarity problem, the existence of a strictly feasible point is equivalent to the nonemptyness and the boundedness of the solution set.) In this paper, we propose a new homotopy formulation for complementarity problems by which a new non–interior-point continuation trajectory is generated. The existence and the boundedness of this non–interior-point trajectory for P_0-complementarity problems are proved under a very mild condition that is weaker than most conditions used in the literature. One prominent feature of this condition is that it may hold even when the often-assumed strict feasibility condition fails to hold. In particular, for a P_*-problem it turns out that the new non–interior-point trajectory exists and is bounded if and only if the problem has a solution. We also study the convergence of this trajectory and characterize its limiting point as the parameter approaches zero.

Key words. complementarity problems, non–interior-point methods, homotopy continuation trajectories, P_0-functions, P_*-functions

1. Introduction.

The standard complementarity problem (CP) is to find a pair $(x, y) \in R^n \times R^n$ such that

$$y = f(x), \quad (x, y) \geq 0, \quad \text{and } x^T y = 0,$$

where $f : R^n \to R^n$ is a continuous function. This problem has many applications in optimization, economics, and engineering. See, for example, Cottle, Pang, and Stone [8], Harker and Pang [14], Heemels, Schumacher, and Weiland [15], van der Schaft and Schumacher [37], and Lötstedt [23].

The first non–interior-point method for the CP was proposed by Chen and Harker [5], and was based on the use of a Chen–Harker–Kanzow–Smale smooth function. Due to the impressive numerical performance of the algorithm, as well as its ideal convenience for application to those CPs in which interiority restriction on the iterates is quite severe, there is a growing interest in non–interior-point methods for the CP, which have yielded many fruitful results; see, e.g., Kanzow [18], Burke and Xu [1, 2, 3, 4], Xu [35], Xu and Burke [36], Chen and Chen [6], Hotta and Yoshise [16], Hotta, Inaba, and Yoshise [17], Qi and Sun [26], and Tseng [32]. In the setting of P_0-CPs, a common feature of the above-mentioned non–interior-point methods is the assumption of the strict feasibility condition (or the nonemptyness and the boundedness conditions

‡Department of Systems Engineering and Engineering Management, The Chinese University of Hong Kong, Shatin, NT, Hong Kong (dli@se.cuhk.edu.hk).

on the solution set) and a properness condition. For instance, Hotta and Yoshise [16] utilized the following condition.

CONDITION 1.1. (i) *f is a P_0-function, i.e., for any distinct vectors x, y in R^n*

$$\max_{x_i \neq y_i} (x_i - y_i)(f_i(x) - f_i(y)) \geq 0.$$

(ii) *There exists a strictly feasible point (x^0, y^0), i.e., $x^0 > 0$ and $y^0 = f(x^0) > 0$.*

(iii) *The set*

$$U^{-1}(D) = \{(u, x, y) \in R^n_+ \times R^{2n} : U(u, x, y) \in D\}$$

is bounded for every compact subset D of $R^n_+ \times V(R^n_{++} \times R^{2n})$, where $V : R^n_+ \times R^{2n} \to R^n$ and $U : R^n_+ \times R^{2n} \to R^n_+ \times R^{2n}$ are given by

$$V(u, x, y) = x + y - \sqrt{(x - y)^2 + 4u}$$

and

$$U(u, x, y) = \begin{pmatrix} u \\ x + y - \sqrt{(x - y)^2 + 4u} \\ y - f(x) \end{pmatrix} = \begin{pmatrix} u \\ V(u, x, y) \\ y - f(x) \end{pmatrix}, \tag{1.1}$$

respectively. All the above algebraic operations are performed componentwise.

The following standard condition was widely used in interior-point methods and non–interior-point methods. See, for example, [2, 3, 6, 16, 17, 19, 20, 21, 26, 38].

CONDITION 1.2. (i) *f is monotone, i.e., $(x - y)^T(f(x) - f(y)) \geq 0$ for any $(x, y) \in R^{2n}$.*

(ii) *There exists a strictly feasible point (x^0, y^0), i.e., $x^0 > 0$ and $y^0 = f(x^0) > 0$.*

Condition 1.2 implies Condition 1.1 (see [16, 26]). Hotta and Yoshise [16] pointed out that Condition 1.1 implies the well known Condition 1.5 in Kojima, Megiddo, and Noma [19]. As observed by Zhao and Li [42] (see also section 3 of this paper), Condition 1.5 in [19] implies that the solution set of the CP is nonempty and bounded. Thus, the above-mentioned Conditions 1.1 and 1.2 imply that the solution set of the CP is nonempty and bounded. Ravindran and Gowda (Corollary 5 in [27]) showed that a P_0-CP with a nonempty and bounded solution set must have a strictly feasible point. Moreover, for monotone CPs the converse is also true, i.e., the solution set of the monotone CP is nonempty and bounded if and only if it has a strictly feasible point. (See also Chen, Chen, and Kanzow [7].) This property of the monotone problem can be extended to the case of P_*-CPs. We recall that a map $f : R^n \to R^n$ is said to be a P_*-function if there exists a constant $\tau \geq 0$ such that

$$(1 + \tau) \sum_{i \in I_+} (x_i - y_i)(f_i(x) - f_i(y)) + \sum_{i \in I_-} (x_i - y_i)(f_i(x) - f_i(y)) \geq 0$$

for all distinct vectors x, y in R^n, where $I_+ = \{i : (x_i - y_i)(f_i(x) - f_i(y)) > 0\}$ and $I_- = \{1, \ldots, n\} \setminus I_+$. (See, Cottle, Pang, and Venkateswaran [9], Kojima et al. [20], Väliaho [33], Zhao and Han [38], and Zhao and Isac [39, 40].) Clearly a monotone function is a P_*-function, but the converse is not true. Zhao and Li [41, 42] pointed out that for a P_*-CP the following three conditions are equivalent:

(i) There exists a strictly feasible point.

(ii) The solution set of the CP is nonempty and bounded.

(iii) The central path of the CP exists.

Since most existing (interior-point and) non–interior-point path-following algorithms for CPs are based on the use of a certain continuation trajectory such as the central path, whose existence is closely related to the existence of a strictly feasible point, we conclude that for P_0-CPs these (interior-point and) non–interior-point algorithms are, in fact, confined to solving a class of strictly feasible problems. Other non-interior-point algorithms in the literature also suffer from the same restriction. For instance, the algorithms developed by Chen and Harker [5], Burke and Xu [1], and Chen and Chen [6] require the P_0 and R_0 assumption, which also implies that the solution set of the CP is nonempty and bounded, and hence the problem is strictly feasible. The strict feasibility condition plays an indispensable role in these known non–interior-point methods. In section 3, we give an example to show that Hotta and Yoshise's non–interior-point trajectory [16] does not necessarily exist when the problem has no strictly feasible point, in which case the solution set of the P_0-CP is unbounded (provided that it is nonempty). An interesting question is how to circumvent this difficulty so that a non–interior-point path-following method can be designed to solve a CP even when there is no strictly feasible point.

In this paper, we shall propose a new homotopy formulation of the CP. Based on this formulation, a new non–interior-point continuation trajectory for the CP can be generated. This new continuation trajectory possesses a desirable feature: For P_0-CPs, the existence and the boundedness of the continuation trajectory can be ensured under a mild condition that is weaker than most existing conditions like Conditions 1.1 and 1.2. The often assumed strict feasibility condition is not required here. In particular, for P_*-CPs, the proposed continuation trajectory exists and is bounded if and only if the problem has a solution. In other words, the existence and the boundedness of the trajectory for P_*-CPs do not require the strict feasibility condition (which is equivalent to the nonemptiness and boundedness of the solution set). We also (i) provide some sufficient conditions for the convergence of the entire trajectory as the parameter approaches zero and (ii) identify the properties of the limiting point of this trajectory. The results presented in the paper provide us with a theoretical basis for devising a new non–interior-point path-following method for CPs. This method can be expected to solve a more general class of complementarity problems than those to which most existing methods can be applied.

This paper is organized as follows. In section 2, we define a new homotopy formulation for the CP. In section 3, we specify a new properness condition that will be used to prove the existence and boundedness of a new continuation trajectory in section 4. We also compare this condition with several others known in the literature. The limiting behavior of the trajectory is studied in section 5. Final remarks are given in section 6.

Notation. We denote by R^n the space of n-dimensional real vectors, and by $R^n_+(R^n_{++}$, respectively) the nonnegative orthant (positive orthant, respectively). If $x \in R^n_+$ (R^n_{++}), we write $x \geq 0$ $(x > 0)$ for simplicity. All vectors, unless otherwise stated, are column vectors. T denotes the transpose of a vector. The symbol e denotes the vector in R^n with all of its components equal to one. For given vectors u, w, v in R^n, the triplet (u, w, v) (the pair (x, y)) denotes the column vector $(u^T, w^T, v^T)^T$ ($(x^T, y^T)^T$). For any $u \in R^n_+$, the symbol u^p denotes the pth power of the vector u, i.e., the vector $(u_1^p, \ldots, u_n^p)^T$, where $p > 0$ is a positive scalar. In particular, when $p = 1/2$, $\sqrt{u}$ denotes the vector $(\sqrt{u_1}, \ldots, \sqrt{u_n})^T$. The symbol diag$(x)$ denotes the $n \times n$ diagonal matrix whose (i, i)th entry is x_i. For any $x, y \in R^n$ with $x \leq y$, we

define the rectangular box $[x_1, y_1] \times \cdots \times [x_n, y_n]$ as $[x, y]$.

2. A new homotopy formulation for CPs. Let $(\bar{u}, \bar{v}, \bar{r})$ be a fixed point in $R^n_{++} \times R^{2n}$ and let

$$\bar{w} = \{\theta(\bar{u}, \bar{v}, \bar{r}) \in R^n_{++} \times R^{2n} : \theta \in (0, 1]\}.$$

Let $U : R^n_+ \times R^{2n} \to R^{3n}$ be defined by (1.1). Set

$$U^{-1}(\bar{w}) = \{z = (u, x, y) \in R^n_{++} \times R^{2n} : U(z) = \theta(\bar{u}, \bar{v}, \bar{r}) \text{ for some } \theta \in (0, 1]\}.$$

Under Condition 1.1, Hotta and Yoshise [16] showed that the above set forms a continuous trajectory leading to a solution of the CP. Based on this fact, they designed a globally convergent path-following method for the CP. However, it is easy to see that the strict feasibility condition plays an essential role in the existence of the Hotta and Yoshise trajectory. In fact, it is impossible to remove the strict feasibility condition from Conditions 1.1 and 1.2 without destroying the existence of their trajectory, as we see in the following example.

Example 2.1. Let $f(x) = Mx + q$, where

$$M = \begin{pmatrix} 0 & -1 \\ 0 & 0 \end{pmatrix}, \quad q = \begin{pmatrix} -1 \\ 0 \end{pmatrix}.$$

This function is a P_0-function and there exists no strictly feasible point. The solution set of the corresponding CP is unbounded. Let $\bar{u} = (\bar{u}_1, \bar{u}_2)^T \in R^2_{++}$, $\bar{v} = (\bar{v}_1, \bar{v}_2)^T \in R^2$, and $\bar{r} = (\bar{r}_1, \bar{r}_2)^T \in R^2$. From Lemma 1.1 in [16], the system $U(u, x, y) = \theta(\bar{u}, \bar{v}, \bar{r})$ can be written as follows:

$$u = \theta\bar{u}, \quad y = f(x) + \theta\bar{r}, \quad x - \theta\bar{v}/2 > 0, \quad y - \theta\bar{v}/2 > 0,$$
$$\operatorname{diag}(x - \theta\bar{v}/2)(y - \theta\bar{v}/2) = \theta\bar{u}.$$

Note that $y = f(x) + \theta\bar{r} = \binom{-x_2 - 1 + \theta\bar{r}_1}{\theta\bar{r}_2}$. The last equation above can be rewritten as

$$(x_1 - \theta\bar{v}_1/2)(-x_2 - 1 + \theta\bar{r}_1 - \theta\bar{v}_1/2) = \theta\bar{u}_1, \tag{2.1}$$

$$(x_2 - \theta\bar{v}_2/2)(\theta\bar{r}_2 - \theta\bar{v}_2/2) = \theta\bar{u}_2.$$

Since $\theta > 0$, the second equation above reduces to

$$(x_2 - \theta\bar{v}_2/2)(\bar{r}_2 - \bar{v}_2/2) = \bar{u}_2. \tag{2.2}$$

Case 1: $\bar{r}_2 \le \bar{v}_2/2$. Since $x_2 - \theta\bar{v}_2/2 > 0$ and $\bar{u}_2 > 0$, the above equation has no solution, and thus the system $U(u, x, y) = \theta(\bar{u}, \bar{v}, \bar{r})$ has no solution.

Case 2: $\bar{r}_2 > \bar{v}_2/2$. In this case, (2.2) can be written as

$$x_2 = (\bar{r}_2 - \bar{v}_2/2)^{-1}\bar{u}_2 + \theta\bar{v}_2/2.$$

Hence, for all sufficiently small $\theta > 0$, we have

$$-x_2 - 1 + \theta\bar{r}_1 - \theta\bar{v}_1/2 = -(\bar{r}_2 - \bar{v}_2/2)^{-1}\bar{u}_2 - \theta\bar{v}_2/2 - 1 + \theta\bar{r}_1 - \theta\bar{v}_1/2 < 0.$$

Since $x_1 - \theta\bar{v}_1/2 > 0$, we deduce from the above that (2.1) has no solution for all sufficiently small $\theta > 0$. Thus, the Hotta–Yoshise trajectory [16] does not exist.

Motivated by the above example, we now introduce a new homotopy formulation for the CP. Let $p \in (0,\infty)$ and $q \in [1,\infty)$ be two fixed numbers throughout the paper. Define the homotopy map $H : R^n_+ \times R^{2n} \to R^{3n}$ as follows:

$$H(u,x,y) = \begin{pmatrix} u \\ x+y-\sqrt{(x-y)^2+4u^q} \\ y-(f(x)+\mathrm{diag}\,(u^p)\,x) \end{pmatrix}, \quad (u,x,y) \in R^n_+ \times R^{2n}.$$

The above homotopy map is the focus of our study. It is worth mentioning that for each fixed vector $u > 0$, the function $f(x) + \mathrm{diag}\,(u^p)\,x$ can be viewed as a form of the renowned Tikhonov regularization of f, which was originally utilized to handle ill-posed problems. Recently, more attention has been paid to such techniques; see, e.g., Venkateswaran [34], Facchinei [10], Facchinei and Kanzow [11], Facchinei and Pang [12], Ravindran and Gowda [27], Gowda and Tawhid [13], Sznajder and Gowda [29], Qi [25], Sun [28], Tseng [31], and Zhao and Li [42]. To deal with the case of nonexistence of a strictly feasible point (or unboundedness of the solution set), we will see from the later discussion that it is a judicious choice to use the above new homotopy formulation of the CP.

The above homotopy map encompasses several extra variants. For instance, when $q = 1$ and $p \to \infty$, the above homotopy map, as u varies within the open rectangular box $(0, e)$, reduces to the one proposed by Hotta and Yoshise [16]. When $q = 2$ and $p \to \infty$, the above homotopy map, as u varies within $(0, e)$, is precisely the one studied by Burke and Xu [2, 3, 4], and Qi and Sun [26].

It is not difficult to see that if $H(u,x,y) = 0$, then (x,y) is a solution to the CP; conversely, if (x,y) is a solution to the CP, then $(0,x,y)$ is a solution to the equation $H(u,x,y) = 0$. Thus, a CP can be solved by locating a solution to the nonlinear equation $H(u,x,y) = 0$. The most widely used continuation method for solving this equation is the path-following algorithm that traces certain continuation trajectories leading to the solution set. We do not study such a numerical algorithm in this paper. The purpose here is to establish a theoretical basis for constructing a new non–interior-point path-following algorithm. Such a method can be used to solve a class of problems that is broader than those to which most existing path-following methods can be applied.

Given $(a,b,c) \in R^n_{++} \times R^{2n}$, we consider the system

$$H(u,x,y) = \theta(a,b,c), \tag{2.3}$$

where $\theta \in (0,1]$. Define $\bar{Z} = \{\theta(a,b,c) : \theta \in (0,1]\}$. In section 4, we will show that the set

$$H^{-1}(\bar{Z}) = \{(u,x,y) \in R^n_{++} \times R^{2n} : H(u,x,y) = \theta(a,b,c),\ \theta \in (0,1]\}$$

forms a unique, continuous curve leading to a solution of the CP under certain mild conditions. We now give two basic results that will be used later. The first result below gives an equivalent formulation of the system (2.3). This result plays a critical role in the analysis throughout the paper. For the given $(a,b,c) \in R^n_{++} \times R^{2n}$, we define the map $\mathcal{Y} : R^n \times (0,1] \to R^n$ by

$$\begin{aligned} \mathcal{Y}(x,\theta) := {} & x + f(x) + \theta^p \mathrm{diag}\,(a^p)\,x + \theta c \\ & + \sqrt{[x-(f(x)+\theta^p \mathrm{diag}\,(a^p)\,x+\theta c)]^2 + 4\theta^q a^q} - \theta b. \end{aligned} \tag{2.4}$$

LEMMA 2.1. *The solutions of* $\mathcal{Y}(x,\theta) = 0$ *are in one-to-one correspondence with those of* $H(u,x,y) = \theta(a,b,c)$. *Specifically, for the given scalar* $\theta \in (0,1]$, *if* (u,x,y) *is a solution to the system* $H(u,x,y) = \theta(a,b,c)$, *then* x *is a solution to the equation* $\mathcal{Y}(x,\theta) = 0$; *conversely, if* x *is a solution to the equation* $\mathcal{Y}(x,\theta) = 0$, *then* (u,x,y), *where* $u = \theta a$ *and* $y = f(x) + diag\{u^p\}x + \theta c$, *is a solution to the system* $H(u,x,y) = \theta(a,b,c)$.

Proof. The result is easy to show. Indeed, the equation $H(u,x,y) = \theta(a,b,c)$ is equivalent to the following system:

$$u = \theta a, \tag{2.5}$$

$$x + y - \sqrt{(x-y)^2 + 4u^q} = \theta b, \tag{2.6}$$

$$y = f(x) + \mathrm{diag}\{u^p\}x + \theta c. \tag{2.7}$$

Substituting (2.5) and (2.7) into (2.6) yields $\mathcal{Y}(x,\theta) = 0$. □

It is well known (see Lemma 1.1 in [16]) that for every nonnegative number $\mu \geq 0$, a triplet $(\alpha,\beta,\gamma) \in R^3$ satisfies

$$\phi(\mu,\alpha,\beta) = \alpha + \beta - \sqrt{(\alpha-\beta)^2 + 4\mu} = \gamma$$

if and only if $(\alpha - \gamma/2, \beta - \gamma/2) \geq 0$ and $(\alpha - \gamma/2)(\beta - \gamma/2) = \mu \geq 0$. Moreover, if $\mu > 0$, then $(\alpha - \gamma/2, \beta - \gamma/2) > 0$. By this fact, from (2.5)–(2.7) we have the following lemma.

LEMMA 2.2. *Let* $(a,b,c) \in R^n_{++} \times R^{2n}$ *be a fixed vector. Then for any* $\theta \in (0,1]$, *the vector* $(u(\theta), x(\theta), y(\theta))$ *is a solution to the system* (2.3) *if and only if it satisfies the following system:*

$$u(\theta) = \theta a, \tag{2.8}$$

$$y(\theta) = f(x(\theta)) + \theta^p \mathrm{diag}\,(a^p)\, x(\theta) + \theta c, \tag{2.9}$$

$$x(\theta) - \theta b/2 > 0, \quad y(\theta) - \theta b/2 > 0, \tag{2.10}$$

$$\mathrm{diag}\,(x(\theta) - \theta b/2)\,(y(\theta) - \theta b/2) = \theta^q a^q. \tag{2.11}$$

Remark 2.1. Since $\theta \in (0,1]$ and f is continuous, it follows from (2.8) and (2.9) that a sequence $\{(u(\theta_k), x(\theta_k), y(\theta_k))\}$, where $\theta_k \in (0,1]$, is unbounded if and only if $\{x(\theta_k)\}$ is unbounded. This fact will be frequently used in the later sections.

3. A new properness condition. In this section, we specify a new condition that is used to prove the existence and boundedness of the trajectory in the next section. To understand this condition better, we show first some properties of a semimonotone function. A map $f : R^n \to R^n$ is said to be semimonotone if, for any distinct vectors x, y in R^n with $x \geq y$, there exists a component i such that $x_i > y_i$ and $f_i(x) \geq f_i(y)$. It is evident that each P_0-function is semimonotone. The following result is a generalization of Lemma 1 in Ravindran and Gowda [27]. The proof is similar to the ones in such works as Tseng [30], Gowda and Tawhid [13], and Facchinei and Kanzow [11].

LEMMA 3.1. *Let* $f : R^n \to R^n$ *be a continuous semimonotone function. Let* $\{z^k\}$ *be an arbitrary sequence with* $\|z^k\| \to \infty$ *and* $z^k \geq \bar{z}$ *for all* k, *where* $\bar{z} \in R^n$ *is a fixed*

vector. Then there exist a subsequence of $\{z^k\}$*, denoted by* $\{z^{k_j}\}$*, and a fixed index* i_0 *such that* $z_{i_0}^{k_j} \to \infty$ *and* $f_{i_0}(z^{k_j})$ *is bounded from below.*

Proof. Passing through a subsequence, we may assume that there exists an index set I such that $z_i^k \to \infty$ for all $i \in I$, and $\{z_i^k\}$ is bounded for all $i \notin I$. Construct $\{y^k\}$ as follows: $y_i^k = \bar{z}_i$ if $i \in I$, and $y_i^k = z_i^k$ if $i \notin I$. Then we have that $z^k \neq y^k$ and $z^k \geq y^k$ for all sufficiently large k. By the semimonotone property of f, for each sufficiently large k there exists at least one index i such that $z_i^k > y_i^k$ and $f_i(z^k) \geq f_i(y^k)$. Thus, there exist an index $i_0 \in I$ and a subsequence of $\{z^k\}$, denoted by $\{z^{k_j}\}$, such that $z_{i_0}^{k_j} > y_{i_0}^{k_j}$ and $f_{i_0}(z^{k_j}) \geq f_{i_0}(y^{k_j})$ for all j. By this construction, $\{y^{k_j}\}$ is bounded and so is $\{f_{i_0}(y^{k_j})\}$. Hence $\{f_{i_0}(z^{k_j})\}$ is bounded from below. □

Given $(a, b, c) \in R^n_{++} \times R^{2n}$ and $\theta \in (0, 1]$, we define a function $\mathcal{F}_{(a,b,c,\theta)} : R^{2n} \to R^{2n}$ as follows:

$$\mathcal{F}_{(a,b,c,\theta)}(x, y) = \begin{pmatrix} Xy \\ y - f(x + \theta b/2) - \theta^p \mathrm{diag}\,(a^p)\, x - \theta c \end{pmatrix}, \tag{3.1}$$

where $X = \mathrm{diag}(x)$. The next property of semimonotone functions is one of the motivations for our new properness condition.

PROPOSITION 3.1. *Let* $f : R^n \to R^n$ *be a continuous semimonotone function. Then for any* $(a, b, c, \theta) \in R^n_{++} \times R^{2n} \times (0, 1]$*, the set*

$$\mathcal{F}^{-1}_{(a,b,c,\theta)}(D) = \{(x, y) \in R^n_{++} : \mathcal{F}_{(a,b,c,\theta)}(x, y) \in D\}$$

is bounded for any compact set D *in* $R^n_+ \times R^n$*.*

Proof. Assume the contrary: there exist certain $(a', b', c', \theta') \in R^n_{++} \times R^{2n} \times (0, 1]$ and a compact set $D' \subseteq R^n_+ \times R^n$ such that $\mathcal{F}^{-1}_{(a',b',c',\theta')}(D')$ is unbounded. Let $\{(x^k, y^k)\} \subseteq \mathcal{F}^{-1}_{(a',b',c',\theta')}(D')$ such that $\|(x^k, y^k)\| \to \infty$. Notice that

$$\mathcal{F}_{(a',b',c',\theta')}(x^k, y^k) = \begin{pmatrix} X^k y^k \\ y^k - f(x^k + \theta' b'/2) - (\theta')^p \mathrm{diag}\,((a')^p)\, x^k - \theta' c' \end{pmatrix} \in D'.$$

There is a sequence $\{(u^k, v^k)\} \subseteq D'$, where $u^k \in R^n_+$ and $v^k \in R^n$, such that for all k we have

$$X^k y^k = u^k \geq 0, \tag{3.2}$$

$$y^k = f(x^k + \theta' b'/2) + (\theta')^p \mathrm{diag}\,((a')^p)\, x^k + \theta' c' + v^k. \tag{3.3}$$

Since $\{(u^k, v^k)\}$ is bounded and since $\|(x^k, y^k)\| \to \infty$, by continuity we conclude that the sequence $\{x^k\}$ is unbounded. Thus, we may assume that $\|x^k\| \to \infty$. Since $x^k \in R^n_+$ for all k, passing through a subsequence we may assume that there exists an index set I such that $x_i^k \to \infty$ for all $i \in I$, and $\{x_i^k\}$ is bounded for all $i \notin I$. Since $x_i^k \to \infty$ for all $i \in I$, it follows from (3.2) that $y_i^k \to 0$ for all $i \in I$. Hence from (3.3) we have

$$f_i(x^k + \theta' b'/2) = y_i^k - (\theta')^p \mathrm{diag}\,((a')^p)\, x_i^k - \theta' c'_i - v_i^k \to -\infty$$

for all $i \in I$. However, by Lemma 3.1 there exists an index $i \in I$ such that $\{f_i(x^k + \theta' b'/2)\}$ is bounded from below. This is a contradiction. □

As a particular case, let $D_r := [0, rv_1] \times [-rv_2, rv_3] \subseteq R^n_+ \times R^n$, where $v_i \in R^n_+ (i = 1, 2, 3)$ and r is a nonnegative number. We deduce from the above proposition that the

set $\mathcal{F}^{-1}_{(a,b,c,r)}(D_r)$ is bounded for any $0 < r < \infty$ if f is continuous and semimonotone. Inspired by this observation, we impose the following properness condition on the CP.

CONDITION 3.1. *For any given $(a, b, c) \in R^n_{++} \times R^{2n}$ and scalar $\hat{t} \geq 0$ there exists a scalar $1 \geq \theta^* > 0$ such that*

$$\bigcup_{\theta \in (0,\theta^*]} \mathcal{F}^{-1}_{(a,b,c,\theta)}(D_\theta)$$

is bounded, where

$$\mathcal{F}^{-1}_{(a,b,c,\theta)}(D_\theta) := \{(x, y) \in R^{2n}_{++} : \mathcal{F}_{(a,b,c,\theta)}(x, y) \in D_\theta\}$$

and

$$D_\theta := [0, \theta a^q] \times [-\theta \hat{t} e, \theta \hat{t} e] \subseteq R^n_+ \times R^n.$$

Notice that for a fixed $\bar{\theta} \in (0, 1)$, the above set $D_\theta \subseteq D_{\bar{\theta}} := [0, \bar{\theta} e] \times [-\bar{\theta} e, \bar{\theta} e]$ for all sufficiently small θ. Thus, we can see that Condition 3.1 holds if the following condition is satisfied.

CONDITION 3.2. *For any given $(a, b, c) \in R^n_{++} \times R^{2n}$ there exists a scalar $1 > \bar{\theta} > 0$ such that*

$$\bigcup_{\theta \in (0,\bar{\theta}]} \mathcal{F}^{-1}_{(a,b,c,\theta)}(D_{\bar{\theta}})$$

is bounded, where $D_{\bar{\theta}} = [0, \bar{\theta} e] \times [-\bar{\theta} e, \bar{\theta} e]$ and

$$\mathcal{F}^{-1}_{(a,b,c,\theta)}(D_{\bar{\theta}}) = \{(x, y) \in R^n_{++} : \mathcal{F}_{(a,b,c,\theta)}(x, y) \in D_{\bar{\theta}}\}.$$

At first glance, Condition 3.1 may seem to be a little unusual. As we will see subsequently, this condition is actually quite weak. A prominent feature of Condition 3.1 is that it may hold even when the solution set of the CP is unbounded or the strict feasibility condition fails to hold. Specifically, for P_0-complementarity problems we will show that previously known conditions such as Condition 1.1, Condition 1.2, the nonemptiness and boundedness assumption of the solution set (in particular, the P_0 together with R_0 property), and Condition 1.5 in [19] all imply Condition 3.1. However, the converse is not true (see Theorem 3.1 below). Before we prove this fact, we list some helpful results. The following result is easy to prove by using the compactness of S and continuity of f. Its proof is omitted.

LEMMA 3.2. *Let S be a compact set in R^n and $(a, b, c) \in R^n_{++} \times R^{2n}$ be a fixed triplet. Let f be a continuous function from R^n into itself.*

(i) *Let*

$$G(x) := x + f(x) - \sqrt{(x - f(x))^2}.$$

Define $\bar{G} : R^n \times (0, 1] \times R^n_+ \times R^n \to R^n$ by

$$\bar{G}(x, \theta, w, v) = x + f(x) + \theta^p \mathrm{diag}\,(a^p)\,(x - \theta b/2) + \theta(c + b/2) + v$$
$$- \sqrt{[x - (f(x) + \theta^p \mathrm{diag}\,(a^p)\,(x - \theta b/2) + \theta(c + b/2) + v)]^2 + 4w} - \theta b.$$

Then for any $\delta > 0$ there exists a scalar $\bar{\theta} \in (0, 1]$ such that for all $\theta \in (0, \bar{\theta}]$ and $(w, v) \in [0, \bar{\theta} e] \times [-\bar{\theta} e, \bar{\theta} e] \subseteq R^n_+ \times R^n$ we have

$$\sup_{x \in S} \|\bar{G}(x, \theta, w, v) - G(x)\| < \delta.$$

(ii) *Given any* $\hat{\theta} \in (0,1)$*, then for any* $\delta > 0$ *there exists a sufficiently small scalar* $\beta > 0$ *such that*

$$\sup_{x \in S} \|\mathcal{Y}(x,\theta) - \mathcal{Y}(x,\hat{\theta})\| < \delta \quad \text{for all } \theta \text{ such that } |\theta - \hat{\theta}| < \beta,$$

where $\mathcal{Y}(x,\theta)$ *is defined by* (2.4).

The next result, which was pointed out by Gowda and Tawhid [13], is very useful for the subsequent analysis.

LEMMA 3.3. *Let* $\Phi(x,v) = x + f(x) - \sqrt{(x - f(x))^2 + v^2}$*, where* $v \in R^n$.

(i) *If* f *is a* P_0*-function, then* $\Phi(x,v)$ *is a* P_0*-function in* x*. Moreover, if* $v^2 \in R^n_{++}$*, then* $\Phi(x,v)$ *is a P-function in* x.

(ii) *If* f *is a P-function, then* $\Phi(x,v)$ *is a P-function in* x.

The following upper-semicontinuity property of a P_0-function is due to Ravindran and Gowda [27].

LEMMA 3.4. *Let* $g : R^n \to R^n$ *be a* P_0*-function. Suppose that* $g^{-1}(0)$ *is nonempty and compact. Then for any given* $\varepsilon > 0$ *there exists a scalar* $\gamma > 0$ *such that for any* P_0*-function* h *with*

$$\sup_{\bar{\Omega}} \|h(x) - g(x)\| < \gamma$$

we have

$$\emptyset \neq h^{-1}(0) \subseteq g^{-1}(0) + \varepsilon B,$$

where B *denotes the open unit ball in* R^n *and* $\bar{\Omega}$ *is the closure of the set* $\Omega = g^{-1}(0) + \varepsilon B$.

We now show that several well-known existing conditions used in the literature of interior-point and non–interior-point methods imply Condition 3.1. However, the converse is not true, since Condition 3.1 may hold for P_0-CPs in the absence of the strict feasibility condition.

THEOREM 3.1. *Let* f *be a* P_0*-function. If one of the following condition holds,*

(i) *Condition* 1.1*,*

(ii) *Condition* 1.2*,*

(iii) *Condition* 1.5 *in Kojima, Magiddo, and Noma* [19]*,*

(iv) *the solution set of the CP is nonempty and bounded,*

(v) f *is a* P_0 *and* R_0 *function* [1, 6]*,*

then Condition 3.1 *holds. However, the converse is not true, i.e., Condition* 3.1 *does not imply any one of the above conditions.*

Proof. The implication (ii) $\Rightarrow$ (i) is pointed out in [16, 26]. It is easy to verify that (i) $\Rightarrow$ (iv). In fact, if (i) holds, Hotta and Yoshise [16] showed that their non–interior-point trajectory exists and a subtrajectory is bounded, and hence each of the accumulation points of the subtrajectory is a solution to the CP. Hence the solution set of the CP is not empty. We further demonstrate that it is bounded. Indeed, by Condition 1.1, there is a point $x^0 > 0$ such that $f(x^0) > 0$. It follows from Lemma 2.1 in [16] that $R^n_- \times R^n_+ \subseteq V(R^n_{++} \times R^{2n})$. Thus, by Condition 1.1 again, the set $U^{-1}(D)$ is bounded for every compact subset D of $R^n_+ \times R^n_- \times R^n_+$. In particular, set

$$D := \{(0,0,0)\} \subseteq R^n_+ \times R^n_- \times R^n_+.$$

Then the set $U^{-1}(0)$ is bounded. The set $U^{-1}(0)$ coincides with the solution set of the CP. Hence (i) $\Rightarrow$ (iv).

By a proof similar to the above, we can show that (iii)⇒ (iv). The implication of (v) ⇒ (iv) is a known result.

Therefore, to show that each condition of (i)–(v) implies Condition 3.1, it is sufficient to prove that (iv) implies Condition 3.1. Indeed, assume that f is a P_0-function and the solution set of the CP is nonempty and bounded. We show that Condition 3.2 holds (and hence Condition 3.1 holds). Let $G : R^n \to R^n$ be given by

$$G(x) := x + f(x) - \sqrt{(x - f(x))^2},$$

which is a P_0-function (Lemma 3.3). Since $G^{-1}(0) = \{x \in R^n : G(x) = 0\}$ coincides with the solution set of the CP, by the assumption, the set $G^{-1}(0)$ is nonempty and bounded; in fact, it is a compact set by the continuity of f. For any scalar $\varepsilon > 0$, by Lemma 3.4 there is a scalar $\delta > 0$ such that for any P_0-function $h : R^n \to R^n$ with

$$\sup_{x \in \bar{\Omega}} \|h(x) - G(x)\| < \delta, \tag{3.4}$$

where $\Omega = G^{-1}(0) + \varepsilon B$,

$$0 \neq h^{-1}(0) \subseteq G^{-1}(0) + \varepsilon B. \tag{3.5}$$

Let (a, b, c) be a fixed triplet in $R^n_{++} \times R^{2n}$, and let $\bar{G}(x, \theta, w, v)$ be given as in Lemma 3.2, where $\theta \in (0, 1]$ and $(w, v) \in R^n_+ \times R^n$. Clearly, the function

$$f(x) + \operatorname{diag}(\theta^p a^p)(x - \theta b/2) + \theta(c + b/2) + v$$

is a P-function in x. Since $w \in R^n_+$, it follows from (ii) of Lemma 3.3 that $\bar{G}(x, \theta, w, v)$ is a P-function in x. By (i) of Lemma 3.2, there exists a sufficiently small number $\bar{\theta} \in (0, 1)$ such that for all $\theta \in (0, \bar{\theta}]$ and $(w, v) \in [0, \bar{\theta}e] \times [-\bar{\theta}e, \bar{\theta}e]$ we have

$$\sup_{x \in \bar{\Omega}} \|\bar{G}(x, \theta, w, v) - G(x)\| < \delta.$$

Thus, setting $h(x) := \bar{G}(x, \theta, w, v)$ in (3.4), we have from (3.5) that

$$\emptyset \neq \bar{G}^{-1}_{(\theta,w,v)}(0) \subseteq G^{-1}(0) + \varepsilon B$$

for all $\theta \in (0, \bar{\theta}]$ and $(w, v) \in [0, \bar{\theta}] \times [-\bar{\theta}e, \bar{\theta}e]$, where

$$\bar{G}^{-1}_{(\theta,w,v)}(0) = \{x \in R^n : \bar{G}(x, \theta, w, v) = 0\}.$$

Hence,

$$\bigcup_{(\theta,w,v) \in (0,\bar{\theta}] \times D_{\bar{\theta}}} \bar{G}^{-1}_{(\theta,w,v)}(0) \subseteq G^{-1}(0) + \varepsilon B,$$

where $D_{\bar{\theta}} = [0, \bar{\theta}e] \times [-\bar{\theta}e, \bar{\theta}e]$. On the other hand, it is easy to verify that

$$\bar{G}(x, \theta, w, v) = 0, \qquad \theta \in (0, \bar{\theta}],\ (w, v) \in D_{\bar{\theta}},$$

if and only if

$$\begin{aligned}
&x - \theta b/2 \geq 0, \qquad y - \theta b/2 \geq 0,\\
&\operatorname{diag}(x - \theta b/2)(y - \theta b/2) = w,\\
&y - \theta b/2 - f(x) - \theta^p \operatorname{diag}(a^p)(x - \theta b/2) - \theta c = v,\\
&\theta \in (0, \bar{\theta}], \qquad (w, v) \in D_{\bar{\theta}}.
\end{aligned}$$

Define $\bar{x} = x - \theta b/2$ and $\bar{y} = y - \theta b/2$. The above system can be rewritten as

$$\mathcal{F}_{(a,b,c,\theta)}(\bar{x}, \bar{y}) \in D_{\bar{\theta}}, \quad (\bar{x}, \bar{y}) \geq 0, \ \theta \in (0, \bar{\theta}],$$

where $\mathcal{F}_{(a,b,c,\theta)}$ is defined by (3.1). Denote

$$\mathcal{F}^{-1}_{(a,b,c,\theta)}(D_{\bar{\theta}}) = \{(u, v) \in R^{2n}_{++} : \mathcal{F}_{(a,b,c,\theta)}(u, v) \in D_{\bar{\theta}}\}.$$

Then from the above discussion, we deduce that

$$\begin{aligned}
&\{x \in R^n : x = \bar{x} + \theta b/2, (\bar{x}, \bar{y}) \in \mathcal{F}^{-1}_{(a,b,c,\theta)}(D_{\bar{\theta}}), \ \theta \in (0, \bar{\theta}]\} \\
&\subseteq \{x \in R^n : x = \bar{x} + \theta b/2, \mathcal{F}_{(a,b,c,\theta)}(\bar{x}, \bar{y}) \in D_{\bar{\theta}}, (\bar{x}, \bar{y}) \geq 0, \ \theta \in (0, \bar{\theta}]\} \\
&= \bigcup_{(\theta,w,v) \in (0,\bar{\theta}] \times D_{\bar{\theta}}} \bar{G}^{-1}_{(\theta,w,v)}(0) \\
&\subseteq G^{-1}(0) + \varepsilon B.
\end{aligned}$$

Since $G^{-1}(0) + \varepsilon B$ is bounded, we deduce from the above that

$$\bigcup_{\theta \in (0,\bar{\theta}]} \mathcal{F}^{-1}_{(a,b,c,\theta)}(D_{\bar{\theta}})$$

is bounded. Hence, Condition 3.2 is satisfied, and thus Condition 3.1 holds.

Since each of the conditions listed in the theorem implies the existence of a strictly feasible point, to show that Condition 3.1 does not imply each of these conditions it suffices to prove that Condition 3.1 may hold even when there is no strictly feasible point. Now consider, in R^2, the following example:

$$f(x) = \begin{pmatrix} 0 & 0 \\ 0 & 2 \end{pmatrix} \begin{pmatrix} x_1 \\ x_2 \end{pmatrix} + \begin{pmatrix} 0 \\ -1 \end{pmatrix} = \begin{pmatrix} 0 \\ 2x_2 - 1 \end{pmatrix},$$

which is a P_0-function. Clearly, f has no strictly feasible point, and the corresponding complementarity problem has an unbounded solution set. However, this example does satisfy Condition 3.1. Indeed, choose $p \in (0, 1]$ and $q \in [1, \infty]$ and let $(a, b, c) \in R^2_{++} \times R^2 \times R^2$ be a fixed vector. We show for each scalar $0 < \theta^* < 1$ that the set $\cup_{\theta \in (0,\theta^*]} \mathcal{F}^{-1}_{(a,b,c,\theta)}(D_\theta)$ is a bounded set, where all symbols are defined as in Condition 3.1. Assume that $\{(x^k, y^k)\}$ is an arbitrary sequence contained in the set. Then $(x^k, y^k) > 0$, and for each (x^k, y^k) there is a scalar $\theta_k \in (0, \theta^*]$ such that $\mathcal{F}_{(a,b,c,\theta_k)}(x^k, y^k) \in D_{\theta_k}$. By the definitions of D_{θ_k} and $\mathcal{F}_{(a,b,c,\theta)}$, there exist two vectors $d^k \in [0, a^q]$ and $\bar{d}^k \in [-\hat{t}e, \hat{t}e]$ such that

$$\begin{aligned}
&X^k y^k = \theta_k d^k \in [0, \theta_k a^q], \\
&y^k - f(x^k + \theta_k b/2) - \theta_k^p \mathrm{diag}(a^p) x^k - \theta_k c = \theta_k \bar{d}^k \in \theta_k [-\hat{t}e, \hat{t}e],
\end{aligned}$$

where $X^k = \mathrm{diag}(x^k)$. For this example, the second equation above can be rewritten as

$$y^k_1 = (\theta_k a_1)^p x^k_1 + \theta_k c_1 + \theta_k \bar{d}^k_1,$$

$$y^k_2 = 2(x^k_2 + \theta_k b_2/2) - 1 + (\theta_k a_2)^p x^k_2 + \theta_k c_2 + \theta_k \bar{d}^k_2.$$

Thus, from $X^k y^k = \theta_k d^k$ we have

$$\theta_k d_1^k = x_1^k y_1^k = (\theta_k a_1)^p (x_1^k)^2 + \theta_k x_1^k c_1 + \theta_k x_1^k \bar{d}_1^k,$$

i.e.,

$$\theta_k^{1-p} d_1^k = a_1^p (x_1^k)^2 + \theta_k^{1-p} (c_1 + \bar{d}_1^k) x_1^k,$$

and

$$\theta_k d_2^k = x_2^k y_2^k = (2 + (\theta_k a_2)^p)(x_2^k)^2 + [\theta_k (b_2 + c_2 + \bar{d}_2^k) - 1] x_2^k.$$

From the above two relations, we conclude that the sequence $\{x^k\}$ is bounded, and by continuity so is $\{y^k\}$. Therefore, the set $\cup_{\theta \in (0,\theta^*]} \mathcal{F}^{-1}_{(a,b,c,\theta)}(D_\theta)$ is bounded, i.e., Condition 3.1 is satisfied. □

4. Existence and boundedness of the trajectory. The purpose of this section is to show the existence and the boundedness of the proposed continuation trajectory for P_0-CPs under Condition 3.1. To begin with, we recall a useful result on the degree of a continuous function. Let Ω be a bounded open set in R^n. The symbols $\bar{\Omega}$ and $\partial\Omega$ denote the closure and boundary of Ω, respectively. Let h be a continuous function from $\bar{\Omega}$ into R^n. For any vector $y \in R^n$ such that $y \notin h(\partial\Omega)$, the degree of h at y with respect to Ω is defined by $\deg(h, \Omega, y)$. The following result can be found in Lloyd [22].

LEMMA 4.1. (i) *If h is injective on R^n, then for any $y \in h(\Omega)$, $|deg(h, \Omega, y)| = 1$.*
(ii) *If $deg(h, \Omega, y) \neq 0$, then the equation $h(x) = y$ has a solution in Ω.*
(iii) *Let g be a continuous function from $\bar{\Omega} \to R^n$. Let*

$$\mathcal{H}(x,t) = tg(x) + (1-t)h(x), \quad 0 \leq t \leq 1.$$

If $y \notin \{\mathcal{H}(x,t) : x \in \partial\Omega, t \in [0,1]\}$, then $deg(g, \Omega, y) = deg(h, \Omega, y)$.

We are ready to prove a general and essential result.

THEOREM 4.1. *Let (a,b,c) be a fixed vector in $R^n_{++} \times R^{2n}$. Let $f : R^n \to R^n$ be a continuous semimonotone function.*
(i) *For each $\theta \in (0,1]$, the system (2.3) has a solution.*
(ii) *If Condition 3.1 holds, then the set*

$$\{(u,x,y) \in \mathcal{T}_\theta : \ \theta \in (0,1]\} := \bigcup_{\theta \in (0,1]} \mathcal{T}_\theta \tag{4.1}$$

is bounded, where

$$\mathcal{T}_\theta := \{(u,x,y) : \ H(u,x,y) = \theta(a,b,c)\}.$$

Proof. Let f be a continuous semimonotone function. We show the result by contradiction. Assume that there is a scalar $\hat{\theta} \in (0,1]$ such that system (2.3) has no solution.

Let $\mathcal{H} : R^n \times [0,1] \to R^n$ be defined by

$$\mathcal{H}(x,t) = t(x - \hat{\theta}b/2) + (1-t)\mathcal{Y}(x,\hat{\theta}), \quad t \in [0,1],$$

where $\mathcal{Y}$ is given by (2.4). We first show that the set

$$\mathcal{S} = \{x \in R^n : \mathcal{H}(x,t) = 0 \ \text{ for some } t \in [0,1]\}$$

is unbounded. Indeed, assume the contrary: $\mathcal{S}$ is bounded. Then for any fixed $\varepsilon > 0$, the set $D := (\{\hat{\theta}b/2\} \cup \mathcal{S}) + \varepsilon B$ is a bounded open set in R^n, where B is the open unit ball in R^n. Clearly, the intersection of $\mathcal{S}$ and the boundary of D is empty, i.e., for all $x \in \partial D, \mathcal{H}(x,t) \neq 0$ for all $t \in [0,1]$. Therefore,

$$|\deg(\mathcal{Y}(\cdot,\hat{\theta}), D, 0)| = |\deg(g, D, 0)| = 1,$$

where $g(x) := x - \hat{\theta}b/2$. The first part of the equation above follows from (iii) of Lemma 4.1, and the second part of the equation follows from (i) of Lemma 4.1 since g is an injective mapping. Thus, it follows from (ii) of Lemma 4.1 that the equation $\mathcal{Y}(x,\hat{\theta}) = 0$ has a solution (in D). Thus, by Lemma 2.1, $H(u,x,y) = \hat{\theta}(a,b,c)$ has a solution. This contradicts our assumption at the beginning of the proof. Therefore, the set $\mathcal{S}$ is unbounded.

Since $\mathcal{S}$ is unbounded, there is a sequence $\{x^k\}$ contained in $\mathcal{S}$ such that $\|x^k\| \to \infty$. We now show that $\{x^k\}$ satisfies the relations

$$x^k - \hat{\theta}b/2 > 0$$

and

$$f(x^k) \leq -\hat{\theta}^p \mathrm{diag}\,(a^p)\, x^k + 2\hat{\theta}^q [\mathrm{diag}(x^k - \hat{\theta}b/2)]^{-1} a^q + \hat{\theta}(b/2 - c)$$

for all sufficiently large k. Indeed, since $\|x^k\| \to \infty$, there is a $k_0 > 0$ such that $\|x^k - \hat{\theta}b/2\| > 0$ for all $k > k_0$. Since $x^k \in \mathcal{S}$, by the definition of $\mathcal{S}$ there is a scalar $t^k \in [0,1]$ such that

$$\mathcal{H}(x^k, t^k) = t^k(x^k - \hat{\theta}b/2) + (1 - t^k)\mathcal{Y}(x^k, \hat{\theta}) = 0.$$

Since $x^k \neq \hat{\theta}b/2$ for all $k > k_0$, we deduce from the above that $t^k \neq 1$ for all $k > k_0$. Since system (2.3) has no solution (by the assumption), i.e., $\mathcal{Y}(x,\hat{\theta}) \neq 0$ for all $x \in R^n$ (Lemma 2.1), it follows from the above equation that $t^k \neq 0$. Therefore, we have that $t^k \in (0,1)$ for all $k > k_0$. The above equation can be written as

$$\begin{aligned} &t^k(x^k - \hat{\theta}b/2) + (1 - t^k)[(x^k - \hat{\theta}b/2) + (y^k - \hat{\theta}b/2)] \\ &- (1 - t^k)\sqrt{[(x^k - \hat{\theta}b/2) - (y^k - \hat{\theta}b/2)]^2 + 4\hat{\theta}^q a^q} = 0, \end{aligned}$$

where

$$y^k = f(x^k) + \hat{\theta}^p \mathrm{diag}\,(a^p)\, x^k + \hat{\theta}c.$$

Define

$$\hat{x}^k = x^k - \hat{\theta}b/2, \qquad \hat{y}^k = y^k - \hat{\theta}b/2.$$

The above equation can be further written as

$$\hat{x}^k + (1 - t^k)\hat{y}^k = (1 - t^k)\sqrt{(\hat{x}^k - \hat{y}^k)^2 + 4\hat{\theta}^q a^q}. \tag{4.2}$$

Squaring both sides of this equation and simplifying (all the algebraic operations are performed componentwise), we obtain

$$t^k(2 - t^k)(\hat{x}^k)^2 + 2(1 - t^k)(2 - t^k)\hat{X}^k\hat{y}^k = 4(1 - t^k)^2\hat{\theta}^q a^q,$$

where $\hat{X}^k = \mathrm{diag}(\hat{x}^k)$. It follows from the above that $\hat{x}_i^k \neq 0$ for all $i = 1, 2, \ldots, n$. Multiplying both sides of the above by $(\hat{X}^k)^{-1}$ and dividing both sides by $2(1-t^k)(2-t^k)$ yield

$$\hat{y}^k = -\frac{t^k}{2(1-t^k)}\hat{x}^k + \frac{2(1-t^k)\hat{\theta}^q}{2-t^k}(\hat{X}^k)^{-1}a^q.$$

Thus, we have

$$\hat{x}^k + (1-t^k)\hat{y}^k = \left(1 - \frac{t^k}{2}\right)\hat{x}^k + \frac{2(1-t^k)^2\hat{\theta}^q}{2-t^k}(\hat{X}^k)^{-1}a^q.$$

If $\hat{x}_i^k \leq 0$ for some i, then we have from the above that $\hat{x}_i^k + (1-t^k)\hat{y}_i^k \leq 0$, which contradicts the right-hand side of (4.2). Thus, $\{\hat{x}^k\} \subseteq R^n_{++}$ and

$$\hat{y}^k \leq \frac{2(1-t^k)\hat{\theta}^q}{2-t^k}(\hat{X}^k)^{-1}a^q \leq 2\hat{\theta}^q(\hat{X}^k)^{-1}a^q.$$

That is, $x^k - \hat{\theta}b/2 > 0$ and

$$f(x^k) \leq -\hat{\theta}^p \mathrm{diag}\,(a^p)\,x^k + 2\hat{\theta}^q\left[\mathrm{diag}\left(x^k - \hat{\theta}b/2\right)\right]^{-1}a^q + \hat{\theta}(b/2 - c) \tag{4.3}$$

for all $k > k_0$. Passing through a subsequence, we may suppose that there is an index set I such that $x_i^k \to \infty$ for all $i \in I$ and $\{x_i^k\}$ is bounded for $i \notin I$. It follows from (4.3) that $f_i(x^k) \to -\infty$ for all $i \in I$. This contradicts the consequence of Lemma 3.1, which states that there exists an index $i \in I$ such that $f_i(x^k)$ is bounded from below. Hence, item (i) of the theorem is shown.

We now prove item (ii) of the theorem, i.e., the boundedness of set (4.1). Assume the contrary: the set $\{(u, x, y) \in \mathcal{T}_\theta : \theta \in (0, 1]\}$ is unbounded, i.e., there exists an unbounded sequence $\{(u(\theta_k), x(\theta_k), y(\theta_k))\}$ contained in the set, where $0 < \theta_k \leq 1$. Thus, the sequence $\{x(\theta_k)\}$ is unbounded (Remark 2.1). Without loss of generality, we assume that $\|x(\theta_k)\| \to \infty$ as $k \to \infty$. Note that $\{(u(\theta_k), x(\theta_k), y(\theta_k))\}$ satisfies the system (2.8)–(2.11), where θ is replaced by θ_k. By the unboundedness of $\{x(\theta_k)\}$ and $x(\theta_k) \geq \hat{\theta}b/2$, it follows from Lemma 3.1 that there exist a subsequence of $\{x(\theta_k)\}$ denoted also by $\{x(\theta_k)\}$ and an index m such that $x_m(\theta_k) \to \infty$ and $f_m(x(\theta_k))$ is bounded from below. From (2.11) we have

$$y_m(\theta_k) - \theta_k b_m/2 = \frac{\theta_k^q a_m^q}{x_m(\theta_k) - \theta_k b_m/2},$$

and by using (2.9) we obtain

$$f_m(x(\theta_k)) = \theta_k b_m/2 + \frac{\theta_k^q a_m^q}{x_m(\theta_k) - \theta_k b_m/2} - \theta_k c_m - (\theta_k a_m)^p x_m(\theta_k).$$

Since $x_m(\theta_k) \to \infty$ and $f_m(x(\theta_k))$ is bounded from below, we deduce from the above that $\theta_k^p \to 0$, and thus $\theta_k \to 0$. Define

$$\hat{x}(\theta_k) = x(\theta_k) - \theta_k b/2, \qquad \hat{y}(\theta_k) = y(\theta_k) - \theta_k b/2.$$

By (2.10) and (2.11), we have

$$(\hat{x}(\theta_k), \hat{y}(\theta_k)) > 0, \qquad \hat{X}(\theta_k)\hat{x}(\theta_k) = \theta_k^q a^q.$$

By using (2.9) again, we have

$$\begin{aligned}
&\hat{y}(\theta_k) - f(\hat{x}(\theta_k) + \theta_k b/2) - \theta_k^p \mathrm{diag}\,(a^p)\,\hat{x}(\theta_k) - \theta_k c \\
&= y(\theta_k) - \theta_k b/2 - f(x(\theta_k)) - \theta_k^p \mathrm{diag}\,(a^p)\,x(\theta_k) + \theta_k^p \mathrm{diag}\,(a^p)\,(\theta_k b/2) - \theta_k c \\
&= -\theta_k b/2 + \theta_k^p \mathrm{diag}\,(a^p)\,(\theta_k b/2) \\
&= \theta_k[-b/2 + \theta_k^p \mathrm{diag}\,(a^p)\,b/2].
\end{aligned}$$

Let $\hat{t} = \| - b/2\|_\infty + \|\mathrm{diag}(a^p)b/2\|_\infty$. Then, for any $\theta^k \in (0,1]$, we have $-\hat{t}e \le -b/2 + \theta_k^p \mathrm{diag}(a^p)b/2 \le \hat{t}e$. Therefore,

$$\theta_k^q a^q = \theta_k(\theta_k^{q-1} a^q) \in [0, \theta_k a^q],$$

$$\theta_k(-b/2 + \theta_k^p \mathrm{diag}\,(a^p)\,b/2) \in \theta_k[-\hat{t}e, \hat{t}e].$$

Therefore,

$$\begin{aligned}
\mathcal{F}_{(a,b,c,\theta_k)}(\hat{x}(\theta_k), \hat{y}(\theta_k)) &= \begin{pmatrix} \hat{X}(\theta_k)\hat{y}(\theta_k) \\ \hat{y}(\theta_k) - f(\hat{x}(\theta_k) + \theta_k b/2) - \theta_k^p \mathrm{diag}\,(a^p)\,\hat{x}(\theta_k) - \theta_k c \end{pmatrix} \\
&\in [0, \theta_k a^q] \times \theta_k[-\hat{t}e, \hat{t}e] =: D_{\theta_k}
\end{aligned}$$

for all $\theta_k \in (0,1]$. That is, $(\hat{x}(\theta_k), \hat{y}(\theta_k)) \in \mathcal{F}^{-1}_{(a,b,c,\theta_k)}(D_{\theta_k})$ for all $\theta_k \in (0,1]$. Hence, for any $1 \ge \theta^* > 0$, the sequence

$$\{(\hat{x}(\theta_k), \hat{y}(\theta_k)) : \theta_k \in (0, \theta^*]\} \subseteq \bigcup_{\theta_k \in (0,\theta^*]} \mathcal{F}^{-1}_{(a,b,c,\theta_k)}(D_{\theta_k}) \subseteq \bigcup_{\theta \in (0,\theta^*]} \mathcal{F}^{-1}_{(a,b,c,\theta)}(D_\theta).$$

By Condition 3.1, there exists a $\theta^* \in (0,1]$ such that the right-hand side of the above is bounded. However, the left-hand side is an unbounded sequence. This contradiction shows that the set (4.1) is indeed bounded. The proof is thus complete. □

Since Condition 3.2 implies Condition 3.1, the following result is an immediate consequence of Theorem 4.1.

COROLLARY 4.1. *Let $f : R^n \to R^n$ be a continuous semimonotone function. If Condition* 3.2 *holds, then the set* (4.1) *is bounded.*

While system (2.3) has a solution for a continuous semimonotone function if Condition 3.1 holds, it is not clear whether the solution of system (2.3) is unique for each $\theta \in (0,1]$. However, for continuous P_0-functions, which are special cases of continuous semimonotone functions, it is easy to prove that for each $\theta \in (0,1]$ system (2.3) has a unique solution which is also continuous in θ. We summarize the result as follows.

THEOREM 4.2. *Let $f : R^n \to R^n$ be a continuous P_0-function.*

(i) *For each $\theta \in (0,1]$, system* (2.3) *has a unique solution $(u(\theta), x(\theta), y(\theta))$ which is continuous in θ.*

(ii) *If Condition* 3.1 *(in particular, Condition* 3.2*) is satisfied, then the entire trajectory $\{(u(\theta), x(\theta), y(\theta)) : \theta \in (0,1]\}$ is bounded. Hence there exists at least a convergence subsequence $(u(\theta_k), x(\theta_k), y(\theta_k))$ converging, as $\theta_k \to 0$, to $(0, x^*, y^*)$, where x^* is a solution to the CP.*

(iii) *If f is continuously differentiable, then $(u(\theta), x(\theta), y(\theta))$ is also continuously differentiable in θ. In this case, the set $\{(u(\theta), x(\theta), y(\theta)) : \theta \in (0,1]\}$ forms a smooth trajectory.*

Proof. Since each P_0-function is a semimonotone function, by Theorem 4.1, system (2.3) has at least one solution. It is sufficient to show that the system has at most one solution. Let

$$g(x,a,c,\theta) = f(x) + \theta^p \mathrm{diag}\,(a^p)\,x + \theta c.$$

Since f is a P_0-function and $a \in R^n_{++}$, the function $g(x,a,c,\theta)$ is a P-function in x. Thus, by Lemma 3.3, the map

$$\mathcal{Y}(x,\theta) = x + g(x,a,c,\theta) - \sqrt{(x - g(x,a,c,\theta))^2 + 4\theta^q a^q} - \theta b$$

is a P-function in x. Since every P-function is univalent (one-to-one), the equation $\mathcal{Y}(x,\theta) = 0$ has at most one solution. Hence system (2.3) has at most one solution, by Lemma 2.1.

The continuity of $(u(\theta), x(\theta), y(\theta))$ follows easily from Lemma 3.4. Indeed, given $\hat{\theta} \in (0,1)$, in order to show the continuity of $(u(\theta), x(\theta), y(\theta))$ at $\hat{\theta}$ it is sufficient to prove the continuity of $x(\theta)$ at $\hat{\theta}$. Since $\mathcal{Y}(x,\theta)$ is a P-function in x, $x(\hat{\theta})$ is the unique element in $\mathcal{Y}^{-1}_{\hat{\theta}}(0) = \{x : \mathcal{Y}(x,\hat{\theta}) = 0\}$. By Lemma 3.4, for any $\varepsilon > 0$ there exists a scalar $\delta > 0$ such that for any P_0-function h satisfying

$$\sup_{x \in \bar{\Omega}} \|h(x) - \mathcal{Y}(x,\hat{\theta})\| < \delta, \tag{4.4}$$

where $\Omega = \mathcal{Y}^{-1}_{\hat{\theta}}(0) + \varepsilon B$, we have

$$\emptyset \neq h^{-1}(0) \subseteq \mathcal{Y}^{-1}_{\hat{\theta}}(0) + \varepsilon B = x(\hat{\theta}) + \varepsilon B. \tag{4.5}$$

For this given δ, it follows from (ii) of Lemma 3.2 that there is a scalar $\beta > 0$ such that

$$\sup_{x \in \bar{\Omega}} \|\mathcal{Y}(x,\theta) - \mathcal{Y}(x,\hat{\theta})\| < \delta$$

for all $\theta > 0$ such that $|\theta - \hat{\theta}| < \beta$. Setting $h(x) := \mathcal{Y}(x,\theta)$ in (4.4), we deduce from (4.5) that $\mathcal{Y}^{-1}_{\theta}(0) = \{x : \mathcal{Y}(x,\theta) = 0\} \subseteq x(\hat{\theta}) + \varepsilon B$ for all θ with $|\theta - \hat{\theta}| < \beta$. By the P-property of $\mathcal{Y}$, $x(\theta)$ is a unique element in $\mathcal{Y}^{-1}_{\theta}(0)$. Thus, $\|x(\theta) - x(\hat{\theta})\| < \varepsilon$ for all $\theta > 0$ such that $|\theta - \hat{\theta}| < \beta$, i.e., $x(\theta)$ is continuous at $\hat{\theta}$. Item (i) of the theorem follows.

Item (ii) follows immediately from Theorem 4.1, since P_0-functions are semimonotone. We now prove Item (iii). Consider the following $3n \times 3n$ matrix

$$A := \begin{pmatrix} I & 0 & 0 \\ -2qU^{q-1}D & I - (X-Y)D & I + (X-Y)D \\ pU^{p-1}X & -(f'(x) + \mathrm{diag}(u^p)) & I \end{pmatrix},$$

where $U = \mathrm{diag}(u), X = \mathrm{diag}(x), Y = \mathrm{diag}(y)$, and $D = \mathrm{diag}(d)$ with $d = (d_1, \ldots, d_n)^T$, where

$$d_i = 1/\sqrt{(x_i - y_i)^2 + 4u_i^q}, \quad i = 1, 2, \ldots, n.$$

If $u \in R^n_{++}$, then it is easy to see that $I - (X-Y)D$ and $I + (X-Y)D$ are positive diagonal matrices for every $(x,y) \in R^{2n}$. Thus, by Lemma 5.4 in Kojima, Megiddo, and Noma [19], the matrix

$$\begin{pmatrix} I - (X-Y)D & I + (X-Y)D \\ -(f'(x) + \mathrm{diag}(u^p)) & I \end{pmatrix}$$

is nonsingular when f is a P_0-function. Hence A is a nonsingular matrix for every $(u, x, y) \in R^n_{++} \times R^{2n}$. Since the matrix A coincides with the Jacobian matrix (with respect to (u, x, y)) of the equation

$$H(u, x, y) - \theta(a, b, c) = 0,$$

by the implicit function theorem, there is a unique smooth (i.e., continuously differentiable) curve $(u(t), x(t), y(t))$ such that

$$H(u(t), x(t), y(t)) = t(a, b, c)$$

for all t sufficiently close to θ, and

$$(u(t), x(t), y(t))|_{t=\theta} = (u(\theta), x(\theta), y(\theta)).$$

In particular, $(u(\cdot), x(\cdot), y(\cdot))$ is continuously differentiable at θ. □

Furthermore, if f is a P_*-function we can obtain a much stronger result. We now consider this important situation and show that for a P_*-function the proposed trajectory exists and is bounded, provided that the solution set of the CP is nonempty. For simplicity, we consider the case of $(a, b, c) \in R^n_{++} \times R^n_- \times R^n$, i.e., the vector b is confined to R^n_-. We also consider the case of $c \in R^n_{++}$ when it is necessary. The stipulation that $b \in R^n_-$ has also been used in some non–interior-point algorithms; see Burke and Xu [3] and Hotta, Inabar, and Yoshise [17], where the iterate $\{(x^k, y^k)\}$ is required to satisfy

$$x^k + y^k - \sqrt{(x^k - y^k)^2 + 4\mu^k} \le 0,$$

which is equivalent to the requirement of "$b \in R^n_-$."

LEMMA 4.2. *Let v^* be an arbitrary solution of the CP, and $(a, b, c) \in R^n_{++} \times R^n_- \times R^n$ be a fixed vector. Let $(u(\theta), x(\theta), y(\theta))$ satisfy the system (2.8)–(2.11) for each $\theta \in (0, 1]$. Then the following inequality holds:*

$$(x_i(\theta) - v_i^*)(f_i(x(\theta)) - f_i(v^*)) \le \theta^q e^T a^q - \theta b^T f(v^*)/2 - \theta^p \min_{1 \le i \le n} M_i,$$

where

$$M_i = a_i^p x_i(\theta)(x_i(\theta) - v_i^*) + \theta^{1-p}(c_i - b_i/2)(x_i(\theta) - v_i^*).$$

Proof. Define $\bar{y}_i(\theta) = y_i(\theta) - \theta b_i/2$ and $\bar{x}_i(\theta) = x_i(\theta) - \theta b_i/2$. Let v^* be an arbitrary solution to the CP. By (2.11) and noting that $(\bar{x}(\theta), \bar{y}(\theta)) > 0$, we have for each i,

$$\begin{aligned}(\bar{y}_i(\theta) - f_i(v^*))(\bar{x}_i(\theta) - v_i^*) &= \bar{y}_i(\theta)\bar{x}_i(\theta) - f_i(v^*)\bar{x}_i(\theta) - \bar{y}_i(\theta)v_i^* \\ &\le \bar{y}_i(\theta)\bar{x}_i(\theta) = \theta^q a_i^q. \end{aligned} \tag{4.6}$$

We also note that

$$\begin{aligned}&(x_i(\theta) - v_i^*)(f_i(x(\theta)) - f_i(v^*)) \\ &= (x_i(\theta) - v_i^*)(y_i(\theta) - (\theta a_i)^p x_i(\theta) - \theta c_i - f_i(v^*)) \\ &= (\bar{x}_i(\theta) - v_i^* + \theta b_i/2)(\bar{y}_i(\theta) + \theta b_i/2 - (\theta a_i)^p x_i(\theta) - \theta c_i - f_i(v^*)) \\ &= (\bar{x}_i(\theta) - v_i^*)(\bar{y}_i(\theta) - f_i(v^*)) + (\bar{x}_i(\theta) - v_i^*)(\theta b_i/2 - (\theta a_i)^p x_i(\theta) - \theta c_i) \\ &\quad + (\theta b_i/2)(\bar{y}_i(\theta) + \theta b_i/2 - (\theta a_i)^p x_i(\theta) - \theta c_i - f_i(v^*)).\end{aligned}$$

Thus, by (4.6) and noting that $b \le 0$ and $\bar{y}(\theta) > 0$, we have the following for all i:

$$\begin{aligned}
&(x_i(\theta) - v_i^*)(f_i(x(\theta) - f_i(v^*)) \\
&\le \theta^q a_i^q + (x_i(\theta) - v_i^* - \theta b_i/2)(\theta b_i/2 - (\theta a_i)^p x_i(\theta) - \theta c_i) \\
&\quad + (\theta b_i/2)(\theta b_i/2 - (\theta a_i)^p x_i(\theta) - \theta c_i - f_i(v^*)) \\
&= \theta^q a_i^q - (\theta a_i)^p x_i(\theta)(x_i(\theta) - v_i^*) \\
&\quad + (\theta b_i/2 - \theta c_i)(x_i(\theta) - v_i^*) - \theta b_i f_i(v^*)/2 \\
&\le \theta^q e^T a^q - \theta b^T f(v^*)/2 \\
&\quad - \theta^p \min_{1\le i\le n} [a_i^p x_i(\theta)(x_i(\theta) - v_i^*) + \theta^{1-p}(c_i - b_i/2)(x_i(\theta) - v_i^*)].
\end{aligned}$$

The last inequality follows from the fact that $a_i^q \le e^T a^q$ and $-b_i f_i(v^*) \le -b^T f(v^*)$ since $b \le 0$ and $f(v^*) \ge 0$. The proof is thus complete. □

We are ready to prove the following result.

THEOREM 4.3. *Let f be a continuous P_*-function and $(a, b, c) \in R^n_{++} \times R^n_- \times R^n$ be a fixed vector. Assume that the solution set of the CP is nonempty.*

(i) *If $p \le 1$ and $q \in [1, \infty)$, then the trajectory $\{(u(\theta), x(\theta), y(\theta)) : \theta \in (0, 1]\}$ generated by* (2.3) *is bounded.*

(ii) *If $p > 1$, $q \in [1, \infty)$, and $c \in R^n_{++}$, then the trajectory $\{(u(\theta), x(\theta), y(\theta)) : \theta \in (0, 1]\}$ generated by* (2.3) *is bounded.*

Proof. We still use the notation

$$(\bar{x}(\theta), \bar{y}(\theta)) = (x(\theta) - \theta b/2,\ y(\theta) - \theta b/2).$$

By (2.11), and noting that $b \le 0$ and $(\bar{x}(\theta), \bar{y}(\theta)) > 0$, we have

$$\begin{aligned}
x(\theta)^T y(\theta) &= (\bar{x}(\theta) + \theta b/2)^T (\bar{y}(\theta) + \theta b/2) \\
&\le \theta^q e^T a^q + \theta^2 \|b\|^2/4. \qquad (4.7)
\end{aligned}$$

Let v^* be an arbitrary solution of the CP. By the P_*-property of f and by Lemma 4.2 we have

$$\begin{aligned}
&(v^*)^T y(\theta) + f(v^*)^T x(\theta) \\
&= -(x(\theta) - v^*)^T (y(\theta) - f(v^*)) + x(\theta)^T y(\theta) \\
&= -(x(\theta) - v^*)^T (f(x(\theta)) + \theta^p \mathrm{diag}(a^p) x(\theta) + \theta c - f(v^*)) + x(\theta)^T y(\theta) \\
&= -(x(\theta) - v^*)^T (f(x(\theta)) - f(v^*)) - \theta^p [\mathrm{diag}(a^p) x(\theta)]^T (x(\theta) - v^*) \\
&\quad - \theta c^T (x(\theta) - v^*) + x(\theta)^T y(\theta) \\
&\le \tau \sum_{i \in I_+} (x_i(\theta) - v_i^*)^T (f_i(x(\theta)) - f_i(v^*)) \\
&\quad - \theta^p [\mathrm{diag}(a^p) x(\theta)]^T (x(\theta) - v^*) - \theta c^T (x(\theta) - v^*) + x(\theta)^T y(\theta) \\
&\le \tau n \max_{1\le i\le n} (x_i(\theta) - v_i^*)^T (f_i(x(\theta)) - f_i(v^*)) \\
&\quad - \theta^p [\ \mathrm{diag}(a^p) x(\theta)]^T (x(\theta) - v^*) - \theta c^T (x(\theta) - v^*) + x(\theta)^T y(\theta) \\
&\le \tau n \left(\theta^q e^T a^q - \theta b^T f(v^*)/2 - \theta^p \min_{1\le i\le n} M_i \right) \\
&\quad - \theta^p [\mathrm{diag}(a^p) x(\theta)]^T (x(\theta) - v^*) - \theta c^T (x(\theta) - v^*) + x(\theta)^T y(\theta).
\end{aligned}$$

The last inequality follows from Lemma 4.2, and M_i is given as in Lemma 4.2. By (4.7) and the above inequality, we have

$$\begin{aligned}
&(v^*)^T\bar{y}(\theta) + f(v^*)^T\bar{x}(\theta)\\
&= (v^*)^T y(\theta) + f(v^*)^T x(\theta) - \theta b^T(v^* + f(v^*))/2\\
&\le \theta^q(1+\tau n)e^T a^q + \theta^2\|b\|^2/4 - \theta\tau n b^T f(v^*)/2 - \theta^p\tau n \min_{1\le i\le n} M_i\\
&\quad -\theta^p[\ \mathrm{diag}\ (a^p)x(\theta)]^T(x(\theta)-v^*) - \theta c^T(x(\theta)-v^*) - \theta b^T(v^*+f(v^*))/2. \qquad (4.8)
\end{aligned}$$

(i) We now consider the case of $p \le 1$. Notice that the left-hand side is nonnegative. Dividing both sides of the above inequality by θ^p and rearranging terms, we have

$$\begin{aligned}
&[\mathrm{diag}(a^p)x(\theta)]^T(x(\theta)-v^*) + \theta^{1-p}c^T(x(\theta)-v^*) + \tau n \min_{1\le i\le n} M_i\\
&\le \theta^{q-p}(1+\tau n)e^T a^q + \theta^{2-p}\|b\|^2/4 - \theta^{1-p}\tau n b^T f(v^*)/2\\
&\quad -\theta^{1-p}b^T(v^*+f(v^*))/2. \qquad (4.9)
\end{aligned}$$

Since $a^p \in R^n_{++}$, $p \le 1$, and $q \in [1,\infty)$, we conclude from the above inequality that the set $\{x(\theta) : \theta \in (0,1]\}$ is bounded, and by continuity the set $\{y(\theta) : \theta \in (0,1]\}$ is also bounded. Item (i) of the theorem is proved.

(ii) If $p > 1$ and $c \in R^n_{++}$, then, since $(\bar{x}(\theta), \bar{y}(\theta)) > 0$ and $b \le 0$, we have

$$\begin{aligned}
M_i &\ge -a_i^p v_i^* x_i(\theta) + \theta^{1-p}(c_i - b_i/2)(\bar{x}_i(\theta) + \theta b_i/2 - v_i^*)\\
&\ge -a_i^p v_i^* \bar{x}_i(\theta) + \theta^{1-p}(c_i - b_i/2)(\theta b_i/2 - v_i^*)\\
&\ge -[\mathrm{diag}(a^p)\bar{x}(\theta)]^T v^* + \theta^{1-p}\min_{1\le i\le n}(c_i - b_i/2)(\theta b_i/2 - v_i^*). \qquad (4.10)
\end{aligned}$$

Since the left-hand side of (4.8) is nonnegative, by (4.10) and (4.8), we have

$$\begin{aligned}
0 &\le \theta^q(1+\tau n)e^T a^q + \theta^2\|b\|^2/4 - \theta\tau n b^T f(v^*)/2\\
&\quad + \theta^p\tau n[\mathrm{diag}(a^p)\bar{x}(\theta)]^T v^* - \theta\tau n \min_{1\le i\le n}(c_i - b_i/2)(\theta b_i/2 - v_i^*)\\
&\quad + \theta^p[\mathrm{diag}(a^p)x(\theta)]^T v^* - \theta c^T x(\theta) + \theta c^T v^* - \theta b^T(v^* + f(v^*))/2\\
&\le \theta^q(1+\tau n)e^T a^q + \theta^2\|b\|^2/4 - \theta\tau n b^T f(v^*)/2\\
&\quad + \theta^p(1+\tau n)[\mathrm{diag}(a^p)\bar{x}(\theta)]^T v^* - \theta\tau n \min_{1\le i\le n}(c_i - b_i/2)(\theta b_i/2 - v_i^*)\\
&\quad + \theta^p[\mathrm{diag}(a^p)v^*]^T b/2 - \theta c^T\bar{x}(\theta) - \theta c^T b/2 + \theta c^T v^* - \theta b^T(v^* + f(v^*))/2.
\end{aligned}$$

Dividing both sides of the above by θ and rearranging terms, we have

$$\begin{aligned}
&\left(c - \theta^{p-1}(1+\tau n)\mathrm{diag}(a^p)v^*\right)^T\bar{x}(\theta)\\
&\le \theta^{q-1}(1+\tau n)e^T a^q + \theta\|b\|^2/4 - \tau n b^T f(v^*)/2\\
&\quad - \tau n \min_{1\le i\le n}(c_i - b_i/2)(\theta b_i/2 - v_i^*)\\
&\quad + \theta^{p-1}[\mathrm{diag}\ (a^p)v^*]^T b/2 - c^T b/2 + c^T v^* - b^T(v^* + f(v^*))/2.
\end{aligned}$$

Since $p > 1$ and $c \in R^n_{++}$, there must exist a $\delta \in (0,1)$ such that for all $\theta \in (0,\delta]$ we have that $c - \theta^{p-1}(1+\tau n)\mathrm{diag}(a^p)v^* \ge c/2 > 0$. Thus we can see from the above inequality that the set $\{\bar{x}(\theta) : \theta \in (0,\delta]\}$ is bounded. Thus, the set $\{x(\theta) : \theta \in (0,\delta]\}$

is bounded. The boundedness of the set $\{x(\theta) : \theta \in [\delta, 1]\}$ can be obtained by (4.8) again. Indeed, if a subsequence in $\{x(\theta) : \theta \in [\delta, 1]\}$ is unbounded, then there exists a subsequence denoted by $\{x(\theta_k)\}$ such that $\|x(\theta_k)\| \to \infty$ as $k \to \infty$, where $\theta_k \in [\delta, 1]$. Applying (4.8) to this sequence, the left-hand side of it is nonnegative. The right-hand side of the inequality (4.8), however, tends to $-\infty$. This is a contradiction. Therefore, we conclude that the entire set $\{x(\theta) : \theta \in (0, 1]\}$ is bounded. So is $\{y(\theta) : \theta \in (0, 1]\}$, by continuity. □

Remark 4.1. The above result shows that the nonemptiness of the solution set implies the boundedness of the entire trajectory $\{(x(\theta), y(\theta)) : \theta \in (0, 1]\}$. Notice that the boundedness of this trajectory in turn implies the nonemptiness of the solution set. Therefore, we may conclude that the boundedness of this trajectory is equivalent to the solvability of the problem.

5. Limiting behavior of the trajectory. We have shown that Condition 3.1 (and hence most of the known conditions used in interior-point and non–interior-point methods) can guarantee the boundedness of the proposed continuation trajectory. Thus, there exists at least one convergent subsequence $\{(u(\theta_k), x(\theta_k), y(\theta_k))\}$ whose limiting point is a solution to the CP. Two natural questions arise: (i) When is the entire trajectory convergent? (ii) What can be said about the limiting point of it? This section is devoted to these questions. For $0 < p < 1$ and $(a, b, c) \in R^n_{++} \times R^n_{-} \times R^n$, or $0 < p \leq q$ and $(a, b, c) \in R^n_{++} \times \{0\} \times \{0\}$, we show (in Theorem 5.1) that if f is a P_*-function and the CP has a least element solution, then the entire trajectory $\{(u(\theta), x(\theta), y(\theta))\}$ generated by (2.3) converges, as $\theta \to 0$, to the unique least element solution, and that if f is monotone, then the entire trajectory is convergent as $\theta \to 0$, and the limiting point is the N-norm least solution, where $N = \mathrm{diag}(a^p)$. For $p > q$ and $(a, b, c) \in R^n_{++} \times \{0\} \times \{0\}$, we show, among other things, that any limiting point of the sequence $\{(u(\theta_k), x(\theta_k), y(\theta_k))\}$ as $\theta \to 0$ is a maximal complementarity solution (see Theorem 5.2).

To begin, we review some concepts that will be used in this section. An element x^* of the set S is said to be the N-norm least element, where N is a positive definite matrix, if $\|N^{1/2}x^*\| \leq \|N^{1/2}u\|$ for all $u \in S$. In particular, if $N = I$, the solution x^* is called the least 2-norm element of S. An element x^* of the set S is said to be a least element of S if $x^* \leq u$ for all $u \in S$ (Pang [24]). An element x^* of the set S is said to be a weak Pareto minimal element if there is no element u in S such that $u < x^*$ (Sznajder and Gowda [29]). It is evident that the (unique) least element is a weak Pareto minimal element, but the converse is not true. If the solution set $\mathrm{SOL}_{cp}(f)$ is convex, it is known that there exists a unique partition of the index set $\{1, \ldots, n\}$ denoted by I, J, and O such that $\{1, \ldots, n\} = I \cup J \cup O$, and the intersection of each pair of them is empty. In fact,

$$I = \{i : x^*_i > 0 \ \text{ for some } x^* \in \mathrm{SOL}_{cp}(f)\},$$

$$J = \{j : f_j(x^*) > 0 \ \text{ for some } x^* \in \mathrm{SOL}_{cp}(f)\},$$

$$O = \{k : x^*_k = f_k(x^*) = 0 \ \text{ for all } x^* \in \mathrm{SOL}_{cp}(f)\}.$$

Since the solution set is convex, there must exist a solution x^* satisfying $x^*_i > 0$ for all $i \in I$, $f_i(x^*) > 0$ for all $i \in J$, and $x^*_i = f_i(x^*) = 0$ for all $i \in O$. Such a solution is called a maximal complementarity solution. When $O = \emptyset$, i.e., $x^* + f(x^*) > 0$, x^* is called a strict complementarity solution. We now prove the following result.

THEOREM 5.1. *Assume that the solution set $SOL_{cp}(f)$ is nonempty. Let p, q, and (a, b, c) satisfy one of the following conditions:*

(C1) $0 < p < 1$, $q \in [1, \infty)$, *and* $(a, b, c) \in R^n_{++} \times R^n_- \times R^n$.
(C2) $0 < p < q$, $q \in [1, \infty)$, *and* $(a, b, c) \in R^n_{++} \times \{0\} \times \{0\}$.

Then the following results hold:

(i) *If f is a continuous P_*-function and the least element solution of the CP exists, then the entire trajectory $\{x(\theta) : \theta \in (0, 1]\}$ generated by (2.3) converges, as $\theta \to 0$, to the unique least element solution.*

(ii) *If f is a continuous monotone mapping, then the entire continuation trajectory $\{x(\theta) : \theta \in (0, 1]\}$ generated by system (2.3) converges, as $\theta \to 0$, to a solution of the CP. This solution, denoted by x^*, is an N-norm least solution, i.e.,*

$$\|N^{1/2}x^*\| \le \|N^{1/2}v^*\| \quad \text{for all } v^* \in SOL_{cp}(f),$$

where $N = \mathrm{diag}(a^p)$. In particular, if $a = \alpha e$, where $\alpha > 0$ is a positive scalar, then this solution is the (unique) least two-norm solution.

Proof. We show first that the result holds under condition (C1). Let v^* be an arbitrary solution of the CP. Then (4.9) holds. By (i) of Theorem 4.3 the entire continuation trajectory $\{(u(\theta), x(\theta), y(\theta))\}$ is bounded, provided that the solution set of the CP is nonempty. Let x^* be an arbitrary accumulation point of $\{x(\theta)\}$ as $\theta \to 0$. Since $0 < p < 1$ and $q \in [1, \infty)$, letting $\theta \to 0$ in (4.9), we have

$$\tau n \min_{1 \le i \le n} a_i^p x_i^*(x_i^* - v_i^*) + [\mathrm{diag}(a^p)(x^*)]^T(x^* - v^*) \le 0. \tag{5.1}$$

Note that v^* is an arbitrary solution of the CP. If the problem has a least element solution u^*, setting $v^* = u^*$ in the above inequality, we deduce that $x^* = u^*$. Since the least element solution is unique, we conclude that the entire trajectory converges to the solution.

Since each monotone map is a P_*-function with the constant $\tau = 0$, the inequality (5.1), in this case, reduces to

$$[\mathrm{diag}(a^p)(x^*)]^T(x^* - v^*) \le 0, \tag{5.2}$$

where v^* is an arbitrary solution of the CP. To show the convergence of the entire trajectory, it is sufficient to show that x^* is unique. Indeed, if there exists another vector u^* such that u^* is also an accumulation point to the trajectory, then we have

$$[\mathrm{diag}(a^p)(u^*)]^T(u^* - v^*) \le 0 \tag{5.3}$$

for all solutions v^*. Since x^* and u^* are solutions to the CP, setting $v^* = u^*$ in (5.2) and $v^* = x^*$ in (5.3), and adding the two inequalities, we obtain

$$(x^* - u^*)^T[\mathrm{diag}(a^p)](x^* - u^*) \le 0.$$

Since $a^p \in R^n_{++}$, it follows from the above that $x^* = u^*$. Hence the trajectory is convergent because it has a unique limiting point. It follows from (5.2) that

$$\|N^{1/2}x^*\|^2 \le \|N^{1/2}x^*\|\|N^{1/2}v^*\|,$$

where $N = \mathrm{diag}(u^p)$ and v^* is an arbitrary solution of the CP. Therefore, $\|N^{1/2}x^*\| \le \|N^{1/2}v^*\|$ for any solution v^*, i.e., x^* is a least N-norm solution. In particular, if $a = \alpha e$ for some positive scalar $\alpha > 0$, then (5.2) reduces to $(x^*)^T(x^* - v^*) \le 0$ for all solutions v^*, which implies that x^* is the unique least 2-norm solution.

We now show the result under (C2). It is evident that, under condition (C2), the inequality (4.8) can be written as:

$$\begin{aligned}(v^*)^T\bar{y}(\theta) + f(v^*)^T\bar{x}(\theta) &\\ \leq \theta^q(1+\tau n)e^T a^q - \theta^p \tau n \min_{1\leq i\leq n} a_i^p x_i(\theta)(x_i(\theta) - x_i^*) &\\ - \theta^p[\mathrm{diag}(a^p)x(\theta)]^T(x(\theta) - v^*).&\end{aligned}$$

Dividing both sides of the above inequality by θ^p, and noting that the left-hand side is nonnegative, we have

$$\begin{aligned}0 \leq \theta^{q-p}(1+\tau n)e^T a^q - \tau n \min_{1\leq n} a_i^p x_i(\theta)(x_i(\theta) - v_i^*)&\\ - [\mathrm{diag}(a^p)x(\theta)]^T(x(\theta) - v^*).&\end{aligned}$$

Since $p < q$, the above inequality implies that $\{x(\theta) : \theta \in (0,1]\}$ is bounded, and thus so is $\{y(\theta) : \theta \in (0,1)\}$, by continuity. Let x^* be an arbitrary accumulation point of $\{x(\theta)\}$ as $\theta \to 0$. Letting $\theta \to 0$ in the above inequality, we obtain inequality (5.1) again. It suffices to repeat the proof of (C1). □

The above result states that when $p < q$ the trajectory of the monotone CP converges to an N-norm least solution. The next result studies the case of $p \geq q$.

THEOREM 5.2. *Assume that f is a monotone function.*

(i) *Let $p \geq q$ and $(a,b,c) \in R^n_{++} \times \{0\} \times \{0\}$. If the trajectory $\{x(\theta) : \theta \in (0,1]\}$ generated by (2.3) has an accumulation point as $\theta \to 0$, then any accumulation point of the trajectory, as $\theta \to 0$, is a maximal complementarity solution of the CP.*

(ii) *Let $p > q$ and $(a,b,c) \in R^n_{++} \times \{0\} \times \{0\}$. Assume that the CP has a strict complementarity solution and the trajectory $\{x(\theta) : \theta \in (0,1]\}$ generated by (2.3) has an accumulation point as $\theta \to 0$. Then any accumulation point $(\hat{x}, \hat{y})$ of the trajectory as $\theta \to 0$ is a maximal strict complementarity solution, in the sense that*

$$\sum_{i\in I} a_i^q \log v_i^* + \sum_{j\in J} a_j^q \log f_j(v^*) \leq \sum_{i\in I} a_i^q \log \hat{x}_i + \sum_{j\in J} a_j^q \log f_j(\hat{x}),$$

where v^* is an arbitrary strict complementarity solution. Furthermore, if f is linear, i.e., $f = Mx + u$, where M is an n by n positive semidefinite matrix and $u \in R^n$ is a vector, then the entire trajectory converges, as $\theta \to 0$, to a unique maximal strict complementarity solution.

Proof. Since each accumulation point of the trajectory, as $\theta \to 0$, is a solution to the CP, then under the assumption of the theorem the solution set of the CP is nonempty. Let v^* be an arbitrary solution to the CP. Thus, the inequality (4.8) remains valid. By assumption, we have $\tau = 0$ and $b = c = 0$. Therefore, (4.8) reduces to

$$\begin{aligned}(v^*)^T\bar{y}(\theta) + f(v^*)^T\bar{x}(\theta) &\leq \theta^q e^T a^q - \theta^p \left[\mathrm{diag}(a^p)x(\theta)\right]^T (x(\theta) - v^*)\\ &\leq \theta^q e^T a^q + \theta^p \left[\mathrm{diag}(a^p)x(\theta)\right]^T v^*.\end{aligned}$$

Notice that the solution set of a monotone CP is convex. Let I, J, O be the unique partition of the indexes $\{1, 2, \ldots, n\}$ as defined at the beginning of this section. Then the above inequality further reduces to

$$(v^*)_I^T \bar{y}_I(\theta) + f_J(v^*)^T \bar{x}_J(\theta) \leq \theta^q e^T a^q + \theta^p \left[\mathrm{diag}(a_I^p)x_I(\theta)\right]^T v_I^*.$$

Since $(\bar{x}(\theta), \bar{y}(\theta)) \in R^{2n}_{++}$, we have

$$\begin{aligned}&(v^*)_I^T \bar{X}_I^{-1}(\theta)\bar{X}_I(\theta)\bar{y}_I(\theta) + f_J(v^*)^T \bar{Y}_J^{-1}(\theta)\bar{Y}_J(\theta)\bar{x}_J(\theta)\\ &\le \theta^q e^T a^q + \theta^p \left[\mathrm{diag}(a_I^p)x_I(\theta)\right]^T v_I^*,\end{aligned}$$

where $\bar{X}_I(\theta) = \mathrm{diag}(\bar{x}_I(\theta))$, and $\bar{Y}_J(\theta) = \mathrm{diag}(\bar{y}_J(\theta))$. Since

$$\bar{X}_I(\theta)\bar{y}_I(\theta) = \theta^q a_I^q, \quad \bar{X}_J(\theta)\bar{y}_J(\theta) = \theta^q a_J^q,$$

from the above inequality we have

$$(5.4)\quad (v^*)_I^T \bar{X}_I^{-1}(\theta)a_I^q + f_J(v^*)^T \bar{Y}_J^{-1}(\theta)a_J^q \le e^T a^q + \theta^{p-q}\left[\mathrm{diag}(a_I^p)x_I(\theta)\right]^T v_I^*.$$

The above inequality holds for all solutions v^*. In particular, let v^* be a solution satisfying $v_I^* > 0$ and $f_J(v^*) > 0$, i.e., let v^* be a maximal complementarity solution. Assume that $(\hat{x}, \hat{y})$ is an accumulation point of $(x(\theta), y(\theta))$ as $\theta \to 0$. Taking $\theta \to 0$ in the above inequality we deduce that $\hat{x}_I > 0$ and $\hat{y}_J > 0$ since $p \ge q$. Notice that $(\hat{x}, \hat{y})$ is a solution of the CP; $(\hat{x}, \hat{y})$ is a maximal complementarity solution. Theorem 5.2(i) follows.

We now prove Theorem 5.2(ii). Let v^* in (5.4) be an arbitrary strict complementarity solution. Assume that $(\hat{x}, \hat{y})$ is an arbitrary accumulation point of $\{x(\theta), y(\theta)\}$ as $\theta \to 0$. We now prove that $(\hat{x}, \hat{y})$ is a strict complementarity solution. Taking the limit in (5.4) and noting that $p > q$, we deduce that $\hat{x}_I > 0$, $\hat{y}_J > 0$, and

$$(v^*)_I^T \hat{X}_I^{-1}(\theta)a_I^q + f_J(v^*)^T atY_I^{-1}(\theta)a_J^q \le e^T a^q.$$

Notice that $\hat{y} = f(\hat{x})$. The above inequality can be further written as

$$\sum_{i\in I} a_i^q (v_i^*/\hat{x}_i) + \sum_{j\in J} a_j^q (f_j(v^*)/f_j(\hat{y})) \le e^T a^q.$$

Since $1 + \log t \le t$ for all $t > 0$, from the above we have

$$\sum_{i\in I} a_i^q [1 + \log(v_i^*/\hat{x}_i)] + \sum_{j\in J} a_j^q [1 + \log(f_j(v^*)/f_j(\hat{y}))] \le e^T a^q.$$

Since a strict complementarity solution exists, we have $I \cup J = \{1, \ldots, n\}$, and thus

$$\sum_{i\in I} a_i^q \log(v_i^*/\hat{x}_i) + \sum_{j\in J} a_j^q \log(f_j(v^*)/f_j(\hat{y})) \le 0.$$

Therefore,

$$(5.5)\qquad \sum_{i\in I} a_i^q \log v_i^* + \sum_{j\in J} a_j^q \log f_j(v^*) \le \sum_{i\in I} a_i^q \log \hat{x}_i + \sum_{j\in J} a_j^q \log f_j(\hat{y}).$$

Since v^* is an arbitrary strict complementarity solution, the first part of Theorem 5.2(ii) is proved.

We now consider the linear case, i.e., $f = Mx + u$. Denote by $\mathrm{SSOL}(f)$ the set of strict complementarity solutions of the CP, which is also a convex set by the convexity of $\mathrm{SOL}_{cp}(f)$. Since f is linear, this fact in turn implies that the following set is also convex:

$$\overline{S} = \{(x, y) : y = Mx + u,\ x \in \mathrm{SSOL}(f)\}.$$

To show the second part of result (ii), it is sufficient to prove that the accumulation point $(\hat{x}, \hat{y})$ satisfying (5.5) is unique. In fact, it is easy to see that $(\hat{x}, \hat{y})$ is the solution to the following strict concave program:

$$\begin{aligned} &\text{Maximize } \sum_{i\in I} a_i^q \log x_i + \sum_{i\in J} a_j^q \log y_i \\ &\text{subject to } (x, y) \in \overline{S}. \end{aligned}$$

Since a strict concave program has at most one solution, $(\hat{x}, \hat{y})$ is the unique solution to the above program, which is a maximal strict complementarity solution of the CP. Thus, the entire trajectory is convergent. □

We close this section by proving a general result concerning the characterization of the limiting point of the trajectory proposed in this paper in the case of semimonotone functions.

THEOREM 5.3. *Let f be a continuous semimonotone function from R^n into R^n. Let p, q, and (a, b, c) satisfy one of the following conditions:*

(C1) $0 < p < 1, q \in [1, \infty)$, *and* $(a, b, c) \in R^n_{++} \times R^{2n}$.

(C2) $0 < p < q, q \in [1, \infty)$, *and* $(a, b, c) \in R^n_{++} \times \{0\} \times \{0\}$.

Let $(u(\theta), x(\theta), y(\theta))$ be a solution to system (2.3) for each $\theta \in (0, 1]$. Assume that there exists an accumulation point to the trajectory $(u(\theta), x(\theta), y(\theta))$ as $\theta \to 0$. Then for any accumulation point $(0, x^*, y^*)$ of this trajectory as $\theta \to 0$, x^* is a weak Pareto minimal solution to the CP.

Proof. Let $(0, x^*, y^*)$ be an arbitrary accumulation point of $(u(\theta), x(\theta), y(\theta))$ as $\theta \to 0$. Then there exists a subsequence $\{\theta_k\} \to 0$ such that

$$\{(u(\theta_k), x(\theta_k), y(\theta_k))\} \to (0, x^*, y^*).$$

Assume the contrary: that x^* is not a weak Pareto minimal solution. Then there exists a solution u^* satisfying $u^* < x^*$. Since $x(\theta_k) \to x^*$, we have $x(\theta_k) > u^*$ for all sufficiently large k. By the semimonotone property of f, for each sufficiently large k there is an index i_k such that

$$x_{i_k}(\theta_k) > u^*_{i_k} \quad \text{and} \quad f_{i_k}(x(\theta_k)) \geq f_{i_k}(u^*).$$

Passing through a subsequence, we may assume that there exists an index l such that

$$x_l(\theta_k) > u^*_l \quad \text{and} \quad f_l(x(\theta_k)) \geq f_l(u^*)$$

for all sufficiently large k. Notice that for each θ, the solution $(u(\theta), x(\theta), y(\theta))$ of system (9) satisfies the system (2.8)–(2.11). We still use the symbols $\bar{y}_i(\theta) = y_i(\theta) - \theta b_i/2 > 0$ and $\bar{x}_i(\theta) = x_i(\theta) - \theta b_i/2 > 0$. By (4.6) we have

$$(\bar{y}_l(\theta_k) - f_l(u^*))(\bar{x}_l(\theta_k) - u^*_l) \leq \theta_k^q a_l^q. \tag{5.6}$$

On the other hand, we have

$$\begin{aligned} &(\bar{y}_l(\theta_k) - f_l(u^*))(\bar{x}_l(\theta_k) - u^*_l) \\ &= (\bar{y}_l(\theta_k) - f_l(u^*))(-\theta_k b_l/2) + (\bar{y}_l(\theta_k) - f_l(u^*))(x_l(\theta_k) - u^*_l) \\ &= (\bar{y}_l(\theta_k) - f_l(u^*))(-\theta_k b_l/2) \\ &\quad + (f_l(x(\theta_k)) + \theta_k^p a_l^p x_l(\theta_k) + \theta_k c_l - \theta_k b_l/2 - f_l(u^*))(x_l(\theta_k) - u^*_l) \\ &= (y_l(\theta_k) - \theta_k b_l/2 - f_l(u^*))(-\theta_k b_l/2) \end{aligned}$$

$$
\begin{aligned}
&+ (f_l(x(\theta_k)) - f_l(u^*))(x_l(\theta_k) - u_l^*) \\
&+ (\theta_k^p a_l^p x_l(\theta_k) + \theta_k c_l - \theta_k b_l/2)\,(x_l(\theta_k) - u_l^*) \\
\geq\ & (y_l(\theta_k) - \theta_k b_l/2 - f_l(u^*))(-\theta_k b_l/2) \\
&+ (\theta_k^p a_l^p x_l(\theta_k) + \theta_k c_l - \theta_k b_l/2)\,(x_l(\theta_k) - u_l^*).
\end{aligned}
$$

Combining inequality (5.6) and the inequality above and dividing both sides by θ_k^p, we have

$$
\begin{aligned}
\theta_k^{q-p} a_l^2 \geq\ & (y_l(\theta_k) - \theta_k b_l/2 - f_l(u^*))(-\theta_k^{1-p} b_l/2) \\
&+ (a_l^p x_l(\theta_k) + \theta_k^{1-p} c_l - \theta_k^{1-p} b_l/2)(x_l(\theta_k) - u_l^*).
\end{aligned}
$$

Let $\theta_k \to 0$. It is easy to see that under either condition (C1) or (C2) we have

$$
a_l^p x_l^*(x_l^* - u_l^*) \leq 0,
$$

which contradicts the assumption $0 \leq u^* < x^*$. □

6. Final remarks. We have proved the existence and the boundedness of a new homotopy continuation trajectory for nonlinear P_0-complementarity problems. The assumption imposed in the paper is weaker than most existing conditions widely used in interior-point and non–interior-point methods. Particularly, this assumption is satisfied if the P_0-CP has a nonempty and bounded solution set. Therefore, the method proposed in this paper can tackle all P_0-CPs with bounded solution sets. Since this assumption can be satisfied even when the strict feasibility condition fails to hold, the proposed method can also be used to tackle some P_0-CPs with unbounded solution sets. For P_*-CPs, the existence and the boundedness of the new continuation trajectory can be guaranteed, provided that the solution set of the CP is nonempty (whether the solution set is bounded or not). Moreover, under some choices of p, q, and (a, b, c), the entire trajectory for any continuous monotone CP always converges to a solution of the CP, provided that a solution exists. Based on the results of this paper, we may design a non–interior-point path-following algorithm for CPs that can solve all solvable P_*-CPs, all P_0-CPs with bounded solution sets, and some P_0-CPs with unbounded solution sets.

Since the proposed method can deal with all solvable P_*-CPs, a natural question is whether this method can attack all solvable P_0-CPs. That is, can Condition 3.1 in Theorem 4.2 be replaced by the nonemptiness assumption of the solution set? The answer is no. For some P_0-CPs with unbounded solution sets, the proposed continuation trajectory might be divergent to infinity. This phenomena has also been seen in the canonical Tikhonov regularization trajectory for a P_0-CP with an unbounded solution set (Sznajder and Gowda [29]). In fact, in section 3.4 of [20], Kojima et al. pointed out that a certain knapsack problem can be transformed into a linear P_0-CP with an unbounded solution set. For this P_0-CP, it is easy to verify that both the canonical Tikhonov regularization trajectory and the continuation trajectory proposed in this paper are divergent to infinity. This implies that the example in section 3.4 of [20] does not satisfy Condition 3.1.

SECOND ORDER METHODS FOR OPTIMAL CONTROL OF TIME-DEPENDENT FLUID FLOW*

MICHAEL HINZE† AND KARL KUNISCH‡

Abstract. Second order methods for open loop optimal control problems governed by the two-dimensional instationary Navier–Stokes equations are investigated. Optimality systems based on a Lagrangian formulation and adjoint equations are derived. The Newton and quasi-Newton methods as well as various variants of SQP methods are developed for applications to optimal flow control, and their complexity in terms of system solves is discussed. Local convergence and rate of convergence are proved. A numerical example illustrates the feasibility of solving optimal control problems for two-dimensional instationary Navier–Stokes equations by second order numerical methods in a standard workstation environment.

Key words. optimal control Navier–Stokes equations, Newton method, SQP method, second order sufficient optimality

1. Introduction.

This research is devoted to the analysis of second methods for solving optimal control problems involving the time-dependent Navier–Stokes equations. Thus we consider

$$\min\ J(y,u) \text{ over } (y,u) \tag{1.1}$$

subject to

$$\begin{cases} \frac{\partial y}{\partial t} + (y\cdot\nabla)y - \nu\Delta y + \nabla p = Bu & \text{in } Q = (0,T)\times\Omega, \\ \operatorname{div} y = 0 & \text{in } Q, \\ y(t,\cdot) = 0 & \text{on } \Sigma = (0,T)\times\partial\Omega, \\ y(0,\cdot) = y_0 & \text{in } \Omega. \end{cases} \tag{1.2}$$

Here Ω is a bounded domain in $\mathbb{R}^2$ with sufficiently smooth boundary $\partial\Omega$. The final time $T > 0$ and the initial condition y_0 are fixed. The vector valued variable y and the scalar valued variable p represent the velocity and the pressure of the fluid. Further, u denotes the control variable and B the control operator. The precise functional analytic setting of problem (1.1), (1.2) will be given in section 2. For the moment it suffices to say that typical cost functionals include tracking-type functionals

$$J(y,u) = \frac{1}{2}\int_Q |y-z|^2 dx\,dt + \frac{\alpha}{2}\,|u|^2 \tag{1.3}$$

and functionals involving the vorticity of the fluid

$$J(y,u) = \frac{1}{2}\int_Q |\text{curl } y(t,\cdot)|^2_{\mathbb{R}^n}\, dx\, dt + \frac{\alpha}{2}\,|u|^2, \tag{1.4}$$

where $\alpha > 0$ and z are given. For the following discussion it will be convenient to formally represent all the equality constraints involved in (1.2) by $\hat{e}(y,p,u) = 0$ so that (1.1), (1.2) can be expressed in the form

$$(P) \qquad \begin{cases} \min\ J(y,u) \text{ over } (y,u) \\ \text{subject to} \\ \hat{e}(y,p,u) = 0. \end{cases}$$

In this form solving (1.1), (1.2) appears at first to be a standard task; see [AM, DHV, G, GT, IK, KS2, NT] and the references given there. However, the formidable size of (1.1), (1.2) and the goal of analyzing second order methods necessitate an independent analysis.

For second order methods applied to optimal control problems two classes can be distinguished depending on whether (y,p) in (1.1), (1.2) are considered as independent variables or as functions of the control variable u. In the former case $\hat{e}(y,p,u) = 0$ represents an explicit constraint for the optimization problem, whereas in the latter case $\hat{e}(y(u),p(u),u) = 0$ serves the purpose of describing the evaluation of (y,p) as a function of u. In fact, (P) can be expressed as the reduced problem

$$(\hat{P}) \qquad \min\ \hat{J}(u) = J(y(u),u) \text{ over } u, \tag{$\hat{P}$}$$

where $y(u)$ is implicitly defined via $\hat{e}(y(u),p(u),u) = 0$.

To obtain a second order method in the case when (y,p) are considered as independent variables, one can derive the optimality system for (P) and apply the Newton algorithm to the optimality system. This is referred to as the sequential quadratic programming (SQP) method. Alternatively, if (y,p) are considered as functions of u, then Newton's method can be applied to $(\hat{P})$ directly. The relative merits of these two approaches will be discussed in section 4. To anticipate some of this discussion let us point out that the difference in numerical effort between these two methods is rather small. In fact, after proper rearrangements, the difference in computational cost per iteration of the SQP method for (P) and the Newton method for $(\hat{P})$ consists in solving either the linearized equation (1.2) or the full nonlinear equation itself. In view of the time dependence of either of these two equations, an iterative procedure is used for their solution so that the difference between solving the linearized and nonlinear equation per sweep is not so significant. A second consideration that may influence the choice between SQP method or Newton method applied to $(\hat{P})$ concerns initialization. Initial guesses (y_0,p_0) and u_0 for (y,p,u) can clearly be used independently of each other in the SQP method, where the states are decoupled from the controls. It is sometimes hinted at that this decoupling is not only important for the initialization but also during the iteration and that as a consequence the SQP method may require fewer iterations than Newton's method for $(\hat{P})$, [H]. As we shall see below, the variables y and p can be initialized independently from u_0 also in the Newton method. Specifically, if (y_0,p_0) and u_0 are available, it is not necessary to abandon (y_0,p_0) and compute $(y(u_0),p(u_0))$ from u_0. As for the choice of the initial guess (y_0,p_0,u_0), one possibility is to rely on one of the suboptimal strategies that were developed in the recent past to obtain approximate solutions to (1.1), (1.2). We mention re-

duced order techniques [IR], proper orthogonal decomposition (POD)-based methods [HK, KV, LT], and the instantaneous control method [CTMK, BMT, CHK, HKK]. As another possibility, one can carry out some gradient steps before one switches to the Newton iteration. Let us stress that the numerical realization of the discussed algorithms does not require the availability of the matrix representation of an approximation to the Hessian of the optimal control problem. In fact, storage of the Hessian would be unfeasible. Rather, only the action of the Hessian to a vector is required. In the context of shape optimization this point was elaborated upon in [LA], for example.

Let us briefly comment on some related contributions. In [AT] optimality systems are derived for problems of the type (1.1), (1.2). A gradient technique is proposed in [GM] for the solution of (1.1), (1.2). Similarly, in [B] gradient techniques are analyzed for a boundary control problem related to (1.1), (1.2). In [FGH] the authors analyze optimality systems for exterior boundary control problems. One of the few contributions focusing on second order methods for optimal control of fluids is given in [GB, H]. These works are restricted to stationary problems, however.

This paper, on the other hand, focuses on second order methods for time-dependent problems. We show that despite the difficulties due to the size of (1.1), (1.2) and the fact that the optimality systems contain a two point boundary value problem, forward in time for the primal and backwards in time for the adjoint variables, second order methods are computationally feasible. We establish that the initial approximation to the reduced Hessian is only a compact perturbation of the Hessian at the minimizer. In addition, we give conditions for second order sufficient optimality conditions of tracking-type problems. These results imply superlinear convergence of quasi-Newton as well as SQP methods. While the present paper focuses on distributed control problems, in a future paper we plan to address the case of velocity control along the boundary.

The paper is organized as follows. Section 2 contains the necessary analytic prerequisites. First and second order derivatives of the cost functional with respect to the control are computed in section 3. Section 4 contains a comparison of second order methods to solve (1.1), (1.2). In section 5, the convergence of the quasi-Newton method and SQP methods applied to $(\hat{P})$ is analyzed. Numerical results for the Newton method and comparisons to a gradient method are contained in section 6.

2. The optimal control problem. In this section we consider the optimal control problem (1.1), (1.2) in the abstract form

$$\begin{cases} \min\ J(y,u) \text{ over } (y,u) \in W \times U \\ \text{subject to } e(y,u) = 0. \end{cases} \tag{2.1}$$

To define the spaces and operators arising in (2.1), we assume Ω to be a bounded domain in $\mathbb{R}^2$ with Lipschitz boundary and introduce the solenoidal spaces

$$H = \{v \in C_0^\infty(\Omega)^2 \colon \text{ div } v = 0\}^{-|\cdot|_{L^2}}, V = \{v \in C_0^\infty(\Omega)^2 \colon \text{ div } v = 0\}^{-|\cdot|_{H^1}},$$

with the superscripts denoting closures in the respective norms. Further, we define

$$W = \{v \in L^2(V) \colon v_t \in L^2(V^*)\} \quad \text{and} \quad Z := L^2(V) \times H,$$

W endowed with the norm

$$|v|_W = (|v|^2_{L^2(V)} + |v_t|^2_{L^2(V^*)})^{1/2},$$

$$H^{2,1}(Q) := \{v \in L^2(V \cap H^2(\Omega)^2); v_t \in L^2(H)\}$$

equipped with the norm

$$|v|^2_{H^{2,1}(Q)} := |v|^2_{L^2(V\cap H^2(\Omega)^2)} + |v_t|^2_{L^2(H)},$$

and we set $\langle\cdot,\cdot\rangle := \langle\cdot,\cdot\rangle_{L^2(V^*),L^2(V)}$ with V^* denoting the dual space of V. Here $L^2(V)$ is an abbreviation for $L^2(0,T;V)$, and similarly $L^2(V^*) = L^2(0,T;V^*)$. Recall that up to a set of measure zero in $(0,T)$ elements $v \in W$ can be identified with elements in $C([0,T];H)$, and elements $w \in H^{2,1}(Q)$ can be identified with elements in $C([0,T];V)$. In (2.1), further, U denotes the Hilbert space of controls which is identified with its dual U^*. For the cost functional $J\colon L^2(V)\times U \to \mathbb{R}$ we make the following assumptions:

(H0)
1. J is bounded from below, i.e., $J(y,u) \geq C > -\infty$ for all $(y,u) \in L^2(V)\times U$.
2. J is weakly lower semicontinuous.
3. J is twice Fréchet differentiable with locally Lipschitzian second derivative.
4. J can be decomposed as $J(y,u) = J_1(y) + J_2(u)$.
5. J is radially unbounded in u, i.e., $J(y,u) \to \infty$ as $|u|_U \to \infty$ for every $y \in W$.

The nonlinear mapping

$$e\colon W \times U \to Z^* = L^2(V^*)\times H$$

is defined by

$$e(y,u) = \left(\frac{\partial y}{\partial t} + (y\cdot\nabla)y - \nu\Delta y - Bu, y(0) - y_0\right),$$

where $B \in \mathcal{L}(U, L^2(V^*))$ and $y_0 \in H$. Comparing (1.1), (1.2) to (2.1), we note that the conservation of mass as well as the boundary condition are realized in the choice of the space W, while the dynamics are described by the condition $e(y,u) = 0$. In variational form the constraints in (2.1) can be equivalently expressed as the following: given $u \in U$ find $y \in W$ such that $y(0) = y_0$ and

$$\langle y_t, v\rangle + \langle (y\cdot\nabla)y, v\rangle + \nu(\nabla y, \nabla v)_{L^2(L^2)} = \langle Bu, v\rangle \text{ for all } v \in L^2(V). \tag{2.2}$$

The following existence result for the Navier–Stokes equations in dimension two is well known [CF, L], [T, Chapter III].

PROPOSITION 2.1. *There exists a constant C such that for every $u \in U$ there exists a unique element $y = y(u) \in W$ satisfying*

$$e(y(u),u) = 0$$

and

$$|y|_{C(0,T;H)} + |y|_W \leq C(|y_0|_H + |u|_U + |y_0|^2_H + |u|^2_U).$$

From Proposition (2.1) we conclude that with respect to existence (2.1) is equivalent to

$$\min \hat{J}(u) = J(y(u),u) \text{ subject to } u \in U, \tag{2.3}$$

where $y(u) \in W$ satisfies $e(y(u), u) = 0$.

THEOREM 2.2. *Problem* (2.1) *admits a solution* $(y^*, u^*) = (y(u^*), u^*) \in W \times U$.

Proof. With the above formalism the proof is quite standard, and we give only a brief outline. Since by assumption (H0) 1 J is bounded from below, there exists a minimizing sequence $\{(y_n, u_n)\} = \{y(u_n), u_n\}$ in $W \times U$. Due to (H0) 4, the radial unboundedness property (H0) 5 of J, and Proposition 2.1, the sequence $\{(y_n, u_n)\}$ is bounded in $W \times U$, and hence there exists a subsequence with a weak limit $(y^*, u^*) \in W \times U$. The weakly lower semicontinuity assumption (H0) 2 of $(y, u) \mapsto J(y, u)$ implies that

$$J(y^*, u^*) = \inf\{J(y, u) \colon (y, u) \in W \times U,\ e(y, u) = 0\},$$

and it remains to show that $y^* = y(u^*)$. This can be achieved by passing to the limit in (2.2) with (y, u) replaced by $(y(u_n), u_n)$. ∎

We shall also require the following result concerning strong solutions to the Navier–Stokes equation [T, Theorem III. 3.10], [T1].

PROPOSITION 2.3. *If* $y_0 \in V$ *and* $B \in \mathcal{L}(U, L^2(H))$, *then for every* $u \in U$ *the solution* $y = y(u) \in W$ *to* $e(y, u) = 0$ *satisfies* $y \in H^{2,1}(Q)$. *Moreover, for every bounded set* $\mathcal{U}$ *in* U

$$\{y(u) \colon u \in \mathcal{U}\} \text{ is bounded in } H^{2,1}(Q).$$

We shall frequently refer to the linearized Navier–Stokes system and the adjoint equations given next:

$$\left\{ \begin{array}{l} v_t + (v \cdot \nabla)y + (y \cdot \nabla)v - \nu \Delta v = f \quad \text{in } \Omega \text{ a.e. on } (0, T], \\ v(0) = v_0 \end{array} \right. \tag{2.4}$$

and

$$\left\{ \begin{array}{l} -w_t + (\nabla y)^t w - (y \cdot \nabla)w - \nu \Delta w = g \quad \text{in } \Omega \text{ a.e. on } [0, T), \\ w(T) = 0. \end{array} \right. \tag{2.5}$$

PROPOSITION 2.4. *Let* $y \in W$, $v_0 \in H$, $f \in L^2(V^*)$, *and* $g \in L^\alpha(V^*) \cap W^*$, *with* $\alpha \in [1, \frac{4}{3}]$. *Then* (2.4) *admits a unique variational solution* $v \in W$, *and* (2.5) *has a unique variational solution* $w \in L^2(V)$ *with* $w_t \in L^\alpha(V^*) \cap W^*$, $w \in C(H)$, *and the first equation in* (2.5) *holding in* $L^\alpha(V^*) \cap W^*$. *Moreover, the following estimates hold.*

(i) $|v|_{L^\infty(H)} + |v|_{L^2(V)} \le C(|y|_{L^2(V)}) \left\{ |f|_{L^2(V^*)} + |v_0|_H \right\}$,

(ii) $|v_t|_{L^2(V^*)} \le C(|y|_{L^2(V)}, |y|_{L^\infty(H)}) \left\{ |f|_{L^2(V^*)} + |v_0|_H \right\}$,

(iii) $|w|_{L^2(V)} + |w_t|_{L^\alpha(V^*)} \le C(|y|_{L^2(V)}, |y|_{L^\infty(H)}) \left\{ |g|_{L^\alpha(V^*)} + |g|_{W^*} \right\}$.

If, in addition, $y \in L^\infty(V)$ *and* $g \in L^2(V^*)$, *then* $w \in W$ *and*

(iv) $|w|_{L^2(V)} + |w_t|_{L^2(V^*)} \le C(|y|_{L^\infty(V)})\, |g|_{L^2(V^*)}$.

For $\partial\Omega \in C^2$, $y \in W \cap L^\infty(V) \cap L^2(H^2(\Omega)^2)$, $v_0 \in V$, *and* $f, g \in L^2(H)$ *the unique solutions* v *of* (2.4) *and* w *of* (2.5) *are elements of* $H^{2,1}(Q)$ *and satisfy the a priori estimates*

(v) $|v|_{H^{2,1}(Q)} \le C(|y|_{L^\infty(V)}, |y|_{L^2(H^2(\Omega)^2)}) \left\{ |f|_{L^2(H)} + |v_0|_V \right\}$

and

(vi) $|w|_{H^{2,1}(Q)} \le C(|y|_{L^\infty(V)}, |y|_{L^2(H^2(\Omega)^2)})\, |g|_{L^2(H)}$.

Proof. The proof can be found in [HH, Appendix]. ∎

3. Derivatives. In this section representations for the first and second derivatives of $\hat{J}$ appropriate for the treatment of (2.3) by the Newton and quasi-Newton method are derived. We shall utilize the notation

$$X = W \times U \text{ and } x = (y, u) \text{ for } (y, u) \in W \times U.$$

PROPOSITION 3.1. *The operator $e = (e^1, e^2)\colon X \to Z^*$ is twice continuously differentiable with Lipschitz continuous second derivative. The action of the first two derivatives of e^1 are given by*

$$\begin{aligned}\langle e^1_x(x)(w,s),\phi\rangle &= \langle w_t,\phi\rangle + \langle (w\cdot\nabla)y,\phi\rangle + \langle (y\cdot\nabla)w,\phi\rangle \\ &\quad + \nu(\nabla w,\nabla\phi)_{L^2(L^2)} - \langle Bs,\phi\rangle,\end{aligned}$$

where $x = (y,u) \in X, (w,s) \in X$, and $\phi \in L^2(V)$, and

$$\begin{aligned}\langle e^1_{xx}(x)(w,s)(v,r),\phi\rangle &= \langle e^1_{yy}(x)(w,v),\phi\rangle \\ &= \langle (w\cdot\nabla)v,\phi\rangle + \langle (v\cdot\nabla)w,\phi\rangle =: \langle v, H(\phi)w\rangle_{W,W^*},\end{aligned} \tag{3.1}$$

where $(v,r) \in X$.

Proof. Since e^2 is linear, we restrict our attention to e^1. Let $b\colon V \times V \times V \to \mathbb{R}$ be defined by

$$b(u,v,\phi) = \langle (u\cdot\nabla)v,\phi\rangle_{V^*,V},$$

and recall that, due to the assumption that $\Omega \subset \mathbb{R}^2$,

$$|b(u,v,\phi)|^2 \le 2|u|_H\,|u|_V\,|v|_H\,|v|_V\,|\phi|_V^2 \tag{3.2}$$

for all $(u,v,\phi) \in V \times V \times V$ [T, p. 293]. To argue local Lipschitz continuity of e, let $x, \tilde{x} \in X$ and $\phi \in L^2(V)$. We find

$$\begin{aligned}\langle e^1(x) - e^1(\tilde{x}),\phi\rangle &= \langle (y-\tilde{y})_t,\phi\rangle + \langle ((y-\tilde{y})\cdot\nabla)\tilde{y},\phi\rangle \\ &\quad + \langle (y\cdot\nabla)(y-\tilde{y}),\phi\rangle + \nu(\nabla(y-\tilde{y}),\nabla\phi)_{L^2(L^2)} + \langle B(\tilde{u}-u),\phi\rangle \\ &\le \sqrt{2}\int_0^T |y-\tilde{y}|_H^{1/2}|y-\tilde{y}|_V^{1/2}(|\tilde{y}|_H^{1/2}|\tilde{y}|_V^{1/2} + |y|_H^{1/2}|y|_V^{1/2})|\phi|_V dt \\ &\quad + C|x-\tilde{x}|_X\,|\phi|_{L^2(V)}.\end{aligned}$$

Here and below, C denotes a constant independent of $x, \tilde{x}$, and ϕ. Due to the continuous embedding of W into $L^\infty(H)$, we have

$$\begin{aligned}\langle e^1(x) - e^1(\tilde{x}),\phi\rangle &\le C\Bigg[|x-\tilde{x}|_X\,|\phi|_{L^2(V)} \\ &\quad + |y-\tilde{y}|_{L^\infty(H)}^{1/2}\left(|\tilde{y}|_{L^\infty(H)}^{1/2} + |y|_{L^\infty(H)}^{1/2}\right)\int_0^T |y-\tilde{y}|_V^{1/2}\left(|\tilde{y}|_V^{1/2} + |y|_V^{1/2}\right)|\phi|_V dt\Bigg].\end{aligned}$$

Using Hölder's inequality this further implies the estimate

$$\begin{aligned}\langle e^1(x) - e^1(\tilde{x}),\phi\rangle &\le C\Bigg[|x-\tilde{x}|_X + |y-\tilde{y}|_{L^\infty(H)}^{1/2} \\ &\quad \times \left(|\tilde{y}|_{L^\infty(H)}^{1/2} + |y|_{L^\infty(H)}^{1/2}\right)\left(\int_0^T |y-\tilde{y}|_V\}\,(|\tilde{y}|_V + |y|_V)\,dt\right)^{1/2}\Bigg]|\phi|_{L^2(V)},\end{aligned}$$

and, consequently, after redefining C one last time,

$$\langle e^1(x) - e^1(\tilde{x}), \phi\rangle \le C\,|x-\tilde{x}|_X(|y|_W + |\tilde{y}|_W)|\phi|_{L^2(V)}. \tag{3.3}$$

This estimate establishes the local Lipschitz continuity of e. To verify that the formula for e_x given above represents the Fréchet derivative of e, we estimate

$$\begin{aligned}
&|e^1(\tilde{x}) - e^1(x) - e^1_x(x)(\tilde{x}-x)|_{L^2(V^*)} = \sup_{|\phi|_{L^2(V)}=1} \int_0^T |b(y-\tilde{y}, y-\tilde{y}, \phi)|\,dt \\
&\le \sup_{|\phi|_{L^2(V)}=1} \int_0^T |y-\tilde{y}|_H\,|y-\tilde{y}|_V\,|\phi|_V dt \\
&\le C|y-\tilde{y}|_W \sup_{|\phi|_{L^2(V)}=1} \int_0^T |y-\tilde{y}|_V|\phi|_V\,dt \;\le\; C|y-\tilde{y}|^2_W,
\end{aligned}$$

and the Fréchet differentiability of e follows. To show Lipschitz continuity of the first derivative, let $x, \tilde{x}$, and (v,r) be in X, and estimate

$$\begin{aligned}
&|(e^1_x(\tilde{x}) - e^1_x(x))(v,r)|_{L^2(V^*)} = \sup_{|\phi|_{L^2(V)}=1} \int_0^T |b(y-\tilde{y}, v, \phi) + b(v, y-\tilde{y}, \phi)|\,dt \\
&\le 2\sqrt{2} \sup_{|\phi|_{L^2(V)}=1} \int_0^T |y-\tilde{y}|_H\,|y-\tilde{y}|_V\,|v|_H\,|v|_V\,|\phi|_V dt \\
&\le C|y-\tilde{y}|_W\,|v|_W.
\end{aligned}$$

The expression for the second derivative can be verified by an estimate analogous to the one for the first derivative. The second derivative is independent of the point at which it is taken, and thus it is necessarily Lipschitz continuous. ∎

From (3.2) it follows that for $\phi \in L^2(V)$ and $w \in W$ the mapping

$$\sigma : v \mapsto \langle v, H(\phi)w\rangle_{W,W^*}$$

is an element of W^*. In section 4 we shall use the fact that σ can also be identified with an element of $L^4(V)^* = L^{4/3}(V^*)$.

LEMMA 3.2. *For $\phi \in L^2(V)$ and $w \in W$ the functional σ can be identified with an element in $W^* \cap L^{4/3}(V^*)$.*

Proof. To argue that $\sigma \in L^{4/3}(V^*)$, let $v \in L^4(V)$ and estimate using (3.2)

$$\begin{aligned}
\sigma(v) = \int_0^T b(w,v,\phi) + b(v,w,\phi)\,dt &\le 2\sqrt{2k}|w|^{\frac{1}{2}}_{L^\infty(H)} \int_0^T |w|^{\frac{1}{2}}_V |v|_V |\phi|_V\,dt \\
&\le 2\sqrt{2k}|w|^{\frac{1}{2}}_{L^\infty(H)}|\phi|_{L^2(V)}|w|^{\frac{1}{2}}_{L^2(V)}|v|_{L^4(V)},
\end{aligned}$$

where k is the embedding constant of V into H. This gives the claim. ∎

PROPOSITION 3.3. *Let $x = (y,u) \in W \times U$. Then $e_y(x)\colon W \to Z^*$ is a homeomorphism. Moreover, if the inverse of its adjoint $e_y^{-*}(x)\colon W^* \to Z$ is applied to an element $g \in W^* \cap L^\alpha(V^*)$, $\alpha \in [1, 4/3]$, then, setting $(w, w_0) := e_y^{-*}(x)g \in L^2(V) \times H$, we have $w_t \in L^\alpha(V^*)$, $w(0) = w_0$, and w is the variational solution to (2.5).*

Proof. Due to Proposition 3.1, $e_y(x)$ is a bounded linear operator. By the closed range theorem the claim follows once it is argued that (2.4) has a unique solution $v \in W$ for every $(f, v_0) \in Z^*$. This is a direct consequence of Proposition 2.4(i) and

(ii). The assertion concerning the adjoint follows from (iii) of the same proposition and its proof. □

As a consequence of Propositions 3.1 and 3.3 and the implicit function theorem, the first derivative of the mapping $u \to y(u)$ at u in direction δu is given by

$$y'(u)\delta u = -e_y^{-1}(x)e_u(x)\delta u, \tag{3.4}$$

where $x = (y(u), u)$. By the chain rule we thus obtain

$$\langle \hat{J}'(u), \delta u\rangle_U = \langle J_u(x) - e_u^*(x)e_y^{-*}(x)J_y(x), \delta u\rangle_U.$$

Introducing the variable

$$\lambda = -e_y^{-*}(x)J_y(x) \in Z, \tag{3.5}$$

we obtain, utilizing Proposition 2.4(iii) with $g = -J_y(x) \in L^2(V^*)$, the Riesz representation for the first derivative of $u \to \hat{J}(u)$:

$$\hat{J}'(u) = J_u(x) + e_u^*\lambda. \tag{3.6}$$

Here $\lambda = (\lambda^1, \lambda^0) \in Z$, $\lambda_t^1 \in L^{4/3}(V^*)$, $\lambda^1 \in C(H)$, and λ^1 is the variational solution of

$$\begin{cases} -\lambda_t^1 + (\nabla y)^t\lambda^1 - (y\cdot\nabla)\lambda^1 - \nu\Delta\lambda^1 = -J_y(x), \\ \lambda^1(T) = 0, \end{cases} \tag{3.7}$$

where the first equation holds in $L^{4/3}(V^*) \cap W^*$.

The computation of the second derivative of $\hat{J}''(u) \in \mathcal{L}(U)$ of $\hat{J}$ is more involved. Let $(\delta u, \delta v) \in U \times U$, and note that the second derivative of $u \to y(u)$ from U to W can be expressed as

$$y''(u)(\delta u, \delta v) = -e_y^{-1}(x)e_{yy}(x)(y'(u)\delta u, y'(u)\delta v). \tag{3.8}$$

By the chain rule and since $W \subset L^2(V)$ and hence $L^2(V^*) \subset W^*$, we have

$$\begin{aligned} \langle \hat{J}''(u)\delta u, \delta v\rangle_U &= \langle J_{yy}(x)y'(u)\delta u, y'(u)\delta v\rangle \\ &\quad + \langle J_y(x), y''(u)(\delta u, \delta v)\rangle + \langle J_{uu}(x)\delta u, \delta v\rangle_U \\ &= \langle J_{yy}(x)y'(u)\delta u, y'(u)\delta v\rangle - \langle J_y(x), e_y^{-1}e_{yy}(x)(y'(u)\delta u, y'(u)\delta v)\rangle \\ &\quad + \langle J_{uu}(x)\delta u, \delta v\rangle_U \\ &= \langle J_{yy}(x)y'(u)\delta u, y'(u)\delta v\rangle + \langle \lambda^1, e_{yy}^1(x)(y'(u)\delta u, y'(u)\delta v)\rangle \\ &\quad + \langle J_{uu}(u)\delta u, \delta v\rangle_U. \end{aligned}$$

We introduce the Lagrangian $L\colon X \times Z \to \mathbb{R}$

$$L(x, \lambda) = J(x) + \langle e(x), \lambda\rangle_{Z^*,Z} \tag{3.9}$$

and the matrix operator

$$T(x) = \begin{pmatrix} -e_y^{-1}(x)e_u(x) \\ Id_U \end{pmatrix} \in \mathcal{L}(U, X). \tag{3.10}$$

We observe that the second derivative of L with respect to x can be expressed as

$$L_{xx}(x, \lambda) = \begin{pmatrix} J_{yy}(x) + & \langle e_{yy}^1(x)(\cdot,\cdot),\, \lambda^1\rangle & 0 \\ & 0 & J_{uu}(x) \end{pmatrix} \in \mathcal{L}(X, X^*).$$

The above computation for $\hat{J}''(u)$ together with (3.4) imply that

$$\hat{J}''(u) = T^*(x)L_{xx}(x, \lambda)T(x), \tag{3.11}$$

where $x = (y(u), u)$.

4. Second order methods. This section contains a description and a comparison of second order methods to solve (2.1). Throughout, u^* denotes a (local) solution to (2.1).

4.1. Newton and quasi-Newton algorithm. For the sake of reference let us specify the Newton algorithm.

ALGORITHM 4.1 (Newton algorithm).

1. *Choose* $u^0 \in N(u^*)$*; set* $k = 0$.
2. *Do until convergence:*
   (i) *solve* $\hat{J}''(u^k)\delta u^k = -\hat{J}'(u^k)$,
   (ii) *update* $u^{k+1} = u^k + \delta u^k$,
   (iii) *set* $k = k + 1$.

Let us consider the linear system in 2(i). Its dimension is that of the control space U. From the characterization of the Hessian $\hat{J}''(u^k)$ we conclude that the number of solutions to the linearized Navier–Stokes equation (3.4) with appropriate right-hand sides that are required for its evaluation equals the dimension of U. If U is infinite dimensional, then an appropriate discretization must be carried out. Let us assume now that the dimension of U is large so that direct evaluation of $\hat{J}''(u^k)$ is not feasible. In this case 2(i) must be solved iteratively, e.g., by a conjugate gradient technique. We shall then refer to 2(i) as the "inner" loop as opposed to the do loop in 2, which is the "outer" loop of the Newton algorithm. The inner loop at iteration level k of the outer loop requires us to

(i) evaluate $\hat{J}'(u^k)$, i.e., given u^k, compute $y(u^k)$ from (1.2) and λ^1 from (3.7) with $x = (y(u^k), u^k)$;
(ii) iteratively evaluate the action of $\hat{J}''(u^k)$ on δ_j^k, the jth iterate of the inner loop on the kth level of the outer loop.

The iterate $q = \hat{J}''(u^k)\delta_j^k$ can be evaluated by successively applying the following steps:

(a) solve in $L^2(V^*)$ for $v \in W$

$$\begin{aligned} v_t + (v \cdot \nabla)y + (y \cdot \nabla)v - \nu\Delta v &= B\delta_j^k, \\ v(0) &= 0, \end{aligned}$$

where $y = y(u^k)$;
(b) evaluate $J_{yy}(x)v + \langle e^1_{yy}(x)(v, \cdot), \lambda^1\rangle$;
(c) solve in W^* for $w \in L^2(V)$

$$e_y(x)^* w \;=\; J_{yy}(x)v + \langle e^1_{yy}(x)(v, \cdot), \lambda^1\rangle;$$

(d) and, finally, set $q := J_{uu}\delta u + B^* w$.

We recall that $\lambda^1 \in L^2(V)$ and that for $s \in W$

$$\langle e^1_{yy}(x)(v, s), \lambda^1\rangle = \int_0^T \int_\Omega ((v \cdot \nabla)s\lambda^1 + (s \cdot \nabla)v\lambda^1)dx\, dt.$$

Moreover, by Lemma 3.2 the functional appearing in (b) is an element of $W^* \cap L^{4/3}(V^*)$. Hence by Proposition 2.4 the adjoint equation in (c) can equivalently be rewritten as

$$\begin{aligned} -w_t + (\nabla y)^t w - (y \cdot \nabla)w - \nu\Delta w &= J_{yy}(x)v + \langle e^1_{yy}(x)(v, \cdot), \lambda^1\rangle, \\ w(T) &= 0, \end{aligned}$$

where the first equation holds in $W^* \cap L^{4/3}(V^*)$. Summarizing, for the outer iteration of the Newton method one Navier–Stokes solve for $y(u^k)$ and one linearized Navier–Stokes solve for $\lambda(u^k)$ are required. For the inner loop one forward (in time) as well as one backward linearized Navier–Stokes solve per iteration are necessary.

Concerning initialization, we observe that if initial guesses $(y_0, u_0) \in W \times U$ are available (with y_0 not necessarily $y(u_0)$), then, alternatively to the initialization in Algorithm 4.1, this information can be used advantageously to compute the adjoint variable λ^1 required for the initial guess for the right-hand side of the linear system as well as to carry out steps (a)–(c) for the evaluation of the Hessian. There is no necessity to recompute $y(u_0)$ from u_0.

To avoid the difficulties of evaluating the action of the exact Hessian in Algorithm 4.1, one can resort to quasi-Newton algorithms. Here we specify one of the most prominent candidates, the BFGS method. For w and z in U we define the rank-one operator $w \otimes z \in \mathcal{L}(U)$, the action of which is given by

$$(w \otimes z)(v) = \langle z, v \rangle_U \, w.$$

In the BFGS method the Hessian $\hat{J}''$ at u^* is approximated by a sequence of operators H^k.

Algorithm 4.2 (BFGS algorithm).

1. *Choose* $u^0 \in N(u^*)$, $H^0 \in \mathcal{L}(U)$ *symmetric, set* $k = 0$.
2. *Do until convergence:*
   - (i) *solve* $H^k \delta u^k = -\hat{J}'(u^k)$,
   - (ii) *update* $u^{k+1} = u^k + \delta u^k$,
   - (iii) *compute* $\hat{J}'(u^{k+1})$,
   - (iv) *set* $s^k = u^{k+1} - u^k$, $d^k = \hat{J}'(u^{k+1}) - \hat{J}'(u^k)$,
   - (v) *update* $H^{k+1} = H^k + \frac{d^k \otimes d^k}{\langle d^k, s^k \rangle_U} - \frac{H^k s^k \otimes H^k s^k}{\langle H^k s^k, s^k \rangle_U}$,
   - (vi) *set* $k = k + 1$.

Note that the BFGS algorithm requires no more system solves than the gradient algorithm applied to (2.1), which is one forward solution of the nonlinear equation to obtain $y(u^k)$ and one backward solve of the linearized equation (3.7) to obtain the adjoint variable $\lambda(u^k)$.

In order to compare Newton's method to the SQP method derived in the next section, we rewrite the update step 2(i) in Algorithm 4.1. To begin with, we observe that the right-hand side in the update step can be written with the help of the adjoint variable λ from (3.5) and the operator $T(x)$ defined in (3.10) as

$$-\hat{J}_u(u) = -J_u(x) - e_u^*(x)\lambda = -T^*(x) \begin{bmatrix} 0 \\ J_u(x) + e_u^*(x)\lambda \end{bmatrix}, \tag{4.1}$$

where we dropped the iteration indices. As a consequence, with $\delta y = y'(u)\delta u$ from (3.3), the update can be written as

$$T^*(x) L_{xx}(x, \lambda) \begin{bmatrix} \delta y \\ \delta u \end{bmatrix} = -T^*(x) \begin{bmatrix} 0 \\ J_u(x) + e_u^*(x)\lambda \end{bmatrix} \tag{4.2}$$

so that

$$L_{xx}(x, \lambda) \begin{bmatrix} \delta y \\ \delta u \end{bmatrix} + \begin{bmatrix} 0 \\ J_u(x) + e_u^*(x)\lambda \end{bmatrix} \in \mathcal{N}(T^*(x))$$

holds. Since $e_x(x) \in \mathcal{L}(X, Z^*)$ and $\mathcal{N}(e_x(x)) = \mathcal{R}(T) \subseteq X$, it follows that $\mathcal{R}(T)$ is closed, and we have the sequence of identities

$$\mathcal{N}(T^*(x)) = \mathcal{R}(T(x))^\perp = \mathcal{N}(e_x(x))^\perp = \mathcal{R}(e_x^*(x)).$$

Thus there exists $\delta\lambda \in Z$ such that

$$-e_x^*(x)\delta\lambda = L_{xx}(x,\lambda) \begin{bmatrix} \delta y \\ \delta u \end{bmatrix} + \begin{bmatrix} 0 \\ J_u(x) + e_u^*(x)\lambda \end{bmatrix}.$$

Using this equation together with the definition of δy, we may rewrite Newton's update as

$$\begin{bmatrix} L_{xx}(x^k,\lambda^k) & e_{x^*}(x^k) \\ e_x(x^k) & 0 \end{bmatrix} \begin{bmatrix} \delta y \\ \delta u \\ \delta\lambda \end{bmatrix} = - \begin{bmatrix} 0 \\ J_u(x) + e_u^*(x)\lambda \\ 0 \end{bmatrix}. \tag{4.3}$$

4.2. Basic SQP method. Here we regard (2.1) as a minimization problem of the functional J over the space X subject to the explicit constraint $e(x) = 0$. The basic SQP algorithm consists in applying Newton's method to the first order optimality system

$$\begin{aligned} L_x(x,\lambda) &= 0 \quad \text{in } X^*, \\ L_\lambda(x,\lambda) &= 0 \quad \text{in } Z^*, \end{aligned} \tag{4.4}$$

where the Lagrangian L is defined in (3.9).

With x^* denoting a solution to problem (P), $e_x(x^*)$ is surjective by Proposition 3.3, and hence there exists a Lagrange multiplier $\lambda^* \in Z$, which is even unique such that (4.4) holds. The SQP method will be well defined and locally second order convergent if in addition to the surjectivity of $e_x(x^*)$ the following second order optimality condition holds.

(H1) There exists $\alpha > 0$ such that
$\langle L_{xx}(x^*,\lambda^*)x, x\rangle_{X^*,X} \geq \alpha\,|x|_X^2$ for all $x \in \ker(e_x(x^*))$.

If (H1) holds, then, due to the regularity properties of e, there exists a neighborhood $B((x^*,\lambda^*))$ such that $L_{xx}(x,\lambda)$ is uniformly positive definite on $\ker(e_x(x))$ for every $x \in B((x^*,\lambda^*))$.

ALGORITHM 4.3 (SQP algorithm).

1. *Choose* $(x^0,\lambda^0) \in B((x^*,\lambda^*))$, *set* $k = 0$.
2. *Do until convergence:*
   (i) *solve*

$$\begin{pmatrix} L_{xx}(x^k,\lambda^k) & e_x^*(x^k) \\ e_x(x^k) & 0 \end{pmatrix} \begin{pmatrix} \delta x^k \\ \delta\lambda^k \end{pmatrix} = - \begin{pmatrix} J_x(x^k) & + e_x^*(x^k)\lambda^k \\ & e(x^k) \end{pmatrix}, \tag{4.5}$$

   (ii) *update* $(x^{k+1},\lambda^{k+1}) = (x^k,\lambda^k) + (\delta x^k, \delta\lambda^k)$,
   (iii) *set* $k = k+1$.

Just as for Newton's method, step 2(i) is the difficult one. While in contrast to Newton's method, neither the Navier–Stokes equation nor its linearization needs to be solved; the dimension of the system matrix which is twice the dimension of the state plus the dimension of the control space is formidable for applications in fluid

mechanics. In addition, from experience with Algorithm 4.3 for other optimal control problems (see [KA, V], for example) it is well known that preconditioning techniques must be applied to solve (4.5) efficiently. As a preconditioner one might consider the (action of the) operator $P\colon X^* \times Z^* \to X \times Z$ given by

$$P = \begin{bmatrix} 0 & 0 & R \\ 0 & J_{uu}(x^k)^{-1} & 0 \\ R^* & 0 & 0 \end{bmatrix},$$

where $R\colon Z^* \to H$ is the inverse to the (discretized) instationary Stokes operator or the (discretized) linearization of the Navier–Stokes equation at the state y^k, either one with homogenous boundary conditions.

One iteration of the preconditioned version of Algorithm 4.3 therefore requires two linear parabolic solves, one forward and one backward in time. As a consequence, even with the application of preconditioning techniques, the numerical expense counted in number of parabolic system solves is less for the SQP method than for Newton's method. However, the number of iterations of iterative methods applied to solve the system equations in Algorithms 4.1 and 4.3 strongly depends on the system dimension, which is much larger for Algorithm 4.3 than for Algorithm 4.1.

To further compare the structure of the Newton and the SQP methods, let us assume, for an instance, that x^k is feasible for the primal equation, i.e., $e(x^k) = 0$ and (x^k, λ^k) is feasible for the adjoint equation (3.5), i.e., $e_y^*(x^k)\lambda^k = -J_y(x^k)$. Then the right-hand side of (4.5) has the form $-[0, J_u(x^k) + e_u^*\lambda^k, 0]^t$, and comparing this to the computation at the end of section 4.1, we observe that the linear systems describing the Newton and the SQP methods coincide. In general, the nonlinear primal and the linearized adjoint equation will not be satisfied by the iterates of the SQP method, and we therefore refer to the SQP method as an outer or unfeasible method, while the Newton method is a feasible one.

4.3. Reduced SQP method. The idea of the reduced SQP method is to replace (4.5) with an equation in $\ker e_x(x)$ so that the reduced system is of smaller dimension than the original one. To develop the reduced system, we follow the lines of [KS]. Recall the definition of $T(x)\colon U \to X$, and define $A(x)\colon Z^* \to X$ by

$$A(x) = \begin{pmatrix} e_y^{-1}(x) \\ 0 \end{pmatrix}. \tag{4.6}$$

Note that A is a right-inverse to $e_x(x)$. In fact, we have

(i) $\ker e_x(x) = \mathcal{R}(T(x)) = \{\begin{pmatrix} -e_y^{-1}(x)e_u(x)v \\ v \end{pmatrix}\colon v \in U\}$,
(ii) $e_x(x)T(x) = 0$ in Z^*,
(iii) $e_x(x)A(x) = I_{Z^*}$.

By Proposition 3.3 and due to $B \in \mathcal{L}(U, L^2(V^*))$, the operator $T(x)$ is an isomorphism from U to $\ker e_x(x)$, and hence the second equality in (4.5) given by

$$e_x(x)\delta x = -e(x)$$

can be expressed as

$$\delta x = T(x)\delta u - A(x)e(x). \tag{4.7}$$

Using this in the first equality of (4.5), we find

$$L_{xx}(x,\lambda)T(x)\delta u - L_{xx}(x,\lambda)A(x)e(x) + e_x^*(x)\delta\lambda = -(J_x(x) + e_x^*(x)\lambda).$$

Applying $T^*(x)$ to this last equation and (ii) from above implies that if δu is a solution coordinate of (4.5), then it also satisfies

$$T^*(x)L_{xx}(x,\lambda)T(x)\delta u = T^*(x)L_{xx}(x,\lambda)A(x)e(x) - T^*(x)J_x(x). \tag{4.8}$$

Once δu is computed from (4.8), then δy and $\delta\lambda$ can be obtained from (4.7) (which requires one forward linear parabolic solve) and the first equation in (4.5) (another backwards linear parabolic solve).

Let us note that if x is feasible, then the first term on the right-hand side of (4.8) is zero and (4.8) is identical to step 2(i) in Newton's algorithm (Algorithm 4.1).

This again reflects the fact that Newton's method can be viewed as an SQP method that obeys the feasibility constraint $e(x) = 0$. It also points at the fact that the amount of work (measured in equation solves) for the inner loop coincides for both the Newton and the reduced SQP methods. The significant difference between the two methods lies in the outer iteration. To make this evident we next specify the reduced SQP algorithm.

ALGORITHM 4.4 (reduced SQP algorithm).

1. *Choose* $x^0 \in B(x^*)$, *set* $k = 0$.
2. *Do until convergence:*
   (i) *Lagrange multiplier update: solve*
   $$e_y^*(x^k)\lambda^k = -J_y(x^k),$$
   (ii) *solve*
   $$\alpha)\ T^*(x^k)L_{xx}(x^k,\lambda^k)T(x^k)\delta u^k = T^*(x^k)L_{xx}(x^k,\lambda^k)A(x^k)e(x^k) - T^*(x^k)J_x(x^k)$$
   $$\beta)\ e_y(x^k)\delta y^k = -e(x^k) - e_u(x^k)\delta u^k,$$
   (iii) *update*
   $$x^{k+1} = x^k + (\delta y^k, \delta u^k),$$
   (iv) *set* $k = k + 1$.

Note that in the algorithm that we specified we did not follow the procedure outlined above for the update of the Lagrange variable. In fact, for reduced SQP methods there is no "optimal" update strategy for λ. The two choices described above are natural and frequently used. To implement Algorithm 4.4 two linear parabolic systems have to be solved in steps 2(i) and 2(ii)β) and, in addition, two linear parabolic systems are necessary to evaluate the term involving the operator A on the right-hand side of 2(ii)α). In applications this term is often neglected since it vanishes at x^*.

The reduced SQP method and Newton's method turn out to be very similar. Let us discuss the points in which they differ:

(i) Most significantly, the velocity field is updated by means of the nonlinear equation in Newton's method and via the linearized equation in the reduced SQP method.

(ii) The right-hand sides of the linear systems differ due to the appearance of the term involving the operator A. As mentioned above, this term is frequently not implemented.

(iii) Formally there is a difference in the initialization procedure in that y^0 is chosen independently from u^0 in the reduced SQP method and $y^0 = y(u^0)$ in Newton's method. However, as explained in section 4.1 above, if a good initial guess y^0 independent from $y(u^0)$ is available, it can be utilized in Newton's method as well.

5. Convergence analysis. We present local convergence results for the algorithms introduced in section 4 for cost functionals J which are of separable type; i.e., (H0) 4 is satisfied. For this purpose it will be essential to derive conditions that ensure positive definiteness of $\hat{J}''(u^*)$ and (H1). The key to these conditions are the a priori estimates of Proposition 2.4. We shall also prove that the difference $\hat{J}''(u^*) - J_{uu}(x^*)$ is compact. This property is required for the rate of convergence analysis of quasi-Newton methods. In our first result we assert positive definiteness of the Hessian provided that $J_y(x)$ is sufficiently small, a condition which is applicable to tracking-type problems.

LEMMA 5.1 (positive definiteness of the Hessian). *Let $u \in U$, and assume that $J_{yy}(x) \in \mathcal{L}(L^2(V), L^2(V^*))$ is positive semidefinite and $J_{uu}(x) \in \mathcal{L}(U)$ is positive definite, where $x = (y(u), u)$. Then the Hessian $\hat{J}''(u)$ is positive definite provided that $|J_y(x)|_{L^2(V^*)}$ is sufficiently small.*

Proof. We recall from (3.11) that

$$\hat{J}''(u) = T^*(x) L_{xx}(x, \lambda) T(x),$$

where $x = (y(u), u)$ and $\lambda = \lambda(x)$ is the solution to (3.7). It follows that

$$\begin{aligned} \hat{J}''(u) = {} & e_u^*(x) e_y^{-*}(x) J_{yy}(x) e_y^{-1}(x) e_u(x) \\ & + e_u^*(x) e_y^{-*}(x) \langle e_{yy}^1(x)(e_y^{-1}(x) e_u(x), \cdot), \lambda^1(x) \rangle + J_{uu}(x). \end{aligned} \tag{5.1}$$

Here we note that for $\delta u \in U$ the functional

$$w \mapsto \langle e_{yy}(x)(e_y^{-1}(x) e_u(x) \delta u, w), \lambda^1 \rangle$$

is an element of W^*. Since $J_{yy}(x)$ is assumed to be positive definite and $J_{uu}(x)$ is positive definite, the result will follow provided the operator norm of

$$\mathcal{R} := e_u^*(x) e_y^{-*}(x) \langle e_{yy}^1(x)(e_y^{-1}(x) e_u(x), \cdot), \lambda^1(x) \rangle \ \in \mathcal{L}(U) \tag{5.2}$$

can be bounded by $|J_y(x)|_{L^2(V^*)}$. Straightforward estimation gives

$$\begin{aligned} \|\mathcal{R}\|_{\mathcal{L}(U)} \ &\leq \ \|e_u^*(x) e_y^{-*}(x)\|_{\mathcal{L}(W^*, U)} \\ &\quad \|\langle e_{yy}^1(x)(\cdot, \cdot), \lambda^1(x) \rangle\|_{\mathcal{L}(W, W^*)} \, \|e_y^{-1}(x) e_u(x)\|_{\mathcal{L}(U, W)} \\ &= \ \|e_y^{-1}(x) e_u(x)\|_{\mathcal{L}(U,W)}^2 \, \|\langle e_{yy}^1(x)(\cdot, \cdot), \lambda^1(x) \rangle\|_{\mathcal{L}(W, W^*)}. \end{aligned} \tag{5.3}$$

From Proposition 2.4 we conclude that

$$\|e_y^{-1}(x) e_u(x)\|_{\mathcal{L}(U,W)} \ \leq \ C(|y|_{L^2(V)}, |y|_{L^\infty(H)}, \|B\|_{\mathcal{L}(U, L^2(V^*))}).$$

To estimate $\|\langle e_{yy}^1(x)(\cdot, \cdot), \lambda^1(x) \rangle\|_{\mathcal{L}(W, W^*)}$ we recall that for $g, h \in W$

$$\langle e_{yy}^1(x)(g, h), \lambda^1(x) \rangle \ = \ \int_0^T \int_\Omega (g \cdot \nabla) h \lambda^1 \ + \ (h \cdot \nabla) g \lambda^1 \, dx dt.$$

Using (3.2) and the continuity of the embedding $W \hookrightarrow L^\infty(H)$, we may estimate

$$|\langle e_{yy}^1(x)(g, h), \lambda^1(x) \rangle| \ \leq \ C \, |g|_W |h|_W \, |\lambda^1|_{L^2(V)},$$

with a constant C independent of g and h. Therefore,

$$\|\mathcal{R}\|_{\mathcal{L}(U)} \;\le\; C(|y|_{L^2(V)}, |y|_{L^\infty(H)}, \|B\|_{\mathcal{L}(U,L^2(V^*))})\,|\lambda^1|_{L^2(V)} \\ \le C(|y|_{L^2(V)}, |y|_{L^\infty(H)}, \|B\|_{\mathcal{L}(U,L^2(V^*))})\,|J_y(x)|_{L^2(V^*)},$$

where we applied (iii) in Proposition 2.4 to (3.7). □

LEMMA 5.2. *Let $x \in X$, and denote by $\lambda = \lambda(x) \in Z$ the function defined in* (3.5). *Then, under the assumptions of Lemma* 5.1 *on J condition,* (H1) *is satisfied with (x^*, λ^*) replaced by (x, λ).*

Proof. Let $(v, u) \in \mathcal{N}(e_x(x))$. Then v solves (2.4) with $v_0 = 0$ and $f = Bu$. Due to Proposition 2.3, $v \in W$ and satisfies

$$|v|_W \;\le\; C(|y|_{L^2(V)}), |y|_{L^\infty(H)}, \|B\|_{\mathcal{L}(U,L^2(V^*))})\,|u|_U. \tag{5.4}$$

Let $\delta > 0$ be chosen such that $J_{uu}(x)(u,u) \ge \delta|u|_U^2$ for all $u \in U$. We find

$$\langle L_{xx}(x,\lambda)(v,u),(v,u)\rangle_{X^*,X} = J_{yy}(x)(v,v) + \langle e^1_{yy}(x)(v,v),\lambda^1\rangle + J_{uu}(x)(u,u) \\ \ge\; \delta\,|u|_U^2 - 2\sqrt{2}\int_0^T |v|_H|v|_V|\lambda^1|_V\,dt \;\ge\; \delta\,|u|_U^2 - C|u|_U^2\,|\lambda^1|_{L^2(V)}.$$

Here and below, C denotes a generic constant independent of (v,u), and $\lambda = \lambda(x)$. Due to (3.5) and Proposition 2.4

$$|\lambda|_{L^2(V)} \;\le\; C\,|J_y(x)|_{L^2(V^*)}.$$

These estimates imply

$$\langle L_{xx}(x,\lambda)(v,u),(v,u)\rangle_{X^*,X} \;\ge\; \big(\delta - C|J_y(x)|_{L^2(V^*)}\big)\,|u|_U^2,$$

and combined with (5.4) the claim follows. □

LEMMA 5.3. *If $B \in \mathcal{L}(U, L^2(H))$, then the difference*

$$\hat{J}''(u) - J_{uu}(x)$$

is compact for every $u \in U$.

Proof. Utilizing (5.2), we may rewrite

$$\hat{J}''(u) - J_{uu}(x) = e_u^*(x)e_y^{-*}(x)J_{yy}(x)e_y^{-1}(x)e_u(x) \,+\, \mathcal{R}, \tag{5.5}$$

where $x = (y(u), u)$. It will be shown that both summands define compact operators on U. For this purpose let $\mathcal{U}$ be a bounded subset of U. Utilizing $B \in \mathcal{L}(U, L^2(H)) \subset \mathcal{L}(U, L^2(V^*))$ and Proposition 2.4, we conclude that

$$S = \{e_y^{-1}(x)e_u(x)\delta u : \delta u \in \mathcal{U}\}$$

is a bounded subset of W and hence of $L^2(V)$. Since by assumption J is twice continuously Fréchet differentiable with respect to y from $L^2(V)$ to $\mathbb{R}$, it follows that $J_{yy}(S)$ is a bounded subset of $L^2(V^*)$. Proposition 2.4(iii) implies that, consequently, $e_y^{-*}(J_{yy}(S))$ is bounded in $W^2_{4/3} \times H$, where $W^2_{4/3} := \{v \in L^2(V) : v_t \in L^{4/3}(V^*)\}$. Since $W^2_{4/3}$ is compactly embedded in $L^2(H)$ [CF] and $B \in \mathcal{L}(U, L^2(H))$, it follows from the fact that $e_u^*(x)(z^1, z^0) = -B^*z^1$ for $z = (z^1, z^0) \in L^2(V) \times H$ that

$$\{e_u^*(x)e_y^{-*}(x)J_{yy}(x)(z) : z \in S\} \tag{5.6}$$

is precompact in U.

Let us turn to the second addend in (5.5). Due to Lemma 3.2 and its proof, the set

$$\{\langle e^1_{yy}(x)(z,\cdot),\lambda^1\rangle : z \in S\}$$

is a bounded subset of $W^* \cap L^{4/3}(V^*)$. It follows, utilizing Proposition 2.4, that

$$\{e_y^{-*}(x)\langle e^1_{yy}(x)(z,\cdot),\lambda^1\rangle : z \in S\}$$

is a bounded subset of $W^2_{4/3} \times H$. As above, the assumption that $B \in \mathcal{L}(U, L^2(H))$ implies that

$$\{e_u^*(x)e_y^{-*}(x)\langle e^1_{yy}(x)(z,\cdot),\lambda^1\rangle; z \in S\}$$

is precompact in U, and the lemma is verified. □

The following lemma concerning the operators $T(x)$ and $A(x)$ defined in (3.10) and (4.6) will be required for the analysis of the reduced SQP method.

LEMMA 5.4. *The mappings $x \mapsto A(x)$ from X to $\mathcal{L}(Z^*, X)$ and $x \mapsto T(x)$ from X to $\mathcal{L}(U, X)$ are Fréchet differentiable with Lipschitz continuous derivatives.*

Proof. The proof is an immediate consequence of (i), (ii) in Proposition 2.4 and the identities (ii) and (iii) in section (4.3) together with the differentiability properties of the mapping $x \mapsto e_x(x)$. □

We are now in the position to prove local convergence for the algorithms discussed in section 4. Throughout we assume that (y^*, u^*) is a local solution to (2.1) and set $y^* = y(u^*)$, $x^* = (y^*, u^*)$. In addition to the general conditions on J, B, and e, we require

(H2) $J_{yy}(x^*) \in \mathcal{L}(L^2(V), L^2(V^*))$ is positive semidefinite, $J_{uu}(x^*) \in \mathcal{L}(U)$ is positive definite, and $|J_y(x^*)|_{L^2(V^*)}$ is sufficiently small.

With (H2) holding, (H1) is satisfied due to Lemma 5.1. In particular, a second order sufficient optimality condition holds, and (y^*, u^*) is a strict local solution to (2.1). The following theorem follows from well-known results on Newton's algorithm.

THEOREM 5.5. *If* (H2) *holds, then there exists a neighborhood $\mathcal{U}(u^*)$ such that for every $u^0 \in \mathcal{U}(u^*)$ the iterates $\{u^n\}_{n\in\mathbb{N}}$ of Newton's algorithm (Algorithm* 4.1*) converge quadratically to u^*.*

THEOREM 5.6. *If* (H2) *holds, then there exists a neighborhood $\mathcal{U}(u^*)$ and $\epsilon > 0$ such that for all $u^0 \in \mathcal{U}(u^*)$ and all positive definite operators $H^0 \in L(U)$ with*

$$|H^0 - \hat{J}''(u^*)|_{\mathcal{L}(U)} < \epsilon,$$

the BFGS method of Algorithm 4.2 *converges linearly to u^*. If in addition $B \in \mathcal{L}(U, L^2(H))$ and $H^0 := J_{uu}(x^*)$, then the convergence is superlinear.*

Proof. For the first part of the theorem we refer to [GR, section 4], for example. For the second claim we observe that the difference $\hat{J}''(u^*) - J_{uu}(x^*)$ is compact by Lemma 5.3 so that the claim follows from [GR, Theorem 5.1]; see also [KS1]. □

THEOREM 5.7. *Assume that* (H2) *holds, and let λ^* be the Lagrange multiplier associated to x^*. Then there exists a neighborhood $\mathcal{U}(x^*, \lambda^*) \subset X \times Z$ such that for*

all $(x^0, \lambda^0) \in \mathcal{U}(x^*, \lambda^*)$ *the SQP algorithm (Algorithm* 4.3*) is well defined, and the iterates* $\{(x^n, \lambda^n)\}_{n\in\mathbb{N}}$ *converge quadratically to* (x^*, λ^*).

Proof. Since J and e are twice continuously differentiable with Lipschitz continuous second derivative, $e_x(x^*)$ is surjective by Proposition 3.3, and (H1) is satisfied, second order convergence of the SQP method follows from standard results; see, for instance, [IK]. ∎

We now turn to the reduced SQP method.

THEOREM 5.8. *Assume that* (H1) *holds, and let* λ^* *denote the Lagrange multiplier associated to* x^*. *Then there exists a neighborhood* $\mathcal{U}(x^*) \subset X$ *such that for all* $x^0 \in \mathcal{U}(x^*)$ *the reduced SQP algorithm (Algorithm* 4.4*) is well defined, and its iterates* $\{x^k\}_{k\in\mathbb{N}}$ *converge two-step quadratically to* x^*, *i.e.,*

$$|x^{k+1} - x^*|_X \;\leq\; C\,|x^{k-1} - x^*|_X^2$$

for some positive constant C *independent of* $k \in \mathbb{N}$.

Proof. First note that (H1) implies positive definiteness of $T(x^*)^* L_{xx}(x^*, \lambda^*) T(x^*)$ in a neighborhood $\tilde{\mathcal{U}}(x^*)$ of x^*. By Lemma 5.4 the mappings $x \mapsto T(x)$ and $x \mapsto A(x)$ are Fréchet differentiable with Lipschitz continuous derivatives. Furthermore, it can be shown that the mapping $x \mapsto \lambda(x)$ is locally Lipschitz continuous, where λ is defined through (3.5) [HH, Lemma 4.5.2]. This, in particular, implies for the Lagrange multiplier updates λ^k the estimate

$$|\lambda^k - \lambda|_Z \;\leq\; C\,|x^k - x^*|_X, \quad x^k \in \tilde{\mathcal{U}}(x^*),$$

where the constant C is positive and depends on x^* and on $\sup\{|J_{yy}(x)|_{\mathcal{L}(L^2(V),L^2(V^*)};\ x \in \tilde{\mathcal{U}}(x^*)\}$. Altogether, the assumptions for Corollary 3.6 in [K] are met, and there exists a neighborhood $\hat{\mathcal{U}}(x^*)$ such that for all $x^0 \in \mathcal{U}(x^*) := \hat{\mathcal{U}}(x^*) \cap \tilde{\mathcal{U}}(x^*)$ the claim follows. ∎

6. Numerical results. Here we present a numerical example that should first demonstrate the feasibility of utilizing Newton's method for optimal control of the two-dimensional instationary Navier–Stokes equations in a workstation environment despite the formidable size of the optimization problem. The total number of unknowns (primal, adjoint, and control variables) in example 1 below, for instance, is of order $2.2{*}10^6$. The time horizon could still be increased or the mesh size decreased by utilizing reduced storage techniques at the expense of additional cpu time, but we shall not pursue this aspect here. The control problem is given by (1.1), (1.2) with cost function J defined by

$$J(y,u) := \frac{1}{2}\int_{Q_o} |y - z|^2\,dxdt + \frac{\alpha}{2}\int_{Q_c} |u|^2\,dxdt, \tag{6.1}$$

where $Q_c := \Omega_c \times (0,T)$ and $Q_o := \Omega_o \times (0,T)$, with Ω_c and Ω_o subsets of $\Omega = (0,1)^2$ denoting the control and observation volumes, respectively. In our example, $T = 1$, $U := L^2(Q_c)$, $\nu = \frac{1}{\mathrm{Re}} = 400$, and B is the indicator function of Q_c. The results for Newton's method will be compared to those of the gradient algorithm, which we recall here for the sake of convenience.

ALGORITHM 6.1 (gradient algorithm).

1. *Set* $k = 0$ *and choose* u^0,
2. *set* $d := -\hat{J}'(u^k)$ *and compute*

$$\rho^* = \arg\min_{\rho>0} I(\rho) := \hat{J}(u^k + \rho d),$$

3. *set*

$$u^{k+1} = u^k + \rho^* d,$$

4. *set* $k = k + 1$ *and goto* 2.

Given a control u, the evaluation of the gradient of J at a point u amounts to solving (1.2) for the state y and (3.7) for the adjoint variable λ. Implementing a stepsize rule to determine an approximation of ρ^* is numerically expensive as every evaluation of the functional J at a control u requires solving the instationary Navier–Stokes equations with right-hand side Bu.

In the numerical example presented below, we use the following procedure to compute an approximation to the step size ρ^*. For a given search direction $d \in U$ we insert the linearization of the mapping $\rho \mapsto y(u + \rho d)$ at $\rho = 0$,

$$y(u + \rho d) \doteq y(u) + \rho y'(u)d,$$

into the cost functional J. This results in the quadratic approximation

$$I_1(\rho) := J(y(u) + \rho y'(u)d, u + \rho d)$$

of the functional $I(\rho)$. Now we use the unique root

$$\rho_1^* = \frac{-\langle \hat{J}'(u), d\rangle_U}{\alpha |d|_U^2 + |v|^2_{L^2(Q_o)}} \tag{6.2}$$

of the equation $I_1'(\rho) = 0$ as approximation of ρ^*, with v given by (2.4) with $f = Bd$ and $v_0 = 0$.

Altogether, every iteration of the gradient algorithm amounts to solving the nonlinear Navier–Stokes equations forward in time and the associated adjoint equations backward in time for the computation of the gradient, and to solving linearized Navier–Stokes equations forward in time for the step size proposal. For a detailed discussion of step size rules for the gradient algorithm, see [HH, Algorithm 4.7.1].

The inner iteration of Newton's method is performed by the conjugate gradient method, the choice of which is justified in a neighborhood of a local solution u^* of the optimal control problem by the positive definiteness of $\hat{J}''(u^*)$, provided the desired state z is sufficiently close to the optimal state $y(u^*)$.

For the numerical tests the target flow z is given by the Stokes flow with boundary condition $z_1 = 1$ in tangential direction (Figure 6.1), and the uncontrolled flow is the Navier–Stokes flow at Re=400 with the same boundary values as z; see Figure 6.3, top left. The termination criterion for the jth iterate u_j^k in the conjugate gradient method is chosen as

$$\frac{|\hat{J}''(u^k)\delta u_j^k + \hat{J}'(u^k)|}{|\hat{J}'(u^0)|} \le \min\left\{ \left(\frac{|\hat{J}'(u^k)|}{|\hat{J}'(u^0)|} \right)^{\frac{3}{2}}, 10^{-2} \frac{|\hat{J}'(u^k)|}{|\hat{J}'(u^0)|} \right\} \text{ or } j \ge 50.$$

The initialization for Newton's method was $u^0 := 0$.

The discretization of the Navier–Stokes equations, its linearization and adjoint, was carried out by using parts of the code developed by Bänsch in [BA], which is based on Taylor–Hood finite elements for spatial discretization. As time step size we took $\delta t = .00625$, which resulted in 160 grid points for the time grid and 545 pressure and

2113 velocity nodes for the spatial discretization. All computations were performed on a DEC-ALPHA^{TM}station 500.

We now present the results for $\Omega_c = \Omega_o = (0,1)^2$ and $\alpha = 10^{-2}$. Table 6.1 confirms superlinear convergence of the inexact Newton method. To achieve the same accuracy as Newton's method the gradient algorithm requires 96 iterations. The computing time with Newton's method is approximately 45 minutes, whereas the gradient method requires 110 minutes. This demonstrates the superiority of Newton's method over the gradient algorithm for this example. For larger values of α and coarser time and space grids the difference in computing time is less drastic. In fact, this difference increases with decreasing α and increasing mesh refinement. As expected, a significant amount of computing time is spent for read-write actions of the variables to the hard disc in the subproblems.

In Figure 6.2 the evolution of the cost functional is documented. It can be observed that Newton's method (left) tends to overestimate the control in the first iteration step, whereas the gradient algorithm (right) approximates the optimal control from below. Graphically there is no significant change after the second iteration for Newton's method. These comments hold for quite a wide range of values for α.

In Figure 6.3 a snapshot of the uncontrolled flow at $t = 1$ together with a snapshot of the control action at t=0.75 and two zooms are presented. As one can see, two major vortices develop; the one in the upper left corner (Figure 6.3, bottom left) is responsible for tearing back the vortex of the uncontrolled flow (Figure 6.3, top left), while the second control vortex (Figure 6.3, bottom right) pushes back this vortex towards the vortex of the target flow (Figure 6.1). The controlled flow at t=1 is optically nearly indistinguishable from the target flow.

In this example the observation volume Ω_o and the control volume Ω_c each cover

the whole spatial domain. From the practical point of view this is not feasible. However, from the numerical standpoint this is a complicated situation, since the inhomogeneities in the primal and adjoint equations are large. Further numerical examples with different observation and control domains can be found in [HH, Chapter 4.7].

GENERAL ORTHONORMAL BASES FOR ROBUST IDENTIFICATION IN H_∞*

HÜSEYIN AKÇAY†

Abstract. In this paper, the problem of system identification in H_∞ with general orthonormal basis functions is investigated. A two-stage algorithm is shown to be robust, provided that the number of basis elements as a function of the amount of data does not increase faster than $O(N^{\frac{2}{5}})$. Worst-case identification error bounds in the H_∞ norm are derived. The algorithm also works on nonuniformly spaced frequency response measurements. An example is provided to illustrate the application of the algorithm.

Key words. robust identification, orthonormal basis functions, H_∞

1. Introduction.

Consider a linear-time-invariant, single-input/single-output, discrete-time system with impulse response $g(k)$. It is assumed that this system is ℓ_2 bounded-input/bounded-output stable so that the associated power-series representation

$$G(z) = \sum_{k=0}^{\infty} g(k) z^k \tag{1.1}$$

lies in $H_\infty(\mathbf{D})$. *Note that the definition of the z-transform is such that the stability corresponds to having no poles in the closed unit disk.* Here $H_\infty(\mathbf{D})$ denotes the space of bounded analytic functions in the open unit disk $\mathbf{D}$. Let $C(\mathbf{T})$ denote the set of continuous functions on $\mathbf{T}$, the unit circle, and let $A(\mathbf{D}) = H_\infty(\mathbf{D}) \cap C(\mathbf{T})$. We further require $G \in A(\mathbf{D})$. In the series expansion, we have employed a set of orthonormal functions $1, z, z^2, \ldots$, where orthogonality is with respect to the inner product

$$\langle f, g \rangle \triangleq \frac{1}{2\pi} \int_0^{2\pi} f(e^{i\omega})\ \overline{g(e^{i\omega})}\, d\omega.$$

Although power-series representation or *finite-impulse response* modelling is suitable for most applications, it fails to be successful when the number of basis coefficients to be estimated from the data becomes very large, especially in the modelling of large flexible structures. This increase in parameter dimension to maintain a certain level of accuracy over a broad range of transfer functions is a drawback of finite-impulse response models in robust controller design. Alternatively, we can write (1.1) in a generalized form as

$$G(z) = \sum_{k=0}^{\infty} a_k B_k(z), \tag{1.2}$$

where $\{B_0, B_1, B_2, \ldots\}$ is an orthonormal set of rational basis functions in $H_2(\mathbf{D})$. Here $L_2(\mathbf{T})$ is the space of square integrable functions on $\mathbf{T}$, and $H_2(\mathbf{D})$ denotes its intersection with the set of analytic functions on $\mathbf{D}$. The choice of basis poles reflects the desire to adapt basis functions to the specific properties of the system. With appropriately chosen basis poles, the convergence rate of the series expansion in (1.2) can be very fast, and hence the number of basis coefficients to be estimated can become very small.

The undermodelling-induced component of the estimation error can be reduced significantly in comparison to the use of a finite-impulse response model structure in (1.1) by employing the well-known *Laguerre* and *Kautz* bases [22, 21]. The use of the Laguerre and Kautz bases for approximation and identification of linear time-invariant dynamics has been investigated in [17, 30, 24, 32, 40, 14, 41, 42, 12]. More recently, in [43, 44] the *rational wavelet* bases have been suggested to robustly estimate linear-time-invariant infinite-dimensional dynamics.

Recently, in [19, 38, 39], the general orthonormal basis functions, which generalize the Laguerre and Kautz bases and to some extent incorporate the dynamics of the underlying system, were introduced and used in a Hilbert-space setting, mostly for time-domain identification. These basis functions are obtained from the rational orthonormal basis functions considered in detail in [28, 29, 2, 4], which are defined by a choice of numbers $z_k \in \mathbf{D}$, $k = 0, 1, \ldots$, as

$$B_k(z) \triangleq \frac{\sqrt{1-|z_k|^2}}{1-\overline{z_k}\,z}\,\psi_k(z), \qquad \psi_k(z) \triangleq \prod_{j=0}^{k-1} \frac{z-z_j}{1-\overline{z_j}\,z}, \quad \psi_0(z) \triangleq 1, \tag{1.3}$$

with the restriction

$$z_{j+nm} = z_j, \qquad j = 1, 2, \ldots, n, \quad m = 1, 2, \ldots, \tag{1.4}$$

where n is a fixed number, $z_0 = 0$, and $1/\overline{z_1}, \ldots, 1/\overline{z_n}$ denote the chosen basis poles in complex conjugate pairs. The general orthonormal basis functions are constructed from an initial set of orthonormal functions by repeated multiplication of an all-pass function that acts as a generalized shift. The rational orthonormal basis functions in (1.3) are *complete* in the spaces $H_p(\mathbf{D})$ $(1 \le p < \infty)$ and $A(\mathbf{D})$ if and only if $\sum_{k=1}^{\infty}(1-|z_k|) = \infty$ [2].

In a series of papers [2, 3, 4, 7, 10, 9], completeness, approximation, and identification properties of the basis functions defined by (1.3) and their continuous-time versions have been investigated. In particular, it was established in [2] that by using a min-max criterion, provided that the basis functions are complete and the model order increases at most linearly with the amount of data, these bases lead to robust estimators for which error bounds in the H_∞ norm can be explicitly quantified. The purpose of the current paper is to establish a similar robust estimation result for the general orthonormal basis functions defined by (1.3)–(1.4), using a two-stage scheme which first appeared in [18].

In this paper, we will consider the problem of system identification in H_∞ initiated by [18] in the general orthonormal basis set-up. The system identification with H_∞ criterion has received a growing interest since the appearance of the H_∞ formulation of robust control [46, 18, 16, 34, 25, 27, 15, 6]. Given N noise-corrupted samples of the frequency response function

$$e_k = G(e^{i\omega_k}) + \nu_k, \qquad k = 1, \ldots, N, \tag{1.5}$$

at the frequencies $\omega_k \in [0, 2\pi)$, $k = 1, \ldots, N$, where ν is the frequency response measurement noise bounded in amplitude by ε, the objective is to find an identification algorithm which maps the data e_k, $k = 1, \ldots, N$, to an identified model $\widehat{G}_N \in A(\mathbf{D})$ such that for all $G \in A(\mathbf{D})$

$$\lim_{\substack{\varepsilon \to 0 \\ N \to \infty}} \sup_{\|\nu\|_\infty \le \varepsilon} \|\widehat{G}_N - G\|_\infty = 0. \tag{1.6}$$

An algorithm that satisfies (1.6) and does not use the prior knowledge of ε and the uncertainty set in which the system lies is called *robustly convergent*. It should be noted that the latter requirement restricts the nature of identification algorithms to be used. If this restriction is removed, a large class of nonlinear *tuned* algorithms that satisfy (1.6) exists. This problem formulation is, in a technical sense, somewhat different from the usual formulation adopted in [18]. The main difference is that in this definition we have not taken a supremum of the identification error over the set of unknown systems. This formulation is similar to the point of view taken in [25].

Several robustly convergent nonlinear algorithms have been proposed for solving this problem of system identification in H_∞ [18, 16, 25, 6]. These algorithms share a common two-stage structure. In the first stage, a (stable and unstable) finite-impulse response model is linearly estimated from the frequency response data. In the second stage, the identified model is obtained by solving a Nehari problem. We will also adapt the same two-stage strategy. In a very recent paper [37], Szabó, Bokor, and Schipp have obtained some general results for the same identification problem. However, our results and algorithm are *quite different from and independent of* those in [37].

In this paper, we obtain explicit worst-case identification error bounds, provided that the number of general orthonormal basis functions used for the estimation does not increase too fast with the amount of data. In comparison to the min-max algorithms in [2], worst-case error bounds are large for small amounts of data and, for a given amount of data, the number of general orthonormal basis functions that could be used for the estimation is rather restricted.

In spite of these weaknesses, a couple of distinct features of our approach deserve to be mentioned. First, due to the linearity of the first stage, the algorithm of this paper is easier to implement and analyze than the min-max algorithms. In this stage, our algorithm is also computationally more efficient. When model complexity is restricted, the second stage could be omitted since the linear estimate diverges very slowly in the worst-case. The second and most compelling reason is that frequently low complexity models are desired for the purpose of subsequent controller design, and by iteratively updating basis poles it may be possible to significantly reduce the undermodelling-induced component of the estimation error.

Now we will briefly describe the contents of this paper. In section 2, uniform approximation of complex-valued continuous functions, by the general orthonormal basis functions defined by (1.3)–(1.4) and the complementary general orthonormal functions, is studied. The basis functions spanning the orthogonal complement of $H_2(\mathbf{D})$ are defined by a choice of numbers $x_k \in \mathbf{D}$, $k = 1, 2, \ldots$, as

$$B_{-k}(z) \triangleq \frac{\sqrt{1 - |x_k|^2}}{z - x_k}\, \phi_k(z), \qquad \phi_{k-1}(z) \triangleq \prod_{j=1}^{k} \frac{1 - \overline{x_j}\, z}{z - x_j}, \quad \phi_0(z) \triangleq 1. \tag{1.7}$$

Then the complementary general orthonormal functions are obtained from (1.7) by setting

$$x_k = z_k \qquad \text{for all } k. \tag{1.8}$$

In section 3, an overdetermined system of linear equations is studied. The purpose of this section is to link the approximation results derived in section 2 to the identification problem. In section 4, the main result of this paper is presented. In section 5, an example is given to illustrate the use of the general orthonormal basis functions defined by (1.3)–(1.4) in an iterative-identification scheme. Section 6 concludes the paper.

We consider only single-input/single-output systems. This is not at all a restriction. The results extend with no modifications to multi-input/multi-output systems. They are also applicable to continuous-time systems, since the bilinear mapping

$$s \triangleq \lambda \frac{1-z}{1+z}, \qquad \lambda > 0,$$

preserves the supremum norms between the space of functions which are analytic and bounded on the upper half plane and $H_\infty(\mathbf{D})$. The details can be found in [1].

2. Approximation of continuous functions. In this section, we derive error bounds in the L_∞ norm for the approximation of continuous functions on $\mathbf{T}$ by a particular weighted Fourier series. These bounds will be used in the analysis of a proposed algorithm that solves the worst-case identification problem posed in section 1.

