It is straightforward to show that this affine control system is GAC; let us notice that this is true since we are in a dimension greater than 2. Now, let us assume that there exists an open dense set $\mathcal{D}$ of $\mathbb{R}^n$ which is invariant with respect to some smooth (on $\mathcal{D}$) stabilizing feedback $k(\cdot)$ and such that its complement $S := (\mathbb{R}^n \setminus \{0\}) \setminus \mathcal{D}$ is repulsive (see (2.10)).

First, since our dynamics reduce to f_0 around the origin, we can assume that $0 \in \mathcal{D}$ and hence that $\mathcal{D}$ is contractible. On the other hand, the control system (2.15) coincides with the dynamical system $\dot{x} = f_0(x)$ on the interior of $\mathcal{A}$. Consequently, by repulsivity the set S cannot intersect $\mathrm{int}(\mathcal{A})$; hence we deduce that S meets the ball $x_0 + \frac{5}{16}\overline{B}$. (If the vector field $f(\cdot, k(\cdot))$ were continuous on this ball, it would have an equilibrium on it by Brouwer's theorem; as a matter of fact the ball would be invariant under the dynamic $\dot{x} = -f(x,k(x))$.) In other words, there exists a nonempty compact set K such that

$$K \subset x_0 + \frac{3}{8}\overline{B} \subset x_0 + \frac{7}{16}B$$

and

$$K \cap \mathcal{D} \neq \emptyset.$$

This means that we can write our set $\mathcal{D}$ as follows:

$$\mathcal{D} = \left(\mathcal{D} \bigcup x_0 + \frac{7}{16}B\right) \setminus K.$$

In fact, we can see $\mathcal{D}$ as an open set minus a compact subset of itself. Such a set can't be contractible (we refer to algebraic topology for the proof of this result).

In particular, this shows by Theorem 2.11 that the control system defined above does not possess a semiconcave (outside the origin) control-Lyapunov function V (with, for instance, $W = V$) and a continuous positive definite function verifying (2.8) and (2.9).

3. Complementary definitions.

3.1. Some facts in nonsmooth analysis. We recall briefly some notions of nonsmooth analysis which are essential for this article. We first define $\partial_P V(x)$ as the *proximal subdifferential* of V at x where the function $V : \mathbb{R}^n \to \mathbb{R}$ is assumed to be locally Lipschitz: ζ belongs to $\partial_P V(x)$ if and only if there exists σ and $\eta > 0$ such that

$$V(y) - V(x) + \sigma\|y - x\|^2 \geq \langle \zeta, y - x \rangle \quad \forall y \in x + \eta B. \tag{3.1}$$

We further state that this object can be empty at some points. Nevertheless it can be proved that the proximal subdifferential is nonempty on a dense set of $\mathbb{R}^n$. Such a property leads us to define the *limiting subdifferential* and the *generalized gradient* which will be nonempty at every point. For all x in $\mathbb{R}^n$, the limiting subdifferential of V at x is defined as follows:

$$\partial_L V(x) := \{\lim \zeta_k : x_k \to x, \zeta_k \in \partial_P V(x_k)\}. \tag{3.2}$$

REMARK 3.1. *Of course, by the construction of the limiting subdifferential and by continuity of $f(\cdot,\cdot)$, the property* (2.4) *given in Definition* 2.3 *is equivalent to the following one:*

$$\forall x \in \mathbb{R}^n \setminus \{0\},\ \forall \zeta \in \partial_L V(x), \quad \min_{u\in U}\langle \zeta, f(x,u)\rangle \le -W(x). \tag{3.3}$$

Finally, we derive the generalized gradient of Clarke as follows:

$$\partial V(x) := \text{co} \quad \partial_L V(x), \tag{3.4}$$

where co$A$ denotes the convex hull of the set A.

It is important to note that in our case of a locally Lipschitz function, the definition of the generalized gradient coincides with the following one based on Rademacher's theorem:

$$\partial V(x) := \text{co}\{\lim \nabla V(x_k) : x_k \to x, x_k \in D_f \setminus N\}, \tag{3.5}$$

where D_f denotes the set of differentiability of f and N is any set of Lebesgue measure zero in $\mathbb{R}^n$.

Moreover, we stress that there exist complete calculi of proximal subdifferentials and generalized gradients, ones that extend all theorems of the usual smooth calculus; our principal references for this theory are the books of Clarke [8] and Clarke et al. [12].

3.2. Results on semiconcave functions. We recall in this subsection some basic properties of the semiconcave functions. Let us first recall this definition; we assume in this section that Ω is a given open subset of $\mathbb{R}^n$.

DEFINITION 3.2. *Let $g : \Omega \longrightarrow \mathbb{R}$ be a continuous function on Ω; it is said to be semiconcave on Ω if for any point $x_0 \in \Omega$ there exist $\rho, C > 0$ such that*

$$g(x) + g(y) - 2g\left(\frac{x+y}{2}\right) \le C\|x-y\|^2 \tag{3.6}$$

for all $x, y \in x_0 + \rho B$.

The property (3.6) amounts to the concavity of $x \mapsto g(x) - 2C\|x\|^2$, as is easily checked. Hence, a semiconcave function g can be seen locally as the sum of a concave function and a smooth function. In particular, this implies that the semiconcave functions are locally Lipschitz. We know different examples of semiconcave functions. Concave functions are of course semiconcave. Another class of semiconcave functions is that of C^1 functions with locally Lipschitz gradient. We can in fact give a characterization of the semiconcavity property of a function g by using the proximal superdifferentials defined as follows:

$$\partial^P g(x) := -\partial_P g(x), \tag{3.7}$$

or, equivalently, $\zeta \in \partial^P g(x)$ if and only if there exists σ and $\eta > 0$ such that

$$g(y) - g(x) - \sigma\|y - x\|^2 \leq \langle \zeta, y - x\rangle \quad \forall y \in x + \eta B. \tag{3.8}$$

This analytic definition enables us to give a characterization of semiconcavity; we refer to [24] for the proof.

PROPOSITION 3.3. *A function $g : \Omega \to \mathbb{R}$ is semiconcave if and only if σ and η of* (3.8) *can be chosen uniform on the compact sets of Ω. Moreover, the superdifferential and the generalized gradients coincide on Ω.*

REMARK 3.4. *We can in fact relate the semiconcavity property of a given function to some geometric properties of its epigraph; we refer to* [24] *for such results. Furthermore we can define the semiconcavity property in a more general setting such that semiconcave functions keep the same behavior of concave functions; hence we can relate their differentiability properties to the ones of concave functions (see, for instance,* [32]*).*

Since the semiconcave functions are locally Lipschitz, we get by Rademacher's theorem that they are differentiable almost everywhere. Actually, since they are locally the sum of a semiconcave function and a smooth function, we can state positively by Alexandroff's theorem (see [2, 14]) that the semiconcave functions are twice differentiable almost everywhere.

A study has been devoted to the set of nondifferentiability of such functions. Alberti, Ambrosio, and Cannarsa [1] were able to provide some upper bounds on the dimension of singular sets of semiconcave functions.

Let $g : \Omega \to \mathbb{R}$ be a semiconcave function. Define

$$\Sigma^k(g) := \{x \in \Omega : \dim(\partial g(x)) = k\},$$

where $k \in [0, n]$ is an integer. Clearly, $\Sigma^0(g)$ represents the set of differentiability of u, and moreover

$$\Omega = \bigcup_{k=0}^{n} \Sigma^k(g). \tag{3.9}$$

We can evaluate the size of these sets.

PROPOSITION 3.5. *For any integer $k \in [0, n]$, the set $\Sigma^k(g)$ has Hausdorff dimension $\leq n - k$.*

We refer to [1] (see also [3]) for the proof and again to the book of Morgan [19] for a serious survey of the Hausdorff dimension.

Finally, Alberti, Ambrosio, and Cannarsa made some useful links between the Bouligand tangent cones of some subsets of the $\Sigma^k(g)$'s and the generalized gradients of g. Let us define for any $\alpha > 0$

$$\Sigma^k_\alpha(f) := \big\{x \in \Omega : \exists B^k_\alpha \subset \partial f(x) \text{ with } \operatorname{diam}(B^k_\alpha) = 2\alpha\big\},$$

where B^k_α denotes a ball of dimension k with diameter α. For any set $S \subset \mathbb{R}^n$, we shall denote by $S^\perp$ the set defined as follows:

$$S^\perp := \{p \in \mathbb{R}^n : q \mapsto \langle q, p\rangle \text{ is constant on } S\}.$$

We have the following result.

PROPOSITION 3.6. *The sets $\Sigma^k_\alpha(g)$ are closed sets, and*

$$T^B_{\Sigma^k_\alpha(g)}(x) \subset [\partial f(x)]^\perp \quad \forall x \in \Sigma^k_\alpha(f) \setminus \Sigma^{k+1}_\alpha(f).$$

We again refer to the paper of Alberti, Ambrosio, and Cannarsa for the proof.

3.3. Discontinuous stabilizing feedbacks. As it has been explained before, there do not exist robust stabilizing feedbacks in general. To overcome this difficulty, we describe a concept of solution of the general Cauchy problem

$$\dot{x} = f(x, u(x)), \quad x(0) = x_0, \tag{3.10}$$

where the feedback $u : \mathbb{R}^n \to U$ is not assumed to be continuous. This concept of solutions for differential equations with discontinuous right-hand side, inspired by the theory of differential games, has been used in the fundamental article of Clarke et al. [10] (see also [9]) to produce discontinuous stabilizing feedbacks; it provides an alternative approach to those developed by Sussmann [31] and Coron [13] (see also Pomet [20]).

Let $\pi = \{t_i\}_{i\geq 0}$ be a partition of $[0, \infty)$, by which we mean a countable, strictly increasing sequence t_i with $t_0 = 0$ such that $t_i \to \infty$ as $i \to \infty$. The *diameter* of π, denoted $\mathrm{diam}(\pi)$, is defined as $\sup_{i\geq 0}(t_{i+1} - t_i)$. Given an initial condition x_0, the π-trajectory $x(\cdot)$ corresponding to π is defined in a step-by-step fashion as follows. Between t_0 and t_1, $x(\cdot)$ is a classical solution of the differential equation

$$\dot{x}(t) = f(x(t), u(x_0)), \quad x(0) = x_0, \quad t_0 \leq t \leq t_1.$$

(Of course in general we do not have uniqueness of the solution, nor is there necessarily even one solution.) We then set $x_1 := x(t_1)$ and restart the system with control value $u(x_1)$:

$$\dot{x}(t) = f(x(t), u(x_1)), \quad x(t_1) = x_1, \quad t_1 \leq t \leq t_2,$$

and so on in this fashion. This resulting trajectory x is a physically meaningful one that corresponds to a natural sampling procedure and piecewise constant controls; this kind of solution, called a system sampling solution, is due to Krasovskii and Subbotin (see [15]). We proceed now to give the definition of the global asymptotic stabilization associated to this concept.

DEFINITION 3.7. *The system* (2.1) *is globally asymptotically stable in the sense of π-trajectories if there exist a function $M : \mathbb{R}_{>0} \longrightarrow \mathbb{R}_{>0}$ such that $\lim_{R\downarrow 0} M(R) = 0$ and two functions $T, \delta : \mathbb{R}_{>0} \times \mathbb{R}_{>0} \longrightarrow \mathbb{R}_{\geq 0}$ with the following property:*

For any $0 < r < R$, for any partition π with $\mathrm{diam}(\pi) \leq \delta(r, R)$, and for each initial state x_0 such that $\|x_0\| \leq R$, the corresponding π-trajectory $x(\cdot)$ is well-defined and satisfies the following:

(1) *for all $t \geq 0, \|x(t)\| \leq M(R)$;*

(2) *for all $t \geq T(r, R), \|x(t)\| \leq r$.*

REMARK 3.8. *This definition is equivalent to another one given by Sontag in* [27]. *In that paper, it was required that there exist a function $\beta \in \mathcal{KL}$ so that the following property held: For each $0 < \epsilon < K$, there exists a $\delta = \delta(\epsilon, K) > 0$ such that, for every sampling schedule π with $\mathrm{diam}(\pi) < \delta$, and for each initial state x_0 with $\|x_0\| \leq K$, the corresponding π-trajectory $x(\cdot)$ of* (2.1) *is well-defined and satisfies*

$$\|x_\pi(t)\| \leq \max\{\beta(K, t), \epsilon\} \quad \forall t \geq 0.$$

We can define from the concept of π-trajectories the notion of Euler trajectories. As presented in [25], we call an Euler solution of (2.2) any uniform limit of π-trajectories of this system with $\mathrm{diam}(\pi) \to 0$. Moreover, we will say that the closed-loop system (2.2) is globally asymptotically stable in the Euler sense (or that

the feedback u stabilizes in the Euler sense) if the two properties given in Definition 2.1 are satisfied for any Euler solutions.

We also recall briefly for the convenience of the reader that a function $x(\cdot) : [0,\infty) \to \mathbb{R}^n$ is called a Carathéodory solution (or trajectory) of our closed-loop system if it satisfies

$$\dot{x}(t) = f(x(t), u(x(t))) \quad \text{a.e. } \forall t \geq 0.$$

We will say in that case that the closed-loop system is stabilizing in the sense of Carathéodory.

4. Proof of Theorem 2.4. We can invoke the main result of [23] to get a control-Lyapunov function V_0 which is semiconcave on $\mathbb{R}^n \setminus \{0\}$. We begin by showing that there exists a smooth function $\gamma : (0,\infty) \to (0,\infty)$ which satisfies

$$\min_{u\in U} \langle \zeta, f(x,u)\rangle \leq -\gamma(V_0(x)) \quad \forall x \in \mathbb{R}^n \setminus \{0\},\ \forall \zeta \in \partial_P V_0(x). \tag{4.1}$$

We use the method given by Clarke, Ledyaev, and Stern in [11]. We set for all $v > 0$,

$$\gamma(v) := \min\{W(x); x \in \Gamma(v)\},$$

where

$$\Gamma(v) := \{x \in \mathbb{R}^n; V_0(x) = v\}.$$

It is not difficult to show that the multifunction Γ is locally Lipschitz, which implies that the function γ is locally Lipschitz on $(0,\infty)$ and verifies (4.1). Moreover, we can approximate γ by a smooth function $\tilde{\gamma}$ such that

$$0 < \tilde{\gamma} \leq \gamma.$$

Finally, without loss of generality we can suppose that γ is smooth and verifies (4.1). Now, we set

$$\Psi(t) := \int_1^t \frac{1}{\gamma(s)} ds. \tag{4.2}$$

This new function from $(0,\infty)$ into $\mathbb{R}$ is increasing, smooth, and verifies the three following properties:

$$\Psi'(t) = \frac{1}{\gamma(t)} \quad \forall t > 0, \tag{4.3}$$

$$\limsup_{t\downarrow 0} \Psi(t) \leq 0, \tag{4.4}$$

and

$$\liminf_{t\to\infty} \Psi(t) \geq 0. \tag{4.5}$$

We are now able to define a new control-Lyapunov function V_1. We set

$$V_1(x) := \begin{cases} V_0(x) e^{c\Psi(V_0(x))} & \text{if } x \neq 0, \\ 0 & \text{if } x = 0. \end{cases} \tag{4.6}$$

By (4.4) and (4.5) and the properties of V_0, this new function is obviously proper, continuous at the origin, and locally Lipschitz on $\mathbb{R}^n \setminus \{0\}$. We now want to make the link between the proximal subdifferentials of V_1 and the proximal subdifferentials of V_0; for that, we give the following lemma.

LEMMA 4.1. *Let there be given two functions $f : \Omega \to \mathbb{R}$ and $F : \mathbb{R} \to \mathbb{R}$. If we assume that f is positive and locally Lipschitz on the open set Ω and that F is a C^2, positive, and increasing ($F' > 0$) function, then for all $x \in \Omega$,*

$$\partial_P[fF(f)](x) = [F(f(x)) + f(x)F'(f(x))]\partial_P f(x).$$

The same formula holds for the proximal superdifferential. Moreover, if the function f is taken to be semiconcave, then the new function $fF(f)$ is semiconcave as well.

Proof. Let us consider $x \in \mathbb{R}^n$ and $\zeta \in \partial_P[fF(f)](x)$; then by (3.1), there exists $\sigma \geq 0$ such that

$$f(y)F(f(y)) - f(x)F(f(x)) + \sigma\|y - x\|^2 \geq \langle \zeta, y - x\rangle \tag{4.7}$$

whenever y is in a neighborhood of x. The function $X \to XF(X)$ is C^2, so we have by Taylor's formula that there exists a constant C such that for all Y in a neighborhood of X,

$$YF(Y) - XF(X) = F(X) + XF'(X)(Y - X) + \frac{C}{2}\|Y - X\|^2 + o(\|Y - X\|^2).$$

We get for $Y = f(y)$ and $X = f(x)$ that $f(y)F(f(y)) - f(x)F(f(x))$ is equal to

$$[F(f(x)) + f(x)F'(f(x))][f(y) - f(x)] + \frac{C}{2}\|f(y) - f(x)\|^2 + h,$$

where $h = o(\|f(y) - f(x)\|^2)$.

We set $D := F(f(x)) + f(x)F'(f(x))$; by the assumptions on f and F, $D > 0$, and so we can divide by D. On the other hand, f being locally Lipschitz, we deduce that there exists a constant $\overline{\sigma} \geq 0$ such that

$$\frac{f(y)}{D} - \frac{f(x)}{D} + \overline{\sigma}\|y - x\|^2 \leq \left\langle \frac{\zeta}{D}, y - x \right\rangle \tag{4.8}$$

whenever y is in a neighborhood of x; and then by the characterization (3.1) we get

$$\partial_P f[F(f)](x) \subset [F(f(x)) + f(x)F'(f(x))]\partial_P f(x).$$

This proves one inclusion; the other is left to the reader. Of course, for the case of the proximal superdifferential, a similar proof is valid.

It remains to show the conservation of semiconcavity. If we assume that f is semiconcave, then by using Proposition 3.3 and following the same proof as above, we show that the different σ remain uniform on the compact sets of Ω. □

We now turn back to the proof of Theorem 2.4; the lemma implies immediately that for all $x \in \mathbb{R}^n \setminus \{0\}$ and all $\zeta \in \partial_P V_1(x) \subset \partial_L V_1(x)$,

$$\begin{aligned}
\min_{u \in U}\langle \zeta, f(x,u)\rangle &\leq -\gamma(V_0(x))[e^{\Psi(V_0(x))} + c\Psi'(V_0(x))V_0(x)e^{\Psi(V_0(x))}] \\
&\leq -V_1(x)\left[\frac{\gamma(V_0(x))}{V_0(x)} + c\gamma(V_0(x))\psi'(V_0(x))\right] \\
&\leq -V_1(x)\left[\frac{\gamma(V_0(x))}{V_0(x)} + c\right] \quad \text{by (4.3)} \\
&\leq -cV_1(x).
\end{aligned}$$

On the other hand, as the initial function V_0 was semiconcave on $\mathbb{R}^n \setminus \{0\}$, we have by Lemma 4.1 that the new function V_1 is semiconcave; the proof of Theorem 2.4 is complete.

5. Proof of Theorems 2.5 and 2.7. We will treat only the case where the control-Lyapunov function is that given by Theorem 2.4. The general case of a control-Lyapunov function related to a function W is left to the reader.

Let V be the semiconcave Lyapunov function given by Theorem 2.4 and two positive constants $r < R$. We set

$$M_R := \max\{V(x) : \|x\| \leq R\} \quad \text{and} \quad M(R) := \max\{\|y\| : V(y) \leq M_R\}.$$

Obviously, the function $M(\cdot)$ is nondecreasing and verifies

$$\lim_{R \downarrow 0} M(R) = 0.$$

We also set two constants depending on r:

$$m_r := \min\{V(x) : \|x\| \geq r\} \quad \text{and} \quad m_{\frac{r}{2}} := \min\left\{V(x) : \|x\| \geq \frac{r}{2}\right\};$$

we can say by definition that if $V(x) \leq \frac{m_{\frac{r}{2}}}{2}$, then $x \in \frac{r}{2}\overline{B}$. On the other hand, the Proposition 3.3 allows us to consider $\sigma := \sigma(\frac{r}{2}, R)$ and δ uniform on the set $\mathcal{A} := \{x : \frac{m_{\frac{r}{2}}}{2} \leq V(x) \leq M_R\} \subset \mathbb{R}^n \setminus \{0\}$.

We get that for all $x \in \mathcal{A}$, all $y \in \mathcal{A}$, and all $\zeta \in \partial_L V(x)$,

$$-V(y) + V(x) + \sigma\|y - x\|^2 \geq \langle -\zeta, y - x\rangle. \tag{5.1}$$

From now on, we denote by M_f the upper bound of f on $R\overline{B} \times U$, by L_f the Lipschitz constant of f on the same set, by m_V the minimum of V, and by L_V the Lipschitz constant of V on $\mathcal{A}$. Let us consider a π-trajectory $x(\cdot)$ associated to a partition $\pi = \{0 = t_0 < t_1 < \cdots\}$ and to nodes $x_i := x(t_i)$ with $x_0 \in \mathcal{A}$. We pick ζ_0 belonging to $\partial_L V(x_0)$. For any $t \in [t_0, t_1]$, we can compute by (5.1)

$$\begin{aligned}
V(x(t)) - V(x_0) &\leq \langle \zeta_0, x(t) - x_0\rangle + \sigma\|x(t) - x_0\|^2 \\
&\leq \left\langle \zeta_0, \int_{t_0}^{t} f(x(s), u(x_0))ds \right\rangle + \sigma\|x(t) - x_0\|^2 \\
&\leq \langle \zeta_0, (t - t_0)f(x_0, u(x_0))\rangle \cdots \\
&\quad + \left\langle \zeta_0, \int_{t_0}^{t} [f(x(s), u(x_0)) - f(x_0, u(x_0))]ds \right\rangle + \sigma\|x(t) - x_0\|^2 \\
&\leq -(t - t_0)V(x_0) + \|\zeta_0\|L_f \max_{s \in [t_0, t_1]} \|x(s) - x_0\|(t - t_0) \cdots \\
&\quad + \sigma\|x(t) - x_0\|^2 \\
&\leq -(t - t_0)V(x_0) + L_V L_f M_f (t - t_0)^2 + \sigma M_f^2 (t - t_0)^2 \\
&\leq (t - t_0)\left[-m_V + (L_f L_V M_f + \sigma M_f^2)(t - t_0)\right].
\end{aligned}$$

More generally, we have for all $t \in [t_i, t_{i+1}]$,

$$V(x(t)) - V(x_i) \leq -(t - t_i)V(x_i) + [L_V L_f M_f + \sigma M_f^2](t - t_i)^2. \tag{5.2}$$

We get that for any n and for all $t \in [t_{n-1}, t_n]$,

$$\begin{aligned} V(x(t)) - V(x_0) &\leq \sum_{i=0}^{n-2} [-(t_{i+1} - t_i)V(x_i) + (L_V L_f M_f + \sigma M_f^2)(t_{i+1} - t_i)^2] \cdots \\ &\quad - (t - t_{n-1})V(t_{n-1}) + (L_f L_V M_f + \sigma M_f^2)(t - t_{n-1})^2 \\ &\leq (t - t_0)[-m_V + (L_f L_V M_f + \sigma M_f^2)\mathrm{diam}(\pi)]. \end{aligned} \tag{5.3}$$

We deduce that if we set

$$\delta(r, R) := \min \left\{ \frac{m_V}{2(L_f L_V M_f + \sigma M_f^2)}, \frac{m_r - m_{\frac{r}{2}}}{2L_V M_f} \right\},$$

we obtain from (5.3) that for every π-trajectory $x(\cdot)$ starting at x_0 and such that $\mathrm{diam}(\pi) \leq \delta(r, R)$, we have

$$\forall t \geq 0, \quad V(x(t)) - V(x_0) \leq -\frac{m_V}{2}(t - t_0). \tag{5.4}$$

That means that the π-trajectory remains in $\{x : V(x) \leq V(x_0)\}$, which is included in $M(R)\overline{B}$, and that for $t \geq T(r, R) := \frac{2M_R - m_{\frac{r}{2}}}{m_V}$,

$$V(x(t)) \leq V(x_0) - \frac{m_V}{2}t \leq \frac{m_{\frac{r}{2}}}{2};$$

that is, $x(t) \in \frac{r}{2}\overline{B}$. There is a possible danger! The work done above is valid only when we stay in the set $\mathcal{A}$. But as $\delta(r, R) \leq \frac{m_r - m_{\frac{r}{2}}}{2L_V M_f}$, there exists a first step i_0 for which $\frac{m_{\frac{r}{2}}}{2} \leq V(x_{i_0}) \leq \frac{m_r}{2}$, and by the same computation as above, the set $\{x : V(x) \leq V(x_{i_0})\}$ is invariant, that is,

$$\forall t \geq t_{i_0}, \quad x(t) \in \{x : V(x) \leq V(x_{i_0})\} \subset r\overline{B}.$$

This completes the proof for the case of π-trajectories.

We get from this proof (more especially from (5.2) and a convergence result of a Riemann's sums) that for any Euler trajectory of (2.2), we have that

$$V(x(t)) - V(x(s)) \leq -\int_s^t V(x(y))dy \quad \forall 0 \leq s \leq t. \tag{5.5}$$

Gronwall's lemma now brings a proof of the property (2.4).

We now make the proof of Theorem 2.7.

Proof. As in the statement of Theorem 2.5, the formula given above considers for all x a limiting subgradient $\zeta_V(x)$ and a function $u(\cdot)$ satisfying

$$\langle \zeta_V(x), f(x, u(x)) \rangle \leq -V(x) \quad \forall x \in \mathbb{R}^n \setminus \{0\}.$$

This construction agrees with the one given in the statement of Theorem 2.5; the result follows. ∎

6. Proof of Theorem 2.9. Theorem 2.9 requires a more subtle proof; we will need the following lemma and refer to the book of Clarke et al. [12] or to [24] for the proof.

LEMMA 6.1. *Let $f : \mathbb{R}^n \to \mathbb{R}$ be a locally Lipschitz function and $x \in \mathbb{R}^n$; if $\partial_P f(x)$ and $\partial^P f(x)$ are nonempty, then*

$$\partial_P f(x) = \partial^P f(x) = \partial f(x) = \{\nabla f(x)\}.$$

We know by Theorem 2.4 and Remark 3.1 that

$$\forall x \in \mathbb{R}^n \setminus \{0\}, \quad \max_{\zeta \in \partial_L V(x)} \min_{u \in U} \langle \zeta, f(x,u) \rangle \leq -V(x) < 0. \tag{6.1}$$

We set the function $\Psi : \mathbb{R}^n \longrightarrow \mathbb{R}$ as follows:

$$\forall x \in \mathbb{R}^n, \quad \Psi(x) := \min_{u \in U} \max_{\zeta \in \partial V(x)} \langle \zeta, f(x,u) \rangle.$$

LEMMA 6.2. *The function Ψ is upper semicontinuous.*

Proof. Since the function $\zeta \mapsto \langle \zeta, f(x,u) \rangle$ is upper continuous and the function f is continuous, we deduce that the function

$$x \mapsto \max_{\zeta \in \partial V(x)} \langle \zeta, f(x,u) \rangle$$

is upper semicontinuous. To conclude, we know that a minimum of upper semicontinuous functions is upper semicontinuous. □

We define now the following sets:

$$\mathcal{D} := \left\{ x \in \mathbb{R}^n \setminus \{0\} \text{ s.t. } \Psi(x) < -\frac{V(x)}{2} \right\} \quad \text{and} \quad S = \mathbb{R}^n \setminus \mathcal{D}.$$

LEMMA 6.3. *The set $\mathcal{D}$ is an open dense set of $\mathbb{R}^n$ and*

$$\mathcal{H} - \dim S \leq n - 1.$$

Proof. Since the multivalued mapping $x \mapsto \partial V(x)$ has a closed graph, the set $\mathcal{D}$ is obviously open. On the other hand, by the density theorem [12, Theorem 3.1], the proximal subdifferential $\partial_P V(x)$ is nonempty on a dense set. Consequently, by the semiconcavity of V, both proximal sub- and superdifferentials are nonempty on this set; it implies that (by Lemma 6.1) $\partial_P V(x) = \partial_L V(x) = \{\nabla V(x)\}$ on a dense subset of $\mathbb{R}^n$. So, we conclude that the min-max and the max-min of (6.1) and of the definition of the set $\mathcal{D}$ coincide on an open dense set of $\mathbb{R}^n$; that means that $\mathcal{D}$ contains this set. Consequently $\mathcal{D}$ is an open dense set of $\mathbb{R}^n$. Moreover, the complement S of $\mathcal{D}$ is included in $\cup_{k=1,\ldots,n} S^k(V)$; therefore we get the upper bound on the Hausdorff dimension of S by Proposition 3.5 given in section 3.2. □

We define the following multifunction on $\mathcal{D}$:

$$\forall x \in \mathcal{D}, \quad G(x) := \left\{ u \in U : \forall \zeta \in \partial V(x), \langle \zeta, f(x,u) \rangle \leq -\frac{V(x)}{2} \right\}.$$

LEMMA 6.4. *The multifunction G has nonempty closed convex values and is lower semicontinuous on $\mathcal{D}$.*

Proof. Since the system is affine in the control, the multifunction G has nonempty closed convex values. We show now that G is lower semicontinuous on $\mathcal{D}$ (we refer to

[6] for a task about semicontinuity of multivalued functions). We then have to prove that for any sequence $(x_n)_n$ of points in $\mathcal{D}$ converging to $x \in \mathcal{D}$, and for any $z \in G(x)$, there exists a sequence $(z_n)_n$ of points in $G(x_n)$ with limit z.

Let $(x_n)_n$ be a sequence in $\mathcal{D}$ converging to $x \in \mathcal{D}$, and let $y = f(x, u_0)$ in $G(x)$. We set, for all n,

$$z_n := f(x_n, u_0).$$

From now on, we denote by M_1 the Lipschitz constant of V, by M_2 the upper bound of $f(\cdot, u_0)$, and by M_3 the Lipschitz constant of $f(\cdot, u_0)$ in a neighborhood of x containing all the x_n (without loss of generality we can assume this condition), and on the other hand we denote by $\beta(A, B)$ the Hausdorff distance between the sets A and B (see [6]). Two cases appear.

1. $\max_{\zeta \in \partial V(x)} \langle \zeta, y \rangle < -\frac{V(x)}{2}$.
   We fix n and we choose $\zeta_n \in \partial V(x_n)$; so we have

$$\begin{aligned}
\langle \zeta_n, z_n \rangle &= \langle \zeta, z_n \rangle + \langle \zeta_n - \zeta, z_n \rangle \quad (\text{where } \zeta := \mathrm{proj}_{\partial V(x)}(\zeta_n)) \\
&\leq \langle \zeta, y \rangle + M_1 \|z_n - y\| + M_2 \beta(\partial V(x_n), \partial V(x)) \\
&< -\frac{V(x)}{2} + M_1 \|z_n - y\| + M_2 \beta(\partial V(x_n), \partial V(x)) \\
&< -\frac{V(x_n)}{2} + \frac{M_3}{2} \|x_n - x\| + M_3 \|x_n - x\| + M_2 \beta(\partial V(x_n), \partial V(x)).
\end{aligned}$$

   Hence, for n sufficiently high, $z_n \in G(x_n)$, and the sequence $(z_n)_n$ converges to $y = f(x, u_0)$ by continuity of f.
2. $\max_{\zeta \in \partial V(x)} \langle \zeta, y \rangle = -\frac{V(x)}{2}$.
   We know by assumption that since $x \in \mathcal{D}$ there exists $u_1 \in U$ such that

$$\forall \zeta \in \partial V(x), \quad \langle \zeta, f(x, u_1) \rangle < -\frac{V(x)}{2}.$$

   Consequently, we can express $y = f(x, u_0)$ as a limit of

$$y_p = t_p y + (1 - t_p) f(x, u_1)$$

   (when $t_p \uparrow 1$) such that $\max_{\zeta \in \partial V(x)} \langle \zeta, y_p \rangle < -\frac{V(x)}{2}$. On the other hand, by the first case each y_p is the limit of some sequence $(z_p^n)_n$; we conclude by a diagonal process.

We conclude that G is a lower semicontinuous multifunction on the set $\mathcal{D}$. ∎

Returning to the proof of our theorem, we can apply the well-known selection theorem of Michael [18, 6] to deduce the existence of a continuous selection u of G on $\mathcal{D}$.

Let us now set $\mathcal{E}$ as the set defined by

$$\mathcal{E} := \left\{ x \in \mathbb{R}^n \setminus \{0\} \text{ s.t. } \Psi(x) = -\frac{V(x)}{2} \right\}.$$

LEMMA 6.5. *For each x in $\mathcal{E}$, there exists a unique $f(x, u) \in U$ such that*

$$\max_{\zeta \in \partial_C V(x)} \langle \zeta, f(x, u) \rangle = -\frac{V(x)}{2}.$$

Proof. This is due to the assumption of strict convexity on the set of control U. If $f_0(x) \neq 0$ we leave it to the reader to prove that, modifying the dynamics if necessary, the lemma holds. □

We are now able to complete the construction of our feedback $u(\cdot)$. We set for each $x \in \mathcal{E}, u(x) := u$, where u is the u of Lemma 6.5. Moreover, for each $x \in S \setminus \mathcal{E} \setminus \{0\}$, we set $u(x) := u$, where u verifies

$$\exists \zeta \in \partial_L V(x), \quad \langle \zeta, f(x,u) \rangle \leq -V(x).$$

We have defined our feedback on all the space (of course, we set $u(0) = 0$). Let us now prove the rest of the theorem. Consider the closed-loop system

$$\dot{x} = f_0(x) + \sum_{i=1}^{m} u_i(x) f_i(x) \tag{6.2}$$

and show that it is globally asymptotically stable with respect to the Carathéodory solutions. Let us first show that the property (2.10) holds for Euler trajectories.

LEMMA 6.6. *For any Euler trajectory $x(\cdot)$ of (6.2), we have*

$$\Psi(x(t)) \leq -\frac{V(x(t))}{2} \quad \forall t > 0 \text{ s.t. } x(t) \neq 0. \tag{6.3}$$

Moreover

$$\dot{x}(t) = f(x(t), u(x(t))) \quad \text{a.e. } t > 0. \tag{6.4}$$

Proof. Let us consider $x_0 \in \mathbb{R}^n \setminus \{0\}$ and $x(\cdot)$ is an Euler trajectory of (6.2) with $x(0) = x_0$. Obviously, if $x_0 = 0$, then since $f(0, u(0)) = 0$ all the Euler solutions of (6.2) starting at $x_0 = 0$ will stay at the origin; then the property (6.4) holds. Let us now assume that $x_0 \neq 0$.

Let t_0 be fixed in $(0, \infty)$; there exists $\sigma > 0$ such that for any $\zeta \in \partial^P V(x(t_0))$, we have that

$$-V(y) + V(x(t_0)) + \sigma \|y - x(t_0)\|^2 \geq \langle -\zeta, y - x(t_0) \rangle$$

whenever y is in a neighborhood of $x(t_0)$. We deduce that for some $s < t_0$ and close to t_0, we have

$$V(x(t_0)) - V(x(s)) + \sigma \|x(s) - x(t_0)\|^2 \geq \langle \zeta, x(t_0) - x(s) \rangle.$$

This implies

$$\begin{aligned} \langle \zeta, x(t_0) - x(s) \rangle &\leq V(x(t_0)) - V(x(s)) + \sigma \|x(s) - x(t_0)\|^2 \\ &\leq -\int_s^{t_0} \frac{V(x(y))}{2} dy + \sigma \|x(s) - x(t_0)\|^2 \quad \text{by (5.5)}. \end{aligned} \tag{6.5}$$

Now, by convexity of $f(x(t), U)$ (since f is affine in the control) there exists a sequence $(s_n)_n$ and u_0 in U such that

$$\lim_{n \to \infty} \frac{x(t_0) - x(s_n)}{t_0 - s_n} = f(x(t_0), u_0). \tag{6.6}$$

Consequently, passing to the limit for the sequence $(s_n)_n$, we obtain

$$\langle \zeta, f(x(t_0), u_0)\rangle \leq -\frac{V(x(t_0))}{2}.$$

We can repeat this argument for all $\zeta \in \partial^P V(x(t_0))$, that is,

$$\forall \zeta \in \partial^P V(x(t_0)), \quad \langle \zeta, f(x(t_0), u_0)\rangle \leq -\frac{V(x(t_0))}{2}.$$

Since $\partial^P V(x(t_0) = \partial V(x(t_0))$, that means that

$$\Psi(x(t_0)) \leq -\frac{V(x(t_0))}{2}.$$

Hence, we deduce that for any $t > 0$, (6.3) is satisfied and

$$x(t) \in \mathcal{D} \cup \mathcal{E}.$$

Two cases appear. If $x(t) \in \mathcal{D}$, then by continuity of $u(\cdot)$ in a neighborhood of $x(t)$, we have $\dot{x}(t) = f(x(t)), u(x(t))$.

Otherwise, $x(t) \in \mathcal{E}$. In this case, Lemma 6.5 asserts that the set of limits of the form (6.6) is a singleton. Thus, we deduce that the function $x(\cdot)$ is left-derivable on $(0, \infty)$ with derivate $f(x(t), u(x(t)))$.

Now, since the trajectory $x(\cdot)$ is locally Lipschitz on $[0, \infty)$, Rademacher's theorem asserts that it is derivable almost everywhere. Then we conclude that this derivate coincides with $f(x(t), u(x(t)))$ almost everywhere; consequently, the Euler trajectories are solutions in the sense of Carathéodory. □

Consider now the case of solutions in the sense of Carathéodory. Let $x_0 \neq 0$ and let $x(\cdot)$ be a Carathéodory solution of (6.2) starting at x_0. Hence, we have a set N of measure zero on $[0, \infty)$ such that

$$\dot{x}(t) = f(x(t), u(x(t))) \quad \forall t \in [0, \infty) \setminus N. \tag{6.7}$$

We have by the mean value inequality (see [12, Exercise 2.7(d), p. 122]) that for any $0 \leq t < t'$, there exists $z_{t,t'} \in [x(t), x(t')]$ and $\zeta_{t,t'} \in \partial_L V(z_{t,t'})$ such that

$$V(x(t')) - V(x(t)) \leq \langle \zeta_{t,t'}, x(t') - x(t)\rangle. \tag{6.8}$$

Now by setting the function $\theta : \mathbb{R}_{\geq 0} \to \mathbb{R}, \theta(t) := V(x(t))$, it means that for any $t, t' \geq 0$

$$\theta(t') - \theta(t) \leq \langle \zeta_{t,t'}, x(t') - x(t)\rangle. \tag{6.9}$$

Since the function f is locally bounded, the function θ is locally Lipschitz and hence by Rademacher's theorem differentiable outside a set of measure zero N'. Therefore, for all $t \in [0, \infty) \setminus N \cup N'$, we obtain by passing to the limit in (6.9)

$$\theta'(t) \leq \langle \zeta, \dot{x}(t)\rangle = \langle \zeta, f(x(t), u(x(t)))\rangle,$$

where $\zeta \in \partial_L V(x(t))$.

LEMMA 6.7. *The Carathéodory trajectory $x(\cdot)$ does not belong to $S \setminus \mathcal{E}$ almost everywhere:*

$$x(t) \notin S \setminus \mathcal{E} \quad \textit{a.e. } t \geq 0.$$

The proof is based on the properties on the sets $S^k(V)$ given in section 3.2 and is postponed to the end of this section.

By Lemma 6.7 there exists a third set N^0 of measure zero such that

$$x(t) \in \mathcal{D} \quad \forall t \in [0,\infty) \setminus N^0.$$

Thus we get by construction of u that for all $t \in [0,\infty) \setminus N \cup N' \cup N^0$,

$$\theta'(t) \leq -\frac{V(x(t))}{2}.$$

Therefore, we deduce by the characterization given in section 3.1 that for any $t \geq 0$

$$\partial\theta(t) \subset \left(-\infty, -\frac{V(x(t))}{2}\right].$$

We deduce that the function $t \mapsto \theta(t) + \int_0^t \frac{V(x(s))}{2} ds$ is nonincreasing, and consequently

$$\forall 0 \leq s \leq t, \quad V(x(t)) - V(x(s)) \leq -\int_s^t \frac{V(x(y))}{2} dy. \tag{6.10}$$

Now if we fix $t_0 > 0$, and if we take $\zeta \in \partial^P V(x(t_0))$, we get by (6.5) and (6.10) that

$$\langle \zeta, x(t_0) - x(s) \rangle \leq -\int_s^{t_0} \frac{V(x(y))}{2} dy + \sigma \|x(s) - x(t_0)\|^2.$$

Then we deduce as in the case of Euler trajectory that for all $t > 0$,

$$x(t) \in \mathcal{D} \cup \mathcal{E}.$$

Now, Gronwall's lemma easily gives

$$\forall t > 0, \quad V(x(t)) \leq e^{-\frac{t}{2}} v(x_0)$$

for any Euler trajectory and any Carathéodory trajectory starting at x_0. We get that the closed-loop system (6.2) is globally asymptotically stable.

It remains to prove Lemma 6.7.

Proof. Assume that the conclusion is false. Then there would exist a subset H of $[0,\infty)$ of positive measure such that $x(\cdot)$ is differentiable in H and

$$x(t) \in S \setminus \mathcal{E} \quad \forall t \in H.$$

On the other hand by (3.9), we can write

$$\begin{aligned} S \setminus \mathcal{E} &= \bigcup_{k=1}^{n} \Sigma^k(V) \cap S \setminus \mathcal{E} \\ &= \bigcup_{k=1}^{n} \bigcup_{p \in \{1,2,\ldots\}} \Sigma^k_{\frac{1}{p}}(V) \cap S \setminus \mathcal{E}. \end{aligned}$$

Thus there exists a couple (k,p) for which

$$x(t) \in \Sigma^k_{\frac{1}{p}}(V) \cap S \setminus \mathcal{E} \subset \Sigma^k_{\frac{1}{p}}(V)$$

on a set of positive measure $H' \subset H$. This implies that there exists a $t_0 \in H'$ such that

$$\dot{x}(t_0) = f(x(t_0), u(x(t_0))) \in T^B_{\Sigma^k_{\frac{1}{p}}(V)}(x(t_0)).$$

Hence we deduce by Proposition 3.6 that

$$\forall \zeta \in \partial V(x), \quad \langle \zeta, f(x(t_0), u(x(t_0)))\rangle = -V(x(t_0)).$$

This last inequality implies that $x(t_0) \in \mathcal{D}$; we get a contradiction. □

7. Proof of Theorem 2.11. Let us recall that

$$\mathcal{D}^\delta_V := \{x \in \mathbb{R}^n \setminus \{0\} : \Psi_V(x) < -\delta(x)\}. \tag{7.1}$$

Since the function Ψ_V is upper semicontinuous, the set $\mathcal{D}^\delta_V$ is open, and since $\delta < V$ on $\mathbb{R}^n \setminus \{0\}$, by the same proof as before (see proof of Theorem 2.9) it is dense. Furthermore, by hypothesis (2.9), it is straightforward to show that there exists a continuous positive definite function $\epsilon : \mathbb{R}^n \to \mathbb{R}$ such that

$$\forall x \in \mathcal{D}^\delta_V, \quad \delta(x) + \epsilon(x) < V(x)$$

and

$$\forall x \in \mathcal{D}^\delta_V, \quad \Psi_V(x) \le -\delta(x) - \epsilon(x).$$

This implies, by the same proof as for Theorem 2.9 (replacing the term $\frac{V(x)}{2}$ by $\delta(x) + \epsilon(x)$), that $\mathcal{D}^\delta_V$ is open dense and that there exists a continuous function

$$u : \mathcal{D}^\delta_V \to U$$

such that for any $x \in \mathcal{D}^\delta_V$,

$$\forall \zeta \in \partial V(x), \quad \langle \zeta, f(x, u(x))\rangle \le -\delta(x) - \epsilon(x).$$

Now, we claim that there exists a function

$$\overline{u} : \mathcal{D}^\delta_V \to U,$$

which is smooth and such that

$$\forall x \in \mathcal{D}^\delta_V, \quad \|u(x) - \overline{u}(x)\| \le \frac{\epsilon(x)}{K_V(x)\sum_{i=1}^m M_i},$$

where $K_V(x)$ denotes the Lipschitz constant of the function V on the ball $\overline{B}(x, \frac{\|x\|}{2})$ and where the M_i's are the upper bounds of the functions f_i's on the ball $2\|x\|\overline{B}$. Such a function brings that for any $x \in \mathcal{D}^\delta_V$ and for any $\zeta \in \partial V(x)$,

$$\begin{aligned}\left\langle \zeta, f_0(x) + \sum_{i=1}^m \overline{u_i}(x) f_i(x) \right\rangle &\le -\delta(x) - \epsilon(x) + \|\zeta\|\|u(x) - \overline{u}(x)\| \sum_{i=1}^m \|f_i(x)\| \\ &\le -\delta(x) - \epsilon(x) + K_V(x) \sum_{i=1}^m M_i \|u(x) - \overline{u}(x)\| \\ &\le -\delta(x).\end{aligned}$$

Finally, considering a Carathéodory solution $x(\cdot)$ of

$$\dot{x} = f_0(x) + \sum_{i=1}^{m} \overline{u_i}(x) f_i(x),$$

starting at $x_0 \in \mathbb{R}^n$ we get that for any $t_0 > 0$ such that $x(t_0) \neq 0$,

$$\Psi_V(x(t_0)) \leq -\delta(x(t_0)).$$

This means by (2.9) that the trajectory $x(\cdot)$ stays in $\mathcal{D}_V^\delta$ for positive times. Theorem 2.11 is proved.

Acknowledgments. The author is grateful to Francis Clarke for comments and several corrections on a previous version of the paper. He is also indebted to Olivier Ley for his help in the writing of this article.

DYNKIN GAMES VIA DIRICHLET FORMS AND SINGULAR CONTROL OF ONE-DIMENSIONAL DIFFUSIONS*

MASATOSHI FUKUSHIMA† AND MICHAEL TAKSAR‡

Abstract. We consider a zero-sum game of optimal stopping in which each of the opponents has the right to stop a one-dimensional diffusion process. There are two types of costs. The first is accumulated continuously at the rate $H(X_t)$, where X_t is the current position of the process. The second is a cost associated with the stopping of the process. It is given by the function $f_1(x)$ for the first player and the function $f_2(x)$ for the second player, where x is the position of the process when the stopping option is exercised.

We study the solution of the free boundary problem associated with this game via Dirichlet forms on the appropriate functional space. Integrating the value function of the game, we get a solution to another free boundary problem which yields the optimal return function for a singular stochastic control problem.

Key words. Dynkin game, Dirichlet form, free boundary problem, singular stochastic control

1. Introduction.

The reflecting diffusion processes are interesting objects to be studied from a variety of different points of view. In particular, the reflecting Brownian motion on a one-dimensional interval was characterized as a solution of a singular control problem [7, 16]. More specifically, let (w_t, P) be a one-dimensional standard Brownian motion starting at the origin and let

$$X_t = x + \sigma w_t + \mu t + A_t^{(1)} - A_t^{(2)}, \qquad x \in \mathbb{R}, \tag{1.1}$$

where $\sigma \neq 0$, μ are constants, and $\mathbb{S} = (A_t^{(1)}, A_t^{(2)})$ is a pair of nonanticipating increasing processes. $\mathbb{S}$ represents a strategy under which the cost function

$$k_x(\mathbb{S}) = E\left(\int_0^\infty e^{-\alpha t} h(X_t)dt + \int_0^\infty e^{-\alpha t}(rdA_t^{(1)} + \ell dA_t^{(2)})\right) \tag{1.2}$$

is to be minimized. Here, α, r, ℓ are preassigned positive constants and $h(x)$ is a given convex function taking its minimum at the origin. It was then shown by Taksar [16] that there exists an optimal strategy $\tilde{\mathbb{S}}$ such that

$$W(x) = \min_{\mathbb{S}} k_x(\mathbb{S}) = k_x(\tilde{\mathbb{S}})$$

and that $\tilde{\mathbb{S}}$ is actually equal to (ℓ_t^a, ℓ_t^b), where ℓ^a, ℓ^b are local times at points a, b for uniquely determined a, b, $a < 0 < b$. Thus the corresponding optimal process (1.1) is the reflecting diffusion on the closed interval $[a, b]$. The proof in [16] was carried out

by solving a related free boundary problem by making use of a solution of an optimal stopping game problem, which had been formulated by Gusein-Zade [6].

The purpose of the present paper is to extend those results in [16] by replacing the process $x + \sigma w_t + \mu t$ appearing in (1.1) on the one hand and constant costs r, ℓ appearing in (1.2) on the other, with a more general diffusion process governed by variable C^1-coefficients $\sigma(x), \mu(x)$ and with variable costs $f_1(x), f_2(x)$, respectively. To this end, we shall employ the Dynkin optimal stopping game and its Dirichlet form characterization due to Zabczyk [18]. As will be explained in section 2, the value function of the Dynkin game for a general symmetric Hunt process was identified in [18] with the solution of a certain variational inequality in a regular Dirichlet space setting. Such an identification had been established by Nagai [14] for a one-sided optimal stopping problem. This sort of an analytic characterization of the stopping game was missing in [6], making the usage of [6] less simple.

We can then proceed along almost the same lines as in [16] in getting the solution of our singular control problem. However, it is more useful to rewrite the infinitesimal generator $\frac{1}{2}\sigma(x)^2 \frac{d^2}{dx^2} + \mu(x)\frac{d}{dx}$ of the controlled diffusion in the Feller canonical form $\frac{d}{dm}\frac{d}{ds}$. The conditions on the data h, f_1, f_2 will be stated in terms of the intrinsic quantities s and m.

In section 3, we shall apply the Dynkin game description of the solution V of a variational inequality presented in [18] to a one-dimensional diffusion with generator $\frac{d}{ds}\frac{d}{dm}$ in showing that an integral function W of V with respect to ds is a solution of a certain free boundary problem involving the operator $\frac{d}{dm}\frac{d}{ds}$, which will then be identified in section 4 with the optimal return function of our singular control of the (σ, μ)-diffusion. The admissible processes X_t to be optimized will be formulated in section 4 by SDE variants of the identity (1.1), and the optimal process will be shown to be the reflecting (σ, μ)-diffusion on the interval specified in the free boundary problem.

We emphasize that our Dirichlet form approach automatically guarantees the quasi continuity (actually the absolute continuity in the present one-dimensional application) of the value function V, which, combined with the saddle point characterization of V, readily implies that its integral function W is the classical solution of the free boundary problem. As a result we get a classical solution to the one-dimensional singular stochastic control problem as opposed to the viscosity solution guaranteed by a general theory (see [3]).

A slight extension of [16] has been considered by Kawabata [11], where the costs r, ℓ were still kept constant, however, and the method of [18] was not utilized.

In a recent paper [10], Karatzas and Wang obtained the same relation as in our case between the value functions of a Dynkin game and a control problem of general bounded variation processes. The method in [10] is more direct and pathwise, but the admissible process to be optimized is purely of bounded variation and the leading martingale part as in our case is absent.

In what follows, $C^k(I)$ (resp., $C_0^k(I)$) will denote the space of k-times continuously differentiable functions (resp., with compact support) on an interval $I \subset \mathbb{R}$, $k = 1, 2$.

2. Dynkin games via Dirichlet forms. Let X be a locally compact separable metric space and m be a positive Radon measure on X with full support. $L^2(X; m)$ denotes the real L^2-space with inner product $(\cdot, \cdot)$. We consider a Dirichlet form $(\mathcal{E}, \mathcal{F})$ on $L^2(X; m)$. By definition, $\mathcal{E}$ is a closed symmetric form with domain $\mathcal{F}$ dense in $L^2(X; m)$ such that the unit contraction operates on it:

$$u \in \mathcal{F} \Longrightarrow v = 0 \vee u \wedge 1 \in \mathcal{F}, \qquad \mathcal{E}(v, v) \leq \mathcal{E}(u, u).$$

Recall that a closed symmetric form is a Dirichlet form if and only if the associated L^2-semigroup $\{T_t, t > 0\}$ is Markovian in the sense that

$$0 \le f \le 1, \qquad f \in L^2 \Longrightarrow 0 \le T_t f \le 1.$$

We let $\mathcal{E}_\alpha(u,v) = \mathcal{E}(u,v) + \alpha(u,v)$ for $\alpha > 0$. We assume that the Dirichlet form $(\mathcal{E}, \mathcal{F})$ is regular in the sense that $\mathcal{F} \cap C_0(X)$ is $\mathcal{E}_1$-dense in $\mathcal{F}$ and uniformly dense in $C_0(X)$, where $C_0(X)$ denotes the space of continuous functions on X with compact support. There exists then a Hunt process (a right continuous, quasi-left continuous strong Markov process) $\mathbf{M} = (X_t, P_x)$ on X such that

$$p_t f(x) = E_x(f(X_t)), \qquad x \in X,$$

is a version of $T_t f$ for all $f \in C_0(X)$ [5].

In what follows, basic notions and relations concerning the regular Dirichlet form $(\mathcal{E}, \mathcal{F})$ and the associated Hunt process $\mathbf{M}$ shall be taken from [5]. In particular, the L^2-resolvent $\{G_\alpha,\ \alpha > 0\}$ associated with the Dirichlet form $(\mathcal{E}, \mathcal{F})$ satisfies

$$G_\alpha f \in \mathcal{F}, \quad \mathcal{E}_\alpha(G_\alpha f, v) = (f, v) \qquad \forall f \in L^2(X; m),\ \forall v \in \mathcal{F},$$

and further the resolvent $\{R_\alpha\ \alpha > 0\}$ of the Hunt process $\mathbf{M}$ defined by

$$R_\alpha f(x) = E_x\left(\int_0^\infty e^{-\alpha t} f(X_t) dt\right), \qquad x \in X,$$

is a quasi-continuous modification of $G_\alpha f$ for any Borel function $f \in L^2(X; m)$. For $v \in \mathcal{F}$, $\tilde{v}$ will denote a quasi-continuous modification of v.

Given $\alpha > 0,\ H \in L^2(X; m)$, and $f_1, f_2 \in \mathcal{F}$ with $-f_1 \le f_2$, we let

$$K = \{u \in \mathcal{F} : -f_1 \le u \le f_2, \quad m\text{-a.e.}\}. \tag{2.1}$$

One looks for a solution $V \in K$ of the inequality

$$\mathcal{E}_\alpha(V, u - V) \ge (H, u - V) \qquad \forall u \in K. \tag{2.2}$$

Such a variational inequality arises in various contexts and goes back to Stampacchia [15].

Proposition 2.1. *There exists a unique function $V \in K$ satisfying* (2.2).

Proof. This is a well-known fact, but we reproduce a proof given by Nagai [14] in a way convenient for later use. First consider the special case that $H = 0$. We can then see the equivalence of the following inequalities holding for $V \in K$:

$$\mathcal{E}_\alpha(V, u - V) \ge 0 \qquad \forall u \in K, \tag{2.3}$$

$$\mathcal{E}_\alpha(V, V) \le \mathcal{E}_\alpha(u, u) \qquad \forall u \in K. \tag{2.4}$$

In fact, (2.3) readily implies (2.4) by the Schwarz inequality. Conversely, suppose (2.4). Take any $u \in K$ and put $w = u - V$. Since K is convex,

$$V + \epsilon w = (1 - \epsilon)V + \epsilon u \in K \qquad \forall \epsilon \in (0, 1).$$

Equation (2.4) then leads us to

$$\mathcal{E}_\alpha(V, V) \le \mathcal{E}_\alpha(V + \epsilon w, V + \epsilon w)$$

and $2\mathcal{E}_\alpha(V,w)+\epsilon\mathcal{E}_\alpha(w,w)\geq 0$. We get (2.3) by letting $\epsilon\downarrow 0$.

Now (2.4) (and equivalently (2.3)) has a unique solution $V\in K$ by virtue of the closedness of the convex set K and the parallelogram law (see, for instance, the proof of [5, Lemma 2.1.2]).

Next consider a general $H\in L^2(X;m)$. By making use of the L^2-resolvent G_α, we can rewrite the inequality (2.2) as

$$\mathcal{E}_\alpha(V-G_\alpha H,(u-G_\alpha H)-(V-G_\alpha H))\geq 0$$

in concluding that the solution V of (2.1) and (2.2) is related to the solution V^0 of

(2.5)
$$K^0=\{u\in\mathcal{F}:-h_1\leq u\leq h_2,\quad m\text{-a.e.}\},\quad h_1=f_1+G_\alpha H,\quad h_2=f_2-G_\alpha H,$$

$$V^0\in K^0,\quad \mathcal{E}_\alpha(V^0,u-V^0)\geq 0\qquad \forall u\in K^0 \tag{2.6}$$

by the relation

$$V=V^0+G_\alpha H. \qquad \square \tag{2.7}$$

Zabczyk has related the solution of the variational inequality (2.2) to the value function of an optimal stopping game (called a *Dynkin game* after [2]) for the associated Hunt process $\mathbf{M}=(X_t,P_x)$ in the following manner [18, Theorem 1].

THEOREM 2.1 (Zabczyk). *For any Borel function $H\in L^2(X;m)$ and for any $f_1,f_2\in\mathcal{F}$ with $-f_1\leq f_2$, we put*

$$\begin{aligned}J_x(\tau,\sigma)&=E_x\left(\int_0^{\tau\wedge\sigma}e^{-\alpha t}H(X_t)dt\right)\\&\quad+E_x\left(e^{-\alpha(\tau\wedge\sigma)}(-I_{\sigma\leq\tau}\tilde{f}_1(X_\sigma)+I_{\tau<\sigma}\tilde{f}_2(X_\tau))\right)\end{aligned} \tag{2.8}$$

for $x\in X$ and for finite stopping times τ,σ. Then the solution of (2.1) *and* (2.2) *admits as its quasi-continuous version the value function of the game*

$$V(x)=\inf_\tau\sup_\sigma J_x(\tau,\sigma)=\sup_\sigma\inf_\tau J_x(\tau,\sigma),\qquad x\in X\setminus N, \tag{2.9}$$

where N is some properly exceptional set with respect to $\mathbf{M}$.

Furthermore if we let

$$E_1=\{x\in X-N:V(x)=-\tilde{f}_1(x)\},\quad E_2=\{x\in X-N:V(x)=\tilde{f}_2(x)\},$$

then the hitting times $\hat{\tau}=\sigma_{E_2}$, $\hat{\sigma}=\sigma_{E_1}$ are the saddle point of the game:

$$J_x(\hat{\tau},\sigma)\leq J_x(\hat{\tau},\hat{\sigma})\leq J_x(\tau,\hat{\sigma}) \tag{2.10}$$

for any $x\in X-N$ and for any stopping times τ, σ. In particular

$$V(x)=J_x(\hat{\tau},\hat{\sigma})\qquad\forall x\in X\setminus N. \tag{2.11}$$

Actually this theorem was shown in [18] only when $H=0$. However, on account of the proof of Proposition 2.1, the statements of Theorem 2.1 for a general Borel function $H\in L^2(X;m)$ can be reduced to this special case. In fact, by what was

proved in [18], the solution of (2.5) and (2.6) admits a quasi-continuous version given by

$$V^0(x) = \inf_\tau \sup_\sigma J_x^0(\tau,\sigma) = \sup_\sigma \inf_\tau J_x^0(\tau,\sigma), \qquad x \in X \setminus N,$$

where N is some properly exceptional set and

$$J_x^0(\tau,\sigma) = E_x\left(e^{-\alpha(\tau\wedge\sigma)}(-I_{\sigma\le\tau}\tilde{h}_1(X_\sigma) + I_{\tau<\sigma}\tilde{h}_2(X_\tau))\right),$$
$$\tilde{h}_1 = \tilde{f}_1 + R_\alpha H, \qquad \tilde{h}_2 = \tilde{f}_2 - R_\alpha H.$$

In view of (2.7), the solution of (2.1) and (2.2) then admits a quasi-continuous version

$$V(x) = V^0(x) + R_\alpha H(x), \qquad x \in X \setminus N,$$

which in turn can be seen to satisfy the identity (2.9), because the Dynkin formula

$$R_\alpha H(x) - E_x\left(e^{-\alpha(\tau\wedge\sigma)}R_\alpha H(X_{\tau\wedge\sigma})\right) = E_x\left(\int_0^{\tau\wedge\sigma} e^{-\alpha t}H(X_t)dt\right)$$

leads us to

$$J_x^0(\tau,\sigma) + R_\alpha H(x) = J_x(\tau,\sigma).$$

The second statement of Theorem 2.1 is also an immediate consequence of that for V^0 and J^0.

We refer to [18] for related literature prior to [18].

3. One-dimensional Dynkin game and free boundary problems. When the underlying space X is one-dimensional, the solution V of the variational inequality (2.1), (2.2) can be described as a solution of a certain free boundary problem. The proof can be carried out using primarily its Dynkin game description (2.9) and (2.10).

More specifically, let $\dot{s}(x)$ and $\dot{m}(x)$ be strictly positive C^1-functions on $\mathbb{R}$. Denote the one-dimensional Lebesgue measure by dx and the measures $\dot{s}(x)dx$, $\dot{m}(x)dx$ by ds, dm, respectively. We assume that both $-\infty$ and ∞ are natural (neither exit nor entrance) boundaries of $\mathbb{R}$ with respect to s, m in Feller's sense [9]:

$$\int_{-\infty<y<x<-1} ds(x)dm(y) = \infty, \qquad \int_{-\infty<y<x<-1} dm(x)ds(y) = \infty,$$
$$\int_{1<x<y<\infty} ds(x)dm(y) = \infty, \qquad \int_{1<x<y<\infty} dm(x)ds(y) = \infty. \tag{3.1}$$

For $A > 0$, we let

$$\mathcal{F} = H^1((-A,A);dx)$$
$$= \{u \in L^2((-A,A);dx) : u \text{ is absolutely continuous, } u' \in L^2((-A,A);dx)\}, \tag{3.2}$$

$$\mathcal{E}(u,v) = \int_{-A}^{A} u'(x)v'(x)\,\frac{1}{\dot{m}(x)}\,dx, \qquad u,v \in \mathcal{F}. \tag{3.3}$$

We can and shall regard $(\mathcal{E},\mathcal{F})$ as a regular local Dirichlet form on $L^2([-A,A];ds)$. The associated Hunt process $\mathbf{M} = (X_t, P_x)$ on the closed interval $[-A,A]$ is a conservative diffusion process, namely, a strong Markov process with continuous sample

paths and infinite life time, and actually it is a reflecting barrier diffusion on $[-A, A]$ with infinitesimal generator $\frac{d}{ds}\frac{d}{dm}$. Since $\mathcal{F}$ is the ordinary Sobolev space $H^1(-A, A)$ on the one-dimensional interval $(-A, A)$ and the metric $\mathcal{E}_1$ on it is equivalent to the square root of the Dirichlet integral plus L^2-norm, we see that each one point set $\{x\} \subset [-A, A]$ has a positive capacity, the quasi continuity reduces to the ordinary continuity, and $\mathbf{M}$ admits no nonempty exceptional set [5, Example 2.1.2].

We now let $V(x)$, $x \in [-A, A]$, be the solution of the variational inequality (2.1), (2.2) for the present Dirichlet form $(\mathcal{E}, \mathcal{F})$ on $L^2([-A, A]; ds)$ under the following assumptions on the data H, f_1, f_2.

ASSUMPTION 3.1. *$H(x)$ is a continuous function on $\mathbb{R}$ such that*

$$H(0) = 0, \quad H(x) \text{ is strictly increasing}, \quad H(x) \to \pm\infty \text{ as } x \to \pm\infty.$$

f_1, f_2 are C^2-functions with $0 < f_1, f_2 \le M$ for some $M > 0$ and

$$f_1'(x) \ge 0, \quad x \in \mathbb{R}, \qquad \frac{d}{ds}\frac{d}{dm} f_1 - H \text{ is strictly decreasing on } (-\infty, 0),$$

$$f_2'(x) \le 0, \quad x \in \mathbb{R}, \qquad \frac{d}{ds}\frac{d}{dm} f_2 + H \text{ is strictly increasing on } (0, \infty).$$

Remark 3.1. (i) The assumptions for f_1, f_2 are trivially satisfied by $f_1 = r, f_2 = \ell$ positive constant functions.

(ii) In the next section, we shall be concerned with controls of a diffusion with generator $\frac{d}{dm}\frac{d}{ds}$, a diffusion with scale ds, and speed measure dm in the sense of Feller [9]. For that purpose, we need to consider in the first part of this section a diffusion with the roles of ds and dm being interchanged.

LEMMA 3.1. *There exists $A > 0$ such that the diffusion $\mathbf{M} = (X_t, P_x)$ on $[-A, A]$ associated with the Dirichlet form* (3.2), (3.3) *satisfies*

$$E_{\xi_1}\left(\int_0^{\sigma_0 \wedge \sigma_{-A}} e^{-\alpha t} H(X_t) dt\right) < -2M, \quad E_{\xi_2}\left(\int_0^{\sigma_0 \wedge \sigma_A} e^{-\alpha t} H(X_t) dt\right) > 2M \tag{3.4}$$

for some $\xi_1 \in (-A, 0)$ and $\xi_2 \in (0, A)$. Here σ_x denotes the hitting time of the one point set $\{x\}$.

Proof. For an open interval $I \subset \mathbb{R}$, we denote by $\mathbb{D}^I$ the absorbing diffusion on I with infinitesimal generator $\frac{d}{ds} \cdot \frac{d}{dm}$ and by R_α^I its resolvent operator. By virtue of the condition (3.1), $\mathbb{D}^{\mathbb{R}}$ is conservative and its α-order hitting probability $E_x\left(e^{-\alpha\sigma_c}\right)$ for any fixed point c tends to zero as $x \to \pm\infty$ [9]. Hence, by Dynkin's formula,

$$\lim_{x \to -\infty} R_\alpha^{(-\infty, c)} 1(x) = \frac{1}{\alpha}, \qquad \lim_{x \to \infty} R_\alpha^{(d, \infty)} 1(x) = \frac{1}{\alpha} \tag{3.5}$$

for any c and d. By Assumption 3.1, we can take $\xi < 0$ such that

$$H(x) < -4\alpha M \qquad \forall x \le \xi.$$

By (3.5), $R_\alpha^{(-\infty, \xi)} 1(\xi_1) > 1/(2\alpha)$ for some $\xi_1 < \xi$. Since $R_\alpha^{(-A, \xi)} 1(\xi_1)$ increases to $R_\alpha^{(-\infty, \xi)} 1(\xi_1)$ as $A \to \infty$, we have $R_\alpha^{(-A, \xi)} 1(\xi_1) > 1/(2\alpha)$ for a sufficiently large A with $-A < \xi_1$.

For such A, let $\mathbf{M}$ be the diffusion on $[-A, A]$ governed by the Dirichlet form (3.2), (3.3). Since the process obtained from $\mathbf{M}$ by killing at time $\sigma_0 \wedge \sigma_{-A}$ coincides

with $\mathbb{D}^{(-A,0)}$, the first expectation appearing in (3.4) equals $R_\alpha^{(-A,0)}H(\xi_1)$, which in turn is not greater than

$$R_\alpha^{(-A,\xi)}H(\xi_1) \le -4\alpha M \cdot R_\alpha^{(-A,\xi)}1(\xi_1) < -2M,$$

proving the first inequality in (3.4). The second one can be shown in the same way. □

In what follows, we shall work with $A > 0$ for which (3.4) is satisfied.

THEOREM 3.1. *There exist unique a, b such that $-A < a < 0 < b < A$ and*

$$-f_1(x) < V(x) < f_2(x), \qquad x \in (a,b), \tag{3.6}$$

$$V(x) = -f_1(x), \quad x \in [-A,a], \qquad V(x) = f_2(x), \quad x \in [b,A], \tag{3.7}$$

$$V'(a) = -f_1'(a), \qquad V'(b) = f_2'(b). \tag{3.8}$$

Furthermore V is C^1 on $(-A,A)$, C^2 on (a,b) and

$$\begin{aligned} \alpha V(x) - \frac{d}{ds}\frac{d}{dm}V(x) &= H(x) && \forall x \in [a,b] \\ &> H(x) && \forall x \in (-A,a) \\ &< H(x) && \forall x \in (b,A). \end{aligned} \tag{3.9}$$

The theorem is divided into three propositions.

PROPOSITION 3.1. (i) $-f_1(0) < V(0) < f_2(0)$.

(ii) $V(x) > -f_1(x)$ *for* $x > 0$ *and* $V(x) < f_2(x)$ *for* $x < 0$.

(iii) *Let*

$$E_1 = \{x \in [-A,A] : V(x) = -f_1(x)\}, \quad E_2 = \{x \in [-A,A] : V(x) = f_2(x)\} \tag{3.10}$$

and $a = \sup E_1$, $b = \inf E_2$. Then

$$-A < a < 0 < b < A.$$

(iv) *If*

$$-f_1(x) < V(x) < f_2(x), \qquad \beta < x < \gamma,$$

for some interval $(\beta,\gamma) \subset (-A,A)$, then V is C^2 on (β,γ) and

$$\left(\alpha - \frac{d}{ds}\frac{d}{dm}\right)V(x) = H(x) \tag{3.11}$$

for $x \in (\beta,\gamma)$. In particular, this equation holds for $x \in (a,b)$.

(v) *If, for some $\beta \in (-A,0)$,*

$$-f_1(x) < V(x), \qquad -A \le x < \beta,$$

then V is C^2 on $(-A,\beta)$, V satisfies (3.11) on $(-A,\beta)$, and $V'(-A) = 0$.

(vi) *If, for some $\gamma \in (0,A)$,*

$$V(x) < f_2(x), \qquad \gamma < x \le A,$$

then V is C^2 on (γ, A), V satisfies (3.11) on (γ, A), and $V'(A) = 0$.

Proof. Denote by σ_E the hitting time of the diffusion $\mathbf{M}$ for a set E. The hitting time for the one point set $\{x\}$ is simply denoted by σ_x. We let $\hat{\sigma} = \sigma_{E_1}$, $\hat{\tau} = \sigma_{E_2}$ be the hitting times for the sets E_1, E_2 defined by (3.10).

(i) We give the proof of the first inequality. The second one can be proved similarly. We have from (2.10) and (2.11) (the exceptional set N is now empty, as was explained in the paragraph below (3.3)) that, for any positive $\epsilon < A$,

$$\begin{aligned} V(0) \geq J_0(\hat{\tau}, \sigma_{-\epsilon}) &= E_0\left(\int_0^{\hat{\tau}\wedge\sigma_{-\epsilon}} e^{-\alpha t} H(X_t)dt\right) \\ &\quad - f_1(-\epsilon)E_0\left(e^{-\alpha\sigma_{-\epsilon}}; \sigma_{-\epsilon} < \hat{\tau}\right) + E_0\left(e^{-\alpha\hat{\tau}} f_2(X_{\hat{\tau}}); \sigma_{-\epsilon} \geq \hat{\tau}\right) \\ &\geq H(-\epsilon)E_0\left(\int_0^{\sigma_{-\epsilon}} e^{-\alpha t}dt\right) - f_1(0)E_0\left(e^{-\alpha\sigma_{-\epsilon}}\right) \\ &= -f_1(0) + \left(f_1(0) + \frac{H(-\epsilon)}{\alpha}\right)\left(1 - E_0(e^{-\alpha\sigma_{-\epsilon}})\right), \end{aligned}$$

which is greater than $-f_1(0)$ for sufficiently small $\epsilon > 0$.

(ii) For $x > 0$,

$$\begin{aligned} V(x) \geq J_x(\hat{\tau}, \sigma_0) &= E_x\left(\int_0^{\hat{\tau}\wedge\sigma_0} e^{-\alpha t} H(X_t)dt\right) \\ &\quad - f_1(0)E_x\left(e^{-\alpha\sigma_0}; \sigma_0 < \hat{\tau}\right) + E_x\left(e^{-\alpha\hat{\tau}} f_2(X_{\hat{\tau}}); \sigma_0 \geq \hat{\tau}\right) \\ &\geq -f_1(0)E_x\left(e^{-\alpha\sigma_0}\right) > -f_1(0) \geq -f_1(x). \end{aligned}$$

The second inequality can be proved similarly.

(iii) Suppose that $V(x) > -f_1(x)$ for any $x \in (-A, 0)$. Then, by (i) and (ii), $P_x(\hat{\sigma} \geq \sigma_{-A}) = 1$ for all x. Further $P_x(\hat{\tau} > \sigma_0) = 1$ for any $x < 0$. Hence

$$P_x(\hat{\sigma} \wedge \hat{\tau} \geq \sigma_{-A} \wedge \sigma_0) = 1 \qquad \forall x < 0,$$

which implies that the function $V(x) = J_x(\hat{\tau}, \hat{\sigma})$ is H-α-harmonic on $(-A, 0)$ in the sense that, for $x \in (-A, 0)$,

$$V(x) = E_x\left(\int_0^{\sigma_0\wedge\sigma_{-A}} e^{-\alpha t} H(X_t)dt\right) + E_x\left(e^{-\alpha(\sigma_0\wedge\sigma_{-A})} V(X_{\sigma_0\wedge\sigma_{-A}})\right). \tag{3.12}$$

Since $V(x) \leq M$ for any $x \in [-A, A]$, we get from the above and (3.4)

$$V(\xi_1) < -2M + M = -M,$$

a contradiction. Hence $-A < a < 0$. The second inequality can be proved similarly.

(iv) As in the proof of (iii), V is then H-α-harmonic on the interval (β, γ) in the sense that the identity (3.12) with $\sigma_0 \wedge \sigma_{-A}$ being replaced by $\sigma_\beta \wedge \sigma_\gamma$ holds for $x \in (\beta, \gamma)$, which is equivalent to the validity of the following equation [5, section 4.3, section 4.4]:

$$\mathcal{E}_\alpha(V, v) = (H, v) \qquad \forall v \in C_0^1((\beta, \gamma)). \tag{3.13}$$

Since H is continuous, this equation in turn implies that V is C^2 on (β, γ), and an integration by parts yields (3.11) on the same interval.

(v) In this case, the identity (3.12) with $\sigma_0 \wedge \sigma_{-A}$ being replaced by $\sigma_\beta \wedge \sigma_{-A}$ holds for $x \in [-A, \beta)$, which is equivalent to the validity of (3.13) for any $v \in C_0^1([-A, \beta))$. Again, an integration by parts gives the validity of (3.11) on $(-A, \beta)$ together with the stated boundary condition.

(vi) is analogous to (v). □

Before proceeding further, we prepare some notation. For $\xi \in (-A, A)$ and $\epsilon > 0$, we denote by $\tau_{\xi,\epsilon}$ the first exit time from the interval $I_{\xi,\epsilon} = (\xi - \epsilon, \xi + \epsilon)$, namely, $\tau_{\xi,\epsilon} = \sigma_{[-A,A]\setminus I_{\xi,\epsilon}}$. We then set

$$h_\alpha^-(\xi,\epsilon) = E_\xi\left(e^{-\alpha\tau_{\xi,\epsilon}}; \sigma_{\xi-\epsilon} < \sigma_{\xi+\epsilon}\right),$$
$$h_\alpha^+(\xi,\epsilon) = E_\xi\left(e^{-\alpha\tau_{\xi,\epsilon}}; \sigma_{\xi-\epsilon} \geq \sigma_{\xi+\epsilon}\right),$$
$$g_\alpha(\xi,\epsilon) = 1 - E_\xi\left(e^{-\alpha\tau_{\xi,\epsilon}}\right).$$

LEMMA 3.2.

$$\lim_{\epsilon \downarrow 0} h_\alpha^\pm(\xi,\epsilon) = \frac{1}{2}.$$

$$g_\alpha(\xi,\epsilon) = o(\epsilon) \quad as \quad \epsilon \downarrow 0.$$

Proof. The first identity for $\alpha = 0$ is evident because

$$h_0^-(\xi,\epsilon) = \frac{\int_\xi^{\xi+\epsilon} \dot{m}(x)dx}{\int_{\xi-\epsilon}^{\xi+\epsilon} \dot{m}(x)dx}. \tag{3.14}$$

Let u be a C^2-function vanishing at $-A$ and A such that

$$\frac{d}{ds}\frac{d}{dm}u(x) = -1, \quad x \in (\xi - \epsilon, \xi + \epsilon).$$

By Dynkin's formula applied to the 0-order resolvent of the process obtained from $\mathbf{M}$ by killing at time $\sigma_{-A} \wedge \sigma_A$,

$$E_\xi(\tau_{\xi,\epsilon}) = u(\xi) - h_0^-(\xi,\epsilon)u(\xi-\epsilon) - h_0^+(\xi,\epsilon)u(\xi+\epsilon),$$

which combined with (3.14) leads us to $E_\xi(\tau_{\xi,\epsilon}) = o(\epsilon)$.

The rest of the proof is obvious since

$$g_\alpha(\xi,\epsilon) = \alpha E_\xi\left(\int_0^{\tau_{\xi,\epsilon}} e^{-\alpha t}dt\right) \leq \alpha E_\xi(\tau_{\xi,\epsilon}). \qquad \square$$

PROPOSITION 3.2. (i) *$V'(a) = -f_1'(a)$ and $V'(x)$ is right continuous at a.*

(ii) *$V'(b) = f_2'(b)$ and $V'(x)$ is left continuous at b.*

Proof. We give the proof of (i) only. The proof of (ii) is analogous. Take any $\epsilon > 0$ with $(a - \epsilon, a + \epsilon) \subset (-A, 0)$. Let θ_t be the shift operator on the probability space Ω for $\mathbf{M}$, that is, $X_s(\theta_t\omega) = X_{s+t}(\omega)$ for all $\omega \in \Omega$ (cf. [5]). If we let $\sigma = \tau_{a,\epsilon} + \hat{\sigma} \circ \theta_{\tau_{a,\epsilon}}$, then

$$\hat{\tau} \wedge \sigma = \tau_{a,\epsilon} + (\hat{\tau} \wedge \hat{\sigma}) \circ \theta_{\tau_{a,\epsilon}},$$

because $\hat{\tau} = \tau_{a,\epsilon} + \hat{\tau} \circ \theta_{\tau_{a,\epsilon}}$. Hence we have

$$V(a) \geq J_a(\hat{\tau}, \sigma) = E_a\left(\int_0^{\tau_{a,\epsilon}} e^{-\alpha t}H(X_t)dt\right) + h_\alpha^-(a,\epsilon)V(a-\epsilon) + h_\alpha^+(a,\epsilon)V(a+\epsilon)$$

and

$$h_\alpha^-(a,\epsilon)V(a-\epsilon)+h_\alpha^+(a,\epsilon)V(a+\epsilon)-E_a\left(e^{-\alpha\tau_{a,\epsilon}}\right)V(a)$$
$$\le g_\alpha(a,\epsilon)V(a)-E_a\left(\int_0^{\tau_{a,\epsilon}}e^{-\alpha t}H(X_t)dt\right)\le\left(V(a)-\frac{H(a-\epsilon)}{\alpha}\right)g_\alpha(a,\epsilon).$$

Therefore

$$h_\alpha^+(a,\epsilon)(-f_1(a+\epsilon)+f_1(a))\le h_\alpha^+(a,\epsilon)(V(a+\epsilon)-V(a))$$
$$\le h_\alpha^-(a,\epsilon)(V(a)-V(a-\epsilon))+\left(V(a)-\frac{H(a-\epsilon)}{\alpha}\right)g_\alpha(a,\epsilon)$$
$$\le h_\alpha^-(a,\epsilon)(-f_1(a)+f_1(a-\epsilon))+\left(V(a)-\frac{H(a-\epsilon)}{\alpha}\right)g_\alpha(a,\epsilon).$$

By dividing each side of the above inequality by ϵ and letting $\epsilon\to 0$, we get from the previous lemma the desired inequality

$$-D_+f_1(a)\le D_+V(a)\le D_-V(a)\le -D_-f_1(a),$$

yielding the first half of (i). Since $V'(x)$ is easily seen to have the right limit at $x=a$ by virtue of Proposition 3.1(iv), it is right continuous at a as well. □

PROPOSITION 3.3. *Let E_1, E_2 be the sets defined by* (3.10).

(i) $E_1=[-A,a]$ *and*

$$\left(\alpha-\frac{d}{ds}\frac{d}{dm}\right)f_1(x)>H(x)\qquad\forall x\in[-A,a).$$

(ii) $E_2=[b,A]$ *and*

$$\left(\alpha-\frac{d}{ds}\frac{d}{dm}\right)f_2(x)<H(x)\qquad\forall x\in(b,A].$$

Proof. We give the proof of (i) only. (ii) can be proved similarly. Putting $x=a+\epsilon$ in (3.11) and letting $\epsilon\downarrow 0$, we get

$$\alpha V(a)-\frac{d+}{ds}\frac{dV}{dm}(a)=H(a), \tag{3.15}$$

where $\frac{d+}{ds}$ denotes the right derivative. On the other hand,

$$\frac{d+}{ds}\frac{dV}{dm}(a)\ge-\frac{d}{ds}\frac{d}{dm}f_1(a). \tag{3.16}$$

In fact, the function $F(x)=V(x)+f_1(x)$ satisfies $F(x)\ge 0, F(a)=0$, and further $F'(a)=0$, $F'(x)$ is right continuous at a by the preceding proposition. Taylor's theorem applies and

$$0\le\frac{F(a+\epsilon)}{\epsilon^2}=F''(a+\theta\epsilon)\to\frac{d+}{dx}F'(a)\qquad\text{as}\quad\epsilon\downarrow 0.$$

Hence

$$\frac{d+}{ds}\frac{dF}{dm}(a)=\frac{1}{\dot s(a)\dot m(a)}\frac{d+}{dx}F'(a)-\frac{\dot m'(a)}{\dot s(a)\dot m(a)^2}F'(a)=\frac{1}{\dot s(a)\dot m(a)}\frac{d+}{dx}F'(a)\ge 0.$$

Now (3.15), (3.16), and Assumption 3.1 lead us to the inequality

$$-\left(\alpha - \frac{d}{ds}\frac{d}{dm}\right) f_1(x) > H(x) \qquad \forall x \in [-A, a). \tag{3.17}$$

Turning to the proof of $E_1 = [-A, a]$ by reduction to a contradiction, we assume that there exists $x_0 \in [-A, a)$ such that $V(x_0) > -f_1(x_0)$. Then we have two possibilities:

(I) There exists $\beta, \gamma \in E_1$ such that $-A \le \beta < x_0 < \gamma \le a$ and $V(x) > -f_1(x)$ for all $x \in (\beta, \gamma)$.

(II) There exists $\beta \in E_1$ such that $-A < x_0 < \beta$ and $V(x) > -f_1(x)$ for all $x \in [-A, \beta)$.

Suppose case (I) occurs. By combining Proposition 3.1(iv) with (3.17), we then see that the function $F = -f_1 - V$ satisfies

$$\left(\alpha - \frac{d}{ds}\frac{d}{dm}\right) F(x) > 0 \tag{3.18}$$

for any $x \in (\beta, \gamma)$. Since $F(\beta) = F(\gamma) = 0$, an integration by parts yields

$$\mathcal{E}_\alpha(F, v) \ge 0 \tag{3.19}$$

for any $v \in C_0^1((\beta, \gamma))$ such that $v \ge 0$. This means that (the restriction to (β, γ) of) F is α-excessive with respect to the part of the Dirichlet form $(\mathcal{E}, \mathcal{F})$ on the interval (β, γ) (see [5, Lemma 2.2.1, Theorem 4.4.3]). In particular, $F(x_0) \ge 0$, a contradiction.

Suppose case (II) occurs. On account of Proposition 3.1(v), (3.17), and Assumption 3.1, we see then that the function F satisfies inequality (3.18) holding for any $x \in (-A, \beta)$ as well as the inequality $F'(-A) \le 0$. Therefore, an integration by parts leads us to the inequality (3.19) holding for any $v \in C_0^1([-A, \beta))$ such that $v \ge 0$. F is then α-excessive with respect to the part of $(\mathcal{E}, \mathcal{F})$ on the interval $[-A, \beta)$, again arriving at the contradiction $F(x_0) \ge 0$. □

By the preceding three propositions, the proof of Theorem 3.1 is complete.

The function V of Theorem 3.1 (the solution of (2.1), (2.2) for the Dirichlet form (3.3) on $L^2([-A, A], ds)$ under the Assumption 3.1 for the data (H, f_1, f_2)) gives rise to a solution of another type of free boundary problem stated below. Let us first extend the function V to whole $\mathbb{R}$ by setting

$$V(x) = -f_1(x), \quad x < -A, \qquad V(x) = f_2(x), \quad x > A. \tag{3.20}$$

In view of Assumption 3.1, we see that the extended function V still satisfies the first inequality of (3.9) on $(-\infty, a)$ and the second inequality on (b, ∞).

We then let, for $x \in \mathbb{R}$,

$$h(x) = \int_0^x H(y)\dot{s}(y)dy + C, \tag{3.21}$$

where C is an arbitrarily taken fixed constant. We further let

$$W(x) = \int_a^x V(y)\dot{s}(y)dy + \frac{1}{\alpha}\left(-\frac{f_1'(a)}{\dot{m}(a)} + h(a)\right). \tag{3.22}$$

THEOREM 3.2. *$W \in C^2(\mathbb{R})$ and there exist a, b with $a < 0 < b$ such that*

$$\begin{aligned} \alpha W(x) - \frac{d}{dm}\frac{d}{ds}W(x) &= h(x), \qquad a < x < b \\ &< h(x), \qquad x < a \ \text{ or } \ x > b, \end{aligned} \tag{3.23}$$

$$-f_1 < \frac{d}{ds}W < f_2 \qquad \text{on} \quad (a, b), \tag{3.24}$$

$$\frac{d}{ds}W = -f_1 \quad \text{on } (-\infty, a], \qquad \frac{d}{ds}W = f_2 \quad \text{on } [b, \infty), \tag{3.25}$$

$$\frac{d}{dx}\frac{d}{ds}W(a) = -f_1'(a), \qquad \frac{d}{dx}\frac{d}{ds}W(b) = f_2'(b). \tag{3.26}$$

Proof. For the function

$$U(x) = \alpha W(x) - \frac{d}{dm}\frac{d}{ds}W(x) - h(x),$$

we have

$$\frac{1}{\dot{s}(x)}U'(x) = \alpha V(x) - \frac{d}{ds}\frac{d}{dm}V(x) - H(x).$$

Consider a, b of Theorem 3.1. Then, by Theorem 3.1 and the remark made before the statement of Theorem 3.2,

$$U(a) = 0; \qquad U'(x) > 0,\ x < a; \qquad U'(x) = 0,\ x \in (a, b); \qquad U'(x) < 0,\ x > b,$$

which implies (3.23). The rest of the proof is obvious. □

4. A singular control of the (σ, μ)-diffusion. Let $\sigma(x)$ and $\mu(x)$ be C^1-functions on $\mathbb{R}$ with $\sigma(x) \neq 0$ for all $x \in \mathbb{R}$. We are concerned with a diffusion on $\mathbb{R}$ with infinitesimal generator

$$Lu(x) = \frac{1}{2}\sigma(x)^2 \frac{d^2u}{dx^2}(x) + \mu(x)\frac{du}{dx}(x), \tag{4.1}$$

which can be converted into the Feller canonical form $\frac{d}{dm}\frac{du}{ds}(x)$ by setting

$$\dot{s}(x) = \exp\left(-\int_0^x \frac{2\mu(y)}{\sigma(y)^2}dy\right), \qquad \dot{m}(x) = \frac{2}{\sigma(x)^2}\exp\left(\int_0^x \frac{2\mu(y)}{\sigma(y)^2}dy\right), \tag{4.2}$$

and $ds(x) = \dot{s}(x)dx$, $dm(x) = \dot{m}(x)dx$. We assume that $-\infty$ and ∞ are natural boundaries with respect to the operator (4.1) in the sense that condition (3.1) is satisfied by $\dot{s}$, $\dot{m}$ of (4.2). Since $\dot{s}$, $\dot{m}$ of (4.2) are strictly positive C^1-functions, all results of section 3 apply.

Throughout this section, we fix $\sigma(x), \mu(x)$ as above and $\dot{s}(x), \dot{m}(x)$ are understood to be defined by (4.2). We call a triplet (S, X, A) *admissible policy* or just *admissible* if the following conditions are satisfied:

(𝔸.1) S is a compact interval of $\mathbb{R}$.

(𝔸.2) There is a filtered measurable space $(\Omega, \{\mathcal{F}_t\}_{t\geq 0})$ subject to usual conditions and probability measures $\{P_x\}_{x\in S}$ on it such that

$X = \{X_t\}_{t\geq 0}$ is an $\{\mathcal{F}_t\}$-adapted right continuous process, and

$A = \{A_t\}_{t\geq 0}$ is an $\{\mathcal{F}_t\}$-adapted right continuous process of bounded variation satisfying

$$E_x\left(\int_{0-}^{\infty} e^{-\alpha t} dA_t^{(1)}\right) < \infty, \quad E_x\left(\int_{0-}^{\infty} e^{-\alpha t} dA_t^{(2)}\right) < \infty, \qquad \forall x \in S, \tag{4.3}$$

where $A^{(1)}$ and $A^{(2)}$ are two $\{\mathcal{F}_t\}$-adapted right continuous increasing processes for which $A_t = A_t^{(1)} - A_t^{(2)}$ is the *minimal* decomposition of the bounded variation process A into a difference of two increasing processes.

(𝔸.3) There is an $\{\mathcal{F}_t\}$-adapted standard Brownian motion $\{w_t\}_{t\geq 0}$ starting at the origin under P_x for any $x \in S$ such that the stochastic differential equation

$$X_t = x + \int_0^t \sigma(X_s) dw_s + \int_0^t \mu(X_s) ds + A_t^{(1)} - A_t^{(2)}, \qquad t \geq 0, \tag{4.4}$$

holds P_x-a.s. for each $x \in S$, and further

$$P_x(X_t \in S \ \forall t \geq 0) = 1 \qquad \forall x \in S. \tag{4.5}$$

We denote by $\mathbb{A}$ the totality of admissible triplets (S, X, A). In what follows we will always represent A in terms of $A^{(1)}$ and $A^{(2)}$ and thus write (S, X, A) and $(S, X, A^{(1)}, A^{(2)})$ interchangeably.

Remark 4.1. (i) The probability space Ω with the filtration $\{\mathcal{F}_t\}$ in (𝔸.2) is not fixed a priori. It is a part of an admissible policy. The filtration $\{\mathcal{F}_t\}$ is assumed to be right continuous and $\mathcal{F}_0$ is assumed to contain every Ω-set which is P_x-negligible for any $x \in S$.

(ii) We shall use the notation

$$\Delta A_t^{(i)} = A_t^{(i)} - A_{t-}^{(i)}, \qquad t \geq 0, \quad i = 1, 2,$$

$$\Delta X_t = X_t - X_{t-}, \quad \Delta u(X)_t = u(X_t) - u(X_{t-}), \qquad t \geq 0.$$

Note that, due to the fact that $A^{(1)}$ and $A^{(2)}$ represent the *minimal* decomposition of A into two increasing processes, $\Delta A_t^{(1)} \Delta A_t^{(2)} = 0$ for each $t \geq 0$. By convention, we let

$$w_t = 0, \quad A_t^{(i)} = 0 \qquad \forall t < 0, \quad i = 1, 2,$$

so that

$$\Delta A_0^{(i)} = A_0^{(i)}, \quad i = 1, 2, \qquad X_{0-} = x \quad P_x\text{-a.s.} \quad \forall x \in S.$$

Further we define the continuous part of $A^{(i)}$ by

$$A_t^{(i),c} = A_t^{(i)} - \sum_{0\leq s\leq t} \Delta A_s^{(i)}, \qquad t \geq 0, \quad i = 1, 2.$$

(iii) The integrals in t in (4.3) involve the possible jump at 0 so that they are the sum of the integrals over $(0, \infty)$ and $A_0^{(i)}$, $i = 1, 2$.

PROPOSITION 4.1. *Let* $(S, X, A^{(1)}, A^{(2)}) \in \mathbb{A}$. *Then, for any* $u \in C^2(\mathbb{R})$, *the following identity holds:*

$$\begin{aligned} u(x) = {} & E_x\left[\int_0^\infty e^{-\alpha t}\left(\alpha - \frac{d}{dm}\frac{d}{ds}\right)u(X_t)dt\right] \\ & + E_x\left[\int_0^\infty e^{-\alpha t}\left(-\frac{du}{ds}(X_t)\dot{s}(X_t)dA_t^{(1),c} + \frac{du}{ds}(X_t)\dot{s}(X_t)dA_t^{(2),c}\right)\right] \\ & - E_x\left[\sum_{0\le t<\infty} e^{-\alpha t}\Delta u(X)_t\right], \qquad x \in S. \end{aligned} \tag{4.6}$$

All expectations in the right side of (4.6) *exist and are finite.*

Proof. By a generalized Ito formula ([13, p. 278]; see also [7, section 4]) applied to the semimartingale (4.4), we have

$$\begin{aligned} e^{-\alpha t}u(X_t) = {} & u(X_0) - \alpha\int_0^t e^{-\alpha s}u(X_s)ds + \int_0^t e^{-\alpha s}u'(X_s)\sigma(X_s)dw_s \\ & + \int_0^t e^{-\alpha s}u'(X_s)\mu(X_s)ds + \int_0^t e^{-\alpha s}u'(X_s)(dA_s^{(1),c} - dA_s^{(2),c}) \\ & + \frac{1}{2}\int_0^t e^{-\alpha s}u''(X_s)\sigma(X_s)^2ds + \sum_{0<s\le t} e^{-\alpha s}\Delta u(X)_s. \end{aligned} \tag{4.7}$$

Rewrite the sum of two terms in the right side of (4.7) as

$$u(X_0) + \sum_{0<s\le t} e^{-\alpha s}\Delta u(X)_s = u(X_{0-}) + \sum_{0\le s\le t} e^{-\alpha s}\Delta u(X)_s,$$

then take the expectation of the both sides of (4.7) with respect to P_x and let $t \to \infty$ to get the identity (4.6). □

LEMMA 4.1. *If* $(S, X, A^{(1)}, A^{(2)}) \in \mathbb{A}$, *then both* $A^{(1)}$ *and* $A^{(2)}$ *are nontrivial in the sense that, for each* $T > 0$,

$$P_x(A_t^{(i)} = A_0^{(i)} \quad \forall t \in [0, T)) = 0 \qquad \forall x \in S, \quad i = 1, 2. \tag{4.8}$$

Proof. Since S is compact, the integrand of the first integral of the right-hand side of (4.4) is bounded and is bounded away from zero, while the integrand of the second is bounded. If both $A^{(1)}$, $A^{(2)}$ were trivial, the process X_t satisfying (4.4) hits therefore any point of $\mathbb{R}$ almost surely as the Brownian motion does [8, pp. 85, pp. 437], a contradiction. If either $A^{(1)}$ or $A^{(2)}$ is trivial, the path of X_t cannot be concentrated on a compact set, again a contradiction. □

PROPOSITION 4.2. *For any finite* $\beta_1 < \beta_2$, *there exists* $([\beta_1, \beta_2], X, A^{(1)}, A^{(2)}) \in \mathbb{A}$ *such that*

$$A_t^{(i)} = \int_0^t I_{\{\beta_i\}}(X_s)dA_s^{(i)} \quad \forall t \ge 0, \qquad P_x\text{-a.s.} \quad \forall x \in [\beta_1, \beta_2], \qquad i = 1, 2. \tag{4.9}$$

Such X_t *and* $A_t^{(i)}$, $i = 1, 2$, *are necessarily continuous in* $t \ge 0$, P_x-a.s. *for any* $x \in [\beta_1, \beta_2]$. *Furthermore, the* P_x*-law of such* $(X, A^{(1)}, A^{(2)})$ *is unique for any* $x \in [\beta_1, \beta_2]$.

Proof. Equation (4.4) subjected to the conditions (4.5) and (4.9) is called the *Skorohod equation* for $[\beta_1, \beta_2]$.

Since $\sigma,\ \mu$ are C^1-functions, the existence and uniqueness of $(X, A^{(1)}, A^{(2)})$ satisfying (4.9) and all admissibility conditions except for the integrability (4.3) follow from Tanaka [17, Theorem 4.1], where the unique existence of the strong solution of the Skorohod equation with Lipschitz continuous coefficients for a multidimensional convex domain was proved. It was also shown in [17] that the solution is necessarily continuous. The integrability (4.3) is then an automatic consequence of (4.7) applied to the C^2-function u such that $u'(\beta_1) = 1,\ u'(\beta_2) = 0$ (resp., $u'(\beta_1) = 0,\ u'(\beta_2) = 1$). □

The triple $(X, A^{(1)}, A^{(2)})$ of Proportion 4.2 is called a *reflecting* (σ, μ)*-diffusion* on the interval $[\beta_1, \beta_2]$.

We are now in the position to formulate our main theorem about a singular control problem for the admissible family $\mathbb{A}$.

Let h, f_1, f_2 be functions on $\mathbb{R}$ satisfying the following conditions.

ASSUMPTION 4.1. *$h(x)$ is a C^1-function on $\mathbb{R}$ such that*

$$h'(0) = 0, \quad \frac{dh}{ds}(x) \text{ is strictly increasing}, \qquad \frac{dh}{ds}(x) \to \pm\infty \quad \text{as } x \to \pm\infty.$$

$f_1,\ f_2$ are C^2-functions with $0 < f_1, f_2 \le M$ for some $M > 0$ and

$$f_1'(x) \ge 0, \quad x \in \mathbb{R}, \qquad \frac{d}{ds}\frac{d}{dm}f_1 - \frac{dh}{ds} \text{ is strictly decreasing on } (-\infty, 0),$$

$$f_2'(x) \le 0, \quad x \in \mathbb{R}, \qquad \frac{d}{ds}\frac{d}{dm}f_2 + \frac{dh}{ds} \text{ is strictly increasing on } (0, \infty).$$

We note that h can be then expressed as (3.21) via a function H satisfying the condition of Assumption 3.1, and further f_1, f_2 satisfy the condition of Assumption 3.1 for this function H. Therefore Theorem 3.2 applies to the present functions h, f_1, f_2.

For each $(S, X, A^{(1)}, A^{(2)}) \in \mathbb{A}$, the cost function k_x is defined, for $x \in S$, by

$$\begin{aligned} k_x(S, X, A^{(1)}, A^{(2)}) &= E_x\left(\int_0^\infty e^{-\alpha t} h(X_t)dt\right) \\ &\quad + E_x\left[\int_0^\infty e^{-\alpha t}\left(f_1(X_t)\dot{s}(X_t)dA_t^{(1),c} + f_2(X_t)\dot{s}(X_t)dA_t^{(2),c}\right)\right] \\ &\quad + E_x\left[\sum_{0\le t<\infty} e^{-\alpha t}\left(\int_{X_{t-}}^{X_{t-}+\Delta A_t^{(1)}} f_1(y)ds(y) + \int_{X_{t-}-\Delta A_t^{(2)}}^{X_{t-}} f_2(y)ds(y)\right)\right]. \end{aligned} \tag{4.10}$$

Some remarks about the cost structure are due at this point. The first integral $\int_0^\infty e^{-\alpha t}h(X_t)dt$ in (4.10) represents the so-called *holding cost* associated with the position of the controlled process X_t. Other integrals represent the *control cost,* which is associated with the "efforts" to change the position of the controlled process. The cost associated with each of the control functionals $A^{(i)}, i = 1, 2$, is proportional to the displacement caused by each of these functionals; however, the coefficient of the proportionality is a function of the position of the control process and is equal to $f_1(x)\dot{s}(x)$ if the controlled process is at the point x. Thus if $A^{(i)}$ is a continuous functional, we can write an approximation to the control cost as $\sum_j e^{-\alpha t_j} f_i(X_{t_j})\dot{s}(X_{t_j})\delta A_j^{(i)}$, where $\delta A_j^{(i)}$ is an increment of $A^{(i)}$ on the interval

$[t_j, t_{j+1}]$. In a limit one gets $\int_0^\infty e^{-\alpha t} f_i(X_t)\dot{s}(X_t)dA_t^{(i)}$. When the control functional has a discontinuity at the point t, which results in a jump of the control process, then we represent this jump as if the real clock is stopped while a new clock is turned on, and the controlled process is moving uniformly in the new time clock up or down from X_{t-} to $X_t = X_{t-} + \Delta A_t^{(i)}$. In such a representation the control cost of this displacement is equal to $\int_{X_{t-}}^{X_{t-}+\Delta A_t^{(i)}} f_i(y)\dot{s}(y)dy$, which corresponds to the last two terms in the right-hand side of (4.10). The same expression in the right-hand side of (4.10) would have been obtained as a limit if we had started with continuous functionals $A^{(i)}$ and then had approximated by them (via a monotone pointwise convergence) discontinuous control functionals.

Of course, when $f_i(x)\dot{s}(x)$ is equal to a constant r_i, the control cost associated with the functional $A^{(i)}$ can be written as $\int_0^\infty e^{-\alpha t} r_i dA_t^{(i)}$, without a need to have a special expression associated with the discontinuities of $A^{(i)}$. This was the case treated in [16]. We extend k_x outside the closed interval S denoted by $[\ell_1, \ell_2]$ as

$$\begin{aligned} k_x(S, X, A^{(1)}, A^{(2)}) &= k_{\ell_1}(S, X, A^{(1)}, A^{(2)}) + \int_x^{\ell_1} f_1(y)ds(y), \qquad x < \ell_1, \\ &= k_{\ell_2}(S, X, A^{(1)}, A^{(2)}) + \int_{\ell_2}^{x} f_2(y)ds(y), \qquad x > \ell_2. \end{aligned} \tag{4.11}$$

Our problem is to find the function

$$W^*(x) = \inf_{(S,X,A^{(1)},A^{(2)})\in\mathbb{A}} k_x(S, X, A^{(1)}, A^{(2)}), \qquad x \in \mathbb{R}, \tag{4.12}$$

called the *optimal return function*, and to find an optimal admissible quadruple $(S, X, A^{(1)}, A^{(2)}) \in \mathbb{A}$ such that

$$W^*(x) = k_x(S, X, A^{(1)}, A^{(2)}) \qquad \forall x \in \mathbb{R}.$$

The solution will be provided by the function W, the values a, b appearing in Theorem 3.2, and the reflecting (σ, μ)-diffusion on $[a, b]$ appearing in Proposition 4.2.

Here we introduce a subfamily $\mathbb{A}_0$ of $\mathbb{A}$ by

$$\mathbb{A}_0 = \{(S, X, A^{(1)}, A^{(2)}) \in \mathbb{A} : A_0^{(i)} = 0,\ P_x\text{-a.s. } \forall x \in S,\ i = 1, 2\}.$$

The reflecting (σ, μ)-diffusion on a compact interval appearing in Proposition 4.2 is a member of $\mathbb{A}_0$.

THEOREM 4.1. *Under Assumption* 4.1 *for functions* h, f_1, f_2, *let* W, a, b *be the function and values in Theorem* 3.2. *Then*

(i) $W(x) \le k_x(S, X, A^{(1)}, A^{(2)})$ *for all* $x \in \mathbb{R}$ *for any* $(S, X, A^{(1)}, A^{(2)}) \in \mathbb{A}$.

(ii) $W(x) = k_x(S, X, A^{(1)}, A^{(2)})$ *for all* $x \in \mathbb{R}$ *for* $(S, X, A^{(1)}, A^{(2)}) \in \mathbb{A}_0$ *if and only if*

$$S = [a, b], \quad (X, A^{(1)}, A^{(2)}) \text{ is the reflecting } (\sigma, \mu)\text{-diffusion on the interval } [a, b]. \tag{4.13}$$

Proof. (i) Take any $(S, X, A^{(1)}, A^{(2)}) \in \mathbb{A}$. Subtracting from (4.10) the identity (4.6) for $u = W$, we have

$$k_x(S, X, A^{(1)}, A^{(2)}) - W(x) = E_x(I_1 + I_2 + I_3 + I_4), \qquad x \in S, \tag{4.14}$$

where

$$I_1 = \int_0^\infty e^{-\alpha t} \left\{ \left(\frac{d}{dm} \frac{d}{ds} - \alpha \right) W(X_t) + h(X_t) \right\} dt,$$

$$I_2 = \int_0^\infty e^{-\alpha t} \left\{ \frac{dW}{ds}(X_t) + f_1(X_t) \right\} \dot{s}(X_t) dA_t^{(1),c},$$

$$I_3 = \int_0^\infty e^{-\alpha t} \left\{ -\frac{dW}{ds}(X_t) + f_2(X_t) \right\} \dot{s}(X_t) dA_t^{(2),c},$$

$$I_4 = \sum_{0 \le t < \infty} e^{-\alpha t} \left(\Delta W(X)_t + \int_{X_{t-}}^{X_{t-} + \Delta A_t^{(i)}} f_1(y) ds(y) + \int_{X_{t-} - \Delta A_t^{(2)}}^{X_{t-}} f_2(y) ds(y) \right).$$

The integrands I_1, I_2, I_3 are nonnegative by virtue of Theorem 3.2. To see that I_4 is nonnegative, let

$$\Gamma_+ = \{t \ge 0 : \Delta A_t^{(1)} > 0\}, \quad \Gamma_- = \{t \ge 0 : \Delta A_t^{(2)} > 0\}.$$

Since $\Gamma_+ \cap \Gamma_- = \phi$ by Remark 4.1, we have for $t \in \Gamma_+$,

$$\Delta X_t = \Delta A_t^{(1)}, \qquad \Delta W(X)_t = W(X_{t-} + \Delta A_t^{(1)}) - W(X_{t-}),$$

and consequently the sum in I_4, taken over all $t \in \Gamma_+$, equals

$$\int_{X_{t-}}^{X_{t-} + \Delta A_t^{(1)}} \left(\frac{dW}{ds}(y) + f_1(y) \right) ds(y).$$

We have a similar expression for $t \in \Gamma_-$ and eventually get

(4.15)
$$I_4 = \sum_{t \in \Gamma_+} e^{-\alpha t} \int_{X_{t-}}^{X_t} \left(\frac{dW}{ds}(y) + f_1(y) \right) ds(y) + \sum_{t \in \Gamma_-} e^{-\alpha t} \int_{X_t}^{X_{t-}} \left(-\frac{dW}{ds}(y) + f_2(y) \right) ds(y),$$

which is nonnegative by Theorem 3.2.

We have seen that $k_x \ge W(x)$, $x \in S$. This inequality extends to $\mathbb{R}$ by the definition (4.11) and Theorem 3.2.

(ii) Suppose $k_x(S, X, A^{(1)}, A^{(2)}) = W(x)$ for all $x \in S$ for some $(S, X, A^{(1)}, A^{(2)}) \in \mathbb{A}_0$. Then all P_x-expectations of I_1, I_2, I_3, I_4 must vanish for any $x \in S$. Notice further that $X_0 = x$, P_x-a.s. for all $x \in S$, because $A_0^{(i)} = 0$, P_x-a.s. for all $x \in S$, $i = 1, 2$. We let $S = [\beta, \gamma]$.

Suppose that $\beta < a$ (resp., $b < \gamma$). Then $E_x(I_1) > 0$ for $x \in (\beta, a)$ (resp., (b, γ)) by (3.23) and the right continuity of X_t. Therefore we have that $[\beta, \gamma] \subset [a, b]$.

In view of Lemma 4.1, both $A^{(1)}$, $A^{(2)}$ are nontrivial. If $a < \beta$ (resp., $\gamma < b$), then $\frac{dW}{ds} + f_1$ $\left(\text{resp., } -\frac{dW}{ds} + f_2\right)$ is strictly positive on S by (3.24), (3.25), and hence either I_2 or the first sum of (4.15) (resp., either I_3 or the second sum of (4.15)) has a positive P_x-expectation for any $x \in S$. We have proven that $S = [a, b]$.

Then, by virtue of (3.24), we see that X_t or, equivalently, $A_t^{(i)}$ $i = 1, 2$, must be continuous in $t \geq 0$, P_x-a.s. for any $x \in S$ in order to make the expectation of I_4 expressed as (4.15) to be zero. Finally, using (3.24) and (3.25), we see that $A^{(i)} = A^{(i),c}$, $i = 1, 2$, must satisfy the relations (4.9) for $\beta_1 = a$, $\beta_2 = b$ in order to make both expectations of I_2, I_3 to be zero. This means that $(X, A^{(1)}, A^{(2)})$ must be the reflecting (σ, μ)-diffusion on the interval $[a, b]$.

Conversely, the cost function k_x of the reflecting (σ, μ)-diffusion on the interval $[a, b]$ is obviously identical with $W(x)$ on $\mathbb{R}$ in view of (4.14). □

COROLLARY 4.1. *Under Assumption* 4.1 *for functions* h, f_1, f_2, *the solution* $W \in C^2(\mathbb{R})$, *and the values* a, b $(a < b)$ *of the free boundary problem* (3.23), (3.24), *and* (3.25) *are unique. The solution* $W(x)$, $x \in \mathbb{R}$, *coincides with the optimal return function* $W^*(x)$ *given by* (4.12).

Proof. In the proof of Theorem 4.1, we have seen that any function W satisfying (3.23), (3.24), and (3.25) for some a, b $(a < b)$ coincides with the function defined by (4.12). Further this function determines a, b uniquely according to (3.23). □

ROBUST FILTERING OF DISCRETE-TIME LINEAR SYSTEMS WITH PARAMETER DEPENDENT LYAPUNOV FUNCTIONS*

J. C. GEROMEL†, M. C. DE OLIVEIRA†, AND J. BERNUSSOU‡

Abstract. Robust filtering of linear time-invariant discrete-time uncertain systems is investigated through a new parameter dependent Lyapunov matrix procedure. Its main interest relies on the fact that the Lyapunov matrix used in stability checking does not appear in any multiplicative term with the uncertain matrices of the dynamic model. We show how to use such an approach to determine high performance H_2 robust filters by solving a linear problem constrained by linear matrix inequalities (LMIs). The results encompass the previous works in the quadratic Lyapunov setting. Numerical examples illustrate the theoretical results.

Key words. linear systems, discrete-time systems, parameter uncertainty, filtering, parameter dependent Lyapunov functions, linear matrix inequalities

1. Introduction.

Filtering is a very important issue in systems diagnosis, surveillance, and control. The problem, which amounts to extracting the information from the measured output to provide an estimate of the state (or a linear combination of the state), has been addressed in the stochastic as well as in the deterministic framework. Seminal works in this domain are the ones of Kalman and Luenberger (see [1, 10] for a complete discussion).

As a dual of the control design problem, the development of robust filters closely follows the same design steps. For linear uncertain systems, the problem can be stated as the minimization of an appropriate bound on a transfer function between an exogenous noise and the estimation error. There have been several contributions using H_2 and H_∞ norms as criteria for filter determination under parameter uncertainty. In the unstructured norm bounded uncertainty case, one can cite [9, 11, 13]. The structured case, which is a bit more complex, has also received some attention in both continuous-time [5, 8] and discrete-time [6, 7] contexts. These approaches are based on the quadratic stability concept, where a single Lyapunov matrix is used for the estimation error norm evaluation over the whole uncertainty domain. If we consider time-invariant uncertain systems, this assumption reveals to be, in fact, a hard constraint, implying a significant degree of sufficiency to these results. In fact, all results based on quadratic stability can also be applied to arbitrarily fast time-variant uncertainties.

In this paper, we use a new stability condition for discrete-time uncertain systems which enables the determination of parameter dependent Lyapunov matrices. This stability condition, which was first introduced in [3], provides results which go beyond the ones attainable by the quadratic approach for time-invariant parameter uncertainty. It is expressed as a linear matrix inequality (LMI) and exhibits a kind

of separation property between the Lyapunov matrices and the uncertain dynamic matrices. Here we show how the given condition can be extended to provide optimal performance in terms of an H_2 norm guaranteed cost problem. Furthermore, we show how to parametrize linear filters so that the synthesis of robust filters can be cast as an LMI optimization problem. We prove that our results encompass the results obtained on the quadratic stability framework [6, 7] and, consequently, reduce to the classical Kalman filter in the absence of uncertainty. The filtering results are generalized to cope with structure constraints such as decentralization.

The outline of the paper is as follows. In section 2, we formulate the problem to be solved. In section 3, we summarize the existent results on robust stability and robust filtering. Then we introduce the new stability and performance conditions in section 4 and illustrate its features with a numerical example. The robust H_2 filtering problem is developed in section 5 and extended to cope with structural constraints in section 6. Several numerical examples illustrate the results in section 7, enlightening the efficiency of the proposed approach by comparing the given results to the existent ones. The paper finishes with some concluding words.

The notation used throughout is as follows. Capital letters denote matrices, and small letters denote vectors. For scalars, we use small Greek letters. For matrices or vectors, $(')$ indicates transposition. For symmetric matrices, $X > 0$ (≥ 0) indicates that X is positive definite (nonnegative definite). For square matrices, trace(X) denotes the trace function of X being equal to the sum of its eigenvalues. For a transfer function $T(\zeta)$ analytic outside the unit circle, $\|T(\zeta)\|_2$ denotes the standard H_2 norm. Finally, for the sake of easing the notation of partitioned symmetric matrices, the symbol $(\bullet)'$ generically denotes each of its symmetric blocks.

2. Problem statement and definitions. Let us consider the linear time-invariant discrete-time system

$$x(k+1) = Ax(k) + Bw(k), \tag{1}$$

$$y(k) = Cx(k) + Dw(k), \tag{2}$$

$$z(k) = Lx(k), \tag{3}$$

where $x \in R^n$ is the state, $w \in R^m$ is a white noise input with zero mean and identity covariance matrix, $y \in R^r$ is the measured output, and $z \in R^s$ is the vector to be estimated. All matrices are of compatible dimension. We assume that matrix L is known and that the time-invariant parameters gathered in the matrix

$$M := \begin{bmatrix} A & B \\ C & D \end{bmatrix} \tag{4}$$

are unknown but belong to the convex polyhedron

$$\mathcal{M} := \left\{ M(\xi) = \sum_{i=1}^{N} \xi_i M_i, \ \sum_{i=1}^{N} \xi_i = 1, \ \xi_i \geq 0 \right\}. \tag{5}$$

The robust H_2 filtering problem considered here is to design an estimate $\hat{z}$ of z given by $\hat{z} = \mathcal{F} \cdot y$. The filter $\mathcal{F}$ is supposed to be a linear, finite dimensional, and causal operator. We characterize $\mathcal{F}$ by the generic element given in the form of a linear time-invariant operator with minimum state space realization

$$\hat{x}(k+1) = A_f \hat{x}(k) + B_f y(k), \tag{6}$$

$$\hat{z}(k) = C_f \hat{x}(k), \tag{7}$$

where the matrices $A_f \in R^{n\times n}$, $B_f \in R^{n\times r}$, and $C_f \in R^{s\times n}$ are to be determined and define the filter transfer function

$$T_f(\zeta) = C_f\,(\zeta I - A_f)^{-1}\,B_f. \tag{8}$$

Moreover, it is considered that the initial condition of system (1)–(3) as well as the initial condition of the filter (6)–(7) are both zero.

The connection of the filter and the system yields, for each element in the set $\mathcal{M}$, a linear system described by the transfer function from the noise input w to the estimation error $e := z - \hat{z}$,

$$T_M(\zeta) := \tilde{C}\left(\zeta I - \tilde{A}\right)^{-1}\tilde{B}, \tag{9}$$

where matrices $\tilde{A}$, $\tilde{B}$, and $\tilde{C}$ of compatible dimensions are given by

$$\tilde{A} := \begin{bmatrix} A & 0 \\ B_f C & A_f \end{bmatrix},\ \tilde{B} := \begin{bmatrix} B \\ B_f D \end{bmatrix},\ \tilde{C} := \begin{bmatrix} L & -C_f \end{bmatrix}. \tag{10}$$

With respect to the transfer function $T_M(\zeta)$, it is possible to determine the quantity $\|T_M(\zeta)\|_2$, called the H_2 norm of $T_M(\zeta)$, that represents a measure of the energy appearing in the output due to the noisy input. Our aim is to solve the problem

$$\inf_{\mathcal{F}} \sup_{M\in\mathcal{M}} \|T_M(\zeta)\|_2^2. \tag{11}$$

Since this problem is very hard to solve, many authors proceed by minimizing an available upper bound to the indicated supremum. In [6, 7], this problem is solved using the concept of quadratic stability to be discussed in the next section.

3. Previous results on robust stability and filtering. As stated before, the robust filtering problem (11) is very difficult, and many authors address the filtering problem by replacing the supremum over $\mathcal{M}$ by an appropriate upper bound. One of the most used upper bounds is based on the concept of quadratic stability, which we briefly review in the next paragraphs.

Consider the following linear time-invariant discrete-time system defined by its transfer function

$$T(\zeta) := C(\zeta I - A)^{-1}B, \tag{12}$$

where the triplet (A, B, C) is composed by matrices of compatible and known dimensions. We are interested in the study of the stability of linear time-invariant systems in the form (12), where the matrices A and B are uncertain. More specifically, we are interested in systems whose uncertain parameters, gathered in the matrix

$$M := \begin{bmatrix} A & B \end{bmatrix}, \tag{13}$$

belong to the convex polyhedron $\mathcal{M}$ previously defined in (5). Our objective is to characterize whenever the set $\mathcal{M}$ defines only stable systems, in which case we say $\mathcal{M}$ is Schur, and to determine whether, for a given $\mu > 0$, it is true that the upper bound

$$\sup_{M\in\mathcal{M}} \|T_M(\zeta)\|_2^2 < \mu \tag{14}$$

holds. As in the previous section, the subscript included in the notation of the transfer function defined in (12) indicates the dependence of $T(\zeta)$ on $M \in \mathcal{M}$. The next lemma provides an answer to these questions expressed in terms of well-known sufficient conditions for robust (quadratic) stability and performance.

LEMMA 3.1. *The following statements are true:*

(a) *The set $\mathcal{M}$ is Schur if there exists a symmetric matrix P of compatible dimension satisfying the LMI*

$$\begin{bmatrix} P & A_i P \\ (\bullet)' & P \end{bmatrix} > 0 \tag{15}$$

for all $i = 1, \ldots, N$.

(b) *For any given $\mu > 0$, the inequality $\|T_M(\zeta)\|_2^2 < \mu$ holds for all $M \in \mathcal{M}$ if there exist symmetric matrices P and W of compatible dimensions satisfying the LMI*

$$\text{trace}(W) < \mu, \quad \begin{bmatrix} W & CP \\ (\bullet)' & P \end{bmatrix} > 0, \quad \begin{bmatrix} P & A_i P & B_i \\ (\bullet)' & P & 0 \\ (\bullet)' & (\bullet)' & I \end{bmatrix} > 0 \tag{16}$$

for all $i = 1, \ldots, N$.

Proof. See [7]. □

The above lemma deserves some comments. First, keeping P constant and independent of the index i is essential to obtain the results. This is on the origin of the *quadratic stability* [2] concept, largely used in robust stability studies of uncertain systems. The main drawback associated with this fact is that a single Lyapunov matrix P must work for all matrices in the uncertain domain $\mathcal{M}$, which ensures the stability of all time-variant systems in the domain. This condition is often too conservative if used with time-invariant systems. The same reasoning can be used for the robust performance provided in part (b). Indeed, it is expected that the use of a single matrix P introduces a significant degree of conservativeness to the estimation of the worst performance attained for some $M \in \mathcal{M}$. A measure of this gap may be obtained by calculating the minimum value of μ given by the optimal solution to the convex programming problem

$$\mu_q := \min\{\mu \ : \ \text{s.t. (16)}\} \tag{17}$$

as compared to $\sup_{M \in \mathcal{M}} \|T_M(\zeta)\|_2^2$. This fact will be illustrated in the examples.

Using Lemma 3.1, the following set of robust filters with guaranteed quadratic performance has been established in [6, 7] as the discrete-time counterpart of the continuous-time robust filter design introduced in [5].

LEMMA 3.2. *Let $\mu > 0$ be given. The estimation error transfer function satisfies the inequality $\|T_M(\zeta)\|_2^2 < \mu$ for all $M \in \mathcal{M}$ provided that the robust filter transfer function is given by*

$$T_f(\zeta) := HR^{-1}\left(\zeta I - QR^{-1}\right)^{-1} F, \tag{18}$$

where $R := Z - Y$ and matrices Q, H, and F and the symmetric matrices Y, Z, and

W satisfy the LMI

$$\text{trace}(W) < \mu, \tag{19}$$

$$\begin{bmatrix} W & L-H & L \\ (\bullet)' & Z & Z \\ (\bullet)' & (\bullet)' & Y \end{bmatrix} > 0, \tag{20}$$

$$\begin{bmatrix} Z & Z & ZA_i & ZA_i & ZB_i \\ (\bullet)' & Y & YA_i + FC_i + Q & YA_i + FC_i & YB_i + FD_i \\ (\bullet)' & (\bullet)' & Z & Z & 0 \\ (\bullet)' & (\bullet)' & (\bullet)' & Y & 0 \\ (\bullet)' & (\bullet)' & (\bullet)' & (\bullet)' & I \end{bmatrix} > 0 \tag{21}$$

for all $i = 1, \ldots, N$.

Proof. See [7]. □

From this theorem, it is clear that a near optimal solution to the design problem (11) is readily calculated from the optimal solution to the convex programming problem

$$\mu_Q := \min\{\mu \ : \ \text{s.t. } (19) - (21)\}, \tag{22}$$

which provides the best filter when a quadratic guaranteed upper bound to the worst error performance is adopted. It is worth mentioning that, for $N = 1$, the system under consideration is completely known, and, in this case, (22) generates the celebrated Kalman filter (see [7] for details).

4. Parameter dependent robust stability. This section presents the main results of this paper related to robust stability and performance of uncertain discrete-time systems. The following theorem constitutes an extension of the stability test recently introduced in [3] and will be used as a basis for the development of the new filter design procedure to be introduced in section 5.

THEOREM 4.1. *The following statements are true:*

(a) *The set $\mathcal{M}$ is Schur if there exist symmetric matrices P_i, $i = 1, \ldots, N$, and a matrix G of compatible dimensions satisfying the LMI*

$$\begin{bmatrix} P_i & A_iG \\ (\bullet)' & G + G' - P_i \end{bmatrix} > 0 \tag{23}$$

for all $i = 1, \ldots, N$.

(b) *For any given $\mu > 0$, the inequality $\|T_M(\zeta)\|_2^2 < \mu$ holds for all $M \in \mathcal{M}$ if there exist symmetric matrices P_i, W_i, $i = 1, \ldots, N$, and a matrix G of compatible dimensions satisfying the LMI*

$$\text{trace}(W_i) < \mu, \quad \begin{bmatrix} W_i & CG \\ (\bullet)' & G + G' - P_i \end{bmatrix} > 0, \quad \begin{bmatrix} P_i & A_iG & B_i \\ (\bullet)' & G + G' - P_i & 0 \\ (\bullet)' & (\bullet)' & I \end{bmatrix} > 0 \tag{24}$$

for all $i = 1, \ldots, N$.

Proof. We prove part (a) by assuming that (23) holds for all $i = 1, \ldots, N$ and calculating the convex combination of inequality (23). That is, we first multiply each

inequality in (23) by the uncertain parameter $\xi_i > 0$ and then evaluate the sum from $i = 1, \ldots, N$ so as to obtain

$$\begin{bmatrix} P(\xi) & A(\xi)G \\ (\bullet)' & G + G' - P(\xi) \end{bmatrix} > 0.$$

From this inequality, we first conclude that $G + G' > P(\xi) > 0$, where $P(\xi) := \sum_{i=1}^{N} \xi_i P_i$. Since $P(\xi) > 0$, the inequality $(P(\xi) - G)' P(\xi)^{-1} (P(\xi) - G) \geq 0$ is true for all values of the uncertain parameter ξ so that $G' P(\xi)^{-1} G \geq G + G' - P(\xi)$. Replacing this in the above inequality, we get

$$\begin{bmatrix} P(\xi) & A(\xi)G \\ (\bullet)' & G' P(\xi)^{-1} G \end{bmatrix} \geq \begin{bmatrix} P(\xi) & A(\xi)G \\ (\bullet)' & G + G' - P(\xi) \end{bmatrix} > 0.$$

Finally, if we multiply the first inequality above by $T(\xi) = \operatorname{diag}\left[I, G^{-1} P(\xi)\right]$ on the right and by $T(\xi)'$ on the left, we recover

$$\begin{bmatrix} P(\xi) & A(\xi)P(\xi) \\ (\bullet)' & P(\xi) \end{bmatrix} > 0,$$

which lets us conclude that the set $\mathcal{M}$ is Schur.

In order to prove part (b), we manipulate the third inequality in (24) following the same steps as in the proof of part (a) so as to obtain

$$\begin{bmatrix} P(\xi) & A(\xi)P(\xi) & B(\xi) \\ (\bullet)' & P(\xi) & 0 \\ (\bullet)' & (\bullet)' & I \end{bmatrix} > 0,$$

which lets us conclude that

$$\|T_M(\zeta)\|_2^2 \leq \operatorname{trace}\left(C P(\xi) C'\right) \quad \forall\ M \in \mathcal{M}. \tag{25}$$

Then, taking the convex combination of the first and the second inequalities in (24) with respect to the uncertain parameters, we get

$$\begin{aligned} \operatorname{trace}\left(C P(\xi) C'\right) &= \operatorname{trace}\left[CG\left(G' P(\xi)^{-1} G\right)^{-1} G' C'\right] \\ &\leq \operatorname{trace}\left[CG\left(G + G' - P(\xi)^{-1}\right) G' C'\right] \\ &\leq \operatorname{trace}\left(\sum_{i=1}^{N} \xi_i W_i\right) \\ &\leq \max_{i=1,\ldots,N} \operatorname{trace}\left(W_i\right) \\ &< \mu, \end{aligned}$$

which, together with (25), concludes the proof of part (b). □

Part (a) of the above theorem first appeared in [3]. Theorem 4.1 represents some important contributions. First, it contains the quadratic stability result as a particular case. Notice that, if we aggregate to the LMI (23) and (24) the additional linear constraints

$$G = G' = P,\ P_i = P,\ i = 1, \ldots, N, \tag{26}$$

then we exactly recover Lemma 3.1. Second, it generalizes the concept of quadratic stability and quadratic robust performance of uncertain systems to cope with parameter dependent Lyapunov functions. As indicated in the proof, the stability of the family of matrices $M(\xi) = \sum_{i=1}^{N} \xi_i M_i$ is tested by the parameter dependent Lyapunov function

$$v(x) = x' \left(\sum_{i=1}^{N} \xi_i P_i \right) x. \tag{27}$$

From part (b), it is possible to determine an upper bound to the H_2 norm of $T_M(\zeta)$ by solving the following convex programming problem:

$$\mu_p := \min \{\mu \ : \ \text{s.t. } (24)\}. \tag{28}$$

Notice that $\mu_p \leq \mu_q$ since the inequality (24) reduces to (16) with the additional constraints (26) and $W_i = W$, $i = 1, \ldots, N$. In practice, the value of μ_p is much less that μ_q since the number of free variables in the problem (28) is much bigger than the number of free variables in the quadratic robust performance design problem (17). This behavior will be illustrated by the numerical examples provided in section 7.

The fact that $\mu_p \leq \mu_q$ will guarantee that the robust filters to be designed in the next section always perform better (no worse) than the ones obtained by the filtering design procedures based on the concept of quadratic stability [7]. Unfortunately, it is hard to quantify how much improvement can be obtained. Nevertheless, the introduced analysis conditions can indeed coincide with the actual robust stability analysis in some examples (see [3] and [4]).

5. A new robust filtering procedure. At this point, after the analysis results presented in the last section, we turn to the following question: *Is it possible to provide a numerically attractive procedure to synthesize a filter that takes advantage of the new robust stability and performance conditions provided in Theorem* 4.1*?* This is the goal of this section. Applying the result given in Theorem 4.1 to the estimation error transfer function (9), we have that, for a given $\mu > 0$, the robust filter under consideration is such that $\|T_M(\zeta)\|_2^2 < \mu$, provided that the inequalities

$$\text{trace}(W_i) < \mu, \quad \begin{bmatrix} W_i & \tilde{C}_i \tilde{G} \\ (\bullet)' & \tilde{G} + \tilde{G}' - \tilde{P}_i \end{bmatrix} > 0, \quad \begin{bmatrix} \tilde{P}_i & \tilde{A}_i \tilde{G} & \tilde{B}_i \\ (\bullet)' & \tilde{G} + \tilde{G}' - \tilde{P}_i & 0 \\ (\bullet)' & (\bullet)' & I \end{bmatrix} > 0 \tag{29}$$

hold for all $i = 1, \ldots, N$. More precisely, we are interested in investigating whether it is possible to convert the nonlinear matrix inequality in terms of the filter parameters in (29) into an LMI. If this goal is accomplished, the robust H_2 filter design problem turns out to be a convex programming problem which can be solved by efficient numerical algorithms.

To this end, we proceed by partitioning $\tilde{G}$ and its inverse as

$$\tilde{G} := \begin{bmatrix} Z^{-1} & ? \\ U & ? \end{bmatrix}, \ \tilde{G}^{-1} := \begin{bmatrix} Y & ? \\ V & ? \end{bmatrix}, \tag{30}$$

where Z, U, Y, V, and "?" denote matrices in $R^{n \times n}$. Notice that, given the quadruple (Z, U, Y, V), we can always calculate blocks "?" in order to have $\tilde{G}\tilde{G}^{-1} = I$. Also

notice that no additional constraints like symmetry or definiteness are present. From this partition of matrix $\tilde{G}$, we introduce the one-to-one change of variables

$$\begin{bmatrix} A_f & B_f \\ C_f & 0 \end{bmatrix} := \begin{bmatrix} V' & 0 \\ 0 & I \end{bmatrix}^{-1} \begin{bmatrix} Q & F \\ H & 0 \end{bmatrix} \begin{bmatrix} UZ & 0 \\ 0 & I \end{bmatrix}^{-1}, \tag{31}$$

where the existence of the indicated inverses will be proven in what follows. Denoting $R := V'UZ$, the next theorem gives a solution, expressed in terms of an LMI, to the robust H_2 filtering problem previously stated.

THEOREM 5.1. *Let $\mu > 0$ be given. The estimation error transfer function satisfies the inequality $\|T_M(\zeta)\|_2^2 < \mu$ for all $M \in \mathcal{M}$, provided that the robust filter transfer function is given by*

$$T_f(\zeta) := HR^{-1}\left(\zeta I - QR^{-1}\right)^{-1} F, \tag{32}$$

where matrices Q, H, F, R, Z, Y and $W_i = W_i'$, $P_i = P_i'$, $S_i = S_i'$, J_i, $i = 1, \ldots, N$, satisfy the LMI

$$\operatorname{trace}(W_i) < \mu, \tag{33}$$

$$\begin{bmatrix} W_i & L - H & L \\ (\bullet)' & Z + Z' - P_i & Z' + Y + R' - J_i \\ (\bullet)' & (\bullet)' & Y + Y' - S_i \end{bmatrix} > 0, \tag{34}$$

$$\begin{bmatrix} P_i & J_i & Z'A_i & Z'A_i & Z'B_i \\ (\bullet)' & S_i & Y'A_i + FC_i + Q & Y'A_i + FC_i & Y'B_i + FD_i \\ (\bullet)' & (\bullet)' & Z + Z' - P_i & Z' + Y + R' - J_i & 0 \\ (\bullet)' & (\bullet)' & (\bullet)' & Y + Y' - S_i & 0 \\ (\bullet)' & (\bullet)' & (\bullet)' & (\bullet)' & I \end{bmatrix} > 0. \tag{35}$$

Furthermore, (29) *holds for some filter if and only if the inequalities* (33)–(35) *are feasible.*

Proof. Let us first suppose that (29) is feasible. We can partition matrix $\tilde{G}$ as indicated in (30) and assume that matrices U and V are nonsingular. We can do that because, given singular matrices U and V, we can always slightly perturb them, keeping feasibility due to the fact that all inequalities are strict. Furthermore, $\tilde{G} + \tilde{G}' > \tilde{P}_i > 0$ ensures that $\tilde{G}^{-1}$ and Z exist, and, consequently, relation (31) defines a one-to-one transformation. So, defining the square and nonsingular matrices

$$\tilde{T} := \begin{bmatrix} Z & Y \\ 0 & V \end{bmatrix}, \quad \tilde{T}'\tilde{P}_i\tilde{T} := \begin{bmatrix} P_i & J_i \\ (\bullet)' & S_i \end{bmatrix},$$

it can be verified that the second inequality in (29), multiplied on the left by the full rank matrix $T' := \operatorname{diag}[I, \tilde{T}']$ and to the right by T, provides the LMI (34). Furthermore, doing the same to the third inequality in (29) with matrix $T := \operatorname{diag}[\tilde{T}, \tilde{T}, I]$, we get the LMI (35), which, together with the first inequality in (29), implies that all inequalities (33)–(35) are feasible. In addition, since R is also a nonsingular matrix, we get

$$\begin{aligned} T_f(\zeta) &= C_f\left(\zeta I - A_f\right)^{-1} B_f \\ &= HZ^{-1}U^{-1}\left(\zeta I - V^{-T}QZ^{-1}U^{-1}\right)^{-1} V^{-T}F \\ &= HR^{-1}\left(\zeta I - QR^{-1}\right)^{-1} F. \end{aligned}$$

For the converse, let us suppose that the LMIs (33)–(35) are feasible. First, notice that

$$\left[\begin{array}{cc} Z+Z' & Z'+Y+R' \\ (\bullet)' & Y+Y' \end{array}\right] > \left[\begin{array}{cc} P_i & J_i \\ (\bullet)' & S_i \end{array}\right] > 0,$$

which, multiplied on the left by $T = \left[\begin{array}{cc} I & -I \end{array}\right]$ and on the right by T', implies that $R + R' > 0$ so that R is a nonsingular matrix. The same inequality implies that $Z + Z' > 0$ and, consequently, that Z is also nonsingular. From the definition $R = V'UZ$, the regularity of matrices U and V holds. Consequently, transformation (31) provides a filter satisfying (29). □

It is important to compare the result of Theorem 5.1 with that of Lemma 3.2. The optimal guaranteed H_2 cost robust filter, provided using a single Lyapunov function, i.e., the quadratic optimal filter, is recovered by imposing on the inequalities (33)–(35) the additional constraints

$$Z = Z',\ Y = Y',\ R = Z - Y, \tag{36}$$

$$W_i = W,\ \left[\begin{array}{cc} P_i & J_i \\ (\bullet)' & S_i \end{array}\right] = \left[\begin{array}{cc} Z & Z \\ (\bullet)' & Y \end{array}\right],\ i = 1, \ldots, N, \tag{37}$$

as a consequence, and, following the same steps as in [7], it is worth noticing that the previous result also contains as a particular case the celebrated Kalman filter when $N = 1$. It is important to remark (see the illustrative examples) that the main issue of this paper is to provide a way to relax the constraints (36)–(37). As illustrated in the previous section, this fact enables us to get smaller guaranteed costs when compared with all other available design procedures based on a single and hence parameter independent Lyapunov function.

Finally, a suboptimal robust filter is readily obtained from

$$\mu_P := \min \{\mu \ :\ \text{s.t.}\ \ (33) - (35)\}, \tag{38}$$

which is still an LMI optimal filtering problem. Notice that it is possible to show that $\mu_P \leq \mu_Q$ holds, where μ_Q is given by (22).

6. Decentralized filtering. As in [6, 7], another interesting point of the design procedure provided in this paper concerns the filter structure. In signal and systems estimation, when the overall system is described by a number of units coupled together by means of an interconnection network, it is of interest to know whether it is possible to connect local filters in order to estimate the local state variables [12]. The model is given by (1)–(3), where B, C, D, and L are block diagonal matrices. The goal is to determine a filter as (6)–(7) with a state space representation (see (32)), where

$$C_f = HR^{-1},\ A_f = QR^{-1},\ B_f = F \tag{39}$$

are block diagonal matrices of compatible dimensions. If possible, the filter can be split into a set of local filters acting on each subsystem level. Recalling that the inverse of a block diagonal matrix is also a block diagonal matrix and that the product of block diagonal matrices is a block diagonal matrix, (39) reveals that our goal is accomplished, provided that we include in the H_2 filtering design problem (34)–(35) the following additional constraints: *Matrices H, R, Q, and F are block diagonal.* Fortunately, this corresponds to constrain some entries of those matrices to be equal to zero, and so convexity is preserved. Also notice that, on the contrary to what

happens in [6, 7], the Lyapunov matrices P_i, S_i, and J_i must not present a block diagonal structure. Another surprising feature is that none of the submatrices of $\tilde{G}$ and its inverse given in (30) must be block diagonal—a direct consequence of the extra degrees of freedom introduced with the new stability condition.

7. Illustrative examples. In this section, we solve the proposed robust filter design problem for several systems in the form (1)–(3). This example is taken from [7], and the results are compared with the ones given by the design procedures in [11] and in [7]. We have a discrete-time system with matrices

$$B = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \end{bmatrix},\ C = \begin{bmatrix} 1 & 0 \end{bmatrix},\ D = \begin{bmatrix} 0 & 0 & \sqrt{2} \end{bmatrix},\ L = \begin{bmatrix} 1 & 1 \end{bmatrix}$$

and a nominal matrix $A = A_0$ given by

$$A_0 = \begin{bmatrix} 0.9 & 0.1 \\ 0.01 & 0.9 \end{bmatrix}.$$

For this nominal system, the Kalman optimal filter $\mathcal{F}_{\mathrm{K}}$ is associated with the minimum H_2 cost equal to 8.0759 and is given by the minimal state space realization

$$A_{\mathrm{K}} = \begin{bmatrix} 0.4427 & 0.1000 \\ -0.1615 & 0.9000 \end{bmatrix},\ B_{\mathrm{K}} = \begin{bmatrix} 0.4573 \\ 0.1715 \end{bmatrix},\ C_{\mathrm{K}} = \begin{bmatrix} 1 & 1 \end{bmatrix}.$$

The first robust filter design we propose copes with the structured uncertainty defined through $A = A_0 + \Delta A$ for

$$\Delta A = \begin{bmatrix} 0 & 0.06\alpha \\ 0.05\beta & 0 \end{bmatrix} = \begin{bmatrix} 0.06 & 0 \\ 0 & 0.05 \end{bmatrix} \begin{bmatrix} \alpha & 0 \\ 0 & \beta \end{bmatrix} \begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix},$$

where $|\alpha| \leq 1$ and $|\beta| \leq 1$. This is a two-block structured uncertainty which can be exactly described by the set $\mathcal{M}$. Although the filter design procedure given in [11] cannot be directly applied to this problem without introducing some conservativeness, we take the best solution it provides without imposing the diagonal structure on the uncertainty parameters for the sake of comparison. This solution is obtained for a parameter $\varepsilon = 1.5264e-04$ and provides a suboptimal guaranteed cost H_2 filter $\mathcal{F}_{\mathrm{S}}$ with minimal state space realization

$$A_{\mathrm{S}} = \begin{bmatrix} 0.0335 & 0.1014 \\ -0.2551 & 0.9117 \end{bmatrix},\ B_{\mathrm{S}} = \begin{bmatrix} 0.8667 \\ 0.2652 \end{bmatrix},\ C_{\mathrm{S}} = \begin{bmatrix} 1 & 1 \end{bmatrix}.$$

Using the result of [7] (Lemma 3.2) with $N = 4$ matrices corresponding to the extreme points of the uncertain domain, we get the optimal quadratic guaranteed cost H_2 filter $\mathcal{F}_{\mathrm{Q}}$ given by

$$A_{\mathrm{Q}} = \begin{bmatrix} 0.0826 & -0.0768 \\ -0.0002 & 0.8543 \end{bmatrix},\ B_{\mathrm{Q}} = \begin{bmatrix} -0.0413 \\ 0.0001 \end{bmatrix},\ C_{\mathrm{Q}} = \begin{bmatrix} -29.8415 & -70.1868 \end{bmatrix}.$$

Finally, for the same set of vertices, Theorem 5.1 provides the optimal filter $\mathcal{F}_{\mathrm{P}}$:

$$A_{\mathrm{P}} = \begin{bmatrix} -0.1312 & 0.0842 \\ -0.0073 & 0.8352 \end{bmatrix},\ B_{\mathrm{P}} = \begin{bmatrix} -0.1151 \\ -0.0007 \end{bmatrix},\ C_{\mathrm{P}} = \begin{bmatrix} -14.7625 & -41.3592 \end{bmatrix}.$$

Table 1 shows, for each filter, the value of the H_2 guaranteed H_2 cost μ as well as the supremum of $\|T_M(\zeta)\|_2^2$ with respect to the matrix $M \in \mathcal{M}$, calculated by brute

TABLE 1

$\sup_{M\in\mathcal{M}} \|T_M(\zeta)\|_2^2$	49.4994	38.2183	30.0664	15.4506

TABLE 2
Filter performance: One-block uncertainty.

Filter	$\mathcal{F}_{\rm K}$	$\mathcal{F}_{\rm O}$	$\mathcal{F}_{\rm Q}$	$\mathcal{F}_{\rm P}$
$N=2$	—	—	9.6796	8.8499
$N=4$	—	—	13.0219	11.5307
$N=8$	—	—	13.0446	11.6053
μ	—	13.0446	13.0446	11.6053
$\sup_{M\in\mathcal{M}} \|T_M(\zeta)\|_2^2$	13.0036	11.8655	11.8655	11.5980

force. As in [7], the Kalman filter, which is optimal for the nominal system, is the worst under parametric uncertainty. The filters of [11] and [7] are both suboptimal with respect to the guaranteed cost—the first one because of the structure of the uncertainty and the second one because of the quadratic stability assumption. It is interesting to observe that the filter determined from Theorem 5.1 is approximately 50% better than the best obtained by the existent procedures with respect to guaranteed H_2 cost as well as with respect to the true worst case value of the H_2 estimation cost.

As a second design, we consider the same uncertain system given before, but we change the uncertainty description to

$$\Delta A = \begin{bmatrix} 0 & 0.06\alpha \\ 0 & 0.05\beta \end{bmatrix} = \begin{bmatrix} 0.06 & 0 \\ 0 & 0.05 \end{bmatrix} \begin{bmatrix} \alpha \\ \beta \end{bmatrix} \begin{bmatrix} 0 & 1 \end{bmatrix},$$

where the uncertain parameters are such that $\alpha^2 + \beta^2 \le 1$. With respect to this one-block unstructured uncertainty, the results of [11] provide the optimal quadratic guaranteed H_2 cost filter $\mathcal{F}_{\rm O}$:

$$A_{\rm O} = \begin{bmatrix} 0.3521 & 0.1069 \\ -0.2211 & 0.9400 \end{bmatrix},\ B_{\rm O} = \begin{bmatrix} 0.5479 \\ 0.2311 \end{bmatrix},\ C_{\rm O} = \begin{bmatrix} 1 & 1 \end{bmatrix}.$$

Although this uncertainty domain cannot be exactly represented by the polytopic domain $\mathcal{M}$, we proceed as in [7] by approximating the ellipsoidal uncertainty domain by the polyhedron associated with the extreme matrices

$$\begin{bmatrix} \alpha_i \\ \beta_i \end{bmatrix} = \begin{bmatrix} \cos(2\pi i/N) \\ \sin(2\pi i/N) \end{bmatrix},\ i = 1, \dots, N.$$

Table 2 shows that, with $N = 8$, the quadratic filter $\mathcal{F}_{\rm Q}$ given by Lemma 3.2 is associated with the same guaranteed cost as $\mathcal{F}_{\rm O}$. Applying Theorem 5.1, it is possible to go even further. Notice that the optimal parameter dependent filter $\mathcal{F}_{\rm P}$,

$$A_{\rm P} = \begin{bmatrix} 0.4491 & 0.0758 \\ 0.0006 & 0.9008 \end{bmatrix},\ B_{\rm P} = \begin{bmatrix} -0.2360 \\ -0.0013 \end{bmatrix},\ C_{\rm P} = \begin{bmatrix} -3.2370 & -8.5027 \end{bmatrix},$$

is associated with a guaranteed cost which virtually matches the actual worst case performance.

8. Conclusion. The robust filtering problem for linear time-invariant discrete-time uncertain systems has been addressed in this paper using parameter dependent Lyapunov functions when convex polytopic uncertainty is present on the dynamic, input, and output matrices. The work is based on a new robust stability condition, which presents a separation between the Lyapunov matrix and the matrices of the dynamic model.

We have shown how to determine optimal H_2 guaranteed cost filters by solving a linear problem constrained by an LMI. The results encompass most of the results available in the literature to date which are based on the quadratic stability framework. We have also shown how to extend the results to cope with decentralized filtering without assuming a block diagonal Lyapunov matrix structure. Some numerical examples have been solved, illustrating the superiority of the results for the design of filters for time-invariant uncertain systems.

GENERATION OF OPTIMAL PERIODIC OSCILLATIONS FOR THE CONTROL OF BOUNDARY LAYERS*

ABDERRAHMANE HABBAL†

Abstract. This paper is devoted to the optimal design problem of periodic surfaces. Solutions to elliptic partial differential equations occurring in oscillating domains exhibit boundary layer behavior, and we intend to control the first order correctors. Using a mathematical framework derived from the homogenization techniques, the existence of an optimal boundary layer control is proved.

1. Introduction.

The importance of understanding the physics of nonhomogeneous media in view of strategic industrial applications is now well established, and the progress in both mathematical models and numerical simulation methods has led to their effective use in industry (see the pioneering works of [Tar86], [Koh86] among many others). These days, software which computes and optimizes microstructured materials is widely available for commercial use. In contrast, the problem of optimal design of coatings is less studied; yet there are many industrial fields where rough surfaces play a central role: acoustic shields, thermal radiators, shark-skin wrapping of planes, or, as reported by Friedman [Liu97], the epithaxial growth of VLSI chips, and the tiled surface covering the space shuttle, as reported by Achdou, Pironneau, and Valentin [AY98]. There is also an obvious advantage in dealing with rough surfaces when, for example, aesthetic or functionality criteria impose a prescribed macroscopic outline of the boundary, allowing only for microscopic engraving of the surface.

The present paper is concerned with the optimal design of the shape of the waving to obtain a prescribed gradient profile. The mathematical approaches developed here, namely, the *transport-homogenization* technique and *bounding* of the unit-cell, are motivated by two reasons. The first is that homogenization, just as in the "volume" case, avoids the meshing of the very small structure of the boundary, which would be very expensive from the computational viewpoint.

The second reason is that the transport technique (see, e.g., [MF76], [Sok]) avoids successive meshing of the unit-cell since the varying cell is the image of a fixed one, and the control variable is simply the underlying mapping, just as is widely used in the shell optimization theory; refer to [Che87], for example, for a comprehensive survey.

Let us notice that since the geometry of the oscillating boundary is intended to vary during the optimization process, *effective boundary conditions*, though usually considered, are not well suited for our purpose. Effective boundary conditions lead to a problem stated in the *whole* domain, with more accurate conditions which involve the shape of the oscillations. However, a change in the shape then implies that one must redo computations in the *whole* domain, which could be very expensive. From

the physical point of view, effective conditions are a macroscopic interpretation which could be achieved as soon as the boundary layer optimization process is finished.

The paper is organized as follows. In section 2 the potential flow in an oscillating domain is presented. Then the mathematical setting for an asymptotic analysis and convergence results are outlined. We set in section 3 the optimal design framework. Finally, in section 4 weak convergence of the states and the existence of an optimum are proved.

2. The potential fluid flow. The potential fluid flow model is a linear approximation for the general nonlinear fluid mechanics when the fluid is inviscid, incompressible, and assumed to be permanent and irrotational. Then one can define a potential U related to the flow velocity $\vec{\mathbf{V}}$ by $\vec{\mathbf{V}} = \vec{\nabla} U$. The potential function U solves the classical Laplace equation with suitable boundary conditions, generally slip conditions, and free-surface conditions.

Many industrial applications related to computational fluid dynamics efficiently use this approximate model, sometimes as a preamble to the simulation of the Navier–Stokes or Euler equations. Good examples of such industries are the shipbuilding, the offshore station designing, and, more generally, the marine technology industries.

Our intention is to use this model as an example to illustrate the general problem of finding *smart coatings* in order to control the boundary velocity profile. We exhibit boundary layer terms which depend on the shape of the waving and are correctors to the velocity profile. They are used in order to minimize the distance to a prescribed profile.

Let us consider a bounded area occupied by a potential fluid. A part of the boundary of this domain is waved with small periodic oscillations. Within the oscillating domain, an open bounded set with Lipschitz boundary, denoted by Ω_ϵ (see Figure 2.1), we consider the following Laplace problem:

$$\left\{\begin{array}{rcll} -\Delta U_\epsilon & = & 0 & \text{in } \Omega_\epsilon, \\ \partial_\nu U_\epsilon & = & 0 & \text{over } \Gamma_\epsilon, \\ \partial_\nu U_\epsilon & = & g & \text{over } \Gamma_N, \\ U_\epsilon & = & 0 & \text{over } \Gamma_D. \end{array}\right. \tag{2.1}$$

The function g describes the normal velocity of the incident flow through the part Γ_N of the boundary. It is assumed to be smooth enough, i.e., $g \in H^{\frac{1}{2}}(\Gamma_N)$ and fulfills the classical compatibility condition.

Setting $H(\Omega_\epsilon) = \left\{v \in H^1(\Omega_\epsilon),\ v = 0 \text{ over } \Gamma_D\right\}$, it is then well known that for any $\epsilon > 0$, there exists a unique $U_\epsilon \in H(\Omega_\epsilon)$ solution to the *variational problem* derived from (2.1):

$$\int_{\Omega_\epsilon} \nabla U_\epsilon . \nabla v \, d\Omega_\epsilon \ = \ \int_{\Gamma_N} g v \, d\Gamma \qquad \forall v \in H(\Omega_\epsilon). \tag{2.2}$$

2.1. The general setting for a two-scale boundary layer approach. In the following, $\Omega \subset \mathbb{R}^N$ is an open bounded set with a C^1-piecewise boundary. We focus our attention on a selected part on this boundary, denoted by Γ_0.

We assume without loss of generality that the boundary Γ_0 is plane, union of small cells homothetic (with a ratio ϵ) to a unit-cell period denoted Y'. Given a positive small enough real number ϵ and an arbitrary positive real $L > 1$, we define the strip B_ϵ as the one obtained by normal inward increasing of the boundary Γ_0: $B_\epsilon = \Gamma_0 \times]0, L\epsilon[$. The unit-cell is defined as $G = Y' \times]0, L[$.

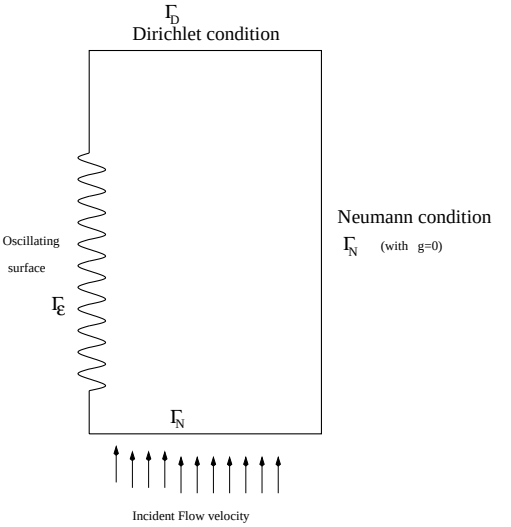

FIG. 2.1. *The oscillating domain and the physical configuration.*

Given a Y'-periodic function, $\vec{\psi} : Y' \to \mathbb{R}^N$, such that $\vec{\psi}_{|_{\partial Y'}} = 0$ (in order to avoid creating fissures) and a positive (small) real number ϵ, we define *an oscillating perturbation* $\vec{\psi}_\epsilon$ of the boundary Γ_0 by

$$\vec{\psi}_\epsilon : (x', 0) \in \Gamma_0 \to \vec{\psi}(x'/\epsilon) \in \mathbb{R}^N.$$

In order to define the oscillating domain Ω_ϵ, one usually applies a *harmonic extension* $\vec{V}_\epsilon$ of $\vec{\psi}_\epsilon$ on the reference domain Ω. The oscillating domain Ω_ϵ is then defined as the image of the reference domain Ω through the mapping $T_\epsilon = I + \epsilon\vec{V}_\epsilon$. It is clear from the definition of Ω_ϵ that the image of Γ_0 through T_ϵ is now an oscillating boundary, which we denote by Γ_ϵ. Moreover, in order to properly apply the two-scale boundary layer technique as presented in section 2.1, we choose perturbation fields $\vec{V}_\epsilon$ which vanish outside the strip $S_\gamma = \Gamma_0 \times\ ]0, \gamma\epsilon[$ with $\gamma \ll L$. Here the width L is intended to be large while γ is of order of the unit, e.g., $\gamma = 1$.

In the present paper, we explicitly consider as perturbations the mappings of the form

$$\vec{V}_\epsilon(x', x_n) = \vec{\psi}(x'/\epsilon)F(x_n/\epsilon), \tag{2.3}$$

where F is a smooth mollifier such as $F(t) = \exp(\frac{-t}{\gamma - t}),\ 0 \le t \le \gamma$.

We shall see in the third section of this paper (the setting of the optimal design framework) that the functions $\vec{\psi}$ should be Lipschitz, with derivatives not only bounded but also of *bounded variation*.

Now, we come back to the potential flow example. The perturbation field $\vec{V}_\epsilon$ waves the selected portion Γ_0, yielding Γ_ϵ, while it does not affect the remaining parts Γ_D and Γ_N of the boundary.

Our aim being to set the model problem in a domain which does not depend on the parameter ϵ, we define the reference Sobolev space by

$$H(\Omega) = \left\{ v \in H^1(\Omega), \quad v = 0 \quad \text{over } \Gamma_D \right\}.$$

Then, from the definition and regularity (algebraic and topological) properties of the mapping $T_\epsilon = I + \epsilon\vec{V}_\epsilon$, the natural norms over the spaces $H(\Omega)$ and $H(\Omega_\epsilon)$ are equivalent. Setting $u_\epsilon = U_\epsilon \circ T_\epsilon$, we get the following *transported* problem:

Find $u_\epsilon \in H(\Omega)$ such that $\forall v \in H(\Omega)$,

$$\int_\Omega (A_\epsilon \nabla u_\epsilon).\nabla v \, dx \;=\; \int_{\Gamma_N} g v \, d\Gamma, \tag{2.4}$$

where

$$A_\epsilon \;=\; (DT_\epsilon)^{-1}(DT_\epsilon)^{-T} |\det(DT_\epsilon)|. \tag{2.5}$$

It is an easy exercise to check that the operator associated to the diffusion matrix[1] A_ϵ is continuous, bounded, and $H(\Omega)$-elliptic (assuming that $\vec{\psi}$ belongs to the unit-ball of $W^{1,\infty}(Y')$). On the other hand, the use of the explicit fields given by (2.3) shows that A_ϵ depends only on the variable $y = x/\epsilon$. Then we define the y'-periodic operator $\overline{A}(y)$ as the restriction of $A_\epsilon(x/\epsilon)$ to the cell G, i.e.,

$$\overline{A}(y) = A_\epsilon(x/\epsilon). \tag{2.6}$$

2.2. The convergence results. Since the frequency and the amplitude of the oscillations are of the same order, only near-boundary effects occur (boundary layers). Far from the boundary, the solution behaves as if it doesn't see the oscillations.

Then the natural limit problem in our case is simply the one without oscillations at all ($\vec{\psi} = 0$), and it is expected that the difference between the nonoscillating solution and the oscillating one is a term which concentrates near the boundary. This fact is expressed by the strong convergence in the H^1-norm of the oscillating solution to the nonoscillating one (which implies that the difference terms are necessarily concentrating near the boundary).

Following [Con98] (in our case, the cell G is *bounded*), let us define the space

$$L^2(\Gamma_0; C_\#(\overline{G})) \;=\; \big\{ v(x', y);\ x' \in \Gamma_0,\ y = (y', y_n) \in G; \quad v(., y) \in L^2(\Gamma_0); \\ v(x', .) \in C(\overline{G})),\ \text{periodic w.r.t. } y' \big\}.$$

Definition 2.1. *Let $(u_\epsilon)_{\epsilon>0}$ be a sequence in $L^2(\Omega)$. It is said to two-scale converge in the sense of boundary layers on Γ_0 if there exists a function $u_0(x', y) \in L^2(\Gamma_0 \times G)$ such that*

$$\lim_{\epsilon\to 0} \frac{1}{\epsilon} \int_{B_\epsilon} u_\epsilon(x) v\left(x', \frac{x}{\epsilon}\right) dx \;=\; \frac{1}{|Y'|} \int_{\Gamma_0 \times G} u_0(x', y) v(x', y) dx' \, dy$$

for any $v \in L^2(\Gamma_0; C_\#(\overline{G}))$.

Let $C^\infty_\#(G)$ (respectively, $C^\infty_{0\#}(G)$) be the space of smooth functions in $\overline{G}$ which are Y'-periodic in y' and have a support in $y_N \in [0, 1]$ (respectively, in $y_N \in [0, 1[$). The space $H^1_\#(G)$ (respectively, $H^1_{0\#}(G)$) is the Sobolev space obtained by completion of $C^\infty_\#(G)$ (respectively, $C^\infty_{0\#}(G)$) with respect to the $H^1(G)$-norm.

Let then consider the nonoscillating solution u, which solves the following problem:

[1] We shall henceforth identify the second order linear elliptic operators and their associated diffusion matrices.

Find $u \in H(\Omega)$ such that $\forall v \in H(\Omega)$,

$$\int_\Omega \nabla u.\nabla v \, dx \;=\; \int_{\Gamma_N} gv \, d\Gamma. \tag{2.7}$$

The asymptotic analysis results presented below are quite classical (generally in the case of semi-infinite unit-strip G); see especially the works of [Lio81], [Lan77], [Cas96], [ole92], [Ami96], and [All99].

The limit equation for the two-scale boundary layer u_1 is obtained by application of the two-scale convergence to (2.4) using test functions *concentrating* on the strip B_ϵ (hence, vanishing over the Neumann boundary Γ_N). It is stated as follows: Find $u_1(x', y) \in L^2(\Gamma_0;\ H^1_\#(G)/\mathbb{R})$ such that for any $v \in L^2(\Gamma_0;\ H^1_{0\#}(G))$,

$$\frac{1}{|Y'|}\int_{\Gamma_0\times G} \overline{A}\nabla_y u_1 \nabla_y v \, dx'dy = -\frac{1}{|Y'|}\int_{\Gamma_0\times G} \overline{A}\nabla u_{|\Gamma_0} \nabla_y v \, dx'dy. \tag{2.8}$$

Note that the assumptions on Ω and on the flow inlet g are enough to allow us to consider the trace $\nabla u_{|\Gamma_0}$ in $L^2(\Gamma_0)$.

The equation above is ill-posed due to the lack in boundary conditions. Indeed, $u_1(x', y)$ is the sum of a unique first order corrector $c_1 \in H^1_{0\#}(G)$ and a first order "tail" term $t_1(x', y)$ whose gradient dies exponentially with respect to L. Let us pose $u_1(x', y) = c_1(x', y) + t_1(x', y)$ with c_1 and t_1 solutions to the following equations:

- Find $c_1(x', y) \in L^2(\Gamma_0;\ H^1_{0\#}(G))$ such that for any $v \in L^2(\Gamma_0;\ H^1_{0\#}(G))$,

$$\frac{1}{|Y'|}\int_{\Gamma_0\times G} \overline{A}\nabla_y c_1 \nabla_y v \, dx'dy = -\frac{1}{|Y'|}\int_{\Gamma_0\times G} \overline{A}\nabla u_{|\Gamma_0} \nabla_y v \, dx'dy. \tag{2.9}$$

- Find $t_1(x', y) \in L^2(\Gamma_0;\ H^1_\#(G)/\mathbb{R})$ such that for any $v \in L^2(\Gamma_0;\ H^1_{0\#}(G))$,

$$\frac{1}{|Y'|}\int_{\Gamma_0\times G} \overline{A}\nabla_y t_1 \nabla_y v \, dx'dy = 0. \tag{2.10}$$

THEOREM 2.2. *The two following statements hold:*

(i) *There exist two positive constants β and C_1 independent from the width L such that*

$$\|t_1\|_{L^2(\Gamma_0;\ H^1_\#(G)/\mathbb{R})} \le C_1 \exp(-\beta L). \tag{2.11}$$

(ii) *There exists a positive constant C_2 independent from L such that*

$$\lim_{\epsilon\to 0} \frac{1}{\sqrt{\epsilon}} \|u_\epsilon(x) - u(x) - \epsilon c_1(x', x/\epsilon)\|_{H^1(\Omega)} \le C_2 \exp(-\beta L/2). \tag{2.12}$$

Moreover, the constant $\beta > 0$ depends only on the operator $\overline{A}$ and on the boundary Γ_0.

Let us remark again that from the corrector equation (2.9) and Theorem 2.2, the trace of the gradient of u (i.e., the profile of u) over the boundary Γ_0 is a source for the generation of the boundary layer term c_1 when the boundary is waved. The gradient near the oscillating boundary is then approximated (in the two-scale boundary layer sense) by the initial profile of the nonoscillating u plus the correcting gradient of c_1. It is then very tempting to see c_1 and, more precisely, the periodic oscillation shape as *boundary layer controls* and pose the question, How can we design the waving in order to get a prescribed behavior of the solutions near the oscillating boundary? The remainder of this paper intends to answer this question.

3. The optimal design framework. To optimize the shape of the oscillations, there are mainly two methods. The first one consists of deriving an effective boundary condition (wall law), which depends on the roughness and on the cell functions but not explicitly on the boundary layer corrector. One obtains a new unknown defined in the whole domain Ω. If one seeks only the control of near-boundary effects with varying roughness, this approach is too expensive.

The second method is as follows: From the corrector convergence theorem of the previous section, it can be easily seen that if one computes the solution u of the nonoscillating domain and then fits the local behavior by controlling the corrector c_1, then the computational cost is slightly reduced. Effective law approach requires us to redo computations in the whole domain when the shape of oscillations varies, as well as the updating of the cell functions. Only the latter is needed in the case of control with c_1.

On the other hand, a drawback of rectification techniques such as the present homotopy one is that one obtains equations with the geometry described by a distributed parameter, which needs to be smoother than naturally expected. The need for midsurfaces of bounded third derivatives in the theory of shells is a good example. In the present case, it comes out from the proof of existence of minima that the shape of the oscillations should have a derivative with *bounded variations*, i.e., belong to the space $BV(Y';\mathbb{R}^N)$; see [Giu84] for a general presentation.

A simple way to avoid the use of such a space is to consider oscillations of bounded second derivatives, although then shapes with corners, such as saw-teeth ones, are forbidden. By working in the space with derivatives in BV, the latter shape is allowed; but again lower-scale oscillations (microstructures *in* the microstructure) are not allowed (since one obtains shapes with second derivatives which are infinite sums of Dirac measures, and this is not a Radon measure).

As usual in optimal design theory, the model which we intend to control is restated, carefully underlying the dependence on the control variable.

Henceforth, the following notation will be used:

- The Banach space of controls is

$$W = \left\{\phi \in W^{1,\infty}(Y';\ \mathbb{R}^N),\ \left(D_j\phi_i\right) \in BV(Y'),\ \phi|_{\partial Y'} = 0\right\},$$

  where

$$\left(D_j\phi_i\right) \ = \ \left(D_{y'}\phi\right)_{ij}, \quad 1 \le i \le N,\ 1 \le j \le N-1,$$

  is the Jacobian matrix of ϕ.
- The set of admissible shapes (vector-valued, with arrow notation omitted) is

$$\Phi_l = \{\phi \in W, \quad \|\phi\|_W \le l\},$$

  where the role of the upper bound $l > 0$ is twofold: from the mathematical viewpoint, it states that the norm of ϕ must be small enough to ensure that the waved boundary is still Lipschitz; from the practical viewpoint, it states that the amount of material used in the waving (or engraving) is limited.
- The Hilbert space of (corrector) state variables is

$$V = L^2(\Gamma_0, H^1_{0\#}(G)).$$

In the definition (2.6) of the y'-periodic diffusion operator, we underline the dependence on the control variable ψ and denote the operator by $\overline{A}(\psi)(y)$.

Then, the energy and source functionals are defined by

$$e : \Phi_l \times V \times V \to \mathbb{R}, \quad e(\psi;\ c,\ v) \ = \ \int_{\Gamma_0 \times G} \overline{A}(\psi) \nabla_y c \nabla_y v \, dx' dy, \tag{3.1}$$

$$S : \quad \Phi_l \times V \to \mathbb{R}, \qquad S(\psi;\ v) \ = \ -\int_{\Gamma_0 \times G} \overline{A}(\psi) \nabla u_{|\Gamma_0} \nabla_y v \, dx' dy. \tag{3.2}$$

Then the following is the state equation: for a given $\psi \in \Phi_l$, find $c(\psi) \in V$ such that

$$\forall v \in V \quad e(\psi;\ c(\psi),\ v) \ = S(\psi;\ v). \tag{3.3}$$

Then, in order to state the optimal design problem, the *observation* functional is defined by

$$J : \Phi_l \times V \to \mathbb{R}, \tag{3.4}$$

$$(\psi;\ v) \to J(\psi;\ v) = \int_{\Gamma_0 \times G} g(x', y, \psi, \xi(\psi;\ v)) \, dx' dy, \tag{3.5}$$

where the auxiliary variable ξ is defined by

$$\xi(\psi;\ v)(x', y) \ = (\xi_1,\ \xi_2) = (D_{y'}\psi(y'), \nabla_y v(x', y)), \tag{3.6}$$

where $D_{y'}\psi$ is the Jacobian matrix of the vector ψ, and the function g defined over $\Gamma_0 \times G \times \mathbb{R}^N \times \mathbb{R}^{N \times N}$ is a Carathéodory integrand (i.e., measurable with respect to (x', y) and continuous with respect to (ψ, ξ)).

We point out that in the present study, the integrand of interest to us is the one considered for the control of the velocity profile over Γ_0, i.e.,

$$g(x', y, \psi, \xi) \ = \ |\xi_2 \ - \ \tau|^2,$$

where $\tau \in L^2(\Gamma_0)$ is a fixed desirable profile. It is quite well known that the observation associated to this integrand is lower semicontinuous. The above presentation as well as the standard growth condition below (obviously fulfilled by g) are presented for the sake of generality.

We assume that the integrand g is *convex* with respect to ξ and satisfies the *standard growth condition*: $\forall r \in \mathbb{R},\ \exists a_r \in (L^1(\Gamma_0 \times G))^{N(N-1)} \times (L^2(\Gamma_0 \times G))^N$, and $b_r \in L^1(\Gamma_0 \times G)$ such that

$$\inf_{|\psi| \le r} g(x', y, \psi, \xi) \ \ge \ \langle a_r(x', y),\ \xi \rangle_{\mathbb{R}^{N(N-1)} \times \mathbb{R}^N} + b_r(x', y). \tag{3.7}$$

The assumptions above are made to ensure that the observation J is lower semicontinuous, a necessary preamble to the proof of existence of minima. These assumptions are quite general and are fulfilled by a very large class of integrands g classically used in the shape optimization problems.

The *cost function* is then defined over the set Φ_l by

$$j(\psi) \ = \ J(\psi;\ c(\psi)),$$

where $c(\psi) \in V$ is the solution to the state equation (3.3).

Finally, the *optimal design problem* is stated as follows:

$$\text{Find } \psi \in \Phi_l \text{ such that } j(\psi) \ = \inf_{\phi \in \Phi_l} j(\phi). \tag{3.8}$$

Now, after a complete setting of the optimization problem, we face in the next section the question of *existence* of a solution to the problem (3.8).

4. Existence of an optimum. Since the set of admissible shapes Φ_l is compact for the weak-$\star$ topology of $W^{1,\infty}(Y',\ \mathbb{R}^N)$, it is well known that a sufficient condition for the existence of a minimum is that the cost function j should satisfy the lower semicontinuity requirement with respect to the same topology, the latter being generally proved in two steps:

1. First, prove the lower semicontinuity of the observation $J(.,.)$ with respect to its two arguments.
2. Then prove the weak convergence of the state variable, i.e., $c(\psi_n) \rightharpoonup c(\psi)$ in V, whenever $\psi_n \overset{\star}{\rightharpoonup} \psi$ in Φ_l.

Thus, one has

$$j(\psi) = J(\psi;\ c(\psi)) \ \leq\ \liminf_{n\to+\infty} J(\psi_n;\ c(\psi_n)) \ =\ \liminf_{n\to+\infty} j(\psi_n). \tag{4.1}$$

4.1. Weak lower semicontinuity of the observation J. Mainly due to the assumptions made on the integrand g, the lower semicontinuity of J is proved by means of the following theorem; see, e.g., [Dac89, Theorem 3.4].

THEOREM 4.1. *Let Ω be an open bounded subset of $\mathbb{R}^{(N-1)} \times \mathbb{R}^N$, and let*

$$g\ :\ \Omega \times \mathbb{R}^N \times \mathbb{R}^{N\times N}\ \mapsto\ \mathbb{R} \cup \{+\infty\}$$

be a Carathéodory integrand satisfying the growth condition

$$g(x,s,\xi)\ \geq\ \langle a(x),\ \xi\rangle_{\mathbb{R}^{N(N-1)}\times\mathbb{R}^N} + b(x) \tag{4.2}$$

for almost every $x \in \Omega$ and $\forall (s,\xi) \in \mathbb{R}^N \times \mathbb{R}^{N\times N}$, with $a \in (L^{q'}(\Omega))^{N\times N}$ (q' is the conjugate of q) and $b \in L^1(\Omega)$.

Assume that $g(x,s,.)$ is convex and that

$$\begin{cases} s_k \to s & \text{in } (L^p(\Omega))^N, \\ \xi_k \rightharpoonup \xi & \text{in } (L^q(\Omega))^{N\times N}. \end{cases} \tag{4.3}$$

Then the functional

$$\mathcal{J}(s,\xi) = \int_\Omega g(x, s(x), \xi(x))dx$$

is lower semicontinuous, i.e.,

$$\mathcal{J}(s,\xi)\ \leq\ \liminf_{k\to\infty} \mathcal{J}(s_k,\xi_k).$$

The theorem above is immediately applicable to our problem if we set

$$\begin{cases} \Omega\ =\ \Gamma_0 \times G, \quad x = (x',y); \\ s(x)\ =\ \psi(y') \in \Phi_l, \quad \xi(\psi,v) = (D_{y'}\psi, \nabla_y v) \quad \text{(refer to (3.4)–(3.6))}; \\ J(\psi,\ v)\ =\ \mathcal{J}(s, \xi(\psi,v)); \end{cases} \tag{4.4}$$

and the convergences are to be understood *in the weak-$\star$ sense* whenever the L^∞-topology is involved. Indeed, if we consider a sequence $(\psi_k,\ v_k)$ such that

$$\begin{cases} \psi_k \overset{\star}{\rightharpoonup} \psi & \text{in } W, \\ v_k \rightharpoonup v & \text{in } V, \end{cases} \tag{4.5}$$

then the weak convergence $\xi_k \rightharpoonup \xi$ must be understood as a product of weak-$\star$ times weak convergences; more precisely,

$$\left\{ \begin{array}{ll} (\xi_k)_1 \overset{\star}{\rightharpoonup} (\xi)_1 & \text{in } L^\infty(Y'), \\ (\xi_k)_2 \rightharpoonup (\xi)_2 & \text{in } L^2(\Gamma_0; L^2(G)). \end{array} \right. \tag{4.6}$$

On the other hand, the embedding of W onto $C(\overline{Y'})$ is compact, so that

$$\psi_k \to \psi \text{ in } C(\overline{Y'}).$$

Hence, we have the strong convergence of the sequence $(s_k) = (\psi_k)$. Moreover, there exists a constant C such that for any $\psi \in \Phi_l$,

$$\sup_{y' \in \overline{Y'}} |\psi(y')| \leq C;$$

then, thanks to the standard growth condition (3.7), one can take $a = a_C$ and $b = b_C$ in order to fulfill the condition (4.2). Hence, one can apply Theorem 4.1, which yields

$$J(\psi,\ v) \ = \ \mathcal{J}(s, \xi(\psi, v)) \leq \ \liminf_{k\to\infty} \mathcal{J}(s_k, \xi_k) = \ \liminf_{k\to\infty} J(\psi_k, v_k),$$

i.e., the functional J is weakly lower semicontinuous over $\Phi_l \times V$.

4.2. Weak continuity of the state variable. Our aim now is to show that $c(\psi_n) \rightharpoonup c(\psi)$ in V for all sequences (ψ_n) such that $\psi_n \overset{\star}{\rightharpoonup} \psi$ in Φ_l.

The weak continuity holds with trivial proof if we restrict the space of controls (and the admissible set) to $W^{2,\infty}(Y';\ \mathbb{R}^N)$. In this case, for any kind of oscillations, we have a *strong* convergence of $\overline{A}(\psi_n)$ to $\overline{A}(\psi)$ in $L^\infty(Y')$, yielding immediately that $c(\psi_n) \rightharpoonup c(\psi)$ in V. In the general case, the weak convergence of states is proved by means of the G-convergence theory. Briefly, a sequence A_n of elliptic operators is said to G-converge to an elliptic operator A if, for any given right-hand side f, one has $A_n^- 1 f \rightharpoonup A^- 1 f$; see, e.g., [G.93].

Recall that the diffusion matrix $\overline{A}(\psi)$ is given by

$$\overline{A}(\psi) \ = \ (I + D_y V)^{-1} (I + D_y V)^{-T} |\det(I + D_y V)|,$$

where the perturbation field V that is considered is the following:

$$\vec{V}(y', y_N) = \psi(y') F(y_N) \tag{4.7}$$

with $F(t) = \exp(\frac{-t}{\gamma - t}),\ 0 \leq t \leq \gamma$.

On the other hand, the matrix norm of the Jacobian $D_y V$ is upperbounded by the norm of ψ in $W^{1,\infty}(Y')$. It is then a simple linear algebra exercise to show that the set

$$\left\{ \overline{A}(\psi), \quad \psi \in \Phi_l \quad \text{with} \ \ l < 1 \right\}$$

is uniformly bounded and equicoercive (in the usual sense of bounded elliptic operators) with respect to the design variable ψ.

All the ingredients are then ready for the application of the G-convergence of elliptic operators. It is straightforward to show that the sequence $(\overline{A}(\psi_n))$ G-converges to a limit $\overline{A}_G$, and that $c(\psi_n) \rightharpoonup c_{_G}$ in V. Then if one proves that $\overline{A}_G$ is equal to $(\overline{A}(\psi))$, this will immediately yield that $c_{_G} = c(\psi)$.

The equality $\overline{A}_G = (\overline{A}(\psi))$ is in fact a byproduct of the strong convergence (see [KO94, p. 150]) of the sequence $(\overline{A}(\psi_n))$ to $(\overline{A}(\psi))$ in $L^2(Y')$, as will be proved below.

Let us first give an explicit formula for the matrix $(\overline{A}(\psi))$, for example, in the two-dimensional case (here $\psi = (\psi_1, \psi_2)$):

(4.8)
$$\overline{A}(\psi) \;=\; \frac{1}{(1+\psi_1' F)(1+\psi_2' F)-\psi_1 F' \psi_2' F} \times \begin{pmatrix} (1+\psi_2 F')^2 + (\psi_1 F')^2 & -\psi_2' F(1+\psi_2 F') - \psi_1 F'(1+\psi_1' F) \\ -\psi_2' F(1+\psi_2 F') - \psi_1 F'(1+\psi_1' F) & (1+\psi_1' F)^2 + (\psi_2' F)^2 \end{pmatrix}.$$

The notation ψ_1' stands for the derivative with respect to $y' \in [0,1]$.

Let us then consider a minimizing sequence (ψ_n) such that $\psi_n \overset{\star}{\rightharpoonup} \psi$ in Φ_l. For the sake of clarity, we shall use scalar notation, although the involved functions and sequences are vector-valued. (The prime signed $(\psi)'$ stands of course for the Jacobian matrix of ψ.)

Due to the compact embedding of the space $W^{1,\infty}(Y';\ \mathbb{R}^N)$ onto the space of continuous functions $C(\overline{Y'})$, one has

$$\psi_n \to \psi \text{ in } C(\overline{Y'}). \tag{4.9}$$

Then, this time using the compactness of the embedding of $BV(Y')$ onto the space $L^1(Y')$, we get

$$(\psi_n)' \to (\psi)' \text{ in } L^1(Y').$$

As the derivatives of the ψ_n's belong also to $L^\infty(Y')$, it is straightforward to show that the strong convergence indeed holds in $L^p(Y')$ for any $1 \le p < +\infty$. A careful examination of the structure of $\overline{A}(\psi)$ easily shows that the whole $(\overline{A}(\psi_n))$ converges to $\overline{A}(\psi)$ in $L^2(Y')$. The conclusion holds of course in any dimension.

THEOREM 4.2. *Under the general setting and assumptions of section* 3, *the optimal design problem*

$$\textit{Find } \psi \in \Phi_l \textit{ such that } j(\psi) \;=\; \inf_{\phi \in \Phi_l} j(\phi)$$

has a solution $\phi \in \Phi_l$.

In order to implement a numerical simulation, the use of descent algorithms in order to achieve numerical computation of the optimum generally requires the user to supply a gradient subroutine. Classically, the fast computation of the gradient is done by means of the adjoint state method, provided that the quantities which depend on the control variable are differentiable. Since we are in a classical linear elliptic framework, it is well known that the state control, the energy, and the cost function are differentiable as soon as the user prescribed observation is. For reference, see [O.84], [Ven78], and [Has96]. Let us remark that the local nature of the considered controls allow for parallel processing of several oscillating parts of the domain, provided that the boundary layers are not sufficiently close to each other to interact.

As a short conclusion, it must be kept in mind that the techniques of boundary layer control introduced in this paper apply only to potential flows, which do not develop genuine boundary layers as they are inviscid by definition. While the techniques applied here could be adapted to the Stokes model with rather minimal effort, this

is not the case when studying the more realistic Navier–Stokes flows, which develop physical boundary layers directly related to the Reynolds number. The interaction between the Reynolds boundary layers and those due to the waving of the boundary is a complex physical phenomenon, and we refer to [AY98] for a good investigation of the subject.

ZERO-SUM SEMI-MARKOV GAMES*

ANNA JAŚKIEWICZ†

Abstract. This paper deals with Borel state and action spaces zero-sum semi-Markov games under the expected long run average payoff criterion. The transition probabilities are assumed to satisfy some generalized geometric ergodicity conditions. The main result states that the optimality equation has a solution, which is approximated by the solutions of some ε-perturbed semi-Markov games. As a corollary, the existence of value and average optimal strategies for the players is established.

Key words. semi-Markov games, Borel state space, long run expected average payoff criterion, Bellman equation

1. Introduction and the model.

This paper deals with zero-sum undiscounted semi-Markov games in Borel spaces satisfying some stochastic stability conditions that imply so-called w-geometric ergodicity of the Markov chains induced by stationary strategies of the players [14, 15]. Assumptions of this type have recently been used in many papers on stochastic control [7, 8, 9] and Markov games [3, 10, 12, 20]. Such an approach enables us to consider unbounded payoffs, which is important from the point of view of many applications, e.g., to queueing models, networks [3], etc.

The main objective in this paper is to prove that the optimality equation for games under consideration has a solution. Our method of proof relies on considering some ε-perturbations of the transition structure of the game. Each ε-perturbed game can be solved by a natural iterative procedure. The solution to the optimality equation for the original game can be shown as a limit of some modifications of solutions for the ε-perturbed models as $\varepsilon \to 0$. This method of proof is essentially different from those used in the theory of Markov games [10, 12] based on the "vanishing discount factor approach."

There are few papers on Borel state space semi-Markov games [19]. The results, provided in [19] concern correlated equilibria in a class of strongly ergodic games with bounded payoffs and transition probabilities dominated by some probability measure on the state space. A predecessor of our paper is the article of Lal and Sinha [13]. They considered a countable state space model with bounded payoff function and much stronger ergodicity properties of the transition law. Their approach, by discounted games, allows only for bounded solutions to the optimality equation.

As noted by Cavazos-Cadena [5], under the same ergodicity assumptions as in [13], the players can restrict attention to some finite subset of the state space. This essentially reduces many interesting applications of stochastic games. Our paper is a considerable generalization of Lal and Sinha's paper [13] to Borel state spaces with unbounded costs. At the same time, our proof is based on different ideas, developed recently in [11].

†Institute of Mathematics, Wrocław University of Technology, Wybrzeże Wyspiańskiego 27, 50-370 Wrocław, Poland (ajaskiew@im.pwr.wroc.pl).

We consider zero-sum semi-Markov games (SMG) with Borel state and action spaces. By a Borel space we mean a nonempty Borel subset of a complete separable metric space, endowed with the σ-algebra $\mathcal{B}(X)$ of all its Borel subsets.

A *zero-sum SMG* is described by the following objects:

(i) X is the *set of states* for the game and is assumed to be a Borel space.

(ii) A and B are the *action spaces* for players 1 and 2, respectively, and are also assumed to be Borel spaces.

(iii) K_A and K_B are nonempty Borel subsets of $X \times A$ and $X \times B$, respectively. We assume that for each $x \in X$, the nonempty x-section

$$A(x) := \{a \in A : (x, a) \in K_A\}$$

of K_A represents the *set of actions available* to player 1 in the state x. Analogously, we define $B(x)$ for each $x \in X$. Define

$$K := \{(x, a, b) : x \in X,\ a \in A(x),\ \text{and } b \in B(x)\}.$$

It follows from [17] that K is a Borel subset of $X \times A \times B$.

(iv) q is a Borel measurable transition probability from K to X called the *law of motion among states*. If x is a state at some stage of the game and the players select actions $a \in A(x)$ and $b \in B(x)$, then $q(\cdot|x, a, b)$ is the probability distribution of the next state of the game.

(v) $Q(\cdot|x, a, b)$ is a distribution function of random variables $t_{n+1} := T_{n+1} - T_n$ and represents the *distribution of the holding (or sojourn) times*; T_n is the nth *jump time* of the process when it is in the state x_{n-1} and the actions are $a_{n-1} \in A(x_{n-1})$, $b_{n-1} \in B(x_{n-1})$ ($n = 0, 1, \ldots$ and $T_0 := 0$).

(vi) $r_1(x_n, a_n, b_n)$ is the *reward function* for player 1 (*cost function* for player 2) incurred at time T_n in state x_n by the control actions $a_n \in A(x_n)$ and $b_n \in B(x_n)$.

(vii) $r_2(x_n, a_n, b_n)$ denotes the *reward rate* for player 1 (*cost rate* for player 2) during the interval $[T_n, T_{n+1})$.

Throughout the remainder of this paper, $\mathbf{R}$ (resp., $\mathbf{R}_+$) stands for the set of real (resp., nonnegative real) numbers. By $P(D)$ we will denote the space of all probability measures on the Borel space D, equipped with the weak topology and the Borel σ-algebra.

Let H_n be the space of *admissible histories* up to the nth transition, i.e.,

$$H_n := (K \times \mathbf{R}_+)^n \times X, \quad \text{where} \quad H_0 := X.$$

An element of H_n is called a *partial history* of the game process and

$$h_n := (x_0, a_0, b_0, t_1, \ldots, x_{n-1}, a_{n-1}, b_{n-1}, t_n, x_n).$$

A randomized *strategy* π for player 1 is a sequence $\pi = (\pi_1, \pi_2, \ldots)$, where each π_n is a conditional probability $\pi_n(\cdot|h_n)$ on X, given the entire history h_n of the game up to its nth stage such that $\pi_n(A(x_n)|h_n) = 1$. (Of course, if $n = 0$, then $h_0 = x_0$.) The *class of all strategies* for player 1 will be denoted by Π. Let F be the set of all Borel measurable transition probabilities f from X to A such that $f(x) \in P(A(x))$ for each $x \in X$. It is well known that F is nonempty and every $f \in F$ can be identified with a Borel measurable mapping from X into $P(A)$ [4]. A *stationary strategy* for player 1 is a sequence $\pi = (f, f, \ldots)$ where $f \in F$. It can be identified with the mapping $f \in F$. Similarly, we define the set Γ (G) of all strategies (stationary strategies) for player 2.

Let $((X \times A \times B \times \mathbf{R}_+)^\infty, \mathcal{F})$ be the measurable space, where $\mathcal{F}$ denotes the corresponding product σ-algebra. Due to the theorem of C. Ionescu Tulcea (see Proposition V.1.1 in [16] or Chapter 7 in [4]), for each initial state $x \in X$ and strategies $\pi \in \Pi$, $\gamma \in \Gamma$ there exists a probability measure $P_x^{\pi\gamma}$ on $\mathcal{F}$ such that for all $A' \in \mathcal{B}(A)$, $B' \in \mathcal{B}(B)$, $X' \in \mathcal{B}(X)$, and $h_n = (x_0, a_0, b_0, t_1, \ldots, x_{n-1}, a_{n-1}, b_{n-1}, t_n, x_n)$ in H_n, $n = 0, 1, \ldots$,

$$P_x^{\pi\gamma}(x_0 = x) = 1,$$

$$P_x^{\pi\gamma}(a_n \in A'|h_n) = \pi_n(A'|h_n),$$

$$P_x^{\pi\gamma}(b_n \in B'|h_n) = \gamma_n(B'|h_n),$$

$$P_x^{\pi\gamma}(x_{n+1} \in X'|h_n, a_n, b_n, t_{n+1}) = q(X'|x_n, a_n, b_n),$$

and

$$P_x^{\pi\gamma}(t_{n+1} \le t|h_n, a_n, b_n) = Q(t|x_n, a_n, b_n), \quad t \ge 0.$$

By $E_x^{\pi\gamma}$ we denote the expectation operator with respect to the probability measure $P_x^{\pi\gamma}$.

Let $\tau(x, a, b)$ denote the *mean holding time*. When the process is in state x and the actions $a \in A(x)$, $b \in B(x)$ are chosen, then

$$\tau(x, a, b) := \int_0^\infty tQ(dt|x, a, b).$$

The *expected average reward per unit time* to player 1 is defined as

$$J(x, \pi, \gamma) := \liminf_{n\to\infty} \frac{E_x^{\pi\gamma}\left(\sum_{k=0}^{n-1} [r_1(x_k, a_k, b_k) + (T_{k+1} - T_k) r_2(x_k, a_k, b_k)]\right)}{E_x^{\pi\gamma}(T_n)}.$$

Making use of the properties of the conditional expectation, the last definition can be rewritten in the form

$$J(x, \pi, \gamma) = \liminf_{n\to\infty} \frac{E_x^{\pi\gamma}\left(\sum_{k=0}^{n-1} r(x_k, a_k, b_k)\right)}{E_x^{\pi\gamma}\left(\sum_{k=0}^{n-1} \tau(x_k, a_k, b_k)\right)},$$

where

$$r(x, a, b) := r_1(x, a, b) + \tau(x, a, b) r_2(x, a, b)$$

for every $(x, a, b) \in K$.

In section 2, we make assumptions under which the expected average reward considered in this paper is well defined.

For any initial state $x \in X$, we put

$$L(x) := \sup_{\pi\in\Pi} \inf_{\gamma\in\Gamma} J(x, \pi, \gamma) \quad \text{and} \quad U(x) := \inf_{\gamma\in\Gamma} \sup_{\pi\in\Pi} J(x, \pi, \gamma). \tag{1}$$

Then L (U) is called the *lower (upper) value* of the average payoff semi-Markov game. It is always true that $L(x) \le U(x)$ for $x \in X$. If $L(x) = U(x)$ for all $x \in X$, then this common function is called the *value* of the stochastic game and is denoted by V.

A strategy $\pi^* \in \Pi$ is called *optimal for player* 1 in the average payoff stochastic game if

$$\inf_{\gamma \in \Gamma} J(x, \pi^*, \gamma) = V(x)$$

for all $x \in X$. Similarly, a strategy $\gamma^* \in \Gamma$ is called *optimal for player* 2 in the average payoff stochastic game if

$$\sup_{\pi \in \Pi} J(x, \pi, \gamma^*) = V(x)$$

for all $x \in X$.

Let $x \in X$, $\nu \in P(A(x))$, and $\rho \in P(B(x))$. For any Borel measurable function $v : X \times A \times B \mapsto \mathbf{R}$, we put

$$v(x, \nu, \rho) := \int_{B(x)} \int_{A(x)} v(x, a, b) \nu(da) \rho(db),$$

provided that this integral exists. Further, for convenience we set

$$v(x, f, g) := v(x, f(x), g(x)),$$

where $f \in F$ and $g \in G$.

2. The assumptions. We are now ready to formulate our basic assumptions.

C1. For each $x \in X$, the sets $A(x)$ and $B(x)$ are nonempty and compact.

C2. For each $(x, a, b) \in K$, $r(x, \cdot, b)$ is upper semicontinuous on $A(x)$, and $r(x, a, \cdot)$ is lower semicontinuous on $B(x)$.

C3. For each $(x, a, b) \in K$ and every set $D \in \mathcal{B}(X)$, the function $q(D|x, \cdot, b)$ is continuous on $A(x)$, while $q(D|x, a, \cdot)$ is continuous on $B(x)$.

C4. For each $(x, a, b) \in K$, $\tau(x, \cdot, b)$ is continuous on $A(x)$, and $\tau(x, a, \cdot)$ is continuous on $B(x)$. Moreover, there exist positive constants m and M such that

$$m \le \tau(x, a, b) \le M$$

for all $(x, a, b) \in K$.

C5. (a) There exist a constant $L > 0$ and a Borel measurable function $w : X \mapsto \mathbf{R}$ such that $w(x) \ge 1$ for each $x \in X$ and $|r(x, a, b)| \le L w(x)$ for each $(x, a, b) \in K$.

(b) For each $(x, a, b) \in K$, the functions

$$\int w(y) q(dy|y, \cdot, b) \quad \text{and} \quad \int w(y) q(dy|x, a, \cdot)$$

are continuous on $A(x)$ and $B(x)$, respectively.

C6. (a) There exists a set $C \in \mathcal{B}(X)$ such that for some $\lambda \in (0, 1)$ and $\eta > 0$, we have

$$\int w(y) q(dy|x, a, b) \le \lambda w(x) + \eta 1_C(x)$$

for each $(x, a, b) \in K$. Here 1_C is the characteristic function of the set C and w is the function introduced in C5(a).

(b) The function w is bounded on C.

C7. There exist a $\delta \in (0,1)$ and a probability measure ζ_{fg}, concentrated on the Borel set C, associated with a pair of stationary strategies $(f,g) \in F \times G$ such that

$$q(D|x,f,g) \geq \delta \zeta_{fg}(D)$$

for each Borel set $D \subset C$ and $x \in C$.

REMARK 1. *Assumptions* C1–C4 *are standard, while* C5(a) *allows for unbounded payoffs. Conditions* C6 *and* C7 *imply that for every $f \in F$ and $g \in G$, the corresponding Markov chain is ψ_{fg}-irreducible for some σ-finite measure ψ_{fg} on X (see Theorem* 11.3.4 *and Chapter* 9 *in* [14]*). The ψ_{fg}-irreducibility means that if $\psi_{fg}(D) > 0$ for some set $D \in \mathcal{B}(X)$, then the chance that the Markov chain (starting at any $x \in X$ and induced by $f \in F$ and $g \in G$) ever enters D is positive. Lal and Sinha* [13] *employed much stronger ergodicity conditions for countable state space games, which correspond to* C6–C7 *with a bounded function w. The main disadvantage of such an approach is that the solution to the optimality (Bellman) equation is bounded. This fact excludes many interesting applications, even in the one-player case (i.e., dynamic programming); see* [1, 2, 3, 5, 21].

The set C in C7 *is called a* small set*, while* C6 *is called the* drift inequality [14]. *Such conditions and related ones are extensively used in the theory of Markov control processes and Markov games* [8, 9, 11, 12, 18, 20].

Assume that the function w in C5 is fixed. For a Borel measurable function $u : X \mapsto \mathbf{R}$, we define the weighted norm as

$$\|u\|_w := \sup_{x \in X} \frac{|u(x)|}{w(x)}.$$

We write L_w^∞ to denote the Banach space of all Borel measurable functions u for which $\|u\|_w$ is finite.

The following result is basic for this paper.

LEMMA 1. *Assume that* C6 *and* C7 *hold. Then for every $f \in F$ and $g \in G$, we have the following:*

(a) *The state process $\{x_n\}$ is a positive recurrent aperiodic Markov chain with the unique invariant probability measure, denoted by π_{fg}.*

(b) $\int w(x)\pi_{fg}(dx) < \infty$.

(c) $\{x_n\}$ *is w-uniformly ergodic, i.e., there exist $\theta > 0$ and $\alpha \in (0,1)$ such that*

$$\left| \int u(y) q^n(dy|x,f,g) - \int u(y)\pi_{fg}(dy) \right| \leq w(x)\|u\|_w \theta \alpha^n$$

for every $u \in L_w^\infty$ and $x \in X$, $n \geq 1$. Here $q^n(\cdot|x,f,g)$ denotes the n-stage transition probability induced by q and strategies f, g.

For a proof of (a) and (b) consult Theorem 11.3.4 and p. 116 in [14]. Part (c) follows from Theorem 2.3 in [15].

A conclusion to Lemma 1 is that for each $f \in F$ and $g \in G$ the expected average payoff is independent of the initial state:

$$J(f,g) := J(x,f,g) = \frac{\int r(y,f,g)\pi_{fg}(dy)}{\int \tau(y,f,g)\pi_{fg}(dy)}.$$

The following lemma is a consequence of our assumptions. It shows in particular how to obtain a solution to the Poisson equation associated with an arbitrary pair of strategies in $F \times G$. For a detailed discussion, see [8, 10].

LEMMA 2. *Suppose that assumptions* C5–C7 *are satisfied. Then for each pair of stationary strategies* $(f, g) \in F \times G$,

(a) *the function* h_{fg} *defined on* X *as*

$$h_{fg}(x) := E_x^{fg}\left(\sum_{n=0}^{\infty}[r(x_n, a_n, b_n) - J(f, g)\tau(x_n, a_n, b_n)]\right)$$

belongs to L_w^∞;

(b) *the pair* $(J(f, g), h_{fg})$ *is the unique solution to the equation*

$$J(f, g)\tau(x, f, g) + h_{fg}(x) = r(x, f, g) + \int h_{fg}(y)q(dy|x, f, g)$$

that satisfies the condition

$$\int h_{fg}(y)\pi_{fg}(dy) = 0.$$

The following auxiliary result follows easily from assumption C6(a) by induction.

LEMMA 3. *Let* C6(a) *hold and let* $\{x_n\}$ *denote the state space process under arbitrarily fixed strategies* $\pi \in \Pi$ *and* $\gamma \in \Gamma$. *Then for each initial state* $x \in X$, *any function* $u \in L_w^\infty$ *and* $n \geq 1$, *we obtain*

$$E_x^{\pi\gamma}|u(x_n)| \leq \|u\|_w\left(\lambda^n w(x) + \eta\sum_{k=0}^{n-1}\lambda^k\right) \leq \|u\|_w\left(w(x) + \frac{\eta}{1-\lambda}\right)$$

and

$$\limsup_{n\to\infty} E_x^{\pi\gamma}|u(x_n)| \leq \|u\|_w\frac{\eta}{1-\lambda}.$$

This lemma and conditions C4–C7 guarantee, for example, that the expected payoff introduced in section 1 is well defined.

We will also make use of the following fact, which follows easily from Proposition 10.1 in [22].

LEMMA 4. *Let* W_1 *be a compact metric space, and let* W_2 *be a nonempty set. Let* $\{v_n\}$ *be a nonincreasing sequence of functions* $v_n : W_1 \times W_2 \mapsto \mathbf{R}$ *such that* $v_n(\cdot, w_2)$ *is upper semicontinuous on* W_1 *for each* $n \geq 1$ *and* $w_2 \in W_2$. *Then*

$$\inf_{w_2\in W_2}\max_{w_1\in W_1}\lim_{n\to\infty} v_n(w_1, w_2) = \lim_{n\to\infty}\inf_{w_2\in W_2}\max_{w_1\in W_1} v_n(w_1, w_2).$$

3. The main results. Let $\varepsilon \in (0, 1)$ and δ_s be the probability measure concentrated at some fixed state $s \in X$. Put

$$q_\varepsilon(\cdot|x, a, b) := (1 - \varepsilon)q(\cdot|x, a, b) + \varepsilon\delta_s(\cdot)$$

for any $(x, a, b) \in K$.

The SMG with q replaced by q_ε is referred to as the ε-perturbed game (say, ε-perturbed SMG).

Let

$$\varepsilon_0 := \frac{1-\lambda}{2[w(s)-\lambda]}$$

and $0 < \varepsilon \le \varepsilon_0$. Then from C6(a), it follows that q_ε also satisfies the drift inequality with λ replaced by $(\lambda+1)/2 < 1$, $\eta > 0$ and the same small set C. Therefore from [15], we infer that for any $u \in L_w^\infty$ it holds that

$$\left| \int u(y) q_\varepsilon^n(dy|x,f,g) - \int u(y) \pi_{fg}^\varepsilon(dy) \right| \le w(x) \|u\|_w \theta_1 \alpha_1^n \tag{2}$$

and α_1 and θ_1 do not depend on ε. Thus a counterpart of Lemma 1 holds for the state process induced by any $f \in F$, $g \in G$, and q_ε. Consequently, for any $f \in F$, $g \in G$, we have

$$J^\varepsilon(f,g) := J^\varepsilon(x,f,g) = \frac{\int r(y,f,g)\pi_{fg}^\varepsilon(dy)}{\int \tau(y,f,g)\pi_{fg}^\varepsilon(dy)}$$

for all $x \in X$. Here $J^\varepsilon(x,f,g)$ stands for the expected average payoff in the ε-perturbed SMG.

PROPOSITION 1. *Under our assumptions* C1–C7*, there exists a positive constant d such that*

$$\sup_{g\in G} \sup_{f\in F} |J(f,g) - J^\varepsilon(f,g)| \le \varepsilon d \tag{3}$$

for $\varepsilon \in (0, \varepsilon_0)$. Constant d is expressed only by the constants used in assumptions C4–C7*.*

The above result has been established in our article [11]. It is worth pointing out that inequality (3) gives the rate of convergence between two expected payoffs: in the ε-perturbed and in the original SMG. Proposition 1 will play an important role in the proof of our main results.

Let $\varepsilon \in (0, \varepsilon_1)$, where $\varepsilon_1 := (1-\lambda)/(2w(s)+1-\lambda)$. Define

$$p(\cdot|x,a,b) := q_\varepsilon(\cdot|x,a,b) - \frac{\tau(x,a,b)\varepsilon}{M}\delta_s(\cdot)$$

for any $(x,a,b) \in K$. Clearly, p is a transition subprobability measure.

Let $T : L_w^\infty \mapsto L_w^\infty$ be the mapping defined by

$$(Tu)(x) = \min_{\rho\in P(B(x))} \max_{\nu\in P(A(x))} \left[r(x,\nu,\rho) + \int u(y) p(dy|x,\nu,\rho) \right], \tag{4}$$

where $x \in X$. Under our assumptions C1–C5 the operator T is well defined, and by Fan's theorem [6], we also have

$$(Tu)(x) = \max_{\nu\in P(A(x))} \min_{\rho\in P(B(x))} \left[r(x,\nu,\rho) + \int u(y) p(dy|x,\nu,\rho) \right] \tag{5}$$

for each $x \in X$.

Our first result deals with the optimality equation for the ε-perturbed SMGs.

THEOREM 1. *Assume* C1 *through* C7 *and that* $\varepsilon \in (0, \varepsilon_1)$. *Then there exists a fixed point* $l_\varepsilon \in L_w^\infty$ *of* T, *i.e.,*

$$l_\varepsilon(x) = (Tl_\varepsilon)(x) \tag{6}$$

for every $x \in X$. *Moreover,*

$$V_\varepsilon = \varepsilon l_\varepsilon(s)/M \tag{7}$$

is the value of the ε*-perturbed SMG.*

Let f and g be maxmin and minmax stationary strategies, respectively, obtained on the right-hand side in (6) (see also (4), (5)). From Lemma 2, Theorem 1, and the dynamic programming methods [8, 11], we conclude that

$$\begin{aligned} V_\varepsilon &= J^\varepsilon(f,g) \\ &= \sup_{\pi\in\Pi}\inf_{\gamma\in\Gamma} J^\varepsilon(x,\pi,\gamma) = \inf_{\gamma\in\Gamma}\sup_{\pi\in\Pi} J^\varepsilon(x,\pi,\gamma) \\ &= \sup_{\pi\in\Pi} J^\varepsilon(x,\pi,g) = \inf_{\gamma\in\Gamma} J^\varepsilon(x,f,\gamma) \end{aligned}$$

for every $x \in X$.

The following assertion concerns the optimality equation for the original SMG.

THEOREM 2. *Assume* C1–C7. *Then there exists a constant* V, *which is the value of the original SMG, and a function* $h \in L_w^\infty$ *unique up to an additive constant such that*

$$\begin{aligned} h(x) &= \min_{\rho\in P(B(x))}\max_{\nu\in P(A(x))}\left[r(x,\nu,\rho) + \int h(y)q(dy|x,\nu,\rho) - V\tau(x,\nu,\rho)\right] \\ &= \max_{\nu\in P(A(x))}\min_{\rho\in P(B(x))}\left[r(x,\nu,\rho) + \int h(y)q(dy|x,\nu,\rho) - V\tau(x,\nu,\rho)\right] \end{aligned}$$

for each $x \in X$. *Moreover, there exist* $f^0 \in F$ *and* $g^0 \in G$ *such that*

$$\begin{aligned} h(x) &= r(x,f^0,g^0) + \int h(y)q(dy|x,f^0,g^0) - V\tau(x,f^0,g^0) \\ &= \max_{\nu\in P(A(x))}\left[r(x,\nu,g^0) + \int h(y)q(dy|x,\nu,g^0) - V\tau(x,\nu,g^0)\right] \\ &= \min_{\rho\in P(B(x))}\left[r(x,f^0,\rho) + \int h(y)q(dy|x,f^0,\rho) - V\tau(x,f^0,\rho)\right] \end{aligned}$$

for each $x \in X$.

The above result implies, by the dynamic programming arguments [11], that

$$\begin{aligned} V &= J(f^0,g^0) \\ &= \sup_{\pi\in\Pi}\inf_{\gamma\in\Gamma} J(x,\pi,\gamma) = \inf_{\gamma\in\Gamma}\sup_{\pi\in\Pi} J(x,\pi,\gamma) \\ &= \sup_{\pi\in\Pi} J(x,\pi,g) = \inf_{\gamma\in\Gamma} J(x,f,\gamma) \end{aligned}$$

for every $x \in X$. Together with (3), the remarks lead to the following.

COROLLARY 1. *Let* $f \in F$, $g \in G$ *be the maxmin and minmax Borel measurable stationary strategies on the right side of* (6). *Then* f *and* g *are* $2d\varepsilon$*-optimal strategies in the original SMG.*

REMARK 2. *As already mentioned, the constant d can be computed using only the primitive data given in our assumptions (*C4–C6*) and an interesting result of Meyn and Tweedie* [15]. *In view of this, Corollary* 1 *is of some importance. In order to find almost optimal strategies for the players in the SMG, it is enough to solve the* ε*-perturbed SMG by iterative procedure. In this way we get the fixed point* l_ε *of operator* T *(see the proof of Theorem* 1*).*

COROLLARY 2. *From Proposition* 1*, it follows that*

$$V = \lim_{\varepsilon \to 0} V_\varepsilon = \lim_{\varepsilon \to 0} \frac{\varepsilon l_\varepsilon(s)}{M}$$

exists. Moreover, V *is a part of the solution to the optimality equation (see the proof of Theorem* 2*).*

4. The proofs.

Proof of Theorem 1. First we show that the operator T has a fixed point. Let $\varepsilon \in (0, \varepsilon_1)$. Using C6(a), it is easy to establish the drift inequality for p:

$$\int w(y)p(dy|x,a,b) \le (1-\varepsilon)\left(\frac{1+\lambda}{2}w(x) + \eta 1_C(x)\right). \tag{8}$$

Let $\mathcal{E}_x^{\pi\gamma}$ denote the expectation operator with respect to the measure induced by the transition subprobability measure p and any strategies $\pi \in \Pi$ and $\gamma \in \Gamma$. Likewise in Lemma 3, one can easily prove by induction using (8) that for any $u \in L_w^\infty$, it holds that

$$\mathcal{E}_x^{\pi\gamma}(|u(x_n)|) \le (1-\varepsilon)^n w(x) N_1$$

for some constant N_1.

Put $u_0(\cdot) \equiv 0$ and define

$$l_n(x) := \inf_{\gamma\in\Gamma} \sup_{\pi\in\Pi} \mathcal{E}_x^{\pi\gamma}\left(\sum_{k=0}^{n-1} r(x_k, a_k, b_k)\right).$$

Using minmax measurable selection theorems [17] and backward induction, one can show that

$$l_n(x) = (T^n u_0)(x)$$

for every $x \in X$. Now, note that under C5(a) there exists a constant N_2 such that for any natural n, N $(n > N)$, we have

$$\begin{aligned}
|l_n(x) - l_N(x)| &\le \sup_{\pi\in\Pi}\sup_{\gamma\in\Gamma}\left|\mathcal{E}_x^{\pi\gamma}\left(\sum_{k=0}^{n-1} r(x_k,a_k,b_k)\right) - \mathcal{E}_x^{\pi\gamma}\left(\sum_{k=0}^{N-1} r(x_k,a_k,b_k)\right)\right| \\
&\le \sup_{\pi\in\Pi}\sup_{\gamma\in\Gamma}\mathcal{E}_x^{\pi\gamma}\left(\sum_{k=N}^{n-1}|r(x_k,a_k,b_k)|\right) \\
&\le \sum_{k=N}^{n-1}(1-\varepsilon)^k w(x) N_2 \\
&\le \frac{(1-\varepsilon)^N}{\varepsilon} w(x) N_2.
\end{aligned}$$

This implies that $\{l_n\}$ is a Cauchy sequence in L_w^∞. Put

$$l_\varepsilon(x) := \lim_{n\to\infty} l_n(x), \quad x \in X.$$

Note that $l_\varepsilon \in L_w^\infty$ and

$$\sup_{x\in X} \frac{|l_n(x) - l_\varepsilon(x)|}{w(x)} \longrightarrow 0 \quad \text{when} \quad n \to \infty. \tag{9}$$

For $n \geq 2$ it holds that

$$l_n(x) = (T^n u_0)(x) = (Tl_{n-1})(x).$$

It only remains to prove that $Tl_{n-1} \to Tl_\varepsilon$ when $n \to \infty$. We have

$$\begin{aligned}|(Tl_n)(x) - (Tl_\varepsilon)(x)| \leq \varepsilon|l_n(s) - l_\varepsilon(s)| + \frac{\varepsilon}{M} \max_{a\in A(x)} \max_{b\in B(x)} \tau(x,a,b)|l_n(s) - l_\varepsilon(s)| \\ + (1-\varepsilon) \max_{a\in A(x)} \max_{b\in B(x)} \int \frac{|l_n(y) - l_\varepsilon(y)|}{w(y)} w(y) q(dy|x,a,b).\end{aligned}$$

Now from C1, C5(b), C4, and (9), we obtain that $Tl_n \to Tl_\varepsilon$ as $n \to \infty$. Hence l_ε is the fixed point of T.

The proof is completed by showing that V_ε (defined as in (7)) is the value of game for ε-perturbed SMG. In order to prove it, note that for every $\nu \in P(A(x))$ we have

$$l_\varepsilon(x) \geq r(x,\nu,g) + \int l_\varepsilon(y) q_\varepsilon(dy|x,\nu,g) - \tau(x,\nu,g)V_\varepsilon,$$

where g is a minmax stationary strategy for player 2 in (6) (see also (4)). If $k \geq 1$, then

$$\begin{aligned}\int l_\varepsilon(y) q_\varepsilon(dy|x_k,\nu,g) &= r(x_k,\nu,g) - \tau(x_k,\nu,g)V_\varepsilon \\ &\quad + \int l_\varepsilon(y) q_\varepsilon(dy|x_k,\nu,g) \\ &\quad - r(x_k,\nu,g) + \tau(x_k,\nu,g)V_\varepsilon \\ &\leq l_\varepsilon(x_k) - r(x_k,\nu,g) + \tau(x_k,\nu,g)V_\varepsilon.\end{aligned}$$

Iterating this inequality, we easily get

$$V_\varepsilon \mathbf{E}_x^{\pi g}\left(\sum_{k=0}^{n-1} \tau(x_k,a_k,b_k)\right) \geq \mathbf{E}_x^{\pi g} l_\varepsilon(x_{n-1}) - l_\varepsilon(x) + \mathbf{E}_x^{\pi g}\left(\sum_{k=0}^{n-1} r(x_k,a_k,b_k)\right). \tag{10}$$

Dividing both sides of (10) by $\mathbf{E}_x^{\pi g}\left(\sum_{k=0}^{n-1} \tau(x_k,a_k,b_k)\right)$, using condition C4 and Lemma 3, and taking $\liminf$ as $n \to \infty$, we obtain

$$V_\varepsilon \geq \sup_{\pi\in\Pi} J^\varepsilon(x,\pi,g) \geq U_\varepsilon(x), \tag{11}$$

where $U_\varepsilon(x)$ is the upper value for ε-perturbed SMGs. On the other hand, if we now take the maxmin stationary strategy $f \in F$ for player 1, it holds that

$$l_\varepsilon(x) \leq r(x,f,\rho) + \int l_\varepsilon(y) q_\varepsilon(dy|x,f,\rho) - \tau(x,f,\rho)V_\varepsilon$$

for every $\rho \in P(B(x))$. For $k \geq 1$, we get

$$\begin{aligned}\int l_\varepsilon(y) q_\varepsilon(dy|x_k, f, \rho) &= r(x_k, f, \rho) - \tau(x_k, f, \rho) V_\varepsilon \\ &\quad + \int l_\varepsilon(y) q_\varepsilon(dy|x_k, f, \rho) \\ &\quad - r(x_k, \nu, g) + \tau(x_k, f, \rho) V_\varepsilon \\ &\geq l_\varepsilon(x_k) - r(x_k, f, \rho) + \tau(x_k, f, \rho) V_\varepsilon.\end{aligned}$$

Along similar lines as above, we obtain

$$V_\varepsilon \geq \inf_{\gamma \in \Gamma} J_\varepsilon(x, f, \gamma) \geq L_\varepsilon(x), \tag{12}$$

where $L_\varepsilon(x)$ is the lower value for ε-perturbed SMGs. Finally, from (11) and (12) we infer

$$V_\varepsilon = \inf_{\gamma \in \Gamma} J_\varepsilon(x, f, \gamma) = L_\varepsilon(x) = \sup_{\pi \in \Pi} J_\varepsilon(x, \pi, g) = U_\varepsilon(x)$$

for every $x \in X$. This completes the proof. □

The proof of Theorem 2 contains a solution to the Bellman equation of the original SMG. Although V_ε tends to V, the sequence of the fixed points of T need not converge to any solution to the optimality equation, because the sequence $\{l_\varepsilon\}$ can be unbounded. By an appropriate modification of this sequence, we will obtain a new one, which is bounded in L_w^∞ and can be used for constructing the solution to the optimality equation. In order to emphasize the main points, the proof is divided into four steps.

Proof of Theorem 2.

Step 1. First we modify the sequence $\{l_\varepsilon\}$ in order to make it uniformly bounded in the space L_w^∞. Let $f \in F$, $g \in G$ be the maxmin and minmax strategies on the right side of (6), respectively. From (6) we have

$$\begin{aligned}l_\varepsilon(x) &= r(x, f, g) + \int l_\varepsilon(y) p(dy|x, f, g) \\ &= r(x, f, g) + \int l_\varepsilon(y) q_\varepsilon(dy|x, f, g) - \frac{\varepsilon}{M} \tau(x, f, g) l_\varepsilon(s).\end{aligned} \tag{13}$$

Define

$$z_\varepsilon(x, f, g) := r(x, f, g) - \frac{\varepsilon}{M} l_\varepsilon(s) \tau(x, f, g). \tag{14}$$

Put

$$h_\varepsilon(x) := \mathbf{E}_x^{fg} \left(\sum_{n=0}^{\infty} z_\varepsilon(x_n, a_n, b_n) \right), \tag{15}$$

where $\mathbf{E}_x^{fg}$ is the expectation operator with respect to the probability measure on $(\Omega, \mathcal{F})$ induced by f, g, and q_ε. Clearly,

$$|z_\varepsilon(x, f, g)| \leq w(x) N_3 \tag{16}$$

for some constant N_3, $f \in F$, $g \in G$, and $\varepsilon \in (0, \varepsilon_1)$. From (14) and (7), we conclude that

$$\int z_\varepsilon(x,f,g)\pi^\varepsilon_{fg}(dx) = 0. \tag{17}$$

Under our assumptions it follows from (15), (17), and the Markov property that

$$h_\varepsilon(x) = z_\varepsilon(x,f,g) + \int h_\varepsilon(y) q_\varepsilon(dy|x,f,g). \tag{18}$$

Recall that the drift inequality is satisfied by q_ε with λ replaced by $(\lambda+1)/2$. Therefore using (2), C5(a), (17), and (16), we infer that there exists some constant N_4 for which

$$|h_\varepsilon(x)| \le w(x) N_4 \tag{19}$$

for all $x \in X$ and $\varepsilon \in (0, \varepsilon_1)$.

Subtracting (13) from (18), it follows that

$$w_\varepsilon(x) = \int w_\varepsilon(y) q_\varepsilon(dy|x,f,g),$$

with $w_\varepsilon(x) = l_\varepsilon(x) - h_\varepsilon(x)$. Hence

$$w_\varepsilon(x) = \int w_\varepsilon(y)\pi^\varepsilon_{fg}(dy) = N_5,$$

where N_5 is some constant. Thus $h_\varepsilon(x) = l_\varepsilon(x) - N_5$ for all $x \in X$ and for every $\varepsilon \in (0, \varepsilon_1)$. Consequently, one can replace $l_\varepsilon(x)$ in (6) by $h_\varepsilon(x)$ and obtain

$$\begin{aligned} h_\varepsilon(x) &= \max_{\nu\in P(A(x))} \min_{\rho\in P(B(x))} \left[r(x,\nu,\rho) - \frac{\varepsilon}{M} l_\varepsilon(s)\tau(x,\nu,\rho) + \int h_\varepsilon(y) q_\varepsilon(dy|x,\nu,\rho) \right] \\ &= \min_{\rho\in P(B(x))} \max_{\nu\in P(A(x))} \left[r(x,\nu,\rho) - \frac{\varepsilon}{M} l_\varepsilon(s)\tau(x,\nu,\rho) + \int h_\varepsilon(y) q_\varepsilon(dy|x,\nu,\rho) \right] \\ &= r(x,f,g) - \frac{\varepsilon}{M} l_\varepsilon(s)\tau(x,f,g) + \int h_\varepsilon(y) q_\varepsilon(dy|x,f,g). \end{aligned} \tag{20}$$

Step 2. The second part of our proof starts with showing that V (see Corollary 2) is indeed the value of the original SMG and the players have optimal stationary strategies.

Fix $x \in X$ and choose any sequence $\{\varepsilon_n\}_{n\ge 2}$ converging to zero. For every $\nu \in P(A(x))$ there exists a sequence $\{\rho_{\varepsilon_n}\}$ (abbreviated $\{\rho_n\}$) (independent on ν) that attains minimum on the right side of inequality (20), i.e.,

$$\begin{aligned} h_{\varepsilon_n}(x) &= \min_{\rho\in P(B(x))} \max_{\nu\in P(A(x))} \left[r(x,\nu,\rho) + \int h_{\varepsilon_n}(y) q_{\varepsilon_n}(dy|x,\nu,\rho) - \tau(x,\nu,\rho) V_{\varepsilon_n} \right] \\ &= \max_{\nu\in P(A(x))} \left[r(x,\nu,\rho_n) + \int h_{\varepsilon_n}(y) q_{\varepsilon_n}(dy|x,\nu,\rho_n) - \tau(x,\nu,\rho_n) V_{\varepsilon_n} \right] \\ &\ge r(x,\nu,\rho_n) + \int h_{\varepsilon_n}(y) q_{\varepsilon_n}(dy|x,\nu,\rho_n) - \tau(x,\nu,\rho_n) V_{\varepsilon_n}. \end{aligned} \tag{21}$$

Since (19) holds, we can take the lim inf on both sides in (21) as $n \to \infty$. By Corollary 2, we put $V = \lim_{n\to\infty} V_{\varepsilon_n}$. The set $P(B(x))$ is compact when endowed with the weak

topology. Hence there exists a subsequence $\{n(k)\}$ of $\{n\}$ such that $\{\rho_{n(k)}\}$ converges weakly to some $\rho_x \in P(B(x))$, and simultaneously $h_*(x) := \liminf_{n\to\infty} h_{\varepsilon_n}(x) = \lim_{k\to\infty} h_{\varepsilon_{n(k)}}(x)$. From (21), Fatou's lemma for varying probability measures (see [8] or [18, Lemma 4]), we obtain

$$\begin{aligned}
h_*(x) &= \liminf_{n\to\infty} h_{\varepsilon_n}(x) \geq \liminf_{n\to\infty} \left(r(x,\nu,\rho_n) + \int h_{\varepsilon_n}(y) q_{\varepsilon_n}(dy|x,\nu,\rho_n) - \tau(x,\nu,\rho_n) V_{\varepsilon_n} \right) \\
&= \liminf_{k\to\infty} \left(r(x,\nu,\rho_{n(k)}) + \int h_{\varepsilon_{n(k)}}(y) q_{\varepsilon_{n(k)}}(dy|x,\nu,\rho_{n(k)}) - \tau(x,\nu,\rho_{n(k)}) V_{\varepsilon_{n(k)}} \right) \\
&\geq r(x,\nu,\rho_x) + \int \liminf_{k\to\infty} h_{\varepsilon_{n(k)}}(y) q(dy|x,\nu,\rho_x) - \tau(x,\nu,\rho_x) V \\
&\geq r(x,\nu,\rho_x) + \int h_*(y) q(dy|x,\nu,\rho_x) - \tau(x,\nu,\rho_x) V.
\end{aligned}$$

Because the last inequality holds for every $\nu \in P(A(x))$, we therefore get in the obvious manner

$$h_*(x) \geq \min_{\rho\in P(B(x))} \max_{\nu\in P(A(x))} \left[r(x,\nu,\rho) + \int h_*(y) q(dy|x,\nu,\rho) - \tau(x,\nu,\rho) V \right] \tag{22}$$

for each $x \in X$. By (22) and minmax measurable selection theorem [17], there exists some $g^* \in G$ such that

$$h_*(x) \geq r(x,\nu,g^*) + \int h_*(y) q(dy|x,\nu,g^*) - \tau(x,\nu,g^*) V.$$

From dynamic programming [11], it follows that

$$V \geq \sup_{\pi\in\Pi} J(x,\pi,g^*) \geq U(x). \tag{23}$$

On the other hand, it is easily seen from (20) that for each $\rho \in P(B(x))$ there exists a sequence $\{\nu_{\varepsilon_n}\}$ (abbreviated $\{\nu_n\}$) (independent on ρ) such that

$$h_{\varepsilon_n}(x) \leq r(x,\nu_n,\rho) + \int h_{\varepsilon_n}(y) q_{\varepsilon_n}(dy|x,\nu_n,\rho) - \tau(x,\nu_n,\rho) V_{\varepsilon_n}.$$

Taking lim sup as $n \to \infty$, we conclude

$$h^*(x) \leq \max_{\nu\in P(A(x))} \min_{\rho\in P(B(x))} \left[r(x,\nu,\rho) + \int h^*(y) q(dy|x,\nu,\rho) - \tau(x,\nu,\rho) V \right], \tag{24}$$

where $h^*(x) := \limsup_{n\to\infty} h_{\varepsilon_n}(x)$. Let $f^* \in F$ be the maxmin strategy in (24). Applying similar arguments, we infer

$$V \leq \inf_{\gamma\in\Gamma} J(x,f^*,\gamma) \leq L(x) \tag{25}$$

for each $x \in X$. Consequently, combining (23) and (25) we get

$$V = \inf_{\gamma\in\Gamma} J(x,f^*,\gamma) = \sup_{\pi\in\Pi} J(x,\pi,g^*) = L(x) = U(x),$$

which is the desired conclusion.

Step 3. Now we are left with the task of finding a solution to the optimality equation of the original SMG. Define

$$\hat{r}(x,a,b) := r(x,a,b) - V\tau(x,a,b)$$

for every $(x,a,b) \in K$. Because V is the value of game in the original SMG and (f^*,g^*) is the pair of the optimal stationary strategies, therefore

$$J_{\hat{r}}(f^*,g^*) := \int \hat{r}(y,f^*,g^*)\pi_{f^*g^*}(dy) = 0. \tag{26}$$

From Lemma 2 there exists a function $h_{f^*g^*} \in L_w^\infty$ such that

$$h_{f^*g^*}(x) = \hat{r}(x,f^*,g^*) + \int h_{f^*g^*}(y)q(dy|x,f^*,g^*) \tag{27}$$

and

$$h_{f^*g^*}(x) = E_x^{f^*g^*}\left(\sum_{k=0}^{\infty} \hat{r}(x_k,a_k,b_k)\right)$$

for all $x \in X$. It is evident that

$$h_*(x) \geq \hat{r}(x,f^*,g^*) + \int h_*(y)q(dy|x,f^*,g^*) \tag{28}$$

and

$$h^*(x) \leq \hat{r}(x,f^*,g^*) + \int h^*(y)q(dy|x,f^*,g^*) \tag{29}$$

for every $x \in X$. If we now subtract (28) from (27), (29) from (27), we get

$$h_*(x) - h_{f^*g^*}(x) \geq \int \left(h_*(y) - h_{f^*g^*}(y)\right) q(dy|x,f^*,g^*)$$

and

$$h^*(x) - h_{f^*g^*}(x) \leq \int \left(h^*(y) - h_{f^*g^*}(y)\right) q(dy|x,f^*,g^*).$$

Iterating these inequalities and taking the limit as $n \to \infty$, we obtain by Lemma 1

$$h_*(x) - h_{f^*g^*}(x) \geq \int \left(h_*(y) - h_{f^*g^*}(y)\right) \pi_{f^*g^*}(dy)$$

and

$$h^*(x) - h_{f^*g^*}(x) \leq \int \left(h^*(y) - h_{f^*g^*}(y)\right) \pi_{f^*g^*}(dy).$$

These inequalities hold for every $x \in X$; therefore

$$h_*(x) - h_{f^*g^*}(x) = \inf_{x\in X}\left(h_*(x) - h_{f^*g^*}(x)\right) = d_1 \quad \text{for a.e. } \pi_{f^*g^*}$$

and

$$h^*(x) - h_{f^*g^*}(x) = \sup_{x\in X}\left(h^*(x) - h_{f^*g^*}(x)\right) = d_2 \quad \text{for a.e. } \pi_{f^*g^*}.$$

Thus (see also [8, 10]) there exist Borel sets $X_1 \subset X$ and $X_2 \subset X$ such that $\pi_{f^*g^*}(X_1) = 1$ and $\pi_{f^*g^*}(X_2) = 1$, on which the above equalities are true, respectively. Moreover, $\pi_{f^*g^*}(X_1 \cap X_2) = 1$. By Proposition 4.2.3 and Theorem 10.4.9 in [14], the Markov chain induced by f^*, g^*, and q has an absorbing Borel set $Z \subset X_1 \cap X_2$, that is, $q(Z|x, f^*, g^*) = 1$ for all $x \in Z$.

Now we show that the optimality equation holds on the set Z. Let $x \in Z$. Substituting $h_{f^*g^*}(x) + d_1$ for $h_*(x)$ in (22) and $h_{f^*g^*}(x) + d_2$ for $h^*(x)$ in (24), we easily get

$$h_{f^*g^*}(x) \geq \max_{\nu \in P(A(x))} \left[\hat{r}(x, \nu, g^*) + \int h_{f^*g^*}(y) q(dy|x, \nu, g^* \right],$$

$$h_{f^*g^*}(x) \leq \min_{\rho \in P(B(x))} \left[\hat{r}(x, f^*, \rho) + \int h_{f^*g^*}(y) q(dy|x, f^*, \rho) \right].$$

Combining these inequalities with (27), we have

$$\begin{aligned} h_{f^*g^*}(x) &= \hat{r}(x, f^*, g^*) + \int h_{f^*g^*}(y) q(dy|x, f^*, g^*) \\ &= \max_{\nu \in P(A(x))} \left[\hat{r}(x, \nu, g^*) + \int h_{f^*g^*}(y) q(dy|x, \nu, g^* \right] \\ &= \min_{\rho \in P(B(x))} \left[\hat{r}(x, f^*, \rho) + \int h_{f^*g^*}(y) q(dy|x, f^*, \rho) \right] \end{aligned}$$

for all $x \in Z$, which gives the assertion on the Borel absorbing set Z.

In order to obtain this equation for each $x \in X$, we improve h_* on the set $X \setminus Z$. For this, we define inductively a sequence of Borel measurable functions $h_k \in L_w^\infty$ and some sequences $\{f_k\}$, $\{g_k\}$ of stationary strategies for players 1 and 2, respectively. Let $h_0 := h_*$, $f_0 := f^*$, and $g_0 := g^*$. Suppose that $h_0, \ldots, h_k$, $f_0, \ldots, f_k$, and $g_0, \ldots, g_k$ have been defined. Let

$$h_{k+1}(x) := \min_{\rho \in P(B(x))} \max_{\nu \in P(A(x))} \left[\hat{r}(x, \nu, \rho) + \int h_k(y) q(dy|x, \nu, \rho) \right] \tag{30}$$

for each $x \notin Z$ and $h_{k+1}(x) := h_*(x)$ for every $x \in Z$. By Fan's minmax theorem [6], we have

$$h_{k+1}(x) = \max_{\nu \in P(A(x))} \min_{\rho \in P(B(x))} \left[\hat{r}(x, \nu, \rho) + \int h_k(y) q(dy|x, \nu, \rho) \right]. \tag{31}$$

Put $f_{k+1}(x) := f^*(x)$ and $g_{k+1}(x) := g^*(x)$ for $x \in Z$. Let f_{k+1} and g_{k+1} be any maxmin and minmax Borel measurable stationary strategies of the players obtained for the right-hand sides in (31) and (30), defined on the set $X \setminus Z$ [17]. From our construction and the optimality equation on the set Z, it follows that

$$h_{k+1}(x) = \min_{\rho \in P(B(x))} \max_{\nu \in P(A(x))} \left[\hat{r}(x, \nu, \rho) + \int h_k(y) q(dy|x, \nu, \rho) \right] \tag{32}$$

for each $x \in X$. By C5(a) and C6(a), every h_k belongs to L_w^∞. Using (22), it is easy to see that the sequence $\{h_k\}$ is nonincreasing. Since Z is absorbing for the Markov chain induced by f^*, g^* this set is absorbing as well for the Markov chain induced by

any f_k, g_k constructed above. Consequently, we infer that $\pi_{f_k g_k} = \pi_{f^* g^*}$ for every k and thus by (26),

$$J_{\hat{r}}(f_k, g_k) = J_{\hat{r}}(f^*, g^*) = 0 \quad \text{and} \quad \int h_k(y)\pi_{f_k g_k}(dy) = \int h_*(y)\pi_{f^* g^*}(dy). \tag{33}$$

We shall prove that $\lim_{k\to\infty} h_k(x)$ exists and belongs to L_w^∞. For this, we show that there exists a constant ξ such that

$$h_k(x) \geq \xi w(x) \tag{34}$$

for every k and $x \in X$. Note that

$$h_k(x) \geq h_{k+1}(x) = \hat{r}(x, f_k, g_k) + \int h_k(y) q(dy|x, f_k, g_k)$$

for every k and $x \in X$. Iterating this inequality, we obtain

$$h_k(x) \geq E_x^{f_k g_k}\left(\sum_{m=0}^{n-1} \hat{r}(x_m, a_m, b_m)\right) + \int h_k(y) q^n(dy|x, f_k, g_k) \tag{35}$$

for every $n \geq 1$ and $x \in X$. Using (33), we conclude from (35) that

$$h_k(x) \geq E_x^{f_k g_k}\left(\sum_{m=0}^{\infty} [\hat{r}(x_m, a_m, b_m) - J_{\hat{r}}(f_k, g_k)]\right) + \int h_*(y)\pi_{f^* g^*}(dy) \tag{36}$$

for every $x \in X$. Now (34) follows from (36), Lemma 1 (with $f = f_k$ and $g = g_k$), and the fact that $h_* \in L_w^\infty$. Taking the limit in (32) as $k \to \infty$ on both sides, using the monotone convergence theorem, and using Lemma 4, we now easily obtain the optimality equation with the function $h(x) := \lim_{k\to\infty} h_k(x)$ and the constant V. The Borel measurable maxmin and minmax strategies that satisfy our assertion can be obtained by applying Fan's minmax theorem [6] and an appropriate measurable selection theorem [17].

Step 4. The uniqueness of the solution to the Bellman equation can be concluded from the proof in the Markov case [12] by taking the payoff function $r(x, a, b) - V\tau(x, a, b)$, where $(x, a, b) \in K$. □

REMARK 3. *In our proof we have taken into account the function h_* as our point of departure and have defined the nonincreasing sequence $\{h_k\}$ as in* (30). *But it is possible to define inductively the nondecreasing sequence $\{h_k\}$ as follows:*

$$h_{k+1}(x) := \max_{\nu \in P(A(x))} \min_{\rho \in P(B(x))} \left[\hat{r}(x, \nu, \rho) + \int h_k(y) q(dy|x, \nu, \rho)\right]$$

with $h_0 := h^*$ (recall (24)*). This sequence can also be used to construct the solution to the optimality equation. A simple modification of the proof of Theorem* 2 *(Step* 3*) yields an upper bound for the sequence $\{h_k\}$. More precisely, one can prove that there exists a positive constant ξ such that*

$$h_k(x) \leq \xi w(x)$$

for all $x \in X$. Then the solution to the optimality equation is the function $h(x) = \lim_{k\to\infty} h_k(x) := \sup_{k\geq 1} h_k(x)$.

Acknowledgments. I wish to express my thanks to Professor Andrzej S. Nowak for suggesting the problem and for several helpful conversations. I am also indebted to the referee for many useful remarks.

A SENSITIVITY AND ADJOINT CALCULUS FOR DISCONTINUOUS SOLUTIONS OF HYPERBOLIC CONSERVATION LAWS WITH SOURCE TERMS*

STEFAN ULBRICH†

Abstract. We present a sensitivity and adjoint calculus for the control of entropy solutions of scalar conservation laws with controlled initial data and source term. The sensitivity analysis is based on shift-variations which are the sum of a standard variation and suitable corrections by weighted indicator functions approximating the movement of the shock locations. Based on a first order approximation by shift-variations in L^1 we introduce the concept of shift-differentiability, which is applicable to operators having functions with moving discontinuities as images and implies differentiability for a large class of tracking-type functionals. In the main part of the paper we show that entropy solutions are generically shift-differentiable at almost all times $t > 0$ with respect to the control. Hereby we admit shift-variations for the initial data which allows us to use the shift-differentiability result repeatedly over time slabs. This is useful for the design of optimization methods with time domain decomposition. Our analysis, especially of the shock sensitivity, combines structural results by using generalized characteristics and an adjoint argument. Our adjoint-based shock sensitivity analysis does not require us to restrict the richness of the shock structure a priori and admits shock generation points. The analysis is based on stability results for the adjoint transport equation with discontinuous coefficients satisfying a one-sided Lipschitz condition. As a further main result we derive and justify an adjoint representation for the derivative of a large class of tracking-type functionals.

1. Introduction.

This paper is concerned with the development of a sensitivity and adjoint calculus for the optimal control of entropy solutions of scalar conservation laws with source terms: Consider the Cauchy problem for an inhomogeneous conservation law

$$\begin{aligned} &\partial_t y + \partial_x f(y) = g(t,x,y,u_1), \quad (t,x) \in \Omega_T \stackrel{\text{def}}{=}]0,T[\times \mathbb{R}, \\ &y(0,x) = u_0(x), \quad x \in \mathbb{R}, \end{aligned} \tag{1.1}$$

where the flux $f : \mathbb{R} \longrightarrow \mathbb{R}$ is twice continuously differentiable, $u = (u_0, u_1) \in L^\infty(\mathbb{R}) \times L^\infty(\Omega_T)^m \stackrel{\text{def}}{=} U$ is the control, and $g : \Omega_T \times \mathbb{R} \times \mathbb{R}^m \to \mathbb{R}$ satisfies a growth condition

(A1) $g \in L^\infty(\Omega_T; C^{0,1}_{loc}(\mathbb{R} \times \mathbb{R}^m))$ and $\forall\ M_u > 0$ there are $C_1, C_2 > 0$ with

$$g(t,x,y,u_1)\ \operatorname{sgn}(y) \le C_1 + C_2\,|y| \quad \forall\,(t,x,y,u_1) \in \Omega_T \times \mathbb{R} \times [-M_u, M_u]^m.$$

Then one can show (e.g., [18, 25]) that (1.1) admits for all $u \in U$ a unique entropy solution $y = y(u) \in L^\infty(\Omega_T) \cap C([0,T]; L^1_{loc}(\mathbb{R}))$. It is well known that in general weak solutions of (1.1) develop discontinuities after finite time and that uniqueness

holds only in the class of entropy solutions. We recall that for given $u \in U$ a function $y = y(u) \in L^\infty(\Omega_T)$ is an entropy solution to (1.1) in the sense of Kružkov [18] if it satisfies the entropy inequality

$$\partial_t \eta(y) + \partial_x q(y) \le \eta'(y) g(t, x, y, u_1) \quad \text{in } \mathcal{D}'(\Omega_T)$$

for all convex functions (entropies) $\eta : \mathbb{R} \longrightarrow \mathbb{R}$ with corresponding entropy fluxes $q(y) = \int_0^y \eta'(s)\, f'(s)\, ds$ and the initial condition in the sense

$$\operatorname*{ess\,lim}_{t \to 0+} \|y(t, \cdot) - u_0\|_{1,K}\, d\tau = 0 \qquad \forall\ K \subset\subset \mathbb{R}.$$

The aim of this paper is to develop and justify—without a priori assumptions on the shock structure—a sensitivity calculus for the control-to-state mapping $u \longmapsto y(u)$ that yields in particular the differentiability and a formula for the derivative of objective functionals

$$J(y(u)) = \int_a^b \phi(y(\bar{t}, \cdot; u), y_d)\, dx \tag{1.2}$$

with data $y_d \in BV([a, b])$, $\phi \in C^{1,1}_{loc}(\mathbb{R}^2)$, and $\bar{t} \in\,]0, T]$. Moreover, we will derive an adjoint formula for the gradient of (1.2). The adjoint equation is a transport equation with source term and its coefficient is discontinuous along shock curves, which requires a careful definition of the adjoint state as a reversible solution to ensure uniqueness and stability. These results are useful for the design of gradient-based methods for the solution of control problems of the type

$$\text{(P)} \qquad \min \tilde{J}(y(u), u) \stackrel{\text{def}}{=} J(y(u)) + R(u) \quad \text{subject to} \quad u \in U_{ad}, \quad y(u) \text{ solves (1.1)}.$$

In [25] we have derived results on the existence of optimal solutions for (P) and the convergence of discretized approximations for the multidimensional case. For example, (P) has an optimal solution if U_{ad} is bounded in $L^\infty(\mathbb{R}) \times L^\infty(\Omega_T)^m$ and compact in $L^1_{loc}(\mathbb{R}) \times L^1_{loc}(\Omega_T)^m$ and if $\tilde{J} : C([0, T]; L^r_{loc}(\mathbb{R})) \times (U_{ad} \subset L^r_{loc}(\mathbb{R}) \times L^r_{loc}(\Omega_T)^m) \longrightarrow \mathbb{R}$ is sequentially lower semicontinuous for some $r \in [1, \infty[$. Moreover, for the present one-dimensional case existence results without compactness assumption on U_{ad} were obtained in [25] using compensated compactness.

The state equation (1.1) is a useful model for the study of control problems involving flows with shocks. In particular, it is shown in [10] that the steady flow of an inviscid fluid in a duct governed by the Euler equations can be reduced to determining the velocity y as a steady state solution of (1.1) for $f(y) = y + 2\bar{\gamma} H/y$, $g(x, y, u_1) = u_1 \bar{\gamma}(y - 2H/y)$, where H is the total enthalpy, $\bar{\gamma} = (\gamma - 1)/(\gamma + 1)$ with the gas constant $\gamma > 1$, and the design variable $u_1 = \partial_x A/A$, $A(x)$ being the cross-sectional area of the duct. Moreover, it is noted in [10] that the corresponding time-dependent problem (1.1) captures some essential features of the time-dependent Euler equations and is therefore a suitable model problem for the study of unsteady duct flows with shocks. Since the flow over a transonic airfoil is qualitatively similar to one-dimensional duct flows, the study of the differentiability properties of (1.1)–(1.2) is thus useful to gain insight into the optimal design of airfoils under unsteady flow conditions. In particular, the sensitivity of flows with shocks with respect to time-dependent changes of the geometry is of practical importance for the control of systems with fluid-structure coupling, e.g., the fluttering problem of airfoils.

In this work we give a rigorous sensitivity analysis and adjoint calculus for solutions of (1.1) with shocks and thereby provide an analytical framework for the study

and numerical solution of optimal control problems governed by hyperbolic balance laws (1.1). The following are main features of our approach:

- We derive a sensitivity calculus based on shift-variations that implies the Fréchet differentiability for objective functionals (1.2).
- We give and rigorously justify a gradient representation for objective functionals (1.2) by using an appropriately defined adjoint state.
- The shock structure does not have to be restricted a priori, and shock generation points are allowed.
- We admit nonentropy-admissible initial data and allow shift-variations of the initial data that move shock locations.

The crucial part is the analysis of the shock sensitivities. In our approach we derive the differentiability of a shock position x_s at time $\bar{t}$ by analyzing the smoothness properties of the functional $u \longmapsto \int_{x_s-\varepsilon}^{x_s+\varepsilon} y(\bar{t},x;u)\,dx$ with the help of an adjoint calculus for $\varepsilon \to 0$. The adjoint argument is mainly based on the stability of the adjoint equation with respect to its coefficients. Then the properties of $u \longmapsto x_s(u)$ follow from basic stability properties of the shock that we derive a priori by using the theory of generalized characteristics. An advantage of this method lies in the fact that the shock structure of the solution does not have to be restricted a priori. In particular, shock generation points are allowed. This approach can, at least in a formal manner, also be applied to hyperbolic systems and gives the correct shock sensitivity if the necessary stability properties of the shock and the adjoint equation actually hold.

It can be shown (see, e.g., [25] for the problem at hand) that the mapping $u \in U \longmapsto y(u) \in C([0,T];L^1_{loc}(\mathbb{R}))$ is locally Lipschitz, but very simple examples show that this mapping is in general not directionally differentiable if $y(u)$ contains shocks, even if L^∞ is replaced by C^∞ in the definition of U. This is caused by the fact that a variation of u results in a shift of the shocks, which cannot be approximated appropriately in the linear structure of L^1_{loc}. Consider, for example, the following family of Riemann problems for the inviscid Burgers equation:

$$\partial_t y_\varepsilon + \partial_x \frac{y_\varepsilon^2}{2} = 0, \quad y_\varepsilon(0,x) = u_0(x) + \varepsilon\delta u_0(x) \stackrel{\text{def}}{=} \begin{cases} 1+\varepsilon & \text{if } x \le 0, \\ -1 & \text{if } x > 0. \end{cases}$$

The solution has a shock η_ε emanating from $(0,0)$ with shock speed

$$\dot{\eta}_\varepsilon(t) = \frac{[(y_\varepsilon(t,\eta_\varepsilon(t)))^2/2]}{[y_\varepsilon(t,\eta_\varepsilon(t))]} = \frac{\varepsilon}{2},$$

according to the jump condition, where $[h(t,x)] = h(t,x-) - h(t,x+)$ denotes the jump of $h(t,\cdot)$ across x. Thus, we have $\eta_\varepsilon(t) = \frac{\varepsilon}{2}t$ and the corresponding entropy solution

$$y_\varepsilon = \begin{cases} 1+\varepsilon & \text{if } x \le t\varepsilon/2, \\ -1 & \text{if } x > t\varepsilon/2. \end{cases}$$

Of course, the Lipschitz continuous map $\varepsilon \longmapsto y_\varepsilon(t,\cdot) \in L^1_{loc}(\mathbb{R})$ is not differentiable, since the difference quotient only converges in a weaker topology—for example, weakly in the space $\mathcal{M}_{loc}(\mathbb{R})$ of locally bounded Borel measures. In fact, $\varepsilon \longmapsto y_\varepsilon(t,\cdot) \in \mathcal{M}_{loc}(\mathbb{R})$ is differentiable in the weak topology and we have, for example, at $\varepsilon = 0$

$$\frac{d}{d\varepsilon} y_\varepsilon(t,\cdot)|_{\varepsilon=0}\,\varepsilon = \mathbf{1}_{\{x<\eta_0(t)\}}\,\varepsilon + [y_0(t,\eta_0(t))]\delta_{\eta_0(t)}\,\frac{t}{2}\,\varepsilon, \tag{1.3}$$

where $\mathbf{1}_I$ denotes the indicator function of a set I, i.e., $\mathbf{1}_I(x) = 1$ if $x \in I$, $\mathbf{1}_I(x) = 0$ else, and δ_x denotes the Dirac measure located at x. Hereby, $\frac{t}{2}\,\varepsilon$ is a linear (in this case, exact) approximation of the actual shock shift $\eta_\varepsilon(t) - \eta_0(t)$. Note, however, that a differentiability result in the weak topology of $\mathcal{M}_{loc}(\mathbb{R})$ is not strong enough to derive the differentiability of the functional (1.2) without additional structural information. To get a first order approximation in L^1_{loc}, we have to leave the linear structure of L^1_{loc} in order to allow for an accurate approximation of the shock movement. A natural way to achieve this is to replace the singular (second) part of the measure (1.3) by the function $\operatorname{sgn}(\frac{t}{2}\varepsilon)[y_0(t,\eta_0(t))]\mathbf{1}_{I(\eta_0(t),\eta_0(t)+\frac{t}{2}\varepsilon)}$, where $I(a,b) \overset{\text{def}}{=} [\min\{a,b\}, \max\{a,b\}]$ and $\operatorname{sgn}(\cdot)$ is the sign function. We thereby obtain a first order approximation of $y_\varepsilon(t) - y_0(t)$ in L^1_{loc} by the *shift-variation*

$$S^{\eta_0(t)}_{y_0(t)}\left(\mathbf{1}_{\{x<\eta_0(t)\}}\varepsilon, \frac{t}{2}\varepsilon\right) \overset{\text{def}}{=} \mathbf{1}_{\{x<\eta_0(t)\}}\,\varepsilon + \operatorname{sgn}\left(\frac{t}{2}\varepsilon\right)[y_0(t,\eta_0(t))]\mathbf{1}_{I(\eta_0(t),\eta_0(t)+\frac{t}{2}\varepsilon)}.$$

In this paper we will develop a sensitivity calculus based on shift-variations for the mapping $u \longmapsto y(\bar{t},\cdot;u)$, $\bar{t} \in [0,T]$, defined in (1.1) in the case $f'' \geq m_{f''} > 0$. Let piecewise C^1 initial data $u_0 \in PC^1(\mathbb{R}; x_1, \ldots; x_N)$ and $u_1 \in L^\infty(0,T; C^1(\mathbb{R})^m)$ be given. Using the theory of generalized characteristics [8] we will show that for a given interval I and time $\bar{t} > 0$ the following situation is generic: $y(\bar{t},\cdot;u)$ has on I finitely many shocks at $\bar{x}_1 < \cdots < \bar{x}_K$, the shock locations depend differentiable on u, and the states connected by the shocks vary differentiable in the strong topology of L^1. From this we will deduce that the variation $y(\bar{t},\cdot;u+\delta u) - y(\bar{t},\cdot;u)$ allows a first order approximation by a shift-variation of the form

$$S^{(\bar{x}_k)}_{y(\bar{t},\cdot;u)}(\delta y, \bar{s}) \overset{\text{def}}{=} \delta y + \sum_k [y(\bar{t},\bar{x}_k;u)]\operatorname{sgn}(\bar{s}_k)\mathbf{1}_{I(\bar{x}_k,\bar{x}_k+\bar{s}_k)}, \tag{1.4}$$

where $(\delta y, \bar{s})$ depends linearly on δu, $\bar{x}_k$ are the shock locations,

$$[y(\bar{t},\bar{x}_k;u)] = y(\bar{t},\bar{x}_k-;u) - y(\bar{t},\bar{x}_k+;u)$$

denotes the jump across the shock, $I(\bar{x}_k, \bar{x}_k + \bar{s}_k)$ is the interval enclosed by the arguments, $\mathbf{1}_{I(\bar{x}_k,\bar{x}_k+\bar{s}_k)}$ is its indicator function, and $\bar{s}_k$ is a linear approximation of the shock shift. To mimic the behavior of $y(\cdot;u)$ at later times, it is natural to go one step further and to admit shift-variations already for the initial data. Roughly speaking, we will in particular show that for (u_0,u_1) as above, $W \overset{\text{def}}{=} PC^1(\mathbb{R}; x_1, \ldots, x_N) \times L^\infty(0,T; C^1(\mathbb{R})^m) \times \mathbb{R}^N$ and for a.a. $\bar{t}$ the mapping

$$(w_0, w_1, \sigma) \in W \longmapsto y(\bar{t},\cdot; u_0 + S^{(x_i)}_{u_0}(w_0,\sigma), u_1 + w_1) \in L^1(I) \tag{1.5}$$

is shift differentiable with respect to (w_0,w_1,σ) at 0 in the sense that its variation admits a first order approximation by a shift-variation of the form (1.4), where $(\delta y, \bar{s})$ depends linearly on $\delta w_0, \delta w_1$, and $s = \delta\sigma$. Hereby, δy can be obtained as the trace $\delta Y(\bar{t})$ of a function δY that is the piecewise solution of the linearization of (1.1) *outside* of the shock set, and $\bar{s}_k$ can be obtained by an adjoint formula. We admit shift-variations of the initial data since this allows us to use the shift-differentiability result repeatedly over time slabs. This is helpful for the design of optimization algorithms with time domain decomposition for the solution of (P). By introducing a general concept of shift-differentiability we will be able to derive results on the Fréchet differentiability of tracking-type functionals of the form (1.2) as long as the discontinuities of y_d and $y(\bar{t},\cdot;u)$ do not coincide. If y_d and $y(\bar{t},\cdot;u)$ share discontinuities

we will still obtain directional differentiability. For objective functionals of the form (1.2) we will derive a gradient representation via an adjoint state. The proper definition of the adjoint state requires an extension of the concept of reversible solutions of backward transport equations with discontinuous coefficients introduced in [1] to the case

$$\begin{aligned} &\partial_t p + f'(y)\partial_x p = -g_y(t,x,y,u_1)\,p, \quad (t,x) \in \Omega_{\bar t} \stackrel{\text{def}}{=}]0,\bar t[\times \mathbb{R}, \\ &p(\bar t, x) = p^{\bar t}(x), \quad x \in \mathbb{R}, \end{aligned} \tag{1.6}$$

with linear source term, where $p^{\bar t}$ are suitable end data.

The results of this paper can be straightforwardly extended to identification problems for the flux f, where f is the control. Identification problems of this type are considered by James and Sepúlveda [17]. The differentiability of the objective function for the hyperbolic case was left open. The techniques of the present paper can be used to obtain a sensitivity and adjoint calculus for flux identification as well.

In recent years several results on sensitivities and adjoints for hyperbolic conservation laws were obtained by other authors [1, 2, 3, 4, 5, 6, 12, 13], but most results assume a priori knowledge of the shock structure (usually one shock separating smooth states) or are restricted to the conservative case $g \equiv 0$. The conservative case admits special techniques, since the characteristics are straight lines and the solution can be represented by the integral formula of Lax [19]. Bouchut and James apply in [2] their existence and stability results of [1] for measure-valued duality solutions of linear conservation laws with discontinuous coefficients to derive for the case $g \equiv 0, f'' > 0$ that $u_0 \in L^\infty \longmapsto y(\cdot;u) \in C([0,T];\mathcal{M}_{loc}(\mathbb{R})\text{–w}^*)$ is directionally differentiable at an entropy-admissible u_0 where the space $\mathcal{M}_{loc}(\mathbb{R})$ of local Borel measures is equipped with the usual weak topology. Note that this topology is too weak to derive directly differentiability results for (1.2) without using additional structural information. Godlewski and Raviart study in [12] (see also [13]) the linearized stability of multidimensional hyperbolic systems of conservation laws for perturbations of the initial data of a base solution with a one-dimensional shock. They define measure solutions for the linearized equations with singular part along the shock and construct numerical schemes for the solution of the linearized problem. For the conservative scalar problem with Riemann initial data, it is shown that the linearization coincides with the first order expansion in $C([0,T];\mathcal{M}_{loc}(\mathbb{R})\text{–w}^*)$ of [2]. In this paper we give further justification of this linearization process for more general situations. Bouchut and James develop in [1] existence and stability results for transport equations with discontinuous coefficients satisfying a one-sided Lipschitz condition that will be extended in the present work for the analysis of the adjoint equation (1.6). Previous results on the adjoint equation were obtained in the context of uniqueness results in [7, 16, 20, 21] and of error estimates for approximate solutions in [24]. In [20] adjoint equations for a class of systems of conservation laws are considered. An extension of our approach to systems seems to be possible by building on this work. In [3] a new differential structure on the space BV obtained by horizontal shifts of the points of the graph is introduced, and it is shown that in the case $g \equiv 0, f'' > 0$ the flow $u_0 \in L^\infty \longmapsto y(t,\cdot;u)$ generated by (1.1) is generically differentiable with respect to (w.r.t.) this structure. The analysis uses the integral formula of Lax. Bressan and Marson [4] use generalized tangent vectors to develop a variational calculus for piecewise Lipschitz solutions of systems of conservation laws. Using our notation (1.4), they show that for piecewise Lipschitz initial data u_0^ε, $\varepsilon \geq 0$, such that $u_0^\varepsilon - u_0 = S_{u_0}^{(x_i)}(\varepsilon\delta u_0, \varepsilon s) + o(\varepsilon)$ in L^1_{loc}, the corresponding solutions y_ε

satisfy $y_\varepsilon(\bar{t},\cdot) - y(\bar{t},\cdot) = S^{(\bar{x}_k)}_{y(\bar{t},\cdot)}(\varepsilon\delta y, \varepsilon\bar{s}) + o(\varepsilon)$ in L^1_{loc} if $\bar{t}$ is so small that y_ε remains piecewise Lipschitz on $[0,\bar{t}]$. While this result applies to systems, it considers only directional variations and requires the structural assumption of piecewise Lipschitz solutions, which is not needed in the present paper. Especially the analysis of the shock sensitivity differs significantly from our approach, since in [4] the linearized Rankine–Hugoniot jump condition, together with the linearized state equation, is used to derive an ODE for the shock sensitivity, while we use an adjoint formula which reduces the necessary structural information on the history of the shock as far as possible. Moreover, we develop an adjoint calculus that gives a gradient representation for objective functionals (1.2). Cliff, Heinkenschloss, and Shenoy study in [5, 6] design problems for one-dimensional steady duct flow. By introducing the single shock location as additional state variable and transforming the space variable such that the shock location is fixed, Fréchet differentiability is shown. Optimality conditions are derived and an adjoint-based gradient representation of the objective function is given. Finally, numerical results for the application of an SQP method to the discretized problem are reported.

This paper is organized as follows. In section 2 we introduce the concept of shift-differentiability for operators having discontinuous functions with moving discontinuities as images, which is based on a first order approximation by shift-variations (1.4). Moreover, we will show that the superposition (1.2) of a shift-differentiable operator $u \longmapsto y(\bar{t},\cdot;u)$ and a tracking-type functional is Fréchet differentiable if $y_d, y(\bar{t},\cdot;u)$ do not share discontinuities and is otherwise directionally differentiable. In section 3 we state the main results of the paper. In section 3.1 we state in Theorem 3.2 a shift-differentiability result for entropy solutions of (1.1) w.r.t. the controls, more precisely of the control-state-mapping (1.5), if a nondegeneracy assumption holds for all shocks at the observation time $\bar{t}$. In Theorem 3.4 we give a formula for the corresponding shift-derivative. Moreover, we sketch the main line of the proofs. Theorem 3.8 shows that the required nondegeneracy assumption holds for all shocks at a.a. times $\bar{t} > 0$ if $u_0 \in PC^2$ and $u_1 \in L^\infty(0,T;C^2_{loc})$. In section 3.2 the results of section 3.1 and the general shift-differentiability calculus are combined to obtain in Theorem 3.9 and Corollary 3.10 the differentiability of tracking-type functionals $u \mapsto J(u)$ in (1.2). In section 3.3 we finally state a convenient adjoint-based gradient representation for the derivative of these objective functionals w.r.t. the inner product of L^2; see Theorem 3.11. The proofs of these main results are prepared in sections 4–8 and finally carried out in section 9. Section 4 provides the necessary stability results and collects structural results of [8] provided by the theory of generalized characteristics. We use this to derive basic differentiability results for the solution along generalized characteristics. In section 5 continuity points are analyzed that are not shock generation points. In sections 5.1 and 5.2 we study continuity points in the exterior and interior of rarefaction waves. In section 5.3 continuity points are analyzed that are located on characteristics emanating from points where discontinuities are produced under shift-variations, and section 5.4 studies points on the boundary of rarefaction waves. In section 6 the stability of shocks and the differentiability of the shock location at a time $\bar{t} > 0$ are shown under a nondegeneracy assumption. The proof of the latter is carried out in section 8, since it requires stability results for the adjoint equation, which are provided in section 7. In section 9 we prove the main results already stated in section 3 by combining the results of the previous sections. Conclusions and future work are presented in section 10. The appendix contains a proof of the results in section 7 on the adjoint equation.

Notations. For Lebesgue-measurable $S \subset \mathbb{R}^n$ the norm of the Lebesgue-spaces $L^r(S), 1 \le r \le \infty$, is denoted by $\|\cdot\|_{r,S}$. In the case $S = \mathbb{R}^n$ we write $\|\cdot\|_r$. By $(\cdot,\cdot)_{2,S}$ we denote the inner product on $L^2(S)$. For an interval $I \subset \mathbb{R}$ the space of functions $v \in L^1(I)$ with bounded variation $|v|_{var}$ is denoted by $BV(I)$. For open $S \subset \mathbb{R}^n$ we mean by $C^k(S)$, $k \in \mathbb{N}_0$, the space of functions with continuous, bounded derivatives on S up to order k equipped with the usual norm $\|v\|_{C^k(S)} = \sum_{|\beta|\le k} \|D^\beta v\|_{\infty,S}$. $C^k(S^{cl})$ is the subspace of functions in $C^k(S)$ that admit a continuous extension of the first k derivatives to S^{cl}. Moreover, we write $C(S)$ instead of $C^0(S)$. $C^{k,\alpha}(S^{cl})$, $0 < \alpha \le 1$, is the usual Hölder space. For closed $I \supset [a,b]$, $a < b$, we denote by $PC^k(I; x_1, \dots, x_N)$ the space of piecewise C^k-functions v with possible discontinuities at $a < x_1 < \cdots < x_N < b$; more precisely $v|_{I_i} \in C^k(I_i^{cl})$, $i = 0, \dots, N$, with $I_i =]x_i, x_{i+1}[$, $i = 1, \dots, N-1$, $I_0 = I \cap \{x < x_1\}$, $I_N = I \cap \{x > x_N\}$. It is endowed with the norm $\|v\|_{PC^k(I;x_1,\dots,x_n)} = \sum_{i=0}^N \|v\|_{C^k(I_i^{cl})}$. The indicator function of a set I is denoted by $\mathbf{1}_I$, i.e., $\mathbf{1}_I(x) = 1$ if $x \in I$ and $\mathbf{1}_I(x) = 0$ else.

2. Shift-differentiability. In this section we introduce a concept of shift-differentiability that yields an extension of classical differentiability to operators $u \longmapsto y(u) \in L^1_{loc}(\mathbb{R})$ having functions with moving discontinuities as images. It is based on shift-variations that are the sum of a standard variation and suitably scaled indicator functions approximating the actual shift of discontinuities. The interesting point is that the shift-differentiability of an operator implies under quite general circumstances the Fréchet differentiability of tracking-type functionals analogously to (1.2).

2.1. Shift-variations and shift-differentiability of operators. As motivated in the introduction we define shift-variations as follows.

Definition 2.1. *Let $I = [a,b]$, $a < b$, and let $w \in BV(I)$. Given $a < x_1 < x_2 < \cdots < x_N < b$, we call $(\delta w, s) \in L^1(I) \times \mathbb{R}^N$ a* generalized variation *of w and associate with it the* shift-variation $S_w^{(x_i)}(\delta w, s) \in L^1(\mathbb{R})$ *of w by*

$$S_w^{(x_i)}(\delta w, s)(x) \stackrel{\text{def}}{=} \delta w(x) + \sum_{i=1}^N [w(x_i)]_+ \operatorname{sgn}(s_i) \mathbf{1}_{I(x_i, x_i+s_i)}(x),$$

where $[w(x_i)]_+ \stackrel{\text{def}}{=} \max\{0, w(x_i-) - w(x_i+)\}$ and $I(\alpha,\beta) \stackrel{\text{def}}{=} [\min\{\alpha,\beta\}, \max\{\alpha,\beta\}]$ for $\alpha, \beta \in \mathbb{R}$.

The restriction that only down-jumps are shifted is motivated by the fact that entropy solutions of (1.1) satisfy Oleinik's entropy condition $y(t,x-) \ge y(t,x+)$ for all $x \in \mathbb{R}$ and a.a. $t \in]0,T]$; see section 4.1.

We call an operator shift-differentiable if its actual variation admits a first order approximation in L^1_{loc} by a shift-variation. The following definition states this more precisely.

Definition 2.2. *Let U be a real Banach space and $I = [a,b]$, $a < b$. For an open subset $D \subset U$ let $u \in D \longmapsto y(u) \in L^\infty(\mathbb{R})$ be locally bounded. Moreover, let $\bar u \in D$ with $y(\bar u) \in BV(I)$. We say that y is shift-differentiable at $\bar u$ if there are $a < \bar x_1 < \bar x_2 < \cdots < \bar x_K < b$ and a bounded linear operator $T_s(\bar u) = D_s y(\bar u) \in \mathcal{L}(U, L^r(I) \times \mathbb{R}^K)$, $r \in]1,\infty]$, such that*

$$\lim_{u \to \bar u} \frac{\|y(u) - y(\bar u) - S_{y(\bar u)}^{(\bar x_k)}(T_s(\bar u) \cdot (u - \bar u))\|_{1,I}}{\|u - \bar u\|_U} = 0.$$

We say that y is continuously shift-differentiable at $\bar u$ if y is shift-differentiable in a

neighborhood of $\bar{u}$ and if the corresponding $T_s(u)$, $\bar{x}_k(u)$, $k = 1, \dots, K$, as well as $y(u)(\bar{x}_k(u)\pm)$, are continuous at $\bar{u}$.

2.2. Differentiability after composition with cost functionals. The property of shift-differentiability is strong enough that it implies the Fréchet differentiability of functionals of the form

$$J(y(u)) \stackrel{\text{def}}{=} \int_a^b \phi(y(u)(x), y_d(x))\, dx \tag{2.1}$$

under quite moderate assumptions on ϕ and y_d.

LEMMA 2.3. *Let $u \longmapsto y(u)$ be shift-differentiable in $\bar{u}$ according to Definition 2.2. Moreover, let $y_d \in L^\infty(I)$ be approximately continuous at $\bar{x}_1, \dots, \bar{x}_K$. Then for any function $\phi \in C^{1,1}_{loc}(\mathbb{R}^2)$ the functional $u \in U \longmapsto J(y(u))$ given by (2.1) is Fréchet differentiable at $\bar{u}$, and with $(\delta y, \bar{s}) \stackrel{\text{def}}{=} T_s(\bar{u}) \cdot \delta u$, $\bar{y} \stackrel{\text{def}}{=} y(\bar{u})$ one has*

$$\begin{aligned} d_u J(\bar{y}) \cdot \delta u &= (\phi_y(\bar{y}, y_d), \delta y)_{2,I} \\ &\quad + \sum_{k=1}^{K} \int_0^1 \phi_y(\bar{y}(\bar{x}_k+) + \tau[\bar{y}(\bar{x}_k)], y_d(\bar{x}_k)) d\tau [\bar{y}(\bar{x}_k)]_+ \bar{s}_k. \end{aligned} \tag{2.2}$$

If y is continuously shift-differentiable at $\bar{u}$ and y_d is continuous in a neighborhood of $\bar{x}_1, \dots, \bar{x}_K$, then $u \longmapsto J(y(u))$ is continuously Fréchet differentiable at $\bar{u}$.

If at least one $\bar{x}_k$ is an approximate discontinuity of y_d, then $J(y(u))$ is still directionally differentiable, and with $(\delta y, \bar{s}) = T_s(\bar{u}) \cdot \delta u$ the directional derivative $\delta_u(J(y(\bar{u})); \delta u)$ is given by (2.2) if $y_d(\bar{x}_k)$ is replaced by $y_d(\bar{x}_k + 0 \cdot \operatorname{sgn}(\bar{s}_k))$.

Proof. Obviously, it is sufficient to consider the case $K = 1$. We set $\bar{x} = \bar{x}_1$. Let $B \subset U$ be a bounded neighborhood of 0 such that $\bar{u} + B \subset D$. Then $\|y(\bar{u} + \delta u)\|_\infty \le M_y$ for all $\delta u \in B$ by Definition 2.2. In what follows we will frequently use the abbreviation $u = \bar{u} + \delta u$ for $\delta u \in B$. Moreover, we will write $y, \bar{y}$ instead of $y(u), y(\bar{u})$ and set $(\delta y, \bar{s}) = T_s(\bar{u}) \cdot \delta u$. Finally, we reduce B such that $\bar{x} + \bar{s} \in I$ for $\delta u \in B$.

Since $y(u)$ is shift-differentiable in $\bar{u}$, we have for all $\delta u \in B$

$$\|y - \bar{y}\|_1 \le o(\|\delta u\|_U) + \|S^{\bar{x}}_{\bar{y}}(\delta y, \bar{s})\|_1 \le o(\|\delta u\|_U) + \|\delta y\|_1 + 2M_y|\bar{s}| \le C_1 \|\delta u\|_U. \tag{2.3}$$

Let L be a Lipschitz constant of ϕ_y w.r.t. y on $[-M_y, M_y] \times [-\|y_d\|_\infty, \|y_d\|_\infty]$. Set

$$\bar{\phi}_y(\delta u) \stackrel{\text{def}}{=} \int_0^1 \phi_y(\tau \bar{y} + (1-\tau)y, y_d)\, d\tau.$$

Then we have $\|\bar{\phi}_y(\delta u)\|_\infty \le C_2$ for all $\delta u \in B$ with a constant $C_2 > 0$ and

$$|J(y) - J(\bar{y}) - (\bar{\phi}_y(\delta u), S^{\bar{x}}_{\bar{y}}(\delta y, \bar{s}))_{2,I}| \le \|\bar{\phi}_y(\delta u)\|_\infty \|y - \bar{y} - S^{\bar{x}}_{\bar{y}}(\delta y, \bar{s})\|_1 = o(\|\delta u\|_U).$$

To compare the last term on the left-hand side with (2.2) we note that

$$(\bar{\phi}_y(\delta u), S^{\bar{x}}_{\bar{y}}(\delta y, \bar{s}))_{2,I} = (\bar{\phi}_y(\delta u), \delta y)_{2,I} + [\bar{y}(\bar{x})]_+ \operatorname{sgn}(\bar{s}) (\bar{\phi}_y(\delta u), \mathbf{1}_{I(\bar{x}, \bar{x}+\bar{s})})_2, \tag{2.4}$$

where we use $\bar{x} + \bar{s} \in I$. For the first term we have with $1/r + 1/r' = 1$ the estimate

$$\begin{aligned} \|\bar{\phi}_y(\delta u)\delta y - \phi_y(\bar{y}, y_d)\delta y\|_1 &\le \|\bar{\phi}_y(\delta u) - \phi_y(\bar{y}, y_d)\|_{r'} \|\delta y\|_r \\ &\le L \|y - \bar{y}\|_{r'} \|T_s(\bar{u})\| \, \|\delta u\|_U = o(\|\delta u\|_U), \end{aligned} \tag{2.5}$$

since the first factor tends to zero by interpolation using (2.3) and the L^∞-bound.

If $[\bar y(\bar x)]_+ = 0$, then the second term in (2.4) vanishes, and since $S^{\bar x}_{\bar y}(\delta y, \bar s) = \delta y$ in this case, the proof is complete. Otherwise, we have $[\bar y(\bar x)]_+ = [\bar y(\bar x)]$. To approximate the second term in (2.4) we observe that with $\delta\bar y \stackrel{\text{def}}{=} \max\{\min\{\delta y, 2M_y\}, -2M_y\}$ obviously

$$\|y - \bar y - S^{\bar x}_{\bar y}(\delta\bar y, \bar s)\|_1 = o(\|\delta u\|_U)$$

also holds. Since the function on the left-hand side has a uniform L^∞-bound, we obtain with the local Lipschitz continuity of ϕ_y

$$\left\| \bar\phi_y(\delta u) - \int_0^1 \phi_y(\bar y + \tau S^{\bar x}_{\bar y}(\delta\bar y, \bar s), y_d)\, d\tau \right\|_1 = o(\|\delta u\|_U). \tag{2.6}$$

This yields for the last factor of the last term in (2.4)

$$(\bar\phi_y(\delta u), \mathbf{1}_{I(\bar x, \bar x+\bar s)})_2 = \left(\textstyle\int_0^1 \phi_y(\bar y + \tau S^{\bar x}_{\bar y}(\delta\bar y, \bar s), y_d) d\tau, \mathbf{1}_{I(\bar x, \bar x+\bar s)}\right)_2 + o(\|\delta u\|_U).$$

Finally, we have

$$\begin{aligned} I_1 &\stackrel{\text{def}}{=} \left| \left(\textstyle\int_0^1 \phi_y(\bar y + \tau S^{\bar x}_{\bar y}(\delta\bar y, \bar s), y_d) d\tau, \mathbf{1}_{I(\bar x, \bar x+\bar s)}\right)_2 - |\bar s| \int_0^1 \phi_y(\bar y(\bar x+) + \tau[\bar y(\bar x)], y_d(\bar x)) d\tau \right| \\ &= \left| \int_{\bar x}^{\bar x+\bar s} \int_0^1 (\phi_y(\bar y + \tau[\bar y(\bar x)]\operatorname{sgn}(\bar s) + \tau\delta\bar y, y_d) - \phi_y(\bar y(\bar x\pm) \pm \tau[\bar y(\bar x)], y_d(\bar x)))\, d\tau dx \right|. \end{aligned}$$

Since the arguments of ϕ_y are bounded, we get with a Lipschitz constant L

$$\begin{aligned} I_1 &\le L\left(\|\delta\bar y\|_{1, I(\bar x, \bar x+\bar s)} + |\bar s| \left| \frac{1}{\bar s} \int_{\bar x}^{\bar x+\bar s} (|\bar y - \bar y(\bar x + 0\operatorname{sgn}(\bar s))| + |y_d - y_d(\bar x)|)\, dx \right| \right) \\ &\le L\|\delta y\|_r |\bar s|^{1/r'} + o(|\bar s|) = o(\|\delta u\|_U). \end{aligned} \tag{2.7}$$

Hereby we have used that y_d is approximately continuous in $\bar x$ and $y(\bar u) \in BV(I)$. Now the Fréchet differentiability of $J(y(u))$ and (2.2) follow by combining (2.4)–(2.7).

Now assume that y_d is continuous in a neighborhood of $\bar x_1, \dots, \bar x_K$ and that y is continuously shift-differentiable in $\bar u$. Then J is Fréchet differentiable in a neighborhood D' of $\bar u$ by the previous arguments. By assumption, $u \in D' \longmapsto \bar x_k(u)$ and $u \in D' \longmapsto y(u)(\bar x_k(u)\pm)$ are continuous at $\bar u$. Hence, the operator in the second term of (2.2) with $y, \bar x_k(u)$ instead of $\bar y, \bar x_k$ acting on $\bar s$ is obviously continuous at $\bar u$. Moreover, we have for all $\delta y \in L^r(I)$ and $u \in D'$ with a local Lipschitz constant L of ϕ_y

$$(\phi_y(y(u), y_d) - \phi_y(y(\bar u), y_d), \delta y)_{2,I} \le L\|y(u) - y(\bar u)\|_{r',I} \|\delta y\|_{r,I}.$$

The first factor tends to zero by interpolating (2.3) and the L^∞-bound. Combining the continuity in $(\delta y, \bar s) \in L^r(I) \times \mathbb{R}^K$ with the continuity of $u \longmapsto T_s(u) \in \mathcal{L}(U, L^r(I) \times \mathbb{R}^K)$ at $\bar u$ now yields the continuity of $d_u J(y(u))$ at $\bar u$.

Finally, if y_d has an approximate discontinuity in $\bar x$ and $y_d(\bar x)$ is replaced by $y_d(\bar x + 0\cdot\operatorname{sgn}(\bar s))$, then the directional differentiability can be shown exactly as above by fixing δu and taking $\varepsilon\delta u$ instead of δu. In fact, the only crucial point is the estimate for the resulting expression I_1. As in (2.7) we obtain $I_1 = o(\varepsilon)$. ∎

In the following sections we will analyze the control-to-state mapping $u \longmapsto y(t,\cdot;u)$ implicitly defined by (1.1). As a main result we will show that (1.5) is in general shift-differentiable. Then we obtain immediately the differentiability properties of objective functionals (1.2) by using Lemma 2.3.

3. Statement of the main results. In this section we state the main results of this paper. The proofs will be prepared and carried out in the remaining sections.

3.1. Shift-differentiability of entropy solutions. As outlined in the introduction our first main result is a shift-differentiability result for entropy solutions $y = y(\cdot;u)$ of

$$\begin{aligned} &\partial_t y + \partial_x f(y) = g(t,x,y,u_1), \quad (t,x) \in \Omega_T \stackrel{\text{def}}{=}]0,T[\times \mathbb{R}, \\ &y(0,x) = u_0(x), \quad x \in \mathbb{R}, \end{aligned} \tag{1.1}$$

w.r.t. the control $u = (u_0, u_1)$ if the initial data u_0 are varied by a shift-variation and u_1 by a conventional additive variation. After this result is shown, we obtain immediately differentiability properties of objective functionals (1.2) by using Lemma 2.3.

More precisely, let $u_0 \in PC^1(\mathbb{R}; x_1, \dots, x_N)$, $x_1 < x_2 < \cdots < x_N$, and $u_1 \in L^\infty(0,T; C^1(\mathbb{R})^m)$ be given and fix some $\bar{t} \in]0,T]$. For

$$W \stackrel{\text{def}}{=} PC^1(\mathbb{R}; x_1, \dots, x_N) \times L^\infty(0,T; C^1(\mathbb{R})^m) \times \mathbb{R}^N$$

consider the mapping

$$(w_0, w_1, \sigma) \in W \longmapsto y(\bar{t}, \cdot; u_0 + S_{u_0}^{(x_i)}(w_0, \sigma), u_1 + w_1) \in L^1(a,b) \tag{3.1}$$

for some $a < b$.

REMARK 3.1. *Of course,* (3.1) *includes the simpler case*

$$(\hat{u}_0, \hat{u}_1) \in PC^1(\mathbb{R}; x_1, \dots, x_N) \times L^\infty(0,T; C^1(\mathbb{R})^m) \longmapsto y(\bar{t}, \cdot; \hat{u}_0, \hat{u}_1),$$

where the initial shocks are not shifted.

We will show (see Theorem 3.2 below) that the mapping (3.1) is continuously shift-differentiable in a sufficiently small neighborhood of $(0,0,0)$ if at time $\bar{t}$ a nondegeneracy condition is satisfied at the shock locations. We will moreover show in Theorem 3.8 that this nondegeneracy condition for the shocks at time $\bar{t}$ holds at a.a. $\bar{t}$ if $u_0 \in PC^2(\mathbb{R}; x_1, \dots, x_N)$ and $u_1 \in L^\infty(0,T; C^2_{loc}(\mathbb{R})^m)$. For a precise statement of the theorems we need the following additional assumptions on f and g.

ASSUMPTIONS:

(A2) (A1) holds, f is twice continuously differentiable, $g \in L^\infty(0,T; C^1_{loc}(\mathbb{R} \times \mathbb{R} \times \mathbb{R}^m))$, and g is Lipschitz continuous w.r.t. x.

(A3) $f'' \geq m_{f''} > 0$ for some $m_{f''} > 0$.

(A4) g is affine linear w.r.t. y.

We have the following result on the shift-differentiability of (3.1).

THEOREM 3.2 (shift-differentiability of entropy solutions). *Let* (A2)–(A4) *hold. Let* $u_0 \in PC^1(\mathbb{R}; x_1, \dots, x_N)$ *with* $x_1 < \cdots < x_N$, *and let* $u_1 \in L^\infty(0,T; C^1(\mathbb{R})^m)$. *For* $u = (u_0, u_1)$ *let* $y(u) \in L^\infty(\Omega_T) \cap C([0,T]; L^1_{loc}(\mathbb{R}))$ *be the entropy solution of* (1.1). *Finally, let* $I = [a,b]$, $a < b$, *and* $\bar{t} \in]0,T]$ *such that* $y(\bar{t}, \cdot; u)$ *has no shock generation points on* I *and finitely many nondegenerate shocks on* I *at* $a < \bar{x}_1 < \cdots < \bar{x}_K < b$ *that are not shock interaction points; see Definition* 6.1. *Finally, let*

$$\begin{aligned} W &\stackrel{\text{def}}{=} PC^1(\mathbb{R}; x_1, \dots, x_N) \times L^\infty(0,T; C^1(\mathbb{R})^m) \times \mathbb{R}^N, \\ \|(w_0, w_1, \sigma)\|_W &\stackrel{\text{def}}{=} \|w_0\|_{PC^1(\mathbb{R}; x_1, \dots, x_N)} + \|w_1\|_{L^\infty(0,\bar{t}; C^1(\mathbb{R}))} + \|\sigma\|_2 \end{aligned}$$

and consider the mapping

$$(w_0, w_1, \sigma) \in W \longmapsto y(\bar{t}, \cdot; u_0 + S_{u_0}^{(x_i)}(w_0, \sigma), u_1 + w_1)|_I \in L^1(I). \tag{3.2}$$

Then the following hold:

(i) *If all x_i, $i = 1, \dots, N$, are discontinuities of u_0, i.e., $u_0(x_i-) \neq u_0(x_i+)$, then the mapping* (3.2) *is continuously shift-differentiable on a neighborhood $\{\|(w,\sigma)\|_W < \rho\}$ for $\rho > 0$ sufficiently small, and the shift-derivative $T_s(0) = D_s y(\bar{t}; u)$ satisfies $T_s(0) \in \mathcal{L}(W, PC(I; \bar{x}_1, \dots, \bar{x}_K) \times \mathbb{R}^K)$.*

(ii) *If some x_i, $i = 1, \dots, N$, are continuity points of u_0, then the mapping* (3.2) *is at least shift-differentiable w.r.t. (w_0, w_1, σ) at $(0,0,0)$, and the shift-derivative $T_s(0) = D_s y(\bar{t}; u)$ satisfies $T_s(0) \in \mathcal{L}(W, PC(I; \tilde{x}_1, \dots, \tilde{x}_{\tilde{K}}) \times \mathbb{R}^K)$, where $\tilde{x}_1 < \dots < \tilde{x}_{\tilde{K}}$ contain in addition to $\bar{x}_1, \dots, \bar{x}_K$ all continuity points in I for which the backward characteristic meets the line $t = 0$ in a continuity point x_i, $i = 1, \dots, N$, of u_0.*

REMARK 3.3. *Several comments on the used terminology are in order:*

- *By "characteristics" we mean generalized characteristics in the sense of Dafermos* [8]*; see section* 4.2.
- *The nondegeneracy of a shock at $(\bar{t}, \bar{x}_k)$ is a nondegeneracy condition on the dependence of forward characteristics on their starting point $(0, z)$ that start close to footpoints $(0, z_\mp)$ of the minimal and maximal backward characteristic through $(\bar{t}, \bar{x}_k)$. See Definition* 6.1 *below.*

The next theorem states a formula for the shift-derivative of entropy solutions ensured by Theorem 3.2.

THEOREM 3.4 (formula for the shift-derivative). *Let the assumptions of Theorem* 3.2 *hold. Then the shift derivative $(\delta y^{\bar{t}}, \bar{s}) = T_s(0) \cdot (\delta w_0, \delta w_1, s)$ ensured by Theorem* 3.2 *is given as follows: With $\bar{x}_0 \overset{\text{def}}{=} a$, $\bar{x}_{K+1} \overset{\text{def}}{=} b$, denote by $\xi_k^\mp$ the minimal/maximal backward characteristic through $(\bar{t}, \bar{x}_k)$, $k = 0, \dots, K+1$, by S_k the domain confined by ξ_k^+ and ξ_{k+1}^-, $k = 0, \dots, K$, and by D_k the domain confined by ξ_k^- and ξ_k^+, $k = 1, \dots, K$.*

Let δY on all S_k be the broad solution of the linearized equation

$$\partial_t \delta Y + \partial_x (f'(y)\delta Y) = g_y(t,x,y,u_1)\delta Y + g_{u_1}(t,x,y,u_1)\delta w_1 \tag{3.3}$$

with initial conditions

$$\delta Y(0,\cdot) = \begin{cases} \delta w_0 & \text{on } (S_k^{cl} \cap \{t=0\}) \setminus \{x_i : \ 1 \le i \le N\}, \\ 0 & \text{on } (S_k^{cl} \cap \{t=0\}) \cap \{x_i : \ 1 \le i \le N\}, \end{cases} \tag{3.4}$$

respectively; see Remarks 5.4 *and* 5.9 *below. Moreover, let p^k, $k = 1, \dots, K$, be the reversible solution $p^k = p$ (cf. Definition* 7.5*) of the adjoint equation*

$$\partial_t p + f'(y)\partial_x p = -g_y(t,x,y,u_1)p, \quad p(\bar{t},\cdot) = p^{\bar{t}} \tag{3.5}$$

for the end data (we recall that $[y(\bar{t}, \bar{x}_k; u)] \overset{\text{def}}{=} y(\bar{t}, \bar{x}_k-; u) - y(\bar{t}, \bar{x}_k+; u)$).

$$p^{\bar{t}} = \frac{1}{[y(\bar{t}, \bar{x}_k; u)]} \mathbf{1}_{\{x = \bar{x}_k\}}(\cdot). \tag{3.6}$$

Then $(\delta y^{\bar{t}}, \bar{s}) = T_s(0) \cdot (\delta w_0, \delta w_1, s)$ is given by

$$\delta y^{\bar{t}} = \delta Y(\bar{t}, \cdot), \tag{3.7}$$

$$\bar{s}_k = (p^k g_{u_1}(\cdot, y, u_1), \delta w_1)_{2, \Omega_{\bar{t}}} + (p^k(0,\cdot), \delta w_0)_2 + \sum_{i=1}^{N} p^k(0, x_i)[u_0(x_i)]_+ s_i. \tag{3.8}$$

Hereby, the adjoint states p^k *for the shock sensitivity* $\bar{s}_k$ *of* $\bar{x}_k$ *have the disjoint supports* D_k^{cl} *and coincide on* D_k^{cl} *with the reversible solution of* (3.5) *for the constant end data* $1/[y(\bar{t}, \bar{x}_k; u)]$.

REMARK 3.5.

- *Broad solutions of the linearized equation* (3.4) *are defined as the solution of the characteristic equation along each generalized characteristic. We discuss this issue in detail in section* 5*; see Lemmas* 5.1, 5.6 *and Remarks* 5.4, 5.9. *This leads to a piecewise definition outside the shock set. In general, these patches yield together* not *a weak solution of* (3.4) *on all of* $\Omega_{\bar{t}}$, *since the jump condition across the shocks, which must hold for weak solutions of the linear conservation law* (3.4), *is in general not satisfied. To compensate the incompatibility across shocks, a measure part has to be added on the shock set. Appropriate global weak solutions of* (3.4) *are measure-valued* duality solutions. *For details we refer to the author's habilitation thesis* [26]. *In* [26] *we extend results of Bouchut and James* [1] *in several respects that are of importance for weak sensitivities in optimal control. See also Remark* 3.7.
- *The adjoint equation* (3.5) *is a transport equation with discontinuous coefficient. Since solutions of* (3.5)–(3.6) *are in general not unique, we extend ideas of* [1] *and consider appropriate* reversible solutions *that enjoy uniqueness and stability. We will introduce the necessary facts on reversible solutions in section* 7. *For a detailed study we refer to our recent works* [27, 26].

For the proof of Theorems 3.2 and 3.4 we will use structural properties of entropy solutions obtained by a careful application of Dafermos' theory of generalized characteristics [8] together with an adjoint-based analysis of the shock sensitivities. The necessary results on the structure of entropy solutions will be developed in sections 4–6. The adjoint-based analysis of the shock sensitivities will be carried out in sections 7–8. Using these results, the proof of Theorems 3.2 and 3.4 is then given in section 9.

The main line of the proof is as follows: With the abbreviation

$$u^s(w, \sigma) = (u_0 + S_{u_0}^{(x_i)}(w_0, \sigma), u_1 + w_1)$$

we can write the control-to-state-mapping (3.2) as

$$(w, \sigma) \in W \longmapsto y(\bar{t}, \cdot; u^s(w, \sigma)). \tag{3.9}$$

Under the assumptions of Theorem 3.2 (which is a generic situation; see Theorem 3.8) we show that the mapping (3.9) has the following properties: on any compact subset $J \subset I \setminus \{\bar{x}_1, \dots, \bar{x}_K\}$ the mapping (3.2) is Fréchet differentiable in $(0, 0)$ as a map to $L^r(J)$, $r \in [1, \infty)$, and even to $L^\infty(J \setminus E)$ if E is an open neighborhood of points on the boundary of rarefaction waves (where we include forward characteristics emanating from a point $(0, x_i)$, $1 \le i \le N$, where u_0 is continuous); see section 5. Hereby the derivative is given by $d_{(w,\sigma)} y(\bar{t}, \cdot; u) \cdot (\delta w, s) = \delta y^{\bar{t}}|_J$, where $\delta y^{\bar{t}} = \delta Y(\bar{t}, \cdot)$ with the broad solution δY of the linearized equation (3.3)–(3.4). Moreover, we show in section 6 that there are neighborhoods J_k of any shock position $\bar{x}_k$, such that for a suitable neighborhood $W_\rho \overset{\text{def}}{=} \{\|(w, \sigma)\|_W < \rho\}$ the shock is stable in the sense that

$$(w, \sigma) \in W_\rho \longmapsto y(\bar{t}, \cdot; u^s(w, \sigma)) \in PC^{0,1}(J_k; \bar{x}_k(u^s(w, \sigma)))$$

is bounded, the shock location $\bar{x}_k(u^s(w, \sigma))$ depends Lipschitz continuously on (w, σ), and left and right states are stable on W_ρ in the sense that

$$\|y(\bar{t}, \cdot; u^s(w, \sigma)) - y(\bar{t}, \cdot; u)\|_{\infty, J_k \setminus I(\bar{x}_k, \bar{x}_k(u^s(w,\sigma)))} \le L_k \|(w, \sigma)\|_{w,\sigma};$$

see Lemma 6.2 and Corollary 6.5 in section 6. Moreover, we show by an adjoint argument in sections 6–8 that the shock location depends Fréchet differentiably on (w, σ), and the shock sensitivity is given by $d_{(w,\sigma)}\bar{x}_k(u)\cdot(\delta w, s) = \bar{s}_k$, with $\bar{s}_k$ according to the adjoint formula (3.8); see Lemma 6.4. If this is shown, then it is straightforward to show the shift-differentiability of (3.9); see section 9.

To show these properties of (3.9) we use the theory of generalized characteristics [8] together with an adjoint argument for the analysis of the shock sensitivity as follows: the theory of generalized characteristics yields that entropy solutions have an at most countable number of shock curves and are continuous on the complement; see section 4, in particular Proposition 4.2. In continuity points $(\bar{t}, \bar{x})$ the solution coincides with the solution of the classical characteristic equation, i.e., with the solution $(\zeta, v)(\cdot; z, \omega, u_1)$ of the characteristic equation

$$\begin{aligned} \dot{\zeta}(t) &= f'(v(t)), & \zeta(0; z, \omega, u_1) &= z, \\ \dot{v}(t) &= g(t, \zeta(t), v(t), u_1(t, \zeta(t))), & v(0; z, \omega, u_1) &= \omega, \end{aligned}$$

one has with some $\bar{z} > 0$

$$\bar{x} = \zeta(\bar{t}; \bar{z}, u_0(\bar{z}), u_1), \quad y(\bar{t}, \bar{x}; u) = v(\bar{t}; \bar{z}, u_0(\bar{z}), u_1) \tag{3.10}$$

if $(\bar{t}, \bar{x})$ is not on a rarefaction wave; otherwise, with some $\bar{\omega} \in [u_0(\bar{z}-), u_0(\bar{z}+)]$,

$$\bar{x} = \zeta(\bar{t}; \bar{z}, \bar{\omega}, u_1), \quad y(\bar{t}, \bar{x}; u) = v(\bar{t}; \bar{z}, \bar{\omega}, u_1). \tag{3.11}$$

In shock points the same holds for the left and right states $y(\bar{t}, \bar{x}\mp; u)$, respectively. If $(\bar{t}, \bar{x})$ is a continuity point that is no shock generation point and not located on a rarefaction wave or on a forward characteristic emanating from a point $(0, x_i)$, $1 \le x_i \le N$, where u_0 is continuous, then the representation (3.10) is valid on a neighborhood and the first equation in (3.10) can be solved for $\bar{z}$, yielding with the second by the implicit function theorem the differentiability of

$$(w, \sigma) \in W_\rho \longmapsto y(\cdot; u^s(w, \sigma)) \in L^r(J(\bar{x})) \tag{3.12}$$

with a neighborhood $J(\bar{x})$ of $\bar{x}$ for $r = \infty$ and $\rho > 0$ small enough; see Lemmas 5.1 and 5.5 of section 5.1 (Case C^c). If $(\bar{t}, \bar{x})$ is a continuity point in the interior of a rarefaction wave, the same holds by solving in the first equation of (3.11) for $\bar{\omega}$ and inserting it in the second; see Lemmas 5.6 and 5.10 of section 5.2 (Case R^c). If $(\bar{t}, \bar{x})$ is on the boundary of a rarefaction wave (Case RB^c), then (3.2) is Fréchet differentiable for all $r \in [1, \infty)$; see Lemma 5.12 in section 5.4. If $(\bar{t}, \bar{x})$ is a point on a forward characteristic emanating from a point $(0, x_i)$, $1 \le x_i \le N$, where u_0 is continuous (Case CB^c), then (3.2) is Fréchet differentiable in $(0, 0)$ for all $r \in [1, \infty)$; see Lemma 5.11 in section 5.3. Moreover, by (3.10) or (3.11) and the implicit function theorem, it is not difficult to show that the derivative of (3.9) is given by $d_{(w,\sigma)}y \cdot (\delta w, s) = \delta Y(\bar{t}, \cdot)|_{J(\bar{x})}$, where δY is the broad solution of the linearized equation (3.3)–(3.4); see Lemmas 5.1 and 5.6 and Remarks 5.4 and 5.9 in section 5.

Now consider an observation time $\bar{t}$ such that $y(\bar{t}, \cdot; u)$ has only nondegenerate shocks and no shock generation points on $I = [a, b]$ (see Theorem 3.8) with continuity points a, b. Then one can show that $y(\bar{t}, \cdot; u)$ has on I finitely many shocks at positions $a < \bar{x}_1 < \cdots < \bar{x}_K < b$. The previous considerations show already that (3.9) maps Fréchet differentiable to $L^1(J)$. It remains to analyze the shock positions. Using the theory of generalized characteristics we show in section 6 that the shocks are stable

in the above sense; see Lemma 6.2 and Corollary 6.5. To show the differentiability of the shock position stated in Lemma 6.4 and Corollary 6.5, we apply in section 8 an adjoint argument: Let $\bar{x}_k = \bar{x}_k(u)$ be a shock position and set $\tilde{u} \stackrel{\text{def}}{=} u^s(w,\sigma)$. We use the abbreviations $\tilde{y} = y(\cdot;\tilde{u})$, $y = y(\cdot;u)$, $\Delta y \stackrel{\text{def}}{=} \tilde{y} - y$, and $\delta u \stackrel{\text{def}}{=} \tilde{u} - u$. With an ε-neighborhood $J_\varepsilon =]\hat{x}_-, \hat{x}_+[\stackrel{\text{def}}{=}]\bar{x}_k - \varepsilon, \bar{x}_k + \varepsilon[$ the stability properties of the shock yield

$$\frac{1}{[y(\bar{t},\bar{x}_k)]} \int_{\hat{x}_-}^{\hat{x}_+} \Delta y(\bar{t},x)\,dx = \bar{x}_k(\tilde{u}) - \bar{x}_k + O((\varepsilon + \|(w,\sigma)\|_W)\|(w,\sigma)\|_W). \tag{3.13}$$

Therefore, in order to obtain the shock sensitivity we compute the derivative of the functional on the left-hand side by adjoint-based techniques and then take the limit $\varepsilon \to 0$. Our adjoint approach uses first an averaged adjoint equation to avoid a linearization of the conservation law at shocks and then uses stability properties of the averaged equation to derive the actual adjoint equation: The difference of (1.1) for $\tilde{y}$ and y yields

$$\partial_t \Delta y + \partial_x(\tilde{a}\Delta y) = \tilde{b}\Delta y + g(t,x,y,\tilde{u}_1) - g(t,x,y,u_1) \tag{3.14}$$

with the averaged coefficients

$$\tilde{a}(t,x) \stackrel{\text{def}}{=} \int_0^1 f'(y(t,x) + \tau\Delta y(t,x))\,d\tau, \quad \tilde{b}(t,x) \stackrel{\text{def}}{=} \int_0^1 g_y(\cdot, y(t,x) + \tau\Delta y(t,x), \tilde{u}_1)\,d\tau.$$

Denote by D_ε the domain confined by the backward characteristics through $(\bar{t}, \hat{x}_\mp)$. Multiplying (3.14) by a sufficiently regular test function $\tilde{p}$ with $\tilde{p}(\bar{t},\cdot) \equiv 1/[y(\bar{t},\bar{x}_k)]$ and integrating by parts on D_ε yields

$$\begin{aligned}(\tilde{p}(\bar{t},\cdot), \Delta y(\bar{t},\cdot))_{2,J_\varepsilon} &= (\tilde{p}(0,\cdot), \delta u_0)_{2,D_\varepsilon^c \cap \{t=0\}} + (\partial_t\tilde{p} + \tilde{a}\partial_x\tilde{p} + \tilde{b}\tilde{p}, \Delta y)_{2,D_\varepsilon} \\ &\quad + (\tilde{p}, g_{u_1}(\cdot,y,u_1)\delta u_1)_{2,D_\varepsilon} + o(\|(w,\sigma)\|_W).\end{aligned}$$

The left-hand side is identical to the left-hand side of (3.13). The remainder term contains boundary terms along the characteristics that can be estimated by the stability properties of the solution and a distributed term from the Taylor expansion of g w.r.t. u_1. Now we choose $\tilde{p}$ as the solution of the averaged adjoint equation

$$\begin{aligned}&\partial_t\tilde{p} + \tilde{a}\partial_x\tilde{p} = -\tilde{b}\tilde{p}, \quad \tilde{p}(\bar{t},\cdot) = p^{\bar{t}}, \\ &p^{\bar{t}} \equiv 1/[y(\bar{t},\bar{x}_k;u)].\end{aligned} \tag{3.15}$$

Then we obtain the duality relation

$$\begin{aligned}(p^{\bar{t}}, \Delta y(\bar{t},\cdot))_{2,J_\varepsilon} &= (\tilde{p}(0,\cdot), \delta u_0)_{2,D_\varepsilon^c \cap \{t=0\}} + (\tilde{p}, g_{u_1}(\cdot,y,u_1)\delta u_1)_{2,D_\varepsilon} \\ &\quad + o(\|(w,\sigma)\|_W).\end{aligned} \tag{3.16}$$

We will show in section 7 that a special class of *reversible* solutions of this transport equation with discontinuous coefficient is stable w.r.t. $\tilde{a}, \tilde{b}$, sufficiently regular for the above calculations, and that $\tilde{p}$ converges in an appropriate space to the reversible solution $p^k = p$ of the limit adjoint equation (3.5) for end data $1/[y(\bar{t},\bar{x}_k;u)]$. Using these stability properties, we can take the limit $(\delta w, s) \to 0$ and then $\varepsilon \to 0$ in (3.16) and deduce quite immediately (3.8) (at least formally, but we will justify the limit transition). Hereby, we use the following convenient fact: by prescribing just the point

data (3.6) we can achieve that the adjoint state p^k has exactly the desired support $D = D_0$, and thus the integration domain D is automatically provided by p^k. Note moreover, that the limit transition in $(\tilde{p}(0,\cdot), \delta u_0)_{2,D_\varepsilon^{cl}\cap\{t=0\}}$ leads to the last two terms in (3.8), since $\delta u_0 = \delta w_0 + S_{u_0}^{(x_i)}(\delta w_0, s)$ is a shift-variation.

REMARK 3.6. *We note that the duality relation* (3.16) *with reversible solutions* $\tilde{p}$ *of* (3.15) *holds also if* J_ε *is replaced by any other interval* $J =]\hat{x}_-, \hat{x}_+[$ *with continuity points* $\hat{x}_\mp$ *and if* D_ε *is replaced by the domain* D *confined by the backward characteristics through* $(\bar{t}, \hat{x}_\mp)$*, i.e.,*

$$(p^{\bar{t}}, \Delta y(\bar{t},\cdot))_{2,J} = (\tilde{p}(0,\cdot), \delta u_0)_{2,D^{cl}\cap\{t=0\}} + (\tilde{p}, g_{u_1}(\cdot, y, u_1)\delta u_1)_{2,D} + o(\|(w,\sigma)\|_W). \tag{3.17}$$

This holds first for Lipschitz continuous end data $p^{\bar{t}}$*, but* (3.16) *extends to all end data* $p^{\bar{t}}$ *that are the limit of a boundedly everywhere convergent sequence of Lipschitz-functions; see Theorem* 7.11*. We will use this to get a gradient representation for tracking-type functionals* (1.2)*.*

If D *lies between neighbored shocks, then it contains only continuity points, and the limit transition in* (3.17) *yields the classical duality relation*

$$(p^{\bar{t}}, \delta Y(\bar{t},\cdot))_{2,J} = (p(0,\cdot), \delta u_0)_{2,D^{cl}\cap\{t=0\}} + (p, g_{u_1}(\cdot, y, u_1)\delta u_1)_{2,D}, \tag{3.18}$$

where δY *is the solution of the linearized equations* (3.3)–(3.4) *and* p *is the reversible solution of the adjoint equation* (3.5)*. See also Remark* 3.13*.*

REMARK 3.7. *By requiring the duality relation* (3.18) *for all* $\bar{t} \in (0,T]$ *and end data* $p^{\bar{t}} \in C_c^{0,1}(\mathbb{R})$*, one can define a measure solution (*duality solution*) of the linearized state equation* (3.3) *on all of* Ω_T*. The linearization of the initial shift-variation* δu_0 *leads then to the initial measure* $\delta w_0 + \sum_{i=1}^N [u_0(x_i)]_+ s_i \delta(\cdot - x_i)$*, with* $\delta(\cdot)$ *denoting the Dirac measure at* 0*. By taking the limit in* (3.16) *one can show that this is the correct "weak" linearization of* (1.1) *in the space of measures. This concept was introduced in* [1, 2] *for the case without a source term. For the present case see the author's habilitation thesis* [26]*. As already mentioned, the topology of measures is too weak to obtain directly differentiability results for tracking-functionals* (1.2)*. Therefore we show shift-differentiability.*

Our next result concerns the nondegeneracy assumptions of Theorems 3.2 and 3.4. They require that at the observation time $\bar{t}$ on $I = [a,b]$ there are no shock generation points, no shock interaction points, and only finitely many shocks that are all nondegenerate. In general, this situation holds very likely at a given time $\bar{t}$, since the number of shock interaction points and shock generation points is at most countable and degeneracy of a shock is—in contrast to nondegeneracy—not stable under perturbations. In fact, under slightly stronger regularity assumptions on u_0 and u_1 we are able to show that the situation assumed in Theorems 3.2 and 3.4 holds actually for a.a. $\bar{t} \in (0,T]$.

THEOREM 3.8 (nondegeneracy of shocks holds for a.a. $\bar{t} \in (0,T]$)*. Let* (A2)–(A3) *hold and assume in addition that* f *is* C^3 *and* $g \in L^\infty(0,T; C^2_{loc}(\mathbb{R}\times\mathbb{R}\times\mathbb{R}^m))$*. If* $u_0 \in PC^2(\mathbb{R}; x_1, \dots, x_N)$*,* $u_1 \in L^\infty(0,T; C^2_{loc}(\mathbb{R})^m)$*, then the assumptions of Theorem* 3.2 *hold for a.a.* $\bar{t} \in]0,T]$*.*

The proof again uses generalized characteristics and is carried out in section 9.

3.2. Differentiability of tracking-type functionals. Using Lemma 2.3 and Theorem 3.2 we get the Fréchet differentiability of a large class of tracking-type func-

tionals (1.2), i.e.,

$$J(y(u)) = \int_a^b \phi(y(\bar{t}, \cdot; u), y_d)\, dx. \tag{1.2}$$

We have the following result.

THEOREM 3.9 (differentiability of tracking-type functionals). *Let the assumptions of Theorem* 3.2 *hold and let* $J(y(\bar{t}, \cdot; u))$ *be defined as in* (1.2) *with* $\phi \in C^{1,1}_{loc}(\mathbb{R}^2)$ *and* $y_d \in L^\infty(I)$ *being approximately continuous in* $\bar{x}_1, \dots, \bar{x}_K$. *Then the functional*

$$(w_0, w_1, \sigma) \in W \longmapsto J(y(\bar{t}, \cdot; u_0 + S^{(x_i)}_{u_0}(w_0, \sigma), u_1 + w_1)) \tag{3.19}$$

has the following differentiability properties:

(i) *The functional* (3.19) *is Fréchet differentiable at* $(0,0,0)$. *The application of the derivative to a direction* $(\delta w_0, \delta w_1, s) \in W$ *is given by* (2.2), *i.e.,*

$$\begin{aligned} d_{(w,\sigma)} J(y) \cdot (\delta w_0, \delta w_1, s) &= (\phi_y(y(\bar{t}, \cdot), y_d), \delta y^{\bar{t}})_{2,I} \\ &+ \sum_{k=1}^{K} \int_0^1 \phi_y(y(\bar{t}, \bar{x}_k+) + \tau[y(\bar{t}, \bar{x}_k)], y_d(\bar{x}_k)) d\tau\, [y(\bar{t}, \bar{x}_k)]_+ \bar{s}_k, \end{aligned} \tag{3.20}$$

where $y = y(\cdot; u)$ *is the entropy solution of* (1.1) *and* $\delta y^{\bar{t}}$, $\bar{s}_k$ *are given by* (3.7) *and* (3.8) *in Theorem* 3.4.

(ii) *If in addition* y_d *is continuous in a neighborhood of* $\bar{x}_1, \dots, \bar{x}_K$ *and if* $x_1, \dots, x_N$ *are discontinuities of* u_0, *then the functional* (3.19) *is continuously Fréchet differentiable on* $\{\|(w,\sigma)\|_W < \rho\}$ *for* $\rho > 0$ *sufficiently small.*

Proof. The theorem follows directly from Lemma 2.3 and Theorem 3.2. ∎

By inserting the shock sensitivities (3.8) in the second part of (3.20) and superimposing suitable multiples of the solutions $p^k = p$ of (3.5)–(3.6) we can rewrite (3.20) more conveniently, as follows.

COROLLARY 3.10. *Under the assumptions of Theorem* 3.9 *the formula* (3.20) *can equivalently be rewritten as*

$$\begin{aligned} d_{(w,\sigma)} J(y) \cdot (\delta w_0, \delta w_1, s) &= (\phi_y(y(\bar{t}, \cdot), y_d), \delta y^{\bar{t}})_{2,I} \\ &+ (p g_{u_1}(\cdot, y, u_1), \delta w_1)_{2,\Omega_{\bar{t}}} + (p(0, \cdot), \delta w_0)_2 + \sum_{i=1}^{N} p(0, x_i)[u_0(x_i)]_+ s_i, \end{aligned} \tag{3.21}$$

where $y = y(\cdot; u)$ *is the entropy solution of* (1.1), $\delta y^{\bar{t}}$ *is given by* (3.7) *in Theorem* 3.4, *and* p *is the reversible solution (cf. Definition* 7.5*) of the adjoint equation*

$$\partial_t p + f'(y)\partial_x p = -g_y(t, x, y, u_1)p, \quad p(\bar{t}, \cdot) = p^{\bar{t}} \tag{3.22}$$

with end data

$$p^{\bar{t}}(x) = \begin{cases} \int_0^1 \phi_y(y(\bar{t}, x+) + \tau[y(\bar{t}, x)], y_d(x))\, d\tau & \text{if } x \in \{\bar{x}_1, \dots, \bar{x}_K\}, \\ 0 & \text{else.} \end{cases} \tag{3.23}$$

Proof. The proof follows by inserting (3.8) in (3.20) and from the observation that the function $p = \sum_k \int_0^1 \phi_y(y(\bar{t}, \bar{x}_k+) + \tau[y(\bar{t}, \bar{x}_k)], y_d(\bar{x}_k))\, d\tau\, [y(\bar{t}, x_k)]_+ p^k$ with p^k from (3.5)–(3.6) is the reversible solution of (3.22) for data (3.23). ∎

3.3. Adjoint calculus for tracking-type functionals. Although the shift-differential is very useful for analytical purposes, the derivative of tracking-type functionals (1.2), (3.19) can more conveniently be computed via an adjoint-based formula, which yields also a gradient representation for (3.19) w.r.t. the scalar product of $L^2(\mathbb{R}) \times L^2(\Omega_{\bar{t}})^m \times \mathbb{R}^N$.

In fact, by using a duality relation (3.18) (see Remark 3.6) between the solution δY of the variational equation (3.3), and the reversible solution p of the adjoint equation (3.22) for end data $p^{\bar{t}} = \phi_y(y(\bar{t},\cdot), y_d)\, \mathbf{1}_{\{x \notin \{\bar{x}_1,\dots,\bar{x}_K\}\}}$, we will be able to obtain also an adjoint-based formula for the first term of (3.21). This leads to the following result.

THEOREM 3.11 (gradient representation for tracking-type functionals). *Let the assumptions of Theorem* 3.9 *hold and let y_d be PC^1. Then*

$$\begin{aligned} d_{(w,\sigma)}J(y)\cdot(\delta w_0, \delta w_1, s) &= (p g_{u_1}(\cdot, y, u_1), \delta w_1)_{2,\Omega_{\bar{t}}} \\ &\quad + (p(0,\cdot), \delta w_0)_2 + \sum_{i=1}^{N} p(0,x_i)[u_0(x_i)]_+ s_i, \end{aligned} \tag{3.24}$$

where p is the reversible solution (cf. Definition 7.5*) of the adjoint equation*

$$\partial_t p + f'(y)\partial_x p = -g_y(t,x,y,u_1)p, \quad p(\bar{t},\cdot) = p^{\bar{t}}, \tag{3.25}$$

$$p^{\bar{t}}(x) = \bar{\phi}_y(x) \stackrel{\text{def}}{=} \begin{cases} \int_0^1 \phi_y(y(\bar{t},x+) + \tau[y(\bar{t},x)], y_d(x))\, d\tau, & x \in I, \\ 0 & \text{else.} \end{cases} \tag{3.26}$$

Thus, the gradient representation of J w.r.t. the scalar product of the Hilbert space $L^2(\mathbb{R}) \times L^2(\Omega_{\bar{t}})^m \times \mathbb{R}^N$ is given by

$$\nabla_{(w,\sigma)}J(y) = \begin{pmatrix} p(0,\cdot) \\ p\, g_{u_1}(\cdot, y, u_1) \\ (p(0,x_i)[u_0(x_i)]_+)_{1\le i\le N} \end{pmatrix}. \tag{3.27}$$

With the domains S_k, D_k from Theorem 3.2 *holds $p|_{D_k} \in C^{0,1}(D_k \cap \{t > \tau\})$ for all $\tau > 0$. Moreover $p|_{S_k}$ is piecewise $C^{0,1}$ on $S_k \cap \{t > \tau\}$ for all $\tau > 0$ with discontinuities along the backward characteristics emanating from discontinuities of y_d. This remains true for $\tau = 0$ on all D_k, S_k that contain no rarefaction wave.*

The proof of this theorem is given in section 9.

REMARK 3.12.

- *The restriction to source terms g that are affine linear w.r.t. y can be dropped without major changes in our analysis if the stability results of Theorem* 7.10 *below for the adjoint equation* (1.6) *can be extended to a discontinuous zeroth order coefficient $g_y(t,x,y,u_1)$. See Remark* 8.1.
- *By Theorem* 3.8 *nondegeneracy for all shocks at time $\bar{t}$ holds for a.a. $\bar{t}$ under slightly stronger regularity assumptions on (u_0, u_1). In this sense, the case of nondegenerate shocks at the observation time $\bar{t}$ is a generic situation.*

REMARK 3.13. *Once the shift-differentiability of* (3.9) *is shown, one could also use the duality relation* (3.17) *with $\tilde{p}$ being a reversible solution of the averaged adjoint equation* (3.15) *with end data* (3.26) *and then take the limit to deduce the gradient formula* (3.24). *For this approach and a detailed analysis of the adjoint equation see the follow-up paper* [27]. *In the present paper it is most straightforward to use the duality relation* (3.18) *to deduce* (3.24) *from* (3.21).

In the next section we start by collecting several structural results of Dafermos [8] that will form the basis of our analysis.

4. Stability and structure of entropy solutions. Our aim is to derive a shift-differentiability result for entropy solutions $y = y(\cdot; u)$ of

$$\begin{aligned} &\partial_t y + \partial_x f(y) = g(t,x,y,u_1), \quad (t,x) \in \Omega_T \stackrel{\text{def}}{=}]0,T[\times \mathbb{R}, \\ &y(0,x) = u_0(x), \quad x \in \mathbb{R}, \end{aligned} \tag{1.1}$$

w.r.t. the control $u = (u_0, u_1)$, where we consider shift-variations of the initial data u_0 and conventional variations of u_1. As explained in section 3.1, we fix $u_0 \in PC^1(\mathbb{R}; x_1, \dots, x_N)$, $x_1 < x_2 < \cdots < x_N$, $u_1 \in L^\infty(0,T; C^1(\mathbb{R})^m)$, an observation time $\bar{t} \in (0,T]$ and consider the mapping

$$(w_0, w_1, \sigma) \in W \longmapsto y(\bar{t}, \cdot; u_0 + S_{u_0}^{(x_i)}(w_0, \sigma), u_1 + w_1) \in L^1(a,b)$$

for some $a < b$, where $W = PC^1(\mathbb{R}; x_1, \dots, x_N) \times L^\infty(0,T; C^1(\mathbb{R})^m) \times \mathbb{R}^N$.

Our analysis is based on the theory of generalized characteristics introduced in [8] to obtain structural information on the solution combined with a duality argument using the adjoint equation to (1.1). This approach has the advantage that we need not restrict a priori the class of considered entropy solutions. Thus, the results apply to solutions with very complicated structure.

In order to ensure the existence of essentially bounded entropy solutions and to allow the application of the theory of generalized characteristics, we make the following assumptions that we have already introduced in section 3.

ASSUMPTIONS:

(A2) (A1) holds, f is twice continuously differentiable, $g \in L^\infty(0,T; C^1_{loc}(\mathbb{R} \times \mathbb{R} \times \mathbb{R}^m))$, and g is Lipschitz continuous w.r.t. x.

(A3) $f'' \geq m_{f''} > 0$ for some $m_{f''} > 0$.

In the next subsection we summarize existence and stability results for entropy solutions of (1.1). In section 4.2 we collect from [8] the necessary results on the structure of solutions provided by the theory generalized characteristics. These ingredients will be used in sections 5–8 to prepare the proof in section 9 of the shift-differentiability result and the other main results that we have stated in section 3.

4.1. Basic properties of entropy solutions. We recall the following existence, uniqueness, and stability properties of the state equation (1.1); see, e.g., [25] and [21].

THEOREM 4.1. *Let* (A1) *hold. Then for all* $u = (u_0, u_1) \in L^\infty(\mathbb{R}) \times L^\infty(\Omega_T)^m \stackrel{\text{def}}{=} U$ *there exists a unique entropy solution* $y = y(u) \in L^\infty(\Omega_T)$. *After modification on a set of measure zero, one has* $y \in C([0,T]; L^1(-R,R))$ *for all* $R > 0$. *Let* $M_u > 0$ *and* $U_{ad} = \{u \in U : \|u_0\|_\infty \leq M_u, \|u_1\|_\infty \leq M_u\}$. *Then there are* $M_y > 0$ *and* $L_y > 0$ *such that for all* $u, \hat{u} \in U_{ad}$ *the corresponding solutions* $y, \hat{y}$ *satisfy*

(i) $\|y(t,\cdot)\|_\infty \leq M_y$,

(ii) $\|y(t,\cdot) - \hat{y}(t,\cdot)\|_{1,[a,b]} \leq L_y(\|u_0 - \hat{u}_0\|_{1,I_t} + \|u_1 - \hat{u}_1\|_{1,[0,t]\times I_t})$

for all $t \in [0,T]$, $a < b$, *where* $I_t = [a - tM_{f'}, b + tM_{f'}]$ *with* $M_{f'} = \max_{|y| \leq M_y} |f'(y)|$.

Moreover, let (A2), (A3) *hold and set* $\hat{U}_{ad} = \{u \in U_{ad} : \|u_1\|_{L^\infty(0,T;C^1)} \leq M_u\}$. *Then there exists a constant* $M_{cr} > 0$ *such that for all* $u \in \hat{U}_{ad}$ *and all* $t \in]0,T]$ *with* $E = M_{cr} m_{f''}$ *Oleinik's entropy condition*

$$\partial_x y(t,\cdot) \leq \frac{1}{(1 - e^{-Et})/M_{cr} + e^{-Et}/M} \tag{4.1}$$

holds in the sense of distributions whenever $M \in [M_{cr}, \infty]$ *is such that* $\partial_x u_0 \leq M$ *in the sense of distributions. In particular,* $y(t,\cdot) \in BV_{loc}(\mathbb{R})$ *for all* $t \in]0,T]$.

Proof. For the first part, see, e.g., [25]. The Oleinik entropy condition in this form can be deduced by a straightforward extension of the proof in [23] to the inhomogeneous case; see also [21]. ∎

Since for all $u \in U_{ad}$ the corresponding solutions $y = y(u)$ of (1.1) satisfy $\|y\|_\infty \leq M_y$, we may modify g for $|y| > M_y$ in such a way that g satisfies instead of the weaker growth condition in (A1) a global Lipschitz condition w.r.t. y. To study $y(u)$ for $u \in U_{ad}$ we may therefore assume that instead of (A2) the following holds.

ASSUMPTION:

(A2′) (A2) is satisfied and g is globally Lipschitz w.r.t. y.

By this modification of g we can achieve also that the backward solutions of the characteristic equations associated with (1.1) remain bounded for all end data and not only for end data obtained from bounded forward solutions. Since we will always deal with bounded entropy solutions, we will assume without restriction that (A2′) holds.

4.2. Generalized characteristics and the structure of solutions. We assume throughout this section that (A2), (A3) hold and consider controls $u \in \hat{U}_{ad}$ with $\hat{U}_{ad}$ from Theorem 4.1. Hence, we may assume without restriction that (A2′) is also satisfied.

Let $u = (u_0, u_1) \in \hat{U}_{ad}$ be given. Then by Theorem 4.1 (1.1) has a unique entropy solution $y = y(u) \in L^\infty(\Omega_T) \cap C([0,T]; L^1_{loc}(\mathbb{R}))$ with $y(t,\cdot) \in BV_{loc}(\mathbb{R})$, $t \in]0,T]$ and $\|y\|_\infty \leq M_y$. Hence, y admits left and right limits w.r.t. x for all $t \in]0,T]$. Moreover, by (4.1) each discontinuity is admissible, i.e.,

$$y(t,x-) \geq y(t,x+) \quad \forall\, t \in]0,T] \text{ and } \forall\, x \in \mathbb{R}.$$

These properties allow the application of the theory of generalized characteristics [8]. For notational convenience we consider the representative for y with $y(t,x) = y(t,x-)$. A Lipschitz continuous curve $x = \xi(t)$ defined on $t \in [a,b] \subset [0,T]$ is a (generalized) characteristic if the differential inclusion holds:

$$\dot{\xi}(t) \in [f'(y(t,\xi(t)+)), f'(y(t,\xi(t)-))] \quad \text{a.e. on } [a,b].$$

The local existence of a characteristic through any $(\bar{t},\bar{x}) \in \Omega_T$ follows from [9]; see also [8]. Assumption (A1) ensures that $\|y\|_\infty \leq M_y$. Thus, characteristics cannot escape and exist on the whole interval $[0,T]$. Hence, we can always set $[a,b] = [0,T]$. Since y is a weak solution of (1.1), it can be deduced [8] that the following actually holds:

$$\dot{\xi}(t) = \begin{cases} f'(y(t,\xi(t))) & \text{if } y(t,\xi(t)-) = y(t,\xi(t)+), \\ \dfrac{[f(y(t,\xi(t)))]}{[y(t,\xi(t))]} & \text{if } y(t,\xi(t)-) \neq y(t,\xi(t)+) \end{cases} \qquad \text{a.e. on [0,T].}$$

A characteristic is called genuine on $[a,b]$ if $y(t,\xi(t)+) = y(t,\xi(t)-)$ for a.a. $t \in [a,b]$.

The study of generalized characteristics in [8] together with the a priori bound $\|y\|_\infty \leq M_y$ yields the following structure of y.

PROPOSITION 4.2 (structure of entropy solutions [8]). *Let $u = (u_0, u_1) \in \hat{U}_{ad}$ with $u_0 \in BV_{loc}(\mathbb{R})$ and denote by $y = y(u)$ the representative of the entropy solution of (1.1) with $y(t,x) = y(t,x-)$. Then the following holds:*

For each fixed $(\bar{t},\bar{x}) \in \Omega_T$ the one-sided limits $y(\bar{t},\bar{x}\pm)$ exist and satisfy the entropy condition $y(\bar{t},\bar{x}-) \geq y(\bar{t},\bar{x}+)$. Moreover, the minimal and maximal backward characteristics $\xi_\mp(t)$ through $(\bar{t},\bar{x})$ are genuine, i.e., $y(t,\xi_\mp(t)-) = y(t,\xi_\mp(t)+)$,

$t \in]0, \bar{t}[$. *Moreover, for any genuine characteristic* $\xi(t)$ *on* $[0, \bar{t}]$ *one has (with our convention for the choice of* y*)*

(4.2)
$$\xi(t) = \zeta(t),\ t \in [0, \bar{t}], \quad y(t, \xi(t)) = v(t),\ t \in]0, \bar{t}[, \quad u_0(\xi(0)-) \le v(0) \le u_0(\xi(0)+),$$
$$y(\bar{t}, \xi(\bar{t})-) \ge v(\bar{t}) \ge y(\bar{t}, \xi(\bar{t})+),$$

where (ζ, v) *solves the classical characteristic equations*

$$\begin{aligned} \dot{\zeta}(t) &= f'(v(t)), \\ \dot{v}(t) &= g(t, \zeta(t), v(t), u_1(t, \zeta(t))). \end{aligned} \tag{4.3}$$

In particular, two different genuine characteristics may intersect only at their end points. Finally, if ξ *is the minimal characteristic* ξ_- *or the maximal characteristic* ξ_+ *through* $(\bar{t}, \bar{x})$*, then* (4.2) *holds with the solution* (ζ, v) *of* (4.3) *for the initial values*

$$(\zeta(\bar{t}), v(\bar{t})) = \begin{cases} (\bar{x}, y(\bar{t}, \bar{x}-)) & \text{if } \xi = \xi_-, \\ (\bar{x}, y(\bar{t}, \bar{x}+)) & \text{if } \xi = \xi_+. \end{cases} \tag{4.4}$$

We remark that for any minimal or maximal backward characteristic $\xi_\mp(t)$ the point $z = \xi_\mp(0)$ is a continuity point of u_0 or a nonentropy-admissible discontinuity, i.e., $u_0(z-) < u_0(z+)$; cf. (4.2).

Denote for $u_1 \in L^\infty(0, T; C^1(\mathbb{R})^m)$ and $z, w \in \mathbb{R}$ by $(\zeta(\cdot; z, w, u_1), v(\cdot; z, w, u_1))$ the solution of (4.3) with

$$\zeta(0; z, w, u_1) = z, \quad v(0; z, w, u_1) = w. \tag{4.5}$$

Let $(\bar{t}, \bar{x}) \in \Omega_T$ be a point of continuity of y w.r.t. x. Then y is by [8] continuous at $(\bar{t}, \bar{x})$ and the backward characteristic ξ through $(\bar{t}, \bar{x})$ is unique and genuine. Moreover, $\bar{z} = \xi(0)$ is a continuity point of u_0 or $u_0(\bar{z}-) < u_0(\bar{z}+)$. In the first case we have

$$\bar{x} = \zeta(\bar{t}; \bar{z}, u_0(\bar{z}), u_1), \tag{4.6}$$
$$y(\bar{t}, \bar{x}) = v(\bar{t}; \bar{z}, u_0(\bar{z}), u_1). \tag{4.7}$$

In the second case $(\bar{t}, \bar{x})$ lies on a rarefaction wave, i.e.,

$$\bar{x} = \zeta(\bar{t}; \bar{z}, \bar{w}, u_1), \tag{4.8}$$
$$y(\bar{t}, \bar{x}) = v(\bar{t}; \bar{z}, \bar{w}, u_1) \tag{4.9}$$

with some $\bar{w} \in [u_0(\bar{z}-), u_0(\bar{z}+)]$.

To study the smoothness of $(t, x, \hat{u}) \longmapsto y(t, x; \hat{u})$ in a suitable neighborhood of $(\bar{t}, \bar{x}, u)$ we will show that (4.6) can locally be solved for $\bar{z}$ (or (4.8) for $\bar{w}$) as long as $(\bar{t}, \bar{x})$ is not a shock generation point yielding with (4.7) (or (4.9)) an expression for y.

We begin by stating smoothness properties of the functions on the right-hand side in (4.8) and (4.9). The following result on ordinary differential equations will be useful.

PROPOSITION 4.3. *Let* $h(t, X, U) \in L^\infty(0, T; C^1_{loc}(\mathbb{R}^n \times \mathbb{R}^m)^n)$ *and Lipschitz w.r.t.* X*. Set* $\bar{H} \stackrel{\text{def}}{=} \{(Z, U) \in \mathbb{R}^n \times L^\infty(0, T; C^1(\mathbb{R}^n)^m) \ : \ \|U\|_{L^\infty(0,T;C^1(\mathbb{R}^n))} < M\}$ *for some* $M > 0$*. Then for all* $(Z, U) \in \bar{H}$ *there exists a unique solution* $X = X(\cdot; Z, U) \in C^{0,1}([0, T])^n$ *of*

$$\dot{X}(t) = h(t, X(t), U(t, X(t))), \quad X(0) = Z,$$

and the mapping $(Z,U) \in (\bar{H}, \|\cdot\|_{\mathbb{R}^n \times L^2(0,T;C^i(\mathbb{R}^n)^m)}) \longmapsto X(\cdot;Z,U) \in C([0,T])^n$ *is Lipschitz continuous for* $i = 0$ *and continuously Fréchet differentiable for* $i = 1$. *Moreover,* $(t,Z) \in [0,T] \times \mathbb{R}^n \mapsto X(t;Z,U)$ *is Lipschitz continuous for* $U \in L^\infty(0,T;C^1(\mathbb{R}^n)^m)$. *Finally, for any closed set* $S \subset \mathbb{R}^r$ *the mapping*

$$(Z,U) \in C(S) \times L^\infty(0,T;C^1(\mathbb{R}^n)^m) \longmapsto X(\cdot;Z(\cdot),U) \in C([0,T] \times S)^n$$

is continuously Fréchet differentiable.

The proof is standard and can, for example, be obtained by a refinement of the analysis in the appendix of [22] using the fact that the Nemyckii operator

$$(Z,U) \in L^\infty(0,T) \times (L^\infty(0,T;C^1(\mathbb{R})), \|\cdot\|_{L^2(0,T;C^1(\mathbb{R}))}) \longmapsto U(\cdot,Z(\cdot)) \in L^2(0,T)$$

is continuously Fréchet differentiable. Since the remainder term in the first order expansion of $(Z,U) \longmapsto X(\cdot;Z,U)$ can be estimated uniformly for all Z in a compact set, the last assertion follows immediately. We omit the technical details.

Now we obtain the following properties for solutions of (4.3).

LEMMA 4.4. *Let* (A2) *hold and denote for* $(z,w,u_1) \in \mathbb{R} \times \mathbb{R} \times L^\infty(0,T;C^1(\mathbb{R})^m)$ *by* $(\zeta,v)(\cdot;z,w,u_1)$ *the solution of* (4.3) *for initial data* (4.5). *Let* $M_w, M_u > 0$ *be given and*

$$H_i \stackrel{\text{def}}{=} \mathbb{R}^2 \times L^2(0,T;C^i(\mathbb{R})^m), \quad i = 0,1,$$
$$H \stackrel{\text{def}}{=} \{(z,w,u_1) \in H_1 \ : \ |w| < M_w, \ \|u_1\|_{L^\infty(0,T;C^1(\mathbb{R}))} < M_u\}.$$

Then the mapping

$$(z,w,u_1) \in (H, \|\cdot\|_{H_i}) \longmapsto (\zeta,v)(\cdot;z,w,u_1) \in C([0,T])^2 \tag{4.10}$$

is Lipschitz continuous for $i = 0$ *and continuously Fréchet differentiable for* $i = 1$, *and on* H *the right-hand side is uniformly Lipschitz w.r.t. t. Moreover, with* $\delta\nu = (\delta z, \delta w, \delta u_1)$ *one has*

$$d_{(z,w,u_1)}(\zeta,v)(\cdot;z,w,u_1) \cdot \delta\nu = (\delta\zeta,\delta v)(\cdot;z,w,u_1;\delta\nu), \tag{4.11}$$

where $(\delta\zeta,\delta v) = (\delta\zeta,\delta v)(\cdot;z,w,u_1;\delta z,\delta w,\delta u_1)$ *solves the linearized equation*

$$\begin{aligned} \dot{\delta\zeta} &= f''(v)\,\delta v, \\ \dot{\delta v} &= g_x(:)\,\delta\zeta + g_y(:)\,\delta v + g_{u_1}(:)\,(\partial_x u_1(t,\zeta)\delta\zeta + \delta u_1(t,\zeta)), \\ \delta\zeta(0) &= \delta z, \quad \delta v(0) = \delta w, \end{aligned} \tag{4.12}$$

with $(:) = (t,\zeta,v,u_1(t,\zeta))$. *The Fréchet derivative* (4.11) *can be continuously extended to* $\mathcal{L}(H_0, C([0,T]))$ *uniformly bounded on bounded subsets of* H. *Finally, for any closed* $S \subset \Omega_T^{cl}$ *and any bounded interval* J *the mapping*

$$\begin{aligned} (z,u_0,u_1) \in C(S;J) \times C^1(J) \times L^\infty(0,T;C^1(\mathbb{R})^m) \\ \longmapsto (\zeta,v)(\cdot_t;z(\cdot),u_0(z(\cdot)),u_1) \in C(S)^2 \end{aligned} \tag{4.13}$$

is continuously Fréchet differentiable, where $\cdot_t$ *denotes the projection* $(t,x) \longmapsto t$. *If* (A2′) *holds, then the same statements are true for backward solutions of* (4.3).

Proof. We can apply Proposition 4.3 if an a priori bound for v in (4.3) is known, since this ensures with (A2) that the right-hand side in (4.3) admits a Lipschitz

constant w.r.t. (ζ, v, u_1) for all (ζ, v, u_1) of interest. To derive such a bound we use (A1) and get constants $C_1, C_2 > 0$ with $\frac{d}{dt}|v(t)| \le C_1 + C_2|v(t)|$, $t \in]0,T[$. Since $|v(0)| = |w| \le M_w$, the Gronwall lemma yields

$$|v(t)| \le (M_w + C_1 T)e^{C_2 T}, \quad t \in [0,T].$$

Now the proof can be obtained by using Proposition 4.3.

The fact that (4.11) can be continuously extended to $\mathcal{L}(H_0, C([0,T]))$ is obvious from the properties of (4.12). The differentiability of (4.13) follows from Proposition 4.3, since the Nemyckii operator

$$(z, u_0) \in C(S;J) \times C^1(J) \longmapsto u_0(z(\cdot)) \in C(S)$$

is continuously Fréchet differentiable.

If (A2′) is satisfied, then we have the stronger growth estimate $|g(t,x,y,u_1)| \le C_1 + C_2|y|$ and the above arguments can be applied to backward solutions. □

To ensure backward stability of solutions to (4.3) for all end data—not only the relevant ones obtained from forward solutions—it will be convenient to assume (A2′) instead of (A2), which may be done without restriction by our considerations at the end of section 4.1.

4.3. Classification of continuity points. For the following analysis of the structure of entropy solutions we assume that $u_0 \in PC^1(\mathbb{R}; x_1, \dots, x_N)$, $x_1 < \cdots < x_N$, and $u_1 \in L^\infty(0,T; C^1(\mathbb{R})^m)$.

For further reference we distinguish several cases for continuity points $(\bar t, \bar x)$. We denote the genuine backward characteristic through $(\bar t, \bar x)$ by ξ and set $\bar z = \xi(0)$. We now consider the following cases.

Case C. Let $(\bar t, \bar x)$ be a continuity point of $y = y(u)$ such that $\bar z \ne x_i$, $i = 1, \dots, N$. Since $u_0 \in PC^1(\mathbb{R}; x_1, \dots, x_N)$, there is an interval J containing $\bar z$ such that $u_0|_J \in C^1(J)$. Now

(4.14)
$$(z, u_0, u_1) \in J \times C^1(J) \times L^\infty(0,T; C^1(\mathbb{R})^m) \longmapsto (\zeta, v)(\cdot; z, u_0(z), u_1) \in C([0,T])^2$$

is continuously Fréchet differentiable by Lemma 4.4. Hence, $\frac{d}{dz}\zeta(t; z, u_0(z), u_1)$ exists and is continuous on $(t,z) \in [0,T] \times J$. Since genuine characteristics may intersect only at their end points and contain only continuity points, it is obvious that [8]

$$\frac{d}{dz}\zeta(t; z, u_0(z), u_1)|_{z=\bar z} \ge 0, \quad 0 \le t \le \bar t. \tag{4.15}$$

Moreover, if $(\bar t, \bar x)$ is not an element of the shock set, i.e., if the unique forward characteristic is genuine until some $\bar t + \tau$, $\tau > 0$, then there is $\beta > 0$ with

$$\frac{d}{dz}\zeta(t; z, u_0(z), u_1)|_{z=\bar z} \ge \beta > 0, \quad 0 \le t \le \bar t. \tag{4.16}$$

In fact, we have

$$\frac{d}{dz}\zeta(t; z, u_0(z), u_1)|_{z=\bar z} = \delta\zeta(t; \bar z, u_0(\bar z), u_1; 1, u_0'(\bar z), 0) \tag{4.17}$$

with $\delta\zeta$ given by (4.12). Moreover, all points on the genuine backward characteristic $\zeta(t) = \zeta(t; \bar z, u_0(\bar z), u_1)$ are continuity points. Assume that $\delta\zeta(\tilde t) = 0$ for the right-hand side of (4.17) holds at some $\tilde t \in [0, \bar t]$. Then $\delta\dot\zeta(\tilde t) \ne 0$, since otherwise, by the

first line in (4.12), $\delta v(\tilde{t}) = 0$. This is impossible because the unique backward solution of (4.12) would vanish in contradiction to the initial values. From (4.15) we thus have $\delta\dot{\zeta}(\tilde{t}) < 0$, and therefore $\frac{d}{dz}\zeta(t; z, u_0(z), u_1)|_{z=\bar{z}} < 0$ for small $t > \tilde{t}$. Hence, the unique forward characteristic through $(\tilde{t}, \zeta(\tilde{t}))$ cannot be genuine, since the unique candidate $\zeta(t) = \zeta(t; \bar{z}, u_0(\bar{z}), u_1)$ is not admissible by (4.15). Since the left-hand side of (4.16) is continuous on $[0, \bar{t}]$, (4.16) must hold for some $\beta > 0$.

Case CB. $(\bar{t}, \bar{x})$ is a continuity point, $\bar{z} = x_i$, and u_0 is continuous at $\bar{z}$. In this case by the same arguments the one-sided derivatives must satisfy (4.15) and in addition (4.16) if $(\bar{t}, \bar{x})$ is not in the shock set.

Cases R, RB. If $(\bar{t}, \bar{x})$ is a continuity point and $\bar{z} = x_i$ with $u_0(\bar{z}-) < u_0(\bar{z}+)$, then three (essentially two) cases can occur.

Case R. All backward characteristics through $(\bar{t}, x)$ with x in a small neighborhood of $\bar{x}$ meet $t = 0$ in $\bar{z}$. Then similar arguments as above show that with $\bar{w}$ from (4.8)

$$\frac{d}{dw}\zeta(t; \bar{z}, w, u_1)|_{w=\bar{w}} \geq 0, \quad 0 \leq t \leq \bar{t}, \tag{4.18}$$

holds, and if $(\bar{t}, x)$ is not a point of the shock set, there is $\beta > 0$ with

$$\frac{d}{dw}\zeta(t; \bar{z}, w, u_1)|_{w=\bar{w}} \geq \beta t > 0, \quad 0 < t \leq \bar{t}. \tag{4.19}$$

Case RB. $(\bar{t}, \bar{x})$ lies on the left or right boundary of a rarefaction wave. In this case the one-sided derivatives satisfy (4.15) and (4.18) (and moreover (4.16) and (4.19) if $(\bar{t}, x)$ is not a shock generation point), respectively.

Finally, it will be convenient to indicate that one of the above cases holds *and* the point is not in the shock set (i.e., not a shock generation point), which means that the unique forward characteristic remains genuine at least until some $\bar{t} + \tau$, $\tau > 0$.

Case C^c, CB^c, R^c, or RB^c. If $(\bar{t}, \bar{x})$ is of type C and (4.16) holds, then we call $(\bar{t}, \bar{x})$ of type C^c. If $(\bar{t}, \bar{x})$ is of type CB and (4.16) holds for the one-sided derivatives, then we call $(\bar{t}, \bar{x})$ of type CB^c. Similarly, if $(\bar{t}, \bar{x})$ is of type R and (4.19) holds, then we call $(\bar{t}, \bar{x})$ of type R^c. If $(\bar{t}, \bar{x})$ is of type RB and (4.16), respectively, (4.19), holds for the one-sided derivatives (see Case RB above), then we call $(\bar{t}, \bar{x})$ of type RB^c.

4.4. Classification of shock points. Now let $(\bar{t}, \bar{x})$ be a shock point located on the shock curve $\eta(t)$. We know from [8] and section 4.2 that the minimal and maximal backward characteristics $\xi_\mp(t)$ through $(\bar{t}, \bar{x})$ are genuine with initial condition (4.4). Thus, if we set $\bar{z}^\mp = \xi_\mp(0)$ we can classify the left and right states of the shock exactly as continuity points before, depending on whether or not $\bar{z}^\mp = x_i$ for some i. Moreover, the corresponding equations (4.6), (4.7) or (4.8), (4.9) hold with $\bar{z}^\mp$ and $y(\bar{t}, \bar{x}\mp)$ instead of $\bar{z}$, $y(\bar{t}, \bar{x})$. In particular, the following cases will be important.

Case $\mathrm{C}^c\mathrm{C}^c$. The extreme backward characteristics $\xi_\mp$ through $(\bar{t}, \bar{x})$ have the same properties as the backward characteristic through a continuity point of type C^c, i.e., we have $\bar{z}^\mp = \xi_\mp(0) \neq x_i$, $i = 1, \ldots, N$, and (4.16) holds for $\xi_\mp$ in $\bar{z} = \bar{z}^\mp$.

Case $\mathrm{R}^c\mathrm{R}^c$. The extreme backward characteristics $\xi_\mp$ through $(\bar{t}, \bar{x})$ have the same properties as the backward characteristic through a continuity point of type R^c; i.e., with $\bar{z}^\mp = \xi_\mp(0)$, $u_0(\bar{z}-) < u_0(\bar{z}+)$ holds for $\bar{z} = \bar{z}^\mp$, (4.8)–(4.9) hold with $(\bar{x}, \bar{z}) = (\bar{x}\mp, \bar{z}^\mp)$, $\bar{w} = \bar{w}^\mp \in (u_0(\bar{z}-), u_0(\bar{z}+))$, and (4.19) holds for $\xi_\mp$ with $(\bar{z}, \bar{w}) = (\bar{z}^\mp, \bar{w}^\mp)$.

Cases $\mathrm{C}^c\mathrm{R}^c$, $\mathrm{R}^c\mathrm{C}^c$. In Case $\mathrm{C}^c\mathrm{R}^c$ the minimal backward characteristic ξ_- has the properties as in Case C^c, the maximal characteristic ξ_+ has the properties as in Case R^c. The converse is true in Case $\mathrm{R}^c\mathrm{C}^c$.

5. Differentiability at continuity points. We start by analyzing the differentiability properties w.r.t. the control at continuity points that are not shock generation points and that are moreover not located on the boundary of a rarefaction wave (Case C^c or R^c).

5.1. Differentiability in continuity points of class C^c. We study first Case C^c; i.e., $(\bar t, \bar x)$ satisfies Case C and is not a shock generation point. By continuity there are $z_- < \bar z < z_+$ such that

(5.1)
$$u_0 \in C^1(J), \quad \frac{d}{dz}\zeta(t; z, u_0(z), u_1) \geq \beta > 0 \quad \forall\, t \in [0, \bar t],\ \forall\, z \in\,]z_- - \rho, z_+ + \rho[\stackrel{\text{def}}{=} J$$

for some $\beta, \rho > 0$. This allows us to solve (4.6) locally for $\bar z$ yielding with (4.7) a local regularity result for y.

5.1.1. Solution of the characteristic equations. We have the following result on the solvability of (4.6) and the resulting properties of y according to (4.7).

LEMMA 5.1. *Let* (A2)–(A3) *hold, let* $u = (u_0, u_1) \in PC^1(\mathbb{R}; x_1, \dots, x_N) \times L^\infty(0, T; C^1(\mathbb{R})^m)$, *and let* (5.1) *hold for some* $\beta, \rho > 0$. *Then there is* $\tau > 0$ *and a neighborhood*

$$V \subset C^1(J) \times L^\infty(0, T; C^1(\mathbb{R})^m)$$

of $u = (u_0, u_1)$ *such that*

$$\frac{d}{dz}\zeta(t; z, \hat u_0(z), \hat u_1) \geq \frac{\beta}{2} > 0 \quad \forall\ (t, z) \in [0, \bar t + \tau] \times J, \quad \forall\ \hat u \in V. \tag{5.2}$$

Moreover, for all $\hat u \in V$ *and all* (t, x) *in the stripe*

$$S = S(\tau) \stackrel{\text{def}}{=} \{(t, x)\ :\ t \in [0, \bar t + \tau],\ x \in [\xi_-(t), \xi_+(t)]\},$$

where $\xi_\mp(t) = \zeta(t; z_\mp, u_0(z_\mp), u_1)$, *the equation*

$$x = \zeta(t; z, \hat u_0(z), \hat u_1) \tag{5.3}$$

has in J *a unique solution* $z = Z(t, x, \hat u)$. *Set*

$$Y(t, x, \hat u) \stackrel{\text{def}}{=} v(t; Z(t, x, \hat u), \hat u_0(Z(t, x, \hat u)), \hat u_1). \tag{5.4}$$

Then $Z(\cdot, \hat u), Y(\cdot, \hat u) \in C^{0,1}(S)$. *The mappings*

$$(x, \hat u) \in\ ]\xi_-(t), \xi_+(t)[\times V \longmapsto (Z, Y)(t, x, \hat u), \quad t \in [0, \bar t + \tau[\,, \tag{5.5}$$

$$\hat u \in V \longmapsto (Z, Y)(\cdot, \hat u) \in C(S)^2 \tag{5.6}$$

are continuously Fréchet differentiable. The derivatives of (5.5) *are*

$$d_{(x,u)}Z(t, x, \hat u) \cdot (\delta x, \delta u) = \frac{\delta x - \delta\zeta(t; z, \hat u_0(z), \hat u_1; 0, \delta u_0(z), \delta u_1)}{\delta\zeta(t; z, \hat u_0(z), \hat u_1; 1, \hat u_0'(z), 0)}, \tag{5.7}$$

(5.8)
$$\begin{aligned} d_{(x,u)}Y(t, x, \hat u) \cdot (\delta x, \delta u) = {} & \delta v(t; z, \hat u_0(z), \hat u_1; 1, \hat u_0'(z), 0)\ d_{(x,u)}Z(t, x, \hat u) \cdot (\delta x, \delta u) \\ & + \delta v(t; z, \hat u_0(z), \hat u_1; 0, \delta u_0(z), \delta u_1), \end{aligned}$$

where $z = Z(t, x, \hat{u})$ *and* $(\delta\zeta, \delta v)$ *are given by* (4.12). *The derivative of* (5.6) *is*

$$d_u(Z, Y)(\cdot, \hat{u}) \cdot \delta u = d_{(x,u)}(Z, Y)(\cdot, \hat{u}) \cdot (0, \delta u). \tag{5.9}$$

NOTATION 5.2. *Given* $\bar{t}, z_-, z_+$ *satisfying* (5.1), *it will be convenient to indicate by*

$$(Y, Z, V, S(\tau), J) = \mathrm{YC}(u, \bar{t}, [z_-, z_+])$$

that the open interval $J \supset [z_-, z_+]$, *the stripe* $S = S(\tau)$, *the neighborhood* V, *and the functions* Y, Z *are obtained by applying Lemma* 5.1.

REMARK 5.3. *By construction,* $Y(\cdot, \hat{u}) \in C^{0,1}(S)$ *is an* S *classical solution of* (1.1) *for the control* $\hat{u} \in V$.

REMARK 5.4. *It is not difficult to show that* $\delta Y = d_u Y(\cdot, u) \cdot \delta u \in C(S)$ *is the unique broad solution (i.e., solution along characteristics) of the linearized equation*

$$\begin{aligned} &\partial_t \delta Y + \partial_x (f'(Y)\delta Y) = g_y(t, x, Y, u_1)\delta Y + g_{u_1}(t, x, Y, u_1)\delta u_1, \quad (t, x) \in S, \\ &\delta Y(0, x) = \delta u_0(x), \quad x \in [z_-, z_+], \end{aligned} \tag{5.10}$$

where $Y = Y(\cdot, u)$. *By Remark* 5.3 *and the differentiability of* (5.6) *we see from*

$$\partial_t Y(\cdot; \hat{u}) + \partial_x f(Y(\cdot; \hat{u})) = g(t, x, Y(\cdot; \hat{u}), \hat{u}_1)$$

with $\hat{u} = u + \sigma\delta u$ *by applying test functions* $p \in C^1(S)$, *integrating by parts, and taking the derivative in* $\sigma = 0$ *that* δY *is also a weak solution of* (5.10). *Even more, for any domain* $D \subset S$ *with Lipschitz boundary and any* $p \in C^{0,1}(D)$, *one has*

$$\begin{aligned} &(p\,(n_1 + n_2 f'(Y)), \delta Y)_{2,\partial D} \\ &= (\partial_t p + f'(Y)\partial_x p + g_y(t, x, Y, u_1)p, \delta Y)_{2,D} + (p\, g_{u_1}(t, x, Y, u_1), \delta u_1)_{2,D}, \end{aligned} \tag{5.11}$$

where $(n_1, n_2)^T$ *is the unit outer normal of* D. *In section* 9.3 *we will choose* p *as a solution of the adjoint equation* (3.25)–(3.26) *to obtain from* (3.21) *the gradient representation* (3.24) *for tracking-type functionals* (1.2), (3.19).

Proof of Lemma 5.1. Let $(\hat{u}_0, \hat{u}_1) \in C^1(J) \times L^\infty(0, T; C^1(\mathbb{R})^m)$. We have already observed that Lemma 4.4 implies the continuous Fréchet differentiability of (4.14). Thus, we deduce from (5.1) by continuity that (5.2) holds with a sufficiently small neighborhood $V \subset C^1(J) \times L^\infty(0, T; C^1(\mathbb{R})^m)$ of u and $\tau > 0$ small enough. Hence, for all $t \in [0, \bar{t} + \tau]$ and $\hat{u} \in V$ the mapping

$$z \in J \longmapsto \zeta(t; z, \hat{u}_0(z), \hat{u}_1)$$

is strictly monotone increasing and $]\zeta(t; z_-, \hat{u}_0(z_-), \hat{u}_1) - \beta\rho/2, \zeta(t; z_+, \hat{u}_0(z_+), \hat{u}_1) + \beta\rho/2[$ is contained in its image. Hence, for sufficiently small V and τ we get by continuity that $[\xi_-(t), \xi_+(t)]$ is contained in the image for all $t \in [0, \bar{t} + \tau]$ and all $\hat{u} \in V$. As a consequence, for all $(t, x) \in S$ and all $\hat{u} \in V$ there exists exactly one solution $z = Z(t, x, \hat{u}) \in J$ of (5.3). Since $Z(t, x, \hat{u}) \in J$ for all considered $x, \hat{u}$, we conclude from (5.2), (5.3) and the continuous Fréchet differentiability of (4.14) by the implicit function theorem that the first component of (5.5) is continuously Fréchet differentiable. By (5.4) and the continuous differentiability of (4.14) the second component in (5.5) is also continuously Fréchet differentiable. The formula (5.7) is an immediate consequence of the implicit function theorem, and (5.8) follows from (5.4). The

Lipschitz continuity of $Z(\cdot,\hat{u})$ follows directly from (5.2) and the Lipschitz continuity of (5.3) w.r.t. t,x. Now the Lipschitz continuity of $Y(\cdot,\hat{u})$ is clear by (5.4) and the Lipschitz continuity of $v(t;z,w,\hat{u}_1)$ w.r.t. t,z,w.

To show the differentiability of (5.6) we observe that for all $\hat{u}\in V$ the function $Z(\cdot,\hat{u})$ is in $C(S;J)$ and satisfies $F(Z(\cdot,\hat{u}),\hat{u})=0$ with the operator

$$\begin{aligned} F:(z,\hat{u}_0,\hat{u}_1)\in C(S;J)\times C^1(J)\times L^\infty(0,T;C^1(\mathbb{R})^m)\\ \longmapsto (\zeta(\cdot_t;z(\cdot),\hat{u}_0(z(\cdot)),\hat{u}_1)-\cdot_x)\in C(S), \end{aligned}$$

where $\cdot_t,\cdot_x$ denote the projections on the t- and x-components, respectively. F is continuously Fréchet differentiable by Lemma 4.4, and we have obviously

$$d_zF(z,\hat{u})\cdot\delta z=\left((t,x)\longmapsto \frac{d}{d\tilde{z}}\zeta(t;\tilde{z},\hat{u}_0(\tilde{z}),\hat{u}_1)|_{\tilde{z}=z(t,x)}\delta z(t,x)\right).$$

By (5.2) we get that $(d_zF(z,\hat{u}))^{-1}$ exists and is bounded for all $z\in C(S;J)$ and all $\hat{u}\in V$. Hence, the first component of (5.6) is continuously Fréchet differentiable by the implicit function theorem, and now by (5.4) and Lemma 4.4 the second is also. The formula (5.9) is obvious. The properties of these mappings follow directly from Lemma 4.4. ∎

5.1.2. Differentiability result in continuity points of type C^c. We are now able to characterize the properties of y in continuity points of class C^c.

LEMMA 5.5 (differentiability properties in continuity points of class C^c). *Let* (A2)–(A3) *hold and let* $u=(u_0,u_1)\in PC^1(\mathbb{R};x_1,\dots,x_N)\times L^\infty(0,T;C^1(\mathbb{R})^m)$. *Let* $(\bar{t},\bar{x})\in\Omega_T$ *be a point of continuity of* $y=y(\cdot;u)$ *of class* C^c, *i.e., outside the shock set such that* $\bar{z}\neq x_i$, $1\le i\le N$, *holds for* $\bar{z}$ *given by* (4.6). *Then the following hold:*

(i) *There is a maximal nonempty open interval* I *such that* $\{\bar{t}\}\times I$ *does not contain points of the shock set and that all backward characteristics through* $(\bar{t},x)$, $x\in I$, *meet* $t=0$ *not in* x_i, $i=1,\dots,N$. $y(\bar{t},\cdot;u)$ *is continuously differentiable on* I.

(ii) *Let* $\hat{I}=]x_-,x_+[$ *be an arbitrary interval with closure in* I, *denote by* $\xi_\mp$ *the genuine backward characteristics through* $(\bar{t},x_\mp)$, *and set* $z_\mp=\xi_\mp(0)$. *Then there are* $\beta>0$, $\rho>0$ *such that* (5.1) *is satisfied. Using Notation* 5.2 *let* $(Y,Z,V,S(\tau),J)=\mathrm{YC}(u,\bar{t},[z_-,z_+])$ *be obtained according to Lemma* 5.1. *Given* $M_\infty>0$ *there are* $R>0$, $\nu>0$ *such that after a possible reduction of* τ *and* V *the following holds:*

$$\begin{aligned} y(t,x;\hat{u})=Y(t,x,\hat{u}_0|_J,\hat{u}_1)\quad\forall\,(t,x)\in S,\quad\forall\,\hat{u}\in\hat{V},\quad \textit{where}\\ \hat{V}\overset{\mathrm{def}}{=}\{(\hat{u}_0,\hat{u}_1)\in L^\infty(\mathbb{R})\times L^\infty(0,T;C^1(\mathbb{R})^m)\ :\ (\hat{u}_0|_J,\hat{u}_1)\in V,\\ \|\hat{u}_0-u_0\|_{\infty,\mathbb{R}\setminus J}<M_\infty,\|\hat{u}_0-u_0\|_{1,[-R,R]\setminus J}<\nu\}. \end{aligned}$$

Hence, the differentiability results of Lemma 5.1 *for* Y *carry over to* $y|_S$.

Proof. (i) $(\bar{t},\bar{x})$ is of class C^c, since $\bar{z}\neq x_i$, $i=1,\dots,N$, and $(\bar{t},\bar{x})$ is a continuity point outside the shock set. Hence, we know that (4.16) holds for some $\beta>0$, and we find $z_-<\bar{z}<z_+$, $\rho>0$ such that (5.1) is satisfied. Therefore, Lemma 5.1 is applicable, yielding $(Y,Z,V,S(\tau),J)=\mathrm{YC}(u,\bar{t},[z_-,z_+])$; see Notation 5.2. Then clearly $u_0\in C^1(J)$, $i=1,\dots,N$. By the above-mentioned results of [8] we have (cf. (4.6), (4.7))

$$y(\bar{t},\bar{x};u)=Y(\bar{t},\bar{x},u).$$

Now $x \longmapsto y(\bar{t}, x; u)$ is continuous outside a countable set and the identities (4.6), (4.7) with $\tilde{x}, \tilde{z}$ instead of $\bar{x}, \bar{z}$ hold for all continuity points $(\bar{t}, \tilde{x})$. Using the backward stability of (4.3) according to Lemma 4.4 we see that $\tilde{z} \to \bar{z}$ for continuity points $\tilde{x}$ with $\tilde{x} \to \bar{x}$. Hence, for all continuity points $\tilde{x} \in]\xi_-(\bar{t}), \xi_+(\bar{t})[$ with $\tilde{z} \in J$ we must have $\tilde{z} = Z(\bar{t}, \tilde{x}, u)$ and thus

$$y(\bar{t}, x; u) = Y(\bar{t}, x, u)$$

for all $x \in \bar{I} \stackrel{\text{def}}{=}]\bar{x}_-, \bar{x}_+[$, where $\bar{I}$ is sufficiently small with $\bar{x} \in \bar{I}$, $\bar{I} \subset]\xi_-(\bar{t}), \xi_+(\bar{t})[$ (first for the dense set of continuity points $x = \tilde{x} \in \bar{I}$ and thus for all $x \in \bar{I}$ by our convention $y(t, x) = y(t, x-)$ for the choice of y). This shows that $y(\bar{t}, \cdot; u)$ is continuously differentiable on $\bar{I} \neq \emptyset$. Moreover $\{\bar{t}\} \times \bar{I}$ does not contain points of the shock set, since (5.1) holds, and all backward characteristics starting in $\{\bar{t}\} \times \bar{I}$ meet $t = 0$ not in x_i, $i = 1, \ldots, N$. Hence, there exists a maximal open nonempty interval I with the asserted properties.

(ii) Let $\hat{I} \stackrel{\text{def}}{=}]x_-, x_+[\neq \emptyset$ be arbitrary with closure in I. Now for any point $\bar{x} \in [x_-, x_+]$ we can argue as above and find an interval-neighborhood $\bar{I}$ with the above properties. Taking a finite covering, we get the following: Denote by $\xi_\mp$ the genuine backward characteristics through $(\bar{t}, x_\mp)$; set $z_\mp = \xi_\mp(0)$. By the finite covering, we obtain $\rho > 0$ and $\beta > 0$ such that (5.1) holds. Hence, Lemma 5.1 yields $(Y, Z, V, S(\tau), J) = \mathrm{YC}(u, \bar{t}, [z_-, z_+])$. Then we have from the proof of (i) that

$$y(\bar{t}, x; u) = Y(\bar{t}, x, u)$$

for all $x \in \hat{I}$. We show also that $y(\cdot; u) = Y(\cdot, u)$ on $S = S(\tau)$ after a possible reduction of $\tau > 0$. In fact, $(\bar{t}, x_\mp)$ are continuity points of $y(\cdot; u)$, since $y(\bar{t}, \cdot; u)$ is continuous at $x_\mp$; cf. [8]. Hence, by (5.1) and [8, Lem. 5.2], $(\bar{t}, x_\mp)$ are not shock generation points, i.e., the genuine characteristics $\xi_\mp$ remain genuine until $\bar{t} + \tau$ after a possible reduction of $\tau > 0$. Now take any $(t, x) \in S$. The extreme backward characteristics through (t, x) are genuine and may not intersect $\xi_\mp$. Hence, they stay in S and must thus coincide with $\zeta(\cdot; Z(t, x, u), u_0(Z(t, x, u)), u_1)$, which yields

$$y(t, x; u) = Y(t, x, u) \quad \forall\, (t, x) \in S.$$

Since $\hat{I} \stackrel{\text{def}}{=}]x_-, x_+[$ was an arbitrary interval with closure in I, the same arguments apply to $\tilde{I} =]x_- - 3\eta, x_+ + 3\eta[$ for $\eta > 0$ small enough, yielding, after a possible reduction of τ, that

$$y(t, x; u) = Y(t, x, u) \quad \forall\, (t, x) \in \tilde{S}, \quad Z(t, x, u) \in J \quad \forall\, (t, x) \in \tilde{S}$$

holds, where $\tilde{S} = \tilde{S}(\tau)$ is confined by the genuine backward characteristics $\tilde{\xi}_\mp$ through $(\bar{t}, x_\mp \mp 3\eta)$. We can clearly choose $\tau > 0$ small enough such that with $\tilde{t} = \bar{t} + \tau$ the inequalities $\tilde{\xi}_-(\tilde{t}) < \xi_-(\tilde{t}) - 2\eta$ and $\tilde{\xi}_+(\tilde{t}) > \xi_+(\tilde{t}) + 2\eta$ hold. Now let $M_\infty > 0$ be given. We will show that there are $R > 0$, $\nu > 0$ such that after a possible reduction of V and $\tau > 0$

$$y(t, x; \hat{u}) = Y(t, x; \hat{u}) \quad \forall\, (t, x) \in S, \quad \forall\, \hat{u} \in \hat{V} \tag{5.12}$$

holds with $\hat{V}$ defined in (ii). To this purpose we note that independent of ν, R there is $M > 0$ such that $\|\hat{u}_0\|_\infty < M$ and $\|\hat{u}_1\|_\infty < M$ for all $\hat{u} \in \hat{V}$. Thus, by Theorem 4.1(i) there is $M_y > 0$ with $\|y(.; \hat{u})\|_\infty \leq M_y$ for all $\hat{u} \in \hat{V}$, and we can thus for convenience

assume (A2′) instead of (A2), ensuring with Lemma 4.4 the local Lipschitz stability of backward characteristics. Thus, if we denote by $(\zeta^{\tilde{t}}, v^{\tilde{t}})(t; x, w, u_1)$ the backward solution of (4.3) with $(\zeta^{\tilde{t}}, v^{\tilde{t}})(\tilde{t}; x, w, u_1) = (x, w)$, we can reduce V and find $\varepsilon > 0$ such that

(5.13)
$$\zeta^{\tilde{t}}(0; x, w, \hat{u}_1) \in J, \quad \zeta^{\tilde{t}}(t; x, w, \hat{u}_1) \begin{cases} < \xi_-(t) \text{ if } x \in [\tilde{\xi}_-(\tilde{t}), \xi_-(\tilde{t}) - \eta], \\ > \xi_+(t) \text{ if } x \in [\xi_+(\tilde{t}) + \eta, \tilde{\xi}_+(\tilde{t})], \end{cases} \quad t \in [0, \tilde{t}],$$

whenever $\hat{u} \in \hat{V}$, $|w - y(\tilde{t}, x; u)| \le \varepsilon$. Now we have for $I_R = [-R, R]$ with sufficiently large $R > 0$ by Theorem 4.1(ii) the local L^1-stability estimate

$$\|y(\tilde{t}, \cdot; \hat{u}) - y(\tilde{t}, \cdot; u)\|_{1, [\tilde{\xi}_-(\tilde{t}), \tilde{\xi}_+(\tilde{t})]} \le C \left(\|\hat{u}_0 - u_0\|_{1, I_R} + \|\hat{u}_1 - u_1\|_{1, [0,T] \times I_R} \right) \tag{5.14}$$

for all $\hat{u} \in \hat{V}$ with C only depending on f, g, u, V, M_∞. From (5.14) and the definition of $\hat{V}$ we deduce that for $\nu > 0$ small enough

$$\operatorname*{ess\,inf}_{x \in I(\tilde{\xi}_\mp(\tilde{t}), \xi_\mp(\tilde{t}) \mp \eta)} |y(\tilde{t}, \cdot; \hat{u}) - y(\tilde{t}, \cdot; u)| < \frac{C\nu}{\eta} \le \varepsilon \tag{5.15}$$

whenever $\hat{u} \in \hat{V}$. Since $y(\tilde{t}, \cdot; \hat{u}) \in BV_{loc}(\mathbb{R})$, we obtain by combining (5.13) and (5.15) that for any $\hat{u} \in \hat{V}$ we can find continuity points $\hat{x}_\mp \in I(\tilde{\xi}_\mp(\tilde{t}), \xi_\mp(\tilde{t}) \mp \eta)$ of $y(\tilde{t}, \cdot; \hat{u})$ such that the genuine backward characteristics $\hat{\xi}_\mp(t) = \zeta^{\tilde{t}}(t; \hat{x}_\mp, y(\tilde{t}, \hat{x}_\mp; \hat{u}), \hat{u}_1)$ satisfy (5.13) with $x = \hat{x}_\mp$, $w = y(\tilde{t}, \hat{x}_\mp; \hat{u})$, respectively. Since $\hat{\xi}_\mp(0) \in J$, we must have $\hat{\xi}_\mp(0) = Z(\tilde{t}, \hat{x}_\mp, \hat{u})$ and therefore $y(\tilde{t}, \hat{x}_\mp; \hat{u}) = Y(\tilde{t}, \hat{x}_\mp, \hat{u})$. Now any genuine backward characteristic ξ of $y(\cdot; \hat{u})$ through $(t, x) \in S$ may not leave the area confined by the genuine characteristics $\hat{\xi}_\mp$. Therefore, $\xi(0) \in J$ and ξ must by Lemma 5.1 coincide with the unique genuine forward characteristic starting in $Z(t, x, \hat{u})$ and, consequently, $y(t, x; \hat{u}) = Y(t, x, \hat{u})$. Thus, (5.12) is proven. ∎

5.2. Differentiability in the interior of rarefaction waves (Case R^c). In a second step, we look at continuity points of class R^c, i.e., located outside the shock set in the interior of a rarefaction wave. Then (4.8), (4.9) hold with $\bar{z} = x_i$, $u_0(\bar{z}-) < u_0(\bar{z}+)$ for some $i \in \{1, \dots, N\}$ and some $\bar{w} \in]u_0(\bar{z}-), u_0(\bar{z}+)[$. Moreover, we obtain from (4.19) by continuity $w_- < \bar{w} < w_+$ and $\beta, \rho > 0$ with

$$\frac{d}{dw} \zeta(t; \bar{z}, w, u_1) \ge \beta t > 0 \quad \forall\, t \in]0, \bar{t}], \quad \forall\, w \in]w_- - \rho, w_+ + \rho[\stackrel{\text{def}}{=} J_w. \tag{5.16}$$

Then we can locally solve (4.8) yielding with (4.9) a representation for rarefaction waves.

5.2.1. Solution of the characteristic equations. The following lemma is a counterpart of Lemma 5.1 for the solution of (4.8) w.r.t. $\bar{w}$ and the resulting properties of y in (4.9).

LEMMA 5.6. *Let assumptions* (A2)–(A3) *hold, let* $(u_0, u_1) \in PC^1(\mathbb{R}; x_1, \dots, x_N) \times L^\infty(0, T; C^1(\mathbb{R})^m)$, *and let* (5.16) *hold for some* $\beta, \rho > 0$. *Then there is* $\tau > 0$ *and a neighborhood* $V_1 \subset L^\infty(0, T; C^1(\mathbb{R})^m)$ *of* u_1 *such that*

$$\frac{d}{dw} \zeta(t; \bar{z}, w, \hat{u}_1) \ge \frac{\beta}{2} t > 0 \quad \forall\, (t, w) \in]0, \bar{t} + \tau] \times J_w, \quad \forall\, \hat{u}_1 \in V_1. \tag{5.17}$$

Moreover, for all $\hat{u}_1 \in V_1$ and all (t,x) in the stripe

$$S \stackrel{\text{def}}{=} \{(t,x) \,:\, t \in]0, \bar{t}+\tau], x \in [\xi_-(t), \xi_+(t)]\}\,, \quad \xi_\mp(t) = \zeta(t; \bar{z}, w_\mp, u_1),$$

the equation

$$x = \zeta(t; \bar{z}, w, \hat{u}_1) \tag{5.18}$$

has in J_w a unique solution $w = W(t,x,\hat{u}_1)$. Set

$$Y_r(t,x,\hat{u}_1) \stackrel{\text{def}}{=} v(t; \bar{z}, W(t,x,\hat{u}_1), \hat{u}_1). \tag{5.19}$$

Then $W(\cdot,\hat{u}_1), Y_r(\cdot,\hat{u}_1) \in C^{0,1}(S \cap \{t \geq \tilde{t}\})$ for any $\tilde{t} \in]0,\bar{t}[$ and the mappings

$$(x,\hat{u}_1) \in\ ]\xi_-(t), \xi_+(t)[\times V_1 \longmapsto (W,Y_r)(t,x,\hat{u}_1), \quad t \in]\tilde{t}, \bar{t}+\tau[\,, \tag{5.20}$$

$$\hat{u}_1 \in V_1 \longmapsto (W,Y_r)(\cdot,\hat{u}_1) \in C(S \cap \{t \geq \tilde{t}\})^2 \tag{5.21}$$

are continuously Fréchet differentiable. The derivatives of (5.20) *are*

$$d_{(x,u_1)} W(t,x,\hat{u}_1) \cdot (\delta x, \delta u_1) = \frac{\delta x - \delta\zeta(t; \bar{z}, w, \hat{u}_1; 0, 0, \delta u_1)}{\delta\zeta(t; \bar{z}, w, \hat{u}_1; 0, 1, 0)}, \tag{5.22}$$

$$\begin{aligned} d_{(x,u_1)} Y_r(t,x,\hat{u}_1) \cdot (\delta x, \delta u_1) = {} & \delta v(t; \bar{z}, w, \hat{u}_1; 0, 1, 0)\ d_{(x,u_1)} W(t,x,\hat{u}_1) \cdot (\delta x, \delta u_1) \\ & + \delta v(t; \bar{z}, w, \hat{u}_1; 0, 0, \delta u_1), \end{aligned} \tag{5.23}$$

where $w = W(t,x,\hat{u}_1)$ and $(\delta\zeta, \delta v)$ are given by (4.12). *The derivative of* (5.21) *is*

$$d_{u_1}(W,Y_r)(\cdot,\hat{u}_1) \cdot \delta u_1 = d_{(x,u_1)}(W,Y_r)(\cdot,\hat{u}_1) \cdot (0, \delta u_1). \tag{5.24}$$

Finally, there is $C > 0$ such that

$$|d_{u_1}(W,Y_r)(\cdot,\hat{u}_1) \cdot \delta u_1| \leq C\, t\, \|\delta u_1\|_{L^\infty(0,T;C(\mathbb{R}))} \quad \text{in } S,$$

which allows a continuous extension to $(0,\bar{z})$ by the value 0.

Proof. Except for the last assertion the proof is very similar to the one of Lemma 5.1 and therefore omitted. For the last statement we observe that with a generic constant C an application of Gronwall's lemma to (4.12) yields $|\delta v(t; \bar{z}, w, \hat{u}_1; 0, 0, \delta u_1)| \leq C\, t\, \|\delta u_1\|_{L^\infty(0,T;C(\mathbb{R}))}$ and then $|\delta\zeta(t; \bar{z}, w, \hat{u}_1; 0, 0, \delta u_1)| \leq C\, t^2\, \|\delta u_1\|_{L^\infty(0,T;C(\mathbb{R}))}$ by the first equation in (4.12). Using this together with (5.17) in (5.22), (5.23) gives the asserted bound. ∎

NOTATION 5.7. *Given $\bar{t}, \bar{z}, w_-, w_+$ satisfying* (5.16) *for some $\beta, \rho > 0$, we indicate by*

$$(Y_r, W, V_1, S(\tau), J_w) = \mathrm{YR}(u, \bar{t}, \bar{z}, [w_-, w_+])$$

that the open interval $J_w \supset [w_-, w_+]$, the stripe $S = S(\tau)$, the neighborhood V_1, and the functions Y_r, Z are obtained by applying Lemma 5.6.

REMARK 5.8. *By construction, $Y_r(\cdot,\hat{u}_1) \in C^{0,1}(S \cap \{t > \tilde{t}\})$ is for any $\tilde{t} \in]0,\bar{t}[$ on $S \cap \{t > \tilde{t}\}$ a classical solution of* (1.1) *for the control $\hat{u}_1 \in V_1$.*

REMARK 5.9. *It can easily be verified that $\delta Y = d_{u_1} Y_r(\cdot, u_1) \cdot \delta u_1 \in C(S)$ is a broad solution of the linearized equation*

$$\begin{aligned} &\partial_t \delta Y + \partial_x (f'(Y_r)\delta Y) = g_y(t,x,Y_r,\hat{u}_1)\delta Y + g_{u_1}(t,x,Y_r,\hat{u}_1)\delta u_1, \quad (t,x) \in S, \\ &\lim_{(t,x)\in S, t\to 0} \delta Y(t,x) = 0. \end{aligned}$$

Moreover, using the same arguments as in Remark 5.4, δY *is also a weak solution, and for every domain* $D \subset S$ *with Lipschitz boundary and any* $p \in C(D)$ *with* $p \in C^{0,1}(D \cap \{t \geq \tilde{t}\})$ *for all* $\tilde{t} \in]0, \bar{t}[$, *the identity* (5.11) *holds. This follows by integrating by parts over* $D \cap \{t > \tilde{t}\}$ *and letting* $\tilde{t} \to 0$.

5.2.2. Differentiability result in continuity points of type $\mathbf{R^c}$. Using Lemma 5.6 we obtain the following regularity result at continuity points that are located on the interior of a rarefaction wave.

LEMMA 5.10 (differentiability properties in continuity points of class R^c). *Let* (A2)–(A3) *hold and let* $u = (u_0, u_1) \in PC^1(\mathbb{R}; x_1, \dots, x_N) \times L^\infty(0, T; C^1(\mathbb{R})^m)$. *Let* $(\bar{t}, \bar{x}) \in \Omega_T$ *be a point of continuity of* $y = y(\cdot; u)$ *outside the shock set such that with* $\bar{z}$, $\bar{w}$ *in* (4.8), (4.9), $u_0(\bar{z}-) < \bar{w} < u_0(\bar{z}+)$ *holds. Then the following statements are true:*

(i) *There is a maximal nonempty open interval* I *such that* $\{\bar{t}\} \times I$ *does not contain points of the shock set and such that all backward characteristics through* $(\bar{t}, x)$, $x \in I$, *meet* $t = 0$ *in* $\bar{z}$. $y(\bar{t}, \cdot; u)$ *is continuously differentiable on* I.

(ii) *Let* J *be an arbitrary neighborhood of* $\bar{z}$. *Let* $\hat{I} =]x_-, x_+[$ *be an arbitrary interval with closure in* I, *and denote by* $\xi_\mp$ *the genuine backward characteristics through* $(\bar{t}, x_\mp)$ *and by* $w_\mp \in]u_0(\bar{z}-), u_0(\bar{z}+)[$ *the corresponding values of* $\bar{w}$ *in* (4.8), (4.9). *Then there are* $\beta > 0$, $\rho > 0$ *such that* (5.16) *is satisfied. Using Notation* 5.7 *let* $(Y_r, W, V_1, S(\tau), J_w) = \mathrm{YR}(u, \bar{t}, \bar{z}, [w_-, w_+])$ *be obtained according to Lemma* 5.6. *Given* $M_\infty > 0$ *and* $\tilde{t} \in]0, \bar{t}[$ *there are* $R > 0$, $\nu > 0$ *such that after a possible reduction of* τ *and* V_1 *the following holds:*

$$y(t, x; \hat{u}) = Y_r(t, x, \hat{u}_1) \quad \forall\, (t, x) \in S \cap \left\{t \geq \tilde{t}\right\}, \quad \forall\, \hat{u} \in \hat{V}, \quad \textit{where}$$
$$\hat{V} \stackrel{\text{def}}{=} \{(\hat{u}_0, \hat{u}_1) \in L^\infty(\mathbb{R}) \times L^\infty(0, T; C^1(\mathbb{R})^m) \ : \ \hat{u}_1 \in V_1, \|\hat{u}_0 - u_0\|_{\infty, \mathbb{R} \setminus J} < M_\infty,$$
$$\|\hat{u}_0 - u_0\|_{\infty, J} < \nu, \quad \|\hat{u}_0 - u_0\|_{1, [-R, R] \setminus J} < \nu\}.$$

Hence, the differentiability properties of Y_r *according to Lemma* 5.6 *hold also for* $y|_S$.

Proof. The proof is very similar to the proof of Lemma 5.5, and we only sketch the differences. One has to use (4.19) instead of (4.16) to obtain the applicability of Lemma 5.6. Then by backward stability all characteristics ξ starting in continuity points $(\bar{t}, \tilde{x})$ close to $(\bar{t}, \bar{x})$ must hit $t = 0$ in $\bar{z}$, since $y(t, \xi(t))$ converges for $t \to 0$, $\tilde{x} \to \bar{x}$ to $\bar{w} \in]u_0(\bar{z}-), u_0(\bar{z}+)[$. Now by Lemma 5.6 the same arguments as in the proof of Lemma 5.5 can be used. Finally, one shows with the L^1-stability estimate that for sufficiently small $\nu > 0$, $\tau > 0$ and V_1 also the backward characteristics of $y(\cdot; \hat{u})$, $\hat{u} \in \hat{V}$, through $(\hat{t}, \hat{x}) \in S \cap \left\{t \geq \tilde{t}\right\}$ must hit $t = 0$ in $\bar{z}$. ∎

Before we proceed to the more involved analysis of shock points in section 6, we consider continuity points of class CB^c and continuity points of class RB^c, i.e., on the boundary of a rarefaction wave.

5.3. Differentiability in continuity points of class $\mathbf{CB^c}$. Next we consider the situation of continuity points $(\bar{t}, \bar{x})$ of class CB^c, i.e., outside of the shock set such that the backward characteristic ξ through $(\bar{t}, \bar{x})$ meets $t = 0$ in a point $\bar{z} = x_i$, $i \in \{1, \dots, N\}$, where u_0 is continuous. Then u_0 is not necessarily differentiable at $\bar{z} = x_i$, and a shift-variation of u_0 can create a discontinuity at x_i, since it allows locally a variation in $PC^1(J; x_i)$ with an interval J containing x_i. Therefore, the

entropy solution $y(\cdot;\hat{u})$ for varied controls $\hat{u}$ can develop a shock or rarefaction wave arbitrarily close to $(\bar{t},\bar{x})$.

We have observed in section 4.3 that the one-sided derivatives in $\bar{z}$ satisfy (4.16). Thus, if we define the C^1-prolongations

$$\begin{aligned} u_0^- &\stackrel{\text{def}}{=} u_0|_{\{z<\bar{z}\}} + (u_0(\bar{z}-) + u_0'(\bar{z}-)(\cdot-\bar{z}))|_{\{z\geq\bar{z}\}}, \\ u_0^+ &\stackrel{\text{def}}{=} u_0|_{\{z>\bar{z}\}} + (u_0(\bar{z}+) + u_0'(\bar{z}+)(\cdot-\bar{z}))|_{\{z\leq\bar{z}\}}, \end{aligned} \tag{5.25}$$

then there are $z_- < \bar{z} < z_+$, $\rho,\beta > 0$ such that (5.1) holds for $u_0^\mp$ instead of u_0. Thus, Lemma 5.1 is applicable for $u_0^\mp$ instead of u_0, yielding with Notation 5.2

$$(Y_\mp, Z_\mp, V_\mp, S_\mp(\tau), J) = \mathrm{YC}(u_0^\mp, u_1, [z_-, z_+]).$$

Now it is obvious from Lemma 5.1 and (5.25) that for $\delta > 0$ small enough and

$$V = \{\hat{u} = (\hat{u}_0, \hat{u}_1) \in \mathcal{V} : \ \|\hat{u} - u\|_{\mathcal{V}} < \delta\}, \quad \mathcal{V} \stackrel{\text{def}}{=} PC^1(J;\bar{z}) \times L^\infty(0,T;C^1(\mathbb{R})^m) \tag{5.26}$$

that the mappings

$$\hat{u} \in V \longmapsto (Z_\mp, Y_\mp)(\cdot, \hat{u}_0^\mp, \hat{u}_1) \in C(S_\mp) \tag{5.27}$$

are continuously differentiable. The next lemma shows that piecing together $Y_\mp$ along ξ yields a first order approximation of $y(\cdot,\hat{u})$ in u for $\hat{u} \in V$.

Lemma 5.11 (differentiability properties in continuity points of class CB^c). *Let* (A2)–(A3) *hold and let* $(\bar{t},\bar{x})$ *be a continuity point of* $y(\cdot;u)$ *of type* CB^c, *i.e., outside of the shock set such that the backward characteristic* ξ *through* $(\bar{t},\bar{x})$ *meets* $t = 0$ *in a continuity point* $\bar{z} = x_i$, $i \in \{1,\dots,N\}$, *of* u_0. *As explained above, define the prolongations* $u_0^\mp$ *in* (5.25) *and let* $z_- < \bar{z} < z_+$ *be close enough to* $\bar{z}$ *such that Lemma* 5.1 *can be applied for* $u_0^\mp$, *yielding with Notation* 5.2 $(Y_\mp, Z_\mp, V_\mp, S_\mp(\tau), J) = \mathrm{YC}(u_0^\mp, u_1, [z_-, z_+])$. *Finally, let* $V, \mathcal{V}$ *be defined as in* (5.26) *with* $\delta > 0$ *small enough. Then the mapping*

$$\begin{aligned} &\hat{u} \in V \longmapsto \tilde{y}(\cdot;\hat{u}) \in C(S_- \cap \{x \leq \xi(t)\}) \cap C(S_+ \cap \{x > \xi(t)\}), \\ &\tilde{y}(t,x;\hat{u}) \stackrel{\text{def}}{=} \begin{cases} Y_-(t,x,\hat{u}_0^-|_J,\hat{u}_1), & (t,x) \in S_- \cap \{x \leq \xi(t)\}, \\ Y_+(t,x,\hat{u}_0^+|_J,\hat{u}_1), & (t,x) \in S_+ \cap \{x > \xi(t)\} \end{cases} \end{aligned} \tag{5.28}$$

is continuously Fréchet differentiable.

For any $M_\infty > 0$ *there are* $R > 0$, $\nu > 0$ *and a neighborhood* $\hat{I} =]x_-, x_+[$ *of* $\bar{x}$ *such that with*

$$\begin{aligned} \hat{V} \stackrel{\text{def}}{=} \{(\hat{u}_0,\hat{u}_1) \in L^\infty(\mathbb{R}) \times L^\infty(0,T;C^1(\mathbb{R})^m) \ : \ &(\hat{u}_0|_J, \hat{u}_1) \in V, \\ &\|\hat{u}_0 - u_0\|_{\infty,\mathbb{R}\setminus J} < M_\infty, \|\hat{u}_0 - u_0\|_{1,[-R,R]\setminus J} < \nu\}, \end{aligned}$$

where V *is given in* (5.26), *for all* $r \in [1,\infty[$

$$\lim_{\substack{\hat{u}\in\hat{V} \\ \|\hat{u}-u\|_{\mathcal{V}}\to 0}} \frac{\|y(\bar{t},\cdot;\hat{u}) - \tilde{y}(\bar{t},\cdot;\hat{u})\|_{r,\hat{I}}}{\|\hat{u}-u\|_{\mathcal{V}}} = 0$$

holds. In particular, $\hat{u} \in (\hat{V}, \|\cdot\|_{\mathcal{V}}) \longmapsto y(\bar{t},\cdot;\hat{u}) \in L^r(\hat{I})$ *is Fréchet differentiable at* u.

Proof. The construction of J, V, $Z_\mp$, and $Y_\mp$ was already justified above. Set $J_\mp = J \cap \{\mp(z-\bar z)>0\}$. Moreover, since (5.27) are continuously Fréchet differentiable, the same is true for (5.28). Since $(\bar t, x)$ is a continuity point outside the shock set, we know that (5.1) holds on an interval J containing $\bar z$ for u_0 (and also for $u_0^\mp$ instead of u_0), and we obtain, as at the beginning of the proof of Lemma 5.5, $x_- < \bar x < x_+$ such that

$$y(\bar t, x; u) = \tilde y(\bar t, x; u) \quad \forall\, x \in \hat I \stackrel{\text{def}}{=}]x_-, x_+[.$$

Given $M_\infty > 0$ and $\varepsilon > 0$ we thus find by Lemma 5.5(ii) $R > 0$ and $\nu > 0$ such that after a possible reduction of δ (and hence V in (5.26)) one has

$$y(\bar t, x; \hat u) = \tilde y(\bar t, x; \hat u) \quad \forall\, x \in \hat I \setminus [\bar x - \varepsilon/2, \bar x + \varepsilon/2], \quad \forall\ \hat u \in \hat V. \tag{5.29}$$

Hereby we have used the fact that $\hat u_0|_{J_\mp} = \hat u_0^\mp|_{J_\mp}$. One easily sees that $R > 0$ and $\nu > 0$ can be chosen independent of $\varepsilon > 0$. In particular, for $\varepsilon > 0$ small enough the genuine backward characteristics $\hat\xi_\mp$ of $y(\cdot;\hat u)$ through $(\bar t, \bar x \mp \varepsilon)$ satisfy $\hat\xi_\mp(0) = Z_\mp(\bar t, \bar x \mp \varepsilon, \hat u) \in J$, and thus $\xi(0) \in J$ holds for all genuine backward characteristics ξ through $(\bar t, x)$, $|x - \bar x| \le \varepsilon$. Let x be an arbitrary continuity point with $|x - \bar x| \le \varepsilon$ and set $z = \xi(0)$. Then we obviously have

$$\begin{aligned} |y(\bar t, x; \hat u) - y(\bar t, x; u)| &\le |v(\bar t; z, \hat u_0(z), \hat u_1) - v(\bar t; z, u_0(z), u_1)| \\ &\quad + L_x |\zeta(\bar t; z, \hat u_0(z), \hat u_1) - \zeta(\bar t; z, u_0(z), u_1)| \\ &\le (1 + L_x) L (|\hat u_0(z) - u_0(z)| + \|\hat u_1 - u_1\|_{L^\infty(0,T;C(\mathbb{R}))}), \end{aligned}$$

where L_x is a Lipschitz constant of $y(\bar t, \cdot; u)$ on $\hat I$, and L is a Lipschitz constant of v; cf. Lemma 4.4. Moreover, $y(\bar t, x; u)$ coincides with $Y_-(\bar t, x, u_0^-, u_1)$ if $x < \bar x$ and with $Y_+(\bar t, x, u_0^+, u_1)$ if $x > \bar x$. Thus, using the local Lipschitz continuity of (5.27), we obtain with a constant $L_Y > 0$

$$|\tilde y(\bar t, x; \hat u) - y(\bar t, x; u)| \le \max\big(|Y_\mp(\bar t, x, \hat u_0^\mp, \hat u_1) - Y_\mp(\bar t, x, u_0^\mp, u_1)|\big) \le L_Y \|\hat u - u\|_{\mathcal{V}}.$$

This together gives, for $r \in [1, \infty[$,

$$\|y(\bar t, \cdot; \hat u) - \tilde y(\bar t, \cdot; \hat u)\|_{r,\hat I} \le C\, \varepsilon^{1/r}\, \|\hat u - u\|_{\mathcal{V}}$$

with $C > 0$ independent of $\hat u \in \hat V$ and ε. In view of (5.29) the proof is complete by letting ε tend to zero. ∎

5.4. Differentiability on the boundary of rarefaction waves (Case RB^c). Finally, we consider continuity points $(\bar t, \bar x)$ of class RB^c, i.e., outside the shock set and on the boundary of a rarefaction wave. If $(\bar t, \bar x)$ is for concreteness on the left boundary of a rarefaction wave, then the backward characteristic meets $t = 0$ in a discontinuity $\bar z = x_i$ of u_0 with $u_0(x_i-) < u_0(x_i+)$, and (4.8), (4.9) hold with $\bar w = u_0(x_i-)$. Finally (4.16) holds for the left-sided, (4.19) for the right-sided derivative, respectively. Hence, using Notation 5.7 we get

$$(Y_r, W, V_1, S_+(\tau), J_w) = \mathrm{YR}(u, \bar t, \bar z, [w_-, w_+])$$

by Lemma 5.6 for suitable $w_- < \bar w < w_+$ and with Notation 5.2

$$(Y_-, Z_-, V_-, S_-(\tau), J) = \mathrm{YC}(u_0^-, u_1, [z_-, z_+])$$

by Lemma 5.1 for suitable $z_- < \bar{z} < z_+$, where u_0^- is the C^1-prolongation (5.25). For V according to (5.26) with $\delta > 0$ small enough we can achieve that $\hat{u} \in V$ implies $\hat{u}_1 \in V_1$ and $(\hat{u}_0^-, \hat{u}_1) \in V_-$. Now it is obvious that $Y_-(\cdot, \hat{u})$ and $Y_r(\cdot, \hat{u}_1)$ can be glued together continuously along the forward characteristic $\hat{\xi}(t) \stackrel{\text{def}}{=} \zeta(t; \bar{z}, \hat{u}_0(\bar{z}-), \hat{u}_1)$ for all $\hat{u} \in V$, yielding a classical solution on $(S_- \cap \{x \le \hat{\xi}(t)\}) \cup (S_+ \cap \{x > \hat{\xi}(t)\})$. The next lemma shows that this function coincides locally with $y(\cdot; \hat{u})$.

LEMMA 5.12 (differentiability properties in continuity points of class RB^c). *Let* (A2)–(A3) *hold and let* $(\bar{t}, \bar{x})$ *be a continuity point of* $y(\cdot; u)$ *outside the shock set on the boundary of a rarefaction wave (Case* RB^c*), i.e., the backward characteristic meets* $t = 0$ *in* $\bar{z} = x_i$ *with* $u_0(\bar{z}-) < u_0(\bar{z}+)$*, and* (4.8), (4.9) *hold with* $\bar{w} = u_0(\bar{z}-)$ *or* $\bar{w} = u_0(\bar{z}+)$.

Given $M_\infty > 0$ *there are* $\delta > 0$, $R > 0$, *and* $\nu > 0$ *such that, with* V *according to* (5.26) *and* $\tilde{V}$ *as in Lemma* 5.11, *the following holds:*

$\hat{\xi} \stackrel{\text{def}}{=} \zeta(\cdot; \bar{z}, \hat{u}(\bar{z}-), \hat{u}_1)$ *is on* $[0, \bar{t}]$ *for all* $\hat{u} \in \hat{V}$ *a genuine forward characteristic of* $y(\cdot; \hat{u})$ *through* $(0, \bar{z})$. *Furthermore:*

(i) *If* $\bar{w} = u_0(\bar{z}-)$, *then let* $(Y_-, Z_-, V_-, S_-(\tau), J) = \mathrm{YC}(u_0^-, u_1, [z_-, z_+])$ *as well as* $(Y_r, W, V_1, S_+(\tau), J_w) = \mathrm{YR}(u, \bar{t}, \bar{z}, [w_-, w_+])$ *be defined as explained above. Then there is a neighborhood* $\hat{I} =]x_-, x_+[$ *of* $\bar{x}$ *such that for all* $\hat{u} \in \hat{V}$

$$y(\bar{t}, x; \hat{u}) \stackrel{\text{def}}{=} \begin{cases} Y_-(\bar{t}, x, \hat{u}_0^-, \hat{u}_1), & x \in]x_-, \hat{\xi}(\bar{t})[\,, \\ Y_r(\bar{t}, x, \hat{u}_1), & x \in]\hat{\xi}(\bar{t}), x_+[\end{cases} \tag{5.30}$$

holds. If $\hat{V}$ *is equipped with the norm*

$$\|(\hat{u}_0, \hat{u}_1)\|_{\mathcal{V}} \stackrel{\text{def}}{=} \|\hat{u}_0\|_{C^1(J_-)} + \|\hat{u}_1\|_{L^\infty(0,T;C^1(\mathbb{R}))},$$

where $J_- \stackrel{\text{def}}{=} J \cap \{z < \bar{z}\}$, *then*

$$\hat{u} \in (\hat{V}, \|\cdot\|_{\mathcal{V}}) \longmapsto y(\bar{t}, \cdot; \hat{u}) \in L^r(\hat{I}) \tag{5.31}$$

is continuously Fréchet differentiable for all $r \in [1, \infty[$ *with derivative*

$$\begin{aligned} d_u y(\bar{t}, \cdot; \hat{u}) \cdot (\delta u_0, \delta u_1) = {} & \mathbf{1}_{]x_-, \hat{\xi}(\bar{t})[}(d_u Y_-(\bar{t}, \cdot, \hat{u}_0^-, \hat{u}_1) \cdot (\delta u_0|_{J_-}, \delta u_1)) \\ & + \mathbf{1}_{]\hat{\xi}(\bar{t}), x_+[}(d_{u_1} Y_r(\bar{t}, \cdot, \hat{u}_1) \cdot \delta u_1). \end{aligned}$$

(ii) *If* $\bar{w} = u_0(\bar{z}+)$, *a completely analogous result holds with left state* Y_r *and right state* Y_+ *obtained from* $(Y_+, Z_+, V_+, S_+(\tau), J) = \mathrm{YC}(u_0^+, u_1, [z_-, z_+])$.

Proof. We only sketch the proof, since it is similar to the proof of Lemma 5.11. First, we obtain that (5.30) holds for u and an appropriate neighborhood $\hat{I}$ of $\bar{x}$. For given $M_\infty > 0$ and $\varepsilon > 0$, we conclude, by applying Lemmas 5.5 and 5.10, that (5.30) holds also on $\hat{I} \cap \{|x - \bar{x}| > \varepsilon/2\}$ for all $\hat{u} \in \hat{V}$ with $\hat{V}$ as in Lemma 5.11 and V as in (5.26). Hence, $y(\bar{t}, x; \hat{u})$ for $x \in [\bar{x} - \varepsilon, \bar{x} + \varepsilon]$ depends only on the values of $\hat{u}_0$ on J_-. But gluing together $Y_-(\cdot, \hat{u})$ and $Y_r(\cdot, \hat{u}_1)$ along $\hat{\xi}$ yields a classical solution that is compatible with the initial data $\hat{u}_0|_{J_-}$ and coincides with $y(\cdot; \hat{u})$ along all genuine backward characteristics through $(\bar{t}, x)$, $x \in \hat{I} \setminus [\bar{x} - \varepsilon, \bar{x} + \varepsilon]$. Hence, (5.30) holds by the uniqueness of entropy solutions.

From (5.30) the continuous differentiability of (5.31) is obvious, since by Lemmas 5.1 and 5.6 the mappings $\hat{u} \in (\hat{V}, \|\cdot\|_{\mathcal{V}}) \longmapsto (Y_-(\bar{t}, \cdot; \hat{u}_0^-, \hat{u}_1), Y_r(\bar{t}, \cdot; \hat{u}_1)) \in C(\hat{I})^2$ are continuously Fréchet differentiable, the functions on the right remain bounded in $C^1(\hat{I})$ on $\hat{V}$, and $\hat{\xi}(\bar{t})$ depends Lipschitz continuously on $\hat{u}$. The formula for the derivative is obvious. ∎

6. Stability of shocks and differentiability of shock position. We turn now to the study of points $(\bar{t},\bar{x})$ in the shock set. Hereby, the following nondegeneracy of shocks will be important.

DEFINITION 6.1 (nondegeneracy of shocks). *Let $u_0 \in PC^1(\mathbb{R};x_1,\dots,x_n)$. A point $(\bar{t},\bar{x}) \in \Omega_T^{cl}$ of the shock set is called* nondegenerate *if $(\bar{t},\bar{x})$ is not a shock interaction point and moreover is of type C^cC^c, R^cR^c, C^cR^c, or R^cC^c according to section* 4.4.

We will show that for a nondegenerate shock point $(\bar{t},\bar{x})$ the following holds for quite general variations $(\hat{u}_0,\hat{u}_1)$ of (u_0,u_1):

- The shock is stable and separates states that coincide locally with representations Y or Y_r obtained by Lemma 5.1 or 5.6, respectively.

Moreover, if $g(t,x,y,u)$ is affine linear w.r.t. y, then the following hold:

- The shock position depends Fréchet differentiably on $(\hat{u}_0,\hat{u}_1)$.
- The sensitivity of the shock position w.r.t. $(\hat{u}_0,\hat{u}_1)$ can be explicitly computed by the adjoint formula (3.8).

6.1. Stability and structure of shocks. The nonlinear stability of shock waves for a single convex conservation law (i.e., $f''>0$, $g\equiv 0$) under variations of the initial data in the Schwartz space $\mathcal{S}$ was shown by Golubitsky and Schaeffer [14]. However, there seem to be no results in the literature on the nonlinear stability of shocks under perturbations of initial data and source term that are directly applicable in our framework. In the following lemma we give a stability result of shock waves based on generalized characteristics that fits our purposes.

For concreteness we consider a shock point $(\bar{t},\bar{x})$ of class $\mathrm{C}^c\mathrm{C}^c$ (see section 4.4).

LEMMA 6.2 (stability of nondegenerate shocks of type $\mathrm{C}^c\mathrm{C}^c$). *Let* (A2)–(A3) *hold, let $u=(u_0,u_1)\in PC^1(\mathbb{R};x_1,\dots,x_N)\times L^\infty(0,T;C^1(\mathbb{R})^m)$, and let $(\bar{t},\bar{x})\in\Omega_T$ be a point of discontinuity of $y(.;u)$ on a shock curve $\eta(t)$. Denote by $\xi_\mp(t)$ the minimal and maximal backward characteristic through $(\bar{t},\bar{x})$ and set $\bar{z}^\mp=\xi_\mp(0)$. Assume that $(\bar{t},\bar{x})$ is a nondegenerate shock point of class C^cC^c according to Definition* 6.1*, i.e., $(\bar{t},\bar{x})$ is not a shock interaction point, $\bar{z}^\mp\neq x_i$, $1\le i\le N$, and* (4.16) *holds with $\bar{z}=\bar{z}^\mp$ for some $\beta>0$. Then there are $z_-^\mp<\bar{z}^\mp<z_+^\mp$, $\rho>0$, and $\beta>0$ such that* (5.1) *holds.*

Using Notation 5.2 *let $(Y_\mp,Z_\mp,V_\mp,S_\mp(\tau),J_\mp)=\mathrm{YC}(u,\bar{t},[z_-^\mp,z_+^\mp])$ be obtained by Lemma* 5.1 *with $z_\mp^-$, $z_\mp^+$ close enough to $\bar{z}^\mp$, respectively. After a possible reduction of $V_\mp$, $\tau>0$ there is a neighborhood $I=]x_-,x_+[$ of $\bar{x}$ such that the following hold:*

(i) *$y(\cdot;u)$ is locally given by*

$$y(t,x;u)=\begin{cases} Y_-(t,x,u), & (t,x)\in S_-\cap\{x<\eta(t)\},\\ Y_+(t,x,u), & (t,x)\in S_+\cap\{x>\eta(t)\}.\end{cases}$$

(ii) *Let $M_\infty>0$ be given. Then there are $R>0$, $\nu>0$ such that for*

$$\hat{V}=\{(\hat{u}_0,\hat{u}_1)\in L^\infty(\mathbb{R})\times L^\infty(0,T;C^1(\mathbb{R})^m):(\hat{u}_0,\hat{u}_1)\in V_-\cap V_+,\ \|\hat{u}_0\|_\infty<M_\infty,\ \|\hat{u}_0-u_0\|_{1,[-R,R]}<\nu\}$$

equipped with the norm

$$\|(\hat{u}_0,\hat{u}_1)\|_{\mathcal{V}}\overset{\text{def}}{=}\|\hat{u}_0\|_{C^1(J_-\cup J_+)}+\|\hat{u}_0\|_{1,[\bar{z}^-,\bar{z}^+]}+\|\hat{u}_1\|_{L^\infty(0,T;C^1(\mathbb{R}))},$$

there is a Lipschitz continuous function

$$x_s:\hat{u}\in(\hat{V},\|\cdot\|_{\mathcal{V}})\longmapsto x_s(\hat{u}) \tag{6.1}$$

with $x_s(u) = \bar{x}$ such that for all $\hat{u} = (\hat{u}_0, \hat{u}_1) \in \hat{V}$ the following holds:

$$y(\bar{t}, x; \hat{u}) = \begin{cases} Y_-(\bar{t}, x, \hat{u}_0|_{J_-}, \hat{u}_1), & x \in]x_-, x_s(\hat{u})[\,, \\ Y_+(\bar{t}, x, \hat{u}_0|_{J_+}, \hat{u}_1), & x \in]x_s(\hat{u}), x_+[\,. \end{cases} \tag{6.2}$$

Hereby, $\hat{u} \in (\hat{V}, \|\cdot\|_{\mathcal{V}}) \longmapsto Y_\mp(\bar{t}, \cdot, \hat{u}_0|_{J_\mp}, \hat{u}_1) \in C(I)$ are continuously Fréchet differentiable.

REMARK 6.3. *We note that all results so far require only* (A2)–(A3) *but not* (A4). *See also Remark* 8.1.

Proof. $(\bar{t}, \bar{x})$ is a point of discontinuity on a shock curve η. Thus, we have by Oleinik's entropy condition (4.1) that $y(\bar{t}, \eta(\bar{t})-; u) > y(\bar{t}, \eta(\bar{t})+; u)$. Since (4.16) holds for $\bar{z} = \bar{z}^\mp$ we obtain by continuity $\beta > 0$, $J_\mp$ such that (5.1) holds. Now Lemma 5.1 yields $(Y_\mp, Z_\mp, V_\mp, S_\mp(\tau), J_\mp) = \mathrm{YC}(u, \bar{t}, [z_-^\mp, z_+^\mp])$ as asserted. By Lemma 5.1 and the definition of $\hat{V}$ in (ii)

$$(\hat{u}_0, \hat{u}_1) \in (\hat{V}, \|\cdot\|_{\mathcal{V}}) \longmapsto Y_\mp(\bar{t}, \cdot, \hat{u}_0|_{J_\mp}, \hat{u}_1) \in C(I)$$

are obviously continuously Fréchet differentiable.

(i) Since $(\bar{t}, \bar{x})$ is not a shock interaction point, we know from [8] that $\bar{t}$ is a continuity point of $t \longmapsto y(t, \eta(t)\pm; u)$. Then by [8, Thm. 4.5] $(\bar{t}, \bar{x})$ is a continuity point of $y(\cdot; u)$ relative to the sets $\mathcal{L}_- = \{(t, x) : x < \eta(t)\}$, $\mathcal{L}_+ = \{(t, x) : x > \eta(t)\}$, the limit being $y(\bar{t}, \eta(\bar{t})\mp; u)$. The extreme backward characteristics $\xi_\mp(t)$ through $(\bar{t}, \bar{x})$ satisfy (4.3) and $\xi_\mp(0) = \bar{z}_\mp \in J_\mp$. Using the backward stability of solutions of (4.3) we find $\delta > 0$ such that the genuine backward characteristic through any continuity point in $Q_\mp \stackrel{\text{def}}{=} \mathcal{L}_\mp \cap \{\|(t, x) - (\bar{t}, \bar{x})\|_\infty \le \delta\}$ meets $t = 0$ in $J_\mp$, respectively. Hence, we must have $y(t, x; u) = Y_\mp(t, x, u)$ for any continuity point in $Q_\mp$, and since the continuity points are dense, for all points in $Q_\mp$ by our convention $y(t, x) = y(t, x-)$. The same is clearly true on the domain covered by these backward characteristics. Possibly after reducing $\tau > 0$ and choosing $z_\mp^-$, $z_\mp^+$ closer to $\bar{z}_\mp$, respectively, we achieve that $S_\mp \cap \mathcal{L}_\mp$ is covered by the backward characteristics through $Q_\mp$. Hence, (i) is proven.

(ii) For notational convenience we write y instead of $y(\cdot; u)$. By the definition of $S_\mp$ it is clear that for sufficiently small $\tau > 0$, $\sigma > 0$ and $x_\mp = \bar{x} \mp \sigma$ one has

$$Q \stackrel{\text{def}}{=}]\bar{t} - \tau, \bar{t} + \tau[\times]x_-, x_+[\subset S_- \cap S_+.$$

Set $I \stackrel{\text{def}}{=}]x_-, x_+[$. As in the proof of Lemma 5.5 there is $M_y > 0$ with $\|y(\cdot; \hat{u})\|_\infty \le M_y$ for all $\hat{u} \in \hat{V}$, and we may choose M_y such that in addition $|Y_\mp(\cdot, \hat{u})| \le M_y$ on $S_\mp$.

By continuity, we may reduce τ such that for some $\Delta > 0$

$$y(t, \eta(t)-) - y(t, \eta(t)+) \ge 2\Delta > 0 \quad \forall\, t \in]\bar{t} - \tau, \bar{t} + \tau[.$$

Since $f'' \ge m_{f''} > 0$, we have for $|t - \bar{t}| < \tau$

$$\dot{\eta}(t) = \frac{f(y(t, \eta(t)-)) - f(y(t, \eta(t)+))}{y(t, \eta(t)-) - y(t, \eta(t)+)} \begin{cases} \le f'(y(t, \eta(t)-)) - m_{f''}\Delta, \\ \ge f'(y(t, \eta(t)+)) + m_{f''}\Delta. \end{cases}$$

In particular, $\dot{\eta}(t)$ is continuous in $\bar{t}$, and we may reduce $V_\mp$, ν, τ, σ such that with $\varepsilon > 0$ the following hold:

$$f'(Y_-(t, x, \hat{u})) \ge \max_{|t-\bar{t}|<\tau} \dot{\eta}(t) + \varepsilon, \tag{6.3}$$

$$Y_-(t, x, \hat{u}) - Y_+(t, x, \hat{u}) \ge \Delta \tag{6.4}$$

for all $(t, x, \hat{u}) \in Q \times \hat{V}$. Finally, reduce $\tau > 0$ such that $\eta(t) \in I$ and

$$|\dot{\eta}(t) - \max_{|t-\bar{t}|<\tau} \dot{\eta}(t)| < \frac{m_{f''}\varepsilon}{8M_{f''}} =: \hat{\varepsilon} \tag{6.5}$$

for all t, $|t - \bar{t}| < \tau$, where $M_{f''} \stackrel{\text{def}}{=} \sup_{|y|\le M_y} f''(y)$.

The following property of genuine backward characteristics will be crucial: Let $\zeta(t)$ be a backward characteristic such that

$$|\zeta(\hat{t}) - \eta(\hat{t})| < \delta, \quad \dot{\zeta}(\hat{t}) < \dot{\eta}(\hat{t}) - 2\hat{\varepsilon} \quad \text{for some } \hat{t} \in [\bar{t} - \tau/2, \bar{t}]. \tag{6.6}$$

From (4.3) we get a constant $M > 0$ with

$$|\ddot{\zeta}(t)| \le M,$$

and we can reduce $\tau > 0$ such that $M\tau < \hat{\varepsilon}/2$. Then

$$\zeta(t) - \eta(t) > \delta \quad \text{for } t = \bar{t} - \tau \text{ if } \delta < \hat{\varepsilon}\tau/8.$$

In fact, by using (6.5) we get the following with $s = \min_{|t-\bar{t}|<\tau} \dot{\eta}(t)$ and $t = \bar{t} - \tau$:

$$\begin{aligned}
\zeta(t) - \eta(t) &\ge \zeta(\hat{t}) - \eta(\hat{t}) + (s - \dot{\zeta}(\hat{t}))(\hat{t} - t) - \tfrac{M}{2}(\hat{t} - t)^2 \\
&\ge -\delta + (s - \dot{\eta}(\hat{t}) + 2\hat{\varepsilon})(\hat{t} - t) - \tfrac{M}{2}(\hat{t} - t)^2 \\
&\ge -\delta + (-\hat{\varepsilon} + 2\hat{\varepsilon} - M\tau)\frac{\tau}{2} \ge \frac{\hat{\varepsilon}\tau}{4} - \delta > \delta.
\end{aligned}$$

Fix these τ and δ and set $Q_\delta \stackrel{\text{def}}{=} Q \cap \{(t, x) : |x - \eta(t)| < \delta\}$. Using a finite covering of $(Q^{cl} \cap \mathcal{L}_\mp) \setminus Q_\delta$ with the stripes S obtained by Lemma 5.5 for varying t, we may reduce $V_\mp$, ν such that for all $\hat{u} \in \hat{V}$

$$y(t, x; \hat{u}) = Y_\mp(t, x, \hat{u}_0|_{J_\mp}, \hat{u}_1) \quad \forall\, (t, x) \in (Q \cap \mathcal{L}_\mp) \setminus Q_\delta, \tag{6.7}$$

respectively. For the rest of the proof it is convenient to set $Y_\mp(\cdot, \hat{u}) = Y_\mp(\cdot, \hat{u}_0|_{J_\mp}, \hat{u}_1)$ for $\hat{u} \in \hat{V}$ on $S_\mp$.

Assume that (6.2) does not hold for all $\hat{u} \in \hat{V}$. Then there is $\hat{u} \in \hat{V}$ and without restriction a continuity point $\hat{x}$, $|\hat{x} - \bar{x}| < \delta$ with $y(\bar{t}, \hat{x}; \hat{u}) \ne Y_\mp(\bar{t}, \hat{x}, \hat{u})$ and thus $\hat{\xi}(0) < \inf J_+$ for the genuine backward characteristic $\hat{\xi}$ through $(\bar{t}, \hat{x})$. For convenience we set $\hat{y} \stackrel{\text{def}}{=} y(\cdot; \hat{u})$. Let $\tilde{x}$ be the infimum of these $\hat{x}$. $(\bar{t}, \tilde{x})$ cannot be a continuity point, since otherwise by continuity $\tilde{\xi}(0) \in J_-$ for the backward characteristic $\tilde{\xi}$ through $(\bar{t}, \tilde{x})$, and thus by Lemma 5.5 $\hat{y}(\bar{t}, x) = Y_-(\bar{t}, x, \hat{u})$ for x close enough to $\tilde{x}$, which is a contradiction. Thus, $(\bar{t}, \tilde{x})$ lies on a shock. We set $\tilde{\eta}(\bar{t}) = \tilde{x}$. By construction the maximal backward characteristic $\tilde{\xi}_+$ through $(\bar{t}, \tilde{x})$ satisfies $\sup J_- < \tilde{\xi}_+(0) < \inf J_+$. Since genuine characteristics may intersect only at their end points, we have by (6.7) necessarily that $(t, \tilde{\xi}_+(t)) \in Q_\delta$ for $\bar{t} - \tau < t \le \bar{t}$. Moreover, it is obvious from $\sup J_- < \tilde{\xi}_+(0) < \inf J_+$ that $\hat{y}(t, \tilde{\xi}_+(t)) \ne Y_\mp(t, \tilde{\xi}_+(t), \hat{u})$ for $\bar{t} - \tau < t \le \bar{t}$. Thus, we find as above for all these t a discontinuity point $\tilde{\eta}(t)$ with left state $Y_-(t, \tilde{\eta}(t), \hat{u})$. Now the unique forward characteristic through $(t - \tau, \tilde{\eta}(t - \tau))$ must be a shock, and it must coincide with $\tilde{\eta}$, since every $(t, \tilde{\eta}(t))$ lies on a shock with left state $Y_-(t, \tilde{\eta}(t), \hat{u})$ and therefore cannot be a shock generation point. Hence, $\tilde{\eta}(t)$ is a shock with left state $Y_-(t, \tilde{\eta}(t), \hat{u})$, and we must have $|\tilde{\eta}(t) - \eta(t)| < \delta$ for $\bar{t} - \tau < t \le \bar{t}$, because $\tilde{\eta}$ may not enter the domain of continuity. Hence, there must exist $\hat{t} \in [\bar{t} - \tau/2, \bar{t}]$ with

$$\dot{\tilde{\eta}}(\hat{t}) \le \max_{|t-\bar{t}|<\tau} \dot{\eta}(t) + \hat{\varepsilon} \tag{6.8}$$

because $\hat{\varepsilon}\tau/2 > 2\delta$ by the choice of δ. Set $y_\mp = \hat{y}(\hat{t}, \tilde{\eta}(t)\mp)$. We show that necessarily $f'(y_+) \le s - 2\hat{\varepsilon}$ with $s = \min_{|t-\bar{t}|<\tau} \dot{\eta}(t)$ as defined above. If not, then we have by (6.3)

$$h \stackrel{\text{def}}{=} f'(y_-) - f'(y_+) \ge s + \varepsilon - (s - 2\hat{\varepsilon}) \ge \varepsilon + 2\hat{\varepsilon} > \varepsilon.$$

Moreover, $y_- - y_+ \ge \frac{h}{M_{f''}}$, and thus with $f'' \ge m_{f''}$ and (6.5)

$$\dot{\tilde{\eta}}(\hat{t}) = \frac{f(y_-) - f(y_+)}{y_- - y_+} \ge f'(y_+) + \frac{m_{f''} h}{2M_{f''}} > s - 2\hat{\varepsilon} + \frac{m_{f''} h}{2M_{f''}} > \max_{|t-\bar{t}|<\tau} \dot{\eta}(t) - 3\hat{\varepsilon} + 4\hat{\varepsilon}.$$

This contradicts (6.8). We conclude that the maximal backward characteristic ζ through $(\hat{t}, \tilde{\eta}(\hat{t}))$ satisfies the scenario (6.6), since $\dot{\zeta}(\hat{t}) = f'(y_+) \le s - 2\hat{\varepsilon}$. Therefore, it would hold $\zeta(\hat{t} - \tau) - \eta(\hat{t} - \tau) > \delta$. This is a contradiction, since then ζ would intersect $\tilde{\xi}_+$. Hence, the assumption was wrong and (6.2) is shown.

It remains to show that $\hat{u} \in (\hat{V}, \|\cdot\|_{\mathcal{V}})) \mapsto x_s(\hat{u})$ is Lipschitz. But this follows directly from (6.2), (6.4) and the L^1-stability according to Theorem 4.1(ii). The continuous differentiability of $\hat{u} \longmapsto Y_\mp(\bar{t}, \cdot, \hat{u}) \in C(I)$ was already shown at the beginning of the proof. ∎

Very similar results can be obtained if left and/or right states are rarefaction waves, i.e., in the Cases $\mathrm{C}^c\mathrm{R}^c$, $\mathrm{R}^c\mathrm{C}^c$, $\mathrm{R}^c\mathrm{R}^c$. See Corollary 6.5 below.

6.2. Differentiability of the shock position and an adjoint formula. We come now to the key point of our analysis. In this subsection we state a differentiability result for the shock position x_s of Lemma 6.2 and derive an explicit formula for the derivative by using an appropriate adjoint state. The advantage of the adjoint approach lies in the fact that we do not have to impose regularity assumptions on y for $t < \bar{t}$.

LEMMA 6.4 (differentiability of shock position and adjoint formula, Case $\mathrm{C}^c\mathrm{C}^c$). *With the assumptions and notations of Lemma* 6.2 *let* $J_0 =]\bar{z}_-, \bar{z}_+[\setminus (J_- \cup J_+)$ *and let* $J_s \subset J_0$ *be an open set that contains only down-jumps of* u_0. *Finally, let* $J \subset J_s$ *be an open set with* $J^{cl} \subset J_s$ *and set* $J_r = J_0 \setminus J$. *Define with* $\hat{V}$ *from Lemma* 6.2

$$\tilde{V} \stackrel{\text{def}}{=} \{(\hat{u}_0, \hat{u}_1) \in \hat{V} \ : \ \partial_x(\hat{u}_0 - u_0)|_{J_s} \le M_L\}$$

for some fixed $M_L > 0$ *equipped with the norm*

$$\|(\hat{u}_0, \hat{u}_1)\|_{\tilde{\mathcal{V}}} \stackrel{\text{def}}{=} \|\hat{u}_0\|_{C^1(J_- \cup J_+)} + \|\hat{u}_0\|_{\infty, J_r} + \|\hat{u}_0\|_{1,J} + \|\hat{u}_1\|_{L^\infty(0,T;C^1(\mathbb{R}))}.$$

Then the following hold:

(i) *Assume that* (A4) *holds, i.e.,* g *is affine linear w.r.t.* y. *Then the shock position*

$$x_s : \hat{u} \in (\tilde{V}, \|\cdot\|_{\tilde{\mathcal{V}}}) \longmapsto x_s(\hat{u})$$

is continuously Fréchet differentiable and

$$d_u x_s(\hat{u}) \cdot (\delta u_0, \delta u_1) = (p(0, \cdot), \delta u_0)_2 + (p\, g_{u_1}(\cdot, \hat{y}, \hat{u}_1), \delta u_1)_{2,\Omega_{\bar{t}}}, \tag{6.9}$$

where p *is the reversible solution of the adjoint equation*

$$\partial_t p + f'(\hat{y})\partial_x p = -g_y(t, x, \hat{y}, \hat{u}_1)p, \quad p(\bar{t}, \cdot) = p^{\bar{t}}, \tag{6.10}$$

$$p(\bar{t}, \cdot) = \frac{1}{[y(\bar{t}, x_s(\hat{u}); \hat{u})]}\, \mathbf{1}_{\{x = x_s(\hat{u})\}}(\cdot). \tag{6.11}$$

Denoting by $\hat{\xi}_{\mp}$ *the minimal/maximal backward characteristic of* $\hat{y} = y(\cdot;\hat{u})$ *through* $(\bar{t}, x_s(\hat{u}))$ *and by* D *the domain confined by them, one has* $p = \hat{p}\,\mathbf{1}_{D^{cl}}(\cdot)$, *where* $\hat{p} \in C^{0,1}_{loc}((0,\bar{t})\times\mathbb{R})$ *is the reversible solution of* (6.10) *for the constant end data* $\hat{p}(\bar{t},\cdot) = 1/[y(\bar{t}, x_s(\hat{u}); \hat{u})]$.

(ii) *If* g *does not depend on* y, *then the same holds for* $x_s : \hat{u} \in (\hat{V}, \|\cdot\|_{\mathcal{V}}) \mapsto x_s(\hat{u})$ *in* (6.1), *and the reversible solution of equation* (6.10) *is simply* $p = 1/[y(\bar{t}, x_s(\hat{u}); \hat{u})]\,\mathbf{1}_{D^{cl}}(\cdot)$.

The proof of this lemma will be postponed to section 8, since part (i) requires an existence and stability result for backward transport equations of the form (6.10) that will be provided in the following section. The essential feature of the adjoint equation is that the coefficient $f'(\hat{y})$ is discontinuous but satisfies by $f'' > 0$ and Oleinik's entropy condition (4.1) a one-sided Lipschitz condition of the form

$$\partial_x f'(\hat{y}(t,\cdot)) \le \frac{C}{t + 1/M}, \quad t \in]0, T[\,,$$

where $M \in [M_{cr}, \infty]$ is such that $\partial_x \hat{u}_0 \le M$.

If the left and/or right state of the shock is a rarefaction wave, then an analogue of Lemmas 6.2 and 6.4 holds.

COROLLARY 6.5 (differentiability of shock position, Cases $\mathrm{R}^c\mathrm{C}^c$, $\mathrm{C}^c\mathrm{R}^c$, $\mathrm{R}^c\mathrm{R}^c$). *Let* $(\bar{t}, \bar{x})$ *be of class* $R^c C^c$, *i.e., with the notations of Lemmas* 6.2 *and* 6.4 $\bar{z}^- = x_i$, $i \in \{1, \dots, N\}$, *holds,* $u_0(x_i-) < \bar{w} < u_0(x_i+)$ *with* $\bar{w}$ *according to* (4.8), *and* (4.19) *holds for the left-sided derivative with* $\bar{z} = \bar{z}^-$, *while the right state is as in Lemmas* 6.2 *and* 6.4.