Let $\mathcal{S}_k f$ denote the partial sums of the Fourier series of $f \in C(\mathbf{T})$ with respect to the orthonormal system (1.3) and (1.7) defined by

$$\mathcal{S}_k f(e^{i\theta}) \triangleq \sum_{j=-k}^{k} \langle f, B_j \rangle \, B_j(e^{i\theta}). \tag{2.1}$$

The (block) Cesàro means of f is defined as

$$\mathcal{F}_m f \triangleq \frac{1}{m+1} \sum_{j=0}^{m} \mathcal{S}_{nj} f. \tag{2.2}$$

We take the (block) de la Vallée Poussin estimate of f defined by

$$\mathcal{V}_m f \triangleq 2\mathcal{F}_{2m+1} f - \mathcal{F}_m f \tag{2.3}$$

as the L_∞-approximant of f. This estimate can be written as

$$\mathcal{V}_m f = \sum_{k=-n(2m+1)}^{n(2m+1)} \chi_m(k) \, \langle f, B_k \rangle \, B_k$$

for a nonnegative symmetric window function χ_m:

$$\begin{aligned} \chi_m(k) &\triangleq 1, \quad k = 0, \ldots, n(m+1), \\ \chi_m\left(n(m+j)+k\right) &\triangleq 1 - \frac{j}{m+1}, \quad k = 1, \ldots, n, \ j = 1, \ldots, m, \\ \chi_m(k) &\triangleq 0, \quad k > n(2m+1). \end{aligned} \tag{2.4}$$

The de la Vallée Poussin estimator was introduced to the field of worst-case identification by Partington [33]. It is possible to use windows other than χ_m provided that the chosen window function satisfies certain regularity conditions. The choice of window functions is discussed in [37].

We want to show that $\mathcal{V}_m f \to f$ uniformly on $\mathbf{T}$ for all continuous functions f. To this end, we first derive a simple expression for the so-called Dirichlet kernel

$$D_{k,k'}(s,\theta) \triangleq \sum_{j=-k'}^{k} \overline{B_j(e^{is})}\, B_j(e^{i\theta}). \tag{2.5}$$

We undertake this as follows.

LEMMA 2.1. *Consider the rational basis functions defined by* (1.3) *and* (1.7). *Let* $D_{k,k'}(s,\theta)$ *be as in* (2.5). *Then*

$$D_{k,k'}(s,\theta) = e^{i\mu_{k,k'}(s,\theta)}\ \frac{\sin\left(\lambda_{k,k'}(s,\theta)\right)}{\sin\left(\frac{\theta-s}{2}\right)}, \tag{2.6}$$

where

$$\begin{aligned} \mu_{k,k'}(s,\theta) &\triangleq \frac{1}{2}\int_s^\theta \left(\sum_{j=0}^{k} |B_j(e^{iy})|^2 - 1 - \sum_{j=-k'}^{-1} |B_j(e^{iy})|^2 \right) dy, \\ \lambda_{k,k'}(s,\theta) &\triangleq \frac{1}{2}\int_s^\theta \sum_{j=-k'}^{k} |B_j(e^{iy})|^2\, dy. \end{aligned} \tag{2.7}$$

Proof. See [10]. This lemma can also be proved using the results in [36] after applying some algebra. □

The partial sums in (2.1) can be written as

$$\mathcal{S}_k f(e^{i\theta}) = \frac{1}{2\pi}\int_{\theta-\pi}^{\theta+\pi} f(e^{is})\, D_{k,k}(s,\theta)\, ds. \tag{2.8}$$

Hence

$$\|\mathcal{S}_k\| \triangleq \sup_{\|f\|_\infty \le 1} \|\mathcal{S}_k f\|_\infty = \sup_\theta \frac{1}{2\pi}\int_0^{2\pi} |D_{k,k}(s,\theta)|\, ds.$$

The right-hand side is called the Lebesgue constant for the basis $\{B_k\}$. Thus the Fourier series (2.1) converges uniformly for every $f \in C(\mathbf{T})$ if and only if the Lebesgue constants are uniformly bounded, and in this case $\{B_k\}$ is said to form a basis for $C(\mathbf{T})$.

It is known [31] that no uniformly bounded orthonormal system can form a basis for the space $C(\mathbf{T})$. This result applies to the disk algebra with the basis functions defined by (1.3) as well. Notice that the uniform boundedness of the basis defined by (1.3) and (1.7) is equivalent to

$$\sup_n \{|z_n|, |x_n|\} \triangleq r < 1. \tag{2.9}$$

Although unbounded, the rational wavelets considered in [43, 44] cannot form a basis for $A(\mathbf{D})$ as well [8]. It is unknown whether there exists an (unbounded) rational basis defined by (1.3) such that every function in $A(\mathbf{D})$ has a convergent Fourier series with respect to this basis. However, Fourier series of every Dini–Lipschitz continuous function with respect to the uniformly bounded orthonormal bases defined by (1.3) and (1.7) always converge uniformly on $\mathbf{T}$ [10].

The situation is quite different if one considers orthonormal systems other than the rational system defined by (1.3). There are certainly orthonormal bases for $H_2(\mathbf{D})$ which consists of rational functions (even polynomials) and also form bases in the disk algebra. See, for example, the construction in [45].

Having seen that the Fourier series of a continuous function may not necessarily converge uniformly with respect to a given (uniformly) bounded basis, we now study the convergence properties of the windowed Fourier series defined in (2.2) with respect to the general orthonormal basis functions. Recall that the general orthonormal basis functions are obtained from the rational functions in (1.3) and (1.7) by enforcing (1.8) and the periodicity condition (1.4).

The Cesàro means of f defined in (2.2) can be written as

$$\mathcal{F}_m f(e^{i\theta}) = \frac{1}{2\pi} \int_{\theta-\pi}^{\theta+\pi} f(e^{is})\, \sigma_m(s,\theta)\, ds, \tag{2.10}$$

where $\sigma_m(s,\theta)$ is the Fejér kernel defined by

$$\sigma_m(s,\theta) \triangleq \frac{1}{m+1} \sum_{k=0}^{m} D_{nk,nk}(s,\theta). \tag{2.11}$$

Assuming that the basis poles are cyclically repeated according to (1.4), we derive a formula for the Fejér kernel in the following.

LEMMA 2.2. *Consider the general orthonormal basis functions defined by* (1.3), (1.7), (1.4), *and* (1.8). *Let* $\sigma_m(s,\theta)$ *be as in* (2.11). *Then*

$$\sigma_m(s,\theta) = \alpha_m(s,\theta) + \beta(s,\theta)\, \frac{1}{m+1}\, \frac{\sin^2\left((m+1)\,\dfrac{\zeta}{2}\right)}{\sin^2\left(\dfrac{\zeta}{2}\right)}, \tag{2.12}$$

where

$$\alpha_m(s,\theta) \triangleq \left\{ \cos\left(m\,\frac{\zeta}{2}\right) - \cos\left(\frac{\eta}{2}\right) \cos\left((m+1)\,\frac{\zeta}{2}\right) \frac{\sin\left(\dfrac{\zeta}{2}\right)}{\sin\left(\dfrac{\eta}{2}\right)} \right\} \frac{\sin\left((m+1)\,\dfrac{\zeta}{2}\right)}{(m+1)\,\sin\left(\dfrac{\zeta}{2}\right)},$$

$$\beta(s,\theta) \triangleq \cos\left(\frac{\zeta}{2}\right) \cos\left(\frac{\eta}{2}\right) \frac{\sin\left(\frac{\zeta}{2}\right)}{\sin\left(\frac{\eta}{2}\right)}, \tag{2.13}$$

$$\begin{aligned} \zeta &\triangleq \sum_{k=1}^{n} \int_{s}^{\theta} \left|B_k(e^{iy})\right|^2 dy, \\ \eta &\triangleq \theta - s. \end{aligned} \tag{2.14}$$

Proof. Since $z_j = x_j$ and $|\psi_j(e^{i\theta})| = |\phi_j(e^{i\theta})| = 1$, note that $|B_j(e^{i\theta})| = |B_{-j}(e^{i\theta})|$ for all j and θ. Thus in (2.7), $\mu_{k,k}(s,\theta) = 0$ for all s, θ, and k. Due to (1.4), we also

have

$$\lambda_{nk,nk}(s,\theta) = \frac{\theta - s}{2} + \int_s^\theta \sum_{j=1}^{nk} \left|B_j(e^{iy})\right|^2 \, dy$$
$$= \frac{\eta}{2} + k\,\zeta.$$

Hence from Lemma 2.1,

$$D_{nk,nk}(s,\theta) = \frac{\sin\left(\frac{\eta}{2} + k\,\zeta\right)}{\sin\left(\frac{\eta}{2}\right)}, \qquad k \geq 0. \tag{2.15}$$

Plugging (2.15) into (2.11), we get (2.12) from several applications of the identities:

$$\sin\theta = \frac{e^{i\theta} - e^{-i\theta}}{2i},$$

$$\sum_{k=0}^{m-1} e^{ik\theta} = \frac{e^{im\theta} - 1}{e^{i\theta} - 1},$$

$$\sin(x+y) = \sin x \cos y + \cos x \sin y. \qquad \square$$

The Cesàro means of f defined in (2.2) and the de la Vallée Poussin estimate of f converge uniformly to f. This will follow from the following lemma.

LEMMA 2.3. *Consider the general orthonormal basis functions defined by* (1.3), (1.7), (1.4), *and* (1.8). *Let* $\sigma_m(s,\theta)$ *be as in* (2.12). *Then for all* $m \geq 1$,

$$\sup_\theta \frac{1}{2\pi} \int_{-\pi}^{\pi} |\sigma_m(s,\theta)| \, ds \leq C_1 + c_m, \tag{2.16}$$

where

$$C_1 \triangleq \frac{4 + 6\pi + 4\ln n}{(1-r)^2},$$
$$c_m \triangleq \frac{28n}{(1-r)^2} \, \frac{\ln(m+1)}{m+1}. \tag{2.17}$$

Proof. From Lemma 2.2, by a change of variables $s = \theta + t$ we have

$$\int_{-\pi}^{\pi} |\sigma_m(s,\theta)| \, ds \leq \int_{-\pi}^{\pi} |\alpha_m(\theta + t, \theta)| \, dt$$
$$+ \int_{-\pi}^{\pi} \frac{|\beta(\theta + t, \theta)|}{m+1} \underbrace{\frac{\sin^2\left((m+1)\,\frac{\zeta(t)}{2}\right)}{\sin^2\left(\frac{\zeta(t)}{2}\right)}}_{[\Upsilon(\zeta(t))]^2} \, dt. \tag{2.18}$$

To bound the first integral on the right-hand side, note from (2.14) that

$$\frac{\zeta}{\eta} = \frac{\displaystyle\sum_{k=1}^{n} \int_{\theta+t}^{\theta} \left|B_k(e^{iy})\right|^2 \, dy}{\theta - (\theta + t)} \leq \sum_{k=1}^{n} \|B_k\|_\infty^2,$$

where the terms $\|B_k\|_\infty^2$ are bounded as

$$\|B_k\|_\infty^2 = \max_t \frac{1 - |z_k|^2}{|1 - \overline{z_k}\, e^{it}|^2} \leq \frac{1+r}{1-r}. \tag{2.19}$$

Hence

$$\frac{\zeta}{\eta} \leq \frac{2n}{1-r}. \tag{2.20}$$

We also have

$$\frac{\zeta}{\eta} \geq \sum_{k=1}^{n} \min_t |B_k(e^{it})| \geq n\, \frac{1-r}{1+r}. \tag{2.21}$$

Thus from (2.20) and (2.21),

$$\frac{n(1-r)}{2} \leq \frac{d\zeta}{d\eta} \leq \frac{2n}{1-r}. \tag{2.22}$$

Next from (2.20), the inequalities $|\sin x| \leq |x|$ for all x, and

$$\frac{\sin x}{x} \geq \frac{2}{\pi}, \qquad |x| \leq \frac{\pi}{2}, \tag{2.23}$$

we get

$$\frac{\left|\sin\left(\dfrac{\zeta}{2}\right)\right|}{\left|\sin\left(\dfrac{\eta}{2}\right)\right|} \leq \frac{\pi\,\zeta}{2\eta} \leq \frac{\pi\, n}{1-r}, \qquad |\eta| \leq \pi. \tag{2.24}$$

Hence

$$\int_{-\pi}^{\pi} |\alpha_m(\theta + t, \theta)|\, dt \leq \frac{1}{m+1} \left(1 + \frac{\pi n}{1-r}\right) \int_{-\pi}^{\pi} |\Upsilon(\zeta(t))|\, dt. \tag{2.25}$$

By a change of the variables $\zeta = \int_{\theta+t}^{\theta} \sum_{k=1}^{n} |B_k(e^{is})|^2\, ds$ and $\eta = -t$, we have from (2.22) the following:

$$\begin{aligned} \int_{-\pi}^{\pi} |\Upsilon(\zeta(t))|\, dt &= \int_{\zeta(\pi)}^{2\pi n + \zeta(\pi)} |\Upsilon(\zeta)| \left(\frac{\mathrm{d}\zeta}{\mathrm{d}\eta}\right)^{-1} d\zeta \\ &\leq \frac{2}{n(1-r)} \int_{\zeta(\pi)}^{2\pi n + \zeta(\pi)} |\Upsilon(\zeta)|\, d\zeta \\ &= \frac{2}{1-r} \int_{-\pi}^{\pi} |\Upsilon(\zeta)|\, d\zeta, \end{aligned} \tag{2.26}$$

where the first two (in)equalities follow from (2.22) and

$$\int_{\theta}^{\theta+2\pi} |B_k(e^{is})|^2\, ds = 2\pi \qquad \text{for all } \theta \text{ and } k, \tag{2.27}$$

and the last equality from the fact that $|\Upsilon(\zeta)|$ is a periodic function with period 2π. The integral in (2.26) can be bounded from (2.23) as follows:

$$\begin{aligned}\int_{-\pi}^{\pi} |\Upsilon(\zeta)|\, d\zeta &= 2\left\{ \int_0^{\frac{\pi}{m+1}} \frac{\left|\sin\left((m+1)\,\frac{\zeta}{2}\right)\right|}{\sin\left(\frac{\zeta}{2}\right)}\, d\zeta + \int_{\frac{\pi}{m+1}}^{\pi} \frac{\left|\sin\left((m+1)\,\frac{\zeta}{2}\right)\right|}{\sin\left(\frac{\zeta}{2}\right)}\, d\zeta \right\} \\ &\le 2\left\{ \int_0^{\frac{\pi}{m+1}} \frac{(m+1)\,\pi}{2}\, d\zeta + \int_{\frac{\pi}{m+1}}^{\pi} \frac{\pi}{\zeta}\, d\zeta \right\} \\ &= \pi^2 + 2\pi\, \ln(m+1).\end{aligned} \tag{2.28}$$

Hence from (2.25), (2.26), and (2.28), we get

$$\begin{aligned}\int_{-\pi}^{\pi} |\alpha_m(\theta+t,\theta)|\, dt &\le \frac{2(\pi n+1-r)}{(m+1)(1-r)^2}\left(\pi^2 + 2\pi\, \ln(m+1)\right) \\ &\le \frac{55\pi n}{(1-r)^2}\, \frac{\ln(m+1)}{m+1}, \qquad m \ge 1.\end{aligned} \tag{2.29}$$

To bound the second integral on the right-hand side of (2.18), change the variables again to $\zeta = \int_{\theta+t}^{\theta} \sum_{k=1}^{n} |B_k(e^{is})|^2\, ds$. Note that ζ is decreasing and (2.27) implies that it maps $[-\pi,\pi]$ onto $[\zeta(\pi), 2\pi n + \zeta(\pi)]$. Thus we may define an inverse map $\Xi : \zeta \mapsto t$. Let $t_k = \Xi(\zeta(\pi) + 2\pi k)$, $k = 0, 1, \ldots, n$, and suppose that for some j, $0 \in [t_{j+1}, t_j)$. Then

$$\begin{aligned}\int_{-\pi}^{\pi} |\beta(\theta+t,\theta)|\, \frac{[\Upsilon(\zeta(t))]^2}{m+1}\, dt &= \int_{\zeta(\pi)}^{2\pi n+\zeta(\pi)} |\beta(\theta+\Xi(\zeta),\theta)| \left(\frac{d\zeta}{d\eta}\right)^{-1} \frac{[\Upsilon(\zeta)]^2}{m+1}\, d\zeta \\ &\le \frac{2}{n(1-r)} \int_{\zeta(\pi)}^{2\pi n+\zeta(\pi)} \underbrace{\frac{\left|\sin\left(\frac{\zeta}{2}\right)\right|}{\left|\sin\left(-\frac{\Xi(\zeta)}{2}\right)\right|}\, \frac{[\Upsilon(\zeta)]^2}{m+1}}_{\Lambda(\zeta)}\, d\zeta,\end{aligned} \tag{2.30}$$

where the inequality follows from (2.22). Split the integral above as follows:

$$\int_{\zeta(\pi)}^{\zeta(\pi)+2\pi n} \Lambda(\zeta)\, d\zeta = \sum_{k=1}^{j-1} \int_{\zeta(t_{k-1})}^{\zeta(t_k)} \Lambda(\zeta)\, d\zeta + \sum_{k=j+3}^{n} \int_{\zeta(t_{k-1})}^{\zeta(t_k)} \Lambda(\zeta)\, d\zeta + \int_{\zeta(t_{j-1})}^{\zeta(t_{j+2})} \Lambda(\zeta)\, d\zeta.$$

Note from (2.22) the following inequalities:

$$\frac{n(1-r)}{2}\,(t_k - t_{k+1}) \le 2\pi = \zeta(t_{k+1}) - \zeta(t_k) \le \frac{2n}{1-r}\,(t_k - t_{k+1}),$$

which imply

$$\frac{\pi(1-r)}{n} \le (t_k - t_{k+1}) \le \frac{4\pi}{n(1-r)}.$$

Thus for $k \ge j+2$,

$$t_k = t_{j+1} + \sum_{l=j+2}^{k} (t_l - t_{l-1}) \le -\frac{\pi(1-r)}{n}(k-j-1), \tag{2.31}$$

and for $k \le j-1$,

$$t_k = t_j + \sum_{l=k+1}^{j} (t_{l-1} - t_l) \ge \frac{\pi(1-r)}{n}(j-k). \tag{2.32}$$

Hence from (2.24), the fact that $\Upsilon^2(\zeta)$ is a periodic function with period 2π, and the identity (see [20])

$$\frac{1}{2\pi}\int_{-\pi}^{\pi} \frac{[\Upsilon(t)]^2}{m+1}\,dt = 1, \tag{2.33}$$

we get

$$\begin{aligned}
\int_{\zeta(t_{j-1})}^{\zeta(t_{j+2})} \Lambda(\zeta)\,d\zeta &\le \frac{\pi n}{1-r}\int_{\zeta(t_{j-1})}^{\zeta(t_{j+2})} \frac{[\Upsilon(\zeta)]^2}{m+1}\,d\zeta \\
&= \frac{\pi n}{1-r}\int_{\zeta(\pi)+2\pi(j-1)}^{\zeta(\pi)+2\pi(j+2)} \frac{[\Upsilon(\zeta)]^2}{m+1}\,d\zeta \\
&\le \frac{6\pi^2 n}{1-r}.
\end{aligned}$$

From (2.23), (2.33), (2.31), and (2.32),

$$\begin{aligned}
\sum_{k\ne j,j+1,j+2}\int_{\zeta(t_{k-1})}^{\zeta(t_k)} \Lambda(\zeta)\,d\zeta &\le 2\pi\sum_{k=1}^{j-1}\frac{\pi}{t_k} - 2\pi\sum_{k=j+3}^{n}\frac{\pi}{t_{k-1}} \\
&\le \frac{2\pi n}{1-r}\left(\sum_{k=1}^{j-1}\frac{1}{j-k} + \sum_{k=j+3}^{n}\frac{1}{k-j-2}\right) \\
&\le \frac{4\pi n}{1-r}\sum_{k=1}^{n}\frac{1}{k} \\
&\le \frac{4\pi n}{1-r}(1+\ln n).
\end{aligned}$$

Hence

$$\frac{1}{2\pi}\int_{-\pi}^{\pi} |\beta(\theta+t,\theta)|\,\frac{|\Upsilon(\zeta(t))|^2}{m+1}\,dt \le \frac{4+6\pi+4\ln n}{(1-r)^2}. \tag{2.34}$$

This bound takes care of the cases $j<2$ and $j>n-3$ for all possible values of n. The combination of the inequalities (2.29), (2.34), and (2.18) yields $\|\sigma_m(\cdot,\theta)\|_1 \le C_1 + c_m$. Then taking the supremum with respect to θ completes the proof. □

Let X_k be the linear span of the general orthonormal basis functions B_j, $|j| \le k$, and define

$$\delta_k(f, C(\mathbf{T})) \triangleq \inf_{g \in X_k} \|g - f\|_\infty, \qquad f \in C(\mathbf{T}). \tag{2.35}$$

Thus $\delta_k(f, C(\mathbf{T}))$ is the best approximation error of f by functions in X_k. A best approximation always exists since X_k is finite-dimensional. Furthermore, $\delta_k(f, C(\mathbf{T})) \to 0$ $(k \to \infty)$ because the basis functions defined by (1.3)–(1.4) and (1.7)–(1.8) are complete in $C(\mathbf{T})$.

Let f be a given function in $C(\mathbf{T})$, and for $k = n(m+1)$ let g be a minimizing solution in (2.35). Let $h = f - g$ denote the approximation error. Observe that $\mathcal{V}_m g = g$ since $g \in X_{n(m+1)}$ and $\chi_m(j) = 1$ for all $|j| \le n(m+1)$. Due to the linearity of $\mathcal{V}_m$, notice also that $\mathcal{V}_m h = \mathcal{V}_m f - \mathcal{V}_m g$. Thus from (2.3), Lemma 2.3, and (2.35) we find

$$\begin{aligned} \|\mathcal{V}_m f - f\|_\infty &= \|\mathcal{V}_m h - h\|_\infty \\ &\le (2\|\mathcal{F}_{2m+1}\| + \|\mathcal{F}_m\|)\, \|h\|_\infty + \|h\|_\infty \\ &\le (3\, C_1 + 3\, c_m + 1)\ \delta_{n(m+1)}(f, C(\mathbf{T})). \end{aligned} \tag{2.36}$$

Hence $\|\mathcal{V}_m f - f\|_\infty \to 0$ $(m \to \infty)$ as claimed.

The inequality (2.36) shows that the approximation error of the estimate defined by (2.3) is $O(\delta_{n(m+1)}(f, C(\mathbf{T})))$, which compares well with the best possible error $\delta_{n(2m+1)}(f, C(\mathbf{T}))$. For example, if $f(z)$ is analytic on a region that contains $\mathbf{T}$, then for some $\gamma \in (0, 1)$, $\delta_k(f, C(\mathbf{T})) = O(\gamma^k)$ and thus $\|\mathcal{V}_m f - f\|_\infty = O(\gamma^{n(m+1)})$. This result is in sharp contrast with the Cesàro means defined in (2.2), where $O(\frac{1}{n(m+1)})$ is the best possible convergence rate for the same f using the trigonometric basis functions $e^{\pm ik\theta}$.

In [7, 28], real-valued impulse response versions of the basis functions defined by (1.3) and (1.7) have been formulated. (The details and examples can be found in [7, section 5].) It was established that the new basis functions denoted by $\widetilde{B}_k$ have the same closure and approximation properties as the original basis functions (1.3) and (1.7). In particular,

$$\mathcal{S}_k f = \sum_{j=-k}^{k} \langle f, \widetilde{B}_j \rangle \widetilde{B}_j \triangleq \widetilde{\mathcal{S}}_k f$$

whenever $\{z_0, \ldots, z_k\}$ contains complex conjugates as well. In this case, if f has a real-valued impulse response, then both $\mathcal{S}_k f$ and $\widetilde{\mathcal{S}}_k f$ will have real-valued impulse responses. Thus the de la Vallée Poussin estimate of f defined by (2.3) always has a real-valued impulse response, since the basis functions are generated by a complex-conjugate closed pole-parameter set $\{z_1, \ldots, z_n\}$ through (1.3), (1.7), (1.4), and (1.8).

3. Overdetermined system of linear equations. In this section, the approximation results derived in section 2 will be linked to the identification problem formulated in section 1.

Let $p(N)$ be a nonnegative integer-valued function. Let

$$\Theta_N \triangleq \begin{bmatrix} B_{-p}(e^{i\omega_1}) & \cdots & B_0(e^{i\omega_1}) & \cdots & B_p(e^{i\omega_1}) \\ \vdots & \ddots & \vdots & \ddots & \vdots \\ B_{-p}(e^{i\omega_N}) & \cdots & B_0(e^{i\omega_N}) & \cdots & B_p(e^{i\omega_N}) \end{bmatrix}, \quad E_N \triangleq \begin{bmatrix} e_1 \\ \vdots \\ e_N \end{bmatrix}. \tag{3.1}$$

For convenience of notation, the columns of Θ_N are indexed from $-p$ to p. Since the frequencies $\{\omega_k\}$ are distinct, Θ_N has full column rank, provided that $N \geq 2p+1$. Then we may compute the Moore–Penrose pseudo-inverse of Θ_N defined by

$$\Theta_N^\dagger \triangleq (\Theta_N^* \Theta_N)^{-1} \Theta_N^*,$$

where Θ_N^* is the complex-conjugated transpose of Θ_N. It is well known that $\Theta_N^\dagger E_N$ is the unique solution of the minimum distance problem:

$$\min_{x \in \mathbf{C}^{2p+1}} \|\Theta_N x - E_N\|_2. \tag{3.2}$$

For each N, we define a map $\mathcal{T}_N : \mathbf{C}^{2p+1} \to C(\mathbf{T})$ by

$$\mathcal{T}_N X(z) \triangleq \sum_{k=-p}^{p} w_p(k)\, [\Theta_N^\dagger X](k)\, B_k(z), \tag{3.3}$$

where w_p is a symmetric nonnegative window function.

Assuming that the frequencies in (1.5) satisfy the condition

$$0 \leq \omega_{k+1} - \frac{2\pi}{N}\, k < \frac{2\pi}{N}, \qquad k = 0, \ldots, N-1, \tag{3.4}$$

we extend the discrete data $\{e_1, \ldots, e_N\}$ into L_∞ as follows:

$$\mathcal{P}_N E_N(e^{i\omega}) \triangleq e_k \ \text{ if } \ \omega \in \left[\frac{2\pi}{N}\,(k-1), \frac{2\pi}{N}\, k\right), \ \ k = 1, 2, \ldots, N. \tag{3.5}$$

Next we define a sequence of operators $\mathcal{W}_N : L_\infty \to C(\mathbf{T})$ as follows:

$$\mathcal{W}_N f(z) \triangleq \sum_{k=-p}^{p} w_p(k)\, \langle f, B_k \rangle\, B_k(z). \tag{3.6}$$

Thus the composite operator $\mathcal{W}_N \mathcal{P}_N$ maps $E_N \in \mathbf{C}^{2p+1}$ into $C(\mathbf{T})$.

In the following result, we derive an upper bound on the difference between the operators $\mathcal{T}_N$ and $\mathcal{W}_N \mathcal{P}_N$, assuming that the frequencies in (1.5) are in one-to-one correspondence with the uniformly spaced frequencies: $\frac{2\pi k}{N}$, $k = 0, \ldots, N-1$.

LEMMA 3.1. *Consider the basis functions defined by* (1.3) *and* (1.7). *Suppose that they are uniformly bounded and let* r *be as in* (2.9). *Let* $\mathcal{T}_N$, $\mathcal{P}_N$, $\mathcal{W}_N$ *be as in* (3.3), (3.5), (3.6), *respectively. Assume that the frequencies in* (1.5) *satisfy* (3.4). *Suppose also that*

$$N \geq 26 p^2 \left(\frac{1+r}{1-r}\right)^2. \tag{3.7}$$

Then for all $p \geq 3$,

$$\|\mathcal{T}_N - \mathcal{W}_N \mathcal{P}_N\| \leq \|w_p\|_\infty\, K_p, \tag{3.8}$$

where

$$K_p \triangleq 76 \left(\frac{1+r}{1-r}\right)^{\frac{5}{2}} \frac{p^{\frac{5}{2}}}{N}. \tag{3.9}$$

Proof. Let

$$\widetilde{e}_N(z) \triangleq \sum_{k=-p}^{p} w_p(k)\,\frac{1}{N}\left[\Theta_N^* E_N\right](k)\,B_k(z). \tag{3.10}$$

Then the sums

$$\frac{1}{N}[\Theta_N^* E_N](k) = \frac{1}{N}\sum_{j=1}^{N} e_j\,\overline{B_k(e^{i\omega_j})}, \quad k = 0, \pm 1, \ldots,$$

are approximations to the Fourier coefficients of $\mathcal{P}_N E_N$,

$$\langle \mathcal{P}_N E_N, B_k\rangle = \frac{1}{2\pi}\int_0^{2\pi} \mathcal{P}_N E_N(e^{is})\,\overline{B_k(e^{is})}\,ds, \quad k = 0, \pm 1, \ldots,$$

since from (3.5) and the mean value theorem for integrals we have

$$\begin{aligned}\frac{1}{2\pi}\int_0^{2\pi} \mathcal{P}_N E_N(e^{is})\,\overline{B_k(e^{is})}\,ds &= \frac{1}{2\pi}\sum_{j=1}^{N} e_j \int_{\frac{2\pi}{N}(j-1)}^{\frac{2\pi}{N}j} \overline{B_k(e^{is})}\,ds \\ &= \frac{1}{N}\sum_{j=1}^{N} e_j\,\overline{B_k(e^{is_j})},\end{aligned}$$

where for each j, s_j lies in the interval $(\frac{2\pi}{N}(j-1), \frac{2\pi}{N}j)$. Then the approximation errors can be bounded from (3.4) as follows:

$$\begin{aligned}\left|\frac{1}{N}[\Theta_N^* E_N](k) - \langle \mathcal{P}_N E_N, B_k\rangle\right| &\le \Omega_{\overline{B_k}}\left(\frac{2\pi}{N}\right)\|E_N\|_\infty \\ &\le \frac{2\pi}{N}\max_s\left|\frac{d}{ds}B_k(e^{is})\right|\|E_N\|_\infty, \quad k = 0, \pm 1, \ldots,\end{aligned} \tag{3.11}$$

where Ω_f is the modulus of continuity of f defined by

$$\Omega_f(\varrho) \triangleq \sup_{|x-y|\le\varrho} |f(x) - f(y)|.$$

It is known from [13] (see also [2, Lem. 13]) that if $g(z)$ is a rational function with poles outside the disk $\{z : |z| < R\}$ $(R > 1)$ and with numerator and denumerator degrees p and q, then

$$\left\|\frac{dg}{dz}\right\|_\infty \le \max\{p, q\}\,\frac{R+1}{R-1}\,\|g\|_\infty.$$

Applying this result to the basis functions B_k, $k \ge 0$, with $R = 1/r$, where r is as defined in (2.9), we get from (2.19)

$$\left\|\frac{\mathrm{d}B_k}{\mathrm{d}z}\right\|_\infty \le \left(\frac{1+r}{1-r}\right)^{\frac{3}{2}} k. \tag{3.12}$$

By the substitution $z \mapsto z^{-1}$, note that the same inequality holds for $k < 0$ with $|k|$ replacing k on the right-hand side. Hence from (3.11) and (3.12) we have

$$\begin{aligned}\sum_{k=-p}^{p} \left| \frac{1}{N}[\Theta_N^* E_N](k) - \langle \mathcal{P}_N E_N, B_k \rangle \right| &\leq \frac{2\pi}{N} \left(\frac{1+r}{1-r} \right)^{\frac{3}{2}} \|E_N\|_\infty \sum_{k=-p}^{p} |k| \\ &\leq \frac{2\pi}{N}\, p(p+1) \left(\frac{1+r}{1-r} \right)^{\frac{3}{2}} \|E_N\|_\infty.\end{aligned}$$

Thus

$$\begin{aligned}\|\mathcal{W}_N \mathcal{P}_N E_N - \widetilde{e}_N\|_\infty &\leq \|w_p\|_\infty \max_{-p \leq k \leq p} \|B_k\|_\infty \sum_{k=-p}^{p} \left| \frac{1}{N}[\Theta_N^* E_N](k) - \langle \mathcal{P}_N E_N, B_k \rangle \right| \\ &\leq \underbrace{\frac{2\pi}{N}\, p(p+1) \left(\frac{1+r}{1-r} \right)^{2}}_{\triangleq \gamma} \|w_p\|_\infty \|E_N\|_\infty. \end{aligned} \tag{3.13}$$

Next, from

$$\mathcal{T}_N E_N - \widetilde{e}_N = \sum_{k=-p}^{p} w_p(k) \left(I - \frac{1}{N}\, \Theta_N^* \Theta_N \right) [\Theta_N^\dagger E_N](k)\, B_k, \tag{3.14}$$

where I denotes the $2p+1$ by $2p+1$ identity matrix, we have

$$\|\mathcal{T}_N E_N - \widetilde{e}_N\|_\infty \leq \|w_p\|_2 \left\| I - \frac{1}{N} \Theta_N^* \Theta_N \right\|_2 \|\Theta_N^\dagger E_N\|_2 \max_{-p \leq k \leq p} \|B_k\|_\infty, \tag{3.15}$$

where $\|A\|_2$ denotes the spectral norm of A. For the entries of the second term in (3.14), upper bounds are derived as follows:

$$\begin{aligned}\left| I_{k,j} - \frac{1}{N}\, [\Theta_N^* \Theta_N]_{k,j} \right| &= \left| \frac{1}{2\pi} \int_0^{2\pi} \overline{B_k(e^{is})}\, B_j(e^{is})\, ds - \frac{1}{N}\, [\Theta_N^* \Theta_N]_{k,j} \right| \\ &= \frac{1}{N} \sum_{l=1}^{N} \left| \frac{N}{2\pi} \int_{\frac{2\pi}{N}(l-1)}^{\frac{2\pi}{N} l} \overline{B_k(e^{is})}\, B_j(e^{is})\, ds - \overline{B_k(e^{i\omega_l})}\, B_j(e^{i\omega_l}) \right| \\ &= \frac{1}{N} \sum_{l=1}^{N} \left| \overline{B_k(e^{is_l})}\, B_j(e^{is_l})\, ds - \overline{B_k(e^{i\omega_l})}\, B_j(e^{i\omega_l}) \right| \\ &\leq \Omega_{\overline{B_k} B_j} \left(\frac{2\pi}{N} \right) \\ &\leq \frac{2\pi}{N} \left(\|B_j\|_\infty \left\| \frac{dB_k}{dz} \right\|_\infty + \|B_k\|_\infty \left\| \frac{dB_j}{dz} \right\|_\infty \right) \\ &\leq \frac{2\pi}{N} \left(\frac{1+r}{1-r} \right)^{2} (|k| + |j|)\,, \end{aligned}$$

where the last equality has followed from the mean-value theorem for integrals and, for each l, s_l, lies in the interval $(\frac{2\pi}{N}(l-1), \frac{2\pi}{N} l)$. Thus from $\|A\|_2^2 \leq \sum_{k,l} |A_{k,l}|^2$, $p \geq 3$, and the last inequality above, we get

$$\left\| I - \frac{1}{N} \Theta_N^* \Theta \right\|_2 \leq \frac{4\pi}{N} \left(\frac{1+r}{1-r} \right)^{2} p^2 \leq 2\gamma. \tag{3.16}$$

Hence using $\|A\|_2^2 = \|A^*A\|_2$ and $\sqrt{1+x} \le 1+(x/2),\ |x| \le 1$, we obtain the following inequalities:

$$\left\| \frac{\Theta_N}{N^{\frac{1}{2}}} \right\|_2 \le 1+\gamma, \qquad \left\| \frac{\Theta_N}{N^{\frac{1}{2}}} \right\|_{\min} \ge 1-\gamma, \tag{3.17}$$

where $\|A\|_{\min}$ denotes the smallest nonzero singular value of A. Therefore

$$\|\Theta_N^\dagger E_N\|_2 \le \frac{\|\Theta_N\|_2\ \|E_N\|_2}{N^{\frac{1}{2}}\ \|\Theta_N\|_{\min}^2} \le \frac{1+\gamma}{1-\gamma}\,\|E_N\|_\infty. \tag{3.18}$$

Thus from (3.15), (3.16), and (3.18) we get

$$\begin{aligned} \|\mathcal{T}_N E_N - \widetilde{e}_N\|_\infty &\le 2\gamma\,\|w_p\|_2\,\frac{1+\gamma}{1-\gamma}\,\left(\frac{1+r}{1-r}\right)^{\frac{1}{2}}\,\|E_N\|_\infty \\ &\le 4\gamma\,\frac{1+\gamma}{1-\gamma}\,\left(\frac{1+r}{1-r}\right)^{\frac{1}{2}}\,p^{\frac{1}{2}}\,\|w_p\|_\infty\,\|E_N\|_\infty, \end{aligned} \tag{3.19}$$

where the second inequality follows from $\|w_p\|_2 \le (2p+1)^{\frac{1}{2}}\|w_p\|_\infty$.

Assuming $p \ge 3$ and $\gamma \le \frac{1}{3}$, an application of the triangle inequality to (3.13) and (3.19) yields

$$\begin{aligned} \sup_{\|E_N\|_\infty \le \varepsilon} \|\mathcal{T}_N E_N - \mathcal{W}_N \mathcal{P}_N E_N\|_\infty &\le \left\{ p^{-\frac{1}{2}} + 4\,\frac{1+\gamma}{1-\gamma}\,\left(\frac{1+r}{1-r}\right)^{\frac{1}{2}} \right\} p^{\frac{1}{2}}\,\gamma\,\|w_p\|_\infty\,\varepsilon \\ &\le 9\left(\frac{1+r}{1-r}\right)^{\frac{1}{2}}\,p^{\frac{1}{2}}\,\gamma\,\|w_p\|_\infty\,\varepsilon. \end{aligned}$$

Hence, from the above inequality and $p \ge 3$, we have

$$\|\mathcal{T}_N - \mathcal{W}_N \mathcal{P}_N\| \le 76\left(\frac{1+r}{1-r}\right)^{\frac{5}{2}}\,\|w_p\|_\infty\,\frac{p^{\frac{5}{2}}}{N},$$

which we set out to prove. Finally, $\gamma \le \frac{1}{3}$ is implied by (3.7). □

Since the system to be identified has a real-valued impulse response, its transfer function $G(z)$ must satisfy the complex-conjugate symmetry:

$$G(e^{-i\omega_k}) = \overline{G(e^{i\omega_k})}, \qquad k = 1, \ldots, N. \tag{3.20}$$

Therefore it suffices to measure the frequency response at frequencies up to π. Then the frequency response on $(\pi, 2\pi)$ is obtained from (3.20). Thus without loss of generality we assume that E_N defined in (3.1) obeys (3.20), which forces E_N to be real-valued at the frequencies 0 and π. That can simply be satisfied by taking the real parts of E_N at those frequencies. Assuming that the frequencies are ordered as $\omega_k < \omega_{k+1}$, $k = 1, \ldots, N$, a subset satisfying (3.4) can be extracted from $\{\omega_k,\ k = 1, \ldots, N\}$ by the following process.

Regularization. Let κ_N be the *maximum frequency gap* defined by

$$\kappa_N \triangleq \max\left\{ \max_{1 \le k < N} (\omega_{k+1} - \omega_k),\, 2\pi + \omega_1 - \omega_N \right\}. \tag{3.21}$$

Let N' be the largest integer rounding $\frac{2\pi}{\kappa_N}$ down. For $j = 1, \ldots, N'$, pick one frequency ω_{k_j} from each interval $[\frac{2\pi(j-1)}{N'}, \frac{2\pi j}{N'})$ and let $e'_j \triangleq e_{k_j}$ and $\omega'_j \triangleq \omega_{k_j}$.

Thus $\{\omega'_j,\ j = 1, \ldots, N'\}$ satisfies (3.7), and Lemma 3.1 applies to the subset of the data $\{e'_j,\ j = 1, \ldots, N'\}$. Henceforth, without loss of generality, we set $N = N'$ and $k_j = j$ for all j. The regularization process does not require two adjacent points to be well separated. Recall the robustness definition that excludes prior information beyond $G(z) \in A(\mathbf{D})$. By removing closely spaced frequencies, we don't expect to lose much information.

Since $\|\mathcal{P}_N\| = 1$, from Lemma 3.1 we have

$$\|\mathcal{T}_N\| \le \|\mathcal{W}_N\| + \|w_p\|_\infty K_p. \tag{3.22}$$

Assuming $\sup_p \|w_p\|_\infty < \infty$ and $p = o(N^{\frac{2}{5}})$, (3.22) then implies $\sup_N \|\mathcal{T}_N\| < \infty$ if $\sup_N \|\mathcal{W}_N\| < \infty$. In addition to $\sup_N \|\mathcal{W}_N\| < \infty$, if the following holds

$$\lim_{p\to\infty} w_p(k) = 1 \qquad \text{for all } \ k, \tag{3.23}$$

then $\|\mathcal{W}_N f - f\|_\infty \to 0$ for all $f \in C(\mathbf{T})$ [11]. This implies by Lemma 3.1 that the sequence of operators $\mathcal{T}_N$ defined in (3.3) asymptotically recovers continuous functions from noise-free samples.

Given a set of arbitrary uniformly bounded basis functions, the problem of finding a window function that satisfies

$$\sup_N \|\mathcal{W}_N\| = \sup_p \max_s \int_{-\pi}^{\pi} \left| \sum_{k=-p}^{p} w_p(k)\, \overline{B_k(e^{is})}\, B_k(e^{i\theta})\, d\theta \right| < \infty \tag{3.24}$$

is nontrivial. In section 2, we demonstrated that (3.24) holds for the general orthonormal basis functions and the de la Vallée Poussin window function. We combine Lemma 2.3 and Lemma 3.1 to obtain the following important result.

LEMMA 3.2. *Consider the general orthonormal basis functions defined by* (1.3), (1.7), (1.4), *and* (1.8). *Let $m(N)$ be a nonnegative integer-valued function. Let $p = n(2m+1)$ and*

$$\widehat{\delta}_m(G) \triangleq \inf \left\{ \|f - G\|_\infty :\ f \in \mathrm{sp}\{B_j\}_{j=0}^{n(m+1)} \right\}. \tag{3.25}$$

Let χ_m be as in (2.4). *Define the* preidentified model*:*

$$\widetilde{G}_N(z) \triangleq \sum_{k=-p}^{p} \chi_m(k)\, [\Theta_N^\dagger E_N](k)\, B_k(z). \tag{3.26}$$

Let C_1, c_m, and K_p be as in (2.17) *and* (3.9). *Then for all $G(z) \in A(\mathbf{D})$,*

$$\sup_{\|\nu\|_\infty \le \varepsilon} \|\widetilde{G}_N - G\|_\infty \le \widehat{\delta}_m(G) + (3C_1 + 3c_m + K_p) \left(\widehat{\delta}_m(G) + \varepsilon \right). \tag{3.27}$$

Proof. Decompose G as $G = g + h$, where $g \in \mathrm{sp}\{B_j\}_{j=0}^{n(m+1)}$ and h is a minimizing solution in (3.25). Let $U_N \triangleq [g(e^{i\omega_1}) \cdots g(e^{i\omega_N})]^T$ and $Y_N \triangleq [h(e^{i\omega_1}) + \nu_1 \cdots h(e^{i\omega_N}) + \nu_N]^T$. Consider $\mathcal{T}_N$ in (3.3) with $w_p = \chi_m$. Thus $E_N = U_N + Y_N$ and $\mathcal{W}_N = \mathcal{V}_m$. Since $\mathcal{T}_N$ is linear,

$$\widetilde{G}_N = \mathcal{T}_N E_N = \mathcal{T}_N U_N + \mathcal{T}_N Y_N.$$

Note that $\mathcal{T}_N U_N = g(z)$ since $g \in \mathrm{sp}\{B_j\}_{j=0}^{n(m+1)}$ and $\chi_m(k) = 1, \;\; k = 0, \ldots, n(m+1)$. To bound $\mathcal{T}_N Y_N$, we first derive an upper bound for $\|\mathcal{T}_N\|$ as follows:

$$\begin{aligned}\|\mathcal{T}_N\| &\le \|\mathcal{W}_N\| + \|w_p\|_\infty K_p \\ &= \|\mathcal{V}_m\| + K_p \\ &\le (2\|\mathcal{F}_{2m+1}\| + \|\mathcal{F}_m\|) + K_p \\ &\le 3(C_1 + c_m) + K_p,\end{aligned}$$

where the second inequality follows from (2.3), and the third from (2.10) and Lemma 2.3. Hence

$$\begin{aligned}\|\mathcal{T}_N Y_N\|_\infty &\le \|\mathcal{T}_N\| \|Y_N\| \\ &\le (3C_1 + 3c_m + K_p)\,(\|h\|_\infty + \|\nu\|_\infty) \\ &\le (3C_1 + 3c_m + K_p)\left(\widehat{\delta}_m(G) + \varepsilon\right),\end{aligned}$$

where the last inequality follows from $\|h\|_\infty = \widehat{\delta}_m(G)$. Thus

$$\begin{aligned}\|G - \widetilde{G}_N\|_\infty &= \|h - \mathcal{T}_N Y_N\|_\infty \\ &\le \|h\|_\infty + \|\mathcal{T}_N Y_N\|_\infty \\ &\le \widehat{\delta}_m(G) + (3C_1 + 3c_m + K_p)\left(\widehat{\delta}_m(G) + \varepsilon\right).\end{aligned}$$

Taking the supremum of the left-hand side with respect to ν completes the proof. □

Now we are in a position to state the main result of this paper in the next section.

4. Two-stage nonlinear algorithm. In the previous section, we computed an approximant to the system from the noisy data. Although this estimate is close enough to the system so that it satisfies the criterion in (1.6), it can not be taken as the identified model since it contains unstable dynamics. The stable identified model is then obtained from $\widetilde{G}_N$ by solving the following nonlinear optimization problem known as the Nehari distance problem:

$$\widehat{G}_N \triangleq \arg \min_{f \in H_\infty} \|\widetilde{G}_N - f\|_\infty. \tag{4.1}$$

The Nehari problem was first used by Helmicki, Jacobson, and Nett [18] to solve the identification problem in H_∞ formulated in section 1. Notice from (4.1) the following inequality:

$$\|\widehat{G}_N - G\|_\infty \le 2\,\|\widetilde{G}_N - G\|_\infty \tag{4.2}$$

from which the main result of this paper follows.

THEOREM 4.1. *Let $\widehat{G}_N$ and κ_N be as in* (4.1) *and* (3.21). *Suppose $\kappa_N \to 0$. Then*

$$\lim_{\substack{\varepsilon \to 0 \\ N \to \infty}} \sup_{\|\nu\|_\infty \le \varepsilon} \|\widehat{G}_N - G\|_\infty = 0 \quad \text{for all} \quad G \in A(\mathbf{D}), \tag{4.3}$$

and the convergence is robust. Furthermore,

$$\sup_{\|\nu\|_\infty \le \varepsilon} \|\widehat{G}_N - G\|_\infty \le 2\widehat{\delta}_m(G) + 2\,(3C_1 + 3c_m + K_p)\left(\widehat{\delta}_m(G) + \varepsilon\right), \tag{4.4}$$

where $p = n(2m+1)$, *and* C_1, c_m, K_p, $\widehat{\delta}_m(G)$ *are defined by* (2.17), (3.9), (3.25).

Assuming $m = o(N^{\frac{2}{5}})$, then from (4.4) asymptotically in N

$$\sup_{\|\nu\|_\infty \le \varepsilon} \|\widehat{G}_N - G\|_\infty \le 2(1+3C_1)\,\widehat{\delta}_m(G) + 6C_1\varepsilon.$$

The right-hand side converges to zero at a geometric rate of m when the data are noise-free and the identified system is exponentially stable. This bound is similar to the asymptotic error bound computed in [6] for the trigonometric basis $\{e^{ik\theta}\}$. This is not unexpected for the general orthonormal basis functions, since $H_2(\mathbf{D})$ can be decomposed into at most n orthogonal subspaces by means of an inner function constructed from the chosen n basis poles. Then, intuitively, a system lying in $A(\mathbf{D})$ can be approximated on the decomposing subspaces, although how this could be achieved is not clear.

A drawback of the algorithm is the amount of required data. The requirement $m = o(N^{\frac{2}{5}})$ is severe. The minimax algorithm studied in [2] principally due to Mäkilä and Partington, on the other hand, has a modest requirement $m = O(N)$. The minimax algorithm is, however, computationally expensive, in particular for large values of m.

5. Example. In this section, we use a simulation example to illustrate the use of the generalized basis functions defined by (1.3)–(1.4) in an iterative-identification scheme. In the example, the Nehari step is omitted and each iteration step involves the estimation of a large-order model followed by a model reduction step leading to a new set of basis poles.

We consider the identification of a fifth-order system with poles (in the usual stability notion) $0.95\pm0.20i$, $0.85\pm0.10i$, 0.55, and zeros $0.96\pm0.28i$, $0.96\pm0.17i$. The transfer function of the system is normalized so that its H_∞ norm satisfies $\|G\|_\infty = 1$. This system was used in [39, 7] to illustrate the use of the basis functions in a one-step identification algorithm.

As in [7], we assume $N = 500$ frequency response measurements

$$e_k = G(e^{i\omega_k}) + \nu_k, \qquad k = 1, \dots, N, \tag{5.1}$$

are available, where ω_k are equally spaced on the interval $[0, 3]$ and the disturbances ν_k are bounded random variables

$$\nu_k = 0.1\, e^{i\alpha_k},$$

where α_k are independent and uniformly distributed random variables in the interval $[0, 2\pi]$. Note that, by this choice of frequencies, the frequency response is not on a uniform grid of frequencies. For a comparison with approximation results, we also consider the possibility $\nu = 0$ in (5.1).

We will estimate G from the data (5.1) by the following iterative algorithm. First, using the basis functions in (1.3) with

$$z_k = \begin{cases} 0.2, & k \text{ odd}, \\ 0.9, & k \text{ even}, \end{cases}$$

a high-order model is computed from (5.1) by the simple least-squares method as

$$H^{(0)}(z) = \sum_{k=0}^{2m} [\Phi^\dagger E_N]_k B_k(z), \tag{5.2}$$

where E_N is as defined in (3.1), and

$$\Phi = \begin{bmatrix} 1 & \cdots & B_{2m}(e^{i\omega_1}) \\ \vdots & \ddots & \vdots \\ 1 & \cdots & B_{2m}(e^{i\omega_N}) \end{bmatrix}. \tag{5.3}$$

This simple choice of basis functions represents both slow and fast dynamics in the model structure by the Laguerre functions. In the simulation, we fixed the number of basis functions as 21.

We reduced $H^{(0)}$ to a fifth order model denoted by $\widehat{G}_N^{(0)}$, by using the subspace-based identification algorithm in [26] for model reduction purposes. The input to the algorithm in [26] was 4096 equally spaced frequency response data on $[0, 2\pi]$. Note that this amounts to evaluating Φ on a uniform grid of 4096 frequencies for which fast algorithms are known to exist. The size of the Hankel matrix in the subspace algorithm was chosen to be 256 by 256. These values will be used throughout the iterations. The step prior to forming a Hankel matrix was a 4096-point inverse fast Fourier transform.

The reduced model starts the iterations. Let $z_1^{(1)}, \ldots, z_5^{(1)}$ denote the inverses of the poles of $\widehat{G}_N^{(0)}(z)$. The updated basis functions $B_0^{(1)}, \ldots, B_{20}^{(1)}$ are computed from (1.3) with $z_0^{(1)} = 0$ and

$$z_{j+5m}^{(1)} = z_j^{(1)}, \qquad j = 1, \ldots, 5, \quad m = 1, 2, 3.$$

Then $H^{(0)}$ in (5.2) is updated to

$$H^{(1)}(z) = \sum_{k=0}^{20} [\Phi^\dagger E_N]_k B_k^{(1)}(z),$$

where Φ in (5.3) is computed with the updated basis functions. Next $H^{(1)}$ is reduced to a fifth order model $\widehat{G}_N^{(1)}$, using the same model reduction technique. This completes the first iteration. The next iteration starts with the inverses of the poles of $\widehat{G}_N^{(1)}(z)$ in place of $z_1^{(2)}, \ldots, z_5^{(2)}$, and so on.

The quality of the estimated models will be assessed by a measure based on the fit between the data and the model. For this purpose, the maximum error defined as

$$\|\widehat{G}_N^{(k)} - E_N\|_{m,\infty} \stackrel{\Delta}{=} \max_{1 \le j \le N} \left| \widehat{G}_N^{(k)}(e^{i\omega_j}) - e_j \right|$$

will be used. The iterations are then terminated when the sequence $\{\|\widehat{G}_N^{(k)} - E_N\|_{m,\infty}\}$ seems to have reached a steady state.

5.1. Results. The results of the simulation are given in Tables 5.1 and 5.2. The iterations converged at $k = 2$ for the noise-free data and at $k = 1$ for the noisy data. For the noisy data, the poles of $\widehat{G}_N^{(1)}$ are $0.94 \pm 0.20i$, $0.86 \pm 0.10i$, 0.53, and the four significant zeros are $0.96 \pm 0.16i$, $0.96 \pm 0.28i$. They all agree well with the system poles and zeros. Thus the major source of the identification errors in Table 5.2 appears to be the measurement error ν. This observation is justified by computing the poles of $\widehat{G}_N^{(0)}$ as $0.91 \pm 0.12i$, $0.90 \pm 0.17i$, 0.52. In Figure 5.1, the magnitudes of $G(e^{i\omega_k})$ and $\widehat{G}_N^{(1)}(e^{i\omega_k})$, and the identification error $\widehat{G}_N^{(1)}(e^{i\omega_k}) - G(e^{i\omega_k})$, are plotted for the noisy data. In the reduction of $H^{(1)}(z)$ for the noisy data, the first seven singular values of the Hankel matrix were computed as 0.5471, 0.2407, 0.1926, 0.0973, 0.0963, 0.0369, 0.0367. The choice of (final) model order was based on this distribution.

TABLE 5.1
Results for the noise-free data, where k is the number of iterations.

k	$\|H^{(k)} - E_N\|_{m,\infty}$	$\|\widehat{G}_N^{(k)} - E_N\|_{m,\infty}$

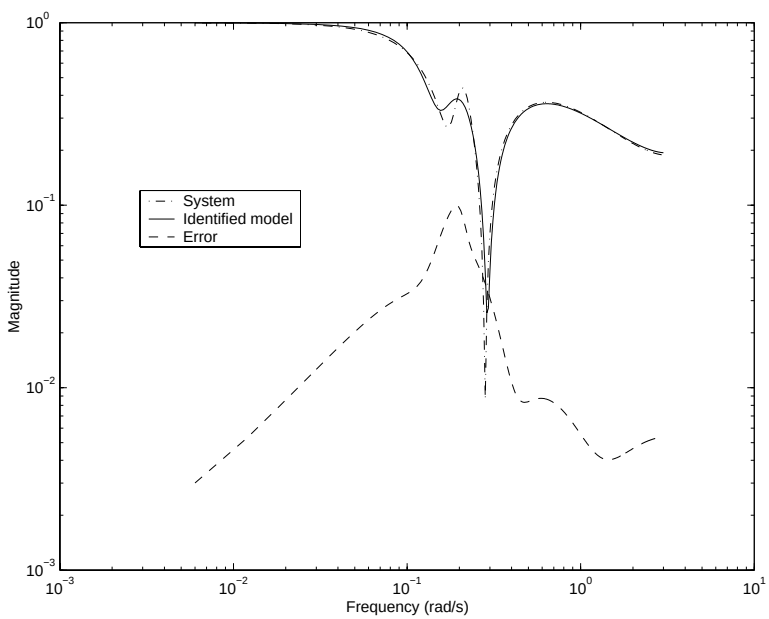

FIG. 5.1. *The magnitude plots of* $G(e^{i\omega_k})$, $\widehat{G}_N^{(1)}(e^{i\omega_k})$, *computed from the noisy data, and the identification error* $\widehat{G}_N^{(1)}(e^{i\omega_k}) - G(e^{i\omega_k})$.

5.2. Discussion. This example has demonstrated that the iterative-identification scheme works. The convergence analysis of this scheme and its relation to other iterative-identification schemes [35, 23] need to be studied. The convergence properties of this scheme with respect to unknown-but-bounded noise are studied in [5].

6. Conclusions. In this paper, we presented a robust two-stage algorithm that uses general orthonormal basis functions to identify linear-time invariant systems from nonuniformly spaced frequency response measurements. We also derived worst-case identification error bounds in the H_∞ norm, assuming that the number of basis

functions does not increase faster than a certain rate relative to the amount of data. The error convergence rate of the algorithm as a function of the number of basis functions, for every choice of basis functions, was shown to be on the order of the best possible.

The work initiated in this paper could be continued in several directions. First, the possibility of extending these results to arbitrary complete bases in $A(\mathbf{D})$ is worth investigating. The second, and practically more relevant, problem is the development of iterative pole updating schemes to improve the quality of transfer function estimates in applications where model complexity is restricted.

PICK MATRIX CONDITIONS FOR SIGN-DEFINITE SOLUTIONS OF THE ALGEBRAIC RICCATI EQUATION*

H. L. TRENTELMAN† AND P. RAPISARDA‡

Abstract. We study the existence of positive and negative semidefinite solutions of algebraic Riccati equations (ARE) corresponding to linear quadratic problems with an indefinite cost functional. The formulation of reasonable necessary and sufficient conditions for the existence of such solutions is a long-standing open problem. A central role is played by certain two-variable polynomial matrices associated with the ARE. Our main result characterizes all unmixed solutions of the ARE in terms of the Pick matrices associated with these two-variable polynomial matrices. As a corollary of this result, we find that the signatures of the extremal solutions of the ARE are determined by the signatures of particular Pick matrices.

Key words. algebraic Riccati equation, existence of semidefinite solutions, two-variable polynomial matrices, Pick matrices, dissipative systems

1. Introduction and problem statement.

Let $A \in \mathbb{R}^{n\times n}$ and $B \in \mathbb{R}^{n\times m}$ be such that (A, B) is a controllable pair. Let $Q \in \mathbb{R}^{n\times n}$ be symmetric and let $R \in \mathbb{R}^{m\times m}$ be nonsingular and symmetric. Finally, let $S \in \mathbb{R}^{m\times n}$. The quadratic equation

$$A^T K + KA + Q - (KB + S^T)R^{-1}(B^T K + S) = 0 \tag{1}$$

in the unknown $n \times n$ matrix K is called the (continuous-time) algebraic Riccati equation (the ARE). Since its introduction in control theory at the beginning of the sixties, the ARE has been studied extensively because of its prominent role in linear quadratic optimal control and filtering, H_∞-optimal control, differential games, and stochastic filtering and control. We refer to the papers collected in [2] for a discussion of the ARE and its applications and for an overview of the existing literature.

In this paper, we restrict ourselves to the case in which R is positive definite. However, the weighting matrix

$$M := \begin{pmatrix} Q & S^T \\ S & R \end{pmatrix}$$

is allowed to be indefinite. Our aim is to address a long-standing open problem concerning the ARE, namely, the problem of formulating reasonable necessary and sufficient conditions for the existence of at least one real positive semidefinite solution or of at least one real negative semidefinite solution. We want to stress that the main difficulty is the *indefiniteness of* M. For the case in which M is positive semidefinite, the problem is already well understood. For this case, necessary and sufficient conditions for the existence of at least one real positive semidefinite solution were obtained

in [5] and [6]. Basically, these necessary and sufficient conditions can be formulated as follows: factor $M = (C\ \ D)^T(C\ \ D)$. Then the ARE (1) has at least one real positive semidefinite solution if and only if the system (A, B, C, D) is output stabilizable (see also [17], [23], or [24]).

For *indefinite* weighting matrices M, the problem was listed in [13] among a series of open problems in the field of systems and control. Partial results for this problem were obtained in [19, 20, 1, 7, 8]. For an overview and a discussion of these results, as well as their relation to the classical problem of the existence of nonnegative storage functions for dissipative systems, we refer to [13].

In the present paper we will present a solution to this open problem, under the assumption that the pair (A, B) is controllable. It will be proven that the signs of the smallest and largest real symmetric solution, respectively, depend on the signs of certain constant $n \times n$ matrices (so called *Pick matrices*, associated with the ARE), which are easily constructed from the parameters appearing in the ARE. A necessary and sufficient condition for the existence of a real symmetric positive semidefinite solution of the ARE (1) will turn out to be that (i) it has at least one real symmetric solution, and (ii) a suitable Pick matrix is negative semidefinite. Likewise, the existence of at least one negative semidefinite solution is determined by the positive semidefiniteness of a suitable Pick matrix. In the process of establishing these conditions we obtain a number of intermediate results, among which are a new characterization of all unmixed real symmetric solutions of the ARE, and a new characterization of the supremal and infimal real symmetric solutions, all in terms of the Pick matrices associated with the ARE.

A few words on notation are required at this point. In this paper we adopt the usual symbols $\mathbb{R}$ and $\mathbb{C}$ in order to denote the real and complex numbers, respectively. The open and closed right half-planes of $\mathbb{C}$ are denoted, respectively, by $\mathbb{C}_+^0$ and $\mathbb{C}_+$. Given $\lambda \in \mathbb{C}$, its complex conjugate is denoted by $\bar{\lambda}$. The space of n-dimensional real, respectively complex, vectors is denoted by $\mathbb{R}^n$, respectively $\mathbb{C}^n$, and the space of $m \times n$ real, respectively complex, matrices, by $\mathbb{R}^{m\times n}$, respectively $\mathbb{C}^{m\times n}$.

The symbol $\mathbb{R}^{\bullet\times n}$ denotes the space of real matrices with n columns, and $\mathbb{R}^{m\times\bullet}$ denotes the space of real matrices with m rows. Given two column vectors x and y, we denote with $\mathrm{col}(x, y)$ the vector obtained by stacking x over y. If $A \in \mathbb{R}^{m\times n}$, then $A^T \in \mathbb{R}^{n\times m}$ denotes its transpose, and if $A \in \mathbb{C}^{m\times n}$, then $A^* \in \mathbb{C}^{n\times m}$ denotes its conjugate transpose $\bar{A}^T$. If $A \in \mathbb{C}^{n\times n}$ is Hermitian, i.e., $A^* = A$, then we define the signature of A as the triple $\mathrm{sign}(A) = (n_-, n_0, n_+)$, where n_- is the number of negative eigenvalues of A, n_0 the algebraic multiplicity of 0 as an eigenvalue of A, and n_+ the number of positive eigenvalues of A.

The ring of polynomials with real coefficients in the indeterminate ξ is denoted by $\mathbb{R}[\xi]$; analogously, the ring of two-variable polynomials with real coefficients in the indeterminates ζ and η is denoted by $\mathbb{R}[\zeta, \eta]$. The space of all $n \times m$ polynomial matrices in the indeterminate ξ is denoted by $\mathbb{R}^{n\times m}[\xi]$, and that consisting of all $n \times m$ polynomial matrices in the indeterminates ζ and η by $\mathbb{R}^{n\times m}[\zeta, \eta]$. The space of polynomial matrices with real coefficients in the indeterminate ξ with n columns is denoted by $\mathbb{R}^{\bullet\times n}[\xi]$, and $\mathbb{R}^{m\times\bullet}[\xi]$ is the space of polynomial matrices with m rows. Given a matrix $R \in \mathbb{R}^{n\times m}[\xi]$, we define $R^\sim(\xi) := R^T(-\xi) \in \mathbb{R}^{m\times n}[\xi]$. If $F \in \mathbb{R}^{m\times n}[\xi]$, then F can be written as $F(\xi) = F_0 + F_1\xi + \cdots + F_L\xi^L$, where $F_j \in \mathbb{R}^{m\times n}$ for $j = 0, 1, \ldots, L$. We call the $m \times (L+1)n$ matrix $\tilde{F} := \begin{pmatrix} F_0 & F_1 & \ldots & F_L \end{pmatrix}$ the *coefficient matrix* of F. It is easy to see that

$$F(\xi) = \tilde{F} \begin{pmatrix} I_n \\ I_n\xi \\ \vdots \\ I_n\xi^L \end{pmatrix}.$$

For a given finite-dimensional Euclidean space X, we denote by $\mathfrak{C}^\infty(\mathbb{R}, X)$ the set of all infinitely differentiable functions from $\mathbb{R}$ to X, and by $\mathfrak{D}(\mathbb{R}, X)$ the subset of $\mathfrak{C}^\infty(\mathbb{R}, X)$ consisting of those functions having compact support. Finally, if K is a symmetric $n \times n$ matrix, the quadratic form on $\mathbb{R}^n$ defined by $x \mapsto x^T K x$ is denoted by $| x |_K^2$.

2. Linear differential systems and quadratic differential forms. In this section we give a brief review of the notion of linear differential systems. The reader is referred to the textbook [9] or to [21] for a thorough exposition. A linear differential system is a linear subspace $\mathcal{B}$ of $\mathfrak{C}^\infty(\mathbb{R}, \mathbb{R}^q)$ of all solutions w of a given system of linear, constant coefficient, higher order differential equations. Such a system of differential equations can always be represented as a single equation

$$R\left(\frac{d}{dt}\right) w = 0, \tag{2}$$

where $R \in \mathbb{R}^{\bullet \times q}[\xi]$ is a real polynomial matrix with q columns. The linear space $\mathcal{B}$ is called the behavior of the linear differential system, and (2) is called a kernel representation of $\mathcal{B}$. The variable w is called the manifest variable of $\mathcal{B}$. An alternative way to represent the behavior of a linear differential system is as an image representation. If $M \in \mathbb{R}^{q \times d}[\xi]$ and $\mathcal{B} = \{w \in \mathfrak{C}^\infty(\mathbb{R}, \mathbb{R}^q) \mid \exists\ l \in \mathfrak{C}^\infty(\mathbb{R}, \mathbb{R}^d)$ such that $w = M(\frac{d}{dt})l\}$, then we call

$$w = M\left(\frac{d}{dt}\right) l \tag{3}$$

an image representation of $\mathcal{B}$. Not all behaviors admit an image representation; indeed, a behavior can be represented in image form if and only if every one of its kernel representations is associated with a polynomial matrix $R \in \mathbb{R}^{\bullet \times q}[\xi]$ such that $\operatorname{rank}(R(\lambda))$ is constant for all $\lambda \in \mathbb{C}$, or equivalently, such that $\mathcal{B}$ is controllable. The image representation (3) of $\mathcal{B}$ is called *observable* if $(M(\frac{d}{dt})l = 0) \Longrightarrow (l = 0)$. It can be shown that this is the case if and only if the matrix $M(\lambda)$ has full column rank for all $\lambda \in \mathbb{C}$.

We proceed to review the notion of state maps introduced in [12]. We will consider only the case of image representations in this paper. Let (3) be an image representation of the behavior $\mathcal{B}$. A polynomial matrix $X \in \mathbb{R}^{n \times d}[\xi]$ is said to induce a *state map* for $\mathcal{B}$ (or, simply, for M) if the latent variable $x := X(\frac{d}{dt})l$ satisfies the *axiom of state*. This means that if we define the *full behavior* as

$$\mathcal{B}_{\text{full}} = \left\{ (w, x) \in \mathfrak{C}^\infty(\mathbb{R}, \mathbb{R}^q \times \mathbb{R}^n) \mid \text{there exists } l \in \mathfrak{C}^\infty(\mathbb{R}, \mathbb{R}^d) \text{ such that } w = M\left(\frac{d}{dt}\right) l,\ x = X\left(\frac{d}{dt}\right) l \right\},$$

then $(w_1, x_1), (w_2, x_2) \in \mathcal{B}_{\text{full}}$ and $x_1(0) = x_2(0)$ imply that $(w_1, x_1) \wedge (w_2, x_2)$, the concatenation of (w_1, x_1) and (w_2, x_2) at $t = 0$, belongs to the closure in the topology

of $\mathfrak{L}^1_{\rm loc}$ of $\mathcal{B}_{\rm full}$ (see [12]). Now assume that the image representation (3) is observable. Then a state map for the system can be computed as follows. If necessary, permute the components of w so that

$$M = \begin{pmatrix} U \\ Y \end{pmatrix} \tag{4}$$

with $U \in \mathbb{R}^{d\times d}[\xi]$, $\det(U) \neq 0$, and YU^{-1} is a proper rational matrix (it can be shown that such a permutation always exists). Now consider the set

$$\{r \in \mathbb{R}^{1\times d}[\xi] \mid \ rU^{-1} \text{ is strictly proper}\}. \tag{5}$$

It is not difficult to show that this set is a vector space over $\mathbb{R}$. It has been proved in [12] that X is a state map for (3) if and only if its rows (interpreted as elements of the vector space $\mathbb{R}^{1\times d}[\xi]$ over $\mathbb{R}$) span the vector space (5), and is a *minimal state map* (i.e., inducing a state variable of minimal possible dimension) if and only if its rows form a basis for (5). If this holds true, the number of rows of X is called the *McMillan degree* of M, denoted $n(M)$, or, referring to the behavior being represented in image form, *the McMillan degree of* $\mathcal{B}$, denoted $n(\mathcal{B})$. It can be shown (see Proposition 3.5.5 of [12]) that $n(M) = \deg(\det(U))$.

In many modeling and control problems it is necessary to study certain functionals of the system variables and their derivatives. In the context of linear systems these functionals are often taken to be quadratic. An efficient representation for such quadratic functionals by means of two-variable polynomial matrices has been proposed in [18]. In this section we review the definitions and results of such a two-variable polynomial framework, which are used in the rest of the paper.

Let $\Phi \in \mathbb{R}^{q_1\times q_2}[\zeta,\eta]$; then Φ can be written in the form

$$\Phi(\zeta,\eta) = \sum_{h,k=0}^{N} \Phi_{h,k}\zeta^h\eta^k,$$

where $\Phi_{h,k} \in \mathbb{R}^{q_1\times q_2}$ and N is an integer. The two-variable polynomial matrix Φ induces a bilinear functional acting on infinitely differentiable trajectories as follows:

$$L_\Phi : \mathfrak{C}^\infty(\mathbb{R},\mathbb{R}^{q_1}) \times \mathfrak{C}^\infty(\mathbb{R},\mathbb{R}^{q_2}) \longrightarrow \mathfrak{C}^\infty(\mathbb{R},\mathbb{R}),$$

$$L_\Phi(w_1,w_2) = \sum_{h,k=0}^{N} \left(\frac{d^h w_1}{dt^h}\right)^T \Phi_{h,k} \frac{d^k w_2}{dt^k}.$$

If Φ is a *symmetric two-variable polynomial matrix*, i.e., if $q_1 = q_2$ and $\Phi_{h,k} = \Phi^T_{k,h}$ for all h, k, then it induces also a quadratic functional $Q_\Phi : \mathfrak{C}^\infty(\mathbb{R},\mathbb{R}^q) \longrightarrow \mathfrak{C}^\infty(\mathbb{R},\mathbb{R})$ defined by $Q_\Phi(w) := L_\Phi(w,w)$. We will call Q_Φ the *quadratic differential form* (QDF) associated with Φ. We denote the set of all symmetric $q\times q$ two-variable polynomial matrices by $\mathbb{R}^{q\times q}_s[\zeta,\eta]$. The QDF Q_Φ is called nonnegative, denoted $Q_\Phi \geq 0$, if $Q_\Phi(w) \geq 0$ for all $w \in \mathfrak{C}^\infty(\mathbb{R},\mathbb{R}^q)$.

With every $\Phi \in \mathbb{R}^{q\times q}_s[\zeta,\eta]$ we associate its *coefficient matrix*, which is defined as the infinite symmetric matrix with a finite number of nonzero elements, given by

$$\tilde{\Phi} := \begin{pmatrix} \Phi_{0,0} & \Phi_{0,1} & \dots & \Phi_{0,N} & \dots \\ \Phi_{1,0} & \Phi_{1,1} & \dots & \Phi_{1,N} & \dots \\ \vdots & \vdots & \vdots & \vdots & \vdots \\ \Phi_{N,0} & \Phi_{N,1} & \dots & \Phi_{N,N} & \dots \\ \vdots & \vdots & \vdots & \vdots & \vdots \end{pmatrix}.$$

Clearly, $Q_\Phi \geq 0$ if and only if $\tilde{\Phi} \geq 0$.

The association of two-variable polynomial matrices with QDFs allows us to develop a calculus that has applications in stability theory, optimal control, and H_∞-control (see [18], [16] and [22]). We restrict our attention to a couple of concepts that are used extensively in this paper. One of them is the map $\partial : \mathbb{R}_s^{q\times q}[\zeta,\eta] \longrightarrow \mathbb{R}^{q\times q}[\xi]$, defined by

$$\partial\Phi(\xi) := \Phi(-\xi,\xi).$$

Observe that for every $\Phi \in \mathbb{R}_s^{q\times q}[\zeta,\eta]$, $\partial\Phi$ is para-Hermitian, i.e., $\partial\Phi = (\partial\Phi)^\sim$. Another feature of the calculus of QDFs that is used in this paper is the derivative of a QDF. Given a QDF Q_Φ we define its derivative as the QDF $\frac{d}{dt}Q_\Phi$ defined by $(\frac{d}{dt}Q_\Phi)(w) := \frac{d}{dt}(Q_\Phi(w))$. Q_Φ is called the derivative of Q_Ψ if $\frac{d}{dt}Q_\Psi = Q_\Phi$. In terms of the two-variable polynomial matrices associated with the QDFs, this relationship is expressed equivalently as $(\zeta+\eta)\Psi(\zeta,\eta) = \Phi(\zeta,\eta)$.

In this paper, we also use integrals of QDFs. In order to make sure that the integrals exist, we assume that the trajectories on which the QDF acts are of compact support, that is, they belong to $\mathfrak{D}(\mathbb{R},\mathbb{R}^q)$. Given a QDF Q_Φ, we define its integral as the functional

$$\int Q_\Phi : \mathfrak{D}(\mathbb{R},\mathbb{R}^q) \longrightarrow \mathbb{R},$$
$$\int Q_\Phi(w) = \int_{-\infty}^{+\infty} Q_\Phi(w)dt.$$

Questions such as when the integral of a QDF is a positive semidefinite operator arise naturally in the study of dissipativity. We call a QDF Q_Φ *average nonnegative* if $\int Q_\Phi \geq 0$, i.e., $\int_{-\infty}^{\infty} Q_\Phi(w)dt \geq 0$ for all $w \in \mathfrak{D}(\mathbb{R},\mathbb{R}^q)$. A QDF can be tested for average nonnegativity by analyzing the behavior of the para-Hermitian matrix $\partial\Phi$ on the imaginary axis. Indeed, it is proven in [18] that

$$\int Q_\Phi \geq 0 \Longleftrightarrow \partial\Phi(i\omega) \geq 0 \quad \forall\, \omega \in \mathbb{R}. \tag{6}$$

3. Storage functions and polynomial spectral factorization. In the context of dissipative systems, a QDF measures the power going into a system: its integral over the real line then measures the net flow of energy going into the system. The concept of storage function emerges in the framework of QDFs as follows. Let $\Phi \in \mathbb{R}_s^{q\times q}[\zeta,\eta]$; the QDF Q_Ψ is said to be a *storage function* for Q_Φ (or Ψ is a storage function for Φ) if the following *dissipation inequality* holds:

$$\frac{d}{dt}Q_\Psi \leq Q_\Phi.$$

Storage functions are related to dissipation functions, which we now define. A QDF Q_Δ is a *dissipation function* for Q_Φ (or Δ is a dissipation function for Φ) if $Q_\Delta \geq 0$ and $\int Q_\Phi = \int Q_\Delta$. There is a close relationship between storage functions, average nonnegativity, and dissipation functions.

PROPOSITION 1. *Let $\Phi \in \mathbb{R}_s^{q\times q}[\zeta,\eta]$. The following conditions are equivalent:*

1. $\int Q_\Phi \geq 0$*;*
2. Φ *admits a storage function;*
3. Φ *admits a dissipation function.*

Moreover, there exists a one-to-one relation between storage functions Ψ and dissipation functions Δ for Φ, defined by

$$\frac{d}{dt}Q_\Psi = Q_\Phi - Q_\Delta$$

or, equivalently,

$$(\zeta + \eta)\Psi(\zeta, \eta) = \Phi(\zeta, \eta) - \Delta(\zeta, \eta). \tag{7}$$

Since storage functions measure the energy stored inside a system, it is to be expected that they are related to the memory, to the state, of the system. This intuition has been formalized in [15] in more general terms than those needed in the rest of this paper. For our purposes, the following result from [15] will do.

PROPOSITION 2. *Let $\mathcal{B}$ be represented by $w = M(\frac{d}{dt})l$, and let $X \in \mathbb{R}^{n\times d}[\xi]$ induce a state map for $\mathcal{B}$. Let P be a symmetric $q \times q$ matrix, and define the two-variable polynomial matrix $\Phi(\zeta, \eta) = M^T(\zeta)PM(\eta)$. Let Q_Ψ be a storage function for Q_Φ. Then Q_Ψ is a quadratic function of the state, i.e., there exists a symmetric $n \times n$ matrix K such that $Q_\Psi(l) = \mid X(\frac{d}{dt})l \mid^2_K$ for all $l \in \mathfrak{C}^\infty(\mathbb{R}, \mathbb{R}^d)$; equivalently, $\Psi(\zeta, \eta) = X^T(\zeta)KX(\eta)$.*

Given an average nonnegative QDF, in general there exist an infinite number of storage functions. It turns out that they all lie between two extremal storage functions.

PROPOSITION 3. *Let $\int Q_\Phi \geq 0$. Then there exist storage functions Ψ_- and Ψ_+ such that any other storage function Ψ for Φ satisfies*

$$Q_{\Psi_-} \leq Q_\Psi \leq Q_{\Psi_+}.$$

In the following we call Q_{Ψ_-} the *smallest* and Q_{Ψ_+} the *largest storage function* of Q_Φ.

In many cases it is of interest to compute explicitly a storage function for a given QDF. We review here a procedure to compute the extremal storage functions Q_{Ψ_-} and Q_{Ψ_+} introduced in Proposition 3. For this we need to introduce the notion of polynomial spectral factorization of a para-Hermitian polynomial matrix. Let P be a para-Hermitian polynomial matrix. A factorization $P = F^\sim F$, with F a real polynomial matrix, is called a *polynomial spectral factorization* of P, and F is called a *spectral factor* of P. The factorization is called *Hurwitz* if F is square and the roots of $\det(F)$ lie in $\mathbb{C}_-$. It is called *semi-Hurwitz* if the roots of $\det(F)$ lie in $\mathbb{C}^0_-$. The factorization is called *(semi-)anti-Hurwitz* if F is square and the roots of $\det(F)$ lie in $\mathbb{C}_+$ (respectively, in $\mathbb{C}^0_+$). It is well known (see, for example, [10]) that P has a semi-Hurwitz and a (semi-)anti-Hurwitz spectral factorization if and only if $P(i\omega) \geq 0$ for all $\omega \in \mathbb{R}$, and a Hurwitz and an anti-Hurwitz spectral factorization if and only if $P(i\omega) > 0$ for all $\omega \in \mathbb{R}$. The following result shows how to use semi-Hurwitz and semi-anti-Hurwitz polynomial spectral factorizations of $\partial\Phi$ to compute the extremal storage functions of Φ.

PROPOSITION 4. *Let $\Phi(\zeta, \eta) \in \mathbb{R}^{\bullet\times\bullet}_s[\zeta, \eta]$. Assume $\det(\partial\Phi) \neq 0$ and $\partial\Phi(i\omega) \geq 0$ for all $\omega \in \mathbb{R}$. Then the smallest and the largest storage functions Ψ_- and Ψ_+ of Φ can be constructed as follows. Let H and A be semi-Hurwitz, respectively semi-anti-*

Hurwitz, polynomial spectral factors of $\partial\Phi$. *Then*

$$\Psi_+(\zeta,\eta) = \frac{\Phi(\zeta,\eta) - A^T(\zeta)A(\eta)}{\zeta+\eta},$$
$$\Psi_-(\zeta,\eta) = \frac{\Phi(\zeta,\eta) - H^T(\zeta)H(\eta)}{\zeta+\eta}.$$

It also turns out that if P is para-Hermitian, and if $P(i\omega) > 0$ for all $\omega \in \mathbb{R}$, then for every factorization of the scalar polynomial $\det(P)$ as $\det(P) = f^\sim f$, where f and $f^\sim$ have no common roots, there exists a polynomial spectral factorization of P as $P = F^\sim F$, with $\det(F) = f$. This result is taken from [3].

PROPOSITION 5. *Let* $P \in \mathbb{R}^{m\times m}[\xi]$ *be para-Hermitian. Assume that* $P(i\omega) > 0$ *for all* $\omega \in \mathbb{R}$. *Then for every factorization* $\det(P) = f^\sim f$, *with* $f \in \mathbb{R}[\xi]$ *such that* f *and* $f^\sim$ *are coprime, there exists* $F \in \mathbb{R}^{m\times m}[\xi]$ *such that* $P = F^\sim F$ *and* $\det(F) = f$.

4. Pick matrices. In this section we discuss Pick matrices associated with average nonnegative quadratic differential forms. In the following, let $\Phi(\zeta,\eta) \in \mathbb{R}^{q\times q}[\zeta,\eta]$. Assume that $\partial\Phi(i\omega) > 0$ for all $\omega \in \mathbb{R}$. Since $\partial\Phi$ is para-Hermitian, the degree of the polynomial $\det(\partial\Phi)$ is even, say $2n$. Also, $\det(\partial\Phi(i\omega)) > 0$ for all $\omega \in \mathbb{R}$, so $\det(\Phi)$ can be factored as $f^\sim f$ with $f \in \mathbb{R}[\xi]$ such that f and $f^\sim$ are coprime. Of course, for a given Φ there are many f's that satisfy these properties. With any such f, we associate a *Pick matrix*, denoted by T_f.

Pick matrices are most easily introduced in the special case in which the singularities of $\partial\Phi$ are semisimple, i.e., every singularity λ of $\partial\Phi$ has the property that its algebraic multiplicity (its multiplicity as a root of $\det(\partial\Phi)$) is equal to its geometric multiplicity (i.e., $q - \operatorname{rank}(\partial\Phi(\lambda))$, the rank deficiency at λ). For the moment, assume this to be the case.

Let $f \in \mathbb{R}[\xi]$ be such that $\det(\partial\Phi) = f^\sim f$ and $(f, f^\sim)$ coprime. Let $\lambda_1, \lambda_2, \dots, \lambda_n$ be the roots of f. We use the convention that if the algebraic multiplicity of λ_i is m_i, then it appears in this list m_i times, and we have ordered the roots in such a way that $\lambda_1, \lambda_2, \dots, \lambda_{m_1}$ are equal, that $\lambda_{m_1+1}, \lambda_{m_1+2}, \dots, \lambda_{m_1+m_2}$ are equal, etc. Clearly, the other singularities of $\partial\Phi$ are then $-\lambda_1, -\lambda_2, \dots, -\lambda_n$, the roots of $f^\sim$. Now for $i = 1, 2, \dots, n$, let $v_i \in \mathbb{C}^q$ be such that

$$\partial\Phi(\lambda_i)v_i = 0,$$

and such that $v_1, v_2, \dots, v_n$ are linearly independent. The Pick matrix associated with f is now defined as the matrix

$$T_f := \begin{pmatrix} \frac{v_1^*\Phi(\bar\lambda_1,\lambda_1)v_1}{\bar\lambda_1+\lambda_1} & \frac{v_1^*\Phi(\bar\lambda_1,\lambda_2)v_2}{\bar\lambda_1+\lambda_2} & \cdots & \frac{v_1^*\Phi(\bar\lambda_1,\lambda_k)v_n}{\bar\lambda_1+\lambda_n} \\ \frac{v_2^*\Phi(\bar\lambda_2,\lambda_1)v_1}{\bar\lambda_2+\lambda_1} & \frac{v_2^*\Phi(\bar\lambda_2,\lambda_2)v_2}{\bar\lambda_2+\lambda_2} & \cdots & \frac{v_2^*\Phi(\bar\lambda_2,\lambda_k)v_n}{\bar\lambda_2+\lambda_n} \\ \vdots & \vdots & \ddots & \vdots \\ \frac{v_n^*\Phi(\bar\lambda_n,\lambda_1)v_1}{\bar\lambda_n+\lambda_1} & \frac{v_n^*\Phi(\bar\lambda_n,\lambda_2)v_2}{\bar\lambda_n+\lambda_2} & \cdots & \frac{v_n^*\Phi(\bar\lambda_n,\lambda_n)v_n}{\bar\lambda_n+\lambda_n} \end{pmatrix}. \tag{8}$$

Note that $T_f = T_f^* \in \mathbb{C}^{n\times n}$, where $2n$ is the degree of $\det(\partial\Phi)$. Note that the n functions $e^{\lambda_1 t}v_1, e^{\lambda_2 t}v_2, \dots, e^{\lambda_n t}v_n$ span an n-dimensional subspace of the $2n$-dimensional complex linear space of solutions of the system of differential equations

$$(\partial\Phi)\left(\frac{d}{dt}\right)w = 0. \tag{9}$$

In the general case in which the singularities of $\partial\Phi$ are not all semisimple, the definition of T_f is also straightforward but notationally more involved. We will introduce the Pick matrix in the general case now.

The definition is most easily understood against the background of computing solutions to the system of differential equations (9). In general, a basis for the linear space of solutions of (9) is obtained by analyzing the structure of the singularities of the polynomial matrix $\partial\Phi$. Again let $\det(\partial\Phi) = f^{\sim}f$ be a given factorization, with $\deg(f) = n$. Let $\lambda_1, \lambda_2, \dots, \lambda_k$ be the roots of f. Again, this list of roots does not necessarily consist of distinct complex numbers. In fact, we use the convention that if a given root λ_i has geometric multiplicity n_i, then we include it n_i times in our list of roots. Hence, $\lambda_1, \lambda_2, \dots, \lambda_{n_1}$ are equal, $\lambda_{n_1+1}, \lambda_{n_1+2}, \dots, \lambda_{n_1+n_2}$ are equal, etc. It is well known that there exist integers $d_1, d_2, \dots, d_k \geq 1$ such that $d_1 + d_2 + \cdots + d_{n_1} = m_1$, the algebraic multiplicity of λ_1, $d_{n_1+1} + d_{n_1+2} + \cdots + d_{n_1+n_2} = m_2$, the algebraic multiplicity of λ_{n_1+1}, etc. The sum $\sum_i m_i$ of the algebraic multiplicities is equal to n, the degree of f.

The n-dimensional subspace of solutions of (9) with exponents in $\{\lambda_1, \lambda_2, \dots, \lambda_k\}$ is then computed as follows. Let $\partial\Phi^{(i)}$ be the ith derivative of $\partial\Phi$. For each $i = 1, 2, \dots, k$ there exist d_i complex vectors $a_{i,0}, a_{i,1}, \dots, a_{i,d_i-1} \in \mathbb{C}^q$ such that

(10)
$$\begin{pmatrix} \binom{0}{0}\partial\Phi^{(0)}(\lambda_i) & \binom{1}{0}\partial\Phi^{(1)}(\lambda_i) & \cdots & \cdots & \binom{d_i-1}{0}\partial\Phi^{(d_i-1)}(\lambda_i) \\ 0 & \binom{1}{1}\partial\Phi^{(0)}(\lambda_i) & \cdots & \cdots & \binom{d_i-1}{1}\partial\Phi^{(d_i-2)}(\lambda_i) \\ 0 & 0 & \ddots & & \vdots \\ \vdots & \vdots & \ddots & \ddots & \vdots \\ 0 & 0 & \cdots & 0 & \binom{d_i-1}{d_i-1}\partial\Phi^{(0)}(\lambda_i) \end{pmatrix} \begin{pmatrix} a_{i,0} \\ a_{i,1} \\ \vdots \\ \vdots \\ a_{i,d_i-1} \end{pmatrix} = 0$$

and such that the n vectors $a_{i,j}$ are linearly independent. Using these vectors we form the matrices $V_i \in \mathbb{C}^{d_i q \times d_i}$ defined by

(11)
$$V_i := \begin{pmatrix} \binom{0}{0}a_{i,0} & \binom{1}{1}a_{i,1} & \cdots & \binom{d_i-2}{d_i-2}a_{i,d_i-2} & \binom{d_i-1}{d_i-1}a_{i,d_i-1} \\ \binom{1}{0}a_{i,1} & \binom{2}{1}a_{i,2} & \cdots & \binom{d_i-1}{d_i-2}a_{i,d_i-1} & 0 \\ \vdots & \vdots & & 0 & 0 \\ \binom{d_i-2}{0}a_{i,d_i-2} & \binom{d_i-1}{1}a_{i,d_i-1} & & \vdots & \vdots \\ \binom{d_i-1}{0}a_{i,d_i-1} & 0 & \cdots & 0 & 0 \end{pmatrix}.$$

For $i = 1, 2, \dots, k$, define the matrix function $W_i : \mathbb{R} \to \mathbb{R}^{q \times d_i}$ by

$$W_i(t) := e^{\lambda_i t} \begin{pmatrix} I_{q\times q} & tI_{q\times q} & \cdots & t^{d_i-1}I_{q\times q} \end{pmatrix} V_i,$$

and the matrix function $W : \mathbb{R} \to \mathbb{R}^{q \times n}$ by

$$W(t) := \begin{pmatrix} W_1(t) & W_2(t) & \cdots & W_k(t) \end{pmatrix}.$$

Then the columns of W form a basis for the n-dimensional subspace of solutions of (9) with exponents in $\{\lambda_1, \lambda_2, \dots, \lambda_k\}$.

We now introduce the Pick matrix T_f associated with Φ and the factorization

$\det(\partial\Phi) = f^{\sim}f$. For $i, j = 1, 2, \ldots, k$, define the nonsingular $d_j \times d_j$ matrix $\Lambda_{i,j}$ by

$$\Lambda_{i,j} = \begin{pmatrix} 1 & 0 & 0 & \cdots & \cdots & 0 \\ \frac{-1}{\bar{\lambda}_i+\lambda_j} & 1 & 0 & \cdots & \cdots & 0 \\ \frac{2!}{(\bar{\lambda}_i+\lambda_j)^2} & \frac{-2!}{\bar{\lambda}_i+\lambda_j} & 1 & 0 & \cdots & 0 \\ \frac{-3!}{(\bar{\lambda}_i+\lambda_j)^3} & \frac{3!}{(\bar{\lambda}_i+\lambda_j)^2} & \frac{-3!}{\bar{\lambda}_i+\lambda_j} & 1 & \ddots & 0 \\ \vdots & \vdots & \ddots & \ddots & \ddots & 0 \\ \frac{(-1)^{d_j-1}(d_j-1)!}{(\bar{\lambda}_i+\lambda_j)^{d_j-1}} & \cdots & \cdots & \frac{(d_j-1)!}{(\bar{\lambda}_i+\lambda_j)^2} & \frac{-(d_j-1)!}{\bar{\lambda}_i+\lambda_j} & 1 \end{pmatrix}. \tag{12}$$

Also, for $i, j = 1, 2, \ldots, k$ we define $\Theta_{i,j} \in \mathbb{C}^{d_i q \times d_j q}$ by

$$\Theta_{i,j} := \begin{pmatrix} \Phi(\bar{\lambda}_i, \lambda_j) & \frac{\partial\Phi}{\partial\eta}(\bar{\lambda}_i, \lambda_j) & \cdots & \frac{\partial^{d_j-1}\Phi}{\partial\eta^{d_j-1}}(\bar{\lambda}_i, \lambda_j) \\ \frac{\partial\Phi}{\partial\zeta}(\bar{\lambda}_i, \lambda_j) & \frac{\partial^2\Phi}{\partial\zeta\partial\eta}(\bar{\lambda}_i, \lambda_j) & \cdots & \frac{\partial^{d_j}\Phi}{\partial\zeta\partial\eta^{d_j-1}}(\bar{\lambda}_i, \lambda_j) \\ \vdots & \vdots & \ddots & \vdots \\ \frac{\partial^{d_i-1}\Phi}{\partial\zeta^{d_i-1}}(\bar{\lambda}_i, \lambda_j) & \frac{\partial^{d_i}\Phi}{\partial\zeta^{d_i-1}\partial\eta}(\bar{\lambda}_i, \lambda_j) & \cdots & \frac{\partial^{d_i+d_j-2}\Phi}{\partial\zeta^{d_i-1}\partial\eta^{d_j-1}}(\bar{\lambda}_i, \lambda_j) \end{pmatrix}. \tag{13}$$

Here, $\frac{\partial^{i+j}\Phi}{\partial\zeta^i\partial\eta^j}(\zeta, \eta)$ denotes the (i, j)th partial derivative with respect to ζ and η of $\Phi(\zeta, \eta)$. We define the shift operator $\sigma : \mathbb{C}^{d_i q \times d_j q} \to \mathbb{C}^{d_i q \times d_j q}$ acting on matrices M that are partitioned into $q \times q$ blocks as follows: if

$$M = \begin{pmatrix} M_{1,1} & M_{1,2} & \cdots & M_{1,d_j} \\ M_{2,1} & M_{2,2} & \cdots & M_{2,d_j} \\ \vdots & \vdots & \ddots & \vdots \\ M_{d_i,1} & M_{d_i,2} & \cdots & M_{d_i,d_j}, \end{pmatrix},$$

then

$$\sigma(M) := \begin{pmatrix} 0 & 0 & \cdots & 0 \\ 0 & M_{1,1} & \cdots & M_{1,d_j-1} \\ \vdots & \vdots & \ddots & \vdots \\ 0 & M_{d_i-1,1} & \cdots & M_{d_i-1,d_j-1} \end{pmatrix}.$$

In terms of $\Theta_{i,j}$ and the shift-operator σ, for $i, j = 1, 2, \ldots, k$, we define the matrices $\Sigma_{i,j} \in \mathbb{C}^{d_i q \times d_j q}$ by

$$\begin{aligned} \Sigma_{i,j} := \frac{1}{\bar{\lambda}_i + \lambda_j}\Theta_{i,j} + \frac{1}{(\bar{\lambda}_i + \lambda_j)^2}\sigma(\Theta_{i,j}) + \frac{1}{(\bar{\lambda}_i + \lambda_j)^3}\sigma^2(\Theta_{i,j}) + \cdots \\ + \frac{1}{(\bar{\lambda}_i + \lambda_j)^{\max(d_i,d_j)-1}}\sigma^{\max(d_i,d_j)-1}(\Theta_{i,j}). \end{aligned} \tag{14}$$

Here, for a given M, $\sigma^2(M)$ is defined as $\sigma(\sigma(M))$, etc. The Pick matrix associated with Φ and the factorization $\det(\partial\Phi) = f^{\sim}f$ is now defined as the matrix $T_f \in \mathbb{C}^{n\times n}$, $T_f = (T_{i,j})_{i,j=1,2,\ldots,k}$, where the (i, j)th block is the complex $d_i \times d_j$ matrix given by

$$T_{i,j} := \Lambda_{j,i}^* V_i^* \Sigma_{i,j} V_j \Lambda_{i,j}. \tag{15}$$

Note that T_f is a Hermitian matrix.

For related material on Pick matrices, their application in interpolation problems, and connections with systems and control, see [4], [25].

5. The Riccati equation, linear matrix inequalities, and storage functions. In this section we study the connection between the existence of real symmetric solutions of the ARE and average nonnegativity of a given QDF associated with the ARE.

We associate with the ARE (1) the system with manifest variable $w = \mathrm{col}(x, u)$ represented by $\frac{d}{dt}x = Ax + Bu$, or equivalently

$$\begin{pmatrix} \frac{d}{dt}I_n - A & -B \end{pmatrix} \begin{pmatrix} x \\ u \end{pmatrix} = 0. \tag{16}$$

Equation (16) constitutes a kernel representation of the behavior

$$\mathfrak{B} = \{\mathrm{col}(x, u) \in \mathfrak{C}^\infty(\mathbb{R}, \mathbb{R}^n) \times \mathfrak{C}^\infty(\mathbb{R}, \mathbb{R}^m) \mid \text{(16) is satisfied}\}. \tag{17}$$

A standing assumption in the remainder of this paper is that the pair (A, B) is controllable. Under this assumption, $\mathfrak{B}$ can be represented in image form. One such representation can be computed as follows. Let $X \in \mathbb{R}^{n\times m}[\xi]$ and $U \in \mathbb{R}^{m\times m}[\xi]$ induce a right coprime factorization of the rational matrix $(\xi I_n - A)^{-1}B$, i.e., $(\xi I_n - A)^{-1}B = X(\xi)U(\xi)^{-1}$ and

$$\mathrm{rank} \begin{pmatrix} X(\lambda) \\ U(\lambda) \end{pmatrix} = m$$

for all $\lambda \in \mathbb{C}$. Then $\mathfrak{B}$ is represented in observable image form as

$$\begin{pmatrix} x \\ u \end{pmatrix} = \begin{pmatrix} X(\frac{d}{dt}) \\ U(\frac{d}{dt}) \end{pmatrix} l. \tag{18}$$

Observe that any such X yields a minimal state map $X(\frac{d}{dt})$ for $\mathfrak{B}$.

Given the matrices $Q = Q^T \in \mathbb{R}^{n\times n}$, $R = R^T \in \mathbb{R}^{m\times m}$, and $S \in \mathbb{R}^{m\times n}$, and the polynomial matrices X and U, we define the symmetric $m\times m$ two-variable polynomial matrix Φ by

$$\Phi(\zeta, \eta) = \begin{pmatrix} X(\zeta)^T & U(\zeta)^T \end{pmatrix} \begin{pmatrix} Q & S^T \\ S & R \end{pmatrix} \begin{pmatrix} X(\eta) \\ U(\eta) \end{pmatrix}. \tag{19}$$

Note that if l and $\mathrm{col}(x, u)$ are related by (18), then the QDF Q_Φ associated with Φ satisfies

$$Q_\Phi(l) = \begin{pmatrix} x^T & u^T \end{pmatrix} \begin{pmatrix} Q & S^T \\ S & R \end{pmatrix} \begin{pmatrix} x \\ u \end{pmatrix}.$$

Of course, $(\xi I_n - A)^{-1}B$ admits many right coprime factorizations. If $X_1U_1^{-1} = X_2U_2^{-1}$ are two right coprime factorizations, then they are related by a unimodular transformation: there exists a unimodular V such that $X_2 = X_1V$ and $U_2 = U_1V$. Hence the associated two-variable polynomial matrices are related by $\Phi_1(\zeta, \eta) = V^T(\zeta)\Phi_2(\zeta, \eta)V(\eta)$.

Example 6. In the Riccati equation (1), let $A = \left(\begin{smallmatrix} 0 & 0 \\ 0 & 1 \end{smallmatrix}\right), B = \left(\begin{smallmatrix} 1 & 0 \\ 0 & 1 \end{smallmatrix}\right), Q = \left(\begin{smallmatrix} 1 & a \\ a & 3 \end{smallmatrix}\right), R = \left(\begin{smallmatrix} 1 & 0 \\ 0 & 1 \end{smallmatrix}\right)$, and $S = \left(\begin{smallmatrix} 0 & 0 \\ 0 & 0 \end{smallmatrix}\right)$. Here a is a parameter taking values in $\mathbb{R}$. Clearly, $(\xi I - A)^{-1}B = X(\xi)U(\xi)^{-1}$, with $X(\xi) = \left(\begin{smallmatrix} 1 & 0 \\ 0 & 1 \end{smallmatrix}\right)$, and $U(\xi) = \left(\begin{smallmatrix} \xi & 0 \\ 0 & \xi - 1 \end{smallmatrix}\right)$. The corresponding two-variable polynomial matrix is $\Phi(\zeta, \eta) = \left(\begin{smallmatrix} 1+\zeta\eta & a \\ a & 3+(\zeta-1)(\eta-1) \end{smallmatrix}\right)$.

The next result connects the average nonnegativity of the QDF associated with (19) with the existence of real symmetric solutions to the linear matrix inequality associated with the ARE (1) and with the existence of storage functions for Q_Φ.

THEOREM 7. *Let $\Phi(\zeta,\eta)$ be defined by (19), where X and U are such that $X(\xi)U(\xi)^{-1}$ is a right coprime factorization of $(\xi I_n - A)^{-1}B$. Then the following statements are equivalent:*

1. *$\int Q_\Phi \geq 0$;*
2. *there exists $K = K^T \in \mathbb{R}^{n\times n}$ such that $\mid X(\frac{d}{dt})l \mid_K^2$ is a storage function for Q_Φ;*
3. *there exists $K = K^T \in \mathbb{R}^{n\times n}$ such that the $(n+m)\times(n+m)$ symmetric matrix*

$$L(K) := \begin{pmatrix} Q - A^TK - KA & -KB + S^T \\ -B^TK + S & R \end{pmatrix}$$

satisfies $L(K) \geq 0$.

In fact, for every $K = K^T \in \mathbb{R}^{n\times n}$ there holds

$$\frac{d}{dt}\left|X\left(\frac{d}{dt}\right)l\right|_K^2 = Q_\Phi(l) - \left|\begin{pmatrix} X(\frac{d}{dt})l \\ U(\frac{d}{dt})l \end{pmatrix}\right|_{L(K)}^2 \tag{20}$$

for all $l \in \mathfrak{C}^\infty(\mathbb{R},\mathbb{R}^m)$; equivalently,

$$(\zeta+\eta)X^T(\zeta)KX(\eta) = \Phi(\zeta,\eta) - \begin{pmatrix} X(\zeta)^T & U(\zeta)^T \end{pmatrix} L(K) \begin{pmatrix} X(\eta) \\ U(\eta) \end{pmatrix}.$$

Consequently, for $K = K^T \in \mathbb{R}^{n\times n}$ the following statements are equivalent:

(i) *$L(K) \geq 0$;*

(ii) *$\mid X(\frac{d}{dt})l \mid_K^2$ is a storage function for Q_Φ;*

(iii)

$$\left|\begin{pmatrix} X(\frac{d}{dt})l \\ U(\frac{d}{dt})l \end{pmatrix}\right|_{L(K)}^2$$

is a dissipation function for Q_Φ.

Proof. We prove the equivalence of (i),(ii), and (iii). The first part of the theorem follows easily from this and from Proposition 1. We need the following lemma.

LEMMA 8. *Let $X \in \mathbb{R}^{n\times m}[\xi]$ and $U \in \mathbb{R}^{m\times m}[\xi]$ be such that $X(\xi)U(\xi)^{-1}$ is a right coprime factorization of $(\xi I - A)^{-1}B$. Then the mapping*

$$\begin{aligned} \mathcal{C}^\infty(\mathbb{R},\mathbb{R}^m) &\to \mathbb{R}^n \times \mathbb{R}^m, \\ l &\mapsto \begin{pmatrix} (X(\frac{d}{dt})l)(0) \\ (U(\frac{d}{dt})l)(0) \end{pmatrix} \end{aligned}$$

is surjective.

Proof of Lemma 8. Let $(x_0,u_0) \in \mathbb{R}^n \times \mathbb{R}^m$. Let $\tilde{u} \in \mathcal{C}^\infty(\mathbb{R},\mathbb{R}^m)$ be such that $\tilde{u}(0) = u_0$. Consider the differential equation $\dot{x} = Ax + B\tilde{u}$, $x(0) = x_0$, and let $\tilde{x} \in \mathcal{C}^\infty(\mathbb{R},\mathbb{R}^n)$ be its solution. Evidently,

$$\operatorname{col}(\tilde{x},\tilde{u}) \in \operatorname{im}\begin{pmatrix} X(\frac{d}{dt}) \\ U(\frac{d}{dt}) \end{pmatrix},$$

so there exists $l \in \mathcal{C}^\infty(\mathbb{R}, \mathbb{R}^m)$ such that

$$\begin{pmatrix} \tilde{x} \\ \tilde{u} \end{pmatrix} = \begin{pmatrix} X(\frac{d}{dt}) \\ U(\frac{d}{dt}) \end{pmatrix} l.$$

Consequently,

$$\begin{pmatrix} x_0 \\ u_0 \end{pmatrix} = \begin{pmatrix} \tilde{x}(0) \\ \tilde{u}(0) \end{pmatrix} = \begin{pmatrix} (X(\frac{d}{dt})l)(0) \\ (U(\frac{d}{dt})l)(0) \end{pmatrix}.$$

This concludes the proof of the lemma.

We resume the proof of Theorem 7. Let $K = K^T \in \mathbb{R}^{n\times n}$. We first prove that, for all l, (20) holds; equivalently,

$$(\zeta + \eta)X(\zeta)^T K X(\eta) = \Phi(\zeta, \eta) - \begin{pmatrix} X(\zeta)^T & U(\zeta)^T \end{pmatrix} L(K) \begin{pmatrix} X(\eta) \\ U(\eta) \end{pmatrix}. \tag{21}$$

Indeed, from the fact that $X(\xi)U(\xi)^{-1} = (\xi I - A)^{-1}B$ it follows that $\xi X(\xi) = AX(\xi) + BU(\xi)$. Consequently,

$$\begin{aligned}(\zeta + \eta)X(\zeta)^T K X(\eta) = {} & X(\zeta)^T A^T K X(\eta) + U(\zeta)^T B^T K X(\eta) \\ & + X(\zeta)^T K A X(\eta) + X(\zeta)^T K B U(\eta),\end{aligned}$$

which can be rewritten as

$$\begin{pmatrix} X(\zeta)^T & U(\zeta)^T \end{pmatrix} \begin{pmatrix} A^T K + KA & KB \\ B^T K & 0 \end{pmatrix} \begin{pmatrix} X(\eta) \\ U(\eta) \end{pmatrix}.$$

With $\Phi(\zeta, \eta)$ defined by (19), equation (21) then follows immediately. Since, by Lemma 8, the map

$$l \mapsto \begin{pmatrix} (X(\frac{d}{dt})l)(0) \\ (U(\frac{d}{dt})l)(0) \end{pmatrix}$$

is surjective, we have

$$\left| \begin{pmatrix} X(\frac{d}{dt})l \\ U(\frac{d}{dt})l \end{pmatrix} \right|^2_{L(K)} \geq 0 \quad \forall\, l \in \mathfrak{C}^\infty(\mathbb{R}, \mathbb{R}^m)$$

if and only if $L(K) \geq 0$. Thus the equivalence of (i), (ii), and (iii) follows immediately from (20).

The equivalence of statements 1. and 2. follows from Propositions 1 and 2. The equivalence of 2. and 3. is an immediate consequence of the equivalence of (i) and (ii). □

If we assume that the matrix R is positive definite, the result of Theorem 7 can be sharpened, and a connection can be established between the QDF $\Phi(\zeta, \eta)$ defined in (19) and the ARE (1).

THEOREM 9. *Let $\Phi(\zeta, \eta)$ be defined by (19), where X and U are such that $X(\xi)U(\xi)^{-1}$ is a right coprime factorization of $(\xi I_n - A)^{-1}B$. Assume $R > 0$. Then the following statements are equivalent:*

1. $\int Q_\Phi \geq 0$;
2. *There exists a real symmetric solution to the* ARE.

In fact, for every $K = K^T \in \mathbb{R}^{n\times n}$ *the following conditions are equivalent:*

(i) $-K$ *satisfies the* ARE;

(ii) $\mid X(\frac{d}{dt})l \mid^2_K$ *is a storage function for* Q_Φ *with associated dissipation function*

$$\Delta(\zeta,\eta) = \begin{pmatrix} X(\zeta)^T & U(\zeta)^T \end{pmatrix} L(K) \begin{pmatrix} X(\eta) \\ U(\eta) \end{pmatrix} = F(\zeta)^T F(\eta),$$

where

$$F(\xi) := R^{-\frac{1}{2}}(-B^TK + S)X(\xi) + R^{\frac{1}{2}}U(\xi);$$

(iii) $\mid X(\frac{d}{dt})l \mid^2_K$ *is a storage function for* Q_Φ*, and the rank of the coefficient matrix of the QDF* $Q_\Phi(l) - \frac{d}{dt} \mid X(\frac{d}{dt})l \mid^2_K$ *is equal to* m.

Proof. We begin by proving the implication 1. $\Rightarrow$ 2. From condition 1. and the equivalence in (6), we obtain $\partial\Phi(i\omega) \geq 0$ for all $\omega \in \mathbb{R}$. Since $\det(\partial\Phi) \neq 0$, there exists a semi-Hurwitz factorization $\partial\Phi = H^\sim H$, with $\det(H) \neq 0$. According to Proposition 4, this yields the smallest storage function as induced by the two-variable polynomial matrix

$$\Psi_-(\zeta,\eta) = \frac{\Phi(\zeta,\eta) - H^T(\zeta)H(\eta)}{\zeta + \eta}.$$

By Proposition 2, there exists $K = K^T \in \mathbb{R}^{n\times n}$ such that $\Psi_-(\zeta,\eta) = X^T(\zeta)KX(\eta)$. We claim that $-K$ satisfies the ARE. Indeed, as in the proof of Theorem 7, we have

$$H^T(\zeta)H(\eta) = \begin{pmatrix} X(\zeta)^T & U(\zeta)^T \end{pmatrix} L(K) \begin{pmatrix} X(\eta) \\ U(\eta) \end{pmatrix}. \tag{22}$$

Since $\det(H) \neq 0$, the coefficient matrix $\tilde{H}$ of H has full row rank m. Since by Lemma 8 the mapping $l \mapsto \mathrm{col}((X(\frac{d}{dt})l)(0), (U(\frac{d}{dt})l)(0))$ is surjective, the coefficient matrix of $\mathrm{col}(X(\eta), U(\eta))$ has full row rank. Consequently, $L(K)$ has rank m. Since $R > 0$, $\mathrm{rank}(L(K)) = m$ if and only if the Schur complement of R in $L(K)$ is zero, that is, if and only if

$$Q - A^TK - KA - (-KB + S^T)R^{-1}(-B^TK + S) = 0,$$

in other words, if and only if $-K$ satisfies the ARE. This concludes the proof of the implication 1. $\Rightarrow$ 2. The implication 2. $\Rightarrow$ 1. follows from the implication (i) $\Rightarrow$ (ii) below.

Next, we prove the equivalence of (i), (ii), and (iii) of Theorem 9.

(i) $\Rightarrow$ (ii). Assume $-K$ satisfies the ARE. Then it is easily seen that

$$L(K) = \begin{pmatrix} R^{-1/2}(-B^TK + S) & R^{1/2} \end{pmatrix}^T \begin{pmatrix} R^{-1/2}(-B^TK + S) & R^{1/2} \end{pmatrix} \geq 0.$$

From Theorem 7 it then follows that $\mid X(\frac{d}{dt})l \mid^2_K$ is a storage function for Q_Φ, with associated dissipation function $F^T(\zeta)F(\eta)$, where $F(\xi) = R^{-1/2}(-B^TK + S)X(\xi) + R^{1/2}U(\xi)$.

(ii) $\Rightarrow$ (iii). According to (ii), $\mathrm{rank}(L(K)) = m$. The coefficient matrix of the QDF $Q_\Phi(l) - \frac{d}{dt} \mid X(\frac{d}{dt})l \mid^2_K$ is equal to

$$\begin{pmatrix} \tilde{X} \\ \tilde{U} \end{pmatrix}^T L(K) \begin{pmatrix} \tilde{X} \\ \tilde{U} \end{pmatrix},$$

with $\mathrm{col}(\tilde{X}, \tilde{U})$ the coefficient matrix of $\mathrm{col}(X, U)$. By Lemma 8 this coefficient matrix has full row rank. This proves the implication.

(iii) $\Rightarrow$ (i). Assume $L(K)$ has rank m. Since $\mathrm{rank}(R) = m$, this implies that the Schur complement of R is equal to zero, equivalently that $-K$ satisfies the ARE. □

Example 6, continued. For the Riccati equation of Example 6 we have $\partial\Phi(\xi) = \left(\begin{smallmatrix} 1-\xi^2 & a \\ a & 4-\xi^2 \end{smallmatrix}\right)$, so $\partial\Phi(i\omega) = \left(\begin{smallmatrix} 1+\omega^2 & a \\ a & 4+\omega^2 \end{smallmatrix}\right)$. By (6), the Riccati equation has a real symmetric solution if and only if $\partial\Phi(i\omega) \geq 0$ for all $\omega \in \mathbb{R}$. This holds if and only if $-2 \leq a \leq 2$.

Connections between the ARE and the linear matrix inequality in statement 3. of Theorem 7 are well-known. See, for example, Chap. 8 of [2], where solutions K of the linear matrix inequality such that $\mathrm{rank}(L(K)) = m$ are called *rank minimizing*. In a behavioral framework, connections between such concepts and storage functions were established in [14]; see also Chapter 5 of [11].

6. Pick matrices and the algebraic Riccati equation. In this section we derive the main result of this paper, a characterization of all unmixed real symmetric solutions of the ARE in terms of the Pick matrices associated with the two-variable polynomial matrix (19). As a corollary of this result, we obtain necessary and sufficient conditions for the existence of sign-definite solutions of the ARE. These conditions are in terms of the Pick matrices associated with the Hurwitz and anti-Hurwitz factorizations of $\det(\partial\Phi)$.

In this section, let $X(\xi)U(\xi)^{-1}$ be an arbitrary right coprime factorization of $(\xi I_n - A)^{-1}B$, and let the two-variable polynomial matrix Φ associated with the ARE be given by (19). From the fact that $\partial\Phi$ is para-Hermitian, we know that $\det(\partial\Phi)$ has even degree. In fact, the degree of $\det(\partial\Phi)$ is twice the dimension of the underlying state space system (17).

LEMMA 10. *Let $\Phi(\zeta, \eta)$ be defined as in* (19)*, and assume $R > 0$. Then the degree of* $\det(\partial\Phi)$ *is* $2n$.

Proof. Observe that $\partial\Phi = X^\sim QX + X^\sim S^T U + U^\sim SX + U^\sim RU$. Multiplying this equality on the right by U^{-1} and on the left by $(U^\sim)^{-1}$ yields $(U^\sim)^{-1}\partial\Phi U^{-1} = (U^\sim)^{-1}X^\sim QXU^{-1} + (U^\sim)^{-1}X^\sim S^T + SXU^{-1} + R$. Now observe that $X(\xi)U^{-1}(\xi) = (\xi I_n - A)^{-1}B$ is a matrix of strictly proper rational functions. It follows that $(U^\sim)^{-1}\partial\Phi U^{-1}$ is a matrix of proper rational functions and consequently $\deg(\det(\partial\Phi)) \leq \deg(\det(U)) + \deg(\det(U^\sim)) = 2n$. We now show that $\deg(\det(\partial\Phi)) = 2n$. Indeed, since $\lim_{|\lambda|\longrightarrow\infty}(U^\sim(\lambda))^{-1}\partial\Phi(\lambda)U(\lambda) = R > 0$, it follows that $(U^\sim)^{-1}\partial\Phi U$ has an inverse whose entries are also proper rational functions. Consequently $\deg(\det(\partial\Phi)) = 2n$. □

Assume now that $\int Q_\Phi \geq 0$, equivalently $\partial\Phi(i\omega) \geq 0$, for all $\omega \in \mathbb{R}$ (see (6)). According to Theorem 9 this is equivalent to the existence of a real symmetric solution of the ARE. Observe that every polynomial spectral factorization of $\partial\Phi$ as $\partial\Phi = F^\sim F$ with $F \in \mathbb{R}^{m\times m}[\xi]$ yields a factorization of $\det(\partial\Phi)$ as $\det(\partial\Phi) = f^\sim f$, with $f = \det(F)$ and $\deg(f) = n$. Let $\mathcal{F}$ be the set of all polynomials of degree n, with positive highest degree coefficient, that can occur as the determinant of a polynomial spectral factor of $\partial\Phi$:

$$\mathcal{F} := \{f \in \mathbb{R}[\xi] \mid f(\xi) = f_0 + f_1\xi + \cdots + f_n\xi^n, \quad f_n > 0,$$
$$\text{(23)} \quad \text{and there exists } F \in \mathbb{R}^{m\times m}[\xi] \text{ such that } \partial\Phi = F^\sim F \text{ and } \det(F) = f\}.$$

Also, let $\mathcal{S}$ be the set of all real symmetric solutions of the ARE:

$$\mathcal{S} := \{K \in \mathbb{R}^{n\times n} \mid K = K^T \text{ and } K \text{ satisfies the ARE}\}.$$

For any $K \in \mathcal{S}$, denote $A_K := A - BR^{-1}(B^TK + S)$ and let χ_{A_K} be the characteristic polynomial of A_K. Our basic result states that there is a one-to-one correspondence between $\mathcal{F}$ and $\mathcal{S}$.

THEOREM 11. *$\mathcal{S} \neq \emptyset$ if and only if $\partial\Phi(i\omega) \geq 0$ for all $\omega \in \mathbb{R}$. In that case there exists a bijection between $\mathcal{F}$ and $\mathcal{S}$. Such bijection* $\mathrm{Ric} : \mathcal{F} \to \mathcal{S}$ *is defined as follows. For any $f \in \mathcal{F}$, let $F \in \mathbb{R}^{m\times m}[\xi]$ be such that $f = \det(F)$ and $\partial\Phi = F^{\sim}F$. Then define* $\mathrm{Ric}(f) = K$, *where $K = K^T \in \mathbb{R}^{n\times n}$ is the unique solution of*

$$\frac{\Phi(\zeta,\eta) - F^T(\zeta)F(\eta)}{\zeta + \eta} = X^T(\zeta)(-K)X(\eta). \tag{24}$$

For any $K \in \mathcal{S}$ we have $\partial\Phi = (F_K)^{\sim}F_K$, where

$$F_K(\xi) := R^{-1/2}(B^TK + S)X(\xi) + R^{1/2}U(\xi).$$

Furthermore, for any $K \in \mathcal{S}$ we have $\det(F_K) = \sqrt{\det(R)}\ \chi_{A_K}$, *whence* $\det(\partial\Phi) = \det(R)\ (\chi_{A_K})^{\sim}\chi_{A_K}$ *and*

$$K = \mathrm{Ric}(\sqrt{\det(R)}\ \chi_{A_K}).$$

Proof. We begin by showing that the map $\mathrm{Ric} : \mathcal{F} \to \mathcal{S}$ is well defined. Let f_1 and f_2 be two elements of $\mathcal{F}$, and let F_1, $F_2 \in \mathbb{R}^{m\times m}[\xi]$ be such that $\partial\Phi = F_1^{\sim}F_1 = F_2^{\sim}F_2$ and $\det(F_i) = f_i$, $i = 1, 2$. It is well known (see, for example, Theorem 5.3 of [10]) that there exists an orthogonal $m \times m$ matrix L such that $F_2 = LF_1$. Now let K_1 and K_2 be $n \times n$ symmetric matrices such that

$$\frac{\Phi(\zeta,\eta) - F_i^T(\zeta)F_i(\eta)}{\zeta + \eta} = X^T(\zeta)(-K_i)X(\eta),$$

$i = 1, 2$. (Such matrices exist because of Theorem 2.) Then necessarily

$$X^T(\zeta)(-K_1)X(\eta) = X^T(\zeta)(-K_2)X(\eta).$$

It follows from the fact that $X(\frac{d}{dt})$ is a minimal state map that the map $l \to (X(\frac{d}{dt})l)(0)$ is surjective. Hence for all $x_0 \in \mathbb{R}^n$ there holds $x_0^T(-K_1)x_0 = x_0^T(-K_2)x_0$, which implies $K_1 = K_2$. This shows that Ric is well defined.

We proceed to show that Ric is bijective. We first prove that it is injective. Assume that $\mathrm{Ric}(f_1) = K_1 = \mathrm{Ric}(f_2) = K_2$. Let F_1 and F_2 be $m \times m$ polynomial matrices such that $\partial\Phi = F_1^{\sim}F_1 = F_2^{\sim}F_2$ and $\det(F_i) = f_i$, $i = 1, 2$. From the fact that $K_1 = K_2$ and from (24) it follows that $F_1^T(\zeta)F_1(\eta) = F_2^T(\zeta)F_2(\eta)$. This implies that

$$\det(F_1(\zeta))\det(F_1(\eta)) = \det(F_2(\zeta))\det(F_2(\eta)),$$

so that $f_1(\zeta)f_1(\eta) = f_2(\zeta)f_2(\eta)$. Given that the highest degree coefficient of f_1 and f_2 is positive (see (23)), we conclude that $f_1 = f_2$. This concludes the proof of the injectivity of Ric. In order to prove that Ric is surjective, let $K = K^T$ be a solution to the ARE. According to Theorem 9 there holds

$$(\zeta + \eta)X^T(\zeta)(-K)X(\eta) = \Phi(\zeta,\eta) - F_K(\zeta)^TF_K(\eta),$$

where $F_K \in \mathbb{R}^{m\times m}[\xi]$ is defined by

$$F_K(\xi) = R^{-\frac{1}{2}}(B^TK + S)X(\xi) + R^{\frac{1}{2}}U(\xi).$$

Note that $\partial\Phi = (F_K)^\sim F_K$. Define now $f := \det(F_K)$. Then $K = \mathrm{Ric}(f)$. This also proves the second statement of the theorem.

Next we prove that for all $K \in \mathcal{S}$ we have $\det(F_K) = \det(R^{1/2})\chi_{A_K}$. Consider the $(n+m)\times(n+m)$ polynomial matrix

$$P(\xi) := \begin{pmatrix} \xi I - A & B \\ -R^{-1/2}(B^TK + S) & R^{1/2} \end{pmatrix}.$$

Computing the determinant of P yields

$$\begin{aligned}\det(P(\xi)) &= \det(\xi I - A)\det(R^{1/2} + R^{-1/2}(B^TK + S)(\xi I - A)^{-1}B) \\ &= \det(R^{1/2})\det(\xi I - A + BR^{-1}(B^TK + S)).\end{aligned}$$

Using the fact that $X(\xi)U(\xi)^{-1}$ is a right coprime factorization of $(\xi I - A)^{-1}B$ and that (A, B) is a controllable pair, we have $\det(U(\xi)) = \det(\xi I - A)$, so we obtain $\det(R^{1/2})\chi_{A_K} = \det(F_K)$. The remaining statements of the theorem follow immediately from this. □

In the above, we have assumed that $\partial\Phi(i\omega) \geq 0$ for all $\omega \in \mathbb{R}$. In the case that, in addition, $\partial\Phi$ is nonsingular along the imaginary axis, equivalently $\partial\Phi(i\omega) > 0$ for all $\omega \in \mathbb{R}$, the one-to-one correspondence between polynomials and the set of real symmetric solutions of the ARE can be made even more explicit. This will be explained next.

Define $\mathcal{F}_{\mathrm{cop}}$ as the set of all real polynomials f such that the *determinant* of $\partial\Phi$ admits a factorization $f^\sim f$ such that f and $f^\sim$ are coprime:

$$\mathcal{F}_{\mathrm{cop}} = \{f \in \mathbb{R}[\xi] \mid f(\xi) = f_0 + f_1\xi + \cdots + f_n\xi^n, \quad f_n > 0,\ (f, f^\sim) \text{ coprime and } \det(\partial\Phi) = f^\sim f\}.$$

It is easily seen that if $\partial\Phi(i\omega) \geq 0$ for all $\omega \in \mathbb{R}$, then $\mathcal{F}_{\mathrm{cop}} \neq \emptyset$ if and only if $\partial\Phi(i\omega) > 0$ for all $\omega \in \mathbb{R}$. Hence it follows from Proposition 5 that $\mathcal{F}_{\mathrm{cop}} \subset \mathcal{F}$. In the remainder of this section we assume that $\partial\Phi(i\omega) > 0$ for all $\omega \in \mathbb{R}$.

Note that if $f \in \mathcal{F}_{\mathrm{cop}}$ and $K = \mathrm{Ric}(f)$, then, according to Theorem 11, $f = \sqrt{\det(R)}\chi_{A_K}$, so χ_{A_K} and $(\chi_{A_K})^\sim$ are coprime; equivalently, $\sigma(A_K) \cap \sigma(-A_K) = \emptyset$. If a solution K of the ARE satisfies this property, we call it *unmixed*. The set of all unmixed solutions of the ARE is denoted by $\mathcal{S}_{\mathrm{unm}}$. It follows immediately from Theorem 11 that Ric defines a bijection between $\mathcal{F}_{\mathrm{cop}}$ and $\mathcal{S}_{\mathrm{unm}}$.

We now explain the connection between the bijection Ric and the Pick matrices T_f associated with Φ. Recall that the bijection Ric between $\mathcal{F}_{\mathrm{cop}}$ and $\mathcal{S}_{\mathrm{unm}}$ is defined as follows. For a given $f \in \mathcal{F}_{\mathrm{cop}}$, let $F \in \mathbb{R}^{m\times m}[\xi]$ be such that $\partial\Phi = F^\sim F$ and $\det(F) = f$, and take $K = \mathrm{Ric}(f)$ to be the unique solution of (24). For the sake of exposition, assume for the moment that the singularities of $\partial\Phi$ are semisimple. We show how to compute, for $f \in \mathcal{F}_{\mathrm{cop}}$, the corresponding unmixed solution $K = \mathrm{Ric}(f)$, using the Pick matrix T_f.

Let $\lambda_1, \lambda_2, \ldots, \lambda_n$ be the roots of f, with the convention that if a root has algebraic multiplicity m_i, then it appears in this list m_i times, and $\lambda_1, \lambda_2, \ldots, \lambda_{m_1}$ are equal, $\lambda_{m_1+1}, \lambda_{m_1+2}, \ldots, \lambda_{m_1+m_2}$ are equal, etc. Let $v_i \in \mathbb{C}^m$ be such that $\partial\Phi(\lambda_i)v_i =$

0 and $v_1, v_2, \dots, v_n$ are linearly independent. Evaluating (24) at $(\zeta, \eta) = (\bar{\lambda}_i, \lambda_j)$, premultiplying the result by v_i^* and postmultiplying it by v_j, we get

$$\frac{v_i^* \Phi(\bar{\lambda}_i, \lambda_j) v_j}{\bar{\lambda}_i + \lambda_j} - \frac{v_i^* F^T(\bar{\lambda}_i) F(\lambda_j) v_j}{\bar{\lambda}_i + \lambda_j} = -v_i^* X^T(\bar{\lambda}_i) K X(\lambda_j) v_j.$$

Note that, by coprimeness of f and $f^\sim$, $\bar{\lambda}_i + \lambda_j \neq 0$ for all (i, j). Now make the crucial observation that for all j

$$F(\lambda_j) v_j = 0.$$

Indeed, by definition of v_j we have $F^T(-\lambda_j) F(\lambda_j) v_j = 0$. Since, however, $F^T(-\lambda_j)$ is nonsingular (by coprimeness of f and $f^\sim$), the claim follows. Thus we immediately obtain

$$\frac{v_i^* \Phi(\bar{\lambda}_i, \lambda_j) v_j}{\bar{\lambda}_i + \lambda_j} = -v_i^* X^T(\bar{\lambda}_i) K X(\lambda_j) v_j,$$

which is equivalent to

$$T_f = -(S_f)^* K S_f,$$

where S_f is the *zero state matrix* associated with f, defined by

$$S_f := \begin{pmatrix} X(\lambda_1)v_1 & \dots & X(\lambda_n)v_n \end{pmatrix}.$$

For a motivation of the terminology zero state matrix, we refer to the proof of Theorem 12 below. Note that $S_f \in \mathbb{C}^{n \times n}$. In Theorem 12 we will prove that for any $f \in \mathcal{F}_{\text{cop}}$ the zero state matrix S_f is nonsingular. This immediately implies that the solution $K = \text{Ric}(f)$ is given by

$$K = \text{Ric}(f) = -(S_f^*)^{-1} T_f (S_f)^{-1}. \tag{25}$$

The above argument can be generalized to the case in which not all singularities of $\partial\Phi$ are semisimple. In the general case, the zero state matrix S_f associated with the polynomial factor f is defined in the following way. Let $\lambda_1, \lambda_2, \dots, \lambda_k$ be the roots of f. As in section 4, we use the convention that if a given root λ_i has geometric multiplicity n_i, then we include it n_i times in our list of roots. For $i = 1, 2, \dots, k$, let $V_i \in \mathbb{C}^{d_i m \times d_i}$ be defined by (10) and (11) (with $q = m$). Furthermore, define the $n \times d_i$ matrix S_i by

$$S_i := \begin{pmatrix} X(\lambda_i) & X^{(1)}(\lambda_i) & \dots & X^{(d_i-1)}(\lambda_i) \end{pmatrix} V_i,$$

where $X^{(j)}$ denotes the jth derivative of X. The zero state matrix in the general case is then defined by

$$S_f := \begin{pmatrix} S_1 & S_2 & \dots & S_k \end{pmatrix}. \tag{26}$$

Again, $S_f \in \mathbb{C}^{n \times n}$.

The following theorem is the main result of this paper. It yields the representation (25) of the bijection Ric in the general, not necessarily semisimple, case.

THEOREM 12. *Assume $\partial\Phi(i\omega) \geq 0$ for all $\omega \in \mathbb{R}$. Then the following three statements are equivalent:*

(i) $\partial\Phi(i\omega) > 0$ *for all* $\omega \in \mathbb{R}$*;*
(ii) $\mathcal{F}_{\rm cop} \neq \emptyset$*;*
(iii) $\mathcal{S}_{\rm unm} \neq \emptyset$.

Assume that this holds. Then $\mathrm{Ric} : \mathcal{F}_{\rm cop} \to \mathcal{S}_{\rm unm}$ *is a bijection. For all* $f \in \mathcal{F}_{\rm cop}$ *the zero state matrix* S_f *defined by* (26) *is nonsingular. Furthermore, for any* $f \in \mathcal{F}_{\rm cop}$*, the corresponding solution* $\mathrm{Ric}(f) \in \mathcal{S}_{\rm unm}$ *is given by*

$$\mathrm{Ric}(f) = -(S_f^*)^{-1} T_f S_f^{-1}. \tag{27}$$

Proof. The claim that conditions (i), (ii), and (iii) of Theorem 12 are equivalent, and the claim that under this condition Ric defines a bijection between $\mathcal{F}_{\rm cop}$ and $\mathcal{S}_{\rm unm}$, follow from Theorem 11.

We prove that the zero state matrix (26) is nonsingular. Let $F \in \mathbb{R}^{m\times m}[\xi]$ be such that $\det(\partial\Phi) = f^\sim f$ and $\det(F) = f$. Let $\xi = \mathrm{col}(\xi_1, \xi_2, \dots, \xi_k)$, with $\xi_i = \mathrm{col}(\xi_{i,1}, \xi_{i,2}, \dots, \xi_{i,d_i}) \in \mathbb{C}^{d_i}$, satisfy $S_f\xi = 0$, equivalently,

$$\sum_{i=1}^{k} \begin{pmatrix} X(\lambda_i) & X^{(1)}(\lambda_i) & \dots & X^{(d_i-1)}(\lambda_i) \end{pmatrix} V_i \xi_i = 0.$$

We will show that $\xi_i = 0$ for $i = 1, 2, \dots, k$.

Recall that the system $\frac{d}{dt}x = Ax + Bu$ has an observable image representation

$$\begin{pmatrix} x \\ u \end{pmatrix} = \begin{pmatrix} X(\frac{d}{dt}) \\ U(\frac{d}{dt}) \end{pmatrix} l, \tag{28}$$

and that $X(\frac{d}{dt})$ is a minimal state map for this system. Consider the extended system $\mathcal{B}_{\rm ext}$, obtained by including $f = F(\frac{d}{dt})l$ as a manifest variable, represented by the image representation

$$\begin{pmatrix} x \\ u \\ f \end{pmatrix} = \begin{pmatrix} X(\frac{d}{dt}) \\ U(\frac{d}{dt}) \\ F(\frac{d}{dt}) \end{pmatrix} l.$$

We claim that in the system $\mathcal{B}_{\rm ext}$, $\mathrm{col}(x, u)$ is output and f is input, and that $X(\frac{d}{dt})$ is a minimal state map also for $\mathcal{B}_{\rm ext}$.

To prove this, first note that

$$F^\sim F = X^\sim Q X + X^\sim S^T U + U^\sim S X + U^\sim R U.$$

Multiplying this equality on the right by U^{-1} and on the left by $(U^\sim)^{-1}$ yields

$$(U^\sim)^{-1} F^\sim F U^{-1} = (U^\sim)^{-1} X^\sim Q X U^{-1} + (U^\sim)^{-1} X^\sim S^T + S X U^{-1} + R.$$

Since XU^{-1} is strictly proper and $R > 0$, this implies that FU^{-1} is a proper rational matrix with nonsingular feedthrough term. This implies that also its inverse, UF^{-1}, is proper, and $XF^{-1} = XU^{-1}UF^{-1}$ is strictly proper. Since, therefore,

$$\begin{pmatrix} X \\ U \end{pmatrix} F^{-1}$$

is a proper rational matrix, in the system $\mathcal{B}_{\rm ext}$, $\mathrm{col}(x, u)$ is output and f is input.

Next we prove that $X(\frac{d}{dt})$ is a minimal state map for $\mathcal{B}_{\text{ext}}$. To prove this, we show that the rows of X form a basis for the real linear space $\mathcal{S}_1 = \{r \in \mathbb{R}^{1\times m}[\xi] \mid rF^{-1} \text{ is strictly proper}\}$. Since X induces a minimal state map for our original system (28), the rows of X form a basis for the real linear space $\mathcal{S}_2 = \{r \in \mathbb{R}^{1\times m}[\xi] \mid rU^{-1} \text{ is strictly proper}\}$. Since UF^{-1} and FU^{-1} are proper, rF^{-1} is strictly proper if and only if rU^{-1} is strictly proper. Hence the two linear spaces $\mathcal{S}_1$ and $\mathcal{S}_2$ coincide, so the rows of X indeed form a basis for $\mathcal{S}_1$.

Define a particular latent variable trajectory for $\mathcal{B}_{\text{ext}}$ by

$$\tilde{l}(t) = \sum_{i=1}^{k} e^{\lambda_i t} \begin{pmatrix} I_{m\times m} & tI_{m\times m} & \dots & t^{d_i-1}I_{m\times m} \end{pmatrix} V_i\xi_i.$$

Then we clearly have $\partial\Phi(\frac{d}{dt})\tilde{l} = 0$. Using the fact that none of the λ_i's is a singularity of $F^{\sim}$, this implies that $F(\frac{d}{dt})\tilde{l} = 0$. Our aim is to prove that $\tilde{l} = 0$. Indeed, look at the trajectory of the system $\mathcal{B}_{\text{ext}}$ corresponding to the choice of latent variable $\tilde{l}$. The input $f = F(\frac{d}{dt})\tilde{l}$ is equal to zero. Furthermore, a straightforward calculation shows that the value of the corresponding state trajectory at time $t = 0$ equals

$$\left(X\left(\frac{d}{dt}\right)\tilde{l}\right)(0) = \sum_{i=1}^{k} \begin{pmatrix} X(\lambda_i) & X^{(1)}(\lambda_i) & \dots & X^{(d_i-1)}(\lambda_i) \end{pmatrix} V_i\xi_i = 0.$$

Hence the output $(x,u) = (X(\frac{d}{dt})\tilde{l}, U(\frac{d}{dt})\tilde{l}$ of $\mathcal{B}_{\text{ext}}$ is zero. By observability of the image representation (28), this implies $\tilde{l} = 0$, as claimed.

Next, we prove that this implies $\xi_i = 0$ for all i. Indeed, since $\tilde{l} = 0$ we have

$$\tilde{l}(0) = \sum_{i=1}^{k} \begin{pmatrix} I_{m\times m} & 0 & \dots & 0 \end{pmatrix} V_i\xi_i = 0.$$

Consequently, $\tilde{l}(0) = \sum_{i=1}^{k}\sum_{j=0}^{d_i-1} a_{i,j}\xi_{i,j} = 0$. Since the vectors $a_{i,j}$ are linearly independent, this yields $\xi_{i,j} = 0$ for all $i = 1,2,\dots,k$ and $j = 1,2,\dots,d_i$. This proves that the zero state matrix S_f is nonsingular.

To prove (27) we use that $K_f = \text{Ric}(f)$ is uniquely defined by

$$\Phi(\zeta,\eta) - F^T(\zeta)F(\eta) = -(\zeta+\eta)X^T(\zeta)K_fX(\eta), \tag{29}$$

with $F \in \mathbb{R}^{m\times m}[\xi]$ such that $\partial\Phi = F^{\sim}F$ and $\det(F) = f$. The idea is to evaluate (29) and its partial derivatives with respect to ζ and η at the points $(\bar{\lambda}_i, \lambda_j)$. For all indices (r,s) we have

$$\begin{aligned}&\frac{\partial^{r+s}\Phi}{\partial\eta^r\partial\zeta^s}(\zeta,\eta) - F^{(s)T}(\zeta)F^{(r)}(\eta)\\ &= sX^{(s-1)T}(\zeta)K_fX^{(r)}(\eta) + rX^{(s)T}(\zeta)K_fX^{(r-1)}(\eta)\\ &\qquad\qquad + (\zeta+\eta)X^{(s)T}(\zeta)K_fX^{(r)}(\eta).\end{aligned}$$

Using this, for $i,j = 1,2,\dots,k$, we form the matrices $\Phi_{i,j}$ defined by (13). Next, with $\Sigma_{i,j}$ defined by (14) and $\Lambda_{i,j}$ defined by (12), a straightforward calculation shows that

$$\begin{aligned}&\Lambda_{j,i}^*V_i^*\Sigma_{i,j}V_j\Lambda_{i,j}\\ &= -V_i^*\begin{pmatrix} X^T(\bar{\lambda}_i)\\ X^{(1)T}(\bar{\lambda}_i)\\ \vdots\\ X^{(d_i-1)T}(\bar{\lambda}_i)\end{pmatrix} K_f \begin{pmatrix} X(\lambda_j) & X^{(1)}(\lambda_j) & \dots & X^{(d_j-1)}(\lambda_j)\end{pmatrix} V_j.\end{aligned} \tag{30}$$

The crucial point here is that the terms involving $F^{(r)T}(\bar{\lambda}_i)F^{(s)}(\lambda_j)$ vanish, since for $i = 1, 2, \ldots, k$ we have

$$(31)\qquad \begin{pmatrix} \binom{0}{0}\partial F^{(0)}(\lambda_i) & \binom{1}{0}\partial F^{(1)}(\lambda_i) & \cdots & \cdots & \binom{d_{i-1}}{0}\partial F^{(d_i-1)}(\lambda_i) \\ 0 & \binom{1}{1}\partial F^{(0)}(\lambda_i) & \cdots & \cdots & \binom{d_i-1}{1}\partial F^{(d_i-2)}(\lambda_i) \\ 0 & 0 & \ddots & & \vdots \\ \vdots & \vdots & \ddots & \ddots & \vdots \\ 0 & 0 & \cdots & 0 & \binom{d_i-1}{d_i-1}\partial F^{(0)}(\lambda_i) \end{pmatrix} V_i = 0.$$

The latter follows from (10), combined with the fact that for $i = 1, 2, \ldots, k$ the matrices $F^T(-\lambda_i)$ are nonsingular. Since (30) holds for all $i, j = 1, 2, \ldots, k$, we obtain $T_f = S_f^* K_f S_f$. This completes the proof. □

This result yields a procedure for computing all unmixed solutions of the ARE (1). We sum up the steps that are required here.

1. Compute a right coprime factorization $X(\xi)U(\xi)^{-1}$ of $(\xi I - A)^{-1}B$.
2. Form the corresponding two-variable polynomial matrix Φ given by (19).
3. Check whether $\partial\Phi(i\omega) > 0$ for all $\omega \in \mathbb{R}$.
4. Factor $\det(\partial\Phi) = f^\sim f$ with f and $f^\sim$ coprime.

The following then computes the unique solution $K = K^T$ of the ARE such that its "closed loop characteristic polynomial" χ_{A_K} equals $\sqrt{\det(R)}\ f$.

5. Compute the zero state matrix S_f.
6. Compute the Pick matrix T_f.
7. Solve the equation $T_f = -S_f^* K S_f$.
8. Set $K = \mathrm{Ric}(f)$.

It is worthwhile to observe that similar results have been obtained in Chapter 5 of [11] for QDFs not necessarily associated with a state space representation (16). Note that the procedure circumvents the need to do a polynomial spectral factorization of $\partial\Phi$.

We now go back to the problem of establishing necessary and sufficient conditions for the existence of sign-definite solutions to the ARE. Our main result here is an immediate consequence of Theorem 12 and is based on the result of Proposition 3, namely, that the largest (smallest) storage function for Φ is associated with an anti-Hurwitz (Hurwitz) factorization of $\partial\Phi$. Let K_- and K_+ be the smallest, respectively the largest, real symmetric solution of the ARE.

COROLLARY 13. *Let $\Phi(\zeta, \eta)$ be defined as in* (19). *Assume that $\partial\Phi(i\omega) > 0$ for all $\omega \in \mathbb{R}$. Factor $\det(\partial\Phi) = (f_A)^\sim f_A = (f_H)^\sim f_H$, where f_A and f_H have their roots in the open right half plane and open left half plane, respectively. Then we have*

$$K_- = -(S_{f_A}^*)^{-1} T_{f_A} S_{f_A}^{-1},$$

$$K_+ = -(S_{f_H}^*)^{-1} T_{f_H} S_{f_H}^{-1}.$$

Consequently, $\mathrm{sign}(K_-) = -\mathrm{sign}(T_{f_H})$ *and* $\mathrm{sign}(K_+) = -\mathrm{sign}(T_{f_A})$. *In particular, the ARE* (1) *has a negative semidefinite (negative definite) solution if and only if the Pick matrix T_{f_A} is positive semidefinite (respectively, positive definite). It has a positive semidefinite (positive definite) solution if and only if the Pick matrix T_{f_H} is negative semidefinite (respectively, negative definite).*

Example 6, *continued.* For the Riccati equation of Example 6 we have $\partial\Phi(\xi) = \left(\begin{smallmatrix} 1-\xi^2 & a \\ a & 4-\xi^2 \end{smallmatrix}\right)$, and we have $\partial\Phi(i\omega) > 0$ for all $\omega \in \mathbb{R}$ if and only if $-2 < a < 2$. Assume

this to be the case. We have $\det(\partial\Phi(\xi)) = (1-\xi^2)(4-\xi^2)-a^2$. Set $k = 3+\sqrt{9+4a^2}$. The singularities of $\partial\Phi$ are then equal to $\lambda_1 = -\sqrt{1+\frac{1}{2}k}$, $\lambda_2 = -\sqrt{4-\frac{1}{2}k}$, $-\lambda_1$, and $-\lambda_2$. Clearly, $\det(\partial\Phi)$ can be factored as $f^{\sim}f$ with $(f^{\sim}, f)$ coprime in four different ways, and the Riccati equation has four real symmetric solutions, all of them unmixed. Here we compute the largest real symmetric solution, i.e., the solution K satisfying $\chi_{A_K} = f_H$, with $f_H(\xi) = (\xi + \sqrt{1+\frac{1}{2}k})(\xi + \sqrt{4-\frac{1}{2}k})$. Note that we are in the semisimple situation, i.e., the algebraic multiplicity of each singularity equals its corresponding rank deficiency. Solving $\partial\Phi(\lambda_1)v_1 = 0$ and $\partial\Phi(\lambda_2)v_2 = 0$ yields $v_1 = \left(\begin{smallmatrix} 2a/k \\ 1 \end{smallmatrix}\right)$ and $v_2 = \left(\begin{smallmatrix} 1 \\ -2a/k \end{smallmatrix}\right)$. The zero state matrix S_{f_H} is hence given by $S_{f_H} = \left(\begin{smallmatrix} 2a/k & 1 \\ 1 & -2a/k \end{smallmatrix}\right)$. Next we compute the Pick matrix corresponding to f_H. Clearly,

$$T_{f_H} = \begin{pmatrix} \frac{v_1^*\Phi(\lambda_1,\lambda_1)v_1}{2\lambda_1} & \frac{v_1^*\Phi(\lambda_1,\lambda_2)v_2}{\lambda_1+\lambda_2} \\ \frac{v_2^*\Phi(\lambda_2,\lambda_1)v_1}{\lambda_2+\lambda_1} & \frac{v_2^*\Phi(\lambda_2,\lambda_2)v_2}{2\lambda_2} \end{pmatrix},$$

which is equal to

(32)
$$T_{f_H} = \begin{pmatrix} \frac{1}{2\lambda_1}\left(\frac{4a^2}{k^2}(2+k) + \frac{2a^2}{k} + \frac{k}{2} + 5 - 2\lambda_1\right) & \frac{1}{\lambda_1+\lambda_2}\left(\frac{2a}{k}(1+\lambda_1\lambda_2) + a - \frac{4a^3}{k^2} - \frac{8a}{k} + \frac{2a}{k}(\lambda_1+\lambda_2)\right) \\ \frac{1}{\lambda_1+\lambda_2}\left(\frac{2a}{k}(1+\lambda_1\lambda_2) + a - \frac{4a^3}{k^2} - \frac{8a}{k} + \frac{2a}{k}(\lambda_1+\lambda_2)\right) & \frac{1}{2\lambda_2}\left(\frac{4a^2}{k^2}(8+2\lambda_2) - \frac{6a^2}{k} - \frac{k}{2} + 5\right) \end{pmatrix}.$$

This yields $K^+ = -(S_{f_H}^T)^{-1}T_{f_H}S_{f_H}$ as the solution corresponding to f_H. Note that this gives the largest real symmetric solution for each value of a between -2 and 2. For example, if $a = 0$, then $k = 6$, so $\lambda_1 = -2$ and $\lambda_2 = -1$. This yields $K^+ = \left(\begin{smallmatrix} 0 & 1 \\ 1 & 0 \end{smallmatrix}\right)\left(\begin{smallmatrix} 3 & 0 \\ 0 & 1 \end{smallmatrix}\right)\left(\begin{smallmatrix} 0 & 1 \\ 1 & 0 \end{smallmatrix}\right) = \left(\begin{smallmatrix} 1 & 0 \\ 0 & 3 \end{smallmatrix}\right)$. Recall that $Q = \left(\begin{smallmatrix} 1 & a \\ a & 3 \end{smallmatrix}\right)$, so for $a = 0$ we have $Q > 0$. In this particular case it follows immediately that the ARE has a positive semidefinite solution (the corresponding linear quadratic problem is positive semidefinite). For values of a satisfying $-2 < a < -\sqrt{3}$ or $\sqrt{3} < a < 2$, Q is indefinite, so for this case it is a nontrivial matter to check whether the ARE has a positive (semi-) definite solution. According to Corollary 13, for a given $a \in (-2, 2)$ the ARE has a positive (semi-) definite solution if and only if for that value of a the Pick matrix (32) is negative (semi-) definite. As an example, take $a = 1.8$. In this case Q is indefinite. The Pick matrix corresponding to this value of a is computed as $T_{f_H} = \left(\begin{smallmatrix} -3.6835 & 0.3111 \\ 0.3111 & -0.2637 \end{smallmatrix}\right)$. The eigenvalues of T_{f_H} are computed as -3.7116 and -0.2356, so we conclude that for $a = 1.8$ our ARE has a positive definite solution. For $a = 1.98$ we compute $T_{f_H} = \left(\begin{smallmatrix} -3.7839 & 0.4375 \\ 0.4375 & 0.0894 \end{smallmatrix}\right)$, which has eigenvalues -3.8327 and 0.1382. For this value of a our ARE does not have a positive semidefinite solution.

In order to check whether for a given a the ARE of this example has at least one negative (semi-) definite solution, one should compute the Pick matrix T_{f_A} associated with the polynomial $f_A(\xi) = (\xi - \sqrt{1+\frac{1}{2}k})(\xi - \sqrt{4-\frac{1}{2}k})$, and check whether it is positive (semi-) definite.

7. Conclusions. In this paper we applied ideas from the calculus of two-variable polynomial matrices to the problem of characterizing all umixed solutions of the algebraic Riccati equation and formulating necessary and sufficient conditions for the existence of (semi) definite solutions.

We started from the two-variable polynomial matrix corresponding to the underlying quadratic functional, and associated with this a nonsingular one-variable

polynomial matrix. Then we showed that there is a bijection between the set of all scalar polynomial spectral factors of the determinant of this one-variable polynomial matrix and the set of all unmixed solutions of the ARE. For every such scalar polynomial spectral factor we defined a constant Hermitian matrix, called the Pick matrix, and we expressed the unmixed solution corresponding to this polynomial spectral factor in terms of its Pick matrix. This enabled us to conclude that the signatures of the extremal solutions of the ARE are determined by the Pick matrices corresponding to these solutions.

In this paper, we have restricted ourselves to the case in which (A, B) is a controllable pair, mainly in order to be able to use image representations. As a possible direction for future research, we mention the extension of our results to the noncontrollable case. Another interesting problem would be to generalize our results to the discrete-time algebraic Riccati equation.

OUTPUT TRACKING THROUGH SINGULARITIES*

R. M. HIRSCHORN†

Abstract. Output tracking for nonlinear systems is complicated by the existence of "singular submanifolds." These are surfaces on which the decoupling matrix loses rank. To provide additional control action we identify a class of smooth vector fields whose integral curves can be *incrementally tracked* using rapidly switched piecewise constant controls. At discrete times the resulting piecewise smooth state trajectories approach the integral curve being tracked. These discontinuous controllers are applied to sliding mode control—we use incremental tracking to move the state toward the sliding surface. The resulting controller achieves approximate output tracking in situations where the usual approach to sliding mode control fails due to the loss of control action on the singular submanifold.

Key words. output tracking, sliding mode control, singularities, Lie brackets, discontinuous state feedback

AMS subject classification. 93C10

1. Introduction.

Tracking in the case where the decoupling matrix loses rank on a "singular submanifold" has been considered by a number of authors (cf. [2, 5, 6, 7, 9, 15]). In [2] the problem of exact tracking is studied using results on singular ordinary differential equations and on the multiplicity of solutions. Conditions under which the singular tracking control is smooth or analytic are given in [9], assuming that the inputs and some of their derivatives are related to the outputs and their derivatives via a singular ordinary differential equation. In [7], output trajectories which the system can track using continuous open loop controls are identified for systems which satisfy a suitable observability condition, and a discontinuous feedback controller is introduced which achieves robust tracking in the face of perturbations. In [5] the relative order is locally increased by keeping the state trajectory near a codimension 1 submanifold. In some sense our approach takes the opposite point of view in that we seek to reduce the relative order by using vibratory controls. These switched controls allow motion in directions other than those of the drift vector field or vector fields in the Lie algebra generated by the control vector fields.

Recently there has been increased interest in the use of patterns in control. The pioneering work of Brockett [1], Pomet [12], Lui and Sussmann [10], and others looks at curves that can be approached by state trajectories of smooth affine systems. For single-input systems these results highlight the very limited class of smooth paths which can be closely approximated by the state trajectory. We introduce the notion of *incremental tracking* of smooth integral curves by state trajectories. The state trajectories are permitted to move far from the integral curve being tracked but are required to approach them arbitrarily closely arbitrarily often. This weaker notion of approximation by the state trajectory lends itself well to sliding mode control where we wish to steer the state to a sliding surface. This is a surface on which the state evolves so that the tracking errors go to zero. We are not concerned about the

path along which the trajectory approaches the sliding surface, as long as any large deviations take place in directions which are not seen directly by the output.

Sliding mode control utilizing discontinuous feedback controllers can achieve robust asymptotic output tracking (cf. [16, 13, 14] and the references therein) under the implicit assumption that the state trajectory can always be steered toward the "sliding surface." That is, the *decoupling matrix* is of full rank everywhere (cf. [8, 11]). In [6], sliding mode control is studied in the case where the decoupling matrix loses rank, and there exists a "singular submanifold" near which the state trajectory cannot be steered toward the sliding surface. For systems whose "singular submanifold" satisfies suitable transversality conditions, a class of smooth output functions y_d is identified which can be approximately tracked using a truncated sliding mode controller. For these outputs the state trajectory passes through the "singular submanifold" a finite number of times. There are, however, many simple systems in which truncated controllers cause the state trajectory to "stick" to the "singular submanifold," so that the state moves ever farther from the sliding surface. For such systems the standard approaches to output tracking are also not very successful. The following example illustrates the difficulties which can arise.

Example 1.1. Consider the affine nonlinear system in $\mathbb{R}^3$

$$\begin{aligned} \dot{x}_1 &= x_3^2 - x_2, \\ \dot{x}_2 &= x_3, \\ \dot{x}_3 &= u. \end{aligned} \tag{1.1}$$

Suppose that we wish to regulate the output $y = x_1$ so that $y(t)$ stays close to $y_d(t)$ while keeping the state vector bounded. If $s = \dot{e} + e$, where $e = y - y_d$, then we can regulate y by keeping the state trajectory on or near to the "sliding surface" $S_t^p = \{s = 0\} = \{x_1 + x_3^2 - x_2 = y_d + \dot{y}_d\}$. We note that without the term x_3^2 this system is linear with relative order 3, but here $\ddot{y} = -x_3 + 2x_3 u$ and the relative order of y is 2 (cf. [6, 8]). In particular,

$$\dot{s} = a(x) + b(x)u,$$

where $a(x,t) = x_3^2 - x_2 - x_3 - \dot{y}_d - \ddot{y}_d$ and $b(x) = 2x_3$. The natural sliding mode controller $u_{sm} = -(a + K)\ \mathrm{sign}(s)/b$ achieves $\dot{s} = -K\ \mathrm{sign}(s)$, whence $x(t)$ reaches S_t^p and stays in S_t^p after a finite time has elapsed (cf. [16], [13]). Inherent in this control scheme is the assumption that b does not vanish along the state trajectory. Of course, in our case b vanishes on the "singular manifold" $N = \{x_3 = 0\}$, and hence u_{sm} can become unbounded as $x(t)$ approaches N. One natural solution is to use the truncated controller $\min\{u_{sm}, L\ \mathrm{sign}(u_{sm})\}$ or the simpler controller

$$u_{sm}^L = -L\ \mathrm{sign}(sb). \tag{1.2}$$

For linear systems, such truncated controllers work on a neighborhood of the origin which expands as L grows. This is not the case here. In fact, suppose that we wish to track $y_d = 0$, where x_1 is positive, x_2 negative, and $x_3 = 0$ ($x \in N$, $s(x)$ is positive). If we perturb x_3 so that $x_3 = \epsilon > 0$, we have $u_{sm}^L < 0$; hence $\dot{x}_3 < 0$ and x returns to N. For $x_3 = -\epsilon$ we have $\dot{x}_3 = u_{sm}^L > 0$, and once again x returns to N. In essence the state trajectory will "stick" to the submanifold $N = \{x_3 = 0\}$. Of course, on N we have $\dot{s} = -x_2$, $\dot{x}_2 = 0$, so that $\dot{s} = -x_2 > 0$ and the state trajectory evolves on N in such a way that

$$s(e(t)) \longrightarrow \infty.$$

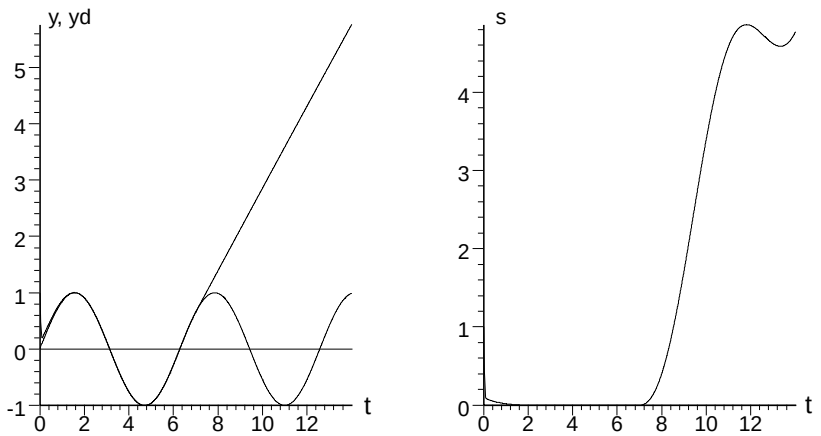

FIG. 1. *Tracking of* $\sin t$ *using a truncated sliding mode controller.*

We can track $y_d = 0$ using this approach if the initial state $x_2(0) > 0$. The larger $x_2(0)$ is, the more we can insulate the system from the above phenomena. On the other hand, if we track $y_d(t) = \sin t$, even with $x_2(0) > 0$, we will inevitably find that x_2 becomes negative and the above problem dominates. This phenomenon is illustrated by Figure 1, which shows the results of a simulation performed using SIMNON/PCW for Windows, Version 2.01 (SSPA Maritime Consulting AB, Sweden). If $x_2(0) < 0$, then the divergence of s and e is immediate. With $x(0) = (1, 11, 0)$ ($x_2(0) = 11$) and controller (1.2) with $L = 30$, the onset of this divergence is only delayed.

It is of interest to note that if we could enforce $s \equiv 0$ exactly in the case $y_d \equiv 0$, then $x_1, \dot{x}_1 \to 0$, $x_2 \to x_3^2 \geq 0$. Thus if $x_3 > 0$, then $\dot{x}_2 = x_3 = \sqrt{x_2}$, and the resulting "zero dynamics" are unstable.

The approximate input-output linearization scheme of [5] applied to this example has similar problems. Tracking schemes which are based on differentiating y until u appears come up against this same obstruction. Tomlin and Sastry have observed a similar phenomenon in the ball and beam example [15], where their switched control scheme is not effective. The above example presents similar obstructions.

Instead of taking more derivatives of s to deal with the singular submanifold N, we use fewer derivatives. As a result we lose direct control over s (as $\dot{s}$ is independent of u) but avoid the problems associated with the "singular manifold." We introduce a switched periodic controller which causes the state to "incrementally track" the integral curve of a vector field obtained from Lie brackets of the drift and control vector fields. The resulting continuous but nonsmooth state trajectory approaches the sliding surface. We will return to this example in section 4.

The rest of the paper is organized as follows. In section 2 we formulate the sliding mode control problem for single-input single-output affine nonlinear systems. In section 3 we introduce our switched controllers and present our results on approximate trajectory tracking for systems with drift. In section 4 we state and prove our main results—applications of incremental tracking to sliding mode control—and continue the above example. Finally, some concluding remarks are offered in section 5.

2. Output tracking and sliding surfaces. Suppose that M is a smooth manifold. Given a smooth function $h : M \to \mathbb{R}$ and a vector field $X(x)$ on M, $Xh(x) = dh_x X(x)$ denotes the *Lie derivative* of $h(x)$ along $X(x)$, and $X_t(x_0)$ the *integral curve* of X passing through x_0 at $t = 0$, so that $\frac{d}{dt}X_t(x_0) = X(X_t(x_0))$. If Y is a smooth vector field on M, then $[X,Y](x) = dY_x X(x) - dX_x Y(x)$ denotes the *Lie bracket* of X and Y, and $ad_X Y = [X,Y]$. Let $\{X,Y\}_{LA}$ denote the *Lie algebra* generated by $\{X,Y\}$, i.e., the smallest vector space containing X and Y and closed under Lie brackets. Suppose that N is a codimension 1 submanifold of M. A vector field X is *transversal to* N if $X(x) \notin T_x N \ \forall x \in N$, where $T_x N$ is the tangent space to N at x. If $P \subset Q$ is a submanifold and $f : M \to Q$ a smooth map of manifolds, then f *is transversal to* P if $\text{Image}(df_x) + T_{f(x)}P = T_{f(x)}Q$.

Consider the nonlinear control system model

$$\begin{aligned} \dot{x} &= f(x) + g(x)u, \qquad x(t_0) = x_0 \in M, \\ y &= h(x), \end{aligned} \tag{2.1}$$

where $M \subset \mathbb{R}^\ell$ is a smooth m-dimensional embedded submanifold of $\mathbb{R}^\ell$, $u : [t_0, \infty) \to \mathbb{R}$ is a piecewise smooth input, $f(x)$ and $g(x)$ are smooth vector fields on M, and h is a smooth output function on M. If $x \in M$, we denote by $||x||$ the norm on M which is induced by the standard norm on $\mathbb{R}^\ell$.

Suppose that $y_d : [t_0, \infty) \to \mathbb{R}$ is a smooth function which we wish the output y of (2.1) to track. The standard approach in sliding mode control (cf. [13, 16]) is to force the evolution of the *output tracking error* $e = y - y_d$ to be governed by a stable differential equation of the form $s(e^{\mathbf{p}}(t)) = 0$, where $e^{\mathbf{p}}(t) = (e(t), e^{(1)}(t), \ldots, e^{(p-1)}(t))$ and $s : \mathbb{R}^p \to \mathbb{R}$ is linear, so that

$$s(e^{\mathbf{p}}(t)) = e^{(p-1)}(t) + a_2 e^{(p-2)}(t) + \cdots + a_p e(t). \tag{2.2}$$

Definition 2.1. *The output of* (2.1) *can* approximately track y_d to degree p *if, given any* $\delta > 0$*, there exists an admissible input* u_δ *and time* $t_\delta > t_0$ *such that* $|s(e^{\mathbf{p}}(t))| \leq \delta$ *and the resulting state* $x(t)$ *is bounded on* $[t_\delta, \infty)$*. We say that* y asymptotically tracks y_d to degree p *if* $s(e^{\mathbf{p}}(t)) = 0$ *and* $x(t)$ *is bounded on* $[t_0, \infty)$*.*

The *relative degree* r of the output y is the least positive integer for which the derivative $y^{(r)}(t)$ is an explicit function of the input u. More precisely, r is the least positive integer for which $gf^{(r-1)}h \not\equiv 0$ (cf. [7, 8]). For single-input systems, the "decoupling matrix" is the 1×1 matrix whose entry is $gf^{(r-1)}h$. Thus the rank of the decoupling matrix changes where $gf^{(r-1)}h$ vanishes. We choose $p \leq r$ to avoid a possibly singular differential equation for u. Thus $y = h(x), y^{(1)} = fh(x), \ldots, y^{(p-1)} = f^{p-1}h(x)$. If we set $h^{\mathbf{p}} = (h, fh, \ldots, f^{p-1}h)$, then $s(e^{\mathbf{p}}(t)) = 0$ is equivalent to the requirement that $s^p(x(t), t) = 0$, where

$$\begin{aligned} s^p(x,t) &= s(h^{\mathbf{p}}(x) - y_d^{\mathbf{p}}(t)) \\ &= s(h^{\mathbf{p}}(x)) - s(y_d^{\mathbf{p}}(t)). \end{aligned} \tag{2.3}$$

In particular, if we let S_t^p denote the *sliding surface*

$$S_t^p = \{x | s^p(x,t) = 0\}, \tag{2.4}$$

then $x(t) \in S_t^p \ \forall t \geq t_f$ implies asymptotic tracking. Similarly, if

$$E_t^p = \{x | h^{\mathbf{p}}(x) = y_d^{\mathbf{p}}(t)\}, \tag{2.5}$$

then $E_t^p \subset S_t^p$, and $x(t) \in E_t^p \ \forall t \geq t_f$ implies $y^{\mathbf{p}} \equiv y_d^{\mathbf{p}}$ and perfect tracking. Our first assumption is that S_t^p is submanifold.

A1. S_t^p is an embedded codimension 1 submanifold of M for all $t \in [t_0, +\infty)$.

Remark 2.2. It is straightforward to show that A1 holds if the map $h^{\mathbf{p}}$ is transversal to the hyperplane $s^{-1}(0) + y_d^{\mathbf{p}}(t)$ (see [4, 6]).

The standard sliding mode controller approach (cf. [6, 13, 16]) is to pick $p = r$, the relative order of the output y. Then u appears explicitly in $\frac{d}{dt}s^r(x(t),t) = a(x(t),t) + b(x(t))u(t)$, where $a(x,t) = f^r h(x) - y_d^{(r)}(t) + \sum_{i=0}^{r-2} a_i(f^{i+1}h(x) - y_d^{(i+1)}(t))$ and $b(x) = gf^{r-1}h(x)$. The standard sliding mode controller takes the form $u_{sm}(x,t) = -(a(x,t) + K \text{ sign}(s^r(x,t)))/b(x)$, where $K > 0$. Using this control, $\frac{d}{dt}s^r(x(t),t) = -K \text{ sign}(s^r(x(t),t))$ and hence, after some finite time $t_f \geq t_0$, we will have $s^r(x(t),t) = 0 \, \forall t \geq t_f$. If, in addition, the system has bounded "zero dynamics" on E_t^p, then asymptotic tracking of an output y_d will be achieved (see [8]). We note that systems which fail to be strongly observable in the sense of [7] can have unstable zero dynamics (cf. [6, 15]). Of course, the assumption that b does not vanish along the state trajectory is strong. It holds in the linear case but is rarer in the nonlinear case. Typically b vanishes on the *singular submanifold* $N = \{gf^{r-1}h(x) = 0\}$, and u_{sm} becomes unbounded when the state trajectory reaches N. A natural solution is to use a truncated controller, but the resulting state trajectory can "stick" to N and evolve in such a way that one travels away from S_t^p on N (such is the case in Example 1.1). We now introduce switched controllers, which permit us to move toward the sliding surface even if $b(x)$ vanishes.

3. Incremental tracking. The set of curves which can be approximately tracked by the state trajectories of affine systems has been characterized in [12]. For single-input systems the state trajectory can only be made to stay close to integral curves of vector fields of the form $f + \alpha g$, where α is a smooth function on M. Thus to make the state approach the sliding surface S_t^r (where r is the relative degree of y) we are limited to the standard sliding mode controller and the problems associated with singular submanifolds. We seek instead to identify vector fields whose integral curves can be approached arbitrarily closely at discrete times by the state trajectory (see Figure 2). If the deviations from the integral curve are "parallel" to S_t^p for some $p \leq r$, we can use these state trajectories to implement sliding mode controllers for which singular manifolds do not pose a problem.

DEFINITION 3.1. *The integral curves of a smooth vector field X are said to be* incrementally tracked *by the state of* (2.1) *if there exist controllers $\{u_n\}$ with the following properties:*

(a) *each $u_n(x,t)$ is smooth with respect to x and is piecewise constant and periodic with respect to t with period $\tau_n = \frac{\beta_n}{n}$, where $0 < \beta_n \leq 1$;*

(b) *if $\alpha(t)$ is an integral curve of X on $[0,1]$, $x_n(t)$ the state trajectory when $u = u_n$, $x_n(0) = \alpha(0)$, and $\epsilon > 0$, then, for n sufficiently large,*

$$|| \, \alpha(k/n) - x_n(\beta_n k/n) \, || < \epsilon$$

for $k = 0, 1, \ldots, n$.

While not essential, we will assume that vector fields are complete. Let $\mathcal{I}$ denote the set of vector fields on M whose integral curves can be incrementally tracked by the state of system (2.1), and $\mathcal{I}_0$ the subset of $\mathcal{I}$ consisting of vector fields X with $\gamma X \in \mathcal{I}$ for all smooth functions $\gamma : M \to \mathbb{R}$.

THEOREM 3.2. *The set of vector fields $\mathcal{I}$ and $\mathcal{I}_0$ whose integral curves can be incrementally tracked by the state of* (2.1) *have the following properties:*

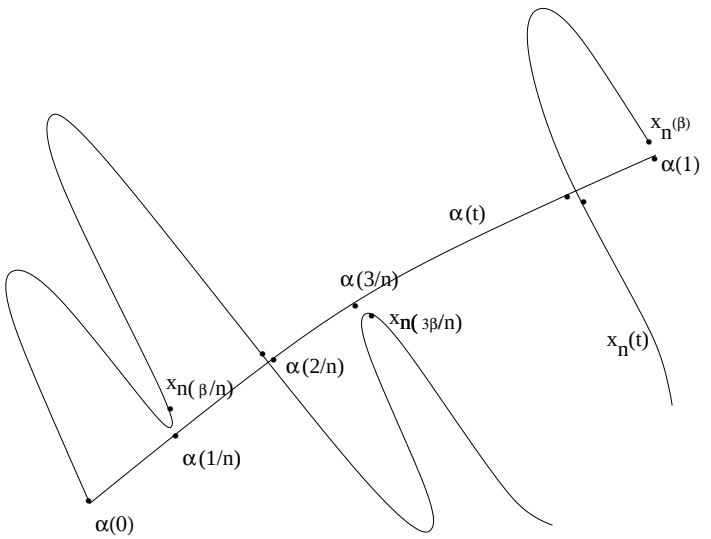

FIG. 2. *Incremental tracking of* $\alpha(t)$.

(i) $f \in \mathcal{I}$, $g \in \mathcal{I}_0$.
(ii) $\mathcal{I}_0$ *is a Lie algebra over* $\mathbb{R}$. *If* $X \in \mathcal{I}$ *and* $Y \in \mathcal{I}_0$, *then* $X + Y \in \mathcal{I}$.
(iii) *Suppose that* $Y \in \mathcal{I}$ *and* $X, ad_X^{k+1} Y \in \mathcal{I}_0$. *Then*
  (a) *if* $[ad_X^i Y, ad_X^j Y] = 0$ *for* $j \le k, i \ge 3k - j$, *then* $ad_X^k Y \in \mathcal{I}$ ($\mathcal{I}_0$ *if* k *is odd*);
  (b) *if* $ad_X^{2k} Y = 0$, *then* $ad_X^k Y \in \mathcal{I}$ ($\mathcal{I}_0$ *if* k *is odd*).
(iv) *If* $ad_g^{k+1} f = 0$, *then* $ad_g^k f \in \mathcal{I}$ ($\mathcal{I}_0$ *if* k *is odd*) *and* $ad_g^k f$ *can be incrementally tracked by the state of* (2.1) *using the periodic switched controllers* $\{u_n\}$ *defined by*

$$u_n(t - t_0) = \begin{cases} -n^{(2k+1)/k}, & 0 \le t - t_0 < 1/n^2, \\ 0, & 1/n^2 \le t - t_0 < 2/n^2, \\ n^{(2k+1)/k}, & 2/n^2 \le t - t_0 < 3/n^2, \end{cases}$$

and $u_n(t + 3/n^2) = u_n(t)$.

Remark 3.3. For the linear system model $\dot{x} = Ax + bu$, $x \in \mathbb{R}^n$, we have $f(x) = Ax \in \mathcal{I}$, $g(x) = b \in \mathcal{I}_0$, $ad_g f = Ab$, $ad_g^2 f = 0$. Thus (iii)(b) or (iv) of Theorem 3.2 implies that $ad_g f = Ab \in \mathcal{I}_0$. Repeating these steps with $ad_g f = Ab$ in place of $g = b$, etc., we find that b, $Ab, \ldots, A^{n-1} b \in \mathcal{I}_0$, and hence these constant vector fields can be incrementally tracked by the state. From this, one can deduce the standard linear result on controllability. We also note that (ii) above implies that incremental tracking of the drift vector field is preserved under smooth static state feedback. We also point out the fact that condition (iv) is nongeneric and will hold only for certain special systems.

We are interested in incremental tracking where large deviations of the state trajectory from the integral curve have only a small effect on the output of the system. We now make this notion more precise.

DEFINITION 3.4. *Suppose that* $\epsilon > 0$ *and* X *is a vector field on* M *whose integral curves can be incrementally tracked by the state* $\{x_n(t)\}$ *of* (2.1) *using controllers*

$\{u_n\}$. *If, for n sufficiently large,*

$$|| h^{\mathbf{p}}(\alpha(t)) - h^{\mathbf{p}}(x_n(\beta_n t)) || < \epsilon \ \ \forall t \in [0,1],$$

we say that the integral curves of X can be incrementally tracked preserving $h^{\mathbf{p}}$.

Let $\mathcal{I}^p$ denote the set of vector fields on M whose integral curves can be incrementally tracked preserving $h^{\mathbf{p}}$, and $\mathcal{I}_0^p$ the subset of $\mathcal{I}^p$ consisting of vector fields X with $\gamma X \in \mathcal{I}^p$ if $\gamma : M \to \mathbb{R}$ is smooth. We assume that $p \le r$.

THEOREM 3.5. *The set of vector fields $\mathcal{I}^p$ and $\mathcal{I}_0^p$ have the following properties:*

(i) $f \in \mathcal{I}^p$, $g \in \mathcal{I}_0^p$.

(ii) $\mathcal{I}_0^p$ *is a Lie algebra over* $\mathbb{R}$. *If* $X \in \mathcal{I}^p$ *and* $Y \in \mathcal{I}_0^p$, *then* $X + Y \in \mathcal{I}^p$.

(iii) *Suppose that* $Y \in \mathcal{I}^p$, $X, ad_X^{k+1} Y \in \mathcal{I}_0^p$, *and* $X h^{\mathbf{p}} = ad_X^{k+1} Y h^{\mathbf{p}} = 0$. *Then*

  (a) *If* $[ad_X^i Y, ad_X^j Y] = 0$ *for* $j \le k$, $i \ge 3k - j$, *then* $ad_X^k Y \in \mathcal{I}^p$ ($\mathcal{I}_0^p$ *if k is odd*).

  (b) *If* $ad_X^{2k} Y = 0$, *then* $ad_X^k Y \in \mathcal{I}^p$ ($\mathcal{I}_0^p$ *if k is odd*).

(iv) *If* $ad_g^{k+1} f = 0$ *and the output of system* (2.1) *has relative order* $r > p$, *then* $ad_g^k f \in \mathcal{I}^p$ ($\mathcal{I}_0^p$ *if k is odd*).

Example 3.6 (*Example* 1.1 *continued*). Here we have $f(x) = (x_3^2 - x_2, x_3, 0)$, $g(x) = (0,0,1)$, $ad_g^2 f(x) = (2,0,0)$, $ad_g^3 f(x) = (0,0,0)$, and $h(x) = x_1$, with $p = 1$ and relative order $r = 2$. Thus condition (iv) of Theorem 3.5 holds and $ad_g^2 f \in \mathcal{I}^p$.

Proof (Theorem 3.2*).*

(i) An integral curve $\alpha(t) = f_t(x)$ of f can be tracked exactly using $u_n = 0$, $\beta_n = 1$. In this case the corresponding state trajectory $x_n(t) = f_t(x) = \alpha(t)$; hence $f \in \mathcal{I}$. Now let $\gamma : M \to \mathbb{R}$ be smooth, and set $t_k = k/n$, $\alpha(t) = \gamma(x) g_t(x)$, $u_n(x,t) = \gamma(x) n$, and $\beta_n = 1/n$. Then

$$x_n(\beta_n t_k) = x_n\left(\frac{k}{n^2}\right) = (f + \gamma n g)_{\frac{k}{n^2}}(x) = \left(\frac{1}{n} f + \gamma g\right)_{\frac{k}{n}}(x),$$

which approximates $\alpha(t_k)$. In particular, we can guarantee that $|| \alpha(t_k) - x_n(\beta_n t_k) || < \epsilon$ for $k = 0, 1, \ldots, n$ and n sufficiently large. This means that $\gamma g \in \mathcal{I}$, hence $g \in \mathcal{I}_0$. Note that in both of the above cases $x_n(t)$ stays close to $\alpha(t)$ $\forall t \in [0,1]$.