Using Notation 5.7 *let* $(Y_-, W, V_1, S_-(\tau), J_w) = \mathrm{YR}(u, \bar{t}, \bar{z}^-, [w_-, w_+])$ *according to Lemma* 5.6 *with appropriate* $w_- < \bar{w} < w_+$. *Then the results of Lemmas* 6.2 *and* 6.4 *remain true if we set* $J_- = \emptyset$ *and define* V_- *for an arbitrary open interval* J *containing* $\bar{z}^-$ *and* $\nu > 0$ *sufficiently small as*

$$V_- \stackrel{\text{def}}{=} \{\hat{u}_0 \in L^\infty(J) \,:\, \|\hat{u}_0 - u_0\|_\infty < \nu\} \times V_1.$$

An analogue result holds if the right state is a rarefaction wave, i.e., $\bar{z}^+ = x_i$, $u_0(x_i-) < \bar{w} < u_0(x_i+)$.

7. The adjoint equation. We consider the backward problem for a transport equation

$$\partial_t p + a\partial_x p = -bp, \quad p(T,\cdot) = p^T \tag{7.1}$$

with $b \in L^\infty(0,T; C^{0,1}(\mathbb{R}))$ and $a \in L^\infty(\Omega_T)$ satisfying the one-sided Lipschitz condition

$$a_x(t,\cdot) \le \alpha(t), \quad \alpha \in L^1(0,T), \tag{7.2}$$

or at least the weakened one-sided Lipschitz condition

$$a_x(t,\cdot) \le \alpha(t), \quad \alpha \in L^1(\sigma,T) \quad \forall\, \sigma \in (0,T). \tag{7.3}$$

The latter case is appropriate by Oleinik's entropy condition (4.1) if we want to consider the adjoint equation for solutions with rarefaction waves (generated by up-jumps of u_0). It is well known [7] that under this one-sided Lipschitz condition on a for any $p^T \in \mathrm{Lip}(\mathbb{R})$ there exists a Lipschitz continuous solution to (7.1) which is not

necessarily unique. For the case $b \equiv 0$ the stability of p w.r.t. a for the special class of *reversible solutions* was extensively studied by Bouchut and James in the recent paper [1]. We will use the results of [1] to study the stability w.r.t. a and b. Due to space limitations we will restrict ourselves to summarizing the definition of *reversible solutions* for (7.1) and the necessary existence, stability, and regularity properties.[1] A detailed analysis is given in the follow-up paper [27]. Our results extend the stability results in [1] to the case $b \neq 0$, which is not straightforward, since the definition of reversible solutions in [1] cannot be directly used.

Denote by $\mathcal{L}_h$ the space of Lipschitz continuous solutions to

$$\partial_t p + a\partial_x p = 0, \quad (t,x) \in \Omega_T. \tag{7.4}$$

We recall the following definition of [1].

DEFINITION 7.1. *$p \in \mathcal{L}_h$ is called a* reversible solution *of* (7.4) *if there exist $p_1, p_2 \in \mathcal{L}_h$ such that $\partial_x p_1 \geq 0$, $\partial_x p_2 \geq 0$, and $p = p_1 - p_2$.*

Then the following holds [1].

THEOREM 7.2. *Let $a \in L^\infty(\Omega_T)$ satisfy the one-sided Lipschitz condition* (7.2)*, i.e., $a_x(t,\cdot) \leq \alpha(t)$ with $\alpha \in L^1(0,T)$. Then for any $p^T \in \mathrm{Lip}(\mathbb{R})$ there exists a unique reversible solution $p \in C^{0,1}_{loc}(\Omega_T^{cl})$ of* (7.4) *with $p(T,\cdot) = p^T$. Moreover,*

$$\|p(t,\cdot)\|_{\infty,I} \leq \|p^T\|_{\infty,J}, \quad \|\partial_x p(t,\cdot)\|_{\infty,I} \leq e^{\int_t^T \alpha} \|\partial_x p^T\|_{\infty,J}$$

with $I =]x_1, x_2[$, $J =]x_1 - \|a\|_\infty (T-t), x_2 + \|a\|_\infty (T-t)[$.

This concept of reversible solution is not directly extendible to the case $b \neq 0$. However, a natural extension can be obtained by using the generalized backward flow associated with a defined in [1].

DEFINITION 7.3. *Let $D_b = \{(s,t) \in \mathbb{R}^2 : 0 \leq t \leq s \leq T\}$. Then the generalized backward flow $X : D_b \times \mathbb{R} \longrightarrow \mathbb{R}$ is defined by the requirement that for any $s \in]0,T]$ $X(s;\cdot,\cdot)$ is the unique reversible solution to*

$$\partial_t X + a\partial_x X = 0, \quad (t,x) \in]0,s[\times \mathbb{R}, \quad X(s;s,x) = x, \quad x \in \mathbb{R}.$$

Moreover, we set $X(0;0,x) = x$.

One can show [1] that $\partial_x X \geq 0$ and $x \longmapsto X(s;t,x)$ is surjective for all $(s,t) \in D_b$ and that for all $0 \leq t \leq \sigma \leq s \leq T$ and $x \in \mathbb{R}$ the composition formula

$$X(s;\sigma, X(\sigma;t,x)) = X(s;t,x) \tag{7.5}$$

is satisfied. Moreover, for all $(t,x) \in \Omega_T$ the following holds [1]:

$$\partial_s X(s;t,x) \in [a(s, X(s;t,x)+), a(s, X(s;t,x)-)] \quad \text{for a.a. } s \in]t,T[. \tag{7.6}$$

Note that by the one-sided Lipschitz condition $\partial_x a(t,\cdot) \leq \alpha(t)$, $\alpha \in L^1(0,T)$, the following holds: $a(t,\cdot) \in BV_{loc}(\mathbb{R})$ for a.a. t. Thus the left- and right-sided limits in (7.6) exist.

REMARK 7.4. *Since $X(t;t,x) = x$, $X(\cdot;t,x)$ is by* (7.6) *the unique forward characteristic through (t,x) in the sense of Filippov. Thus, if y is the entropy solution of* (1.1) *and $a = f'(y)$, then $X(\cdot;t,x)$ is the generalized forward characteristic through (t,x).*

[1] For convenience, the proofs are added in the appendix.

Finally, it is shown in [1] that for $b \equiv 0$ the reversible solution of (7.1) is given by $p(t,x) = p^T(X(T;t,x))$ and is thus the broad solution along the generalized characteristics. This leads us to the following definition of reversible solutions for (7.1).

DEFINITION 7.5. *Denote by $B(\mathbb{R})$ the Banach space of bounded functions equipped with the* sup*-norm and let*

$$B_{\mathrm{Lip}}(\mathbb{R}) \stackrel{\mathrm{def}}{=} \left\{ w \in B(\mathbb{R}) \colon \begin{array}{l} w \text{ is the pointwise everywhere limit of a sequence} \\ (w_n) \text{ in } C^{0,1}(\mathbb{R}),\ (w_n) \text{ bounded in } C(\mathbb{R}) \cap H^{1,1}_{loc}(\mathbb{R}) \end{array} \right\}.$$

Let $a \in L^\infty(\Omega_T)$, $\partial_x a(t,\cdot) \le \alpha(t)$, $\alpha \in L^1(0,T)$, and $b \in L^\infty(0,T;C^{0,1}(\mathbb{R}))$. Then a reversible solution of (7.1) *is defined as follows. For any $z \in \mathbb{R}$ define $p(t, X(t;0,z))$ as a solution of*

$$\begin{aligned} &p(T, X(T;0,z)) = p^T(X(T;0,z)), \\ &\tfrac{d}{dt} p(t, X(t;0,z)) = -b(t, X(t;0,z))\, p(t, X(t;0,z)), \quad t \in [0,T]. \end{aligned} \tag{7.7}$$

If it holds only that $\alpha \in L^1(\sigma,T)$ for all $\sigma > 0$, then we define p first on the domains $(\sigma,T)\times\mathbb{R}$ and then on Ω_T by exhaustion.

REMARK 7.6. *Since by* (7.5) *with $x = X(s;0,z)$, $X(t;s,x) = X(t;0,z)$ holds for $s \le t \le T$, then* (7.7) *implies that for all $0 \le s < T$ and $x \in \mathbb{R}$*

$$\begin{aligned} &p(T, X(T;s,x)) = p^T(X(T;s,x)), \\ &\tfrac{d}{dt} p(t, X(t;s,x)) = -b(t, X(t;s,x)) p(t, X(t;s,x)), \quad t \in [s,T]. \end{aligned} \tag{7.8}$$

With (7.6) *this shows that the value of $p(s,x)$ depends only on the values of a and b in the triangle $\{(t,z) \in \Omega_T \,:\, t \in [s,T], z \in [x - \|a\|_\infty (t-s), x + \|a\|_\infty (t-s)]\}$.*

With this definition of reversible solutions we have the following existence and uniqueness result under the strong one-sided Lipschitz condition (7.2).

THEOREM 7.7. *Let $a \in L^\infty(\Omega_T)$, $\partial_x a(t,\cdot) \le \alpha(t)$ with $\alpha \in L^1(0,T)$, and $b \in L^\infty(0,T;C^{0,1}(\mathbb{R}))$. Then for all $p^T \in C^{0,1}(\mathbb{R})$ there exists a unique reversible solution p of* (7.1)*. Moreover, $p \in C^{0,1}(\Omega_T)$ and p solves* (7.1) *a.e. on Ω_T.*

Furthermore, for all $t \in [0,T]$, $z_1 < z_2$, and $0 \le t_1 < t_2 \le T$, the following hold with $I = [z_1, z_2]$, $J = [z_1 - \|a\|_\infty (T-t), z_2 + \|a\|_\infty (T-t)]$:

$$\|p(t,\cdot)\|_{\infty,I} \le \|p^T\|_{\infty,J} e^{\|b\|_\infty (T-t)}, \tag{7.9}$$

$$\|p(t_2,\cdot) - p(t_1,\cdot)\|_{1,I} \le (t_2 - t_1)\, C, \tag{7.10}$$

where C depends only on I, $\|p^T\|_{H^{1,1}(J)}$, $\|a\|_{\infty,[0,T]\times J}$, $\|b\|_{L^\infty(0,T;C^{0,1}(J))}$. Finally, one has $p \in H^{1,1}(]0,T[\times I)$, where $\|p\|_{H^{1,1}(]0,T[\times I)}$ does not depend on α.

The proof can be obtained by using the properties of the backward flow X. A detailed analysis can be found in the follow-up paper [27].[2]

A key point for our analysis is the following stability result.

THEOREM 7.8. *Let (a_n) be a bounded sequence in $L^\infty(\Omega_T)$ with $a_n \to a$ in $L^\infty(\Omega_T)$-weak*, $\partial_x a(t,\cdot) \le \alpha(t)$, $\alpha \in L^1(0,T)$, and $\partial_x a_n(t,\cdot) \le \alpha_n(t)$, (α_n) bounded in $L^1(0,T)$. Let (b_n) be a bounded sequence in $L^\infty(0,T;C^{0,1}(\mathbb{R}))$ with $b_n \to b$ in $L^\infty(0,T;C_{loc}(\mathbb{R}))$, $b \in L^\infty(0,T;C^{0,1}(\mathbb{R}))$. Finally, let p_n^T be bounded in $C^{0,1}(\mathbb{R})$ with $p_n^T \to p^T$ in $C_{loc}(\mathbb{R})$. Then the reversible solutions p_n of*

$$\partial_t p_n + a_n \partial_x p_n = -b_n p_n, \quad p_n(T,\cdot) = p_n^T$$

[2]For convenience, a proof can be found in the appendix.

converge for any $R > 0$ in $C([0,T] \times [-R,R])$ to the reversible solution p of (7.1).

The proof can be obtained by using the following stability result of [1]: if X and X_n denote the backward flows according to Definition 7.3 for a and a_n, respectively, then by [1] $X_n \to X$ in $C(D_b \times [-R,R])$ for any $R > 0$. Again, the details can be found in the follow-up paper [27] and a proof can be found in the appendix.

REMARK 7.9. *Theorem* 7.8 *shows in particular that reversible solutions are stable w.r.t. smoothing of the coefficients and data by convolution with an averaging kernel.*

By Oleinik's entropy condition (4.1) the case $\alpha(t) = C/t$ is of special interest if the initial data contain an up-jump. Then merely $\alpha \in L^1(\sigma,T)$ for $\sigma > 0$ (cf. the weakened one-sided Lipschitz condition (7.3)) and Theorem 7.7 is only applicable on $]\sigma,T[\times\mathbb{R}$, $\sigma > 0$, instead of Ω_T. For $\sigma \to 0+$ this yields the definition of p on the open set Ω_T. Moreover, we see from (7.9)–(7.10) that $p \in H^{1,1}(]0,T[\times]-R,R[) \cap L^\infty(\Omega_T) \cap C^{0,1}(]0,T];L^1_{loc}(\mathbb{R}))$ for all $R > 0$ and thus admits an L^1-trace $p(0,\cdot) \in L^\infty(\Omega_T)$ with $p(t,\cdot) \to p(0,\cdot)$ as $t \to 0+$ in $L^r_{loc}(\mathbb{R})$ for all $r \in [1,\infty[$. Finally, $p \in L^\infty(0,T;H^{1,1}_{loc}(\mathbb{R}))$, and thus $p(0,\cdot) \in BV_{loc}(\mathbb{R})$. So we have the following extension of Theorem 7.8.

THEOREM 7.10. *Let the assumptions of Theorem* 7.8 *hold with the relaxation that α, α_n are only uniformly bounded in $L^1(\sigma,T)$ for each fixed $\sigma > 0$. Then there exist unique reversible solutions $p, p_n \in C^{0,1}_{loc}(\Omega_T) \cap C^{0,1}(]0,T];L^1_{loc}(\mathbb{R}))$ satisfying* (7.8) *for all $s \in]0,T[$. Moreover,* (7.9)–(7.10) *hold, p, p_n are uniformly bounded in $L^\infty(\Omega_T) \cap H^{1,1}(\Omega_T) \cap C^{0,1}(]0,T];L^1_{loc}(\mathbb{R}))$ and can thus be extended to $C^{0,1}([0,T];L^1_{loc}(\mathbb{R}))$. The traces $p(0,\cdot), p_n(0,\cdot)$ at $t = 0$ are uniformly bounded in $L^\infty(\mathbb{R}) \cap BV_{loc}(\mathbb{R})$. Finally, $p_n \to p$ in $C_{loc}(\Omega_T) \cap C([0,T];L^r_{loc}(\mathbb{R}))$ for all $r \in [1,\infty[$.*

Proof. The statements are immediately clear by Theorems 7.7 and 7.8, Remark 7.6, and the previous considerations. ∎

It will be useful for our adjoint calculus to extend reversible solutions to the case where $p^T \in B_{\mathrm{Lip}}(\mathbb{R})$ with $B_{\mathrm{Lip}}(\mathbb{R})$ as in Definition 7.5. Note that Definition 7.5 covers this case and makes perfect sense. The following theorem shows that the corresponding broad solutions are pointwise limits of Lipschitz backward solutions if p^T is in $B_{\mathrm{Lip}}(\mathbb{R})$.

THEOREM 7.11. *Let a, b be as in Theorem* 7.10. *Then for $p^T \in B_{\mathrm{Lip}}(\mathbb{R})$ the corresponding reversible solution p according to Definition* 7.5 *is unique, and $p \in B(\Omega_T)$ and satisfies* (7.9). *If $p^T_n \in C^{0,1}(\mathbb{R})$ is a sequence, bounded in $C(\mathbb{R}) \cap H^{1,1}_{loc}(\mathbb{R})$, that converges boundedly everywhere to p^T, then the corresponding reversible solutions p^n according to Theorem* 7.7 *converge boundedly everywhere to p.*

The proof follows easily by the definition of reversible solutions as broad solutions; see [27].

8. Differentiability of shock position: Proof of Lemma 6.4. We are now in the position to prove Lemma 6.4.

Proof of Lemma 6.4. We prove (i) and will easily deduce (ii). Throughout the proof we will use the notations of Lemma 6.2.

Let $\hat{u} \in \tilde{V}$ be fixed and $\tilde{u} \in \tilde{V}$ be arbitrary. In the following we write $\hat{y}$ and $\tilde{y}$ instead of $y(\cdot;\hat{u})$ and $y(\cdot;\tilde{u})$ and set $\Delta y \overset{\text{def}}{=} \tilde{y} - \hat{y}$, $\delta u = \tilde{u} - \hat{u}$.

For all sufficiently small $\varepsilon > 0$ one has

$$\hat{x}_\mp \overset{\text{def}}{=} x_s(\hat{u}) \mp \varepsilon \in]x_-, x_+[\tag{8.1}$$

with $x_\mp$ as in Lemma 6.2. Our proof is based on the observation that

$$\int_{\hat{x}_-}^{\hat{x}_+} \Delta y(\bar{t},x)\,dx = (x_s(\tilde{u}) - x_s(\hat{u}))\,[\hat{y}(\bar{t},\hat{x}_s)] + O((\varepsilon + \|\delta u\|_{\mathcal{V}})\|\delta u\|_{\mathcal{V}}). \tag{8.2}$$

In fact, let $\hat{x}_s = x_s(\hat{u})$ and $x_{s,\mp} \stackrel{\text{def}}{=} \min/\max\{x_s(\hat{u}), x_s(\tilde{u})\}$, respectively. Since obviously $[\hat{y}(\bar{t}, \hat{x}_s)] = Y_-(\bar{t}, \hat{x}_s, \hat{u}) - Y_+(\bar{t}, \hat{x}_s, \hat{u})$, we obtain by Lemma 6.2(ii)

$$\begin{aligned}
&\int_{\hat{x}_-}^{\hat{x}_+} \Delta y(\bar{t}, x)\, dx - (x_s(\tilde{u}) - x_s(\hat{u}))\, [\hat{y}(\bar{t}, \hat{x}_s)] \\
&= \int_{\hat{x}_s - \varepsilon}^{x_{s,-}} (Y_-(\bar{t}, x, \tilde{u}) - Y_-(\bar{t}, x, \hat{u}))\, dx + \int_{x_{s,+}}^{\hat{x}_s + \varepsilon} (Y_+(\bar{t}, x, \tilde{u}) - Y_+(\bar{t}, x, \hat{u}))\, dx \\
&\quad + \int_{x_{s,-}}^{\hat{x}_s} (Y_-(\bar{t}, \hat{x}_s, \hat{u}) - Y_-(\bar{t}, x, \hat{u}) + Y_+(\bar{t}, x, \tilde{u}) - Y_+(\bar{t}, \hat{x}_s, \hat{u}))\, dx \\
&\quad + \int_{\hat{x}_s}^{x_{s,+}} (Y_+(\bar{t}, \hat{x}_s, \hat{u}) - Y_+(\bar{t}, x, \hat{u}) + Y_-(\bar{t}, x, \tilde{u}) - Y_-(\bar{t}, \hat{x}_s, \hat{u}))\, dx \\
&\stackrel{\text{def}}{=} R_1 + R_2 + R_3 + R_4.
\end{aligned}$$

Using the Lipschitz continuity of $Y_\mp$ w.r.t. $\tilde{u}$ (cf. Lemma 5.1), we get

$$|R_1 + R_2| \le \varepsilon C \|\delta u\|_{\mathcal{V}}$$

with C independent of ε. Since x_s in (6.1) is Lipschitz by Lemma 6.2 and there is by Lemma 5.1 also a uniform Lipschitz constant of $Y_\mp$ w.r.t. x for all $\tilde{u} \in \tilde{V}$, we have

$$|R_3 + R_4| \le C \|\delta u\|_{\mathcal{V}}^2$$

with C not depending on ε.

Main line of the proof. The main line of the proof for the analysis of the shock sensitivity is therefore to compute the derivative of the special functional $\int_{\hat{x}_-}^{\hat{x}_+} \Delta y(\bar{t}, x)\, dx$ appearing on the left-hand side of (8.2) with $\hat{x}_\mp$ according to (8.1) by adjoint-based techniques and then to take the limit $\varepsilon \to 0$. See also the proof sketch in section 3.1.

To this end we compute the left-hand side of (8.2) by using an adjoint equation with "averaged" coefficients and then using the stability w.r.t. the coefficients to derive the actual adjoint equation for the shock sensitivity.

The difference of (1.1) for $\tilde{y}$ and $\hat{y}$ yields

$$\partial_t \Delta y + \partial_x (f(\tilde{y}) - f(\hat{y})) = g(t, x, \tilde{y}, \tilde{u}_1) - g(t, x, \hat{y}, \hat{u}_1). \tag{8.3}$$

We now define the functions

$$a \stackrel{\text{def}}{=} f'(\hat{y}), \quad \tilde{a}(t, x) \stackrel{\text{def}}{=} \int_0^1 f'(\hat{y}(t, x) + \tau \Delta y(t, x))\, d\tau, \tag{8.4}$$

$$\tilde{b} \stackrel{\text{def}}{=} g_y(\cdot, \tilde{u}_1), \quad b \stackrel{\text{def}}{=} g_y(\cdot, \hat{u}_1). \tag{8.5}$$

Then by the definition of $\tilde{a}, \tilde{b}$ and since g is affine linear in y, we can rewrite (8.3) as

$$\partial_t \Delta y + \partial_x (\tilde{a} \Delta y) = \tilde{b} \Delta y + g(t, x, \hat{y}, \tilde{u}_1) - g(t, x, \hat{y}, \hat{u}_1). \tag{8.6}$$

Let $\tilde{p}$ be a test function satisfying

$$\tilde{p} \in C^{0,1}([\sigma, \bar{t}] \times [-R, R]) \cap C([0, \bar{t}]; L^2_{loc}(\mathbb{R})) \quad \forall\, \sigma > 0, R > 0. \tag{8.7}$$

Denote by $\hat\zeta_\mp$ the genuine backward characteristic of $\hat y = y(\cdot;\hat u)$ through $(\bar t, \hat x_\mp)$. Then by (8.1) and Lemma 6.2 one has with the minimal/maximal backward characteristics $\hat\xi_\mp$ through $\hat x_s$

$$\hat\zeta_\mp(0) \in J_\mp \quad \text{and} \quad \hat\zeta_-(t) \le \hat\xi_-(t) \le \hat\xi_+(t) \le \hat\zeta_+(t) \quad \forall\, t \in [0,\bar t].$$

By Lemma 5.5 there are $\delta > 0$ and $\eta > 0$ such that $\tilde y = Y_\mp(\cdot,\tilde u)$ on $\{(t,x) \ : \ t \in [0,\bar t], |x - \hat\zeta_\mp(t)| < \delta\}$ if $\|\delta u\|_{\tilde{\mathcal{V}}} \le \eta$.

Denote by D_ε the domain between $\hat\zeta_\mp$ for $t \in [0,\bar t]$. Oleinik's entropy condition (4.1) implies $\tilde y, \hat y \in BV([\sigma,\bar t] \times [-R,R])$ for all $\sigma > 0$ and $R > 0$; see Theorem 4.1. Hence, the same is true for Δy, $\tilde a \Delta y$. Therefore, if we multiply (8.6) by $\tilde p$ satisfying (8.7) and integrate over the domain $D_\varepsilon \cap \{t \ge \sigma\}$ between $\hat\zeta_\mp$ for $t \in [\sigma,\bar t]$ we may apply integration by parts (first for $\tilde p$ in C^1 (see [11]) but then for $\tilde p$ satisfying (8.7) by a density argument in $C \cap H^{1,1}$). Now $\Delta y(\sigma,\cdot) \to \delta u_0$ and $\tilde p(\sigma,\cdot) \to \tilde p(0,\cdot)$ in $L^2_{loc}(\mathbb{R})$ as $\sigma \to 0+$ by the initial condition and (8.7). Therefore, the integration by parts can be extended until $\sigma = 0$, i.e., over all of D_ε. Since $\frac{d}{dt}\hat\zeta_\mp(t) = f'(\hat y(t,\hat\zeta_\mp(t)))$ this gives

$$\begin{aligned}
&\int_{\hat x_-}^{\hat x_+} \tilde p(\bar t,x)\Delta y(\bar t,x)\,dx \\
&= \int_{\hat\zeta_-(0)}^{\hat\zeta_+(0)} \tilde p(0,x)\delta u_0(x)\,dx + \int_0^{\bar t}\int_{\hat\zeta_-(t)}^{\hat\zeta_+(t)} \Delta y\,(\partial_t\tilde p + \tilde a\partial_x\tilde p + \tilde b\tilde p)\,dxdt \\
&\quad + \int_0^{\bar t}\int_{\hat\zeta_-(t)}^{\hat\zeta_+(t)} \tilde p\ (g(t,x,\hat y,\tilde u_1) - g(t,x,\hat y,\hat u_1))\,dxdt \\
&\quad + \int_0^{\bar t} \tilde p(t,\hat\zeta_-(t))\ (-f'(\hat y)\Delta y + f(\tilde y) - f(\hat y))(t,\hat\zeta_-(t))\,dt \\
&\quad + \int_0^{\bar t} \tilde p(t,\hat\zeta_+(t))\ (f'(\hat y)\Delta y - f(\tilde y) + f(\hat y))(t,\hat\zeta_+(t))\,dt \\
&\overset{\text{def}}{=} I_1 + I_2 + I_3 + I_4 + I_5.
\end{aligned} \tag{8.8}$$

Our aim is to choose $\tilde p$ as a reversible solution of the "averaged" adjoint equation

$$\partial_t\tilde p + \tilde a\partial_x\tilde p = -\tilde b\tilde p, \quad \tilde p(\bar t,\cdot) = p^{\bar t} \equiv 1/[y(\bar t, x_s(\hat u);\hat u)]. \tag{8.9}$$

In the following, we justify that $\tilde p$ exists and satisfies (8.7), and we study $\tilde p$ for $\tilde u \to \hat u$.

From the stability estimates of Theorem 4.1 we know that $\|\tilde y\|_\infty \le M_y$ for all $\tilde u \in \tilde V$ and

$$\|\Delta y\|_{1,loc} \to 0 \quad \text{as } \|\delta u\|_{\tilde{\mathcal{V}}} \to 0.$$

Hence, we have $\tilde a \in L^\infty(\Omega_{\bar t})$ uniformly bounded and

$$\tilde a \to f'(\hat y) \overset{\text{def}}{=} a \quad \text{in } L^1_{loc}(\Omega_{\bar t}) \text{ and in } L^\infty(\Omega_{\bar t})\text{-weak}^* \quad \text{as } \|\delta u\|_{\tilde{\mathcal{V}}} \to 0. \tag{8.10}$$

Moreover, since $f'' > 0$ we get by Oleinik's entropy condition (4.1) that there exists a constant $C > 0$ with

$$\partial_x\tilde a(t,\cdot), \partial_x a(t,\cdot) \le \frac{C}{t}. \tag{8.11}$$

By assumption (A4), the coefficients $\tilde{b}, b$ in (8.5) do not depend on y, and we have $\tilde{b}, b \in L^\infty(0,T;C^{0,1}(\mathbb{R}))$ by (A2).

Thus, (8.9) has by Theorem 7.10 a unique reversible solution $\tilde{p}$ satisfying (8.7) ($\tilde{p} \in C([0,T];L^2_{loc}(\mathbb{R}))$ follows from $\tilde{p} \in C([0,T];L^1_{loc}(\mathbb{R})) \cap L^\infty(\Omega_T)$). Denote moreover by p the reversible solution of (6.10) (i.e., of (8.9) with a, b instead of $\tilde{a}, \tilde{b}$), which exists for the same reasons by Theorem 7.10.

Let $M_u > 0$ such that $\|\tilde{u}_1\|_\infty \le M_u$ for all $\tilde{u} \in \tilde{V}$. By (A2) and (A4) g_y admits a Lipschitz constant $L_{g'}$ for u_1 on $[-M_u, M_u]^m$ and thus

$$\|\tilde{b} - b\|_{L^\infty(0,T;C(\mathbb{R}))} \le L_{g'} \|\delta u_1\|_\infty \le L_{g'} \|\delta u\|_{\tilde{\mathcal{V}}}.$$

Thus, we obtain with (8.10) by Theorem 7.10 that the reversible solutions $\tilde{p}$ of (8.9) and p of (6.10) satisfy for all $\sigma > 0$, $R > 0$

$$\tilde{p}, p \in C^{0,1}([\sigma, \bar{t}] \times [-R, R]) \tag{8.12}$$

and for all $r \in [1, \infty)$

$$\tilde{p} \to p \text{ in } C([\sigma,\bar{t}] \times [-R,R]) \cap C([0,\bar{t}];L^r(-R,R)) \quad \text{as } \|\delta u\|_{\tilde{\mathcal{V}}} \to 0. \tag{8.13}$$

We show that even

$$\|\tilde{p}(0,\cdot) - p(0,\cdot)\|_{C(J)} \to 0 \quad \text{as } \|\delta u\|_{\tilde{\mathcal{V}}} \to 0. \tag{8.14}$$

In fact, since u_0 has only admissible discontinuities (down-jumps) on J_s, there is by the definition of $\tilde{V}$ some $M_0 > 0$ with $\partial_x \tilde{u}_0|_{J_s} \le M_0$ in the sense of distributions for all $\tilde{u} \in \tilde{V}$. Since J has its closure in J_s, there exists $\rho > 0$ such that $J_{2\rho} \subset J_s$ for the 2ρ-neighborhood $J_{2\rho}$ of J. Moreover, $\|\tilde{a}\|_\infty \le M_a$ for $M_a = \sup_{|y| \le M_y} |f'(y)|$ and all $\tilde{u} \in \tilde{V}$. Thus, there is $\sigma_0 > 0$ such that

$$K_p \overset{\text{def}}{=} \{(t,x) \in [0,\bar{t}] \times \mathbb{R} : \operatorname{dist}(x,J) \le M_a t\} \subset ([0,\sigma] \times J_\rho) \cup ([\sigma,\bar{t}] \times \mathbb{R})$$

for all $\sigma \in]0, \sigma_0]$. The propagation speed of $\tilde{y}$ is uniformly bounded by M_a for all $\tilde{u} \in \tilde{V}$. Hence, there is $\sigma \in]0, \sigma_0]$ such that $\tilde{y}|_{[0,\sigma]\times J_\rho}$ does only depend on $(\tilde{u}_0|_{J_s}, \tilde{u}_1)$. Smoothing $\tilde{u}_0$ outside J_s thus yields by (4.1) that $\partial_x \tilde{y}|_{[0,\sigma]\times J_\rho} \le M_1$ for some $M_1 > 0$ and thus $\partial_x \tilde{a}|_{[0,\sigma]\times J_\rho} \le M_2$. Together with (8.11) we have, possibly after increasing M_2,

$$\partial_x \tilde{a}|_{K_p} \le M_2.$$

By Remark 7.6, $\tilde{p}|_{K_p}$ depends only on the values of $\tilde{a}$, $\tilde{b}$ on K_p. Thus, by Theorem 7.8

$$\tilde{p} \to p \text{ in } C(K_p) \quad \text{as } \|\delta u\|_{\tilde{\mathcal{V}}} \to 0,$$

which implies (8.14).

We now consider the terms $I_1, \dots, I_5$ in (8.8). Since $\tilde{p}$ solves (8.9) a.e. by Theorem 7.10, we have $I_2 = 0$. Moreover, (7.9) yields $M_p > 0$ with $\|\tilde{p}\|_\infty \le M_p$ for all $\tilde{u} \in \tilde{V}$, and we obtain by Lemma 5.1

$$|I_{4/5}| \le \int_0^{\bar{t}} M_p\, M_{f''}\, |\Delta y(t, \hat{\zeta}_\mp(t))|^2\, dt \le \bar{t}\, M_p\, M_{f''} \|Y_\mp(\cdot;\tilde{u}) - Y_\mp(\cdot;\hat{u})\|^2_{\infty, S_\mp} \le C\|\delta u\|^2_{\mathcal{V}}$$

with C independent of ε. Moreover, we have with (A2) and the dominated convergence theorem

$$\|g(\cdot,\hat{y},\tilde{u}_1) - g(\cdot,\hat{y},\hat{u}_1) - g_{u_1}(\cdot,\hat{y},\hat{u}_1)\delta u_1\|_{1,D_\varepsilon} = o(\|\delta u_1\|_\infty)$$

independently of ε. Therefore,

$$\left| I_3 - \int_{D_\varepsilon} p\, g_{u_1}(t,x,\hat{y},\hat{u}_1)\delta u_1 \, d(t,x) \right| \le \|p\|_\infty o(\|\delta u_1\|_\infty) + C\|\tilde{p}-p\|_{1,D_\varepsilon}\|\delta u_1\|_\infty$$

with C independent of ε. From the backward stability of genuine backward characteristics we find $L_\zeta > 0$ independent of ε with $|\hat{\zeta}_\mp(t) - \hat{\xi}_\mp(t)| \le L_\zeta \varepsilon$ for all $t \in [0,\bar{t}]$. Thus, we obtain with the last inequality

$$\left| I_3 - \int_0^{\bar{t}} \int_{\hat{\xi}_-(t)}^{\hat{\xi}_+(t)} p\, g_{u_1}(t,x,\hat{y},\hat{u}_1)\delta u_1 \, dxdt \right| \le C(\varepsilon + \|\tilde{p}-p\|_{1,D_\varepsilon})\|\delta u\|_{\mathcal{V}} + o(\|\delta u\|_{\mathcal{V}})$$

for some $C > 0$ independent of ε. Moreover, since $\hat{\xi}_\mp(0), \hat{\zeta}_\mp(0) \in J_\mp$

$$\begin{aligned}\left| I_1 - \int_{\hat{\xi}_-(0)}^{\hat{\xi}_+(0)} p\,\delta u_0 \, dx \right| &\le (L_\zeta\varepsilon\|\tilde{p}(0,\cdot)\|_\infty + \|(\tilde{p}-p)(0,\cdot)\|_{1,J_r\cup J_-\cup J_+})\|\delta u_0\|_{\infty,J_r\cup J_-\cup J_+} \\ &\quad + \|(\tilde{p}-p)(0,\cdot)\|_{\infty,J}\|\delta u_0\|_{1,J} \\ &\le C(\varepsilon + \|(\tilde{p}-p)(0,\cdot)\|_{1,J_r\cup J_-\cup J_+} + \|(\tilde{p}-p)(0,\cdot)\|_{\infty,J})\|\delta u\|_{\tilde{\mathcal{V}}}.\end{aligned}$$

Using the estimates for $I_1,\dots,I_5$, $R_1,\dots,R_4$ together with (8.13), (8.14), the Fréchet differentiability of $x_s : (\tilde{V}, \|\cdot\|_{\tilde{\mathcal{V}}}) \longrightarrow \mathbb{R}$ is obvious and the adjoint formula (6.9) is shown with $p\mathbf{1}_{D^{cl}}(\cdot)$ instead of p, where $D = D_0$ is the domain between $\hat{\xi}_\mp$, $0 \le t \le \bar{t}$. But it is obvious from Definition 7.5 that $p\mathbf{1}_{D^{cl}}(\cdot)$ is nothing else but the reversible solution of (6.10) for the initial data (6.10), i.e., $p^{\bar{t}} = 1/[y(\bar{t},x_s(\hat{u});\hat{u})]\,\mathbf{1}_{\{x=x_s(\hat{u})\}}(\cdot)$, since then p has automatically the support D^{cl}, and coincides on D^{cl} with the reversible solution for the end data $p^{\bar{t}} \equiv 1/[y(\bar{t},x_s(\hat{u});\hat{u})]$. In fact, p is by Definition 7.5 and Remark 7.4 transported along the backward characteristics.

The derivative is also continuous. In fact, denote by $\tilde{p}$ now the reversible solution of (8.9) with $\tilde{p}^{\bar{t}} = 1/[\tilde{y}(\bar{t},x_s(\tilde{u}))]$, $\tilde{a} = f'(\tilde{y})$, $\tilde{b} = g_y(\cdot,\tilde{u}_1)$. Then we already know that $\tilde{p}^{\bar{t}} \to p^{\bar{t}}$ in $C(\mathbb{R})$ as $\|\delta u\|_{\tilde{\mathcal{V}}} \to 0$ and $\tilde{a}$, $\tilde{b}$ have the same properties as above. Thus, we obtain again that (8.13), (8.14) hold. Together with the Lipschitz continuity of $\hat{u} \in (\tilde{V}, \|\cdot\|_{\tilde{\mathcal{V}}}) \longmapsto \hat{\xi}_\mp(\cdot) \in C([0,T])$ and the definition of $\|.\|_{\tilde{\mathcal{V}}}$ this shows immediately that the derivative of x_s is continuous.

(ii) In this case the adjoint equation has no source term and (8.9) as well as (6.10) have both the reversible solutions $\tilde{p} = p \equiv 1/[y(\bar{t},x_s(\hat{u});\hat{u})]$. Taking $(\tilde{V}, \|\cdot\|_{\tilde{\mathcal{V}}})$ instead of $(\hat{V}, \|.\|_{\mathcal{V}})$ was only necessary to ensure (8.12)–(8.14), which are now trivial. The proof is now exactly as before but less technical since $\tilde{p} = p = \text{const}$. □

REMARK 8.1. *If g is not affine linear w.r.t. y, then the mean value coefficient $\tilde{b}$ in* (8.5) *has the form*

$$\tilde{b} = \int_0^1 g_y(\cdot,\hat{y}(t,x+) + \tau\Delta y(t,x),\tilde{u}_1)\,d\tau, \tag{8.15}$$

where we define $\Delta y(t,x)$ everywhere by setting

$$\Delta y(t,x) = \max\left(\tilde{y}(t,x-) - \hat{y}(t,x+), \tilde{y}(t,x+) - \hat{y}(t,x-)\right). \tag{8.16}$$

Then $\tilde{b}$ is discontinuous at shocks of $\hat{y}$ and $\tilde{y}$. Nevertheless, we can again define solutions of the "averaged" adjoint equation (8.9) *along the characteristics as in Definition* 7.5. *But now the definition of the limit coefficient b at the shocks is important, since it influences the value of the adjoint state on the domain covered by backward characteristics emanating from both sides of the shock. Since the backward characteristics corresponding to the mean value coefficient $\tilde{a}$ propagate close to a shock of $\hat{y}$ in the area between the shock fronts of $\hat{y}$, the limit coefficient b in the adjoint equation has to be defined by*

$$b = \int_0^1 g_y(\cdot, \hat{y}(t, x+) + \tau[\hat{y}(t, x)], \tilde{u}_1)\, d\tau.$$

One can now show by the results of sections 4–8 *that $\tilde{b} \to b$ in all continuity points of $\hat{y}$ and in all nondegenerate shock points. The limit coefficient b is discontinuous, but the singular parts of $\partial_x \tilde{b}, \partial_x b$ have densities w.r.t. $\partial_x \tilde{a}, \partial_x a$, respectively. We believe that this allows us to derive at least a bound for $\tilde{p}, p$ in $H^{1,2}$.*

We briefly sketch how a stability result can be obtained in the case of a piecewise Lipschitz continuous solution with a nondegenerate shock $\hat{\eta}$: then we know that the shock is stable and also $\tilde{y}$ has a shock $\tilde{\eta}$ that connects uniformly varying Lipschitz continuous states. Denote the area between the shock fronts $\hat{\eta}$ and $\tilde{\eta}$ by S. Generalized backward characteristics of the averaged equation cannot enter S from outside. Thus they start in $\{\bar{t}\} \times I(\hat{\eta}, \tilde{\eta})$ and leave at some point $(s, \hat{\eta}(s))$ or $(s, \tilde{\eta}(s))$. They define a Lipschitz continuous function $\tilde{p}|_S$ that converges uniformly to $p(t, \hat{\eta}(t))$, the reversible solution of the limit equation along the shock. In particular, $\tilde{p}(t, \hat{\eta}(t)), \tilde{p}(t, \tilde{\eta}(t)) \to p(t, \hat{\eta}(t))$ uniformly. Outside of S, $\tilde{p}$ is obtained by integrating along the characteristics starting from the Lipschitz continuous boundary data $\tilde{p}(t, \hat{\eta}(t))$, $\tilde{p}(t, \tilde{\eta}(t))$, and $p^{\bar{t}}(x)$, $x \notin I(\hat{\eta}, \tilde{\eta})$, respectively. Thus, $\tilde{p}$ is Lipschitz continuous and converges uniformly to p, since p is obtained by integrating along the characteristics starting from the boundary data $p(t, \hat{\eta}(t))$, $p^{\bar{t}}(x)$ that are the uniform limit of the boundary data of $\tilde{p}$.

A complete study of the adjoint equation in the general case is in progress. We emphasize that our analysis extends to general source terms as soon as the stability of the adjoint state is established.

REMARK 8.2. *The applied techniques for the shock sensitivity analysis are quite universal and can formally be extended to systems. The domain D_ε must then be chosen between the fastest characteristic field through $\hat{x}_-$ and the slowest through $\hat{x}_+$ corresponding to the mean value Jacobian $\tilde{a}$. Then similar arguments can be used if appropriate stability properties of shock, state, and adjoint equation hold. The appropriate adjoint state must be stable w.r.t. the coefficients. This is an interesting and challenging topic for future research.*

9. Proof of the main results. In this section we will use the results of the previous sections to prove the main results of this section that we have already stated in section 3.

9.1. Shift-differentiability of entropy solutions. In this subsection we will prove the shift-differentiability result for entropy solutions stated in Theorem 3.2 as well as the formula for the shift derivative given in Theorem 3.4.

Proof of Theorem 3.2 *and Theorem* 3.4. The proof has three parts. We consider first shock points then continuity points.

Step 1. We show first the shift-differentiability in a neighborhood of a shock point. Set $y = y(\cdot; u)$. By assumption, $y(\bar{t}, \cdot)$ contains on I finitely many shocks

at $\bar{x}_1, \dots, \bar{x}_K$ satisfying the assumptions of Lemma 6.2 or Corollary 6.5. Let us for concreteness assume that $\bar{x}_k$ is of type $\mathrm{C}^c\mathrm{C}^c$, i.e., satisfies the scenario of Lemma 6.2. The case where left and/or right states lie on a rarefaction wave can be treated very similarly using Corollary 6.5.

Thus, for $\bar{x} = \bar{x}_k$ Lemmas 6.2 and 6.4 are applicable. We denote by $\xi_\mp$ the extreme backward characteristics through $(\bar{t}, \bar{x})$ and by D_k the confined domain. We verify that with the notation of Lemma 6.2 for $\|(w,\sigma)\|_W < \rho$, $\rho > 0$ sufficiently small, one has

(9.1)
$$u^s \stackrel{\text{def}}{=} (u_0 + w_0^s, u_1 + w_1) \in \hat{V}, \quad \|(w_0^s, w_1)\|_{\mathcal{V}} \le C\,\|(w,\sigma)\|_W \text{ for } w_0^s \stackrel{\text{def}}{=} S_{u_0}^{(x_i)}(w_0,\sigma).$$

In fact, there is $\rho > 0$ with $w_0^s|_{J_\mp} = w_0|_{J_\mp}$ whenever $\|\sigma\|_2 < \rho$, and for all $R > 0$

$$\|S_{u_0}^{(x_i)}(w_0,\sigma)\|_{1,[-R,R]} \le 2R\|w_0\|_\infty + 2\|y(\bar{t},\cdot;u)\|_\infty \|\sigma\|_1 \le C\,\|(w,\sigma)\|_W.$$

Hence, for sufficiently small $\rho > 0$, (9.1) is obvious and Lemma 6.2 holds for $\hat{u} = u^s$ according to (9.1) if $\|(w,\sigma)\|_W < \rho$. As a consequence, $y(\bar{t},\cdot;u^s)$ has in a neighborhood $\hat{I} =]x_-, x_+[$ of $\bar{x}$ the form (6.2), and the shock position $x_s(u^s)$ in (6.1) depends by (9.1) and Lemma 6.2(ii) Lipschitz continuously on $(w,\sigma) \in W$.

We now show that $(w,\sigma) \in W \mapsto x_s(u^s)$ is Fréchet differentiable at 0 by applying the differentiability result of Lemma 6.4(i). Since $S_{u_0}^{(x_i)}(w_0,\sigma)$ can create small additional up-jumps, it will be useful to introduce the slight modification

$$\tilde{S}_{u_0}^{(x_i)}(w_0,\sigma)(x) \stackrel{\text{def}}{=} w_0(x) + \sum_{i=1}^{N} [(u_0+w_0)(x_i), u_0(x_i)]_+ \operatorname{sgn}(\sigma_i)\mathbf{1}_{I(x_i, x_i+\sigma_i)}(x),$$

where

$$[(u_0+w_0)(x_i), u_0(x_i)]_+ \stackrel{\text{def}}{=} \begin{cases} [(u_0+w_0)(x_i)]_+ & \text{if } [u_0(x_i)]_+ > 0, \\ 0 & \text{else.} \end{cases}$$

Now choose the open sets J_s and $J \subset J_s$ in Lemma 6.4(i) such that J and J_s contain all down-jumps of u_0 between J_- and J_+. Then we have for $\|(w,\sigma)\|_W < \rho$, $\rho > 0$ sufficiently small, in addition to (9.1), that with $\tilde{V}, \tilde{\mathcal{V}}$ from Lemma 6.4

$$\left.\begin{array}{c} (u_0 + \tilde{w}_0^s, u_1 + w_1) \in \tilde{V} \\ \|(\tilde{w}_0^s, w_1)\|_{\tilde{\mathcal{V}}} \le C\,\|(w,\sigma)\|_W \end{array}\right\} \quad \text{for } \tilde{w}_0^s \stackrel{\text{def}}{=} \tilde{S}_{u_0}^{(x_i)}(w_0,\sigma). \tag{9.2}$$

In fact, since $\tilde{S}_{u_0}^{(x_i)}(w_0,\sigma)$ shifts only down-jumps without creating additional jumps, there are $M_L > 0$, $\rho > 0$ such that $\|(w,\sigma)\|_W < \rho$ implies $\tilde{w}_0^s|_{J_\mp \cup J_r} = w_0|_{J_\mp \cup J_r}$ and $\partial_x(u_0 + \tilde{w}_0^s)|_{J_s} \le M_L$.

We are now in the position to show that $(w,\sigma) \in W \longmapsto x_s(u^s)$ is Fréchet differentiable at 0. Consider $(\delta w, s) \in W$ with $\|(\delta w, s)\|_W < \rho$ and set

$$\hat{u} = (u_0 + \delta w_0^s, u_1 + \delta w_1), \quad \tilde{u} = (u_0 + \delta\tilde{w}_0^s, u_1 + \delta w_1)$$

with

$$\delta w_0^s = S_{u_0}^{(x_i)}(\delta w_0, s), \quad \delta\tilde{w}_0^s = S_{u_0+\delta w_0}^{(x_i)}(\delta w_0, s). \tag{9.3}$$

Then for $\|(\delta w, s)\|_W < \rho$, and by using (9.2), Lemma 6.4(i) yields

$$|x_s(\tilde{u}) - x_s(u) - d_u x_s(u) \cdot (\delta \tilde{w}_0^s, \delta w_1)| = o(\|\delta w, s\|_W).$$

Moreover, by (9.3) it holds that

$$\|\delta \tilde{w}_0^s - \delta w_0^s\|_1 \leq \|(\delta \tilde{w}_0^s, \delta w_1) - (\delta w_0^s, \delta w_1)\|_{\mathcal{V}} \leq \sum_{i=1}^{N} |[\delta w_0(x_i)]|\, |s_i| \leq C\, \|(\delta w, s)\|_W^2$$

and thus by the Lipschitz continuity of (6.1) also that

$$|x_s(\hat{u}) - x_s(u) - d_u x_s(u)(\delta w_0^s, \delta w_1)| = o(\|(\delta w, s)\|_W),$$

where we utilize that by Lemma 6.4, and by (6.9) with the reversible solution p of (6.10)–(6.11), it holds that

$$|d_u x_s(u) \cdot (\delta \tilde{w}_0^s - \delta w_0^s, 0)| \leq \|p(0,\cdot)\|_\infty \|\delta \tilde{w}_0^s - \delta w_0^s\|_1 = o(\|(\delta w, s)\|_W).$$

Finally, we have again by Lemma 6.4 with $\bar{s}_k$ according to (3.8) that

$$|d_u x_s(u) \cdot (\delta w_0^s, \delta w_1) - \bar{s}_k| \leq \sum_{i=1}^{N} [u_0(x_i)]_+ \left| \int_{x_i}^{x_i + s_i} |p(0,x) - p(0,x_i)|\, dx \right| = o(\|s\|_2),$$

where we have used that $p(0,x)$ is continuous in all down-jumps x_i; cf. (8.14) and recall that p vanishes in a neighborhood of the remaining down-jumps, since $\operatorname{supp} p = D_k^{cl}$. This concludes the proof that

$$(w_0, w_1, \sigma) \in W \longmapsto x_s(u^s) \tag{9.4}$$

is Fréchet differentiable in 0 with derivative (3.8). We can now show that

$$(w_0, w_1, \sigma) \in W \longmapsto y(\bar{t}, \cdot; u^s)|_{\hat{I}} \tag{9.5}$$

is shift-differentiable at 0. We know that (6.2) holds on $\|(w,\sigma)\|_W < \rho$. Hereby, the mappings $\bar{u} \in (\hat{V}, \|\cdot\|_{\mathcal{V}}) \longmapsto Y_\mp(\bar{t}, \cdot, \bar{u}_0|_{J_\mp}, \bar{u}_1) \in C(\hat{I})$ are continuously differentiable. We have already observed that $w_0^s|_{J_\mp} = w_0|_{J_\mp}$ on $\|(w,\sigma)\|_W < \rho$ and deduce directly from (9.1) that

$$(w_0, w_1, \sigma) \in W \longmapsto Y_\mp(\bar{t}, \cdot, u_0^s|_{J_\mp}, u_1^s) \in C(\hat{I}) \tag{9.6}$$

are continuously differentiable on $\|(w,\sigma)\|_W < \rho$. According to Remark 5.4

$$\delta Y_\mp \overset{\text{def}}{=} (d_u Y_\mp(\cdot, u) \cdot (\delta w_0|_{J_\mp}, \delta w_1))|_{S_\mp} \tag{9.7}$$

are on $S_\mp$ broad solutions of the variational equation (3.3) and satisfy on $J_\mp = S_\mp^{cl} \cap \{t = 0\}$ the initial condition (3.4). Now set

$$\delta y^{\bar{t}} = \delta Y_-(\bar{t}, \cdot)|_{]x_-, x_s(u)[} + \delta Y_+(\bar{t}, \cdot)|_{]x_s(u), x_+[} \tag{9.8}$$

as claimed in (3.7). With

$$\tilde{y}(\bar{t}, \cdot) \overset{\text{def}}{=} Y_-(\bar{t}, \cdot, \hat{u})|_{]x_-, \bar{x}[} + Y_+(\bar{t}, \cdot, \hat{u})|_{]\bar{x}, x_+[}, \quad \hat{y}(\bar{t}, \cdot) = y(\bar{t}, \cdot; \hat{u})$$

we get by (9.7), (9.8) that $\|\tilde{y}(\bar{t},\cdot) - y(\bar{t},\cdot) - \delta y\|_{\infty,\hat{I}} = o(\|\delta w, s\|_W)$ and thus

$$\begin{aligned}(9.9)\qquad &\|\hat{y}(\bar{t},\cdot) - y(\bar{t},\cdot) - S^{(\bar{x}_k)}_{y(\bar{t},\cdot)}(\delta y^{\bar{t}}, \bar{s})\|_{1,\hat{I}} \\ &\quad = \|\hat{y}(\bar{t},\cdot) - \tilde{y}(\bar{t},\cdot) - \operatorname{sgn}(\bar{s}_k)[y(\bar{t},\bar{x})]_+ \mathbf{1}_{I(\bar{x},\bar{x}+\bar{s}_k)}\|_{1,\hat{I}} + o(\|\delta w, s\|_W).\end{aligned}$$

Using (6.2) and the definition of $\tilde{y}$, we obtain

$$(9.10)\qquad \hat{y}(\bar{t},\cdot)|_{\hat{I}} - \tilde{y}(\bar{t},\cdot)|_{\hat{I}} = \operatorname{sgn}(x_s(\hat{u}) - \bar{x})(Y_-(\bar{t},\cdot,\hat{u}) - Y_+(\bar{t},\cdot,\hat{u}))\, \mathbf{1}_{I(\bar{x},x_s(\hat{u}))},$$

and since $Y_\mp(\bar{t},\cdot,\cdot)$ are Lipschitz continuous at $(\bar{x},u)$ by Lemma 5.1, we have

$$(9.11)\qquad \|Y_-(\bar{t},\cdot,\hat{u}) - Y_+(\bar{t},\cdot,\hat{u}) - [y(\bar{t},\bar{x})]\|_{\infty,I(\bar{x},x_s(\hat{u}))} = O(\|(\delta w, s)\|_W).$$

Oleinik's entropy condition yields $[y(\bar{t},\bar{x})] = [y(\bar{t},\bar{x})]_+$, and thus we have by (9.10) and (9.11)

$$\begin{aligned}&\|\hat{y}(\bar{t},\cdot) - \tilde{y}(\bar{t},\cdot) - \operatorname{sgn}(\bar{s}_k)[y(\bar{t},\bar{x})]_+ \mathbf{1}_{I(\bar{x},\bar{x}+\bar{s}_k)}\|_{1,\hat{I}} \\ &\quad = [y(\bar{t},\bar{x})]_+ |\bar{x} + \bar{s}_k - x_s(\hat{u})| + O(\|(\delta w, s)\|_W^2) = o(\|(\delta w, s)\|_W).\end{aligned}$$

Inserting this in (9.9) yields the shift-differentiability of (9.5) on $\hat{I}$ with $(\delta y^{\bar{t}}|_{\hat{I}}, \bar{s}_k) = T_{s,\hat{I}}(0)\cdot(\delta w, s)$ according to (3.7), (3.8). As mentioned above shock points with a rarefaction wave as left and/or right states can be treated similarly as in Corollary 6.5.

Step 2. We show that (9.5) is even continuously shift-differentiable on $\{\|(w,\sigma)\|_W < \rho\}$ for sufficiently small $\rho > 0$. In fact, on $\{\|(w,\sigma)\|_W < \rho\}$ the function on the right-hand side of (9.5) is of the form (6.2). Fix an arbitrary $(w,\sigma) \in W$, $\|(w,\sigma)\|_W < \rho$ and consider the corresponding control

$$(9.12)\qquad (u_0^s, u_1^s) = u^s \overset{\text{def}}{=} (u_0 + S^{(x_i)}_{u_0}(w_0,\sigma), u_1 + w_1).$$

Then u_0^s is again piecewise C^1, and u_1^s has the same regularity as u_1. Moreover,

$$u_0 + S^{(x_i)}_{u_0}(w_0 + \delta w_0, \sigma + s) = u_0^s + S^{(x_i+\sigma_i)}_{u_0^s}(\delta w_0, s);$$

i.e., varying $(\delta w, s)$ produces a shift-variation of u_0^s. Thus, the arguments of Step 1 show that (9.5) is also shift-differentiable at (w,σ). As above, the shift-derivative $(\delta y^{\bar{t},s}|_{\hat{I}}, \bar{s}^s) = T_{s,\hat{I}}(w,\sigma)\cdot(\delta w, s)$ on $\hat{I}$ is given by (3.7), (3.8) with u, y, x_i replaced by $u^s, y(.;u^s), x_i^s = x_i + \sigma_i$. Consequently, it suffices to show the continuity of the shift-derivative in 0. The continuity of (9.4) and (9.6) implies the continuity of $(w,\sigma) \longmapsto y(\bar{t}, x_s(u^s)\pm; u^s)$ for u^s according to (9.12). It remains to show that $(w,\sigma) \in W \longmapsto T_{s,\hat{I}}(w,\sigma) \in \mathcal{L}(W, L^r(\hat{I}) \times \mathbb{R})$ is continuous for some $r > 1$. Since (9.4) is continuous and (9.6) are continuously Fréchet differentiable, it is obvious from (9.7), (9.8) with u^s instead of u that the mapping $(w,\sigma) \in W \longmapsto \delta y^{\bar{t},s}|_{\hat{I}} \in L^r(\hat{I})$ depends continuously on $(w,\sigma) \in W$ in a neighborhood of 0 for all $r \in]1,\infty[$.

We denote again the extreme backward characteristics of y through $(\bar{t}, x_s(u))$ by $\xi_\mp$, the confined domain by D_k, and the extreme backward characteristics of $y^s \overset{\text{def}}{=} y(\cdot;u^s)$ through $(\bar{t}, x_s(u^s))$ by $\xi^s_\mp$. With $I_k \overset{\text{def}}{=} D_k^{cl} \cap \{t = 0\}$ we obtain by (3.8)

$$\begin{aligned}|\bar{s}_k^s - \bar{s}_k| &\le \|p^s(0,\cdot) - p(0,\cdot)\|_{1,I_k} \|\delta w_0\|_{\infty,I_k} + (\|\xi_- - \xi_-^s\|_{\infty,[0,\bar{t}]} + \|\xi_+ - \xi_+^s\|_{\infty,[0,\bar{t}]}) \\ &\quad \cdot (\|p^s(0,\cdot)\|_{\infty,J_-\cup J_+} \|\delta w_0\|_{\infty,J_-\cup J_+} + \|p^s\, g_{u_1}(\cdot, y^s, u_1^s)\|_{\infty,\Omega_{\bar{t}}} \|\delta w_1\|_{\infty,\Omega_{\bar{t}}}) \\ &\quad + \|p^s\, g_{u_1}(\cdot, y^s, u_1^s) - p\, g_{u_1}(\cdot, y, u_1)\|_{1,D_k} \|w_1\|_{\infty,D_k} \\ &\quad + \sum_{x_i \in I_k} (|[u_0^s(x_i^s)]_+ - [u_0(x_i)]_+| |p^s(0,x_i^s)| + |[u_0(x_i)]_+| |p^s(0,x_i^s) - p(0,x_i)|)\, |s_i|,\end{aligned}$$

where p is the reversible solution of (3.5) and p^s is the reversible solution of (3.5) for y^s instead of y and $x_s(u^s)$ instead of $\bar{x}_k = x_s(u)$. We deduce that

$$\sup_{\|(\delta w,s)\|_W=1} |\bar{s}_k^s - \bar{s}_k| \to 0 \quad \text{as} \quad \|(w,\sigma)\|_W \to 0$$

from the following observations. By (6.2) and the continuity of (9.4), (9.6) it follows that $\|\xi_\mp^s - \xi_\mp\|_{\infty,[0,\bar{t}]} \to 0$ as $\|(w,\sigma)\|_W \to 0$. Moreover, y^s is bounded in L^∞ with $y^s \to y$ in $L^1_{loc}(\Omega_T)$, and exactly the same arguments as in the proof of Lemma 6.4(i) show with Theorem 7.10 that for all $\tau > 0$, $R > 0$ we have $p^s, p \in C^{0,1}([\tau,\bar{t}]\times[-R,R])$ and for all $r \in [1,\infty[$

$$p^s \to p \ \text{ in } \ C([\tau,\bar{t}]\times[-R,R]) \cap C([0,\bar{t}]; L^r_{loc}(\mathbb{R})) \ \text{ as } \ \|(w,\sigma)\|_W \to 0.$$

In particular, we obtain $\|p^s\, g_{u_1}(\cdot, y^s, u_1^s) - p\, g_{u_1}(\cdot, y, u_1)\|_{1,D_k} \to 0$ by the Lebesgue dominated convergence theorem and a subsequence-subsequence argument, since g_{u_1} is by (A2) a Carathéodory function. To estimate the sum in the last term we observe that $[u_0^s(x_i+\sigma_i)] = [u_0(x_i)]$ for $\|\sigma\|_2$ small enough. We still have to show that $|p^s(0,x_i+\sigma_i) - p(0,x_i)| \to 0$ if $[u_0(x_i)]_+ \neq 0$. Recall that $p^s(0,\cdot)$, $p(0,\cdot)$ are continuous in the admissible discontinuities $x_i+\sigma_i$, x_i of u_0^s and u_0; cf. (8.14). Fix an arbitrarily small $\tau > 0$. We know that $p(\tau,\cdot) \in C^{0,1}_{loc}(\mathbb{R})$ and that $\|p^s(\tau,\cdot) - p(\tau,\cdot)\|_{C([-R,R])} \to 0$. Let η, η^s be the shocks of y, y^s emanating from x_i and $x_i+\sigma_i$, respectively. Clearly, for all $\tau > 0$ sufficiently small $y(\tau,\cdot)$ satisfies the framework of Lemma 6.2 in a neighborhood of $\eta(\tau)$. Hence, we know from the first part of the proof that $\eta^s(\tau) \to \eta(\tau)$ as $\|(w,\sigma)\|_W \to 0$. $p(t,\eta(t))$ and $p^s(t,\eta^s(t))$ satisfy by Remarks 7.4 and 7.6 an ordinary differential equation of the form (7.8). We thus obtain

$$\begin{aligned} |p^s(0,x_i^s) - p(0,x_i)| \le\ & |p^s(\tau,\eta_s(\tau)) - p(\tau,\eta(\tau))| \\ & + \tau\, \|p\, g_{u_1}(\cdot,y,u_1) - p^s\, g_{u_1}(\cdot,y^s,u_1^s)\|_{\infty,D_k}, \end{aligned}$$

and the right-hand side becomes arbitrarily small for τ and $\|(w,\sigma)\|_W$ sufficiently small.

Step 3. It remains to consider the continuity points. Since $y(\bar{t},\cdot;u)$ contains no shock generation points, all continuity points satisfy the scenario of Lemma 5.5, 5.10, 5.11, or 5.12, respectively, corresponding to the Cases C^c, R^c, CB^c, and RB^c. In Case C^c there are by Lemma 5.5(ii) $\hat{I} =]x_-, x_+[\ni \bar{x}$ and $z_- < \bar{z} < z_+$ such that for $(Y,Z,V,S,J) = \mathrm{YC}(u,\bar{t},[z_-,z_+])$ obtained by Lemma 5.1 it holds that

$$y(\bar{t},\cdot;\hat{u})|_{\hat{I}} = Y(\bar{t},\cdot;\hat{u}_0|_J, \hat{u}_1)|_{\hat{I}} \tag{9.13}$$

for all $\hat{u} \in \hat{V}$ with $\hat{V}$ defined in Lemma 5.5(ii). Hereby, $x_i \notin J$, $i = 1,\dots,N$. Let $M_\infty > 0$ be chosen large enough in the definition of $\hat{V}$. Then we find $\rho > 0$ such that on $\{\|(w,\sigma)\|_W < \rho\}$ with u^s in (9.1), $u_0^s|_J = (u_0+w_0)|_J \in C^1(J)$ holds, and moreover $u^s \in \hat{V}$. Hence, (9.13) holds on $\{\|(w,\sigma)\|_W < \rho\}$, and it follows by Lemma 5.1 that

$$(w,\sigma) \in W \longmapsto y(\bar{t},\cdot;u^s)|_{\hat{I}} \in C(\hat{I}) \tag{9.14}$$

is continuously Fréchet differentiable on $\{\|(w,\sigma)\|_W < \rho\}$. From Lemma 5.1 we have with Remark 5.4 that

$$\delta Y \overset{\text{def}}{=} (d_u Y(\cdot,u)(\delta w_0|_J, \delta w_1))|_S$$

is the broad solution of the linearized state equation (3.3) on S for initial data (3.4). Hence, the derivative of (9.14) in 0 is given by (3.7).

In Case CB^c Lemma 5.11 can be applied. Then $\bar{z} = x_i$ and u_0 is continuous (but not necessarily differentiable) in x_i. Let $\hat{I} =]x_-, x_+[\ni \bar{x}$, J with $\bar{z} = \xi(0) \in J$, and let $S_\mp$, $Y_\mp$, and $\hat{V}$ be given according to Lemma 5.11. Then for $\rho > 0$ sufficiently small we have $u^s \in \hat{V}$ on $\{\|(w,\sigma)\|_W < \rho\}$, since $u_0^s|_J = (u_0 + w_0)|_J \in PC^1(J;\bar{z})$. Hence,

$$(w,\sigma) \in W \longmapsto y(\bar{t},\cdot;u^s) \in L^r(\hat{I}) \tag{9.15}$$

is by Lemma 5.11 Fréchet differentiable at 0 for all $r \in [1,\infty[$, and the derivative coincides with the derivative of $(w,\sigma) \in W \longmapsto \tilde{y}(\bar{t},\cdot;u^s) \in L^r(\hat{I})$, where $\tilde{y}$ is defined in (5.28). Using (5.28), the derivative of (9.15) is thus clearly

$$d_u\tilde{y}(\bar{t},\cdot;u)\cdot(\delta w_0|_J, \delta w_1) = \delta Y_-(\bar{t},\cdot)|_{]x_-,\bar{x}[} + \delta Y_+(\bar{t},\cdot)|_{]\bar{x},x_+[} \overset{\text{def}}{=} \delta y^{\bar{t}}, \tag{9.16}$$

where with $S_{\mp,\xi} \overset{\text{def}}{=} S_\mp \cap \{\mp(x - \xi(t)) > 0\}$ and the prolongations $u_0^\mp$ and $w_0^\mp$ as in (5.25),

$$\delta Y_\mp = (d_u Y_\mp(\cdot; u_0^\mp|_J, u_1)\cdot(\delta w_0^\mp|_J, \delta w_1))|_{S_{\mp,\xi}}.$$

Since ξ is a genuine forward characteristic of $y(\cdot,u)$ through $(0,\bar{z})$, it is clear that $\delta Y_\mp$ depend in $S_{\mp,\xi}$ only on the values of $u_0, \delta w_0$ on $J \cap \{\mp(x-\bar{z}) > 0\}$, respectively, and are thus by Remark 5.4 on $S_{\mp,\xi}$ broad solutions of the linearized state equation (3.3) for initial values (3.4). Hence, (9.16) is exactly (3.7) on $\hat{I}$.

If $\bar{x}$ is a continuity point on a rarefaction wave (Case R^c) or on the boundary of a rarefaction wave (Case RB^c), then Lemma 5.10 or 5.12 is applicable. Now the Fréchet differentiability of (9.14) or (9.15) can be proven completely analogous. In Case R^c (9.14) is continuously Fréchet differentiable on $\{\|(w,\sigma)\|_W < \rho\}$, $\rho > 0$ small enough; in Case RB^c at least (9.15) is continuously Fréchet differentiable for all $r \in [1,\infty[$. On the rarefaction wave the broad solution δY of (3.3) in (3.7) is now defined according to Remark 5.9 and thus satisfies the initial condition (3.4).

Now combining the shift-differentiability of (9.5) in a neighborhood of a shock point and the Fréchet differentiability of (9.14) or (9.15), respectively, in a neighborhood of continuity points, the shift-differentiability of (3.2) in 0 is obvious by selecting a finite covering of I. Moreover, we have shown that $(\delta y^{\bar{t}}, \bar{s}) = T_s(0)\cdot(\delta w, s)$ is actually given by (3.7), (3.8). By using the local properties of the derivatives according to Lemmas 5.1 and 5.6 we conclude that $T_s(0) \in \mathcal{L}(W, PC(I;\tilde{x}_1,\dots,\tilde{x}_{\tilde{K}})\times\mathbb{R}^K)$ with $(\tilde{x}_k)$ comprising the shock locations and the points of class CB^c.

Consider finally the case that $u_0(x_i-) \neq u_0(x_i+)$ for all x_i. Then the scenario of Lemma 5.11, i.e., Case CB^c, does not occur. We have seen that (9.5) is continuously shift-differentiable and (9.14) in Cases C^c, R^c, or at least (9.15) for all $r \in [1,\infty[$ in Case RB^c are continuously Fréchet differentiable on $\{\|(w,\sigma)\|_W < \rho\}$, $\rho > 0$ sufficiently small. Hence, we obtain in fact continuous shift-differentiability of (3.2) on $\{\|(w,\sigma)\|_W < \rho\}$ by choosing a finite covering of I by intervals $\hat{I}$. □

Remark 9.1. *At the boundary of a rarefaction wave and along the backward characteristic through points $(\bar{t},\bar{x})$ of class CB^c, the broad solutions of the linearized equation according to Remark* 5.4 *or* 5.9 *cannot be pieced together continuously. Nevertheless, the obtained broad solution is a weak solution across the jump, since obviously the jump condition is satisfied.*

REMARK 9.2. *We have already mentioned in Remark* 3.5 *that weak solutions* δY *of the variational equation* (5.10) *can be defined on all of* $\Omega_{\bar{t}}$. *However, since the broad solutions to both sides of a shock do not in general satisfy the jump condition across shocks,* δY *is a measure with singular part at shocks. This reflects the fact that the mapping* $u \mapsto y(t,\cdot;u)$ *is at best differentiable in* $\mathcal{M}_{loc}(\mathbb{R})$–$w^*$. *For the conservative case (i.e.,* $g_y \equiv 0$, $g_{u_1} \equiv 0$*) the concept of duality solutions introduced in* [1] *yields solutions of this type; see also* [12]. *An analysis of duality solutions for the general variational equation* (5.10) *can be found in the author's habilitation thesis* [26]. *See also Remark* 3.7.

9.2. Differentiability of tracking-type functionals (proof of Theorem 3.9 and Corollary 3.10). Now since Theorems 3.2 and 3.4 are proven, also the differentiability results for tracking-type functionals (1.2), (3.19) in Theorem 3.9, and Corollary 3.10 in section 3.2 are shown. (Relying on Theorems 3.2 and 3.4 we have already proven them in section 3.2 by using Lemma 2.3.)

9.3. Adjoint calculus for tracking-type functionals (proof of Theorem 3.11). We are finally in the position to justify the adjoint-based gradient representation for tracking-type functionals (1.2), (3.19) stated in Theorem 3.11.

Proof of Theorem 3.11. The differentiability of J in (1.2), (3.19) is a direct consequence of Theorem 3.9. It remains to justify (3.24). We will show that (3.24) follows from (3.21).

We use the following notation: p denotes the reversible solution of (3.25)–(3.26) according to Theorem 7.11, which appears in (3.24). $\tilde{p}$ denotes the reversible solution of (3.25) for end data (3.23); then (3.21) holds with $\tilde{p}$ instead of p, i.e.,

$$\begin{aligned} d_{(w,\sigma)}J(y)\cdot(\delta w_0,\delta w_1,s) &= (\phi_y(y(\bar{t},\cdot),y_d),\delta y^{\bar{t}})_{2,I} \\ &\quad + (\tilde{p}g_{u_1}(\cdot,y,u_1),\delta w_1)_{2,\Omega_{\bar{t}}} + (\tilde{p}(0,\cdot),\delta w_0)_2 + \sum_{i=1}^{N}\tilde{p}(0,x_i)[u_0(x_i)]_+ s_i. \end{aligned} \tag{9.17}$$

Let D_k and S_k be defined as in Theorem 3.4. p and $\tilde{p}$ are by Definition 7.5 and Remark 7.4 transported along the backward characteristics. Hence, the values of the end data $p^{\bar{t}}$ and $\tilde{p}^{\bar{t}}$ on an interval $[x_-,x_+]$ determine the values of p and $\tilde{p}$ in the domain confined by the minimal/maximal backward characteristic through $x_\mp$, respectively. Thus, p vanishes outside the domain confined by the genuine backward characteristics through the continuity points $(\bar{t},a)$ and $(\bar{t},b)$.

Moreover, p and $\tilde{p}$ coincide on each domain D_k^{cl} and $\operatorname{supp}\tilde{p} \subset \bigcup_k D_k^{cl}$. Therefore, using the solution p for end data (3.26) we can rewrite (9.17) in the form

$$\begin{aligned} d_{(w,\sigma)}J(y)\cdot(\delta w,s) &= (p^{\bar{t}},\delta y^{\bar{t}})_{2,I} + \sum_{i=1}^{N} p(0,x_i)[u_0(x_i)]_+ s_i \\ &\quad + \sum_{k=1}^{K}\Big((p\,g_{u_1}(\cdot,y,u_1),\delta w_1)_{2,D_k} + (p(0,\cdot),\delta w_0)_{2,I_k}\Big), \end{aligned} \tag{9.18}$$

where $I_k \overset{\text{def}}{=} D_k^{cl} \cap \{t=0\}$, $k=1,\dots,K$. For the second term we have used that all down-jumps x_i are contained in the union of I_k, $k=1,\dots,K$.

We still have to rewrite the first expression on the right-hand side by means of the adjoint state. Fix an arbitrary stripe S_k. Since y is continuous on S_k, all characteristics are genuine. If S_k contains backward characteristics emanating at $t=\bar{t}$

from the finitely many discontinuities of y_d in I or forward characteristics emanating from $(0, x_i)$ with $u_0(x_i-) = u_0(x_i+)$, these characteristics divide S_k in finitely many substripes. Consider one of these substripes S. Then there are $x_- < x_+$ such that S is the domain confined by the maximal/minimal backward characteristic through $(\bar t, x_\mp)$, respectively, and Remark 5.4 applies with $Y = y(\cdot; u)$ outside of rarefaction waves, and Remark 5.9 applies with $Y_r = y(\cdot; u)$ inside of rarefaction waves. By the choice of S we have $y(\bar t, .), y_d \in C^{0,1}(]x_-, x_+[)$, and thus the function $p^{\bar t}$ in (3.26) is in $C^{0,1}(]x_-, x_+[)$. Since the reversible solution p of (3.25) depends on S only on $p^{\bar t}|_{]x_-,x_+[}$, we conclude exactly as in the proof of Lemma 6.4 that $p|_S \in C^{0,1}(S \cap \{t > \tau\}) \cap C([0, \bar t], L^2_{loc}(\mathbb{R}))$ for all $\tau > 0$. Remarks 5.4 and 5.9 thus yield (5.11) for $D = S \cap \{t > \tau\}$. Since the L^2-traces of p and y exist at $t = 0$ and $p|_S$ satisfies (3.25) a.e. by Theorem 7.7, (5.11) gives for $\tau \to 0$

$$(p^{\bar t}, \delta y^{\bar t})_{2,]x_-,x_+[} = (p(0,\cdot), \delta w_0)_{2,S^{cl}\cap\{t=0\}} + (p\, g_{u_1}(t, x, Y, u_1), \delta w_1)_{2,S};$$

see (3.18) and Remark 3.6. The boundary terms along the confining characteristics $\xi_\mp$ drop out, since the outer normal $(n_1, n_2)^T$ is a multiple of $(f'(y(t, \xi_\mp(t))), -1)^T$. Summing over all stripes S and inserting the result in (9.18) yields (3.24).

We already know from Theorem 7.10 that for all $\tau > 0$, $p|_{D_k} \in C^{0,1}(D_k \cap \{t > \tau\})$ holds and that $p|_{S_k}$ is piecewise $C^{0,1}$ on $S_k \cap \{t > \tau\}$ with discontinuities along the backward characteristics emanating from discontinuities of y_d and that the same holds for $\tau = 0$ whenever S_k or D_k contains no rarefaction wave. ∎

9.4. Nondegeneracy of shocks (proof of Theorem 3.8). We finally show that the nondegeneracy assumptions of Theorem 3.2 hold for a.a. $\bar t \in [0, T]$ under slightly stronger smoothness assumptions on (u_0, u_1).

Proof of Theorem 3.8. By [8, Lem. 4.1, Cor. 4.2] the set of shocks is at most countable, and for each shock η the functions $t \mapsto y(t, \eta(t)\mp)$ are continuous outside of an at most countable set. Thus, for all except countably many times $\bar t \in]0, T[$ for all shocks η the functions $t \mapsto y(t, \eta(t)\mp)$ are continuous at $\bar t$ and the extreme backward characteristics through $(\bar t, \eta(\bar t))$ do not propagate at the boundary of a rarefaction wave or reach $t = 0$ in one of the points x_i, $i = 1, \dots, N$, where u_0 is continuous. Denote by $B \subset]0, T[$ the set of all $\bar t$ having this property. Fix some $\bar t \in B$. If all shocks satisfy the framework of Lemma 6.2 or Corollary 6.5, i.e., are nondegenerate according to Definition 6.1, then $y(\bar t, \cdot)$ has obviously only finitely many shocks on each compact interval I and Theorem 3.2 is applicable.

Now assume that there exists a shock η and a set $R \subset B$ with outer measure $\mu^*(R) > 0$ such that η for all $\bar t \in R$ does not satisfy the framework of Lemma 6.2 or Corollary 6.5. Fix an arbitrary density point $\hat t \in R$ of R w.r.t. μ^*.

Assume for concreteness that η has no rarefaction wave as left or right state at time $\hat t$. Since $t \mapsto y(t, \eta(t)\mp)$ are continuous at $\hat t$, the left or right state is also not a rarefaction wave for all times t in a sufficiently close neighborhood S of $\hat t$, and since $\hat t \in R$ is a density point of R, we may reduce R such that $R = R \cap S$. By assumption, (4.19) must be violated for all $\bar t \in R$ with $\bar z$ being one of the intersection points $z_\mp = \xi_\mp(0; \bar t, \eta(\bar t))$ of the minimal or maximal backward characteristic of y through $(\bar t, \eta(\bar t))$ with $\{t = 0\}$. Without restriction assume that for all $\bar t \in R$ (4.19) is violated on the left side of the shock, i.e., $z(\bar t) \overset{\text{def}}{=} \bar z = \xi_-(0; \bar t, \eta(\bar t))$. Then with $F(t, z) \overset{\text{def}}{=} \frac{d}{dz}\zeta(t; z, u_0(z), u_1)$ we must have

$$F(\bar t, z(\bar t)) = 0, \quad F(t, z(\bar t)) > 0, \quad 0 \le t < \bar t \quad \forall\, \bar t \in R. \tag{9.19}$$

Since genuine backward characteristics may not intersect, the mapping $t \in S \mapsto z(t)$ is strictly monotone decreasing and thus almost everywhere differentiable. Without restriction, we may thus reduce R such that $z(t)$ is differentiable in all $\bar{t} \in R$ and still $\mu^*(R) > 0$. Now let $\tilde{t} \in R$ be a density point of R w.r.t. μ^* and set $\tilde{z} = z(\tilde{t})$. Since $F(t,z) = \delta\zeta(t; z, u_0(z), u_1; 1, u_0'(z), 0)$ we obtain from (4.12) that F is continuously differentiable w.r.t. t, and since u_0 is C^2 in a neighborhood of $\tilde{z}$ we conclude by using Lemma 4.4 and applying Proposition 4.3 to (4.12) that $(t,z) \mapsto \zeta(t; z, u_0(z), u_1)$ is C^2 in a neighborhood Q of $(\tilde{t}, \tilde{z})$. Moreover, we know from section 4.3 that $\partial_t F(\tilde{t}, \tilde{z}) \neq 0$ and hence by (9.19) that $\partial_t F(\tilde{t}, \tilde{z}) < 0$; cf. also [8, Lem. 5.5]. Since $\tilde{t} \in R$ is a density point of R, there exists a strictly monotone increasing sequence $(t_k) \subset R$ with $t_k \nearrow \tilde{t}$. By the continuity of $t \mapsto y(t, \eta(t)-)$ in $\tilde{t}$ and the stability of genuine backward characteristics we have $z(t_k) \searrow z(\tilde{t}) = \tilde{z}$ as $k \to \infty$ and thus eventually $(t_k, z(t_k)) \in Q$. Now we get by (9.19) and $\partial_t F(\tilde{t}, \tilde{z}) < 0$

$$0 = \lim_{k\to\infty} \frac{F(t_k, z(t_k)) - F(\tilde{t}, z(\tilde{t}))}{t_k - \tilde{t}} = \partial_t F(\tilde{t}, \tilde{z}) + \partial_z F(\tilde{t}, \tilde{z})\dot{z}(\tilde{t}) < \partial_z F(\tilde{t}, \tilde{z})\dot{z}(\tilde{t})$$

and deduce from $\dot{z}(\tilde{t}) \leq 0$ that $\partial_z F(\tilde{t}, \tilde{z}) = \frac{d^2}{dz^2}\zeta(\tilde{t}; z, u_0(z), u_1)|_{z=\tilde{z}} < 0$. Hence, we obtain from $z(t_k) \searrow z(\tilde{t}) = \tilde{z}$ that for all sufficiently large k

$$\zeta(\tilde{t}; z(t_k), u_0(z(t_k)), u_1) < \zeta(\tilde{t}; z(\tilde{t}), u_0(z(\tilde{t})), u_1) = \eta(\tilde{t}),$$

i.e., the continuation of the genuine characteristic through $(t_k, \eta(t_k))$ intersects the genuine backward characteristic through $(\tilde{t}, \eta(\tilde{t}))$ at some time $t \in]t_k, \tilde{t}[$ and must thus intersect the shock η a second time on $]t_k, \tilde{t}[$. This is impossible, since the angle between the genuine backward characteristics and η is bounded away from zero independently of k, and also the curvature of the continuation of the characteristics is uniformly bounded. Hence, the assumption was wrong and the hypotheses of Lemma 6.2 cannot be violated on a set of nonzero measure. Applying a similar argument in the case of a rarefaction wave as left or right state concludes the proof. ∎

10. Conclusions and future work. We have presented a sensitivity calculus for entropy solutions of hyperbolic conservation laws with source terms that is based on a first order approximation by shift-variations. The obtained shift-differentiability result for the control-to-state mapping implies differentiability properties for a large class of tracking-type functionals. For this class of functionals we have derived a gradient representation by using the adjoint state. Hereby, the adjoint state is the unique reversible solution of a transport equation with discontinuous coefficient that guarantees uniqueness only for the class of reversible solutions. These results can be used to state optimality conditions for the optimal control of flows with shocks and provide an analytical justification for the use of gradient-based methods. In particular, it turns out that the numerical scheme used to compute the adjoint state should converge to the reversible solution in order to be consistent with the original problem. Since we allow shift-variations of the initial data, the shift-differentiability result can be repeatedly used over time slabs. We plan to exploit this in the design and analysis of a class of SQP methods with time domain decomposition.

Our analysis uses structural results for the state and the stability of reversible solutions of the adjoint equation with respect to its coefficients. This approach can formally be extended to systems and multidimensional problems and yields a correct sensitivity and adjoint calculus if the necessary stability properties of state and adjoint state actually hold.

The results of section 7 on the adjoint equation are discussed in detail in the follow-up paper [27]; see also the author's habilitation thesis [26]. In [26] we also extend the results of [1] on duality solutions for the corresponding forward problem to the case with source term, which yields the correct linearization of the state equation.

We plan to use the adjoint calculus of this paper for the formulation of optimality conditions and the analysis of gradient-based methods for the optimal control of flows with shocks. For the numerical approximation we have started to analyze which schemes for the discretization of the state equation lead to numerical adjoint schemes that converge to the correct reversible adjoint state, thus yielding consistent gradient approximations. First results on the discretization of backward transport equations with discontinuous coefficients and the corresponding conservative forward problem were obtained for the case without source term by Gosse and James in the very recent paper [15]. By extending these results, we have recently [26] obtained convergence results for discrete adjoints and the corresponding gradient approximations.

Appendix. Analysis of the adjoint equation. For convenience we present proofs of the existence and stability results for the adjoint equation that we stated in section 7. For a detailed analysis we refer to our recent works [27, 26]. In [26] we consider also measure solutions for the corresponding conservative forward problem with source term.

One can show [1] that the generalized backward flow X satisfies

(A.1)
$$\|\partial_s X\|_{\infty,\overset{\circ}{D}_b\times\mathbb{R}} \le \|a\|_\infty, \quad \|\partial_t X\|_{\infty\times\mathbb{R},\overset{\circ}{D}_b} \le \|a\|_\infty e^{\int_0^T \alpha}, \quad \|\partial_x X(s;t,\cdot)\|_\infty \le e^{\int_t^s \alpha},$$

where $(s,t) \in D_b$ in the last inequality. Moreover,

$$\partial_s \partial_x X(s;t,x) \le \alpha(s)\partial_x X(s;t,x) \quad \text{for a.a. } s \in]0,T[\tag{A.2}$$

on $\overset{\circ}{D}_b \times\mathbb{R}$. Thus, for arbitrary $z_1 < z_2$ and $0 \le t \le \sigma \le s \le T$

$$X(s;t,z_2) - X(s;t,z_1) \le X(\sigma;t,z_2) - X(\sigma;t,z_1) + \int_\sigma^s \alpha(\tau)(X(\tau;t,z_2) - X(\tau;t,z_1))d\tau,$$

and hence

$$X(s;t,z_2) - X(s;t,z_1) \le (X(\sigma;t,z_2) - X(\sigma;t,z_1))e^{\int_\sigma^s \alpha} \quad \forall\, t \le \sigma \le s \le T. \tag{A.3}$$

Proof of Theorem 7.7. We show first that p is well defined. Let $(t,x) \in \Omega_T$ be arbitrary. Since $z \longmapsto X(t;0,z)$ is surjective, there is $z \in \mathbb{R}$ with $x = X(t;0,z)$. Now (7.7) defines the values of p on the curve $(s, X(s;0,z))$, $t \le s \le T$. If z is not unique, then we get for all $\tilde{z}$ with $x = X(t;0,\tilde{z})$ by (A.3) $X(s;0,\tilde{z}) = X(s;0,z)$ for all $s \in [t,T]$. Hence, the definition does not depend on the choice of z. As a simple consequence of (A.1) and (7.7) we get (7.9). Hence, there exists a unique $p \in L^\infty(\Omega_T)$ satisfying (7.7). We show that p is Lipschitz continuous. Let $z_1 < z_2$ be arbitrary. Then $\Delta p(t) \overset{\text{def}}{=} p(t, X(t;0,z_2)) - p(t, X(t;0,z_1))$ satisfies $\Delta p(T) = p^T(X(T;0,z_2)) - p^T(X(T;0,z_1))$ and

$$\tfrac{d}{dt}\Delta p(t) = -b(t, X(t;0,z_2))\Delta p(t) - (b(t, X(t;0,z_2)) - b(t, X(t;0,z_1)))p(t, X(t;0,z_1)).$$

Thus, setting $I(t) = [X(t;0,z_1), X(t;0,z_2)]$ we get for all $\tau \in [0,T]$

$$\begin{aligned}|\Delta p(\tau)| \le{}& \int_\tau^T \|b(s)\|_{\infty,I(s)} |\Delta p(s)|\,ds + |p^T(X(T;0,z_2)) - p^T(X(T;0,z_1))| \\ &+ \int_\tau^T \|p(s)\|_{\infty,I(s)} |b(s,X(s;0,z_2)) - b(s,X(s;0,z_1))|\,ds.\end{aligned} \tag{A.4}$$

Hence, we have by (A.3) with $\Delta X(t) \stackrel{\text{def}}{=} X(t;0,z_2) - X(t;0,z_1)$

$$|\Delta p(\tau)| \le \left(\|\partial_x p^T\|_\infty + \|b\|_{L^1(0,T;C^{0,1})}\|p\|_\infty\right) e^{\int_\tau^T \alpha} \Delta X(\tau) + \|b\|_\infty \int_\tau^T |\Delta p(s)|\,ds$$

and by the Gronwall lemma for all $t \in [0,T]$

$$|\Delta p(t)| \le \Delta X(t) \left(\|\partial_x p^T\|_\infty + \|b\|_{L^1(0,T;C^{0,1})}\|p\|_\infty\right) e^{(T-t)\|b\|_\infty + \int_t^T \alpha}.$$

This yields a uniform bound for $\|\partial_x p\|_\infty$. Finally, let $z \in \mathbb{R}$ and $t_1, t_2 \in [0,T]$, $t_1 < t_2$, be arbitrary; then by (A.1)

$$\begin{aligned}&|p(t_2, X(t_1;0,z)) - p(t_1, X(t_1;0,z))| \\ &\le |p(t_2, X(t_2;0,z)) - p(t_1, X(t_1;0,z))| + |p(t_2, X(t_2;0,z)) - p(t_2, X(t_1;0,z))| \\ &\le (\|b\|_\infty \|p\|_\infty + \|a\|_\infty \|\partial_x p\|_\infty)|t_2 - t_1|.\end{aligned} \tag{A.5}$$

Hence, $p \in C^{0,1}(\Omega_T)$. Finally, p solves (7.1) a.e. in Ω_T. In fact, for a.a. $(t,x) = (t, X(t;0,z))$ in Ω_T the Lipschitz-function p is differentiable. Moreover, since $a(t,\cdot) \in BV_{loc}(\mathbb{R})$ for a.a. t by the one-sided Lipschitz condition, we have $a(t,x-) = a(t,x+)$ for a.a. $(t,x) \in \Omega_T$, and thus from (7.6) we have that

$$\partial_s X(t;0,z) = a(t, X(t;0,z))$$

for a.a. $(t,x) = (t, X(t;0,z))$. Now the chain rule yields with (7.7) that (7.1) is satisfied for all of these (t,x).

Since for $w \in C^{0,1}(\mathbb{R})$, $|w|_{var} = \|\partial_x w\|_1$ holds, we obtain by summing (A.4) for suitable $z_1^0 < z_2^0 = z_1^1 < z_2^1 = \cdots$ that for all $0 \le t \le \tau \le T$

$$\begin{aligned}\|\partial_x p(\tau)\|_{1,I(\tau)} \le{}& \int_\tau^T \|b(s)\|_{\infty,I(s)} \|\partial_x p(s)\|_{1,I(s)}\,ds + \|\partial_x p^T\|_{1,I(T)} \\ &+ \int_\tau^T \|p(s)\|_{\infty,I(s)} \|\partial_x b(s)\|_{1,I(s)}\,ds.\end{aligned}$$

With $I = I(t)$ and $J = [X(t;0,z_1) - \|a\|_\infty (T-t), X(t;0,z_2) + \|a\|_\infty (T-t)]$, we have by (A.1) that $I(s) \subset J$, $t \le s \le T$, and by the Gronwall lemma it follows that

$$\|\partial_x p(t)\|_{1,I} \le (\|\partial_x p^T\|_{1,J} + \|\partial_x b\|_{1,[t,T]\times J} \|p\|_{\infty,[t,T]\times J}) e^{(T-t)\|b\|_{\infty,[0,T]\times J}}. \tag{A.6}$$

Since p solves (7.1) a.e. in Ω_T, we get for arbitrary $0 < t_1 < t_2 < T$ and with $|I|$ denoting the length of I

$$\begin{aligned}\|\partial_t p\|_{1,[t_1,t_2]\times I} &\le \|bp\|_{1,[t_1,t_2]\times I} + \|a\|_{\infty,[t_1,t_2]\times I} \|\partial_x p\|_{1,[t_1,t_2]\times I} \\ &\le (t_2 - t_1)(|I| \|bp\|_{\infty,[t_1,t_2]\times I} + \|a\|_{\infty,[t_1,t_2]\times I} \|\partial_x p\|_{L^\infty(t_1,t_2;L^1(I))}).\end{aligned} \tag{A.7}$$

Now (7.10) and the asserted properties of the constant C follow directly from (7.9), (A.6), and (A.7). Moreover, we see that $p \in H^{1,1}(]0,T[\times I)$ with norm not depending on α. ∎

Proof of Theorem 7.8. Denote by X and X_n the backward flows according to Definition 7.3 for a and a_n, respectively. By [1] it holds that $X_n \to X$ in $C(D_b \times [-R,R])$ for any $R > 0$. By the definition of reversible solutions we have for all $z \in \mathbb{R}$

$$\begin{aligned} p_n(T, X_n(T;0,z)) &= p_n^T(X_n(T;0,z)), \\ \tfrac{d}{dt} p_n(t, X_n(t;0,z)) &= -(b_n p_n)(t, X_n(t;0,z)). \end{aligned}$$

For the reversible solution p of (7.1), equation (7.7) holds. Fix some $R > 0$ and consider an arbitrary $(t,x) \in [0,T] \times [-R,R]$. Then there exist $z, z_n \in \mathbb{R}$ with $x = X(t;0,z) = X_n(t;0,z_n)$, and we have $X(s;0,z), X_n(s;0,z_n) \in [R - M_a T, R + M_a T] \stackrel{\text{def}}{=} J$ according to (A.1) for all $s \in [t,T]$ with an upper bound M_a for $\|a_n\|_\infty$ and $\|a\|_\infty$. Since $X(s;t,x) = X(s;0,z)$ and $X_n(s;t,x) = X_n(s;0,z)$ by (7.5), we have

$$\begin{aligned} p_n(T, X_n(T;t,x)) &= p_n^T(X_n(T;t,x)), \\ \tfrac{d}{ds} p_n(s, X_n(s;t,x)) &= -(b_n p_n)(s, X_n(s;t,x)), \quad s \in]t,T[, \end{aligned}$$

and the same holds with p, X, p^T, b instead of p_n, X_n, p_n^T, b_n. Therefore, the difference $\Delta p_n(s) \stackrel{\text{def}}{=} p(s, X(s;t,x)) - p_n(s, X_n(s;t,x))$ satisfies

$$\begin{aligned} |\Delta p_n(T)| &= |p^T(X(T;t,x)) - p_n^T(X_n(T;t,x))| \\ &\le \|p^T - p_n^T\|_{C(J)} + \|\partial_x p^T\|_{\infty,J} \|X - X_n\|_{C(D_b \times J)} \end{aligned}$$

and for $s \in]t,T[$

$$\begin{aligned} \tfrac{d}{ds} \Delta p_n(s) = {} & (b_n(s, X_n(s;t,x)) - b(s, X(s;t,x))) p(s, X(s;t,x)) \\ & - b_n(s, X_n(s;t,x)) \Delta p_n(s). \end{aligned}$$

Thus, we get with $J_T \stackrel{\text{def}}{=} [0,T] \times J$

$$\begin{aligned} |\Delta p_n(s)| \le {} & T\|p\|_{C(J_T)} (\|b_n - b\|_{L^\infty(0,T;C(J))} + \|\partial_x b\|_{\infty,J_T} \|X - X_n\|_{C(D_b \times J)}) \\ & + |\Delta p_n(T)| + \int_s^T \|b_n\|_{L^\infty(0,T;C(J))} |\Delta p_n(\tau)| \, d\tau, \end{aligned}$$

and we deduce by the Gronwall lemma that

$$\lim_{n \to \infty} \|p - p_n\|_{C([0,T] \times [-R,R])} = 0. \qquad \blacksquare$$

ON THE CONTROLLABILITY OF PARABOLIC SYSTEMS WITH A NONLINEAR TERM INVOLVING THE STATE AND THE GRADIENT*

A. DOUBOVA†, E. FERNÁNDEZ-CARA†, M. GONZÁLEZ-BURGOS†, AND E. ZUAZUA‡

Abstract. We present some results concerning the controllability of a quasi-linear parabolic equation (with linear principal part) in a bounded domain of $\mathbb{R}^N$ with Dirichlet boundary conditions. We analyze the controllability problem with distributed controls (supported on a small open subset) and boundary controls (supported on a small part of the boundary). We prove that the system is null and approximately controllable at any time if the nonlinear term $f(y, \nabla y)$ grows slower than $|y| \log^{3/2}(1+|y|+|\nabla y|)+|\nabla y| \log^{1/2}(1+|y|+|\nabla y|)$ at infinity (generally, in this case, in the absence of control, blow-up occurs). The proofs use global Carleman estimates, parabolic regularity, and the fixed point method.

Key words. controllability, parabolic equations, nonlinear gradient terms

1. Introduction and main results. Let $\Omega \subset \mathbb{R}^N$ be a bounded connected open set with boundary $\partial\Omega$ of class C^2. Let $\mathcal{O} \subset \Omega$ be a nonempty open subset, let $\gamma \subset \partial\Omega$ be a nonempty relative open subset of the boundary, and assume that $T > 0$. We will use the following notation: $Q = \Omega \times (0,T)$, $\Sigma = \partial\Omega \times (0,T)$. For any $p \in [1, +\infty]$, we will denote by $\|\cdot\|_p$ the usual norm in $L^p(Q)$.

We will consider parabolic systems of the form

$$\left\{ \begin{array}{lll} \partial_t y - \Delta y + f(y, \nabla y) = v 1_{\mathcal{O}} & \text{in} & Q, \\ y = 0 & \text{on} & \Sigma, \\ y(x,0) = y_0(x) & \text{in} & \Omega \end{array} \right. \tag{1}$$

and

$$\left\{ \begin{array}{lll} \partial_t y - \Delta y + f(y, \nabla y) = 0 & \text{in} & Q, \\ y = v 1_{\gamma} & \text{on} & \Sigma, \\ y(x,0) = y_0(x) & \text{in} & \Omega, \end{array} \right. \tag{2}$$

where y_0 and v are given in appropriate spaces. In (1) and (2),

$$f : \mathbb{R} \times \mathbb{R}^N \to \mathbb{R}$$

is a locally Lipschitz-continuous function and $1_{\mathcal{O}}$ and 1_{γ} denote the characteristic functions of the sets $\mathcal{O}$ and γ, respectively. We will assume that $y_0 \in W^{1,\infty}(\Omega) \cap H_0^1(\Omega)$ (for simplicity), $v \in L^\infty(\mathcal{O} \times (0,T))$ in (1), and $v \in L^\infty(\gamma \times (0,T))$ in (2).

The main goal of this paper is to analyze the controllability properties of (1) and (2). It will be said that (1) (resp., (2)) is null-controllable at time T if, for each $y_0 \in W^{1,\infty}(\Omega) \cap H_0^1(\Omega)$ (resp., $y_0 \in W^{1,\infty}(\Omega) \cap V$, where V is given below by (10)), there exists $v \in L^\infty(\mathcal{O} \times (0,T))$ (resp., $v \in L^\infty(\gamma \times (0,T))$) such that the corresponding initial boundary problem (1) (resp., (2)) admits a solution $y \in C^0([0,T]; L^2(\Omega))$ satisfying

$$y(x,T) = 0 \quad \text{in} \quad \Omega. \tag{3}$$

On the other hand, it will be said that (1) (resp., (2)) is approximately controllable in $L^2(\Omega)$ at time T if, for any $y_0 \in W^{1,\infty}(\Omega) \cap H_0^1(\Omega)$ (resp., $y_0 \in W^{1,\infty}(\Omega) \cap V$), any $y_d \in L^2(\Omega)$, and any $\varepsilon > 0$, there exists a control $v \in L^\infty(\mathcal{O} \times (0,T))$ (resp., $v \in L^\infty(\gamma \times (0,T))$) such that the corresponding initial boundary problem (1) (resp., (2)) possesses a solution $y \in C^0([0,T]; L^2(\Omega))$, with

$$\|y(\cdot,T) - y_d\|_{L^2} \le \varepsilon. \tag{4}$$

The controllability of linear and semilinear parabolic systems has been analyzed in several recent papers. Among them, let us mention [I], [FI], [F], [B], [AB], and [FZ2] in what concerns null controllability and [FPZ], [Z2], and [FZ2] for approximate controllability.

This paper generalizes all previous results, in particular those in [FZ2], where the nonlinear term is assumed to be of the form $f(y)$.

Notice that, under the hypothesis above, we can write

$$f(s,p) = f(0,0) + g(s,p)s + G(s,p) \cdot p \qquad \forall (s,p) \in \mathbb{R} \times \mathbb{R}^N \tag{5}$$

for some L^∞_{loc} functions g and G. These are respectively given by

$$g(s,p) = \int_0^1 \frac{\partial f}{\partial s}(\lambda s, \lambda p)\, d\lambda, \qquad G_i(s,p) = \int_0^1 \frac{\partial f}{\partial p_i}(\lambda s, \lambda p)\, d\lambda \quad \text{for } 1 \le i \le N.$$

Our first result is the following one.

THEOREM 1.1. *Assume that f is locally Lipschitz-continuous, $f(0,0) = 0$ and*

$$\lim_{|(s,p)|\to\infty} \frac{|g(s,p)|}{\log^{3/2}(1+|s|+|p|)} = 0, \quad \lim_{|(s,p)|\to\infty} \frac{|G(s,p)|}{\log^{1/2}(1+|s|+|p|)} = 0. \tag{6}$$

Then (1) is null-controllable at any time $T > 0$.

REMARK 1.1. *This result generalizes at least two cases that have been studied exhaustively before. First, the case of a globally Lipschitz-continuous function f, i.e., when $g \in L^\infty(\mathbb{R} \times \mathbb{R}^N)$ and $G \in L^\infty(\mathbb{R} \times \mathbb{R}^N)^N$. In this case, f is a function with sublinear behavior at infinity, and the proof of the corresponding controllability result is easier (cf.* [IY]*). Second, the case where $G \equiv 0$ and $g = g(s)$ satisfies $g(0) = 0$ and*

$$\lim_{|s|\to\infty} \frac{|g(s)|}{\log^{3/2}(1+|s|)} = 0. \tag{7}$$

The proof is again easier (cf. [FZ2]*).*

REMARK 1.2. *In* [FZ2]*, it is proved that, for each $\beta > 2$, there exist functions $f = f(s)$ with $f(0) = 0$ and*

$$|f(s)| \sim |s| \log^\beta (1+|s|) \quad \text{as} \quad |s| \to \infty \tag{8}$$

such that (1) *is not null-controllable for all* $T > 0$. *In view of Theorem* 1.1, *we see that when* f *satisfies* (8) *with* $3/2 \le \beta \le 2$, *the null controllability problem of* (1) *is an open question.*

REMARK 1.3. *Theorem* 1.1 *says in particular that, under assumption* (6), *for each* y_0 *there exists a control* v *such that* (1) *possesses a solution globally defined in* $[0,T]$. *This claim is not true for any right-hand side and any* $y_0 \in W^{1,\infty}(\Omega) \cap H_0^1(\Omega)$, *since we are in the range in which blow-up may occur (for instance, see* [CH]*).*

A consequence of Theorem 1.1 is the approximate controllability of (1). In this case, $f(0,0)$ will not be necessarily 0 and we will assume that f verifies (5) and (9), a condition slightly different from (6). Thus, our second main result is the following.

THEOREM 1.2. *Let* $T > 0$. *Assume that* $f : \mathbb{R} \times \mathbb{R}^N \to \mathbb{R}$ *is locally Lipschitz-continuous and verifies*

$$\begin{cases} \displaystyle\lim_{|(s,p)|\to\infty} \frac{1}{\log^{3/2}(1+|s|+|p|)} \left| \int_0^1 \frac{\partial f}{\partial s}(s_0+\lambda s, p_0+\lambda p)\, d\lambda \right| = 0, \\ \displaystyle\lim_{|(s,p)|\to\infty} \frac{1}{\log^{1/2}(1+|s|+|p|)} \left| \int_0^1 \frac{\partial f}{\partial p_i}(s_0+\lambda s, p_0+\lambda p)\, d\lambda \right| = 0 \end{cases} \tag{9}$$

uniformly in $(s_0, p_0) \in K$ *for every compact set* $K \subset \mathbb{R} \times \mathbb{R}^N$. *Then* (1) *is approximately controllable at time* T.

REMARK 1.4. *It will be seen in section* 4 *that, for systems like* (1), *the approximate controllability result is actually a consequence of the exact controllability to the trajectories in* $C^0([0,T]; W^{1,\infty}(\Omega))$.

REMARK 1.5. *Again, Theorem* 1.2 *generalizes two known results. First, the case where* f *is globally Lipschitz-continuous, i.e., the case in which* $\partial f/\partial s$ *and* $\partial f/\partial p_i$ $(1 \le i \le N)$ *are uniformly bounded (cf.* [Z2]*). On the other hand, Theorem* 1.2 *is also a generalization of the approximate controllability result in* [FZ2], *where* $G \equiv 0$, $g = g(s)$, *and* (7) *is satisfied.*

In the first draft of this paper (and also in the approximate controllability results in [FZ2]*), an additional assumption was imposed in Theorem* 1.2, *namely, the existence of a globally defined solution* y^* *corresponding to appropriate data* y_0^* *and* v^*. *But one of the referees provided an argument that shows that this hypothesis is in fact unnecessary (see the proof of Theorem* 1.2 *in section* 4*).*

REMARK 1.6. *In particular,* (9) *holds whenever* $\partial f/\partial s$ *and* $\partial f/\partial p_i$ $(1 \le i \le N)$ *satisfy*

$$\lim_{|(s,p)|\to\infty} \frac{\left|\dfrac{\partial f}{\partial s}(s,p)\right|}{\log^{3/2}(1+|s|+|p|)} = 0, \qquad \lim_{|(s,p)|\to\infty} \frac{\left|\dfrac{\partial f}{\partial p_i}(s,p)\right|}{\log^{1/2}(1+|s|+|p|)} = 0.$$

On the other hand, the assumptions (9) *can be easily interpreted when* $f = f(s)$. *Indeed, in this case they simply read as follows:*

$$\begin{cases} \displaystyle\lim_{|s|\to\infty} \frac{1}{\log^{3/2}(1+|s|)} \left| \int_0^1 f'(s_0+\lambda s)\, d\lambda \right| = 0 \\ \text{uniformly in } s_0 \in K \text{ for every compact set } K \subset \mathbb{R}. \end{cases}$$

The arguments in [FZ2] *show that this is equivalent to* (7) *and also to*

$$\lim_{|s|\to\infty} \frac{1}{\log^{3/2}(1+|s|)} \int_0^1 f'(\lambda s)\, d\lambda = 0.$$

REMARK 1.7. *It is proved in* [FZ2] *that, for each* $\beta > 2$*, there exists a function* $f = f(s)$ *satisfying* (8) *such that the corresponding system* (1) *is not approximately controllable for all* $T > 0$*. As in the case of null controllability, for* f *satisfying* (8) *with* $3/2 \leq \beta \leq 2$*, the approximate controllability of* (1) *is an open question.*

We can establish similar results for (2) under hypotheses of the same kind for f and y_0. More precisely, let us introduce the Hilbert space

$$V = \{\, z \in H^1(\Omega) \,:\, z = 0 \text{ on } \partial\Omega \setminus \gamma \,\}. \tag{10}$$

One has the following.

THEOREM 1.3. *Let* $T > 0$*. Assume that the assumptions in Theorem* 1.1 *are satisfied. Then* (2) *is null-controllable at any time* $T > 0$*.*

THEOREM 1.4. *Let* $T > 0$*. Assume that* f *is locally Lipschitz-continuous and verifies* (9)*. Then* (2) *is approximately controllable at time* T*.*

REMARK 1.8. *In the proofs of the previous controllability results, we will construct controls satisfying the appropriate properties. These controls are smooth. In particular, they will be such that the associated solutions of* (1) *and* (2) *belong to* $C^0([0,T]; W^{1,\infty}(\Omega))$*, a space where we can ensure uniqueness.*

The rest of this paper is organized as follows. Section 2 is devoted to proving some technical lemmas we will use below. In section 3, we will prove Theorem 1.1. In section 4, we will give the proof of the approximate controllability result for system (1) (Theorem 1.2). Finally, the proofs of Theorems 1.3 and 1.4 will be sketched in section 5.

2. Some technical results. Before giving the proofs of the theorems above, we have to present some technical results.

Let us consider the linear problem

$$\begin{cases} \partial_t y - \Delta y + B \cdot \nabla y + ay = F & \text{in} \quad Q, \\ y = 0 & \text{on} \quad \Sigma, \\ y(x,0) = y_0(x) & \text{in} \quad \Omega, \end{cases} \tag{11}$$

where y_0 and F are given, $a \in L^\infty(Q)$, and $B \in L^\infty(Q)^N$. One has the following lemma, whose proof is essentially given in [LSU].

LEMMA 2.1. *Assume that* $F \in L^q(Q)$ *with* $q > N + 2$*,* $y_0 \in W^{2,p}(\Omega) \cap H_0^1(\Omega)$ *with* $p > N$*,* $a \in L^\infty(Q)$*, and* $B \in L^\infty(Q)^N$*. Then the solution* y *of* (11) *satisfies*

$$\begin{cases} y \in L^q(0,T; W^{2,\beta}(\Omega)),\ \partial_t y \in L^q(0,T; L^\beta(\Omega)), \\ \textit{with} \quad \beta = \min(p,q) > N \end{cases} \tag{12}$$

and

$$\begin{cases} \|y\|_{L^q(0,T;W^{2,\beta})} + \|\partial_t y\|_{L^q(0,T;L^\beta)} \\ \qquad \leq C(\Omega, T, \|a\|_\infty, \|B\|_\infty)\,(\|y_0\|_{W^{2,p}} + \|F\|_q)\,. \end{cases} \tag{13}$$

Furthermore, we also have $y \in C^0([0,T]; W^{1,\infty}(\Omega))$ *and*

$$\|y\|_{C^0([0,T];W^{1,\infty})} \leq M(\Omega, T, \|a\|_\infty, \|B\|_\infty)\,(\|y_0\|_{W^{2,p}} + \|F\|_q)\,, \tag{14}$$

where

$$\begin{cases} M(\Omega, T, \|a\|_\infty, \|B\|_\infty) \\ \qquad = \exp\left[M_0\left(1 + T + (T + T^{1/2})\|a\|_\infty + (T + T^{1/2})\|B\|_\infty^2\right)\right] \end{cases} \tag{15}$$

and M_0 is a positive constant depending only on Ω.

For the reader's convenience, we have sketched the proof of this result in the appendix.

We will also recall a global Carleman inequality from [IY] for the linear problem

$$\begin{cases} -\partial_t \varphi - \Delta \varphi = F_0 + \sum_{i=1}^{N} \dfrac{\partial F_i}{\partial x_i} & \text{in } Q, \\ \varphi = 0 & \text{on } \Sigma, \\ \varphi(x,T) = \varphi_T(x) & \text{in } \Omega, \end{cases} \tag{16}$$

where F_0, $F_i \in L^2(Q)$ $(1 \le i \le N)$ and $\varphi_T \in L^2(\Omega)$. One has the following.

LEMMA 2.2. *There exists a smooth function $\alpha_0 = \alpha_0(x)$ that is defined and strictly positive for $x \in \overline{\Omega}$, and there exist positive constants C_0 and σ_0 (only depending on Ω and $\mathcal{O}$) such that*

$$\begin{aligned} s^3 \iint_Q e^{-2s\alpha} t^{-3} (T-t)^{-3} |\varphi|^2 \le C_0 \Bigg(& s^3 \iint_{\mathcal{O}\times(0,T)} e^{-2s\alpha} t^{-3} (T-t)^{-3} |\varphi|^2 \\ & + \iint_Q e^{-2s\alpha} |F_0|^2 + s^2 \sum_{i=1}^{N} \iint_Q e^{-2s\alpha} t^{-2} (T-t)^{-2} |F_i|^2 \Bigg) \end{aligned} \tag{17}$$

for all $s \ge s_0 = \sigma_0(T+T^2)$, where φ is the solution of (16) *associated to $\varphi_T \in L^2(\Omega)$. In* (17)*, the function $\alpha = \alpha(x,t)$ is given by*

$$\alpha(x,t) = \frac{\alpha_0(x)}{t(T-t)}\,.$$

REMARK 2.1. *The inequality* (17) *is based on a similar Carleman inequality for the heat equation with a right-hand side in $L^2(Q)$. The precise way s_0 depends on T has been analyzed in* [FZ1] *and is essential in our analysis.*

In what follows, unless otherwise specified, C will stand for a generic positive constant depending only on Ω and $\mathcal{O}$, whose value can change from line to line. Let us introduce the following (adjoint) system:

$$\begin{cases} -\partial_t q - \Delta q - \nabla \cdot (qB) + aq = 0 & \text{in } Q, \\ q = 0 & \text{on } \Sigma, \\ q(x,T) = q_T(x) & \text{in } \Omega, \end{cases} \tag{18}$$

where $q_T \in L^2(\Omega)$. Arguing as in [FZ1], we can deduce from the Carleman estimates (17) an observability inequality for (18), as follows.

THEOREM 2.3. *For any $a \in L^\infty(Q)$, $B \in L^\infty(Q)^N$, and $q_T \in L^2(\Omega)$, one has*

$$\|q(\cdot,0)\|_{L^2}^2 \le \exp\left[C\, B(T, \|a\|_\infty, \|B\|_\infty)\right] \iint_{\mathcal{O}\times(0,T)} |q|^2, \tag{19}$$

where

$$B(T, \|a\|_\infty, \|B\|_\infty) = 1 + \frac{1}{T} + T\|a\|_\infty + \|a\|_\infty^{2/3} + (1+T)\|B\|_\infty^2$$

and q is the solution to the corresponding system (18).

Proof. Let a, B, and q_T be given and let q be the solution to (18). Let us first see that

$$\iint_{\Omega\times(T/4,3T/4)} |q|^2 \le \exp\left[C\left(1+\frac{1}{T}+\|a\|_\infty^{2/3}+\|B\|_\infty^2\right)\right]\iint_{\mathcal{O}\times(0,T)}|q|^2\,. \tag{20}$$

We can write (17) for $\varphi = q$. This gives

$$\begin{aligned} s^3\iint_Q e^{-2s\alpha}t^{-3}(T-t)^{-3}|q|^2 \le C_0\Bigg(&s^3\iint_{\mathcal{O}\times(0,T)} e^{-2s\alpha}t^{-3}(T-t)^{-3}|q|^2 \\ &+\iint_Q e^{-2s\alpha}|aq|^2+s^2\iint_Q e^{-2s\alpha}t^{-2}(T-t)^{-2}|Bq|^2\Bigg) \end{aligned} \tag{21}$$

for all $s \ge s_0$. We can estimate the terms on the right as follows:

$$\iint_Q e^{-2s\alpha}|aq|^2 \le 2^{-6}T^6\|a\|_\infty^2\iint_Q e^{-2s\alpha}t^{-3}(T-t)^{-3}|q|^2$$

and

$$\iint_Q e^{-2s\alpha}t^{-2}(T-t)^{-2}|Bq|^2 \le 2^{-2}T^2\|B\|_\infty^2\iint_Q e^{-2s\alpha}t^{-3}(T-t)^{-3}|q|^2.$$

Thus, we deduce from (21) that

$$\iint_Q e^{-2s\alpha}t^{-3}(T-t)^{-3}|q|^2 \le C\iint_{\mathcal{O}\times(0,T)} e^{-2s\alpha}t^{-3}(T-t)^{-3}|q|^2, \tag{22}$$

provided

$$s \ge s_1 = \max\left(s_0, 2^{-4/3}C_0^{1/3}T^2\|a\|_\infty^{2/3}, C_0T^2\|B\|_\infty^2\right).$$

On the other hand, it can be easily verified that

$$e^{-2s\alpha}t^{-3}(T-t)^{-3} \le 2^6T^{-6}\exp\left(-CsT^{-2}\right) \quad \forall (x,t)\in\overline{Q} \tag{23}$$

and

$$e^{-2s\alpha}t^{-3}(T-t)^{-3} \ge \left(\frac{16}{3}\right)^3 T^{-6}\exp\left(-CsT^{-2}\right) \quad \forall (x,t)\in\overline{\Omega}\times[T/4,3T/4] \tag{24}$$

whenever

$$s \ge s_2 = \max\left(s_1, 3T^2\left(8\min_{x\in\overline{\Omega}}\alpha_0(x)\right)^{-1}\right).$$

Analyzing the definitions of s_1 and s_2, we see that $s_2 \le s_3$, where s_3 is of the form

$$s_3 = \sigma_3\left(T+T^2+T^2\|a\|_\infty^{2/3}+T^2\|B\|_\infty^2\right)$$

and σ_3 depends only on Ω and $\mathcal{O}$. From now on, we fix s, with $s = s_3$. Taking into account (23) and (24) and coming back to (22) (written for $s = s_3$), we deduce that (20) is satisfied for any solution q of (18).

Let us now prove that

$$\|q(\cdot,T/4)\|_2^2 \le \exp\left[C\left(\frac{1}{T}+T\|a\|_\infty+T\|B\|_\infty^2\right)\right]\iint_{\Omega\times(T/4,3T/4)}|q|^2. \tag{25}$$

Multiplying (18) by q and integrating in Ω, we obtain

$$-\frac{1}{2}\frac{d}{dt}\int_\Omega |q|^2\,dx+\int_\Omega|\nabla q|^2\,dx=-\int_\Omega qB\cdot\nabla q\,dx-\int_\Omega a|q|^2\,dx \qquad \forall t\ge 0.$$

Thus,

$$-\frac{d}{dt}\int_\Omega |q|^2\,dx+\int_\Omega|\nabla q|^2\,dx\le\left(\|B\|_\infty^2+2\|a\|_\infty\right)\int_\Omega|q|^2\,dx$$

and

$$\frac{d}{dt}\left(\exp\left((2\|a\|_\infty+\|B\|_\infty^2)t\right)\int_\Omega|q|^2\,dx\right)\ge 0 \tag{26}$$

for all $t\ge 0$. Integrating this inequality with respect to the time variable in $[T/4,t]$, where $t\in[T/4,3T/4]$, we obtain

$$\begin{cases}\displaystyle\int_\Omega|q(x,t)|^2\,dx\ge\exp\left[\left(2\|a\|_\infty+\|B\|_\infty^2\right)(T/4-t)\right]\int_\Omega|q(x,T/4)|^2\,dx\\ \qquad\qquad\displaystyle\ge\exp\left[-\left(\|a\|_\infty+\frac{1}{2}\|B\|_\infty^2\right)T\right]\int_\Omega|q(x,T/4)|^2\,dx\end{cases} \tag{27}$$

for all $t\in[T/4,3T/4]$. Integrating (27) again with respect to t, we find that

$$\frac{T}{2}\int_\Omega|q(x,T/4)|^2\,dx\le\exp\left[\left(\|a\|_\infty+\frac{1}{2}\|B\|_\infty^2\right)T\right]\iint_{\Omega\times(T/4,3T/4)}|q(x,t)|^2, \tag{28}$$

whence we easily deduce (25).

Finally, let us prove that

$$\int_\Omega|q(x,0)|^2\,dx\le\exp\left[CT\left(\|a\|_\infty+\|B\|_\infty^2\right)\right]\int_\Omega|q(x,T/4)|^2\,dx. \tag{29}$$

This, together with (25) and (20), will lead to the desired observability estimate (19).

To prove (29), it suffices to integrate (26) in the time interval $[0,T/4]$. Indeed, we find at once that

$$\int_\Omega|q(x,0)|^2\,dx\le\exp\left[\left(2\|a\|_\infty+\|B\|_\infty^2\right)\frac{T}{4}\right]\int_\Omega|q(x,T/4)|^2\,dx$$

and thus (29) holds. This completes the proof of Theorem 2.3. □

In fact, for the analysis of the controllability of (1) and (2), where f is not necessarily globally Lipschitz-continuous, we need a refined version of the observability inequality (19). This is furnished by the following result.

THEOREM 2.4. *For any $a\in L^\infty(\Omega)$, $B\in L^\infty(\Omega)^N$, and $q_T\in L^2(\Omega)$, one has*

$$\|q(\cdot,0)\|_{L^2}^2\le\exp\left[C\,K\left(T,\|a\|_\infty,\|B\|_\infty\right)\right]\left(\iint_{\mathcal{O}\times(0,T)}|q|\right)^2, \tag{30}$$

where

$$K\,(T,\|a\|_\infty,\|B\|_\infty)=1+\frac{1}{T}+T+(T+T^{1/2})\|a\|_\infty+\|a\|_\infty^{2/3}+(1+T)\|B\|_\infty^2. \tag{31}$$

Proof. Let $\mathcal{O}'$ be a nonempty open set such that $\mathcal{O}'\subset\subset\mathcal{O}$. From Theorem 2.3 applied to $\mathcal{O}'$ and the time interval $[T/4,3T/4]$, we deduce that

$$\|q(\cdot,T/4)\|_{L^2}^2\le\exp\left[CK'(T,\|a\|_\infty,\|B\|_\infty)\right]\iint_{\mathcal{O}'\times(T/4,3T/4)}|q|^2, \tag{32}$$

where q is the solution of (18) associated to $q_T\in L^2(\Omega)$, $K'(T,\|a\|_\infty,\|B\|_\infty)$ is given by

$$K'(T,\|a\|_\infty,\|B\|_\infty)=1+\frac{1}{T}+T\|a\|_\infty+\|a\|_\infty^{2/3}+(1+T)\,\|B\|_\infty^2,$$

and C is a new positive constant depending only on $\mathcal{O}'$ (i.e., on $\mathcal{O}$) and Ω. Using (26), we obtain

$$\int_\Omega|q(x,0)|^2\,dx\le\exp\left[\frac{T}{4}\left(2\|a\|_\infty+\|B\|_\infty^2\right)\right]\int_\Omega|q(x,T/4)|^2\,dx,$$

and combining this with (32), we find that

$$\|q(\cdot,0)\|_{L^2}^2\le\exp\left[CK'(T,\|a\|_\infty,\|B\|_\infty)\right]\iint_{\mathcal{O}'\times(T/4,3T/4)}|q|^2. \tag{33}$$

At this point, we are going to use a technical result, related to the regularizing effect of the heat equation, whose proof will be given below.

LEMMA 2.5. *Let $\mathcal{O}_i$, T_i, r_i, and γ_i $(i=0,1)$ be given, with*

$$\begin{cases}\mathcal{O}'\subset\mathcal{O}_0\subset\subset\mathcal{O}_1\subset\mathcal{O},\quad 0\le T_1<T_0<T/2,\quad 1\le r_1<r_0<\infty,\\ 1\le\gamma_1<\gamma_0<\infty,\qquad \dfrac{1}{\gamma_1}-\dfrac{1}{\gamma_0}+\dfrac{N}{2}\left(\dfrac{1}{r_1}-\dfrac{1}{r_0}\right)<\dfrac{1}{2}\,.\end{cases}$$

Then

$$\begin{cases}\left(\displaystyle\int_{T_0}^{T-T_0}\left(\int_{\mathcal{O}_0}|q|^{r_0}\,dx\right)^{\gamma_0/r_0}dt\right)^{1/\gamma_0}\\ \qquad\le C\,T^\lambda H(T,T_0,T_1,\|a\|_\infty,\|B\|_\infty)\left(\displaystyle\int_{T_1}^{T-T_1}\left(\int_{\mathcal{O}_1}|q|^{r_1}\,dx\right)^{\gamma_1/r_1}dt\right)^{1/\gamma_1}\end{cases} \tag{34}$$

for all $q_T\in L^2(\Omega)$, with $C=C(\Omega,\mathcal{O}_i,r_i,\gamma_i,N)$, $\lambda=\lambda(r_i,\gamma_i,N)$, and

$$\begin{cases}H(T,T_0,T_1,\|a\|_\infty,\|B\|_\infty)\\ \qquad=1+\dfrac{T^{1/2}}{T_0-T_1}+T^{1/2}(1+\|a\|_\infty)+(1+T^{1/2})\|B\|_\infty.\end{cases} \tag{35}$$

We will now apply this lemma together with (33). To this end, let us set $r_0=\gamma_0=2$ and let us introduce the numbers γ_i and r_i, given by the equalities

$$\frac{1}{\gamma_i}=\frac{1}{r_i}=\frac{1}{2}+\frac{i}{2(N+2)},\qquad 1\le i\le N+2.$$

It is immediate that $\gamma_{N+1} > 1$, $r_{N+1} > 1$, and $\gamma_{N+2} = r_{N+2} = 1$. Now, let us set $\delta = T/4(N+2)$. Accordingly,

$$[T/4 - (N+2)\delta, 3T/4 + (N+2)\delta] = [0, T].$$

Let us also introduce a family of open sets $\mathcal{O}_i$ such that

$$\mathcal{O}' = \mathcal{O}_0 \subset\subset \mathcal{O}_1 \subset\subset \mathcal{O}_2 \subset\subset \cdots \subset\subset \mathcal{O}_{N+1} \subset\subset \mathcal{O}_{N+2} = \mathcal{O}.$$

For $0 \le i \le N+1$, we can use inequality (34) with $\mathcal{O}_0$, $\mathcal{O}_1$, T_0, T_1, r_0, r_1, γ_0, and γ_1, respectively, replaced by $\mathcal{O}_i, \mathcal{O}_{i+1}$, $T/4 - i\delta$, $T/4 - (i+1)\delta$, r_i, r_{i+1}, γ_i, and γ_{i+1}. The whole set of these inequalities gives

$$\left(\iint_{\mathcal{O}' \times (T/4, 3T/4)} |q|^2 \right)^{1/2} \le C T^{\alpha} H(T, \|a\|_\infty, \|B\|_\infty)^{\beta} \left(\iint_{\mathcal{O} \times (0,T)} |q| \right), \tag{36}$$

where $\beta = N+2$ and α is the sum of the exponents λ_i. If we now combine the inequalities (33) and (36), we obtain (30). This completes the proof of Theorem 2.4. □

Proof of Lemma 2.5. Let ρ_1 and ρ_2 be functions in $\mathcal{D}(\mathcal{O}_1)$ and $\mathcal{D}((T_1, T - T_1))$, respectively, such that

$$\rho_1 \equiv 1 \text{ in } \mathcal{O}_0, \qquad \rho_2 \equiv 1 \text{ in } (T_0, T - T_0),$$

and $0 \le \rho_1, \rho_2 \le 1$. Let us put $\rho(x,t) = \rho_1(x)\rho_2(t)$ and $u = \rho q$, where q is the solution to (18) associated to $q_T \in L^2(\Omega)$. Obviously,

$$\operatorname{supp} u \subset \mathcal{O}_1 \times (T_1, T - T_1)$$

and

$$\begin{cases} -\partial_t u - \Delta u = -a\rho q + \nabla \cdot (\rho q B) - (\partial_t \rho + \Delta \rho) q - 2\nabla \rho \cdot \nabla q - (\nabla \rho \cdot B) q & \text{in } Q, \\ u = 0 & \text{on } \Sigma, \\ u(x,T) = 0 & \text{in } \Omega. \end{cases}$$

In order to clarify the computations, let us put $\widetilde{u}(x,t) = u(x, T-t)$ for $(x,t) \in Q$. In a similar way, let us introduce the functions $\widetilde{a}$, $\widetilde{B}$, $\widetilde{\rho}$, and $\widetilde{q}$. We then have

$$\begin{cases} \partial_t \widetilde{u} - \Delta \widetilde{u} = F & \text{in } Q, \\ \widetilde{u} = 0 & \text{on } \Sigma, \\ \widetilde{u}(x,0) = 0 & \text{in } \Omega, \end{cases}$$

where F is given by

$$F = -\widetilde{a}\widetilde{\rho}\widetilde{q} + \nabla \cdot (\widetilde{\rho}\widetilde{q}\widetilde{B}) + (\partial_t \widetilde{\rho} - \Delta \widetilde{\rho})\widetilde{q} - 2\nabla \widetilde{\rho} \cdot \nabla \widetilde{q} - (\nabla \widetilde{\rho} \cdot \widetilde{B})\widetilde{q}.$$

Let us denote by $\{S(t) : t \ge 0\}$ the semigroup generated by the heat equation with Dirichlet boundary conditions. Then one has

$$\widetilde{u}(\cdot, t) = \int_0^t S(t-s) F(\cdot, s)\, ds, \tag{37}$$

where the integral can be understood, for instance, in $L^{r_0}(\Omega)$.

Thanks to the regularizing effect of the heat equation, taking L^{r_0}-norms in (37), we obtain the following for $t \in (T_1, T - T_1)$:

$$\begin{aligned}\|\widetilde{u}(\cdot,t)\|_{L^{r_0}} \le C \Bigg[& (\|B\|_\infty + 1) \int_{T_1}^t (t-s)^{-\frac{N}{2}\left(\frac{1}{r_1}-\frac{1}{r_0}\right)-\frac{1}{2}} \|\widetilde{q}(\cdot,s)\|_{L^{r_1}(\mathcal{O}_1)} ds \\ & + \left(1 + \frac{1}{T_0 - T_1} + \|a\|_\infty + \|B\|_\infty\right) \int_{T_1}^t (t-s)^{-\frac{N}{2}\left(\frac{1}{r_1}-\frac{1}{r_0}\right)} \|\widetilde{q}(\cdot,s)\|_{L^{r_1}(\mathcal{O}_1)} ds \Bigg].\end{aligned} \tag{38}$$

Here, C is a positive constant depending on $\mathcal{O}_0$ and $\mathcal{O}_1$. This gives

$$\|\widetilde{u}(\cdot,t)\|_{L^{r_0}} \le C\, H \int_{T_1}^t (t-s)^{-\frac{N}{2}\left(\frac{1}{r_1}-\frac{1}{r_0}\right)-\frac{1}{2}} \|\widetilde{q}(\cdot,s)\|_{L^{r_1}(\mathcal{O}_1)} ds \tag{39}$$

for all $t \in (T_1, T - T_1)$, where $H = H(T, T_0, T_1, \|a\|_\infty, \|B\|_\infty)$ is given by (35). Due to the assumption

$$\frac{N}{2}\left(\frac{1}{r_1} - \frac{1}{r_0}\right) + \frac{1}{\gamma_1} - \frac{1}{\gamma_0} < \frac{1}{2}$$

we can apply Young's inequality to (39) and estimate the $L^{\gamma_0}(0,T;L^{r_0}(\Omega))$-norm of $\widetilde{u}$ as follows:

$$\left(\int_{T_1}^{T-T_1} \|\widetilde{u}(\cdot,t)\|_{L^{r_0}}^{\gamma_0} dt\right)^{1/\gamma_0} \le C\, H T^\lambda \left(\int_{T_1}^{T-T_1} \|\widetilde{u}(\cdot,t)\|_{L^{r_1}(\mathcal{O}_1)}^{\gamma_1} dt\right)^{1/\gamma_1}. \tag{40}$$

Here, C is a new positive constant only depending on Ω, $\mathcal{O}_i$, r_i, and γ_i, and N and H are given by (35) and

$$\lambda = -\left[\frac{N}{2}\left(\frac{1}{r_1} - \frac{1}{r_0}\right) + \frac{1}{\gamma_1} - \frac{1}{\gamma_0}\right] + \frac{1}{2}.$$

Inequality (34) is directly obtained from (40). This completes the proof of Lemma 2.5. □

REMARK 2.2. *As an easy consequence of Theorem* 2.4 *and* (30)*, we can also deduce for each* $r \in (1,\infty)$ *an observability inequality in* $L^r(\mathcal{O} \times (0,T))$*:*

$$\|q(\cdot,0)\|_{L^2}^2 \le \exp\left[C_r\, K\left(T, \|a\|_\infty, \|B\|_\infty\right)\right] \left(\iint_{\mathcal{O}\times(0,T)} |q|^r\right)^{\frac{2}{r}} \tag{41}$$

for any $a \in L^\infty(\Omega)$, $B \in L^\infty(\Omega)^N$, *and* $q_T \in L^2(\Omega)$. *In* (41), $K\left(T, \|a\|_\infty, \|B\|_\infty\right)$ *is given by* (31) *and* C_r *only depends on* Ω, $\mathcal{O}$, *and* r.

3. Proof of the null controllability result. This section is devoted to proving Theorem 1.1. Using Theorem 2.4, we will first establish a null controllability result for a similar linear heat equation with controls in $L^\infty(\mathcal{O} \times (0,T))$. We will then apply a fixed point argument to obtain the desired result. The structure of the proof (the controllability of a similar linear system together with a fixed point argument) is rather general. It was introduced in [Z1] in the context of the boundary controllability of the semilinear wave equation. For other results proved in a similar way, see, for instance, [FPZ] and [FI].

3.1. A null controllability result for a linear problem. We will consider the linear system

$$\left\{\begin{array}{lll} \partial_t y - \Delta y + B\cdot\nabla y + ay = v1_{\mathcal{O}} & \text{in} & Q,\\ y=0 & \text{on} & \Sigma,\\ y(x,0)=y_0(x) & \text{in} & \Omega, \end{array}\right. \tag{42}$$

where $a\in L^\infty(Q)$, $B\in L^\infty(Q)^N$, and $y_0\in L^2(\Omega)$ are given. The following holds.

THEOREM 3.1. *Assume that $T>0$, $a\in L^\infty(Q)$, $B\in L^\infty(Q)^N$, and $y_0\in L^2(\Omega)$. Then there exists a control $\widehat{v}\in L^\infty(\mathcal{O}\times(0,T))$ such that the corresponding solution of* (42) *satisfies*

$$\widehat{y}(x,T)=0 \quad \textit{in } \Omega. \tag{43}$$

Furthermore, $\widehat{v}$ can be chosen in such a way that

$$\|\widehat{v}\|_{L^\infty(\mathcal{O}\times(0,T))}\le \exp\left[C\,K\left(T,\|a\|_\infty,\|B\|_\infty\right)\right]\|y_0\|_{L^2}, \tag{44}$$

where $K(T,\|a\|_\infty,\|B\|_\infty)$ is given by (31).

Proof. For every $\varepsilon>0$, let us consider the functional J_ε, with

$$J_\varepsilon(q_T)=\frac{1}{2}\left(\iint_{\mathcal{O}\times(0,T)}|q|\right)^2+\varepsilon\|q_T\|_{L^2}+\int_\Omega q(x,0)\,y_0(x)\,dx \qquad \forall q_T\in L^2(\Omega). \tag{45}$$

Here, q is the solution of (18) associated to $q_T\in L^2(\Omega)$.

It is easy to see that J_ε is a continuous and strictly convex functional in $L^2(\Omega)$. Furthermore, from (22), it is immediate to deduce the following unique continuation property for (18): *If $q=0$ in $\mathcal{O}\times(0,T)$, then $q\equiv 0$.*

Thus, arguing as in [FPZ], we also see that

$$\liminf_{\|q_T\|_{L^2}\to\infty}\frac{J_\varepsilon(q_T)}{\|q_T\|_{L^2}}\ge\varepsilon$$

and, therefore, J_ε achieves its minimum at a unique point $\widehat{q}_T^\varepsilon\in L^2(\Omega)$.

Let $\widehat{q}_\varepsilon$ be the solution of (18) associated to $\widehat{q}_T^\varepsilon$. Taking $v=\widehat{v}_\varepsilon$ in (42) with

$$\widehat{v}_\varepsilon\in(\operatorname{sgn}\widehat{q}_\varepsilon)\left(\int_{\mathcal{O}\times(0,T)}|\widehat{q}_\varepsilon|\right)1_{\mathcal{O}} \tag{46}$$

and arguing as in [FPZ], we see that the associated solution $\widehat{y}_\varepsilon$ satisfies

$$\|\widehat{y}_\varepsilon(\cdot,T)\|_{L^2}\le\varepsilon. \tag{47}$$

It is not difficult to see that

$$\|\widehat{v}_\varepsilon\|_{L^\infty(\mathcal{O}\times(0,T))}=\iint_{\mathcal{O}\times(0,T)}|\widehat{q}_\varepsilon|\le\exp\left[C\,K\left(T,\|a\|_\infty,\|B\|_\infty\right)\right]\|y_0\|_{L^2} \tag{48}$$

for all $\varepsilon>0$. Indeed, the fact that

$$\|\widehat{v}_\varepsilon\|_{L^\infty(\mathcal{O}\times(0,T))}=\iint_{\mathcal{O}\times(0,T)}|\widehat{q}_\varepsilon|$$

is implied by (46). On the other hand, since

$$J_\varepsilon(\widehat{q}_T^\varepsilon) \le J_\varepsilon(0) = 0,$$

we see from (45) that

$$\frac{1}{2}\left(\iint_{\mathcal{O}\times(0,T)} |\widehat{q}_\varepsilon|\right)^2 \le -\int_\Omega \widehat{q}_\varepsilon(x,0)y_0(x)\,dx \le \|\widehat{q}_\varepsilon(\cdot,0)\|_{L^2}\|y_0\|_{L^2}.$$

In view of (30), (48) holds.

Since $\widehat{v}_\varepsilon$ is uniformly bounded in $L^\infty(\mathcal{O}\times(0,T))$, at least for an appropriate subsequence we must have

$$\widehat{v}_\varepsilon \to \widehat{v} \quad \text{weakly-}* \text{ in } L^\infty(\mathcal{O}\times(0,T)), \tag{49}$$

where $\widehat{v} \in L^\infty(\mathcal{O}\times(0,T))$ satisfies (44). Accordingly,

$$\widehat{y}_\varepsilon(T) \to \widehat{y}(T) \quad \text{in } L^2(\Omega),$$

where $\widehat{y}$ is the solution of (42) associated to $\widehat{v}$. Since we have (47) for all $\varepsilon > 0$, (43) is satisfied. This ends the proof. □

3.2. Proof of Theorem 1.1. We are now ready to prove Theorem 1.1. First, observe that we can assume in this theorem that $y_0 \in W^{2,p}(\Omega)\cap H_0^1(\Omega)$, with $p > N$. Indeed, it suffices to set $v = 0$ for $t \in [0,\delta]$ and to work in the time interval $[\delta, T]$, looking at $y(\cdot,\delta)$ as the initial state.

As we said above, a fixed point argument will be used. For convenience, it will be assumed in a first step that g and G are continuous.

3.2.1. The case in which g and G are continuous. Let y_0 be given in $W^{2,p}(\Omega)\cap H_0^1(\Omega)$ with $p > N$. We will assume that

$$g \in C^0(\mathbb{R}\times\mathbb{R}^N), \qquad G \in C^0(\mathbb{R}\times\mathbb{R}^N)^N, \tag{50}$$

and (6) is satisfied. It is then clear that, for each $\varepsilon > 0$, there exists $C_\varepsilon > 0$ such that

$$|g(s,p)|^{2/3} + |G(s,p)|^2 \le C_\varepsilon + \varepsilon\log(1+|s|+|p|) \quad \forall (s,p) \in \mathbb{R}\times\mathbb{R}^N. \tag{51}$$

Let us set $Z = C^0([0,T];W^{1,\infty}(\Omega))$ and let $R > 0$ be a constant whose value will be determined below. We will use the truncation functions $\mathrm{T}_R : \mathbb{R} \mapsto \mathbb{R}$ and $\mathbf{T}_R : \mathbb{R}^N \mapsto \mathbb{R}^N$, given as follows:

$$\mathrm{T}_R(s) = \begin{cases} s & \text{if } |s| \le R, \\ R\,\mathrm{sgn}\,(s) & \text{otherwise} \end{cases}$$

and

$$\mathbf{T}_R(p) = (\mathrm{T}_R(p_i))_{1\le i\le N} \quad \forall p \in \mathbb{R}^N.$$

For each $z \in Z$, we will consider the corresponding linear systems

$$\begin{cases} \partial_t y - \Delta y + G\left(\mathrm{T}_R(z), \mathbf{T}_R(\nabla z)\right)\cdot\nabla y + g\left(\mathrm{T}_R(z), \mathbf{T}_R(\nabla z)\right) y = v1_{\mathcal{O}} & \text{in } Q, \\ y = 0 & \text{on } \Sigma, \\ y(x,0) = y_0(x) & \text{in } \Omega. \end{cases} \tag{52}$$

We are going to associate to z a family $U(z)$ of L^∞-controls which serve to drive the solutions to zero. Observe that (52) is of the form (42) with

$$\left\{\begin{array}{l} a = a_z = g\left(\mathrm{T}_R(z), \mathbf{T}_R(\nabla z)\right) \in L^\infty(Q), \\ B = B_z = G\left(\mathrm{T}_R(z), \mathbf{T}_R(\nabla z)\right) \in L^\infty(Q)^N. \end{array}\right. \tag{53}$$

Consequently, we can apply Theorem 3.1 to (52). In fact, we are going to apply this result in an adequate (eventually smaller) time interval $(0, T_z)$, where

$$T_z = \min\left\{T, \|g\left(\mathrm{T}_R(z), \mathbf{T}_R(\nabla z)\right)\|_\infty^{-2/3}, \|g\left(\mathrm{T}_R(z), \mathbf{T}_R(\nabla z)\right)\|_\infty^{-1/3}\right\}. \tag{54}$$

This is a key point in our proof that will lead to appropriate estimates (this idea is taken from [FZ2]).

From Theorem 3.1, we directly deduce the existence of a control $\widehat{v}_z \in L^\infty(\mathcal{O} \times (0, T_z))$ such that the solution of (52) in $\Omega \times (0, T_z)$ with $v = \widehat{v}_z$ satisfies

$$\widehat{y}_z(x, T_z) = 0 \quad \text{in } \Omega$$

and, moreover,

$$\|\widehat{v}_z\|_{L^\infty(\mathcal{O}\times(0,T_z))} \leq \exp\left[C\, K(T_z, \|a_z\|_\infty, \|B_z\|_\infty)\right] \|y_0\|_{L^2}.$$

(K is given by (31) and a_z and B_z are given by (53).)

Let $\widetilde{v}_z$ and $\widetilde{y}_z$ be the extensions by zero of $\widehat{v}_z$ and $\widehat{y}_z$ to the whole cylinder $Q = \Omega \times (0, T)$. It is clear that $\widetilde{y}_z$ is the corresponding solution of (52) associated to $\widetilde{v}_z$ and

$$\widetilde{y}_z(x, T) = 0 \quad \text{in } \Omega. \tag{55}$$

From the definition of T_z, we see that

$$\|\widetilde{v}_z\|_{L^\infty(\mathcal{O}\times(0,T))} \leq \exp\left[C\left(1 + \|a_z\|_\infty^{2/3} + \|B_z\|_\infty^2\right)\right] \|y_0\|_{L^2}, \tag{56}$$

where the positive constant C now depends on Ω, $\mathcal{O}$, and T.

On the other hand, from (50) and Lemma 2.1, we obtain that

$$\widehat{y}_z \in C^0([0, T_z]; W^{1,\infty}(\Omega))$$

and

$$\|\widehat{y}_z\|_{C^0([0,T_z];W^{1,\infty})} \leq M(\Omega, T_z, \|a_z\|_\infty, \|B_z\|_\infty)\left(\|y_0\|_{W^{2,p}} + \|\widehat{v}_z\|_{L^\infty(\mathcal{O}\times(0,T_z))}\right)$$

(M is given by (15)). Taking into account once again the definition of T_z, the estimate (56), and the definition of $\widetilde{y}_z$, we find that $\widetilde{y}_z \in Z$ and

$$\|\widetilde{y}_z\|_Z \leq \exp\left[C\left(1 + \|a_z\|_\infty^{2/3} + \|B_z\|_\infty^2\right)\right] \|y_0\|_{W^{2,p}}, \tag{57}$$

where (again) $C = C(\Omega, \mathcal{O}, T)$.

The estimates (56) and (57) can be written in the form

$$\|\widetilde{v}_z\|_{L^\infty(\mathcal{O}\times(0,T))} \leq C_1(\Omega, \mathcal{O}, T, z)\|y_0\|_{L^2} \tag{58}$$

and

$$\|\widetilde{y}_z\|_Z \le C_1(\Omega, \mathcal{O}, T, z)\|y_0\|_{W^{2,p}}, \tag{59}$$

where

$$C_1(\Omega, \mathcal{O}, T, z) = \exp\left[C\left(1 + \|a_z\|_\infty^{2/3} + \|B_z\|_\infty^2\right)\right]. \tag{60}$$

For any given $v \in L^\infty(\mathcal{O} \times (0,T))$, let $y_v \in Z$ be the solution of (52) in Q with right-hand side v. (In order to simplify the notation, we omit the dependence on z.) With this notation in mind, let us now set for each $z \in Z$

$$U(z) = \left\{v \in L^\infty(\mathcal{O} \times (0,T)) \,:\, y_v(T) = 0, \quad \|v\|_{L^\infty(\mathcal{O}\times(0,T))} \le C_1(\Omega, \mathcal{O}, T, z)\|y_0\|_{L^2}\right\}$$

and

$$\Lambda(z) = \{y_v \,:\, v \in U(z), \quad \|y_v\|_Z \le C_1(\Omega, \mathcal{O}, T, z)\|y_0\|_{W^{2,p}}\}. \tag{61}$$

In this way, we have been able to introduce a set-valued mapping on Z

$$z \mapsto \Lambda(z).$$

We will prove that this mapping possesses at least one fixed point y. We will also prove that, for some R, every fixed point of Λ verifies

$$\|y\|_Z \le R. \tag{62}$$

Of course, this will imply the existence of a control $v \in L^\infty(\mathcal{O} \times (0,T))$ such that (1) has a solution satisfying (3).

Let us see that Kakutani's fixed point theorem can be applied to Λ. (For the statement and proof of this result, see [A, Chapter 9, pp. 119–126].) First, from (58) and (59), we deduce that $\Lambda(z)$ is, for every $z \in Z$, a nonempty set. Moreover, it is easy to check that $\Lambda(z)$ is a uniformly bounded closed convex subset of Z. Owing to the regularity hypothesis on y_0 and Lemma 2.1, we have (12) (here $\beta = p$) and the estimate

$$\|y\|_{L^\infty(0,T;W^{2,p})} + \|\partial_t y\|_{L^\infty(0,T;L^p)} \le C(\Omega, \mathcal{O}, T, R, \|y_0\|_{W^{2,p}})$$

(where $C(\Omega, \mathcal{O}, T, R, \|y_0\|_{W^{2,p}})$ is independent of z) for any $y \in \Lambda(z)$. Since $p > N$, we can apply well-known compactness results and conclude that there exists a compact set $K \subset Z$ (which depends on R) such that

$$\Lambda(z) \subset K \quad \forall z \in Z \tag{63}$$

(for instance, see [S]).

Let us now prove that the mapping $z \mapsto \Lambda(z)$ is *upper hemicontinuous*, i.e., that the real-valued function

$$z \in Z \mapsto \sup_{y \in \Lambda(z)} \langle \mu, y \rangle$$

is *upper semicontinuous* for each bounded linear form $\mu \in Z'$. In other words, let us see that

$$B_{\alpha,\mu} = \left\{ z \in Z \,:\, \sup_{y \in \Lambda(z)} \langle \mu, y \rangle \ge \alpha \right\}$$

is a closed set of Z for every $\alpha \in \mathbb{R}$ and every $\mu \in Z'$. Thus, let $\{z_n\}$ be a sequence in $B_{\alpha,\mu}$ such that $z_n \to z$ in Z. Our aim is to prove that $z \in B_{\alpha,\mu}$. In view of the continuity hypothesis on g and G, we have

$$g(\mathrm{T}_R(z_n), \mathbf{T}_R(\nabla z_n)) \to g(\mathrm{T}_R(z), \mathbf{T}_R(\nabla z)) \quad \text{in} \quad L^\infty(Q)$$

and

$$G(\mathrm{T}_R(z_n), \mathbf{T}_R(\nabla z_n)) \to G(\mathrm{T}_R(z), \mathbf{T}_R(\nabla z)) \quad \text{in} \quad L^\infty(Q)^N.$$

Since all sets $\Lambda(z_n)$ are compact and satisfy (63), we deduce that

$$\alpha \leq \sup_{y \in \Lambda(z_n)} \langle \mu, y \rangle = \langle \mu, y_n \rangle \tag{64}$$

for some $y_n \in \Lambda(z_n)$. From the definitions of $\Lambda(z_n)$ and $U(z_n)$, there must exist $v_n \in L^\infty(\mathcal{O} \times (0,T))$ such that

$$\partial_t y_n - \Delta y_n + G\left(\mathrm{T}_R(z_n), \mathbf{T}_R(\nabla z_n)\right) \cdot \nabla y_n + g\left(\mathrm{T}_R(z_n), \mathbf{T}_R(\nabla z_n)\right) y_n = v_n 1_{\mathcal{O}}$$

in Q. Furthermore,

$$\|v_n\|_{L^\infty(\mathcal{O}\times(0,T))} \leq C_1(\Omega, \mathcal{O}, T, z_n)\|y_0\|_{L^2}$$

and

$$\|y_n\|_Z \leq C_1(\Omega, \mathcal{O}, T, z_n)\|y_0\|_{W^{2,p}},$$

whence y_n (resp., v_n) is uniformly bounded in Z (resp., $L^\infty(\mathcal{O} \times (0,T))$). Therefore, we can write the following at least for a subsequence:

$$y_n \to \widehat{y} \quad \text{strongly in } Z$$

(recall that (63) is satisfied) and

$$v_n \to \widehat{v} \quad \text{weakly-}* \text{ in } L^\infty(\mathcal{O} \times (0,T)).$$

Now, it is not difficult to check that

$$\begin{cases} \partial_t \widehat{y} - \Delta \widehat{y} + G\left(\mathrm{T}_R(z), \mathbf{T}_R(\nabla z)\right) \cdot \nabla \widehat{y} + g\left(\mathrm{T}_R(z), \mathbf{T}_R(\nabla z)\right) \widehat{y} = \widehat{v} 1_{\mathcal{O}} & \text{in} \quad Q, \\ \widehat{y} = 0 & \text{on} \quad \Sigma, \\ \widehat{y}(x,0) = y_0(x), \quad \widehat{y}(x,T) = 0 & \text{in} \quad \Omega, \end{cases}$$

i.e., that $\widehat{v} \in U(z)$ and $\widehat{y} \in \Lambda(z)$. Consequently, we can take limits in (64) and deduce that

$$\alpha \leq \langle \mu, \widehat{y} \rangle \leq \sup_{y \in \Lambda(z)} \langle \mu, y \rangle,$$

that is to say, $z \in B_{\alpha,\mu}$. This proves that $z \mapsto \Lambda(z)$ is upper hemicontinuous.

As a consequence, for any fixed $R > 0$ Kakutani's theorem can be applied, ensuring the existence of a fixed point of Λ. As we said above, we will finish the proof by showing that we can choose $R > 0$ in such a way that any fixed point of Λ satisfies (62). It is just here where the assumptions (6) (in fact (51)) will be used.

Thus, let y be a fixed point of Λ associated to the control $v \in U(y)$. Then (59), (60), and (51) lead to the estimates

$$\begin{aligned}\|y\|_Z &\le \exp\left(C\left(1+\|g(\mathrm{T}_R(y),\mathbf{T}_R(\nabla y))\|_\infty^{2/3}+\|G(\mathrm{T}_R(y),\mathbf{T}_R(\nabla y))\|_\infty^2\right)\right)\|y_0\|_{W^{2,p}}\\ &\le \exp\left(C\left(1+C_\varepsilon+\varepsilon\log\left(1+2R\right)\right)\right)\|y_0\|_{W^{2,p}}\\ &= \exp\left(C\left(1+C_\varepsilon\right)\right)(1+2R)^{C\varepsilon}\|y_0\|_{W^{2,p}},\end{aligned}$$

where $C = C(\Omega, \mathcal{O}, T)$. Taking $\varepsilon = 1/(2C)$, we find that

$$\|y\|_Z \le C(1+2R)^{1/2}\|y_0\|_{W^{2,p}},$$

whence (62) holds whenever R is large enough (depending on Ω, $\mathcal{O}$, T, g, and G). We have then proved Theorem 1.1 in the case of smooth data.

3.2.2. The general case. Let us now suppose that f is a locally Lipschitz-continuous function satisfying assumption (5) (with $f(0,0) = 0$) and (6). Let us introduce a function $\rho \in \mathcal{D}(\mathbb{R}\times\mathbb{R}^N)$ such that $\rho \ge 0$ in $\mathbb{R}\times\mathbb{R}^N$, $\operatorname{supp}\rho \subset \overline{B}(0,1)$, and

$$\iint_{\mathbb{R}\times\mathbb{R}^N} \rho(s,p)\,ds\,dp = 1.$$

We consider the functions ρ_n, g_n, and G_n $(n \ge 1)$, with

$$\rho_n(s,p) = n^{N+1}\rho(ns,np) \quad \forall (s,p)\in\mathbb{R}\times\mathbb{R}^N,$$

$$g_n = \rho_n * g, \qquad G_n = \rho_n * G.$$

Then it is not difficult to check that the following properties of g_n and G_n hold:

1. $g_n \in C^0(\mathbb{R}\times\mathbb{R}^N)$ and $G_n \in C^0(\mathbb{R}\times\mathbb{R}^N)^N$ for all $n \ge 1$.
2. If we put $f_n(s,p) = g_n(s,p)s + G_n(s,p)\cdot p$ for all $(s,p)\in\mathbb{R}\times\mathbb{R}^N$, then
$$f_n \to f \quad \text{uniformly in the compact sets of } \mathbb{R}\times\mathbb{R}^N.$$
3. For any given $M > 0$, there exists $C(M) > 0$ such that
$$\sup_{|(s,p)|\le M}\left(|g_n(s,p)| + |G_n(s,p)|\right) \le C(M) \quad \forall n \ge 1.$$
4. The functions g_n and G_n verify (6) uniformly in n, that is to say, for any $\varepsilon > 0$, there exists $M(\varepsilon) > 0$ such that
$$\text{(65)} \qquad \begin{cases} |g_n(s,p)| \le \varepsilon\log^{3/2}(1+|s|+|p|),\\ |G_n(s,p)| \le \varepsilon\log^{1/2}(1+|s|+|p|)\end{cases}$$
whenever $|(s,p)| \ge M(\varepsilon)$ for all $n \ge 1$.

For every n, we can argue as in section 3.2.1 and find a control $v_n \in L^\infty(\mathcal{O}\times(0,T))$ such that the system

$$\text{(66)} \qquad \begin{cases} \partial_t y_n - \Delta y_n + f_n(y_n,\nabla y_n) = v_n 1_{\mathcal{O}} & \text{in } Q,\\ y_n = 0 & \text{on } \Sigma,\\ y_n(x,0) = y_0(x) & \text{in } \Omega\end{cases}$$

possesses at least one solution $y_n \in Z$ satisfying

$$y_n(x,T) = 0 \quad \text{in } \Omega.$$

From the properties satisfied by g_n and G_n, and thanks to the estimates obtained in section 3.2.1, we deduce that

$$\|v_n\|_{L^\infty(\mathcal{O}\times(0,T))} \le C \quad \text{and} \quad \|y_n\|_Z \le C$$

for all $n \ge 1$. In fact, in view of Lemma 2.1 we have $y_n \in K$ for all n, where K is a fixed compact set in Z. Accordingly, we can assume that, at least for a subsequence,

$$v_n \to v \quad \text{weakly-}* \text{ in } L^\infty(\mathcal{O}\times(0,T))$$

and

$$y_n \to y \quad \text{strongly in } Z.$$

Hence, passing to the limit in (66), we find a control $v \in L^\infty(\mathcal{O}\times(0,T))$ such that (1) possesses a solution y satisfying (3). This ends the proof of Theorem 1.1. ∎

REMARK 3.1. *Analyzing the proof of Theorem* 1.1*, we deduce that the null controllability result remains valid if we change* (6) *by the following assumptions:*

$$\limsup_{|(s,p)|\to\infty} \frac{|g(s,p)|}{\log^{3/2}(1+|s|+|p|)} \le l_1 < \infty, \qquad \limsup_{|(s,p)|\to\infty} \frac{|G(s,p)|}{\log^{1/2}(1+|s|+|p|)} \le l_2 < \infty,$$

where l_1 and l_2 are positive and sufficiently small (depending only on Ω and $\mathcal{O}$).

REMARK 3.2. *In Theorem* 1.1*, we can consider as well a more general nonlinear term of the form $f(x,t;s,p)$, with $(x,t) \in Q$ and $(s,p) \in \mathbb{R}\times\mathbb{R}^N$. The assumptions on f have to be the following in this case:*

1. *$f(x,t;0,0) = 0$ for all $(x,t) \in Q$,*
2. *$f(\cdot;s,p) \in L^\infty(Q)$ for all $(s,p) \in \mathbb{R}\times\mathbb{R}^N$,*
3. *$f(x,t;\cdot)$ is locally Lipschitz-continuous for (x,t) a.e. in Q, with Lipschitz constants independent of (x,t) in the bounded sets of $\mathbb{R}\times\mathbb{R}^N$,*
4. *$f(\cdot;s,p) = g(\cdot;s,p)s + G(\cdot;s,p)\cdot p$ for all $(s,p) \in \mathbb{R}\times\mathbb{R}^N$, with*

$$\lim_{|(s,p)|\to\infty} \frac{|g(x,t;s,p)|}{\log^{3/2}(1+|s|+|p|)} = 0, \qquad \lim_{|(s,p)|\to\infty} \frac{|G(x,t;s,p)|}{\log^{1/2}(1+|s|+|p|)} = 0$$

uniformly in $(x,t) \in Q$.

REMARK 3.3. *Adapting the arguments used in the proof of Theorem* 1.1*, we can deduce a local null controllability result for* (1) *with a general nonlinear term $f(s,p)$ satisfying $f(0,0) = 0$. To be precise, if f is given, there exists $\delta = \delta(\Omega,\mathcal{O},T,f) > 0$ such that for every $y_0 \in W^{2,p}(\Omega)\cap H_0^1(\Omega)$ $(p > N)$ with $\|y_0\|_{W^{2,p}} \le \delta$, a control $v \in L^\infty(\mathcal{O}\times(0,T))$ can be found such that the corresponding problem has a unique solution $y \in L^\infty(0,T;W^{1,\infty}(\Omega))$ which satisfies*

$$y(x,T) = 0 \quad \text{in } \Omega.$$

4. Proof of the approximate controllability result. In this section we will prove Theorem 1.2. Let us fix $T > 0$, $\varepsilon > 0$, $y_0 \in W^{1,\infty}(\Omega) \cap H_0^1(\Omega)$, and $y_d \in W^{2,p}(\Omega) \cap H_0^1(\Omega)$ with $p > N$ (for instance). Obviously, it will be sufficient to consider final data in $W^{2,p}(\Omega) \cap H_0^1(\Omega)$, since this space is dense in $L^2(\Omega)$. We will present the proof in several steps and start with a result concerning the exact controllability to the trajectories in $C^0([0,T]; W^{1,\infty}(\Omega))$.

LEMMA 4.1. *Assume the hypotheses on f in Theorem 1.2 are satisfied. Let $y_0 \in W^{1,\infty}(\Omega) \cap H_0^1(\Omega)$ be given and let y^* be a solution to (1) in $C^0([0,T]; W^{1,\infty}(\Omega))$ corresponding to the data*

$$y_0^* \in W^{1,\infty}(\Omega) \cap H_0^1(\Omega), \quad v^* \in L^\infty(\mathcal{O} \times (0,T)).$$

There exists a control $v \in L^\infty(\mathcal{O} \times (0,T))$ and a state $y \in C^0([0,T]; W^{1,\infty}(\Omega))$ associated to y_0 and v such that

$$y(x,T) = y^*(x,T) \quad \textit{in} \quad \Omega.$$

Proof. Let us put $y = y^* + w$. We will look for a control $u \in L^\infty(\mathcal{O} \times (0,T))$ such that the solution of

$$\text{(67)} \qquad \begin{cases} \partial_t w - \Delta w + F(x,t;w,\nabla w) = u 1_{\mathcal{O}} & \text{in} \quad Q, \\ w = 0 & \text{on} \quad \Sigma, \\ w(0) = y_0 - y_0^* & \text{in} \quad \Omega \end{cases}$$

satisfies

$$w(x,T) = 0 \quad \text{in} \quad \Omega.$$

Here, F is given by

$$F(x,t;s,p) = f(y^*(x,t) + s, \nabla y^*(x,t) + p) - f(y^*(x,t), \nabla y^*(x,t))$$

for all $(x,t) \in Q$ and $(s,p) \in \mathbb{R} \times \mathbb{R}^N$. The proof of this lemma will be achieved if we check that such a control u exists.

Notice that

$$F(x,t;s,p) = \widetilde{g}(x,t;s,p)s + \widetilde{G}(x,t;s,p) \cdot p,$$

where

$$\widetilde{g}(x,t;s,p) = \int_0^1 \frac{\partial f}{\partial s}(y^*(x,t) + \lambda s, \nabla y^*(x,t) + \lambda p)\, d\lambda$$

and

$$\widetilde{G}_i(x,t;s,p) = \int_0^1 \frac{\partial f}{\partial p_i}(y^*(x,t) + \lambda s, \nabla y^*(x,t) + \lambda p)\, d\lambda \qquad \text{for } 1 \le i \le N.$$

Thus, in view of (9) and the fact that $y^* \in C^0([0,T]; W^{1,\infty}(\Omega))$, it is clear that F satisfies the assumptions of Remark 3.2. This is sufficient to ensure that u exists. This completes the proof of this lemma. ∎

Now, we argue as follows:

• There exists $\delta_0 > 0$, depending only on Ω, y_d, and f, such that the system

$$\left\{\begin{array}{lll} \partial_t w - \Delta w + f(w, \nabla w) = 0 & \text{in} & \Omega \times (0, \delta_0), \\ w = 0 & \text{on} & \partial\Omega \times (0, \delta_0), \\ w(x, 0) = y_d(x) & \text{in} & \Omega \end{array}\right. \tag{68}$$

has exactly one solution $w \in C^0([0, \delta_0]; W^{1,\infty}(\Omega))$ also satisfying

$$w(\cdot, t) \in W^{2,p}(\Omega) \cap H_0^1(\Omega) \qquad \forall t \in [0, \delta_0]. \tag{69}$$

Obviously, we can associate to ε a parameter $\delta_1 \in (0, \delta_0]$ (small enough) such that

$$\|w(\cdot, t) - y_d\|_{L^2} \leq \varepsilon \qquad \forall t \in [0, \delta_1]. \tag{70}$$

In what follows, we fix δ_1 verifying (70).

• There exists $v_1 \in L^\infty(\mathcal{O} \times (0, \delta_1))$ such that the corresponding system

$$\left\{\begin{array}{lll} \partial_t y - \Delta y + f(y, \nabla y) = v_1 1_{\mathcal{O}} & \text{in} & \Omega \times (0, \delta_1), \\ y = 0 & \text{on} & \partial\Omega \times (0, \delta_1), \\ y(x, 0) = y_0(x) & \text{in} & \Omega \end{array}\right. \tag{71}$$

possesses exactly one solution $y_1 \in C^0([0, \delta_1]; W^{1,\infty}(\Omega))$, with

$$y_1(x, \delta_1) = w(x, \delta_1) \quad \text{in} \quad \Omega.$$

This is a consequence of Lemma 4.1.

• On the other hand, there exists $\widetilde{v} \in L^\infty(\mathcal{O} \times (0, \delta_1))$ such that the system

$$\left\{\begin{array}{lll} \partial_t y - \Delta y + f(y, \nabla y) = \widetilde{v} 1_{\mathcal{O}} & \text{in} & \Omega \times (0, \delta_1), \\ y = 0 & \text{on} & \partial\Omega \times (0, \delta_1), \\ y(x, 0) = w(x, \delta_1) & \text{in} & \Omega \end{array}\right. \tag{72}$$

possesses exactly one solution $\widetilde{y} \in C^0([0, \delta_1]; W^{1,\infty}(\Omega))$, with

$$\widetilde{y}(x, \delta_1) = w(x, \delta_1) \quad \text{in} \quad \Omega.$$

This is again a consequence of Lemma 4.1.

• Assume that $T = n\delta_1 + \delta$ for some integer $n \geq 0$ and some $\delta \in [0, \delta_1)$. Let us put $I_k = [k\delta_1, (k+1)\delta_1)$ for $0 \leq k \leq n-1$ and $I_n = [n\delta_1, T]$. We will construct the control v as follows.

For $t \in I_0$, we set $v(x, t) = v_1(x, t)$ a.e., where v_1 is the control arising in (71). Then, for $1 \leq k \leq n-1$ and $t \in I_k$, we set $v(x, t) = \widetilde{v}(x, t - k\delta_1)$, where $\widetilde{v}$ is the control in (72).

If $\delta = 0$, we have constructed in this way a control $v \in L^\infty(\mathcal{O} \times (0, T))$ such that the associate state y satisfies

$$y(x, T) = w(x, \delta_1) \quad \text{in} \quad \Omega. \tag{73}$$

In view of (70), (4) is satisfied.

If $\delta \in (0, \delta_1)$, then we complete the definition of v by setting $v(x, t) = \widehat{v}(x, t - n\delta_1)$ for all $t \in I_n$. Here, $\widehat{v} \in L^\infty(\mathcal{O} \times (0, \delta))$ is a control such that the system

$$\left\{\begin{array}{lll} \partial_t y - \Delta y + f(y, \nabla y) = \widehat{v} 1_{\mathcal{O}} & \text{in} & \Omega \times (0, \delta), \\ y = 0 & \text{on} & \partial\Omega \times (0, \delta), \\ y(x, 0) = w(x, \delta_1) & \text{in} & \Omega \end{array}\right. \tag{74}$$

possesses exactly one solution $\hat{y} \in C^0([0,\delta]; W^{1,\infty}(\Omega))$ satisfying

$$\hat{y}(x,\delta) = w(x,\delta) \quad \text{in} \quad \Omega.$$

(Once more, the existence of $\hat{v}$ is implied by Lemma 4.1.) Now, the state y associated to y_0 and v satisfies

$$y(x,T) = w(x,\delta) \quad \text{in} \quad \Omega. \tag{75}$$

Again, taking (70) into account, we see that (4) is satisfied in this case.

This completes the proof of Theorem 1.2.

5. Sketch of the proofs of the boundary controllability results. We devote this section to sketching briefly the proofs of Theorems 1.3 and 1.4. Both results are implied by the results established in the case of internal controllability.

For instance, let us refer to the proof of Theorem 1.3. Let us assume, for simplicity, that $y_0 \in W^{2,p}(\Omega) \cap V$ for some $p > N$ (recall that V is given by (10)). We have assumed that $f : \mathbb{R} \times \mathbb{R}^N \mapsto \mathbb{R}$ is a locally Lipschitz-continuous function that satisfies $f(0,0) = 0$ and (6). Let D be a bounded open set with boundary ∂D of class C^2 such that $\Omega \subset D$ and $\partial\Omega \cap D = \gamma$. Let $\mathcal{O}$ be an open subset of $D \setminus \overline{\Omega}$. There exists a function $\widetilde{y}_0 \in W^{2,p}(D) \cap H_0^1(D)$ such that $\widetilde{y}_0 = y_0$ in Ω and

$$\|\widetilde{y}_0\|_{W^{2,p}(D)} \leq C \, \|y_0\|_{W^{2,p}(\Omega)},$$

where C is a positive constant depending only on Ω and D.

Let $\widetilde{v} \in L^\infty(\mathcal{O} \times (0,T))$ be a control, furnished by Theorem 1.1, such that

$$\begin{cases} \partial_t \widetilde{y} - \Delta \widetilde{y} + f(\widetilde{y}, \nabla \widetilde{y}) = \widetilde{v} 1_{\mathcal{O}} & \text{in} \quad D \times (0,T), \\ \widetilde{y} = 0 & \text{on} \quad \partial D \times (0,T), \\ \widetilde{y}(x,0) = \widetilde{y}_0(x) & \text{in} \quad D \end{cases}$$

possesses exactly one solution $\widetilde{y} \in C^0([0,T]; W^{1,\infty}(D))$ with

$$\widetilde{y}(x,T) = 0 \qquad \text{in } D.$$

Let v be the trace of $\widetilde{y}$ on $\gamma \times (0,T)$. Then $v \in L^\infty(\gamma \times (0,T))$, and the restriction to $\Omega \times (0,T)$ of $\widetilde{y}$ solves the corresponding system (2). This proves Theorem 1.3.

In order to prove Theorem 1.4, it suffices to argue in a similar way.

Appendix. Proof of Lemma 2.1. The statement (12) and the inequality (13) are proved in [LSU, Theorem 9.1, p. 342]. The inequality (14) is not explicitly proved in [LSU], but it can be deduced (in several ways) from other results of this book. One of the arguments is as follows.

From Theorem 16.3 in [LSU] (p. 412), we deduce the inequalities

$$\|S(t)\varphi\|_{L^\gamma} \leq C t^{-\frac{N}{2}(\frac{1}{r}-\frac{1}{\gamma})} \|\varphi\|_{L^r}$$

and

$$\|S(t)\varphi\|_{W^{1,\gamma}} \leq C t^{-\frac{N}{2}(\frac{1}{r}-\frac{1}{\gamma})-\frac{1}{2}} \|\varphi\|_{L^r},$$

which hold for all $t > 0$ and $r, \gamma \in [1,\infty]$ with $\gamma \geq r$. Here, $S(t)$ is the semigroup generated by the heat equation with Dirichlet boundary conditions. With these inequalities in mind, one can prove the following.

LEMMA A.1. *Let y be the solution of (11). If $y \in L^\infty(0,T;W^{1,r}(\Omega))$ with $r \le 2N$, then*

$$y \in L^\infty(0,T;W^{1,\gamma}(\Omega)), \quad \text{where} \quad \gamma = \begin{cases} \left(\dfrac{1}{r} - \dfrac{1}{2N}\right)^{-1} & \text{if } r < 2N, \\ \infty & \text{if } r = 2N \end{cases} \tag{76}$$

and

$$\begin{cases} \|y\|_{L^\infty(0,T;W^{1,\gamma})} \le e^{C(1+T)} \left(\|y_0\|_{W^{2,p}} + \|F\|_q\right) \\ \qquad\qquad + e^{C(1+T^{1/2}\|B\|_\infty^2 + T^{1/2}\|a\|_\infty)} \|y\|_{L^\infty(0,T;W^{1,r})}. \end{cases}$$

Proof. The solution y of (11) can be written in the form $y(t) = z(t) - w(t)$, with

$$z(t) = S(t)y_0 + \int_0^t S(t-s)F(s)\,ds$$

and

$$w(t) = \int_0^t S(t-s)\left[ay + B\cdot\nabla y\right](s)\,ds.$$

Since $y_0 \in W^{2,p}(\Omega)$ with $p > N$ and $F \in L^q(Q)$ with $q > N+2$, it is not difficult to see that $z \in L^\infty(0,T;W^{1,\infty}(\Omega))$ and

$$\|z\|_{L^\infty(0,T;W^{1,\infty})} \le C\|y_0\|_{W^{2,p}} + \frac{C}{\alpha(q)} T^{\alpha(q)} \|F\|_q \le e^{C_q(1+T)} \left(\|y_0\|_{W^{2,p}} + \|F\|_q\right),$$

where

$$\alpha(q) = \frac{q-(N+2)}{2(q-1)}.$$

On the other hand, the usual Sobolev imbeddings give $y \in L^\infty(0,T;L^\gamma(\Omega))$ (γ is given in (76)). Moreover, we can write the following for all $t > 0$:

$$\begin{cases} \|w(\cdot,t)\|_{W^{1,\gamma}} \le C \displaystyle\int_0^t (t-s)^{-1/2} \|(ay)(\cdot,s)\|_{L^\gamma}\,ds \\ \qquad\qquad + C \displaystyle\int_0^t (t-s)^{-1/4} \|(B\cdot\nabla y)(\cdot,s)\|_{L^r}\,ds. \end{cases}$$

We can now apply Young's inequality to obtain

$$\|w\|_{L^\infty(W^{1,\gamma})} \le C\left(T^{1/2}\|a\|_\infty + T^{1/4}\|B\|_\infty\right) \|y\|_{L^\infty(0,T;W^{1,r})}.$$

This completes the proof of Lemma A.1. ∎

We are now ready to prove (14). Since $y_0 \in H_0^1(\Omega)$ and $F \in L^2(Q)$, the classical energy estimates give

$$y \in L^\infty(0,T;H_0^1(\Omega)) \cap L^2(0,T;H^2(\Omega)),$$

with

$$\|y\|_{L^\infty(0,T;H_0^1)} + \|y\|_{L^2(0,T;H^2)} \le e^{C(1+T+(T+T^{1/2})\|a\|_\infty + T\|B\|_\infty^2)} \left(\|y_0\|_{W^{2,p}} + \|F\|_q\right).$$

We can now apply Lemma A.1 with $r = 2$ and obtain $y \in L^\infty(0,T;W^{1,r_1}(\Omega))$, where

$$\frac{1}{r_1} = \frac{1}{2} - \frac{1}{2N}$$

and

$$\begin{cases} \|y\|_{L^\infty(0,T;W^{1,r_1})} \le e^{C(1+T)} \left(\|y_0\|_{W^{2,p}} + \|F\|_q\right) \\ \qquad\qquad + e^{C(1+T^{1/2}\|B\|_\infty^2 + T^{1/2}\|a\|_\infty)} \|y\|_{L^\infty(0,T;H_0^1)}. \end{cases}$$

Combining the last two inequalities, we obtain

$$\|y\|_{L^\infty(0,T;W^{1,r_1})} \le e^{C(1+T+(T+T^{1/2})\|a\|_\infty + (T+T^{1/2})\|B\|_\infty^2)} \left(\|y_0\|_{W^{2,p}} + \|F\|_q\right).$$

We can repeat this process for $i = 2, \dots, N$, with

$$r_i = \left(\frac{1}{2} - \frac{i}{2N}\right)^{-1} \quad \text{for } i \le N-1 \quad \text{and} \quad r_N = \infty.$$

Obviously, this leads to (14).

Acknowledgments. The authors thank the referees for their interesting comments and suggestions. In particular, they are indebted to referee no. 1 for having suggested the argument used in the proof of Theorem 1.2.

SOLUTION OF A FUNCTIONAL EQUATION ARISING IN CONTINUOUS GAMES: A DYNAMIC PROGRAMMING APPROACH*

K. D. SENAPATI† AND G. PANDA‡

Abstract. This paper deals with a functional equation in a zero sum continuous game. The existence of the solution for this equation is proved through a dynamic programming approach. Also, the authors have tried to prove the uniqueness and effectiveness of the solution.

Key words. continuous game, dynamic programming, fixed point

1. Introduction. In this paper, we have considered a multistage allocation process where some decisions are made to maximize and some to minimize. This type of situation occurs in the theory of games. Consider a two-person zero sum game in which both players A and B choose from a continuous domain. Suppose the real numbers x and y are treated as resource or state variables of A and B, respectively; A allocates a certain quantity u of his resource x, $0 \le u \le x$, and B allocates a certain quantity v of his resource y, $0 \le v \le y$. u and v are treated as decision variables. S is the state space, and D is the decision space.

As a result of the above allocations, A receives a payoff $R(x, y, u, v)$, and B receives a payoff $-R(x, y; u, v)$, where $R : S \times D \to R$ and R is the set of real numbers. In addition to these payoffs, there is an alternation to their resources. x becomes $T(x, y, u, v)$ and y becomes $T'(x, y; u, v)$, where T, $T' : S \times D \to R$. We assume that the R, T, and T' are continuous functions of x, y, u, and v. Bhakta and Mitra [2] proved some existence theorems in game theory through a dynamic programming approach. The functional equation (by Bellman [1, Chapter x]) we shall consider is

$$f(x,y) \;:\; \operatorname*{Max}_{G} \operatorname*{Min}_{G} \left\lfloor \int_u \int_v [R(x,y;u,v) + h(x,y;u,v) f(T,T')] dG(u) dG'(v) \right\rfloor$$

$$= \operatorname*{Max}_{G} \operatorname*{Min}_{G} [- - - - - -], \tag{1}$$

where $T = T(x, y; u, v)$ and $T' = T'(x, y; u, v)$. To simplify our notation, we write the above equation as

$$f(x,y) \;:\; \operatorname*{Max}_{G} \operatorname*{Min}_{G} F(x,y;f;G,G')$$

$$= \operatorname*{Max}_{G} \operatorname*{Min}_{G} [- - - - - -],$$

where $F(x, y; u, v) = \int_u \int_v [R(x, y; u, v) + h(x, y; u, v) f(T, T')] dG(u) dG'(v)$ and G and G' are the distribution functions for A and B, respectively. To prove the existence of the solution of (1), we use the following preliminary lemmas.

2. Some preliminary lemmas.

LEMMA 2.1. *If, for* $i = 1, 2$,

$$\Psi_i(x,y) \;:\; \operatorname*{Max}_G \operatorname*{Min}_G \left[\int_u \int_v [R(x,y;u,v) + h(x,y;u,v) f(T,T')] dG(u) dG'(v)\right]$$
$$= \operatorname*{Max}_G \operatorname*{Min}_G [- - - - - -],$$

then $|\Psi_1(x,y) - \Psi_2(x,y)| \le \mathrm{Max}_u \mathrm{Max}_v [|(x,y;u,v)|\,|f_1(T,T') - f_2(T,T')|]$, *where* T *and* T' *are defined as in section* 1.

Proof. To simplify, we denote

$$\Psi_i(x,y) \;:\; \operatorname*{Max}_G \operatorname*{Min}_{G'} F(x,y;f_i;G,G')$$
$$= \operatorname*{Max}_{G'} \operatorname*{Min}_G [- - - - - -].$$

Let G_i, G_i' be a pair of functions yielding the optimal value of $\Psi_i(x,y)$ for $i = 1, 2$.

Then $\Psi_1(x,y) = F(x,y;f_1;G_1,G_2') \ge F(x,y;f_1;G_2,G_1')$ and $\Psi_1(x,y) \le F(x,y;f_1;G_1,G_2')$.

Again, $\Psi_2(x,y) = F(x,y;f_2;G_2,G_2') \ge F(x,y;f_2;G_1,G_2')$ and $\Psi_2(x,y) \le F(x,y;f_2;G_2,G_1')$.

Combining these inequalities, we get

$$\int_u \int_v [h(x,y;u,v)(f_1(T,T') - f_2(T,T'))] dG_2(u) dG_1'(v)$$
$$\le \Psi_1(x,y) - \Psi_2(x,y)$$
$$\le \int_u \int_v [h(x,y;u,v)(f_1(T,T') - f_2(T,T'))] dG_1(u) dG_2'(v).$$

This implies that

$$|\Psi_1(x,y) - \Psi_2(x,y)| \le \operatorname*{Max}_u \operatorname*{Max}_v [|h(x,y;u,v)|\,|f_1(T,T') - f_2(T,T')|]. \qquad \square$$

LEMMA 2.2. *Let* $\langle M, \rho\rangle$ *be a complete metric space.* A *is a mapping from* M *into itself. If the following conditions hold, then* A *has a unique fixed point.*

(i) *For any* x, $y \in M$, $\rho(Ax, Ay) \le \phi(\rho(x,y))$, *where* $\phi : [0,\infty) \to [0,\infty)$ *is nondecreasing continuous on the right and* $\phi(r) < r$ *for* $r > 0$.

(ii) *For every* $x \in M$, *there is a positive number* k *such that* $\rho(x, A^n x) \le k$ *for all* n.

LEMMA 2.3. *Let* $\langle M, \rho\rangle$ *be a complete metric space, and let* A *be a mapping of* M *into itself. Suppose that, for all* x, y *in* M, $\rho(Ax, Ay) \le \phi(\rho(x,y))$, *where* $\phi : [0,\infty) \to [0,\infty)$ *is nondecreasing, and, for every positive number* r, *the series* $\sum \phi^n(r)$ *is convergent. Then* A *has a unique fixed point.*

Lemma 2.2 is an extension of Brauer's fixed-point theorem [3], and the proof of Lemma 2.3 is in light of [4, Theorem 3.2, p. 12], which is easy and straightforward.

3. Solution of the functional equation.

THEOREM 3.1. *The functional equation* (1) *possesses unique bounded solution on* S *under the following conditions:*

(i) R *and* h *are bounded;*

(ii) $\mathrm{Max}_u\mathrm{Max}_v[|h(x,y;u,v)|\,|f_1(T,T') - f_2(T,T')|] \le \phi(\mathrm{Max}_u\mathrm{Max}_v[|f_1(T,T') - f_2(T,T')|])$,

where $\phi : [0,\infty) \to [0,\infty)$ *is nondecreasing and continuous on the right such that* $\phi(r) < r$ *for* $r > 0$.

Proof. Let $B(S)$ be the set of all real valued bounded functions on S. For Ψ_1, $\Psi_2 \in B(S)$, let

$$\rho(\Psi_1,\Psi_2) = \operatorname*{Max}_u \operatorname*{Max}_v \left[|\Psi_1(x,y) - \Psi_2(x,y)|\right].$$

Then ρ is a metric on $B(S)$ and $\langle B(S),\rho\rangle$ is a complete metric space. Let A be any function defined on $B(S)$ by $Ag = \Psi$ for any $g \in B(S)$,

$$\Psi(x,y) \;:\; \operatorname*{Max}_G \operatorname*{Min}_{G'} \left[\int_u\int_v [R(x,y;u,v) + h(x,y;u,v)g(T,T')]\,dG(u)dG'(v)\right]$$
$$= \operatorname*{Min}_{G'} \operatorname*{Max}_G[-----].$$

Since R, h, and g are bounded, Ψ is also bounded, and $\Psi \in B(S)$. Hence $A : B(S) \to B(S)$. For $\Psi_1\Psi_2 \in B(S)$, let

$$\Psi_i(x,y) : \operatorname*{Max}_G \operatorname*{Min}_{G'} \left[\int_u\int_v [R(x,y;u,v) + h(x,y;u,v)g_i(T,T')]dG(u)dG'(v)\right]$$
$$\operatorname*{Min}_{G'} \operatorname*{Max}_G[-----].$$

Let G_i, G_i' be the distribution functions yielding $\Psi_i(x,y)$ for $i = 1,2$. Then, using Lemma 2.1 and condition (ii), we have

$$|\Psi_1(x,y) - \Psi_2(x,y)| \le \phi\left(\operatorname*{Max}_u \operatorname*{Max}_v[|g_1(T,T') - g_2(T,T')|]\right) = \phi(\rho(g_1,g_2)),$$

i.e., $\rho(Ag_1,Ag_2) \le \phi(\rho(g_1,g_2))$. Let $A^ng = g_n$ for $g \in B(S)$, where

$$g_n(x,y) \;:\; \operatorname*{Max}_G \operatorname*{Min}_{G'} \left[\int_u\int_v [R(x,y;u,v) + h(x,y;u,v)g_{n-1}(T,T')]dG(u)dG'(v)\right]$$
$$= \operatorname*{Min}_{G'} \operatorname*{Max}_G[-----]$$

for $n = 2,3,\ldots$, and

$$g_1(x,y) \;:\; \operatorname*{Max}_G \operatorname*{Min}_{G'} \left[\int_u\int_v R(x,y;u,v)dG(u)dG'(v)\right]$$
$$= \operatorname*{Min}_{G'} \operatorname*{Max}_G[-----].$$

Since R, h, and g are all bounded functions, $|R(x,y;u,v)| \le \lambda_1$, $|h(x,y;u,v)g_n(T,T')| \le \lambda_2$, and $|g(x,y)| \le \lambda_3$ for all $(x,y) \in S$, $(u,v) \in D$, $g(T,T') \in R$, where λ_1, λ_2, λ_3 are constants. This yields that $|g_n(x,y)| \le \lambda_1 + \lambda_2\lambda_3$ for all $(x,y) \in S$. Now

$$|g(x,y) - g_n(x,y)| \le |g(x,y)| + |g_n(x,y)| \le \lambda_1 + \lambda_2\lambda_3 + \lambda_3 = \lambda \text{ for all } n.$$

So $\rho(g,g_n) = \rho(g,A^ng) \le \lambda$ for all n. Therefore, by Lemma 2.2, the mapping A has a unique fixed point; i.e., the functional equation (1) has a unique bounded solution on S. ∎

THEOREM 3.2. *Let $h: S \times D \to \mathbf{R}$ be such that $|h(x,y;u,v)| \le a < 1$ for all $(x,y) \in S$, $(u,v) \in D$ is bounded, and condition* (ii) *of Theorem* 3.1 *is satisfied. Then the functional equation* (1) *possesses a unique bounded solution on S.*

Proof. Let $\phi : [0,\infty) \to [0,\infty)$ be defined by $\phi(r) = ar$, $r > 0$. Then ϕ is nondecreasing and continuous on the right. Also $\sum \phi^n(r) = r \sum a^n$. Since $a < 1$, $\sum \phi^n(r)$ is convergent for a very positive number r. Proceeding as in Theorem 3.1 and using Lemma 2.1, we have

$$\begin{aligned}\rho(Ag_1, Ag_2) = \rho(\Psi_1, \Psi_2) &\le \operatorname*{Max}_u \operatorname*{Max}_v [|h(x,y;u,v)|\,|g_1(x,y) - g_2(x,y)|] \\ &\le \phi\left(\operatorname*{Max}_u \operatorname*{Max}_v [|g_1(x,y) - g_2(x,y)|]\right) \\ &= \phi(\rho(g_1, g_2)).\end{aligned}$$

Hence, by Lemma 2.3 the functional equation (1) possesses a unique bounded solution on S. □

THEOREM 3.3. *Suppose the following conditions hold:*

(i) $|f(T,T')| \le \|(T,T')\| \le \phi(\|(x,y)\|)$ *for all* $(x,y) \in S$, *where* ϕ: $[0,\infty] \to [0,\infty)$ *is nondecreasing, and, for every positive number* r, $\sum \phi^n(r)$ *is convergent.*

(ii) $0 \le R(x,y;u,v) \le \|(x,y)\|$ *for all* $(u,v) \in D$.

(iii) $0 \le h(x,y;u,v) f(T,T') \le 1 f(T,T')|$.

Then the functional equation (1) *possesses a unique solution on S.*

Proof. Let $\{f_n\}$ be a sequence of functions defined on S by

$$\begin{aligned}f_0(x,y) \;:\; &\operatorname*{Max}_G \operatorname*{Min}_{G'} \left[\int_u \int_v R(x,y;u,v)\,dG(u)\,dG'(v)\right] \\ &= \operatorname*{Min}_{G'} \operatorname*{Max}_G [------].\end{aligned}$$

and

$$\begin{aligned}f_{n+1}(x,y) \;:\; &\operatorname*{Max}_G \operatorname*{Min}_{G'} \left[\int_u \int_v R(x,y;u,v) + h(x,y;u,v) f_n(T,T')\,dG(u)\,dG'(v)\right] \\ &= \operatorname*{Min}_{G'} \operatorname*{Max}_G [------].\end{aligned}$$

By (ii), $f_0(x,y) \ge 0$ for all $(x,y) \in S$.

$$\begin{aligned}f_1(x,y) \;:\; &\operatorname*{Max}_G \operatorname*{Min}_{G'} \left[\int_u \int_v R(x,y;u,v) + h(x,y;u,v) f_0(T,T')\,dG(u)\,dG'(v)\right] \\ &= \operatorname*{Min}_{G'} \operatorname*{Max}_G [------] \\ &\ge f_0(x,y).\end{aligned}$$

Let $f_n(x,y) \ge f_{n-1}(x,y)$.

Then

$$\begin{aligned}f_{n+1}(x,y) \;:\; &\operatorname*{Max}_G \operatorname*{Min}_{G'} F(x,y;f_n;G,G') \\ &= \operatorname*{Min}_{G'} \operatorname*{Max}_G [------].\end{aligned}$$

As in Lemma 2.1, if G_1, G_1' and G_2, G_2' yield the value of $f_{n+1}(x,y)$ and $f_n(x,y)$, we get

$$f_{n+1}(x,y) - f_n(x,y) \geq \int_u \int_v h(x,y;u,v)[f_n(T,T') - f_{n-1}(T,T')]dG_2'(u)dG_1'(v) \geq 0;$$

i.e., $f_{n+1}(x,y) \geq f_n(x,y)$ for all n. Thus $\{f_n(x,y)\}$ is a monotonically increasing sequence. To show that $\{f_n(x,y)\}$ is bounded above, let $(x,y) \in S$ and r be a positive number such that $\|(x,y)\| = r$. Since $0 \leq R(x,y;u,v) \leq \|(x,y)\|$ for all $(u,v) \in D$, $0 \leq f_0(x,y) \leq \|(x,y)\|$. Again,

$$\begin{aligned} 0 \leq f_1(x,y) &\leq R(x,y;u,v) + h(x,y;u,v)f_0(T,T') \\ &\leq \|(x,y)\| + |f_0(T,T')| \\ &\leq \|(x,y)\| + \|(T,T')\|. \end{aligned}$$

Thus $0 \leq f_1(x,y) \leq \|(x,y)\| + \phi(\|(x,y)\|)$. Next

$$\begin{aligned} 0 \leq f_2(x,y) &\leq R(x,y;u,v) + h(x,y;u,v)f_1(T,T') \\ &\leq \|(x,y)\| + |f_1(T,T')| \\ &\leq \|(x,y)\| + \|(T,T')\| + \phi(\|(T,T')\|) \\ &\leq \|(x,y)\| + \phi\|(x,y)\|) + \phi^2(\|(x,y)\|); \end{aligned}$$

i.e., $0 \leq f_2(x,y) \leq r + \phi(r) + \phi^2(r)$. Proceeding in this way, we obtain $0 \leq f_n(x,y) \leq \sum \phi^n(r)$. Since $\sum \phi^n(r)$ is convergent, $\{f_n(x,y)\}$ is bounded hence convergent.

Let $\bar{f}(x,y) = \lim_{n\to\infty} f_n(x,y)$.

Next show that $\bar{f}(x,y)$ is the solution of the functional equation (1). Since f_n is increasing and $\bar{f}$ is its limit, $f_{n+1}(x,y) \leq \bar{f}(x,y)$; i.e.,

$$\operatorname*{Max}_{G} \operatorname*{Min}_{G'} \left[\int_u \int_v R(x,y;u,v) + h(x,y;u,v)f_n(T,T')dG(u)dG'(v)\right] \leq \bar{f}(x,y).$$

Letting $n \to \infty$,

$$\operatorname*{Max}_{G} \operatorname*{Min}_{G'} \left[\int_u \int_v R(x,y;u,v) + h(x,y;u,v)\bar{f}(T,T')dG(u)dG'(v)\right] \leq \bar{f}(x,y). \tag{2}$$

For any $(x,y) \in S$, $(u,v) \in D$, and any positive integer n, we have

$$f_n(x,y) \leq \operatorname*{Max}_{G} \operatorname*{Min}_{G'} \left[\int_u \int_v R(x,y;u,v) + h(x,y;u,v)\bar{f}(T,T')dG(u)dG'(v)\right].$$

Letting $n \to \infty$,

$$\bar{f}(x,y) \leq \operatorname*{Max}_{G} \operatorname*{Min}_{G'} \left[\int_u \int_v R(x,y;u,v) + h(x,y;u,v)\bar{f}(T,T')dG(u)dG'(v)\right]. \tag{3}$$

From (2) and (3),

$$\begin{aligned} \bar{f}(x,y) &\leq \operatorname*{Max}_{G} \operatorname*{Min}_{G'} \left[\int_u \int_v R(x,y;u,v) + h(x,y;u,v)\bar{f}(T,T')dG(u)dG'(v)\right] \\ &= \operatorname*{Min}_{G'} \operatorname*{Max}_{G}[------]. \end{aligned}$$

If we let $Ax = T(x,y;u,v)$ and $Ay = T'(x,y;u,v)$, then $\|(Ax,Ay)\| = \|(T,T')\| \leq \phi(\|(x,y)\|)$, and the above solution is unique by Lemma 2.3. □

4. Conclusion (effective of the solution). In a multistage allocation process, the functional equation discussed above has some importance in game theory. We have established the existence of its solution under several assumptions that this infinite process admits a value to both of the players. The solution is effective if it gives sufficient information to the players to obtain this value. Suppose that G, G' yield the value of the game. Then the corresponding solution becomes effective if A uses a distribution function $G(u)$; whatever B may use, A can guarantee himself a return of at least $f(x, y)$. At this fixed strategy, A's return will be at worst determined by the functional equation

$$F(x,y) \leq \operatorname*{Min}_{G'} \left[\int_u \int_v R(x,y;u,v) + h(x,y;u,v) F(T,T') dG(u) dG'(v) \right].$$

Under the assumptions of our theorems, the above equation has a unique solution, and the solution is obtained by the successive approximation of the functions

$$F_0(x,y) = \operatorname*{Min}_{G'} \int_u \int_v R(x,y;u,v) dG(u) dG'(v),$$

$$F_{n+1}(x,y) = \operatorname*{Min}_{G'} \left[\int_u \int_v R(x,y;u,v) + h(x,y;u,v) f_n(T,T') dG(u) dG'(v) \right].$$

It is clear that $F = f_1$ and $F_{n+1} = f_{n+1}$. Thus $F(x, y) = \lim_{n\to\infty} F_n = \lim_{n\to\infty} f_n = f(x, y)$.

Hence the solution is effective. A similar result holds if B uses a distribution function $G'(v)$, whatever A may use.

Acknowledgment. The authors are thankful to the referees for their valuable suggestions in preparing the final version of this paper.

LIMIT HAMILTON–JACOBI–ISAACS EQUATIONS FOR SINGULARLY PERTURBED ZERO-SUM DYNAMIC (DISCRETE TIME) GAMES*

PENG SHI†

Abstract. In this paper we study a singularly perturbed zero-sum dynamic game with full information. We introduce the upper (lower) value function of the dynamic game, in which the minimizer (maximizer) can be guaranteed if at the beginning of each interval his move (the choice of decision) precedes the move of the maximizer (minimizer). We show that when the singular perturbations parameter tends to zero, the upper (lower) value function of the dynamic game has a limit which coincides with a viscosity solution of a Hamilton–Jacobi–Isaacs-type equation. Two examples are given to demonstrate the potential of the proposed technique.

Key words. discrete time games, Hamilton–Jacobi–Isaacs equations, singularly perturbed systems, value functions, viscosity solutions

1. Introduction.

Singularly perturbed control systems (SPCS) evolving in a discrete time scale arise in many applications as well as in the construction of the difference approximations of SPCS evolving in continuous time. Despite this, discrete time SPCS were studied in the literature much less intensively than their continuous time counterparts. A reason for such a discrepancy might be the fact that a common approach to SPCS was one based on the boundary layer method [25, 30, 31], which is not easy to adapt to deal with the discrete time SPCS.

Recently, a number of averaging-type methods allowing one to treat general SPCS in continuous time were developed (see, e.g., [1, 2, 8, 9, 10, 11, 16, 18, 32]). These methods are much more adaptable to the discrete time scale. For example, a full analogy between the averaging procedures in problems of optimal control of SPCS evolving in continuous and discrete times was established in [17].

In this paper, we extend a similar analogy by showing that the results about averaging in singularly perturbed (SP) zero-sum differential games obtained in [12] have their counterparts in a discrete time setting. More specifically, we will show that the upper and lower values of an SP dynamic (discrete time) game with full information converge (as the SP parameter tends to zero) to the viscosity solutions of some Hamilton–Jacobi-type equations, with Hamiltonians being the limit averages of the upper and (respectively) lower value functions of a certain associated "fast" discrete time game. This result leads, in particular, to a very important conclusion that states that if the limit averages of the upper and lower values of the associated fast game coincide, then the limits of the upper and lower values of the original discrete time SP game coincide too and, thus, the latter has value in the limit as the singular perturbations parameter tends to zero.

†Land Operations Division, Defence Science and Technology Organisation, Department of Defence, P.O. Box 1500, Edinburgh 5111 SA, Australia (peng.shi@dsto.defence.gov.au). This work was carried out while the author was with the Centre for Industrial and Applicable Mathematics, School of Mathematics, The University of South Australia.

An important issue in the theory of SPCS is a justification of a so-called reduction technique approach (RTA). According to this approach the fast variables are replaced by their steady states obtained with "frozen" slow variables and controls, and the slow dynamics is approximated by the corresponding reduced order system. Although the RTA may fail to provide a proper approximation for the SPCS in a general case [9, 10, 11], its application was very successful in many important special cases (see [15, 24, 22, 23, 28, 29] and the references therein). In the differential game context the efficiency of the RTA was established for SP linear quadratic games in [14, 21] and for the SP H^∞ problem with linear dynamics in [26, 27].

The general averaging approach that we develop in this paper allows us to verify applicability of the RTA in SP discrete time games. This point is illustrated by a special example with linear fast variables and controls dynamics.

It should be mentioned that the motivation for the study in this paper stems from the work of [7] and [12]. In [7], the differential game and its properties were studied, but by discretizing the continuous time systems and using a discrete approach. By looking at the behavior of small time intervals (tending to zero), the solution to the differential game was thus provided. While stimulated by the work of [7], the continuous time counterpart of this paper was investigated in [12]. Both the results obtained in [12] and in this paper were encouraged by the pioneering work of [7], but emphasis is laid on the impact of singular perturbations and its asymptotic behavior. By the results in [7] and [12], the PDE (2.24) would be helpful to solve discrete time games by looking at the discrete instant behavior. As we mention in Remark 4.3, Theorem 4.1 is asymptotic in nature. Our emphasis is to establish the convergence of the upper and lower values of the singularly perturbed dynamic game to the viscosity solutions of corresponding limited Hamilton–Jacobi–Isaacs (LHJI) equations.

This paper is organized as follows. In section 2, we describe our main results without going into technical details. In section 3, these results are illustrated by a consideration of a special class of SP discrete time games and two examples, one of which illustrates an applicability of RTA. In section 4, we introduce our main assumptions and establish one theorem about the convergence of the upper and lower value functions of an SP discrete time zero-sum game to the viscosity solutions of the corresponding LHJI equations (defined in section 2). Assumptions 4.4, 4.5, and 4.6 are verified in section 5.

Notation. Throughout this paper R^n and $R^{n\times m}$ denote, respectively, the n-dimensional Euclidean space and the set of all $n \times m$ real matrices. $\|\cdot\|$ will refer to the L_∞ norm in the finite-dimensional space. That is, for $q \in R^k$ and $A \in R^{n\times k}$, $\|q\| = \max_{i=1,2,\ldots,k} |q_i|$ and $\|A\| = \max_{\|q\|=1} \|Aq\|$. $\lfloor x \rfloor$ stands for the greatest integer which is smaller than or equal to x.

2. Problem formulation and preliminaries.

2.1. Singularly perturbed discrete time game. Consider a discrete time system

$$z(k+1) = z(k) + \epsilon f_1\left(z(k), y(k), u_k, v_k\right), \tag{2.1}$$

$$y(k+1) = y(k) + f_2\left(z(k), y(k), u_k, v_k\right) \tag{2.2}$$

for $k = l, l+1, \ldots, N_\epsilon - 1$ with $N_\epsilon \stackrel{\text{def}}{=} \lfloor \frac{T}{\epsilon} \rfloor$ and

$$z(l) = z, \quad y(l) = y, \tag{2.3}$$

where $l = 0, 1, \ldots, N_\epsilon - 1$. Here ϵ is a small positive parameter, $T > 0$ defines the final time, and $f_1(\cdot)$ and $f_2(\cdot)$ are maps from $R^m \times R^n \times R^p \times R^q$ to R^m and R^n, respectively.

The appearance of the small parameter in the right-hand side of (2.1) implies that the rate of change of the z-components of the phase vector is of the order ϵ and, thus, this component can be considered to be slow with respect to the y-components changing with the rate $O(1)$. The number of discrete moments of time in which the phase vector changes its values according to (2.1)–(2.2) has the order $\frac{1}{\epsilon}$. Hence, the slow components z may have significant (not tending with ϵ to zero) deviations from their initial values. Systems allowing similar properties on a continuous time scale are commonly called singularly perturbed (SP). Adopting this terminology, we shall call (2.1)–(2.2) a *singularly perturbed discrete time (SPDT) system*.

Assume that there are two controllers in our system, one responsible for the choice of u_k (maximizer) and the other for the choice of v_k (minimizer). The controls are chosen to satisfy the inclusions

$$u_k \in U, \quad v_k \in V, \quad k = l, l+1, \ldots, N_\epsilon - 1, \tag{2.4}$$

where U and V are given compact subsets of R^p and R^q, respectively. Motivated by the results in [7], we consider a sequence, $l = 0, 1, \ldots, N_\epsilon - 1$, of the dynamic games each starting at the moment l and consisting of $N_\epsilon - l$ steps. The strategies of the players are defined in these games as follows:

Let Γ_l^l and Δ_l^l be any vectors in U and V. Let Γ_{l+k}^l and Δ_{l+k}^l be any maps:

$$\Gamma_{l+k}^l : \quad \underbrace{(U \times V) \times (U \times V) \times \cdots \times (U \times V)}_{k} \to U,$$

$$\Delta_{l+k}^l : \quad \underbrace{(U \times V) \times (U \times V) \times \cdots \times (U \times V)}_{k} \to V$$

with $k = 1, \ldots, N_\epsilon - l - 1$.

The vector

$$\Gamma^l = \left(\Gamma_l^l, \ldots, \Gamma_{N_\epsilon - 1}^l\right)$$

is called a *strategy for the maximizer* in the game starting at the moment l, while the vector

$$\Delta^l = \left(\Delta_l^l, \ \ldots, \ \Delta_{N_\epsilon - 1}^l\right)$$

is called a *strategy for the minimizer* in the game starting at the moment l.

Given any pair (Γ^l, Δ^l) one can uniquely construct the control sequences

$$u^l = (u_k, \ k = l, \ldots, N_\epsilon - 1), \quad v^l = (v_k, \ k = l, \ldots, N_\epsilon - 1)$$

with $u_l \stackrel{\text{def}}{=} \Gamma_l^l$, $v_l \stackrel{\text{def}}{=} \Delta_l^l$ and

$$u_k = \Gamma_k^l \left(u_l, v_l, \ldots, u_{k-1}, v_{k-1}\right), \tag{2.5}$$

$$v_k = \Delta_k^l \left(u_l, v_l, \ldots, u_{k-1}, v_{k-1}\right) \tag{2.6}$$

for $k = l + 1, \ldots, N_\epsilon - 1$. This pair of control sequences is called the outcome of (Γ^l, Δ^l).

Let (Γ^l, Δ^l) be a pair of strategies of the players in the game starting at the moment l, let $(u^l, v^l) = \{(u_k, v_k),\ k = l, l+1, \dots, N_\epsilon - 1\}$ be its outcome, and let $(z(k), y(k))$ be the corresponding solution of (2.1)–(2.2). Define the payoff of the game by the equation

$$P_\epsilon(l, z, y, \Gamma^l, \Delta^l) = P_\epsilon(l, z, y, u^l, v^l) \stackrel{\text{def}}{=} G(z(N_\epsilon)) + \epsilon \sum_{k=l}^{N_\epsilon - 1} \Phi\left(z(k), y(k), u_k, v_k\right),$$

$$l = 0, 1, \dots, N_\epsilon - 1, \tag{2.7}$$

where $G : R^m \to R^1, \Phi : R^m \times R^n \times R^p \times R^q \to R^1$.

Define the *upper* and *lower value functions* of the SPDT game as follows:

$$B_\epsilon^{up}(l, z, y) = \inf_{\Delta_l^l} \sup_{\Gamma_l^l} \dots \inf_{\Delta_{N_\epsilon - 1}^l} \sup_{\Gamma_{N_\epsilon - 1}^l} P_\epsilon\ (l, z, y, \Gamma^l, \Delta^l), \quad l = 0, 1, \dots, N_\epsilon - 1 \tag{2.8}$$

$$B_\epsilon^{lo}(l, z, y) = \sup_{\Gamma_l^l} \inf_{\Delta_l^l} \dots \sup_{\Gamma_{N_\epsilon - 1}^l} \inf_{\Delta_{N_\epsilon - 1}^l} P_\epsilon(l, z, y, \Gamma^l, \Delta^l), \quad l = 0, 1, \dots, N_\epsilon - 1, \tag{2.9}$$

and also take

$$B_\epsilon^{up}(N_\epsilon, z, y) = B_\epsilon^{lo}(N_\epsilon, z, y) = G(z). \tag{2.10}$$

Given any l, z, and y, $B_\epsilon^{up}(l, z, y)$ is the value of the payoff functional (2.7) which the v-player (the minimizer) can be guaranteed if at the beginning of each interval k his move (the choice of Δ_k) precedes the move of the u-player (the choice of Γ_k), whereas $B_\epsilon^{lo}(l, z, y)$ is the value which the u-player (the maximizer) can be guaranteed if at the beginning of each interval his move precedes the move of the minimizer.

Notice that using an argument similar to that in [7], one can show that $B_\epsilon^{up(lo)}(l, z, y)$ also allows the following representations:

$$B_\epsilon^{up}(l, z, y) = \inf_{v_l} \sup_{u_l} \dots \inf_{v_{N_\epsilon - 1}} \sup_{u_{N_\epsilon - 1}} P_\epsilon(l, z, y, u^l, v^l), \tag{2.11}$$

$$B_\epsilon^{lo}\ (l, z, y) = \sup_{u_l} \inf_{v_l} \dots \sup_{u_{N_\epsilon - 1}} \inf_{v_{N_\epsilon - 1}} P_\epsilon(l, z, y, u^l, v^l), \tag{2.12}$$

where the sups and infs are sought over $u_l \in U$ and $v_l \in V$ and $(u^l, v^l) = (u_k, v_k),\ k = l, l+1, \dots, N_\epsilon - 1$.

Definition 2.1. *We shall say that the* SPDT game has value in the limit *if corresponding to any compact set $D_1 \times P_1 \subset R^m \times R^n$ there exists a function $\mu(\epsilon)$ tending to zero as ϵ tends to zero such that*

$$\left|B_\epsilon^{up}\ (l, z, y) - B_\epsilon^{lo}\ (l, z, y)\right| \le \mu(\epsilon) \quad \forall l = 0, 1, \dots, N_\epsilon - 1,\ (z, y) \in D_1 \times P_1. \tag{2.13}$$

2.2. Associated fast discrete time game. Consider a system

$$\tilde{y}(k+1) = \tilde{y}(k) + f_2(z, \tilde{y}(k), \tilde{u}_k, \tilde{v}_k), \qquad \tilde{y}(0) = y, \quad z = constant,$$
$$k = 0, 1, \dots, N - 1, \tag{2.14}$$

where N is a positive integer number. In contrast to (2.2), z here is a vector of constant parameters. System (2.14) is called an *associated system*.