(ii) Suppose that $X, Y \in \mathcal{I}_0$, $\alpha(t)$ is an integral curve for $X + Y$ on $[0,1]$, and $\epsilon > 0$. Then $2X, 2Y \in \mathcal{I}_0$, and if $\ell > 0$, we define the "switched integral curve" $\gamma(t) = 2Y_t(x)$ for $0 \le t < 1/2\ell$, and $\gamma(t) = 2X_t(2Y_{1/2\ell}(x))$ for $1/2\ell \le t < 1/\ell$. It follows that

$$\gamma(1/\ell) = (2X)_{1/2\ell}((2Y)_{1/2\ell}(x)) = X_{1/\ell}(Y_{1/\ell}(x)) = Z(\ell)_{1/\ell}(x) = (Z(\ell)/\ell)_1(x),$$

where $Z(\ell) = (X + Y) + \frac{1}{2\ell}[X, Y] + \cdots$ (cf. [17, 18]). Continuing to switch between integral curves of X and Y we get

$$\gamma(2/\ell) = X_{1/\ell}(Y_{1/\ell}(X_{1/\ell}(Y_{1/\ell}(x)))) = (Z(\ell)/\ell)_1^2(x), \cdots, \gamma(k/\ell) = (Z(\ell)/\ell)_1^k(x).$$

Here $Z(\ell) \to X + Y$ as $\ell \to \infty$; hence $(Z(\ell)/\ell)_1^\ell(x) \to (X + Y)_1(x)$ as $k \to \ell$ and $\ell \to \infty$ (cf. [17]). In particular, for ℓ sufficiently large, $|| \alpha(t_k) - \gamma(t_k) || < \epsilon/2$, where $t_k = k/\ell$ and $k = 0, 1, \ldots, \ell$. Since $2Y \in \mathcal{I}_0$ we know that given $\epsilon' > 0$ there exist piecewise constant periodic w.r.t. t controllers $\{u_n\}$, with period $\tau_n = \beta_n/n$ ($0 < \beta_n \le 1$), such that the integral curves of $2Y$ are incrementally tracked by the corresponding state trajectory $x_n(t)$. Thus we have $|| 2Y_{k/n}(\alpha(0)) - x_n(\beta_n k/n) || < \epsilon'/2$ for $k = 0, 1, \ldots, n$ and n sufficiently large. In particular, if $p = 2Y_{1/2\ell}(\alpha(0))$,

we can arrange that $|| p - x_n(\beta_n k/n) || < \epsilon'/2$ for some k and n sufficiently large. Similarly, $2Y \in \mathcal{I}_0$, so there exist controllers $\{u'_n\}$ with period $\tau'_n = \beta'_n/n$ such that $|| 2X_{1/2\ell}(p) - x'_n(\beta'_n k'/n') || < \epsilon'/2$ for some k', n'. Thus this concatenation of $\{u'_n\}$ and $\{u_n\}$ results in a piecewise smooth state trajectory $\tilde{x}_n$ which achieves $|| \alpha(t_1) - \tilde{x}_n(\tilde{\beta}_n t_1) || < \epsilon'$ for appropriate $\tilde{\beta}_n$ and n sufficiently large. Now we repeat the pattern (u_n followed by u'_n) to generate a piecewise smooth state trajectory $\tilde{x}_n$ for which $|| \alpha(t_k) - \tilde{x}_n(\tilde{\beta}_n t_k) || < k\epsilon'$ holds (k applications of the triangle inequality). Thus we can choose $\epsilon' = \epsilon/n$ to achieve incremental tracking of $X + Y$, hence $X + Y \in \mathcal{I}$. Now we can repeat the above argument using $\alpha X, \alpha Y$ to conclude that $\alpha(X+Y) \in \mathcal{I}$, hence $X + Y \in \mathcal{I}_0$. To show that $[X, Y] \in \mathcal{I}_0$ we argue as above. If $\ell > 0$, then $\sqrt{\ell}X, \sqrt{\ell}Y \in \mathcal{I}$. Consider the "switched integral curve" $\gamma(t)$ produced by following the integral curve for $-\sqrt{\ell}Y$ for $1/4\ell$ units of time, then the integral curve for $-\sqrt{\ell}X$ for $1/4\ell$ units of time, then the integral curve for $\sqrt{\ell}Y$ followed by that of $\sqrt{\ell}X$. Then

$$\gamma(1/\ell) = 4\sqrt{\ell}X_{1/4\ell}(4\sqrt{\ell}Y_{1/4\ell}(4\sqrt{\ell}X_{-1/4\ell}(4\sqrt{\ell}Y_{-1/4\ell}(x)))),$$

so that $\gamma(1/\ell) = X_{1/\sqrt{\ell}}(Y_{1/\sqrt{\ell}}(X_{-1/\sqrt{\ell}}(Y_{-1/\sqrt{\ell}}(x)))) = (Z(\ell)/\ell)_1(x)$, where $Z(\ell) \to [X, Y]$ as $\ell \to \infty$, hence $(Z_\ell/\ell)^\ell_1(x) \to [X, Y]_1(x)$ as $\ell \to \infty$, assuming X, Y, x fixed (cf. [18]). Continuing to switch between these integral curves, we generate $\gamma(k/\ell)$ for $k = 0, \ldots, \ell$. Thus, for ℓ sufficiently large,

$$|| \alpha(t_k) - \gamma(t_k) || < \epsilon/2,$$

where $\alpha(t)$ is an integral curve for $[X, Y]$ on $[0, 1]$, $t_k = k/\ell$, and $k = 0, 1, \ldots, \ell$. Since $4\sqrt{\ell}X, 4\sqrt{\ell}Y \in \mathcal{I}_0$, they can be incrementally tracked using periodic switched controllers $\{u_n\}$ and $\{u'_n\}$. We then argue as above to show that $[X, Y] \in \mathcal{I}$. Repeating these steps with $\sqrt{a}X, \sqrt{a}Y$ shows that $a[X, Y] \in \mathcal{I}$, hence $[X, Y] \in \mathcal{I}_0$. Finally, suppose that $X \in \mathcal{I}$, $Y \in \mathcal{I}_0$. Let $\alpha(t)$ be an integral curve for $X + Y$ on $[0, 1]$, m a positive integer, and $\epsilon > 0$. Then $mY \in \mathcal{I}$, and we define the "switched integral curve" $\gamma(t) = mY_t(x)$ for $0 \le t < 1/m\ell$, and $\gamma(t) = X_t(mY_{1/m\ell}(x))$ for $1/m\ell \le t < (m + 1)/m\ell$. Thus

$$\gamma\left(\frac{m+1}{m\ell}\right) = (X)_{1/\ell}((mY)_{1/m\ell}(x)) = X_{1/\ell}(Y_{1/\ell}(x)) = (Z(\ell)/\ell)_1(x),$$

where $Z(\ell) = (X + Y) + \frac{1}{2\ell}[X, Y] + \cdots$ (cf. [17, 18]). Continuing to switch between integral curves of X and Y, we get

$$\gamma\left(\frac{2(m+1)}{m\ell}\right) = X_{1/\ell}(Y_{1/\ell}(X_{1/\ell}(Y_{1/\ell}(x)))) = \left(\frac{Z(\ell)}{\ell}\right)^2_1(x), \ldots, \gamma\left(\frac{k}{\ell}\right) = \left(\frac{Z(\ell)}{\ell}\right)^k_1(x).$$

Then $Z(\ell) \to X + Y$ as $k \to \ell$ and $\ell \to \infty$ [17]. Now $\frac{k(m+1)}{m\ell} \to \frac{k}{\ell}$ as $m \to \infty$ so, for ℓ and m sufficiently large, $|| \alpha(t_k) - \gamma(t_k) || < \epsilon/2$, where $t_k = k/\ell$ and $k = 0, 1, \ldots, \ell$. Now repeat the argument used to show that $\mathcal{I}_0$ is closed under sums to conclude that $X + Y \in \mathcal{I}$.

(iii)(a) Suppose that $Y \in \mathcal{I}$, $X, ad^{k+1}_X Y \in \mathcal{I}_0$, and $[ad^i_X Y, ad^j_X Y] = 0$ for $j \le k$, $i \ge 3k - j$. Set $X^+ = n^{(2k+1)/k}X$, $X^- = -n^{(2k+1)/k}X \in \mathcal{I}_0$, and denote by $\psi(t)$ the switched integral curve which results from following the integral curve for X^- for $1/n^2$ units of time, where $\psi(0) = x \in M$, then following the integral curve for Y for $1/n^2$ units of time, and finally following the integral curve for X^+ for $1/n^2$ units of time. By construction,

$$\psi(3/n^2) = X_{n^{1/k}}(Y_{1/n^2}(X_{-n^{1/k}}(x))).$$

Noting that

$$X_t(Y_s(X_{-t}(x))) = s\sum_{n=0}^{\infty}\frac{t^n}{n!}ad_X^iY(x),$$

an absolutely convergent series for all t (cf. [17, 18]), we see that

$$\psi(3/n^2) \quad = \quad (G(n)+B(n))_{\frac{1}{n}}(x),$$

where

$$\begin{array}{lcl} G(n) & = & \frac{1}{n}Y + \frac{n^{1/k}}{n}ad_XY + \cdots + ad_X^kY, \\ B(n) & = & n^{1/k}ad_X^{k+1}Y + \cdots + n^{\ell/k}ad_X^{k+\ell}Y + \cdots. \end{array} \tag{3.1}$$

Since X and $ad_X^{k+1}Y \in \mathcal{I}_0$, a Lie algebra from (ii) above, it follows that $B(n) \in \mathcal{I}_0\ \forall n > 0$. In particular, the integral curve for $-B$ (writing B, G for $B(n), G(n)$) can be incrementally tracked by the state. This means that the switched integral curve $\gamma(t)$ which results from following the integral curve for $-nB$ for time $1/n^2$, followed by the switched integral curve $\psi(t)$, results in

$$\gamma(4/n^2) = (G+B)_{\frac{1}{n}}((B)_{-\frac{1}{n}}(x)). \tag{3.2}$$

Using the Baker–Campbell–Hausdorff formula [17], which converges for n sufficiently large, we have

$$\gamma\left(\frac{1}{n^2}\right) = \left(G + \frac{1}{2n}[G,B] + \frac{1}{12n^3}\{2[B,[G,B]] + [G,[G,B]]\} + \cdots\right)_{\frac{1}{n}}(x).$$

From the definitions for $G(n)$ and $B(n)$ and in light of *hypothesis* of Theorem 3.2(iii)(a) we have

$$\frac{1}{2n}[G(n),B(n)] = \sum_{j=0}^{k}\sum_{\ell=1}^{k-j-1}\frac{n^{\frac{j+\ell}{k}}}{n}[ad_X^jY, ad_X^{k+\ell}Y];$$

hence $\frac{1}{2n}[G(n),B(n)] \to 0$ as $n \to \infty$. Tedious applications of the Jacobi identity show that $\frac{1}{12n^3}\{2[B(n),[G(n),B(n)]] + [G(n),[G(n),B(n)]]\} \to 0$ as $n \to \infty$ as a consequence of Theorem 3.2(iii)(a), and the same conclusion applies to the higher order terms in the Baker–Campbell–Hausdorff series. In particular, we see that $\gamma(4/n^2) = (Z(n)/n)_1(x)$, where $Z(n) \to ad_X^kY$ as $n \to \infty$. Repeating ℓ times the switched integral curves used to generate $\gamma(t)$, we arrive at the state $\gamma(4\ell/n^2)$ and observe that $\gamma(4/n) = (Z(n)/n)_1^n(x) \to ad_X^kY_1(x)$ as $n \to \infty$. Thus $\gamma(t)$ is a switched integral curve of vector fields which can be incrementally tracked by the state of system (2.1). Furthermore, if $\beta_n = 4/n$ and $t_\ell = \ell/n$, then $\gamma(\beta_n t_\ell) \to (ad_X^\ell Y)_{t_\ell}(x)$ as $n \to \infty$. If $\alpha(t)$ is the integral curve for ad_X^kY with $\alpha(0) = x$, we have $\| \alpha(t_\ell) - \gamma(\beta_n t_\ell) \| < \epsilon/2$ for n sufficiently large and $\ell = 0, 1, \ldots, n$. Here γ switched between integral curves of vector fields which can be incrementally tracked. Thus we can repeat the argument used in (ii) above to show that there exist piecewise constant periodic controllers $\{u_n\}$ with periods $\tau_n = \beta_n/n$, where $\beta = 4/n$ such that $\| \alpha(t_\ell) - x_n(\beta_n t_\ell) \| < \epsilon$ for n sufficiently large and $\ell = 0, 1, 2, \ldots n$. This implies that $ad_X^kY \in \mathcal{I}$. If k is odd, we replace X with $-X$ and proceed as above to conclude that $-ad_X^kY \in \mathcal{I}$, from which we deduce that $ad_X^kY \in \mathcal{I}_0$.

(iii)(b) This is a particular case of (iii)(a).

(iv) This result is a consequence of (i) and (iii)(a). If we set $Y = f$ and $X = g$, then $Y \in \mathcal{I},\ X \in \mathcal{I}_0$ as a consequence of (i). Since $ad_X^{k+1}Y = 0$, it follows that $ad_X^{2k}Y = 0$; hence $ad_x^i Y = 0$ for $i \geq 3k - j$ and $j \leq k$, and (iii)(a) holds (and also (iii)(b)). In particular, we can conclude that $ad_X^k Y = ad_g^k f \in \mathcal{I}$. One can check that the controller u_n defined in (iv) is precisely the one used in the proof of (iii)(a). A more direct approach to the proof of (iv) is illuminating and is outlined below. Using the control $u_n(t)$ defined in (iv) (and $t_0 = 0$, to save accounting) we have

$$x_n(3/n^2) = (f + n^{(2k+1)/k} g)_{1/n^2}(f_{1/n^2}((f - n^{(2k+1)/k} g)_{1/n^2}(x_0))).$$

Applying the Baker–Campbell–Hausdorff formula (cf. [17]) two times, we can write $x_n(3/n^2) = (X(n)/n)_1(x_0)$. In the case $k = 2$ this yields (with the help of MAPLE V, Version 5.00 (Waterloo Maple, Waterloo, ON)) the expression

$$\begin{aligned} X(n) \;=\; & \tfrac{3}{n} f + \tfrac{2}{n^{1/2}}[g,f] + \tfrac{5}{6}[g,[g,f]] + \tfrac{1}{144n^4}[[f,g],[f,[f,g]]] \\ & + \tfrac{1}{72n^{3/2}}[[f,g],[g,[f,g]]] + \tfrac{1}{96n^{7/2}}[[f,[f,g]],[g,[f,g]]] \\ & + \tfrac{1}{576n^{11/2}}[[f,g],[[f,g],[f,[f,g]]]] - \tfrac{1}{576n^3}[[f,g],[[f,g],[g,[f,g]]]] \\ & + \tfrac{1}{3456n^5}[[g,[f,g]],[[f,g],[f,[f,g]]]] \\ & - \tfrac{1}{3456n^{5/2}}[[g,[f,g]],[[f,g],[f,[f,g]]]] + \cdots . \end{aligned}$$

Because $ad_g^3 f = 0$ it is not hard to show that all terms in $X(n)$, other than $ad_g^2 f = 0$, are multiplied by negative powers of n. In particular, $\lim_{n\to\infty} X(n) = \frac{5}{6}[g,[g,f]]$. A similar situation holds for other values of k, that is, $\lim_{n\to\infty} X(n) = c_k[g,[g,f]]$, where $c_k > 0$. Repeating the above, we find that $x_n(3\ell/n^2) = (X(n)/n)_1^\ell(x_0)$ and $x_n(3/n) = (X(n)/n)_1^n(x_0)$. But $\lim_{n\to\infty}(X(n)/n)^n(x_0) = \lim_{n\to\infty} X(n)_1(x_0) = c_k ad_g^k f_1(x_0)$, and hence $ad_g^k f$ is incrementally tracked by the state of system (2.1). □

Proof (*Theorem* 3.5).

(i) We can track an integral curve $\alpha(t)$ of f exactly using $u_n = 0$; thus $|| h^{\mathbf{P}}(\alpha(t)) - h^{\mathbf{P}}(x_n(t)) || = 0 \quad \forall t \in [0,1]$. This means that $f \in \mathcal{I}^p$. As noted in the proof of Theorem 3.2, we can find controllers u_n such that the corresponding state trajectory x_n closely follows the integral curves for γg for all $t \in [0,1]$ (not just for discrete times). Since the state trajectory x_n makes no large deviation from the integral curve of γg we have incremental tracking preserving $h^{\mathbf{P}}$.

(ii) In the proof of Theorem 3.2(ii) we saw that an integral curve $\alpha(t)$ of $X + Y$ can be tracked by switched integral curves of X and Y which stay close to $\alpha(t)$ for all $t \in [0,1]$. Since $X, Y \in \mathcal{I}^p$, we can find switched controllers $u_n,\ u'_n$ such that the corresponding state trajectories $x_n,\ x'_n$ incrementally track the integral curves of X and Y while preserving $h^{\mathbf{P}}$. Thus the image under $h^{\mathbf{P}}$ of the concatenation of $x_n,\ x'_n$ used to incrementally track $\alpha(t)$ will stay close to $h^{\mathbf{P}}(\alpha(t))$, and we will have incremental tracking of $X + Y$ preserving $h^{\mathbf{P}}$. The same situation holds in the case of $[X, Y]$.

(iii)(a) In the proof of Theorem 3.2(iii)(a), we constructed switched integral curves of X and Y which incrementally track integral curves of $ad_X^k Y$ but need not closely approximate these curves except at a discrete set of times. Thus the controllers u_n produce state trajectories x_n which incrementally track the integral curve $\alpha : t \mapsto (ad_X^k Y)(x)$ while making frequent and large deviations from $\alpha(t)$. By construction, these large motions are along integral curves for the vector fields X and $B(n) = \sum_{\ell=1}^{\infty} n^{\ell/k} ad_X^{k+\ell} Y$. Since $Xh = ad_X^{k+1} Y h^{\mathbf{P}} = 0$, we have $(X ad_X^{k+1} Y h^{\mathbf{P}} -$

$ad_X^{k+1}YXh^{\mathbf{p}}) = [X, ad_X^{k+1}Y]h^{\mathbf{p}} = 0$, and hence $\forall Z \in \{X, ad_X^{k+1}Y\}_{LA}$ we have $Zh^{\mathbf{p}} = 0$. In particular, $B(n)h^{\mathbf{p}} = 0$, and it follows that the large motions of the state trajectory x_n are in directions in which $h^{\mathbf{p}}$ does not vary. Thus we achieve incremental tracking of $\alpha(t)$ preserving $h^{\mathbf{p}}$.

(iii)(b) This is a particular case of (iii)(a).

(iv) Since $ad_g^{k+1}f = 0$ we have $g, ad_g^{k+1}f \in \mathcal{I}_0^p$. Clearly $ad_g^{k+1}fh^{\mathbf{p}} = 0$ and $gh^{\mathbf{p}} = (gh, gfh, \cdots, gf^{p-1}h)$. Since $p < r$ and $gf^ih = 0$ if $i \leq r-2$ (definition of relative order) we have $gh^{\mathbf{p}} = 0$, and the result follows from (iii)(b) above. □

4. Incremental sliding mode controllers. In the nonsingular case, the simple sliding mode controller (1.2) gives rise to vector fields $f + Lg$ and $f - Lg$ with several noteworthy properties. Given any compact subset C there exists $L > 0$, $\sigma_1, \sigma_2, \delta > 0$ such that

(i) on the set C

$$\begin{aligned}(f - Lg)s(h^{\mathbf{r}}) &< -\delta - \sigma_1,\\ (f + Lg)s(h^{\mathbf{r}}) &> +\delta + \sigma_2;\end{aligned}$$

(ii) $(f \pm Lg)h^{\mathbf{r-1}}(x) = fh^{\mathbf{r-1}}(x)$ if $r > 1$.

Remark 4.1. Suppose that y_d is a smooth function satisfying

$$-\sigma_1 \leq \frac{d}{dt}s(y_d^{\mathbf{r}}(t)) \leq \sigma_2$$

on $[t_0, +\infty)$. Then condition (i) implies that if the state stays in C, then the output will asymptotically track y_d using the simplified controller (1.2). In particular, if $s^p(x(t), t) > 0$ (so that we are "above" the sliding surface $\{s^p(x,t) = 0\}$) and $u = -L$, we have

$$\frac{d}{dt}s^p(x(t), t) = \frac{d}{dt}s(h^p(x(t)) - \frac{d}{dt}s(y_d^{\mathbf{r}}(t)).$$

From the definition of s (s is linear) we have $\frac{d}{dt}s(y^p(t)) = s(\dot{y}^p(t))$. Furthermore, $\frac{d}{dt}s(h^p(x(t))) = d(s\circ h^p)_{x(t)}\dot{x}(t) = d(s\circ h^p)_{x(t)}(f - Lg)(x(t)) = (f - Lg)(s\circ h^p)(x(t)) = (f - Lg)s(h^p(x(t))) < -\delta - \sigma_1$. This, combined with our assumption that $-\sigma_1 \leq s(\dot{y}_d^{\mathbf{r}}(t))$ or $-\frac{d}{dt}s(y_d^{\mathbf{r}}(t)) \leq \sigma_1$, yields $\frac{d}{dt}s^p(x(t), t) \leq -\delta_1 - \sigma_1 + \sigma_1 = -\delta_1$. In particular, the state trajectory returns to the sliding surface $\{s^p(x,t) = 0\}$. A similar situation results when $s^p(x(t), t) < 0$ and $u = L$.

Remark 4.2. Condition (ii) follows from the definition of the relative order r, since $gf^ih = 0$ for $i < r - 1$. That this is important in sliding mode control can be seen as follows: when the state "slides" on the sliding surface S_t^r, the trajectory is the integral curve of the "equivalent vector field" on S_t^r, which has the form $X = \alpha(f + Lg) + (1 - \alpha)(f - Lg)$, where $|\alpha(x)| \leq 1$ and $Xs(h^{\mathbf{r}}) = 0$ (cf. [3]). Note that $Xh^{\mathbf{r-1}} = (\alpha f + (1-\alpha)f)h^{\mathbf{r-1}} = fh^{\mathbf{r-1}}$. As a consequence, along this integral curve the tracking error satisfies the stable differential equation $s(e^{\mathbf{r}}(t)) = 0$, where s is defined by (2.2).

We seek to weaken the above in several ways. First we use the sliding surface S_t^p, where p is allowed be smaller than the relative order r of y. As a consequence of Theorem 3.5, $f \pm Lg \in \mathcal{I}^p$. We relax (ii) by allowing vector fields of the form $d^+, d^- \in \mathcal{I}^p$ such that $d^{\pm}h^{\mathbf{p-1}} = fh^{\mathbf{p-1}}$ and only require (i) above to hold on an open subset of Z of M which is invariant under the integral curves of d^+, d^-. We summarize these observations as follows.

DEFINITION 4.3. *Let X be a vector field on M. An open subset Z of M is said to be* invariant *with respect to a vector field X if, for all $x \in Z$, the integral curve $t \mapsto X_t(x)$ stays in Z.*

A2. There exists an open subset $Z \subset M$, invariant with respect to vector fields $d^+, d^- \in \mathcal{I}^p$, and constants $\alpha_1, \alpha_2 \in \mathbb{R}$, $\sigma_1, \sigma_2, \delta > 0$ such that

(i) on Z

$$\begin{array}{rcll} d^- s(h^{\mathbf{p}}) & < & -\delta - \sigma_1, & \text{when } \{s(h^{\mathbf{p}}) \geq \alpha_1\}, \\ d^+ s(h^{\mathbf{p}}) & > & +\delta + \sigma_2, & \text{when } \{s(h^{\mathbf{p}}) \leq \alpha_2\}; \end{array}$$

(ii) $d^{\pm} h^{\mathbf{p-1}}(x) = f h^{\mathbf{p-1}}(x)$ if $p > 1$.

If A2 holds for constants $\alpha_1, \alpha_2, \sigma_1, \sigma_2$, we define the following restricted class of desired output functions:

$$\mathcal{Y}_d = \{y_d \mid \alpha_1 \leq s(y_d^{\mathbf{p}}(t)) \leq \alpha_2,\ -\sigma_1 \leq s(\dot{y}_d^{\mathbf{p}}(t)) \leq \sigma_2 \ \ \forall t \geq t_0\}.$$

We will show that these outputs can be approximately tracked. We note that in the nonsingular case, A2 holds with $Z = M$, $d^+ = f + Lg$, and $d^- = f - Lg$ for L sufficiently large. If A2 holds with $d^{\pm} \in \mathcal{I}^p$, we define the set-valued map $F_d(x,t)$ by

$$F_d(x,t) = \begin{cases} d^+(x), & x \in \{s^p(x,t) < 0\}, \\ d^-(x), & x \in \{s^p(x,t) > 0\}, \\ \overline{\text{co}}\,\{d^+(x), d^-(x)\}, & x \in \{s^p(x,t) = 0\}, \end{cases} \tag{4.1}$$

where $\overline{\text{co}}\,\{d^+(x), d^-(x)\}$ is the closed convex hull generated by the $\{d^+(x), d^-(x)\}$.

THEOREM 4.4. *Suppose* A1, A2 *hold for system* (2.1). *Then there exist d^+, $d^- \in \mathcal{I}^p$ and an open subset $Z \subset M$ such that, for all smooth functions $y_d \in \mathcal{Y}_d$,*

(i) *the differential inclusion $\dot{x} \in F_d(x,t)$ with $x(t_0) \in Z$ has a unique solution $x_F(t) \in Z$ defined on $[t_0, +\infty)$;*

(ii) *for any solution x_f to $\dot{x} \in F_d(x,t)$ there exists $t_f \geq t_0$ such that $x_F(t) \in Z \cap S_t^p$ on $[t_f, +\infty)$;*

(iii) *for $t \geq t_f$ the curve $t \mapsto y_F(t) = h(x_F(t))$ is a smooth function of t which satisfies $s(y_F^{\mathbf{p}}(t) - y_d^{\mathbf{p}}(t)) = 0$. In particular, $\lim_{t\to\infty}(y_F^{\mathbf{p}}(t) - y_d^{\mathbf{p}}(t)) = 0$.*

Proof. By construction, $F_d(x,t)$ is nonempty, compact, and convex, and it is straightforward to show that F_d is upper semicontinuous with respect to x, t. Thus the *basic conditions* of [3, p. 76] are satisfied; the proof that local solutions to the *differential inclusion* $\dot{x}(t) = F_d(x(t),t)$ exist can be found in [3, pp. 67–68 and pp. 77–78] and is omitted here. That solutions stay in Z follows from A2, i.e., the assumption that Z is strongly invariant with respect to d^+, d^-. To establish uniqueness we note that both d^+ and d^- are transversal to $S_t^P \cap Z$ as a consequence of A2(i). Furthermore, the limiting vector fields on $S_t^P \cap Z$, which result from $d^+(x)(d^-(x))$ when x approaches $\{s^p = 0\}$ from $\{s^p > 0\}(\{s^p < 0\})$, define the opposite orientations on $S_t^P \cap Z$. Thus [3, Corollary 2, p. 108] implies that there is exactly one solution to this differential inclusion starting at $x(t_0) \in Z$.

(ii) Suppose that $y_d \in \mathcal{Y}_d$ and $s^p(x_F(t_0), t_0) < 0$. Then, from the definition of $\mathcal{Y}_d$, we have $-\sigma_1 \leq s(\dot{y}_d^{\mathbf{p}}(t)) \leq \sigma_2$. But $d^+ s(h^{\mathbf{p}}(x_F(t))) > \delta + \sigma_2$ by A2(i). Thus $\frac{d}{dt} s^p(x_F(t),t) = d^+ s(h^{\mathbf{p}}(x_F(t))) - s(\dot{y}_d^{\mathbf{p}}(t)) \geq \delta + \sigma_2 - \sigma_2 = \delta > 0$, and $s^p(x,t)$ is strictly increasing along integral curves of d^+ if $\{s^p < 0\}$. Similarly, $s^p(x,t)$ is strictly decreasing along integral curves of d^- in $\{s^p > 0\}$. Since $x_F(t) \in Z\ \forall t \geq t_0$ by (i), we have established (ii).

(iii) For $t \geq t_f$, x_F is a smooth integral curve for the equivalent vector field X defined in Remark 4.2. Here $Xh^{\mathbf{p-1}} = fh^{\mathbf{p-1}}$ as a consequence of A2(ii), hence $y^{(i)} = X^i h = f^i h$ for $i = 1, 2, \ldots, p-1$. From section 2 we know that if $y^{(i)} = f^i h$ for $i = 1, 2, \ldots, p-1$, then $s(y^{\mathbf{p}}(t) - y_d^{\mathbf{p}}(t)) = s(e^{\mathbf{p}}(t)) = 0$ is equivalent to $s^p(x(t), t) = 0$ or $x(t) \in S_t^p$. In particular, since $x_F(t) \in S_t^p$ from (ii), we have $s(e^{\mathbf{p}}(t)) = 0 \; \forall t > t_f$ and $\lim_{t\to\infty}(y_F^{\mathbf{p}}(t) - y_d^{\mathbf{p}}(t)) = 0$. □

A necessary condition for approximate tracking of y_d is that both $y_d^{\mathbf{p}}$ and the state trajectory remain bounded. In the nonsingular case the state trajectory and the solution to the differential inclusion $\dot{x} \in F_d(x, t)$ are identical, and it suffices to ensure that solutions to $\dot{x} \in F_d(x, t)$ with $x(t_0) \in E_t^p \cap Z$ remain bounded. In our case the same assumption suffices.

A3. Suppose that A2 holds for system (2.1) and $y_d \in \mathcal{Y}_d$. Then solutions to the differential inclusion $\dot{x} \in F_d(x, t)$, with initial state $x(t_0) \in E_t^p \cap Z$, remain bounded for $t \in [t_0, +\infty)$.

Remark 4.5. Note that in light of Theorem 4.4 (ii) it suffices to study the trajectory on S_t^p. Since there is a unique vector field $G(x, t)$ in $\overline{\text{co}}\,\{d^+(x), d^-(x)\}$ that makes $\frac{\partial}{\partial t} + G(x, t)$ tangent to S_t^p, it suffices to check that this one integral curve is bounded. A sufficient (but far from necessary) condition for A3 to hold is that $Z \cap S_t^p$ be bounded.

Suppose that A1, A2, A3 hold for system (2.1) with initial state $x(t_0) \in Z$, where Z is an open subset of M invariant with respect to vector fields $d^+,\ d^- \in \mathcal{I}^p$. If we could make the state of (2.1) exactly track the solution $x_F(t)$ to $\dot{x} \in F_d(x, t)$, then Theorem 4.4 would imply asymptotic tracking of y_d. We now describe a "digital controller" which allows us to incrementally track x_F and approximately track y_d. We are motivated by the typical "sample and hold" digital controller with fixed sample rate T. That is, if $u(x, t)$ is a smooth function of x and t, the digital controller $u_k(t)$ takes the form

$$\begin{aligned} u_k(t) &= u(x_k, t_k) \quad \text{for } t_k \leq t < t_{k+1}, \\ t_{k+1} &= t_k + T, \\ x_k &= x(t_k), \end{aligned}$$

where $x(t_k)$ is the state at time t_k which results from using the control u_k on the time interval $[t_{k-1}, t_k)$. We have controllers $u_n^+(x, t)$ and $u_n^-(x, t)$, which are piecewise constant periodic functions of t with periods $\tau_n^+ = \beta_n^+/n$ and $\tau_n^- = \beta_n^-/n$, respectively, and which cause the state of (2.1) to incrementally track integral curves of $d^+,\ d^-$, respectively. Thus we require a digital controller with variable sampling rate. We define our *digital controller* for system (2.1) as follows:

$$\begin{aligned} u_k(x, t) &= \begin{cases} u_n^+(x, t) & \text{for } t_k \leq t < t_{k+1},\ s^p(x_k, t_k) < 0, \\ u_n^-(x, t) & \text{for } t_k \leq t < t_{k+1},\ s^p(x_k, t_k) \geq 0, \end{cases} \\ t_{k+1} &= \begin{cases} t_k + \tau_n^+ & \text{if } s^p(x_k, t_k) < 0, \\ t_k + \tau_n^- & \text{if } s^p(x_k, t_k) \geq 0, \end{cases} \\ x_k &= x(t_k). \end{aligned} \tag{4.2}$$

We observe that while $u_k(x, t)$ is not constant with respect to t over $[t_k, t_{k+1})$, it is piecewise constant due to the piecewise constant time dependence of u_n^+ and u_n^-.

THEOREM 4.6. *Under assumptions* A1, A2, A3*, the switched controller* (4.2) *achieves the following property for the closed loop system: if* $x(t_0) = x_0 \in Z$ *and*

$y_d \in \mathcal{Y}_d$, then, for n sufficiently large, the output y of (2.1) approximately tracks y_d to degree p.

Proof. Let $x_F(t)$ denote the solution to the differential inclusion $\dot{x} \in F_d(x,t)$; $x(t_0) = x_0 \in Z$ and let $\epsilon > 0$. From Theorem 4.4 there exists $t_f \geq t_0$ such that $x_F(t) \in Z \cap S_t^p \ \forall t \geq t_f$ and $\lim_{t\to\infty}(y_F^{\mathbf{p}}(t) - y_d^{\mathbf{p}}(t)) = \lim_{t\to\infty}(h^{\mathbf{p}}(x_F(t)) - y_d^{\mathbf{p}}(t)) = 0$. This implies that $x_F(t) \to E_t^p \cap Z$ as $t \to \infty$ and, in light of A3, $x_F(t)$ is a bounded function of t. We first consider the case where $s^p(x_0,t_0) < 0$. Then for $t_0 \leq t < t_f$ we have $s^p(x_F(t),t) < 0$, $F_d(x_F(t),t) = d^+(x_F(t))$, $u_k = u_n^+$, $t_1 = t_0 + \tau_n^+ = t_0 + \beta_n^+/n$, $t_2 = t_0 + 2\beta_n^+/n, \ldots,$ and $t_k = t_0 + k\beta_n^+/n$. The vector field d^+ is incrementally tracked by the state trajectory x_n^+ produced by u_n^+. We now calculate the rate of change of $s^p(x(t),t)$ when $x(t)$ is the integral curve $x_F(t)$ of d^+ but time t is rescaled to match the time rescaling which occurs in incremental tracking. For $t < t_f$ we have, from A2 and the linearity of s,

$$\begin{aligned}
\tfrac{d}{dt}s^p(x_F(t_0+t), t_0+\beta_n^+ t) &= d^+ s(h^{\mathbf{p}}(x_F(t_0+t))) - \tfrac{d}{dt}s(y^{\mathbf{p}}(t_0+\beta_n^+ t)) \\
&\geq \delta + \sigma_2 - s(\beta_n^+ \dot{y}^{\mathbf{p}}(t_0+\beta_n^+ t)) \\
&= \delta + \sigma_2 - \beta_n^+ s(\dot{y}^{\mathbf{p}}(t_0+\beta_n^+ t)) \\
&\geq \delta + \sigma_2 - \beta_n^+ \sigma_2 \\
&\geq \delta
\end{aligned}$$

as $0 < \beta_n \leq 1$. Thus there is some least time $t_1 > 0$ such that $s^p(x_F(t_0+t_1), t_0 + \beta_n^+ t_1) = 0$ and some positive integer k_1 (depending on n) such that $x_F(t_0 + k/n) \leq x_F(t_0+t_1) \leq x_F(t_0+(k+1)/n)$. We can make $||x_F(t_0+t_1) - x_F(t_0+(k_1+1)/n)||$ arbitrarily small by increasing n, and hence

$$||s^p(x_F(t_0+(k_1+1)/n), t_0+\beta_n^+(k_1+1)/n)|| < \epsilon/4$$

for n sufficiently large. Since $x_F(t)$ is incrementally tracked by $x_n^+(t)$, we have $||x_F(t_0+k/n) - x_n^+(t_0+\beta_n^+ k/n)|| \to 0$ as $n \to \infty$. Therefore by picking n large enough we ensure that $||s^p(x_n^+(t_0+\beta_n^+ k/n), t_0+\beta_n^+ k/n)|| < \epsilon/2$ for $k = 0, \ldots, n$. In particular, using the "digital" controller (4.2) results in a state trajectory $x_n^+(t)$ for (2.1) with the property that, for n sufficiently large, $s^p(x_n^+(t_k), t_k) < 0$ for $k = 0, 1, \ldots, \ell_1 - 1$, $s^p(x_n^+(t_{\ell_1}), t_{\ell_1}) > 0$, and $||s^p(x_n^+(t_{\ell_1}), t_{\ell_1})|| < \epsilon/2$. Thus $u_k = u_n^+$ for $k = 0, \ldots, \ell_1 - 1$ and $u_{\ell_1} = u_n^-$. We can now repeat the above, starting from the initial state $x(t_{\ell_1}) = x_n^+(t_{\ell_1})$. Since $s^p(x_n^+(t_{\ell_1}), t_{\ell_1}) > 0$ we now incrementally track the integral curve of d^- until $s^p(x_n^-(t_{\ell_2}), t_{\ell_2}) < 0$ and $||s^p(x_n^-(t_{\ell_2}), t_{\ell_2})|| < \epsilon/2$ (increasing n if necessary). Because the integral curve $x_F(t)$ is bounded, we can choose n sufficiently large to continue the above switching and ensure that the state trajectory x_n resulting from the controller (4.2) satisfies

$$||s^p(x_n(t_k), t_k)|| < \epsilon/2 \quad \forall k \geq \ell_1.$$

Incremental tracking ensures that x_n is close to x_F at discrete times $\{t_k\}$, but for $t_k < t < t_{k+1}$ we may have $x_n(t)$ far from $x_F(t)$. We now use the fact that $d^{\pm} \in \mathcal{I}^p$, and thus are incrementally tracked preserving $h^{\mathbf{p}}$, to show that s^p is unaffected by these deviations. In particular, on $[t_0, t_f]$ we have $||h^{\mathbf{p}}(x_F(t_0+t)) - h^{\mathbf{p}}(x_n^+(t_0+\beta_n t))|| \to 0$ as $n \to \infty$, by definition of incrementally tracking. This allows us to ensure that $||s^p(x_n(t),t)|| < \epsilon \ \forall t \geq t_0 + \ell_1/n$ for n sufficiently large. Because $\beta \leq 1$ this implies that, for n sufficiently large,

$$||s^p(x_n(t),t)|| < \epsilon \quad \forall t \geq t_f,$$

and $x_n(t)$ is bounded; hence the output y of (2.1) approximately tracks y_d to degree p. □

Let $\mathcal{R}(x_0)$ denote the set of states which can be reached from the initial state $x(t_0) = x_0$. Theorem 4.6 ensures approximate tracking if $x_0 \in Z$, and so it is natural to look for a controller which steers x_0 to the open set Z in finite time. It will often be the case that $\mathcal{R}(x_0) \cap Z \neq \emptyset$. In particular, we need to use the above theorem when the state trajectory "sticks" to the singular submanifold under the naive truncated sliding mode controller. Thus if Z intersects the singular submanifold it is likely reachable from the initial state. Suppose that C is compact, Z is an open subset of M, and $u_0(x,t)$ is a controller for system (2.1) which transfers the state from $x(t_0) = x_0 \in M$ to $x(t_1) = x_1 \in Z \cap C$. Define the hybrid controller as

$$u_d(x,t) = \begin{cases} u_0(x,t), & t \in [t_0, t_1), \\ u_k(x,t), & t \in [t_k, t_{k+1}), \end{cases} \tag{4.3}$$

where u_k is the digital controller (4.2), and $k \geq 1$.

THEOREM 4.7. *Suppose that* A1, A2, A3 *hold, $C \subset M$ is compact, and there exists a controller $u_0(x,t)$ which transfers the state of system* (2.1) *to $Z \cap C$ at time $t_1 \geq t_0$. Then, for n sufficiently large, the hybrid switched controller* (4.3) *achieves the following property for the closed loop system: if $y_d \in \mathcal{Y}_d$, then the output y of* (2.1) *approximately tracks y_d to degree p.*

Proof. For an initial state $x(t_1) = x_1 \in Z \cap C$, Theorem 4.6 implies that, for n_1 sufficiently large, the controller (4.3) achieves approximate tracking of y_d. From the continuity of solutions to $\dot{x} \in F_d(x,t)$ with respect to the initial conditions (cf. [3]), we have approximate tracking of y_d for any initial state in some open neighbourhood U_1 of x_1. Because $Z \cap C$ is compact we can obtain a finite open covering $\cup_{i=1}^{m} U_i$ of $Z \cap C$ by such open sets. Thus the hybrid switched controller (4.3) with $n \geq max\{n_i | i = 1, \ldots, m\}$ results in approximate tracking of y_d. □

Remark 4.8. We note that the hypotheses of Theorem 4.7 are satisfied for affine systems whose singular set $\{gf^{r-1}h(x) = 0\}$ is empty. In this case we use $p = r$, $Z = M$, and $d^{\pm} = f \pm Lg$, and u_0 is not needed. To verify the hypotheses of Theorem 4.7 for a given system model, one could start by using Theorems 3.2 and 3.5 to find vector fields which the state trajectory can incrementally track. If the natural sliding mode controller has a singular submanifold N, check to see if the vector fields which can be incrementally tracked preserving the output map are sufficient for A2 to hold. Then, if A3 holds as well (see Remark 4.5), Theorems 4.6 and 4.7 yield a controller. Example 1.1 is a case in point.

Example 4.9 (*Example* 1.1 *continued*). We have seen that $f, ad_g^2 f \in \mathcal{I}^p$ for $p = 1$, and so it is natural to choose a sliding surface with $p = 1$. We set $s(e^{\mathbf{p}}) = e$, where $e = y - y_d$. Then $p = 1$, $s^1(x,t) = x_1 - y_d(t)$, $s(h^{\mathbf{p}}(x)) = x_1$, and $S_t^1 = E_t^1 = \{x_1 = y_d(t)\}$. Clearly the set S_t^1 is an embedded submanifold (2-dimensional) for each fixed time t, so that A1 holds. Here $gs(h^{\mathbf{p}}) = 0$, but $fs(h^{\mathbf{p}}(x)) = x_3^2 - x_2$ and $(ad_g^2 f)s(h^{\mathbf{p}}(x)) = 2$. To satisfy A2(i) we want $(ad_g^2 f)s(h^{\mathbf{p}}) > 0$ and $fs(h^{\mathbf{p}}) < 0$ on some open set Z, so it is natural to look for a set invariant with respect to $f, ad_g^2 f$ and on which $x_2 \approx q_2 > 0$, $x_3 \approx 0$. For many systems a systematic approach to finding a suitable subset Z may not be possible, but for the example under consideration x_2, x_3 satisfy a linear differential equation. Thus we can find such a set by constructing a Lyapunov function. In particular, let $z_1(x) = x_2 - q_2$, $z_2(x) = x_3$, and $u = -a_0 z_1 - a_1 z_2$ $(a_0, a_1 > 0)$.

Then $\dot{z} = Az$ for

$$A = \begin{bmatrix} 0 & 1 \\ -a_0 & -a_1 \end{bmatrix}.$$

We can find a Lyapunov function $V = z^T Q z$ for $\dot{z} = Az$ by solving Lyapunov equations $A^T Q + QA = -I$ for the positive definite matrix

$$Q = \begin{bmatrix} a & b \\ b & c \end{bmatrix},$$

where $a = (a_1^2 + a_0(a_0+1))/(2a_0a_1)$, $b = 1/2a_0$, $c = (a_0+1)/(2a_0a_1)$. Then for $q_0 > 0$ we define

$$Z(q_0) = \{x \in \mathbb{R}^3 \mid z(x)^T Q z(x) < q_0\} = \{a(x_2 - q_2)^2 + 2b(x_2 - q_2)x_3 + cx_3^2 < q_0\},$$

where $q_0 > 0$. By construction, $Z(q_0)$ is invariant with respect to $f - (a_0 z_1 + a_1 z_2)g = f + \gamma g$, where $\gamma(x) = -a_0(x_2 - q_2) - a_1 x_3$. Since $g \in \mathcal{I}_0^p$ and $f \in \mathcal{I}^p$, we have $d^- = f + \gamma g \in \mathcal{I}^p$ as a consequence of Theorem 3.2. Since, by construction, V is decreasing along the integral curves of d^-, we have $Z(q_0)$ invariant with respect to d^-. Because $Z(q_0)$ puts no restrictions on x_1 it is also invariant with respect to $d^+ = q_1 a d_g^2 f \in \mathcal{I}^p$, where $q_1 > 0$. To verify that A2 holds we first note that $s(h^{\mathbf{p}}(x)) = x_1$; hence $d^- s(h^{\mathbf{p}}(x)) = (f + \gamma g)x_1 = x_3^2 - x_2$ and $d^+ s(h^{\mathbf{p}}(x)) = q_1 a d_g^2 f x_1 = 2q_1 > 0$. Note that by shrinking q_0 we can ensure that in the set $Z(q_0)$ we have x_3 arbitrarily close to 0 and x_2 arbitrarily close to q_2. In particular, given *any* constants $\alpha_1, \alpha_2 \in \mathbb{R}$, $\sigma_1, \sigma_2, \delta > 0$, we can choose q_0, q_1, q_2 such that on the set $Z = Z(q_0)$ we have

$$\begin{array}{lcll} d^- s(h^{\mathbf{p}}) & < & -\delta - \sigma_1 & \text{when } \{s(h^{\mathbf{p}}) \geq \alpha_1\}, \\ d^+ s(h^{\mathbf{p}}) & > & +\delta + \sigma_2 & \text{when } \{s(h^{\mathbf{p}}) \leq \alpha_2\}. \end{array}$$

Thus A2(i) holds and A2(ii) holds automatically as $p = 1$. In light of Remark 4.5, assumption A3 will hold if $Z \cap S_t^p$ is bounded. Here $Z = Z(q)$ is a bounded set by construction, and hence A3 holds. Thus A1, A2, A3 hold and Theorem 4.7 implies that we can approximately track to degree 1 the set of output paths

$$\mathcal{Y}_d = \{y_d \mid \alpha_1 \leq s(y_d^{\mathbf{p}}(t)) \leq \alpha_2,\ -\sigma_1 \leq s(\dot{y}_d^{\mathbf{p}}(t)) \leq \sigma_2 \ \ \forall t \geq t_0\}.$$

The construction of the controller u_0 which moves the state into Z is simplified here because Z is the level set $\{V(z(x)) = q_0\}$ of a Lyapunov function for $\dot{z} = Az$, where $u = \gamma g$. We set $u_0(x,t) = \gamma(x)$. For any $x(t_0)$ there will be $t_1 \geq t_0$ such that $x(t_1) \in Z$. We incrementally track d^- using $u_n^-(x,t) = \gamma(x)$ ($\beta_n^- = 1$) and incrementally track d^+ using the controller from Theorem 3.2(iv) with $k = 2$, namely,

$$u_n^+(x,t) = \begin{cases} -n^{5/2}, & t_k \leq t < t_k + 1/n^2, \\ 0, & t_k + 1/n^2 \leq t < t_k + 2/n^2, \\ n^{5/2}, & t_k + 2/n^2 \leq t < t_k + 3/n^2, \end{cases}$$

where $\beta_n^+ = 3/n$, $\tau_n^- = 1/n$, and $\tau_n^+ = 3/n^2$. If we want $y_d(t) = \sin t \in \mathcal{Y}_d$, we can define Z by choosing $q_0 = 0.5$, $q_1 = 1$, $q_2 = 2$, $a_1 = 40$, $a_2 = 400$. To ensure close tracking we pick $\epsilon = 0.1$. Figure 3 shows a SIMNON simulation using the controller (4.3) with $n = 5$ and $x(0) = (2, 2, 0) \in Z$. The tracking performance is not particularly sensitive to variations in these parameters. Increasing n gives tighter tracking but requires more control effort.

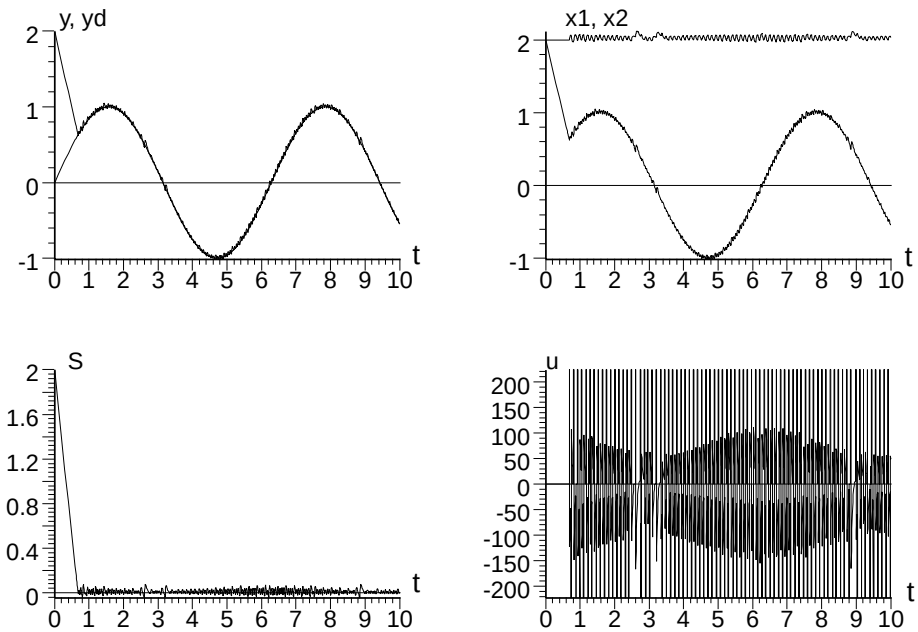

FIG. 3. *Approximate tracking of a* $y_d(t) = \sin t$ *with* $x_0 \in Z$.

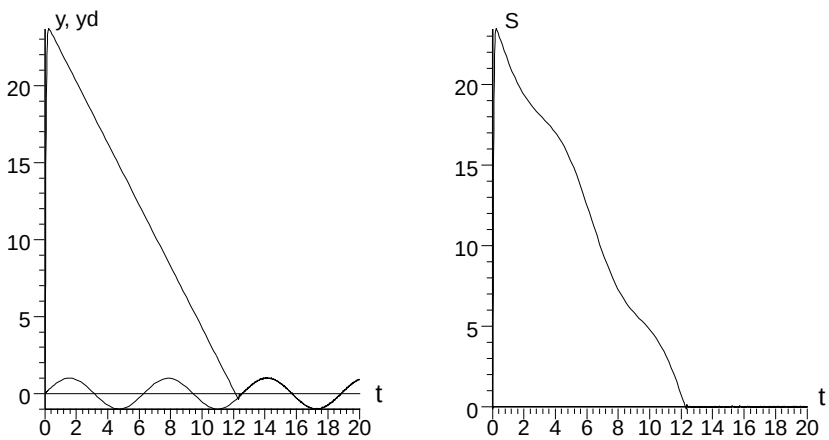

FIG. 4. *Approximate tracking of a* $y_d(t) = \sin t$ *with* $x_0 \notin Z$.

In Figure 4 we show the effect of an initial state which is initially well outside of Z ($x_2(0) = -0.1 < 0$).

We note that in this situation state trajectories resulting from controllers based on relative degree will stick to the singular manifold $N = \{x_3 = 0\}$ and send $s(e^{\mathbf{r}}(t)) \to \infty$. Our approach has the state passing back and forth across N. The initial delay is due to the requirement that the state must enter Z before our switched controller can act to reduce s.

5. Conclusions. There are situations in which it is useful to be able to control the state of a system so that it closely approaches a given curve at discrete times. We have introduced the concept of *incremental tracking* of integral curves, where the state trajectory (with reparametrized time) closely approaches an integral curve at discrete times. These controllers were then applied to sliding mode control, where the state trajectory used to reach the sliding surface is not very critical. Our discontinuous "digital sliding mode controller" achieved approximate tracking in situations where the natural truncated sliding mode controller (and the natural truncated smooth controller based on inversion) fails.

RATE OF CONVERGENCE FOR CONSTRAINED STOCHASTIC APPROXIMATION ALGORITHMS*

ROBERT BUCHE† AND HAROLD J. KUSHNER†

Abstract. There is a large literature on the rate of convergence problem for general unconstrained stochastic approximations. Typically, one centers the iterate θ_n about the limit point $\bar{\theta}$ and then normalizes by dividing by the square root of the step size ϵ_n. Then some type of convergence in distribution or weak convergence of U_n, the centered and normalized iterate, is proved. For example, one proves that the interpolated process formed by the U_n converges weakly to a stationary Gaussian diffusion, and the variance of the stationary measure is taken to be a measure of the rate of convergence. See the references in [A. Benveniste, M. Metivier, and P. Priouret, *Adaptive Algorithms and Stochastic Approximation*, Springer-Verlag, Berlin, New York, 1990; L. Gerencér, *SIAM J. Control Optim.*, 30 (1992), pp. 1200–1227; H. J. Kushner and D. S. Clark, *Stochastic Approximation for Constrained and Unconstrained Systems*, Springer-Verlag, Berlin, New York, 1978; H. J. Kushner and G. Yin, *Stochastic Approximation Algorithms and Applications*, Springer-Verlag, Berlin, New York, 1997; M. T. Wasan, *Stochastic Approximation*, Cambridge University Press, Cambridge, UK, 1969] for algorithms where the step size either goes to zero or is small and constant. Large deviations provide an alternative approach to the rate of convergence problem [P. Dupuis and H. J. Kushner, *SIAM J. Control Optim.*, 23 (1985), pp. 675–696; P. Dupuis and H. J. Kushner, *SIAM J. Control Optim.*, 27 (1989), pp. 1108–1135; P. Dupuis and H. J. Kushner, *Probab. Theory Related Fields*, 75 (1987), pp. 223–244; A. P. Korostelev, *Stochastic Recurrent Processes*, Nauka, Moscow, 1984; H. J. Kushner and G. Yin, *Stochastic Approximation Algorithms and Applications*, Springer-Verlag, Berlin, New York, 1997]. When the iterates of the algorithm are constrained to lie in some bounded set, the limit point is frequently on the boundary. With the exception of the large deviations type [P. Dupuis and H. J. Kushner, *SIAM J. Control Optim.*, 23 (1985), pp. 675–696; P. Dupuis and H. J. Kushner, *Probab. Theory Related Fields*, 75 (1987), pp. 223–244], the rate of convergence literature is essentially confined to the case where the limit point is not on a constraint boundary.

When the limit point is on the boundary of the constraint set the usual steps are hard to carry out. In particular, the stability methods which are used to prove tightness of the normalized iterates cannot be carried over in general, and there is the problem of proving tightness of the normalized process and characterizing the limit process.

This paper develops the necessary techniques and shows that the stationary Gaussian diffusion is replaced by an appropriate stationary reflected linear diffusion, whose variance plays the same role as a measure of the rate of convergence. An application to constrained function minimization under inequality constraints $q^i(x) \leq 0, i \leq p$, is given, where both the objective function and the constraints are observed in the presence of noise. The iteration is on both the basic state variable and a Lagrange multiplier, which is constrained to be nonnegative. If a limit multiplier value for an active constraint is zero, then the classical method for computing the rate cannot be used, but (under appropriate conditions) it is a special case of our results. Rate of convergence results are important because, among other reasons, they immediately yield the advantages of iterate averaging methods, as noted in [H. J. Kushner and G. Yin, *Stochastic Approximation Algorithms and Applications*, Springer-Verlag, Berlin, New York, 1997].

1. Introduction. There is an extensive theory concerning the rate of convergence of the SA (stochastic approximation)-type algorithms of the forms

$$\theta_{n+1}^\epsilon = \theta_n^\epsilon + \epsilon Y_n^\epsilon, \text{ constant step size,} \tag{1.1}$$

and

$$\theta_{n+1} = \theta_n + \epsilon_n Y_n, \text{ decreasing step size, } \epsilon_n \to 0. \tag{1.2}$$

Here the adjustable parameter or state θ is in $\mathbb{R}^r$, Euclidean r-space. See [21] for a comprehensive development of rate results under both probability one and weak convergence assumptions on the $\{\theta_n^\epsilon\}$ or $\{\theta_n\}$. The theory also covers correlated and state dependent noise. See also [2, 14]. Let us write

$$\begin{aligned} Y_n^\epsilon &= g(\theta_n^\epsilon) + \xi_n^\epsilon, \\ Y_n &= g(\theta_n) + \xi_n, \end{aligned} \tag{1.3}$$

where $g(\cdot)$ plays the role of a "mean" or "centering" function and ξ_n^ϵ, ξ_n are the so-called "noises" on which we will make further assumptions below.

In proving rate of convergence results, one usually starts by assuming some appropriate type of convergence of θ_n or θ_n^ϵ to a limit point $\bar\theta$. For θ_n, this convergence might be in either the probability one or in the weak convergence senses, and for θ_n^ϵ it is in the weak convergence sense. Define the matrix $g_\theta(\cdot)$, whose ith *row* is the gradient of the ith component of the "centering" vector $g(\cdot)$ with respect to θ. Define $A = g_\theta(\bar\theta)$. The usual procedure is to work with the normalized iterates defined by $U_n^\epsilon = (\theta_n^\epsilon - \bar\theta)/\sqrt{\epsilon}$ and $U_n = (\theta_n - \bar\theta)/\sqrt{\epsilon_n}$, resp. Define the interpolated processes $U^\epsilon(\cdot)$ by $U^\epsilon(t) = U_n^\epsilon$ for $t \in [n\epsilon, n\epsilon + \epsilon)$. For the decreasing step case, define $t_n = \sum_{i=0}^{n-1} \epsilon_i$. Then, define $U^n(\cdot)$ by $U^n(0) = U_n$ and, for $t > 0$, $U^n(t) = U_{n+i}$ for $t \in [t_{n+i} - t_n, t_{n+i+1} - t_n)$. Let $m(t)$ denote the unique value of n such that $t_n \le t < t_{n+1}$.

One starts the proof of the "rate" result for the unconstrained case by proving tightness of the set of interest (under appropriate conditions, and where n_ϵ might have to go to infinity as $\epsilon \to 0$)

$$\{U_n^\epsilon; \epsilon > 0, n \ge n_\epsilon\} \tag{1.4a}$$

or of

$$\{U_n, n < \infty\}. \tag{1.4b}$$

Given this tightness, one continues the proof by proving the weak convergence of either $U^\epsilon(t_\epsilon + \cdot)$ (as $\epsilon \to 0$, with t_ϵ going to infinity fast enough) or of $U^n(\cdot)$ (as $n \to \infty$) to a stationary diffusion process of the type

$$dU = AU dt + \sigma dw \tag{1.5a}$$

or of the type

$$dU = \left[A + \frac{I}{2}\right] U dt + \sigma dw. \tag{1.5b}$$

Here σ is a constant matrix, and $w(\cdot)$ is a standard vector-valued Wiener process. Equation (1.5a) is the goal under (2.5a) or if the step size is ϵ. Equation (1.5b) is

the goal under (2.5b). In (1.5a) it is assumed that A is Hurwitz, and in (1.5b) that $A + I/2$ is Hurwitz. The stationary covariance Σ_U of $U(\cdot)$ is taken to be the desired measure of the rate of convergence. Note that the result implies that U_n converges in distribution to a normally distributed random variable with mean zero and covariance Σ_U, and similarly for U_n^ϵ if $n \to \infty$ fast enough as $\epsilon \to 0$. If A (resp., $A + I/2$) is Hurwitz, then the theory is well known under quite general conditions.

The constrained problem. The SA algorithm is often constrained by some mechanism that keeps the iterates in some desired set H, by a projection or other means. The convergence of the θ_n or θ_n^ϵ for constrained versions of the algorithms (1.1) and (1.2) is also well treated in the literature. Convergence with probability one for constrained forms of (1.2) is treated in [21, Chapter 5] under a martingale noise condition. In [21, Chapter 6] more general noise conditions are used. The essential condition is that there be a point $\bar{\theta}$ which is asymptotically stable for the constrained ODE, analogously to what is required for the unconstrained problem. This reference also contains more general results concerning convergence to local minima or chain recurrent points. One can then treat the rate of convergence to such points. A quite general result for probability one convergence for the constrained problem is in [10, Section 8]. That section verifies a basic condition (Assumption 2.2) of [10] for constrained algorithms under a variety of conditions on the noise (those in [10, Section 5], which cover a large proportion of those commonly used). Then under the above-mentioned stability condition, the probability one convergence theorem [10, Theorem 3.1] holds. The classical reference [18, Chapter 5] also contains probability one convergence results for the constrained problem. Additionally, [21, 18] contain extensive results concerning weak convergence for the constrained forms of both (1.1) and (1.2), under very general conditions.

There is virtually nothing available concerning the rate of convergence for the constrained problem. Reference [21] did deal with this rate problem but where the limit point $\bar{\theta}$ was interior to the constraint set H. In this case, the results are the same as for the unconstrained case. When $\bar{\theta}$ is on the boundary of H, then additional problems arise. In this paper, we will give a fairly complete treatment for a large class of systems, when $\bar{\theta} \in \partial H$. We write the ith component of a vector x as x^i. For an $\mathbb{R}^r$-valued function $g(\cdot) = \{g^i(\cdot), i \le r\}$ on $\mathbb{R}^r$, we write $g_\theta(\cdot)$ as the matrix whose ith row is the gradient of $g^i(\cdot)$ with respect to θ.

Unless noted otherwise, we will suppose that the physical constraint set is

$$H = \left\{\theta : 0 \le \theta^i \le b^i, \text{ some subset of components } i\right\}, \tag{1.6}$$

where $0 < b^i \le \infty$. Thus, some components might not be constrained. The constraint is enforced by using an orthogonal projection onto H if the iterate attempts to leave H [21]; i.e., the iterate is returned to the closest point in H. To simplify notation, it will always be assumed that if $\bar{\theta}^i$ is at the end of its allowed interval, then $\bar{\theta}^i = 0$.

By simple affine transformations, coordinate by coordinate, the constraint set includes the cases where the ith components $\theta_n^{i,\epsilon}$ and θ_n^i of the iterates are constrained to lie in some finite interval $[a^i, b^i]$. Keep in mind that, under Assumption 2.4 (below) or its weak convergence counterpart, all that matters is *the shape of the constraint set in a small neighborhood of the limit point* $\bar{\theta}$. This local description will be referred to as L. For example, in the two dimensional case where the physical constraint set is the bounded box $[a_1, b_1] \times [a_2, b_2]$ and $\bar{\theta}^1 = a_1, a_2 < \bar{\theta}^2 < b_2$, the local description about $\bar{\theta}$, after an affine change in each coordinate, is the half plane $L = \{x : x^1 \ge 0, x^2 \text{ unconstrained}\}$.

The constrained form of the algorithms can be written as

$$\theta_{n+1}^{\epsilon} = \theta_n^{\epsilon} + \epsilon Y_n^{\epsilon} + \epsilon Z_n^{\epsilon}, \tag{1.7}$$

$$\theta_{n+1} = \theta_n + \epsilon_n Y_n + \epsilon_n Z_n, \tag{1.8}$$

where ϵZ_n^{ϵ} and $\epsilon_n Z_n$ are the correction terms due to the projection back onto H, if any.

The methods and results follow the general outline used for the case where boundaries are not a factor and (1.5a) and (1.5b) are replaced by a stationary reflected linear diffusion process. There are additional complications in the tightness proofs and in characterizing the mean drift at the limit point. The basic issues are well illustrated by two dimensional problems, with martingale difference noise. Thus for maximal clarity we start with those cases and discuss the extensions afterwards. For appropriate definitions of the matrices A and $\Sigma = \sigma\sigma'$, $\sigma = \{\sigma_{ij}; i, j\}$, the weak sense limit of the $U^n(\cdot)$ will be a stationary solution to a Skorohod problem (reflected diffusion process) of either the form

$$dU = AUdt + \sigma dw + dz, \text{ when } \epsilon_n = \epsilon \text{ or } \epsilon_n \to 0, \text{ under (2.5a)} \tag{1.9a}$$

or of the form

$$dU = \left[A + \frac{I}{2}\right] Udt + \sigma dw + dz, \text{ when } \epsilon_n \to 0, \text{ under (2.5b)}, \tag{1.9b}$$

where $z(\cdot)$ is the reflection term which keeps the values in the correct set. Given $A, \sigma, w(\cdot), U(0)$, and the reflection directions (orthogonal to the boundary faces), there are unique strong sense and adapted solutions $U(\cdot), z(\cdot)$ to (1.9a) and (1.9b), and they are continuous. The process $z^i(\cdot)$ can increase only at t where $U^i(t) = 0$, and it is the minimum such process which forces $U^i(t) \geq 0$ [7]. The precise definition of the Skorohod problem is given below (see (6.5)). The exact forms of the limit equation will be given in section 5 for the various cases.

As is usual in rate of convergence studies, we make an assumption about convergence. In order not to overencumber the development, unless otherwise noted we will work with the form (1.8) with probability one convergence assumed. Much effort was spent in [21] on the weak convergence case as well. The theory of convergence for this case is usually much simpler than the probability one case, particularly when the noise structure is complicated, and it contains virtually the same information (see [21]). Additionally, it is the only type of convergence that can be used with (1.7), and even with (1.8), if the step sizes go to zero slowly enough, or if the noise structure is complex. With probability one convergence, by starting at a large enough time, we can suppose that the iterate is always in an arbitrarily small neighborhood of the limit point, and this facilitates the proofs of the rate results. This is not necessarily true under weak convergence. However, in [21], it is shown that (under weak convergence and with a probability arbitrarily close to unity) the iterate remains in an arbitrarily small neighborhood of the limit point for a long enough time before possibly leaving so that the probability one "localization" technique can still be used. Such a method will work here as well but is omitted due to lack of space and because the adaptation is similar. Details will be found in [5]. Thus the entire theory holds for the "small constant" step size algorithm (1.7).

Section 6 deals with various results in ergodic theory that are needed to complete the proof that the weak sense limit processes are stationary. For simplicity throughout

the paper, the main development assumes martingale difference noise. Section 7 shows the changes that are needed when more general noise is used. An application to a Lagrangian algorithm is given in section 8. Section 9 contains a few comments concerning generalizing the constraint set. Under suitable conditions the basic ideas carry over, but verification of some conditions becomes more complicated. Since one cannot readily compute the stationary covariance matrix for reflected diffusions, even of the simple type which occurs here, combined analysis/simulation was used to get some feeling for the effect of the constraint on the asymptotic variances. A few comments appear in section 10.

The proof of the tightness of $\{U_n\}$ is one of the crucial steps of the development. In general, this requires a special Liapunov function which accounts for the constraint or reflection. Its construction motivated by [11] and the necessary changes in their proof to get the form that we need are in the appendix.

2. Two dimensional problems: Martingale difference noise; assumptions. Let E_n denote the expectation conditioned on $\{\theta_0, Y_i, i < n\}$.

ASSUMPTION 2.1. *There is $\bar{\theta}$ such that $\theta_n \to \bar{\theta}$ with probability one.*

ASSUMPTION 2.2. *There is an $\mathbb{R}^r$-valued "centering" function $g(\cdot)$ on $\mathbb{R}^r$ whose partial derivatives up to second order are continuous in some neighborhood of $\bar{\theta}$, and, for small $\rho > 0$ and some positive definite symmetric matrix $\Sigma = \{\Sigma_{ij}; i, j\}$,* (1.3) *holds and*

$$E_n \xi_n = 0, \tag{2.1}$$

$$E_n \left[\xi_n \xi_n' - \Sigma\right] I_{\{|\theta_n - \bar{\theta}| \le \rho\}} \to 0 \tag{2.2}$$

in the mean as $n \to \infty$.

Write $\Sigma = \sigma\sigma'$, where σ is a square root of Σ.

ASSUMPTION 2.3. *Suppose that, for each small $\rho > 0$,*

$$\left\{|\xi_n|^2 I_{\{|\theta_n - \bar{\theta}| < \rho\}}, n < \infty\right\} \text{ is uniformly integrable,} \tag{2.3}$$

$$\sup_n E_n |\xi_n|^2 I_{\{|\theta_n - \bar{\theta}| < \rho\}} < \infty \text{ with probability 1.} \tag{2.4}$$

ASSUMPTION 2.4. *$\epsilon_n > 0, \epsilon_n \to 0$, $\sum_n \epsilon_n = \infty$, and either*

$$\sqrt{\frac{\epsilon_n}{\epsilon_{n+1}}} = 1 + o(\epsilon_n), \tag{2.5a}$$

or

$$\epsilon_n = 1/n. \tag{2.5b}$$

Even for the martingale difference noise case, [21] uses weaker conditions (second order asymptotic stationarity not required) on the noise for the case where $\bar{\theta} \in H^0$, the interior of H, and those same conditions will work here. Essentially, one needs only that (5.5) converges weakly to a Wiener process. Comments on the correlated noise case are in section 7. Expand

$$g(\theta_n) = g(\bar{\theta}) + g_\theta(\bar{\theta})(\theta_n - \bar{\theta}) + \mu_n, \tag{2.6}$$

where

$$\mu_n = \int_0^1 \left[g_\theta(\bar\theta + s(\theta_n - \bar\theta)) - g_\theta(\bar\theta)\right](\theta_n - \bar\theta)ds.$$

In the classical unconstrained case where $\bar\theta \in H^0$, we must have $g(\bar\theta) = 0$. Then, under (2.5a) and appropriate conditions on the noise, the method in [18, 21] shows that $U^n(\cdot)$ converges weakly to the stationary Gauss–Markov process satisfying (1.5a) and then computes the stationary variance [21]. Under (2.5b), and with $A + I/2$ assumed Hurwitz, the limit is the stationary solution to (1.5b).

It is not necessarily the case that $g(\bar\theta) = 0$ when $\bar\theta \in \partial H$, the boundary of H. Of course, in any case one must have $g^i(\bar\theta) \le 0, i \le r$, since otherwise the limit point cannot be on the boundary. If $g^i(\bar\theta) < 0$, we say either that there is a *forcing term to the boundary* or that *coordinate i has a forcing term to the boundary.* There are several natural divisions of the possibilities, depending on whether there are boundary forcing terms and whether $\bar\theta^i > 0$ for any $i \le r$.

To gain insight into the various issues, in the remainder of this section and in the next, we confine ourselves to the two dimensional problem. In all cases, $b^i > 0$. The general dimensional problem is dealt with in subsequent sections. The first case to be treated is for H having either of the forms $H = \{\theta : b^i \ge \theta^i \ge 0, i \le 2\}$ or $H = \{\theta : b_1 \ge \theta^1 \ge 0\}$ and where

$$g^1(\bar\theta) < 0,\ g^2(\bar\theta) = 0 \text{ and } \bar\theta^1 = 0,\ b_2 > \bar\theta^2 > 0. \tag{2.7}$$

Here $\bar\theta$ is on an open face of H, coordinate 1 has a forcing term to the boundary, and the limit for coordinate 2 is interior to its constraint set. The second case is for $H = \{\theta : b^i \ge \theta^i \ge 0, i \le 2\}$ and

$$g^1(\bar\theta) < 0,\ g^2(\bar\theta) = 0 \text{ and } \bar\theta^1 = \bar\theta^2 = 0. \tag{2.8}$$

Here $\bar\theta$ is in a corner of H, so that both coordinates are on the ends of their constraint sets, and coordinate 1 has a forcing term to the boundary. In the third and fourth cases, defined by (2.9) and (2.10), respectively, there are no forcing terms to the boundary:

$$g(\bar\theta) = 0 \text{ and } \bar\theta^1 = 0,\ \bar\theta^2 > 0, H = \{\theta : b^i \ge \theta^i \ge 0, i \le 2\}, \text{ or } \{\theta : b^1 \ge \theta^1 \ge 0\}. \tag{2.9}$$

$$g(\bar\theta) = 0 \text{ and } \bar\theta = 0, H = \{\theta : \theta^i \ge 0, i \le 2\}. \tag{2.10}$$

The results for the remaining possibilities can be read off from the results for these.

The crucial problem in the proofs of rate of convergence is the proof of tightness (equivalently, boundedness in probability) of the set (1.4b). This will be dealt with in section 3 for the above cases and in section 4 for the general case. Owing to the fact that $\bar\theta \in \partial H$ for all cases, the traditional Liapunov function cannot always be used for the proof. Then, after showing the tightness of (1.4b), section 5 treats the weak convergence of $U^n(\cdot)$ to a solution of (1.9) and characterizes the limit reflection term. The stationarity of the limit is easy to show when $\bar\theta \in H^0$, since the initial time for (1.5) is arbitrary in that we can work with $U^n(-T + \cdot)$ for arbitrary large positive T and use the linearity of (1.5). This is harder for (1.9) and is dealt with in section 6.

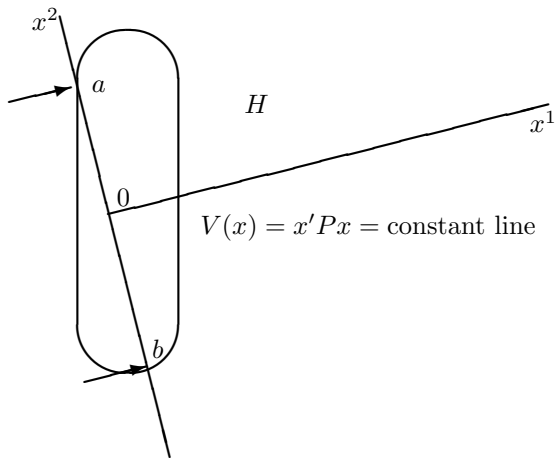

FIG. 3.1. *Projection to b increases* $V(\cdot)$.

3. Tightness of $\{U_n, n < \infty\}$. Part I. In this section, we work with a two dimensional problem, where the Liapunov function $V(U) = |U|^2/2$ can be used. The same methods work in any dimension where this Liapunov function works. This would be the case if the centering function $g(\cdot)$ is the negative of the gradient of a smooth function $f(\cdot)$, which we are minimizing via the SA, and the Hessian of $f(\cdot)$ at $\bar{\theta}$ is positive definite. The problem with a quadratic form Liapunov function that is not of the type $V(U) = |U|^2/2$ is that the reflection or projection onto H will increase its value in part of the state space. This is illustrated in Figure 3.1. Reflection to point b increases $V(\theta)$. The simpler cases of this section more clearly illustrate the role of the forcing term to the boundary. When the Liapunov function $|U|^2/2$ cannot be used, we need to use a Liapunov function which accounts for the boundary behavior (i.e., the reflection or projection). This is much more complicated and is the subject of the next section.

3.1. Cases (2.7), (2.8). Let

$$cg^1(\bar{\theta}) < 0,\ g^2(\bar{\theta}) = 0,\ \bar{\theta}^1 = 0,\ b_2 > \bar{\theta}^2 > 0, \tag{3.1}$$

$$g^2_{\theta^2}(\bar{\theta}) < 0 \text{ under (2.5a)}, \text{ and } g^2_{\theta^2}(\bar{\theta}) < -1/2 \text{ under (2.5b)}.$$

THEOREM 3.1. *Assume that Assumptions* 2.1–2.4 *and* (3.1) *hold. Then* $\{U_n, n < \infty\}$ *is tight. The tightness also holds for the case* (2.8).

The localization method. The proof uses the *localization method* [21], which is defined as follows, and will be used frequently in the subsequent analysis. Since $\theta_n \to \bar{\theta}$ with probability one, for any $\delta > 0, \rho > 0$,

$$P\left\{\sup_{m \geq n} |\theta_m - \bar{\theta}| \geq \rho\right\} \leq \delta$$

for large n. Thus, for the purposes of proving tightness and characterizing the limits of $U^n(\cdot)$ (which involves only the "tail" of the sequence $\{\theta_n\}$), without loss of generality we can modify the process on a set of arbitrarily small measure and reset the time origin so that we can suppose that

$$|\theta_n - \bar{\theta}| \leq \rho \quad \text{for all } n$$

for any desired $\rho > 0$. The value of ρ will usually be chosen small enough so that errors due to linearization are dominated by the linear terms.

Proof. The development will be for the case (2.5a). The proof under (2.5b) differs only in the following expansion: Under (2.5a), $\sqrt{\epsilon_n}/\sqrt{\epsilon_{n+1}} = 1 + o(\epsilon_n)$. Under (2.5b), the ratio equals $1 + \epsilon_n/2 + o(\epsilon_n)$.

The case (2.7). The proof for case (2.7) is essentially classical and uses the Liapunov function $V(U) = U'U/2$. Since $\bar{\theta}^2 > 0$, by the localization argument, we can suppose that $Z_n^2 = 0$. By the hypotheses, $\theta_n^1 - \bar{\theta}^1 \geq 0,\ U_n^1 \geq 0$. Define

$$\tilde{U}_{n+1} = \frac{\sqrt{\epsilon_n}}{\sqrt{\epsilon_{n+1}}} \left[U_n + \sqrt{\epsilon_n} Y_n\right].$$

Then, by centering (1.8) at $\bar{\theta}$ and dividing each side by $\sqrt{\epsilon_{n+1}}$, we can write

$$U_{n+1} = \tilde{U}_{n+1} + \frac{\sqrt{\epsilon_n}}{\sqrt{\epsilon_{n+1}}} \sqrt{\epsilon_n} Z_n. \tag{3.2}$$

Note that $\tilde{U}_{n+1}$ is the normalized value before projection back onto H (or is U_{n+1} if no projection is needed).

Define $\delta_n = \theta_n - \bar{\theta}$ and expand (via a truncated Taylor series)

$$g(\bar{\theta} + \delta_n) - g(\bar{\theta}) = \begin{pmatrix} g_{\theta^1}^1(\bar{\theta})\delta_n^1 + g_{\theta^2}^1(\bar{\theta})\delta_n^2 \\ [g_\theta^2(\bar{\theta})]'\delta_n \end{pmatrix} + y_n\delta_n = g_\theta(\bar{\theta})\delta_n + y_n\delta_n, \tag{3.3}$$

where

$$y_n\delta_n = \int_0^1 \left[g_\theta(\bar{\theta} + s\delta_n) - g_\theta(\bar{\theta})\right] \delta_n ds.$$

Using the above expansion and (2.5a), write

$$\tilde{U}_{n+1} = U_n + \sqrt{\epsilon_n} g(\bar{\theta}) + \epsilon_n \bar{A} U_n + \epsilon_n y_n U_n + \sqrt{\epsilon_n}\xi_n + o(\epsilon_n)\left[g(\theta_n) + \xi_n + U_n\right], \tag{3.4}$$

where $\bar{A} = g_\theta(\bar{\theta})$. By the localization hypothesis and the continuity of $g(\cdot)$ at $\bar{\theta}$, without loss of generality we can suppose that $|\epsilon_n y_n U_n| + o(\epsilon_n)|U_n| \leq c_1\epsilon_n|U_n|$, where c_1 is as small as desired, and that the $g(\theta_n)$ are bounded. The $o(\epsilon_n)$ in (3.4) is due to the expansion $\epsilon_n/\sqrt{\epsilon_{n+1}} = \sqrt{\epsilon_n} + o(\epsilon_n)$, under (2.5a).

Using the localization argument again, and Assumption 2.3, yields

$$E_n|\tilde{U}_{n+1}|^2/2 - |U_n|^2/2 = \sqrt{\epsilon_n} U_n^1 g^1(\bar{\theta}) + \epsilon_n U_n' \left[g_\theta(\bar{\theta}) U_n\right] + o(\epsilon_n)\left|U_n\right|^2 + O(\epsilon_n). \tag{3.5}$$

Since the projection onto H, if any, does not increase the norm $|u|$ defined by the Liapunov function,

$$E_n\left|U_{n+1}\right|^2/2 - \left|U_n\right|^2/2 \leq \text{ right-hand side of (3.5)}. \tag{3.6}$$

By the localization argument, without loss of generality, for any $K < \infty$ we can suppose that

$$\sqrt{\epsilon_n} U_n^1 g^1(\bar{\theta}) \leq -\epsilon_n K [U_n^1]^2. \tag{3.7}$$

The second term on the right-hand side of (3.5) is

$$\epsilon_n \left[[U_n^1]^2 g_{\theta^1}^1(\bar{\theta}) + U_n^1 U_n^2 \left[g_{\theta^1}^2(\bar{\theta}) + g_{\theta^2}^1(\bar{\theta})\right] + [U_n^2]^2 g_{\theta^2}^2(\bar{\theta})\right]. \tag{3.8}$$

The first term of (3.8) is dominated by $\epsilon_n K[U_n^1]^2/8$ (see (3.7)) since K can be supposed to be arbitrarily large. The middle term of (3.8) is dominated in absolute value by $|g^2_{\theta^1}(\bar\theta) + g^1_{\theta^2}(\bar\theta)| = K_1$ times

$$[U_n^1]^2/c + c[U_n^2]^2$$

for any $c > 0$. Choose c small, but so that $K_1/c < K/8$. Write $\gamma = -g^2_{\theta^2}(\bar\theta) > 0$. Then, summarizing, we have

$$E_n\left|U_{n+1}\right|^2/2 - \left|U_n\right|^2/2 \le -\epsilon_n K|U_n^1|^2/2 - \epsilon_n(\gamma-\delta)|U_n^2|^2 + O(\epsilon_n), \tag{3.9}$$

where K is as large and δ is as small as desired. Equation (3.9) implies that, under the localization method, $\sup_n E|U_n|^2 < \infty$, which yields the tightness (see [21, Chapter 10]).

The case (2.8). The main difference between the treatment of (2.7) and (2.8) is that now we can no longer assume that $Z_n^2 = 0$, since $\bar\theta^2 = 0$. However, the projection still does not increase the norm $|u|$ defined by the Liapunov function, so the analysis for (2.7) carries over with no change. □

Note that $g_1(\bar\theta) < 0$ created a "force" pushing U_n^1 to zero (hence the appellation "forcing term to the boundary"). This simplified the analysis, since it dominated the interactions between U_n^1 and U_n^2.

3.2. A simple form of the cases (2.9) and (2.10).

THEOREM 3.2. *Assume that Assumptions* 2.1–2.4 *hold. Let* $A = g_\theta(\bar\theta)$ *be Hurwitz, and suppose that* $A + I/2$ *is Hurwitz, under* (2.5b). *Let* $V(x) = |x|^2$ *be a Liapunov function for the ODE* $\dot x = Ax$, *in that* $A + A'$ *is negative definite. Then* $\{U_n, n < \infty\}$ *is tight for the cases of* (2.9) *and* (2.10).

Comment on the proof. Under the localization method, the right-hand side of (3.5) can be written as

$$\epsilon_n\left[A + A'\right]U_n/2 + o(\epsilon_n)|U_n|^2 + O(\epsilon_n).$$

Since the projection does not increase the norm defined by the Liapunov function, a standard argument of the type used for the unconstrained case [21, Chapter 10] shows the tightness of $\{U_n, n < \infty\}$. □

A comment on the general case of (2.9) or (2.10). Suppose that $A + A'$ is not negative definite. Then, given any positive definite and symmetric C, there is a positive definite symmetric P such that $A'P + PA = -C$. Thus $x'Px$ is a Liapunov function for the ODE $\dot x = Ax$ and could be used to get tightness if $\bar\theta \in H^0$ for the classical unconstrained case. However, for the constrained case, under the norm defined by $x'Px$ (unless P is diagonal), some of the possible projections will not be norm reducing, in the sense that we will not always have $U'_{n+1}PU_{n+1} \le \tilde U'_{n+1}P\tilde U_{n+1}$.[1] See Figure 3.1.

Thus $U'PU$ cannot be used as a Liapunov function for the general constrained problem. When $|U|^2/2$ fails, we need to construct a Liapunov function which takes the projection (equivalently, the boundary behavior) into account. This is another major distinction between the constrained and unconstrained cases. The construction of the needed Liapunov function is given in the appendix and is based on that of [11]. The result is stated and used in the next section. This same Liapunov function will serve as the basis of the stability argument for the more general correlated noise case.

[1] As noted earlier, if $g(\cdot)$ is the negative of the gradient of a smooth function $f(\cdot)$, and the Hessian of $f(\cdot)$ is positive definite at $\bar\theta$, then $|U|^2/2$ can be used.

4. A general Liapunov function. Tightness, part II. *A high dimensional extension of the cases of section* 3. There is one important extension of the results of section 3 to an arbitrary number of dimensions. It is convenient to partition the coordinates to separate out those which have forcing terms to the boundary, i.e., those for which $g^i(\bar{\theta}) < 0$. Thus, suppose that $g^i(\bar{\theta}) = 0, i \leq k$, $g^i(\bar{\theta}) < 0, i = k+1, \ldots, r$. Let $g_a(\cdot), \bar{\theta}_a, U_{a,n}, U_a, \theta_{a,n}$, etc., denote the vectors composed of the first k components. Let $g_b(\cdot)$, etc., denote the vectors composed of the last $r-k$ components. Of course, we could have $k = r$.

ASSUMPTION 4.1. *Define A to be the $k \times k$ matrix whose ith row is the gradient of $g^i(\cdot)$ with respect to θ_a at $\theta = \bar{\theta}$ for $i \leq k$. Suppose that A is Hurwitz under* (2.5a) *and $A + I/2$ is Hurwitz under* (2.5b). *Finally, suppose that $\bar{\theta}^i > 0, i \leq k$, and $\bar{\theta}^i = 0$ for the other coordinates. Let H be the set where $\theta^i \in [0, b^i]$, $i = k+1, \ldots, r$, and either the other coordinates are unconstrained or else $\bar{\theta}^i$ lies in the interior of $[0, b^i]$.*

THEOREM 4.1. *Assume that Assumptions* 2.1–2.4 *and Assumption* 4.1 *hold. Then $\{U_n, n < \infty\}$ is tight.*

Proof. Assumption 4.1 says that the only components of $\bar{\theta}$ which lie on the boundary are those associated with forcing terms to the boundary. In this case, using the localization argument, we can suppose that $\theta_n^i, i > k$, are always within their constraints, hence never projected.

For some positive definite symmetric matrix P, let $\theta_a' P \theta_a$ be a Liapunov function for $\dot{\theta}_a = A\theta_a$, with $PA + A'P = -C$ (or for $\dot{\theta}_a = (A + I/2)\theta_a$, according to the case), where C is positive definite and symmetric. Now with the Liapunov function

$$V(U) = |U_b|^2/2 + U_a{}'PU_a/2,$$

we follow the analysis of Theorem 3.1 to get the desired result. Actually the method is that used in [21], with the addition of the method of Theorem 3.1 to exploit the negativity of the $g^i(\bar{\theta})$ for the i associated with forcing terms to the boundary. □

The general case. We now turn to the general case. First, we state a result (Theorem 4.2) concerning the existence of a Liapunov function for a deterministic Skorohod problem. The construction and proof are based on [11] and are given in the appendix. The state space here is assumed to satisfy the following condition. The integer k is as in Assumption 4.1. As noted in section 1, the set L in Assumption 4.2 is supposed to represent the "local structure" of H about the point $\bar{\theta}$ for those components that do not have forcing terms to the boundary.

ASSUMPTION 4.2. *There is an integer $\nu \leq k$ such that*

$$L = \{x : x^i \geq 0, i \leq \nu\} \subset \mathbb{R}^k.$$

Thus the first ν coordinates are constrained, and the last $k-\nu$ are not. Let ∂L_i denote the faces of L, and n_i the interior normal to ∂L_i. Interior to ∂L_i, the reflection direction is denoted by the unit vector d_i, and $\langle d_i, n_i \rangle > 0$ for each i. The reflection directions on the intersections of the ∂L_i are arbitrary vectors in the convex hull of the directions on the adjoining faces. At each edge and corner, there is a convex combination of the directions on the adjoining faces that points strictly interior to L.

The conditions are more general than we need for our original SA problem, where the reflection directions are orthogonal to the boundary faces, but are useful for the extension in which the reflections are oblique to the boundary faces. In any case, it is the form set up in [11]. For $x \in \mathbb{R}^k$, let $\text{In}(x)$ denote the indices $i \leq \nu$ such that $x^i \leq 0$. For an index set I, let $\text{cone}\{d_i, i \in I\}$ denote the closed infinite cone generated by the linear combinations (with nonnegative coefficients) of the vectors $d_i, i \in I$. Under the

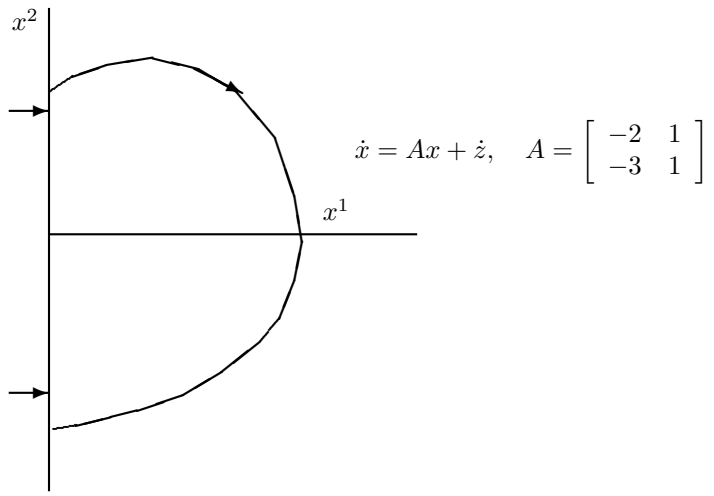

FIG. 4.1. *Flow for Hurwitz A, but nonconvergence to the origin.*

conditions on the reflection directions in Assumption 4.3, there are unique continuous solutions $(x(\cdot), z(\cdot))$ to (4.1a) and (4.1b) for each initial condition [7].

ASSUMPTION 4.3. *Consider the deterministic Skorohod problem for $x \in \mathbb{R}^k$:*

$$dx = Axdt + dz,\ x(t) \in L,\ \textit{under}\ (2.5a), \tag{4.1a}$$

$$dx = \left[A + \frac{I}{2}\right] xdt + dz,\ x(t) \in L,\ \textit{under}\ (2.5b), \tag{4.1b}$$

where $z(\cdot)$ is the reflection term, which can change only when $x(t) \in \partial L$. For almost all t, $\dot{z}(t)$ takes values in the convex cone cone$\{d_i, i \in In(x(t))\}$. For each initial condition $x(0) \in L$, the corresponding solution $x(\cdot)$ converges to zero as $t \to \infty$.

Note on Assumption 4.3 *and the convergence of the SA algorithm.* The key part of the assumption is the convergence of $x(\cdot)$ to zero. This is not necessarily guaranteed (for (4.1a)) even if A is Hurwitz, L an orthant, and the reflection directions normal to the faces. Refer to Figure 4.1 for an illustration of nonconvergence with Hurwitz A. Figure 4.2 illustrates a convergent case.

The hypothesis of convergence Assumption 2.1 would not hold under the situation in Figure 4.1, where A corresponds to the coordinates without forcing terms to the boundary, but it would hold for the case of Figure 4.2. A crucial difference between the unconstrained and constrained cases is that stability of the linearization of the averaged dynamics does not necessarily imply even local convergence of the algorithm.

The proof of the next theorem is in the appendix. For $\epsilon > 0$, let $N_\epsilon(B)$ denote the ϵ-neighborhood of the set $B \in \mathbb{R}^k$.

THEOREM 4.2. *Assume that Assumptions* 4.2 *and* 4.3 *hold. Then there exists a real-valued function $V(\cdot)$ on $\mathbb{R}^k - \{0\}$ with the following properties. It is continuous, together with its partial derivatives up to second order. There is a (twice continuously differentiable) surface ∂S such that any ray from the origin crosses ∂S only once and for a scalar $\alpha > 0$ and $x \in \partial S$, $V(\alpha x) = \alpha V(x)$.*[2] *Thus, the second partial derivatives*

[2]Thus the gradient is the same at all points on any ray from the origin.

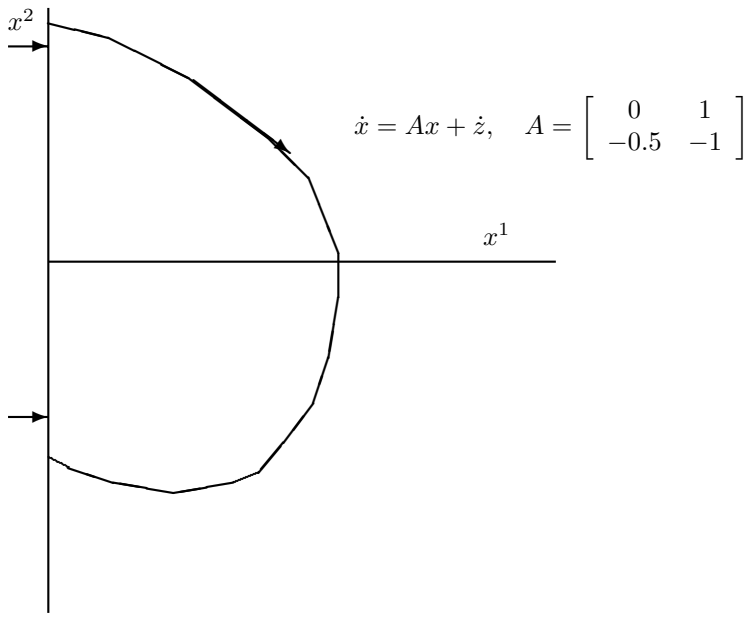

FIG. 4.2. *Flow for Hurwitz A, and convergence to the origin.*

are of the order of $1/|x|$ *as* $|x| \to \infty$ *and*

$$V_v(v)\Big|_{v=\alpha x} = V_x(x).$$

Also, for some real c_i, d_i

$$c_1|x| + c_2 \geq V(x) \geq d_1|x|.$$

There are $c > 0$ *and* $\epsilon > 0$ *such that, for* $x \in \mathbb{R}^k - N_\epsilon(0)$, $V'_x(x)Ax \leq -c|x|$. *For* $x \in \mathbb{R}^k - L - N_\epsilon(0)$, $V'_x(x)d_i \leq -1, i \in In(x)$. *If* $\tilde{x} \in \mathbb{R}^k - L - \{0\}$, *and* x *is the closest point on* ∂L *in a reflection direction in cone*$\{d_i, i \in In(\tilde{x})\}$, *then* $V(x) \leq V(\tilde{x})$. *Define* $V(0) = 0$. *Then* $V(\cdot)$ *is globally Lipschitz continuous.*

The Liapunov function $V(\cdot)$ can be applied to our problem. This will be done in several steps, depending on whether there are forcing terms to the boundary.

No forcing terms to the boundary: $g(\bar{\theta}) = 0$. Here, $k = r$. Some components θ_n^i of θ_n are constrained to the interval $[0, b^i]$, and others are unconstrained. In the proofs of the results of this section, the localization argument will be used without specific mention. Now, $L \in \mathbb{R}^r$ is the intersection of the half spaces corresponding to $x^i \geq 0$ for those i (and only those i) for which θ_n^i is constrained to $[0, b^i]$ and $\bar{\theta}^i = 0$.

THEOREM 4.3. *Let* A *be the matrix whose* i*th row is the gradient of* $g^i(\cdot)$ *with respect to* θ *at* $\theta = \bar{\theta}$. *Assume that* $g(\bar{\theta}) = 0$, *Assumptions* 2.1–2.4 *hold, and Assumption* 4.3 *holds. Let* $d_i = n_i$, *an orthogonal reflection. Then* $\{U_n, n < \infty\}$ *is tight.*

Proof. Only the case (2.5a) will be dealt with. We first work with U_n such that $|U_n|$ is larger than some arbitrarily large K_1, and suppose (without loss of generality) that $E|U_0| < \infty$. Recall the definition of $\tilde{U}_{n+1}$ above (3.2). For the $V(\cdot)$ of Theorem 4.2, we can write

$$E_n V(\tilde{U}_{n+1}) - V(U_n) = \epsilon_n V'_x(U_n) g(\theta_n) + \epsilon_n O(1)\, |V_{xx}(\theta_n)| + O(\epsilon_n). \tag{4.2}$$

By expanding $g(\theta_n)$ as in Theorem 3.1, we dominate the right-hand side by

$$\epsilon_n V_x'(U_n) A U_n + \epsilon_n O(1)\,|V_{xx}(\theta_n)| + O(\epsilon_n).$$

Since the projection is norm decreasing (norm $V(\cdot)$), we have $V(U_{n+1}) \le V(\tilde{U}_{n+1})$. By Theorem 4.2, $V_x'(U_n)AU_n \le -c|U_n|, c > 0$. By this and the linear bounds on $V(\cdot)$ in Theorem 4.2, there are positive q_i such that $V_x'(U_n)AU_n \le -q_1 V(U_n) + q_2$. Putting all of this together, we see that there are $\alpha_i > 0$ such that

$$E_n V(U_{n+1}) \le (1 - \alpha_1\epsilon_n)\, V(U_n) + \alpha_2\epsilon_n. \tag{4.3}$$

Now, consider $|U_n| \le K_1$. Under Assumption 2.3 and the global Lipschitz condition on $V(\cdot)$, there is real K_0 such that $E_n V(U_{n+1}) - V(U_n) \le K_0\sqrt{\epsilon_n}$. Thus, there is real K_2 such that if $|U_n| \le K_1$, then $E_n V(U_{n+1}) \le K_2$. Thus,

$$E_n V(U_{n+1}) \le \max\left\{(1 - \alpha_1\epsilon_n)V(U_n) + \alpha_2\epsilon_n, K_2\right\}.$$

Define $\hat{V}(U) = V(U) - K_2$. Then

$$E_n \hat{V}(U_{n+1}) \le \max\left\{(1 - \alpha_1\epsilon_n)\hat{V}(U_n) + O(\epsilon_n), 0\right\}. \tag{4.4}$$

Equation (4.4) implies that $V(U_n) = O(1)$, which yields the theorem. □

Forcing terms to the boundary. Now, let us consider the general case in which there are forcing terms to the boundary. The procedure is similar to that used in Theorem 3.1. Suppose that $g^i(\bar{\theta}) < 0$ for $i = k+1, \ldots, r$. Partition the coordinates such that $U_n = (U_{a,n}, U_{b,n})$, where $U_{a,n}$ (resp., $U_{b,n}$) consists of the first k (resp., last $r-k$) components of U_n. Partition $\theta, \bar{\theta}$, and $g(\cdot)$ analogously.

THEOREM 4.4. *Assume that $g^i(\bar{\theta}) = 0, i \le k$, and $g^i(\bar{\theta}) < 0, i > k$. Let $d_i = n_i$, an orthogonal reflection. Let A denote the matrix whose ith row is the gradient of $g_a(\cdot)$ with respect to θ_a at $\bar{\theta}$. Assume that Assumptions* 2.1–2.4 *and* 4.3 *hold. Then $\{U_n, n < \infty\}$ is tight.*

Proof. Again, only the case (2.5a) will be dealt with. Since manipulations with Liapunov functions can be tedious, we will present only the main steps. Let $V(\cdot)$ be the Liapunov function of Theorem 4.2, but which is applied to the k dimensional system $dx = Axdt + dz, x \in L$. We will use the expansion

$$g(\theta) - g(\bar{\theta}) = \begin{bmatrix} A & B \\ C & D \end{bmatrix} \begin{pmatrix} \theta_a - \bar{\theta}_a \\ \theta_b - \bar{\theta}_b \end{pmatrix} + \text{higher order terms},$$

where B, C, D are matrices and the higher order terms are

$$\int_0^1 \left[g_\theta(\bar{\theta} + s(\theta - \bar{\theta}) - g_\theta(\bar{\theta})\right](\theta - \bar{\theta})\, ds,$$

as in (3.3).

For some large C_0, which will be determined later, define the Liapunov function $\bar{V}(U) = V^2(U_a)/2 + C_0|U_b|^2/2$. We can write

$$\begin{aligned} E_n\bar{V}(\tilde{U}_{n+1}) - \bar{V}(U_n) \le{}& V(U_{a,n})V_x'(U_{a,n})\left[\epsilon_n A U_{a,n} + \epsilon_n B U_{b,n} + o(\epsilon_n)|U_n|\right] \\ &+ o(\epsilon_n)|U_n| + O(\epsilon_n)|V_x(U_{a,n})|^2 + O(\epsilon_n) + O(\epsilon_n)|V_{xx}(U_{a,n})||V(U_{a,n})| \\ &+ C_0 U_{b,n}'\left[\sqrt{\epsilon_n} g_b(\bar{\theta}) + \epsilon_n C U_{a,n} + \epsilon_n D U_{b,n}\right] + C_0 O(\epsilon_n). \end{aligned} \tag{4.5}$$

First, suppose that $|U_{a,n}| \geq K_1$, large. The value of C_0 is not important at this step. Then bound (see Theorem 3.1) $\sqrt{\epsilon_n} g_b(\bar{\theta}) \leq -\epsilon_n \bar{K} U_{b,n}$, where $\bar{K}$ is a diagonal matrix whose diagonal components are $K > 0$, which (using the localization argument) is as large as desired. Thus we can bound

$$\sqrt{\epsilon_n} C_0 U'_{b,n} g_b(\bar{\theta}) \leq -\epsilon_n C_0 K \left|U_{b,n}\right|^2. \tag{4.6}$$

Following the idea in Theorem 3.1, we trade off by selecting K large enough (and using properties P5 and P7 at the end of the appendix) so that, for some $\alpha > 0$,

$$\begin{aligned} -C_0 K \left|U_{b,n}\right|^2 + C_0 U'_{b,n} C U_{a,n} + C_0 U'_{b,n} D U_{b,n} + V(U_{a,n}) V'_x(U_{a,n}) [A U_{a,n} + B U_{b,n}] \\ \leq -\frac{C_0 K}{2} |U_{b,n}|^2 - \alpha |U_{a,n}|^2 + O(1). \end{aligned} \tag{4.7}$$

As $|U_{a,n}| \to \infty$, $|V_{xx}(U_{a,n})| \to 0$, as $1/|U_{a,n}|$ and $|V_{xx}(U_{a,n})||V(U_{a,n})| = O(1)$.

Using the above bounds, property P6 at the end of the appendix, and the fact that $\bar{V}(U_{n+1}) \leq \bar{V}(\tilde{U}_{n+1})$, we have for some $\alpha_2 > 0$

$$E_n \bar{V}(U_{n+1}) - \bar{V}(U_n) \leq -\epsilon_n \alpha_2 \bar{V}(U_n) + O(\epsilon_n). \tag{4.8}$$

This estimate is for $|U_{a,n}| \geq K_1$, some large number.

Now, consider the case where $|U_{a,n}| \leq K_1$ but $|U_{b,n}| \geq K_1$. As in Theorem 4.3,

$$E_n V^2(U_{a,n+1}) - V^2(U_{a,n}) \leq O(\epsilon_n). \tag{4.9}$$

The difference $|U_{b,n+1}|^2 - |U_{b,n}|^2$ is expanded as in (4.5), and we use the bound in (4.6). Choose C_0 large enough so that $-\epsilon_n C_0 K |U_{b,n}|^2/4 \leq -\epsilon_n |U_{a,n}|^2$. Then, for some $\alpha_3 > 0$ we can write

$$E_n \bar{V}(U_{n+1}) - \bar{V}(U_n) \leq -\epsilon_n \alpha_3 C_0 |U_{b,n}|^2 - \epsilon_n \alpha_3 |U_{a,n}|^2 + O(\epsilon_n). \tag{4.10}$$

Thus, unless both $|U_{a,n}|$ and $|U_{b,n}|$ are less than K_1, (4.10) holds for some $\alpha_3 > 0$. When both are less than K_1, the estimate is obtained as in Theorem 4.3, and then the proof is completed as there. □

5. Weak convergence of the $U^n(\cdot)$ to a reflected diffusion. Let $U^{i,n}(\cdot)$ denote the ith component of $U^n(\cdot)$. The weak convergence uses the Skorohod topology on the path space $D(\mathbb{R}^r; 0, \infty)$, the space of $\mathbb{R}^r$-valued functions on $[0, \infty)$ which are right continuous and have limits from the left. See [3, 13] for the general theory of weak convergence, and [21] for the details of the theory as it applies to the SA problem and for further references.

Now that tightness of the set $\{U_n, n < \infty\}$ has been shown under the various conditions used in section 4, we need to prove the weak convergence of the continuous time interpolations $U^n(\cdot)$ and characterize the weak sense limit process. The localization argument noted at the beginning of Theorem 3.1 will be used where needed, usually without explicit mention. The tightness proof concerned the behavior of the iterates U_n for all time. Given this, to deal with the weak convergence of the $U^n(\cdot)$ we need only work with these processes on an arbitrary finite time interval. The possible unboundedness of U_n is a complication in proving tightness of the set of processes $\{U^n(\cdot), n < \infty\}$ (as opposed to the tightness of the set of random variables $\{U_n, n < \infty\}$). The most convenient approach for proving tightness and characterizing the weak sense limits uses a truncation device, which is discussed in detail in

[17]. It is designed to avoid the problem of unbounded dynamical terms. The idea is to truncate the processes $U^n(\cdot)$, prove the weak convergence of the truncated forms, and then use the properties of the associated weak sense limits of these to show that (asymptotically) the truncation is actually unnecessary.

The truncated processes. To facilitate working with the shifted processes $U^n(\cdot)$ which start at iterate n, for $j \geq 0$ define $\epsilon_j^n = \epsilon_{n+j}, \theta_j^n = \theta_{n+j}, \xi_j^n = \xi_{n+j}$, $Z_j^n = Z_{n+j}$, and $y_j^n = y_{n+j}$. For each integer M, let $q_M(\cdot)$ be a continuous real-valued function on $\mathbb{R}^r$ satisfying $0 \leq q_M(x) \leq 1$, $q_M(x) = 1$ for $|x| \leq M$, and $q_M(x) = 0$ for $|x| \geq M+1$. Let $\bar{A}$ denote the matrix whose ith row is the gradient of $g^i(\cdot)$ with respect to θ at $\bar{\theta}$. Define the truncated iterates $U_j^{n,M}$ by $U_0^{M,n} = U_n$, and for $j \geq 0$ set

$$\begin{aligned} U_{j+1}^{M,n} &= U_j^{M,n} + \sqrt{\epsilon_j^n} g(\bar{\theta}) + \epsilon_j^n \bar{A} U_j^{M,n} q_M(U_j^{M,n}) + \epsilon_j^n y_j^{M,n} U_j^{M,n} q_M(U_j^{M,n}) \\ &\quad + \sqrt{\epsilon_j^n}\xi_j^n + \sqrt{\epsilon_j^n} Z_j^{M,n} + o(\epsilon_j^n)\left[g(\theta_j^n) + U_j^{M,n} q_M(U_j^{M,n}) + \xi_j^n + Z_j^{M,n}\right]. \end{aligned} \tag{5.1}$$

By comparing (3.4) and (5.1), we see that $U_j^{M,n} = U_{n+j}$, until the first index $j > 0$ at which U_{n+j} exceeds M in norm, and that the terms with coefficient $\sqrt{\epsilon_j^n}$ in (5.1) are not truncated. The $Z_j^{M,n}$ are the reflection terms which serve to keep the iterate in H. Define the interpolation $U^{M,n}(\cdot)$ analogously to the way in which the interpolation $U^n(\cdot)$ was defined but using the truncated iterates $U_j^{M,n}$.

No forcing terms to the boundary. We will first work with the case where there is no forcing term to the boundary. Hence $k = r$ and $g(\bar{\theta}) = 0$ in Theorems 4.1 and 4.3. Define the state space $H \subset \mathbb{R}^r$ to be the set of x such that $x^i \in [0, b^i]$ for some subset of coordinates, with the others unconstrained. To get L, center about $\bar{\theta}$ and use "local" coordinates. Thus $L \subset \mathbb{R}^r$ is the set of points x for which $x^i \geq 0$ for all coordinates i that are constrained and such that $\bar{\theta}^i = 0$.

THEOREM 5.1. *Assume that Assumptions* 2.1–2.4 *and* 4.3 *hold. Suppose that there are no forcing terms to the boundary and define L and H as above. Then $U^n(\cdot)$ is tight, and the weak limit of any weakly convergent subsequence satisfies* (1.9a) *or* (1.9b)*, according to the case, where σ is defined below Assumption* 2.2 *and $U(t) \in L$. Thus, the weak sense limits differ only in the initial condition. The processes $(U(\cdot), z(\cdot))$ are nonanticipative with respect to the Wiener process.*

Proof. Again, we work with (2.5a) only. Tightness of the set of initial conditions $U_n = U^n(0)$ was proved in Theorems 4.1 and 4.3. Given this tightness, one first proves tightness of the set of truncated random processes $\{U^{M,n}(\cdot), n < \infty\}$ and then characterizes the limit of any weakly convergent subsequence. Abusing terminology, we suppose that the chosen subsequence is indexed by n also. The result will not depend on the chosen subsequence.

It will be shown that the weak sense limit $U^M(\cdot)$ of the truncated processes $U^{M,n}(\cdot)$ satisfies

$$dU^M = AU^M q_M(U^M)dt + \sigma dw + dz^M, \tag{5.2}$$

where $A = \bar{A}$ and $w(\cdot)$ is a standard vector-valued Wiener process. By the tightness of $\{U_n, n < \infty\}$, the set of all possible $U^M(0)$ (over all convergent subsequences and all M) is tight. Then, the process (5.2) has the property that, for any $T > 0$, and where the limit (as $C \to \infty$) is taken on uniformly in the chosen subsequence,

$$\lim_{C\to\infty} \sup_M P\left\{\sup_{t\leq T} \left|U^M(t)\right| \geq C\right\} = 0. \tag{5.3}$$

(Equation (5.3) is obtained using the Lipschitz condition on the map taking the driving process $w(\cdot)$ to the reflection process for the Skorohod problem, which was proved in [7].) Then (5.2), together with the weak convergence of $U^{M,n}(\cdot)$ to $U^M(\cdot)$, implies that the original sequence $U^n(\cdot)$ satisfies

$$\lim_{C\to\infty} \sup_n P\left\{\sup_{t\le T}|U^n(t)| \ge C\right\} = 0. \tag{5.4}$$

This boundedness in probability, in turn, together with the tightness of $\{U^{M,n}(\cdot), n < \infty\}$ for each M, implies that the untruncated sequence is also tight and satisfies (1.9a). The weak sense limits can differ only in the initial condition.

Now, return to the proof of (5.2). Fix M until further notice. Using the localization method, we will suppose without loss of generality that $|\theta_n - \bar\theta|$ is as small as desired. Hence the $Z_j^{i,M,n}$ (the ith component of $Z_j^{M,n}$) can be supposed to equal zero for those i for which $\bar\theta^i \ne 0$. Define the process

$$W^n(t) = \sum_{i=n}^{m(t_n+t)-1} \sqrt{\epsilon_i}\xi_i. \tag{5.5}$$

Then, $W^n(\cdot)$ converges weakly to a Wiener process with covariance matrix Σ [21, Theorem 10.2.1]. Now, keep in mind that $|Uq_M(U)|$ is bounded by M. Hence, the processes defined by the interpolation of the fourth term on the right-hand side of (5.1) clearly converge weakly to the "zero" process. The processes defined by the interpolations of the first two terms in the bracket on the right-hand side of (5.1) also converge weakly to the "zero" process. Recall that the state space of concern is $L = \{x : x^j \ge 0, \text{ for } j \text{ such that } \bar\theta^j = 0 \text{ and coordinate } j \text{ is constrained}\}$.

It remains to treat the effects of $Z_j^{i,n,M}$ for those coordinates i which are constrained and for which $\bar\theta^i = 0$. We next outline the proof that $Z^{M,n}(\cdot)$ is "asymptotically continuous." Adapting a method of [19], it will be shown that for each $T > 0$ and $\nu > 0$

$$\lim_{\delta\to 0} \limsup_n P\left\{\sup_{t\le T}\sup_{s\le\delta}\left|Z^{n,M}(t+s) - Z^{n,M}(t)\right| \ge \nu\right\} = 0, \tag{5.6}$$

where $Z^{n,M}(\cdot)$ is the continuous time interpolation of the $Z_i^{n,M}$. The limit equality (5.6) implies the tightness and that each weak sense limit process has continuous paths with probability one. We refer to the property (5.6) as "asymptotic continuity."

It is clear that (5.6) holds for the processes defined by the interpolations of any of the terms on the right-hand side of (5.1), except possibly that due to the Z-term. Suppose that (5.6) does not hold for some $T > 0$ and $\nu > 0$. Then there are $0 < \delta_n \to 0$ and $\eta > 0$ such that

$$\limsup_n P\left\{\sup_{t\le T}\left|Z^{M,n}(t+\delta_n) - Z^{M,n}(t)\right| \ge \nu\right\} \ge \eta. \tag{5.7}$$

By the truncation and the convergence of the process defined by the sum of the noise terms to a Wiener process, for any $T > 0$, the maximum value of the (non-Z) terms on the right-hand side of (5.1) goes to zero as $n \to \infty$, where the maximum is taken over $i \le m(t_n + T) - n$.

Consider only coordinates i which are constrained and are such that $\bar\theta^i = 0$. The $Z_j^{i,M,n}$ can be nonzero only for those j such that the unprojected iterate $\tilde U_{j+1}^{i,M,n}$ is

negative, and then $\epsilon_j Z_j^{i,M,n}$ is the minimum value which keeps $U_{j+1}^{i,M,n} \geq 0$. By the comments in the last paragraph,

$$\sup_{i \leq m(t_n+T)-n} \sqrt{\epsilon_i^n} Z_j^{i,M,n} \to 0$$

in probability as $n \to \infty$, and (with an arbitrarily high probability) $Z_j^{i,M,n}$ can be nonzero only when $U_j^{i,M,n}$ is arbitrarily close to zero. These facts imply that (5.7) is not possible. Hence (5.6) holds.

Now, take a weakly convergent subsequence of all of the interpolated processes (indexed also by n). By what has been said, the limit satisfies (5.2), where $z^M(\cdot)$ is the reflection term. The proof (except for the nonanticipativity) is now concluded as discussed in the second paragraph of the proof.

It only remains to show the nonanticipativity. This also follows a standard procedure. Let $\mathcal{F}_t$ denote the filtration engendered by $\{U(s), z(s), w(s), s \leq t\}$, $h(\cdot)$ be a bounded real-valued function of its arguments, and $f(\cdot)$ be a twice continuously differentiable real-valued function on $\mathbb{R}^r$ with compact support. For arbitrary $p, t, \tau, s_i \leq t < t+\tau, i \leq p$, suppose that

$$\begin{aligned} &Eh(U(s_i), z(s_i), w(s_i), i \leq p) \\ &\quad \times \left[f(w(t+\tau)) - f(w(t)) - \frac{1}{2} \int_t^{t+\tau} \sum_{i,j} f_{w^i w^j}(w(s)) ds \right] = 0. \end{aligned} \tag{5.8}$$

Then $w(\cdot)$ is an $\mathcal{F}_t$-martingale and an $\mathcal{F}_t$-Wiener process. To prove (5.8), one shows that

$$\begin{aligned} &Eh(U^n(s_i), Z^n(s_i), w^n(s_i), i \leq p) \\ &\quad \times \left[f(w^n(t+\tau)) - f(w^n(t)) - \frac{1}{2} \int_t^{t+\tau} \sum_{i,j} f_{w^i w^j}(w^n(s)) \Sigma_{ij} ds \right] \to 0 \end{aligned}$$

and uses the weak convergence. Details for many such computations can be found in [17] and are omitted. □

Forcing terms to the boundary. Define H as for Theorem 5.1. Since $U_b^n(\cdot)$ will be shown to converge weakly to the "zero" process, L is defined only for the remaining coordinates. It is the state space of the limit process $U_a(t)$.

THEOREM 5.2. *Suppose that there are forcing terms to the boundary, in that $k < r$ in Theorem* 4.1 *or* 4.4. *Redefine A to be the matrix whose ith row is the gradient of $g_a^i(\cdot)$ with respect to θ_a, at $\bar{\theta}$. Assume that Assumptions* 2.1–2.4 *and* 4.3 *hold. Then $U^n(\cdot)$ is tight. The sequence $U_b^n(\cdot)$ converges weakly to the "zero" process. The limit of any weakly convergent subsequence of $U_a^n(\cdot)$ satisfies*

$$dU_a = AU_a dt + \sigma_a dw_a + dz_a, \text{ under (2.5a)}, \tag{5.9a}$$

or

$$dU_a = \left[A + \frac{I}{2} \right] U_a dt + \sigma_a dw_a + dz_a \text{ when } \epsilon_n \to 0, \text{ under (2.5b)}. \tag{5.9b}$$

In (5.9), $U_a(t) \in L$, σ_a *is the square root of the upper left hand $k \times k$ submatrix of Σ, $w_a(\cdot)$ is a standard $\mathbb{R}^k$-valued Wiener process, and $z_a(\cdot)$ is the reflection term.*

Thus the weak sense limits differ only in the initial condition. The $(U_a(\cdot), z_a(\cdot))$ *is nonanticipative with respect to* $w_a(\cdot)$.

Proof. The proof is similar to that of Theorem 5.1. In view of the proof of Theorem 5.1 and the tightness of $\{U_n, n < \infty\}$, we need only show that $U_b^n(\cdot)$ converges weakly to the "zero" process. The truncation method will be used again. Thus we need only show that $U_b^{M,n}(\cdot)$ converges weakly to the "zero" process for each M.

Return to (5.1), and using the fact of the truncation write the b-component as

$$U_{b,j+1}^{M,n} = U_{b,j}^{M,n} + \sqrt{\epsilon_j^n} g_b(\bar{\theta}) + \epsilon_j^n O(1) + \sqrt{\epsilon_j^n}\xi_{b,j}^n + \sqrt{\epsilon_j^n} Z_{b,j}^{M,n} + o(\epsilon_j^n)\left[g_b(\theta_j^n) + O(1) + \xi_{b,j}^n + Z_{b,j}^{M,n}\right]. \tag{5.10}$$

First note that the continuous time interpolation of the components of $\sqrt{\epsilon_j^n} g_b(\bar{\theta})$ converges to $-\infty$. It is then apparent from the weak convergence of the interpolation of the noise terms to a Wiener process and the boundedness of the coefficients of ϵ_n and of $o(\epsilon_n)$ that $U_b^{n,M}(\cdot)$ converges weakly to the zero process. Given this, use the proof in Theorem 5.1 for $U_a^{n,M}(\cdot)$. The $U_b^{n,M}(\cdot)$ does not appear in the limit. □

6. Stationarity of the limit solution.

6.1. Convergence to invariant measures: General results. The proof of the stationarity of the limit processes (1.9) or (5.9) rests on the following ergodic results.

ASSUMPTION 6.1. *Let* $L \subset \mathbb{R}^k$ *be the intersection of a finite number of half-planes and the closure of its interior. Let* $x(\cdot)$ *be a Markov–Feller process with a stationary transition function and with paths in* $D(L; 0, \infty)$. *Let* $P(x, t, \cdot)$ *denote the measure of* $x(t)$, *given that* $x(0) = x$, *and let it be mutually absolutely continuous with respect to Lebesgue measure for each* $t > 0$ *and each* $x \in L$.

Recall that the process $x(\cdot)$ with values in L is a *Feller* process if for each bounded continuous real-valued function $f(\cdot)$ on L and each $t > 0$,

$$\int f(y) P(x, t, dy) \text{ is continuous in } x. \tag{6.1}$$

Also, a Markov–Feller process is a strong Markov process. The process is said to be *strong Feller* if the continuity holds for any bounded and measurable $f(\cdot)$.

Comment. The crucial result (6.2) is implied by Theorem 4 of [6] (with modified notation). The rest of the proof is straightforward and the details are omitted. More detail is in [5].

THEOREM 6.1. *Assume that Assumption* 6.1 *holds. Let* $\mu(\cdot)$ *be an invariant probability measure for* $x(\cdot)$, *which we suppose exists. Then,* $\mu(\cdot)$ *is mutually absolutely continuous with respect to Lebesgue measure. Also,*

$$P(x, t, E) \to \mu(E) \text{ for each } x \in L \text{ and Borel set } E \subset L. \tag{6.2}$$

Hence $\mu(\cdot)$ *is the unique invariant probability measure. Furthermore,* (i) $x(\cdot)$ *is a strong Feller process;* (ii) *for any nonempty compact set* $C \subset L$ *and* $t > 0$, $\{P(x, t, \cdot), x \in C\}$ *is uniformly absolutely continuous with respect to Lebesgue measure* $l(\cdot)$ *on* L, *in that for each* $\epsilon > 0$ *there is* $\delta > 0$ *such that* $l(E) \le \delta$ *implies that* $P(x, t, E) \le \epsilon, x \in C$. *Assume, in addition, that for each* $\epsilon > 0$ *and compact set* $C_1 \subset L$

$$\lim_{t \to 0} \sup_{x \in C_1} P_x \{|x(t) - x| \ge \epsilon\} = 0. \tag{6.3}$$

Then (iii) *the uniformity in the absolute continuity holds for* $(x,t) \in C \times [t_0, t_1]$ *for any* t_0, t_1 *satisfying* $0 < t_0 < t_1 < \infty$.

Now, assume (6.1) *in addition. Let* $\mu(\cdot)$ *be an invariant measure for* $x(\cdot)$. *For* α *in some index set, let* $\{q_\alpha(\cdot)\}$ *be a tight family of probability measures on* L. *Then for each Borel set* $E \subset L$

$$\int q_\alpha(dx) P(x,t,E) \to \mu(E) \tag{6.4}$$

uniformly in α *as* $t \to \infty$.

6.2. Ergodic results for the Skorohod problem. We will be concerned with the solution to the Skorohod problem in a state space L satisfying Assumption 4.2 and the following conditions. The condition is more general than needed, but it is the natural formulation.

ASSUMPTION 6.2. *There are constants* $a_i > 0$ *such that for all* i

$$a_i \langle n_i, d_i \rangle > \sum_{j \neq i} a_j \left| \langle n_i, d_j \rangle \right|.$$

The condition needs to hold only for the faces adjoining each individual edge or corner of L *separately.*

ASSUMPTION 6.3. $\sigma(\cdot)$ *is an* $r \times r$ *matrix, bounded and Hölder continuous, with* $a(x) = \sigma(x)\sigma'(x)$ *positive definite, uniformly in* x. *Let* $b(\cdot)$ *be Hölder continuous and* $|b(x)| \leq K(1 + |x|)$ *for some* $K < \infty$.

These conditions hold for the case of interest for the SA in this paper. Indeed, for our cases, the reflection directions are normal to the boundary ($d_i = n_i$), and L is the set used in section 4 where some components are unconstrained and others are constrained to be nonnegative. Also for our case, $b(x) = Ax$, and $\sigma(x) = \sigma$ is constant.

Let $r(x)$ denote the set of reflection directions at $x \in L$. The Skorohod problem of interest is defined by

$$dx = b(x)dt + \sigma(x)dw + dz,\ x(t) \in L \text{ for all } t, \tag{6.5}$$

where $z(\cdot)$ is the reflection term and $w(\cdot)$ is a standard vector-valued Wiener process. Let $|z|(t)$ denote the variation of $z(\cdot)$ on $[0,t]$. Suppose (as holds for our case) that $b(\cdot)$ and $\sigma(\cdot)$ are Lipschitz continuous. Then [7] $|z|(t) < \infty$ with probability one for each t, and

$$|z|(t) = \int_0^t I_{\{x(s) \in \partial L\}} d|z|(s),$$

$$z(t) = \int_0^t \gamma(s) d|z|(s),$$

where $\gamma(\cdot)$ is a measurable function such that, for almost all (ω, t), $\gamma(t) \in r(x(t))$. It is a consequence of the results in [7] that a strong sense solution to (6.5) exists on $[0, \infty)$ and is unique in the strong sense for each initial condition $x(0) = x \in L$. (Thus $x(\cdot)$ is a well-defined Markov–Feller process with a transition function $P(x,t,\cdot)$.) Also, by Assumption 4.2 the variation of $z(\cdot)$ on any finite time interval is bounded in probability, uniformly in the initial condition in any bounded set [19, Theorem 11.1.1.]. Consider the Skorohod problem $x(t) = \phi(t) + z(t)$, where $\phi(\cdot) \in$

$D(\mathbb{R}^k; 0, \infty)$ and the reflection directions and state space satisfy Assumption 4.2. Let (x_1, ϕ_1, z_1) and (x_2, ϕ_2, z_2) be any solutions of the corresponding Skorohod problem. Then Assumption 6.2 implies that [7] there is a real K_1 such that for all t

$$\sup_{s \le t} [|z_1(s) - z_2(s)| + |x_1(s) - x_2(s)|] \le K_1 \sup_{s \le t} |\phi_1(s) - \phi_2(s)|.$$

This Lipschitz condition can be used to prove strong sense existence and uniqueness of the solution to (6.5) under a Lipschitz condition on $b(\cdot), \sigma(\cdot)$. This is its only purpose here.

We now restate and slightly extend (with essentially the same proof) the material from Harrison and Williams [15, section 7]. The proof of the next theorem is just that of [15, Lemma 7.2], nearly word for word, and the details are omitted. Theorems 6.3 and 6.4 together imply uniform mutual absolute continuity of the transition function and Lebesgue measure which is needed to apply Theorem 6.1.

THEOREM 6.2. *Assume that Assumptions* 4.2 *and* 6.2–6.3 *hold. Suppose that the nonanticipative solution to* (6.5) *exists and is unique in the weak sense for each initial condition. Then*

$$E_x \int_0^\infty I_{\partial L}(x(s)) ds = 0 \tag{6.6}$$

for each initial value $x \in L$. Furthermore,

$$P(x, t, \partial L) = 0, \ t > 0, \ \text{and all } x \in L. \tag{6.7}$$

More strongly, for any compact set $C \subset L$ and $t > 0$,

$$\lim_{\delta \to 0} \sup_{x \in C} P(x, t, N_\delta(\partial L)) = 0, \tag{6.8}$$

where $N_\delta(\partial L)$ is a δ-neighborhood of the boundary.

The next theorem essentially follows from Theorems 6.1 and 6.2, the properties of the unconstrained process from [12], and the argument in [15, Lemma 7.9]; the details are omitted. Theorem 6.4 is a consequence of Theorems 6.1 and 6.3. See [5] for more detail.

THEOREM 6.3. *Assume that Assumptions* 4.2 *and* 6.2–6.3 *hold. Suppose that the nonanticipative solution to* (6.5) *exists and is unique in the weak sense for each initial condition. Then for $t > 0$ the transition probability $P(x, t, \cdot)$ is mutually absolutely continuous with respect to Lebesgue measure for each $x \in L$ and is absolutely continuous with respect to Lebesgue measure uniformly for (x, t) in any compact set of the form $C \times [t_0, t_1]$, where $C \subset L$ is compact and $t_1 > t_0 > 0$.*

THEOREM 6.4. *Assume that Assumptions* 4.2 *and* 6.2–6.3 *hold. Suppose that the nonanticipative solution to* (6.5) *exists and is unique in the weak sense for each initial condition. Then $x(\cdot)$ is a strong Feller process. Let the sets E below be contained in a compact set $C_1 \subset L$, and suppose that $C \subset C_1^0$ is compact. Let $\epsilon > 0$ be arbitrary. Then there is $\delta > 0$ such that, for $t_1 > t_0 > 0$,*

$$\inf_{t_1 \ge t \ge t_0} \inf_{x \in C} \inf_{\{E : l(E) \ge \epsilon\}} P(x, t, E) \ge \delta. \tag{6.9}$$

6.3. Stationarity of the limit $U(\cdot)$ process.

THEOREM 6.5. *Under the conditions of Theorem* 5.1*, any weak sense limit* $U(\cdot)$ *of* $U^n(\cdot)$ *is stationary and the stationary process is unique. The analogous result holds for the weak sense limit* $U_a(\cdot)$ *under the conditions of Theorem* 5.2.

Outline of proof. We apply Theorem 6.1 and work with the case of Theorem 5.1 only (the case of Theorem 5.2 is treated identically). Owing to the tightness of $\{U_n, n < \infty\}$, the set

$$\{U(t), t < \infty, \text{all possible weak sense limits } U(\cdot)\}$$

is tight. This and the Markov–Feller property of $U(\cdot)$ imply that there is an invariant measure. Theorem 6.3 ensures the absolute continuity property (with respect to Lebesgue measure) needed in Theorem 6.1. Let $\mu(\cdot)$ denote the unique invariant measure, and $P(u, t, \cdot)$ the transition function for the process $U(\cdot)$. Let $\{\pi_\alpha(\cdot)\}$ denote a tight set of probability measures. The next step is to show that

$$\int \pi_\alpha(du) P(u, t, A) \to \mu(A)$$

as $t \to \infty$, uniformly in α. However, this is implied by Theorem 6.1.

To complete the proof, we use a "time shift" argument analogous to what was done in [21, Chapter 10]. Define $U_n = U_0$ for $n \leq 0$. We start the $U^n(\cdot)$ processes "earlier." Let $s > 0$ be an integer. Define the process $U^{s,n}(\cdot)$ by $U^{s,n}(0) = U_{m(t_n - s)}$ and, for $t > 0$, $U^{s,n}(t) = U_{m(t_n + t - s)}$. Thus $U^n(0) = U^{s,n}(s)$. The set $\{U^n(\cdot), U^{s,n}(\cdot)\}$ is tight for each fixed s. Take a subsequence n_i such that $(U^{n_i}(\cdot), U^{s,n_i}(\cdot))$ converges weakly to weak sense limits denoted by $(U(\cdot), U^s(\cdot))$. The processes $U(\cdot)$ and $U^s(\cdot)$ satisfy (1.9a) or (1.9b), according to the case. Also, $U(0) = U^s(s)$. As $s \to \infty$, take further weakly convergent subsequences. Owing to the tightness of $\{U^s(0), s > 0\}$ and (6.4), we see that $U(0)$ must be the stationary initial condition. □

7. More general noise. The tightness results of sections 3 and 4 depended on the assumption that the ξ_n were martingale differences. The proof of weak convergence in section 5 did not need the martingale difference condition. It required only that the process defined by (5.5) converge weakly to a Wiener process. (This, in itself, will not get the nonanticipativity, but the required addition is minor and is dealt with in [21].) Still, the key issue is the tightness of $\{U_n, n < \infty\}$. For a large class of correlated noise processes, this can be proved by use of the perturbed Liapunov function method [4, 17, 21]. We will make a few comments concerning the method for the case of Theorem 4.3. The cases of Theorems 4.1 and 4.4 are similar.

The main problem with correlated noise is that we no longer have $E_n V_x'(U_n)\xi_n = 0$ and $E_n|\xi_n|^2$ uniformly bounded when $\theta_n - \bar{\theta}$ is small. To simplify the development, work with (2.5a) and suppose that ξ_n is bounded. Then, the term $[\sqrt{\epsilon_n} + o(\epsilon_n)]\xi_n = \epsilon_n \xi_n / \sqrt{\epsilon_{n+1}}$ in (3.4) leads to the additional term $\sqrt{\epsilon_n} V_x'(U_n) E_n \xi_n$ in (4.1). Following the perturbed Liapunov function method used in [17, 21], define the perturbation

$$\delta F^n = \sum_{j=n}^{\infty} E_n \xi_j. \tag{7.1}$$

Assume that it is well defined and that the conditional expectations go to zero fast enough so that it is bounded by some constant B, uniformly in all variables. Now, define the Liapunov function perturbation $\delta V^n = [\epsilon_n / \sqrt{\epsilon_{n+1}}] V_x'(U_n) \delta F_n$. We will

use the perturbed Liapunov function $V^n = V(U_n) + \delta V^n$. Modifying the method in Theorem 4.3 by following the procedures for the perturbed Liapunov functions in [17, 21], one can prove the tightness of $\{U_n, n < \infty\}$.

8. An application: Constrained stochastic approximation via a Lagrangian method. Consider the problem of minimizing the real-valued function $f(x)$ on $\mathbb{R}^r$ subject to constraints $q^i(x) \leq 0, i \leq p$. Both $f(x)$ and the $q^i(x)$ are unknown but are observed with additive noise. A "Lagrangian" SA method for dealing with this problem was introduced in [18, 20], where convergence (with probability one) was proved.

Suppose that $f(\cdot)$ is strictly convex and twice continuously differentiable, and that the $q^i(\cdot)$ are twice continuously differentiable and convex. To simplify the discussion, suppose that we observe the derivatives plus (martingale difference) noise. Otherwise, the Kiefer–Wolfowitz procedure is used, and the finite difference bias error needs to be accounted for. Define the Lagrangian

$$L(x, \lambda) = f(x) + \sum_i \lambda^i q^i(x), \qquad \lambda^i \geq 0.$$

There is a unique saddle point $(\bar{X}, \bar{\lambda})$ and $\bar{\lambda}^i \geq 0$. Suppose that finite a^i, b^i, c^i are known for which $\bar{\lambda}^i < a^i$ and $b^i < \bar{X}^i < c^i$. The SA algorithm is [18, 20]

$$X_{n+1} = X_n - \epsilon_n L_x(X_n, \lambda_n) + \epsilon_n \xi_{x,n} + \epsilon_n Z_{x,n},$$

$$\lambda_{n+1} = \lambda_n + \epsilon_n L_\lambda(X_n, \lambda_n) + \epsilon_n \xi_{\lambda,n} + \epsilon_n Z_{\lambda,n},$$

where the $Z_{x,n}, Z_{\lambda,n}$ are reflection terms, which keep the iterate within the hard boundary, $0 \leq \lambda^i \leq a^i$, $b^i \leq x^i \leq c^i$. The $\xi_{x,n}, \xi_{\lambda,n}$ are observation noises. Define $\theta = (X, \lambda)$, and suppose that $\xi_n = (\xi_{x,n}, \xi_{\lambda,n})$ satisfies Assumptions 2.2 and 2.3. For specificity, suppose that (2.5a) holds. Then [18] θ_n converges weakly to its unique limit $\bar{\theta} = (\bar{X}, \bar{\lambda})$. Under stronger conditions on the $\epsilon_n \xi_n$, there is probability one convergence [18]. Let us suppose probability one convergence. Under our assumptions, $\bar{X}$ is inside its hard constraint box and $\bar{\lambda}^i < a^i$. Then, by the localization hypothesis, we can suppose that $Z_{x,n} = 0$. Also, we can suppose that $Z^i_{\lambda,n} = 0$ for all i such that $\bar{\lambda}^i > 0$.

Define

$$U_{x,n} = \frac{X_n - \bar{X}}{\sqrt{\epsilon_n}}, \; U_{\lambda,n} = \frac{\lambda_n - \bar{\lambda}}{\sqrt{\epsilon_n}}.$$

If $0 < \bar{\lambda}^i$ for all i, then $\bar{\theta}$ is interior to its hard constraint set, and the classical rate of convergence theory can be used. Thus, suppose that $\bar{\lambda}^i = 0$ for some i. Then the classical theory cannot be used. If $\bar{\lambda}^i = 0$, then we could have either $q^i(\bar{X}) < 0$ or $q^i(\bar{X}) = 0$.

Let us next deal with the latter case, where $q^i(\bar{X}) = 0$ for all i. Define the matrix

$$A = \begin{bmatrix} -L_{xx}(\bar{X}, \bar{\lambda}) & -q'_x(\bar{X}) \\ q_x(\bar{X}) & 0 \end{bmatrix}.$$

Note that $L_{xx}(\bar{X}, \bar{\lambda})$ is positive definite. Suppose that the vectors $q_{i,x}(\bar{X}), i \leq p$, are linearly independent. Consider the deterministic Skorohod problem

$$\begin{pmatrix} \dot{x} \\ \dot{\lambda} \end{pmatrix} = A \begin{pmatrix} x \\ \lambda \end{pmatrix} + \begin{pmatrix} 0 \\ \dot{z}_\lambda \end{pmatrix}.$$

The solution corresponding to any initial condition goes to zero as $t \to \infty$. This can be seen from the following Liapunov function argument. Use $V(\theta) = |x|^2/2 + |\lambda|^2/2$. Then, using the fact that $\lambda' \dot{z}_\lambda = 0$, we have

$$\dot{V}(\theta) = -x' L_{xx}(x) x.$$

This implies that $V(\theta(t))$ is bounded for each initial condition and that the solution goes to the set where $x = 0$. But this, in turn (using the linear independence of the $q_x^i(\bar{X}), i \le p$), implies that the solution $\theta(t)$ tends to zero.

With this result in hand, Theorem 4.3 and the results of sections 5 and 6 yield that $U^n(\cdot)$ converges weakly to the stationary solution to

$$\begin{pmatrix} dU_x \\ dU_\lambda \end{pmatrix} = A \begin{pmatrix} U_x \\ U_\lambda \end{pmatrix} dt + \sigma dw(t) + \begin{pmatrix} 0 \\ dz_\lambda \end{pmatrix},$$

where $\dot{z}_\lambda^i(t) = 0$ unless $\bar{\lambda}^i = 0$.

The case where $q^i(\bar{X}) < 0$ for some i corresponds to a forcing term to the boundary for the component λ_n^i, and the process defined by $U_{\lambda,n}^i$ will converge to zero. Then such $U_{\lambda,n}^i$ can be dropped, and the rate of convergence equation can be developed for the remaining components.

9. Nonorthogonal reflection directions. The convergence results for constrained algorithms in [21] are for reflections which return the iterate to the closest point in the hyperrectangular constraint set. However, the proofs can be modified to allow constraint sets which are just the closures of their interiors and have piecewise linear boundaries. Suppose that the constraint set H and the reflection directions simply satisfy Assumption 4.2 and that Assumption 4.3 holds. Then Theorem 4.2 holds, so one can construct the Liapunov function $V(\cdot)$.

Suppose that there are no forcing terms to the boundary. Then one can repeat all of the steps in Theorem 4.3. With the tightness of $\{U_n, n < \infty\}$ given, the only new problem is the proof of the tightness of the reflection processes $Z^{M,n}(\cdot)$ in Theorem 5.1. This can be done by essentially the method in Theorem 5.1, since the condition on the reflection directions in Assumption 4.2 can be used to show asymptotic continuity of these processes. While there is no analytical problem when there are no forcing terms to the boundary, the interaction of the oblique reflection directions and the limit linearized dynamics $\dot{x} = Ax + \dot{z}$ can be very complicated. When there are forcing terms to the boundary, as under the assumptions of Theorem 3.1, the individual components of $U^n(\cdot)$ can be separated into two subsets. One converges to the "zero" process, and the other to the limit reflected diffusion.

10. Discussion: Comparisons with the unconstrained case. For the unconstrained case, the stationary distribution of either form of (1.5) is normal with zero mean, and the covariance can be computed analytically. Consider the constrained problem. Suppose that the components of θ can be divided into two classes, where the first corresponds to forcing terms to the boundary and, for the latter, $\bar{\theta}^i$ is interior to the constraint interval. Then the steady state distribution is simple: The normalized mean square errors of the components with forcing terms to the boundary are zero. The others are unconstrained in the limit, and their distribution is normal with zero mean and can be computed analytically. The variances can be much smaller than those for the original unconstrained problem, since the dimension is smaller. It is common for constrained problems to have some components with forcing terms to the boundary.

If, however, some components without forcing terms to the boundary have $\bar{\theta}^i$ at the end of the constraint interval, then we have to deal with the general reflected diffusion of one of the forms in (1.9). The form of the stationary distribution of (1.9) is not known, and some sort of simulation seems to be called for to evaluate it. The stationary means and covariances were evaluated for several two dimensional systems. For those examples, where there were no forcing terms to the boundary, the constraints did not increase the mean square values. Generally, the mean square values of the limit variances for the constrained problem were close to the variances for the unconstrained problem, perhaps a little smaller. However, the mean of the limit distribution was not zero. Thus, the limit variances were smaller than those for the unconstrained problem, suggesting that the constrained problem has less asymptotic variability, even when the limit point is the same as that for the unconstrained problem. If one of the components did have a forcing term to the boundary, then even if the other component of the limit was on the boundary, its stationary variance was smaller (again, perhaps much smaller), since the effective dimension is reduced. A method for analytically evaluating or approximating the first two moments for the constrained problem is needed.

Appendix. Construction of the Liapunov function $V(\cdot)$. Theorem 4.2 will be proved in this section. Consider an unconstrained system $\dot{x} = b(x)$. Uniform asymptotic stability of this ODE implies the existence of a Liapunov function. This Liapunov function can be smoothed to make it twice continuously differentiable and then used to prove the recurrence of the process defined by the unconstrained SDE $dx = b(x)dt + \sigma(x)dw$ if $\sigma(\cdot)$ is bounded. The aim is to do this for the reflected SDE of concern, where the deterministic (fluid) model is (4.1a) ((4.1b) is obviously similar) and the reflected SDE is (1.9a). If the result is to be adapted for use on the discrete parameter SA algorithm, then we need to allow reflection from a neighborhood "a little outside" of L, the state space of the limit process (1.9). A serious problem, which is not present in the unconstrained case, is that there are two vector fields to be dealt with, the drift in L and the reflection on the boundary and just outside of the boundary.

This problem was solved in [11] for the case where the drift vector $b(x)$ was simply a constant vector $\bar{b}$. The general idea of the proof there can be extended to cover our case, where $b(x) = Ax$, but a number of alterations need to be made. Since the proof in [11] is complicated, we will provide a detailed guide to the necessary changes. Their state space was the orthant $\{x : x^i \geq 0, i \leq k\}$. In our case, some components are unconstrained, and we use the L defined in Assumption 4.2, where components $1, \ldots, \nu$ are constrained and components $\nu + 1, \ldots, k$ are unconstrained. This alteration is insignificant and, in itself, requires only a minor notational change in [11]. The radial homogeneity of the dynamical terms, drift, and reflection (i.e., they have the same value at all points on each ray from the origin) was heavily used in [11]. This is the reason for the use of the form $dx = [Ax/|x|]\,dt + dz$ below. The paths of this normalized model, when plotted in phase space, are the same as those of the original fluid model (1.5a), and actual paths differ only by a time scaling. Thus, we work with

$$dx = \frac{Ax}{|x|}dt + dz, \qquad x \in L, \tag{A.1}$$

and assume that Assumption 4.2 holds.

The method of analysis uses an extension of the dynamics to all of $\mathbb{R}^k - \{0\}$. The

major difficulty concerns the need to get a smooth Liapunov function in $\mathbb{R}^k - \{0\}$, where the dynamical term is discontinuous on ∂L, where it switches from the drift to the reflection.

The main steps of the proof in [11], adjusted to our form of L but where $dx = \bar{b}dt + dz$, are the following.

1. First define the extended system $\dot{x} = v(x)$: For $x \in L - \{0\}$, set $v(x) = \bar{b}$, where $\bar{b}$ is their constant drift vector. For $x \in \mathbb{R}^k - L - \{0\}$, set $v(x) = r_0(x)$, where $r_0(x)$ is any unit vector in cone$\{d_i : i \in \text{In}(x)\}$, where $\text{In}(x) = \{i : x^i = 0\}$. The definitions at the origin are arbitrary.
2. Smooth $v(\cdot)$: Let $\rho(\cdot)$ be a smoothing kernel and for small $a > 0$ define

$$v^a(x) = c(a|x|) \int \rho\left(\frac{x-y}{a|x|}\right) v(y)dy,$$

where $c(a)$ is the normalizing constant which ensures that the integral is unity when $v(\cdot) \equiv 1$.
3. Form a convex combination of $v^a(\cdot)$ and the original dynamics as follows. Let $d(x, M) = \inf_{y \in M} |x - y|$ denote the distance between x and the set M. Define the real-valued, infinitely differentiable, and nonincreasing function on $[0, \infty)$ by $g(s) = 1, s \in [0, .5]$, $g(s) = 0, s \in [1, \infty)$. Define

$$v_i^a(x) = g\left(\frac{d(x, \partial L_i)}{a|x|}\right) d_i + \left[1 - g\left(\frac{d(x, \partial L_i)}{a|x|}\right)\right] v^a(x), \qquad 1 \le i \le \nu,$$

$$v_0^a(x) = g\left(\frac{d(x, L)}{a|x|}\right) \bar{b} + \left[1 - g\left(\frac{d(x, L)}{a|x|}\right)\right] v^a(x).$$

4. Define the set-valued function

$$K^a(x) = \text{conv}\left\{v_i^a(x), 0 \le i \le \nu\right\},$$

where conv denotes the set of all convex combinations. For each x, define $K(x)$ as the "limit" set containing points y satisfying the following condition: there exists $a_n \to 0, x_n \to x, y_n \to y$, where $y_n \in K^{a_n}(x_n)$. Define the ODE with the set-valued right-hand side

$$\dot{\phi} \in K^a(\phi), \ \phi(0) \in \text{ some compact set.} \tag{A.2}$$

5. Let $k(\cdot)$ be a $[0, 1]$-valued, infinitely differentiable, and nondecreasing function on $[0, \infty)$ such that $k(s) = 0$ for $s \in [0, 1]$ and $k(s) = 1$ for $s \in [2, \infty)$. Define the first "tentative" Liapunov function

$$V^a(x) = \sup_{\phi} \int_0^\infty k(|\phi(s)|)ds,$$

where the sup is over all solutions to (A.2) with $\phi(0) = x$.
6. For small $b > 0$, smooth $V^a(\cdot)$ as

$$V^{a,b}(x) = c(b) \int \rho\left(\frac{x-y}{b}\right) V^a(y)dy.$$

7. There is a star-shaped set $S \subset \mathbb{R}^k$ such that, for some $\bar{v} > 0$,

$$\partial S = \left\{x : V^{a,b}(x) = \bar{v}\right\}$$

is twice continuously differentiable. Now define the final Liapunov function $V(y), y \in \mathbb{R}^k - \{0\}$ by

$$V(\alpha x) = \alpha V^{a,b}(x),\ \alpha > 0, x \in \partial S, \quad \text{for } y = \alpha x.$$

8. $V(\cdot)$ is twice continuously differentiable in $\mathbb{R}^k - \{0\}$. For $\alpha > 0, x \neq 0$, $V(\alpha x) = \alpha V(x)$ and $\alpha V_{yy}(y)\big|_{y=\alpha x} = V_{xx}(x)$, and hence $V_{xx}(x)$ goes to zero as $O(1/|x|)$ as $x \to \infty$. There is $\epsilon > 0$ such that for $x \in L - N_\epsilon(0), V'_x(x)\bar{b} \leq -c,\ c > 0$, and for $x \in \mathbb{R}^k - L - N_\epsilon(0)$, $V'_x(x)d \leq -c$, $d \in r(x)$. The bounds in Theorem 4.2 hold.

In our case, $Ax/|x|$ replaces the constant vector $\bar{b}$ in steps 1 and 3, but all other steps and definitions are the same. The radial homogeneity which played such an important part in [11] holds. Suppose that the Liapunov function has the same properties for our case but with $Ax/|x|$ replacing $\bar{b}$. Then $V'_x(x)Ax/|x| \leq -c$ for $x \in L - N_\epsilon(0)$. Hence $V'_x(x)Ax \leq -c|x|$ there. For $x \in \mathbb{R}^k - L - N_\epsilon(0)$, the fact that $V'_x(x)d \leq -c$ for all $d \in r(x)$ implies that $V(x) \leq V(\tilde{x})$, where $\tilde{x} \in \mathbb{R}^k - L - N_\epsilon(0)$ and x is its "projection" onto L in any feasible reflection direction. This fact is used to get that $V(U_{n+1}) \leq V(\tilde{U}_{n+1})$ for large U_n. We next outline the required modifications of the proof in [11]. This will be done in a series of lemmas which go over the main steps in the reference but are adjusted for our case.

The properties of $K^a(\cdot)$ and $K(\cdot)$ given in [11] are easily seen to still hold. Specifically, we have the following:

1. For each $a > 0$, $K^a(\cdot)$ is the convex hull of $\nu + 1$ vector-valued functions that are locally Lipschitz continuous on $\mathbb{R}^k - \{0\}$. This holds since $Ax/|x|$ is locally Lipschitz at $x \neq 0$.
2. For each $a > 0$, $\alpha > 0$, and $x \in \mathbb{R}^k$, $K^a(\alpha x) = K^a(x)$.
3. Let $x \neq 0$. If $d(x, L) \leq a|x|/2$, then $Ax/|x| \in K^a(x)$. If $d(x, \partial L_i) \leq a|x|/2$, then $d_i \in K^a(x)$.
4. Let $\lambda(x) = \{i \leq \nu : x^i < 0\}$. If $d(x, L) > 0$, then $K(x)$ is contained in $\text{conv}\{d_i : i \in \lambda(x)\}$.
5. If $x \in L^0$, the interior of L, then $K(x) = \{Ax/|x|\}$, and if $x \in \partial L$, then

$$K(x) = \text{conv}\left(\{Ax/|x|\} \cup \{d_i : i \in \text{In}(x)\}\right).$$

6. $K(x)$ is an upper-semicontinuous function of $x \in \mathbb{R}^k - \{0\}$, in the sense that $x_n \to x$, $v_n \to v$, and $v_n \in K(x_n)$ implies that $v \in K(x)$.

We say that a solution $\phi(\cdot)$ to a reflected ODE is *attracted to the origin* if for any $\epsilon > 0$ there exists $T < \infty$ such that $t \geq T$ implies that $|\phi(t)| \leq \epsilon$. This is the same as saying that all solutions converge to the origin.

LEMMA A.1 (see Proposition 3.3 in [11]). *Let $\Gamma(a)$ denote the set of solutions to*

$$\dot{\phi}(t) \in K^a\left(\phi(t)\right), \quad \phi(0) = x^a,$$

where $\{x^a,\ a \in (0,\ 1]\}$ is any bounded set in $\mathbb{R}^k$. We then have the following conclusions:

(i) *The set $\{\Gamma(a),\ a \in (0,\ 1]\}$ is precompact.*

(ii) *Suppose that* $a_n \to 0$. *Suppose that* $\phi^{a_n}(\cdot) \to \phi(\cdot)$ *uniformly on each bounded time interval, where* $\phi^{a_n}(\cdot) \in \Gamma(a_n)$, *and* $x^{a_n} = \phi^{a_n}(0) \to x$. *Then we have the following:* (a) *If* $x \in L$, *then modulo a rescaling of time,* $\phi(\cdot), \phi(0) = x$ *solves* (A.1). (b) *If* $x \notin L$, *then* $\phi(\tau) \in L$ *for some* $\tau < \infty$. *Furthermore, modulo a rescaling of time,* $\phi(\cdot + \tau)$ *solves* (A.1).

Comment on the proof. Since $K^a(x)$ is uniformly bounded over all x and a, Ascoli's theorem can easily be applied to prove (i) exactly the same as in [11].

For part (ii), it is first shown in [11] that if $\phi^a(\cdot) \to \phi(\cdot)$, as $a \to 0$, where $\phi^a(\cdot) \in \Gamma(a)$, then $\phi(\cdot)$ satisfies

$$\dot{\phi}(t) \in K(\phi(t)), \text{ almost all } t \in [0, \infty). \tag{A.3}$$

The proof of this relies on the uniform boundedness of $K^a(u)$, which we still have, and the proof is the same as in the reference, except for one point. The proof is slightly different by the fact that a Lipschitz continuous function $\phi(\cdot)$, which satisfies $\dot{\phi}(t) \in K(\phi(t))$ for almost all t, can be written as the convex combination

$$\begin{aligned} \dot{\phi}(t) &= q_0(t)\frac{A\phi(t)}{|\phi(t)|} + \sum_{i \in \mathrm{In}(\phi(t))} q_i(t) d_i, \\ q_0(t) &+ \sum_{i \in \mathrm{In}(\phi(t))} q_i(t) = 1, \end{aligned}$$

where $q_i(t)$ are nonnegative measurable functions. Following the general approach in the reference, Michael's selection theorem [1] is used to obtain the functions $q_i(\cdot)$, $i = 0, \ldots, \nu$. The details are omitted here and can be found in [5].

LEMMA A.2 (see Proposition 3.4 in [11]). *Assume that all solutions of* (A.1) *are attracting to the origin. Then the following conclusions hold:* (i) *Given* $\alpha > 0$, *there exist* $r > 0$ *and* $a_0 > 0$ *such that for all* $a \in (0, a_0)$

$$\dot{\phi} \in K^a(\phi) \quad \textit{and} \quad |\phi(0)| \le r$$

implies that

$$|\phi(t)| \le \alpha \quad \textit{for all } t \ge 0.$$

(ii) *Given* $r > 0$ *and* $R < \infty$, *there exist* $T < \infty$ *and* $a_0 > 0$ *such that, for all* $a \in (0, a_0)$,

$$\dot{\phi} \in K^a(\phi) \quad \textit{and} \quad |\phi(0)| \le R$$

implies that

$$|\phi(t)| \le r \quad \textit{for some } t \le T.$$

Comment on the proof. The proof is the same as in [11]. If part (ii) did not hold, then the assumption that the solutions to (A.1) are attracting to the origin would be violated in view of Lemma A.1. To prove part (i), choose $R = 1$ and $r = 1/2$ in part (ii) of this lemma and define

$$\kappa = \sup_{a \in (0, a_0)} \sup_{\phi(\cdot): |\phi(0)| \le 1, \dot{\phi}(t) \in K^a(\phi(t))} \sup_{0 \le t \le \tau_\phi} |\phi(t)|, \tag{A.4}$$

where $\tau_\phi = \inf\{t : |\phi(t)| \le \frac{1}{2}\}$. We have $\kappa < \infty$ for $a_0 > 0$ sufficiently small; otherwise the assumption of the lemma is violated.

So far we have shown part (i) for the case in which $\alpha = \kappa$, and $r = 1$ can be used. We will now show that given an *arbitrary* $\alpha > 0$, we may choose $r = \alpha/\kappa$. Given $\phi_\alpha(0)$ satisfying $|\phi_\alpha(0)| \le \alpha/\kappa$, define $\phi(0)$ such that $\phi_\alpha(0) = \alpha\phi(0)/\kappa$. For any path $\phi(\cdot)$ with such an initial condition and $\dot\phi \in K^a(\phi)$, define $\tau_{\phi,\alpha,\kappa} = \inf\{t : |\phi(t)| \le \alpha/(2\kappa)\}$. Then from the radial homogeneity of the vector field and (A.4),

$$\alpha = \sup_{a\in(0,a_0)} \sup_{\phi_\kappa(\cdot):\dot\phi_\kappa(t)\in K^a(\phi_\kappa(t)),|\phi_\kappa(0)|\le\alpha/\kappa} \sup_{0\le t\le\tau_{\phi,\alpha,\kappa}} |\phi(t)|,$$

This proves part (i). □

The following lemmas give some properties of $V^a(u)$.

LEMMA A.3 (see Proposition 3.5 in [11]). *Recall the definition of $k(\cdot)$ given below* (A.2). *There exist $a_0 > 0$ and $r_0 > 0$ such that, for all $a \in (0, a_0)$, $V^a(x) = 0$ for $|x| \le r_0$, $V^a(\cdot)$ is finite and locally Lipschitz continuous on $\mathbb{R}^k$, and*

$$[V_x^a(x)]'y \le -k(x) \tag{A.5}$$

for almost all $x \in \mathbb{R}^k - \{0\}$ and every $y \in K^a(x)$.

Comment on the proof. The proof is the same as in [11], but we will make a few comments. The fact that $V^a(x) = 0$ for $a \in (0, a_0)$ and $|x| \le r_0$ follows easily from Lemma A.2. Specifically we have, for $r = r_0$ small enough, that for any $a \in (0, a_0)$, $|\phi(t)| \le 1\ \forall t \ge 0$, where $\dot\phi \in K^a(\phi)$. Thus $k(\phi(t)) = 0\ \forall t \ge 0$, and the result follows from the definition of $V^a(\cdot)$.

That $V^a(\cdot)$ is finite also follows easily from Lemma A.2. By part (ii), for given $r > 0$ and $|x| < R$, there is an a_0 such that for any $a \in (0, a_0)$, $|\phi(t)| \le r$ for some $t < T$. Choosing r small enough and using the analysis in the previous paragraph gives that $0 \le V^a(x) < \infty$ for $|x| < R$. Finally, the radial homogeneity of $K^a(\cdot)$ gives that $0 \le V^a(x) < \infty$ for all x, and where $a > 0$ is sufficiently small.

The proof that $V^a(\cdot)$ is locally Lipschitz follows from the same method given in [11, pp. 693–694]. In particular, recall that $K^a(\cdot)$ is the convex hull of vector value functions that are locally Lipschitz continuous in $\mathbb{R}^k - \{0\}$. The proof that $V^a(\cdot)$ is locally Lipschitz follows from this property and the local Lipschitz continuity of $k(\cdot)$.

We now show (A.5). Let $V^a(\cdot)$ be differentiable at x. From the definition of $V^a(\cdot)$ we know that, for any $\gamma > 0$,

$$V^a(x) \ge \int_0^\gamma k(\phi(s))ds + \int_\gamma^\infty k(\phi(s))ds, \tag{A.6}$$

where $\phi(0) = x$ and $\dot\phi \in K^a(\phi)$. First we will specify a path $\phi(\cdot)$ in the time intervals $[0, \gamma]$ and $[\gamma, \infty)$, where γ is small and $\gamma > 0$. Then we examine (A.6) using this $\phi(\cdot)$.

For $s \in [0, \gamma]$ choose $\phi(\cdot)$ such that $\dot\phi(s) \in K^a(\phi(s))$, but $\dot\phi(s) \to \dot\phi(0)$ as $s \to 0$. Write $w = \phi(\gamma)$. Let $\epsilon > 0$ be arbitrary. For $s \in [\gamma, \infty)$, choose $\phi(s) = \phi^{\epsilon,w}(s - \gamma)$, where $\phi^{\epsilon,w}(\cdot)$ is such that

$$\phi^{\epsilon,w}(0) = w, \quad \dot\phi^{\epsilon,w}(s) \in K^a\left(\phi^{\epsilon,w}(s)\right),$$

and

$$V^a(w) \le \int_0^\infty k(\phi^{\epsilon,w}(s))ds + \epsilon. \tag{A.7}$$

By the continuity of $k(\cdot)$, the first integral in (A.6) can be written as $\gamma k(x)+o(\gamma)$. The second integral can be written as

$$\int_0^\infty k(\phi(s+\gamma))ds = \int_0^\infty k\left(\phi^{\epsilon,w}(s)\right) ds.$$

Thus

$$V^a(x) \geq \gamma k(x) + o(\gamma) + V^a(w) - \epsilon. \tag{A.8}$$

By the fact that $\dot{\phi}(s) \to \dot{\phi}(0)$, $w = x + \gamma\dot{\phi}(0) + o(\gamma)$. Let $\epsilon \to 0$. Then we can write

$$V^a(x) \geq \gamma k(x) + o(\gamma) + V^a(x + \gamma\dot{\phi}(0) + o(\gamma)).$$

Sending $\gamma \to 0$ and using the differentiability of $V^a(\cdot)$ at x gives the result. □

LEMMA A.4 (see Proposition 3.6 in [11]). *There exist constants $d_1 > 0$ and d_2 such that*

$$V^a(x) \geq d_1|x| - d_2. \tag{A.9}$$

Comment on the proof. The proof is the same as in [11]. Since $K^a(\cdot)$ is uniformly bounded, $\dot{\phi}(t) \in K^a(\phi(t))$ is uniformly bounded. Thus there is a lower bound on the time it takes for a solution to the differential inclusion to reach a small neighborhood of the origin. This leads to (A.9). □

LEMMA A.5 (see Proposition 3.7 in [11]). *Let $x \neq 0$ be a point at which $V^a(\cdot)$ is differentiable. Then*

$$[V_x^a(x)]' x/|x| \geq V^a(x)/|x|.$$

Comment on the proof. The proof is the same as in [11]. Let $\alpha > 0$. By radial homogeneity, the evolution of a path $\phi(t)$ satisfying the differential inclusion (A.2) and $\phi(0) = x$ can be used to construct a path $\theta^\alpha(t)$ satisfying the same differential inclusion and $\theta^\alpha(0) = (1+\alpha)x$. That is, we let $\theta^\alpha(t) = (1+\alpha)\phi(t/(1+\alpha))$. From this we can get $V^a((1+\alpha)x) - V^a(x) \geq \alpha V^a(x)$, and the conclusion of the lemma follows from this inequality. □

The construction and properties of $V(\cdot)$. Since $V^a(\cdot)$ is only Lipschitz continuous and our final Liapunov function $V(\cdot)$ needs to be twice continuously differentiable, $V^a(\cdot)$ was smoothed to create $V^{a,b}(\cdot)$:

$$V^{a,b}(x) = c(b) \int \rho\left(\frac{x-y}{b}\right) V^a(y)dy.$$

From (A.5), for large enough $M < \infty$ and $b \in (0,1]$ we have

$$\left[V_x^{a,b}(x)\right]' Ax/|x| \leq -1, \quad |x| \geq M,$$

and

$$\left[V_x^{a,b}(x)\right]' d_i \leq -1, \quad i \in \mathrm{In}(x),\ |x| \geq M. \tag{A.10}$$

Let

$$E = \sup_{x:|x|\leq M_1} V^a(x),$$

where $M \leq M_1 < \infty$ and is such that $[V_x^a(x)]' x/|x| \geq C_0$ for some $C_0 > 0$ when $|x| \geq M_1 - 1$.

The existence of such M and M_1 follows from Lemmas A.4 and A.5. We have the following properties for $V^a(\cdot)$:

(i) $\{x : V^a(x) = E+2\} \subset \{x : M_1 < |x| < M_2\}$, where $M < M_1 < M_2 < \infty$ and M_2 is such that $|x| \geq M_2$ implies $V^a(x) \geq E+3$.
(ii) $[V_x^a(x)]' x/|x| \geq C_0$, for $|x| \geq M_1 - 1$ and some $C_0 > 0$.
(iii) $V^a(x) \leq E$ for $|x| \leq M_1$.

By the local Lipschitz continuity of $V^a(\cdot)$ given in Lemma A.3 and the definition of $V^{a,b}(\cdot)$ it is easy to see that, for small enough b, properties (i)–(iii) hold for $V^{a,b}(\cdot)$ if for part (ii) we substitute $C_0/2$ for C_0 and for part (iii) we substitute $E+1$ for E. Define the set

$$S = \left\{x : V^{a,\,b}(x) \leq E+2\right\}.$$

These properties imply that S is star-shaped; i.e., a segment containing the origin and a point in S is contained in the interior of S. Then, as in [11], the final Liapunov function $V(\cdot)$ is defined by its level sets as

$$\{x : V(x) \leq l\} = \{lx : x \in S\}.$$

The star-shaped property implies that $V(\cdot)$ is well defined; i.e., for each $u \in \mathbb{R}^r$ there exists a unique l such that $u \in \partial(lS)$. These details are in [11, pp. 697–698].

There are several easily seen properties of $V(\cdot)$ which are useful for the tightness proofs of the normalized iterates in section 4. We list these properties and briefly comment on some of them.

P1. $V(\cdot)$ is twice continuously differentiable on $\mathbb{R}^k - \{0\}$. The proof uses the implicit function theorem, and the details are in [11, pp. 697–698].
P2. $V(\alpha x) = \alpha V(x)$. This is easily seen from the construction of $V(\cdot)$.
P3. $V_y(y)\big|_{y=\alpha x} = V_x(x)$.
P4. $\alpha V_{yy}(y)\big|_{y=\alpha x} = V_{xx}(x)$. Hence $|V_{xx}(x)| \to 0$ as $1/|x|$.
P5. For some real $c_1 > 0$, $c_2 > 0$, and $d_1 > 0$, $c_1|x| + c_2 \geq V(x) \geq d_1|x|$. This is a consequence of the fact that the gradient in the radial direction is constant.
P6. For $x \in \mathbb{R}^k - \{0\}$, $0 < V(x)/|x| \leq C$ for some $C > 0$. To see this, from P5 we have

$$c_1 + \frac{c_2}{|x|} \geq \frac{V(x)}{|x|} \geq d_1 > 0.$$

Since $V(\alpha x)/|\alpha x| = V(x)/|x|$, substituting αx for x in the above inequality, where α is arbitrarily large, we have that for some $C > c_1$

$$0 < \frac{V(x)}{|x|} \leq C \quad \text{for } x \in \mathbb{R}^K - \{0\}.$$

P7. There exists a $c > 0$ such that
$V_x'(x)Ax/|x| \leq -c$ and
$V_x'(x)d_i \leq -c$, $i \in \mathrm{In}(x)$.
This follows from the analogous inequalities for $V^{a,b}(\cdot)$.
P8. With the definition $V(0) = 0$, $V(\cdot)$ is continuous on $\mathbb{R}^k$ and globally Lipschitz continuous. The continuity follows from the construction. The global Lipschitz continuity follows from property P6.
P9. $V(x) \leq V(\tilde{x})$, where $\tilde{x} \in \mathbb{R}^k - L - N_\epsilon(0)$ and its projection onto L is x. This follows from P7.

NONLINEAR TRACKING OVER COMPACT SETS WITH LINEAR DYNAMICALLY VARYING H^∞ CONTROL*

STEPHAN BOHACEK† AND EDMUND JONCKHEERE†

Abstract. Linear dynamically varying H^∞ controllers are developed for tracking natural trajectories of a broad class of nonlinear systems defined over compact sets. It is shown that the existence of a suboptimal H^∞ controller is related to the existence of a bounded solution to a functional algebraic Riccati equation. Even though nonlinear systems running over compact sets could exhibit sensitive dependence on initial conditions, the Riccati solution is continuous in the suboptimal case, but it may be discontinuous in the optimal case.

Key words. nonlinear systems, trajectory tracking, linear parametrically and dynamically varying systems, state space H^∞ robust control, functional algebraic Riccati equation

1. Introduction.

Nonlinear tracking has been thoroughly investigated. A popular approach is to linearize the system around an operating point, generate a linear controller for each operating point, and "schedule" the controllers in such a way that the closed-loop system remains stable as the operating point changes. In this approach, the nonlinear tracking error system is modeled, approximately, as a linear system with parameters that vary as the operating point varies. Such systems have been extensively studied [3], [4], [5], [6], [25], [28], [33] and are known as *linear parametrically varying* (LPV) systems.

For the purpose of comparing the various LPV concepts, it is convenient to introduce *linear set-valued dynamically varying* (LSVDV) systems [11]:

$$\text{(1)}\qquad \begin{bmatrix} x(k+1) \\ z(k) \end{bmatrix} = \begin{bmatrix} A_{\theta(k)} & B_{1_{\theta(k)}} & B_{2_{\theta(k)}} \\ C_{\theta(k)} & D_{1_{\theta(k)}} & D_{2_{\theta(k)}} \end{bmatrix} \begin{bmatrix} x(k) \\ w(k) \\ u(k) \end{bmatrix},$$
$$\theta(k+1) \in \mathcal{F}(\theta(k)) \subseteq \Theta,$$
$$\text{with } \theta(0) = \theta_o \text{ and } x(0) = x_o.$$

Here the parameter vector θ varies according to a set-valued dynamical system, continuous for the Hausdorff metric; w is the disturbance input, u the control, and z the controlled output.

In the most traditional LPV approach [4], [6], [5], [23], [25], all that is known about the parameter dynamics is that $\mathcal{F}(\theta) = \Theta$. The advantage of this model is that if Θ is a convex polytope, then there are many computationally efficient controller synthesis methods [14]. Most of these approaches generate a suboptimal solution via a *linear matrix inequality* (LMI). However, these approaches can be conservative.

A slight refinement of the above LPV method consists of putting bounds on the rate at which the system parameters vary, i.e., $\mathcal{F}(\theta(k)) = \mathcal{B}_{\theta(k)}(\Delta)$, the ball with

radius Δ and with its center at $\theta(k)$. There are efficient methods based on functional LMIs for designing controllers for these modified LPV systems [16], [33], [34], [35]. However, these design methods could fail when the parameters vary drastically, for example, when the controller needs to account for failures which lead to sudden changes in the system parameters [21]. Also, typically, these methods are conservative. Nonconservative LPV approaches are pursued in [11] and [29].

Another popular type of LPV system is the *jump linear* (JL) system [15], [19]. Here $\Theta = \{\Theta_1, \Theta_2, \dots\}$ is discrete, and $\mathcal{F}(\theta(k))$ is equipped with a probability measure depending on $\theta(k)$ only, so that the transition among the Θ_i's is a Markov chain. The jump linear method for designing a controller for a such system is optimal (hence, nonconservative). The controller is provided by the solution to a system of coupled Riccati equations. Furthermore, there are efficient methods to compute the optimal controller [1], [2], [12].

A *linear dynamically varying* (LDV) system is a LSVDV system in which the parameter dynamics are completely known, that is, $\mathcal{F}(\theta(k))$ is reduced to a point $f(\theta(k))$. In [8] it was shown that a linear-quadratic (LQ) controller for such a system (with $w = 0$) can be found by solving a *functional* algebraic Riccati equation (FARE). It should be noted that this functional algebraic Riccati *equation* is the LDV substitute for the functional linear matrix *inequality* of most other LPV approaches. Furthermore, the FARE of LDV design provides the *optimal* solution, while the functional LMI only provides a *suboptimal* solution. The mathematical difficulty with the LDV approach is proving that the solution to the FARE is continuous, in which case the feedback gain matrix is a continuous function of the parameters. The LPV approaches described above avoid this continuity question by assuming a priori that the solution to the relevant functional LMI is continuous [33], polynomial [35], affine [16], [34], or even constant [4], [6], [5], [23], [25]. Since an arbitrary accuracy approximation of a discontinuous function has to duplicate the *exact* behavior at the discontinuity points, which are potentially uncountable in number, a discontinuous solution is numerically intractable, so that the continuity assumption is justifiable. However, it is important to know how constraining this continuity assumption is.

Tracking trajectories of the important class of hyperbolic nonlinear systems on compact sets can be accomplished by modeling the dynamics as a Markov chain [22] and resorting to JL methods. However, the resulting closed-loop system is only *stochastically* stable, and it is not possible to show directly that the system is robustly stable. For this reason, the typical JL approach is not appropriate for the nonlinear tracking problem. The connection between JL and LDV control systems designs is examined in [10].

While in [8] LDV systems were stabilized using LQ methods, here the same systems are stabilized by means of H^∞ methods. This paper shows that, if the parameter dynamics are completely known, then the existence of a suboptimal H^∞ controller is equivalent to the existence of a continuous solution to the FARE. Of particular interest are LDV systems that arise as linearized versions of nonlinear tracking error dynamics. In this case, it can be shown that the linearization error is a bounded feedback around the linearized system, so that the H^∞ formulation is well-suited to minimize the effect of the error due to linearization and amplify the domain of attraction.

The paper proceeds as follows. The next section formalizes the tracking control problem of interest and shows how the tracking error dynamics can be approximated as an LDV system. Section 3 formally develops LDV systems. Section 4 develops the

suboptimal H^∞ controller for this class of systems. Section 5 provides the proofs of the main technical results. Section 6 shows that these linear controllers are suitable for stabilization of nonlinear dynamical systems.

Notation: $|x(k)| := (x'(k)\,x(k))^{1/2}$, $\|x\|_{[k,j]} := (\sum_{i=k}^{j} x'(i)\,x(i))^{1/2}$, and $\|x\|_{l_2} := \|x\|_{[0,\infty)}$. If $x \in \mathbb{R}^n$, then $\|x\|_\infty := \max_{i\le n} |x_i|$ and, if $x \in \mathbb{R}^{n\times\mathbb{Z}}$, then $\|x\|_{l_\infty} := \sup_{k\in\mathbb{Z}} |x(k)|$. If A is a matrix, then $\|A\| := \sup_{|x|=1} |Ax|$, whereas, if $T : l_2 \to l_2$, then $\|T\| := \sup_{\|x\|_{l_2}=1} \|Tx\|_{l_2}$; the context in which these norms are used will resolve potential confusion. If $f : \Theta \times \mathbb{R}^m \to \Theta$ with $\Theta \subset \mathbb{R}^n$, then $\frac{\partial f}{\partial \theta}(\theta, u)$ denotes the Jacobian matrix of f where the derivatives are taken with respect to θ and are evaluated at $(\theta, u) \in \Theta \times \mathbb{R}^m$. Define $\frac{\partial f}{\partial u}(\theta, u)$ similarly. With reference to system (1), let $z_{\theta_o}(u, w, x_o)$ denote the output signal z due to initial conditions $\theta(0) = \theta_o$ and $x(0) = x_o$, and input signals u and w. Let $z_{\theta_o}(u, w, x_o; k)$ denote this output at time k. Let $z_{\theta_o}(F, w, x_o)$ and $z_{\theta_o}(F, w, x_o; k)$ be defined similarly, except that the control u is replaced by the control law defined by F. For succinctness, we often write $f(\theta) := f(\theta, 0)$.

2. Problem statement. A dynamical system $\theta(k+1) = f(\theta(k))$, where $f \in C^1(\mathbb{R}^n, \mathbb{R}^n)$, gives rise to a string of nested invariant subsets $P(f) \subseteq \overline{P(f)} \subseteq \overline{R(f)} \subseteq NW(f)$, where $P(f)$ is the periodic set, $\overline{P(f)}$ its closure, $\overline{R(f)}$ the closure of the recurrent set, and $NW(f)$ the nonwandering set [22]. We specifically consider systems where $NW(f)$ is bounded, in which case $\overline{P(f)}$, $\overline{R(f)}$, and $NW(f)$ are compact, and we choose the domain Θ to be any of those compact invariant sets. More generally, Θ could be taken to be any compact invariant subset. In particular, if f is an Axiom A diffeomorphism satisfying the strong transversality condition, then $NW(f)$ is a disjoint union of attractors [27], which by definition are compact and invariant and hence could be taken to be Θ. If the uniform hyperbolic conditions fails, f could still have an attractor, which could be taken to be Θ.

We take the control u to be a small perturbation of the parameters of the nominal dynamics f. More specifically, the nominal and perturbed dynamics are, respectively,

$$\theta(k+1) = f(\theta(k), 0) + v_1(k), \quad \text{with } \theta(0) = \theta_o, \tag{2}$$

$$\varphi(k+1) = f(\varphi(k), u(k)) + v_2(k), \quad \text{with } \varphi(0) = \varphi_o, \tag{3}$$

where

1.
$$f \in C^1(\mathbb{R}^n \times \mathbb{R}^m, \mathbb{R}^n); \tag{4}$$

2. $f(\Theta, 0) \subset \Theta$, i.e., Θ is f-invariant, and $f(\cdot, 0) : \Theta \to \Theta$;
3. Θ is a compact subset of $\mathbb{R}^n$.

Here $\{\theta(k) : k \ge 0\}$ is the desired trajectory, and $\varphi(k)$ is the state of the system under control. The exogenous inputs $v_1(k)$ and $v_2(k)$ are typically small with $\theta(k+1) \in \Theta$. The purpose of v_1 is to allow the desired trajectory to occasionally jump from a point on one orbit to a nearby point on another orbit [9]. On the other hand, v_2 is to allow for some modeling inaccuracies. At time k, it is assumed that both $\theta(k)$ and $\varphi(k)$ are known. The basic objective is to find a control u such that, when $v_1 = v_2 = 0$ and for $|\theta(0) - \varphi(0)|$ small enough, we have $\lim_{k\to\infty} |\varphi(k) - \theta(k)| = 0$.

A distinguishing feature of the present approach is that the tracking controller takes the form of a *spatially varying* gain $F : \Theta \to \mathbb{R}^{m\times n}$, guaranteed to be continuous under suitable conditions. As the first and most generic application, given

an *arbitrary* desired trajectory $\{\theta(k) : k = 0, \dots\}$, evaluating the controller F along the trajectory $\{\theta(k) : k = 0, \dots\}$ yields the time-varying controller $F_{\theta(k)}$ that makes the nonlinear system $\varphi(k+1) = f(\varphi(k), F_{\theta(k)}(\varphi(k) - \theta(k)))$ asymptotically track $\theta(k+1) = f(\theta(k))$. More importantly, the *globally* defined controller F becomes fully motivated in those specialized applications where there is a need to quickly adapt the tracking controller to a new reference trajectory without recomputing a new time-varying controller along the new trajectory [9], [13], [20], [21].

If $v_1 = v_2 = 0$, then stability of the closed-loop system, which implies asymptotic tracking, is guaranteed if $|\varphi(0) - \theta(0)| < R_{Capture}$, where $R_{Capture} > 0$. If $v_1 \neq 0$ and/or $v_2 \neq 0$, then asymptotic tracking can still be guaranteed if $\|v_1 - v_2\|_{l_\infty}$ and $|\varphi(0) - \theta(0)|$ are small enough and $v_1(k) - v_2(k)$ is intermittent enough. If $v_1 - v_2$ is persistent, then one cannot expect asymptotic tracking; however, under suitable conditions, the gain $\frac{\|\theta - \varphi\|_{\ell_\infty}}{\|v_1 - v_2\|_{\ell_\infty}}$ can easily be shown to be bounded [7]. Besides, the effect of the model uncertainty v_2 can be minimized using standard H^∞ methods. Therefore we shall not pursue investigation of the effects of v_1, v_2 any further.

The tracking controller design relies on linearizing the tracking error dynamics as follows. Define the tracking error

$$x(k) := \varphi(k) - \theta(k).$$

Then

$$x(k+1) = f(\varphi(k), u(k)) - f(\theta(k), 0).$$

The first-degree Taylor approximation of $f(\varphi(k), u(k))$ around $\varphi(k) = \theta(k)$ and $u(k) = 0$ yields

$$\begin{aligned} f(\varphi(k), u(k)) = {} & f(\theta(k), 0) + A_{\theta(k)}(\varphi(k) - \theta(k)) \\ & + B_{2_{\theta(k)}} u(k) + \eta(x(k), u(k), \theta(k)), \end{aligned}$$

where

$$A_\theta := \frac{\partial f}{\partial \theta}(\theta, 0), \quad B_{2_\theta} := \frac{\partial f}{\partial u}(\theta, 0), \tag{5}$$

and $\eta(x(k), u(k), \theta(k))$ accounts for nonlinear terms. Thus

$$x(k+1) = A_{\theta(k)} x(k) + B_{2_{\theta(k)}} u(k) + \eta(x(k), u(k), \theta(k)). \tag{6}$$

Since $f \in C^1$, η can be decomposed as

$$\eta(x(k), u(k), \theta(k)) = \eta_x(x(k), u(k), \theta(k))\, x(k) + \eta_u(x(k), u(k), \theta(k))\, u(k), \tag{7}$$

where

$$\eta_x(x, u, \theta)_{i,j} = \int_0^1 \left(\frac{\partial f_i}{\partial x_j}(tx + \theta, tu) - \frac{\partial f_i}{\partial x_j}(\theta, 0) \right) dt \tag{8}$$

and

$$\eta_u(x, u, \theta)_{i,j} = \int_0^1 \left(\frac{\partial f_i}{\partial u_j}(tx + \theta, tu) - \frac{\partial f_i}{\partial u_j}(\theta, 0) \right) dt. \tag{9}$$

Since $f \in C^1$ and Θ is compact, if x and u are bounded, then $\frac{\partial f_i}{\partial x_j}(tx+\theta, tu) - \frac{\partial f_i}{\partial x_j}(\theta, 0)$ is uniformly continuous. In particular, for any $\varepsilon > 0$ there is a $\delta > 0$ such that, if $|x|, |u| < \delta$, then $|\frac{\partial f_i}{\partial x_j}(tx+\theta, tu) - \frac{\partial f_i}{\partial x_j}(\theta, 0)| < \varepsilon$. Therefore,

$$\lim_{\bar{x}\to 0, \bar{u}\to 0} \sup\{\|\eta_x(x,u,\theta)\| : |x| < \bar{x},\ |u| < \bar{u},\ \theta \in \Theta\} = 0 \tag{10}$$

and

$$\lim_{\bar{x}\to 0, \bar{u}\to 0} \sup\{\|\eta_u(x,u,\theta)\| : |x| < \bar{x},\ |u| < \bar{u},\ \theta \in \Theta\} = 0. \tag{11}$$

If u and x are small, we can approximate the error dynamics as

$$\begin{aligned} x(k+1) &= A_{\theta(k)} x(k) + B_{2_{\theta(k)}} u(k), \\ \theta(k+1) &= f(\theta(k), 0). \end{aligned} \tag{12}$$

This system is linear in the tracking error x, but the coefficient matrices A and B vary (generally in a nonlinear way) as θ varies. Since $\theta(k)$ varies according to (2), the system described in (12) is an *LDV* system. Before controllers can be developed for such systems, linear systems with dynamically varying parameters must be formalized.

3. Linear dynamically varying systems and LQ control. Motivated by the preceding considerations, a general LDV system is defined as

$$\begin{bmatrix} x(k+1) \\ z(k) \end{bmatrix} = \begin{bmatrix} A_{\theta(k)} & B_{1_{\theta(k)}} & B_{2_{\theta(k)}} \\ C_{\theta(k)} & D_{1_{\theta(k)}} & D_{2_{\theta(k)}} \end{bmatrix} \begin{bmatrix} x(k) \\ w(k) \\ u(k) \end{bmatrix}, \tag{13}$$

$$\begin{aligned} \theta(k+1) &= f(\theta(k)), \\ \text{with } \theta(0) &= \theta_o \text{ and } x(0) = x_o, \end{aligned} \tag{14}$$

subject to the following general conditions:

1. $\Theta \subset \mathbb{R}^n$ is compact and $f : \Theta \to \Theta$ is a continuous function.
2. $A : \Theta \to \mathbb{R}^{n\times n}$, $B_1 : \Theta \to \mathbb{R}^{n\times l}$, $B_2 : \Theta \to \mathbb{R}^{n\times m}$, $C : \Theta \to \mathbb{R}^{p\times n}$, $D_1 : \Theta \to \mathbb{R}^{p\times l}$, and $D_2 : \Theta \to \mathbb{R}^{p\times m}$ are functions that need not be continuous.

In the above, $\theta(k) \in \Theta$ is the state of the dynamic system, $x(k) \in \mathbb{R}^n$ is the state of the linear system, $u(k) \in \mathbb{R}^m$ is the control input, $w(k) \in \mathbb{R}^l$ is the disturbance input, and $z(k) \in \mathbb{R}^p$ is the output to be controlled.

It is often assumed that the system coefficient matrices A, B_1, B_2, C, D_1, and D_2 are continuous. We will refer to such systems as *continuous* LDV systems. In section 2 it was assumed that $f \in C^1$, and since A and B are matrices of partial derivatives of f, A and B are indeed continuous. Thus the tracking error system associated with (2) and (3) can be approximated by a *continuous* LDV system. However, if a feedback $F : \Theta \to \mathbb{R}^{m\times n}$ is used to stabilize a continuous LDV system, then the resulting closed-loop system is a continuous LDV system if and only if F is continuous. Although this paper will focus on stabilizing continuous LDV systems, we cannot assume a priori that the feedback is continuous. Therefore the definition of an LDV system must allow for possibly discontinuous coefficient matrices.

Since an LDV system is an uncountable collection of linear time-varying systems indexed by $\theta(0)$, the concept of stability is slightly more complex in the dynamically varying case than it is in the time-varying case.

DEFINITION 3.1. *The LDV system* (13) *is uniformly exponentially stable if, for* $u(k) = 0$ *and* $w(k) = 0$, *there exist an* $\alpha \in [0,1)$ *and a* $\beta < \infty$ *such that, for all* $\theta(0) \in \Theta$,

$$|x(k)| \leq \beta \alpha^k |x(0)|.$$

System (13) *is exponentially stable if, for* $u(k) = 0$, $w(k) = 0$, *and for each* $\theta(0) \in \Theta$, *there exist an* $\alpha_{\theta(0)} \in [0,1)$ *and a* $\beta_{\theta(0)} < \infty$ *such that, for all* $x(j)$ *and* $j \leq k$,

$$|x(k)| \leq \beta_{\theta(0)} \alpha_{\theta(0)}^{k-j} |x(j)|.$$

System (13) *is asymptotically stable if, for* $u(k) = 0$, $w(k) = 0$, *any* $|x(0)| < \infty$, *and any* $\theta(0) \in \Theta$,

$$|x(k)| \to 0 \quad \text{as} \quad k \to \infty.$$

Note that an exponentially stable system is stable uniformly in time k, but not necessarily uniformly in the initial condition $\theta(0)$. That is, along any given positive trajectory $\left\{f^k(\theta(0)) : k \geq 0\right\}$, an exponentially stable system is (uniformly in time) exponentially stable; however, if $\{\theta(0)_i : i \geq 0\}$ is a convergent sequence, with $\theta(0) = \lim_{i\to\infty} \theta(0)_i$, it is possible that $\alpha_{\theta(0)_i} \to 1$ while $\alpha_{\theta(0)} < 1$, in which case the system is exponentially stable, but not $\theta(0)$-uniformly exponentially stable. To emphasize the difference between exponential and uniformly exponential stability, exponential stability will occasionally be referred to as uniform *in time* exponential stability.

In the case of continuous LDV systems, asymptotic, exponential, and uniform exponential stability are equivalent (Proposition 2 in [8]). Since uniformly exponentially stable systems are inherently more robust than exponentially stable systems, it is preferable to remain within the confines of continuous LDV systems. Thus, when synthesizing a feedback for controlling a continuous LDV system, it is important to ensure that the feedback is not only asymptotically stabilizing but also continuous. However, to maintain generality, an LDV system is considered stabilizable if there exists an exponentially stabilizing feedback, that is, the following holds.

DEFINITION 3.2. *System* (13) *is stabilizable if there exists a (not necessarily continuous) function* $F : \mathbb{Z} \times \Theta \to \mathbb{R}^{m\times n}$ *with bound* $\overline{F}_{\theta(0)} < \infty$ *such that, for all* $\theta(0) \in \Theta$ *and for all* $k \geq 0$, *we have* $\left\|F_{\theta(0)}(k)\right\| \leq \overline{F}_{\theta(0)}$, *and the system*

$$\begin{aligned} x(k+1) &= \left(A_{\theta(k)} + B_{2_{\theta(k)}} F_{\theta(0)}(k)\right) x(k), \\ \theta(k) &= f^k(\theta(0)) \end{aligned}$$

is exponentially stable. That is, there exist $\alpha_{\theta(0)} \in [0,1)$ *and* $\beta_{\theta(0)} < \infty$ *such that, for any* $\theta(0) \in \Theta$, *there exists a time-varying, bounded feedback* $F_{\theta(0)}(k)$, *which may depend on* $\theta(0)$, *such that*

$$\left\| \prod_{i=j}^{k-1} \left(A_{f^i(\theta(0))} + B_{2_{f^i(\theta(0))}} F_{\theta(0)}(i) \right) \right\| \leq \beta_{\theta(0)} \alpha_{\theta(0)}^{k-j},$$

where the factors of the matrix product are taken in the proper order.

Therefore, along every trajectory $\left\{f^k(\theta(0)) : k \geq 0\right\}$, the time-varying system is (uniformly in time) exponentially stabilizable by means of a function F which, as defined in Definition 3.2, depends on the initial condition $\theta(0)$. In this sense, the

control is not quite "closed-loop," and more importantly there are no assumptions about the global properties of the feedback F. In particular, the feedback may not be a continuous nor even a uniformly bounded function of $\theta(0)$. However, in the case of continuous LDV systems, it was shown in [8] that a stabilizable system has a continuous, uniformly exponentially stabilizing feedback $F : \Theta \to \mathbb{R}^{m\times n}$. In this case, the feedback gain takes the form $F_{\theta(k)}$ and does not depend on the initial condition $\theta(0)$, but only the current state $\theta(k)$. Hence the controller is "closed-loop."

The dual concept of detectability has two versions. The first one is *uniform* detectability.

DEFINITION 3.3. *System* (13) *is uniformly detectable if there exists a (not necessarily continuous) function* $H : \Theta \to \mathbb{R}^{n\times p}$ *with uniform bound* $\bar{H} < \infty$ *such that, for all* $\theta \in \Theta$, *we have* $\|H_\theta\| \le \bar{H}$, *and the system*

$$\begin{aligned} x(k+1) &= \left(A_{\theta(k)} + H_{\theta(k)}C_{\theta(k)}\right)x(k), \\ \theta(k) &= f^k(\theta(0)) \end{aligned}$$

is uniformly exponentially stable. That is, there exist an $\alpha_d \in [0,1)$ *and a* $\beta_d < \infty$ *such that, for all* $\theta(0) \in \Theta$,

$$\|x(k)\| \le \beta_d \alpha_d^k \|x(0)\|.$$

DEFINITION 3.4. *System* (13) *is detectable if there exists a (not necessarily continuous), function* $H : \mathbb{Z} \times \Theta \to \mathbb{R}^{n\times p}$ *with bound* $\bar{H}_{\theta(0)} < \infty$ *such that, for all* $\theta(0) \in \Theta$ *and all* k, *we have* $\left\|H_{\theta(0)}(k)\right\| \le \overline{H}_{\theta(0)} < \infty$, *and the system*

$$\begin{aligned} x(k+1) &= \left(A_{\theta(k)} + H_{\theta(0)}(k)\, C_{\theta(k)}\right)x(k), \\ \theta(k) &= f^k(\theta(0)) \end{aligned}$$

is exponentially stable.

If f is invertible, the LDV system has an adjoint system running backwards in time. If a continuous LDV is detectable and f is invertible, then the adjoint system is stabilizable. It is easily shown that this implies that the adjoint LDV is in fact *uniformly* stabilizable and therefore that the LDV system is *uniformly* detectable. Thus, if f is invertible and the LDV system is continuous, then uniform detectability and detectability are equivalent. Although stabilizability and uniform detectability are slightly asymmetric, to avoid putting extra assumptions on f, stabilizable and uniformly detectable continuous LDV systems will be considered.

Since stabilizability only depends on A, B_2, and f, we will say that the triple (A, B_2, f) is stabilizable to mean that system (13) is stabilizable. Similarly, we say that the triple (A, C, f) is uniformly detectable to mean that system (13) is uniformly detectable.

Since an LDV system is a collection of time-varying systems, the following time-varying Lyapunov stability theorem is useful.

THEOREM 3.5. *Assume that system* (13) *is uniformly detectable and* $w \equiv 0$. *Then there exist an* $\alpha_{\theta_o} \in [0,1)$ *and a* $\beta_{\theta_o} < \infty$ *such that, for* $\theta(0) = \theta_o$ *and any* $x(j) \in \mathbb{R}^n$,

$$|x(k)| \le \beta_{\theta_o} \alpha_{\theta_o}^{k-j} |x(j)|$$

if and only if there exists a sequence $\left\{X_{f^k(\theta_o)} : k \ge 0\right\}$ *with bound* $\bar{X} : \Theta \to \mathbb{R}$ *such that* $\left\|X_{f^k(\theta_o)}\right\| \le \bar{X}_{\theta_o} < \infty$, $X_{f^k(\theta_o)} = X'_{f^k(\theta_o)} \ge 0$, *and*

$$A'_{f^k(\theta_o)} X_{f^{k+1}(\theta_o)} A_{f^k(\theta_o)} - X_{f^k(\theta_o)} \le -C'_{f^k(\theta_o)} C_{f^k(\theta_o)}. \tag{15}$$

Furthermore, if (15) *is satisfied, then* α_{θ_o} *and* β_{θ_o} *can be taken to depend only on the bound* $\bar{X}_{\theta_o}$ *and on* α_d *and* β_d *in the definition of detectability.*

Proof. For $\theta(0)$ fixed, the system is a time-varying system. Thus the theorem is simply a statement about the stability of linear time-varying systems and can be found on page 41 in [18]. □

COROLLARY 3.6. *Assume that system* (13) *is uniformly detectable and* $w \equiv 0$. *Then there exist an* $\alpha \in [0,1)$ *and a* $\beta < \infty$ *such that*

$$|x(k)| \leq \beta \alpha^k |x(0)|$$

if and only if there exists a uniformly bounded function $X : \Theta \to \mathbb{R}^{n \times n}$ *with* $X_\theta = X_\theta' \geq 0$ *such that, for all* $\theta_o \in \Theta$,

$$A'_{f^k(\theta_o)} X_{f^{k+1}(\theta_o)} A_{f^k(\theta_o)} - X_{f^k(\theta_o)} \leq -C'_{f^k(\theta_o)} C_{f^k(\theta_o)}. \tag{16}$$

Proof. Since X_θ is uniformly bounded and the system is uniformly detectable, Theorem 3.5 can be applied at each $\theta_o \in \Theta$. □

The main result of [8] is the following.

THEOREM 3.7. *Suppose that these conditions hold.*

1. $f : \Theta \to \Theta$ *is continuous and* Θ *is compact.*
2. *The functions* A, B_2, C, D_2 *are continuous.*
3. $D'_{2_\theta} D_{2_\theta} > 0$.
4. $C'_\theta D_{2_\theta} = 0$ *for all* $\theta \in \Theta$, *and* (A, C, f) *is uniformly detectable.*

Then the triple (A, B_2, f) *is stabilizable if and only if there exists a unique, uniformly bounded solution* $X_2 : \Theta \to \mathbb{R}^{n \times n}$ *such that*

1. X_2 *satisfies the FARE*

$$\begin{aligned} X_{2_\theta} &= A'_\theta X_{2_{f(\theta)}} A_\theta \\ &\quad - A'_\theta X_{2_{f(\theta)}} B_{2_\theta} \left(D'_{2_\theta} D_{2_\theta} + B'_{2_\theta} X_{2_{f(\theta)}} B_{2_\theta} \right)^{-1} B'_{2_\theta} X_{2_{f(\theta)}} A_\theta + C'_\theta C_\theta; \end{aligned} \tag{17}$$

2. $X_{2_\theta} \geq 0$.

In this case, the closed-loop control

$$u_{LQ}(k) := -\left(D'_{2_{\theta(k)}} D_{2_{\theta(k)}} + B'_{2_{\theta(k)}} X_{2_{f(\theta(k))}} B_{2_{\theta(k)}} \right)^{-1} B'_{2_{\theta(k)}} X_{2_{f(\theta(k))}} A_{\theta(k)} x(k) \tag{18}$$

uniformly exponentially stabilizes system (13). *Moreover, for* $|x(0)| < \infty$ *and* $w \equiv 0$,

$$x'(0) X_{2_{\theta(0)}} x(0) = \inf \left\{ \sum_{k=0}^{\infty} |z(k)|^2 : u \in l_2 \right\}, \tag{19}$$

where the infimum is attained for $u = u_{LQ}$. *Furthermore,* X_2 *is a uniformly continuous function. Finally, if* $X_{2_\theta}(k, N+1)$ *solves the finite horizon Riccati equation, i.e.,*

$$\begin{aligned} X_{2_\theta}(k, N+1) &= A'_{f^k(\theta)} X_{2_\theta}(k+1, N+1) A_{f^k(\theta)} + C'_{f^k(\theta)} C_{f^k(\theta)} \\ &\quad - A'_{f^k(\theta)} X_{2_\theta}(k+1, N+1) B_{2_{f^k(\theta)}} \\ &\quad \times \left(D'_{2_{f^k(\theta)}} D_{2_{f^k(\theta)}} + B'_{2_{f^k(\theta)}} X_{2_\theta}(k+1, N+1) B_{2_{f^k(\theta)}} \right)^{-1} \\ &\quad \times B'_{2_{f^k(\theta)}} X_{2_\theta}(k+1, N+1) A_{f^k(\theta)} \end{aligned} \tag{20}$$

with

$$X_{2_\theta}(N+1,N+1) = C'_{f^{N+1}(\theta)} C_{f^{N+1}(\theta)},$$

then $X_{2_\theta}(0,N+1) \to X_{2_\theta}$ *uniformly in* θ.

4. Linear dynamically varying H^∞ control. In the following, the H^∞ control problem for LDV systems of the general form (13) will be formulated and the solution will be provided. There are two related problems.

The first is the finite horizon problem. For all $\theta \in \Theta$, let the terminal weighting $X_\theta(N+1,N+1) \geq 0$ be given. The objective in this problem is to find a controller F_u such that, if

$$u(k) = F_{u_{\theta_o}}(k,N+1) \begin{bmatrix} x(k) \\ w(k) \end{bmatrix} \quad \text{for } k \leq N,$$

then we have the following.

Objective A. For $x(0) = 0$ there exists an $\varepsilon > 0$ such that, for $w \in l_2[0,N]$ and $\theta_o \in \Theta$,

$$\|z\|^2_{[0,N]} - \gamma^2 \|w\|^2_{[0,N]} + x'(N+1) X_{\theta_o}(N+1,N+1) x(N+1) \leq -\varepsilon \|w\|^2_{[0,N]}.$$

The second problem is the infinite horizon problem, where the objective is to find a uniformly exponentially stabilizing controller F_u such that, if

$$u(k) = F_{u_{\theta_o}}(k) \begin{bmatrix} x(k) \\ w(k) \end{bmatrix},$$

then our objective becomes the following.

Objective B. For $x(0) = 0$ there exists an $\varepsilon > 0$ such that, for $w \in l_2$ and $\theta_o \in \Theta$,

$$\|z\|^2_{l_2} - \gamma^2 \|w\|^2_{l_2} \leq -\varepsilon \|w\|^2_{l_2},$$

and if $w = 0$ and $x(0) \neq 0$, then $x(k) \to 0$.

If Objective B is achieved, then

$$\frac{\|z\|_{l_2}}{\|w\|_{l_2}} < \gamma.$$

It will be shown that the solution to Objective B is the limit as $N \to \infty$ of solutions to Objective A.

4.1. Finite horizon full information controller. For notational simplicity, we define

$$\begin{bmatrix} A_\theta & \bar{B}_\theta \\ \bar{C}_\theta & \bar{D}_\theta \end{bmatrix} := \begin{bmatrix} A_\theta & B_{1_\theta} & B_{2_\theta} \\ C_\theta & D_{1_\theta} & D_{2_\theta} \\ 0 & I_l & 0 \end{bmatrix} \quad \textit{and} \quad J =: \begin{bmatrix} I_p & 0 \\ 0 & -\gamma^2 I_l \end{bmatrix}.$$

Let $X_{\theta_o}(N+1,N+1) \geq 0$ be given. In a recursive manner, define

$$\begin{aligned} X_{\theta_o}(k,N+1) = {} & A'_{f^k(\theta_o)} X_{\theta_o}(k+1,N+1) A_{f^k(\theta_o)} + C'_{f^k(\theta_o)} C_{f^k(\theta_o)} \\ & - L_{\theta_o}(k,N+1)' R^{-1}_{\theta_o}(k,N+1) L_{\theta_o}(k,N+1), \end{aligned} \tag{21}$$

where

$$R_{\theta_o}(k,N+1) := \bar{D}'_{f^k(\theta_o)} J \bar{D}_{f^k(\theta_o)} + \bar{B}'_{f^k(\theta_o)} X_{\theta_o}(k+1,N+1)\, \bar{B}_{f^k(\theta_o)}, \tag{22}$$

$$L_{\theta_o}(k,N+1) := \bar{D}'_{f^k(\theta_o)} J \bar{C}_{f^k(\theta_o)} + \bar{B}'_{f^k(\theta_o)} X_{\theta_o}(k+1,N+1)\, A_{f^k(\theta_o)}. \tag{23}$$

We partition $R = \left[\begin{smallmatrix} R_1 & R_2' \\ R_2 & R_3 \end{smallmatrix}\right]$ and $L = \left[\begin{smallmatrix} L_1 \\ L_2 \end{smallmatrix}\right]$ such that $R_3 \in \mathbb{R}^{m\times m}$ and $L_2 \in \mathbb{R}^{m\times n}$. With the assumption that $R_{\theta_o}(k,N+1)$ is nonsingular, the Schur decomposition yields

$$\begin{aligned} &R_{\theta_o}(k,N+1) \\ &= \begin{bmatrix} I & R'_{2_{\theta_o}}(k,N+1,\theta_o)\, R^{-1}_{3_{\theta_o}}(k,N+1) \\ 0 & I \end{bmatrix} \begin{bmatrix} \nabla_{\theta_o}(k,N+1) & 0 \\ 0 & R_{3_{\theta_o}}(k,N+1) \end{bmatrix} \\ &\times \begin{bmatrix} I & 0 \\ R^{-1}_{3_{\theta_o}}(k,N+1)\, R_{2_{\theta_o}}(k,N+1) & I \end{bmatrix}, \end{aligned}$$

where

$$\nabla_{\theta_o}(k,N+1) := R_{1_{\theta_o}}(k,N+1) - R'_{2_{\theta_o}}(k,N+1)\, R^{-1}_{3_{\theta_o}}(k,N+1)\, R_{2_{\theta_o}}(k,N+1). \tag{24}$$

Note that since $R_{3_{\theta_o}}(k,N+1) = D'_{2_{f^k(\theta_o)}} D_{2_{f^k(\theta_o)}} + B'_{2_{f^k(\theta_o)}} X_{\theta_o}(k,N+1)\, B_{2_{f^k(\theta_o)}}$ and $D'_{2_{f^k(\theta_o)}} D_{2_{f^k(\theta_o)}} > 0$, we have

$$R_{3_{\theta_o}}(k,N+1) > 0 \tag{25}$$

whenever $X_{\theta_o}(k,N+1) \geq 0$. Hence, if

$$X_{\theta_o}(k,N+1) \geq 0, \tag{26}$$

$$\nabla_{\theta_o}(k,N+1) \leq -\varrho I, \tag{27}$$

then $R_{\theta_o}(k,N+1)$ is nonsingular.

For X, R, and ∇ defined as above, it is possible to show by completion of squares (see [17, p. 485]) that for all $x(k)$ and all $u, w \in l_2[0,N]$ we have

$$\begin{aligned} &\|z\|^2_{[k,N]} - \gamma^2 \|w\|^2_{[k,N]} + x'(N+1)\, X_{\theta_o}(N+1,N+1)\, x(N+1) \\ &= x'(k)\, X_{\theta_o}(k,N+1)\, x(k) \\ &+ \sum_{j=k}^{N} (u(j) - u_N(j))'\, R_{3_{\theta_o}}(j,N+1)\, (u(j) - u_N(j)) \\ &+ \sum_{j=k}^{N} (w(j) - w_N(j))'\, \nabla_{\theta_o}(j,N+1)\, (w(j) - w_N(j)), \end{aligned} \tag{28}$$

with

$$\begin{aligned} w_N(k) &:= -\nabla^{-1}_{\theta_o}(k,N+1)\, L_{\nabla_{\theta_o}}(k,N+1)\, x(k), \\ u_N(k) &:= -R^{-1}_{3_{\theta_o}}(k,N+1) \begin{bmatrix} L_{2_{\theta_o}}(k,N+1) & R_{2_{\theta_o}}(k,N+1) \end{bmatrix} \begin{bmatrix} x(k) \\ w(k) \end{bmatrix}, \end{aligned} \tag{29}$$

and where

(30)
$$L_{\nabla_{\theta_o}}(k,N+1) := L_{1_{\theta_o}}(k,N+1) - R'_{2_{\theta_o}}(k,N+1)\, R^{-1}_{3_{\theta_o}}(k,N+1)\, L_{2_{\theta_o}}(k,N+1).$$

From (25), (27), and (28), it is clear that, for $\theta(0) = \theta_o$,

(31)
$$x'_o X_{\theta_o}(0,N+1)\, x_o = \sup_{w\in l_2[0,N]} \inf_{u\in l_2[0,N]} \left\{ \|z\|^2_{[0,N]} - \gamma^2 \|w\|^2_{[0,N]} + x'(N+1)\, X_{\theta_o}(N+1,N+1)\, x(N+1) \right\}.$$

The above is summarized by the following theorem, which is a straightforward extension of [17, p. 484].

THEOREM 4.1. *Let us suppose that* $D'_{2_{f^k(\theta_o)}} D_{2_{f^k(\theta_o)}} > 0$ *for all* $k \le N$ *and* $X_{\theta_o}(N+1,N+1) \ge 0$. *In this case, there exists a causal full information control* $u(k) = F_{u_{\theta_o}}(k,N+1) \left[\begin{smallmatrix} x(k) \\ w(k) \end{smallmatrix} \right]$ *that satisfies Objective A if and only if, for* $0 \le k \le N+1$, *the following conditions hold:*

1. $X_{\theta_o}(k,N+1)$ *satisfies the time-varying Riccati recursion* (21).
2. *For some* $\varrho > 0$, (26) *and* (27) *hold.*

In this case, the control given by (29) *achieves Objective* A.

4.2. Infinite horizon full information controller. The second problem is the infinite horizon problem where the objective is to find a (uniformly in time) exponentially stabilizing controller F such that, if

$$u(k) = F_{\theta_o}(k) \begin{bmatrix} x(k) \\ w(k) \end{bmatrix},$$

then Objective B can be achieved. The following assumptions on system (13) are needed:

1. $f : \Theta \to \Theta$ is continuous and Θ is compact.
2. The system parameters A, B_1, B_2, C, D_1, and D_2 are matrix-valued continuous functions of θ.
3. $D'_{2_\theta} D_{2_\theta} > 0$ for all $\theta \in \Theta$.
4. For all $\theta \in \Theta$, we have $D'_{2_\theta} \begin{bmatrix} C_\theta & D_{1_\theta} \end{bmatrix} = 0$, and the triple (A, C, f) is uniformly detectable.
5. The triple (A, B_2, f) is stabilizable.

Assumption 4 is equivalent to the following.

4′ The triple $(A - B_2 (D'_2 D_2)^{-1} D'_2 C, (I - D_2 (D'_2 D_2)^{-1} D'_2)C, f\ )$ is uniformly detectable.

Indeed, if Assumption 4′ holds, then the feedback

$$u(k) = -\left(D'_{2_{f^k(\theta)}} D_{2_{f^k(\theta)}}\right)^{-1} D'_{2_{f^k(\theta)}} C_{f^k(\theta)} x(k) - \left(D'_{2_{f^k(\theta)}} D_{2_{f^k(\theta)}}\right)^{-1} D'_{2_{f^k(\theta)}} D_{1_{f^k(\theta)}} w(k) + r(k)$$

converts it to Assumption 4. Perhaps these assumptions could be weakened (for example, see [30]), but they are common.

The main result of the paper is the following.

THEOREM 4.2. *Suppose Assumptions* 1–5 *hold. There exists a (uniformly in time) exponentially stabilizing controller* $u(k) = F_{u_{\theta_o}}(k) \left[\begin{smallmatrix} x(k) \\ w(k) \end{smallmatrix}\right]$ *such that Objective* B *can be achieved if and only if there exists a uniformly bounded map* $X_\infty : \Theta \to \mathbb{R}^{n \times n}$ *such that the following hold:*

1. X_∞ *satisfies the FARE*

$$X_{\infty_\theta} = C'_\theta C_\theta + A'_\theta X_{\infty_{f(\theta)}} A_\theta - L'_\theta R_\theta^{-1} L_\theta, \tag{32}$$

where

$$\begin{aligned} R_\theta &:= \overline{D}'_\theta J \overline{D}_\theta + \bar{B}'_\theta X_{\infty_{f(\theta)}} \bar{B}_\theta, \\ L_\theta &:= \overline{D}'_\theta J \bar{C}_\theta + \bar{B}'_\theta X_{\infty_{f(\theta)}} A_\theta. \end{aligned} \tag{33}$$

2. *For some* $\varrho > 0$ *and all* $\theta \in \Theta$,

$$\begin{aligned} X_{\infty_\theta} &\geq 0, \\ \nabla_\theta &:= R_{1_\theta} - R'_{2_\theta} R_{3_\theta}^{-1} R_{2_\theta} \leq -\varrho I. \end{aligned} \tag{34}$$

3. *The closed-loop system*

$$x(k+1) = \left(A_{\theta(k)} - \bar{B}_{\theta(k)} R_{\theta(k)}^{-1} L_{\theta(k)} \right) x(k) \tag{35}$$

is uniformly exponentially stable.

In this case, the control

$$u_\infty(k) := -R_{3_{\theta(k)}}^{-1} \left[\begin{smallmatrix} L_{2_{\theta(k)}} & R_{2_{\theta(k)}} \end{smallmatrix}\right] \left[\begin{smallmatrix} x(k) \\ w(k) \end{smallmatrix}\right] \tag{36}$$

achieves Objective B, X_∞ *is continuous, and the closed-loop system with control* (36), *that is,*

$$\begin{aligned} x(k+1) = &\left(A_{f^k(\theta_o)} - B_{2_{f^k(\theta_o)}} R_{3_{f^k(\theta_o)}}^{-1} L_{2_{f^k(\theta_o)}} \right) x(k) \\ &+ \left(B_{1_{f^k(\theta_o)}} - B_{2_{f^k(\theta_o)}} R_{3_{f^k(\theta_o)}}^{-1} L_{2_{f^k(\theta_o)}} \right) w(k), \end{aligned}$$

is a uniformly (in θ*) exponentially stable system.*

The proof of this theorem is withheld until section 5. The proof entails the major difficulty of proving continuity relative to $\theta(0)$, an issue that does not exist in the traditional time-varying case of [18] and [26]. Even though our approach is inspired by [17], [30], and [31], the continuity issue of the LDV case makes it of interest in its own right.

The control $u(k)$ produced by Theorem 4.2 depends on $w(k)$. Since $w(k)$ is meant to model the linearization error (see section 6), it will likely depend on $u(k)$. Thus $u(k)$ and $w(k)$ are linked by some algebraic relationship, which may not be easily solved. The following shows how to find a control $u(k)$ that depends on the information $x(k)$ only. This type of control is referred to as *strictly causal*.

COROLLARY 4.3. *Suppose the assumptions of Theorem* 4.2 *hold and there exists a controller as described. Suppose also that* $R_{1_\theta} \leq -\varrho I$. *Then the above control can be taken to be strictly proper. In particular, the control*

$$\begin{aligned} u_*(k) := &- \left(R_{3_{\theta(k)}} - R_{2_{\theta(k)}} R_{1_{\theta(k)}}^{-1} R'_{2_{\theta(k)}} \right)^{-1} \\ &\times \left(L_{2_{\theta(k)}} - R_{2_{\theta(k)}} R_{1_{\theta(k)}}^{-1} L_{1_{\theta(k)}} \right) x(k) \\ = &-\Delta_{\theta(k)}^{-1} L_{\Delta_{\theta(k)}} x(k), \end{aligned}$$

where

$$\Delta_\theta := R_{3_\theta} - R_{2_\theta} R_{1_\theta}^{-1} R_{2_\theta}'$$

and

$$L_{\Delta_\theta} := L_{2_\theta} - R_{2_\theta} R_{1_\theta}^{-1} L_{1_\theta},$$

achieves Objective B.

Proof. This corollary follows as a minor variation of the proof of Theorem 4.2. □

Remark 1. The above results show the importance of the FARE (32). Solving a functional equation may be computationally difficult. However, in [8], [10] several methods for solving the FARE associated with a LQ objective were developed. These methods can easily be extended to solving the FARE (32). Furthermore, the stability of (35) can be checked via their respective FAREs.

Remark 2. The continuity of the solution to the FARE is crucial when numerically computing it. For example, suppose that $\Theta = [0, 1]$, that there exists a jump discontinuity at some point $0 \leq \rho \leq 1$, and that

$$X_\theta := \begin{cases} 0 \text{ if } \theta \leq \rho, \\ \delta \text{ otherwise.} \end{cases}$$

Consider the construction of $\hat{X}$, an approximation of X, with error $\varepsilon < \delta$, i.e., $\|X_\theta - \hat{X}_\theta\| < \varepsilon$ for all $\theta \in \Theta$. In general, the point ρ would be estimated via some search method. However, unless ρ is known *exactly* (which entails an infinite search), $\|X_{\theta^*} - \hat{X}_{\theta^*}\| > \varepsilon$ for some $\theta^* \in \Theta$. If θ^* is a fixed point of f, then $\|X_{f^k(\theta^*)} - \hat{X}_{f^k(\theta^*)}\| > \varepsilon$ for all k, and a similar problem occurs if θ^* is a recurrent point of f. In general, if $X : \Theta \to \mathbb{R}^{n \times n}$ is continuous and Θ is compact, then X can be estimated by its value at a finite number of points. If X is not continuous, such an estimate is not possible in general. It is this continuity issue, and hence the ability to numerically evaluate the Riccati solution, that is the main distinction between an LDV controller and a family of infinite horizon, time-varying controllers.

Remark 3. Another difference between an LDV controller and a family of infinite horizon, time-varying controllers is that the LDV controller guarantees that the closed-loop system is uniformly exponentially stable, whereas the family of time-varying controllers only guarantees stability along every trajectory $\{\theta(k) : k \geq 0\}$. One situation in which this distinction is important is noise rejection. For example, suppose that the signal w in system (13) is bounded as $\|w\|_{l_\infty} \leq \bar{w}$. Such a situation arises when the f in (2) is different from the f in (3). Then it follows from section 6 that the maximum allowable $\bar{w}$ depends on the parameters α_{θ_o} and β_{θ_o} in the definition of stability. Hence we write $\bar{w}_{\theta_o}$. Now suppose that the system is not *uniformly* exponentially stable, i.e., there exists a sequence $\{\theta(0)_i : i \geq 0\}$ such that either $\lim_{i \to \infty} \alpha_{\theta(0)_i} = 1$ or $\lim_{i \to \infty} \beta_{\theta(0)_i} = \infty$. In this case, even though $\bar{w}_{\theta_o} > 0$ for each θ_o, we have $\lim_{i \to \infty} \bar{w}_{\theta(0)_i} = 0$; that is, there is no positive bound on the noise that results in a stable system for all initial conditions θ_o.

5. Proof of main theorem.

5.1. Necessity.

In the subsequent discussion, we assume the following.

Assumption A. Assumptions 1–5 of Theorem 4.2 hold, and there exists a stabilizing controller that achieves Objective B.

Since (A, C, f) is uniformly detectable, $D_{2_\theta}' D_{2_\theta} > 0$, and (A, B_2, f) is stabilizable, the optimal stabilizing LDV linear-quadratic controller exists (Theorem 3.7). That is, there exists a unique, continuous, bounded function $X_2 : \Theta \to \mathbb{R}^{n \times n}$ such that $X_{2_\theta}' = X_{2_\theta} \geq 0$ solves (17). Furthermore, for $w \equiv 0$,

$$\inf_{u \in l_2} \|z\|_{l_2}^2 = x_o' X_{2_\theta} x_o, \tag{37}$$

and this infimum is attained for u given by (18).

Define $X_{\theta_o}(k, N+1)$ as in (21) with terminal cost $X_{2_{f^{N+1}(\theta_o)}}$. It will be shown (in Lemma 5.10) that

$$X_{\infty_\theta} = \lim_{N \to \infty} X_\theta(0, N+1) \tag{38}$$

provides a solution to (32) (see Lemma 5.6) such that system (35) is uniformly exponentially stable (see Lemma 5.9) and inequalities (34) are satisfied (see inequalities (59) and (60)). Furthermore, the convergence in (38) is uniform in θ, and hence X_{∞_θ} is a continuous function in θ (see Lemma 5.10) and the control given by (36) satisfies Objective B (see Lemma 5.4).

The proof of the following lemma follows from an easy adaptation of the arguments of Section B.2.3 of [17] and from [31].

LEMMA 5.1. *If Assumption* A *holds,* $X_{\theta_o}(k, N+1)$ *is given by* (21)*, and* $\nabla_{\theta_o}(k, N+1)$ *is given by* (24)*, then*

1. *for* $\theta_o = \theta(0) \in \Theta$*, all* $k \leq N+1$*, and* $N \geq 0$*, we have* $\nabla_{\theta_o}(k, N+1) \leq -\varrho I$ *and* $X_{\theta_o}(k, N+1) \geq 0$*;*
2. *for all* $\theta_o \in \Theta$*, there exists a* $\bar{X}_{\infty_{\theta_o}} < \infty$ *such that* $\|X_{\theta_o}(k, N+1)\| \leq \bar{X}_{\infty_{\theta_o}}$ *for all* $k \leq N+1$ *and all* $N \geq 0$*;*
3. $X_{\theta_o}(k, N+1)$ *is monotone increasing in* N*.*

The bound $\bar{X}_{\infty_{\theta_o}}$ depends on θ_o, so we cannot say that there exists a single bound on $X_{\theta_o}(k, N+1)$ for all $\theta_o \in \Theta$. Since Θ is compact, if $\bar{X}_\infty$ is continuous, then $\bar{X}_\infty$ is bounded. However, we have not yet shown that $\bar{X}_\infty$ is continuous.

For fixed θ_o, $X_{\theta_o}(k, N+1)$ exists, is bounded, and is nondecreasing in N. Thus

$$X_{\theta_o}(k) := \lim_{N \to \infty} X_{\theta_o}(k, N+1)$$

exists for $k < \infty$. Furthermore, $X_{\theta_o}(k)$ solves

$$X_{\theta_o}(k) = A_{f^k(\theta_o)}' X_{\theta_o}(k+1) A_{f^k(\theta_o)} + C_{f^k(\theta_o)}' C_{f^k(\theta_o)} - L_{\theta_o}'(k) R_{\theta_o}^{-1}(k) L_{\theta_o}(k), \tag{39}$$

where

$$R_{\theta_o}(k) := \overline{D}_{f^k(\theta_o)}' J \overline{D}_{f^k(\theta_o)} + \bar{B}_{f^k(\theta_o)}' X_{\theta_o}(k+1) \bar{B}_{f^k(\theta_o)},$$
$$L_{\theta_o}(k) := \overline{D}_{f^k(\theta_o)}' J \bar{C}_{f^k(\theta_o)} + \bar{B}_{f^k(\theta_o)}' X_{\theta_o}(k+1) A_{f^k(\theta_o)}.$$

This is simply the Riccati equation associated with the infinite horizon, time-varying H^∞ control problem. Note that, since $X_{\theta_o}(k, N+1) \geq 0$,

$$X_{\theta_o}(k) \geq 0. \tag{40}$$

Next, since $X_{\theta_o}(k, N+1)$ converges, $\nabla_{\theta_o}(k) := \lim_{N \to \infty} \nabla_{\theta_o}(k, N+1)$ exists. Furthermore, $\nabla_{\theta_o}(k, N+1) \leq -\varrho I$ (from the finite horizon problem) implies that $\nabla_{\theta_o}(k)$

$\leq -\varrho I$. Furthermore, since $X_{\theta_o}(k)$ is bounded and $D'_{2_\theta} D_{2_\theta} > 0$ for all $\theta \in \Theta$, it is clear from (24) that $\nabla_{\theta_o}(k)$ is bounded from below. Hence

$$-\infty < \nabla_{\theta_o}(k) \leq -\varrho I. \tag{41}$$

Similarly, define $L_{\nabla_{\theta_o}}(k)$ as the limit of (30).

Next define

$$u_\infty(k) := F_{u_{\theta_o}}(k) \begin{bmatrix} x(k) \\ w(k) \end{bmatrix} := -R_{3_{\theta_o}}^{-1}(k) \begin{bmatrix} L_{2_{\theta_o}}(k) & R_{2_{\theta_o}}(k) \end{bmatrix} \begin{bmatrix} x(k) \\ w(k) \end{bmatrix} \tag{42}$$

and

$$w_\infty(k) := F_{w_{\theta_o}}(k)\, x(k) := -\nabla_{\theta_o}^{-1}(k)\, L_{\nabla_{\theta_o}}(k)\, x(k). \tag{43}$$

It will be shown that, with $\theta(0) = \theta_o$, (42) is the best control and (43) is the worst disturbance (in the sense of Objective B).

LEMMA 5.2. *For $w = 0$, the control $u(k) = u_\infty(k)$ given by (42) makes the closed-loop system $x(k+1) = A_{u_{\theta_o}}(k)x(k)$, where*

$$A_{u_{\theta_o}}(k) := A_{\theta(k)} - B_{2_{\theta(k)}} R_{3_{\theta_o}}^{-1}(k)\, L_{2_{\theta_o}}(k), \tag{44}$$

exponentially stable.

Proof. Since $u_\infty(k) = -R_{3_{\theta_o}}^{-1}(k)\, L_{2_{\theta_o}}(k)\, x(k) - R_{3_{\theta_o}}^{-1}(k)\, R_{2_{\theta_o}}(k)\, w(k)$, the closed-loop system with $w = 0$ and $u = u_\infty$ is

$$\begin{aligned} x(k+1) &= \left(A_{\theta(k)} - B_{2_{\theta(k)}} R_{3_{\theta_o}}^{-1}(k)\, L_{2_{\theta_o}}(k)\right) x(k) \\ &= A_{u_{\theta_o}}(k)\, x(k). \end{aligned}$$

Set $\Gamma_{\theta_o}(k) = X_{\theta_o}(k) - X_{2_{f^k(\theta_o)}}$. By Lemma 5.1, $X_{\theta_o}(k, N+1) \geq X_{\theta_o}(k,k) = X_{2_{f^k(\theta_o)}}$. Thus $X_{\theta_o}(k) = \lim_{N\to\infty} X_{\theta_o}(k, N+1) \geq X_{2_{f^k(\theta_o)}}$ and $\Gamma_{\theta_o}(k) \geq 0$. It is possible to show (see [17, equation (B.2.39)]) that

$$\begin{aligned} \Gamma_{\theta_o}(k) \geq{}& A'_{u_{\theta_o}}(k)\, \Gamma_{\theta_o}(k+1)\, A_{u_{\theta_o}}(k) \\ &+ A'_{u_{\theta_o}}(k)\, \Gamma_{\theta_o}(k+1)\, B_{2_{\theta(k)}} \\ &\times \left(R_{3_{\theta_o}}(k) - B'_{2_{\theta(k)}} \Gamma_{\theta_o}(k+1)\, B_{2_{\theta(k)}}\right)^{-1} B'_{2_{\theta(k)}} \Gamma_{\theta_o}(k+1)\, A_{u_{\theta_o}}(k). \end{aligned} \tag{45}$$

However,

$$A_\theta - B_{2_\theta} \left(D'_{2_\theta} D_{2_\theta} + B'_{2_\theta} X_{2_{f(\theta)}} B_{2_\theta}\right)^{-1} B'_{2_\theta} X_{2_{f(\theta)}} A_\theta$$

is the closed-loop system if the LQ feedback is used, that is, if $w = 0$ and $u = u_{LQ}$, where u_{LQ} is given by (18). After some manipulation, we find

$$\begin{aligned} &A_{f^k(\theta_o)} - B_{2_{f^k(\theta_o)}} \left(D'_{2_{f^k(\theta_o)}} D_{2_{f^k(\theta_o)}} + B'_{2_{f^k(\theta_o)}} X_{2_{f^{k+1}(\theta_o)}} B_{2_{f^k(\theta_o)}}\right)^{-1} \\ &\quad \times B'_{2_{f^k(\theta_o)}} X_{2_{f^{k+1}(\theta_o)}} A_{f^k(\theta_o)} \\ &= A_{u_{\theta_o}}(k) \\ &+ B_{2_{f^k(\theta_o)}} \left(R_{3_{\theta_o}}(k) - B'_{2_{f^k(\theta_o)}} \Gamma_{\theta_o}(k+1)\, B_{2_{f^k(\theta_o)}}\right)^{-1} B'_{2_{f^k(\theta_o)}} \Gamma_{\theta_o}(k+1)\, A_{u_{\theta_o}}(k) \end{aligned}$$

and

$$B_{2_{f^k(\theta)}}\left(R_{3_{\theta_o}}(k)-B'_{2_{f^k(\theta)}}\Gamma_{\theta_o}(k+1)B_{2_{f^k(\theta)}}\right)^{-1}$$
$$=B_{2_{f^k(\theta)}}\left(D'_{2_{f^k(\theta)}}D_{2_{f^k(\theta)}}+B'_{2_{f^k(\theta)}}X_{2_{f^{k+1}(\theta_o)}}B_{2_{f^k(\theta)}}\right)^{-1},$$

which is bounded since $D'_{2_\theta}D_{2_\theta}>0$ and $X_{2_\theta}\geq 0$ for all $\theta\in\Theta$. Therefore

$$\xi(k+1)=A_{u_{\theta_o}}(k)\xi(k),$$
$$\upsilon(k)=B'_{2_{\theta(k)}}\Gamma_{\theta_o}(k+1)A_{u_{\theta_o}}(k)\xi(k)$$

is a uniformly detectable system. Moreover,

$$\left(R_{3_{\theta_o}}(k)-B'_{2_{f^k(\theta_o)}}\Gamma_{\theta_o}(k+1)B_{2_{f^k(\theta_o)}}\right)^{-1}>0$$

and $\|\Gamma_{\theta_o}(k)\|=\|X_{\theta_o}(k)-X_{2_{f^k(\theta_o)}}\|\leq\|X_{\theta_o}(k)\|\leq\bar{X}_{\infty_{\theta_o}}<\infty$. Therefore (45) is a Lyapunov equation, and Theorem 3.5 implies that

$$x(k+1)=A_{u_{\theta_o}}(k)x(k)$$

is an exponentially stable system. □

We cannot as yet claim that A_u as defined by (44) is uniformly exponentially stable in the sense of Definition 3.1. To conclude uniformly exponential stability, $\Gamma_{\theta_o}(k)$, the solution to the Lyapunov equation (45), must be uniformly bounded for all $\theta_o\in\Theta$ and all k. $\Gamma_{\theta_o}(k)$ is uniformly bounded only if $X_{\theta_o}(k)$, the solution to (39), is uniformly bounded. Lemma 5.7 will show that $X_{\theta_o}(k)$ is uniformly bounded.

LEMMA 5.3. *Let* $u_\infty(k)=F_{u_{\theta_o}}(k)\left[\begin{smallmatrix}x(k)\\ w(k)\end{smallmatrix}\right]$, *where* F_u *is given by* (42). *Let* $w_\infty(k)=F_{w_{\theta_o}}(k)x(k)$ *be defined as in* (43). *Then, for* $w\in l_2$,

$$\|z_{\theta_o}(F_u,w,x_o)\|_{l_2}^2-\gamma^2\|w\|_{l_2}^2$$
$$=x'_oX_{\theta_o}(k)x_o+\sum_{k=0}^{\infty}\left(w(k)-w_\infty(k)\right)'\nabla_{\theta_o}(k)\left(w(k)-w_\infty(k)\right). \tag{46}$$

(See the end of section 1 for the definition of the notation $z_{\theta_o}(F_u,w,x_o)$.)

Proof. By the previous lemma, $u_\infty(k)=F_{u_{\theta_o}}(k)\left[\begin{smallmatrix}x(k)\\ w(k)\end{smallmatrix}\right]$ is exponentially stabilizing. Hence if $w\in l_2$, then $x\in l_2$ and $x(k)\to 0$. Furthermore, $X_{\theta_o}(k)$ is bounded and, by (41), $-\infty<\nabla_{\theta_o}(k)\leq-\varrho I$. Thus $F_{w_{\theta_o}}(k)$ is bounded, where F_w is defined by (43). Hence $w_\infty\in l_2$. Thus letting $N\to\infty$ in (28) yields (46). □

Now it is shown that the control u_∞ achieves Objective B.

LEMMA 5.4. *If* $x(0)=0$ *and* $u(k)=u_\infty(k)=F_{u_{\theta_o}}(k)\left[\begin{smallmatrix}x(k)\\ w(k)\end{smallmatrix}\right]$, *then, for all* $w\in l_2$, $\|z\|_{l_2}^2-\gamma^2\|w\|_{l_2}^2\leq-\varepsilon\|w\|_{l_2}^2$.

Proof. By Assumption A, there exists an exponentially stabilizing control u_* that satisfies Objective B, that is, if $u=u_*$, $x(0)=0$, and $w\in l_2$, then $x\in l_2$ and $\|z_{\theta_o}(u_*,w,0)\|_{l_2}^2-\gamma^2\|w\|_{l_2}^2\leq-\varepsilon\|w\|_{l_2}^2$. Since $X_{\theta_o}(k)$ is bounded and $\nabla_{\theta_o}(k)\leq-\varrho I$, $F_{u_{\theta_o}}(k)$ and $F_{w_{\theta_o}}(k)$ are bounded. Therefore $u_\infty(k)=F_{u_{\theta_o}}(k)\left[\begin{smallmatrix}x_{\theta_o}(u_*,w,0;k)\\ w(k)\end{smallmatrix}\right]\in l_2$, and $w_\infty(k)=F_{w_{\theta_o}}(k)x_{\theta_o}(u_*,w,0;k)\in l_2$. Thus we can take the limit of (28) as

$N \to \infty$, which yields

$$
\begin{aligned}
-\varepsilon \|w\|_{l_2}^2 &\geq \|z_{\theta_o}(u_*, w, 0)\|_{l_2}^2 - \gamma^2 \|w\|_{l_2}^2 \\
&= \sum_{k=0}^{\infty} (u_*(k) - u_\infty(k))' R_{3_{\theta_o}}(k) (u_*(k) - u_\infty(k)) \\
&\qquad + \sum_{k=0}^{\infty} (w(k) - w_\infty(k))' \nabla_{\theta_o}(k) (w(k) - w_\infty(k)) \\
&\geq \sum_{k=0}^{\infty} (w(k) - w_\infty(k))' \nabla_{\theta_o}(k) (w(k) - w_\infty(k)) \\
&= \|z_{\theta_o}(F_u, w, 0)\|_{l_2}^2 - \gamma^2 \|w\|_{l_2}^2,
\end{aligned} \tag{47}
$$

where the last equality follows from Lemma 5.3. □

From (47), it is clear that u_∞ is the best control and w_∞ is the worst disturbance in the sense of Objective B.

LEMMA 5.5. $\sup_{w \in l_2} \inf_{u \in l_2} \|z_{\theta_o}(u, w, x_o)\|_{l_2}^2 - \gamma^2 \|w\|_{l_2}^2 = \|z_{\theta_o}(F_u, w_\infty, x_o)\|_{l_2}^2 - \gamma^2 \|w_\infty\|_{l_2}^2 = x_o' X_{\theta_o}(0) x_o$.

Proof. Since $\nabla_{\theta_o}(k) \leq -\varrho I$, if $u(k) = u_\infty(k) = F_{u_{\theta_o}}(k) \left[\begin{smallmatrix} x(k) \\ w(k) \end{smallmatrix} \right]$, then (46) implies that

$$
\begin{aligned}
&\sup_{w \in l_2} \|z_{\theta_o}(F_u, w, x_o)\|_{l_2}^2 - \gamma^2 \|w\|_{l_2}^2 \\
&= x_o' X_{\theta_o}(0) x_o + \sup_{w \in l_2} \sum_{k=0}^{\infty} (w(k) - w_\infty(k))' \nabla_{\theta_o}(k) (w(k) - w_\infty(k)) \\
&= x_o' X_{\theta_o}(k) x_o,
\end{aligned}
$$

where $w_\infty(k) = F_{w_{\theta_o}}(k) x(k)$. Therefore

$$
\begin{aligned}
\sup_{w \in l_2} \inf_{u \in l_2} \|z_{\theta_o}(u, w, x_o)\|_{l_2}^2 - \gamma^2 \|w\|_{l_2}^2 &\leq \sup_{w \in l_2} \|z_{\theta_o}(F_u, w, x_o)\|_{l_2}^2 - \gamma^2 \|w\|_{l_2}^2 \\
&= x_o' X_{\theta_o}(k) x_o.
\end{aligned} \tag{48}
$$

Similarly, if $w = w_\infty$, then $\inf_{u \in l_2} \|z_{\theta_o}(u, w_\infty, x_o)\|_{l_2}^2 - \gamma^2 \|w_\infty\|_{l_2}^2 = \|z_{\theta_o}(F_u, w_\infty, x_o)\|_{l_2}^2 - \gamma^2 \|w_\infty\|_{l_2}^2 = x_o' X_{\theta_o}(k) x_o$. Therefore

$$
\begin{aligned}
\sup_{w \in l_2} \inf_{u \in l_2} \|z_{\theta_o}(u, w, x_o)\|_{l_2}^2 - \gamma^2 \|w\|_{l_2}^2 &\geq \inf_{u \in l_2} \|z_{\theta_o}(u, w_\infty, x_o)\|_{l_2}^2 - \gamma^2 \|w_\infty\|_{l_2}^2 \\
&= x_o' X_{\theta_o}(k) x_o.
\end{aligned} \tag{49}
$$

Combining inequalities (48) and (49) yields the desired result. □

Up to this point, $\theta(0) = \theta_o \in \Theta$ has been fixed. $X_{\theta_o}(k)$ is nothing more than the stabilizing solution of the time-varying Riccati equation associated with the time-varying system

$$
\begin{aligned}
x(k+1) &= A_{f^k(\theta_o)} x(k) + B_{1_{f^k(\theta_o)}} w(k) + B_{2_{f^k(\theta_o)}} u(k), \\
z(k) &= C_{f^k(\theta_o)} x(k) + D_{1_{f^k(\theta_o)}} w(k) + D_{2_{f^k(\theta_o)}} u(k).
\end{aligned}
$$

Since θ_o is arbitrary, for all $\theta \in \Theta$, define $X_\infty : \Theta \to \mathbb{R}^{n\times n}$ by

$$X_{\infty_\theta} := \lim_{N\to\infty} X_\theta(0, N+1). \tag{50}$$

LEMMA 5.6. *The function*

$$X_\infty : \Theta \to \mathbb{R}^{n\times n},$$
$$\theta \mapsto X_{\infty_\theta}$$

satisfies the FARE (32)–(33)*, viz.,*

$$\begin{aligned} X_{\infty_\theta} &= A'_\theta X_{\infty_{f(\theta)}} A_\theta + C'_\theta C_\theta \\ &\quad - \left(\bar{D}'_\theta J \bar{C}_\theta + \bar{B}'_\theta X_{\infty_{f(\theta)}} A_\theta\right)' \left(\bar{D}'_\theta J \bar{D}_\theta + \bar{B}'_\theta X_{\infty_{f(\theta)}} \bar{B}_\theta\right)^{-1} \left(\bar{D}'_\theta J \bar{C}_\theta + \bar{B}'_\theta X_{\infty_{f(\theta)}} A_\theta\right). \end{aligned} \tag{51}$$

Proof. Let $f(\theta_1) = \theta_2$. Clearly,

$$X_{\theta_1}(N+1, N+1) = X_{2_{f^{N+1}(\theta_1)}} = X_{2_{f^N(\theta_2)}} = X_{\theta_2}(N, N). \tag{52}$$

Next, by (21),

$$\begin{aligned} &X_{\theta_1}(N, N+1) \\ &= A'_{f^N(\theta_1)} X_{\theta_1}(N+1, N+1) A_{f^N(\theta_1)} + C'_{f^N(\theta_1)} C_{f^N(\theta_1)} \\ &- \left(\bar{D}'_{f^N(\theta_1)} J \bar{C}_{f^N(\theta_1)} + \bar{B}'_{f^N(\theta_1)} X_{\theta_1}(N+1, N+1) A_{f(\theta_1)}\right)' \\ &\times \left(\bar{D}'_{f^N(\theta_1)} J \bar{D}_{f^N(\theta_1)} + \bar{B}'_{f^N(\theta_1)} X_{\theta_1}(N+1, N+1) \bar{B}_{f^N(\theta_1)}\right)^{-1} \\ &\times \left(\bar{D}'_{f^N(\theta_1)} J \bar{C}_{f^N(\theta_1)} + \bar{B}'_{f^N(\theta_1)} X_{\theta_1}(N+1, N+1) A_{f^N(\theta_1)}\right) \\ &= A'_{f^{N-1}(\theta_2)} X_{\theta_2}(N, N) A_{f^{N-1}(\theta_2)} + C'_{f^{N-1}(\theta_2)} C_{f^{N-1}(\theta_2)} \\ &- \left(\bar{D}'_{f^{N-1}(\theta_2)} J \bar{C}_{f^{N-1}(\theta_2)} + \bar{B}'_{f^{N-1}(\theta_2)} X_{\theta_2}(N, N) A_{f^{N-1}(\theta_2)}\right)' \\ &\times \left(\bar{D}'_{f^{N-1}(\theta_2)} J \bar{D}_{f^{N-1}(\theta_2)} + \bar{B}'_{f^{N-1}(\theta_2)} X_{\theta_2}(N, N) \bar{B}_{f^{N-1}(\theta_2)}\right)^{-1} \\ &\times \left(\bar{D}'_{f^{N-1}(\theta_2)} J \bar{C}_{f^{N-1}(\theta_2)} + \bar{B}'_{f^{N-1}(\theta_2)} X_{\theta_2}(N, N) A_{f^{N-1}(\theta_2)}\right) \\ &= X_{\theta_2}(N-1, N). \end{aligned} \tag{53}$$

Repeating the above, we reach the result:

$$X_{\theta_1}(k, N+1) = X_{\theta_2}(k-1, N). \tag{54}$$

Setting $k = 0$ and $\theta = \theta_1$ in (21) and substituting $X_{\theta_2}(0, N)$ for $X_{\theta_1}(1, N+1)$ into the right-hand side yields

$$\begin{aligned} X_{\theta_1}(0, N+1) &= A'_{\theta_1} X_{\theta_2}(0, N) A_{\theta_1} + C'_{\theta_1} C_{\theta_1} \\ &\quad - \left(\bar{D}'_{\theta_1} J \bar{C}_{\theta_1} + \bar{B}'_{\theta_1} X_{\theta_2}(0, N) A_{\theta_1}\right)' \left(\bar{D}'_{\theta_1} J \bar{D}_{\theta_1} + \bar{B}'_{\theta_1} X_{\theta_2}(0, N) \bar{B}_{\theta_1}\right)^{-1} \\ &\quad \times \left(\bar{D}'_{\theta_1} J \bar{C}_{\theta_1} + \bar{B}'_{\theta_1} X_{\theta_2}(0, N) A_{\theta_1}\right). \end{aligned} \tag{55}$$

Next we take the limit as $N \to \infty$. In order to take this limit, we must ensure that the right-hand side is continuous in $X_{\theta_2}(0, N)$. Since $R_{3_{\theta_2}}(0, N) \geq D'_{2_{\theta_2}} D_{2_{\theta_2}} > 0$ and

$\nabla_{\theta_2}(0,N) \leq -\varrho I$ for all N, and since R_3 and ∇ are continuous functions of $X_{\theta_2}(0,N)$, we have $\lim_{N\to\infty} R_{3_{\theta_2}}(0,N) \geq D'_{2_{\theta_2}} D_{2_{\theta_2}} > 0$ and $\lim_{N\to\infty} \nabla_{\theta_2}(0,N) \leq -\varrho I$. Thus $\left(\bar{D}'_{\theta_1} J \bar{D}_{\theta_1} + B'_{\theta_1} Y B_{\theta_1}\right)^{-1}$ exists for Y in a neighborhood of $X_{\infty_{\theta_2}}$. Therefore

$$\lim_{N\to\infty} \left(\bar{D}'_{\theta_1} J \bar{D}_{\theta_1} + \bar{B}'_{\theta_1} X_{\theta_2}(0,N)\, \bar{B}_{\theta_1}\right)^{-1} = \left(\bar{D}'_{\theta_1} J \bar{D}_{\theta_1} + \bar{B}'_{\theta_1} X_{\infty_{\theta_2}} \bar{B}_{\theta_1}\right)^{-1}. \tag{56}$$

Likewise,

$$\lim_{N\to\infty} \left(\bar{D}'_{\theta_1} J \bar{C}_{\theta_1} + \bar{B}'_{\theta_1} X_{\theta_2}(0,N)\, A_{\theta_1}\right) = \left(\bar{D}'_{\theta_1} J \bar{C}_{\theta_1} + \bar{B}'_{\theta_1} X_{\infty_{\theta_2}} A_{\theta_1}\right). \tag{57}$$

Thus

$$\begin{aligned}
X_{\infty_{\theta_1}} &= \lim_{N\to\infty} X_{\theta_1}(0,N+1) \\
&= \lim_{N\to\infty} \left(A'_{\theta_1} X_{\theta_2}(0,N)\, A_{\theta_1} + C'_{\theta_1} C_{\theta_1}\right. \\
&\quad - \left(\bar{D}'_{\theta_1} J \bar{C}_{\theta_1} + \bar{B}'_{\theta_1} X_{\theta_2}(0,N)\, A_{\theta_1}\right)' \left(\bar{D}'_{\theta_1} J \bar{D}_{\theta_1} + \bar{B}'_{\theta_1} X_{\theta_2}(0,N)\, \bar{B}_{\theta_1}\right)^{-1} \\
&\quad \left. \times \left(\bar{D}'_{\theta_1} J \bar{C}_{\theta_1} + \bar{B}'_{\theta_1} X_{\theta_2}(0,N)\, A_{\theta_1}\right)\right) \\
&= A'_{\theta_1} X_{\infty_{\theta_2}} A_{\theta_1} + C'_{\theta_1} C_{\theta_1} \\
&\quad - \left(\bar{D}'_{\theta_1} J \bar{C}_{\theta_1} + \bar{B}'_{\theta_1} X_{\infty_{\theta_2}} A_{\theta_1}\right)' \left(\bar{D}'_{\theta_1} J \bar{D}_{\theta_1} + \bar{B}'_{\theta_1} X_{\infty_{\theta_2}} \bar{B}_{\theta_1}\right) \\
&\quad \times \left(\bar{D}'_{\theta_1} J \bar{C}_{\theta_1} + \bar{B}'_{\theta_1} X_{\infty_{\theta_2}} A_{\theta_1}\right).
\end{aligned} \tag{58}$$

Since $f(\theta_1) = \theta_2$, equation (51) follows. □

Now we can drop the dependence on the initial condition θ_o in R, L, and ∇, that is, $R_{\theta(k)} := R_{\theta_o}(k)$, $L_{\theta(k)} := L_{\theta_o}(k)$, $\nabla_{\theta(k)} := \nabla_{\theta_o}(k)$. As a simple consequence of (40), we find

$$X_{\infty_\theta} \geq 0, \tag{59}$$

and by (41), we get

$$\nabla_\theta \leq -\varrho I. \tag{60}$$

Thus the best control u_∞ and worst disturbance w_∞ feedback matrices depend only on the current state $\theta(k)$. That is, (42) and (43) can be rewritten as

$$u_\infty(k) = F_{u_{\theta(k)}} \begin{bmatrix} x(k) \\ w(k) \end{bmatrix} := -R^{-1}_{3_{\theta(k)}} \begin{bmatrix} L_{2_{\theta(k)}} & R_{2_{\theta(k)}} \end{bmatrix} \begin{bmatrix} x(k) \\ w(k) \end{bmatrix} \tag{61}$$

and

$$w_\infty(k) = F_{w_{\theta(k)}} x(k) := -\nabla^{-1}_{\theta(k)} L_{\nabla_{\theta(k)}} x(k). \tag{62}$$

LEMMA 5.7. *The function X_∞ given by* (50) *is uniformly bounded. That is, there exists a $\bar{X}_\infty < \infty$ such that $\|X_{\infty_\theta}\| < \bar{X}_\infty$.*

Proof. Let $X_{2_\theta} = X'_{2_\theta} \geq 0$ be the solution to (17), and define

$$A_{LQ_\theta} := A_\theta - B_{2_\theta} \left(D'_{2_\theta} D_{2_\theta} + B'_{2_\theta} X_{2_{f(\theta)}} B_{2_\theta}\right)^{-1} B'_{2_\theta} X_{2_{f(\theta)}} A_\theta$$

to be the closed-loop state transition matrix with $w = 0$ and $u = u_{LQ}$ given by (18). Define

$$v(k) := \sum_{i=k}^{\infty} \left(\prod_{j=k}^{i} A_{LQ_{f^j(\theta_o)}}\right)' \left(X_{2_{f^{i+1}(\theta_o)}} B_{1_{f^i(\theta_o)}} w(i) + C'_{f^{i+1}(\theta_o)} D_{1_{f^{i+1}(\theta_o)}} w(i+1)\right)$$

and

$$G_{\theta_o}(w,x_o;k) := \left(D'_{2_{f^k(\theta_o)}} D_{2_{f^k(\theta_o)}} + B'_{2_{f^k(\theta_o)}} X_{2_{f^{k+1}(\theta_o)}} B_{2_{f^k(\theta_o)}}\right)^{-1} B'_{2_{f^k(\theta_o)}} \times \left(X_{2_{f^{k+1}(\theta_o)}} A_{f^k(\theta_o)} x(k) - v(k)\right). \tag{63}$$

It is possible to show (see [26, Claim 3, p. 257] or [30, Lemma 9.6]) that if $w \in l_2$, then

$$G_{\theta_o}(w,x_o) = \arg\inf\left\{\|z_{\theta_o}(u,w,x_o)\|_{l_2} : u \in l_2\right\}, \tag{64}$$

where the notation $z_{\theta_o}(u,w,x_o)$ was introduced at the end of section 1. Note that $G_{\theta_o}(w,x_o)$ and therefore $z_{\theta_o}(G_{\theta_o}(w,x_o),w,x_o)$ are linear in (w,x_o).

By assumption, there exists a control satisfying Objective B. Thus $G_{\theta_o}(w,0)$ must also satisfy Objective B, that is,

$$\|z_{\theta_o}(G_{\theta_o}(w,0),w,0)\|_{l_2}^2 - \gamma^2\|w\|_{l_2}^2 \le -\varepsilon\|w\|_{l_2}^2 \tag{65}$$

and

$$\|z_{\theta_o}(G_{\theta_o}(w,0),w,0)\|_{l_2} < \gamma\|w\|_{l_2}. \tag{66}$$

If $w \equiv 0$, then $v = 0$, and by comparing (18) and (63) we see that $G_{\theta_o}(0,x_o;k) = u_{LQ}(k)$, that is, $G_{\theta_o}(0,x_o;k)$ is the optimal LQ control given by (18). Thus, if $w = 0$, then by (19) we obtain

$$\|z_{\theta_o}(G_{\theta_o}(0,x_o),0,x_o)\|_{l_2}^2 = \inf_{u\in l_2}\|z_{\theta_o}(u,0,x_o)\|_{l_2}^2 = x'_o X_{2_{\theta_o}} x_o, \tag{67}$$

where X_{2_θ} is the solution to the Riccati equation (17). It was shown in [8] that X_2 is uniformly bounded. Denote this bound by $\bar{X}_2$, that is, for all $\theta \in \Theta$, $\|X_{2_\theta}\| \le \bar{X}_2 < \infty$. Hence

$$\|z_{\theta_o}(G_{\theta_o}(0,x_o),0,x_o)\|_{l_2}^2 = x'_o X_{2_{\theta_o}} x_o \le \bar{X}_2|x_o| < \infty. \tag{68}$$

Combining (65), (66), and (68) yields

$$\begin{aligned}
&\|z_{\theta_o}(G_{\theta_o}(w,x_o),w,x_o)\|_{l_2}^2 - \gamma^2\|w\|_{l_2}^2 \\
&= \|z_{\theta_o}(G_{\theta_o}(0,x_o),0,x_o) + z_{\theta_o}(G_{\theta_o}(w,0),w,0)\|_{l_2}^2 - \gamma^2\|w\|_{l_2}^2 \\
&= \|z_{\theta_o}(G_{\theta_o}(0,x_o),0,x_o)\|_{l_2}^2 + 2\langle z_{\theta_o}(G_{\theta_o}(w,0),w,0), z_{\theta_o}(G_{\theta_o}(0,x_o),0,x_o)\rangle \\
&+ \|z_{\theta_o}(G_{\theta_o}(w,0),w,0)\|_{l_2}^2 - \gamma^2\|w\|_{l_2}^2 \\
&\le \|z_{\theta_o}(G_{\theta_o}(0,x_o),0,x_o)\|_{l_2}^2 \\
&+ 2\langle z_{\theta_o}(G_{\theta_o}(w,0),w,0), z_{\theta_o}(G_{\theta_o}(0,x_o),0,x_o)\rangle - \varepsilon\|w\|_{l_2}^2 \\
&\le x'_o X_{2_{\theta_o}} x_o + 2\gamma\|w\|_{l_2}\sqrt{x'_o x_o \bar{X}_2} - \varepsilon\|w\|_{l_2}^2 \\
&= x'_o X_{2_{\theta_o}} x_o + \|w\|_{l_2}\left(2\gamma|\sqrt{x'_o x_o \bar{X}_2} - \varepsilon\|w\|_{l_2}\right) \\
&\le x'_o X_{2_{\theta_o}} x_o + \max_{\|w\|\in\mathbb{R}}\left\{\|w\|_{l_2}\left(2\gamma|x_o|\sqrt{\bar{X}_2} - \varepsilon\|w\|_{l_2}\right)\right\} \\
&\le x'_o X_{2_{\theta_o}} x_o + \frac{\gamma^2\bar{X}_2|x_o|^2}{\varepsilon} \le |x_o|^2\left(\bar{X}_2 + \frac{\gamma^2\bar{X}_2}{\varepsilon}\right) < \infty.
\end{aligned} \tag{69}$$

Thus

$$\sup_{w\in l_2}\inf_{u\in l_2}\|z_{\theta_o}(u,w,x_o)\|_{l_2}^2-\gamma^2\|w\|_{l_2}^2$$
$$=\sup_{w\in l_2}\|z_{\theta_o}(G_{\theta_o}(w,x_o),w,x_o)\|_{l_2}^2-\gamma^2\|w\|_{l_2}^2\le|x_o|^2\left(\bar{X}_2+\frac{\gamma^2\bar{X}_2}{\varepsilon}\right)<\infty.$$

Lemma 5.5 implies that

(70)
$$x_o'X_{\infty_{\theta_o}}x_o=\sup_{w\in l_2}\inf_{u\in l_2}\|z_{\theta_o}(u,w,x_o)\|_{l_2}^2-\gamma^2\|w\|_{l_2}^2\le|x_o|^2\left(\bar{X}_2+\frac{\gamma^2\bar{X}_2}{\varepsilon}\right)<\infty,$$

which concludes the proof. □

Note that the worst disturbance has the property,

$$\|w_\infty\|_{l_2}^2\le P|x_o|^2, \tag{71}$$

where

$$P:=\frac{4\gamma^2\bar{X}_2}{\varepsilon^2}|x_o|^2. \tag{72}$$

To see this, observe that if $\|w_\infty\|_{l_2}^2>P|x_o|^2$, equation (69) implies that

$$\begin{aligned}&\|z_{\theta_o}(G_{\theta_o}(w_\infty,x_o),w_\infty,x_o)\|_{l_2}^2-\gamma^2\|w_\infty\|_{l_2}\\&\le x_o'X_{2_{\theta_o}}x_o+\|w\|_{l_2}\left(2\gamma|x_o|\sqrt{\bar{X}_2}-\varepsilon\|w\|_{l_2}\right)\\&<x_o'X_{2_{\theta_o}}x_o=\|z_{\theta_o}(G_{\theta_o}(0,x_o),0,x_o)\|_{l_2}^2.\end{aligned}$$

That is, the cost resulting from $w\equiv0$ is larger than the cost resulting from $w=w_\infty$, which contradicts the maximizing property of w_∞.

LEMMA 5.8. *For $w=0$, $u(k)=u_\infty(k)$ uniformly exponentially stabilizes the system.*

Proof. Since X_∞ is uniformly bounded, $\bar{X}_\infty(\theta)$ defined in Lemma 5.1 is uniformly bounded. The proof of Lemma 5.2 can be applied with no changes to conclude that A_u is uniformly exponentially stable. □

LEMMA 5.9. *The closed-loop system with $u(k)=u_\infty(k)$ and $w(k)=w_\infty(k)$ is uniformly exponentially stable. In other words, the system $x(k+1)=(A_{\theta(k)}-\bar{B}_{\theta(k)}R_{\theta(k)}^{-1}L_{\theta(k)})x(k)$ is uniformly exponentially stable.*

Proof. Let $|x_o|\le1$. Define w_∞ as

$$w_\infty(k)=F_{w_{\theta(k)}}x_{\theta_o}(F_u,w_\infty,x_o;k).$$

Then w_∞ is a linear function of x_o. By Lemmas 5.5 and 5.7,

$$\begin{aligned}\sup_{w\in l_2}\inf_{u\in l_2}\|z_{\theta_o}(u,w,x_o)\|_{l_2}^2-\gamma^2\|w\|_{l_2}^2&=\|z_{\theta_o}(F_u,w_\infty,x_o)\|_{l_2}^2-\gamma^2\|w_\infty\|_{l_2}^2\\&=x_o'X_{\infty_{\theta_o}}x_o\le\bar{X}_\infty|x_o|^2,\end{aligned}$$

and, by (71), $\|w_\infty\|_{l_2}^2\le P|x_o|^2$. Thus

$$\|z_{\theta_o}(F_u,w_\infty,x_o)\|_{l_2}^2=\gamma^2\|w_\infty\|_{l_2}^2+x_o'X_{\infty_{\theta_o}}x_o\le\left(\gamma^2P+\bar{X}_\infty\right)|x_o|^2. \tag{73}$$

Note that, if $w(k) = w_\infty(k)$ and $u(k) = F_{u_{\theta(k)}}\left[\begin{smallmatrix} x(k) \\ w_\infty(k) \end{smallmatrix}\right]$, then $x(k+1) = (A_{\theta(k)} - \bar{B}_{\theta(k)} R^{-1}_{\theta(k)} L_{\theta(k)}) x(k)$.

Define the system

$$x(k+1) = \left(A_{\theta(k)} - \bar{B}_{\theta(k)} R^{-1}_{\theta(k)} L_{\theta(k)}\right) x(k) + r(k), \tag{74}$$
$$v(k) = \begin{bmatrix} -\nabla^{-1}_{\theta(k)} L_{\nabla_{\theta(k)}} \\ \tilde{C}_{\theta(k)} \end{bmatrix} x(k),$$

where

$$\tilde{C} = C - D_1 \nabla^{-1} L_\nabla + D_2 \left(R_3^{-1} R_2 \nabla^{-1} L_\nabla - R_3^{-1} L_2\right).$$

Then $v = \left[\begin{smallmatrix} w_\infty \\ z_{\theta_o}(F_u, w_\infty, x_o) \end{smallmatrix}\right]$. Fix $j \geq 0$ and set $r(k) = r_o \delta(k-j)$, that is, $r(k) = 0$ for $k \neq j$ and $r(j) = r_o$. Then (73) implies that $\left\| z_{f^j(\theta_o)}(F_u, w_\infty, r_o) \right\|^2_{l_2} \leq \left(\gamma^2 P + \bar{X}_\infty\right) |r_o|^2$. Likewise, $\|w_\infty\|^2_{l_2} \leq P |r_o|^2$. Therefore

$$\|v\|^2_{l_2} = \left\| z_{f^j(\theta_o)}(F_u, w_\infty, r_o) \right\|^2_{l_2} + \|w\|^2_{l_2} \leq \left(\left(\gamma^2 P + \bar{X}_\infty\right) + P\right) |r_o|^2. \tag{75}$$

Note that there exists a matrix $\left[\begin{smallmatrix} H_1 & H_2 \end{smallmatrix}\right]$ such that

$$\left(A - \bar{B} R^{-1} L\right) + \begin{bmatrix} H_1 & H_2 \end{bmatrix} \begin{bmatrix} -\nabla^{-1} L_\nabla \\ \left(C - D_1 \nabla^{-1} L_\nabla + D_2 \left(R_3^{-1} R_2 \nabla^{-1} L_\nabla - R_3^{-1} L_2\right)\right) \end{bmatrix} \tag{76}$$

is uniformly exponentially stable. For example, set $H_1 = -B_1 - H_2 D_1$ and $H_2 = H_d C (C'C)^+ C' - B_2 (D_2' D_2)^{-1} D_2'$, where H_d is the feedback such that $A - H_d C$ is uniformly exponentially stable, the existence of which is guaranteed by the detectability assumption, and $(C'C)^+$ is the pseudoinverse of $C'C$. Since H_d is bounded, $D_2' D_2 > 0$, D_2, B_1, C, D_1 are uniformly continuous, Θ is compact, and $C (C'C)^+ C'$ is bounded,[1] there is an $\bar{H} < \infty$ such that $\left[\begin{smallmatrix} H_1 & H_2 \end{smallmatrix}\right]' \left[\begin{smallmatrix} H_1 & H_2 \end{smallmatrix}\right] \leq \bar{H}$.

Now, let

$$y(k+1) = \left(\left(A_{\theta(k)} - \bar{B}_{\theta(k)} R^{-1}_{\theta(k)} L_{\theta(k)}\right) + \begin{bmatrix} H_{1_{\theta(k)}} & H_{2_{\theta(k)}} \end{bmatrix} \begin{bmatrix} \tilde{C}_{\theta(k)} \\ \nabla^{-1}_{\theta(k)} L_{\nabla_{\theta(k)}} \end{bmatrix}\right) y(k) \tag{77}$$
$$- \begin{bmatrix} H_{1_{\theta(k)}} & H_{2_{\theta(k)}} \end{bmatrix} v(k) + r_o \delta(k-j),$$

that is, y is an estimate of x. Since system (77) is uniformly exponentially stable, there exists an $R < \infty$ such that

$$\begin{aligned} \|y\|_{l_2} &\leq R \left\| r - \begin{bmatrix} H_1 & H_2 \end{bmatrix} v \right\|_{l_2} \leq R \|r\|_{l_2} + \bar{H} R \|v\|_{l_2} \\ &\leq R |r_o| + \bar{H} R \sqrt{\left(\left(\gamma^2 P + \bar{X}_\infty\right) + P\right)} |r_o| \\ &\leq \left(R + R \bar{H} \sqrt{\left(\left(\gamma^2 P + \bar{X}_\infty\right) + P\right)}\right) |r_o|. \end{aligned}$$

[1] Although $C (C'C)^+ C$ is not continuous, $\|C (C'C)^+ C\| \leq 1$.

On the other hand, if the system is initially at rest, that is, $y(0) = x(0) = 0$, then $y(k) = x(k)$. Thus $\|y\|_{l_2} = \|x\|_{l_2}$, and therefore

$$\|x\|_{l_2} \leq \left(R + R\bar{H}\sqrt{\left(\left(\gamma^2 P + \bar{X}_\infty\right) + P\right)} \right) |r_o| .$$

Let $\Phi_{\theta_o}(k,j)$ be the state transition matrix of system (74) with initial conditions $\theta(0) = \theta_o$, $x(0) = 0$, and let $r(i) = r_o \delta(i-j)$. Then we have

$$\begin{aligned} \|x\|^2_{[j,\infty)} &= \sum_{i=j}^{\infty} x'(i)\, x(i) = \sum_{i=j}^{\infty} \|\Phi_{\theta_o}(i,j)\, r(j)\|^2 \\ &\leq \left(R + R\bar{H}\sqrt{\left(\left(\gamma^2 P + \bar{X}_\infty\right) + P\right)} \right)^2 |r_o|^2 . \end{aligned}$$

Furthermore, for $i \geq j$, $\|\Phi_{\theta_o}(i,j)\|^2 \leq (R + R\bar{H}\sqrt{\left(\left(\gamma^2 P + \bar{X}_\infty\right) + P\right)})^2$. Applying standard techniques, we find that

$$\begin{aligned} K\,\|\Phi_{\theta_o}(j+K,j)\|^2 &= \sum_{i=j}^{K} \|\Phi_{\theta_o}(j+K,j)\|^2 \\ &\leq \sum_{i=j}^{K} \|\Phi_{\theta_o}(j+K,i)\|^2 \|\Phi_{\theta_o}(i,j)\|^2 \\ &\leq \left(R + R\bar{H}\sqrt{\left(\left(\gamma^2 P + \bar{X}_\infty\right) + P\right)} \right)^2 \sum_{i=j}^{K} \|\Phi_{\theta_o}(i,j)\|^2 \\ &\leq \left(R + R\bar{H}\sqrt{\left(\left(\gamma^2 P + \bar{X}_\infty\right) + P\right)} \right)^4 . \end{aligned}$$

Choosing $K \in \mathbb{Z}$ such that $K \geq \sqrt{2}(R + R\bar{H}\sqrt{((\gamma^2 P + \bar{X}_\infty) + P)})^4$ yields $\|\Phi(j+K, j, \theta_o)\|^2 \leq 1/\sqrt{2}$. Since this is true for all j and all θ_o, setting $M \in \mathbb{Z}$ with $M \geq 0$ and $k - (j + MK) < K$, we conclude that

$$\begin{aligned} \|\Phi_{\theta_o}(k,j)\| &\leq \|\Phi_{\theta_o}(k, j+MK)\| \prod_{m=1}^{M} \|\Phi_{\theta_o}(j+mK, j+(m-1)K)\| \\ &\leq \left(R + R\bar{H}\sqrt{\left(\left(\gamma^2 P + \bar{X}_\infty\right) + P\right)} \right) \left(\frac{1}{2}\right)^M \\ &\leq \left(R + R\bar{H}\sqrt{\left(\left(\gamma^2 P + \bar{X}_\infty\right) + P\right)} \right) 2 \left(\frac{1}{2}\right)^{\frac{k-j}{K}} . \end{aligned}$$

That is, system (74) is uniformly exponentially stable. □

LEMMA 5.10. *As $N \to \infty$, $X_\theta(0, N+1) \to X_{\infty_\theta}$ uniformly in θ and X_∞ is a continuous function.*

Proof. Let $x(k+1) = (A_{\theta(k)} - \bar{B}_{\theta(k)} R^{-1}_{\theta(k)} L_{\theta(k)}) x(k)$. Then, by Lemma 5.9, $x(k) \to 0$ uniformly exponentially fast. Set $w_\infty(k) = F_{w_{\theta(k)}} x(k)$ as in (62) and define

$$\tilde{w}_N(k) := \begin{cases} w_\infty(k) & \text{for } k \leq N, \\ 0 & \text{otherwise.} \end{cases}$$

Since X_∞ is uniformly bounded and $\nabla_\theta \leq -\varrho I$, it follows that F_w is uniformly bounded. Since $x(k) \to 0$ uniformly exponentially fast and F_w is bounded, $w_\infty \to 0$ uniformly exponentially fast. Therefore $\lim_{N\to\infty} \|w_\infty - \tilde{w}_N\|_{l_2} = \lim_{N\to\infty} \|w_\infty\|_{[N+1,\infty)} = 0$, where the convergence is uniformly exponentially fast.

Recall the following: (31) states that

$$
\begin{aligned}
(78)\qquad & x_o' X_{\theta_o}(0, N+1)\, x_o \\
&= \sup_{w\in l_2[0,N]} \inf_{u\in l_2[0,N]} \Big\{ \|z\|^2_{[0,N]} - \gamma^2 \|w\|^2_{[0,N]} \\
&\qquad\qquad + x'(N+1)\, X_{\theta_o}(N+1, N+1)\, x(N+1) \Big\}.
\end{aligned}
$$

From (19) of Theorem 3.7, it follows that

$$
(79)\qquad x(N+1)' X_{2_{f^{N+1}(\theta_o)}} x(N+1) = \inf_{u\in l_2} \|z\|^2_{[N+1,\infty)}.
$$

From (64), we have

$$
(80)\qquad \inf_{u\in l_2} \|z_{\theta_o}(u, w, x_o)\|^2_{[0,\infty)} - \gamma^2 \|w\|^2_{[0,\infty)} = \|z_{\theta_o}(G_{\theta_o}(w, x_o), w, x_o)\|^2_{[0,\infty)} - \gamma^2 \|w\|^2_{[0,\infty)}.
$$

Combining (64) and Lemma 5.5 yields

$$
(81)\qquad \|z_{\theta_o}(G_{\theta_o}(w_\infty, x_o), w_\infty, x_o)\|^2_{[0,\infty)} - \gamma^2 \|w_\infty\|_{l_2} = x_o' X_{\infty_{\theta_o}} x_o.
$$

From (66), we have

$$
(82)\qquad \|z_{\theta_o}(G_{\theta_o}(w, 0), w, 0)\|^2_{[0,\infty)} < \gamma^2 \|w\|^2_{[0,\infty)},
$$

and, from inequality (71), we have

$$
(83)\qquad \|w_\infty\|^2_{l_2} \leq P |x_o|^2.
$$

Combining the preceding relations yields the following string:

$$
\begin{aligned}
& x_o' X_{\theta_o}(0, N+1)\, x_o \\
&= \sup_{w\in l_2[0,N]} \inf_{u\in l_2[0,N]} \Big\{ \|z_{\theta_o}(u, w, x_o)\|^2_{[0,N]} - \gamma^2 \|w\|^2_{[0,N]} \\
&\qquad\qquad + x'(N+1)\, X_{2_{f^{N+1}(\theta_o)}} x(N+1) \Big\} \\
&= \sup_{\{w\in l_2 : w(k)=0,\ k\geq N\}} \inf_{u\in l_2} \Big\{ \|z_{\theta_o}(u, w, x_o)\|^2_{[0,\infty)} - \gamma^2 \|w\|^2_{[0,\infty)} \Big\} \\
&= \sup_{\{w\in l_2 : w(k)=0,\ k\geq N\}} \Big\{ \|z_{\theta_o}(G_{\theta_o}(w, x_o), w, x_o)\|^2_{[0,\infty)} - \gamma^2 \|w\|^2_{[0,\infty)} \Big\} \\
&\geq \|z_{\theta_o}(G_{\theta_o}(\tilde{w}_N, x_o), \tilde{w}_N, x_o)\|^2_{[0,\infty)} - \gamma^2 \|\tilde{w}_N\|^2_{[0,\infty)} \\
&= \|z_{\theta_o}(G_{\theta_o}(w_\infty, x_o), w_\infty, x_o) + z_{\theta_o}(G_{\theta_o}(\tilde{w}_N - w_\infty, 0), \tilde{w}_N - w_\infty, 0)\|^2_{[0,\infty)} \\
&\quad - \gamma^2 \|\tilde{w}_N\|^2_{[0,\infty)}
\end{aligned}
$$

$$
\begin{aligned}
&= \|z_{\theta_o}\left(G_{\theta_o}\left(w_\infty, x_o\right), w_\infty, x_o\right)\|^2_{[0,\infty)} + \|z_{\theta_o}\left(G_{\theta_o}\left(\tilde{w}_N - w_\infty, 0\right), \tilde{w}_N - w_\infty, 0\right)\|^2_{[0,\infty)} \\
&\quad - \gamma \|\tilde{w}_N\|^2_{[0,\infty)} \\
&\quad + 2\left\langle z_{\theta_o}\left(G_{\theta_o}\left(w_\infty, x_o\right), w_\infty, x_o\right), z_{\theta_o}\left(G_{\theta_o}\left(\tilde{w}_N - w_\infty, 0\right), \tilde{w}_N - w_\infty, 0\right)\right\rangle \\
&\geq \|z_{\theta_o}\left(G_{\theta_o}\left(w_\infty, x_o\right), w_\infty, x_o\right)\|^2_{[0,\infty)} - \gamma^2 \|\tilde{w}_N\|^2_{[0,\infty)} \\
&\quad + 2\left\langle z_{\theta_o}\left(G_{\theta_o}\left(w_\infty, x_o\right), w_\infty, x_o\right), z_{\theta_o}\left(G_{\theta_o}\left(\tilde{w}_N - w_\infty, 0\right), \tilde{w}_N - w_\infty, 0\right)\right\rangle \\
&\geq \|z_{\theta_o}\left(G_{\theta_o}\left(w_\infty, x_o\right), w_\infty, x_o\right)\|^2_{[0,\infty)} - \gamma^2 \|w_\infty\|^2_{[0,\infty)} \\
&\quad - 2\|z_{\theta_o}\left(G_{\theta_o}\left(w_\infty, x_o\right), w_\infty, x_o\right)\|_{[0,\infty)} \|z_{\theta_o}\left(G_{\theta_o}\left(\tilde{w}_N - w_\infty, 0\right), \tilde{w}_N - w_\infty, 0\right)\|_{[0,\infty)} \\
&\geq x_o' X_{\infty_{\theta_o}} x_o - 2\left(\sqrt{\gamma^2 \|w_\infty\|^2 + x_o' X_{\infty_{\theta_o}} x_o}\right)\gamma \|w_\infty - \tilde{w}_N\|_{[0,\infty)} \\
&\geq x_o' X_{\infty_{\theta_o}} x_o - 2\left|x_o\right|\left(\sqrt{\gamma^2 P + \bar{X}_\infty}\right)\gamma \|w_\infty - \tilde{w}_N\|_{[0,\infty)}.
\end{aligned}
$$

Lemma 5.1 implies that $X_{\infty_{\theta_o}} - X_{\theta_o}(0, N+1) \geq 0$. Thus

$$
0 \leq x_o'\left(X_{\infty_{\theta_o}} - X_{\theta_o}(0, N+1)\right) x_o \leq 2\gamma\left|x_o\right|\left(\sqrt{\gamma^2 P + \bar{X}_\infty}\right)\|w_\infty - \tilde{w}_N\|_{[0,\infty)}.
$$

Since $\|w_\infty - \tilde{w}_N\|_{[0,\infty)} \to 0$ uniformly in θ and exponentially in N, and since $2\gamma(\sqrt{\gamma^2 P + \bar{X}_\infty})$ does not depend on θ_o, we have $X_{\theta_o}(0, N+1) \to X_{\infty_{\theta_o}}$ uniformly in θ and exponentially in N.

Since X_2 is continuous, $X_\theta(0, N+1)$ is continuous in θ for $N < \infty$. Since Θ is compact, and $X(0, N+1) \to X_\infty$ in the uniform metric, Theorem 7.1.4 in [24] implies that X_∞ is continuous. □

The time-invariant version of the first claim of this lemma can be found in [31].

5.2. Sufficiency. Suppose that the assumptions of the theorem hold and that (32), (33), and (34) hold. It will be shown that the control given by (36) is internally stabilizing and, if $u = u_\infty$ as defined by (42), then Objective B is satisfied. This proof is similar to the proof given in [17].

Under the above conditions, (32) can be written as

$$
X_{\infty_\theta} = C_\theta' C_\theta + A_\theta' X_{\infty_{f(\theta)}} A_\theta - L_{2_\theta}' R_{3_\theta}^{-1} L_{2_\theta} - L_{\nabla_\theta}' \nabla_\theta^{-1} L_{\nabla_\theta}.
$$

It follows that

$$
\begin{aligned}
&\begin{bmatrix} A_\theta' & C_\theta' \\ B_{2_\theta}' & D_{2_\theta}' \end{bmatrix}\begin{bmatrix} X_{\infty_{f(\theta)}} & 0 \\ 0 & I \end{bmatrix}\begin{bmatrix} A_\theta & B_{2_\theta} \\ C_\theta & D_{2_\theta} \end{bmatrix} \\
&= \begin{bmatrix} X_{\infty_\theta} + L_{\nabla_\theta}' \nabla_\theta^{-1} L_{\nabla_\theta} & 0 \\ 0 & 0 \end{bmatrix} + \begin{bmatrix} L_{2_\theta}' \\ R_{3_\theta} \end{bmatrix} R_{3_\theta}^{-1} \begin{bmatrix} L_{2_\theta} & R_{3_\theta} \end{bmatrix}.
\end{aligned}
$$

Multiplying both sides of this equality, by $\begin{bmatrix} I & 0 \\ -R_{3_\theta}^{-1} L_{2_\theta} & I \end{bmatrix}$ on the right and by the transpose on the left, and taking the (1,1) block yields

$$
\begin{aligned}
X_{\infty_\theta} &= \left(A_\theta - B_{2_\theta} R_{3_\theta}^{-1} L_{2_\theta}\right)' X_{\infty_{f(\theta)}}\left(A_\theta - B_{2_\theta} R_{3_\theta}^{-1} L_{2_\theta}\right) \\
&\quad - L_{\nabla_\theta}' \nabla_\theta^{-1} \nabla_\theta \nabla_\theta^{-1} L_{\nabla_\theta} + \left(C_\theta - D_{2_\theta} R_{3_\theta}^{-1} L_{2_\theta}\right)'\left(C_\theta - D_{2_\theta} R_{3_\theta}^{-1} L_{2_\theta}\right).
\end{aligned} \tag{84}
$$

Since $A_\theta - \bar{B}_\theta R_\theta^{-1} L_\theta = A_\theta - B_{2_\theta} R_{3_\theta}^{-1} L_{2_\theta} - \left(B_{1_\theta} - B_{2_\theta} R_{3_\theta}^{-1} L_{2_\theta}\right) \nabla_\theta^{-1} L_{\nabla_\theta}$ is assumed to be uniformly exponentially stable, we conclude that the triple

$$\left(\left(A_\theta - B_{2_\theta} R_{3_\theta}^{-1} L_{2_\theta}\right), \left(\nabla_\theta^{-1} L_{\nabla_\theta}\right), f\right)$$

is uniformly detectable. Since $\nabla_\theta \leq -\varrho I$, ∇_θ^{-1} is uniformly bounded. Since X_∞ is uniformly bounded, $\nabla_\theta^{-1} L_{\nabla_\theta}$ is uniformly bounded. Thus (84) is a Lyapunov equation, and Corollary 3.6 implies that

$$\xi(k+1) = \left(A_{\theta(k)} - B_{2_{\theta(k)}} R_{3_{\theta(k)}}^{-1} L_{2_{\theta(k)}}\right) \xi(k) \tag{85}$$

is a uniformly exponentially stable system. Therefore the control $u = u_\infty$ is uniformly exponentially stabilizing.

Since system (85) is uniformly exponentially stable, if $u = u_\infty$ and $w \in l_2$, then $x \in l_2$ and $\lim_{k\to\infty} x(k) = 0$. Thus, if $u = u_\infty$, then (28) implies that, for all N,

$$\begin{aligned} &\|z\|_{[0,N]}^2 - \gamma^2 \|w\|_{[0,N]}^2 + x'(N+1) X_{\infty_{f^{N+1}(\theta_o)}} x(N+1) \\ &\quad = x'(0) X_{\infty_{\theta_o}} x(0) + \sum_{k=0}^{N} \left(w(k) - w_\infty(k)\right)' \nabla_{f^k(\theta_o)} \left(w(k) - w_\infty(k)\right), \end{aligned} \tag{86}$$

where $w_\infty(k) := -\nabla_{f^k(\theta_o)}^{-1} L_{\nabla_{f^k(\theta_o)}} x(k)$. Since $x, w \in l_2$, it follows that $u, z \in l_2$. Furthermore, ∇ is bounded. Thus we can let $N \to \infty$ in (86), and for $x_o = 0$,

$$\|z\|_{l_2}^2 - \gamma \|w\|_{l_2}^2 = \sum_{k=0}^{\infty} \left(w(k) - w_\infty(k)\right)' \nabla_{f^k(\theta_o)} \left(w(k) - w_\infty(k)\right). \tag{87}$$

Since system (85) is stable and causal, the closed-loop system with $u = u_\infty$, viz.,

$$\begin{aligned} &\begin{bmatrix} x(k+1) \\ w(k) - w_\infty(k) \end{bmatrix} \\ &= \begin{bmatrix} \left(A_{\theta(k)} - B_{2_{\theta(k)}} R_{3_{\theta(k)}}^{-1} L_{2_{\theta(k)}}\right) & \left(B_{1_{\theta(k)}} - B_{2_{\theta(k)}} R_{3_{\theta(k)}}^{-1} R_{2_{\theta(k)}}\right) \\ \left(\nabla_{\theta(k)}^{-1} L_{\nabla_{\theta(k)}}\right) & I \end{bmatrix} \begin{bmatrix} x(k) \\ w(k) \end{bmatrix}, \end{aligned} \tag{88}$$

is l_2-stable and causal. The inverse of this system (see [36]) is

$$\begin{bmatrix} \xi(k+1) \\ w(k) \end{bmatrix} = \begin{bmatrix} \tilde{A}_{\theta(k)} & -\tilde{B}_{\theta(k)} \\ \tilde{C}_{\theta(k)} & \tilde{D}_{\theta(k)} \end{bmatrix} \begin{bmatrix} \xi(k) \\ w(k) - w_\infty(k) \end{bmatrix}$$

with

$$\begin{aligned} \tilde{A}_\theta &= A_\theta - B_{2_\theta} R_{3_\theta}^{-1} L_{2_\theta} - \left(B_{1_\theta} - B_{2_\theta} R_{3_\theta}^{-1} R_{2_\theta}\right) \nabla_\theta^{-1} L_{\nabla_\theta} \\ &= A_\theta - \bar{B}_\theta R_\theta^{-1} L_\theta, \\ \tilde{B}_\theta &= -\left(B_{1_\theta} - B_{2_\theta} R_{3_\theta}^{-1} R_{2_\theta}\right), \\ \tilde{C}_\theta &= -\nabla_\theta^{-1} L_{\nabla_\theta}, \\ \tilde{D}_\theta &= I. \end{aligned}$$

Since $\xi(k+1) = (A_{\theta(k)} - \bar{B}_{\theta(k)} R_{\theta(k)}^{-1} L_{\theta(k)})\xi(k)$ is uniformly exponentially stable, the inverse of system (88) is uniformly exponentially stable and hence l_2 stable. Thus there exists a $\delta > 0$ such that, for all $\theta_o \in \Theta$,

$$\|w\|_{l_2}^2 \leq \frac{1}{\delta} \|w - w_\infty\|_{l_2}^2 .$$

Since $\nabla \leq -\varrho I$, equation (87) implies that

$$\|z\|_{l_2}^2 - \gamma^2 \|w\|_{l_2}^2 \leq -\varrho \|w - w_\infty\|_{l_2}^2 \leq -\delta\varrho \|w\|_{l_2}^2 = -\varepsilon \|w\|_{l_2}^2 \ . \qquad \square$$

6. Controlling nonlinear systems with linear dynamically varying H^∞ controllers. In the preceding section, a technique for stabilizing an LDV system subject to an H^∞ disturbance rejection requirement was developed. Here, it will first be shown that the LDV controller for the *linearized* tracking error system can also be used to stabilize the *nonlinear* tracking error dynamics, in a scheme that works along every trajectory, provided that the initial tracking error is small enough (section 6.1). Next, some issues quite specific to the H^∞ implementation of the tracking scheme (to be published elsewhere) will be briefly surveyed.

6.1. Stability of a closed-loop nonlinear system. To make H^∞ design relevant to nonlinear tracking performance improvement, the guiding idea is to write the nonlinearity η in the tracking error dynamics (6) as a feedback from an output $z(k)$ to a disturbance $w(k)$. To this end, we introduce the factorization

(89)
$$\eta(x,u,\theta) = \begin{bmatrix} \eta_x(x,u,\theta) & \eta_u(x,u,\theta) \end{bmatrix} \begin{bmatrix} x \\ u \end{bmatrix} = B_{1_\theta} \tilde{\eta}(x,u,\theta) \begin{bmatrix} C_\theta & D_{2_\theta} \end{bmatrix} \begin{bmatrix} x \\ u \end{bmatrix}.$$

Here we simply take

(90)
$$B_{1_\theta} := I_{n\times n}, \quad C_\theta := \begin{bmatrix} I_{n\times n} \\ 0_{m\times n} \end{bmatrix}, \quad D_{2_\theta} := \begin{bmatrix} 0_{n\times m} \\ I_{m\times m} \end{bmatrix},$$
$$\tilde{\eta}(x,u,\theta) := \begin{bmatrix} \eta_x(x,u,\theta) & \eta_u(x,u,\theta) \end{bmatrix},$$

where η_x and η_u are defined by (8) and (9). The error due to linearization can be modeled as a feedback from z to w:

$$\begin{aligned} \eta(x(k),u(k),\theta(k)) &= B_{1_{\theta(k)}} w(k), \\ w(k) &= \tilde{\eta}(x(k),u(k),\theta(k))\, z(k), \\ z(k) &= C_{\theta(k)} x(k) + D_{2_{\theta(k)}} u(k). \end{aligned}$$

Here $D_1 = 0$. Clearly $B_1 : \Theta \to \mathbb{R}^{n\times n}$, $C : \Theta \to \mathbb{R}^{(n+m)\times n}$, and $D_2 : \Theta \to \mathbb{R}^{(n+m)\times m}$ are continuous functions, and the triple (A, C, f) is detectable. Hence, assuming that (A, B_2, f) is stabilizable, Theorem 4.2 or Corollary 4.3 can be applied to generate a controller.

THEOREM 6.1. *Let (4) hold. Define A, B_1, B_2, C, D_1, and D_2 as above and assume that the triple (A, B_2, f) is stabilizable. Let F be the H^∞ controller such that $\sup_{w\in l_2} \|z\|_{l_2}/\|w\|_{l_2} < \gamma$ for some $\gamma < \infty$. Then there exists an $R_{Capture} > 0$ such that, if $u(k) = F_{\theta(k)}(\varphi(k) - \theta(k))$ and $|\varphi(0) - \theta(0)| < R_{Capture}$, then $|\varphi(k) - \theta(k)| \to 0$ as $k \to \infty$.*

Proof. Define $\bar{\eta}(\bar{x},\bar{u}) := \sup\{\|\tilde{\eta}(x,u,\theta)\| : |x| \le \bar{x}, |u| \le \bar{u}, \theta \in \Theta\}$. By (10) and (11), we obtain

$$\bar{\eta}(\bar{x},\bar{u}) \to 0 \quad \text{as} \quad \bar{x},\bar{u} \to 0. \tag{91}$$

It follows that there exist $x^*, u^* > 0$ such that $\bar{\eta}(x^*,u^*) \le \frac{1}{\gamma}$. Now define

$$h(x,u,\theta) := \begin{cases} \tilde{\eta}(x,u,\theta) & \text{for } |x| < x^* \text{ and } |u| < u^*, \\ 0_{n\times(n+m)} & \text{otherwise.} \end{cases} \tag{92}$$

Thus, for all x and u, $\sup_{\theta\in\Theta}\|h(x,u,\theta)\| \le \frac{1}{\gamma}$. Consider the following closed-loop LDV system:

$$\begin{aligned} \xi(k+1) &= A_{\theta(k)}\xi(k) + B_{1_{\theta(k)}}\omega(k) + B_{2_{\theta(k)}}\upsilon(k), \\ \zeta(k) &= C_{\theta(k)}\xi(k) + D_{2_{\theta(k)}}\upsilon(k), \\ \omega(k) &= h(\xi(k),\upsilon(k),\theta(k))\zeta(k), \\ \upsilon(k) &= F_{\theta(k)}\xi(k), \\ \theta(k+1) &= f(\theta(k)). \end{aligned} \tag{93}$$

Since $\sup_{w\in l_2}\|z\|_{l_2}/\|w\|_{l_2} < \gamma$, the small gain theorem of [32] implies that system (93) is externally l_2 stable. Since $A_\theta + B_{2_\theta}F_\theta$ is uniformly exponentially stable, system (93) is also internally l_2 stable. Therefore there exist a $G_x \ge 1$ and a $G_u > 0$ such that $\|\xi\|_{l_\infty} \le \|\xi\|_{l_2} < G_x|\xi(0)|$ and $\|\upsilon\|_{l_\infty} \le \|\upsilon\|_{l_2} < G_u|\xi(0)|$. Now set

$$R_{Capture} := \min\left(\frac{x^*}{G_x}, \frac{u^*}{G_u}\right).$$

If $|\xi(0)| \le R_{Capture}$, then

$$\|\xi\|_{l_\infty} < G_x|\xi(0)| \le x^*$$

and

$$\|\upsilon\|_{l_\infty} < G_u|\xi(0)| \le u^*.$$

By the above inequalities and (92), we conclude that, for all k, $h(\xi(k),\upsilon(k),\theta(k)) = \tilde{\eta}(\xi(k),\upsilon(k),\theta(k))$. Thus, if

$$|x(0)| < \min\left(\frac{x^*}{G_x}, \frac{u^*}{G_u}\right),$$

then, by the uniqueness of solutions to difference equations, the closed-loop LDV system

$$\begin{aligned} x(k+1) &= A_{\theta(k)}x(k) + B_{1_{\theta(k)}}w(k) + B_{2_{\theta(k)}}u(k), \\ z(k) &= C_{\theta(k)}x(k) + D_{2_{\theta(k)}}u(k), \\ w(k) &= \tilde{\eta}(x(k),u(k),\theta)z(k), \\ u(k) &= F_{\theta(k)}x(k), \\ \theta(k+1) &= f(\theta(k)) \end{aligned} \tag{94}$$

is l_2 stable, and furthermore, $\|x\|_{l_\infty} < x^*$ and $\|u\|_{l_\infty} < u^*$. Since (94) is the tracking error of the closed-loop nonlinear system, we conclude that $|x(k)| = |\varphi(k) - \theta(k)| \to 0$ as $k \to \infty$. ∎

6.2. Further considerations. Writing the nonlinearity $\eta(x, u, \theta)$ as a bounded feedback $\tilde{\eta}(x, u, \theta)$ from an output z to the input w (see (10), (11), (89)) yields an H^∞ design that attenuates the effect of the nonlinearity and hence amplifies the initial allowable tracking error. It is further possible to optimize this procedure by factoring $\tilde{\eta}$ in such a way that $\|\tilde{\eta}\| \leq 1$ (see [7] for details). The suboptimal H^∞ controller is continuous, and therefore an approximation of the LDV H^∞ controller can be constructed in the same way that an approximation of the LDV quadratic controller was constructed in [8]. The fact that the H^∞ controller is guaranteed to be continuous under the condition that it be suboptimal does not prove that the suboptimality condition for continuity is necessary. In fact, an example based on the Hénon map shows that the suboptimal controller becomes discontinuous as γ approaches γ_o, the optimal H^∞ tolerance.

7. Conclusion. Suboptimal H^∞ controllers for LDV systems have been developed. Like the LDV quadratic controllers, these H^∞ controllers are continuous functions. The H^∞ method has distinct advantages over the LQ method, in that H^∞ can be tuned to minimize the effect of linearization and it is possible to find a lower bound on the maximum allowable initial tracking error.

A CONSTRUCTIVE SOLUTION TO INTERCONNECTION AND DECOMPOSITION PROBLEMS WITH MULTIDIMENSIONAL BEHAVIORS*

E. ZERZ† AND V. LOMADZE‡

Abstract. By a multidimensional behavior, we mean the solution space of a linear constant-coefficient system of partial difference or differential equations. Within the behavioral framework, a natural concept of interconnection has been introduced by J. C. Willems. The regular interconnection problem can be formulated as follows: Given a behavior (the plant), find—if possible—another behavior (a controller) such that their interconnection is not redundant and is equal to a certain desired behavior. We give a constructive solution to this problem, which is in terms of polynomial matrix equations that can be solved using the theory of Gröbner bases. We also study a dual problem concerning the existence of direct sum decompositions of multidimensional behaviors. Finally, we present a unified framework for studying both problems as special cases of constructing relative complements in the lattice of behaviors.

Key words. multidemensional systems, behavioral approach, regular interconnection, direct sum decomposition, multivariate polynomial modules, split exact sequences

1. Introduction.

Feedback control is based on the interconnection of systems: Given a dynamical system (the plant), the goal of feedback control is to design another system (a controller) in such a way that the interconnection of the two systems has certain desired properties. As an example, consider a plant given in classical state space form

$$\dot{x} = Ax + Bu$$

and let the controller be specified by the feedback law $u = Fx + v$. Then the interconnection (the closed loop system) is

$$\dot{x} = (A + BF)x + Bv. \tag{1.1}$$

A typical aim of the controller design in this setting is spectral assignment; that is, a condition is given on the desired location of the eigenvalues of $A + BF$.

Note that interconnection means nothing more than combining the equations that determine plant and controller, respectively, and looking at their common solutions. For instance, combining the plant given by

$$\begin{bmatrix} \frac{d}{dt}I - A, & -B, & 0 \end{bmatrix} \begin{bmatrix} x \\ u \\ v \end{bmatrix} = 0$$

with the controller given by

$$\begin{bmatrix} F, & -I, & I \end{bmatrix} \begin{bmatrix} x \\ u \\ v \end{bmatrix} = 0$$

yields the interconnected system

$$\begin{bmatrix} \frac{d}{dt}I - A, & -B, & 0 \\ F, & -I, & I \end{bmatrix} \begin{bmatrix} x \\ u \\ v \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix},$$

from which we may eliminate u to get (1.1). It is worth noting that this interconnection is regular in a sense to be defined below.

The behavioral approach to systems theory developed by J. C. Willems—see [14] for a survey—provides an elegant framework for dealing with such interconnection problems as well as more general ones. A behavior is the set of signals w that obey a certain system law, say a system of linear differential equations, which may be written as

$$P_1(\tfrac{d}{dt})w = 0.$$

In the example above, $w = (x, u, v)^t$, where $(\cdot)^t$ denotes transposition, and

$$P_1\left(\tfrac{d}{dt}\right) = \begin{bmatrix} \frac{d}{dt}I - A, & -B, & 0 \end{bmatrix}.$$

Similarly, let the controller be determined by $P_2(\frac{d}{dt})w = 0$. Then the interconnection is determined by the system law

$$\begin{bmatrix} P_1 \\ P_2 \end{bmatrix} (\tfrac{d}{dt})\ w = 0.$$

In what follows, we will consider the multidimensional case, that is, systems of partial instead of ordinary differential equations.

A dual problem concerns direct sum decompositions of behaviors: Is it possible to write a behavior as the superposition of two smaller systems such that each trajectory of the overall behavior has a unique representation as the sum of two trajectories of the respective building blocks? A prominent example from classical one-dimensional systems theory is the so-called controllable-autonomous decomposition. Consider $\dot{x} = Ax + Bu$. In a suitably chosen basis of the state space, these equations take the form

$$\frac{d}{dt}\begin{bmatrix} x_1 \\ x_2 \end{bmatrix} = \begin{bmatrix} A_1 & A_2 \\ 0 & A_3 \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \end{bmatrix} + \begin{bmatrix} B_1 \\ 0 \end{bmatrix} u,$$

where (A_1, B_1) is a reachable matrix pair. This is the well-known Kalman reachability decomposition. Now each trajectory $w = (x_1, x_2, u)^t$ can be uniquely written in the form $w = w_1 + w_2$, where w_1 belongs to the controllable part of the system (governed by $\dot{x}_1 = A_1x_1 + B_1u$, $x_2 = 0$) and w_2 belongs to a suitably defined autonomous part of the system.

For one-dimensional behaviors, i.e., systems governed by ordinary differential equations, the regular interconnection problem was formulated and solved by J. C. Willems [14, 15]. In the multidimensional situation, the problem was first tackled by

P. Rocha and J. Wood [10, 11], who provided a foundation for the control theory of multidimensional behaviors, based on prior work of U. Oberst [9]. Several authors have noted that the controllable-autonomous decomposition is, in general, no longer a direct sum decomposition in dimensions greater than one [6]. A more general treatment of decompositions of two-dimensional systems has been offered by M. E. Valcher and M. Bisiacco [2, 13]. Both problems can be treated within the unified framework of lattice theory; see [9, 12].

This paper is organized as follows. In section 2, we give some introductory material as well as the main mathematical tool for the subsequent discussion. We use this tool to solve the regular interconnection problem in section 3. Section 4 is devoted to the dual problem of direct sum decompositions. Finally, a unified approach to studying both problems is proposed in section 5. We conclude with three worked examples which are collected in section 6.

2. Preliminaries. Let K be a field, n a positive integer, and $\mathcal{D} = K[s_1, \ldots, s_n]$ the polynomial ring over K in n indeterminates $s_1, \ldots, s_n$.

By a linear n-dimensional system Σ with signal number q, we mean a submodule N of $\mathcal{D}^q$. Such a module admits a representation

$$N = \operatorname{im}(P^t) = P^t\mathcal{D}^g \quad \text{for some } P \in \mathcal{D}^{g\times q},$$

where g is a suitable integer and P^t is the transpose of P. The matrix P is called a representation of Σ.

The connection with behaviors, as described in the introduction, is as follows. Let $P \in \mathcal{D}^{g\times q}$ be given. Consider the solution space of the associated system of linear constant-coefficient partial differential equations, that is,

$$\mathcal{B} = \ker_{\mathcal{A}}(P) = \{w \in \mathcal{A}^q \mid P(\underline{\partial})w := P(\partial_1, \ldots, \partial_n)w = 0\}.$$

The signal space $\mathcal{A}$ is either the space of smooth functions or of distributions on $\mathbb{R}^n$. (The base field K is assumed to be either $\mathbb{R}$ or $\mathbb{C}$.) Oberst [9] showed that $\mathcal{B} \subseteq \mathcal{A}^q$ and the submodule of $\mathcal{D}^q$ generated by the columns of P^t are in fact equivalent data, and this motivates our definition of a system given above. Indeed,

$$\mathcal{B} = \ker_{\mathcal{A}}(P) \quad \rightarrow \quad M(\mathcal{B}) := \{p^t \in \mathcal{D}^q \mid p(\underline{\partial})w = 0 \ \forall w \in \mathcal{B}\}$$

and

$$\mathcal{B}(N) := \{w \in \mathcal{A}^q \mid p(\underline{\partial})w = 0 \ \forall p^t \in N\} \quad \leftarrow \quad N = \operatorname{im}(P^t) = P^t\mathcal{D}^g$$

are order-reversing bijections between behaviors in $\mathcal{A}^q$ and submodules of $\mathcal{D}^q$, and they are inverse to each other. We have the correspondences

$$\mathcal{B}_1 \cap \mathcal{B}_2 \quad \leftrightarrow \quad N_1 + N_2$$

(that is to say, $M(\mathcal{B}_1 \cap \mathcal{B}_2) = M(\mathcal{B}_1) + M(\mathcal{B}_2)$ and $\mathcal{B}(N_1 + N_2) = \mathcal{B}(N_1) \cap \mathcal{B}(N_2)$) and similarly

$$\mathcal{B}_1 + \mathcal{B}_2 \quad \leftrightarrow \quad N_1 \cap N_2.$$

A similar interpretation is valid for discrete systems, i.e., for behaviors given by difference instead of differential equations. For the sake of simplicity, we will restrict our analysis to the continuous case throughout this paper.

Given two behaviors $\mathcal{B}_1, \mathcal{B}_2 \subseteq \mathcal{A}^q$, their *interconnection* $\mathcal{B}$ is defined as [15]

$$\mathcal{B} = \mathcal{B}_1 \cap \mathcal{B}_2.$$

Thus, the interconnected behavior consists of the trajectories that obey the system laws of both $\mathcal{B}_1$ and $\mathcal{B}_2$; that is, if $\mathcal{B}_i = \ker_{\mathcal{A}}(P_i)$, then $\mathcal{B} = \ker_{\mathcal{A}}(P)$ with

$$P = \begin{bmatrix} P_1 \\ P_2 \end{bmatrix}. \tag{2.1}$$

The module-theoretic counterpart is the following: Given two systems Σ_1 and Σ_2 with the same signal number q, we define their interconnection $\Sigma := \Sigma_1 \wedge \Sigma_2$ by

$$N := N_1 + N_2.$$

A representation P of Σ is obtained from representations P_i of Σ_i by (2.1).

The interconnection is said to be *regular* if we have

$$N = N_1 \oplus N_2,$$

that is, if $N_1 \cap N_2 = \{0\}$. In terms of behaviors, this signifies

$$\mathcal{B}_1 + \mathcal{B}_2 = \mathcal{A}^q,$$

and in terms of representations, an interconnection (2.1) is regular if

$$\operatorname{rank}(P) = \operatorname{rank}(P_1) + \operatorname{rank}(P_2).$$

We say that a system Σ_1 is *less powerful* than Σ if $N_1 \subseteq N$. This implies the reverse relation for the corresponding behaviors: $\mathcal{B}_1 \supseteq \mathcal{B}$. In terms of representations, this means $P_1 = CP$ for some polynomial matrix C. Certainly, Σ_1 and Σ_2 themselves are always less powerful than $\Sigma_1 \wedge \Sigma_2$.

The basic mathematical tool for the following discussion is the notion of a *split exact sequence*. Let R be a commutative ring, and let L, L_1, L_2 be R-modules. Let $f : L_1 \to L$ and $g : L \to L_2$ be R-linear maps. The sequence

$$0 \to L_1 \xrightarrow{f} L \xrightarrow{g} L_2 \to 0 \tag{2.2}$$

is called *exact* if f is injective, g is surjective, and $\operatorname{im}(f) = \ker(g)$. An exact sequence (2.2) is said to be *split* if the following equivalent conditions are satisfied:

1. There exists a homomorphism $k : L \to L_1$ such that kf is the identity map on L_1, denoted by id_{L_1}.
2. There exists a homomorphism $h : L_2 \to L$ such that $gh = \mathrm{id}_{L_2}$.
3. $\operatorname{im}(f) = \ker(g)$ is a direct summand of L.

THEOREM 2.1. *Let R be a commutative ring. Let F_0, F_1 be finitely generated free R-modules, and let L, L_1, L_2 be arbitrary R-modules. Suppose that the following diagram is commutative with exact rows:*

$$\begin{array}{ccccccccc} & & F_1 & \xrightarrow{\alpha} & F_0 & \xrightarrow{\beta} & L_2 & \to & 0 \\ & & & & \pi \downarrow & & \| & & \\ 0 & \to & L_1 & \xrightarrow{f} & L & \xrightarrow{g} & L_2 & \to & 0. \end{array}$$

Then the following are equivalent:

1. *The lower sequence is split.*
2. *There exists a homomorphism* $\xi : F_0 \to L_1$ *such that*

$$f\xi\alpha = \pi\alpha. \tag{2.3}$$

Proof. $1 \Rightarrow 2$. Suppose there exists a homomorphism $h : L_2 \to L$ such that $gh = \mathrm{id}$. Then $g\pi = \beta = gh\beta$, and thus

$$\mathrm{im}(\pi - h\beta) \subseteq \ker(g) = \mathrm{im}(f).$$

Let B be a basis of F_0. Since f is injective, there exists, for any $b \in B$, a unique $\xi(b) \in L_1$ such that

$$f(\xi(b)) = (\pi - h\beta)(b).$$

This defines a homomorphism $\xi : F_0 \to L_1$ with

$$f\xi\alpha = (\pi - h\beta)\alpha = \pi\alpha.$$

$2 \Rightarrow 1$. Let $\xi : F_0 \to L_1$ be such that $(\pi - f\xi)\alpha = 0$, that is,

$$\ker(\beta) = \mathrm{im}(\alpha) \subseteq \ker(\pi - f\xi).$$

Then there is a well-defined homomorphism $h : L_2 \to L$ that assigns to each $l_2 = \beta(x)$, independently of the choice of such an $x \in F_0$,

$$h(l_2) := (\pi - f\xi)(x).$$

We have $gh(l_2) = g(\pi - f\xi)(x) = g\pi(x) = \beta(x) = l_2$ for all $l_2 \in L_2$. ∎

There is a close connection between the above theorem and the theory of extension modules. The reader is referred to [5] for a general introduction to this concept, and to [8] for its application to the regular interconnection problem.

3. The regular interconnection problem. We will consider the following control problem: Given Σ_1 and Σ, with Σ_1 less powerful than Σ, does there exist a system Σ_2 such that

$$\Sigma_1 \wedge \Sigma_2 = \Sigma$$

and the interconnection is regular? If yes, we say that Σ can be *achieved* from Σ_1 by regular interconnection. Moreover, in that case, we are looking for an explicit construction of such a Σ_2.

One should think of these systems as follows: Σ_1 is the given plant, Σ is a specified desired system, and Σ_2 is the controller to be constructed.

For this, let $P_1 \in \mathcal{D}^{g_1 \times q}$ and $P \in \mathcal{D}^{g \times q}$ be representations of Σ_1 and Σ, respectively, and define $N_1 := \mathrm{im}(P_1^t)$, $N := \mathrm{im}(P^t)$. By assumption, $N_1 \subseteq N$, that is, $P_1 = CP$ for some polynomial matrix C. Define $M := \mathrm{coker}(P^t) = \mathcal{D}^q/N$ and $M_1 := \mathrm{coker}(P_1^t)$.

The problem is to decide whether N_1 is a direct summand of N and, if so, to construct a complementary summand N_2. By the definition of a split exact sequence, the regular interconnection problem is solvable, i.e., N_1 is a direct summand of N if and only if the exact sequence

$$0 \to N_1 \hookrightarrow N \to N/N_1 \to 0$$

is split. In view of Theorem 2.1, consider the diagram

$$\begin{array}{ccccccccc} & & & & \mathcal{D}^k & \xrightarrow{A} & \mathcal{D}^g & \to & N/N_1 & \to & 0 \\ & & & & & & {\scriptstyle P^t}\downarrow & & \| & & \\ 0 & \to & N_1 & \hookrightarrow & N & \to & N/N_1 & \to & 0. & & \end{array}$$

The construction of A with the desired property, that is, exactness of the upper sequence, or equivalently

$$\mathcal{D}^g/\mathrm{im}(A) \cong N/N_1,$$

will be discussed in section 3.1. Note that the matrix representation of any homomorphism $\xi : \mathcal{D}^g \to N_1 = \mathrm{im}(P_1^t)$ has the form $P_1^t Y$, where $Y \in \mathcal{D}^{g_1 \times g}$. Thus we can write (2.3) in terms of the following polynomial matrix equation:

$$(P_1^t Y - P^t)A = 0. \tag{3.1}$$

The regular interconnection problem is solvable if and only if this linear matrix equation possesses a polynomial solution Y. In [8], this condition was derived using the concept of extension modules. Here, we have given an alternative proof without making use of that tool.

To check the solvability of (3.1), we rewrite it using the *Kronecker product* of two matrices; see, e.g., [3]. This is defined as follows: Let

$$A = \begin{bmatrix} a_{11} & \dots & a_{1l} \\ \vdots & & \vdots \\ a_{k1} & \dots & a_{kl} \end{bmatrix}$$

be a $k \times l$ matrix, and let B be an $m \times n$ matrix; then the Kronecker product $A \otimes B$ is the $km \times ln$ matrix defined by

$$A \otimes B = \begin{bmatrix} a_{11}B & \dots & a_{1l}B \\ \vdots & & \vdots \\ a_{k1}B & \dots & a_{kl}B \end{bmatrix}.$$

The vector $\mathrm{vec}(\cdot)$ is obtained from a matrix by stacking its columns into one long column vector, that is,

$$\mathrm{vec}(A) = [a_{11}, \dots, a_{k1}, \dots, a_{1l}, \dots, a_{kl}]^t.$$

For any three matrices A, B, Y of compatible size, we have

$$\mathrm{vec}(BYA) = (A^t \otimes B)\mathrm{vec}(Y).$$

Using this in (3.1), we get

$$(A^t \otimes P_1^t)\,\mathrm{vec}(Y) = \mathrm{vec}(P^t A). \tag{3.2}$$

This reduces the problem to checking whether $\mathrm{vec}(P^t A)$ is contained in the module spanned by the columns of $A^t \otimes P_1^t$. Also this question can be answered algorithmically, and the computations are based on Gröbner basis techniques, as discussed in the next section.

3.1. Computational issues. We need the following basic tools from the constructive theory of Gröbner bases, which was developed by Buchberger [4]; see also [1]. We list the algorithms briefly, and without detail.

Division with remainder. Given a polynomial matrix $P \in \mathcal{D}^{g\times q}$ and a vector $f \in \mathcal{D}^q$, this algorithm constructs $h \in \mathcal{D}^g$ and $r \in \mathcal{D}^q$ such that

$$f = P^t h + r \quad \text{and} \quad r \text{ is in normal form modulo } P. \tag{3.3}$$

Note that, in general, neither h nor the "remainder" r are uniquely determined.

Deciding module membership. We call P a Gröbner matrix if the columns of P^t are a Gröbner basis of the module $N = \mathrm{im}(P^t)$ that they generate. If P is a Gröbner matrix, then f admits a representation $f = P^t h$ (that is, $f \in N$) if and only if $r = 0$ in one, or equivalently, in all, representations (3.3). For any matrix P, we may compute a Gröbner matrix P_G such that $\mathrm{im}(P_G^t) = \mathrm{im}(P^t)$. Thus module membership is decidable for arbitrary polynomial matrices.

Computing minimal annihilators. Given a polynomial matrix $P \in \mathcal{D}^{g\times q}$, this algorithm yields a matrix Q such that $\ker(P^t) = \mathrm{im}(Q^t)$; that is,

1. $QP = 0$, and
2. any polynomial matrix Q_1 with $Q_1 P = 0$ has a representation $Q_1 = XQ$, where X is a polynomial matrix.

We call Q a minimal left annihilator of P.

Application to the regular interconnection problem. Given polynomial matrices $P \in \mathcal{D}^{g\times q}$ and $P_1 \in \mathcal{D}^{g_1\times q}$ with $\mathrm{im}(P_1^t) \subseteq \mathrm{im}(P^t)$, there exists a polynomial matrix $C \in \mathcal{D}^{g_1\times g}$ such that $P_1 = CP$. Such a C can be constructed by means of the division with remainder algorithm.

Next, we look for a matrix $A \in \mathcal{D}^{g\times k}$ (where k is suitably chosen) such that

$$\mathrm{coker}(A) = \mathcal{D}^g/\mathrm{im}(A) \cong \mathrm{im}(P^t)/\mathrm{im}(P_1^t) = P^t\mathcal{D}^g/P^tC^t\mathcal{D}^{g_1}.$$

We give the following easy lemma without proof.

LEMMA 3.1. *There is an isomorphism*

$$P^t\mathcal{D}^g/P^tC^t\mathcal{D}^{g_1} \cong \mathcal{D}^g/(\ker(P^t) + C^t\mathcal{D}^{g_1}).$$

Let Q be a minimal left annihilator of P, that is, $\ker(P^t) = \mathrm{im}(Q^t)$. Then the preceding lemma suggests the definition

$$A = \begin{bmatrix} Q^t, & C^t \end{bmatrix}, \tag{3.4}$$

and this will be used in Theorem 3.2 below.

3.2. Constructing controllers. In the case where the regular interconnection problem is solvable for given systems Σ and Σ_1, the following theorem yields a concrete formula for a controller Σ_2; that is, it allows us to construct a representation P_2 of Σ_2 directly from the data, i.e., from P and P_1. Note that the expression for A found in (3.4) is used to reformulate (3.1).

THEOREM 3.2. *Let P and P_1 be polynomial matrices with $\mathrm{im}(P_1^t) \subseteq \mathrm{im}(P^t)$. Let C be such that $P_1 = CP$, and let Q be a minimal left annihilator of P. The following are equivalent:*

1. *There exists a polynomial matrix P_2 such that*

$$\mathrm{im}(P^t) = \mathrm{im}(P_1^t) \oplus \mathrm{im}(P_2^t). \tag{3.5}$$

2. *The matrix equation*

$$(P_1^t Y - P^t) \begin{bmatrix} Q^t, & C^t \end{bmatrix} = 0 \tag{3.6}$$

possesses a polynomial solution Y.

Moreover, if such a Y *exists, then* $P_2^t := P_1^t Y - P^t$ *is a matrix satisfying* (3.5).

Proof. It suffices to show that $P_2^t = P_1^t Y - P^t$ satisfies (3.5). As $P_1^t = P^t C^t$, we have $P_2^t = P^t(C^t Y - I)$. It is easy to see that $\operatorname{im}(P^t) = \operatorname{im}(P_1^t) + \operatorname{im}(P_2^t)$ as

$$\begin{bmatrix} P_1^t, & P_2^t \end{bmatrix} = P^t \begin{bmatrix} C^t, & C^t Y - I \end{bmatrix}$$

and

$$P^t = \begin{bmatrix} P_1^t, & P_2^t \end{bmatrix} \begin{bmatrix} Y \\ -I \end{bmatrix}.$$

It remains to show that $\operatorname{im}(P_1^t) \cap \operatorname{im}(P_2^t) = \{0\}$. Suppose that

$$a = P_1^t x = P_2^t y = (P_1^t Y - P^t) y.$$

Define $z := Yy - x$; then

$$P^t C^t z = P_1^t z = P^t y.$$

Thus $y - C^t z \in \ker(P^t) = \operatorname{im}(Q^t)$, that is, $y \in \operatorname{im}[Q^t, C^t]$, and hence, due to (3.6), $a = (P_1^t Y - P^t) y = 0$. □

Note that in the situation of Theorem 3.2, (3.6) can be rewritten as

$$(P_1^t Y - P^t) Q^t = P_1^t Y Q^t = 0 \quad \text{and} \quad (P_1^t Y - P^t) C^t = P_1^t (Y C^t - I) = 0.$$

This has interesting consequences for the one-dimensional case ($n = 1$), as discussed in the following corollary. In particular, we recover a result of Willems [15]. Recall that a univariate polynomial matrix is said to be *left prime* if it possesses a polynomial right inverse.

COROLLARY 3.3. *Let* P, P_1, C, Q *be as described above. The regular interconnection problem is solvable if and only if there exists a polynomial matrix* Y *such that*

$$P_1^t Y Q^t = 0 \quad \textit{and} \quad P_1^t (Y C^t - I) = 0.$$

In the one-dimensional case ($n = 1$), *we may assume without loss of generality that* P *and* P_1 *have full row rank. Then* $Q = 0$ *and the equations simplify to*

$$Y C^t = I;$$

i.e., the regular interconnection problem is solvable if and only if C *is left prime. Certainly, left primeness of* P_1 *implies left primeness of* C. *Hence, the regular interconnection problem is always solvable provided that* P_1 *is left prime. In terms of behaviors, any subsystem of a controllable behavior* $\mathcal{B}_1$ *can be achieved from* $\mathcal{B}_1$ *by regular interconnection* [15, Theorem 6].

4. The direct sum decomposition problem. In the previous section, we have considered the direct sum decomposition

$$N_1 + N_2 = N \quad \text{and} \quad N_1 \cap N_2 = \{0\},$$

where N_1, N_2, N are submodules of $\mathcal{D}^q$. The dual problem, corresponding to a direct sum decomposition of the associated behaviors, is

$$N_1 \cap N_2 = N \quad \text{and} \quad N_1 + N_2 = \mathcal{D}^q.$$

THEOREM 4.1. *Let P_1 and P be polynomial matrices with*

$$N = \operatorname{im}(P^t) \subseteq N_1 = \operatorname{im}(P_1^t) \subseteq \mathcal{D}^q.$$

The following are equivalent:

1. *There exists a polynomial matrix P_2 such that*

$$\operatorname{im}(P_1^t) \cap \operatorname{im}(P_2^t) = \operatorname{im}(P^t) \quad \textit{and} \quad \operatorname{im}(P_1^t) + \operatorname{im}(P_2^t) = \mathcal{D}^q. \tag{4.1}$$

2. *There exists a polynomial matrix P_2 such that*

$$\operatorname{coker}(P^t) \cong \operatorname{coker}(P_1^t) \oplus \operatorname{coker}(P_2^t).$$

   In particular, $N_1/N \cong \operatorname{coker}(P_2^t)$ is a direct summand of $\mathcal{D}^q/N = \operatorname{coker}(P^t)$.

3. *There exist polynomial matrices X and Y such that*

$$P^t X + P_1^t Y P_1^t = P_1^t. \tag{4.2}$$

Proof. The implication $1 \Rightarrow 2$ is straightforward. For $2 \Rightarrow 3$, we again invoke Theorem 2.1. Consider the diagram

$$\begin{array}{ccccccccc} & & & & \mathcal{D}^{g_1} & \xrightarrow{P_1^t} & \mathcal{D}^q & \to & \operatorname{coker}(P_1^t) & \to & 0 \\ & & & & & & \| & & \| & & \\ 0 & \to & N_1 & \hookrightarrow & \mathcal{D}^q & \to & \mathcal{D}^q/N_1 & \to & 0. & & \end{array}$$

The splitting condition for the lower sequence reads

$$(P_1^t Y - I)P_1^t = 0.$$

However, we are actually interested in the splitting of

$$0 \to N_1/N \hookrightarrow \mathcal{D}^q/N \to \mathcal{D}^q/N_1 \to 0;$$

that is, the condition becomes

$$(P_1^t Y - I)P_1^t \equiv 0 \quad \text{modulo} \quad N = \operatorname{im}(P^t).$$

That is to say,

$$(P_1^t Y - I)P_1^t + P^t X = 0$$

for some polynomial matrix X.

Finally, for showing $3 \Rightarrow 1$, suppose that (4.2) is satisfied. We show that

$$P_2^t = \begin{bmatrix} P_1^t Y - I, & P^t \end{bmatrix}$$

satisfies (4.1). By construction, $\mathrm{im}(P^t) \subseteq \mathrm{im}(P_1^t) \cap \mathrm{im}(P_2^t)$. For the converse direction, let $a = P_1^t x = P_2^t y = (P_1^t Y - I)y_1 + P^t y_2$. This implies that $y_1 \in \mathrm{im}(P_1^t)$; say, $y_1 = P_1^t z$. Then

$$a = P_1^t x = (P_1^t Y P_1^t - P_1^t)z + P^t y_2 = -P^t X z + P^t y_2,$$

showing that $a \in \mathrm{im}(P^t)$ as desired.

To see that $\mathcal{D}^q = \mathrm{im}(P_1^t) + \mathrm{im}(P_2^t)$, it suffices to note that any $x \in \mathcal{D}^q$ can be written as $x = P_1^t Y x + (I - P_1^t Y)x$. The first summand is contained in $\mathrm{im}(P_1^t)$, and the second in $\mathrm{im}(P_2^t)$. □

Again, condition (4.2) can be tested by means of the Kronecker product. Rewrite (4.2) as

$$(I \otimes P^t)\mathrm{vec}(X) + (P_1 \otimes P_1^t)\mathrm{vec}(Y) = \mathrm{vec}(P_1^t).$$

The test amounts to checking whether $\mathrm{vec}(P_1^t)$ is in the module spanned by the columns of

$$\left[\ I \otimes P^t, \quad P_1 \otimes P_1^t\ \right].$$

4.1. Constructing complementary behaviors. It is worth noting that the proof of Theorem 4.1 contains an actual construction procedure for the desired complementary cokernel module (if it exists). The following corollary summarizes the resulting decomposition result for behaviors

$$\mathcal{B} = \ker_{\mathcal{A}}(P) = \{w \in \mathcal{A}^q \mid P(\partial_1, \ldots, \partial_n)w = 0\},$$

where $P \in \mathcal{D}^{g \times q}$. The signal space $\mathcal{A}$ is supposed to satisfy Oberst's duality [9]. This is true, e.g., for the spaces of smooth functions or of distributions on $\mathbb{R}^n$.

COROLLARY 4.2. *Let $\mathcal{B}_1 \subseteq \mathcal{B} \subseteq \mathcal{A}^q$ be behaviors with kernel representations P_1 and P, respectively. The following are equivalent:*

1. *There exists a behavior $\mathcal{B}_2$ such that $\mathcal{B}_1 \oplus \mathcal{B}_2 = \mathcal{B}$.*
2. *There exist polynomial matrices X and Y such that*

$$P^t X + P_1^t Y P_1^t = P_1^t.$$

Moreover, if such matrices X, Y exist, a complementary behavior may be constructed as follows:

$$\mathcal{B}_2 = \ker_{\mathcal{A}} \begin{bmatrix} Y^t P_1 - I \\ P \end{bmatrix} = \ker_{\mathcal{A}}(Y^t P_1 - I) \cap \mathcal{B}.$$

For the two-dimensional case ($n = 2$), an equivalent condition has been derived by Bisiacco and Valcher [2]; see also Valcher's earlier work [13]. The following corollary concerns the one-dimensional case. We recover a well-known decomposition result on controllable subsystems being direct summands.

COROLLARY 4.3. *Let $n = 1$. Then we may assume that P_1 has full row rank. Let $P = EP_1$; then* (4.2) *reduces to*

$$E^t X + Y P_1^t = I.$$

In particular, when P_1 is left prime, this equation is always solvable (take $X = 0$ and let Y be a polynomial left inverse of P_1^t). Thus any controllable subbehavior of $\mathcal{B}$ is a direct summand of $\mathcal{B}$.

5. A unified view of interconnection and decomposition. The two problems discussed in this paper are special cases of finding *relative complements* in the lattice of behaviors [12] in $\mathcal{A}^q$ or in the lattice of submodules of $\mathcal{D}^q$, respectively. The set of submodules of $\mathcal{D}^q$ is partially ordered by inclusion, and it becomes a lattice via

$$\inf(N_1, N_2) = N_1 \cap N_2 \quad \text{and} \quad \sup(N_1, N_2) = N_1 + N_2.$$

Given three modules $N_l \subseteq N_1 \subseteq N_u \subseteq \mathcal{D}^q$, the problem is to decide whether there exists a relative complement N_2 of N_1, that is, a submodule of $\mathcal{D}^q$ with

$$\inf(N_1, N_2) = N_l \quad \text{and} \quad \sup(N_1, N_2) = N_u.$$

In terms of matrix representations, this problem has a solution if and only if there exist polynomial matrices X and Y such that

$$P_l^t X + (P_1^t Y - P_u^t) A = 0,$$

where $A = [Q^t, C^t]$ with $P_1 = CP_u$ and Q being a minimal left annihilator of P_u. A solution is then given by

$$P_2^t = \begin{bmatrix} P_1^t Y - P_u^t, & P_l^t \end{bmatrix}.$$

The problem reduces to the regular interconnection problem when $N_l = \{0\}$ (i.e., $P_l = 0$) and to the direct sum decomposition problem if $N_u = \mathcal{D}^q$ (i.e., without loss of generality, $P_u = I$ and $A = P_1^t$). Specializing even more, we may decide whether a given module $N_1 = \operatorname{im}(P_1^t)$ possesses a complement, that is, a module N_2 with $N_1 \oplus N_2 = \mathcal{D}^q$. This is true if and only if the equation

$$P_1^t Y P_1^t = P_1^t \tag{5.1}$$

has a polynomial solution Y. This is equivalent to the splitting of

$$0 \to N_1 \hookrightarrow \mathcal{D}^q \to \mathcal{D}^q / N_1 \to 0$$

or

$$\operatorname{im}(P_1^t) \oplus \operatorname{coker}(P_1^t) \cong \mathcal{D}^q.$$

In particular, $\operatorname{im}(P^t)$ is projective and hence free, due to the Quillen–Suslin theorem (see, e.g., [16]). Then we may assume without loss of generality that P_1 has full row rank, and thus (5.1) simplifies to

$$Y P_1^t = I.$$

These considerations are summarized in the following corollary.

COROLLARY 5.1. *Let N_1 be a submodule of $\mathcal{D}^q$. The following are equivalent:*

1. *N_1 has a complement; that is, there exists a submodule N_2 of $\mathcal{D}^q$ such that $N_1 \oplus N_2 = \mathcal{D}^q$.*
2. *For any polynomial matrix P_1 with $N_1 = \operatorname{im}(P_1^t)$, there exists a polynomial matrix Y such that*

$$P_1^t Y P_1^t = P_1^t.$$

3. *There exist polynomial matrices* P_1, Y *such that* $N_1 = \mathrm{im}(P_1^t)$ *and*

$$YP_1^t = I.$$

Moreover, in that case, $N_2 = \mathrm{im}(P_2^t)$ *with* $P_2^t = I - P_1^t Y$ *is a complement of* N_1.

In terms of behaviors, we say that $\mathcal{B}_1$ has a complement if there exists $\mathcal{B}_2$ such that $\mathcal{B}_1 \oplus \mathcal{B}_2 = \mathcal{A}^q$. In other words, the question is whether the zero behavior can be achieved from a given behavior $\mathcal{B}_1$ by regular interconnection. Let us call this property *controllability to zero.* Parts of the following result can also be found in [11].

COROLLARY 5.2. *Let* $\mathcal{B}_1$ *be a behavior in* $\mathcal{A}^q$. *The following are equivalent:*

1. $\mathcal{B}_1$ *is controllable to zero.*
2. $\mathcal{B}_1$ *has a complement, i.e., there exists a behavior* $\mathcal{B}_2$ *with* $\mathcal{B}_1 \oplus \mathcal{B}_2 = \mathcal{A}^q$.
3. $\mathcal{B}_1$ *is strongly controllable, i.e., it possesses a zero left prime representation matrix; that is,* $\mathcal{B}_1 = \ker_{\mathcal{A}}(P_1)$ *with* $YP_1^t = I$ *for some polynomial matrix* Y.
4. *For any kernel representation* P_1 *of* $\mathcal{B}_1$,

$$P_1^t Y P_1^t = P_1^t$$

has a polynomial solution Y.

Moreover, if such a Y *exists, then* $\mathcal{B}_2 = \ker_{\mathcal{A}}(P_2)$ *with* $P_2 = I - Y^t P_1$ *is a complement of* $\mathcal{B}_1$.

6. Examples. The first two examples are taken from [11], and the third one is taken from [2].

Example 1. Let

$$P_1 = \begin{bmatrix} s_1^2 - 1, & s_1 - s_2 \end{bmatrix}$$

and

$$P = \begin{bmatrix} s_1 + 1 & s_2 \\ 0 & -s_1 \end{bmatrix}.$$

Certainly, P_1 is less powerful than P, as

$$P_1 = \begin{bmatrix} s_1 - 1, & s_2 - 1 \end{bmatrix} P.$$

As P has full row rank, we may take $Q = 0$ and $A = C^t$; thus

$$A = \begin{bmatrix} s_1 - 1 \\ s_2 - 1 \end{bmatrix}.$$

We compute

$$A^t \otimes P_1^t = \begin{bmatrix} (s_1 - 1)(s_1^2 - 1) & (s_2 - 1)(s_1^2 - 1) \\ (s_1 - 1)(s_1 - s_2) & (s_2 - 1)(s_1 - s_2) \end{bmatrix}$$

and

$$\mathrm{vec}(P^t A) = \begin{bmatrix} s_1^2 - 1 \\ s_1 - s_2 \end{bmatrix}.$$

Equation (3.2) possesses the solution

$$\begin{bmatrix} \frac{1}{s_1 - 1} - \frac{t(s_2 - 1)}{s_1 - 1} \\ t \end{bmatrix}$$

over the field of rational functions (t is a rational parameter). It is impossible to choose t such that the solution becomes polynomial. Thus (3.2) has no polynomial solution, and we conclude that the regular interconnection problem is not solvable in this example.

Example 2. Consider

$$P_1 = \begin{bmatrix} s_1 s_2, & s_1 + 1, & s_2 \end{bmatrix}$$

and

$$P = \begin{bmatrix} 0 & s_1 + s_2 + 1 & s_2 \\ s_1 s_2 & -s_1^2 - s_1 s_2 + 1 & -s_1 s_2 + s_2 \\ -s_1^2 - s_1 s_2 & s_1 + s_2 & 0 \end{bmatrix}.$$

Clearly, P_1 is less powerful than P, as $P_1 = CP$ with

$$C = \begin{bmatrix} s_1, & 1, & 0 \end{bmatrix}.$$

Using the computer algebra system SINGULAR [7], we obtain the following reduced expression for A:

$$A = \begin{bmatrix} -s_2 & s_1 \\ 1 & 1 \\ s_2 & 0 \end{bmatrix}.$$

We compute

$$A^t \otimes P_1^t = \begin{bmatrix} -s_1 s_2^2 & s_1 s_2 & s_1 s_2^2 \\ -s_1 s_2 - s_2 & s_1 + 1 & s_1 s_2 + s_2 \\ -s_2^2 & s_2 & s_2^2 \\ s_1^2 s_2 & s_1 s_2 & 0 \\ s_1^2 + s_1 & s_1 + 1 & 0 \\ s_1 s_2 & s_2 & 0 \end{bmatrix}$$

and

$$\operatorname{vec}(P^t A) = \begin{bmatrix} s_1 s_2 - s_1 s_2^2 - s_1^2 s_2 \\ -s_1 s_2 - s_2 - s_1^2 + 1 \\ -s_2^2 - s_1 s_2 + s_2 \\ s_1 s_2 \\ s_1 + 1 \\ s_2 \end{bmatrix}.$$

It is easily checked that (3.2) is solvable; in fact, a solution is given by

$$Y = \begin{bmatrix} 1, & 1 - s_1, & 0 \end{bmatrix}.$$

As a controller, we get

$$P_2 = \begin{bmatrix} s_1 s_2 & -s_2 & 0 \\ -s_1^2 s_2 & s_1 s_2 & 0 \\ s_1^2 + s_1 s_2 & -s_1 - s_2 & 0 \end{bmatrix}.$$

Noting that the second row is a multiple of the first one, we may replace this solution by

$$P_2 = \begin{bmatrix} s_1 s_2 & -s_2 & 0 \\ s_1^2 & -s_1 & 0 \end{bmatrix}.$$

Using different methods, Rocha and Wood [11] derive another controller for the present example.

Example 3. Let

$$P_1 = [s_1 + s_2 + 1] \quad \text{and} \quad P = \begin{bmatrix} s_1 + 1 \\ s_2 + 1 \end{bmatrix} P_1.$$

In order to test whether $\ker_{\mathcal{A}}(P_1)$ is a direct summand of $\ker_{\mathcal{A}}(P)$, we have to check whether there exist polynomials x_1, x_2, y such that (compare (4.2))

$$(s_1 + s_2 + 1) \begin{bmatrix} s_1 + 1, & s_2 + 1 \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \end{bmatrix} + y(s_1 + s_2 + 1)^2 = s_1 + s_2 + 1.$$

This is obviously solvable; take

$$x_1 = 1, \quad x_2 = 1, \quad y = -1.$$

To find a complementary behavior $\ker_{\mathcal{A}}(P_2)$ as indicated in the proof of Theorem 4.1, we compute

$$P_2 = \begin{bmatrix} yP_1 - 1 \\ P \end{bmatrix} = \begin{bmatrix} -(s_1 + s_2 + 2) \\ (s_1 + 1)(s_1 + s_2 + 1) \\ (s_2 + 1)(s_1 + s_2 + 1) \end{bmatrix}.$$

This representation may be simplified by computing a Gröbner matrix P_{2G} of P_2. We obtain the equivalent solution

$$P_{2G} = \begin{bmatrix} s_1 + 1 \\ s_2 + 1 \end{bmatrix}.$$

7. Conclusion. The behavioral approach to systems theory provides a neat setting for modeling the interconnection of systems. We have considered the following basic linear control problem: Given a system Σ_1 (the plant), does there exist a system Σ_2 (a controller) such that the regular interconnection $\Sigma_1 \wedge \Sigma_2$ equals a certain prescribed system Σ (a desired controlled system)? Based on a homological approach, we have given an algebraic criterion for the solvability of this problem. This criterion boils down to a certain linear matrix equation when dealing with concrete representations of the systems Σ and Σ_1.

Using different methods, Rocha and Wood [11] give another solution of the regular interconnection problem. Their approach is based on a characterization of behaviors with direct sum decompositions, which is in terms of zero skew-coprimeness of polynomial matrices. For bivariate matrices, an analogous characterization comes from Bisiacco and Valcher [2]; see also [13]. The condition used there is actually equivalent to the one given in Corollary 4.2 of the present paper. Indeed, the regular interconnection problem and the direct sum decomposition problems are dual. The present paper provides a unified framework for treating both in terms of relative complements in the lattice of behaviors.

Moreover, our solution to the regular interconnection problem features an appealing simplicity. In particular, the polynomial matrix equation (3.1) allows us to decide whether the problem is solvable, by means of basic tools from the theory of Gröbner bases: computing minimal annihilators, division with remainder, and testing module membership. Moreover, the solution is constructive, as it provides a concrete formula for a controller (if one exists).

ON OPEN- AND CLOSED-LOOP BANG-BANG CONTROL IN NONZERO-SUM DIFFERENTIAL GAMES*

GEERT JAN OLSDER†

Abstract. The Nash equilibria of two two-person nonzero-sum differential games with hard constraints on the controls are studied. For both games the open-loop as well as the closed-loop solutions, and their relationships, are discussed. As is well-known for "smooth" nonzero-sum games, these solutions are generally different. Because of the constraints, the optimal controls are of the bang-bang type, and the solutions of the two problems under consideration are nonsmooth. One deals with non-Lipschitzian differential equations (considering the problem as an optimal control problem for one player while the bang-bang feedback control of the other player is assumed to be fixed), and the corresponding value functions possess singular surfaces. General conditions for the existence and uniqueness of the feedback solutions in this framework are not yet known. It is shown that in the two examples the open-loop and closed-loop solutions differ. As a by-product, the paper aims at a modest exploration of singular surfaces in nonzero-sum games.

Key words. bang-bang control, nonzero-sum game, differential game, feedback, singular surface, switching surface, value function, open-loop control, Nash equilibrium

1. Introduction.

This paper deals with open-loop as well as closed-loop (equivalently, feedback) bang-bang control in nonzero-sum games. The author knows of only one other paper in this direction, viz., [14]. The goal originally set was to extend the definition of viscosity solutions (see [1],[2]) to nonzero-sum differential games in which discontinuities in the solutions appear. For that purpose some simple nonzero-sum differential games with bang-bang solutions have been formulated in the hope that open-loop as well as feedback solutions can be obtained that can be intuitively understood. With such solutions in mind one might then get a feeling for the "suitability" of possible definitions of viscosity solutions in this context. With respect to the equilibrium concept, only Nash solutions are considered.

As it soon turned out, this goal was set too high. What remains is the presentation of two examples for which the optimal open-loop as well as the optimal feedback solutions are given. The latter solution is surrounded by some question marks, however, for both examples. The optimal open-loop solutions by themselves have some interesting singular curves and other features. These examples may have an interest by themselves and can function as benchmark problems for further studies. What has been shown is that the synthesis of the optimal open-loop solutions does not lead to the optimal feedback solutions. Thus the optimal feedback solutions, generally hard to obtain and with no results on uniqueness, are fundamentally different from the optimal open-loop ones.

The models that we will consider can formally be described by

$$\dot{x} = f(x, u_1, u_2)$$

with a given initial condition, and where the state $x \in \mathrm{R}^n$ and the controls $u_i \in \mathrm{R}^{m_i}$. The dot on x refers to the time derivative; $\dot{x} = \frac{\mathrm{d}x}{\mathrm{d}t}$, where time itself is (as usual) indicated by the variable t. Decision maker i chooses $u_i(\cdot)$, $i = 1, 2$. Sometimes one has restrictions on the controls of the form $u_i \in U_i \subset \mathrm{R}^{m_i}$; U_i is called the admissible region for u_i. This model will be considered on an interval $0 \leq t \leq T$, where T is defined as

$$T = \inf\{t | l(t, x(t)) = 0\}$$

for a given scalar function l. Thus the final time T is not necessarily fixed, but can depend on the controls chosen. The decision makers have different cost functions, which they try to minimize: $\min_{u_i} J_i(u_1, u_2)$, $i = 1, 2$, where

$$J_i(u_1, u_2) = \left(\int_0^T g_i(x, u_1, u_2)\mathrm{d}t + q_i(x(T)) \right).$$

(If one would add a minus sign to the cost functions, the minimization becomes a maximization; therefore there is no essential difference in whether the players are maximizing or minimizing.) The problem just formulated belongs to the realm of game theory. To emphasize the time aspect in these problems one also talks about the theory of differential, or dynamic, games. If it happens that $g_1 = -g_2$ and $q_1 = -q_2$, then one talks about a zero-sum game. The two problems to be discussed in this paper are both *nonzero-sum*. In the literature (as well as in this paper) the notation varies somewhat. Instead of the controls u_1 and u_2 one also sees the notation u and v; this is the case in problem statement 2 of this paper, for instance.

The problem statement is not yet complete. One needs an equilibrium concept. The one adopted here is the Nash equilibrium (u_1^*, u_2^*), which satisfies, by definition [3],

(1.1) $J_1(u_1^*, u_2^*) \leq J_1(u_1, u_2^*)$, $\quad J_2(u_1^*, u_2^*) \leq J_2(u_1^*, u_2)$ $\quad \forall$ admissible u_1 and u_2.

For an additional remark on "admissible controls," see Remark 1.1 below.

The last item needed to make the problem statement complete is the information on which the players base their decisions. Both players know the model, the initial condition, their own and their opponent's cost functions, and the equilibrium concept according to which the game will be played. If the control functions are furthermore based only on time, written as $u_i(t)$, then we talk about open-loop solutions. If the control functions can (also) depend on the current state x (i.e., at time t), then we write $u_i(t, x)$ and such controls are called feedback or closed-loop controls, or simply strategies. In the case of closed-loop control, at time t the player has the state $x(t)$ at his disposition; in the case of open-loop control, the player knows only the time t upon which he must base his decision. Apart from robustness considerations, it is also necessary to make the distinction between open-loop and closed-loop controls, since the corresponding optimal solutions will generally be different; this was first observed in [15], [16] (see further [3]).

Please note the following. The open-loop solution depends on the initial condition, although this is not explicitly shown in the conventional notation $u_i(t)$. (We could have written $u_i(t, x(0))$.) To be precise, and strictly speaking in contradiction with the foregoing, the feedback solution $u_i(t, x)$ will, by definition, *not* depend on the initial state. If we allow such a dependence, which could be written as $u_i(t, x, x(0))$, a plethora of informationally nonunique Nash equilibria arises; see [3], section 6.3.2.

If the functions f, l, and g_i are independent of t, then the feedback controls (as well as the value functions to be introduced later in this section) will also be independent of t, i.e., we can write $u_i(x)$.

The usual necessary and/or sufficient conditions for the optimal controls to satisfy are either given in terms of the so-called maximum principle of Pontryagin or in terms of the Hamilton–Jacobi–Bellman (HJB) theory, the latter of which essentially is a mathematical consequence of the principle of dynamic programming. Well-known references are [4] and [5]. We will give these conditions in some detail for optimal control problems (i.e., problems with only one player). The reason why it is useful to consider optimal control theory is that in a game with the Nash equilibrium concept, each player tries to solve an optimal control problem, keeping the control or strategy of the other player fixed. For the application of the maximum principle, one defines (for a single player, with obvious notation) the Hamiltonian

$$H = \lambda(t) f(x,u) + g(x,u),$$

where $\lambda(t) \in \mathrm{R}^n$, and where λf is the innerproduct of the vectors λ and f. The costate function $\lambda(t)$ satisfies $\dot{\lambda} = -\frac{\partial H}{\partial x}$ with boundary condition $\lambda(T) = \frac{\mathrm{d}q(x(T))}{\mathrm{d}x}$ along $l(t,x) = 0$. The optimal u satisfies $u^* = \arg\max_u H$. With this approach one obtains u^* as a function of t, i.e., as an open-loop control. In contrast, application of the HJB theory yields the optimal u as a function of the current time and the current state: $u^*(t,x)$. It is obtained by introduction of the so-called value function V, which is, by definition,

$$V(t,x) = \min_u \left(\int_t^T g(x,u)\mathrm{d}t + q(x(T)) \right),$$

with the assumption that at time t the state is x (these t and x are the arguments of V). It satisfies the HJB PDE

$$-\frac{\partial V}{\partial t} = \min_u \left(\frac{\partial V}{\partial x} f + g \right),$$

with boundary condition $V(T,x) = q(x(T))$ along $l(t,x) = 0$.

REMARK 1.1. *The conditions on f, l, g, and q under which the maximum principle and/or the HJB theory are applicable have not been formulated explicitly; the reader is referred to the literature. In addition, one must also carefully define the class of admissible u_1 and u_2 in* (1.1). *The formalization is involved, and for the so-called regularity conditions, especially for feedback controls, the reader is referred to* [10].

REMARK 1.2. *The difference in these two approaches (optimal open-loop solutions with conditions based on the Pontryagin maximum principle and optimal closed-loop solutions with conditions based on the HJB equation) also shows up if one tries to apply Pontryagin when all players would play closed-loop strategies. For the games to be discussed in the paper, the Hamiltonian and the costate vector corresponding to the first player are indicated by H_1, respectively λ. For the second player these quantities are, respectively, H_2 and μ. Expressed in these quantities, the difference in the conditions given for the closed-loop case is that the differential equations for the costate vectors must be adapted to $\dot{\lambda} = -\frac{\partial H_1}{\partial x} - \frac{\partial H_1}{\partial u_2}\frac{\partial u_2}{\partial x}$ and $\dot{\mu} = -\frac{\partial H_2}{\partial x} - \frac{\partial H_2}{\partial u_1}\frac{\partial u_1}{\partial x}$.*

For the so-called linear quadratic games (see [3]*) with no restrictions on the controls, more explicit results exist in terms of Riccati differential equations; the form of these equations depends on whether open-loop or closed-loop solutions are considered.*

As formulated above, the HJB equation is a necessary condition for the optimal control and value function to satisfy. A sufficiency condition in terms of the HJB equation is known under the name of verification theorem. For that purpose an essential condition is that $V(t,x)$ must be twice differentiable in x. Solutions of many optimal control problems do not have such smooth value functions; in particular, when bang-bang controls are involved, this is usually not the case. One speaks of bang-bang control if the optimal control jumps from one boundary point of the admissible region to another. In such cases, V is often only piecewise continuous or piecewise continuously differentiable. The boundaries between areas in the (t,x) space where V is smooth are called singular surfaces or singular lines. Especially in zero-sum differential game theory such singular surfaces are a well-studied subject [7],[11]. See also [12] for some in-depth discussions on singular surfaces. In nonzero-sum differential games such singular surfaces are largely unexplored. As a by-product, this paper yields one of the first (see also [14]), though modest, explorations in this direction.

It is worth mentioning that other definitions of closed-loop equilibrium solutions exist. One such equilibrium is based on the threat or punishment principle that one often encounters in the theory of repeated games. Briefly, if one player decides to deviate from his optimal strategy within the context of this equilibrium, then the other player immediately plays worst-case against this deviating player. In other words, the threat is that the other player will try to maximize the cost function of the deviating player (who himself wants to minimize this function), thereby totally disregarding his own cost function. More information on this equilibrium concept, which does not satisfy the dynamic programming principle, can be found in [8], [9].

2. Problem statement 1. The problem studied is a nonzero-sum differential game with two players. The model is

$$\dot{x} = (1-x)u_1 - xu_2, \tag{2.1}$$

and the criteria are

$$\max_{u_1} \int_0^T (c_1 x - u_1)\mathrm{d}t, \quad \max_{u_2} \int_0^T (c_2(1-x) - u_2)\mathrm{d}t. \tag{2.2}$$

The state x as well as the controls u_i are one-dimensional quantities. The choice of the controls is subject to

$$0 \le u_i(t) \le 1, \qquad i = 1,2. \tag{2.3}$$

The quantities c_i are positive constants. The final time T is supposed to be fixed. This model and both criteria are known to both players (they have full information). We are interested in the Nash equilibrium solutions of this game. In the next section such open-loop solutions will be studied, and in section 4 we get to the heart of this paper, the study of feedback solutions.

This model was mentioned in [13]. A possible interpretation is as follows. Players P1 and P2 are firms on the same market and produce the same product. The number of customers allotted to P1 at time t is $x(t)$; the number of customers allotted to P2 at time t are those remaining, i.e., $1-x(t)$. The total number of customers is assumed to be constant and has been normalized to 1. The controls u_i refer to advertising intensities (amount of money spent on advertising per unit of time). If P1 advertises, then his number of customers will increase proportionally to the advertising rate and the number of customers not already allotted to him (the term $(1-x)u_1$ in the

model). On the other hand, advertising by P2 will decrease the number of customers of P1, also proportionally to the advertising rate and the number of customers not already allotted to P2 (the term $-xu_2$ in the model). The criteria represent the profits made by each player. This profit, per unit of time, is proportional to the number of customers allotted to the player concerned (with a proportionality factor c_i) minus the amount of money spent on advertising.

3. Optimal trajectories—The open-loop case. Consider the two Hamiltonians

$$H_1 = \lambda_1(u_1(1-x) - u_2x) + c_1x - u_1, \tag{3.1}$$

$$H_2 = \mu_1(u_1(1-x) - u_2x) + c_2(1-x) - u_2. \tag{3.2}$$

The costate variables λ_i satisfy

$$\dot{\lambda}_1 = -\frac{\partial H_1}{\partial x} = -(-\lambda_1u_1 - \lambda_1u_2) - c_1, \qquad \lambda_1(T) = 0, \tag{3.3}$$

$$\dot{\mu}_1 = -\frac{\partial H_2}{\partial x} = -(-\mu_1u_1 - \mu_1u_2) + c_2, \qquad \mu_1(T) = 0. \tag{3.4}$$

Notice that

$$\mu_1 \equiv -\frac{c_2\lambda_1}{c_1}. \tag{3.5}$$

The optimal controls must satisfy

$$u_1 = \text{Heav}(\lambda_1(1-x) - 1), \tag{3.6}$$

$$u_2 = \text{Heav}(-\mu_1x - 1), \tag{3.7}$$

where Heav stands for the Heaviside function, i.e.,

$$\text{Heav}(x) = \begin{cases} 0 \text{ if } x < 0, \\ \text{undetermined if } x = 0, \\ 1 \text{ if } x > 0. \end{cases}$$

The switching function for u_1 is

$$\lambda_1(t)(1 - x(t)) - 1.$$

Close to T we have $u_i = 0,\ i = 1, 2$, and the switching curve, to be denoted by l_1, in the (t, x)-plane is

$$\lambda_1(t)(1 - x(t)) - 1 = -c_1(t - T)(1 - x) - 1 = 0.$$

We have to check whether this switching curve is a real one (i.e., instead of a real switch one might get shattering or a singular arc). It easily follows that the switching function indeed will change sign (hence shattering is not possible, provided u_2 remains zero). Moreover, it follows from some elementary though tedious calculations not shown here that neither control will have another switch (i.e., in retrograde time u_1 switches from 0 to 1 and u_2 does not switch at all), provided that $c_1 < 4$.

A similar reasoning holds with respect to the switching curve (l_2) for u_2, which satisfies

$$-\mu_1(t)x(t) - 1 = -c_2(t - T)x - 1 = 0.$$

These two curves intersect at

$$x_{\rm s} = \frac{c_1}{c_1+c_2}, \quad t_{\rm s} = T - \frac{c_1+c_2}{c_1 c_2}.$$

Suppose that this point lies in the area of interest, i.e., $0 < x_{\rm s} < 1$ and $0 < t_s < T$. A singular arc ($l_{\rm s}$) exists to left of the point $t_{\rm s}, x_{\rm s}$, along which

$$u_1 = \frac{c_1^2 c_2}{(c_1+c_2)^2}, \quad u_2 = \frac{c_1 c_2^2}{(c_1+c_2)^2}, \tag{3.8}$$

provided that these values lie in the interval $[0,1]$, which is satisfied for $0 \le c_i \le 4$. This singular arc has been obtained by studying

$$\lambda_1(1-x) - 1 \equiv 0, \quad -\mu_1 x - 1 \equiv 0,$$

and calculating their time derivatives:

$$\lambda_1 u_2 - c_1(1-x) \equiv 0, \quad c_2 x + \mu_1 u_1 \equiv 0.$$

Together with (3.5) it is then easily shown that the singular arc given above is the only one possible. Along the same lines it can be shown that a singular arc with respect to only one control (its switching function being zero and the switching function of the other control being nonzero) does not exist.

4. Optimal trajectories—The feedback case.

4.1. By means of HJB.

4.1.1. Synthesis approach. The meaning of "synthesis" is the following. Since the whole (t,x) space (at least the relevant part) is covered with open-loop trajectories (see Figure 4.1) to each point (t,x) there corresponds a unique trajectory (in forward time direction) with corresponding local u_i values. If these values are written as $u_i(t,x)$, we speak of synthesis. The central question in this subsection will be whether these feedback functions constitute the *optimal* feedback strategies. The answer will turn out to be no. The space R^2, with one axis being the t-axis and the other one the x-axis, will be denoted by Ω.

The two HJB equations are

$$\begin{aligned} -\frac{\partial V_1}{\partial t} &= \max_{u_1}\left(\frac{\partial V_1}{\partial x}((1-x)u_1 - x u_2) + c_1 x - u_1\right) \\ &= \left[\frac{\partial V_1}{\partial x}(1-x) - 1\right]^+ - x\frac{\partial V_1}{\partial x}\mathrm{Heav}\left(-\frac{\partial V_2}{\partial x}x - 1\right) + c_1 x, \end{aligned} \tag{4.1}$$

$$\begin{aligned} -\frac{\partial V_2}{\partial t} &= \max_{u_2}\left(\frac{\partial V_2}{\partial x}((1-x)u_1 - x u_2) + c_2(1-x) - u_2\right) \\ &= \left[-x\frac{\partial V_2}{\partial x} - 1\right]^+ + \frac{\partial V_2}{\partial x}(1-x)\mathrm{Heav}\left(\frac{\partial V_1}{\partial x}(1-x) - 1\right) \\ &\quad + c_2(1-x), \end{aligned} \tag{4.2}$$

where $[a]^+ = 0$ if $a \le 0$, and $[a]^+ = a$ if $a > 0$. Formally $\frac{\partial V_i}{\partial x}$, $i = 1,2$, satisfy

$$\frac{\mathrm{d}}{\mathrm{d}t}\left(\frac{\partial V_1}{\partial x}\right) = \frac{\partial V_1}{\partial x}(u_1+u_2) - c_1 + \frac{\partial V_1}{\partial x}x\frac{\partial u_2}{\partial x}, \quad \frac{\partial V_1(T,x)}{\partial x} = 0, \tag{4.3}$$

$$\frac{\mathrm{d}}{\mathrm{d}t}\left(\frac{\partial V_2}{\partial x}\right) = \frac{\partial V_2}{\partial x}(u_1+u_2) + c_2 - \frac{\partial V_2}{\partial x}(1-x)\frac{\partial u_1}{\partial x}, \quad \frac{\partial V_2(T,x)}{\partial x} = 0, \tag{4.4}$$

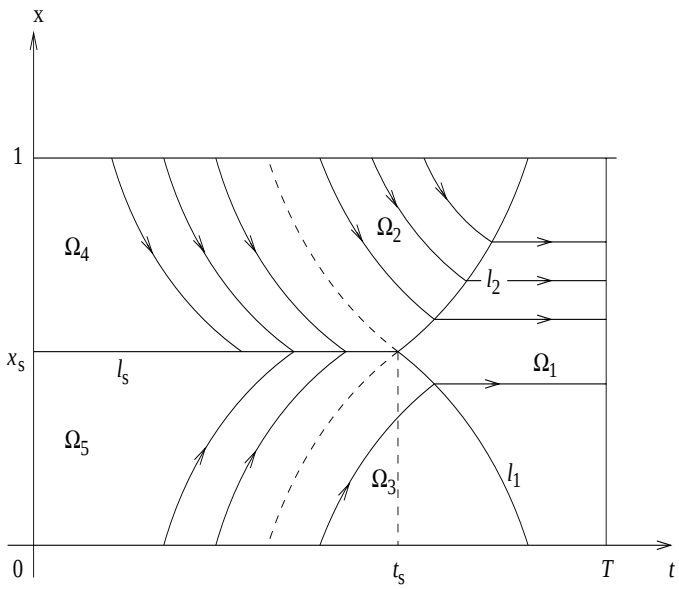

FIG. 4.1. *The open-loop trajectories in the (state, time) plane.*

where

$$u_2 = \text{Heav}\left(-\frac{\partial V_2}{\partial x}x - 1\right), \tag{4.5}$$

$$u_1 = \text{Heav}\left(\frac{\partial V_1}{\partial x}(1-x) - 1\right). \tag{4.6}$$

Above we wrote "formally," since the partial derivatives $\frac{\partial u_i}{\partial x}$ do not necessarily exist.

Since the open-loop solutions cover the whole Ω space, we can calculate the cost to go from each point in Ω. If we obtain identities by substituting these costs into (4.1) and (4.2), then the conclusion would be that the optimal open-loop solutions also form a set of optimal feedback solutions (tacitly assuming that an extension of the verification theorem, without the differentiability assumptions, will hold for this situation). For this purpose, Ω will be split up into five subregions as indicated in Figure 4.1; Ω_4, for instance, consists of those starting points for which first $u_1 = 0$, $u_2 = 1$, then a singular part and, during the last part, both controls are zero. For a point $(\tilde{t}, \tilde{x}) \in \Omega_4$ it is a straightforward calculation to show that

(4.7)
$$V_1(\tilde{t}, \tilde{x}) = c_1\left(\tilde{x} - \frac{c_1}{c_1 + c_2}\right) + \frac{c_1^3}{(c_1 + c_2)^2}(T - t^*) + \frac{c_1}{c_1 + c_2},$$

(4.8)
$$V_2(\tilde{t}, \tilde{x}) = (c_2 - 1)\ln\left(\tilde{x}\frac{c_1 + c_2}{c_1}\right) + c_2\left(-\tilde{x} + \frac{c_1}{c_1 + c_2}\right) + \frac{c_2^3}{(c_1 + c_2)^2}(T - t^*) + \frac{c_2}{c_1 + c_2}.$$

where $t^* = \tilde{t} + \ln(\tilde{x}\frac{c_1+c_2}{c_1})$. To simplify the calculations somewhat, suppose $c_1 = c_2 = 2$. Then

$$V_1(\tilde{t},\tilde{x}) = 2\tilde{x} - \frac{1}{2}\ln(2\tilde{x}) + \frac{1}{2}(T-\tilde{t}) - \frac{1}{2}, \tag{4.9}$$

$$V_2(\tilde{t},\tilde{x}) = -2\tilde{x} + \frac{1}{2}\ln(2\tilde{x}) + \frac{1}{2}(T-\tilde{t}) + \frac{3}{2}. \tag{4.10}$$

These equations are now substituted into (4.1), together with $u_2 = 1$ (which is the open-loop u_2-solution in Ω_4), and into (4.2), together with $u_1 = 0$ (which is the open-loop u_1-solution in Ω_4), resulting in

$$\begin{aligned} \frac{1}{2} &= \max_{u_1}\left(\left(2 - \frac{1}{2\tilde{x}}\right)((1-\tilde{x})u_1 - \tilde{x}) + 2\tilde{x} - u_1\right) \\ &= \max_{u_1}\left(u_1\left(\frac{3}{2} - 2\tilde{x} - \frac{1}{2\tilde{x}}\right)\right) + \frac{1}{2}, \end{aligned} \tag{4.11}$$

$$\begin{aligned} \frac{1}{2} &= \max_{u_2}\left(\left(-2 + \frac{1}{2\tilde{x}}\right)(-\tilde{x}u_2) + 2(1-\tilde{x}) - u_2\right) \\ &= \max_{u_2}\left(u_2\left(2\tilde{x} - \frac{3}{2}\right)\right) + 2(1-\tilde{x}). \end{aligned} \tag{4.12}$$

Equation (4.11) is an identity; (4.12), however, is not. Equation (4.12) is an identity only if $\tilde{x} > \frac{3}{4}$ (with $u_2 = 1$). For $\frac{1}{2} < \tilde{x} < \frac{3}{4}$ it yields $u_2 = 0$, however, which does not lead to an identity and which does not coincide with the open-loop solution. Thus we have shown that the optimal open-loop solution does not constitute an optimal feedback solution.

4.1.2. Optimal feedback solution. If one would change the control values along the singular arc from the values given in (3.8) to $u_1 = u_2 = 0$ (educated guess), then the optimal trajectories obtained do not change in the (x,t)-space. Calculation of the value functions with this change leads to (taking again $c_1 = c_2 = 2$ and a point $(\tilde{x},\tilde{t}) \in \Omega_4$)

$$V_1(\tilde{t},\tilde{x}) = T - 1 - \tilde{t} + 2\tilde{x} - \ln(2\tilde{x}), \tag{4.13}$$

$$V_2(\tilde{t},\tilde{x}) = T + 1 - \tilde{t} - 2\tilde{x}. \tag{4.14}$$

If one does the same exercise again as in the previous subsection, i.e., substitution of these value functions into (4.1) and (4.2), then it turns out that two identities result. Hence one may conclude that a set of optimal Nash feedback strategies has been found. Nothing is known about its uniqueness.

5. Other approaches. In this section three other, as yet not very fruitful, approaches are briefly indicated.

5.1. Brute force numerical solutions. Numerical integration of (4.1) and (4.2) by means of simple integration schemes did not seem to lead to any kind of convergence of the numerical outcome if the stepsizes were made smaller and smaller.

5.2. By means of the maximum principle. In this subsection a method is given for integrating (4.3) and (4.4) backward in time. The functions u_1 and u_2 are determined by the right-hand sides of (4.1) and (4.2). The crucial step is that δ-functions (the derivatives of u_i with respect to x) appear and that they will be

replaced by rectangles of width ϵ and height $\frac{1}{\epsilon}$. After the calculations have been made including this ϵ, we take $\lim_{\epsilon \downarrow 0}$.

Consider (4.4), with $u_1 = u_2 = 0$, assuming that we integrate backwards starting from $t = T$. Once we hit l_1 at $t = t_{1s}$, the right-hand side contains $\frac{\partial u_1}{\partial x}$, which will be interpreted as a negative δ-function (along a line $t =$ constant, u_1 first equals 1 and subsequently 0 for increasing x). Thus we obtain

$$\frac{\partial V_2}{\partial x}(t_{1s}-) = e^{-(1-x(t_{1s}))}\frac{\partial V_2}{\partial x}(t_{1s}+).$$

Thus $\frac{\partial V_2}{\partial x}$ has a jump at $t = t_{1s}$. Technically we can handle this jump, but is it not known what its real meaning for the solution of the problem might be. Imagining a horizontal singular arc in the feedback case, just as l_{s}, then integrating along this l_{s}, one is faced with an ongoing δ-function. This does not make sense at all. It is very possible that other kinds of singular surfaces will play a role. Such surfaces are well-known in zero-sum pursuit evasion games; see [7] and [11].

5.3. The unpaved road of viscosity solutions. The standard definitions of viscosity solutions do not apply here due to the discontinuous right-hand sides of (4.1) and (4.2). In order to smooth the discontinuities, one can add noise to the system equations (and then let the noise intensity go to zero). This approach does not seem attractive from an analytic point of view.

6. Problem statement 2. Consider the model

$$\frac{\mathrm{d}}{\mathrm{d}t}\begin{pmatrix} x_1 \\ x_2 \end{pmatrix} = \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}\begin{pmatrix} x_1 \\ x_2 \end{pmatrix} + \begin{pmatrix} 0 \\ 1 \end{pmatrix} u + \frac{1}{2}\begin{pmatrix} 0 \\ 1 \end{pmatrix} v. \tag{6.1}$$

The constraints on the scalar controls are $|u| \leq 1$ and $|v| \leq 1$. The final time T is defined as the first instant at which $x_1 = x_2$. Starting from an arbitrary initial condition, the u-player wants to minimize T and the v-player wants to maximize $x_1(T)$. Thus a nonzero-sum differential game has been formulated. This game is time-invariant in the sense that calendar time does not enter into the problem statement. (This in contrast to the previous problem, where the calendar time is present in terms of the fixed final time T.) Hence the value functions will be functions of the state only (and not also of time, as was the case in the previous problem). No physical or economical meaning is envisaged here. It is a generalization of the optimal control problem in Example 5.2 of [3]. We will concentrate on the solution in the south-east of the state space, defined by $x_1 > x_2$. The solution in the north-west is a point-mirrored (through the origin) copy of the one to be obtained in the south-east.

7. Analysis. If the costate vectors are given by $\lambda = (\lambda_1, \lambda_2)$ and $\mu = (\mu_1, \mu_2)$ for the u-, respectively v-, player, the Hamiltonians are

$$H_1 = 1 + \lambda_1 x_2 + \lambda_2\left(u + \frac{1}{2}v\right), \tag{7.1}$$

$$H_2 = \mu_1 x_2 + \mu_2\left(u + \frac{1}{2}v\right). \tag{7.2}$$

The optimal controls satisfy

$$u^* = -\mathrm{sgn}(\lambda_2), \quad v^* = \mathrm{sgn}(\mu_2).$$

In the open-loop case, the differential equations for the costate variables are

$$\dot{\lambda}_1 = 0, \quad \dot{\lambda}_2 = -\lambda_1, \quad \dot{\mu}_1 = 0, \quad \dot{\mu}_2 = -\mu_1.$$

In the feedback case, the differential equations for the costate variables are (provided they make sense)

$$\dot{\lambda}_1 = -\frac{1}{2}\lambda_2 \frac{\partial v}{\partial x_1}, \quad \dot{\lambda}_2 = -\lambda_1 - \frac{1}{2}\lambda_2 \frac{\partial v}{\partial x_2}, \tag{7.3}$$

$$\dot{\mu}_1 = -\mu_2 \frac{\partial u}{\partial x_1}, \quad \dot{\mu}_2 = -\mu_1 - \mu_2 \frac{\partial u}{\partial x_2}. \tag{7.4}$$

Let the final state $x(T)$ be parametrized by $x_1 = x_2 = a$. Termination can be enforced by the u-player as long as $a \leq \frac{1}{2}$. With a "cooperative" v-player, termination can occur for all $a \leq \frac{3}{2}$. Later on we will see that the v-player will cooperate in this sense of terminating the game—it is in his own interest, and thus it is not pure cooperation.