Let $\tilde{\Gamma}_0$ and $\tilde{\Delta}_0$ be any functions in U and V and let $\tilde{\Gamma}_j$ and $\tilde{\Delta}_j$ be any map from

$$\underbrace{(U \times V) \times \dots \times (U \times V)}_{j}$$

into U and V, respectively, for $j = 1, \ldots, N-1$. The vectors

$$\tilde{\Gamma} = (\tilde{\Gamma}_0, \ldots, \tilde{\Gamma}_{N-1}), \quad \tilde{\Delta} = (\tilde{\Delta}_0, \ldots, \tilde{\Delta}_{N-1})$$

are called *strategies* for $\tilde{u}$- and $\tilde{v}$-players in the associated fast discrete time (AFDT) game, respectively. Similar to (2.5)–(2.6), given a pair $(\tilde{\Gamma}, \tilde{\Delta})$, one can construct the corresponding outcome, that is, the sequence of control pairs

$$(\tilde{u}, \tilde{v}) = (\tilde{u}_k, \tilde{v}_k), \qquad k = 0, 1, \ldots, N-1,$$

with

$$\tilde{u}_k \in U, \quad \tilde{v}_k \in V, \qquad k = 0, 1, \ldots, N-1, \tag{2.15}$$

and thus determine the solution $y_z = \tilde{y}_z(k)$ of (2.14).

Define the *payoff* of the AFDT game corresponding to the pair $(\tilde{\Gamma}, \tilde{\Delta})$ by the equation

$$\begin{aligned} Q(z, \lambda, N, y, \tilde{\Gamma}, \tilde{\Delta}) \; &= \; Q(z, \lambda, N, y, \tilde{u}, \tilde{v}) \\ &\stackrel{\text{def}}{=} N^{-1} \sum_{k=0}^{N-1} \Big[\Phi\left(z, \tilde{y}_z(k), \tilde{u}_k, \tilde{v}_k\right) + \lambda^T f_1\left(z, \tilde{y}_z(k), \tilde{u}_k, \tilde{v}_k\right) \Big], \end{aligned} \tag{2.16}$$

where Φ is the same as in the payoff functional (2.7), $f_1(\cdot)$ is the function defining the slow subsystem (2.1), and $z \in R^m$ and $\lambda \in R^m$ are vectors of constant parameters. The *upper* and *lower value functions* of the AFDT game are defined by the following equations:

$$R^{up}(z, \lambda, N, y) = \inf_{\tilde{\Delta}_0} \sup_{\tilde{\Gamma}_0} \ldots \inf_{\tilde{\Delta}_{N-1}} \sup_{\tilde{\Gamma}_{N-1}} \; Q(z, \lambda, N, y, \tilde{\Gamma}, \tilde{\Delta}), \tag{2.17}$$

$$R^{lo}(z, \lambda, N, y) = \sup_{\tilde{\Gamma}_0} \inf_{\tilde{\Delta}_0} \ldots \sup_{\tilde{\Gamma}_{N-1}} \inf_{\tilde{\Delta}_{N-1}} \; Q(z, \lambda, N, y, \tilde{\Gamma}, \tilde{\Delta}). \tag{2.18}$$

Similar to (2.11) and (2.12), $R^{up(lo)}(z, \lambda, N, y)$ allows the representations [7]

$$R^{up}(z, \lambda, N, y) = \inf_{\tilde{v}_0} \sup_{\tilde{u}_0} \ldots \inf_{\tilde{v}_{N-1}} \sup_{\tilde{u}_{N-1}} \; Q(z, \lambda, N, y, \tilde{u}, \tilde{v}), \tag{2.19}$$

$$R^{lo}(z, \lambda, N, y) = \sup_{\tilde{u}_0} \inf_{\tilde{v}_0} \ldots \sup_{\tilde{u}_{N-1}} \inf_{\tilde{v}_{N-1}} \; Q(z, \lambda, N, y, \tilde{u}, \tilde{v}), \tag{2.20}$$

where the sups and infs are sought over $\tilde{u}_j \in U$ and $\tilde{v}_j \in V$.

In what follows we shall use the following assumption about the upper and lower value functions of the AFDT game.

Assumption 2.1. There exist the limits

$$\lim_{N \to \infty} \; R^{up}(z, \lambda, N, y) \stackrel{\text{def}}{=} \; R^{up}(z, \lambda), \tag{2.21}$$

$$\lim_{N \to \infty} \; R^{lo}(z, \lambda, N, y) \stackrel{\text{def}}{=} \; R^{lo}(z, \lambda) \tag{2.22}$$

which do not depend on the initial values y in (2.14).

Remark 2.1. Assumption 2.1 is a discrete-time counterpart of the one introduced in [12]. Note that from a control theory point of view, if a system is controllable, then it is possible to drive the system from any initial state to any specified state within a certain time. Consequently, the limit behavior of the upper and lower value functions of the AFDT game should not depend upon the initial state y.

We shall say that the *AFDT game has value in the limit* if

$$R^{up}(z, \lambda) = R^{lo}(z, \lambda) \stackrel{\text{def}}{=} R(z, \lambda) \quad \forall (z, \lambda) \in R^m \times R^m. \tag{2.23}$$

2.3. LHJI equations for the SPDT game. Let us consider the Hamilton–Jacobi-type equations

$$-\frac{\partial B(t,z)}{\partial t} + H\left(z, \frac{\partial B(t,z)}{\partial z}\right) = 0, \qquad (t,z) \in [0,T) \times R^m, \tag{2.24}$$

with Hamiltonians $H(z,\lambda)$ being equal to $-R^{up}(z,\lambda)$, $-R^{lo}(z,\lambda)$, or $-R(z,\lambda)$ in the case in which (2.23) is true. These equations will be referred to as LHJI equations for the SPDT game. Let us denote by $B^{up}(t,z)$, $B^{lo}(t,z)$, $B(t,z)$ the viscosity solutions of these equations which satisfy the boundary condition

$$B(T,z) = G(z) \quad \forall z \in R^m. \tag{2.25}$$

In the following sections it will be shown that the upper and lower value functions of the SPDT game, $B^{up}_\epsilon(l,z)$ and $B^{lo}_\epsilon(l,z)$, converge to $B^{up}(t,z)$ and $B^{lo}(t,z)$, respectively, as ϵ tends to zero. This will imply in particular that if the AFDT game has the value in the limit, that is, (2.23) is true, then both $B^{up}_\epsilon(t,z)$ and $B^{lo}_\epsilon(t,z)$ converge to $B(t,z)$ as ϵ tends to zero, and thus the SPDT game has the value in the limit as well.

As in SP differential games, the above results can be considered to be a justification of a decomposition of the SPDT game into the AFDT game, allowing one to describe an asymptotically optimal behavior of the players if the slow parameters are fixed and the LHJI equations are responsible for a "near-optimality" of the slow dynamics.

Notice that for some classes of dynamic games (see the examples in section 3) the SPDT and AFDT games can be interpreted as in the Isaacs equations [19] for some specially constructed "slow" differential games.

3. Special case. To illustrate the results mentioned above let us consider a special case. Let

$$y^T = (y_1^T, y_2^T), \quad f_2^T(z,y,u,v) = \left(f_{21}^T(z,y_1,u), f_{22}^T(z,y_2,v)\right), \tag{3.1}$$

$$y^T(0) = (y_{10}^T, y_{20}^T), \qquad y_i \in R^{n_i},\ f_{2i} \in R^{n_i},\ n_1 + n_2 = n, \tag{3.2}$$

$$f_1(z,y,u,v) = f_{10}(z) + f_{11}(z,y_1,u) + f_{12}(z,y_2,v), \tag{3.3}$$

$$\Phi(z,y,u,v) = \Phi_1(z,y_1,u) + \Phi_2(z,y_2,v). \tag{3.4}$$

It can be easily shown that under the above assumptions about the structure of the SPDT game, the AFDT game is equivalent to two optimal control problems:

$$\sup_{u_k \in U} \Bigg\{ N^{-1} \sum_{k=0}^{N-1} \left[\Phi_1\left(z, y_1(k), u_k\right) + \lambda^T f_{11}\left(z, y_1(k), u_k\right)\right] \Bigg| \ y_1(k+1) = y_1(k) + f_{21}(z, y_1(k), u_k),\ y_1(0) = y_{10} \Bigg\} \stackrel{\text{def}}{=} r_1(z, \lambda, N, y_{10}) \tag{3.5}$$

and

$$\inf_{v_k \in V} \Bigg\{ N^{-1} \sum_{k=0}^{N-1} \left[\Phi_2\left(z, y_2(k), v_k\right) + \lambda^T f_{12}\left(z, y_2(k), v_k\right)\right] \Bigg| \ y_2(k+1) = y_2(k) + f_{22}(z, y_2(k), v_k),\ y_2(0) = y_{20} \Bigg\} \stackrel{\text{def}}{=} r_2(z, \lambda, N, y_{20})\ . \tag{3.6}$$

It can be shown, in particular, that

$$\begin{aligned} R^{up}(z,\lambda,N,y) &= R^{lo}(z,\lambda,N,y) \\ &= \lambda^T f_{10}(z) + r_1(z,\lambda,N,y_{10}) + r_2(z,\lambda,N,y_{20}), \end{aligned} \tag{3.7}$$

which implies that

$$R^{up}(z,\lambda) = R^{lo}(z,\lambda) = R(z,\lambda) = \lambda^T f_{10}(z) + r_1(z,\lambda) + r_2(z,\lambda), \tag{3.8}$$

where $r_i(z,\lambda)$ is the limit of $r_i(z,\lambda,N,y_{i0})$ as N tends to infinity, $i = 1,2$.

Example 3.1. Assume in addition to (3.1)–(3.4) that

$$\begin{aligned} f_{11}(z,y_1,u) &= L_1(z)y_1 + C_1(z)u, \\ f_{12}(z,y_2,v) &= L_2(z)y_2 + C_2(z)v, \\ f_{21}(z,y_1,u) &= I_1(z) + J_1(z)y_1 + K_1(z)u, \\ f_{22}(z,y_2,v) &= I_2(z) + J_2(z)y_2 + K_2(z)v, \end{aligned}$$

where C_i, I_i, J_i, K_i, and L_i are matrix functions of appropriate dimensions, with $J_i(z)$, $i = 1,2$, is nonsingular and the eigenvalues of $J_i(z) + I, i = 1,2$, are inside the unit circle for any $z \in R^m$. The latter condition ensures, in particular, the fulfillment of Assumption 2.1 (see Remark 4.4 below). Assume that $\Phi_1(z,y_1,u)$ is concave in (y_1,u) and $\Phi_2(z,y_2,v)$ is convex in (y_2,v) and also that U and V are convex compact sets. Similar to the example in [11, p. 892], it can be shown that

$$r_1(z,\lambda) = \max_u \left\{ \Phi_1\left(z,\psi_1(z,u),u\right) + \lambda^T f_{11}(z,\psi_1(z,u),u) \mid u \in U \right\}, \tag{3.9}$$

$$r_2(z,\lambda) = \min_v \left\{ \Phi_2\left(z,\psi_2(z,v),v\right) + \lambda^T f_{12}(z,\psi_2(z,v),v) \mid v \in V \right\}, \tag{3.10}$$

where $y_1 = \psi_1(z,u)$ and $y_2 = \psi_2(z,v)$ are the roots of the equations

$$f_{21}(z,y_1,u) = 0, \quad f_{22}(z,y_2,v) = 0.$$

That is,

$$\psi_1(z,u) \stackrel{\text{def}}{=} -\left(J_1(z)\right)^{-1} \left(I_1(z) + K_1(z)u\right), \tag{3.11}$$

$$\psi_2(z,v) \stackrel{\text{def}}{=} -\left(J_2(z)\right)^{-1} \left(I_2(z) + K_2(z)v\right). \tag{3.12}$$

It is easy to see that the LHJI equation (2.24) with

$$H(z,\lambda) = -\left(\lambda^T f_{10}(z) + r_1(z,\lambda) + r_2(z,\lambda)\right),$$

where $r_i(z,\lambda)$, $i = 1,2$, are defined by (3.9)–(3.12), coincides with the Isaacs equation for the "slow" differential game with the dynamics described by the equation

$$\dot{z} = f_{10}(z) + f_{11}(z,\psi_1(z,u),u) + f_{12}(z,\psi_2(z,v),v),$$

with the payoff function being

$$\int_0^T \Big[\Phi_1\left(z,\psi_1(z,u),u\right) + \Phi_2\left(z,\psi_2(z,v),v\right) \Big] dt.$$

Notice that this game is similar to a game which would be obtained if one uses an RTA to an SP control system

$$\begin{aligned}\dot{z}(t) &= f_1(z(t), y(t), u(t), v(t)),\\ \epsilon\dot{y}(t) &= f_2(z(t), y(t), u(t), v(t)),\\ &\qquad u(t) \in U,\ v(t) \in V,\ \forall t \in [0, T],\end{aligned}$$

evolving on a continuous time scale (see [12, 14, 21] for more details).

Example 3.2. Assume that $f_{1i}, f_{2i}, \Phi_i, i = 1, 2$, in (3.1)–(3.4) do not depend on z and $f_{10}(z) = Az,\ G(z) = C^T z$, where $A \in R^{m\times m}$ is a constant matrix and $C \in R^m$ is a constant vector.

The optimal values of (3.5), (3.6) do not depend on z in this case. Let us denote by $r_1(\lambda),\ r_2(\lambda)$ the limits of these values as N tends to infinity. By (3.8),

$$R^{up}(z, \lambda) = R^{lo}(z, \lambda) = R(z, \lambda) = \lambda^T Az + r_1(\lambda) + r_2(\lambda).$$

The LHJI equation (2.24) and the boundary conditions (2.25) in this case take the form

$$\begin{aligned}&\frac{\partial B(t,z)}{\partial t} + \left(\frac{\partial B(t,z)}{\partial z}\right)^T Az + r_1\left(\frac{\partial B(t,z)}{\partial z}\right) + r_2\left(\frac{\partial B(t,z)}{\partial z}\right) = 0,\\ &\qquad B(T, z) = C^T z.\end{aligned} \tag{3.13}$$

It can be verified via a direct substitution that the solution of (3.13) allows an explicit representation

$$B(t, z) = \lambda^T(t)z + \int_t^T \left[r_1\left(\lambda(\theta)\right) + r_2\left(\lambda(\theta)\right)\right] d\theta,$$

where $\lambda(t)$ is the solution of the system

$$\dot{\lambda}(\theta) = -A^T\lambda(\theta),\ \lambda(T) = C.$$

Notice that (3.13) is the Isaacs equation for the dynamic game with the payoff functional $C^T z(T)$ and the dynamics described by the equation

$$z(k + 1) = Az(k) + w_1(k) + w_2(k), \quad z(l) = z,$$

where the maximizer chooses $w(\theta) \in W_1$ and the minimizer chooses $w_2(\theta) \in W_2$. W_1 and W_2 are convex compact sets defined by their supporting functions,

$$\max_{w\in W_1}\{\lambda^T w\} = r_1(\lambda), \quad \min_{w\in W_2}\{\lambda^T w\} = r_2(\lambda).$$

4. Convergence of the upper and lower value functions of the SPDT game. Before presenting our main results in this paper, we introduce the following assumptions.

Assumption 4.1. All the functions used in the definitions of the SPDT and AFDT games in section 2 are continuous on $R^m \times R^n \times U \times V \times [0, T]$, and they also satisfy the local Lipschitz conditions in (z, y).

Assumption 4.2. Corresponding to any compact set $D \times P \subset R^m \times R^n$, there exists a compact set $D_1 \times P_1 \in R^m \times R^n$ such that if the initial values $(z, y) \in D \times P$,

then all the solutions of (2.1)–(2.2) obtained with different control functions satisfying (2.4) do not leave $D_1 \times P_1$.

Assumption 4.3. Corresponding to any compact set $D \times P \in R^m \times R^n$, there exists a compact set $P_1 \in R^n$ such that if $z \in D$ and the vector of initial values $y \in P$, then the solutions of (2.14) obtained with different control functions satisfying (2.15) do not leave P_1.

Remark 4.1. It is worthwhile to mention that Assumptions 4.2 and 4.3 might be replaced by some equivalent conditions with the help of the viability theory [3], which may provide another way to verify the correctness of these two assumptions.

Assumption 4.4. Assumption 2.1 is true and the convergence in (2.21) and (2.22) is uniform with respect to (z, λ, y) from any compact subset of $R^m \times R^m \times R^n$. That is, corresponding to any compact set $D \times \Lambda \times P \in R^m \times R^m \times R^n$, there exists a function $\gamma(N)$ tending to zero as N tends to infinity such that for any $(z, \lambda, y) \in D \times \Lambda \times P$,

$$\left| R^{up(lo)}(z, \lambda, N, y) - R^{up(lo)}(z, \lambda) \right| \leq \gamma(N). \tag{4.1}$$

Assumption 4.5. Corresponding to any compact set $D \times \Lambda \times P \subset R^m \times R^m \times R^n$, there exists a monotone function $\nu(\alpha)$ satisfying

$$\lim_{\alpha \to 0} \nu(\alpha) = 0 \tag{4.2}$$

such that

$$\left| R^{up(lo)}(z^1, \lambda) - R^{up(lo)}(z^2, \lambda) \right| \leq \nu(\|z^1 - z^2\|) \quad \forall z^i \in D,\ i = 1, 2. \tag{4.3}$$

Remark 4.2. Notice that we used (originally to establish our main result; see Theorem 4.1 below) a much stronger assumption (see Assumption 4.5 in [13]) which is similar to the corresponding assumption in [12] for continuous time differential games. It was noted by Artstein that this assumption can be replaced by a weaker one (similar to Assumption 4.5 above) in optimal control setting. The replacement of the assumption by a weaker one leads to changes in the proof (with respect to the one shown in [13]). We introduce these changes using some ideas suggested in [1].

Assumption 4.6. Corresponding to any compact set $[0, T] \times D_1 \times P_1 \subset [0, T] \times R^m \times R^n$, there exist a constant $L > 0$ and continuous functions $\omega_1(\alpha)$ and $\omega_2(\alpha)$ tending to zero as α tends to zero such that for any (l_1, z_1, y_1) and $(l_2, z_2, y_2) \in [0, T] \times D_1 \times P_1$,

$$\left| B_\epsilon^{up(lo)}(l_1, z_1, y_1) - B_\epsilon^{up(lo)}(l_2, z_2, y_2) \right| \leq \epsilon L |l_1 - l_2| + \omega_1(|z_1 - z_2|) + \omega_2(\epsilon)$$

with

$$B_\epsilon^{up(lo)}(N_\epsilon, z, y) = G(z) \quad \forall (z, y) \in R^m \times R^n. \tag{4.4}$$

Notice that Assumptions 4.4, 4.5, and, particularly, 4.6 imposed on the upper and lower value functions of SPDT games are hard to verify in a general case. In Remark 4.4 below we shall provide some sufficient conditions for these assumptions to be satisfied.

Now, we are ready to formulate the main result of this paper.

THEOREM 4.1. *Let Assumptions* 4.1–4.3 *and* 4.4–4.6 *be satisfied. Then there exists a function* $\mu(\epsilon)$ *tending to zero as* ϵ *tends to zero such that*

$$\left| B_\epsilon^{up(lo)}(l, z, y) - B^{up(lo)}(l\epsilon, z) \right| \leq \mu(\epsilon), \qquad l = 0, 1, \ldots, N_\epsilon - 1, \tag{4.5}$$

with the convergence being uniform on any compact subset of $R^m \times R^n$ *with* $l = 0, 1, \ldots, N_\epsilon - 1$.

From Theorem 4.1, the following corollary immediately follows.

COROLLARY 4.2. *If the AFDT game has value in the limit, that is,* (2.23) *is true and the LHJI equation* (2.24) *with* $H(z, \lambda) = -R(z, \lambda)$ *has the unique viscosity solution* $B(t, z)$*, then the SPDT game has value in the limit as well, and*

$$\left| B_\epsilon^{up}(l, z, y) - B(l\epsilon, z) \right| \le \mu(\epsilon), \qquad l = 0, 1, 2, \ldots, N_\epsilon - 1,$$

$$\left| B_\epsilon^{lo}(l, z, y) - B(l\epsilon, z) \right| \le \mu(\epsilon), \qquad l = 0, 1, 2, \ldots, N_\epsilon - 1.$$

Remark 4.3. An upper semicontinuous function $X(t, z)$ is called a *viscosity subsolution* of (2.24) if

$$-\frac{\partial x(\bar{t}, \bar{z})}{\partial t} + H\left(\bar{z}, \frac{\partial x(\bar{t}, \bar{z})}{\partial z}\right) \le 0$$

for any $(\bar{t}, \bar{z}) \in [0, T) \times R^m$ and for each function $x(t, z)$ which has continuous partial derivatives on $[0, T) \times R^m$ and satisfies the conditions $x(\bar{t}, \bar{z}) = X(\bar{t}, \bar{z})$ and $x(t, z) \ge X(t, z)$ in some neighborhood of $(\bar{t}, \bar{z})$.

A lower semicontinuous function $X(t, z)$ is called a *viscosity supersolution* of (2.24) if

$$-\frac{\partial x(\bar{t}, \bar{z})}{\partial t} + H\left(\bar{z}, \frac{\partial x(\bar{t}, \bar{z})}{\partial z}\right) \ge 0$$

for any $(\bar{t}, \bar{z}) \in [0, T) \times R^m$ and for each function $x(t, z)$ which has continuous partial derivatives on $[0, T) \times R^m$ and which satisfies the conditions $x(\bar{t}, \bar{z}) = X(\bar{t}, \bar{z})$ and $x(t, z) \le X(t, z)$ in some neighborhood of $(\bar{t}, \bar{z})$. A function $X(t, z)$ which is *both a viscosity sub- and a supersolution* is called a *viscosity solution* of (2.24).

As shown in a number of works (see [5] and the references therein), upper and lower values of a differential game coincide with the viscosity solutions of the corresponding Hamilton–Jacobi–Isaacs equations. In contrast to these results, Theorem 4.1 is of an asymptotic nature. We establish the convergence of the upper and lower values of the SP dynamic game to the viscosity solutions of LHJI equations which do not explicitly include a part of phase variables representing the fast motions.

Remark 4.4. Similar to Theorems 6.1 and 7.1 in [12], it can be established that Assumptions 4.4, 4.5, and 4.6 will be satisfied if the following assumption is true.

Assumption 4.7. Corresponding to any compact set $D \subset R^m$ there exists a sequence $\xi(k)$ tending to zero as k tends to infinity such that for any $z \in D$ the solutions of (2.14), $\tilde{y}_z^i(k)$, $i = 1, 2$, obtained with arbitrary initial conditions $\tilde{y}_z^i(0) = y^i$, $i = 1, 2$, and any control pairs $(\tilde{u}_k, \tilde{v}_k) \in U \times V$ satisfy the inequality

$$\|\tilde{y}_z^1(k) - \tilde{y}_z^2(k)\| \le \xi(k)\|y^1 - y^2\|.$$

It should be remarked that Assumption 4.7 is of stability type, which was used in [9]. The difference between the solutions of (2.14) induced by a difference in the initial values is decreasing to zero as time tends to infinity. Also, it is easy to see that this assumption is satisfied if the function $f_2(\cdot)$ in the right-hand side of (2.2) is presented in the form

$$f_2(z, y, u, v) = q(z, y) + p(u, v)$$

and $g(z,y) \stackrel{\text{def}}{=} y+q(z,y)$ defines a contractive operator. More precisely, if corresponding to any compact set $D \subset R^m$ there exists a constant $\alpha_D \in (0,1)$ such that for any y^1 and y^2 in R^n

$$\|g(z,y^2)-g(z,y^1)\| \le \alpha_D \|y^2-y^1\| \quad \forall z \in D,$$

then Assumption 4.7 is satisfied with $\xi(k)=\alpha_D^k$.

Proof of Theorem 4.1. Let $t_l = l\epsilon,\ l=0,1,\ldots,N_\epsilon = \lfloor \frac{T}{\epsilon} \rfloor$. For any $t \in [0,T]$, we define

$$\begin{aligned}
&\bar{B}_\epsilon^{up(lo)}(t,z,y) \\
&= \begin{cases} (1-\frac{t-t_l}{t_{l+1}-t_l})B_\epsilon^{up(lo)}(l,z,y) + \frac{(t-t_l)}{t_{l+1}-t_l}B_\epsilon^{up(lo)}(l+1,z,y), \\ \qquad\qquad\qquad\qquad t \in [t_l,t_{l+1}],\ l=0,1,\ldots,N_\epsilon-1; \\ B_\epsilon^{up(lo)}(N_\epsilon,z,y)=G(z), \qquad t \in [t_{N_\epsilon},T]. \end{cases}
\end{aligned} \tag{4.6}$$

Notice that $\bar{B}_\epsilon^{up(lo)}(t,z,y)$ is defined in $[0,T]\times R^m \times R^n$ and is continuous in t for $t \in [0,T]$.

Also note that if $l_1 \le l_2 < N_\epsilon - 1$, then for any (t_1,z_1,y_1) and $(t_2,z_2,y_2) \in [0,T]\times R^m \times R^n$ and $t_1 \in [t_{l_1},t_{l_1+1}]$, $t_2 \in [t_{l_2},t_{l_2+1}]$ one has

$$\begin{aligned}
&\left|\bar{B}_\epsilon^{up(lo)}(t_1,z_1,y_1)-\bar{B}_\epsilon^{up(lo)}(t_2,z_2,y_2)\right| \\
&\le \left|\bar{B}_\epsilon^{up(lo)}(t_1,z_1,y_1)-\bar{B}_\epsilon^{up(lo)}(t_2,z_1,y_1)\right| + \left|\bar{B}_\epsilon^{up(lo)}(t_2,z_1,y_1)-\bar{B}_\epsilon^{up(lo)}(t_2,z_2,y_2)\right|.
\end{aligned} \tag{4.7}$$

Using the expressions (4.6) and Assumption 4.6, one can evaluate the first and second terms in the right-hand side of (4.7) as follows:

$$\begin{aligned}
&\left|\bar{B}_\epsilon^{up(lo)}(t_1,z_1,y_1)-\bar{B}_\epsilon^{up(lo)}(t_2,z_1,y_1)\right| \\
&\le \left|\bar{B}_\epsilon^{up(lo)}(t_1,z_1,y_1)-\bar{B}_\epsilon^{up(lo)}(t_{l_1},z_1,y_1)\right| \\
&\qquad + \left|\bar{B}_\epsilon^{up(lo)}(t_{l_1},z_1,y_1)-\bar{B}_\epsilon^{up(lo)}(t_{l_2},z_1,y_1)\right| \\
&\qquad + \left|\bar{B}_\epsilon^{up(lo)}(t_{l_2},z_1,y_1)-\bar{B}_\epsilon^{up(lo)}(t_2,z_1,y_1)\right| \\
&\le \frac{t_1-t_{l_1}}{t_{l_1+1}-t_{l_1}}\left|B_\epsilon^{up(lo)}(l_1+1,z_1,y_1)-B_\epsilon^{up(lo)}(l_1,z_1,y_1)\right| \\
&\qquad + \left|B_\epsilon^{up(lo)}(l_1,z_1,y_1)-B_\epsilon^{up(lo)}(l_2,z_1,y_1)\right| \\
&\qquad + \frac{t_2-t_{l_2}}{t_{l_2+1}-t_{l_2}}\left|B_\epsilon^{up(lo)}(l_2+1,z_1,y_1)-B_\epsilon^{up(lo)}(l_2,z_1,y_1)\right| \\
&\le 4\epsilon L + 3\omega_2(\epsilon) + 2\epsilon L|t_1-t_2|
\end{aligned} \tag{4.8}$$

and

$$\begin{aligned}
&\left|\bar{B}_\epsilon^{up(lo)}(t_2,z_1,y_1)-\bar{B}_\epsilon^{up(lo)}(t_2,z_2,y_2)\right| \\
&\le \left|\bar{B}_\epsilon^{up(lo)}(t_2,z_1,y_1)-\bar{B}_\epsilon^{up(lo)}(t_{l_2},z_1,y_1)\right|
\end{aligned}$$

$$
\begin{aligned}
&\quad + \left|\bar{B}_\epsilon^{up(lo)}(t_{l_2}, z_1, y_1) - \bar{B}_\epsilon^{up(lo)}(t_2, z_2, y_2)\right| \\
&\le \frac{t_2 - t_{l_2}}{t_{l_2+1} - t_{l_2}} \left|B_\epsilon^{up(lo)}(l_2+1, z_1, y_1) - B_\epsilon^{up(lo)}(l_2, z_1, y_1)\right| \\
&\quad + \left|\bar{B}_\epsilon^{up(lo)}(t_{l_2}, z_1, y_1) - \bar{B}_\epsilon^{up(lo)}(t_{l_2}, z_2, y_2)\right| \\
&\quad + \left|\bar{B}_\epsilon^{up(lo)}(t_{l_2}, z_2, y_2) - \bar{B}_\epsilon^{up(lo)}(t_2, z_2, y_2)\right| \\
&\le \frac{t_2 - t_{l_2}}{t_{l_2+1} - t_{l_2}} \left|B_\epsilon^{up(lo)}(l_2+1, z_1, y_1) - B_\epsilon^{up(lo)}(l_2, z_1, y_1)\right| \\
&\quad + \left|B_\epsilon^{up(lo)}(l_2, z_1, y_1) - B_\epsilon^{up(lo)}(l_2, z_2, y_2)\right| \\
&\quad + \frac{t_2 - t_{l_2}}{t_{l_2+1} - t_{l_2}} \left|B_\epsilon^{up(lo)}(l_2+1, z_2, y_2) - B_\epsilon^{up(lo)}(l_2, z_2, y_2)\right| \\
&\le 2\epsilon L + \omega_1(|z_1 - z_2|) + 3\omega_2(\epsilon). \qquad (4.9)
\end{aligned}
$$

Substituting (4.8) and (4.9) back into (4.7), one obtains

$$
\begin{aligned}
&\left|\bar{B}_\epsilon^{up(lo)}(t_1, z_1, y_1) - \bar{B}_\epsilon^{up(lo)}(t_2, z_2, y_2)\right| \\
&\qquad \le 6\epsilon L + \omega_1(|z_1 - z_2|) + 6\omega_2(\epsilon) + \epsilon L|t_1 - t_2|. \qquad (4.10)
\end{aligned}
$$

Let us introduce the notation

$$
\bar{B}_\epsilon^{up}(t, z, 0) \stackrel{\text{def}}{=} X_\epsilon(t, z).
$$

By Assumption 4.6, if (t, z, y) belongs to a compact set $[0, T] \times D_1 \times P_1$, then

$$
\begin{aligned}
&\left|\bar{B}_\epsilon^{up}(t, z, y) - X_\epsilon(t, z)\right| \le \omega_2(\epsilon) \qquad (4.11) \\
&\quad \Longrightarrow |B_\epsilon^{up}(l, z, y) - X_\epsilon(l\epsilon, z)| \le \omega_2(\epsilon) \quad \forall l = 0, 1, \ldots, N_\epsilon - 1.
\end{aligned}
$$

Hence, to prove (4.5) it is sufficient to show that

$$
\lim_{\epsilon \to 0} X_\epsilon(t, z) = B^{up}(t, z), \qquad (4.12)
$$

where the convergence is uniform with respect to (t, z) from any compact subset of $[0, T] \times R^m$. For the sake of brevity we shall refer to this sort of convergence as *U-convergence* and the corresponding limits will be called *U-limits*.

From (4.10) and (4.11) it follows that for any $(t_i, z_i) \in D_1 \times P_1, i = 1, 2,$

$$
|X_\epsilon(t_1, z_1) - X_\epsilon(t_2, z_2)| \le 6\epsilon L + \omega_1(|z_1 - z_2|) + 6\omega_2(\epsilon) + \epsilon L|t_1 - t_2|. \qquad (4.13)
$$

Before completing the proof of Theorem 4.1, let us recall the following lemma needed in our derivation.

LEMMA 4.3 (see [12]). *Given any sequence ϵ_i tending to zero, one can find a subsequence $\epsilon_{i_j} = \epsilon_j$ of this sequence such that there exists the U-limit*

$$
\lim_{\epsilon_j \to 0} X_{\epsilon_j}(t, z) \stackrel{\text{def}}{=} X(t, z). \qquad (4.14)
$$

Let us show that any function obtained as U-limit (4.14) coincides with $B^{up}(t, z)$. Notice that, by (4.13), any such function $X(t, z)$ is continuous on $[0, T] \times R^m$ and, by (4.4) and (4.11), it satisfies the condition

$$
X(T, z) = G(z) \quad \forall z \in R^m.
$$

Thus, to show that it coincides with $B^{up}(t,z)$, it is enough to show that it is a viscosity solution of (2.24) with $H(z,\lambda) = -R^{up}(t,z)$.

Let $n(\epsilon)$ be a function of ϵ taking positive integer values such that

$$n(\epsilon) \longrightarrow \infty \qquad \text{and} \qquad \epsilon n(\epsilon) \longrightarrow 0 \qquad \text{as } \epsilon \to 0. \tag{4.15}$$

For any $\bar{t} \in [0,T)$ and any $\epsilon > 0$, there exists $l(\epsilon) > 0$ such that $\bar{t} \in [l(\epsilon)\epsilon, (l(\epsilon)+1)\epsilon]$, where $l(\epsilon) = \lfloor \frac{\bar{t}}{\epsilon} \rfloor$.

Let $(z(k), y(k))$ be the solution of (2.1), (2.2) on the interval $[\epsilon l(\epsilon), \epsilon l(\epsilon) + \epsilon n(\epsilon)]$ obtained with the initial conditions $(z(l(\epsilon)), y(l(\epsilon))) = (\bar{z}, \bar{y})$ and with the use of the control $(u_k, v_k) \in U \times V$, $k = l(\epsilon), l(\epsilon)+1, \ldots, l(\epsilon)+n(\epsilon)-1$.

By (4.11),

$$\bar{B}^{up}_{\epsilon}(\bar{t}, \bar{z}, \bar{y}) = X_{\epsilon}(\bar{t}, \bar{z}) + O(\omega_2(\epsilon)). \tag{4.16}$$

Using representation (2.11) and the estimate (4.10), one can obtain

$$\begin{aligned}
\bar{B}^{up}_{\epsilon}(\bar{t}, \bar{z}, \bar{y}) &= B^{up}_{\epsilon}(l(\epsilon), \bar{z}, \bar{y}) + O(\epsilon) \\
&= \inf_{v_{l(\epsilon)}} \sup_{u_{l(\epsilon)}} \cdots \inf_{v_{l(\epsilon)+n(\epsilon)-1}} \sup_{u_{l(\epsilon)+n(\epsilon)-1}} \left\{ \epsilon \sum_{k=l(\epsilon)}^{l(\epsilon)+n(\epsilon)-1} \Phi(z(k), y(k), u_k, v_k) \right. \\
&\qquad \left. + B^{up}_{\epsilon}(l(\epsilon)+n(\epsilon), z(l(\epsilon)+n(\epsilon)), y(l(\epsilon)+n(\epsilon))) \right\} + O(\epsilon) \\
&= \inf_{v_{l(\epsilon)}} \sup_{u_{l(\epsilon)}} \cdots \inf_{v_{l(\epsilon)+n(\epsilon)-1}} \sup_{u_{l(\epsilon)+n(\epsilon)-1}} \left\{ \epsilon \sum_{k=l(\epsilon)}^{l(\epsilon)+n(\epsilon)-1} \Phi(z(k), y(k), u_k, v_k) \right. \\
&\qquad \left. + \bar{B}^{up}_{\epsilon}(t_{l(\epsilon)+n(\epsilon)}, z(l(\epsilon)+n(\epsilon)), y(l(\epsilon)+n(\epsilon))) \right\} + O(\epsilon) \\
&= \inf_{v_{l(\epsilon)}} \sup_{u_{l(\epsilon)}} \cdots \inf_{v_{l(\epsilon)+n(\epsilon)-1}} \sup_{u_{l(\epsilon)+n(\epsilon)-1}} \left\{ \epsilon \sum_{k=l(\epsilon)}^{l(\epsilon)+n(\epsilon)-1} \Phi(z(k), y(k), u_k, v_k) \right. \\
&\qquad \left. + X_{\epsilon}(t_{l(\epsilon)+n(\epsilon)}, z(l(\epsilon)+n(\epsilon))) \right\} + O(\epsilon) + O(\omega_2(\epsilon)).
\end{aligned} \tag{4.17}$$

Let D and P be compact sets such that $(\bar{t}, \bar{z}, \bar{y}) \in [0,T) \times D \times P$. Then, by Assumption 4.2, $(z(l(\epsilon)+n(\epsilon)), y(l(\epsilon)+n(\epsilon))) \in D_1 \times P_1$, where D_1 and P_1 are compact sets in R^m and R^n. Since the convergence in (4.14) is uniform with respect to (t,z) from any compact subset of $[0,T] \times R^m$, there exists a function $\tilde{\nu}(\epsilon_j)$,

$$\lim_{\epsilon_j \to 0} \tilde{\nu}(\epsilon_j) = 0, \tag{4.18}$$

such that

$$\left| X_{\epsilon_j}(t,z) - X(t,z) \right| \le \tilde{\nu}(\epsilon_j) \quad \forall (t,z) \in [0,T] \times D_1.$$

Using this and (4.11), one obtains from (4.6) with (4.17)

$$X(\bar{t},\bar{z}) = \inf_{v_{l(\epsilon_j)}} \sup_{u_{l(\epsilon_j)}} \dots \inf_{v_{l(\epsilon_j)+n(\epsilon_j)-1}} \sup_{u_{l(\epsilon_j)+n(\epsilon_j)-1}} \left\{ \epsilon_j \sum_{k=l(\epsilon_j)}^{l(\epsilon_j)+n(\epsilon_j)-1} \Phi(z(k),y(k),u_k,v_k) \right.$$

$$\left. + X(t_{l(\epsilon_j)+n(\epsilon_j)},\ z(l(\epsilon_j)+n(\epsilon_j))) \right\} + O(\tilde{\mu}(\epsilon_j)), \tag{4.19}$$

where

$$\tilde{\mu}(\epsilon_j) = \max\{\omega_2(\epsilon_j),\ \tilde{\nu}(\epsilon_j),\epsilon_j\}. \tag{4.20}$$

Now let $x(t,z)$ have continuous partial derivatives and satisfy the conditions $x(\bar{t},\bar{z}) = X(\bar{t},\bar{z})$ and $x(t,z) \geq X(t,z)$ for (t,z) in some neighborhood of $(\bar{t},\bar{z})$. From (4.19) it then follows that

$$x(\bar{t},\bar{z}) \leq \inf_{v_{l(\epsilon_j)}} \sup_{u_{l(\epsilon_j)}} \dots \inf_{v_{l(\epsilon_j)+n(\epsilon_j)-1}} \sup_{u_{l(\epsilon_j)+n(\epsilon_j)-1}} \left\{ \epsilon_j \sum_{k=l(\epsilon_j)}^{l(\epsilon_j)+n(\epsilon_j)-1} \Phi(z(k),y(k),u_k,v_k) \right.$$

$$\left. + x(t_{l(\epsilon_j)+n(\epsilon_j)}, z(l(\epsilon_j)+n(\epsilon_j))) \right\} + O(\tilde{\mu}(\epsilon_j)). \tag{4.21}$$

By definition

$$z\big(l(\epsilon_j)+n(\epsilon_j)\big) = \bar{z} + \epsilon_j \sum_{k=l(\epsilon_j)}^{l(\epsilon_j)+n(\epsilon_j)-1} f_1(z(k),y(k),u_k,v_k) \tag{4.22}$$

and

$$t_{l(\epsilon_j)+n(\epsilon_j)} = \big(l(\epsilon_j)+n(\epsilon_j)\big)\epsilon_j = \bar{t} + O(\epsilon_j) + \epsilon_j n(\epsilon_j).$$

Since the function $f_1(\cdot)$ is continuous and its arguments belong to compact sets, the second term in the right-hand side of (4.22) is of the order $O(\epsilon_j n(\epsilon_j))$. Thus, substituting (4.22) into (4.21) and using Taylor's expansion of $x(t_{l(\epsilon_j)+n(\epsilon_j)}, z(l(\epsilon_j)+n(\epsilon_j)))$ at $(\bar{t},\bar{z})$, one obtains

$$\frac{\partial x(\bar{t},\bar{z})}{\partial t} + \frac{1}{\epsilon_j n(\epsilon_j)} \inf_{v_{l(\epsilon_j)}} \sup_{u_{l(\epsilon_j)}}$$

$$\dots \inf_{v_{l(\epsilon_j)+n(\epsilon_j)-1}} \sup_{u_{l(\epsilon_j)+n(\epsilon_j)-1}} \left\{ \epsilon_j \sum_{k=l(\epsilon_j)}^{l(\epsilon_j)+n(\epsilon_j)-1} \left[\Phi(z(k),y(k),u_k,v_k) \right.\right.$$

$$\left.\left. + \left(\frac{\partial x(\bar{t},\bar{z})}{\partial z}\right)^T f_1(z(k),y(k),u_k,v_k) \right] \right\} + \frac{O(\tilde{\mu}(\epsilon_j))}{\epsilon_j n(\epsilon_j)} + \frac{o(\epsilon_j n(\epsilon_j))}{\epsilon_j n(\epsilon_j)} \geq 0. \tag{4.23}$$

To proceed with the proof, one needs to establish the following.

LEMMA 4.4. *Let $K(\epsilon)$ be a function of ϵ having integer values and satisfying the conditions*

$$K(\epsilon) \to \infty \qquad as\ \epsilon \to 0, \quad K(\epsilon) \le \frac{1}{2\ln(1+C)} \ln \frac{1}{\epsilon}, \tag{4.24}$$

where C is a Lipschitz constant of the function f_2 on the compact set containing the trajectories of (2.1), (2.2), *and* (2.14) *(see Assumptions* 4.1–4.3*). Let $(z(k), y(k))$, $k = l, l+1, \dots, l+K(\epsilon)$, be the solutions of* (2.1), (2.2) *obtained with some controls (u_k, v_k), $k = l, l+1, \dots, l+K(\epsilon)-1$, and with the initial values* (2.3). *Let $\tilde{y}_{\bar{z}}(k)$, $k = l, l+1, \dots, l+K(\epsilon)$, be the solution of the system*

$$\tilde{y}_{\bar{z}}(k+1) = \tilde{y}_{\bar{z}}(k) + f_2(\bar{z}, \tilde{y}_{\bar{z}}, u_k, v_k) \tag{4.25}$$

obtained with the same sequence of controls as above, (u_k, v_k), $k = l, l+1, \dots, l+K(\epsilon)-1$, and with the initial conditions

$$\tilde{y}_{\bar{z}}(l) = y, \tag{4.26}$$

the same as in (2.3). *Assume that $\bar{z}$ in* (4.25) *satisfies the inequality*

$$\|\bar{z} - z(k)\| \le M\epsilon K(\epsilon) \quad \forall k = l, l+1, \dots, l+K(\epsilon)-1, \tag{4.27}$$

with some constant M. Then

$$\max_{k=l,l+1,\dots,l+K(\epsilon)} \|y(k) - \tilde{y}_{\bar{z}}(k)\| \le \gamma_1(\epsilon), \tag{4.28}$$

where

$$\gamma_1(\epsilon) \stackrel{\text{def}}{=} M\epsilon K(\epsilon)(1+C)^{K(\epsilon)+1} \to 0 \qquad as\ \epsilon \to 0. \tag{4.29}$$

The fact that $\gamma_1(\epsilon)$ tends to zero follows from the second inequality in (4.24).

Proof. Subtracting (4.25) from (2.2) and using Lipschitz conditions, one obtains

$$\begin{aligned}
&\|y_z(k+1) - \tilde{y}_{\bar{z}}(k+1)\| \\
&\le \|y_z(k) - \tilde{y}_{\bar{z}}(k)\| + C\left(\|z(k) - \bar{z}\| + \|y_z(k) - \tilde{y}_{\bar{z}}(k)\|\right) \\
&\le CM\epsilon K(\epsilon) + (1+C)\|y_z(k) - \tilde{y}_{\bar{z}}(k)\|,
\end{aligned}$$

which implies

$$\begin{aligned}
&\|y(k) - \tilde{y}_{\bar{z}}(k)\| \\
&\le M\epsilon K(\epsilon)(1+C)^{k+1-l} \\
&\le M\epsilon K(\epsilon)(1+C)^{K(\epsilon)+1} \quad \forall k = l, l+1, \dots, l+K(\epsilon).
\end{aligned}$$

This justifies (4.28). ∎

COROLLARY 4.5. *Let $\phi(z, y, u, v)$ satisfy Lipschitz conditions in z and y. Then*

$$\begin{aligned}
&\left| \frac{1}{K(\epsilon)} \sum_{k=l}^{l+K(\epsilon)-1} \phi(z(k), y(k), u_k, v_k) - \frac{1}{K(\epsilon)} \sum_{k=l}^{l+K(\epsilon)-1} \phi(\bar{z}, \tilde{y}_{\bar{z}}(k), u_k, v_k) \right| \\
&\le C_1 K(\epsilon)\left(M\epsilon K(\epsilon) + \gamma_1(\epsilon)\right) \stackrel{\text{def}}{=} \gamma_2(\epsilon),
\end{aligned} \tag{4.30}$$

where C_1 is a Lipschitz constant of ϕ.

Notice that, by (4.29), (4.24),

$$\gamma_2(\epsilon) \to 0 \qquad as\ \epsilon \to 0. \tag{4.31}$$

Returning to the proof of the main theorem let us define

$$n(\epsilon_j) = r(\epsilon_j)K(\epsilon_j) + K(\epsilon_j) \tag{4.32}$$

with

$$r(\epsilon_j) = \left\lfloor \frac{(\tilde{\mu}(\epsilon_j))^{1/2}}{\epsilon_j K(\epsilon_j)} \right\rfloor. \tag{4.33}$$

Notice that

$$\epsilon_j n(\epsilon_j) \to 0 \qquad \text{as}\ \ \epsilon_j \to 0. \tag{4.34}$$

Denoting for the brevity

$$\Phi(z,y,u,v) - \left(\frac{\partial x(\bar{t},\bar{z})}{\partial z}\right)^T f_1(z,y,u,v) \stackrel{\text{def}}{=} \phi(z,y,u,v), \tag{4.35}$$

let us rewrite the second term in (4.23) as follows:

$$\begin{aligned}
&\frac{1}{n(\epsilon_j)} \underbrace{\inf\sup\cdots\inf\sup}_{n(\epsilon_j)} \sum_{k=l(\epsilon_j)}^{l(\epsilon_j)+n(\epsilon_j)-1} \phi(z(k),y(k),u_k,v_k) \\
&= \frac{1}{r(\epsilon_j)+1} \Bigg[\underbrace{\inf\sup\cdots\inf\sup}_{K(\epsilon_j)} \frac{1}{K(\epsilon_j)} \left\{ \sum_{k=l(\epsilon_j)}^{l(\epsilon_j)+K(\epsilon_j)-1} \phi(z(k),y(k),u_k,v_k) \right. \\
&+ \underbrace{\inf\sup\cdots\inf\sup}_{K(\epsilon_j)} \left\{ \frac{1}{K(\epsilon_j)} \sum_{k=l(\epsilon_j)+K(\epsilon_j)}^{l(\epsilon_j)+2K(\epsilon_j)-1} \phi(z(k),y(k),u_k,v_k) + \cdots \right. \\
&+ \underbrace{\inf\sup\cdots\inf\sup}_{K(\epsilon_j)} \left\{ \frac{1}{K(\epsilon_j)} \sum_{k=l(\epsilon_j)+(r(\epsilon_j)-1)K(\epsilon_j)}^{l(\epsilon_j)+r(\epsilon_j)K(\epsilon_j)-1} \phi(z(k),y(k),u_k,v_k) \right. \\
&\left. \left. \left. + \underbrace{\inf\sup\cdots\inf\sup}_{K(\epsilon_j)} \left\{ \frac{1}{K(\epsilon_j)} \sum_{k=l(\epsilon_j)+r(\epsilon_j)K(\epsilon_j)}^{l(\epsilon_j)+(r(\epsilon_j)+1)K(\epsilon_j)-1} \phi(z(k),y(k),u_k,v_k) \underbrace{\Big\}\Big\}\Big\}\cdots\Big\}}_{r(\epsilon_j)+1} \right] \right.
\end{aligned} \tag{4.36}$$

where the inf sups in the right-hand side of (4.36) are taken over the controls included in the corresponding sums. Let us consider the last sum in the right-hand side of (4.36). Notice that for any controls

$$\|z(k) - \bar{z}_r\| \le M\epsilon_j K(\epsilon_j) \quad \forall k = l(\epsilon_j) + r(\epsilon_j)K(\epsilon_j) + 1, \ldots, l(\epsilon_j) + n(\epsilon_j), \tag{4.37}$$

where M is some constant and

$$\bar{z}_r \stackrel{\text{def}}{=} z(l(\epsilon_j) + r(\epsilon_j)K(\epsilon_j)).$$

By Lemma 4.4,

$$\|y(k) - \tilde{y}_{\bar{z}_r}(k)\| \le \gamma_1(\epsilon) \quad \forall k = l(\epsilon_j) + r(\epsilon_j)K(\epsilon_j) + 1, \dots, l(\epsilon_j) + (r(\epsilon_j) + 1)K(\epsilon_j), \tag{4.38}$$

where $\tilde{y}_{\bar{z}_r}(k)$ is the solution of system (4.25) with $\bar{z} = \bar{z}_r$ and with the initial conditions

$$\tilde{y}_{\bar{z}_r}(l(\epsilon_j) + r(\epsilon_j)K(\epsilon_j)) = y(l(\epsilon_j) + r(\epsilon_j)K(\epsilon_j)) \stackrel{\text{def}}{=} \bar{y}_r. \tag{4.39}$$

Estimates (4.37), (4.38) imply the inequality (see Corollary 4.5)

$$\begin{aligned} &\left| \frac{1}{K(\epsilon_j)} \sum_{k=l(\epsilon_j)+r(\epsilon_j)K(\epsilon_j)}^{l(\epsilon_j)+(r(\epsilon_j)+1)K(\epsilon_j)-1} \phi(z(k), y(k), u_k, v_k) \right. \\ &\left. - \frac{1}{K(\epsilon_j)} \sum_{k=l(\epsilon_j)+r(\epsilon_j)K(\epsilon_j)}^{l(\epsilon_j)+(r(\epsilon_j)+1)K(\epsilon_j)-1} \phi(\bar{z}_r, \tilde{y}_{\bar{z}_r}(k), u_k, v_k) \right| \\ &\le \gamma_2(\epsilon). \end{aligned} \tag{4.40}$$

This inequality is satisfied uniformly with respect to (u_k, v_k). Hence, the application of the operations inf sups do not violate the inequality. Thus, the last $r(\epsilon_j) + 1$ term in the right-hand side of (4.38) can be presented in the form

$$R^{up}\left(\bar{z}_r, \frac{\partial x(\bar{t}, \bar{z})}{\partial z}, K(\epsilon_j), \bar{y}_r\right) + \theta_{r(\epsilon_j)+1}, \tag{4.41}$$

with

$$\left|\theta_{r(\epsilon_j)+1}\right| \le \gamma_2(\epsilon_j). \tag{4.42}$$

By Assumption 4.4,

$$R^{up}\left(\bar{z}_r, \frac{\partial x(\bar{t}, \bar{z})}{\partial z}, K(\epsilon_j), \bar{y}_r\right) = R^{up}\left(\bar{z}_r, \frac{\partial x(\bar{t}, \bar{z})}{\partial z}\right) + \Gamma_{r(\epsilon_j)}, \tag{4.43}$$

where

$$\left|\Gamma_{r(\epsilon_j)}\right| \le \gamma(K(\epsilon_j)). \tag{4.44}$$

Also, by Assumption 4.5,

$$R^{up}\left(\bar{z}_r, \frac{\partial x(\bar{t}, \bar{z})}{\partial z}\right) = R^{up}\left(\bar{z}, \frac{\partial x(\bar{t}, \bar{z})}{\partial z}\right) + \Delta_{r(\epsilon_j)}, \tag{4.45}$$

$$\left|\Delta_{r(\epsilon_j)}\right| \le \nu\left(M\epsilon_j n(\epsilon_j)\right), \tag{4.46}$$

where the last estimate is obtained on the basis of the fact that

$$|\bar{z}_r - \bar{z}| \le M\epsilon_j r(\epsilon_j)K(\epsilon_j) \le M\epsilon_j n(\epsilon_j). \tag{4.47}$$

Summing up, one can conclude that the $r(\epsilon_j)+1$ term in (4.36) is equal to

$$R^{up}\left(\bar{z}, \frac{\partial x(\bar{t},\bar{z})}{\partial z}, K(\epsilon_j)\right) + \eta_{r(\epsilon_j)+1}, \tag{4.48}$$

with

$$\left|\eta_{r(\epsilon_j)+1}\right| \le \gamma_2(\epsilon_j) + \gamma(K(\epsilon_j)) + \nu\left(M\epsilon_j n(\epsilon_j)\right). \tag{4.49}$$

As follows from (4.48), the $r(\epsilon_j)+1$ term in (4.36) does not depend (within the proximity given in (4.49)) on the values of controls (u_k, v_k) for $k < l(\epsilon_j)+r(\epsilon_j)K(\epsilon_j)$. This allows us to obtain a similar estimate for the term $r(\epsilon_j)$ (next to the last) in the right-hand side of (4.36). Proceeding in the same way $r(\epsilon_j)+1$ times, one can obtain that the second term in (4.23) is equal to

$$R^{up}\left(\bar{z}, \frac{\partial x(\bar{t},\bar{z})}{\partial z}\right) + \eta(\epsilon_j), \tag{4.50}$$

$$|\eta(\epsilon_j)| \le \gamma_2(\epsilon_j) + \gamma(K(\epsilon_j)) + \nu\left(M\epsilon_j n(\epsilon_j)\right), \tag{4.51}$$

which after the substitution to (4.23) gives

$$\begin{aligned}\frac{\partial x(\bar{t},\bar{z})}{\partial t} + R^{up}\left(\bar{z}, \frac{\partial x(\bar{t},\bar{z})}{\partial z}, K(\epsilon_j)\right) + O\left(\gamma_2(\epsilon_j)\right) + O\left(\gamma(K(\epsilon_j))\right) \\ + O\left(\nu\left(M\epsilon_j n(\epsilon_j)\right)\right) + \frac{O(\tilde{\mu}(\epsilon_j))}{\epsilon_j n(\epsilon_j)} + \frac{o(\epsilon_j n(\epsilon_j))}{\epsilon_j n(\epsilon_j)} \ge 0.\end{aligned} \tag{4.52}$$

Notice that, by (4.33),

$$\frac{\tilde{\mu}(\epsilon_j)}{\epsilon_j n(\epsilon_j)} \le \frac{\tilde{\mu}(\epsilon_j)}{\epsilon_j} \frac{1}{\frac{(\tilde{\mu}(\epsilon_j))^{1/2}}{\epsilon_j}} = \left(\tilde{\mu}(\epsilon_j)\right)^{1/2}.$$

Taking into account this as well as (4.23) and passing to the limit as ϵ_j tends to zero, one obtains

$$\frac{\partial x(\bar{t},\bar{z})}{\partial t} + R^{up}\left(\bar{z}, \frac{\partial x(\bar{t},\bar{z})}{\partial z}\right) \ge 0 \Rightarrow -\frac{\partial x(\bar{t},\bar{z})}{\partial t} + H\left(\bar{z}, \frac{\partial x(\bar{t},\bar{z})}{\partial z}\right) \le 0.$$

This establishes that $X(t,z)$ is a viscosity subsolution of (2.24) on $[0,T)\times R^m$. Similarly, taking $x(t,z)$ having continuous partial derivatives and satisfying the conditions $x(\bar{t},\bar{z}) = X(\bar{t},\bar{z})$ and $x(t,z) \le X(t,z)$ in some neighborhood of $(\bar{t},\bar{z}) \in [0,T)\times R^m$, one can obtain that

$$-\frac{\partial x(\bar{t},\bar{z})}{\partial t} + H\left(\bar{z}, \frac{\partial x(\bar{t},\bar{z})}{\partial z}\right) \ge 0,$$

which means that $X(t,z)$ is a viscosity supersolution of (2.24) on $[0,T)\times R^m$. Thus, $X(t,z)$ is a viscosity solution (2.24) on $[0,T)\times R^m$ and, consequently, it coincides with $B^{up}(t,z)$.

This proves that $\bar{B}^{up}_{\epsilon}(t,z,y)$ U-converges (as ϵ tends to zero) to $B^{up}(t,z)$ (since, otherwise, by Lemma 4.3, one would be able to choose a subsequence ϵ_j tending to zero such that the U-limit (4.14) does not coincide with $B^{up}(t,z)$).

Similarly, it is established that $\bar{B}^{lo}_{\epsilon}(t,z,y)$ U-converges to $\bar{B}^{lo}(t,z)$ as ϵ tends to zero. □

Remark 4.5. It should be noted in Theorem 4.1 that, from [6, 20], the continuous viscosity solution $B^{up}(t,z)$, $(B^{lo}(t,z))$ of (2.24) with $H(z,\lambda) = -R^{up}(z,\lambda)(-R^{lo}(z,\lambda))$ satisfying boundary conditions (2.25) is unique. Notice that the Hamiltonians of the LHJI equations mentioned in the theorems are continuous under the assumptions made.

Remark 4.6. The conditions that U and V are compact sets introduced in the definition of the SP game can be replaced by the coercivity-type condition. Namely, one can assume that corresponding to any compact set $D \times \Lambda \times P \in R^m \times R^m \times R^n$, there exists a constant M such that for any $(z,\lambda,y) \subset D \times \Lambda \times P$, $l = 0,1,\dots,N_\epsilon$ and $N > 0$, the upper and lower values (2.8), (2.9) and (2.17), (2.18) are not changed with the replacement of U and V by

$$U_M = \{u | u \in U, \| u \| \leq M\}, \quad V_M = \{v | v \in V, \| v \| \leq M\}.$$

Remark 4.7. Note that since the closed-loop strategies are considered in this paper, in our future studies the connections between SPDT games and positional differential games would be worth further investigation, in which feedback strategies would be used (see, for example, [4]). We conjecture that our results (and approach) will be useful for the readers working in the fields of (SP) positional differential games.

5. Asymptotics of the AFDT game: Verification of assumptions. We have the following result.

THEOREM 5.1. *Assumptions* 4.1*,* 4.3*, and* 4.7 *imply Assumption* 4.4.

The proof of Theorem 5.1 is based on the following.

LEMMA 5.2. *Corresponding to any compact set $D \times \Lambda \times P \subset R^m \times R^m \times R^n$, there exists a constant L and a monotone function $\gamma_1(N)$ tending to zero as N tends to infinity such that for any $(z,\lambda,y) \in D \times \Lambda \times P$ and any $y^i \in P, i = 1,2,$*

$$\left| R^{up(lo)}(z,\lambda,N,y^1) - R^{up(lo)}(z,\lambda,N,y^2) \right| \leq \gamma_1(N), \qquad N = 0,1,2,\dots; \tag{5.1}$$

$$\left| R^{up(lo)}(z,\lambda,lK,y) - R^{up(lo)}(z,\lambda,K,y) \right| \leq \gamma_1(K) \quad \forall K = 0,1,2,\dots,\ l = 0,1,2,\dots; \tag{5.2}$$

$$\left| R^{up(lo)}(z,\lambda,N_1,y) - R^{up(lo)}(z,\lambda,N_2,y) \right| \leq L\left(\frac{1}{N_1} + \frac{N_2 - N_1}{N_2}\right), \qquad N_2 \geq N_1 \geq 1. \tag{5.3}$$

Proof of Theorem 5.1. We need to show that there exist the limits

$$\lim_{K \to \infty} R^{up(lo)}(z,\lambda,K,y) \stackrel{\text{def}}{=} R^{up(lo)}(z,\lambda). \tag{5.4}$$

By (5.2) and (5.3), for any integers $K_1 \geq K_0$, $K_2 \geq K_0$, and $K_0 > 0$,

$$\begin{aligned}
&\left| R^{up(lo)}(z,\lambda,K_2,y) - R^{up(lo)}(z,\lambda,K_1,y) \right| \\
&\leq \left| R^{up(lo)}(z,\lambda,K_2,y) - R^{up(lo)}\left(z,\lambda,\left\lfloor \frac{K_2}{K_0} \right\rfloor K_0, y\right) \right| \\
&\quad + \left| R^{up(lo)}\left(z,\lambda,\left\lfloor \frac{K_2}{K_0} \right\rfloor K_0, y\right) - R^{up(lo)}(z,\lambda,K_0,y) \right|
\end{aligned}$$

$$
\begin{aligned}
&+\left|R^{up(lo)}(z,\lambda,K_0,y)-R^{up(lo)}\left(z,\lambda,\left\lfloor\frac{K_1}{K_0}\right\rfloor K_0,y\right)\right|\\
&+\left|R^{up(lo)}\left(z,\lambda,\left\lfloor\frac{K_1}{K_0}\right\rfloor K_0,y\right)-R^{up(lo)}(z,\lambda,K_1,y)\right|\\
&\le L\left(\frac{1}{\lfloor\frac{K_2}{K_0}\rfloor K_0}+\frac{(K_2-\lfloor\frac{K_2}{K_0}\rfloor K_0)}{K_2}\right)\\
&\quad+2\gamma_1(K_0)+L\left(\frac{1}{\lfloor\frac{K_1}{K_0}\rfloor K_0}+\frac{(K_1-\lfloor\frac{K_1}{K_0}\rfloor K_0)}{K_1}\right)\\
&\le 2\gamma_1(K_0)+\frac{2L}{K_0}+\frac{LK_0}{K_1}+\frac{LK_0}{K_2}.
\end{aligned}
$$

Choosing $K_i \ge K_0^2,\ i=1,2$, one obtains

$$
\left|R^{up(lo)}(z,\lambda,K_2,y)-R^{up(lo)}(z,\lambda,K_1,y)\right| \le 2\gamma_1(K_0)+\frac{4L}{K_0},
$$

which implies the existence of the limits (5.4). Passing to the limit as l tends to infinity in (5.2) then allows us to obtain

$$
\left|R^{up(lo)}(z,\lambda)-R^{up(lo)}(z,\lambda,K,y)\right| \le \gamma_1(K).
$$

Note that from (5.1), the above inequalities will hold for any $y \in P$, which establishes (4.1). □

Proof of Lemma 5.2. By Assumption 4.3, the trajectories of (2.14) which started at $y \in P$ do not leave a compact set P_1. By Assumption 4.1, the functions Φ and f_1 satisfy Lipschitz conditions in z and y on $D \times P_1$ with some constant L_1. Hence, for any admissible pair of controls $\tilde{u}_k, \tilde{v}_k$

$$
\begin{aligned}
&\left|Q(z,\lambda,N,y^1,\tilde{u},\tilde{v})-Q(z,\lambda,N,y^2,\tilde{u},\tilde{v})\right|\\
&\le (L_1+\parallel\lambda\parallel L_1)\,N^{-1}\sum_{k=0}^{N-1}\parallel y_z^1(k)-y_z^2(k)\parallel\\
&\le L_1\left(1+\max_{\lambda\in\Lambda}\parallel\lambda\parallel\right)\left(N^{-1}\sum_{k=0}^{N-1}\xi(k)\|y^1-y^2\|\right)\stackrel{\text{def}}{=}\gamma_1(N). \qquad (5.5)
\end{aligned}
$$

Notice that from the fact that $\xi(k)$ tends to zero as k tends to infinity, it follows that $\gamma_1(N)$ tends to zero as N tends to infinity. Also without loss of generality $\gamma_1(N)$ can be taken to be a monotone function. Inequality (5.5) and representations (2.19), (2.20) imply (5.1).

Let us verify (5.2). For $l=1$ it is obvious. Let us use induction to show that (5.2) is true for R^{up}. Assume that for $l=r\ge 1$,

$$
|R^{up}(z,\lambda,rK,y)-R^{up}(z,\lambda,K,y)| \le \gamma_1(K), \qquad (5.6)
$$

with $\gamma_1(N)$ being a monotone function which tends to zero as N tends to infinity and which allows (5.1) with $y^i \in P_1, i=1,2$, where P_1 is a compact set containing all the trajectories of (2.14) started in P. Using (2.19) one can write

$$R^{up}(z,\lambda,(r+1)K,y)=\inf_{\tilde v_0}\sup_{\tilde u_0}\dots\inf_{\tilde v_{rK-1}}\sup_{\tilde u_{rK-1}}\left\{\frac{1}{(r+1)K}\sum_{k=0}^{rK-1}q(z,\tilde y_z(k),\tilde u_k,\tilde v_k)\right.$$

$$\left.+\frac{1}{r+1}R^{up}(z,\lambda,K,\tilde y_z(rK))\right\},\tag{5.7}$$

where $q(z,y,u,v)\overset{\text{def}}{=}\Phi(z,y,u,v)+\lambda^T f_1(z,y,u,v)$ and $\tilde y_z(k)$ is the solution of (2.14) obtained with a control pair $(\tilde u_k,\tilde v_k)$ and with the initial conditions $\tilde y_z(0)=y$. By (5.1),

$$\left|\frac{1}{r+1}R^{up}(z,\lambda,K,\tilde y_z(rK))-\frac{1}{r+1}R^{up}(z,\lambda,K,y)\right|\le\frac{\gamma_1(K)}{r+1}.$$

Hence,

$$\begin{aligned}R^{up}(z,\lambda,(r+1)K,y)&\le\inf_{\tilde v_0}\sup_{\tilde u_0}\dots\inf_{\tilde v_{rK-1}}\sup_{\tilde u_{rK-1}}\left\{\frac{r}{(r+1)}\cdot\frac{1}{rK}\sum_{k=0}^{rK-1}q(z,\tilde y_z(k),\tilde u_k,\tilde v_k)\right\}\\&\quad+\frac{1}{r+1}R^{up}(z,\lambda,K,y)+\frac{\gamma_1(K)}{r+1}\\&=\frac{r}{r+1}R^{up}(z,\lambda,rK,y)+\frac{1}{r+1}R^{up}(z,\lambda,K,y)+\frac{\gamma_1(K)}{r+1}\end{aligned}\tag{5.8}$$

and, similarly,

$$R^{up}(z,\lambda,(r+1)K,y)\ge\frac{r}{r+1}R^{up}(z,\lambda,rK,y)+\frac{1}{r+1}R^{up}(z,\lambda,K,y)-\frac{\gamma_1(K)}{r+1}.\tag{5.9}$$

From (5.8) and (5.6) it follows that

$$\begin{aligned}R^{up}(z,\lambda,(r+1)K,y)&\le\frac{r}{r+1}(R^{up}(z,\lambda,K,y)+\gamma_1(K))\\&\quad+\frac{1}{r+1}R^{up}(z,\lambda,K,y)+\frac{\gamma_1(K)}{r+1}\\&=R^{up}(z,\lambda,K,y)+\gamma_1(K).\end{aligned}$$

In the same way, from (5.9) and (5.6) it follows that

$$R^{up}(z,\lambda,(r+1)K,y)\ge R^{up}(z,\lambda,K,y)-\gamma_1(K).$$

This completes the proof of (5.2) for R^{up}. The proof for R^{lo} is similar.

To prove (5.3) let us notice that for any control pairs $(\tilde u_k,\tilde v_k)$ defined on $[0,N_2]$ $(N_2\ge N_1\ge 1)$,

$$|N_2Q(z,\lambda,N_2,\tilde u,\tilde v)-N_1Q(z,\lambda,N_1,\tilde u,\tilde v)|\le M\,(N_2-N_1)\,,\tag{5.10}$$

where

$$M=\max\left\{|\Phi(z,y,u,v)|+\|\lambda\|\,\|f_1(z,y,u,v)\|\right.$$

$$\left.\Big|(z,\lambda,y,u,v)\in D\times\Lambda\times P_1\times U\times V\right\},\tag{5.11}$$

where P_1 is a compact subset of R^n containing all the trajectories of (2.14) which start in P. On the basis of (5.10), (2.19), and (2.20), it can be easily verified that

$$|N_2 R^{up(lo)}(z,\lambda,N_2,y) - N_1 R^{up(lo)}(z,\lambda,N_1,y)| \le M\,(N_2 - N_1)\,. \tag{5.12}$$

By (5.11), $|R^{up(lo)}(z,\lambda,N,y)| \le M\ \forall N \ge 0$, which along with (5.12) allows us to establish the inequalities

$$\begin{aligned}
&\left|R^{up(lo)}(z,\lambda,N_2,y) - R^{up(lo)}(z,\lambda,N_1,y)\right| \\
&\le \left|R^{up(lo)}(z,\lambda,N_2,y) - N_1 {N_2}^{-1} R^{up(lo)}(z,\lambda,N_1,y)\right| \\
&\quad + \left|N_1 {N_2}^{-1} - 1\right| \left|R^{up(lo)}(z,\lambda,N_1,y)\right| \\
&\le 2M\,(N_2 - N_1)\,{N_2}^{-1},
\end{aligned}$$

which implies (5.3), where L can be taken to be equal to $2M$.

THEOREM 5.3. *Assume that all assumptions of Theorem* 5.1 *are satisfied and the function* $\xi(k)$ *in Assumption* 4.7 *has the form* $\xi(k) = \xi^k C$, *where* $0 < \xi < 1$ *and* $C > 0$ *is a constant. Then Assumptions* 4.5 *and* 4.6 *are true.*

Proof. It can be worked out essentially following a similar line as in the proof of the results of Gaitsgory [12] and combining with Lemma 5.4 below. □

LEMMA 5.4. *Let* $\tilde{z}(k)$ *be an arbitrary function belonging to a compact set for* $k = 0, 1, \ldots, N$. *Let* $\tilde{u}_k$ *be an arbitrary admissible control and let* $\tilde{y}(k)$ *and* $\tilde{y}_z(k)$ *be the solutions of the system*

$$\tilde{y}(k+1) = \tilde{y}(k) + f_2(\tilde{z}(k), \tilde{y}(k), \tilde{u}_k), \quad \tilde{y}(0) = y, \tag{5.13}$$

and the system

$$\tilde{y}_z(k+1) = \tilde{y}_z(k) + f_2(z, \tilde{y}_z(k), \tilde{u}_k), \quad \tilde{y}_z(0) = y, \tag{5.14}$$

respectively (where, in contrast to (5.13), z *is constant in* (5.14)*). Then*

$$\max_{k=0,1,\ldots,N} \|\tilde{y}(k) - \tilde{y}_z(k)\| \le C \max_{k=0,1,\ldots,N} \|\tilde{z}(k) - z\|, \tag{5.15}$$

where $C_1 > 0$ *is a constant.*

Proof of Lemma 5.4. The proof can be carried out by similar techniques as those in [9].

Choose a natural number K in such a way that

$$C_1 \xi^K \stackrel{\text{def}}{=} \delta < 1 \tag{5.16}$$

and define $\tau_l = lK,\ l = 0, 1, \ldots, \lfloor \frac{N}{K} \rfloor,\ \tau_{l+1} \stackrel{\text{def}}{=} N$.

To continue the proof, we need the following simple proposition.

PROPOSITION 5.5. *Let* $\alpha_k \ge 0,\ k = \tau_l, \tau_l + 1, \ldots, \tau_{l+1}$, *satisfy the inequalities*

$$\alpha_{\tau_l} \le M_1 \Delta, \tag{5.17}$$

$$\alpha_{k+1} \le M_2 \Delta + M_3 \sum_{i=\tau_l}^{k} \alpha_i, \tag{5.18}$$

where M_i, $i = 1, 2, 3$, are constants and Δ is a positive parameter. Then there exists a constant θ such that

$$\alpha_k \le \theta\Delta, \qquad k = \tau_l, \tau_l + 1, \ldots, \tau_{l+1}. \tag{5.19}$$

Proof. It can be easily derived by induction. □

Returning to the proof of the main lemma, denote by $\tilde{y}_z^l(k)$, $k = \tau_l, \tau_l+1, \ldots, \tau_{l+1}$, the solution of (5.14) obtained with the controls $\tilde{u}_k$ and the initial condition

$$\tilde{y}_z^l(\tau_l) = \tilde{y}(\tau_l). \tag{5.20}$$

By definition $\tilde{y}_z^l(k)$ satisfies the equation

$$\tilde{y}_z^l(k+1) = \tilde{y}(\tau_l) + \sum_{\tau=\tau_l}^{k} f_2\left(z, \tilde{y}_z^l(\tau), \tilde{u}_\tau\right). \tag{5.21}$$

Also, $\tilde{y}(k)$ satisfies the equation

$$\tilde{y}(k+1) = \tilde{y}(\tau_l) + \sum_{\tau=\tau_l}^{k} f_2\left(\tilde{z}, \tilde{y}(\tau), \tilde{u}_\tau\right). \tag{5.22}$$

Subtracting (5.21) from (5.22) and using Lipschitz conditions ($f_2(\cdot)$ is assumed to satisfy these conditions in z and y with the constant L), one obtains

$$\|\tilde{y}_z^l(k+1) - \tilde{y}(k+1)\| \le LK\Delta + L\sum_{\tau=\tau_l}^{k} \|\tilde{y}_z^l(\tau) - \tilde{y}(\tau)\|, \tag{5.23}$$

where

$$\Delta \stackrel{\text{def}}{=} \max_{k=0,1,\ldots,N} \|z(k) - z\|. \tag{5.24}$$

Denoting

$$\|\tilde{y}_z^l(k) - \tilde{y}(k)\| \stackrel{\text{def}}{=} \alpha_k$$

and taking

$$M_1 = 0, \quad M_2 = LK, \quad M_3 = L,$$

one obtains from Proposition 5.5 that there exists a constant θ_1 such that

$$\|\tilde{y}_z^l(k) - \tilde{y}(k)\| \le \theta_1\Delta, \qquad k = \tau_l, \tau_l + 1, \ldots, \tau_{l+1}. \tag{5.25}$$

On the basis of the assumption on $\xi(k)$ in Theorem 5.3, and (5.16) and (5.25), one can write

$$\begin{aligned}
&\|\tilde{y}_z(\tau_{l+1}) - \tilde{y}(\tau_{l+1})\| \\
&\le \|\tilde{y}_z(\tau_{l+1}) - \tilde{y}_z^l(\tau_{l+1})\| + \|\tilde{y}_z^l(\tau_{l+1}) - \tilde{y}(\tau_{l+1})\| \\
&\le \delta\|\tilde{y}_z(\tau_l) - \tilde{y}_z^l(\tau_l)\| + \theta_1\Delta \\
&= \delta\|\tilde{y}_z(\tau_l) - \tilde{y}(\tau_l)\| + \theta_1\Delta \\
&\le \delta\left(\delta\|\tilde{y}_z(\tau_{l-1}) - \tilde{y}(\tau_{l-1})\| + \theta_1\Delta\right) + \theta_1\Delta \\
&\ldots\ldots \\
&\le (\delta^{l-1} + \delta^{l-2} + \cdots + 1)\theta_1\Delta \le \frac{\theta_1\Delta}{1-\delta}\,.
\end{aligned} \tag{5.26}$$

The solution $\tilde{y}_z(k)$ of (5.14) satisfies the equation

$$\tilde{y}_z(k+1) = \tilde{y}_z(k) + \sum_{\tau=\tau_l}^{k} f_2\left(z, \tilde{y}_z(\tau), \tilde{u}_\tau\right). \tag{5.27}$$

Subtracting this from (5.22), one obtains, by using (5.26),

$$\begin{aligned} &\|\tilde{y}(k+1) - \tilde{y}_z(k+1)\| \\ &\le \|\tilde{y}(\tau_l) - \tilde{y}_z(\tau_l)\| + LK\Delta + L\sum_{\tau=\tau_l}^{k} \|\tilde{y}(\tau_l) - \tilde{y}_z(\tau)\| \\ &\le \left[\frac{\theta_1}{1-\delta} + LK\right]\Delta + L\sum_{\tau=\tau_l}^{k} \|\tilde{y}(\tau_l) - \tilde{y}_z(\tau)\|. \end{aligned} \tag{5.28}$$

Denoting

$$\|\tilde{y}(k) - \tilde{y}_z(k)\| = \alpha_k$$

and taking

$$M_1 = \frac{\theta_1\Delta}{1-\delta}, \quad M_2 = \frac{\theta_1}{1-\delta} + LK, \quad M_3 = L,$$

one obtains from Proposition 5.5 that there exists a constant θ_2 such that

$$\|\tilde{y}(k) - \tilde{y}_z(k)\| \le \theta_2\Delta, \qquad k = \tau_l, \tau_l + 1, \ldots, \tau_{l+1}. \tag{5.29}$$

Note that the constant θ_2 does not depend on l and, hence, (5.29) proves the lemma with $C = \theta_2$. □

6. Conclusions. In this paper, the problem of singularly perturbed zero-sum dynamic games with full information has been investigated. With the aid of an associated fast game, it has been shown that the upper and lower value functions of this game have limits as the singular perturbations parameter tends to zero. It has also been established that these limits coincide with viscosity solutions of some Hamilton–Jacobi-type equations. Two examples were presented to illustrate the general results.

Acknowledgments. The author would like to express his sincere gratitude and appreciation to Professor Vladimir Gaitsgory from the University of South Australia for discussion and encouragement during this work. Also, the author wishes to thank the associate editor and referees for their valuable comments and suggestions which have improved the presentation.

SIMPLE MECHANICAL CONTROL SYSTEMS WITH CONSTRAINTS AND SYMMETRY*

J. CORTÉS†, S. MARTÍNEZ†, J. P. OSTROWSKI‡, AND H. ZHANG§

Abstract. We develop tools for studying the control of underactuated mechanical systems that evolve on a configuration space with a principal fiber bundle structure. Taking the viewpoint of affine connection control systems, we derive reduced formulations of the Levi–Civita and the nonholonomic affine connections, along with the symmetric product, in the presence of symmetries and nonholonomic constraints. We note that there are naturally two kinds of connections to be considered here, affine and principal connections, leading to what we term a "connection within a connection." These results are then used to describe controllability tests that are specialized to simple, underactuated mechanical systems on principal fiber bundles, including the notion of fiber configuration controllability. We present examples of the use of these tools in studying the planar rigid body with a variable direction (vectored) thruster and the snakeboard robot.

Key words. nonlinear control, reduction, configuration controllability, symmetric product

1. Introduction.

In the area of control for mechanical systems, there is a newly emerging body of work that utilizes the special Lagrangian structure of such systems to help focus the control analysis [5, 6, 8, 12, 20, 21]. This perspective, in which the dynamics of simple mechanical systems is interpreted using an affine connection, has led to new insights into both control and motion planning for a number of underactuated mechanical systems. In this paper, we study the effect of symmetries and constraints on the tools that are used in studying affine connection control systems, namely, the *affine connection* and the *symmetric product*.

In studying the controllability of a mechanical system, classical tools from nonlinear control theory [27] suggest that one compute the closure by the Lie bracket of all the control inputs and the drift vector field. When the control inputs enter in as forcing terms for second-order ODEs, such as is the case with forces or torques, this procedure requires the system to be transformed into a first-order form. The drawback of this, however, is that the conversion requires that one treat the velocities as a part of the state and, more importantly, that the intrinsic structure of the mechanical system as a second-order Lagrangian system is covered up. However, work by Lewis and Murray [21] has shown that a proper geometric interpretation of simple mechanical systems can be achieved through the use of the affine connection formalism and the symmetric product that derives from it.

Bullo, Leonard, and Lewis later applied these results to underactuated Lagrangian systems evolving on a Lie group [6, 7]. They took advantage of the special Lie group structure to derive algorithms for generating the control inputs that lead to motion along the directions generated through the operation of the symmetric product. This work serves as a starting point for this paper, in which we explore a generalization of these ideas to systems that evolve on principal fiber bundles, which are locally the product of a Lie group and a general smooth manifold.

We also note that there has been extensive work in the area of understanding the role of symmetries in mechanical systems (see, e.g., [2, 4, 9, 10, 16, 23, 24, 25] and references therein). We focus on one aspect of such systems, where internal shape variables play an important role in determining the motion of a system along a Lie group. Lagrangian reduction provides powerful tools for analyzing mechanical systems on fiber bundles. Generally (as is the case for our examples), the Lie group describes the position and orientation of the system, while the remaining variables constitute an internal shape space. Some examples of the shape variables that result are the thruster angle of a blimp [35, 36], the leg angle of a robot leg [21], and the wheel direction angles of a snakeboard [30, 31]. Through a local trivialization, we can use the internal symmetries of the system to decouple the dynamics into two parts, vertical and horizontal, and connect them with a mechanical connection (or constraints) [4, 31]. Likewise, we can apply the same technique to the computation of covariant derivatives by finding the vertical and horizontal parts and then use the Lie bracket and symmetric product to take advantage of the geometric structure of the system, leading to simplified tests of configuration accessibility and controllability. When nonholonomic constraints are present, the situation is further complicated, though it was shown by Lewis [20] that one can use a *nonholonomic affine connection* that directly extends the controllability results.

Our motivation for studying this class of systems comes from robotics, where it has been noted that *robotic locomotion systems* possess this structure—the dynamics evolve on a product bundle between a Lie group and a general "shape" manifold [15, 28, 31]. This leads us to consider mechanical systems on principal fiber bundles, in which the motion of the system is generated through a complex interaction of thrusts/forces and internal changes in the shape or configuration of the robot. There is an extensive literature studying such systems, including kinematic versions [15], dynamic systems that evolve purely on Lie groups [6], and dynamic systems with nonholonomic constraints [28, 30]. An important quantity for such robotic systems that is highlighted here is the notion of *fiber controllability*, introduced by Kelly and Murray [15] for driftless, kinematic systems. The notion of fiber controllability stems from the fact that, for many robotic systems of this form, one cares only that the robot be able to control its position and orientation, without regard to the configuration of its internal shape. Thus the emphasis is on understanding whether a system is controllable only along the fiber (position and orientation). We extend this notion to dynamic systems with symmetries living on trivial principal fiber bundles.

The paper is organized as follows. In section 2, we give some background on simple mechanical control systems and the role of symmetries. In section 3, we study the reduced version of the Levi–Civita affine connection and hence the symmetric product for principal fiber bundles. We present the computations in terms of local forms of the quantities that arise, including the *mechanical connection* and the *locked inertia tensor*, since these allow for a reduced and compact representation. We follow up this derivation in section 4 with a parallel formulation of the nonholonomic affine

connection that arises when constraints are present. In section 5, we describe how these results extend previous notions of configuration controllability to fiber bundles and introduce a new concept of fiber controllability. In section 6, we demonstrate the use of these tools in two motivating examples: the underactuated rigid body (or planar blimp) and the snakeboard. Finally, section 7 is devoted to some concluding remarks.

2. Background on simple mechanical control systems. In this section, we describe the geometric framework utilized in the study of mechanical control systems. We follow [20, 21] in the exposition of affine connection control systems. The reader is referred to [1, 17] for more details on notions such as principal bundles or affine connections.

2.1. Affine connection control systems. Let Q be an n-dimensional manifold. We denote by TQ the tangent bundle of Q, by $\mathfrak{X}(Q)$ the set of vector fields on Q, and by $C^\infty(Q)$ the set of smooth functions on Q. A *simple mechanical control system* is defined by a tuple $(Q, \mathcal{G}, V, \mathcal{F})$, where Q is the manifold of configurations of the system, $\mathcal{G}$ is a Riemannian metric on Q (the kinetic energy metric of the system), $V \in C^\infty(Q)$ is the potential function, and $\mathcal{F} = \{F^1, \dots, F^m\}$ is a set of m linearly independent 1-forms on Q, which physically correspond to forces or torques.

The dynamics of simple mechanical control systems is classically described by the *forced Euler–Lagrange equations*

$$\frac{d}{dt}\left(\frac{\partial L}{\partial \dot{q}}\right) - \frac{\partial L}{\partial q} = \sum_{i=1}^{m} u_i(t) F^i, \tag{2.1}$$

where $L(q, \dot{q}) = \frac{1}{2}\mathcal{G}(\dot{q}, \dot{q}) - V(q)$ is the *Lagrangian* of the system.

Alternatively, one can express the control equations (2.1) using the natural affine connection associated to the metric $\mathcal{G}$, the Levi–Civita connection. An *affine connection* [17] is defined as an assignment

$$\begin{array}{rccc} \nabla : & \mathfrak{X}(Q) \times \mathfrak{X}(Q) & \longrightarrow & \mathfrak{X}(Q) \\ & (X, Y) & \longmapsto & \nabla_X Y, \end{array}$$

which is $\mathbb{R}$-bilinear and satisfies $\nabla_{fX} Y = f \nabla_X Y$ and $\nabla_X (fY) = f \nabla_X Y + X(f) Y$ for any X, $Y \in \mathfrak{X}(Q)$, $f \in C^\infty(Q)$. In local coordinates,

$$\nabla_X Y = \left(\frac{\partial Y^a}{\partial q^b} X^b + \Gamma^a_{bc} X^b Y^c\right) \frac{\partial}{\partial q^a},$$

where $\Gamma^a_{bc}(q)$ are the *Christoffel symbols* of the affine connection defined by

$$\nabla_{\frac{\partial}{\partial q^b}} \frac{\partial}{\partial q^c} = \Gamma^a_{bc} \frac{\partial}{\partial q^a}. \tag{2.2}$$

For simple mechanical control systems, the *Levi–Civita connection* $\nabla^{\mathcal{G}}$ associated to the metric $\mathcal{G}$ is determined by the formula

$$\begin{aligned} 2\,\mathcal{G}(Z, \nabla_X Y) = {} & X(\mathcal{G}(Z, Y)) + Y(\mathcal{G}(Z, X)) - Z(\mathcal{G}(Y, X)) + \mathcal{G}(X, [Z, Y]) \\ & + \mathcal{G}(Y, [Z, X]) - \mathcal{G}(Z, [Y, X]), \quad X, Y, Z \in \mathfrak{X}(Q). \end{aligned} \tag{2.3}$$

One can compute the Christoffel symbols of $\nabla^{\mathcal{G}}$ to be

$$\Gamma^a_{bc} = \frac{1}{2}\mathcal{G}^{ad}\left(\frac{\partial \mathcal{G}_{db}}{\partial q^c} + \frac{\partial \mathcal{G}_{dc}}{\partial q^b} - \frac{\partial \mathcal{G}_{bc}}{\partial q^d}\right),$$

where $(\mathcal{G}^{ad})$ denotes the inverse matrix of $(\mathcal{G}_{da} = \mathcal{G}(\frac{\partial}{\partial q^d}, \frac{\partial}{\partial q^a}))$. Instead of the input forces $F^1, \ldots, F^m$, we shall make use of the vector fields $Y_1, \ldots, Y_m$, defined as $Y_i = \sharp_{\mathcal{G}}(F^i)$, where $\sharp_{\mathcal{G}} = \flat_{\mathcal{G}}^{-1}$ and $\flat_{\mathcal{G}} : TQ \longrightarrow T^*Q$ is the musical isomorphism given by $\flat_{\mathcal{G}}(X)(Y) = \mathcal{G}(X, Y)$. In local coordinates, we have that $Y_i^a = \mathcal{G}^{ab}F_b^i$ for each $1 \leq i \leq m$. Roughly speaking, this corresponds to considering the effect of the controls on "accelerations" rather than on forces. The control equations (2.1) for the mechanical system may then be recast as

$$\nabla^{\mathcal{G}}_{\dot{c}(t)}\dot{c}(t) = -\operatorname{grad} V + \sum_{i=1}^{m} u^i(t) Y_i(c(t)), \tag{2.4}$$

where $\operatorname{grad} V = \sharp_{\mathcal{G}}(dV)$. Observe that we can use a general affine connection in (2.4) instead of the Levi–Civita connection without changing the structure of the equation. This is particularly interesting, since nonholonomic mechanical control systems also give rise to equations of the form of (2.4), as we review in the following [20]. This observation is actually very powerful, since controllability analyses based on a general affine connection (cf. section 5) are valid for both unconstrained and constrained control systems.

A *constrained mechanical control system* $(Q, \mathcal{G}, V, \mathcal{F}, \mathcal{D})$ is a simple mechanical control system $(Q, \mathcal{G}, V, \mathcal{F})$ subject to the constraints given by the $(n-l)$-dimensional (nonholonomic) distribution $\mathcal{D}$ on Q. In a local description, $\mathcal{D}$ can be defined by the vanishing of l independent constraint functions $\omega_j(q)\dot{q}$, $1 \leq j \leq l$. The application of Lagrange–d'Alembert's principle leads to the constrained equations of motion

$$\frac{d}{dt}\left(\frac{\partial L}{\partial \dot{q}}\right) - \frac{\partial L}{\partial q} = \sum_{i=1}^{m} u_i(t) F^i + \sum_{j=1}^{l} \lambda^j \omega_j, \tag{2.5}$$

which, together with the constraint equations $\omega_j(q)\dot{q} = 0$, describe the dynamics of the nonholonomic system. Here, the λ^j are the Lagrange multipliers. The term $\sum_{j=1}^{l} \lambda^j \omega_j$ represents the "reaction force" due to the constraints.

The second-order equation (2.5) can alternatively be written as

$$\begin{cases} \nabla^{\mathcal{G}}_{\dot{c}(t)}\dot{c}(t) = \lambda(t) - \operatorname{grad} V + \sum_{i=1}^{m} u_i(t) Y_i(c(t)), \\ \dot{c}(t) \in \mathcal{D}_{c(t)}, \end{cases} \tag{2.6}$$

where now λ is seen as a section of $\mathcal{D}^{\perp}$, the $\mathcal{G}$-orthogonal complement to $\mathcal{D}$, along the curve c. Letting $\mathcal{P} : TQ \longrightarrow \mathcal{D}$, $\mathcal{Q} : TQ \longrightarrow \mathcal{D}^{\perp}$ denote the complementary $\mathcal{G}$-orthogonal projectors, we can define an affine connection

$$\overline{\nabla}_X Y = \nabla^{\mathcal{G}}_X Y + (\nabla^{\mathcal{G}}_X \mathcal{Q})(Y) = \mathcal{P}(\nabla^{\mathcal{G}}_X Y) + \nabla^{\mathcal{G}}_X(\mathcal{Q}(Y)),$$

such that the nonholonomic control equations (2.6) can be rewritten as

$$\overline{\nabla}_{\dot{c}(t)}\dot{c}(t) = -\mathcal{P}(\operatorname{grad} V) + \sum_{i=1}^{m} u_i(t) \mathcal{P}(Y_i(c(t))), \tag{2.7}$$

and where we select the initial velocity in $\mathcal{D}$ (cf. [20] for details). Observe that the inputs Y_i act on the system only through their $\mathcal{D}$-component. Indeed, the Lagrange multiplier $\lambda \in \mathcal{D}^{\perp}$ absorbs their $\mathcal{D}^{\perp}$-components. The connection $\overline{\nabla}$ is called the

nonholonomic affine connection [3, 19, 20, 33]. Note that (2.4) and (2.7) have the same structure.

It can be easily deduced from its definition that $\overline{\nabla}$ restricts to $\mathcal{D}$; that is,

$$\overline{\nabla}_X Y = \mathcal{P}(\nabla^{\mathcal{G}}_X Y) \in \mathcal{D} \text{ for all } Y \in \mathcal{D},\ X \in \mathfrak{X}(Q).$$

This kind of affine connection, which restricts to a given distribution, has been studied in [19]. In particular, such a behavior implies that the distribution $\mathcal{D}$ is *geodesically invariant*; that is, for every geodesic $c(t)$ of $\overline{\nabla}$ starting from a point in $\mathcal{D}$, $\dot{c}(0) \in \mathcal{D}_{c(0)}$, we have that $\dot{c}(t) \in \mathcal{D}_{c(t)}$.

As we shall see later, a key tool in the controllability analysis and description of mechanical control systems is the *symmetric product* $\langle \cdot : \cdot \rangle$ associated to an affine connection ∇ (see [13, 21, 34]). Given X, $Y \in \mathfrak{X}(Q)$, define

$$\langle X : Y \rangle = \nabla_X Y + \nabla_Y X.$$

The symmetric product characterizes geodesically invariant distributions. Indeed, one can prove that $\mathcal{D}$ is geodesically invariant for the nonholonomic connection if and only if $\langle X : Y \rangle \in \mathcal{D}$ for all X, $Y \in \mathcal{D}$ (see [19]). Recently, Bullo [5] has shown that the evolution of mechanical control systems when starting from rest can be described by a series involving repeated symmetric products of the input vector fields, extending the possibilities of use of the symmetric product to the design of motion control algorithms.

2.2. Principal fiber bundles. The notion of principal fiber bundles is present in many locomotion and robotic systems, since they commonly exhibit translational and rotational symmetries. Examining the configuration space Q, one can observe that there exists a splitting $Q = G \times M$ between variables describing the position and orientation of the robot, i.e., the *pose* coordinates $g \in G$, and variables describing the internal shape of the system, the *shape* coordinates $r \in M$. This exactly corresponds to the case of a trivial principal fiber bundle, decomposed into *fiber* space, G, and *base* space, M, respectively.

Geometrically, this situation is described as follows. Assume there is a Lie group G acting on Q

$$\begin{array}{rccl} \Phi: & G \times Q & \longrightarrow & Q \\ & (g, q) & \longmapsto & \Phi(g, q) = \Phi_g(q) = gq. \end{array}$$

The orbit through a point q is $\mathrm{Orb}_G(q) = \{gq \mid g \in G\}$. We denote by $\mathfrak{g}$ the Lie algebra of G. For any element $\xi \in \mathfrak{g}$, let ξ_Q denote the corresponding infinitesimal generator of the group action on Q. Then

$$T_q(\mathrm{Orb}_G(q)) = \{\xi_Q(q) \mid \xi \in \mathfrak{g}\}.$$

If the action Φ is free and proper, we can endow the quotient space $Q/G \cong M$ with a manifold structure such that the canonical projection $\pi : Q \longrightarrow M$ is a surjective submersion. Then we have that $Q(M, G, \pi)$ is a principal bundle with bundle space Q, base space M, structure group G, and projection π. Note that the kernel of $\pi_*(= T\pi)$ consists of the *vertical* tangent vectors, i.e., the vectors tangent to the orbits of G in Q. We denote the bundle of vertical vectors by $\mathcal{V}$, with $\mathcal{V}_q = T_q(\mathrm{Orb}_G(q))$, $q \in Q$.

Throughout the paper, we will usually deal with general principal fiber bundles, unless otherwise stated. Locally, one can always trivialize Q and work with $Q \supset$

$\pi^{-1}(U) \equiv G \times U$, where $U \subset M$ is an open subset of M. In the bundle coordinates (g, r), the projection reads $\pi(g, r) = r$, and the Lagrangian L can be written as

$$L(q, \dot{q}) = \frac{1}{2}(\dot{g}^T \, \dot{r}^T) \, \mathcal{G} \begin{pmatrix} \dot{g} \\ \dot{r} \end{pmatrix} - V(g, r),$$

where we note the abuse of notation resulting from changing between $\dot{g}$ as an argument in TG and as a vector (the same stands for $\mathcal{G}$ seen as a bilinear form or as a matrix). In the remainder of the paper, we will often make use of the same notation for coordinate-free and matrix formulas. The precise meaning should be clear from the context.

A *principal connection* on $Q(M, G, \pi)$ can be defined as a G-invariant distribution $\mathcal{H}$ on Q satisfying $T_qQ = \mathcal{H}_q \oplus \mathcal{V}_q$ for all $q \in Q$. The subspace $\mathcal{H}_q$ of T_qQ is called the *horizontal subspace* at q determined by the connection.

Alternatively, a principal connection can be characterized by a $\mathfrak{g}$-valued 1-form $\mathcal{A}$ on Q satisfying the following conditions:

(i) $\mathcal{A}(\xi_Q(q)) = \xi$ for all $\xi \in \mathfrak{g}$,

(ii) $\mathcal{A}((\Phi_g)_* X) = \mathrm{Ad}_g(\mathcal{A}(X))$ for all $X \in TQ$.

The horizontal subspace at q is then given by $\mathcal{H}_q = \{v_q \in T_qQ \mid \mathcal{A}(v_q) = 0\}$. In coordinates, using (i) and (ii), we can write

$$\begin{aligned} \mathcal{A}(g, r, \dot{g}, \dot{r}) &= \mathcal{A}(g(e, r, \xi, \dot{r})) = Ad_g \mathcal{A}(e, r, \xi, \dot{r}) \\ &= Ad_g(\mathcal{A}(e, r, \xi, 0) + \mathcal{A}(e, r, 0, \dot{r})) = Ad_g(\xi + A(r)\dot{r}). \end{aligned}$$

Note that A depends only on the shape variables. It is called the *local form of the connection* $\mathcal{A}$.

Given a principal connection, we have that every vector $v \in T_qQ$ can be uniquely written as $v = v^{hor} + v^{ver}$, with $v^{hor} \in \mathcal{H}_q$ and $v^{ver} = \mathcal{A}(v)_Q(q) \in \mathcal{V}_q$. The curvature $\mathcal{B}$ of the principal connection $\mathcal{A}$ is a $\mathfrak{g}$-valued 2-form on Q defined as follows: for each $q \in Q$ and $u, v \in T_qQ$,

$$\mathcal{B}(u, v) = d\mathcal{A}(u^{hor}, v^{hor}) = -\mathcal{A}([u^{hor}, v^{hor}]).$$

The curvature measures the lack of integrability of the horizontal distribution and plays a fundamental role in the theory of geometric phases (see [17] for a comprehensive treatment). In a local representation, the curvature can be written as

$$\mathcal{B}((g\xi, v), (g\eta, w)) = (B(r)(v, w)) = B^a_{\alpha\beta} v^\alpha w^\beta Ad_g e_a,$$

where $\{e_a\}_{a=1}^k$ is a basis of the Lie algebra $\mathfrak{g}$ and

$$B^a_{\alpha\beta} = \frac{\partial A^a_\alpha}{\partial r^\beta} - \frac{\partial A^a_\beta}{\partial r^\alpha} + c^a_{bc} A^b_\alpha A^c_\beta.$$

The c^a_{bc} are the *structure constants* of the Lie algebra defined by $[e_b, e_c] = c^a_{bc} e_a$.

An additional derivative operator related to a principal connection will appear in the derivations below. Let κ be a $\bigotimes_\nu \mathfrak{g}^*$-valued function on Q, $\kappa : Q \longrightarrow \bigotimes_\nu \mathfrak{g}^*$. Define then the *derivative of* κ *along* $\mathcal{A}$, $D\kappa : TQ \longrightarrow \bigotimes_\nu \mathfrak{g}^*$, by

$$D\kappa(\dot{q})(\xi_1, \ldots, \xi_\nu) = d\kappa(\dot{q})(\xi_1, \ldots, \xi_\nu) + \sum_{k=1}^{\nu} \kappa(q)(\xi_1, \ldots, ad_{\mathcal{A}\dot{q}} \xi_k, \ldots, \xi_\nu).$$

If the mapping κ is G-equivariant, $\kappa(g,r) = Ad^*_{g^{-1}}\kappa_{\rm loc}(r)$, where $\kappa_{\rm loc}(r) = \kappa(e,r)$, meaning

$$\kappa(g,r)(\xi_1,\ldots,\xi_\nu) = \kappa_{\rm loc}(r)(Ad_{g^{-1}}\xi_1,\ldots,Ad_{g^{-1}}\xi_\nu),$$

then one can see that

$$D\kappa(\dot g,\dot r) = Ad^*_{g^{-1}}D\kappa_{\rm loc}(\dot r).$$

In bundle coordinates, $D\kappa_{\rm loc}(\dot r)(\xi_1,\ldots,\xi_\nu) = (D\kappa_{\rm loc})_{\alpha a_1\ldots a_\nu}\dot r^\alpha \xi_1^{a_1}\ldots\xi_\nu^{a_\nu}$, where

$$(D\kappa_{\rm loc})_{\alpha a_1\ldots a_\nu} = \frac{\partial(\kappa_{\rm loc})_{a_1\ldots a_\nu}}{\partial r^\alpha} + \sum_{k=1}^{\nu}(\kappa_{\rm loc})_{a_1\ldots d_k\ldots a_\nu}A^e_\alpha c^{d_k}_{ea_k}.$$

2.3. Systems with symmetry. In the reduction of unconstrained mechanical systems with symmetry, there naturally arises a principal connection called the *mechanical* connection A^{mech}. Assume that the control system $(Q,\mathcal{G},V,\mathcal{F})$ is *invariant* under the action of a Lie group G, that is, $\Phi_g^*\mathcal{G} = \mathcal{G}$, $\Phi_g^*V = V$, and $\Phi_g^*F^i = F^i$ for $1 \le i \le m$ and all $g \in G$. (Note that it may happen that a particular element of the control system is invariant under the action of a larger Lie group H, $G \subseteq H$, but we are considering only Lie groups which leave invariant *all* the components of the problem.) The horizontal subspace of the mechanical connection is then given by the orthogonal complement of the vertical bundle $\mathcal{V}$ with respect to the kinetic energy metric $\mathcal{G}$, $\mathcal{H} = \mathcal{V}^\perp$. An explicit formula for its associated 1-form is the following. Define the *locked inertia tensor* at configuration $q \in Q$, $\mathcal{I}(q) : \mathfrak{g} \longrightarrow \mathfrak{g}^*$ by

$$\langle \mathcal{I}(q)\xi,\eta\rangle = \mathcal{G}(\xi_Q(q),\eta_Q(q)).$$

In local coordinates, this can be expressed as $\mathcal{I}(r,g) = Ad^*_{g^{-1}}I(r)Ad_{g^{-1}}$. $I(r)$, the *local form of* $\mathcal{I}$, has the interpretation of the inertia of the system when frozen at shape r. If we further defined the *momentum map* $J : TQ \longrightarrow \mathfrak{g}^*$ by $\langle J(\dot q),\xi\rangle = \langle \frac{\partial L}{\partial \dot q}(\dot q),\xi_Q(q)\rangle$, then the mechanical connection is just $A^{mech}(\dot q) = I(q)^{-1}J(\dot q)$.

The invariance of the metric and the potential function implies also that $L(g,r,\dot g,\dot r) = L(e,r,g^{-1}\dot g,\dot r) = \ell(r,\dot r,\xi)$, where $\xi = g^{-1}\dot g$. The function $\ell : TQ/G \longrightarrow \mathbb{R}$ is given by

$$\ell(r,\dot r,\xi) = \frac{1}{2}(\xi^T\ \dot r^T)\,\hat{\mathcal{G}}\begin{pmatrix}\xi\\ \dot r\end{pmatrix} - V(r),$$

where $\hat{\mathcal{G}}$ stands for the reduced metric [28]

$$\hat{\mathcal{G}} = \begin{pmatrix} I(r) & I(r)A(r)\\ A(r)^TI(r) & m(r)\end{pmatrix}. \tag{2.8}$$

Here A denotes the local form of the mechanical connection. This reduced metric is block diagonalized if we write it in terms of the shape variables $(r,\dot r)$ and the *locked body angular velocity*, $\Omega = \xi + A(r)\dot r$. Indeed, one can see that $\hat{\mathcal{G}}$ takes the form

$$\tilde{\mathcal{G}} = \begin{pmatrix} I(r) & 0\\ 0 & m(r) - A^T(r)I(r)A(r)\end{pmatrix} = \begin{pmatrix} I(r) & 0\\ 0 & \Delta(r)\end{pmatrix}.$$

We will see below that the terms I and Δ play a central role in deriving a local expression for the Levi–Civita affine connection.

The study of nonholonomic systems with symmetry has by now many contributions, starting from the work by Koiller on the kinematic case [16] and going through the use of the Hamiltonian formalism [2], Lagrangian reduction [4], the geometry of the tangent bundle [9, 10], and Poisson methods [23], among others. We review here some of the results found in [4, 28] for such systems which will be relevant for establishing later the decomposition for the nonholonomic affine connection.

Assume that the constrained mechanical control system is *invariant* under the action of a Lie group G, meaning that both $(Q, \mathcal{G}, V, \mathcal{F})$ and the constraint distribution $\mathcal{D}$ are invariant. Assume further that $\mathcal{D} + \mathcal{V} = TQ$ (the so-called *dimension assumption* [4]). We are interested in knowing which symmetry directions (i.e., tangent to the action of the Lie group) are compatible with the constraints. Consequently, we consider the intersection $S_q = \mathcal{V}_q \cap \mathcal{D}_q$ at each $q \in Q$. Since $S \subset \mathcal{V}$, we can consider a bundle $\mathfrak{g}^{\mathcal{D}} \longrightarrow Q$ whose fiber is given by $\mathfrak{g}^q = \{\xi \in \mathfrak{g} : \xi_Q(q) \in S_q\}$. The nonholonomic momentum map is then defined as

$$\begin{array}{rccccccc} J^{nh}: & TQ & \longrightarrow & \mathfrak{g}^{\mathcal{D}^*}, & & & & \\ & (q,\dot{q}) & \longmapsto & J^{nh}(q,\dot{q}): & \mathfrak{g}^q & \to & \mathbb{R}, \\ & & & & \xi^q & \longmapsto & \langle \frac{\partial L}{\partial \dot{q}}(\dot{q}), \xi_Q^q(q) \rangle. \end{array}$$

This momentum map can be used to "augment" the constraints and provide a principal connection on $Q \longrightarrow Q/G$, the so-called nonholonomic principal connection [4]. The horizontal subspace at $q \in Q$ of this connection is given by the orthogonal complement of S in the constraint distribution, $\mathcal{H}_q = S_q^{\perp} \cap \mathcal{D}_q$.

Alternatively, let $\{e_1(r), \ldots, e_s(r), e_{s+1}(r), \ldots, e_k(r)\} \in \mathfrak{g}$ be a basis of $\mathfrak{g}$ such that the first s elements span $\mathfrak{g}^{(r,e)}$ and both sets of generators are orthogonal in the kinetic energy metric restricted to $\mathcal{V}$. Denote by $\frac{\partial e_i}{\partial r^\alpha} = \sum_{a=1}^{k} \gamma_{i\alpha}^a e_a$ a notation which will be useful later. Define the momentum

$$p_i = \left\langle \frac{\partial \ell}{\partial \xi}, e_i(r) \right\rangle, \quad 1 \leq i \leq s.$$

Now consider the map

$$\begin{array}{rccc} A^{sym}: & T_qQ & \longrightarrow & S_q \\ & (q,\dot{q}) & \longmapsto & (\tilde{\mathcal{I}}^{-1}(q) J^{nh}(q,\dot{q}))_Q, \end{array}$$

where $\tilde{\mathcal{I}}(q) : \mathfrak{g}^{\mathcal{D}} \longrightarrow \mathfrak{g}^{\mathcal{D}^*}$ is the locked inertia tensor relative to $\mathfrak{g}^{\mathcal{D}}$. Notice that A^{sym} maps S onto itself. Additionally, let $A^{kin} : T_qQ \longrightarrow S_q^{\perp}$ be the orthogonal projection relative to the kinetic energy metric. The constraints plus the momentum can be written as

$$A^{kin}(q)\dot{q} = 0, \quad A^{sym}(q)\dot{q} = (\tilde{\mathcal{I}}^{-1}(q)p)_Q.$$

The nonholonomic connection 1-form is then given by

$$A^{nh} = A^{kin} + A^{sym}.$$

It is an instructive exercise to verify that A^{nh} indeed satisfies conditions (i) and (ii) defining a principal connection (cf. section 2.2). This principal connection plays a fundamental role in the reduction of nonholonomic systems with symmetry [4].

3. Decomposition of the Levi–Civita connection under symmetry. Given a mechanical control system with symmetry, it seems reasonable that the controllability tests can be simplified by taking into account the symmetry properties of the problem. In order to do that, we will obtain decompositions of the Levi–Civita connection and the nonholonomic affine connection according to the principal fiber bundle structure of the configuration space Q. This will be the subject of the following two sections.

Let $(Q, \mathcal{G}, V, \mathcal{F})$ be a simple mechanical control system invariant under the action of a Lie group G. The following simple lemma [14] will be helpful.

LEMMA 3.1. *The Levi–Civita connection associated to a left-invariant metric H on the Lie group G is given by*

$$\nabla^H_{g\xi} g\eta = \frac{1}{2} g \left([\xi, \eta] - \sharp_H \left(ad^*_\xi \flat_H \eta + ad^*_\eta \flat_H \xi \right) \right),$$

where $g\xi$ stands for $(L_g)_* \xi$ and so on. Consequently, the symmetric product associated to ∇^H takes the form

$$\langle g\xi : g\eta \rangle_H = -g \sharp_H \left(ad^*_\xi \flat_H \eta + ad^*_\eta \flat_H \xi \right).$$

Now we come to the main result of this section, where we derive the properties of the "connection within a connection." Emphasis is placed on the role of I, A, and Δ in determining $\nabla^{\mathcal{G}}$.

PROPOSITION 3.2. *Given G-invariant vector fields on Q, $X = (g\xi, v)$ and $Y = (g\eta, w)$, with $\xi(r)$, $\eta(r) \in \mathfrak{g}$ and v, $w \in TM$, the covariant derivative of Y along X can be expressed as*

$$\nabla^{\mathcal{G}}_X Y = g \left\{ \begin{pmatrix} \nabla^I_\Omega \Psi \\ \nabla^\Delta_v w \end{pmatrix} - \frac{1}{2} \begin{pmatrix} I^{-1}\mathbb{L} \\ \Delta^{-1}\mathbb{S} \end{pmatrix} \right\}, \tag{3.1}$$

where

$$\begin{aligned} \mathbb{L} &= -D(I\Omega)(\cdot, w) - D(I\Psi)(\cdot, v) + I([\Omega, \Psi] - [\xi, \eta] + \xi_r w - \eta_r v - A[v, w]) \\ &\quad + 2\, I(A(\nabla^{\mathcal{G}}_X Y)_M) \in \mathfrak{g}^*, \\ \mathbb{S} &= I(\Omega, B(w, \cdot)) + I(\Psi, B(v, \cdot)) + DI(\cdot)(\Omega, \Psi) \in T^*M, \end{aligned}$$

and $\Omega = \xi + Av$, $\Psi = \eta + Aw$, $\xi_r \equiv \frac{\partial \xi}{\partial r}$, $\eta_r \equiv \frac{\partial \eta}{\partial r}$.

Proof. As we have recalled above, the Levi–Civita connection can be characterized as the unique affine connection verifying (2.3). Let Z be a G-invariant vector field, $Z = (g\mu, u)$. The invariance of the metric implies

$$\mathcal{G}(Z, Y) = \hat{\mathcal{G}} \left((\mu, u), (\eta, w) \right) = \tilde{\mathcal{G}} \left((\Theta, u), (\Psi, w) \right),$$

where $\Theta = \mu + Aw$. The first three terms in (2.3) can be expanded in a similar way:

$$X(\mathcal{G}(Z, Y)) = X(\Theta^T I \Psi + u^T \Delta w) = v(\Theta^T I \Psi) + v(u^T \Delta w).$$

For the remaining ones, we have that

$$\begin{aligned} \mathcal{G}(X, [Z, Y]) &= \tilde{\mathcal{G}} \left((\Omega, v), ([\mu, \eta] + \eta_r u - w\mu_r + A[u, w], [u, w]) \right) \\ &= \Omega^T I[\mu, \eta] + \Omega^T I(\eta_r u - w\mu_r + A[u, w]) + v^T \Delta [u, w]. \end{aligned}$$

As a result, (2.3) can be written as $2\,\mathcal{G}(Z, \nabla^{\mathcal{G}}_X Y) = \langle(\delta, \gamma), (\mu, u)\rangle$, where $\delta = \delta_1 + \delta_2$, $\gamma = \gamma_1 + \gamma_2$, and

$$
\begin{aligned}
\delta_1 &= \xi^T I[\cdot, \eta] + \eta^T I[\cdot, \xi] - \cdot^T I[\eta, \xi],\\
\delta_2 &= \cdot^T v(I\Psi) + \cdot^T w(I\Omega) + (Av)^T I[\cdot, \eta] + (Aw)^T I[\cdot, \xi] - \cdot^T I(\xi_r w - \eta_r v + A[w, v]),\\
\gamma_1 &= v(\cdot^T \Delta w) + w(\cdot^T \Delta v) - \cdot(w^T \Delta v) + v^T \Delta[\cdot, w] + w^T \Delta[\cdot, v] - \cdot^T \Delta[w, v],\\
\gamma_2 &= v((A\cdot)^T I\Psi) + w((A\cdot)^T I\Omega) - \cdot(\Psi^T I\Omega) + \Omega^T I(\eta_r \cdot + A[\cdot, w])\\
&\quad + \Psi^T I(\xi_r \cdot + A[\cdot, v]) - (A\cdot)^T I([\eta, \xi] + \xi_r w - \eta_r v + A[w, v]).
\end{aligned}
$$

On the other hand, we have that

$$
2\,\mathcal{G}(Z, \nabla^{\mathcal{G}}_X Y) = 2\,(\mu^T, u^T) \begin{pmatrix} I & IA \\ A^T I & m \end{pmatrix} \begin{pmatrix} (\nabla^{\mathcal{G}}_X Y)_{\mathfrak{g}} \\ (\nabla^{\mathcal{G}}_X Y)_M \end{pmatrix}.
$$

As both expansions for $\mathcal{G}(Z, \nabla^{\mathcal{G}}_X Y)$ are valid for any Z, we can conclude that

$$
\begin{aligned}
2 \begin{pmatrix} (\nabla^{\mathcal{G}}_X Y)_{\mathfrak{g}} \\ (\nabla^{\mathcal{G}}_X Y)_M \end{pmatrix} &= \begin{pmatrix} I & IA \\ A^T I & m \end{pmatrix}^{-1} \begin{pmatrix} \delta \\ \gamma \end{pmatrix}\\
&= \begin{pmatrix} I^{-1} + A\Delta^{-1}A^T & -A\Delta^{-1} \\ -\Delta^{-1}A^T & \Delta^{-1} \end{pmatrix} \begin{pmatrix} \delta \\ \gamma \end{pmatrix}.
\end{aligned} \tag{3.2}
$$

Noting that $\delta_1 = 2I\nabla^I_\xi \eta$ (see Lemma 3.1) and $\gamma_1 = 2\Delta\nabla^{\Delta}_v w$, we can further develop the right-hand side of (3.2) as

$$
\begin{aligned}
&\begin{pmatrix} I^{-1} & 0 \\ 0 & \Delta^{-1} \end{pmatrix} \begin{pmatrix} \delta \\ \gamma \end{pmatrix} + \begin{pmatrix} A\Delta^{-1}A^T & -A\Delta^{-1} \\ -\Delta^{-1}A^T & 0 \end{pmatrix} \begin{pmatrix} \delta \\ \gamma \end{pmatrix}\\
&= 2 \begin{pmatrix} \nabla^I_\xi \eta \\ \nabla^{\Delta}_v w \end{pmatrix} + \begin{pmatrix} I^{-1} & 0 \\ 0 & \Delta^{-1} \end{pmatrix} \left\{ \begin{pmatrix} \delta_2 \\ \gamma_2 \end{pmatrix} + \begin{pmatrix} IA\Delta^{-1}A^T & -IA\Delta^{-1} \\ -A^T & 0 \end{pmatrix} \begin{pmatrix} \delta \\ \gamma \end{pmatrix} \right\}.
\end{aligned}
$$

In this way, we get

$$
\begin{pmatrix} (\nabla^{\mathcal{G}}_X Y)_{\mathfrak{g}} \\ (\nabla^{\mathcal{G}}_X Y)_M \end{pmatrix} = \begin{pmatrix} \nabla^I_\xi \eta \\ \nabla^{\Delta}_v w \end{pmatrix} - \frac{1}{2} \begin{pmatrix} I^{-1} & 0 \\ 0 & \Delta^{-1} \end{pmatrix} \begin{pmatrix} \mathbb{L}' \\ \mathbb{S} \end{pmatrix},
$$

where $\mathbb{L}' = -\delta_2 - IA\Delta^{-1}\mathbb{S} + IA\Delta^{-1}\gamma_1$ and $\mathbb{S} = A^T\delta - \gamma_2$. To complete the proof, we have only to identify these terms in a more geometrical manner, which we do in the following.

We begin with $\mathbb{S}$. Noting that

$$
A^b_\beta \frac{\partial v^\beta}{\partial r^\alpha} + \frac{\partial \xi^b}{\partial r^\alpha} - \frac{\partial \Omega^b}{\partial r^\alpha} = -\frac{\partial A^b_\beta}{\partial r^\alpha} v^\beta,
$$

we can rewrite γ_2 as

$$
\begin{aligned}
\gamma_2 = {} & v^\beta A^b_\alpha \frac{\partial (I\Psi)_b}{\partial r^\beta} + w^\beta A^b_\alpha \frac{\partial (I\Omega)_b}{\partial r^\beta} - \Psi^b \frac{\partial I_{ba}}{\partial r^\alpha} \Omega^a\\
& + (I\Psi)_b \left\{ \frac{\partial A^b_\alpha}{\partial r^\beta} - \frac{\partial A^b_\beta}{\partial r^\alpha} \right\} v^\beta + (I\Omega)_b \left\{ \frac{\partial A^b_\alpha}{\partial r^\beta} - \frac{\partial A^b_\beta}{\partial r^\alpha} \right\} w^\beta\\
& - A^b_\alpha I_{ba} c^a_{de} \eta^d \xi^e - A^b_\alpha I_{ba} \left\{ \frac{\partial \xi^a}{\partial r^\beta} w^\beta - \frac{\partial \eta^a}{\partial r^\beta} v^\beta + A^a_\beta [w, v]^\beta \right\}.
\end{aligned}
$$

Substituting the latter into the expression for $\mathbb{S}$, one obtains after some computations

$$\begin{aligned}-\mathbb{S} &= (I\Psi)_b \left\{ \frac{\partial A^b_\alpha}{\partial r^\beta} - \frac{\partial A^b_\beta}{\partial r^\alpha} + A^c_\beta E^b_{\alpha c} \right\} v^\beta + (I\Omega)_b \left\{ \frac{\partial A^b_\alpha}{\partial r^\beta} - \frac{\partial A^b_\beta}{\partial r^\alpha} + A^c_\beta E^b_{\alpha c} \right\} w^\beta \\ &\quad -\Psi^b \frac{\partial I_{ba}}{\partial r^\alpha}\Omega^a - \Omega^d I_{db} E^b_{\alpha e}\Psi^e - \Psi^d I_{db} E^b_{\alpha e}\Omega^e \\ &= -I(\Psi, B(v,\cdot)) - I(\Omega, B(w,\cdot)) - DI(\cdot)(\Omega,\Psi),\end{aligned}$$

where $E^b_{\alpha c} = c^b_{dc} A^d_\alpha$. Now we turn our attention to $\mathbb{L}'$. Note that

$$\begin{aligned}\mathbb{L}' &= IA\Delta^{-1}(\gamma_1 - \mathbb{S}) - \delta_2 \\ &= 2IA\left(\nabla^\Delta_v w - \frac{1}{2}\Delta^{-1}\mathbb{S}\right) - \delta_2 = 2IA(\nabla^{\mathcal{G}}_X Y)_M - \delta_2.\end{aligned}$$

Moreover, we have

$$\begin{aligned}\delta_2 = v^\alpha \frac{\partial (I\Psi)_a}{\partial r^\alpha} + w^\alpha \frac{\partial (I\Omega)_a}{\partial r^\alpha} + A^d_\alpha v^\alpha I_{db} c^b_{ae}\eta^e + A^d_\alpha w^\alpha I_{db} c^b_{ae}\xi^e \\ -I_{ba}\left\{ \frac{\partial \xi^b}{\partial r^\beta} w^\beta - \frac{\partial \eta^b}{\partial r^\beta} v^\beta + A^b_\beta [w,v]^\beta \right\}.\end{aligned}$$

Adding and subtracting $(I\Psi)_b E^b_{\alpha a} v^\alpha$ and $(I\Omega)_b E^b_{\alpha a} w^\alpha$ and regrouping, we obtain

$$\begin{aligned}\delta_2 = D(I\Psi)(\cdot, v) + D(I\Omega)(\cdot, w) + 2I\nabla^I_\Omega \Psi - 2I\nabla^I_\xi \eta \\ -I(\cdot, [\Omega,\Psi]) + I(\cdot, [\xi,\eta]) - I(\cdot, \xi_r w - \eta_r v + A[w,v]).\end{aligned}$$

Finally, we can write

$$(\nabla^{\mathcal{G}}_X Y)_{\mathfrak{g}} = \nabla^I_\xi \eta - \frac{1}{2} I^{-1}\mathbb{L}' = \nabla^I_\Omega \Psi - \frac{1}{2} I^{-1}\mathbb{L},$$

where $\mathbb{L}$ is as above. □

As a consequence of this proposition, we have the following interesting result.

COROLLARY 3.3. *The symmetric product associated to the Levi–Civita connection $\nabla^{\mathcal{G}}$ of two G-invariant vector fields, $X = (g\xi, v)$ and $Y = (g\eta, w)$, is given by*

$$\langle X : Y\rangle_{\mathcal{G}} = g\left\{ \begin{pmatrix} \langle \Omega : \Psi\rangle_I \\ \langle v : w\rangle_\Delta \end{pmatrix} - \begin{pmatrix} I^{-1}\mathbb{L}^s \\ \Delta^{-1}\mathbb{S} \end{pmatrix} \right\}, \tag{3.3}$$

where

$$\begin{aligned}\mathbb{L}^s &= -D(I\Omega)(\cdot, w) - D(I\Psi)(\cdot, v) + IA\left(\langle v : w\rangle_\Delta - \Delta^{-1}\mathbb{S}\right) \in \mathfrak{g}^*, \\ \mathbb{S} &= I(\Omega, B(w,\cdot)) + I(\Psi, B(v,\cdot)) + DI(\cdot)(\Omega,\Psi) \in T^*M,\end{aligned}$$

and $\langle\cdot:\cdot\rangle_I$, $\langle\cdot:\cdot\rangle_\Delta$ denote the symmetric products defined by the Levi–Civita connections ∇^I and ∇^Δ, respectively.

We shall return to these results in section 6 in computing the symmetric product in specific examples.

4. Decomposition of the nonholonomic affine connection under symmetry. Let $(Q, \mathcal{G}, V, \mathcal{F}, \mathcal{D})$ be a constrained mechanical control system invariant under the action of a Lie group G. As expected, the invariance of the Levi–Civita connection and the nonholonomic distribution $\mathcal{D}$ can be combined to find a decomposition of the nonholonomic affine connection similar to that of Proposition 3.2.

First, notice that if $\mathcal{D}$ is generated by a basis of G-invariant vector fields X_i, $1 \leq i \leq n-l$, the projector $\mathcal{P} : TQ \longrightarrow \mathcal{D}$ with respect to the orthogonal decomposition $TQ = \mathcal{D} \oplus \mathcal{D}^\perp$ is given by

$$\mathcal{P}(Z) = \sum_{i,j} C^{ij} \mathcal{G}(X_i, Z) X_j, \quad Z \in \mathfrak{X}(Q),$$

where (C^{ij}) is the inverse matrix of $(C_{ij} = \mathcal{G}(X_i, X_j))$. A geometrically revealing choice of generators of $\mathcal{D}$ making use of the exposition in section 2.3 is the following. Recall that the nonholonomic principal connection A^{nh} induces a decomposition of the tangent bundle, $TQ = \mathcal{H} \oplus \mathcal{V}$. This, in particular, implies that

$$\mathcal{D} = \mathcal{H} \oplus S.$$

On the one hand, we know that $S_{(r,e)} = \operatorname{span}\{e_1(r)_Q, \ldots, e_s(r)_Q\}$. Furthermore, the generators of $\mathcal{H}_{(r,e)}$ are of the form $(-\mathbb{A}\dot{r}, \dot{r})$, where $\mathbb{A}$ denotes the local form of A^{nh}. Hence we have that

$$\mathcal{D}_{(r,g)} = g\mathcal{D}_{(r,e)} = g \operatorname{span}\left\{(-\mathbb{A}\dot{r}, \dot{r}), (e_i, 0)\right\}.$$

For these vector fields, we compute

$$\begin{aligned}
\mathcal{G}\left(g\left(e_i, 0\right), g\left(e_j, 0\right)\right) &= e_i^T I e_j = e_i^T \tilde{I} e_j, \\
\mathcal{G}\left(g\left(-\mathbb{A}(\dot{r}), \dot{r}\right), g\left(e_j, 0\right)\right) &= -(\mathbb{A}\dot{r})^T I e_j + (A\dot{r})^T I e_j = (\tilde{A}\dot{r})^T I e_j = 0, \\
\mathcal{G}\left(g\left(-\mathbb{A}(\dot{r}), \dot{r}\right), g\left(-\mathbb{A}(\dot{r}), \dot{r}\right)\right) &= (\mathbb{A}\dot{r})^T I \mathbb{A}\dot{r} - (\mathbb{A}\dot{r})^T I A\dot{r} - (A\dot{r})^T I \mathbb{A}\dot{r} + \dot{r}^T m \dot{r} \\
&= \dot{r}^T (m + \mathbb{A}^T I \mathbb{A} - \mathbb{A}^T I A - A^T I \mathbb{A}) \dot{r} = \dot{r}^T \tilde{\Delta} \dot{r},
\end{aligned}$$

where $\tilde{A} = A - \mathbb{A}$, $\tilde{\Delta} = m - A^T I A + \tilde{A}^T I \tilde{A}$, and we have used the fact that $\tilde{A}\dot{r} \in S^\perp$. Hence we can write the matrix C as

$$C = \begin{pmatrix} \tilde{I} & 0 \\ 0 & \tilde{\Delta} \end{pmatrix}.$$

Now we are in a position to prove the following result.

PROPOSITION 4.1. *Given G-invariant vector fields, $X = (g\xi, v) \in TQ$, $Y = (g\eta, w) \in \mathcal{D}$ on Q, with $\xi(r)$, $\eta(r) \in \mathfrak{g}$ and v, $w \in TM$, the nonholonomic affine connection $\overline{\nabla}$ can be expressed as*

$$\overline{\nabla}_X Y = g\left\{ \begin{pmatrix} A^{sym}(\nabla^I_{\bar{\Omega}} \bar{\Psi}) \\ \nabla^{\tilde{\Delta}}_v w \end{pmatrix} - \frac{1}{2} \begin{pmatrix} \tilde{I}^{-1} \tilde{\mathbb{L}} + 2\mathbb{A}(\overline{\nabla}_X Y)_M \\ \tilde{\Delta}^{-1} \tilde{\mathbb{S}} \end{pmatrix} \right\}, \tag{4.1}$$

where

$$\begin{aligned}
\tilde{\mathbb{L}} &= -\mathbb{D}(I\bar{\Omega})(\cdot, w) - \mathbb{D}(I\bar{\Psi})(\cdot, v) + I(\tilde{A}v, \gamma.w - [\cdot, \eta]) + I(\tilde{A}w, \gamma.v - [\cdot, \xi]) \\
&\quad + I([\bar{\Omega}, \bar{\Psi}] - [\xi, \eta] + \xi_r w - \eta_r v - \mathbb{A}[v, w]) \in \mathfrak{g}^{\mathcal{D}^*}, \\
\tilde{\mathbb{S}} &= I(\bar{\Psi}, B(v, \cdot)) + I(\bar{\Omega}, B(w, \cdot)) + I(\tilde{A}w, \mathbb{B}(v, \cdot)) + I(\tilde{A}v, \mathbb{B}(w, \cdot)) \\
&\quad - D(I\bar{\Psi})(\tilde{A}\cdot, v) - D(I\bar{\Omega})(\tilde{A}\cdot, w) + \mathbb{D}I(\cdot)(\bar{\Omega} + \tilde{A}v, \bar{\Psi} + \tilde{A}w) - \mathbb{D}I(\cdot)(\tilde{A}v, \tilde{A}w) \\
&\quad - I([\xi, \eta], \tilde{A}\cdot) - I(\eta_r v - \xi_r v, \tilde{A}\cdot) - I(\mathbb{A}[v, w], \tilde{A}\cdot) \in T^*M,
\end{aligned}$$

and $\mathbb{D}$, $\mathbb{B}$ *denote, respectively, the local forms of the derivative along and the curvature of the nonholonomic connection* A^{nh} *and* $\bar{\Omega} = \xi + \mathbb{A}v$, $\bar{\Psi} = \eta + \mathbb{A}w$.

Proof. Since $Y \in \mathcal{D}$, $\overline{\nabla}_X Y = \mathcal{P}(\nabla^{\mathcal{G}}_X Y) = \sum C^{ij}\mathcal{G}(X_i, \nabla^{\mathcal{G}}_X Y)X_j$. We first compute

$$\mathcal{G}\left(g\left(e_i, 0\right), \nabla^{\mathcal{G}}_X Y\right) = e_i^T I\left\{(\nabla^{\mathcal{G}}_X Y)_{\mathfrak{g}} + A(\nabla^{\mathcal{G}}_X Y)_M\right\}, \tag{4.2}$$

$$\begin{aligned}\mathcal{G}\left(g\left(-\mathbb{A}\dot{r}, \dot{r}\right), \nabla^{\mathcal{G}}_X Y\right) &= (\tilde{A}\dot{r})^T I(\nabla^{\mathcal{G}}_X Y)_{\mathfrak{g}} + \dot{r}^T(m - A^T I\mathbb{A})(\nabla^{\mathcal{G}}_X Y)_M \\ &= (\tilde{A}\dot{r})^T I\left\{(\nabla^{\mathcal{G}}_X Y)_{\mathfrak{g}} + A(\nabla^{\mathcal{G}}_X Y)_M\right\} + \dot{r}^T\Delta(\nabla^{\mathcal{G}}_X Y)_M.\end{aligned} \tag{4.3}$$

Let us denote $(\nabla^{\mathcal{G}}_X Y)_{\mathfrak{g}} + A(\nabla^{\mathcal{G}}_X Y)_M = \widetilde{\nabla^{\mathcal{G}}_X Y}$ for brevity. In terms of $\bar{\Omega}$, $\bar{\Psi}$ and using Proposition 3.2, it can be expanded as

$$\begin{aligned}\widetilde{\nabla^{\mathcal{G}}_X Y} = \nabla^I_{\bar{\Omega}}\bar{\Psi} - \frac{1}{2}I^{-1}\Big\{ &- \mathbb{D}(I\bar{\Omega})(\cdot, w) - \mathbb{D}(I\tilde{A}v)(\cdot, w) - \mathbb{D}(I\bar{\Psi})(\cdot, v) \\ &- \mathbb{D}(I\tilde{A}w)(\cdot, v) - I(\tilde{A}w, [\cdot, \bar{\Omega}]) - I(\tilde{A}v, [\cdot, \bar{\Psi}]) \\ &+ I([\bar{\Omega}, \bar{\Psi}] - [\xi, \eta] + \xi_r w - \eta_r v - A[v, w], \cdot)\Big\}.\end{aligned}$$

Before plugging this expression into (4.2), notice that

$$-\mathbb{D}(I\tilde{A}v)(e_i, w) - I(\tilde{A}v, [e_i, \bar{\Psi}]) = I(\tilde{A}v, \gamma_i w - [e_i, \eta]),$$

where we have used the facts that $e_i \in S$ and $\tilde{A}v \in S^{\perp}$. After substituting, we find that (4.2) can be expressed as $\mathcal{G}\left(g\left(e_i, 0\right), \nabla^{\mathcal{G}}_X Y\right) = \langle I(\nabla^I_{\bar{\Omega}}\bar{\Psi}, \cdot) - \frac{1}{2}\tilde{\mathbb{L}}, e_i\rangle$, where

$$\begin{aligned}\tilde{\mathbb{L}} = &-\mathbb{D}(I\bar{\Omega})(\cdot, w) - \mathbb{D}(I\bar{\Psi})(\cdot, v) + I(\tilde{A}v, \gamma.w - [\cdot, \eta]) + I(\tilde{A}w, \gamma.v - [\cdot, \xi]) \\ &+ I([\bar{\Omega}, \bar{\Psi}] - [\xi, \eta], \cdot) - I(\eta_r v - \xi_r w + \mathbb{A}[v, w], \cdot).\end{aligned}$$

On the other hand, it is easy to see that

$$\begin{aligned}\Delta(\nabla^{\mathcal{G}}_X Y)_M &= \Delta\nabla^{\Delta}_v w - \frac{1}{2}\mathbb{S} \\ &= \tilde{\Delta}\nabla^{\tilde{\Delta}}_v w - D\nabla^D_v w - \frac{1}{2}\mathbb{S} = \tilde{\Delta}\nabla^{\tilde{\Delta}}_v w - \left(D\nabla^D_v w + \frac{1}{2}\mathbb{S}\right),\end{aligned}$$

where $D = \tilde{A}^T I\tilde{A}$ and $D\nabla^D_v w$ is a shorthand notation to denote the expression (2.3) for the symmetric tensor D. Then we can rewrite (4.3) as

$$\dot{r}^T\left(\tilde{\Delta}\nabla^{\tilde{\Delta}}_v w - \left(D\nabla^D_v w + \frac{1}{2}\mathbb{S} - \tilde{A}^T I\widetilde{\nabla^{\mathcal{G}}_X Y}\right)\right).$$

Therefore, $\overline{\nabla}_X Y$ becomes

$$\overline{\nabla}_X Y = \mathcal{P}(\nabla^{\mathcal{G}}_X Y) = \begin{pmatrix} g(\overline{\nabla}_X Y)_{\mathfrak{g}} \\ (\overline{\nabla}_X Y)_M \end{pmatrix},$$

with

$$\begin{aligned}(\overline{\nabla}_X Y)_{\mathfrak{g}} &= \tilde{I}^{-1}\left\{I(\nabla^I_{\bar{\Omega}}\bar{\Psi}, \cdot) - \frac{1}{2}\tilde{\mathbb{L}}\right\} - \mathbb{A}(\overline{\nabla}_X Y)_M \\ &= A^{sym}(\nabla^I_{\bar{\Omega}}\bar{\Psi}) - \frac{1}{2}\tilde{I}^{-1}\tilde{\mathbb{L}} - \mathbb{A}(\overline{\nabla}_X Y)_M, \\ (\overline{\nabla}_X Y)_M &= \nabla^{\tilde{\Delta}}_v w - \tilde{\Delta}^{-1}\left(D\nabla^D_v w + \frac{1}{2}\mathbb{S} - \tilde{A}^T I\widetilde{\nabla^{\mathcal{G}}_X Y}\right),\end{aligned}$$

where we have used the fact that $A^{sym}(\zeta) \equiv A^{sym}(\zeta_Q(e,r)) = \tilde{I}^{-1} I(\zeta)$ for $\zeta \in \mathfrak{g}$. To end the proof, let us write explicitly the terms in $(\overline{\nabla}_X Y)_M$. Adding and subtracting terms in the expression for $2\, D\nabla^D_v w$, we can find that

$$\begin{aligned}
2\, D\nabla^D_v w &= v^\beta \frac{\partial \tilde{A}^a_\alpha}{\partial r^\beta} I_{ab} \tilde{A}^b_\gamma w^\gamma + D(I\tilde{A}w)(\tilde{A}\cdot, v) - I(\tilde{A}v, [Aw, \tilde{A}\cdot]) \\
&\quad + w^\beta \frac{\partial \tilde{A}^a_\alpha}{\partial r^\beta} I_{ab} \tilde{A}^b_\gamma v^\gamma + D(I\tilde{A}v)(\tilde{A}\cdot, w) - I(\tilde{A}w, [Av, \tilde{A}\cdot]) \\
&\quad - w^\beta v^\gamma \frac{\partial \tilde{A}^a_\beta I_{ab} \tilde{A}^b_\gamma}{\partial r^\alpha} + \tilde{A}^T I \tilde{A}[v, w] \\
&= D(I\tilde{A}w)(\tilde{A}\cdot, v) + D(I\tilde{A}v)(\tilde{A}\cdot, w) + I(\tilde{A}w)B(\cdot, v) + I(\tilde{A}w)\mathbb{B}(v, \cdot) \\
&\quad + I(\tilde{A}v)B(\cdot, w) + I(\tilde{A}v)\mathbb{B}(w, \cdot) - \mathbb{D}I(\tilde{A}v, \tilde{A}w) + \tilde{A}^T I \tilde{A}[v, w].
\end{aligned}$$

On the other hand,

$$\begin{aligned}
\mathbb{S} &= I(\Omega, B(w, \cdot)) + I(\Psi, B(v, \cdot)) + DI(\cdot)(\Omega, \Psi) \\
&= I(\Omega, B(w, \cdot)) + I(\Psi, B(v, \cdot)) + \mathbb{D}I(\cdot)(\Omega, \Psi) + I(\Omega, [\tilde{A}\cdot, \Psi]) + I(\Psi, [\tilde{A}\cdot, \Omega]),
\end{aligned}$$

and the term $\tilde{A}^T I \widetilde{\nabla^{\mathcal{G}}_X Y}$ can be written as

$$\begin{aligned}
-\tilde{A}^T I \widetilde{\nabla^{\mathcal{G}}_X Y} = &- \tilde{A}^T I \nabla^I_\Omega \Psi + \frac{1}{2}(-D(I\Psi)(\tilde{A}\cdot, v) - D(I\Omega)(\tilde{A}\cdot, w) \\
&+ I([\Omega, \Psi] - [\xi, \eta], \tilde{A}\cdot) - I(\eta_r v - \xi_r v, \tilde{A}\cdot) - \tilde{A}^T I A[v, w]).
\end{aligned}$$

Summing up these terms, we get the expression for $\tilde{\mathbb{S}}$ stated in the proposition. □

COROLLARY 4.2. *The symmetric product associated to $\overline{\nabla}$ of two G-invariant vector fields, $X = (g\xi, v) \in \mathcal{D}$ and $Y = (g\eta, w) \in \mathcal{D}$, is given by*

(4.4)
$$\langle X : Y \rangle = g \left\{ \begin{pmatrix} A^{sym}(\langle \bar{\Omega} : \bar{\Psi} \rangle_I) \\ \langle v : w \rangle_{\tilde{\Delta}} \end{pmatrix} - \begin{pmatrix} \tilde{I}^{-1} \tilde{\mathbb{L}}^s + \mathbb{A}\left(\langle v : w \rangle_{\tilde{\Delta}} - \tilde{\Delta}^{-1} \tilde{\mathbb{S}}^s \right) \\ \tilde{\Delta}^{-1} \tilde{\mathbb{S}}^s \end{pmatrix} \right\},$$

where

$$\begin{aligned}
\tilde{\mathbb{L}}^s &= -\mathbb{D}(I\bar{\Omega})(\cdot, w) - \mathbb{D}(I\bar{\Psi})(\cdot, v) + I(\tilde{A}v, \gamma.w - [\cdot, \eta]) + I(\tilde{A}w, \gamma.v - [\cdot, \xi]) \in \mathfrak{g}^{\mathcal{D}^*}, \\
\tilde{\mathbb{S}}^s &= I(\bar{\Psi}, B(v, \cdot)) + I(\bar{\Omega}, B(w, \cdot)) + I(\tilde{A}w, \mathbb{B}(v, \cdot)) + I(\tilde{A}v, \mathbb{B}(w, \cdot)) - D(I\bar{\Psi})(\tilde{A}\cdot, v) \\
&\quad -D(I\bar{\Omega})(\tilde{A}\cdot, w) + \mathbb{D}I(\cdot)(\bar{\Omega} + \tilde{A}v, \bar{\Psi} + \tilde{A}w) - \mathbb{D}I(\cdot)(\tilde{A}v, \tilde{A}w) \in T^*M,
\end{aligned}$$

and $\langle \cdot : \cdot \rangle_{\tilde{\Delta}}$ denotes the symmetric product defined by the Levi–Civita connection $\nabla^{\tilde{\Delta}}$.

5. Controllability analysis. The point in the approach of Lewis and Murray to simple mechanical control systems is precisely to know what is happening to configurations, rather than to states, since, in many of these systems, configurations may be controlled but not configurations and velocities at the same time. The basic question they pose is "what is the set of configurations that are attainable from a given configuration starting from rest?"

Consider the control equation

$$\nabla_{\dot{c}(t)} \dot{c}(t) = \sum_{i=1}^m u_i(t) Y_i(c(t)), \tag{5.1}$$

where the affine connection ∇ can be either the Levi–Civita affine connection associated to a kinetic energy metric or the nonholonomic affine connection for a constrained system. (Recall that, in the latter case, we select $\dot{c}(0) \in \mathcal{D}$ and Y_i denotes the projection by $\mathcal{P}$ to $\mathcal{D}$ of the ith input vector field.) Notice that we are considering now that $V \equiv 0$. The absence of the potential makes the picture considerably more clear while capturing the essential aspects of the analysis. On the other hand, a potential function could be incorporated to the controllability tests along the lines of [21].

Take $q_0 \in Q$, and let $U \subset Q$ be a neighborhood of q_0. Define

$$\mathcal{R}_Q^U(q_0, T) = \{q \in Q \,|\, \text{there exists a solution } (c, u) \text{ of (5.1) such that } \dot{c}(0) = 0_{q_0}, c(t) \in U \text{ for } t \in [0, T], \text{ and } \dot{c}(T) \in T_q Q\},$$

and denote $\mathcal{R}_Q^U(q_0, \leq T) = \cup_{0 \leq t \leq T} \mathcal{R}_Q^U(q_0, t)$.

We shall focus our attention on the following notions of accessibility and controllability [21].

DEFINITION 5.1. *The system* (5.1) *is* locally configuration accessible (LCA) at $q_0 \in Q$ *if there exists* $T > 0$ *such that* $\mathcal{R}_Q^U(q_0, \leq t)$ *contains a nonempty open set of* Q *for all neighborhoods* U *of* q_0 *and all* $0 \leq t \leq T$. *If this holds for any* $q_0 \in Q$, *then the system is called* LCA.

DEFINITION 5.2. *The system* (5.1) *is* small-time locally configuration controllable (STLCC) at $q_0 \in Q$ *if there exists* $T > 0$ *such that* $\mathcal{R}_Q^U(q_0, \leq t)$ *contains a nonempty open set of* Q *to which* q_0 *belongs for all neighborhoods* U *of* q_0 *and all* $0 \leq t \leq T$. *If this holds for any* $q_0 \in Q$, *then the system is called* STLCC.

Given the input vector fields $\mathcal{Y} = \{Y_1, \ldots, Y_m\}$, let us denote by $\overline{Sym}(\mathcal{Y})$ the distribution obtained by closing the set $\mathcal{Y}$ under the symmetric product and by $\overline{Lie}(\mathcal{Y})$ the involutive closure of $\mathcal{Y}$. With these ingredients, one can prove the following theorem.

THEOREM 5.3 (see [21]). *The control system* (5.1) *is LCA at* q *if* $\overline{Lie}(\overline{Sym}(\mathcal{Y}))_q = T_q Q$.

If P is a symmetric product of vector fields in $\mathcal{Y}$, we let $\gamma_i(P)$ denote the number of occurrences of Y_i in P. The *degree* of P will be $\gamma_1(P) + \cdots + \gamma_m(P)$. We say that P is *bad* if $\gamma_i(P)$ is even for each $1 \leq i \leq m$. Otherwise, we say that P is *good*. The following theorem gives sufficient conditions for STLCC.

THEOREM 5.4. *Suppose that the system* (5.1) *is LCA at* q *and that every bad symmetric product* P *at* q *in* $\mathcal{Y}$ *can be written as a linear combination of good symmetric products at* q *of lower degree than* P. *Then it is STLCC at* q.

Remark 5.1. This theorem was proved in [21] as an application to mechanical systems of previous work by Sussmann [32] on general control systems with drift. There has been some effort in trying to obtain sufficient *and* necessary conditions for configuration controllability. A conjecture that remains open is that the system (5.1) is STLCC at q if and only if there exists a basis of vector fields generating the input distribution which satisfies the sufficient conditions of the theorem. Lewis [18] proved the validity of the conjecture for the one-input case. Recently, Cortés and Martínez [11] have proved that it is also valid for underactuated systems by one control.

The exposed controllability analysis can be further refined for mechanical control systems with symmetry, taking into account the results of the previous sections. Assume that the control system (5.1) is invariant under the action of a Lie group G. Let us denote by $\mathfrak{B} = \{B_1, \ldots, B_m\}$ the representatives of the input vector fields

$\mathcal{Y} = \{Y_1, \ldots, Y_m\}$ at $\mathfrak{g} \times TM$, that is,

$$Y_i(r,g) = gB_i(r,e) = g \begin{pmatrix} \xi_i(r) \\ v_i \end{pmatrix}, \quad 1 \leq i \leq m.$$

Due to the invariance of the system, we have that $\langle Y_i : Y_j \rangle = \langle gB_i : gB_j \rangle \equiv g\langle B_i : B_j \rangle$ for all $1 \leq i, j \leq m$. The explicit expression in bundle coordinates for this symmetric product is given by Corollaries 3.3 and 4.2. Note also that the Lie brackets $[Y_i, Y_j]$ can be written as

$$[Y_i, Y_j] \equiv g[B_i, B_j] = g \begin{pmatrix} [\xi_i, \xi_j]_{\mathfrak{g}} + \frac{\partial \xi_j}{\partial r} v_i - \frac{\partial \xi_i}{\partial r} v_j \\ [v_i, v_j]_M \end{pmatrix}.$$

As a result, we have the following version of the former results.

THEOREM 5.5. *Let the control system* (5.1) *be invariant under the action of a Lie group G.*

(i) *The system is LCA at $q = (r,g) \in Orb_G(r,e)$ if $\overline{Lie}(\overline{Sym}(\mathfrak{B}))_{(r,e)} = \mathfrak{g} \times T_r M$.*

(ii) *Suppose that the system is LCA at (r,e) and that every bad symmetric product P at (r,e) in $\mathfrak{B}$ can be written as a linear combination of good symmetric products at (r,e) of lower degree than P. Then* (5.1) *is STLCC at $q \in Orb_G(r,e)$.*

These simplified tests of the accessibility and controllability properties of mechanical control systems under symmetry are indeed quite useful in practical examples, since they remove completely the dependence on the Lie group elements $g \in G$ from the computations. In examples such as the blimp, the underwater vehicle, the snakeboard, and the roller racer, where symmetry plays an important role, this property may be a definitive advantage.

An additional important simplification from the computational point of view stems from the fact that, for many dynamic robotic locomotion systems, the set of inputs consists of the full tangent bundle of the shape space M. This essentially corresponds to the observation that the system can adjust its shape as desired. For such problems, we can state the following result.

THEOREM 5.6. *Let the control system* (5.1) *be invariant under the action of a Lie group G. Additionally assume that the system is fully actuated in the shape space; i.e., the set of input forces consists of $F^1 = dr^1, \ldots, F^m = dr^m$, where m now also denotes the dimension of M. Then the locked body angular velocities of the input vector fields all vanish: $\Omega_i = 0$, $1 \leq i \leq m$. Moreover, in the presence of nonholonomic constraints, the projections of the input vector fields to $\mathcal{D}$ also have $\bar{\Omega}_i = 0$, $1 \leq i \leq m$.*

Proof. It is not difficult to verify that the input vector fields are of the form $\left(-gA\Delta^{-1}\dot{r}, \Delta^{-1}\dot{r}\right)$. Then $\Omega_i = 0$ follows. On the other hand, their projections to the constraint distribution $\mathcal{D}$ can be written as $(-g\mathbb{A}\tilde{\Delta}^{-1}\dot{r}, \tilde{\Delta}^{-1}\dot{r})$, which implies that $\bar{\Omega}_i = 0$. ∎

As a consequence of Theorem 5.6, the necessary calculations in the controllability analysis of the successive symmetric products involving the input vector fields (cf. Corollary 3.3) or their projections to $\mathcal{D}$ (cf. Corollary 4.2) are further simplified. In fact, for two vector fields $X = (g\xi, v)$ and $Y = g(\eta, w)$ having vanishing associated locked body angular velocities $\Omega = 0$, $\Psi = 0$, we have by Corollary 3.3 that

$$\langle X : Y \rangle_{\mathcal{G}} = g \begin{pmatrix} -A \langle v : w \rangle_{\Delta} \\ \langle v : w \rangle_{\Delta} \end{pmatrix},$$

which also has vanishing locked body angular velocity. On the other hand, for two vector fields $X = (g\xi, v) \in \mathcal{D}$ and $Y = g(\eta, w) \in \mathcal{D}$ having $\bar{\Omega} = 0$, $\bar{\Psi} = 0$, respectively, we have by Corollary 4.2 that

$$\langle X : Y \rangle = g \begin{pmatrix} -\tilde{I}^{-1}\tilde{\mathbb{L}}^{s} - \mathbb{A}\left(\langle v : w \rangle_{\tilde{\Delta}} - \tilde{\Delta}^{-1}\tilde{\mathbb{S}}^{s}\right) \\ \langle v : w \rangle_{\tilde{\Delta}} - \tilde{\Delta}^{-1}\tilde{\mathbb{S}}^{s} \end{pmatrix},$$

with $\tilde{\mathbb{L}}^{s} = I(\tilde{A}v, \gamma.w - [\cdot, \eta]) + I(\tilde{A}w, \gamma.v - [\cdot, \xi])$ and $\tilde{\mathbb{S}}^{s} = I(\tilde{A}w, \mathbb{B}(v, \cdot)) + I(\tilde{A}v, \mathbb{B}(w, \cdot))$.

Notice also that the tests we have obtained here for principal fiber bundles are the natural extension of the results developed in [7] for mechanical control systems on Lie groups. The major difference is that, on Lie groups, G-invariance implies that the tests are expressed in $\mathfrak{g}$ in a *purely algebraic* way, whereas, on principal fiber bundles, we have to take into account the role of the shape space M, and, therefore, *differentiation* is still required.

Another interesting aspect of this kind of mechanical control system is the adaptation of the concept of *weak controllability* for kinematic systems defined in [15]. This notion essentially means controllability in the fiber, without regard to the intermediate or final positions of the shape variables. This type of controllability is meaningful for locomotion systems, where the group elements correspond to positions and orientation (and therefore are the most interesting variables to control), and one really does not care about the shapes the system is describing. In the following, we discuss it for the second-order dynamical problems we are considering.

Assume then that we are dealing with a *trivial* principal fiber bundle; that is, the decomposition $Q = G \times M$ holds globally. Let V^{τ} denote any subset of Q such that $\tau(V^{\tau})$ is an open subset of G, where $\tau : Q \equiv G \times M \longrightarrow G$ denotes the natural projection. Let $q_0 = (r_0, g_0)$ and $U \subset Q$ as before. Then we have the following definitions.

DEFINITION 5.7. *The system* (5.1) *is* locally fiber configuration accessible (LFCA) at $q_0 \in Q$ *if there exists* $T > 0$ *such that* $\mathcal{R}_Q^U(q_0, \leq t)$ *contains a nonempty subset* V^{τ} *of* Q *for all neighborhoods* U *of* q_0 *and all* $0 \leq t \leq T$. *If this holds for any* $q_0 \in Q$, *then the system is called* LFCA.

DEFINITION 5.8. *The system* (5.1) *is* small-time locally fiber configuration controllable (STLFCC) at $q_0 \in Q$ *if there exists* $T > 0$ *such that* $\mathcal{R}_Q^U(q_0, \leq t)$ *contains a nonempty subset* V^{τ} *of* Q *such that* $g_0 \in \tau(V^{\tau})$ *for all neighborhoods* U *of* q_0 *and all* $0 \leq t \leq T$. *If this holds for any* $q_0 \in Q$, *then the system is called* STLFCC.

From the discussion above, one can prove the following theorem.

THEOREM 5.9. *Let the mechanical control system* (5.1) *be invariant under* G.

(i) *The system is LFCA at* $q = (r, g)$ *if* $\tau_* \overline{Lie}(\overline{Sym}(\mathfrak{B}))_{(r,e)} = \mathfrak{g}$.

(ii) *Suppose that the system is LFCA at* q *and that the projection through* τ *of every bad symmetric product* P *at* q *in* $\mathfrak{B}$, $\tau_* P$, *can be written as a linear combination of projections through* τ *of good symmetric products at* q *of lower degree than* P. *Then* (5.1) *is STLFCC at* q.

Proof. Along the zero section of TQ, $q \longmapsto 0_q$, we have that the decomposition $T_{0_q}TQ \equiv T_qQ \oplus T_qQ$ holds, where the first factor corresponds to configurations and the second one to velocities. Then, from [21], we know that the accessibility distribution $\mathcal{C}$ corresponding to the full control system (that is, considering as states both the configurations and the velocities) can be decomposed as $\mathcal{C}_{0_q} = \mathcal{C}_{hor}(q) \oplus \mathcal{C}_{ver}(q)$, with $\mathcal{C}_{hor}(q) = \overline{Lie}(\overline{Sym}(\mathcal{Y}))_q$ and $\mathcal{C}_{ver}(q) = \overline{Sym}(\mathcal{Y})_q$. If $\tau_* \overline{Lie}(\overline{Sym}(\mathfrak{B}))_{(r,e)} = \mathfrak{g}$, we can conclude that $T_gG \subset \mathcal{C}_{hor}(q)$, and hence the system (5.1) is LFCA at q. The other claim follows from the invariance of the system and Sussmann's result in [32]. □

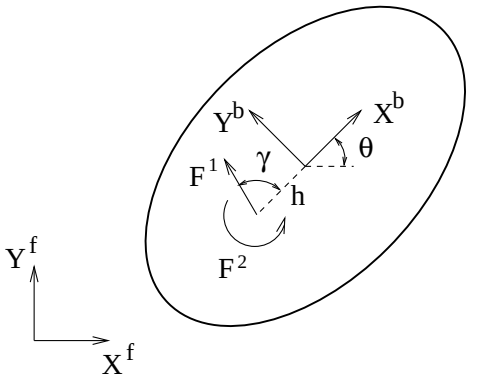

FIG. 6.1. *A planar blimp with rotating thruster.*

6. Examples.

6.1. The blimp. Consider a rigid body moving in $SE(2)$ with a thruster to adjust its pose (see Figure 6.1). The original motivation for this problem is the blimp system developed by Zhang and Ostrowski [35] restricted to the vertical plane. The control inputs are the thruster force F^1 and a torque F^2 that actuates its orientation with respect to the body axis $\{X^b, Y^b\}$. The acting point of the thruster is assumed to be located along the body's long axis, at a distance h from the center of mass.

The configuration of the blimp is determined by a tuple (x, y, θ, γ), where (x, y) is the position of the center of mass, θ is the orientation of the blimp with respect to the fixed basis $\{X^f, Y^f\}$, and γ denotes the orientation of the thrust with respect to the body basis $\{X^b, Y^b\}$. The configuration manifold is then $Q = SE(2) \times \mathbb{S}^1$.

For simplicity, we assume the thruster is massless. Then the Riemannian metric of the system is

$$\mathcal{G} = m(dx \otimes dx + dy \otimes dy) + (J_1 + J_2)d\theta \otimes d\theta + J_2 d\gamma \otimes d\gamma + J_2(d\theta \otimes d\gamma + d\gamma \otimes d\theta),$$

where m denotes the mass of the blimp, J_1 is its moment of inertia, and J_2 is the inertia of the thruster. The Lagrangian of the system is the kinetic energy associated to this metric; that is,

$$L = \frac{1}{2}m(\dot{x}^2 + \dot{y}^2) + \frac{1}{2}J_1\dot{\theta}^2 + \frac{1}{2}J_2(\dot{\gamma} + \dot{\theta})^2.$$

Finally, the input forces are given by

$$F^1 = \cos(\theta + \gamma)dx + \sin(\theta + \gamma)dy - h\sin\gamma d\theta, \quad F^2 = d\gamma.$$

The corresponding input vector fields can be computed to be

$$Y_1 = \frac{1}{m}\cos(\theta + \gamma)\frac{\partial}{\partial x} + \frac{1}{m}\sin(\theta + \gamma)\frac{\partial}{\partial y} - \frac{h}{J_1}\sin\gamma\frac{\partial}{\partial \theta} + \frac{h}{J_1}\sin\gamma\frac{\partial}{\partial \gamma},$$
$$Y_2 = -\frac{1}{J_1}\frac{\partial}{\partial \theta} + \frac{J_1 + J_2}{J_1 J_2}\frac{\partial}{\partial \gamma}.$$

This simple mechanical control system is invariant under the left multiplication of the Lie group $G = SE(2)$,

$$\begin{array}{rcl} \Phi : \quad G \times Q & \longrightarrow & Q \\ ((a, b, \alpha), (x, y, \theta, \gamma)) & \longmapsto & (x\cos\alpha - y\sin\alpha + a, x\sin\alpha + y\cos\alpha + b, \theta + \alpha, \gamma)\,. \end{array}$$

The reduced representation of the input vector fields at $\mathfrak{g} \times TM$ is given by

$$B_1 = \frac{1}{m}\cos\gamma\frac{\partial}{\partial x} + \frac{1}{m}\sin\gamma\frac{\partial}{\partial y} - \frac{h}{J_1}\sin\gamma\frac{\partial}{\partial\theta} + \frac{h}{J_1}\sin\gamma\frac{\partial}{\partial\gamma},$$
$$B_2 = -\frac{1}{J_1}\frac{\partial}{\partial\theta} + \frac{J_1+J_2}{J_1J_2}\frac{\partial}{\partial\gamma}.$$

Let $\{e_x, e_y, e_\theta\}$ be the canonical basis of the Lie algebra $se(2)$. Given the metric $\mathcal{G}$, we can readily identify from its reduced form (2.8) the local form of the mechanical connection and the inertia tensor

$$I = \begin{pmatrix} m & 0 & 0 \\ 0 & m & 0 \\ 0 & 0 & J_1+J_2 \end{pmatrix}, \quad A = \begin{pmatrix} 0 \\ 0 \\ \frac{J_2}{J_1+J_2} \end{pmatrix}.$$

As the shape space is one-dimensional and B^{mech} is skew-symmetric, we deduce that $B^{mech} = 0$. Some computations yields that DI also vanishes. Consequently, $\mathbb{S} = 0$. In addition,

$$D(I\eta)(\xi, v) = \left\{ \begin{pmatrix} m\frac{\partial\eta^1}{\partial\gamma} \\ m\frac{\partial\eta^2}{\partial\gamma} \\ (J_1+J_2)\frac{\partial\eta^3}{\partial\gamma} \end{pmatrix}^T + \frac{mJ_2}{J_1+J_2}\begin{pmatrix} \eta^2 \\ -\eta^1 \\ 0 \end{pmatrix}^T \right\} \begin{pmatrix} \xi^1 \\ \xi^2 \\ \xi^3 \end{pmatrix} v.$$

Note that $\Delta = (\frac{J_1J_2}{J_1+J_2})$. Therefore, the Christoffel symbols of ∇^Δ vanish and

$$\langle v : w \rangle_\Delta = \frac{\partial w}{\partial\gamma}v + \frac{\partial v}{\partial\gamma}w.$$

Summing up, we conclude that $\mathbb{L}^s$ in 3.3 for $X = (g\xi, v)$, $Y = (g\eta, w)$ is given by

$$\mathbb{L}^s = -\begin{pmatrix} m\left(\frac{\partial\xi^1}{\partial\gamma}w + \frac{\partial\eta^1}{\partial\gamma}v\right) \\ m\left(\frac{\partial\xi^2}{\partial\gamma}w + \frac{\partial\eta^2}{\partial\gamma}v\right) \\ (J_1+J_2)\left(\frac{\partial\xi^3}{\partial\gamma}w + \frac{\partial\eta^3}{\partial\gamma}v\right) \end{pmatrix} - \frac{mJ_2}{J_1+J_2}\begin{pmatrix} \Omega^2 w + \Psi^2 v \\ -\Omega^1 w - \Psi^1 v \\ 0 \end{pmatrix}.$$

Following Lemma 3.1, we can compute the symmetric product defined by ∇^I:

$$\langle \Omega : \Psi \rangle_I = \begin{pmatrix} -\Omega^2\Psi^3 - \Omega^3\Psi^2 \\ \Omega^1\Psi^3 + \Omega^3\Psi^1 \\ 0 \end{pmatrix}.$$

With these ingredients, we are now ready to perform the controllability analysis along the lines of section 5. Consider the following symmetric brackets:

$$\langle B_1 : B_1 \rangle_\mathcal{G} = \tfrac{h^2}{J_1^2}\sin(2\gamma)\begin{pmatrix} 0 \\ 0 \\ -1 \\ 1 \end{pmatrix}, \qquad \langle B_1 : B_2 \rangle_\mathcal{G} = \begin{pmatrix} -\frac{1}{mJ_2}\sin\gamma \\ \frac{1}{mJ_2}\cos\gamma \\ -\frac{h(J_1+J_2)}{J_1^2J_2}\cos\gamma \\ \frac{h(J_1+J_2)}{J_1^2J_2}\cos\gamma \end{pmatrix},$$

$$\langle B_2 : B_2 \rangle_\mathcal{G} = 0, \qquad \langle B_2 : \langle B_1 : B_1 \rangle_\mathcal{G} \rangle_\mathcal{G} = 2\tfrac{h^2}{J_1^2}\tfrac{J_1+J_2}{J_1J_2}\cos(2\gamma)\begin{pmatrix} 0 \\ 0 \\ -1 \\ 1 \end{pmatrix}.$$

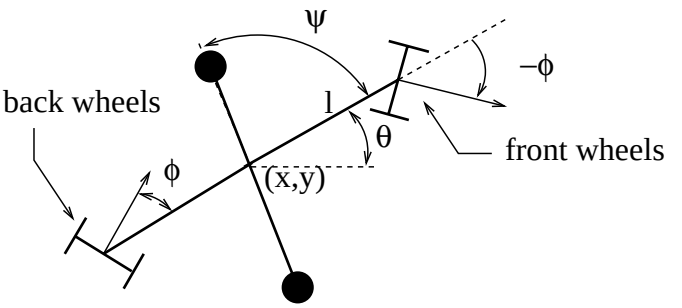

FIG. 6.2. *The snakeboard model.*

Note that $\{B_1, B_2, \langle B_1 : B_2\rangle_{\mathcal{G}}, \langle B_1 : B_1\rangle_{\mathcal{G}}, \langle B_2 : \langle B_1 : B_1\rangle_{\mathcal{G}}\rangle_{\mathcal{G}}\}$ span $\mathfrak{g} \times TM$ at every point (e, r), and hence the system is LCA. However, the bad bracket $\langle B_1 : B_1\rangle_{\mathcal{G}}$ is not in general a linear combination of the lower-order good brackets B_1 and B_2. Therefore, we can not conclude that the system is STLCC. In any case, at $\gamma = 0$, we have that $\langle B_1 : B_1\rangle_{\mathcal{G}}(e, 0) = 0$, and we can assure that the system is STLCC at $(g, 0)$ for all $g \in G$. However, if we restrict our attention to fiber configuration controllability, we can see that $\tau_*\langle B_1 : B_1\rangle_{\mathcal{G}} \in \text{span}\{\tau_* B_2\}$, and, therefore, the blimp is STLFCC. Physically, fiber controllability corresponds to the fact that we can use the shape torque to control the orientation angle θ to a desired value, but not θ and γ simultaneously.

6.2. The snakeboard. The snakeboard [22, 28] is a variant of the skateboard in which the passive wheel assemblies can pivot freely about a vertical axis. By coupling the twisting of the human torso with the appropriate turning of the wheels (where the turning is controlled by the rider's foot movement), the rider can generate a snake-like locomotion pattern without having to kick off the ground.

A simplified model is shown in Figure 6.2. We assume that the front and rear wheel axles move through equal and opposite rotations. This is based on the observations of human snakeboard riders who use roughly the same phase relationship. A momentum wheel rotates about a vertical axis through the center of mass, simulating the motion of a human torso.

The position and orientation of the snakeboard is determined by the coordinates of the center of mass (x, y) and its orientation θ. The shape variables are (ψ, ϕ), and so the configuration space is $Q = SE(2) \times \mathbb{S}^1 \times \mathbb{S}^1$. The physical parameters for the system are the mass of the board, m; the inertia of the rotor, J_r; the inertia of the wheels about the vertical axes, J_w; and the half-length of the board, l. A key component of the snakeboard is the use of the rotor inertia to drive the body. To keep the rotor and body inertias on similar scales, we make the additional simplifying assumption [4, 30] that the inertias of the system satisfy $J + J_r + 2J_w = ml^2$.

The Riemannian metric of this system is

$$\begin{aligned}\mathcal{G} = m(dx \otimes dx + dy \otimes dy) + (J + J_r + 2J_w)d\theta \otimes d\theta \\ + J_r(d\theta \otimes d\psi + d\psi \otimes d\theta) + J_r d\psi \otimes d\psi + 2J_w d\phi \otimes d\phi.\end{aligned}$$

The control torques are assumed to be applied to the rotation of the wheels and the rotor. Hence we consider

$$F^1 = d\psi, \quad F^2 = d\phi.$$

Observe that the snakeboard is an example of the type of dynamic locomotion systems we mentioned earlier, since the set of control inputs fully actuate the shape variables, $\operatorname{span}\{F^1, F^2\} = T^*M$. The corresponding input vector fields via the diffeomorphism $\sharp_{\mathcal{G}}$ are

$$Y_1 = -\frac{1}{J + 2J_w}\frac{\partial}{\partial\theta} + \frac{ml^2}{J_r(J + 2J_w)}\frac{\partial}{\partial\psi}, \quad Y_2 = \frac{1}{2J_w}\frac{\partial}{\partial\phi}.$$

The assumption that the wheels do not slip in the direction of the wheels axles yields the following two nonholonomic constraints:

$$\begin{aligned} &-\sin(\theta+\phi)\dot{x} + \cos(\theta+\phi)\dot{y} - l\cos\phi\,\dot{\theta} = 0,\\ &-\sin(\theta-\phi)\dot{x} + \cos(\theta-\phi)\dot{y} + l\cos\phi\,\dot{\theta} = 0. \end{aligned}$$

A quick set of calculations shows that this constrained mechanical system is invariant under the left multiplication in the Lie group $SE(2)$. The intersection $S = \mathcal{V} \cap \mathcal{D}$ can be seen to be one-dimensional. Moreover, we have that $S_{(e,r)} = e_{1Q}$, where $e_1 = l\cos\phi e_x - \sin\phi e_\theta$. We complete the basis by adding two elements generating $S^{\perp}_{(e,r)}$:

$$e_2 = e_y, \quad e_3 = \frac{1}{l}\tan\phi e_x + e_\theta.$$

Taking into account the discussion of the preceding sections, we can identify the following elements:

$$I = \begin{pmatrix} m & 0 & 0 \\ 0 & m & 0 \\ 0 & 0 & ml^2 \end{pmatrix}, \quad A = \begin{pmatrix} 0 & 0 \\ 0 & 0 \\ \frac{J_r}{ml^2} & 0 \end{pmatrix}, \quad \mathbb{A} = \begin{pmatrix} -\frac{J_r}{2ml}\sin(2\phi) & 0 \\ 0 & 0 \\ \frac{J_r}{ml^2}\sin^2\phi & 0 \end{pmatrix}.$$

Our choice of generators of $\mathcal{D}_{(e,r)}$, following section 2.3, is then

$$\mathcal{D}_{(r,e)} = \operatorname{span}\left\{\frac{\partial}{\partial\psi} + \frac{J_r}{ml^2}\sin\phi e_1, \frac{\partial}{\partial\phi}, e_1\right\}.$$

The projections to $\mathcal{D}$ of the input vector fields under the orthogonal decomposition $TQ = \mathcal{D} \oplus \mathcal{D}^{\perp}$ are

$$\begin{aligned} \mathcal{B}_1 &= \mathcal{P}(B_1) = \frac{ml^2}{J_r(ml^2 - J_r\sin^2\phi)}\left(\frac{\partial}{\partial\psi} + \frac{J_r}{ml^2}\sin\phi e_1\right),\\ \mathcal{B}_2 &= \mathcal{P}(B_2) = \frac{1}{2J_w}\frac{\partial}{\partial\phi}. \end{aligned}$$

For the sake of completeness, we have computed the terms $\tilde{\mathbb{L}}^s \in \mathfrak{g}^{\mathcal{D}}$ and $\tilde{\mathbb{S}}^s$ in 4.4 for any G-invariant vector fields $X = (g\xi, v)$ and $Y = (g\eta, w)$, although we already pointed out in section 5 (cf. Theorem 5.6) that the amount of calculations for the controllability tests can be made quite lighter, taking into account the fact that $\bar{\Omega}_i = 0$

for $\mathcal{B}_i$, $i = 1, 2$.

$$\tilde{\mathbb{L}}^s = -\left\{ ml\cos\phi \sum_{\alpha=1}^{2} \left(\frac{\partial \bar{\Psi}^1}{\partial r^\alpha} v^\alpha + \frac{\partial \bar{\Omega}^1}{\partial r^\alpha} w^\alpha \right) - ml^2 \sin\phi \sum_{\alpha=1}^{2} \left(\frac{\partial \bar{\Psi}^3}{\partial r^\alpha} v^\alpha + \frac{\partial \bar{\Omega}^3}{\partial r^\alpha} w^\alpha \right) + J_r \cos\phi (v^2 w^1 + w^2 v^1) + \frac{J_r}{2l} \sin(2\phi) \sin\phi (w^1 \xi^2 + v^1 \eta^2) \right\} e_1^*,$$

$$\tilde{\mathbb{S}}^s = -\frac{J_r^2}{2ml^2} \sin(2\phi) \begin{pmatrix} w^1 v^2 + w^2 v^1 \\ -2 v^1 w^1 \end{pmatrix}.$$

The controllability analysis yields the following results at the point $\mathbf{0} = (0, 0, 0, 0, 0)$:

$$\begin{array}{cc} \langle \mathcal{B}_1 : \mathcal{B}_1 \rangle(\mathbf{0}) = 0, & \langle \mathcal{B}_1 : \mathcal{B}_2 \rangle(\mathbf{0}) = \frac{1}{2J_w ml} e_x, \\ \langle \mathcal{B}_2 : \mathcal{B}_2 \rangle(\mathbf{0}) = 0, & [\mathcal{B}_1, \mathcal{B}_2](\mathbf{0}) = \frac{1}{2J_w ml} e_x, \\ [\mathcal{B}_2, [\mathcal{B}_1, \mathcal{B}_2]](\mathbf{0}) = -\frac{1}{2J_w^2 ml^2} e_\theta, & [\mathcal{B}_2, [\mathcal{B}_1, [\mathcal{B}_2, [\mathcal{B}_1, \mathcal{B}_2]]]](\mathbf{0}) = -\frac{1}{4J_w^3 m^2 l^3} e_y - \frac{1}{2J_w^3 m^2 l^4} e_\theta. \end{array}$$

Note that $\{\mathcal{B}_1, \mathcal{B}_2, \langle \mathcal{B}_1 : \mathcal{B}_2 \rangle, [\mathcal{B}_2, [\mathcal{B}_1, \mathcal{B}_2]], [\mathcal{B}_2, [\mathcal{B}_1, [\mathcal{B}_2, [\mathcal{B}_1, \mathcal{B}_2]]]]\}$ span $\mathfrak{g} \times T_{(0,0)}M$, and so the system is LCA at $(g, 0, 0)$ for all $g \in G$. Moreover, the bad symmetric products $\langle \mathcal{B}_1 : \mathcal{B}_1 \rangle$ and $\langle \mathcal{B}_2 : \mathcal{B}_2 \rangle$ vanish at $\mathbf{0}$, and the remaining ones are either 0 or in span$\{\mathcal{B}_2(\mathbf{0}), \langle \mathcal{B}_1 : \mathcal{B}_2 \rangle(\mathbf{0})\}$, and so we can conclude that the snakeboard is STLCC at $(g, 0, 0)$ for all $g \in G$.

7. Conclusions. We have developed a new set of tools that can be used in the study of simple mechanical systems evolving on principal fiber bundles. These tools have direct application to a large class of problems in robotic locomotion. Using the Lie group symmetries that are associated with an invariant mechanical system on a principal fiber bundle, we have given an explicit formulation of the affine connection in terms of the mechanical and nonholonomic connections for unconstrained and constrained systems, respectively. This formulation can greatly reduce the amount of computation necessary to derive controllability tests, as was observed during the analysis of the snakeboard system.

We have defined a new notion of fiber configuration controllability, which can be used to focus the analysis on the important components of a locomotion system, namely, the fiber variables of position and orientation. The tools developed in this paper were applied to two systems—the planar rigid body and the snakeboard robot.

We are currently working on applying these tools to motion planning for such systems (see [26]). Recent work by Bullo, Leonard, and Lewis [6] suggests an excellent avenue for applying the affine connection in a motion planning framework. We will also explore connections of these tools to steering for dynamic systems as, for example, was done by Ostrowski [29] using the reduced equations for the snakeboard [31].

Acknowledgments. The first three authors wish to thank F. Bullo and A. D. Lewis for interesting and helpful conversations. J. Cortés and S. Martínez wish to thank F. Cantrijn and M. de León for their support. We would also like to thank the anonymous reviewers for their useful comments.

AFFINE INVARIANT CONVERGENCE ANALYSIS FOR INEXACT AUGMENTED LAGRANGIAN-SQP METHODS*

S. VOLKWEIN† AND M. WEISER‡

Abstract. An affine invariant convergence analysis for inexact augmented Lagrangian-SQP methods is presented. The theory is used for the construction of an accuracy matching between iteration errors and truncation errors, which arise from the inexact linear system solvers. The theoretical investigations are illustrated numerically by an optimal control problem for the Burgers equation.

Key words. nonlinear programming, multiplier methods, affine invariant norms, Burgers' equation

1. Introduction.

This paper is concerned with an optimization problem of the following type:

$$(\mathsf{P}) \qquad \text{minimize } J(x) \text{ subject to } e(x) = 0,$$

where $J : X \to \mathbb{R}$ and $e : X \to Y$ are sufficiently smooth functions and X, Y are real Hilbert spaces. These types of problems occur, for example, in the optimal control of systems described by partial differential equations. To solve (P) we use the augmented Lagrangian-SQP (sequential quadratic programming) technique as developed in [11]. In this method the differential equation is treated as an equality constraint, which is enforced by a Lagrangian term together with a penalty functional. We present an algorithm which has second-order convergence rate and depends upon a second-order sufficient optimality condition. In comparison with SQP methods the augmented Lagrangian-SQP method has the advantage of a more global behavior. For certain examples we found it to be less sensitive with respect to the starting values, and the region for second-order convergence rate was reached earlier; see, e.g., [11, 15, 17]. We shall point out that the penalty term of the augmented Lagrangian functional need not to be implemented but rather that it can be realized by a first-order Lagrangian update.

Augmented Lagrangian-SQP methods applied to problem (P) are essentially Newton-type methods applied to the Kuhn–Tucker equations for an augmented optimization problem. Newton methods and their behavior under different linear transformations were studied by several authors; see [5, 6, 7, 8, 10], for instance. In this paper, we combine both lines of work and present an affine invariant setting for analysis and implementation of augmented Lagrangian-SQP methods in Hilbert spaces. An affine invariant convergence theory for inexact augmented Lagrangian-SQP methods is presented. Then the theoretical results are used for the construction of an accuracy

matching between iteration errors and truncation errors, which arise from the inexact linear system solvers.

The paper is organized as follows. In section 2 the augmented Lagrangian-SQP method is introduced and necessary prerequisites are given. The affine invariance is introduced in section 3. In section 4 an affine invariant convergence result for the augmented Lagrangian-SQP method is presented. Two invariant norms for optimal control problems are analyzed in section 5, and the inexact Lagrangian-SQP method is studied in section 6. In the last section we report on some numerical experiments done for an optimal control problem for the Burgers equation, which is a one-dimensional model for nonlinear convection-diffusion phenomena.

2. The augmented Lagrangian-SQP method. Let us consider the constrained optimal control problem

$$\text{(P)} \qquad \text{minimize } J(x) \text{ subject to } e(x) = 0,$$

where $J : X \to \mathbb{R}$, $e : X \to Y$, and X, Y are real Hilbert spaces. Throughout we do not distinguish between a functional in the dual space and its Riesz representation in the Hilbert space. The Hilbert space $X \times Y$ is endowed with the Hilbert space product topology and, for brevity, we set $Z = X \times Y$.

Let us present an example for (P) that illustrates our theoretical investigations and that is used for the numerical experiments carried out in section 7. For more details we refer the reader to [18].

Example 2.1. Let Ω denote the interval $(0,1)$ and set $Q = (0,T) \times \Omega$ for given $T > 0$. We define the space $W(0,T)$ by

$$W(0,T) = \left\{ \varphi \in L^2(0,T;H^1(\Omega)) : \ \varphi_t \in L^2(0,T;H^1(\Omega)') \right\},$$

which is a Hilbert space endowed with the common inner product. For controls $u, v \in L^2(0,T)$ the state $y \in W(0,T)$ is given by the weak solution of the unsteady Burgers equation with Robin-type boundary conditions, i.e., y satisfies

$$y(0,\cdot) = y_0 \quad \text{in } L^2(\Omega) \tag{2.1a}$$

and

$$\begin{aligned} &\langle y_t(t,\cdot),\varphi\rangle_{(H^1)',H^1} + \sigma_1(t)y(t,1)\varphi(1) - \sigma_0(t)y(t,0)\varphi(0) \\ &+ \int_\Omega \nu y_x(t,\cdot)\varphi' + \big(y(t,\cdot)y_x(t,\cdot) - f(t,\cdot)\big)\varphi \, dx = v(t)\varphi(1) - u(t)\varphi(0) \end{aligned} \tag{2.1b}$$

for all $\varphi \in H^1(\Omega)$ and $t \in (0,T)$ a.e., where $\langle\cdot,\cdot\rangle_{(H^1)',H^1}$ denotes the duality pairing between $H^1(\Omega)$ and its dual. We suppose that $f \in L^2(\Omega)$, $y_0 \in L^\infty(\Omega)$, $\sigma_0, \sigma_1 \in L^\infty(0,T)$, and $\nu > 0$. Recall that $W(0,T)$ is continuously embedded into the space of all continuous functions from $[0,T]$ into $L^2(\Omega)$, denoted by $C([0,T];L^2(\Omega))$; see, e.g., [3, p. 473]. Therefore, (2.1a) makes sense. With controls u, v we associate the cost of tracking type

$$J(y,u,v) = \frac{1}{2}\int_Q |y-z|^2 \, dxdt + \frac{1}{2}\int_0^T \alpha \, |u|^2 + \beta \, |v|^2 \, dt,$$

where $z \in L^2(Q)$ and $\alpha, \beta > 0$ are fixed. Let $X = W(0,T) \times L^2(0,T) \times L^2(0,T)$, $Y = L^2(0,T;H^1(\Omega)) \times L^2(\Omega)$, and $x = (y,u,v)$. We introduce the bounded operator

$$\tilde{e} : X \to L^2(0,T;H^1(\Omega)'),$$

whose action is defined by

$$\begin{aligned}\langle \tilde{e}(y,u,v),\lambda\rangle_{L^2(0,T;H^1(\Omega)'),L^2(0,T;H^1(\Omega))}&\\ = \int_0^T \langle y_t(t,\cdot),\lambda(t,\cdot)\rangle_{(H^1)',H^1}\,dt + \int_Q (\nu y_x\lambda_x + y y_x\lambda - f\lambda)\,dxdt&\\ + \int_0^T \big((\sigma_1 y(\cdot,1)-v)\lambda(\cdot,1) - (\sigma_0 y(\cdot,0)-u)\lambda(\cdot,0)\big)\,dt&\end{aligned}$$

for $\lambda \in L^2(0,T;H^1(\Omega))$. Define $e : X \to Y$ by

$$e(y,u,v) = \big((-\Delta + I)^{-1}\tilde{e}(y,u,v), y(0,\cdot) - y_0\big),$$

where for given $g \in H^1(\Omega)'$ the mapping $(-\Delta + I)^{-1} : H^1(\Omega)' \to H^1(\Omega)$ is the Neumann solution operator associated with

$$\int_\Omega v'\varphi' + v\varphi\,dx = \langle g,\varphi\rangle_{(H^1)',H^1} \quad \text{for all } \varphi \in H^1(\Omega).$$

Now the optimal control problem can be written in the form (P).

For $c \geq 0$ the augmented Lagrange functional $L_c : Z \to \mathbb{R}$ associated with (P) is defined by

$$L_c(x,\lambda) = J(x) + \langle e(x),\lambda\rangle_Y + \frac{c}{2}\,\|e(x)\|_Y^2.$$

The following assumption is rather standard for SQP methods in Hilbert spaces and is supposed to hold throughout the paper.

ASSUMPTION 1. *Let $x^* \in X$ be a reference point such that*

(a) *J and e are twice continuously Fréchet-differentiable, and the mappings J'' and e'' are Lipschitz-continuous in a neighborhood of x^*;*

(b) *the linearization $e'(x^*)$ of the operator e at x^* is surjective;*

(c) *there exists a Lagrange multiplier $\lambda^* \in Y$ satisfying the first-order necessary optimality conditions*

$$L_c'(x^*,\lambda^*) = 0, \quad e(x^*) = 0 \quad \text{for all } c \geq 0, \tag{2.2}$$

where the Fréchet-derivative with respect to the variable x is denoted by a prime; and

(d) *there exists a constant $\kappa > 0$ such that*

$$\langle L_0''(x^*,\lambda^*)\chi,\chi\rangle_X \geq \kappa\,\|\chi\|_X^2 \quad \text{for all } \chi \in \ker e'(x^*),$$

where ker $e'(x^*)$ *denotes the kernel or null space of $e'(x^*)$.*

Remark 2.2. In the context of Example 2.1 we write $x^* = (y^*,u^*,v^*)$. It was proved in [18] that Assumption 1 holds, provided $\|y^* - z\|_{L^2(Q)}$ is sufficiently small.

The next proposition follows directly from Assumption 1. For a proof we refer to [12] and [13], for instance.

PROPOSITION 2.3. *With Assumption* 1 *holding, x^* is a local solution to* (P). *Furthermore, there exists a neighborhood of (x^*,λ^*) such that (x^*,λ^*) is the unique solution of* (2.2) *in this neighborhood.*

The mapping $x \mapsto L_c(x,\lambda^*)$ can be bounded from below by a quadratic function. This fact is referred to as augmentability of L_c and is formulated in the next proposition. For a proof we refer the reader to [11].

PROPOSITION 2.4. *There exist a neighborhood $\hat{U}$ of x^* and a constant $\bar{c} \geq 0$ such that the mapping $x \mapsto L_c''(x, \lambda^*)$ is coercive on the whole space X for all $x \in \hat{U}$ and $c \geq \bar{c}$.*

Remark 2.5. Due to Assumption 1 and Proposition 2.4 there are convex neighborhoods $U(x^*) \subset X$ of x^* and $U(\lambda^*) \subset Y$ of λ^* such that for all $(x, \lambda) \in U = U(x^*) \times U(\lambda^*)$

(a) $J(x)$ and $e(x)$ are twice Fréchet-differentiable, and their second Fréchet-derivatives are Lipschitz-continuous in $\overline{U(x^*)}$;
(b) $e'(x)$ is surjective;
(c) $L_0''(x, \lambda)$ is coercive on the kernel of $e'(x)$;
(d) the point $z^* = (x^*, \lambda^*)$ is the unique solution to (2.2) in U; and
(e) there exist $\tilde{\kappa} > 0$ and $\bar{c} \geq 0$ such that

$$\langle L_c''(x, \lambda)\chi, \chi \rangle_X \geq \tilde{\kappa} \|\chi\|_X^2 \quad \text{for all } \chi \in X \text{ and } c \geq \bar{c}. \tag{2.3}$$

To shorten notation let us introduce the operator

$$F_c(x, \lambda) = \begin{pmatrix} L_c'(x, \lambda) \\ e(x) \end{pmatrix} \quad \text{for all } (x, \lambda) \in U.$$

Then the first-order necessary optimality conditions (2.2) can be expressed as

$$F_c(x^*, \lambda^*) = 0 \quad \text{for all } c \geq 0. \tag{OS}$$

To find x^* numerically we solve (OS) by the Newton method. The Fréchet-derivative of the operator F_c in U is given by

$$\nabla F_c(x, \lambda) = \begin{pmatrix} L_c''(x, \lambda) & e'(x)^\star \\ e'(x) & 0 \end{pmatrix}, \tag{2.4}$$

where $e'(x)^\star : Y \to X$ denotes the adjoint of the operator $e'(x)$.

Remark 2.6. With Assumption 1 holding, there exists a constant $C > 0$ satisfying

$$\|\nabla F_c(x, \lambda)^{-1}\|_{\mathcal{B}(Z)} \leq C \quad \text{for all } (x, \lambda) \in U \tag{2.5}$$

(see, e.g., in [9, p. 114]), where $\mathcal{B}(Z)$ denotes the Banach space of all bounded linear operators on Z.

Now we formulate the augmented Lagrangian-SQP method.

ALGORITHM 1.

(a) *Choose $(x^0, \lambda^0) \in U$, $c \geq 0$, and put $k = 0$.*
(b) *Set $\tilde{\lambda}^k = \lambda^k + ce(x^k)$.*
(c) *Solve for $(\Delta x, \Delta\lambda)$ the linear system*

$$\nabla F_0(x^k, \tilde{\lambda}^k) \begin{pmatrix} \Delta x \\ \Delta\lambda \end{pmatrix} = -F_0(x^k, \tilde{\lambda}^k). \tag{2.6}$$

(d) *Set $(x^{k+1}, \lambda^{k+1}) = (x^k + \Delta x, \tilde{\lambda}^k + \Delta\lambda)$, $k = k + 1$, and go back to* (b).

Remark 2.7. Since X and Y are Hilbert spaces, (x^{k+1}, λ^{k+1}) can equivalently be obtained by solving the linear system

$$\nabla F_c(x^k, \lambda^k) \begin{pmatrix} \Delta x \\ \Delta\lambda \end{pmatrix} = -F_c(x^k, \lambda^k) \tag{2.7}$$

and setting $(x^{k+1}, \lambda^{k+1}) = (x^k + \Delta x, \lambda^k + \Delta\lambda)$. Equation (2.7) corresponds to a Newton step applied to (OS). This form of the iteration requires the implementation of $e'(x^k)^\star e'(x^k)$, whereas steps (b) and (c) of Algorithm 1 do not—see [11]. In the case of Example 2.1 this requires at least one additional solve of the Poisson equation.

3. Affine invariance. Let $\tilde{B} : X \to X$ be an arbitrary isomorphism. We transform the x variable by $x = \tilde{B}y$. Thus, instead of (P) we study the whole class of equivalent transformed minimization problems

$$\text{minimize } J(\tilde{B}y) \text{ subject to } e(\tilde{B}y) = 0 \tag{3.1}$$

with the transformed solutions $\tilde{B}y^* = x^*$. Setting

$$B = \begin{pmatrix} \tilde{B} & 0 \\ 0 & I \end{pmatrix} \quad \text{and} \quad G_c(y,\xi) = B^\star F_c(x,\lambda) \quad \text{with } (x,\lambda) = (\tilde{B}y,\xi),$$

the first-order necessary optimality conditions have the form

$$G_c(y,\xi) = 0 \quad \text{for all } c \geq 0. \tag{$\widehat{\mathsf{OS}}$}$$

Applying Algorithm 1 to ($\widehat{\mathsf{OS}}$) we get an equivalent sequence of transformed iterates.

THEOREM 3.1. *Suppose that Assumption* 1 *holds. Let* $(x^0,\lambda^0) \in U$ *and* $(y^0,\xi^0) = (\tilde{B}^{-1}x^0,\lambda^0)$ *be the starting iterates for Algorithm* 1 *applied to the optimality conditions* (OS) *and* ($\widehat{\mathsf{OS}}$)*, respectively. Then both sequences of iterates are well-defined and equivalent in the sense of*

$$(\tilde{B}y^k,\xi^k) = (x^k,\lambda^k) \quad \textit{for } k = 0,1,\ldots . \tag{3.2}$$

Proof. First note that the Fréchet-derivative of the operator G_c is given by

$$\nabla G_c(y,\xi) = B^\star \nabla F_c(x,\lambda)B \quad \text{with } (x,\lambda) = (\tilde{B}y,\xi). \tag{3.3}$$

To prove (3.2) we use an induction argument. By assumption the identity (3.2) holds for $k = 0$. Now suppose that (3.2) is satisfied for $k \geq 0$. This implies $\tilde{B}y^k = x^k$ and $\xi^k = \lambda^k$. Using step (b) of Algorithm 1, it follows that $\tilde{\xi}^k = \xi^k + ce(\tilde{B}y^k) = \tilde{\lambda}^k$. From (3.3),

$$\nabla F_0(x^k,\tilde{\lambda}^k)\begin{pmatrix}\Delta x\\ \Delta\lambda\end{pmatrix} = -F_0(x^k,\tilde{\lambda}^k), \quad \text{and} \quad \nabla G_0(y^k,\tilde{\xi}^k)\begin{pmatrix}\Delta y\\ \Delta\xi\end{pmatrix} = -G_0(y^k,\tilde{\xi}^k),$$

we conclude that $(\Delta y,\Delta\xi) = (\tilde{B}^{-1}\Delta x,\Delta\lambda)$. Utilizing step (d) of Algorithm 1 we get the desired result. ∎

Due to the previous theorem the augmented Lagrangian-SQP method is *invariant under arbitrary transformations* $\tilde{B}$ of the state space X. This nice property should, of course, be inherited by any convergence theory and termination criteria. In section 4 we develop such an invariant theory.

Example 3.2. The usual local Newton–Mysovskii convergence theory (cf. [14, p. 412]) is *not* affine invariant, which leads to an unsatisfactory description of the domain of local convergence. Consider the optimization problem

$$\min \eta^2 + (\xi+\eta)^3 - \xi - \eta \text{ subject to } \xi + 2\eta = 0 \tag{3.4}$$

with unique solution $x^* = (\xi^*,\eta^*) = (2/3,-1/3)$ and associated Lagrange multiplier $\lambda^* = -2/3$. Note that the Jacobian ∇F_0 does not depend on λ here but only on $x = (\xi,\eta)$. In the context of Remark 2.5 we choose the neighborhood

$$U = U(x^*) \times U(\lambda^*) = \{(\xi,\eta) \in \mathbb{R}^2 : |\xi+\eta-1/3| < 0.16\sqrt{2}\} \times \mathbb{R}.$$

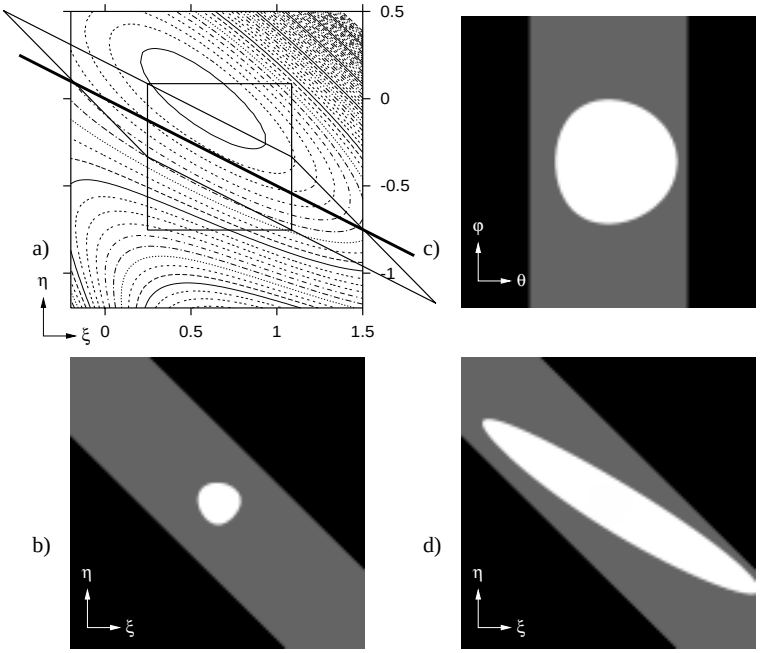

FIG. 3.1. *Illustration for Example* 3.2. (a) *Contour lines of the cost functional, the constraint, and the areas occupied by the other subplots.* (b) *Neighborhood* $U(x^*)$ *(gray) and Kantorovich ball of theoretically assured convergence (white) for the original problem formulation.* (c) $U(x^*)$ *and Kantorovich ball for the "better" formulation.* (d) $U(x^*)$ *and Kantorovich ball for the "better" formulation plotted in coordinates of the original formulation.*

Defining

$$\alpha = \sup_{x\in U(x^*)} \|\nabla F_0(x)^{-1}\| \quad \text{and} \quad \beta = \sup_{x,y\in U(x^*),x\neq y} \frac{\|\nabla F_0(x) - \nabla F_0(y)\|}{\|x-y\|_2},$$

the Newton–Mysovskii theory essentially guarantees convergence for all starting points in the Kantorovich region

$$K := \left\{ z \in U : \|\nabla F_0(z)^{-1} F_0(z)\|_2 \leq \frac{2}{\alpha\beta} \right\}.$$

Here, $\|\cdot\|$ denotes the spectral norm for symmetric matrices and $\|\cdot\|_2$ is the Euclidean norm. For our choice of U, resulting in $\alpha \approx 1.945$ and $\beta = 12\sqrt{2}$, a section of the Kantorovich region at $\lambda = \lambda^*$ is plotted in Figure 3.1(b). A different choice of coordinates, however, yields a significantly different result. With the transformation

$$\xi = 2\vartheta - \phi, \quad \eta = \phi - \vartheta,$$

problem (3.4) can be written as

$$\min(\phi - \vartheta)^2 + \vartheta^3 - \vartheta \text{ subject to } \phi = 0.$$

For the same neighborhood U, the better constants $\alpha \approx 1.859$ and $\beta = 6$ result. Again, a section of the Kantorovich region at $\lambda = \lambda^*$ is shown in Figure 3.1(c).

Transformed back to (ξ, η) space, Figure 3.1(d) reveals a much larger domain of theoretically assured convergence. This "better" formulation of the problem is, however, not at all evident. In contrast, a convergence theory that is invariant under linear transformations automatically includes the "best" formulation.

Remark 3.3. The invariance of Newton's method is not limited to transformations of type (3.1). In fact, Newton's method is invariant under arbitrary transformations of domain and image space; i.e., it behaves exactly the same for $AF_c(B\tilde{z}) = 0$ as for $F_c(z) = 0$—see [5]. Because F_c has a special gradient structure in the optimization context, *meaningful* transformations are coupled due to the chain rule. Meaningful transformations result from transformations of the underlying optimization problem, i.e., transformations of the domain space and the image space of the constraints. Those are of the type

$$\begin{pmatrix} B_1^\star & 0 \\ 0 & B_2^\star \end{pmatrix} F_c \left(\begin{pmatrix} B_1 & 0 \\ 0 & B_2 \end{pmatrix} \begin{pmatrix} \tilde{x} \\ \tilde{\lambda} \end{pmatrix} \right).$$

For such general transformations there is no possibility of defining a norm in an invariant way, since both the domain and the image space of the constraints are transformed independently: $B_2^\star e(B_1\tilde{x})$. For this reason, different types of transformations have been studied for different problems; see, e.g., [6, 7, 10].

4. Affine invariant convergence theory. To formulate the convergence theory and termination criteria in terms of an appropriate norm, we use a norm that is invariant under the transformation (3.1).

DEFINITION 4.1. *Let $z \in U$. Then the norms $\|\cdot\|_z : Z \to \mathbb{R}$, $z \in U$, are called* affine invariant *for* (OS) *if*

$$\|\nabla F_c(\tilde{z})\Delta z\|_z = \|\nabla G_c(B^{-1}\tilde{z})B^{-1}\Delta z\|_{B^{-1}z} \quad \text{for all } \tilde{z} \in U \text{ and } \Delta z \in Z. \tag{4.1}$$

We call $\{\|\cdot\|_z\}_{z\in U}$ a γ-continuous family of invariant norms *for* (OS) *if*

$$\big|\|r\|_{z+\Delta z} - \|r\|_z\big| \le \gamma \, \|\nabla F_c(z)\Delta z\|_z \|r\|_z \tag{4.2}$$

for every $r, \Delta z \in Z$ and $z \in U$ such that $z + \Delta z \in U$.

Using affine invariant norms we are able to present an affine invariant convergence theorem for Algorithm 1.

THEOREM 4.2. *Assume that Assumption* 1 *holds and that there are constants $\omega \ge 0, \gamma \ge 0$, and a γ-continuous family of affine invariant norms $\{\|\cdot\|_z\}_{z\in U}$ such that the operator ∇F_c satisfies*

$$\|(\nabla F_c(z + s\Delta z) - \nabla F_c(z))\Delta z\|_{z+\eta\Delta z} \le s\omega\|\nabla F_c(z)\Delta z\|_z^2 \tag{4.3}$$

for $s, \eta \in [0, 1]$, $z \in U$, and $\Delta z \in Z$ such that $\operatorname{co}\{z, z + \Delta z\} \subset U$, where $\operatorname{co} A$ denotes the convex hull of A. For $k \in \mathbb{N}$ let $h_k = \omega\|F_c(z^k)\|_{z^k}$ and let

$$\mathcal{L}(z) = \Big\{\zeta \in U : \|F_c(\zeta)\|_\zeta \le \Big(1 + \frac{\gamma}{4}\|F_c(z)\|_z\Big)\|F_c(z)\|_z\Big\}. \tag{4.4}$$

Suppose that $h_0 < 2$ and that the level set $\mathcal{L}(z^0)$ is closed. Then the iterates stay in U and the residuals converge to zero at a rate of

$$h_{k+1} \le \frac{1}{2}\, h_k^2.$$

Additionally, we have

$$\|F_c(z^{k+1})\|_{z^k} \le \|F_c(z^k)\|_{z^k}. \tag{4.5}$$

Proof. By induction, assume that $\mathcal{L}(z^k)$ is closed and that $h_k < 2$ for $k \ge 0$. Due to Remark 2.5 the neighborhood U is assumed to be convex, so that $z + \eta\Delta z \in U$ for all $\eta \in [0,1]$. From $\nabla F_c(z^k)\Delta z^k = -F_c(z^k)$ we conclude that

$$\begin{aligned} F_c(z^k + \eta\Delta z^k) &= F_c(z^k) + \int_0^\eta \nabla F_c(z^k + s\Delta z^k)\Delta z^k \, ds \\ &= (1-\eta)F_c(z^k) + \int_0^\eta (\nabla F_c(z^k + s\Delta z^k) - \nabla F_c(z^k))\Delta z^k \, ds \end{aligned}$$

for all $\eta \in [0,1]$. Applying (4.2), (4.3), and $h_k = \omega\|F_c(z^k)\|_{z^k}$, and $h_k < 2$ we obtain

$$\begin{aligned} &\|F_c(z^k + \eta\Delta z^k)\|_{z^k+\eta\Delta z^k} \\ &\quad\le (1-\eta)(1+\eta\gamma\|F_c(z^k)\|_{z^k})\|F_c(z^k)\|_{z^k} + \int_0^\eta s\omega\|\nabla F_c(z^k)\Delta z^k\|_{z^k}^2 \, ds \\ &\quad= \Big((1-\eta)(1+\eta\gamma\|F_c(z^k)\|_{z^k}) + \frac{\eta^2 h_k}{2}\Big)\|F_c(z^k)\|_{z^k} \\ &\quad< \big(1 + (\eta - \eta^2)\gamma\|F_c(z^k)\|_{z^k}\big)\|F_c(z^k)\|_{z^k}. \end{aligned} \tag{4.6}$$

With $\eta \in [0,1]$,

$$\|F_c(z^k + \eta\Delta z^k)\|_{z^k+\eta\Delta z^k} \le \Big(1 + \frac{\gamma}{4}\|F_c(z^k)\|_{z^k}\Big)\|F_c(z^k)\|_{z^k}$$

holds. If $z^k + \Delta z^k \notin \mathcal{L}(z^k)$, there exists an $\bar\eta \in [0,1]$ such that $z^k + \bar\eta\Delta z^k \in U\backslash\mathcal{L}(z^k)$, i.e.,

$$\|F_c(z^k + \bar\eta\Delta z^k)\|_{z^k+\bar\eta\Delta z^k} > \Big(1 + \frac{\gamma}{4}\|F_c(z^k)\|_{z^k}\Big)\|F_c(z^k)\|_{z^k},$$

which is a contradiction. Hence, $z^{k+1} \in \mathcal{L}(z^k)$ and, inserting $\eta = 1$ in (4.6),

$$\|F(z^{k+1})\|_{z^{k+1}} \le \omega\|F_c(z^k)\|_{z^k}^2/2.$$

Thus, we have $h_{k+1} \le h_k^2/2$ and $\mathcal{L}(z^{k+1}) \subset \mathcal{L}(z^k)$. Since $\mathcal{L}(z^k)$ is closed, every Cauchy sequence in $\mathcal{L}(z^{k+1})$ converges to a limit point in $\mathcal{L}(z^k)$, which is, by (4.4) and the continuity of the norm, also contained in $\mathcal{L}(z^{k+1})$. Hence, $\mathcal{L}(z^{k+1})$ is closed. Finally, using $\eta = 1$ in (4.6), the result (4.5) is obtained. ∎

Remark 4.3. We choose simplicity over sharpness here. The definition of the level set $\mathcal{L}(z)$ can be sharpened somewhat by a more careful estimate of the term $(\gamma\|F_c(z^k)\|_{z^k} - 1)\eta + (h_k/2 - \gamma\|F_c(z^k)\|_{z^k})\eta^2$.

Theorem 4.2 guarantees that $\lim_{k\to\infty} h_k = 0$. To ensure that $z^k \to z^*$ in Z as $k \to \infty$ we have to require that the canonical norm $\|\cdot\|_Z$ on Z can be bounded appropriately by the affine invariant norms $\|\cdot\|_z$.

COROLLARY 4.4. *If, in addition to the assumptions of Theorem* 4.2*, there exists a constant* $\tilde C > 0$ *such that*

$$\|\zeta\|_Z \le \tilde C\,\|\nabla F_c(z)\zeta\|_z \quad \textit{for all } \zeta \in Z \textit{ and } z \in U,$$

then the iterates converge to the solution $z^* = (x^*, \lambda^*)$ *of* (OS).

Proof. By assumption and Theorem 4.2 we have

$$\|\Delta z^k\|_Z \le \tilde{C}\,\|F_c(z^k)\|_{z^k} \le \tilde{C}\left(\frac{h_0}{2}\right)^k \|F_c(z^0)\|_{z^0}.$$

Thus, $\{z^k\}_{k\in\mathbb{N}}$ is a Cauchy sequence in $\mathcal{L}(z^0) \subset U$. Since $\mathcal{L}(z^0)$ is closed, the claim follows by Remark 2.5(d). ∎

For actual implementation of Algorithm 1 we need a *convergence monitor* indicating whether or not the assumptions of Theorem 4.2 may be violated and a *termination criterion* deciding whether or not the desired accuracy has been achieved.

From (4.5), a new iterate z^{k+1} is accepted whenever

$$\|F_c(z^{k+1})\|_{z^k} < \|F_c(z^k)\|_{z^k}. \tag{4.7}$$

Otherwise, the assumptions of Theorem 4.2 are violated and the iteration is considered to be nonconvergent. The use of the norm $\|\cdot\|_{z^k}$ for both the old and the new iterate permits an efficient implementation. Since in many cases the norm $\|F_c(z^{k+1})\|_{z^k}$ is defined in terms of $\overline{\Delta z^{k+1}} = \nabla F_c(z^k)^{-1} F_c(z^{k+1})$, the derivative need not be evaluated at the new iterate. If a factorization of $\nabla F_c(z^k)$ is available via a direct solver, it can be reused at negligible cost even if the convergence test fails. If an iterative solver is used, $\overline{\Delta z^{k+1}}$ in general provides a good starting point for computing Δz^{k+1} such that the additional cost introduced by the convergence monitor is minor.

The SQP iteration will be terminated with a solution z^{k+1} as soon as

$$\|F_c(z^{k+1})\|_{z^k} \le \mathrm{TOL}\;\|F_c(z^0)\|_{z^0}$$

with a user-specified tolerance TOL. Again, the use of the norm $\|\cdot\|_{z^k}$ allows an efficient implementation.

5. Invariant norms for optimization problems. What remains to be done is the construction of a γ-continuous family of invariant norms. In this section we introduce two different norms.

5.1. First invariant norm. The first norm takes advantage of the parameter c in the augmented Lagrangian. As we mentioned in Remark 2.5, there exists a $\bar{c} \ge 0$ such that $L_c''(z)$ is coercive on X for all $z \in U$ and $c \ge \bar{c}$. Hence, the operator $L_c''(z)^{-1}$ belongs to $\mathcal{B}(Z)$ for all $c \ge \bar{c}$.

Let us introduce the operator $S_c : U \to \mathcal{B}(Z)$ by

$$S_c(z) = \begin{pmatrix} L_c''(z) & 0 \\ 0 & I \end{pmatrix} \quad \text{for all } z \in U \text{ and } c \ge 0. \tag{5.1}$$

Since $L_c''(z)$ is self-adjoint for all $z \in U$, $S_c(z)$ is self-adjoint as well. Due to (2.3) the operator $S_c(z)$ is coercive for all $z \in U$ and $c \ge \bar{c}$. Thus, for all $z \in U$

$$\|S_c^{1/2}(z)\cdot\| = \sqrt{\langle S_c(z)\cdot,\cdot\rangle_Z} \tag{5.2}$$

is a norm on Z for $c \ge \bar{c}$.

PROPOSITION 5.1. *Let $c \ge \bar{c}$. Then for every $z \in U$ the mapping*

$$\|r\|_z = \|S_c(z)^{1/2}\nabla F_c(z)^{-1} r\| \quad \textit{for } r \in Z \tag{5.3}$$

defines an affine invariant norm for (2.2).