Suppose $a < 0$. Then close to the end we will have $u^* = v^* = 1$ (obvious, but which also can be seen as the outcome of a trivial static nonzero-sum game, assuming that u and v are constant during the last part of the game), which leads to

$$\lambda_1(T) = \frac{\partial V_1}{\partial x_1} = \frac{1}{\frac{3}{2} - a}, \quad \lambda_2(T) = \frac{\partial V_1}{\partial x_2} = \frac{-1}{\frac{3}{2} - a},$$

$$\mu_1(T) = \frac{\partial V_2}{\partial x_1} = \frac{1}{1 - \frac{2}{3}a}, \quad \mu_2(T) = \frac{\partial V_2}{\partial x_2} = \frac{-\frac{2}{3}a}{1 - \frac{2}{3}a}.$$

As an example of how these terminal conditions have been calculated, see Figure 7.1. Suppose that T_1 is the terminal point and that a perturbation Δx_1 occurs such that the state is temporarily in point B. From there onward, the game will end in the new endpoint T. In this state space figure, the velocity vector $\dot{x}_1 = x_2$, $\dot{x}_2 = \frac{3}{2}$ has been superimposed (the origin of this vector being situated at point B). Now we get

$$\tan\beta = \frac{-x_2}{\frac{3}{2}} = \frac{\overline{\mathrm{TC}}}{\overline{\mathrm{TA}}} = \frac{\Delta x_1 - \overline{\mathrm{T_1A}}}{\overline{\mathrm{T_1A}}},$$

which leads to

$$\overline{\mathrm{T_1A}} = \overline{\mathrm{TA}} = \frac{\frac{3}{2}\Delta x_1}{-x_2 + \frac{3}{2}}.$$

Substitution of these expressions into

$$\frac{\Delta V_1}{\Delta x_1} = \frac{\text{time needed to go from B to T}}{\Delta x_1} = \frac{\frac{2}{3}\overline{\mathrm{TA}}}{\Delta x_1}, \quad \frac{\Delta V_2}{\Delta x_1} = \frac{\overline{\mathrm{T_1A}}}{\Delta x_1},$$

leads immediately to the expressions for $\lambda_1(T)$ and $\mu_1(T)$ given above. A bar over a line segment denotes its length in these formulas. One can use the same figure for deriving the expressions for $\lambda_2(T)$ and $\mu_2(T)$ if one starts with T_2 as the original unperturbed termination point.

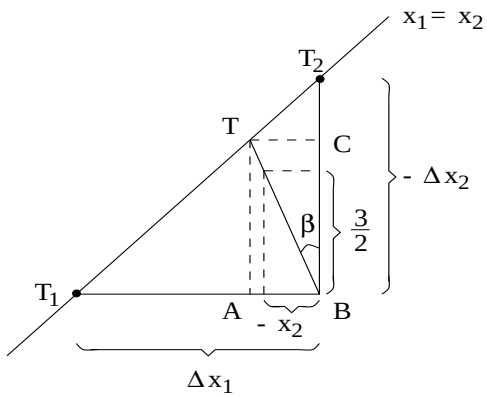

FIG. 7.1. *Perturbations at termination point; all quantities related to length are positively valued.*

Now solving for the costate variables, the switching functions become

$$\lambda_2(t) = \frac{-1}{\frac{3}{2} - a}(t - T + 1), \quad \mu_2(t) = \frac{-1}{1 - \frac{2}{3}a}\left(t - T + \frac{2}{3}a\right).$$

The control v will not have a switch. The control u will have a switch for $t = T - 1$.

Suppose now that $0 < a < \frac{1}{2}$. Then close to the end we have $u^* = 1,\ v^* = -1$ and, performing an analysis similar to that given above, we obtain

$$\lambda_1(T) = \frac{2}{1 - 2a}, \quad \lambda_2(T) = \frac{-2}{1 - 2a},$$
$$\mu_1(T) = \frac{1}{1 - 2a}, \quad \mu_2(T) = \frac{-2a}{1 - 2a}.$$

The switching functions now become

$$\lambda_2(t) = -\frac{2}{1 - 2a}(t - T + 1), \quad \mu_2(t) = -\frac{t - T + 2a}{1 - 2a}.$$

The control u will have a switch for $t = T - 1$, and the control v will have a switch for $t = T - 2a$.

8. Optimal trajectories—The open-loop case. Three cases will be distinguished: $a < 0$, $0 < a < \frac{1}{2}$, and $\frac{1}{2} < a < \frac{3}{2}$.

8.1. The case $a < 0$. The optimal trajectories during $T - 1 \le t \le T$ are, with $u^* = v^* = 1$,

$$x_1(t) = \frac{3}{4}(t - T)^2 + a(t - T) + a, \tag{8.1}$$

$$x_2(t) = \frac{3}{2}(t - T) + a. \tag{8.2}$$

At $t = T - 1$, a switch (for u) occurs. The switching line is given by $x_1 = \frac{3}{4},\ x_2 = a - \frac{3}{2}$. In retrograde time the trajectories continue with $u^* = -1,\ v^* = 1$, leading to

$$x_1(t) = -\frac{1}{4}(t - T + 1)^2 + \left(a - \frac{3}{2}\right)(t - T + 1) + \frac{3}{4}, \tag{8.3}$$

$$x_2(t) = -\frac{1}{2}(t - T + 1) + a - \frac{3}{2}. \tag{8.4}$$

8.2. The case $0 < a < \frac{1}{2}$. Close to the line of termination we have $u^* = 1$, $v^* = -1$, and the corresponding trajectories are

$$x_1(t) = \frac{1}{4}(t-T)^2 + a(t-T) + a, \tag{8.5}$$

$$x_2(t) = \frac{1}{2}(t-T) + a. \tag{8.6}$$

A switch (for v) occurs at $t = T-2a$; the switching line is given by $x_1 = -a^2+a$, $x_2 = 0$. In retrograde time the trajectories continue with $u^* = v^* = 1$, and another switch (now for u) occurs for $t = T-1$. At $t = T-1$ we are at

$$x_1(T-1) = \frac{3}{4}(-1+2a)^2 - a^2 + a, \tag{8.7}$$

$$x_2(T-1) = \frac{3}{2}(-1+2a). \tag{8.8}$$

Elimination of a leads to the switching curve $x_1 = \frac{2}{9}x_2^2 + \frac{1}{4}$, with $-\frac{3}{2} \le x_2 \le 0$. In further retrogade time the trajectories are determined by $u = -1$, $v = 1$. The trajectories of this case and the previous one fill the whole state space (i.e., the south-eastern part). This is shown in Figure 8.1. Whether these trajectories are really the optimal ones will be discussed in the next subsection. In Figure 8.1, the curve GA is a barrier for the u-player, but not for the v-player.

8.3. The case $\frac{1}{2} < a < \frac{3}{2}$. The situation is somewhat subtle here. Of the interval $\frac{1}{2} < a \le \frac{3}{2}$, only the point $a = \frac{3}{2}$ will indicate a termination point. On this interval the u-player by himself cannot force a termination; he needs the help of player v. It is in the interest of the latter to terminate at the largest possible x_1 (remember the cost function). The optimal control v^* is not unique here. This nonuniqueness will not influence the outcome of the v-player; it will, however, influence the outcome of the u-player. In order to continue with a unique v^*, assume that the v-player goes as slowly as possible to the point $a = \frac{3}{2}$. This is the worst case from the u-player point of view. Thus $u^* = 1$, $v^* = -1$ until the trajectory hits the parabola $x_1 = \frac{1}{3}x_2^2 + \frac{3}{4}$. Once this parabola has been hit, the trajectory follows this parabola ($u^* = v^* = 1$) until the termination point has been reached. The u-player may prefer terminating the game at the point characterized by $a = \frac{3}{2}$ and hence playing $u = 1$, rather than playing $u = -1$, which will lead to a terminal point characterized by $a \le \frac{1}{2}$, which may lead to a higher T. Hence a dispersal line (the direction in which to go is to be chosen by the u-player) can be expected to exist.

In Figure 8.2 all results obtained so far have been put together; the trajectories terminating on $a = x_1 = x_2$, $\frac{1}{2} < a \le \frac{3}{2}$, form a kind of patchwork in the previous Figure 8.1. The optimal trajectories are provided with arrows (indicating the direction in forward time). Point A corresponds to $a = \frac{1}{2}$, point B to $a = \frac{3}{2}$. The curve GKCH is the switching curve for u; the line segment OG is the switching curve for v. The curve MN is the dispersal line; its location has not been calculated explicitly. On this line, the u-player determines whether to go north or south. (Remember that the u-player minimizes T.) In the cone NABDM, the v-control is nonunique; the v-player can always make sure that B will be the terminal point. The trajectories drawn refer to the slowest possible such trajectories, i.e., first $u = 1$ and $v = -1$, until the barrier

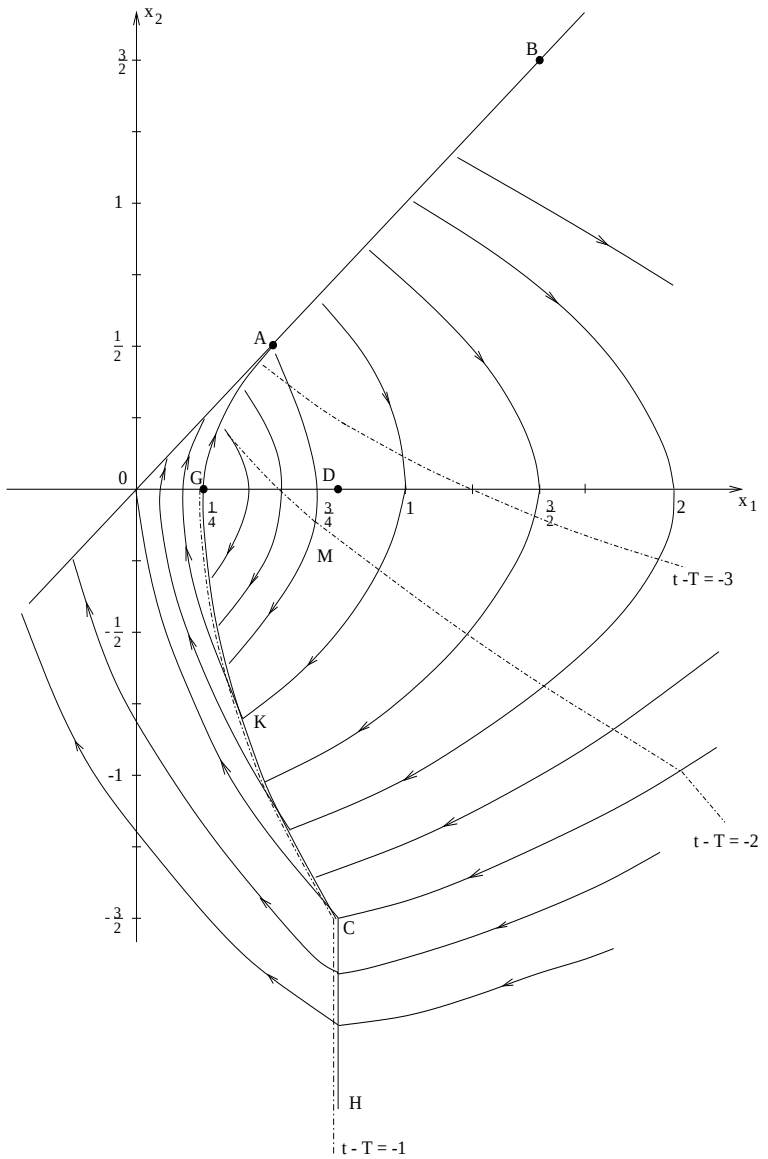

FIG. 8.1. *The open-loop trajectories in the state space, terminating with* $a < \frac{1}{2}$.

BD is hit. The curve DM is part of the parabola $x_1 = x_2^2 + \frac{3}{4}$ (with u=1, $v = -1$). Along the barrier BD, $u = 1$ and $v = 1$. One can calculate the coordinates of the point M by realizing that the times needed to go in either direction towards the line $x_1 = x_2$ must be equal. This leads to $x_2(M) = -\sqrt{9/52}$ and $x_1(M) = x_2^2(M) + \frac{3}{4}$. Both GA and DB are barriers for both players. There is a third barrier, for the v-player only; it is part of the parabola above and through point M, with formula $x_1 = -x_2^2 + c$ (corresponding to $u = -1$, $v = 1$), with c chosen such that point M is indeed part of this parabola. Some level curves of constant time to go (for the u-player) are indicated by means of dotted curves.

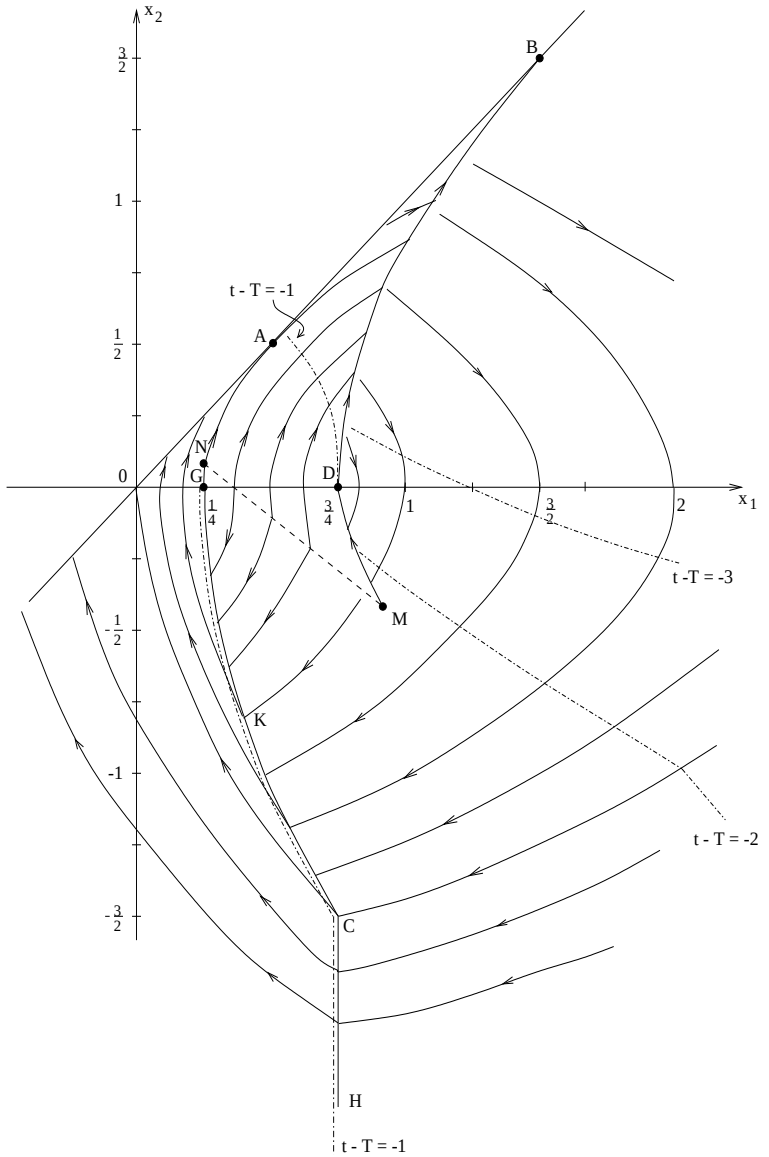

FIG. 8.2. *The optimal open-loop trajectories in the state space.*

9. Optimal trajectories—The feedback case.

9.1. By means of the maximum principle.

9.1.1. $a < 0$. At $t = T - 1$ the control u switches from $+1$ to -1 in retrograde time. Will this have an influence on μ_2, and hence on v? Towards that end consider

$$\dot{\mu}_1 = -\mu_2 \frac{\partial u}{\partial x_1}, \quad \dot{\mu}_2 = -\mu_1 - \mu_2 \frac{\partial u}{\partial x_2}.$$

At the switch we make the plausible, though mathematically not well-funded, assumption that

$$\frac{\partial u}{\partial x_1} = -2\delta\left(x_1 - \frac{3}{4}\right), \quad \frac{\partial u}{\partial x_2} = 0,$$

where δ denotes the Dirac-function. This leads to

$$\mu_2((T-1)^-) = \mu_2((T-1)^+) = 1,$$

$$\mu_1((T-1)^-) = \mu_1((T-1)^+) + 2 = \frac{1}{1-\frac{2}{3}a} + 2 = \frac{9-4a}{3-2a} > 0,$$

$$\mu_2(t) = -\frac{9-4a}{3-2a}(t-T+1) + 1 \quad \text{for } t - T < -1.$$

The notation $\mu(t^+)$ stands for $\lim_{s \downarrow t} \mu(s)$, and similarly $\mu(t^-)$ stands for $\lim_{s \uparrow t} \mu(s)$. Because $\mu_2(t) > 0$ for $t < T-1$, v will have no switch (from $+1$ to -1) for $t < T-1$.

9.1.2. $0 < a < \frac{1}{2}$. The control v switches (in retrograde time from -1 to $+1$) at $t = T - 2a$, which gives rise to the switching line OG and to a δ-function in (7.3). Again, we make a plausible, though not well-funded, assumption:

$$\frac{\partial v}{\partial x_1} = 0, \quad \frac{\partial v}{\partial x_2} = -2\delta(x_2).$$

This leads to

$$\lambda_1(t) = \frac{2}{1-2a} \quad \forall t \le T,$$

$$\lambda_2(t) = -\frac{2}{1-2a}(t-T+1), \qquad T - 2a < t \le T,$$

$$\lambda_2((T-2a)^-) = \frac{\lambda_2((T-2a)^+)}{e} = -\frac{2}{e},$$

$$\lambda_2(t) = \frac{-2}{1-2a}(t-T+2a) - \frac{2}{e} \quad \forall t < T - 2a.$$

The control u will face a switch when $\lambda_2 = 0$, i.e., for $t = T - 2a - \frac{1-2a}{e}$. It is easily shown that the corresponding curve has the equation

$$x_1 = \left(\frac{1}{3} - \frac{e^2}{9}\right)x_2^2 + \frac{1}{4}, \qquad -\frac{3}{2e} \le x_2 \le 0, \tag{9.1}$$

which is different from the curve GKC in Figure 8.2.

REMARK 9.1. *In the latter case, some analysis, not shown here, has been performed for the construction of the further backward trajectories starting from the last switching curve* $x_1 = (\frac{1}{3} - \frac{e^2}{9})x_2^2 + \frac{1}{4}$. *A new switching curve, now again for* v, *seems to result (depending on* a; *for a certain range of* a *no more switches arise). However, the trajectories do not pass this new switching curve, but are reflected. This phenomenon has not yet been investigated and/or clarified. Also a "void" (see* [7]) *seems to show up here.*

In subsection 9.3 *we will see that this approach with* δ*-functions does not lead to the correct answers, at least not when these* δ*-functions are considered as limits of rectangles with arbitrarily small basis and with area* 1.

REMARK 9.2. *It follows directly from* (7.3) *that* u *cannot be singular on a time interval with positive length. The same remark holds for* v.

9.2. By means of HJB–The synthesis approach. The value functions $V_i(x_1, x_2)$, $i = 1, 2$, provided they exist, satisfy the coupled set of HJB equations

$$1 + \frac{\partial V_1}{\partial x_1} x_2 - \left| \frac{\partial V_1}{\partial x_2} \right| + \frac{1}{2} \frac{\partial V_1}{\partial x_2} \operatorname{sgn} \frac{\partial V_2}{\partial x_2} = 0, \tag{9.2}$$

$$\frac{\partial V_2}{\partial x_1} x_2 + \frac{1}{2} \left| \frac{\partial V_2}{\partial x_2} \right| - \frac{\partial V_2}{\partial x_2} \operatorname{sgn} \frac{\partial V_1}{\partial x_2} = 0. \tag{9.3}$$

The boundary conditions are

$$V_1(x_1 = x_2) = 0, \quad V_2(x_1 = x_2) = x_1. \tag{9.4}$$

What we want to know is whether the synthesized open-loop solutions also form feedback solutions. For this example the synthesized controls will have the format $u(x_1, x_2)$ and $v(x_1, x_2)$. The central question of this section is whether these feedback functions will constitute the feedback optimal strategies.

In principle, we can calculate such synthesized V_i functions by tracing the open-loop trajectories and calculate the time till termination (for the u-player) and the termination point (for the v-player). Take, for instance, a point $(x_1 = p,\ x_2 = q)$ in the neighborhood of the point $(x_1 = 1,\ x_2 = -1)$. In this area $\frac{\partial V_1}{\partial x_2} > 0$ and $\frac{\partial V_2}{\partial x_2} > 0$, and hence the set of two HJB equations becomes two uncoupled ones:

$$1 + \frac{\partial V_1}{\partial x_1} x_2 - \frac{1}{2} \frac{\partial V_1}{\partial x_2} = 0, \tag{9.5}$$

$$\frac{\partial V_2}{\partial x_1} x_2 - \frac{1}{2} \frac{\partial V_2}{\partial x_2} = 0. \tag{9.6}$$

The (open-loop) optimal trajectory through the point (p, q) intersects the switching curve CKG at a point $(x_{1\mathrm{s}},\ x_{2\mathrm{s}})$, say. Then

$$x_{2\mathrm{s}} = -\sqrt{\frac{9}{11}\left(p + q^2 - \frac{1}{4}\right)}.$$

The time needed to go from $(x_1 = p,\ x_2 = q)$ to $(x_{1\mathrm{s}},\ x_{2\mathrm{s}})$ equals $2(q - x_{2\mathrm{s}})$, and hence

$$V_1(p, q) = 1 + 2\left(q + \sqrt{\frac{9}{11}\left(p + q^2 - \frac{1}{4}\right)}\right).$$

Now it easily follows that this V_1 is indeed a solution of (9.5). Along the same lines,

$$V_2(p, q) = \frac{1 - \sqrt{\frac{4}{11}(p + q^2) - \frac{1}{11}}}{2},$$

and this function turns out to be a solution of (9.6).

Right away we cannot conclude that the V's found are the correct value functions, since the verification theorem, a sufficiency result, does not hold. (This verification theorem (see, e.g., [7]) would apply if the value functions found would be twice differentiable, which is not true in our situation.) Despite the fact that V_1 satisfies (9.5) and V_2 (9.6), the following argument will give rise to some doubts as to whether these

value functions are the ones we are looking for. For that purpose consider initial points in the first quadrant, to the right of curve BD, e.g., point ($x_1 = \frac{3}{2},\ x_2 = \frac{1}{2}$). It pays here for the v-player to play $v = -1$ rather than $v = +1$ according to the open-loop solution. With $v = -1$ the trajectory moves in direction south-south-east, which leads to a better result for the v-player than the indicated open-loop solution (with $v = +1$), which moves in the direction south-east. In this part of the state space it therefore looks plausible that the optimal feedback strategies are $u = -1,\ v = -1$, which have a smooth continuation with the trajectories in the fourth quadrant as indicated in Figure 8.2.

Some further ad hoc calculations seem to point to the following feedback solution. Starting from Figure 8.2, the switching curve GKC is replaced by the parabola $x_1 = -\frac{2}{3}x_2^2 + \frac{1}{4}$ for $-\frac{1}{2} \le x_2 \le 0$ (see subsection 9.3 for the derivation) and the parabola $x_1 = \frac{1}{3}x_2^2$ for $-\frac{3}{2} \le x_2 \le -\frac{1}{2}$. The patchwork surrounded by the letters NABDG remains roughly as it is (though the position of the curve NM will be slightly higher). In the north-east of the state space, the optimal strategies are $u = -1$ and $v = -1$ as made plausible in the previous paragraph.

9.3. By means of additional common sense. The real optimal feedback solution as we think of it is given in Figure 9.1. Based on the remarks made earlier, $v = -1$ for all points x for which $x_2 > 0$, and $v = +1$ for all points x for which $x_2 < 0$. The switching curve GE for u, with formula $x_1 = -\frac{2}{3}x_2^2 + \frac{1}{4}$, has been obtained as follows. It is assumed that the trajectory starting from x_1, x_2 with $\frac{1}{4} \le x_1 \le \frac{1}{3}$ and $x_2 = 0$ will do this with $u = -1$ and $v = +1$. At a certain time, indicated by the point $x_2 = \gamma$, the optimal u control will switch to $+1$, and then the trajectory will continue with $u = v = +1$ until it reaches $x_2 = 0$, where v will now switch to the value -1, and finally the trajectory ends on $a = x_1 = x_2,\ 0 \le a \le \frac{1}{2}$. Minimizing the total time needed with respect to γ leads to the curve GE. Note that the equation for this curve is different from (9.1). This shows that one cannot formally proceed with δ-functions as we did previously; that may lead to wrong answers.

What remains to be shown is that the trajectories starting at x with $\frac{1}{3} < x_1 < 3$ and $x_2 = 0$ will continue with $u = -1$ and $v = +1$ until they reach the parabola EFC with equation $x_1 = \frac{1}{3}x_2^2$. This parabola is a semiuniversal surface as introduced in [7, pp. 196, 197]. Other options for optimal trajectories are indicated in Figure 9.2. The curved cone enclosed by FE with equation $x_1 = -x_2^2 + \frac{1}{3}$ (i.e., the optimal trajectory upstream point E in Figure 9.1) and by EC with equation $x_1 = \frac{1}{3}x_2^2$ can be considered as a void. Point E in Figure 9.2 is the same as in Figure 9.1. Suppose the point J is an arbitrary initial point within this void. Three possible candidate optimal trajectories are given in the figure which all end up in point E. Which one is the optimal one? It turns out to be the trajectory from J to P (with $u = -1,\ v = +1$) and then to E (with $u = v = +1$). This follows if one applies the approach with Green's theorem as given in [6, pp. 120, 121].

Finally, the patchwork consisting of the optimal trajectories that terminate at $a = \frac{3}{2}$ has to be hung in the already constructed field of solutions. Note that the dispersal line M'N' has a slightly different position when compared to the dispersal line MN of Figure 8.2. It is easy to show that the x_2 coordinate of point M' equals $\frac{2}{3}(1 - \sqrt{2})$.

Now we would like to show that (9.2) and (9.3) hold for these claimed optimal feedback trajectories. This is not straightforward, however. Take, for instance, again a point (p, q) in the neighborhood of $(x_1 = 1,\ x_2 = -1)$. In this area $V_2 \equiv 0$ and subsequently $\frac{\partial V_2}{\partial x_2} = 0$, and (9.2) is not well-defined. Both V_1, which equals

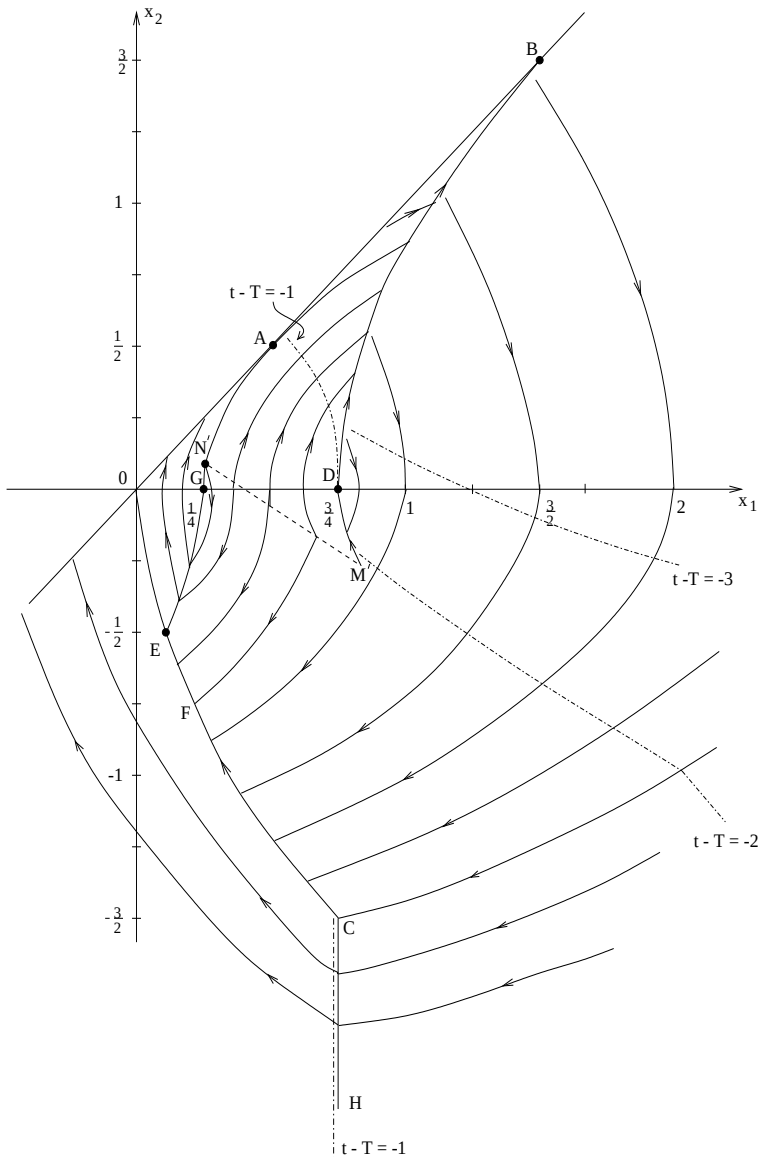

FIG. 9.1. *The optimal feedback solution.*

$2q + \frac{4}{3}\sqrt{3(p+q^2)}$, and $V_2 \equiv 0$ do satisfy (9.5) (respectively, (9.6)), however. Hence if we choose $\text{sgn}(\frac{\partial V_2}{\partial x_2}) = \text{sgn}(0) = 1$, then everything seems to fit. Suppose next that we take a point (p, q) in the neighborhood of $(x_1 = \frac{3}{2},\ x_2 = 1)$. For this area, $V_1 = \frac{2}{3} + \frac{4}{3}\sqrt{3p+q^2}$, $V_2 \equiv 0$, and hence again $\frac{\partial V_2}{\partial x_2} = 0$. We try $\text{sgn}(\frac{\partial V_2}{\partial x_2}) = \alpha$, for some suitable α with $-1 \leq \alpha \leq 1$ to be determined. A little analysis then shows that for $\alpha = -1$ equation (9.2) becomes an identity.

A conclusion of all this analysis is that the set of equations (9.2) and (9.3), together with the boundary conditions (9.4), allows at least two different solution sets (V_1, V_2), one sketched in Figure 8.2 and the other in Figure 9.1. An important question to be answered is whether a definition of viscosity solutions can be found such that a unique

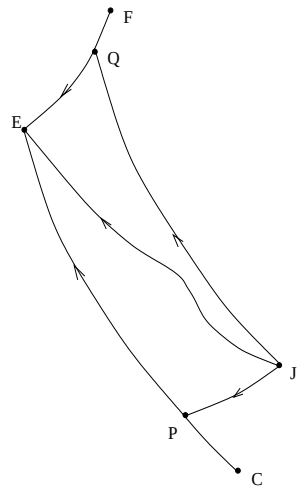

FIG. 9.2. *Comparing candidate optimal trajectories by Green's function method.*

solution of the PDEs and the boundary conditions results (and appropriate for the optimal feedback solutions). See [1], [2] for viscosity solution concepts for problems not as wild (i.e., discontinuous) as those considered in the current paper. Another reference in which differential equations are studied with non-Lipschitzian right-hand sides is [10]. (If we keep the feedback bang-bang control of one player fixed and view the remaining problem as an optimal control problem for the other player, then the model is such a non-Lipschitzian differential equation.)

10. Conclusions. Two simple, at least in their formulation, nonzero-sum dynamic games with bang-bang control have been discussed. Both have a unique optimal open-loop solution. For the first one, we found an optimal feedback solution which is almost identical to the synthesized open-loop solution; the difference is in the control values along a singular arc. For the second problem, two candidates for the optimal feedback solutions have been found. Neither jumping nor corner conditions for the costate equations along (or across) singular arcs nor appropriate extensions of the viscosity solution concept have been attempted to answer questions related to uniqueness of the optimality of the feedback solutions constructed. The solutions to these examples may help in formulating such concepts and with related analysis in the future.

It so happened that for both examples one could not uniquely solve the controls $u_i,\ i = 1, 2$, from $\dot{x} = f(x, u_1, u_2)$ and thus express them in $\dot{x}$ and x. In other words, given a trajectory in the (t, x) space (or in the x space for time-independent problems), there may be many controls which realize this given trajectory. Whether this feature leads to specific difficulties and/or phenomena is not known.

ANALYSIS AND OPTIMIZATION OF NONSMOOTH ARCHES*

A. IGNAT†, J. SPREKELS‡, AND D. TIBA‡§

Abstract. It is our aim to present a new treatment for some classical models of arches and for their optimization. In particular, our approach allows us to study nonsmooth arches, while the standard assumptions from the literature require $W^{3,\infty}$-regularity for the parametric representation. Moreover, by a duality-type argument, the deformation of the arches may be explicitly expressed by integral formulas.

As examples for the shape optimization problems under study, we mention the design of the middle curve of a clamped arch such that, under a prescribed load, the obtained deflection satisfies certain desired properties. In all cases, no smoothness is required for the design parameters.

Key words. Lipschitz arches, flexural arches, shape optimization

AMS subject classifications. 49Q10, 35J35, 34A55

PII. S0363012900374427

1. Introduction. If $\varphi\colon [0,1] \to \mathbb{R}^2$ is a smooth clamped arch and $c\colon [0,1] \to \mathbb{R}$ denotes its curvature, then the classical Kirchhoff–Love model (with normalized mechanical constants) is given by

$$\begin{aligned} &\int_0^1 \left[\frac{1}{\varepsilon}(v_1' - c\,v_2)(u_1' - c\,u_2) + (v_2' + c\,v_1)'(u_2' + c\,u_1)'\right] ds \\ &= \int_0^1 (f_1\,u_1 + f_2\,u_2)\,ds \qquad \forall\, u_1 \in H_0^1(0,1)\,, \quad \forall\, u_2 \in H_0^2(0,1)\,. \end{aligned} \tag{1.1}$$

Here, $\sqrt{\varepsilon}$ is the constant thickness of the arch; $v_1 \in H_0^1(0,1)$, $v_2 \in H_0^2(0,1)$ are the tangential, respectively the normal, components of the deformation in the local coordinate system associated with the arch; and $[f_1, f_2]$ is a similar representation of the forces, including the internal and external loading of the arch, which are assumed to act in the same plane.

A thorough presentation via Dirichlet's principle and Korn's inequality of the existence and the uniqueness of the solution for (1.1) may be found in Ciarlet [11, p. 432]. In Chenais and Paumier [8] the "locking" problem, in connection with the numerical approximation of (1.1) and of shells, is discussed: If the discretization parameter is of the same order as ε, then the obtained numerical approximation may be meaningless, and special finite element schemes are necessary in order to solve (1.1).

In section 1, we introduce a new variational formulation for (1.1), based on optimal control theory, which is valid also for Lipschitz (or, by reparametrization—see Remark 2.8—absolutely continuous) mappings φ. Using duality-type arguments, we derive explicit integration rules for (1.1). If φ is smooth, we show that our solution satisfies

(1.1). In the general case, if φ is approximated by a sequence of smooth functions φ_δ with $\delta \to 0$ (obtained by a regularization via Friedrichs mollifiers), the approximation remains valid for the corresponding solutions as well.

This shows that our variational formulation is a natural extension of (1.1) to the case of nonsmooth arches. It also provides, by its explicit character, a complete solution of the above-mentioned "locking" problem in dimension one. We also study the behavior for $\varepsilon \to 0$ and obtain, under the weak optimal control formulation of (1.1), the analogue of flexural models in the sense of Ciarlet [12]. Some of the results of this section were announced without proofs in Sprekels and Tiba [22]. Our arguments use neither the Dirichlet principle nor the Korn inequality. Moreover, although the arch may have an infinity of corners, we do not impose transmission conditions as were used by Geymonat and Sanchez-Palencia [14]—they are implicitly contained in our approach. Models for shells and rods, under low geometrical regularity conditions, are also discussed in Blouza and Le Dret [5] and Chapelle [7].

In order to make the basic ideas more transparent, we now present a very simple example of how our variational approach based on optimal control theory works. To this end, let us consider the fourth order boundary value problem:

$$y'''' = f \quad \text{in }]0,1[\,, \tag{1.2}$$

$$y(0) = y(1) = 0\,, \tag{1.3}$$

$$y''(0) = y''(1) = 0\,, \tag{1.4}$$

with $f \in L^2(0,1)$.

The usual variational approach to (1.2)–(1.4) is given by the minimization of the energy,

$$\operatorname*{Min}_{y \in H^2(0,1) \cap H_0^1(0,1)} \left\{ \frac{1}{2} \int_0^1 (y'')^2 \, ds - \int_0^1 f\, y \, ds \right\}. \tag{1.5}$$

We rewrite (1.5) as an unconstrained optimal control problem, namely,

$$\operatorname{Min} \left\{ \frac{1}{2} \int_0^1 \underline{z}^2 \, ds - \int_0^1 f\, y \, ds \right\}, \tag{1.6}$$

$$y'' = \underline{z} \quad \text{in }]0,1[\,, \tag{1.7}$$

$$y(0) = y(1) = 0\,. \tag{1.8}$$

Relations (1.6)–(1.8) define a standard control problem with the newly introduced unknown $\underline{z} \in L^2(0,1)$ playing the role of the control. By coercivity and strict convexity, the existence of a unique optimal pair $[y^*, \underline{z}^*] \in [H^2(0,1) \cap H_0^1(0,1)] \times L^2(0,1)$ follows immediately. The first order optimality conditions for (1.6)–(1.8) are expressed by (1.7), (1.8) (where $y = y^*$, $\underline{z} = \underline{z}^*$), the adjoint system

$$p'' = f \quad \text{in }]0,1[\,, \tag{1.9}$$

$$p(0) = p(1) = 0\,, \tag{1.10}$$

and the Pontryagin maximum principle

$$\underline{z}^* = p \quad \text{in } [0,1]\,. \tag{1.11}$$

This can easily be inferred from the Euler equation associated with (1.6). Eliminating p from (1.7)–(1.11), we obtain the usual decomposition of (1.2)–(1.4) as a system of two second order differential equations. That is, (1.2)–(1.4), or (1.5), or (1.6)–(1.8), or (1.7)–(1.11) all constitute equivalent formulations of the same problem. Notice as well that (1.9)–(1.11) yield the regularity $\underline{z}^* \in H^2(0,1) \cap H_0^1(0,1)$, although the control space is only $L^2(0,1)$. (Such regularity properties are specific for unconstrained control problems.) This shows that the solution to (1.6)–(1.8) induces a strong solution for (1.2) with maximal regularity corresponding to $f \in L^2(0,1)$.

Next, we further modify (1.6) by integrating twice by parts in the second integral. If we denote by $g \in H^2(0,1) \cap H_0^1(0,1)$ the unique solution to $g'' = f, g(0) = g(1) = 0$, then the cost functional (1.6) can be rewritten as

$$\frac{1}{2}\int_0^1 \underline{z}^2\,ds - \int_0^1 f\,y\,ds = \frac{1}{2}\int_0^1 \underline{z}^2\,ds - \int_0^1 g\,\underline{z}\,ds = \frac{1}{2}\int_0^1 (\underline{z}-g)^2\,ds - \frac{1}{2}\int_0^1 g^2\,ds.$$

We redenote $\underline{z} - g$ again by $\underline{z}$. Then the control problem (1.6)–(1.8) becomes

$$\text{Min}\left\{\frac{1}{2}\int_0^1 \underline{z}^2\,ds\right\}, \tag{1.6}'$$

$$y'' = \underline{z} + g \quad \text{in }]0,1[\,, \tag{1.7}'$$

$$y(0) = y(1) = 0\,. \tag{1.8}'$$

Variants of such transformations and other mathematical modifications will be applied in section 2 to (1.1). In this respect, the mapping g (or g_1, g_2 defined in (2.2), (2.3)) will be used to write the explicit integration rules.

Moreover, in view of how the control problem (1.6)–(1.8) was introduced by starting from the quadratic functional (1.5), in our approach to problem (1.1) the following differential control system will play a key role:

$$v_1' - c\,v_2 = z_1 \quad \text{in }]0,1[\,, \tag{1.12}$$

$$v_2' + c\,v_1 = z_2 \quad \text{in }]0,1[\,. \tag{1.13}$$

The corresponding correct boundary conditions, the control mappings z_1, z_2, and the adequate notion of a weak solution to (1.12), (1.13) will be defined in detail in section 2.

In section 3, we use the optimal control formulation from the previous section in its equivalent form obtained by a variant of Pontryagin's maximum principle. For given $[f_1, f_2]$, we study the shape optimization problem of finding φ in a closed bounded subset of the space of Lipschitz arches, such that the obtained deflection $[v_1, v_2]$ has certain desired properties.

It should be noted that in this setting the considered optimization problem appears as a nonconvex control-into-coefficients problem. We prove the existence of the minimizer and derive the first order optimality conditions by computing the directional derivative of the cost. Similar problems were studied by Rousselet, Piekarski, and Myslinski [17], Chenais and Rousselet [9], and Chenais, Rousselet, and Benedict [10] under differentiability assumptions.

The last section collects numerical experiments related to arches and to their optimization. For simple input functions, the deformations can be computed by MAPLE. In the optimization case, local gradient methods are combined with some

global search, due to the nonconvexity of the problem. We have succeeded in finding, in some examples, global minimum points which have been theoretically justified a posteriori.

Finally, we point out that the core of our methods is a variety of special decompositions of (1.1) obtained via the first order optimality conditions for appropriately defined control problems. In this respect, the present work continues the investigations of Sprekels and Tiba from [18, 19, 20, 21, 22]. In particular, similar results may be obtained in the case of clamped plate models involving a discontinuous thickness (see Sprekels and Tiba [23]). The main tools that we use here are control theory and duality.

2. The control approach. Let $\theta(t)$ denote the angle between the tangent vector to the arch (given by φ') and the horizontal axis. If φ is smooth, then $\theta' = c$ (see [11, p. 432]). If $\varphi \in (W^{1,\infty}(0,1))^2$, then $\theta \in L^\infty(0,1)$, and this is the assumption we impose in what follows. Note that in this case the variational formulation (1.1) is not meaningful. However, it is still possible to define mild solutions for the system (1.12), (1.13) by the variation of constants formula (see (2.4)).

To this end, we introduce the fundamental matrix W (see Pontryagin [16, p. 110]) of the homogeneous linear ODE system $v_1' = c\,v_2$, $v_2' = -c\,v_1$:

$$W(t) = \begin{pmatrix} \cos\theta(t) & \sin\theta(t) \\ -\sin\theta(t) & \cos\theta(t) \end{pmatrix}, \tag{2.1}$$

which is meaningful for $\theta \in L^\infty(0,1)$. The affine part of the control system (compare with (1.7)′) is here given by the functions l, h, g_1, g_2 that are constructed from $f_1, f_2 \in L^2(0,1)$ as follows:

$$g_1 = \varepsilon\, l, \qquad -g_2'' = h, \qquad g_2(0) = g_2(1) = 0, \tag{2.2}$$

$$\begin{bmatrix} l \\ h \end{bmatrix}(t) = -\int_0^t W(t)\, W^{-1}(s) \begin{bmatrix} f_1(s) \\ f_2(s) \end{bmatrix} ds. \tag{2.3}$$

While (2.3) is similar to the definition of g from (1.7)′ and uses the state operator (2.4), relation (2.2) takes into account the ε and the supplementary derivative from the second integrand in (1.1). We then define the control system corresponding to (1.12), (1.13) and with z_1, z_2 replaced by $u + g_1, z + g_2$, respectively:

$$\begin{bmatrix} v_1 \\ v_2 \end{bmatrix}(t) := \int_0^t W(t)\, W^{-1}(s) \begin{bmatrix} u + g_1 \\ z + g_2 \end{bmatrix}(s)\, ds. \tag{2.4}$$

Since (2.4) takes into account just the initial conditions appearing in (1.1), the unconstrained problem (1.6)′–(1.8)′ is replaced by the constrained optimal control problem

$$\mathrm{Min}\left\{ \frac{1}{2\varepsilon} \int_0^1 u^2\, ds + \frac{1}{2} \int_0^1 (z')^2\, ds \right\}, \tag{P_ε}$$

subject to $u \in L^2(0,1)$, $z \in H_0^1(0,1)$, such that the mappings $[v_1, v_2] \in (L^\infty(0,1))^2$, given by (2.4), satisfy $v_1(1) = v_2(1) = 0$ in the sense that

$$\int_0^1 W^{-1}(s) \begin{bmatrix} u(s) + g_1(s) \\ z(s) + g_2(s) \end{bmatrix} ds = \begin{bmatrix} 0 \\ 0 \end{bmatrix}. \tag{2.5}$$

Clearly, $u = -g_1$, $z = -g_2$ give an admissible control pair for (P_ε). From the coercivity and strict convexity of the cost, there follows the existence of a unique minimizer $[u_\varepsilon, z_\varepsilon] \in L^2(0,1) \times H_0^1(0,1)$.

Denote by $S \subset L^2(0,1) \times H_0^1(0,1)$ the closed subspace of admissible variations for (P_ε). Then, $[\mu, \xi] \in S$ if and only if

$$\int_0^1 W^{-1}(s) \begin{bmatrix} \mu(s) \\ \xi(s) \end{bmatrix} ds = \begin{bmatrix} 0 \\ 0 \end{bmatrix}. \tag{2.6}$$

The Euler equation associated with $[u_\varepsilon, z_\varepsilon]$ is

$$\frac{1}{\varepsilon} \int_0^1 u_\varepsilon \, \mu \, ds + \int_0^1 z'_\varepsilon \, \xi' \, ds = 0 \quad \forall \, [\mu, \xi] \in S. \tag{2.7}$$

In particular, (2.7) says that $[u_\varepsilon, z_\varepsilon] \in S_\varepsilon^\perp$, where $S_\varepsilon^\perp$ denotes the orthogonal subspace of $S \subset L^2(0,1) \times H_0^1(0,1)$ with respect to the modified scalar product defined by the left-hand side of (2.7).

Remark 2.1. If $\theta \in W^{1,1}(0,1)$, then $c \in L^1(0,1)$, and relation (2.4) can be written in differential form as

$$v_1' - c\, v_2 = u + g_1 \qquad \text{a.e. in } (0,1), \tag{2.8}$$

$$v_2' + c\, v_1 = z + g_2 \qquad \text{a.e. in } (0,1). \tag{2.9}$$

Relation (2.4) gives the "mild" solution of (2.8), (2.9) with null initial conditions in the sense of semigroup theory; see Bénilan [4], Barbu [3]. If (2.8), (2.9) give the state equations of the control problem (P_ε), then (2.5) is a state constraint. It is expressed directly in the form of a control constraint, since the system (2.8), (2.9) is integrated by (2.4), and $W(t)$ is a nonsingular matrix.

We denote by $[v_1^\varepsilon, v_2^\varepsilon] \in (L^\infty(0,1))^2$ the optimal state of (P_ε), obtained from $[u_\varepsilon, z_\varepsilon]$ via (2.4).

THEOREM 2.2. *If $\varphi \in (W^{3,\infty}(0,1))^2$, then $[v_1^\varepsilon, v_2^\varepsilon]$ is the solution to* (1.1).

Proof. Under this regularity assumption, (2.4) can be written in the form (2.8), (2.9).

For any $u_1 \in H_0^1(0,1)$, $u_2 \in H_0^2(0,1)$, we introduce

$$\tilde{\mu} = u_1' - c\, u_2 \in L^2(0,1), \tag{2.10}$$

$$\tilde{\xi} = u_2' + c\, u_1 \in H_0^1(0,1), \tag{2.11}$$

and we have, consequently,

$$\begin{bmatrix} u_1 \\ u_2 \end{bmatrix}(t) = \int_0^t W(t)\, W^{-1}(s) \begin{bmatrix} \tilde{\mu} \\ \tilde{\xi} \end{bmatrix}(s)\, ds. \tag{2.12}$$

Since u_1, u_2 vanish at both ends of $[0,1]$, it follows from (2.12) and (2.6) that $[\tilde{\mu}, \tilde{\xi}] \in S$. Hence they may be used in (2.7). Taking into account relations (2.8), (2.9) satisfied by $v_1^\varepsilon, v_2^\varepsilon$, as well as (2.10), (2.11), and (2.2), we obtain that

$$\begin{aligned} 0 &= \frac{1}{\varepsilon} \int_0^1 ((v_1^\varepsilon)' - c\, v_2^\varepsilon - g_1)(u_1' - c u_2) ds + \int_0^1 ((v_2^\varepsilon)' + c\, v_1^\varepsilon - g_2)'\, (u_2' + c\, u_1)'\, ds \\ &= \frac{1}{\varepsilon} \int_0^1 \big((v_1^\varepsilon)' - c\, v_2^\varepsilon\big)(u_1' - c\, u_2)\, ds + \int_0^1 ((v_2^\varepsilon)' + c\, v_1^\varepsilon)'(u_2' + c\, u_1)'\, ds \\ &\quad - \int_0^1 l(u_1' - c\, u_2)\, ds - \int_0^1 h(u_2' + c\, u_1)\, ds. \end{aligned}$$

By the regularity assumption, (2.3) can be rewritten in the differential form (2.8), (2.9), and we can infer that

$$\int_0^1 l(u_1' - c\,u_2)\,ds + \int_0^1 h(u_2' - c\,u_1)\,ds$$
$$= -\int_0^1 u_1(l' - c\,h)\,ds - \int_0^1 u_2(h' + c\,l)\,ds = \int_0^1 (f_1\,u_1 + f_2\,u_2)\,ds.$$

The last two relations give (1.1) and the proof is finished. □

Remark 2.3. The approach via problem (P_ε) is constructive and does not use either Dirichlet's principle or Korn's inequality. As the formulation of (P_ε) is valid for $\theta \in L^\infty(0,1)$, this method may give solutions even in nonsmooth situations when Korn's inequality is not valid. For such cases, we refer to Geymonat and Gilardi [13].

In the general case, the following extension of Theorem 2.2 holds true.

THEOREM 2.4. *If* $\varphi \in (W^{1,\infty}(0,1))^2$, *then we have for any* $[\mu,\xi] \in S$

$$\frac{1}{\varepsilon}\int_0^1 (u_\varepsilon + g_1)\mu\,ds + \int_0^1 (z_\varepsilon + g_2)'\,\xi'\,ds = \int_0^1 (f_1\,u_1 + f_2\,u_2)\,ds\,, \tag{2.13}$$

with $u_1, u_2 \in L^\infty(0,1)$ *given by*

$$\begin{bmatrix} u_1 \\ u_2 \end{bmatrix}(s) = -\int_s^1 W(s)\,W^{-1}(t)\begin{bmatrix} \mu(t) \\ \xi(t) \end{bmatrix} dt \qquad \text{for almost every } s \in (0,1). \tag{2.14}$$

Proof. Since $[u_\varepsilon, z_\varepsilon] \in S_\varepsilon^\perp$ (see (2.7)), we obtain that

$$\frac{1}{\varepsilon}\int_0^1 (u_\varepsilon + g_1)\mu\,ds + \int_0^1 (z_\varepsilon + g_1)'\xi'\,ds$$
$$= \frac{1}{\varepsilon}\int_0^1 g_1\,\mu\,ds - \int_0^1 \xi\,g_2''\,ds = \int_0^1 [\mu,\xi]\begin{bmatrix} l \\ h \end{bmatrix} dt$$
$$= -\int_0^1 [\mu,\xi](t)\int_0^t W(t)\,W^{-1}(s)\begin{bmatrix} f_1(s) \\ f_2(s) \end{bmatrix} ds\,dt$$
$$= -\int_0^1\int_0^t \big[f_1(s), f_2(s)\big]W(s)\,W^{-1}(t)\begin{bmatrix} \mu(t) \\ \xi(t) \end{bmatrix} ds\,dt,$$

due to the orthogonality of the matrix $W(t)$ and to (2.2), (2.3). Fubini's theorem and (2.14) imply the result. □

Remark 2.5. It is possible to prove Theorem 2.2 via Theorem 2.4. These results show that the problem (P_ε) provides a notion of weak solution for the arch problem which is a natural extension of the classical one. This will be further justified below in Theorem 3.2 and Remark 3.6, via an approximation argument.

We now introduce the mappings $w_1, w_2 \in H^2(0,1) \cap H_0^1(0,1)$ given by

$$w_1''(s) = \sin\theta(s) \qquad \text{a.e. in } (0,1), \tag{2.15}$$

$$w_2''(s) = -\cos\theta(s) \qquad \text{a.e. in } (0,1). \tag{2.16}$$

Taking into account (2.1), relation (2.6) can be rewritten as

$$\int_0^1 \Big[\mu(s)\,\cos\theta(s) - \xi(s)\,\sin\theta(s)\Big]\,ds = 0,$$

$$\int_0^1 \Big[\mu(s)\,\sin\theta(s)\,-\,\xi(s)\,\cos\theta(s)\Big]\,ds\,=\,0.$$

Replacing the coefficients of $\xi(s)$ according to (2.15), (2.16) and integrating once by parts, relation (2.6) may be put into the equivalent form

$$\frac{1}{\varepsilon}\int_0^1 \varepsilon\,\cos\theta(s)\,\mu(s)\,ds\,+\,\int_0^1 w_1'(s)\,\xi'(s)\,ds\,=\,0, \tag{2.17}$$

$$\frac{1}{\varepsilon}\int_0^1 \varepsilon\,\sin\theta(s)\,\mu(s)\,ds\,+\,\int_0^1 w_2'(s)\,\xi'(s)\,ds\,=\,0. \tag{2.18}$$

From the definition of S using the modified scalar product from (2.7) it follows that the (linearly independent) vectors $[\varepsilon\cos\theta(\cdot), w_1(\cdot)]$ and $[\varepsilon\sin\theta(\cdot), w_2(\cdot)]$ provide a basis of the two-dimensional space $S_\varepsilon^\perp$.

In addition, from relations (2.5) and (2.6) we can infer that $[u_\varepsilon+g_1\,,\,z_\varepsilon+g_2]\in S$. Consequently, relation (2.7) gives us that

$$[u_\varepsilon, z_\varepsilon]\,=\,-\,\mathrm{proj}_{S_\varepsilon^\perp}[g_1, g_2], \tag{2.19}$$

where the projection is computed in the norm generated by the modified scalar product from (2.7).

Then, (2.17)–(2.19) yield that

$$[u_\varepsilon, z_\varepsilon]\,=\,\lambda_1^\varepsilon\,[\varepsilon\,\cos\theta\,,\,w_1]+\lambda_2^\varepsilon\,[\varepsilon\,\sin\theta\,,\,w_2] \tag{2.19$'$}$$

for some $\lambda_1^\varepsilon, \lambda_2^\varepsilon\in\mathbb{R}$. By virtue of the definition of the projection operator, and owing to (2.19), (2.19)$'$, we see that $(\lambda_1^\varepsilon,\,\lambda_2^\varepsilon)$ is the unique minimizer of the unconstrained optimization problem

$$\begin{aligned}(\mathrm{D}_\varepsilon)\qquad \min_{\lambda_1,\,\lambda_2\,\in\,\mathbb{R}}\ \Bigg\{&\frac{1}{2\varepsilon}\int_0^1\Big(\lambda_1\,\varepsilon\,\cos\theta(s)\,+\,\lambda_2\,\varepsilon\,\sin\theta(s)\,+\,\varepsilon\,l(s)\Big)^2\,ds\\ &+\,\frac{1}{2}\int_0^1\Big[(\lambda_1\,w_1\,+\,\lambda_2\,w_2\,+\,g_2)'\Big]^2\,ds\Bigg\}.\end{aligned}$$

Problem (D_ε) can be solved explicitly by imposing that the derivatives of the quadratic form with respect to λ_1, λ_2, are zero at the optimum point. This gives a linear algebraic system with a strictly positive determinant (by the Cauchy–Schwarz inequality and the structure of the basis of $S_\varepsilon^\perp$). We indicate the system for subsequent use:

$$\begin{aligned}&\varepsilon\,\lambda_1\int_0^1\cos^2\,\theta(s)\,ds\,+\,\lambda_1\,\big|w_1\big|^2_{H_0^1(0,1)}\,+\,\varepsilon\,\lambda_2\int_0^1\cos\theta(s)\,\sin\theta(s)\,ds\\ &\quad+\,\lambda_2\int_0^1 w_1'(s)\,w_2'(s)\,ds\,+\,\varepsilon\int_0^1 l(s)\,\cos\theta(s)\,ds\,+\,\int_0^1 g_2'(s)\,w_1'(s)\,ds\,=\,0,\\ &\varepsilon\,\lambda_1\int_0^1\cos\theta(s)\,\sin\theta(s)\,ds\,+\,\lambda_1\int_0^1 w_1'(s)\,w_2'(s)\,ds\,+\,\varepsilon\,\lambda_2\int_0^1\sin^2\theta(s)\,ds\\ &\quad+\,\lambda_2\big|w_2\big|^2_{H_0^1(0,1)}\,+\,\varepsilon\int_0^1 l(s)\sin\theta(s)\,ds\,+\,\int_0^1 g_2'(s)\,w_2'(s)\,ds\,=\,0.\end{aligned} \tag{2.20}$$

We have proved the following result.

THEOREM 2.6. *The solution of* (1.1) *(or of* (P_ε)*, if* $\theta \in L^\infty(0,1)$*) is given by* (2.19)′ *and* (2.4)*, with* $(\lambda_1^\varepsilon, \lambda_2^\varepsilon)$ *being the unique solution of* (D_ε)*, and with* w_1, w_2*,* g_1, g_2 *defined by* (2.2), (2.3), (2.15), (2.16).

Remark 2.7. In optimization theory, (D_ε) is the dual problem of (P_ε). Its complete solution is possible since the constraints from (P_ε) are affine and finite-dimensional. In simple examples of mappings θ, f_1, f_2, explicit formulas can be derived for the deformation $[v_1, v_2]$. In the general situation, numerical approximation is needed just to evaluate the occurring integrals. See section 4 for examples. In particular, Theorem 2.6 provides a complete solution of the "locking" problem discussed by Chenais and Paumier [8], in dimension one.

Remark 2.8. We also notice that, if $\tilde{\varphi}\colon [a,b] \to \mathbb{R}^2$ is an absolutely continuous Jordan arc of length one such that $\tilde{\varphi}' \neq 0$ a.e. in (a,b), then, by the usual reparametrization via the arc length function $s\colon [a,b] \to [0,1]$, $s(0) = 0$, $s'(\cdot) = \left|\tilde{\varphi}'(\cdot)\right|_{\mathbb{R}^2}$, we get that $\varphi(t) = \tilde{\varphi}(s^{-1}(t))$ satisfies $\left|\varphi'(t)\right|_{\mathbb{R}^2} = 1$ for almost every $t \in (0,1)$, i.e., it is Lipschitzian, and our results still apply.

Remark 2.9. If $\theta \in L^\infty(0,1)$, then $v_1^\varepsilon, v_2^\varepsilon$ as defined by Theorem 2.6 (see (2.4)) belong to $L^\infty(0,1)$. However, their global Cartesian representation is

$$W(t)^{-1} \begin{bmatrix} v_1^\varepsilon \\ v_2^\varepsilon \end{bmatrix}(t)$$

and belongs to $(W^{1,2}(0,1))^2$. This means that the lack of smoothness is due to the local coordinates (θ is defined a.e. and may have jumps) and that the constructed deformation is continuous.

The next result gives a characterization of the solution of the problem (P_ε) (or, equivalently, of the problem (D_ε)) as a system of first order differential equations which will be used frequently in what follows. Implicitly, it provides a nonstandard decomposition of (1.1) in the case of nonsmooth coefficients. Basically, this is given by the first order necessary conditions for (P_ε), but the form is different from the classical Pontryagin principle.

THEOREM 2.10. *The optimality system for the problem* (P_ε) *is given by*

$$\text{(2.21)}\quad \begin{bmatrix} v_1^\varepsilon \\ v_2^\varepsilon \end{bmatrix}(t) = \int_0^t W(t)\, W^{-1}(s) \begin{bmatrix} u_\varepsilon(s) + g_1(s) \\ z_\varepsilon(s) + g_2(s) \end{bmatrix} ds \quad \textit{for almost every } t \in (0,1)\,,$$

$$\text{(2.22)}\quad \int_0^1 W^{-1}(s) \begin{bmatrix} u_\varepsilon(s) + g_1(s) \\ z_\varepsilon(s) + g_2(s) \end{bmatrix} ds = \begin{bmatrix} 0 \\ 0 \end{bmatrix},$$

$$\text{(2.23)}\quad \begin{bmatrix} p_\varepsilon \\ q_\varepsilon \end{bmatrix}(t) = W(t) \begin{bmatrix} \lambda_1^\varepsilon \\ \lambda_2^\varepsilon \end{bmatrix} \quad \textit{for almost every } t \in (0,1)\,,$$

$$\text{(2.24)}\quad u_\varepsilon = \varepsilon\, p_\varepsilon \qquad \textit{a.e. in } (0,1)\,,$$

$$\text{(2.25)}\quad z_\varepsilon'' = -\, q_\varepsilon \quad \textit{a.e. in } (0,1)\,, \quad z_\varepsilon(0) = z_\varepsilon(1) = 0.$$

Under smoothness hypotheses, it is possible to write (2.21)–(2.25) in differential form. (Compare with (3.1)–(3.5) and (3.7)–(3.16) in the next section.)

Proof. Assume first that u_ε, z_ε satisfy (2.21)–(2.25) with some $\lambda_1^\varepsilon, \lambda_2^\varepsilon \in \mathbb{R}$, $p_\varepsilon, q_\varepsilon, v_1^\varepsilon, v_2^\varepsilon \in L^\infty(0,1)$. Then clearly, $[u_\varepsilon + g_1, z_\varepsilon + g_2] \in S$, i.e., $[u_\varepsilon\,, z_\varepsilon]$ is admissible for (P_ε). Using (2.23)–(2.25), the definition of S, and the orthogonality of

$W(t)$, we find that for any $[\mu, \xi] \in S$

$$\frac{1}{\varepsilon}\int_0^1 u_\varepsilon\,\mu\,ds \;+\; \int_0^1 z_\varepsilon'\,\xi'\,ds = \int_0^1 p_\varepsilon\,\mu\,ds + \int_0^1 q_\varepsilon\,\xi\,ds = \int_0^1 [\mu,\xi]W(s)\begin{bmatrix}\lambda_1^\varepsilon\\ \lambda_2^\varepsilon\end{bmatrix} ds$$

$$= [\lambda_1^\varepsilon, \lambda_2^\varepsilon]\int_0^1 W(s)^{-1}\begin{bmatrix}\mu\\ \xi\end{bmatrix}(s)\,ds = 0.$$

Consequently, $[u_\varepsilon\,,\, z_\varepsilon] \in S_\varepsilon^\perp$. Together with the admissibility of $[u_\varepsilon, z_\varepsilon]$, noticed above, this immediately gives that $[u_\varepsilon\,,\, z_\varepsilon]$ is the unique minimizer of (P_ε).

Conversely, we remark that (2.23)–(2.25) give a complete description of the two-dimensional space $S_\varepsilon^\perp$ when $\lambda_1, \lambda_2 \in \mathbb{R}$ are arbitrary. By (2.6), we know that the optimal control $[u_\varepsilon\,,\, z_\varepsilon]$ belongs to $S_\varepsilon^\perp$. Hence, there are $\lambda_1^\varepsilon, \lambda_2^\varepsilon \in \mathbb{R}$ such that $[u_\varepsilon\,,\, z_\varepsilon]$ can be represented via (2.23)–(2.25). (This is, in fact, the same representation as in (2.19)′.) Moreover, $[u_\varepsilon\,,\, z_\varepsilon]$ also satisfy (2.21), (2.22) by their admissibility for (P_ε). This ends the proof. □

As a first application of Theorem 2.10, we study the behavior for $\varepsilon \to 0$ of the problem (P_ε). Since arches are special cases of cylindrical shells, after passing to the limit a "flexural" model will be obtained (Ciarlet [12]). The treatment that we indicate below is valid under the weak regularity condition $\theta \in L^\infty(0,1)$. We shall also assume that θ is nonconstant in $[0,1]$, i.e., the arch is not a bar. For constant θ the results also remain valid, but some adaptation of the argument is necessary, since the dimension of $S_\varepsilon^\perp$ reduces to one in this case, if $\varepsilon = 0$.

THEOREM 2.11. *As $\varepsilon \searrow 0$, the mappings $v_1^\varepsilon, v_2^\varepsilon, p_\varepsilon, q_\varepsilon$ are bounded in $L^\infty(0,1)$, $\lambda_1^\varepsilon\,,\, \lambda_2^\varepsilon$ are bounded in $\mathbb{R}$, z_ε is bounded in $H^2(0,1)$, and u_ε strongly converges to 0 in $L^\infty(0,1)$. If we denote without ε their weak or weak* limits (on a subsequence) in the corresponding spaces, then these satisfy the conditions*

$$\begin{bmatrix}v_1\\ v_2\end{bmatrix}(t) = \int_0^t W(t)\,W^{-1}(s)\begin{bmatrix}0\\ z(s)+g_2(s)\end{bmatrix} ds\,,$$

$$\int_0^1 W^{-1}(s)\begin{bmatrix}0\\ z(s)+g_2(s)\end{bmatrix} ds = \begin{bmatrix}0\\ 0\end{bmatrix},$$

$$\begin{bmatrix}p\\ q\end{bmatrix}(t) = W(t)\begin{bmatrix}\lambda_1\\ \lambda_2\end{bmatrix},$$

$$z'' = -q\,, \qquad z(0) = z(1) = 0\,.$$

Proof. The explicit calculus indicated in Theorem 2.6 and (2.20) shows directly that $\lambda_1^\varepsilon, \lambda_2^\varepsilon$ are bounded in $\mathbb{R}$ for $\varepsilon \to 0$. For instance, the determinant of the system is

$$\left[\varepsilon\int_0^1 \cos^2\theta(s)\,ds + \Big|w_1\Big|^2_{H_0^1(0,1)}\right]\cdot\left[\varepsilon\int_0^1 \sin^2\theta(s)\,ds + \Big|w_2\Big|^2_{H_0^1(0,1)}\right]$$

$$-\left[\varepsilon\int_0^1 \cos\theta(s)\cdot\sin\theta(s)\,ds + \int_0^1 w_1'(s)w_2'(s)\,ds\right]^2 \underset{\varepsilon\to 0}{\longrightarrow} \Big|w_1\Big|^2_{H_0^1}\cdot\Big|w_2\Big|^2_{H_0^1}$$

$$-\Big\langle w_1, w_2\Big\rangle^2_{H_0^1} > 0.$$

Here the assumption that θ is nonconstant is necessary, since for $\varepsilon = 0$ and θ constant the vectors used in (2.19)′ become proportional. (In this case only one parameter λ is necessary and a simpler argument works.)

Thus, by (2.23), p_ε and q_ε are bounded in $L^\infty(0,1)$. Relation (2.24) gives $u_\varepsilon \to 0$ strongly in $L^\infty(0,1)$, and (2.25) shows that z_ε is bounded in $H^2(0,1)$, for instance. By (2.21), we see that $v_1^\varepsilon, v_2^\varepsilon$ are bounded in $L^\infty(0,1)$ as well. Definition (2.2) gives that g_1 depends on ε (and has the strong limit 0 in $L^\infty(0,1)$), while g_2 is independent of ε.

Finally, we can pass to the limit in (2.21)–(2.25) on a subsequence, and we obtain the desired conclusion. □

Remark 2.12. The system obtained by Theorem 2.11 characterizes, in the sense of Theorem 2.10, the following constrained optimal control problem:

$$\mathrm{Min}\left\{\frac{1}{2}|z|^2_{H^1_0(0,1)}\right\},$$

subject to $z \in H^1_0(0,1)$, such that the mappings

$$\begin{bmatrix} v_1 \\ v_2 \end{bmatrix}(t) \,=\, \int_0^t W(t)\, W^{-1}(s) \begin{bmatrix} 0 \\ z(s) + g_2(s) \end{bmatrix} ds$$

satisfy $v_1(1) = v_2(1) = 0$ in the sense that

$$\int_0^1 W^{-1}(s) \begin{bmatrix} 0 \\ z(s) + g_2(s) \end{bmatrix} ds \,=\, \begin{bmatrix} 0 \\ 0 \end{bmatrix}.$$

The structure of this problem is very similar to (P_ε), and the proof follows closely that of Theorem 2.10, by considering the subspace $Z \subset H^1_0(0,1)$, defined by

$$\int_0^1 W^{-1}(s) \begin{bmatrix} 0 \\ \xi(s) \end{bmatrix} ds \,=\, \begin{bmatrix} 0 \\ 0 \end{bmatrix},$$

and its orthogonal subspace $Z^\perp$. If $\theta \in L^\infty(0,1)$ is not constant, $Z^\perp$ has dimension two, and we can argue as above.

Remark 2.13. If $\theta \in W^{2,\infty}(0,1)$, then one can show, as in Theorem 2.2, that v_1, v_2 defined in Remark 2.12 satisfy the "flexural" arch model:

$$\int_0^1 (v_2' \,+\, c v_1)'\,(u_2' \,+\, c\, u_1)'\, ds \,=\, \int_0^1 (f_1\, u_1 \,+\, f_2\, u_2)\, ds$$

$$\forall\ (u_1, u_2) \in V_F \,=\, \Big\{(u_1, u_2) \in H^1_0(0,1) \,\times\, H^2_0(0,1)\,;\, u_1' \,-\, c\, u_2 \,=\, 0\Big\},$$

$$(v_1, v_2) \in V_F.$$

Such asymptotic properties have been discussed in detail by Ciarlet [12] for the case of shells. Theorem 2.11 shows that they remain valid for nonsmooth arches and under our variational formulation via optimal control theory.

3. Optimization of nonsmooth arches. One advantage of the method presented in the previous section is that in the study of related optimization problems nonsmooth arches may be taken into consideration. Let $\mathcal{K} \subset L^\infty(0,1)$ be a closed subset. We shall study the model problem

$$(\mathrm{Q}) \qquad \mathop{\mathrm{Min}}_{\theta\,\in\,\mathcal{K}} \left\{\frac{1}{2}\int_0^1 v_2^2\, ds\right\},$$

subject to

$$\begin{bmatrix} v_1 \\ v_2 \end{bmatrix}(t) = \int_0^t W_\theta(t)\, W_\theta^{-1}(s) \begin{bmatrix} u(s) + g_1(s) \\ z(s) + g_2(s) \end{bmatrix} ds \quad \text{for almost every } t \in (0,1), \tag{3.1}$$

$$\int_0^1 W_\theta^{-1}(s) \begin{bmatrix} u(s) + g_1(s) \\ z(s) + g_2(s) \end{bmatrix} ds = \begin{bmatrix} 0 \\ 0 \end{bmatrix}, \tag{3.2}$$

$$\begin{bmatrix} p \\ q \end{bmatrix}(t) = W_\theta(t) \begin{bmatrix} \lambda_1^\varepsilon \\ \lambda_2^\varepsilon \end{bmatrix} \quad \text{for almost every } t \in (0,1), \tag{3.3}$$

$$u = \varepsilon\, p \quad \text{a.e. in } (0,1), \tag{3.4}$$

$$z'' = -\,q \quad \text{a.e. in } (0,1), \quad z(0) = z(1) = 0. \tag{3.5}$$

The matrix W_θ is given by (2.1), and the new notation just puts into evidence the dependence on the arch (characterized by θ). The state system (3.1)–(3.5) is exactly the decomposition of the Kirchhoff–Love model provided by Theorem 2.10. It should be noted that all the quantities appearing in it (including the data g_1, g_2 defined by (2.2), (2.3)) depend on θ. This is due to W_θ and to the fact that $[f_1, f_2]$ (the load) depends on θ by the local choice of the coordinates system. In what follows, we shall write $v_1(\theta), v_2(\theta), \lambda_1(\theta), \lambda_2(\theta)$, etc. ($\varepsilon$ is fixed now).

Remark 3.1. The shape optimization problem (Q) is a nonconvex control-into-coefficients problem. In the given subset $\mathcal{K}$, the arch that minimizes the normal deflection (in the L^2-norm) is sought. This is a natural safety requirement. Various other cost functionals may be studied as well.

THEOREM 3.2. *If $\theta_n \to \theta$ in $L^\infty(0,1)$ and $f_i(\theta_n) \to f_i(\theta)$ in $L^1(0,1), i = 1,2$, then $W_{\theta_n} \to W_\theta$ in $(L^\infty(0,1))^4$, $\lambda_1(\theta_n) \to \lambda_1(\theta)$, $\lambda_2(\theta_n) \to \lambda_2(\theta)$, $g_1(\theta_n) \to g_1(\theta)$, $h(\theta_n) \to h(\theta)$, and $l(\theta_n) \to l(\theta)$ in $L^\infty(0,1), g_2(\theta_n) \to g_2(\theta)$ in $W^{2,\infty}(0,1)$, $p(\theta_n) \to p(\theta)$, $u(\theta_n) \to u(\theta)$, and $q(\theta_n) \to q(\theta)$ in $L^\infty(0,1)$, $z(\theta_n) \to z(\theta)$ in $W^{2,\infty}(0,1)$, and $v_1(\theta_n) \to v_1(\theta)$, $v_2(\theta_n) \to v_2(\theta)$ in $L^\infty(0,1)$. If $\theta_n \to \theta$ in $C[0,1]$, then the above convergences are also valid in $C[0,1]$ and $C^2[0,1]$, respectively.*

Proof. If $\theta_n \to \theta$ in $L^\infty(0,1)$, then $\cos\theta_n \to \cos\theta$ and $\sin\theta_n \to \sin\theta$ in $L^\infty(0,1)$. Consequently, $W_{\theta_n} \to W_\theta$, $W_{\theta_n}^{-1} \to W_\theta^{-1}$, strongly in $(L^\infty(0,1))^4$. Moreover, (2.15), (2.16) show that $w_1(\theta_n) \to w_1(\theta)$ and $w_2(\theta_n) \to w_2(\theta)$ in $W^{2,\infty}(0,1)$. If $\Delta(\theta_n)$ is the determinant associated with the system (2.20) (written for θ_n), a direct calculus gives that $\Delta(\theta_n) \to \Delta(\theta)$.

From the relation (2.3) we infer that for almost every $t \in (0,1)$

$$\begin{aligned}
&\left| \begin{bmatrix} l(\theta_n) \\ h(\theta_n) \end{bmatrix}(t) - \begin{bmatrix} l(\theta) \\ h(\theta) \end{bmatrix}(t) \right|_{\mathbb{R}^2} \\
&\le \left| W_{\theta_n} - W_\theta \right|_{(L^\infty(0,1))^4} \left| W_{\theta_n}^{-1} \right|_{(L^\infty(0,1))^4} \left| \begin{bmatrix} f_1(\theta_n) \\ f_2(\theta_n) \end{bmatrix} \right|_{(L^1(0,1))^2} \\
&\quad + \left| W_\theta \right|_{(L^\infty(0,1))^4} \left| W_{\theta_n}^{-1} - W_\theta^{-1} \right|_{(L^\infty(0,1))^4} \left| \begin{bmatrix} f_1(\theta_n) \\ f_2(\theta_n) \end{bmatrix} \right|_{(L^1(0,1))^2} \\
&\quad + \left| W_\theta \right|_{(L^\infty(0,1))^4} \left| W_\theta^{-1} \right|_{(L^\infty(0,1))^4} \left| \begin{bmatrix} f_1(\theta_n) \\ f_2(\theta_n) \end{bmatrix} - \begin{bmatrix} f_1(\theta) \\ f_2(\theta) \end{bmatrix} \right|_{(L^1(0,1))^2}.
\end{aligned} \tag{3.6}$$

It follows that $l(\theta_n) \to l(\theta)$, $h(\theta_n) \to h(\theta)$, strongly in $L^\infty(0,1)$. By (2.2), the same is valid for $g_1(\theta_n) \to g_1(\theta)$, while $g_2(\theta_n) \to g_2(\theta)$ strongly in $W^{2,\infty}(0,1)$. Then one obtains $\lambda_1(\theta_n) \to \lambda_1(\theta)$ and $\lambda_2(\theta_n) \to \lambda_2(\theta)$ from (2.20).

Equations (3.3)–(3.5) give the assertion for $p(\theta_n)$, $q(\theta_n)$, $u(\theta_n)$, $z(\theta_n)$. The argument for the convergence $v_1(\theta_n) \to v_1(\theta)$, $v_2(\theta_n) \to v_2(\theta)$, strongly in $L^\infty(0,1)$, is similar to that in the inequality (3.6). If $\theta_n \to \theta$ in $C[0,1]$, the proof follows the same lines, with minor modifications. □

COROLLARY 3.3. *The shape optimization problem* (Q) *has at least one solution if* $\mathcal{K}$ *is compact in* $L^\infty(0,1)$.

Proof. This is a direct consequence of Theorem 3.2, observing that it is possible to pass to the limit in (3.2) and in the cost functional, if $\theta_n \to \theta$ strongly in $L^\infty(0,1)$. □

Remark 3.4. In addition to Remark 2.9, we notice that the convergence of the global Cartesian representation of the displacement

$$W_{\theta_n}^{-1}(t) \begin{bmatrix} v_1(\theta_n) \\ v_2(\theta_n) \end{bmatrix} (t)$$

is valid in $(W^{1,\infty}(0,1))^2$. Here, we also use the fact that by (3.4) the solution $[u,z]$ of the problem (P_ε) belongs to $(L^\infty(0,1))^2$.

Remark 3.5. If the curvature c corresponding to the arches associated with $\theta \in \mathcal{K}$ is bounded in some $L^r(0,1)$, $r > 1$, then $\mathcal{K}$ is compact in $C[0,1]$. This shows that the compactness assumption from Theorem 3.2 and Corollary 3.3 is very weak in comparison with those used in the existing literature.

Remark 3.6. For any $\theta \in L^\infty(0,1)$, we may define a smooth sequence θ_n converging to θ in $L^r(0,1)\,\forall\, r \geq 1$ by a regularization process with a Friedrichs mollifier. Then, keeping $[f_1, f_2] \in (L^2(0,1))^2$ fixed, it is possible to modify (3.6) and the other arguments in the proof of Theorem 3.2 to show that for the corresponding solutions we have $v_n^1 \to v^1$, $v_n^2 \to v^2$ in $L^r(0,1)\,\forall\, r \geq 1$. If θ is continuous, the obtained convergences are uniform. We also note that the global Cartesian representation

$$W_{\theta_n}^{-1}(t) \begin{bmatrix} v_n^1 \\ v_n^2 \end{bmatrix} (t)$$

is convergent in $(W^{1,r}(0,1))^2\,\forall\, r \geq 1$. Since for θ_n the corresponding solution of (P_ε) then coincides with the solution of (1.1) (by Theorem 2.2), we see that for any $\theta \in L^\infty(0,1)$ the optimal state of (P_ε) can be approximated by usual solutions of (1.1).

The remainder of this section is devoted to the sensitivity analysis of the Kirchhoff–Love model. We proceed in two steps. First, we assume that $c \in L^1(0,1)$ and that, consequently, $\theta \in W^{1,1}(0,1)$, and we compute the gradient of the cost in this case. Then, we use an approximation argument to reduce the general case $\theta \in L^\infty(0,1)$ to the previous one.

Under the assumption $c \in L^1(0,1)$ and recalling definition (2.1) of W_θ as a fundamental matrix, the state system (3.1)–(3.5) for problem (Q) can be written in differential form:

$$v_1' - c\, v_2 = u + g_1\,, \tag{3.7}$$

$$v_2' + c\, v_1 = z + g_2\,, \tag{3.8}$$

$$v_1(0) = v_2(0) = 0\,, \tag{3.9}$$

$$v_1(1) = v_2(1) = 0\,, \tag{3.10}$$

$$p' - c\,q = 0\,, \tag{3.11}$$

$$q' + c\,p = 0\,, \tag{3.12}$$

$$p(0) = \lambda_1 \cos\theta(0) + \lambda_2 \sin\theta(0)\,, \quad q(0) = -\lambda_1 \sin\theta(0) + \lambda_2 \cos\theta(0)\,, \tag{3.13}$$

$$u = \varepsilon\, p\,, \tag{3.14}$$

$$z'' = -q\,, \tag{3.15}$$

$$z(0) = z(1) = 0\,. \tag{3.16}$$

We shall denote by $v_1(c), v_2(c), \ldots$ the dependence of the solution of (3.7)–(3.16) on $c \in L^1(0,1)$, which is now considered instead of the related dependence on θ. We study its Gâteaux differentiability, and we take variations of the form $c + \delta\, d$ with $d \in L^1(0,1), \delta \in \mathbb{R}$ "small."

The definitions of g_1, g_2, given in (2.2) and (2.3), can also be rewritten in differential form:

$$g_1 = \varepsilon\, l\,, \tag{3.17}$$

$$g_2'' = -h\,, \tag{3.18}$$

$$g_2(0) = g_2(1) = 0\,, \tag{3.19}$$

$$l' - c\,h = -f_1\,, \tag{3.20}$$

$$h' + c\,l = -f_2\,, \tag{3.21}$$

$$l(0) = h(0) = 0\,. \tag{3.22}$$

We have, by (3.20), (3.21),

$$\frac{l(c+\delta\, d)' - l(c)'}{\delta} - (c+\delta\, d)\frac{h(c+\delta\, d) - h(c)}{\delta} = d\,h(c) - \frac{f_1(c+\delta\, d) - f_1(c)}{\delta}\,, \tag{3.23}$$

$$\frac{l(c+\delta\, d)' - h(c)'}{\delta} + (c+\delta\, d)\frac{l(c+\delta\, d) - l(c)}{\delta} = -d\,l(c) - \frac{f_2(c+\delta\, d) - f_2(c)}{\delta}\,. \tag{3.24}$$

We interpret $f_1, f_2 : L^1(0,1) \to L^1(0,1)$ as nonlinear operators, and we assume that they are Gâteaux differentiable. Multiplying (3.23), (3.24) by $[\frac{l(c+\delta\, d)-l(c)}{\delta}, \frac{h(c+\delta\, d)-h(c)}{\delta}]$ and integrating over $[0,t]$, we find that

$$\begin{aligned} \frac{1}{2}\left\| \begin{bmatrix} \dfrac{l(c+\delta\, d) - l(c)}{\delta} \\ \dfrac{h(c+\delta\, d) - h(c)}{\delta} \end{bmatrix}(t) \right\|^2_{\mathbb{R}^2} \\ \leq \int_0^t \left\langle \begin{matrix} d\,h(c) - \dfrac{f_1(c+\delta\, d) - f_1(c)}{\delta} \\ -d\,l(c) - \dfrac{f_2(c+\delta\, d) - f_2(c)}{\delta} \end{matrix} ; \begin{matrix} \dfrac{l(c+\delta\, d) - l(c)}{\delta} \\ \dfrac{h(c+\delta\, d) - h(c)}{\delta} \end{matrix} \right\rangle_{\mathbb{R}^2} ds \end{aligned} \tag{3.25}$$

with obvious notations for the norm and the scalar product in $\mathbb{R}^2$.

The Brezis [6] variant of Gronwall's lemma and (3.25) imply that $\{\frac{l(c+\delta\, d)-l(c)}{\delta}\}$, $\{\frac{h(c+\delta\, d)-h(c)}{\delta}\}$ are bounded in $L^\infty(0,1)$ for $\delta \to 0$. From (3.23), (3.24), we see that the boundedness is even valid in $W^{1,1}(0,1)$, and we also have equi-uniform continuity due to the equi-absolute integrability of $\{\frac{f_i(c+\delta\, d)-f_i(c)}{\delta}\}$, $i = 1,2$. Consequently, by taking a subsequence, we get convergence and the Gâteaux differentiability of $l(c), h(c)$ in $L^2(0,1)$, for instance. Relations (3.17)–(3.19) then show that $g_1(\cdot) : L^1(0,1) \to L^2(0,1), g_2(\cdot) : L^1(0,1) \to W^{2,2}(0,1)$ are also Gâteaux differentiable.

The auxiliary mappings w_1, w_2 defined in (2.15), (2.16) are clearly Gâteaux differentiable. Recalling that $\theta' = c$ and assuming that the perturbation $\tilde{\theta'}_\delta = c + \delta d$ satisfies $\tilde{\theta}_\delta(0) = \theta(0) + \delta\, \eta(0)$, if $\bar{w}_1, \bar{w}_2$ denote the directional derivatives at c in the direction d, we see that

$$\bar{w}_1'' = \left(\eta(0) + \int_0^t d(s)\, ds\right) \cos\left(\theta(0) + \int_0^t c(s)\, ds\right),\ \bar{w}_1(0) = \bar{w}_1(1) = 0\,, \tag{3.26}$$

$$\bar{w}_2'' = \left(\eta(0) + \int_0^t d(s)\, ds\right) \sin\left(\theta(0) + \int_0^t c(s)\, ds\right),\ \bar{w}_2(0) = \bar{w}_2(1) = 0\,. \tag{3.27}$$

Next we recall, by (2.20), that $\lambda_1(c), \lambda_2(c)$ are solutions of an affine system with $\Delta(c) > 0$ and coefficients which are Gâteaux differentiable, by (3.26), (3.27). Then, $\lambda_1(c), \lambda_2(c)$ are as well Gâteaux differentiable from $L^1(0,1)$ into $\mathbb{R}$. Moreover, (3.12), (3.13) imply the Gâteaux differentiability of $p, q : L^1(0,1) \to L^2(0,1)$, for instance. It follows immediately that $u : L^1(0,1) \to L^2(0,1)$ and $z : L^1(0,1) \to W^{2,2}(0,1)$ are Gâteaux differentiable. Finally, applying arguments similar to (3.23)–(3.25) to (3.7)–(3.9), we obtain that $v_1, v_2 : L^1(0,1) \to L^2(0,1)$ are also Gâteaux differentiable.

We denote by $\bar{v}_1, \bar{v}_2, \dots$ the directional derivatives of the mappings defined by (3.7)–(3.16) with respect to $c \in L^1(0,1)$ and in the direction $d \in L^1(0,1)$.

We thus have established the following result.

THEOREM 3.7. *The mappings defined in* (3.7)–(3.16) *are Gâteaux differentiable, and the directional derivatives satisfy the system*

$$\bar{v}_1' - c\,\bar{v}_2 = d\, v_2(c) + \bar{u} + \bar{g}_1\,, \tag{3.28}$$

$$\bar{v}_2' + c\,\bar{v}_1 = -\,d\, v_1(c) + \bar{z} + \bar{g}_2\,, \tag{3.29}$$

$$\bar{v}_1(0) = \bar{v}_2(0) = 0\,, \tag{3.30}$$

$$\bar{v}_1(1) = \bar{v}_2(1) = 0\,, \tag{3.31}$$

$$\bar{p}' - c\,\bar{q} = d\, q(c)\,, \tag{3.32}$$

$$\bar{q}' + c\,\bar{p} = -\,d\, p(c)\,, \tag{3.33}$$

$$\begin{aligned} \bar{p}(0) &= \bar{\lambda}_1 \cos\theta(0) + \bar{\lambda}_2 \sin\theta(0) + \eta(0)\left[\lambda_2 \cos\theta(0) - \lambda_1 \sin\theta(0)\right], \\ \bar{q}(0) &= -\,\bar{\lambda}_1 \sin\theta(0) + \bar{\lambda}_2 \cos\theta(0) - \eta(0)\left[\lambda_1 \cos\theta(0) + \lambda_2 \sin\theta(0)\right], \end{aligned} \tag{3.34}$$

$$\bar{u} = \varepsilon\, \bar{p}\,, \tag{3.35}$$

$$\bar{z}'' = -\,\bar{q}\,, \tag{3.36}$$

$$\bar{z}(0) = \bar{z}(1) = 0\,. \tag{3.37}$$

Remark 3.8. The system (3.28)–(3.37) admits a unique solution, since its homogeneous variant may be reformulated in the language of the control problem (P_ε). Here, homogeneous means that $\bar g_1 = 0, \bar g_2 = 0, d = 0, \eta(0) = 0$, and the corresponding solution of (P_ε) is in this situation clearly identically zero in $[0,1]$. Consequently, the limits defining $\bar v_1, \bar v_2, \dots$ are valid without taking subsequences; we have convergence of the entire sequences.

Next, we introduce the adjoint system associated with (3.28)–(3.37):

$$P_1' - c\,P_2 = 0\,, \tag{3.38}$$

$$P_2' + c\,P_1 = -\,v_2(c)\,, \tag{3.39}$$

$$P_3' - c\,P_4 = R\,, \tag{3.40}$$

$$P_4' + c\,P_3 = Q\,, \tag{3.41}$$

$$Q'' = -\,P_2\,, \tag{3.42}$$

$$R = \varepsilon\,P_1\,, \tag{3.43}$$

$$Q(0) = Q(1) = P_3(0) = P_3(1) = P_4(0) = P_4(1) = 0\,. \tag{3.44}$$

Proposition 3.9. *The system* (3.38)–(3.44) *has a unique solution such that* $P_1, P_2,\ P_3, P_4, R \in W^{1,1}(0,1)$ *and* $Q \in W^{2,\infty}(0,1)$.

Proof. Let $\mu_1, \mu_2 \in \mathbb{R}^2$ be some arbitrary initial conditions for (3.38), (3.39). Then

$$\begin{bmatrix} P_1 \\ P_2 \end{bmatrix}(t) = W_c(t) \begin{bmatrix} \mu_1 \\ \mu_2 \end{bmatrix} + \begin{bmatrix} \gamma_1(t) \\ \gamma_2(t) \end{bmatrix},$$

where

$$\begin{bmatrix} \gamma_1(t) \\ \gamma_2(t) \end{bmatrix} = \int_0^t W_c(t)\, W_c^{-1}(s) \begin{bmatrix} 0 \\ -\,v_2(c) \end{bmatrix}(s)\, ds,$$

and $P_1, P_2 \in W^{1,1}(0,1)$ if $c \in L^1(0,1)$. Here, W_c is a new notation for the matrix W that puts into evidence its dependence on c.

Consequently, $R(t) = \varepsilon P_1$ and $Q(t)$ depend in an affine manner on μ_1, μ_2 and belong to $W^{1,1}(0,1)$ and $W^{2,\infty}(0,1)$, respectively. Then,

$$\begin{bmatrix} P_3 \\ P_4 \end{bmatrix}(t) = -\int_t^1 W_c(t) W_c^{-1}(s) \begin{bmatrix} R(s) \\ Q(s) \end{bmatrix} ds$$

belongs to $(W^{1,1}(0,1))^2$. We have used the final null conditions. Notice that the constraint

$$\int_0^1 W_c^{-1}(s) \begin{bmatrix} R(s) \\ Q(s) \end{bmatrix} ds = \begin{bmatrix} 0 \\ 0 \end{bmatrix} \tag{3.45}$$

should be fulfilled to obtain the initial null conditions (3.44) for P_3, P_4. By writing (3.45) explicitly, we obtain a linear system like (2.20) for μ_1, μ_2. Since its determinant is positive, it has a unique solution, and the proof is finished. ∎

Theorem 3.10. *The directional derivative of the cost functional in the problem* (Q) *at the point* $c \in L^1(0,1)$ *and in the direction* $d \in L^1(0,1)$ *is given by*

$$\int_0^1 d\Big(P_1\, v_2(c) - P_2\, v_1(c) + g_1'(c)^* P_1 + g_2'(c)^* P_2 - P_3\, q(c) + P_4\, p(c)\Big)\, ds\,. \tag{3.46}$$

Here, $g_i'(c)$, $i = 1, 2$, denote the Gâteaux derivative of g_i at $c \in L^1(0,1)$, and $g_i'(c)^* : L^2(0,1) \to L^\infty(0,1)$ is the adjoint operator.

Proof. We have (by (3.38), (3.39), partial integration, etc.) that

$$\begin{aligned}
&\lim_{\delta \to 0} \frac{1}{2\delta} \left[\int_0^1 (v_2(c + \delta\, d))^2 \, ds - \int_0^1 (v_2(c))^2 \, ds \right] = \int_0^1 v_2(c)\, \bar v_2 \, ds \\
&= - \int_0^1 (P_2' + c\, P_1) \bar v_2 \, ds - \int_0^1 (P_1' - c\, P_2)\, \bar v_1 \, ds \\
&= \int_0^1 P_1(\bar v_1' - c\, \bar v_2)\, ds + \int_0^1 P_2(\bar v_2' + c\, \bar v_1)\, ds \\
&= \int_0^1 d(P_1\, v_2(c) - P_2\, v_1(c))\, ds + \int_0^1 P_1(\bar u + \bar g_1)\, ds + \int_0^1 P_2(\bar z + \bar g_2)\, ds\,,
\end{aligned}$$

owing to (3.28), (3.29). Now recall that

$$\bar g_1 = g_1'(c)\, d\,, \quad \bar g_2 = g_2'(c)\, d\,.$$

Hence, using (3.40) and (3.41), we can write

$$\begin{aligned}
&\int_0^1 v_2(c)\, \bar v_2 \, ds = \int_0^1 d(P_1\, v_2(c) - P_2\, v_1(c) + g_1'(c)^* P_1 + g_2'(c)^* P_2)\, ds \\
&+ \int_0^1 \varepsilon^{-1}\, R\, \bar u \, ds - \int_0^1 Q''\, \bar z \, ds = \int_0^1 d(\dots)\, ds + \int_0^1 R\, \bar p \, ds + \int_0^1 Q\, \bar q \, ds \\
&= \int_0^1 d(\dots)\, ds + \int_0^1 \bar p (P_3' - c\, P_4)\, ds + \int_0^1 \bar q (P_4' + c\, P_3)\, ds\,.
\end{aligned}$$

From this, again using partial integration together with (3.32), (3.33), we obtain (3.46), and the proof is finished. ∎

Next, we shall study the differentiability properties of (Q) in the general case $\theta \in L^\infty(0,1)$. We consider variations of the form $\theta + \sigma\, \eta, \eta \in L^\infty(0,1), \sigma \in \mathbb{R}$ small. We assume that $f_i : L^\infty(0,1) \to L^2(0,1)$, $i = 1, 2$, depend directly on θ and are Gâteaux differentiable. A direct calculus starting from (2.3) and taking into account the dependence of $W(t)$ on θ leads to

$$\begin{aligned}
\begin{bmatrix} \bar l \\ \bar h \end{bmatrix}(t) = &- \int_0^t W_\theta(t)\, W_\theta^{-1}(s) \begin{bmatrix} \bar f_1(s) \\ \bar f_2(s) \end{bmatrix} ds - \begin{pmatrix} 0 & \eta(t) \\ -\eta(t) & 0 \end{pmatrix} \begin{bmatrix} l(\theta) \\ h(\theta) \end{bmatrix}(t) \\
&+ \int_0^t \begin{pmatrix} 0 & \eta(s) \\ -\eta(s) & 0 \end{pmatrix} W_\theta(t)\, W_\theta^{-1}(s) \begin{bmatrix} f_1(\theta) \\ f_2(\theta) \end{bmatrix}(s)\, ds\,.
\end{aligned} \tag{3.47}$$

By (2.2), it holds that

$$\bar g_1 = \varepsilon\, \bar l\,, \quad -\bar g_2'' = \bar h\,, \quad \bar g_2(0) = \bar g_2(1) = 0\,. \tag{3.48}$$

Comparing (3.47) with (3.20)–(3.22), we see that the integral formulation is more difficult to handle since it involves more products which generate more terms via differentiation.

For the auxiliary mappings w_1, w_2 defined in (2.15), (2.16), we write directly the increment ratios corresponding to θ and $\theta + \sigma\eta$, and we compute the limit corresponding to $\sigma \to 0$ to obtain that

$$\begin{aligned}
&\bar w_1'' = \eta \cos\theta\,, \quad \bar w_2'' = \eta \sin\theta\,, \\
&\bar w_i(0) = \bar w_i(1) = 0\,, \quad i = 1, 2\,.
\end{aligned} \tag{3.49}$$

Relations (3.47)–(3.49) also show the continuous dependence in $L^2(0,1)$ of $\bar g_i, \bar w_i$, $i = 1, 2$, and $\bar l, \bar h$ with respect to regularizations of η and θ, if the same is assumed for $f_i, \bar f_i, i = 1, 2$. For $\bar w_i, i = 1, 2$, and $\bar g_2$, this is valid even in $H^2(0,1)$. An elementary calculus, starting from (2.20), shows that the same continuity property remains valid for $\bar\lambda_1, \bar\lambda_2$.

From relation (3.3), we obtain that

$$\begin{bmatrix} \bar p \\ \bar q \end{bmatrix}(t) = \begin{pmatrix} 0 & \eta(t) \\ -\eta(t) & 0 \end{pmatrix} W_\theta(t) \begin{bmatrix} \lambda_1(\theta) \\ \lambda_2(\theta) \end{bmatrix} + W_\theta(t) \begin{bmatrix} \bar\lambda_1 \\ \bar\lambda_2 \end{bmatrix}, \tag{3.50}$$

with the same continuity property in $(L^2(0,1))^2$ with respect to regularizations of η and θ. By (3.4), (3.5), this property is preserved by $\bar u, \bar z$, and we have

$$\bar u = \varepsilon\, \bar p\,, \quad \bar z'' = -\,\bar q\,, \quad \bar z(0) = \bar z(1) = 0\,. \tag{3.51}$$

Finally, (3.1) gives

$$\begin{aligned} \begin{bmatrix} \bar v_1 \\ \bar v_2 \end{bmatrix}(t) = \int_0^t W_\theta(t)\, W_\theta^{-1}(s) \begin{bmatrix} \bar u(s) + \bar g_1(s) \\ \bar z(s) + \bar g_2(s) \end{bmatrix} ds + \begin{pmatrix} 0 & \eta(t) \\ -\eta(t) & 0 \end{pmatrix} \begin{bmatrix} v_1(\theta) \\ v_2(\theta) \end{bmatrix}(t) \\ - \int_0^t \begin{pmatrix} 0 & \eta(s) \\ -\eta(s) & 0 \end{pmatrix} W_\theta(t)\, W_\theta^{-1}(s) \begin{bmatrix} u(\theta) + g_1(\theta) \\ z(\theta) + g_2(\theta) \end{bmatrix}(s)\, ds \end{aligned} \tag{3.52}$$

with the same conclusion on the continuous dependence on η, θ. Let us now explicitly introduce the regularizations of θ and η,

$$\theta_\delta(t) = \int_R \theta(t - \delta\, y)\, \rho(y)\, dy\,, \quad \eta_\delta\,(t) = \int_R \eta(t - \delta\, y)\, \rho(y)\, dy\,, \tag{3.53}$$

where θ and η are extended by 0 outside the interval $[0,1]$, $\delta > 0$, and where $\rho \in C_0^\infty(\mathbb{R})$ is a Friedrichs mollifier. We also define $d_\delta = \eta_\delta', c_\delta = \theta_\delta'$ which exist in $L^1(0,1)$ but have no good convergence properties for $\delta \to 0$. Then, the systems (3.7)–(3.16), (3.28)–(3.37), and (3.38)–(3.44) can be solved for the data c_δ, d_δ. Let us denote the corresponding solutions with an index or an exponent δ. Then we can prove the following result.

THEOREM 3.11. *The gradient of the cost functional of the problem* (Q) *at the point* $\theta \in L^\infty(0,1)$ *and in the direction* $\eta \in L^\infty(0,1)$ *is given by*

$$\begin{aligned} \int_0^1 v_2(\theta)\, \bar v_2\, ds = \int_0^1 \eta \Big[g_1'(\theta)^* P_1 + g_2'(\theta)^* P_2 - v_1(\theta)\, v_2(\theta) \\ - P_1(\theta)\, (z(\theta) + g_2(\theta)) + P_2(\theta)\, (u(\theta) + g_1(\theta)) + q(\theta)\, R(\theta) - p(\theta)\, Q(\theta) \Big]\, ds\,. \end{aligned} \tag{3.54}$$

Here, $v_1(\theta), v_2(\theta), u(\theta), z(\theta), p(\theta), q(\theta)$ are obtained by (3.1)–(3.5) with $g_1(\theta), g_2(\theta)$ given by (2.2), (2.3), and P_1, P_2, P_3, P_4, R, Q are computed via (3.38)–(3.44) rewritten in integral form (which is obvious).

Proof. By (3.52), (3.53), we can write

$$\int_0^1 v_2(\theta)\, \bar v_2\, ds = \lim_{\delta \to 0} \int_0^1 v_2^\delta\, \bar v_2^\delta\, ds\,. \tag{3.55}$$

From Theorem 3.10, we obtain that

$$\int_0^1 v_2^\delta\, \bar v_2^\delta\, ds = \int_0^1 d_\delta \left(P_1^\delta\, v_2^\delta - P_2^\delta\, v_1^\delta - P_3^\delta\, q^\delta + P_4^\delta\, p^\delta + P_1^\delta\, \bar g_1^\delta + P_2^\delta\, \bar g_2^\delta \right) ds.$$

Using the boundary conditions and the differentiability properties, we first compute

$$\begin{aligned}
&\int_0^1 d_\delta \left(P_1^\delta\, v_2^\delta \,-\, P_2^\delta\, v_1^\delta \,-\, P_3^\delta\, q^\delta \,+\, P_4^\delta\, p^\delta\right) ds \\
&= -\int_0^1 \eta_\delta \left((P_1^\delta)'\, v_2^\delta \,+\, P_1^\delta\, (v_2^\delta)' \,+\, \cdots \,+\, (P_4^\delta)'\, p^\delta \,+\, P_4^\delta\, (p^\delta)'\right) ds \\
&= -\int_0^1 \eta_\delta \left(v_1^\delta\, v_2^\delta \,+\, P_1^\delta\, (z^\delta \,+\, g_2^\delta) \,-\, P_2^\delta (u^\delta \,+\, g_1^\delta) \,-\, q^\delta\, R^\delta \,+\, p^\delta\, Q^\delta\right) ds.
\end{aligned} \tag{3.56}$$

We indicate only a partial calculation on how the last equality in (3.56) is established:

$$\begin{aligned}
&(P_4^\delta)'\, p^\delta \,+\, P_4^\delta\, (p^\delta)' \,-\, (P_3^\delta)'\, q^\delta \,-\, P_3^\delta\, (q^\delta)' \\
&= (P_4^\delta)'\, p^\delta \,+\, P_4^\delta\, c_\delta\, q^\delta \,-\, (P_3^\delta)'\, q^\delta \,+\, P_3^\delta\, c_\delta\, p^\delta \\
&= q^\delta(-\,(P_3^\delta)' \,+\, c_\delta\, P_4^\delta) \,+\, p^\delta((P_4^\delta)' \,+\, c_\delta\, P_3^\delta) \\
&= -\,q^\delta\, R^\delta \,+\, p^\delta\, Q^\delta
\end{aligned}$$

by (3.11), (3.12) and (3.40), (3.41).

We also consider the term

$$\begin{aligned}
&\int_0^1 \left(P_1^\delta\, \bar{g}_1^\delta \,+\, P_2^\delta\, \bar{g}_2^\delta\right) ds \,=\, \int_0^1 \left(P_1^\delta\, g_1'(\theta_\delta)\, \eta_\delta \,+\, P_2^\delta\, g_2'(\theta_\delta)\eta_\delta\right) ds \\
&= \int_0^1 \eta_\delta \left[(g_1^\delta)'(\theta_\delta)^* P_1^\delta \,+\, (g_2^\delta)'(\theta_\delta)^* P_2^\delta\right] ds.
\end{aligned} \tag{3.57}$$

The derivatives of g_1, g_2 may be taken directly with respect to θ. This can be clearly seen from (3.23)–(3.25), where f_i may depend on θ, without modifying the argument.

We combine (3.55)–(3.57), and we pass to the limit as $\delta \to 0$. The continuity properties with respect to both η_δ and θ_δ have been explained in (3.47)–(3.52). We remark that the continuous dependence on $\delta \to 0$ is valid for $P_1^\delta, P_2^\delta, P_3^\delta, P_4^\delta, R^\delta, Q^\delta$ since the system (3.38)–(3.44) can be put into integral (mild) form as well. □

Remark 3.12. The gradient provided by Theorem 3.11 will be used in section 4 in the computation of numerical examples of shape optimization. It is also possible to write the first order optimality conditions for problem (Q) by requiring (3.54) to be positive in the admissible directions of variation.

4. Numerical experiments. We have computed several examples of arches, including their shape optimization, using the methods developed in this paper. Numerical examples concerning plates and beams have been reported in the works of Arnăutu, Langmach, Sprekels, and Tiba [2] and Sprekels and Tiba [23], where different (but related) approaches were used.

In Figures 1–4, deformations of various arches (Roman, gothic, closed) with different thicknesses $\varepsilon > 0$ and under certain square integrable loads $[f_1, f_2]$ are shown. The algorithm is based on Theorem 2.6 with explicit solutions of (2.20) obtained via MAPLE. The integrals appearing in the coefficients of (2.20) and elsewhere can be computed explicitly in the case of simple arches and simple forces (purely tangential or purely normal, etc.). Otherwise, standard numerical integration procedures on the real line should be applied.

The parametric representation of an arch associated to some function θ on a prescribed interval is given by $[\varphi_1, \varphi_2]$ with $\varphi_1' = \cos\theta, \varphi_2' = \sin\theta$, and with null

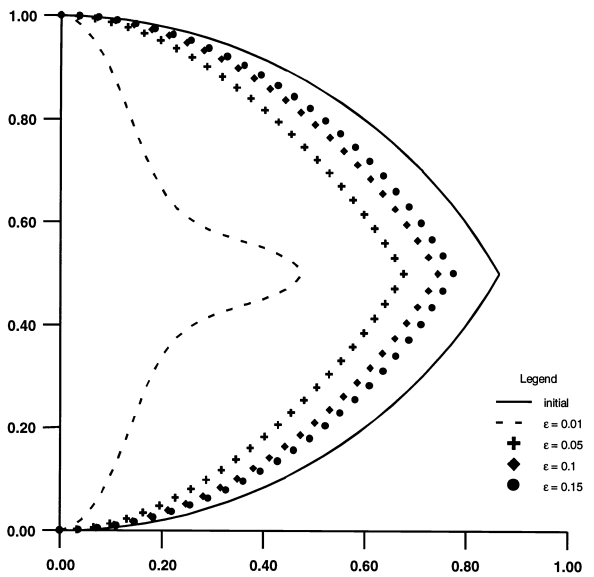

FIG. 1. $\theta(t) = t,\ t \in [0, \pi/3],\ \theta(t) = t + \pi/3,\ t \in [\pi/3, 2\pi/3],\ f_1(t) = 0,\ f_2(t) = 1(SE),\ E = 10.$

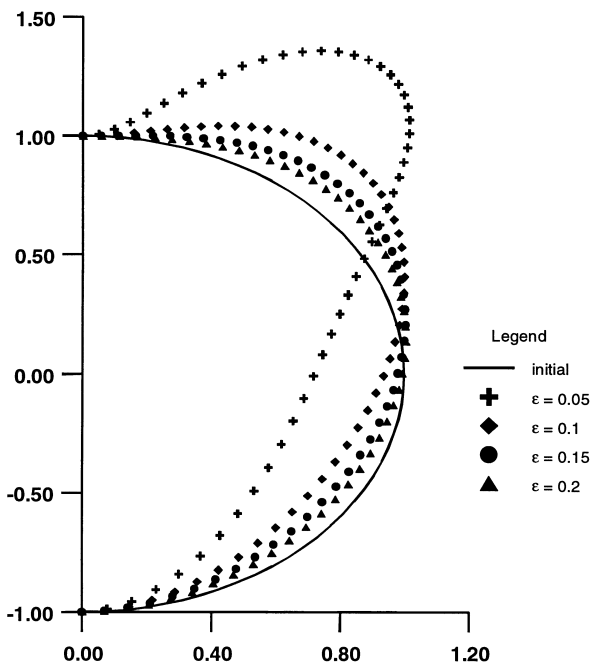

FIG. 2. $\theta(t) = t,\ t \in [0, \pi],\ f_1(t) = \sin(t)/S,\ f_2(t) = \cos(t)/S.$

initial conditions. Notice that in Figure 1, θ is discontinuous and $\varphi = [\varphi_1\,, \varphi_2]$ is just Lipschitz, which shows the importance of relaxing the regularity assumptions in (1.1) as is done in problem (P_ε) in section 2. Figures 2 and 4 show the same type of

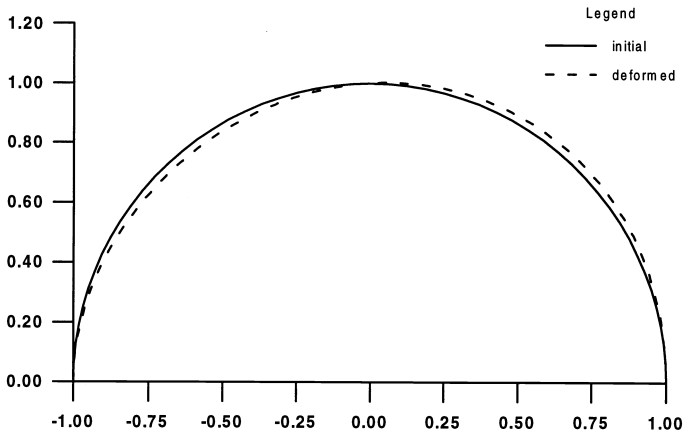

FIG. 3. $\theta(t) = t,\ f_1(t) = \sin(t),\ f_2(t) = 2\cos(t),\ t \in [0, \pi]$.

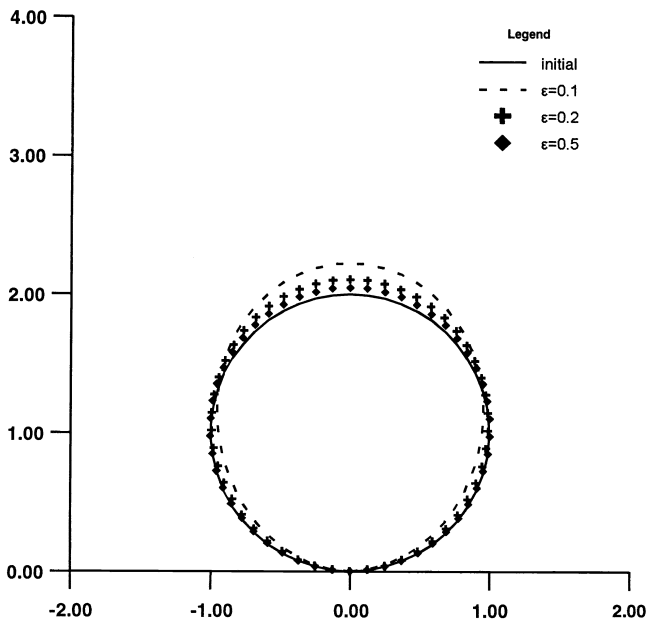

FIG. 4. $\theta(t) = t,\ f_1(t) = \sin(t)/(SE),\ f_2(t) = \cos(t)/(SE),\ t \in [0, 2\pi],\ E = 100$.

arch with similar loading. The difference in the shape of the obtained deformations is due to the fact that the first arch is clamped at both ends, while the closed arch is clamped only in the point $(0, 0)$. Figure 3 refers to the "flexural" model briefly explained in Theorem 2.11 and Remark 2.8. The constant E is the Young modulus of the material, while $S = \varepsilon^{3/2}$ gives the influence of the thickness $\varepsilon > 0$. We indicate, as a short example, the explicit form of the deformation $[v_1, v_2]$ corresponding to the situation described in Figure 2:

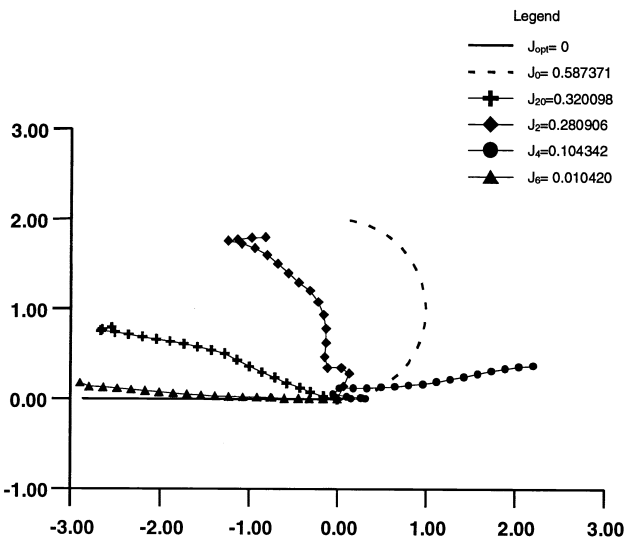

FIG. 5. $\theta(t) \in [0,\pi],\ f_1(t) = 1/S,\ f_2(t) = 0,\ \theta_0(t) = t,\ t \in [0,\pi]$.

$$v_1(t) = (6\,\varepsilon \sin t + 4 \sin t + 2\,\pi\,\varepsilon \sin t + \pi\,\varepsilon^2\, t \sin t - 4\,\varepsilon\, t \cos t - 2\,\varepsilon^2 \sin t$$
$$- 2\,\varepsilon\, t^2 \sin t - \varepsilon^2\, t^2 \sin t + \pi\, t \sin t - 4\, t \cos t - t^2 \sin t - 2\,\pi - 2\,\varepsilon\,\pi$$
$$+ 2\,\pi \cos t + 2\,\pi\,\varepsilon \cos t)/4\,\varepsilon^{3/2}(\varepsilon + 1)\,,$$
$$v_2(t) = (\varepsilon + 1)\,(2\, t \sin t + \pi\, t \cos t - \pi \sin t - t^2 \cos t)/4\,\varepsilon^{3/2}\,.$$

Figures 5–9 and Tables 1 and 2 concern optimization procedures for arches, according to the theory developed in section 3. For the computation of the gradient of the cost functional, as given in (3.54), it is necessary to obtain the numerical solution of the state system (3.1)–(3.5), of the adjoint system (3.38)–(3.44), and the approximation of the mappings $[g_1'(\theta)]^* P_1$ and $[g_2'(\theta)]^* P_2$. It is obvious that by the nature of the data an explicit calculation is not possible in the optimization routine.

We have considered an equidistant division of the interval of definition, denoted here by $[0, L]$, into N_0 (a natural number) subintervals $[t_i, t_{i+1}]$, with $t_i = i\,h, h = \frac{L}{N_0}$. The mapping $\theta \in L^\infty(0, L)$ is approximated, in different examples, by piecewise linear splines or by piecewise constant functions. The integrals are computed accordingly by standard quadrature formulas, and the solution of the ordinary differential system is obtained via linear finite elements. The scalars $\lambda_1^\varepsilon, \lambda_2^\varepsilon$ from (3.3) are found from the algebraic system (2.20). Similarly, the unknown initial conditions μ_1, μ_2 for (3.38), (3.39) satisfy a system of the same type as (2.20) with the mappings l, g_2 replaced by γ_1, γ with $\gamma'' = -\gamma_2, \gamma(0) = \gamma(L) = 0$ (see Proposition 3.9 and its proof). The functions $[g_1'(\theta)]^* P_1$ and $[g_2'(\theta)]^* P_2$ have been approximated in the following way:

$$[g_k'(\theta)]^* P_k(t_i) \simeq \frac{1}{h} \int_{t_i}^{t_{i+1}} [g_k'(\theta)]^*\, P_k(s)\, ds$$
$$= \frac{1}{h} \int_0^L P_k(s)\, \left(\bar{g}_k\, \chi_{[t_i, t_{i+1}]}\right)(s)\, ds\,, \quad k = 1, 2\,, \quad i = \overline{0, N-1}\,,$$
$$[g_k'(\theta)]^* P_k(L) \simeq 0\,, \quad k = 1, 2\,.$$

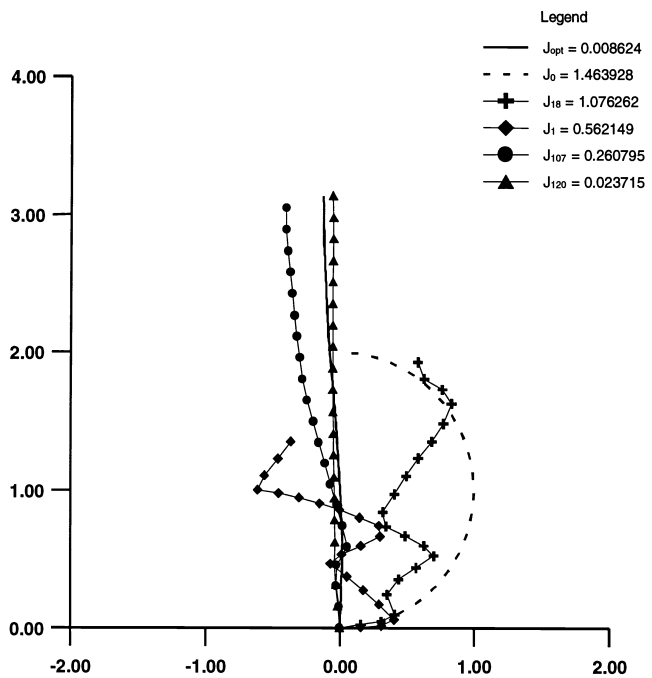

FIG. 6. $\theta(t) \in [0, \pi]$, $f_1(t) = \sin(\theta(t))/S$, $f_2(t) = \cos(\theta(t))/S$, $\theta_0(t) = t$, $t \in [0, \pi]$.

For the determination of $\bar{g}_k$ the relation (3.48) is used, and $\chi_{[t_i, t_{i+1}]}$ is the characteristic function of $[t_i, t_{i+1}]$.

Although the studied optimization problems are nonconvex, adaptations of Rosen's and Uzawa's gradient algorithms with projection (Gruver and Sachs [15], Arnăutu [1]), have been used. A maximal number of iterations (between 200 and 300) has been prescribed, and the solution has been chosen as the one which gives the best value of the cost. The algorithm stops as well if the value of the gradient or of the cost is zero.

For a given example, several tests have been performed with various values of the parameters N_0, α (the parameter from the Rosen algorithm) and with both algorithms. In general, the Rosen algorithm gives better results than the Uzawa algorithm. In the optimization problems, we have fixed $\varepsilon = 0.1$. A typical line search procedure is to subdivide the open-closed interval $]0, 1]$ into N_1 equal parts and to give the line search parameter the values $\frac{i}{N_1}, i = \overline{1, N_1}$. The one which gives the best cost will generate the next iteration. We have avoided, with good numerical results, the usual computation of the line search parameter by a one-dimensional optimization problem, which may be very time-consuming. The procedure used combines in an ad hoc manner the gradient algorithm principle and a global search. A projection on the admissible set has been performed in each iteration. The optimization problem (Q) looks for the shape of the arch which ensures the minimal normal deformation (in some integral sense) under the action of a prescribed force. We have examined purely tangential ($f_2 = 0$) or normal ($f_1 = 0$) forces (since they give the basis in the local system of axes), as well as forces not depending on the unknown arch. This last case is described in the local system of coordinates by $f_1(t) = \sin(\theta(t))/S$ and $f_2(t) = \cos(\theta(t))/S$ (for the force of modulus one and parallel to the vertical axis),

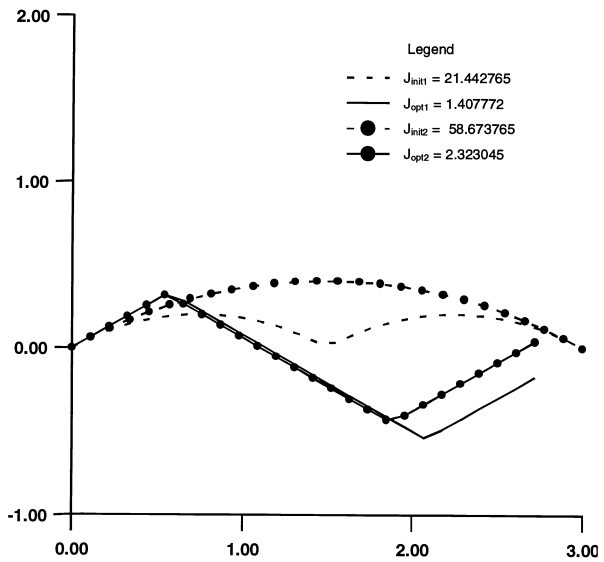

FIG. 7. $\theta(t) \in [\pi/3, 2\pi/3]$, $f_1(t) = \cos(\theta(t))/S$, $f_2(t) = \sin(\theta(t))/S$, $t \in [0, \pi]$, $\theta_{01}(t) = (2t + \pi)/3$, $t \in [0, \pi/2)$, $\theta_{01}(t) = 2t/3$, $t \in [\pi/2, \pi]$, $\theta_{02}(t) = (t + \pi)/3$, $t \in [0, \pi]$.

and in converse order for forces parallel to the horizontal axis. It should be noticed that the force is independent of the arch, but its local representation is dependent via θ.

The constraints for θ were given by subintervals of $[0, \pi]$ as indicated in the figures. This suffices for many applications and avoids the self-intersection of arches. However, some degenerate case is still possible, according to Figure 9.

In Figure 5, under the action of a tangential force, and starting with the initial iteration given by the Roman arch, it is seen that the global solution is the beam, which clearly has no normal deflection under such a load. In our representation, two global solutions (beams) are put into evidence, associated to $\theta = 0$ and to $\theta = \pi$. The figure shows some iterations produced by the algorithm and the corresponding values of the cost. In this experiment, we have used $N_0 = 200, n_1 = 10, \alpha = 0,75$, and the arch close to the beam was obtained in iteration $I = 24$. We underline that in this example, an infinity of global solutions (beams of any slope) exists, and this shows the difficulty of the numerical computations.

In Figure 6, the initial iteration is again the Roman arch, but the force is of constant modulus one and parallel to the vertical axis. The iterations that are represented show how the routine again finds the (unique if θ is constrained in $[0, \pi]$) global solution which is given by a vertical beam characterized by $\theta = \frac{\pi}{2}$. In this configuration, the prescribed force becomes purely tangential to the arch, and the global solution is a special case of the previous example (but not the problem as a whole). We have used $N_0 = 200, N_1 = 10, \alpha = 1$, and the global optimum was obtained at iteration $I = 139$.

The numerical results from Figures 5 and 6 match perfectly with the physical interpretation. This gives a strong validation of the notion of weak solutions that we are using and shows the stability of our methods.

In Figures 8 and 9, the case of a purely normal load is discussed, the difference

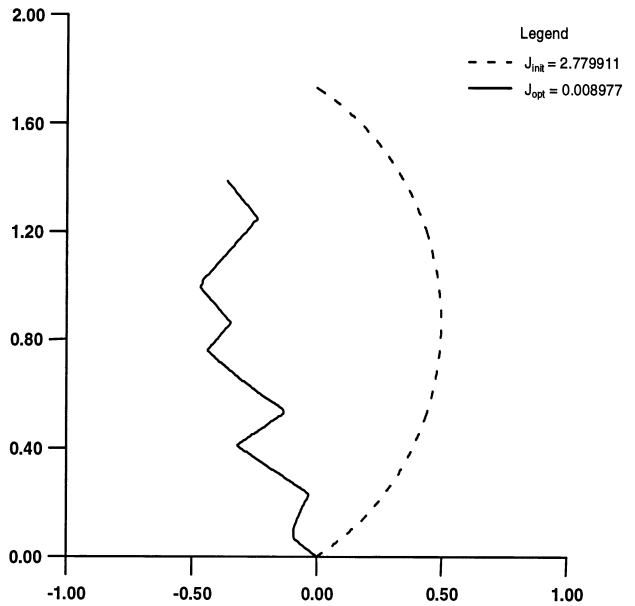

FIG. 8. $\theta(t) \in [\pi/6, 5\pi/6]$, $f_1(t) = 0$, $f_2(t) = 1/S$, $\theta_0(t) = t + \pi/3$, $t \in [0, 2\pi/3]$, $J_{init} = 2.779911$, $J_{opt} = 0.008977$.

being given by the constraints imposed on $\theta : \left[\frac{\pi}{6}, \frac{5\pi}{6}\right]$, respectively $[0, \pi]$. In Figure 9, the "optimal" found θ is represented, not the arch as usual. As the solution is bang-bang, $\theta \in \{0, \pi\}$ a.e. $t \in [0, \pi]$; then the arch degenerates and cannot be graphically represented. Suggested by the bang-bang structure of the obtained solution (the computations were made with $N_0 = 200, N_1 = 20, \alpha = 1, 5, I = 27$), we have simply generated a sequence θ^N, by giving to the new parameter N the values listed in Table 2 and to θ^N the values 0 and π, alternatively on subsequent subintervals. We have directly computed the costs $J(\theta^N)$ associated with such oscillating arches and listed them in Table 2. The conclusion is that the sequence θ^N is a very efficient minimizing sequence for this problem, ensuring for $N \geq 50$ lower values of the cost than the one computed by the complete numerical procedure (although this provides a satisfactory result as well). We stress that the oscillatory nature of the minimizing sequence $\{\theta^N\}$ is related to the noncompactness of the constraint set $\{\theta \in L^\infty(\Omega)\,;\, \theta(t) \in [0, \pi]$ for almost every $t \in (0, \pi)\}$ in $L^\infty(0, \pi)$. This set is only bounded and closed, which is not enough to ensure the existence of the optimal θ as discussed in Theorem 3.2 and Corollary 3.3. This numerical example can be interpreted as showing that the assumptions of Corollary 3.3 are sharp. We also underline that such compactness comments apply to Figures 5 and 6 as well, although global minimum points exist in these examples.

Figure 8 represents the initial (Roman) arch and the obtained solution, in the same problem as in Figure 9, with the constraints given by the set $[\frac{\pi}{6}, \frac{5\pi}{6}]$ in order to avoid degeneracy. The numerical test used $N_0 = 300, N_1 = 10, \alpha = 1, 5$, and the obtained optimum corresponded to the iteration $I = 160$. The bang-bang structure of the solution is again clear (recall that θ is the angle between the tangent to the arch and the horizontal axis). However, Table 1 shows that the simple sequence $\{\theta^N\}$, constructed as in the previous example but with the values $\pi/6, 5\pi/6$, is no

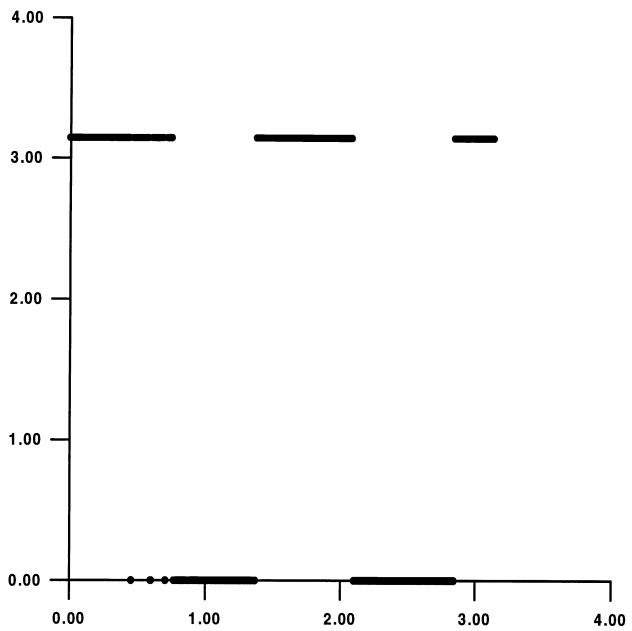

FIG. 9. $\theta(t) \in [0,\pi],\ f_1(t) = 0,\ f_2(t) = 1/S,\ \theta_0(t) = t,\ t \in [0,\pi],\ J_{init} = 82.922993,\ J_{opt} = 0.0024772.$

TABLE 1
$\theta(t) \in \{\pi/6, 5\pi/6\}, f_1(t) = 0,\ f_2(t) = 1/S, t \in [0, 2\pi/3].$

longer a minimizing sequence for this problem. The commuting points for the bang-bang solution are not equidistant in this example. Finally, in Figure 7, a "realistic" example is studied: the construction of a most resistant roof subject to a vertical constant load of modulus one. The reader should note that in this figure we have interchanged the axes to make the representation look more "physical." To perform a more precise calculation, we have fixed $N_0 = 500, N_1 = 100, \alpha = 10$. Two experiments are reported in Figure 7, one with the initial iteration given by a fragment of Roman arch, and another with the initial iteration given by two coupled fragments of Roman arch. In both cases, the numerical solutions were obtained in the first iteration, $I = 1$, and are very similar. In this example (as in Figure 8), the theoretical optimal value is "far" from zero, and the computed values are very good.

We close this presentation by underlining that working with low regularity assumptions was essential for the optimization applications in view of the bang-bang structure of the optimal θ, as found in many examples. However, in Figure 6 the

TABLE 2
$\theta(t) \in \{0, \pi\}, f_1(t) = 0,\ f_2(t) = 1/S, t \in [0, \pi]$.

global solution is not bang-bang, and this property seems to be related just to the applied force. That is why we did not study bang-bang properties in section 3, although such properties are known for plates, according to Sprekels and Tiba [19, 20]. We also underline the nonlocal optimization character of our numerical experiments as this is obvious from the reported results.

SENSITIVITY TO INFINITESIMAL DELAYS IN NEUTRAL EQUATIONS*

W. MICHIELS†, K. ENGELBORGHS†, D. ROOSE†, AND D. DOCHAIN‡

Abstract. The stability of a steady state solution of a neutral functional differential equation can be sensitive to infinitesimal changes in the delays. This phenomenon is caused by the behavior of the essential spectrum and is determined by the roots of an exponential polynomial. Avellar and Hale [*J. Math. Anal. Appl.*, 73 (1980), pp. 434–452] have considered the case of multiple fixed and nonzero delays. In the first part of this paper their results are illustrated by means of spectral plots. In the second part we extend the theory of Avellar and Hale to the limit case whereby some of the delays are brought to zero, which may lead to characteristic roots with arbitrarily large real part. Necessary and sufficient conditions are provided. Using these results we show that the ratio of the delays plays a crucial role when several delays tend to zero simultaneously. As an illustration of the theory, we analyze the robustness of a boundary controlled PDE in the presence of a small feedback delay.

1. Introduction.

In this paper we study the behavior of the roots of the exponential polynomial

$$H(\lambda) \triangleq 1 - \sum_{j=1}^{N} a_j e^{-\lambda \tau_j}, \quad \tau_j \in \mathbb{R}_0^+, \quad a_j \in \mathbb{R}, \quad j = 1, \ldots, N, \tag{1.1}$$

in the complex plane. $H(\lambda) = 0$ is the characteristic equation of the functional difference equation $x(t) = \sum_{j=1}^{N} a_j x(t - \tau_j)$, which determines the essential spectrum of the solution operator of the neutral functional differential equation (NFDE),

$$\frac{d}{dt}\left(x(t) - \sum_{j=1}^{N} a_j x(t - \tau_j) \right) = b_0 x(t) - \sum_{j=1}^{N} b_j x(t - \tau_j). \tag{1.2}$$

It is well known that the spectrum of (1.2) determines the stability of its zero solution, since equations of this form satisfy the spectrum determined growth condition; see [8, Corollary IX.3.1]. However, the stability of the zero solution may be sensitive to arbitrarily small changes in the delays τ_j. Since this sensitivity is caused by the essential spectrum, which is determined by (1.1) (see [9]), we perform a detailed study

of (1.1). In terms of the characteristic roots of (1.1), this sensitivity is caused by the occurrence of so-called infinite root chains, sequences of roots whose imaginary parts grow unbounded, yet whose real parts have a finite limit. It was shown by Avellar and Hale [1] that, as a consequence, the smallest upper bound $c = \sup\{\Re(\lambda) : H(\lambda) = 0\}$ is not continuous w.r.t. the delays τ_j. Hence it is possible that arbitrarily small changes in the delays destabilize the NFDE system. This is of importance in control problems, since such critical delay changes can be caused by a small delay in the application of the control action.

NFDEs arise, for example, in models of distributed networks [13, 12], combustion [20], and the control of structures through delayed forcing depending on the acceleration [2].

The lack of robustness w.r.t. small changes in the delays is also observed for boundary controlled (hyperbolic) PDEs [4, 5, 6, 7, 9, 10, 15, 19, 21] and feedback controlled descriptor systems [14]: a small delay in the application of the control action, which is inevitable in practice due to, e.g., measurements or AD-DA conversion, can lead to instability of the stable undelayed system. Hence it is very important to include all possible delays in the model.

In the literature, basically two approaches are used to analyze such problems. A first approach, which will be followed in this paper, studies directly the influence of delay perturbations on the characteristic roots of equations of the form (1.1). In [1] Avellar and Hale consider (1.1) and show that the rational (in)dependency of the delays plays a crucial role for the robustness properties of the given system. However, in [1] only perturbations of fixed, nonzero delays are considered. These results do not safely apply to the case discussed in this paper, where zero delays are perturbed to (small nonzero) delays. In the latter case, infinite root chains occur, whose real part may tend to $+\infty$, a phenomenon which does not occur in the presence of perturbations of (only) nonzero delays. As in [1], we allow a general dependency structure on the delay perturbations and derive sufficient and necessary conditions for the occurrence of characteristic roots with large real part for *vanishing* delays. Furthermore, we discuss the occurrence of roots with large positive real but small imaginary part. We prove that the occurrence of these phenomena is determined by what we call the "small delay" part of the characteristic equation (except for some degenerate cases).

On the other hand, for the analysis of a small time-delay in feedback systems, another approach can be followed. In [15, 16] Logemann and coworkers rewrite the closed loop system as an input-output mapping $H(s)$ with (delayed) unity feedback $e^{-\epsilon s}$, where ϵ represents a small feedback delay, and formulate conditions for robustness and nonrobustness of stability against the small time-delay on the open loop transfer function $H(s)$. They show that, depending on the properties of $H(s)$, a small time-delay may not only result in instability but may also cause characteristic roots with arbitrarily large imaginary and real part. While [16] assumes regularity of $H(s)$, some extensions are made in [15] to the case where $H(s)$ is non well-posed. In [17] Logemann and Townley use this approach to show that when a NFDE

$$\frac{d}{dt}\mathcal{D}x_t = \mathcal{L}x_t + Bu(t), \qquad \mathcal{D}x_t = x(t) - \sum_i D_i x(t - h_i), \tag{1.3}$$

with control input $u(t)$, has an exponentially unstable difference operator $\mathcal{D}$, any stabilizing state feedback law is not robust against a small perturbation of the feedback delays. Since the essential spectrum is determined by the difference equation inside the differentiation operator, such a feedback law should include velocity feedback

$u = -\frac{d}{dt}(\sum_j F_j x(t-k_j))$, $k_j > 0$, which leads to a closed loop system with the essential spectrum determined by

$$\det\left(I - \sum_i D_i e^{-\lambda h_i} + \sum_j F_j e^{-\lambda(k_j+\epsilon)}\right) = 0, \tag{1.4}$$

where ϵ represents a small perturbation in the feedback delays. Since there is only one perturbation ϵ on the (fixed and nonzero) delays h_i, k_j in (1.4), the analysis of this robustness problem can be recast in the framework of [16]. That procedure is not possible for the broader class of delay perturbations considered in this paper.

Note that for some problems both approaches described above can be used. For instance, in section 6 we apply the theory developed throughout this paper to a boundary controlled wave equation, which was also analyzed in [16].

In section 2 we repeat the main results of [1] and introduce necessary notation. In section 3 we visualize and interpret these results by means of plots of the characteristic roots, thereby explaining the nature of the instability mechanisms. We explain that the sensitivity of c to arbitrary small changes of the delays is necessarily caused by roots with large imaginary part. In section 4 we demonstrate with a simple example that the theory of [1, 17] is not sufficient to deal with vanishing delays. We prove under which conditions characteristic roots with large real part can occur and give a thorough discussion of these results. We conclude in section 6 with two illustrative examples.

2. Analysis with fixed delays. In this section we briefly describe the main results of [1], where the case of fixed and nonzero delays is considered.

2.1. Definitions and notation. Throughout this section we consider the roots of exponential polynomials of the form

$$H(\lambda) \triangleq 1 - \sum_{j=1}^{N} a_j e^{-\lambda\tau_j}, \tag{2.1}$$

where we assume that the delays τ_j are fixed and satisfy $0 < \tau_1 < \tau_2 < \cdots < \tau_N$.

Define the collection of the real parts of all the roots of (2.1) as Z,

$$Z = \{\Re(\lambda) : H(\lambda) = 0\},$$

and denote its closure by $\bar{Z}$. The smallest upper bound of $\bar{Z}$, which is important for stability considerations, is

$$c = \sup\{\Re(\lambda) : H(\lambda) = 0\}.$$

Assume that the N delays τ_j, $j = 1, \ldots, N$, depend on $M \leq N$ so-called independent delays $r_1, \ldots, r_M$:

$$\tau_j = \sum_{k=1}^{M} \gamma_{j,k} r_k = \gamma_j \cdot r, \tag{2.2}$$

whereby $\gamma_j = (\gamma_{j,1}, \ldots, \gamma_{j,M}) \in \mathbb{N}^M$ are nonzero vectors with nonnegative integer coefficients and $r \in (0, \infty)^M$. Dependency of the kind (2.2) often appears in difference

equations arising from practical applications, as, for example, in (delayed) boundary controlled wave equations (see section 6). The same holds when dealing with vector valued difference equations. Indeed, the characteristic equation of

$$x(t) = \sum_{k=1}^{M} A_k x(t - r_k), \quad x(t) \in \mathbb{R}^n, \quad A_k \in \mathbb{R}^{n\times n},\ l = 1, \dots, M,$$

is given by

$$\det\left(I - \sum_{k=1}^{M} A_k e^{-\lambda r_k}\right) = 0,$$

which is seen, using an explicit formula for the determinant, to be an exponential polynomial with dependent delays.

2.2. Rationally dependent and rationally independent delays. The numbers $r_1, r_2, \dots, r_M$ are rationally independent if and only if

$$\sum_{k=1}^{M} n_k r_k = 0, \quad n_k \in \mathbb{Z},$$

implies $n_k = 0$, $k = 1, \dots, M$. For example, two numbers are rationally independent if their ratio is an irrational number. An important property of rationally independent numbers which will be used throughout the paper is given by Kronecker's theorem [11, Theorem 444].

THEOREM 2.1. *Given $r = (r_1, r_2, \dots, r_M)$ with rationally independent components and $\theta = (\theta_1, \dots, \theta_M)$ arbitrary, there exists a sequence of real numbers $\{d_n\}_{n\geq 1}$ such that*

$$\lim_{n\to\infty} e^{i(d_n r_k - \theta_k)} \to 1, \quad k = 1, \dots, M.$$

We now provide a useful characterization of $\bar{Z}(r)$ and its dependence on r. First, consider the following definitions. For any two sets E and $F \subset \mathbb{R}$ and any $\rho \in \mathbb{R}$, let

$$\begin{gathered} d(\rho, E) = \inf_{t\in E} |\rho - t|, \\ \delta(E, F) = \sup_{\rho\in E} d(\rho, F), \quad \text{and} \\ D(E, F) = \max\left\{\delta(E, F), \delta(F, E)\right\}. \end{gathered}$$

The number $D(E, F)$ is called the Hausdorff distance between the sets E and F.

We will illustrate with examples that $\bar{Z}(r)$ is not continuous w.r.t. the delays $r \in (0, \infty)^M$ since arbitrarily small delay changes can change their rational (in)dependence. However, the following weaker property holds [1, Lemma 2.5].

THEOREM 2.2. *$\bar{Z}(r)$ is lower semicontinuous in r; that is, for each $r_0 \in (0, \infty)^M$,*

$$\lim_{r\to r_0} \delta(\bar{Z}(r_0), \bar{Z}(r)) = 0.$$

When the delays r are rationally independent, we have [1, Theorem 2.2].

THEOREM 2.3. *$\bar{Z}(r)$ is continuous in the Hausdorff metric for rationally independent delays r.*

This result is important because it implies the continuity of the supremum $c(r)$ of $\bar{Z}(r)$ at rationally independent r. In this case the set $\bar{Z}(r)$ is completely characterized by [1, Theorem 3.1 and Corollary 3.2].

THEOREM 2.4. *If the components of r are rationally independent, then the following statements are equivalent:*

$$\alpha \in \bar{Z}(r)$$
$$\Updownarrow$$
$$\exists \theta = (\theta_1, \ldots, \theta_M) \text{ with } \theta_k \in [0, 2\pi],\ k = 1, \ldots, M,$$
$$\text{such that } 1 - \sum_{j=1}^{N} a_j e^{-\alpha \gamma_j \cdot r} e^{-i \gamma_j \cdot \theta} = 0.$$

COROLLARY 2.5. *$\bar{Z}$ is the union of a finite number of intervals.*

The combination of Theorems 2.2 and 2.3 is very important for control problems because the right-most characteristic roots determine stability: suppose, for example, that r_0 is given with rationally dependent components and denote the maximum of $\bar{Z}(r_0)$ by $c(r_0)$. On the other hand, consider a sequence of rationally independent delays $\{r_n\}_{n \geq 1}$ with limit r_0 and denote by $c(r_n)$ the maximum of $\bar{Z}(r_n)$. Then from Theorems 2.2 and 2.3 it follows that

$$c(r_0) \leq \lim_{n \to \infty} c(r_n). \tag{2.3}$$

In other words, the supremum of $\bar{Z}$ is always higher when one considers the given delays as independent. In section 3 it will be shown that inequality (2.3) can be strict. This means that when the delays in the characteristic equation modelling a physical system are results of independent phenomena (for example, independent measurements), one has always to consider the delays as rationally independent in order to obtain a reliable upper bound on the real parts of the spectrum. In section 3 will be explained what happens with the individual characteristic roots when one deals with rationally independent delays close to rationally dependent delays.

2.3. Special cases.

Fully independent delays. This corresponds to the case where $M = N$, $\gamma_j = e_j$, the jth unity vector in $\mathbb{R}^N$, and the delays $\tau_1, \tau_2, \ldots, \tau_N$ are rationally independent. Theorem 2.4 can be rewritten as the following.

THEOREM 2.6. *When the delays are rationally independent,*

$$c = \sup \{\Re(\lambda) : H(\lambda) = 0\}$$

satisfies

$$1 - \sum_{j=1}^{N} |a_j| e^{-c\tau_j} = 0. \tag{2.4}$$

The solution c of (2.4) also serves as a (nonstrict) upper bound in the case of rationally dependent delays.

Commensurate delays. This is the case when $M = 1$. Thus delays $\tau_1, \ldots, \tau_n$ are commensurate if and only if there exists a real number r such that $\tau_j = n_j r$ with $n_j \in \mathbb{N}$, $j = 1, \ldots, N$; i.e., all the delays are integer multiples of a same number. In this case (2.1) can be rewritten as a polynomial in $e^{-\lambda r}$. As a consequence, $\bar{Z}(r)$ consists of a finite number of points, and the spectrum is vertically periodic with period $\frac{2\pi}{r} i$.

3. Visualization and interpretation. In the previous section the delays r were considered fixed. When one approaches rationally dependent delays r_0, the supremum of the real parts of the characteristic roots can have a discontinuity. First, we illustrate how this discontinuity is compatible with the continuous movement of individual roots as r approaches r_0. Second, we discuss the consequences for control applications.

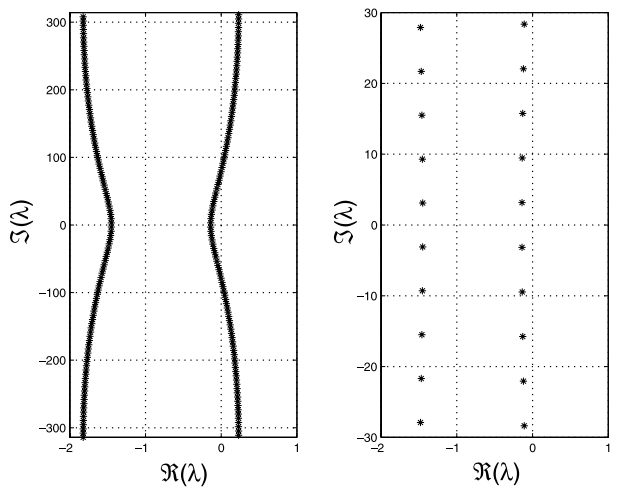

FIG. 3.1. *Part of the spectrum of* (3.1) *on two different scales for* $h = 0.01$.

3.1. Nonuniform convergence. Consider, as an example, the characteristic equation

$$H(\lambda, h) \triangleq 1 + 1.1e^{-\lambda} + 0.2e^{-\lambda(2+h)} = 0, \tag{3.1}$$

with delays 1 and $2 + h$. When h is zero, (3.1) is a quadratic equation in $e^{-\lambda}$ and the roots are $\lambda \approx -1.4704 + i(2l+1)\pi,\ l \in \mathbb{Z}$, and $\lambda \approx -0.1391 + i(2l+1)\pi,\ l \in \mathbb{Z}$. When $h > 0$ and irrational (and therefore the two delays are rationally independent), the supremum $c(h) = \sup\{\Re(\lambda) \,|\, H(\lambda) = 0\}$ satisfies

$$1 - 1.1e^{-c(h)} - 0.2e^{-c(h)(2+h)} = 0, \tag{3.2}$$

which yields $\lim_{h\to 0} c(h) \approx 0.2302 > c(0) \approx -0.1391$. Hence $c(h)$, and the corresponding stability of the associated essential spectrum changes discontinuously w.r.t. h. Individual (single) roots, however, move continuously w.r.t. the delays. From

$$1 + 1.1e^{-\lambda} + 0.2e^{-\lambda(2+h)} = 0$$

one derives

$$\frac{d\lambda}{dh} = \frac{-0.2\lambda e^{-\lambda(2+h)}}{1.1e^{-\lambda} + 0.2(2+h)e^{-\lambda(2+h)}}.$$

But this "sensitivity" of the individual roots increases to infinity as their modulus $|\lambda| \to \infty$. Figure 3.1 shows part of the spectrum of (3.1) on two different scales when $h = 0.01$. When h is reduced to zero, the spectrum converges *pointwise* and nonuniformly to the limit case $h = 0$, as shown in Figure 3.2.

3.2. Unstable difference equations cannot be stabilized. Consider the following control system with input $u(t)$:

$$\frac{d}{dt}(x(t) + 2x(t-1)) = ax(t) + bx(t-\tau) + u(t). \tag{3.3}$$

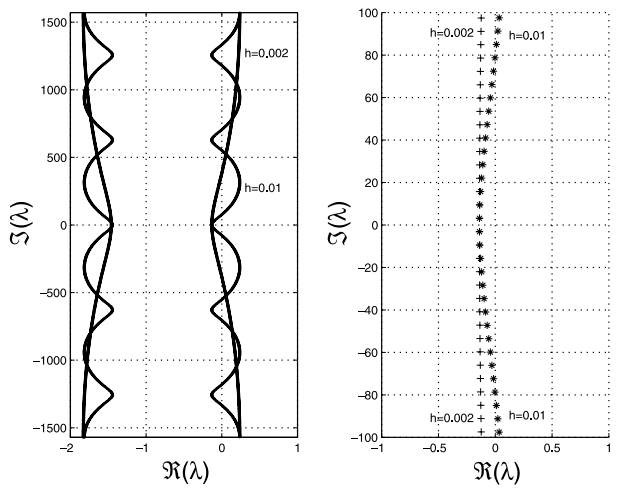

FIG. 3.2. *Part of the spectrum of* (3.1) *for* $h = 0.01$ *and* $h = 0.002$.

When $u(t) \equiv 0$, the difference equation

$$x(t) + 2x(t-1) = 0 \tag{3.4}$$

determines the essential spectrum of the semigroup associated with (3.3); see [8]. The zero solution of (3.4) is clearly unstable: all eigenvalues have real part $\log(2)$. In [17] it is shown that such an equation cannot be stabilized robustly in the presence of a small time-delay in the application of the feedback law.

When applying the velocity feedback $u(t) = \frac{3}{2}\dot{x}(t-1-h)$, the difference equation is modified to

$$x(t) + 2x(t-1) - \frac{3}{2}x(t-1-h) = 0, \tag{3.5}$$

where h models the estimation error of the delay. For $h = 0$ the difference equation is clearly stabilized: all roots have real part $-\log(2)$. However, for irrational h the supremum $c(h)$ of the real parts of the spectrum can be calculated from

$$1 - 2e^{-c(h)} - \frac{3}{2}e^{-c(h)(1+h)} = 0,$$

from which follows $\lim_{h\to 0} c(h) = \log(3.5) > \log(2)$. Thus a practical feedback destabilizes the original system even more. This is shown in Figure 3.3.

Because sensitivity to small changes of the delays is caused by roots of (2.1) with large modulus, and because the set of the real parts of the roots of (2.1) is contained in a finite number of intervals, such roots have large imaginary part. Thus sensitivity to infinitesimal changes in the delays is caused by modes of very high frequency. This is shown in Figure 3.4. Note that the control of (3.3) works for low frequency modes while it does not for high frequency modes (see Figure 3.3). We remark that the question arises whether the model used is a valid description of the modelled reality for such frequencies. In reality one (usually) expects larger damping for larger frequencies. Whether this damping occurs strongly and soon enough depends on

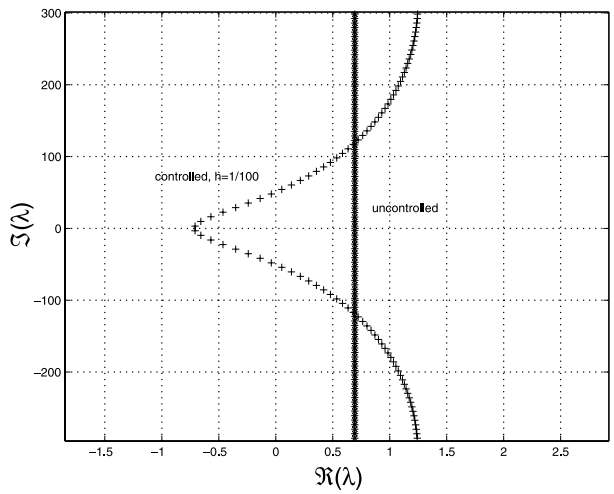

FIG. 3.3. *Part of the spectrum of the uncontrolled system* (3.4) *and the controlled system* (3.5) *for* $h = 0.01$.

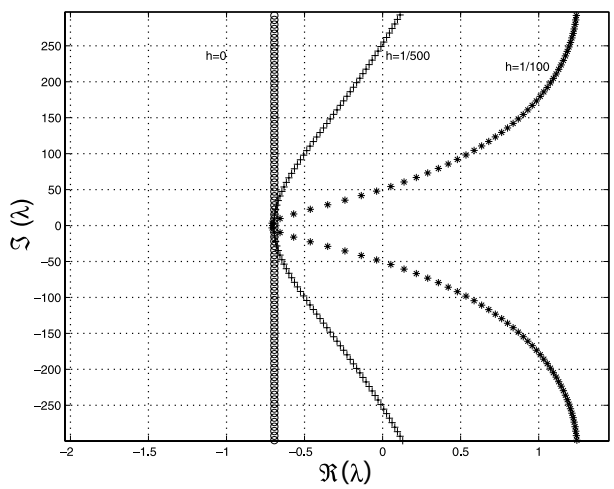

FIG. 3.4. *When* $h \to 0$, *the spectrum of* (3.5) *converges pointwise to the spectrum of* $x(t) + \frac{1}{2}x(t-1) = 0$.

the particular application. In section 4 we will see that our generalization leads to situations where sensitivity is *not necessarily* caused by high frequency modes.

4. Vanishing delays. The analysis in section 2 is valid under the assumption that all the delays are fixed, different, and nonzero. These assumptions can be relaxed to the requirements that, first, the smallest delays are not arbitrary close to zero and, second, that the largest delays are not arbitrary close to each other. In this section we explicitly deal with these limit cases. We show that vanishing delays can give rise to roots with unbounded positive real parts and that, in a similar way, coinciding largest delays can give rise to roots with unbounded negative real part. Since the latter is of less importance for applications, we mention only briefly the occurrence of this phenomenon.

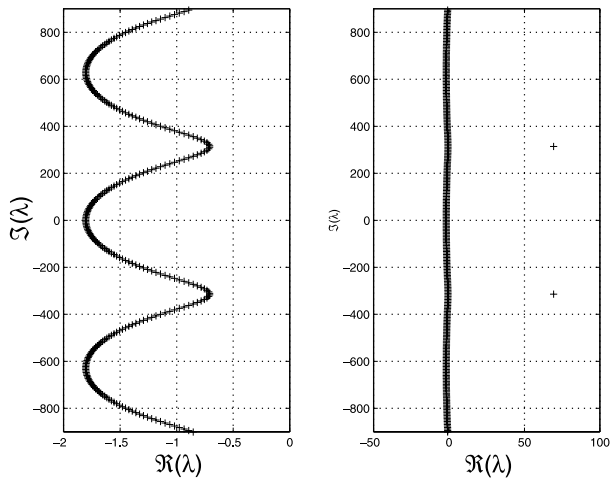

FIG. 4.1. *Zeros of* (4.1) *for* $h = 0.01$ *in two different regions of the complex plane.*

4.1. Introductory example. We investigate the zeros of

$$H(\lambda, h) = 1 + 2e^{-\lambda h} - \frac{1}{2}e^{-\lambda} \tag{4.1}$$

as $h \to 0+$.

If we set h to 0 in (4.1), all roots of $H(\lambda, 0)$ are of the form $\lambda = -\log(6) + i2\pi l$, $l \in \mathbb{Z}$, and the collection of real parts of the roots of $H(\lambda, 0)$ is $\bar{Z}(0) = \{-\log(6)\}$. However, from the analysis of section 2, we know that for h and 1 rationally independent (i.e., h irrational), $\bar{Z}(h)$ coincides with the α-components of all solutions $(\alpha, \theta_1, \theta_2)$ of

$$1 + 2e^{-\alpha h}e^{-i\theta_1} - \frac{1}{2}e^{-\alpha}e^{-i\theta_2} = 0. \tag{4.2}$$

If h goes to 0 in (4.2), we are led to the conclusion that

$$\lim_{h \to 0+} \bar{Z}(h) = [-\log(6), -\log(2)], \tag{4.3}$$

i.e., that, although the real part of each individual root of $H(\lambda, h)$ approaches $-\log(6)$ as h goes to zero, at the same time the collection of all the real parts of all roots converges to (4.3).

Figure 4.1 (left panel) shows part of the roots of (4.1) for $h = 0.01$. At first glance this confirms the above conclusions. However, if we look at a larger region in the complex plane (see the right panel of Figure 4.1) we see that there exist additional roots of $H(\lambda, h)$ with quite different behavior. When h is further reduced, the real parts of the roots at $\Re(\lambda) \approx 69.3$ move off to $+\infty$, approximately as the solutions of

$$1 + 2e^{-\lambda h} = 0. \tag{4.4}$$

Indeed, if the real part of λ is large, we cannot set λh to zero. Rather, we can neglect $\frac{1}{2}e^{-\lambda}$, leading to (4.4) and

$$\lambda \approx \frac{1}{h}\left(\log 2 + i(2l+1)\pi\right), \quad l \in \mathbb{Z}. \tag{4.5}$$

Formula (4.5) clearly illustrates that arbitrarily small delays ($0 < h \ll 1$) can lead to arbitrarily unstable characteristic roots ($\Re(\lambda) \gg 1$).

The situation can be summarized as follows. When h tends to zero, the spectrum consists partly of roots with bounded real part, which can be analyzed along the lines of section 2, and partly of "diverging" roots, whose real part grows without bound as the solutions of the "small-delay part" (4.4) of (4.1). In the rest of this section these properties will be generalized to the multiple delay case.

4.2. Notation. The general form of the exponential polynomial studied within this section is

$$H(\lambda, r, s) = 1 - \sum_{i \in I} a_i e^{-\lambda \tau_i} - \sum_{j \in J} b_j e^{-\lambda \tau_j}, \tag{4.6}$$

where

$$\forall i \in I : \tau_i = \gamma_i \cdot r, \quad \forall j \in J : \tau_j = \gamma_j \cdot r + \nu_j \cdot s,$$

and where

$$I = \{1, 2, \ldots, N_1\}, \quad J = \{N_1 + 1, N_1 + 2, \ldots, N_1 + N_2\}$$

are used for notational convenience. The components of $r \in [0, +\infty)^M$ and $s \in [0, +\infty)^L$ are the independent delays; $\gamma_i \in \mathbb{N}^M$, $\gamma_j \in \mathbb{N}^M$, and $\nu_j \in \mathbb{N}^L$ are vectors with nonnegative integer coefficients. γ_i and ν_j are nonzero vectors; that is, both have at least one nonzero element for all i and j. Splitting the independent delays into r and s opens the possibility of dealing with a combination of "normal" and arbitrarily small delays by letting $r \to 0$ combined with constant $s > 0$.

We also extend the definition of the inner product "$\cdot$" to the situation with $\gamma_i \in \mathbb{N}^M$ and $R \in [0, +\infty]^M$. Then

$$\gamma_i \cdot R = \sum_{j=1}^{M} \gamma_{i,j} R_j$$

has the usual meaning, except that $\gamma_{i,j} \times (R_j = +\infty)$ is taken to be 0 when $\gamma_{i,j} = 0$, and $+\infty$ otherwise. The underlying rationale for this is that $R_j = +\infty$ will be the result of some limit while the $\gamma_{i,j}$ are fixed.

4.3. Arbitrarily unstable characteristic roots. The "small-delay part" of (4.6) is

$$1 - \sum_{i \in I} a_i e^{-\lambda \tau_i}.$$

We now prove how its solutions determine when arbitrarily small delays can lead to arbitrarily unstable characteristic roots.

THEOREM 4.1. *The following statements are equivalent:*

$$\exists \theta \in [0, 2\pi]^M,\ \exists R \in [0, +\infty]^M \text{ such that } 1 - \textstyle\sum_{i \in I} a_i e^{-\gamma_i \cdot R} e^{-i \gamma_i \cdot \theta} = 0$$
$$\Updownarrow$$
$$\exists \{r_n\}_{n \geq 1},\ \{c_n\}_{n \geq 1},\ \{d_n\}_{n \geq 1},$$
$$\text{with } \lim_{n \to \infty} c_n = \infty,\ r_n \geq 0, \text{ and } \lim_{n \to \infty} \|r_n\| = 0 \text{ and such that}$$
$$\lim_{n \to \infty} H(c_n + i d_n, r_n, s) = 0 \text{ for fixed } s > 0.$$

Proof of $\Downarrow$. Consider a (re)ordered partition of $R = (R_1, \ldots, R_K, R_{K+1}, \ldots, R_M)$ such that $R_1, \ldots, R_K$ are finite and $R_{K+1}, \ldots, R_M$ are infinite. That is, let $R = (R^{[1]}, R^{[2]})$ with $R^{[1]} = (R_1, R_2, \ldots, R_K) \in \mathbb{R}^K$ and $R^{[2]} = (\infty, \infty, \ldots, \infty) = \infty^{M-K}$. Likewise, consider the corresponding partition for θ and γ_i: $\theta = (\theta^{[1]}, \theta^{[2]})$ and $\gamma_i = (\gamma_i^{[1]}, \gamma_i^{[2]})$, with $\theta^{[1]} = (\theta_1, \theta_2, \ldots, \theta_K)$ the first K components and $\theta^{[2]} = (\theta_{K+1}, \theta_{K+2}, \ldots, \theta_M)$ the remaining $M-K$ components of θ, and similarly for $\gamma_i^{[1]}$ and $\gamma_i^{[2]}$, $i \in I$. Define the set of indices $I_1 \subseteq I$, whereby for $i \in I_1$ the last $M-K$ components of γ_i are zero, that is, where $\gamma_i^{[2]} = 0^{M-K}$, and set $I_2 = I \setminus I_1$. Obviously

$$1 - \sum_{i \in I} a_i e^{-\gamma_i \cdot R} e^{-i\gamma_i \cdot \theta} = 0$$

can be written as

$$1 - \sum_{i \in I_1} a_i e^{-\gamma_i^{[1]} \cdot R^{[1]}} e^{-i\gamma_i^{[1]} \cdot \theta^{[1]}} = 0.$$

Because the components of $R^{[1]}$ may be rationally dependent, consider a sequence $\{u_n^{[1]}\}_{n \geq 1}$ that converges to $R^{[1]}$ but whereby the components of $u_n^{[1]} \in (0, +\infty)^K$ are rationally independent for each n. Choose a (strictly positive) sequence of real numbers $\{\epsilon_n\}_{n \geq 1}$ with $\lim_{n \to \infty} \epsilon_n = 0$ such that

$$\|u_n^{[1]} - R^{[1]}\| < \epsilon_n.$$

Because $u_n^{[1]}$ has rationally independent coefficients, due to Theorem 2.1, there exists, for each n, a sequence of real numbers $\{v_{n,m}\}_{m \geq 1}$ such that

$$\lim_{m \to \infty} e^{i\gamma_i^{[1]} \cdot (v_{n,m} u_n^{[1]} - \theta^{[1]})} = 1 \ \forall i \in I_1;$$

hence $\exists m^*(n)$ such that $|e^{i\gamma_i^{[1]} \cdot (v_{n,m^*(n)} u_n^{[1]} - \theta^{[1]})} - 1| < \epsilon_n \ \forall i \in I_1$. Set $v_n = v_{n,m^*(n)}$. We have created $\{u_n^{[1]}\}_{n \geq 1}$ and $\{v_n\}_{n \geq 1}$ with

$$\begin{gathered} \|u_n^{[1]} - R^{[1]}\| < \epsilon_n, \\ |e^{i\gamma_i^{[1]} \cdot (v_n u_n^{[1]} - \theta^{[1]})} - 1| < \epsilon_n \ \forall i \in I_1, \text{ and} \\ \lim_{n \to \infty} \epsilon_n = 0. \end{gathered}$$

Choose further $\{u_n^{[2]}\}_{n \geq 1}$, with $u_n^{[2]} \in (0, +\infty)^{M-K}$ and with $\lim_{n \to \infty} u_n^{[2]} = \infty^{M-K}$, and define $\{u_n\}_{n \geq 1}$ as $u_n = (u_n^{[1]}, u_n^{[2]}) \in (0, +\infty)^M$.

We are now in a position to choose a sequence of real parts c_n. Choose $\{c_n\}_{n \geq 1}$ with $c_n \in (0, +\infty)$ such that c_n goes to infinity faster than every component of u_n, that is, such that $\lim_{n \to \infty} c_n = +\infty$ and $\lim_{n \to \infty} \frac{1}{c_n} u_n = 0^M$. Second, define a sequence of imaginary parts $\{d_n\}_{n \geq 1}$ as $d_n = c_n v_n$, and a sequence of vanishing delays $\{r_n\}_{n \geq 1}$ as $r_n = \frac{1}{c_n} u_n$.

We now have

$$\begin{aligned} &H(c_n + id_n, r_n, s) \\ &\quad = 1 - \sum_{i \in I} a_i e^{-c_n \gamma_i \cdot r_n} e^{-id_n \gamma_i \cdot r_n} - \sum_{j \in J} b_j e^{-c_n(\gamma_j \cdot r_n + \nu_j \cdot s)} e^{-id_n(\gamma_j \cdot r_n + \nu_j \cdot s)} \\ &\quad = 1 - \sum_{i \in I} a_i e^{-\gamma_i \cdot u_n} e^{-i\gamma_i \cdot v_n u_n} - \sum_{j \in J} b_j e^{-c_n(\gamma_j \cdot r_n + \nu_j \cdot s)} e^{-id_n(\gamma_j \cdot r_n + \nu_j \cdot s)}. \end{aligned}$$

The second term can be split into, first, $\sum_{i\in I_1} a_i e^{-\gamma_i\cdot u_n} e^{-i\gamma_i\cdot v_n u_n}$, whereby the last $M-K$ components of γ_i are zero and thus $\gamma_i\cdot u_n = \gamma_i^{[1]}\cdot u_n^{[1]}$, and, second, $\sum_{i\in I_2} a_i e^{-\gamma_i\cdot u_n} e^{-i\gamma_i\cdot v_n u_n}$, whereby $\lim_{n\to\infty}\gamma_i\cdot u_n = +\infty$.

Hence

$$
\begin{aligned}
&H(c_n + id_n, r_n, s)\\
&= 1 - \sum_{i\in I_1} a_i e^{-\gamma_i^{[1]}\cdot R^{[1]}} e^{-i\gamma_i^{[1]}\cdot\theta^{[1]}} e^{-\gamma_i^{[1]}\cdot(u_n^{[1]}-R^{[1]})} e^{-i\gamma_i^{[1]}\cdot(v_n u_n^{[1]}-\theta^{[1]})}\\
&\quad - \sum_{i\in I_2} a_i e^{-\gamma_i\cdot u_n} e^{-i\gamma_i\cdot v_n u_n} - \sum_{j\in J} b_j e^{-c_n(\gamma_j\cdot r_n+\nu_j\cdot s)} e^{-id_n(\gamma_j\cdot r_n+\nu_j\cdot s)}\\
&= 1 - \sum_{i\in I_1} a_i e^{-\gamma_i^{[1]}\cdot R^{[1]}} e^{-i\gamma_i^{[1]}\cdot\theta^{[1]}} \underbrace{e^{-\gamma_i^{[1]}\cdot(u_n^{[1]}-R^{[1]})}}_{\to 1} \underbrace{e^{-i\gamma_i^{[1]}\cdot(v_n u_n^{[1]}-\theta^{[1]})}}_{\to 1}\\
&\quad - \sum_{i\in I_2} a_i e^{-\overbrace{\gamma_i\cdot u_n}^{\to\infty}} e^{-i\gamma_i\cdot v_n\bar{u}_n} - \sum_{j\in J} b_j e^{-c_n\overbrace{\nu_j\cdot s}^{\neq 0}} e^{-\overbrace{c_n\gamma_j\cdot r_n}^{\to\infty}} e^{-id_n(\gamma_j\cdot r_n+\nu_j\cdot s)}
\end{aligned}
$$

tends to zero as n approaches infinity, which completes this part of the proof.

Proof of $\Uparrow$. The $\lim_{n\to\infty} H(c_n + id_n, r_n, s) = 0$ implies

$$\lim_{n\to\infty} 1 - \sum_{i\in I} a_i e^{-\gamma_i\cdot c_n r_n} e^{-i\gamma_i\cdot d_n r_n} = 0, \tag{4.7}$$

because the other term vanishes at infinity.

Consider the sequence $\{c_n r_n\}_{n\geq 1}$ with elements $c_n r_n = (c_n r_{n,1}, \ldots, c_n r_{n,M})$. For each sequence of the kth component, $\{c_n r_{n,k}\}_{n\geq 1}$, there are two possibilities as n tends to infinity: either the sequence is unbounded (with or without limit) or the sequence is bounded (with or without limit). Suppose that $\{c_n r_{n,k}\}_{n\geq 1}$ is unbounded. Then there exists a subsequence with limit infinity. When, on the other hand, $\{c_n r_{n,k}\}_{n\geq 1}$ is bounded, a subsequence with finite limit exists.

This way one can repeatedly construct subsequences to obtain an infinite set of indices S_1 such that for each $k\in\{1, 2\ldots, M\}$, $\lim_{n\to\infty, n\in S_1} c_n r_{n,k}$ exists in $[0, +\infty]$. We still have

$$\lim_{n\to\infty, n\in S_1} 1 - \sum_{i\in I} a_i e^{-\gamma_i\cdot c_n r_n} e^{-i\gamma_i\cdot d_n r_n} = 0, \tag{4.8}$$

and because each γ_i is a vector of integer coefficients, $e^{-i\gamma_i\cdot d_n r_n}$ equals $e^{-i\gamma_i\cdot((d_n r_n) \bmod 2\pi)}$ and thus

$$\lim_{n\to\infty, n\in S_1} 1 - \sum_{i\in I} a_i e^{-\gamma_i\cdot c_n r_n} e^{-i\gamma_i\cdot((d_n r_n) \bmod 2\pi)} = 0.$$

Consider the sequence of vectors $\{(d_n r_n) \bmod 2\pi\}_{n\geq 1, n\in S_1}$, which is bounded and thus contained in a compact set (w.r.t. some norm). Consequently, it must have a converging subsequence, denoted by the indices $S_2 \subset S_1$. Finally,

$$\lim_{n\to\infty, n\in S_2} 1 - \sum_{i\in I} a_i e^{-\gamma_i\cdot c_n r_n} e^{-i\gamma_i\cdot((d_n r_n) \bmod 2\pi)} = 0,$$

and we define

$$R_k = \lim_{n\to\infty, n\in S_2} c_n r_{n,k} \in [0,+\infty], \quad k = 1,2,\ldots,M,$$

and

$$\theta_k = \lim_{n\to\infty, n\in S_2} (d_n r_{n,k}) \bmod 2\pi \in [0,2\pi], \quad k = 1,2,\ldots,M.$$

Hence we have defined every component of R and θ in such a way that

$$1 - \sum_{i\in I} a_i e^{-\gamma_i\cdot R} e^{-i\gamma_i\cdot\theta} = 0,$$

which completes the proof. □

We now strengthen the results of the previous theorem: we prove the existence of a sequence of *roots* λ_n of $H(\lambda, r_n, s) = 0$ with real part tending to $+\infty$, in other words, that arbitrarily small delays cause roots with arbitrarily large real part.

THEOREM 4.2. *Consider the statements*

(a) $\exists\theta \in [0,2\pi]^M$, $\exists R \in [0,+\infty]^M$ *such that* $1 - \sum_{i\in I} a_i e^{-\gamma_i\cdot R} e^{-i\gamma_i\cdot\theta} = 0$;

(b) $\exists i \in I$ *such that* $\gamma_i \cdot R \neq 0$ *and* $\gamma_i \cdot R \neq +\infty$;

(c) $\exists \{r_n\}_{n\geq 1}$, $\{\lambda_n = e_n + if_n\}_{n\geq 1}$ *with* $\lim_{n\to\infty} e_n = +\infty$, $r_n \geq 0$, *and* $\lim_{n\to\infty} r_n = 0^M$ *such that* $H(\lambda, r_n, s) = 0$.

Then the following hold:

(1) (a) *and* (b) $\Rightarrow$ (c),

(2) (c) $\Rightarrow$ (a).

The special case where (a) holds but (b) is violated is treated separately in subsection 4.5. This corresponds to a degenerate case where the "small delay part" of the characteristic equation doesn't provide enough information about the existence of roots with large real part for vanishing delays.

Proof of (2). This proof is trivial (Theorem 4.1).

Proof of (1). Following Theorem 4.1 there exist sequences $\{r_n\}_{n\geq 1}$, $\{c_n\}_{n\geq 1}$, and $\{d_n\}_{n\geq 1}$, with $\lim_{n\to\infty} c_n = +\infty$, $r_n \geq 0$, and $\lim_{n\to\infty} r_n = 0^M$, such that

$$\lim_{n\to\infty} H(c_n + id_n, r_n, s) = 0,$$

and the proof has provided us with a way to construct such sequences.

Choose $\{\epsilon_n\}_{n\geq 1}$, $\{u_n^{[1]}\}_{n\geq 1}$, and $\{v_n\}_{n\geq 1}$ as in Theorem 4.1 and such that

$$\left| 1 - \sum_{i\in I_1} a_i e^{-\gamma_i^{[1]}\cdot R^{[1]}} e^{-i\gamma_i^{[1]}\cdot\theta^{[1]}} e^{-\gamma_i^{[1]}\cdot(u_n^{[1]} - R^{[1]})} e^{-i\gamma_i^{[1]}\cdot(v_n u_n^{[1]} - \theta^{[1]})} \right| < e^{-n}.$$

Further requirements on the decay-rate, which can be chosen arbitrarily fast, will be given later in the proof (see formulae (4.9) and (4.10)). Choose $\{c_n\}_{n\geq 1}$ as $c_n = n$, $\{u_n^{[2]}\}_{n\geq 1}$ as $u_n^{[2]} = \sqrt{n}(1,1,\ldots,1)$, $\{d_n\}_{n\geq 1}$ as $d_n = v_n c_n$, $\{u_n\}_{n\geq 1}$ as $u_n = (u_n^{[1]}, u_n^{[2]})$, and $\{r_n\}_{n\geq 1}$ as $r_n = \frac{1}{c_n} u_n$.

Consider the functions $\bar{H}_n(\lambda) = c_n H(\lambda, r_n, s)$. Using the particular choices above it is straightforward to show that

$$\lim_{n\to\infty} \bar{H}_n(c_n + id_n) = 0, \qquad \lim_{n\to\infty} \frac{d\bar{H}_n}{d\lambda}(c_n + id_n) = Q,$$

where

$$Q = \sum_{i \in I_1} a_i \gamma_i^{[1]} \cdot R^{[1]} e^{-\gamma_i^{[1]} \cdot R^{[1]}} e^{-i\gamma_i^{[1]} \cdot \theta^{[1]}} \in \mathbb{C}$$

and

$$\lim_{n \to \infty} \frac{d^k \bar{H}_n}{d\lambda^k}(c_n + id_n) = 0, \quad k \geq 2.$$

Around $c_n + id_n$, the analytic function $\bar{H}_n$ can be expanded as

$$\bar{H}_n(\lambda) = \sum_{k=0}^{\infty} \frac{d^k \bar{H}_n}{d\lambda^k}\bigg|_{c_n + id_n} (\lambda - (c_n + id_n))^k,$$

and when defining $\mu = \lambda - (c_n + id_n)$,

$$\bar{H}_n(\mu) = \sum_{k=0}^{\infty} \frac{d^k \bar{H}_n}{d\lambda^k}\bigg|_{c_n + id_n} \mu^k.$$

We will now show that $\bar{H}_n(\mu)$ converges uniformly on $|\mu| \leq 1$ to the function $\bar{H}(\mu) = Q\mu$ or, equivalently, that the function

$$D_n(\mu) = \bar{H}_n(\mu) - Q\mu$$

converges uniformly to zero in $|\mu| \leq 1$. In the appendix it is shown (Lemma A.1) that this implies that $\bar{H}_n(\mu)$ has a root near $\mu = 0$ for sufficiently large n when $Q \neq 0$. One should emphasize that μ is in fact a local coordinate depending on n: we compare the local behavior of each function $\bar{H}_n(\lambda)$ near $c_n + id_n$ with $\bar{H}(\mu) = Q\mu$.