Proof. Let $z \in U$ be arbitrary. Since $\|S_c^{1/2}(z)\cdot\|$ defines a norm on Z for $c \geq \bar{c}$ and $\nabla F_c(z)$ is continuously invertible by Remark 2.6, it follows that $\|\cdot\|_z$ is a norm on Z. Now we prove the invariance property (4.1). Let $\tilde{L}_c$ denote the augmented Lagrangian associated with the transformed problem (3.1). Then we have $\tilde{L}_c''(\zeta) = \tilde{B}^\star L_c''(z)\tilde{B}$ for $z = B\zeta \in U$. Hence, setting $\tilde{S}_c(\zeta) = B^\star S_c(z)B$ we get

$$\|r\|_\zeta = \|\tilde{S}_c(\zeta)^{1/2}\nabla G_c(\zeta)^{-1}r\| \quad \text{for } r \in Z.$$

From (3.3) we conclude that

$$\nabla F_c(z)^{-1}\nabla F_c(\tilde{z}) = B\nabla G_c(\zeta)^{-1}\nabla G_c(\tilde{\zeta})B^{-1} \tag{5.4}$$

with $z = B\zeta, \tilde{z} = B\tilde{\zeta} \in U$. Using (5.3) and (5.4) we obtain

$$\begin{aligned}\|\nabla F_c(\tilde{z})\delta z\|_z &= \|S_c(z)^{1/2}\nabla F_c(z)^{-1}\nabla F_c(\tilde{z})\delta z\| \\ &= \|S_c(z)^{1/2}B\nabla G_c(\zeta)^{-1}\nabla G_c(\tilde{\zeta})B^{-1}\delta z\| \\ &= \|(B^\star S_c(z)B)^{1/2}\nabla G_c(\zeta)^{-1}\nabla G_c(\tilde{\zeta})B^{-1}\delta z\| = \|\nabla G_c(\tilde{\zeta})B^{-1}\delta z\|_\zeta,\end{aligned}$$

which gives the claim. ∎

In order to show the γ-continuity (4.2) required for Theorem 4.2, we need the following lemma.

LEMMA 5.2. *Suppose that $c \geq \bar{c}$ and that there exists a constant $\omega \geq 0$ such that*

$$\|(\nabla F_c(z+\delta z) - \nabla F_c(z))\zeta\|_{z+\delta z} \leq \omega\, \|\nabla F_c(z)\delta z\|_z \|\nabla F_c(z)\zeta\|_z \tag{5.5}$$

for all $\zeta \in Z$, $z \in U$, and $\delta z \in Z$ such that $z + \delta z \in U$. Then we have

$$\|S_c(z+\delta z)^{1/2}\zeta\| \leq \sqrt{1 + \omega(1+C_e)\, \|\nabla F_c(x,\lambda)\delta z\|_z}\, \|S_c(z)^{1/2}\zeta\|,$$

where

$$C_e = \sup\left\{ \frac{\|e'(x)\xi\|_Y^2}{\langle L_c''(x,\lambda)\xi,\xi\rangle_X} : (x,\lambda) \in \overline{U}, \xi \in X\backslash\{0\} \right\} > 0.$$

Proof. Let $\zeta = (\zeta_1,\zeta_2)^\mathsf{T} \in Z$ and $z \in U$. From (5.1) and (5.2) we infer

$$\begin{aligned}\|S_c(z+\delta z)^{1/2}\zeta\|^2 &= \langle S_c(z+\delta z)\zeta,\zeta\rangle_Z \\ &= \langle S_c(z)\zeta,\zeta\rangle_Z + \langle (S_c(z+\delta z) - S_c(z))\zeta,\zeta\rangle_Z \\ &\leq \|S_c(z)^{1/2}\zeta\|^2 + \langle (L_c''(z+\delta z) - L_c''(z))\zeta_1,\zeta_1\rangle_X.\end{aligned} \tag{5.6}$$

By assumption, $S_c(z)$ is continuously invertible. Utilizing the Lipschitz assumption (5.5), the second additive term on the right-hand side can be estimated as

$$\begin{aligned}&\langle (L_c''(z+\delta z) - L_c''(z))\zeta_1,\zeta_1\rangle_X \\ &\quad= \langle (\nabla F_c(z+\delta z) - \nabla F_c(z))(\zeta_1,0)^\mathsf{T}, (\zeta_1,0)^\mathsf{T}\rangle_Z \\ &\quad= \langle \nabla F_c(z)S_c(z)^{-1}S_c(z)\nabla F_c(z)^{-1}(\nabla F_c(z+\delta z) - \nabla F_c(z))(\zeta_1,0)^\mathsf{T}, (\zeta_1,0)^\mathsf{T}\rangle_Z \\ &\quad= \langle S_c(z)\nabla F_c(z)^{-1}(\nabla F_c(z+\delta z) - \nabla F_c(z))(\zeta_1,0)^\mathsf{T}, S_c(z)^{-1}\nabla F_c(z)(\zeta_1,0)^\mathsf{T}\rangle_Z \\ &\quad\leq \|S_c(z)^{1/2}\nabla F_c(z)^{-1}(\nabla F_c(z+\delta z) - \nabla F_c(z))(\zeta_1,0)^\mathsf{T}\| \\ &\qquad\cdot \|S_c(z)^{-1/2}\nabla F_c(z)(\zeta_1,0)^\mathsf{T}\| \\ &\quad= \|(\nabla F_c(z+\delta z) - \nabla F_c(z))(\zeta_1,0)^\mathsf{T}\|_z \|S_c(z)^{-1/2}\nabla F_c(z)(\zeta_1,0)^\mathsf{T}\| \\ &\quad\leq \omega\, \|\nabla F_c(z)\delta z\|_z\, \|\nabla F_c(z)(\zeta_1,0)^\mathsf{T}\|_z\, \|S_c(z)^{-1/2}\nabla F_c(z)(\zeta_1,0)^\mathsf{T}\| \\ &\quad\leq \omega\, \|\nabla F_c(z)\delta z\|_z\, \|S_c(z)^{1/2}\zeta\|\, \|S_c(z)^{-1/2}\nabla F_c(z)(\zeta_1,0)^\mathsf{T}\|.\end{aligned}$$

Note that

$$\begin{aligned}&\|S_c(z)^{-1/2}\nabla F_c(z)(\zeta_1,0)^{\mathsf{T}}\|^2\\&\quad=\langle\nabla F_c(z)(\zeta_1,0)^{\mathsf{T}},S_c(z)^{-1}\nabla F_c(z)(\zeta_1,0)^{\mathsf{T}}\rangle_Z=\langle L_c''(z)\zeta_1,\zeta_1\rangle_X+\|e'(x)\zeta_1\|_Y^2\\&\quad\le(1+C_e)\ \langle L_c''(z)\zeta_1,\zeta_1\rangle_X=(1+C_e)\ \|S_c(z)^{1/2}(\zeta_1,0)^{\mathsf{T}}\|^2.\end{aligned}$$

This implies

$$\langle(L_c''(z+\delta z)-L_c''(z))\zeta_1,\zeta_1\rangle_X\le\omega(1+C_e)\ \|\nabla F_c(z)\delta z\|_z\ \|S_c(z)^{1/2}\zeta\|^2. \tag{5.7}$$

Inserting (5.7) into (5.6), the claim follows. ∎

PROPOSITION 5.3. *Let all hypotheses of Lemma* 5.2 *be satisfied. Then* $\{\|\cdot\|_z\}_{z\in U}$ *is an* $\omega(3+C_e)/2$*-continuous family of invariant norms with*

$$\|\zeta\|_Z\le\frac{1}{\sqrt{\tilde\kappa}}\ \|\nabla F_c(z)\zeta\|_z \tag{5.8}$$

for all $\zeta\in Z$ *and* $z\in U$*, where* $\tilde\kappa>0$ *was introduced in* (2.3).

Proof. From (5.3) it follows that

$$\begin{aligned}\|r\|_{z+\delta z}&\le\|S_c(z+\delta z)^{1/2}\nabla F_c(z)^{-1}r\|\\&\quad+\|S_c(z+\delta z)^{1/2}(\nabla F_c(z+\delta z)^{-1}-\nabla F_c(z)^{-1})r\|.\end{aligned}$$

We estimate the additive terms on the right-hand side separately. Using Lemma 5.2 we find

$$\|S_c(z+\delta z)^{1/2}\nabla F_c(z)^{-1}r\|\le\sqrt{1+\omega(1+C_e)\|\nabla F_c(z)\delta z\|_z}\|r\|_z.$$

Applying (5.3) and (5.5) we obtain

$$\begin{aligned}&\|S_c(z+\delta z)^{1/2}(\nabla F_c(z+\delta z)^{-1}-\nabla F_c(z)^{-1})r\|\\&\quad=\|S_c(z+\delta z)^{1/2}\nabla F_c(z+\delta z)^{-1}(\nabla F_c(z)-\nabla F_c(z+\delta z))\nabla F_c(z)^{-1}r\|\\&\quad=\|(\nabla F_c(z)-\nabla F_c(z+\delta z))\nabla F_c(z)^{-1}r\|_{z+\delta z}\le\omega\ \|\nabla F_c(z)\delta z\|_z\|r\|_z.\end{aligned}$$

Hence, using $\sqrt{1+x}\le1+x/2$ for $x\ge0$,

$$\|r\|_{z+\delta z}\le\Big(1+\frac{\omega}{2}(3+C_e)\|\nabla F_c(z)\delta z\|_z\Big)\|r\|_z,$$

and it follows that $\{\|\cdot\|_z\}_{z\in U}$ is an $\omega(3+C_e)/2$-continuous family of invariant norms. Finally, from

$$\begin{aligned}\|\nabla F_c(z)\zeta\|_z^2&=\langle S_c(z)\nabla F_c(z)^{-1}\nabla F_c(z)\zeta,\nabla F_c(z)^{-1}\nabla F_c(z)\zeta\rangle_Z\\&=\langle S_c(z)\zeta,\zeta\rangle_Z\ge\tilde\kappa\ \|\zeta\|_Z^2\end{aligned}$$

we infer (5.8). ∎

5.2. Second invariant norm. In section 5.1 we introduced an invariant norm, provided the augmentation parameter in Algorithm 1 satisfies $c\ge\bar c$. But in many applications the constant $\bar c$ is not explicitly known. Thus, $L_c''(x,\lambda)^{-1}$ need not to be bounded for $c\in[0,\bar c)$, so that $S_c(x,\lambda)$ given by (5.1) might be singular. To overcome these difficulties we define a second invariant norm that is based on a splitting $X=$

$\ker e'(x) \oplus \bar{X}$ such that at least the coercivity of $L_0''(x,\lambda)$ on $\ker e'(x)$ can be utilized. Even though the thus-defined norm can be used with $c = 0$, a larger value of c may improve the global convergence properties—see [16, section 2.3].

To begin with, let us introduce the bounded linear operator $T_c(x,\lambda) : \ker e'(x) \times Y \to X$ by

$$T_c(x,\lambda) = (L_c''(x,\lambda)\ \ e'(x)^\star) \quad \text{for } (x,\lambda) \in U \text{ and } c \geq 0.$$

LEMMA 5.4. *For every $(x,\lambda) \in U$ and $c \geq 0$ the operator $T_c(x,\lambda)$ is an isomorphism.*

Proof. Let $r \in X$ be arbitrary. Then the equation $T_c(x,\lambda)\zeta = r$ for $\zeta = (\zeta_1,\zeta_2)^\mathsf{T} \in \ker e'(x) \times Y$ is equivalent to

$$\nabla F_c(x,\lambda) \begin{pmatrix} \zeta_1 \\ \zeta_2 \end{pmatrix} = \begin{pmatrix} r \\ 0 \end{pmatrix}. \tag{5.9}$$

Due to Remark 2.6 the operator $\nabla F_c(x,\lambda)$ is continuously invertible for all $(x,\lambda) \in U$ and $c \geq 0$. Thus, ζ is uniquely determined by (5.9), and the claim follows. ∎

We define the bounded linear operator $R_c(x,\lambda) : \ker e'(x) \times Y \to Z$ as

$$R_c(x,\lambda) = \begin{pmatrix} L_c''(x,\lambda) & 0 \\ 0 & I \end{pmatrix} \quad \text{for } (x,\lambda) \in U \text{ and } c \geq 0. \tag{5.10}$$

Note that $R_c(x,\lambda)$ is coercive and self-adjoint. Next we introduce the invariant norm

$$\|(r_1,r_2)^T\|_z^2 = \langle R_c(z)T_c(z)^{-1}r_1, T_c(z)^{-1}r_1\rangle_{Z\times Y} + \|r_2\|_Y^2 \tag{5.11}$$

for $z \in U$ and $(r_1,r_2)^T \in Z$. To shorten notation, we write $\|R_c(z)^{1/2}T_c(z)^{-1}r_1\|^2$ for the first additive term.

PROPOSITION 5.5. *For every $z \in U$ the mapping given by* (5.11) *is an affine invariant norm for* (OS)*, which is equivalent to the usual norm on Z.*

Proof. Let $z \in U$ be arbitrary. Since $R_c(z)$ is coercive and $T_c(z)$ is continuously invertible, it follows that $\|\cdot\|_z$ defines a norm which is indeed equivalent to the usual norm on Z. Now we prove the invariance property (4.1). For $(x,\lambda) = (\tilde{B}y,\xi) \in U$ we have

$$(\tilde{B}^\star L_c''(y,\xi)\tilde{B}\ \ \tilde{B}^\star e'(y)^\star) = B^\star T_c(x,\lambda) \begin{pmatrix} B & 0 \\ 0 & I \end{pmatrix}. \tag{5.12}$$

Utilizing (3.3), (5.11), and (5.12) the invariance property follows. ∎

The following proposition guarantees that $\{\|\cdot\|_z\}_{z\in U}$ is a γ-continuous family of invariant norms for (OS).

PROPOSITION 5.6. *Suppose that there exists a constant $\omega \geq 0$ such that*

$$\|(\nabla F_c(z+\delta z) - \nabla F_c(z))\zeta\|_{z+\delta z} \leq \omega\ \|\nabla F_c(z)\delta z\|_z \|\nabla F_c(z)\zeta\|_z \tag{5.13}$$

for all $\zeta \in Z$, $z \in U$, and $\delta z \in Z$ such that $z + \delta z \in U$. Then we have

$$\|r\|_{z+\delta z} \leq \Big(1 + \frac{3\omega}{2}\ \|\nabla F_c(z)\delta z\|_z\Big)\|r\|_z.$$

For the proof of the previous proposition, we will use the following lemmas.

LEMMA 5.7. *With the assumption of Proposition* 5.6 *holding and* $z = (x, \lambda)$*, it follows that*

$$\|R_c(z+\delta z)^{1/2}\zeta\| \le \sqrt{1+\omega\|\nabla F_c(z)\delta z\|_z}\,\|R_c(z)^{1/2}\zeta\|$$

for all $\zeta \in \ker e'(x) \times Y$ *and* $c \ge 0$.

Proof. Let $z = (x,\lambda) \in U$ and $\zeta = (\zeta_1,\zeta_2)^{\mathsf{T}} \in \ker e'(x) \times Y$. Using (5.10) and (5.11) we obtain

$$\|R_c(z+\delta z)^{1/2}\zeta\|^2 \le \|R_c(z)^{1/2}\zeta\|^2 + \langle (L_c''(z+\delta z) - L_c''(z))\zeta_1, \zeta_1\rangle_X. \tag{5.14}$$

For all $c \ge 0$ the operator $R_c(z)$ is continuously invertible. Furthermore, $R_c(z)$ is self-adjoint. Thus, applying (5.13) and

$$\nabla F_c(z)(\zeta_1,0)^{\mathsf{T}} = T_c(z)(\zeta_1,0)^{\mathsf{T}} = R_c(z)(\zeta_1,0)^{\mathsf{T}},$$

we can estimate the second additive term on the right-hand side of (5.14) as

$$\begin{aligned}
&\langle (L_c''(z+\delta z) - L_c''(z))\zeta_1,\zeta_1\rangle_X \\
&\quad = \langle T_c(z)R_c(z)^{-1}R_c(z)T_c(z)^{-1}(L_c''(z+\delta z) - L_c''(z))\zeta_1,\zeta_1\rangle_Z \\
&\quad = \langle R_c(z)T_c(z)^{-1}(L_c''(z+\delta z) - L_c''(z))\zeta_1, R_c(z)^{-1}T_c(z)^{\star}\zeta_1\rangle_{Z\times Y} \\
&\quad \le \|R_c(z)^{1/2}T_c(z)^{-1}(L_c''(z+\delta z) - L_c''(z))\zeta_1\|\ \|R_c(z)^{-1/2}T_c(z)^{\star}\zeta_1\| \\
&\quad \le \|(\nabla F_c(z+\delta z) - \nabla F_c(z))(\zeta_1,0)^{\mathsf{T}}\|_z\ \|R_c(z)^{-1/2}T_c(z)^{\star}\zeta_1\| \\
&\quad \le \omega\|\nabla F_c(z)\delta z\|_z\|\nabla F_c(z)(\zeta_1,0)^{\mathsf{T}}\|_z\|R_c(z)^{1/2}(\zeta_1,0)^{\mathsf{T}}\| \\
&\quad = \omega\ \|\nabla F_c(z)\delta z\|_z\|R_c(z)^{1/2}\zeta\|^2.
\end{aligned}$$

Inserting this bound in (5.14), the claim follows. ∎

LEMMA 5.8. *Let the assumptions of Theorem* 5.6 *be satisfied. Then*

$$\|((T_c(z+\delta z) - T(z))T_c(z)^{-1}r, 0)^{\mathsf{T}}\|_{z+\delta z} \le \omega\|\nabla F_c(z)\delta z\|_z\|(r,0)^{\mathsf{T}}\|_z \quad \textit{for all } r \in X.$$

Proof. For arbitrary $r \in X$ we set $\zeta = (\zeta_1,\zeta_2)^{\mathsf{T}} = T_c(z)^{-1}r$. Using (5.9) and (5.13) we estimate

$$\begin{aligned}
&\|((T_c(z+\delta z) - T_c(z))T_c(z)^{-1}r,0)^{\mathsf{T}}\|_{z+\delta z} \\
&\quad \le \|(\nabla F_c(z+\delta z) - \nabla F_c(z))(\zeta_1,\zeta_2)^{\mathsf{T}}\|_{z+\delta z} \le \omega\ \|\nabla F_c(z)\delta z\|_z\|\nabla F_c(z)(\zeta_1,\zeta_2)^{\mathsf{T}}\|_z \\
&\quad = \omega\ \|\nabla F_c(z)\delta z\|_z\|(r,0)^{\mathsf{T}}\|_z,
\end{aligned}$$

so that the claim follows. ∎

Proof of Proposition 5.6. Let $z, z+\delta z \in U$. Utilizing (5.11) and Lemmas 5.7 and 5.8 we find

$$\begin{aligned}
\|(r_1,0)^{\mathsf{T}}\|_{z+\delta z} &= \|R_c(z+\delta z)^{1/2}T_c(z+\delta z)^{-1}r_1\| \\
&\le \|R_c(z+\delta z)^{1/2}T_c(z)^{-1}r_1\| + \|R_c(z+\delta z)^{1/2}(T_c(z+\delta z)^{-1} - T_c(z)^{-1})r_1\| \\
&\le \sqrt{1+\omega\|\nabla F_c(z)\delta z\|_z}\|(r_1,0)^{\mathsf{T}}\|_z + \|((T_c(z) - T_c(z+\delta z))T_c(z)^{-1}r_1,0)^{\mathsf{T}}\|_{z+\delta z} \\
&\le \sqrt{1+\omega\|\nabla F_c(z)\delta z\|_z}\|(r_1,0)^{\mathsf{T}}\|_z + \omega\|\nabla F_c(z)\delta z\|_z\|(r_1,0)^{\mathsf{T}}\|_z \\
&\le \Big(1 + \frac{3\omega}{2}\ \|\nabla F_c(z)\delta z\|_z\Big)\|(r_1,0)^{\mathsf{T}}\|_z,
\end{aligned}$$

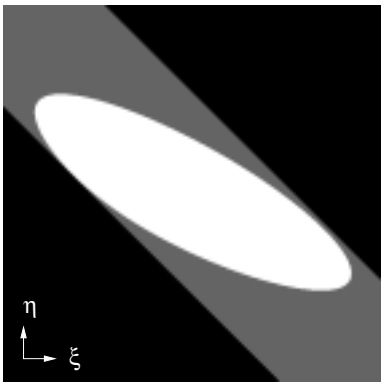

FIG. 5.1. *Illustration for Examples* 3.2 *and* 5.10. *Neighborhood* $U(x^*)$ *(gray) and affine invariant domain of theoretically assured convergence (white).*

and therefore

$$\begin{aligned}\|r\|_{z+\delta z}^2 &= \|(r_1,0)^{\mathsf{T}}\|_{z+\delta z}^2 + \|r_2\|^2 \\ &\le \Big(1+\frac{3\omega}{2}\,\|\nabla F_c(z)\delta z\|_z\Big)^2 \|(r_1,0)^{\mathsf{T}}\|_z^2 + \|r_2\|^2 \\ &\le \Big(1+\frac{3\omega}{2}\,\|\nabla F_c(z)\delta z\|_z\Big)\|r\|_z^2.\end{aligned}$$

Hence, $\{\|\cdot\|_z\}_{z\in U}$ is a $3\omega/2$-continuous family of invariant norms. ∎

Remark 5.9. Note that the Lipschitz constant of the second norm does not involve C_e and hence is independent of the choice of c. In contrast, choosing c too small may lead to a large Lipschitz constant of the first norm and thus can affect the algorithm.

Example 5.10. Let us return to Example 3.2. Using the second norm with $c = 0$, the theoretically assured, affine invariant domain of convergence is shown in Figure 5.1, to be compared with Figures 3.1(b) and (d). Its shape and size is clearly more similar to the noninvariant domain of convergence for the "better" formulation and, by definition, does not change when the coordinates change.

5.3. Computational efficiency. The affine invariance of the two norms developed in the previous sections does not come free: the evaluation of the norms is more involved than the evaluation of some standard norm.

Nevertheless, the computational overhead of the first norm defined in section 5.1 is almost negligible, since it can in general be implemented by one additional matrix vector multiplication. It requires, however, a sufficiently large parameter c.

On the other hand, the second norm defined in section 5.2 works for arbitrary $c \ge 0$ but requires one additional system solve with the same Jacobian but different right-hand side. In the case in which a factorization of the matrix is available, the computational overhead is negligible—compare the CPU times of the exact Newton method in section 7. If, however, the system is solved iteratively, the additional system solve may incur a substantial cost, in which case the first norm should be preferred.

5.4. Connection to the optimization problem. When solving optimization problems of type (P), feasibility $e(x) = 0$ and optimality are the relevant quantities. This is well reflected by the proposed norms $\|\cdot\|_z$. Let $z = (x, \lambda)$ and

$\Delta z = (\Delta x, \Delta\lambda)^{\mathsf{T}} = -\nabla F_c(z)^{-1} F_c(z)$. Using Taylor's theorem (see [19, p. 148]) and the continuity of L_0'', we obtain for the first norm

$$\begin{aligned}
\|F_c(z)\|_z^2 &= \langle S_c(z)\Delta z, \Delta z\rangle_Z \\
&= \langle L_c''(z)\Delta x, \Delta x\rangle_X + \|\Delta\lambda\|_Y^2 \\
&= \langle L_0''(z)\Delta x, \Delta x\rangle_X + c\|e'(x)\Delta x\|_Y^2 + \|\Delta\lambda\|_Y^2 \\
&= \langle L_0''(z^*)\Delta x, \Delta x\rangle_X + o(\|z^* - z\|_Z^2) + c\|e'(x)\Delta x\|_Y^2 + \|\Delta\lambda\|_Y^2 \\
&= 2(L_0(z) - L_0(z^*)) + o(\|z^* - z\|_Z^2) + c\|e(x)\|_Y^2 + \|\Delta\lambda\|_Y^2 \\
&= 2\big(J(x) - J(x^*) - \langle\lambda, e(x)\rangle_Y\big) + c\|e(x)\|_Y^2 + \|\Delta\lambda\|_Y^2 + o(\|z^* - z\|_Z^2).
\end{aligned}$$

The second norm is based on the partitioning $F_c(x,\lambda) = (L_c'(x,\lambda), e(x))^{\mathsf{T}}$ and correspondingly on a splitting of the Newton correction into an *optimizing* direction $\nabla F_c(x,\lambda)(\zeta_1,\zeta_2)^{\mathsf{T}} = -(L_c'(x,\lambda), 0)^{\mathsf{T}}$ tangential to the constraints manifold and a *feasibility* direction $\nabla F_c(x,\lambda)(\xi_1,\xi_2)^{\mathsf{T}} = -(0, e(x))^{\mathsf{T}}$. Since $e'(x)\zeta_1 = 0$, we have for $z = (x,\lambda)$

$$\begin{aligned}
\|F_c(z)\|_z^2 &= \langle L_c''(z)\zeta_1, \zeta_1\rangle_X + \|\zeta_2\|_Y^2 + \|e(x)\|_Y^2 \\
&= \langle L_0''(z)\zeta_1, \zeta_1\rangle_X + \|\zeta_2\|_Y^2 + \|e(x)\|_Y^2 \\
&= \langle L_0''(z^*)\zeta_1, \zeta_1\rangle_X + o(\|z^* - z\|_Z^2) + \|\zeta_2\|_Y^2 + \|e(x)\|_Y^2 \\
&= 2(L_0(z) - L_0(z^*)) + \|\zeta_2\|_Y^2 + \|e(x)\|_Y^2 + o(\|z^* - z\|_Z^2) \\
&= 2\big(J(x) - J(x^*) - \langle\lambda, e(x)\rangle_Y\big) + \|e(x)\|_Y^2 + \|\zeta_2\|_Y^2 + o(\|z^* - z\|_Z^2).
\end{aligned}$$

Recall that $\Delta\lambda = \zeta_2 + \xi_2$. Thus, in the proximity of the solution, both affine invariant norms measure the quantities we are interested in when solving optimization problems, in addition to the error in the Lagrange multiplier and the optimizing direction's Lagrange multiplier component, respectively.

6. Inexact augmented Lagrangian-SQP methods. Taking into account discretization errors or truncation errors resulting from iterative solution of linear systems, we have to consider inexact Newton methods, where an inner residual remains:

$$\begin{aligned}
\nabla F_c(z^k)\delta z^k &= -F_c(z^k) + r^k, \\
z^{k+1} &= z^k + \delta z^k.
\end{aligned} \tag{6.1}$$

Such inexact Newton methods have been studied in a nonaffine invariant setting by Dembo, Eisenstat, and Steihaug [4] and Bank and Rose [1].

With slightly stronger assumptions than before and a suitable control of the inner residual, a similar convergence theory can be established as in section 4.

Note that exact affine invariance is preserved only in the case in which the inner iteration is affine invariant, too.

THEOREM 6.1. *Assume that Assumption* 1 *holds and that there are constants* $\omega \geq 0$, $\gamma \geq 0$, *and a* γ*-continuous family of affine invariant norms* $\{\|\cdot\|_z\}_{z\in U}$ *such that the operator* ∇F_c *satisfies*

$$\|(\nabla F_c(z + s\delta z) - \nabla F_c(z))\delta z\|_{z+\eta\delta z} \leq \omega s\|\nabla F_c(z)\delta z\|_z^2 \tag{6.2}$$

for $s, \eta \in [0,1]$, $z \in U$, *and* $\delta z \in Z$ *such that* $z + \delta z \in U$. *Choose some* $0 < \Theta < 1$ *and define the level sets*

$$\mathcal{L}(z) = \Big\{\zeta \in U : \|F_c(\zeta)\|_\zeta \leq \Big(1 + \frac{\gamma\Theta}{2\omega}\Big)\|F_c(z)\|_z\Big\}.$$

Suppose that $z^0 \in U$ and that $\mathcal{L}(z^0)$ is closed. If the inner residual r^k resulting from the inexact solution of the Newton correction (6.1) *is bounded by*

$$\|r^k\|_{z^k} \le \delta_k \, \|F_c(z^k)\|_{z^k}, \tag{6.3}$$

where

$$(1+\gamma\|\nabla F_c(z^k)\delta z^k\|_{z^k})\delta_k + (1+\delta_k)\frac{\omega}{2}\|\nabla F_c(z^k)\delta z^k\|_{z^k} \le \Theta, \tag{6.4}$$

then the iterates stay in U and the residuals converge to zero as $k \to \infty$ at a rate of

$$\|F_c(z^{k+1})\|_{z^{k+1}} \le \Theta \|F_c(z^k)\|_{z^k}. \tag{6.5}$$

Proof. Analogously to the proof of Theorem 4.2, one obtains

$$F_c(z^k+\eta\delta z^k) = (1-\eta)F_c(z^k) + \eta r^k + \int_0^\eta (\nabla F_c(z^k+s\delta z^k) - \nabla F_c(z^k))\delta z^k \, ds \tag{6.6}$$

for all $\eta \in [0,1]$. Using (6.6), (6.2), (4.2), and (6.3), we find for $\phi \in [0,1]$

$$\begin{aligned}
&\|F_c(z^k+\eta\delta z^k)\|_{z^k+\phi\delta z^k} \\
&\quad \le (1-\eta)\|F_c(z^k)\|_{z^k+\phi\delta z^k} + \eta\|r^k\|_{z^k+\phi\delta z^k} + \int_0^\eta s\omega\|\nabla F_c(z^k)\delta z^k\|_{z^k}^2 \, ds \\
&\quad \le (1+\gamma\phi\|\nabla F_c(z^k)\delta z^k\|_{z^k}) \left((1-\eta)\|F_c(z^k)\|_{z^k} + \eta\|r^k\|_{z^k}\right) \\
&\qquad + \frac{\omega\eta^2}{2} \, \|\nabla F_c(z^k)\delta z^k\|_{z^k}^2 \\
&\quad \le (1+\gamma\phi\|\nabla F_c(z^k)\delta z^k\|_{z^k})(1-\eta+\delta_k\eta)\|F_c(z^k)\|_{z^k}) \\
&\qquad + \frac{\omega\eta^2}{2} \, \|\nabla F_c(z^k)\delta z^k\|_{z^k}^2.
\end{aligned} \tag{6.7}$$

From (6.1) and (6.3) we have

$$(1-\delta_k)\|F_c(z^k)\|_{z^k} \le \|\nabla F_c(z^k)\delta z^k\|_{z^k} = \|F_c(z^k) - r^k\|_{z^k} \le (1+\delta_k)\|F_c(z^k)\|_{z^k} \tag{6.8}$$

and thus, setting $\phi = \eta$ in (6.7) and $\chi = \gamma\|\nabla F_c(z^k)\delta z^k\|_{z^k}$ and using (6.4), it follows that

$$\begin{aligned}
&\frac{\|F_c(z^k+\eta\delta z^k)\|_{z^k+\eta\delta z^k}}{\|F_c(z^k)\|_{z^k}} \\
&\quad \le (1+\gamma\eta\|\nabla F_c(z^k)\delta z^k\|_{z^k})(1-\eta+\delta_k\eta) + (1+\delta_k)\frac{\omega\eta^2}{2}\|\nabla F_c(z^k)\delta z^k\|_{z^k} \\
&\quad \le (1+\eta\chi)(1-\eta) + (1+\eta\chi)\delta_k\eta + (1+\delta_k)\frac{\omega\eta^2}{2}\|\nabla F_c(z^k)\delta z^k\|_{z^k} \\
&\quad \le (1+\eta\chi)(1-\eta) + \eta\Theta \\
&\quad \le 1 - \eta(1-\Theta) + \eta(1-\eta)\chi.
\end{aligned} \tag{6.9}$$

From (6.4) we have $\|\nabla F_c(z^k)\delta z^k\|_{z^k} \le 2\Theta/\omega$. Since $1-\Theta > 0$, we conclude that

$$\|F_c(z^k+\eta\delta z^k)\|_{z^k+\eta\delta z^k} \le \Big(1+\frac{\gamma\Theta}{2\omega}\Big)\|F_c(z^k)\|_{z^k}. \tag{6.10}$$

If $z^{k+1} \notin U$, then there is some $\eta^* \in [0,1]$ such that $\mathrm{co}\{z^k, z^k+\eta\delta z^k\} \subset U$ for $\eta \in [0,\eta^*)$ and $z^k+\eta^*\delta z^k \notin \mathcal{L}(z^k)$, i.e., $\|F_c(z^k+\eta^*\delta z^k)\|_{z^k+\eta^*\delta z^k} > (1+\gamma\Theta/(2\omega))\|F_c(z^k)\|_{z^k}$, which contradicts (6.10). Thus, $z^{k+1} \in U$. Furthermore, inserting $\eta = 1$ into (6.9) yields

$$\|F_c(z^{k+1})\|_{z^{k+1}} \le \Theta\|F_c(z^k)\|_{z^k},$$

and therefore $\mathcal{L}(z^{k+1}) \subset \mathcal{L}(z^k)$ is closed. ∎

The next corollary follows analogously as Corollary 4.4.

COROLLARY 6.2. *If, in addition to the assumptions of Theorem* 6.1*, there exists a constant* $\hat{C} > 0$ *such that*

$$\|\zeta\|_Z \le \hat{C}\|\nabla F_c(z)\zeta\|_z$$

for all $\zeta \in Z$ *and* $z \in U$*, then the iterates converge to the solution* $z^* = (x^*, \lambda^*)$ *of* (OS).

For actual implementation of an inexact Newton method following Theorem 6.1, we need to satisfy the accuracy requirement (6.4). Thus, we need not only an error estimator for the inner iteration computing δ_k but also easily computable estimates $[\omega]$ and $[\gamma]$ for the Lipschitz constants ω and γ in case no suitable theoretical values can be derived. Setting $\eta = 1$ in (6.6), we readily obtain

$$\|F_c(z^{k+1}) - r^k\|_{z^k} \le \frac{\omega}{2}\|\nabla F_c(z^k)\delta z^k\|^2_{z^k}$$

and hence a lower bound

$$\frac{2\ \|F_c(z^{k+1}) - r^k\|_{z^k}}{\|\nabla F_c(z^k)\delta z^k\|^2_{z^k}} \le \omega.$$

Unfortunately, the norms involve solutions of Newton-type systems and therefore cannot be computed exactly. Assuming the relative accuracy of evaluating the norms are $\hat{\delta}_k$ and $\tilde{\delta}_k$, respectively, we define the actually computable estimate

$$[\omega]_k = 2\frac{1-\hat{\delta}_k}{(1+\tilde{\delta}_k)^2}\frac{\|F_c(z^{k+1}) - r^k\|_{z^k}}{\|\nabla F_c(z^k)\delta z^k\|^2_{z^k}} \le \omega.$$

We would like to select a δ_k such that the accuracy matching condition (6.4) is satisfied. Unfortunately, due to the local sampling of the global Lipschitz constant ω and the inexact computation of the norms, the estimate $[\omega]_k$ is possibly too small, translating into a possibly too large tolerance for the inexact Newton correction. In order to compensate for that, we introduce a safety factor $\rho < 1$ and require the approximate accuracy matching condition

$$(1+[\gamma]_k\|\nabla F_c(z^k)\delta z^k\|_{z^k})\delta_k + (1+\delta_k)\frac{[\omega]_k}{2}\|\nabla F_c(z^k)\delta z^k\|_{z^k} \le \rho\Theta \tag{6.11}$$

to hold. An obvious choice for ρ would be $(1-\hat{\delta}_k)/(1+\tilde{\delta}_k)$. From Propositions 5.3 and 5.6 we infer that γ is of the same order of magnitude as ω. Thus we take the estimate

$$[\gamma]_k = 3[\omega]_k/2,$$

currently ignoring C_e when using the first norm.

Again, the convergence monitor (4.7) can be used to detect nonconvergence. In the inexact setting, however, the convergence monitor may also fail due to δ_k chosen too large. Therefore, whenever (4.7) is violated and a reduction of δ_k is promising (e.g., $(1+([\gamma]_k+[\omega]_k/2)\|\nabla F_c(z^k)\delta z^k\|_{z^k})\delta_k \geq [\omega]_k/10\|\nabla F_c(z^k)\delta z^k\|_{z^k}$), the Newton correction should be recomputed with reduced δ_k.

Remark 6.3. If an inner iteration is used for approximately solving the Newton equation (6.1) which provides the *orthogonality relation* $(\delta z^k, \Delta z^k - \delta z^k)_{z^k} = 0$ in a scalar product $(\cdot,\cdot)_{z^k}$ that induces the affine invariant norm, the estimate (6.11) can be tightened by substituting $(1+\delta_k)^2$ by $1+\delta_k^2$. Furthermore, the norm $\|\Delta z^k\|_{z^k}$ of the exact Newton correction is computationally available, which permits the construction of algorithms that are robust even for large inaccuracies δ_k. The application of a conjugate gradient method that is confined to the null space of the linearized constraints [2] to augmented Lagrangian-SQP methods can be the focus of future research.

7. Numerical experiments. This section is devoted to presenting numerical tests for Example 2.1 that illustrate the theoretical investigations of the previous sections. To solve (P) we apply the so-called optimize-then-discretize approach: we compute an approximate solution by discretizing Algorithm 1, i.e., by discretizing the associated system (2.6). In the context of Example 2.1 we have $x^k = (y^k, u^k, v^k)$, $\delta x = (\delta y, \delta u, \delta v) \in W(0,T)\times L^2(0,T)\times L^2(0,T)$. To reduce the size of the system we take advantage of a relationship between the SQP steps δu, δv for the controls and the SQP step $\delta\lambda$ for the Lagrange multiplier. In fact, from

$$\begin{aligned}
\frac{\partial^2 L_0}{\partial u^2}(x^k,\tilde{\lambda}^k)\delta u + \frac{\partial e}{\partial u}(x^k)^\star \delta\lambda &= -\frac{\partial L_0}{\partial u}(x^k,\tilde{\lambda}^k),\\
\frac{\partial^2 L_0}{\partial v^2}(x^k,\tilde{\lambda}^k)\delta v + \frac{\partial e}{\partial v}(x^k)^\star \delta\lambda &= -\frac{\partial L_0}{\partial v}(x^k,\tilde{\lambda}^k)
\end{aligned}$$

we infer that

$$\begin{aligned}
\delta u &= -\frac{1}{\alpha}\Big(\tilde{\lambda}^k(\cdot,0) - \lambda^k(\cdot,0) + \delta\lambda(\cdot,0)\Big) \quad \text{in } (0,T),\\
\delta v &= \frac{1}{\beta}\Big(\tilde{\lambda}^k(\cdot,1) - \lambda^k(\cdot,1) + \delta\lambda(\cdot,1)\Big) \qquad \text{in } (0,T),
\end{aligned} \tag{7.1}$$

where $\tilde{\lambda}^k = \lambda^k + ce(x^k)$ by step (b) of Algorithm 1. Inserting (7.1) into (2.6) we obtain a system only in the unknowns $(\delta y, \delta\lambda)$. Note that the second Fréchet-derivative of the Lagrangian is given by

$$\langle L_0''(x^k,\tilde{\lambda}^k)\zeta,\xi\rangle_X = \int_Q \zeta_1\xi_1\big(1+2\tilde{\lambda}^k\big)\,dx + \int_0^T \alpha\zeta_2\xi_2 + \beta\zeta_3\xi_3\,dt$$

for $\zeta = (\zeta_1, \zeta_2, \zeta_3)$, $\xi = (\xi_1, \xi_2, \xi_3) \in X$. The solution $(\delta y, \delta u, \delta v, \delta\lambda)$ of (2.6) is computed as follows: First we solve

$$
\begin{aligned}
y_t - \nu y_{xx} + (y^k y)_x &= -e^k && \text{in } Q,\\
\nu y_x(\cdot,0) + \sigma_0 y(\cdot,0) + \frac{\lambda(\cdot,0)}{\alpha} &= \frac{1}{\alpha}\left(\lambda^k(\cdot,0) - \tilde\lambda^k(\cdot,0)\right) && \text{in } (0,T),\\
\nu y_x(\cdot,1) + \sigma_1 y(\cdot,1) - \frac{\lambda(\cdot,1)}{\beta} &= \frac{1}{\beta}\left(\tilde\lambda^k(\cdot,1) - \lambda^k(\cdot,1)\right) && \text{in } (0,T),\\
y(0,\cdot) &= 0 && \text{in } \Omega,\\
(1-\tilde\lambda_x^k)y - \lambda_t - \nu\lambda_{xx} - y^k\lambda_x &= y^k - z && \text{in } Q,\\
\nu\lambda_x(\cdot,0) + (y(\cdot,0)+\sigma_0)\lambda(\cdot,0) &= 0 && \text{in } (0,T),\\
\nu\lambda_x(\cdot,1) + (y(\cdot,1)+\sigma_1)\lambda(\cdot,1) &= 0 && \text{in } (0,T),\\
\lambda(T,\cdot) &= 0 && \text{in } \Omega,
\end{aligned}
\tag{7.2}
$$

where $e^k = y_t^k - \nu y_{xx}^k + y^k y_x^k - f$, and set $\delta y = y$ and $\delta\lambda = \lambda$. Then we obtain δu and δv from (7.1). For more details we refer the reader to [18].

For the time integration we use the backward Euler scheme while the spatial variable is approximated by piecewise linear finite elements. The programs were written in MATLAB, version 5.3, and executed on a Pentium III 550 MHz personal computer.

Run 7.1 (Neumann control). In the first example we choose $T = 1$, $\nu = 0.1$, $\sigma_0 = \sigma_1 = 0$, $f = 0$, and

$$
y_0 = \begin{cases} 1 & \text{in } (0, 0.5],\\ 0 & \text{otherwise.}\end{cases}
$$

The grid is given by

$$
x_i = \frac{i}{50} \quad \text{for } i = 0,\dots,50 \quad \text{and} \quad t_j = \frac{jT}{50} \quad \text{for } j = 0,\dots,50.
$$

To solve (2.1) for $u = v = 0$ we apply the Newton method at each time step. The algorithm needs one second CPU time. The value of the cost functional is 0.081.

Now we turn to the optimal control problem. We choose $\alpha = \beta = 0.01$, and the desired state is $z(t,\cdot) = y_0$ for $t \in (0,T)$. In view of the choice of z and the nonlinear convection term yy_x in (2.1b) we can interpret this problem as determining u in such a way that it counteracts the uncontrolled dynamics which smooths the discontinuity at $x = 0.5$ and transports it to the left as t increases. The discretization of (7.2) leads to an indefinite system,

$$
H^k \begin{pmatrix}\delta y\\ \delta\lambda\end{pmatrix} = r^k \quad \text{with} \quad H^k = \begin{pmatrix} A^k & (B^k)^{\mathsf T}\\ B^k & C^k\end{pmatrix}. \tag{7.3}
$$

As starting values for Algorithm 1 we take $y^0 = 0$, $u^0 = v^0 = 0$, and $\lambda^0 = 0$.

(i) First we solve (7.3) by an LU-factorization (MATLAB routine `lu`) so that the theory of section 4 applies. According to section 4 we stop the SQP iteration if

$$
\|F_c(z^{k+1})\|_{z^k} \le 10^{-3} \cdot \|F_c(z^0)\|_{z^0}. \tag{7.4}
$$

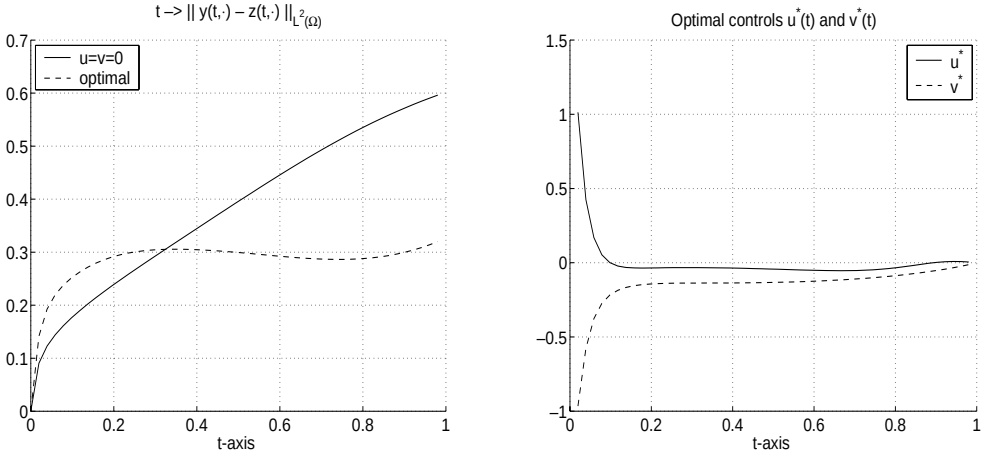

FIG. 7.1. *Run* 7.1*: residuum* $t \mapsto \|y(t,\cdot) - z(t,\cdot)\|_{L^2(\Omega)}$ *and optimal controls.*

In case $\|F_c(z^0)\|_{z^0}$ is very large, the factor 10^{-3} on the right-hand side of (7.4) might be too big. To avoid this situation Algorithm 1 is terminated if (7.4) and, in addition,

$$\|F_c(z^{k+1})\|_{z^k} < 10^{-3}$$

hold. The augmented Lagrangian-SQP method stops after four iterations. The CPU times for different values of c can be found in Tables 7.6 and 7.7. Let us mention that for $c = 0.1$ the algorithm needs 102.7 seconds and for $c = 1$ we observe divergence of Algorithm 1. As it was proved in [15] the set of admissible starting values reduces whenever c enlarges. The value of the cost functional is 0.041. In Figure 7.1 the residuum $t \mapsto \|y(t,\cdot) - z(t,\cdot)\|_{L^2(\Omega)}$ for the solution of (2.1) for $u = v = 0$ as well as for the optimal state is plotted. Furthermore, the optimal controls are presented. The decay of $\|F_c(z^{k+1})\|_{z^k}$, $k = 0, \ldots, 3$, for the first invariant norm given by (5.3) and for different values of c is shown in Table 7.1. Recall that the invariant norm is defined only for $c \geq \bar{c}$. Unfortunately, the constant $\bar{c} \geq 0$ is unknown. We proceed as follows: Choose a fixed value for c and compute

$$[\kappa]_k = \frac{\langle L_c''(x^k, \lambda^k)\delta x, \delta x\rangle_X}{\|\delta x\|_X^2}$$

in each level of the SQP iteration. Whenever $[\kappa]_k$ is greater than zero, we have coercivity in the direction of the SQP step. Otherwise, c needs to be increased. In

TABLE 7.1
Run 7.1(i): *decay of* $\|F_c(z^{k+1})\|_{z^k}$ *for the first norm.*

	$c = 0$	$c = 10^{-3}$	$c = 10^{-2}$

TABLE 7.2
Run 7.1(i): *values of* $[\kappa]_k$ *for different* c.

	$c = 0$	$c = 10^{-3}$	$c = 10^{-2}$
$[\kappa]_0$	0.020	0.020	0.020
$[\kappa]_1$	0.019	0.019	0.020
$[\kappa]_2$	0.004	0.023	0.024
$[\kappa]_3$	0.021	0.022	0.025

TABLE 7.3
Run 7.1(i): *decay of* $\|F_c(z^{k+1})\|_{z^k}$ *for the second norm.*

$\|F_0(z^0)\|_{z^0}$	$\|F_0(z^1)\|_{z^0}$	$\|F_0(z^2)\|_{z^1}$	$\|F_0(z^3)\|_{z^2}$	$\|F_0(z^4)\|_{z^3}$
26.77865	4.91492	0.63812	0.0105	0.00002

Table 7.2 we present the values for $[\kappa]_k$. We observed numerically that $[\kappa]_k$ is positive for $k = 0, \ldots, 3$. Moreover, $[\kappa]_k$ increased if c increased.

Next we tested the second norm introduced in (5.11) for $c = 0$. Again, the augmented Lagrangian-SQP method stops after four iterations and needs 97.4 seconds CPU time. Thus, both invariant norms lead to a similar performance of Algorithm 1. The decay of $\|F_c(z^{k+1})\|_{z^k}$ can be found in Table 7.3.

(ii) Now we solve (7.3) by an inexact generalized minimum residual (GMRES) method (MATLAB routine `gmres`). For a preconditioner for the GMRES method we took an incomplete LU-factorization of the matrix

$$D = \begin{pmatrix} I & P^{\mathsf{T}} \\ P & 0 \end{pmatrix} \tag{7.5}$$

by utilizing the MATLAB function `luinc(`D`,1e-03)`. Here, the matrix P is the discretization of the heat operator $y_t - \nu y_{xx}$ with the homogeneous Robin boundary conditions $\nu y_x(\cdot, 0) + \sigma_0 y(\cdot, 0) = \nu y_x(\cdot, 1) + \sigma_1 y(\cdot, 1) = 0$ in $(0, T)$. The same preconditioner is used for all Newton steps.

We chose $\Theta_k = 0.6$ for all k. In section 6 we introduced estimators for the constants ω and γ, denoted by $[\omega]_k$ and $[\gamma]_k$, respectively. Thus, for $k \geq 0$ we calculate $[\omega]_k$ and $[\gamma]_k$, and then we determine δ_{k+1} as follows:

$\delta_{k+1} = \Theta_k$;
while $(1 + [\gamma]_k \|\nabla F_c(z^k)\delta z^k\|_{z^k})\delta_{k+1} + (1 + \delta_{k+1})\dfrac{[\omega]_k}{2}\|\nabla F_c(z^k)\delta z^k\|_{z^k} > \rho_k \Theta_k$ **do**
  $\delta_{k+1} = \dfrac{\delta_{k+1}}{2}$;
end (while);

where $\rho_k = (1 + \hat{\delta}_k)/(1 + \tilde{\delta}_k)$ for all $k \geq 0$. For the first norm $\|\nabla F_c(z^k)\delta z^k\|_{z^k}$ is already determined by the computation of the previous Newton correction. Thus we have $\tilde{\delta}_k = \delta_k$, but in the case of the second norm, $\|\nabla F_c(z^k)\delta z^k\|_{z^k}$ has to be calculated with a given tolerance $\tilde{\delta}_k$. In our tests we take $\tilde{\delta}_k = \hat{\delta}_k$ for all $k \geq 0$. As starting values we choose $\delta_0 = 10^{-10}$ and $\hat{\delta}_0 = \delta_0$. We test four strategies for the choice of $\hat{\delta}_k$ for $k \geq 1$: $\hat{\delta}_k = 0.1$, $\hat{\delta}_k = 0.01$, $\hat{\delta}_k = 0.001$, and $\hat{\delta}_k = \delta_k$. It turns out that for $\hat{\delta}_k = 0.1$ we obtain the best performance with respect to CPU times. Hence, in the following test examples we take $\delta_k = 0.1$ for $k \geq 1$.

The decay of $\|F(z^k)\|_{z^k}$ is presented in Table 7.4. Algorithm 1 stops after at most seven iterations. Let us mention that for $c \in \{0, 10^{-3}, 10^{-2}\}$ the estimates $[\kappa]_k$ for the coercivity constant are positive. In particular, for $c = 10^{-2}$ the augmented Lagrangian-SQP method has the best performance. In Table 7.5 the values of the estimators $[\omega]_k$ are presented. In Table 7.6 the CPU times for the first norm are presented. It turns out that the performance of the inexact method does not change significantly for different values of Θ_k. Since we have to solve an additional linear system at each level of the SQP iteration in order to compute the second norm, the first norm leads to a better performance of the inexact method with respect to the CPU time. Compared to part (i) the CPU time is reduced by about 50% if one takes the first norm. In the case of the second norm the reduction is about 45% for $\Theta_k \in \{0.3, 0.4, 0.5, 0.6, 0.6\}$; see Table 7.7. Finally we test the inexact method using

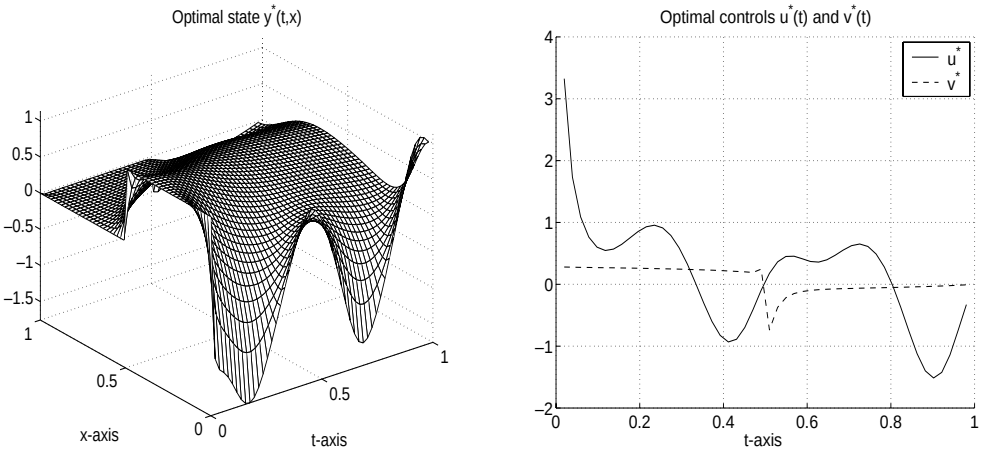

FIG. 7.2. *Run* 7.2*: optimal state and controls.*

decreasing Θ_k. We choose $\Theta_0 = 0.9$ and $\Theta_k = \Theta_{k-1}/2$ for $k \geq 1$. It turns out that this strategy speeds up the inexact method for both norms, as can be expected from the theoretical complexity model developed in [7].

Run 7.2 (Robin control). We choose $T = 1$, $\nu = 0.05$, $\sigma_0(t) = \sin(4\pi t)$, $f = 0$, $\alpha = \beta = 0.01$,

$$\sigma_1 = \begin{cases} -10 & \text{in } \left(0, \frac{T}{2}\right), \\ 0 & \text{otherwise,} \end{cases} \quad \text{and} \quad y_0 = \begin{cases} 1 & \text{in } \left(0, \frac{1}{2}\right), \\ 0 & \text{otherwise.} \end{cases}$$

The desired state was taken to be $z(t, \cdot) = y_0 \cos(4\pi t)$ for $t \in [0, T]$.

(i) First we again solve (7.3) by an LU-factorization. We take the same starting values and stopping criteria as in Run 7.1. The augmented Lagrangian-SQP method stops after four iteration and needs 105 seconds CPU time. The discrete optimal solution is plotted in Figure 7.2. From Table 7.8 it follows that (4.7) is satisfied numerically. Let us mention that $[\kappa]_0, \ldots, [\kappa]_3$ are positive for $c \in \{0, 10^{-3}, 10^{-2}\}$. For the needed CPU times we refer to Tables 7.10 and 7.11.

(ii) Now we solve (7.3) by an inexact GMRES method. For a preconditioner we take the same as in Run 7.1. We choose $\Theta_k = 0.5$ for all k. The decay of $\|F(z^k)\|_{z^k}$ is presented in Table 7.9. As in part (i) we find that $[\kappa]_k > 0$ for all test runs. The needed

CPU times are shown in Tables 7.10 and 7.11. As we can see, the inexact augmented Lagrangian-SQP method with GMRES is much faster than the exact one using the *LU*-factorization. For the first norm the CPU time is reduced by about 55%, and for the second norm by about 50% for $\Theta_k \in \{0.3, 0.4, 0.5, 0.6, 0.7\}$. Moreover, for our example the best choice for c is $c = 10^{-3}$. For smaller values of Θ_k the method does not speed up significantly. As in Run 7.1 we test the inexact method using decreasing Θ_k. Again we choose $\Theta_0 = 0.9$ and $\Theta_k = \Theta_{k-1}/2$ for $k \geq 1$. As in Run 7.1, this strategy speeds up the inexact method significantly for both norms. The reduction is about 9% compared to the CPU times for fixed Θ_k; see Table 7.11.

ROBUST OPTIMAL SWITCHING CONTROL FOR NONLINEAR SYSTEMS*

JOSEPH A. BALL†, JERAWAN CHUDOUNG‡, AND MARTIN V. DAY†

Abstract. We formulate a robust optimal control problem for a general nonlinear system with finitely many admissible control settings and with costs assigned to switching of controls. We formulate the problem both in an L_2-gain/dissipative system framework and in a game-theoretic framework. We show that, under appropriate assumptions, a continuous switching-storage function is characterized as a viscosity supersolution of the appropriate system of quasi-variational inequalities (the appropriate generalization of the Hamilton–Jacobi–Bellman–Isaacs equation for this context) and that the minimal such switching-storage function is equal to the continuous switching lower-value function for the game. Finally, we show how a prototypical example with one-dimensional state space can be solved by a direct geometric construction.

Key words. running cost, switching cost, worst-case disturbance attenuation, differential game, state-feedback control, nonanticipating strategy, storage function, lower-value function, system of quasi-variational inequalities, viscosity solution

1. Introduction.

We consider a state-space system Σ_{sw}

$$\dot{y} = f(y, a, b), \tag{1.1}$$

$$z = h(y, a, b), \tag{1.2}$$

where $y(t) \in \mathbb{R}^N$ is the state, $a(t) \in A$ is the control input, $b(t) \in B \subset \mathbb{R}^M$ is the deterministic unknown disturbance, and $z(t) \in \mathbb{R}$ is the cost function. We assume that the set A of admissible control values is a finite set, $A = \{a^1, \dots, a^r\}$. The control signals $a(t)$ are then necessarily piecewise constant with values in A. We normalize control signals $a(t)$ to be right continuous and refer to the value $a(t)$ as the *new current control* and $a(t^-)$ as the *old current control* at time t. We assume that there is a distinguished input index i_0 for which $f(0, a^{i_0}, 0) = 0$ and $h(0, a^{i_0}, 0) = 0$ so that 0 is an equilibrium point for the autonomous system induced by setting $a(t) = a^{i_0}$ and $b(t) = 0$. In addition, we assume that a cost $k(a^i, a^j) \geq 0$ is assigned at each time instant τ_n at which the controller switches from the old current control $a(\tau_n^-) = a^i$ to the new current control $a(\tau_n) = a^j$. For a given old initial control $a(0^-)$, the associated control decision is to choose switching times

$$0 \leq \tau_1 < \tau_2 < \cdots, \qquad \lim_{n\to\infty} \tau_n = \infty,$$

and controls

$$a(\tau_1),\ a(\tau_2),\ a(\tau_3), \dots$$

such that the controller switches from the old current control $a(\tau_n^-)$ to the new current control $a(\tau_n) \neq a(\tau_n^-)$ at time τ_n, where we set

$$a(t) = \begin{cases} a(0^-), & t \in [0, \tau_1), \\ a(\tau_n), & t \in [\tau_n, \tau_{n+1}),\ n = 1, 2, \dots, \end{cases}$$

if $\tau_1 > 0$ and

$$a(t) = a(\tau_n), \qquad t \in [\tau_n, \tau_{n+1}),\ n = 1, 2, \dots,$$

otherwise. We assume that the state $y(\cdot)$ of (1.1) does not jump at the switching time τ_n; i.e., the solution $y(\cdot)$ is assumed to be absolutely continuous. The cost of running the system up to time $T \geq 0$ with initial state $y(0) = x$, old initial control $a(0^-) = a^j$, control signal a for $t \geq 0$, and disturbance signal b is given by

$$C_{T^-}(x, a^j, a, b) = \int_0^T h(y_x(t, a, b), a(t), b(t))\ dt + \sum_{\tau:\ 0 \leq \tau < T} k(a(\tau^-), a(\tau)).$$

We have used the notation $y_x(\cdot, a, b)$ for the unique solution of (1.1) corresponding to the choices of the initial condition $y(0) = x$, the control $a(\cdot)$, and the disturbance $b(\cdot)$. In what follows, we will often abbreviate $y_x(\cdot, a, b)$ to $y_x(\cdot)$ or $y(\cdot)$; the precise meaning should be clear from the context.

As the running cost $h(y(t), a(t), b(t)) + k(a(t^-), a(t))$, where $a(t^-) = a^j$ if $t = 0$, involves not only the value $y(t)$ of the state along with the value of the control $a(t)$ and the value of the disturbance $b(t)$ at time t but also the value of the old current control $a(t^-)$, it makes sense to think of the old current control $a(t^-)$ at time t as part of an augmented state vector $y^{aug}(t) = (y(t), a(t^-))$ at time t. This can be done formally by including $a(t^-)$ as part of the state vector, in which case a switching control problem becomes an *impulse* control problem (see [10], where problems of this sort are set in the general framework of hybrid systems). We shall keep the switching-control formalism here; however, in implementing optimization algorithms, we shall see that it is natural to consider augmented state-feedback controls $(x, a^j) \to a(x, a^j)$ rather than merely state-feedback controls $x \to a(x)$ in order to obtain solutions. We shall refer to such augmented state-feedback controls $(x, a^j) \to a(x, a^j) \in A$ as simply *switching state-feedback* controllers. Note that, while the augmented state is required to compute the instantaneous running cost at time t, only the (nonaugmented) state vector $y(t)$ at time t is needed to determine the state trajectory past time t for a given input signal $(a(\cdot), b(\cdot))$ past time t.

The precise formulation of our optimal control problem is as follows. First, for a prescribed attenuation level $\gamma > 0$ and a given augmented initial state (x, a^j), we seek an admissible control signal $a(\cdot) = a_{x,j}(\cdot)$ with $a(0^-) = a^j$ so that

$$C_{T^-}(x, a^j, a, b) \leq \gamma^2 \int_0^T |b(t)|^2\ dt + U_\gamma^j(x) \tag{1.3}$$

for all locally L_2 disturbances b, all positive real numbers T, and some nonnegative-valued bias function $U_\gamma^j(x)$ with $U_\gamma^{i_0}(0) = 0$. Note that this inequality corresponds to an input-output system having L_2-gain at most γ, where C_{T^-} replaces the L_2-norm of the output signal over the time interval $[0, T]$, and where the equilibrium point is taken to be $(0, a^{i_0})$ in the augmented state space. The dissipation inequality (1.3) then can be viewed as an L_2-gain inequality, and our problem can be viewed as

the analogue of the nonlinear H^∞-control problem for systems with switching costs (see [20]). In the *switching state-feedback* version of the problem, $a(\cdot)$ is a function of the current state and the current old control; i.e., one decides what control to use at time t based on knowledge of the current augmented state $(y(t), a(t^-))$. In the standard game-theoretic formulation of the problem, $a(\cdot)$ is a nonanticipating function $a(\cdot) = \alpha_x^j[b](\cdot)$ (called a *strategy*) of the disturbance b depending also on the initial state x and initial old control value a^j; i.e., for a given augmented initial state (x, a^j), the computation of the control value $\alpha_x^j[b](t)$ at time t uses knowledge only of the past and current values of the disturbance $b(\cdot)$. Second, we ask for the admissible control a with $a(0^-) = a^j$ (with whatever information structure) which gives the best system performance in the sense that the nonnegative functions $U_\gamma^j(x)$ are as small as possible. A closely related problem formulation is to view the switching-control system as a game with payoff function

$$J_{T^-}(x, a^j, a, b) = \int_{[0,T)} l(y_x(t), a^j, a(t), b(t)), \qquad a(0^-) = a^j,\ j = 1, \dots, r,$$

where we view $l(y_x, a^j, a, b)$ as the measure given by

$$\begin{aligned} l(y(t), a^j, a(t), b(t)) &= [h(y(t), a(t), b(t)) - \gamma^2 |b(t)|^2]\ dt + k(a(t^-), a(t))\delta_t, \\ &\text{with } a(0^-) = a^j, \end{aligned}$$

where δ_t is the unit point-mass distribution at the point t. In this game setting, the disturbance player seeks to use $b(t)$ and T to maximize the payoff, while the control player seeks to use the choice of piecewise-constant right-continuous function $a(t)$ to minimize the payoff. The *switching lower value* $V_\gamma = (V_\gamma^1, \dots, V_\gamma^r)$ of this game is then given by

$$V_\gamma^j(x) = \inf_\alpha \sup_{b,\, T} J_{T^-}(x, a^j, \alpha_x^j[b], b), \quad j = 1, \dots, r, \tag{1.4}$$

where the supremum is over all nonnegative real numbers T and all locally L_2-disturbance signals b, while the infimum is over all nonanticipating control strategies $b \to \alpha_x^j[b]$ depending on the initial augmented state (x, a^j). By letting T tend to 0, we see that each component of the switching lower value $V_\gamma(x) = (V_\gamma^1(x), \dots, V_\gamma^r(x))$ is nonnegative. Then, by construction, $(V_\gamma^1, \dots, V_\gamma^r)$ gives the smallest possible value which can satisfy (1.3) (with V_γ^j in place of U_γ^j) for some nonanticipating strategy $(x, a^j, b) \to \alpha_x^j[b](\cdot) = a(\cdot)$.

In the standard theory of nonlinear H^∞-control, the notion of *storage function* for a dissipative system plays a prominent role (see [20]). For our setting with switching costs, we say that a nonnegative vector function $S_\gamma = (S_\gamma^1, \dots, S_\gamma^r)$ on $\mathbb{R}^N$ is a *switching-storage function* for the system (1.1)–(1.2) with strategy α if, for all $y(0) = x \in \mathbb{R}^N$, b measurable with values in B and $0 \le t_1 < t_2$, the following inequality holds:

$$\begin{aligned} S_\gamma^{j(t_2)}(y_x(t_2, \alpha_x^j[b], b)) - S_\gamma^{j(t_1)}(y_x(t_1, \alpha_x^j[b], b)) \\ \le \int_{t_1}^{t_2} [\gamma^2 |b(s)|^2 - h(y_x(s), \alpha_x^j[b](s), b(s))]\ ds \\ - \sum_{t_1 \le \tau < t_2} k(\alpha_x^j[b](\tau^-), \alpha_x^j[b](\tau)) \end{aligned} \tag{1.5}$$

(where $j(t)$ is specified by $\alpha_x^j[b](t^-) = a^{j(t)}$). The control problem then is to find the switching strategy $\alpha : (x, a^j, b) \to \alpha_x^j[b](\cdot)$ which gives the best performance, as measured by obtaining the minimal possible $S_\gamma(x) = (S_\gamma^1(x), \dots, S_\gamma^r(x))$ as the associated closed-loop switching-storage function. Note that any switching-storage function may serve as the vector bias function $U_\gamma = (U_\gamma^1, \dots, U_\gamma^r)$ in the L_2-gain inequality (1.3) if, in addition, $S_\gamma^{i_0}(0) = 0$. This suggests that the *available switching-storage function* (i.e., the minimal possible switching-storage function over all possible switching strategies) should equal the switching lower-value V_γ (1.4) for the game described above. We shall see that this is indeed the case with appropriate hypotheses imposed.

Our main results concerning the robust optimal switching-cost problem are as follows: *Under minimal smoothness assumptions on the problem data and compactness of the set B, the following hold:*

(i) $V_\gamma^j(x) \le \min_{i \ne j}\{V_\gamma^i(x) + k(a^j, a^i)\},\ x \in \mathbb{R}^N,\ j = 1, \dots, r.$

(ii) *If continuous, V_γ is a viscosity solution in $\mathbb{R}^N$ of the system of quasi-variational inequalities (SQVI) defined in section* 2 *(see* (2.5)*).* (The precise definition of viscosity subsolution, supersolution, and solution will be given in section 2.)

(iii) *If $S_\gamma = (S_\gamma^1, \dots, S_\gamma^r)$ is a continuous switching-storage function for some strategy α, then S_γ is a nonnegative continuous viscosity supersolution of the SQVI* (2.5).

(iv) *If $U_\gamma = (U_\gamma^1, \dots, U_\gamma^r)$ is a nonnegative, continuous viscosity supersolution of the SQVI* (2.5) *and U_γ has the property* (i)*, then there is a canonical choice of switching state-feedback control strategy $\alpha_{U_\gamma} : (x, a^j, b) \to \alpha_{U_\gamma, x}^j[b]$ such that U_γ is a switching-storage function for the closed-loop system formed by using the strategy α_{U_γ}; thus*

$$U_\gamma^j(x) \ge \sup_{b,\ T}\left\{\int_{[0,T)} l(y_x(s), a^j, \alpha_{U_\gamma, x}^j[b](s), b(s))\right\} \ge V_\gamma^j(x).$$

The switching lower-value V_γ, if continuous, is characterized as the minimal, nonnegative continuous viscosity supersolution of (2.5) *having property* (i) *above as well as the minimal continuous function satisfying property* (i)*, which is a switching-storage function for the closed-loop system associated with some nonanticipating strategy α.*

In the precise formulation of our problem, for technical convenience, we impose the condition that the disturbance signals $b(t)$ take values in a bounded subset B of $\mathbb{R}^M$; hence our setup technically does not include the linear-quadratic case (where f is linear and h is quadratic). In general, this issue has been a stumbling block for application of the nonlinear dynamic programming formalism to this class of problems. In [21], this difficulty was overcome by an ad hoc reparametrization technique, whereby the general unbounded case was reduced to the bounded case. This would be one approach to removing the boundedness assumption which we have imposed here; however, see also Remark 1 in section 3 below.

The usual formulation of the H^∞-control problem also involves a stability constraint. We also prove that, under appropriate conditions, the closed-loop system associated with switching strategy α_{U_γ} corresponding to the nonnegative continuous supersolution U_γ of the SQVI is stable. The main idea is to use the supersolution U_γ as a Lyapunov function for trajectories of the closed-loop system. Related stability problems for systems with control switching are discussed, e.g., by Branicky in [11].

Infinite-horizon optimal switching-control problems are discussed in [6, Chapter III, section 4.4] but with a discount factor in the running cost and no disturbance

term. Differential games with switching strategies and switching costs for the case of finite horizon problems is discussed in [23], while the case of an infinite horizon with both control and competing disturbance but with a discount factor in the running cost is discussed in [24]. These authors, under their various assumptions, were able to show that the value function is continuous and is the unique solution of the appropriate system of quasi-variational inequalities. However, our formulation has no discount factor in the running cost, so the running cost is not guaranteed to be integrable over the infinite interval $[0, \infty)$. This forces the introduction of the extra "disturbance player" T in (1.4). We establish a dynamic programming principle (DPP) for this setting and derive from it the appropriate system of quasi-variational inequalities (SQVI) to be satisfied by V_γ. While elements of our derivation of the DPP closely follow the known proofs for other cases (see [23], [24]), these proofs do not carry over directly due to a lack of positive discount factor and the presence of the extra disturbance player T. Our lower-value function V_γ probably in general is not continuous and, moreover, cannot be characterized simply as the unique solution of the SQVI as is the case for finite-horizon problems and problems with a positive discount factor. Our formulation of the optimal switching-cost problem is a precise analogue of the standard nonlinear H^∞-control problem; our results (particularly the characterization of the switching lower value as the minimal viscosity supersolution of the appropriate SQVI) parallel those of Soravia [21] obtained for the standard nonlinear H^∞-control problem (see also [13], [22], and [6, Appendix B] for later, closely related refinements of the nonlinear H_∞ results).

Another approach to the derivation of the Hamilton–Jacobi–Bellman–Isaacs (HJBI) equation satisfied by the value function for a differential game is as an application of a comparison principle for the HJBI equation (see [12] or [6]). In [1], this approach was adapted to provide an alternative derivation of the SQVI satisfied by the lower-value function for the robust switching-control problem studied here.

In our companion paper [2], we present a parallel analysis for another analogue of the nonlinear H^∞-control problem, namely, a *robust stopping-time control problem*, where the only control is a decision as to when to stop the system, and there is an instantaneous cost for stopping (dependent on the final state) in addition to the running cost. In this setting, the storage function (or value function if one uses the game interpretation) is a solution of a single variational inequality rather than a coupled system of quasi-variational inequalities as is the case here. The results and general techniques from [2] parallel those of the present paper, but specific details necessarily differ due to the differences in settings. A connection between the two problems is explained in Remark 2 in section 3.

More general types of impulse-control problems have been studied in the literature (see, e.g., [7], [17], [18]) where a general (not necessarily discrete) measure is allowed to enter both the dynamics and the running cost. Such generality leads to a number of complications, such as what is meant by a trajectory of the closed-loop system, how to implement the DPP for discontinuous Hamiltonians, etc. Again, these authors' formulations focus on a finite horizon or assume a discount factor in the running cost. Our purpose here is to work out the details for the switching-control analogue of the standard nonlinear H^∞-control problem, where there is an infinite horizon with no discount factor in the running cost for the simpler situation where the singularities in the control are simple jumps.

Original motivation for our work arose from the problem of designing a real-time feedback control for traffic signals at a highway intersection (see [3], [4]), where the

size of the cost imposed on switching can be used as a tuning parameter to lead to more desirable types of traffic-light signalization. Also, a positive switching cost eliminates the chattering present in the solution otherwise.

The paper is organized as follows. In section 2, we discuss assumptions and definitions. Section 3 presents the main results on the connection between value functions (and storage functions) with systems of quasi-variational inequalities. Section 4 presents stability of the closed-loop switching control system. Finally, section 5 presents an example with one-dimensional state-space, where the value function and associated robust state-feedback control are explicitly computable; a similar example for the setting of the robust stopping-time problem is presented in [1].

2. Preliminaries. Let $A = \{a^1, a^2, \dots, a^r\}$ be a finite set, and let B be a compact subset of $\mathbb{R}^M$ containing the origin 0. We consider a general nonlinear system Σ_{sw} (see (1.1)–(1.2)) with a switching-cost function k. We make the following assumptions on problem data $f,\ h,\ k$:

(A1) $f : \mathbb{R}^N \times A \times B \to \mathbb{R}^N$ and $h : \mathbb{R}^N \times A \times B \to \mathbb{R}$ are continuous;

(A2) f and h are bounded on $B(0,R) \times A \times B$ for all $R > 0$;

(A3) there are moduli ω_f and ω_h such that

$$|f(x,a,b) - f(y,a,b)| \le \omega_f(|x-y|, R),$$
$$|h(x,a,b) - h(y,a,b)| \le \omega_h(|x-y|, R)$$

for all $x, y \in B(0,R)$, $R > 0$, $a \in A$, and $b \in B$;

(A4) $(f(x,a,b) - f(y,a,b)) \cdot (x-y) \le L|x-y|^2$ for all $x, y \in \mathbb{R}^N,\ a \in A$, and $b \in B$;

(A5) $k : A \times A \to \mathbb{R}$ and

$$k(a^j, a^i) < k(a^j, a^d) + k(a^d, a^i),$$
$$k(a^j, a^i) > 0,$$
$$k(a^j, a^j) = 0$$

for all $a^d,\ a^i,\ a^j \in A,\ d \ne i \ne j$;

(A6) $h(x,a,0) \ge 0$ for all $x \in \mathbb{R}^N,\ a \in A$.

The set of admissible controls for our problem is the set

$$\mathcal{A} = \left\{ a(\cdot) = \sum_{i \ge 1} a_{i-1} 1_{[\tau_{i-1}, \tau_i)}(\cdot) \mid a_i \in A,\ a_i \ne a_{i-1} \text{ for } i \ge 1, \right.$$
$$\left. 0 = \tau_0 \le \tau_1 < \tau_2 < \cdots,\ \tau_i \uparrow \infty \right\}$$

consisting of piecewise-constant right-continuous functions on $[0, \infty)$ with values in the control set A, where we denote by $\tau_1, \tau_2, \dots$ the points at which control switchings occur. The set of admissible disturbances is $\mathcal{B}$, which consists of measurable functions on $[0, \infty)$ with values in the set B:

$$\mathcal{B} = \{b : [0, \infty) \to B \mid b \text{ is measurable on } [0, \infty)\}.$$

Note that any admissible disturbance b is then locally integrable by the assumption that the disturbance set B is bounded. A *strategy* is a map $\alpha \colon \mathbb{R}^N \times A \times \mathcal{B} \to \mathcal{A}$

with value at (x, a^j, b) denoted by $\alpha_x^j[b](\cdot)$. The strategy α assigns control function $a(t) = \alpha_x^j[b](t)$ if the augmented initial condition is (x, a^j) and the disturbance is $b(\cdot)$. Thus, if it happens that $\tau_1 > \tau_0 = 0$, then $a(t) = a_0 = a^j$ for $t \in [\tau_0, \tau_1)$. Otherwise, $a(t) = a_1 \neq a^j$ for $t \in [0, \tau_2) = [\tau_1, \tau_2)$, and an instantaneous charge of $k(a^j, a(0))$ is incurred at time 0 in the cost function. A strategy α is said to be *nonanticipating* if, for each $x \in \mathbb{R}^N$ and $j \in \{1, \dots, r\}$, for any $T > 0$ and $b,\ \bar{b} \in \mathcal{B}$, with $b(s) = \bar{b}(s)$ for all $s \leq T$, it follows that $\alpha_x^j[b](s) = \alpha_x^j[\bar{b}](s)$ for all $s \leq T$. We denote by Γ the set of all nonanticipating strategies:

$$\Gamma = \{\alpha \colon \mathbb{R}^N \times A \times \mathcal{B} \to \mathcal{A} \mid \alpha_x^j \text{ is nonanticipating for each } x \in \mathbb{R}^N \text{ and } j = 1, \dots, r\}.$$

We consider trajectories of the nonlinear system

$$\begin{cases} \dot{y}(t) = f(y(t), a(t), b(t)), \\ y(0) = x. \end{cases} \tag{2.1}$$

Under the assumptions (A1), (A2), and (A4), for given $x \in \mathbb{R}^N,\ a \in \mathcal{A}$, and $b \in \mathcal{B}$, the solution of (2.1) exists uniquely for all $t \geq 0$. We denote by $y_x(\cdot, a, b)$ or simply $y_x(\cdot)$ the unique solution of (2.1) corresponding to the choice of the initial condition $x \in \mathbb{R}^N$, the control $a(\cdot) \in \mathcal{A}$, and the disturbance $b(\cdot) \in \mathcal{B}$. We also have the usual estimates on the trajectories (see, e.g., [6, pp. 97–99]:

$$|y_x(t, a, b) - y_z(t, a, b)| \leq e^{Lt}|x - z|, \quad t > 0, \tag{2.2}$$

$$|y_x(t, a, b) - x| \leq M_x t, \quad t \in [0, 1/M_x], \tag{2.3}$$

$$|y_x(t, a, b)| \leq (|x| + \sqrt{2Kt})e^{Kt} \tag{2.4}$$

for all $a \in \mathcal{A},\ b \in \mathcal{B}$, where

$$M_x = \max\{|f(z, a, b)| \mid |x - z| \leq 1,\ a \in A,\ b \in B\},$$
$$K = L + \max\{|f(0, a, b)| \mid a \in A,\ b \in B\}.$$

For a specified gain tolerance $\gamma > 0$, we define the Hamiltonian function $H^j : \mathbb{R}^N \times \mathbb{R}^N \to \mathbb{R}$ by setting

$$H^j(y, p) = \min_{b \in B}\{-p \cdot f(y, a^j, b) - h(y, a^j, b) + \gamma^2|b|^2\}, \quad j = 1, \dots, r.$$

Note that $H^j(y, p) < +\infty$ for all $y, p \in \mathbb{R}^N$ by (A2). Under assumptions (A1)–(A4), one can show that the Hamiltonian H^j is continuous on $\mathbb{R}^N \times \mathbb{R}^N$ and satisfies

$$|H^j(x, p) - H^j(y, p)| \leq L|x - y||p| + \omega_h(|x - y|, R)$$
$$\text{for all } p \in \mathbb{R}^N,\ x, y \in B(0, R),\ R > 0, \text{ and}$$
$$|H^j(x, p) - H^j(x, q)| \leq L(|x| + 1)|p - q| \text{ for all } x, p, q \in \mathbb{R}^N.$$

We now introduce the system of quasi-variational inequalities (SQVI): for $j = 1, 2, \dots, r$,

$$\max\left\{H^j(x, Du^j(x)),\ u^j(x) - \min_{i \neq j}\{u^i(x) + k(a^j, a^i)\}\right\} = 0, \quad x \in \mathbb{R}^N. \tag{2.5}$$

DEFINITION 1. *A vector function $u = (u^1, u^2, \dots, u^r)$, where $u^j \in C(\mathbb{R}^N)$, is a viscosity subsolution of the SQVI* (2.5) *if, for any $\varphi^j \in C^1(\mathbb{R}^N)$,*

$$\max\left\{H^j(x_0, D\varphi^j(x_0)),\ u^j(x_0) - \min_{i\neq j}\{u^i(x_0) + k(a^j, a^i)\}\right\} \le 0, \quad j = 1, 2, \dots, r,$$

at any local maximum point $x_0 \in \mathbb{R}^N$ of $u^j - \varphi^j$. Similarly, u is a viscosity supersolution of the SQVI (2.5) *if, for any $\varphi^j \in C^1(\mathbb{R}^N)$,*

$$\max\left\{H^j(x_1, D\varphi^j(x_1)),\ u^j(x_1) - \min_{i\neq j}\{u^i(x_1) + k(a^j, a^i)\}\right\} \ge 0, \quad j = 1, 2, \dots, r,$$

at any local minimum point $x_1 \in \mathbb{R}^N$ of $u^j - \varphi^j$. Finally, u is a viscosity solution of the SQVI (2.5) *if it is simultaneously a viscosity sub- and supersolution.*

3. Main results. In this section, we show the connection of the lower value function $V_\gamma = (V_\gamma^1, \dots, V_\gamma^r)$ (see (1.4)) (and a switching-storage function) with the SQVI (2.5).

We begin with the application of the DPP to this setting and then derive some properties of the lower-value vector function V_γ (see (1.4)). We then use these properties to show that V_γ, if continuous, is a viscosity solution of the SQVI (2.5). Throughout this section, we assume that V_γ is finite.

PROPOSITION 3.1. *Assume* (A1)–(A5). *Then, for $j = 1, 2, \dots, r$ and $x \in \mathbb{R}^N$, the lower-value vector function $V_\gamma = (V_\gamma^1, \dots, V_\gamma^r)$ given by* (1.4) *satisfies*

$$V_\gamma^j(x) \le \min_{i\neq j}\{V_\gamma^i(x) + k(a^j, a^i)\}.$$

Proof. Fix a pair of indices $i, j \in \{1, \dots, r\}$ with $i \neq j$. For a given $x \in \mathbb{R}^n$, $\alpha \in \Gamma$, $b \in \mathcal{B}$, and $T > 0$, we have

$$\int_{[0,T)} l(y_x(s), a^j, \alpha_x^j[b](x), b(s)) = k(a^j, \alpha_x^j[b](0)) + \int_{[0,T)} l(y_x(s), \alpha_x^j[b](0), \alpha_x^j[b](s), b(s)).$$

Note that there are three cases to consider: (i) $\alpha_x^j[b](0) = j$, (ii) $\alpha_x^j[b](0) = i$, (iii) $\alpha_x^j[b](0) \neq j \neq i$. If (i) or (ii) occurs, then

$$\begin{aligned}\int_{[0,T)} & l(y_x(s), a^j, \alpha_x^j[b](x), b(s)) \\ &< k(a^j, a^i) + k(a^i, \alpha_x^j[b](0)) + \int_{[0,T)} l(y_x(s), \alpha_x^j[b](0), \alpha_x^j[b](s), b(s)) \\ &= k(a^j, a^i) + \int_{[0,T)} l(y_x(s), a^i, \alpha_x^j[b](s), b(s)). \end{aligned} \tag{3.1}$$

If (iii) occurs, then

$$
\begin{aligned}
&\int_{[0,T)} l(y_x(s), a^j, \alpha_x^j[b](x), b(s)) \\
&\quad = k(a^j, \alpha_x^j[b](0)) - k(a^i, \alpha_x^j[b](0)) \\
&\qquad + k(a^i, \alpha_x^j[b](0)) + \int_{[0,T)} l(y_x(s), \alpha_x^j[b](0), \alpha_x^j[b](s), b(s)) \\
&\quad = k(a^j, \alpha_x^j[b](0)) - k(a^i, \alpha_x^j[b](0)) + \int_{[0,T)} l(y_x(s), a^i, \alpha_x^j[b](s), b(s)) \\
&\quad < k(a^j, a^i) + \int_{[0,T)} l(y_x(s), a^i, \alpha_x^j[b](s), b(s)),
\end{aligned} \tag{3.2}
$$

where the last inequality follows from (A5). By the definition of $V_\gamma^j(x)$, we have

$$V_\gamma^j(x) \le \sup_{b\in\mathcal{B}, T\ge 0} \int_{[0,T)} l(y_x(s), a^j, \alpha_x^j[b](s), b(s))$$

for all $\alpha \in \Gamma$. Taking the supremum over $b \in \mathcal{B}$ and $T \ge 0$ on the right-hand side of (3.1) or (3.2) therefore gives

$$V_\gamma^j(x) \le k(a^j, a^i) + \sup_{b\in\mathcal{B}, T\ge 0} \int_{[0,T)} l(y_x(s), a^i, \alpha_x^j[b](s), b(s)). \tag{3.3}$$

Given any strategy $\alpha \in \Gamma$, we can always find another $\widetilde{\alpha} \in \Gamma$ with $\widetilde{\alpha}_x^i[b] = \alpha_x^j[b]$ for each $b \in \mathcal{B}$, and, conversely, for any $\widetilde{\alpha} \in \Gamma$, there is an $\alpha \in \Gamma$ so that $\widetilde{\alpha}_x^i$ is determined by α in this way. Hence, taking the infimum over all $\alpha \in \Gamma$ in the last terms on the right-hand side of (3.3) leaves us with $V_\gamma^i(x)$. Thus

$$V_\gamma^j(x) \le k(a^j, a^i) + V_\gamma^i(x).$$

Since $i \ne j$ is arbitrary, the result follows. □

THEOREM 3.2 (DPP). *Assume* (A1)–(A4). *Then, for* $j = 1, 2, \dots, r$, $t > 0$, *and* $x \in \mathbb{R}^N$, *we have*

$$
\begin{aligned}
V_\gamma^j(x) = \inf_{\alpha\in\Gamma} \sup_{b\in\mathcal{B},\ T>0} \Bigg\{ &\int_{[0,t\wedge T)} l(y_x(s, a^j, \alpha_x^j[b], b), \alpha_x^j[b](s), b(s)) \\
&+ 1_{[0,T)}(t) V_\gamma^i(y_x(t, \alpha_x^j[b], b)) \text{ such that } \alpha_x^j[b](t^-) = a^i \Bigg\},
\end{aligned} \tag{3.4}
$$

where

$$l(y(s), a^j, a(s), b(s)) = [h(y(s), a(s), b(s)) - \gamma^2 |b(s)|^2] ds + k(a(s^-), a(s))\delta_s$$

with $a(0^-) = a^j$.

Proof. Fix $x \in \mathbb{R}^N$, $j \in \{1, 2, \dots, r\}$, and $t > 0$. We denote by $\omega(x)$ the right-hand side of (3.4). Let $\epsilon > 0$. For any $z \in \mathbb{R}^N$ and any $a^\ell \in A$, we pick $\bar{\alpha} \in \Gamma$ such that

$$V_\gamma^\ell(z) + \epsilon \ge \int_{[0,T)} l(y_z(s), a^\ell, \bar{\alpha}_z^\ell[b](s), b(s)) \quad \text{for all } b \in \mathcal{B}, \text{ for all } T > 0. \tag{3.5}$$

We first want to show that $\omega(x) \geq V_\gamma^j(x)$. Choose $\hat{\alpha} \in \Gamma$ such that

$$\omega(x) + \epsilon \geq \sup_{b \in \mathcal{B},\, T \geq 0} \left\{ \int_{[0,t\wedge T)} l(y_x(s), a^j, \hat{\alpha}_x^j[b](s), b(s)) + 1_{[0,T)}(t) V_\gamma^i(y_x(t)),\ \hat{\alpha}_x^j[b](t^-) = a^i \right\}. \tag{3.6}$$

For each $b \in \mathcal{B}$ and $T > 0$, choose $\delta \in \Gamma$ so that

$$\delta_x^j[b](s) = \begin{cases} \hat{\alpha}_x^j[b](s), & s < t \wedge T, \\ \bar{\alpha}_z^i[b(\cdot + t \wedge T)](s - (t \wedge T)), & s \geq t \wedge T, \end{cases}$$

with $z = y_x(t\wedge T, \hat{\alpha}_x^j[b], b)$ and $a^i = \hat{\alpha}_x^j[b](t\wedge T)$. Clearly, δ_x^j is nonanticipating because $\hat{\alpha}_x^j$ and $\bar{\alpha}_z^i$ are. Note that

$$y_x(s + t \wedge T, \delta_x^j[b], b) = y_z(s, \bar{\alpha}_z^i[b(\cdot + t \wedge T)], b(\cdot + t \wedge T)) \text{ for } s \geq 0.$$

Thus, by the change of variables $\tau = s + t \wedge T$, we have

$$\int_{[0,T-(t\wedge T))} l(y_z(s), a^i, \bar{\alpha}_z^i[b(\cdot + t \wedge T)](s), b(s + t \wedge T)) = \int_{[t\wedge T,T)} l(y_x(\tau), a^j, \delta_x^j[b](\tau), b(\tau)). \tag{3.7}$$

As a consequence of (3.5), (3.6), and (3.7), we have

$$\begin{aligned} 2\omega(x) + 2\epsilon &\geq \sup_{b \in \mathcal{B},\, T>0} \left\{ \int_{[0,t\wedge T)} l(y_x(s), a^j, \hat{\alpha}_x^j[b](s), b(s)) + 1_{[0,T)}(t) \int_{[t\wedge T,T)} l(y_z(s), a^i, \bar{\alpha}_z^i[b](s), b(s)) \right\} \\ &= \sup_{b \in \mathcal{B},\, T>0} \left\{ \int_{[0,T)} l(y_x(s), a^j, \delta_x^j[b](s), b(s)) \right\} \\ &\geq \inf_{\alpha \in \Gamma} \sup_{b \in \mathcal{B},\, T>0} \left\{ \int_{[0,T)} l(y_x(s), a^j, \alpha_x^j[b](s), b(s)) \right\} \\ &= V_\gamma^j(x). \end{aligned}$$

Since $\epsilon > 0$ is arbitrary, we conclude that $\omega(x) \geq V_\gamma^j(x)$.

Next we want to show that $\omega(x) \leq V_\gamma^j(x)$. From the definition of $\omega(x)$, choose $b_1 \in \mathcal{B}$ and $T_1 \geq 0$ such that

$$\omega(x) - \epsilon \leq \int_{[0,T_1\wedge t)} l(y_x(s), a^j, \bar{\alpha}_x^j[b_1](s), b_1(s)) + 1_{[0,T_1)}(t) V_\gamma^i(y_x(t)), \tag{3.8}$$

where $\bar{\alpha}_x^j$ is defined as in (3.5) and $\bar{\alpha}_x^j[b_1](t^-) = a^i$ for some $a^i \in A$. If $t \geq T_1$, we

have

$$\begin{aligned}\omega(x)-\epsilon &\le \int_{[0,T_1)} l(y_x(s),a^j,\bar\alpha_x^j[b_1](s),b_1(s))\\ &\le \sup_{b\in\mathcal{B},\,T>0}\left\{\int_{[0,T)} l(y_x(s),a^j,\bar\alpha_x^j[b](s),b(s))\right\}\\ &\le V_\gamma^j(x)+\epsilon,\end{aligned}$$

where the last inequality follows from (3.5). If $t<T_1$, we have

$$\omega(x)-\epsilon \le \int_{[0,t)} l(y_x(s),\bar\alpha_x^j[b_1](s),b_1(s)) + V_\gamma^i(y_x(t)). \tag{3.9}$$

Set $z=y_x(t,\bar\alpha_x^j[b_1],b_1)$. For each $b\in\mathcal{B}$, define $\tilde b\in\mathcal{B}$ by

$$\tilde b(s)=\begin{cases} b_1(s), & s<t,\\ b(s-t), & s\ge t,\end{cases}$$

and choose $\widehat\alpha\in\Gamma$ so that

$$\widehat\alpha_z[b](s)=\bar\alpha_x^j[\tilde b](s+t)\qquad \text{for } s\ge 0.$$

By definition of V_γ^i, choose $b_2\in\mathcal{B}$ and $T_2>0$ such that

$$V_\gamma^i(z)-\epsilon \le \int_{[0,T_2)} l(y_z(s),a^i,\widehat\alpha_z[b_2](s),b_2(s)).$$

Then, by change of variable $\tau=s+t$, we have

$$V_\gamma^i(z)-\epsilon \le \int_{[t,t+T_2)} l(y_x(\tau),a^j,\bar\alpha_x^j[\tilde b_2](\tau),\tilde b_2(\tau)). \tag{3.10}$$

As a consequence of (3.9) and (3.10), we have

$$\begin{aligned}\omega(x)-2\epsilon &\le \int_{[0,t)} l(y_x(s),a^j,\bar\alpha_x^j[b_1](s),b_1(s)) + \int_{[t,t+T_2)} l(y_x(\tau),a^j,\bar\alpha_x^j[\tilde b_2](\tau),\tilde b_2(\tau))\\ &= \int_{[0,t+T_2)} l(y_x(\tau),a^j,\bar\alpha_x^j[\tilde b_2](\tau),\tilde b_2(\tau))\\ &\le \sup_{b\in\mathcal{B},\,T>0}\left\{\int_{[0,T)} l(y_x(\tau),a^j,\bar\alpha_x^j[b](\tau),b(\tau))\right\}\\ &\le V_\gamma^j(x)+\epsilon,\end{aligned}$$

where the last inequality follows from (3.5). Since $\epsilon>0$ is arbitrary, for both cases we have $\omega(x)\le V_\gamma^j(x)$ as required. □

COROLLARY 3.3. *Assume* (A1)–(A4) *and* (A6). *Then, for each* $j\in\{1,\dots,r\}$, $x\in\mathbb{R}^N$, *and* $t>0$, *we have*

$$V_\gamma^j(x) \le \sup_{b\in\mathcal{B},\,T>0}\left\{\int_0^{t\wedge T}[h(y_x(s),a^j,b(s))-\gamma^2|b(s)|^2]ds + 1_{[0,T)}(t)V_\gamma^j(y_x(t))\right\} \tag{3.11}$$

$$\le \sup_{b\in\mathcal{B}}\int_0^t [h(y_x(s),a^j,b(s))-\gamma^2|b(s)|^2]\,ds + V_\gamma^j(y_x(t)). \tag{3.12}$$

Proof. Fix $j \in \{1, \dots, r\}$, $x \in \mathbb{R}^N$, and $t > 0$. Define $\alpha \in \Gamma$ by setting $\alpha_x^j[b](s) = a^j$ for all $s \geq 0$ for each $b \in \mathcal{B}$. By Theorem 3.2, we have

$$V_\gamma^j(x) \leq \sup_{b \in \mathcal{B},\, T>0} \left\{ \int_0^{t \wedge T} [h(y_x(s), a^j, b(s)) - \gamma^2 |b(s)|^2] ds + 1_{[0,T)}(t) V_\gamma^j(y_x(t)) \right\},$$

and (3.11) follows.

To prove the second inequality (3.12), consider any $b \in \mathcal{B}$ and T with $0 < T < t$. Define a new $\bar{b} \in \mathcal{B}$ by $\bar{b}(s) = b(s)$ for $s \leq T$ and $\bar{b}(s) = 0$ for $s > T$. It follows that $y_x(s, a^j, b) = y_x(s, a^j, \bar{b})$ for $0 \leq s \leq T$. For $s > T$, we have

$$h(y_x(s), a^j, b(s)) - \gamma^2 |b(s)|^2 = h(y_x(s), a^j, 0) \geq 0$$

(by (A6)). Since we also know that $V_\gamma^j(x) \geq 0$ for all $x \in \mathbb{R}^N$ (take $T = 0$ in the definition (1.4)), we get

$$\begin{aligned} &\int_0^{t \wedge T} [h(y_x(s), a^j, b(s)) - \gamma^2 |b(s)|^2] \, ds + 1_{[0,T)}(t) V_\gamma^j(y_x(t)) \\ &\leq \int_0^t [h(y_x(s), a^j, \bar{b}(s)) - \gamma^2 |b(s)|^2] \, ds + V_\gamma^j(y_x(t, a^j, \bar{b})), \end{aligned}$$

and (3.12) follows as well. ∎

PROPOSITION 3.4. *Assume* (A1)–(A5). *Suppose that, for each* $j \in \{1, \dots, r\}$, V^j *is continuous. If* $V_\gamma^j(x) < \min_{i \neq j}\{V_\gamma^i(x) + k(a^j, a^i)\}$, *then there exists* $\tau = \tau_x > 0$ *such that, for* $0 < t < \tau_x$,

$$V_\gamma^j(x) = \sup_{b \in \mathcal{B},\, T>0} \left\{ \int_0^{t \wedge T} [h(y_x(s), a^j, b(s)) - \gamma^2 |b(s)|^2] ds + 1_{[0,T)}(t) V_\gamma^j(y_x(t)) \right\}.$$

Proof. We assume $V_\gamma^j(x) < \min_{i \neq j}\{V_\gamma^i(x) + k(a^j, a^i)\}$. From Corollary 3.3, we know that, for all $t > 0$,

$$V_\gamma^j(x) \leq \sup_{b \in \mathcal{B},\, T>0} \left\{ \int_0^{t \wedge T} [h(y_x(s), a^j, b(s)) - \gamma^2 |b(s)|^2] ds + 1_{[0,T)}(t) V_\gamma^j(y_x(t)) \right\}.$$

Suppose there is a sequence $\{t_n\}$ with $0 < t_n < \frac{1}{n}$ for $n = 1, 2, \dots$ such that

(3.13)
$$V_\gamma^j(x) < \sup_{b \in \mathcal{B},\, T>0} \left\{ \int_0^{t_n \wedge T} [h(y_x(s), a^j, b(s)) - \gamma^2 |b(s)|^2] ds + 1_{[0,T)}(t_n) V_\gamma^j(y_x(t_n)) \right\}.$$

Let $w(x, t_n)$ be the right-hand side of (3.13). For each t_n, define $\epsilon_n = \frac{1}{3}[w(x, t_n) - V_\gamma^j(x)]$. As $t_n \to 0$ as $n \to \infty$, from (3.13) we see that $w(x, t_n) \to V_\gamma^j(x)$, and hence $\epsilon_n \to 0$ as $n \to \infty$. It follows that

$$V_\gamma^j(x) + \epsilon_n < w(x, t_n) - \epsilon_n. \tag{3.14}$$

Choose $b_n \in \mathcal{B}$ and $T_n \geq 0$ such that

(3.15)
$$w(x, t_n) - \epsilon_n \leq \int_0^{t_n \wedge T_n} [h(y_x(s), a^j, b_n(s)) - \gamma^2 |b_n(s)|^2] ds + 1_{[0,T_n)}(t_n) V_\gamma^j(y_x(t_n)).$$

By Theorem 3.2, choose $\alpha_n \in \Gamma$ such that

(3.16)
$$V_\gamma^j(x) + \epsilon_n \geq \int_{[0,t_n\wedge T_n]} l(y_x(s), a^j, (\alpha_n)_x^j[b_n](s), b_n(s)) + 1_{[0,T_n)}(t_n)V_\gamma^{i_n}(y_x(t_n)),$$

where $(\alpha_n)_x^j[b_n](t_n^-) = a^{i_n} \in A$. From (3.14), (3.15), and (3.16), we have

(3.17)
$$\begin{aligned} &\int_{[0,t_n\wedge T_n)} l(y_x(s), a^j, (\alpha_n)_x^j[b_n](s), b_n(s)) + 1_{[0,T_n)}(t_n)V_\gamma^{i_n}(y_x(t_n)) \\ &< \int_0^{t_n\wedge T_n} [h(y_x(s), a^j, b_n(s)) - \gamma^2|b_n(s)|^2]ds + 1_{[0,T_n)}(t_n)V_\gamma^j(y_x(t_n)). \end{aligned}$$

This implies that $(\alpha_n)_x^j[b_n]$ jumps in the interval $[0, t_n\wedge T_n]$. Without loss of generality, assume the number of switchings is equal to d_n. If $t_n < T_n$ for infinitely many n, by going down to a subsequence we may assume that $t_n \leq T_n$ for all n. From (3.16), we have

$$\begin{aligned} V_\gamma^j(x) &\geq \limsup_{n\to\infty} \left\{ \int_{[0,t_n\wedge T_n)} l(y_x(s), a^j, \alpha_{x,n}^j[b_n](s), b_n(s)) \right. \\ &\qquad \left. + 1_{[0,T_n)}(t_n)V_\gamma^{i_n}(y_x(t_n)),\ \alpha_{x,n}^j[b_n](t_n^-) = a^{i_n} \in A \right\} \\ &= \limsup_{n\to\infty} \left\{ \int_0^{t_n} [h(y_x(s), \alpha_{x,n}^j[b_n](s), b_n(s)) - \gamma^2|b_n(s)|^2]ds \right. \\ &\qquad \left. + \sum_{m=1}^{d_n} k(a_{m-1}, a_m) + V_\gamma^{i_n}(y_x(t_n)),\ \alpha_{x,n}^j[b_n](t_n) = a^{i_n} \in A \right\} \\ &= \limsup_{n\to\infty} \left\{ \sum_{m=1}^{d_n} k(a_{m-1}, a_m) + V_\gamma^{i_n}(y_x(t_n)),\ \alpha_{x,n}^j[b_n](t_n^-) = a^{i_n} \in A \right\}. \end{aligned}$$

By using the continuity of $V_\gamma^{i_n}$ and $\sum_{m=1}^{d_n} k(a_{m-1}, a_m) > k(a^j, a^{i_n})$, we have

$$V_\gamma^j(x) \geq \min_{i\neq j}\{V_\gamma^i(x) + k(a^j, a^i)\},$$

which contradicts one of the assumptions. If $t_n \geq T_n$ for infinitely many n, again without loss of generality we may assume that $t_n \geq T_n$ for all n. From (3.17), we have

$$\begin{aligned} &\liminf_{n\to\infty} \left\{ \int_{[0,T_n]} l(y_x(s), a^j\alpha_{x,n}^j[b_n](s), b_n(s)) \right\} \\ &\leq \limsup_{n\to\infty} \left\{ \int_0^{T_n} [h(y_x(s), a^j, b_n(s)) - \gamma^2|b_n(s)|^2]ds \right\}, \end{aligned}$$

or, equivalently,

$$\begin{aligned} &\liminf_{n\to\infty} \left\{ \int_0^{T_n} [h(y_x(s), \alpha_{x,n}^j[b_n](s), b_n(s)) - \gamma^2|b_n(s)|^2]ds + \sum_{m=1}^{d_n} k(a_{m-1}, a_m) \right\} \\ &\leq \limsup_{n\to\infty} \left\{ \int_0^{T_n} [h(y_x(s), a^j, b_n(s)) - \gamma^2|b_n(s)|^2]ds \right\}. \end{aligned}$$

Thus

$$\liminf_{n\to\infty}\left\{\sum_{m=1}^{d_n} k(a_{m-1},a_m)\right\} \le \limsup_{n\to\infty}\left\{\int_0^{T_n} h(y_x(s),a^j,b_n(s))ds\right\} - \liminf_{n\to\infty}\left\{\int_0^{T_n} h(y_x(s),\alpha^j_{x,n}[b_n](s),b_n(s))ds\right\},$$

and in this case $T_n \to 0$ as $n \to \infty$. Note that the integral terms tend to 0 uniformly with respect to $b_n \in \mathcal{B}$ as $T_n \to 0$ by assumption (A2), the uniform estimate (2.3), and the continuity assumption (A1) on h. Thus we have

$$\liminf_{n\to\infty}\left\{\sum_{m=1}^{d_n} k(a_{m-1},a_m)\right\} \le 0,$$

which contradicts (A5). □

LEMMA 3.5. *Assume* (A1)–(A6) *and* $V^j_\gamma \in C(\mathbb{R}^N)$, $j = 1,\dots,r$. *If* $V^j_\gamma(x) < \min_{i\neq j}\{V^i_\gamma(x) + k(a^j,a^i)\}$, *then there exists* $\tau = \tau_x > 0$ *such that*

$$V^j_\gamma(x) \ge \sup_{b\in\mathcal{B}}\left\{\int_0^t [h(y_x(s),a^j,b(s)) - \gamma^2|b(s)|^2]ds + V^j_\gamma(y_x(t))\right\} \quad \textit{for all } t \in (0,\tau_x).$$

Proof. From Proposition 3.4, choose $\tau = \tau_x > 0$ such that, for all $t \in (0,\tau)$,

$$V^j_\gamma(x) = \sup_{b\in\mathcal{B},\, T>0}\left\{\int_0^{t\wedge T} [h(y_x(s),a^j,b(s)) - \gamma^2|b(s)|^2]ds + 1_{[0,T)}(t)V^j_\gamma(y_x(t))\right\}.$$

Thus

$$\begin{aligned} V^j_\gamma(x) &\ge \sup_{b\in\mathcal{B},\, T>t}\left\{\int_0^{t\wedge T} [h(y_x(s),a^j,b(s)) - \gamma^2|b(s)|^2]ds + 1_{[0,T)}(t)V^j_\gamma(y_x(t))\right\} \\ &= \sup_{b\in\mathcal{B}}\left\{\int_0^t [h(y_x(s),a^j,b(s)) - \gamma^2|b(s)|^2]ds + V^j_\gamma(y_x(t))\right\}. \end{aligned}$$ □

THEOREM 3.6. *Assume* (A1)–(A6) *and* $V^j_\gamma \in C(\mathbb{R}^N)$, $j = 1,\dots,r$. *Then* V_γ *is a viscosity solution of the SQVI* (2.5)

(3.18)
$$\max\left\{H^j(x,DV^j_\gamma(x)),\ V^j_\gamma(x) - \min_{i\neq j}\{V^i_\gamma(x) + k(a^j,a^i)\}\right\} = 0, x \in \mathbb{R}^N,\ j = 1,\dots,r.$$

Proof. We first show that V^j_γ is a viscosity supersolution of the SQVI (3.18). Fix $x_0 \in \mathbb{R}^N$ and $a^j \in A$. Let $\varphi^j \in C^1(\mathbb{R}^N)$, and x_0 is a local minimum of $V^j_\gamma - \varphi^j$. We want to show that

$$\max\left\{H^j(x_0,D\varphi^j(x_0)),\ V^j_\gamma(x_0) - \min_{i\neq j}\{V^i_\gamma(x_0) + k(a^j,a^i)\}\right\} \ge 0. \tag{3.19}$$

We have two cases to consider.

Case 1. $V^j_\gamma(x_0) = \min_{i\neq j}\{V^i_\gamma(x_0) + k(a^j,a^i)\}$.

Case 2. $V_\gamma^j(x_0) < \min_{i\neq j}\{V_\gamma^i(x_0) + k(a^j, a^i)\}$.
If Case 1 occurs, we have

$$\begin{aligned}&\max\left\{H^j(x_0, D\varphi^j(x_0)),\ V_\gamma^j(x_0) - \min_{i\neq j}\{V_\gamma^i(x_0) + k(a^j, a^i)\}\right\}\\ &\geq V_\gamma^j(x_0) - \min_{i\neq j}\{V_\gamma^i(x_0) + k(a^j, a^i)\}\\ &\geq 0.\end{aligned}$$

If Case 2 occurs, we want to show that $H^j(x_0, D\varphi^j(x_0)) \geq 0$. Fix $b \in B$, and set $b(s) = b$ for all $s \geq 0$. From Lemma 3.5, choose $\bar{t}_0 > 0$ such that, for $t \in (0, \bar{t}_0)$,

$$V_\gamma^j(x_0) - V_\gamma^j(y_{x_0}(t)) \geq \int_0^t [h(y_{x_0}(s), a^j, b) - \gamma^2|b|^2]\, ds. \tag{3.20}$$

Since x_0 is a local minimum of $V_\gamma^j - \varphi^j$, by (2.3) there exists $\hat{t}_0 > 0$ such that

$$\varphi^j(x_0) - \varphi^j(y_{x_0}(s), a^j, b(s)) \geq V_\gamma^j(x_0) - V_\gamma^j(y_{x_0}(s), a^j, b(s)), \quad 0 < s < \hat{t}_0. \tag{3.21}$$

Set $t_0 = \min\{\bar{t}_0,\ \hat{t}_0\}$. As a consequence of (3.20) and (3.21), we have

$$\varphi^j(x_0) - \varphi^j(y_{x_0}(t)) \geq \int_0^t [h(y_{x_0}(s), a^j, b) - \gamma^2|b|^2]ds, \quad 0 < t < t_0. \tag{3.22}$$

Divide both sides by t, and let $t \to 0$ to get

$$-D\varphi^j(x_0) \cdot f(x_0, a^j, b) - h(x_0, a^j, b) + \gamma^2|b|^2 \geq 0.$$

Since $b \in B$ is arbitrary, we have $H^j(x_0, D\varphi^j(x_0)) \geq 0$.

We next show that V_γ^j is a viscosity subsolution of the SQVI (3.18). Fix $x_1 \in \mathbb{R}^N$ and $a^j \in A$. Let $\varphi^j \in C^1(\mathbb{R}^N)$, and x_1 is a local maximum of $V_\gamma^j - \varphi^j$. We want to show that

$$\max\left\{H^j(x_1, D\varphi^j(x_1)),\ V_\gamma^j(x_1) - \min_{i\neq j}\{V_\gamma^i(x_1) + k(a^j, a^i)\}\right\} \leq 0. \tag{3.23}$$

From Proposition 3.1, $V_\gamma^j(x_1) \leq \min_{i\neq j}\{V_\gamma^i(x_1) + k(a^j, a^i)\}$. Thus we want to show that $H^j(x_1, D\varphi^j(x_1)) \leq 0$.

Let $t > 0$ and $\epsilon > 0$. From (3.12) in Corollary 3.3, we may choose $\hat{b} = \hat{b}_{t,\epsilon} \in \mathcal{B}$ such that

$$V_\gamma^j(x_1) \leq \int_0^t [h(y_{x_1}(s), a^j, \hat{b}(s)) - \gamma^2|\hat{b}(s)|^2]\, ds + V_\gamma^j(y_{x_1}(t, \hat{b})) + \epsilon t, \tag{3.24}$$

and hence

$$V_\gamma^j(x_1) - V_\gamma^j(y_{x_1}(t, \hat{b})) \leq \int_0^t [h(y_{x_1}(s), a^j, \hat{b}(s)) - \gamma^2|\hat{b}(s)|^2]\, ds + \epsilon t. \tag{3.25}$$

Since x_1 is a local maximum of $V_\gamma^j - \varphi^j$, by (2.3) we may assume that

$$\varphi^j(x_1) - \varphi^j(y_{x_1}(s), a^j, \hat{b}(s)) \leq V_\gamma^j(x_1) - V_\gamma^j(y_{x_1}(s), a^j, \hat{b}(s)), \quad 0 < s \leq t. \tag{3.26}$$

Combine (3.25) and (3.26) to get

$$\varphi^j(x_1) - \varphi^j(y_{x_1}(t, a^j, \hat{b}(t))) \le \int_0^t [h(y_{x_1}(s), a^j, \hat{b}(s)) - \gamma^2 |\hat{b}(s)|^2]\, ds + \epsilon t. \tag{3.27}$$

Observe that (2.3) and (A3) imply

$$|f(y_{x_1}(s), a^j, \hat{b}(s)) - f(x_1, a^j, \hat{b}(s))| \le \omega_f(M_x s, |x| + M_x t_0) \text{ for } 0 < s < t_0 \tag{3.28}$$

and

$$|h(y_x(s), a^j, \hat{b}(s)) - h(x_1, a^j, \hat{b}(s))| \le \omega_h(M_{x_1} s, |x| + M_{x_1} t_0) \text{ for } 0 < s < t_0, \tag{3.29}$$

where t_0 does not depend on ϵ, t, or $\hat{b}$. By (3.29), the integral on the right-hand side of (3.27) can be written as

$$\int_0^t [h(x_1, a^j, \hat{b}(s)) - \gamma^2 |\hat{b}(s)|^2]\, ds + \mathrm{o}(t) \text{ as } t \to 0.$$

Thus

$$\varphi^j(x_1) - \varphi^j(y_{x_1}(t, a^j, \hat{b}(t))) \le \int_0^t [h(x_1, a^j, \hat{b}(s)) - \gamma^2 |\hat{b}(s)|^2]\, ds + \epsilon t + \mathrm{o}(t). \tag{3.30}$$

Moreover,

$$\begin{aligned} \varphi^j(x_1) - \varphi^j(y_{x_1}(t, a^j, \hat{b})) &= -\int_0^t \frac{d}{ds} \varphi^j(y_{x_1}(s, a^j, \hat{b}))\, ds \\ &= -\int_0^t D\varphi^j(y_{x_1}(s, a^j, \hat{b})) \cdot f(y_{x_1}(s), a^j, \hat{b}(s))\, ds \\ &= -\int_0^t D\varphi^j \cdot f(x_1, a^j, \hat{b}(s))\, ds + \mathrm{o}(t), \end{aligned} \tag{3.31}$$

where we used (2.3), (3.28), and $\varphi^j \in C^1$ in the last equality to estimate the difference between $D\varphi^j \cdot f$ computed at $y_{x_1}(s)$ and at x_1, respectively. Plugging (3.31) into (3.30) gives

$$\int_0^t -D\varphi^j(x_1) \cdot f(x_1, a^j, \hat{b}(s))\, ds \le \int_0^t [h(x_1, a^j, \hat{b}(s)) - \gamma^2 |\hat{b}|^2]\, ds + \epsilon t + \mathrm{o}(t).$$

Thus

$$\int_0^t [-D\varphi^j(x_1) \cdot f(x_1, a^j, \hat{b}(s)) - h(x_1, a^j, \hat{b}(s)) + \gamma^2 |\hat{b}(s)|^2]\, ds \le \epsilon t + \mathrm{o}(t). \tag{3.32}$$

We estimate the left-hand side of this inequality from below next to get

$$\inf_{b \in B} \{-D\varphi^j(x_1) \cdot f(x_1, a^j, b) - h(x_1, a^j, b) + \gamma^2 |b|^2\} \cdot t \le \epsilon t + \mathrm{o}(t). \tag{3.33}$$

Divide by t, and pass to the limit as $t \to 0$ to get

$$\inf_{b \in B} \{-D\varphi^j(x) \cdot f(x, a^j, b) - h(x, a^j, b) + \gamma^2 |b|^2\} \le \epsilon.$$

Since $\epsilon > 0$ is arbitrary, we conclude that $H^j(x, D\varphi^j(x)) \le 0$. ∎

We next give a connection of a switching storage (vector) function with the SQVI (3.18).

THEOREM 3.7. *Assume* (A1)–(A5), *and assume that* $S = (S^1, \dots, S^r)$ *is a continuous switching-storage function for the closed-loop system formed by the nonanticipating strategy* $\alpha \in \Gamma$. *Then* S *is a viscosity supersolution of SQVI* (3.18).

Proof. The proof follows exactly as the proof that the lower-value function V^γ is a viscosity subsolution in the proof of Theorem 3.6 once we verify the following analogue of Lemma 3.5 for switching-storage functions. ∎

LEMMA 3.8. *Assume* (A1)–(A6), *and assume that* $S = (S^1, \dots, S^r)$ *is a continuous switching-storage function. If* $S^j(x) < \min_{i \ne j}\{S^i(x) + k(a^j, a^i)\}$, *then there exists* $\tau = \tau_x > 0$ *such that*

$$S^j(x) \ge \sup_{b \in \mathcal{B}} \left\{ \int_0^t [h(y_x(s), a^j, b(s)) - \gamma^2 |b(s)|^2] ds + S^j(y_x(t)) \right\} \quad \text{for all } t \in (0, \tau_x).$$

Proof. By the defining condition (1.5) for a storage function (1.5) (with attenuation level γ), we have

$$S^j(x) \ge \int_0^t [h(y_x(s), \alpha_x^j[b](s), b(s)) - \gamma^2 |b(s)|^2] \, ds + \sum_{0 \le \tau < t} k(\alpha_x^j[b](\tau^-), \alpha_x^j[b](\tau)) + S^{j(t)}(y_x(t, \alpha_x^j[b], b)). \tag{3.34}$$

Due to the assumed boundedness of B and the boundedness of h (see (A2)), it is clear that, given $\epsilon > 0$, we may choose $\tau = \tau_\epsilon$ so that

$$\sup_{b \in \mathcal{B}} \left\{ \int_0^t [h(y_x(s), a^j, b(s)) - \gamma^2 |b(s)|^2] ds \right\} > -\epsilon$$

for all $t \in [0, \tau_\epsilon)$. We conclude that, for any such t,

$$S^j(x) \ge -\epsilon + \sum_{0 \le \tau < t} k(\alpha_x^j[b](\tau^-), \alpha_x^j[b](\tau)) + S^{j(t)}(y_x(t, \alpha_x^j[b], b)). \tag{3.35}$$

If we now choose $\epsilon = \frac{1}{2}[\min_{i \ne j}\{S^i(x) + k(a^j, a^i)\} - S^j(x)] > 0$ and use the continuity of S^j for each j, the estimate (3.35) in the presence of any jumps in the interval $[0, \tau_\epsilon)$ leads to a contradiction. Since we are now assured that there are no jumps, (3.34) collapses to

$$S^j(x) \ge \int_0^t [h(y_x(s), \alpha_x^j[b](s), b(s)) - \gamma^2 |b(s)|^2] \, ds + S^j(y_x(t, \alpha_x^j[b], b))$$

for $0 \le t < \tau_\epsilon$ and for all $b \in \mathcal{B}$. Taking the supremum of $b \in \mathcal{B}$ now leads to the desired result. This concludes the proof of Lemma 3.8 and of Theorem 3.7. ∎

We now proceed to the synthesis of a switching-control strategy achieving the dissipation inequality for a given viscosity supersolution $U = (U^1, \dots, U^r)$ of SQVI (3.18). Given a continuous nonnegative vector function $U = (U^1, \dots, U^r)$ on $\mathbb{R}^N$ satisfying the condition

$$U^j(x) \le \min_{i \ne j}\{U^i(x) + k(a^j, a^i)\} \text{ for all } x \in \mathbb{R}^N, \ j = 1, \dots, r,$$

we associate a state-feedback switching strategy $\alpha_U : (y(t), a^j) \to \alpha^j(y(t))$ by the rule

$$\alpha^j(y(t)) = \begin{cases} a^j & \text{if } U^j(y(t)) < \min_{i\neq j}\{U^i(y(t)) + k(a^j, a^i)\}, \\ a^\ell & \text{for any } \ell \in \arg\min_{i\neq j}\{U^i(y(t)) + k(a^j, a^i)\} \text{ otherwise.} \end{cases} \tag{3.36}$$

In other words, the associated feedback switching strategy is as follows: *if the current state is $y(t)$ and the current old control is $a(t^-) = a^j$, then set $a(t) = \alpha^j(y(t))$.* Such a strategy can also be expressed as a nonanticipating strategy $\alpha_U : (x, a^j, b) \to \alpha^j_{U,x}[b]$; explicitly, for this particular case α_U, we have that $\alpha^j_{U,x}[b]$ is given by

$$\alpha^j_{U,x}[b](t) = \sum_{n\geq 1} a_{n-1} 1_{[\tau_{n-1},\tau_n)}(t) \text{ for } t \geq 0 \tag{3.37}$$

and $\alpha^j_{U,x}[b](0^-) = a_0$, where

$$\tau_0 = 0, \quad a_0 = a^{j_0} = a^j,$$

and, for $n = 1, 2, 3, \ldots$, $\tau_n[b]$ is the infimum over $t > \tau_{n-1}$ for which

$$\begin{aligned} &U^{j_{n-1}}(y_{y(\tau_{n-1})}(t - \tau_{n-1}, a^{j_{n-1}}, b(\cdot - \tau_{n-1}))) \\ &\qquad = \min_{i\neq j_{n-1}} \{U^i(y_{y(\tau_{n-1})}(t - \tau_{n-1}, a^{j_{n-1}}, b(\cdot - \tau_{n-1}))) + k(a^{j_{n-1}}, a^i)\}\}, \end{aligned}$$

or $+\infty$ if the preceding set is empty; and $a_n = a^{j_n} =$ any $a^l \neq a^{j_{n-1}}$ for which

$$\begin{aligned} &\min_{i\neq j_{n-1}} \{U^i(y_{y(\tau_{n-1})}(\tau_n - \tau_{n-1}, a^{j_{n-1}}, b(\cdot - \tau_{n-1}))) + k(a^{j_{n-1}}, a^i)\} \\ &\qquad = U^l(y_{y(\tau_{n-1})}(\tau_n - \tau_{n-1}, a^{j_{n-1}}, b(\cdot - \tau_{n-1}))) + k(a^{j_{n-1}}, a^l) \end{aligned}$$

if $\tau_n < \infty$ or undefined if $\tau_n = \infty$. Note that, if $\tau_1 = \tau_0 = 0$, there is an immediate switch from a_0 to a_1 at time 0, and the $n = 1$ term in (3.37) is vacuous. Moreover, by (A5), $\tau_n > \tau_{n-1}$ for $\tau_{n-1} < \infty$, and $n > 1$. To see this, we assume that $\tau_n = \tau_{n-1} < \infty$ for some $n > 1$. From the definition of τ_{n-1} and τ_n, we would have

$$\begin{aligned} U^{j_{n-2}}(y(\tau_{n-1})) &= U^{j_{n-1}}(y(\tau_{n-1})) + k(a^{j_{n-2}}, a^{j_{n-1}}) \\ &= U^{j_n}(y(\tau_{n-1})) + k(a^{j_{n-1}}, a^{j_n}) + k(a^{j_{n-2}}, a^{j_{n-1}}) \text{ (hence } j_n \neq j_{n-2}) \\ &> U^{j_n}(y(\tau_{n-1})) + k(a^{j_{n-2}}, a^{j_n}) \\ &\geq \min_{i\neq j_{n-2}} \{U^i(y(\tau_{n-1})) + k(a^{j_{n-2}}, a^i)\}, \end{aligned}$$

which gives a contradiction. Moreover, as shown in the proof of the next theorem, if $\tau_n < \infty$ for all n, it still holds that $\lim_{n\to\infty} \tau_n = \infty$, so the closed-loop trajectory is defined for all $t > 0$.

THEOREM 3.9. *Assume the following.*

(i) (A1)–(A5) *hold.*

(ii) $U = (U^1, \ldots, U^r)$ *is a nonnegative continuous viscosity supersolution in* $\mathbb{R}^N$ *of the SQVI* (3.18)

$$\max\left\{H^j(x, DU^j(x)),\ U^j(x) - \min_{i\neq j}\{U^i(x) + k(a^j, a^i)\}\right\} = 0,\ x \in \mathbb{R}^N,\ j = 1, \ldots, r.$$

(iii) $U^j(x) \le \min_{i \neq j}\{U^i(x) + k(a^j, a^i)\},\ x \in \mathbb{R}^N,\ j \in \{1, \dots, r\}$.

Let α_U be the state-feedback strategy defined by (3.36) *or, equivalently, the nonanticipating disturbance-feedback strategy α_U defined by* (3.37). *Then $U = (U^1, \dots, U^r)$ is a storage function for the closed-loop system formed by the strategy α_U. In particular, we have*

$$U^j(x) \ge \sup_{b \in \mathcal{B},\ T \ge 0} \left\{ \int_{[0,T)} l(y_x(s), a^j, \alpha^j_{U,x}[b](s), b(s)) \right\} \ge V^j_\gamma(x)$$

for each $x \in \mathbb{R}^N$ and $a^j \in A$. Thus V_γ, if continuous, is characterized as the minimal, nonnegative continuous viscosity supersolution of the SQVI (3.18) *satisfying condition* (iii) *as well as the minimal continuous switching-storage function satisfying condition* (iii) *for the closed-loop system associated with some nonanticipating strategy α_{V_γ}.*

Proof. Let $\alpha^j_{U,x}[b](t)$ be the switching strategy defined as in (3.37). We claim that

$$\tau_n \to \infty \ \text{ as } \ n \to \infty.$$

If $\tau_n = \infty$ for some n, then it is trivially true. Otherwise, since we observed just before the statement of Theorem 3.9 that $\{\tau_n\}$ is a nondecreasing sequence, it would follow that

$$\lim_{n \to \infty} \tau_n = T < \infty \tag{3.38}$$

with $0 \le \tau_n < T$ for all n. From (3.38), we have that $\{\tau_n\}$ is a Cauchy sequence, and hence for all $\nu > 0$ there is some n such that $\tau_n < \tau_{n-1} + \nu$. By the definition of τ_n,

$$U^{j_{n-1}}(y_x(\tau_n)) = U^l(y_x(\tau_n)) + k(a^{j_{n-1}}, a^l) \text{ for some } a^l \neq a^{j_{n-1}}. \tag{3.39}$$

(We have written $y_x(t)$ for $y_x(t, \alpha^j_x[b], b)$.) By definition of τ_{n-1}, we have

$$U^{j_{n-2}}(y_x(\tau_{n-1})) = U^{j_{n-1}}(y_x(\tau_{n-1})) + k(a^{j_{n-2}}, a^{j_{n-1}}). \tag{3.40}$$

By (iii), we have

$$\begin{aligned} U^{j_{n-2}}(y_x(\tau_{n-1})) &\le \min_{i \neq j_{n-2}} \{U^i(y_x(\tau_{n-1})) + k(a^{j_{n-2}}, a^i)\} \\ &\le U^l(y_x(\tau_{n-1})) + k(a^{j_{n-2}}, a^l) \text{ if } l \neq j_{n-2}, \end{aligned}$$

and hence

$$U^{j_{n-2}}(y_x(\tau_{n-1})) \le U^l(y_x(\tau_{n-1})) + k(a^{j_{n-2}}, a^l) \tag{3.41}$$

if $l \neq j_{n-2}$. If $l = j_{n-2}$, (3.41) holds with equality (by (A5)), and hence (3.41) in fact holds without restriction. From (3.40) and (3.41), we have

$$k(a^{j_{n-2}}, a^{j_{n-1}}) - k(a^{j_{n-2}}, a^l) \le U^l(y_x(\tau_{n-1})) - U^{j_{n-1}}(y_x(\tau_{n-1})). \tag{3.42}$$

As a consequence of (3.39) and (3.42), we have

$$\begin{aligned} 0 &< k(a^{j_{n-2}}, a^{j_{n-1}}) + k(a^{j_{n-1}}, a^l) - k(a^{j_{n-2}}, a^l) \\ &\le U^l(y_x(\tau_{n-1})) - U^l(y_x(\tau_n)) + U^{j_{n-1}}(y_x(\tau_n)) - U^{j_{n-1}}(y_x(\tau_{n-1})) \\ &\le \omega_l(\nu) + \omega_{j_{n-1}}(\nu), \end{aligned}$$

and hence (by the strict triangle inequality in (A5))

$$0 < \min_{i,j,l:\ i\neq j\neq l} \left\{k(a^i,a^j)+k(a^j,a^l)-k(a^i,a^l)\right\} \le \omega_\ell(\nu)+\omega_j(\nu),$$

where, in general, ω_j is a modulus of continuity for $U^j(y_x(\cdot))$ on the interval $[0,T]$. Letting ν tend to zero now leads to a contradiction, and the claim follows.

Hence $\alpha_x^j[b](t) = \sum a_{n-1} 1_{[\tau_{n-1},\tau_n)}(t) \in \Gamma$. Since U is a viscosity supersolution of the SQVI (3.18), we have $H^{j_n}(y_x(s), DU^{j_n}(y_x(s))) \ge 0$ in the viscosity-solution sense for $\tau_n < s < \tau_{n+1}$. Thus (see [6, section II.5.5])

$$U^{j_n}(y_x(s)) - U^{j_n}(y_x(t)) \ge \int_s^t [h(y_x(s), a^{j_n}, b(s)) - \gamma^2 |b(s)|^2] ds \tag{3.43}$$

for all $b \in \mathcal{B}$, $\tau_n < s \le t < \tau_{n+1}$. (This argument uses the boundedness of the disturbance set B.) Letting $s \to \tau_n^+$ and $t \to \tau_{n+1}^-$, we get

$$U^{j_n}(y_x(\tau_n)) - U^{j_n}(y_x(\tau_{n+1})) \ge \int_{\tau_n}^{\tau_{n+1}} [h(y_x(s), a^{j_n}, b(s)) - \gamma^2 |b(s)|^2] ds \quad \text{for all } b \in \mathcal{B}. \tag{3.44}$$

We also have

$$U^{j_n}(y_x(\tau_{n+1})) = U^{j_{n+1}}(y_x(\tau_{n+1})) + k(a^{j_n}, a^{j_{n+1}}) \text{ for } \tau_{n+1} < \infty. \tag{3.45}$$

Adding (3.44) over $\tau_n \le T$ and using (3.45), we have

$$\begin{aligned} U^{j_0}(x) &\ge \int_0^T [h(y_x(s), \alpha_x^j[b](s), b(s)) - \gamma^2 |b(s)|^2] ds + \sum_{\tau_n \le T} k(a_{n-1}, a_n) + U^{j_n}(y_x(T)) \\ &\ge \int_0^T [h(y_x(s), \alpha_x^j[b](s), b(s)) - \gamma^2 |b(s)|^2] ds + \sum_{\tau_n \le T} k(a_{n-1}, a_n). \end{aligned}$$

Since this inequality holds for arbitrary $b \in \mathcal{B}$ and $T \ge 0$, we have

$$U^j(x) \ge \sup_{b\in\mathcal{B},\ T\ge 0} \left\{ \int_{[0,T]} l(y_x(s), a^j, \alpha_x^j[b](s), b(s)) \right\}.$$

Thus $U^j(x) \ge V_\gamma^j(x)$. By Theorem 3.6, we know that V_γ is a viscosity supersolution of the SQVI (3.18) if it is continuous. (Note that the proof of the viscosity-supersolution property of V_γ in Theorem 3.6 does not use the assumption (A6).) Also, V_γ has the property (iii) by Proposition 3.1. Thus we conclude that, if continuous, V_γ is the minimal, nonnegative continuous viscosity supersolution of SQVI (3.18) which satisfies condition (iii)

The first part of Theorem 3.9, already proved, then implies that V_γ is a switching-storage function. Moreover, if S is any continuous, switching-storage function for some nonanticipating strategy α_{V_γ}, from Theorem 3.7 we see that S is a viscosity supersolution of the SQVI (3.18). Again, from the first part of this theorem, already proved, we then see that $S \ge V_\gamma$ if S has the property (iii), and hence V_γ is also the minimal continuous switching-storage function satisfying the condition (iii), as asserted. □

Remark 1. The proof of Theorem 3.9 required deduction of an integral inequality (3.43) from knowledge of an inequality of the form $H(y(x), DU(y(x)) \geq 0$ holding in the viscosity sense; the proof of this fact from [6, section II.5.5] ultimately uses the boundedness of the disturbance set B. However, the paper [13] obtains such an integral inequality without a boundedness assumption by using other tools of nonsmooth analysis (e.g., "contingent epiderivative" and viability theory). By using this alternative nonsmooth framework rather than restricting oneself to "viscosity-sense supersolutions," one can get a version of Theorem 3.9 which does not rely on the boundedness of B.

Remark 2. The results of this section reduce the computation of robust state-feedback switching strategy α to computing the solution $(U = U^1, \ldots, U^r)$ (or, more precisely, the minimal viscosity supersolution) of the SQVI of the form

(SQVI)
$$\max\left\{H^j(x, DU^j(x)),\, U^j(x) - \min_{i \neq j}\{U^i(x) + k(a^j, a^i)\}\right\} = 0, \quad j = 1, \ldots, r.$$

This leaves open the issue of how one computes such a solution of an SQVI. A connection can be made with the easier problem of solving a single variational inequality as follows.

If $U = (U^1, \ldots, U^r)$ (with $U^j \in C(\mathbb{R}^N)$ for $j = 1, \ldots, r$) is the minimal viscosity supersolution of (SQVI), then each U^j can be interpreted as the minimal viscosity supersolution of the variational inequality (VI)

$$\max\{H(x, DU(x)), U(x) - \Phi(x)\} = 0 \tag{VI}$$

with Hamiltonian H equal to H^j and with stopping cost Φ equal to $\Phi^j = \min_{i \neq j}\{U^i + k(a^j, a^i)\}$. This suggests defining an iteration map F as follows. Given an r-tuple $U = (U^1, \ldots, U^r)$ of nonnegative real-valued functions, define a new r-tuple $F(U) = (F(U)^1, \ldots, F(U)^r)$ of nonnegative real-valued functions by

$$F(U)^j = \text{ the minimal viscosity supersolution of (VI) with } H = H^j \text{ and } \Phi = \Phi^j.$$

Note that U is the minimal viscosity supersolution of (SQVI) if and only if $F(U) = U$, i.e., if and only if U is a fixed point of F. Formally, one can solve the fixed point problem by guessing a starting point $U_0 = (U_0^1, \ldots, U_0^r)$ and then iterating

$$U_{n+1} = F(U_n),\ n = 0, 1, 2, \ldots, .$$

If $U_n \to U_\infty$ and F is continuous, then, from $U_{n+1} = F(U_n)$, one can take the limit to get $U_\infty = F(U_\infty)$, from which we see that U_∞ is a fixed point for F. For finite horizon problems or problems with a positive discount factor in the running cost, the connection is a little cleaner; in this situation, one has a uniqueness theorem for solutions of the relevant SQVI.

A similar remark giving a connection between the impulsive control problem and the stopping time problem is given in [6, Chapter III, section 4.3], where some convergence results are also given. It would be of interest to develop similar convergence results for the SQVI associated with an optimal switching-control problem.

4. Stability for switching-control problems. In this section, we show how the solution of the SQVI (3.18) can be used for stability analysis.

We consider the system (1.1)–(1.2) with some control strategy α plugged in to get a closed-loop system with the disturbance signal as the only input:

$$\Sigma_{sw}\left\{\begin{array}{rcl}\dot{y} &=& f(y,\alpha_x^j[b],b),\ y(0)=x,\ a(0^-)=a^j,\\ z &=& h(y,\alpha_x^j[b],b).\end{array}\right.$$

An example of such a strategy α is the canonical strategy α_U (see (3.36) or (3.37)) determined by a continuous supersolution of the SQVI (3.18). Moreover, if $V_\gamma = (V_\gamma^1,\dots,V_\gamma^r)$ is the vector lower-value function for the associated game as in (1.4) and we assume that 0 is an equilibrium point for the autonomous system formed from (1.1)–(1.2) by taking $a(s)=a^{i_0}$ and $b(s)=0$ (so $f(0,a^{i_0},0)=0$ and $h(0,a^{i_0},0)=0$), then it is easy to check that $V_\gamma^{i_0}(0)=0$. Furthermore, the associated strategy $\alpha=\alpha_{V_\gamma}$ has the property that

$$\alpha_0^{i_0}[0]=a^{i_0}, \tag{4.1}$$

so 0 is an equilibrium point of the closed-loop system Σ_{sw} with $\alpha=\alpha_{V_\gamma}$ and $a(0^-)=a^{i_0}$ as well. Our goal is to give conditions which guarantee a sort of converse, starting with any continuous supersolution U of the SQVI (3.18).

We first need a few preliminaries. The following elementary result can be found, e.g., in [19].

LEMMA 4.1. *If $\phi(\cdot):\mathbb{R}\to\mathbb{R}$ is a nonnegative, uniformly continuous function such that $\int_0^\infty \phi(s)\,ds<\infty$, then $\lim_{t\to\infty}\phi(t)=0$.*

We say that the closed-loop switching system Σ_{sw} is *zero-state observable* for initial control setting a^j if whenever $h(y_x(t),\alpha_x^j[0](t),0)=0$ for all $t\ge 0$, then $y_x(t)=y_x(t,\alpha_x^j[0],0)=0$ for all $t\ge 0$. We say that the closed-loop system Σ_{sw} is *zero-state detectable* for initial control setting a^j if

$$\lim_{t\to\infty} h(y_x(t),\alpha_x^j[0](t),0)=0 \text{ implies that } \lim_{t\to\infty} y_x(t,\alpha_x^j[0],0)=0.$$

The following proposition gives conditions which guarantee that a particular component U^j of a viscosity supersolution $U=(U^1,\dots,U^r)$ is positive-definite, a conclusion which will be needed as a hypothesis in the stability theorem to follow.

PROPOSITION 4.2. *Assume the following:*

(i) (A1)–(A6) *hold;*

(ii) Σ_{sw} *is zero-state observable for some initial control setting a^j;*

(iii) $U=(U^1,\dots,U^r)$ *is a nonnegative continuous viscosity supersolution of the SQVI* (3.18)

$$\max\left\{H^j(x,DU^j(x)),U^j(x)-\min_{i\ne j}\{U^i(x)+k(a^j,a^i)\}\right\}=0,\quad x\in\mathbb{R}^N,\ j=1,\dots,r;$$

(iv) $U^j(x)\le \min_{i\ne j}\{U^i(x)+k(a^j,a^i)\},\ x\in\mathbb{R}^N,\ j=1,\dots,r.$

Then $U^j(x)>0$ for $x\ne 0$.

Proof. Let $x\in\mathbb{R}^N$. By Theorem 3.9, U is a storage function for Σ_{sw} if we use $\alpha=\alpha_U$ given by (3.36) or, equivalently, (3.37). Thus

$$\begin{aligned}U^j(x)&\ge\int_{[0,T)} l(y_x(s),a^j,\alpha_{U,x}^j[0](s),0)\,ds+U^{j(T)}(y_x(T,\alpha_{U,x}^j[0],0))\\ &\ge\int_{[0,T)} l(y_x(s),a^j,\alpha_{U,x}^j[0](s),0)\,ds\ \text{ for all } T>0.\end{aligned}$$

Since k is nonnegative, we have

$$U^j(x) \geq \int_0^T h(y_x(s), \alpha_x^j[0](s), 0)\, ds \quad \text{for all } T \geq 0.$$

Thus, if $U^j(x) = 0$, then $h(y_x(s, \alpha_x^j[0], 0), \alpha_x^j[0](s), 0) = 0$ for all $s \geq 0$ because h is nonnegative by assumption (A6). Since Σ_{sw} is zero-state observable for initial control setting a^j, it follows that $y_x(s, \alpha_x^j[0], 0) = 0$ for all $s \geq 0$. Thus $x = y_x(0, \alpha_x[0], 0) = 0$. Since U^j is nonnegative, we conclude that, if $x \neq 0$, then $U^j(x) > 0$. ∎

PROPOSITION 4.3. *Assume the following:*

(i) (A1)–(A6) *hold;*

(ii) $U = (U^1, \dots, U^r)$ *is a nonnegative continuous viscosity supersolution of the SQVI* (3.18)

$$\max\left\{H^j(x, DU^j(x)), U^j(x) - \min_{i \neq j}\{U^i(x) + k(a^j, a^i)\}\right\} = 0, \quad x \in \mathbb{R}^N,\ j = 1, \dots, r;$$

(iii) $U^j(x) \leq \min_{i \neq j}\{U^i(x) + k(a^j, a^i)\},\ x \in \mathbb{R}^N,\ j = 1, \dots, r;$

(iv) *there is an* $i_0 \in \{1, \dots, r\}$ *such that* $U^{i_0}(0) = 0$ *and* $U^{i_0}(x) > 0$ *for* $x \neq 0$.

(v) Σ_{sw} *is zero-state detectable for all initial control settings* $a^j \in A$.

Then the strategy α_U *associated with* U *as in* (3.36) *or* (3.37) *is such that* $\alpha_{U,0}^{i_0}[0](s) = a^{i_0}$ *for all* s *and* 0 *is an equilibrium point for the system* $\dot{y} = f(y, a_0^i, 0)$. *Moreover,* 0 *is a globally asymptotically stable equilibrium point for the system* Σ_{sw} *in the sense that the solution* $y(t) = y_x^j(t, \alpha_{U,x}^j[0], 0)$ *of*

$$\dot{y} = f(y, \alpha_{U,x}^j[0], 0), \quad y(0) = x,$$

has the property that

$$\lim_{t \to \infty} y_x^j(t, \alpha_{U,x}^j[0], 0) = 0$$

for all $x \in \mathbb{R}^N$ *and all* $a^j \in A$.

Proof. Suppose that $U^{i_0}(0) = 0$ and $U^{i_0}(x) > 0$ for $x \neq 0$. Let $T \geq 0$ and $x \in \mathbb{R}^N$. Since U is a storage function for the closed-loop system formed from (1.1)–(1.2) with $\alpha = \alpha_U$, we have

$$U^{i_0}(x) \geq \int_0^T h(y_x(s), \alpha_x^{i_0}[0](s), 0)\, ds + \sum_{\tau < T} k(\alpha_{U,x}^{i_0}(\tau^-), \alpha_{U,x}^{i_0}(\tau)) + U^{j(T)}(y_x(T, \alpha_{U,x}^{i_0}[0], 0)). \tag{4.2}$$

Since $h,\ k,\ U$ are nonnegative and $U^{i_0}(0) = 0$ by our assumptions, substitution of $x = 0$ in (4.2) forces

$$\sum_{\tau < T} k(\alpha_{U,0}^{i_0}[0](\tau^-), \alpha_{U,0}^{i_0}[0](\tau)) = 0.$$

This implies that $\alpha_{U,0}^{i_0}[0](t) = a^{i_0}$ for all $0 \leq t \leq T$. Thus

$$0 \leq U^{j(T)}(y_0(T, \alpha_{U,0}^{i_0}[0], 0)) = U^{i_0}(y_0(T, \alpha_{U,0}^{i_0}[0], 0)) \leq U^{i_0}(0) = 0.$$

By the positive definite property of U^{i_0}, we have $y_0(T, \alpha^{i_0}_{U,0}[0], 0) = 0$. Since $T \geq 0$ is arbitrary, we conclude that 0 is an equilibrium point of the system $\dot{y} = f(y, a^{i_0}, 0)$.

Next we want to show that 0 is a globally asymptotically stable equilibrium point for the closed-loop switching system Σ_{sw} with $\alpha = \alpha_U$. Again, from the storage-function property of $U = (U^1, \ldots, U^r)$ for the system Σ_{sw} with $\alpha = \alpha_U$, we have

$$\int_0^T h(y_x(s), \alpha^j_{U,x}[0](s), 0)\, ds \leq U^j(x) < \infty \text{ for all } T > 0.$$

Thus $\lim_{t\to\infty} h(y_x(t), \alpha^j_{U,x}[0], 0) = 0$ by Lemma 4.1. By the detectability assumption (v), we have $\lim_{t\to\infty} y_x(t, \alpha^j_{U,x}[0], 0) = 0$ as required. □

5. An example. We consider in this section an optimal switching problem with one-dimensional state space ($x \in \mathbb{R}^1$) for which the value function and corresponding control are explicitly computable via a simple geometric construction. There will be two controls: $a \in \{1, 2\}$. The switching cost will be symmetric: $k(1, 2) = k(2, 1) = \beta > 0$. For each a value, we will use $a' = 3 - a$ to denote the other control value. The system dynamics will be given by

$$f(y, 1, b) = -y + b; \quad f(y, 2, b) = -\mu(y - 1) + b, \tag{5.1}$$

with output function h taken simply to be the squared state

$$h(y, a, b) = y^2. \tag{5.2}$$

We use the specific parameter values

$$\mu = 3, \quad \beta = .4, \quad \gamma = 2$$

throughout.

This example satisfies all of our hypotheses except that we take $B = \mathbb{R}$, which is not compact. Our purpose is to make the SQVI (2.5) more tangible in the context of the example, to show how the optimal strategy α_* is determined, and to show how one might establish its optimality. We note that, even apart from the fact that our B is not compact, Theorem 3.9 would not by itself imply that our solution V^a of the SQVI is that value of the game (i.e., that α_* is optimal); an additional argument to establish the minimality of V^a among nonnegative solutions is also necessary. Instead we will outline a direct proof of the optimality of α_*. Since we are not appealing to any of the theorems above, the fact that the compactness hypothesis on B is not satisfied does not pose a problem. (It would be possible to modify the example so that $B = [-M, M]$ could be used for some sufficiently large M. For instance, if the $f(y, a, b)$ were bounded (nonlinear) functions of y, this would be possible. However, the linear-affine dynamics of (5.1) are simpler to work with, so we have kept them.)

Our task is to construct the appropriate solution of the SQVI (2.5). With just two control values a, the SQVI reduces to the following: for each a,

$$V^a(x) \leq \beta + V^{a'}(x) \text{ for all } x, \tag{5.3}$$

$$H^a(x, D^+V^a(x)) \leq 0 \text{ for all } x, \tag{5.4}$$

$$H^a(x, D^-V^a(x)) \geq 0 \text{ for those } x \text{ with } V^a(x) < \beta + V^{a'}(x). \tag{5.5}$$

Here we have used the standard notation $D^+V^a(x)$ to refer to the set of all possible slopes $\varphi'(x)$ of smooth test functions φ for which $V^a - \varphi$ has a local maximum at x,

usually called the *superdifferential* of V^a at x. Similarly, the *subdifferential* $D^-V^a(x)$ denotes the set of all $\varphi'(x)$ for smooth test functions φ such that $V^a(x) - \varphi$ has a local minimum at x. (See [6, page 29].) At points x where both V^1 and V^2 are differentiable, (5.3)–(5.5) can be expressed more explicitly as

$$|V^1(x) - V^2(x)| \le \beta,$$

together with the following.

1. If $V^1(x) - V^2(x) = \beta$, then $(V^1)'(x) = (V^2)'(x) =: q(x)$ (since $V^1 - V^2$ has a maximum at x), and

$$H^1(x, q(x)) \le 0, \quad H^2(x, q(x)) = 0.$$

2. If $V^1(x) - V^2(x) = -\beta$, then, similarly, $(V^1)'(x) = (V^2)'(x) =: q(x)$ and

$$H^1(x, q(x)) = 0, \quad H^2(x, q(x)) \le 0.$$

3. If $|V^1(x) - V^2(x)| < \beta$, then

$$H^1(x, (V^1)'(x)) = 0, \quad H^2(x, (V^2)'(x)) = 0.$$

Where one or the other of V^a is not differentiable, we must revert to (5.3)–(5.5). However, one of the cases 1–3 above will apply at most x.

The two Hamiltonian functions are

$$H^1(x,p) = px - x^2 - \frac{1}{4\gamma^2}p^2,$$
$$H^2(x,p) = \mu p(1-x) - x^2 - \frac{1}{4\gamma^2}p^2.$$

These are both instances of the general formula

$$\begin{aligned} H(x,p) &= \inf_b\{-(g(x)+b)\cdot p - x^2 + \gamma^2 b^2\} \\ &= -pg(x) - x^2 - \frac{1}{4\gamma^2}p^2 \\ &= (\gamma g(x))^2 - x^2 - \left(\frac{1}{2\gamma}p + \gamma g(x)\right)^2, \end{aligned} \tag{5.6}$$

where $g(x) = -x$ for $a = 1$ and $g(x) = -\mu(x-1)$ for $a = 2$. We are interested in $V'(x) = p(x)$ solving $H(x, p(x)) = 0$. Provided $|x| < \gamma|g(x)|$, the equation $H(x,p) = 0$ has two distinct real solutions:

$$-2\gamma^2 g(x) \pm 2\gamma\sqrt{\gamma^2 g(x)^2 - x^2}.$$

For each a, we need to select an appropriate branch $p^a(x)$ of the solution to $H^a(x,p) = 0$. For $a = 1$, we take

$$p^1(x) = 2\rho x,$$

where $\rho = \gamma^2 - \gamma\sqrt{\gamma^2 - 1}$. Note that, for $x < 0$, $p^1(x)$ is the larger of the two solutions of $H^1(x,p) = 0$, and so

$$H^1(x,p) \le 0 \text{ for all } p \ge p^1(x),\ x < 0. \tag{5.7}$$

For $x > 0$, however, $p^1(x)$ is the smaller of the two solutions, and so

$$H^1(x,p) \le 0 \text{ for all } p \le p^1(x),\ x > 0. \tag{5.8}$$

For $p^2(x)$, we note that $H^2(x,p) = 0$ has no solution for $\frac{6}{7} < x < \frac{6}{5}$ because, with $g(x) = -\mu(x-1)$, $|x| > \gamma|g(x)|$ there. We take

$$p^2(x) = \begin{cases} 2\gamma^2\mu(x-1) - 2\gamma\sqrt{\gamma^2\mu^2(x-1)^2 - x^2} & \text{for } x \ge \frac{6}{5}, \\ 2\gamma^2\mu(x-1) + 2\gamma\sqrt{\gamma^2\mu^2(x-1)^2 - x^2} & \text{for } x \le \frac{6}{7}. \end{cases}$$

Let

$$W^1 = \rho x^2$$

and

$$W^2(x) = \int p^2(x)\,dx.$$

This determines W^2 up to two constants, one each for $(-\infty, 6/7)$ and $(6/5, \infty)$. Those constants are determined uniquely by

$$W^2(x) = \beta + W^1(x) \text{ for } x = 0, 3/2. \tag{5.9}$$

These are solutions of $H^a(x, DW^a(x)) = 0$. The desired solutions of the SQVI are given by

$$V^2(x) = \begin{cases} W^2(x) & \text{for } x < 0, \\ \beta + W^1(x) & \text{for } 0 \le x \le x_1, \\ W^2(x) & \text{for } x_1 < x \end{cases} \tag{5.10}$$

and

$$V^1(x) = \begin{cases} \beta + W^2(x) & \text{for } x \le x_2, \\ W^1(x) & \text{for } x_2 < x < x_3, \\ \beta + W^2(x) & \text{for } x_3 \le x, \end{cases} \tag{5.11}$$

where $x_2 = -1.3175\ldots$, $x_1 = 3/2$, $x_3 = 2.55389\ldots$, values whose significance will emerge below. Graphs are presented in Figure 5.1.

We now outline the verification that V^a as defined above do satisfy the SQVI, leaving many of the details to the interested reader. First, consider $0 < x < x_1$. Here $V^{1\,\prime}(x) = p^1(x)$ so that $H^1(x, V^{1\,\prime}(x)) = 0$. Since $V^2 = \beta + V^1$, we also have $V^{2\,\prime}(x) = p^1(x)$. Case 2 above requires $H^2(x, p^1(x)) \le 0$, which is true up to $x = 3/2 = x_1$ but not beyond. For $x_1 < x < x_3$, we have $H^a(x, V^{a\,\prime}(x)) = H^a(x, p^a(x)) = 0$ for both a, so all of the necessary derivative conditions are satisfied. Note that (5.9) ensures that V^2 is continuous at x_1. Moreover, $H^2(x, p^1(x)) = 0$ at $x = x_1$ because $DW^1(x_1) = p^1(x_1) = p^2(x_1) = DW^2(x_1)$ there. This means V^2 is C^1 at x_1. We have $V^1(x) - \beta < V^2(x) < \beta + V^1(x)$ for $x_1 < x < x_3$, but at x_3 we find $V^1(x_3) - \beta = V^2(x_3)$. (This determines the value of x_3.) Next consider $x > x_3$. Here $V^{2\,\prime} = p^2(x)$ so that $H^2(x, V^{2\,\prime}(x)) = 0$. Since $V^1(x) = \beta + V^2(x)$, $V^{1\,\prime}(x) = V^{2\,\prime}(x) = p^2(x)$ and otherwise case 1 requires only that $H^1(x, p^2(x)) \le 0$, which does hold. Note that the choice of x_3 makes V^1 continuous at x_3, but it is not differentiable there. One finds

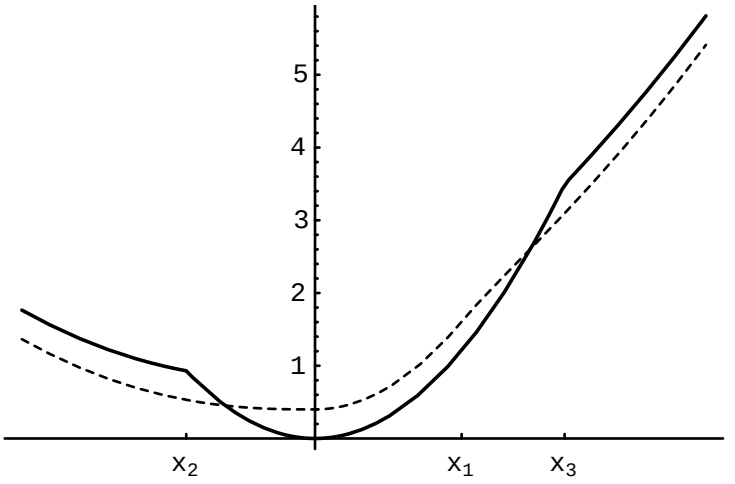

FIG. 5.1. V^1 *(solid) and* V^2 *(dashed).*

that $D^-V^1(x_3) = \emptyset$ and $D^+V^1(x_3)$ is the interval $[p^2(x_3), p^1(x_3)]$. By virtue of (5.8), the viscosity solution requirement $H^1(x_3, D^+V^1(x_3)) \le 0$ is satisfied.

Next consider $x_2 < x < 0$. Here again we have $V^{a\,\prime}(x) = p^a(x)$ so that, for both a,

$$H^a(x, p^a(x)) = 0.$$

We also have $V^1(x) - \beta < V^2(x) < \beta + V^1(x)$, but at x_2 we find $V^1(x_2) - \beta = V^2(x_2)$. This determines x_2 and makes V^1 continuous at x_2. For $x < x_2$, we have $V^{1\,\prime}(x) = V^{2\,\prime}(x) = p^2(x)$ so that case 1 above requires $H^2(x, p^2(x)) = 0$ and $H^1(x, p^2(x)) \le 0$, both of which are true for $x < x_2$. Note that V^1 is not differentiable at x_2. One finds that $D^-V^1(x_2) = \emptyset$ and $D^+V^1(x_2)$ is the interval $[p^1(x_2), p^2(x_1)]$. By virtue of (5.7), the viscosity solution requirement $H^1(x_2, D^+V^1(x_2)) \le 0$ is satisfied.

The strategy α^* associated with our solution (5.10), (5.11) is easy to describe in state-feedback terms. Define the *switching sets*

$$S_1 = \{x : \ V^2(x) = \beta + V^1(x)\} = [0, x_1],$$
$$S_2 = \{x : \ V^1(x) = \beta + V^2(x)\} = (-\infty, x_2] \cup [x_3, \infty).$$

The strategy α^* will instantly switch from $a = 1$ to $a = 2$ whenever $y(t) \in S_2$ and will instantly switch from $a = 2$ to $a = 1$ whenever $y(t) \in S_1$. We will prove directly that, in fact, $V^a_\gamma = V^a$ and that our strategy α^* is optimal. To be precise, we shall show that, for any j and any strategy $\alpha \in \Gamma$,

(5.12)
$$V^j(y(0)) \le \sup_{b \in \mathcal{B}} \sup_{T > 0} \left\{ \int_0^T [h(y_x(s), \alpha^j_x[b](s), b(s)) - \gamma^2 |b(s)|^2]\, ds + \sum_{\tau_i \le T} k(a_{i-i}, a_i) \right\}.$$

Moreover, for our strategy α^*, (5.12) will be an equality for all x, j. The key to this is the existence of a particular "worst case" disturbance, as claimed by the following proposition. (This proposition is intended only in the context of the particular example and the parameter values described above.)

PROPOSITION 5.1. *For any $x \in \mathbb{R}^N$, $j \in \{1,2\}$, and strategy $\alpha \in \Gamma$, there exists a disturbance $b^* = b^*_{\alpha_x^j} \in \mathcal{B}$ with the property that*

$$b^*(t) = \frac{1}{2\gamma^2}(V^{\alpha_x^j[b^*])(t)})'(y_x(t, \alpha_x^j[b], b))$$

holds for all but finitely many t in every interval $[0,T]$.

A proof can be based on the obvious construction. Given $\alpha \in \Gamma$, an initial control j, and an initial point $x \in \mathbb{R}^N$, consider the solution of

$$\dot{y} = f\left(y, j, \frac{1}{\gamma^2}(V^j)'(y)\right); \quad y(0) = x. \tag{5.13}$$

We simply take $b^*(t) = (V^j)'(y(t))$ up until the first time τ_1 that the policy $\alpha_x^j[b^*]$ calls for a switch from $a = j$ to $a = j'$. For $t > \tau_1$, we continue by solving

$$\dot{y} = f\left(y, j', \frac{1}{\gamma^2}(V^{j'})'(y)\right)$$

with initial value $y(\tau_1)$ as already determined. We take $b^*(t) = (V^{j'})'(y(t))$ for $\tau_1 < t$ up until the next time τ_2 that $\alpha_x^j[b^*]$ calls for a switch from $a = j'$ to $a = j$. We continue this construction iteratively.

A number of observations are needed to justify the construction. One is the existence of a unique solution to (5.13). For $j = 2$, the right side is C^1, so the solution is uniquely determined. For $j = 1$, the right side has discontinuities at x_2 and x_3, but, since $f(x, 1, \frac{1}{\gamma^2}(V^1)'(x))$ does not change sign across the discontinuities, the solution *is* uniquely determined. Graphs of $f(y, a, \frac{1}{\gamma^2}(V^a)'(y))$ are provided in Figures 5.2 and 5.3 below. (We comment that, although the graphs appear piecewise linear, they are not. Figure 5.2 is linear only for $0 < x < x_1$, and Figure 5.3 is linear only for $x_2 < x < x_3$, as inspection of the formulas shows.) One can check that $y\dot{y} < 0$ for sufficiently large $|y|$, which implies that solutions of (5.13) are defined for all $t \geq 0$. Observe also for $j = 1$ that, for any solution of (5.13), there is at most one value of t for which $y(t)$ is at one of the discontinuities of $(V^1)'$ and for which there is any ambiguity in the specification $b^*(t) = (V^j)'(y(t))$.

The other concern is that the sequence τ_i of switching times generated by our construction might have a finite accumulation point: $\lim \tau_i = s < \infty$. Our hypotheses on the strategy α disallow this, however, for the following reason. If it were the case that $\lim \tau_i = s < \infty$, then extend our definition of b^* in any way to $t \geq s$, say, $b^*(t) = 0$. By hypothesis, $\alpha_x^j[b^*]$ is an admissible control in $\mathcal{A}$, which means, in particular, that its switching times τ_i do not have a finite accumulation point. However, extension of b^* for $t > s$ does not alter the switching times $\tau_i < s$ by the nonanticipating property of α. This would mean that $\alpha[b^*]$ does have an infinite number of switching times $\tau_i < s$, which is a contradiction. Finally, by our comments above, on each interval $[\tau_i, \tau_{i+1}]$, there is at most a single t value at which $b^*(t) = (V^{\alpha_x^j[b^*]})'(y(t))$ is ambiguous. Thus there are at most a finite number of such t in any $[0,T]$.

Consider now any strategy $\alpha \in \Gamma$, initial position $x = y(0)$, and control setting j, and let $b^*(t)$ be the disturbance described in the proposition. We will let $a_i = \alpha_x^j[b^*](t)$ denote the control settings on the intervals $[\tau_i, \tau_{i+1}]$ between consecutive switching times. In particular, $a_0 = j$. On each interval $[\tau_i, \tau_{i+1}]$, (5.4) and the fact that $b^*(t)$ achieves the infimum in (5.6) for $x = y(t)$ and $p = (V^{a_i})'(x)$ imply that (for all but

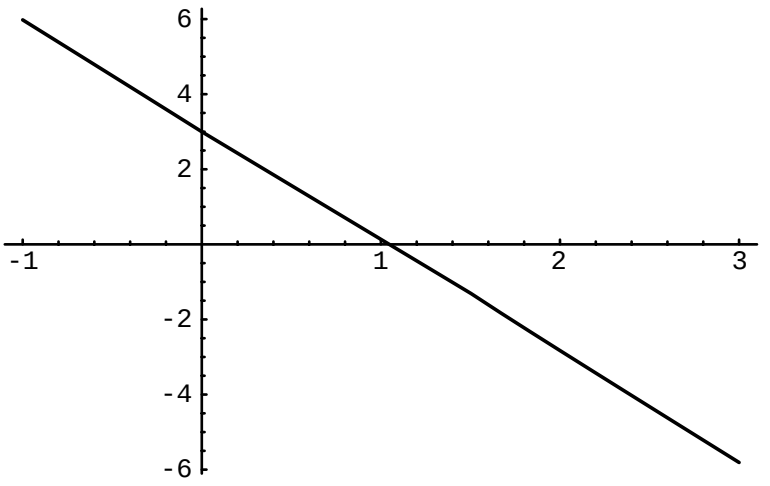

FIG. 5.2. *Plot of* $f(x, 2, \frac{1}{2\gamma^2} V^{2\,\prime}(x))$.

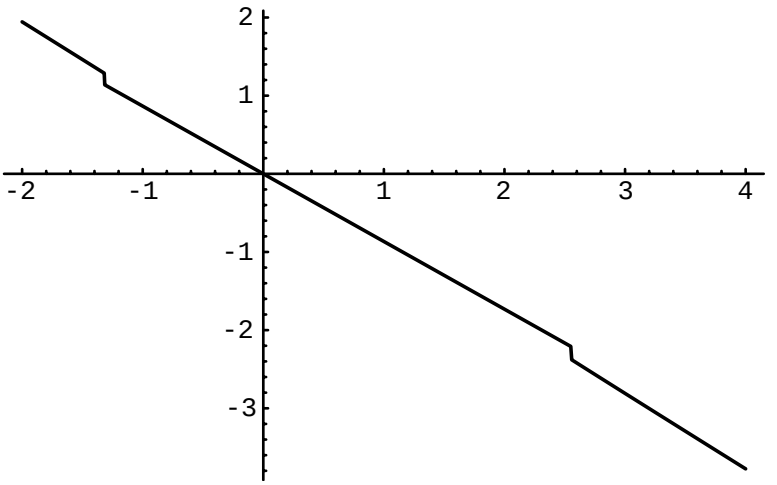

FIG. 5.3. *Plot of* $f(x, 1, \frac{1}{2\gamma^2} V^{1\,\prime}(x))$.

one t)

$$\frac{d}{dt} V^{a_i}(y(t)) \geq \gamma^2 b^*(t)^2 - h(y(t), a_i, b^*(t)).$$

Thus, for any $\tau_i < t \leq \tau_{i+1}$, we have

$$V^{a_i}(y(t)) - V^{a_i}(y(\tau_i)) \geq \int_{\tau_i}^{t} [\gamma^2 |b^*(s)|^2 - h(s)]\, ds.$$

Across a switching time τ_i, we have from (5.3)

$$V^{a_i}(y(\tau_i)) - V^{a_{i-1}}(y(\tau_i)) \geq -\beta = -k(a_{i-1}, a_i).$$

Adding these inequalities over $\tau_i \le T$, we see that

$$V^{\alpha[b^*](T)}(y(T)) - V^{\alpha[b^*](0)}(y(0)) \ge -\left\{ \int_0^T [h(s) - \gamma^2 |b^*(s)|^2]\, ds + \sum_{\tau_i \le T} k(a_{i-1}, a_i) \right\}.$$

A rearrangement of this gives

(5.14)
$$V^{\alpha[b^*](T)}(y(T)) + \left\{ \int_0^T [h(s) - \gamma^2 |b^*(s)|^2]\, ds + \sum_{\tau_i \le T} k(a_{i-1}, a_i) \right\} \ge V^{\alpha[b^*](0)}(y(0)).$$

When we consider α^* specifically, we recognize that

$$H^{a_i}(y(t), (V^{a_i})'(y(t))) = 0$$

for t between two τ_i's, and at τ_i we have

$$V^{a_{i+1}}(y(\tau_i)) - V^{a_i}(y(\tau_i)) = -\beta = -k(a_{i+1}, a_i).$$

This means that (5.14) is an equality for α^* specifically.

To finish our optimality argument, we will show that, for α, a general strategy, initial condition (x, a^j), and associated disturbance $b^* = b^*_{\alpha_x^j}$ as above, as $T \to \infty$ we must have either $y(T) \to 0$ and $\alpha[b^*](T) \to 1$, or else

$$\int_0^T [h(s) - \gamma^2 |b^*(s)|^2]\, ds + \sum_{\tau_i \le T} k(a_{i-1}, a_i) \to +\infty. \tag{5.15}$$

In the case of $\alpha = \alpha^*$ specifically, we will have the former possibility. Since $V^1(0) = 0$ and is continuous, these facts imply (5.12) as claimed. The verification of these asserted limiting properties for the case of general α depends on some particular inequalities for $(V^a)'(x)$ as determined by (5.11), (5.10). First, we assert that, for both a values,

$$h(y(t), a, b^*(t)) - \gamma^2 |b^*(t)|^2 = |y(t)|^2 - \frac{1}{4\gamma^2}[(V^a)'(y(t))]^2 > 0 \text{ for } x \ne 0. \tag{5.16}$$

Moreover, $|x|^2 - \frac{1}{4\gamma^2}[(V^a)'(x)^2$ has a positive lower bound on $\{x : |x| \ge \epsilon\}$ for each $\epsilon > 0$. Instead of what would be a very tedious algebraic demonstration of this, we simply offer the graphical demonstration in Figure 5.4. We have plotted $b^* = \frac{1}{2\gamma}(V^a)'(x)$ (solid lines) and $q = x$ (dashed lines) as functions of x. The validity of (5.16) is apparent.

The other fact we need is that, for $a = 2$ and the corresponding disturbance $b^*(t)$, the state-dynamics do not have an equilibrium at 0. This is easy to see because at $x = 0$ we have $b^* = \frac{1}{2\gamma^2}(V^2)'(0) = 0$, but $f(0, 2, b^*) = -\mu + b^*$. A graph of $f(x, 2, b^*) = -\mu(x - 1) + \frac{1}{2\gamma^2}(V^2)'(x)$ is provided in Figure 5.2, where we see the unique equilibrium just beyond $x = 1$.

In the case of $a = 1$, however, $\dot{x} = f(x, 1, \frac{1}{2\gamma^2}(V^1)'(x))$ has a unique globally asymptotically stable equilibrium at $x = 0$, as is evident in Figure 5.3.

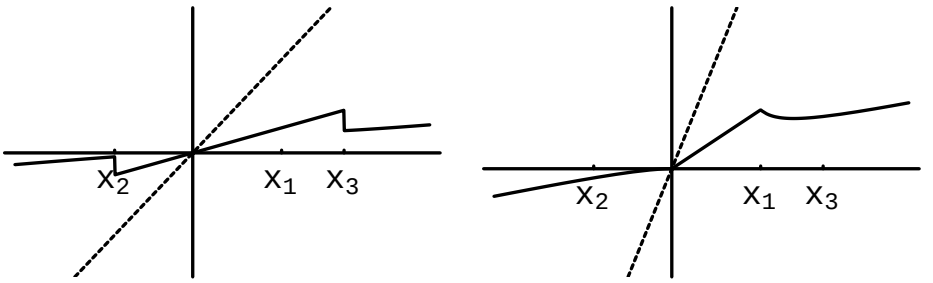

FIG. 5.4. *Graphical verification of* (5.16) *for* $V^{1\prime}$ *(left) and* $V^{2\prime}$ *(right).*

We turn then to the verification of the assertion of (5.15) or its alternative: assuming (5.15) to be false, we claim that $y(T) \to 0$ and $\alpha[b^*](T) \to 1$. By the nonnegativity from (5.16), we must have both

$$\sum_{\tau_i < \infty} k(a_{i-1}, a_i) < \infty \text{ and } \int_0^\infty [h(y(s)) - \gamma^2 |b^*(s)|^2]\, ds < \infty. \tag{5.17}$$

The first of these implies that there are only a finite number of switches; $\alpha[b^*](t) = a^{i^*}$ is constant from some time on. It is not possible that $i^* = 2$ because, in that case, $y(t)$ would be converging to the positive equilibrium of Figure 5.2, which implies by (5.16) that, as $t \to \infty$,

$$h(y(t), a^{i^*}, b^*(t)) - \gamma^* |b^*(t)|^2 \to C > 0.$$

This contradicts the second part of (5.17). Therefore, $i^* = 1$, which shows that $\alpha[b^*](T) \to 1$. However, since $\alpha[b^*](t) = 1$ from some point on, the stability illustrated in Figure 5.3 means that $y(t) \to 0$ as claimed. This completes our verification of the optimality of the strategy α^*.

NONLINEAR OBSERVER DESIGN IN THE SIEGEL DOMAIN*

ARTHUR J. KRENER† AND MINGQING XIAO‡

Abstract. We extend the method of Kazantzis and Kravaris [*Systems Control Lett.*, 34 (1998), pp. 241–247] for the design of an observer to a larger class of nonlinear systems. The extended method is applicable to any real analytic observable nonlinear system. It is based on the solution of a first-order, singular, nonlinear PDE. This solution yields a change of state coordinates which linearizes the error dynamics. Under very general conditions, the existence and uniqueness of the solution is proved. Lyapunov's auxiliary theorem and Siegel's theorem are obtained as corollaries. The technique is constructive and yields a method for constructing approximate solutions.

Key words. nonlinear systems, nonlinear observers, linearizable error dynamics, output injection, Siegel domain, Lyapunov's auxiliary theorem, Siegel's theorem

1. Introduction.

We consider the problem of estimating the current state $x(t)$ of a nonlinear dynamical system, described by a system of first-order differential equations,

$$\begin{aligned} \dot{x} &= f(x), \\ y &= h(x), \end{aligned} \tag{1.1}$$

from the past observations $y(s), s \le t$. The vector fields $f : \mathbf{R}^n \to \mathbf{R}^n$ and $h : \mathbf{R}^n \to \mathbf{R}^p$ are assumed to be real analytic functions with $f(0) = 0,\ h(0) = 0$. One technique of constructing an observer is to find a nonlinear change of state and output coordinates which transforms the system (1.1) into a system with linear output map and linear dynamics driven by nonlinear output injection. The design of an observer for such systems is relatively easy [8], [6], [2], and the error dynamics is linear in the transformed coordinates. Recently Kazantzis and Kravaris proposed a simpler method [5]. One seeks a change of state coordinates $z = \theta(x)$ such that the dynamics of (1.1) is linear driven by nonlinear output injection

$$\dot{z} = Az - \beta(y), \tag{1.2}$$

where A is an $n \times n$ matrix and $\beta : \mathbf{R}^p \to \mathbf{R}^n$ is a real analytic vector field. One does not have to linearize the output map.

Such a θ must satisfy the following first-order PDE:

$$\frac{\partial \theta}{\partial x}(x) f(x) = A\theta(x) - \beta(h(x)). \tag{1.3}$$

Using a particular form of the Lyapunov auxiliary theorem [10], Kazantzis and Kravaris showed that (1.3) has a unique solution under certain assumptions.

*Received by the editors July 14, 2000; accepted for publication (in revised form) February 22, 2002; published electronically September 19, 2002. A preliminary version of this paper appeared in the Proceedings of the 2001 IEEE Conference on Decision and Control.

THEOREM [10]. *Assume that* $f : \mathbf{R}^n \to \mathbf{R}^n, h : \mathbf{R}^n \to \mathbf{R}^p$, *and* $\beta : \mathbf{R}^p \to \mathbf{R}^n$ *are analytic vector fields with* $f(0) = 0$, $h(0) = 0$, $\beta(0) = 0$ *and* $F = \frac{\partial f}{\partial x}(0)$, $H = \frac{\partial h}{\partial x}(0)$, $B = \frac{\partial \beta}{\partial x}(0)$. *Let the eigenvalues of* F *be* $(\lambda_1, \ldots, \lambda_n)$ *and the eigenvalues of* A *be* $(\mu_1, \ldots, \mu_n)$. *If*

1. 0 *does not lie in the convex hull of* $(\lambda_1, \ldots, \lambda_n)$,
2. *there do not exist nonnegative integers* $m_1, m_2, \ldots, m_n$ *not all zero such that* $\sum_{i=1}^{n} m_i \lambda_i = \mu_j$,

then the first-order PDE (1.3), *with initial condition* $\theta(0) = 0$, *admits a unique analytic solution* θ *in a neighborhood of* $x = 0$.

Based on the above theorem, Kazantzis and Kravaris proposed a nonlinear observer design method [5], where the state observer is constructed using the coordinate transformation $z = \theta(x)$ and the output injection $\beta(y)$.

KAZANTZIS AND KRAVARIS THEOREM [5]. *Assume that* f, h, θ, β *are as in the above theorem and additionally that*

3. θ *is a local diffeomorphism,*
4. A *is Hurwitz.*

Then the local state observer for (1.1) *given by*

$$\dot{\hat{x}} = f(\hat{x}) - \left[\frac{\partial \theta}{\partial \hat{x}}(\hat{x})\right]^{-1} (\beta(y) - \beta(h(\hat{x}))) \tag{1.4}$$

has locally asymptotically stable error dynamics. In z *coordinates, the system is given by* (1.2), *the observer is*

$$\dot{\hat{z}} = A\hat{z} - \beta(y), \tag{1.5}$$

and the error $\tilde{z} = z - \hat{z}$ *dynamics is*

$$\dot{\tilde{z}} = A\tilde{z}. \tag{1.6}$$

One can show that if the conditions of this theorem hold, then (H, F) is an observable pair and (A, B) is a controllable pair. On the other hand, if (H, F) is an observable pair, then one can choose an invertible T and B so that $A = (TF + BH)T^{-1}$ satisfies 2, 3, and if the solution of (1.3) exists for some β such that $\beta(0) = 0$, $\frac{\partial \beta}{\partial x}(0) = B$, then θ is a local diffeomorphism. The size of the neighborhood of 0 on which θ is a diffeomorphism varies with the higher derivatives of β, hence the advantage of allowing them to be different from zero.

The approach of Kazantzis and Kravaris has an advantage over that of Krener and Respondek [8] and similar attempts to transform the dynamics and output map into observer form. The former uses the Lyapunov auxiliary theorem, which depends on a nonresonance condition, assumption 2 above, while the latter depends on integrability conditions. The nonresonance condition is generically satisfied while the integrability conditions are generically not satisfied. However, assumption 1 of Kazantzis and Kravaris is quite restrictive, as it requires the system to be locally asymptotically stable to the origin in either forward or reverse time. If the system is stable in forward time, then an observer is not needed, as we know where it is going. If the system is stable in reverse time, then it is unstable in forward time, so what good is a local observer?

Assumption 1 requires that the eigenvalues of the linear part of $f(x)$ at the origin lie in the *Poincaré domain*, whose definition follows.

DEFINITION 1. *An n-tuple $\lambda = (\lambda_1, \ldots, \lambda_n)$ of complex numbers belongs to the Poincaré domain if the convex hull of $(\lambda_1, \ldots, \lambda_n)$ does not contain zero. An n-tuple of complex numbers belongs to the Siegel domain if zero lies in the convex hull of $(\lambda_1, \ldots, \lambda_n)$.*

Clearly, requiring the spectrum of F to be in the Poincaré domain rules out many interesting problems, including critical ones where there are eigenvalues on the imaginary axis [9]. In this paper we extend the observer design method of Kazantzis and Kravaris to the Siegel domain [1]. We start with a definition.

DEFINITION 2. *Given an $n \times n$ matrix F with spectrum $\sigma(F) = \lambda = (\lambda_1, \ldots, \lambda_n)$ and constants $C > 0$, $\nu > 0$, we say a complex number μ is of type (C, ν) with respect to $\sigma(F)$ if for any vector $m = (m_1, m_2, \ldots, m_n)$ of nonnegative integers, $|m| = \sum m_i > 0$, we have*

$$|\mu - m \cdot \lambda| \geq \frac{C}{|m|^\nu}. \tag{1.7}$$

Now we are ready to state the main result of this paper.

MAIN THEOREM. *Assume that $f : \mathbf{R}^n \to \mathbf{R}^n$, $h : \mathbf{R}^n \to \mathbf{R}^p$, and $\beta : \mathbf{R}^p \to \mathbf{R}^n$ are analytic vector fields with $f(0) = 0$, $h(0) = 0$, $\beta(0) = 0$ and $F = \frac{\partial f}{\partial x}(0)$, $H = \frac{\partial h}{\partial x}(0)$, $B = \frac{\partial \beta}{\partial y}(0)$. Suppose there exists*

1. *an invertible $n \times n$ matrix T so that $TF = AT - BH$;*
2. *a $C > 0$, $\nu > 0$ such that all the eigenvalues of A are of type (C, ν) with respect to $\sigma(F)$.*

Then there exists a unique analytic solution $z = \theta(x)$ to the PDE (1.3) locally around $x = 0$ with $\frac{\partial \theta}{\partial x}(0) = T$, so θ is a local diffeomorphism.

Notes. We have stated this theorem for real analytic functions because we are applying it to a real analytic system. However, it is true for complex analytic functions, as can be seen from the proof. Assumption 2 implies that the eigenvalues of A are distinct from those of F. We shall show the following. Assumptions 1 and 2 imply that (H, F) is an observable pair. On the other hand, if (H, F) is an observable pair, then one can let $T = I$ and set the spectrum of A arbitrarily by choice of B. Almost all complex numbers are of type (C, ν) with respect to $\sigma(F)$, so assumption 2 is hardly a restriction on A when (H, F) is an observable pair. If A is chosen to be Hurwitz, then the state estimator is given by (1.4) and the error dynamics is locally asymptotically stable as before. We defer the proof of the main theorem to the next section.

CONVERSE TO THE MAIN THEOREM. *Consider the class of nonlinear systems described by the following equation:*

$$\begin{aligned} \dot{z} &= g(z), \\ y &= h(z), \end{aligned} \tag{1.8}$$

where $z \in \mathbf{R}^n$, $y \in \mathbf{R}^p$, and g, h are continuous vector fields on $\mathbf{R}^n$, $\mathbf{R}^p$, respectively, with $g(0) = 0$ and $h(0) = 0$. If there exists a nonlinear observer

$$\dot{\hat{z}} = \hat{g}(\hat{z}, y) \tag{1.9}$$

such that the error $\tilde{z} = z - \hat{z}$ dynamics is linear,

$$\dot{\tilde{z}} = A\tilde{z}, \tag{1.10}$$

where A is an $n \times n$ matrix, then there exists a continuous vector field $\beta : \mathbf{R}^p \to \mathbf{R}^n$ such that

$$g(z) = Az - \beta(h(z)), \tag{1.11}$$

$$\hat{g}(\hat{z}, y) = A\hat{z} - \beta(y). \tag{1.12}$$

Proof. The error dynamics is

$$\dot{\tilde{z}} = A\tilde{z} = g(z) - \hat{g}(\hat{z}, y).$$

Assume $z = 0$. Then

$$A\hat{z} = \hat{g}(\hat{z}, 0).$$

Assume $\tilde{z} = 0$. Then

$$g(z) = \hat{g}(z, h(z)).$$

Define

$$\beta(\hat{z}, y) = \hat{g}(\hat{z}, 0) - \hat{g}(\hat{z}, y).$$

Then

$$\begin{aligned} A\tilde{z} &= g(z) - \hat{g}(\hat{z}, y) \\ &= \hat{g}(z, h(z)) - \hat{g}(\hat{z}, h(z)) \\ &= \hat{g}(z, 0) - \beta(z, h(z)) - \hat{g}(\hat{z}, 0) + \beta(\hat{z}, h(z)) \\ &= Az - \beta(z, h(z)) - A\hat{z} + \beta(\hat{z}, h(z)). \end{aligned}$$

So

$$\beta(z, h(z)) = \beta(\hat{z}, h(z)).$$

But the left side does not depend on $\hat{z}$, so neither does the right, and thus

$$\beta(\hat{z}, h(z)) = \beta(h(z)).$$

Therefore

$$\begin{aligned} \hat{g}(\hat{z}, y) &= A\hat{z} - \beta(y), \\ g(z) &= Az - \beta(h(z)). \end{aligned}$$ □

Note. This converse shows that if a system (1.1) admits an observer with linear error dynamics after a smooth change of coordinates, it is because the PDE (1.3) is solvable for some smooth θ and continuous β.

The rest of the paper is organized as follows. Section 2.1 discusses the relationship between the linear part of the nonlinear system (1.1) and the terms of degree 1 of the solution (1.3). A unique formal solution of (1.3) is given in section 2.2 and this is shown to be convergent in section 2.3. We also show in section 2.1 that (1.3) has a unique solution for any choice of the eigenvalues of A except for a set of zero measure in $\mathbf{C}^n$. Several examples are treated in section 3. Section 4 applies the main result to the case when the system has inputs.

2. Solution of the PDE.

2.1. Terms of degree 1. If we focus on the terms of degree 1 in (1.3), we obtain the equation

$$TF = AT - BH. \tag{2.1}$$

We view this as a linear equation for T in terms of given F, H, A, B.

LEMMA 1. *Equation* (2.1) *admits a unique solution* T *if and only if the eigenvalues of* F *and* A *are distinct, that is,* $\sigma(F) \cap \sigma(A) = \emptyset$.

Proof. We give the proof when F admits a basis of right eigenvectors, $\{\mathbf{v}^j, j = 1, \ldots, n\}$, and A admits a basis of left eigenvectors, $\{\mathbf{w}_i, i = 1, \ldots, n\}$. The general case is similar using bases of generalized eigenvectors. Define an operator $\mathcal{F} : T \longmapsto TF - AT$ on the space of $n \times n$ matrices $\{T\}$. Let λ_i be the eigenvalue of F corresponding to the right eigenvector $\mathbf{w}_i$, and let μ_j be the eigenvalue of F corresponding to left eigenvector $\mathbf{v}^j$. Now $\{\mathbf{v}^j\mathbf{w}_i, i, j = 1, \ldots, n\}$ is a basis for $\{T\}$ and

$$\begin{aligned}\mathcal{F}(\mathbf{v}^j\mathbf{w}_i) &= (\mathbf{v}^j\mathbf{w}_i)F - A(\mathbf{v}^j\mathbf{w}_i)\\ &= (\lambda_i - \mu_j)\mathbf{v}^j\mathbf{w}_i.\end{aligned}$$

Thus $\mathcal{F}$ is invertible if and only if $\lambda_i - \mu_j \neq 0$ for all possible i and j. Therefore $\mathcal{F}T = -BH$ admits a unique solution if and only if $\sigma(F) \cap \sigma(A) = \emptyset$. □

LEMMA 2. *Suppose* $\sigma(F) \cap \sigma(A) = \emptyset$. *If* T *is invertible, then* (H, F) *is observable and* (A, B) *is controllable.*

Proof. Suppose (H, F) is not observable. Then there exist $\lambda_i \in \sigma(F)$ and a vector $x \in \mathbf{R}^{n\times 1}$, $x \neq 0$, such that $Hx = 0$ and $Fx = \lambda_i x$. Multiply (2.1) by x to obtain

$$\lambda_i Tx = TFx = ATx + BHx = ATx.$$

Since $Tx \neq 0$, this implies that $\lambda_i \in \sigma(A)$, a contradiction.

Similarly, suppose (A, B) is not controllable. Then there is $\mu_j \in \sigma(A)$ and a vector $\xi \in \mathbf{R}^{1\times n}$ such that $\xi A = \mu_j \xi$ and $\xi B = 0$. Multiply (2.1) by ξ to obtain

$$\xi TF = \xi AT + \xi BH = \mu_j \xi T.$$

Since $\xi T \neq 0$, this implies that $\mu_j \in \sigma(F)$, a contradiction. □

LEMMA 3. *If* T *is an invertible solution to* (2.1)*, then* A *is conjugate to* F *modified by output injection.*

Proof. Since T satisfies equation

$$TF + BH = AT$$

and T is invertible, we thus have

$$T(F + T^{-1}BH)T^{-1} = A. \qquad \square$$

LEMMA 4. *If* $\sigma(F) \cap \sigma(A) = \emptyset$ *and* A *is conjugate to* F *modified by output injection, then there exists* B *such that the unique solution to* (2.1) *is invertible.*

Proof. Since A is conjugate to F modified by output injection, there exist an $n \times n$ invertible matrix S and an $n \times p$ matrix G such that

$$S(F + GH)S^{-1} = A.$$

Hence we have $SF = AS - SGH$. Let $B = SG$. Then $SF = AS - BH$, so $T = S$ according to Lemma 1. Therefore T is invertible. □

Loosely speaking, a complex number μ is of type (C, ν) with respect to $\sigma(F) = \lambda$ if $|\mu - m \cdot \lambda|$ is never zero and does not approach zero too fast as $|m| \to \infty$. If ν is large enough, then the set of μ's which are of type (C, ν) for some $C > 0$ is dense in the complex plane.

LEMMA 5. *If $C > 0$ and $\nu > \frac{n}{2}$, then*

$$\text{meas}\left\{\mu : \mu \text{ is not of type } (C,\nu)\right\} \le k(n,\nu)C^2, \tag{2.2}$$

where $k(n, \nu)$ is a constant which depends only on n and ν.

If $\nu > \frac{n}{2}$, then the set of points which are not of type (C, ν) for any $C > 0$ is a set of zero measure.

Proof. Clearly, the set $\{\mu : \mu \text{ is not of type } (C, \nu)\}$ is

$$\bigcup_{|m|\ge 1} \text{Ball}\left(m \cdot \lambda,\ \frac{C}{|m|^\nu}\right),$$

where $\text{Ball}(p, r)$ stands for an open ball in $\mathbf{C}$ centered at $p \in \mathbf{C}$ with radius r. The measure of the $\text{Ball}(m \cdot \lambda, \frac{C}{|m|^\nu})$ is $\frac{\pi C^2}{|m|^{2\nu}}$. There are no more than $(d+1)^{n-1}$ choices of $m = (m_1, m_2, \ldots, m_n)$ such that $|m| = d$. To see this note that each of $m_1, \ldots, m_{n-1}$ must lie between 0 and d, and then $m_n = d - m_1 - \cdots - m_{n-1}$. Since $(d + 1) \le 2d$, we have

$$\text{meas} \bigcup_{|m|=d} \text{Ball}\left(m \cdot \lambda,\ \frac{C}{|m|^\nu}\right) \le \pi C^2 (2d)^{n-1-2\nu}.$$

Therefore, if $n - 1 - 2\nu < -1$, then

$$\text{meas} \bigcup_{|m|>0} \text{Ball}\left(m \cdot \lambda,\ \frac{C}{|m|^\nu}\right) \le \pi C^2 \left(\sum_{d=1}^{\infty} (2d)^{n-1-2\nu}\right),$$

so (2.2) follows. □

2.2. The formal solution of the PDE. Assume the hypothesis of the main theorem holds. We show that there is a unique solution to the PDE (1.3) within the class of formal power series. It is convenient to assume that F and A are diagonal; the proof in the general case is similar but much messier. We expand the terms in power series

$$\begin{aligned} f(x) &= Fx + f^{[2]}(x) + f^{[3]}(x) + \cdots, \\ \beta(h(x)) &= BHx + \beta^{[2]}(x) + \beta^{[3]}(x) + \cdots, \\ \theta(x) &= Tx + \theta^{[2]}(x) + \theta^{[3]}(x) + \cdots, \end{aligned}$$

where $f^{[d]}$, $\beta^{[d]}$, and $\theta^{[d]}$ are homogeneous polynomial vector fields of degree d in x. The knowns are f, h, β, T and the unknowns are the higher degree terms $\theta^{[2]}, \theta^{[3]}, \ldots$. The linear terms satisfy (2.1) by the above assumption.

The degree d part of (1.3) is

$$\frac{\partial \theta^{[d]}}{\partial x}(x)Fx - A\theta^{[d]}(x) = -\tilde{\beta}^{[d]}(x), \tag{2.3}$$

where

$$\tilde{\beta}^{[d]}(x) = \beta^{[d]}(x) + Tf^{[d]}(x) + \sum_{j=2}^{d-1} \frac{\partial \theta^{[j]}}{\partial x}(x) f^{[d+1-j]}(x). \tag{2.4}$$

Let $\mathbf{e}^k$ denote the kth unit vector in z space and let $x^m = x_1^{m_1} \cdots x_n^{m_n}$. Then the above terms can be expanded as

$$\tilde{\beta}^{[d]}(x) = \sum_{k=1}^{n} \sum_{|m|=d} \tilde{\beta}_{k,m} \mathbf{e}^k x^m,$$

$$\theta^{[d]}(x) = \sum_{k=1}^{n} \sum_{|m|=d} \theta_{k,m} \mathbf{e}^k x^m,$$

and we obtain the equations

$$(\mu_k - m \cdot \lambda)\theta_{k,m} = \tilde{\beta}_{k,m}. \tag{2.5}$$

These equations have unique solutions because $m \cdot \lambda - \mu_k \neq 0$. □

The formal approach yields a method for constructing an observer with approximately linear error dynamics. Start by choosing a T, A, B satisfying the linear equation (2.1). Then successively solve (2.3) up to some degree d. At each step $\beta^{[j]}$ can be chosen to make $\theta^{[j]}$ smaller and thereby try to keep $\theta(x)$ close to its globally invertible linear part Tx. The approximate solution

$$\theta(x) = Tx + \theta^{[2]}(x) + \theta^{[3]}(x) + \cdots + \theta^{[d]}(x),$$
$$\beta(y) = By + \beta^{[2]}(y) + \beta^{[3]}(y) + \cdots + \beta^{[d]}(y)$$

transforms the system (1.1) into

$$\dot{z} = Az - \beta(y) + O(x)^{d+1},$$

so the observer (1.4) has approximately linearizable error dynamics. The error is $O(x, \hat{x})^{d+1}$. When implementing the method, the matrices F, A need not be diagonal, but this makes solving (2.3) very easy.

2.3. Convergence of the formal solution. Let $|x| = \max\{|x_1|, \ldots, |x_n|\}$. We write

$$f(x) = Fx + \bar{f}(x),$$
$$\beta(y) = BHx + \bar{\beta}(x),$$

where $AT - TF = BH$. We first show that the sequence of PDEs

$$A\theta_2(x) - \frac{\partial}{\partial x}\theta_2(x)Fx = T\bar{f}(x) + \bar{\beta}(x),$$
$$A\theta_k(x) - \frac{\partial}{\partial x}\theta_k(x)Fx = \frac{\partial}{\partial x}\theta_{k-1}(x)\bar{f}(x)$$

admits a sequence of analytical solutions $\theta_2(x), \theta_3(x), \ldots$ in some neighborhood of the origin. Then we show that the sum

$$Tx + \theta_2(x) + \theta_3(x) + \cdots$$

converges to an analytic function which solves (1.3).

We define a positive real function $b_k : [0,1) \to [0,\infty)$ to be

$$b_k(q) := \max_{d\in\mathbf{Z}_+, d\geq k} \left[C^{-1} d^{\nu} q^{\frac{d}{2}} \right],$$

where $C > 0$ and $\nu > 0$ are given. We start with an important theorem.

THEOREM 1. *Let $P(x)$ be a real analytic function in $|x| < r$ with $P(0) = 0$ and $\frac{\partial P}{\partial x}(0) = 0$. Suppose all of the eigenvalues of A are of type (C,ν) with respect to $\sigma(F)$. Then the first-order PDE*

$$A\theta(x) - \frac{\partial \theta(x)}{\partial x} Fx = P(x) \tag{2.6}$$

admits a unique analytic solution $\theta(x)$ in $|x| < r$ with $\theta(0) = 0$.

Proof. The analyticity of $P(x)$ implies that $P(x)$ can be expanded into a Taylor series

$$P(x) = P^{[k]}(x) + P^{[k+1]}(x) + \cdots \qquad \text{for} \quad |x| < r$$

with

$$P^{[d]}(x) = \sum_{j=k}^{n} \sum_{|m|=d} p_{j,m} \mathbf{e}^j x^m,$$

where $k \geq 2$ is the lowest degree of $P(x)$. We assume a series solution

$$\theta(x) = \theta^{[k]}(x) + \theta^{[k+1]}(x) + \cdots + \theta^{[d]}(x) + \cdots \tag{2.7}$$

with

$$\theta^{[d]}(x) = \sum_{j=1}^{n} \sum_{|m|=d} \theta_{j,m} \mathbf{e}^j x^m.$$

If we plug (2.7) into (2.6), then we have

$$\theta_{j,m} = \frac{p_{j,m}}{\mu_j - m\cdot\lambda} \qquad \text{for } |m| \geq k, \quad 1 \leq j \leq n.$$

Since the eigenvalues of A are of type (C,ν) with respect to $\sigma(F)$, we have

$$|\theta_{j,m}| = \left|\frac{p_{j,m}}{\mu_j - m\cdot\lambda}\right| \leq \frac{|m|^{\nu}|p_{j,m}|}{C}.$$

We shall show that (2.7) converges on the closed polydisk $|x| \leq qr$ for any $0 < q < 1$. Hence (2.7) converges on $|x| < r$.

Consider a new series

$$\hat{P}(x) = \hat{P}^{[k]}(x) + \hat{P}^{[k+1]}(x) + \cdots \tag{2.8}$$

with

$$\hat{P}^{[d]}(x) = \sum_{j=k}^{n} \sum_{|m|=d} \frac{|m|^{\nu}|p_{j,m}|}{C} \mathbf{e}^j x^m, \qquad d \geq k.$$

We next claim that (2.8) converges in $|x| \le qr$. Let $\xi := (qr, qr, \dots, qr)$. Then

$$\begin{aligned}|\hat{P}^{[d]}(x)| &\le \max_{1\le j\le n} \sum_{|m|=d} \frac{|m|^\nu |p_{j,m}|}{C} |x|^m \le \max_{1\le j\le n} \sum_{|m|=d} \frac{|m|^\nu |p_{j,m}|}{C} |\xi|^m \\ &\le \max_{1\le j\le n} \sum_{|m|=d} |m|^\nu C^{-1} q^{\frac{|m|}{2}} |p_{j,m}| (\sqrt{q}r)^{|m|} \\ &\le b_k(q) \max_{1\le j\le n} \sum_{|m|=d} |p_{j,m}| (\sqrt{q}r)^{|m|}.\end{aligned}$$

Notice that $P(x)$ is an analytic function for $|x| < r$, so its Taylor series converges there absolutely, which yields

$$|\hat{P}(x)| \le b_k(q) \max_{1\le j\le n} \sum_{d=k}^{\infty} \left(\sum_{|m|=d} |p_{j,m}| (\sqrt{q}r)^{|m|} \right) < +\infty.$$

Thus (2.7) defines an analytic function $\theta(x)$ for $|x| < r$, which solves (2.6). ∎

From Theorem 1, we immediately have the following corollary.

COROLLARY 1. *Suppose all of the eigenvalues of A are of type (C, ν) with respect to $\sigma(F)$. The PDEs*

$$A\theta_2(x) - \frac{\partial \theta_2}{\partial x}(x) Fx = T\bar{f}(x) + \bar{\beta}(x), \qquad \theta_2(0) = 0, \tag{2.9}$$

$$A\theta_k(x) - \frac{\partial \theta_k}{\partial x}(x) Fx = \frac{\partial \theta_{k-1}}{\partial x}(x) \bar{f}(x), \qquad \theta_k(0) = 0, \quad k \ge 3, \tag{2.10}$$

admit analytic solutions in $|x| < r$.

The next step is to prove that

$$\theta_2(x) + \theta_3(x) + \cdots + \theta_k(x) + \cdots$$

converges near the origin and solves the PDE (1.3).

Since $\bar{f}(x) = O(|x|^2)$ is an analytic function in the polydisk $|x| \le r$, it can be expanded into a Taylor series:

$$\bar{f}(x) = f^{[2]}(x) + f^{[3]}(x) + \cdots, \qquad |x| \le r,$$

where $f^{[d]}(x) = \sum_{j=1}^n \sum_{|m|=d} f_{j,m} \mathbf{e}^j x^m$. Thus the following series converges:

$$\sum_{|m|=2} |f_{j,m}| r^2 + \sum_{|m|=3} |f_{j,m}| r^3 + \cdots := M_j$$

for $j = 1, 2, \dots, n$. We define

$$\bar{M}_f := \max \left\{ \frac{M_1}{r^2}, \dots, \frac{M_n}{r^2} \right\}$$

and

$$\|P(x)\| := \max_{1\le i\le n} \sum_m |p_{i,m} x^m|$$

if $P(x)$ is analytic in $|x| < r$ with

$$P(x) = \left(\sum_m p_{1,m} x^m, \sum_m p_{2,m} x^m, \ldots, \sum_m p_{n,m} x^m \right).$$

LEMMA 6. *There exists $0 < r_1 < r$ such that if $P(x)$ is analytic in $|x| < r_1$, where $\|P(x)\| \le N$, then*

$$\left\| \frac{\partial P}{\partial x}(x) \bar{f}(x) \right\| \le N \qquad in \quad |x| < r_1.$$

Proof. First it is easy to see that for any $r_1 < r$ we have

$$|\bar{f}(x)| \le r_1^2 \bar{M}_f \qquad \text{for} \quad |x| \le r_1,$$

since for $j = 1, 2, \ldots, n$

$$\begin{aligned} &\sum_{|m|=2} |f_{j,m}| r_1^2 + \sum_{|m|=3} |f_{j,m}| r_1^3 + \cdots \\ &\quad = r_1^2 \left(\sum_{|m|=2} |f_{j,m}| + \sum_{|m|=3} |f_{j,m}| r_1^1 + \cdots \right) \\ &\quad \le r_1^2 \frac{M_j}{r^2} \le r_1^2 \bar{M}_f. \end{aligned} \tag{2.11}$$

Next let

$$P(x) = (P_1(x), P_2(x), \ldots, P_n(x)),$$

with $P_i(x) = \sum_m p_{i,m} x^m$ and

$$N(r) := \max_{|x| \le r} \|P(x)\|.$$

The analyticity of $P(x)$ implies that

$$\frac{\partial P_i}{\partial x_j}(x) = \sum_m \frac{\partial}{\partial x_j} (p_{i,m} x^m) = \sum_m p_{i,m} m_j x_1^{m_1} \cdots x_j^{m_j - 1} \cdots x_n^{m_n}, \qquad |x| < r_1,$$

and for any given $\varepsilon > 0$ there exists $K > 0$ such that when $|m| > K$

$$\sum_{m, |m| \ge K} \left| p_{i,m} m_j x_1^{m_1} \cdots x_j^{m_j - 1} \cdots x_n^{m_n} \right| < \varepsilon$$

for $|x| < r_1$. Thus

$$\sum_{m, |m| \le K} |p_{i,m} m_j x_1^{m_1} \cdots x_j^{m_j - 1} \cdots x_n^{m_n}| \|\bar{f}_j(x)\| \le \sum_{m, |m| \le K} |p_{i,m}| m_j r_1^{|m|} r_1 \bar{M}_f.$$

Let r_1 be small enough such that

$$\sum_{m, |m| \le K} |p_{i,m}| m_j r_1^{|m|} r_1 \bar{M}_f \le \frac{N(r_1)}{n}.$$

Then for $|x| < r_1$

$$\sum_m \left| \frac{\partial}{\partial x_j} (p_{i,m} x^m) \right| \left\| \bar{f}_j(x) \right\| < \frac{N(r_1)}{n} + \varepsilon r_1^2 \bar{M}_f.$$

Thus we have

$$\left\| \frac{\partial P_i}{\partial x_j}(x) \bar{f}_j(x) \right\| \leq \sum_m \left| \left(\frac{\partial}{\partial x_j} (p_{i,m} x^m) \right) \right| \left\| \bar{f}_j(x) \right\| \leq \frac{N(r_1)}{n}.$$

Therefore

$$\left\| \frac{\partial P}{\partial x}(x) \bar{f}(x) \right\| \leq \max_{1 \leq i \leq n} \sum_{j=1}^{n} \left\| \frac{\partial P_i}{\partial x_j}(x) \bar{f}_j(x) \right\| \leq N(r_1). \qquad \square$$

In the definition of type (C, ν), without lose of generality we can assume that ν is a positive integer since if ν is not, we can replace it by a larger integer.

LEMMA 7. *Let $r_2 := r_1/n$, where r_1 is given in Lemma 6. Let $\theta_k(x)$ be the solution of*

$$A\theta_k(x) - \frac{\partial \theta_k}{\partial x}(x) Fx = \frac{\partial \theta_{k-1}}{\partial x}(x) \bar{f}(x).$$

Then if $\|\theta_{k-1}(x)\| \leq N$ for $|x| < r_2$, we have

$$\|\theta_k(x)\| \leq \frac{NP(|x_1| + |x_2| + \cdots + |x_n|)}{C\left(r_1 - (|x_1| + |x_2| + \cdots + |x_n|)\right)^{\nu+1}}$$

for $|x| < r_2$, where P is a polynomial of degree ν with coefficients depending only on r_1.

Proof. We first let $g(x) := \frac{\partial \theta_{k-1}}{\partial x}(x) \bar{f}(x)$ and

$$\phi(x) := \frac{N r_1}{r_1 - (x_1 + \cdots + x_n)}.$$

Clearly for $|x| < r_2$,

$$\begin{aligned} \phi(x) &= \frac{N}{1 - (x_1 + \cdots + x_n)/r_1} = N \sum_{d=0}^{\infty} \left(\frac{x_1 + \cdots + x_n}{r_1} \right)^d \\ &= N \sum_{d=0}^{\infty} \frac{1}{r_1^d} \sum_{|m|=d} \frac{|m|!}{m!} x^m \end{aligned}$$

and

$$D^m \phi(0) = N |m|! r_1^{-|m|}.$$

By the previous lemma, $|g(x)| \leq N$ for $|x| < r_1$, so the Cauchy estimate yields

$$|D^m g(0)| \leq N |m|! r_1^{-|m|},$$

where D^m is a partial differential operator of order m defined to be

$$D^m = \frac{\partial^m}{\partial x_1^{m_1} \cdots \partial x_n^{m_n}}.$$

Let

$$g(x) = g^{[k]}(x) + g^{[k+1]}(x) + \cdots + g^{[d]}(x) + \cdots$$

with $g^{[d]}(x) = \sum_{j=1}^{n} \sum_{|m|=d} g_{j,m} \mathbf{e}^j x^m$, where

$$|g_{j,m}| = \left| \frac{1}{m!} D^m g(0) \right| \le N \frac{|m|!}{m!} r_1^{-|m|}$$

and

$$\theta_k(x) = \theta_k^{[k]}(x) + \theta_k^{[k+1]}(x) + \cdots + \theta_k^{[d]}(x) + \cdots$$

with $\theta_k^{[d]}(x) = \sum_{j=1}^{n} \sum_{|m|=d} \theta_{j,m} \mathbf{e}^j x^m$. Then (2.12) implies that

$$\theta_{j,m} = \frac{g_{j,m}}{\mu_j - \lambda \cdot m}.$$

Since the eigenvalues of A are of type (C, ν) with respect to $\sigma(F)$, it follows that

$$|\theta_{j,m}| = \left| \frac{g_{j,m}}{\mu_j - \lambda \cdot m} \right| \le \frac{|m|^\nu}{C} |g_{j,m}| \le \frac{|m|^\nu |m|!}{Cm!} r_1^{-|m|}.$$

Next we claim that

$$N \sum_{d=0}^{\infty} \frac{1}{r_1^d} \sum_{|m|=d} \frac{|m|^\nu |m|!}{m! C} x^m = \frac{NP(x_1 + x_2 + \cdots + x_n)}{C(r_1 - x_1 - x_2 - \cdots - x_n)^{\nu+1}}.$$

For convenience, we denote $\hat{x} = x_1 + \cdots + x_n$. Notice that for $|x| < r_2$,

$$\frac{r_1}{r_1 - (x_1 + \cdots + x_n)} = \sum_{d=0}^{\infty} \frac{1}{r_1^d} \sum_{|m|=d} \frac{|m|!}{m!} x^m.$$

We differentiate above both sides with respect to $\hat{x}$ and then multiply both sides by $\hat{x}$,

$$\frac{r_1 \hat{x}}{(r_1 - \hat{x})^2} = \sum_{d=0}^{\infty} \frac{1}{r_1^d} \sum_{|m|=d} \frac{|m||m|!}{m!} x^m.$$

We repeat this procedure ν times and obtain

$$\frac{P(\hat{x})}{(r_1 - \hat{x})^{\nu+1}} = \sum_{d=0}^{\infty} \frac{1}{r_1^d} \sum_{|m|=d} \frac{|m|^\nu |m|!}{m!} x^m,$$

where $P(\hat{x})$ is a polynomial of degree ν with coefficients depending only on r_1. Hence

$$\sum_{d=0}^{\infty} \frac{1}{r_1^d} \sum_{|m|=d} \frac{|m|^\nu |m|!}{m!} |x^m| = \frac{P(|x_1| + \cdots + |x_n|)}{(r_1 - (|x_1| + \cdots + |x_n|))^{\nu+1}},$$

which yields the conclusion. □

Let $r_3 := r_2/2$ and

$$\hat{N} := \max_{|x| \le r_3} \frac{P(|x_1| + \cdots + |x_n|)}{C(r_1 - (|x_1| + \cdots + |x_n|))^{\nu+1}}$$

and

$$M := \max_{|x|\le r} \sum_{d=2}^{\infty} \left(|\beta^{[d]}(x)| + |Tf^{[d]}(x)| \right).$$

THEOREM 2. *Let $\theta_k(x)$ be the solution of*

$$A\theta_k(x) - \frac{\partial \theta_k}{\partial x}(x)Fx = \frac{\partial \theta_{k-1}}{\partial x}(x)\bar{f}(x), \qquad \theta_k(0) = 0.$$

Then for any $|x| \le qr_3$ with $0 < q < 1$ we have

$$\|\theta_k(x)\| \le b_k(q)\hat{N}^{k-2}M.$$

Proof. According to the previous lemma, we know that

$$\|\theta_2(x)\| \le M\hat{N} \quad \text{for} \quad |x| \le r_3.$$

Applying the lemma in a recursive way yields

$$\|\theta_k(x)\| \le M\hat{N}^{k-1} \quad \text{for} \quad |x| \le r_3 \quad \text{and} \quad k = 3, 4, \ldots.$$

Let $g(x) = \frac{\partial \theta_{k-1}}{\partial x}(x)\bar{f}(x)$. Then $g(x)$ can be expanded into a Taylor series in $|x| \le r_3$:

$$g(x) = g^{[k]}(x) + g^{[k+1]}(x) + \cdots$$

with $g^{[d]}(x) = \sum_{j=1}^{n} \sum_{|m|=d} g_{j,m}\mathbf{e}^j x^m$. Similar to the proof given in Theorem 1,

$$\|\theta_k(x)\| \le b_k(q) \sum_{d=k}^{\infty} \left(\sum_{|m|=d} |g_{j,m}|(\sqrt{q}r_3)^{|m|} \right) \le b_k(q)\hat{N}^{k-2}M,$$

and the proof is complete. ∎

COROLLARY 2. *When q is small enough, the series*

$$\theta_2(x) + \theta_3(x) + \cdots + \theta_k(x) + \cdots$$

converges in $|x| \le qr_3$, where $\theta_d(x)$ for $d = 2, 3, \ldots$ is the solution of (2.10).

Proof. Let $q \le \frac{1}{2^{\nu+1}\hat{N}}$. It is sufficient to show that

$$\theta_k(x) + \theta_{k+1}(x) + \cdots$$

converges for some fixed k in $|x| \le qr_3$. According to the definition of $b_k(q)$, we know that when $k \ge 2\nu/\ln\frac{1}{q}$, the following holds:

$$b_k(q) > b_{k+1}(q) > \cdots > b_d(q) > \cdots \to 0 \qquad \text{as} \quad d \to \infty.$$

Choose $k \ge 2\nu/\ln\frac{1}{q}$ and notice that

$$b_k(q) = k^\nu q^k, \quad b_{k+1} = (k+1)^\nu q^{k+1}, \ldots, \quad b_d(q) = d^\nu q^d, \ldots.$$

According to Theorem 2, we have

$$\|\theta_k(x)\| + \|\theta_{k+1}(x)\| + \cdots \le b_k(q)\hat{N}^{k-2}M + b_{k+1}(q)\hat{N}^{k-1}M + \cdots.$$

Since

$$\frac{b_{d+1}(q)\hat{N}^{d-1}M}{b_d(q)\hat{N}^{d-2}M} = \left(1+\frac{1}{d}\right)^{\nu} q\hat{N} < 2^{\nu} q\hat{N} \le \frac{1}{2}, \qquad d \ge k,$$

we thus complete the proof. □

From Corollary 2, we know that series

$$\theta_2(x) + \theta_3(x) + \cdots + \theta_d(x) + \cdots \tag{2.12}$$

defines an analytic function in $|x| \le qr_3$. Now we are ready to prove the main result of this paper.

Proof of the main theorem. We first define two functions in $|x| \le qr_3$:

$$\theta(x) := Tx + \theta_2(x) + \theta_3(x) + \cdots + \theta_d(x) + \cdots$$

and

$$\theta^L(x) := Tx + \theta_2(x) + \theta_3(x) + \cdots + \theta_L(x),$$

where $\theta_2(x), \theta_3(x), \ldots$ are the solutions of (2.9), (2.10). We next show that $\theta(x)$ solves (1.3). Now

$$\begin{aligned} &A\theta^L(x) - \frac{\partial\theta^L(x)}{\partial x} f(x) - \beta(h(x)) \\ &\quad = A\theta^L(x) - \frac{\partial\theta^L(x)}{\partial x}(Fx + \bar{f}(x)) - (BHx + \bar{\beta}(x)) \\ &\quad = \frac{\partial\theta_L(x)}{\partial x}\bar{f}(x). \end{aligned}$$

If $|x| \le qr_3$, then $\|\theta_L(x)\| \le b_L(q)\hat{N}^{L-2}M$ and

$$\left\| \frac{\partial\theta_L(x)}{\partial x}\bar{f}(x) \right\| \le b_L(q)\hat{N}^{L-2}M \to 0 \qquad \text{as} \quad L \to \infty$$

since series

$$b_k(q)\hat{N}^{k-2}M + b_{k+1}(q)\hat{N}^{k-1}M + \cdots$$

converges. Therefore $\theta(x)$ is an analytic solution of (1.3). Uniqueness follows from the uniqueness of the formal power series. □

A slight modification of the proof of the main theorem yields the following.

COROLLARY 3 (Lyapunov's auxiliary theorem). *Assume that $f : \mathbf{R}^n \to \mathbf{R}^n$ and $\gamma : \mathbf{R}^n \to \mathbf{R}^n$ are analytic vector fields with $f(0) = 0$, $\frac{\partial f}{\partial x}(0) = F$, and $\gamma(0) = 0$. Suppose that the eigenvalues $\lambda_1, \ldots, \lambda_n$ of F lie wholly in the open left half plane or lie wholly in the open right half plane. Let A be an $n \times n$ matrix with eigenvalues $\mu_1, \ldots, \mu_n$ such that there do not exist nonnegative integers $m_1, m_2, \ldots, m_n$ not all zero such that $\sum_{i=1}^n m_i\lambda_i = \mu_j$. Then there is a unique analytic solution in some neighborhood of the origin of the first-order PDE:*

$$\frac{\partial\theta}{\partial x}(x) f(x) - A\theta(x) + \gamma(x) = 0$$

with initial condition $\theta(0) = 0$.

Proof. Let $h(x) = x$ and $\beta(h(x) = \gamma(x)$. The main theorem cannot be applied directly because the Lyapunov auxiliary theorem does not require $\theta(x)$ to be a local diffeomorphism. But the proof stills holds provided we can show that the spectrum of A is of class (C, ν) with respect to the spectrum of F. Suppose the spectrum of F lies wholly in the open right half plane. Then there is a constant $c > 0$ such that $c \leq Re\ \lambda_i$, $i = 1, \ldots, n$. Suppose $M \geq Re\ \mu_j$, $j = 1, \ldots, n$. Then

$$|m \cdot \lambda - \mu_j| \geq 1$$

whenever $|m| \geq \frac{M+1}{c}$. Let $\nu = 1$ and choose $0 < C \leq 1$ satisfying

$$|m \cdot \lambda - \mu_j| \geq C$$

whenever $|m| < \frac{M+1}{c}$. This is possible because the left side is never zero. We have shown that the spectrum of A is of class (C, ν) with respect to the spectrum of F. □

COROLLARY 4 (Siegel's theorem). *Assume that $f : \mathbf{R}^n \to \mathbf{R}^n$ is an analytic vector field with $f(0) = 0$, $\frac{\partial f}{\partial x}(0) = F$. Suppose, for some $C > 0, \nu > 0$, the eigenvalues of F are of type (C, ν) with respect to $\sigma(F)$. Then there is an analytic solution in some neighborhood of the origin of the first-order PDE:*

$$\frac{\partial \theta}{\partial x}(x) f(x) = F\theta(x)$$

with initial condition $\theta(0) = 0$. Moreover $z = \theta(x)$ is a local analytic diffeomorphism around $x = 0$ which transforms the differential equation

$$\dot{x} = f(x)$$

into its linear part

$$\dot{z} = Fz.$$

Proof. Apply the main theorem with $\beta = 0$, $A = F$, and $T = I$. □

Note. Lyapunov's auxiliary theorem and Siegel's theorem are usually stated for complex analytic vector fields. We have stated them for real analytic vector fields since we stated our main theorem that way. But the proof of the main theorem holds for complex vector fields too.

3. Examples. As discussed in the introduction, there are distinct advantages to considering *nonlinear output injection* $\beta(y)$. It is desirable that θ be a diffeomorphism over as large a range as possible, for this is the domain of convergence of the observer. Nonlinear output injection can make θ a global diffeomorphism.

To illustrate this, we consider a Duffing oscillator

$$\begin{aligned} \ddot{x} &= x - x^3, \\ y &= x, \end{aligned}$$

which is equivalent to the planar system

$$\begin{aligned} \begin{bmatrix} \dot{x}_1 \\ \dot{x}_2 \end{bmatrix} &= \begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \end{bmatrix} + \begin{bmatrix} 0 \\ -x_1^3 \end{bmatrix}, \\ y &= x_1. \end{aligned}$$

This system is trivially transformed into a linear system with output injection (1.2)

$$\begin{bmatrix} \dot{z}_1 \\ \dot{z}_2 \end{bmatrix} = \begin{bmatrix} -2 & 1 \\ -2 & 0 \end{bmatrix} \begin{bmatrix} z_1 \\ z_2 \end{bmatrix} - \begin{bmatrix} -2y \\ -3y + y^3 \end{bmatrix}$$

by

$$\begin{aligned} \theta(x) &= x, \\ \beta(y) &= \begin{bmatrix} -2y \\ -3y + y^3 \end{bmatrix}. \end{aligned}$$

Notice that β is nonlinear and θ is trivially a global diffeomorphism. The observer (1.4) is

$$\begin{bmatrix} \dot{\hat{x}}_1 \\ \dot{\hat{x}}_2 \end{bmatrix} = \begin{bmatrix} -2 & 1 \\ -2 & 0 \end{bmatrix} \begin{bmatrix} \hat{x}_1 \\ \hat{x}_2 \end{bmatrix} - \begin{bmatrix} -2y \\ -3y + y^3 \end{bmatrix},$$

and the error dynamics

$$\begin{bmatrix} \dot{\tilde{x}}_1 \\ \dot{\tilde{x}}_2 \end{bmatrix} = \begin{bmatrix} -2 & 1 \\ -2 & 0 \end{bmatrix} \begin{bmatrix} \tilde{x}_1 \\ \tilde{x}_2 \end{bmatrix}$$

is linear and exponentially stable with poles at $-1 \pm i$.

The example is trivial but illustrates two important facts. The first is the advantage of allowing nonlinear β. We could take it to be linear,

$$\beta(y) = \begin{bmatrix} -2 \\ -3 \end{bmatrix} y,$$

and still solve the PDE (1.3) for θ. But the solution might be hard to find, it could have an infinite power series expansion, and it might not be a global diffeomorphism.

The second point is that the Duffing oscillator is truly nonlinear; it has three equilibria and two homoclinic orbits, and the rest of the trajectories are limit cycles. Yet it is possible to build a globally convergent error with linear error dynamics.

Next we consider a Van der Pol oscillator,

$$\begin{aligned} \ddot{x} &= -(x^2 - 1)\dot{x} - x, \\ y &= x, \end{aligned}$$

which is equivalent to the planar system

$$\begin{aligned} \begin{bmatrix} \dot{x}_1 \\ \dot{x}_2 \end{bmatrix} &= \begin{bmatrix} 0 & 1 \\ -1 & 1 \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \end{bmatrix} - \begin{bmatrix} 0 \\ x_1^2 x_2 \end{bmatrix}, \\ y &= \begin{bmatrix} 1 & 0 \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \end{bmatrix}. \end{aligned}$$

Now we have

$$\begin{aligned} f(x) &= \begin{bmatrix} x_2 \\ -x_1 + x_2 - x_1^2 x_2 \end{bmatrix}, \qquad h(x) = x_1, \\ F &= \begin{bmatrix} 0 & 1 \\ -1 & 1 \end{bmatrix}, \qquad H = \begin{bmatrix} 1 & 0 \end{bmatrix}. \end{aligned}$$

We look for a nonlinear coordinate transformation $z = \theta(x)$ such that in the new coordinates z, the system can be described in the form

$$\dot{z} = Az - \beta(y).$$

Let us choose A and β to be

$$A = \begin{bmatrix} b_1 & 1 \\ b_2 - 1 & 1 \end{bmatrix}, \qquad \beta(y) = \begin{bmatrix} b_1 y + \frac{y^3}{3} \\ b_2 y + \frac{y^3}{3} \end{bmatrix},$$

where b_1, b_2 are constants such that $1 + b_1 < 0$, $b_1 - b_2 + 1 > 0$. Clearly, A is stable since $\operatorname{trace}(A) = 1 + b_1 < 0$ and $\det(A) = b_1 - b_2 + 1 > 0$. Moreover $A = F + BH$ with $B = [b_1, b_2]'$. The solution of (1.3) in this case is given by

$$\theta(x) = \begin{bmatrix} x_1 \\ x_2 + \frac{x_1^3}{3} \end{bmatrix}.$$

Note that θ is polynomial and *globally invertible* on $\mathbf{R}^2$. This is because we chose a nonlinear β. The resulting observer is again globally convergent with exponentially stable linear error dynamics in $\tilde{z}$ coordinates despite the nonlinearities of the Van der Pol oscillator. See Figure 1.

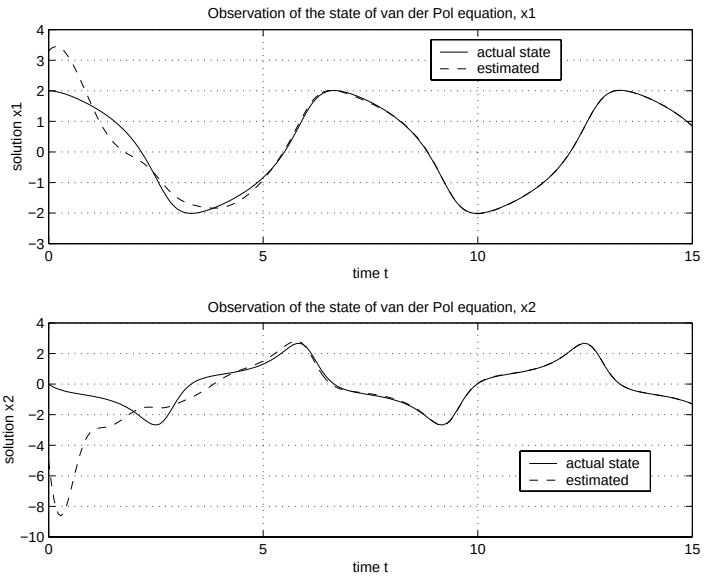

FIG. 1. *Observation of Van der Pol oscillator.*

Both these examples could be treated by the method of Krener and Respondek [8]. In particular, they showed that any observable two-dimensional system of the form

$$\begin{aligned} y &= x_1, \\ \dot{x}_1 &= x_2, \\ \dot{x}_2 &= f_2(x) = a(x_1) + b(x_1)x_2 + c(x_1)x_2^2, \end{aligned}$$

where $a(x_1), b(x_1), c(x_1)$ are smooth functions, admits a local observer with linear error dynamics in transformed coordinates. But their method is not applicable to more general f_2. The above method is applicable to any observable system with arbitrary f_2. The conditions of Krener and Respondek become more restrictive as the dimension of the system is increased, while there are no additional conditions for the above method.

The next example cannot be treated by the method of Krener and Respondek:

$$\begin{aligned} y &= x_1, \\ \dot{x}_1 &= 2x_2, \\ \dot{x}_2 &= 2x_1 - 3x_1^2 - x_2(x_1^3 - x_1^2 + x_2^2). \end{aligned}$$

There is a saddle at $(0,0)$ and an unstable source at $(2/3,0)$. The stable and unstable manifolds of the saddle form a homoclinic orbit given by $x_1^3 - x_1^2 + x_2^2 = 0$ which wraps around the unstable source.

The system is linearly observable around $x = 0$ with

$$F = \begin{bmatrix} 0 & 2 \\ 2 & 0 \end{bmatrix}, \quad H = \begin{bmatrix} 1 & 0 \end{bmatrix}.$$

The spectrum of F is $\lambda = (2, -2)$. We choose a linear output injection based on a long time Kalman filter for the linear part of the system corrupted by standard white noises, and this leads to

$$A = \begin{bmatrix} -\sqrt{17} & 2 \\ -2 & 0 \end{bmatrix}, \quad B = \begin{bmatrix} -\sqrt{17} \\ -4 \end{bmatrix}.$$

The spectrum of A is

$$\frac{-\sqrt{17} \pm 1}{2},$$

and clearly these are not resonant with the spectrum of F because they are not even integers.

First we compute θ for up to degree 3 with $\beta^{[2]} = 0$, $\beta^{[3]} = 0$:

$$\begin{aligned} \theta^{[1]}(x) &= \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \end{bmatrix}, \\ \theta^{[2]}(x) &= \begin{bmatrix} 1.2188 & -0.7731 & -0.2812 \\ 1.7394 & 0.2812 & -1.3529 \end{bmatrix} \begin{bmatrix} x_1^2 \\ x_1 x_2 \\ x_2^2 \end{bmatrix}, \\ \theta^{[3]}(x) &= \begin{bmatrix} -20.4026 & 19.1878 & 20.8159 & -20.1972 \\ -21.7136 & 20.8245 & 20.6972 & -20.8216 \end{bmatrix} \begin{bmatrix} x_1^3 \\ x_1^2 x_2 \\ x_1 x_2^2 \\ x_2^3 \end{bmatrix}. \end{aligned}$$

Figure 2 shows the system starting at $x_1 = 0.5, x_2 = 0$ and the observer starting at $\hat{x}_1 = 0, \hat{x}_2 = 0$. Clearly this observer does not converge; in particular, the observer seems to stall around $(0.3, 0.4)$. The problem appears to be caused by the large sizes of $\theta^{[2]}$ and $\theta^{[3]}$.

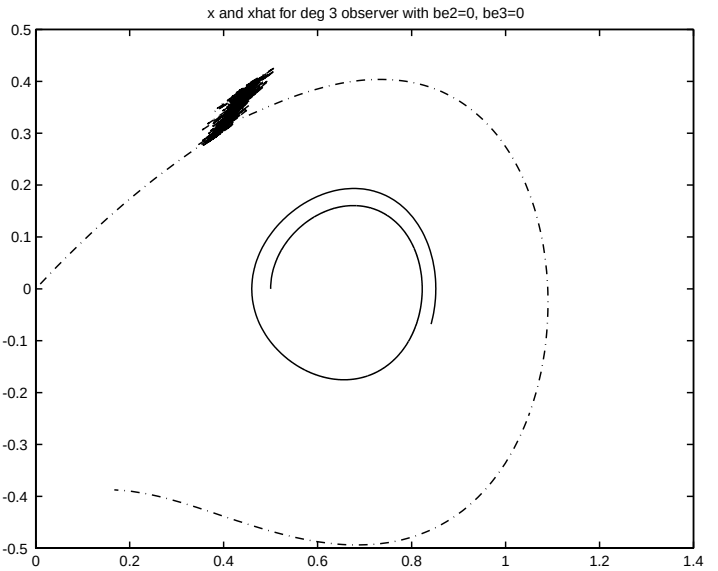

FIG. 2. *Solid line: state trajectory. Dashed line: observer trajectory.*

Next we choose $\beta^{[2]}$ to minimize the Euclidean norm of the coefficients of $\theta^{[2]}$, and then we choose $\beta^{[3]}$ to minimize the Euclidean norm of the coefficients of $\theta^{[3]}$. The result is

$$\theta^{[1]}(x) = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \end{bmatrix},$$

$$\theta^{[2]}(x) = \begin{bmatrix} 0.0000 & -0.0000 & 0.0000 \\ 0.0000 & -0.0000 & 0.0000 \end{bmatrix} \begin{bmatrix} x_1^2 \\ x_1x_2 \\ x_2^2 \end{bmatrix},$$

$$\theta^{[3]}(x) = \begin{bmatrix} 0.0330 & 0.0938 & -0.2219 & 0.1925 \\ -0.4030 & -0.1514 & 0.3075 & 0.1749 \end{bmatrix} \begin{bmatrix} x_1^3 \\ x_1^2x_2 \\ x_1x_2^2 \\ x_2^3 \end{bmatrix},$$

$$\beta(y) = \begin{bmatrix} -4.1231 & 0.0000 & -1.1296 \\ -4.0000 & 3.0000 & 0.2368 \end{bmatrix} \begin{bmatrix} y \\ y^2 \\ y^3 \end{bmatrix}.$$

Notice how much smaller $\theta^{[2]}$ and $\theta^{[3]}$ are. The resulting observer performs much better, as can be seen from Figure 3.

4. Nonlinear observer design with inputs. We now consider a nonlinear system with inputs:

$$\dot{x} = f(x,u), \tag{4.1}$$

$$y = h(x,u), \tag{4.2}$$

where $f : \mathbf{R}^n \times \mathbf{R}^m \to \mathbf{R}^n$ and $h : \mathbf{R}^n \times \mathbf{R}^m \to \mathbf{R}^p$ are continuous. We assume here that

$$f(x,u) = f_0(x) + f_1(x,u), \qquad h(x,u) = h_0(x) + h_1(x,u)$$

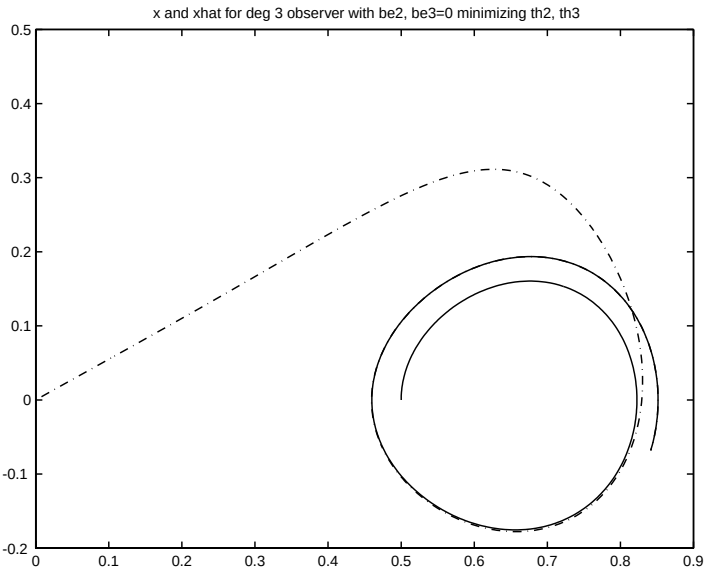

FIG. 3. *Solid line: state trajectory. Dashed line: observer trajectory.*

with $f_1(x,0) \equiv 0, h_1(x,0) \equiv 0$, and $f_0 : \mathbf{R}^n \to \mathbf{R}^n$ and $h_0 : \mathbf{R}^n \to \mathbf{R}^p$ are real analytic functions with $f_0(0) = 0, h_0(0) = 0$. Let $\beta : \mathbf{R}^p \to \mathbf{R}^n$ be a real analytic function and $F = \frac{\partial f_0}{\partial x}(0)$, $H = \frac{\partial h_0}{\partial x}(0)$, and $B = \frac{\partial \beta}{\partial x}(0)$. We further assume that

1. for a given $n \times n$ matrix A, there exists an invertible $n \times n$ matrix T so that $TFT^{-1} = A - BH$;
2. there exists a $C > 0, \nu > 0$ such that all the eigenvalues of A are of type (C, ν) with respect to $\sigma(F)$.

Then according to the main result of this paper, we know that the first-order PDE

$$\frac{\partial \phi}{\partial x}(x) f_0(x) = A\phi(x) - \beta(h_0(x)) \tag{4.3}$$

has a unique analytic solution $z = \phi$, which is a diffeomorphism in some neighborhood U of the origin with $\frac{\partial \phi}{\partial x}(0) = T$.

Now we let the estimate of the true state obey the equation

$$\dot{\hat{x}} = f(\hat{x}, u) - \left[\frac{\partial \phi}{\partial \hat{x}}\right]^{-1} (\beta(y) - \beta(h(\hat{x}, u))). \tag{4.4}$$

Let e denote

$$e = \phi(\hat{x}) - \phi(x).$$

Then e satisfies the differential equation

$$\begin{aligned} \dot{e} &= \frac{\partial \phi}{\partial \hat{x}} f(\hat{x}, u) - (\beta(y) - \beta(h(\hat{x}, u))) - \frac{\partial \phi}{\partial x} f(x, u) \\ &= \frac{\partial \phi}{\partial \hat{x}} (f_0(\hat{x}) + f_1)(\hat{x}, u) - (\beta(y) - \beta(h(\hat{x}, u))) - \frac{\partial \phi}{\partial x} (f_0(x) + f_1(x, u)). \end{aligned}$$

Since

$$\frac{\partial \phi}{\partial \hat{x}} f_0(\hat{x}) = A\phi(\hat{x}) - \beta(h_0(\hat{x})),$$
$$\frac{\partial \phi}{\partial x} f_0(x) = A\phi(x) - \beta(h_0(x)),$$

this yields

$$\dot{e} = Ae + N(\hat{x}, u) - N(x, u), \tag{4.5}$$

where the nonlinear function N is defined to be

$$N(x, u) := \frac{\partial \phi}{\partial x}(x) f_1(x, u) + \beta(h(x, u)) - \beta(h_0(x)). \tag{4.6}$$

We further assume that $f_1(\cdot, u)$ is locally Lipschitz about the origin; then there exists a positive constant $L(u)$ such that

$$\|N(x_1, u) - N(x_2, u)\| \leq L(u)\|x_1 - x_2\|$$

for all x_1, x_2 in some open neighborhood U containing the origin. If we choose A to be Hurwitz, then for any given positive-definite $Q \in \mathbf{R}^{n\times n}$ there exists a unique positive-definite $P \in \mathbf{R}^{n\times n}$ such that

$$A^T P + PA = -2Q.$$

Now we consider the Lyapunov function

$$V(e) = e^T P e.$$

The derivative of $V(e)$ evaluated along the solution of the error dynamics is given by

$$\dot{V}(e) = \dot{e}^T P e + e^T P \dot{e} = -2e^T Q e + 2e^T P[N(x + e, u) - N(x, u)].$$

Therefore we have

$$\begin{aligned} \dot{V}(e) &\leq -2e^T Q e + 2L(u)\|Pe\|\|e\| \\ &\leq (-2\lambda_{\min}(Q) + 2L(u)\lambda_{\max}(P))\|e\|, \end{aligned}$$

where $\lambda_{\min}(Q)$ is the minimum eigenvalue of Q and $\lambda_{\max}(P)$ is the maximum eigenvalue of P. Hence if

$$\lambda_{\min}(Q)/\lambda_{\max}(P) > L(u),$$

then $e = 0$ is local asymptotically stable.

MULTISCALE SINGULARLY PERTURBED CONTROL SYSTEMS: LIMIT OCCUPATIONAL MEASURES SETS AND AVERAGING*

VLADIMIR GAITSGORY† AND MINH-TUAN NGUYEN†‡

Abstract. An averaging technique for nonlinear multiscale singularly perturbed control systems is developed. Issues concerning the existence and structure of limit occupational measures sets generated by such systems are discussed. General results are illustrated with special cases.

Key words. multiscale singularly perturbed control systems, occupational measures, averaging method, limit occupational measures sets, nonlinear control, approximation of slow motions

1. Introduction.

In this paper we consider a singularly perturbed control system containing several small parameters $\epsilon_1, \dots, \epsilon_m$ ($m \geq 1$). The parameters are introduced in such a way that the state variables of the system are decomposed into a group of "slow" variables which change their values with the rates of the order $O(1)$ and m groups of "fast" variables which change their values with the rates of the orders $O(\epsilon_1^{-1}), O(\epsilon_1^{-1}\epsilon_2^{-1}), \dots, O(\epsilon_1^{-1}\epsilon_2^{-1}\dots\epsilon_m^{-1})$, respectively.

The main contribution of the paper is the description of the structure of the limit control system, the solutions of which allow us to approximate the slow variables when the parameters ϵ_i, $i = 1, \dots, m$, tend to zero. The role of controls in the limit system is played by probability measures defined on the product of the original control set and a subset of the state space containing all the fast trajectories (both are assumed to be compact). These probability measures are chosen from a limit set of occupational measures generated by the admissible controls and trajectories of an associated system which describes the dynamics of the fast variables if the slow ones are "frozen" (see exact definitions below). The existence of such a set (called limit occupational measures set (LOMS)) and its structure are the central issues discussed in the paper.

Singularly perturbed control systems (SPCS) with one small parameter ($m = 1$) have been intensively studied in the literature, the most common approaches being related either to Tikhonov-type theorems justifying the equating of the small parameter to zero with further application of the boundary layer method (see [24], [30]) to asymptotically describe the fast dynamics (see, e.g., [13], [21], [22], [25], [28], [31]) or to different types of averaging techniques (see [1], [2], [3], [4], [5], [8], [11], [14], [15], [16], [17], [18], [19], [20], [27], [32]) which allow us to deal with the situation when the equating of the parameter to zero may not lead to a right approximation.

The literature on multiscale SPCS ($m > 1$) is much less intensive. Most available references concern linear control systems (see, e.g., [12], [26], and references therein).

‡Present address: Joint Systems Branch, DSTO, P.O. Box 1500, Edinburgh SA 5111, Australia (minh@linus.levels.unisa.edu.au).

A technique of averaging type applicable to nonlinear control systems having a triangular structure (weakly coupled) was proposed in [20].

In [18] an averaging technique allowing us to deal with a general form of SPCS containing two small parameters ($m = 2$) was developed. The extension of the technique to the case $m > 2$ is, however, hardly possible since it involves a multiple averaging over time and leads to really complex expressions which are difficult to comprehend. In this paper, an averaging over time is replaced by averaging over measures from the LOMS. It resembles approaches used in dealing with stochastic SPCS (see, e.g., [9], [23], [34]) and makes the transition from the case $m = k$ to the case $m = k + 1$ ($\forall k = 1, 2, \ldots$) very natural.

Different issues related to averaging over occupational measures in SPCS with one small parameter were discussed in [2], [3], [4], [5], [17], [32]. In [17], in particular, LOMS for control systems without small parameters were considered. In this paper, we introduce and study such sets for singularly perturbed control systems (as is the associated system if the original system is multiscale).

The paper is organized as follows. Section 1 is this introduction. In section 2 statements about approximation of the slow motions by the solutions of the averaged system are formulated under the assumption that the LOMS of the associated system exists. An application of these results to problems of optimal control is demonstrated and a special case concerning systems linear in fast variables and controls is considered. In section 3 issues of existence and structure of the LOMS are addressed and a multistage averaging procedure for the construction of the LOMS is presented. The procedure is then illustrated with a special case of control systems which have a triangular structure (similar to those studied in [20]). Proofs of most of the statements are provided in section 4.

2. Averaging of multiscale SPCS.

2.1. Preliminaries. Given a compact metric space W, $\mathcal{B}(W)$ will stand for the σ-algebra of its Borel subsets and $\mathcal{P}(W)$ will denote the set of probability measures defined on $\mathcal{B}(W)$. The set $\mathcal{P}(W)$ will always be treated as a compact metric space with a metric ρ, which is consistent with its weak convergence topology. That is, a sequence $\gamma^k \in \mathcal{P}(W)$, $k = 1, 2, \ldots$, converges to $\gamma \in \mathcal{P}(W)$ in this metric if and only if

$$\lim_{k\to\infty} \int_W \phi(w)\gamma^k(dw) \;=\; \int_W \phi(w)\gamma(dw)$$

for any continuous $\phi(w) : W \to \mathbb{R}^1$.

Using the metric ρ, one can define the Hausdorff metric ρ_{H} on the set of subsets of $\mathcal{P}(W)$:

$$\rho_{\text{H}}(\Gamma_1, \Gamma_2) \stackrel{\text{def}}{=} \max\Big\{ \sup_{\gamma\in\Gamma_1} \rho(\gamma, \Gamma_2), \sup_{\gamma\in\Gamma_2} \rho(\gamma, \Gamma_1)\Big\} \quad \forall \Gamma_1, \Gamma_2 \in \mathcal{P}(W), \tag{2.1}$$

$$\text{where} \qquad \rho(\gamma, \Gamma_i) \stackrel{\text{def}}{=} \inf_{\gamma'\in\Gamma_i} \rho(\gamma, \gamma'), \quad i = 1, 2.$$

We will deal with the convergence in the Hausdorff metric of sets in $\mathcal{P}(W)$ defined as unions of occupational measures. Given a measurable function $w(t) : [0, T] \to W$, the occupational measure $p^{w(\cdot)} \in \mathcal{P}(W)$ generated by this function is defined by taking

$$p^{w(\cdot)}(Q) \stackrel{\text{def}}{=} \frac{1}{T}\text{meas}\Big\{ t \mid w(t) \in Q\Big\} \quad \forall Q \in \mathcal{B}(W), \tag{2.2}$$

where meas $\{\cdot\}$ stands for the Lebesgue measure on $[0, T]$.

2.2. Setting. Consider the SPCS

$$\begin{aligned}
\epsilon_1\epsilon_2\dots\epsilon_{m-1}\epsilon_m\dot{y}_1(t) &= f_1\big(u(t),y_1(t),\dots,y_m(t),z(t)\big),\\
&\vdots\ \vdots\ \vdots \qquad \vdots\ \vdots\ \vdots\\
\epsilon_{m-1}\epsilon_m\dot{y}_{m-1}(t) &= f_{m-1}\big(u(t),y_1(t),\dots,y_m(t),z(t)\big),\\
\epsilon_m\dot{y}_m(t) &= f_m\big(u(t),y_1(t),\dots,y_m(t),z(t)\big),\\
\dot{z}(t) &= g\big(u(t),y_1(t),\dots,y_m(t),z(t)\big),
\end{aligned} \tag{2.3}$$

where $\epsilon \stackrel{\text{def}}{=} (\epsilon_1,\epsilon_2,\dots,\epsilon_m)$ is a vector of small positive parameters, $t\in[0,T]$, and the functions $f_i : U\times\mathbb{R}^{M_1}\times\dots\times\mathbb{R}^{M_m}\times\mathbb{R}^N\to\mathbb{R}^{M_i}$, $i=1,\dots,m$, and $g : U\times\mathbb{R}^{M_1}\times\dots\times\mathbb{R}^{M_m}\times\mathbb{R}^N\to\mathbb{R}^N$ are continuous and satisfy Lipschitz conditions in $(y_1,\dots,y_m,z)$. Admissible controls are Lebesgue measurable functions $u(t):[0,T]\to U$, where U is a compact metric space.

Consider also the system

$$\begin{aligned}
\epsilon_1\epsilon_2\dots\epsilon_{m-1}\dot{y}_1(\tau) &= f_1\big(u(\tau),y_1(\tau),\dots,y_m(\tau),z\big),\\
&\vdots\ \vdots\ \vdots \qquad \vdots\ \vdots\ \vdots\\
\epsilon_{m-1}\dot{y}_{m-1}(\tau) &= f_{m-1}\big(u(\tau),y_1(\tau),\dots,y_m(\tau),z\big),\\
\dot{y}_m(\tau) &= f_m\big(u(\tau),y_1(\tau),\dots,y_m(\tau),z\big),\\
z &= \text{constant},
\end{aligned} \tag{2.4}$$

in which z is fixed and $\tau\in[0,S]$. This system will be referred to as an *associated system* with respect to SPCS (2.3). It is formally obtained from the "fast" subsystem of (2.3) via the replacement of the time scale $\tau = t\epsilon_m^{-1}$. Admissible controls for the associated system (2.4) are Lebesgue measurable functions $u(\tau):[0,S]\to U$. The solutions of (2.3) and (2.4) which are obtained with admissible controls are called admissible trajectories.

Assumption 2.1. (i) *There exist compact sets $Y_i''\subseteq Y_i'\subset\mathbb{R}^{M_i}$, $i=1,\dots,m$, and $Z''\subseteq Z'\subset\mathbb{R}^N$ such that the admissible trajectories of SPCS* (2.3) *which satisfy the initial conditions*

$$\big(y_1(0),\dots,y_m(0),z(0)\big)\in Y_1''\times\dots\times Y_m''\times Z'' \tag{2.5}$$

do not leave the set $Y_1'\times\dots\times Y_m'\times Z'$ on the interval $[0,T]$.

(ii) *There exist compact sets Y_i ($Y_i'\subseteq Y_i$), $i=1,\dots,m$, and Z ($Z'\in\operatorname{int}Z$) such that for any z from Z, the admissible trajectories of system* (2.4) *which satisfy the initial conditions*

$$\big(y_1(0),\dots,y_m(0)\big)\in Y_1'\times\dots\times Y_m' \tag{2.6}$$

do not leave the set $Y_1\times\dots\times Y_m$ on the interval $[0,\infty)$.

Note that to verify this assumption, one can use results from viability theory (see Chapter 5 in [6] and also [29] for further references).

Let us introduce the following notation:

$$y(\tau)\stackrel{\text{def}}{=}\big(y_1(\tau),\dots,y_m(\tau)\big),\quad Y\stackrel{\text{def}}{=}Y_1\times\dots\times Y_m,$$

and also $Y'\stackrel{\text{def}}{=}Y_1'\times\dots\times Y_m'$, $Y''\stackrel{\text{def}}{=}Y_1''\times\dots\times Y_m''$.

Let $u(\tau)$ be an admissible control defined on the interval $[0,S]$ and let $y(\tau)$ be the solution of the associated system (2.4) obtained with this control and the initial conditions (2.6). Let $p^{(u(\cdot),y(\cdot))} \in \mathcal{P}(U\times Y)$ be the occupational measure generated by the pair $\big(u(\tau),y(\tau)\big):[0,S]\to U\times Y$ and let

$$\Gamma\big(z,\epsilon_1,\dots,\epsilon_{m-1},S,y(0)\big) \stackrel{\text{def}}{=} \bigcup_{(u(\cdot),y(\cdot))} \Big\{p^{(u(\cdot),y(\cdot))}\Big\}, \tag{2.7}$$

where the union is taken over all admissible controls and the corresponding solutions of (2.4). Notice that the dependence on $(z,\epsilon_1,\dots,\epsilon_{m-1})$ in (2.7) is due to the dependence of the solutions of (2.4) on these parameters.

Assumption 2.2. *For any $z\in Z$, there exists a convex and compact set $\Gamma(z)\subset \mathcal{P}(U\times Y)$ such that*

$$\rho_{\text{H}}\Big(\Gamma\big(z,\epsilon_1,\dots,\epsilon_{m-1},S,y(0)\big),\Gamma(z)\Big) \le \nu(\epsilon_1,\dots,\epsilon_{m-1},S) \quad \forall y(0)\in Y', \tag{2.8}$$

where $\lim_{(\epsilon_1,\dots,\epsilon_{m-1},S^{-1})\to 0}\nu(\epsilon_1,\dots,\epsilon_{m-1},S)=0$.

The set $\Gamma(z)$ introduced in Assumption 2.2 will be referred to as the *limit occupational measures set* (LOMS). Some sufficient conditions for the existence of the LOMS are considered in section 3.

Assumption 2.3. *For any $S>0$, any absolutely continuous function $\tilde z(\tau):[0,S]\to Z$, and any admissible control $u(\tau)\colon[0,S]\to U$,*

$$\max_{\tau\in[0,S]}\big\|y^z(\tau)-\tilde y(\tau)\big\| \le c\max_{\tau\in[0,S]}\big\|z-\tilde z(\tau)\big\| + \kappa(\epsilon_1,\dots,\epsilon_{m-1}), \quad c=\text{const}, \tag{2.9}$$

where $y^z(\tau)$ is the solution of (2.4) obtained with a given $z\in Z$ and $\tilde y(\tau)$ is the solution of the same system obtained with the replacement of z by the function $\tilde z(\tau)$. Initial conditions for $y^z(\tau)$ and $\tilde y(\tau)$ are the same: $y^z(0)=\tilde y(0)\in Y'$ and the function $\kappa(\epsilon_1,\dots,\epsilon_{m-1})$ is either zero (for $m=1$) or tends to zero as $(\epsilon_1,\dots,\epsilon_{m-1})$ tends to zero (for $m>1$).

Lemma 2.4. *Let Assumptions* 2.1–2.3 *be satisfied. Then for any vector function $h(u,y,z):U\times Y\times Z\to\mathbb{R}^j$, $j=1,2,\dots$, which is continuous in (u,y,z) and satisfies Lipschitz conditions in (y,z), there exists a constant c_h such that*

$$\mathrm{d}_{\text{H}}\big(V_h(z'),V_h(z'')\big)\le c_h\|z'-z''\| \quad \forall z',z''\in Z, \tag{2.10}$$

where

$$V_h(z)\stackrel{\text{def}}{=}\bigcup_{p\in\Gamma(z)}\int_{U\times Y} h(u,y,z)p\,(du,dy). \tag{2.11}$$

Note that $\mathrm{d}_{\text{H}}(\cdot,\cdot)$ in (2.10) stands for the Hausdorff metric in a finite-dimensional space. That is, for arbitrary bounded subsets V_1, V_2 of $\mathbb{R}^j$ $(j=1,2,\dots)$,

$$\mathrm{d}_{\text{H}}(V_1,V_2)\stackrel{\text{def}}{=}\max\Big\{\sup_{v\in V_1}\mathrm{d}(v,V_2),\ \sup_{v\in V_2}\mathrm{d}(v,V_1)\Big\}, \quad \mathrm{d}(v,V_i)\stackrel{\text{def}}{=}\inf_{v'\in V_i}\|v-v'\|, \tag{2.12}$$

where $\|\cdot\|$ is a norm in $\mathbb{R}^j$.

The proof of Lemma 2.4 is in section 4.1.

Note that Assumption 2.3 is satisfied automatically if the functions $f_1,\dots,f_{m-1}$ defining the right-hand side of the associated systems (2.4) do not depend on z. In a

general case, Assumption 2.3 can be verified to be valid if the associated system (2.4) satisfies stability conditions similar to that introduced in [16] (see [16, Assumption 4.1, Lemma 4.1]), the latter being implied by the existence of a Lyapunov-like function (as in [17, p. 467]). For the case $m = 1$ (one singular perturbation parameter), Assumption 2.3 can be replaced by the assumption that the statement of Lemma 2.4 is valid (see [17]). A slightly different assumption which can replace Assumption 2.3 for $m > 1$ is discussed in Remark 4.1.

2.3. Approximation of the slow trajectories. Let the function $\tilde{g}(\gamma, z) : \mathcal{P}(U \times Y) \times \mathbb{R}^N \to \mathbb{R}^N$ be defined as follows:

$$\tilde{g}(\gamma, z) \stackrel{\text{def}}{=} \int_{U\times Y} g(u, y, z)\, \gamma(du, dy). \tag{2.13}$$

We will assume that the metric ρ of $\mathcal{P}(U\times Y)$ is chosen in such a way that the function $\tilde{g}(\gamma, z)$ satisfies the Lipschitz conditions:

$$\|\tilde{g}(\gamma', z') - \tilde{g}(\gamma'', z'')\| \le b(\rho(\gamma', \gamma'') + \|z' - z''\|) \quad \forall z', z'',\ \forall \gamma', \gamma'', \tag{2.14}$$

where b is a positive constant. Let us consider the system

$$\dot{z}(t) = \tilde{g}\big(\gamma(t), z(t)\big), \tag{2.15}$$

which will be referred to as the *averaged system*. The role of controls in the averaged system is played by functions $\gamma(t)$ satisfying the inclusion

$$\gamma(t) \in \Gamma\big(z(t)\big). \tag{2.16}$$

Note that the fact that the functions $\gamma(t)$ are measure valued underlines the similarity of our description with classical relaxed control setting (see [33]).

DEFINITION 2.5. *A pair* $\big(\gamma(t), z(t)\big) : [0, T] \to \mathcal{P}(U\times Y)\times\mathbb{R}^N$ *is called admissible for the averaged system if* $\gamma(t)$ *is Lebesgue measurable,* $z(t)$ *is absolutely continuous, and* (2.15)–(2.16) *are satisfied for almost all* $t \in [0, T]$.

THEOREM 2.6. *Let Assumptions* 2.1–2.3 *be satisfied and let* $h(u, y, z) : U \times Y \times Z \to \mathbb{R}^j$, $j = 1, 2, \ldots$, *be an arbitrary Lipschitz continuous vector function. There exist* $\mu(\epsilon, T)$ *and* $\mu_h(\epsilon, T)$,

$$\lim_{\epsilon\to 0} \mu(\epsilon, T) = 0, \qquad \lim_{\epsilon\to 0} \mu_h(\epsilon, T) = 0, \tag{2.17}$$

such that the following two statements are valid:

(i) *Let* $u(t)$ *be an admissible control and let* $\big(y(t), z(t)\big)$ *be the corresponding trajectory of SPCS* (2.3) *which satisfies initial condition* (2.5). *There exists an admissible pair* $\big(\gamma^a(t), z^a(t)\big)$ *of the averaged system* (2.15) *with the initial conditions* $z^a(0) = z(0)$ *such that*

$$\max_{t\in[0,T]} \big\|z(t) - z^a(t)\big\| \le \mu(\epsilon, T), \tag{2.18}$$

and also

$$\left\| \int_0^T h\big(u(t), y(t), z(t)\big) dt \ - \ \int_0^T \tilde{h}\big(\gamma^a(t), z^a(t)\big) dt \right\| \ \le \ \mu_h(\epsilon, T), \tag{2.19}$$

where

$$\tilde{h}(\gamma, z) \stackrel{\text{def}}{=} \int_{U\times Y} h(u, y, z)\, \gamma(du, dy). \tag{2.20}$$

(ii) *Conversely, let* $\big(\gamma^a(t), z^a(t)\big)$ *be an admissible pair of the averaged system* (2.15)*, which satisfies initial conditions* $z^a(0) \in Z''$*. One can construct an admissible control* $u(t)$ *such that the trajectory* $\big(y(t), z(t)\big)$ *of SPCS* (2.3) *obtained with this control and initial conditions* (2.5) $\big(z(0) = z^a(0)\big)$ *will satisfy* (2.18)–(2.19)*.*

The proof of the theorem is in section 4.1. Estimates (2.18)–(2.19) of Theorem 2.6 are not uniform with respect to the length T of the time interval. Additional assumptions are needed to make them uniform. The assumption we use in this paper is as follows.

ASSUMPTION 2.7. *There exist positive definite matrices* C*,* D *and a constant* a *such that corresponding to any* z', z'' *from* Z *and any* $\gamma' \in \Gamma(z')$ *there exists* $\gamma'' \in \Gamma(z'')$ *such that*

$$\big(\tilde{g}(\gamma', z') - \tilde{g}(\gamma'', z'')\big)^T\ C\ (z' - z'') \le -\|z' - z''\|_D^2 \tag{2.21}$$

and

$$\rho(\gamma', \gamma'') \le a\|z' - z''\|, \tag{2.22}$$

where $\|x\|_D^2$ *in* (2.21) *(and in what follows) stands for* $x^T Dx$*.*

Note that Assumption 2.7 is satisfied if the inequality (2.21) is valid for any $\gamma' = \gamma''$ and the LOMS $\Gamma(z)$ is independent of z (that is, the associated system does not depend on z).

THEOREM 2.8. *Let Assumptions* 2.1–2.3 *and* 2.7 *be satisfied. Assume also that all the admissible trajectories of averaged system* (2.15) *which start in* Z'' *do not leave* Z' *and those which start in* Z' *do not leave* $\mathrm{int} Z$ *on the infinite time horizon. Then there exist* $\mu(\epsilon)$ *and* $\mu_h(\epsilon)$*,*

$$\lim_{\epsilon\to 0} \mu(\epsilon) = 0, \qquad \lim_{\epsilon\to 0} \mu_h(\epsilon) = 0,$$

such that statements (i) *and* (ii) *of Theorem* 2.6 *remain valid with*

$$\sup_{t>0} \big\|z(t) - z^a(t)\big\| \le \mu(\epsilon) \tag{2.23}$$

replacing (2.18) *and*

$$\sup_{T>T_0} \left\| T^{-1} \int_0^T h\big(u(t), y(t), z(t)\big) dt \ - \ T^{-1} \int_0^T \tilde{h}\big(\gamma^a(t), z^a(t)\big) dt \right\| \le \mu_h(\epsilon), \quad T_0 = \text{const} \tag{2.24}$$

replacing (2.19) *for any Lipschitz continuous vector function* $h(u, y, z) : U \times Y \times Z \to \mathbb{R}^j$*,* $j = 1, 2, \ldots$*, such that the corresponding* $\tilde{h}(\gamma, z)$ *defined by* (2.20) *satisfies the Lipschitz condition*

$$\|\tilde{h}(\gamma', z') - \tilde{h}(\gamma'', z'')\| \le a_h(\rho(\gamma', \gamma'') + \|z' - z''\|) \quad \forall z', z'',\ \forall \gamma', \gamma'', \tag{2.25}$$

where a_h *is some positive constant.*

The proof of the theorem is in section 4.1.

2.4. Application to optimal control. Let $h(u,y,z) : U \times Y \times Z \to \mathbb{R}^1$ be continuous and satisfy the Lipschitz conditions in (y,z). Consider the optimal control problem

$$\inf_{(u(\cdot),y(\cdot),z(\cdot))} \left\{ \int_0^T h(u(t),y(t),z(t))dt \right\}, \tag{2.26}$$

where inf is sought over all admissible controls and trajectories of (2.3). Under the assumptions of Theorem 2.6, the optimal value of this problem converges to the optimal value of the problem

$$\inf_{(\gamma(\cdot),z(\cdot))} \left\{ \int_0^T \tilde{h}(\gamma(t),z(t))dt \right\}, \tag{2.27}$$

where $\tilde{h}(\gamma,z)$ is defined according to (2.20) and inf is over the admissible pairs of the averaged system (2.15). Near optimal controls of (2.26) can also be constructed on the basis of the solution of (2.27). These will be the controls which provide the validity of (2.18)–(2.19) for the admissible pair $(\gamma^a(t), z^a(t))$ which delivers the optimal (or near optimal) value to (2.27) (see statement (ii) of Theorem 2.6). If the assumptions of Theorem 2.8 are satisfied, then a similar approximation of a problem on the infinite time horizon with a time average criterion is possible.

In some cases the "limit" problem (2.27) can be significantly simplified with the help of the following proposition.

PROPOSITION 2.9. *Let $\phi(y_i) : Y_i \to \mathbb{R}^1$ be continuously differentiable. Then*

$$\int_{U\times Y} (\phi'(y_i))^T f_i(u,y,z)\gamma(du,dy) \;=\; 0 \quad \forall \gamma \in \Gamma(z), \tag{2.28}$$

and, in particular,

$$\int_{U\times Y} f_i(u,y,z)\gamma(du,dy) \;=\; 0 \quad \forall \gamma \in \Gamma(z), \tag{2.29}$$

where $f_i(u,y,z)$, $i = 1,\dots,m$, are the functions defining the right-hand side of (2.4).

The proof of the proposition is in section 4.1. To illustrate how this proposition can be applied let us consider the following special case. Assume that the set U is convex and the functions $f_i(u,y,z)$, $g(z,y,u)$ are linear in fast variables and controls. That is,

$$f_i(u,y,z) = \sum_{j=1}^m A_{i,j}(z)y_j + A_{i,m+1}(z)u + A_{i,m+2}(z), \quad i = 1,\dots,m, \tag{2.30}$$

$$g(u,y,z) = \sum_{j=1}^m A_{0,j}(z)y_j + A_{0,m+1}(z)u + A_{0,m+2}(z), \tag{2.31}$$

where $A_{i,j}$ are matrix functions of the corresponding dimensions. By (2.31), the averaged system is equivalent to

$$\dot{z}(t) = g(\bar{u}(t),\bar{y}(t),z(t)), \quad (\bar{u}(t),\bar{y}(t)) \in \Omega(z(t)), \tag{2.32}$$

where $\Omega(z)$ is the set of the first moments corresponding to the probability measures from the LOMS $\Gamma(z)$:

$$\Omega(z) \stackrel{\text{def}}{=} \left\{(\bar{u},\bar{y}) \mid (\bar{u},\bar{y}) = \int_{Y\times U}(u,y)\gamma(du,dy), \quad \gamma\in\Gamma(z)\right\}.$$

By (2.29) and (2.30), this set allows the representation

$$\Omega(z) = \{(\bar{u},\bar{y}) \mid f_i(\bar{u},\bar{y},z) = 0, \quad i = 1,\dots,m, \quad \bar{u}\in U\}, \tag{2.33}$$

and thus (2.32) is equivalent to the control system

$$\dot{z}(t) = g(\bar{u}(t),\psi(\bar{u}(t),z(t)),z(t)), \quad \bar{u}(t)\in U, \tag{2.34}$$

where $\bar{y} = \psi(\bar{u},z)$ is the root of the system of equations $f_i(\bar{u},\bar{y},z) = 0$, $i = 1,\dots,m$. This is a so-called reduced system and can be obtained from (2.3) via formally equating ϵ to zero. If, in addition, the function $h(u,y,z)$ used in (2.26) is convex in (u,y), then limit problem (2.27) becomes equivalent to

$$\inf_{(\bar{u}(\cdot),z(\cdot))}\left\{\int_0^T h(\bar{u}(t),\psi(\bar{u}(t),z(t)),z(t))dt\right\}, \tag{2.35}$$

where inf is over the admissible controls and corresponding trajectories of (2.34). Notice that the reasoning above is valid if Assumptions 2.1–2.3 are satisfied. It can be shown (although it is quite technical and we do not prove it in this paper) that these assumptions are satisfied if the eigenvalues of the matrices $A_{l,l}^{(l-1)}(z)$, $l = 1,\dots,m$, defined below have negative real parts for all z from a sufficiently large domain. The matrices are defined recursively for $l = 1,\dots,m$ by the equations

$$A_{i,j}^{(l)}(z) = A_{i,j}^{(l-1)}(z) - A_{i,l}^{(l-1)}(z)(A_{l,l}^{(l-1)}(z))^{-1}A_{l,j}^{(l-1)}(z) \tag{2.36}$$

($i = l+1,\dots,m$, $j = l+1,\dots,m+2$), with $A_{i,j}^{(0)}(z) \stackrel{\text{def}}{=} A_{i,j}(z)$ ($i = 1,\dots,m$, $j = 1,\dots,m+2$). Note that the condition that the matrices (2.36) have negative real parts is similar to that used in [12] to asymptotically describe the reachability set of a multiscale linear SPCS.

3. Existence of LOMS.

3.1. Approximation of the occupational measures set. Let $u(t)$ be an admissible control and let $\big(y(t),z(t)\big)$ be the corresponding admissible trajectory of SPCS (2.3) which satisfies initial conditions (2.5). Let $p^{(u(\cdot),y(\cdot),z(\cdot))}\in\mathcal{P}(U\times Y\times Z)$ be the occupational measure generated by the vector function $\big(u(\cdot),y(\cdot),z(\cdot)\big)\colon [0,T]\to U\times Y'\times Z'\subset U\times Y\times Z$ and let

$$\Gamma\big(\epsilon,T,y(0),z(0)\big) \stackrel{\text{def}}{=} \bigcup_{(u(\cdot),y(\cdot),z(\cdot))}\left\{p^{(u(\cdot),y(\cdot),z(\cdot))}\right\}, \tag{3.1}$$

where the union is taken over all admissible controls and the corresponding trajectories of SPCS (2.3). In this section, we will describe the asymptotics of this set as the vector of small parameters $\epsilon = (\epsilon_1,\dots,\epsilon_{m-1},\epsilon_m)$ tends to zero.

Let $(\gamma(t),z(t)) : [0,T]\to\mathcal{P}(U\times Y)\times Z$ be an admissible pair of the averaged system (2.15) with the initial condition

$$z(0)\in Z''. \tag{3.2}$$

Let $p^{(\gamma(t),z(t))} \in \mathcal{P}\big(\mathcal{P}(U\times Y)\times Z\big)$ be the occupational measure generated by this pair and let $\tilde{\Gamma}(T,z(0))$ be the union of the occupational measures generated by all such pairs

$$\tilde{\Gamma}\big(T,z(0)\big) \stackrel{\text{def}}{=} \bigcup_{(\gamma(\cdot),z(\cdot))} \Big\{p^{(\gamma(\cdot),z(\cdot))}\Big\}. \tag{3.3}$$

We will use $\tilde{\Gamma}(T,z(0))$ to specify the limit of (3.1) as ϵ tends to zero. To do that let us define a map $\psi(p) : p \in \mathcal{P}\big(\mathcal{P}(U\times Y)\times Z\big) \to \mathcal{P}(U\times Y\times Z)$ in such a way that for any $Q\in\mathcal{B}(U\times Y)$ and any $F\in\mathcal{B}(Z)$,

$$\psi(p)(Q\times F) = \int_{\mathcal{P}(U\times Y)\times Z} \gamma(Q)\chi_F(z)p(d\gamma,dz), \tag{3.4}$$

where $\chi_F(\cdot)$ is the indicator function of F. The integration in (3.4) is legitimate since the function

$$\gamma(Q)\chi_F(z):\ (\gamma,z)\in\mathcal{P}(U\times Y)\times Z \to [0,1] \tag{3.5}$$

is measurable with respect to $\mathcal{B}(\mathcal{P}(U\times Y)\times Z)$ (see [10, Proposition 7.25, p. 133]). Notice that for any $p\in\mathcal{P}\big(\mathcal{P}(U\times Y)\times Z\big)$ and any continuous function $h(u,y,z) : U\times Y\times Z\to\mathbb{R}^j$, $j=1,2,\dots,$

$$\int_{U\times Y\times Z} h(u,y,z)\psi(p)(du,dy,dz) = \int_{\mathcal{P}(U\times Y)\times Z} \tilde{h}(\gamma,z)p(d\gamma,dz), \tag{3.6}$$

where $\tilde{h}(\gamma,z)$ is defined by (2.20). For $p=p^{(\gamma(\cdot),z(\cdot))}$ (that is, for p being the occupational measure generated by an admissible pair $\big(\gamma(\cdot),z(\cdot)\big)$ of (2.15))

$$\int_{U\times Y\times Z} h(u,y,z)\psi\Big(p^{(\gamma(\cdot),z(\cdot))}\Big)(du,dy,dz) = \frac{1}{T}\int_0^T \tilde{h}\big(\gamma(t),z(t)\big)dt. \tag{3.7}$$

Let us now define the set $\Gamma(T,z(0))\subset\mathcal{P}(U\times Y\times Z)$ as follows:

$$\Gamma(T,z(0)) \stackrel{\text{def}}{=} \bigcup_{p\in\tilde{\Gamma}(T,z(0))} \Big\{\psi(p)\Big\} = \bigcup_{(\gamma(\cdot),z(\cdot))} \Big\{\psi\Big(p^{(\gamma(\cdot),z(\cdot))}\Big)\Big\}, \tag{3.8}$$

where the second union is taken over all admissible pairs of (2.15) satisfying initial conditions (3.2). (The second equality follows from the definition (3.3) of the set $\tilde{\Gamma}\big(T,z(0)\big)$.)

THEOREM 3.1. (i) *Let the assumptions of Theorem* 2.6 *be satisfied. Then there exists* $\nu(\epsilon,T)$, $\lim_{\epsilon\to 0}\nu(\epsilon,T)=0$, *such that*

$$\rho_{\text{H}}\Big(\Gamma\big(\epsilon,T,y(0),z(0)\big),\Gamma\big(T,z(0)\big)\Big)\le\nu(\epsilon,T)\quad\forall\big(y(0),z(0)\big)\in Y''\times Z''. \tag{3.9}$$

(ii) *Let the assumptions of Theorem* 2.8 *be satisfied and let there be a sequence* $q_k(u,y,z) : U\times Y\times Z\to\mathbb{R}^1$, $k=1,2,\dots,$ *of Lipschitz continuous functions such that it is dense in* $C(U\times Y\times Z)$ *and for any*

$$h(z,y,u) \stackrel{\text{def}}{=} (q_1(u,y,z),\dots,q_j(u,y,z)),\quad j=1,2,\dots, \tag{3.10}$$

the corresponding $\tilde{h}(\gamma, z)$ *defined by* (2.20) *satisfies Lipschitz condition* (2.25). *Then estimate* (3.9) *becomes uniform with respect to* $T \geq T_0$. *That is, there exists* $\nu(\epsilon)$, $\lim_{\epsilon \to 0} \nu(\epsilon) = 0$, *such that* $\forall T \geq T_0$,

$$\rho_{\text{H}}\Big(\Gamma\big(\epsilon, T, y(0), z(0)\big), \Gamma\big(T, z(0)\big)\Big) \leq \nu(\epsilon) \quad \forall \big(y(0), z(0)\big) \in Y'' \times Z''. \tag{3.11}$$

The proof of the theorem is in section 3.4.

3.2. LOMS of the averaged system and LOMS of the multiscale SPCS.

PROPOSITION 3.2. *Let the uniform estimate* (3.11) *be valid and let the LOMS of the averaged system* (2.15) *exist. That is, there exists the convex and compact set* $\tilde{\Gamma} \subset \mathcal{P}\big(\mathcal{P}(U \times Y) \times Z\big)$ *such that*

$$\rho_{\text{H}}\Big(\tilde{\Gamma}\big(T, z(0)\big), \tilde{\Gamma}\Big) \leq \tilde{\mu}(T) \quad \forall z(0) \in Z'', \tag{3.12}$$

where $\lim_{T \to \infty} \tilde{\mu}(T) = 0$. *Then the set*

$$\Gamma \stackrel{\text{def}}{=} \bigcup_{p \in \tilde{\Gamma}} \Big\{\psi(p)\Big\} \subset \mathcal{P}\big(U \times Y \times Z\big) \tag{3.13}$$

is convex and compact, and the following estimate is valid:

$$\rho_{\text{H}}\Big(\Gamma\big(T, z(0)\big), \Gamma\Big) \leq \mu(T) \quad \forall z(0) \in Z'', \tag{3.14}$$

where $\lim_{T \to \infty} \mu(T) = 0$. *Also,*

$$\rho_{\text{H}}\Big(\Gamma\big(\epsilon, T, y(0), z(0)\big), \Gamma\Big) \leq \mu(T) + \nu(\epsilon) \quad \forall \big(y(0), z(0)\big) \in Y'' \times Z'', \tag{3.15}$$

where $\mu(T)$ *and* $\nu(\epsilon)$ *are as in* (3.14) *and* (3.11), *respectively. Thus,* Γ *is the LOMS of SPCS* (2.3).

Proof. The validity of (3.14) is implied by (3.12) and by the fact that the map $\psi(p)$ defined by (3.4) is continuous (see Lemma 4.3 in section 4.2). This continuity implies also the fact that the set Γ is compact. The convexity of Γ follows from the linearity of $\psi(p)$. Estimate (3.15) follows from (3.14), (3.11), and the triangle inequality. ∎

THEOREM 3.3. *Let the assumptions of Theorem* 3.1(ii) *be satisfied. Then*

(i) *the LOMS* $\tilde{\Gamma}$ *of the averaged system* (2.15) *exists and the estimate* (3.12) *is valid;*

(ii) *the LOMS* Γ *of the SPCS system* (2.3) *exists and the estimate* (3.15) *is valid;* Γ *is presented in the form* (3.13).

Proof. The statements included in (ii) follow from Theorem 3.1(ii), Proposition 3.2, and Theorem 3.3(i). The proof of Theorem 3.3(i) is in section 4.2. ∎

3.3. LOMS via multistage averaging. System (2.4), which was introduced as associated with respect to (2.3), is singularly perturbed itself. One can thus consider a system which would be associated with respect to (2.4):

$$\begin{aligned}
\epsilon_1 \epsilon_2 \dots \epsilon_{m-2} \dot{y}_1(\tau) &= f_1\big(u(\tau), y_1(\tau), \dots, y_{m-1}(\tau), y_m, z\big), \\
&\vdots \quad \vdots \quad \vdots \qquad \vdots \quad \vdots \quad \vdots \\
\epsilon_{m-2} \dot{y}_{m-2}(\tau) &= f_{m-2}\big(u(\tau), y_1(\tau), \dots, y_{m-1}(\tau), y_m, z\big), \\
\dot{y}_{m-1}(\tau) &= f_{m-1}\big(u(\tau), y_1(\tau), \dots, y_{m-1}(\tau), y_m, z\big), \\
(y_m, z) &= \text{constant},
\end{aligned} \tag{3.16}$$

in which both y_m and z are fixed. For the sake of convenience, in this section we will refer to (2.4) and (3.16) as to y_m- and y_{m-1}-associated systems, respectively (by the name of the group of variables changing their values with rates of the order $O(1)$). One can also consider y_{m-2}-, $\dots$, y_2- and y_1-associated systems, the latter two being of the form

$$\begin{aligned} \epsilon_1 \dot{y}_1(\tau) &= f_1\big(u(\tau), y_1(\tau), y_2(\tau), y_3, \dots, y_m, z\big), \\ \dot{y}_2(\tau) &= f_2\big(u(\tau), y_1(\tau), y_2(\tau), y_3, \dots, y_m, z\big), \\ (y_3, \dots, y_m, z) &= \text{constant} \end{aligned} \tag{3.17}$$

and

$$\begin{aligned} \dot{y}_1(\tau) &= f_1\big(u(\tau), y_1(\tau), y_2, y_3, \dots, y_m, z\big), \\ (y_2, y_3, \dots, y_m, z) &= \text{constant}. \end{aligned} \tag{3.18}$$

Assume that the LOMS $\Gamma_1(y_2, y_3, \dots, y_m, z) \subset \mathcal{P}\big(U \times Y_1\big)$ of system (3.18) exists (sufficient conditions for the existence of LOMS of systems which, like (3.18), do not involve small parameters were discussed in [17]) and that Theorem 2.6 is applicable to system (3.17). Then y_2-components of the trajectories of this system are approximated by the trajectories of the averaged system

$$\dot{y}_2(\tau) = \tilde{f}_2\big(\gamma_1(\tau), y_2(\tau), y_3, \dots, y_m, z\big), \quad \gamma_1(\tau) \in \Gamma_1(y_2(\tau), y_3, \dots, y_m, z), \tag{3.19}$$

where $(y_3, \dots, y_m, z)$ are fixed and

$$\tilde{f}_2\big(\gamma_1, y_2, y_3, \dots, y_m, z\big) \stackrel{\text{def}}{=} \int_{U \times Y_1} f_2\big(u, y_1, y_2, y_3, \dots, y_m, z\big)\gamma_1(du, dy_1). \tag{3.20}$$

Suppose that the LOMS $\tilde{\Gamma}_2(y_3, \dots, y_m, z) \subset \mathcal{P}\big(\mathcal{P}(U \times Y_1) \times Y_2\big)$ of system (3.19) exists and that the other assumptions of Proposition 3.2 or Theorem 3.3 are satisfied. One then can come to the conclusion that the LOMS $\Gamma_2(y_3, \dots, y_m, z) \subset \mathcal{P}\big(U \times Y_1 \times Y_2\big)$ of system (3.17) exists and is presented in the form

$$\Gamma_2(y_3, \dots, y_m, z) \;=\; \bigcup_{p \in \tilde{\Gamma}_2(y_3, \dots, y_m, z)} \Big\{\psi_1(p)\Big\}, \tag{3.21}$$

where the map $\psi_1(p) : p \in \mathcal{P}\big(\mathcal{P}(U \times Y_1) \times Y_2\big) \to \mathcal{P}(U \times Y_1 \times Y_2)$ is such (compare with (3.4) above) that for any $Q \in \mathcal{B}(U \times Y_1)$ and any $F \in \mathcal{B}(Y_2)$,

$$\psi_1(p)(Q \times F) = \int_{\mathcal{P}(U \times Y_1) \times Y_2} \gamma_1(Q)\chi_F(y_2)p(d\gamma_1, dy_2), \tag{3.22}$$

$\chi_F(\cdot)$ being the indicator function of F. Assuming further that Proposition 3.2 or Theorem 3.3 can be applied step by step to y_3-, $\dots$, y_m-associated systems, one can establish the existence of the LOMS $\Gamma(z) \stackrel{\text{def}}{=} \Gamma_m(z)$ of system (2.4), which is presented in the form

$$\Gamma_m(z) \;=\; \bigcup_{p \in \tilde{\Gamma}_m(z)} \Big\{\psi_{m-1}(p)\Big\}, \tag{3.23}$$

with the corresponding definition of $\psi_{m-1}(p)$ and $\tilde{\Gamma}_m(z)$ being the LOMS of the averaged system

$$\dot{y}_m(\tau) = \tilde{f}_m\big(\gamma_{m-1}(\tau), y_m(\tau), z\big), \quad \gamma_{m-1}(\tau) \in \Gamma_{m-1}(y_m(\tau), z), \tag{3.24}$$

where $z = \text{const}$, $\Gamma_{m-1}(y_m, z)$ is the LOMS of the y_{m-1}-associated system, and

$$\tilde{f}_m\big(\gamma_{m-1}, y_m, z\big) \stackrel{\text{def}}{=} \int_{U\times Y_1\times\cdots\times Y_{m-1}} f_m\big(u, y_1, \dots, y_{m-1}, y_m, z\big)\gamma_{m-1}(du, dy_1, \dots, dy_{m-1}).$$

The applicability of Theorem 3.3 to each of the above systems is easy to verify, for example, if

$$f_i(u, y, z) \stackrel{\text{def}}{=} f_i(u, y_1, \dots, y_i), \quad i = 1, \dots, m. \tag{3.25}$$

That is, the dynamics of y_i-components in (2.3) is not influenced by the dynamics of y_{i+1}-, $\dots$, y_m- and z-components. Assuming that this is the case, let us also introduce the following assumption about the functions $f_i(\cdot)$.

ASSUMPTION 3.4. *There exist positive definite matrices C_i, D_i $(i = 1, \dots, m)$ such that for any $u \in U$ and any $y_1, \dots, y_{i-1}, y_i', y_i''$,*

$$\big(f_i(u, y_1, \dots, y_{i-1}, y_i') - f_i(u, y_1, \dots, y_{i-1}, y_i'')\big)^T\, C_i\, (y_i' - y_i'') \le -\|y_i' - y_i''\|^2_{D_i}. \tag{3.26}$$

By (3.25), the y_1-associated system (3.18) does not depend on $(y_2, \dots, y_m, z)$ and, by (3.26) with $i = 1$, the LOMS Γ_1 of this system exists (see Proposition 3.3 in [17]). Again, by (3.25), the dependence on $(y_3, \dots, y_m, z)$ in the function (3.20) defining the right-hand side of (3.19) disappears and, by (3.26) with $i = 2$, this function satisfies the inequality

$$\big(\tilde{f}_2(\gamma_1, y_2') - \tilde{f}_2(\gamma_1, y_2'')\big)^T\, C_2\, (y_2' - y_2'') \le -\|y_2' - y_2''\|^2_{D_2} \quad \forall \gamma_1 \in \mathcal{P}(U \times Y_1),$$

$\forall y_2', y_2'' \in \mathbb{R}^{M_2}$ and $\forall \gamma_1 \in \mathcal{P}(U \times Y_1)$. This implies the applicability of Theorem 3.3 according to which the LOMS $\tilde{\Gamma}_2$ of averaged system (3.19) and the LOMS Γ_2 of the y_2-associated system both exist and the representation (3.21) is valid. Continuing in a similar way, one can finally verify that the LOMS $\tilde{\Gamma}_m$ of averaged system (3.24) and the LOMS Γ_m of y_m-associated system (2.4) exist and that the representation (3.23) is valid. The applicability of Theorem 3.3 at this final stage can be verified by using the fact that the function $\tilde{f}_m\big(\gamma_{m-1}, y_m\big)$ defining the right-hand side of the averaged system (3.24) (which, by (3.25), does not involve the dependence on z) satisfies the inequality

$$\big(\tilde{f}_m(\gamma_{m-1}, y_m') - \tilde{f}_m(\gamma_{m-1}, y_m'')\big)^T\, C_m\, (y_m' - y_m'') \le -\|y_m' - y_m''\|^2_{D_m}$$

$\forall y_m', y_m'' \in \mathbb{R}^{M_m}$ and $\forall \gamma_{m-1} \in \mathcal{P}(U \times Y_1 \times \cdots \times Y_{m-1})$.

Note that a different multistage averaging procedure for SPCS with $f_i(\cdot)$ having the form (3.25) and satisfying an assumption similar to Assumption 3.4 (with C_i, D_i being identity matrices) was suggested in [20].

3.4. Basic lemma and the proof of Theorem 3.1. The proofs of Theorems 3.1 and 3.3 are based on the lemma and its corollaries presented below. Let W be a compact metric space and $q_k(w) : W \to \mathbb{R}^1$, $k = 1, 2, \dots$, be a sequence of Lipschitz continuous functions which is dense in $C(W)$.

LEMMA 3.5. *Let $\Gamma^i(\alpha, \beta) \subset \mathcal{P}(W)$, $i = 1, 2$, where α and β take values in some metric spaces $\mathcal{A}$ and $\mathcal{B}$. Assume that corresponding to any vector function*

$$h(w) = \big(q_1(w), \dots, q_j(w)\big), \quad j = 1, 2, \dots, \tag{3.27}$$

there exists a function

$$\nu_h(\alpha) : \mathcal{A} \to \mathbb{R}^1, \quad \lim_{\alpha \to \alpha_0} \nu_h(\alpha) = 0, \tag{3.28}$$

such that

$$\sup_{v \in V_h^1(\alpha,\beta)} \mathrm{d}\big(v, V_h^2(\alpha,\beta)\big) \le \nu_h(\alpha), \tag{3.29}$$

where

$$V_h^i(\alpha,\beta) \stackrel{\text{def}}{=} \bigcup_{\gamma \in \Gamma^i(\alpha,\beta)} \left\{ \int_W h(w)\gamma(dw) \right\}, \quad i = 1, 2, \dots. \tag{3.30}$$

Then there also exists another function

$$\nu(\alpha) : \mathcal{A} \to \mathbb{R}^1, \quad \lim_{\alpha \to \alpha_0} \nu(\alpha) = 0, \tag{3.31}$$

such that

$$\sup_{\gamma \in \Gamma^1(\alpha,\beta)} \rho\big(\gamma, \Gamma^2(\alpha,\beta)\big) \le \nu(\alpha). \tag{3.32}$$

Corollary 3.6. *If for any $h(w) : W \to \mathbb{R}^j$ as in* (3.27) *there exists a function* (3.28) *such that*

$$\mathrm{d}_{\mathrm{H}}\big(V_h^1(\alpha,\beta), V_h^2(\alpha,\beta)\big) \le \nu_h(\alpha), \tag{3.33}$$

then there also exists a function (3.31) *such that*

$$\rho_{\mathrm{H}}\big(\Gamma^1(\alpha,\beta), \Gamma^2(\alpha,\beta)\big) \le \nu(\alpha). \tag{3.34}$$

Corollary 3.7. *Let $\Gamma(\alpha,\beta) \subset \mathcal{P}(W)$ for $(\alpha,\beta) \in \mathcal{A} \times \mathcal{B}$, and for any $h(w) : W \to \mathbb{R}^j$ as in* (3.27) *there exists a convex and compact set $V_h \subset \mathbb{R}^j$ and a function* (3.28) *such that*

$$\mathrm{d}_{\mathrm{H}}\big(V_h(\alpha,\beta), V_h\big) \le \nu_h(\alpha), \tag{3.35}$$

where

$$V_h(\alpha,\beta) = \bigcup_{\gamma \in \Gamma(\alpha,\beta)} \left\{ \int_W h(w)\gamma(dw) \right\}. \tag{3.36}$$

Then there exists a function (3.31) *such that*

$$\rho_{\mathrm{H}}\big(\Gamma(\alpha,\beta), \Gamma\big) \le \nu(\alpha), \tag{3.37}$$

where Γ is a convex and compact subset of $\mathcal{P}(W)$ defined by

$$\Gamma \stackrel{\text{def}}{=} \left\{ \gamma \,\middle|\, \gamma \in \mathcal{P}(W), \int_W h(w)\gamma(dw) \in V_h \ \forall h(w)\colon W \to \mathbb{R}^j \text{ as in } (3.27) \right\}. \tag{3.38}$$

The proof of Lemma 3.5 is in section 4.2. Corollary 3.6 is implied by Lemma 3.5 in an obvious way. The proof of Corollary 3.7 is similar to the proof of Theorem 3.1(i) in [17].

Proof of Theorem 3.1. Let $h(u,y,z): U\times Y\times Z\to\mathbb{R}^j$, $j=1,2,\dots$, be an arbitrary Lipschitz continuous vector function. Let $u(t)$ be an admissible control and let $\big(y(t),z(t)\big)$ be the corresponding admissible trajectory of SPCS (2.3) which satisfies initial conditions (2.5). Let $V_h\big(\epsilon,T,y(0),z(0)\big)$ be the set of time averages

$$V_h\big(\epsilon,T,y(0),z(0)\big)\stackrel{\text{def}}{=}\bigcup_{(u(\cdot),y(\cdot),z(\cdot))}\left\{\frac{1}{T}\int_0^T h\big(u(t),y(t),z(t)\big)dt\right\},\tag{3.39}$$

where the union is taken over all admissible controls and the corresponding trajectories of (2.3). Notice that by definition (3.1) of $\Gamma\big(\epsilon,T,y(0),z(0)\big)$, the set (3.39) also allows the representation

$$V_h\big(\epsilon,T,y(0),z(0)\big)=\bigcup_{\gamma\in\Gamma(\epsilon,T,y(0),z(0))}\left\{\int h(u,y,z)\gamma(du,dy,dz)\right\}.\tag{3.40}$$

Let the set $\tilde V_h\big(T,z(0)\big)$ be defined as follows:

$$\begin{aligned}\tilde V_h\big(T,z(0)\big)&\stackrel{\text{def}}{=}\bigcup_{\gamma\in\Gamma(T,z(0))}\left\{\int h(u,y,z)\gamma(du,dy,dz)\right\}\\&=\bigcup_{(\gamma(\cdot),z(\cdot))}\left\{\int h(u,y,z)\psi\big(p^{(\gamma(\cdot),z(\cdot))}\big)(du,dy,dz)\right\},\end{aligned}\tag{3.41}$$

where, as in (3.8), the second union is taken over all admissible pairs of (2.15) which satisfy the initial conditions (3.2).

By (3.7), the set $\tilde V_h\big(T,z(0)\big)$ can also be represented in the form

$$\tilde V_h\big(T,z(0)\big)=\bigcup_{(\gamma(\cdot),z(\cdot))}\left\{\frac{1}{T}\int_0^T\tilde h\big(\gamma(\cdot),z(\cdot)\big)\right\}.\tag{3.42}$$

Using estimate (2.19) from Theorem 2.6 and comparing (3.39) and (3.42), one obtains

$$\mathrm{d_H}\Big(V_h\big(\epsilon,T,y(0),z(0)\big),\tilde V_h\big(T,z(0)\big)\Big)\le\frac{1}{T}\mu_h(\epsilon,T)\tag{3.43}$$

$\forall\big(y(0),z(0)\big)\in Y''\times Z''$. Having in mind representations (3.40), (3.41) and applying Corollary 3.6, one proves (3.9). Under the conditions of Theorem 2.8, estimate (3.43) can be rewritten in the uniform with respect to the $T\ge T_0$ form

$$\mathrm{d_H}\Big(V_h\big(\epsilon,T,y(0),z(0)\big),\tilde V_h\big(T,z(0)\big)\Big)\le\mu_h(\epsilon)\quad\forall T\ge T_0,$$

where $h(\cdot)$ is as in (3.10). This, by Corollary 3.6, proves (3.11). □

4. Proofs and auxiliary results.

4.1. Proofs for section 2.

Proof of Lemma 2.4. Consider the set of the time averages

$$V_h\big(z,\bar\epsilon,S,y(0)\big)\stackrel{\text{def}}{=}\bigcup_{(u(\cdot),y(\cdot))}\left\{\frac{1}{S}\int_0^S h\big(u(\tau),y(\tau),z\big)\right\},\tag{4.1}$$

where $\bar\epsilon \stackrel{\text{def}}{=} (\epsilon_1, \dots, \epsilon_{m-1})$ and the union is taken over all admissible controls and the corresponding trajectories of (2.4). By Assumption 2.3,

$$\max_{\tau\in[0,S]} \big\|y^{z'}(\tau) - y^{z''}(\tau)\big\| \le c\|z' - z''\| + \kappa(\bar\epsilon) \quad \forall z', z'' \in Z, \tag{4.2}$$

where $y^{z'}(\tau)$ and $y^{z''}(\tau)$ are solutions of (2.4) obtained with the same control and initial conditions and with $z = z'$ and $z = z''$, respectively. Hence,

$$\mathrm{d_H}\Big(V_h\big(z', \bar\epsilon, S, y(0)\big), V_h\big(z'', \bar\epsilon, S, y(0)\big)\Big) \le c_h\|z' - z''\| + c_h\kappa(\bar\epsilon) \quad \forall z', z'' \in Z, \tag{4.3}$$

where c_h is a constant which is expressed via the Lipschitz constant of $h(\cdot)$ and c from (4.2) in an obvious way.

By definition (2.7) of $\Gamma\big(z, \bar\epsilon, S, y(0)\big)$, the set $V_h\big(z, \bar\epsilon, S, y(0)\big)$ defined in (4.1) allows also the representation

$$V_h\big(z, \bar\epsilon, S, y(0)\big) = \bigcup_{p\in\Gamma(z,\bar\epsilon,S,y(0))} \Big\{\int_{U\times Y} h(u,y)p(du,dy)\Big\}. \tag{4.4}$$

It follows from Assumption 2.2 that there exists a function $\nu_h(\bar\epsilon, S)$ such that

$$\lim_{(\bar\epsilon, S^{-1})\to 0} \nu_h(\bar\epsilon, S) = 0$$

and

$$\mathrm{d_H}\Big(V_h\big(z, \bar\epsilon, S, y(0)\big), V_h(z)\Big) \le \nu_h(\bar\epsilon, S) \quad \forall z \in Z,\ \forall y(0) \in Y'. \tag{4.5}$$

Passing to the limit as $(\bar\epsilon, S^{-1})$ tends to zero in (4.3), one obtains (2.10). □

Proof of Theorem 2.6. Let $\bar g(u,y,z) \stackrel{\text{def}}{=} \big(g(u,y,z), h(u,y,z)\big)$. Consider the set of time averages

$$V\big(z, \bar\epsilon, S, y(0)\big) = \bigcup_{(u(\cdot),y(\cdot))} \Big\{\frac{1}{S}\int_0^T \bar g\big(u(\tau), y(\tau), z\big)d\tau\Big\} \subset \mathbb{R}^{N+j},$$

where, as in (4.1), the union is taken over all admissible controls and corresponding trajectories of (2.4). From Assumption 2.2 it follows (similarly to (4.5)) that there exists $\bar\nu(\bar\epsilon, S)$, $\lim_{(\bar\epsilon,S^{-1})\to 0} \bar\nu(\bar\epsilon, S) = 0$ such that

$$\mathrm{d_H}\Big(V\big(z, \bar\epsilon, S, y(0)\big), V(z)\Big) \le \bar\nu(\bar\epsilon, S) \quad \forall z \in Z,\ \forall y(0) \in Y', \tag{4.6}$$

where

$$V(z) \stackrel{\text{def}}{=} \Big\{(v,w) \mid (v,w) = \big(\tilde g(\gamma, z), \tilde h(\gamma, z)\big),\ \gamma \in \Gamma(z)\Big\} \subset \mathbb{R}^{N+j}, \tag{4.7}$$

with $\tilde g$ and $\tilde h$ being defined by (2.13) and (2.20), respectively.

Let us augment the averaged system (2.15) with the equation

$$\dot\theta(t) = \tilde h\big(\gamma(t), z(t)\big), \quad \theta(0) = 0. \tag{4.8}$$

The map $V(z)\colon Z \to 2^{\mathbb{R}^{N+j}}$ defined by (4.7) is convex and compact valued. It also satisfies the Lipschitz conditions (Lemma 2.4)

$$\mathrm{d_H}\big(V(z'), V(z'')\big) \le \bar c\|z' - z''\| \quad \forall z', z'' \in Z, \quad \bar c = \text{const}. \tag{4.9}$$

By the Filippov theorem (see, e.g., [7, Theorem 8.2.10, p. 316]), the set of admissible trajectories $\big(z(t),\theta(t)\big) \stackrel{\text{def}}{=} \bar z(t)$ of systems (2.15) and (4.8) coincides with the set of solutions of the differential inclusion

$$\dot{\bar z}(t) \in V\big(z(t)\big). \tag{4.10}$$

Let us augment system (2.3) with the equation

$$\dot\theta(t) = h\big(u(t), y_1(t), \dots, y_m(t), z(t)\big), \quad \theta(0) = 0, \tag{4.11}$$

and again denote $\bar z(\tau) \stackrel{\text{def}}{=} \big(z(\tau),\theta(\tau)\big)$. To prove the theorem it is enough to show that, corresponding to any admissible trajectory $\big(y(t),\bar z(t)\big)$ of (2.3) and (4.11), there exists a solution $\bar z^a(t)$ of (4.10) satisfying the inequality

$$\max_{t\in[0,T]} \big\|\bar z(t) - \bar z^a(t)\big\| \le \bar\mu(\epsilon,T), \quad \lim_{\epsilon\to 0}\bar\mu(\epsilon,T) = 0, \tag{4.12}$$

and, conversely, for any solution $\bar z^a(t)$ of (4.10), there exists an admissible trajectory $\big(y(\tau),\bar z(\tau)\big)$ of (2.3) and (4.11) which satisfies (4.12).

The proof of these statements is similar to Lemma 2.1 in [16] or Theorem 3.1 in [19]. □

REMARK 4.1. *Note that an important step of the proof is an introduction of the new time scale* $\tau \stackrel{\text{def}}{=} t\epsilon_m^{-1}$ *and a partition of the interval* $[0, T\epsilon_m^{-1}]$ *by the points* $\tau_l = lS(\epsilon_m)$, $l = 0, 1, \dots$, *where* $S(\epsilon_m) > 0$ *is a function of* ϵ_m *such that* $\lim_{\epsilon_m\to 0} S(\epsilon_m) = \infty$ *and* $\lim_{\epsilon_m\to 0} \epsilon_m S(\epsilon_m) = 0$. *At the cost of making the proof slightly more involved, one can replace Assumption* 2.3 *by the assumption that the statement of Lemma* 2.4 *is valid and that the* y_{m-1}*-associated system* (3.16) *has a property similar to* (2.9), *with* (y_m, z) *playing the role of* z.

Proof of Theorem 2.8. The proof is based on the following result.

PROPOSITION 4.2. *Given a solution* $\big(z^1(t),\theta^1(t)\big)$ *of the differential inclusion* (4.10) *satisfying the initial condition* $\big(z^1(0),\theta^1(0)\big) = (z^1,\theta^1) \in Z' \times \mathbb{R}^j$ *and a vector* $(z^2,\theta^2) \in Z' \times \mathbb{R}^j$, *there exists a solution* $\big(z^2(t),\theta^2(t)\big)$ *of* (4.10) *which satisfies the initial condition* $\big(z^2(0),\theta^2(0)\big) = (z^2,\theta^2)$, *and the following inequalities hold:*

$$\big\|z^1(t) - z^2(t)\big\| \le b_1 e^{-\beta t}\|z^1 - z^2\|, \tag{4.13}$$

$$\big\|\theta^1(t) - \theta^2(t)\big\| \le \|\theta^1 - \theta^2\| + b_2\|z^1 - z^2\|, \tag{4.14}$$

where b_1, b_2, β *are some positive constants.*

Proof of Proposition 4.2. As mentioned above, the map $V(z)$ defined in (4.7) is convex and compact valued and satisfies Lipschitz conditions. Also, from Assumption 2.7 (see (2.21)–(2.22)) it follows that it has the following property: for any $z' \in Z$, $(v', w') \in V(z')$ and any $z'' \in Z$, there exists $(v'', w'') \in V(z'')$ such that

$$(v' - v'')^T C(z' - z'') \le -\|z' - z''\|_D^2, \tag{4.15}$$

$$\|w' - w''\| \le b_h\|z' - z''\|. \tag{4.16}$$

The claim of the proposition follows now from Lemma A.2 in [18]. □

To prove Theorem 2.8 let us choose T_0 in such a way that

$$b_1 e^{-\beta T_0} \stackrel{\text{def}}{=} \delta < 1, \tag{4.17}$$

and let $\big(y(t), z(t), \theta(t)\big)$ be an admissible trajectory of the systems (2.3) and (4.11) which satisfies the initial conditions $(y(0), z(0)) \in Y'' \times Z''$, $\theta(0) = 0$. By Theorem 2.6, there exists a solution $\big(z^a(t), \theta^a(t)\big)$ of the differential inclusion (4.10) satisfying the initial condition $\big(z^a(0), \theta^a(0)\big) = \big(z(0), 0\big)$ such that

$$\big\|z(t) - z^a(t)\big\| \le \mu(\epsilon, T_0), \ \big\|\theta(t) - \theta^a(t)\big\| \le \mu_h(\epsilon, T_0) \quad \forall t \in [0, T_0]. \tag{4.18}$$

When Theorem 2.6 is applied again, one can establish that there exists a solution $\big(\tilde{z}^a(t), \tilde{\theta}^a(t)\big)$ of (4.10) on the interval $[T_0, 2T_0]$ such that it satisfies the initial conditions $\big(\tilde{z}^a(T_0), \tilde{\theta}^a(T_0)\big) = \big(z(T_0), \theta(T_0)\big)$ and, also, such that the following estimates are valid:

$$\big\|z(t) - \tilde{z}^a(t)\big\| \le \mu(\epsilon, T_0), \quad \big\|\theta(t) - \tilde{\theta}^a(t)\big\| \le \mu_h(\epsilon, T_0) \quad \forall t \in [T_0, 2T_0]. \tag{4.19}$$

It follows from Proposition 4.2 that the solution $\big(z^a(t), \theta^a(t)\big)$ used in (4.18) can be extended to the interval $[T_0, 2T_0]$ in such a way that for any $t \in [T_0, 2T_0]$,

$$\begin{aligned}
&\big\|\tilde{z}^a(t) - z^a(t)\big\| \le b_1 e^{-\beta(t-T_0)}\big\|z(T_0) - z^a(T_0)\big\|,\\
&\big\|\tilde{\theta}^a(t) - \theta^a(t)\big\| \le \big\|\theta(T_0) - \theta^a(T_0)\big\| + b_2\big\|z(T_0) - z^a(T_0)\big\|.
\end{aligned}$$

These along with (4.19) allow us to establish that for any $t \in [T_0, 2T_0]$,

$$\begin{aligned}
&\big\|z(t) - z^a(t)\big\| \le \mu(\epsilon, T_0) + b_1 e^{-\beta(t-T_0)}\big\|z(T_0) - z^a(T_0)\big\|,\\
&\big\|\theta(t) - \theta^a(t)\big\| \le \mu_h(\epsilon, T_0) + \big\|\theta(T_0) - \theta^a(T_0)\big\| + b_2\big\|z(T_0) - z^a(T_0)\big\|.
\end{aligned}$$

Continuing in a similar fashion, one can construct a solution of (4.10) such that the following inequalities are satisfied $\forall t \in [lT_0, (l+1)T_0]$, $l = 1, 2, \ldots$:

$$\big\|z(t) - z^a(t)\big\| \le \mu(\epsilon, T_0) + b_1 e^{-\beta(t-lT_0)}\big\|z(lT_0) - z^a(lT_0)\big\|, \tag{4.20}$$

$$\big\|\theta(t) - \theta^a(t)\big\| \le \mu_h(\epsilon, T_0) + \big\|\theta(lT_0) - \theta^a(lT_0)\big\| + b_2\big\|z(lT_0) - z^a(lT_0)\big\|. \tag{4.21}$$

It follows now from (4.17) and (4.20)–(4.21) that

$$\begin{aligned}
&\Big\|z\big((l+1)T_0\big) - z^a\big((l+1)T_0\big)\Big\| \le \mu(\epsilon, T_0) + \delta\big\|z(lT_0) - z^a(lT_0)\big\|,\\
&\Big\|\theta\big((l+1)T_0\big) - \theta^a\big((l+1)T_0\big)\Big\| \le \mu_h(\epsilon, T_0) + \big\|\theta(lT_0) - \theta^a(lT_0)\big\| + b_2\big\|z(lT_0) - z^a(lT_0)\big\|,
\end{aligned}$$

which imply that

$$\begin{aligned}
&\big\|z(lT_0) - z^a(lT_0)\big\| \le \frac{\mu(\epsilon, T_0)}{1-\delta}, \quad l = 1, 2, \ldots,\\
&\big\|\theta(lT_0) - \theta^a(lT_0)\big\| \le l\bigg(\mu_h(\epsilon, T_0) + \frac{b_2}{1-\delta}\mu(\epsilon, T_0)\bigg), \quad l = 1, 2, \ldots.
\end{aligned}$$

These and (4.20)–(4.21) lead to statement (i) of the theorem (see also the proof of Lemma 3.2 in [18]). The proof of (ii) is similar. □

Proof of Proposition 2.9. Let $\gamma \in \Gamma(z)$. By (2.8), there exist sequences $\bar{\epsilon}^k$, S^k, and $\gamma^k \in \Gamma(z, \bar{\epsilon}^k, S^k, y(0))$ such that $(\bar{\epsilon}^k, (S^k)^{-1}) \to 0$ and $\gamma^k \to \gamma$ as k tends to infinity. The latter convergence is in the metric consistent with the weak convergence topology of $\mathcal{P}(U \times Y)$ and, hence, it implies in particular that

$$\lim_{k\to\infty} \int_{U\times Y} (\phi\prime(y_i))^T f_i(u, y, z)\gamma^k(du, dy) \ = \ \int_{U\times Y} (\phi\prime(y_i))^T f_i(u, y, z)\gamma(du, dy). \tag{4.22}$$

According to the definition of the set $\Gamma(z, \bar{\epsilon}^k, S^k, y(0))$ (see (2.7)) and the fact that $\gamma^k \in \Gamma(z, \bar{\epsilon}^k, S^k, y(0))$, there exists an admissible control $u^k(\tau)$ and the corresponding trajectory $y^k(\tau)$ of system (2.4) such that

$$\int_{U\times Y} (\phi\prime(y_i))^T f_i(u,y,z)\gamma^k(du,dy) \;=\; \frac{1}{S^k}\int_0^{S^k} (\phi\prime(y_i^k(\tau)))^T f_i(u^k(\tau), y^k(\tau), z)d\tau.$$

The second integral is apparently equal to $\frac{\phi(y_i^k(S^k))-\phi(y_i^k(0))}{S^k}$, which tends to zero as S^k tends to infinity (since, by Assumption 2.1, the solutions of (2.4) stay in the bounded area). This and (4.22) imply the validity of the proposition. □

4.2. Proofs for section 3.

LEMMA 4.3. *The map $\psi(p)$ defined by* (3.4) *is continuous. That is, $\psi(p_l)$ converges to $\psi(p)$ in the weak convergence topology of $\mathcal{P}(U\times Y\times Z)$ if p_l converges to p in the weak convergence topology of $\mathcal{P}\big(\mathcal{P}(U\times Y)\times Z\big)$.*

Proof of Lemma 4.3. Let $h(u,y,z)\colon U\times Y\times Z\to\mathbb{R}^1$ be a continuous function. Then

$$\lim_{p_l\to p}\int h(u,y,z)\psi(p_l)(du,dy,dz) = \lim_{p_l\to p}\int\left(\int h(u,y,z)\gamma(du,dy)\right)p_l(d\gamma,dz)$$
$$= \int\left(\int h(u,y,z)\gamma(du,dy)\right)p(d\gamma,dz) = \int h(u,y,z)\psi(p)(du,dy,dz),$$

where it is taken into account that, because $h(u,y,z)$ is continuous, it follows that the function $\tilde{h}(\gamma,z)$ defined by (2.20) is continuous as well. Since the last equalities are valid for any continuous $h(\cdot)$, it follows that $\lim_{p_l\to p}\psi(p_l)=\psi(p)$. □

Proof of Lemma 3.5. Let the metric ρ of $\mathcal{P}(W)$ be defined as follows:

$$\rho(\gamma',\gamma'') = \sum_{k=0}^{\infty}\frac{1}{2^k}\,\frac{|\langle\gamma',q_k\rangle-\langle\gamma'',q_k\rangle|}{1+|\langle\gamma',q_k\rangle-\langle\gamma'',q_k\rangle|}\quad\forall\gamma',\gamma''\in\mathcal{P}(W) \tag{4.23}$$

where $q_k: W\to\mathbb{R}^1$, $k=0,1,\dots$, is a sequence of Lipschitz continuous functions which is dense in the space of continuous functions $C(W)$ and $\langle\gamma,q_k\rangle=\int_W q_k(w)\gamma(dw)$. Note that this metric is consistent with the weak convergence topology of $\mathcal{P}(W)$. Define

$$\nu(\alpha)\stackrel{\text{def}}{=}\sup_{\beta\in\mathcal{B}}\sup_{\gamma\in\Gamma^1(\alpha,\beta)}\rho\big(\gamma,\Gamma^2(\alpha,\beta)\big) \tag{4.24}$$

and show that $\nu(\alpha)$ tends to zero as α tends to α_0. Assume that it does not. Then there exists a number $\delta>0$ and sequences $(\alpha_l,\beta_l)\in\mathcal{A}\times\mathcal{B}$, $\gamma^l\in\Gamma^1(\alpha_l,\beta_l)$, $l=1,2,\dots$, such that $\lim_{l\to\infty}\alpha_l=\alpha_0$ and $\rho(\gamma^l,\gamma)\ge\delta\;\forall\,\gamma\in\Gamma^2(\alpha,\beta)$. That is,

$$\sum_{k=0}^{\infty}\frac{1}{2^k}\,\frac{|\langle\gamma^l,q_k\rangle-\langle\gamma,q_k\rangle|}{1+|\langle\gamma_l,q_k\rangle-\langle\gamma,q_k\rangle|}\ge\delta\quad\forall\,\gamma\in\Gamma^2(\alpha,\beta). \tag{4.25}$$

Hence, for some integer K,

$$\sum_{k=1}^{K}|\langle\gamma^l,q_k\rangle-\langle\gamma,q_k\rangle|\ge\frac{\delta}{2}\quad\forall\gamma\in\Gamma^2(\alpha,\beta). \tag{4.26}$$

Let $h(w) \stackrel{\text{def}}{=} \big(q_1(w), \dots, q_k(w)\big) \colon W \to \mathbb{R}^K$. Assume that the norm of a vector in (2.12) is defined as the sum of the absolute values of its components. Then, by (3.30), one can rewrite (4.26) in the form

$$\mathrm{d}(v^l, v) \geq \frac{\delta}{2} \quad \forall v \in V_h^2(\alpha_l, \beta_l), \text{ where } v^l \stackrel{\text{def}}{=} \int_W h(w)\gamma^l(dw) \in V_h^1(\alpha_l, \beta_l).$$

Hence, $\mathrm{d}\big(v^l, V_h^2(\alpha_l, \beta_l)\big) \geq \frac{\delta}{2}$, $l = 1, 2, \dots$, which contradicts (3.29) and thus proves the lemma. □

Proof of Theorem 3.3(i). Let $\tilde{h}(\gamma, z) \colon \mathcal{P}(U \times Y) \times Z \to \mathbb{R}^j$, $j = 1, 2, \dots$, be an arbitrary Lipschitz continuous vector function. That is,

$$\|\tilde{h}(\gamma', z') - \tilde{h}(\gamma'', z'')\| \leq c_{\tilde{h}}(\|z' - z''\| + \rho(\gamma', \gamma'')), \quad c_{\tilde{h}} = \text{const}. \tag{4.27}$$

Consider a set-valued map $V(z)$ defined by (4.7) with $\tilde{h}(\gamma, z)$ as above. Note that this map is not necessarily convex valued since $\tilde{h}(\gamma, z)$ may not be represented as the integral (2.20). By (2.14), (4.27), and (2.22) (see Assumption 2.7), it satisfies Lipschitz conditions (4.9). Hence, by the relaxation theorem (see, e.g., [7, Theorem 10.4.4, p. 402]), the set of solutions of the differential inclusion (4.10) is dense in the set of solutions of the differential inclusion

$$\dot{\bar{z}}(t) \in \mathrm{co}V\big(z(t)\big), \tag{4.28}$$

where $\mathrm{co}V(z)$ is the convex hull of $V(z)$.

By Corollary 3.7, to establish the existence of a convex and compact set $\tilde{\Gamma} \subset \mathcal{P}(\mathcal{P}(U \times Y) \times Z)$ satisfying (3.12) it is enough to show that for any Lipschitz continuous $\tilde{h}(\gamma, z) \colon \mathcal{P}(U \times Y) \times Z \to \mathbb{R}^j$, $j = 1, 2, \dots$, there exist a convex and compact set $V_{\tilde{h}} \subset \mathbb{R}^j$ and a function $\mu_{\tilde{h}}(T)$ such that

$$\mathrm{d_H}\Big(V_{\tilde{h}}\big(T, z(0)\big), V_{\tilde{h}}\Big) \leq \mu_{\tilde{h}}(T) \quad \forall z(0) \in Z'', \quad \lim_{T \to \infty} \mu_{\tilde{h}}(T) = 0, \tag{4.29}$$

where

$$\begin{aligned} V_{\tilde{h}}\big(T, z(0)\big) &= \bigcup_{p \in \tilde{\Gamma}(T, z(0))} \left\{ \int_{\mathcal{P}(U \times Y) \times Z} \tilde{h}(\gamma, z) p(d\gamma, dz) \right\} \\ &= \bigcup_{(\gamma(\cdot), z(\cdot))} \left\{ \frac{1}{T} \int_0^T \tilde{h}\big(\gamma(t), z(t)\big) dt \right\}, \end{aligned} \tag{4.30}$$

with the second union being taken over all admissible pairs of averaged system (2.15). The closure of the set (4.30), $\mathrm{cl}V_{\tilde{h}}\big(T, z(0)\big)$, allows also the representations

$$\mathrm{cl}V_{\tilde{h}}\big(T, z(0)\big) = \mathrm{cl} \bigcup_{\bar{z}(\cdot)} \left\{ \frac{\theta(T)}{T} \right\} = \bigcup_{\bar{z}(\cdot)} \left\{ \frac{\theta(T)}{T} \right\}, \tag{4.31}$$

where the first union is taken over the solutions of (4.10) and the second over the solutions of (4.28), which satisfy the initial conditions $\bar{z}(0) = (z(0), 0)$.

As in the proof of Proposition 4.2, from Assumption 2.7 it follows that for any $z' \in Z$, $(v', w') \in V(z')$, and $z'' \in Z$, there exists $(v'', w'') \in V(z'')$ such that (4.15)–(4.16) are satisfied. It can be verified that the map $\mathrm{co}V(z)$ has a similar property. That is, for any $z' \in Z$, $(v', w') \in \mathrm{co}V(z')$, and $z'' \in Z$, there exists

$(v'', w'') \in \mathrm{co}V(z'')$ such that (4.15)–(4.16) are satisfied. As with Proposition 4.2, this allows us to establish that, given a solution $\big(z^1(t), \theta^1(t)\big)$ of the differential inclusion (4.28) satisfying the initial condition $\big(z^1(0), \theta^1(0)\big) = (z^1, \theta^1) \in Z' \times \mathbb{R}^j$ and a vector $(z^2, \theta^2) \in Z' \times \mathbb{R}^j$, there exists a solution $\big(z^2(t), \theta^2(t)\big)$ of (4.28) which satisfies the initial condition $\big(z^2(0), \theta^2(0)\big) = (z^2, \theta^2)$ such that estimates (4.13)–(4.14) will be valid.

It follows from (4.14) that

$$\mathrm{d_H}\big(\mathrm{cl}V_{\tilde{h}}(T, z^1), \mathrm{cl}V_{\tilde{h}}(T, z^2)\big) \leq b_2 T^{-1} \quad \forall z^i \in Z',\ i = 1, 2, \quad \forall T \geq 0. \tag{4.32}$$

Now applying results from [15] or [19, Proposition 3.2], one can establish the existence of a convex and compact set $V_{\tilde{h}}$ and a function $\mu_{\tilde{h}}(T) = O(T^{-1/2})$ which satisfy (4.29). This completes the proof of the theorem. □

A STOCHASTIC DECENTRALIZED CONTROL PROBLEM WITH NOISY COMMUNICATION*

KAMBIZ SHOARINEJAD†, JASON L. SPEYER‡, AND IOANNIS KANELLAKOPOULOS§

Abstract. A simple decentralized stochastic control problem is considered where the nonclassical nature of the information pattern is induced by the uncertainty on the information transmission in the system. This is, in fact, a reformulation of the Witsenhausen counterexample, where the first station is allowed to send its information to the second station through a noisy channel. Nonconvexity of the problem in this new formulation has been established, and it is shown how this formulation relates to a classical problem and the Witsenhausen problem, respectively, when the transmission noise intensity goes to zero or infinity. Assuming small transmission noise intensity, we then use an asymptotic approach in order to find an approximated cost. A necessary condition for asymptotically optimal strategies has been obtained using a variational approach, and it is shown that the linear strategies, with slightly different coefficients than the noiseless transmission case, satisfy the necessary condition.

Key words. optimal stochastic control, decentralized systems, asymptotic analysis

1. Introduction.

Coordinating and controlling dynamic systems in spatial networks has always been a challenging problem for system designers. It is now attracting more attention as various new applications are emerging in a very wide range from autonomous vehicles in formation to flow and congestion control in computer networks. However, there are still some major difficulties in dealing with such systems. The main characteristics of any decentralized system is that the information is distributed among different stations and the performance of the system depends highly on the corresponding information pattern, i.e., *who knows what and when*. The stations may communicate with each other possibly by signaling through noisy channels. Even though there might be some physical constraints on the information structure of the system (e.g., locations of the sensors, the actuators, and the transmitters), in general, an optimal information pattern should be obtained. Then, based on the locally available information, a set of coordinated local strategies should be designed in order to achieve a common objective. In many cases, however, we will end up with nonconvex functional optimization problems, which are usually very difficult to solve.

One such class of problems is when a decentralized system has a *nonclassical* information pattern which is not partially nested. The information pattern is called nonclassical when the distributed stations do not have access to the same information and/or some stations do not have perfect recall (i.e., they lose information). Moreover,

a nonclassical information pattern is not partially nested when some stations cannot reconstruct the previous actions of other stations which have affected their own local information. Unfortunately, this happens in many decentralized systems.

In 1968, Witsenhausen provided a simple example in [1] in which there are only two stations, the dynamics are linear, the underlying uncertainties are additive and Gaussian, and the cost is quadratic. The information pattern, however, is nonclassical. This example motivated much research on the links between decentralized stochastic control problems and team theory and the effects of different information patterns on decentralized systems. Although it is a very simple example, it demonstrates the main difficulties induced by nonclassical information patterns. In this example, one station acts first and affects the information available to the next station, while there is no way for the second station to determine the action of the first station. The existence of the optimal design was established in [1], where a nonlinear set of strategies was also proposed which showed that no affine strategy could be optimal.

This seemingly simple example, which is also called Witsenhausen's counterexample, turned out to be extremely hard. It is still outstanding after more than 30 years. It was later shown in [2] that when the uncertainty on the information available to the first station is small, linear strategies would still be optimal over a large class of nonlinear strategies. Intuitively, when the uncertainty on the information of the first station is small, the second station will also be able to *guess* what that information was. Therefore, since the problem is cooperative in the sense that the stations are aware of each others' strategies, the second station can almost reconstruct the action of the first station, and there is no need for any kind of signaling among the stations through the dynamics of the system. In Witsenhausen's problem, the nonclassical nature of the information pattern is a result of the fact that the information available to the first station is completely inaccessible for the second station. However, recent advances in computing and communication technologies make it possible for the stations in many decentralized systems to communicate different pieces of information. But communications can never be perfect, and there is always some uncertainty involved. Unfortunately, such uncertainty will again induce a nonclassical nature on the information pattern of the system.

In this paper, we reformulate Witsenhausen's problem by allowing the first station to communicate its information with the second station through a noisy channel. Then we show that as long as there is noise in the transmission, the main difficulties will persist. Specifically, the cost might still be nonconvex with respect to the strategies. We then consider the two limit cases where the transmission uncertainty becomes either very large or negligible. We show how this new formulation covers a wide range of problems, from the classical linear quadratic Gaussian (LQG) problem to the Witsenhausen counterexample.

When the transmission noise intensity is small, one would expect the optimal strategies to be very close to the corresponding strategies for the noiseless transmission case. Our next objective in this paper is to investigate this case through an asymptotic analysis.

In section 2, we present the problem formulation. In section 3, we obtain an alternative form for the performance index, which clearly shows the possible nonconvexity of the cost with respect to the strategies. In section 4, we consider the two limit cases, i.e., when the transmission noise intensity goes to zero or infinity. In section 5 we assume a small uncertainty on the transmission and approximate the cost by expanding it in terms of the small transmission noise intensity. In section 6, we use a variational approach in order to find a necessary condition for the strategies that

minimize the approximated cost. As we shall see, we will actually have a singular optimization problem. We then show that the asymptotically optimal strategies can still be linear with slightly different coefficients than the corresponding strategies for the noiseless transmission case. We provide concluding remarks in the final section.

2. Problem description. Consider a two-stage stochastic problem with the following state equations:

$$x_1 = x_0 + u_1, \tag{2.1}$$

$$x_2 = x_1 - u_2, \tag{2.2}$$

where x_0 is the initial state, which is assumed to be a zero mean Gaussian random variable with variance σ_0^2. The information pattern of the system is specified by the following output equations:

$$z_1 = x_0, \tag{2.3}$$

$$z_2 = \begin{bmatrix} x_0 + v_t \\ x_0 + u_1 + v_2 \end{bmatrix} := \begin{bmatrix} z_{21} \\ z_{22} \end{bmatrix}, \tag{2.4}$$

where v_2 is the measurement noise for the second station, which is also assumed to be a zero mean Gaussian random variable with unit variance. As we can see, the information available to the first station is being transmitted to the second station, and the communication uncertainty is modeled by an additive Gaussian noise $v_t \sim \mathcal{N}\left(0, \epsilon^2\right)$. Also, x_0, v_2, and v_t are all assumed to be independent of each other. It is clear that we have simply modeled the received information signal as the transmitted signal plus the Gaussian transmission noise. While this model can be quite realistic for analog communication systems, it may not be well justified when digital communication is used. In digital communication systems the signal is quantized, coded, and sent through the channel. Still, the channel noise may realistically be assumed to be additive and Gaussian, but sophisticated modulation and coding schemes make it difficult to assume a simple additive Gaussian uncertainty for the received *information signal.* However, if we try to incorporate the quantization effects along with the bit error probability distribution for some *good* coding and modulation schemes in order to model the communication uncertainties, we will end up with models which could still be approximated, to some degree, by simple additive Gaussian models. Moreover, since there are already major difficulties in dealing with decentralized nonclassical information patterns, using more complex models for communication uncertainties may not seem very reasonable at this point. Furthermore, we believe that the results obtained under such a simplifying assumption would still serve as a guideline for finding the true nature of the optimal decentralized strategies. The objective is now to design the control strategies γ_1 and γ_2,

$$u_1 = \gamma_1\left(z_1\right), \tag{2.5}$$

$$u_2 = \gamma_2\left(z_2\right), \tag{2.6}$$

in order to minimize the cost function

$$J = E\left[k^2 u_1^2 + x_2^2\right], \tag{2.7}$$

where $k^2 > 0$ is a given constant. Note that this is a sequential stochastic control problem in the sense that the second station acts after the first station. In other words,

the order in which the stations apply their control actions does not depend on the uncertainties in the system. We see that the first controller has perfect information but its action is costly. In contrast, the second controller has inexpensive control but noisy information. Since the second station does not know what the first station knew, due to the transmission noise, we do not have perfect recall, and hence we still have a nonclassical pattern. If there was no transmission noise, we would have a classical information pattern for which the unique optimal strategies are known to be linear in the information.

3. An alternative form for the performance index. In this section, we show how the performance index may be expressed in terms of the Fisher information matrix, which indicates that the cost may not be convex in the strategies.

For simplicity, and similarly to the Witsenhausen problem, we define

$$f(z_1) := z_1 + \gamma_1(z_1) = x_0 + u_1, \tag{3.1}$$

$$g(z_2) := \gamma_2(z_2) = u_2. \tag{3.2}$$

Then the cost can be expressed as

$$\begin{aligned} J &= E\left[k^2 u_1^2 + x_2^2\right] \\ &= E\left[k^2 (z_1 - f(z_1))^2 + (f(z_1) - g(z_2))^2\right] \\ &:= J(f, g). \end{aligned} \tag{3.3}$$

If we fix the function f, the optimal strategy g will clearly be obtained as the conditional expectation, i.e.,

$$g^*(z_2) = \arg\min_g J(f, g) = E[f(z_1) \,|\, z_2]. \tag{3.4}$$

Substituting the above equation back in the cost, we get

$$\begin{aligned} J^*(f) &:= J(f, g^*) \\ &= k^2 E\left[(z_1 - f(z_1))^2\right] + E\left[(f(z_1) - g^*(z_2))^2\right] \\ &= k^2 E\left[(z_1 - f(z_1))^2\right] + E\left[(f(z_1))^2\right] - E\left[(g^*(z_2))^2\right], \end{aligned} \tag{3.5}$$

where we have used the orthogonality property of the conditional expectation

$$E[(f(z_1) - g^*(z_2))\, g^*(z_2)] = 0. \tag{3.6}$$

It is important to note the minus sign in the third term in (3.5). As we shall see, this minus sign could indeed destroy the convexity of the cost with respect to the strategies.

The objective is now to express the cost $J^*(f)$ in terms of only one strategy f. In doing so, we use the following lemma, which shows how $g^*(z_2)$ may be expressed in terms of information z_2 and its probability density function.

LEMMA 3.1. *The optimal strategy $g^*(z_2)$ can be expressed as*

$$g^*(z_2) = z_{22} + \frac{\partial}{\partial z_{22}} \ln p(z_2), \tag{3.7}$$

where $p(z_2) = p(z_{21}, z_{22})$ is the probability density function for the information available to the second station.

Proof. We have

$$\begin{aligned} g^*(z_2) &= \int f(z_1)\, p(z_1 | z_2)\, dz_1 \\ &= \frac{\int f(z_1)\, p(z_1, z_2)\, dz_1}{\int p(z_1, z_2)\, dz_1}, \end{aligned} \tag{3.8}$$

where $p(z_1, z_2)$ is the joint probability density of z_1 and z_2. At the same time, one can write

$$f(z_1)\, p(z_1, z_2) = z_{22} p(z_1, z_2) + \frac{\partial}{\partial z_{22}} p(z_1, z_2). \tag{3.9}$$

This can be shown as

$$\begin{aligned} z_{22} p(z_1, z_2) + \frac{\partial}{\partial z_{22}} p(z_1, z_2) &= z_{22} p(z_1, z_2) + \frac{\partial}{\partial z_{22}} p(z_2 | z_1)\, p(z_1) \\ &= z_{22} p(z_1, z_2) + \frac{\partial}{\partial z_{22}} p_{(v_t, v_2)} \left(\begin{bmatrix} z_{21} \\ z_{22} \end{bmatrix} - \begin{bmatrix} z_1 \\ f(z_1) \end{bmatrix} \right) p(z_1) \\ &= z_{22} p(z_1, z_2) + \frac{\partial}{\partial z_{22}} \left(\frac{1}{2\pi\epsilon} \exp\left(-\frac{(z_{21} - z_1)^2}{2\epsilon^2} - \frac{(z_{22} - f(z_1))^2}{2} \right) \right) p(z_1) \\ &= f(z_1)\, p(z_1, z_2), \end{aligned} \tag{3.10}$$

where we have used the specific form of the information available to the second station and the fact that $v_t \sim \mathcal{N}(0, \epsilon^2)$ and $v_2 \sim \mathcal{N}(0, 1)$ are independent. By substituting for $f(z_1)\, p(z_1, z_2)$ from (3.9) back in (3.8) and integrating with respect to z_1, the expression in (3.7) is obtained. □

As we shall see, when we try to express the performance index in terms of only a single strategy f, a *Fisher information* term comes up in the cost. Fisher information is originally obtained in the Cramer–Rao bound, which is a measure for the minimum error in estimating a parameter based on the value of a random variable. However, by introducing a location parameter, an alternative form of the Fisher information may be defined for a random variable with a given distribution. This alternative form is, in fact, related to the entropy measure (see [3, p. 494]). We first present the definition for the Fisher information matrix.

DEFINITION 3.2. *The Fisher information matrix for a random vector Z is defined as*

$$I_f(Z) := E\left[\nabla_z^T \ln p(z) \cdot \nabla_z \ln p(z) \right], \tag{3.11}$$

where $p(z)$ is the probability density function for the random variable Z and ∇_z denotes the gradient vector with respect to z:

$$\nabla_z := \left[\frac{\partial}{\partial z_1} \cdots \frac{\partial}{\partial z_n} \right], \tag{3.12}$$

where z_i is the ith component in the random vector.

We are now ready to present the alternative expression for the performance index.

THEOREM 3.3. *The performance index* (3.5) *can be written as*

$$J^*(f) = k^2 E\left[(z_1 - f(z_1))^2 \right] + 1 - I_f(Z_2)_{22}, \tag{3.13}$$

where $I_f\,(Z_2)_{22}$ *is, in fact, the* $(2,2)$ *element of the* Fisher information matrix *for the random vector* Z_2*. The subscript* f *indicates the fact that it actually depends on the form of the strategy* f*, which is present in the definition of* z_2 *and would affect its probability density function.*

Proof. Using (3.7), we first obtain $E[(g^*(z_2))^2]$. We have

$$E\left[z_{22}^2\right] = E\left[\left(f\left(z_1\right)\right)^2\right] + 1, \tag{3.14}$$

and

$$E\left[z_{22}\frac{\partial}{\partial z_{22}}\ln p\left(z_2\right)\right] = \int\!\!\int_{-\infty}^{+\infty} z_{22}\frac{\partial}{\partial z_{22}}\ln\left(p\left(z_{21},z_{22}\right)\right)p\left(z_{21},z_{22}\right)dz_{21}dz_{22}. \tag{3.15}$$

If we integrate by parts with respect to z_{22}, we get

$$\begin{aligned}\int_{-\infty}^{+\infty} z_{22}\frac{\partial}{\partial z_{22}}\ln\left(p\left(z_{21},z_{22}\right)\right)p\left(z_{21},z_{22}\right)dz_{22} &= z_{22}p\left(z_{21},z_{22}\right)|_{-\infty}^{+\infty} - \int_{-\infty}^{+\infty} p\left(z_{21},z_{22}\right)dz_{22}\\ &= -p\left(z_{21}\right),\end{aligned} \tag{3.16}$$

where z_{22} is assumed to have a finite mean value, and therefore the first term becomes zero. Hence,

$$E\left[z_{22}\frac{\partial}{\partial z_{22}}\ln p\left(z_2\right)\right] = -1. \tag{3.17}$$

Therefore,

$$E\left[\left(g^*\left(z_2\right)\right)^2\right] = -1 + E\left[\left(f\left(z_1\right)\right)^2\right] + I_f\left(Z_2\right)_{22}, \tag{3.18}$$

where

$$I_f\left(Z_2\right)_{22} = E\left[\left(\frac{\partial}{\partial z_{22}}\ln p\left(z_2\right)\right)^2\right]. \tag{3.19}$$

Substituting (3.18) back in (3.5), we get (3.13) as an alternative form for representing the performance index. ∎

As we see, the cost is now expressed only in terms of one strategy f. Also, this somehow shows us that in order to minimize the cost, we need to get the lowest possible cost associated with the first station, while we transfer as much information as possible to the second station through the dynamics of the system. The possible nonconvexity of the cost with respect to f can also be seen from this alternative expression. It can be shown that the Fisher information term is a convex functional [4]. Therefore, $1 - I_f\left(Z_2\right)_{22}$ is concave and the sum of a convex and a concave functional may not be convex.

4. Limit cases. In this section we consider the two limit cases. First we consider the case where the transmission is noiseless, and then we investigate the case where the transmission noise intensity goes to infinity.

4.1. Noiseless transmission. Assume there is no uncertainty in transmitting information from the first to the second station, i.e., $\epsilon = 0$ and hence $z_{21} = z_1$. In this case, we have perfect recall and the information pattern is classical. We can write

$$\begin{aligned} p(z_2) &= p(z_{21}, z_{22}) = p(z_{22}|z_{21})\, p(z_{21}) \\ &= p(z_{22}|z_1)\, p(z_1) = \frac{1}{\sqrt{2\pi}} \exp\left(-\frac{(z_{22} - f(z_1))^2}{2}\right) p(z_1). \end{aligned} \tag{4.1}$$

Then, from (3.7), we have

$$g^*(z_2) = f(z_1) = f(z_{21}), \tag{4.2}$$

which could directly be obtained from the original definition for g^*, i.e.,

$$g^*(z_2) = E[f(z_1)|\, z_2] = f(z_1), \tag{4.3}$$

because z_1 is exactly known when z_2 is given. Substituting this back in (3.5) and minimizing with respect to the strategy f, we have

$$g^*(z_2) = f(z_1) = z_1, \tag{4.4}$$

and hence

$$\gamma_1(z_1) = 0, \tag{4.5}$$

$$\gamma_2(z_2) = z_1, \tag{4.6}$$

which is the unique linear set of optimal strategies. This indeed turns out to be a very simple example of the well-known classical LQG problem.

4.2. Infinite transmission noise intensity. Another limit case is when the transmission noise intensity increases to infinity. In this case, z_{21} and z_{22} become independent and we have

$$p(z_2) = p(z_{21}, z_{22}) = p(z_{21})\, p(z_{22}). \tag{4.7}$$

The Fisher information term can now be written as

$$\begin{aligned} I_f(Z_2)_{22} &= \int\int_{-\infty}^{+\infty} \left(\frac{\partial}{\partial z_{22}} \ln p(z_{21}, z_{22})\right)^2 p(z_{21}, z_{22})\, dz_{21} dz_{22} \\ &= \int_{-\infty}^{+\infty} \left(\frac{\partial}{\partial z_{22}} \ln p(z_{22})\right)^2 p(z_{22})\, dz_{22} \\ &= I_f(Z_{22}), \end{aligned} \tag{4.8}$$

which is indeed the Fisher information content of z_{22} only. Hence,

$$J^*(f) = k^2 E\left[(z_1 - f(z_1))^2\right] + 1 - I_f(Z_{22}). \tag{4.9}$$

This is the same result that was presented for the Witsenhausen counterexample in [1]. Intuitively, when we have infinite transmission noise intensity, we might as well deny the access to z_1 for the second station, and this is exactly the case in Witsenhausen's counterexample. The optimal strategies for this case are still unknown. Witsenhausen

showed that the optimal solution exists, even if x_0 has a general distribution with a finite second moment [1]. He then showed that if one of the strategies is restricted to being affine, the other optimal strategy would also be affine. But then he provided a set of nonlinear strategies that could achieve a lower cost for some values of k^2 and σ_0.

Different approaches have been taken in order to find the optimal strategies. As mentioned before, an asymptotic approach was used in [2] for the case where σ_0 is small. More recently, in [5], [6], [7] it was shown how a neural network, trained by stochastic approximation techniques, can be employed as a nonlinear function approximator in order to approximate $f(z_1)$. It was demonstrated that the optimal $f^*(z_1)$ may not be strictly piecewise, as was suggested by Witsenhausen, but slightly sloped. Some researchers have tried to attack the problem numerically and use some sample and search techniques to find the solution. A discretized version of the problem was formulated in [8], which was later shown in [9] to be NP-complete and computationally intractable. It is recently asserted in [10] and [11] that a global optimum would be achieved by searching directly in the strategy space using the generalized step functions to approximate $f(z_1)$.

So far we have shown, through a simple example, how any uncertainty in the transmission of information between the stations in a distributed system can make the optimal control design very complicated and even intractable. Then, by considering the two limit cases, we showed how our example covers a very wide range of scenarios. Namely, we saw that for the noiseless transmission case, the unique optimal strategies, which are linear in the information, are easily obtained, whereas for the infinite transmission noise intensity, the optimal strategies are still unknown. Now a very feasible case to investigate is when the uncertainty on the information transmission is small. In fact, when the transmission noise intensity ϵ is small, one would still expect behavior similar to the noiseless transmission case for the optimal strategies. In the following sections, we consider this case. Namely, we assume a small intensity for v_t. Under this assumption, we obtain the first few terms in the expansion of the performance index in terms of ϵ. We then use the Hamiltonian approach in order to find a necessary condition for the strategies that minimize the approximated cost.

We show that the linear strategies, with slightly different coefficients than the corresponding coefficients for the noiseless transmission case, do indeed satisfy the necessary condition. This asymptotic analysis not only gives us insight on how the optimal strategies change as the transmission uncertainty is introduced but also provides us with a better sense of the complexities in the design procedure.

5. An expansion for the cost. Assume that the first station communicates with the second station through a low noise channel. In other words, the transmission noise intensity ϵ is assumed to be small. In this section, we will find an expansion for the cost in terms of ϵ. For this purpose, we first find an expansion for the probability density function of the information available to the second station, i.e., $p(z_2)$. Then we use (3.7) in order to find the corresponding expansion for $g^*(z_2)$. By substituting back in (3.5), we will obtain the expanded cost only in terms of f.

The probability density function for z_2 can be written as

$$p_\epsilon(z_2) := p(z_2) = \int_{-\infty}^{+\infty} p(z_{22}, z_{21}, z_1)\, dz_1 \tag{5.1}$$

$$= \int_{-\infty}^{+\infty} p(z_{22}|z_{21}, z_1)\, p(z_{21}|z_1)\, p(z_1)\, dz_1 \tag{5.2}$$

$$= \int_{-\infty}^{+\infty} p\left(z_{22}|z_1\right) p\left(z_{21}|z_1\right) p\left(z_1\right) dz_1 \tag{5.3}$$

$$= \int_{-\infty}^{+\infty} p\left(z_{22}|z_1\right) p_{v_t}\left(z_{21}-z_1\right) p\left(z_1\right) dz_1 \tag{5.4}$$

$$= \int_{-\infty}^{+\infty} \frac{1}{\sqrt{2\pi}} \exp\left(-\frac{\left(z_{22}-f\left(z_1\right)\right)^2}{2}\right) \frac{1}{\sqrt{2\pi}\epsilon} \exp\left(-\frac{\left(z_{21}-z_1\right)^2}{2\epsilon^2}\right) \times \frac{1}{\sqrt{2\pi}\sigma_0} \exp\left(-\frac{z_1^2}{2\sigma_0^2}\right) dz_1, \tag{5.5}$$

where for (5.3) we have used the facts that the σ-fields generated by $\{z_{21}, z_1\}$ and $\{z_1, v_t\}$ are the same and z_1, v_t, and v_2 are mutually independent. At this point, one should note that even though the joint probability density function $p\left(z_{22}, z_{21}, z_1\right)$ can be explicitly expressed as in (5.5), introduction into the performance index shows that determination of $f\left(z_1\right)$ still requires averaging over all random variables. This is another way of looking at the effect of a nonclassical information pattern, which is not partially nested. We therefore decide to follow an asymptotic approach.

For small ϵ, we now approximate $\ln p_\epsilon\left(z_2\right)$ by considering only the first three terms of its expansion around $\epsilon = 0$. Namely,

$$\ln p_\epsilon\left(z_2\right) \simeq \ln p_0\left(z_2\right) + \frac{\partial}{\partial\epsilon} \ln p_\epsilon\left(z_2\right)\Big|_{\epsilon=0} \epsilon + \frac{\partial^2}{\partial\epsilon^2} \ln p_\epsilon\left(z_2\right)\Big|_{\epsilon=0} \epsilon^2. \tag{5.6}$$

By making the change of variables

$$\epsilon y := z_1 - z_{21} \Rightarrow \epsilon dy = dz_1, \tag{5.7}$$

we can write $p_\epsilon\left(z_2\right)$ in the following form:

$$p_\epsilon\left(z_2\right) = \int_{-\infty}^{+\infty} \frac{1}{\sqrt{2\pi}} \exp\left(-\frac{\left(z_{22}-\bar{f}_\epsilon(y)\right)^2}{2}\right) \frac{1}{\sqrt{2\pi}\sigma_0} \exp\left(-\frac{\left(z_{21}+\epsilon y\right)^2}{2\sigma_0^2}\right) \frac{1}{\sqrt{2\pi}} \exp\left(-\frac{y^2}{2}\right) dy, \tag{5.8}$$

where

$$\bar{f}_\epsilon(y) := f\left(\epsilon y + z_{21}\right). \tag{5.9}$$

It is now clear that

$$p_0\left(z_2\right) = \frac{1}{\sqrt{2\pi}} \exp\left(-\frac{\left(z_{22}-f\left(z_{21}\right)\right)^2}{2}\right) \frac{1}{\sqrt{2\pi}\sigma_0} \exp\left(-\frac{z_{21}^2}{2\sigma_0^2}\right), \tag{5.10}$$

and hence

$$\ln p_0\left(z_2\right) = -\frac{\left(z_{22}-f\left(z_{21}\right)\right)^2}{2} - \frac{z_{21}^2}{2\sigma_0^2} + \ln\left(\frac{1}{2\pi\sigma_0}\right). \tag{5.11}$$

For the first order term, we have

$$\frac{\partial}{\partial\epsilon} \ln p_\epsilon\left(z_2\right)\Big|_{\epsilon=0} = \frac{1}{p_0\left(z_2\right)} \frac{\partial}{\partial\epsilon} p_\epsilon\left(z_2\right)\Big|_{\epsilon=0}. \tag{5.12}$$

On the other hand,

$$\begin{aligned}\frac{\partial}{\partial\epsilon}p_\epsilon(z_2)\bigg|_{\epsilon=0} &= \int_{-\infty}^{+\infty}\frac{\partial}{\partial\epsilon}\left\{\frac{1}{\sqrt{2\pi}}e^{-\frac{(z_{22}-\bar{f}_\epsilon(y))^2}{2}}\frac{1}{\sqrt{2\pi}\sigma_0}e^{-\frac{(z_{21}+\epsilon y)^2}{2\sigma_0^2}}\right\}\bigg|_{\epsilon=0}\frac{1}{\sqrt{2\pi}}e^{-\frac{y^2}{2}}dy\\ &= \int_{-\infty}^{+\infty}\frac{1}{\sqrt{2\pi}}(z_{22}-f(z_{21}))\,yf'(z_{21})\,e^{-\frac{(z_{22}-f(z_{21}))^2}{2}}\frac{1}{\sqrt{2\pi}\sigma_0}e^{-\frac{z_{21}^2}{2\sigma_0^2}}\frac{1}{\sqrt{2\pi}}e^{-\frac{y^2}{2}}dy\\ &+\int_{-\infty}^{+\infty}\frac{1}{\sqrt{2\pi}}e^{-\frac{(z_{22}-f(z_{21}))^2}{2}}\frac{1}{\sqrt{2\pi}\sigma_0}\left(-\frac{z_{21}}{\sigma_0^2}\right)ye^{-\frac{z_{21}^2}{2\sigma_0^2}}\frac{1}{\sqrt{2\pi}}e^{-\frac{y^2}{2}}dy=0.\end{aligned} \tag{5.13}$$

Therefore,

$$\frac{\partial}{\partial\epsilon}\ln p_\epsilon(z_2)\bigg|_{\epsilon=0}=0. \tag{5.14}$$

We could somehow expect this result. This is because we would expect the behavior of $p_\epsilon(z_2)$ to depend only on the variance of the Gaussian transmission noise, i.e., ϵ^2. Using (5.14), we can now obtain the second order term as

$$\frac{\partial^2}{\partial\epsilon^2}\ln p_\epsilon(z_2)\bigg|_{\epsilon=0}=\frac{1}{p_0(z_2)}\,\frac{\partial^2}{\partial\epsilon^2}p_\epsilon(z_2)\bigg|_{\epsilon=0}. \tag{5.15}$$

After some tedious but straightforward manipulations, we get

$$\begin{aligned}\frac{\partial^2}{\partial\epsilon^2}\ln p_\epsilon(z_2)\bigg|_{\epsilon=0} &= -f'^2(z_{21})+f''(z_{21})(z_{22}-f(z_{21}))+f'^2(z_{21})(z_{22}-f(z_{21}))^2\\ &\quad+2f'(z_{21})(z_{22}-f(z_{21}))\left(-\frac{z_{21}}{\sigma_0^2}\right)-\frac{1}{2\sigma_0^2}+\frac{z_{21}^2}{\sigma_0^4}.\end{aligned} \tag{5.16}$$

We can now obtain a second order approximation for $\ln p_\epsilon(z_2)$ by substituting the corresponding terms from (5.11), (5.14), and (5.16) back into the expansion (5.6). In the next step, we substitute the expansion for $\ln p_\epsilon(z_2)$ in (3.7) in order to find the corresponding expansion for $g^*(z_2)$. Remember that $g^*(z_2)$ is the optimal strategy for the second station, assuming that the first station has a fixed strategy $\gamma_1(z_1)=f(z_1)-z_1$. We have

$$\begin{aligned}g^*(z_2) &= z_{22}+\frac{\partial}{\partial z_{22}}\ln p(z_2)\\ &\simeq z_{22}+\frac{\partial}{\partial z_{22}}\ln p_0(z_2)+\epsilon^2\frac{\partial}{\partial z_{22}}\left(\frac{\partial^2}{\partial\epsilon^2}\ln p_\epsilon(z_2)\bigg|_{\epsilon=0}\right)\\ &= z_{22}-(z_{22}-f(z_{21}))\\ &\quad+\epsilon^2\left[f''(z_{21})+2f'^2(z_{21})(z_{22}-f(z_{21}))+2f'(z_{21})\left(-\frac{z_{21}}{\sigma_0^2}\right)\right].\end{aligned} \tag{5.17}$$

Our goal is to get an expansion for the cost, which as we know from (3.5) can be written as

$$J^*(f)=k^2E\left[(z_1-f(z_1))^2\right]+E\left[(f(z_1))^2\right]-E\left[(g^*(z_2))^2\right]. \tag{5.18}$$

Using the expansion for $g^*(z_2)$ from (5.17), we have

$$E\left[(g^*(z_2))^2\right] \simeq E\left[(f(z_{21}))^2\right]$$
$$+2\epsilon^2 E\left[f(z_{21})\left(f''(z_{21})+2f'^2(z_{21})(z_{22}-f(z_{21}))+2f'(z_{21})\left(-\frac{z_{21}}{\sigma_0^2}\right)\right)\right], \tag{5.19}$$

where we have neglected the fourth order term in ϵ. Substituting this expansion back in (5.18), we will obtain the following expansion for the cost:

$$J^*(f) = k^2 E\left[(z_1-f(z_1))^2\right] + E\left[(f(z_1))^2\right] - E\left[(f(z_{21}))^2\right]$$
$$-2\epsilon^2 E\left[f(z_{21})\left(f''(z_{21})+2f'^2(z_{21})(z_{22}-f(z_{21}))+2f'(z_{21})\left(-\frac{z_{21}}{\sigma_0^2}\right)\right)\right]. \tag{5.20}$$

Note that when the transmission is noiseless, i.e., $\epsilon = 0$ and therefore $z_{21} = z_1$, we have

$$J^*(f) = k^2 E\left[(z_1-f(z_1))^2\right], \tag{5.21}$$

and $f(z_1) = z_1$ is the obvious unique optimal solution. The above expansion, however, is not exactly in our desired form yet. This is because the third term on the right-hand side, which is an average over z_{21}, still depends on ϵ. We shall now rewrite the expansion in (5.20) by explicitly expressing the expectations based on the corresponding probability densities:

$$\begin{aligned} J^*(f) = &\int_{-\infty}^{+\infty}\left[k^2(t-f(t))^2+f^2(t)\right]\frac{1}{\sqrt{2\pi}\sigma_0}e^{-\frac{t^2}{2\sigma_0^2}}dt \\ &-\int_{-\infty}^{+\infty}\left[f^2(t)+2\epsilon^2\left(f(t)f''(t)-2f(t)f'(t)\frac{t}{\sigma_0^2}\right)\right]\frac{1}{\sqrt{2\pi(\sigma_0^2+\epsilon^2)}}e^{-\frac{t^2}{2\left(\sigma_0^2+\epsilon^2\right)}}dt \\ &-\int_{-\infty}^{+\infty}\int_{-\infty}^{+\infty}4\epsilon^2 f(t)f'^2(t)(\tau-f(t))\frac{1}{\sqrt{2\pi}}e^{-\frac{(\tau-f(t))^2}{2}}\frac{1}{\sqrt{2\pi}\sigma_0}e^{-\frac{t^2}{2\sigma_0^2}}dtd\tau, \end{aligned} \tag{5.22}$$

where we have substituted $p(z_2) = p(z_{22}, z_{21}) \simeq p_0(z_2)$ in the third term, since the higher order terms would be multiplied by ϵ^2 and would then be neglected. Now the third term turns out to be zero, because

$$\begin{aligned} &\int_{-\infty}^{+\infty}\int_{-\infty}^{+\infty}4\epsilon^2 f(t)f'^2(t)(\tau-f(t))\frac{1}{\sqrt{2\pi}}e^{-\frac{(\tau-f(t))^2}{2}}\frac{1}{\sqrt{2\pi}\sigma_0}e^{-\frac{t^2}{2\sigma_0^2}}dt \\ &=\int_{-\infty}^{+\infty}4\epsilon^2 f(t)f'^2(t)\frac{1}{\sqrt{2\pi}\sigma_0}e^{-\frac{t^2}{2\sigma_0^2}}\left(\int_{-\infty}^{+\infty}(\tau-f(t))\frac{1}{\sqrt{2\pi}}e^{-\frac{(\tau-f(t))^2}{2}}d\tau\right)dt = 0. \end{aligned} \tag{5.23}$$

At the same time, we can expand the probability density of z_{21} up to the second order in ϵ. It is actually straightforward to obtain

$$\frac{1}{\sqrt{2\pi(\sigma_0^2+\epsilon^2)}}e^{-\frac{t^2}{2\left(\sigma_0^2+\epsilon^2\right)}} \simeq \frac{1}{\sqrt{2\pi}\sigma_0}e^{-\frac{t^2}{2\sigma_0^2}} + \epsilon^2\frac{1}{\sqrt{2\pi}\sigma_0^5}\left(t^2-\sigma_0^2\right)e^{-\frac{t^2}{2\sigma_0^2}}. \tag{5.24}$$

Substituting (5.23) and the above expansion back in (5.22) and neglecting the higher order terms in ϵ, we can finally get the following expansion for the cost:

$$J^*(f) = \int_{-\infty}^{+\infty} \left[k^2 \left(t - f(t)\right)^2\right] \frac{1}{\sqrt{2\pi}\sigma_0} e^{-\frac{t^2}{2\sigma_0^2}} dt + \epsilon^2 \int_{-\infty}^{+\infty} \left[4f(t)f'(t)\frac{t}{\sigma_0^2} - 2f(t)f''(t) + f^2(t)\frac{\sigma_0^2 - t^2}{\sigma_0^4}\right] \frac{1}{\sqrt{2\pi}\sigma_0} e^{-\frac{t^2}{2\sigma_0^2}} dt$$
$$:= J_0^* + \epsilon^2 J_1^*. \tag{5.25}$$

The objective is now to obtain the function f, which minimizes the above approximated cost. In the next section, we use a variational approach in order to find a necessary condition for such a function and show how the linear strategies still satisfy this necessary condition.

6. Minimizing the approximated cost. So far, we have obtained an expansion for the cost assuming that the transmission noise intensity is small. We have, in fact, approximated the cost by including only up to the second order term in ϵ. We should now try to minimize this approximated cost in order to find the asymptotically optimal f^*. Obviously, this strategy would be optimal only for a small transmission noise intensity. However, it would still be very helpful for the analysis of the behavior of the optimal strategies when we deviate a little bit from the classical information pattern by introducing a small communication uncertainty.

We now use the Hamiltonian approach in order to find the necessary conditions for the function $f(t)$, which minimizes our approximated cost. For simplicity, denote

$$x_1(t) := f(t), \tag{6.1}$$
$$x_2(t) := \dot{x}_1(t) = f'(t), \tag{6.2}$$
$$u(t) := \dot{x}_2(t) = \ddot{x}_1(t) = f''(t), \tag{6.3}$$
$$p(t) := \frac{1}{\sqrt{2\pi}\sigma_0} e^{-\frac{t^2}{2\sigma_0^2}}. \tag{6.4}$$

The Hamiltonian is then defined as [12]

$$\mathcal{H} = k^2 \left(t - x_1(t)\right)^2 p(t) + \epsilon^2 \left(4x_1(t)x_2(t)\frac{t}{\sigma_0^2} - 2x_1(t)u(t) + x_1^2(t)\frac{\sigma_0^2 - t^2}{\sigma_0^4}\right) p(t) + \lambda_1(t)x_2(t) + \lambda_2(t)u(t), \tag{6.5}$$

where λ_1 and λ_2 are the Lagrange multipliers that should satisfy

$$\dot{\lambda}_1(t) = -\mathcal{H}_{x_1} = \left(2k^2\left(t - x_1(t)\right) - 4\epsilon^2 x_2(t)\frac{t}{\sigma_0^2} - 2\epsilon^2 x_1(t)\frac{\sigma_0^2 - t^2}{\sigma_0^4} + 2\epsilon^2 u(t)\right) p(t), \tag{6.6}$$

$$\dot{\lambda}_2(t) = -\mathcal{H}_{x_2} = -4\epsilon^2 x_1(t)\frac{t}{\sigma_0^2} p(t) - \lambda_1(t). \tag{6.7}$$

But as we can see, the Hamiltonian is linear in $u(t)$ and we actually have a *singular* optimization problem. The singular surface will be characterized by setting $\mathcal{H}_u$ and its derivatives with respect to t equal to zero, that is,

$$\mathcal{H}_u = -2\epsilon^2 x_1(t)p(t) + \lambda_2(t) = 0, \tag{6.8}$$

and

$$\frac{d}{dt}\mathcal{H}_u = -2\epsilon^2\dot{x}_1(t)p(t) - 2\epsilon^2 x_1(t)\dot{p}(t) + \dot{\lambda}_2(t) = 0. \tag{6.9}$$

Substituting $\dot{p}(t) = -\frac{t}{\sigma_0^2}p(t)$ and also $\dot{\lambda}_2$ from (6.7), we get

$$\frac{d}{dt}\mathcal{H}_u = -2\epsilon^2 x_2(t)p(t) - 2\epsilon^2 x_1(t)\frac{t}{\sigma_0^2}p(t) - \lambda_1(t) = 0. \tag{6.10}$$

Differentiating again and substituting $\dot{\lambda}_1$ from (6.6), we have

$$\frac{d^2}{dt^2}\mathcal{H}_u = -4\epsilon^2 u(t)p(t) + 4\epsilon^2\frac{t}{\sigma_0^2}x_2(t)p(t) - 2k^2\left(t - x_1(t)\right)p(t) = 0. \tag{6.11}$$

Therefore, the corresponding $u(t)$ on the singular surface is

$$u(t) = x_2(t)\frac{t}{\sigma_0^2} - \frac{k^2}{2\epsilon^2}\left(t - x_1(t)\right). \tag{6.12}$$

Note that the first order generalized Legendre–Clebsch condition, which is a necessary condition for $u(t)$ to be minimizing on the singular surface, is also satisfied, namely,

$$\frac{\partial}{\partial u}\left(\frac{d^2}{dt^2}\mathcal{H}_u\right) \leq 0. \tag{6.13}$$

Therefore, the corresponding $x_1(t)$ and $x_2(t)$, which minimize our approximated cost, should necessarily satisfy the following differential equations:

$$\dot{x}_1(t) = x_2(t), \tag{6.14}$$

$$\dot{x}_2(t) = x_2(t)\frac{t}{\sigma_0^2} - \frac{k^2}{2\epsilon^2}\left(t - x_1(t)\right). \tag{6.15}$$

Since ϵ is assumed to be small, we may assume the following form in order to obtain the solutions for the above differential equations:

$$x_1(t) = a_0(t) + \epsilon^2 a_2(t) + \epsilon^4 a_4(t) + \cdots, \tag{6.16}$$

$$x_2(t) = b_0(t) + \epsilon^2 b_2(t) + \epsilon^4 b_4(t) + \cdots. \tag{6.17}$$

Interestingly enough, by substituting the above x_1 and x_2 back into the differential equations and comparing the coefficients of the terms with the same order in ϵ, we get

$$x_1(t) = \left[1 - \frac{2\epsilon^2}{k^2\sigma_0^2} + \left(\frac{2\epsilon^2}{k^2\sigma_0^2}\right)^2 - \left(\frac{2\epsilon^2}{k^2\sigma_0^2}\right)^3 + \cdots\right]t = \frac{t}{\left(1 + \frac{2\epsilon^2}{k^2\sigma_0^2}\right)}. \tag{6.18}$$

Back to our original notation, we actually have

$$f(z_1) = \frac{z_1}{\left(1 + \frac{2\epsilon^2}{k^2\sigma_0^2}\right)}. \tag{6.19}$$

As we can see, the solution is still linear with a coefficient which is slightly different than the corresponding coefficient for the noiseless transmission case. Remember that

$f(z_1) = z_1$ is the optimal solution when there is no transmission noise, and note that for $\epsilon = 0$ in (6.19) we get exactly the same solution as expected. Given the above function $f(z_1)$, the corresponding $g^*(z_2)$ can easily be obtained using (3.4). Note that it will also be linear because of the Gaussian assumption for the underlying uncertainties.

We could somehow expect the optimal strategies to be linear from the beginning. As we mentioned in section 2, linear strategies were shown to be asymptotically optimal for the Witsenhausen example when the uncertainty on the information available to the first station is small [2]. In this paper, however, we have considered a reformulation of Witsenhausen's problem where the first station sends its information to the second station through a low noise channel. These two scenarios are somewhat similar. Namely, in both scenarios, the second station can determine the information available to the first station fairly accurately. Specifically, in the first scenario, the second station almost knows z_1 because of its small uncertainty, while in the second scenario it can determine z_1 from the information that is transmitted through a low noise channel.

We would also expect the optimal strategies to approach the corresponding strategies for the noiseless transmission case as the value of z_1 and, in some sense, the *signal-to-noise ratio* increases. This does not seem to happen in the solution (6.19). One may justify this by looking at the exponential function in the cost (5.25). This function drives the integrand of the cost to zero exponentially fast for large values of z_1. Therefore, the structure of the cost really does not force the optimal solution to approach $f(z_1) = z_1$ as z_1 increases.

We shall now obtain the corresponding value of the cost. Substituting $f(t)$ from (6.19) back into the cost (5.25), we get

$$\begin{aligned} J^*(f) &= \int_{-\infty}^{+\infty} \left[k^2 \left(t - \frac{t}{1 + \frac{2\epsilon^2}{k^2\sigma_0^2}} \right)^2 \right] \frac{1}{\sqrt{2\pi}\sigma_0} e^{-\frac{t^2}{2\sigma_0^2}} dt \\ &\quad + \epsilon^2 \int_{-\infty}^{+\infty} \left[4 \frac{t}{\left(1 + \frac{2\epsilon^2}{k^2\sigma_0^2}\right)^2} \frac{t}{\sigma_0^2} + \frac{t^2}{\left(1 + \frac{2\epsilon^2}{k^2\sigma_0^2}\right)^2} \frac{\sigma_0^2 - t^2}{\sigma_0^4} \right] \frac{1}{\sqrt{2\pi}\sigma_0} e^{-\frac{t^2}{2\sigma_0^2}} dt \\ &= \frac{1}{\left(1 + \frac{2\epsilon^2}{k^2\sigma_0^2}\right)^2} \left(2\epsilon^2 + \frac{4\epsilon^4}{k^2\sigma_0^2} \right) \\ &\simeq 2\epsilon^2 - \frac{4\epsilon^4}{k^2\sigma_0^2}\,, \end{aligned} \tag{6.20}$$

where we have used

$$\int_{-\infty}^{+\infty} t^2 \frac{1}{\sqrt{2\pi}\sigma_0} e^{-\frac{t^2}{2\sigma_0^2}} dt = \sigma_0^2, \tag{6.21}$$

$$\int_{-\infty}^{+\infty} t^4 \frac{1}{\sqrt{2\pi}\sigma_0} e^{-\frac{t^2}{2\sigma_0^2}} dt = 3\sigma_0^4. \tag{6.22}$$

The optimal cost for the noiseless transmission case is zero. But if we use $f(z_1) = z_1$ when the transmission is noisy, we get the following cost:

$$J^*(f) = 2\epsilon^2. \tag{6.23}$$

In other words, if we fix the strategies to be the optimal strategies for the noiseless transmission case while introducing a small transmission noise, the increase in the cost will be proportional to the transmission noise intensity. However, if we use (6.19), we can indeed improve the cost by the fourth order in ϵ.

One should note from (6.19) and (6.20) that as the value of $k^2\sigma_0^2$ increases, the asymptotically optimal solution approaches $f(z_1) = z_1$, and the change in the cost becomes smaller. In other words, increasing $k^2\sigma_0^2$ has an effect similar to decreasing the communication uncertainty. To explain this, we note from the performance index that increasing k^2 implies a more expensive control action for the first station, which, in turn, results in smaller u_1. This then implies that the information available to the second station is less affected by the action of the first station. At the same time, increasing σ_0^2 implies a higher level of uncertainty on x_0, which, incidentally, is the piece of information that is being transmitted between the stations.

This brings up an example of a very interesting fundamental issue: the notion of *information value* and how it could be different for control and communication purposes. In fact, we know from information theory that a higher level of uncertainty for a piece of information implies a higher level of *entropy* and therefore a more valuable piece of information for transmission. On the other hand, however, a more uncertain piece of information would probably be less valuable for control purposes and would have smaller effect on the control strategies. In other words, a control designer would probably be willing to spend less on installing transmitters on the stations for communicating more uncertain pieces of information. While defining a notion for the value of information for control purposes has been occasionally addressed in the literature for quite a long time, it still remains an open problem. This is mostly because of the fact that the value of information for control purposes would highly depend on how the cost is defined for the control design, and this could be quite different in various applications.

7. Concluding remarks. We analyzed an example of a decentralized stochastic system. This example was a reformulation of the Witsenhausen counterexample where the first station was allowed to send its information to the second station through a noisy channel. The dynamics were linear, all the underlying uncertainties were assumed to be Gaussian, and the cost was quadratic. It was shown that as soon as any uncertainty is introduced in the communication among the stations, the information pattern again becomes nonclassical, which is not partially nested. We then showed how the performance index can be alternatively expressed such that the possible nonconvexity of the cost, with respect to the control strategies, becomes more transparent. Therefore, in general, we will end up with a nonconvex functional optimization problem when we try to obtain the decentralized optimal control algorithms. We then considered two limit cases. Namely, the case where there is no communication uncertainty and the case in which the transmission noise intensity increases to infinity. The former case was shown to be a trivial example of a classical LQG problem, whereas the latter case corresponds to Witsenhausen's counterexample, the optimal solution of which is still unknown.

We then focused on the case where the communication uncertainty was small. We followed an asymptotic approach where we approximated the cost based on its expansion in terms of the small transmission noise intensity. We showed how minimizing the approximated cost can be seen as a singular optimization problem. We then used a variational approach in order to find the necessary conditions for the asymptotically optimal strategies and showed that some reasonable linear strategies

would actually satisfy those conditions. We also provided some intuitive explanations for the behavior of those linear strategies and obtained the corresponding cost.

Note that while we have focused on the reformulated Witsenhausen counterexample, our main result is quite general. In fact, we have shown through an example that communication uncertainties in decentralized systems generally result in nonclassical information patterns, which, in turn, can destroy the convexity of the associated functional optimization problems. Moreover, our approach is indeed a very general approach, which have been applied to various other problems before. More specifically, expanding a cost function in terms of some small parameters is a common practice in variational and perturbation-based approaches. Furthermore, using Hamiltonian approach in order to obtain the necessary conditions for the optimal strategies obviously is not specific to our reformulated Witsenhausen problem. However, finding the exact function (6.19), which is obtained in closed form, satisfies the necessary condition for optimality, and shows how the optimal strategies could change upon introduction of some communication uncertainty, could be very specific to our problem.

All the derivations and the results in this paper show some of the difficulties involved in dealing with decentralized systems as soon as we deviate a little bit from a classical, or at least a partially nested, information pattern. On the other hand, even though we have modeled the communication uncertainty in the simplest possible way, we have tried to emphasize the role of communication uncertainties in generating such information patterns that are very difficult to handle.

Finally, it should be mentioned that even though the optimization problem is generally difficult for this class of systems, in some applications one might be able to exploit the specific structure of the system in order to obtain some reasonably good *suboptimal* strategies, which could yield an acceptable performance.

STRONG OPTIMALITY FOR A BANG-BANG TRAJECTORY*

ANDREI A. AGRACHEV†, GIANNA STEFANI‡, AND PIERLUIGI ZEZZA§

Abstract. In this paper we give sufficient conditions for a bang-bang regular extremal to be a strong local optimum for a control problem in the Mayer form; strong means that we consider the C^0 topology in the state space. The controls appear linearly and take values in a polyhedron, and the state space and the end point constraints are finite-dimensional smooth manifolds. In the case of bang-bang extremals, the kernel of the first variation of the problem is trivial, and hence the usual second variation, which is defined on the kernel of the first one, does not give any information. We consider the finite-dimensional subproblem generated by perturbing the switching times, and we prove that the sufficient second order optimality conditions for this finite-dimensional subproblem yield local strong optimality. We give an explicit algorithm to check the positivity of the second variation which is based on the properties of the Hamiltonian fields.

1. Introduction.

This paper is part of a general research program whose aim is to further extend the use of Hamiltonian methods in the study of optimal control problems. We believe that these methods can play a relevant role in control theory because they allow a general approach to sufficient conditions for strong local optimality, as we wish to show here.

The Hamiltonian approach to strong optimality consists of constructing a field of state extremals covering a neighborhood of a given trajectory which has to be tested. This field of extremals is obtained by projecting on the state manifold M the flow $\mathcal{H}_t$ of the maximized Hamiltonian emanating from the Lagrangian submanifold of the initial transversality conditions. If this projection admits a Lipschitz continuous local inverse, then we can estimate the variation of the cost function at a neighboring trajectory by a function ψ which depends only on the final point, and it is hence independent of the control differential equation; in this way we reduce the problem to a finite-dimensional one. The existence of a Lipschitz continuous local inverse is guaranteed by the surjectivity of the projection on M of the tangent map to the flow $\mathcal{H}_t$. This construction corresponds to the classical one of a nonselfintersecting family of state extremals. This is enough to obtain optimality if the final point is fixed since the submanifold of the final end points reduces to a singleton; otherwise we need some further optimality condition on the function ψ.

We use the relations existing between a suitable second variation and the symplectic properties of the Hamiltonian flow to show that when this second variation is positive definite then the projection on the state manifold M of the tangent map to

the flow $\mathcal{H}_t$ is surjective; moreover the positivity of this second variation leads also to the sufficient optimality conditions for the function ψ.

To make this general approach possible we need an intrinsic formulation of the second variation as an accessory linear-quadratic minimization problem on the tangent space; this will allow us to exploit one of the crucial ideas underlying the Hamiltonian approach: the tangent map of the flow of the maximized Hamiltonian is the linear Hamiltonian flow of an associated linear-quadratic problem, i.e., the flow of the Jacobi system.

Another important issue is that, when the initial point is not free, it is not possible to cover a neighborhood of the initial point by the projection of the Hamiltonian flow. In the calculus of variations this problem has been solved by perturbing the initial time, but this method does not always work in optimal control because the projection could be singular for a time interval of positive length; this is always the case for bang-bang controls if there is a constraint on the initial point. We propose a different approach: when the second variation is positive we add a penalty term, which allows us to reduce the original problem to another one without constraints on the initial point.

Some of these issues have already been addressed. In [ASZ98b] we stated sufficient conditions for strong local optimality for an optimal control problem in $\mathbb{R}^n$ with unbounded controls, while in [ASZ98a] we gave an intrinsic expression of the accessory problem and studied the relations between the Hamiltonian flow and the index of the second variation. The geometric properties of the field of extremals necessary for proving sufficient conditions for strong optimality were studied in [ASZ99].

In this paper we study a control problem in the Mayer form where the controls appear linearly and take values in a polyhedron, the state space and the end point constraints are finite-dimensional smooth submanifolds, and we give sufficient conditions for a bang-bang extremal to be a strong local minimizer.

In the bang-bang case we have to face some new problems. Since the maximized Hamiltonian is not smooth at the switching points we need to give conditions (see Assumptions 2.1, 2.2, 2.3) which assure us that its flow is defined and piecewise smooth around the reference adjoint covector. Moreover, in the case of bang-bang extremals, the kernel of the first variation of the problem is trivial, and hence the usual second variation, which is defined on the kernel of the first one, does not give any information. We solve this problem by considering the finite-dimensional subproblem generated by perturbing the switching times. The usual (finite-dimensional) second order optimality conditions for this problem give an appropriate second variation. Indeed we prove that the positivity of this second variation yields that the Hamiltonian flow has the properties we have described so that we can prove strong local optimality for the reference trajectory. The set of admissible variations on which we test the second variation can be very small, its dimension can be less than the state space dimension, and when it is zero, we directly have optimality.

By introducing an analogue of the strict Legendre condition, Assumption 2.3, we can eliminate the control from the extremality conditions for the second variation, and its extremals are then described by a discrete version of the Jacobi system, (2.9); the flow of this system describes the tangent subspaces to the flow of the maximized Hamiltonian at the points of nonsmoothness. Since the optimality can be lost only at these points, then the positivity of the second variation can be checked by an algorithm (see Lemma 2.8) which is based on the properties of the discrete flow of the bang-bang Jacobi system. For analogous conditions in the case of unbounded controls, see [ASZ98b].

The literature on second order sufficient conditions for the optimality of a bang-bang trajectory is scarce; we refer to [PS00] and the references therein for results based on the existence of a regular synthesis, and to [Sar92] and [Sar97], where the author studies local minima in the L^1 norm on the control in the time-optimal case. For a general description of the classical study of strong local optimality in the one-dimensional calculus of variations, see [GH96a, GH96b].

2. Statement of the results. Let $X_i,\ i = 1, 2, \dots, m$, be distinct C^∞ vector fields defined on the C^∞ finite-dimensional manifold M and let $\Delta = co\,\{e_1,\, e_2,\, \dots,\, e_m\}$ be the unitary simplex in $\mathbb{R}^m$.

We are interested in the optimal control problem

$$\text{Minimize} \quad J(\xi) := c_0(\xi(0)) + c_T(\xi(T))$$

subject to

$$\dot\xi(t) = \sum_{i=1}^{m} u_i(t)\, X_i(\xi(t)), \quad u(t) \in \Delta \tag{2.1}$$

$$\xi(0) \in N_0\ ,\ \xi(T) \in N_T, \tag{2.2}$$

where the time interval $[0, T]$ is fixed, N_0, N_T are given C^∞ submanifolds of M, and c_0, c_T are real-valued smooth functions. We will give sufficient conditions for a trajectory to be a strong local optimum, where strong means that we consider the C^0 topology in the state space.

As a candidate optimal solution we are given a *bang-bang Pontryagin extremal* $(\hat\xi, \hat u)$, that is, an absolutely continuous solution $\hat\xi : [0, T] \to M$ of system (2.1)–(2.2) with corresponding control $\hat u$ satisfying the Pontryagin maximum principle (PMP); moreover there is a partition of $[0, T]$

$$0 = t_0 < t_1 < t_2 < \cdots < t_r < t_{r+1} = T$$

such that

$$\hat u(t) = e_{j_i}, \quad t \in (t_{i-1}, t_i),$$

for some $j_i \in \{1, 2, \dots, m\}$. Therefore $\hat\xi$ is a solution of

$$\dot\xi(t) = X_{j_i}(\xi(t)), \quad t \in [t_{i-1}, t_i], \tag{2.3}$$

in each subinterval. The values t_i for $i = 1, 2, \dots, r$ will be called *switching times*, and we set

$$x_0 := \hat\xi(0), \quad x_T := \hat\xi(T)$$

to simplify notation. Corresponding to the reference extremal we define the time-dependent vector field

$$\hat h : [0, T] \times M \to TM \quad \text{as} \quad \hat h_{|(t_{i-1}, t_i)} := X_{j_i},$$

and we set $h_i := X_{j_i}$. Therefore the reference trajectory is a solution of the differential equation

$$\dot\xi(t) = \hat h_t(\xi(t)), \quad t \in [0, T]. \tag{2.4}$$

By lifting the vector field $\hat{h}_t$ to the cotangent bundle, we define the time-dependent Hamiltonian

$$\widehat{H} : [0,T] \times T^*M \to \mathbb{R}, \quad (t,\ell) \mapsto \langle \ell, \hat{h}_t(\pi\ell)\rangle,$$

where $\pi : T^*M \to M$ is the canonical projection; let us set $H_i := \widehat{H}_{|(t_{i-1},t_i)}$.

For our problem the maximized Hamiltonian

$$H : T^*M \to \mathbb{R}, \quad \ell \mapsto \max_{u\in\Delta} \left\langle \ell, \sum_{i=1}^{m} u_i\, X_i(\pi\ell) \right\rangle$$

is well defined and Lipschitz.

Recall that any piecewise smooth Hamiltonian $H_t : T^*M \to \mathbb{R}$ defines a Hamiltonian vector field $\vec{H}_t$ whose flow will be denoted by $\mathcal{H}_t$. Moreover for any time-independent vector field Y we denote its flow by $(t,x) \mapsto \exp t\, Y(x)$; see [Arn80].

We can express the PMP by saying that there exist $p_0 \in \{0,1\}$ and a lift $\hat{\lambda}$ of $\hat{\xi}$ to the cotangent bundle, which is a solution of

$$\dot{\lambda}(t) = \vec{\widehat{H}}_t(\lambda(t)),$$

$$\lambda(0) = p_0\, dc_0(x_0) \quad \text{on } T_{x_0}N_0, \tag{2.5}$$

$$\lambda(T) = -p_0\, dc_T(x_T) \quad \text{on } T_{x_T}N_T \tag{2.6}$$

such that

$$|p_0| + \|\hat{\lambda}\| \neq 0,$$
$$\widehat{H}_t(\hat{\lambda}(t)) = H(\hat{\lambda}(t)).$$

Let us now introduce our first assumption.

Assumption 2.1 (bang-bang regular extremal). *The maximum*

$$\max_{u\in\Delta} \left\langle \hat{\lambda}(t), \sum_{i=1}^{m} u_i\, X_i(\hat{\xi}(t)) \right\rangle$$

is attained at a vertex of Δ *for all* $t \in [0,T],\ t \neq t_1, t_2, \dots, t_r$.

Assumption 2.1 means that on each subinterval $(t_{i-1},\, t_i)$ there is a unique index j_i such that

$$H(\hat{\lambda}(t)) = \langle \hat{\lambda}(t),\, X_{j_i}(\hat{\xi}(t))\rangle.$$

The smooth functions $p_0\, c_0$ and $p_0\, c_T$ are defined on N_0 and N_T, respectively, but they can be extended to the whole manifold M in such a way that the transversality conditions (2.5) and (2.6) hold on the whole tangent space. We denote by $\alpha, \beta : M \to \mathbb{R}$ two functions such that

$$\alpha = p_0\, c_0 \quad \text{on } N_0, \quad \beta = p_0\, c_T \quad \text{on } N_T,$$

$$\hat{\lambda}(0) = d\,\alpha(x_0) \quad \text{on } T_{x_0}M, \quad \hat{\lambda}(T) = -d\,\beta(x_T) \quad \text{on } T_{x_T}M. \tag{2.7}$$

Consider the two Lagrangian submanifolds

$$\Lambda_0 := \left\{ d\,\alpha(x) + (T_xN_0)^\perp \ \middle|\ x \in N_0 \right\},$$
$$\Lambda_T := \left\{ -d\,\beta(x) + (T_xN_T)^\perp \ \middle|\ x \in N_T \right\};$$

the transversality conditions (2.5) and (2.6) of the PMP can be equivalently stated by saying that

$$\lambda(0) \in \Lambda_0, \quad \lambda(T) \in \Lambda_T.$$

In the normal case ($p_0 = 1$) α, β are cost functions equivalent to the original ones, while in the abnormal case ($p_0 = 0$) they are extensions of the zero function. When $p_0 = 0$ all the costs disappear, and indeed we will study a problem with a zero cost; therefore, proving that $\hat{\xi}$ is a *strict* strong minimizer will imply that it is isolated with respect to the C^0 topology among the admissible trajectories. In the case of sub-Riemannian metrics isolated trajectories are called rigid geodesics.

The sufficient conditions will be derived by studying the following optimal control problem, which is equivalent to the original one:

$$\text{(P)} \qquad \text{Minimize} \quad J(\xi) := \alpha(\xi(0)) + \beta(\xi(T))$$

subject to (2.1) and (2.2).

The points

$$\ell_i := \hat{\lambda}(t_i), \quad i = 0, 1, \dots, r+1,$$

will be called the *switching points* of the adjoint covector $\hat{\lambda}$. From the PMP we can deduce the following relations, which represent necessary optimality conditions:

$$H_i(\ell_i) = H_{i+1}(\ell_i), \quad i = 1, 2, \dots, r,$$
$$\langle d(H_{i+1} - H_i), \vec{H}_{i+1} \rangle(\ell_i) \geq 0, \quad i = 1, 2, \dots, r.$$

To state sufficient conditions for $\hat{\xi}$ to be a strong local minimizer we need to strengthen these two conditions, and hence we assume the following.

Assumption 2.2 (simple switching points). *The maximum*

$$\max_{u \in \Delta} \left\langle \hat{\lambda}(t), \sum_{i=1}^{m} u_i \, X_i(\hat{\xi}(t)) \right\rangle$$

is attained along a one-dimensional edge of Δ *for* $t = t_1, t_2, \dots, t_r$.

Assumption 2.3 (strict bang-bang Legendre condition).

$$\langle d(H_{i+1} - H_i), \vec{H}_{i+1} \rangle(\ell_i) > 0, \quad i = 1, 2, \dots, r.$$

Remark 2.4. The PMP implies that the switching point ℓ_i belongs to the level set $H_{i+1} - H_i = 0$ for $i = 1, 2, \dots, r$. The strict bang-bang Legendre condition yields that, near the point ℓ_i, this level set is a hypersurface which will be called the *switching surface*.

Our assumptions are strictly related to the properties of the flow of the maximized Hamiltonian H, and they guarantee that the Hamiltonian flow is piecewise smooth; see Corollary 4.2. In particular, Assumptions 2.1 yields that locally around the reference extremal we can switch from one vector field to another only on the switching surfaces, while Assumption 2.2 yields that, on the switching surfaces, we can choose only between two vector fields, and the last one, Assumption 2.3, yields that we are forced to switch. Let $\boldsymbol{s}$ be the Liouville one form in T^*M and denote by $\boldsymbol{\sigma} = d\boldsymbol{s}$ the

canonical symplectic two form on T^*M; see [Arn80] for the definitions. Taking into account the basic properties of $\boldsymbol{\sigma}$, Assumption 2.3 can be equivalently written as

$$\begin{aligned}\langle d(H_{i+1}-H_i), \vec{H}_{i+1}\rangle(\ell_i) &= \boldsymbol{\sigma}\left(\vec{H}_i, \vec{H}_{i+1}\right)(\ell_i)\\ &= \{H_i, H_{i+1}\}(\ell_i)\\ &= \langle \ell_i, [h_i, h_{i+1}](\hat{\xi}(t_i)\rangle \geq 0,\end{aligned}$$

where $\{\ ,\ \}$ and $[\ ,\ ]$ denote the Poisson and Lie brackets, respectively.

2.1. A finite-dimensional subproblem. We are going to choose an appropriate r-dimensional family of variations corresponding to bang-bang trajectories; they are generated by perturbing the switching times. The optimality with respect to these variations will be not only necessary but also sufficient (under the previously stated assumptions) to prove that the reference trajectory is a strong local minimizer.

For a given $a > 0$ such that $\min_{i=1,\dots,r+1}(t_i - t_{i-1}) > 2a$, let $\varepsilon \in B(0,a) \subset \mathbb{R}^r$, set $\varepsilon_0 = \varepsilon_{r+1} = 0$, and consider the time-dependent vector field

$$(\varepsilon, x) \mapsto h_t(\varepsilon, x) = h_i(x) \quad \text{if} \quad t \in (t_{i-1} + \varepsilon_{i-1}, t_i + \varepsilon_i).$$

This new vector field is obtained from the reference one by moving the switching time t_i by ε_i.

Remark 2.5. A small ε corresponds to a control variation which is small in the L^1 norm but not in the L^∞ norm.

Denote the flow of $\dot{\xi}(t) = h_t(\varepsilon, \xi(t))$ by

$$S_t : M \times B(0,a) \to M$$

and consider the following finite-dimensional subproblem of problem (P):

$$\text{(sub-P)} \qquad \text{Minimize} \quad \gamma(x,\varepsilon) := \alpha(x) + \beta(S_T(x,\varepsilon))$$

subject to

$$x \in N_0, \quad S_T(x,\varepsilon) \in N_T.$$

Note that $\widehat{S}_t := S_t(\cdot, 0)$ is the flow of $\hat{h}_t$, $S_t(x_0, 0) = \hat{\xi}(t)$ and $(x_0, 0)$ is the candidate optimal solution for the subproblem.

By using the relations (2.7) and the extremality properties of the reference trajectory, it is easy to prove that $(x_0, 0)$ is a critical point for γ, that is,

$$d\gamma(x_0, 0) = 0,$$

and hence

$$J'' := \frac{1}{2} D^2\gamma(x_0, 0)$$

is a well-defined quadratic form on $T_{x_0}M \times \mathbb{R}^r$, which gives the second order approximation of γ. The second variation of (sub-P) is the restriction of J'' to the linearization of the constraints; namely, if we set

$$\mathcal{N} = \left\{(\delta x, \varepsilon) \in T_{x_0}N_0 \times \mathbb{R}^r : S_{T*}(\delta x, \varepsilon) \in T_{x_T}N_T\right\}, \tag{2.8}$$

then the second variation of (sub-P) is $J''_{|\mathcal{N}}$, and it will be called the *second variation at the switching points*. Let us remark that $J''_{|\mathcal{N}} \geq 0$ is a necessary optimality condition when the subproblem is normal.

The main result of the paper states that under the regularity conditions on the maximized Hamiltonian previously stated, the positivity of the second variation at the switching points is sufficient to prove that the reference trajectory $(\hat{\xi}, \hat{u})$ is a strict local minimizer for the original problem in the C^0 topology on the state (strong minimizer).

From an intuitive point of view the idea underlying this result can be summarized by saying that the flow of the maximized Hamiltonian projects onto the trajectories of the finite-dimensional subproblem, which then generates a field of extremals that can be used to prove sufficiency.

THEOREM 2.6. *Assume that the given bang-bang Pontryagin extremal $\hat{\xi}$ is regular and has simple switching points and that the strict bang-bang Legendre condition is satisfied. If the second variation at the switching points is positive definite, then $\hat{\xi}$ is a strict strong local minimizer, i.e., a strict local minimizer in the C^0 topology. In the abnormal case $\hat{\xi}$ is an isolated admissible solution of the constrained control system.*

Remark 2.7. If $\mathcal{N}$ reduces to $\{0\}$, then the second variation at the switching points is positive definite, and hence we obtain a first order sufficient condition.

2.2. The bang-bang Jacobi system. We can check the positivity of the second variation at the switching points in a complete Hamiltonian form. Let

$$\Pi := T_{\pi\,\ell} M \hookrightarrow T_\ell T^* M$$

be the *vertical* subspace and define

$$L_0 := T_{\ell_0} \Lambda_0, \quad L_T := T_{\ell_T} \Lambda_T.$$

The regularity assumptions on the maximized Hamiltonian yield that $\mathcal{H}_t$ is smooth everywhere except at the switching times where it is left and right smooth; see Corollary 4.2. The positivity of the second variation at the switching points can be checked through the properties of the tangent subspaces to $\mathcal{H}_{t_k}(\Lambda_0)$ from the left and from the right and by their relative positions with respect to Π. Thanks to the strict bang-bang Legendre condition, these Lagrangian subspaces can be described through the flow of the following discrete version of the Jacobi system:

$$\text{(2.9)} \qquad \begin{cases} \delta\ell_k^- = \left(\exp(t_{k+1} - t_k)\, \vec{H}_{k+1}\right)_*\, \delta\ell_{k-1}^+, \\ \delta\ell_k^+ = \delta\ell_k^- + \dfrac{\boldsymbol{\sigma}(\delta\ell_k^-, (\vec{H}_k - \vec{H}_{k+1})(\ell_k))}{\boldsymbol{\sigma}(\vec{H}_k, \vec{H}_{k+1})(\ell_k)}\, (\vec{H}_k - \vec{H}_{k+1})(\ell_k). \end{cases}$$

Denote the flow of $\delta\ell_k^-$ and $\delta\ell_k^+$ by Δ_k^-, Δ_k^+ and set

$$L_k^- := \Delta_k^- L_0, \quad L_k^+ := \Delta_k^+ L_0.$$

In section 4 we prove that L_k^+, L_k^- are the left and right tangent subspaces to $\mathcal{H}_{t_k}(\Lambda_0)$; see Remark 4.6.

LEMMA 2.8. *The positivity of the second variation at the switching points can be checked through the following algorithm.*

STEP 1: Set $k = 1$.

STEP 2: If $k \leq r$, then go to STEP 3
else go to STEP 4.

STEP 3: If $(\vec{H}_k - \vec{H}_{k+1})(\ell_k) \notin L_k^- + \Pi$ or $(\vec{H}_k - \vec{H}_{k+1})(\ell_k) \in L_k^-$, then set $k = k+1$ and go to STEP 2.
else
if $L_k^+ \cap \Pi \subseteq L_k^- \cap \Pi$ and for every $\delta\ell^+ \in L_k^+$, $\delta\ell^- \in L_k^-$ such that $\pi_* \delta\ell^+ = \pi_* \delta\ell^-$ we have that $\boldsymbol{\sigma}(\delta\ell^-, \delta\ell^+) \geq 0$, then set $k = k+1$ and go to STEP 2.
else $J''_{|\mathcal{N}}$ is not positive definite, STOP.

STEP 4: If for every $\delta\ell \in L_{r+1}^-$, $\delta\ell_T \in L_T$ such that $\pi_* \delta\ell = \pi_* \delta\ell_T \neq 0$ we have that $\boldsymbol{\sigma}(\delta\ell, \delta\ell_T) > 0$, then $J''_{|\mathcal{N}}$ is positive definite, END.
else $J''_{|\mathcal{N}}$ is not positive definite, STOP.

Remark 2.9. Let us explain the meaning of each step of this algorithm.

1. The algorithm first checks the positivity of the second variation associated to the corresponding problem with fixed final point (STEP 3).
2. Each iteration of the algorithm is associated to a new variation obtained by perturbing the corresponding switching time; this procedure generates an increasing family of variations.
3. STEP 3 deserves some comment: if $(\vec{H}_k - \vec{H}_{k+1})(\ell_k) \notin L_k^- + \Pi$, then there is no new variation, and hence there is no condition to check; if $(\vec{H}_k - \vec{H}_{k+1})(\ell_k) \in L_k^-$, then the flow $\mathcal{H}_t$ is differentiable also at t_k and the properties of the second variation remain unchanged.
4. STEP 4 checks the positivity conditions related to the presence of a nontrivial final cost, and hence when the final point is fixed, STEP 4 is void and the algorithm becomes the following.

   STEP 1: $k = 1$.

   STEP 2: If $k \leq r$, then go to STEP 3
   else $J''_{|\mathcal{N}}$ is positive definite, END.

   STEP 3: If $(\vec{H}_k - \vec{H}_{k+1})(\ell_k) \notin L_k^- + \Pi$ or $(\vec{H}_k - \vec{H}_{k+1})(\ell_k) \in L_k^-$, then set $k = k+1$ and go to STEP 2.
   else
   if $L_k^+ \cap \Pi \subseteq L_k^- \cap \Pi$ and for every $\delta\ell^+ \in L_k^+$, $\delta\ell^- \in L_k^-$ such that $\pi_* \delta\ell^+ = \pi_* \delta\ell^-$ we have $\boldsymbol{\sigma}(\delta\ell^-, \delta\ell^+) \geq 0$, then set $k = k+1$ and go to STEP 2.
   else $J''_{|\mathcal{N}}$ is not positive definite, STOP.

Since the maximized Hamiltonian is a piecewise lift of a vector field on M, then the vertical directions remain vertical under the action of the flow, and at the switching points the dimension of the projection increases at most by one. To obtain a flow which projects locally onto M we will reduce the problem to an equivalent one with free initial point; for this reason we describe explicitly the algorithm in this special case.

COROLLARY 2.10. *If the initial point is free, we have that* $L_0 \cap \Pi = \{0\}$, *and hence the algorithm becomes the following.*

STEP 1: Set $k = 1$.

STEP 2: If $k \leq r$, then go to STEP 3
else go to STEP 4.

STEP 3: If $(\vec{H}_k - \vec{H}_{k+1})(\ell_k) \in L_k^-$, then set $k = k+1$ and go to STEP 2.
else
if $\pi_* L_k^+ = T_{\hat{\xi}(t_k)} M$ and for every $\delta\ell^+ \in L_k^+$, $\delta\ell^- \in L_k^-$ such that $\pi_*\delta\ell^+ = \pi_*\delta\ell^-$ we have that $\boldsymbol{\sigma}(\delta\ell^-, \delta\ell^+) \geq 0$, then set $k = k+1$ and go to STEP 2.
else $J''_{|\mathcal{N}}$ is not positive definite, STOP.

STEP 4: If for every $\delta\ell \in L_{r+1}^-$, $\delta\ell_T \in L_T$ such that $\pi_*\delta\ell = \pi_*\delta\ell_T \neq 0$ we have that $\boldsymbol{\sigma}(\delta\ell, \delta\ell_T) > 0$, then $J''_{|\mathcal{N}}$ is positive definite, END.
else $J''_{|\mathcal{N}}$ is not positive definite, STOP.

Remark 2.11. In STEP 3 we check the fixed final point problem, and the algorithm stops when we find a direction on which the quadratic form is negative or zero. For this reason we call the corresponding switching time t_k the *conjugate point*; a conjugate point can occur only at a switching time.

2.3. The Bolza problem. We deal with an optimal control problem in the Mayer form only for simplicity; all the results can be stated for a problem in the Bolza form when the cost function includes an integral term, that is,

$$\text{Minimize} \quad J(\xi) := c_0(\xi(0)) + c_T(\xi(T)) + \int_0^T \sum_{i=1}^m u_i(t)\, X_i^0(\xi(t))\, dt$$

subject to (2.1) and (2.2), where X_i^0, $i = 1, 2, \ldots, m$, are C^∞ functions defined on M.

The same proofs can be carried out using as reference and maximized Hamiltonian those defined as

$$\widehat{H} : \ell \mapsto \langle \ell, \hat{h}(\pi\ell) \rangle - p_0 \sum_{i=1}^m \hat{u}_i(t)\, X_i^0(\pi\ell),$$

$$H : \ell \mapsto \max_{u \in \Delta} \left(\left\langle \ell, \sum_{i=1}^m u_i\, X_i(\pi\ell) \right\rangle - p_0 \sum_{i=1}^m u_i\, X_i^0(\pi\ell) \right).$$

3. The second variation at the switching points. This section is necessarily technical, but it contains the main ideas and the technical lemmas needed to carry out this kind of approach.

To study the relations existing between the second variation at the switching points and the properties of the Hamiltonian flow, let us reduce (sub-P) to a single-input affine problem with piecewise constant control maps having the t_i's as switching times. This reduction can be achieved by the following time reparametrization:

$$\dot{\varphi}(\tau) = 1 + \nu(\tau), \quad \nu \in (-1, 1),$$
$$\varphi(0) = 0, \quad \varphi(T) = T,$$

where ν is piecewise constant, i.e., $\nu(\tau) \equiv \nu_i$, $\tau \in [t_{i-1}, t_i)$.

Any solution of this boundary value problem is an increasing isomorphism of the interval $[0, T]$ onto itself. If we set $\varepsilon_i := \varphi(t_i) - t_i$, $i = 1, 2, \ldots, r$, then we have that $S_{\varphi(\tau)}(x, \varepsilon)$ is the solution of the differential equation

$$\dot{\zeta}(\tau) = [1 + \nu(\tau)]\, \hat{h}_\tau(\zeta(\tau)), \quad \zeta(0) = x. \tag{3.1}$$

If we set $u_i := \nu_i\,(t_i - t_{i-1})$, then from our construction it follows that $\varepsilon_i = \sum_{j=1}^{i} u_j$ and $\sum_{j=1}^{r+1} u_j = 0$ as it follows from the boundary condition $\varphi(T) = T$. Therefore we can take as control space the r-dimensional vector space

$$U := \left\{ (u_1, u_2, \dots, u_{r+1}) \in \mathbb{R}^{r+1} \;\middle|\; \sum_{j=1}^{r+1} u_j = 0 \right\}.$$

For a given $u \in U$ we denote by ν_u the corresponding control map. Since there is a one-to-one correspondence between ε and u we still denote by $\mathcal{N}$ the subset of $T_{x_0}N_0 \times U$ corresponding to $\mathcal{N} \subseteq T_{x_0}N_0 \times \mathbb{R}^r$, which is defined in (2.8). We can now study the second variation of the problem of minimizing $\alpha(\zeta(0)) + \beta(\zeta(T))$ subject to (3.1) with the boundary conditions $\zeta(0) \in N_0$ and $\zeta(T) \in N_T$.

Following the same approach used in [ASZ98a] we can define the second variation as a linear quadratic problem on $T_{x_0}\,M$ by the using pull-back system defined through the time-dependent vector field

$$\hat{g}_t := \widehat{S}_{t*}^{-1}\,\hat{h}_t \circ \widehat{S}_t. \tag{3.2}$$

$\hat{g}_t$ is piecewise constant with the same switching times as $\hat{h}_t$, and we set $g_i := \hat{g}_{|(t_{i-1},t_i)}$. Consider the pull-back control system

$$\dot{\eta}(t) = \nu(t)\,\hat{g}_t(\eta(t)) \tag{3.3}$$

and the associated linearized equation at $\eta(t) \equiv x_0$,

$$\dot{\delta\eta}(t) = \nu(t)\,\hat{g}_t(x_0). \tag{3.4}$$

If we also pull back the costs by setting

$$\hat{\beta} = \beta \circ \widehat{S}_T, \quad \hat{\gamma} = \alpha + \hat{\beta},$$

then, reasoning as in [ASZ98a], the second variation at the switching points can be equivalently written as the restriction to $\mathcal{N}$ of the linear-quadratic form

$$J''[\delta e]^2 = \frac{1}{2} D^2\hat{\gamma}(x_0)[\delta x]^2 + \int_0^T \nu_u(s)\,\langle Q_s, \delta\eta_s(\delta e)\rangle\,ds,$$

where $\delta e := (\delta x, u) \in T_{x_0}M \times U$ and

$$\langle Q_t, \delta x\rangle = \langle D\langle D\,\hat{\beta}, \hat{g}_t\rangle(x_0),\, \delta x\rangle.$$

The Hamiltonian associated with this linear-quadratic problem is

$$(\omega, \delta x, u) \mapsto G_t''(\omega, \delta x)\nu_u(t),$$

where G_t'' is the following piecewise constant linear Hamiltonian:

$$G_t'' : T_{x_0}^*M \times T_{x_0}M \to \mathbb{R}, \quad (\omega, \delta x) \mapsto \langle \omega, \hat{g}_t(x_0)\rangle + \langle Q_t, \delta x\rangle.$$

With notation analogous to previous ones, we set $G_i'' := G''_{\,|(t_{i-1},t_i)}$ and define the Lagrangian subspace of the initial and final transversality conditions as

$$L_0'' := \left\{ \left(-D^2\hat{\gamma}(x_0)(\delta x, \cdot) + \omega,\, \delta x\right) \;|\; \delta x \in T_{x_0}N_0,\; \omega \in \left(T_{x_0}N_0\right)^{\perp} \right\},$$

$$L_T'' := \left(T_{x_0}\widehat{S}_T^{-1}(N_T)\right)^{\perp} \times T_{x_0}\widehat{S}_T^{-1}(N_T).$$

We want to express the value of the form J'' in Hamiltonian notation. Let $\delta e = (\delta x, u)$ and $\delta f = (\delta y, v)$ belong to $T_{x_0}M \times U$ and let $\delta\ell \in L_0''$ be such that

$$\pi_* \delta\ell = \delta x.$$

If we denote by $\mathcal{G}_t''(\delta\ell, u) := (\omega_t(\delta\ell, u), \delta\eta_t(\delta e))$ the solution of the Hamiltonian system

$$\dot\lambda(t) = \vec G_t''(\lambda(t))\, \nu_u(t), \quad \lambda(0) = \delta\ell, \tag{3.5}$$

then we obtain, as in the proof of Lemma 4 in [ASZ98a, p. 700],

$$\begin{aligned} J''(\delta e, \delta f) &= D^2\hat\gamma(x_0)(\delta x, \delta y) + \int_0^T \langle Q_s, \nu_u(s)\delta\eta_s(\delta f) + \nu_v(s)\delta\eta_s(\delta e)\rangle\, ds \\ &= D^2\hat\gamma(x_0)(\delta x, \delta y) - \langle \omega_T(\delta\ell, u), \delta\eta_T(\delta f)\rangle + \langle \omega_0(\delta\ell, u), \delta y\rangle \\ &\quad + \int_0^T G_t''\Big(\mathcal{G}_t''(\delta\ell, u)\Big)\, \nu_v(t)\, dt. \end{aligned} \tag{3.6}$$

The positivity of the second variation at the switching points will be checked in two steps. We first consider the problem with fixed final point and check the positivity of the corresponding second variation, that is, J'' restricted to

$$V := \{(\delta x, u) \in T_{x_0}N_0 \times U \mid \delta\eta(\delta x, \nu_u, T) = 0\} \subseteq \mathcal{N}.$$

Afterwards we check the positivity of J'' on $\mathcal{N} \cap V^{\perp_{J''}}$, where $\perp_{J''}$ means orthogonality with respect to J''.

To study the signature of the second variation on V we take an increasing sequence of subspaces $V_k \subset V$ obtained by considering as admissible controls those u for which ν_u is zero from t_{k+1} on; i.e., we will study the second variation on each

$$V_k := \{(\delta x, u) \in V \mid u_j = 0 \text{ for } j \geq k+2\}.$$

The extremals of J'' on V are essential in the study of its signature, and they are those δe belonging to $V \cap V^{\perp_{J''}}$. For this reason we characterize the J''-orthogonality in the following integral version of the Jacobi system.

LEMMA 3.1. *For $k \in \{1, 2, \ldots, r\}$, $\delta e = (\delta x, u) \in \mathcal{N} \cap V_k^{\perp_{J''}}$ if and only if there exists $\delta\ell \in L_0''$ such that*

$$\pi_* \delta\ell = \delta x, \quad \pi_*\, \mathcal{G}_T''(\delta\ell, u) \in \pi_*\, L_T'', \tag{3.7}$$

$$\int_0^T G_t''\Big(\mathcal{G}_t''(\delta\ell, u)\Big)\, \nu_v(t)\, dt = 0 \quad \forall v:\ v_j = 0,\ j \geq k+2. \tag{3.8}$$

Proof. $\delta e \in \mathcal{N} \cap V_k^{\perp_{J''}}$ if and only if there exist $\bar\omega_0 \in (T_{x_0}N_0)^\perp$ and $\bar\omega_T \in \Pi$ such that

$$J''(\delta e, \delta f) = \langle \bar\omega_0,\, \delta y\rangle + \langle \bar\omega_T,\, \delta\eta_T(\delta f)\rangle$$

for all $\delta f = (\delta y, v) \in T_{x_0}M \times U$ such that $v_j = 0,\ j \geq k+2$.

If we choose

$$\delta\ell = (-D^2\hat\gamma_0(\delta x, \cdot) + \bar\omega_0,\, \delta x),$$

then $\delta\ell \in L_0''$ and (3.7) is satisfied. For $v = 0$, from (3.6) we obtain

$$-\omega_T(\delta\ell, u) = \bar{\omega}_T$$

and hence (3.8).

To prove the converse, let us remark that (3.7) yields that $\delta e \in \mathcal{N}$; moreover, using (3.6) for $\delta f \in V_k$, from (3.7) and (3.8), it follows that $J''[\delta e, \delta f] = 0$. ∎

COROLLARY 3.2. *Let $\delta e = (\delta x, u) \in \mathcal{N} \cap V^{\perp_{J''}}$ and let $\delta\ell \in L_0''$ be the one given in Lemma* 3.1. *If $\delta\ell_1 \in L_T''$ is such that $\pi_*\delta\ell_1 = \pi_*\mathcal{G}_T''(\delta\ell, u)$, then*

$$J''\,[\delta e]^2 = \boldsymbol{\sigma}\Big(\delta\ell_1, \mathcal{G}_T''(\delta\ell, u)\Big). \tag{3.9}$$

Let $\delta e = (\delta x, u) \in V_k \cap V_{k-1}^{\perp_{J''}}$ and let $\delta\ell \in L_0''$ be the one given in Lemma 3.1. *Then*

$$J''[\delta e]^2 = \boldsymbol{\sigma}\Big(\mathcal{G}_{t_k}''(\delta\ell, u), u_{k+1}(\vec{G}_{k+1}'' - \vec{G}_k'')\Big). \tag{3.10}$$

Proof. Equality (3.9) is an easy consequence of Lemma 3.1 and (3.6). Integrating by parts and using the symplectic properties of the Hamiltonian flow, again from (3.6), it follows that

$$\begin{aligned} J''[\delta e]^2 &= \int_{t_{k-1}}^{t_k} G_k''\Big(\mathcal{G}_t''(\delta\ell, u)\Big)\,\frac{-u_{k+1}}{t_k - t_{k-1}}\,dt + \int_{t_k}^{t_{k+1}} G_{k+1}''\Big(\mathcal{G}_t''(\delta\ell, u)\Big)\,\nu_u(t)\,dt \\ &= -u_{k+1}G_k''\Big(\mathcal{G}_{t_k}''(\delta\ell, u)\Big) + u_{k+1}G_{k+1}''\Big(\mathcal{G}_{t_{k+1}}''(\delta\ell, u)\Big) \\ &= u_{k+1}\Big(G_{k+1}'' - G_k''\Big)\Big(\mathcal{G}_{t_k}''(\delta\ell, u)\Big). \end{aligned}$$

Equality (3.10) now follows thanks to the symplectic properties of the Hamiltonian flow. ∎

Let us remark that (3.7) characterizes those δe in $\mathcal{N}$, while (3.8) characterizes those in $V_k^{\perp_{J''}}$. In particular the extremals of the second variation are described by those $\delta\ell \in L_0''$, $u \in U$ such that $\mathcal{G}_T''(\delta\ell, u) \in L_T''$, and

$$\int_0^T G_t''\Big(\mathcal{G}_t''(\delta\ell, u)\Big)\,\nu_v(t)\,dt = 0 \quad \forall\ v \in U. \tag{3.11}$$

The relations between the second variation and the Hamiltonian of the original problem can be better understood by using the following map:

$$\boxed{\imath : T_{x_0}^*M \times T_{x_0}M \to T_{\ell_0}T^*M, \quad (\omega, \delta x) \mapsto -\omega + d(-\hat{\beta})_*\delta x}$$

It is easy to check that the map $\imath$ is an antisymplectic isomorphism

$$\boldsymbol{\sigma}\,(\imath\,\delta\ell_1, \imath\,\delta\ell_2\,) = -\boldsymbol{\sigma}\,(\delta\ell_1, \delta\ell_2\,) \tag{3.12}$$

and that it is an isomorphism between L_0'' and L_0 which acts as

$$\imath\,\delta\ell = d\alpha_*\pi_*\delta\ell.$$

The map $\imath$ connects the Hamiltonians associated with the second variation with the original ones through the following relation:

$$\imath\,\vec{G}_k'' = \widehat{\mathcal{H}}_{t_{k*}}^{-1}\vec{H}_k(\ell_k) = \widehat{\mathcal{H}}_{t_{k-1}*}^{-1}\vec{H}_k(\ell_{k-1}). \tag{3.13}$$

Equation (3.13) can be proved starting from the equality

$$\vec{G}''_k = \Big(-D\langle D\,\hat{\beta}, g_k\rangle(x_0),\, g_k(x_0)\Big)$$

and applying the map $\imath$ to obtain, in coordinates,

$$\imath\,\vec{G}''_k = \Big(d\hat{\beta}(x_0)\,Dg_k(x_0), g_k(x_0)\Big);$$

finally since $d\hat{\beta}(x_0) = -d\alpha(x_0)$, then (3.13) follows.

Thanks to the above properties of the map $\imath$ we can restate the *strict bang-bang Legendre condition* as

$$\boldsymbol{\sigma}\left(\vec{G}''_k,\, \vec{G}''_{k+1}\right) < 0, \quad k = 1, 2, \ldots, r. \tag{3.14}$$

The strict bang-bang Legendre condition allows us to solve recursively equation (3.11) with respect to the control, and hence we are able to define a discrete version of the Jacobi system by substituting this control back into (3.5). The resulting system is defined below, and its construction is described in the subsequent Lemma 3.4.

Definition 3.3. *Suppose that the strict bang-bang Legendre condition is satisfied and consider the discrete dynamical system on* $\mathbb{R} \times T^*(T_{x_0} M)$,

$$\begin{cases} \mathrm{w}_k = \dfrac{\boldsymbol{\sigma}\Big(\delta\ell_{k-1}, \vec{G}''_k - \vec{G}''_{k+1}\Big)}{\boldsymbol{\sigma}\Big(\vec{G}''_k, \vec{G}''_{k+1}\Big)}, \\ \\ \delta\ell_k = \delta\ell_{k-1} + (\vec{G}''_k - \vec{G}''_{k+1})\,\mathrm{w}_k. \end{cases}$$

For $k = 1, 2, \ldots, r$ *we define the flows of* w_k *and* $\delta\ell_k$ *as the linear functions*

$$\omega_k : L''_0 \to \mathbb{R}$$

and the symplectic isomorphisms

$$\mathcal{G}^k_T : L''_0 \to T^*_{x_0} M \times T_{x_0} M.$$

Lemma 3.4. *Suppose that the strict bang-bang Legendre condition is satisfied and let* $(\delta\ell, u) \in L''_0 \times U$*; then* (3.8) *holds if and only if*

$$u_i = \langle(\omega_i - \omega_{i-1}),\, \delta\ell\rangle, \quad i = 1, 2, \ldots, k,$$
$$\mathcal{G}''_{t_i}(\delta\ell, u) = \mathcal{G}^i_T(\delta\ell) + \langle\omega_i,\, \delta\ell\rangle\, \vec{G}''_{i+1}, \quad i = 1, 2, \ldots, k.$$

Proof. From the properties of the Hamiltonian flows, by integrating by parts equality (3.8), it follows that

$$\int_0^T G''_t\Big(\mathcal{G}''_t(\delta\ell, u)\Big)\,\nu_v(t)\,dt$$
$$= \sum_{i=1}^{k} v_i \left(G''_i\Big(\mathcal{G}''_{t_i}(\delta\ell, u)\Big) - G''_{k+1}\Big(\mathcal{G}''_{t_{k+1}}(\delta\ell, u)\Big)\right) = 0$$

for all $v \in U$ such that $v_j = 0,\ j \geq k+2$. Hence (3.8) is equivalent to

$$G''_1\Big(\mathcal{G}''_{t_1}(\delta\ell, u)\Big) = G''_2\Big(\mathcal{G}''_{t_2}(\delta\ell, u)\Big) = \cdots = G''_{k+1}\Big(\mathcal{G}''_{t_{k+1}}(\delta\ell, u)\Big).$$

If we compute explicitly

$$\Big(G''_i - G''_{i+1}\Big)(\mathcal{G}''_{t_{i-1}}(\delta\ell, u) + u_i\,\vec{G}''_i) = 0,$$

we obtain, for each $i = 1, 2, \dots, k$,

$$\boldsymbol{\sigma}\Big(\mathcal{G}''_{t_{i-1}}(\delta\ell, u) + u_i\,\vec{G}''_i, \vec{G}'''_i - \vec{G}'''_{i+1}\Big) = 0.$$

The equivalence now follows by finite induction and from Definition 3.3. □

Remark 3.5. Let us remark that being J''-orthogonal to V_k implies that the values of the control maps $u_1, u_2, \dots, u_k$ are uniquely determined by the value of $\delta\ell$. Moreover we obtain the flow of the Hamiltonian system of the second variation up to time t_k through the flow of the discrete bang-bang Jacobi system. More precisely, if we define the control $\mathrm{w}^k : L''_0 \to U$ as

$$\begin{cases} \mathrm{w}^k_i := (\omega_i - \omega_{i-1}), & i = 1, 2, \dots, k, \\ \mathrm{w}^k_{k+1} := -\omega_k, & \\ \mathrm{w}^k_i := 0, & i \geq k+2, \end{cases} \tag{3.15}$$

then from Lemma 3.4 it follows that this control is such that $(\delta\ell, \langle \mathrm{w}^k,\, \delta\ell\rangle)$ satisfies (3.8) and

$$\mathcal{G}^k_T(\delta\ell) = \mathcal{G}''_T(\delta\ell, \langle \mathrm{w}^k,\, \delta\ell\rangle).$$

A possible way to check the positivity of J'' on V_k is to study the behavior of J'' on $V_k \cap V_{k-1}^{\perp_{J''}}$. Thanks to the properties of the bang-bang Jacobi system the variations belonging to $V_k \cap V_{k-1}^{\perp_{J''}}$ and the values of J'' can be described through the following subspaces:

$$L''_k := \mathcal{G}^k_T\, L''_0.$$

The results are given in the two following lemmas. Let us notice that the first statement of the next lemma states that the extremals of J'' on V_k are the solutions of the Jacobi system that become vertical at step k and that the third statement characterizes the occurrence of a new variation.

Lemma 3.6. *Suppose that the strict bang-bang Legendre condition is satisfied. The following statements hold:*

1. *$\delta e = (\delta x, u) \in V_k \cap V_k^{\perp_{J''}}$ if and only if there exists $\delta\ell \in L''_0$ such that*

$$\pi_*\delta\ell = \delta x, \quad u = \langle \mathrm{w}^k,\, \delta\ell\rangle, \quad \mathcal{G}^k_T(\delta\ell) \in \Pi.$$

2. *$\delta e \in V_k \cap V_{k-1}^{\perp_{J''}}$ if and only if there exists $\delta\ell \in L''_0$ such that*

$$\pi_*\delta\ell = \delta x, \quad u_j = \langle \mathrm{w}^{k-1}_j,\, \delta\ell\rangle, \quad j = 1, 2, \dots, k-1,$$
$$\mathcal{G}^{k-1}_T(\delta\ell) - u_{k+1}\,(\vec{G}''_k - \vec{G}''_{k+1}) \in \Pi,$$

and in this case we have that

$$J''[\delta e]^2 = \boldsymbol{\sigma}\Big(\mathcal{G}^{k-1}_T(\delta\ell) - u_{k+1}\vec{G}''_k, -u_{k+1}(\vec{G}''_k - \vec{G}'''_{k+1})\Big). \tag{3.16}$$

3. *If* $J''_{|V_{k-1}} > 0$, *then* $V_k = V_{k-1}$ *if and only if* $\vec{G}''_k - \vec{G}''_{k+1} \notin L''_{k-1} + \Pi$.
4. *If* $\delta\ell_{k-1} \in L''_{k-1}$ *and* $\delta\ell_k \in L''_k \setminus L''_{k-1}$ *are such that*

$$\pi_* \delta\ell_{k-1} = \pi_* \delta\ell_k,$$

then there exists a nontrivial $\delta e \in V_k \cap V_{k-1}^{\perp_{J''}}$ *such that*

$$J[\delta e]^2 = \boldsymbol{\sigma}\left(\delta\ell_k,\, \delta\ell_{k-1}\right).$$

Proof. 1. From (3.7) and (3.8) and from the properties of the control (3.15) it follows that

$$u = \langle \mathrm{w}^k,\, \delta\ell \rangle \quad \text{and} \quad \mathcal{G}''_T(\delta\ell, u) = \mathcal{G}^k_T(\delta\ell) \in \Pi.$$

2. Letting $\delta e \in V_k \cap V_{k-1}^{\perp_{J''}}$ be the first part is an immediate consequence of Lemmas 3.1 and 3.4. Once again from the properties of the control (3.15) we have that

$$\begin{aligned}\mathcal{G}''_{t_{k+1}}(\delta\ell, u) &= \mathcal{G}^{k-1}_T(\delta\ell) + \langle \omega_{k-1},\, \delta\ell \rangle\, \vec{G}''_k + u_k\, \vec{G}''_k + u_{k+1}\, \vec{G}''_{k+1} \\ &= \mathcal{G}^{k-1}_T(\delta\ell) - u_{k+1}\,(\vec{G}''_k - \vec{G}''_{k+1}).\end{aligned}$$

From (3.10) it follows that

$$\begin{aligned}J''[\delta e]^2 &= \boldsymbol{\sigma}\Big(\mathcal{G}''_{t_k}(\delta\ell, u),\, -u_{k+1}(\vec{G}''_k - \vec{G}''_{k+1})\Big) \\ &= \boldsymbol{\sigma}\Big(\mathcal{G}^{k-1}_T(\delta\ell) - u_{k+1}\vec{G}''_k, -u_{k+1}(\vec{G}''_k - \vec{G}''_{k+1})\Big).\end{aligned}$$

3. $\vec{G}''_k - \vec{G}''_{k+1} \notin L''_{k-1} + \Pi$ if and only if

$$\mathcal{G}^{k-1}_T(\delta\ell) - u_{k+1}\,(\vec{G}''_k - \vec{G}''_{k+1}) \in \Pi \Rightarrow u_{k+1} = 0.$$

From statement 2 we have that $J[\delta e]^2 = 0$, and hence the statement follows.

4. By definition there are $\delta\ell_0,\, \delta\ell_1 \in L''_0$ such that

$$\delta\ell_{k-1} = \mathcal{G}^{k-1}_T(\delta\ell_0), \quad \delta\ell_k = \mathcal{G}^k_T(\delta\ell_1).$$

From the assumptions we have that

$$\mathcal{G}^k_T(\delta\ell_1) - \mathcal{G}^{k-1}_T(\delta\ell_0) = \mathcal{G}^{k-1}_T(\delta\ell_1) - \mathcal{G}^{k-1}_T(\delta\ell_0) + \langle \omega_k, \delta\ell_1 \rangle\, (\vec{G}''_k - \vec{G}''_{k+1}) \in \Pi.$$

If we define $\delta\ell := \delta\ell_1 - \delta\ell_0$ and $\delta e := (\pi_*\delta\ell, \langle \mathrm{w}^k,\, \delta\ell_1 \rangle - \langle \mathrm{w}^{k-1},\, \delta\ell_0 \rangle)$, then we have that $u_{k+1} = -\langle \omega_k, \delta\ell_1 \rangle$, and from statement 2 we have that $\delta e \in V_k \cap V_{k-1}^{\perp_{J''}}$, and it is nontrivial because if $u_{k+1} = 0$, then $\delta\ell_k \in L''_{k-1}$. Moreover we have that

$$\begin{aligned}J''[\delta e]^2 &= \boldsymbol{\sigma}\left(\mathcal{G}^{k-1}_T(\delta\ell_1 - \delta\ell_0) - u_{k+1}\,\vec{G}''_k,\, -u_{k+1}(\vec{G}''_k - \vec{G}''_{k+1})\right) \\ &= \boldsymbol{\sigma}\left(-\mathcal{G}^{k-1}_T(\delta\ell_0),\, \mathcal{G}^k_T(\delta\ell_1)\right) + \boldsymbol{\sigma}\left(\mathcal{G}^{k-1}_T(\delta\ell_0),\, \mathcal{G}^{k-1}_T(\delta\ell_1)\right) \\ &\quad - u_{k+1}\,\boldsymbol{\sigma}\left(\mathcal{G}^{k-1}_T(\delta\ell_1) + \langle \omega_k,\, \delta\ell_1 \rangle\, \vec{G}''_k,\, \vec{G}''_k - \vec{G}''_{k+1}\right).\end{aligned}$$

The final statement now follows because the second addend is zero since both the arguments belong to the same Lagrangian subspace L''_{k-1} and the third one is zero by the properties of ω_k. ∎

LEMMA 3.7. *$J''_{|V} > 0$ if and only if one of the following statements holds for each $k = 1, 2, \dots, r$:*

1. $\vec{G}''_k - \vec{G}''_{k+1} \notin L''_{k-1} + \Pi$.
2. $\vec{G}''_k - \vec{G}''_{k+1} \in L''_{k-1}$.
3. $L''_k \cap \Pi \subseteq L''_{k-1} \cap \Pi$ *and for all* $\delta\ell_k \in L''_k$ *and* $\delta\ell_{k-1} \in L''_{k-1}$ *such that* $\pi_* \delta\ell_k = \pi_* \delta\ell_{k-1}$, *we have that* $\boldsymbol{\sigma}(\delta\ell_k, \delta\ell_{k-1}) \geq 0$.

Proof. The idea of the proof is the following: we first show that these conditions together with $J''_{|V_{k-1}} > 0$ imply that

$$J''_{|V_k \cap V_{k-1}^{\perp_{J''}}} > 0$$

and hence $J''_{|V_k} > 0$; since $V_0 = \{0\}$, then the lemma will follow by finite induction on k. Let us show that the induction step is valid for each k if and only if one of the statements of the lemma holds.

Assume that $J''_{|V_{k-1}} > 0$.

- From statement 2 of Lemma 3.6 it follows that $\vec{G}''_k - \vec{G}''_{k+1} \notin L''_{k-1} + \Pi$ is equivalent to $V_k \cap V_{k-1}^{\perp_{J''}} = \{0\}$ and the induction step is trivial.
- If $\vec{G}''_k - \vec{G}''_{k+1} \in L''_{k-1}$, then $L''_k = L''_{k-1}$; moreover we can choose $u_{k+1} = 1$ in part 2 of Lemma 3.6 to show that $V_k \cap V_{k-1}^{\perp_{J''}} \neq \{0\}$ to obtain a nontrivial $\delta e \in V_k \cap V_{k-1}^{\perp_{J''}}$ such that

$$\begin{aligned} J''[\delta e]^2 &= \boldsymbol{\sigma}\Big(\mathcal{G}_T^{k-1}(\delta\ell) - \vec{G}''_k, -(\vec{G}''_k - \vec{G}''_{k+1})\Big) \\ &= \boldsymbol{\sigma}\Big(\vec{G}''_{k+1}, \vec{G}''_k\Big). \end{aligned}$$

  Equation (3.14) completes the proof.
- If $\vec{G}''_k - \vec{G}''_{k+1} \in \{L''_{k-1} + \Pi\} \setminus L''_{k-1}$, then $\dim V_k \cap V_{k-1}^{\perp_{J''}} = 1$. From the first statement of Lemma 3.6 it follows that the condition $L''_k \cap \Pi \subseteq L''_{k-1} \cap \Pi$ is equivalent to

$$V_k \cap V_k^{\perp_{J''}} = V_{k-1} \cap V_{k-1}^{\perp_{J''}} = \{0\},$$

  and hence it will be enough to prove that $J''_{|V_k \cap V_{k-1}^{\perp_{J''}}} \geq 0$.