To construct an upper bound on $|D_n(\mu)|$ for $|\mu| \leq 1$, first define strictly positive numbers Δ_i, Δ_j, β_i and integer P such that, for $n \geq P$,

$$\begin{gathered} \gamma_j \cdot r_n \leq \Delta_j, \quad j \in J, \\ \gamma_i \cdot c_n r_n \leq \gamma_i^{[1]} \cdot R^{[1]} + \Delta_i, \quad i \in I_1, \\ \gamma_i \cdot r_n \leq 1, \quad i \in I = I_1 \cup I_2, \text{ and} \\ \gamma_i \cdot c_n r_n \geq \beta_i \sqrt{n}, \quad i \in I_2. \end{gathered}$$

Second, the decay rate of $\{\epsilon_n\}_{n \geq 1}$ should be chosen in such a way that for $n \geq P$

$$n \left| 1 - \sum_{i \in I_1} a_i e^{-\gamma_i \cdot c_n r_n} e^{-i\gamma_i \cdot d_n r_n} \right| \leq \frac{1}{n} \sum_{i \in I_1} |a_i| \tag{4.9}$$

and

$$\left| \sum_{i \in I_1} a_i \gamma_i \cdot c_n r_n e^{-\gamma_i \cdot c_n r_n} e^{-i\gamma_i \cdot d_n r_n} - Q \right| \leq \frac{1}{n} \sum_{i \in I_1} |a_i| (\gamma_i^{[1]} \cdot R^{[1]} + \Delta_i). \tag{4.10}$$

In this way we can compute bounds for $D_n(0)$ and its derivatives in $\mu = 0$, $n \geq P$:

$$\begin{aligned} |D_n(0)| &\leq n \left| 1 - \sum_{i \in I_1} a_i e^{-\gamma_i \cdot c_n r_n} e^{-i\gamma_i \cdot d_n r_n} \right| + n \left| \sum_{i \in I_2} a_i e^{-\gamma_i \cdot c_n r_n} e^{-i\gamma_i \cdot d_n r_n} \right| \\ &\quad + n \sum_{j \in J} \left| b_j e^{-\nu_j \cdot s c_n} e^{-\gamma_j \cdot c_n r_n} e^{-i\gamma_j \cdot d_n r_n} \right| \\ &\leq \frac{1}{n} \sum_{i \in I_1} |a_i| + \sum_{i \in I_2} n e^{-\beta_i \sqrt{n}} |a_i| + \sum_{j \in J} n e^{-n\nu_j \cdot s} |b_j|, \end{aligned}$$

and, concerning the derivatives,

$$\left|\frac{dD_n}{d\mu}(0)\right| \leq \frac{1}{n}\sum_{i\in I_1}|a_i|(\gamma_i^{[1]}\cdot R+\Delta_i)+\sum_{i\in I_2} ne^{-\beta_i\sqrt{n}}|a_i| + \sum_{j\in J} n(\Delta_j+\nu_j\cdot s)e^{-n\nu_j\cdot s}|b_j|,$$

and for $k\geq 2$,

$$\left|\frac{d^kD_n}{d\mu^k}(0)\right| \leq \frac{1}{n}\sum_{i\in I_1}|a_i|(\gamma_i^{[1]}\cdot R^{[1]}+\Delta_i)+\sum_{i\in I_2} ne^{-\beta_i\sqrt{n}}|a_i| + \sum_{j\in J} n(\Delta_j+\nu_j\cdot s)^k e^{-n\nu_j\cdot s}|b_j|.$$

Finally, for each μ with $|\mu|\leq 1$,

$$\begin{aligned}
|D_n(\mu)| &\leq \sum_{k=0}^{\infty}\frac{1}{k!}\left|\frac{d^kD}{d\mu^k}\right| \\
&\leq \sum_{i\in I_1}\frac{1}{n}|a_i|(\gamma_i^{[1]}\cdot R^{[1]}+\Delta_i)\sum_{k=0}^{\infty}\frac{1}{k!}+\sum_{i\in I_2} ne^{-\beta_i\sqrt{n}}\sum_{k=0}^{\infty}|a_i|\frac{1}{k!} \\
&\quad+\sum_{j\in J} ne^{-n\nu_j\cdot s}|b_j|\sum_{k=0}^{\infty}\frac{(\Delta_j+\nu_j\cdot s)^k}{k!} \\
&\leq \sum_{i\in I_1}\frac{1}{n}|a_i|(\gamma^{[1]}\cdot R^{[1]}+\Delta_i)e+\sum_{i\in I_2} ne^{-\beta_i\sqrt{n}}|a_i|e \\
&\quad+\sum_{j\in J} ne^{-n\nu_j\cdot s}|b_j|e^{(\Delta_j+\nu_j\cdot s)}
\end{aligned}$$

can thus be bounded uniformly, whereby the upper bound tends to zero as $n\to\infty$.

Because the series $\{\bar{H}_n(\mu)\}_{n\geq 1}$ converges uniformly to a function $\bar{H}(\mu)=Q\mu$, due to Lemma A.1, there must be a number $N\in\mathbb{N}$ such that for $\forall n\geq N$, $\bar{H}_n(\mu)$ has a root which converges to zero as $n\to\infty$ whenever $Q\neq 0$. Returning to the original problem, this means that c_n+id_n asymptotically coincides with a root e_n+if_n of $\bar{H}_n(\lambda)$, which is of course a root of $H(\lambda,r_n,s)$. Thus $\forall n\geq N$, $\exists e_n+if_n : H(e_n+if_n,r_n,s)=0$ and $\lim_{n\to\infty}(c_n-e_n)+i(d_n-f_n)=0$. By renumbering the sequences starting from $n=N$, the proof is complete in the case $Q\neq 0$.

We will now show that when $Q=0$ there always exists an integer k such that $\sum_{i\in I_1} a_i(\gamma_i^{[1]}\cdot R^{[1]})^l e^{-\gamma_i^{[1]}\cdot R^{[1]}}e^{-i\gamma_i^{[1]}\cdot\theta^{[1]}}=0$ for $l<k$ and $Q'=\sum_{i\in I_1} a_i(\gamma_i^{[1]}\cdot R^{[1]})^k e^{-\gamma_i^{[1]}\cdot R^{[1]}}e^{-i\gamma_i^{[1]}\cdot\theta^{[1]}}\neq 0$. In this case, $c_n^kH(\lambda,r_n,s)$ will converge locally to $Q'(\lambda-(c_n+id_n))^k$, and the proof proceeds as in the case $Q\neq 0$.

We prove that if Q' does not exist, (b) is necessarily violated. For notational convenience, define $\hat{a}_i = a_ie^{-\gamma_i^{[1]}\cdot R^{[1]}}e^{-i\gamma_i^{[1]}\cdot\theta^{[1]}}$. Given $\sum_{i\in I_1}\hat{a}_i=1$, $\sum_{i\in I_1}(\gamma_i^{[1]}\cdot R^{[1]})\hat{a}_i=0$, and $\sum_{i\in I_1}(\gamma_i^{[1]}\cdot R^{[1]})^2\hat{a}_i=0,\ldots$ (because Q' does not exist), multiply these equations with scalars and add them together to obtain

$$p(0)=\sum_{i\in I_1}\hat{a}_ip(\gamma_i^{[1]}\cdot R^{[1]}) \tag{4.11}$$

for all polynomials $p(\lambda)$. In (4.11) it is possible that for some indices $k, l \in I_1$, $\gamma_k^{[1]} \cdot R^{[1]} = \gamma_l^{[1]} \cdot R^{[1]}$ or $\gamma_k^{[1]} \cdot R^{[1]} = 0$. We group these factors:

$$g_0 p(0) + \sum g_j p(\gamma_j^{[1]} \cdot R^{[1]}) = 0.$$

If we choose for $p(\lambda)$ an interpolating (complex) polynomial such that $p(0) = \bar{g}_0$ and $p(\gamma_j^{[1]} \cdot R^{[1]}) = \bar{g}_j \ \forall j$, this leads to

$$|g_0|^2 + \sum |g_j|^2 = 0 \Rightarrow g_0 = 0,\ g_j = 0 \quad \forall j \Rightarrow g_0 + \sum g_j e^{\gamma_j^{[1]} \cdot R^{[1]}} = 0$$

or

$$1 - \sum_{i \in I_1} a_i e^{-i\gamma_i^{[1]} \cdot \theta^{[1]}} = 0.$$

This means that in $1 - \sum_{i \in I} a_i e^{-\gamma_i \cdot R} e^{-i\gamma_i \cdot \theta} = 0 \ \forall i \in I$, $\gamma_i \cdot R$ is zero or infinity, which contradicts statement (b). □

For control applications the following theorem is important. It provides sufficient and necessary conditions for (4.6) to have roots with arbitrarily large real part but small imaginary part in the presence of vanishing delays.

THEOREM 4.3. *Consider the statements*

(a) $\exists R \in [0, +\infty]^M$ *such that* $1 - \sum_{i \in I} a_i e^{-\gamma_i \cdot R} = 0$;

(b) $\exists i \in I$ *such that* $\gamma_i \cdot R \neq 0$ *and* $\gamma_i \cdot R \neq +\infty$;

(c) $\exists \{r_n\}_{n \geq 1}$, $\{\lambda_n\}_{n \geq 1}$ *with* $\lambda_n \in \mathbb{C}$, $\lim_{n \to \infty} \Re(\lambda_n) = +\infty$, $\lim_{n \to \infty} \Im(\lambda_n) = 0$, $r_n \geq 0$, *and* $\lim_{n \to \infty} \|r_n\| = 0$ *and such that* $H(\lambda_n, r_n, s) = 0$.

Then the following hold:

(1) (a) *and* (b) $\Rightarrow$ (c),

(2) (c) $\Rightarrow$ (a).

The above results can easily be shown by following the lines of the proofs of Theorems 4.1 and 4.2. Note that the occurrence of arbitrarily large roots does not depend on whether the small delays are rationally (in)dependent.

4.4. Interpretation and illustration. When the delays r in (4.6) approach zero, the real part of each characteristic root remains bounded or moves to $+\infty$. We call the set of these roots the *finite* (respectively, the *infinite*) part of the spectrum.

The supremum of the real parts of the finite part of the spectrum, c_{f}, can be calculated as the right-most solution α of

$$1 - \sum_{i \in I} a_i e^{-i\gamma_i \cdot \theta_1} - \sum_{j \in J} b_j e^{-\alpha \nu_j \cdot s} e^{-i(\gamma_j \cdot \theta_1 + \nu_j \cdot \theta_2)} = 0, \tag{4.12}$$

which corresponds to applying Theorem 2.4 and putting αr to zero. This last step is allowed because the delays r are arbitrarily small and α is infinite.

The infinite part of the spectrum is empty if

$$1 - \sum_{i \in I} a_i e^{-\gamma_i \cdot R} e^{-i\gamma_i \cdot \theta} = 0 \tag{4.13}$$

has no solution with $R \in [0, +\infty]^M$. Otherwise, we can conclude that arbitrarily unstable roots exist, except in the degenerate case where all the solutions of (4.13) with $R \geq 0$ satisfy that $\gamma_i \cdot R$ is zero or infinite for all $i \in I$. For this degenerate case, the

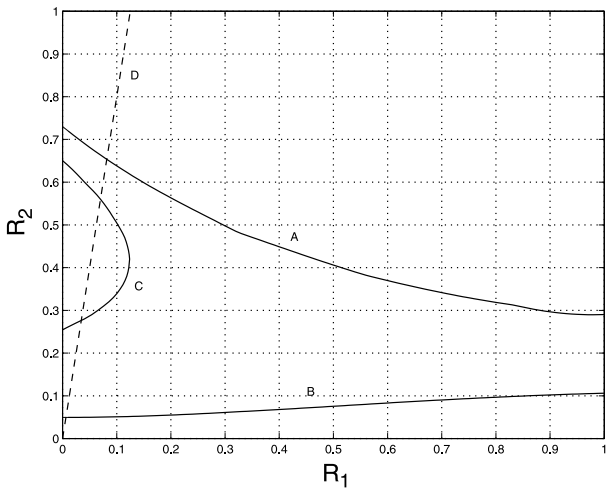

FIG. 4.2. *Projection of solutions of* (4.16).

small-delay part of the exponential polynomial does not provide enough information about the existence of the infinite spectrum, as will be shown in section 4.5.

We now illustrate how the solutions of (4.13) determine the structure of the infinite part of the spectrum and raise and partially answer an important open question which naturally arises from our analysis.

In both Theorems 4.2 and 4.3 we have allowed complete freedom in the way the independent delays approach zero. In practical applications it may be of interest to know whether additional dependencies between the delays (like, e.g., $r_1 < r_2 \to 0$) can influence the stability results. For this consider the following example:

$$1 - 2e^{-\lambda(r_1+r_2)} + 4e^{-\lambda 8 r_2} - \frac{1}{2}e^{-\lambda 2} = 0, \tag{4.14}$$

which has as small-delay part, when r_1 and $r_2 \to 0+$,

$$1 - 2e^{-\lambda(r_1+r_2)} + 4e^{-\lambda 8 r_2} = 0. \tag{4.15}$$

The supremum of the real parts of the finite part of the spectrum is $c_{\mathrm{f}} = -\frac{1}{2}\log 2 < 0$. The infinite part of the spectrum is nonempty if and only if

$$1 - 2e^{-(R_1+R_2)}e^{-i(\theta_1+\theta_2)} + 4e^{-8R_2}e^{-i8\theta_2} = 0 \tag{4.16}$$

has solutions with R_1 and $R_2 \in [0, +\infty]$. In Figure 4.2 the *area* between curves A, B, and C is the projection on the (R_1, R_2)-plane of the solutions of (4.16). Using Theorem 4.3, (4.14) has roots with real part tending to $+\infty$ but small imaginary part if and only if (4.16) has a solution with R_1 and $R_2 \in [0, +\infty]$ and $\theta_1 = \theta_2 = 0$. These solutions form the *curve* C in Figure 4.2.

Following Theorem 4.2 the solutions of $1 - \sum_{i\in I} a_i e^{-\gamma_i \cdot R} e^{-i\gamma_i \cdot \theta} = 0$ determine the existence of roots with large real part.

When the delays approach zero with a fixed ratio these solutions further provide a complete characterization of the structure of the diverging characteristic roots. This will be illustrated for the example discussed above. We will consider only the solutions of (4.15), since one can show that these solutions asymptotically coincide with solutions of (4.14) as $(r_1, r_2) \to (0, 0)$ (proof similar to that for Theorem 4.2).

Suppose (4.16) has the following interval of solutions parameterized by α:

$$(R_1, R_2) = \alpha(R_1^*, R_2^*), \quad 0 < \alpha_1 \leq \alpha \leq \alpha_2,$$

whereby we assume at the moment that R_1^* and R_2^* are finite and rationally independent. Then for each α we have

$$1 - 2e^{-\alpha k \frac{R_1^* + R_2^*}{k}} e^{-(\theta_1+\theta_2)} + 4e^{-8\alpha k \frac{R_2^*}{k}} e^{-8\theta_2} = 0,$$

whereby θ_1 and θ_2 depend on α. Applying Theorem 2.4 to this formula, it is clear that for the vanishing delays $(R_1, R_2) = (\frac{R_1^*}{k}, \frac{R_2^*}{k}), k \to \infty$, (4.15) has solutions with real part arbitrarily close to $k\alpha$, $\alpha_1 \leq \alpha \leq \alpha_2$. This leads to the following conclusion: the intervals in Figure 4.2 which form the intersection of a line through the origin and the projected solution surface of (4.16) correspond to intervals of $\bar{Z}$ which move to infinity ($k \to \infty$) when the delays approach zero in the ratio determined by the slope of the line. Second, the number and lengths of these intervals, when existing, depend on the way (with what ratio) the delays approach zero.

Using the same kind of arguments, the intersection of a line through the origin with curve C in Figure 4.2 corresponds to a real root going to infinity. As can be seen from the picture, the *occurrence* of this phenomenon depends on additional dependencies between the delays such as their having a fixed ratio. Whether the same is true for the occurrence of roots with large real part but arbitrary imaginary part remains an open question.

Note that when $\frac{R_1^*}{R_2^*}$ would be rational, the delays are commensurate and $\bar{Z}$ consists of a number of points. However, when the ratio is close[1] to an irrational number (due to the lower semicontinuity of $\bar{Z}$ w.r.t. the delays), these points will fill up the intervals (rationally independent case) quite well. Figure 4.3 shows some of the roots of (4.15) for the delays $(R_1, R_2) = (\frac{1}{k}, \frac{8}{k})$, which correspond to line D in Figure 4.2. For computational convenience these delays are chosen to be rationally dependent, but the resonance is relatively weak: the two intervals predicted by Figure 4.2 are already visible. The two real roots correspond to the intersection of curves D and C in Figure 4.2.

One can remark that when the delays approach zero the imaginary parts of the nonreal roots increase to infinity. As already mentioned, when dealing with practical control problems the question arises whether the damping at very high frequencies is underestimated in the model (and the corresponding exponential polynomial) or not. In any case the large real roots are important. When one can estimate the ratio of the delays in the real system, one can predict whether such unstable behavior occurs, using diagrams like Figure 4.2.

4.5. Degenerate case. We call the exponential polynomial (4.6) degenerate if and only if all solutions with $R \geq 0$ of

$$1 - \sum_{i \in I} a_i e^{-\gamma_i \cdot R} e^{-i\gamma_i \cdot \theta} = 0 \tag{4.17}$$

satisfy

$$\gamma_i \cdot R = 0 \text{ or } \gamma_i \cdot R = +\infty \quad \forall i \in I.$$

[1] A (positive) rational number a is close to an irrational number if and only if $a = \frac{N_1}{N_2}$, whereby N_1 and $N_2 \in \mathbb{N}$ are large and coprime.

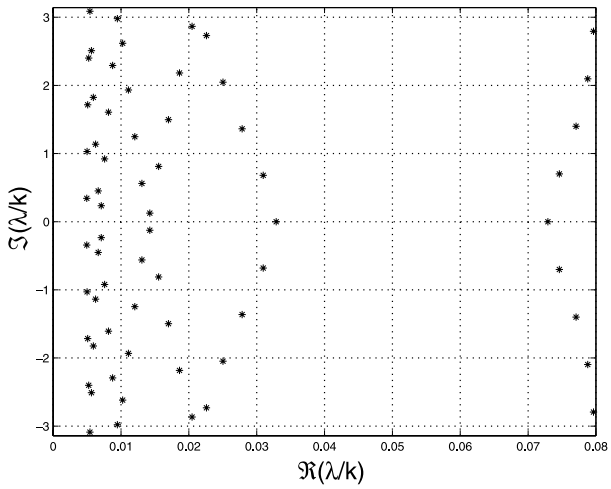

FIG. 4.3. *Part of the spectrum of* (4.15) *for the delays* $(r_1, r_2) = (\frac{1}{k}, \frac{8}{k})$*, corresponding to the dashed line* D *in Figure* 4.2.

For instance,

$$1 - \sum_{i=1}^{N} a_i \left(e^{-\lambda . r}\right)^i - \sum_{j \in J} b_j e^{-\lambda(\gamma_j r + \nu_j \cdot s)} = 0$$

is degenerate if and only if the polynomial $1 - \sum_{i=1}^{N} a_i x^i$ has some roots on, and all other roots outside, the unit circle. For $N = 2$, the equation $1 - a_1 e^{-\lambda r_1} - a_2 e^{-\lambda r_2} - \sum_{j \in J} b_j e^{-\lambda(\gamma_j \cdot r + \nu_j \cdot s)} = 0$ is degenerate if and only if $|a_1| + |a_2| = 1$.

Note that we are now in the case where statement (b) is not satisfied in Theorems 4.2 and 4.3. By means of an example, we show that in such a situation the large-delay part plays a role in the existence of arbitrarily large characteristic roots for vanishing delays. Therefore, consider first

$$H(\lambda, h) \triangleq 1 + e^{-h\lambda} + e^{-2\lambda} - e^{-(2+h)\lambda} = 0, \tag{4.18}$$

whose "small-delay" part is degenerate. With

$$h_n = \tfrac{1}{n+\frac{1}{2}}, \qquad d_n = (n + \tfrac{1}{2})\pi,$$

we have

$$H(c + id_n, h_n) = 0 \Leftrightarrow e^{-ch_n} = \tanh(c);$$

hence there are roots with arbitrarily large real part as $n \to \infty$. However, when one modifies (4.18) to

$$1 + e^{-h\lambda} + e^{-2\lambda} + e^{-(2+h)\lambda} = 0, \tag{4.19}$$

degeneration is preserved while there are *no* roots with arbitrarily large real part since (4.19) can be factored into $(1 + e^{-h\lambda})(1 + e^{-2\lambda})$.

5. Largest delays coincide. In the previous section we showed that in the presence of both normal and arbitrarily small delays there may exist roots with arbitrarily large real part. An analogous phenomenon occurs when the largest delays are arbitrarily close together. Then roots may exist with real part moving to $-\infty$. From a control point of view this phenomenon is less important (no stability problem), and therefore we give only an illustrative example. Sufficient and necessary conditions can be found in [18].

In the characteristic equation,

$$1 + e^{-\lambda} - 3e^{-\lambda 2} + 2e^{-\lambda(2+h)} = 0, \tag{5.1}$$

the largest delays 2 and $2 + h$ coincide as $h \to 0$. Multiplying this equation by $e^{\lambda 2}$ yields

$$e^{\lambda 2} + e^{\lambda} - 3 + 2e^{-\lambda h} = 0,$$

and the roots of $-3 + 2e^{-\lambda h}$,

$$\lambda = \frac{-\log(3/2) + i2\pi l}{h}, \quad l \in \mathbb{N},$$

approximate corresponding roots of (5.1) as $h \to 0+$.

6. Applications and examples. We illustrate the results obtained in this paper by means of two examples.

6.1. Boundary controlled PDE. This example and the phenomena which occur are also described in [5, 16]. Consider

$$w_{xx} = w_{tt}, \quad 0 \le t < \infty, \quad 0 \le x \le 1, \tag{6.1}$$

subject to the boundary conditions

$$\begin{cases} w(0,t) = 0, \\ w_x(1,t) = -kw_t(1,t-h), \end{cases} \tag{6.2}$$

where $h \ge 0$, $k > 0$. Formulae (6.1) and (6.2) describe the transversal movement of a beam clamped at one side and stabilized by applying a force at the other side; h represents a small delay in the velocity feedback. Substituting a solution of the form $w(x,t) = e^{\lambda t}z(x)$ into (6.1) and taking the boundary conditions into account, the following characteristic equation is obtained:

$$e^{\lambda h} + k\tanh(\lambda) = 0, \tag{6.3}$$

which can be rewritten as

$$1 + e^{-\lambda 2} + ke^{-\lambda h} - ke^{-\lambda(2+h)} = 0. \tag{6.4}$$

Remark. The damped wave equation $\bar{w}_{tt} - \bar{w}_{xx} + 2a\bar{w}_t + a^2\bar{w} = 0$ with boundary conditions $\bar{w}(0,t) = 0$ and $\bar{w}_x(1,t) = -\bar{k}\bar{w}_t(1,t-h)$, which was analyzed in [16], can be transformed into (6.1)–(6.2) using the relations $\bar{k} = e^{-ah}k$, $\bar{w} = e^{-at}w$, the latter introducing a shift a of the spectrum.

6.1.1. Analysis of the undelayed case. When $h = 0$, the characteristic roots are

$$\lambda = -\frac{1}{2}\mathrm{Log}\left(\frac{1+k}{1-k}\right) + i\pi l, \quad l \in \mathbb{Z},$$

where Log denotes the principal value of the logarithm. Because $c(0) = \Re(\mathrm{Log}(\frac{1+k}{1-k})) < 0$ for $k > 0$, the undelayed system is stable, i.e., all roots lie in the left half plane. When k approaches 1, the real part of the characteristic roots moves to $-\infty$, which indicates superstability. This can be explained as follows. The general solution of (6.1) can be written as a combination of two travelling waves, a solution $\phi(x-t)$ moving to the right and a solution $\psi(x+t)$ moving to the left. When $k = 1$, $\phi(x-t)$ satisfies the second boundary condition, and thus the reflection coefficient at $x = 1$ is zero; at $x = 0$ the wave $\phi(x+t)$ is reflected completely. Consequently, all perturbations disappear in a finite time (at most 2 time-units).

6.1.2. Analysis for arbitrarily small delays. Equation (6.4) is very interesting from a theoretical point of view. The three delays h, 2, and $2+h$ are functions of only two independent delays, 2 and h. When $h \to 0$ there is an arbitrarily small delay, and the largest delays asymptotically coincide.

When the delays 2 and h are rationally independent, c_{f} is calculated as the rightmost solution α of

$$1 + e^{-2\alpha}e^{-i\theta_1} + ke^{-i\theta_2} - ke^{-2\alpha}e^{-i(\theta_1+\theta_2)} = 0, \tag{6.5}$$

which, after multiplication with $e^{2\alpha}e^{i(\theta_1+\theta_2)}$, can be rewritten as

$$e^{2\alpha}e^{i\theta_1} = \frac{k - e^{i\theta_2}}{k + e^{i\theta_2}}$$

and can be interpreted for each α as the intersection points of two circles in the complex plane. Note that in this case the obtained upper bound will equal the upper bound calculated when all delays are considered independent:

$$|1-k| - e^{-2c_{\mathrm{f}}} - ke^{-2c_{\mathrm{f}}} = 0. \tag{6.6}$$

Indeed, (6.5) is transformed into (6.6) when choosing $\theta_1 = \theta_2 = \pi$ if $k < 1$ and $\theta_1 = 0$, $\theta_2 = \pi$ if $k > 1$. Thus the upper bound c_{f} in the case of rationally independent delays satisfies

$$c_{\mathrm{f}} = \frac{1}{2}\mathrm{Log}\left(\frac{1+k}{1-k}\right). \tag{6.7}$$

Following Theorem 4.2 there are characteristic roots with arbitrarily large real part (for arbitrarily small delays) if $\exists R \in (0, +\infty]$ and $\theta \in [0, 2\pi]$ such that $1 + ke^{-R}e^{-i\theta} = 0$. This is the case when $k > 1$. These roots have large imaginary part (no solution with $\theta = 0$). When $k = 1$ we have a degenerate case: (6.4) becomes (4.18), for which the existence of an infinite spectrum is shown in subsection 4.5.

One can prove that there are roots whose real part moves off to $-\infty$ for vanishing h when $k < 1$ [18].

The obtained results are summarized in Figure 6.1.

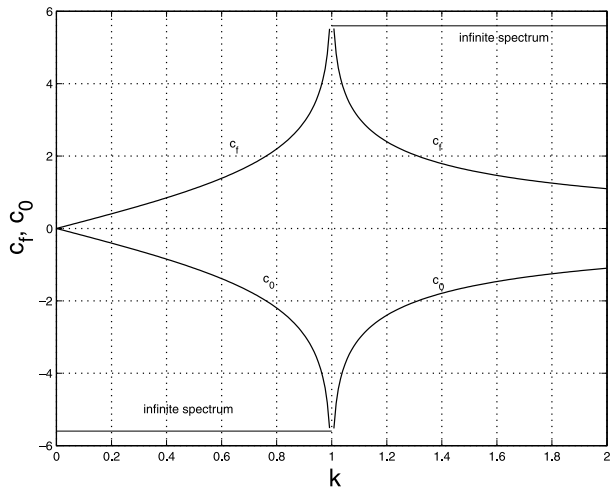

FIG. 6.1. *Upper bounds on the spectrum of* (6.1): $c(0) = c_0$ *is the real part of all characteristic roots in the undelayed case,* c_f *the supremum of the finite part of the spectrum for an arbitrarily small delay,* $h \to 0+$.

6.2. Bifurcation diagram: Parameter dependence. As a last example, we discuss the position of the roots of the characteristic equation

$$1 + ae^{-\lambda h} + be^{-\lambda 2h} \tag{6.8}$$

as a function of the parameters a and b. Note that (3.1) is a special case of (6.8).

First we fix h. The delays h and $2h$ are clearly dependent, and the roots of (6.8) can be calculated from

$$e^{-\lambda h} = \frac{-a \pm \sqrt{a^2 - 4b}}{2b}. \tag{6.9}$$

Hence when $a^2 - 4b < 0$ (> 0) the spectrum is situated on one (two) vertical lines in the complex plane. The positions of these lines depend on the parameters. For $a^2 - 4b > 0$, one can show that such a line crosses the imaginary axis when $a = b + 1$ and when $a = -b - 1$, indicating a change of stability of the line under consideration. When $a^2 - 4b < 0$, the single line crosses the imaginary axis when $b = 1$. The corresponding curves in two-parameter space (a, b) are shown in Figure 6.2.

When h and $2h$ should be considered to be independent, i.e., when these delays are perturbed in such a way that their rational dependency is lost, the upper bound $c(h)$ can be calculated from

$$1 - |a|e^{-c(h)h} - |b|e^{-2c(h)h} = 0,$$

and thus the system is stable when $|a| + |b| \leq 1$. Comparing the dependent with the independent case, one can see that the dangerous area in the parameter space, i.e., the parameter values for which small changes in the delays destroy stability, is enclosed by the triangles $(0, 1), (1, 0), (1, 2)$ and $(0, -1), (1, 0), (1, -2)$ (see Figure 6.2).

Equation (6.8) corresponds to the small-delay part of

$$1 + ae^{-\lambda h} + be^{-\lambda 2h} + de^{-\lambda} = 0 \tag{6.10}$$

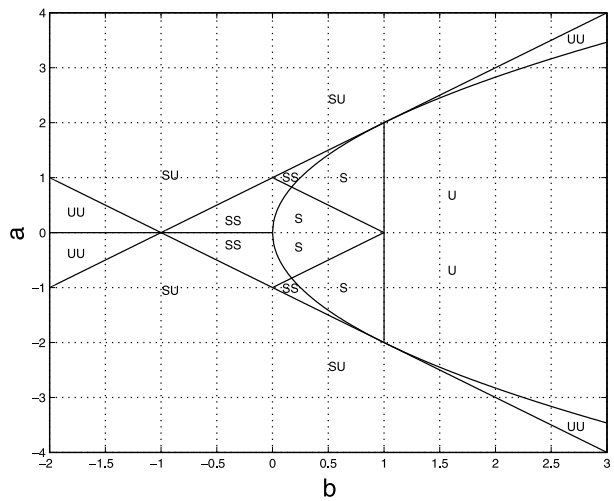

FIG. 6.2. *Stability areas of* (6.8). *When the delays are dependent, "S" denotes a stable vertical line of characteristic roots in the complex plane, and "U" an unstable line. When the delays are independent, the system is stable for parameter values inside the curve* $|a| + |b| = 1$.

as $h \to 0+$. One can show that when the three delays are considered to be independent, (6.10) has roots with real part $\to \infty$ for parameter values a and b outside the curve $|a| + |b| = 1$, and that there are arbitrarily unstable roots with small imaginary part when $b < \frac{a^2}{4}$ if $a \leq -2$ and $b < -a - 1$ if $a \geq -2$. All roots of (6.10) are in the open left half plane when $|a| + |b| < 1$ and $|d| < 1 - |a| - |b|$.

7. Conclusions. Sensitivity of NFDEs to infinitesimal changes of the delays is caused by the behavior of the essential spectrum which is determined by the roots of an exponential polynomial. A remarkable conclusion of the theory developed in [1, 9], concerning the roots of exponential polynomials, is that the supremum of the real parts of the spectrum can change discontinuously w.r.t. the delays, whereas the individual roots move continuously. In the first part of this paper the underlying mechanisms are interpreted and explained by means of spectral plots. For example, when rationally independent delays approach rationally dependent delays, this gives rise to a pointwise but nonuniform convergence of the spectrum, whereby the sensitivity of an individual root increases as its modulus increases. In a second part, we extend the theory developed in [1] to the case where some of the delays are arbitrarily small, which can result in characteristic roots with arbitrarily large real part. Sufficient and necessary conditions are provided. Thereby we also treat the special case of roots with large real part but small imaginary part. We further show that when the small delays are brought to zero in a fixed ratio, the structure of the set of the roots with large real part depends strongly on this ratio. The paper ends with two illustrative examples.

Appendix. We formulate a lemma which is used in the proof of Theorem 4.2. The lemma is a modification of Hurwitz's theorem; see, e.g., [3].

LEMMA A.1. *Let* $f(\lambda)$ *and the sequence* $\{f_n(\lambda)\}_{n\geq 1}$ *be analytic functions on an (open) domain* D. *Suppose that* $\{f_n(\lambda)\}_{n\geq 1}$ *converges uniformly to* $f(\lambda)$ *on the disc* $\{\lambda : |\lambda| \leq R\} \subset D$ *for some* $R > 0$, *and that on this disc* $f(\lambda)$ *only has a zero in* $\lambda = 0$ *with multiplicity* k. *Then there exists a number* $N \in \mathbb{N}$ *such that,* $\forall n \geq N$, $f_n(\lambda)$ *has exactly* k *zeros* $\lambda_{n,1}, \ldots, \lambda_{n,k}$ *in* $|\lambda| \leq R$, *whereby* $\lim_{n\to\infty} \lambda_{n,j} = 0$ $\forall j \in \{1, \ldots, k\}$.

Proof. Consider for some $0 < r \leq R$ the curve $\Gamma : [0, 2\pi] \to \mathbb{C} : t \to \Gamma(t) = re^{it}$. The function $|f(\lambda)|$ attains a minimum M on Γ whereby $M > 0$. Because the sequence of functions $f_n(\lambda)$ is uniformly converging,

$$\exists N \text{ such that } \forall n \geq N : |f_n(\lambda) - f(\lambda)| < M \leq |f(\lambda)| \text{ on } \Gamma.$$

Consequently,

$$\left| 1 - \frac{f_n(\lambda)}{f(\lambda)} \right| < 1$$

on Γ.

For each $n \geq N$ the curve $\gamma(t) = \frac{f_n(re^{it})}{f(re^{it})}, \quad t \in [0, 2\pi]$, satisfies

$$|1 - \gamma_n(t)| < 1,$$

and, because it can be embedded in a closed disc not containing the origin, the winding number of the curve w.r.t. the origin, $n(\gamma_n, 0)$, is zero:

$$n(\gamma_n, 0) = \frac{1}{2\pi i} \int_{\gamma_n} \frac{d\lambda}{\lambda} = \frac{1}{2\pi i} \int_0^{2\pi} \frac{\gamma_n'(t)}{\gamma_n(t)} dt = 0.$$

Using the definition of $\gamma_n(t)$, $\frac{1}{2\pi i} \int_0^{2\pi} \frac{\gamma_n'(t)}{\gamma_n(t)} dt$ can be written as $\frac{1}{2\pi i} \int_\Gamma (\frac{f_n'(\lambda)}{f_n(\lambda)} - \frac{f'(\lambda)}{f(\lambda)}) d\lambda$. This integral is well defined because from the previous it follows that neither f_n nor f are zero in $\{\lambda : r - \epsilon_n < |\lambda| < r + \epsilon_n\}$ for some $\epsilon_n \in \mathbb{R}_0^+$.

But this implies

$$\frac{1}{2\pi i} \int_\Gamma \frac{f'}{f} d\lambda = \frac{1}{2\pi i} \int_\Gamma \frac{f_n'}{f_n} d\lambda \quad \forall n \geq N.$$

Following the theorem of the principle of the argument (see, for example, [22]), these integrals correspond to the zero-pole excess of f and f_n (number of zeros − number of poles) inside Γ and in this case to the number of zeros. When taking $r = R$ the first statement of the lemma is proven. The second statement follows from the fact that r can be chosen arbitrarily small. ∎

VISCOSITY SOLUTIONS METHODS FOR SINGULAR PERTURBATIONS IN DETERMINISTIC AND STOCHASTIC CONTROL*

OLIVIER ALVAREZ† AND MARTINO BARDI‡

Abstract. Viscosity solutions methods are used to pass to the limit in some penalization problems for first order and second order, degenerate parabolic, Hamilton–Jacobi–Bellman equations. This characterizes the limit of the value functions of singularly perturbed optimal control problems for deterministic systems and for controlled degenerate diffusions. The results apply to cases where the usual order reduction method does not give the correct limit, and to systems with fast state variables depending nonlinearly on the control. Some connections with ergodic control and periodic homogenization are discussed.

Key words. singular perturbations, deterministic optimal control, stochastic optimal control, nonlinear systems, order reduction, viscosity solutions, Hamilton–Jacobi–Bellman equations, penalization, periodic homogenization, ergodic control, state constraints

Introduction. In this paper we study three penalization problems for fully nonlinear partial differential equations motivated by the optimal control theory for systems with different time scales. In all the problems the limit PDE is of lower dimension, and the limit operator is not obvious to guess. Problems of this kind were first studied by Jensen and Lions [29] for classic solutions of quasilinear uniformly elliptic PDEs. Here we study a first order Hamilton–Jacobi (H–J) equation and a degenerate parabolic, fully nonlinear, Hamilton–Jacobi–Bellman (H–J–B) equation in the framework of viscosity solutions.

The first problem we consider is the limit as $\varepsilon \to 0+$ of

$$-\partial_t u_\varepsilon + H\left(x, y, D_x u_\varepsilon, \frac{D_y u_\varepsilon}{\varepsilon}\right) = 0 \quad \text{in } (0,T)\times\mathbb{R}^n \times Y \tag{1}$$

for the Hamiltonian

$$H(x,y,p,q) = \max_{\alpha\in A}\{-(p, f(x,y,\alpha)) - (q, g(x,y,\alpha)) - l(x,y,\alpha)\},$$

where $(\cdot,\cdot)$ denotes the scalar product, and $Y \subseteq \mathbb{R}^m$ is open, bounded, connected, and smooth. This is the H–J–B equation associated via dynamic programming with the minimization of the functional

$$J(t,x,y,\alpha.) := \int_t^T l(x_s, y_s, \alpha_s)\, ds + h(x_T, y_T)$$

on the trajectories of the system

$$\dot{x}_s = f(x_s, y_s, \alpha_s), \qquad \dot{y}_s = \frac{1}{\varepsilon} g(x_s, y_s, \alpha_s), \tag{2}$$

with $x_t = x$, $y_t = y$, where $\alpha_\cdot$ is the control function subject to $\alpha_s \in A$. Singular perturbation problems for deterministic controlled systems were studied by many authors; see, e.g., the books by Kokotović, Khalil, and O'Reilly [32], Bensoussan [12], and Dontchev and Zolezzi [18], as well as the recent articles by Artstein and Gaitsgory [22, 4, 3, 5], Veliov [40], Subbotina [39], Bagagiolo and Bardi [6], and the references therein. We recall that the theory of singular perturbations has many important applications, in particular to the order reduction of large scale systems.

As in [6] (see also [9, 7]) we assume the Hamiltonian H to be coercive in the $q = D_y u$ variables, which amounts to the complete controllability of the fast variables y of the system, and consider the boundary condition on ∂Y corresponding to the state-space constraint on the fast variables

$$y_s \in \overline{Y} \quad \text{for all } t \le s \le T.$$

In [6] a separability assumption on the controls acting on the fast and the slow variables yielded a simple explicit formula for the Hamiltonian $\overline{H}$ of the limit PDE. Here we show that in general the limit Hamiltonian $\overline{H} = \overline{H}(x,p)$ is the unique constant such that the boundary value problem

$$H(x, y, p, D_y\chi) \ge \overline{H} \quad \text{in } \overline{Y}, \qquad H(x, y, p, D_y\chi) \le \overline{H} \quad \text{in } Y$$

has a viscosity solution $\chi = \chi(y)$ for fixed (x,p). The existence and uniqueness of the *effective Hamiltonian* $\overline{H}$ was proved by Capuzzo-Dolcetta and Lions [16] in connection with ergodic control problems. We prove that the viscosity solution $u_\varepsilon(t,x,y)$ of (1) with constrained boundary conditions on ∂Y and the terminal condition

$$u_\varepsilon(T, x, y) = h(x, y)$$

converges uniformly as $\varepsilon \to 0+$ to the viscosity solution $u = u(t,x)$ of

$$-\partial_t u + \overline{H}(x, Du) = 0 \text{ in } (0,T) \times \mathbb{R}^n \quad \text{and} \quad u(T,x) = \underline{h}(x) := \inf_y h(x,y) \text{ for } x \in \mathbb{R}^n.$$

The effective Hamiltonian $\overline{H}$ admits a representation as the long time limit of the value function of a control problem in $\overline{Y} \subseteq \mathbb{R}^m$; see [16, 9]. This formula shows the strong connection between our result and the recent work of Artstein and Gaitsgory [5], even if they do not consider state constraints, make somewhat different assumptions, and use completely different methods. We also give a new representation of $\overline{H}$ as the Bellman Hamiltonian associated to a suitable set of "limiting" relaxed controls. This provides an interpretation of the limit u as the value function of an optimal control problem with n-dimensional state space, which is therefore the appropriate limit of the previous problem for the $(n+m)$-dimensional system (2) as $\varepsilon \to 0+$. One might guess from (2) that in the limit the fast variables satisfy $g(x_s, y_s, \alpha_s) \equiv 0$ and the Hamiltonian becomes

$$H_0(x,p) := \sup_{\{(\alpha,y):\, g(x,y,\alpha)=0\}} \{-(p, f(x,y,\alpha)) - l(x,y,\alpha)\}.$$

This is indeed the case in many classic problems [32, 12], and we give some examples where $\overline{H} = H_0$. In general, however, $H_0(x,p) \le \overline{H}(x,p)$ and the inequality can be

strict when the fast variables oscillate very rapidly in the limit. In this case we can pass to the limit because an averaging phenomenon occurs; this was studied, for instance, in [22, 4, 5, 41], and see the references therein for earlier literature on averaging in ordinary differential equations. Our main new contribution is a PDE approach to the problem, where the theory of viscosity solutions provides many useful tools: the characterization of the effective Hamiltonian, the perturbed test function method of Evans [19, 20], and the relaxed semilimits of Barles and Perthame [11, 9] that we slightly modify here.

The viscosity solutions methods allow us to treat our second and third problem in a very similar way. They are the limits as $\varepsilon \to 0+$ of

$$-\partial_t u_\varepsilon + H\left(x, y, D_x u_\varepsilon, \frac{D_y u_\varepsilon}{\varepsilon}, D^2_{xx} u_\varepsilon, \frac{D^2_{yy} u_\varepsilon}{\varepsilon^{2\gamma}}, \frac{D^2_{xy} u_\varepsilon}{\varepsilon^{\gamma}}\right) = 0 \quad \text{in } (0,T)\times\mathbb{R}^n \times Y$$

for $\gamma = \frac{1}{2}$ and $\gamma = 1$, respectively, where

$$H(x,y,p,q,X,Y,Z) = \sup_{\alpha\in A}\left\{-\frac{1}{2}[\operatorname{tr}(\sigma\sigma^T X) + \operatorname{tr}(\tau\tau^T Y) + \operatorname{tr}(\tau\sigma^T Z) + \operatorname{tr}(Z\tau\sigma^T)]\right.$$
$$\left. -(p, f(x,y,\alpha)) - (q, g(x,y,\alpha)) - l(x,y,\alpha)\right\},$$

and the coefficients σ, τ, f, g, l are functions of (x, y, α). This is the fully nonlinear, degenerate parabolic, H–J–B equation arising in the minimization of the expectation $E\,J(t,x,y,\alpha)$ for the singularly perturbed controlled degenerate diffusion process

$$\begin{aligned} dx_s &= f(x_s, y_s, \alpha_s)\,ds + \sigma(x_s, y_s, \alpha_s)\,dW_s, \\ dy_s &= \frac{1}{\varepsilon} g(x_s, y_s, \alpha_s)\,ds + \frac{1}{\varepsilon^\gamma}\tau(x_s, y_s, \alpha_s)\,dW_s. \end{aligned} \tag{3}$$

Problems of this nature with $\gamma = 1/2$ can be found in [12] for dispersion matrices σ, τ that are not degenerate and are independent of α, and in the book by Kushner [33] for possibly degenerate diffusions that are still independent of α and for uncontrolled fast drift g. The more recent papers by Kabanov and colleagues [31, 30], for $\gamma < 1/2$ and $\gamma = 1/2$, respectively, allow the fast drift to depend linearly on the control, whereas both dispersion matrices are uncontrolled. Here we allow all the terms of the fast dynamics to depend nonlinearly on the control. On the other hand, we limit ourselves to the case of fast variables constrained on an m-dimensional torus, that is, $Y = [0,1]^m$, all the data are 1-periodic in the y variable, and periodic boundary conditions are imposed on ∂Y. In this case the existence, uniqueness, and representation of the effective (second order) Hamiltonian can be taken from a recent article by Arisawa and Lions [2], and the simplicity of the boundary conditions reduces the technical difficulties of the proof. Moreover, we do not try here to represent the solution of the limit problem as a value function, nor to prove the convergence of nearly optimal controls. Among other technical conditions, we suppose that the terminal cost h is independent of y and make some mild restrictions on the slow dynamics. Concerning assumptions about fast dynamics, we shall make the one introduced by Arisawa and Lions [2] that guarantees some averaging behavior (ergodicity) in the fast dynamics.

Section 2 is devoted to the classic scaling of (3) corresponding to $\gamma = 1/2$. Our results include the following three cases as well as several combinations.

- The diffusions (in the fast and slow variables) are uniformly nondegenerate.
- The problem is deterministic and the dynamical system in the fast variable is controllable.
- The system in the fast variable is independent of x and y and satisfies the nonresonance condition of [2] (see section 2 for a precise statement).

The second case is the one covered by the first section in the state constraint setting. We remark that we have to make some nontrivial modifications to the perturbed test function method of Evans [20] in order to avoid the crucial assumption that the Hamiltonian be uniformly continuous in all variables. For control problems this corresponds to the restrictive condition that the dynamics do not depend on the state variables.

Section 3 discusses the less usual case $\gamma = 1$. Our motivation for studying this scaling is homogenization. For this problem, the dynamical system is

$$dx_s = f\left(x_s, \frac{x_s}{\varepsilon}, \alpha_s\right) ds + \sigma\left(x_s, \frac{x_s}{\varepsilon}, \alpha_s\right) dW_s.$$

This corresponds to the singular perturbation problem for the artificial fast variable $y_s = x_s/\varepsilon$ with $\gamma = 1$, $g = f$, and $\tau = \sigma$. For homogenization, our assumption is one of the following:

- The diffusion is uniformly nondegenerate.
- The problem is deterministic and controllable.
- The system is purely stochastic ($f \equiv 0$), is independent of x and y, and satisfies the nonresonance condition.

In this generality, the results for the stochastic problems seem to be new. They extend in various ways previous work on periodic homogenization for uniformly elliptic, nondivergence form, quasilinear equations by Bensoussan, Boccardo, and Murat [13] and Evans [19, 20], and for first order H–J equations by Lions, Papanicolaou, and Varadhan [35] and Evans [20]. See also the additional references on the viscosity solutions approach to homogenization in section 3.

The main goal of this paper is to illustrate a unified PDE approach to singular perturbations for deterministic and stochastic systems, and we do not pursue the minimal assumptions. We believe our method works for several other problems such as, for instance, deterministic systems under weaker controllability assumptions or with state constraints on the slow variables x as well, and stochastic systems with fast variables subject to more general state constraints or governed by a diffusion reflected on ∂Y (giving raise to Neumann boundary conditions). We will come back to some of these problems in future papers.

The first application of viscosity solutions methods to singular perturbation problems in control goes back to Lions [34], and more references can be found in [6]. To our knowledge the present paper is the first using these methods for the second order PDEs associated with controlled diffusion processes.

1. Deterministic control with state constraints on the fast variables.

1.1. The ε-problem. Let $T > 0$ be fixed. For every $\varepsilon > 0$, we consider the control problem in $(0, T] \times \mathbb{R}^n \times \mathbb{R}^m$ with dynamics

$$\dot{x}_s = f(x_s, y_s, \alpha_s), \qquad \dot{y}_s = \frac{1}{\varepsilon} g(x_s, y_s, \alpha_s)$$

for $s \geq t$, with $x_t = x$, $y_t = y$, and the constraint on the fast variables

$$y_s \in \overline{Y} \quad \text{for all } t \leq s \leq T,$$

where $\overline{Y} \subseteq \mathbb{R}^m$ is a given compact set. The control functions are measurable $\alpha : (0,T] \to A$, where A is a compact set, such that the corresponding trajectory satisfies the state constraint; we denote this set with $\mathcal{A}_{(x,y)}$. The value function is defined on $(0,T] \times \mathbb{R}^n \times \overline{Y}$ by

$$u_\varepsilon(t,x,y) = \inf_{\alpha \in \mathcal{A}_{(x,y)}} \left\{ \int_t^T l(x_s, y_s, \alpha_s)\, ds + h(x_T, y_T) \right\}.$$

Now we begin to list the hypotheses of section 1. The list will end at the beginning of the next subsection.

— A is a compact metric space.

— $Y \subseteq \mathbb{R}^m$ is a bounded connected open set with Lipschitz boundary in the following sense: there exist $\eta : \overline{Y} \to \mathbb{R}^m$ bounded and uniformly continuous and $c > 0$ such that

$$B(y + t\eta(y), ct) \subseteq Y \quad \text{for all } y \in \overline{Y},\ 0 < t \le c. \tag{4}$$

— The functions f, g, l, and h are continuous and bounded.

— The functions f and g are Lipschitz continuous in (x,y) uniformly in α; the functions l and h are uniformly continuous in (x,y) uniformly in α.

We set

$$\underline{h}(x) = \inf_y h(x,y).$$

It is easy to see that under the preceding hypotheses $\underline{h}$ is uniformly continuous and bounded.

We continue the list of hypotheses.

— The problem is controllable in y, i.e., there exists $r > 0$ such that

$$B(0,r) \subset \overline{\text{conv}}\{g(x,y,\alpha) \mid \alpha \in A\}.$$

— $\mathcal{A}_{(x,y)} \neq \emptyset$ for all $y \in \overline{Y}$, and u_ε is continuous in $(0,T] \times \mathbb{R}^n \times \overline{Y}$.

Remark. The last assumption is not a consequence of the previous hypotheses on the data if the boundary of Y has corners and $g(x,y,A)$ is not convex, as it is easy to see on simple examples. However, it is automatically satisfied if the boundary is smooth, say C^2, by a result of Soner (see [37] or sect. IV.5 of [9]), based on the "interior field condition"

$$\min_{a \in A} g(x,y,a) \cdot n(y) < 0 \quad \text{for all } y \in \partial Y,\ x \in \mathbb{R}^n,$$

where $n(y)$ is the exterior normal to Y at y, which holds in our case because of the controllability assumption on the fast variables. A more general sufficient condition for the continuity of u_ε that allows for piecewise smooth ∂Y is the following:

$$\overline{Y} = \{y \in \mathbb{R}^m \mid g_i(y) \le 0 \quad \text{for all } i = 1, \dots, p\}$$

for some $g_i \in C^{1,1}(\mathbb{R}^m)$ with $|Dg_i| > 0$, $i = 1, \dots, p$, and

$$\min_{a \in A} \max_{\{i \mid g_i(y) = 0\}} g(x,y,a) \cdot Dg_i(y) < 0 \quad \text{for all } y \in \partial Y,\ x \in \mathbb{R}^n. \tag{5}$$

This is proved in Theorem A.1 of [6]. Note that (5) is automatically satisfied if $g(x,y,A)$ is convex, in addition to the controllability assumption. In the general case

of merely Lipschitz ∂Y, a suitable formulation of the interior field condition can be found in the paper of Ishii and Koike [27], where the continuity of the value function is proved for the infinite horizon problem.

THEOREM 1. *The value function u_ε is the unique viscosity solution in $BC((0,T]\times\mathbb{R}^n\times\overline{Y})$ of the terminal-boundary value problem*

$$\begin{cases} -\partial_t u_\varepsilon + H(x,y,D_x u_\varepsilon, \frac{D_y u_\varepsilon}{\varepsilon}) \geq 0 & \text{in } (0,T)\times\mathbb{R}^n\times\overline{Y}, \\ -\partial_t u_\varepsilon + H(x,y,D_x u_\varepsilon, \frac{D_y u_\varepsilon}{\varepsilon}) \leq 0 & \text{in } (0,T)\times\mathbb{R}^n\times Y, \\ u(T,\cdot) = h \quad \text{in } \mathbb{R}^n\times\overline{Y}, \end{cases} \tag{6}$$

for the Hamiltonian

$$H(x,y,p,q) = \max_{\alpha\in A}\{-(p,f(x,y,\alpha)) - (q,g(x,y,\alpha)) - l(x,y,\alpha)\}.$$

Proof. The fact that a continuous value function satisfies the appropriate H–J–B equation in the viscosity sense is a standard consequence of the dynamic programming principle; for the boundary condition on ∂Y due to the state constraint, see [37] or [9]. The uniqueness can be proved by combining the proof of Theorem III.3.7 in [9] with Soner's argument on ∂Y (see [37] or sect. IV.5 of [9]). □

1.2. The effective Hamiltonian and the limit problem. We introduce the auxiliary m-dimensional system with the same vector field as the fast variables but with $\varepsilon = 1$ and frozen x

$$\dot{y}_s = g(x,y_s,\alpha_s), \qquad y_0 = y,$$

and denote with $\mathcal{A}_y = \mathcal{A}_y^x$ the set of measurable $\alpha : (0,T] \to A$ such that $y_s \in \overline{Y}$ for all $s \geq 0$. In this subsection the notation y_s will always be used for trajectories of this system for some admissible $\alpha \in \mathcal{A}_y$ and fixed x. Our last hypothesis is the following.

— For all $y \in \partial Y$, $x \in \mathbb{R}^n$, and $\varepsilon > 0$ there are controls in $\mathcal{A}_y$ such that the corresponding trajectory satisfies $y_\varepsilon \in Y$ and $y_{-\varepsilon} \in Y$, respectively.

Remark. This assumption follows immediately from the controllability hypothesis if ∂Y is smooth or if $g(x,y,A)$ is convex.

THEOREM 2. *For fixed $(\overline{x},\overline{p})$ there exists a unique constant $\lambda = \overline{H}(\overline{x},\overline{p})$ such that the problem*

$$H(\overline{x},y,\overline{p},D_y\chi) \geq \lambda \quad \text{in } \overline{Y}, \qquad H(\overline{x},y,\overline{p},D_y\chi) \leq \lambda \quad \text{in } Y \tag{7}$$

has a Lipschitz continuous solution χ. Moreover, $\overline{H}(\overline{x},\overline{p}) = \lim_{\delta\to 0+}\delta w_{\delta,\overline{x},\overline{p}}(y)$ uniformly in y, where

$$w_{\delta,x,p}(y) := \sup_{\alpha\in\mathcal{A}_y}\left\{\int_0^{+\infty} e^{-\delta s}\big(-(p,f(x,y_s,\alpha_s)) - l(x,y_s,\alpha_s)\big)\,ds \;\middle|\; \dot{y}_s = g(x,y_s,\alpha_s), y_0 = y\right\},$$

and $Lip(\chi) \leq Cr^{-1}(||l||_\infty + |\overline{p}|\,||f||_\infty)$, where C depends only on the set Y and r is the radius appearing in the controllability assumption.

For the proof we need the following property of sets with Lipschitz boundary.

LEMMA 3. *Let Y be a bounded connected open set with Lipschitz boundary, i.e.,* (4) *holds, and define*

$$d(y,\overline{y}) := \inf\{length(\gamma)|\,\gamma \subseteq Y \text{ polygonal with endpoints } y \text{ and } \overline{y}\}.$$

Then

(i) *there exist $\rho, C > 0$ such that for all $z \in \overline{Y}$*

$$d(y,\overline{y}) \le C|y-\overline{y}| \qquad \text{for all } y,\overline{y} \in Y \cap B(z,\rho);$$

(ii) *there exists $M > 0$ such that all $y,\overline{y} \in \overline{Y}$ can be joined by a polygonal $\gamma \subset \overline{Y}$ with $length(\gamma) \le M$.*

Proof. Since Y is open and connected, d is finite for all $y,\overline{y} \in Y$. Let us first consider the case $z \in \partial Y$. By Proposition A.2 and Remark A.3 in [10] there exist $r', L > 0$ independent of z such that, in $B(z,2r')$, Y is the epigraph of a Lipschitz function defined on the hyperplane orthogonal to a vector ξ and with Lipschitz constant bounded by L. Then there is k independent of z such that

$$B(y+t\xi, kt) \subseteq Y \qquad \text{for all } 0 < t < k,\ y \in \overline{Y} \cap B(z,r').$$

If we set $v = y-\overline{y}/|y-\overline{y}|$, the segments $\{y+t\xi-tkv|\,0<t<k\}$ and $\{\overline{y}+t\xi+tkv|\,0<t<k\}$ lie in Y, and they intersect for $t = |y-\overline{y}|/2k$, which is acceptable for $|y-\overline{y}| < 2k^2$. Thus, for $\rho = r' \wedge 2k^2$, two points $y,\overline{y} \in \overline{Y} \cap B(z,\rho)$ can be joined by a polygonal of length $|y-\overline{y}|/k$ and lying in Y, except possibly for the endpoints. This proves (i) in a neighborhood of ∂Y, and (i) is trivial in the complement of this neighborhood.

To prove (ii), we redefine d by allowing polygonals $\gamma \subseteq \overline{Y}$. Since ∂Y is Lipschitz, $d(y,\overline{y})$ is finite for all $y,\overline{y} \in \overline{Y}$, and it is a metric on $\overline{Y}$. Moreover, it is locally uniformly equivalent to the Euclidean metric, because it satisfies (i) for all $y,\overline{y} \in \overline{Y} \cap B(z,\rho)$, whereas the inequality $|y-\overline{y}| \le d(y,\overline{y})$ is trivial. Then the topology induced by d is equivalent to the usual one, so $\overline{Y}$ is compact for this topology and therefore it is bounded for the metric d, which gives the desired conclusion. □

Proof of Theorem 2. The proof is essentially the same as that of Theorem VIII.1 in [16] or Theorem VII.1.1 in [9], once we prove that $w_\delta(\cdot) := w_{\delta,x,p}(\cdot)$ is Lipschitz with constant independent of δ. In fact, this implies that δw_δ converges uniformly to a constant λ as $\delta \to 0+$ and, for a fixed $y^* \in \overline{Y}$, $w_\delta(y) - w_\delta(y^*) \to \chi(y)$ uniformly, at least along a subsequence. By a standard viscosity solutions argument the pair (χ,λ) satisfies (7). An argument based on the comparison principle for constrained viscosity solutions shows the uniqueness of the constant λ in (7), so $\lambda = \lim_{\delta\to 0+} w_\delta(y)$.

To prove the Lipschitz estimate for w_δ we claim that for some $\rho > 0$, for all $z \in \overline{Y}$, $y,\overline{y} \in \overline{Y} \cap B(z,\rho)$, $\varepsilon > 0$, there exists a control in $\mathcal{A}_y$ such that

$$y_s = \overline{y}, \qquad s \le \frac{C}{r}|y-\overline{y}| + \varepsilon,$$

where C depends only on the set Y and r is the radius appearing in the controllability assumption. Then a simple argument yields

$$|w_\delta(y) - w_\delta(\overline{y})| \le \frac{C}{r}(||l||_\infty + |\overline{p}|\,||f||_\infty)|y-\overline{y}|, \tag{8}$$

as in Proposition III.2.3 of [9].

To prove the claim we first consider $y, \overline{y} \in Y \cap B(z,\rho)$, where ρ comes from Lemma 3(i), so that there is a polygonal $\gamma \subseteq Y$ of length $\sigma \le C|y-\overline{y}| + \varepsilon/2$ joining y and $\overline{y}$. By the controllability assumption and standard results in control theory, γ can be approximated uniformly by trajectories $y_\cdot$ in Y with speed r and $y_0 = y$. Then for any $\tau > 0$ there is a control in $\mathcal{A}_y$ such that $|y_{\sigma/r} - \overline{y}| \le \tau$, and by using the controllability again we build a trajectory in Y joining y and $\overline{y}$ in a time $s \le \sigma/r + \tau C'/r \le C|y-\overline{y}|/r + \varepsilon$, which proves the claim in this case.

If either y or $\overline{y}$ belongs to ∂Y, we use the assumption of this subsection to move y forward to some $y' \in Y$ and $\overline{y}$ backward to $\overline{y}' \in Y$, spending a time 2ε, then piece together these trajectories with the one previously built joining y' and $\overline{y}'$ and complete the proof of the claim.

Finally, the estimate on the Lipschitz constant of χ is obtained by letting $\delta \to 0+$ in (8). □

Remark. The effective Hamiltonian $-\overline{H}(x,p)$ is the optimal average cost of an ergodic control problem in the y variable, i.e., it satisfies the formula

$$\overline{H}(x,p) = \sup_{\alpha\in\mathcal{A}_y} \limsup_{t\to+\infty} \left\{ -\frac{1}{t}\int_0^t \big((p, f(x,y_s,\alpha_s)) + l(x,y_s,\alpha_s)\big)\, ds \right. \tag{9}$$
$$\left. \mid \dot{y}_s = g(x,y_s,\alpha_s), y_0 = y \right\}$$

for all $y \in \overline{Y}$, by Prop. VII.1.3 in [9]. It is also the rescaled limit of the value functions of finite horizon problems as the horizon goes to infinity:

$$\overline{H}(x,p) = \lim_{t\to+\infty} \sup_{\alpha\in\mathcal{A}_y} \left\{ -\frac{1}{t}\int_0^t \big((p, f(x,y_s,\alpha_s)) + l(x,y_s,\alpha_s)\big)\, ds \right. \tag{10}$$
$$\left. \mid \dot{y}_s = g(x,y_s,\alpha_s), y_0 = y \right\}$$

for all $y \in \overline{Y}$, and the convergence is uniform in y as $t \to +\infty$. To see this, consider the value function

$$v(t,y) = \inf_{\alpha\in\mathcal{A}_y} \left\{ \int_0^t \big((p, f(x,y_s,\alpha_s)) + l(x,y_s,\alpha_s)\big)\, ds \mid \dot{y}_s = g(x,y_s,\alpha_s), y_0 = y \right\}.$$

It solves the H–J equation

$$\begin{aligned} \partial_t v + H(\overline{x}, y, \overline{p}, D_y v) &\ge 0 \quad \text{in } (0,+\infty)\times\overline{Y}, \\ \partial_t v + H(\overline{x}, y, \overline{p}, D_y v) &\le 0 \quad \text{in } (0,+\infty)\times Y, \end{aligned}$$

with the initial condition $v(0,\cdot) \equiv 0$. By Theorem 2, the function $\chi(y) - t\overline{H}(\overline{x},\overline{p})$ is a solution of the same Cauchy problem but with a different initial condition. The comparison principle implies that $v(t,y) - \chi(y) + t\overline{H}(\overline{x},\overline{p})$ is bounded, so that $v(t,y)/t \to -\overline{H}(\overline{x},\overline{p})$ as $t \to +\infty$, uniformly in y. See also Theorem VIII.1 in [16] and Exercise VII.1.1 in [9].

Our next result gives the regularity of the effective Hamiltonian.

PROPOSITION 4. *The effective Hamiltonian $\overline{H}$ has the following properties:*

(i) *For all x, p*

$$\inf_y \inf_q H(x,y,p,q) \le \overline{H}(x,p) \le \sup_y H(x,y,p,0);$$

(ii) $\overline{H}$ *is convex in* p;
(iii) *for all* x, p, p'

$$|\overline{H}(x,p) - \overline{H}(x,p')| \le ||f||_\infty |p - p'|;$$

(iv) *for all* x, x', p

$$|\overline{H}(x',p) - \overline{H}(x,p)| \le Lip(f)|p|\,|x'-x| + \omega_l(|x'-x|) + Lip(g)C\frac{||l||_\infty + |p|\,||f||_\infty}{r}|x'-x|,$$

where ω_l *is the modulus of continuity of* l *with respect to* x *and* C *depends only on* Y;
(v) $\overline{H}$ *is uniformly continuous on* $\mathbb{R}^n \times B(0,R)$ *for all* $R > 0$.

The proof is essentially the same as that of Proposition 3 in [1]. The bound for the Lipschitz continuity in x follows easily from the bound on $Lip(\chi)$ of Theorem 2.

The last result of this subsection gives the solution of the limit problem.

PROPOSITION 5. *There exists a unique viscosity solution in* $BC((0,T] \times \mathbb{R}^n)$ *of*

$$-\partial_t u + \overline{H}(x, Du) = 0 \text{ in } (0,T) \times \mathbb{R}^n \quad \text{and} \quad u(T,\cdot) = \underline{h} \text{ on } \mathbb{R}^n. \tag{11}$$

Proof. In view of the regularity of $\overline{H}$, in particular of

$$|\overline{H}(x',p) - \overline{H}(x,p)| \le C|p|\,|x'-x| + \omega(|x'-x|),$$

where ω is a modulus, a comparison theorem holds for (11); see, e.g., Theorem III.3.7 and Exercise V.1.5 in [9]. The existence can be proved by the Perron–Ishii method (see, e.g., section V.2.2 of [9]), or by representing the effective Hamiltonian $\overline{H}$ as the Bellman Hamiltonian of a control problem and then proving that the value function of such a problem solves (11). □

1.3. An example: Separated controls. In [6] the controls acting on the slow and the fast variables are separated, in the sense that $\alpha = (\beta, \gamma) \in B \times C$ with

$$f = f(x,y,\beta), \quad l = l(x,y,\beta), \quad g = g(x,y,\gamma).$$

In this case the Hamiltonian of the ε-problem is

$$H(x,y,p,q) = H_1(x,y,p) + H_2(x,y,q),$$

$$H_1(x,y,p) := \max_{\beta\in B}\{-(p, f(x,y,\beta)) - l(x,y,\beta)\}, \quad H_2(x,y,q) = \sup_{\gamma\in C}\{-(q, g(x,y,\gamma))\},$$

and we expect that the effective Hamiltonian will be

$$\overline{H}(x,p) = \max_{y\in\overline{Y}} H_1(x,y,p). \tag{12}$$

In fact, from the representation (10) of $\overline{H}$ we get, for all $y \in \overline{Y}$,

$$\overline{H}(x,p) = \lim_{t\to+\infty} \sup_{\gamma_\cdot} \left\{ \frac{1}{t}\int_0^t H_1(x, y_s, p)\, ds \mid \dot{y}_s = g(x, y_s, \gamma_s),\ y_0 = y,\ y_s \in \overline{Y} \right\}. \tag{13}$$

This gives immediately $\overline{H}(x,p) \le \max_{y\in\overline{Y}} H_1(x,y,p)$. For the opposite inequality we fix $\overline{y}$ such that $H_1(x,\overline{y},p) = \max_y H_1(x,y,p)$. If there is a control $\overline{\gamma}$ such that $g(x,\overline{y},\overline{\gamma}) = 0$, we choose $y = \overline{y}$ in the right-hand side of (13) and the sup is attained

by $\gamma = \overline{\gamma}$ because the average cost is $H_1(x, \overline{y}, p)$. If such a control $\overline{\gamma}$ does not exist, but $\overline{y} \in Y$, we deduce from the controllability assumption on the fast variables that for any $\varepsilon > 0$ there is a control γ such that $y_0 = \overline{y}$ implies $|y_s - \overline{y}| \le \varepsilon$ for all $s > 0$. The average cost associated with this control is bounded below by $\inf_{B(\overline{y},\varepsilon)\cap\overline{Y}} H_1(x, y, p)$. By taking the limit as $\varepsilon \to 0$, the continuity of H_1 gives $\overline{H}(x, p) \ge H_1(x, \overline{y}, p)$. In the remaining case of $\overline{y} \in \partial Y$ we use the assumption of subsection 1.2 to move the system from $y_0 = \overline{y}$ to $\widetilde{y} \in Y \cap B(\overline{y}, \varepsilon/2)$ in a short time, and then we can use the controllability assumption as before to keep the trajectory in $B(\overline{y}, \varepsilon)$ forever. Therefore we reach the desired inequality as in the previous case.

In conclusion, the representation (12) of the effective Hamiltonian holds under the current hypotheses, and we recover the main result of [6] as a special case of the convergence theorem proved later in this section (under slightly different assumptions).

Remark. In this case the limit problem (11) has a simple control interpretation. In fact its solution is the value function of the problem of minimizing the functional

$$\underline{J}(t, x, \alpha_\cdot, y_\cdot) := \int_t^T l(x_s, y_s, \alpha_s)\, ds + \underline{h}(x_T) \tag{14}$$

on the trajectories of the system

$$\dot{x}_s = f(x_s, y_s, \alpha_s), \qquad x_t = x,$$

with measurable controls $\alpha_\cdot : (0, T] \to A$ and $y_\cdot : (0, T] \to \overline{Y}$. Therefore the fast variables become controls in the limit problem.

1.4. Connections with the order reduction method. If we try to follow the classical Levinson–Tichonov approach to singularly perturbed ordinary differential equations, we have to set formally $\varepsilon = 0$ in the dynamical system and get $g(x_s, y_s, \alpha_s) \equiv 0$. This leads to the conjecture that the limit dynamics are governed by the differential inclusion

$$\dot{x}_s = f(x_s, y_s, \alpha_s), \qquad (y_s, \alpha_s) \in Z(x_s), \tag{15}$$

where

$$Z(x) := \{(y, \alpha) \in \overline{Y} \times A |\, g(x, y, \alpha) = 0\},$$

and of course (15) makes sense if $Z(x_s) \ne \emptyset$ for almost every s. The conjecture turns out to be true in many important problems that can be put in the reduced order form; see, e.g., [32, 12] and the references therein. In this case the limit Hamiltonian is

$$H_0(x, p) := \sup_{(y,\alpha)\in Z(x)} F(x, y, \alpha, p),$$

where

$$F(x, y, \alpha, p) := -(p, f(x, y, \alpha)) - l(x, y, \alpha).$$

LEMMA 6. *Assume in addition that $Z(x) \ne \emptyset$. Then $H_0(x, p) \le \overline{H}(x, p)$ for all $x, p \in \mathbb{R}^n$.*

Proof. Fix (x, p) and $(\overline{\alpha}, \overline{y}) \in Z(x)$. Since $y_s \equiv \overline{y}$ solves $\dot{y}_s = f(x, y_s, \alpha_s)$ for $\alpha_s \equiv \overline{\alpha}$,

$$F(x, \overline{y}, \overline{\alpha}, p) \le \sup_{\alpha\in\mathcal{A}} \left\{ -\frac{1}{t} \int_0^t \big((p, f(x, y_s, \alpha_s)) + l(x, y_s, \alpha_s) \big)\, ds \right\}$$

for all $t > 0$ and all solutions of $\dot{y}_s = g(x, y_s, \alpha_s)$, $y_0 = y$, $y_s \in \overline{Y}$. Then (10) implies $F(x, \overline{y}, \overline{\alpha}, p) \le \overline{H}(x, p)$, and we conclude by the arbitrariness of $(\overline{y}, \overline{\alpha})$. □

If the multifunction $Z(\cdot)$ is regular enough, say Lipschitz continuous in the Hausdorff metrics, then the value function $v(t, x)$ of the problem with dynamics (15) and cost functional $\underline{J}$ defined by (14) is the viscosity solution of

$$-\partial_t v + H_0(x, Dv) = 0 \text{ in } (0, T) \times \mathbb{R}^n \quad \text{and} \quad v(T, \cdot) = \underline{h} \text{ on } \mathbb{R}^n;$$

see, e.g., [15]. Then a comparison theorem gives $v \ge u$, where u is the solution of the limit problem (11).

Next we give three examples where $H_0 = \overline{H}$, and therefore $v = u$. In the first two we make assumptions on the m-dimensional control problem of minimizing $\int_0^t F(x, y_s, \alpha_s, p)\, ds$ for fixed (x, p), that is connected to $\overline{H}$ by the formulas (9) and (10).

Example 1: *The affine-convex case.* Suppose that A and Y are convex and, for all fixed x, f and g are affine and l is convex with respect to (y, a). Note that $g(x, y, A)$ is convex, so it contains 0 by the controllability assumption and $Z(x) \ne \emptyset$. We define

$$G(x, \alpha, p) := \limsup_{t \to +\infty} \frac{1}{t} \int_0^t F(x, y_s, \alpha_s, p)\, ds, \qquad \alpha \in \mathcal{A}_{y_0}, \tag{16}$$

where y_0 is fixed and $\dot{y}_s = g(x, y_s, \alpha_s)$. By the representation formula (9),

$$\overline{H}(x, p) = \sup_{\alpha \in \mathcal{A}_{y_0}} G(x, \alpha, p)$$

for any choice of y_0. We fix $\alpha \in \mathcal{A}_{y_0}$ and choose $t_n \to +\infty$ such that

$$G(x, \alpha, p) = \lim_n \frac{1}{t_n} \int_0^{t_n} F(x, y_s, \alpha_s, p)\, ds. \tag{17}$$

By the convexity and compactness of A and $\overline{Y}$ we can extract a subsequence such that

$$\lim_n \frac{1}{t_n} \int_0^{t_n} y_s\, ds = \overline{y} \in \overline{Y}, \qquad \lim_n \frac{1}{t_n} \int_0^{t_n} \alpha_s\, ds = \overline{\alpha} \in A.$$

The assumptions of this example imply the concavity of $F(x, \cdot, \cdot, p)$ for all fixed (x, p), so

$$G(x, \alpha, p) \le \lim_n F\left(x, \frac{1}{t_n} \int_0^{t_n} y_s\, ds, \frac{1}{t_n} \int_0^{t_n} \alpha_s\, ds, p\right) = F(x, \overline{y}, \overline{\alpha}, p).$$

Moreover,

$$g\left(x, \frac{1}{t} \int_0^t y_s\, ds, \frac{1}{t} \int_0^t \alpha_s\, ds\right) = \frac{1}{t} \int_0^t g(x, y_s, \alpha_s)\, ds = \frac{1}{t}(y_t - y_0).$$

Here we set $t = t_n$ and pass to the limit to get, by the boundedness of $\overline{Y}$, $g(x, \overline{y}, \overline{\alpha}) = 0$. Then

$$G(x, \alpha, p) \le \sup_{(\overline{y}, \overline{\alpha}) \in Z(x)} F(x, \overline{y}, \overline{\alpha}, p) = H_0(x, p).$$

Since $\alpha \in \mathcal{A}$ is arbitrary we obtain $\overline{H}(x,p) \le H_0(x,p)$, and we can conclude that $\overline{H} = H_0$ by the preceding lemma.

Example 2: *The case of an asymptotically stable optimal trajectory.* Here we follow Example 7.4 in [5] and suppose for all (x,p) that for some y_0 there is a control $\alpha^* \in \mathcal{A}$ such that

$$\int_0^t F(x, y_s^*, \alpha_s^*, p)\, ds = \sup_{\alpha \in \mathcal{A}} \int_0^t F(x, y_s, \alpha_s, p)\, ds \qquad \text{for all } t > 0,$$

where $\dot{y}_s^* = g(x, y_s^*, \alpha_s^*)$, $y_0^* = y_0$, and

$$\lim_{s \to +\infty} \alpha_s^* = \alpha^*, \qquad \lim_{s \to +\infty} y_s^* = y^*$$

for some $\alpha^* = \alpha^*(x,p) \in A$, $y^* = y^*(x,p) \in \overline{Y}$. Then $g(x, y^*(x,p), \alpha^*(x,p)) = 0$ and

$$\lim_{t \to +\infty} \frac{1}{t} \int_0^t F(x, y_s^*, \alpha_s^*, p)\, ds = F(x, y^*(x,p), \alpha^*(x,p), p).$$

By the representation formula (10) we get

$$\overline{H}(x,p) = F(x, y^*(x,p), \alpha^*(x,p), p) \le \sup_{(y,\alpha) \in Z(x)} F(x,y,\alpha,p) = H_0(x,p),$$

and the equality $\overline{H} = H_0$ follows from the preceding lemma.

Example 3: *Separated controls.* In the case of subsection 1.3, formula (12) implies $\overline{H} \le H_0$, and therefore $\overline{H} = H_0$, if for all x and y there exists $\gamma^* \in C$ such that $g(x,y,\gamma^*) = 0$. Note that this condition follows from the controllability assumption on the fast variables if in addition $g(x,y,C)$ is a convex set for all x, y; this is the case, for instance, if one uses relaxed controls $\gamma_\cdot$.

It is obvious that the equality $H_0 = \overline{H}$ cannot hold at points where $Z(x) = \emptyset$, but it is known that the equality may also fail at points where $Z(x) \ne \emptyset$; see, e.g., [4]. We end this subsection with a simple example that exhibits this phenomenon and satisfies our assumptions.

Example 4: $-\infty < H_0 < \overline{H}$. Consider $A = [-1,1]$, $Y =]-1/2, 1/2[$, $g(y,\alpha) = \alpha - y$, $l(x,y,\alpha) = l_1(x) + |y|^2 - |\alpha|^2$, with l_1 continuous and bounded, and any f so that the assumptions of subsection 1.1 are satisfied. Then $H_0(x,0) = -l_1(x)$. On the other hand, by switching fast enough from $\alpha = 1$ to $\alpha = -1$ we can keep the solution y_s of $\dot{y}_s = g(x, y_s, \alpha_s)$, $y_0 = 0$, in any neighborhood of 0, so $\sup_\alpha \frac{1}{t} \int_0^t F(x, y_s, \alpha_s, 0)\, ds = -l_1(x) + 1$ and then $\overline{H}(x,0) = -l_1(x) + 1$ by (10).

1.5. A control interpretation for the limit problem. Now we construct an optimal control problem whose Hamiltonian is $\overline{H}$. Let $(\overline{Y} \times A)^r$ be the set of Radon probability measures on $\overline{Y} \times A$, and extend $\varphi = f, l, g$ to functions f^r, l^r, g^r defined on $R^n \times (\overline{Y} \times A)^r$ as it is usually done for relaxed controls, namely,

$$\varphi^r(x,\mu) := \int_{\overline{Y} \times A} \varphi(x,y,a) d\mu(y,a), \qquad \mu \in (\overline{Y} \times A)^r.$$

We call a *limiting relaxed control* a measure $\mu \in (\overline{Y} \times A)^r$ such that, for some $\alpha \in \mathcal{A}$, $t_n \to +\infty$, and y_0,

$$\mu_n := \frac{1}{t_n} \int_0^{t_n} \delta_{(y_s, \alpha_s)} ds \to \mu \qquad \text{weak star},$$

where $\delta_{(y,\alpha)}$ is the Dirac's mass at (y,α) and $\dot{y}_s = g(x, y_s, \alpha_s)$. Note that, for any Borel $Q \subseteq Y \times A$, $\mu_n(Q)$ is the proportion of time spent by (y_s, α_s) in Q, that is,

$$\mu_n(Q) = \frac{1}{t_n} |\{s \in [0, t_n] \,:\, (y_s, \alpha_s) \in Q\}|, \tag{18}$$

where $|\cdot|$ denotes the Lebesgue measure, so μ_n is an *occupational probability measure* in the terminology of [23]. We denote with $Z_l(x)$ the set of limiting relaxed control. The reason for the notation is that

$$Z_l(x) \subseteq Z^r(x) := \{\mu \in (\overline{Y} \times A)^r \,|\, g^r(x,\mu) = 0\}.$$

In fact,

$$g^r\left(x, \frac{1}{t_n}\int_0^{t_n} \delta_{(y_s,\alpha_s)} ds\right) = \frac{1}{t_n}\int_0^{t_n} g^r(x, \delta_{(y_s,\alpha_s)}) ds = \frac{1}{t_n}\int_0^{t_n} g(x, y_s, \alpha_s) ds$$
$$= \frac{1}{t_n}(y_{t_n} - y_0),$$

and the limit as $n \to +\infty$ gives $g^r(x,\mu) = 0$ by definition of weak star convergence.

Now we define

$$H_l^r(x,p) := \sup_{\mu \in Z_l(x)} F^r(x,\mu,p), \qquad F^r(x,\mu,p) := -(p, f^r(x,\mu)) - l^r(x,\mu).$$

THEOREM 7. *For all $x, p \in \mathbb{R}^n$, $\overline{H}(x,p) = H_l^r(x,p)$.*

Proof. The proof is similar to the affine-convex example of the previous subsection and we use the same notations. Let $\mu \in Z_l(x)$ be generated by $\alpha_\cdot, y_\cdot$, and the sequence $t_n \to +\infty$. Then

$$\frac{1}{t_n}\int_0^{t_n} F(x, y_s, \alpha_s, p) ds = \frac{1}{t_n}\int_0^{t_n} F^r(x, \delta_{(y_s,\alpha_s)}, p) ds = F^r\left(x, \frac{1}{t_n}\int_0^{t_n} \delta_{(y_s,\alpha_s)} ds, p\right),$$

and the right-hand side converges to $F^r(x,\mu,p)$ as $n \to +\infty$ by definition of weak star convergence. This proves

$$G(x,\alpha,p) = F^r(x,\mu,p), \tag{19}$$

where G is defined by (16). By taking the sup over $\mu \in Z_l(x)$ we get

$$H_l^r(x,p) \le \sup_{\alpha \in \mathcal{A}} G(x,\alpha,p) = \overline{H}(x,p).$$

To prove the opposite inequality we fix α, y_0, and $t_n \to +\infty$ such that

$$G(x,\alpha,p) = \lim_n \frac{1}{t_n}\int_0^{t_n} F(x, y_s, \alpha_s, p) ds.$$

By the compactness of $(\overline{Y} \times A)^r$ we can extract a subsequence, that we do not relabel, such that $\frac{1}{t_n}\int_0^{t_n} \delta_{(y_s,\alpha_s)} ds$ converges weak star to some μ, and $\mu \in Z_l(x)$. By taking the sup over $\alpha \in \mathcal{A}$ in (19) we then get, again by using (10),

$$\overline{H}(x,p) \le H_l^r(x,p),$$

which completes the proof. □

Remark. The control problem associated with the Hamiltonian H_l^r and the terminal cost $\underline{h}$ is the minimization of

$$\underline{J}^r(t,x,\mu) := \int_t^T l^r(x_s,\mu_s)\,ds + \underline{h}(x_T)$$

for the system

$$\dot{x}_s = f^r(x_s,\mu_s), \qquad \mu_s \in Z_l(x_s), \qquad x_t = x,$$

and measurable control functions $\mu : [0,T] \to (\overline{Y} \times A)^r$. If the multifunction $Z_l(\cdot)$ is regular enough, say it takes compact values and is Lipschitz continuous with respect to the Hausdorff metrics [15], then the value function of this control problem is continuous and it is the solution of the limit problem (11). We postpone to a future paper the investigation of the properties of Z_l and the connections with Artstein's invariant measures [3] and the related limit control problems of Vigodner [41].

After this paper was completed, Gaitsgory pointed out to us that under the current assumptions Z_l coincides with the *limit occupational measures set* constructed in his paper with Leizarowitz [23]; indeed, it is easy to deduce from (18) that any limiting relaxed control is a limit occupational measure, while the converse statement is based on the controllability of the fast variables and the results and methods of [23].

Remark. In connection with the reduced order method, we note that

$$H_0 \le \overline{H} = H_l^r \le H_0^r := \sup_{\mu \in Z^r(x)} F^r(x,\mu,p).$$

1.6. Convergence.

THEOREM 8. *As $\varepsilon \to 0+$ the functions $\{u_\varepsilon\}$ converge uniformly on compact subsets of $(0,T) \times \mathbb{R}^n \times \overline{Y}$ to the unique solution u of* (11)*; if h does not depend on y, the convergence is uniform on compact subsets of $(0,T] \times \mathbb{R}^n \times \overline{Y}$.*

Proof. We define the weak limits in the viscosity sense, or relaxed semilimits

$$\underline{u}(t,x) := \liminf_{*\varepsilon \to 0} \inf_y u_\varepsilon(t,x,y) := \liminf_{\varepsilon \to 0,\, t' \to t,\, x' \to x} \inf_y u_\varepsilon(t',x',y)$$

and $\overline{u} = \limsup^* \sup_y u_\varepsilon$.

We redefine $\overline{u}$ at $t = T$ by setting

$$\widetilde{u}(T,x) := \limsup_{t' \to T_-,\, x' \to x} \overline{u}(t',x') \quad \text{and} \quad \widetilde{u}(t,x) := \overline{u}(t,x) \quad \text{for } 0 < t < T.$$

We will show that $\underline{u}$ is a supersolution of (11) and $\widetilde{u}$ is a subsolution of (11). By comparison this gives $\underline{u} = \overline{u} = u$ in $(0,T) \times \mathbb{R}^n$ and implies the convergence of $\{u_\varepsilon\}$ to u uniformly on compact subsets of $(0,T) \times \mathbb{R}^n \times \mathbb{R}^m$.

To prove that $\widetilde{u}$ is a subsolution of the limit H–J equation we consider a strict maximum point $(\overline{t},\overline{x})$ of $\overline{u} - \varphi$ with $0 < \overline{t} < T$ and φ smooth. We want to show that

$$-\partial_t \varphi(\overline{t},\overline{x}) + \overline{H}(\overline{x}, D\varphi(\overline{t},\overline{x})) \le 0 \tag{20}$$

and suppose by contradiction that

$$-\partial_t \varphi(\overline{t},\overline{x}) + \lambda > 0 \quad \text{for } \lambda = \overline{H}(\overline{x},\overline{p}), \quad \overline{p} = D\varphi(\overline{t},\overline{x}).$$

Let χ be the solution of the cell problem at $(\overline{x},\overline{p})$, and define the perturbed test function as

$$\varphi_\varepsilon(t,x,y)=\varphi(t,x)+\varepsilon\chi(y).$$

We claim that for some $r>0$, φ_ε is a viscosity supersolution of

$$-\partial_t\varphi_\varepsilon+H\left(x,y,D_x\varphi_\varepsilon,\frac{D_y\varphi_\varepsilon}{\varepsilon}\right)\geq 0\quad\text{in } I_r\times B(\overline{x},r)\times\overline{Y}, \tag{21}$$

where $I_r=(\overline{t}-r,\overline{t}+r)$. To prove the claim we take a smooth ψ such that $\varphi_\varepsilon-\psi$ attains its minimum over $I_r\times B(\overline{x},r)\times\overline{Y}$ at $(\widetilde{t},\widetilde{x},\widetilde{y})$, and $(\varphi_\varepsilon-\psi)(\widetilde{t},\widetilde{x},\widetilde{y})=0$. Then the function $y\mapsto\chi(y)-\varepsilon^{-1}\psi(\widetilde{t},\widetilde{x},y)$ has a minimum at $\widetilde{y}$, so the definition of χ gives

$$H\left(\overline{x},\widetilde{y},\overline{p},\frac{D_y\psi}{\varepsilon}(\widetilde{t},\widetilde{x},\widetilde{y})\right)\geq\lambda.$$

Since χ is Lipschitz continuous it is easy to check that $|\varepsilon^{-1}D_y\psi(\widetilde{t},\widetilde{x},\widetilde{y}))|\leq Lip(\chi)$. Now we set $\gamma:=(-\partial_t\varphi(\overline{t},\overline{x})+\lambda)/2$ and use the continuity of H in (x,p), uniformly for $y\in\overline{Y}$ and $|\varepsilon^{-1}D_y\psi|\leq Lip(\chi)$, to find δ such that

$$H\left(x,\widetilde{y},p,\frac{D_y\psi}{\varepsilon}(\widetilde{t},\widetilde{x},\widetilde{y})\right)\geq\lambda-\gamma$$

for $|x-\overline{x}|<\delta$ and $|p-\overline{p}|<\delta$. Now choose $0<r\leq\delta$ such that

$$\left|D_x\varphi(\overline{t},\overline{x})-D_x\varphi(\widetilde{t},\widetilde{x})\right|<\delta\quad\text{and}\quad\left|\partial_t\varphi(\overline{t},\overline{x})-\partial_t\varphi(\widetilde{t},\widetilde{x})\right|<\gamma.$$

Note that the choice of r is independent of ψ. Since $D_x\psi(\widetilde{t},\widetilde{x},\widetilde{y})=D_x\varphi(\widetilde{t},\widetilde{x})$ and $\partial_t\psi(\widetilde{t},\widetilde{x},\widetilde{y})=\partial_t\varphi(\widetilde{t},\widetilde{x})$, we get

$$\left[-\partial_t\psi+H\left(\cdot,\cdot,D_x\psi,\frac{D_y\psi}{\varepsilon}\right)\right](\widetilde{t},\widetilde{x},\widetilde{y})\geq-\partial_t\varphi(\overline{t},\overline{x})-\gamma+\lambda-\gamma=0,$$

which completes the proof of the claim.

In view of (21), we can use a comparison principle for the mixed boundary value problem with prescribed data on $\partial(I_r\times B(\overline{x},r))$ and state-constrained condition at ∂Y (see, e.g., Theorem IX.1 in [16]) to obtain

$$\sup_{I_r\times B(\overline{x},r)\times\overline{Y}}(u_\varepsilon-\varphi_\varepsilon)\leq\sup_{\partial(I_r\times B(\overline{x},r))\times\overline{Y}}(u_\varepsilon-\varphi_\varepsilon).$$

It is not hard to deduce from this and the definitions of $\overline{u}$ and φ_ε that

$$(\overline{u}-\varphi)(\overline{t},\overline{x})\leq\sup_{\partial(I_r\times B(\overline{x},r))}(\overline{u}-\varphi),$$

and this is in contradiction to the fact that $(\overline{t},\overline{x})$ is a strict maximum point of $\overline{u}-\varphi$. This completes the proof of (20).

Next we show that $\underline{u}$ is a supersolution of the limit H–J equation. Now $(\overline{t},\overline{x})$ is a strict minimum point of $\underline{u}-\varphi$ and we assume by contradiction that $-\partial_t\varphi(\overline{t},\overline{x})+\lambda<0$, where $\lambda=\overline{H}(\overline{x},D\varphi(\overline{t},\overline{x}))$ as before. We also define χ and φ_ε as before, and now claim that φ_ε is a viscosity subsolution of

$$-\partial_t\varphi_\varepsilon+H\left(x,y,D_x\varphi_\varepsilon,\frac{D_y\varphi_\varepsilon}{\varepsilon}\right)\leq 0\quad\text{in } I_r\times B(\overline{x},r)\times Y.$$

The proof is essentially the same as the proof of (21). Now we exploit the fact that u_ε is a (constrained) supersolution of the same PDE in $I_r \times B(\overline{x}, r) \times \overline{Y}$ and the comparison principle for the mixed Dirichlet-constrained boundary value problem (see, e.g., Theorem IX.1 in [16]) to get

$$\inf_{I_r \times B(\overline{x},r) \times \overline{Y}} (u_\varepsilon - \varphi_\varepsilon) \geq \inf_{\partial(I_r \times B(\overline{x},r)) \times \overline{Y}} (u_\varepsilon - \varphi_\varepsilon).$$

This implies

$$(\underline{u} - \varphi)(\overline{t}, \overline{x}) \geq \inf_{\partial(I_r \times B(\overline{x},r))} (\underline{u} - \varphi),$$

a contradiction with the choice of $(\overline{t}, \overline{x})$. Therefore

$$-\partial_t \varphi(\overline{t}, \overline{x}) + \overline{H}(\overline{x}, D\varphi(\overline{t}, \overline{x})) \geq 0,$$

and so $\underline{u}$ is a supersolution of the limit H–J equation.

Finally we check the terminal condition. The hypotheses on f and l imply easily the estimate

$$u_\varepsilon(t, x, y) \geq -(T-t)||l||_\infty + \inf\{\underline{h}(x') : |x' - x| \leq ||f||_\infty (T-t)\}$$

for all $\varepsilon > 0$. Since $\underline{h}$ is continuous, in the limit we obtain $\underline{u}(T, x) \geq \underline{h}(x)$.

For $\widetilde{u}$, we note that

$$u_\varepsilon(t, x, y) \leq (T-t)||l||_\infty + \inf_{\alpha \in \mathcal{A}_{(x,y)}} h(x, y_T^t) + \omega_h(|x - x_T^t|),$$

where (x_T^t, y_T^t) denote the position of the system at time T if the position at time t is (x, y), and ω_h is the modulus of continuity of h. Since $|x - x_T^t| \leq (T-t)||f||_\infty$, the first and third term on the right-hand side of the preceding estimate tend to 0 as $t \to T-$. To reach the conclusion we are going to prove that

$$\limsup_{\varepsilon \to 0,\, t' \to t,\, x' \to x} \sup_y \inf_{\alpha \in \mathcal{A}_{(x',y)}} h(x', y_T^{t'}) \leq \underline{h}(x)$$

for all $t < T$.

Without loss of generality we can assume that

$$B(0, r) \subset \{g(x, y, \alpha) \mid \alpha \in A\}.$$

In fact, if we take relaxed controls or use Carathéodory's theorem (as in Lemma 2.7 of [6]) to convexify $g(x, y, A)$, the value function u_ε does not change because the Hamiltonian H is the same. Then it is easy to see by means of a standard selection lemma (e.g., as in Lemma 2.8 of [6]) that any polygonal $\gamma \subset \overline{Y}$ is the trajectory of a solution y_t of the system, with speed r/ε. Therefore, by Lemma 3(ii), for some constant M the system can reach any point $\overline{y} \in \overline{Y}$ from any $y \in \overline{Y}$ within the time $M\varepsilon/r$. Then, for any initial position $y \in \overline{Y}$ of the system,

$$\inf_{\alpha \in \mathcal{A}_{(x',y)}} h(x', y_T^{t'}) = \underline{h}(x') \quad \text{if } t' \geq t + \frac{M\varepsilon}{r}.$$

For any $t < T$ we can restrict $\varepsilon < r(T-t)/M$ and get

$$\limsup_{\varepsilon \to 0,\, t' \to t,\, x' \to x} \sup_y \inf_{\alpha \in \mathcal{A}_{(x',y)}} h\left(x', y_T^{t'}\right) = \limsup_{x' \to x} \underline{h}(x') = \underline{h}(x),$$

where in the last equality we used the continuity of $\underline{h}$. Therefore $\widetilde{u}(T,x) \le \underline{h}(x)$ and the proof of the first statement is complete.

In the case of $h = h(x)$ we have, for $0 \le (T-t)||f||_\infty \le 1$, $|x-x'| \le 1$, and all y,

$$|u_\varepsilon(t,x',y) - h(x)| \le (T-t)||l||_\infty + \omega(|x-x'| + (T-t)||f||_\infty),$$

where ω is the modulus of continuity of h in $\overline{B}(x,2)$. Therefore $\underline{u}(T,x) = \overline{u}(T,x) = \widetilde{u}(T,x) = h(x)$, and the convergence of u_ε is uniform on compact subsets up to time $t = T$. □

2. Stochastic control with periodic fast variables.

2.1. The ε-control problem. For $\varepsilon > 0$ fixed, we now consider the following finite horizon stochastic control problem in $(0,T] \times \mathbb{R}^n \times \mathbb{R}^m$. Let $(\Omega, \mathcal{F}, P)$ be a probability space, endowed with a right-continuous filtration $(\mathcal{F}_t)_{0 \le t \le T}$ and an r-dimensional adapted Brownian motion W_t. Given a progressively measurable α with values in a compact set A, the stochastic differential equation

$$\begin{aligned} dx_s &= f(x_s, y_s, \alpha_s)\, ds + \sigma(x_s, y_s, \alpha_s)\, dW_s, \\ dy_s &= \varepsilon^{-1} g(x_s, y_s, \alpha_s)\, ds + \varepsilon^{-1/2} \tau(x_s, y_s, \alpha_s)\, dW_s \end{aligned}$$

for $s \ge t$, starting from $x_t = x \in \mathbb{R}^n$, $y_t = y \in \mathbb{R}^m$, has a pathwise unique adapted strong solution when the functions f, g, σ, τ are Lipschitz continuous in (x,y) uniformly in α. The variable x is called the slow variable and y the fast variable. We refer to Fleming and Soner [21] for a presentation of the theory of stochastic control and its relationship to the theory of viscosity solutions. We shall always assume that all of the functions are $\mathbb{Z}^m$-periodic in the fast variable y.

The associated value function with running cost l and terminal cost h is given by

$$u_\varepsilon(t,x,y) = \inf_\alpha E\left\{ \int_t^T l(x_s, y_s, \alpha_s)\, ds + h(x_T) \right\}.$$

Under the assumptions we recall below, it is continuous and bounded on $(0,T] \times \mathbb{R}^n \times \mathbb{R}^m$ uniformly in ε. It is also periodic in the fast variable y.

We shall make throughout the following set of assumptions that are classic in the theory of stochastic control.

- The control set A is a compact metric space.
- The functions f, g, σ, τ, and l are bounded continuous functions in $\mathbb{R}^n \times \mathbb{R}^m \times A$ with values, respectively, in $\mathbb{R}^n$, $\mathbb{R}^m$, $\mathbb{M}^{n,r}$ (the set of the $n \times r$ real matrices), $\mathbb{M}^{m,r}$, and $\mathbb{R}$. They are $\mathbb{Z}^m$-periodic in the fast variable y.
- The drift vectors f and g and the dispersion matrices σ and τ are Lipschitz continuous in (x,y), uniformly in α.
- The running cost l is uniformly continuous in (x,y), uniformly in α.
- The terminal cost $h : \mathbb{R}^n \to \mathbb{R}$ is bounded uniformly continuous.

2.2. The H–J–B equation. Consider the diffusion matrices

$$a = \frac{\sigma\sigma^T}{2}, \qquad b = \frac{\tau\tau^T}{2}, \qquad c = \frac{\tau\sigma^T}{2},$$

and associate the Hamiltonian

$$\begin{aligned} H(x,y,p,q,X,Y,Z) = \max_{\alpha \in A} \{ &-\mathrm{tr}(a(x,y,\alpha)X) - \mathrm{tr}(b(x,y,\alpha)Y) - \mathrm{tr}(c(x,y,\alpha)Z) \\ &-\mathrm{tr}(Zc(x,y,\alpha)) - (p, f(x,y,\alpha)) - (q, g(x,y,\alpha)) - l(x,y,\alpha)\}. \end{aligned}$$

It is defined on $\mathbb{R}^n\times\mathbb{R}^m\times\mathbb{R}^n\times\mathbb{R}^m\times\mathbb{S}^n\times\mathbb{S}^m\times\mathbb{M}^{n,m}$, where $\mathbb{S}^n$ designates the set of the symmetric $n\times n$ matrices. Given a function $u(t,x,y)$ defined on $(0,T]\times\mathbb{R}^n\times\mathbb{R}^m$, we consider the partial gradients $\partial_t u$, $D_x u$, and $D_y u$. We also define the partial Hessian matrices $D^2_{xx}u$, $D^2_{yy}u$, and $D^2_{xy}u=\left(\partial^2_{x_i,y_j}u\right)_{1\le i\le n,1\le j\le m}$, so that the full Hessian matrix of u with respect to (x,y) is

$$D^2u=\begin{pmatrix} D^2_{xx}u & D^2_{xy}u\\ (D^2_{xy}u)^T & D^2_{yy}u\end{pmatrix}.$$

By the dynamic programming principle, the value function u_ε is a viscosity solution of the second order degenerate parabolic H–J–B equation

$$\begin{cases} -\partial_t u_\varepsilon + H(x,y,D_xu_\varepsilon,\frac{D_yu_\varepsilon}{\varepsilon},D^2_{xx}u_\varepsilon,\frac{D^2_{yy}u_\varepsilon}{\varepsilon},\frac{D^2_{xy}u_\varepsilon}{\sqrt{\varepsilon}})=0 \quad \text{in } (0,T)\times\mathbb{R}^n\times\mathbb{R}^m,\\ u_\varepsilon(T,\cdot)=h \quad \text{on } \mathbb{R}^n\times\mathbb{R}^m.\end{cases} \tag{22}$$

The following theorem records these facts. We refer to [21] for a proof and a detailed discussion.

THEOREM 9. *For every $\varepsilon>0$, the value function u_ε is the unique bounded continuous viscosity solution of* (22) *in* $(0,T]\times\mathbb{R}^n\times\mathbb{R}^m$.

For further use, we recall that the uniqueness statement in the theorem takes the form of the following comparison principle. If u is a bounded u.s.c. viscosity subsolution of (22) and v is a bounded l.s.c. viscosity supersolution, then we have $u\le v$ in $(0,T]\times\mathbb{R}^n\times\mathbb{R}^m$. We refer to [17, 21] for the precise definitions of a subsolution and a supersolution and for the proof of the comparison principle.

2.3. The ergodic control problem in the fast variable and the effective Hamiltonian. We shall make one of the following three assumptions to guarantee some averaging properties of the fast dynamics.

(I) The diffusions in the fast variable are uniformly nondegenerate, i.e., there is a constant $\nu>0$ such that

$$b(x,y,\alpha)\ge\nu I_m \quad \text{for all } (x,y,\alpha),$$

where I_m denotes the m-dimensional identity matrix. Moreover, the running cost $l(x,\cdot,\alpha)$ is Hölder continuous for some exponent $0<\beta\le 1$, uniformly on (x,α).

(II) The diffusions in the fast variable are independent of x ($b\equiv b(y,\alpha)$) and there is a deterministic controllable subsystem in the fast variable, i.e., there is some $r>0$ and some $A'\subset A$ so that

$$b(y,\alpha)=0 \quad \text{for all } \alpha\in A' \quad\text{and}\quad B(0,r)\subset\overline{\text{conv}}\{g(x,y,\alpha)\mid\alpha\in A'\}$$

for all (x,y).

(III) The drifts and diffusions in the fast variable do not depend on x, y ($g\equiv g(\alpha)$ and $b\equiv b(\alpha)$) and satisfy the nonresonance condition

$$\text{for every } k\in\mathbb{Z}^m \text{ there is } \alpha\in A \text{ such that } \quad (g(\alpha),k)\ne 0 \text{ or } b(\alpha)k\ne 0.$$

In terms of the Hamiltonian, case (I) corresponds to the uniform ellipticity of H in Y,

$$H(x,y,p,q,X,Y+W,Z)\le H(x,y,p,q,X,Y,Z)-\nu\text{tr}W, \qquad W\ge 0,$$

while (II) corresponds to the coercivity with respect to q:

$$H(x,y,p,q,X,Y,Z) \geq r|q| - C(1+|p|+|X|).$$

The preceding assumptions are of two different natures. Some of them demand that some quantities in the fast dynamics are independent of the slow variable. They are needed to ensure enough regularity of the averaged quantities with respect to the slow variables. It is an open question whether they can be dispensed with. The second kind of assumption is more fundamental. They guarantee the solvability of the ergodic control problem in the fast variable. These assumptions correspond to some of the cases studied by Arisawa and Lions [2]. In our context, their results read as follows.

THEOREM 10. *Assume that either* (I) *or* (II) *or* (III) *holds. Let* (x,p,X) *be fixed. For every* $\delta > 0$, *let* w_δ *denote the unique viscosity solution of the stationary problem in the fast variable*

$$\delta w_\delta + H(x,y,p,D_y w_\delta, X, D^2_{yy} w_\delta, 0) = 0 \quad \text{in } \mathbb{R}^m, \qquad w_\delta \text{ periodic.} \tag{23}$$

Then, as $\delta \to 0+$, *the family* $\{\delta w_\delta\}$ *converges to a constant* $-\overline{H}(x,p,X)$, *uniformly with respect to* y.

When one looks at the solution w_δ of the H–J–B equation (23) as the value function of a discounted control problem in the fast variable, the theorem asserts that

$$\begin{aligned}\overline{H}(x,p,X) &= \lim_{\delta\to 0+} \sup_{\alpha} \Big\{ \delta E \int_0^\infty e^{-\delta s}\big(-\operatorname{tr}(a(x,y_s,\alpha_s)X) - (p, f(x,y_s,\alpha_s)) - l(x,y_s,\alpha_s)\big)\, ds \\ &\qquad\qquad \mid dy_s = g(x,y_s,\alpha_s)\, ds + \tau(x,y_s,\alpha_s)\, dW_s,\ y_0 = y \Big\},\end{aligned} \tag{24}$$

the convergence being uniform in y.

In cases (I) and (II), one can characterize the effective Hamiltonian in the more convenient form of section 1. It is the unique constant $\overline{H}$ for which the cell problem

$$H(x,y,p,D_y\chi, X, D^2_{yy}\chi, 0) = \overline{H} \quad \text{in } \mathbb{R}^m, \qquad \chi \text{ periodic},$$

has a continuous solution χ. However, such a characterization is not available in case (III), for it may happen that the cell problem has no solution. We refer to [2] for an explicit example.

The above assumptions are three of the five cases studied by Arisawa and Lions [2]. Among the remaining two cases, the one-dimensional one in the fast variable ($m = 1$) can be handled in a similar way as (II); we omit it for simplicity. On the other hand, for the viscosity solution techniques to apply, the uniform convergence of $\{\delta w_\delta\}$ is essential. This is why we do not consider the fifth case that assumes (roughly) that at least one diffusion is uniformly nondegenerate (and not all, as in (I)), because the convergence of $\{\delta w_\delta\}$ may not be uniform (but in L^p for every $1 \leq p < \infty$). An example in which this happens is given in [2].

2.4. Examples for the effective Hamiltonian.

Example 1: *The coercive and separated case.* The first example, as in section 1, is the case of separated controls. We assume that the fast variable is controlled independently of the slow variable and that there is a controllable deterministic subsystem

(case (II)). The controls are of the form $\alpha = (\beta, \gamma)$ and $f = f(x, y, \beta)$, $\sigma = \sigma(x, y, \beta)$, $g = g(x, y, \gamma)$, and $\tau = \tau(x, y, \gamma)$. We also assume that $l = l(x, y, \beta)$. Under these assumptions, the representation formula reads as

$$\begin{aligned}
&\overline{H}(x, p, X)\\
&\quad = \lim_{\delta \to 0} \sup_{(\beta,\gamma)} \Big\{ \delta E \int_0^\infty e^{-\delta s} \big(- \operatorname{tr}(a(x, y_s, \beta_s)X) - (p, f(x, y_s, \beta_s)) - l(x, y_s, \beta_s) \big)\, ds\\
&\qquad\qquad\qquad\qquad\qquad\qquad \mid dy_s = g(x, y_s, \gamma_s)\, ds + \tau(x, y_s, \gamma_s)\, dW_s \Big\},\\
&\quad = \lim_{\delta \to 0} \sup_{\gamma} \left\{ \delta E \int_0^\infty e^{-\delta s} H_1(x, y_s, p, X)\, ds \mid dy_s = g(x, y_s, \gamma_s)\, ds + \tau(x, y_s, \gamma_s)\, dW_s \right\}
\end{aligned}$$

for

$$H_1(x, y, p, X) = \sup_{\beta} \{ -\operatorname{tr}(a(x, y, \beta)X) - (p, f(x, y, \beta)) - l(x, y, \beta) \}.$$

Arguing as in section 1, we deduce from the controllability assumption that

$$\overline{H}(x, p, X) = \sup_{y} H_1(x, y, p, X).$$

Thus the effective Hamiltonian corresponds to the original control problem where the fast variable plays the role of an additional control.

Example 2: *Uncontrolled and nondegenerate diffusion of the fast variables.* The second example assumes that the fast variable is an uncontrolled uniformly nondegenerate diffusion. Since we are in case (I), we know that the effective Hamiltonian is characterized by the solvability of the linear cell problem

$$H_1(x, y, p, X) - \operatorname{tr}(b(x, y) D^2_{yy} \chi) - (D_y \chi, g(x, y)) = \overline{H}(x, p, X) \quad \text{in } \mathbb{R}^m, \qquad \chi \text{ periodic}$$

(where H_1 is given above, with α instead of β). Assuming that the functions b and g are smooth in y, there is a unique solution μ_x (the invariant measure) of the adjoint equation

$$-\sum_{i,j} \frac{\partial^2}{\partial y_i \partial y_j} (b_{ij}(x, y)\mu_x) + \sum_i \frac{\partial}{\partial y_i} (g_i(x, y)\mu_x) = 0 \quad \text{in } \mathbb{R}^m, \qquad \mu_x \text{ periodic},$$

with mean $\int_{(0,1)^m} \mu_x(y)\, dy = 1$. This follows from the Fredholm alternative (see, for instance, [14] or [13]). A necessary and sufficient condition for the cell problem to have a solution is that

$$\overline{H}(x, p, X) = \int_{(0,1)^m} H_1(x, y, p, X)\mu_x(y)\, dy.$$

If, in addition, b and g are independent of y (and more generally when $g_i = \sum_j \frac{\partial b_{ij}}{\partial y_j}$), we have $\mu_x \equiv 1$. The effective Hamiltonian is therefore the average

$$\overline{H}(x, p, X) = \int_{(0,1)^m} H_1(x, y, p, X)\, dy.$$

This example is a variant of the results of Jensen and Lions [29] and Evans [19].

2.5. Regularity properties of the effective Hamiltonian.

PROPOSITION 11. *The effective Hamiltonian $\overline{H}$ is degenerate elliptic in X and convex in (p, X). Moreover, we have the bounds*

$$\inf_y H(x, y, p, 0, X, 0, 0) \le \overline{H}(x, p, X) \le \sup_y H(x, y, p, 0, X, 0, 0). \tag{25}$$

Proof. The bounds for $\overline{H}$ are a consequence of the observation that the constant functions

$$-\delta^{-1} \sup_y H(x, y, p, 0, X, 0, 0), \qquad -\delta^{-1} \inf_y H(x, y, p, 0, X, 0, 0)$$

are, respectively, a subsolution and a supersolution of (23). Therefore, by the comparison principle, we get

$$-\sup_y H(x, y, p, 0, X, 0, 0) \le \delta w_\delta \le -\inf_y H(x, y, p, 0, X, 0, 0).$$

Sending $\delta \to 0$ yields (25).

Degenerate ellipticity and convexity can be derived by analytical means as in [1]. They are also simple consequences of the representation formula (24). Indeed, for every δ fixed and every control α_s, the function

$$\delta E \int_0^\infty e^{-\delta s} \big(-\operatorname{tr}(a(x, y_s, \alpha_s)X) - (p, f(x, y_s, \alpha_s)) - l(x, y_s, \alpha_s) \big)\, ds$$

is linear in (p, X) and nonincreasing in X. Taking the supremum over the controls yields a function that is convex in (p, X) and nonincreasing in X, as is the limit as $\delta \to 0$. □

The continuity of the effective Hamiltonian is a consequence of the following result.

PROPOSITION 12. *There are a constant $C > 0$ and a modulus ω such that*

$$|\overline{H}(x, p', X') - \overline{H}(x, p, X)| \le C(|p' - p| + |X' - X|) \tag{26}$$

for all (x, p, p', X, X') and

$$|\overline{H}(x', p, X) - \overline{H}(x, p, X)| \le C|x' - x|(1 + |p| + |X|) + \omega(|x' - x|) \tag{27}$$

for all (x, x', p, X).

Proof. The first inequality follows at once from the representation formula (24) by taking the constant $C = \max(\|f\|_{L^\infty}, \|a\|_{L^\infty})$.

The second inequality is more delicate. When the drift and diffusion in the fast variable are independent of x (case (III)), the inequality follows from the representation formula for the constant $C = \max\big(Lip(f), Lip(a)\big)$ and for the modulus $\omega = \omega_l$. We give a second proof of this elementary result, which we shall modify in the other two cases. Since the drift and diffusion for the fast variable are independent of x, the Hamiltonian H satisfies

$$H(x', y, p, q, X, Y, 0) \le H(x, y, p, q, X, Y, 0) + C|x' - x|(1 + |p| + |X|) + \omega(|x' - x|). \tag{28}$$

Therefore, the function $w_\delta(\cdot, x, p, X)$ is a subsolution of

$$\delta w_\delta + H(x', y, p, D_y w_\delta, X, D^2_{yy} w_\delta, 0) \le C|x' - x|(1 + |p| + |X|) + \omega(|x' - x|).$$

By the comparison principle, we obtain the uniform bound

$$\delta w_\delta(\cdot,x,p,X) \le \delta w_\delta(\cdot,x',p,X) + C|x'-x|(1+|p|+|X|) + \omega(|x'-x|).$$

Sending $\delta \to 0$ yields

$$\overline{H}(x,p,X) \ge \overline{H}(x',p,X) - C|x'-x|(1+|p|+|X|) - \omega(|x'-x|).$$

We get (27) after exchanging x and x'.

We now assume (II). As g may now depend on x (but not b), we have to replace (28) by

$$H(x',y,p,q,X,Y,0) \le H(x,y,p,q,X,Y,0) + C|x'-x|\big(1+|p|+|q|+|X|\big) + \omega(|x'-x|). \tag{29}$$

The controllability assumption gives the coercivity of H in q, uniformly in Y, as

$$H(x,y,p,q,X,Y,0) \ge r|q| - C(1+|p|+|X|).$$

Since

$$\|\delta w_\delta\|_{L^\infty} \le \sup_y |H(x,y,p,0,X,0,0)| \le C(1+|p|+|X|),$$

we deduce that the solution of (23) is Lipschitz continuous with the bound

$$\|D_y w_\delta(\cdot,x,p,X)\|_{L^\infty} \le r^{-1}\big(\|\delta w_\delta\|_{L^\infty} + C(1+|p|+|X|)\big) \le C(1+|p|+|X|). \tag{30}$$

We deduce from (29) that $w_\delta(\cdot,x,p,X)$ is a subsolution of

$$\begin{aligned}\delta w_\delta + H(x',y,p,D_y w_\delta, X, D^2_{yy} w_\delta, 0) &\\ \le C|x'-x|(1+|p|+|X|+\|D_y w_\delta\|_{L^\infty}) + \omega(|x'-x|) &\\ \le C|x'-x|(1+|p|+|X|) + \omega(|x'-x|).&\end{aligned}$$

The inequality for $\overline{H}$ is deduced as before from the comparison principle.

We finally consider case (I). As g and b now depend on x, the inequality for H reads as

$$\begin{aligned}H(x',y,p,q,X,Y,0) \le H(x,y,p,q,X,Y,0)&\\ + C|x'-x|\big(1+|p|+|q|+|X|+|Y|\big) + \omega(|x'-x|).&\end{aligned} \tag{31}$$

We claim that the solution w_δ of (23) is in $C^{2,\overline{\beta}}$ for some exponent $0 < \overline{\beta} \le \beta$ with

$$\|w_\delta(\cdot,x,p,X) - w_\delta(0,x,p,X)\|_{C^{2,\overline{\beta}}(\mathbb{R}^m)} \le C(1+|p|+|X|). \tag{32}$$

Admitting this temporarily, we deduce that $w_\delta(\cdot,x,p,X)$ is a subsolution of

$$\begin{aligned}\delta w_\delta + H(x',y,p,D_y w_\delta, X, D^2_{yy} w_\delta, 0) &\\ \le C|x'-x|(1+|p|+|X|+\|D_y w_\delta\|_{L^\infty} + \|D^2_{yy} w_\delta\|_{L^\infty}) + \omega(|x'-x|) &\\ \le C|x'-x|(1+|p|+|X|) + \omega(|x'-x|).&\end{aligned}$$

Inequality (27) for $\overline{H}$ follows as before by comparison.

The proof of (32) relies on the regularity theory for uniformly elliptic H–J–B equations (see Gilbarg and Trudinger [24] and Safonov [36]). Our argument is patterned

after the one of Arisawa and Lions [2]. We give a sketch of it to exhibit the linear growth in (p, X) of the bound. The first step is to establish the uniform bound

$$\|w_\delta(\cdot, x, p, X) - w_\delta(0, x, p, X)\|_{L^\infty(\mathbb{R}^m)} \le C(1 + |p| + |X|) \tag{33}$$

for all (x, p, X) and $0 < \delta < \overline{\delta}$, for some constant C and some $\overline{\delta} > 0$. Suppose that (33) is false. Then there is a sequence $(\delta_\kappa, x_k, p_k, X_k)$ with $\delta_k \to 0$ for which the solution $w_k = w_{\delta_k}(\cdot, x_k, p_k, X_k)$ of (23) satisfies

$$\|w_k - w_k(0)\|_{L^\infty} \ge k(1 + |p_k| + |X_k|).$$

We set $\eta_k = \|w_k - w_k(0)\|_{L^\infty}^{-1}$ and $\widetilde{w}_k = \eta_k(w_k - w_k(0))$. Then, $\widetilde{w}_k(0) = 0$, $\|\widetilde{w}_k\|_{L^\infty} = 1$, and $\widetilde{w}_k$ is a solution of

$$\delta_k \widetilde{w}_k + \eta_k \delta_k w_k(0) + \sup_{\alpha \in A}\{ - \operatorname{tr}(b(x_k, y, \alpha) D^2 \widetilde{w}_k) \\ -(D\widetilde{w}_k, g(x_k, y, \alpha)) - \eta_k L(y, \alpha, x_k, p_k, X_k)\} = 0$$

for

$$L(y, \alpha, x, p, X) = \operatorname{tr}(a(x, y, \alpha)X) + (p, f(x, y, \alpha)) + l(x, y, \alpha).$$

Since

$$\|\delta w_\delta\|_{L^\infty} \le C(1 + |p| + |X|)$$

and

$$\|L(\cdot, \alpha, x, p, X)\|_{C^{0,\beta}} \le C(1 + |p| + |X|),$$

we have

$$|\eta_k \delta_k w_k(0)| + \|\eta_k L(\cdot, \alpha, x_k, p_k, X_k)\|_{C^{0,\beta}} \le C\eta_k(1 + |p_k| + |X_k|) \le \frac{C}{k}.$$

The regularity theory for uniformly elliptic H–J–B equations therefore yields the uniform boundedness of $\widetilde{w}_k$ in $C^{2,\overline{\beta}}$ for some $\overline{\beta}$, depending only on m, the ellipticity constant ν, and β. Moreover, for α_0 fixed, the families $\{b(x_k, \cdot, \alpha_0)\}$ and $\{g(x_k, \cdot, \alpha_0)\}$ are equi-bounded and equi-continuous. Therefore, along a subsequence, the functions $\widetilde{w}_k$ and their derivatives of order ≤ 2, respectively $b(x_k, \cdot, \alpha_0)$ and $g(x_k, \cdot, \alpha_0)$, converge uniformly to some function $\widetilde{w}$ in $C^{2,\overline{\beta}}$ and its derivatives of order ≤ 2, respectively to b and g. The function b is clearly $\ge \nu I_p$, while $\widetilde{w}$ is a periodic function in $C^{2,\overline{\beta}}$ such that $\widetilde{w}(0) = 0$ and $\|\widetilde{w}\|_{L^\infty} = 1$. Since $\delta_k \widetilde{w}_k$, $\eta_k \delta_k w_k(0)$, and $\eta_k L(\cdot, \alpha, x_k, p_k, X_k)$ converge to 0 uniformly, we deduce from the stability results for viscosity solutions that $\widetilde{w}$ is a classic subsolution of the uniformly elliptic linear equation

$$-\operatorname{tr}(b(y) D^2 \widetilde{w}) - (D\widetilde{w}, g(y)) \le 0.$$

Since $\widetilde{w}$ is periodic, it achieves its maximum at some point. By the strong maximum principle, it must be constant. This is impossible, for we must have $\widetilde{w}(0) = 0$ and $\|\widetilde{w}\|_{L^\infty} = 1$.

Recalling that the running cost $L(\cdot, \alpha, x, p, X)$ is Hölder continuous with $C^{0,\beta}$ norm growing linearly in p and X, we deduce from the bound (33) and from the

regularity theory for uniformly elliptic H–J–B equations that there is some $0 < \overline{\beta} \le \beta$, $\overline{\beta}$ depending only on m, ν, and β, such that

$$\begin{aligned}\|w_\delta - w_\delta(0)\|_{C^{2,\overline{\beta}}} &\le C\left(\|w_\delta - w_\delta(0)\|_{L^\infty} + |\delta w_\delta(0)| + \sup_\alpha \|L(\cdot,\alpha,x,p,X)\|_{C^{0,\beta}}\right)\\ &\le C(1+|p|+|X|).\end{aligned}$$

This is (32). □

In order to solve the limit equation with Hamiltonian $\overline{H}$, one needs to strengthen slightly the regularity of $\overline{H}$ in Proposition 12. One of the following properties is sufficient to invoke results from the theory of viscosity solutions.

— The effective Hamiltonian is uniformly elliptic and satisfies (27).
— The effective Hamiltonian is of first order and satisfies (27).
— The effective Hamiltonian is degenerate elliptic and satisfies the following structure condition (see [17]): there is a modulus ω such that, for every $\kappa > 0$ and every $x, x' \in \mathbb{R}^n$, $X, X' \in \mathbb{S}^n$ so that

$$-3\kappa \begin{pmatrix} I & 0 \\ 0 & I \end{pmatrix} \le \begin{pmatrix} X & 0 \\ 0 & -X' \end{pmatrix} \le 3\kappa \begin{pmatrix} I & -I \\ -I & I \end{pmatrix},$$

we have

$$\overline{H}\left(x', \kappa(x-x'), X'\right) \le \overline{H}(x, \kappa(x-x'), X) + \omega\left(\kappa|x'-x|^2 + |x'-x|\right). \tag{34}$$

Condition (34) is the most general but it is an open question whether it is true in general. We can only prove it when the drift and diffusion in the fast variable do not depend on x. This leads us to make one of the following assumptions about the dynamics.

(IV) The diffusions in the slow variable are uniformly nondegenerate, i.e., there is a constant $\mu > 0$ such that

$$a(x,y,\alpha) \ge \mu I_n \qquad \text{for all} \quad (x,y,\alpha).$$

(V) The problem in the slow variable is deterministic ($a \equiv 0$).
(VI) The drifts and diffusions in the fast variable are independent of x ($g \equiv g(y,\alpha)$ and $b \equiv b(y,\alpha)$).

From the representation formula (24), it is obvious that $\overline{H}$ is uniformly elliptic with constant μ in case (IV) and that it is of first order in case (V). Condition (34) also follows in case (VI) from the representation formula, since the fast dynamics are independent of x (and because we have classically $-\mathrm{tr}(a(x',y,\alpha)X') \le -\mathrm{tr}(a(x,y,\alpha)X) + C\kappa|x'-x|^2$ when the matrices X and X' satisfy the inequality in (34)).

We can now invoke the theory of viscosity solutions to obtain the solvability of the limit equation. We refer to [17] as well as to [28] for the results and proofs.

PROPOSITION 13. *Assume either* (I) *or* (II) *or* (III)*, and either* (IV) *or* (V) *or* (VI)*. Then there is a unique bounded continuous viscosity solution of the limit equation*

$$-\partial_t u + \overline{H}(x, Du, D^2u) = 0 \quad \text{in } (0,T)\times\mathbb{R}^n, \qquad u(T,\cdot) = h \quad \text{on } \mathbb{R}^n. \tag{35}$$

Moreover, if u is a bounded u.s.c. subsolution and v is a bounded l.s.c. supersolution, then $u \le v$ on $(0,T]\times\mathbb{R}^n$.

2.6. Convergence.

THEOREM 14. *Assume either* (I) *or* (II) *or* (III) *and either* (IV) *or* (V) *or* (VI). *Then, as* $\varepsilon \to 0+$, *the collection* $\{u_\varepsilon\}$ *converges uniformly on the compact subsets of* $(0,T]\times\mathbb{R}^n\times\mathbb{R}^m$ *to the unique viscosity solution* u *of* (35).

Proof. The functions u_ε are bounded in $(0,T]\times\mathbb{R}^n\times\mathbb{R}^m$ uniformly in ε. We can therefore define the half-relaxed limits on $(0,T]\times\mathbb{R}^n$:

$$\underline{u}(t,x)=\liminf_{\varepsilon\to 0,\ t'\to t,\ x'\to x}\ \inf_y u_\varepsilon(t',x',y),\qquad \overline{u}(t,x)=\limsup_{\varepsilon\to 0,\ t'\to t,\ x'\to x}\ \sup_y u_\varepsilon(t',x',y).$$

As in the first section, we shall prove that $\underline{u}$ is a supersolution of (35) and that $\overline{u}$ is a subsolution of (35). By the comparison principle, we shall get $\underline{u}=\overline{u}=u$ in $(0,T]\times\mathbb{R}^n$. This gives classically the uniform convergence on the compact subsets of $(0,T]\times\mathbb{R}^n\times\mathbb{R}^m$ of $\{u_\varepsilon\}$ to u.

We only check that $\overline{u}$ is a subsolution of (35), the proof that $\underline{u}$ is a supersolution being analogous. Let $w(t,x)$ be the continuous viscosity solution of

$$-\partial_t w+\inf_y H(x,y,D_x w,0,D^2_{xx}w,0,0)=0\quad\text{in }(0,T)\times\mathbb{R}^n,\qquad w(T,\cdot)=h\quad\text{on }\mathbb{R}^n.$$

It is clearly a viscosity supersolution of (22). By the comparison principle, we have $u_\varepsilon(t,x,y)\le w(t,x)$ for all $\varepsilon>0$, $0<t\le T$, x, y. Taking the semilimit, we deduce that $\overline{u}(T,\cdot)\le h$ on $\mathbb{R}^n$. This proves that $\overline{u}$ is a subsolution at the terminal boundary.

We next prove that $\overline{u}$ is a subsolution in $(0,T)\times\mathbb{R}^n$. Let $(\overline{t},\overline{x})\in(0,T)\times\mathbb{R}^n$ be a strict maximum point of $\overline{u}(t,x)-\varphi(t,x)$ with $\overline{u}(\overline{t},\overline{x})=\varphi(\overline{t},\overline{x})$. We argue by contradiction, assuming that

$$-\partial_t\varphi(\overline{t},\overline{x})+\overline{H}(\overline{x},D\varphi(\overline{t},\overline{x}),D^2\varphi(\overline{t},\overline{x}))>0.$$

Put $\overline{H}=\overline{H}(\overline{x},D\varphi(\overline{t},\overline{x}),D^2\varphi(\overline{t},\overline{x}))$. Let v_ε be the periodic solution of

$$\varepsilon v_\varepsilon+H(\overline{x},y,D\varphi(\overline{t},\overline{x}),D_y v_\varepsilon,D^2\varphi(\overline{t},\overline{x}),D^2_{yy}v_\varepsilon,0)=\overline{H}\quad\text{in }\mathbb{R}^m.$$

By Theorem 10 and the definition of the effective Hamiltonian, we know that $\varepsilon\big(v_\varepsilon-\varepsilon^{-1}\overline{H}\big)$ converges uniformly to $-\overline{H}$. Therefore, $\varepsilon v_\varepsilon$ converges uniformly to 0. For $\varepsilon>0$, we consider the perturbed test function

$$\psi_\varepsilon(t,x,y)=\varphi(t,x)+\varepsilon v_\varepsilon(y).$$

We will show that there is a small $r\in(0,\overline{t}\wedge(T-\overline{t}))$ so that ψ_ε is a supersolution of (22) in $Q_r=(\overline{t}-r,\overline{t}+r)\times B(\overline{x},r)\times\mathbb{R}^m$ for ε small. We suppose this has been proved and reach a contradiction. Since $\{\psi_\varepsilon\}$ converges uniformly to φ on $\overline{Q_r}$, we have

$$\limsup_{\varepsilon\to 0,\ t'\to t,\ x'\to x}\ \sup_y(u_\varepsilon-\psi_\varepsilon)=\overline{u}(t,x)-\varphi(t,x).$$

But $(\overline{t},\overline{x})$ is a strict maximum point of $\overline{u}-\varphi$, so the above relaxed upper limit is <0 on ∂Q_r. By compactness (recall that u_ε and ψ_ε are periodic in y), one can find $\eta>0$ so that $u_\varepsilon-\psi_\varepsilon\le-\eta$ on ∂Q_r for ε small, i.e., $\psi_\varepsilon\ge u_\varepsilon+\eta$ on ∂Q_r. Since ψ_ε is a supersolution of (22) in Q_r, we deduce from the comparison principle that $\psi_\varepsilon\ge u_\varepsilon+\eta$ in Q_r for ε small. Taking the upper semilimit, we get $\varphi\ge\overline{u}+\eta$ in $(\overline{t}-r,\overline{t}+r)\times B(\overline{x},r)$. This is impossible for $\varphi(\overline{t},\overline{x})=\overline{u}(\overline{t},\overline{x})$.

We have to show that ψ_ε is a supersolution of (22) in Q_r for r small, for all ε small. For every $(t,x,y) \in Q_r$, we have

$$
\begin{aligned}
(36)\qquad & -\partial_t \psi_\varepsilon + H\left(x, y, D_x\psi_\varepsilon, \frac{D_y\psi_\varepsilon}{\varepsilon}, D^2_{xx}\psi_\varepsilon, \frac{D^2_{yy}\psi_\varepsilon}{\varepsilon}, \frac{D^2_{xy}\psi_\varepsilon}{\sqrt{\varepsilon}}\right) \\
& \qquad = -\partial_t\varphi(t,x) + H(x, y, D\varphi(t,x), D_y v_\varepsilon(y), D^2\varphi(t,x), D^2_{yy} v_\varepsilon(y), 0).
\end{aligned}
$$

When g and b are independent of x (case (III)), the Hamiltonian satisfies

$$
\begin{aligned}
H(x,y,p,q,X,Y,0) \ge\ & H(\overline{x}, y, \overline{p}, q, \overline{X}, Y, 0) \\
& -C|x-\overline{x}|\big(1+|\overline{p}|+|\overline{X}|\big) - \omega(|x-\overline{x}|) - C|p-\overline{p}| - C|X-\overline{X}|
\end{aligned}
$$

for $\overline{p} = D\varphi(\overline{t},\overline{x})$ and $\overline{X} = D^2\varphi(\overline{t},\overline{x})$. Therefore, the quantity in (36) is bounded from below by

$$
\begin{aligned}
& -\partial_t\varphi(\overline{t},\overline{x}) + H(\overline{x}, y, D\varphi(\overline{t},\overline{x}), D_y v_\varepsilon(y), D^2\varphi(\overline{t},\overline{x}), D^2_{yy} v_\varepsilon(y), 0) - o(1) \\
(37)\qquad & \qquad = -\partial_t\varphi(\overline{t},\overline{x}) - \varepsilon v_\varepsilon + \overline{H} - o(1),
\end{aligned}
$$

where $o(1)$ goes to 0 as $(t,x) \to (\overline{t},\overline{x})$ uniformly in ε. Since $\varepsilon v_\varepsilon$ converges uniformly to 0 and since $-\partial_t\varphi(\overline{t},\overline{x}) + \overline{H} > 0$, we can find $r > 0$ so that the quantity is ≥ 0 in Q_r for ε small. We conclude that

$$
-\partial_t\psi_\varepsilon + H\left(x, y, D_x\psi_\varepsilon, \frac{D_y\psi_\varepsilon}{\varepsilon}, D^2_{xx}\psi_\varepsilon, \frac{D^2_{yy}\psi_\varepsilon}{\varepsilon}, \frac{D^2_{xy}\psi_\varepsilon}{\sqrt{\varepsilon}}\right) \ge 0 \quad \text{in } Q_r.
$$

The inequality was derived a bit formally. Using the smoothness of φ, it is an easy exercise to check that the inequality holds in the viscosity sense (see section 1).

The modifications for the cases (I) and (II) are analogous to those performed in Proposition 12. We only sketch them here. When b is independent of x (case (II)), the Hamiltonian now satisfies (29), where the additional q term appears. In (37) there is therefore the extra term $|x-\overline{x}|\,|D_y v_\varepsilon|$. By the coercivity of H, we know that $|D_y v_\varepsilon|$ is bounded uniformly in y and ε by $C(1+|\overline{p}|+|\overline{X}|)$ (see (30)). So the extra term converges uniformly on ε and y to 0 as $x \to \overline{x}$. The above argument therefore applies and guarantees the existence of a small $r > 0$ so that ψ_ε is a supersolution in Q_r for ε small.

When both g and b may depend on x (case (I)), we must use the inequality (31) for the Hamiltonian. But one now controls $D_y v_\varepsilon$ and $D^2_{yy} v_\varepsilon$ uniformly on ε (see (32)). Thus, the extra term $|x-\overline{x}|(|D_y v_\varepsilon| + |D^2_{yy} v_\varepsilon|)$ converges uniformly to 0 as $x \to \overline{x}$, and the argument still works. □

3. Homogenization and stochastic control.

3.1. Homogenization. In the case of a periodic fast variable, a special singular perturbation problem is homogenization. We briefly illustrate this and refer to [19, 20, 8, 25, 26, 1, 38] for recent developments in the theory of homogenization of H–J equations, which was introduced by Lions, Papanicolaou, and Varadhan [35]. For an optimal control problem, homogenization corresponds to dynamics of the form

$$
dx_s = f\left(x_s, \frac{x_s}{\varepsilon}, \alpha_s\right) ds + \sigma\left(x_s, \frac{x_s}{\varepsilon}, \alpha_s\right) dW_s
$$

and the value function

$$v_\varepsilon(t,x) = \inf_\alpha E\left\{\int_t^T l\left(x_s, \frac{x_s}{\varepsilon}, \alpha_s\right)\, ds + h(x_T) \mid x_t = x\right\}.$$

All the functions are of course assumed to be periodic in the second variable. Adding the new variable $y_s = x_s/\varepsilon$, the dynamical system becomes

$$\begin{aligned} dx_s &= f(x_s, y_s, \alpha_s)\, ds + \sigma(x_s, y_s, \alpha_s)\, dW_s, \\ dy_s &= \varepsilon^{-1} f(x_s, y_s, \alpha_s)\, ds + \varepsilon^{-1}\sigma(x_s, y_s, \alpha_s)\, dW_s \end{aligned} \tag{38}$$

with starting point $x_t = x$ and $y_t = x/\varepsilon$.

When the problem is deterministic ($\sigma \equiv 0$) or when there is no drift ($f \equiv 0$), the value function v_ε can be expressed in terms of the value function u_ε of the singular perturbation problem of the preceding section (with $g \equiv f$ and $\tau \equiv \sigma$) as follows:

$$v_\varepsilon(t,x) = u_\varepsilon\left(t, x, \frac{x}{\varepsilon}\right) \qquad \text{and} \qquad v_\varepsilon(t,x) = u_{\varepsilon^2}\left(t, x, \frac{x}{\varepsilon}\right), \qquad \text{respectively.}$$

The convergence of u_ε to the solution of the limit equation (which will be uniform in y by periodicity) of course implies the convergence of v_ε to the same limit. In general, however, the scaling in (38) differs from that of the previous section. We explain briefly how the results can be adapted.

3.2. The associated singular perturbation problem. For $\varepsilon > 0$ fixed, we therefore consider a finite horizon stochastic control problem in $(0,T] \times \mathbb{R}^n \times \mathbb{R}^m$ similar to the one of the preceding section but with the dynamics

$$\begin{aligned} dx_s &= f(x_s, y_s, \alpha_s)\, ds + \sigma(x_s, y_s, \alpha_s)\, dW_s, \\ dy_s &= \varepsilon^{-1} g(x_s, y_s, \alpha_s)\, ds + \varepsilon^{-1}\tau(x_s, y_s, \alpha_s)\, dW_s. \end{aligned}$$

The value function

$$u_\varepsilon(t,x,y) = \inf_\alpha E\left\{\int_t^T l(x_s, y_s, \alpha_s)\, ds + h(x_T)\right\}$$

is now the unique bounded continuous viscosity solution of the H–J–B equation

$$\begin{cases} -\partial_t u_\varepsilon + H\left(x, y, D_x u_\varepsilon, \dfrac{D_y u_\varepsilon}{\varepsilon}, D^2_{xx} u_\varepsilon, \dfrac{D^2_{yy} u_\varepsilon}{\varepsilon^2}, \dfrac{D^2_{xy} u_\varepsilon}{\varepsilon}\right) = 0 \quad \text{in } (0,T) \times \mathbb{R}^n \times \mathbb{R}^m, \\ u_\varepsilon(T, \cdot) = h \quad \text{on } \mathbb{R}^n \times \mathbb{R}^m \end{cases} \tag{39}$$

for the Hamiltonian of the preceding section.

In an attempt to apply the method of the preceding section, we were lead to assume that $\sigma \equiv 0$ in case (II) and $g \equiv 0$ in case (III). As explained above, the scaling is unchanged under one of these assumptions. The new result therefore concerns case (I) in which drifts and diffusions appear. We recall the assumption for convenience.

(I) The diffusions in the fast variable are uniformly nondegenerate and the running cost $l(x, \cdot, \alpha)$ is Hölder continuous uniformly on (x, α).

THEOREM 15. *Assume that* (I) *holds and let* (x, p, X) *be fixed. For every* $\delta > 0$, *let* w_δ *denote the unique viscosity solution of the stationary problem in the fast variable*

$$\delta w_\delta + H\left(x, y, p, 0, X, D^2_{yy} w_\delta, 0\right) = 0 \quad \textit{in } \mathbb{R}^m, \qquad w_\delta \textit{ periodic.}$$

Then, as $\delta \to 0+$, the family $\{\delta w_\delta\}$ converges to a constant $-\overline{H}(x,p,X)$ uniformly with respect to y.

The theorem is a special case of Theorem 10 of the preceding section, because the actual Hamiltonian in the theorem corresponds to the original one with $g \equiv 0$. The new effective Hamiltonian therefore has the regularity stated in Propositions 11 and 12. As a consequence, the limit equation (35) has a unique bounded continuous viscosity solution under either (IV) or (V) or (VI), provided we drop the reference to g in this last condition:

(VI) the diffusions in the fast variable are independent of x ($b \equiv b(y,\alpha)$).

THEOREM 16. *Assume* (I) *and either* (IV) *or* (V) *or* (VI). *Then, as $\varepsilon \to 0+$, the collection $\{u_\varepsilon\}$ converges uniformly on the compact subsets of $(0,T]\times\mathbb{R}^n\times\mathbb{R}^m$ to the unique viscosity solution u of* (35).

Proof. We keep the notations of the proof of Theorem 14 and mention only the changes. To prove that $\overline{u}$ is a subsolution in $(0,T)\times\mathbb{R}^n$, we consider a strict maximum point $(\bar t,\bar x)\in(0,T)\times\mathbb{R}^n$ of $\overline{u}(t,x)-\varphi(t,x)$ with $\overline{u}(\bar t,\bar x)=\varphi(\bar t,\bar x)$ and assume that $-\partial_t\varphi(\bar t,\bar x)+\overline{H}>0$ for $\overline{H}=\overline{H}(\bar x,D\varphi(\bar t,\bar x),D^2\varphi(\bar t,\bar x))$. If v_ε is the periodic solution of

$$\varepsilon^2 v_\varepsilon + H\left(\bar x, y, D\varphi(\bar t,\bar x), 0, D^2\varphi(\bar t,\bar x), D^2_{yy}v_\varepsilon, 0\right) = \overline{H} \quad \text{in } \mathbb{R}^m,$$

the family $\{\varepsilon^2 v_\varepsilon\}$ converges uniformly to 0. A contradiction is achieved by showing that the perturbed test function

$$\psi_\varepsilon(t,x,y) = \varphi(t,x) + \varepsilon^2 v_\varepsilon(y)$$

is a supersolution of (22) in $Q_r=(\bar t-r,\bar t+r)\times B(\bar x,r)\times\mathbb{R}^m$ for some $r>0$ and for ε small. For every $(t,x,y)\in Q_r$, we compute

$$\begin{aligned}
&-\partial_t\psi_\varepsilon + H\left(x,y,D_x\psi_\varepsilon,\frac{D_y\psi_\varepsilon}{\varepsilon},D^2_{xx}\psi_\varepsilon,\frac{D^2_{yy}\psi_\varepsilon}{\varepsilon^2},\frac{D^2_{xy}\psi_\varepsilon}{\varepsilon}\right)\\
&\quad= -\partial_t\varphi(t,x) + H\left(x,y,D\varphi(t,x),\varepsilon D_y v_\varepsilon(y),D^2\varphi(t,x),D^2_{yy}v_\varepsilon(y),0\right)\\
&\quad\ge -\partial_t\varphi(t,x) + H\left(x,y,D\varphi(t,x),0,D^2\varphi(t,x),D^2_{yy}v_\varepsilon(y),0\right) - C\varepsilon|D_y v_\varepsilon|,
\end{aligned}$$

where $C=\|g\|_{L^\infty}$. The term $\varepsilon|D_y v_\varepsilon|$ converges uniformly to 0 as $\varepsilon\to 0$ because we have the bound $\|D_y v_\varepsilon\|_{L^\infty}\le C$ under (I) (see (32)). The remaining two terms correspond to the case $g\equiv 0$; they can be handled as in the proof of Theorem 14. We conclude that the expression is ≥ 0 in Q_r for some $r>0$ and for ε small, so that ψ_ε is a supersolution. This completes the proof. ∎

Acknowledgments. We are grateful to Z. Artstein for sending us the first and second drafts of the preprint [5] that stimulated this research and to V. Gaitsgory for useful talks on the singular perturbation literature and on [23].

MINIMAX LQG CONTROL OF STOCHASTIC PARTIALLY OBSERVED UNCERTAIN SYSTEMS*

VALERY A. UGRINOVSKII† AND IAN R. PETERSEN†

Abstract. We consider an infinite-horizon linear-quadratic minimax optimal control problem for stochastic uncertain systems with output measurement. A new description of stochastic uncertainty is introduced using a relative entropy constraint. For the stochastic uncertain system under consideration, a connection between the worst-case control design problem and a specially parametrized risk-sensitive stochastic control problem is established. Using this connection, a minimax optimal LQG controller is constructed which is based on a pair of algebraic matrix Riccati equations arising in risk-sensitive control. It is shown that this minimax optimal controller absolutely stabilizes the stochastic uncertain system.

Key words. robust control, LQG control, stochastic control, stochastic risk-sensitive control, stochastic dynamic games

1. Introduction.

One of the important ideas in modern robust control theory emerges from the fact that many robust control problems can be formulated as optimization problems. The advantage of this approach is that it allows one to readily convert a problem of robust controller design into a mathematically tractable game-type minimax optimization problem. For linear systems with full state measurement, this methodology leads to a robust version of the linear quadratic regulator (LQR) approach to state feedback controller design [15, 18]. However, the development of a robust version of the LQG technique appears to be a challenging problem. The problem becomes especially difficult in situations in which one wishes to take into account the fact that in real physical systems, noise disturbances entering into the controlled plant differ from Gaussian white noise. A suitable way of introducing noise disturbances in this case may be to treat the disturbances as uncertain stochastic processes. A formalization of this idea leads to the concept of an *uncertain stochastic system* introduced in recent papers [11, 12, 19].

Note that in the case of a finite time horizon, the uncertain systems framework introduced in [12, 19] allows one to extend the standard LQG design methodology into a partial information minimax optimal control methodology for stochastic uncertain systems. The problem considered in [12, 19] involves constructing a controller which minimizes worst-case performance in the face of system uncertainty which satisfies a certain stochastic uncertainty constraint. This constraint restricts the *relative entropy* between an uncertain probability measure related to the distribution of the uncertainty input and the reference probability measure. This relative entropy constraint can be thought of as a stochastic counterpart of the deterministic integral quadratic constraint uncertainty description; see [15, 23]. One advantage of the relative entropy uncertainty description is that it allows for stochastic uncertainty inputs

to depend dynamically on the uncertainty outputs.

In this paper, we address an infinite-horizon version of the robust LQG problems considered in [12, 19]. As we proceed from a finite time interval to an infinite time interval, the fact that the systems under consideration are those with additive noise becomes important. The solutions of such systems do not necessarily belong to $L_2[0,\infty)$. Hence, the approaches used to describe admissible uncertainties in the deterministic case (e.g., see [15]) and the multiplicative noise case [18] are not applicable here. Note that the class of admissible uncertainties defined using the approach of [15, 18] is consistent with the notion of absolute stabilizability defined in terms of the $L_2[0,\infty)$-summability of uncertainty inputs and corresponding solutions to the closed-loop system. However, in the present paper the uncertainty inputs and solutions need not be $L_2[0,\infty)$-summable. Instead, we will consider the time-averaged properties of the system solutions. This requires us to correspondingly modify the definitions of admissible uncertainty and absolute stabilizability in order to properly account for the nature of the systems under consideration. In particular, our new definition of the class of admissible uncertainties is one of the contributions of this paper. In the case of an uncertain system with additive noise considered on the infinite time interval, we use an approximating sequence of martingales to describe the class of admissible uncertainties. In particular, we give an example which shows that H^∞ norm-bounded uncertainty can be incorporated into the proposed framework by constructing a corresponding sequence of martingales.

The main result of the paper is a robust LQG control synthesis procedure based on a pair of algebraic Riccati equations arising in risk-sensitive optimal control; see [9]. We show that solutions to a certain specially parametrized risk-sensitive control problem provide us with a controller which guarantees an optimal upper bound on the time-averaged performance of the closed-loop system in the presence of admissible uncertainties.

2. Definitions. Let $(\Omega,\mathcal{F},P)$ be a complete probability space on which a p-dimensional standard Wiener process $W(\cdot)$ and a Gaussian random variable $x_0\colon \Omega\to\mathbf{R}^n$ with mean $\check{x}_0$ and nonsingular covariance matrix Y_0 are defined, $p=r+l$. The first r entries of the vector process $W(\cdot)$ correspond to the system noise, while the last l entries correspond to the measurement noise. The space Ω can be thought of as the noise space $\mathbf{R}^n\times\mathbf{R}^l\times C([0,\infty),\mathbf{R}^p)$ [1]. The probability measure P can then be defined as the product of a given probability measure on $\mathbf{R}^n\times\mathbf{R}^l$ and the standard Wiener measure on $C([0,\infty),\mathbf{R}^p)$. The space Ω is endowed with a filtration $\{\mathcal{F}_t, t\ge 0\}$ which has been completed by including all sets of probability zero. The filtration $\{\mathcal{F}_t, t\ge 0\}$ can be thought of as the filtration generated by the mappings $\{\Pi_t, t\ge 0\}$, where $\Pi_0(x,\eta,W(\cdot))=(x,\eta)$ and $\Pi_t(x,\eta,W(\cdot))=W(t)$ for $t>0$ [1]. The random variable x_0 and the Wiener process $W(\cdot)$ are stochastically independent in $(\Omega,\mathcal{F},P)$.

2.1. The nominal system. On the probability space $(\Omega,\mathcal{F},P)$ defined above, we consider the system and measurement dynamics driven by the noise input $W(\cdot)$ and a control input $u(\cdot)$. These dynamics are described by the following stochastic differential equation:

$$
\begin{aligned}
dx(t) &= (Ax(t)+B_1u(t))dt + B_2dW(t), \qquad x(0)=x_0,\\
z(t) &= C_1x(t)+D_1u(t),\\
dy(t) &= C_2x(t)dt + D_2dW(t), \qquad y(0)=0.
\end{aligned}
\tag{1}
$$

In the above equations, $x(t) \in \mathbf{R}^n$ is the state, $u(t) \in \mathbf{R}^m$ is the control input, $z(t) \in \mathbf{R}^q$ is the uncertainty output, and $y(t) \in \mathbf{R}^l$ is the measured output. System (1) is referred to as the nominal system. All coefficients in (1) are assumed to be constant matrices of corresponding dimensions. Also, we assume that $D_2 D_2' > 0$.

In the minimax optimal control problem to be considered in this paper, our attention will be restricted to linear output-feedback controllers of the form

$$\begin{aligned} d\hat{x} &= A_c \hat{x} + B_c dy, \\ u &= K\hat{x}, \end{aligned} \tag{2}$$

where $\hat{x} \in \mathbf{R}^{\hat{n}}$ is the state of the controller and $A_c \in \mathbf{R}^{\hat{n}\times\hat{n}}$, $K \in \mathbf{R}^{m\times\hat{n}}$, and $B_c \in \mathbf{R}^{\hat{n}\times q}$. Let $\mathcal{U}$ denote this class of linear controllers. Note that the controller (2) is adapted to the filtration $\{\mathcal{Y}_t, t \geq 0\}$ generated by the observation process y. The closed-loop nominal system corresponding to controller (2) is described by a linear Ito differential equation of the form

$$\begin{aligned} d\bar{x} &= \bar{A}\bar{x}dt + \bar{B}dW(t), \\ z &= \bar{C}\bar{x}, \\ u &= \begin{bmatrix} 0 & K \end{bmatrix} \bar{x} \end{aligned} \tag{3}$$

and is considered on the probability space $(\Omega, \mathcal{F}, P)$. In (3), $\bar{x} = [x' \ \hat{x}']' \in \mathbf{R}^{n+\hat{n}}$ is the state of the closed-loop system. Also, the following notation is used:

$$\bar{A} = \begin{bmatrix} A & B_1 K \\ B_c C_2 & A_c \end{bmatrix}, \qquad \bar{B} = \begin{bmatrix} B_2 \\ B_c D_2 \end{bmatrix}, \qquad \bar{C} = \begin{bmatrix} C_1 & D_1 K \end{bmatrix}. \tag{4}$$

2.2. The stochastic uncertain system. In this paper, we introduce an uncertainty description for stochastic uncertain systems with additive noise which can be regarded as an extension of the uncertainty description considered in [12, 19] to the case of an infinite time horizon. As in [12, 19], the stochastic uncertain systems to be considered are described by the nominal system (1) considered over the probability space $(\Omega, \mathcal{F}, P)$, and also by a set of perturbations of the reference probability measure P. These perturbations are defined as follows. Consider the set $\mathcal{M}$ of continuous positive martingales $(\zeta(t), \mathcal{F}_t, t \geq 0)$ such that for each $T \geq 0$, $\mathbf{E}\zeta(T) = 1$; here, $\mathbf{E}$ denotes the expectation with respect to the probability measure P. Note that the set $\mathcal{M}$ is convex.

Every martingale $\zeta(\cdot) \in \mathcal{M}$ gives rise to a probability measure Q^T on the measurable space $(\Omega, \mathcal{F}_T)$ defined by the equation

$$Q^T(d\omega) = \zeta(T) P^T(d\omega). \tag{5}$$

Here, P^T denotes the restriction of the reference probability measure P to $(\Omega, \mathcal{F}_T)$. From this definition, for every $T > 0$, the probability measure Q^T is absolutely continuous with respect to the probability measure P^T, $Q^T \ll P^T$. The uncertain system is described by the stochastic differential equation (1) considered over the probability space $(\Omega, \mathcal{F}_T, Q^T)$ for every $T > 0$. The expectation in this probability space is denoted $\mathbf{E}^{Q^T}$.

We now present an infinite-horizon uncertainty description for stochastic uncertain systems with additive noise. This uncertainty description may be regarded as an extension of the uncertainty description considered in [19] to the infinite-horizon case. Also, this uncertainty description can be thought of as an extension of the

deterministic integral quadratic constraint uncertainty description [15, 16, 23] and the stochastic integral quadratic constraint uncertainty description [18] to the case of stochastic uncertain systems with additive noise. Recall that the integral quadratic constraints arising in [15, 16, 23, 18] exploit a sequence of times $\{t_i\}_{i=1}^{\infty}$ to "localize" the uncertainty inputs and uncertainty outputs to time intervals $[0, t_i]$. The consideration of the system dynamics on these finite time intervals then allows one to deal with bounded energy processes. However, in this paper the systems under consideration are those with additive noise. For this class of stochastic systems, it is natural to consider bounded power processes rather than bounded energy processes. This motivates us to propose the relative entropy uncertainty description given below in Definition 1 to accommodate bounded power processes.

In contrast to the case of deterministic integral quadratic constraints, the uncertainty description considered in this paper exploits a sequence of continuous positive martingales $\{\zeta_i(t), \mathcal{F}_t, t \geq 0\}_{i=1}^{\infty} \subset \mathcal{M}$ which converges to a limiting martingale $\zeta(\cdot)$ in the following sense: For any $T > 0$, the sequence $\{\zeta_i(T)\}_{i=1}^{\infty}$ converges weakly to $\zeta(T)$ in $L_1(\Omega, \mathcal{F}_T, P^T)$. Using the martingales $\zeta_i(t)$, we define a sequence of probability measures $\{Q_i^T\}_{i=1}^{\infty}$ as follows:

$$Q_i^T(d\omega) = \zeta_i(T) P^T(d\omega). \tag{6}$$

From the definition of the martingales $\zeta_i(t)$, it follows that for each $T > 0$ the sequence $\{Q_i^T\}_{i=1}^{\infty}$ converges to the probability measure Q^T corresponding to a limiting martingale $\zeta(\cdot)$ in the following sense: For any bounded $\mathcal{F}_T$-measurable random variable η,

$$\lim_{i \to \infty} \int_{\Omega} \eta Q_i^T(d\omega) = \int_{\Omega} \eta Q^T(d\omega). \tag{7}$$

We denote this fact by $Q_i^T \Rightarrow Q^T$ as $i \to \infty$.

Remark 1. The property $Q_i^T \Rightarrow Q^T$ implies that the sequence of probability measures Q_i^T converges weakly to the probability measure Q^T. Indeed, consider the Polish space of probability measures on the measurable space $(\Omega, \mathcal{F}_T)$ endowed with the topology of weak convergence of probability measures. Note that Ω is a metric space. Hence, such a topology can be defined; e.g., see [2]. For the sequence $\{Q_i^T\}$ to converge weakly to Q^T, it is required that (7) hold for all bounded continuous random variables η. Obviously, this requirement is satisfied if $Q_i^T \Rightarrow Q^T$.

As in the finite-horizon case [12, 19], we describe the class of admissible uncertainties in terms of the relative entropy functional $h(\cdot\|\cdot)$; for the definition and properties of the functional $h(\cdot\|\cdot)$, see Appendix A and also [2].

DEFINITION 1. *Let d be a given positive constant. A martingale $\zeta(\cdot) \in \mathcal{M}$ is said to define an admissible uncertainty if there exists a sequence of continuous positive martingales $\{\zeta_i(t), \mathcal{F}_t, t \geq 0\}_{i=1}^{\infty} \subset \mathcal{M}$ which satisfies the following conditions:*

(i) *For each i, $h(Q_i^T \| P^T) < \infty$ for all $T > 0$;*

(ii) *For all $T > 0$, $Q_i^T \Rightarrow Q^T$ as $i \to \infty$;*

(iii) *The following* stochastic uncertainty constraint *is satisfied: For any sufficiently large $T > 0$, there exists a constant $\delta(T)$ such that $\lim_{T \to \infty} \delta(T) = 0$ and*

$$\inf_{T' > T} \frac{1}{T'} \left[\frac{1}{2} \mathbf{E}^{Q_i^{T'}} \int_0^{T'} \|z(t)\|^2 dt - h(Q_i^{T'} \| P^{T'}) \right] \geq -\frac{d}{2} + \delta(T) \tag{8}$$

for all $i = 1, 2, \ldots$. In (8), the uncertainty output $z(\cdot)$ is defined by (1) considered on the probability space $(\Omega, \mathcal{F}_T, Q_i^T)$.

In the above conditions, Q_i^T is the probability measure defined by (6) *corresponding to the martingale $\zeta_i(t)$ and time $T > 0$. We let Ξ denote the set of martingales $\zeta(\cdot) \in \mathcal{M}$ corresponding to admissible uncertainties. Elements of Ξ are also called admissible martingales.*

Observe that the reference probability measure P corresponds to the admissible martingale $\zeta(t) \equiv 1$. Hence, the set Ξ is not empty. Indeed, choose $\zeta_i(t) = 1$ for all i and t. Then $Q_i^T = P^T$ for all i. It follows from the identity $h(P^T \| P^T) = 0$ that

$$\inf_{T'>T} \frac{1}{T'} \left[\frac{1}{2} \mathbf{E}^{Q_i^{T'}} \int_0^{T'} \|z(t)\|^2 dt - h(Q_i^{T'} \| P^{T'}) \right] = \inf_{T'>T} \frac{1}{2T'} \mathbf{E} \int_0^{T'} \|z(t)\|^2 dt.$$

Note that the expectations are well defined. Also, the infimum on the right-hand side of the above equation is nonnegative for any $T > 0$. Therefore, for any constant $d > 0$, one can find a sufficiently small $\delta = \delta(T)$ such that $\lim_{T\to\infty} \delta(T) = 0$ and the constraint (8) is satisfied strictly in this case.

Remark 2. Note that condition (8) implies that

$$\liminf_{T\to\infty} \frac{1}{T} \left[\frac{1}{2} \mathbf{E}^{Q_i^T} \int_0^T \|z(t)\|^2 dt - h(Q_i^T \| P^T) \right] \geq -\frac{d}{2}$$

for all $i = 1, 2, \ldots$.

In what follows, we will use the following notation. Let $\mathcal{P}_T$ be the set of probability measures Q^T on $(\Omega, \mathcal{F}_T)$ such that $h(Q^T \| P^T) < \infty$. Also, the notation $\mathcal{M}_\infty$ will denote the set of martingales $\zeta(\cdot) \in \mathcal{M}$ such that $h(Q^T \| P^T) < \infty$ for all $T > 0$. It is readily verified that the set $\mathcal{M}_\infty$ is convex. Note that the martingales $\zeta_i(\cdot)$ from Definition 1 belong to $\mathcal{M}_\infty$.

2.3. A discussion of the class of stochastic uncertain systems under consideration. In this section, we give more insight into the class of stochastic uncertain systems under consideration. In the integral quadratic constraint approach to robust control theory, the uncertainty is described in terms of a given set of uncertainty input signals. In contrast, Definition 1 presents a martingale uncertainty description or, equivalently, a probability measure uncertainty description. The motivation behind Definition 1 is as follows. The proposed uncertain system model allows us to obtain a tractable solution to the corresponding problem of minimax optimal LQG controller design. Also, the stochastic uncertainty description presented in Definition 1 encompasses many important classes of uncertainty arising in robust control theory. In particular, it includes H^∞ norm-bounded linear time-invariant (LTI) uncertainties and cone-bounded nonlinear uncertainties. This makes the approach developed in this paper applicable to a broad range of control system design problems. We show below that H^∞ norm-bounded uncertainties satisfy the requirements of Definition 1.

The definition of admissible uncertainties given above involves a collection of martingales $\{\zeta_i(\cdot)\}_{i=1}^\infty$ which has a given uncertainty martingale $\zeta(\cdot)$ as its limit point. In the deterministic case and the multiplicative noise case, similar approximations have been defined by restricting uncertainty inputs to finite time intervals and then extending the restricted processes by zero beyond these intervals; e.g., see [15, 16, 18]. In the case of a stochastic uncertain system with additive noise considered on an infinite time interval, we apply a similar idea. However, in contrast to the deterministic and multiplicative noise cases, we use a sequence of martingales and corresponding probability measures in Definition 1. This procedure may be thought of as involving

a spatial restriction rather than the temporal restriction used previously. Indeed, a natural way to define the required sequence of martingales and corresponding probability measures is to consider martingales corresponding to the uncertainty inputs as "truncated" at certain Markov times $\mathfrak{t}_i$. For example, this can be achieved by choosing an expanding sequence of compact sets K_i in the uncertainty input space and letting $\mathfrak{t}_i$ be the Markov time when the uncertainty input reaches the boundary of the set K_i. In this case, we focus on spatial domains rather than time intervals on which the uncertainty inputs and uncertainty outputs are then constrained. An illustration of this idea will be given in section 2.3.2.

2.3.1. A connection between uncertainty input signals and martingale uncertainty. A connection between the uncertainty input signal uncertainty model and the perturbation martingale uncertainty model is based on Novikov's theorem [6]. Using the result of Novikov's theorem, a given uncertainty input $\xi(\cdot)$ satisfying the conditions of this theorem on every finite interval $[0,T]$ can be associated with a martingale $\zeta(\cdot) \in \mathcal{M}$. This result is summarized in the following lemma.

LEMMA 1. *Suppose a random process $(\xi(t), \mathcal{F}_t)$, $0 \le t \le T$, satisfies the conditions:*

$$P\left(\int_0^T \|\xi(s)\|^2 ds < \infty\right) = 1,$$

$$\mathbf{E} \exp\left(\frac{1}{2}\int_0^T \|\xi(s)\|^2 ds\right) < \infty. \tag{9}$$

Then the equation

$$\zeta(t) = 1 + \int_0^t \zeta(s)\xi(s)' dW(s) \tag{10}$$

defines a continuous positive martingale $\zeta(t)$. Furthermore, the stochastic process

$$\tilde{W}(t) = W(t) - \int_0^t \xi(t) dt \tag{11}$$

is a Wiener process with respect to the system $\{\mathcal{F}_t, 0 \le t \le T\}$ and the probability measure Q^T defined by (5)*, where $\zeta(\cdot)$ is defined by* (10)*.*

Proof. Conditions (9) are the conditions of Novikov's theorem (e.g., see Theorem 6.1 on page 216 of [6]). It follows from this theorem that the random process $(\zeta(t), \mathcal{F}_t)$, $0 \le t \le T$, defined by (10) is a continuous martingale and, in particular, $\mathbf{E}\zeta(T) = 1$. Furthermore, this martingale is given by

$$\zeta(t) = \exp\left(\int_0^t \xi'(s) dW(s) - \frac{1}{2}\|\xi(s)\|^2 ds\right). \tag{12}$$

The statement of the lemma now follows from Girsanov's theorem; e.g., see Theorem 6.3 on page 232 of [6]. □

We now consider an uncertain system with H^∞ norm-bounded LTI uncertainty and driven by a Gaussian white noise process $v(t)$ as shown in Figure 1. We will show that such an uncertain system can be described in terms of the stochastic uncertain system framework defined above. Note that if $\Delta(s) \equiv 0$ and $\xi(\cdot) = 0$, then $w(t) = v(t)$.

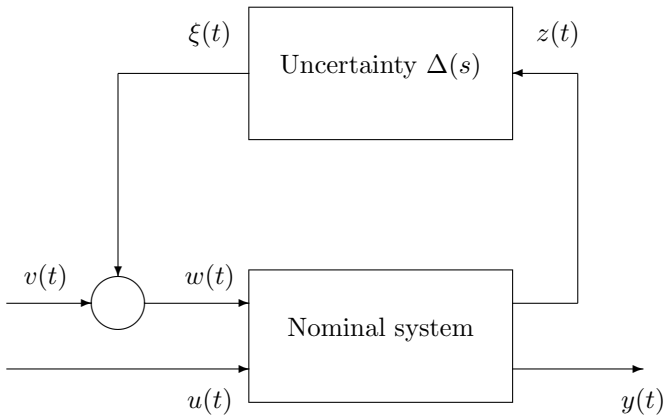

FIG. 1. *An uncertain system.*

That is, the nominal system is driven by a Gaussian white noise. However, in the presence of uncertainty, the input $w(\cdot)$ ceases to be a Gaussian white noise.

For each $T > 0$, a rigorous mathematical description of the system shown in Figure 1 can be given by the equations

$$\begin{aligned} dx &= (Ax + B_1 u + B_2 \xi)dt + B_2 d\tilde{W}(t), \\ z &= C_1 x + D_1 u, \\ dy &= (C_2 x + D_2 \xi)dt + D_2 d\tilde{W}(t) \end{aligned} \tag{13}$$

considered on the probability space $(\Omega, \mathcal{F}_T, Q^T)$, where Q^T is the probability measure constructed in Lemma 1. Also, the uncertainty input is related to the uncertainty output by the relation $\xi = \Delta(s)z$. Now, the substitution of (11) into (13) leads to a set of equations of the form (1) considered on the probability space $(\Omega, \mathcal{F}_T, Q^T)$. Thus, the uncertain system shown in Figure 1 can be considered in the stochastic uncertain system framework defined above. In what follows, we will show that an H^∞ norm bound on the LTI uncertainty $\Delta(s)$ implies the satisfaction of the relative entropy constraint described above. Note that the case $\xi(\cdot) = 0$ corresponds to $\zeta(t) \equiv 1$ and $Q^T = P^T$.

2.3.2. H^∞ norm-bounded uncertainty and the relative entropy constraint. In this section we will show that if the LTI uncertainty $\Delta(s)$ shown in Figure 1 satisfies an H^∞ norm bound, then the corresponding stochastic uncertain system satisfies the relative entropy constraint defined above. This completes the proof of our assertion that the standard H^∞ norm-bounded uncertainty description can be incorporated into the framework of Definition 1. In a similar fashion, one can also show that a cone-bounded nonlinear uncertainty defines an admissible uncertainty according to Definition 1. This proof has been removed for the sake of brevity.

In what follows, we will use the following well-known property of linear stochastic systems. On the probability space $(\Omega, \mathcal{F}, \tilde{P})$, consider the following linear system driven by the Wiener process $\tilde{W}(\cdot)$ and a disturbance input $\xi(t)$, $t \in [0, T]$:

$$d\bar{x} = (\bar{A}\bar{x} + \bar{B}\xi(t))dt + \bar{B}d\tilde{W}(t). \tag{14}$$

PROPOSITION 1. *If for some constant* $\rho > 0$

$$\tilde{\mathbf{E}} \int_0^T \|\xi(t)\|^2 dt \leq \rho, \tag{15}$$

then the corresponding solution to (14) *is mean square bounded on the interval* $[0, T]$. *Here* $\tilde{\mathbf{E}}$ *denotes the expectation with respect to the probability measure* $\tilde{P}$.

Proof. The proof of the proposition follows straightforwardly using standard Lyapunov arguments. □

Consider an uncertain system of the form (1) on the probability space $(\Omega, \mathcal{F}, P)$, driven by a controller (2). Associated with the system (1) and controller (2), consider the disturbance input $\xi(\cdot)$ defined by the convolution operator

$$\xi(t) = \int_0^t g(t-\theta) z(\theta) d\theta \tag{16}$$

corresponding to a given causal uncertainty transfer function $\Delta(s)$ which belongs to the Hardy space H^∞. In (16), $z(\cdot)$ is the uncertainty output of the closed-loop system corresponding to the system (1) and the given controller (2).

LEMMA 2. *Let an uncertainty transfer function* $\Delta(s) \in H^\infty$ *be given which satisfies the norm bound condition*

$$\|\Delta(s)\|_\infty \leq 1. \tag{17}$$

Also, suppose that the random process $(\zeta(t), \mathcal{F}_t)$ *defined by* (10) *is a martingale; here* $\xi(\cdot)$ *is the disturbance input generated by the operator* (16). *Then this martingale satisfies the conditions of Definition* 1.

Remark 3. The requirements of Lemma 2 are satisfied if $\Delta(s)$ is a stable rational transfer function satisfying condition (17). Indeed, in this case one can show that the augmented dynamics $[x'(\cdot), \hat{x}'(\cdot), \eta'(\cdot), z'(\cdot), \xi'(\cdot)]'$ are described by a linear system driven by a Wiener process, with Gaussian initial condition; here η denotes the state of the uncertainty. Hence for any $T > 0$ there exists a constant δ_T such that

$$\sup_{t \leq T} \mathbf{E} \exp(\delta_T \|\xi(t)\|^2) < \infty;$$

see the remark on page 138 of [6]. This implies that $\zeta(t)$ is a martingale; see Example 3 on page 220 of [6]. Hence, any uncertainty described by a stable rational transfer function satisfying condition (17) will belong to the class Ξ of uncertainties admissible for system (1) controlled by a linear output-feedback controller of the form (2).

Proof of Lemma 2. Since the random process $(\zeta(t), \mathcal{F}_t)$, $0 \leq t \leq T$, defined by (10) is a martingale and $\mathbf{E}\zeta(T) = 1$, it follows from Girsanov's theorem that the random process $\tilde{W}(\cdot)$ defined by (11) is a Wiener process with respect to the filtration $\{\mathcal{F}_t, 0 \leq t \leq T\}$ and the probability measure Q^T defined as in (5); see [6]. Note that on the probability space $(\Omega, \mathcal{F}_T, Q^T)$, system (1) becomes a system of the form (13).

To verify that the martingale $\zeta(t)$ corresponding to the H^∞ norm-bounded uncertainty under consideration defines an admissible uncertainty, we need to prove the existence of a sequence of martingales $\{\zeta_i(t)\}_{i=1}^\infty$ satisfying the conditions of Definition 1. To construct such a sequence, consider the following family of Markov stopping times $\{\mathfrak{t}_\rho, \rho > 0\}$ [6]. For any $\rho > 0$, define

$$\mathfrak{t}_\rho := \begin{cases} \inf\{t \geq 0 : \int_0^t \|\xi(s)\|^2 ds > \rho\} & \text{if } \int_0^\infty \|\xi(s)\|^2 ds > \rho, \\ \infty & \text{if } \int_0^\infty \|\xi(s)\|^2 ds \leq \rho. \end{cases}$$

The family $\{\mathfrak{t}_\rho\}$ is monotonically increasing and $\mathfrak{t}_\rho \to \infty$ P-a.s.

We now are in a position to construct an approximating sequence of martingales $\{\zeta_i(t)\}_{i=1}^{\infty}$ using the above sequence of Markov stopping times. First, note that the stochastic integral $\mu(t) := \int_0^t \xi(s)' dW(s)$ defines a local continuous martingale; see Definition 6 on page 69 of [6]. Also, for any stopping time $\mathfrak{t}_\rho$ defined above,

$$\mu(t \wedge \mathfrak{t}_\rho) = \int_0^{t\wedge\mathfrak{t}_\rho} \xi(s)' dW(s) = \int_0^t \xi_\rho(s)' dW(s) = \int_0^t \xi(s)' dW(s \wedge \mathfrak{t}_\rho),$$

where the process $\xi_\rho(\cdot)$ is defined as follows:

$$\xi_\rho(t) = \xi(t)\chi_{\{\mathfrak{t}_\rho \geq t\}}. \tag{18}$$

Here, χ_Λ denotes the indicator function of a set $\Lambda \subseteq \Omega$. In the above definitions, the notation $\mathfrak{t} \wedge t := \min\{t, \mathfrak{t}\}$ is used.

Associated with the positive continuous martingale $\zeta(t)$ and the family of stopping times $\{\mathfrak{t}_\rho, \rho > 0\}$ defined above, consider the stopped process

$$\zeta_\rho(t) = \zeta(t \wedge \mathfrak{t}_\rho).$$

From this definition, $\zeta_\rho(t)$ is a continuous martingale; e.g., see Lemma 3.3 on page 69 of [6]. Furthermore, using the representation (10) of the martingale $\zeta(t)$, it follows that $\zeta_\rho(t)$ is an Ito process with the stochastic differential

$$d\zeta_\rho(t) = \zeta_\rho(t)\xi_\rho'(t)dW(t) = \zeta_\rho(t)d\mu(t \wedge \mathfrak{t}_\rho); \quad \zeta_\rho(0) = 1. \tag{19}$$

From (19), the martingale $\zeta_\rho(t)$ admits the following representation:

$$\zeta_\rho(t) = \exp\left(\int_0^t \xi_\rho' dW(s) - \frac{1}{2}\int_0^t \|\xi_\rho(s)\|^2 ds\right). \tag{20}$$

Also, $\mathbf{E}\zeta_\rho(t) = \mathbf{E}\zeta_\rho(0) = 1$. Hence, $\zeta_\rho(\cdot) \in \mathcal{M}$.

Using the martingale $\zeta_\rho(t)$ defined above, we define probability measures Q_ρ^T on $(\Omega, \mathcal{F}_T)$ as follows:

$$Q_\rho^T(d\omega) = \zeta(T \wedge \mathfrak{t}_\rho)P^T(d\omega).$$

From (20), the relative entropy between the probability measures Q_ρ^T and P^T is given by

$$h(Q_\rho^T \| P^T) = \frac{1}{2}\mathbf{E}^{Q_\rho^T}\int_0^T \|\xi_\rho(s)\|^2 ds = \frac{1}{2}\mathbf{E}^{Q_\rho^T}\int_0^{\mathfrak{t}_\rho \wedge T} \|\xi(s)\|^2 ds. \tag{21}$$

From this equation and from (18), it follows that $h(Q_\rho^T \| P^T) \leq (1/2)\rho < \infty$ for all $T > 0$. Thus, condition (i) of Definition 1 is satisfied.

Also, using part 1 of Theorem 3.7 on page 62 of [6], we observe that for every $T > 0$ the family $\{\zeta(\mathfrak{t}_\rho \wedge T), \rho > 0\}$ is uniformly integrable. Also, since $\mathfrak{t}_\rho \to \infty$ with probability one as $\rho \to \infty$, then $\zeta_\rho(T) \to \zeta(T)$ with probability one. This fact together with the property of uniform integrability of the family $\{\zeta_\rho(T), \rho > 0\}$ implies that

$$\lim_{\rho\to\infty} \mathbf{E}(|\zeta(T \wedge \mathfrak{t}_\rho) - \zeta(T)|\big|\mathcal{G}) = 0 \qquad P\text{-a.s.} \tag{22}$$

for any σ-algebra $\mathcal{G} \subset \mathcal{F}_T$; see the Corollary on page 16 of [6]. We now observe that for any $\mathcal{F}_T$-measurable bounded random variable η with values in $\mathbf{R}$

$$\mathbf{E}|\eta\zeta(T \wedge \mathfrak{t}_\rho) - \eta\zeta(T)| \leq \sup_\omega |\eta| \cdot \mathbf{E}|\zeta(T \wedge \mathfrak{t}_\rho) - \zeta(T)|.$$

Therefore, it follows from the definition of the probability measures Q_ρ^T and Q^T and from (22) that $Q_\rho^T \Rightarrow Q^T$ as $\rho \to \infty$ for all $T > 0$. Thus, we have verified that the family of martingales $\zeta_\rho(t)$ satisfies condition (ii) of Definition 1.

We now consider system (1) on the probability space $(\Omega, \mathcal{F}_T, Q_\rho^T)$. Equivalently, we consider system (13) driven by the uncertainty input $\xi_\rho(t)$ on the probability space $(\Omega, \mathcal{F}_T, Q_\rho^T)$. Note that since $\int_0^T \|\xi_\rho(t)\|^2 \leq \rho$ P-a.s., Proposition 1 implies that the corresponding output $z(\cdot)$ of system (1) satisfies the conditions

$$\mathbf{E}^{Q_\rho^T} \int_0^T \|z(s)\|^2 ds < \infty, \quad \int_0^T \|z(s)\|^2 ds < \infty \quad Q_\rho^T\text{-a.s.} \tag{23}$$

for any $T > 0$. We now use the fact that condition (17) implies that for any pair $(\tilde{z}(\cdot), \tilde{\xi}(\cdot))$, $\tilde{z}(\cdot) \in L_2[0,T]$, $T > 0$, related by (16)

$$\int_0^T \|\tilde{\xi}(t)\|^2 dt \leq \int_0^T \|\tilde{z}(t)\|^2 dt;$$

e.g., see [25]. Hence from this observation and from (23), it follows that the pair $(z(\cdot), \xi(\cdot))$, where $z(\cdot)$ and $\xi(\cdot)$ are defined by system (1) and the operator (16), satisfies the condition

$$\int_0^T \|\xi(t)\|^2 dt \leq \int_0^T \|z(t)\|^2 dt \quad Q_\rho^T\text{-a.s.} \tag{24}$$

Then, the definition of the uncertainty input $\xi_\rho(\cdot)$ and condition (24) imply that for each $T > 0$

$$\frac{1}{T} \int_0^T \left[\|z(s)\|^2 - \|\xi_\rho(s)\|^2\right] ds \geq 0 \quad Q_\rho^T\text{-a.s.} \tag{25}$$

From the above condition, it follows that for each $\rho > 0$

$$\inf_{T' > T} \frac{1}{T'} \int_0^{T'} \mathbf{E}^{Q_\rho^{T'}} \left[\|z(s)\|^2 - \|\xi_\rho(s)\|^2\right] ds \geq 0.$$

Note that the expectation on the left-hand side of the above inequality exists by virtue of (23). Obviously in this case, one can find a constant $d > 0$ and a variable $\delta(T)$ which is independent of ρ and such that $\lim_{T\to\infty} \delta(T) = 0$ and

$$\inf_{T' > T} \frac{1}{2T'} \mathbf{E}^{Q_\rho^{T'}} \int_0^{T'} \left[\|z(s)\|^2 - \|\xi_\rho(s)\|^2\right] ds \geq -\frac{d}{2} + \delta(T).$$

This, along with the representation of the relative entropy between the probability measure Q_ρ^T and the reference probability measure P^T given in (21), leads us to the conclusion that for the H^∞ norm-bounded uncertainty under consideration, the corresponding martingale $\zeta_\rho(t)$, $\rho > 0$, satisfies the constraint (8). This completes the proof of the lemma. □

Remark 4. In the special case where the uncertainty is modeled by the operator (16) with L_2-induced norm less then one, and where the uncertainty output $z(\cdot)$ of the closed-loop system is known to be Q^T mean square–integrable on any interval $[0,T]$, the above proof shows that such an uncertainty can be characterized directly in terms of the martingale $\zeta(t)$ and the associated probability measures Q^T. That is, one can choose $\zeta_i(t)=\zeta(t)$ and $Q_i^T=Q^T$ in Definition 1. This will be true, for example, if the chosen controller is a stabilizing controller; see Definition 2. However, in the general case, the connection between the uncertainty output $z(\cdot)$ and the uncertainty input $\xi(\cdot)$ can be of a more complex nature than that described by (16). In this case, the Q^T mean square–integrability of the uncertainty output $z(\cdot)$ is not known a priori. Hence, one cannot guarantee that $h(Q^T\|P^T)<\infty$ for all $T>0$. Also, the expectation

$$\frac{1}{T}\left[\mathbf{E}^{Q^T}\int_0^T \|z(t)\|^2 dt - h(Q^T\|P^T)\right]$$

may not exist for all $T>0$ unless it has already been proved that the controller (2) is a stabilizing controller. In this case, the approximations of the martingale $\zeta(t)$ allow us to avoid the difficulties arising when defining an admissible uncertainty for the uncertain system (1) controlled by a generic linear output-feedback controller.

3. Absolute stability and absolute stabilizability. An important issue in any optimal control problem on an infinite time interval concerns the stabilizing properties of the optimal controller. For example, a critical issue addressed in [15, 16, 18] was to prove the absolutely stabilizing property of the optimal control schemes presented in those papers. In this paper, the systems under consideration are subject to additive noise. Hence, we need a definition of absolute stabilizability which properly accounts for this feature of the systems under consideration.