Under our assumptions there is $\delta\ell \in L''_{k-1}$ such that $\langle \omega_k, \delta\ell \rangle = 1$. If we set

$$\delta\ell_k := \delta\ell + (\vec{G}''_k - \vec{G}''_{k+1}) \in L''_k,$$

then we can find $\delta\ell_{k-1} \in L''_{k-1}$ such that $\pi_* \, \delta\ell_{k-1} = \pi_* \, \delta\ell_k$. From the fourth statement of Lemma 3.6 it follows that

$$J[\delta e]^2 = \boldsymbol{\sigma}\left(\delta\ell_k, \delta\ell_{k-1}\right).$$

Since $\dim V_k \cap V_{k-1}^{\perp_{J''}} = 1$ then $J_{|V_k \cap V_{k-1}^{\perp_{J''}}} \geq 0$ if and only if $\boldsymbol{\sigma}\left(\delta\ell_k, \delta\ell_{k-1}\right) \geq 0$. ∎

LEMMA 3.8. *Assume that $J''_{|V} > 0$; then the quadratic form $J''_{|\mathcal{N} \cap V^{\perp_{J''}}}$ is positive definite if and only if for every $\delta\ell \in L''_0$ and $\delta\ell_T \in L''_T$ such that*

$$\pi_* \, \delta\ell_T = \pi_* \, \mathcal{G}_T^r(\delta\ell) \neq 0$$

we have

$$\boldsymbol{\sigma}(\delta\ell_T, \mathcal{G}^r_T(\delta\ell)) > 0.$$

Proof. From Lemma 3.1 and the properties of the control w^k (see (3.15)), we have that $\delta e = (\delta x, u) \in \mathcal{N} \cap V^{\perp_{J''}}$ if and only if there is $\delta\ell \in L_0''$ such that

$$\pi_*\delta\ell = \delta x, \quad u = \langle \mathrm{w}^r, \delta\ell\rangle, \quad \pi_*\mathcal{G}^r_T(\delta\ell) \in \pi_* L''_T.$$

If $\pi_*\mathcal{G}^r_T(\delta\ell) = 0$, then $\delta e \in V \cap V^{\perp_{J''}}$ and hence $\delta e = 0$; otherwise we can use equation (3.9). □

3.1. The algorithm. We have essentially already shown that the algorithm can be used to check the positivity of the second variation at the switching points. This can be easily seen since from (3.12), (3.13), it follows that

$$L_k^- = \widehat{\mathcal{H}}_{t_{k*}} \imath\, L''_{k-1} \quad \text{for } k = 1, 2, \dots, r+1,$$
$$L_k^+ = \widehat{\mathcal{H}}_{t_{k*}} \imath\, L''_k \quad \text{for } k = 1, 2, \dots, r.$$

Moreover STEP 3 follows from Lemma 3.7, while STEP 4 follows from Lemma 3.8, taking into account (3.12).

4. Proof of the theorem. In order to demonstrate the Hamiltonian method we now give the proof of our main result step by step following the approach described in the introduction.

All the proofs make strong use of the properties (see [Arn80]) of the Poincaré–Cartan form $\boldsymbol{\omega} = \boldsymbol{s} - H\,dt$ on $I \times T^*M$ associated to the Hamiltonian H. Namely,

- $\boldsymbol{\omega}$ evaluated along a lift of a solution of (2.1) is nonpositive and it is zero along $\hat{\lambda}$;
- $\boldsymbol{\omega}$ is exact on the Legendre submanifold generated by the flow of $\vec{H}$ emanating from a Lagrangian submanifold.

4.1. Flow properties. The first step shows that our assumptions guarantee that the flow of the maximized Hamiltonian is locally well defined and piecewise C^∞ and describes the structure of the switching surfaces.

LEMMA 4.1. *There exists a neighborhood $\mathcal{U}$ of ℓ_0 such that we can define recursively for $i = 1, \dots, r$ the C^∞-maps*

$$\tau_i : \mathcal{U} \to \mathbb{R} \quad \textit{and} \quad \phi_i : \mathcal{U} \to T^*M$$

in the following way: set

$$\tau_0 := 0, \quad \phi_0 := Id.$$

The τ_i's are implicitly defined by

$$\begin{cases} (H_i - H_{i+1})\left(\exp \tau_i(\ell)\vec{H}_i(\phi_{i-1}(\ell))\right) = 0, \\ \tau_i(\ell_i) = t_i, \end{cases}$$

while the ϕ_i's are defined as

$$\phi_i := \ell \mapsto \exp(-\tau_i(\ell)\vec{H}_{i+1}) \circ \exp \tau_i(\ell)\vec{H}_i\,(\phi_{i-1}(\ell)).$$

The neighborhood $\mathcal{U}$ can be chosen such that

$$\sup_{\ell\in\mathcal{U}} \tau_i(\ell) < \inf_{\ell\in\mathcal{U}} \tau_{i+1}(\ell), \tag{4.1}$$

and the ϕ_i's are C^∞ symplectic diffeomorphisms.

Proof. Thanks to the strict bang-bang Legendre condition we can apply the implicit function theorem to show that the τ_i's are well defined and C^∞. Therefore, by continuity, we can guarantee that (4.1) holds. Let us show by induction that ϕ_i's are symplectic diffeomorphisms. From the definition of the τ_i's we have that

$$\boldsymbol{\sigma}\left(\vec{H}_i, \vec{H}_{i+1}\right) d\,\tau_i(\ell) = \boldsymbol{\sigma}\left((\exp \tau_i(\ell)\vec{H}_i)_* \phi_{i-1\,*}, \vec{H}_i - \vec{H}_{i+1}\right), \tag{4.2}$$

and from the definition of the ϕ_i's we have that

$$\begin{aligned} \phi_{i*} &= \exp(-\tau_i(\ell)\vec{H}_{i+1})_* \exp(\tau_i(\ell)\vec{H}_i)_* \phi_{i-1\,*} \\ &+\Big\{\exp(-\tau_i(\ell)\vec{H}_{i+1})_* \vec{H}_i\Big(\exp(\tau_i(\ell)\vec{H}_i(\phi_{i-1}(\ell))\Big) - \vec{H}_{i+1}(\phi_i(\ell))\Big\} d\,\tau_i(\ell). \end{aligned} \tag{4.3}$$

The result now follows from (4.2) and from the general fact that $\exp(s\,\vec{G})$ is a symplectic diffeomorphism for any Hamiltonian vector field $\vec{G}$. ∎

Let $\mathcal{U}$ be the neighborhood of ℓ_0 given in Lemma 4.1. If we set

$$\mathcal{O}_i := \Big\{(t,\ell) \mid \ell\in\mathcal{U},\ \tau_{i-1}(\ell) \le t \le \tau_i(\ell)\Big\} \subseteq [0,T]\times T^*M,$$

then the $\mathcal{O}_i$'s are $2\,n+1$-dimensional C^∞ submanifolds with boundary $\partial\mathcal{O}_i = S_{i-1}\cup S_i$, where

$$S_i := \mathcal{O}_i \cap \mathcal{O}_{i+1} = \Big\{(\tau_i(\ell),\ell)\ ,\quad \ell\in\mathcal{U}\Big\}.$$

From Lemma 4.1 we can easily deduce the following.

Corollary 4.2. *Under Assumptions* 2.1, 2.2, *and* 2.3 *the Hamiltonian system*

$$\begin{aligned} \dot\lambda(t) &= \vec{H}(\lambda(t)), \\ \lambda(0) &= \ell \end{aligned}$$

has a unique solution, which can be represented on $[0,T]\times\mathcal{U}$ by the map $\mathcal{H} : (t,\ell)\mapsto (t,\mathcal{H}_t(\ell))$ given by

$$\mathcal{H}_t(\ell) = \exp t\vec{H}_{i+1}(\phi_i(\ell)), \quad t\in[\tau_i(\ell),\tau_{i+1}(\ell)], \tag{4.4}$$

where $\tau_{r+1}\equiv T$; moreover the flow $\mathcal{H}$ is C^∞ on each $\mathcal{O}_i$.

Let us remark that every solution of the Hamiltonian system (4.4) has the same number of switches as the reference trajectory $\hat\xi$; moreover, from the above equation (4.4), we can deduce that for $t\in[\tau_{i-1}(\ell),\tau_i(\ell)]$ we can write

$$\mathcal{H}_t(\ell) = \exp(t-\tau_{i-1}(\ell))\vec{H}_i \circ\cdots\circ \exp(\tau_2(\ell)-\tau_1(\ell))\vec{H}_2 \circ \exp\tau_1(\ell)\vec{H}_1\,(\ell)$$

and the ϕ_i's can be written as

$$\phi_i(\ell) = \exp(-\tau_i(\ell)\vec{H}_{i+1}) \circ \mathcal{H}_{\tau_i(\ell)}\,(\ell).$$

Remark 4.3. We can interpret Lemma 4.1 as saying that, thanks to the strict bang-bang Legendre condition, we can define, in a tube around the adjoint covector, a time-dependent maximized Hamiltonian as

$$(t,\ell) \mapsto H_i(t,\ell) \quad \text{if} \quad \mathcal{H}^{-1}(t,\ell) \in \mathcal{O}_i.$$

This Hamiltonian switches from one vector field to another when its flow crosses the switching surfaces and hence when changing the vector field results in an energy increase. Assumptions 2.1 and 2.2 ensure that with this choice we obtain the maximized Hamiltonian.

4.2. Hamiltonian methods. For a general introduction to the use of these methods and their application to optimal control, we refer to [AG90, AG97].

Without loss of generality we can assume that $\Lambda_0 \subseteq \mathcal{U}$ and that Λ_0 is a smooth simply connected Lagrangian submanifold; if necessary we take the restriction to a neighborhood of x_0. Define

$$\Omega_i := \Big\{(t,\ell) \in \mathcal{O}_i \mid \ell \in \Lambda_0\Big\}, \quad \Sigma_i := \Omega_i \cap \Omega_{i+1},$$

and

$$\Omega := \bigcup_{i=1}^{r+1} \Omega_i.$$

The Ω_i's are $n+1$-dimensional C^∞ submanifolds with boundary $\partial\Omega_i = \Sigma_{i-1} \cup \Sigma_i$.

From (4.4) it follows that $\mathcal{H}_t(\Lambda_0)$ is a Lagrangian submanifold, although it might be not C^1 at the switching surfaces. We now investigate the properties of the Cartan form $\boldsymbol{\omega}$ and of the map

$$\pi_t := \pi \circ \mathcal{H}_t : \Lambda_0 \mapsto M.$$

LEMMA 4.4. *The form $\mathcal{H}^*\boldsymbol{\omega}$ is closed on each Ω_i and hence exact on Ω so that it can be written as*

$$\mathcal{H}^*\boldsymbol{\omega} = d\,\vartheta,$$

where ϑ is a continuous function on $[0,T] \times \Lambda_0$, which is C^∞ on each Ω_i. Moreover ϑ can be chosen such that

$$\vartheta(0,\cdot) := \vartheta_0 = \alpha \circ \pi.$$

If π_t is Lipschitz invertible, then

$$d(\vartheta_t \circ \pi_t^{-1}) = \mathcal{H}_t \circ \pi_t^{-1}.$$

Proof. The proof of the first statement is a standard consequence of the properties of $\boldsymbol{\omega}$ (see [Arn80]).

Let $\gamma : [a,b] \to M$ be a Lipschitz curve; then from the first part of the lemma it follows that

$$\int_\gamma \mathcal{H}_t \circ \pi_t^{-1} = \int_{\mathcal{H}_t \circ \pi_t^{-1} \circ \gamma} \boldsymbol{s} = \int_{\pi_t^{-1} \circ \gamma} \mathcal{H}_t^*\,\boldsymbol{s} = \vartheta_t \circ \pi_t^{-1}\Big|_{\gamma(a)}^{\gamma(b)},$$

and the statement follows. ∎

If $\lambda : [0,T] \to T^*M$ is a Lipschitz lift of a solution ξ of equation (2.1) such that $(t,\lambda(t)) \in \Omega$ for $t \in [0,T]$, then

$$\int_\lambda \boldsymbol{\omega} \le 0 \quad \text{and} \quad \int_{\hat\lambda} \boldsymbol{\omega} = 0 \tag{4.5}$$

because $\boldsymbol{\omega}$ is defined by the maximized Hamiltonian H. From this property and by the previous lemma, we obtain that

$$J(\pi\lambda) - J(\hat\xi) \ge \vartheta_T\Big(\mathcal{H}_T^{-1}(\lambda(T))\Big) - \vartheta_T(\ell_0) + \beta(\xi(T)) - \beta(x_T). \tag{4.6}$$

Hence, as we mentioned in the introduction, the variation of the cost is estimated from below by the function $\vartheta_T + \beta \circ \pi$, which depends only on the final point.

Let us remark that if π_T is invertible, then the same estimate can be obtained by the function

$$\chi := \vartheta_T \circ \pi_T^{-1} + \beta.$$

For this function, Lemma 4.4 and the transversality conditions imply that

$$d\,\chi(x_T) = 0.$$

4.3. An equivalent free initial point problem. To be able to lift to Ω any trajectory in a neighborhood of the reference one, we need that π_t is locally onto for each t and in particular for $t = 0$. This last condition can be fulfilled by constructing an equivalent problem with a free initial point. Let Q be any nonnegative quadratic form on $T_{x_0}M$, whose nullity is $T_{x_0}N_0$. We extend it to $T_{x_0}M \times \mathbb{R}^r$ by setting $Q[\delta x, \epsilon]^2 = Q[\delta x]^2$. If the quadratic form J'' is positive on $\mathcal{N}$, then we can find $\rho > 0$ such that

$$J'' + \frac{1}{2}\,\rho\, Q > 0 \quad \text{on } \Big\{(\delta x, \varepsilon) \in T_{x_0}M \times \mathbb{R}^r : S_{T*}(\delta x, \varepsilon) \in T_{x_T}N_T\Big\},$$

as can be easily proved by elementary arguments of linear algebra. Let us choose a function α_ρ such that

$$\begin{aligned} \alpha_\rho &= \alpha \quad \text{on } N_0, \\ d\alpha_\rho &= d\alpha \quad \text{on } T_{x_0}N_0, \\ D^2\alpha_\rho(x_0) &= D^2\alpha(x_0) + \rho\, Q \end{aligned}$$

and consider the problem

$$\text{Minimize} \quad \alpha_\rho(\xi(0)) + \beta(\xi(T)) \tag{4.7}$$

subject to

$$\begin{gathered} \dot\xi(t) = \sum_{i=1}^m u_i(t)\, X_i(\xi(t)), \quad u \in \Delta, \\ \xi(T) \in N_T. \end{gathered}$$

Since the reference trajectory satisfies the initial boundary conditions, then proving that it is optimal for this new problem yields its optimality for the original one. Therefore without loss of generality we can assume that the original problem has already free

initial point, i.e., $N_0 \equiv M$ and $\alpha \equiv \alpha_\rho$; in this case the initial Lagrangian submanifold is horizontal and its projection covers a neighborhood of the initial point x_0.

Remark 4.5. This reduction is possible because the new cost on the initial point contains an exact penalty which can be constructed assuming that the second variation is positive definite.

Let us now see which properties of the symplectic map $\mathcal{H}_{t*} : T_{\ell_0}\Lambda_0 \to T_{\hat\lambda(t)}M$ lead to the optimality of $\hat\xi$. Let us remark that (4.4) yields, for $\delta\ell \in L_0$,

$$\mathcal{H}_{t*}(\delta\ell) = (\exp t\vec{H}_{i+1})_*\phi_{i*}\delta\ell \quad \text{for } t \in (t_i, t_{i+1}), \tag{4.8}$$

$$\mathcal{H}_{t_i\,*}(\delta\ell) = \begin{cases} (\exp t_i\vec{H}_i)_*\phi_{i-1\,*}\delta\ell & \text{for } \langle d\,\tau_i(\ell_0), \delta\ell\rangle \le 0, \\ (\exp t_i\vec{H}_{i+1})_*\phi_{i*}\delta\ell & \text{for } \langle d\,\tau_i(\ell_0), \delta\ell\rangle \ge 0. \end{cases} \tag{4.9}$$

Remark 4.6. By (4.2) and (4.3) one can easily see that $L_k^- = (\exp t_k\vec{H}_k)_*\phi_{k-1\,*}\,L_0$ and $L_k^+ = (\exp t_k\vec{H}_{k+1})_*\phi_{k*}$; therefore L_k^- and L_k^+ are tangent to $\mathcal{H}_{t_k}(L_0)$ from the left and from the right, respectively. Moreover if $d\,\tau_k(\ell_0)_{|L_0} = 0$, then the flow is differentiable at (t_k, ℓ_0).

LEMMA 4.7. *If the map $\pi_*\,\mathcal{H}_{t*} : L_0 \to T_{\hat\xi(t)}M$ is onto for $t \in [0,T]$, then there exists a neighborhood $\mathcal{V} \subseteq \Lambda_0$ of ℓ_0 such that $[0,T]\times\mathcal{V}$ is mapped by $\pi\,\mathcal{H}$ onto a neighborhood of $\hat\xi$ in $[0,T]\times M$ and $\pi\,\mathcal{H}$ has a piecewise C^∞ local inverse. Without loss of generality we set $\mathcal{V} = \Lambda_0$.*

Proof. Thanks to the invertibility assumption on $\pi_*\,\mathcal{H}_{t_i\,*}$ and by possibly taking a smaller neighborhood of ℓ_0, we can apply the inverse function theorem on each submanifold with boundary Ω_i to show that the image under $\pi\,\mathcal{H}$ of Ω is a neighborhood of $\hat\xi$ in $[0,T]\times M$. □

THEOREM 4.8. *The equality*

$$\pi_*\mathcal{H}_{t*}\,L_0 = T_{\hat\xi(t)}M$$

holds for $t \in [0,T]$ if and only if the following statements hold for $i = 1, 2, \dots, r$:

1. $\pi_*\phi_{i*}L_0 = T_{x_0}M$.
2. *If $\delta\ell_1,\ \delta\ell_2 \in L_0$ are such that*

$$\pi_*\left[(\exp t_i\vec{H}_i)_*\phi_{i-1\,*}\delta\ell_1\right] = \pi_*\left[(\exp t_i\vec{H}_{i+1})_*\phi_{i*}\delta\ell_2\right],$$

then

$$\boldsymbol{\sigma}\left((\exp t_i\vec{H}_i)_*\phi_{i-1\,*}\delta\ell_1, (\exp t_i\vec{H}_{i+1})_*\phi_{i*}\delta\ell_2\right) \ge 0.$$

Proof. Since $\exp t\vec{H}_i$ transforms horizontal submanifolds into horizontal submanifolds, then (4.8)–(4.9) imply that the map $\pi_*\,\mathcal{H}_{t*}$ is onto for $t \in [0,T]$ if and only if it is onto for $t = t_i,\ i = 1, 2, \dots, r$.

Let us now check that conditions 1 and 2 are equivalent to

$$\pi_*\mathcal{H}_{t_i*}\,L_0 = T_{\hat\xi(t_i)}M. \tag{4.10}$$

If $d\,\tau_i(\ell_0) = 0$ on L_0, then the maps $(\exp t_i\vec{H}_i)_*\phi_{i-1\,*}$ and $(\exp t_i\vec{H}_{i+1})_*\phi_{i*}$ coincide, and hence (4.10) is equivalent to condition 1, and moreover condition 2 holds with the equality sign.

Otherwise we have that (4.10) holds if and only if

$$\pi_* \phi_{i-1\,*} L_0 = \pi_* \phi_{i*} L_0 = T_{x_0} M$$

and the two half-spaces

$$\left\{ \pi_* (\exp t_i \vec{H}_i)_* \phi_{i-1\,*} \delta\ell,\ \langle d\,\tau_i(\ell_0), \delta\ell \rangle \le 0 \right\},$$
$$\left\{ \pi_* (\exp t_i \vec{H}_{i+1})_* \phi_{i*} \delta\ell,\ \langle d\,\tau_i(\ell_0), \delta\ell \rangle \ge 0 \right\}$$

do not coincide. To check this we can show that for every $\delta\ell_1,\ \delta\ell_2 \in L_0$ such that

$$\pi_* \left[(\exp t_i \vec{H}_i)_* \phi_{i-1\,*} \delta\ell_1 \right] = \pi_* \left[(\exp t_i \vec{H}_{i+1})_* \phi_{i*} \delta\ell_2 \right]$$

one has

$$\langle d\,\tau_i(\ell_0), \delta\ell_1 \rangle \, \langle d\,\tau_i(\ell_0), \delta\ell_2 \rangle \ge 0.$$

By (4.3) we obtain that

$$\boldsymbol{\sigma} \left((\exp t_i \vec{H}_i)_* \phi_{i-1\,*} \delta\ell_1, (\exp t_i \vec{H}_{i+1})_* \phi_{i*} \delta\ell_2 \right)$$
$$= \boldsymbol{\sigma} \left((\exp t_i \vec{H}_i)_* \phi_{i-1\,*} \delta\ell_1, (\vec{H}_i - \vec{H}_{i+1})(\ell_i) \right) \langle d\,\tau_i(\ell_0), \delta\ell_2 \rangle.$$

Finally by the strict bang-bang Legendre condition and by (4.2) we obtain that

$$\boldsymbol{\sigma} \left((\exp t_i \vec{H}_i)_* \phi_{i-1\,*} \delta\ell_1, (\vec{H}_i - \vec{H}_{i+1})(\ell_i) \right)$$

has the same sign as $\langle d\,\tau_i(\ell_0), \delta\ell_1 \rangle$, and the statement is proved. ∎

Remark 4.9. Theorem 4.8 states that in the bang-bang case, a *conjugate point* can occur only at a switching time; moreover condition 1 states that the projection has full dimension, while condition 2 says that there is not a fold.

THEOREM 4.10. *Let the map* $\pi_* \mathcal{H}_{t*} : L_0 \to T_{\hat{\xi}(t)} M$ *be onto for* $t \in [0, T]$. *If the form*

$$\delta x \mapsto \boldsymbol{\sigma} \Big(d(\vartheta_T \circ \pi_T^{-1})_* \delta x, d(-\beta)_* \delta x \Big) = \boldsymbol{\sigma} \left((\mathcal{H}_T \circ \pi_T^{-1})_* \delta x, d(-\beta)_* \delta x \right)$$

is positive definite on $T_{x_T} N_T$, *then* $\hat{\xi}$ *is a strict strong local minimizer for the problem* (P).

Proof. By (4.6) if we prove that x_T is a local minimizer on N_T of $\chi = \vartheta_T \circ \pi_T^{-1} + \beta$, then $\hat{\xi}$ is a strong local minimizer for the problem (P). As we pointed out before, $d\,\chi(x_T) = 0$; thus the second derivative of χ is well defined at x_T, and we have that

$$D^2\,\chi(x_T)[\delta x]^2 = \boldsymbol{\sigma} \left(d(\vartheta_T \circ \pi_T^{-1})_* \delta x, d(-\beta)_* \delta x \right),$$

which ends the first part of the proof.

Let us now prove that the minimum is locally uniquely attained. First of all let us notice that under our assumptions $\hat{\xi}(T)$ is a strict local minimum for the function χ. Assume now by contradiction that there exists another admissible trajectory ξ with the same cost and the same final point $\xi(T) = \hat{\xi}(T)$; denote by $\lambda := t \mapsto \pi_t^{-1}(\xi(t))$ its lift. By (4.6) and (4.5) we have that

$$\int_\lambda \boldsymbol{\omega} = 0;$$

thus, since H is the maximized Hamiltonian, we have that

$$\langle \mathcal{H}_t(\lambda(t)), \dot{\xi}(t)\rangle - H(\mathcal{H}_t(\lambda(t))) = 0 \quad \text{a.e. } t \in [0,T].$$

Thanks to Assumption 2.1, for all t such that $(t,\lambda(t)) \in \operatorname{int} \Omega_i$ we have that

$$\dot{\xi}(t) = h_i(\xi(t));$$

this equation yields that

$$\dot{\lambda}(t) = 0,$$

and hence, from inequality (4.1), it follows that $\lambda(t)$ is constant, say k_i, for $t \in [\tau_{i-1}(k_i), \tau_i(k_i)]$. When $\tau_i(k_i) \le t \le \tau_i(k_{i+1})$ we have that $(t,\lambda(t)) \in \Sigma_i$, and hence there is $\mu \in [0,1]$ such that

$$\dot{\xi}(t) = (1-\mu)h_{i+1}(\xi(t)) + \mu h_i(\xi(t)).$$

For $t \in [\tau_r(k_r), T]$ we have that $\lambda(t) \in \Omega_{r+1}$, and hence λ is as smooth as ξ; moreover on the last time interval $[t_r, T]$ we have that $\lambda(t) = \ell_0$. Let us now show that λ cannot remain on the switching surface for a time interval of positive measure or, equivalently, that $\tau_r(k_r) = t_r$. By contradiction, if $k_r \neq \ell_0$, then

$$(t,\xi(t)) \in \pi\mathcal{H}(\Sigma_r) \subseteq \pi\mathcal{H}(\Omega_{r+1}), \quad t \in [\tau_r(k_r), t_r].$$

If we differentiate the identities

$$t = \tau_r(\lambda(t)), \quad \pi\mathcal{H}_t(\lambda(t)) = \xi(t),$$

we obtain, a.e. $t \in [\tau_r(k_r), t_r]$,

$$\langle d\,\tau_r(\lambda(t)), \dot{\lambda}(t)\rangle = 1, \quad \dot{\xi}(t) = h_{r+1}(\xi(t)) + \pi_* \mathcal{H}_{t\,*}\dot{\lambda}(t). \tag{4.11}$$

From Assumption 2.2 it follows that for a.a. $t \in [\tau_r(k_r), t_r]$ there exists $\mu_t \in [0,1]$ such that

$$\dot{\xi}(t) = (1-\mu_t)\, h_{r+1}(\xi(t)) + \mu_t\, h_r(\xi(t)),$$

and hence

$$\pi_* \mathcal{H}_{t\,*}\dot{\lambda}(t) = \mu_t \Big(h_r(\xi(t)) - h_{r+1}(\xi(t)) \Big).$$

Since $\dot{\lambda}(t)$ and μ_t are bounded we can take a sequence $t_i \to t_r$ such that $\dot{\lambda}(t_i) \to \delta\ell \in L_0$ and $\mu_{t_i} \to \mu$. Taking into account (4.11) we can say that $\delta\ell \neq 0$, and since we have that $\pi_* \mathcal{H}_{t_r\,*}$ is injective, then from

$$\pi_* \mathcal{H}_{t_r\,*}\delta\ell = \mu \Big(h_r(\xi(t_r)) - h_{r+1}(\xi(t_r)) \Big)$$

it follows that also $\mu \neq 0$. On the other hand from (4.4) and (4.3) we obtain

$$\begin{aligned} \pi_* \left(\exp t_r \vec{H}_r \right)_* \phi_{r-1\,*}\delta\ell &= \pi_* \mathcal{H}_{t_r\,*}\delta\ell - \Big(h_r(\xi(t_r)) - h_{r+1}(\xi(t_r)) \Big) \\ &= (\mu - 1) \Big(h_r(\xi(t_r)) - h_{r+1}(\xi(t_r)) \Big). \end{aligned}$$

Once again the last term has to be nonzero. If we set $\delta\ell_1 := \frac{\mu}{\mu-1}\delta\ell$, then

$$\langle d\,\tau_r(\ell_0), \delta\ell\rangle \, \langle d\,\tau_r(\ell_0), \delta\ell_1\rangle = \frac{\mu}{\mu-1} < 0,$$

and from Theorem 4.8 we obtain a contradiction. Therefore $k_r = \ell_0$, and hence $\tau_r(k_r) = \tau_r(\ell_0) = t_r$. We can do the same proof on each interval proceeding backwards in time to prove that the trajectory is constant. ∎

4.4. The proof. As we pointed out in Remark 4.6 if we have a regular bang-bang extremal with simple switching times and the strict bang-bang Legendre condition is satisfied, then

$$L_k^- = (\exp t_k \vec{H}_k)_* \varphi_{k-1\,*}\, L_0 \quad \text{for } k = 1, 2, \dots, r+1,$$
$$L_k^+ = (\exp t_k \vec{H}_{k+1})_* \varphi_{k\,*}\, L_0 \quad \text{for } k = 1, 2, \dots, r.$$

On the other hand we are considering a free initial point problem; therefore if $J''_{|V} > 0$, then from STEP 3 of the algorithm described in Corollary 2.10 it follows that we can apply Theorem 4.8, and hence we have that $\pi_* \mathcal{H}_{t*}\, L_0 = T_{\hat{\xi}(t)} M$ for all $t \in [0, T]$ and

$$L_{r+1}^- = \left(\mathcal{H}_T \circ \pi_T^{-1}\right)_* T_{x_T} M.$$

Therefore STEP 4 of the algorithm described in Corollary 2.10 yields that we can apply Theorem 4.10.

In the abnormal case the cost is zero, and hence the existence of a *strict* strong local minimizer is equivalent to the fact that the reference trajectory is isolated among the admissible trajectories in the C^0 topology.

A LEADER-FOLLOWER STOCHASTIC LINEAR QUADRATIC DIFFERENTIAL GAME*

JIONGMIN YONG†

Abstract. A leader-follower stochastic differential game is considered with the state equation being a linear Itô-type stochastic differential equation and the cost functionals being quadratic. We allow that the coefficients of the system and those of the cost functionals are random, the controls enter the diffusion of the state equation, and the weight matrices for the controls in the cost functionals are not necessarily positive definite. The so-called open-loop strategies are considered only. Thus, the follower first solves a stochastic linear quadratic (LQ) optimal control problem with the aid of a stochastic Riccati equation. Then the leader turns to solve a stochastic LQ problem for a forward-backward stochastic differential equation. If such an LQ problem is solvable, one obtains an open-loop solution to the two-person leader-follower stochastic differential game. Moreover, it is shown that the open-loop solution admits a state feedback representation if a new stochastic Riccati equation is solvable.

Key words. leader-follower stochastic differential game, linear quadratic optimal control problem, forward-backward stochastic differential equation, stochastic Riccati equation

1. Introduction.

Let $(\Omega, \mathcal{F}, \mathbf{P}, \{\mathcal{F}_t\}_{t\geq 0})$ be a complete filtered probability space on which a one-dimensional standard Brownian motion $W(\cdot)$ is defined such that $\{\mathcal{F}_t\}_{t\geq 0}$ is the natural filtration generated by $W(\cdot)$, augmented by all the $\mathbf{P}$-null sets in $\mathcal{F}$. We consider the following controlled linear stochastic differential equation (SDE):

$$\begin{cases} dx(t) = [A(t)x(t) + B_1(t)u_1(t) + B_2(t)u_2(t)]dt \\ \qquad\qquad + [C(t)x(t) + D_1(t)u_1(t) + D_2(t)u_2(t)]dW(t), \qquad t \in [0,T], \\ x(0) = \xi, \end{cases} \tag{1.1}$$

where $A(\cdot)$, $B_1(\cdot)$, $B_2(\cdot)$, $C(\cdot)$, $D_1(\cdot)$, and $D_2(\cdot)$ are matrix-valued $\{\mathcal{F}_t\}_{t\geq 0}$-adapted processes of suitable dimensions, and $\xi \in \mathbb{R}^n$, the standard n-dimensional Euclidean space. In the above, $x(\cdot)$ is the *state process* with values in $\mathbb{R}^n$, and $u_1(\cdot)$ and $u_2(\cdot)$ are *control processes* taken by the two players in the game, labeled 1 and 2, with values in $\mathbb{R}^{m_1}$ and $\mathbb{R}^{m_2}$, respectively. It is seen that the controls enter the diffusion of the state equation. Let $\mathcal{U}_1[0,T] \triangleq L^2_{\mathcal{F}}(0,T;\mathbb{R}^{m_1})$, the set of all $\mathbb{R}^{m_1}$-valued $\{\mathcal{F}_t\}_{t\geq 0}$-adapted processes $u_1 : [0,T]\times\Omega \to \mathbb{R}^{m_1}$ such that $E\int_0^T |u_1(t)|^2 dt < \infty$. The set $\mathcal{U}_2[0,T] \triangleq L^2_{\mathcal{F}}(0,T;\mathbb{R}^{m_2})$ is defined similarly. The control processes $u_1(\cdot)$ and $u_2(\cdot)$ are taken from $\mathcal{U}_1[0,T]$ and $\mathcal{U}_2[0,T]$, respectively.

Under some mild conditions on the coefficients, for any $(\xi, u_1(\cdot), u_2(\cdot)) \in \mathbb{R}^n \times \mathcal{U}_1[0,T]\times\mathcal{U}_2[0,T]$, there exists a unique (strong) solution $x(\cdot) \equiv x(\cdot\,;\xi, u_1(\cdot), u_2(\cdot)) \in$

$L^2_{\mathcal{F}}(0,T;\mathbb{R}^n)$ to (1.1). Thus, we can define the *cost functionals* for the players as follows:

$$J_i(\xi;u_1(\cdot),u_2(\cdot)) = E\left\{\int_0^T \big[\langle Q_i x(t),x(t)\rangle + \langle R_i u_i(t),u_i(t)\rangle\big]dt + \langle G_i x(T),x(T)\rangle\right\}, \qquad i=1,2, \tag{1.2}$$

where, for $i=1,2$, Q_i and R_i are $(n\times n)$ and $(m_i\times m_i)$ symmetric matrix-valued $\{\mathcal{F}_t\}_{t\geq 0}$-adapted processes, respectively, and G_i is an $(n\times n)$ symmetric matrix-valued $\mathcal{F}_T$-measurable random variable. We emphasize here that no nonnegative conditions are assumed on any of Q_i, R_i, and G_i. In particular, R_1 and R_2 are not necessarily positive definite. It is possible to consider more general forms of cost functionals (for example, $J_1(\cdot)$ also explicitly contains $u_2(\cdot)$, etc.). We take the above form for simplicity of the presentation in this paper.

Roughly speaking, in the above, Player i wants to minimize his/her own cost functional $J_i(\xi;u_1(\cdot),u_2(\cdot))$ by choosing a suitable control $u_i(\cdot)\in\mathcal{U}_i[0,T]$. We refer to this problem as a stochastic linear quadratic (LQ) differential game.

Let us now explain the leader-follower feature of the game. In the game, Player 2 is the leader, and Player 1 is the follower. For any choice $u_2(\cdot)\in\mathcal{U}_2[0,T]$ of Player 2 and a fixed initial state $\xi\in\mathbb{R}^n$, Player 1 would like to choose a $\overline{u}_1(\cdot)\in\mathcal{U}_1[0,T]$ so that $J_1(\xi;\overline{u}_1(\cdot),u_2(\cdot))$ is the minimum of $J_1(\xi;u_1(\cdot),u_2(\cdot))$ over $u_1(\cdot)\in\mathcal{U}_1[0,T]$. Knowing the follower would take such an optimal control $\overline{u}_1(\cdot)$ (supposing it exists, which depends on the choice $u_2(\cdot)$ of the leader and the initial state ξ, in general), Player 2 (the leader) would like to choose some $\overline{u}_2(\cdot)\in\mathcal{U}_2[0,T]$ to minimize $J_2(\xi;\overline{u}_1(\cdot),u_2(\cdot))$ over $u_2(\cdot)\in\mathcal{U}_2[0,T]$. We refer to such a problem as a *leader-follower stochastic LQ differential game*.

In a little more rigorous way, Player 1 wants to find a map $\overline{\alpha}_1:\mathcal{U}_2[0,T]\times\mathbb{R}^n\to\mathcal{U}_1[0,T]$ and Player 2 wants to find a control $\overline{u}_2(\cdot)\in\mathcal{U}_2[0,T]$ such that

$$\begin{cases} J_1(\xi;\overline{\alpha}_1[u_2(\cdot),\xi](\cdot),u_2(\cdot)) = \min\limits_{u_1(\cdot)\in\mathcal{U}_1[0,T]} J_1(\xi;u_1(\cdot),u_2(\cdot)) \quad \forall u_2(\cdot)\in\mathcal{U}_2[0,T], \\ J_2(\xi;\overline{\alpha}_1[\overline{u}_2(\cdot),\xi](\cdot),\overline{u}_2(\cdot)) = \min\limits_{u_2(\cdot)\in\mathcal{U}_2[0,T]} J_2(\xi;\overline{\alpha}_1[u_2(\cdot),\xi](\cdot),u_2(\cdot)). \end{cases} \tag{1.3}$$

If the above pair $(\overline{\alpha}_1[\cdot],\overline{u}_2(\cdot))$ exists, we refer to it as an *open-loop solution* to the above leader-follower differential game. Note that the map $\overline{\alpha}_1$ could be "anticipating"; i.e., $\overline{\alpha}_1[u_2(\cdot),\xi](t)$ could depend on the future value $u_2(s)$ ($s\in[t,T]$) of $u_2(\cdot)$ (see below). Thus, to make the open-loop solution (if it exists) more useful, we will make a great effort to find a state feedback representation for the open-loop solution. This can be regarded as one of the main contributions in this paper. See [26] for a similar result of feedback representation for the open-loop solution in a deterministic case.

We recall that there are several frameworks of studying differential games as far as the strategies are concerned. For open-loop strategies (or pure strategies) in finite-dimensional deterministic differential games, see [1, 3, 9, 26, 28]; the infinite-dimensional counterpart can be found in [2, 17, 22]; some corresponding stochastic cases can be found in [14, 15, 16]. For "nonanticipating" and/or closed-loop strategies of deterministic or stochastic differential games, there is substantial literature; see [1, 2, 4, 10, 11, 12, 13, 16, 17, 21, 22, 29, 30] and the references cited therein. In the present paper, we consider only open-loop strategies. The open-loop solution

and its state feedback representation will be discussed. It is also possible to consider problems with closed-loop strategies together with some kind of equilibrium. However, at this moment, we do not have publishable results for this. We hope to address these problems in future work.

Now, let us make some simple comparisons of our formulation with others in the literature. First, all the formulations of stochastic differential games in the above-mentioned literature have the restriction that the controls do not enter into the diffusion. Also, in most cases (except [14, 15, 16]), all the coefficients are deterministic. Hence, this paper might be the first one for random coefficient stochastic differential games with the diffusion that contains controls. Second, recently the stochastic LQ control problems in which the weight matrix for the control in the cost functionals are not necessarily nonnegative have been studied extensively [6, 7, 8, 34]. This kind of problem has some interesting applications in mathematical finance [34]. This paper might also be the first time that a similar kind of problem is formulated for differential games.

To summarize the above, we see that the novelty of the formulation in this paper is the following: (i) The controls enter into the diffusion, and all coefficients are possibly random; (ii) the weight matrices of the controls in the cost functionals are not necessarily nonnegative; and (iii) the state feedback representation of an open-loop solution to such a differential game is obtained via a new stochastic Riccati equation.

Next, let us briefly look at the procedure of finding an open-loop solution to the above leader-follower differential game. First, we solve an LQ problem for Player 1. For given $u_2(\cdot) \in \mathcal{U}_2[0,T]$, the follower (Player 1) wants to solve the following stochastic LQ problem.

Problem $(\mathrm{LQ})_1$. For given $\xi \in \mathbb{R}^n$, find a $\overline{u}_1(\cdot) \in \mathcal{U}_1[0,T]$ such that

$$J_1(\xi; \overline{u}_1(\cdot), u_2(\cdot)) = \inf_{u_1(\cdot) \in \mathcal{U}_1[0,T]} J_1(\xi; u_1(\cdot), u_2(\cdot)). \tag{1.4}$$

Any $\overline{u}_1(\cdot) \in \mathcal{U}_1[0,T]$ satisfying (1.4) is called an *optimal control*, the corresponding state process $\overline{x}(\cdot)$ is called an *optimal state process*, and $(\overline{x}(\cdot), \overline{u}_1(\cdot))$ is called an *optimal pair* of Problem $(\mathrm{LQ})_1$, respectively. This problem will be studied in section 2. Here, we state some relevant results only. To this end, let us introduce the following SDE:

$$\begin{cases} dP = -\big\{PA + A^TP + C^TPC + \Lambda C + C^T\Lambda + Q_1 \\ \qquad\quad - \big(PB_1 + \Lambda D_1 + C^TPD_1\big)\big(R_1 + D_1^TPD_1\big)^{-1}\big(B_1^TP + D_1^T\Lambda + D_1^TPC\big)\big\}dt \\ \qquad\qquad\qquad + \Lambda dW(t), \qquad t \in [0,T], \\ P(T) = G_1, \\ R_1 + D_1^TP(t)D_1 > 0, \qquad t \in [0,T], \text{ a.s.} \end{cases} \tag{1.5}$$

This is a terminal value problem for an SDE, which is known by now as a *backward stochastic differential equation* (BSDE; see [24, 27, 34] for details). We call (1.5) the *stochastic Riccati equation* for Problem $(\mathrm{LQ})_1$ (see [5, 6, 7, 8, 31, 34]). The unknown for (1.5) is the pair of $(n \times n)$ symmetric matrix-valued $\{\mathcal{F}_t\}_{t\geq 0}$-adapted processes $(P(\cdot), \Lambda(\cdot))$. If such a pair exists, we call it an *adapted solution* of (1.5). Note that (1.5) is a nonlinear BSDE with some singularities in the unknown $(P(\cdot), \Lambda(\cdot))$. In [7], a general local solvability result, as well as a couple of results on the solvability to some special case of such BSDEs, was presented. We should point out that the general solvability of (1.5) remains widely open. Now, suppose (1.5) admits an *adapted*

solution $(P(\cdot),\Lambda(\cdot))$. With such a pair at hand, we introduce another BSDE:

$$
\begin{cases}
d\varphi = -\Big\{[A^T-(PB_1+\Lambda D_1+C^TPD_1)(R_1+D_1^TPD_1)^{-1}B_1^T]\varphi \\
\qquad\quad +[C^T-(PB_1+\Lambda D_1+C^TPD_1)(R_1+D_1^TPD_1)^{-1}D_1^T]\theta \\
\qquad\quad +\big[-(PB_1+\Lambda D_1+C^TPD_1)(R_1+D_1^TPD_1)^{-1}D_1^TPD_2 \\
\qquad\quad +PB_2+\Lambda D_2+C^TPD_2\big]u_2\Big\}dt+\theta dW(t), \qquad t\in[0,T], \\
\varphi(T)=0.
\end{cases} \tag{1.6}
$$

Again, the unknown here is a pair $(\varphi(\cdot),\theta(\cdot))$ of $\mathbb{R}^n$-valued $\{\mathcal{F}_t\}_{t\geq 0}$-adapted processes. Now, let us formally state the following result for Problem $(\mathrm{LQ})_1$ (omitting some technical assumptions). A precise statement will be given in the next section.

THEOREM 1.1. *Suppose* (1.5)–(1.6) *admit adapted solutions* $(P(\cdot),\Lambda(\cdot))$ *and* $(\varphi(\cdot),\theta(\cdot))$*, respectively. Then Problem* $(\mathrm{LQ})_1$ *admits an optimal control* $\overline{u}_1(\cdot)$ *of a state feedback form,*

$$
\overline{u}_1(t)=-\widehat{R}_1(t)^{-1}\widehat{S}_1(t)x(t)-\widehat{R}_1(t)^{-1}f(t), \qquad t\in[0,T], \tag{1.7}
$$

where

$$
\begin{cases}
\widehat{R}_1\triangleq R_1+D_1^TPD_1, \qquad \widehat{S}_1\triangleq B_1^TP+D_1^T\Lambda+D_1^TPC, \\
f\triangleq B_1^T\varphi+D_1^T\theta+D_1^TPD_2u_2.
\end{cases} \tag{1.8}
$$

If we define the right-hand side of (1.7) as $\overline{\alpha}_1[u_2(\cdot),\xi](t)$, then the first equality in (1.3) holds. Note that in the above, $(P(\cdot),\Lambda(\cdot))$ does not depend on $(u_1(\cdot),u_2(\cdot))$, whereas $(\varphi(\cdot),\theta(\cdot))$ does depend on $u_2(\cdot)$ although it still does not depend on $u_1(\cdot)$. Moreover, since (1.6) is a BSDE, the value $(\varphi(t),\theta(t))$ of $(\varphi(\cdot),\theta(\cdot))$ at time t depends on $\{u_2(s)\bigm| s\in[0,T]\}$. Thus, $f(t)$ and hence $\overline{u}_1(t)$ depend on $\{u_2(s)\bigm| s\in[0,T]\}$ as well (see (1.7)–(1.8)). This means that $\overline{\alpha}_1[u_2(\cdot),\xi]\equiv\overline{u}_1(\cdot)$ is anticipating, in general (unless $B_1^T\varphi+D_1^T\theta=0$), as we pointed out earlier.

Once Problem $(\mathrm{LQ})_1$ is solved, we return to the leader (Player 2). Note that when the follower takes his optimal control $\overline{u}_1(\cdot)$ given by (1.7), the leader ends up with the following state equation:

$$
\begin{cases}
dx(t)=\big\{\widehat{A}x(t)+\widehat{F}_1\varphi(t)+\widehat{B}_1\theta(t)+\widehat{B}_2u_2(t)\big\}dt, \\
\qquad\qquad +\big\{\widehat{C}x(t)+\widehat{B}_1^T\varphi(t)+\widehat{D}_1\theta(t)+\widehat{D}_2u_2(t)\big\}dW(t), \\
d\varphi(t)=-\big\{\widehat{A}^T\varphi(t)+\widehat{C}^T\theta(t)+\widehat{F}_2^Tu_2(t)\big\}dt+\theta(t)dW(t), \\
x(0)=\xi, \qquad \varphi(T)=0,
\end{cases} \tag{1.9}
$$

where

$$
\begin{cases}
\widehat{A}\triangleq A-B_1\widehat{R}_1^{-1}\widehat{S}_1, \qquad \widehat{F}_1\triangleq -B_1\widehat{R}_1^{-1}B_1^T, \\
\widehat{B}_1\triangleq -B_1\widehat{R}_1^{-1}D_1^T, \qquad \widehat{B}_2\triangleq B_2-B_1\widehat{R}_1^{-1}D_1^TPD_2, \\
\widehat{C}\triangleq C-D_1\widehat{R}_1^{-1}\widehat{S}_1, \qquad \widehat{F}_2\triangleq \widehat{S}_2-D_2^TPD_1\widehat{R}_1^{-1}\widehat{S}_1, \\
\widehat{D}_1\triangleq -D_1\widehat{R}_1^{-1}D_1^T, \qquad \widehat{D}_2\triangleq D_2-D_1\widehat{R}_1^{-1}D_1^TPD_2, \\
\widehat{S}_2\triangleq B_2^TP+D_2^T\Lambda+D_2^TPC.
\end{cases} \tag{1.10}
$$

The cost functional is $J_2(\xi;\overline{u}_1(\cdot),u_2(\cdot))$, with $\overline{u}_1(\cdot)$ being of form (1.7), which is still a quadratic form. Equation (1.9) is a two-point boundary value problem for SDEs, which is what we call a *forward-backward stochastic differential equation* (FBSDE; see [24, 32, 33]). This FBSDE is decoupled. One can first solve the backward equation for $(\varphi(\cdot),\theta(\cdot))$, then solve the forward equation for $x(\cdot)$. Hence, we end up with an LQ problem for an FBSDE. Let us keep in mind that the "state" for (1.9) is the triple $(x(\cdot),\varphi(\cdot),\theta(\cdot))$. We mention here that the LQ control problem for BSDEs was studied in [23].

Solving the LQ problem for an FBSDE (1.9) itself is interesting. In solving this problem, we obtain an optimal control $\overline{u}_2(\cdot)$ of a "state" feedback via a new stochastic Riccati equation in which the "state" is $(x(\cdot),\varphi(\cdot),\theta(\cdot))$. Then $(\overline{u}_1(\cdot),\overline{u}_2(\cdot))$ gives an open-loop solution to the leader-follower differential game. We have seen that $\overline{u}_1(\cdot)$ is anticipating in general. Since $(\varphi(\cdot),\theta(\cdot))$ could be anticipating, then so could $\overline{u}_2(\cdot)$. Thus, the open-loop solution $(\overline{u}_1(\cdot),\overline{u}_2(\cdot))$ of the game is anticipating in general. The next big job in this paper is to represent $\overline{u}_1(\cdot)$ and $\overline{u}_2(\cdot)$ in terms of the original state $x(\cdot)$. This makes the whole current paper nontrivial and meaningful.

Readers are referred to [19] for some classical deterministic LQ problems, to [31, 5] for classical stochastic LQ problems, to [20, 25] for stochastic control systems with control entering the diffusion, and to [6, 7, 8, 34] for stochastic LQ problems with control entering into the diffusion of the state equation without assuming the nonnegativity of control weight in the cost functional. Finally, some classical results for differential games can be found in [18].

The rest of the paper is organized as follows. Section 2 is devoted to a brief study of the LQ problem for the follower, together with some other preliminary results. In section 3, we discuss the LQ problem for the leader. A new kind of Riccati equation is derived. In section 4, we present two one-dimensional cases. In section 5, we investigate the deterministic coefficients case, for which we obtain an open-loop solution and its state feedback representation to the leader-follower differential game.

2. LQ problem for the follower. Let us first introduce some notation which will be used throughout the paper.

Let $\mathbb{R}^{n\times m}$ be the set of all $(n\times m)$ matrices, and let $\mathcal{S}^n$ be the set of all $(n\times n)$ symmetric matrices. For any Banach space H (for example, $H=\mathbb{R}^n,\mathbb{R}^{n\times m},\mathcal{S}^n$), let $L^\infty_{\mathcal{F}}(0,T;H)$ (resp., $C_{\mathcal{F}}([0,T];H)$) be the set of all H-valued $\{\mathcal{F}_t\}_{t\geq 0}$-adapted bounded (resp., bounded continuous) processes. For any $1\leq p<\infty$, let $L^p_{\mathcal{F}}(0,T;H)$ be the set of all H-valued $\{\mathcal{F}_t\}_{t\geq 0}$-adapted processes $\varphi:[0,T]\times\Omega\to H$ such that $E\int_0^T|\varphi(t)|^p_H dt<\infty$, and let $L^p_{\mathcal{F}_T}(\Omega;H)$ be the set of all $\mathcal{F}_T$-measurable random variable $\eta:\Omega\to H$ such that $E|\eta|^p_H<\infty$. The spaces of deterministic functions $L^p(0,T;H)$ and $C([0,T];H)$ are defined in the usual way.

Let us introduce the following assumptions, which will be used later.

(S) Let

$$
(2.1)\quad \begin{cases} A,C\in L^\infty_{\mathcal{F}}(0,T;\mathbb{R}^{n\times n}),\\ B_i\in L^\infty_{\mathcal{F}}(0,T;\mathbb{R}^{n\times m_i}),\quad D_i\in C_{\mathcal{F}}([0,T];\mathbb{R}^{n\times m_i}),\qquad i=1,2,\\ Q_i\in C_{\mathcal{F}}([0,T];\mathcal{S}^n),\quad R_i\in C_{\mathcal{F}}([0,T];\mathcal{S}^{m_i}),\quad G_i\in L^\infty_{\mathcal{F}_T}(\Omega;\mathcal{S}^n),\qquad i=1,2. \end{cases}
$$

Note that under (S), the coefficients of the control system and the cost functional are random. Now, let us discuss Problem $(\mathrm{LQ})_1$. Similarly to [7, 8], we introduce the following notion.

DEFINITION 2.1. *For given $u_2(\cdot)\in\mathcal{U}_2[0,T]$, Problem* $(\mathrm{LQ})_1$ *is said to be*

(i) *finite at* $\xi \in \mathbb{R}^n$ *if*

$$\inf_{u_1(\cdot)\in\mathcal{U}_1[0,T]} J_1(\xi; u_1(\cdot), u_2(\cdot)) > -\infty; \tag{2.2}$$

(ii) *(uniquely) solvable at* $\xi \in \mathbb{R}^n$ *if there exists a (unique)* $\overline{u}_1(\cdot) \in \mathcal{U}_1[0,T]$ *such that* (1.4) *holds.*

Using a similar idea found in [8] (see [34] also), we are able to prove the following result.

PROPOSITION 2.2. *Let* (S) *hold and* $u_2(\cdot) \in \mathcal{U}_2[0,T]$ *be given.*

(i) *Let Problem* $(\mathrm{LQ})_1$ *be finite at some* $\xi \in \mathbb{R}^n$. *Then for any* $u_1(\cdot) \in \mathcal{U}_1[0,T]$, *the unique adapted solution* $(x^0(\cdot), p^0(\cdot), q^0(\cdot))$ *of the FBSDE*

$$\begin{cases} dx^0(t) = [Ax^0(t) + B_1u_1(t)]dt + [Cx^0(t) + D_1u_1(t)]dW(t), \\ dp^0(t) = -[A^Tp^0(t) + C^Tq^0(t) + Q_1x^0(t)]dt + q^0(t)dW(t), \\ x^0(0) = 0, \qquad p^0(T) = G_1x^0(T) \end{cases} \tag{2.3}$$

satisfies

$$E\int_0^T \langle\, R_1u_1(t) + B_1^Tp^0(t) + D_1^Tq^0(t), u_1(t)\,\rangle\, dt \geq 0. \tag{2.4}$$

(ii) *Let the conclusion of* (i) *hold. Then Problem* $(\mathrm{LQ})_1$ *is (uniquely) solvable with* $(\overline{x}(\cdot), \overline{u}_1(\cdot))$ *being a (the only) optimal pair if and only if there exists a (unique)* 4*-tuple* $(\overline{x}(\cdot), \overline{u}_1(\cdot), \overline{p}(\cdot), \overline{q}(\cdot))$ *satisfying the FBSDE*

$$\begin{cases} d\overline{x}(t) = [A\overline{x}(t) + B_1\overline{u}_1(t) + B_2u_2(t)]dt + [C\overline{x}(t) + D_1\overline{u}_1(t) + D_2u_2(t)]dW(t), \\ d\overline{p}(t) = -[A^T\overline{p}(t) + C^T\overline{q}(t) + Q_1\overline{x}(t)]dt + \overline{q}(t)dW(t), \\ \overline{x}(0) = \xi, \qquad \overline{p}(T) = G_1\overline{x}(T) \end{cases} \tag{2.5}$$

such that

$$R_1\overline{u}_1(t) + B_1^T\overline{p}(t) + D_1^T\overline{q}(t) = 0, \qquad t \in [0,T], \text{ a.s.} \tag{2.6}$$

Next, by the idea of "four-step scheme" found in [24] (see also [33, 34]), we can heuristically derive the stochastic Riccati equation (1.5) and BSDE (1.6). With these, we have the following sufficient condition for the solvability of Problem $(\mathrm{LQ})_1$, which makes the statement of Theorem 1.1 precise.

THEOREM 2.3. *Let* (S) *hold. Suppose* (1.5)–(1.6) *admit adapted solutions* $(P(\cdot), \Lambda(\cdot)) \in C_{\mathcal{F}}([0,T];\mathcal{S}^n) \times L^2_{\mathcal{F}}(0,T;\mathcal{S}^n)$ *and* $(\varphi(\cdot), \theta(\cdot)) \in C_{\mathcal{F}}([0,T];\mathbb{R}^n) \times L^2_{\mathcal{F}}(0,T;\mathbb{R}^n)$, *respectively, such that* $\widehat{R}_1 \equiv R_1 + D_1^TPD_1 > 0$, *and*

$$\begin{cases} B_1\widehat{R}_1^{-1}\widehat{S}_1, \qquad D_1\widehat{R}_1^{-1}\widehat{S}_1 \in L^\infty_{\mathcal{F}}(0,T;\mathbb{R}^{n\times n}), \\ B_1\widehat{R}_1^{-1}f, \qquad D_1\widehat{R}_1^{-1}f \in L^\infty_{\mathcal{F}}(0,T;\mathbb{R}^n), \end{cases} \tag{2.7}$$

where $\widehat{S}_1$ *and* f *are given by* (1.8). *Then Problem* $(\mathrm{LQ})_1$ *is solvable with the optimal control* $\overline{u}_1(\cdot)$ *being of a state feedback form* (1.7), *and*

$$\begin{aligned} \inf_{u_1(\cdot)\in\mathcal{U}_1[0,T]} J_1(\xi; u_1(\cdot), u_2(\cdot)) &= \langle\, P(0)\xi, \xi\,\rangle + 2\,\langle\, \varphi(0), \xi\,\rangle \\ &+ E\int_0^T \big\{2\,\langle\, B_2^T\varphi(t) + D_2^T\theta(t), u_2(t)\,\rangle + \langle\, D_2^TP(t)D_2u_2(t), u_2(t)\,\rangle \\ &\qquad - |\widehat{R}_1(t)^{-\frac{1}{2}}f(t)|^2\big\}dt \qquad \forall \xi \in \mathbb{R}^n. \end{aligned} \tag{2.8}$$

Proof. By our assumption, the following SDE admits a unique strong solution $\overline{x}(\cdot)$:

$$\begin{cases} d\overline{x}(t) = \big\{\big[A - B_1\widehat{R}_1^{-1}\widehat{S}_1\big]\overline{x}(t) - B_1\widehat{R}_1^{-1}f + B_2u_2(t)\big\}dt \\ \qquad\qquad + \big\{\big[C - D_1\widehat{R}_1^{-1}\widehat{S}_1\big]\overline{x}(t) - D_1\widehat{R}_1^{-1}f + D_2u_2(t)\big\}dW(t), \\ \overline{x}(0) = \xi. \end{cases} \tag{2.9}$$

It is clear that the control $\overline{u}_1(\cdot)$ defined by (1.7) is in $\mathcal{U}_1[0,T]$. Now, for any $u_1(\cdot) \in \mathcal{U}_1[0,T]$, $u_2(\cdot) \in \mathcal{U}_2[0,T]$, let $x(\cdot)$ be the corresponding state process. Applying Itô's formula to $\langle\, P(\cdot)x(\cdot), x(\cdot)\,\rangle$ and $\langle\, \varphi(\cdot), x(\cdot)\,\rangle$, with some computation, we have

$$\begin{aligned} &J_1(\xi; u_1(\cdot), u_2(\cdot)) - \langle\, P(0)\xi, \xi\,\rangle - 2\langle\, \varphi(0), \xi\,\rangle \\ &= E\int_0^T \Big\{|\widehat{R}_1^{\frac{1}{2}}[u_1 + \widehat{R}_1^{-1}\widehat{S}_1x + \widehat{R}_1^{-1}f]|^2 - |\widehat{R}_1^{-\frac{1}{2}}f|^2 \\ &\qquad\qquad + 2\langle\, B_2^T\varphi + D_2^T\theta, u_2\,\rangle + \langle\, D_2^TPD_2u_2, u_2\,\rangle\Big\}\,dt. \end{aligned} \tag{2.10}$$

Note that $P(\cdot)$ does not depend on $(u_1(\cdot), u_2(\cdot))$ and $(\varphi(\cdot), \theta(\cdot))$ does not depend on $u_1(\cdot)$ (although it might depend on $u_2(\cdot)$). By (1.8), $f(\cdot)$ does not depend on $u_1(\cdot)$. Consequently, we obtain

$$\begin{aligned} &J_1(\xi; u_1(\cdot), u_2(\cdot)) - J_1(\xi; \overline{u}_1(\cdot), u_2(\cdot)) \\ &= E\int_0^T \big|\widehat{R}_1^{\frac{1}{2}}[u_1 + \widehat{R}_1^{-1}\widehat{S}_1x + \widehat{S}_1f]\big|^2dt \ge 0, \end{aligned} \tag{2.11}$$

which implies that $\overline{u}_1(\cdot)$ is an optimal control. It also leads to (2.8). ∎

3. LQ problem for the leader. Now, let Problem $(\mathrm{LQ})_1$ be uniquely solvable for any given $(\xi, u_2(\cdot)) \in \mathbb{R}^n \times \mathcal{U}_2[0,T]$. Then the follower takes his optimal control $\overline{u}_1(\cdot)$ of form (1.7). Consequently, the leader has the state equation (1.9) with the coefficients given by (1.10). Note that $\widehat{F}_1$ and $\widehat{D}_1$ are symmetric. As we mentioned before, (1.9) is an FBSDE whose adapted solution is a triple $(x(\cdot), \varphi(\cdot), \theta(\cdot))$ of $\{\mathcal{F}_t\}_{t\ge0}$-adapted processes. The leader would like to choose his control so that his cost functional (with $u_1(\cdot) = \overline{u}_1(\cdot)$ being of the form (1.7)) is minimized. To be more precise, we define

$$\begin{aligned} &\widehat{J}_2(\xi; u_2(\cdot)) \triangleq J_2(\xi; \overline{u}_1(\cdot), u_2(\cdot)) \\ &= E\left\{\int_0^T \big[\,\langle\, Q_2x(t), x(t)\,\rangle + \langle\, R_2u_2(t), u_2(t)\,\rangle\,\big]dt + \langle\, G_2x(T), x(T)\,\rangle\right\}, \end{aligned} \tag{3.1}$$

where $x(\cdot)$ is the first component of the adapted solution $(x(\cdot), \varphi(\cdot), \theta(\cdot))$ of (1.9). The LQ problem for the leader can be stated as follows.

Problem $(\mathrm{LQ})_2$. For given $\xi \in \mathbb{R}^n$, find a $\overline{u}_2(\cdot) \in \mathcal{U}_2[0,T]$ such that

$$\widehat{J}_2(\xi, \overline{u}_2(\cdot)) = \min_{u_2(\cdot)\in\mathcal{U}_2[0,T]} \widehat{J}_2(\xi; u_2(\cdot)). \tag{3.2}$$

The above Problem $(\mathrm{LQ})_2$ is an LQ problem for an FBSDE. Similarly to the previous section, we can introduce the following notion.

Definition 3.1. *Problem* $(\mathrm{LQ})_2$ *is said to be*

(i) *finite at* $\xi \in \mathbb{R}^n$ *if*

$$\inf_{u_2(\cdot)\in\mathcal{U}_2[0,T]} \widehat{J}_2(\xi; u_2(\cdot)) > -\infty; \tag{3.3}$$

(ii) *(uniquely) solvable at* $\xi \in \mathbb{R}^n$ *if there exists a (unique)* $\overline{u}_2(\cdot) \in \mathcal{U}_2[0,T]$ *such that* (3.2) *holds.*

Any $\overline{u}_2(\cdot) \in \mathcal{U}_2[0,T]$ *satisfying* (3.2) *is called an optimal control, and the corresponding state* $(\overline{x}(\cdot), \overline{\varphi}(\cdot), \overline{\theta}(\cdot))$ *is called an optimal state process, and* $(\overline{x}(\cdot), \overline{\varphi}(\cdot), \overline{\theta}(\cdot), \overline{u}_2(\cdot))$ *is called an optimal* 4*-tuple, for the Problem* $(\mathrm{LQ})_2$*, respectively.*

Similarly to Proposition 2.2, we have the following Pontryagin-type maximum principle for Problem $(\mathrm{LQ})_2$.

THEOREM 3.2. *Let* (S) *hold.*

(i) *Let Problem* $(\mathrm{LQ})_2$ *be finite at some* $\xi \in \mathbb{R}^n$*. Then for any* $u_2(\cdot) \in \mathcal{U}_2[0,T]$*, the unique adapted solution* $(x^0(\cdot), \varphi^0(\cdot), \theta^0(\cdot), y^0(\cdot), z^0(\cdot), \psi^0(\cdot))$ *of the FBSDE*

$$\begin{cases} dx^0(t) = \big[\widehat{A}x^0(t) + \widehat{F}_1\varphi^0(t) + \widehat{B}_1\theta^0(t) + \widehat{B}_2u_2(t)\big]dt, \\ \qquad\qquad + \big[\widehat{C}x^0(t) + \widehat{B}_1^T\varphi^0(t) + \widehat{D}_1\theta^0(t) + \widehat{D}_2u_2(t)\big]dW(t), \\ d\varphi^0(t) = -\big[\widehat{A}^T\varphi^0(t) + \widehat{C}^T\theta^0(t) + \widehat{F}_2^Tu_2(t)\big]dt + \theta^0(t)dW(t), \\ dy^0(t) = -\big[\widehat{A}^Ty^0(t) + \widehat{C}^Tz(t) + Q_2x^0(t)\big]dt + z^0(t)dW(t), \\ d\psi^0(t) = \big[\widehat{A}\psi^0(t) + \widehat{F}_1y^0(t) + \widehat{B}_1z^0(t)\big]dt \\ \qquad\qquad + \big[\widehat{C}\psi^0(t) + \widehat{B}_1^Ty^0(t) + \widehat{D}_1z^0(t)\big]dW(t), \\ x^0(0) = 0, \qquad \varphi(T) = 0, \qquad y^0(T) = G_2x^0(T), \qquad \psi^0(0) = 0 \end{cases} \tag{3.4}$$

satisfies

$$\widehat{J}_2(0; u_2(\cdot)) = E\int_0^T \langle\, R_2u_2(t) + \widehat{B}_2^Ty^0(t) + \widehat{D}_2^Tz^0(t) + \widehat{F}_2\psi^0(t), u_2(t)\,\rangle\, dt \geq 0. \tag{3.5}$$

(ii) *Let the conclusion of* (i) *hold. Then Problem* $(\mathrm{LQ})_2$ *is solvable at* $\xi \in \mathbb{R}^n$ *with* $(\overline{x}(\cdot), \overline{\varphi}(\cdot), \overline{\theta}(\cdot), \overline{u}_2(\cdot))$ *being an optimal* 4*-tuple if and only if* $(\overline{x}(\cdot), \overline{\varphi}(\cdot), \overline{\theta}(\cdot))$ *is the adapted solution of* (1.9) *corresponding to* $(\xi, \overline{u}_2(\cdot))$ *and the FBSDE*

$$\begin{cases} d\overline{y} = -(\widehat{A}^T\overline{y} + \widehat{C}^T\overline{z} + Q_2\overline{x})dt + \overline{z}dW(t), \\ d\overline{\psi} = (\widehat{A}\overline{\psi} + \widehat{F}_1\overline{y} + \widehat{B}_1\overline{z})dt + (\widehat{C}\overline{\psi} + \widehat{B}_1^T\overline{y} + \widehat{D}_1\overline{z})dW(t), \\ \overline{y}(T) = G_2\overline{x}(T), \qquad \overline{\psi}(0) = 0 \end{cases} \tag{3.6}$$

admits a unique adapted solution $(\overline{y}(\cdot), \overline{z}(\cdot), \overline{\psi}(\cdot))$ *such that*

$$R_2\overline{u}_2 + \widehat{B}_2^T\overline{y} + \widehat{D}_2^T\overline{z} + \widehat{F}_2\overline{\psi} = 0. \tag{3.7}$$

Proof. For any fixed $\xi \in \mathbb{R}^n$ and $\overline{u}_2(\cdot) \in \mathcal{U}_2[0,T]$, FBSDE (1.9) admits a unique adapted solution $(\overline{x}(\cdot), \overline{\varphi}(\cdot), \overline{\theta}(\cdot))$, and FBSDE (3.6) also admits a unique adapted solution $(\overline{y}(\cdot), \overline{z}(\cdot), \overline{\psi}(\cdot))$. (One can solve the BSDE for $(\overline{y}(\cdot), \overline{z}(\cdot))$ first, then solve the FSDE for $\overline{\psi}(\cdot)$.) Similarly, for any $u_2(\cdot) \in \mathcal{U}_2[0,T]$, (3.6) admits a unique adapted

solution $(x^0(\cdot),\varphi^0(\cdot),\theta^0(\cdot),y^0(\cdot),z^0(\cdot),\psi^0(\cdot))$. By Itô's formula, we obtain

$$\begin{aligned}
&E\langle G_2\overline{x}(T),x^0(T)\rangle\\
&=E\big[\langle \overline{y}(T),x^0(T)\rangle-\langle y(0),x^0(0)\rangle-\langle \overline{\psi}(T),\varphi^0(T)\rangle+\langle \overline{\psi}(0),\varphi^0(0)\rangle\big]\\
&=E\int_0^T\big[-\langle \widehat{A}^T\overline{y}+\widehat{C}^T\overline{z}+Q_2\overline{x},x^0\rangle+\langle \overline{y},\widehat{A}x^0+\widehat{F}_1\varphi^0+\widehat{B}_1\theta^0+\widehat{B}_2u_2\rangle\\
&\qquad+\langle \overline{z},\widehat{C}x^0+\widehat{B}_1^T\varphi^0+\widehat{D}_1\theta^0+\widehat{D}_2u_2\rangle-\langle \widehat{A\psi}+\widehat{F}_1\overline{y}+\widehat{B}_1\overline{z},\varphi^0\rangle\\
&\qquad+\langle \overline{\psi},\widehat{A}^T\varphi^0+\widehat{C}^T\theta^0+\widehat{F}_2^Tu_2\rangle-\langle \widehat{C\psi}+\widehat{B}_1^T\overline{y}+\widehat{D}_1\overline{z},\theta^0\rangle\big]dt\\
&=E\int_0^T\big[-\langle Q_2\overline{x},x^0\rangle+\langle u_2,\widehat{B}_2^T\overline{y}+\widehat{D}_2^T\overline{z}+\widehat{F}_2\overline{\psi}\rangle\big]dt.
\end{aligned}\tag{3.8}$$

Similarly, we have

$$E\langle G_2x^0(T),x^0(T)\rangle=E\int_0^T\big[-\langle Q_2x^0,x^0\rangle+\langle u_2,\widehat{B}_2^Ty^0+\widehat{D}_2^Tz^0+\widehat{F}_2\psi^0\rangle\big]dt,\tag{3.9}$$

which implies

$$\widehat{J}_2(0;u_2(\cdot))=E\int_0^T\langle R_2u_2(t)+\widehat{B}_2^Ty^0(t)+\widehat{D}_2^Tz^0(t)+\widehat{F}_2\psi^0(t),u_2(t)\rangle\,dt.\tag{3.10}$$

Then, for any $\lambda\in\mathbb{R}$,

$$\begin{aligned}
&\widehat{J}_2(\xi;\overline{u}_2(\cdot)+\lambda u_2(\cdot))-\widehat{J}_2(\xi;\overline{u}_2(\cdot))\\
&=2\lambda E\left\{\int_0^T\big[\langle Q_2\overline{x},x^0\rangle+\langle R_2\overline{u}_2,u_2\rangle\big]dt+\langle G_2\overline{x}(T),x^0(T)\rangle\right\}\\
&\qquad+\lambda^2E\left\{\int_0^T\big[\langle Q_2x^0,x^0\rangle+\langle R_2u_2,u_2\rangle\big]dt+\langle G_2x^0(T),x^0(T)\rangle\right\}\\
&=2\lambda E\int_0^T\langle u_2,R_2\overline{u}_2+\widehat{B}_2^T\overline{y}+\widehat{D}_2^T\overline{z}+\widehat{F}_2\overline{\psi}\rangle\,dt\\
&\qquad+\lambda^2E\int_0^T\langle u_2,R_2u_2+\widehat{B}_2^Ty^0+\widehat{D}_2^Tz^0+\widehat{F}_2\psi^0\rangle\,dt.
\end{aligned}\tag{3.11}$$

Hence, when Problem $(\mathrm{LQ})_2$ is finite at some $\xi\in\mathbb{R}^n$, (3.5) must hold. Further, if (3.5) holds, then $\overline{u}_2(\cdot)$ is optimal if and only if (3.7) holds. □

We note that when

$$Q_2(t)\geq 0,\quad R_2(t)\geq 0,\quad G_2\geq 0,\qquad t\in[0,T],\ \text{a.s.}\tag{3.12}$$

holds, (3.5) holds automatically.

The above result gives us an equivalence between the solvability of Problem $(\mathrm{LQ})_2$ and that of an FBSDE. As usual, we refer to (3.6) as the adjoint equation of (1.9) along the optimal 4-tuple. Condition (3.7) together with (3.5) can be regarded as the maximum condition in Pontryagin's maximum principle. In the current case, due to the linear quadratic nature of the problem, (3.5) implies that the functional $u_2(\cdot)\mapsto\widehat{J}_2(\xi;u_2(\cdot))$ is convex. Thus, (3.7) becomes a sufficient condition for the existence of an optimal control. We refer to (1.9), (3.6)–(3.7) as the *optimality system*

of Problem $(\mathrm{LQ})_2$. It is clear that (1.9) and (3.6) are two (decoupled) FBSDEs which are coupled through condition (3.7).

Similar to typical (stochastic) LQ problems, the representation of optimal control $\overline{u}_2(\cdot)$ through (3.7) is not satisfactory since in order to determine $(\overline{y}(t),\overline{z}(t))$ at time $t\in[0,T)$, one needs to solve the BSDE in (3.6), for which $\overline{x}(T)$ (a future information of the state) has to be known. This is not realistic. We expect to have some kind of state feedback representation for the optimal control via a certain Riccati equation. To make the problem clearer, let us put (1.9) and (3.6) together, dropping bars in $\overline{x}$, etc. (but keeping the bar in $\overline{u}_2$), for notational simplicity:

$$
\begin{cases}
dx(t)=\big[\widehat{A}x(t)+\widehat{F}_1\varphi(t)+\widehat{B}_1\theta(t)+\widehat{B}_2\overline{u}_2(t)\big]dt,\\
\qquad\qquad +\big[\widehat{C}x(t)+\widehat{B}_1^T\varphi(t)+\widehat{D}_1\theta(t)+\widehat{D}_2\overline{u}_2(t)\big]dW(t),\\
d\varphi(t)=-\big[\widehat{A}^T\varphi(t)+\widehat{C}^T\theta(t)+\widehat{F}_2^T\overline{u}_2(t)\big]dt+\theta(t)dW(t),\\
dy(t)=-\big[\widehat{A}^Ty(t)+\widehat{C}^Tz(t)+Q_2x(t)\big]dt+z(t)dW(t),\\
d\psi(t)=\big[\widehat{A}\psi(t)+\widehat{F}_1y(t)+\widehat{B}_1z(t)\big]dt+\big[\widehat{C}\psi(t)+\widehat{B}_1^Ty(t)+\widehat{D}_1z(t)\big]dW(t),\\
x(0)=\xi,\qquad \varphi(T)=0,\qquad y(T)=G_2x(T),\qquad \psi(0)=0,\\
R_2\overline{u}_2+\widehat{B}_2^Ty+\widehat{D}_2^Tz+\widehat{F}_2\psi=0.
\end{cases}
\tag{3.13}
$$

Note that the equations for $(x(\cdot),\varphi(\cdot))$ form a coupled FBSDE, and those for $(y(\cdot),\psi(\cdot))$ form another coupled FBSDE. These two FBSDEs are further coupled through the last relation. Hence, the above is a coupled system of FBSDEs. We may look at the above in a different way. To this end, let us set

$$
\begin{cases}
X=\begin{pmatrix}x\\ \psi\end{pmatrix},\quad Y=\begin{pmatrix}y\\ \varphi\end{pmatrix},\quad Z=\begin{pmatrix}z\\ \theta\end{pmatrix},\quad X_0\triangleq\begin{pmatrix}\xi\\ 0\end{pmatrix},\\
\widehat{\mathcal{A}}\triangleq\begin{pmatrix}\widehat{A}&0\\ 0&\widehat{A}\end{pmatrix},\quad \widehat{\mathcal{F}}_1=\begin{pmatrix}0&\widehat{F}_1\\ \widehat{F}_1&0\end{pmatrix},\quad \widehat{\mathcal{B}}_1=\begin{pmatrix}0&\widehat{B}_1\\ \widehat{B}_1&0\end{pmatrix},\quad \widehat{\mathcal{B}}_2=\begin{pmatrix}\widehat{B}_2\\ 0\end{pmatrix},\\
\widehat{\mathcal{C}}\triangleq\begin{pmatrix}\widehat{C}&0\\ 0&\widehat{C}\end{pmatrix},\quad \widehat{\mathcal{D}}_1=\begin{pmatrix}0&\widehat{D}_1\\ \widehat{D}_1&0\end{pmatrix},\quad \widehat{\mathcal{D}}_2=\begin{pmatrix}\widehat{D}_2\\ 0\end{pmatrix},\\
\widehat{\mathcal{Q}}_2\triangleq\begin{pmatrix}Q_2&0\\ 0&0\end{pmatrix},\quad \widehat{\mathcal{F}}_2=\begin{pmatrix}0&\widehat{F}_2\end{pmatrix},\quad \widehat{\mathcal{G}}_2=\begin{pmatrix}G_2&0\\ 0&0\end{pmatrix}.
\end{cases}
\tag{3.14}
$$

Then (3.13) is equivalent to the FBSDE

$$
\begin{cases}
dX=\big(\widehat{\mathcal{A}}X+\widehat{\mathcal{F}}_1Y+\widehat{\mathcal{B}}_1Z+\widehat{\mathcal{B}}_2\overline{u}_2\big)dt\\
\qquad\quad +\big(\widehat{\mathcal{C}}X+\widehat{\mathcal{B}}_1^TY+\widehat{\mathcal{D}}_1Z+\widehat{\mathcal{D}}_2\overline{u}_2\big)dW(t),\\
dY=-\big(\widehat{\mathcal{Q}}_2X+\widehat{\mathcal{A}}^TY+\widehat{\mathcal{C}}^TZ+\widehat{\mathcal{F}}_2^T\overline{u}_2\big)dt+ZdW(t),\\
X(0)=X_0,\qquad Y(T)=\widehat{\mathcal{G}}_2X(T),
\end{cases}
\tag{3.15}
$$

together with the following condition:

$$
R_2\overline{u}_2+\widehat{\mathcal{B}}_2^TY+\widehat{\mathcal{F}}_2X+\widehat{\mathcal{D}}_2^TZ=0. \tag{3.16}
$$

FBSDE (3.15) is of a standard form. We should point out that only $\widehat{\mathcal{F}}_1$, $\widehat{\mathcal{D}}_1$, $\widehat{\mathcal{Q}}_2$, and $\widehat{\mathcal{G}}_2$ are symmetric; $\widehat{\mathcal{A}}$, $\widehat{\mathcal{C}}$, and $\widehat{\mathcal{B}}_1$ are not necessarily symmetric and/or skew-symmetric (although they look like so). Thus, the seemingly special form (3.14) of the coefficients

does not give us any additional helps in solving the linear FBSDE (3.15). We now use the idea of the four-step scheme (see [24, 32, 33]) to study the solvability of the above FBSDE. Suppose we have the relation

$$Y(t) = \widehat{P}(t)X(t), \qquad t \in [0,T], \tag{3.17}$$

with $\widehat{P}(\cdot)$ being an $\mathcal{S}^{2n}$-valued process satisfying

$$\begin{cases} d\widehat{P}(t) = \widehat{\Gamma}(t)dt + \widehat{\Lambda}(t)dW(t), & t \in [0,T], \\ \widehat{P}(T) = \widehat{\mathcal{G}}_2 \end{cases} \tag{3.18}$$

for some undetermined $\mathcal{S}^{2n}$-valued processes $\widehat{\Gamma}(\cdot)$ and $\widehat{\Lambda}(\cdot)$. Applying Itô's formula to (3.17), we obtain (suppressing t below)

$$\begin{aligned} &\big(\widehat{\Gamma}X + \widehat{P}\widehat{\mathcal{A}}X + \widehat{P}\widehat{\mathcal{F}}_1\widehat{P}X + \widehat{P}\widehat{\mathcal{B}}_1 Z + \widehat{P}\widehat{\mathcal{B}}_2\overline{u}_2 \\ &\qquad + \widehat{\Lambda}\widehat{\mathcal{C}}X + \widehat{\Lambda}\widehat{\mathcal{B}}_1^T\widehat{P}X + \Lambda\widehat{\mathcal{D}}_1 Z + \widehat{\Lambda}\widehat{\mathcal{D}}_2\overline{u}_2\big)dt \\ &\qquad + \big(\widehat{\Lambda}X + \widehat{P}\widehat{\mathcal{C}}X + \widehat{P}\widehat{\mathcal{B}}_1^T\widehat{P}X + \widehat{P}\widehat{\mathcal{D}}_1 Z + \widehat{P}\widehat{\mathcal{D}}_2\overline{u}_2\big)dW(t) \\ &= d[\widehat{P}X] = dY \\ &= -\big(\widehat{\mathcal{Q}}_2 X + \widehat{\mathcal{A}}^T\widehat{P}X + \widehat{\mathcal{C}}^T Z + \widehat{\mathcal{F}}_2^T\overline{u}_2\big)dt + ZdW(t). \end{aligned} \tag{3.19}$$

Hence, comparing the diffusion terms, we have

$$\big(I - \widehat{P}\widehat{\mathcal{D}}_1\big)Z = \big(\widehat{\Lambda} + \widehat{P}\widehat{\mathcal{C}} + \widehat{P}\widehat{\mathcal{B}}_1^T\widehat{P}\big)X + \widehat{P}\widehat{\mathcal{D}}_2\overline{u}_2, \tag{3.20}$$

and by comparing the drift terms in (3.19), we have

$$\begin{aligned} 0 &= \widehat{\Gamma}X + \widehat{P}\widehat{\mathcal{A}}X + \widehat{P}\widehat{\mathcal{F}}_1\widehat{P}X + \widehat{P}\widehat{\mathcal{B}}_1 Z + \widehat{P}\widehat{\mathcal{B}}_2\overline{u}_2 \\ &\quad + \widehat{\Lambda}\widehat{\mathcal{C}}X + \widehat{\Lambda}\widehat{\mathcal{B}}_1^T\widehat{P}X + \widehat{\Lambda}\widehat{\mathcal{D}}_1 Z + \widehat{\Lambda}\widehat{\mathcal{D}}_2\overline{u}_2 \\ &\quad + \widehat{\mathcal{Q}}_2 X + \widehat{\mathcal{A}}^T\widehat{P}X + \widehat{\mathcal{C}}^T Z + \widehat{\mathcal{F}}_2^T\overline{u}_2 \\ &= (\widehat{\Gamma} + \widehat{P}\widehat{\mathcal{A}} + \widehat{\mathcal{A}}^T\widehat{P} + \widehat{P}\widehat{\mathcal{F}}_1\widehat{P} + \widehat{\mathcal{Q}}_2 + \widehat{\Lambda}\widehat{\mathcal{C}} + \widehat{\Lambda}\widehat{\mathcal{B}}_1^T\widehat{P})X \\ &\quad + (\widehat{P}\widehat{\mathcal{B}}_1 + \widehat{\Lambda}\widehat{\mathcal{D}}_1 + \widehat{\mathcal{C}}^T)Z + (\widehat{P}\widehat{\mathcal{B}}_2 + \widehat{\Lambda}\widehat{\mathcal{D}}_2 + \widehat{\mathcal{F}}_2^T)\overline{u}_2. \end{aligned} \tag{3.21}$$

We should keep in mind that (3.19) is equivalent to (3.20)–(3.21). Next, assuming the existence of $\big(I - \widehat{P}\widehat{\mathcal{D}}_1\big)^{-1}$, one obtains (from (3.20))

$$Z = \big(I - \widehat{P}\widehat{\mathcal{D}}_1\big)^{-1}\big[\big(\widehat{\Lambda} + \widehat{P}\widehat{\mathcal{C}} + \widehat{P}\widehat{\mathcal{B}}_1^T\widehat{P}\big)X + \widehat{P}\widehat{\mathcal{D}}_2\overline{u}_2\big]. \tag{3.22}$$

Hence, it follows from (3.16) that

$$\begin{aligned} 0 &= R_2\overline{u}_2 + \widehat{\mathcal{B}}_2^T Y + \widehat{\mathcal{F}}_2 X + \widehat{\mathcal{D}}_2^T Z \\ &= \big[R_2 + \widehat{\mathcal{D}}_2^T\big(I - \widehat{P}\widehat{\mathcal{D}}_1\big)^{-1}\widehat{P}\widehat{\mathcal{D}}_2\big]\overline{u}_2 \\ &\quad + \big[\widehat{\mathcal{D}}_2^T\big(I - \widehat{P}\widehat{\mathcal{D}}_1\big)^{-1}\big(\widehat{\Lambda} + \widehat{P}\widehat{\mathcal{C}} + \widehat{P}\widehat{\mathcal{B}}_1^T\widehat{P}\big) + \widehat{\mathcal{B}}_2^T\widehat{P} + \widehat{\mathcal{F}}_2\big]X. \end{aligned} \tag{3.23}$$

We point out that

$$\big(I - \widehat{P}\widehat{\mathcal{D}}_1\big)^{-1}\widehat{P} = \widehat{P}\big(I - \widehat{\mathcal{D}}_1\widehat{P}\big)^{-1} \tag{3.24}$$

is symmetric (which can be proved by multiplying both sides by $(I-\widehat{P}\widehat{\mathcal{D}}_1)$ from left and by $(I-\widehat{\mathcal{D}}_1\widehat{P})$ from right). Let us now assume that

$$\widehat{R}_2 \triangleq R_2+\widehat{\mathcal{D}}_2^T\big(I-\widehat{P}\widehat{\mathcal{D}}_1\big)^{-1}\widehat{P}\widehat{\mathcal{D}}_2 \tag{3.25}$$

is invertible (which is an $\mathcal{S}^{m_2}$-valued process). Consequently, by (3.23),

$$\overline{u}_2=-\widehat{R}_2^{-1}\big[\widehat{\mathcal{D}}_2^T\big(I-\widehat{P}\widehat{\mathcal{D}}_1\big)^{-1}\big(\widehat{\Lambda}+\widehat{P}\widehat{\mathcal{C}}+\widehat{P}\widehat{\mathcal{B}}_1^T\widehat{P}\big)+\widehat{\mathcal{B}}_2^T\widehat{P}+\widehat{\mathcal{F}}_2\big]X. \tag{3.26}$$

Plugging the above into (3.22), one has

$$\begin{aligned} Z=&\big(I-\widehat{P}\widehat{\mathcal{D}}_1\big)^{-1}\big\{\widehat{\Lambda}+\widehat{P}\widehat{\mathcal{C}}+\widehat{P}\widehat{\mathcal{B}}_1^T\widehat{P}\\ &-\widehat{P}\widehat{\mathcal{D}}_2\widehat{R}_2^{-1}\big[\widehat{\mathcal{D}}_2^T\big(I-\widehat{P}\widehat{\mathcal{D}}_1\big)^{-1}\big(\widehat{\Lambda}+\widehat{P}\widehat{\mathcal{C}}+\widehat{P}\widehat{\mathcal{B}}_1^T\widehat{P}\big)+\widehat{\mathcal{B}}_2^T\widehat{P}+\widehat{\mathcal{F}}_2\big]\big\}X. \end{aligned} \tag{3.27}$$

Substituting (3.26)–(3.27) into (3.21), we end up with

$$\begin{aligned} 0=&(\widehat{\Gamma}+\widehat{P}\widehat{\mathcal{A}}+\widehat{\mathcal{A}}^T\widehat{P}+\widehat{P}\widehat{\mathcal{F}}_1\widehat{P}+\widehat{\mathcal{Q}}_2+\widehat{\Lambda}\widehat{\mathcal{C}}+\widehat{\Lambda}\widehat{\mathcal{B}}_1^T\widehat{P})X\\ &+(\widehat{P}\widehat{\mathcal{B}}_1+\widehat{\Lambda}\widehat{\mathcal{D}}_1+\widehat{\mathcal{C}}^T)\big(I-\widehat{P}\widehat{\mathcal{D}}_1\big)^{-1}\big\{\widehat{\Lambda}+\widehat{P}\widehat{\mathcal{C}}+\widehat{P}\widehat{\mathcal{B}}_1^T\widehat{P}\\ &-\widehat{P}\widehat{\mathcal{D}}_2\widehat{R}_2^{-1}\big[\widehat{\mathcal{D}}_2^T\big(I-\widehat{P}\widehat{\mathcal{D}}_1\big)^{-1}\big(\widehat{\Lambda}+\widehat{P}\widehat{\mathcal{C}}+\widehat{P}\widehat{\mathcal{B}}_1^T\widehat{P}\big)+\widehat{\mathcal{B}}_2^T\widehat{P}+\widehat{\mathcal{F}}_2\big]\big\}X\\ &-(\widehat{P}\widehat{\mathcal{B}}_2+\widehat{\Lambda}\widehat{\mathcal{D}}_2+\widehat{\mathcal{F}}_2^T)\widehat{R}_2^{-1}\big\{\widehat{\mathcal{D}}_2^T\big[I-\widehat{P}\widehat{\mathcal{D}}_1\big]^{-1}\big[\widehat{\Lambda}+\widehat{P}\widehat{\mathcal{C}}+\widehat{P}\widehat{\mathcal{B}}_1^T\widehat{P}\big]\\ &\qquad+\widehat{\mathcal{B}}_2^T\widehat{P}+\widehat{\mathcal{F}}_2\big\}X. \end{aligned} \tag{3.28}$$

Thus, process $\widehat{\Gamma}$ should be chosen as follows:

$$\begin{aligned} \widehat{\Gamma}=&-(\widehat{P}\widehat{\mathcal{A}}+\widehat{\mathcal{A}}^T\widehat{P}+\widehat{P}\widehat{\mathcal{F}}_1\widehat{P}+\widehat{\mathcal{Q}}_2+\widehat{\Lambda}\widehat{\mathcal{C}}+\widehat{\Lambda}\widehat{\mathcal{B}}_1^T\widehat{P})\\ &-(\widehat{P}\widehat{\mathcal{B}}_1+\widehat{\Lambda}\widehat{\mathcal{D}}_1+\widehat{\mathcal{C}}^T)\big(I-\widehat{P}\widehat{\mathcal{D}}_1\big)^{-1}\big\{\widehat{\Lambda}+\widehat{P}\widehat{\mathcal{C}}+\widehat{P}\widehat{\mathcal{B}}_1^T\widehat{P}\\ &\qquad-\widehat{P}\widehat{\mathcal{D}}_2\widehat{R}_2^{-1}\big[\widehat{\mathcal{D}}_2^T\big(I-\widehat{P}\widehat{\mathcal{D}}_1\big)^{-1}\big(\widehat{\Lambda}+\widehat{P}\widehat{\mathcal{C}}+\widehat{P}\widehat{\mathcal{B}}_1^T\widehat{P}\big)+\widehat{\mathcal{B}}_2^T\widehat{P}+\widehat{\mathcal{F}}_2\big]\big\}\\ &+(\widehat{P}\widehat{\mathcal{B}}_2+\widehat{\Lambda}\widehat{\mathcal{D}}_2+\widehat{\mathcal{F}}_2^T)\widehat{R}_2^{-1}[\widehat{\mathcal{D}}_2^T\big(I-\widehat{P}\widehat{\mathcal{D}}_1\big)^{-1}\big(\widehat{\Lambda}+\widehat{P}\widehat{\mathcal{C}}+\widehat{P}\widehat{\mathcal{B}}_1^T\widehat{P}\big)+\widehat{\mathcal{B}}_2^T\widehat{P}+\widehat{\mathcal{F}}_2]. \end{aligned} \tag{3.29}$$

In other words, if $\widehat{\Gamma}(\cdot)$ is defined by (3.29), then (3.28) holds.

Next, by substituting (3.17), (3.26), and (3.27) into the equation for $X(\cdot)$ in (3.15), we obtain

$$\begin{cases} dX=\overline{\mathcal{A}}Xdt+\overline{\mathcal{C}}XdW(t),\\ X(0)=X_0, \end{cases} \tag{3.30}$$

where

$$\begin{cases} \overline{\mathcal{A}}=\widehat{\mathcal{A}}+\widehat{\mathcal{F}}_1\widehat{P}+\widehat{\mathcal{B}}_1\big(I-\widehat{P}\widehat{\mathcal{D}}_1\big)^{-1}\big\{\widehat{\Lambda}+\widehat{P}\widehat{\mathcal{C}}+\widehat{P}\widehat{\mathcal{B}}_1^T\widehat{P}\\ \qquad-\widehat{P}\widehat{\mathcal{D}}_2\widehat{R}_2^{-1}\big[\widehat{\mathcal{D}}_2^T\big(I-\widehat{P}\widehat{\mathcal{D}}_1\big)^{-1}\big(\widehat{\Lambda}+\widehat{P}\widehat{\mathcal{C}}+\widehat{P}\widehat{\mathcal{B}}_1^T\widehat{P}\big)+\widehat{\mathcal{B}}_2^T\widehat{P}+\widehat{\mathcal{F}}_2\big]\big\}\\ \qquad-\widehat{\mathcal{B}}_2\widehat{R}_2^{-1}\big[\widehat{\mathcal{D}}_2^T\big(I-\widehat{P}\widehat{\mathcal{D}}_1\big)^{-1}\big(\widehat{\Lambda}+\widehat{P}\widehat{\mathcal{C}}+\widehat{P}\widehat{\mathcal{B}}_1^T\widehat{P}\big)+\widehat{\mathcal{B}}_2^T\widehat{P}+\widehat{\mathcal{F}}_2\big],\\ \overline{\mathcal{C}}=\widehat{\mathcal{C}}+\widehat{\mathcal{B}}_1^T\widehat{P}+\widehat{\mathcal{D}}_1\big(I-\widehat{P}\widehat{\mathcal{D}}_1\big)^{-1}\big\{\widehat{\Lambda}+\widehat{P}\widehat{\mathcal{C}}+\widehat{P}\widehat{\mathcal{B}}_1^T\widehat{P}\\ \qquad-\widehat{P}\widehat{\mathcal{D}}_2\widehat{R}_2^{-1}\big[\widehat{\mathcal{D}}_2^T\big(I-\widehat{P}\widehat{\mathcal{D}}_1\big)^{-1}\big(\widehat{\Lambda}+\widehat{P}\widehat{\mathcal{C}}+\widehat{P}\widehat{\mathcal{B}}_1^T\widehat{P}\big)+\widehat{\mathcal{B}}_2^T\widehat{P}+\widehat{\mathcal{F}}_2\big]\big\}\\ \qquad-\widehat{\mathcal{D}}_2\widehat{R}_2^{-1}\big[\widehat{\mathcal{D}}_2^T\big(I-\widehat{P}\widehat{\mathcal{D}}_1\big)^{-1}\big(\widehat{\Lambda}+\widehat{P}\widehat{\mathcal{C}}+\widehat{P}\widehat{\mathcal{B}}_1^T\widehat{P}\big)+\widehat{\mathcal{B}}_2^T\widehat{P}+\widehat{\mathcal{F}}_2\big]. \end{cases} \tag{3.31}$$

Now, if $X(\cdot)$ is the unique strong solution of (3.30) and if $Y(\cdot)$, $Z(\cdot)$, and $u_2(\cdot)$ are defined by (3.16), (3.25), and (3.26), respectively (assuming that $(\widehat{P}(\cdot), \widehat{\Lambda}(\cdot))$ is an adapted solution of (3.18) and that $(I - \widehat{P}\widehat{\mathcal{D}}_1)^{-1}$ and $\widehat{R}_2^{-1}$ exist), then (3.15)–(3.16) hold.

We now make some rearrangement for the right-hand side of (3.29). First of all,

$$
\begin{aligned}
&(\widehat{P}\widehat{\mathcal{B}}_1 + \widehat{\Lambda}\widehat{\mathcal{D}}_1 + \widehat{\mathcal{C}}^T)\big(I - \widehat{P}\widehat{\mathcal{D}}_1\big)^{-1}\big(\widehat{\Lambda} + \widehat{P}\widehat{\mathcal{C}} + \widehat{P}\widehat{\mathcal{B}}_1^T\widehat{P}\big)\\
&= (\widehat{P}\widehat{\mathcal{B}}_1 + \widehat{\mathcal{C}}^T)(I - \widehat{P}\widehat{\mathcal{D}}_1)^{-1}\widehat{P}(\widehat{\mathcal{B}}_1^T\widehat{P} + \widehat{\mathcal{C}}) + \widehat{\Lambda}\widehat{\mathcal{D}}_1(I - \widehat{P}\widehat{\mathcal{D}}_1)^{-1}\widehat{\Lambda}\\
&\qquad + (\widehat{P}\widehat{\mathcal{B}}_1 + \widehat{\mathcal{C}}^T)(I - \widehat{P}\widehat{\mathcal{D}}_1)^{-1}\widehat{\Lambda} + \widehat{\Lambda}\widehat{\mathcal{D}}_1(I - \widehat{P}\widehat{\mathcal{D}}_1)^{-1}\widehat{P}(\widehat{\mathcal{B}}_1^T\widehat{P} + \widehat{\mathcal{C}})\\
&= (\widehat{P}\widehat{\mathcal{B}}_1 + \widehat{\mathcal{C}}^T)(I - \widehat{P}\widehat{\mathcal{D}}_1)^{-1}\widehat{P}(\widehat{\mathcal{B}}_1^T\widehat{P} + \widehat{\mathcal{C}}) + \widehat{\Lambda}\widehat{\mathcal{D}}_1(I - \widehat{P}\widehat{\mathcal{D}}_1)^{-1}\widehat{\Lambda}\\
&\qquad + (\widehat{P}\widehat{\mathcal{B}}_1 + \widehat{\mathcal{C}}^T)(I - \widehat{P}\widehat{\mathcal{D}}_1)^{-1}\widehat{\Lambda} + \widehat{\Lambda}[(I - \widehat{P}\widehat{\mathcal{D}}_1)^{-1} - I](\widehat{\mathcal{B}}_1^T\widehat{P} + \widehat{\mathcal{C}}).
\end{aligned}
\tag{3.32}
$$

Next, one has

$$
\begin{aligned}
&(\widehat{P}\widehat{\mathcal{B}}_1 + \widehat{\Lambda}\widehat{\mathcal{D}}_1 + \widehat{\mathcal{C}}^T)\big(I - \widehat{P}\widehat{\mathcal{D}}_1\big)^{-1}\widehat{P}\widehat{\mathcal{D}}_2\widehat{R}_2^{-1}\big[\widehat{\mathcal{D}}_2^T\big(I - \widehat{P}\widehat{\mathcal{D}}_1\big)^{-1}\big(\widehat{\Lambda} + \widehat{P}\widehat{\mathcal{C}} + \widehat{P}\widehat{\mathcal{B}}_1^T\widehat{P}\big)\\
&\qquad + \widehat{\mathcal{B}}_2^T\widehat{P} + \widehat{\mathcal{F}}_2\big]\\
&+ (\widehat{P}\widehat{\mathcal{B}}_2 + \widehat{\Lambda}\widehat{\mathcal{D}}_2 + \widehat{\mathcal{F}}_2^T)\widehat{R}_2^{-1}\big[\widehat{\mathcal{D}}_2^T\big(I - \widehat{P}\widehat{\mathcal{D}}_1\big)^{-1}\big(\widehat{\Lambda} + \widehat{P}\widehat{\mathcal{C}} + \widehat{P}\widehat{\mathcal{B}}_1^T\widehat{P}\big) + \widehat{\mathcal{B}}_2^T\widehat{P} + \widehat{\mathcal{F}}_2\big]\\
&= \big[(\widehat{P}\widehat{\mathcal{B}}_1 + \widehat{\Lambda}\widehat{\mathcal{D}}_1 + \widehat{\mathcal{C}}^T)\big(I - \widehat{P}\widehat{\mathcal{D}}_1\big)^{-1}\widehat{P}\widehat{\mathcal{D}}_2 + (\widehat{P}\widehat{\mathcal{B}}_2 + \widehat{\Lambda}\widehat{\mathcal{D}}_2 + \widehat{\mathcal{F}}_2^T)\big]\widehat{R}_2^{-1}\\
&\quad\cdot\big[\widehat{\mathcal{D}}_2^T\big(I - \widehat{P}\widehat{\mathcal{D}}_1\big)^{-1}\big(\widehat{\Lambda} + \widehat{P}\widehat{\mathcal{C}} + \widehat{P}\widehat{\mathcal{B}}_1^T\widehat{P}\big) + \widehat{\mathcal{B}}_2^T\widehat{P} + \widehat{\mathcal{F}}_2\big].
\end{aligned}
\tag{3.33}
$$

Note that

$$
\begin{aligned}
&(\widehat{P}\widehat{\mathcal{B}}_1 + \widehat{\Lambda}\widehat{\mathcal{D}}_1 + \widehat{\mathcal{C}}^T)\big(I - \widehat{P}\widehat{\mathcal{D}}_1\big)^{-1}\widehat{P}\widehat{\mathcal{D}}_2 + \widehat{P}\widehat{\mathcal{B}}_2 + \widehat{\Lambda}\widehat{\mathcal{D}}_2 + \widehat{\mathcal{F}}_2^T\\
&= (\widehat{P}\widehat{\mathcal{B}}_1 + \widehat{\Lambda}\widehat{\mathcal{D}}_1 + \widehat{\mathcal{C}}^T)\widehat{P}\big(I - \widehat{\mathcal{D}}_1\widehat{P}\big)^{-1}\widehat{\mathcal{D}}_2 + \widehat{\Lambda}\widehat{\mathcal{D}}_2 + \widehat{P}\widehat{\mathcal{B}}_2 + \widehat{\mathcal{F}}_2^T\\
&= (\widehat{P}\widehat{\mathcal{B}}_1\widehat{P} + \widehat{\mathcal{C}}^T\widehat{P})(I - \widehat{\mathcal{D}}_1\widehat{P})^{-1}\widehat{\mathcal{D}}_2 + \widehat{\Lambda}\big[\big(I - \widehat{\mathcal{D}}_1\widehat{P}\big)^{-1} - I\big]\widehat{\mathcal{D}}_2\\
&\qquad + \widehat{\Lambda}\widehat{\mathcal{D}}_2 + \widehat{P}\widehat{\mathcal{B}}_2 + \widehat{\mathcal{F}}_2^T\\
&= (\widehat{P}\widehat{\mathcal{B}}_1\widehat{P} + \widehat{\mathcal{C}}^T\widehat{P} + \widehat{\Lambda})\big(I - \widehat{\mathcal{D}}_1\widehat{P}\big)^{-1}\widehat{\mathcal{D}}_2 + \widehat{P}\widehat{\mathcal{B}}_2 + \widehat{\mathcal{F}}_2^T.
\end{aligned}
\tag{3.34}
$$

Hence, the right-hand side of (3.34) reads

$$
\begin{aligned}
&\big[(\widehat{P}\widehat{\mathcal{B}}_1\widehat{P} + \widehat{\mathcal{C}}^T\widehat{P} + \widehat{\Lambda})\big(I - \widehat{\mathcal{D}}_1\widehat{P}\big)^{-1}\widehat{\mathcal{D}}_2 + \widehat{P}\widehat{\mathcal{B}}_2 + \widehat{\mathcal{F}}_2^T\big]\widehat{R}_2^{-1}\\
&\quad\cdot\big[\widehat{\mathcal{D}}_2^T\big(I - \widehat{P}\widehat{\mathcal{D}}_1\big)^{-1}\big(\widehat{P}\widehat{\mathcal{C}} + \widehat{P}\widehat{\mathcal{B}}_1^T\widehat{P} + \widehat{\Lambda}\big) + \widehat{\mathcal{B}}_2^T\widehat{P} + \widehat{\mathcal{F}}_2\big].
\end{aligned}
\tag{3.35}
$$

Combining (3.31)–(3.35), we obtain

$$
\begin{aligned}
-\widehat{\Gamma} \equiv\ & -\widehat{\Gamma}(t, \widehat{P}, \widehat{\Lambda}) \triangleq \widehat{P}\widehat{\mathcal{A}} + \widehat{\mathcal{A}}^T\widehat{P} + \widehat{P}\widehat{\mathcal{F}}_1\widehat{P} + \widehat{\mathcal{Q}}_2\\
&+ (\widehat{P}\widehat{\mathcal{B}}_1 + \widehat{\mathcal{C}}^T)\big(I - \widehat{P}\widehat{\mathcal{D}}_1\big)^{-1}\widehat{P}\big(\widehat{\mathcal{C}} + \widehat{\mathcal{B}}_1^T\widehat{P}\big) + \widehat{\Lambda}\widehat{\mathcal{D}}_1\big(I - \widehat{P}\widehat{\mathcal{D}}_1\big)^{-1}\widehat{\Lambda}\\
&+ \big(\widehat{P}\widehat{\mathcal{B}}_1 + \widehat{\mathcal{C}}^T\big)\big(I - \widehat{P}\widehat{\mathcal{D}}_1\big)^{-1}\widehat{\Lambda} + \widehat{\Lambda}\big(I - \widehat{\mathcal{D}}_1\widehat{P}\big)^{-1}\big(\widehat{\mathcal{B}}_1^T\widehat{P} + \widehat{\mathcal{C}}\big)\\
&- \big[\big(\widehat{P}\widehat{\mathcal{B}}_1\widehat{P} + \widehat{\mathcal{C}}^T\widehat{P} + \widehat{\Lambda}\big)\big(I - \widehat{\mathcal{D}}_1\widehat{P}\big)^{-1}\widehat{\mathcal{D}}_2 + \widehat{P}\widehat{\mathcal{B}}_2 + \widehat{\mathcal{F}}_2^T\big]\widehat{R}_2^{-1}\\
&\quad\cdot\big[\widehat{\mathcal{D}}_2^T\big(I - \widehat{P}\widehat{\mathcal{D}}_1\big)^{-1}\big(\widehat{P}\widehat{\mathcal{C}} + \widehat{P}\widehat{\mathcal{B}}_1^T\widehat{P} + \widehat{\Lambda}\big) + \widehat{\mathcal{B}}_2^T\widehat{P} + \widehat{\mathcal{F}}_2\big]\\
=\ & \widehat{P}\widehat{\mathcal{A}} + \widehat{\mathcal{A}}^T\widehat{P} + \widehat{P}\widehat{\mathcal{F}}_1\widehat{P} + \widehat{\mathcal{Q}}_2\\
&+ \begin{pmatrix} \widehat{P}\widehat{\mathcal{B}}_1 + \widehat{\mathcal{C}}^T & \widehat{\Lambda} \end{pmatrix}\begin{pmatrix} (I - \widehat{P}\widehat{\mathcal{D}}_1)^{-1}\widehat{P} & (I - \widehat{P}\widehat{\mathcal{D}}_1)^{-1}\\ (I - \widehat{\mathcal{D}}_1\widehat{P})^{-1} & \widehat{\mathcal{D}}_1(I - \widehat{P}\widehat{\mathcal{D}}_1)^{-1}\end{pmatrix}\begin{pmatrix} \widehat{\mathcal{B}}_1^T\widehat{P} + \widehat{\mathcal{C}}\\ \widehat{\Lambda}\end{pmatrix}\\
&- \big[\big(\widehat{P}\widehat{\mathcal{B}}_1\widehat{P} + \widehat{\mathcal{C}}^T\widehat{P} + \widehat{\Lambda}\big)\big(I - \widehat{\mathcal{D}}_1\widehat{P}\big)^{-1}\widehat{\mathcal{D}}_2 + \widehat{P}\widehat{\mathcal{B}}_2 + \widehat{\mathcal{F}}_2^T\big]\widehat{R}_2^{-1}\\
&\quad\cdot\big[\widehat{\mathcal{D}}_2^T\big(I - \widehat{P}\widehat{\mathcal{D}}_1\big)^{-1}\big(\widehat{P}\widehat{\mathcal{C}} + \widehat{P}\widehat{\mathcal{B}}_1^T\widehat{P} + \widehat{\Lambda}\big) + \widehat{\mathcal{B}}_2^T\widehat{P} + \widehat{\mathcal{F}}_2\big].
\end{aligned}
\tag{3.36}
$$

Once we write the map $\widehat{\Gamma}$ in the above form, we have that for any $\widehat{P}, \widehat{\Lambda} \in \mathcal{S}^{2n}$, provided $(I - \widehat{P}\widehat{\mathcal{D}}_1)^{-1}$ and $\widehat{R}_2^{-1}$ exist, $\widehat{\Gamma}(t, \widehat{P}, \widehat{\Lambda}) \in \mathcal{S}^{2n}$, i.e., for any symmetric $\widehat{P}$ and $\widehat{\Lambda}$, image $\Gamma(t, \widehat{P}, \widehat{\Lambda})$ of $(\widehat{P}, \widehat{\Lambda})$ under the map $\widehat{\Gamma}$ is also symmetric. Here, we should note that similarly to (3.24),

$$\widehat{\mathcal{D}}_1\big(I - \widehat{P}\widehat{\mathcal{D}}_1\big)^{-1} = \big(I - \widehat{\mathcal{D}}_1\widehat{P}\big)^{-1}\widehat{\mathcal{D}}_1 \tag{3.37}$$

is symmetric and $\mathcal{S}^{2m_1}$-valued. Now, the Riccati equation for $(\widehat{P}(\cdot), \widehat{\Lambda}(\cdot))$ is given by

$$\begin{cases} d\widehat{P}(t) = \widehat{\Gamma}(t, \widehat{P}(t), \widehat{\Lambda}(t))dt + \widehat{\Lambda}(t)dW(t), \qquad t \in [0, T], \\ \widehat{P}(T) = \widehat{\mathcal{Q}}_2, \\ \det[I - \widehat{P}(t)\widehat{\mathcal{D}}_1(t)] \neq 0, \\ \det[R_2(t) + \widehat{\mathcal{D}}_2(t)^T\big(I - \widehat{P}(t)\widehat{\mathcal{D}}_1(t)\big)^{-1}\widehat{P}(t)\widehat{\mathcal{D}}_2(t)] \neq 0, \end{cases} \tag{3.38}$$

with $\widehat{\Gamma}(t, \widehat{P}, \widehat{\Lambda})$ given by (3.36). We summarize the above as follows.

THEOREM 3.3. *Let* (S) *hold. Let Riccati equation* (3.38) *admit an adapted solution* $(\widehat{P}(\cdot), \widehat{\Lambda}(\cdot))$. *Let* $X(\cdot)$ *be the solution of* (3.30). *Define* $(Y(\cdot), Z(\cdot), \overline{u}_2(\cdot))$ *by* (3.17), (3.26), *and* (3.27). *Then* (3.15)–(3.16) *holds. Moreover, for such a* $\overline{u}_2(\cdot)$, *the following holds:*

$$\widehat{J}_2(\xi; \overline{u}_2(\cdot)) = \langle\, \widehat{P}_2(0)\xi, \xi \,\rangle, \tag{3.39}$$

where $\widehat{P}(\cdot) = \begin{pmatrix} \widehat{P}_2(\cdot) & \widehat{P}_3(\cdot) \\ \widehat{P}_3(\cdot)^T & \widehat{P}_4(\cdot) \end{pmatrix}$. *When* (i) *of Theorem* 3.2 *holds, in particular, if* (3.12) *holds, the state feedback control* $\overline{u}_2(\cdot)$ *defined by* (3.26) *is an optimal control of Problem* $(\mathrm{LQ})_2$.

Proof. We need only prove (3.39). Similarly to (3.8)–(3.10), we are able to show that

$$\begin{aligned} \widehat{J}_2(\xi; u_2(\cdot)) &= \langle\, Y(0), X(0) \,\rangle + E\int_0^T \langle\, u_2, R_2u_2 + \widehat{\mathcal{B}}_2^TY + \widehat{\mathcal{D}}_2^TZ + \widehat{\mathcal{F}}_2X \,\rangle\, dt \\ &= \langle\, \widehat{P}_2(0)\xi, \xi \,\rangle. \end{aligned}$$

The rest is clear. □

Note that optimal control $\overline{u}_2(\cdot)$ has a "state" feedback representation (3.26) with the "state" $X(\cdot) \equiv \begin{pmatrix} x(\cdot) \\ \psi(\cdot) \end{pmatrix}$ being the solution of (3.30), or $X(\cdot)$ is the solution of the system

$$\begin{cases} dX = \big[\widetilde{\mathcal{A}}X + \widetilde{\mathcal{B}}_2\overline{u}_2\big]dt + \big[\widetilde{\mathcal{C}}X + \widetilde{\mathcal{D}}_2\overline{u}_2\big]dW(t), \\ X(0) = X_0 \end{cases} \tag{3.40}$$

corresponding to the feedback control $\overline{u}_2(\cdot)$ given by (3.26), where

$$\begin{cases} \widetilde{\mathcal{A}} = \widehat{\mathcal{A}} + \widehat{\mathcal{F}}_1\widehat{P} + \widehat{\mathcal{B}}_1(I - \widehat{P}\widehat{\mathcal{D}}_1)^{-1}(\widehat{\mathcal{A}} + \widehat{P}\widehat{\mathcal{C}} + \widehat{P}\widehat{\mathcal{B}}_1\widehat{P}), \\ \widetilde{C} = \widehat{\mathcal{C}} + \widehat{\mathcal{B}}_1^T\widehat{P} + \widehat{\mathcal{D}}_1(I - \widehat{P}\widehat{\mathcal{D}}_1)^{-1}(\widehat{\mathcal{A}} + \widehat{P}\widehat{\mathcal{C}} + \widehat{P}\widehat{\mathcal{B}}_1\widehat{P}), \\ \widetilde{\mathcal{B}}_2 = \widehat{\mathcal{B}}_2 + \widehat{\mathcal{B}}_1(I - \widehat{P}\widehat{\mathcal{D}}_1)^{-1}\widehat{P}\widehat{\mathcal{D}}_2, \quad \widetilde{\mathcal{D}}_2 = \widehat{\mathcal{D}}_2 + \widehat{\mathcal{D}}_1(I - \widehat{P}\widehat{\mathcal{D}}_1)^{-1}\widehat{P}\widehat{\mathcal{D}}_2. \end{cases} \tag{3.41}$$

The point here is that $\overline{u}_2(\cdot)$ given by (3.26) is nonanticipating. Likewise, for the follower, the optimal control $\overline{u}_1(\cdot)$ can also be represented in a nonanticipating way.

In fact, by (1.7)–(1.8), we have

$$
\begin{aligned}
\overline{u}_1 &= -\widehat{R}_1^{-1}\big\{\widehat{S}_1 x - \widehat{R}_1^{-1}\widehat{\mathcal{B}}_1^T Y + \widehat{\mathcal{D}}_1^T Z + D_1^T P D_2 u_2\big\} \\
&= -\widehat{R}_1^{-1}\Big\{ \begin{pmatrix} \widehat{S}_1 & 0 \end{pmatrix} - \widehat{R}_1^{-1}\widehat{\mathcal{B}}_1^T\widehat{P} + \widehat{\mathcal{D}}_1^T\big(I - \widehat{P}\widehat{\mathcal{D}}_1\big)^{-1}\big\{\widehat{\Lambda} + \widehat{P}\widehat{\mathcal{C}} + \widehat{P}\widehat{\mathcal{B}}_1^T\widehat{P} \\
&\quad - \widehat{P}\widehat{\mathcal{D}}_2\widehat{R}_2^{-1}\big[\widehat{\mathcal{D}}_2^T\big(I - \widehat{P}\widehat{\mathcal{D}}_1\big)^{-1}\big(\widehat{\Lambda} + \widehat{P}\widehat{\mathcal{C}} + \widehat{P}\widehat{\mathcal{B}}_1^T\widehat{P}\big) + \widehat{\mathcal{B}}_2^T\widehat{P} + \widehat{\mathcal{F}}_2\big]\big\} \\
&\quad - D_1^T P D_2\widehat{R}_2^{-1}\big[\widehat{\mathcal{D}}_2^T\big(I - \widehat{P}\widehat{\mathcal{D}}_1\big)^{-1}\big(\widehat{\Lambda} + \widehat{P}\widehat{\mathcal{C}} + \widehat{P}\widehat{\mathcal{B}}_1^T\widehat{P}\big) + \widehat{\mathcal{B}}_2^T\widehat{P} + \widehat{\mathcal{F}}_2\big]\Big\}X.
\end{aligned} \tag{3.42}
$$

Hence, under assumptions in Theorems 2.3 and 3.2, our differential game admits an open-loop solution $(\overline{u}_1(\cdot), \overline{u}_2(\cdot))$, and they admit a state feedback representation (3.26) and (3.42).

Remark 3.4. From (3.36), one can see that the equations for each block $\widehat{P}_2(\cdot)$, $\widehat{P}_3(\cdot)$, and $\widehat{P}_4(\cdot)$ of $\widehat{P}(\cdot)$ in (3.38) are heavily coupled (even for very simple cases; this is mainly due to the appearance of the controls in the diffusion and the randomness of the coefficients; see below). In particular, one might not be able to solve the equation for $\widehat{P}_2(\cdot)$ first, and then the remaining equations for $\widehat{P}_3(\cdot)$ and $\widehat{P}_4(\cdot)$. Although from (3.39), it seems that only $\widehat{P}_2(\cdot)$ plays a particular role, blocks $\widehat{P}_3(\cdot)$, $\widehat{P}_4(\cdot)$, and $\widehat{\Lambda}(\cdot)$ actually play equally important roles. We note that in (2.8), only $P(0)$ and $\varphi(0)$ appear. However, $\Lambda(\cdot)$ and $\theta(\cdot)$ play crucial roles as well. This is a similar situation. We expect that there might be some interesting relations among blocks $\widehat{P}_i(\cdot)$ $(i = 2, 3, 4)$, but we are currently not able to find them. We hope to say something about this in future papers.

We now look at a special case in which the follower does not appear. In this case the problem is reduced to a typical LQ problem. Let us still regard it as if the follower does appear but does not affect the game at all, i.e., we assume that

$$
B_1 = D_1 = 0, \quad Q_1 = 0, \quad G_1 = 0, \quad R_1 = I. \tag{3.43}
$$

In the above case, Riccati equation (1.5) admits a unique solution $(P(\cdot), \Lambda(\cdot)) = (0, 0)$. Consequently, by (1.10), one has

$$
\begin{cases}
\widehat{A} = A, \quad \widehat{F}_1 = 0, \quad \widehat{B}_1 = 0, \quad \widehat{B}_2 = B_2, \\
\widehat{C} = C, \quad \widehat{F}_2 = 0, \quad \widehat{D}_1 = 0, \quad \widehat{D}_2 = D_2.
\end{cases} \tag{3.44}
$$

The above further implies that (see (3.14))

$$
\begin{cases}
\widehat{\mathcal{A}} \triangleq \begin{pmatrix} A & 0 \\ 0 & A \end{pmatrix}, \quad \widehat{\mathcal{F}}_1 = 0, \quad \widehat{\mathcal{B}}_1 = 0, \quad \widehat{\mathcal{B}}_2 = \begin{pmatrix} B_2 \\ 0 \end{pmatrix}, \\
\widehat{\mathcal{C}} \triangleq \begin{pmatrix} C & 0 \\ 0 & C \end{pmatrix}, \quad \widehat{\mathcal{D}}_1 = 0, \quad \widehat{\mathcal{D}}_2 = \begin{pmatrix} D_2 \\ 0 \end{pmatrix}, \\
\widehat{\mathcal{Q}}_2 \triangleq \begin{pmatrix} Q_2 & 0 \\ 0 & 0 \end{pmatrix}, \quad \widehat{\mathcal{F}}_2 = 0, \quad \widehat{\mathcal{G}}_2 = \begin{pmatrix} G_2 & 0 \\ 0 & 0 \end{pmatrix}.
\end{cases} \tag{3.45}
$$

Then (3.36) becomes

$$
\begin{aligned}
-\widehat{\Gamma} \equiv -\widehat{\Gamma}(t, \widehat{P}, \widehat{\Lambda}) &\triangleq \widehat{P}\widehat{\mathcal{A}} + \widehat{\mathcal{A}}^T\widehat{P} + \widehat{\mathcal{Q}}_2 + \widehat{\mathcal{C}}^T\widehat{P}\widehat{\mathcal{C}} + \widehat{\mathcal{C}}^T\widehat{\Lambda} + \widehat{\Lambda}\widehat{\mathcal{C}} \\
&\quad - \big[\big(\widehat{\mathcal{C}}^T\widehat{P} + \widehat{\Lambda}\big)\widehat{\mathcal{D}}_2 + \widehat{P}\widehat{\mathcal{B}}_2\big]\widehat{R}_2^{-1}\big[\widehat{\mathcal{D}}_2^T\big(\widehat{P}\widehat{\mathcal{C}} + \widehat{\Lambda}\big) + \widehat{\mathcal{B}}_2^T\widehat{P}\big].
\end{aligned} \tag{3.46}
$$

If $(\widehat{P}(\cdot),\widehat{\Lambda}(\cdot))$ is an adapted solution of (3.38), and if we let

$$\widehat{P}(\cdot)=\begin{pmatrix}\widehat{P}_2(\cdot) & \widehat{P}_3(\cdot)\\ \widehat{P}_3(\cdot)^T & \widehat{P}_4(\cdot)\end{pmatrix},\quad \widehat{\Lambda}(\cdot)=\begin{pmatrix}\widehat{\Lambda}_2(\cdot) & \widehat{\Lambda}_3(\cdot)\\ \widehat{\Lambda}_3(\cdot)^T & \widehat{\Lambda}_4(\cdot)\end{pmatrix}, \tag{3.47}$$

then $(\widehat{P}_2(\cdot),\widehat{\Lambda}_2(\cdot))$ is an adapted solution of

$$\begin{cases} d\widehat{P}_2=-\big\{\widehat{P}_2A+A^T\widehat{P}_2+Q_2+C^T\widehat{P}_2C+C^T\widehat{\Lambda}_2+\widehat{\Lambda}_2C\\ \quad -[(C^T\widehat{P}_2+\widehat{\Lambda}_2)D_2+\widehat{P}_2B_2](R_2+D_2^T\widehat{P}_2D_2)^{-1}[D_2^T(\widehat{P}_2C+\widehat{\Lambda}_2)+B_2^T\widehat{P}]\big\}dt\\ \qquad\quad +\widehat{\Lambda}_2dW(t),\\ \widehat{P}_2(T)=Q_2. \end{cases} \tag{3.48}$$

This is the Riccati equation for the LQ problem (found in [6, 7, 8]) with the state equation (1.1) in which $B_1=D_1=0$ and with the cost functional (1.2) (with $i=2$). Thus, we might regard our differential game problem as a generalization of LQ problems.

To conclude this section, we would like to point out that the general solvability of Riccati equation (3.38) is very difficult. It remains a very challenging open question. We are not able to attack the general case in this paper. Instead, we would like to look at some special and interesting cases in section 5.

4. Two one-dimensional cases. In this section, we present two one-dimensional cases with some very special coefficients, in which we want to address two points: (i) Due to the randomness of the coefficients and the appearance of the controls in the diffusion, even for a very simple problem, the explicit solution might not be expected; and (ii) due to the appearance of the controls in the diffusion, the Isaacs-type condition does not necessarily hold, which results in that the "equilibrium" does not necessarily exist.

We now first assume the following:

$$\begin{cases} n=m_1=m_2=1,\quad A=C=B_1=B_2=Q_1=Q_2=0,\\ D_1=D_2=R_1=R_2=1,\quad G_1=G_2=\eta\triangleq e^{\frac{T}{2}+W(T)}-1, \end{cases} \tag{4.1}$$

where $W(T)$ is the value, at $t=T$, of the Brownian motion $W(\cdot)$ appearing in the state equation. We choose the above special form of η merely for the later computation to be easier. Other choices are also possible. The point here is that η is not deterministic. When (4.1) holds, we can rewrite the state equation (1.1) as follows:

$$\begin{cases} dx(t)=[u_1(t)+u_2(t)]dW(t), & t\in[0,T],\\ x(0)=\xi, \end{cases} \tag{4.2}$$

and the cost functionals can be written as follows:

$$J_i(\xi;u_1(\cdot),u_2(\cdot))=E\left\{\int_0^T|u_i(t)|^2dt+\eta x(T)^2\right\},\qquad i=1,2. \tag{4.3}$$

We see that the problem looks to be extremely simple. In this case, Riccati equation (1.5) reads

$$\begin{cases} dP=\dfrac{\Lambda^2}{P+1}dt+\Lambda dW(t), & t\in[0,T],\\ P(T)=\eta,\\ P(t)+1>0, & t\in[0,T],\ \text{a.s.} \end{cases} \tag{4.4}$$

One can check that the adapted solution of (4.4) is given by

$$\begin{cases} P(t) = e^{\frac{t}{2}+W(t)} - 1, \\ \Lambda(t) = P(t) + 1 \equiv e^{\frac{t}{2}+W(t)}. \end{cases} \tag{4.5}$$

Consequently, BSDE (1.6) takes the following form:

$$\begin{cases} d\varphi = (\theta - u_2)dt + \theta dW(t), \qquad t \in [0,T], \\ \varphi(T) = 0. \end{cases} \tag{4.5}$$

The optimal control $\overline{u}_1(\cdot)$ is given by

$$\overline{u}_1(t) = -x(t) - \frac{\theta(t) + P(t)u_2(t)}{P(t)+1}, \qquad t \in [0,T], \tag{4.6}$$

and the optimal cost is given by (note $P(0) = 0$)

$$\begin{aligned} &\inf_{u_1(\cdot)\in\mathcal{U}_1[0,T]} J_1(\xi, u_1(\cdot), u_2(\cdot)) = J_1(\xi, \overline{u}_1(\cdot), u_2(\cdot)) \\ &= 2\varphi(0)\xi + E\int_0^T \left\{ 2\theta(t)u_2(t) + P(t)u_2(t)^2 - \frac{|\theta(t) + P(t)u_2(t)|^2}{P(t)+1} \right\} dt \\ &= 2\varphi(0)\xi + E\int_0^T \frac{P(t)u_2(t)^2 + 2\theta(t)u_2(t) - \theta(t)^2}{P(t)+1} dt. \end{aligned} \tag{4.7}$$

We note that since $\theta(\cdot)$ (determined by (4.5)) is anticipating, so is $\overline{u}_1(\cdot)$ defined by (4.6). Next, with

$$\widehat{R}_1 \triangleq P + 1, \quad \widehat{S}_1 = \widehat{S}_2 \triangleq \Lambda \equiv P + 1, \tag{4.8}$$

we have

$$\begin{cases} \widehat{A} = \widehat{F}_1 = \widehat{B}_1 = \widehat{B}_2 = 0, \quad \widehat{C} \triangleq -\widehat{R}_1^{-1}\widehat{S}_1 = -1, \\ \widehat{D}_1 \triangleq -\widehat{R}_1^{-1} = -\dfrac{1}{P+1}, \quad \widehat{D}_2 \triangleq 1 - \dfrac{P}{P+1} = \dfrac{1}{P+1}, \\ \widehat{F}_2 \triangleq \widehat{S}_2 - P\widehat{R}_1^{-1}\widehat{S}_1 = 1. \end{cases} \tag{4.9}$$

Then

$$\begin{cases} \widehat{\mathcal{A}} = \widehat{\mathcal{F}}_1 = \widehat{\mathcal{B}}_1 = \widehat{\mathcal{Q}}_2 = 0, \quad \widehat{\mathcal{B}}_2 = 0, \\ \widehat{\mathcal{C}} = -I, \quad \widehat{\mathcal{D}}_1 = -\dfrac{1}{P+1}\begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, \quad \widehat{\mathcal{D}}_2 = \dfrac{1}{P+1}\begin{pmatrix} 1 \\ 0 \end{pmatrix}, \\ \widehat{\mathcal{F}}_2 = \begin{pmatrix} 0 & 1 \end{pmatrix}, \quad \widehat{\mathcal{G}}_2 = \eta\begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}. \end{cases} \tag{4.10}$$

Note that

$$\begin{aligned} (I - \widehat{P}\widehat{\mathcal{D}}_1)^{-1} &= \left(I + \frac{1}{P+1}\widehat{P}\begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix} \right)^{-1} \\ &= (P+1)\begin{pmatrix} P+1+\widehat{P}_3 & \widehat{P}_2 \\ \widehat{P}_4 & P+1+\widehat{P}_3 \end{pmatrix}^{-1} \\ &= \frac{P+1}{(P+1+\widehat{P}_3)^2 - \widehat{P}_2\widehat{P}_4}\begin{pmatrix} P+1+\widehat{P}_3 & -\widehat{P}_2 \\ -\widehat{P}_4 & P+1+\widehat{P}_3 \end{pmatrix}. \end{aligned} \tag{4.11}$$

Thus,

$$\begin{aligned}
&(I-\widehat{P}\widehat{\mathcal{D}}_1)^{-1}\widehat{P}\\
&\quad=\frac{P+1}{(P+1+\widehat{P}_3)^2-\widehat{P}_2\widehat{P}_4}\begin{pmatrix}P+1+\widehat{P}_3 & -\widehat{P}_2\\ -\widehat{P}_4 & P+1+\widehat{P}_3\end{pmatrix}\begin{pmatrix}\widehat{P}_2 & \widehat{P}_3\\ \widehat{P}_3 & \widehat{P}_4\end{pmatrix}\\
&\quad=\frac{P+1}{(P+1+\widehat{P}_3)^2-\widehat{P}_2\widehat{P}_4}\begin{pmatrix}(P+1)\widehat{P}_2 & (P+1+\widehat{P}_3)\widehat{P}_3-\widehat{P}_2\widehat{P}_4\\ (P+1+\widehat{P}_3)\widehat{P}_3-\widehat{P}_2\widehat{P}_4 & (P+1)\widehat{P}_4\end{pmatrix}
\end{aligned}\tag{4.12}$$

and

$$\widehat{\mathcal{D}}_1(I-\widehat{P}\widehat{\mathcal{D}}_1)^{-1}=\frac{-1}{(P+1+\widehat{P}_3)^2-\widehat{P}_2\widehat{P}_4}\begin{pmatrix}-\widehat{P}_2 & P+1+\widehat{P}_3\\ P+1+\widehat{P}_3 & -\widehat{P}_4\end{pmatrix}.\tag{4.13}$$

Then it follows that

$$\begin{aligned}
\widehat{R}_2&\triangleq R_2+\widehat{\mathcal{D}}_2^T\big(I-\widehat{P}\widehat{\mathcal{D}}_1\big)^{-1}\widehat{P}\widehat{\mathcal{D}}_2\\
&=1+\frac{\widehat{P}_2}{(P+1+\widehat{P}_3)^2-\widehat{P}_2\widehat{P}_4}=\frac{(P+1+\widehat{P}_3)^2-\widehat{P}_2\widehat{P}_4+\widehat{P}_2}{(P+1+\widehat{P}_3)^2-\widehat{P}_2\widehat{P}_4}.
\end{aligned}\tag{4.14}$$

Hence, we can compute

$$\begin{aligned}
-\widehat{\Gamma}&\equiv-\widehat{\Gamma}(t,\widehat{P},\widehat{\Lambda})=\big(I-\widehat{P}\widehat{\mathcal{D}}_1\big)^{-1}\widehat{P}+\widehat{\Lambda}\widehat{\mathcal{D}}_1\big(I-\widehat{P}\widehat{\mathcal{D}}_1\big)^{-1}\widehat{\Lambda}\\
&\quad+\big(I-\widehat{P}\widehat{\mathcal{D}}_1\big)^{-1}\widehat{\Lambda}+\widehat{\Lambda}\big(I-\widehat{\mathcal{D}}_1\widehat{P}\big)^{-1}\\
&\quad-\big[\big(\widehat{P}+\widehat{\Lambda}\big)\big(I-\widehat{\mathcal{D}}_1\widehat{P}\big)^{-1}\widehat{\mathcal{D}}_2+\widehat{\mathcal{F}}_2^T\big]\widehat{R}_2^{-1}\big[\widehat{\mathcal{D}}_2^T\big(I-\widehat{P}\widehat{\mathcal{D}}_1\big)^{-1}\big(\widehat{P}+\widehat{\Lambda}\big)+\widehat{\mathcal{F}}_2\big]\\
&=\frac{P+1}{(P+1+\widehat{P}_3)^2-\widehat{P}_2\widehat{P}_4}\begin{pmatrix}(P+1)\widehat{P}_2 & (P+1+\widehat{P}_3)\widehat{P}_3-\widehat{P}_2\widehat{P}_4\\ (P+1+\widehat{P}_3)\widehat{P}_3-\widehat{P}_2\widehat{P}_4 & (P+1)\widehat{P}_4\end{pmatrix}\\
&\quad-\frac{1}{(P+1+\widehat{P}_3)^2-\widehat{P}_2\widehat{P}_4}\widehat{\Lambda}\begin{pmatrix}-\widehat{P}_2 & P+1+\widehat{P}_3\\ P+1+\widehat{P}_3 & -\widehat{P}_4\end{pmatrix}\widehat{\Lambda}\\
&\quad-\frac{P+1}{(P+1+\widehat{P}_3)^2-\widehat{P}_2\widehat{P}_4}\begin{pmatrix}P+1+\widehat{P}_3 & -\widehat{P}_2\\ -\widehat{P}_4 & P+1+\widehat{P}_3\end{pmatrix}\widehat{\Lambda}\\
&\quad-\frac{P+1}{(P+1+\widehat{P}_3)^2-\widehat{P}_2\widehat{P}_4}\widehat{\Lambda}\begin{pmatrix}P+1+\widehat{P}_3 & -\widehat{P}_4\\ -\widehat{P}_2 & P+1+\widehat{P}_3\end{pmatrix}\\
&\quad-\frac{(P+1+\widehat{P}_3)^2-\widehat{P}_2\widehat{P}_4}{(P+1+\widehat{P}_3)^2-\widehat{P}_2\widehat{P}_4+\widehat{P}_2}\\
&\quad\cdot\left\{\frac{1}{(P+1+\widehat{P}_3)^2-\widehat{P}_2\widehat{P}_4}(\widehat{P}+\widehat{\Lambda})\begin{pmatrix}P+1+\widehat{P}_3 & -\widehat{P}_4\\ -\widehat{P}_2 & P+1+\widehat{P}_3\end{pmatrix}\begin{pmatrix}1\\0\end{pmatrix}+\begin{pmatrix}0\\1\end{pmatrix}\right\}\\
&\quad\cdot\left\{\frac{1}{(P+1+\widehat{P}_3)^2-\widehat{P}_2\widehat{P}_4}\begin{pmatrix}1 & 0\end{pmatrix}\begin{pmatrix}P+1+\widehat{P}_3 & -\widehat{P}_2\\ -\widehat{P}_4 & P+1+\widehat{P}_3\end{pmatrix}(\widehat{P}+\widehat{\Lambda})+\begin{pmatrix}0 & 1\end{pmatrix}\right\}\\
&=\frac{P+1}{(P+1+\widehat{P}_3)^2-\widehat{P}_2\widehat{P}_4}\begin{pmatrix}(P+1)\widehat{P}_2 & (P+1+\widehat{P}_3)\widehat{P}_3-\widehat{P}_2\widehat{P}_4\\ (P+1+\widehat{P}_3)\widehat{P}_3-\widehat{P}_2\widehat{P}_4 & (P+1)\widehat{P}_4\end{pmatrix}\\
&\quad-\frac{1}{(P+1+\widehat{P}_3)^2-\widehat{P}_2\widehat{P}_4}\widehat{\Lambda}\begin{pmatrix}-\widehat{P}_2 & P+1+\widehat{P}_3\\ P+1+\widehat{P}_3 & -\widehat{P}_4\end{pmatrix}\widehat{\Lambda}
\end{aligned}$$

$$
\begin{aligned}
&- \frac{P+1}{(P+1+\widehat{P}_3)^2-\widehat{P}_2\widehat{P}_4}\begin{pmatrix} P+1+\widehat{P}_3 & -\widehat{P}_2 \\ -\widehat{P}_4 & P+1+\widehat{P}_3 \end{pmatrix}\widehat{\Lambda} \\
&- \frac{P+1}{(P+1+\widehat{P}_3)^2-\widehat{P}_2\widehat{P}_4}\widehat{\Lambda}\begin{pmatrix} P+1+\widehat{P}_3 & -\widehat{P}_4 \\ -\widehat{P}_2 & P+1+\widehat{P}_3 \end{pmatrix} \\
&- \frac{(P+1+\widehat{P}_3)^2-\widehat{P}_2\widehat{P}_4}{(P+1+\widehat{P}_3)^2-\widehat{P}_2\widehat{P}_4+\widehat{P}_2} \\
&\cdot \left\{ \frac{1}{[(P+1+\widehat{P}_3)^2-\widehat{P}_2\widehat{P}_4]^2}(\widehat{P}+\widehat{\Lambda})\begin{pmatrix} (P+1+\widehat{P}_3)^2 & -\widehat{P}_2(P+1+\widehat{P}_3) \\ -\widehat{P}_2(P+1+\widehat{P}_3) & \widehat{P}_2^2 \end{pmatrix}(\widehat{P}+\widehat{\Lambda}) \right. \\
&+ \frac{1}{(P+1+\widehat{P}_3)^2-\widehat{P}_2\widehat{P}_4}(\widehat{P}+\widehat{\Lambda})\begin{pmatrix} 0 & P+1+\widehat{P}_3 \\ 0 & -\widehat{P}_2 \end{pmatrix} \\
&\left. + \frac{1}{(P+1+\widehat{P}_3)^2-\widehat{P}_2\widehat{P}_4}\begin{pmatrix} 0 & 0 \\ P+1+\widehat{P}_3 & -\widehat{P}_2 \end{pmatrix}(\widehat{P}+\widehat{\Lambda}) + \begin{pmatrix} 0 & 0 \\ 0 & 1 \end{pmatrix} \right\}.
\end{aligned}
$$

From the above, we can easily see that in the Riccati equation

$$
\begin{cases}
d\widehat{P}(t) = \widehat{\Gamma}(t,\widehat{P}(t),\widehat{\Lambda}(t))dt + \widehat{\Lambda}(t)dW(t), & t\in[0,T], \\
\widehat{P}(T) = 0, & \\
P(t)+1+\widehat{P}_3(t)-\widehat{P}_2(t)\widehat{P}_4(t)\neq 0, & t\in[0,T], \\
[P(t)+1+\widehat{P}_3(t)]^2-\widehat{P}_2(t)\widehat{P}_4(t)+\widehat{P}_2(t)\neq 0, & t\in[0,T],
\end{cases} \tag{4.15}
$$

the components $\widehat{P}_2(\cdot)$, $\widehat{P}_3(\cdot)$, and $\widehat{P}_4(\cdot)$ are heavily coupled. Thus, an explicit solution of (4.16) is not expected. The reason for the complexity is the appearance of the controls in the diffusion and the randomness of the coefficients.

Let us now look at another special case:

$$
\begin{cases}
n = m_1 = m_2 = 1, \quad A = C = B_1 = B_2 = Q_1 = Q_2 = R_1 = R_2 = 0, \\
D_1 = D_2 = G_1 = -G_2 = 1.
\end{cases} \tag{4.16}
$$

Then the state equation is the same as (4.2) and the cost functionals are

$$
J(\xi;u_1(\cdot),u_2(\cdot)) \triangleq J_1(\xi;u_1(\cdot),u_2(\cdot)) = E\Big\{|x(T)|^2\Big\} = -J_2(\xi;u_1(\cdot),u_2(\cdot)). \tag{4.17}
$$

Thus, our leader-follower differential game becomes a zero-sum differential game with the state equation (4.2) and the cost functional $J(\xi;u_1(\cdot),u_2(\cdot))$, in which Player 1 is the minimizer and Player 2 is the maximizer. If we denote the upper and lower values (in the sense of Elliot–Kalton [10]) by $V^+(t,x)$ and $V^-(t,x)$, respectively, then a formal application of Bellman's dynamic programming principle leads to the following Isaacs equations for these two functions:

$$
\begin{cases}
V_t^+(t,x) + H^+(V_{xx}^+(t,x)) = 0, \\
V^+(T,x) = x^2,
\end{cases} \tag{4.18}
$$

$$
\begin{cases}
V_t^-(t,x) + H^-(V_{xx}^-(t,x)) = 0, \\
V^-(T,x) = x^2,
\end{cases} \tag{4.19}
$$

where

$$\begin{cases} H^+(K) \triangleq \inf\limits_{u_1\in\mathbb{R}^{m_1}} \sup\limits_{u_2\in\mathbb{R}^{m_2}} \left\{\dfrac{1}{2}(u_1+u_2)^2K\right\} = \begin{cases} 0, & K\le 0,\\ +\infty, & K>0,\end{cases}\\ H^-(K) \triangleq \sup\limits_{u_2\in\mathbb{R}^{m_2}} \inf\limits_{u_1\in\mathbb{R}^{m_1}} \left\{\dfrac{1}{2}(u_1+u_2)^2K\right\} = \begin{cases} 0, & K\ge 0,\\ -\infty, & K<0.\end{cases}\end{cases} \tag{4.20}$$

Clearly, the usual Isaacs condition does not hold. We can check that the solutions of (4.19) and (4.20) are given by the following:

$$V^+(t,x) = \begin{cases} +\infty, & (t,x)\in[0,T)\times\mathbb{R},\\ x^2, & t=T,\ x\in\mathbb{R},\end{cases} \tag{4.21}$$

and

$$V^-(t,x) = x^2, \qquad (t,x)\in[0,T]\times\mathbb{R}. \tag{4.22}$$

They are not equal. Thus, the value (in the sense of Elliot–Kalton) does not exist. On the other hand, we may look at the problem using open-loop strategies. Since

$$\begin{cases} J_1(\xi;u_1(\cdot),u_2(\cdot)) = \xi^2 + E\displaystyle\int_0^T |u_1(t)+u_2(t)|^2dt,\\ J_2(\xi;u_1(\cdot),u_2(\cdot)) = -\xi^2 - E\displaystyle\int_0^T |u_1(t)+u_2(t)|^2dt,\end{cases} \tag{4.23}$$

we see easily that

$$\begin{cases} \inf\limits_{u_1(\cdot)\in\mathcal{U}_1[0,T]} J_1(\xi;u_1(\cdot),u_2(\cdot)) = \xi^2 \quad \forall u_2(\cdot)\in\mathcal{U}_2[0,T],\\ \inf\limits_{u_2(\cdot)\in\mathcal{U}_2[0,T]} J_2(\xi;u_1(\cdot),u_2(\cdot)) = -\infty \quad \forall u_1(\cdot)\in\mathcal{U}_1[0,T].\end{cases} \tag{4.24}$$

This coincides with the above conclusion.

Remark 4.1. The above shows that if the controls enter into the diffusion, one might not expect to have the existence of the value for a zero-sum differential game (unless some other compatibility conditions hold between the state equation and the cost functional; we hope to address this in future work). The main reason is that the Isaacs-type condition does not necessarily hold in the current case. At this moment, we might realize why almost all formulations of stochastic differential games in the literature avoided the controls entering the diffusion. Due to this, we study only the leader-follower case in the present paper. This can be regarded as a first step to approaching the stochastic differential games with controls in the diffusion.

5. Deterministic coefficient cases. In this section, we concentrate on the case in which all the coefficients are deterministic. For simplicity, we will consider only the constant coefficient case. To be more precise, we introduce the following assumption.

(DI) Let

$$A,C\in\mathbb{R}^{n\times n}, \quad B_i,D_i\in\mathbb{R}^{n\times m_i}, \quad Q_i,G_i\in\mathcal{S}^n, \quad R_i\in\mathcal{S}^{m_i}, \qquad i=1,2. \tag{5.1}$$

According to [6, 7], under (DI), the Riccati equation for Problem $(\mathrm{LQ})_1$ takes the following form:

$$\begin{cases} \dot{P} + PA + A^T P + C^T PC + Q_1 \\ \quad - (PB_1 + C^T PD_1)(R_1 + D_1^T PD_1)^{-1}(B_1^T P + D_1^T PC) = 0, \qquad t \in [0,T], \\ P(T) = G_1, \\ R_1 + D_1^T P(t) D_1 > 0 \qquad \text{a.e. } t \in [0,T]. \end{cases} \tag{5.2}$$

In fact, if $P(\cdot)$ is a solution of (5.2), then $(P(\cdot), 0)$ is an adapted solution of (1.5), with which (1.6) becomes

$$\begin{cases} d\varphi = -\Big\{ [A^T - (PB_1 + C^T PD_1)(R_1 + D_1^T PD_1)^{-1} B_1^T]\varphi \\ \qquad\qquad + [C^T - (PB_1 + C^T PD_1)(R_1 + D_1^T PD_1)^{-1} D_1^T]\theta \\ \qquad\qquad + \big[- (PB_1 + C^T PD_1)(R_1 + D_1^T PD_1)^{-1} D_1^T PD_2 \\ \qquad\qquad + PB_2 + C^T PD_2 \big] u_2 \Big\} dt + \theta dW(t), \qquad t \in [0,T], \\ \varphi(T) = 0. \end{cases} \tag{5.3}$$

This is still a BSDE, since $u_2(\cdot) \in \mathcal{U}_2[0,T]$ is random in general. For the current case, we still have Proposition 2.2 and Theorem 2.3. Note that these results are incomplete in the sense that we still do not know when Problem $(\mathrm{LQ})_1$ is solvable, unless we know when either the FBSDE (2.5) (together with (2.6)) or the Riccati equation (5.2) is solvable. Our first goal of this section is to present some sufficient conditions for the solvability of (2.5) and/or (5.2). We now introduce the following further assumption.

(H1) Matrix R_1 has an inverse. Moreover,

$$B_1 R_1^{-1} D_1^T = 0, \quad C = 0, \tag{5.4}$$

and

$$R_1 + D_1^T G_1 D_1 > 0. \tag{5.5}$$

We emphasize here that R_1 is not necessarily positive semidefinite. Also, B_1 and D_1 are not necessarily zero. Here is a simple example:

$$B_1 = D_1 = \begin{pmatrix} 1 & 1 \\ 1 & 1 \end{pmatrix}, \quad R_1 = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}. \tag{5.6}$$

One can easily check that (H1) holds for B_1, D_1 and R_1 given in (5.6). The following lemma tells us the role that assumption (H1) is playing.

LEMMA 5.1. *Let R_1^{-1} exist and let the first relation in* (5.4) *hold. Then for any $P \in \mathbb{R}^{n\times n}$ such that $(R_1 + D_1^T PD_1)^{-1}$ exists, the following holds:*

$$B_1(R_1 + D_1^T PD_1)^{-1} = B_1 R_1^{-1}. \tag{5.7}$$

Proof. We observe the following:

$$\begin{aligned} &B_1(R_1 + D_1^T PD_1)^{-1} - B_1 R_1^{-1} = B_1\big[(R_1 + D_1^T PD_1)^{-1} - R_1^{-1}\big] \\ &= B_1 R_1^{-1}[R_1 - R_1 - D_1^T PD_1](R_1 + D_1^T PD_1)^{-1} \\ &= -B_1 R_1^{-1} D_1^T PD_1 (R_1 + D_1^T PD_1)^{-1} = 0, \end{aligned} \tag{5.8}$$

proving (5.7). □

Under assumption (H1) (noting Lemma 5.1), Riccati equation (5.2) takes the following form:

$$\begin{cases} \dot{P} + PA + A^T P + Q_1 - PB_1 R_1^{-1} B_1^T P = 0, & t \in [0,T], \\ P(T) = G_1, \\ R_1 + D_1^T P(t) D_1 > 0 \qquad \text{a.e. } t \in [0,T], \end{cases} \tag{5.9}$$

and BSDE (5.3) becomes

$$\begin{cases} d\varphi = -\Big\{[A^T - PB_1 R_1^{-1} B_1^T]\varphi - PB_1 R_1^{-1} D_1^T \theta \\ \qquad\qquad - [PB_1 R_1^{-1} D_1^T P D_2 - PB_2]u_2\Big\}dt + \theta dW(t), \qquad t \in [0,T], \\ \varphi(T) = 0. \end{cases} \tag{5.10}$$

On the other hand, the FBSDE (2.5) becomes (the bars are dropped)

$$\begin{cases} dx(t) = [Ax(t) + B_1 u_1(t) + B_2 u_2(t)]dt + [D_1 u_1(t) + D_2 u_2(t)]dW(t), \\ dp(t) = -[A^T p(t) + Q_1 x(t)]dt + q(t)dW(t), \\ x(0) = \xi, \qquad p(T) = G_1 x(T). \end{cases} \tag{5.11}$$

We note that without looking at the third constraint, (5.9) looks like a standard Riccati equation for deterministic LQ problems. However, we should keep in mind that there are no positive semidefiniteness conditions imposed on either Q_1 and R_1. Also, the third constraint is not obviously to be satisfied if there is no positivity of Q_1 and R_1.

Now, let $(x(\cdot), u_1(\cdot))$ be an optimal pair of Problem $(\mathrm{LQ})_1$ and let $(p(\cdot), q(\cdot))$ be the adapted solution of BSDE in (5.11). Since R_1^{-1} exists, the optimal control $\overline{u}_1(\cdot)$ has the form (note (5.4))

$$\overline{u}_1(t) = -R_1^{-1}[B_1^T p(t) + D_1^T q(t)] = -R_1^{-1} B_1^T p(t), \qquad t \in [0,T]. \tag{5.12}$$

Plugging (5.12) into (5.11), we obtain

$$\begin{cases} dx(t) = \big[Ax(t) - B_1 R_1^{-1} B_1^T p(t) + B_2 u_2(t)\big]dt \\ \qquad\qquad + [-D_1 R_1^{-1} D_1^T q(t) + D_2 u_2(t)]dW(t), \\ dp(t) = -\big[Q_1 x(t) + A^T p(t)\big]dt + q(t)dw(t), \\ x(0) = \xi, \qquad p(T) = G_1 x(T). \end{cases} \tag{5.13}$$

This is a coupled linear FBSDE. To obtain sufficient conditions for the solvability of such an FBSDE via the result of [32], let us make some reductions. For notational

simplicity, in what follows we suppress the argument t. Let $\eta = p - G_1 x$. Then

$$
\begin{aligned}
d\eta &= dp - G_1 dx \\
&= \big[- Q_1 x - A^T p - G_1(Ax - B_1 R_1^{-1} B_1^T p + B_2 u_2)\big] dt \\
&\quad + \big[(I + G_1 D_1 R_1^{-1} D_1^T) q - G_1 D_2 u_2\big] dW \\
&= \big[(-Q_1 - G_1 A)x + (-A^T + G_1 B_1 R_1^{-1} B_1^T)(\eta + G_1 x) - G_1 B_2 u_2\big] dt \\
&\quad + \big[(I + G_1 D_1 R_1^{-1} D_1^T) q - G_1 D_2 u_2\big] dW \\
&= \big[(-Q_1 - G_1 A - A^T G_1 + G_1 B_1 R_1^{-1} B_1^T G_1) x \\
&\quad + (-A^T + G_1 B_1 R_1^{-1} B_1^T)\eta - G_1 B_2 u_2\big] dt \\
&\quad + \big[(I + G_1 D_1 R_1^{-1} D_1^T) q - G_1 D_2 u_2\big] dW.
\end{aligned} \tag{5.14}
$$

We define

$$
\zeta = (I + G_1 D_1 R^{-1} D_1^T) q. \tag{5.15}
$$

A direct computation shows that

$$
(I + G_1 D_1 R_1^{-1} D_1^T)^{-1} = I - G_1 D_1 (R_1 + D_1^T G_1 D_1)^{-1} D_1^T. \tag{5.16}
$$

This means that $(I + G_1 D_1 R_1^{-1} D_1^T)^{-1}$ exists, and from (5.15) we have

$$
q = (I + G_1 D_1 R_1^{-1} D_1^T)^{-1} \zeta. \tag{5.17}
$$

Consequently,

$$
\begin{aligned}
dx &= \big[Ax - B_1 R_1^{-1} B_1^T (\eta + G_1 x) + B_2 u_2\big] dt \\
&\qquad + \big[- D_1 R_1^{-1} D_1^T (I + G_1 D_1 R_1^{-1} D_1^T)^{-1} \zeta + D_2 u_2\big] dW \\
&= \big[(A - B_1 R_1^{-1} B_1^T G_1) x - B_1 R_1^{-1} B_1^T \eta + B_2 u_2\big] dt \\
&\qquad + [-D_1 (R_1 + D_1^T G_1 D_1)^{-1} D_1^T \zeta + D_2 u_2] dW.
\end{aligned} \tag{5.18}
$$

Also,

$$
\begin{aligned}
d\eta = \big[&(-Q_1 - G_1 A - A^T G_1 + G_1 B_1 R_1^{-1} B_1^T G_1) x \\
&+ (-A^T + G_1 B_1 R_1^{-1} B_1^T)\eta - G_1 B_2 u_2\big] dt + [\zeta - G_2 D_2 u_2] dW.
\end{aligned} \tag{5.19}
$$

Hence, (5.11) becomes

$$
\begin{cases}
dx(t) = \big[(A - B_1 R_1^{-1} B_1^T G_1) x(t) - B_1 R_1^{-1} B_1^T \eta(t) + B_2 u_2(t)\big] dt \\
\qquad\quad + \big[- D_1 (R_1 + D_1^T G_1 D_1)^{-1} D_1^T \zeta(t) + D_2 u_2(t)\big] dW(t), \\
d\eta(t) = \big[(-Q_1 - G_1 A - A^T G_1 + G_1 B_1 R_1^{-1} B_1^T G_1) x(t) \\
\qquad\quad + (-A^T + G_1 B_1 R_1^{-1} B_1^T)\eta(t) - G_1 B_2 u_2(t)\big] dt \\
\qquad\quad + [\zeta(t) - G_1 D_2 u_2(t)] dW(t), \\
x(0) = \xi, \qquad \eta(T) = 0.
\end{cases} \tag{5.20}
$$

We denote

$$
\begin{aligned}
&\mathcal{A} \triangleq \begin{pmatrix} A - B_1 R_1^{-1} B_1^T G_1 & -B_1 R_1^{-1} B_1^T \\ -Q_1 - G_1 A - A^T G_1 + G_1 B_1 R_1^{-1} B_1^T G_1 & -A^T + G_1 B_1 R_1^{-1} B_1^T \end{pmatrix}, \\
&\mathcal{C}_1 \triangleq \begin{pmatrix} -D_1 (R_1 + D_1^T G_1 D_1)^{-1} D_1^T \\ I \end{pmatrix}, \quad \mathcal{B}_2 \triangleq \begin{pmatrix} B_2 \\ -G_1 B_2 \end{pmatrix}, \quad \mathcal{D}_2 \triangleq \begin{pmatrix} D_2 \\ -G_1 D_2 \end{pmatrix}.
\end{aligned} \tag{5.21}
$$

Then (5.20) can further be written as

$$\begin{cases} d\begin{pmatrix} x(t) \\ \eta(t) \end{pmatrix} = \Big\{\mathcal{A}\begin{pmatrix} x(t) \\ \eta(t) \end{pmatrix} + \mathcal{B}_2 u_2(t)\Big\}dt + \Big\{\mathcal{C}_1\zeta(t) + \mathcal{D}_2 u_2(t)\Big\}dW(t), \\ x(0) = \xi, \quad \eta(T) = 0. \end{cases} \tag{5.22}$$

Next, we introduce the following Riccati equation for FBSDE (5.20):

$$\begin{cases} \dot\Pi(t) + \Pi(t)(A - B_1R_1^{-1}B_1^TG_1) + (A - B_1R_1^{-1}B_1^TG_1)^T\Pi(t) \\ \qquad - \Pi(t)B_1R_1^{-1}B_1^T\Pi(t) + [Q_1 + G_1A + A^TG_1 - G_1B_1R_1^{-1}B_1^TG_1] = 0, \\ \Pi(T) = 0. \end{cases} \tag{5.23}$$

It is easy to see that solution $\Pi(\cdot)$ of (5.23) and that $P(\cdot)$ of (5.9) are related by the following:

$$P(t) = G_1 + \Pi(t), \qquad t \in [0,T]. \tag{5.24}$$

The following was proved in [32].

THEOREM 5.2. *Let* (H1) *hold and let*

$$\begin{cases} \det\Big\{ \begin{pmatrix} 0 & I \end{pmatrix} e^{\mathcal{A}t}\begin{pmatrix} 0 \\ I \end{pmatrix}\Big\} > 0, \\ \det\Big\{ \begin{pmatrix} 0 & I \end{pmatrix} e^{\mathcal{A}t}\mathcal{C}_1\Big\} > 0, \end{cases} \qquad t \in [0,T]. \tag{5.25}$$

Then (5.23) *admits a unique solution* $\Pi(\cdot)$ *which has the following representation:*

$$\Pi(t) = -\Big[\begin{pmatrix} 0 & I \end{pmatrix} e^{\mathcal{A}(T-t)}\begin{pmatrix} 0 \\ I \end{pmatrix}\Big]^{-1}\begin{pmatrix} 0 & I \end{pmatrix} e^{\mathcal{A}(T-t)}\begin{pmatrix} I \\ 0 \end{pmatrix}, \qquad t \in [0,T]. \tag{5.26}$$

Moreover, (5.24) *gives the solution of* (5.9).

Combining Theorem 5.2 and (5.24), we see that when (H1) and (5.25) hold, Riccati equation (5.9) admits a unique solution $P(\cdot)$, which leads to the solvability of Problem $(\mathrm{LQ})_1$ for any given $(\xi, u_2(\cdot)) \in \mathbb{R}^n \times \mathcal{U}_2[0,T]$. It is important to note that conditions (H1) and (5.25) are checkable, in principle.

Now, under (H1) and (5.25), we have the solution $P(\cdot)$ of Riccati equation (5.9) and FBSDE (1.9) becomes

$$\begin{cases} dx(t) = \big[\widehat{A}x(t) + \widehat{F}_1\varphi(t) + B_2u_2(t)\big]dt + \big[\widehat{D}_1\theta(t) + \widehat{D}_2u_2(t)\big]dW(t), \\ d\varphi(t) = -\big[\widehat{A}^T\varphi(t) + PB_2u_2(t)\big]dt + \theta(t)dW(t), \\ x(0) = \xi, \qquad \varphi(T) = 0, \end{cases} \tag{5.27}$$

where

$$\begin{cases} \widehat{A} \triangleq A - B_1R_1^{-1}B_1^TP, \qquad \widehat{F}_1 \triangleq -B_1R_1^{-1}B_1^T, \\ \widehat{D}_1 \triangleq -D_1\widehat{R}_1^{-1}D_1^T, \qquad \widehat{D}_2 \triangleq D_2 - D_1\widehat{R}_1^{-1}D_1^TPD_2. \end{cases} \tag{5.28}$$

FBSDE (3.6) becomes (we again drop the bars)

$$\begin{cases} dy = (\widehat{A}^Ty + Q_2x)dt + zdW(t), \\ d\psi = (\widehat{A}\psi + \widehat{F}_1y)dt + \widehat{D}_1zdW(t), \\ y(T) = G_2x(T), \quad \psi(0) = 0. \end{cases} \tag{5.29}$$

Next, similarly to (H1), we introduce the following assumption.

(H2) Let R_2^{-1} exist. Moreover,

$$B_2R_2^{-1}D_2^T = 0 \tag{5.30}$$

and

$$R_2 + D_2^T G_2 D_2 > 0. \tag{5.31}$$

We note that under (H2), the following holds:

$$B_2R_2^{-1}\widehat{D}_2^T = B_2R_2^{-1}D_2^T(I - D_1\widehat{R}_1^{-1}D_1^T) = 0. \tag{5.32}$$

Further, under (H1)–(H2), (3.7) implies

$$\overline{u}_2 = -R_2^{-1}\big(B_2^T y + \widehat{D}_2^T z + B_2^T P\psi\big). \tag{5.33}$$

Thus, by setting $X = \begin{pmatrix} x \\ \psi \end{pmatrix}$, $Y = \begin{pmatrix} y \\ \varphi \end{pmatrix}$, and $Z = \begin{pmatrix} z \\ \theta \end{pmatrix}$, we have the following:

$$\begin{cases} dX = \left\{ \begin{pmatrix} \widehat{A} & -B_2R_2^{-1}B_2^TP \\ 0 & \widehat{A} \end{pmatrix} X + \begin{pmatrix} -B_2R_2^{-1}B_2^T & \widehat{F}_1 \\ \widehat{F}_1 & 0 \end{pmatrix} Y \right\} dt \\ \qquad\quad + \begin{pmatrix} -\widehat{D}_2R_2^{-1}\widehat{D}_2 & \widehat{D}_1 \\ \widehat{D}_1 & 0 \end{pmatrix} Z dW(t), \\ dY = -\left\{ \begin{pmatrix} Q_2 & 0 \\ 0 & -PB_2R_2^{-1}B_2^TP \end{pmatrix} X + \begin{pmatrix} \widehat{A}^T & 0 \\ -PB_2R_2^{-1}B_2^T & \widehat{A}^T \end{pmatrix} Y \right\} dt \\ \qquad\quad + Z dW(t), \\ X(0) = \begin{pmatrix} \xi \\ 0 \end{pmatrix} \triangleq \widehat{\xi}, \qquad Y(T) = \begin{pmatrix} G_2 & 0 \\ 0 & 0 \end{pmatrix} X(T) \triangleq \widehat{G}_2 X(T). \end{cases} \tag{5.34}$$

Now, we set

$$\widehat{\mathcal{A}} = \begin{pmatrix} \widehat{A} & -B_2R_2^{-1}B_2^TP & -B_2R_2^{-1}B_2^T & \widehat{F}_1 \\ 0 & \widehat{A} & \widehat{F}_1 & 0 \\ -Q_2 & 0 & -\widehat{A}^T & 0 \\ 0 & PB_2R_2^{-1}B_2^TP & PB_2R_2^{-1}B_2^T & -\widehat{A}^T \end{pmatrix}, \quad \widehat{\mathcal{C}}_1 = \begin{pmatrix} -\widehat{D}_2R_2^{-1}\widehat{D}_2 & \widehat{D}_1 \\ \widehat{D}_1 & 0 \\ I & 0 \\ 0 & I \end{pmatrix}.$$

Then (5.34) becomes

$$\begin{cases} d\begin{pmatrix} X(t) \\ Y(t) \end{pmatrix} = \widehat{\mathcal{A}}(t)\begin{pmatrix} X(t) \\ Y(t) \end{pmatrix} dt + \widehat{\mathcal{C}}_1(t)Z(t)dW(t), \\ X(0) = \widehat{\xi}, \qquad Y(T) = \widehat{G}_2X(T). \end{cases} \tag{5.35}$$

Note that (5.35) is an FBSDE with time-dependent and deterministic coefficients. Thus, we need only take $Z(\cdot) = 0$ and $(X(\cdot), Y(\cdot))$ to be a solution of the following ODE:

$$\begin{cases} d\begin{pmatrix} X(t) \\ Y(t) \end{pmatrix} = \widehat{\mathcal{A}}(t)\begin{pmatrix} X(t) \\ Y(t) \end{pmatrix} dt, \\ X(0) = \widehat{\xi}, \qquad Y(T) = \widehat{G}_2X(T). \end{cases} \tag{5.36}$$

Hence, by letting $\Theta(\cdot)$ be the solution of

$$\begin{cases} \dfrac{d}{dt}\Theta(t,s) = \widehat{\mathcal{A}}(t)\Theta(t,s), & t \in [s,T], \\ \Theta(s,s) = I, \end{cases} \tag{5.37}$$

one knows that any solution $(X(\cdot), Y(\cdot))$ is given by

$$\begin{pmatrix} X(t) \\ Y(t) \end{pmatrix} = \Theta(t,0) \begin{pmatrix} \widehat{\xi} \\ \widehat{\eta} \end{pmatrix}, \qquad t \in [0,T], \tag{5.38}$$

with $\widehat{\eta}$ being in $\mathbb{R}^m$ such that

$$0 = \begin{pmatrix} -\widehat{G}_2 & I \end{pmatrix} \Theta(T,0) \begin{pmatrix} \widehat{\xi} \\ \widehat{\eta} \end{pmatrix}. \tag{5.39}$$

This is equivalent to

$$\begin{pmatrix} \widehat{G}_2 & -I \end{pmatrix} \Theta(T,0) \begin{pmatrix} \widehat{\xi} \\ 0 \end{pmatrix} = \begin{pmatrix} -\widehat{G}_2 & I \end{pmatrix} \Theta(T,0) \begin{pmatrix} 0 \\ I \end{pmatrix} \widehat{\eta}. \tag{5.40}$$

This proves the following.

THEOREM 5.3. *Let* (DI), (H1), (H2), *and* (5.25) *hold. Suppose further that*

$$\det \left\{ \begin{pmatrix} -\widehat{G}_2 & I \end{pmatrix} \Theta(T,0) \begin{pmatrix} 0 \\ I \end{pmatrix} \right\} \neq 0. \tag{5.41}$$

Then (5.35) *is solvable. Consequently, if the conclusions of Proposition* 2.2(i) *and of Theorem* 3.2(i) *hold, in particular, if* Q_i, R_i, *and* G_i *are nonnegative, then the leader-follower differentiable game admits an open-loop solution which admits a state feedback representation.*

THE TOPOLOGICAL ASYMPTOTIC EXPANSION FOR THE DIRICHLET PROBLEM*

PH. GUILLAUME† AND K. SID IDRIS†

Abstract. The topological sensitivity analysis provides an asymptotic expansion of a shape function when creating a small hole inside a domain. This expansion yields a descent direction which can be used for shape optimization if one wishes to keep a classical domain throughout the optimization process. In this paper, such an expansion is obtained for the Poisson equation for a large class of cost functions and arbitrarily shaped holes. In the three-dimensional case, this expansion depends on the shape of the hole but not on its orientation if the cost function involves only the solution u to the underlying partial differential equation, whereas it may also depend on its orientation if the cost function involves the gradient ∇u. In contrast, the asymptotic expansion is independent of the shape in the two-dimensional case. A numerical example illustrates the use of the asymptotic expansion, which yields a minimizing sequence of classical domains in a case where no classical solution exists.

1. Introduction.

In many shape optimization problems, there is no "classical solution"; that is, a minimizing sequence of domains does not converge to a domain. In such cases, relaxed formulations or homogenization are often involved (see, e.g., [5, 6, 1, 25, 3, 18]), leading to the introduction of some "intermediate material" or micro-structures. The drawback is precisely that the optimal solution is not a classical design: it is a distribution of composite materials. Then penalization methods must be applied in order to retrieve a "feasible" shape. Hence, keeping a minimizing sequence of classical domains might be preferred (with a stopping criterion or additional constraints defined by the user). In that direction, global optimization techniques like genetic algorithms or simulated annealing have been proposed (see, e.g., [26]), but these methods have a high computational cost and can hardly be applied to industrial problems. Another approach, introduced by the works of Schumacher [27] and Sokołowski and Żochowski [28], is presented and analyzed in this paper in the case of the Poisson equation with Dirichlet boundary conditions for a large class of cost functions.

The shape optimization problem consists of minimizing a function $j(\Omega) := J(\Omega, u_\Omega)$ where the solution u_Ω to the Poisson equation is defined on a variable open and bounded subset Ω of $\mathbb{R}^n$. For $\varepsilon > 0$, let $\Omega_\varepsilon = \Omega \backslash (\overline{x_0 + \varepsilon\omega})$ be the subset obtained by removing a small part $\overline{x_0 + \varepsilon\omega}$ from Ω, where $x_0 \in \Omega$ and $\omega \subset \mathbb{R}^n$ is a fixed open and bounded subset containing the origin. Then, an asymptotic expansion of the function j is obtained in the following form:

$$j(\Omega_\varepsilon) = j(\Omega) + \rho(\varepsilon)\delta j(x_0) + o(\rho(\varepsilon)),$$
$$\lim_{\varepsilon \to 0} \rho(\varepsilon) = 0, \quad \rho(\varepsilon) > 0.$$

The "topological sensitivity" $\delta j(x_0)$ provides information for creating a small hole located at x_0: if $\delta j(x_0) < 0$, then $j(\Omega_\varepsilon) < j(\Omega)$ for small ε. For example, in the case of a circular hole and $n = 3$, and for a class of cost functions involving u_Ω but not ∇u_Ω, the first variation of the function j reads

$$j(\Omega_\varepsilon) = j(\Omega) + 4\pi\varepsilon\, u_\Omega(x_0)v_\Omega(x_0) + o(\varepsilon),$$

where v_Ω is the adjoint state. It is interesting to observe that the first order optimality condition $u_\Omega v_\Omega \geq 0$ given by Buttazzo and Dal Maso [5] follows straightforwardly from this expansion. More generally, the function δj can be used like a descent direction in an optimization process. The step length then consists of choosing the proportion of the domain which is "removed," located where $\delta j(x)$ is the most negative. The idea of this algorithm goes back to Céa, Gioan, and Michel [8] and was presented in the topological optimization context in [9]. For the sake of completeness, the principle of this algorithm is recalled in section 6. The main motivation of this approach is to provide an optimization method in which the iterated domains may have a varying topology but still remain classical domains, which may be required for feasibility when no mixture of materials is wanted. Of course, there is a drawback: there may be no solution to the optimization problem, and, in particular, the solution to the discretized problem may be mesh dependent. This is illustrated by an example in section 6, where a minimizing sequence of classical domains is obtained. Nevertheless, in contrast to classical shape optimization, which allows only moving the boundary (thus keeping fixed the topology, at least for small variations), the topological asymptotic expansion allows one to modify the topology of the domain during the optimization process, and can naturally be coupled with classical shape optimization.

A topological sensitivity framework using an adaptation of the adjoint method [7] and a truncation technique was introduced by Masmoudi [23] in the case of the Laplace equation with a circular hole. In the present paper, we analyze the case of the Poisson equation with noncircular holes. For this purpose, the technique used in [15, 16] for the elasticity equations with homogeneous Neumann conditions imposed on the boundary of the hole is adapted to Dirichlet boundary conditions, nonzero right-hand sides, and a large class of cost functions involving u_Ω or ∇u_Ω. In the three-dimensional case, it will be shown that the topological sensitivity $\delta j(x_0)$ depends on the shape of the hole but not on its orientation if the cost function involves only u_Ω, whereas it may also depend on its orientation if the cost function involves ∇u_Ω. In contrast, it will be shown that in the two-dimensional case the topological sensitivity is independent of the shape of the hole. Apart from the theoretical aspect, the consideration of noncircular holes may have some interesting applications, for example, in the study of cracks, which are beyond the scope of this paper.

First, the adaptation of the adjoint method to the topology shape optimization is recalled in section 2. Next, the formulation of the problem is presented in section 3. The truncation technique, which provides an efficient and general theoretical frame, is then applied to the problem in section 4. Section 5 presents the main results, whose proofs are reported in section 7. In the case of a circular hole, explicit expressions of the topological sensitivity are given for Dirichlet boundary conditions and for dimensions $n = 2$ or 3. Finally a numerical example in section 6 illustrates the use of the topological sensitivity in a shape optimization problem.

2. The generalized adjoint method. In this section, we recall the framework introduced in [23, 16] which extends the adjoint method [7] to the topology shape optimization. Let $\mathcal{V}$ be a Hilbert space. For $\varepsilon \geq 0$, let a_ε be a bilinear and symmetric

form on $\mathcal{V}$ and let l_ε be a linear form on $\mathcal{V}$ such that for all $\varepsilon \geq 0$,

$$\begin{aligned} a_\varepsilon(u,v) &\leq M_1\|u\|\,\|v\| \qquad \forall u,\, v \in \mathcal{V},\\ a_\varepsilon(u,u) &\geq \alpha\|u\|^2 \qquad \forall u \in \mathcal{V},\\ |l_\varepsilon(v)| &\leq M_2\|v\| \qquad \forall v \in \mathcal{V}, \end{aligned}$$

where the constants $\alpha > 0$, $M_1 > 0$, and $M_2 \geq 0$ are independent of ε.

Assume that there exist a bilinear and continuous form δa, a linear and continuous form δl, and a real function $\rho(\varepsilon) > 0$ defined on $\mathbb{R}_+$ such that

$$\|a_\varepsilon - a_0 - \rho(\varepsilon)\delta a\|_{\mathcal{L}_2(\mathcal{V})} = o(\rho(\varepsilon)), \tag{1}$$

$$\|l_\varepsilon - l_0 - \rho(\varepsilon)\delta l\|_{\mathcal{L}(\mathcal{V})} = o(\rho(\varepsilon)), \tag{2}$$

$$\lim_{\varepsilon \to 0} \rho(\varepsilon) = 0,$$

where $\mathcal{L}(\mathcal{V})$ (respectively, $\mathcal{L}_2(\mathcal{V})$) denotes the space of continuous and linear (respectively, bilinear) forms on $\mathcal{V}$. The same function ρ is used here for both asymptotic expansions (1)–(2). It does not exclude the case where $a_\varepsilon - a_0$ and $l_\varepsilon - l_0$ have different behaviors in $O(\rho_1(\varepsilon))$ and $O(\rho_2(\varepsilon))$, in which case ρ is chosen the "slowest" between ρ_1 and ρ_2, that is, $\rho_i(\varepsilon) = O(\rho(\varepsilon))$, $i = 1, 2$.

For $\varepsilon \geq 0$, let u_ε be the solution to the following problem: find $u_\varepsilon \in \mathcal{V}$ such that

$$a_\varepsilon(u_\varepsilon, v) = l_\varepsilon(v) \qquad \forall v \in \mathcal{V}.$$

LEMMA 2.1 (see [16]). *For $\varepsilon \geq 0$, this problem has a unique solution u_ε, and*

$$\|u_\varepsilon - u_0\| = O(\rho(\varepsilon)).$$

Consider now a function $j(\varepsilon) := J_\varepsilon(u_\varepsilon)$, where J_ε is defined on $\mathcal{V}$ for $\varepsilon \geq 0$, and J_0 is differentiable with respect to u, its derivative being denoted $DJ_0(u)$. Moreover, suppose that there exists a function δJ defined on $\mathcal{V}$ such that

$$J_\varepsilon(v) - J_0(u) = DJ_0(u)(v-u) + \rho(\varepsilon)\delta J(u) + o(\|v-u\| + \rho(\varepsilon)).$$

This expression looks like a first order (total) derivative and would be in fact the first order derivative of the function $\mathcal{J}(s,u)$ defined by $\mathcal{J}(s,u) := J_{\rho^{-1}(s)}(v) - J_0(u)$, with the change of variable $s = \rho(\varepsilon)$. Next, the Lagrangian L_ε is defined by

$$L_\varepsilon(u,v) = J_\varepsilon(u) + a_\varepsilon(u,v) - l_\varepsilon(v) \qquad \forall u, v \in \mathcal{V}.$$

Its variation with respect to ε is given by

$$\begin{aligned} \delta L(u,v) &= \delta J(u) + \delta a(u,v) - \delta l(v),\\ L_\varepsilon(u,v) - L_0(u,v) &= \rho(\varepsilon)\delta L(u,v) + o(\rho(\varepsilon)). \end{aligned}$$

THEOREM 2.2 (see [16]). *The function j has the following asymptotic expansion:*

$$j(\varepsilon) = j(0) + \rho(\varepsilon)\delta L(u_0, v_0) + o(\rho(\varepsilon)),$$

where v_0 is the solution to the following adjoint problem: find $v_0 \in \mathcal{V}$ such that

$$a_0(w, v_0) = -DJ_0(u_0)w \qquad \forall w \in \mathcal{V}.$$

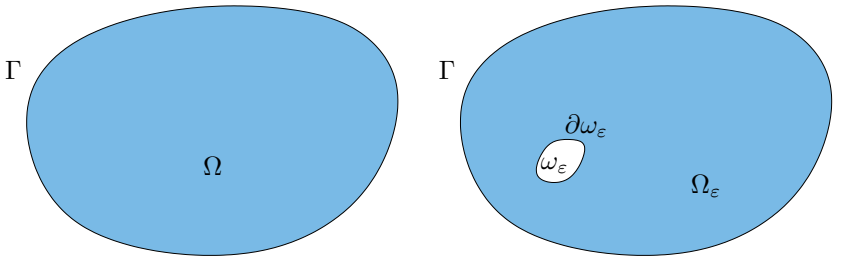

FIG. 1. *The initial domain shown before and after inclusion of the hole.*

3. Formulation of the problem. Let Ω be an open and bounded subset of $\mathbb{R}^n$ with boundary Γ, $n = 2$ or 3. The Poisson equation with homogeneous Dirichlet boundary conditions reads

$$\left\{ \begin{array}{rl} -\Delta u_\Omega = f & \text{in } \Omega, \\ u_\Omega = 0 & \text{on } \Gamma. \end{array} \right. \tag{3}$$

Some regularity is required from f, at least $f \in L^q(\Omega)$, $q > n/2$. (In fact, that will be needed only around x_0.) This equation has a unique solution in $H_0^1(\Omega)$, and due to the regularity of f, this solution is continuous in Ω [12]. The case of a nonhomogeneous boundary condition on Γ can be treated similarly.

For a given $x_0 \in \Omega$, consider the modified open subset $\Omega_\varepsilon = \Omega \backslash \overline{\omega_\varepsilon}$, $\omega_\varepsilon = x_0 + \varepsilon\omega$, where ω is a fixed open and bounded subset of $\mathbb{R}^n$ containing the origin ($\omega_\varepsilon = \emptyset$ if $\varepsilon = 0$), whose boundary $\partial\omega$ is connected and piecewise of class $\mathcal{C}^1$ (see Figure 1). The modified solution u_{Ω_ε} satisfies

$$\left\{ \begin{array}{rl} -\Delta u_{\Omega_\varepsilon} = f & \text{in } \Omega_\varepsilon, \\ u_{\Omega_\varepsilon} = 0 & \text{on } \Gamma, \\ u_{\Omega_\varepsilon} = 0 & \text{on } \partial\omega_\varepsilon. \end{array} \right. \tag{4}$$

Note that for $\varepsilon = 0$, one has $u_{\Omega_0} = u_\Omega$.

In the context of identification of conductivity imperfections, the asymptotic behavior of the voltage potential $u_{\Omega_\varepsilon} - u_\Omega$ was studied in [13, 10] for the Laplace equation. Here we consider a right-hand side and a cost function which can be defined on Ω_ε. The adjoint technique is used for computing the variation of the cost function. It will be shown that the adjoint state is independent of the location of the hole.

The function u_{Ω_ε} is defined on the variable open subset Ω_ε, and thus it belongs to a functional space which depends on ε. Hence, if we want to derive the asymptotic expansion of a function of the form

$$j(\varepsilon) := \widetilde{J}_\varepsilon(u_{\Omega_\varepsilon}) \tag{5}$$

with $\widetilde{J}_\varepsilon$ being defined on $H^1(\Omega_\varepsilon)$ for $\varepsilon \geq 0$, we cannot apply directly the tools of section 2, which require a fixed functional space. In classical shape optimization, this requirement can be satisfied with the help of a domain parameterization technique [24, 22, 17]. This technique involves a fixed domain and a bi-Lipschitz map between this domain and the modified one. In the topology optimization context, such a map does not exist between Ω and Ω_ε. However, a functional space independent of ε can be constructed by using the following domain truncation technique. Let $R > 0$ be such that the closed ball $\overline{B}(x_0, R)$ is included in Ω. It is supposed throughout this

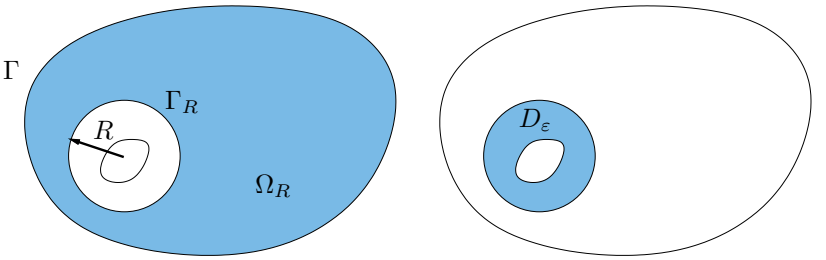

FIG. 2. *The truncated domain.*

paper that ε remains small enough so that $\overline{\omega_\varepsilon} \subset B(x_0, R)$. The truncated open subset is defined by (see Figure 2)

$$\Omega_R = \Omega \backslash \overline{B}(x_0, R).$$

In section 4 the following are defined:

- a Hilbert space $\mathcal{V}_R$ independent of ε;
- a $\mathcal{V}_R$-elliptic bilinear and continuous form a_ε;
- a linear and continuous form l_ε

such that the solution u_ε to the equation

$$a_\varepsilon(u_\varepsilon, v) = l_\varepsilon(v) \qquad \forall v \in \mathcal{V}_R$$

is equal to the restriction of u_{Ω_ε} to Ω_R. A bilinear form δa satisfying (1) and a linear form δl satisfying (2) will be obtained in section 7, from which the asymptotic expansion of the cost function will be derived by using the framework described in section 2. The main results and the particular case of a spherical hole are detailed in section 5.

A natural question is, Why do we need such a truncation technique? For $\varepsilon \geq 0$, one could simply define a_ε on $H_0^1(\Omega) \times H_0^1(\Omega)$ by

$$a_\varepsilon(u, v) = \int_{\Omega_\varepsilon} \nabla u . \nabla v \, dx$$

and work with functions of $H_0^1(\Omega_\varepsilon)$ extended by 0 on ω_ε. The main difficulty with this approach is that we cannot apply the Lagrangian technique described in section 2, because there is no bilinear and continuous form δa such that $\|a_\varepsilon - a_0 - \rho(\varepsilon)\delta a\|_{\mathcal{L}_2(H_0^1(\Omega))} = o(\rho(\varepsilon))$ for some adequate positive function ρ. Indeed, we have

$$a_\varepsilon(u, v) - a_0(u, v) = -\int_{\omega_\varepsilon} \nabla u . \nabla v \, dx,$$

and for smooth functions u, v, and $n = 3$ (for example) we have

$$a_\varepsilon(u, v) - a_0(u, v) = -\varepsilon^3 \nabla u(x_0) . \nabla v(x_0) \int_\omega dx + o(\varepsilon^3).$$

But $\delta a(u, v) := \nabla u(x_0) . \nabla v(x_0)$ cannot be continuously extended on $H_0^1(\Omega) \times H_0^1(\Omega)$. Besides, if u_{Ω_ε} is extended by 0 on ω_ε, the behavior of $\|u_{\Omega_\varepsilon} - u_\Omega\|_{H^1(\Omega)}$ is not of order ε^3 but only of order $\varepsilon^{1/2}$ (see Lemma 7.3). This change of order comes from the lack

of continuity of the above bilinear form δa. In contrast, the bilinear form a_ε defined in the next section will be associated to a bilinear and *continuous* form δa which will satisfy $a_\varepsilon - a_0 = \varepsilon\delta a + o(\varepsilon)$ (see Proposition 7.6), and the associated solution u_ε will yield the same order: $\|u_\varepsilon - u_0\|_{H^1(\Omega_R)} = O(\varepsilon)$ (consequence of Lemma 2.1). Moreover, it will be seen that $\delta a(u,v)$ involves $u(x_0)$ and $v(x_0)$, and not $\nabla u(x_0)$ and $\nabla v(x_0)$. Another point is that the truncation technique can be applied to the case of a Neumann boundary condition on the hole [16], or even to more general boundary conditions.

4. The truncated problem. The open subset $B(x_0,R)\setminus\overline{\omega_\varepsilon}$ is denoted by D_ε (see Figure 2). For $\varphi\in H^{1/2}(\Gamma_R)$ and $\varepsilon>0$, let $u_\varepsilon^{f,\varphi}\in H^1(D_\varepsilon)$ be the solution to the following problem: find $u_\varepsilon^{f,\varphi}$ such that

$$\left\{\begin{array}{rl} -\Delta u_\varepsilon^{f,\varphi} = f & \text{in } D_\varepsilon,\\ u_\varepsilon^{f,\varphi} = \varphi & \text{on } \Gamma_R,\\ u_\varepsilon^{f,\varphi} = 0 & \text{on } \partial\omega_\varepsilon,\end{array}\right. \tag{6}$$

where Γ_R is the boundary of the ball $B(x_0,R)$. For $\varepsilon=0$, $u_0^{f,\varphi}$ is the solution to

$$\left\{\begin{array}{rl} -\Delta u_0^{f,\varphi} = f & \text{in } B(x_0,R),\\ u_0^{f,\varphi} = \varphi & \text{on } \Gamma_R.\end{array}\right. \tag{7}$$

Clearly we have

$$u_\varepsilon^{f,\varphi} = u_\varepsilon^{f,0} + u_\varepsilon^{0,\varphi}. \tag{8}$$

For $\varepsilon\geq 0$, the Dirichlet-to-Neumann operator T_ε is defined by

$$\begin{array}{rcl} T_\varepsilon : H^{1/2}(\Gamma_R) & \longrightarrow & H^{-1/2}(\Gamma_R),\\ \varphi & \longmapsto & T_\varepsilon\varphi = \nabla u_\varepsilon^{0,\varphi}.\mathbf{n},\end{array}$$

and the function $f_\varepsilon\in H^{-1/2}(\Gamma_R)$ is defined by

$$f_\varepsilon = -\nabla u_\varepsilon^{f,0}.\mathbf{n},$$

where the normal $\mathbf{n}$ is chosen outward to D_ε on Γ_R and $\partial\omega_\varepsilon$. Thus we have

$$\nabla u_\varepsilon^{f,\varphi}.\mathbf{n} = T_\varepsilon\varphi - f_\varepsilon.$$

Finally, we define for $\varepsilon\geq 0$ the solution u_ε to the truncated problem

$$\left\{\begin{array}{rl} -\Delta u_\varepsilon = f & \text{in } \Omega_R,\\ u_\varepsilon = 0 & \text{on } \Gamma,\\ -\nabla u_\varepsilon.\mathbf{n} + T_\varepsilon u_\varepsilon = f_\varepsilon & \text{on } \Gamma_R.\end{array}\right. \tag{9}$$

The variational formulation associated to (9) is the following: find $u_\varepsilon\in\mathcal{V}_R$ such that

$$a_\varepsilon(u_\varepsilon,v) = l_\varepsilon(v) \qquad \forall v\in\mathcal{V}_R, \tag{10}$$

where the functional space $\mathcal{V}_R$, the bilinear form a_ε, and the linear form l_ε are defined by

$$\mathcal{V}_R = \left\{u\in H^1(\Omega_R);\ u=0 \text{ on } \Gamma\right\},$$

$$a_\varepsilon(u,v) = \int_{\Omega_R}\nabla u.\nabla v\,dx + \int_{\Gamma_R} T_\varepsilon uv\,d\gamma(x), \tag{11}$$

$$l_\varepsilon(v) = \int_{\Omega_R} fv\,dx + \int_{\Gamma_R} f_\varepsilon v\,d\gamma(x). \tag{12}$$

Here $x.y$ denotes the usual dot product of $\mathbb{R}^n$ and $d\gamma(x)$ is the Lebesgue measure on the boundary. Symmetry, continuity, and coercivity of a_ε, and continuity of l_ε follow directly from

$$\int_{\Gamma_R} T_\varepsilon \varphi\psi \, d\gamma(x) = \int_{D_\varepsilon} \nabla u_\varepsilon^{0,\varphi}.\nabla u_\varepsilon^{0,\psi} \, dx,$$
$$\int_{\Gamma_R} f_\varepsilon \psi \, d\gamma(x) = \int_{D_\varepsilon} f u_\varepsilon^{0,\psi} \, dx.$$

Notice that $\int_{D_\varepsilon} \nabla u_\varepsilon^{f,0}.\nabla u_\varepsilon^{0,\psi} \, dx = 0$. The proof of the following result is standard.

PROPOSITION 4.1. *Let $\varepsilon \geq 0$. Problems* (4) *and* (9) *have a unique solution. Moreover, the restriction to Ω_R of the solution u_{Ω_ε} to* (4) *is the solution u_ε to* (9)*, and on D_ε we have*

$$(u_{\Omega_\varepsilon})_{|D_\varepsilon} = u_\varepsilon^{f,0} + u_\varepsilon^{0,\varphi}, \tag{13}$$

where φ is the trace of u_ε on Γ_R.

We now have at our disposal the fixed Hilbert space $\mathcal{V}_R$ required by section 2. The cost function (5) can be redefined in the following way: for $u \in \mathcal{V}_R$, let $\widetilde{u}_\varepsilon \in H^1(\Omega_\varepsilon)$ be the extension of u which coincides with u on Ω_R and with $u_\varepsilon^{f,\varphi}$ on D_ε for $\varphi = u_{|\Gamma_R}$. Then a function J_ε can be defined on $\mathcal{V}_R$ by

$$J_\varepsilon(u) := \widetilde{J}_\varepsilon(\widetilde{u}_\varepsilon). \tag{14}$$

Particularly, it follows from the previous proposition that

$$j(\varepsilon) = \widetilde{J}_\varepsilon(u_{\Omega_\varepsilon}) = J_\varepsilon(u_\varepsilon). \tag{15}$$

Notice that $J_\varepsilon(u_\varepsilon)$ is independent of the choice of R. For example, for a given target function u_{d} defined on Ω, if

$$\widetilde{J}_\varepsilon(u_{\Omega_\varepsilon}) = \int_{\Omega_\varepsilon} |u_{\Omega_\varepsilon} - u_{\mathrm{d}}|^2 dx,$$

then we have

$$J_\varepsilon(u) = \int_{\Omega_R} |u - u_{\mathrm{d}}|^2 dx + \int_{D_\varepsilon} |u_\varepsilon^{f,\varphi} - u_{\mathrm{d}}|^2 dx, \qquad u \in \mathcal{V}_R, \quad \varphi = u_{|\Gamma_R}.$$

5. Asymptotic expansion of the cost function. This section contains the main results of this paper. All the proofs are reported in section 7. Henceforth we have to distinguish the cases $n = 2$ and $n = 3$. This is due to the fact that the fundamental solutions to the Laplace equation in $\mathbb{R}^2$ and $\mathbb{R}^3$ have an essentially different asymptotic expansion at infinity, and Problem (16) has generally no solution if $n = 2$.

5.1. The three-dimensional case. Possibly changing the coordinate system, we can suppose for convenience that $x_0 = 0$. Let v_ω be the solution to the exterior problem

$$\begin{cases} -\Delta v_\omega = 0 & \text{in } \mathbb{R}^3 \backslash \overline{\omega}, \\ v_\omega = 0 & \text{at } \infty, \\ v_\omega = u_\Omega(x_0) & \text{on } \partial\omega, \end{cases} \tag{16}$$

where u_Ω is the solution to (3). Recall that $f \in L^q(\Omega)$, $q > n/2$, so that u_Ω is continuous inside Ω and the above boundary condition is well defined. The function v_ω can be expressed by a single layer potential on $\partial\omega$. Let

$$E(y) = \frac{1}{4\pi r} \tag{17}$$

with $r = \|y\|$. It is a fundamental solution for the Laplace equation in $\mathbb{R}^3$. Then the function v_ω reads

$$v_\omega(y) = \int_{\partial\omega} E(y-x) p_\omega(x)\, d\gamma(x), \qquad y \in \mathbb{R}^3 \backslash \overline{\omega}, \tag{18}$$

where $p_\omega \in H^{-1/2}(\partial\omega)$ is the solution to boundary integral equation [12]

$$\int_{\partial\omega} E(y-x) p_\omega(x)\, d\gamma(x) = u_\Omega(x_0) \qquad \forall y \in \partial\omega.$$

For x bounded and large $r = \|y\|$, we have

$$E(y-x) = E(y) + O\left(\frac{1}{r^2}\right),$$

and the asymptotic expansion at infinity of the function v_ω is given by

$$v_\omega(y) = P_\omega(y) + W_\omega(y), \tag{19}$$

$$P_\omega(y) = A_\omega(u_\Omega(x_0)) E(y), \tag{20}$$

$$A_\omega(u_\Omega(x_0)) = \int_{\partial\omega} p_\omega(x)\, d\gamma(x), \tag{21}$$

$$W_\omega(y) = O\left(\frac{1}{r^2}\right).$$

Notice that $P_\omega \in L^m_{\mathrm{loc}}(\mathbb{R}^3)$ for all $m < 3$. Clearly, the function $\alpha \longmapsto A_\omega(\alpha)$ is linear on $\mathbb{R}$, and the number $A_\omega(\alpha)$ depends on the shape of ω. For example, if ω is changed in $k\omega$, $k > 0$, then $v_{k\omega}(ky) = v_\omega(y)$ in (16), and it follows from (18) that $k p_{k\omega}(kx) = p_\omega(x)$ for $x \in \partial\omega$. Then using (21) we obtain $A_{k\omega}(u_\Omega(x_0)) = k A_\omega(u_\Omega(x_0))$. However, it is interesting to observe that $A_\omega(\alpha)$ is independent of the orientation of the hole ω: if R is a rotation, one obtains in a similar way $A_{R\omega}(u_\Omega(x_0)) = A_\omega(u_\Omega(x_0))$. Next we consider the constant $Q_\omega \in \mathbb{R}$ defined by

$$Q_\omega = \frac{A_\omega(u_\Omega(x_0))}{4\pi R} = (P_\omega)_{|\Gamma_R}. \tag{22}$$

The main result is the following, which will be proved in section 7. It is based on the fact that

$$\varepsilon(Q_\omega - P_\omega)_{|D_\varepsilon} \tag{23}$$

is the *first order approximation* of $(u_\varepsilon^{f,\varphi} - u_0^{f,\varphi})_{|D_\varepsilon}$ with $\varphi = (u_\Omega)_{|\Gamma_R}$, in a sense which will be stated precisely in section 7. Observe that it depends on the shape of ω through the term $A_\omega(u_\Omega(x_0))$ involved in (20). The stronger hypothesis $f \in L^q(\Omega)$, $q > n$, is used in the study of the variation of the linear form l_ε (12); cf. Proposition 7.7, which

involves the $\mathcal{C}^1$ norm of u_0 around x_0. If l_ε does not depend on ε (which happens, for example, if f vanishes on D_0), then $f \in L^q(\Omega)$, $q > n/2$, is sufficient.

THEOREM 5.1. *Let $f \in L^q(\Omega)$, $q > n$, and let J_ε be a function defined on $\mathcal{V}_R$ for all $\varepsilon \geq 0$. Suppose that for all $v \in \mathcal{V}_R$ and $\varepsilon > 0$, one has*

$$J_\varepsilon(v) - J_0(u_0) = DJ_0(u_0)(v - u_0) + \varepsilon\,\delta J(u_0) + o(\varepsilon + \|v - u_0\|_{\mathcal{V}_R}), \tag{24}$$

where $DJ_0(u_0)$ is linear and continuous on $\mathcal{V}_R$, and u_ε, $\varepsilon \geq 0$, is the solution to (10). *Let $v_0 \in \mathcal{V}_R$ be the solution to the adjoint equation*

$$a_0(w, v_0) = -DJ_0(u_0)w \qquad \forall w \in \mathcal{V}_R. \tag{25}$$

Let $j(\varepsilon) = J_\varepsilon(u_\varepsilon)$, $\varepsilon \geq 0$. Then the function j has the asymptotic expansion

$$j(\varepsilon) = j(0) + \varepsilon\,\delta j(x_0) + o(\varepsilon)$$

with

(26)

$$\delta j(x_0) = -\int_{\Gamma_R} \nabla P_\omega.\mathbf{n}\, v_0\, d\gamma(x) + \delta J(u_0) = \frac{A_\omega(u_\Omega(x_0))}{4\pi R^2} \int_{\Gamma_R} v_0(x)\, d\gamma(x) + \delta J(u_0).$$

The function $\delta j(x_0)$ is called the *topological sensitivity* or the *topological gradient*. Moreover, as j is usually independent of R (at least when it is of the form (15), which is the "natural" way of posing the problem) and $\delta j(x_0)$ is independent of ε, it follows from the uniqueness of an asymptotic expansion that $\delta j(x_0)$ is also independent of R. This is not necessarily true for the terms $\delta a(u_0, v_0)$, $\delta l(v_0)$ (see section 7), or $\delta J(u_0)$ considered separately, because a, l, and J do depend on R.

Practically, what is computed is the solution u_Ω to (3) and the solution v_Ω to

$$\int_\Omega \nabla w.\nabla v_\Omega\, dx = -D\widetilde{J}_0(u_\Omega)w \qquad \forall w \in H_0^1(\Omega). \tag{27}$$

As observed in Proposition 4.1, u_0 is the restriction to Ω_R of u_Ω. The same property holds for v_0 and v_Ω. This can easily be seen by observing that for $w \in H_0^1(\Omega)$ such that $\Delta w = 0$ in D_0, and denoting by v_R and w_R the restrictions of v_Ω and w to Ω_R, on the one hand we have

$$\begin{aligned} a_0(w_R, v_R) &= \int_{\Omega_R} \nabla w_R.\nabla v_R\, dx + \int_{\Gamma_R} T_0 w_R v_R\, d\gamma(x) \\ &= \int_\Omega \nabla w.\nabla v_\Omega\, dx, \end{aligned} \tag{28}$$

and on the other hand, due to (14), we have $\widetilde{J}_0(u) = J_0(u_R)$ for all $u \in H_0^1(\Omega)$ such that $-\Delta u = f$ in D_0 (with $u_R = u_{|\Omega_R}$); hence

$$D\widetilde{J}_0(u_\Omega)w = DJ_0(u_0)w_R. \tag{29}$$

Then, gathering (28), (27), and (29), we obtain

$$a_0(w_R, v_R) = -DJ_0(u_0)w_R \qquad \forall w_R \in \mathcal{V}_R,$$

which proves that v_R is the solution to (25), that is, v_0 is the restriction to Ω_R of v_Ω. The basic property of an adjoint technique is here also satisfied, in that the function

u_Ω and the adjoint state v_Ω do not depend on x_0. Hence *only two systems have to be solved* in order to compute the topological sensitivity $\delta j(x)$ for all $x \in \Omega$.

Thanks to Green's formula, $P_\omega = Q_\omega$ on Γ_R and $\nabla Q_\omega = 0$, the integral in (26) also reads

$$-\int_{\Gamma_R} \nabla P_\omega.\mathbf{n}\, v_0\, d\gamma(x) = \int_{\Gamma_R} \nabla v_\Omega.\mathbf{n}\, P_\omega\, d\gamma(x) - \nabla P_\omega.\mathbf{n}\, v_\Omega\, d\gamma(x) - \int_{D_0} \Delta v_\Omega Q_\omega\, dx.$$

When v_Ω is smooth enough, it follows from Newton's potential theory [12] that

$$v_\Omega(x_0) = \int_{\Gamma_R} \nabla v_\Omega.\mathbf{n}\, E\, d\gamma(x) - \nabla E.\mathbf{n}\, v_\Omega\, d\gamma(x) - \int_{D_0} \Delta v_\Omega E\, dx.$$

Multiplying by $A_\omega(u_\Omega(x_0))$ and using $P_\omega = A_\omega(u_\Omega(x_0))E$ yields

$$\int_{\Gamma_R} \nabla v_\Omega.\mathbf{n}\, P_\omega\, d\gamma(x) - \nabla P_\omega.\mathbf{n}\, v_\Omega\, d\gamma(x) = \int_{D_0} \Delta v_\Omega P_\omega\, dx + A_\omega(u_\Omega(x_0))v_\Omega(x_0).$$

Then using (26) leads to the following result.

COROLLARY 5.2. *Under the assumptions of Theorem* 5.1, *if* $\Delta v_\Omega \in L^q(D_0)$, $q > n/2$, *then*

$$\delta j(x_0) = A_\omega(u_\Omega(x_0))v_\Omega(x_0) + \int_{D_0} \Delta v_\Omega(P_\omega - Q_\omega)\, dx + \delta J(u_0). \tag{30}$$

Proposition 5.3 will show that, in fact, the two last terms in the right-hand side of (30) cancel each other for a class of cost functions which do not involve ∇u_Ω. In that case, the dependence on the shape of ω occurs only through the term $A_\omega(u_\Omega(x_0))$ (21). For example, if ω is changed in $k\omega$, $k > 0$, we have observed previously that $A_{k\omega}(u_\Omega(x_0)) = kA_\omega(u_\Omega(x_0))$. Hence ε is changed in $k\varepsilon$, which is not surprising. We have also observed that $A_\omega(u_\Omega(x_0))$ was independent of the orientation of ω; hence it remains true for $\delta j(x_0)$. However, $\delta j(x_0)$ can depend on the orientation of ω if the cost function involves ∇u_Ω; see Proposition 5.4. What will be more surprising is that in the two-dimensional case, $\delta j(x_0)$ is independent of ω (size, shape, orientation); see Propositions 5.5 and 5.6.

When ω is the unit ball $B(0,1)$, then $v_\omega(y)$, $P_\omega(y)$, $W(y)$, and Q_ω can be computed explicitly:

$$v_\omega(y) = \frac{u_\Omega(x_0)}{r} = P_\omega(y), \qquad W(y) = 0, \quad 0 \neq y \in \mathbb{R}^3,$$
$$Q_\omega = u_\Omega(x_0).$$

Then it follows from (17) and (20) that

$$A_\omega(u_\Omega(x_0)) = 4\pi u_\Omega(x_0).$$

It can also be easily checked that

$$p_\omega(y) = u_\Omega(x_0) \qquad \forall y \in \partial\omega.$$

We examine now two particular cases of cost functions.

5.1.1. First example. The first example consists of functions of the form

$$\widetilde{J}_\varepsilon(u) = \int_{\Omega_\varepsilon} g(x, u(x))\,dx, \qquad u \in H^1(\Omega_\varepsilon). \tag{31}$$

The hypotheses on g are the following:

- for all $x \in \Omega$, the function $s \mapsto g(x,s)$ is of class $\mathcal{C}^1$ on $\mathbb{R}$, its derivative being denoted by $g_s(x,s)$;
- for all $x \in \Omega$, the function $s \mapsto g_s(x,s)$ is Lipschitz continuous and there exists a constant M such that

$$|g_s(x,t) - g_s(x,s)| \le M\,|t-s| \qquad \forall (x,s,t) \in \Omega \times \mathbb{R} \times \mathbb{R}; \tag{32}$$

- the function $x \mapsto g_s(x,0)$ belongs to $L^2(\Omega)$ and $x \mapsto g(x,0)$ belongs to $L^{3/2}(\Omega)$ (or to $L^p(\Omega)$, $p > 1$, if $n = 2$; cf. section 5.2).

These hypotheses imply that for all $(x,s) \in \Omega \times \mathbb{R}$

$$|g(x,s)| \le |g(x,0)| + |g_s(x,0)s| + \frac{M}{2}s^2, \tag{33}$$

$$|g_s(x,s)| \le |g_s(x,0)| + M\,|s|\,, \tag{34}$$

and the functions $x \mapsto g(x,u(x))$ and $x \mapsto g_s(x,u(x))^2$ are integrable on Ω for all $u \in L^2(\Omega)$. If $u \in L^6(\mathcal{O})$ (or $L^m(\mathcal{O})$, $m > 2$, if $n = 2$), then the function $x \mapsto g(x,u(x))$ belongs to $L^{3/2}(\mathcal{O})$ (or to $L^{p'}(\mathcal{O})$, $1 < p' = \min(p, 2m/(m+2), m/2)$, if $n = 2$). The usual example

$$g(x,s) = |s - u_{\mathrm{d}}(x)|^2$$

satisfies these hypotheses if u_{d} belongs to $L^3(\Omega)$ (or to $L^{2p}(\Omega)$ if $n = 2$).

REMARK 5.1. *These assumptions are standard in shape optimization (see, for example,* [6]*), with the difference that $x \mapsto g(x,0)$ is usually supposed to be in $L^1(\Omega)$ only. Equation* (60) *is the only place where $g(.,0) \in L^{3/2}(\Omega)$ is used. That comes from the choice made on the function $\widetilde{J}_\varepsilon$. When $\widetilde{J}_\varepsilon$ is of the form*

$$\widetilde{J}_\varepsilon(u) = \int_{\Omega} g(x, u(x))\,dx, \quad u \in H^1(\Omega_\varepsilon) \text{ extended by } 0 \text{ on } \omega_\varepsilon,$$

then the term (60) *disappears, $g(.,0) \in L^1(\Omega)$ is sufficient, and the result remains the same.*

PROPOSITION 5.3. *If these hypotheses are satisfied and if $f \in L^q(\Omega)$, $q > n$, then*

$$\delta J(u_0) = \int_{D_0} g_s(x, u_\Omega)(Q_\omega - P_\omega)\,dx,$$
$$\Delta v_\Omega = g_s(x, u_\Omega)$$

with $v_\Omega \in H_0^1(\Omega)$, and the function j has the following asymptotic expansion:

$$j(\varepsilon) = j(0) + \varepsilon\, A_\omega(u_\Omega(x_0))v_\Omega(x_0) + o(\varepsilon).$$

If ω is the unit ball $B(0,1)$, then

$$j(\varepsilon) = j(0) + 4\pi\varepsilon\, u_\Omega(x_0)v_\Omega(x_0) + o(\varepsilon).$$

5.1.2. Second example. The second example consists of functions of the form

$$\widetilde{J}_\varepsilon(u) = \frac{1}{2}\int_{\Omega_\varepsilon} B(x)\nabla(u-u_{\rm d}).\nabla(u-u_{\rm d})\,dx, \qquad u \in H^1(\Omega_\varepsilon), \tag{35}$$

where $B \in W^{1,\infty}(\Omega, \mathbb{R}^{3\times 3})$, $B(x)$ is a symmetric matrix for all $x \in \Omega$, and $u_{\rm d} \in H^1(\Omega)$. Here tr $B(x)$ denotes the trace of the matrix $B(x)$, div denotes the divergence operator, and $W^{m,\infty}(\Omega)$ is the Sobolev space of distributions whose derivatives up to the order m are in $L^\infty(\Omega)$.