Definition 2. *A controller of the form* (2) *is said to be an* absolutely stabilizing output-feedback controller *for the stochastic uncertain system* (1), (8) *if the process* $x(\cdot)$ *defined by the closed-loop system corresponding to this controller satisfies the following condition. There exist constants* $c_1>0$, $c_2>0$ *such that for any admissible uncertainty martingale* $\zeta(\cdot)\in\Xi$

$$\limsup_{T\to\infty}\frac{1}{T}\left[\mathbf{E}^{Q^T}\int_0^T \left(\|x(t)\|^2+\|u(t)\|^2\right)dt + h(Q^T\|P^T)\right]\le c_1+c_2 d. \tag{26}$$

The property of absolute stability is defined as a special case of Definition 2 corresponding to $u(\cdot)\equiv 0$. In this case, system (1) becomes a system of the form

$$\begin{aligned} dx(t) &= Ax(t)dt + B_2 dW(t),\\ z(t) &= C_1 x(t). \end{aligned} \tag{27}$$

Definition 3. *The stochastic uncertain system corresponding to the state equations* (27) *with uncertainty satisfying the relative entropy constraint* (8) *is said to be* absolutely stable *if there exist constants* $c_1>0$, $c_2>0$ *such that for any admissible uncertainty martingale* $\zeta(\cdot)\in\Xi$

$$\limsup_{T\to\infty}\frac{1}{T}\left[\mathbf{E}^{Q^T}\int_0^T \|x(t)\|^2 dt + h(Q^T\|P^T)\right]\le c_1+c_2 d. \tag{28}$$

In what follows, the following property of mean square stable systems will be used; see [21]. For the sake of completeness, the proof of the following lemma is given in Appendix B.

LEMMA 3. *Suppose the stochastic nominal system* (27) *is mean square stable; i.e.,*

$$\limsup_{T\to\infty} \frac{1}{T}\mathbf{E}\int_0^T \|x(t)\|^2 dt < \infty. \tag{29}$$

Also, suppose the pair (A, B_2) *is stabilizable. Then, the matrix* A *must be stable.*

4. Infinite-horizon minimax optimal control problem. Associated with the stochastic uncertain system (1), (8), consider a cost functional $J(\cdot)$ of the form

$$J(u(\cdot),\zeta(\cdot)) = \limsup_{T\to\infty} \frac{1}{2T}\mathbf{E}^{Q^T}\int_0^T F(x(t),u(t))dt, \tag{30}$$

defined on solutions $x(\cdot)$ to (1). In (30),

$$F(x,u) := x'Rx + u'Gu,$$

and R and G are positive-definite symmetric matrices, $R \in \mathbf{R}^{n\times n}$, $G \in \mathbf{R}^{m\times m}$. Also, in (30), Q^T is the probability measure corresponding to the martingale $\zeta(\cdot)$; see (5).

In this paper, we are concerned with a minimax optimal control problem associated with system (1), cost functional (30), and uncertainty set Ξ. In this problem, we seek to find a controller $u^*(\cdot)$ of the form (2) which minimizes the worst-case value of the cost functional J in the face of uncertainty $\zeta(\cdot) \in \Xi$ satisfying the constraint (8):

$$\sup_{\zeta(\cdot)\in\Xi} J(u^*(\cdot),\zeta(\cdot)) = \inf_{u(\cdot)\in\mathcal{U}} \sup_{\zeta(\cdot)\in\Xi} J(u(\cdot),\zeta(\cdot)). \tag{31}$$

The derivation of a solution to the above minimax optimal control problem relies on a duality relationship between free energy and relative entropy established in [1]; see Lemma 8 of Appendix A. Associated with system (1), consider the parameter-dependent risk-sensitive cost functional

$$\Im_{\tau,T}(u(\cdot)) := \frac{2\tau}{T}\log\mathbf{E}\left\{\exp\left(\frac{1}{2\tau}\int_0^T F_\tau(x(t),u(t))dt\right)\right\}, \tag{32}$$

where $\tau > 0$ is a given constant and

$$F_\tau(x,u) := x'R_\tau x + 2x'\Upsilon_\tau u + u'G_\tau u, \tag{33}$$

$$R_\tau := R + \tau C_1'C_1,$$

$$G_\tau := G + \tau D_1'D_1,$$

$$\Upsilon_\tau := \tau C_1'D_1. \tag{34}$$

We will apply the duality result of Lemma 8 of Appendix A; also, see [1]. When applied to system (1) and the risk-sensitive cost functional (32) (see Corollary 3.1 and Remark 3.2 of [1]), this result states that for each admissible controller $u(\cdot)$

$$\sup_{Q^T\in\mathcal{P}_T} J_{\tau,T}(u(\cdot),Q^T) = \frac{1}{2}\Im_{\tau,T}(u(\cdot)), \tag{35}$$

where

$$J_{\tau,T}(u(\cdot),Q^T) := \frac{1}{T}\left[\frac{1}{2}\mathbf{E}^{Q^T}\int_0^T F_\tau(x(t),u(t))dt - \tau h(Q^T\|P^T)\right]. \tag{36}$$

The use of the duality result (35) is a key step that enables us to replace the minimax optimal control problem by a risk-sensitive optimal control problem. Hence, we will be interested in constructing an output-feedback controller of the form (2) solving the following stochastic risk-sensitive optimal control problem:[1]

$$\inf_{u(\cdot)\in\mathcal{U}} \lim_{T\to\infty} \Im_{\tau,T}(u(\cdot)). \tag{37}$$

5. A connection between risk-sensitive optimal control and minimax optimal control. In this section, we present results establishing a connection between the risk-sensitive optimal control problem (37) and the minimax optimal control problem (31).

For a given constant $\tau > 0$, let V_τ denote an optimal value of the risk-sensitive control problem (37); i.e.,

$$\begin{aligned} V_\tau &:= \inf_{u(\cdot)\in\mathcal{U}} \lim_{T\to\infty} \Im_{\tau,T}(u(\cdot)) \\ &= \inf_{u(\cdot)} \lim_{T\to\infty} \frac{2\tau}{T}\log\mathbf{E}\left\{\exp\left[\frac{1}{2\tau}\int_0^T F_\tau(x(s),u(s))ds\right]\right\}. \end{aligned}$$

THEOREM 1. *Suppose that for a given $\tau > 0$ the risk-sensitive control problem* (37) *admits an optimal controller $u_\tau(\cdot) \in \mathcal{U}$ of the form* (2) *which guarantees a finite optimal value: $V_\tau < \infty$. Then this controller is an absolutely stabilizing controller for the stochastic uncertain system* (1) *satisfying the relative entropy constraint* (8). *Furthermore,*

$$\sup_{\zeta(\cdot)\in\Xi} J(u_\tau(\cdot),\zeta(\cdot)) \le \frac{1}{2}(V_\tau + \tau d). \tag{38}$$

Proof. It follows from the condition of the theorem that

$$V_\tau = \lim_{T\to\infty} \frac{2\tau}{T}\log\mathbf{E}\left\{\exp\left[\frac{1}{2\tau}\int_0^T F_\tau(x(s),u_\tau(s))ds\right]\right\} < \infty,$$

where $u_\tau(\cdot)$ is the risk-sensitive optimal controller of the form (2) corresponding to the given τ. We wish to prove that this risk-sensitive optimal controller satisfies condition (26) of Definition 2.

[1] A risk-sensitive control problem of the form (37) was considered in [9]. That paper defines the class of admissible infinite-horizon risk-sensitive controllers as those controllers which satisfy a certain causality condition. This causality condition is formulated in terms of corresponding martingales and ensures that the probability measure transformations required in [9] are well defined. As observed in [9], linear controllers satisfy this causality condition. Furthermore, it is shown in [9] that a solution to the risk-sensitive optimal control problem (37), in the broader class of nonlinear output-feedback controllers satisfying such a causality condition, is attained by a linear controller of the form (2). This implies that the class of admissible controllers in the risk-sensitive control problem (37) can be restricted to include only linear output-feedback controllers.

Using the duality result (35), we obtain

$$\lim_{T\to\infty}\sup_{Q^T\in\mathcal{P}_T}\frac{1}{T}\left[\frac{1}{2}\mathbf{E}^{Q^T}\int_0^T F_\tau(x(s),u_\tau(s))ds-\tau h(Q^T\|P^T)\right]=\frac{V_\tau}{2}. \tag{39}$$

Equation (39) implies that, for any sufficiently large $T>0$, one can choose a sufficiently small positive constant $\hat{\delta}=\hat{\delta}(T)>0$ such that $\lim_{T\to\infty}\hat{\delta}(T)=0$ and

$$\sup_{Q^{T'}\in\mathcal{P}_{T'}}\frac{1}{T'}\left[\frac{1}{2}\mathbf{E}^{Q^{T'}}\int_0^{T'} F_\tau(x(s),u_\tau(s))ds-\tau h(Q^{T'}\|P^{T'})\right]\le\frac{V_\tau}{2}+\hat{\delta}(T) \tag{40}$$

for all $T'>T$. Thus, for the chosen constants $T>0$ and $\hat{\delta}(T)>0$ and for all $T'>T$,

$$\frac{1}{T'}\left[\frac{1}{2}\mathbf{E}^{Q^{T'}}\int_0^{T'} F_\tau(x(s),u_\tau(s))ds-\tau h(Q^{T'}\|P^{T'})\right]\le\frac{V_\tau}{2}+\hat{\delta}(T)$$

for any $Q^{T'}\in\mathcal{P}_{T'}$. Furthermore, if $Q^{T'}\in\mathcal{P}_{T'}$ for all $T'>T$, then

$$\sup_{T'>T}\frac{1}{T'}\left[\frac{1}{2}\mathbf{E}^{Q^{T'}}\int_0^{T'} F_\tau(x(s),u_\tau(s))ds-\tau h(Q^{T'}\|P^{T'})\right]\le\frac{V_\tau}{2}+\hat{\delta}(T). \tag{41}$$

Let $\zeta(\cdot)\in\Xi$ be a given admissible uncertainty martingale and let $\zeta_i(\cdot)$ be a corresponding sequence of martingales as in Definition 1. Recall that the corresponding probability measures Q_i^T belong to the set $\mathcal{P}_T$ for all $T>0$. Hence each probability measure Q_i^T satisfies condition (41); i.e.,

$$\sup_{T'>T}\frac{1}{T'}\left[\frac{1}{2}\mathbf{E}^{Q_i^{T'}}\int_0^{T'} F_\tau(x(s),u_\tau(s))ds-\tau h(Q_i^{T'}\|P^{T'})\right]\le\frac{V_\tau}{2}+\hat{\delta}(T). \tag{42}$$

Note that in condition (42), $\hat{\delta}(T)$ and T are the constants which are independent of i.

Since $F(x,u)\ge 0$ and $\tau>0$, condition (42) implies

$$\sup_{T'>T}\frac{1}{T'}\left[\frac{1}{2}\mathbf{E}^{Q_i^{T'}}\int_0^{T'}\|z(s)\|^2ds-h(Q_i^{T'}\|P^{T'})\right]<\infty.$$

From this, it follows from (42) that for each integer i

$$\begin{aligned}
&\sup_{T'>T}\frac{1}{2T'}\mathbf{E}^{Q_i^{T'}}\int_0^{T'}F(x(s),u_\tau(s))ds\\
&\quad+\tau\inf_{T'>T}\frac{1}{T'}\left[\frac{1}{2}\mathbf{E}^{Q_i^{T'}}\int_0^{T'}\|z(s)\|^2ds-h(Q_i^{T'}\|P^{T'})\right]\\
&\le\sup_{T'>T}\frac{1}{T'}\left[\frac{1}{2}\mathbf{E}^{Q_i^{T'}}\int_0^{T'}\left(F(x(s),u_\tau(s))+\tau\|z(s)\|^2\right)ds-\tau h(Q_i^{T'}\|P^{T'})\right]\\
&\le\frac{1}{2}V_\tau+\hat{\delta}(T).
\end{aligned}$$

This implies

$$\begin{aligned}
&\sup_{T'>T} \frac{1}{2T'} \mathbf{E}^{Q_i^{T'}} \int_0^{T'} F(x(s), u_\tau(s)) ds \\
&\leq \frac{V_\tau}{2} + \hat{\delta}(T) - \tau \inf_{T'>T} \frac{1}{T'} \left[\frac{1}{2} \mathbf{E}^{Q_i^{T'}} \int_0^{T'} \|z(s)\|^2 ds - h(Q_i^{T'} \| P^{T'}) \right] \\
&\leq \frac{1}{2}(V_\tau + \tau d) + \hat{\delta}(T) - \tau \delta(T). \qquad (43)
\end{aligned}$$

The derivation of the last line of inequality (43) uses the fact that the probability measure Q_i^T satisfies condition (8). Also, note that in condition (43), the constants $\hat{\delta}(T)$, $\delta(T)$, and T are independent of i and $T' > T$.

We now let $i \to \infty$ in inequality (43). This leads to the following proposition.

PROPOSITION 2. *For any admissible uncertainty* $\zeta(\cdot) \in \Xi$,

$$\sup_{T'>T} \frac{1}{2T'} \mathbf{E}^{Q^{T'}} \int_0^{T'} F(x(s), u_\tau(s)) ds \leq \frac{1}{2}(V_\tau + \tau d) + \hat{\delta}(T) - \tau \delta(T). \qquad (44)$$

To establish this proposition, consider the space $L_1(\Omega, \mathcal{F}_{T'}, P^{T'})$ endowed with the topology of weak convergence of random variables, where $T' > T$. We denote this space by L_1^w. Define the functional

$$\phi(\nu) := \frac{1}{T'} \mathbf{E} \left[\nu \int_0^{T'} F(x(s), u_\tau(s)) ds \right], \qquad (45)$$

mapping L_1^w into the space of extended reals $\mathfrak{R} = \mathbf{R} \cup \{-\infty, \infty\}$. Also, consider a sequence of functionals mapping $L_1^w \to \mathfrak{R}$ defined by

$$\phi_N(\nu) := \frac{1}{T'} \mathbf{E} \left[\nu \int_0^{T'} F_N(x(s), u_\tau(s)) ds \right], \quad N = 1, 2, \ldots, \qquad (46)$$

where each function $F_N(\cdot)$ is defined as follows:

$$F_N(x, u) := \begin{cases} F(x, u) & \text{if } F(x, u) \leq N, \\ N & \text{if } F(x, u) > N. \end{cases}$$

Note that from the above definition, the sequence $\phi_N(\nu)$ is monotonically increasing in N for each ν. Also, we note that for any $N > 0$

$$P\left(\frac{1}{T'} \int_0^{T'} F_N(x(s), u_\tau(s)) ds \leq N \right) = 1.$$

Hence, if $\nu_i \to \nu$ weakly, then $\phi_N(\nu_i) \to \phi_N(\nu)$. That is, each functional $\phi_N(\cdot)$ is continuous on the space L_1^w. Therefore, the functional

$$\phi(\nu) = \lim_{N \to \infty} \phi_N(\nu)$$

is lower semicontinuous; e.g., see Theorem 10 on page 330 of [13]. Now let $\nu = \zeta(T')$ be the Radon–Nikodým derivative of the probability measure $Q^{T'}$, and let $\nu_i = \zeta_i(T')$

be the Radon–Nikodým derivative of the probability measure $Q_i^{T'}$. Then, the fact that $\zeta_i(T') \to \zeta(T')$ weakly implies

$$\frac{1}{2T'}\mathbf{E}^{Q^{T'}}\int_0^{T'} F(x(s),u_\tau(s))ds \le \liminf_{i\to\infty}\frac{1}{2T'}\mathbf{E}^{Q_i^{T'}}\int_0^{T'} F(x(s),u_\tau(s))ds$$
$$\le \frac{1}{2}(V_\tau+\tau d)+\hat{\delta}(T)-\tau\delta(T). \tag{47}$$

Since the constants on the right-hand side of (47) are independent of $T' > T$, condition (44) of the proposition now follows. This completes the proof of the proposition.

Note that from the above proposition, (38) follows. Indeed, for any $\zeta(\cdot) \in \Xi$, Proposition 2 and the fact that $\hat{\delta}(T), \delta(T) \to 0$ as $T \to \infty$ together imply

$$J(u_\tau(\cdot),\zeta(\cdot)) = \lim_{T\to\infty}\sup_{T'>T}\frac{1}{2T'}\mathbf{E}^{Q^{T'}}\int_0^{T'} F(x(s),u_\tau(s))ds$$
$$\le \frac{1}{2}(V_\tau+\tau d). \tag{48}$$

From condition (48), equation (38) of the theorem follows.

We now establish the absolute stabilizing property of the risk-sensitive optimal controller $u_\tau(\cdot)$. Indeed, since the matrices R and G are positive-definite, inequality (44) implies

$$\limsup_{T\to\infty}\frac{1}{T}\mathbf{E}^{Q^T}\int_0^T \left(\|x(s)\|^2+\|u_\tau(s)\|^2\right)ds \le \alpha\left(V_\tau+\tau d\right), \tag{49}$$

where α is a positive constant which depends only on R and G.

To complete the proof, it remains to prove that there exist constants $c_1, c_2 > 0$ such that

$$\limsup_{T\to\infty}\frac{1}{T}h(Q^T\|P^T) < c_1 + c_2 d. \tag{50}$$

To this end, we note that for any sufficiently large T and for all $T' > T$, the constraint (8) implies

$$\frac{1}{T'}h(Q_i^{T'}\|P^{T'}) \le \frac{1}{2T'}\mathbf{E}^{Q_i^{T'}}\int_0^{T'}\|z(s)\|^2 ds + \frac{d}{2} - \delta(T) \tag{51}$$

for all $i = 1, 2, \ldots$. We now observe that condition (43) implies that for all $T' > T$

$$\frac{1}{2T'}\mathbf{E}^{Q_i^{T'}}\int_0^{T'}\|z(s)\|^2 ds \le \bar{c}\left(\frac{1}{2}(V_\tau+\tau d)+\hat{\delta}(T)-\tau\delta(T)\right), \tag{52}$$

where $\bar{c}$ is a positive constant determined only by the matrices R, G, C_1, and D_1. From conditions (51), (52), Remark 1, and the fact that the relative entropy functional is lower semicontinuous, it follows that

$$\frac{1}{T'}h(Q^{T'}\|P^{T'}) \le \liminf_{i\to\infty}\frac{1}{T'}h(Q_i^{T'}\|P^{T'})$$
$$\le \bar{c}\left(\frac{1}{2}(V_\tau+\tau d)+\hat{\delta}(T)-\tau\delta(T)\right)+\frac{d}{2}-\delta(T)$$

for any $T' > T$. This inequality and the fact that $\delta(T) \to 0$ and $\hat{\delta}(T) \to 0$ as $T \to \infty$ together imply that

$$\limsup_{T\to\infty} \frac{1}{T} h(Q^T \| P^T) \leq \frac{1}{2}(\bar{c}V_\tau + (1+\bar{c}\tau)d).$$

Combining this condition and inequality (49), we obtain condition (26), where the constants c_1, c_2 are defined by V_τ, τ, α, $\bar{c}$, and hence independent of $\zeta(\cdot) \in \Xi$. □

Remark 5. It is straightforward to extend the result of Theorem 1 to the case in which the uncertainty output is structured; i.e.,

$$\begin{aligned} z_1(t) &= C_{1,1}x(t) + D_{1,1}u(t), \\ &\vdots \\ z_k(t) &= C_{1,k}x(t) + D_{1,k}u(t). \end{aligned}$$

In this case, we need k relative entropy uncertainty constraints of the form (8) to define the admissible uncertainty. The corresponding risk-sensitive control problem involves k scaling parameters $\tau_1 \geq 0, \ldots, \tau_k \geq 0$, $\sum_{j=1}^{k} \tau_j > 0$.

To formulate conditions under which a converse to Theorem 1 holds, we consider the closed-loop system corresponding to system (1) and a linear time-invariant output-feedback controller of the form (2). Recall that the closed-loop nominal system corresponding to controller (2) is described by the linear Ito differential equation (3) on the probability space $(\Omega, \mathcal{F}, P)$. In what follows, we will consider the class of linear controllers of the form (2) satisfying the following assumptions: the matrix $\bar{A}$ is stable, the pair $(\bar{A}, \bar{B})$ is controllable, and the pair $(\bar{A}, \bar{R})$ is observable, where

$$\bar{R} = \begin{bmatrix} R & 0 \\ 0 & K'GK \end{bmatrix}. \tag{53}$$

Also, let $\mathfrak{D}_0$ be the set of all linear functions $\phi(\bar{x}) = \Phi\bar{x}$ such that the matrix $\bar{A} + \bar{B}\Phi$ is stable. Note that the pair $(\bar{A} + \bar{B}\Phi, \bar{B})$ is controllable since the pair $(\bar{A}, \bar{B})$ is controllable. Under these assumptions, the Markov process generated by the linear system

$$d\bar{x}_\phi(t) = (\bar{A} + \bar{B}\Phi)\bar{x}_\phi(t)dt + \bar{B}dW(t) \tag{54}$$

has a unique invariant probability measure ν^ϕ on $\mathbf{R}^{n+\hat{n}}$; e.g., see [24]. It is shown in [24] that the probability measure ν^ϕ is a Gaussian probability measure.

LEMMA 4. *For every function $\phi(\bar{x}) = \Phi\bar{x}$, $\phi(\cdot) \in \mathfrak{D}_0$, there exists a martingale $\zeta(\cdot) \in \mathcal{M}_\infty$ such that for any $T > 0$ the process*

$$\tilde{W}(t) = W(t) - \int_0^t \Phi\bar{x}(s)ds \tag{55}$$

is a Wiener process with respect to $\{\mathcal{F}_t, t \in [0,T]\}$ and the probability measure Q^T corresponding to the martingale $\zeta(\cdot)$. In (55), $\bar{x}(\cdot)$ is the solution to the nominal closed-loop system (3) with initial probability distribution ν^ϕ.

Furthermore,

$$d\bar{x} = (\bar{A} + \bar{B}\Phi)\bar{x}dt + \bar{B}d\tilde{W}(t), \tag{56}$$

considered on the probability space $(\Omega, \mathcal{F}_T, Q^T)$*, admits a stationary solution* $\bar{x}_\zeta(\cdot)$ *such that*

$$Q^T(\bar{x}_\zeta(t) \in d\bar{x}) = \nu^\phi(d\bar{x}). \tag{57}$$

Proof. Let ν^ϕ be the Gaussian invariant probability measure corresponding to a given $\phi(\cdot) \in \mathfrak{D}_0$. Consider a stochastic process $\bar{x}(t)$ defined by (3) and having initial probability distribution ν^ϕ; i.e., $P(\bar{x}(0) \in d\bar{x}) = \nu^\phi(d\bar{x})$. Since the probability measure ν^ϕ is Gaussian, there exists a constant $\delta_0 > 0$ such that

$$\mathbf{E} \exp(\delta_0 \|\bar{x}(0)\|^2) = \int \exp(\delta_0 \|\bar{x}\|^2) \nu^\phi(d\bar{x}) < \infty.$$

Hence, using the multivariate version of Theorem 4.7 on page 137 of [6] along with Example 3 on page 220 of [6], this leads to the satisfaction of the conditions of Lemma 1, which shows that the random process $\tilde{W}(\cdot)$ defined by (55) is a Wiener process with respect to $\{\mathcal{F}_t, t \in [0,T]\}$ and the probability measure Q^T defined in Lemma 1.

We now consider system (56) on the probability space $(\Omega, \mathcal{F}_T, Q^T)$ with initial distribution ν^ϕ. Also, consider system (54) on the probability space $(\Omega, \mathcal{F}_T, P^T)$ with initial distribution ν^ϕ. It follows from Proposition 3.10 on page 304 of [4] that the stochastic process $\bar{x}_\zeta(\cdot)$ defined by (56) and the corresponding stochastic process $\bar{x}_\phi(\cdot)$ defined by (54) have the same probability distribution under their respective probability measures. Also, as in [2, 1],

$$h(Q^T \| P^T) = \frac{1}{2} \mathbf{E}^{Q^T} \int_0^T \|\Phi \bar{x}(t)\|^2 dt = \frac{1}{2} \int \|\Phi \bar{x}\|^2 \nu^\phi(d\bar{x}) < \infty$$

for each $T < \infty$, since $\bar{x}(t)$ is the solution to system (3) with Gaussian initial distribution ν^ϕ. Thus, $Q^T \in \mathcal{P}_T$ for all $T > 0$. Hence, $\zeta(\cdot) \in \mathcal{M}_\infty$. From this, the lemma follows. □

We now present a converse to Theorem 1.

THEOREM 2. *Suppose that there exists a controller* $u^*(\cdot) \in \mathcal{U}$ *such that the following conditions are satisfied:*

(i) $\sup_{\zeta(\cdot) \in \Xi} J(u^*(\cdot), \zeta(\cdot)) < c < \infty$.

(ii) *The controller* $u^*(\cdot)$ *is an absolutely stabilizing controller such that the corresponding closed-loop matrix* $\bar{A}$ *is stable, the pair* $(\bar{A}, \bar{B})$ *is controllable, and the pair* $(\bar{A}, \bar{R})$ *is observable.*

Then there exists a constant $\tau > 0$ *such that the corresponding risk-sensitive optimal control problem* (37) *has a solution which guarantees a finite optimal value. Furthermore,*

$$\frac{1}{2}(V_\tau + \tau d) < c. \tag{58}$$

The proof of this theorem follows along the same lines as the proof of the necessity part of the main result of [21]. For the sake of completeness, the modification of this proof adapted to the condition of Theorem 2 is presented below.

We first establish the following lemma.

LEMMA 5. *Consider the uncertain closed-loop system* (3), (8) *in which the pair* $(\bar{A}, \bar{B})$ *is controllable. Also, consider a nonnegative-definite matrix* $\bar{R}$ *such that the pair* $(\bar{A}, \bar{R})$ *is observable. If the system* (3), (8) *is absolutely stable, then there exists a positive constant* $\tau_0 > 0$ *such that the Riccati equation*

$$\bar{A}'\Pi + \Pi\bar{A} + \bar{R} + \tau_0\bar{C}'\bar{C} + \frac{1}{\tau_0}\Pi\bar{B}\bar{B}'\Pi = 0 \tag{59}$$

admits a positive-definite stabilizing solution.

Proof. Since the uncertain system (3), (8) is absolutely stable, there exists a positive constant $\tilde{c}$ such that for all $\zeta(\cdot) \in \Xi$

$$\liminf_{T\to\infty} \frac{1}{2T}\mathbf{E}^{Q^T}\int_0^T \bar{x}(s)'\bar{R}\bar{x}(s)ds + \bar{\varepsilon}\liminf_{T\to\infty} \frac{1}{2T}\mathbf{E}^{Q^T}\int_0^T \|\bar{x}(t)\|^2 dt \le \tilde{c}. \tag{60}$$

Here $\bar{\varepsilon} > 0$ is a sufficiently small positive constant.

Consider the functionals

$$\begin{aligned}\mathcal{G}_0(\zeta(\cdot)) &:= \tilde{c} - \liminf_{T\to\infty} \frac{1}{2T}\mathbf{E}^{Q^T}\int_0^T \bar{x}(s)'\bar{R}\bar{x}(s)ds \\ &\quad - \bar{\varepsilon}\liminf_{T\to\infty} \frac{1}{2T}\mathbf{E}^{Q^T}\int_0^T \|\bar{x}(t)\|^2 dt, \\ \mathcal{G}_1(\zeta(\cdot)) &:= -\frac{d}{2} - \liminf_{T\to\infty} \frac{1}{T}\left[\frac{1}{2}\mathbf{E}^{Q^T}\int_0^T \|z(s)\|^2 ds - h(Q^T\|P^T)\right].\end{aligned} \tag{61}$$

Note that since the system (3), (8) is absolutely stable, both of these functionals are well defined on the set Ξ.

Now consider a martingale $\zeta(\cdot) \in \mathcal{M}_\infty$ such that

$$\mathcal{G}_1(\zeta(\cdot)) \le 0. \tag{62}$$

This condition implies that the martingale $\zeta(\cdot)$ satisfies the conditions of Definition 1 with $\zeta_i(\cdot) = \zeta(\cdot)$. Indeed, condition (i) of Definition 1 is satisfied since $\zeta(\cdot) \in \mathcal{M}_\infty$. Condition (ii) is trivial in this case. Also, let $\delta(T)$ be any function chosen to satisfy the conditions $\lim_{T\to\infty}\delta(T) = 0$ and

$$\inf_{T'>T} \frac{1}{T'}\left[\frac{1}{2}\mathbf{E}^{Q^{T'}}\int_0^{T'} \|z(s)\|^2 ds - h(Q^{T'}\|P^{T'})\right] \ge -\frac{d}{2} + \delta(T)$$

for all sufficiently large $T > 0$. The existence of such a function $\delta(T)$ follows from condition (62). Then condition (8) of Definition 1 is also satisfied. Thus, condition (62) implies that each martingale $\zeta(\cdot) \in \mathcal{M}_\infty$ satisfying this condition is an admissible uncertainty martingale. That is, $\zeta(\cdot) \in \Xi$. From condition (60), it follows that $\mathcal{G}_0(\zeta(\cdot)) \ge 0$.

We have now shown that the satisfaction of condition (60) implies that the following condition is satisfied:

$$\text{If } \mathcal{G}_1(\zeta(\cdot)) \le 0, \text{ then } \mathcal{G}_0(\zeta(\cdot)) \ge 0. \tag{63}$$

Furthermore, the set of martingales satisfying condition (62) has an interior point $\zeta(t) \equiv 1$; see the remark following Definition 1. Also, it follows from the properties

of the relative entropy functional that the functionals $\mathcal{G}_0(\cdot)$ and $\mathcal{G}_1(\cdot)$ are convex. We have now verified all of the conditions needed to apply the Lagrange multiplier result (e.g., see [7]). Indeed, Theorem 1 on page 217 of [7] implies that there exists a constant $\tau_0 \geq 0$ such that

$$\mathcal{G}_0(\zeta(\cdot)) + \tau_0 \mathcal{G}_1(\zeta(\cdot)) \geq 0 \tag{64}$$

for all $\zeta(\cdot) \in \mathcal{M}_\infty$. We now show that the conditions of the theorem guarantee that $\tau_0 > 0$.

PROPOSITION 3. *In inequality* (64), $\tau_0 > 0$.

Consider system (56) where $\phi(\bar{x}) := \Phi\bar{x}$ belongs to $\mathfrak{D}_0$. From Lemma 4, the corresponding martingale $\zeta_\Phi(\cdot)$ belongs to the set $\mathcal{M}_\infty$.

Now consider the quantity

$$\liminf_{T\to\infty} \frac{1}{2T} \mathbf{E}^{Q_\Phi^T} \int_0^T \bar{x}(t)' \bar{R} \bar{x}(t) dt.$$

Here, Q_Φ^T is the probability measure corresponding to the martingale $\zeta_\Phi(\cdot)$, and $\bar{x}(\cdot)$ is the solution to the corresponding system (1) considered on the probability space $(\Omega, \mathcal{F}_T, Q_\Phi^T)$. Also, consider the Lyapunov equation

$$(\bar{A} + \bar{B}\Phi)'\Pi + \Pi(\bar{A} + \bar{B}\Phi) + \bar{R} = 0. \tag{65}$$

Since the matrix $\bar{A} + \bar{B}\Phi$ is stable, then this matrix equation admits a nonnegative-definite solution Π. Using Ito's formula, it is straightforward to show that (65) leads to the inequality

$$\liminf_{T\to\infty} \frac{1}{T} \mathbf{E}^{Q_\Phi^T} \int_0^T \bar{x}(t)' \bar{R} \bar{x}(t) dt \geq \operatorname{tr} \bar{B}\bar{B}'\Pi.$$

This condition implies that

$$\sup_{\zeta(\cdot)\in\mathcal{M}_\infty} \liminf_{T\to\infty} \frac{1}{2T} \mathbf{E}^{Q^T} \int_0^T \bar{x}(t)' \bar{R} \bar{x}(t) dt \geq \sup_{\Phi:\bar{A}+\bar{B}\Phi \text{ is stable}} \frac{1}{2} \operatorname{tr} \bar{B}\bar{B}'\Pi = \infty. \tag{66}$$

Using (66), the proposition follows. Indeed, suppose that $\tau_0 = 0$. Then condition (64) implies that

$$\sup_{\zeta(\cdot)\in\mathcal{M}_\infty} \left[\begin{array}{l} \liminf_{T\to\infty} \frac{1}{2T} \mathbf{E}^{Q^T} \int_0^T \bar{x}(t)' \bar{R} \bar{x}(t) dt \\ +\bar{\varepsilon} \liminf_{T\to\infty} \frac{1}{2T} \mathbf{E}^{Q^T} \int_0^T \|\bar{x}(t)\|^2 dt \end{array} \right] \leq \tilde{c} < \infty. \tag{67}$$

Inequality (67) leads to a contradiction with condition (66). From this, it follows that $\tau_0 > 0$.

PROPOSITION 4. *The Riccati equation* (59) *with* τ_0 *defined above admits a positive-definite stabilizing solution.*

We first note that the pair $(\bar{A}, \bar{R} + \tau_0 \bar{C}'\bar{C})$ is observable, since the pair $(\bar{A}, \bar{R})$ is observable. Hence, if $\Pi \geq 0$ satisfies (59), then $\Pi > 0$. Thus, it is sufficient to prove that (59) admits a nonnegative-definite stabilizing solution. This is true if and only if the following bound on the H^∞ norm of the corresponding transfer function is satisfied:

$$\|\mathcal{H}_{\tau_0}(s)\|_\infty \leq 1, \tag{68}$$

where

$$\mathcal{H}_{\tau_0}(s) := \begin{bmatrix} \frac{1}{\sqrt{\tau_0}}\bar{R}^{1/2} \\ \bar{C} \\ \frac{\sqrt{\bar{\varepsilon}}}{\sqrt{\tau_0}} I \end{bmatrix} (sI - \bar{A})^{-1}\bar{B};$$

see Lemma 5 and Theorem 5 of [22].

In order to prove the above claim, we note that condition (64) implies that for any martingale $\zeta(\cdot) \in \mathcal{M}_\infty$

$$\begin{aligned} \liminf_{T\to\infty} \frac{1}{T}\mathbf{E}^{Q^T} \int_0^T \frac{1}{2\tau_0}\bar{x}(t)'\bar{R}\bar{x}(t)dt + \frac{\bar{\varepsilon}}{\tau_0} \liminf_{T\to\infty} \frac{1}{2T}\mathbf{E}^{Q^T} \int_0^T \|\bar{x}(t)\|^2 dt \\ + \liminf_{T\to\infty} \frac{1}{T}\left[\frac{1}{2}\mathbf{E}^{Q^T}\int_0^T \|z(s)\|^2 ds - h(Q^T\|P^T)\right] \\ \leq \frac{\tilde{c}}{\tau_0} - \frac{d}{2}. \end{aligned} \tag{69}$$

We will show that the satisfaction of condition (68) follows from (69).

Suppose condition (68) is not true. That is, suppose that

$$\|\mathcal{H}_{\tau_0}(s)\|_\infty > 1. \tag{70}$$

Consider a set $\mathfrak{P}^+$ of deterministic power signals $\xi(t)$, $t \in (-\infty, \infty)$, for which the autocorrelation matrix exists and is finite and for which the power spectral density function exists. Furthermore, $\xi(t) = 0$ if $t < 0$. It can be shown that $\|\mathcal{H}_{\tau_0}\|_{\mathfrak{P}^+} = \|\mathcal{H}_{\tau_0}\|_\infty$, where $\|\mathcal{H}_{\tau_0}\|_{\mathfrak{P}^+}$ denotes the induced norm of the convolution operator $\mathfrak{P}^+ \to \mathfrak{P}^+$ defined by the transfer function $\mathcal{H}_{\tau_0}(s)$. The proof of this fact is a minor variation of the proof of the corresponding fact given in [25].

Now consider the following state space realization of the transfer function $\mathcal{H}_{\tau_0}(s)$:

$$\begin{aligned} \frac{d\bar{x}_1}{dt} &= \bar{A}\bar{x}_1 + \bar{B}\xi(t), \\ z_1 &= \begin{bmatrix} \frac{1}{\sqrt{\tau_0}}\bar{R}^{1/2} \\ \bar{C} \\ \frac{\sqrt{\bar{\varepsilon}}}{\sqrt{\tau_0}} I \end{bmatrix} \bar{x}_1. \end{aligned} \tag{71}$$

Then, the fact that $\|\mathcal{H}_{\tau_0}\|_{\mathfrak{P}^+} = \|\mathcal{H}_{\tau_0}\|_\infty > 1$ leads to the following conclusion:

$$\sup_{\xi(\cdot)\in\mathfrak{P}^+} \lim_{T\to\infty} \frac{1}{T}\int_0^T \left(\|z_1(t)\|^2 dt - \|\xi(t)\|^2\right) dt = \infty. \tag{72}$$

In (72), $z_1(\cdot)$ is the output of system (71) corresponding to the input $\xi(\cdot) \in \mathfrak{P}^+$ and an arbitrarily chosen initial condition $\bar{x}_1(0)$.[2] That is, for any $N > 0$ there exists an uncertainty input $\xi_N(\cdot) \in \mathfrak{P}^+$ such that

$$\lim_{T\to\infty} \frac{1}{T}\int_0^T \left(\|z_1(t)\|^2 dt - \|\xi_N(t)\|^2\right) dt > N.$$

[2]Note that the limit on the left-hand side of (72) is independent of the initial condition of system (71).

This condition implies that for a sufficiently small $\varepsilon > 0$ there exists a constant $T(\varepsilon, N) > 0$ such that

$$\frac{1}{T}\int_0^T \left(\|z_1(t)\|^2 dt - \|\xi_N(t)\|^2\right) dt > N - \varepsilon \tag{73}$$

for all $T > T(\varepsilon, N)$. We now suppose that the initial condition of system (71) is a random variable $\bar{x}_0$. This system is driven by the input $\xi_N(\cdot)$. In this case, system (71) gives rise to an $\mathcal{F}_0$-measurable stochastic process $\bar{x}_1(\cdot)$. Furthermore, for all $T > T(\varepsilon, N)$, inequality (73) holds with probability one. Now note that the signal $\xi_N(\cdot)$ is a deterministic signal; hence, it satisfies the conditions of Lemma 1. Therefore, for this process, the martingale $\zeta_N(\cdot) \in \mathcal{M}$, the probability measure Q_N^T, and the Wiener process $\tilde{W}(\cdot)$ can be constructed as described in Lemma 1. Also, since $\xi_N(\cdot) \in \mathfrak{P}^+$ and is deterministic, then for any $T > 0$

$$\mathbf{E}^{Q_N^T}\int_0^T \|\xi_N(t)\|^2 dt = \int_0^T \|\xi_N(t)\|^2 dt < \infty.$$

From this observation, it follows that $\zeta_N(\cdot) \in \mathcal{M}_\infty$, and also the random variable on the left-hand side of inequality (73) has the finite expectation with respect to the probability measure Q_N^T. Furthermore, using inequality (73), one can prove that the system

$$d\bar{x} = (\bar{A}\bar{x} + \bar{B}\xi_N(t))dt + \bar{B}d\tilde{W}(t), \quad \bar{x}(0) = \bar{x}_0, \tag{74}$$

considered on the probability space $(\Omega, \mathcal{F}_T, Q_N^T)$, satisfies the following condition:

$$\frac{1}{T}\mathbf{E}^{Q_N^T}\int_0^T \left(\bar{x}'(t)\left(\frac{1}{\tau_0}\bar{R} + \bar{C}'\bar{C}\right)\bar{x}(t) + \frac{\bar{\varepsilon}}{\tau_0}\|\bar{x}(t)\|^2 - \|\xi_N(t)\|^2\right) dt > N - \varepsilon.$$

This condition can be established using the same arguments as those used in proving the corresponding fact in [19]. Hence,

$$\lim_{T\to\infty}\frac{1}{T}\mathbf{E}^{Q_N^T}\int_0^T \left(\bar{x}'(t)\left(\frac{1}{\tau_0}\bar{R} + \bar{C}'\bar{C}\right)\bar{x}(t) + \frac{\bar{\varepsilon}}{\tau_0}\|\bar{x}(t)\|^2 - \|\xi_N(t)\|^2\right) dt \geq N. \tag{75}$$

Letting $N \to \infty$ in (75) and using the representation of the relative entropy $h(Q_N^T\|P^T)$, we obtain a contradiction with (69):

$$\begin{aligned}
&\sup_{\zeta\in\mathcal{M}_\infty}\left\{\begin{array}{l}
\liminf_{T\to\infty}\frac{1}{T}\mathbf{E}^{Q^T}\int_0^T \frac{1}{2\tau_0}\bar{x}(t)'\bar{R}\bar{x}(t)dt \\
+\frac{\bar{\varepsilon}}{\tau_0}\liminf_{T\to\infty}\frac{1}{2T}\mathbf{E}^{Q^T}\int_0^T \|\bar{x}(s)\|^2 ds \\
+\liminf_{T\to\infty}\frac{1}{T}\left[\frac{1}{2}\mathbf{E}^{Q^T}\int_0^T \|z(s)\|^2 ds - h(Q^T\|P^T)\right]
\end{array}\right\} \\
&\geq \sup_{N>0}\left\{\begin{array}{l}
\lim_{T\to\infty}\frac{1}{T}\mathbf{E}^{Q_N^T}\int_0^T \frac{1}{2\tau_0}\bar{x}(t)'\bar{R}\bar{x}(t)dt \\
+\frac{\bar{\varepsilon}}{\tau_0}\lim_{T\to\infty}\frac{1}{2T}\mathbf{E}^{Q_N^T}\int_0^T \|\bar{x}(s)\|^2 ds \\
+\lim_{T\to\infty}\frac{1}{2T}\mathbf{E}^{Q_N^T}\int_0^T (\|z(s)\|^2 - \|\xi_N(s)\|^2) ds
\end{array}\right\} \\
&= \infty.
\end{aligned}$$

Thus, condition (68) holds. As observed above, the proposition follows from this condition. Consequently, Lemma 5 follows from Proposition 4. □

Proof of Theorem 2. This proof exploits a large deviation result established in [14].

We first note that since the given controller $u^*(\cdot)$ is an absolutely stabilizing controller and the pair $(\bar{A}, \bar{R})$ is observable, the uncertain closed-loop system (3), (8) is absolutely stable. Furthermore, condition (i) of the theorem implies that there exists a sufficiently small positive constant $\bar{\varepsilon} > 0$ such that for all $\zeta(\cdot) \in \Xi$

$$\liminf_{T\to\infty} \frac{1}{2T}\mathbf{E}^{Q^T} \int_0^T \bar{x}(s)'\bar{R}\bar{x}(s)ds + \bar{\varepsilon} \liminf_{T\to\infty} \frac{1}{2T}\mathbf{E}^{Q^T} \int_0^T \|\bar{x}(t)\|^2 dt \le c - \bar{\varepsilon}. \tag{76}$$

Here $\bar{R}$ is the matrix corresponding to the controller $u^*(\cdot)$ as defined in (53). Also, $c > 0$ is the constant defined in condition (i) of the theorem. Then, it follows from Lemma 5 that there exists a positive constant $\tau_0 > 0$ such that the Riccati equation (59) has a positive-definite stabilizing solution. The existence of such a constant τ_0 is established using condition (76) in the same manner as in the proof of Lemma 5. Also, as in the proof of Lemma 5, it follows that for any martingale $\zeta(\cdot) \in \mathcal{M}_\infty$,

$$\begin{aligned} \liminf_{T\to\infty} \frac{1}{T}\mathbf{E}^{Q^T} \int_0^T \frac{1}{2}\bar{x}(t)'\bar{R}\bar{x}(t)dt + \bar{\varepsilon} \liminf_{T\to\infty} \frac{1}{2T}\mathbf{E}^{Q^T} \int_0^T \|\bar{x}(t)\|^2 dt \\ + \liminf_{T\to\infty} \frac{1}{T}\left[\frac{1}{2}\mathbf{E}^{Q^T} \int_0^T \|z(s)\|^2 ds - h(Q^T\|P^T)\right] \\ \le c - \bar{\varepsilon} - \frac{d}{2}\tau_0. \end{aligned} \tag{77}$$

Furthermore, the matrix $\bar{A}$ is stable, the pair $(\bar{A}, \bar{B})$ is controllable, and the pair $(\bar{A}, \bar{R} + \tau_0\bar{C}'\bar{C})$ is observable. The above conditions and the condition that Riccati equation (59) has a positive-definite stabilizing solution are the conditions of Example 2.2 of [14]. It follows from this example that

$$\begin{aligned} \lim_{T\to\infty} \frac{\tau_0}{T} \log \mathbf{E} \exp\left\{\frac{1}{2\tau_0}\int_0^T \bar{x}'(t)(\bar{R} + \tau_0\bar{C}'\bar{C})\bar{x}(t)dt\right\} \\ = \frac{1}{2}\int \left[\bar{x}'(\bar{R} + \tau_0\bar{C}'\bar{C})\bar{x} - \tau_0\|\phi(x)\|^2\right] \nu^\phi(d\bar{x}), \end{aligned} \tag{78}$$

where $\phi(\bar{x}) = 1/\tau_0\bar{B}'\Pi\bar{x}$ and Π is the positive-definite stabilizing solution to Riccati equation (59). On the left-hand side of (78), $\bar{x}(\cdot)$ is the solution to (3) corresponding to the given controller of form (2) and a given initial condition. It is shown in [14] that the value on both sides of (78) is independent of this initial condition.

For the function $\phi(\cdot)$ defined above, consider the martingale $\zeta(\cdot) \in \mathcal{M}_\infty$ and the corresponding stationary solution $\bar{x}(\cdot)$ to system (56) with initial distribution ν^ϕ constructed as in Lemma 4. For this martingale $\zeta(\cdot)$ and stationary solution $\bar{x}(\cdot)$, condition (78) leads to the following expression for the risk-sensitive cost:

$$
\begin{aligned}
&\lim_{T\to\infty}\frac{\tau_0}{T}\log\mathbf{E}\exp\left\{\frac{1}{2\tau_0}\int_0^T \bar{x}'(t)(\bar{R}+\tau_0\bar{C}'\bar{C})\bar{x}(t)dt\right\}\\
&=\frac{1}{2}\int\left[\bar{x}'(\bar{R}+\tau_0\bar{C}'\bar{C})\bar{x}-\tau_0\|\phi(x)\|^2\right]\nu^{\phi}(d\bar{x})\\
&=\liminf_{T\to\infty}\frac{1}{2T}\mathbf{E}^{Q^T}\int_0^T F(x(s),u^*(s))ds\\
&\quad+\tau_0\liminf_{T\to\infty}\frac{1}{T}\left[\frac{1}{2}\mathbf{E}^{Q^T}\int_0^T\|z(s)\|^2ds-h(Q^T\|P^T)\right].
\end{aligned}
\tag{79}
$$

Also, note that the right-hand side of the above equation is independent of the initial condition of system (56). This fact is readily established using Ito's formula and the fact that the matrix $\bar{A}+\frac{1}{\tau_0}\bar{B}\bar{B}'\Pi$ is stable. Therefore, on the right-hand side of inequality (79), the stationary process $\bar{x}(\cdot)$ can be replaced by the solution $\bar{x}(\cdot)$ to system (56) corresponding to the given initial condition. Then, (79) and (77) imply that

$$
\lim_{T\to\infty}\frac{\tau_0}{T}\log\mathbf{E}\exp\left\{\frac{1}{2\tau_0}\int_0^T \bar{x}'(t)(\bar{R}+\tau_0\bar{C}'\bar{C})\bar{x}(t)dt\right\}\le c-\bar{\varepsilon}-\frac{\tau_0}{2}d. \tag{80}
$$

Thus,

$$
V_{\tau_0}\le\lim_{T\to\infty}\frac{2\tau_0}{T}\log\mathbf{E}\exp\left[\frac{1}{2\tau_0}\int_0^T \bar{x}'(t)(\bar{R}+\tau_0\bar{C}'\bar{C})\bar{x}(t)dt\right]<2c-\tau_0 d.
$$

Hence the optimal value of the corresponding risk-sensitive control problem (37) is finite. □

6. Design of the infinite-horizon minimax optimal controller. In this section, we present the main result of the paper. This result shows that the solution to an infinite-horizon minimax optimal control problem of the form (31) can be obtained via optimization over solutions to a scaled risk-sensitive control problem of the form (37). Therefore, this result extends the corresponding result of [19] to the case where the underlying system is considered on an infinite time interval.

Consider the class $\mathcal{U}$ of linear controllers of the form (2). In what follows, we will focus on linear output feedback controllers of the form (2) having a controllable and observable state-space realization. The class of such controllers is denoted by $\mathcal{U}_0$.

The derivation of the main result of this paper makes use of parameter-dependent algebraic Riccati equations. Let $\tau>0$ be a constant. We consider the algebraic Riccati equations

$$
\begin{aligned}
&(A-B_2D_2'(D_2D_2')^{-1}C_2)Y_\infty+Y_\infty(A-B_2D_2'(D_2D_2')^{-1}C_2)'\\
&-Y_\infty\left(C_2'(D_2D_2')^{-1}C_2-\frac{1}{\tau}R_\tau\right)Y_\infty+B_2(I-D_2'(D_2D_2')^{-1}D_2)B_2'=0,
\end{aligned}
\tag{81}
$$

$$
\begin{aligned}
&X_\infty(A-B_1G_\tau^{-1}\Upsilon_\tau')+(A-B_1G_\tau^{-1}\Upsilon_\tau')'X_\infty\\
&+(R_\tau-\Upsilon_\tau G_\tau^{-1}\Upsilon_\tau')-X_\infty\left(B_1G_\tau^{-1}B_1'-\frac{1}{\tau}B_2B_2'\right)X_\infty=0.
\end{aligned}
\tag{82}
$$

The subsequent development relies on Theorem 3 of [9]. We now present a version of this theorem adapted to the notation used in this paper. We first note that some

of the conditions of Theorem 3 of [9] are automatically satisfied. Indeed, using the notation

$$\tilde{C}_1 := \begin{bmatrix} \frac{1}{\sqrt{\tau}} R^{1/2} \\ 0 \\ C_1 \end{bmatrix}, \quad \tilde{D}_1 := \begin{bmatrix} 0 \\ \frac{1}{\sqrt{\tau}} G^{1/2} \\ D_1 \end{bmatrix},$$

we obtain $R_\tau - \Upsilon_\tau G_\tau^{-1} \Upsilon_\tau' = \tau \tilde{C}_1'(I - \tilde{D}_1(\tilde{D}_1'\tilde{D}_1)^{-1}\tilde{D}_1')\tilde{C}_1 \geq 0$. Also, the pair $(A - B_1 G_\tau^{-1}\Upsilon_\tau', R_\tau - \Upsilon_\tau G_\tau^{-1}\Upsilon_\tau')$ is detectable since the matrix

$$\begin{bmatrix} A - sI & B_1 \\ R^{1/2} & 0 \\ 0 & G^{1/2} \\ \sqrt{\tau} C_1 & \sqrt{\tau} D_1 \end{bmatrix}$$

has full column rank for all s such that $\mathrm{Re} s \geq 0$.

LEMMA 6. *Consider the risk-sensitive optimal control problem* (37) *with underlying system* (1). *Suppose the pair*

$$(A - B_2 D_2'(D_2 D_2')^{-1} C_2, B_2(I - D_2'(D_2 D_2')^{-1} D_2)) \tag{83}$$

is stabilizable. Also, suppose that there exists a constant $\tau > 0$ *such that the following assumptions are satisfied:*

(i) *Algebraic Riccati equation* (81) *admits a minimal positive-definite solution* Y_∞.
(ii) *Algebraic Riccati equation* (82) *admits a minimal nonnegative-definite solution* X_∞.
(iii) *The matrix* $I - \frac{1}{\tau} Y_\infty X_\infty$ *has only positive eigenvalues; that is, the spectral radius of the matrix* $Y_\infty X_\infty$ *satisfies the condition*

$$\rho(Y_\infty X_\infty) < \tau; \tag{84}$$

where $\rho(\cdot)$ *denotes the spectral radius of a matrix.*

If $Y_\infty \geq Y_0$, *then there exists a controller solving risk-sensitive optimal control problem* (37) *where the infimum is taken over the set* $\mathcal{U}$. *This optimal risk-sensitive controller is a controller of the form* (2) *with*

$$\begin{aligned} K &:= -G_\tau^{-1}(B_1' X_\infty + \Upsilon_\tau'), \\ A_c &:= A + B_1 K - B_c C_2 + \frac{1}{\tau}(B_2 - B_c D_2) B_2' X_\infty, \\ B_c &:= \left(I - \frac{1}{\tau} Y_\infty X_\infty\right)^{-1} (Y_\infty C_2' + B_2 D_2')(D_2 D_2')^{-1}. \end{aligned} \tag{85}$$

The corresponding optimal value of the risk-sensitive cost is given by

$$\begin{aligned} V_\tau &:= \inf_{u \in \mathcal{U}} \lim_{T \to \infty} \Im_{\tau,T}(u(\cdot)) \\ &= \mathrm{tr} \begin{bmatrix} Y_\infty R_\tau + \\ (Y_\infty C_2' + B_2 D_2')(D_2 D_2')^{-1}(C_2 Y_\infty + D_2 B_2') X_\infty (I - \frac{1}{\tau} Y_\infty X_\infty)^{-1} \end{bmatrix}. \end{aligned} \tag{86}$$

Proof. See Theorem 3 of [9]. □

Remark 6. The condition $Y_\infty \geq Y_0$ required by Lemma 6 is a technical condition needed to apply the results of [9] to risk-sensitive control problem (37). However, it can be seen from Lemma 6 that the resulting optimal risk-sensitive controller and the optimal risk-sensitive cost are independent of the matrix Y_0. Therefore, the condition of Lemma 6 requiring $Y_\infty \geq Y_0$ can always be satisfied by a suitable choice of the matrix Y_0.

Reference [9] does not address the issue of stability for the closed-loop system corresponding to the optimal risk-sensitive controller. However, Theorem 1 shows that the controller (2), (85) leads to a robustly stable closed-loop system. This fact is consistent with results showing that risk-sensitive controllers enjoy certain robustness properties; e.g., see [3, 20]. The following results show that the conditions of Lemma 6 are not only sufficient conditions, but also necessary conditions for the existence of a solution to the risk-sensitive optimal control problem under consideration, if such a solution is sought in the class of linear stabilizing controllers; cf. [8].

LEMMA 7. *Suppose the pair* (83) *is controllable and for some* $\tau' > 0$ *there exists an absolutely stabilizing controller* $\tilde{u}(\cdot) \in \mathcal{U}_0$ *such that*

$$V^0_{\tau'} := \lim_{T\to\infty} \Im_{\tau',T}(\tilde{u}) = \inf_{u\in\mathcal{U}_0} \lim_{T\to\infty} \Im_{\tau',T}(u) < +\infty. \tag{87}$$

Then there exists a constant $\tau > 0$ *which satisfies conditions* (i)–(iii) *of Lemma* 6.

Furthermore, if for this τ *the corresponding pairs* (A_c, B_c) *and* (A_c, K) *defined by* (85) *are controllable and observable, respectively, then*

$$V^0_\tau = \operatorname{tr}\left[\begin{array}{l} Y_\infty R_\tau + \\ (Y_\infty C_2' + B_2 D_2')(D_2 D_2')^{-1}(C_2 Y_\infty + D_2 B_2')X_\infty (I - \frac{1}{\tau} Y_\infty X_\infty)^{-1} \end{array}\right]. \tag{88}$$

In the proof of Lemma 7, the following proposition is used.

PROPOSITION 5. *Suppose the pair* (83) *is controllable. Then, for any controller* $u(\cdot) \in \mathcal{U}_0$, *the pair* $(\bar{A}, \bar{B})$ *in the corresponding closed-loop system is controllable and the pair* $(\bar{A}, \bar{R})$ *is observable.*

The proof of this proposition is given in Appendix B.

Proof of Lemma 7. We prove the lemma by contradiction. Suppose that for any $\tau > 0$ at least one of conditions (i)–(iii) of Lemma 6 does not hold. That is, either (81) does not admit a positive-definite stabilizing solution, or (82) does not admit a nonnegative-definite stabilizing solution, or (84) fails to hold. Note that conditions (i)–(iii) of Lemma 6 are standard conditions arising in H^∞ control. Since for any stabilizing controller $u(\cdot) \in \mathcal{U}_0$ the corresponding matrix $\bar{A}$ is stable (see Proposition 5 and Lemma 3), then it follows from standard results on H^∞ control that if at least one of conditions (i)–(iii) of Lemma 6 fails to hold, then for any controller of the form (2)

$$\left\| \left[\begin{array}{cc} \tilde{C}_1 & \tilde{D}_1 K \end{array}\right] (j\omega I - \bar{A})^{-1} \bar{B} \right\|_\infty \geq 1; \tag{89}$$

see Theorem 3.1 of [10]. It is straightforward to verify that the conditions of Theorem 3.1 of [10] are satisfied. Furthermore, the strict bounded real lemma implies that the Riccati equation

$$\bar{A}'\bar{X} + \bar{X}\bar{A} + \frac{1}{\tau}\bar{X}\bar{B}\bar{B}'\bar{X} + \bar{R} + \tau\bar{C}'\bar{C} = 0 \tag{90}$$

does not have a stabilizing positive definite solution. In this case, Lemma 5 implies that none of the controllers $u(\cdot) \in \mathcal{U}_0$ leads to an absolutely stable closed-loop system. This leads to a contradiction with the assumption that an absolutely stabilizing

controller exists and belongs to $\mathcal{U}_0$. This completes the proof by contradiction that there exists a constant τ which satisfies conditions (i)–(iii) of Lemma 6.

It remains to prove (88). Note that Lemma 6 states that for each $\tau > 0$ satisfying the conditions of that lemma, the optimal controller solving risk-sensitive control problem (86) is the controller (2), (85). Furthermore, it is assumed that the state-space realization of this controller is controllable and observable, and hence the optimal controller from Lemma 6 belongs to the set $\mathcal{U}_0$. Therefore,

$$V_\tau^0 = \inf_{u\in\mathcal{U}_0} \lim_{T\to\infty} \Im_{\tau,T}(u(\cdot)) = \inf_{u\in\mathcal{U}} \lim_{T\to\infty} \Im_{\tau,T}(u(\cdot)) = V_\tau. \tag{91}$$

From this observation, (88) follows. □

We now define a set $\mathcal{T} \subset \mathbf{R}$ as the set of constants $\tau \in \mathbf{R}$ satisfying the conditions of Lemma 6. It follows from Lemma 6 that, for any $\tau \in \mathcal{T}$, the controller of form (2) with coefficients given by (85) represents an optimal controller in the risk-sensitive control problem (37), which guarantees the optimal value (88).

THEOREM 3. *Assume that the pair* (83) *is controllable.*

(i) *Suppose that the set* $\mathcal{T}$ *is nonempty and that* $\tau_* \in \mathcal{T}$ *attains the infimum in*

$$\inf_{\tau\in\mathcal{T}} \frac{1}{2}(V_\tau^0 + \tau d), \tag{92}$$

where V_τ^0 *is defined in* (88). *Then the corresponding controller* $u^*(\cdot) := u_{\tau_*}(\cdot)$ *of the form* (2) *defined by* (85), *with the pair* (A_c, B_c) *being controllable and the pair* (A_c, K) *being observable, is an output-feedback controller guaranteeing that*

$$\inf_{u\in\mathcal{U}_0} \sup_{\zeta\in\Xi} J(u,\zeta) \le \sup_{\zeta\in\Xi} J(u^*,\zeta) \le \inf_{\tau\in\mathcal{T}} \frac{1}{2}(V_\tau^0 + \tau d). \tag{93}$$

Furthermore, this controller is an absolutely stabilizing controller for the stochastic uncertain system (1), (8).

(ii) *Conversely, if there exists an absolutely stabilizing minimax optimal controller* $\tilde{u}(\cdot) \in \mathcal{U}_0$ *for the stochastic uncertain system* (1), (8) *such that*

$$\sup_{\zeta\in\Xi} J(\tilde{u},\zeta) < \infty,$$

then the set $\mathcal{T}$ *is nonempty. Moreover,*

$$\inf_{\tau\in\mathcal{T}} \frac{1}{2}(V_\tau^0 + \tau d) \le \sup_{\zeta\in\Xi} J(\tilde{u},\zeta). \tag{94}$$

Proof. Part (i). The conditions of this part of the theorem guarantee that $u^*(\cdot) \in \mathcal{U}_0$. Then $V_{\tau_*}^0 = V_{\tau_*}$. This fact together with Theorem 1 implies that

$$\inf_{u\in\mathcal{U}_0} \sup_{\zeta\in\Xi} J(u,\zeta) \le \sup_{\zeta\in\Xi} J(u^*,\zeta) \le \frac{1}{2}(V_{\tau_*}^0 + \tau_* d) = \inf_{\tau\in\mathcal{T}} \frac{1}{2}(V_\tau^0 + \tau d). \tag{95}$$

Also from Theorem 1, the controller $u^*(\cdot)$ solving the corresponding risk-sensitive control problem is an absolutely stabilizing controller. From this observation, part (i) of the theorem follows.

Part (ii). Note that the controller $\tilde{u}(\cdot) \in \mathcal{U}_0$ satisfies the conditions of Theorem 2; see Proposition 5. Let c be a constant such that

$$\sup_{\zeta\in\Xi} J(\tilde{u},\zeta) < c.$$

When proving Theorem 2, it was shown that there exists a constant $\tau > 0$ such that Riccati equation (90) has a stabilizing positive-definite solution and

$$\frac{1}{2}\lim_{T\to\infty}\Im_{\tau,T}(\tilde{u}) < c - \frac{\tau}{2}d < \infty; \tag{96}$$

see (80). Hence, $V_\tau^0 < \infty$. From the above conditions and using Lemma 7, we conclude that the set $\mathcal{T}$ is nonempty.

We now prove (94). Consider a sequence $\{c_i\}$, $i = 1, 2, \ldots$, such that

$$c_i \downarrow \sup_{\zeta\in\Xi} J(\tilde{u}, \zeta) \quad \text{as } i \to \infty.$$

From (96) it follows that

$$\inf_{\tau\in\mathcal{T}} \frac{1}{2}(V_\tau^0 + \tau d) < c_i.$$

Hence, letting i approach infinity leads to the satisfaction of (94). □

The first part of Theorem 3 provides a sufficient condition for the existence of an optimal solution to the minimax LQG control problem considered in this section. This condition is given in terms of certain Riccati equations. This makes the result useful in practical controller design since there is a wide range of software available for solving such Riccati equations.

In the control literature, there is a great deal of interest concerning the issue of conservatism in robust controller design. For example, a significant issue considered in [15, 16, 18] is to prove that the results on the minimax optimal control considered in those papers are not conservative, in that the corresponding Riccati equations fail to have stabilizing solutions if the minimax optimal controller does not exist. Thus, the conditions for the existence of a minimax optimal controller presented in those sections are necessary and sufficient conditions. The second part of Theorem 3 is analogous to the necessity results of [15, 16, 18, 19]. It follows from this part of Theorem 3 that the controller $u^*(\cdot)$ constructed in the first part of Theorem 3 represents a minimax optimal controller in the subclass $\mathcal{U}_{0,\text{stab}} \subset \mathcal{U}_0$ of stabilizing linear output feedback controllers. This result is summarized in the following theorem.

THEOREM 4. *Assume that the conditions of part* (i) *of Theorem* 3 *are satisfied. Then, the controller* $u^*(\cdot)$ *constructed in part* (i) *of Theorem* 3 *is the minimax optimal controller such that*

$$\inf_{u\in\mathcal{U}_{0,\text{stab}}}\sup_{\zeta\in\Xi} J(u,\zeta) = \sup_{\zeta\in\Xi} J(u^*,\zeta) = \inf_{\tau\in\mathcal{T}}\frac{1}{2}(V_\tau^0 + \tau d). \tag{97}$$

Proof. It was shown in part (i) of Theorem 3 that the controller $u^*(\cdot)$ belongs to the set $\mathcal{U}_{0,\text{stab}}$. Hence,

$$\inf_{u\in\mathcal{U}_{0,\text{stab}}}\sup_{\zeta\in\Xi} J(u,\zeta) \le \sup_{\zeta\in\Xi} J(u^*,\zeta) \le \inf_{\tau\in\mathcal{T}}\frac{1}{2}(V_\tau^0 + \tau d). \tag{98}$$

Furthermore, condition (98) implies that

$$\inf_{u\in\mathcal{U}_{0,\text{stab}}}\sup_{\zeta\in\Xi} J(u,\zeta) < \infty.$$

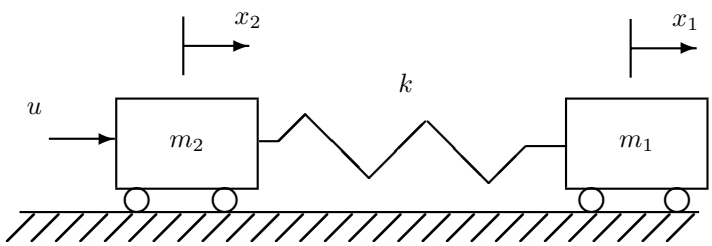

FIG. 2. *A two mass spring system.*

That is, for any sufficiently small $\varepsilon > 0$, there exists a controller $\tilde{u}(\cdot) \in \mathcal{U}_{0,\text{stab}}$ such that

$$\sup_{\zeta\in\Xi} J(\tilde{u},\zeta) \le \inf_{u\in\mathcal{U}_{0,\text{stab}}} \sup_{\zeta\in\Xi} J(u,\zeta) + \varepsilon.$$

This controller satisfies the conditions of part (ii) of Theorem 3. Therefore, it follows from Theorem 3 that

$$\inf_{\tau\in\mathcal{T}} \frac{1}{2}(V_\tau^0 + \tau d) \le \inf_{u\in\mathcal{U}_{0,\text{stab}}} \sup_{\zeta\in\Xi} J(u,\zeta) + \varepsilon.$$

The above inequality holds for any infinitesimal $\varepsilon > 0$. Therefore,

$$\inf_{\tau\in\mathcal{T}} \frac{1}{2}(V_\tau^0 + \tau d) \le \inf_{u\in\mathcal{U}_{0,\text{stab}}} \sup_{\zeta\in\Xi} J(u,\zeta).$$

This inequality together with (98) implies (97). □

7. Illustrative example. We now consider the tracking problem which was used as an illustrative example in [15, 17]. In this tracking problem, the goal is to design an output-feedback controller so that the controlled output of a two-cart system tracks a reference step input. The system to be controlled is shown in Figure 2.

As in [15, 17], the masses of the carts are assumed to be $m_1 = 1$ and $m_2 = 1$. Furthermore, the spring constant k is treated as an uncertain parameter subject to the bound $0.5 \le k \le 2.0$. From this, a corresponding uncertain system was derived in [17]. This uncertain system is described by the following state equations:

$$\begin{aligned}
\dot{x} &= \begin{bmatrix} 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ -1.25 & 1.25 & 0 & 0 \\ 1.25 & -1.25 & 0 & 0 \end{bmatrix} x + \begin{bmatrix} 0 \\ 0 \\ 0 \\ 1 \end{bmatrix} u + \begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ -0.70 & 0 & 0 \\ 0.80 & 0 & 0 \end{bmatrix} \xi, \\
z &= \begin{bmatrix} 1 & -1 & 0 & 0 \end{bmatrix} x, \\
y &= \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \end{bmatrix} x + \begin{bmatrix} 0 & 0.05 & 0 \\ 0 & 0 & 0.05 \end{bmatrix} \xi, \\
y_T &= \begin{bmatrix} 1 & 0 & 0 & 0 \end{bmatrix} x.
\end{aligned} \tag{99}$$

Here, the uncertainty is subject to an integral quadratic constraint which will be specified below. The output y_T is the output which is required to track a step input.

The control problem solved in [17] involved finding a controller which absolutely stabilized the system and also ensured that the output y_T tracks a reference step input. In [17], the system was transformed into the form:

$$\begin{aligned}
\dot{\bar{x}} &= \begin{bmatrix} 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & -2.5 & 0 \end{bmatrix} \bar{x} + \begin{bmatrix} 0 \\ 0.5 \\ 0 \\ -0.5 \end{bmatrix} u + \begin{bmatrix} 0 & 0 & 0 \\ 0.05 & 0 & 0 \\ 0 & 0 & 0 \\ -0.75 & 0 & 0 \end{bmatrix} \xi, \\
z &= \begin{bmatrix} 0 & 0 & 2 & 0 \end{bmatrix} \bar{x}, \\
\bar{y} &= \begin{bmatrix} 1 & 0 & 1 & 0 \\ 1 & 0 & -1 & 0 \end{bmatrix} \bar{x} + \begin{bmatrix} 0 & 0.05 & 0 \\ 0 & 0 & 0.05 \end{bmatrix} \xi, \\
y_T - \tilde{y}_T &= \begin{bmatrix} 1 & 0 & 1 & 0 \end{bmatrix} \bar{x},
\end{aligned} \tag{100}$$

where

$$\bar{y} := y - \begin{bmatrix} 1 \\ 1 \end{bmatrix} \eta.$$

Here, η denotes the state of the reference input signal model:

$$\begin{aligned}
&\dot{\eta} = 0, \quad \eta(0) = 1, \\
&\tilde{y}_T = \eta.
\end{aligned} \tag{101}$$

The above transformation involved the following change of variables:

$$\begin{aligned}
\bar{x}_1 &= (x_1 + x_2)/2 - \eta, \\
\bar{x}_2 &= (\dot{x}_1 + \dot{x}_2)/2 = (x_3 + x_4)/2, \\
\bar{x}_3 &= (x_1 - x_2)/2, \\
\bar{x}_4 &= (\dot{x}_1 - \dot{x}_2)/2 = (x_3 - x_4)/2.
\end{aligned} \tag{102}$$

To construct the required controller, the following cost function was used:

$$\int_0^\infty [(y_T - \tilde{y}_T)^2 + 0.1\|\bar{x}\|^2 + u^2]dt. \tag{103}$$

Hence, the matrices R and G are as defined in [17]:

$$R = \begin{bmatrix} 1.1 & 0 & 1 & 0 \\ 0 & 0.1 & 0 & 0 \\ 1 & 0 & 1.1 & 0 \\ 0 & 0 & 0 & 0.1 \end{bmatrix} > 0, \qquad G = 1.$$

In (100), the uncertainty input $\xi(\cdot)$ has three components,

$$\xi(\cdot) = [\xi_1(\cdot),\ \xi_2(\cdot),\ \xi_3(\cdot)]'.$$

The uncertainty input $\xi_1(\cdot)$ describes the uncertainty in the spring rate. This uncertainty satisfies the constraint

$$|\xi_1(t)| \le |z(t)|.$$

The components ξ_2 and ξ_3 of the uncertainty input vector ξ are fictitious uncertainty inputs which were added to system (99) in [17] in order to fit this system into the framework of the method presented in that paper. Specifically, it was assumed in [17] that the uncertainty input $\xi(\cdot)$ satisfies the following integral quadratic constraint:

$$\int_0^{t_i} \|\xi(t)\|^2 dt \leq \int_0^{t_i} \|z(t)\|^2 dt + \bar{x}_0' S \bar{x}_0, \tag{104}$$

where $\{t_i\}$ is a sequence of times as discussed in [17]. Also, in [17], the initial condition of system (100) was chosen to be $\bar{x}_0 = [-1\ 0\ 0\ 0]'$. This choice of the initial condition corresponds to a zero initial condition on the system dynamics and an initial condition of $\eta(0) = 1$ on the reference input dynamics. Also, the mismatch matrix S was chosen to be

$$S = \begin{bmatrix} 0.1 & 0 & 0 & 0 \\ 0 & 0.1 & 0 & 0 \\ 0 & 0 & 0.1 & 0 \\ 0 & 0 & 0 & 0.1 \end{bmatrix} > 0.$$

The output-feedback robust controller designed in [17] was a suboptimal time-varying controller. We now apply the controller design procedure presented in this paper to design a time-invariant output-feedback minimax optimal controller solving the above tracking problem. We will use the state space transformation (102), which reduces the original tracking problem to a regulator problem. However, in order to apply the results of this paper to this robust control problem, we must introduce a stochastic description of the system. To satisfy this requirement, a noise input will be added to the system, and the controller will be designed for the system with additive noise. That is, we replace the nominal system corresponding to (100) with $\xi(\cdot) \equiv 0$ with a stochastic system described by the following stochastic differential equation:

$$\begin{aligned}
d\bar{x} &= \left[\begin{bmatrix} 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & -2.5 & 0 \end{bmatrix} \bar{x} + \begin{bmatrix} 0 \\ 0.5 \\ 0 \\ -0.5 \end{bmatrix} u \right] dt + \begin{bmatrix} 0 & 0 & 0 \\ 0.05 & 0 & 0 \\ 0 & 0 & 0 \\ -0.75 & 0 & 0 \end{bmatrix} dW(t), \\
z &= \begin{bmatrix} 0 & 0 & 2 & 0 \end{bmatrix} \bar{x}, \\
d\bar{y} &= \begin{bmatrix} 1 & 0 & 1 & 0 \\ 1 & 0 & -1 & 0 \end{bmatrix} \bar{x} dt + \begin{bmatrix} 0 & 0.05 & 0 \\ 0 & 0 & 0.05 \end{bmatrix} dW, \\
y_T - \tilde{y}_T &= \begin{bmatrix} 1 & 0 & 1 & 0 \end{bmatrix} \bar{x},
\end{aligned} \tag{105}$$

where $W(t) = [W_1(t),\ W_2(t),\ W_3(t)]'$ is a 3-dimensional Wiener process on a certain measurable space $(\Omega, \mathcal{F}, P)$. Here, P is the reference probability measure. Also, the uncertain system (100) is replaced by an uncertain system of the form (105) considered on an uncertain measurable space defined using an uncertain martingale $\zeta(\cdot)$. Also, as noted in section 2, uncertain systems of this type can be described using a stochastic differential equation of the form (13). System (105) is a system of the form (1) to which the design technique presented in this paper is applicable.

Note that in this example, a robust controller is sought which stabilizes the system in the face of stochastic uncertainty. It can readily be shown using Lemma 5 that the absolute stability of the stochastic closed-loop system consisting of system

(105) and this controller implies the robust stability of the closed-loop system corresponding to the deterministic system (100) driven by the same linear output-feedback controller. Indeed, Lemma 5 shows that the corresponding Riccati equation (59) has a nonnegative-definite stabilizing solution. Then, using the strict bounded real lemma leads to the conclusion that the corresponding deterministic closed-loop system with norm-bounded uncertainty is quadratically stable [5]. Also, the corresponding deterministic closed-loop system with the uncertainty modeled using an integral quadratic constraint of the form (104) is absolutely stable [23]. It follows from this observation that a robust output-feedback controller designed for the uncertain stochastic system (105) also serves as a robust controller for the original uncertain system (100). Thus, a controller designed for stochastic uncertain system (105) will solve the original tracking problem.

We now proceed to the derivation of a robust output-feedback controller for system (105). We first replace the integral quadratic constraint (104) by the following stochastic uncertainty constraint: For any $T > 0$

$$\frac{1}{2T}\mathbf{E}^{Q^T}\int_0^T \|\xi(t)\|^2 dt \le \frac{1}{2T}\mathbf{E}^{Q^T}\int_0^T \|z(t)\|^2 dt + d, \quad d = \frac{1}{2}\bar{x}_0' S \bar{x}_0. \tag{106}$$

It was shown in section 2 that the uncertainty class defined by the constraint (106) can be embedded into an uncertainty class described by the corresponding relative entropy uncertainty constraint of the form (8).

The cost functional is chosen to have the form

$$\limsup_{T\to\infty} \frac{1}{2T}\int_0^T \mathbf{E}^{Q^T}[(y_T - \tilde{y}_T)^2 + 0.1\|\bar{x}\|^2 + u^2]dt. \tag{107}$$

We are now in a position to apply the design procedure outlined in Theorem 3. For each value of $\tau > 0$, the Riccati equations (81) and (82) are solved, and then a line search is carried out to find the value of $\tau > 0$ which attains the minimum of the function $1/2(V_\tau^0 + \tau d)$ defined in Theorem 3. A graph of $1/2(V_\tau^0 + \tau d)$ versus τ for this example is shown in Figure 3. It was found that the optimal value of the parameter τ is $\tau = 5.6931$.

With this optimal value of τ, the following positive-definite stabilizing solutions to Riccati equations (82) and (81) were obtained:

$$X_\infty = \begin{bmatrix} 4.0028 & 6.8156 & -6.3708 & 3.8312 \\ 6.8156 & 18.3891 & -20.6541 & 9.3784 \\ -6.3708 & -20.6541 & 48.5330 & -5.8268 \\ 3.8312 & 9.3784 & -5.8268 & 12.5738 \end{bmatrix},$$

$$Y_\infty = \begin{bmatrix} 0.0007 & 0.0003 & -0.0005 & -0.0014 \\ 0.0003 & 0.0008 & -0.0017 & -0.0108 \\ -0.0005 & -0.0017 & 0.0077 & 0.0236 \\ -0.0014 & -0.0108 & 0.0236 & 0.1641 \end{bmatrix}.$$

Furthermore, a corresponding time-invariant controller of the form (2), (85) was

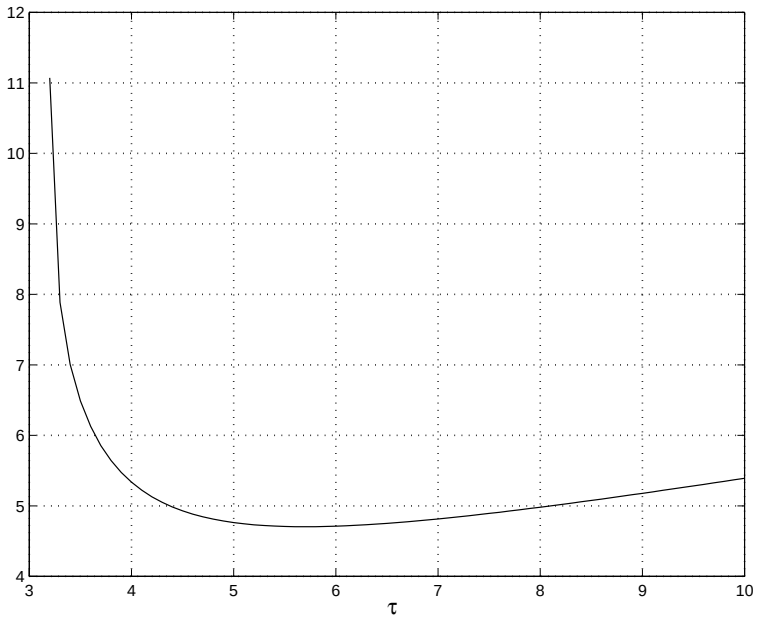

FIG. 3. *Cost bound* $\frac{1}{2}(V_\tau^0 + \tau d)$ *versus the parameter* τ.

constructed to be

$$d\hat{x} = \begin{bmatrix} -0.5868 & 1.0000 & 0.4581 & 0 \\ -1.0384 & -2.3064 & 5.7466 & 0.7202 \\ 0.4581 & 0 & -7.6627 & 1.0000 \\ 2.6530 & 3.0582 & -34.7464 & 0.3817 \end{bmatrix} \hat{x}dt + \begin{bmatrix} 0.0643 & 0.5225 \\ -0.8702 & 1.1403 \\ 3.6023 & -4.0604 \\ 13.2633 & -14.8366 \end{bmatrix} dy(t),$$

$$u = \begin{bmatrix} -1.4922 & -4.5053 & 7.4137 & 1.5977 \end{bmatrix} \hat{x}.$$

Then referring to system (99), the required tracking control system is constructed by replacing the time-varying controller of [17] with the above time-invariant controller as shown in Figure 4. To verify the robust tracking properties of this control system, Figure 5 shows the step response of the system for various values of the spring constant parameter k. It can be seen from these plots that the stochastic minimax optimization approach of this paper leads to a robust tracking system which exhibits transient behavior similar to the behavior of the tracking system designed using the deterministic approach of [17]. However, the controller designed using the approach of this paper is time-invariant.

Appendix A. Relative entropy. This appendix presents a result on the duality between free energy and relative entropy which is exploited in this paper. This result is taken from [1].

Let $(\Omega, \mathcal{F})$ be a measurable space, and let $\mathcal{P}(\Omega)$ be the set of probability measures on $(\Omega, \mathcal{F})$.

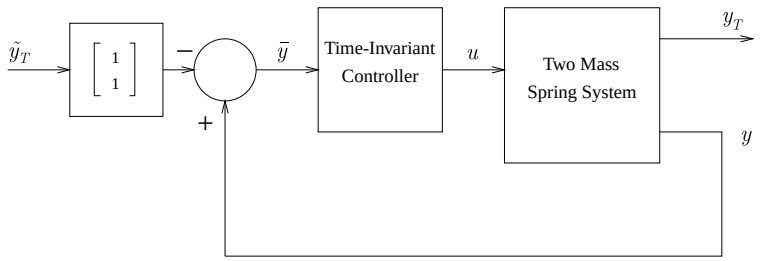

FIG. 4. *Block diagram of a tracking control system.*

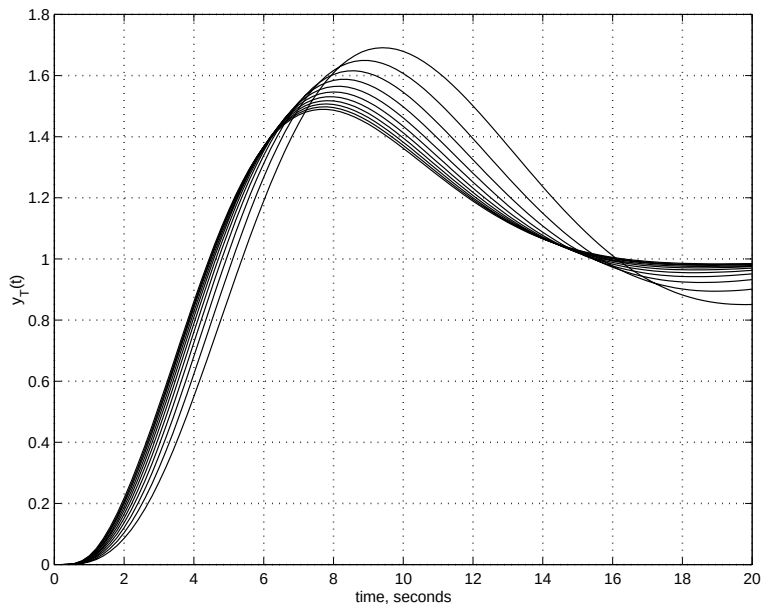

FIG. 5. *Control system step response for various spring constants.*

DEFINITION 4. *Let $P \in \mathcal{P}(\Omega)$, and $\psi : \Omega \to \mathbf{R}$ be a measurable function. The quantity*

$$\mathbb{E} := \log\left(\int e^{\psi} P(d\omega)\right)$$

is called the free energy of ψ with respect to P.

DEFINITION 5. *Given any two probability measures $Q, P \in \mathcal{P}(\Omega)$, the relative entropy of the probability measure Q with respect to the probability measure P is defined by*

$$h(Q\|P) := \begin{cases} \int \log\left(\frac{dQ}{dP}\right) Q(d\omega) & \text{if } Q \ll P \text{ and } \log\left(\frac{dQ}{dP}\right) \in L_1(\Omega, \mathcal{F}, Q), \\ +\infty & \text{otherwise.} \end{cases} \tag{A.1}$$

In the above definition, $\frac{dQ}{dP}$ is the Radon–Nikodým derivative of the probability measure Q with respect to the probability measure P. Note that the relative entropy is a convex, lower semicontinuous functional of Q; e.g., see [2]. It is shown in [1]

that the functions $\mathbb{E}(\psi)$ and $h(Q\|P)$ are in duality with respect to a Legendre-type transform as follows.

LEMMA 8.

(i) *For every* $Q \in \mathcal{P}(\Omega)$,

$$h(Q\|P) = \sup_{\substack{e^{\psi} \in L_1(\Omega,\mathcal{F},P),\\ \psi \text{ bounded below}}} \left\{ \int \psi Q(d\omega) - \mathbb{E}(\psi) \right\}; \tag{A.2}$$

(ii) *For every* ψ *bounded from below,*

$$\mathbb{E}(\psi) = \sup_{h(Q\|P)<\infty} \left\{ \int \psi Q(d\omega) - h(Q\|P) \right\}. \tag{A.3}$$

Moreover, if $\psi e^{\psi} \in L_1(\Omega, \mathcal{F}, P)$, *then the supremum in* (A.3) *is attained at* Q^* *given by*

$$\frac{dQ^*}{dP} = \frac{e^{\psi}}{\int e^{\psi} P(d\omega)}.$$

Proof. See [1]. □

Appendix B. Proofs.

Proof of Lemma 3. Since the stochastic nominal system (27) satisfies condition (29), then for any vector y

$$\limsup_{T\to\infty} \frac{1}{T} \int_0^T y' \mathbf{E}\left[x(t)x'(t)\right] y dt < \infty. \tag{B.1}$$

We will prove that the stability of the matrix A follows from condition (B.1). This proof is by contradiction.

Suppose that the matrix A is not stable and therefore it has a left eigenvalue λ such that $\mathrm{Re}\lambda \geq 0$. Consider the left eigenvector y of the matrix A corresponding to the eigenvalue λ. Hence, $y'A = y'\lambda$. Here, y' denotes the Hermitian conjugate of y. Since the pair (A, B_2) is stabilizable, it follows that $y'B_2 \neq 0$ and, consequently,

$$y' B_2 B_2' y > 0. \tag{B.2}$$

We now consider the following two cases.

Case 1. $\mathrm{Re}\lambda > 0$. In this case, we obtain the following bound on $y'\mathbf{E}\left[x(t)x'(t)\right] y$:

$$\begin{aligned} y'\mathbf{E}\left[x(t)x'(t)\right] y &= y' e^{At} \mathbf{E}\left[x(0)x'(0)\right] e^{A't} y + \int_0^t y' e^{A(t-s)} B_2 B_2' e^{A'(t-s)} y ds \\ &= e^{2\mathrm{Re}\lambda t} y' \mathbf{E}\left[x(0)x'(0)\right] y + \int_0^t e^{2\mathrm{Re}\lambda(t-s)} y' B_2 B_2' y ds \\ &\geq \frac{e^{2\mathrm{Re}\lambda t} - 1}{2\mathrm{Re}\lambda} y' B_2 B_2' y. \end{aligned}$$

Thus for any $T > 0$

$$\frac{1}{T} \int_0^T y' \mathbf{E}\left[x(t)x'(t)\right] y dt \geq y' B_2 B_2' y \cdot \frac{1}{T} \int_0^T \frac{e^{2\mathrm{Re}\lambda t} - 1}{2\mathrm{Re}\lambda} dt. \tag{B.3}$$

Case 2. $\mathrm{Re}\lambda = 0$. In this case, we obtain the following bound on $y'\mathbf{E}\left[x(t)x'(t)\right]y$:

$$\begin{aligned} y'\mathbf{E}\left[x(t)x'(t)\right]y &= y'e^{At}\mathbf{E}\left[x(0)x'(0)\right]e^{A't}y + \int_0^t y'e^{A(t-s)}B_2B_2'e^{A'(t-s)}y ds \\ &= y'\mathbf{E}\left[x(0)x'(0)\right]y + \int_0^t y'B_2B_2'y ds \\ &\geq t\cdot y'B_2B_2'y. \end{aligned}$$

Thus for any $T > 0$

$$\frac{1}{T}\int_0^T y'\mathbf{E}\left[x(t)x'(t)\right]y dt \geq y'B_2B_2'y\cdot\frac{1}{T}\frac{T^2}{2} = y'B_2B_2'y\frac{T}{2}. \tag{B.4}$$

Since $y'B_2B_2'y > 0$, the expressions on the right-hand side of inequalities (B.3) and (B.4) both approach infinity as $T\to\infty$. That is, in both cases,

$$\limsup_{T\to\infty}\frac{1}{T}\int_0^T y'\mathbf{E}\left[x(t)x'(t)\right]y dt = \infty.$$

This yields the desired contradiction with (B.1). □

Proof of Proposition 5. Note that by definition, for any controller $u(\cdot)\in\mathcal{U}_0$, the corresponding pair (A_c, B_c) is controllable and the pair (A_c, K) is observable.

To prove the controllability of the pair $(\bar{A},\bar{B})$, we first note that the matrix

$$\begin{bmatrix} A'-sI & C_2' \\ B_2' & D_2' \end{bmatrix} \tag{B.5}$$

has full column rank for all $s\in\mathbb{C}$ [25].

Next, consider the matrix pair

$$(\bar{A},\bar{B}) = \left(\begin{bmatrix} A & B_1K \\ B_cC_2 & A_c \end{bmatrix}, \begin{bmatrix} B_2 \\ B_cD_2 \end{bmatrix}\right). \tag{B.6}$$

For this matrix pair to be controllable, the equations

$$(A'-sI)x_1 + C_2'B_c'x_2 = 0, \tag{B.7a}$$

$$B_2'x_1 + D_2'B_c'x_2 = 0, \tag{B.7b}$$

$$K'B_1'x_1 + (A_c'-sI)x_2 = 0 \tag{B.7c}$$

must imply that $x_1 = 0$ and $x_2 = 0$ for every $s\in\mathbb{C}$. Equations (B.7a) and (B.7b) can be written as follows:

$$\begin{bmatrix} A'-sI & C_2' \\ B_2' & D_2' \end{bmatrix}\begin{bmatrix} x_1 \\ B_c'x_2 \end{bmatrix} = 0.$$

It was noted above that the matrix (B.5) has full column rank for all $s\in\mathbb{C}$. Hence, the above equation and (B.7c) imply that

$$x_1 = 0,\quad B_c'x_2 = 0,\quad (A_c'-sI)x_2 = 0.$$

Since the pair (A_c, B_c) is controllable, then the two last equations imply that $x_2 = 0$. Thus, the pair (B.6) is controllable.

In order to prove the observability of the pair $(\bar{A}, \bar{R})$, we need to show that the equations

$$(A - sI)x_1 + B_1 K x_2 = 0, \tag{B.8a}$$

$$B_c C_2 x_1 + (A_c - sI)x_2 = 0, \tag{B.8b}$$

$$R^{1/2} x_1 = 0, \tag{B.8c}$$

$$G^{1/2} K x_2 = 0 \tag{B.8d}$$

imply that $x_1 = 0$, $x_2 = 0$ for every $s \in \mathbb{C}$. Indeed, since the matrices R, G are positive-definite, then it follows from (B.8c) and (B.8d) that $x_1 = 0$ and $Kx_2 = 0$. Using these equations, we also obtain from (B.8b) that $(A_c - sI)x_2 = 0$. Since the pair (A_c, K) is observable, this implies that $x_1 = 0$ and $x_2 = 0$. Thus, the pair $(\bar{A}, \bar{R})$ is observable. □

A CHARACTERIZATION OF THE LIE ALGEBRA RANK CONDITION BY TRANSVERSE PERIODIC FUNCTIONS*

PASCAL MORIN† AND CLAUDE SAMSON†

Abstract. The Lie algebra rank condition plays a central role in nonlinear systems control theory. The present paper establishes that the satisfaction of this condition by a set of smooth control vector fields is equivalent to the existence of smooth transverse periodic functions. The proof here enclosed is constructive and provides an explicit method for the synthesis of such functions.

Key words. controllability, driftless system, transversality, Lie algebra

1. Introduction. Let $X_1, \dots, X_m$ denote smooth vector fields (v.f.) on a smooth n-dimensional manifold M. By definition, the Lie algebra rank condition at a point $p_0 \in M$ ($LARC(p_0)$) is the property that[1]

$$M_{p_0} = \mathrm{Span}\{X(p_0) : X \in \mathrm{Lie}(X_1, \dots, X_m)\},$$

where $\mathrm{Lie}(X_1, \dots, X_m)$ denotes the Lie algebra of v.f. generated by $X_1, \dots, X_m$. This condition plays a major role in the study of controllability properties of nonlinear control systems, as shown in the classical works of Chow [2], Lobry [10], Hermann [4], Sussmann and Jurdjevic [18], and others. For example, the well-known "Chow's theorem" states that if $LARC(p_0)$ is satisfied for the v.f. $X_1, \dots, X_m$, then the set of points reachable from p_0 by trajectories of the control system

$$\dot{p} = \sum_{i=1}^{m} u_i X_i(p) \tag{1}$$

contains a neighborhood of p_0. While the Lie algebra rank condition provides a systematic tool to test the controllability of system (1), its use at the control design level is usually not direct. For instance, even though $LARC(p_0)$ implies the existence of elements $X_{m+1}, \dots, X_{\bar{n}}$ of $\mathrm{Lie}(X_1, \dots, X_m)$ such that

$$\forall p \in \mathcal{V}, \quad M_p = \mathrm{Span}\{X_1(p), \dots, X_m(p)\} + \mathrm{Span}\{X_{m+1}(p), \dots, X_{\bar{n}}(p)\}, \tag{2}$$

where $\mathcal{V}$ denotes a neighborhood of p_0, the "generation of motion" in the direction of the v.f. $X_{m+1}, \dots, X_{\bar{n}}$ by means of the control variables u_i is not simple. Although general results have been obtained for this problem in both the open-loop [9] and closed-loop [11] contexts, their application to physical systems usually raises several difficult issues—complexity, robustness, etc.

In this paper, we present a characterization of the Lie algebra rank condition which allows us to consider the control of system (1) from a slightly different perspective. More precisely, the following result is proved.

*Received by the editors January 20, 2000; accepted for publication (in revised form) May 22, 2001; published electronically December 7, 2001.

†INRIA, B.P. 93, 06902 Sophia-Antipolis Cedex, France (pascal.morin@inria.fr,claude.samson@inria.fr).

[1]Throughout the paper, the notation N_q is used to denote the tangent space of a manifold N at q, whereas T_qF denotes the tangent mapping of a smooth map F at q.

THEOREM 1. *Let $\mathbb{T} = \mathbb{R}/2\pi\mathbb{Z}$ denote the one-dimensional torus, and let $X_1, \ldots, X_m$ denote smooth v.f. on a smooth n-dimensional manifold M, such that the accessibility distribution $\Delta(p) \triangleq Span\{X(p) : X \in Lie(X_1, \ldots, X_m)\}$ is of constant dimension n_0 in a neighborhood of p_0. Then the following properties are equivalent:*

1. *$n_0 = n$; i.e., the Lie algebra rank condition at p_0, $LARC(p_0)$, is satisfied for the v.f. $X_1, \ldots, X_m$.*
2. *There exist $\bar{n} \in \mathbb{N}$ and, for any neighborhood $\mathcal{U}$ of p_0, a function $F \in \mathcal{C}^\infty(\mathbb{T}^{\bar{n}-m}; \mathcal{U})$ such that*

$$\forall \theta \in \mathbb{T}^{\bar{n}-m}, \quad M_{F(\theta)} = Span\{X_1(F(\theta)), \ldots, X_m(F(\theta))\} + T_\theta F(\mathbb{T}^{\bar{n}-m}_\theta)\,. \tag{3}$$

REMARK 1.

1. *Relation (3) is reminiscent of the transversality property for functions—see, e.g.,* [1, Section 3.5] *for a definition.*
2. *It is clear that $\bar{n}$ is at least equal to n. For some systems—in particular, for free systems introduced later—it can be chosen equal to n, so that the sum in the right-hand side of (3) becomes direct, and F is an immersion.*

Roughly speaking, by comparison with (2), equality (3) implies that at any point $F(\theta) \in M$, the directions $X_{m+1}(F(\theta)), \ldots, X_{\bar{n}}(F(\theta))$, which are not directly available for control, are spanned by the partial derivatives of the smooth function F. An important property of this characterization is that the function F can be directly used for control design purposes. In order to briefly illustrate this fact (for more details on potential applications, the reader is referred to [13]), let us consider the well-known chain system on $\mathbb{R}^3$, where $p = (p_1, p_2, p_3)^T \in \mathbb{R}^3$:

$$\dot{p} = u_1 X_1(p) + u_2 X_2\,, \quad X_1(p) = (1, 0, p_2)^T\,, X_2 = (0, 1, 0)^T \tag{4}$$

for which LARC(0) is clearly satisfied. For this system, (3) is satisfied with $\bar{n} = 3$—so that $\mathbb{T}^{\bar{n}-m} = \mathbb{T}$—and, for example, any function F_ϵ ($\epsilon > 0$) defined by

$$F_\epsilon(\theta) = \begin{pmatrix} \epsilon \sin\theta \\ \epsilon \cos\theta \\ \dfrac{\epsilon^2}{4} \sin 2\theta \end{pmatrix}.$$

Indeed, (3) is in this case equivalent to the condition

$$\forall \theta \in \mathbb{T}\,, \quad \mathrm{Det}\left(H(\theta) \triangleq \left[X_1(F_\epsilon(\theta)) \;\; X_2 \;\; -\frac{\partial F_\epsilon}{\partial \theta}(\theta)\right]\right) \neq 0, \tag{5}$$

the satisfaction of which is readily verified. Let us now introduce a new state vector φ defined by

$$\varphi(p, \theta) \triangleq \begin{pmatrix} p_1 - F_{\epsilon,1}(\theta) \\ p_2 - F_{\epsilon,2}(\theta) \\ p_3 - F_{\epsilon,3}(\theta) - p_1\,(p_2 - F_{\epsilon,2}(\theta)) \end{pmatrix}.$$

A direct calculation shows that for any function of time $\theta(.)$ the time derivative of φ along any solution to (4) satisfies

$$\dot{\varphi}(p, \theta) = C(p) H(\theta) (u_1, u_2, \dot{\theta})^T$$

with

$$C(p) = \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & -p_1 & 1 \end{pmatrix}.$$

Since both matrices $C(p)$ and $H(\theta)$ are invertible for any $p \in \mathbb{R}^3$ and any $\theta \in \mathbb{T}$, it is straightforward, by considering $(u_1, u_2, \dot{\theta})$ as a new control vector, to globally asymptotically stabilize φ to zero. For instance, uniform exponential stabilization of $\varphi = 0$ is obtained by setting

$$(u_1, u_2, \dot{\theta})^T = -kH^{-1}(\theta)C^{-1}(p)\varphi(p, \theta), \qquad k > 0\,.$$

In terms of the state p, this yields a control law which globally stabilizes a neighborhood of the origin, the size of which can be made arbitrarily small by choosing ϵ as small as needed. Let us remark that, although it was not formalized in this way, this idea has been used implicitly in [3] for the problem of tracking a unicycle-type vehicle.

Based on this simple example, potential applications of Theorem 1 to various control problems are easily envisioned. Direct applications concern practical feedback stabilization of either systems without drift—as illustrated in the above example—or systems with a nonvanishing drift v.f. (see, e.g., [13], where potential application to nonholonomic motion planning is also briefly discussed). Other applications in the domain of nonlinear observer design or control of PDEs might also be considered.

This paper is organized as follows: Theorem 1 is proved[2] in section 2, and an example to illustrate the construction of transverse functions F is provided in section 3. Let us finally indicate that a presentation of Theorem 1 was accepted at the IEEE Conference on Decision and Control 2000 [12] in the form of a regular paper which did not contain the proof.

The following notation is used throughout the paper.

- δ_i^j denotes the Kronecker delta.
- $B_n(0, \delta)$ denotes the closed ball in $\mathbb{R}^n$ centered at zero and of radius δ.
- For $h \in \mathcal{C}^\infty(\mathbb{R}^n; \mathbb{R}^m)$ and $g \in \mathcal{C}^\infty(\mathbb{R}^n; \mathbb{R})$ with $g(x) \neq 0$ for $x \neq 0$, we write $h = o(g)$ when $|h(x)|/|g(x)| \longrightarrow 0$ as $x \longrightarrow 0$.
- $\mathbf{d}$ denotes the exterior derivative.

2. Proof of Theorem 1. By considering a system of local coordinates $x = (x_1, \dots, x_n)$ on M, which maps p_0 to $0 \in \mathbb{R}^n$, and a—globally defined—frame[3] $\{\frac{\partial}{\partial\theta_{m+1}}, \dots, \frac{\partial}{\partial\theta_{\bar{n}}}\}$ on $\mathbb{T}^{\bar{n}-m}$, Theorem 1 rewrites as follows.

COROLLARY 1. *Let $g_1, \dots, g_m$ denote smooth v.f. on $\mathbb{R}^n$ such that the accessibility distribution is of constant dimension in a neighborhood of the origin. Then the following properties are equivalent:*

1. *LARC(0): the system*

$$S: \qquad \dot{x} = \sum_{i=1}^{m} u_i g_i(x)$$

satisfies the Lie algebra rank condition at the origin.

[2]Note added in proof: A simpler proof has recently been obtained. More details are available from the authors.

[3]The dual basis—coframe—will be denoted $(\mathrm{d}\theta_{m+1}, \dots, \mathrm{d}\theta_{\bar{n}})$.

2. *TC(0): there exist* $\bar{n} \in \mathbb{N}$ *and a family of functions* $f_\epsilon \in \mathcal{C}^\infty(\mathbb{T}^{\bar{n}-m}; B_n(0,\epsilon))$ $(\epsilon > 0)$ *such that, for any* $\epsilon > 0$*, the following transversality condition holds:*

$$\forall \theta \in \mathbb{T}^{\bar{n}-m}, \quad \text{Rank} \left(g_1(f_\epsilon(\theta)) \quad \dots \quad g_m(f_\epsilon(\theta)) \quad \frac{\partial f_\epsilon}{\partial \theta_{m+1}}(\theta) \quad \dots \quad \frac{\partial f_\epsilon}{\partial \theta_{\bar{n}}}(\theta) \right) = n \,. \tag{6}$$

We now focus on the proof of this equivalent formulation of Theorem 1.

2.1. TC(0) $\Longrightarrow$ LARC(0). We assume that $LARC(0)$ is not satisfied and show that $TC(0)$ cannot be satisfied either. By assumption, the accessibility distribution is of constant dimension n_0 in a neighborhood of the origin. Therefore, if $n_0 < n$, the Frobenius theorem guarantees the existence of local coordinates $\phi(x)$ such that ϕ_n is constant along the trajectories of S, i.e., for some neighborhood $\mathcal{U}$ of the origin,

$$\forall x \in \mathcal{U},\ \forall i = 1, \dots, m, \qquad \frac{\partial \phi_n}{\partial x}(x) \neq 0, \quad \text{and} \quad \frac{\partial \phi_n}{\partial x}(x) g_i(x) = 0 \,. \tag{7}$$

Now assume that $TC(0)$ is satisfied, and choose any f_ϵ satisfying (6) and such that $B_n(0,\epsilon) \subset \mathcal{U}$. By the compactness of $\mathbb{T}^{\bar{n}-m}$, the smooth function $\theta \longmapsto \phi_n(f_\epsilon(\theta))$ from $\mathbb{T}^{\bar{n}-m}$ to $\mathbb{R}$ attains its maximum value for some $\bar{\theta}$, i.e.,

$$\forall i = m+1, \dots \bar{n}, \qquad \frac{\partial \phi_n}{\partial x}(f_\epsilon(\bar{\theta})) \frac{\partial f_\epsilon}{\partial \theta_i}(\bar{\theta}) = 0 \ . \tag{8}$$

From (8) and from (7) evaluated at $x = f_\epsilon(\bar{\theta})$, we obtain

$$\frac{\partial \phi_n}{\partial x}(f_\epsilon(\bar{\theta})) \left(g_1(f_\epsilon(\bar{\theta})) \quad \dots \quad g_m(f_\epsilon(\bar{\theta})) \quad \frac{\partial f_\epsilon}{\partial \theta_{m+1}}(\bar{\theta}) \quad \dots \quad \frac{\partial f_\epsilon}{\partial \theta_{\bar{n}}}(\bar{\theta}) \right) = 0 \ ,$$

which is in contradiction with $TC(0)$. □

2.2. LARC(0) $\Longrightarrow$ TC(0).

2.2.1. Notation and recalls. Prior to addressing the proof itself, we specify some notation and recall a few basic definitions and results that are extensively used in what follows. These recalls are about homogeneity on one hand and free Lie algebras on the other hand. For a more complete survey about these issues, we refer the reader to [5, 6] for the properties associated with homogeneity, and to [7, 17] for the role of free Lie algebras in control theory.

About homogeneity. Given $\mu > 0$ and a *weight vector* $r = (r_1, \dots, r_n)$ $(r_i > 0\ \forall i)$, a *dilation* Δ^r_μ on $\mathbb{R}^n$ is a map from $\mathbb{R}^n$ to $\mathbb{R}^n$ defined by $\forall z = (z_1, \dots, z_n) \in \mathbb{R}^n$, $\Delta^r_\mu z \triangleq (\mu^{r_1} z_1, \dots, \mu^{r_n} z_n)$. A function $f \in \mathcal{C}^0(\mathbb{R}^n; \mathbb{R})$ is *homogeneous of degree* l *with respect to the family of dilations* $(\Delta^r_\mu)_{\mu>0}$ or, more concisely, Δ^r*-homogeneous of degree* l if $\forall \mu > 0$, $f(\Delta^r_\mu z) = \mu^l f(z)$. A Δ^r*-homogeneous norm* is defined as a positive definite function on $\mathbb{R}^n$, Δ^r-homogeneous of degree one. A smooth v.f. X on $\mathbb{R}^n$ is Δ^r*-homogeneous of degree* d if, $\forall i = 1, \dots, n$, the function $x \longmapsto X_i(x)$ is Δ^r-homogeneous of degree $d + r_i$. The system

$$S_{ap}: \qquad \dot{z} = \sum_{i=1}^{m} b_i(z) u_i \tag{9}$$

is a Δ^r-*homogeneous approximation* of S if there exists a change of coordinates $\phi: x \longmapsto z$ which transforms S into

$$\dot{z} = \sum_{i=1}^{m} (b_i(z) + h_i(z))\, u_i\,, \tag{10}$$

where b_i is Δ^r-homogeneous of degree -1, and h_i denotes higher-order terms; i.e., for any j, the jth component $h_{i,j}$ of h_i satisfies $h_{i,j} = o(\rho^{r_j - 1})$, where ρ is any Δ^r-homogeneous norm.

The main motivation for introducing such approximations comes from the following result.

PROPOSITION 1 (see [5, 15]). *For any system S of smooth v.f. which satisfies LARC(0), there exists a Δ^r-homogeneous approximation S_{ap} which also satisfies LARC(0).*

Finally, we say that a set $\{b_1, \dots, b_m\}$ of v.f., or the associated system (9), is *nilpotent of order* $d+1$ if any Lie bracket of these v.f. of length larger than, or equal to, $d+1$ is identically zero. It is simple to verify that any set $\{b_1, \dots, b_m\}$ of smooth v.f. with the b_i's Δ^r-homogeneous of degree -1 is nilpotent of order $1 + \mathrm{Max}\{r_i : i = 1, \dots, n\}$.

About free Lie algebras. Let us consider a finite set of indeterminates $X_1, \dots, X_m$ and denote by $\mathrm{Lie}(X)$ the free Lie algebra over $\mathbb{R}$ generated by the X_i's. We also denote by $\mathcal{F}(X)$ the set of formal brackets in the X_i's. For any set $\mathbf{b} \stackrel{\Delta}{=} \{b_1, \dots, b_m\}$ of smooth v.f. and any $B \in \mathcal{F}(X)$, we denote by $\mathrm{Ev}_{\mathbf{b}}(B)$ the *evaluation map*, i.e., $\mathrm{Ev}_{\mathbf{b}}(X_i) = b_i$, and

$$\mathrm{Ev}_{\mathbf{b}}([B_\lambda, B_\rho]) = [\mathrm{Ev}_{\mathbf{b}}(B_\lambda), \mathrm{Ev}_{\mathbf{b}}(B_\rho)]\,.$$

The definition of a (generalized) P. Hall basis of $\mathrm{Lie}(X)$ is recalled below.

DEFINITION 1. *A P. Hall basis $\mathcal{B}$ of Lie(X) is a totally ordered subset of $\mathcal{F}(X)$ such that*

1. *each X_i belongs to $\mathcal{B}$;*
2. *if $B = [B_\lambda, B_\rho] \in \mathcal{F}$ with $B_\lambda, B_\rho \in \mathcal{F}$, then $B \in \mathcal{B}$ if and only if $B_\lambda, B_\rho \in \mathcal{B}$ with $B_\lambda < B_\rho$, and either* (i) *B_ρ is one of the X_i's or* (ii) *$B_\rho = [B_{\lambda\rho}, B_{\rho^2}]$ with $B_{\lambda\rho} \leq B_\lambda$;*
3. *if $B \in \mathcal{B}$ is a bracket of length $\ell(B) \geq 2$, i.e., $B = [B_\lambda, B_\rho]$, with $B_\lambda, B_\rho \in \mathcal{B}$, then $B_\lambda < B$.*

In order to simplify the forthcoming analysis we choose a specific P. Hall basis $\mathcal{B}$ associated with a specific total order. The P. Hall basis so obtained is in fact a Hall basis in the original (narrow) sense (see, e.g., [14, Section IV.5]).

Specific order.

$$\begin{cases} \ell(B) < \ell(B') \Longrightarrow B < B', \\ X_i < X_j \Longleftrightarrow i < j, \\ \text{For } \ell(B) = \ell(B') > 1, B < B' \Longleftrightarrow B_\lambda < B'_\lambda, \text{ or } B_\lambda = B'_\lambda \text{ and } B_\rho < B'_\rho\,. \end{cases} \tag{11}$$

We denote by

$$\mathcal{B} = \{B_1, B_2, \dots, B_q, \dots\},\ B_1 < B_2 < \cdots < B_q < \cdots\,, \tag{12}$$

the P. Hall basis associated with the total order (11), and also by $\ell(i)$ the length of any bracket B_i of this basis. From (11) and the definition of a P. Hall basis, we deduce the following properties which will be extensively used in what follows:

$$i \in \{1, \dots, m\} \Longleftrightarrow \ell(i) = 1 \Longleftrightarrow B_i = X_i, \tag{13}$$

$$i > m \Longleftrightarrow \ell(i) > 1 \Longleftrightarrow B_i = [B_{\lambda(i)}, B_{\rho(i)}], \tag{14}$$

where $\lambda(i)$ and $\rho(i)$ are uniquely defined integers. By extension of this notation, and whenever this will make sense, we will use the symbols $\lambda^2(i), \lambda\rho(i), \rho^2(i), \dots$, to index the elements of $\mathcal{B}$. For instance, if $\ell(\rho(i)) \geq 2$, we can write $B_{\rho(i)} = [B_{\lambda\rho(i)}, B_{\rho^2(i)}]$. Finally, it also follows from (11) and the definition of a P. Hall basis that

$$\ell(i) > 1 \Longrightarrow \lambda(i) < \rho(i) < i\,.$$

Letting $0 < d \in \mathbb{N}$, we denote by $\mathrm{Lie}_d(X)$ the subspace of $\mathrm{Lie}(X)$ generated by brackets of length at most equal to d. Then the subset of $\mathcal{B}$ composed of all brackets B_j such that $\ell(j) \leq d$ is a basis of $\mathrm{Lie}_d(X)$ denoted as $\mathcal{B}_d$. Let $n(d)$ denote the dimension of $\mathrm{Lie}_d(X)$ so that

$$\mathcal{B}_d = \{B_1, \dots, B_{n(d)}\} \quad \text{and } \ell(n(d)) = d\,.$$

One can associate the following *free system* with $\mathcal{B}_d$:

$$\left\{ \begin{array}{rcll} \dot{x}_i & = & u_i, & i = 1, \dots, m, \\ \dot{x}_i & = & x_{\lambda(i)} \dot{x}_{\rho(i)}, & i = m+1, \dots, n(d). \end{array} \right. \tag{15}$$

REMARK 2. *Since there is a one-to-one correspondence between the components of the state vector x associated with the free system* (15) *and the element of $\mathcal{B}_d$, it would be natural to index each component of x by the corresponding element of $\mathcal{B}_d$, as done, for example, in* [7]. *We have preferred here to write B_i for an element of $\mathcal{B}_d$ and x_i for the corresponding component of x in order to lighten the notation.*

It is straightforward to verify that (15) defines a control-affine driftless system:

$$S(m,d): \qquad \dot{x} = \sum_{i=1}^{m} u_i b_i(x), \tag{16}$$

where the components $b_{i,j}$ of the v.f. b_i are defined by

$$b_{i,j}(x) = \left\{ \begin{array}{ll} \delta_i^j & \text{if } \ell(j) = 1, \\ x_{\lambda(j)} b_{i,\rho(j)} & \text{otherwise.} \end{array} \right. \tag{17}$$

The following properties of free systems will be used in what follows. For the first two properties, we refer to [7]. The third property has been proved in [8, Section 3] in a formal algebraic framework. A proof of the fourth property is given in the appendix.

LEMMA 1. *For $i = m+1, \dots, n(d)$, let b_i denote the v.f. $Ev_{\mathbf{b}}(B_i)$, where $\mathbf{b} = \{b_1, \dots, b_m\}$. Then the following properties hold.*

1. *For any $i \in \{1, \dots, n(d)\}$, $b_i = a_i \partial/\partial x_i + \sum_{j>i} b_{i,j} \partial/\partial x_j$ for some nonzero constant a_i and some smooth functions $b_{i,j}$ so that $S(m,d)$ satisfies $LARC(x)$ for any $x \in \mathbb{R}^{n(d)}$.*

2. *The v.f. b_i are Δ-homogeneous of degree $-\ell(i)$ with Δ_μ ($\mu > 0$), the dilation defined by*

$$\Delta_\mu x = (\mu^{\ell(1)} x_1, \dots, \mu^{\ell(n(d))} x_{n(d)}) \tag{18}$$

so that $S(m,d)$ is nilpotent of order $d+1$.

3. *For any $p \in \mathcal{C}^\infty(\mathbb{R}^{n(d)};\mathbb{R})$, Δ-homogeneous of degree $d' < d$, and any $j \in \{1,\dots,m\}$, there exists $q^j \in \mathcal{C}^\infty(\mathbb{R}^{n(d)};\mathbb{R})$, Δ-homogeneous of degree $d'+1$, such that*

$$\forall i \in \{1,\dots,m\}, \qquad L_{b_i} q^j = \begin{cases} p & \text{if } i = j, \\ 0 & \text{otherwise.} \end{cases} \tag{19}$$

4. *For any $i \in \{1,\dots,n(d)\}$ and any $p \in \mathcal{C}^\infty(\mathbb{R}^{n(d)};\mathbb{R})$, Δ-homogeneous of degree $d' - \ell(i)$ with $d' \le d$, there exist h_1 and $h_{2,j}$ ($1 < \ell(j) \le d'$) in $\mathcal{C}^\infty(\mathbb{R}^{n(d)};\mathbb{R})$, Δ-homogeneous of degree d' and $d' - \ell(j)$, respectively, such that*

$$p(x)\mathrm{d}x_i = \mathbf{d}h_1 + \sum_{j:1<\ell(j)\le d'} h_{2,j}(x)\left(\mathrm{d}x_j - x_{\lambda(j)}\mathrm{d}x_{\rho(j)}\right). \tag{20}$$

Remark 3.

1. *The functions p, q^j, h_1, and $h_{2,j}$ in properties 3 and 4 are polynomial in x because they are smooth and homogeneous.*
2. *Since the smooth functions q^j in property 3 are homogeneous of degree $d'+1$, it can depend only on the $n(d'+1)$ first components of x.*

After these preliminary recalls, we can now proceed with the proof of Theorem 1. It is composed of three steps which are summarized in the following three propositions.

Proposition 2. *If $TC(0)$ holds for a homogeneous approximation S_{ap} of a system S, then $TC(0)$ holds for S also.*

Proposition 3. *If, for any $d \in \mathbb{N}-\{0\}$, $TC(0)$ holds for the free system $S(m,d)$ with $\bar{n} = n(d)$, then $TC(0)$ holds for any smooth driftless system S_{hom} which satisfies $LARC(0)$ and whose control v.f. are Δ^r-homogeneous of degree -1 for some dilation Δ^r_μ.*

Proposition 4. *For any $d \in \mathbb{N}-\{0\}$, $TC(0)$ holds for the free system $S(m,d)$ with $\bar{n} = n(d)$.*

From Proposition 1, if S satisfies $LARC(0)$, it has a homogeneous approximation which also satisfies $LARC(0)$. This property, combined with the three propositions above, clearly implies that $LARC(0) \Longrightarrow TC(0)$. There remains to prove these three propositions.

2.2.2. Proof of Proposition 2. S rewrites, in some coordinates $z = \phi(x)$, as

$$\dot{z} = \sum_{i=1}^{m} u_i \left(\tilde{b}_i(z) + h_i(z)\right), \tag{21}$$

where the $\tilde{b}_i$'s, Δ^r-homogeneous of degree -1 (for some dilation Δ^r), are the v.f. of the homogeneous approximation S_{ap}, and h_i denotes higher-order terms, i.e.,

$$h_{i,j} = o(\rho^{r_j - 1}), \tag{22}$$

with ρ denoting any Δ^r-homogeneous norm. We want to show that if $TC(0)$ holds for S_{ap}, then it also holds for S. Since $TC(0)$ is independent of the system of coordinates,

it is sufficient to show that $TC(0)$ holds in the coordinates z. Let $\bar{n}$ and $(f_\epsilon)_{\epsilon>0}$ denote an integer and a family of functions which satisfy (6) with the v.f. of the approximation S_{ap}. We show below that S satisfies $TC(0)$ by considering the same integer $\bar{n}$ and the family of functions $(\bar{f}_\epsilon)_{\epsilon>0}$ defined by

$$\bar{f}_\epsilon(\theta) = \Delta^r_{\mu(\epsilon)} f_1(\theta)\,, \tag{23}$$

with $\mu(\epsilon)$ denoting a strictly positive number which is (i) smaller than some adequately chosen $\mu_0 > 0$ and (ii) such that $\sup_{\theta\in\mathbb{T}^{\bar{n}-m}} |\Delta^r_{\mu(\epsilon)} f_1(\theta)| \le \epsilon$. Note that $\mu(\epsilon)$ always exists because $f_1(\mathbb{T}^{\bar{n}-m})$ is a compact set so that $\lim_{\mu\to 0} \sup_{\theta\in\mathbb{T}^{\bar{n}-m}} |\Delta^r_\mu f_1(\theta)| = 0$.

With z denoting a vector in $\mathbb{R}^n$, one deduces from (22) that

$$\lim_{\mu\to 0} \frac{h_{i,j}(\Delta^r_\mu z)}{\rho^{r_j-1}(\Delta^r_\mu z)} = \lim_{\mu\to 0} \frac{h_{i,j}(\Delta^r_\mu z)}{\mu^{r_j-1}\rho^{r_j-1}(z)} = 0.$$

Therefore,

$$h_{i,j}(\Delta^r_\mu z) = c_{i,j}(\mu, z)\mu^{r_j-1},$$

where $|c_{i,j}(\mu, z)|$ tends to zero as μ tends to zero. Moreover, the convergence is uniform with respect to the z variable when $z \in B_n(0, 1)$. The above equation can also be written in vectorial form as

$$h_i(\Delta^r_\mu z) = \mu^{-1}\Delta^r_\mu c_i(\mu, z) \tag{24}$$

with $c_i = (c_{i,1}, \ldots, c_{i,n})^T$.

Let us now evaluate the rank of the matrix

$$A(\epsilon,\theta) \triangleq \left((\tilde{b}_1 + h_1)(\bar{f}_\epsilon(\theta)) \quad \ldots \quad (\tilde{b}_m + h_m)(\bar{f}_\epsilon(\theta)) \quad \frac{\partial \bar{f}_\epsilon}{\partial\theta_{m+1}}(\theta) \quad \ldots \quad \frac{\partial \bar{f}_\epsilon}{\partial\theta_{\bar{n}}}(\theta) \right).$$

Using (23), (24), and the fact that each $\tilde{b}_i$ is homogeneous of degree -1,

$$A(\epsilon,\theta) \;=\; \bar{A}(\epsilon,\theta)\; D(\mu(\epsilon))$$

with

$$\begin{aligned}
&\bar{A}(\epsilon,\theta)\\
&\quad\triangleq \left(\Delta^r_{\mu(\epsilon)}\tilde{b}_1(f_1(\theta)) \quad \ldots \quad \Delta^r_{\mu(\epsilon)}\tilde{b}_m(f_1(\theta)) \quad \Delta^r_{\mu(\epsilon)}\frac{\partial f_1}{\partial\theta_{m+1}}(\theta) \quad \ldots \quad \Delta^r_{\mu(\epsilon)}\frac{\partial f_1}{\partial\theta_{\bar{n}}}(\theta) \right)\\
&\quad+ \left(\Delta^r_{\mu(\epsilon)}c_1(\mu(\epsilon), f_1(\theta)) \quad \ldots \quad \Delta^r_{\mu(\epsilon)}c_m(\mu(\epsilon), f_1(\theta)) \quad 0 \quad \ldots \quad 0 \right),
\end{aligned}$$

and

$$D(\mu(\epsilon)) \triangleq \mathrm{diag}\{1/\mu(\epsilon), \ldots, 1/\mu(\epsilon), 1, \ldots, 1\}\,.$$

Since $D(\mu(\epsilon))$ is nonsingular, it readily follows that

$$\begin{aligned}
\mathrm{Rank}\, A(\epsilon,\theta) = \mathrm{Rank} \Big(&\tilde{b}_1(f_1(\theta)) + c_1(\mu(\epsilon), f_1(\theta)) \quad \ldots \quad \tilde{b}_m(f_1(\theta)) + c_m(\mu(\epsilon), f_1(\theta))\\
&\frac{\partial f_1}{\partial\theta_{m+1}}(\theta) \quad \ldots \quad \frac{\partial f_1}{\partial\theta_{\bar{n}}}(\theta) \Big).
\end{aligned} \tag{25}$$

Now, by assumption,

(26)
$$\forall \theta \in \mathbb{T}^{\bar{n}-m}, \qquad \text{Rank} \left(\tilde{b}_1(f_1(\theta)) \quad \dots \quad \tilde{b}_m(f_1(\theta)) \quad \frac{\partial f_1}{\partial \theta_{m+1}}(\theta) \quad \dots \quad \frac{\partial f_1}{\partial \theta_{\bar{n}}}(\theta) \right) = n\,.$$

In view of (25) and (26) and using the facts that $f_1(\theta) \in B_n(0,1)$ and that $|c_{i,j}(\mu, z)|$ tends uniformly (with respect to $z \in B_n(0,1)$) to zero as μ tends to zero, there exists a strictly positive number μ_0 such that

$$\mu(\epsilon) \leq \mu_0 \Longrightarrow \forall \theta \in \mathbb{T}^{\bar{n}-m}\,,\ \text{Rank}\ A(\epsilon, \theta) = n.$$

This concludes the proof of Proposition 2. □

REMARK 4. *The previous analysis implies—by setting* $\forall i,\ h_i \equiv 0$ *in* (21)*—that for a homogeneous system, if a function* $f \in \mathcal{C}^\infty(\mathbb{T}^{\bar{n}-m}; \mathbb{R}^n)$ *satisfies* (6)*, then, for any* $\mu > 0$, $\Delta_\mu f$ *also satisfies* (6)*. Therefore,* $TC(0)$ *is satisfied for this homogeneous system with the functions* $f_\epsilon \stackrel{\Delta}{=} \Delta_{\mu(\epsilon)} f$*, where* $\mu(\epsilon)$ *is any strictly positive value such that* $\sup_{\theta \in \mathbb{T}^{\bar{n}-m}} |\Delta_{\mu(\epsilon)} f(\theta)| \leq \epsilon$.

2.2.3. Proof of Proposition 3. Consider a smooth driftless system

$$S_{hom}: \qquad \dot{z} = \sum_{i=1}^{m} \tilde{b}_i(z) u_i, \tag{27}$$

whose v.f. $\tilde{b}_i$ $(i = 1, \dots, m)$ are Δ^r-homogeneous of degree -1 for some dilation Δ^r_μ and satisfy $LARC(0)$. Since S_{hom} is nilpotent of some order $d+1$, it can be associated with the free system $S(m,d)$ whose v.f. b_i are defined in (17). We show below that any family $(f_\epsilon)_{\epsilon>0}$ which satisfies $TC(0)$ for the free system $S(m,d)$ induces a family $(\tilde{f}_\epsilon)_{\epsilon>0}$ which satisfies $TC(0)$ for S_{hom}. In fact, from Remark 4 above, we need only to show the existence of a single function $\tilde{f} \in \mathcal{C}^\infty(\mathbb{T}^{n(d)-m}; \mathbb{R}^n)$, which satisfies the transversality condition (6) for S_{hom}.

Let f denote any of the functions f_ϵ which satisfy the transversality condition for $S(m,d)$. From property 1 of Lemma 1, the vectors $b_1(x), \dots, b_{n(d)}(x)$ are linearly independent at any $x \in \mathbb{R}^{n(d)}$. Therefore, there exist (unique) smooth functions $u_{i,j}$ such that

$$\forall j = m+1, \dots, n(d),\ \forall \theta \in \mathbb{T}^{n(d)-m}\,, \qquad \frac{\partial f}{\partial \theta_j}(\theta) = \sum_{i=1}^{n(d)} u_{i,j}(\theta) b_i(f(\theta)). \tag{28}$$

Also, using the fact that f satisfies the transversality condition (6) for $S(m,d)$,

$$\forall \theta \in \mathbb{T}^{n(d)-m}, \qquad \text{Det}\, U(\theta) \neq 0 \quad \text{with} \quad U(\theta) \stackrel{\Delta}{=} \big(u_{i,j}(\theta)\big)_{i,j=m+1,\dots,n(d)}. \tag{29}$$

Let us now define the function $\tilde{f}$. To this purpose, let us pick an arbitrary couple $(\theta_0, z_0) \in (\mathbb{T}^{n(d)-m} \times \mathbb{R}^n)$ and consider an element θ of $\mathbb{T}^{n(d)-m}$. Consider also a smooth path $\gamma : t \in [0,1] \longrightarrow \gamma(t) \in \mathbb{T}^{n(d)-m}$ which connects θ_0 to θ, i.e., such that $\gamma(0) = \theta_0$ and $\gamma(1) = \theta$. Let $z_\gamma(t)$ denote the solution, for $t \in [0,1]$, of

$$\dot{z} = \sum_{i=1}^{n(d)} \bar{U}_i(\gamma(t), \dot{\gamma}(t))\ \tilde{b}_i(z), \qquad z(0) = z_0\,, \tag{30}$$

where

$$\bar{U}_i(\gamma,\dot{\gamma}) = \sum_{j=m+1}^{n(d)} u_{i,j}(\gamma)\mathrm{d}\theta_j(\dot{\gamma})\,, \tag{31}$$

and, for $i = m+1,\dots,n(d)$, $\tilde{b}_i \triangleq Ev_{\tilde{\mathbf{b}}}(B_i)$. Note that $z_\gamma(t)$ is well defined for $t \in [0,1]$. Indeed, finite-time escape is not possible because the v.f. $\tilde{b}_i$ are homogeneous of negative degree (by assumption). Let us show that $z_\gamma(1)$ is independent of the path γ chosen to connect θ_0 to θ. To this purpose, consider two paths γ_i $(i=1,2)$ which map 0 to θ_0 and 1 to θ. We must show that the solution $z_{\gamma_1}(1)$ of (30) at $t=1$ with $\gamma=\gamma_1$ is the same as the solution $z_{\gamma_2}(1)$ of (30) at $t=1$ with $\gamma=\gamma_2$. To show this, we will use the properties stated in the following lemma, which are easily derived from well-known results. (See the appendix for details.)

LEMMA 2. *Consider the P. Hall basis $\mathcal{B}$ of Lie$(X_1,\dots,X_m)$ defined by* (12). *Then there exist mappings $(T,u) \longmapsto c_i(T,u)$ such that, for any set $\mathbf{g} = \{g_1,\dots,g_m\}$ of v.f. nilpotent of order $d+1$, and any $u \in \mathcal{C}^\infty([0,T];\mathbb{R}^{n(d)})$, the solution at time T of*

$$\dot{x} = \sum_{i=1}^{n(d)} u_i(t)\, g_i(x)\,, \qquad x(0) = x_0, \tag{32}$$

is

$$x(T) = \exp\left(\sum_{i=1}^{n(d)} c_i(T,u)\, g_i\right) x_0, \tag{33}$$

where $g_i \triangleq Ev_{\mathbf{g}}(B_i)$ $(i = m+1,\dots,n(d))$. Furthermore, if $g_1,\dots,g_m$ are the control v.f. of the $(n(d)$-dimensional) free system $S(m,d)$, then for any $x_0 \in \mathbb{R}^{n(d)}$ the mapping

$$(c_1,\dots,c_{n(d)}) \longmapsto \exp\left(\sum_{i=1}^{n(d)} c_i\, g_i\right) x_0 \tag{34}$$

from $\mathbb{R}^{n(d)}$ to $\mathbb{R}^{n(d)}$ is one-to-one.

Applying the first result stated in the lemma to (30) yields

$$\forall k = 1,2, \qquad z_{\gamma_k}(1) = \exp\left(\sum_{i=1}^{n(d)} c_i\left(1, \bar{U}(\gamma_k,\dot{\gamma}_k)\right)\, \tilde{b}_i\right) z_0\,. \tag{35}$$

Consider now the following equation parameterized by $k=1,2$ (compare with (30)):

$$\dot{x} = \sum_{i=1}^{n(d)} \bar{U}_i(\gamma_k(t),\dot{\gamma}_k(t))\; b_i(x), \qquad x(0) = f(\theta_0)\,. \tag{36}$$

From (28) and (31), $f(\gamma_k(.))$ is a solution to (36). Therefore, applying the first result stated in the lemma to this equation and using the fact that $f(\theta) = f(\gamma_k(1))$ for $k=1,2$ yields

$$\exp\left(\sum_{i=1}^{n(d)} c_i\left(1, \bar{U}(\gamma_1,\dot{\gamma}_1)\right)\; b_i\right) f(\theta_0) = \exp\left(\sum_{i=1}^{n(d)} c_i\left(1, \bar{U}(\gamma_2,\dot{\gamma}_2)\right)\; b_i\right) f(\theta_0)\,.$$

The second result stated in the lemma then implies that

$$\forall i = 1, \dots, n(d), \qquad c_i\left(1, \bar{U}(\gamma_1, \dot{\gamma}_1)\right) = c_i\left(1, \bar{U}(\gamma_2, \dot{\gamma}_2)\right), \tag{37}$$

and it follows, in view of (35), that $z_{\gamma_1}(1) = z_{\gamma_2}(1)$. This in turn establishes that the mapping $(\theta, \gamma) \to z_\gamma(1)$ is a function of θ solely. This is the function $\tilde{f}$ which we were looking for. At this point, it remains only to verify that the function $\tilde{f}$ so defined satisfies the transversality condition (6) for S_{hom}. Recalling that $\tilde{f}(\theta)$ is obtained as the solution of (30) at $t = 1$ and that this solution does not depend on the path γ which passes thru θ at time $t = 1$, one deduces that along any smooth curve $\theta(.)$ the mapping $t \longmapsto \tilde{f}(\theta(t))$ is differentiable with

$$\frac{d}{dt}\tilde{f}(\theta(t)) = \sum_{i=1}^{n(d)} \bar{U}_i(\theta(t), \dot{\theta}(t))\, \tilde{b}_i(\tilde{f}(\theta(t)))\,.$$

This in turn implies that $\tilde{f}$ is smooth and satisfies

$$\forall \theta \in \mathbb{T}^{n(d)-m}, \quad \frac{\partial \tilde{f}}{\partial \theta_j}(\theta) = \sum_{i=1}^{n(d)} u_{i,j}(\theta)\, \tilde{b}_i(\tilde{f}(\theta))\,. \tag{38}$$

This implies that

$$\left(\tilde{b}_1(\tilde{f}(\theta)), \dots, \tilde{b}_m(\tilde{f}(\theta)), \frac{\partial \tilde{f}}{\partial \theta_{m+1}}(\theta), \dots, \frac{\partial \tilde{f}}{\partial \theta_{n(d)}}(\theta)\right) = \left(\tilde{b}_1(\tilde{f}(\theta)), \dots, \tilde{b}_{n(d)}(\tilde{f}(\theta))\right) \begin{pmatrix} I_m & \star \\ 0 & U(\theta) \end{pmatrix},$$

where $I_m \in \mathbb{R}^{m\times m}$ is the identity matrix. Using (29) and the fact that S_{hom} satisfies $LARC(x)$ for $x \in \mathbb{R}^n$—indeed, it satisfies $LARC(0)$ so that, by continuity it satisfies $LARC(x)$ in a neighborhood of the origin and therefore, by homogeneity, in $\mathbb{R}^n$ itself—one easily deduces from the above equality that $\tilde{f}$ satisfies the transversality condition (6) for S_{hom}. □

2.2.4. Proof of Proposition 4. From Remark 4 and property 2 of Lemma 1, it is sufficient to prove the existence of a single function $f \in \mathcal{C}^\infty(\mathbb{T}^{n(d)-m}; \mathbb{R}^{n(d)})$ for which the transversality condition (6) is satisfied. In order to simplify some of the forthcoming analysis, we will use the formalism of differential forms, from which condition (6) can be written as

$$\forall \theta \in \mathbb{T}^{n(d)-m}, \quad (\mathrm{d}x_1 \wedge \cdots \wedge \mathrm{d}x_{n(d)}) \left(b_1, \dots, b_m, \frac{\partial f}{\partial \theta_{m+1}}, \dots, \frac{\partial f}{\partial \theta_{n(d)}}\right)_{|x=f(\theta)} \neq 0.$$

By skew-symmetry of the wedge product, this is equivalent to the condition that

$$\forall \theta \in \mathbb{T}^{n(d)-m}, \tag{39}$$
$$(\mathrm{d}x_1 \wedge \cdots \wedge \mathrm{d}x_m \wedge \omega^x_{m+1} \wedge \cdots \wedge \omega^x_{n(d)}) \left(b_1, \dots, b_m, \frac{\partial f}{\partial \theta_{m+1}}, \dots, \frac{\partial f}{\partial \theta_{n(d)}}\right)_{|x=f(\theta)} \neq 0,$$

where $\omega_i^x = \mathrm{d}x_i - x_{\lambda(i)}\mathrm{d}x_{\rho(i)}$ $(i = m+1, \dots, n(d))$. From (17),

$$\forall j = 1, \dots, m \quad \left\{ \begin{array}{rcll} \mathrm{d}x_i(b_j) & = & \delta_i^j & \text{if } i \in \{1, \dots, m\}, \\ \omega_i^x(b_j) & = & 0 & \text{if } i \in \{m+1, \dots, n(d)\} \end{array} \right.$$

so that one easily rewrites (39) as

$$\forall \theta \in \mathbb{T}^{n(d)-m}, \quad \left(\omega_{m+1} \wedge \cdots \wedge \omega_{n(d)}\right)(\theta) \neq 0, \tag{40}$$

with ω_i the differential one-form on $\mathbb{T}^{n(d)-m}$ defined by

$$\omega_i = \mathbf{d}f_i - f_{\lambda(i)}\mathbf{d}f_{\rho(i)}\,. \tag{41}$$

Design algorithm. The function f is defined by setting $f \triangleq f^{n(d)}$, with the function $f^{n(d)}$ denoting the last function obtained via a recursive construction which starts with some function f^{m+1}. For each $k = m+1, \dots, n(d)$, the function $f^k \in \mathcal{C}^\infty(\mathbb{T}^{k-m}; \mathbb{R}^{n(d)})$ is required to verify the following property:

$$\forall \theta^k = (\theta_{m+1}, \dots, \theta_k) \in \mathbb{T}^{k-m}, \quad \left(\omega_{m+1}^k \wedge \cdots \wedge \omega_k^k\right)(\theta^k) \neq 0\,, \tag{42}$$

with ω_i^k the differential one-form on $\mathbb{T}^{k-m}$ defined by

$$\omega_i^k = \mathbf{d}f_i^k - f_{\lambda(i)}^k \mathbf{d}f_{\rho(i)}^k\,. \tag{43}$$

$\boldsymbol{f^{m+1}}$. A possible choice for f^{m+1} is as follows:

$$f_i^{m+1}(\theta_{m+1}) = \left\{ \begin{array}{ll} \sin\theta_{m+1} & \text{for } i = \lambda(m+1), \\ \cos\theta_{m+1} & \text{for } i = \rho(m+1), \\ \dfrac{1}{4}\sin 2\theta_{m+1} & \text{for } i = m+1, \\ 0 & \text{otherwise}\,. \end{array} \right. \tag{44}$$

Indeed, it readily follows from this definition that

$$\forall \theta^{m+1} \in \mathbb{T}, \quad \omega_{m+1}^{m+1}(\theta^{m+1}) = \frac{1}{2}\,.$$

$\boldsymbol{f^{k-1} \longrightarrow f^k}$. Assume now that, for some $k-1 \in \{m+1, \dots, n(d)-1\}$, a function $f^{k-1} \in \mathcal{C}^\infty(\mathbb{T}^{k-1-m}; \mathbb{R}^{n(d)})$ which verifies the property (42) for $k-1$ has been obtained. We show below how to construct from this function a new function $f^k \in \mathcal{C}^\infty(\mathbb{T}^{k-m}; \mathbb{R}^{n(d)})$ which verifies the property (42).

Let Δ_μ^k $(\mu > 0)$ denote the dilation defined on $\mathbb{R} \times \mathbb{R} \times \mathbb{R}^{n(d)}$ by

$$\Delta_\mu^k(s, c, f) = \left(\mu^{\ell(\lambda(k))}s, \mu^{\ell(\rho(k))}c, \Delta_\mu(f)\right) \text{ with } \Delta_\mu(f) \triangleq \left(\mu^{\ell(1)}f_1, \dots, \mu^{\ell(n(d))}f_{n(d)}\right). \tag{45}$$

Denote also p_i^k $(i = 1, \dots, n(d))$ the functions defined on $\mathbb{R} \times \mathbb{R}$ by

$$p_i^k(s, c) = s\,\delta_i^{\lambda(k)} + c\,\delta_i^{\rho(k)} + \frac{m_k^k}{2} sc\,\delta_i^k \tag{46}$$

with

$$m_i^k = \begin{cases} 0 & \text{if } \ell(i) \leq \ell(\lambda(k)) \text{ or } \lambda(i) \neq \lambda(k), \\ 1 + m_{\rho(i)}^k & \text{otherwise}. \end{cases} \tag{47}$$

The next step consists in finding polynomial functions $q_{i,j}^k \in \mathcal{C}^\infty(\mathbb{R}^{n(d)}; \mathbb{R})$ for $i = 1, \ldots, n(d)$ and $j = 1, \ldots, j_{i,k} \triangleq \max\{j : \ell(i) - j\ell(\lambda(k)) \geq 0\}$ such that the two following properties are verified.

P1(*i*) (for $i = 1, \ldots, n(d)$). Each function $q_{i,j}^k$ is Δ-homogeneous of degree $\ell(i) - j\ell(\lambda(k))$.

P2(*i*) (for $i = m+1, \ldots, k$).

$$\bar{\omega}_i^k = \left(\mathrm{d}f_i - f_{\lambda(i)}\mathrm{d}f_{\rho(i)} + \bar{\gamma}_i^k\right) + \sum_{j=m+1}^{i-1} t_{i,j}(s,f)\left(\mathrm{d}f_j - f_{\lambda(j)}\mathrm{d}f_{\rho(j)} + \bar{\gamma}_j^k\right), \tag{48}$$

where

$$\forall i = m+1, \ldots, k, \qquad \bar{\omega}_i^k \triangleq \mathbf{d}\bar{f}_i^k - \bar{f}_{\lambda(i)}^k \mathbf{d}\bar{f}_{\rho(i)}^k, \tag{49}$$

$$\bar{f}_i^k : (s,c,f) \longmapsto f_i + p_i^k(s,c) + \sum_{j=1}^{j_{i,k}} s^j q_{i,j}^k(f), \tag{50}$$

the $t_{i,j}$'s are smooth functions, and $\bar{\gamma}_i^k$ is a differential one-form on $\mathbb{R} \times \mathbb{R} \times \mathbb{R}^{n(d)}$ such that

$$\bar{\gamma}_i^k = \bar{\gamma}_{i,1}^k \mathrm{d}s + \bar{\gamma}_{i,2}^k \mathrm{d}c$$

with $\bar{\gamma}_{i,1}$, $\bar{\gamma}_{i,2}$, Δ^k-homogeneous of degree $\ell(i) - \ell(\lambda(k))$ and $\ell(i) - \ell(\rho(k))$, respectively, and

(51)

$$\begin{cases} \bar{\gamma}_{i,1}^k \equiv 0 & \text{if } i < \lambda(k), \\ \bar{\gamma}_{i,1}^k \equiv 1 & \text{if } i = \lambda(k), \\ \bar{\gamma}_{i,1}^k(s,c,0) = 0 & \text{if } \lambda(k) < i < k, \\ \bar{\gamma}_{i,1}^k(s,c,0) = \dfrac{m_k^k}{2}\, c & \text{for } i = k, \end{cases} \qquad \begin{cases} \bar{\gamma}_{i,2}^k \equiv 0 & \text{if } i < \rho(k), \\ \bar{\gamma}_{i,2}^k \equiv 1 & \text{if } i = \rho(k), \\ \bar{\gamma}_{i,2}^k(s,c,0) = 0 & \text{if } \rho(k) < i < k, \\ \bar{\gamma}_{i,2}^k(s,c,0) = -\dfrac{m_k^k}{2}\, s & \text{for } i = k\,. \end{cases}$$

LEMMA 3. *There exist functions $q_{i,j}^k$, which are solutions to the problems* **P1(*i*)** *and* **P2(*i*)**. *In particular, one can always choose*

$$\begin{cases} q_{i,j}^k \equiv 0 & \text{if } i \in \{1, \ldots, \mathrm{Max}\{m, \lambda(k)\}\} \cup \{k+1, \ldots, n(d)\} \\ & \text{and} \quad j \in \{1, \ldots, j_{i,k}\}, \\ q_{i,1}^k \equiv 0 & \text{if } \mathrm{Max}\{m, \lambda(k)\} < i \leq k \text{ and} \quad \lambda(i) < \lambda(k), \\ q_{i,1}^k(f) = m_i^k f_{\rho(i)} & \text{if } \mathrm{Max}\{m, \lambda(k)\} < i \leq k \text{ and} \quad \lambda(i) = \lambda(k). \end{cases} \tag{52}$$

Once suitable functions $q_{i,j}^k$ are determined so that the functions $\bar{f}_i^k$ in (50) are also defined, we set

$$f^k \triangleq \bar{f}^k \circ \bar{g}_\eta^k \quad \text{with} \quad \bar{g}_\eta^k(\theta^k) \triangleq \left(\eta^{\ell(\lambda(k))} \sin\theta_k, \eta^{\ell(\rho(k))} \cos\theta_k, f^{k-1}(\theta^{k-1})\right). \tag{53}$$

LEMMA 4. *For η larger than some positive value η_0, (42) is satisfied with the function f^k defined by (53).*

Therefore, Proposition 4 is proved once Lemmas 3 and 4 are proved.

REMARK 5. *It is simple to verify that each function $\bar{f}_i^k$ in (53) is polynomial in its arguments and Δ^k-homogeneous of degree $\ell(i)$ with respect to the dilation defined by (45). The proof of the lemmas much relies on this property.*

Proof of Lemma 3. We distinguish three cases.

Case 1. $1 \leq i \leq \mathrm{Max}\{m, \lambda(k)\}$. We define $q_{i,j}^k$ according to (52) so that **P1(*i*)** is clearly verified for these values of i. If $i \leq m$, **P2(*i*)** is irrelevant. If $m+1 \leq i \leq \lambda(k)$, it readily follows from (46), (49), (50), and (52) that

$$\bar{\omega}_i^k = \mathrm{d}f_i - f_{\lambda(i)}\mathrm{d}f_{\rho(i)} + \bar{\gamma}_i^k, \tag{54}$$

where $\bar{\gamma}_i^k \equiv 0$ if $i < \lambda(k)$ and $\bar{\gamma}_i^k = \mathrm{d}s$ if $i = \lambda(k)$. Therefore, **P2(*i*)** is also verified.

Case 2. $\mathrm{Max}\{m, \lambda(k)\} < i \leq k$. We define $q_{i,1}^k$ according to (52), which is consistent with **P1(*i*)**. To define the other functions $q_{i,j}^k$, we consider a construction which is recursive in the index i. More precisely, let us assume that functions $q_{1,j}^k, \ldots, q_{i-1,j}^k$ have been defined so that **P1(1)**, ..., **P1(*i*-1)** and **P2(1)**, ..., **P2(*i*-1)** are verified. We show below how to obtain functions $q_{i,j}^k$ so that **P1(*i*)** and **P2(*i*)** are also verified.

We first note that

$$\lambda(i) < \rho(k)\,. \tag{55}$$

Assume, on the contrary, that $\lambda(i) \geq \rho(k)$. Then, from the definition of a P. Hall basis, $\lambda(i) < \rho(i)$. This implies that

$$\ell(i) = \ell(\lambda(i)) + \ell(\rho(i)) \geq 2\ell(\rho(k)) \geq \ell(k)\,.$$

If $\ell(i) > \ell(k)$, then $i > k$, and this contradicts the assumption. Otherwise, $\ell(i) = \ell(k)$, and we also get $i > k$ because of (11) and the fact that $\lambda(i) \geq \rho(k) > \lambda(k)$.

We introduce the following definitions for the sake of simplifying some aspects of the forthcoming analysis.

DEFINITION 2. *A differential one-form $r = r_s\mathrm{d}s + r_c\mathrm{d}c + \sum_{j=1}^{n(d)} r_j\mathrm{d}f_j$, with r_s, r_c, r_j homogeneous of degree $\ell(i) - \ell(\lambda(k))$, $\ell(i) - \ell(\rho(k))$, and $\ell(i) - \ell(j)$, respectively, is said to be of*

- *type* 1 *if $r_j \equiv 0$ for each j, and both r_s and r_c are identically zero at $f = 0$;*
- *type* 2 *if $r_c \equiv r_j \equiv 0$ for each j, and $r_s = as^\kappa$ with $a \in \mathbb{R}$ and $1 \leq \kappa \in \mathbb{N}$;*
- *type* 3 *if $r_s \equiv r_c \equiv 0$ and, for each j, $r_j(s, c, f)$ is in the form $r_j(s, c, f) = s^{2+\kappa_j} r_j'(f)$ with $\kappa_j \in \mathbb{N}$.*

An upper-left index i for a one-form will indicate its type, e.g., ${}^2r$ indicates that ${}^2r$ is of type 2.

Next, we develop $\bar{\omega}_i^k$ and examine the terms involved in this development. From (49) and (50), we have

$$\begin{aligned}\bar{\omega}_i^k = \;& \mathrm{d}f_i + \mathbf{d}p_i^k + \mathbf{d}\left(\sum_{j=1}^{j_{i,k}} s^j q_{i,j}^k\right) \\ & - \left(f_{\lambda(i)} + p_{\lambda(i)}^k + \sum_{j=1}^{j_{\lambda(i),k}} s^j q_{\lambda(i),j}^k\right)\left(\mathrm{d}f_{\rho(i)} + \mathbf{d}p_{\rho(i)}^k + \mathbf{d}\left(\sum_{j=1}^{j_{\rho(i),k}} s^j q_{\rho(i),j}^k\right)\right)\end{aligned} \tag{56}$$

and, by rearranging the terms in the right-hand side of this equality,

$$\bar{\omega}_i^k = \mathrm{d}f_i - f_{\lambda(i)}\mathrm{d}f_{\rho(i)} + \mathbf{d}\left(\sum_{j=2}^{j_{i,k}} s^j q_{i,j}^k\right) + \alpha_1 + \alpha_2 + \alpha_3 + {}^1r + {}^2r + {}^3r \tag{57}$$

with

$$\begin{cases} \alpha_1 \triangleq \mathbf{d}p_i^k - p_{\lambda(i)}^k \mathbf{d}p_{\rho(i)}^k, \\ \alpha_2 \triangleq s\mathbf{d}q_{i,1}^k - sq_{\lambda(i),1}^k \mathrm{d}f_{\rho(i)} - sf_{\lambda(i)}\mathbf{d}q_{\rho(i),1}^k - p_{\lambda(i)}^k \mathrm{d}f_{\rho(i)}, \\ \alpha_3 \triangleq -\mathbf{d}p_{\rho(i)}^k \sum_{j=2}^{j_{\lambda(i),k}} s^j q_{\lambda(i),j}^k \,. \end{cases} \tag{58}$$

In (57), ${}^1r$, ${}^2r$, and ${}^3r$ just correspond to terms which do not need to be specified further and are of type 1, 2, and 3, following Definition 2. In order to obtain (57), we have used the following two arguments: (i) each function $q_{j,1}^k$ $(j \leq i)$ vanishes at the origin—this follows from (52) if $\lambda(j) \leq \lambda(k)$; otherwise, $\lambda(j) > \lambda(k)$ so that $\ell(j) > \ell(\lambda(k))$, and this follows from the fact that $q_{j,1}^k$ is Δ^k-homogeneous of positive degree; (ii) from (55), $\lambda(i) < \rho(k)$ so that (46) implies that $p_{\lambda(i)}^k(s,c)$ is either s or zero. Note also that the homogeneity properties of the components of ${}^1r$, ${}^2r$, and ${}^3r$ follow directly from the homogeneity of $\bar{f}_i^k$ (see Remark 5).

Let us now focus our attention on the terms α_i which are specified in (58). We first note that

$$\alpha_3 \equiv 0 \,. \tag{59}$$

Indeed, assume on the contrary that α_3 is not the null function. Then, in view of (52), it is necessary that $\lambda(i) > \lambda(k)$. (Otherwise, $q_{\lambda(i),j}^k$, and thus α_3, would be equal to zero.) Since $\lambda(i) < \rho(i)$ (from the definition of a P. Hall basis), we also have $\rho(i) \geq \rho(k)$. (Otherwise, $p_{\rho(i)}^k$, and thus α_3, would be equal to zero.) This implies that $i > k$, which is in contradiction with the assumption.

We now consider the term α_2 in (58). We have

$$\lambda(i) < \lambda(k) \Longrightarrow \alpha_2 \equiv 0 \,. \tag{60}$$

This follows from (46) and (52) after noticing that either $\ell(\rho(i)) = 1$ so that $q_{\rho(i),1}^k \equiv 0$, or $\ell(\rho(i)) > 1$ and $\lambda\rho(i) \leq \lambda(i) < \lambda(k)$ (from the definition of a P. Hall basis), so that we still obtain $q_{\rho(i),1}^k \equiv 0$. Then

$$\lambda(i) = \lambda(k) \quad \text{with} \quad \left.\begin{array}{c} \ell(\rho(i)) = 1 \\ \text{or} \\ \lambda\rho(i) < \lambda(k) \end{array}\right\} \Longrightarrow \alpha_2 \equiv 0 \,. \tag{61}$$

Indeed, if the left-hand side of the above implication holds, then (46), (47), and (52) imply

$$\begin{aligned} \alpha_2 &= s\left(m_i^k \mathrm{d}f_{\rho(i)} - f_{\lambda(i)}\mathbf{d}q_{\rho(i),1}^k - \mathrm{d}f_{\rho(i)}\right) \\ &= s\left(m_i^k \mathrm{d}f_{\rho(i)} - \mathrm{d}f_{\rho(i)}\right) \\ &\equiv 0 \,. \end{aligned} \tag{62}$$

From the definition of a P. Hall basis, $\lambda\rho(i) \leq \lambda(i)$ so that the case where $\lambda(i) = \lambda(k)$ with $\lambda\rho(i) > \lambda(k)$ cannot happen. Therefore, if $\lambda(i) = \lambda(k)$, the last possible case is $\lambda\rho(i) = \lambda(k)$. We have

$$\left.\begin{array}{l} \lambda(i) = \lambda(k) \text{ and } \lambda\rho(i) = \lambda(k) \end{array}\right\} \Longrightarrow \alpha_2 = s\, m^k_{\rho(i)} \left(\mathrm{d}f_{\rho(i)} - f_{\lambda\rho(i)}\mathrm{d}f_{\rho^2(i)}\right). \tag{63}$$

Indeed, from (52),

$$\begin{aligned} \alpha_2 &= s\left(m^k_i \mathrm{d}f_{\rho(i)} - f_{\lambda\rho(i)}\mathrm{d}q^k_{\rho(i),1} - \mathrm{d}f_{\rho(i)}\right) \\ &= s\left(m^k_i \mathrm{d}f_{\rho(i)} - f_{\lambda\rho(i)} m^k_{\rho(i)}\mathrm{d}f_{\rho^2(i)} - \mathrm{d}f_{\rho(i)}\right), \end{aligned}$$

and (63) follows from (47). Concerning α_2, there remains only to examine the case where $\lambda(i) > \lambda(k)$. In this case $p^k_{\lambda(i)} \equiv 0$—since, by (55), $\lambda(i) < \rho(k)$—so that

$$\alpha_2 = s\left(\mathbf{d}q^k_{i,1} - q^k_{\lambda(i),1}\mathrm{d}f_{\rho(i)} - f_{\lambda(i)}\mathbf{d}q^k_{\rho(i),1}\right). \tag{64}$$

Each term within the above parentheses is a sum of terms $p_{i,j}(f)\mathrm{d}f_j$, where each $p_{i,j}$ is homogeneous of degree $\ell(i) - \ell(\lambda(k)) - \ell(j)$. By applying property 4 in Lemma 1 to the term $q^k_{\lambda(i),1}\mathrm{d}f_{\rho(i)} + f_{\lambda(i)}\mathbf{d}q^k_{\rho(i),1}$ and by replacing x with f in Lemma 1, we obtain

$$\alpha_2 = s\left(\mathbf{d}q^k_{i,1} - \mathbf{d}h_1 + \sum_{1<\ell(j)\leq\ell(i)-\ell(\lambda(k))} h_{2,j}(f)\left(\mathrm{d}f_j - f_{\lambda(j)}\mathrm{d}f_{\rho(j)}\right)\right)$$

for some functions h_1 and $h_{2,j}$ Δ^k-homogeneous of degree $\ell(i) - \ell(\lambda(k))$ and $\ell(i) - \ell(\lambda(k)) - \ell(j)$, respectively. Furthermore, by choosing

$$q^k_{i,1} = h_1 \tag{65}$$

(this choice is clearly consistent with **P1(*i*)**), we get

$$\alpha_2 = s \sum_{1<\ell(j)\leq\ell(i)-\ell(\lambda(k))} h_{2,j}(f)\left(\mathrm{d}f_j - f_{\lambda(j)}\mathrm{d}f_{\rho(j)}\right). \tag{66}$$

From what precedes, we finally obtain

$$\alpha_2 = \begin{cases} s\displaystyle\sum_{j=m+1}^{\min\{i,\rho(k)\}-1} h_{2,j}(f)\left(\mathrm{d}f_j - f_{\lambda(j)}\mathrm{d}f_{\rho(j)} + \bar\gamma^k_j\right) - s\sum_{j=m+1}^{\min\{i,\rho(k)\}-1} h_{2,j}(f)\bar\gamma^k_j & \text{if } i < k, \\ s\, m^k_{\rho(k)}\left(\mathrm{d}f_{\rho(k)} - f_{\lambda\rho(k)}\mathrm{d}f_{\rho^2(k)} + \bar\gamma^k_{\rho(k)}\right) - s\, m^k_{\rho(k)}\bar\gamma^k_{\rho(k)} & \text{if } i = k. \end{cases} \tag{67}$$

The second equation is a consequence of (63) when $\lambda\rho(k) = \lambda(k)$, and of (47) and (61) otherwise. As for the first equation, we argue as follows. If $\lambda(i) < \lambda(k)$, the result follows directly from (60) with $h_{2,j} \equiv 0$. If $\lambda(i) = \lambda(k)$ so that $\rho(i) < \rho(k)$, the result follows from (61) or (63). Finally, if $\lambda(i) > \lambda(k)$, then, by (11) and the assumption $i < k$, $\ell(i) < \ell(k)$, so that $\ell(i) - \ell(\lambda(k)) < \ell(\rho(k))$, and the result follows from (66).

Let us now consider the term ${}^3r$ in (57). From Definition 2, ${}^3r$ is a sum of one-forms $s^{2+\kappa_j} r'_j \mathrm{d}f_j$, where each r'_j is a polynomial function of f, Δ^k-homogeneous of degree

$$\ell(i) - \ell(j) - (2+\kappa_j)\ell(\lambda(k)) < \min\{\ell(i) - \ell(j), \ell(\rho(k)) - \ell(j)\}.$$

By applying property 4 in Lemma 1 to each one-form $r'_j \mathrm{d}f_j$, we get

$$(68)\quad {}^3r = s^2 \left(\sum_j s^{\kappa_j} \mathbf{d}h_{1,j} + \sum_{j=m+1}^{\min\{i,\rho(k)\}-1} h'_{2,j}(s,f) \left(\mathrm{d}f_j - f_{\lambda(j)} \mathrm{d}f_{\rho(j)} + \bar{\gamma}_j^k \right) - \sum_{j=m+1}^{\min\{i,\rho(k)\}-1} h'_{2,j}(s,f) \bar{\gamma}_j^k \right),$$

where the functions $h_{1,j}$ are Δ^k-homogeneous of positive degree and therefore vanish at the origin.

We can now define the functions $q_{i,j}^k$. Let us note that $q_{i,1}^k$ has already been defined by (52) if $\lambda(i) \leq \lambda(k)$ and by (65) otherwise. For the definition of $q_{i,j}^k$ with $j > 1$, we distinguish two cases according to whether i is smaller than or equal to k.

If $i < k$, by using (59), (67), and (68), relation (57) can be rewritten in the form (48), with

$$(69)\quad \bar{\gamma}_i^k = \mathbf{d} \left(\sum_{j=2}^{j_{i,k}} s^j q_{i,j}^k \right) + \alpha_1 +^1 r +^2 r - s \sum_{j=m+1}^{\min\{i,\rho(k)\}-1} \left(h_{2,j} + s h'_{2,j} \right)(s,f) \bar{\gamma}_j^k + \sum_j s^{2+\kappa_j} \mathbf{d}h_{1,j}$$

and smooth functions $t_{i,j}$ which we do not need to specify further. The functions $h_{2,j}$ and $s h'_{2,j}$, involved in the above expression of $\bar{\gamma}_i^k$, are polynomial in s and f. From the induction hypothesis and (51), the $\bar{\gamma}_j^k$'s in the right-hand side of (69) are such that $\bar{\gamma}_j^k = \bar{\gamma}_{j,1}^k \mathrm{d}s$ because $j < \rho(k)$. Furthermore, $\bar{\gamma}_{j,1}^k$ depends on s and f only because it is homogeneous of degree $\ell(j) - \ell(\lambda(k)) \leq \ell(\rho(k))$, and $\bar{\gamma}_{j,1}^k(s,c,0) = 0$. As a consequence, we have

$$(70)\quad -s \sum_{j=m+1}^{\min\{i,\rho(k)\}-1} \left(h_{2,j} + s h'_{2,j} \right)(s,f) \bar{\gamma}_j^k = s h'(s,f) \mathrm{d}s = a_0 s^{\kappa'} \mathrm{d}s + h'' \mathrm{d}s$$

with $a_0 \in \mathbb{R}$, $1 \leq \kappa' \in \mathbb{N}$, h' and h'' functions of s and f only, and h'' identically zero when $f = 0$. From Definition 2, (70) can be rewritten as

$$(71)\quad -s \sum_{j=m+1}^{\min\{i,\rho(k)\}-1} \left(h_{2,j} + s h'_{2,j} \right)(s,f) \bar{\gamma}_j^k =^1 r' +^2 r'.$$

From (46), (58), and the fact that $i < k$ implies that either $\lambda(i) < \lambda(k)$ or $\lambda(k) \leq \lambda(i) < \rho(i) < \rho(k)$, we deduce that $\alpha_1 = \mathbf{d}p_i^k$. Therefore, by using (71) in (69),

$$(72)\quad \bar{\gamma}_i^k = \mathbf{d} \left(\sum_{j=2}^{j_{i,k}} s^j q_{i,j}^k \right) + \mathbf{d}p_i^k +^1 r'' + \mathbf{d}(a s^{2+\kappa}) + \sum_j s^{2+\kappa_j} \mathbf{d}h_{1,j},$$

where we have used the fact that any function of type 2 is the differential of a polynomial $a s^q$ with $q \geq 2$. From there, the functions $q_{i,j}^k$ $(j > 1)$ are uniquely defined by setting

$$(73)\quad \sum_{j=2}^{j_{i,k}} s^j q_{i,j}^k \triangleq -a s^{2+\kappa} - \sum_j s^{2+\kappa_j} h_{1,j}.$$

It is simple to check that **P1(*i*)** is verified with this choice. This yields, in view of (72),

$$\bar\gamma_i^k = \mathbf{d}p_i^k +^1 r'' - \sum_j h_{1,j}\mathbf{d}\left(s^{2+\kappa_j}\right) = \mathbf{d}p_i^k +^1 r''',$$

where the last equality comes from the fact that $h_{1,j}(0) = 0$, as mentioned after (68). By using the definition of one-forms of type 1, it follows that (51) is satisfied and thus that **P2(*i*)** is verified—note that, if ${}^1r''' = r_s\mathrm{d}s + r_c\mathrm{d}c$ and $i \le \rho(k)$, then r_c is homogeneous of nonpositive degree so that it is necessarily a constant, which in fact is equal to zero since r_c vanishes at $f = 0$.

For the last case, $i = k$, we proceed similarly. By using (59), (67), and (68), relation (57) can again be rewritten in the form (48), this time with

(74)
$$\bar\gamma_k^k = \mathbf{d}\left(\sum_{j=2}^{j_{k,k}} s^j q_{k,j}^k\right) + \alpha_1 - s m_{\rho(k)}^k \bar\gamma_{\rho(k)}^k +^1 r +^2 r - s^2 \sum_{j=m+1}^{\rho(k)-1} h_{2,j}(s,f)\bar\gamma_j^k + \sum_j s^{2+\kappa_j}\mathbf{d}h_{1,j}$$

instead of (69). From (46), (47), (58), and the induction hypothesis **P2($\rho(k)$)** if $\rho(k) > m$,

(75)
$$\begin{aligned}\alpha_1 - s\, m_{\rho(k)}^k \bar\gamma_{\rho(k)}^k &= \alpha_1 - s\, m_{\rho(k)}^k \mathrm{d}c - s\, m_{\rho(k)}^k \bar\gamma_{\rho(k),1}^k \mathrm{d}s \\ &= \frac{m_k^k}{2}(c\mathrm{d}s - s\mathrm{d}c) - s\, m_{\rho(k)}^k \bar\gamma_{\rho(k),1}^k \mathrm{d}s\,.\end{aligned}$$

If $\rho(k) \le m$ so that $\lambda(k) < \rho(k) \le m < k$, these equalities are still valid since (47) implies that $m_{\rho(k)}^k = 0$. Using (75), (74) rewrites as

(76)
$$\begin{aligned}\bar\gamma_k^k = \mathbf{d}\left(\sum_{j=2}^{j_{k,k}} s^j q_{k,j}^k\right) + \frac{m_k^k}{2}(c\mathrm{d}s - s\mathrm{d}c) +^1 r +^2 r - s^2 \sum_{j=m+1}^{\rho(k)-1} h_{2,j}(s,f)\bar\gamma_j^k \\ - s\, m_{\rho(k)}^k \bar\gamma_{\rho(k),1}^k \mathrm{d}s + \sum_j s^{2+\kappa_j}\mathbf{d}h_{1,j}.\end{aligned}$$

From here, we proceed as for the previous case in order to rewrite the above equation as (compare with (72))

$$\bar\gamma_k^k = \mathbf{d}\left(\sum_{j=2}^{j_{k,k}} s^j q_{k,j}^k\right) + \frac{m_k^k}{2}(c\mathrm{d}s - s\mathrm{d}c) +^1 r'' + \mathbf{d}(as^{2+\kappa}) + \sum_j s^{2+\kappa_j}\mathbf{d}h_{1,j}\,. \tag{77}$$

Using again (73) to define the functions $q_{k,j}^k$ $(j > 1)$ yields

$$\bar\gamma_k^k = \frac{m_k^k}{2}(c\mathrm{d}s - s\mathrm{d}c) +^1 r''',$$

and it is simple to check that the one-form $\bar\gamma_k^k$ satisfies (51) so that **P2(*i*)** is verified. This ends the study of Case 2.

Case 3. $k < i \le n(d)$. We define $q_{i,j}^k \equiv 0$ according to (52) so that both **P1(*i*)** and **P2(*i*)** are readily verified. This ends the proof of Lemma 3.

Proof of Lemma 4. Since $f^k = \bar{f}^k \circ \bar{g}^k_\eta$, we deduce from (43), (48), and (49) that, for $i \in \{m+1, \dots, k\}$,

$$\begin{aligned} \omega^k_i &= \bar{\omega}^k_i \circ \mathbf{d}\bar{g}^k_\eta \\ &= \left(\omega^{k-1}_i + \gamma^k_i \mathrm{d}\theta_k\right) + \sum_{j=m+1}^{i-1} t'_{i,j} \left(\omega^{k-1}_j + \gamma^k_j \mathrm{d}\theta_k\right), \end{aligned} \tag{78}$$

where

$$\gamma^k_i(\theta^k) = \bar{\gamma}^k_{i,1}(\bar{g}^k_\eta(\theta^k))\eta^{\ell(\lambda(k))} \cos\theta_k - \bar{\gamma}^k_{i,2}(\bar{g}^k_\eta(\theta^k))\eta^{\ell(\rho(k))} \sin\theta_k \,. \tag{79}$$

By skew-symmetry of the wedge product, it follows from (78) that

$$\omega^k_{m+1} \wedge \cdots \wedge \omega^k_k = \left(\omega^{k-1}_{m+1} + \gamma^k_{m+1}\mathrm{d}\theta_k\right) \wedge \cdots \wedge \left(\omega^{k-1}_k + \gamma^k_k \mathrm{d}\theta_k\right).$$

Since each ω^{k-1}_i is a one-form on $\mathbb{T}^{k-m-1}$, we deduce from the above equation (using multilinearity and skew-symmetry of the wedge product) that

$$\omega^k_{m+1} \wedge \cdots \wedge \omega^k_k = \sum_{i=m+1}^{k} \gamma^k_i \left(\omega^{k-1}_{m+1} \wedge \cdots \wedge \omega^{k-1}_{i-1} \wedge \mathrm{d}\theta_k \wedge \omega^{k-1}_{i+1} \wedge \cdots \wedge \omega^{k-1}_k\right). \tag{80}$$

From (45) and (53),

$$\begin{aligned} \bar{\gamma}^k_{i,1}(\bar{g}^k_\eta(\theta^k)) &= \bar{\gamma}^k_{i,1}(\Delta^k_\eta(\sin\theta_k, \cos\theta_k, \Delta_{1/\eta} f^{k-1}(\theta^{k-1}))) \\ &= \eta^{\ell(i)-\ell(\lambda(k))}\bar{\gamma}^k_{i,1}(\sin\theta_k, \cos\theta_k, \Delta_{1/\eta} f^{k-1}(\theta^{k-1})) \\ &= \eta^{\ell(i)-\ell(\lambda(k))}\bar{\gamma}^k_{i,1}(\sin\theta_k, \cos\theta_k, 0) + \sum_{j<\ell(i)-\ell(\lambda(k))} \eta^j \bar{\beta}_{i,j}(\theta^k), \end{aligned} \tag{81}$$

where the $\bar{\beta}_{i,j}$'s denote smooth functions on $\mathbb{T}^{k-m}$. The second equality in the above equation comes from the fact that $\bar{\gamma}^k_{i,1}$ is Δ^k-homogeneous of degree $\ell(i) - \ell(\lambda(k))$, and the third one from the fact that $\bar{\gamma}^k_{i,1}(s, c, f)$ is polynomial in s, c, and f. A similar calculation yields

$$\bar{\gamma}^k_{i,2}(\bar{g}^k_\eta(\theta^k)) = \eta^{\ell(i)-\ell(\rho(k))}\bar{\gamma}^k_{i,2}(\sin\theta_k, \cos\theta_k, 0) + \sum_{j<\ell(i)-\ell(\rho(k))} \eta^j \bar{\bar{\beta}}_{i,j}(\theta^k). \tag{82}$$

From (51), (79), (81), and (82),

$$\gamma^k_i(\theta^k) = \begin{cases} \eta^{\ell(k)}\dfrac{m^k_k}{2} + \displaystyle\sum_{1<j<\ell(k)} \eta^j \beta_{k,j}(\theta^k) & \text{if } i = k, \\ \displaystyle\sum_{1<j<\ell(k)} \eta^j \beta_{i,j}(\theta^k) & \text{otherwise} \end{cases} \tag{83}$$

for some smooth functions $\beta_{i,j}$ on $\mathbb{T}^{k-m}$. In view of (80) and (83),

$$\left(\omega^k_{m+1} \wedge \cdots \wedge \omega^k_k\right)(\theta^k) = \eta^{\ell(k)}\frac{m^k_k}{2}\left(\omega^{k-1}_{m+1} \wedge \cdots \wedge \omega^{k-1}_{k-1}\right)(\theta^{k-1}) + \sum_{1\le j<\ell(k)} \eta^j \beta'_{k,j}(\theta^k)$$

for some other smooth functions $\beta'_{k,j}$ on $\mathbb{T}^{k-m}$. By the compacity of $\mathbb{T}^{k-m}$ and the induction hypothesis, (42) follows when η is larger than some $\eta_0 > 0$. ∎

3. Example. We illustrate the construction of transverse functions, as specified in the proof of Proposition 4, in the case of the free system $S(2,3)$ on $\mathbb{R}^5$. The associated truncated P. Hall basis is $\mathcal{B}_3 = \{B_1, \dots, B_5\}$, where

$$B_1 \triangleq X_1, B_2 \triangleq X_2, B_3 \triangleq [B_1, B_2] = [X_1, X_2], B_4 \triangleq [B_1, B_3], B_5 \triangleq [B_2, B_3]\,. \tag{84}$$

We have to compute $f = f^{n(d)} = f^5$, starting from $f^{m+1} = f^3$. From (14) and (84), $\lambda(3) = 1$ and $\rho(3) = 2$. Therefore, in view of (44),

$$f^3(\theta_3) = \left(\sin\theta_3, \cos\theta_3, \frac{\sin 2\theta_3}{4}, 0, 0\right)^T . \tag{85}$$

Let us now compute f^4 from f^3. From (14) and (84), $\lambda(4) = 1$ and $\rho(4) = 3$. Then (46), (47), (50), and (52) give

$$\bar{f}^4(s,c,x) = x + \begin{pmatrix} s \\ 0 \\ c \\ s\,c \\ 0 \end{pmatrix} + \begin{pmatrix} 0 \\ 0 \\ sq^4_{3,1}(x) + s^2 q^4_{3,2}(x) \\ sq^4_{4,1}(x) + s^2 q^4_{4,2}(x) + s^3 q^4_{4,3}(x) \\ 0 \end{pmatrix}. \tag{86}$$

From (52)

$$\begin{cases} q^4_{3,1}(x) = m^4_3\, x_{\rho(3)} = x_{\rho(3)} = x_2, \\ q^4_{4,1}(x) = m^4_4\, x_{\rho(4)} = 2x_{\rho(4)} = 2x_3. \end{cases} \tag{87}$$

Let us now proceed with the determination of $\bar{\omega}^4_3$, as defined by (49). Since $q^4_{3,2}$ is by definition homogeneous of degree $\ell(3) - 2\ell(1) = 0$, it is a constant function. A direct calculation gives

$$\bar{\omega}^4_3 = \mathrm{d}x_3 - x_1\mathrm{d}x_2 + (x_2 + 2sq^4_{3,2})\mathrm{d}s + \mathrm{d}c\,.$$

With the simple choice

$$q^4_{3,2} \equiv 0\,, \tag{88}$$

consistent with **P1(3)**, it follows that (48) is verified with $\bar{\gamma}^4_3 \triangleq x_2\mathrm{d}s + \mathrm{d}c$, a one-form which satisfies the conditions in **P2(3)**. There remains to determine $q^4_{4,2}$ and $q^4_{4,3}$. Again, $q^4_{4,3}$ is homogeneous of degree zero, and thus it is a constant function. A simple calculation gives

$$\begin{aligned} \bar{\omega}^4_4 =& \mathrm{d}x_4 - x_1\mathrm{d}x_3 + s(\mathrm{d}x_3 - x_1\mathrm{d}x_2 + \bar{\gamma}^4_3) + s^2(\mathbf{d}q^4_{4,2} - \mathrm{d}x_2) - (x_1 + s)\mathrm{d}c \\ &+ (c + 2x_3 + 2sq^4_{4,2} + 3s^2 q^4_{4,3} - x_1x_2 - 2sx_2)\mathrm{d}s\,. \end{aligned}$$

The choice

$$q^4_{4,2}(x) = x_2\,, \quad q^4_{4,3} \equiv 0\,, \tag{89}$$

is clearly consistent with **P1(4)** and allows us to rewrite $\bar{\omega}_4^4$ in the form (48), with $\bar{\gamma}_4^4 \triangleq (c + 2x_3 - x_1x_2)\mathrm{d}s - (x_1 + s)\mathrm{d}c$ a one-form which satisfies the conditions in **P2(4)**. We finally obtain the following from (86), (87), (88), and (89):

$$\bar{f}^4(s,c,x) = x + \begin{pmatrix} s \\ 0 \\ c + sx_2 \\ s\,c + 2sx_3 + s^2x_2 \\ 0 \end{pmatrix}. \tag{90}$$

The expression of f^4 is then obtained by application of (53). As for the parameter η_4, it must be chosen large enough so that (42) is satisfied for $k = 4$. By inspection the (conservative) condition $\eta_4 \geq 5/2$ can be derived.

The determination of f^5 from f^4 is performed in the same way. We obtain (details are left to the reader)

$$\bar{f}^5(s,c,x) = x + (0, s, c, 0, s\,c/2 + sx_3)^T. \tag{91}$$

Then, (53) gives the expression of $f = f^5$. One verifies from (85), (90), and (91) that

$$f(\theta^5) = \begin{pmatrix} \sin\theta_3 + \eta_4 \sin\theta_4 \\ \cos\theta_3 + \eta_5 \sin\theta_5 \\ \dfrac{1}{4}\sin 2\theta_3 + \eta_4^2\cos\theta_4 + \eta_4 \sin\theta_4\cos\theta_3 + \eta_5^2\cos\theta_5 \\ \dfrac{\eta_4^3}{2}\sin 2\theta_4 + \dfrac{\eta_4}{2}\sin\theta_4\sin 2\theta_3 + \eta_4^2\sin^2\theta_4\cos\theta_3 \\ \dfrac{\eta_5^3}{4}\sin 2\theta_5 + \eta_5\sin\theta_5(f_3(\theta_5) - \eta_5^2\cos\theta_5) \end{pmatrix}.$$

For practical purposes, adequate values for the parameters η_4 and η_5 must be specified. In this respect, let us mention only that numerical computations tend to indicate that for $\eta_4 = 3$ any value $\eta_5 \geq 7$ guarantees the satisfaction of (42).

Appendix.

Proof of Lemma 1 (*property* 4). We assume that $i \in \{1, \ldots, m\}$, since otherwise a simple algebraic manipulation yields

$$\begin{aligned} \mathrm{d}x_i = (\mathrm{d}x_i - x_{\lambda(i)}\mathrm{d}x_{\rho(i)}) + \sum_{r=1}^{\bar{r}} x_{\lambda(i)}x_{\lambda\rho(i)}\ldots x_{\lambda\rho^{r-1}(i)}(\mathrm{d}x_{\rho^r(i)} - x_{\lambda\rho^r(i)}\mathrm{d}x_{\rho^{r+1}}) \\ + x_{\lambda(i)}x_{\lambda\rho(i)}\ldots x_{\lambda\rho^{\bar{r}}(i)}\mathrm{d}x_{\rho^{\bar{r}+1}(i)}, \end{aligned}$$

where $\bar{r}$ is the smallest integer such that $\rho^{\bar{r}+1}(i) \in \{1, \ldots, m\}$. It is sufficient to specify some functions h_1 and $h_{2,j}$ such that equality (20) holds when each side is applied to any element of the basis $\{b_r, \partial/\partial x_s,\ r = 1, \ldots, m,\ s = m+1, \ldots, n(d)\}$ of the tangent space to $\mathbb{R}^n$. From (17),

$$\forall i = 1, \ldots, m \quad \begin{cases} \mathrm{d}x_j(b_i) = \delta_i^j & \text{if } j \in \{1, \ldots, m\}, \\ \omega_j(b_i) = 0 & \text{if } j \in \{m+1, \ldots, n(d)\}, \end{cases} \tag{92}$$

where $\omega_j = \mathrm{d}x_j - x_{\lambda(j)}\mathrm{d}x_{\rho(j)}$. Therefore, (20) applied to any b_r holds by setting $h_1 = q^i$ defined by (19). Finally, the functions $h_{2,j}$ are defined recursively, for $\ell(j)$ decreasing from d' to 2, by setting

$$\begin{cases} h_{2,j} = -\dfrac{\partial h_1}{\partial x_j}, & \ell(j) = d', \\ h_{2,j} = -\dfrac{\partial h_1}{\partial x_j} + \displaystyle\sum_{\ell(j)<\ell(j')\le d'} h_{2,j'} x_{\lambda(j')} \mathrm{d}x_{\rho(j')}(\partial/\partial x_j), & 1 < \ell(j) < d'. \end{cases} \qquad \square$$

Proof of Lemma 2. Since the set $\{g_1, \dots, g_m\}$ is nilpotent of order $d+1$, it follows from the definition of the P. Hall basis that $\{g_1, \dots, g_{n(d)}\}$ is a basis of $\mathrm{Lie}\{g_1, \dots, g_m\}$. Therefore, it is clearly a basis of $\mathrm{Lie}\{g_1, \dots, g_{n(d)}\}$. Then, (33) follows from the well-known fact that the solution of (32) is an exponential Lie series (see, e.g., [16] for details).

Let us finally prove that the mapping defined by (34) is one-to-one. Consider the system

$$\dot{x} = \sum_{i=1}^{n(d)} c_i g_i(x). \tag{93}$$

From property 2 of Lemma 1, each v.f. g_i is smooth and Δ-homogeneous of strictly negative degree. Therefore, its kth component $g_{i,k}$ can depend only on the components x_j of x such that $j < k$. From this and property 1 of Lemma 1, we deduce that the kth component of (93) can be written as

$$\dot{x}_k = c_k a_k + h_k(x_k^-, c_k^-), \tag{94}$$

where the notation y_k^- for a vector $y \in \mathbb{R}^n$ denotes the subvector $(y_1, \dots, y_{k-1})$, and h_k is some smooth function. Using (94), one easily proves by induction on k that any solution to (93) satisfies

$$\forall k = 1, \dots, n\,, \forall t, \qquad x_k(t) = x_k(0) + t c_k a_k + f_k(x_k^-(0), c_k^-, t)$$

for some smooth function f_k. Therefore,

$$\forall k = 1, \dots, n\,, \qquad \left[\exp\left(\sum_{i=1}^{n(d)} c_i g_i\right) x_0\right]_k = x_{0,k} + c_k a_k + f_k(x_{0,k}^-, c_k^-, 1),$$

and one easily infers from these equalities that

$$(c_1, \dots, c_{n(d)}) \neq (c'_1, \dots, c'_{n(d)}) \Longrightarrow \exp\left(\sum_{i=1}^{n(d)} c_i g_i\right) x_0 \neq \exp\left(\sum_{i=1}^{n(d)} c'_i g_i\right) x_0\,. \qquad \square$$

A STOCHASTIC CONTROL APPROACH TO PORTFOLIO PROBLEMS WITH STOCHASTIC INTEREST RATES*

RALF KORN† AND HOLGER KRAFT‡

Abstract. We consider investment problems where an investor can invest in a savings account, stocks, and bonds and tries to maximize her utility from terminal wealth. In contrast to the classical Merton problem, we assume a stochastic interest rate. To solve the corresponding control problems it is necessary to prove a verification theorem without the usual Lipschitz assumptions.

Key words. optimal portfolios, stochastic interest rate, verification theorem

1. Introduction. The continuous-time portfolio problem has its origin in the pioneering work of Merton (1969, 1971, 1973). It is concerned with finding the optimal investment strategy of an investor. More precisely, the investor looks for an optimal decision on how many shares of which security she should hold at every time instant between now and a time horizon T to maximize her expected utility from wealth at the time horizon. In the classical Merton problem the investor can allocate her money into a riskless savings account and d different risky stocks. By describing the actions of the investor via the portfolio process (i.e., the percentages of wealth invested in the different securities), Merton was able to reduce the portfolio problem to a control problem which could be solved by using standard stochastic control methodology.

A drawback of this approach, however, is the assumption of a deterministic interest rate.[1] Our main objective in the current paper is to overcome this restriction. We assume that the interest rate follows an Ito process and particularly consider the case of the Ho–Lee (see Ho and Lee (1986)) model and the Vasicek (see Vasicek (1977)) model for the short rate. Such problems are treated rarely in the literature.[2] Further, our theory will enable us to consider mixed bond and stock portfolio problems. We give explicit solutions for both the value functions and the optimal strategies in section 2.

On the theoretical side, the introduction of stochastic interest rates into the portfolio problem has the consequence that the SDE describing the wealth process does not satisfy the usual Lipschitz assumptions needed to apply standard verification theorems. However, due to the special structure of this equation, the wealth equation, we are able to prove a suitable verification result in the appendix. This is possible as some assumptions of the standard verification results as, e.g., given in Fleming and Soner (1993) can be weakened substantially via proving some special estimates.

[1]The other main approach to optimal portfolios, the martingale method, plays no role in this paper. We refer to Korn (1997) for an introduction to it.

[2]For related problems see Klüppelberg and Korn (1998), Canestrelli and Pontini (1998), and Sørensen (1999). In particular, in Sørensen (1999) the martingale approach of portfolio optimization is used in contrast to our stochastic control approach.

Important future research topics are the solution of the problems treated in this paper for other interest rate models such as the Cox–Ingersoll–Ross (see Cox, Ingersoll, and Ross (1985)) or the corresponding Hull–White (see Hull and White (1990)) approach. This is particularly interesting as those models have some desirable features (such as nonnegative interest rates) that the Ho–Lee or Vasicek model do not have.

2. Two portfolio problems. We consider an economy with $d+1$ assets which are continuously traded on a frictionless market. All traders are assumed to be price takers. The uncertainty is modelled by a probability space $(\Omega, \mathcal{F}, P)$. On this space an m-dimensional Brownian motion $\{(W(t), \mathcal{F}_t)\}_{t\geq 0}$ is defined, where $\{\mathcal{F}_t\}_{t\geq 0}$ denotes the Brownian filtration. One of the assets is a savings account following the differential equation

$$dB(t) = B(t)r(t)dt$$

with $B(0) = 1$. Here r denotes the short rate which can be interpreted as the annualized interest for the infinitesimal period $[t, t+dt]$.

In contrast to Merton's classical model,[3] we assume a short rate modelled by the SDE

$$dr(t) = a(t)dt + b\, dW(t),$$

$t \in [0, T^*]$, $b > 0$, with initial data $r(0) = r_0$. As explicit examples we will consider the Ho–Lee model given by $a(t) = \tilde{a}(t) + b\zeta(t)$ and a Vasicek approach with $a(t) = \theta(t) - \alpha r(t) + b\zeta(t)$, $\alpha > 0$, respectively. The risk premium (RP) ζ is assumed to be deterministic and continuous which implies the progressive measurability of ζ. This assumption particularly guarantees that ζ is bounded on each compact interval. Furthermore, let the initial forward rate curve $f^*(0,T)$, $0 \leq T \leq T^*$, be continuously differentiable, which leads to $\tilde{a}(t) = f^*_T(0,t) + b^2 t$ and $\theta(t) = f^*_T(0,t) + \alpha f^*(0,t) + \frac{b^2}{2\alpha}(1 - e^{-2\alpha t})$.[4] The price processes of the remaining d assets which can be stocks and/or (discount) bonds are assumed to follow Ito processes of the form

$$dP_i(t) = P_i(t)\Big[\mu_i(t)dt + \sigma_i(t)dW(t)\Big]$$

with $P_i(0) = p_i > 0$ and where $\mu(\cdot)$ is $\mathbb{R}^d$-valued and $\sigma_i(\cdot)$ denotes the ith row of the $d \times m$-matrix $\sigma(\cdot)$.

We consider an investor who starts with an initial wealth $x_0 > 0$ at time $t = 0$. In the beginning this initial wealth is invested in the different assets, and she is allowed to adjust her holdings continuously up to a fixed planning horizon T. Her investment behavior is modelled by a portfolio process $\pi = (\pi_1, \ldots, \pi_d)$ which is progressively measurable (with respect to $\{\mathcal{F}_t\}_{t\geq 0}$). Here, $\pi_i(t)$, $i = 0, \ldots, d$ denotes the percentage of total wealth invested in the ith asset at time t. Obviously, the percentage invested in the savings account is given by $1 - \pi'\underline{1}$, where $\underline{1} := (1, \ldots, 1)' \in \mathbb{R}^d$.

If we restrict our considerations to self-financing portfolio processes, her wealth process follows the SDE

$$dX(t) = X(t)\Big[\big(\pi(t)'(\mu(t) - r(t)\cdot\underline{1}) + r(t)\big)dt + \pi(t)'\sigma(t)dW(t)\Big] \tag{2.1}$$

with $X(0) = x_0$.[5]

[3] See Merton (1969, 1971, 1990), Fleming and Rishel (1975), pp. 160f, Duffie (1992), pp.145ff, Fleming and Soner (1993), pp. 174ff, and Korn (1997), pp. 48ff.

[4] See, for example, Musiela and Rutkowski (1997), pp. 323f.

[5] See, for example, Korn (1997), pp. 23f.

The wealth equation can be interpreted as a controlled SDE with the control being the portfolio process $\pi(\cdot)$. In this setting the investor chooses a portfolio process to maximize her utility. We assume that her preferences can be represented by the utility function $U(x) = x^\gamma$, $x \geq 0$, $0 < \gamma < 1$. Furthermore, the investor is allowed only to pick out a portfolio process which is admissible in the sense of Definition 3.1 and leads to a *positive* wealth process X^π. Now we are in the position to formulate her optimization problem:[6]

$$\max_{\pi(\cdot)\in\mathcal{A}^*(0,x_0)} \mathrm{E}(X^\pi(T))^\gamma \tag{2.2}$$

with

$$\begin{aligned} dX^\pi(t) &= X^\pi(t)\Big[(\pi(t)'(\mu(t) - r(t)\cdot\underline{1}) + r(t))dt + \pi(t)\sigma(t)dW(t)\Big], \\ X^\pi(0) &= x_0, \end{aligned}$$

and

$$\mathcal{A}^*(0,x_0) := \Big\{\pi(\cdot)\in\mathcal{A}(0,x_0) \,:\, X^\pi(s)\geq 0 \;\; P-\text{a.s. for } s\in[0,T]\Big\}.$$

We emphasize that applying optimal control methods to this problem does not automatically yield a positive state process. However, Corollary 3.1 and the special form of the coefficients in the wealth equation (2.1) will indeed guarantee the positivity of $X^\pi(t)$. Therefore, we obtain $\mathcal{A}^*(0,x_0) = \mathcal{A}(0,x_0)$.

2.1. A bond portfolio problem. We start by considering a portfolio problem where the investor can split up his wealth in a savings account and a (zero) bond with maturity $T_1 > T$. We assume that the asset price processes can be represented by the Ito processes

$$\begin{aligned} dB(t) &= B(t)r(t)dt, \\ dP(t,T_1) &= P(t,T_1)\Big[\underbrace{(r(t)+\zeta(t)\sigma(t))}_{=:\mu(t)}dt + \sigma(t)dW(t)\Big], \end{aligned}$$

where W is a one-dimensional Brownian motion. In the Ho–Lee and the Vasicek models the volatility of the bond is given by $\sigma(t) = -b(T_1 - t)$ and $\sigma(t) = \frac{b}{\alpha}(\exp(-\alpha(T_1 - t)) - 1)$, respectively.[7] Let $\pi(t)$ be the percentage invested in the bond. This leads to a wealth equation of the form

$$\begin{aligned} dX(t) &= X(t)\Big[(\pi(t)\mu(t) + (1-\pi(t))r(t))dt + \pi(t)\sigma(t)dW(t)\Big] \\ &= X(t)\Big[(\pi(t)\zeta(t)\sigma(t) + r(t))dt + \pi(t)\sigma(t)dW(t)\Big] \end{aligned} \tag{2.3}$$

with initial data $X(0) = x_0$.

In contrast to the classical Merton problem, we assume a stochastic short rate; the drift coefficient includes the additional stochastic term $r(t)$. Thus, to solve the

[6] Here $\mathcal{A}(0,x_0)$ denotes the set of all admissible controls corresponding to the initial condition $(0,x_0)$. See Definition 3.1 in the appendix.

[7] See, for example, Musiela and Rutkowski (1997), pp. 323ff.

portfolio problem (2.2) by stochastic control methods, we have to look at a two-dimensional state process $Y = (X, r)$. Note that the second component cannot be controlled via $\pi(\cdot)$. Using the notation of (3.1) in the appendix, we get[8]

$$\begin{aligned}
Y(t) &= (X(t), r(t))', \\
\Lambda(t,x,r,\pi) &= (x(\pi\zeta\sigma + r), a)', \\
\Sigma(t,x,r,\pi) &= (x\pi\sigma, b)', \\
\Sigma^*(t,x,r,\pi) &= \begin{pmatrix} x^2\pi^2\sigma^2 & bx\pi\sigma \\ bx\pi\sigma & b^2 \end{pmatrix}, \\
A^\pi G(t,x,r) &= G_t + 0.5(x^2\pi^2\sigma^2 G_{xx} + 2x\pi b\sigma G_{xr} + b^2 G_{rr}) \\
&\quad + x(\pi\zeta\sigma + r)G_x + aG_r.
\end{aligned}$$

Hence the following Hamilton–Jacobi–Bellman (HJB) equation has to be solved:

$$\begin{aligned}
\sup_{|\pi|\le\delta} A^\pi G(t,x,r) &= 0, \\
G(T,x,r) &= x^\gamma,
\end{aligned}$$

where $\delta > 0$ will be specified later.

Note that due to the presence of the product rx in the above setting usual verification theorems which require Lipschitz conditions are not applicable to our situation as both the wealth process and the short rate are unbounded processes. We therefore give a suitable verification result (Corollary 3.2) in the appendix. This result then allows us to solve the HJB equation with the usual three step procedure. By this, we would like to emphasize our opinion that the third step, verification of all assumptions of both Corollary 3.2 and those made to perform the following calculations, is an essential part of the solution.

We start with the calculation of the optimal bond position $\pi(\cdot)$.

1st step. Assuming $G_{xx} < 0$, we get the following candidate for the optimal bond position:

$$\pi^* = -\frac{\zeta}{\sigma}\frac{G_x}{xG_{xx}} - \frac{b}{\sigma}\frac{G_{xr}}{xG_{xx}}. \tag{2.4}$$

2nd step. Inserting $\pi^*(t,x,r;G)$ into the HJB equation leads to the PDE

$$\begin{aligned}
0 &= G_t G_{xx} - 0.5\zeta^2 G_x^2 - 0.5b^2 G_{xr}^2 + 0.5b^2 G_{rr} G_{xx} \\
&\quad - b\zeta G_x G_{xr} + xrG_x G_{xx} + aG_r G_{xx}
\end{aligned} \tag{2.5}$$

with the terminal condition $G(T,x,r) = x^\gamma$. Note that $\zeta = (\mu - r)/\sigma$.

The form of this condition recommends the following separation ansatz:

$$G(t,x,r) = f(t,r)\cdot x^\gamma \quad \text{with } f(T,r) = 1 \text{ for all } r.$$

This leads to a second-order PDE for f of the form

$$\begin{aligned}
0 &= (\gamma-1)ff_t - 0.5b^2\gamma f_r^2 - 0.5\zeta^2\gamma f^2 + 0.5b^2(\gamma-1)ff_{rr} \\
&\quad - b\zeta\gamma f f_r + r\gamma(\gamma-1)f^2 + a(\gamma-1)ff_r
\end{aligned}$$

[8]For simplicity we often neglect the functional dependencies with respect to t, x, and r.

with terminal condition $f(T,r)=1$. Using the ansatz

$$f(t,r)=g(t)\cdot\exp(\beta(t)\cdot r)$$

with terminal conditions $\beta(T)=0$ and $g(T)=1$ and simplification yields

$$\begin{aligned}0&=(\gamma-1)\cdot g'+(\gamma-1)\,(\gamma+\beta')\cdot rg\\&\quad-\left(0.5\zeta^2\gamma+0.5b^2\beta^2+b\zeta\gamma\beta\right)\cdot g+a(\gamma-1)\beta\cdot g.\end{aligned}\tag{2.6}$$

Our ansatz for f will only be meaningful if we get an ODE for g which does not include the short rate r.

In the Ho–Lee model the drift a of the short rate is a function of t, whereas in the Vasicek model it is a function of t and r. Therefore, we treat the two interest rate models separately.

Ho–Lee model. In our Ho–Lee setting PDE (2.6) has the form

$$\begin{aligned}0&=(\gamma-1)\cdot g'+(\gamma-1)\,(\gamma+\beta')\cdot rg\\&\quad+\underbrace{\left(-0.5\zeta^2\gamma-0.5b^2\beta^2-b\zeta\gamma\beta+a(\gamma-1)\beta\right)}_{=:h_1(t)}\cdot g.\end{aligned}\tag{2.7}$$

Since $a(t)=f_T^*(0,t)+b^2t+b\zeta(t)$ and ζ is assumed to be deterministic and continuous, h_1 is a continuous and deterministic function. Choosing $\beta(t)=\gamma(T-t)$, we infer from (2.7) the following first-order ODE for g:

$$0=(\gamma-1)\cdot g'+h_1(t)\cdot g$$

with $g(T)=1$. Separation of variables leads to

$$g(t)=\exp\left(\tfrac{1}{1-\gamma}(H_1(t)-H_1(T))\right),$$

where H_1 is a primitive of h_1. Hence we obtain

$$G(t,x,r)=x^\gamma\cdot\exp\left(\frac{1}{1-\gamma}(H_1(t)-H_1(T))+\gamma(T-t)r\right)$$

as a candidate for the value function. Inserting this into (2.4) gives the corresponding control

$$\begin{aligned}\pi^*(t)&=\frac{1}{1-\gamma}\cdot\frac{\zeta(t)+b\beta(t)}{-\sigma(t)}\\&=\frac{1}{1-\gamma}\cdot\frac{\zeta(t)+b(T-t)\gamma}{-b(T_1-t)}.\end{aligned}$$

Obviously, $\pi^*(\cdot)$ is continuous, deterministic, and therefore bounded.

Vasicek model. With the Vasicek specification of a the PDE (2.6) has the following form:

$$\begin{aligned}0&=(\gamma-1)\cdot g'+\underbrace{(\gamma-1)(\beta'-\alpha\beta+\gamma)}_{(*)}\cdot rg\\&\quad+(\underbrace{\theta(\gamma-1)\beta-b\zeta\beta-0.5b^2\beta^2-0.5\zeta^2\gamma}_{=:h_2(t)})\cdot g.\end{aligned}$$

Our ansatz for f is only meaningful if β can be calculated so that the factor $(*)$ becomes zero. As a result, we have to solve an inhomogeneous ODE for β which has the following form:

$$\beta'(t) = \alpha\beta(t) - \gamma$$

with $\beta(T) = 0$ leading to

$$\beta(t) = \frac{\gamma}{\alpha}(1 - \exp(\alpha(t - T))).$$

Choosing β as calculated, we again get a first-order homogeneous ODE for g,

$$0 = (\gamma - 1) \cdot g' + h_2(t) \cdot g,$$

with $g(T) = 1$. Hence

$$g(t) = \exp\left(\frac{1}{1-\gamma}(H_2(t) - H_2(T))\right),$$

where H_2 is a primitive of h_2. Therefore,

$$G(t, x, r) = x^\gamma \cdot \exp\left(\frac{1}{1-\gamma}(H_2(t) - H_2(T)) + \frac{\gamma}{\alpha}(1 - \exp(\alpha(t - T)))r\right).$$

The corresponding control reads as follows:

$$\begin{aligned}\pi^*(t) &= \frac{1}{1-\gamma} \cdot \frac{\zeta(t) + b\beta(t)}{\sigma(t)} \\ &= \frac{1}{1-\gamma} \cdot \frac{\zeta(t) + b \cdot \frac{\gamma}{\alpha}(1 - \exp(\alpha(t - T)))}{\frac{b}{\alpha}(\exp(-\alpha(T_1 - t)) - 1)}.\end{aligned}$$

Again, $\pi^*(\cdot)$ is continuous, deterministic, and therefore bounded.

In both cases one can choose δ in an appropriate way so that the optimal bond position fulfills the condition $\pi(\cdot) \le \delta$. Moreover, the respective $\pi^*(\cdot)$ is of the form

$$\pi^*(t) = \underbrace{\frac{1}{1-\gamma} \cdot \frac{\zeta(t)}{\sigma(t)}}_{\text{Merton result}} - \underbrace{\frac{\gamma}{1-\gamma} \cdot \kappa(t)}_{\text{correction term}}$$

with $\kappa(t) = \frac{T-t}{T_1-t}$ in the Ho–Lee model and $\kappa(t) = \frac{1-e^{-\alpha(T-t)}}{1-e^{-\alpha(T_1-t)}}$ in the Vasicek model. The first term coincides with the classical optimal one in Merton (1969, 1971, 1973) when the coefficients are deterministic. The second term can be interpreted as a correction term which is positive and monotonously decreasing to zero up to the terminal date T. Thus we first have a bigger, negative deviation from the classical result which vanishes at the time horizon. Moreover, the correction term increases with the investor's risk aversion because the less risky savings account will become more attractive if her risk aversion increases. This correction results from the fact that the investor tries to hedge his portfolio against the additional interest rate risk.

3rd step. At first we justify our use of Corollary 3.2, although the state process $Y = (X, r)'$ is two-dimensional: Note that the short rate process does not include the control $\pi(\cdot)$. Therefore, one can prove conditions (i) and (iii) in Definition 3.1 independently of a specified control. Consider the SDE

$$dr(t) = a(t)dt + b\,dW(t) \tag{2.8}$$

of the short rate r with $r(0) = r_0$. The coefficients meet the growth and Lipschitz conditions of the existence and uniqueness theorem for the SDE.[9] Hence (2.8) has a unique solution. Using a theorem of Krylov (1980, p. 85), we get

$$\mathrm{E}\Big(\max_{0\le s\le T} |r(s)|^{\rho}\Big) < +\infty \tag{2.9}$$

with $\rho \in \mathbb{N}$. Therefore, independently of the control under consideration, the conditions (i) and (iii) are fulfilled by the second component of the state process Y. As a result we can treat our problem as if the state process consists only of X. Note that then the wealth equation is a linear controlled SDE.

We can apply Corollary 3.2 if we are able to prove the following assumptions:

(1) $\pi^*(\cdot)$ is progressively measurable;
(2) $\pi^*(\cdot)$ meets condition (ii) in definition 3.1;
(3) $\pi^*(\cdot)$ meets condition (iii) in definition 3.1;
(4) G is a $C^{1,2}$-solution of the HJB;
(5) condition (3.12) is met.

Furthermore, the portfolio process has to lead to a positive wealth process, so

(6) $X^{\pi^*} \ge 0$.

Proof of (1). The respective solution $\pi^*(\cdot)$ is continuous and deterministic, hence progressively measurable.

Proof of (2). Property (ii) of an admissible control is met because the respective $\pi^*(\cdot)$ is bounded.

Proof of (3). By Corollary 3.1 the wealth equation (2.3) for $\pi^*(\cdot)$ has the solution

$$\begin{aligned} X^*(t) = x_0 \exp\Bigg(&\int_0^t \pi^*(s)\zeta(s)\sigma(s) + r(s) - 0.5(\pi^*(s)\sigma(s))^2\,ds \\ &+ \int_0^t \pi^*(s)\sigma(s)\,dW(s)\Bigg). \end{aligned} \tag{2.10}$$

Note that (2.9) implies

$$\mathrm{E}\left(\left|\int_0^T r(s)\,ds\right|\right) \le T \cdot \mathrm{E}\Big(\max_{0\le s\le T} |r(s)|\Big) < +\infty$$

and hence

$$\int_0^T r(s)\,ds < +\infty, \quad P - \text{a.s.}$$

The other assumptions of Corollary 3.1 are obviously met.

[9] See Fleming and Soner (1993, pp. 397f).

With an appropriate constant $K > 0$ we obtain the following estimate. (Be aware of the fact that $\pi^*(\cdot)$, $\sigma(\cdot)$, and $\zeta(\cdot)$ are bounded and that $|uv| \le u^2 + v^2$ for $u, v \in \mathbb{R}$.)

$$
\begin{aligned}
(2.11)\qquad X^*(t)^k &= x_0^k \cdot \exp\left(k \int_0^t \pi^*(s)\zeta(s)\sigma(s) + r(s) - 0.5(\pi^*(s)\sigma(s))^2 \, ds \right. \\
&\qquad \left. + k \int_0^t \pi^*(s)\sigma(s) \, dW(s) \right) \\
&\le K \cdot \exp\left(k \int_0^t r(s) \, ds + k \int_0^t \pi^*(s)\sigma(s) \, dW(s) \right) \\
&\le K \cdot \exp\left(2k \int_0^t r(s) \, ds \right) + K \cdot \exp\left(2k \int_0^t \pi^*(s)\sigma(s) \, dW(s) \right).
\end{aligned}
$$

Now consider the integral $\int_0^t r(s) \, ds$. With the form of the short rate process, in the *Ho–Lee model* we get[10]

$$
\begin{aligned}
(2.12)\qquad \int_0^t r(s) \, ds &= \int_0^t \left(r_0 + \int_0^s a(u) \, du + \int_0^s b \, dW(u) \right) ds \\
&= r_0 t + \int_0^t \int_0^s a(u) \, du ds + b \int_0^t \int_0^s dW(u) ds \\
&= \cdots + b \int_0^t (t-u) \, dW(u).
\end{aligned}
$$

The dots represent a term which is deterministic and bounded on $[0, T]$. Using the variation of constants formula for the SDE[11] in the *Vasicek model*, we obtain

$$
r(t) = e^{-\alpha t} \left(r_0 + \int_0^t e^{\alpha u} \Big(\theta(u) + b\zeta(u) \Big) \, du + \int_0^t b e^{\alpha u} \, dW(u) \right).
$$

Hence

$$
\begin{aligned}
(2.13)\qquad \int_0^t r(s) \, ds &= \int_0^t e^{-\alpha s} \left(r_0 + \int_0^s e^{\alpha u} \Big(\theta(u) + b\zeta(u) \Big) \, du \right) ds \\
&\quad + b \int_0^t \int_0^s e^{\alpha(u-s)} \, dW(u) ds \\
&= \cdots + b \int_0^t \int_u^t e^{\alpha(u-s)} \, ds dW(u).
\end{aligned}
$$

The dots represent a term which is deterministic and bounded on $[0, T]$.

In both cases the problem is reduced to find an estimate for terms of the form $\exp(\int_0^t h(s) \, dW(s))$ with a deterministic and bounded function h, namely,

$$
\begin{aligned}
&\exp\left(\int_0^t h(s) \, dW(s) \right) \\
&\qquad = \underbrace{\exp\left(\int_0^t 0.5 h^2(s) \, ds \right)}_{=const.} \cdot \underbrace{\exp\left(- \int_0^t 0.5 h^2(s) \, ds + \int_0^t h(s) \, dW(s) \right)}_{=:Z(t)}
\end{aligned}
$$

[10] See Ikeda and Watanabe (1981, pp. 117ff) for the interchange of the Lebesgue and the Ito integral.

[11] See Korn (1997, p. 313).

with

$$dZ(t) = Z(t)h(t)dW(t),$$
$$Z(0) = 1.$$

Using Krylov (1980, p. 85), we find that

$$\mathrm{E}\Big(\max_{0\le t\le T} Z(t)\Big) < +\infty.$$

Because of (2.11) and (2.12) or (2.13), respectively, $(X^*)^k$ can be estimated by processes of the same form as Z in both models. Therefore, property (3) is proved.

Proof of (4). Since the condition $G_{xx} < 0$ is met in both models, G is obviously a $C^{1,2}$-solution of the HJB equation.

Proof of (5). It is sufficent to prove that (3.12) is met by all *bounded* admissible bond positions $\pi(\cdot)$. Then the respective $\pi^*(\cdot)$ dominates all admissible bond positions. Let $(t', x', r') \in [0,T] \times \mathbb{R}^2_+ := \{y \in \mathbb{R}^2 : y > 0\}$ and $t' \le t \le T$. We consider the models separately.

Ho–Lee model. The candidate for the value function is

$$G(t,x,r) = x^\gamma \cdot \exp\left(\tfrac{1}{1-\gamma}(H_1(t) - H_1(T)) + \gamma(T-t)r\right),$$

where H_1 denotes a deterministic function which is continuously differentiable. Let K_i, $i = 1,2,3$, be appropriate constants. As H_1, π, ζ, σ, and a are bounded functions, an application of Ito's formula yields

$$\begin{aligned}
&G(t, X(t), r(t))\\
&= X(t)^\gamma \cdot \exp\left(\frac{1}{1-\gamma}(H_1(t) - H_1(T)) + \gamma(T-t)r(t)\right)\\
&= (x')^\gamma \exp\left(\gamma\int_{t'}^t \pi(s)\zeta(s)\sigma(s) + r(s) - 0.5(\pi(s)\sigma(s))^2\,ds\right.\\
&\qquad\qquad \left. +\gamma\int_{t'}^t \pi(s)\sigma(s)\,dW(s)\right)\\
&\quad \cdot \exp\left(\frac{1}{1-\gamma}(H_1(t) - H_1(T))\right) \cdot \exp\left(r(t)\gamma(T-t)\right)\\
&\le K_1 \cdot \exp\left(\gamma\int_{t'}^t r(s)\,ds + \gamma\int_{t'}^t \pi(s)\sigma(s)\,dW(s)\right) \cdot \exp(\gamma T r(t)) \cdot \exp(-\gamma t r(t))\\
&= K_1 \cdot \exp\left(\gamma\int_{t'}^t r(s)\,ds + \gamma\int_{t'}^t \pi(s)\sigma(s)\,dW(s)\right) \cdot \exp\left(\gamma T\int_{t'}^t dr(s)\right)\\
&\quad \cdot \exp\left(-\gamma\int_{t'}^t s\,dr(s) - \gamma\int_{t'}^t r(s)\,ds\right)\\
&= K_1 \cdot \exp\left(\gamma\int_{t'}^t \pi(s)\sigma(s)\,dW(s)\right) \cdot \exp\left(\gamma\int_{t'}^t (T-s)(a(s)\,ds + b\,dW(s))\right)\\
&\le K_2 \cdot \exp\left(\gamma\int_{t'}^t \pi(s)\sigma(s) + b(T-s)\,dW(s)\right)\\
&\le K_3 \cdot \exp\left(\gamma\int_{t'}^t \pi(s)\sigma(s) + b(T-s)dW(s)\right.\\
&\qquad\qquad \left. -0.5\gamma^2\int_{t'}^t \Big(\pi(s)\sigma(s) + b(T-s)\Big)^2 ds\right)\\
&=: K_3 \cdot Z(t),
\end{aligned}$$

where Z is the unique solution of

$$dZ(t) = Z(t)\Big(\gamma(\pi(t)\sigma(t) + b(T-t))\Big)dW(t) \quad \text{mit} \quad Z(t') = 1.$$

Using Krylov (1980, p. 85), we arrive at

$$\mathrm{E}\left(\sup_{t\in[t',T]} |G(t, X(t), r(t))|^2\right) \le K_3 \cdot \mathrm{E}\left(\sup_{t\in[t',T]} |Z(t)|^2\right) < \infty.$$

Hence we have just proved (3.12) in the Ho–Lee model.

Vasicek model. Our candidate for the value function is

$$G(t,x,r) = x^\gamma \cdot \exp\left(\frac{1}{1-\gamma}(H_2(t) - H_2(T)) + \frac{\gamma}{\alpha}(1 - \exp(\alpha(t-T)))r\right),$$

where H_2 is a continuously differentiable and deterministic function. With appropriate constants K_i, $i = 1, \dots, 6$, we find that

$$\begin{aligned}
&G(t, X(t), r(t)) \\
&= X(t)^\gamma \cdot \exp\left(\frac{1}{1-\gamma}(H_2(t) - H_2(T)) + \frac{\gamma}{\alpha}(1 - \exp(\alpha(t-T)))r(t)\right) \\
&\le K_1 \cdot X(t)^\gamma \cdot \exp\left(\frac{\gamma}{\alpha}(1 - \exp(\alpha(t-T)))r(t)\right) \\
&\le K_2 \cdot \exp\left(\gamma \int_{t'}^t \pi(s)\zeta(s)\sigma(s) + r(s) - 0.5(\pi(s)\sigma(s))^2\, ds \right. \\
&\qquad\qquad \left. + \gamma \int_{t'}^t \pi(s)\sigma(s)\, dW(s)\right) \cdot \exp\left(\frac{\gamma}{\alpha}(1 - \exp(\alpha(t-T))) \cdot r(t)\right) \\
&\le K_3 \cdot \exp\left(\gamma \int_{t'}^t r(s)\, ds + \gamma \int_{t'}^t \pi(s)\sigma(s)\, dW(s)\right) \cdot \exp\left(\frac{\gamma}{\alpha} r(t)\right) \\
&\quad \cdot \exp\left(-\frac{\gamma}{\alpha} \exp(\alpha(t-T)) \cdot r(t)\right).
\end{aligned}$$

With the definition $f^h(t,r) := \exp(\alpha(t-T)) \cdot r$ an application of Ito's formula yields

$$\begin{aligned}
&f^h(t, r(t)) \\
&= f^h(t', r') + \int_{t'}^t \alpha \exp(\alpha(s-T)) r(s)\, ds + \int_{t'}^t \exp(\alpha(s-T))\, dr(s) \\
&= f^h(t', r') + \int_{t'}^t \exp(\alpha(s-T)) \cdot (\theta(s) + b\zeta(s))\, ds + \int_{t'}^t b\, \exp(\alpha(s-T))\, dW(s).
\end{aligned}$$

Hence, by virtue of the stochastic integral equation of the short rate, we have

$$\begin{aligned}
&G(t, X(t), r(t)) \\
&\qquad \le K_4 \cdot \exp\left(\gamma \int_{t'}^t r(s)\, ds + \gamma \int_{t'}^t \pi(s)\sigma(s)\, dW(s)\right) \cdot \exp\left(\frac{\gamma}{\alpha} r(t)\right) \\
&\qquad\quad \cdot \exp\left(-\frac{\gamma}{\alpha} \int_{t'}^t b\, \exp(\alpha(s-T))\, dW(s)\right)
\end{aligned}$$

$$
\begin{aligned}
&= K_4 \cdot \exp\left(\gamma \int_{t'}^{t} r(s)\,ds + \gamma \int_{t'}^{t} \pi(s)\sigma(s)\,dW(s)\right)\\
&\quad \cdot \exp\left(\frac{\gamma}{\alpha} r' + \frac{\gamma}{\alpha}\int_{t'}^{t} (\theta(s) - \alpha r(s) + b\zeta(s))\,ds + \frac{\gamma}{\alpha}\int_{t'}^{t} b\,dW(s)\right)\\
&\quad \cdot \exp\left(-\frac{\gamma}{\alpha}\int_{t'}^{t} b\,\exp(\alpha(s-T))\,dW(s)\right)\\
&\le K_5 \cdot \exp\left(\int_{t'}^{t} \gamma\pi(s)\sigma(s) + \frac{\gamma}{\alpha} b\Big(1 - \exp(\alpha(s-T))\Big)\,dW(s)\right)\\
&\le K_6 \cdot \exp\left(\int_{t'}^{t} \gamma\pi(s)\sigma(s) + \frac{\gamma}{\alpha} b\Big(1 - \exp(\alpha(s-T))\Big)\,dW(s)\right.\\
&\qquad \left. - \int_{t'}^{t} 0.5\left[\gamma\pi(s)\sigma(s) + \frac{\gamma}{\alpha} b\Big(1 - \exp(\alpha(s-T))\Big)\right]^2 ds\right)\\
&=: K_6 \cdot \tilde{Z}(t).
\end{aligned}
$$

Since the process $\tilde{Z}$ has the same properties as Z in the Ho–Lee model, an analogous argument leads to (3.12).

Proof of (6). By virtue of (2.10), we have $X^* \ge 0$.

The following theorem summarizes our results.

THEOREM 2.1 (bond portfolio problem). *The optimal portfolio processes in the above bond portfolio problems are given by*

$$\pi^*(t) = \frac{1}{1-\gamma} \cdot \frac{\zeta(t)}{\sigma(t)} - \frac{\gamma}{1-\gamma} \cdot \kappa(t)$$

with

(a) *Ho–Lee case:* $\kappa(t) = \frac{T-t}{T_1-t}$,

(b) *Vasicek case:* $\kappa(t) = \frac{1-e^{-\alpha(T-t)}}{1-e^{-\alpha(T_1-t)}}$.

2.2. A mixed stock and bond portfolio problem. In this subsection we assume that the investor can put his money on a savings account, in a stock, or in a bond with maturity $T_1 > T$. The dynamics of these assets are given by

$$
\begin{aligned}
dB(t) &= B(t)r(t)dt,\\
dS(t) &= S(t)\Big[\mu_S(t)dt + \sigma_S(t)dW_S(t) + \sigma_{SB}(t)dW_B(t)\Big],\\
dP(t) &= P(t)\Big[\underbrace{(r(t) + \zeta_B(t)\sigma_B(t))}_{=:\mu_B(t)}dt + \sigma_B(t)dW_B(t)\Big],
\end{aligned}
$$

where (W_S, W_B) is a two-dimensional Brownian motion and where, for ease of notation, we write $P(t)$ instead of $P(t, T_1)$. In our model the stock price depends on two risk factors: The first factor W_S contains the specific risk of the stock, and the second W_B comes from the stochastic interest rate model.

In Merton's portfolio problem we can split up the (deterministic) drift μ_S of the stock into a liquidity premium (LP) and an excess return, which should be interpreted as RP in this context:[12]

$$\mu_S = \underbrace{r}_{\text{LP}} + \underbrace{\mu_S - r}_{\text{RP}}.$$

[12]There is no uniform use of the words excess return, RP, and market price of risk. Apart from the above interpretation of the drift, throughout the paper we denote $\lambda = \mu - r$ as excess return, $\frac{\lambda}{\sigma}$ as RP, and $\frac{\lambda}{\sigma^2}$ as market price of risk.

The drift of the stock S under consideration can also be

$$\mu_S(t) = r(t) + \underbrace{\mu_S(t) - r(t)}_{=:\lambda_S(t)},$$

where λ_S denotes the RP of the stock

In the following, we assume that the excess return $\lambda_S(\cdot)$ of the stock is deterministic and continuous. This implies that $\lambda_S(\cdot)$ is progressively measurable and bounded on $[0,T]$. Furthermore, assume that the coefficients $\sigma_S(\cdot)$, $\sigma_{SB}(\cdot)$, and $\sigma_B(\cdot)$ are deterministic and continuous. In addition, let $\sigma_S(\cdot)$ and $\sigma_B(\cdot)$ be bounded away from zero.

As before, we consider both a Ho–Lee and a Vasicek model:

$$dr(t) = a(t)dt + bdW_B(t)$$

with $a(t) = \tilde{a}(t) + b\zeta(t)$ in the Ho–Lee model and $a(t) = \theta(t) - \alpha r(t) + b\zeta(t)$ in the Vasicek model.

Moreover, we have $\sigma_B(t) = -b(T_1 - t)$ in the Ho–Lee model and $\sigma_B(t) = \frac{b}{\alpha}(\exp(-\alpha(T_1 - t)) - 1)$ in the Vasicek model.

In this framework the wealth equation (2.1) has the following form:

$$\begin{aligned} dX(t) = X(t)\Big[&(\pi_S(t)\lambda_S(t) + \pi_B(t)\lambda_B(t) + r(t))dt \\ &+\pi_S(t)\sigma_S(t)dW_S(t) + (\pi_S(t)\sigma_{SB}(t) + \pi_B(t)\sigma_B(t))dW_B(t)\Big], \end{aligned}$$

where $\lambda_B(t) := \mu_B(t) - r(t)$ and $\pi := (\pi_S, \pi_B)$.

Using the notations of (3.1) in the appendix, we have

$$\begin{aligned} Y(t) &= (X(t), r(t))', \\ \Lambda(t,x,r,\pi) &= (x(\pi_S\lambda_S + \pi_B\lambda_B + r), a)', \\ \Sigma(t,x,r,\pi) &= \begin{pmatrix} x\pi_S\sigma_S & x(\pi_S\sigma_{SB} + \pi_B\sigma_B) \\ 0 & b \end{pmatrix}, \\ \Sigma^*(t,x,r,\pi) &= \begin{pmatrix} x^2(\pi_S^2\sigma_S^2 + (\pi_S\sigma_{SB} + \pi_B\sigma_B)^2) & bx(\pi_S\sigma_{SB} + \pi_B\sigma_B) \\ bx(\pi_S\sigma_{SB} + \pi_B\sigma_B) & b^2 \end{pmatrix}, \\ A^\pi G(t,x,r) &= G_t + 0.5x^2(\pi_S^2\sigma_S^2 + (\pi_S\sigma_{SB} + \pi_B\sigma_B)^2)G_{xx} + 0.5b^2G_{rr} \\ &\quad + bx(\pi_S\sigma_{SB} + \pi_B\sigma_B)G_{xr} + x(\pi_S\lambda_S + \pi_B\lambda_B + r)G_x + aG_r. \end{aligned}$$

Hence we have to solve the following HJB equation:

$$\begin{aligned} \sup_{|\pi| \le \delta} A^\pi G(t,x,r) &= 0, \\ G(T,x,r) &= x^\gamma. \end{aligned}$$

This will again be done by the three-step-algorithm.

1*st step.* Assuming $G_{xx} < 0$, we calculate the candidates for the optimal portfolio positions

$$\pi_S^* = -\underbrace{(\eta_S - \tfrac{\sigma_{SB}}{\sigma_B}\eta_{BS})}_{=:\hat{\eta}_S} \cdot \frac{G_x}{xG_{xx}}, \tag{2.14}$$

$$\pi_B^* = -\underbrace{\left((1+\tfrac{\sigma_{SB}^2}{\sigma_S^2})\eta_B - \tfrac{\sigma_{SB}}{\sigma_B}\eta_S\right)}_{=:\hat{\eta}_B} \cdot \frac{G_x}{xG_{xx}} - \frac{b}{\sigma_B} \cdot \frac{G_{xr}}{xG_{xx}} \tag{2.15}$$

with $\eta_S := \lambda_S/\sigma_S^2$, $\eta_B := \lambda_B/\sigma_B^2$ and $\eta_{BS} := \lambda_B/\sigma_S^2$.

2*nd step.* Inserting $\pi_S^*(t,x,r;G)$ and $\pi_B^*(t,x,r;G)$ in the HJB equation yields the PDE

$$\begin{aligned} 0 = G_t G_{xx} + (\underbrace{0.5\sigma_S^2\hat{\eta}_S^2 + 0.5(\sigma_{SB}\hat{\eta}_S + \sigma_B\hat{\eta}_B)^2 - \lambda_S\hat{\eta}_S - \lambda_B\hat{\eta}_B}_{=:\tilde{\zeta}(t)})G_x^2 \\ -0.5b^2G_{xr}^2 + 0.5b^2G_{rr}G_{xx} - b\tfrac{\lambda_B}{\sigma_B}G_xG_{xr} + xrG_xG_{xx} + aG_rG_{xx} \end{aligned}$$

with $G(T,x,r) = x^\gamma$. This PDE is of the same form as the corresponding PDE (2.5) above.[13] Note that $\tilde{\zeta}$, in analogy to ζ in (2.5), is a continuous and deterministic function. Therefore, in the Ho–Lee model we get

$$G(t,x,r) = x^\gamma \cdot \exp\left(\frac{1}{1-\gamma}(H_3(t) - H_3(T)) + \gamma(T-t)r\right)$$

and in the Vasicek model

$$G(t,x,r) = x^\gamma \cdot \exp\left(\frac{1}{1-\gamma}(H_4(t) - H_4(T)) + \frac{\gamma}{\alpha}(1-\exp(\alpha(t-T)))r\right),$$

with appropriate continuously differentiable functions H_3 and H_4, respectively. Insertion into (2.14) and (2.15) yields in *both* models for the optimal stock and bond position

$$\begin{aligned} \pi_S^*(t) &= \frac{1}{1-\gamma} \cdot \left(\eta_S(t) - \frac{\sigma_{SB}(t)}{\sigma_B(t)}\eta_{BS}(t)\right) \\ &= \frac{1}{1-\gamma} \cdot \hat{\eta}_S(t), \\ \pi_B^*(t) &= \frac{1}{1-\gamma} \cdot \left(\left(1 + \frac{\sigma_{SB}^2(t)}{\sigma_S^2(t)}\right)\eta_B(t) - \frac{\sigma_{SB}(t)}{\sigma_B(t)}\eta_S(t) - \gamma \cdot \kappa(t)\right) \\ &= \frac{1}{1-\gamma} \cdot \left(\hat{\eta}_B(t) - \gamma \cdot \kappa(t)\right), \end{aligned}$$

where $\kappa(t) = \frac{T-t}{T_1-t}$ in the *Ho–Lee model* and $\kappa(t) = \frac{1-e^{-\alpha(T-t)}}{1-e^{-\alpha(T_1-t)}}$ in the *Vasicek model*.

Both positions are continuous and deterministic processes and are hence bounded.

3*rd step.* With the same argument as in subsection 2.1 we can apply Corollary 3.2. Therefore, in both models we must check the following assumptions:

(1) $\pi^*(\cdot)$ is progressively measurable;

(2) $\pi^*(\cdot)$ meets condition (ii) in Definition 3.1;

[13] One will obtain the PDE (2.5) if $\lambda_S \equiv 0$, $\sigma_S \equiv 0$, and $\sigma_{SB} \equiv 0$.

(3) $\pi^*(\cdot)$ meets condition (iii) in Definition 3.1;
(4) G is a $C^{1,2}$-solution of the HJB equation;
(5) condition (3.12) is met;
(6) $X^{\pi^*} \geq 0$.

Note that $\pi^* := (\pi_S^*, \pi_B^*)'$.

Conditions (1) and (2) are met because in both models $\pi^*(\cdot)$ is a continuous and deterministic process. Obviously, (4) is fulfilled. Condition (6) is met since variation of constants leads to

$$\begin{aligned} X(t) = x_0 \exp\Bigg(& \int_0^t \pi_S(s)\lambda_S(s) + \pi_B(s)\lambda_B(s) + r(s) \\ & - 0.5\Big((\pi_S(s)\sigma_S(s))^2 + (\pi_S(s)\sigma_{SB}(s) + \pi_B(s)\sigma_B(s))^2\Big)\, ds \\ & + \int_0^t \pi_S(s)\sigma_S(s)\, dW_S(s) + \int_0^t \pi_S(s)\sigma_{SB}(s) + \pi_B(s)\sigma_B(s)\, dW_B(s)\Bigg) \end{aligned}$$

for an admissable control $\pi(\cdot)$. Furthermore, since the wealth process has the same properties as in subsection 2.1, we can prove (3) and (5) using the analogous arguments.

The following theorem summarizes our results.

THEOREM 2.2 (mixed portfolio problem). *The optimal portfolio processes in the above mixed portfolio problem are given by*

$$\pi_S^*(t) = \frac{1}{1-\gamma} \cdot \left(\underbrace{\eta_S(t) - \frac{\sigma_{SB}(t)}{\sigma_B(t)}\eta_{BS}(t)}_{=:\hat{\eta}_S} \right), \qquad \textit{(stock)}$$

$$\pi_B^*(t) = \frac{1}{1-\gamma} \cdot \left(\underbrace{\left(1 + \frac{\sigma_{SB}^2(t)}{\sigma_S^2(t)}\right)\eta_B(t) - \frac{\sigma_{SB}(t)}{\sigma_B(t)}\eta_S(t)}_{=:\hat{\eta}_B} - \gamma \cdot \kappa(t) \right) \qquad \textit{(bond)}$$

with

(a) *Ho–Lee case:* $\kappa(t) = \frac{T-t}{T_1-t}$,
(b) *Vasicek case:* $\kappa(t) = \frac{1-e^{-\alpha(T-t)}}{1-e^{-\alpha(T_1-t)}}$.

Considering the optimal positions the analogy to the pure bond problem becomes clear: The variables $\hat{\eta}_S$ and $\hat{\eta}_B$ can be interpreted as modified market prices of risk, where both are weighted differences of η_S and η_{BS} or η_B and η_S, respectively. In the optimal stock position the market price of risk of the stock is corrected by η_{BS}, which stands for the market price of risk of the bond with respect to the stock.

Similarly, the market price of risk of the bond contains a correction of the optimal bond position by the market price of risk of the stock. Both these corrections are plausible ones as an increase of the market price of risk of the bond makes stock investment less attractive and vice versa. Apart from this remark, the interpretation of the bond part as given in section 2.1 remains valid.

Furthermore, we will get the optimal bond position of subsection 2.1 if we choose $\sigma_S \equiv 0$ and $\sigma_{SB} \equiv 0$ in $\pi_B(\cdot)$.

However, as the detailed proof of Theorem 2.2 would have been much more complicated than that of Theorem 2.1, we have decided to only present the one for Theorem 2.1 as it contains the main ideas.

3. Appendix. In this appendix we will present the technical results and details which enabled us to solve the foregoing portfolio problems by stochastic control methods. Let, therefore, $(\Omega, \mathcal{F}, P)$ be a complete probability space. Assume that on this space an m-dimensional Brownian motion $\{(W(t), \mathcal{F}_t)\}_{t\in[0,\infty)}$ is defined with $\{\mathcal{F}_t\}_{t\in[0,\infty)}$ being the Brownian filtration. All adapted or progressively measurable processes are adapted or progressively measurable with respect to the Brownian filtration. Let, further, $|\cdot|$ denote the Euclidean norm or the operator norm, respectively.

As usual we will look at a state process given by a controlled SDE of the form

$$dY(t) = \Lambda(t, Y(t), u(t))dt + \Sigma(t, Y(t), u(t))dW(t) \tag{3.1}$$

with initial value of $Y(t_0) = y_0$ and a d-dimensional control process $u(\cdot)$. Let $[t_0, t_1]$ with $0 \le t_0 < t_1 < \infty$ be the relevant time interval. A control strategy $u(\cdot)$ (for short, control) is a progressively measurable process with $u(t) \in U$ for all $t \in [t_0, t_1]$, where the set $U \subset \mathbb{R}^d$, $d \in \mathbb{N}$, is assumed to be closed. Further, let $Q_0 := [t_0, t_1) \times \mathbb{R}^n$, $n \in \mathbb{N}$. The coefficient functions

$$\Lambda : \bar{Q}_0 \times U \to \mathbb{R}^n,$$
$$\Sigma : \bar{Q}_0 \times U \to \mathbb{R}^{n,m},$$

$m \in \mathbb{N}$, are all assumed to be continuous. Further, for all $v \in U$, let $\Lambda(\cdot,\cdot,v)$ and $\Sigma(\cdot,\cdot,v)$ be in $C^1(\bar{Q}_0)$. We then define the following.

DEFINITION 3.1 (admissible control). *A control $\{(u(t), \mathcal{F}_t)\}_{t\in[t_0,t_1]}$ will be called admissible*[14] *if*

(i) *for all $y_0 \in \mathbb{R}^n$ the corresponding controlled SDE* (3.1) *with initial condition $Y(t_0) = y_0$ admits a pathwise unique solution $\{Y^u(t)\}_{t\in[t_0,t_1]}$;*

(ii) *for all $k \in \mathbb{N}$ the integrability condition*

$$\mathrm{E}\left(\int_{t_0}^{t_1} |u(s)|^k \, ds\right) < \infty$$

is satisfied;

(iii) *the corresponding state process Y^u satisfies*

$$\mathrm{E}^{t_0,y_0}\left(\sup_{t\in[t_0,t_1]} |Y^u(t)|^k\right) < \infty.$$

Let $\mathcal{A}(t_0, y_0)$ denote the set of all admissible controls corresponding to the initial condition $(t_0, y_0) \in Q$.

In the following, the above definition will prove to be extremely useful when we have to overcome some technical difficulties which have their origin in the fact that the wealth equation does not satisfy the usual Lipschitz conditions needed in the standard verification theorems of stochastic control.

To ensure existence and uniqueness of the solution of the controlled SDE (3.1), one typically requires the following Lipschitz and growth conditions for the coefficient functions which imply that controls with property (ii) are already admissible (i.e.,

[14] This definition is more restrictive than the usual one as, e.g., given in Fleming and Rishel (1975, p. 156). However, due to the special form of our control problem, all (optimal) controls in this paper will satisfy the more restrictive requirements of our definition.

they also satisfy properties (i) and (iii)).[15] With a constant $C > 0$ these conditions are

$$|\Lambda_t| + |\Lambda_y| \le C, \tag{3.2}$$
$$|\Sigma_t| + |\Sigma_y| \le C,$$
$$|\Lambda(s,y,v)| \le C(1 + |y| + |v|), \tag{3.3}$$
$$|\Sigma(s,y,v)| \le C(1 + |y| + |v|)$$

for all $s \in [t_0, t_1]$, $y \in \mathbb{R}$, and $v \in U$.

Typically, in our applications the conditions (3.2) and (3.3) will not be satisfied. On the other hand we have only to deal with linear controlled SDEs. This will imply that requirement (ii) on an admissible control already ensures requirement (i) too.

COROLLARY 3.1 (variation of constants). *Let $(t_0, y_0) \in Q$, and let $A_1^{(j)}$, $j = 1, \dots, d$, A_2, $B_1^{(i,j)}$, $i = 1, \dots, m$, $j = 1, \dots, d$, $B_2^{(i)}$, $i = 1, \dots, m$ be progressively measurable real-valued processes satisfying the integrability conditions*

$$\int_{t_0}^{t_1} |A_2(s)|\, ds < \infty \quad P\text{-a.s., } t \ge 0,$$
$$\int_{t_0}^{t_1} \left(\sum_{j=1}^{d} A_1^{(j)}(s)^2 + \sum_{i=1}^{m} B_2^{(i)}(s)^2 \right) ds < \infty \quad P\text{-a.s., } t \ge 0,$$
$$\int_{t_0}^{t_1} \left(\sum_{i=1}^{m} \sum_{j=1}^{d} B_1^{(i,j)}(s)^4 \right) ds < \infty \quad P\text{-a.s., } t \ge 0.$$

Further, let $u(\cdot)$ be a control with property (ii) *of Definition* 3.1. *Then the linear controlled SDE*

$$dY^u(t) = Y^u(t)\Big[(A_1(t)'u(t) + A_2(t))dt + (B_1(t)u(t) + B_2(t))'dW(t)\Big] \tag{3.4}$$

admits the Lebesgue $\bigotimes P$ unique solution

$$Y^u(t) = y_0 \cdot \exp\left(\int_{t_0}^{t_1} \Big(A_1(s)'u(s) + A_2(s) - 0,5|B_1(s)u(s) + B_2(s)|^2 \Big) ds + \int_{t_0}^{t_1} \Big(B_1(s)u(s) + B_2(s) \Big)' dW(s) \right).$$

If we consider only bounded admissible controls, then the following conditions are sufficient:

$$\int_{t_0}^{t_1} \left(\sum_{j=1}^{d} |A_1^{(j)}(s)| + |A_2(s)| \right) ds < \infty \quad P\text{-a.s., } t \ge 0,$$
$$\int_{t_0}^{t_1} \left(\sum_{i=1}^{m} \sum_{j=1}^{d} B_1^{(i,j)}(s)^2 + \sum_{i=1}^{m} B_2^{(i)}(s)^2 \right) ds < \infty \quad P\text{-a.s., } t \ge 0.$$

Proof of Corollary 3.1. The integrability assumptions together with property (ii) of an admissible control imply the requirements of the variation of constants formula given in Korn (1997). Applying it implies all assertions of the corollary. □

Consequently, for our applications it will be enough to verify properties (ii) and (iii) to obtain admissibility of a control. From now on, controlled SDEs (3.4) with

[15] See Fleming and Soner (1993, p. 398).

coefficients satisfying the conditions of Corollary (3.1) will be referred to as linear controlled SDEs.

We will now formulate a standard verification theorem and afterwards derive a version suitable for our applications by modifying the relevant parts of the proof of the standard theorem. Therefore, we look at the following setting: Let $\mathcal{O} \subset \mathbb{R}^n$ be an open subset of $\mathbb{R}^n$. In the case of $\mathcal{O} \neq \mathbb{R}^n$ we additionally assume that its boundary $\partial\mathcal{O}$ is a compact $(n-1)$-dimensional C^3-manifold. In analogy to Q_0 we define $Q := [t_0, t_1) \times \mathcal{O}$. Further, let

$$\tau := \inf\{t \in [t_0, t_1] : (t, Y(t)) \notin Q\}$$

denote the exit time of Y from $\mathcal{O}$. Hence we have

$$(\tau, Y(\tau)) \in \partial^* Q := ([t_0, t_1) \times \partial\mathcal{O}) \cup (\{t_1\} \times \bar{\mathcal{O}}).$$

We now consider continuous, real-valued functions L and Ψ that satisfy the polynomial growth conditions

$$|L(t, y, v)| \leq C(1 + |y|^k + |v|^k), \tag{3.5}$$

$$|\Psi(t, y)| \leq C(1 + |y|^k) \tag{3.6}$$

on $\bar{Q} \times U$ and $\bar{Q}$ for suitable constants $k \in \mathbb{N}$ and $C > 0$. Here L and Ψ model the running and the terminal utility resulting from the control and the position of the controlled process, respectively. It will be our goal to determine an admissible control $u(\cdot)$ such that for each initial value (t_0, y_0) the utility functional

$$J(t_0, y_0; u) := \mathrm{E}^{t_0, y_0}\left(\int_{t_0}^{\tau} L(s, Y^u(s), u(s))\, dt + \Psi(\tau, Y^u(\tau))\right)$$

will be maximized; i.e., we want to solve $\max_{u \in \mathcal{A}(t_0, y_0)} J(t_0, y_0; u)$.

Therefore, define the value function

$$V(t, y) := \sup_{u \in \mathcal{A}(t,y)} J(t, y; u), \quad (t, y) \in Q.$$

For each function $G \in C^{1,2}(Q)$ and $(t, y) \in Q$, $v \in U$, we consider the following differential operator:

$$A^v G(t, y) := G_t(t, y) + 0,5 \sum_{i,j=1}^{n} \Sigma^*_{ij}(t, y, v) \cdot G_{y_i y_j}(t, y) + \sum_{i=1}^{n} \Lambda_i(t, y, v) \cdot G_{y_i}(t, y)$$

with $\Sigma^* := \Sigma\Sigma'$. Then, we have the following theorem.[16]

THEOREM 3.1 (verification theorem). *Let the conditions* (3.2) *and* (3.3) *on the coefficient functions of the controlled SDE* (3.1) *be satisfied. Further, assume conditions* (3.5) *and* (3.6). *Let G be a function with the following properties:*

(a) *We have*

$$G \in C^{1,2}(Q) \cap C(\bar{Q}), \tag{3.7}$$

$$|G(t, y)| \leq K(1 + |y|^k) \tag{3.8}$$

for suitable $K > 0$ and $k \in \mathbb{N}$.

[16] See Fleming and Soner (1993, p. 163).

(b) *G solves the HJB equation:*

$$\sup_{v\in U}\Big\{A^vG(t,y)+L(t,y,v)\Big\}=0, \qquad (t,y)\in Q, \tag{3.9}$$

$$G(t,y)=\Psi(t,y), \quad (t,y)\in\partial^*Q. \tag{3.10}$$

Then we obtain the following result:

(i) *$G(t,y)\geq J(t,y;u)$ for all $(t,y)\in Q$ and $u(\cdot)\in\mathcal{A}(t,y)$.*

(ii) *If for $(t,y)\in Q$ there exists a control $u^*(\cdot)\in\mathcal{A}(t,y)$ with*

$$u^*(s)\in\arg\max_{v\in U}\Big(A^vG(s,Y^*(s))+L(s,Y^*(s),v)\Big) \tag{3.11}$$

for all $s\in[t,\tau]$, where Y^* is the solution of the controlled SDE corresponding to $u^*(\cdot)$, then we have

$$G(t,y)=V(t,y)=J(t,y;u^*),$$

i.e., $u^*(\cdot)$ is an optimal control and G coincides with the value function.

Besides conditions (3.2) and (3.3), the growth condition (3.8) is not satisfied in our applications either. Thus we need to modify the above verification result in a suitable way.

Corollary 3.2 (to the verification theorem). *Consider a linear controlled SDE with coefficients satisfying the assumptions of Corollary* 3.1. *Assume, further, that the functions L and ψ satisfy the conditions* (3.5) *and* (3.6). *Finally, let the function $G\in C^{1,2}(Q)\cap C(\bar{Q})$ be a solution to the HJB equation* (3.9) *with boundary condition* (3.10). *Assume that for all $(t,y)\in Q$ and all admissible controls $u(\cdot)\in\mathcal{A}(t,y)$ there exists a $\rho>1$ such that we have*

$$\mathrm{E}\left(\sup_{s\in[t,t_1]}|G(s,Y(s))|^\rho\right)<\infty. \tag{3.12}$$

Then assertions (i) *and* (ii) *of the verification theorem are valid.*

Proof of Corollary 3.2. Looking at the proof of the verification theorem as given in Fleming and Soner (1993, pp. 163f), we realize the following:

(i) Conditions (3.2) and (3.3) ensure the existence and uniqueness of a solution of the controlled SDE for controls with property (ii) of Definition 3.1. We can then apply the Ito formula to obtain

$$\begin{aligned}G(\theta,Y(\theta))-G(t,y)-\int_t^\theta A^{u(s)}G(s,Y(s))\,ds\\ =\int_t^\theta G_y(s,Y(s))\cdot\Sigma(s,Y(s),u(s))\,dW(s)\end{aligned} \tag{3.13}$$

which corresponds to relation (3.9) in Fleming and Soner (1993).

(ii) The growth condition (3.3) is used to prove the relation

$$\mathrm{E}^{t,y}\left(\int_t^\theta G_y(s,Y(s))\cdot\Sigma(s,Y(s),u(s))\,dW(s)\right)=0 \tag{3.14}$$

for bounded $\mathcal{O}$. (This corresponds to $\mathrm{E}_{tx}M(\theta)=0$ for bounded $\mathcal{O}$ in the notation of Fleming and Soner (1993).)

(iii) The growth condition (3.8) is used to show the uniform integrability of $\{G(\theta_p, Y(\theta_p))\}_p$, where θ_p are stopping times with $t \le \theta_p \le t_1$. (In the notation of Fleming and Soner (1993) this corresponds to the uniform integrability of $\{W(\theta_p, x(\theta_p))\}_p$. There, one also finds the exact definition of the stopping times θ_p, which is irrelevant for our argumentation.)

We now demonstrate that we also have these three properties under the assumptions of our corollary:

(i) For admissible controls the linear controlled SDE admits a unique solution which is explicitly given in Corollary 3.1. Of course, we can apply the Ito formula to such solutions. Thus relation (3.13) remains valid.

(ii) To show property (3.14) note that the diffusion coefficient of the linear controlled SDE is $\Sigma(t, y, v) = y(B_1(t)v + B_2(t))$. As in Fleming and Soner (1993), we look at a bounded set $\mathcal{O}$ and obtain the following estimate for an admissible control $u(\cdot)$:

$$\begin{aligned}\int_{t_0}^{t_1} |\Sigma(s, Y(s), u(s))|^2 \, ds &= \int_{t_0}^{t_1} |Y(s)(B_1(s)u(s) + B_2(s))|^2 \, ds \\ &\le \sup_{s\in[t,t_1]} |Y(s)|^2 \int_{t_0}^{t_1} (|B_1(s)u(s)| + |B_2(s)|)^2 \, ds \\ &\le 2\,\mathrm{diam}(\mathcal{O}) \int_{t_0}^{t_1} |B_1(s)u(s)|^2 + |B_2(s)|^2 \, ds \\ &\le 2\,\mathrm{diam}(\mathcal{O}) \int_{t_0}^{t_1} |B_1(s)|^4 + |u(s)|^4 + |B_2(s)|^2 \, ds.\end{aligned}$$

Here we have made multiple uses of $2|vw| \le v^2 + w^2$ for $v, w \in \mathbb{R}$. Due to property (ii) of an admissible control and the integrability conditions of the coefficients of the linear controlled SDE, we obtain

$$\mathrm{E}^{t,y}\left(\int_t^\theta |G_y(s, Y(s)) \cdot \Sigma(s, Y(s), u(s))|^2 \, ds\right) < \infty$$

and thus (3.14).

(iii) Condition (3.12) implies uniform integrability of $\{G(\theta_p, Y(\theta_p))\}_p$. □

ON THE BOUNDED SLOPE CONDITION AND THE VALIDITY OF THE EULER LAGRANGE EQUATION*

ARRIGO CELLINA†

Abstract. Under the bounded slope condition on the boundary values of a minimization problem for a functional of the gradient of u, we show that a continuous minimizer w is, in fact, Lipschitzian. An application of this result to prove the validity of the Euler Lagrange equation for w is presented.

Key words. bounded slope condition, weak maximum principle, Euler Lagrange equation

AMS subject classification. 49K20

1. Introduction. The bounded slope condition was introduced by Hartman and Nirenberg [5] and, in a variational context, by Stampacchia [9], with the purpose of obtaining pointwise bounds a.e. on the norm of the gradient $\nabla u(x)$ of a solution u to a minimum problem of the form

$$(P) \qquad \text{minimize} \int_\Omega f(\nabla u(x))\,dx \quad \text{on} \quad u - u^0 \in W_0^{1,1}(\Omega).$$

The purpose of this paper is to extend the applicability of this condition and to use the result so obtained to prove the validity of the Euler Lagrange equation for the minimizer, without assuming growth conditions from above for the integrand f. More precisely, our Theorem 4.1 below extends Stampacchia's theorem to a wider class of integrands f, while requiring less regularity on the solutions. Stampacchia's result is based on the a priori assumption that the solution is Lipschitzian, and it yields an estimate on the value of the Lipschitz constant. Our result requires that the solution be continuous, and it derives that it is, in fact, Lipschitzian. This step demands a different proof: Stampacchia's proof was based on the fact that the minimizer satisfies the Euler Lagrange equation; however, without the a priori assumption of Lipschitzianity, proving the validity of the Euler Lagrange equation under the conditions on f required by Stampacchia's theorem is still an open and challenging problem. As a consequence of our Theorem 4.1, we provide in Theorem 4.7 a result on the validity of the Euler Lagrange equation for the minimizer that does not require, as do those commonly used in the literature, growth assumptions *from above* on the integrand f.

For the proof of Theorem 4.1 we use the method of translations. This method has been used in contexts similar to the one here by, e.g., Brezis and Stampacchia [2], Brezis and Sibony [1], and, more recently, Treu and Vornicescu [10]. In all of the above papers the functional considered is

$$\int_\Omega [f(\nabla u(x)) + g(u(x))]\,dx,$$

and the argument used depends on g being strictly monotone; i.e., the case $g = 0$ is excluded. In the proof presented here, we develop an argument that allows us to

extend the method of translations to the case $g = 0$, the case of interest in this paper. Theorem 4.2 below, instrumental to the proof of our main result, is a weak maximum principle under rather general assumptions on f.

2. Notations and preliminary results. The closed ball of radius ρ about the origin is B_ρ. The subgradient of a convex function f is denoted by ∂f and its domain by $Dom(\partial f)$. The closure of its domain, $cl(Dom(\partial f))$, is a convex set [8]. A (possibly extended valued) convex function f is called *strictly convex* if it is strictly convex on its effective domain. A *face* of a convex set is a convex extremal subset. The collection of the relative interiors of the faces of a convex set is a partition of the convex set. We say that a set Ω has the *segment property* if, given $x^0 \in \partial\Omega$, there exist a neighborhood U^0 containing x^0 and a nonzero vector k such that $x + tk \in \Omega$ whenever $x \in \overline{\Omega} \cap U^0$ and $t \in (0, 1]$. Every convex set has the segment property. Let Ω be bounded and open. We say that $u \in W^{1,1}(\Omega)$ satisfies $u \leq 0$ on $\partial\Omega$ in the sense of $W^{1,1}(\Omega)$ if $u^+ \in W_0^{1,1}(\Omega)$.

3. The bounded slope condition $(BSC)_K$.

DEFINITION 3.1. *Let K be a positive real, Ω a bounded convex set. The boundary datum u^0 satisfies $(BSC)_K$ if for every $x^0 \in \partial\Omega$ there exist vectors $k^+(x^0)$ and $k^-(x^0)$, $\|k^+(x^0)\| \leq K, \|k^-(x^0)\| \leq K$, such that for every $x \in \partial\Omega$ we have*

$$u^0(x) - u^0(x^0) \leq \langle k^+(x^0), x - x^0 \rangle$$

and

$$u^0(x) - u^0(x^0) \geq \langle k^-(x^0), x - x^0 \rangle.$$

The validity of $(BSC)_K$ for some K depends on the smoothness of $\partial\Omega$ and of u^0, as can be seen from the classical results of Miranda [7] and of Hartman [6].

Following Stampacchia, let us call an integrand f *regular* if $f \in C^2(\Re^N)$ and the $N \times N$ matrix of partial derivatives is positive definite at every point. Stampacchia's theorem [9] is as follows.

THEOREM 3.2. *Let f be a regular integrand. Let $u(x)$ be a minimizing function for problem (P) among all Lipschitz functions which have the same boundary values $u^0(x)$ satisfying $(BSC)_K$. If, moreover, $u \in C^1(\Omega) \cap H^2(\Omega)$, then*

$$\max_{x \in \overline{\Omega}} |u_{x_i}| \leq K.$$

4. Main results. It is our purpose to prove the following theorem, our main result.

THEOREM 4.1. *Let Ω be open, bounded, and convex; let f be a (possibly extended valued) lower semicontinuous strictly convex function. Let $u^0 : \Omega \to \Re$ be Lipschitzian and let it satisfy $(BSC)_K$. Let w in $C(\Omega) \cap W^{1,1}(\Omega)$ be a solution to problem (P):*

$$\text{minimize} \int_\Omega f(\nabla u(x))\, dx \,:\, u - u^0 \in W_0^{1,1}(\Omega).$$

Then w is Lipschitzian and, for almost every x in Ω, $\|\nabla w(x)\| \leq K$.

Under the conditions of Stampacchia's theorem on f and Ω and assuming that the boundary datum satisfies $(BSC)_K$, the fact that the solution is *Lipschiztian* implies that the Lipschitz constant of the solution is K. Our Theorem 4.1 says that under the conditions of Theorem 4.1 on f and Ω and assuming that the boundary datum satisfies

$(BSC)_K$ for *some* constant K, knowing that the solution is *continuous* implies that the solution is *Lipschitzian*.

The following theorem is a generalized version of the weak maximum principle, to be used in the proof of Theorem 4.1.

THEOREM 4.2. *Let Ω in $\Re^N$ be open and bounded with the segment property; let f be a (possibly extended valued) lower semicontinuous, convex function. Let $u^0(x)$ in $W^{1,1}(\Omega)$ and $\ell(x) = \langle a, x\rangle + b$ be given such that in $\partial\Omega$, $u^0(x) \le \ell(x)$ in the sense of $W^{1,1}(\Omega)$. If the infimum in problem (P) is finite and attained by some function w, then the inequality*

$$w(x) \le \ell(x) \quad \text{for almost every } x \in \Omega$$

follows from either (i) *or* (ii) *below:*

(i) $a \notin Int(Dom(\partial f))$.

(ii) $a \in Int(Dom(\partial f))$ *and the face of $epi(f)$ whose relative interior contains $(a, f(a))$ has dimension less than N.*

(The latter condition is immediate when f is strictly convex.)

Remark. Let f be the indicator function of the unit disk $D \subset \Re^2$; i.e., $f(\xi) = 0$ when $\|\xi\| \le 1, f(\xi) = +\infty$ otherwise. Let $\overline{\Omega}$ be D and u^0 be $= 0$. Finally, let $\ell(x) = 0$. Then $a = 0 \in Int(Dom(f))$ and for $\|x\| = 1$, $\ell(x) \ge u^0(x)$. However, the function $w : \Omega \to \Re$ defined by $w(x) = 1 - \|x\|$, for which $\|\nabla w\| = 1$ a.e. in Ω, is a solution to the minimization problem (P) for the given f and u^0, but it is not true that $\ell(x) \ge w(x)$ a.e. in Ω. The face of $epi(f)$ containing $(0, 0)$ in its relative interior is of dimension $N = 2$.

For the proof of Theorem 4.2 we shall need the following lemma.

LEMMA 4.3. *Let f, Ω, $u^0(x)$, and ℓ be as in Theorem* 4.2. *Let $w - u^0$ be in $W_0^{1,1}(\Omega)$. Let $E^+ = \{x \in \Omega : w(x) > \ell(x)\}$. Then, for every $l \in \Re^N$,*

$$\int_{E^+} \langle l, \nabla w(x) - a\rangle \, dx = 0.$$

Proof. Since $u^0(x) \le \ell(x)$ on $\partial\Omega$ in the sense of $W^{1,1}(\Omega)$, we have

$$0 \le (w - \ell)^+ = [(u^0 - \ell) + (w - u^0)]^+ \le (u^0 - \ell)^+ + (w - u^0)^+,$$

so that $(w - \ell)^+ \in W_0^{1,1}(\Omega)$, i.e., $(w - \ell) \le 0$ on $\partial\Omega$ in the sense of $W^{1,1}(\Omega)$. Hence [11, Lemma 1.59] there exists a sequence (ψ_n), $\psi_n \in C^\infty(\overline{\Omega})$ and $\psi_n(x) \ge 0$ for x in $\partial\Omega$, converging to $(\ell - w)$ in $W^{1,1}(\Omega)$. Let $w_n = \ell - \psi_n$ and assume we have selected a subsequence of the sequence (w_n) converging to w pointwise as well as in $W^{1,1}(\Omega)$. Let $E^- = \{x \in \Omega : w(x) < \ell(x)\}$, $E_0 = \{x \in \Omega : w(x) = \ell(x)\}$, $E_n = \{x \in \Omega : w_n(x) - \ell(x) > 0\}$. Then $\chi_{E_n}(x) \to 1$ for almost every x in E^+, and $\chi_{E_n}(x) \to 0$ for almost every x in E^-.

We have

$$\int_{E^+} \langle l, \nabla w(x) - a\rangle \, dx = \int_\Omega \langle l, \nabla w(x) - a\rangle \chi_{E_n} \, dx + \int_\Omega \langle l, \nabla w(x) - a\rangle (\chi_{E^+} - \chi_{E_n}) \, dx.$$

The last integral is the sum of the same integral over E^+, over E^-, and over E^0. The first two integrals tend to zero from an application of the dominated convergence theorem; the third is zero since, on E^0, $\nabla w(x) = a$ a.e. Hence

$$\int_\Omega \langle l, \nabla w(x) - a\rangle (\chi_{E^+} - \chi_{E_n}) \, dx \to 0.$$

Moreover,

$$\int_\Omega \langle l, \nabla w(x) - a\rangle \chi_{E_n}\, dx = \int_{E_n} \langle l, \nabla w_n(x) - a\rangle\, dx + \int_{E_n} \langle l, \nabla w(x) - \nabla w_n(x)\rangle\, dx.$$

The second integral tends to zero since $w_n \to w$ in $W^{1,1}(\Omega)$. To prove the lemma it suffices to show that $\int_{E_n} \langle l, \nabla w_n(x) - a\rangle\, dx = 0$.

Let $\mathbf{l} = l/\|l\|$. Let P^l be the plane through the origin orthogonal to $\mathbf{l}$, O^l the projection of Ω on P^l, and $L^l(x'), x' \in O^l$, the line $\{x' + \mathbf{l}\tau; \tau \in \Re\}$. The intersection of a line $L^l(x')$ with the open set E_n can be described as $\{x' + \mathbf{l}\tau : \tau \in \cup_i(\alpha_i(x'), \beta_i(x'))\}$, where some or all of the points of $x' + \mathbf{l}\alpha_i(x')$ and of $x' + \mathbf{l}\beta_i(x')$ can belong to $\partial\Omega$. Then

$$int_{E_n} \langle l, \nabla w_n(x) - a\rangle\, dx = \int_{O^l} \left(\int_{E_n \cap L^l(x')} \langle l, \nabla w_n(x' + \mathbf{l}\tau) - a\rangle\, d\tau \right) dx'$$

$$= \int_{O^l} \left(\Sigma_i \int_{\alpha_i(x')}^{\beta_i(x')} \langle l, \nabla w(x' + \mathbf{l}\tau) - a\rangle\, d\tau \right)\, dx'.$$

We have

$$\int_{\alpha_i(x')}^{\beta_i(x')} \langle l, \nabla w_n(x' + \mathbf{l}\tau) - a\rangle\, d\tau = \int_{\alpha_i(x')}^{\beta_i(x')} \|l\| \frac{d}{d\tau}[w_n(x' + \mathbf{l}\tau) - \ell(x' + \mathbf{l}\tau)] d\tau$$

$$= \|l\|\{[w_n(x' + \mathbf{l}\beta_i(x')) - \ell(x' + \mathbf{l}\beta_i(x'))] - [w_n(x' + \mathbf{l}\alpha_i(x')) - \ell(x' + \mathbf{l}\alpha_i(x'))]\}.$$

For each i, when $x' + \mathbf{l}\alpha_i(x')$ is in Ω, w_n and ℓ coincide, and the same is true for $x' + \mathbf{l}\beta_i(x')$. Since at $\partial\Omega$, $w_n(x) \le \ell(x)$ for all $x' + \mathbf{l}\alpha_i(x')$ while $x' + \mathbf{l}\alpha_i(x')$ is the limit of points where $w_n(x) > \ell(x)$, and the same is true for $x' + \mathbf{l}\beta_i(x')$, we have that the last integral is zero. This ends the proof that $\int_{E^+} \langle l, \nabla w(x) - a\rangle\, dx = 0$. □

Proof of Theorem 4.2. We wish to prove that E^+ has measure zero. We assume that it is not so and will show that this leads to a contradiction in either case (i) or (ii).

We must have that $\nabla w(x)$ is a.e. in $Dom(f)$, hence in $cl(Dom(\partial f))$; otherwise the integral would not be finite.

(a) Assume (i), i.e., $a \notin Int(Dom(\partial f))$. Then a can be separated by a hyperplane from the convex and closed set $cl(Dom(\partial f))$, i.e., there exists $h \neq 0$ such that $\langle h, a\rangle \ge \sup_{d \in Dom(\partial f)} \langle h, d\rangle$. Hence for almost every $x \in \Omega$, in particular for almost every $x \in E^+$, we have the following inequality:

$$\langle h, \nabla w(x) - a\rangle \le 0.$$

The proof of case (i) continues in step (e) below.

(b) Assume (ii). Fix k in $\partial f(a)$. Let $\eta^+ = (w - \ell)^+$; since

$$0 \le (w - \ell)^+ = (w - u^0 + u^0\ell)^+ \le (w - u^0)^+ (u^0 - \ell)^+,$$

and both maps at the right-hand side are in $W_0^{1,1}(\Omega)$, so is $(w-\ell)^+$. We thus have

$$(w-\eta^+)(x) = \begin{cases} w(x) & \text{if } w(x) \le \ell(x), \\ \ell(x) & \text{otherwise,} \end{cases}$$

$$\nabla(w-\eta^+)(x) = \begin{cases} \nabla w(x) & \text{if } w(x) \le \ell(x), \\ a & \text{otherwise.} \end{cases}$$

Hence, by the convexity of f and applying Lemma 4.3, we obtain

$$\int_\Omega (f(\nabla w(x)) - f(\nabla(w-\eta^+)(x)))\,dx = \int_{E^+} (f(\nabla w(x)) - f(a))\,dx$$

$$\ge \int_{E^+} \langle k, \nabla w(x) - a\rangle\,dx = 0.$$

(c) Since w is a minimizer, we also have

$$0 \ge \int_\Omega (f(\nabla w(x)) - f(\nabla(w-\eta^+)(x)) = \int_{E^+} (f(\nabla w(x)) - f(a))\,dx \ge 0;$$

hence, from the conclusion of (b),

$$\int_{E^+} \{f(\nabla w(x)) - [f(a) + \langle k, \nabla w(x) - a\rangle]\}dx = 0.$$

The integrand above is nonnegative, so we obtain that, a.e. in E^+, $f(\nabla w(x)) = f(a) + \langle k, \nabla w(x) - a\rangle$, i.e., the $N+1$-dimensional vector $(f(\nabla w(x)), \nabla w(x))$ belongs, for almost every x, to H, the intersection of the epigraph of f with the hyperplane $z = f(a) + \langle k, \xi - a\rangle$. H is a face of $epi(f)$: it is either of dimension less than N or its dimension is N. Let $H^N = \{\xi : f(\xi) = f(a) + \langle k, \xi - a\rangle\}$ be its projection on $\Re^N$.

(d) By assumption, the face of $epi(f)$, containing $(a, f(a))$ in its relative interior, has dimension less than N, and so does F_a^N, its projection on $\Re^N$. F_a^N is a face of H^N: there is a (nonzero) N-vector τ that properly separates F_a^N from H^N, $\langle \tau, \xi - a\rangle = 0$, $\xi \in F_a^N$, $\langle \tau, \xi - a\rangle \le 0$, $\xi \in H^N$, and there is some $z \in (H^N \setminus F_a^N)$ such that $\langle \tau, z - a\rangle < 0$. Hence, for $\xi \in H^N$,

$$f(\xi) \ge f(a) + \langle k, \xi - a\rangle \ge f(a) + \langle k + \tau, \xi - a\rangle.$$

Since, for $x \in E^+$, we have $\nabla w(x) \in H^N$, in particular we have, for $x \in E^+$,

$$f(\nabla w(x)) \ge f(a) + \langle k + \tau, \nabla w(x) - a\rangle.$$

Again, since w is a minimizer, we have

$$0 \ge \int_\Omega (f(\nabla w(x)) - f((\nabla(w-\eta^+)(x))) = \int_{E^+} (f(\nabla w(x)) - f(a))\,dx$$

$$\ge \int_{E^+} \langle k + \tau, \nabla w(x) - a\rangle\,dx = 0,$$

where the last equality follows from Lemma 4.3. Hence

$$\int_{E^+} \{f(\nabla w(x)) - [f(a) + \langle k + \tau, \nabla w(x) - a\rangle]\}dx = 0,$$

and, since $f(\nabla w(x)) \geq f(a)+\langle k+\tau, \nabla w(x)-a\rangle$ a.e. in E^+, it follows that $f(\nabla w(x)) = f(a) + \langle k + \tau, \nabla w(x) - a\rangle$. From the conclusion of (c) we obtain that, a.e. in E^+,

$$\langle \tau, \nabla w(x) - a\rangle = 0.$$

(e) By the conclusion of (a) in case (i) and by the above construction in case (ii), there is a nonzero N-dimensional vector, $k^\perp$, such that $\langle k^\perp, \nabla w(x) - a\rangle \leq 0$ a.e. in E^+. Choose a line $\{x' + k^\perp t\}$ intersecting E^+ on a set of positive measure and such that $t \to w(x' + ht)$ is absolutely continuous. Let $T^+ = \{t : x' + ht \in E^+\}$ and let t^+ be in T^+, i.e., such that for $x^+ = x' + k^\perp t^+$, $\eta^+(x^+)$ is positive. Since the gradient of η^+ is

$$\nabla \eta^+(x) = \begin{cases} 0 & \text{on } \Omega \setminus E^+, \\ \nabla w(x) - a & \text{otherwise,} \end{cases}$$

we have

$$0 < (w - \ell)^+(x' + t^+h) = \int_{-\infty}^{t^+} \left(\frac{d}{dt}(w - \ell)^+(x' + th)\right) dt$$

$$= \int_{(-\infty, t^+]\cap T^+} \langle h, \nabla w(x' + th) - a\rangle \, dt$$

$$\leq \int_{(-\infty, t^+]\cap T^+} \left(\sup_{d \in Dom(\partial f)} \{\langle h, d - a\rangle\}\right) dt \leq 0,$$

a contradiction. So E^+ has measure zero. □

For the proof of Theorem 4.1 we shall need the following preliminary results.

LEMMA 4.4. *Let $\Omega^i, i = 1, 2$, be open and let g^i be in $W_0^{1,1}(\Omega^i)$ and such that for almost every x in Ω^i, $g^i(x) \geq 0$. Then* $\min(g^1(x), g^2(x)) \in W_0^{1,1}(\Omega^1 \cap \Omega^2)$.

Proof. Let $g_n^i : \Omega^i \to \Re, i = 1, 2$, be two sequences of Lipschitzian maps with compact support in Ω^i, g_n^i converging to g^i in $W_0^{1,1}(\Omega^i)$ and pointwise a.e. Set $G(x) = \min(g^1(x), g^2(x))$, $E^1 = \{x \in (\Omega^1 \cap \Omega^2) : g^1(x) < g^2(x)\}$, $E^2 = \{x \in (\Omega^1 \cap \Omega^2) : g^2(x) < g^1(x)\}$, $E^0 = \{x \in (\Omega^1 \cap \Omega^2) : g^1(x) = g^2(x)\}$; set also $G_n(x) = \min((g_n^1(x), g_n^2(x))$: the maps G_n are Lipschitzian with compact support contained in $(\Omega^1 \cap \Omega^2)$. One has

$$\int_{\Omega^1\cap\Omega^2} |G - G_n| = \int_{E^1} |G - G_n| + \int_{E^2} |G - G_n| + \int_{E^0} |G - G_n|.$$

To evaluate the first integral, set $E_n^{1,1} = E^1 \cap \{x : g_n^1 < g_n^2\}, E_n^{1,2} = E^1 \cap \{x : g_n^2 < g_n^1\}, E_n^{1,0} = E^1 \cap \{x : g_n^1 = g_n^2\}$. Then

$$\int_{E^1} |G - G_n| = \int_{E_n^{1,1}} |g^1 - g_n^1| + \int_{E_n^{1,0}} |g^1 - g_n^1| + \int_{E_n^{1,2}} |g^1 - g_n^2|,$$

and the first two integrals converge to zero since $g_n^1 \to g^1$ in $W^{1,1}(\Omega^1)$. Also, g_n^2 converges pointwise to g^2; hence $\chi_{E_n^{1,2}} \to 0$ pointwise a.e. The sequence $(|g^1 - g_n^2|)$ is equiintegrable, since g_n^2 converges in $L^1(\Omega^2)$; by Egoroff's theorem $\int_{E_n^{1,2}} |g^1 - g_n^2| \to 0$. Similarly for the other cases and for $\int_{\Omega^1\cap\Omega^2} \|\nabla G - \nabla G_n\|$. □

LEMMA 4.5. *Let f be strictly convex on its effective domain. For every pair (a, b) in its effective domain, $a \neq b$, for every $\lambda, 0 < \lambda < 1$, we have*

$$f(a + \lambda(b-a)) - f(a) + f(b - \lambda(b-a)) - f(b) < 0.$$

Proof. Consider the restriction of f to the line oriented from a to b. Under the conditions of the Lemma, the map $c \to \frac{f(c+\lambda(b-a))-f(c)}{\lambda(b-a)}$ is strictly monotonic. □

Proof of Theorem 4.1. It is convenient to set $\Psi^+(x) = \inf_{x^0 \in \partial\Omega} \langle k^+(x^0), x - x^0\rangle + u^0(x^0)$ and $\Psi^-(x) = \sup_{x^0 \in \partial\Omega} \langle k^-(x^0), x - x^0\rangle + u^0(x^0)$; the maps Ψ^+ and Ψ^- are Lipschitzian with Lipschitz constant K. Applying Theorem 4.2 to each of the affine maps $\langle k^+(x^0), x - x^0\rangle + u^0(x^0)$, we infer that the solution w satisfies $w \leq \Psi^+$. Applying the same theorem to the problem $\tilde{P}$ whose data are $\tilde{f}(\xi) = f(-\xi)$ and $\tilde{u}^0 = -u^0$, we obtain $\Psi^- \leq w$.

To prove the theorem it is enough to show that there cannot exist a unit vector $\mathbf{v}$, a scalar $M > K$, and a set $E \subset \Omega$ with $\mu(E) > 0$ such that, for x in E, $\langle \nabla w(x), \mathbf{v}\rangle > M$. Let us assume that $M, \mathbf{v}, E$ exist and derive a contradiction.

(a) There exists a representative of w that is absolutely continuous on almost every line parallel to $\mathbf{v}$. Since it coincides with w a.e. in Ω, on almost every such line $\{x = t\mathbf{v} + a : t \in \Re\}$, it coincides with w for almost every t; by continuity, they coincide for all t on every such line. Hence w is absolutely continuous on almost every line parallel to $\mathbf{v}$. On a plane orthogonal to $\mathbf{v}$ there exists a set of points of positive $(N-1)$ measure, such that lines parallel to $\mathbf{v}$ through these points meet E in a set of positive one-dimensional measure. Let us fix one such line; let x^* be a point on it that is at once in E and such that the map $t \to w(x^* + t\mathbf{v})$ is differentiable at $t = 0$ with derivative

$$\frac{d}{dt}[w(x^* + t\mathbf{v})]|_{t=0} = \langle \nabla w(x^*), \mathbf{v}\rangle = M + \zeta, \qquad \zeta > 0.$$

Then there exists $h^* > 0$ such that for every $0 < h \leq h^*$

$$w(x^* + h\mathbf{v}) - w(x^*) - Mh > 0.$$

(b) We wish to prove the following claim. Let x^{**} be a point in Ω such that $t \to w(x^{**} + t\mathbf{v})$ is differentiable at $t = 0$ with derivative $D^{**} > M$, and let $h^{**} > 0$ be such that for every $0 < h \leq h^{**}$, $x^{**} + h\mathbf{v}$ is in Ω and

$$w(x^{**} + h\mathbf{v}) - w(x^{**}) - Mh > 0.$$

Then $t \to w(x^{**} + t\mathbf{v})$ is affine on $[0, h^{**}]$ with derivative D^{**}.

Proof of the claim. Fix any $h \in (0, h^{**}]$. On the convex set $\Omega_h = \Omega \cap (\Omega - h\mathbf{v})$ both $x \to w(x)$ and $x \to w(x + h\mathbf{v})$ are defined. By assumption, the set

$$E_h^+ = \{x \in \Omega_h; w(x + h\mathbf{v}) > w(x) + hM\}$$

is an open subset of Ω_h containing x^{**}. For $x \in E_h^+$, we have that $y = x + h\mathbf{v}$ is such that $y - h\mathbf{v}$ is in Ω and $w(y - h\mathbf{v}) < w(y) - hM$. The set

$$E_h^- = \{y \in \Omega_{-h}; w(y - h\mathbf{v}) < w(y) - hM\}$$

is a translate of $E_h^+ : E_h^- - h\mathbf{v} = E_h^+$. Let $\eta_h^+(x)$ on Ω_h be $(w(x+h\mathbf{v}) - w(x) - hM)^+$ and $\eta_h^-(x)$ on Ω_{-h} be $(w(x - h\mathbf{v}) - w(x) + hM)^-$. We wish to show that η_h^+ and η_h^-

are admissible variations, i.e., that they are in $W_0^{1,1}(\Omega)$. From the Lipschitzianity of Ψ^+ and of Ψ^- we obtain

$$\eta^+(x) \le \Psi^+(x+h\mathbf{v}) - Mh - w(x) \le \Psi^+(x) - w(x),$$

$$\eta^+(x) \le w(x+h\mathbf{v}) - Mh - \Psi^-(x+h\mathbf{v}) + Kh \le w(x+h\mathbf{v}) - \Psi^-(x+h\mathbf{v});$$

i.e., $\eta_h^+ \le \min(\Psi^+(x) - w(x), w(x+h\mathbf{v}) - \Psi^-(x+h\mathbf{v}))$.

Apply Lemma 4.4 with $\Omega^1 = \Omega, \Omega^2 = \Omega_h, g^1(x) = \Psi^+(x) - w(x), g^2(x) = w(x+h\mathbf{v}) - \Psi^-(x+h\mathbf{v})$ to infer that η_h^+ is an admissible variation, and the same is true for η_h^-. Since w is a minimum, we must have that for all λ

$$\int_\Omega f(\nabla w(x) + \lambda \nabla \eta_h^+(x))\, dx \ge \int_\Omega f(\nabla w(x))\, dx,$$

$$\int_\Omega f(\nabla w(x) + \lambda \nabla \eta_h^-(x))\, dx \ge \int_\Omega f(\nabla w(x))\, dx.$$

We have

$$\nabla \eta_h^+ = \begin{cases} \nabla w(x+h\mathbf{v}) - \nabla w(x) & \text{if } x \in E_h^+, \\ 0 & \text{otherwise,} \end{cases}$$

and

$$\nabla \eta_h^- = \begin{cases} \nabla w(x-h\mathbf{v}) - \nabla w(x) & \text{if } x \in E_h^-, \\ 0 & \text{otherwise,} \end{cases}$$

so that the above inequalities yield

$$\int_{E_h^+} f(\nabla w(x) + \lambda[\nabla w(x+h\mathbf{v}) - \nabla w(x)]) - f(\nabla w(x))\, dx \ge 0,$$

$$\int_{E_h^-} f(\nabla w(x) + \lambda[\nabla w(x-h\mathbf{v}) - \nabla w(x)]) - f(\nabla w(x))\, dx \ge 0.$$

Making the change of variables $y = x + h\mathbf{v}$ and adding the two inequalities, one obtains

$$\int_{E_h^+} \{f(\nabla w(x) + \lambda[\nabla w(x+h\mathbf{v}) - \nabla w(x)]) - f(\nabla w(x)) + f(\nabla w(x+h\mathbf{v})$$

$$-\lambda[\nabla w(x+h\mathbf{v}) - \nabla w(x)]) - f(\nabla w(x+h\mathbf{v}))\}\, dx \ge 0.$$

From Lemma 4.5 we obtain that, for every x such that $\nabla w(x) \ne \nabla w(x+h\mathbf{v})$, the integrand is negative. Since E_h^+ is a nonempty open set, this is a contradiction unless, a.e. in E_h^+, $\nabla w(x) = \nabla w(x+h\mathbf{v})$.

The set E_h^+ contains a ball B_h about x^{**}; for x in this ball, $\nabla w(x) - \nabla w(x+h\mathbf{v}) = 0$ a.e. By the continuity of w, there exists a constant C such that, on $B_h, w(x) - w(x+h\mathbf{v}) = C$. Then, since the limit

$$\lim_{t\to 0} \frac{1}{t}[w(x^{**} + t\mathbf{v}) - w(x^{**})]$$

exists and equals D^{**}, so does

$$\lim_{t\to 0}\frac{1}{t}[w(x^{**}+t\mathbf{v}+h\mathbf{v})-w(x^{**}+h\mathbf{v})].$$

In particular, the derivative at $t=0$ of the map $t\to w(x^*+h\mathbf{v}+t\mathbf{v})$ exists and equals D^{**}. This reasoning holds for every $0<h\le h^{**}$, thus proving the claim.

(c) The previous claim applies at x^*. Hence the map $t\to w(x^*+t\mathbf{v})$ is affine on $[0,h^*]$ with derivative $M+\zeta$. Let $[0,\Lambda]$ be the maximal interval on which this map is affine. We claim that $x^*+\Lambda\mathbf{v}$ is in $\partial\Omega$. If it is in Ω for some $\varepsilon>0$, then so is $x^*+(\Lambda+\tau)\mathbf{v}$ for $0\le\tau<\varepsilon$. Choose λ in $(0,\Lambda)$. The map $t\to w(x^*+t\mathbf{v})$ is differentiable at λ with derivative $\langle\nabla w(x),\mathbf{v}\rangle$. Moreover we have that $w(x^*+\Lambda\mathbf{v})-w(x^*+\lambda\mathbf{v})=(M+\zeta)(\Lambda-\lambda)$, i.e.,

$$w((x^*+\lambda\mathbf{v})+(\Lambda-\lambda)\mathbf{v})-w(x^*+\lambda\mathbf{v})-(\Lambda-\lambda)M=\zeta M.$$

Hence, by the continuity of w, for all $\tau\le\varepsilon_1<\varepsilon$,

$$w((x^*+\lambda\mathbf{v})+(\Lambda-\lambda+\tau)\mathbf{v})-w(x^*+\lambda\mathbf{v})-(\Lambda-\lambda+\tau)M>0.$$

The point $x^*+\lambda\mathbf{v}$ can be used as x^{**} with $h^{**}=(\Lambda-\lambda+\varepsilon_1)$. Applying the claim of part (b), we have that the map $t\to w(x^*+t\mathbf{v})$ is affine on $[0,\Lambda+\varepsilon_1]$, contradicting the maximality of Λ. Hence $x^*+\Lambda\mathbf{v}$ is in $\partial\Omega$.

(d) Let x^{***} be $x^*+\Lambda\mathbf{v}$; since u^0 is continuous, the conditions $u^0\le\ell$ and $u^0\ge\ell$ on $\partial\Omega$ in $W^{1,1}$ in sense and pointwise coincide. Thus, by Theorem 4.2, for every $x\in\Omega$ (in particular for x^*)

$$u^0(x^{***})+\langle k^-(x^{***}),x-x^{***}\rangle\le w(x)\le u^0(x^{***})+\langle k^+(x^{***}),x-x^{***}\rangle.$$

Hence, from point (c),

$$w(x^{***})=w(x^*)+\|x^*-x^{***}\|(M+\zeta)>w(x^*)-\langle k^-(x^{***}),x^*-x^{***}\rangle\ge u^0(x^{***}),$$

while, for every $x\in\Omega$,

$$w(x)\le u^0(x^{***})+\langle k^+(x^{***}),x-x^{***}\rangle.$$

The above inequalities are incompatible whenever $\|x-x^{***}\|$ is sufficiently small. This is a contradiction. □

COROLLARY 4.6. *Under the same assumptions on Ω, f, and u^0 as in Theorem 4.2, let solutions to problem (P) be continuous. Then problem (P) and problem $(P)_K$,*

$$\textit{minimize}\int_\Omega f(\nabla u(x))\,dx\quad\textit{on}\quad u-u^0\in W_0^{1,1}(\Omega)\ \textit{and}\ \|\nabla u(x)\|\le K,$$

are equivalent, in the sense that they have the same solutions.

Known results on the validity of the Euler Lagrange equation for a minimizer w hold under growth assumptions *from above* on f, i.e., under slow growth assumptions. (An exception to this statement is [4], whose results are for integrands f that tend to $+\infty$ at the boundary of $Dom(f)$, under conditions different from those presented here.)

THEOREM 4.7. *Let $f:\Re^N\to\Re$ be C^1, strictly convex, and such that for some α and $\beta>0$, $f(\xi)\ge\alpha+\beta\|\xi\|^p$, $p>N$. Let Ω be bounded and convex and let u^0*

satisfy $(BSC)_K$ *for some constant* K. *Let* w *be a solution to problem* (P). *Then* w *is Lipschitzian and it satisfies the Euler Lagrange equation in the sense that*

$$\int_\Omega \langle \nabla f(\nabla w(x)), \nabla \eta(x) \rangle \, dx = 0$$

for every Lipschitzian η, $\eta|_{\partial\emptyset} = 0$.

Proof. From the growth assumptions we know that $w \in W^{1,p}(\Omega)$; hence we know that it is continuous. Theorem 4.1 applies and $\|\nabla w(x)\| \leq K$ a.e. in Ω. Fix η and let λ be so small that $\lambda \|\nabla \eta\| \leq 1$. Let $M = \max_{\xi \in B_{K+1}} \{\|\nabla f(\xi)\|\}$. Since w is a minimum, one has

$$0 \leq \left(\frac{1}{\lambda}\right) \int (f(\nabla w + \lambda \nabla \eta) - f(\nabla w)) = \int \langle \nabla f(\nabla (w(x) + \sigma(x) \lambda \nabla \eta(x)), \nabla \eta(x) \rangle \, dx,$$

and the term under the integral sign, that converges pointwise to $\langle \nabla f(\nabla w(x)), \nabla \eta(x) \rangle$ as $\lambda \to 0$, is bounded in norm by M. Hence, applying the dominated convergence theorem, the result follows. □

OPTIMALITY CONDITIONS FOR IRREGULAR INEQUALITY-CONSTRAINED PROBLEMS*

A. F. IZMAILOV† AND M. V. SOLODOV‡

Abstract. We consider feasible sets given by conic constraints, where the cone defining the constraints is convex with nonempty interior. We study the case where the feasible set is not assumed to be regular in the classical sense of Robinson and obtain a constructive description of the tangent cone under a certain new second-order regularity condition. This condition contains classical regularity as a special case, while being weaker when constraints are twice differentiable. Assuming that the cone defining the constraints is finitely generated, we also derive a special form of primal-dual optimality conditions for the corresponding constrained optimization problem. Our results subsume optimality conditions for both the classical regular and second-order regular cases, while still being meaningful in the more general setting in the sense that the multiplier associated with the objective function is nonzero.

Key words. tangent cone, regularity, constraint qualification, optimality conditions

1. Introduction.

Let X and Y be normed linear spaces. We consider the sets given by

$$D = \{x \in X \mid F(x) \in K\}, \tag{1.1}$$

where the constraint mapping $F : X \to Y$ is smooth enough and K is a closed convex cone in Y with nonempty interior. The problem of an accurate and constructive description of the tangent cone to a set at a given point is fundamental for many reasons, one of which is deriving optimality conditions. Recall that a vector $h \in X$ is called *tangent* to a set $D \subset X$ at a point $\bar{x} \in D$ if there exists a mapping $r : \Re_+ \to X$ such that

$$\bar{x} + th + r(t) \in D \quad \forall\, t \in \Re_+, \quad \|r(t)\| = o(t). \tag{1.2}$$

The set of all such vectors h in X is the *tangent cone* to the set D at the point $\bar{x}$, which we shall denote by $T_D(\bar{x})$. As is well known,

$$T_D(\bar{x}) \subset \{h \in X \mid F'(\bar{x})h \in T_K(F(\bar{x}))\}, \tag{1.3}$$

which is the first-order necessary condition for tangency. To obtain a *precise* description of $T_D(\bar{x})$, i.e., a sufficient condition for tangency, some regularity (also called constraint qualification) condition is needed. One classical condition in this setting is Robinson's condition [27]:

$$0 \in \operatorname{int}(F(\bar{x}) + \operatorname{Im} F'(\bar{x}) - K). \tag{1.4}$$

Note that in (1.4) cone K is not required to have a nonempty interior. If (1.4) is satisfied, then (1.3) holds as an equality, e.g., [12, Corollary 2.91]. Deriving an accurate constructive description of the tangent cone without assuming (1.4) and, more generally, when (1.3) does not necessarily hold as an equality, is one of the principal goals of this paper. Our approach is based on a certain new notion of second-order regularity, which in the setting of K with nonempty interior is weaker than (1.4); see Definition 2.1 and Remark 2.1. An immediate application of this description is the primal form of necessary optimality conditions for the problem

$$\min\{f(x) \mid x \in D\}, \tag{1.5}$$

where the objective function $f : X \to \Re$ is smooth enough.

Our second goal is to obtain primal-dual optimality conditions for the irregular case, with a nonzero multiplier associated to the objective function. If $\bar{x}$ is a local solution of (1.5), (1.1), then the classical F. John–type first-order necessary optimality conditions (e.g., see [11]) state that there exists a generalized Lagrange multiplier $(y_0, y^*) \in (\Re \times Y^*) \setminus \{0\}$ such that

$$\begin{aligned} &y_0 f'(\bar{x}) - (F'(\bar{x}))^* y^* = 0, \\ &F(\bar{x}) \in K,\ y^* \in K^*,\ \langle y^*, F(\bar{x})\rangle = 0,\ y_0 \geq 0, \end{aligned} \tag{1.6}$$

where Y^* is the dual space of Y, $(F'(\bar{x}))^*$ is the adjoint operator of $F'(\bar{x})$, and K^* is the dual cone of K. If $y_0 = 0$, the F. John conditions hold trivially independently of the objective function and therefore their utility for describing optimality in that case is very limited (at least without some further developments). Assumptions that guarantee the existence of a multiplier (y_0, y^*) with $y_0 \neq 0$ are again constraint qualification conditions, such as (1.4). For problems with a finitely generated cone K, without assuming (1.4) or equality in (1.3), we obtain a special form of primal-dual optimality conditions under our assumption of second-order regularity. Our optimality conditions resemble the structure of (1.6), where $y_0 \neq 0$ and a certain term involving the second derivative of F is added to the standard Lagrangian; see Theorem 3.2. Our optimality conditions subsume those for the classical regular case of (1.4), as well as those for the more general second-order regular case of [7, 8]; see section 4.

In section 4, we compare our results with other approaches relevant for irregular inequality-constrained problems. We also provide an example showing that our results can be used to verify optimality in cases where other known approaches appear not to be applicable. We note that those cases do not seem pathological or exotic; see Example 4.1.

Finally, we note that in the case of the nonlinear programming problem, i.e., when $Y = \Re^m \times \Re^s$ and $K = \Re^m_- \times \{0\}$, Robinson's regularity condition (1.4) reduces to the classical Mangasarian–Fromovitz constraint qualification [23], and with $y_0 \neq 0$ optimality conditions (1.6) become the classical Karush–Kuhn–Tucker conditions.

Our notation is fairly standard. If Σ is a topological linear space, then Σ^* denotes its (topologically) dual space and $\langle\cdot, \cdot\rangle$ is the pairing of elements in Σ^* and Σ, i.e., $\langle\sigma^*, \sigma\rangle$ is the value of the linear functional $\sigma^* \in \Sigma^*$ on $\sigma \in \Sigma$. For a cone C in Σ, the positive dual cone (sometimes also referred to as the polar cone) of C is $C^* := \{\sigma^* \in \Sigma^* \mid \langle\sigma^*, \sigma\rangle \geq 0 \quad \forall\, \sigma \in C\}$. For an arbitrary set Ω in Σ, the set orthogonal to Ω is $\Omega^\perp := \{\sigma^* \in \Sigma^* \mid \langle\sigma^*, \sigma\rangle = 0 \quad \forall\, \sigma \in \Omega\}$. If Υ and Σ are topological linear spaces and $\Lambda : \Upsilon \to \Sigma$ is a continuous linear operator, then $\Lambda^* : \Sigma^* \to \Upsilon^*$ denotes the adjoint operator of Λ. The interior and the closure of a set Ω (in appropriate topology) are denoted by $\operatorname{int}\Omega$ and $\operatorname{cl}\Omega$, respectively, and linear and

conic hulls of this set (in appropriate linear space) by $\operatorname{lin}\Omega$ and $\operatorname{cone}\Omega$, respectively. A cone C in a linear space Σ is referred to as finitely generated if either it is empty or there exists a positive integer s and some elements $\sigma^i \in \Sigma$, $i = 1, \ldots, s$, such that $\operatorname{cl} C = \operatorname{cone}\{\sigma^1, \ldots, \sigma^s\} \cup \{0\}$. When we write that a mapping F is twice Fréchet-differentiable at a point $\bar{x}$, we mean that it is Fréchet-differentiable on a neighborhood of $\bar{x}$, and its derivative is Fréchet-differentiable at $\bar{x}$ (and similarly for higher-order Fréchet-differentiability).

Some auxiliary facts from convex analysis that are used throughout the paper are collected in the appendix.

2. Tangent cone description. As is well known [24], [12, Lemma 2.99], in our setting where $\operatorname{int} K \neq \emptyset$, Robinson's regularity condition (1.4) is equivalent to

$$\exists\, \bar{\xi} \in X \text{ such that } F(\bar{x}) + F'(\bar{x})\bar{\xi} \in \operatorname{int} K. \tag{2.1}$$

This condition implies that for $h \in T_D(\bar{x})$ the inclusion

$$F'(\bar{x})h \in T_K(F(\bar{x})) = \operatorname{cl}(K + \operatorname{lin}\{F(\bar{x})\}) \tag{2.2}$$

is both necessary and sufficient, e.g., [12, Corollary 2.91]. In the irregular case, $T_D(\bar{x})$ can be smaller than the set of $h \in X$ satisfying (2.2), and a more refined description is needed. To this end, it is natural to take into account the second-order information about F at $\bar{x}$. We proceed with a second-order characterization of the tangent cone, starting with the following definition.

DEFINITION 2.1. *We say that conic constraints in* (1.1) *are* second-order regular *at a feasible point* $\bar{x}$ with respect to a direction $h \in X$ *if*

$$\exists\, (\bar{\xi}, \bar{h}) \in X \times X \text{ such that } F(\bar{x}) + F'(\bar{x})\bar{h} \in K,$$
$$F(\bar{x}) + F'(\bar{x})\bar{\xi} + F''(\bar{x})[h, \bar{h}] \in \operatorname{int} K.$$

Remark 2.1. If Robinson's condition (2.1) is satisfied, then second-order regularity holds with respect to *every* $h \in X$, including $h = 0$. (To verify this, just choose $\bar{\xi}$ satisfying (2.1) and $\bar{h} = 0$.)

Observe further that Definition 2.1 is equivalent to saying that

$$\exists\, \bar{h} \in X \text{ such that } F'(\bar{x})\bar{h} \in T_K^r(F(\bar{x})) = K + \operatorname{lin}\{F(\bar{x})\}, \tag{2.3}$$
$$F''(\bar{x})[h, \bar{h}] \in \operatorname{int} K + \operatorname{lin}\{F(\bar{x})\} + \operatorname{Im} F'(\bar{x}), \tag{2.4}$$

where $T_K^r(y)$ stands for the so-called radial tangent cone to K at $y \in K$. This form of second-order regularity will be used in the subsequent analysis. We are now ready to state the main result of this section.

THEOREM 2.2. *Let X and Y be normed linear spaces and let K be a closed convex cone in Y with a nonempty interior. Let set D be given by* (1.1), *where $F : X \to Y$ is twice Fréchet-differentiable at a point $\bar{x} \in D$. Then the following statements hold.*

1. *Every $h \in T_D(\bar{x})$ satisfies* (2.2) *as well as the following condition:*

$$F''(\bar{x})[h]^2 \in \operatorname{cl}(K + \operatorname{lin}\{F(\bar{x})\} + \operatorname{Im} F'(\bar{x})). \tag{2.5}$$

2. *If $h \in X$ satisfies*

$$F'(\bar{x})h \in K + \operatorname{lin}\{F(\bar{x})\} \tag{2.6}$$

and (2.5), *and if constraints in* (1.1) *are second-order regular at $\bar{x}$ with respect to this h, then $h \in T_D(\bar{x})$.*

Proof. Take an arbitrary $h \in T_D(\bar{x})$. Relation (2.2) is standard, so we have to prove only (2.5). By twice differentiability of F, for every $t > 0$ we have that

$$\begin{aligned}\frac{1}{2}F''(\bar{x})[th]^2 &= F(\bar{x} + th + r(t)) - F(\bar{x}) - F'(\bar{x})(th + r(t)) \\ &\quad - \frac{1}{2}F''(\bar{x})[r(t)]^2 - F''(\bar{x})[th, r(t)] + \omega_2(t),\end{aligned}$$

where $\omega_2 : \Re_+ \to Y\,, \|\omega_2(t)\| = o(t^2)$. Observe that the first term in the right-hand side is in K due to (1.2), the second is in $\mathrm{lin}\{F(\bar{x})\}$, and the third is in $\mathrm{Im}F'(\bar{x})$. Dividing by t^2 and passing onto the limit as $t \to 0+$, we obtain (2.5).

Assume now that some $h \in X$ satisfies (2.6) and (2.5). Then there exist $y_1 \in K$ and $\lambda_1 \in \Re$ such that $F'(\bar{x})h = y_1 + \lambda_1 F(\bar{x})$. Consider first the case where

$$F''(\bar{x})[h]^2 \in \mathrm{int}\, K + \mathrm{lin}\{F(\bar{x})\} + \mathrm{Im}\, F'(\bar{x}), \tag{2.7}$$

so that there exist $y_2 \in \mathrm{int}\, K$, $\lambda_2 \in \Re$, and $x \in X$ such that $F''(\bar{x})[h]^2 = y_2 + \lambda_2 F(\bar{x}) + F'(\bar{x})x$. In that case, we obtain that

$$\begin{aligned}F\left(\bar{x} + th - \frac{t^2}{2}x\right) &= F(\bar{x}) + F'(\bar{x})\left(th - \frac{t^2}{2}x\right) \\ &\quad + \frac{1}{2}F''(\bar{x})\left[th - \frac{t^2}{2}x\right]^2 + \omega_2(t) \\ &= F(\bar{x}) + t(y_1 + \lambda_1 F(\bar{x})) - \frac{t^2}{2}F'(\bar{x})x \\ &\quad + \frac{t^2}{2}(y_2 + \lambda_2 F(\bar{x}) + F'(\bar{x})x) + \omega_2(t) \\ &= \left(1 + t\lambda_1 + \frac{t^2}{2}\lambda_2\right)F(\bar{x}) + ty_1 + \frac{t^2}{2}y_2 + \omega_2(t) \\ &\in \mathrm{int}\, K,\end{aligned}$$

where $\omega_2 : \Re_+ \to Y\,, \|\omega_2(t)\| = o(t^2)$, and the inclusion follows from Lemma A.5 for every $t > 0$ sufficiently small. In particular, we conclude that if (2.7) holds, then $h \in T_D(\bar{x})$.

If (2.7) does not hold, but there exists a sequence $\{h^k\} \subset X$ converging to h such that (2.7) is satisfied for every element of this sequence, then again $h \in T_D(\bar{x})$ by the closedness of $T_D(\bar{x})$. We proceed to explicitly construct the desired sequence $\{h^k\}$ under the hypothesis of the theorem that there exists an element $\bar{h} \in X$ for which (2.3), (2.4) are satisfied. Let us take $h^k = (1 - 1/k)h + \bar{h}/k$, $k = 1, 2, \ldots$. For each index k we then obtain

$$F'(\bar{x})h^k = \left(1 - \frac{1}{k}\right)F'(\bar{x})h + \frac{1}{k}F'(\bar{x})\bar{h} \in K + \mathrm{lin}\{F(\bar{x})\},$$

where the inclusion follows from (2.6), (2.3). We further obtain

$$\begin{aligned}F''(\bar{x})[h^k]^2 &= \left(1 - \frac{1}{k}\right)^2 F''(\bar{x})[h]^2 \\ &\quad + \frac{1}{k}\left(2\left(1 - \frac{1}{k}\right)F''(\bar{x})[h, \bar{h}] + \frac{1}{k}F''(\bar{x})[\bar{h}]^2\right) \\ &\in \mathrm{int}\, K + \mathrm{lin}\{F(\bar{x})\} + \mathrm{Im}\, F'(\bar{x}),\end{aligned}$$

where the inclusion holds for all k sufficiently large, due to (2.4), (2.5) and Lemmas A.2 and A.5. This construction completes the proof. □

In section 4, we compare this theorem (as well as the other results of this paper) with related facts and approaches to irregular inequality constraints and provide an illustrative example. Here, we note that in the regular case (1.4) implies that

$$K + \lin\{F(\bar{x})\} + \operatorname{Im} F'(\bar{x}) = Y, \tag{2.8}$$

and thus (2.5) holds trivially for every $h \in X$. This observation together with Remark 2.1 show that Theorem 2.2 subsumes (when K has nonempty interior) the classical result on the tangent cone in the regular case. In the irregular case, the right-hand side of (2.5) does not coincide with Y (again, in our setting of $\operatorname{int} K \neq \emptyset$), and therefore condition (2.5) is nontrivial.

Remark 2.2. If K is a finitely generated cone, then (2.6) is equivalent to (2.2), as the right-hand sides of these relations coincide (this follows from Lemma A.3). But in the general case, one cannot substitute the weaker condition (2.2) into the sufficiency part of the theorem, as illustrated by the following example.

EXAMPLE 2.1. Let $X = \Re$, $Y = \Re^3$, and

$$K = \operatorname{cone}\{y \in \Re^3 \mid y_1 = 1,\ y_3 = |y_2|^{3/2}\},$$
$$F : \Re \to \Re^3, \quad F(x) = (1,\, x,\, x^2).$$

For the point $\bar{x} = 0 \in \Re$, we have $F(0) \in K$, $\operatorname{cl}(K + \lin\{F(\bar{x})\}) = \operatorname{cl}(K + \lin\{F(\bar{x})\} + \operatorname{Im} F'(\bar{x})) = \{y \in \Re^3 \mid y_3 \geq 0\}$, and, as is easy to see, for element $h = 1$ conditions (2.3), (2.4) hold with $\bar{h} = h$. At the same time, 0 is obviously an isolated point of the set D given by (1.1), and hence $T_D(\bar{x}) = \{0\}$.

3. Optimality conditions. We now turn our attention to the optimization problem (1.5), where the feasible set is given by (1.1). We assume that K is a closed convex cone with nonempty interior (for primal-dual optimality conditions, also finitely generated), the objective function f is Fréchet-differentiable at the point $\bar{x} \in D$ under consideration, and the mapping F is twice Fréchet-differentiable at $\bar{x}$.

Following the developments of section 2, we first introduce some relevant cones. Let $H_2(\bar{x})$ be the set of all elements satisfying the second-order necessary conditions of tangency (2.2), (2.5) stated in Theorem 2.2, i.e.,

$$H_2(\bar{x}) := \left\{ h \in X \;\middle|\; \begin{array}{l} F'(\bar{x})h \in T_K(F(\bar{x})) = \operatorname{cl}(K + \lin\{F(\bar{x})\}) \\ F''(\bar{x})[h]^2 \in \operatorname{cl}(K + \lin\{F(\bar{x})\} + \operatorname{Im} F'(\bar{x})) \end{array} \right\},$$

and $\tilde{H}_2(\bar{x})$ be the set of elements satisfying the two relations (2.6) and (2.5), which appear in the sufficiency part:

$$\tilde{H}_2(\bar{x}) := \left\{ h \in X \;\middle|\; \begin{array}{l} F'(\bar{x})h \in T_K^r(F(\bar{x})) = K + \lin\{F(\bar{x})\} \\ F''(\bar{x})[h]^2 \in \operatorname{cl}(K + \lin\{F(\bar{x})\} + \operatorname{Im} F'(\bar{x})) \end{array} \right\}.$$

Finally, let $\bar{H}_2(\bar{x})$ consist of all elements satisfying the sufficient conditions of tangency stated in Theorem 2.2, i.e.,

$$\bar{H}_2(\bar{x}) := \left\{ h \in \tilde{H}_2(\bar{x}) \;\middle|\; \exists\, \bar{h} \in X \;:\; \begin{array}{l} F'(\bar{x})\bar{h} \in K + \lin\{F(\bar{x})\} \\ F''(\bar{x})[h,\, \bar{h}] \in \operatorname{int} K + \lin\{F(\bar{x})\} + \operatorname{Im} F'(\bar{x}) \end{array} \right\}.$$

By these definitions,

$$\bar{H}_2(\bar{x}) \cup \{0\} \subset \tilde{H}_2(\bar{x}) \subset H_2(\bar{x}). \tag{3.1}$$

Note that if the second-order regularity condition holds with respect to all $h \in \tilde{H}_2(\bar{x}) \setminus \{0\}$, then the first inclusion in (3.1) holds as an equality. If cone K is finitely generated, then the second inclusion is also an equality (recall Remark 2.2). By Theorem 2.2, we also have that

$$\bar{H}_2(\bar{x}) \cup \{0\} \subset T_D(\bar{x}) \subset H_2(\bar{x}). \tag{3.2}$$

If K is finitely generated and the second-order regularity condition holds with respect to all $h \in \tilde{H}_2(\bar{x}) \setminus \{0\}$, then we have equalities throughout (3.2).

The left-hand inclusion in (3.2) immediately implies the following primal necessary optimality condition for our problem.

THEOREM 3.1. *Let X and Y be normed linear spaces, and let K be a closed convex cone in Y with a nonempty interior. Assume that $f : X \to \Re$ is Fréchet-differentiable, and $F : X \to Y$ is twice Fréchet-differentiable at a point $\bar{x} \in D$, where D is given by* (1.1). *If $\bar{x}$ is a local solution of* (1.5), (1.1), *then*

$$\langle f'(\bar{x}),\, h\rangle \geq 0 \quad \forall\, h \in \bar{H}_2(\bar{x}). \tag{3.3}$$

If X is finite-dimensional, the right-hand inclusion in (3.2) implies that the following condition is sufficient for $\bar{x}$ to be a strict local solution of our problem:

$$\langle f'(\bar{x}),\, h\rangle > 0 \quad \forall\, h \in H_2(\bar{x}) \setminus \{0\}. \tag{3.4}$$

Dualizing (3.3), we can write that

$$f'(\bar{x}) \in (\bar{H}_2(\bar{x}))^*,$$

which is the primal-dual form of necessary optimality conditions. Explicit evaluation of the dual cone in the right-hand side of the above relation in full generality is an extremely difficult problem. However, we are able to give some meaningful results under additional assumptions. Specifically, if cone K is finitely generated and for some $h \in \bar{H}_2(\bar{x})$ the inequality in (3.3) holds as an equality, we derive an explicit primal-dual form of necessary optimality conditions. Note that further study of such "critical direction" h is of particular importance in view of the violation of the sufficient optimality condition (3.4). Assumptions of this type are quite common in the literature [7, 8, 25].

In the proof below, we shall also need the following generalization of the tangent cone description in the *regular* case. Let, in addition to our standard assumptions, C be a closed finitely generated cone in a normed linear space Z, and let $A : X \to Z$ be a continuous linear operator. Consider the set $\Delta = D \cap E$, where $E = \{x \in X \mid Ax \in C\}$, and a point $\bar{x} \in \Delta$. If there exists $\bar{\xi} \in X$ satisfying $A\bar{\xi} \in T_C(A\bar{x})$ and Robinson's condition (2.1), then

$$T_\Delta(\bar{x}) = \{h \in X \mid Ah \in T_C(A\bar{x}),\, F'(\bar{x})h \in T_K(F(\bar{x}))\}. \tag{3.5}$$

This generalization is essentially based on the well-known fact that linearity of constraints can be regarded as a special regularity-type assumption.

THEOREM 3.2. *Suppose that the assumptions of Theorem* 3.1 *are satisfied. Let K be a finitely generated cone, and let the point $\bar{x}$ be a local minimizer for problem* (1.5), (1.1). *Assume that*

$$\exists\, h \in \bar{H}_2(\bar{x}) \text{ such that } \langle f'(\bar{x}),\, h\rangle = 0. \tag{3.6}$$

Then there exist two functionals

$$y_1^* = y_1^*(h) \in K^* \cap \{F(\bar{x})\}^\perp \cap \{F'(\bar{x})h\}^\perp \tag{3.7}$$

and

$$y_2^* = y_2^*(h) \in K^* \cap \{F(\bar{x})\}^\perp \cap (\operatorname{Im} F'(\bar{x}))^\perp \cap \{F''(\bar{x})[h]^2\}^\perp \tag{3.8}$$

such that

$$f'(\bar{x}) = (F'(\bar{x}))^* y_1^* + (F''(\bar{x})[h])^* y_2^*. \tag{3.9}$$

Proof. It can be easily seen that there exists a neighborhood U of h in X such that

$$H_2(\bar{x}) \cap U \subset \bar{H}_2(\bar{x}).$$

(Just recall that since cone K is finitely generated, the second inclusion in (3.1) holds as an equality, and observe that for a neighborhood U small enough, one can choose the same $\bar{h}$ in the definition of $\bar{H}_2(\bar{x})$ for all $h \in U$.) Hence, by Theorem 3.1, we have that

$$\langle f'(\bar{x}), \xi \rangle \geq 0 \quad \forall\, \xi \in H_2(\bar{x}) \cap U.$$

The latter relation and (3.6) imply that h is a local solution of the optimization problem

$$\min \{ \langle f'(\bar{x}), \xi \rangle \mid \xi \in H_2(\bar{x}) \}.$$

By the classical necessary optimality conditions, it then follows that

$$\langle f'(\bar{x}), \xi \rangle \geq 0 \quad \forall\, \xi \in T_{H_2(\bar{x})}(h),$$

or, equivalently,

$$f'(\bar{x}) \in (T_{H_2(\bar{x})}(h))^*. \tag{3.10}$$

We now have to evaluate the cone $T_{H_2(\bar{x})}(h)$ and its dual. The latter problem is now solvable with the help of Lemma A.4, because our second-order regularity condition with respect to h implies that the cone $T_{H_2(\bar{x})}(h)$ is actually given by the linearized model of constraints defining $H_2(\bar{x})$. Indeed, using the assumption that cone K is closed and finitely generated, and applying Lemma A.3 and relation (3.5) to appropriate data, we obtain

$$T_{H_2(\bar{x})}(h) = \left\{ \xi \in X \,\middle|\, \begin{matrix} F'(\bar{x})\xi \in K + \operatorname{lin}\{F(\bar{x})\} + \operatorname{lin}\{F'(\bar{x})h\} \\ F''(\bar{x})[h,\, \xi] \in \operatorname{cl}(K + \operatorname{lin}\{F(\bar{x})\} + \operatorname{Im} F'(\bar{x}) + \operatorname{lin}\{F''(\bar{x})[h]^2\}) \end{matrix} \right\}. \tag{3.11}$$

Note that cone $K + \operatorname{lin}\{F(\bar{x})\} + \operatorname{lin}\{F'(\bar{x})h\}$ is closed and finitely generated. Also, $\dim Y < \infty$. (This is implied by our assumption that a finitely generated cone K has nonempty interior.) In particular, it follows that $\dim(\operatorname{Im} F'(\bar{x})) < \infty$. Hence, cone $K + \operatorname{lin}\{F(\bar{x})\} + \operatorname{Im} F'(\bar{x}) + \operatorname{lin}\{F''(\bar{x})[h]^2\}$ is also closed and finitely generated. Now applying Lemma A.4 to (3.11), we obtain the equality

$$\begin{aligned} (T_{H_2(\bar{x})}(h))^* = {} & (F'(\bar{x}))^*(K^* \cap \{F(\bar{x})\}^\perp \cap \{F'(\bar{x})h\}^\perp) \\ & + (F''(\bar{x})[h])^*(K^* \cap \{F(\bar{x})\}^\perp \cap (\operatorname{Im} F'(\bar{x}))^\perp \cap \{F''(\bar{x})[h]^2\}^\perp), \end{aligned}$$

from which the conclusion of the theorem follows immediately. ∎

Theorem 3.2 subsumes classical first-order necessary optimality conditions for the regular case. Indeed, suppose that h in the requirements of Theorem 3.2 satisfies (2.7). Note that this will always be so in the regular case because, by (2.8) and Lemma A.2, the right-hand side of (2.7) coincides with the entire space Y. Then, using Lemma A.1, we have that

$$K^* \cap \{F(\bar{x})\}^\perp \cap (\operatorname{Im} F'(\bar{x}))^\perp \cap \{F''(\bar{x})[h]^2\}^\perp = \{0\}. \tag{3.12}$$

Therefore in that case $y_2^* = 0$, and representation (3.7)–(3.9) reduces to

$$f'(\bar{x}) = (F'(\bar{x}))^* y_1^*, \tag{3.13}$$

with y_1^* satisfying (3.7). Furthermore, by Remark 2.1, in the regular case Theorem 3.2 can be applied by choosing $h = 0$. With this choice, (3.7) takes the form

$$y_1^* \in K^* \cap \{F(\bar{x})\}^\perp. \tag{3.14}$$

Combined with feasibility condition $F(\bar{x}) \in K$, relations (3.13), (3.14) coincide with the classical optimality conditions (1.6), where the nonsingular multiplier $y_0 = 1$ is chosen. In terms of the nonlinear programming problem, the inclusion $y_1^* \in K^*$ is the nonnegativity condition for the Lagrange multipliers, and the inclusion $y_1^* \in \{F(\bar{x})\}^\perp$ is the condition of complementary slackness.

As will be shown in section 4, Theorem 3.2 also contains optimality conditions under the second-order regularity of [7, 8] but can be applicable when the latter is not.

4. Comparisons and an example. In this section, we provide a comparison of the results obtained above with known approaches to irregular problems, and illustrate our development by an example.

First, we mention Abadie's and Kuhn–Tucker's constraint qualifications (CQs) for nonlinear programming (see [22]; there are also some other CQs of similar type). These are weaker than the Mangasarian–Fromovitz constraint qualification (MFCQ) but still guarantee that the tangent cone is given by the linearized model of the constraints; e.g., see [23, 22]. From the point of view of the problem data, these CQs are less constructive than MFCQ, which is closer to our development. (MFCQ is subsumed by our framework.) Such CQs of nonalgebraic nature are usually rather difficult to verify directly. Perhaps even more importantly, we deal here with a more general case in which the tangent cone does not necessarily coincide with the linearized cone.

The next issue that deserves to be discussed is reformulating inequality constraints as equalities, with the aim of subsequently using results available for the latter. This technique is known to be useful for regular inequality-constrained problems; e.g., see [9]. Analogously, one might try to apply known optimality conditions for (irregular) equality-constrained problems to reformulations of irregular inequality constraints. For example, the theory of 2-regularity [29, 4, 6, 5, 16, 1, 13, 20, 17, 15] offers optimality conditions for the case in which irregularity of the problem is induced only by equality constraints, with inequality constraints being either absent or regular. We next show that in our context, applicability of this approach is very limited.

For simplicity, let us take $Y = \Re^m$, $K = \Re^m_-$, and $F(\bar{x}) = 0$, and reformulate the inequality-constrained set D by introducing slacks:

$$\Delta = \{(x, u) \in X \times \Re^m \mid F(x) + u = 0,\ u \geq 0\}.$$

The new set Δ is given by equality and "simple" inequality constraints. Clearly, the equality constraint in Δ is regular at every point, but MFCQ is still violated at $(\bar{x}, 0)$. Hence, the classical results for the regular case are not applicable. Results from the theory of 2-regularity are obviously also not useful, as there are simply no irregular equality constraints in Δ.

Another possibility is a purely equality-constrained reformulation:

$$\Delta = \{(x, u) \in X \times \Re^m \mid F(x) + u^2 = 0\},$$

where the square is componentwise. Here, the equality constraint is irregular at $(\bar{x}, 0)$, and 2-regularity theory is applicable, at least formally. However, this application leads to something meaningful only when $\ker F'(\bar{x}) \neq \{0\}$, which is an unnatural requirement for inequality constraints. Our approach is certainly free of this restriction. Moreover, even if $\ker F'(\bar{x}) \neq \{0\}$, for inequality constraints this subspace can have little to do with the tangent cone, as in Example 4.1 below. Without going into detail, we shall mention that there are also some other limitations in the "brute force" approach of applying results known for irregular equality constraints to equation reformulations of irregular inequality constraints. It seems that developing a special approach specifically designed for inequality constraints is really necessary. An initial step in the direction pursued in the present paper was made in [14].

Another known approach to irregular problems consists of second-order necessary and sufficient optimality conditions of Levitin–Milyutin–Osmolovskii type, e.g., [21, 18, 7, 8, 1, 2] (see also recent work in [10, 25]), which employ F. John first-order necessary conditions (with undefined multiplier corresponding to the objective function). This approach is effective when applied to inequality-constrained problems, but it leads to results of a completely different nature, which makes comparison with the present paper difficult. We note that this approach is not principally associated with precise description of the tangent cone, i.e., it does not deal with sufficient conditions for tangency beyond the regular case.

Next, we discuss the well-known second-order CQ [7, 8], which was introduced using second-order parabolic tangent sets, and which is especially relevant for irregular inequality-constrained problems. In our setting, this CQ can be stated as follows:

$$\exists\, h \in X \text{ such that } \langle f'(\bar{x}), h\rangle = 0, \tag{4.1}$$

$$F'(\bar{x})h \in K + \operatorname{lin}\{F(\bar{x})\}, \tag{4.2}$$

$$F''(\bar{x})[h]^2 \in \operatorname{int} K + \operatorname{lin}\{F(\bar{x})\} + \operatorname{Im} F'(\bar{x}). \tag{4.3}$$

This condition is also weaker than Robinson's regularity (in the regular case, (4.1)–(4.3) hold with $h = 0$), yet it guarantees that if $\bar{x}$ is a local solution of (1.5), (1.1), then F. John-necessary conditions are satisfied with a nonzero multiplier corresponding to the objective function. Note that relations (4.2) and (4.3) already appear in Theorem 2.2 (see (2.6) and (2.7)), where they are used to explicitly construct a parabolic feasible arc tangent to h. But observe that in Theorem 2.2 we consider a larger set of directions. Namely, for an element h satisfying second-order necessary conditions of tangency, this theorem gives constructive sufficient conditions for h to be a limit point of elements satisfying (4.2), (4.3). This is important, because it is certainly possible that (4.1) does not hold for any h satisfying (4.2), (4.3), but that it does hold for some limit point of such elements. Moreover, Example 4.1 below illustrates that this situation (i.e., the second-order CQ (4.1)–(4.3) is violated, but our Theorem 3.2 is applicable) is in fact quite likely to occur.

Finally, note that if h is an element satisfying (4.1)–(4.3), then (3.6) also holds, and the assumptions of Theorem 3.2 are satisfied. Moreover, in this case, (3.12) holds. Hence, relation (3.8) in Theorem 3.2 implies that $y_2^* = 0$. We conclude that optimality conditions under the second-order CQ (4.1)–(4.3) are a particular case of Theorem 3.2 (under the additional assumption that K is finitely generated).

To complete this section, we present an example illustrating all the results derived above, and showing that they can be applicable when the F. John-optimality conditions and optimality conditions based on classical (first- and second-order) CQs are not useful. Note that our example is not pathological or exotic.

EXAMPLE 4.1. Let $X = Y = \Re^2$, $K = \Re^2_-$, and consider a family of functions

$$f : \Re^2 \to \Re, \quad f(x) = ax_1 + bx_2 + \omega_1(x)$$

and the mapping

$$F : \Re^2 \to \Re^2, \quad F(x) = \left(-x_1, -\frac{1}{2}(x_1^2 - x_2^2)\right) + \omega_2(x),$$

where $\omega_1 : \Re^2 \to \Re$, $|\omega_1(x)| = o(\|x\|)$, and $\omega_2 : \Re^2 \to \Re^2$, $\|\omega_2(x)\| = o(\|x\|^2)$.

Consider the point $\bar{x} = 0$ in $\Re^2$. We have that $F(0) = 0$, so that $0 \in D$, where D is given by (1.1). It can be easily seen that MFCQ does not hold here, and so classical theory does not apply. By direct computations, we obtain that

$$H_2(0) = \tilde{H}_2(0) = \{h \in \mathbf{R}^2 \mid h_1 \geq 0,\ h_1^2 - h_2^2 \geq 0\},$$
$$\bar{H}_2(0) = \{h \in H_2(0) \mid \exists\, \bar{h} \in \mathbf{R}^2 : \bar{h}_1 \geq 0,\ h_1\bar{h}_1 - h_2\bar{h}_2 > 0\} = H_2(0).$$

Hence, by Theorem 2.2,

$$T_D(0) = H_2(0) = \{h \in \mathbf{R}^2 \mid h_1 \geq |h_2|\},$$

which is actually geometrically obvious. Observe further that the linearized cone is given by

$$\{h \in \mathbf{R}^2 \mid F'(\bar{x})h \in T_K(F(\bar{x}))\} = \{h \in \mathbf{R}^2 \mid h_1 \geq 0\},$$

which is different from $T_D(0)$. Hence, the Kuhn–Tucker, Abadie, and any other CQs guaranteeing that the tangent and linearized cones coincide are violated in this example. Note that in this case, the tangent cone is actually polyhedral, just different from the linearized one. This shows that our description can be useful even when the tangent cone is "simple."

It is easy to see that for all values of parameters a and b, the F. John conditions (1.6) for problem (1.5), (1.1) hold at 0 with $y_0 = 0$. Furthermore, y_0 can be nonzero only if $b = 0$ and $a \leq 0$. For all other values of the parameters, F. John conditions are not meaningful for describing optimality.

As is easy to see, the set of elements satisfying (4.2), (4.3) is $\{h \in \mathbf{R}^2 \mid h_1 > |h_2|\}$. Clearly, if 0 is a local minimizer, conditions (4.1)–(4.3) can hold for some h simultaneously only if $a = b = 0$. Hence, for all other values of the parameters, the classical second-order CQ (4.1)–(4.3) does not hold, and the corresponding results are not applicable.

We next illustrate our approach, considering several characteristic values of the parameters.

If $a = 1$, $b = -1$, then 0 is a (nonisolated) local minimizer for problem (1.5), (1.1). As is easy to see,

$$\langle f'(0), h\rangle \geq 0 \quad \forall\, h \in H_2(0), \tag{4.4}$$

which illustrates Theorem 3.1. Note that for $h = (1, 1) \in H_2(0)$, the latter inequality holds as equality, and our primal-dual optimality conditions (3.7)–(3.9) are satisfied with the multipliers

$$y_1^* = (0, \alpha) \in \Re^2, \quad \alpha \in \Re_-, \quad y_2^* = (0, -1) \in \Re^2\,.$$

This gives an illustration for Theorem 3.2. Note that for $h \in H_2(0) \setminus \mathrm{lin}\{(1, 1)\}$, a similar representation does not hold. The reason is that for such h, strict inequality holds in (4.4).

If $a = 1$, $b = 0$, then (4.4) holds as a strict inequality for every $h \in H_2(0) \setminus \{0\}$, and 0 is an isolated local minimizer. This illustrates sufficient optimality condition (3.4).

Finally, if $a = 0$, $b = 1$, then it is easy to see that (4.4) does not hold for those elements $h \in H_2(0)$ for which $h_2 < 0$. Theorem 3.1 implies that 0 is not a local minimizer in this case. We could similarly use Theorem 3.2 to verify this conclusion. Indeed, for the element $h = (1, 0) \in H_2(0)$, (4.4) holds as an equality, but there exist no multipliers y_1^*, $y_2^* \in \Re^2$ for which (3.9) holds.

5. Some further developments. In conclusion, we present some further developments of the optimality conditions obtained above. The first one has to do with a certain form of second-order (in terms of the objective function) necessary optimality conditions, and the second outlines an extension to mixed equality–inequality-constrained problems.

5.1. Second-order optimality conditions. To derive second-order optimality conditions, we need the following notion. Let X and Σ be normed linear spaces, and let a mapping $\Phi : X \to \Sigma$ be twice Fréchet-differentiable at a point $\bar{x} \in X$. Suppose that $\Sigma_1 = \mathrm{Im}\,\Phi'(\bar{x})$ is closed and has a closed complementary subspace Σ_2 in Σ. Let P be a projector onto Σ_2 parallel to Σ_1 in Σ. (By assumptions above, this projector is continuous.) In this setting, the mapping Φ is referred to as 2-*regular at the point* $\bar{x}$ *with respect to an element* $h \in X$ (see [29, 4, 6, 5, 16, 1, 13, 20, 17]) if

$$\mathrm{Im}(\Phi'(\bar{x}) + P\Phi''(\bar{x})[h]) = \Sigma.$$

We note that the 2-regularity property of Φ does not depend on a choice of the complementary subspace Σ_2.

The following generalization of the classical Lyusternik's theorem can be found in [29, 5, 16, 20, 17].

PROPOSITION 5.1. *Let X and Σ be Banach spaces. Assume that a mapping $\Phi : X \to \Sigma$ is three times Fréchet-differentiable at a point $\bar{x} \in X$ such that $\Phi(\bar{x}) = 0$. Assume further that Φ is 2-regular at $\bar{x}$ with respect to an element $h \in X$ such that*

$$h \in \mathrm{Ker}\,\Phi'(\bar{x}), \quad \Phi''(\bar{x})[h]^2 \in \mathrm{Im}\,\Phi'(\bar{x}).$$

Then there exist a number $\delta > 0$ and a mapping $r : (-\delta, \delta) \to X$ such that

$$\Phi(\bar{x} + th + r(t)) = 0 \ \ \forall\, t \in (-\delta, \delta)\,, \quad \|r(t)\| = O(t^2).$$

We next derive a special form of higher-order necessary optimality conditions using the results obtained in section 3.

THEOREM 5.2. *Let X and Y be Banach spaces, let K be a closed finitely generated cone in Y with a nonempty interior, and let $f : X \to \Re$ be twice and $F : X \to Y$ be three times Fréchet-differentiable at the point $\bar{x}$, which is a local minimizer for problem* (1.5), (1.1). *Assume that* (3.6) *holds, and let $\tilde{\Pi}$ be a (continuous) projector onto some closed complementary subspace $\tilde{Y}$ of* $\lin\{F(\bar{x}),\, F'(\bar{x})h\}$ *in Y. Assume finally that*

$$\tilde{\Pi}F''(\bar{x})[h]^2 \in \tilde{\Pi}\,\mathrm{Im}\,F'(\bar{x}) \tag{5.1}$$

and that the mapping $\Phi : X \to \tilde{Y}$, $\Phi(x) = \tilde{\Pi}F(x)$, is 2-regular at the point $\bar{x}$ with respect to h. Then for every $y_1^*, y_2^* \in Y^*$ satisfying (3.7)–(3.9), *it holds that*

$$f''(\bar{x})[h]^2 - \langle y_1^*,\, F''(\bar{x})[h]^2\rangle - \frac{1}{3}\langle y_2^*,\, F'''(\bar{x})[h]^3\rangle \geq 0. \tag{5.2}$$

Proof. By the definition of $\tilde{\Pi}$, we have

$$\Phi'(\bar{x})h = \tilde{\Pi}F'(\bar{x})h = 0.$$

Hence, taking into account (5.1), Proposition 5.1 is applicable (with $\Sigma = \tilde{Y}$). So for some number $\delta > 0$ and some mapping $r : (-\delta, \delta) \to X$, we have that $\forall\, t \in (-\delta, \delta)$

$$\tilde{\Pi}F(\bar{x} + th + r(t)) = 0, \quad \|r(t)\| = O(t^2),$$

where the first equality means that

$$F(\bar{x} + th + r(t)) \in \lin\{F(\bar{x}),\, F'(\bar{x})h\}. \tag{5.3}$$

By (3.7), $y_1^* \in (\lin\{F(\bar{x}),\, F'(\bar{x})h\})^\perp$. Hence, $\forall\, t \in (-\delta, \delta)$ we have

$$\begin{aligned} 0 &= \langle y_1^*,\, F(\bar{x} + th + r(t))\rangle \\ &= \langle y_1^*,\, F'(\bar{x})r(t)\rangle + \frac{1}{2}\langle y_1^*,\, F''(\bar{x})[th]^2\rangle + o(t^2). \end{aligned} \tag{5.4}$$

Similarly, by (3.8), $y_2^* \in (\lin\{F(\bar{x}),\, F'(\bar{x})h\})^\perp$ and also $y_2^* \in (\mathrm{Im}\,F'(\bar{x}))^\perp$, which implies that

$$\begin{aligned} 0 &= \langle y_2^*,\, F(\bar{x} + th + r(t))\rangle \\ &= \langle y_2^*,\, F''(\bar{x})[th,\, r(t)]\rangle + \frac{1}{6}\langle y_2^*,\, F'''(\bar{x})[th]^3\rangle + o(t^3). \end{aligned} \tag{5.5}$$

By (5.3), there exist $\lambda_1,\, \lambda_2 : (-\delta,\, \delta) \to \Re$ such that

$$F(\bar{x} + th + r(t)) = \lambda_1(t)F(\bar{x}) + \lambda_2(t)F'(\bar{x})h.$$

On the other hand, by differentiability of F,

$$F(\bar{x} + th + r(t)) = F(\bar{x}) + tF'(\bar{x})h + o(t).$$

Therefore, we can take $\lambda_1(t) = 1 + o(t),\ \lambda_2(t) = t + o(t)$. Since $h \in \tilde{H}_2(\bar{x})$, we have that $F'(\bar{x})h = y + \lambda F(\bar{x})$ for some $y \in K$, $\lambda \in \Re$. We further obtain

$$\begin{aligned} F(\bar{x} + th + r(t)) &= (1 + o(t))F(\bar{x}) + (t + o(t))(y + \lambda F(\bar{x})) \\ &= (1 + \lambda t + o(t))F(\bar{x}) + (t + o(t))y. \end{aligned}$$

Taking into account that $F(\bar{x}) \in K$ and $y \in K$, it is clear now that if $\delta > 0$ is small enough, then $\bar{x} + th + r(t) \in D \ \forall\, t \in (0, \delta)$, and since $\bar{x}$ is a local minimizer, by differentiability of f it follows that $\forall\, t \in (0, \delta)$

$$0 \le f(\bar{x} + th + r(t)) - f(\bar{x}) = \langle f'(\bar{x}),\, r(t)\rangle + \frac{1}{2} f''(\bar{x})[th]^2 + o(t^2),$$

where we have also used (3.6). Combining the latter relation with (5.4) and (5.5) (divided by -1 and $-t$, respectively), we obtain

$$\begin{aligned}
0 &\le \langle f'(\bar{x}),\, r(t)\rangle - \langle y_1^*,\, F'(\bar{x})r(t)\rangle - \langle y_2^*,\, F''(\bar{x})[h, r(t)]\rangle \\
&\quad + \frac{1}{2} f''(\bar{x})[th]^2 - \frac{1}{2}\langle y_1^*,\, F''(\bar{x})[th]^2\rangle - \frac{1}{6t}\langle y_2^*,\, F'''(\bar{x})[th]^3\rangle + o(t^2) \\
&= \langle f'(\bar{x}) - (F'(\bar{x}))^* y_1^* - (F''(\bar{x})[h])^* y_2^*,\, r(t)\rangle \\
&\quad + \frac{t^2}{2}\left(f''(\bar{x})[h]^2 - \langle y_1^*,\, F''(\bar{x})[h]^2\rangle - \frac{1}{3}\langle y_2^*,\, F'''(\bar{x})[h]^3\rangle \right) + o(t^2) \\
&= \frac{t^2}{2}\left(f''(\bar{x})[h]^2 - \langle y_1^*,\, F''(\bar{x})[h]^2\rangle - \frac{1}{3}\langle y_2^*,\, F'''(\bar{x})[h]^3\rangle \right) + o(t^2),
\end{aligned}$$

where the last equality follows from (3.9). Dividing by $t^2/2$ and passing onto the limit as $t \to 0$, we obtain (5.2). □

Note that the mapping Φ defined in Theorem 5.2 could be regular (rather than 2-regular) only if the Robinson's regularity condition were to be satisfied at $\bar{x}$.

The next example illustrates that Theorem 5.2 provides additional information that can be used to eliminate candidates for optimality.

EXAMPLE 5.1. Consider the setting of Example 4.1, where $a = 1$, $b = -1$, $\omega_2(\cdot) \equiv 0$ on $\Re^2$, and $\omega_1 : \Re^2 \to \Re$ is a quadratic form negative on $h = (1, 1)$. Then the first-order necessary conditions given by Theorems 3.1 and 3.2 are satisfied at 0 (see Example 4.1), but by direct inspection it can be seen that the second-order necessary optimality conditions given by Theorem 5.2 are violated. Indeed, $F'(\bar{x})h = (-1, 0)$, and so one can take $\tilde{Y} = \mathrm{lin}\{(0, 1)\}$. Then Φ can be considered as a scalar-valued function

$$\Phi : \Re^2 \to \Re, \quad \Phi(x) = -\frac{1}{2}(x_1^2 - x_2^2).$$

This function is certainly 2-regular at 0 with respect to every nonzero element. (For scalar-valued functions, the latter property is equivalent to saying that 0 is a nondegenerate critical point [3].) In particular, Φ is 2-regular at 0 with respect to h, which obviously satisfies (5.1.) We further have that

$$f''(\bar{x})[h]^2 - \langle y_1^*,\, F''(\bar{x})[h]^2\rangle - \frac{1}{3}\langle y_2^*,\, F'''(\bar{x})[h]^3\rangle = 2\omega_1(h) < 0,$$

which is in contradiction with (5.2). We conclude that 0 is not a local minimizer for problem (1.5), (1.1).

5.2. Mixed equality and inequality constraints. In contrast to the regular case, it appears very difficult (if not impossible) to extend the results for irregular equality- or inequality-constrained problems to the case with mixed inequality and equality constraints, except for some special cases. (For a complete modification of this kind, one would have to avoid the condition that cone K has a nonempty

interior.) One special case, specifically where the singularity/irregularity is due to equality-type constraints only, is studied thoroughly in [5, 20] (those results were already mentioned in section 4). Let us consider briefly the opposite case, i.e., where irregularity is induced by inequality constraints, while equality constraints are regular. Let set D now be given by

$$D = \{x \in X \mid F(x) \in K,\ G(x) = 0\}. \tag{5.6}$$

Assume $G : X \to Z$ is three times continuously differentiable, where X and Z are Banach spaces. Suppose G is regular at a point $\bar{x} \in D$, i.e.,

$$\operatorname{Im} G'(\bar{x}) = Z,$$

and there exists a continuous projector Π on $\operatorname{Ker} G'(\bar{x})$ in Z. According to the classical facts of nonlinear analysis (see, e.g., [3, 13]), under those assumptions there exist a neighborhood U of 0 in X and a mapping $\rho : U \to X$ such that $\rho(0) = \bar{x}$, $\rho(U)$ is a neighborhood of $\bar{x}$ in X, ρ is a C^3-diffeomorphism from U onto $\rho(U)$, and

$$\begin{aligned} G(\rho(x)) &= G'(\bar{x})x \quad \forall\, x \in U, \\ \rho'(x) &= (R(x))^{-1}R(0) \quad \forall\, x \in U, \end{aligned} \tag{5.7}$$

where

$$R(x) : X \to Y \times \operatorname{Ker} G'(\bar{x}), \quad R(x)\xi = (G'(\rho(x))\xi,\ \Pi\xi), \quad x \in U.$$

Now instead of a feasible point $\bar{x}$ of problem (1.5), (5.6), we can consider for local analysis the feasible point 0 of the *inequality-constrained* problem

$$\min\{\varphi(x) \mid x \in \Delta\}, \quad \Delta = \{x \in \tilde{X} \cap U \mid \Phi(x) \in K\},$$

where $\tilde{X} = \operatorname{Ker} G'(\bar{x})$,

$$\varphi(x) = f(\rho(x)), \quad \Phi(x) = F(\rho(x)), \quad x \in U.$$

Note that taking advantage of (5.7), it is easy to obtain explicit formulas for the first three derivatives of φ and Φ, and so the analysis developed in this paper is applicable to the derivation of optimality conditions for problem (1.5), (5.6).

Appendix. Auxiliary results. All results in this section can be found in standard books on convex analysis [28, 3, 19, 26] or follow from results contained therein.

LEMMA A.1. *Let Σ be a topological linear space, L be a linear subspace in Σ, and C be a convex cone in Σ such that* $\operatorname{int} C \neq \emptyset$. *Then*

$$\operatorname{int} C \cap L = \emptyset \quad \Leftrightarrow \quad C^* \cap L^\perp \neq \{0\}.$$

LEMMA A.2. *Let Σ be a topological linear space and Ω_1, Ω_2 be convex sets in Σ, with* $\operatorname{int} \Omega_1 \neq \emptyset$. *Then*

$$\operatorname{int}(\Omega_1 + \Omega_2) = \operatorname{int} \Omega_1 + \Omega_2.$$

LEMMA A.3. *Let Σ be a normed linear space and C_1, C_2 be finitely generated cones in Σ. Then*

$$\operatorname{cl}(C_1 + C_2) = \operatorname{cl} C_1 + \operatorname{cl} C_2.$$

LEMMA A.4. *Let Υ and Σ be normed linear spaces,* $\dim \Sigma < \infty$, $\Lambda : \Upsilon \to \Sigma$ *be a continuous linear operator, and C be a nonempty closed finitely generated cone in Σ. Then for a cone $\Gamma = \{\xi \in \Upsilon \mid \Lambda\xi \in C\}$ it holds that*

$$\Gamma^* = \Lambda^* C^*.$$

LEMMA A.5. *Let Σ be a locally convex topological linear space, and C be a convex cone in Σ. Then*

$$\sigma^1 \in \operatorname{cl} C\,,\ \sigma^2 \in \operatorname{int} C \quad \Rightarrow \quad \sigma^1 + \sigma^2 \in \operatorname{int} C.$$

Acknowledgments. We are grateful to the two anonymous referees and the editor for constructive suggestions which led to considerable improvement of the paper.

INDEFINITE STOCHASTIC LINEAR QUADRATIC CONTROL AND GENERALIZED DIFFERENTIAL RICCATI EQUATION*

M. AIT RAMI†, J. B. MOORE‡, AND XUN YU ZHOU†

Abstract. A stochastic linear quadratic (LQ) control problem is indefinite when the cost weighting matrices for the state and the control are allowed to be indefinite. Indefinite stochastic LQ theory has been extensively developed and has found interesting applications in finance. However, there remains an outstanding open problem, which is to identify an appropriate Riccati-type equation whose solvability is *equivalent* to the solvability of the indefinite stochastic LQ problem. This paper solves this open problem for LQ control in a finite time horizon. A new type of differential Riccati equation, called the generalized (differential) Riccati equation, is introduced, which involves algebraic equality/inequality constraints and a matrix pseudoinverse. It is then shown that the solvability of the generalized Riccati equation is not only sufficient, but also *necessary*, for the well-posedness of the indefinite LQ problem and the existence of optimal feedback/open-loop controls. Moreover, all of the optimal controls can be identified via the solution to the Riccati equation. An example is presented to illustrate the theory developed.

Key words. stochastic LQ control, indefinite costs, generalized Riccati equation, matrix pseudoinverse, matrix minimum principle, dynamic programming

1. Introduction.

Consider the following stochastic linear quadratic (LQ) optimal control problem in a finite time horizon $[0, T]$:

(1.1)
$$\text{Minimize} \quad J = E\left\{\int_0^T [x(t)'Q(t)x(t) + u(t)'R(t)u(t)]dt + x(T)'Hx(T)\right\},$$
$$\text{subject to} \quad \begin{cases} dx(t) = [A(t)x(t) + B(t)u(t)]dt + [C(t)x(t) + D(t)u(t)]dW(t), \\ x(0) = x_0 \in \mathbf{R}^n. \end{cases}$$

Here $W(t)$ is a standard one-dimensional Brownian motion, and the control $u(\cdot)$ takes value in some Euclidean space.

In optimal LQ control theory, the Riccati equation approach has been used systematically to provide an optimal feedback control (see [14, 20, 4] for the deterministic case, and [23, 6, 11] for the stochastic case). In the literature it is typically assumed that the cost function has a positive definite weighting matrix, R, for the control term, and a positive semidefinite weighting matrix, Q, for the state term. In this case, the solvability of the Riccati equation is both necessary and sufficient for the solvability of the underlying LQ problem.

However, it was found in [7] for the first time that a stochastic LQ problem with *indefinite* Q and R may still be well-posed. This phenomenon has to do with the

deep nature of the uncertainty involved; see [7] for a detailed discussion and many examples. Follow-up research on indefinite stochastic LQ control in a finite time horizon has been carried out in [8, 16, 9] to incorporate more complicated features such as random coefficients and integral constraints. The infinite-time-horizon case, in which the stability becomes a crucial issue, was treated in [2, 24] via techniques in linear matrix inequality and semidefinite programming [21]. On the other hand, applications of indefinite LQ control to portfolio selection problems and a contingent claim problem can be found in [25, 17] and [15], respectively. We would also like to mention a recent paper [12] in which the stochastic H^∞ problem is dealt with via a Riccati equation that has a structure similar to the one in [7].

In the first paper [7] on indefinite stochastic LQ control, it is shown that if the following type of Riccati equation, called the stochastic Riccati equation (t is suppressed),

(1.2)
$$\begin{cases} \dot{P} + PA + A'P + C'PC - (PB + C'PD)(R + D'PD)^{-1}(B'P + D'PC) + Q = 0, \\ P(T) = H, \\ R + D'PD > 0, \quad \text{a.e. } t \in [0, T], \end{cases}$$

has a solution $P(\cdot)$, then the original (indefinite) LQ problem is well-posed and an optimal feedback control can be constructed explicitly via $P(\cdot)$. (Note that the third positive definiteness constraint in (1.2) is *part* of that equation and must be satisfied by any solution.) In other words, the solvability of the stochastic Riccati equation (1.2) is *sufficient*, but not *necessary* in general, for the well-posedness as well as the solvability of the LQ problem. A natural question then is what can we say about the indefinite LQ problem if (1.2) does *not* have a solution at all? Note that the positive definiteness constraint of $R + D'PD$ in (1.2) is very restrictive, which likely leads to the nonexistence of its solutions. As a consequence, it may happen that the original indefinite LQ problem is well-posed and there exist optimal controls, while (1.2) still has no solution, in which case (1.2) becomes useless. This is quite different from the deterministic counterpart (as mentioned earlier), which in turn suggests that (1.2) may not be *the* right Riccati equation for indefinite LQ control.

Let us look at an example to illustrate the above discussion.

Example 1.1. Consider LQ problem (1.1) with $T = 1$, $A(t) = B(t) = D(t) = 1$, $C(t) = -1$, $Q(t) = -1$, $R(t) = -\frac{2e^{3(1-t)}+1}{3}$, and $H = 1$. Note that Q and R are both *negative* here. Equation (1.2) in this case specializes to

$$\begin{cases} \dot{P}(t) + 3P(t) - 1 = 0, \\ P(1) = 1, \\ R(t) + P(t) > 0, \quad \text{a.e. } t \in [0, T]. \end{cases} \tag{1.3}$$

The only solution that satisfies the first two constraints of the above equation is $P(t) = \frac{2e^{3(1-t)}+1}{3}$. Hence $R(t) + P(t) \equiv 0$, violating the third constraint. This shows that (1.3) has no solution and the result in [7] fails to apply to this case. However, the original LQ problem is well-posed. To see this, let $P(t) = \frac{2e^{3(1-t)}+1}{3}$, and apply Itô's formula to $P(t)x(t)^2$. We then obtain

$$d[P(t)x(t)^2] = [x(t)^2 + P(t)u(t)^2]dt + \{\cdots\}dW(t).$$

Integrating from 0 to 1, and taking expectation, we have $J \equiv P(0)x_0^2$. This implies that the cost function takes a *constant* value $P(0)x_0^2$ regardless of the control being applied. In particular, the LQ problem is well-posed and does have optimal controls.

The above example suggests that the stochastic Riccati equation (1.3) introduced in [7] may not be able to handle certain indefinite stochastic LQ problems. Finding a more appropriate Riccati-type equation, in the sense that its solvability should be *equivalent* to that of the underlying LQ problem, remains an outstanding open problem. The objective of this paper is to tackle this open problem, thereby enabling us to deal with general indefinite stochastic LQ problems, including pathological situations such as the one in Example 1.1. The key to achieving this goal is the introduction of a new type of differential Riccati equation—called a *generalized Riccati equation*—where the positive definiteness constraint of $R + D'PD$ is relaxed. This equation involves a matrix pseudoinverse and an additional algebraic constraint due to the possible singularity of the term $R+D'PD$. This new Riccati equation turns out to be the right one for studying indefinite LQ problems, as the solvability of this equation is not only sufficient, but also *necessary*, for the well-posedness of the LQ problem as well as the attainability of its optimal controls. Moreover, we are able to derive *all* optimal controls via the solution of the generalized Riccati equation.

It is worth mentioning that even for deterministic singular LQ problems (see [22, 13, 18, 10], among others), which are a special case of the problem treated in this paper, our formulation and results are still new; for details see section 3.

The remainder of this paper is organized as follows. Section 2 formulates the indefinite stochastic LQ problem and gives some preliminaries. The generalized Riccati equation (GRE) is also introduced. Section 3 shows that the solvability of the GRE is sufficient for the well-posedness of the LQ problem and the existence of an optimal control. Moreover, all the optimal controls are identified via the solution of the GRE. Sections 4 and 5 prove that the solvability of the GRE is also necessary for the existence of optimal linear feedback controls and optimal open-loop controls, respectively. An example is presented in section 6 to illustrate the results obtained. Finally, section 7 gives some concluding remarks.

2. Problem formulation and preliminaries.

2.1. Notation. We make use of the following notation in this paper:

$\mathbf{N}$	:	the set of positive integers.
$\mathbf{R}$	:	the set of real numbers.
$\mathbf{R}^n$	:	n-dimensional Euclidean space.
M'	:	the transpose of a matrix M.
$M^\dagger$	:	the Moore–Penrose pseudoinverse of a matrix M.
$\mathbf{Tr}(M)$	:	the sum of diagonal elements of a square matrix M.
$\|x\|$	:	$= \sqrt{\sum x_i^2}$ for a vector $x = (x_1, \ldots, x_n)'$.
$\mathbf{R}^{n\times m}$	:	the space of all $n \times m$ matrices.
$\mathcal{S}^n$	:	the space of all $n \times n$ symmetric matrices.
$\mathcal{S}_+^n$	:	the subspace of all positive semidefinite matrices of $\mathcal{S}^n$.
$\hat{\mathcal{S}}_+^n$	:	the subspace of all positive definite matrices of $\mathcal{S}^n$.

Given a filtered probability space $(\Omega, \mathcal{F}, \mathcal{P}; \mathcal{F}_t)$, where $t \in [0, T]$, and a Hilbert space X with the norm $\|\cdot\|_X$, define the Hilbert space

$$L^2_{\mathcal{F}}(0, T; X) = \Big\{\phi(\cdot)| \quad \phi(\cdot) \text{ is an } \mathcal{F}_t\text{-adapted, } X\text{-valued measurable process on } [0, T], \\ \text{and } E\int_0^T \| \phi(t, \omega) \|_X^2 \, dt < +\infty\Big\},$$

with the norm

$$\| \phi(\cdot) \|_{\mathcal{F},2} = \left(E \int_0^T \| \phi(t,\omega) \|_X^2 \, dt \right)^{\frac{1}{2}}.$$

2.2. Problem formulation. Let $(\Omega, \mathcal{F}, \mathcal{P}; \mathcal{F}_t)$ be a given filtered probability space with a standard one-dimensional Brownian motion $W(t)$ on $[0,T]$ (with $W(0) = 0$). Consider the following linear Itô stochastic differential equation:

$$\begin{cases} dx(t) = [A(t)x(t) + B(t)u(t)]dt + [C(t)x(t) + D(t)u(t)]dW(t), \\ x(s) = y, \end{cases} \tag{2.1}$$

where $(s,y) \in [0,T) \times \mathbf{R}^n$ are the initial time and initial state, respectively, and $u(\cdot)$, the admissible control, is an element in $U_{ad} \equiv L^2_{\mathcal{F}}(0,T;\mathbf{R}^{n_u})$. In order to simplify exposition we assume that the Brownian motion is one-dimensional. There is no essential difficulty with the multidimensional case.

For each (s,y) and $u(\cdot) \in U_{ad}$, the associated cost is

$$J(s,y;u(\cdot)) = E\left\{ \int_s^T [x(t)'Q(t)x(t) + u(t)'R(t)u(t)]dt + x(T)'Hx(T) \right\}. \tag{2.2}$$

The solution $x(\cdot)$ of (2.1) is called the response of the control $u(\cdot) \in U_{ad}$, and $(x(\cdot), u(\cdot))$ is called an *admissible pair*. The objective of the optimal control problem is to minimize the cost function $J(s,y;u(\cdot))$, for a given $(s,y) \in [0,T) \times \mathbf{R}^n$, over all $u(\cdot) \in U_{ad}$. The value function is defined as

$$V(s,y) = \inf_{u(\cdot) \in U_{ad}} J(s,y;u(\cdot)). \tag{2.3}$$

Definition 2.1. *The optimization problem* (2.1)–(2.3) *is called* well-posed *if*

$$V(s,y) > -\infty \quad \forall (s,y) \in [0,T) \times \mathbf{R}^n.$$

An admissible pair $(x^*(\cdot), u^*(\cdot))$ *is called* optimal *(with respect to the initial condition* (s,y)*) if* $u^*(\cdot)$ *achieves the infimum of* $J(s,y;u(\cdot))$.

The following basic assumption will be in force throughout this paper.

Assumption **(A)**. The data appearing in the LQ problem (2.1)–(2.3) satisfy

$$\begin{aligned} &A, C \in L^\infty(0,T;\mathbf{R}^{n\times n}), \\ &B, D \in L^\infty(0,T;\mathbf{R}^{n\times n_u}), \\ &Q \in L^\infty(0,T;\mathcal{S}^n), \\ &R \in L^\infty(0,T;\mathcal{S}^{n_u}), \\ &H \in \mathcal{S}^n. \end{aligned}$$

We emphasize again that we are dealing with an *indefinite* LQ problem, namely that Q, R, and H are all possibly indefinite.

2.3. Generalized (differential) Riccati equation. We start by recalling properties of a pseudo matrix inverse [19].

Proposition 2.2. *Let a matrix* $M \in \mathbf{R}^{m\times n}$ *be given. Then there exists a unique matrix* $M^\dagger \in \mathbf{R}^{n\times m}$ *such that*

$$\begin{cases} MM^\dagger M = M, \quad M^\dagger MM^\dagger = M^\dagger, \\ (MM^\dagger)' = MM^\dagger, \quad (M^\dagger M)' = M^\dagger M. \end{cases} \tag{2.4}$$

The matrix $M^\dagger$ above is called the *Moore–Penrose pseudoinverse* of M.

Now, we introduce a new type of Riccati equation associated with the LQ problem (2.1)–(2.3).

DEFINITION 2.3. *The constrained differential equation (with the time argument t suppressed)*

(2.5)
$$\begin{cases} \dot{P} + PA + A'P + C'PC - (PB + C'PD)(R + D'PD)^\dagger(B'P + D'PC) + Q = 0, \\ P(T) = H, \\ (R + D'PD)(R + D'PD)^\dagger(B'P + D'PC) - (B'P + D'PC) = 0, \\ R + D'PD \geq 0, \quad a.e.\ t \in [0, T], \end{cases}$$

is called a generalized (differential) Riccati equation *(GRE).*

If the term $(R + D'PD)$ is further required to be nonsingular, then the GRE reduces to the stochastic Riccati equation (1.2) that was introduced in [7].

Another interesting special case is that in which $(R + D'PD) \equiv 0$; the GRE reduces to the following linear differential matrix system:

$$\begin{cases} \dot{P} + PA + A'P + C'PC + Q = 0, \\ P(T) = H, \\ B'P + D'PC = 0, \\ R + D'PD = 0, \quad \text{a.e. } t \in [0, T]. \end{cases} \tag{2.6}$$

2.4. Some useful lemmas.

LEMMA 2.4. *Let $M(\cdot)$ be a given continuously differentiable (in t) matrix function taking values in $\mathcal{S}^n$. Then for any admissible pair $(x(\cdot), u(\cdot))$ of the system* (2.1)*, we have*

$$\begin{aligned} &E[x(t)'Mx(T)] - y'M(s)y - E\int_s^T [x'(\dot{M} + A'M + MA + C'MC)x](t)dt \\ &-E\int_s^T [2u'(B'M + D'MC)x + u'D'MDu](t)dt = 0. \end{aligned} \tag{2.7}$$

Proof. Using Itô's formula, we have (t is suppressed)

$$\begin{aligned} &d(x'Mx) - [(Ax + Bu)'Mx + x'\dot{M}x + x'M(Ax + Bu) - (Cx + Du)'M(Cx + Du)]dt \\ &\quad - [x'M(Cx + Du) + (Cx + Du)'Mx]dW(t) = 0. \end{aligned}$$

Taking expectations and integrations we obtain (2.7). □

LEMMA 2.5. *Let a symmetric matrix S be given. Then*

(i) $S^\dagger = S^{\dagger'}$.

(ii) $S \geq 0$ *if and only if* $S^\dagger \geq 0$.

(iii) $SS^\dagger = S^\dagger S$.

Proof. Since S is symmetric, it has a singular value decomposition of the following form:

$$S = V \begin{bmatrix} \Sigma & 0 \\ 0 & 0 \end{bmatrix} V',$$

where Σ is a nonsingular diagonal matrix and V a matrix such that $VV' = V'V = I$. Now, $S^\dagger$ is given by

$$S^\dagger = V \begin{bmatrix} \Sigma^{-1} & 0 \\ 0 & 0 \end{bmatrix} V'.$$

Using the above expression of $S^\dagger$, it is easy to show that items (i)–(iii) hold. □

LEMMA 2.6 (Extended Schur's lemma [3]). *Let matrices $M = M', N$, and $R = R'$ be given with appropriate sizes. Then the following conditions are equivalent:*

(i) $M - NR^\dagger N' \geq 0$, $R \geq 0$, *and* $N(I - RR^\dagger) = 0$.

(ii) $\begin{bmatrix} M & N \\ N' & R \end{bmatrix} \geq 0$.

(iii) $\begin{bmatrix} R & N' \\ N & M \end{bmatrix} \geq 0$.

The following lemma plays a key technical role in this paper.

LEMMA 2.7. *Let matrices L, M, and N be given with appropriate sizes. Then the matrix equation*

$$LXM = N \tag{2.8}$$

has a solution X if and only if

$$LL^\dagger NM^\dagger M = N. \tag{2.9}$$

Moreover, any solution to (2.8) *is represented by*

$$X = L^\dagger NM^\dagger + S - L^\dagger LSMM^\dagger, \tag{2.10}$$

where S is a matrix with an appropriate size.

Proof. If X satisfies the equation $LXM = N$, then we have

$$N = LXM = LL^\dagger LXMM^\dagger M = LL^\dagger NM^\dagger M.$$

Conversely, if (2.9) is satisfied, then $L^\dagger NM^\dagger$ is a solution of $LXM = N$. This proves the first part of the lemma. Now, let Y be any matrix with appropriate size and define $\tilde{X} = Y - L^\dagger LYMM^\dagger$. Then $\tilde{X}$ satisfies the homogeneous equation $L\tilde{X}M = 0$. Hence $L^\dagger NM^\dagger + \tilde{X}$ must satisfy (2.8). On the other hand, let X be a solution to (2.8). Then by (2.9), one has $LSM = 0$, where $S = X - L^\dagger NM^\dagger$. Hence

$$X = L^\dagger NM^\dagger + S - L^\dagger LSMM^\dagger.$$

This completes the proof. □

3. Sufficiency of the GRE. In this section, we will show that the solvability of the GRE (2.5) is sufficient for the well-posedness of the LQ problem and the existence of an optimal linear state feedback control. Moreover, any optimal control can be obtained via the solution to the GRE.

THEOREM 3.1. *If the GRE* (2.5) *admits a solution $P(\cdot)$, then the stochastic LQ problem* (2.1)–(2.3) *is well-posed. Moreover, the set of all the optimal controls with respect to the initial $(s, y) \in [0, T) \times \mathbf{R}^n$ is determined by the following (parameterized by (Y, z)):*

$$\begin{aligned} u_{(Y,z)}(t) = -\Big\{ & [R(t) + D(t)'P(t)D(t)]^\dagger [B(t)'P(t) + D(t)'P(t)C(t)] + Y(t) \\ & - [R(t) + D(t)'P(t)D(t)]^\dagger [R(t) + D(t)'P(t)D(t)]Y(t) \Big\} x(t) \\ & + z(t) - [R(t) + D(t)'P(t)D(t)]^\dagger [R(t) + D(t)'P(t)D(t)]z(t), \end{aligned} \tag{3.1}$$

where $Y(\cdot) \in L^2_{\mathcal{F}}(s, T; \mathbf{R}^{n_u \times n})$ and $z(\cdot) \in L^2_{\mathcal{F}}(s, T; \mathbf{R}^{n_u})$. Furthermore, the value function is uniquely determined by $P(\cdot)$:

$$V(s, y) \equiv \inf_{u(\cdot) \in U_{ad}} J(s, y; u(\cdot)) = y'P(s)y. \tag{3.2}$$

Proof. Let $P(\cdot)$ be a solution of GRE (2.5). Applying Lemma 2.4, we can express the cost function as follows:

$$J(s,y;u(\cdot)) = y'P(s)y + E\int_s^T \Big[x'(\dot P + PA + A'P + C'PC + Q)x + 2u'(B'P + D'PC)x + u'(D'PD + R)u\Big](t)dt. \tag{3.3}$$

Now, let $Y(\cdot) \in L^2_{\mathcal{F}}(s,T;\mathbf{R}^{n_u\times n})$ and $z(\cdot) \in L^2_{\mathcal{F}}(s,T;\mathbf{R}^{n_u})$ be given. Set

$$\begin{aligned} L_1(t) &= Y(t) - [R(t) + D'(t)P(t)D(t)]^\dagger [R(t) + D'(t)P(t)D(t)]Y(t),\\ L_2(t) &= z(t) - [R(t) + D'(t)P(t)D(t)]^\dagger [R(t) + D'(t)P(t)D(t)]z(t). \end{aligned}$$

Applying Proposition 2.2 and Lemma 2.5(iii), we have

$$[R(t) + D'(t)P(t)D(t)]L_i(t) = [R(t) + D'(t)P(t)D(t)]^\dagger L_i(t) = 0, \qquad i = 1,2, \tag{3.4}$$

and

$$[P(t)B(t) + C'(t)P(t)D(t)]L_i(t) = 0, \qquad i = 1,2. \tag{3.5}$$

Then identity (3.3) can be expressed as

$$\begin{aligned} &J(s,y;u(\cdot))\\ &\quad = y'P(s)y + E\textstyle\int_s^T \Big\{x'[\dot P + PA + A'P + C'PC + Q\\ &\qquad - (PB + C'PD)(R + D'PD)^\dagger (B'P + D'PC)]x\\ &\qquad + \big[u + \big((R + D'PD)^\dagger (B'P + D'PC) + L_1\big)x + L_2\big]'\\ &\qquad \times (R + D'PD)\big[u + \big((R + D'PD)^\dagger (B'P + D'PC) + L_1\big)x + L_2\big]\Big\}(t)dt\\ &\quad = y'P(s)y + E\textstyle\int_s^T \Big\{\big[u + \big((R + D'PD)^\dagger (B'P + D'PC) + L_1\big)x + L_2\big]'\\ &\qquad \times (R + D'PD)\big[u + \big((R + D'PD)^\dagger (B'P + D'PC) + L_1\big)x + L_2\big]\Big\}(t)dt. \end{aligned} \tag{3.6}$$

Hence, $J(s,y;u(\cdot))$ is minimized by the control given by (3.1) with the optimal value being $y'P(s)y$.

What remains to show is that *any* optimal control can be represented by (3.1) for some $Y(\cdot)$ and $z(\cdot)$. To this end, let $u(\cdot)$ be an optimal control. Then by (3.6) the integrand in the right-hand side of (3.6) must be zero almost everywhere in t. This implies (t is suppressed)

$$(R + D'PD)^{1/2}\big[u + \big((R + D'PD)^\dagger (B'P + D'PC) + L_1\big)x + L_2\big] = 0,$$

which leads to

$$(R + D'PD)[u + \big((R + D'PD)^\dagger (B'P + D'PC) + L_1\big)x + L_2] = 0,$$

or, equivalently (noting (3.4)),

$$[R(t) + D(t)'P(t)D(t)]u(t) + [B(t)'P(t) + D(t)'P(t)C(t)]x(t) = 0, \quad \text{a.e. } t \in [s,T]. \tag{3.7}$$

To solve the above equation in $u(t)$, we apply Lemma 2.7 with

$$L = R(t) + D(t)'P(t)D(t), \quad M = I, \quad N = -[B(t)'P(t) + D(t)'P(t)C(t)]x(t).$$

Notice that condition (2.9) in the present case is implied by the third constraint in GRE (2.5); hence the general solution (2.10) with $z(t) = S$ and $Y(t) = 0$ yields that $u(t)$ can be represented by (3.1). □

COROLLARY 3.2. *The optimal controls are obtained in the following special cases:*

(i) *If* $R(t) + D(t)'P(t)D(t) \equiv 0$, a.e. $t \in [s,T]$, *then any admissible control is optimal.*

(ii) *If* $R(t) + D(t)'P(t)D(t) > 0$, a.e. $t \in [s,T]$, *then there is a unique optimal control that is given by the following linear feedback law:*

$$u(t) = -[R(t) + D(t)'P(t)D(t)]^{-1}[B(t)'P(t) + D(t)'P(t)C(t)]x(t). \tag{3.8}$$

Proof. The proofs here are straightforward from Theorem 3.1. □

As an immediate consequence of Theorem 3.1, we have the uniqueness of the solution to GRE (2.5).

COROLLARY 3.3. *If there is a solution to the GRE* (2.5), *then it must be the only solution to* (2.5).

Proof. Let $P_1(\cdot)$ and $P_2(\cdot)$ be two solutions of GRE (2.5). Then Theorem 3.1 implies that

$$y'P_1(s)y = y'P_2(s)y \ \ \forall y \in \mathbf{R}^n \ \ \forall s \in [0,T].$$

Hence $P_1(t) \equiv P_2(t)$. □

It is interesting to see the specialization of our results in the deterministic case (i.e., $C(t) = D(t) \equiv 0$). The control weight $R(t)$ is given as satisfying $R(t) \geq 0$, so it is a possibly singular case. The corresponding GRE is

$$\begin{cases} \dot{P}(t) + P(t)A(t) + A(t)'P(t) - P(t)B(t)R(t)^\dagger B(t)'P(t) + Q(t) = 0, \\ P(T) = H, \\ R(t)R(t)^\dagger B(t)'P(t) - B(t)'P(t) = 0 \ \ \forall t \in [0,T]. \end{cases} \tag{3.9}$$