PROPOSITION 5.4. *If these hypotheses are satisfied and if f and $\Delta u_{\rm d}$ belong to $L^q(\Omega)$, $q > n$, then*

$$\delta J(u_0) = \frac{1}{2}\int_{\mathbb{R}^3\setminus\overline{\omega}} B(x_0)\nabla v_\omega(y).\nabla v_\omega(y)\,dy + \int_{D_0} \Delta v_\Omega(Q_\omega - P_\omega)\,dx,$$
$$-\Delta v_\Omega = \operatorname{div}\left(B(\nabla u_\Omega - \nabla u_{\rm d})\right)$$

with $v_\Omega \in H^1_0(\Omega)$, and the function j has the following asymptotic expansion:

$$j(\varepsilon) = j(0) + \varepsilon A_\omega(u_\Omega(x_0)).v_\Omega(x_0) + \frac{\varepsilon}{2}\int_{\mathbb{R}^3\setminus\overline{\omega}} B(x_0)\nabla v_\omega(y).\nabla v_\omega(y)\,dy + o(\varepsilon). \tag{36}$$

If ω is the unit ball, then

$$v_\omega = \frac{u_\Omega(x_0)}{r}$$

and the integral can be computed explicitly:

$$j(\varepsilon) = j(0) + \varepsilon\left(4\pi u_\Omega(x_0)v_\Omega(x_0) + \frac{2\pi u_\Omega(x_0)^2}{3}\operatorname{tr} B(x_0)\right) + o(\varepsilon).$$

Here, due to the form of the integral in (36) and the definition of v_ω, one can observe that the topological sensitivity will usually depend on the orientation of the hole ω, unless, for example, the matrix $B(x_0)$ is proportional to the identity.

5.2. The two-dimensional case. We briefly describe the transposition of the previous results to the two-dimensional case. As before, u_Ω and the adjoint state v_Ω are, respectively, the solutions to (3) and (27). A fundamental solution for the Laplace equation in $\mathbb{R}^2$ is given by

$$E(y) = \frac{-1}{2\pi}\log r.$$

The exterior problem must now be defined differently than in (16). Let v_ω be the solution to

$$\begin{cases} -\Delta v_\omega = 0 & \text{in } \mathbb{R}^2\setminus\overline{\omega}, \\ v_\omega(y)/\log r = u_\Omega(x_0) & \text{at } \infty, \\ v_\omega = 0 & \text{on } \partial\omega. \end{cases}$$

The function v_ω has the form

$$v_\omega(y) = u_\Omega(x_0)\log\|y\| + P_\omega + W_\omega(y),$$

where P_ω is constant and $W_\omega(y) = o(1)$ at infinity [12]. The *first order approximation* of $(u_\varepsilon^{f,\varphi} - u_0^{f,\varphi})_{|D_\varepsilon}$ with $\varphi = (u_\Omega)_{|\Gamma_R}$ is now (compare with (23))

$$\frac{1}{\log(R/\varepsilon)}\left(u_\Omega(x_0)\left(\log\frac{\|x\|}{\varepsilon} - \log\frac{R}{\varepsilon}\right)\right)_{|D_\varepsilon} \simeq -\frac{u_\Omega(x_0)\log(\|x\|/R)_{|D_\varepsilon}}{\log\varepsilon}.$$

In the following propositions (where ω is not supposed to be a ball), one can observe that in the two-dimensional case the topological sensitivity does not depend on the shape of the hole ω, in contrast to the three-dimensional case.

PROPOSITION 5.5. *The assumptions are the same as in Proposition* 5.3, *with* $\widetilde{J}_\varepsilon$ *of the form*

$$\widetilde{J}_\varepsilon(u) = \int_{\Omega_\varepsilon} g(x, u(x))\,dx, \qquad u \in H^1(\Omega_\varepsilon).$$

Then the function j *has the following asymptotic expansion:*

$$j(\varepsilon) = j(0) - \frac{2\pi u_\Omega(x_0)v_\Omega(x_0)}{\log\varepsilon} + o\left(\frac{-1}{\log\varepsilon}\right).$$

In the next proposition, the first expression of $j(\varepsilon)$ is given for comparison with the three-dimensional case.

PROPOSITION 5.6. *The assumptions are the same as in Proposition* 5.4, *with* $\widetilde{J}_\varepsilon$ *of the form*

$$\widetilde{J}_\varepsilon(u) = \frac{1}{2}\int_{\Omega_\varepsilon} B(x)\nabla(u - u_{\mathrm{d}}).\nabla(u - u_{\mathrm{d}})\,dx, \qquad u \in H^1(\Omega_\varepsilon).$$

Then the function j *has the following asymptotic expansion* (*with* $D_\varepsilon/\varepsilon = B(0, R/\varepsilon)/\overline{\omega}$):

$$\begin{aligned} j(\varepsilon) &= j(0) - \frac{2\pi}{\log\varepsilon}u_\Omega(x_0)v_\Omega(x_0) + \frac{1}{2\log^2\varepsilon}\int_{D_\varepsilon/\varepsilon} B(x_0)\nabla v_\omega(y).\nabla v_\omega(y)\,dy + o\left(\frac{-1}{\log\varepsilon}\right) \\ &= j(0) - \frac{1}{\log\varepsilon}\left(2\pi u_\Omega(x_0)v_\Omega(x_0) + \frac{\pi}{2}u_\Omega(x_0)^2\operatorname{tr} B(x_0)\right) + o\left(\frac{-1}{\log\varepsilon}\right). \end{aligned}$$

The proofs use the same tools as for the three-dimensional case (see section 7) and will not be repeated for the two-dimensional case.

6. A numerical example. We illustrate the use of the asymptotic expansion given by Proposition 5.3 on an example taken from [6], to which we refer the reader for more details on its construction. It consists of minimizing

$$j(\Omega) = \int_{B(0,1)} (u_\Omega - u_d)^2\,dx,$$

where the solution $u_\Omega \in H_0^1(\Omega)$ to

$$-\Delta u_\Omega = 1 \quad \text{in } \Omega \subset \overline{B}(0,1) \subset \mathbb{R}^2 \tag{37}$$

is extended by 0 on $\overline{B}(0,1)\backslash\overline{\Omega}$ (see, however, Remark 5.1) and

$$u_d(x) = \begin{cases} \frac{r_1^2 - r^2}{4} + a & \text{if } r \le r_1, \\ a & \text{if } r_1 \le r \le 1. \end{cases}$$

Here $0 < a < 3/16$, $r = \|x\|$, and r_1 is the first minimum of the function

$$q(r_1) = 2\pi \int_{r_1}^{1} \left(\left(a - \frac{1 - r_1^2}{4} \right) \frac{\log r}{\log r_1} + \frac{1 - r^2}{4} - a \right)^2 r\, dr.$$

We use the value $a = 1/19$, which gives $r_1 \simeq 0.503$. This problem has no classical solution. We seek a minimizing sequence of classical solutions, when obtaining a classical approximate solution is a constraint imposed on the optimization process.

The relaxed formulation reads

$$\min_{\mu} \int_{B(0,1)} (u_\mu - u_d)^2\, dx, \tag{38}$$

where $u_\mu \in H_0^1(B(0,1))$ is the solution to

$$-\Delta u_\mu + \mu u_\mu = 1 \quad \text{in } B(0,1)$$

and μ is a nonnegative Borel measure on $B(0,1)$ which vanishes on all sets of capacity zero. For this example, the solution to (38) is known: it is given by

$$\mu = \gamma H^1_{\partial B(0,r_1)}, \quad \gamma = \frac{4a - 1 + r_1^2}{4 a r_1 \log r_1},$$

$$u_\mu(x) = \begin{cases} u_d(x) & \text{if } r \le r_1, \\ \left(a - \frac{1 - r_1^2}{4} \right) \frac{\log r}{\log r_1} + \frac{1 - r^2}{4} & \text{if } r_1 \le r \le 1, \end{cases}$$

where $H^1_{\partial B(0,r_1)}$ denotes the Hausdorff measure on the circle $\partial B(0, r_1)$. The minimum of the (relaxed) cost function is

$$\int_{B(0,1)} (u_\mu - u_d)^2\, dx = q(r_1) \simeq 1.12\, 10^{-3}. \tag{39}$$

A minimizing sequence $(\Omega_N)_{N \ge 1}$ for the optimal design problem (38) is given by ($\mathbb{R}^2$ is identified with the complex plane)

$$\Omega_N = B(0,1) \backslash \bigcup_{k=1}^{N} \left\{ z \in \mathbb{C}\,;\, \left| z - \mathrm{e}^{2i\pi k/N} \right| \le \mathrm{e}^{-N/\gamma r_1} \right\}. \tag{40}$$

Using the topological asymptotic expansion of j in a way similar to that described in [16], we retrieve the above minimizing sequence in less than 20 iterations for different values of the mesh size h. One can observe in Figure 3 that the number of "holes" is approximately proportional to $\log h$. This agrees with the fact that if the size of the holes in (40) is set to $h = \mathrm{e}^{-N/\gamma r_1}$, then $N = -\gamma r_1 \log h$. The cost function at each step is illustrated by Figure 4. The obtained minimum is not far from the exact (relaxed) minimum (39).

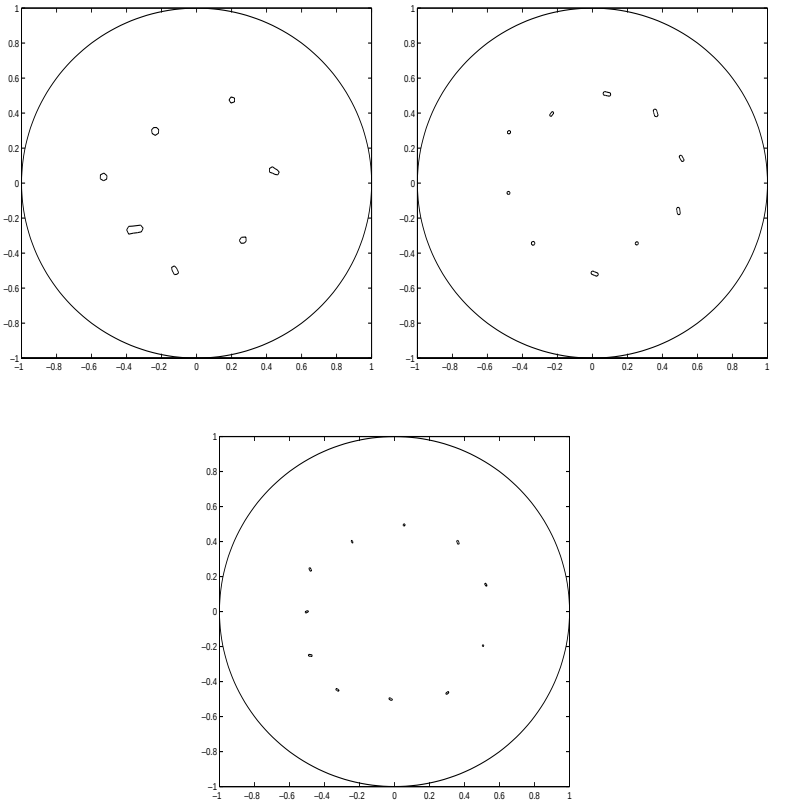

FIG. 3. *Solution for* $h = .05$, $h = .025$ *(top) and* $h = .0125$ *(bottom).*

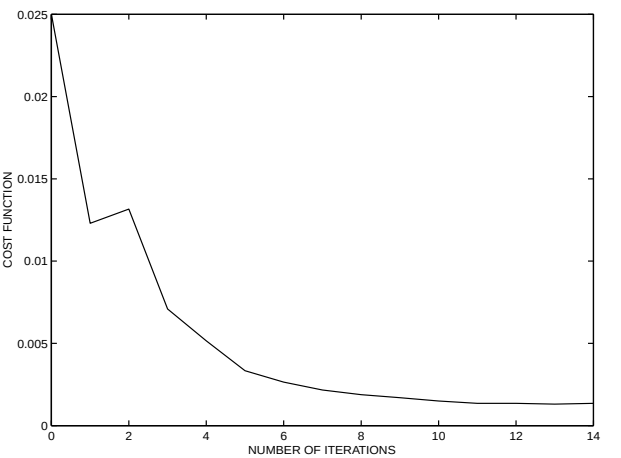

FIG. 4. $j(\Omega_k)$ *for* $h = 0.025$.

For completeness, we recall here the topology optimization algorithm [16]. Let $(m_k)_{k\geq 0}$ be a decreasing sequence of volume constraints, with $m_0 = \text{meas}(B(0,1))$. For example, a geometrical sequence may be chosen. At the kth iteration, the topological sensitivity is denoted by $\delta j_k(x)$. The algorithm is as follows:

- Initialization: chose $\Omega_0 = B(0,1)$, and set $k = 0$.
- Repeat until target is reached:
  1. solve (37) in Ω_k,
  2. compute the topological sensitivity δj_k,
  3. set $\Omega_{k+1} = \{x \in \Omega_k,\ \delta j_k(x) \geq c_{k+1}\}$, where c_{k+1} is chosen such that $\text{meas}(\Omega_{k+1}) = m_{k+1}$,
  4. $k \leftarrow k+1$.

This algorithm can be seen as a descent method where the descent direction is determined by the topological sensitivity δj_k, and the step length is given by the volume variation $m_{k+1} - m_k$. One possible stopping criterion is when no more improvement can be done, or simply when the optimality condition $\delta j_k(x) \geq 0$ for all $x \in \Omega_k$ is satisfied.

7. Proofs. This section consists of the proofs of Theorem 5.1 and Propositions 5.3 and 5.4. The variations of the bilinear form a_ε and the linear form l_ε (see (11) and (12)) read

$$a_\varepsilon(u,v) - a_0(u,v) = \int_{\Gamma_R} (T_\varepsilon - T_0)uv\, d\gamma(x),$$
$$l_\varepsilon(v) - l_0(v) = \int_{\Gamma_R} (f_\varepsilon - f_0)v\, d\gamma(x).$$

Hence, the problem reduces to the analysis of $(T_\varepsilon - T_0)\varphi$ for $\varphi \in H^{1/2}(\Gamma_R)$ and of $f_\varepsilon - f_0$ in $H^{-1/2}(\Gamma_R)$. More precisely, it will be shown in sections 7.3 and 7.4 that there exist an operator $\delta T \in \mathcal{L}(H^{1/2}(\Gamma_R); H^{-1/2}(\Gamma_R))$ and a function $\delta f \in H^{-1/2}(\Gamma_R)$ such that

$$\|T_\varepsilon - T_0 - \varepsilon\delta T\|_{\mathcal{L}(H^{1/2}(\Gamma_R);\, H^{-1/2}(\Gamma_R))} = O(\varepsilon^2), \tag{41}$$
$$\|f_\varepsilon - f_0 - \varepsilon\delta f\|_{H^{-1/2}(\Gamma_R)} = O(\varepsilon^2). \tag{42}$$

Consequently, defining δa and δl by

$$\delta a(u,v) = \int_{\Gamma_R} \delta T uv\, d\gamma(x), \qquad u,\, v \in \mathcal{V}_R,$$
$$\delta l(v) = \int_{\Gamma_R} \delta f\, v\, d\gamma(x), \qquad v \in \mathcal{V}_R,$$

will yield straightforwardly

$$\|a_\varepsilon - a_0 - \varepsilon\delta a\|_{\mathcal{L}_2(\mathcal{V}_R)} = O(\varepsilon^2),$$
$$\|l_\varepsilon - l_0 - \varepsilon\delta l\|_{\mathcal{L}(\mathcal{V}_R)} = O(\varepsilon^2).$$

In order to derive (41)–(42), we need some definitions and preliminary lemmas.

7.1. Definitions. For convenience, the following norms and seminorms are chosen for the functional spaces which will be used.

- For a bounded and open subset $\mathcal{O} \subset \mathbb{R}^3$ and $m \geq 0$, the Sobolev space $H^m(\mathcal{O})$ is equipped with the norm defined by

$$\|u\|^2_{m,\mathcal{O}} = \sum_{k=0}^{m} |u|^2_{k,\mathcal{O}}\,,$$

where the seminorms $|u|^2_{k,\mathcal{O}}$ are given by

$$|u|^2_{k,\mathcal{O}} := \sum_{|\alpha|=k} \int_{\mathcal{O}} |\partial_\alpha u|^2\, dx. \tag{43}$$

- For a given $\varepsilon > 0$, the space $H^{1/2}(\Gamma_{R/\varepsilon})$ is equipped with the following norm:

$$\|v\|_{1/2,\Gamma_{R/\varepsilon}} = \inf\left\{\|u\|_{1,C(R/(2\varepsilon),R/\varepsilon)};\quad u = v \quad \text{on} \quad \Gamma_{R/\varepsilon}\right\},$$

where $C(r,r') := \left\{x \in \mathbb{R}^3;\quad r < \|x\| < r'\right\}$.

- The dual space $H^{-1/2}(\Gamma_{R/\varepsilon})$ is equipped with the natural norm

$$\|w\|_{-1/2,\Gamma_{R/\varepsilon}} = \sup\left\{\langle w, v\rangle_{-1/2,1/2}\,;\quad v \in H^{1/2}(\Gamma_{R/\varepsilon}),\, \|v\|_{1/2,\Gamma_{R/\varepsilon}} = 1\right\}.$$

It can easily be checked that if $\psi \in H^1(C(R/2,R))$ with $\Delta\psi = 0$ in $C(R/2,R)$, then

$$\|\nabla\psi.\mathbf{n}\|_{-1/2,\Gamma_R} \leq c\ |\psi|_{1,C(R/2,R)}\,. \tag{44}$$

Here and in what follows, c is a positive constant independent of the data (e.g., on ε).

7.2. Preliminary lemmas. Recall that $x_0 = 0$. We will use extensively the following change of variable: for a given function u defined on a subset $\mathcal{O}$, the function $\widetilde{u}$ is defined on $\widetilde{\mathcal{O}} := \mathcal{O}/\varepsilon$ by

$$\widetilde{u}(y) = u(x), \qquad y = x/\varepsilon.$$

Due to $\nabla u(x) = \nabla\widetilde{u}(y)/\varepsilon$ and to definition (43), we have

$$|u|^2_{1,\mathcal{O}} = \int_{\mathcal{O}} |\nabla u|^2\ dx = \frac{1}{\varepsilon^2}\int_{\widetilde{\mathcal{O}}} |\nabla\widetilde{u}|^2\ \varepsilon^3 dy;$$

hence

$$|u|_{1,\mathcal{O}} = \varepsilon^{1/2}\,|\widetilde{u}|_{1,\widetilde{\mathcal{O}}}\,. \tag{45}$$

Similarly, we have

$$\|u\|_{0,\mathcal{O}} = \varepsilon^{3/2}\,\|\widetilde{u}\|_{0,\widetilde{\mathcal{O}}}\,. \tag{46}$$

LEMMA 7.1. *For $\varphi \in H^{1/2}(\partial\omega)$ let v be the solution to the problem*

$$\begin{cases} -\Delta v = 0 & \text{in } \mathbb{R}^3\backslash\overline{\omega}, \\ v = 0 & \text{at } \infty, \\ v = \varphi & \text{on } \partial\omega. \end{cases} \tag{47}$$

The function v is split into

$$v(y) = V(y) + W(y),$$
$$V(y) = E(y) \int_{\partial\omega} p(x)\, d\gamma(x),$$

where $E(y) = 1/4\pi \|y\|$, and $p \in H^{-1/2}(\partial\omega)$ is the unique solution to

$$\int_{\partial\omega} E(y-x)p(x)d\gamma(x) = \varphi(y) \qquad \forall y \in \partial\omega. \tag{48}$$

There exists a constant $c > 0$ (independent of φ and ε) such that

$$\begin{aligned}
\|V\|_{0,C(R/(2\varepsilon),R/\varepsilon)} &\le c\,\varepsilon^{-1/2}\|\varphi\|_{1/2,\partial\omega},\\
|V|_{1,C(R/(2\varepsilon),R/\varepsilon)} &\le c\,\varepsilon^{1/2}\|\varphi\|_{1/2,\partial\omega},\\
\|V\|_{0,D_\varepsilon/\varepsilon} &\le c\,\varepsilon^{-1/2}\|\varphi\|_{1/2,\partial\omega},\\
|V|_{1,D_\varepsilon/\varepsilon} &\le c\,\|\varphi\|_{1/2,\partial\omega},\\
\|W\|_{0,C(R/(2\varepsilon),R/\varepsilon)} &\le c\,\varepsilon^{1/2}\|\varphi\|_{1/2,\partial\omega},\\
|W|_{1,C(R/(2\varepsilon),R/\varepsilon)} &\le c\,\varepsilon^{3/2}\|\varphi\|_{1/2,\partial\omega},\\
\|W\|_{1,D_\varepsilon/\varepsilon} &\le c\,\|\varphi\|_{1/2,\partial\omega}.
\end{aligned}$$

Proof. The function v reads

$$v(y) = \int_{\partial\omega} E(y-x)p(x)\, d\gamma(x), \qquad y \in \mathbb{R}^3\backslash\overline{\omega}.$$

Using a Taylor expansion of E computed at the point y and the well-posedness of (48) we have for large $\|y\|$

$$\begin{aligned}
|V(y)| &\le \frac{c}{r}\|\varphi\|_{1/2,\partial\omega}, \qquad |W(y)| \le \frac{c}{r^2}\|\varphi\|_{1/2,\partial\omega},\\
|\nabla V(y)| &\le \frac{c}{r^2}\|\varphi\|_{1/2,\partial\omega}, \qquad |\nabla W(y)| \le \frac{c}{r^3}\|\varphi\|_{1/2,\partial\omega},
\end{aligned}$$

from which the above inequalities follow straightforwardly. ∎

LEMMA 7.2. *For $\varphi \in H^{1/2}(\Gamma_R)$, let v_ε be the solution to the problem*

$$\begin{cases} -\Delta v_\varepsilon = 0 & \text{in } D_\varepsilon,\\ v_\varepsilon = \varphi & \text{on } \Gamma_R,\\ v_\varepsilon = 0 & \text{on } \partial\omega_\varepsilon. \end{cases} \tag{49}$$

There exist a constant $c > 0$ (independent of φ and ε) and $\varepsilon_1 > 0$ such that for all $0 < \varepsilon < \varepsilon_1$,

$$\|v_\varepsilon\|_{1,D_\varepsilon} \le c\, \|\varphi\|_{1/2,\Gamma_R}.$$

Proof. Let $\varepsilon_0 > 0$. Problem (49) is well-posed; hence there exists a constant c such that

$$|v_{\varepsilon_0}|_{1,D_{\varepsilon_0}} \le c\,\|\varphi\|_{1/2,\Gamma_R}.$$

Let $\varepsilon_1 \leq \varepsilon_0$ be such that $D_{\varepsilon_0} \subset D_\varepsilon$ for all $\varepsilon < \varepsilon_1$. Let $\widehat{v}_{\varepsilon_0}$ be the extension of v_{ε_0} to D_ε by 0. The function v_ε minimizes the energy $|v|_{1,D_\varepsilon}$ over the affine space

$$\left\{v \in H^1(D_\varepsilon);\ v = \varphi \text{ on } \Gamma_R \text{ and } v = 0 \text{ on } \partial\omega_\varepsilon\right\};$$

hence, for all $\varepsilon \leq \varepsilon_1$ we have

$$|v_\varepsilon|_{1,D_\varepsilon} \leq |\widehat{v}_{\varepsilon_0}|_{1,D_\varepsilon} = |v_{\varepsilon_0}|_{1,D_{\varepsilon_0}} \leq c\,\|\varphi\|_{1/2,\Gamma_R}.$$

We also have

$$\|v_0\|_{0,D_0} \leq c\ \|\varphi\|_{1/2,\Gamma_R}.$$

Then, denoting by $\widehat{v}_\varepsilon$ the extension by 0 of v_ε to D_0 and using the Poincaré inequality on D_0 yields

$$\begin{aligned}\|v_\varepsilon\|_{0,D_\varepsilon} = \|\widehat{v}_\varepsilon\|_{0,D_0} &\leq \|\widehat{v}_\varepsilon - v_0\|_{0,D_0} + \|v_0\|_{0,D_0}\\ &\leq c\ |\widehat{v}_\varepsilon - v_0|_{1,D_0} + \|v_0\|_{0,D_0}\\ &\leq c\ |\widehat{v}_\varepsilon|_{1,D_0} + c\ \|v_0\|_{1,D_0} = c\ |v_\varepsilon|_{1,D_\varepsilon} + c\ \|v_0\|_{1,D_0}\\ &\leq c\ \|\varphi\|_{1/2,\Gamma_R}.\qquad \square\end{aligned}$$

LEMMA 7.3. *For $\varepsilon > 0$ and $\psi \in H^1(D_0)$, let u_ε be the solution to the problem*

$$\left\{\begin{array}{rl} -\Delta u_\varepsilon = 0 & \text{in } D_\varepsilon,\\ u_\varepsilon = 0 & \text{on } \Gamma_R,\\ u_\varepsilon = \psi & \text{on } \partial\omega_\varepsilon.\end{array}\right. \tag{50}$$

There exist a constant $c > 0$ (independent of ψ and ε) and $\varepsilon_1 > 0$ such that for all $0 < \varepsilon < \varepsilon_1$,

$$\begin{aligned}|u_\varepsilon|_{1,C(R/2,R)} &\leq c\,\varepsilon\|\psi(\varepsilon y)\|_{1/2,\partial\omega},\\ \|u_\varepsilon\|_{0,D_\varepsilon} &\leq c\,\varepsilon\ \|\psi(\varepsilon y)\|_{1/2,\partial\omega},\\ |u_\varepsilon|_{1,D_\varepsilon} &\leq c\,\varepsilon^{1/2}\ \|\psi(\varepsilon y)\|_{1/2,\partial\omega}.\end{aligned}$$

Proof. Let $\widetilde{v}_\varepsilon$ be the solution to the exterior problem

$$\left\{\begin{array}{ll} -\Delta\widetilde{v}_\varepsilon = 0 & \text{in } \mathbb{R}^3\backslash\overline{\omega},\\ \widetilde{v}_\varepsilon = 0 & \text{at } \infty,\\ \widetilde{v}_\varepsilon = \psi(\varepsilon y) & \text{on } \partial\omega.\end{array}\right.$$

The function u_ε can be written

$$u_\varepsilon = v_\varepsilon - w_\varepsilon,$$

where $v_\varepsilon(x) = \widetilde{v}_\varepsilon(x/\varepsilon)$. The function w_ε itself is the solution to

$$\left\{\begin{array}{rl} -\Delta w_\varepsilon = 0 & \text{in } D_\varepsilon,\\ w_\varepsilon = v_\varepsilon & \text{on } \Gamma_R,\\ w_\varepsilon = 0 & \text{on } \partial\omega_\varepsilon.\end{array}\right.$$

It follows from (45), (46), and Lemmas 7.1 and 7.2 that there exist $c > 0$ and $\varepsilon_1 > 0$ such that for all $0 < \varepsilon < \varepsilon_1$,

$$\begin{aligned}
|v_\varepsilon|_{1,C(R/2,R)} &\le c\,\varepsilon^{1/2}|\widetilde{v}_\varepsilon|_{1,C(R/2\varepsilon,R/\varepsilon)} \le c\,\varepsilon\,\|\psi(\varepsilon y)\|_{1/2,\partial\omega}\,,\\
\|w_\varepsilon\|_{1,D_\varepsilon} &\le c\,\|v_\varepsilon\|_{1/2,\Gamma_R}\\
&\le c\,\|v_\varepsilon\|_{1,C(R/2,R)}\\
&\le c\,(|v_\varepsilon|_{0,C(R/2,R)} + |v_\varepsilon|_{1,C(R/2,R)})\\
&= c\,(\varepsilon^{3/2}|\widetilde{v}_\varepsilon|_{0,C(R/2\varepsilon,R/\varepsilon)} + \varepsilon^{1/2}|\widetilde{v}_\varepsilon|_{1,C(R/2\varepsilon,R/\varepsilon)})\\
&\le c\,\varepsilon\,\|\psi(\varepsilon y)\|_{1/2,\partial\omega}\,. \qquad (51)
\end{aligned}$$

Hence

$$\begin{aligned}
|u_\varepsilon|_{1,C(R/2,R)} &= |v_\varepsilon - w_\varepsilon|_{1,C(R/2,R)} \le |v_\varepsilon|_{1,C(R/2,R)} + |w_\varepsilon|_{1,D_\varepsilon}\\
&\le c\,\varepsilon\,\|\psi(\varepsilon y)\|_{1/2,\partial\omega}\,.
\end{aligned}$$

Similarly we have

$$\begin{aligned}
\|v_\varepsilon\|_{0,D_\varepsilon} &= \varepsilon^{3/2}\,\|\tilde{v}_\varepsilon\|_{0,D_\varepsilon/\varepsilon} \le c\,\varepsilon\,\|\psi(\varepsilon y)\|_{1/2,\partial\omega}\,,\\
|v_\varepsilon|_{1,D_\varepsilon} &= \varepsilon^{1/2}\,|\tilde{v}_\varepsilon|_{1,D_\varepsilon/\varepsilon} \le c\,\varepsilon^{1/2}\,\|\psi(\varepsilon y)\|_{1/2,\partial\omega}
\end{aligned}$$

and

$$\begin{aligned}
\|u_\varepsilon\|_{0,D_\varepsilon} &\le c\,\varepsilon\,\|\psi(\varepsilon y)\|_{1/2,\partial\omega}\,,\\
|u_\varepsilon|_{1,D_\varepsilon} &\le c\,\varepsilon^{1/2}\,\|\psi(\varepsilon y)\|_{1/2,\partial\omega}\,. \qquad \square
\end{aligned}$$

Lemmas 7.2 and 7.3 are summarized in the following lemma.

LEMMA 7.4. *Let v_ε be the solution to the problem*

$$\begin{cases} -\Delta v_\varepsilon = 0 & \text{in } D_\varepsilon,\\ v_\varepsilon = \varphi & \text{on } \Gamma_R,\\ v_\varepsilon = \psi & \text{on } \partial\omega_\varepsilon, \end{cases}$$

where $\varphi \in H^{1/2}(\Gamma_R)$ and $\psi \in H^1(D_0)$. There exist a constant $c > 0$ (independent of φ, ψ, and ε) and $\varepsilon_1 > 0$ such that for all $0 < \varepsilon < \varepsilon_1$,

$$\begin{aligned}
|v_\varepsilon|_{1,C(R/2,R)} &\le c\,\left(\|\varphi\|_{1/2,\Gamma_R} + \varepsilon\,\|\psi(\varepsilon y)\|_{1/2,\partial\omega}\right),\\
\|v_\varepsilon\|_{0,D_\varepsilon} &\le c\,\left(\|\varphi\|_{1/2,\Gamma_R} + \varepsilon\,\|\psi(\varepsilon y)\|_{1/2,\partial\omega}\right),\\
|v_\varepsilon|_{1,D_\varepsilon} &\le c\,\left(\|\varphi\|_{1/2,\Gamma_R} + \varepsilon^{1/2}\,\|\psi(\varepsilon y)\|_{1/2,\partial\omega}\right).
\end{aligned}$$

7.3. Variation of the bilinear form. The variation of the bilinear form a_ε reads

$$a_\varepsilon(u,v) - a_0(u,v) = \int_{\Gamma_R} (T_\varepsilon - T_0)uv\,d\gamma(x).$$

For $\varphi \in H^{1/2}(\Gamma_R)$, recall that $u_\varepsilon^{0,\varphi}$ is the solution to (6) or (7) if $\varepsilon = 0$. Let $v_\omega^{0,\varphi}$ be the solution to

$$\begin{cases} -\Delta v_\omega^{0,\varphi} = 0 & \text{in } \mathbb{R}^3\backslash\overline{\omega},\\ v_\omega^{0,\varphi} = 0 & \text{at } \infty,\\ v_\omega^{0,\varphi} = u_0^{0,\varphi}(x_0) & \text{on } \partial\omega. \end{cases} \qquad (52)$$

As (19)–(22), let $P_\omega^{0,\varphi}(y) = A_\omega(u_0^{0,\varphi}(x_0))E(y)$ be the dominant part of $v_\omega^{0,\varphi}$, and let $Q_\omega^{0,\varphi} = A_\omega(u_0^{0,\varphi}(x_0))/(4\pi R)$, $P_\omega^{0,\varphi}(x) = Q_\omega^{0,\varphi}$ on Γ_R. The linear operator δT (independent of ε) is defined as follows:

$$\begin{array}{rcl} \delta T : H^{1/2}(\Gamma_R) & \longrightarrow & H^{-1/2}(\Gamma_R), \\ \varphi & \longmapsto & \delta T\varphi := -\nabla P_\omega^{0,\varphi}.\mathbf{n}. \end{array} \tag{53}$$

PROPOSITION 7.5. *The asymptotic expansion of T_ε is*

$$\|T_\varepsilon - T_0 - \varepsilon\delta T\|_{\mathcal{L}(H^{1/2}(\Gamma_R);\, H^{-1/2}(\Gamma_R))} = O(\varepsilon^2). \tag{54}$$

Proof. Let $\varphi \in H^{1/2}(\Gamma_R)$. For simplicity we drop the subscripts $(.)^{0,\varphi}$. For $y = x/\varepsilon$, we have $v_\omega(y) = P_\omega(y) + W_\omega(y)$ with $P_\omega(x/\varepsilon) = \varepsilon P_\omega(x)$ and $W_\omega(y) = O(1/\|y\|^2)$. Let

$$\psi_\varepsilon(x) = (T_\varepsilon - T_0 - \varepsilon\delta T)\varphi(x).$$

We have

$$\begin{aligned} \psi_\varepsilon(x) &= \left(\nabla u_\varepsilon - \nabla u_0 + \varepsilon\nabla\left(P_\omega - Q_\omega\right)\right).\mathbf{n} \\ &= \nabla(w_\varepsilon(x) - W_\omega(x/\varepsilon)).\mathbf{n}, \end{aligned}$$

where w_ε is defined by

$$w_\varepsilon(x) = u_\varepsilon(x) - u_0(x) + v_\omega(x/\varepsilon) - \varepsilon Q_\omega.$$

The function w_ε is the solution to

$$\left\{ \begin{array}{ll} -\Delta w_\varepsilon = 0 & \text{in } D_\varepsilon, \\ w_\varepsilon = v_\omega(x/\varepsilon) - \varepsilon Q_\omega & \text{on } \Gamma_R, \\ w_\varepsilon = -u_0(x) + u_0(x_0) - \varepsilon Q_\omega & \text{on } \partial\omega_\varepsilon. \end{array} \right.$$

In order to apply Lemma 7.4, we have to estimate the two right-hand sides.

On Γ_R, due to $P_\omega(x) = Q_\omega$, we have

$$v_\omega(x/\varepsilon) - \varepsilon Q_\omega = W_\omega(x/\varepsilon).$$

Using (45), (46), Lemma 7.1, and elliptic regularity we obtain

$$\begin{aligned} \|v_\omega(x/\varepsilon) - \varepsilon Q_\omega\|_{1/2,\Gamma_R} &= \|W_\omega(x/\varepsilon)\|_{1/2,\Gamma_R} \\ &\le c\,\|W_\omega(x/\varepsilon)\|_{1,C(R/2,R)} \\ &\le c\,(\|W_\omega(x/\varepsilon)\|_{0,C(R/2,R)} + |W_\omega(x/\varepsilon)|_{1,C(R/2,R)}) \\ &= c\,(\varepsilon^{3/2}|W_\omega(y)|_{0,C(R/2\varepsilon,R/\varepsilon)} + \varepsilon^{1/2}|W_\omega(y)|_{1,C(R/2\varepsilon,R/\varepsilon)}) \\ &\le c\,\varepsilon^2\,\|u_0(x_0)\|_{1/2,\partial\omega} \\ &\le c\,\varepsilon^2\,\|\varphi\|_{1/2,\Gamma_R}. \end{aligned}$$

On ω_ε, putting $\theta_\varepsilon(x) := (-u_0(x) + u_0(x_0) - \varepsilon Q_\omega)/\varepsilon$, we have for small ε

$$\begin{aligned} \|\theta_\varepsilon(\varepsilon y)\|_{1/2,\partial\omega} &\le c\,\|\theta_\varepsilon(\varepsilon y)\|_{1,\omega} \\ &= c\,\left\|\frac{u_0(\varepsilon y) - u_0(x_0)}{\varepsilon} + Q_\omega\right\|_{1,\omega} \\ &\le c\,(\|u_0\|_{\mathcal{C}^1(B(0,R/2))} + |Q_\omega|) \\ &\le c\,(\|\varphi\|_{1/2,\Gamma_R} + |u_0(x_0)|) \\ &\le c\,\|\varphi\|_{1/2,\Gamma_R}. \end{aligned}$$

We can now apply Lemma 7.4, which gives

$$\begin{aligned}|\omega_\varepsilon(x)|_{1,C(R/2,R)} &\le c\,(\varepsilon^2\,\|\varphi\|_{1/2,\Gamma_R} + \varepsilon\,\|\varepsilon\theta_\varepsilon(\varepsilon y)\|_{1/2,\partial\omega})\\ &\le c\,\varepsilon^2\ \|\varphi\|_{1/2,\Gamma_R}.\end{aligned}$$

Finally it follows from (44), (45), and Lemma 7.1 that

$$\begin{aligned}\|\psi\|_{-1/2,\Gamma_R} &= \|\nabla(\omega_\varepsilon - W_\omega(x/\varepsilon)).\mathbf{n}\|_{-1/2,\Gamma_R}\\ &\le c\,(|w_\varepsilon|_{1,C(R/2,R)} + |W_\omega(x/\varepsilon)|_{1,C(R/2,R)})\\ &= c\,(|w_\varepsilon|_{1,C(R/2,R)} + \varepsilon^{1/2}|W_\omega(y)|_{1,C(R/2\varepsilon,R/\varepsilon)})\\ &\le c\,\varepsilon^2\|\varphi\|_{1/2,\Gamma_R}.\end{aligned}$$

Hence

$$\|(T_\varepsilon - T_0 - \varepsilon\delta T)\varphi\|_{-1/2,\Gamma_R} = O(\varepsilon^2). \qquad \square$$

The asymptotic expansion of the bilinear form a_ε follows now straightforwardly.

PROPOSITION 7.6. *Let*

$$\delta a(u,v) = \int_{\Gamma_R} \delta T uv\, d\gamma(x), \qquad u,\, v \in \mathcal{V}_R.$$

Then the asymptotic expansion of the bilinear form a_ε is given by

$$\|a_\varepsilon - a_0 - \varepsilon\delta a\|_{\mathcal{L}_2(\mathcal{V}_R)} = O(\varepsilon^2).$$

7.4. Variation of the linear form. The technique is the same as in section 7.3. The difference comes from the boundary condition imposed on $\partial\omega$ to the solution to the exterior problem: $v_\omega^{0,\varphi} = u_0^{0,\varphi}(x_0)$ in (52) for the study of the bilinear form, and $v_\omega^{f,0} = u_0^{f,0}(x_0)$ in (55) for the study of the linear form. Hence estimations involving $\|\varphi\|_{1/2,\Gamma_R}$ are replaced by estimations involving $\|f\|_{L^q}$.

The variation of the linear form l_ε reads

$$l_\varepsilon(v) - l_0(v) = \int_{\Gamma_R} (f_\varepsilon - f_0)v\, d\gamma(x).$$

Recall that $u_\varepsilon^{f,0}$ is the solution to (6) or (7) if $\varepsilon = 0$. Let $v_\omega^{f,0}$ be the solution to

$$\left\{\begin{array}{ll} -\Delta v_\omega^{f,0} = 0 & \text{in } \mathbb{R}^3\backslash\overline{\omega},\\ v_\omega^{f,0} = 0 & \text{at } \infty,\\ v_\omega^{f,0} = u_0^{f,0}(x_0) & \text{on } \partial\omega. \end{array}\right. \tag{55}$$

As with (19)–(22), let $P_\omega^{f,0}(y) = A_\omega(u_0^{f,0}(x_0))E(y)$ be the dominant part of $v_\omega^{f,0}$, and let $Q_\omega^{f,0} = A_\omega(u_0^{f,0}(x_0))/(4\pi R)$, $P_\omega^{f,0}(x) = Q_\omega^{f,0}$ on Γ_R. The function $\delta f \in H^{-1/2}(\Gamma_R)$ (independent of ε) is defined by

$$\delta f = \nabla P_\omega^{f,0}.\mathbf{n}. \tag{56}$$

PROPOSITION 7.7. *Let $f \in L^q(\Omega)$, $q > n$. The asymptotic expansion of f_ε with respect to ε is*

$$\|f_\varepsilon - f_0 - \varepsilon\delta f\|_{-1/2,\Gamma_R} = O(\varepsilon^2).$$

Proof. The proof runs as in Proposition 7.5 (we drop the subscripts $(.)^{f,0}$) with w_ε and θ_ε defined by

$$w_\varepsilon(x) = u_\varepsilon(x) - u_0(x) + v_\omega(x/\varepsilon) - \varepsilon Q_\omega,$$
$$\theta_\varepsilon(x) = (-u_0(x) + u_0(x_0) - \varepsilon Q_\omega)/\varepsilon.$$

The only difference lies in the elliptic regularity estimate [20, 21]

$$|u_0(x_0)| \le \|u_0\|_{\mathcal{C}^0(D_0)} \le \|f\|_{L^q},$$

and for small ε,

$$\begin{aligned}
\|\theta_\varepsilon(\varepsilon y)\|_{1/2,\partial\omega} &\le c\,\|\theta_\varepsilon(\varepsilon y)\|_{1,\omega} \\
&\le c\,\left\|\frac{u_0(\varepsilon y) - u_0(x_0)}{\varepsilon} + Q_\omega\right\|_{1,\omega} \\
&\le c\,(\|u_0\|_{\mathcal{C}^1(B(0,R/2))} + |Q_\omega|) \\
&\le c\,(\|f\|_{L^q} + |u_0(x_0)|) \\
&\le c\,\|f\|_{L^q}. \qquad \square
\end{aligned}$$

The asymptotic expansion of the linear form l_ε now follows straightforwardly.

PROPOSITION 7.8. *Let*

$$\delta l(v) = \int_{\Gamma_R} \delta f v\, d\gamma(x), \qquad v \in \mathcal{V}_R.$$

Then the asymptotic expansion of linear form l_ε is given by

$$\|l_\varepsilon - l_0 - \varepsilon\delta l\|_{\mathcal{L}(\mathcal{V}_R)} = O(\varepsilon^2).$$

7.5. Proof of Theorem 5.1. The fundamental hypotheses (1) and (2) are satisfied; hence we can apply Theorem 2.2:

$$j(\varepsilon) = j(0) + (\delta a(u,v) - \delta l(v) + \delta J(u))\varepsilon + o(\varepsilon).$$

It follows from (13), (16), (52), and (55) that

$$v_\omega = v_\omega^{f,0} + v_\omega^{0,\varphi},$$

which implies

$$P_\omega = P_\omega^{f,0} + P_\omega^{0,\varphi}.$$

Then, using (53), (56), and Propositions 7.6 and 7.8, we obtain

$$\begin{aligned}
\delta a(u,v) - \delta l(v) &= \int_{\Gamma_R} -\left(\nabla P_\omega^{0,\varphi} + \nabla P_\omega^{f,0}\right).\mathbf{n}\, v\, d\gamma(x) \\
&= -\int_{\Gamma_R} \nabla P_\omega.\mathbf{n}\, v\, d\gamma(x),
\end{aligned}$$

which achieves the proof of Theorem 5.1.

7.6. Proof of Proposition 5.3. This section describes the variations of $J_\varepsilon(u) = \widetilde{J}_\varepsilon(\widetilde{u}_\varepsilon)$ (see (14)) when $\widetilde{J}_\varepsilon$ is of the form (31)

$$\widetilde{J}_\varepsilon(v) = \int_{\Omega_\varepsilon} g(x, v(x))\, dx, \qquad v \in H^1(\Omega_\varepsilon).$$

The hypotheses on g (32)–(34) described in section 5 are supposed to be satisfied. Throughout this and the next subsection, $\widetilde{u}_\varepsilon \in H^1(\Omega_\varepsilon)$, $\varepsilon \geq 0$, denotes the extension of $u \in \mathcal{V}_R$ which coincides with u on Ω_R and with $u_\varepsilon^{f,\varphi}$ on D_ε for $\varphi = u_{|\Gamma_R}$.

LEMMA 7.9. *Let $\varphi \in H^{1/2}(\Gamma_R)$ and $f \in L^q(\Omega)$, $q > n$. Let $u_\varepsilon^{f,\varphi}$ and $u_0^{f,\varphi}$ be, respectively, the solutions to* (6) *and* (7). *Then*

$$\left\| u_\varepsilon^{f,\varphi} - u_0^{f,\varphi} - \varepsilon(Q_\omega^{f,\varphi} - P_\omega^{f,\varphi}) \right\|_{0,D_\varepsilon} = O(\varepsilon^{3/2}), \tag{57}$$

$$\left\| u_\varepsilon^{f,\varphi} - u_0^{f,\varphi} - \varepsilon Q_\omega^{f,\varphi} + v_\omega^{f,\varphi}(x/\varepsilon) \right\|_{1,D_\varepsilon} = O(\varepsilon^{3/2}), \tag{58}$$

where $P_\omega^{f,\varphi}$ is the dominant part (19) *of the solution $v_\omega^{f,\varphi}$ to the exterior problem* (16) *with $u_0^{f,\varphi}(x_0)$ substituted for $u_\Omega(x_0)$ and $Q_\omega^{f,\varphi}$ is the associated constant* (22).

Proof. Recall that $v_\omega = P_\omega + W_\omega$ (19) with $P_\omega(x/\varepsilon) = \varepsilon P_\omega(x)$ and $W_\omega(y) = O(1/\|y\|^2)$ (we drop the subscripts $(.)^{f,\varphi}$). Let

$$\begin{aligned} w_\varepsilon(x) &= (u_\varepsilon - u_0 - \varepsilon(Q_\omega - P_\omega))(x) + W_\omega(x/\varepsilon) \\ &= u_\varepsilon(x) - u_0(x) + v_\omega(x/\varepsilon) - \varepsilon Q_\omega. \end{aligned} \tag{59}$$

The function w_ε is the solution to

$$\begin{cases} -\Delta w_\varepsilon = 0 & \text{in } D_\varepsilon, \\ w_\varepsilon = v_\omega(x/\varepsilon) - \varepsilon Q_\omega & \text{on } \Gamma_R, \\ w_\varepsilon = -u_0(x) + u_0(x_0) - \varepsilon Q_\omega & \text{on } \partial\omega_\varepsilon. \end{cases}$$

Using the same arguments as in the proofs of Propositions 7.5 and 7.7 we obtain

$$\begin{aligned} \|v_\omega(x/\varepsilon) - \varepsilon Q_\omega\|_{1/2,\Gamma_R} &\leq c\,\varepsilon^2 \|u_0(x_0)\|_{1/2,\partial\omega} \\ &\leq c\,\varepsilon^2 \left(\|\varphi\|_{1/2,\Gamma_R} + \|f\|_{L^q} \right), \\ \| - u_0(\varepsilon y) + u_0(x_0) - \varepsilon Q_\omega\|_{1/2,\partial\omega} &\leq c\,\varepsilon \left(\|\varphi\|_{1/2,\Gamma_R} + \|f\|_{L^q} \right). \end{aligned}$$

It follows from Lemma 7.4 that

$$\begin{aligned} \|w_\varepsilon\|_{0,D_\varepsilon} &\leq c\,\varepsilon^2 \left(\|\varphi\|_{1/2,\Gamma_R} + \|f\|_{L^q} \right), \\ \|w_\varepsilon\|_{1,D_\varepsilon} &\leq c\,\varepsilon^{3/2} \left(\|\varphi\|_{1/2,\Gamma_R} + \|f\|_{L^q} \right). \end{aligned}$$

The second equation proves (58). Due to (46), Lemma 7.1, and elliptic regularity we also have

$$\begin{aligned} \|W_\omega(x/\varepsilon)\|_{0,D_\varepsilon} &= \varepsilon^{3/2} \|W_\omega\|_{0,D_\varepsilon/\varepsilon} \\ &\leq c\,\varepsilon^{3/2} \|u_0(x_0)\|_{1/2,\partial\omega} \\ &\leq c\,\varepsilon^{3/2} \left(\|\varphi\|_{1/2,\Gamma_R} + \|f\|_{L^q} \right). \end{aligned}$$

We conclude by using $u_\varepsilon - u_0 - \varepsilon(Q_\omega - P_\omega) = w_\varepsilon(x) - W_\omega(x/\varepsilon)$. ∎

The variation $J_\varepsilon(u) - J_0(u)$ is given by the next lemma.

LEMMA 7.10. *For $u \in \mathcal{V}_R$ we have*

$$J_\varepsilon(u) = J_0(u) + \varepsilon \delta J(u) + o(\varepsilon),$$
$$\delta J(u) = \int_{D_0} g_s(x, \widetilde{u}_0(x))(Q_\omega - P_\omega)\, dx,$$

where Q_ω and P_ω are defined as in Lemma 7.9 with $\varphi = u_{|\Gamma_R}$.

Proof. Let

$$I_\varepsilon = J_\varepsilon(u) - J_0(u) - \varepsilon \int_{D_0} g_s(x, \widetilde{u}_0)(Q_\omega - P_\omega)\, dx.$$

On D_ε we have $\widetilde{u}_\varepsilon = u_\varepsilon^{f,\varphi}$ for $\varepsilon \geq 0$, $\varphi = u$ on Γ_R, and on Ω_R we have $\widetilde{u}_\varepsilon = \widetilde{u}_0$. Hence

$$\begin{aligned} I_\varepsilon &= \widetilde{J}_\varepsilon(\widetilde{u}_\varepsilon) - \widetilde{J}_0(\widetilde{u}_0) - \varepsilon \int_{D_0} g_s(x, \widetilde{u}_0)(Q_\omega - P_\omega)\, dx \\ &= \int_{\Omega\varepsilon} g(x, \widetilde{u}_\varepsilon)\, dx - \int_\Omega g(x, \widetilde{u}_0)\, dx - \varepsilon \int_{D_0} g_s(x, \widetilde{u}_0)(Q_\omega - P_\omega)\, dx \\ &= \int_{D_\varepsilon} g(x, u_\varepsilon^{f,\varphi}) - g(x, u_0^{f,\varphi})\, dx - \int_{\omega_\varepsilon} g(x, u_0^{f,\varphi})\, dx - \varepsilon \int_{D_0} g_s(x, u_0^{f,\varphi})(Q_\omega - P_\omega)\, dx. \end{aligned}$$

Due to the hypotheses on g (32) and (33), we have for all $(x, s, t) \in \Omega \times \mathbb{R} \times \mathbb{R}$

$$g(x,t) - g(x,s) = g_s(x,s)(t-s) + \theta(x,s,t)(t-s)^2,$$
$$|\theta(x,s,t)| \leq \frac{M}{2}.$$

Then

$$\begin{aligned} I_\varepsilon = &\int_{D_\varepsilon} g_s(x, u_0^{f,\varphi}) \left(u_\varepsilon^{f,\varphi} - u_0^{f,\varphi} - \varepsilon(Q_\omega - P_\omega) \right) dx \\ &- \varepsilon \int_{\omega_\varepsilon} g_s(x, u_0^{f,\varphi})(Q_\omega - P_\omega)\, dx - \int_{\omega_\varepsilon} g(x, u_0^{f,\varphi})\, dx \\ &+ \int_{D_\varepsilon} \theta(x, u_0^{f,\varphi}, u_\varepsilon^{f,\varphi})(u_\varepsilon^{f,\varphi} - u_0^{f,\varphi})^2\, dx \end{aligned}$$

and

$$\begin{aligned} |I_\varepsilon| \leq &\int_{D_\varepsilon} \left| g_s(x, u_0^{f,\varphi}) \left(u_\varepsilon^{f,\varphi} - u_0^{f,\varphi} - \varepsilon(Q_\omega - P_\omega) \right) \right| dx + \varepsilon \int_{\omega_\varepsilon} \left| g_s(x, u_0^{f,\varphi})(Q_\omega - P_\omega) \right| dx \\ &+ \int_{\omega_\varepsilon} \left| g(x, u_0^{f,\varphi}) \right| dx + \int_{D_\varepsilon} \frac{M}{2} (u_\varepsilon^{f,\varphi} - u_0^{f,\varphi})^2\, dx. \end{aligned}$$

It follows from the hypotheses on g (32)–(34), Lemma 7.9, the regularity of $u_0^{f,\varphi}$ (which implies that $x \mapsto g(x, u_0^{f,\varphi}(x))$ is in $L^{3/2}(B(0, R/2))$), $\|P_\omega\|_{0,\omega_\varepsilon} = c\,\varepsilon^{1/2}$, and $\|g_s(., u_0^{f,\varphi}(.))\|_{0,\omega_\varepsilon} = o(1)$ that

$$\begin{aligned} \int_{D_\varepsilon} \left| g_s(x, u_0^{f,\varphi}) \left(u_\varepsilon^{f,\varphi} - u_0^{f,\varphi} - \varepsilon(Q_\omega - P_\omega) \right) \right| dx &\leq c \left\| u_\varepsilon^{f,\varphi} - u_0^{f,\varphi} - \varepsilon(Q_\omega - P_\omega) \right\|_{0,D_\varepsilon} \\ &= O(\varepsilon^{3/2}), \\ \int_{D_\varepsilon} \frac{M}{2} (u_\varepsilon^{f,\varphi} - u_0^{f,\varphi})^2\, dx &= O(\varepsilon^2), \end{aligned}$$

$$\varepsilon \int_{\omega_\varepsilon} \left| g_s(x, u_0^{f,\varphi})(Q_\omega - P_\omega) \right| \, dx \le \varepsilon \left\| g_s(., u_0^{f,\varphi}(.)) \right\|_{0,\omega_\varepsilon} \|Q_\omega - P_\omega\|_{0,\omega_\varepsilon}$$
$$= o(\varepsilon^{3/2}),$$

$$\int_{\omega_\varepsilon} \left| g(x, u_0^{f,\varphi}) \right| \, dx \le \left(\int_{\omega_\varepsilon} \left| g(x, u_0^{f,\varphi}) \right|^{3/2} \, dx \right)^{2/3} \left(\int_{\omega_\varepsilon} dx \right)^{1/3} \tag{60}$$
$$= o(\varepsilon).$$

Hence

$$I_\varepsilon = o(\varepsilon). \qquad \square$$

We can now check hypothesis (24) involved by Theorem 5.1.

PROPOSITION 7.11. *The function J_0 is differentiable on $\mathcal{V}_R$, and we have for all $u, v \in \mathcal{V}_R$*

$$J_\varepsilon(v) - J_0(u) = \varepsilon \delta J(u) + DJ_0(u)(v - u) + o(\varepsilon + \|v - u\|_{\mathcal{V}_R}).$$

Proof. We have

$$J_0(u) = \widetilde{J}_0(\widetilde{u}) = \int_\Omega g(x, \widetilde{u}(x)) \, dx.$$

It follows from the hypotheses on g (32) that the function $\widetilde{J}_0$ is differentiable on $H^1(\Omega)$ with

$$D\widetilde{J}_0(\widetilde{u}_0)w = \int_\Omega g_s(x, \widetilde{u}_0) w \, dx, \qquad w \in H^1(\Omega).$$

Thus J_0 is differentiable on $\mathcal{V}_R$, and for $w \in \mathcal{V}_R$ extended by $\widehat{w} \in H^1(\Omega)$ with $\Delta \widehat{w} = 0$ in D_0, we have

$$DJ_0(u)w = D\widetilde{J}_0(\widetilde{u}_0)\widehat{w}.$$

Hence, applying Lemma 7.10 yields

$$\begin{aligned} J_\varepsilon(v) - J_0(u) &= J_\varepsilon(v) - J_0(v) + J_0(v) - J_0(u) \\ &= \varepsilon \delta J(v) + o(\varepsilon) + DJ_0(u)(v - u) + o(\|v - u\|_{\mathcal{V}_R}) \\ &= \varepsilon \delta J(u) + DJ_0(u)(v - u) + o(\varepsilon + \|v - u\|_{\mathcal{V}_R}) \\ &\quad + \varepsilon(\delta J(v) - \delta J(u)). \end{aligned}$$

It remains to prove that $\varepsilon(\delta J(v) - \delta J(u)) = o(\varepsilon + \|v - u\|_{\mathcal{V}_R})$. For this it is sufficient to prove that $\delta J(v) - \delta J(u) = O(\|v - u\|_{\mathcal{V}_R})$. With the notation defined below in (61) and (62), it follows from Lemma 7.10 that

$$\begin{aligned} \delta J(v) - \delta J(u) &= \int_{D_0} g_s(x, \widetilde{v}_0)(Q_\omega^v - P_\omega^v) - g_s(x, \widetilde{u}_0)(Q_\omega^u - P_\omega^u) \, dx \\ &= \int_{D_0} \left[g_s(x, \widetilde{v}_0) - g_s(x, \widetilde{u}_0) \right] (Q_\omega^v - P_\omega^v) \, dx \\ &\quad + \int_{D_0} g_s(x, \widetilde{u}_0) \left[(Q_\omega^v - P_\omega^v) - (Q_\omega^u - P_\omega^u) \right] \, dx. \end{aligned}$$

Hence, using the hypotheses on g (32)–(33) we obtain

$$|\delta J(v) - \delta J(u)| \leq \int_{D_0} M\,|\widetilde{v}_0 - \widetilde{u}_0|\,|Q_\omega^v - P_\omega^v|\,dx \\ + \int_{D_0} (|g_s(x,0)| + M\,|\widetilde{u}_0|)\,(|Q_\omega^v - Q_\omega^u| + |P_\omega^v - P_\omega^u|)\,dx.$$

We conclude by using linearity and continuity of

$$\begin{array}{ccccccc} \mathcal{V}_R & \to & H^{1/2}(\Gamma_R) & \to & H^1(D_0) & \to & L^2(D_0), \\ u & \mapsto & \varphi := u_{|\Gamma_R} & \mapsto & u_0^{f,\varphi} & \mapsto & P_\omega^u := A_\omega(u_0^{f,\varphi})(x_0))E \end{array} \tag{61}$$

and

$$\begin{array}{ccccc} \mathcal{V}_R & \to & H^{1/2}(\Gamma_R) & \to & \mathbb{R}, \\ u & \mapsto & (P_\omega^u)_{|\Gamma_R} & \mapsto & Q_\omega^u. \end{array} \tag{62}$$

□

Hence, hypothesis (24) is fulfilled and we can apply Theorem 5.1. The adjoint equation (27) reads

$$\int_\Omega \nabla v_\Omega.\nabla w\,dx = -\int_\Omega g_s(x,u_\Omega)w\,dx,$$

and hence

$$\Delta v_\Omega = g_s(x,u_\Omega). \tag{63}$$

It follows from (30), Lemma 7.10, and (63) that

$$\begin{aligned} \delta j(x_0) &= A_\omega(u_\Omega(x_0))v_\Omega(x_0) + \int_{D_0} \Delta v_\Omega(P_\omega - Q_\omega)\,dx + \delta J(u_0) \\ &= A_\omega(u_\Omega(x_0))v_\Omega(x_0) + \int_{D_0} \Delta v_\Omega(P_\omega - Q_\omega)\,dx + \int_{D_0} g_s(x,u_\Omega)(Q_\omega - P_\omega)\,dx \\ &= A_\omega(u_\Omega(x_0))v_\Omega(x_0), \end{aligned}$$

which achieves the proof of Proposition 5.3.

7.7. Proof of Proposition 5.4. Here $\widetilde{J}_\varepsilon$ is of the form (35):

$$\widetilde{J}_\varepsilon(v) = \frac{1}{2}\int_{\Omega_\varepsilon} B(x)\nabla(v - u_{\mathrm{d}}).\nabla(v - u_{\mathrm{d}})\,dx, \qquad v \in H^1(\Omega_\varepsilon).$$

The notation is the same as in the previous subsection. For $u \in \mathcal{V}_R$, we have

$$J_\varepsilon(u) = \widetilde{J}_\varepsilon(\widetilde{u}_\varepsilon) = \frac{1}{2}\int_{\Omega_\varepsilon} B\nabla(\widetilde{u}_\varepsilon - u_{\mathrm{d}}).\nabla(\widetilde{u}_\varepsilon - u_{\mathrm{d}})\,dx.$$

Due to the assumption on u_{d} and to $f \in L^q(\Omega)$, $q > n$, we have ∇u_{d}, $\nabla\,\widetilde{u}_0 \in \mathcal{C}^0(\overline{B}(0,R/2))^3$ [12], and hence

$$\int_{\omega_\varepsilon} B\nabla(\widetilde{u}_0 - u_{\mathrm{d}}).\nabla(\widetilde{u}_0 - u_{\mathrm{d}})\,dx = O(\varepsilon^3).$$

This and the fact that $b_{ij}(x) = b_{ji}(x)$ yields

$$J_\varepsilon(u) - J_0(u) = \frac{1}{2}\int_{D_\varepsilon} 2\, B\nabla(\widetilde{u}_0 - u_{\mathrm{d}}).\nabla(\widetilde{u}_\varepsilon - \widetilde{u}_0) + B\nabla(\widetilde{u}_\varepsilon - \widetilde{u}_0).\nabla(\widetilde{u}_\varepsilon - \widetilde{u}_0)\, dx + o(\varepsilon).$$

Equation (59) reads here

$$w_\varepsilon(x) = \widetilde{u}_\varepsilon(x) - \widetilde{u}_0(x) + v_\omega(x/\varepsilon) - \varepsilon Q_\omega$$

with Q_ω constant, and

$$\begin{aligned} J_\varepsilon(u) - J_0(u) = &\int_{D_\varepsilon} B\nabla(\widetilde{u}_0 - u_{\mathrm{d}}).\nabla(w_\varepsilon - v_\omega(x/\varepsilon))\, dx \\ &+\frac{1}{2}\int_{D_\varepsilon} B\nabla(w_\varepsilon - v_\omega(x/\varepsilon)).\nabla(w_\varepsilon - v_\omega(x/\varepsilon))\, dx + o(\varepsilon). \end{aligned}$$

Recall that $v_\omega = P_\omega + W_\omega$ (19) with $P_\omega(x/\varepsilon) = \varepsilon P_\omega(x)$ and $W_\omega(y) = O(1/\|y\|^2)$. Then

$$\begin{aligned} J_\varepsilon(u) - J_0(u) = &\int_{D_\varepsilon} B\nabla(\widetilde{u}_0 - u_{\mathrm{d}}).\nabla w_\varepsilon(x)\, dx \\ &- \varepsilon\int_{D_\varepsilon} B\nabla(\widetilde{u}_0 - u_{\mathrm{d}}).\nabla P_\omega(x)\, dx \\ &-\int_{D_\varepsilon} B\nabla(\widetilde{u}_0 - u_{\mathrm{d}}).\nabla_x W_\omega(x/\varepsilon)\, dx \\ &+\frac{1}{2}\int_{D_\varepsilon} B\nabla w_\varepsilon.\nabla w_\varepsilon\, dx - \int_{D_\varepsilon} B\nabla_x v_\omega(x/\varepsilon).\nabla w_\varepsilon\, dx \\ &+\frac{1}{2}\int_{D_\varepsilon} B\nabla_x v_\omega(x/\varepsilon).\nabla_x v_\omega(x/\varepsilon)\, dx + o(\varepsilon). \end{aligned}$$

Here ∇_x denotes the derivative with respect to x, and particularly $\nabla(v(x/\varepsilon)) = \nabla_x v(x/\varepsilon) = \nabla v(x/\varepsilon)/\varepsilon$. It follows from Lemmas 7.1 and 7.9 that $\|v_\omega(x/\varepsilon)\|_{1,D_\varepsilon} = O(\varepsilon^{1/2})$ and $\|w_\varepsilon\|_{1,D_\varepsilon} = O(\varepsilon^{3/2})$; hence

$$\begin{aligned} \int_{D_\varepsilon} B\nabla(\widetilde{u}_0 - u_{\mathrm{d}}).\nabla w_\varepsilon(x)\, dx &= O(\varepsilon^{3/2}), \\ \int_{D_\varepsilon} B\nabla w_\varepsilon.\nabla w_\varepsilon\, dx &= O(\varepsilon^3), \\ -\int_{D_\varepsilon} B\nabla_x v_\omega(x/\varepsilon).\nabla w_\varepsilon\, dx &= O(\varepsilon^2). \end{aligned}$$

We have $\|\nabla_x W_\omega(x/\varepsilon)\|_{L^1(D_\varepsilon)} = \varepsilon^2 \|\nabla W_\omega\|\,|_{L^1(D_\varepsilon/\varepsilon)} = O(\varepsilon^2|\log\varepsilon|)$, and thus

$$\begin{aligned} \left|\int_{D_\varepsilon} B\nabla(\widetilde{u}_0 - u_{\mathrm{d}}).\nabla_x W_\omega(x/\varepsilon)\, dx\right| &\le \|B\nabla(\widetilde{u}_0 - u_{\mathrm{d}})\|_\infty \|\nabla_x W_\omega(x/\varepsilon)\|_{L^1(D_\varepsilon)} \\ &\le (\|\widetilde{u}_0\|_{3,D_0} + \|u_{\mathrm{d}}\|_{1,\infty,D_0}) \|\nabla_x W_\omega(x/\varepsilon)\|_{L^1(D_\varepsilon)} \\ &= o(\varepsilon). \end{aligned}$$

Using $\nabla P_\omega = O(1/r^2)$, which implies that $\int_{\omega_\varepsilon} B\nabla(\widetilde{u}_0 - u_\mathrm{d}).\nabla P_\omega\,dx = O(\varepsilon)$, we obtain (with $\nabla Q_\omega = 0$)

$$J_\varepsilon(u) - J_0(u) = -\varepsilon \int_{D_0} B\nabla(\widetilde{u}_0 - u_\mathrm{d}).\nabla(P_\omega - Q_\omega)\,dx + \frac{1}{2}\int_{D_\varepsilon} B\nabla_x v_\omega(x/\varepsilon).\nabla_x v_\omega(x/\varepsilon)\,dx + o(\varepsilon).$$

The adjoint equation implies for all $\varphi \in \mathcal{D}(D_0)$

$$\int_{D_0} -\Delta v_\Omega\,\varphi\,dx = -\int_{D_0} B\nabla(u_\Omega - u_\mathrm{d}).\nabla\varphi\,dx. \tag{64}$$

Due to $B \in W^{1,\infty}(\Omega)^{3\times 3}$ and Δu_d, $f \in L^q(\Omega)$ (thus $D^2 u_\mathrm{d}$, $D^2 u_\Omega \in L^q(D_0)$; cf. the Calderon–Zygmund theorem [12]), we have $-\Delta v_\Omega = \operatorname{div}[B\nabla(u_\Omega - u_\mathrm{d})] \in L^q(D_0)$. Moreover, $q > n/2$ and $P_\omega - Q_\omega \in L^m(D_0)$ for all $m < 3$; thus $\Delta v_\Omega(P_\omega - Q_\omega) \in L^1(D_0)$. Hence, as $P_\omega - Q_\omega$ vanishes on Γ_R, (64) still holds for $\varphi = P_\omega - Q_\omega$, and

$$J_\varepsilon(u_0) - J_0(u_0) = -\int_{D_0} \varepsilon\Delta v_\Omega.(P_\omega - Q_\omega) + \frac{1}{2}\int_{D_\varepsilon} B\nabla_x v_\omega(x/\varepsilon).\nabla_x v_\omega(x/\varepsilon)\,dx + o(\varepsilon).$$

Then the proof can be achieved as in section 7.6. It follows from (30) that

$$j(\varepsilon) = j(0) + \varepsilon A_\omega(u_\Omega(x_0))v_\Omega(x_0) + \frac{1}{2}\int_{D_\varepsilon} B\nabla_x v_\omega(x/\varepsilon).\nabla_x v_\omega(x/\varepsilon)\,dx + o(\varepsilon).$$

Using Lebesgue's convergence theorem, we deduce that

$$\begin{aligned}\int_{D_\varepsilon} B(x)\nabla_x v_\omega(x/\varepsilon).\nabla_x v_\omega(x/\varepsilon)\,dx &= \varepsilon\int_{D_\varepsilon/\varepsilon} B(\varepsilon y)\nabla v_\omega(y).\nabla v_\omega(y)\,dy \\ &= \varepsilon\int_{\mathbb{R}^3\setminus\overline{\omega}} B(x_0)\nabla v_\omega(y).\nabla v_\omega(y)\,dy + o(\varepsilon),\end{aligned}$$

which proves that

$$j(\varepsilon) = j(0) + \varepsilon A_\omega(u_\Omega(x_0))v_\Omega(x_0) + \frac{\varepsilon}{2}\int_{\mathbb{R}^3\setminus\overline{\omega}} B(x_0)\nabla v_\omega(y).\nabla v_\omega(y)\,dy + o(\varepsilon).$$

If ω is the unit ball, then we have the evident solution $v_\omega = u_\Omega(x_0)/r$ and

$$\begin{aligned}\int_{\mathbb{R}^3\setminus\overline{\omega}} B(x_0)\nabla v_\omega(y).\nabla v_\omega(y)\,dy &= u_\Omega(x_0)^2\int_{\mathbb{R}^3\setminus B(0,1)} \frac{1}{r^4} B(x_0)\mathbf{e}_\mathrm{r}.\mathbf{e}_\mathrm{r}\,dy \\ &= u_\Omega(x_0)^2\,\operatorname{tr} B(x_0)\frac{1}{3}\int_{\mathbb{R}^3\setminus B(0,1)}\frac{dy}{r^4} \\ &= \frac{4\pi u_\Omega(x_0)^2}{3}\operatorname{tr} B(x_0),\end{aligned}$$

where $\mathbf{e}_\mathrm{r}(y) = y/\|y\|$. This completes the proof of Proposition 5.4.

Acknowledgment. The authors are grateful to the referees for their comments and suggestions, which have greatly helped improve this work and its presentation.

CONTINUOUS-TIME DYNKIN GAMES WITH MIXED STRATEGIES*

NIZAR TOUZI† AND NICOLAS VIEILLE‡

Abstract. Let (X, Y, Z) be a triple of payoff processes defining a Dynkin game

$$\tilde{R}(\sigma,\tau) = E\left[X_\sigma \mathbf{1}_{\{\tau>\sigma\}} + Y_\tau \mathbf{1}_{\{\tau<\sigma\}} + Z_\tau \mathbf{1}_{\{\tau=\sigma\}}\right],$$

where σ and τ are stopping times valued in $[0, T]$. In the case $Z = Y$, it is well known that the condition $X \leq Y$ is needed in order to establish the existence of value for the game, i.e., $\inf_\tau \sup_\sigma \tilde{R}(\sigma,\tau) = \sup_\sigma \inf_\tau \tilde{R}(\sigma,\tau)$.

In order to remove the condition $X \leq Y$, we introduce an extension of the Dynkin game by allowing for an extended set of strategies, namely, the set of mixed strategies. The main result of the paper is that the extended Dynkin game has a value when $Z \leq Y$, and the processes X and Y are restricted to be semimartingales continuous at the terminal time T.

1. Introduction.

Dynkin games have been introduced by Dynkin (1967) as a generalization of optimal stopping problems. Since then, many authors contributed to solve the problem both in discrete and continuous-time models; see, e.g., Dynkin and Yushkevich (1968), Bensoussan and Friedman (1974), Neveu (1975), Bismut (1977), Stettner (1982), Alario, Lepeltier, and Marchal (1982), Morimoto (1984), Lepeltier and Maingueneau (1984), Cvitanić and Karatzas (1996), and Karatzas and Wang (2001), among others.

The setting of the problem is very simple. There are two players, labeled Player 1 and Player 2, who observe two payoff processes X and Y defined on a probability space $(\Omega, \mathcal{F}, P)$. Player 1 (resp., 2) chooses a stopping time σ (resp., τ) as control for this optimal stopping problem. At (stopping) time $\sigma \wedge \tau$ the game is over, and Player 2 pays the amount $X_\sigma \mathbf{1}_{\{\tau>\sigma\}} + Y_\tau \mathbf{1}_{\{\tau<\sigma\}} + Z_\tau \mathbf{1}_{\{\tau=\sigma\}}$ to Player 1. Therefore the objective of Player 1 is to maximize this payment, while Player 2 wishes to minimize it. It is then natural to introduce the lower and upper values of the game:

$$\sup_\sigma \inf_\tau E\left[X_\sigma \mathbf{1}_{\{\tau>\sigma\}} + Y_\tau \mathbf{1}_{\{\tau<\sigma\}} + Z_\tau \mathbf{1}_{\{\tau=\sigma\}}\right],$$

$$\inf_\tau \sup_\sigma E\left[X_\sigma \mathbf{1}_{\{\tau>\sigma\}} + Y_\tau \mathbf{1}_{\{\tau<\sigma\}} + Z_\tau \mathbf{1}_{\{\tau=\sigma\}}\right].$$

If the above values are equal, then the game is said to have a value. In the previously cited literature, it is proved that the game has a value essentially under the conditions $X_\cdot \leq Y_\cdot = Z_\cdot$, P-a.s. A precise discussion of this is given in section 2.

The purpose of this paper is to remove the condition $X_\cdot \leq Y_\cdot = Z_\cdot$, P-a.s. by suitably convexifying the set of strategies of the players. This is achieved by introducing

the notion of mixed strategies, standard in (discrete-time) game theory literature. Loosely speaking, instead of choosing a stopping time, we shall allow both players to choose a distribution on the set of stopping times. Namely, at each time, both players fix a probability of stopping and decide whether or not to stop according to this probability.

This leads us to define mixed strategies as nondecreasing right-continuous processes with zero initial data and final data less than 1. In section 7 of this paper, we provide two justifications of this definition. The first is obtained by enlarging the probability space in order to allow for an independent randomizing device for each player. The second justification consists of defining the notion of randomized stopping time by means of functional analysis arguments, as in Bismut (1979).

Section 3 reports the precise definition of the extended Dynkin game and the main result of the paper: the extended Dynkin game has a value, provided the payoff processes X and Y are semimartingales continuous at the terminal time T, and $Z_\cdot \leq Y_\cdot$, P-a.s. For ease of presentation, we split the proof as follows. Section 4 provides the main steps of the proof, which basically relies on the two following technical results. In the first one, reported in section 5, we prove that the players' strategy sets can be reduced without affecting the lower and the upper values of the game. The second one states that the game with restricted strategies has a value. The proof of the last claim, reported in section 6, is obtained by an application of Sion's min-max theorem.

Before concluding this introduction, let us set up some notation which will be extensively used in the paper.

Given a right-continuous process with left limits S, we denote $S_{t-} := \lim_{s\uparrow t} S_s$. The jumps of S are denoted by $\Delta S_t := S_t - S_{t-}$. We shall denote by ΔS the process of jumps of S, and by S_- the process of left limits of S.

We shall denote by λ the Lebesgue measure on $[0,T]$, and by E_λ the associated expectation operator. For a nondecreasing process A, we denote by m_A the positive finite measure induced by A. If S is a semimartingale, then it admits a decomposition $S = M + A$, where A is a finite variation process and M is a martingale. We shall denote by m_M the measure induced by the (nondecreasing) predictable quadratic variation process $\langle M, M\rangle$ of M, i.e., $m_M(B) = E_\lambda[\mathbf{1}_B \langle M\rangle_\infty]$. We abuse the latter notation by saying that some property holds m_S-a.s. whenever it holds both m_A-a.s. and m_M-a.s.

2. Dynkin game with pure strategies. In this section, we recall the classical formulation of a Dynkin game, as suggested by Dynkin and Yushkevich (1968), Neveu (1975), and Bismut (1977).

Let $(\Omega, \mathcal{F}, P)$ be a complete probability space, and let $T > 0$ be a fixed terminal time. Let $X = \{X_t,\, 0 \leq t \leq T\}$, $Y = \{Y_t,\, 0 \leq t \leq T\}$, and $Z = \{Z_t,\, 0 \leq t \leq T\}$ be real-valued càdlàg processes, satisfying the integrability condition

$$E\left[\sup_t |X_t| + \sup_t |Y_t| + \sup_t |Z_t|\right] < +\infty. \tag{2.1}$$

We denote by $\mathbb{F} = \{\mathcal{F}_t,\, 0 \leq t \leq T\}$ the P-augmentation of the filtration generated by (X, Y, Z), and by $\mathcal{T}$ the set of all stopping times for $\mathbb{F}$.

The structure of a Dynkin game is the following. Two players observe the triple of stochastic processes (X, Y, Z). Player 1 chooses a stopping time $\sigma \in \mathcal{T}$, and Player 2 chooses a stopping time $\tau \in \mathcal{T}$. Player 2 pays Player 1 the amount

$$X_\sigma \mathbf{1}_{\{\tau > \sigma\}} + Y_\tau \mathbf{1}_{\{\tau < \sigma\}} + Z_\tau \mathbf{1}_{\{\tau = \sigma\}}.$$

The payoff of the game is then defined by the expected value of the above payoff:

$$\tilde{R}(\sigma,\tau) := E\left[X_\sigma \mathbf{1}_{\{\tau>\sigma\}} + Y_\tau \mathbf{1}_{\{\tau<\sigma\}} + Z_\tau \mathbf{1}_{\{\tau=\sigma\}}\right].$$

Player 1 wishes to maximize $\tilde{R}(\sigma,\tau)$, while Player 2 wishes to minimize it. It is then natural to define the lower and upper values of the game:

$$\underline{V} := \sup_\sigma \inf_\tau \tilde{R}(\sigma,\tau) \qquad \text{and} \qquad \overline{V} := \inf_\tau \sup_\sigma \tilde{R}(\sigma,\tau),$$

which satisfy $\underline{V} \le \overline{V}$. If it happens that

$$\underline{V} = \overline{V},$$

then the above Dynkin game is said to have a value.

There is extensive literature providing sufficient conditions for the existence of the value for the continuous-time Dynkin game in the case $Z = Y$. Bismut (1977) proved existence of the value under the condition

$$X_\cdot \le Y_\cdot = Z_\cdot, \qquad P\text{-a.s.} \tag{2.2}$$

as well as some regularity conditions and Mokobodski's hypothesis (namely, that there exist positive bounded supermartingales Z and Z' satisfying $X \le Z - Z' \le Y$). The regularity assumption was weakened by Alario, Lepeltier, and Marchal (1982), and then Lepeltier and Maingueneau (1984) established the existence of the value without Mokobodski's hypothesis, assuming only $X_\cdot \le Y_\cdot = Z_\cdot$.

We also mention the paper by Cvitanić and Karatzas (1996), which derives the latter result in the context of a Brownian filtration by means of doubly reflected backward stochastic differential equations.

3. Dynkin game with mixed strategies. The chief goal of this paper is to remove condition (2.2) by "convexifying" the set of stopping times. A precise discussion of the problem of extending the set of strategies is provided in section 7. In this section, we give only the main intuition in order to obtain an extended version of the Dynkin game, and we state the main result of the paper.

The main idea is to identify stopping times with $\{0,1\}$-valued, nondecreasing processes. Then convexifying the set of these processes leads naturally to considering the set $\mathcal{V}^+$ of all adapted, nondecreasing, right-continuous processes A with $A_{0-} = 0$ and $A_T \le 1$.

More precisely, let $\mathcal{V}_{0,1}$ be the subset of $\{0,1\}$-valued processes of $\mathcal{V}^+$. For every stopping time τ, define the process F^τ by

$$F^\tau_t := \mathbf{1}_{\{\tau\le t\}}, \qquad 0 \le t \le T.$$

It is clear that $F^\tau \in \mathcal{V}_{0,1}$. Conversely, given $F \in \mathcal{V}_{0,1}$, let

$$\tau_F := \inf\{t \in [0,T] : \ F_t > 0\}$$

with the usual convention $\inf \emptyset = +\infty$. From the right-continuity of F, it is clear that τ_F is a stopping time for $\mathbb{F}$. This provides an identification of $\mathcal{V}_{0,1}$ and $\mathcal{T}$. Clearly, the payoff function $\tilde{R}$ can be written in terms of $F, G \in \mathcal{V}_{0,1}$ as

$$R(F,G) := \tilde{R}(\tau_F,\tau_G) = E\left[\int_0^T X(1-G)dF + \int_0^T Y(1-F)dG + \sum_{[0,T]} Z\Delta F\Delta G\right].$$

Observe that the right-hand side expression is well defined for $F, G \in \mathcal{V}^+$. Our interest is in the extended Dynkin game, in which players choose elements of $\mathcal{V}^+$, and the payoff is given by R. A rigorous justification of the set $\mathcal{V}^+$ as being the set of mixed strategies is reported in section 7, as well as the extension of the payoff function $\tilde{R}$ to $\mathcal{V}^+$.

The following is the main result of the paper.

THEOREM 3.1. *Let (X, Y, Z) be a triple of payoff processes satisfying* (2.1). *Suppose that X and Y are semimartingales with trajectories continuous at time T, P-a.s. Assume further that $Z \leq Y$. Then*

$$\sup_{F \in \mathcal{V}^+} \inf_{G \in \mathcal{V}^+} R(F, G) = \inf_{G \in \mathcal{V}^+} \sup_{F \in \mathcal{V}^+} R(F, G),$$

i.e., the extended Dynkin game has a value.

This theorem states that the Dynkin game has a value when the set of strategies $\mathcal{V}_{0,1}$ is convexified in the natural way. The only conditions required for this result are $Z \leq Y$, and X and Y are semimartingales continuous at the terminal time T. The reason for the restriction to semimartingales is explained in Remark 5.1.

An alternative way of convexifying the set $\mathcal{T}$ of stopping times is to allow the players to choose a randomized stopping time, i.e., a probability distribution over stopping times. This corresponds to the concept of mixed strategy in game theory. Although in some respect more natural, this approach is more technically demanding, as it requires an abstract construction by means of functional analysis tools (see section 7 and Bismut (1979)).

The connection between the two approaches is that any process in $\mathcal{V}^+$ can intuitively be viewed as the random distribution function of a randomized stopping time. Another interpretation is that each player chooses randomly, at each time t, whether to stop or not. This corresponds to the concept of behavioral strategy in game theory.

There is entensive literature in game theory, starting with Kuhn (1953), on the equivalence between mixed strategies and behavioral strategies. In discrete time, both notions are equivalent under fairly general assumptions (see Mertens, Sorin, and Zamir (1994)).

A by-product of section 7 is that, in the context of the simple game studied in this paper, behavioral strategies and mixed strategies are equivalent.

4. Proof of the main result. We prove the result by applying the following well-known min-max theorem.

THEOREM 4.1 (see Sion (1958)). *Let S and T be convex subsets of topological vector spaces, one of which is compact, and let $g : S \times T \longrightarrow \mathbb{R}$. Assume that for every real c, the sets $\{t : g(s_0, t) \leq c\}$ and $\{s : g(s, t_0) \geq c\}$ are closed and convex for every $(s_0, t_0) \in S \times T$. Then*

$$\sup_{s \in S} \inf_{t \in T} g(s, t) = \inf_{t \in T} \sup_{s \in S} g(s, t).$$

If S (resp., T) is compact, then sup *(resp.,* inf*) may be replaced by* max *(resp.,* min*), i.e., the corresponding player has an optimal strategy.*

The main difficulty in the proof of Theorem 3.1 is that the above min-max theorem does not apply directly to the set of strategies $\mathcal{V}^+$ (see the proofs of Lemmas 6.3 and 6.4). We therefore start by reducing the set of strategies to some subsets of $\mathcal{V}^+$ for which the min-max theorem applies.

We first restrict the strategies of the first player. Define

$$\mathcal{V}_1 := \left\{ F \in \mathcal{V}^+ : \ F \text{ is continuous, } P\text{-a.s. } \right\}.$$

As for the second player, we introduce the subset of strategies:

$$\mathcal{V}_2 := \left\{ G \in \mathcal{V}^+ : \ G_T = 1 \text{ on } \{Y_T < 0 < X_T\}, \text{ and } Y_T \Delta G_T \leq 0 \right\}.$$

We shall prove that the restriction of the strategies of Player 2 from $\mathcal{V}^+$ to $\mathcal{V}_2$ does not change the value of the game. The following is an intuitive justification of this claim. On the event set $\{Y_T < 0 < X_T\}$, it follows from the continuity of the payoff processes X and Y at T that it is optimal for Player 2 to stop the game before time T; recall that $Z_\cdot \leq Y_\cdot$, implying that the situation is even better for Player 2 if Player 1 stops at the same time. On the other hand, on the event set $\{Y_T > 0\}$, Player 2 can obtain the same value of the game by smoothing his strategy at time T, again taking advantage of the continuity at time T of the process Y.

Also, given that the strategies of Player 2 are restricted to $\mathcal{V}_2$, we shall prove that the restriction of the strategies of Player 1 to $\mathcal{V}_1$ does not change the value of the game; i.e., Player 1 can achieve the same value by means of continuous strategies.

For ease of presentation, the proof of the following two propositions will be reported in section 5.

PROPOSITION 4.1. *Let (X, Y, Z) be a triple of payoff processes satisfying* (2.1). *Then*

$$\sup_{F \in \mathcal{V}_1} \inf_{G \in \mathcal{V}_2} R(F, G) = \sup_{F \in \mathcal{V}_1} \inf_{G \in \mathcal{V}^+} R(F, G).$$

PROPOSITION 4.2. *Under the assumptions of Theorem* 3.1, *we have*

$$\inf_{G \in \mathcal{V}_2} \sup_{F \in \mathcal{V}_1} R(F, G) = \inf_{G \in \mathcal{V}_2} \sup_{F \in \mathcal{V}^+} R(F, G).$$

We then apply the min-max theorem to the strategy sets $S = \mathcal{V}_1$ and $T = \mathcal{V}_2$.

PROPOSITION 4.3. *Let (X, Y, Z) be a triple of processes satisfying* (2.1). *Assume further that X and Y are semimartingales. Then, we have*

$$\sup_{F \in \mathcal{V}_1} \inf_{G \in \mathcal{V}_2} R(F, G) = \inf_{G \in \mathcal{V}_2} \sup_{F \in \mathcal{V}_1} R(F, G).$$

The proof of the last proposition will be carried out in section 6. We now complete the proof of Theorem 3.1. By Proposition 4.2 and the fact that $\mathcal{V}_2 \subset \mathcal{V}^+$, we see that

$$\inf_{G \in \mathcal{V}_2} \sup_{F \in \mathcal{V}_1} R(F, G) = \inf_{G \in \mathcal{V}_2} \sup_{F \in \mathcal{V}^+} R(F, G) \ \geq \ \inf_{G \in \mathcal{V}^+} \sup_{F \in \mathcal{V}^+} R(F, G).$$

Similarly, it follows from Proposition 4.1 and the fact that $\mathcal{V}_1 \subset \mathcal{V}^+$ that

$$\sup_{F \in \mathcal{V}_1} \inf_{G \in \mathcal{V}_2} R(F, G) = \sup_{F \in \mathcal{V}_1} \inf_{G \in \mathcal{V}^+} R(F, G) \ \leq \ \sup_{F \in \mathcal{V}^+} \inf_{G \in \mathcal{V}^+} R(F, G).$$

In view of Proposition 4.3, this provides

$$\inf_{G \in \mathcal{V}^+} \sup_{F \in \mathcal{V}^+} R(F, G) \leq \sup_{F \in \mathcal{V}^+} \inf_{G \in \mathcal{V}^+} R(F, G),$$

which ends the proof, as the reverse inequality is trivial.

5. A priori restrictions on strategies. This section is devoted to the proofs of Propositions 4.1 and 4.2.

5.1. Proof of Proposition 4.1. Let F be a fixed strategy of Player 1 in the set $\mathcal{V}_1$. For each $G \in \mathcal{V}^+$, we define $\overline{G} \in \mathcal{V}_2$ by

$$\begin{aligned}
\overline{G}_T &= 1 \quad \text{on the event set } \{X_T > 0 > Y_T\},\\
\overline{G}_T &= G_{T-} \quad \text{on the event set } \{Y_T > 0\},\\
\overline{G} &= G \quad \text{otherwise.}
\end{aligned}$$

Then it is immediately checked that

$$\begin{aligned}
R(F,\overline{G}) - R(F,G) &= E\left[X_T(\Delta G_T - \Delta\overline{G}_T)\Delta F_T\right]\\
&\quad + E\left[Y_T(1-F_T)(\Delta\overline{G}_T - \Delta G_T)\right]\\
&\quad + E\left[Z_T\Delta F_T(\Delta\overline{G}_T - \Delta G_T)\right]\\
&= E\left[Y_T(1-F_T)(\Delta\overline{G}_T - \Delta G_T)\right]
\end{aligned}$$

since F is continuous. By definition of $\overline{G}$, we have $\Delta\overline{G}_T = 0$ on $\{Y_T > 0\}$ and $\Delta\overline{G}_T \geq \Delta G_T$ on $\{Y_T < 0\}$. It follows that $R(F,\overline{G}) - R(F,G) \leq 0$, and therefore

$$\sup_{F\in\mathcal{V}_1}\inf_{G\in\mathcal{V}_2} R(F,G) \leq \sup_{F\in\mathcal{V}_1}\inf_{G\in\mathcal{V}^+} R(F,G).$$

The required result follows from the fact that $\mathcal{V}_2 \subset \mathcal{V}^+$.

5.2. Proof of Proposition 4.2. We introduce the subset of strategies $\mathcal{W}_1$ defined by

$$\mathcal{W}_1 = \left\{F \in \mathcal{V}^+ : \quad \Delta F_T = 0 \ \text{ on } \{X_T > 0, Y_T \geq 0\}\right\}.$$

In order to prove Proposition 4.2, we first need to prove that the restriction of the strategies of Player 1 from $\mathcal{V}^+$ to $\mathcal{W}_1$ does not change the value of the game. As we shall see in the subsequent proof, this is a consequence of the continuity of the payoff processes X and Y at time T.

LEMMA 5.1. *Let (X,Y,Z) be a triple of processes satisfying (2.1). Assume further that X and Y have continuous trajectories at time T. Then, for any $G \in \mathcal{V}_2$ and $F \in \mathcal{V}^+$, there exists a sequence $(F^n)_n$ in $\mathcal{W}_1$ such that*

$$\limsup_{n\to\infty} R(F^n,G) \geq R(F,G).$$

Proof. We organize the proof in four steps.

Step 1. Let $\mathcal{T}_{[t,T]}$ denote the set of $[t,T]$-valued stopping times. We introduce the two Snell envelopes U and V defined by

$$\begin{aligned}
U_t &:= \operatorname{ess}\sup_{\zeta\in\mathcal{T}_{[t,T]}} E[X_\zeta|\mathcal{F}_t],\\
V_t &:= \operatorname{ess}\inf_{\zeta\in\mathcal{T}_{[t,T]}} E[Y_\zeta|\mathcal{F}_t].
\end{aligned}$$

In view of our assumptions on X and Y, the processes U and V can be considered in their càdlàg modifications; see, e.g., Appendix D in Karatzas and Shreve (1998). In

the rest of this step, we prove that

$$U \text{ and } V \text{ are continuous at } T, \quad P\text{-a.s.}$$

To see this, observe that

$$0 \leq U_t - E[X_T|\mathcal{F}_t] \leq E\left[\sup_{t\leq s\leq T} X_s - X_T|\mathcal{F}_t\right], \tag{5.1}$$

and, by Theorem VI.6 in Dellacherie and Meyer (1975),

$$E[X_T|\mathcal{F}_t] \longrightarrow E[X_T|\mathcal{F}_{T-}] = X_T \quad \text{as } t \nearrow T \tag{5.2}$$

by continuity of X at T. Now, notice that the process $A_t := \sup_{t\leq s\leq T} X_s - X_T$ is decreasing. Then, for fixed $s < T$, we have

$$0 \leq \limsup_{t\nearrow T} E[A_t|\mathcal{F}_t] \leq E[A_s|\mathcal{F}_{T-}].$$

By sending s to T, it follows from the dominated convergence theorem that

$$0 \leq \limsup_{t\nearrow T} E[A_t|\mathcal{F}_t] \leq E[A_T|\mathcal{F}_{T-}] = 0, \tag{5.3}$$

where we used the continuity of A at T inherited from X. The required continuity result follows from (5.1)–(5.3).

Step 2. For each $\varepsilon > 0$, define

$$\theta^\varepsilon := \inf\{t \geq T-\varepsilon : X_t \geq 0,\ U_t - \varepsilon \leq X_t \text{ and } V_t \geq -\varepsilon\} \wedge T.$$

Since X, U, and V are right-continuous, θ^ε is a stopping time. Observe that $\theta^\varepsilon \to T$, P-a.s., as $\varepsilon \to 0$.

Next, for each integer $n \geq 1$, define the sequence of stopping times

$$\theta^{\varepsilon,n} := T \wedge \left(\theta^\varepsilon + \frac{1}{n}\right).$$

We define $(F^{\varepsilon,n}) \in \mathcal{V}^+$ to be a continuous process on $(\theta^\varepsilon, \theta^{\varepsilon,n}]$ such that

$$F^{\varepsilon,n} = F \text{ on } [0,\theta^\varepsilon] \qquad \text{and} \qquad F^{\varepsilon,n} = 1 \text{ on } [\theta^{\varepsilon,n}, T].$$

Since X, Y, U, and V are continuous at T, $F^{\varepsilon,n}$ is a sequence in $\mathcal{W}_1$. We intend to prove that

$$\limsup_{\varepsilon\to 0} \limsup_{n\to\infty} R(F^{\varepsilon,n}, G) \geq R(F,G),$$

which will provide the required result.

First, since $F^{\varepsilon,n}$ is continuous on $(\theta^\varepsilon, T]$ and $F^{\varepsilon,n} = 1$ on $[\theta^{\varepsilon,n}, T]$, we have

$$\begin{aligned} R(F^{\varepsilon,n}, G) &= A + E\left[\xi^\varepsilon \int_{\theta^\varepsilon}^{T} X(1-G)dF^{\varepsilon,n} + Y(1-F^{\varepsilon,n})dG\right] \\ &= A + E\left[\xi^\varepsilon \int_{\theta^\varepsilon}^{\theta^{\varepsilon,n}} X(1-G)dF^{\varepsilon,n}\right] + E\left[\xi^\varepsilon \int_{\theta^\varepsilon}^{\theta^{\varepsilon,n}} Y(1-F^{\varepsilon,n})dG\right], \end{aligned}$$

where $\xi^\varepsilon = \mathbf{1}_{\{\theta^\varepsilon < T\}}$ and

$$A = E\left[\int_0^{\theta^\varepsilon} X(1-G)dF + Y(1-F)dG + \sum_{[0,\theta^\varepsilon]} Z\Delta F\Delta G\right].$$

Step 3. We now fix $\varepsilon > 0$ and let n go to infinity. As for the second expectation on the right-hand side of (5.4), observe that $Y_t\xi^\varepsilon(1-F_t^{\varepsilon,n})\mathbf{1}_{[\theta^\varepsilon,T]}(t)$ converges P-a.s. to zero for all $t \in (\theta^\varepsilon, T]$. Since G is right-continuous, this implies that $Y_t\xi^\varepsilon(1-F_t^{\varepsilon,n})\mathbf{1}_{[\theta^\varepsilon,T]}(t)$ converges $m_G \otimes P$-a.s. to zero. Therefore, by dominated convergence (see Theorem I.4.31 in Jacod and Shiryaev (1987)), we have

$$\lim_{n\to\infty} E\left[\xi^\varepsilon \int_{\theta^\varepsilon}^{\theta^{\varepsilon,n}} Y(1-F^{\varepsilon,n})dG\right] = 0.$$

As for the first expectation on the right-hand side of (5.4), we have

$$\begin{aligned}
\limsup_{n\to\infty} E\left[\xi^\varepsilon \int_{\theta^\varepsilon}^{\theta^{\varepsilon,n}} X(1-G)dF^{\varepsilon,n}\right] &\geq \limsup_{n\to\infty} E\left[\xi^\varepsilon \inf_{[\theta^\varepsilon,\theta^{\varepsilon,n}]}(X(1-G)) \int_{\theta^\varepsilon}^{\theta^{\varepsilon,n}} dF^{\varepsilon,n}\right] \\
&= \limsup_{n\to\infty} E\left[\xi^\varepsilon \inf_{[\theta^\varepsilon,\theta^{\varepsilon,n}]}(X(1-G))(1-F_{\theta^\varepsilon})\right] \\
&= E\left[\xi^\varepsilon X_{\theta^\varepsilon}(1-G_{\theta^\varepsilon})(1-F_{\theta^\varepsilon})\right],
\end{aligned}$$

where the last equality follows by dominated convergence and right-continuity of $X(1-G)$. This yields

$$\begin{aligned}
\limsup_{n\to\infty} R(F^{\varepsilon,n},G) - R(F,G) &\geq E\left[\xi^\varepsilon X_{\theta^\varepsilon}(1-G_{\theta^\varepsilon})(1-F_{\theta^\varepsilon})\right] \\
&\quad -E\left[\xi^\varepsilon \int_{\theta^\varepsilon}^{T} X(1-G)dF + Y(1-F)dG\right] \\
&\quad -E\left[\xi^\varepsilon \sum_{(\theta^\varepsilon,T]} Z\Delta F\Delta G\right] \\
&= E\left[\xi^\varepsilon X_{\theta^\varepsilon}(1-G_{\theta^\varepsilon})(1-F_{\theta^\varepsilon})\right] \\
&\quad -E\left[\xi^\varepsilon \int_{\theta^\varepsilon}^{T} X(1-G)dF + Y(1-F_-)dG\right] \\
&\quad +E\left[\xi^\varepsilon \sum_{(\theta^\varepsilon,T]} (Y-Z)\Delta F\Delta G\right] \\
&\geq E\left[\xi^\varepsilon X_{\theta^\varepsilon}(1-G_{\theta^\varepsilon})(1-F_{\theta^\varepsilon})\right] \\
&\quad -E\left[\xi^\varepsilon \int_{\theta^\varepsilon}^{T} X(1-G)dF + Y(1-F_-)dG\right],
\end{aligned}$$

where we used the condition $Z \leq Y$ of Theorem 3.1. Set $\widetilde{F} := F - \Delta F\mathbf{1}_{\{T\}}$ and $\widetilde{G}$

$:= G - \Delta G \mathbf{1}_{\{T\}}$. Then

$$\begin{aligned}\limsup_{n\to\infty} R(F^{\varepsilon,n}, G) - R(F,G) &\geq E\left[\xi^\varepsilon X_{\theta^\varepsilon}(1-G_{\theta^\varepsilon})(1-F_{\theta^\varepsilon}) - \xi^\varepsilon X_T(1-G_T)\Delta F_T\right] \\ &\quad - E\left[\xi^\varepsilon \int_{\theta^\varepsilon}^T X(1-G)d\widetilde{F} + Y(1-F_-)d\widetilde{G}\right] \\ &\quad - E\left[\xi^\varepsilon Y_T(1-F_T)\Delta G_T\right] \\ &\geq E\left[\xi^\varepsilon X_{\theta^\varepsilon}(1-G_{\theta^\varepsilon})(1-F_{\theta^\varepsilon}) - \xi^\varepsilon X_T(1-G_T)\Delta F_T\right] \\ &\quad - E\left[\xi^\varepsilon \int_{\theta^\varepsilon}^T X(1-G)d\widetilde{F} + Y(1-F_-)d\widetilde{G}\right] \qquad (5.4)\end{aligned}$$

since $Y_T \Delta G_T \leq 0$ by definition of $\mathcal{V}_2$.

Step 4. We now take limits as ε goes to zero. Since $\theta^\varepsilon \to T$, and both $\widetilde{F}$ and $\widetilde{G}$ are continuous at T, the second expectation on the right-hand side of (5.4) converges to zero. We now use the following claim, whose proof will be carried out later:

$$\xi^\varepsilon X_{\theta^\varepsilon} \longrightarrow \mathbf{1}_{\{0\leq X_T, Y_T\}} X_T, \quad P\text{-a.s.} \qquad (5.5)$$

Then, by dominated convergence and the fact that $G_{T-} \leq G_T$,

$$\begin{aligned}&\lim_{\varepsilon\to 0} E\left[\xi^\varepsilon X_{\theta^\varepsilon}(1-G_{\theta^\varepsilon})(1-F_{\theta^\varepsilon}) - \xi^\varepsilon X_T(1-G_T)\Delta F_T\right] \\ &\geq E\left[\mathbf{1}_{\{0\leq X_T,Y_T\}} X_T(1-G_T)(1-F_{T-}-\Delta F_T)\right] \\ &= E\left[\mathbf{1}_{\{0\leq X_T,Y_T\}} X_T(1-G_T)(1-F_T)\right] \\ &\geq 0\end{aligned}$$

by definition of F and G. Hence

$$\lim_{\varepsilon\to 0}\limsup_{n\to\infty} R(F^{\varepsilon,n}, G) - R(F,G) \geq 0.$$

It remains to prove (5.5). By definition of θ^ε, it is clear that θ^ε (hence also ξ^ε) increases as ε decreases to zero. Thus,

$$\xi^\varepsilon \longrightarrow \mathbf{1}_{\cap_{\varepsilon>0}\{\theta^\varepsilon < T\}}, \quad P\text{-a.s.}$$

Now, observe that $0 \leq X_T, 0 \leq Y_T$ on the event $\{\theta^\varepsilon < T \text{ for all } \varepsilon\}$ by continuity at T of the Snell envelopes U and V. Conversely, on the event $\{0 < X_T, 0 \leq Y_T\}$, it is clear that $\theta^\varepsilon < T$ for all ε, again by continuity of U and V. This provides claim (5.5). □

Given the result of Lemma 5.1, the statement of Proposition 4.2 follows directly from the following reduction of strategies of Player 1 from $\mathcal{W}_1$ to $\mathcal{V}_1$.

LEMMA 5.2. *Let (X,Y,Z) be a triple of processes satisfying (2.1). Assume further that X is a semimartingale and $Z \leq Y$. Then, for any $G \in \mathcal{V}_2$ and $F \in \mathcal{W}_1$, there exists a sequence (F^n) in $\mathcal{V}_1$ such that*

$$\limsup_{n\to\infty} R(F^n, G) \geq R(F,G).$$

Proof. For each integer n, define $\widetilde{F}^n \in \mathcal{V}^+$ by

$$\widetilde{F}^n_t = F_t - \sum_{s\leq t} \Delta F_s \mathbf{1}_{\{\Delta F_s \leq n^{-1}\}}$$

so that the jumps of $\widetilde{F}^n$ are of size greater than n^{-1}, and therefore $\widetilde{F}^n$ has a finite number of jumps. Clearly, we have the pointwise convergence

$$\widetilde{F}^n_t \longrightarrow F_t, \quad 0 \le t \le T, \quad P\text{-a.s.} \tag{5.6}$$

Since $\widetilde{F}^n$ has a finite number of jumps, it follows from a diagonal extraction argument that there exists a sequence of *continuous* processes $F^n \in \mathcal{V}^+$ such that $F^n - \widetilde{F}^n_- \to 0$ pointwise, P-a.s. From the pointwise convergence (5.6), this provides

$$F^n \longrightarrow F_-, \quad P\text{-a.s.}$$

In order to obtain the required result, we shall prove that

$$\lim_{n\to\infty} R(F^n, G) \ge R(F, G). \tag{5.7}$$

First, observe that by Itô's lemma (see, e.g., Theorem I.4.57 in Jacod and Shiryaev (1987)), we have

$$\begin{aligned} R(F,G) &= E\left[\int_0^T Y(1-F_-)dG\right] - E\left[\int_0^T F_- d(X(1-G))\right] \\ &\quad + E\left[\sum_{[0,T]} (Z-Y)\Delta F \Delta G\right] \\ &\quad + E\left[X_T(1-G_T)F_{T-}\right] + E\left[X_T(1-G_T)\Delta F_T\right] \\ &\le E\left[\int_0^T Y(1-F_-)dG\right] - E\left[\int_0^T F_- d(X(1-G))\right] \\ &\quad + E\left[X_T(1-G_T)F_{T-}\right] + E\left[X_T(1-G_T)\Delta F_T\right], \end{aligned} \tag{5.8}$$

where we used the condition $Z \le Y$ of Theorem 3.1. Since $F^n \to F_-$, m_G and $m_{X(1-G)}$-a.s., it follows from dominated convergence that

$$\lim_{n\to\infty} E\left[\int_0^T Y(1-F^n)dG\right] = E\left[\int_0^T Y(1-F_-)dG\right],$$

$$\lim_{n\to\infty} E\left[\int_0^T F^n d(X(1-G))\right] = E\left[\int_0^T F_- d(X(1-G))\right],$$

$$\lim_{n\to\infty} E\left[X_T(1-G_T)F^n_T\right] = E\left[X_T(1-G_T)F_{T-}\right].$$

In view of (5.8), and since F^n is continuous, this proves that

$$\lim_{n\to\infty} R(F^n, G) \ge R(F,G) - E\left[X_T(1-G_T)\Delta F_T\right].$$

Finally, observe that

$$\begin{aligned} X_T(1-G_T)\Delta F_T &\le X_T(1-G_T)\Delta F_T \mathbf{1}_{\{X_T>0\}}\mathbf{1}_{\{G_T<1\}} \\ &= X_T(1-G_T)\Delta F_T \mathbf{1}_{\{0<X_T, 0\le Y_T\}}\mathbf{1}_{\{G_T<1\}} \\ &= 0, \end{aligned}$$

where we used the fact that $G \in \mathcal{V}_2$ and $F \in \mathcal{W}_1$. This ends the proof of (5.7), and the proof of Lemma 5.2 is complete. □

Remark 5.1. In the last proof, we used for the first time the fact that X is a semimartingale. The reason is that we needed to apply integration by parts in the integral $\int_0^T X(1-G)dF$, and therefore we needed the stochastic integral with respect to process X to be well defined. Similar integration by parts are involved in the proofs of Lemmas 6.3 and 6.4, which then require the assumption that X and Y are semimartingales.

6. The value on restricted strategy spaces. This section is devoted to the proof of Proposition 4.3. As argued earlier, we shall apply Sion's theorem to the sets $S = \mathcal{V}_1$ and $T = \mathcal{V}_2$. We first define a suitable topology on $\mathcal{V}_1$ and $\mathcal{V}_2$.

Let $\mathcal{S}$ be the set of all $\mathbb{F}$-adapted processes Z satisfying $Z_{0-} = 0$ and

$$E\left[\int_0^T Z_t^2 dt + (\Delta Z_T)^2\right] < +\infty, \quad \text{where } \Delta Z_T = Z_T - \liminf_{t \nearrow T} Z_t.$$

The space $\mathcal{S}$ is a separable Hilbert space when endowed with the scalar product

$$\frac{1}{T+1} E\left[\int_0^T W_t Z_t dt + \Delta W_T \Delta Z_T\right].$$

Notice that $\mathcal{V}_1$ and $\mathcal{V}_2$ are convex subsets of $B_{\mathcal{S}}$, the unit ball of $\mathcal{S}$.

LEMMA 6.1. *The set $\mathcal{V}_2$ is compact for the weak topology $\sigma(\mathcal{S}, \mathcal{S})$.*

Proof. Since $B_{\mathcal{S}}$ is compact for the weak topology $\sigma(\mathcal{S}, \mathcal{S})$, it suffices to prove that $\mathcal{V}_2$ is closed for the weak topology or, equivalently, for the strong topology, by convexity.

Let (Z^n) be a sequence in $\mathcal{V}_2$, which converges strongly to some $Z \in \mathcal{S}$. Then, possibly along some subsequence,

$$Z^n \longrightarrow Z, \quad \lambda \otimes P\text{-a.s.}, \tag{6.1}$$

and

$$Z_T^n \longrightarrow Z_T, \quad P\text{-a.s.} \tag{6.2}$$

Clearly, this shows that Z inherits the nondecrease of (Z^n), $Z_{0-} = 0$, and $Z_T \le 1$. We now check that $\Delta Z_T^n \to \Delta Z_T$, P-a.s. By Fubini's theorem, it follows from (6.1) that, P-a.s., $Z_t^n \to Z_t$ for λ-a.e. $t \in [0,T]$. Since Z^n and Z are nondecreasing, we see that, P-a.s., $Z_{t-}^n \to Z_{t-}$ for every $t \in [0,T]$. Thus, from (6.2), this yields $\Delta Z_T^n \to \Delta Z_T$, P-a.s. The required result follows from the fact that $\Delta Z_T^n = 0$ on the event $\{Y_T > 0\}$. Observe finally that $Z_T^n = 1$ for every n implies $Z_T = 1$. □

LEMMA 6.2. *Let $(F^n)_n$ be a sequence in $\mathcal{V}_1$ converging to some $F \in \mathcal{V}_1$ in the sense of the strong topology of $\mathcal{S}$. Then*

$$\lim_{n\to\infty} F_t^n = F_t \qquad \textit{for all } \ t \in [0,T], \qquad P\textit{-a.s.}$$

after possibly passing to a subsequence.

Proof. Let (F^n) be as in the statement of the lemma. Then, by possibly passing to a subsequence, $F^n \longrightarrow F$, $\lambda \otimes P$-a.s., and $F_T^n \longrightarrow F_T$, P-a.s. By the same argument as in the previous proof, we use Fubini's theorem and the nondecrease of F_n and F

to see that $F^n_{t-} \longrightarrow F_{t-}$ for all $t \in [0,T]$, P-a.s. The required result follows from the continuity of F_n and F. □

LEMMA 6.3. *Let (X,Y,Z) be a triple of processes satisfying (2.1). Assume further that X is a semimartingale. Then, for all $G \in \mathcal{V}_2$, the function $R(.,G)$ is continuous on $\mathcal{V}_1$ in the sense of the strong topology of $\mathcal{S}$.*

Proof. By Itô's lemma,

$$\begin{aligned} X_T(1-G_T)F_T &= \int_0^T X(1-G_-)dF + \int_0^T F(1-G_-)dX - \int_0^T FXdG \\ &= \int_0^T X(1-G)dF + \int_0^T F(1-G_-)dX - \int_0^T FXdG \end{aligned}$$

since F is a continuous process. Then

$$\begin{aligned} R(F,G) = E\left[\int_0^T YdG\right] - E\left[\int_0^T F(1-G_-)dX\right] + E\left[X_T(1-G_T)F_T\right] \\ +E\left[\int_0^T (X-Y)FdG\right]. \end{aligned}$$

Let $(F^n)_n$ be a sequence in $\mathcal{V}_1$ converging to $F \in \mathcal{V}_1$. We intend to prove that

$$\lim_{n\to\infty} R(F^n,G) = R(F,G).$$

Consider any subsequence (F^{n_k}) such that $\lim_k R(F^{n_k},G)$ exists. It suffices to prove that this limit is independent of the subsequence and equal to $R(F,G)$. For ease of notation, rename the subsequence (F^n). From Lemma 6.2, by possibly passing to a subsequence, we can assume that, P-a.s.,

$$\lim_n F^n_t = F_t \quad \text{for all } t \in [0,T].$$

Then, $F^n \to F$, $m_X \otimes P$-a.s., and $m_G \otimes P$-a.s. and the result follows by dominated convergence. □

LEMMA 6.4. *Let (X,Y,Z) be a triple of processes satisfying (2.1). Assume further that Y is a semimartingale. Then, for all $F \in \mathcal{V}_1$, the function $R(F,.)$ is continuous on $\mathcal{V}_2$ in the sense of the strong topology of $\mathcal{S}$.*

Proof. As in the previous proof, let (G^n) be a sequence in $\mathcal{V}_2$ converging to $G \in \mathcal{V}_2$. We intend to prove that

$$\lim_{n\to\infty} R(F,G^n) = R(F,G).$$

Consider any subsequence (G^{n_k}) such that $\lim_k R(F,G^{n_k})$ exists. It suffices to prove that this limit is independent of the subsequence and equal to $R(F,G)$. For ease of notation, rename the subsequence (G^n). Recall that G is nondecreasing. Then, applying the same argument as in the proof of Lemma 6.1, we see that by possibly passing to a subsequence, we can assume that

$$G^n \longrightarrow G, \quad \lambda \otimes P\text{-a.s.}, \qquad G^n_- \longrightarrow G_-, \quad P\text{-a.s.}$$

and

$$G^n_T \longrightarrow G_T, \quad P\text{-a.s.}$$

Set $\widehat{Y} := Y(1-F)$. By Itô's formula and the continuity of F,

$$\int_0^T Y(1-F)dF^n = \widehat{Y}_T G_T^n - \int_0^T G^n d\hat{Y} + \sum_{0\le t\le T} \Delta Y_t (1-F_{t-})\Delta G_t^n$$
$$= \widehat{Y}_T G_T^n - \int_0^T G^n d\hat{Y}^c + \sum_{0\le t\le T} \Delta Y_t (1-F_t) G_{t-}^n.$$

Since F and $\widehat{Y}^c$ are continuous, $G^n \to G$, $m_F \otimes P$-a.s. and $m_{\widehat{Y}^c} \otimes P$-a.s, and the result follows by dominated convergence. □

Proof of Proposition 4.3. The strategy sets $S = \mathcal{V}_1$ and $T = \mathcal{V}_2$ are convex topological spaces when endowed with the weak topology $\sigma(\mathcal{S}, \mathcal{S})$. From Lemma 6.1, $\mathcal{V}_2$ is compact for $\sigma(\mathcal{S}, \mathcal{S})$.

Since $R(F, G)$ is bilinear, the sets $\{G \in \mathcal{V}_2 : R(F^0, G) \le c\}$ and $\{F \in \mathcal{V}_1 : R(F, G^0) \ge c\}$ are convex for all $F^0 \in \mathcal{V}_1$, $G^0 \in \mathcal{V}_2$, and $c \in \mathbb{R}$. Then in order to prove that they are closed for the weak topology $\sigma(\mathcal{S}, \mathcal{S})$, it suffices to prove that they are closed for the strong topology of $\mathcal{S}$. The latter is a direct consequence of Lemmas 6.3 and 6.4. We are then in the context of Sion's theorem, and the proof is complete. □

7. Extended problem and randomized stopping times. In this section, we first provide a justification of $\mathcal{V}^+$ as being the natural mixed strategy set, which has been described heuristically in section 3. Then we derive rigorously the payoff function $R(F, G)$ defined in the extended strategy set $\mathcal{V}^+ \times \mathcal{V}^+$.

For ease of exposition, we shall discuss the case $Z = Y$ only. The general case follows immediately by adding up the jump term induced by Z.

In game theory, mixed strategies are defined as probability distributions over pure strategies. In the context of Dynkin games, pure strategies are stopping times. At this stage, the main problem is to define a measurable structure on the set of stopping times. There are two ways to avoid this difficulty. Following Aumann (1964), one may define mixed strategies by enlarging the probability space; this viewpoint is discussed in section 7.1. An alternative approach consists of defining the notion of randomized stopping time by means of functional analysis arguments; this is discussed in section 7.2. We shall (essentially) show that $\mathcal{V}^+$ is in one-to-one correspondence with the set of mixed strategies and with the set of randomized stopping times. Therefore, both approaches are equivalent.

7.1. Mixed strategies. We enlarge the probability space from (Ω, P) to $([0,1] \times \Omega, \lambda_1 \otimes P)$, where λ_1 is the Lebesgue measure. A mixed strategy (for Player 1) is then defined as a $\lambda_1 \otimes P$ measurable function ϕ mapping $[0,1] \times \Omega$ into $[0,T]$ such that

$$\text{for } \lambda_1\text{-a.e., } r \in [0,1], \qquad \sigma_r := \phi(r, \cdot) \text{ is a stopping time.}$$

We denote by Φ the space of mixed strategies. Loosely speaking, $([0,1], \lambda_1)$ is a randomizing device for Player 1. In order to introduce an independent randomizing device for Player 2, we need to have an independent copy $([0,1], \lambda_2)$ of the probability space $([0,1], \lambda_1)$. The corresponding set of mixed strategies is denoted by Ψ; a generic element of Ψ will be denoted by ψ, and, for $r \in [0,1]$, we set $\tau_r := \psi(r, \cdot)$.

Hence, the underlying probability space for the extended Dynkin game is $([0,1] \times [0,1] \times \Omega, \lambda_1 \otimes \lambda_2 \otimes P)$.

Recall that the payoff function on the stopping times is denoted by $\widetilde{R}$, and its extension to $\mathcal{V}^+$ is denoted by R. The following result provides a justification of the

definition of $\mathcal{V}^+$ as the set of mixed strategies, and R as the payoff function on the extended strategy sets.

PROPOSITION 7.1. (i) *There exists a mapping H from Φ (or Ψ) onto $\mathcal{V}^+$.*

(ii) *For every $(\phi,\psi)\in\Phi\times\Psi$, we have*

$$E_{\lambda_1\otimes\lambda_2}\left[\widetilde{R}(\sigma,\tau)\right]=R(H(\phi),H(\psi)).$$

Proof. We only prove (i) for the set Φ. For $\phi\in\Phi$, define the process $H(\phi)$ by

$$H(\phi)_t=\int\mathbf{1}_{\{\sigma_r\le t\}}\lambda_1(dr)\;=\;E_{\lambda_1}[\mathbf{1}_{\{\sigma\le t\}}]\quad\text{for } t\in[0,T].$$

Clearly, $H(\phi)_{0-}=0$, $H(\phi)$ is nondecreasing, right-continuous and $H(\phi)_T\le 1$. Since σ_r is a stopping time for λ_1-a.e., $r\in[0,1]$, the process $H(\phi)$ is $\mathbb{F}$-adapted. This proves that $H(\phi)\in\mathcal{V}^+$. To see that H is onto, define

$$\phi^F(r,\omega):=\inf\{s\ge 0:\;F_s(\omega)>r\}\quad\text{for } F\in\mathcal{V}^+.$$

Observe that $\phi^F\in\Phi$, since F is $\mathbb{F}$-adapted and right-continuous. Set $\sigma_r:=\phi^F(r,\cdot)$. For $t\in[0,T]$, we compute

$$H(\phi^F)_t=\int\mathbf{1}_{\{\sigma_r\le t\}}\lambda_1(dr)\;=\;\int\mathbf{1}_{\{F_t\ge r\}}\lambda_1(dr)\;=\;F_t,$$

which concludes the proof of (i).

Let $(\phi,\psi)\in\Phi\times\Psi$, and set $F_t=\mathbf{1}_{\{\sigma\le t\}}$ and $G_t=\mathbf{1}_{\{\tau\le t\}}$. By Fubini's theorem,

$$E_{\lambda_1\otimes\lambda_2\otimes P}\left[\int_0^T X(1-G)dF\right]=E_{\lambda_1\otimes P}\left[\int_0^T X(1-H(\psi))dF\right].$$

By Itô's lemma, this provides

$$\begin{aligned}E_{\lambda_1\otimes\lambda_2\otimes P}\left[\int_0^T X(1-G)dF\right]&=E_{\lambda_1\otimes P}\left[X_T(1-H(\psi)_T)F_T-\int_0^T F_-d(X(1-H(\psi))\right]\\&=E_P\left[X_T(1-H(\psi)_T)H(\phi)_T-\int_0^T H(\phi)_-d(X(1-H(\psi))\right],\end{aligned}$$

where we again used Fubini's theorem. By another application of Itô's lemma, we get

$$E_{\lambda_1\otimes\lambda_2\otimes P}\left[\int_0^T X(1-G)dF\right]=E_P\left[\int_0^T X(1-H(\psi))dH(\phi)\right].$$

The same argument applies to the second integral $\int_0^T Y(1-F_-)dG$. Hence,

$$\begin{aligned}E_{\lambda_1\otimes\lambda_2}\left[\widetilde{R}(\sigma,\tau)\right]&=E_P\left[\int_0^T X(1-H(\psi))dH(\phi)+Y(1-H(\phi)_-)dH(\psi)\right]\\&=R(H(\phi),H(\psi)).\qquad\square\end{aligned}$$

7.2. Randomized stopping times. In this section, we describe briefly the functional analysis approach in order to define the notion of randomized stopping times introduced by Bismut (1979). We shall recall a representation theorem which connects randomized stopping times to our set $\mathcal{V}^+$.

Let $\mathcal{Y}$ be the space of càdlàg optional processes Y defined on $[0,T]$ such that

$$E\left[\sup_{t\in[0,T]}|Y_t|\right] < +\infty. \tag{7.1}$$

Observe that $\mathcal{Y}$ is a Banach space when endowed with the norm defined by (7.1). We denote by $\mathcal{Y}'$ the dual space of $\mathcal{Y}$. Then we have the following representation result of elements of $\mathcal{Y}'$.

PROPOSITION 7.2 (see Bismut (1979)). *For any $\mu \in \mathcal{Y}'$, there exist two right-continuous adapted processes with finite variation A and B valued in $\mathbb{R}\cup\{+\infty\}$ such that*

$$\langle \mu, Y\rangle \;=\; E\left[\int_0^T Y dA + Y_- dB\right] \quad \textit{for all } Y \in \mathcal{Y}.$$

Proposition 1.3 in Bismut (1979) provides a uniqueness result for such a representation under further restrictions on A and B.

DEFINITION 7.1. *A randomized stopping time is an element $\mu \in \mathcal{Y}'$, for which there exists a representation with $B = 0$, A nondecreasing and $A_T \le 1$.*

The following easy consequence establishes the connection between our set of extended strategies $\mathcal{V}^+$ and the set of randomized stopping times.

COROLLARY 7.1. *There is a bijection between $\mathcal{V}^+$ and the set of randomized stopping times.*

Proof. To every randomized stopping time μ, we can associate $A \in \mathcal{V}^+$ by the above representation. Conversely, given $A \in \mathcal{V}^+$, it is easy to check that $Y \mapsto E\int_0^T Y dA$ belongs to $\mathcal{Y}'$. □

THE SOLUTION OF THE H^2/H^∞ PROBLEM BY DIRECT METHODS*

M. A. DA SILVEIRA† AND R. ADES‡

Abstract. The H^2/H^∞ problem is formulated in a Hilbertian context. It has a unique solution, which is the strong limit of sequences generated by Galerkin methods based on convenient, but not necessarily orthogonal, generator sets. Using these results, a methodology to solve the problem by a Galerkin method is proposed, and an example is solved and compared to other approaches.

Key words. optimal control, robust control, H^2/H^∞ problem, linear control systems, weighted Hardy spaces

1. Introduction. The simplest H^2/H^∞ problem is to find a function $K(.)$ in the Hardy class H_+^∞ minimizing the quadratic criterion

$$J[K(.)] = \int_{-\infty}^{\infty} \{K(-i\omega)\Gamma(i\omega)K(i\omega) + K(-i\omega)\gamma(i\omega)\}d\omega,$$

under the H^∞ constraint

$$\operatorname{ess\,sup}|A(i\omega)K(i\omega) + B(i\omega)| \leq \lambda,$$

where $\Gamma(.)$, $\gamma(.)$, $A(.)$, and $B(.)$ are known rational functions, λ is a given positive real number, and the essential supremum is taken on the set of real numbers ω. This problem arises in quadratic optimal control theory for linear systems when robustness conditions or filtering constraints are imposed on the controller. This paper shows that, in spite of the H^∞ constraint, the above optimal control problem is well-posed in a larger space, $H_+^{2,-1}$, a Hilbert space to be defined here. It means that the optimal control problem has a unique solution in this space with desired regularity properties, under suitable conditions on the functional $J[.]$. Moreover, this functional setting leads to the definition of generator sets such that Galerkin methods converge to the optimal control problem solution. A significant remark is that it is possible to measure the approached solution quality when the proposed method is coupled with the dual method presented in [1]. The design of a pitch optimal control of a fighter airplane is presented as an example to show the numerical viability and to allow for comparison with other design methods.

The crucial point in this paper is the construction of a Hilbert space containing the usual Hardy spaces H_+^2, H_+^∞ such that bounded and closed sets in both spaces are also bounded closed in this new space. The embedding of the original problem in this new setting allows the use of Hilbert space convex optimization tools to solve

the problem. The H_+^∞ constraint carries the optimal solution into this last space with no further considerations about the H_+^∞ non-Hilbertian topology. Besides, this construction will be necessary to build a chain of Hilbert spaces needed to represent the optimal solution regularity, which is essential information for the Galerkin method convergence properties.

In the remainder of this section, a survey of the H^2/H^∞ problem and the notation to be used will be presented. The geometry of the Hilbert spaces $H_+^{2,-1}$ and $H_+^{2,-k}$ is presented in section 2. The unconstrained H^2 optimal control problem is rewritten in section 3 as a minimum norm problem in a suitable space $H_+^{2,-k}$ according to the data; this clarifies its existence and regularity properties. The constrained H^2/H^∞ optimal control problem is solved in Theorem 7 of section 4, which states the existence and uniqueness results cited above. The convergence of Galerkin methods is the subject of section 5, and a numerical example is presented and discussed in section 6. Some extensions of those results are shown in the last section, particularly to multivariable problems. All proofs which are not in the main text can be found in Appendix A.

After the introduction of the Youla–Kučera parameterization [2], [3], quadratic criteria for Wiener–Hopf linear-quadratic optimal control problems have been considered, allowing the manipulation of well-defined technical or physical optimal solution characteristics, as rms transient error, plant saturation and closed-loop sensitivity [2], transient specifications against shape-deterministic exogenous inputs [4], performance measures [5], [6], [7], servomechanism specifications [8], and transient specifications [9]. The work in [9] presents a heuristic procedure to choose the criteria weighting filters in such a way that a trade-off between overshoot and time constant can be obtained. All these papers consider the controller set as an optimization variable, with the set of controllers being parameterized by real-rational proper stable rational matrices. Explicit expressions for the optimal solutions are derived.

These linear-quadratic criteria have been enriched by quadratic of H^∞ constraints to consider performance or robustness conditions in [6], [7], [10], and [11]. In particular, H^∞ constraints have been used to impose a prespecified robustness degree to the optimal solution (see [12]), but they can be used also to impose other specifications, such as filter constraints (see [13]).

Other methods have been proposed to solve the H^2/H^∞ problem as well. Some of these methods modify the original optimization criteria to obtain new mathematical problems but obscuring the original physical interpretation. Examples are the methods described in [5], [10], and [11]. Direct methods, using expansions in series, do not modify the original criteria; they were proposed in [14] in a different context, and in [15], [16], [17], and [18]. Reference [17] considers discrete-time linear systems, presenting an algorithm to solve an approximate version such that the optimal parameter is exponentially stable. The other references consider the continuous-time case by using Laguerre functions as a generator set but do not prove the existence of an optimal solution. Reference [18] addresses the existence proof discussed in [19]. However, [19] does not contain such a proof but simply states that "it is easy to show that [the quadratic functional] has a unique minimum h_* on [the constraint set]". It is worth noting that these papers assume the Youla parameter in the usual quadratic Hardy space, a functional space not containing biproper rational functions. Moreover, [18] presents an extension of the algorithm already proposed in [17]. These assumptions are addressed in the last section. In [20], the use of linear matrix inequalities (LMIs) is proposed to solve the H^2/H^∞ problem but under assumptions too restrictive and unnatural.

A recent methodology was presented in [1] where a sequence of H^2 constraints approaching the original H^∞ constraint was built. In this method, each H^2 constraint defines a pure H^2 problem solved by a dual problem whose solution is explicitly given. The present paper shows that this solution defines a lower bound to the original optimal cost, with the sequence of these solutions monotonically approaching the optimal solution, when they exist. Such an algorithm will be used here as a part of a methodology to establish lower bounds to the optimal criterion value.

Actually, it is possible to obtain only approximate solutions. Indeed, paper [19] presents a theorem stating that the optimal solution is infinite-dimensional when the H^∞ constraint is active, which forces the designer to find rational approximations to the optimal solution. Moreover, [19] shows that the optimal parameter cannot be exponentially stable.

A first explicit proof for the existence and uniqueness of the H^2/H^∞ problem solution was given by the authors in [21], searching for the solution in the space generated by completing the set of real-rational proper stable functions under the norm defined by the quadratic criterion term. This result was further developed in [22], allowing a complete methodology to solve the H^2/H^∞ problem without changes in the criteria and in the constraints other than projections on finite-dimensional spaces. This methodology will, in part, be shown here. The present paper develops a more complete mathematical theory for the problem, determining the existence, uniqueness, and regularity to the solutions under natural assumptions and proving the convergence of the Galerkin approximating sequence to the optimal solution.

Notations. Let $\mathbb{N}$, $\mathbb{Z}$, $\mathbb{R}$, and $\mathbb{C}$ denote the natural numbers (i.e., the positive integers), the integers, the real, and the complex numbers, respectively. Also, let $|s|$, $\bar{s}$, and $\mathrm{Re}\{s\}$ denote the modulus, the conjugate, and the real part of a complex number s, respectively.

With i denoting $\sqrt{-1}$, let $i\mathbb{R} = \{i\omega, \omega \in \mathbb{R}\}$, $C_+^0 = \{s \in \mathbb{C}\colon \mathrm{Re}\{s\} > 0\}$, and $C_-^0 = \{s \in \mathbb{C}\colon \mathrm{Re}\{s\} < 0\}$. The functions $f : A \to B$ are denoted as f, $f(.)$, or $f(s)$, with $f(s)$ also denoting its value at $s \in A$. A function $f(.)$ is real if it maps real numbers in real numbers.

If $f(.) = n(.)/d(.)$ is rational, with $n(.)$ and $d(.)$ being polynomials, $\partial_r(f)$ denotes its relative degree, defined as the integer "degree of $d(.)$ − degree of $n(.)$." Also $f^*(s) = f(-s)$, $|f(i\omega)|^2 = \bar{f}(i\omega)f(i\omega)$ (or $f^*(i\omega)f(i\omega)$ if $f(.)$ is real).

The usual inner product and the usual quadratic norm are defined by

$$\langle f, g\rangle_2 = \int_{-\infty}^{\infty} \bar{f}(i\omega)f(i\omega)d\omega \qquad \text{and} \qquad \|f\|_2 = [\langle f, f\rangle_2]^{1/2} = \left[\int_{-\infty}^{\infty} |f(i\omega)|^2 d\omega\right]^{1/2}.$$

The H^∞ norm is defined by

$$\|f\|_\infty = \mathrm{ess\,sup}|f(i\omega)|,$$

the supremum taken on $\omega \in \mathbb{R}$. The symbols R_m, R_m^+, and R_m^- denote the classes of rational functions with relative degree greater than or equal to m, without poles in $i\mathbb{R}$, in $i\mathbb{R} \cup C_+^0$ (stable functions), and in $i\mathbb{R} \cup C_-^0$ (completely unstable functions), respectively.

The symbols H_+^2, H_-^2, H_+^∞, and H_-^∞ represent the usual Hardy classes studied in [23], [24]. The principal features of these spaces to be used here are given in what follows. The two spaces of stable functions are defined by

$$H_+^2 = \{f\colon C_+^0 \to \mathbb{C} \text{ analytic in } C_+^0 : \exists\, M < \infty \text{ with } \|f(a + i\omega\|_2 < M\ \forall\ a > 0\},$$

$$H_+^\infty = \{f\colon C_+^0 \to \mathbb{C} \text{ analytic and bounded in } \mathbb{C}_+^0\},$$

H_-^2 and H_-^∞ defined analogously by changing the symbol "+" by "−" and assuming $a < 0$.

Also, if

$$L^2(i\mathbb{R}) = \{f : i\mathbb{R} \to \mathbb{C} : \|f\|_2 < \infty\},$$

it can be proved that $\langle f, g\rangle_2$ is an inner product in $L^2(i\mathbb{R})$, H_+^2, and H_-^2, with all these spaces being Hilbert spaces under this inner product. The functional spaces H_+^2 and H_-^2 can be identified to be orthogonal subspaces of $L^2(i\mathbb{R})$ so that $L^2(i\mathbb{R}) = H_+^2 \oplus H_-^2$ (an orthogonal sum of subspaces). The symbols $[f]_+$ and $[f]_-$ denote the orthogonal projection of $f \in L^2(i\mathbb{R})$ in H_+^2 and H_-^2, respectively, and H_+^∞, H_-^∞ are Banach spaces under the norm $\|.\|_\infty$.

The symbol A_0 denotes the subset of H_+^∞-functions continuous on the completed imaginary axis. The symbol $\hat{A}(\beta_1)$ denotes the class of Laplace transforms of distributions in the Callier–Desoer algebra $A(\beta_1)$, and $\hat{A}_-(\beta)$ denotes the set of functions belonging to $\hat{A}(\beta_1)$ for some $\beta_1 < \beta$.

If H represents a locally convex topological vector space [25], H' denotes its topological dual endowed with its strong topology. If H and V are such spaces, $H + V$ and $H \oplus V$ denote their sums and their direct sums, respectively. The latter means $H \cap V = \{0\}$, the trivial subspace. Further information about these concepts can be found in [25], [26], or [27].

2. A functional setting for the optimal control problem. This section presents the functional setting to formulate the H^2/H^∞ problem as a well-posed problem. The basic idea is to define spaces containing H_+^2 and H_+^∞ such that the quadratic functional to be minimized is continuous and the constraints convex, closed, and bounded. Actually, a chain of spaces like H_+^2 will be defined to utilize the problem regularity.

DEFINITION 1. *Let* $\Phi_{-k} = (s+1)^{-k}$, $k \in \mathbb{Z}$, *let*

$$\langle f, g\rangle_{2,-k} = \int_{-\infty}^{\infty} f^*(i\omega)\Phi_{-k}^*(i\omega)\Phi_{-k}(i\omega)f(i\omega)d\omega,$$

and let

$$\|f\|_{2,-k} = [\langle f, f\rangle_{2,-k}]^{1/2} = \left[\int_{-\infty}^{\infty} |\Phi_{-k}(i\omega)f(i\omega)|^2 d\omega\right]^{1/2}.$$

Set

$$L_{-k}^2(i\mathbb{R}) = \{f : i\mathbb{R} \to \mathbb{C} : \|f\|_{2,-k} < \infty\},$$
$$H_+^{2,-k} = \{f : C_+^0 \to \mathbb{C} \text{ is analytic in } C_+^0 : \exists\, M < \infty \text{ such that } \|f(a+i\omega)\|_{2,-k} < M \ \forall\ a > 0\},$$

$H_-^{2,-k}$ *the analogous space using* $a < 0$ *and* C_-^0 *in its definition.*

As $\langle f, g\rangle_{2,-k} = \langle \Phi_{-k}f, \Phi_{-k}g\rangle_2$ and $\|f\|_{2,-k} = \|\Phi_{-k}f\|_2$, it is easy to prove that $\langle f, g\rangle_{2,-k}$ defines an inner product and $\|f\|_{2,-k}$ is the associated norm in the spaces defined above (see Appendix A). Moreover, the usual $L^2(i\mathbb{R})$, H_+^2, and H_-^2 spaces are the special cases where $k = 0$. The next theorem presents the geometrical properties of the spaces defined here.

THEOREM 1. *Let the spaces* $L_{-k}^2(i\mathbb{R})$, $H_+^{2,-k}$, $H_-^{2,-k}$ *be as in Definition* 1.

(a) $L^2_{-k}(i\mathbb{R})$, $H^{2,-k}_+$, $H^{2,-k}_-$ *are the completion of the sets* R_{1-k}, R^+_{1-k}, *and* R^-_{1-k} *in the norm* $\|.\|_{2,-k}$, *respectively. Moreover, they are Hilbert spaces with respect to the corresponding inner product.*

(b) $H^{2,-k}_+$ *and* $H^{2,-k}_-$ *are closed subspaces of* $L^2_{-k}(i\mathbb{R})$.

(c) $L^2_{-k}(i\mathbb{R}) = H^{2,-k}_+ + H^{2,-k}_-$. *If* $k \le 0$, *then* $H^{2,-k}_+ \cap H^{2,-k}_-$ *is empty. If* $k \ge 1$, *then* $H^{2,-k}_+ \cap H^{2,-k}_-$ *contains the polynomials in* s *with degree less than or equal to* $k-1$ *and the functions defined by* $\sum_{m=1}^{\infty} \alpha_m e^{-st_m}$, *where* $\sum_{m=1}^{\infty} |\alpha_m| < \infty$ *and, for any* m, $t_m > 0$.

Remark 1. It is worth noting that a rational function $f(s)$ without poles in $i\mathbb{R}$ belongs to $L^2_{-k}(i\mathbb{R})$ if and only if $\partial_r(f) \ge 1-k$. Alternatively, if $\partial_r(f) = m$ and $f(s)$ has no poles in $i\mathbb{R}$, then $f(s) \in L^2_{-k}(i\mathbb{R})$ for each $k \ge 1-m$.

The next theorem collects some results relating the topologies of H^∞_+, $L^2_{-k}(i\mathbb{R})$, and $H^{2,-k}_+$ for different indexes k.

THEOREM 2. *Let the spaces* $L^2_{-k}(i\mathbb{R})$, $H^{2,-k}_+$, $H^{2,-k}_-$ *be as in Definition* 1 *and let* $k < m$.

(a) $L^2_{-k}(i\mathbb{R}) \subset L^2_{-m}(i\mathbb{R})$. *The linear spaces* $L^2_{-k}(i\mathbb{R})$ *and* $L^2_{-m}(i\mathbb{R})$ *are isometrically isomorphic, the isometry from* $L^2_{-k}(i\mathbb{R})$ *to* $L^2_{-m}(i\mathbb{R})$ *being injective and the inverse isometry being surjective. Therefore, the* $L^2_{-k}(i\mathbb{R})$ *topology is strictly finer than the* $L^2_{-m}(i\mathbb{R})$ *topology.*

(b) $H^{2,-k}_+ \subset H^{2,-m}_+$. *The* $H^{2,-k}_+$ *topology is strictly finer than the* $H^{2,-m}_+$ *topology.*

(c) $L^2_{-k}(i\mathbb{R})$ *is dense in* $L^2_{-m}(i\mathbb{R})$, $H^{2,-k}_+$ *is dense in* $H^{2,-m}_+$. *In particular, if* $k \ge 1$, *the sets* R_0, R^+_0, *and* R^-_0 *are dense in* $L^2_{-k}(i\mathbb{R})$, $H^{2,-k}_+$, *and* $H^{2,-k}_-$, *respectively.*

(d) $H^\infty_+ \subset H^{2,-1}_+$, *the* H^∞_+ *topology being strictly finer than the one of* $H^{2,-1}_+$.

Remark 2. Property (c) says that biproper rational functions can be approached in $H^{2,-1}_+$ by strictly proper rational functions, diminishing the relative degree at the limit. As an example, $f_n(s) = n(s+n)^{-1}$ converges to the constant function $f(s) \equiv 1$ in the $H^{2,-1}_+$ topology. This explains why it is possible to find complete sets for $H^{2,-k}_+$, $k \ge 1$, formed by strictly proper real-rational stable functions (R^+_0 functions).

Remark 3. Let $S(i\mathbb{R})$ denote the space of functions going quickly to zero at infinity and $(S(i\mathbb{R}))'$ its topological dual (the space of temperate distributions) [26], [27]. Define $S_+(i\mathbb{R})$ as $S(i\mathbb{R}) \cap H^2_+$ and $(S_+(i\mathbb{R}))'$ as its closure in the $(S(i\mathbb{R}))'$ topology. With these notations it is possible to prove that, for any $k > 1$,

$$
\begin{array}{lllllll}
S(i\mathbb{R}) \subset & L^2_k(i\mathbb{R}) \subset & L^2_1(i\mathbb{R}) \subset & L^2(i\mathbb{R}) \subset & L^2_{-1}(i\mathbb{R}) \subset & L^2_{-k}(i\mathbb{R}) \subset & (S(i\mathbb{R}))' \\
\cup & \cup & \cup & \cup & \cup & \cup & \cup \\
S_+(i\mathbb{R}) \subset & H^{2,k}_+ \subset & H^{2,1}_+ \subset & H^2_+ \subset & H^{2,-1}_+ \subset & H^{2,-k}_+ \subset & (S_+(i\mathbb{R}))' \\
 & & & & \cup & & \\
 & & & & H^\infty_+. & &
\end{array}
$$

Each space is dense in the next bigger one in the chain. An analogous sequence can be built for unstable functions spaces. The original H^2/H^∞ problem will be embedded in these chains of Hilbert spaces, as will be shown in the next section.

Remark 4. Let $\mathbb{H}_k$ denote the order k Sobolev space [26], [27]. As $\mathbb{H}_k$ is the Fourier transform image of $L^2_k(i\mathbb{R})$ (by an adaptation of a construction found in [26]), it is possible to define stable Sobolev spaces $[\mathbb{H}_k]^+$ as the inverse Fourier transform image of H^k_+. Then, it is possible to build a corresponding sequence of stable Sobolev

spaces also beginning in $S_+(i\mathbb{R})$ and ending in $(S_+(i\mathbb{R}))'$. Also, from the structure theorem (see [26, p. 255]), it is possible to show that the temperate distributions in $(S_+(i\mathbb{R}))'$ are derivatives of some finite order of functions in $[\mathbb{H}_2]^+$.

Now, the crucial point for embedding the H^2/H^∞ problem in $H_+^{2,-k}$ will be considered.

THEOREM 3. *Consider the spaces presented in Definition* 1.

(a) *If $k \leq m$, the bounded subsets of $L^2_{-k}(i\mathbb{R})$ are bounded in $L^2_{-m}(i\mathbb{R})$, and the bounded closed subsets of $L^2_{-k}(i\mathbb{R})$ are bounded and closed in $L^2_{-m}(i\mathbb{R})$, the same relations existing between sets in $H_+^{2,-k}$ and $H_+^{2,-m}$.*

(b) *The bounded subsets of H_+^∞ are bounded in $H_+^{2,-1}$, and the bounded closed subsets of H_+^∞ are bounded and closed in $H_+^{2,-1}$.*

Remark 5. Here it is essential that the subset be bounded. The spaces H_+^∞ and H_+^2 are closed and unbounded in its own topologies, but they are dense in $H_+^{2,-1}$ in the coarser topology. Also, closed balls in H_+^∞ have empty interiors in relation to $H_+^{2,-1}$ topology.

The next step is to collect the properties of linear and quadratic functionals in $H_+^{2,-k}$, preparing more tools for minimizing the quadratic criteria defined in section 1.

THEOREM 4. *Let $\gamma(s)$ be a real-rational function without poles in $i\mathbb{R}$.*

(a) *The linear functional*

$$F(f) = \int_{-\infty}^{\infty} f^*(i\omega)\gamma(i\omega)d\omega$$

is continuous on $H_+^{2,-k}$ if and only if $\partial_r(\gamma) \geq k+1$.

(b) *The space of continuous linear functional on $H_+^{2,-k}$ can be identified to $H_+^{2,k}$ for any k.*

THEOREM 5. *Let $\Gamma(s)$ be a real rational para-Hermitian function in R_{2k} without poles or zeros in $i\mathbb{R}$, i.e., $\Gamma(s) = \Gamma^*(s)$ and $|\Gamma(i\omega)| > 0$ for each finite ω.*

(a) *$\Gamma(s) = \Phi^*(s)\Phi(s)$, $\Phi(s)$ being a real-rational stable function in R_k^+ with all its zeros in C_+^0 (i.e., minimum-phase).*

(b) *The quadratic functional*

$$f \mapsto \int_{-\infty}^{\infty} f^*(i\omega)\Gamma(i\omega)f(i\omega)d\omega = \langle \Phi f, \Phi f\rangle_2 = \|\Phi f\|_2^2$$

is continuous in $H_+^{2,-m}$ if and only if $m \leq k$. It is coercive in $H_+^{2,-m}$ (i.e., there is a real number $\alpha > 0$ such that $\langle \Phi f, \Phi f\rangle_2 \geq \alpha^2 \|f\|_{2,-m}^2$ for all $f \in H_+^{2,-m}$) if and only if $m = k$. Moreover, it is strictly convex, and $\|\Phi f\|_2$ defines a norm in $H_+^{2,-k}$ equivalent to $\|f\|_{2,-k}$.

3. Optimal H^2 unconstrained control problems. This section presents the mathematical extension of the usual H^2 unconstrained optimal control problem on the mathematical framework developed in the last section. New conditions about its solution will be obtained, clarifying the ones in [8], [9]. This extension will be used in the next section to solve the H^2/H^∞ optimal control problem.

The unconstrained H^2 problem can be defined as follows: Find a function $\breve{K}(s)$ solution to

$$\inf_K \left\{ \int_{-\infty}^{\infty} [K^*(i\omega)\Gamma(i\omega)K(i\omega) - 2K^*(i\omega)\gamma(i\omega)]d\omega \right\} = \inf_K J[K], \tag{3.1}$$

where the functions $K(s)$ belong to some $H_+^{2,-k}$ space, or, formally, to $(S_+)'$, a space containing $H_+^{2,-k}$ for all integer k. $\Gamma(s)$ and $\gamma(s)$ are given real-rational functions. Recall that $K(s)$ is the parameter describing the set of stabilizing controllers (or the set of controllers solving a given servomechanism problem), initially a free real-rational stable and proper function. To define the functional $J[\,.\,]$ some assumptions are needed:

(A1) $\Gamma(s) = \Phi^*(s)\Phi(s)$ is a para-Hermitian real-rational function in R_{2k} without poles or zeros in $i\mathbb{R}$, $\Phi(s)$ being a real-rational stable function in R_k^+ with all its zeros in C_+^0 (i.e., minimum-phase);

(A2) $\gamma(s)$ is a real-rational function without poles in $i\mathbb{R}$, $\partial_r(\gamma) = p$.

The functional $J[\,.\,]$ will be finite only for a meager parameter subset if $\Gamma(s)$ or $\gamma(s)$ have poles on the imaginary axis, as both are rational functions. Indeed, if such happens, $J[K]$ will be finite only for $K(s)$ with zeros on those imaginary poles. The other conditions on assumption A1 are natural for quadratic functional on $H_+^{2,-k}$ spaces, according to Theorem 5 above. Indeed, it is possible to represent all integral quadratic real functional on $H_+^{2,-k}$ spaces as an integral quadratic operator with a para-Hermitian kernel by a procedure similar to the autoadjoint representation for integral quadratic functional on L^2 spaces. Moreover, $\Gamma(s)$ is assumed with no zeros on the imaginary axis because this allows unstable solutions (see Remark 8). Finally, the Wiener–Hopf factorization $\Gamma = \Phi^*\Phi$ is a consequence of the known Youla factorization theorem cited above as Theorem 5(a) [28].

LEMMA 1. *Under assumptions* A1 *and* A2, *let* $m = \min\{k, p-1\}$. *Then the functional* $J[\,.\,]$ *is continuous in* $H_+^{2,-m}$ *but not well-defined in larger spaces, i.e., the integrals in* $J[K]$ *diverge for* $K \in (S_+)' - H_+^{2,-k}$ (*the complement of* $H_+^{2,-k}$ *in* $(S_+)'$).

Proof. The first statement follows from continuity conditions in Theorems 4 and 5(b). For the second statement, if $K \in (S_+)' - H_+^{2,-k}$ is a rational function, $J[K]$ is not defined because $\partial_r(K^*\Gamma K) \le 1$ or $\partial_r(K^*\gamma) \le 1$. □

DEFINITION 2. *The space* $H_+^{2,-m}$ *in Lemma* 1 *will be called the effective domain of the function* $J[\,.\,]$. *This terminology is inherited from convex analysis and adapted to the chain of spaces defined here.*

Now, note that, for $K \in H_+^{2,-m}$ and m as in Lemma 1, $\Phi K \in H_+^2$. Then the functional $J[K]$ can be written as

$$J[K] = \|\Phi K\|_2^2 - 2\int_{-\infty}^{\infty} \{[\Phi(i\omega)K(i\omega)]^*[\Phi^*(i\omega)]^{-1}\gamma(i\omega)\}d\omega. \tag{3.2}$$

As $(\Phi^*)^{-1}\gamma \in L_{p-k-1}^2(i\mathbb{R})$, it can be factorized as a sum of a function in $H_+^{2,p-k-1}$ with a function in $H_-^{2,p-k-1}$, according to Theorem 1(c).

If $p \le k$, this factorization is not unique because $p-k-1 \le -1$. As $(\Phi^*)^{-1}\gamma$ is rational, it is possible to choose a factorization where the polynomial part of $(\Phi^*)^{-1}\gamma$ is taken on the unstable factor. This factorization will be denoted by

$$(\Phi^*)^{-1}\gamma = [(\Phi^*)^{-1}\gamma]_+ + [(\Phi^*)^{-1}\gamma]_-,$$

with $\partial_r([(\Phi^*)^{-1}\gamma]_+) \ge 1$, $[(\Phi^*)^{-1}\gamma]_+ \in H_+^{2,p-k-1}$, $[(\Phi^*)^{-1}\gamma]_- \in H_-^{2,p-k-1}$.

Actually, $[(\Phi^*)^{-1}\gamma]_+ \in H_+^2$ because it is a stable strictly proper rational function with all its poles in C_-^0.

If $p+1 \ge k$, $L_{p-k-1}^2(i\mathbb{R}) \subset L^2(i\mathbb{R})$, $p-k-1 \ge 0$. The above factorization will be interpreted as $[(\Phi^*)^{-1}\gamma]_+ \in H_+^{2,p-k-1} \subset H_+^2$, $[(\Phi^*)^{-1}\gamma]_- \in H_-^{2,p-k-1} \subset H_-^2$, because

$\partial_r([(\Phi^*)^{-1}\gamma]_+) \geq p-k \geq 1$. Note that all the stable projections in different spaces $H_-^{2,p-k-1}$ are denoted by the same symbol $[\,.\,]_+$, but the spaces will be clear from the context.

With this notation, the linear part of $J[K]$ becomes

$$\begin{aligned} &-2\langle \Phi K, [(\Phi^*)^{-1}\gamma]_+\rangle_2 - 2\int_{-\infty}^{\infty} K^*(i\omega)\Phi^*(i\omega)[(\Phi^*(i\omega))^{-1}\gamma(i\omega)]_- d\omega \\ &= -2\langle \Phi K, [(\Phi^*)^{-1}\gamma]_+\rangle_2, \end{aligned}$$

the integral being zero since all the integrand poles are in C_+^0 and its relative degree is less than or equal to 2. (The residue theorem applied to a circuit involving C_-^0 proves the statement; see [8].) In other words, the unstable term $[(\Phi^*)^{-1}\gamma]_-$ is orthogonal to the stable function ΦK. Then, completing the square in (3.2), we get

$$\begin{aligned} J[K] &= \|\Phi K\|_2^2 - 2\langle \Phi K, [(\Phi^*)^{-1}\gamma]_+\rangle_2 + \|[(\Phi^*)^{-1}\gamma]_+\|_2^2 - \|[(\Phi^*)^{-1}\gamma]_+\|_2^2 \\ &= \|\Phi K - [(\Phi^*)^{-1}\gamma]_+\|_2^2 - \|[(\Phi^*)^{-1}\gamma]_+\|_2^2. \end{aligned}$$

Therefore, the minimum of $J[\,.\,]$ is attained at a parameter $\breve{K}$ such that $\Phi\breve{K} - [(\Phi^*)^{-1}\gamma]_+ = 0$, but only if $J[\breve{K}] < \infty$, i.e., only if $\breve{K}$ belongs to the effective domain of $J[\,.\,]$, that is, to $H_+^{2,-m}$. These conclusions are collected in the next theorem.

THEOREM 6. *Let assumptions* A1 *and* A2 *be verified, and let* $\breve{K}$ *be a rational function given by*

$$\breve{K} = \Phi^{-1}[(\Phi^*)^{-1}\gamma]_+, \tag{3.3}$$

where $[(\Phi^*)^{-1}\gamma]_+$ *denotes the stable strictly proper part of* $(\Phi^*)^{-1}\gamma$, $m = \min\{k, p-1\}$. *If* $\breve{K} \in H_+^{2,-m}$ *(the* $J[\,.\,]$ *effective domain), then* $\inf\{J[K]\} = J[\breve{K}]$ *in* $H_+^{2,-m}$.

As commented above, in common H^2/H^∞ problems, $K(s)$ is a proper stable real-rational function, which means $\partial_r(K) \geq 0$. In the mathematical framework presented here, this implies $K \in H_+^{2,-1}$. This situation is explored in the next corollary, easily proved from Theorem 6 and the calculations above. Note that the condition $H_+^{2,-m} \supset H_+^{2,-1}$ is not necessary, but only the condition $\breve{K} \in H_+^{2,-q} \subset H_+^{2,-1}$ with $H_+^{2,-q} \subset H_+^{2,-m}$ for some $q \leq 1$.

COROLLARY 1. *Under the same assumptions as in Theorem* 6, $\partial_r(\breve{K}) \geq 0$ *if and only if* $\partial_r([(\Phi^*)^{-1}\gamma]_+) \geq k$. *Sufficient conditions for this conclusion are* $p = \partial_r(\gamma) \geq 2k$ *or* $k = \partial_r(\Phi) \leq 1$.

Remark 6. The conditions presented in Corollary 1 are sufficient but not necessary. Indeed, for any Φ with $\partial_r(\Phi) = k$ and for any $q \leq k$, it is possible to find a function $\gamma(s)$ as in (3.1) such that $\partial_r(\breve{K}) = 1-q$ and $J[\breve{K}] < \infty$. For that, let $\gamma = \Phi^* B$, $B \in L^2(i\mathbb{R})$ such that $\partial_r([B]_+) = 1+k-q$, which is always possible if $q \leq k$. Note that $k \leq p-1 = \partial_r(\gamma) - 1$, which implies that $J[\,.\,]$ is well-defined in $H_+^{2,-k}$. Then

$$\partial_r(\breve{K}) = \partial_r(\Phi^{-1}[(\Phi^*)^{-1}\Phi^* B]_+) = \partial_r(\Phi^{-1}[B]_+) = 1-q.$$

Also, $\breve{K} \in H_+^{2,-k}$, then $J[\breve{K}] < \infty$.

In the control context, criteria such as (3.1) usually appear as a functional in the form

$$\begin{aligned}&\|AK+B\|_2^2\\ &=\int_{-\infty}^{\infty}\{K^*(i\omega)A^*(i\omega)A(i\omega)K(i\omega)-2K^*(i\omega)A^*(i\omega)B(i\omega)+B^*(i\omega)B(i\omega)\}d\omega,\end{aligned}\tag{3.4}$$

where $B(i\omega)\in L^2(i\mathbb{R})$ is a real-rational strictly proper function with $\partial_r(B)\geq 1$. For each simple functional, by direct verification, $\Phi(s)=A(s)$, $\gamma(s)=A^*(s)B(s)$. Therefore $\partial_r(\gamma)=\partial_r(\Phi)+\partial_r(B)$, which implies the condition:

$$\partial_r(\gamma)\geq\partial_r(\Phi)+1.\tag{3.5}$$

Condition (3.5) is inherited by sums of quadratic functionals as in (3.4) and will greatly simplify the use of Theorem 6. Indeed, under such condition, the function $[\Phi^*(i\omega)]^{-1}\gamma(i\omega)\in L^2(i\mathbb{R})$ because (3.5) corresponds to $p+1\geq k$. Then the decomposition used to prove Theorem 6 will be the usual $L^2(i\mathbb{R})=H_+^2\oplus H_-^2$. In other words, $[(\Phi^*)^{-1}\gamma]_+$ is the usual projection on H_+^2. Moreover, $m=\min\{k,p-1\}=k$. Therefore, $\breve{K}=\Phi^{-1}[(\Phi^*)^{-1}\gamma]_+$ is a rational function with $\partial_r(\breve{K})\geq\partial_r([(\Phi^*)^{-1}\gamma]_+)-\partial_r(\Phi)=1-k$, which implies $J[\breve{K}]<\infty$ and $\breve{K}\in H_+^{2,-m}=H_+^{2,-k}$ with no further condition. In the other sense, if $H_+^{2-m}=H_+^{2,-k}$, then $m=k\leq p-1$, which implies (3.5).

These remarks are collected in the next corollary.

COROLLARY 2. *Let assumptions* A1 *and* A2 *hold. Then condition* (3.5) *is equivalent to saying that the effective domain of* $J[\,.\,]$ *is* $H_+^{2,-k}$. *In this case the function* $\breve{K}(s)$ *given by* (3.3) *is such that* $\inf\{J[K]\}=J[\breve{K}]$ *in* $H_+^{2,-k}$, $[\,.\,]_+$ *denoting the usual orthogonal projection on* H_+^2.

Remark 7. The conditions found in the literature about the unconstrained problem are particular cases of assumptions in Corollaries 1 and 2 [8]. See especially [9], in which a well-motivated criterion is presented such that these conditions are naturally verified.

Remark 8. If $\Gamma(s)$ has zeros on the imaginary axis, $\Phi(s)$ will have the same zeros if the generalized Wiener–Hopf factorization is used as in [28]. Then $\breve{K}$ given in (3.2) will have these zeros as poles, being unstable. In other words, the completion of R_0 in the norm induced by the quadratic part of $J[\,.\,]$ will contain, in this case, unstable rational functions, the minimum being attained in such a function.

Remark 6 shows that $\partial_k(\breve{K})$ can be different from $1-m$, where the $J[\,.\,]$ effective domain is $H_+^{2,-m}$. This possibility will be essential to the algorithm convergence regularity; see section 5 above. Corollary 1 gives conditions for $\partial_r(\breve{K})\geq 0$ if $m\geq 1$. The same considerations used in its proof can be generalized to any relative degree for the optimal solution. Actually, much of the work found in the literature can be linked with this search for regularity, and it was essential in the existence proofs in [8], [9] and in some seminal but unclear comments in [2]. Moreover, a lot of work was needed in [9] to define a natural criterion such that $\partial_r(\breve{K})\geq 0$ for all linear systems for which the proposed servomechanism problem there is solvable. This natural criteria verify assumptions A1, A2 and condition (3.5) with $k=p=1$. Then, by Corollary 2, $m=k$, the effective domain is exactly $H_+^{2,-1}$, which eases considerably the application of the methodology proposed therein.

4. Optimal H^2/H^∞ control problems. This section presents the mathematical extension of the usual H^2/H^∞ control problem on the mathematical framework developed in section 2. The optimal solution existence and uniqueness will be proved in the following and regularity results will be presented.

In the H^2/H^∞ optimal control problem the goal is to find a function $\hat{K}(s)$ solution to

$$\inf_{K\in\Omega\cap\Theta}\left\{\int_{-\infty}^{\infty}[K^*(i\omega)\Gamma(i\omega)K(i\omega)-2K^*(i\omega)\gamma(i\omega)]d\omega\right\}\equiv\inf_{K\in\Omega\cap\Theta}J[K], \tag{4.1}$$

where Ω is a bounded closed convex subset of H_+^∞ and Θ is a bounded closed convex subset of H_+^2. The usual examples of sets Ω and Θ arising from performance, filtering, and robustness specifications are

$$\Omega=\bigcap_{m=1}^{M}\Omega_m;\qquad \Omega_m=\{K\in H_+^\infty:\|A_mK+B_m\|_\infty\le\lambda_m\},$$
$$A_m \text{ and } B_m \text{ functions in } H_+^\infty;$$
$$\Theta=\bigcap_{n=1}^{N}\Theta_n;\qquad \Theta_n=\{K\in H_+^2:\|C_nK+D_n\|_2\le\mu_n\},\quad C_n\in H_+^\infty \text{ and } D_n\in H_+^2;$$

λ_m and μ_n are positive real numbers so that the set Ω is nonempty.

Now, under the assumptions of Lemma 1, the criterion functional in (4.1) is strictly convex and continuous in its effective domain, $H_+^{2,-m}$. From Theorem 3(a), the set Θ is convex, bounded, and closed in $H_+^{2,-m}$ for $m\ge 0$ as a convex, bounded, and closed subset of H_+^2. From Theorem 3(b), Ω is convex, bounded, and closed in $H_+^{2,-1}$ as a convex, bounded, and closed subset of H_+^∞. Then Ω is convex, bounded, and closed in $H_+^{2,-m}$ for $m\ge 1$, from Theorem 3(a). Therefore, we can apply a well-known theorem [29, Theorem 2.6.1, p. 50] to show the existence and uniqueness of the optimal solution for problem (4.1).

THEOREM 7. *Let assumptions* A1 *and* A2 *with* $\partial_r(\Gamma)\ge 2$, $\partial_r(\gamma)\ge 2$ *be verified. Then*

(a) *if the constraint set* $\Omega\cap\Theta$ *is nonempty, the optimal control problem* (4.1) *has one and only one solution in* $H_+^{2,-1}$*;*

(b) *if* Ω *is nonempty, the optimal solution is in* H_+^∞*; if* Θ *is nonempty, the optimal solution is in* H_+^2*.*

Proof. (a) is proved in the above comments. The second statement is clear. ∎

Naturally, it is possible to add $H_+^{2,-1}$ closed convex subsets as new constraints without changing the above conclusions.

Remark 9. A direct consequence of this last theorem is the convergence of the approximating sequence generated by the algorithm proposed in [1] to the optimal solution of problem (4.1). In the same paper it is shown that the optimal control, if it exists, belongs to the H^∞ constraint boundary. Also, the H^2 optimal control problem is explicitly solved with only H^2 constraints by duality, a key to the method proposed therein.

Before the presentation of numerical methods to solve the optimal control problem (4.1) it will be interesting to rewrite it as a minimal norm problem, a step in the strong convergence proof. Assume that $\breve{K}\in H_+^{2,-q}\subset H_+^{2,-m}$ for some $q\le m=\inf\{k,p-1\}$.

Then $\Phi\breve{K} \in H_+^2$. Now, the calculations used to prove Theorem 6 give

$$\begin{aligned} J[K] &= \|\Phi\{K - \Phi^{-1}[(\Phi^*)^{-1}\gamma]_+\}\|_2^2 - \|\Phi\{\Phi^{-1}[(\Phi^*)^{-1}\gamma]_+\}\|_2^2 \\ &= \|\Phi(K - \breve{K})\|_2^2 - \|\Phi\breve{K}\|_2^2. \end{aligned} \tag{4.2}$$

Notation. Let $\|f\|_\Gamma = \|\Phi f\|_2$ be a norm associated to the $J[\,.\,]$ quadratic term, and let $\langle f, g\rangle_\Gamma = \langle \Phi f, \Phi g\rangle_\Gamma$ be the associated internal product.

Theorem 5(b) says that if assumption A1 is verified, $\|f\|_\Gamma$ defines a norm on $H_+^{2,-k}$ equivalent to the norm $\|\,.\,\|_{2,-k}$. Then

$$J[K] = \|K - \breve{K}\|_\Gamma^2 - \|\breve{K}\|_\Gamma^2. \tag{4.3}$$

Therefore, under the assumptions of Theorem 7, the optimal control problem (4.1) is equivalent to finding a function $\hat{K}$ solution to

$$\inf_{\Omega\cap\Theta} \|K - \breve{K}\|_\Gamma^2, \tag{4.4}$$

a best approximation problem in $H_+^{2,-k}$. Note that if condition (3.5) is verified, $H_+^{2,-k} = H_+^{2,-m}$, but here it is needed only that $\breve{K} \in H_+^{2,-q} \subset H_+^{2,-m} \subset H_+^{2,-k}$.

COROLLARY 3. *Let assumptions* A1 *and* A2 *hold with* $\partial_r(\Gamma) \geq 2$, $\partial_r(\gamma) \geq 2$. *Problems* (4.1) *and* (4.4) *are equivalent if and only if* $\breve{K} \in H_+^{2,-q} \subset H_+^{2,-m} \subset H_+^{2,-k}$, *i.e.,* $\partial_r(\breve{K}) \geq 1 - m$, $m = \min\{k, p-1\}$. *Moreover, assumptions* A1 *and* A2 *with* $\partial_r(\Gamma) \geq 2$, $\partial_r(\gamma) \geq 2$ *and condition* (3.5) *are sufficient for the same conclusion.*

Proof. According to the above comments, the first statement is a consequence of Theorem 7 and the second statement is a consequence of Theorem 7 and Corollary 2. □

The optimal control problem (4.1) can be rewritten as a minimal norm problem in $H_+^{2,-k}$ if this space is translated by $\breve{K}$. For that, redefine $G = K - \breve{K}$, $\Omega' = \Omega - \breve{K}$, $\Theta' = \Theta - \breve{K}$. Note that Ω' and Θ' are convex, bounded, and closed in $H_+^{2,-k}$ because these properties are not changed by translations in a Hilbert space. In these notations the optimization problem (4.4) can be translated as the new problem: Find a $\hat{G} \in H_+^{2,-k}$ solution to

$$\inf_{G\in\Omega'\cap\Theta'} \|G\|_\Gamma^2, \tag{4.5}$$

a minimal norm problem. Note that $\breve{K}$ could not belong to $H_+^{2,-1}$. Thus (4.5) shall be solved carefully from a numerical point of view.

Regularity now is essential: if the optimal control problem needs to be solved in some $H_+^{2,-q}$ as a minimal norm problem, beyond the existence conditions in Theorem 7, the condition $H_+^{2,-q} = H_+^{2,-k} \subset H_+^{2,-m}$ will also be needed. This means $q = k \leq m$, with $\breve{K} \in H_+^{2,-q}$, or, more exactly, $\breve{K} \in H_+^{2,-r}$ for some $r \leq q$. For that, Corollary 1 (and its extensions) and Corollary 2 are useful. The usual setting is $q = 1$ as in [8], [21], [22], or, in a more restricted way, $q = k = 1$, as in [9]. In the present paper this setting is generalized to better understand the weak and strong convergence of the algorithm proposed in the next section.

5. The Galerkin method. If $\{\beta_n, n \in N\}$ is a generator set for $H_+^{2,-1}$, not necessarily orthogonal, denote by H_n the finite-dimensional subspace generated by the n first vectors in the generator set. Let Ω_n be defined as $\Omega\cap\Theta\cap H_n$. If Ω_n is nonempty,

it is possible to project the optimal control problem (2.3) in H_n, which defines the following finite-dimensional optimization problem: Find a $\hat{K}_n$ in H_n solution to

$$\inf_{K\in\Omega_n}\{\|K\|_\Gamma^2 - 2\langle K,\gamma\rangle_2\}. \tag{5.1}$$

As Ω_n is a bounded closed convex subset of H_n and the criterion is strictly convex, this optimal control problem has one and only one solution $\hat{K}_n$ in H_n for each $n\in\mathbb{N}$ (see [29, p. 50]). The Galerkin method consists of approximating the optimal solution $\hat{K}$ to the optimal control problem (4.1) by $\hat{K}_n$ if the sequence $\{\hat{K}_n\}$ converges to the optimal solution $\hat{K}$.

We need a technical assumption to have Ω_n nonempty for n sufficiently large.

(A3) Let A_0 denote the set of H_+^∞-functions continuous in the closed right convex semiplane. Assume that $\Omega\cup A_0$ has a nonempty relative interior in A_0 with respect to the H_+^∞ topology.

This assumption is verified for the usual sets Ω_m presented in section 4 because this set has a nonempty interior in H_+^∞ and A_0 is a closed subspace of the same space. Moreover, A_0 is the closure of the rational proper stable functions in H_+^∞ [30, p. 668].

THEOREM 8. *Let the assumptions in Theorem* 7 *and assumption* A3 *be verified. Also, assume that the unconstrained optimal solution* $\breve{K}$ *does not belong to* $\Omega\cap\Theta$. *(Otherwise the optimal solution will be* $\breve{K}$.*) Then the sequence* $\{\hat{K}_n\}$ *generated by the Galerkin method converges weakly in* $H_+^{2,-1}$ *to the unique optimal solution* $\hat{K}$ *to the optimal control problem* (4.1).

Under the assumptions of Corollary 3, including (3.5), the optimal control problem (4.1) can be rewritten as minimal norm problems (4.4) and (4.5), which will allow us to show the strong convergence of the sequence $\{\hat{K}_n\}$ in suitable spaces. For that, let $\{\beta_n, n\in\mathbb{N}\}$ be a generator set for $H_+^{2,-k}$ and let $\|.\|_\Gamma$ be the norm defined in section 4. Thus we can define the projection of the minimal norm problem (4.4) in H_n as some $\hat{K}_n$ in H_n solution to

$$\inf_{K\in\Omega_n}\|K-\breve{K}\|_\Gamma^2, \tag{5.2}$$

where $\breve{K}_n$ is the projection of $\breve{K}$ in H_n. Analogously, translating H_n by $\breve{K}_n$, the minimal norm problem (4.5) can be projected to finding a $\hat{G}_n$ solution of

$$\inf_{G\in\Omega_n'}\|G\|_\Gamma^2, \tag{5.3}$$

where $\Omega_n' = \Omega_n - \breve{K}_n$. As Ω_n and Ω_n' are bounded closed convex sets, the optimization problems (5.2) and (5.3) have one and only one solution, defining sequences of functions approximating the optimal solution to optimal norm problems (4.4) and (4.5) for $n\in\mathbb{N}$.

THEOREM 9. *Let assumptions* A1, A2, A3 *and condition* (3.5) *be verified. Also, assume that* $\partial_r(\Gamma)\geq 2$, $\partial_r(\gamma)\geq 2$, *and that* $\breve{K}$ *does not belong to* $\Omega\cap\Theta$. *Then the sequences* $\{\hat{K}_n\}$ *and* $\{\hat{G}_n\}$ *of all solutions to* (5.2) *and* (5.3) *for all* $n\in\mathbb{N}$ *converge strongly in* $H_+^{2,-k}$ *to the optimal solutions to* (4.4) *and* (4.5), *respectively.*

Remark 10. Note that the strong convergence in $H_+^{2,-1}$ happens only if $k=1$ and condition (3.5) is verified, as in [9].

In the proof of Theorem 8, (5.1) and (5.2) are characterized by linear variational inequalities on $H_+^{2,-k}$. Galerkin methods are powerful for solving this type of inequality in functional spaces [31], generating linear matrix inequalities (LMIs) after the

choice of a basis for $H_+^{2,-k}$. Another approach to problems (4.4) and (4.5) is the one presented under the name of best approximation, using convex projections or proximinal maps (the mapping from $\check{K}$ to $\hat{K}$). This approach is interesting for minimum norm problems in Hilbert spaces, as in the present paper, where the proximinal map is continuous (see [32, pp. 157, 164]). The same reference shows the difficulties when the problem is considered in H_+^∞, which is not a reflexive Banach space (see [32, p. 77]).

Theorems 8 and 9 deal with convergence in $H_+^{2,-1}$, not in H_+^∞. In general, strong $H_+^{2,-1}$ convergence does not imply H_+^∞ strong convergence. It allows spikes in sequences converging to zero, as in $f_n(s) = (ns+1)^{-1}$ (see the proof of Remark 5 in Appendix A). Actually, $\hat{K}_n \to \hat{K}$ strongly in $H_+^{2,-1}$ implies $\Phi_{-1}\hat{K}_n \to \Phi_{-1}\hat{K}$ in measure on the imaginary axis and $\hat{K}_n \to \hat{K}$ in measure on any finite measure subset of the imaginary axis. (In this case the $H_+^{2,-1}$ and H_+^2 strong topologies coincide.) From [33, Theorem 7.11, p. 73], this implies the almost uniform convergence on the finite measure subset. But this result does not imply H_+^∞ strong convergence even in those subsets. In spite of these difficulties, the next theorem and remark show some relevant results in H_+^∞.

THEOREM 10. *If the sequence $\hat{K}_n$ converges to $\hat{K}$ strongly in $H_+^{2,-1}$, as in Theorem 9, then it converges to $\hat{K}$ in the weak topology of H_+^∞.*

Remark 11. If the sequence $\hat{K}_n$ converges to $\hat{K}$ weakly in $H_+^{2,-1}$, as in Theorem 8, then it is possible to prove, after some identifications, that $\hat{K}_n$ converges to $\hat{K}$ in the weak-star topology of $(H_+^\infty)'$.

To end the theoretical presentation of Galerkin methods, some generator set for $H_+^{2,-1}$ and for $H_+^{2,-k}$ must be presented. Due to the density of H_+^2 in $H_+^{2,-k}$, $k \geq 1$, any one of the bases obtained from the Runge theorem [34] for the space of analytic functions on C_+^0 can be used. Note that the topology used in the Runge theorem (the topology of the uniform convergence in all compacts in C_+^0) is finer than the $L^2(i\mathbb{R})$ topology. An example, already used in [15], is the Laguerre orthonormal basis in H_+^2:

$$\left\{ L_n = \sqrt{2a}\ \frac{(s-a)^{n-1}}{(s+a)^n}, \quad n \in \mathbb{N} \right\} \text{ for each positive real number } a.$$

The numerical experiments in [22] show the interest in the use of redundant sets of generators, as

$$\left\{ L_0 = 1, L_n = \sqrt{2a}\ \frac{(s-a)^{n-1}}{(s+a)^n}, \quad n \in \mathbb{N} \right\} \text{ for each positive real number } a,$$

which capture more quickly the asymptotic behavior of the optimal solutions. The proofs of Theorems 8 and 9 apply to these redundant sets without changes.

An orthonormal basis for $H_+^{2,-1}$, in relation to the inner product $\langle \ldots, \ldots \rangle_{\Gamma_{-1}}$, is given by

$$\left\{ M_0 = 1, M_n = \sqrt{2a}\ (1-s)\ \frac{(s-a)^{n-1}}{(s_a)^n}, \quad n \in \mathbb{N} \right\}.$$

Note that $\partial_r(M_n) = 0$, which differs from the Laguerre basis. Reference [22] presents other orthonormal bases for $H_+^{2,-k}$ built under the same principle, with the poles of Φ^* as the zeros of the basis functions. The numerical solution of (5.2) needs some mathematical programming development [22], which will be presented in a future paper. Some comments about the numerical procedure following the developments in [22] will be presented next.

After the choice of a redundant generator set, say $\{1, \beta_n, n \in \mathbb{N}\}$, and the choice of the number of poles of $K_n(s)$, say n, the functions $K_n(s)$ in the finite-dimensional space H_n can be represented as

$$K_n(s) = \sum_{m=0}^{n} \alpha_m \beta_m(s),$$

where $\beta_0(s)$ represents the constant function. By substitution of this last expression in (5.1) or (5.2) an $(n+1)$-dimensional programming problem is defined, whose variable is the $(n+1)$-vector $\vec{\alpha} = (\alpha_0, \alpha_1, \ldots, \alpha_n)^T$. The integrals in the quadratic functional calculation can be performed analytically, being this functional quadratic in $\vec{\alpha}$. Quadratic constraints are differentiable and can be considered by usual methods [22], but not the H^∞ constraints. Actually, there is no need to explicitly calculate these hard constraints, but only a generalized gradient. The reason is that the finite-dimensional constrained optimization problem was solved by a penalty method coupled with the known BFGS algorithm, where the position of the H^∞ constraint gradient (which does not exist) was provided by a generalized gradient. If this constraint is represented by

$$\sup |A(i\omega)K_n(i\omega) + B(i\omega)| - \lambda \leq 0,$$

it is proved in [22] that the derivative of $|A(i\omega)K_n(i\omega) + B(i\omega)|$ for $\omega = \omega_0$, ω_0 being one of the values where this function assumes its maximum, is a generalized gradient for the constraint. The ω_0 calculation uses the tools of H^∞ theory, as shown in [6]. Note that the procedure should consider also the case where $\omega_0 = \infty$. The convergence of this procedure was proved in [22], and the authors did not find significant problems in obtaining the optimal parameters $\hat{K}_n$ after performing the functional calculations through state variable and Lyapunov equation tools.

6. Numerical example. The example shown here was developed in [22], where a more complete discussion can be found. It represents the pitch optimal control of a fighter airplane described in [35] to exemplify LQG/LQR design, and it is used in [36] to exemplify the dual method from Corrêa [1]. In this example the transfer function from the elevation angle to the attitude angle is

$$P(s) = \frac{-(948{,}12s^3 + 30325s^2 + 56482s + 1215.3)}{s^6 + 64.554s^5 + 1167s^4 + 372.86s^3 - 5495.4s^2 + 1102s + 708.1},$$

the quadratic criterion being the one defined in [9] with weighting filters and weighting coefficients given by

$$\phi_w(s) = 0, \quad \phi_d(s) = \frac{1}{s^2 + 2s + 2}, \quad \phi_v(s) = \frac{1}{s + 10}, \quad \rho_v = \rho_d^n = \rho_v^u = 1.$$

After some calculations, the optimal control problem criterion can be transformed in

$$J_2[K(s)] = \|A(s) + B(s)K(s)\|_2^2 + J_F,$$

where $A(s)$ and $B(s)$ are 14th- and 10th-order rational functions (presented in Appendix B), both with unitary relative degree, $J_F = 0.30612$, and $K(s)$ is the rational proper and stable Youla parameter. The stability margin functional for the control problem, after some transformations to put it in Nehari form [22], is given by

$$J_\infty[K(s)] = \|K(s) - F_0(s)\|_\infty,$$

TABLE 1
Characteristics of some related controllers.

$K(s)$	$J_2[K(s)]$	$J_\infty[K(s)]$	Order
$K_{H2}(s)$	0.306120137	2.07804793	17
$K_{H\infty}(s)$	3.964188309	0.61051297	1
$K_{SPQ}(s)$	2.141469573	0.67180700	29
$K_{SPQR}(s)$	2.141470588	0.67193138	14

$F_0(s)$ being a second-order unstable proper rational function (also presented in Appendix B) with unitary relative degree. The minimum value for $J_\infty[K(s)]$, i.e., the optimal stability margin, is 0.610513.

If we define the robustness constraint allowing a 10% degradation of the optimal stability margin, the H^2/H^∞ problem to be solved becomes

$$\text{Find } K(s) \text{ minimizing } J_2[K(s)] \text{ subject to } J_\infty[K(s)] \leq \gamma = 0.6715643.$$

Assumptions A1 and A2, with $k = p = 1$, condition (3.5), and the others conditions on Theorem 7 are verified. Then, by Theorem 7 this problem has one and only one solution in $H_+^{2,-1}$, belonging to H_+^∞. Also, by Theorem 9 the sequence of functions generated by the Galerkin method, as exposed in section 5, converges strongly to the H^2/H^∞ problem optimal solution for any basis or redundant generator set in $H_+^{2,-1}$.

Table 1 presents some characteristics of controllers solving related optimal control problems, where $K(s)$ is the optimization parameter used to obtain a controller by the Youla parameterization. In the first column,

- $K_{H2}(s)$ represents the Youla parameter corresponding to the controller minimizing the quadratic criterion $J_2[K(s)]$ without constraints (the H^2 optimal controller);
- $K_{H\infty}(s)$ represents the Youla parameter corresponding to the controller minimizing the stability margin (the H^∞ optimal controller);
- $K_{SPQ}(s)$ represents the Youla parameter corresponding to an infeasible controller approximating the H^2/H^∞ problem solution (with $\gamma = 0.6715643$) calculated by the dual method from Corrêa [1];
- $K_{SPQR}(s)$ represents the Youla parameter corresponding to a reduced order controller generated from $K_{SPQ}(s)$ by truncation of a balanced realization.

Note that $K_{SPQ}(s)$ and $K_{SPQR}(s)$ do not verify the stability margin constraint, as expected, i.e., they are not feasible.

Table 2 presents the same characteristics for the controllers obtained by Galerkin method, $n = 1, \ldots, 9$, using the redundant generator set based on Laguerre functions as in section 4, $\gamma = 0.6715643$.

First, all solutions are feasible, as expected. Second, the greater the order, the smaller the quadratic criterion value. Third, comparing the values of $K_9(s)$ and $K_{SPQ}(s)$ and using the dual solutions properties, we verify that

$$J_2[K_{SPQ}(s)] = 2.141469573 < J_2[\hat{K}(s)] < 2.175038 = J_2[K_9(s)],$$

$\hat{K}(s)$ being the H^2/H^∞ problem optimal solution. Therefore, the difference between the quadratic criterion value error of $K_9(s)$ and the quadratic criterion value error of the optimal solution is less than 1.54%.

Table 3 presents the same characteristics for the optimal controllers obtained by the Galerkin method using an $H_+^{2,-1}$ basis generated step by step by minimization

of the quadratic criterion (under the H^∞ constraint) as a function of both the basis coefficients and the basis poles [22]. The optimization problem to be solved for each dimension n is not convex. Then the usual optimization algorithms give only H_n locally optimal solutions, depending on the algorithm initialization. The BFGS method extended for generalized gradients was used to solve the finite-dimensional optimization problems, the constraints considered by a Lagrangian method [22]. As above, $\gamma = 0.6715643$.

Note that $K_{4A}(s)$ and $K_{5A}(s)$ are equal: the new dimension did not allow a smaller criterion value for the chosen initialization vector. The local character of the n-dimensional numerical optimization and its dependence on the initialization vector is shown by the worst behavior of $K_{2A}(s)$ in relation to $K_2(s)$. In spite of those difficulties, the 6th-order controller attains a smaller criterion value than $K_9(s)$, which allows us to find a best estimation for the criterion optimal value and a best approximation for the optimal controller (corresponding to $K_{6A}(s)$):

$$J_2[K_{SPQ}(s)] = 2.141469573 < J_2[\hat{K}(s)] < 2.164122 = J_2[K_{6A}(s)],$$

with a relative error smaller than 1.05%.

For the sake of comparison, Figures 1, 2, and 3 show the Bode diagrams for the functions $K_{SPQ}(s) - F_0(s)$, $K_9(s) - F_0(s)$, and $K_{6A}(s) - F_0(s)$, respectively. It was verified in [22] that Bode diagrams for the Galerkin approximations do not show significant changes after a sufficiently great dimension n, and they do not present "spikes" in spite of the discussion just before Theorem 10. Numerical calculations were performed on a PC using MATLAB.

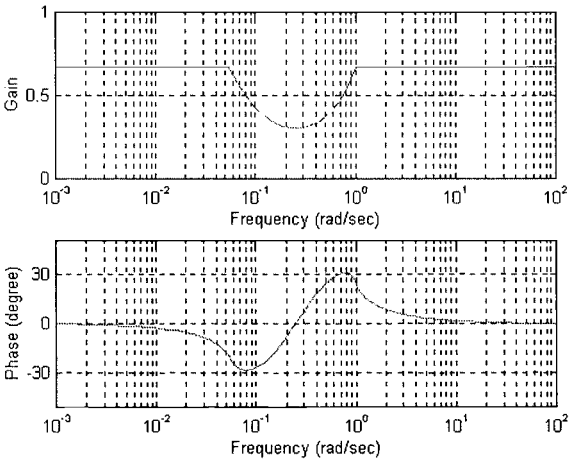

FIG. 1. *Bode diagrams for the function* $K_{SPQ}(s) - F_0(s)$.

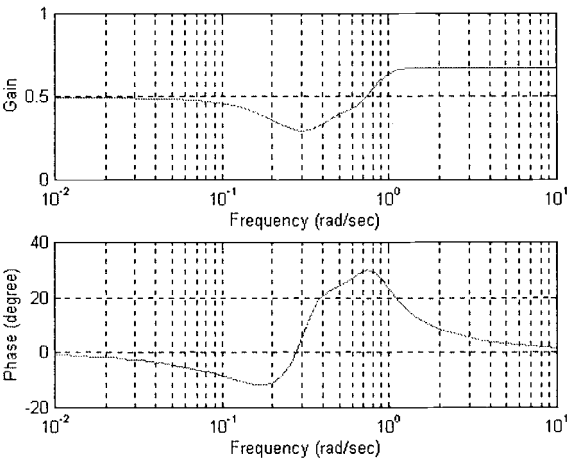

FIG. 2. *Bode diagrams for the function* $K_9(s) - F_0(s)$.

7. Conclusions and comments. In this paper the H^2/H^∞ problem was studied in the context of weighted Hardy spaces, allowing the proof of the existence and uniqueness of its solution and the proof of the convergence of the Galerkin method. Note that this method solves only one convex programming problem after the choice of the controller order.

The extension of these results to the multivariable case is straightforward but tedious, in light of the existing techniques presented, for example, in [8] and [37]. Essentially, consider the following notations: $M[A]$ denotes the set of matrices with entries in A and the dimensions established by the context, K^T denotes the transpose of the matrix K, $[K(s)]^* = [K(-s)]^T$, $\Phi(s)$ denotes a maximal rank real-rational matrix in $M[R_{1-k}]$ with all its poles and zeros in C_+^0, and $\Gamma(s) = \Phi^*(s)\Phi(s)$ denotes a maximal rank real-rational para-Hermitian matrix,

$$\langle K, G\rangle_\Gamma = \int_{-\infty}^{\infty} \mathrm{Trace}\{K^*(i\omega)\Gamma(i\omega)G(i\omega)\}d\omega,$$

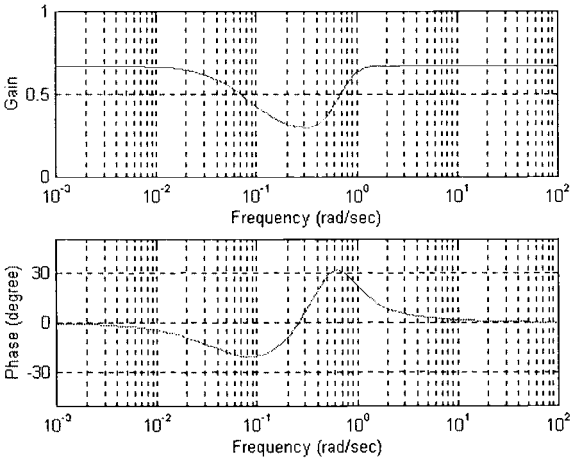

FIG. 3. *Bode diagrams for the function* $K_{6A}(s) - F_0(s)$.

$\|K\|_\Gamma = [\langle K, K\rangle_\Gamma]^{1/2}$, $\|K\|_\infty = \bar{\sigma}\{\|K_{jk}\|_\infty\}$ (the greatest singular value of the matrix whose entries are the H^∞ norm of the K-entries). With these notations the results presented in this paper can be rewritten *ipsis literis* on the spaces $M[L^2_{-k}(i\mathbb{R})]$, $M[H^{2,-k}_+]$, $M[H^{2,-k}_-]$, $M[H^\infty_+]$, and $M[H^\infty_-]$, with the use of $M[R_k]$, $M[R^+_k]$, and $M[R^-_k]$ and the obvious adaptations in notation and proofs. The conditions on zeros and poles can be written as $\det\{s^2\Gamma(i\omega)\} > \eta$ for some $\eta > 0$ and for each real number ω. This assumption is verified by the functional defined in section 2 [8], [9]. A serious problem not considered in this paper is the great number of entries in a multivariable basis, which increases dramatically the number of parameters in the optimization problems (4.1), (4.2), and (4.3). The most parsimonious basis, with the same poles in all the entries of the rational matrix $K(s)$, uses as many parameters as the product of the entry number by the number of parameters in the one-dimensional problem (i.e., for an m-dimensional problem on H_n, we have an nm-dimensional optimization problem).

The algorithms presented in sections 5 and 6 do not explore all the theoretical possibilities. The freedom in the choice of a generator set allowed by the Runge theorem linked to a convenient use of model order reduction algorithms by balanced realizations can be used to build an algorithm optimizing, in a certain sense, the generator set used in each step of the Galerkin method. The numerical behavior and the convergence of such an algorithm are better than the simpler algorithms proposed in this paper, as is shown in [22]. The presentation of the "optimized basis" methodology will be the subject of a future paper, where the mathematical programming algorithms to be used will be carefully developed.

Now, some regularity results will be considered, linking our results with [17], [18], and [19]. First, in Theorem 7 it is assumed that $\partial_r(\Gamma) \geq 2$ and $\partial_r(\gamma) \geq 2$, which imposes $H^{2,-1}_+$ as the natural space for the Youla parameter $K(s)$. Almost all the literature, in particular [14], [15], [16], [17], [18], [19], and [20], assume this parameter in H^2_+, which means $\partial_r(\Gamma) = 0$ and $\partial_r(\gamma) \geq 1$. Under these conditions, the optimal unconstrained parameter $\breve{K}$ belongs to H^2_+, $J[K] < \infty$ if and only if $K \in H^2_+$ (see section 3). Also the norm in problem (4.4) is equivalent to the H^2_+ norm. This problem can be relaxed to $H^{2,-1}_+$, where $J[\,.\,]$ is a strictly convex upper semicontinuous

functional [38]. As $\Omega \cap \Theta$ is a nonempty, convex, bounded, and closed subset of $H_+^{2,-1}$, problem (4.1) has one and only one solution $\hat{K}$ in this space [38]. But it is easy to show that there exists almost one $K \in \Omega \cap \Theta \cap H_+^2$. As $J[\hat{K}] \leq J[K] < \infty$, then $J[\hat{K}] < \infty$, which implies that $\hat{K} \in H_+^2$.

THEOREM 11. *Let assumptions* A1, A2, *and* A3 *with* $\partial_r(\Gamma) = 0$, $\partial_r(\gamma) \geq 1$ *be verified. If the constraint set* $\Omega \cap \Theta$ *is nonempty, then the optimal control problem* (4.1) *has one and only one solution in* H_+^2.

The algorithm in section 5 applies without changes if used with the original Laguerre basis or any other complete set for H_+^2. Thus the sequence $\hat{K}_n$ generated by the Galerkin method approaches the optimal solution strongly in H_+^2 and weakly in H_+^∞.

Another optimal control problem (presented in [18] to obtain rational approximations in H_+^∞) searches for solutions in A_0, the class of continuous functions in the extended imaginary axis. It is known that $A_0 \cap H_+^\infty$ is the closure of the proper rational functions in H_+^∞ [30, p. 668]. Then we can redefine problems (4.1) and (4.4) with constraint set $\Omega_0 = \Omega \cap A_0$. As A_0 is a closed linear subspace of H_+^∞, Ω_0 is also closed and all the results apply. But the sequences defined in section 5 are the same for Ω as for Ω_0. Thus the optimal solutions for both the problems are the same, which implies that $\hat{K} \in A_0$. In spite of that regularity, $\hat{K}$ does not represent an exponentially stable linear system (except for trivial cases), as a consequence of [19]. Recall that exponentially stable systems with finite numbers of inputs and outputs are characterized by their transfer functions being in the algebra $\hat{A}_-(0)$ defined in section 1 (see [30, p. 364]).

THEOREM 12. *Let assumptions* A1, A2, *and* A3 *with* $\partial_r(\Gamma) = 2k$, $\partial_r(\gamma) \geq 2k+1$, $k \geq 0$, *be verified. The optimal solution* $\hat{K}(s)$ *to* (4.1) *or* (4.4) *belongs to* A_0, *but it is not a transfer function of an exponentially stable system; i.e., it does not belong to the algebra* $\hat{A}_-(0)$ *(except for trivial cases).*

This theorem rules out functions as e^{-s}, but not $e^{-s}/(s+1)$. Actually, $A_0 \supsetneq \hat{A}_-(0)$, the latter algebra being dense in the former (because $\hat{A}_-(0)$ contains the Laguerre functions). Thus (4.1) with a constraint defined by $\Omega' = \Omega \cap \hat{A}_-(0)$ is not well-posed, the optimal solution in this case being the same as in the former problem, i.e., outside Ω', or, more precisely, in its H_+^∞-boundary.

In [18] a new optimal control problem is defined with an exponentially stable solution. The last paragraph shows that it is necessary to change the problem structure to force optimal controllers in $\hat{A}(0)$. An example of such a new problem, simpler than the one proposed in [18], is to find $\hat{K}_\varepsilon$ such that

$$J_\varepsilon(\hat{K}_\varepsilon) = \inf_{K \in \Omega_\varepsilon} \left\{ \int_{-\infty}^{\infty} [K^*(s)\Gamma(s)K(s) - 2K^*(s)\gamma(s)]_{s=i\omega-\varepsilon} d\omega \right\}, \tag{7.1}$$

where Ω_ε has the same definition as Ω but with the supremum taken in the imaginary axis translated to the left by ε, the positive real number ε sufficiently small to have $s\Gamma(s)$ bounded from zero and without poles or zeros and $\gamma(s)$ without poles in the vertical strip

$$\{s = \sigma + i\omega, \omega \in \mathbb{R}, -\varepsilon \leq \sigma \leq \varepsilon\}.$$

This new problem can be solved in the spaces $H_{+,\varepsilon}^{2,-1}$ and $H_{+,\varepsilon}^\infty$, defined on the semiplane $\{s \in \mathbb{C} : \mathrm{Re}\{s\} > -\varepsilon\}$ similarly to $H_+^{2,-1}$ and H_+^∞ but with the norms calculated on the translated imaginary axis $i\mathbb{R}_\varepsilon = \{s = -\varepsilon + i\omega, \omega \in \mathbb{R}\}$. It is straightforward to

extend calculations in sections 4 and 5 to this new problem, proving the existence and uniqueness of solutions. Applying the Galerkin method to a generator set composed by rational functions with all poles at the left of $i\mathbb{R}_\varepsilon$, we can find an approaching sequence $\hat{K}_{n\varepsilon}$ which converges to the optimal parameter $\hat{K}_\varepsilon$, strongly in $H^{2,-1}_{+,\varepsilon}$ and weakly in $H^{\infty}_{+,\varepsilon}$. Moreover, the optimal solution $\hat{K}_\varepsilon$ is analytic in an open strip containing the imaginary axis. Thus $\hat{K}_\varepsilon \in \hat{A}_-(0)$ is exponentially stable. We can show that (7.1) and the optimal control problem solved in [18] are approximations to (4.1) in the same sense. In spite of all these convergence results, conditions to $\hat{K}_n$ and $\hat{K}_\varepsilon$ converge to $\hat{K}$ strongly in H^{∞}_{+} remain an open problem.

Finally, the algorithm proposed in the present paper can be computed in polynomial time as the resolution of a finite-dimensional convex optimization problem by a quasi-Newton algorithm (in this case the generalized BFGS algorithm) after the choice of the controller order.

Appendix A. In this appendix we provide the proofs not presented in the main text.

Proof of comments after Definition 1. As $\langle f, g\rangle_{2,-k} = \langle \Phi_{-k} f, \Phi_{-k} g\rangle_2$ and $\Phi^*_{-k}(i\omega)\Phi_{-k}(i\omega) > 0$ for all ω, the announced properties are inherited from the inner product and the norm in $L^2(i\mathbb{R})$ if the integrals are finite. If $f \in R_{k-1}$, this last property is a consequence of f being a rational function without poles in $i\mathbb{R}$ and

$$\partial_r(f^*\Phi^*_{-k}\Phi_{-k}f) \geq (1-k) + 2k + (1-k) = 2$$

(then integrable on $i\mathbb{R}$). □

Proof of Theorem 1. (a) The function f belongs to $L^2_{-k}(i\mathbb{R})$ if and only if $\Phi_{-k}f$ belongs to $L^2(i\mathbb{R})$, by definition. As R_1 is dense in $L^2(i\mathbb{R})$ [26], $\Phi^{-1}_{-k}R_1$ is dense in $L^2_{-k}(i\mathbb{R})$. But $\Phi^{-1}_{-k}R_1 = R_{1-k}$. Indeed, if $f \in R_{1-k}$, $g = (\Phi_{-k})f$ belongs to R_1 because $\partial_r(\Phi_{-k}f) \geq 1$ and g has no poles in $i\mathbb{R}$. In the reverse direction, if f belongs to R_1, then $\Phi^{-1}_{-k}f$ belongs to R_{1-k} because $\partial_r(\Phi_{-k}f) \geq 1-k$ and f has no poles in $i\mathbb{R}$. Therefore, R_{1-k} is dense in $L^2_{-k}(i\mathbb{R})$. The same specified argument, when applied to R^+_1 and H^2_+, R^+_{1-k} and $H^{2,-k}_+$, R^-_1 and H^2_-, and R^-_{1-k} and $H^{2,-k}_-$, proves the stated densities. The final statement in (a) is a consequence of $L^2_{-k}(i\mathbb{R})$ being the completion of R_{1-k} in the norm $\|\,.\,\|_{2,-k}$; the same applies to H^2_+ in relation to R^+_1, to $H^{2,-k}_+$ in relation to R^+_{1-k}, etc.

(b) $H^{2,-k}_+$ and $H^{2,-k}_-$, as closures of R^+_{1-k} and R^-_{1-k} in $L^2_{-k}(i\mathbb{R})$, are closed subspaces.

(c) Theorem 1(c) follows straightforwardly from (a). Note that $e^{-s\Delta} \in H^{\infty}_+$ for Δ a positive real number because $e^{(a+\omega i)\Delta}$ is bounded on each vertical straight line in C^0_+ for each real $a < 0$. Then $e^{-s\Delta}$ belongs to $H^{2,-1}_+$.

Proof of Theorem 2. (a) As $k < m$, $\Phi_{-m} = \Phi\Phi_{-k}$ for some real-rational stable and minimum phase function with $\partial_r(\Phi) = m - k > 0$. Then a function f belongs to $L^2_{-m}(i\mathbb{R})$ if and only if Φf belongs to $L^2_{-k}(i\mathbb{R})$ as a consequence of Definition 3 and as a consequence of $\|f\|_{2,-m} = \|\Phi_{-m}f\|_2 = \|\Phi\Phi_{-k}f\|_2 = \|\Phi f\|_{2,-k}$. Therefore, the operator $f \to \Phi f$ is an isometry from $L^2_{-m}(i\mathbb{R})$ to $L^2_{-k}(i\mathbb{R})$, the inverse isometry being $g \to \Phi^{-1}_g$. By the Cauchy–Schwarz inequality applied in $L^2(i\mathbb{R})$,

$$\|f\|_{2,-m} = \|\Phi\Phi_{-k}f\|_2 \leq \|\Phi\|_2\|\Phi_k f\|_2 = \|\Phi\|_2\|f\|_{2,-k},$$

and, as $\|\Phi\|_2 < \infty$, $L^2_{-k}(i\mathbb{R}) \subset L^2_{-m}(i\mathbb{R})$. Then the isometry from $L^2_{-k}(i\mathbb{R})$ to $L^2_{-m}(i\mathbb{R})$ is an injective mapping and its inverse is a surjective mapping.

(b) Theorem 2(b) is a direct consequence of Theorems 1(b) and 2(a).

(c) Let $k \geq 0$. First, we will prove that R_1 is dense in R_0 in the $L^2_{-1}(i\mathbb{R})$ topology. Actually, we need only show that the constant function $f(s) \equiv 1$ is a limit of R_1-functions in this topology. Defining $f_n(s) = n(s+n)^{-1}$,

$$\|f_n - 1\|^2_{2,-1} = \int_{-\infty}^{\infty} \frac{\omega^2}{n^2+\omega^2} \frac{1}{1+\omega^2} d\omega = \frac{\pi}{n+1},$$

which converges to zero if n goes to ∞, showing the desired convergence and the stated density.

Second, as $R_0 \subset R_1 \subset L^2_{-1}(i\mathbb{R})$, R_1 is also dense in $L^2_{-1}(i\mathbb{R})$.

Third, as $R_1 \subset L^2(i\mathbb{R}) \subset L^2_{-1}(i\mathbb{R})$, the density of R_1 in $L^2_{-1}(i\mathbb{R})$ implies the density of $L^2(i\mathbb{R})$ in $L^2_{-1}(i\mathbb{R})$.

Fourth, more generally, let M be a total set in $L^2_{-k}(i\mathbb{R})$, $k < m$, and assume $f(s) \in L^2_{-m}(i\mathbb{R})$. Set

$$\int_{-\infty}^{\infty} f^*(i\omega)\Phi^*_{-m}(i\omega)\Phi_{-m}(i\omega)g(i\omega)d\omega = 0 \ \forall \ g(s) \in M,$$

which makes sense because $g(s) \in L^2_{-k}(i\mathbb{R}) \subset L^2_{-m}(i\mathbb{R})$. Then,

$$f\Phi_{-m}\Phi^*_{-m} \in L^2_{-m}(i\mathbb{R}) \subset L^2_k(i\mathbb{R}) \approx [L^2_{-k}(i\mathbb{R})]'$$

(where the symbol $\approx$ denotes the identification to be shown in Theorem 4(a) below, proved independently from the present theorem), implying that $f\Phi_{-m}\Phi^*_{-m}$ can be taken as the zero function. This implies that $f(s) \equiv 0$ because $\Phi_{-m}(i\omega)\Phi^*_{-m}(i\omega)$ is strictly positive for all real ω. Therefore, as $g(s)$ is any function in a total set, the set M is also total in $L^2_{-m}(i\mathbb{R})$ by a known corollary of the Hahn–Banach theorem. From $k < m$, $L^2_{-k}(i\mathbb{R}) \subset L^2_{-m}(i\mathbb{R})$, proving the density of the first in the second.

Analogous arguments can be used for $H^{2,-k}_+$ and $H^{2,-k}_-$.

(d) Assume that f_n converges to f in H^∞_+. Then

$$\begin{aligned}
\|f_n - f\|^2_{2,-1} &= \int_{-\infty}^{\infty} |f_n(i\omega) - f(i\omega)|^2 \ |\Phi_{-1}(i\omega)|^2 \, d\omega \\
&\leq \operatorname*{ess\,sup}_{\omega \in R} \ \{|f_n(i\omega) - f(i\omega)|^2\} \int_{-\infty}^{\infty} \Phi^*_{-1}(i\omega)\Phi_{-1}(i\omega)d\omega \\
&\leq \|f_n - f\|^2_\infty \|\Phi_{-1}\|^2_2,
\end{aligned}$$

and because $\|\Phi_{-1}\|^2_2$ is finite, f_n converges to f in $L^2_{-1}(i\mathbb{R})$. The stability of f is assured because $f \in H^\infty_+$. To complete the proof, let us now exhibit a function in $H^{2,-1}_+$ that does not belong to H^∞_+. First, note that there are unbounded functions in $L^2(i\mathbb{R})$, as $g(i\omega) = |i\omega|^{-1/4}\chi_{[-1,1]}$, where $\chi_{[-1,1]}$ denotes the characteristic function of the closed interval $[-1,1]$. Straightforward calculations show that $\|g\|_2 = 2$ and that $|g(i\omega)|$ diverges when ω goes to zero. As a $L^2(i\mathbb{R})$ function, $g = g_+ + g_-$, where $g_+ \in H^2_+$ and $g_- \in H^2_-$. Both functions cannot be simultaneously bounded, because g is not bounded. If g_+ is unbounded, it is the example completing the proof, because $g_+ \in H^2_+ \subset H^{2,-1}_+$ but $g_+ \notin H^\infty_+$. If g_+ is bounded, g_- is unbounded, and $g^*_-(s) = g_-(-s) \in H^2_+ \subset H^{2,-1}_+$ and is unbounded because $|g^*_-(s)| = |g_-(s)|$, $g^*_-(s)$ being the example, and completing the proof. ∎

Proof of Remark 2. Remark 2 is proved in (c) above if we note that

$$\|f_n\|_2^2 = \int_{-\infty}^{\infty} \frac{n^2}{n^2+\omega^2} d\omega = n\pi,$$

which implies that the sequence $\{f_n\}$ does not converge in $L^2(i\mathbb{R})$ when n goes to ∞, in spite of its convergence in $H_+^{2,-1}$. □

Proof of Theorem 3. (a) As $k \le m$, $\Phi_{-m} = \Phi\Phi_{-k}$ for some real-rational stable and minimum phase function with $\partial_r(\Phi) = m - k \ge 0$. First, if $\|f\|_{2,-k} \le M$, by the Cauchy–Schwarz inequality

$$\|f\|_{2,-k} \le \|f\|_{2,-m}\|\Phi\|_2 \le M\|\Phi\|_2,$$

proving the first part of the statement. Second, the closed balls of $L^2_{-k}(i\mathbb{R})$ are closed in $L^2_{-m}(i\mathbb{R})$ as an inverse image of closed sets by an isometric isomorphism (see Lemma 2).[1]

Third, if Ω is a bounded closed set in $L^2_{-k}(i\mathbb{R})$, it is within a closed ball in $L^2_{-k}(i\mathbb{R})$, which is a closed subset of $L^2_{-m}(i\mathbb{R})$. As Ω is closed in a closed subset of a metric subspace of $L^2_{-m}(i\mathbb{R})$, Ω is also closed in $L^2_{-m}(i\mathbb{R})$ (see Theorem 2,II,9,2,b in [25], page 27). Fourth, as $H_+^{2,-k}$ is a closed subspace of $L^2_{-k}(i\mathbb{R})$, the last property is inherited by $H_+^{2,-k}$.

(b) First, if $\|f\|_\infty \le M$,

$$\|f\|_{2,-1}^2 = \int_{-\infty}^{\infty} |f(i\omega)|^2\, |\Phi_{-1}(i\omega)|^2 d\omega \le \|f\|_\infty^2 \|\Phi_{-1}\|_2^2 \le M^2\|\Phi_{-1}\|_2^2 < \infty,$$

which shows that bounded subsets of H_+^∞ are bounded in the $L^2_{-1}(i\mathbb{R})$ metric.

Second, it will be shown that the closed balls in H_+^∞ are closed in $H_+^{2,-1}$. For that, let $\{f_n\}$ be a sequence in a closed ball of H_+^∞ with radius M, i.e., $\|f_n\|_\infty \le M$ for all $n \in \mathbb{N}$. Let $f \in H_+^\infty$ with $\|f\|_\infty > M$. Thus there is a positive real number ε so that $\|f\|_\infty$ is strictly greater than $M + 2\varepsilon$. The definition of "essential supremum" implies that there exists a set $E \subset \mathbb{R}$ with strictly positive measure so that $|f(i\omega)| > M + \varepsilon$ for all $\omega \in E$. Therefore, f_n does not converge to f in $H_+^{2,-1}$ because

$$\begin{aligned}
\|f_n - f\|_{2,-1}^2 &= \int_{-\infty}^{\infty} |f_n(i\omega) - f(i\omega)|^2\, |\Phi_{-1}(i\omega)|^2\, d\omega \\
&\ge \int |f_n(i\omega) - f(i\omega)|^2\, |\Phi_{-1}(i\omega)|^2\, d\omega \\
&\ge \int_E |f(i\omega)^2 |\Phi_{-1}(i\omega)|^2 d\omega - \int_E |f_n(i\omega)|^2\, |\Phi_{-1}(i\omega)|^2 d\omega \\
&> [(M+\varepsilon) - M] \int_E |\Phi_{-1}(i\omega)|^2 d\omega = \varepsilon \int_E |\Phi_{-1}(i\omega)|^2 d\omega > 0,
\end{aligned}$$

[1] A more direct proof uses the weak continuity of the multiplication by Φ. Indeed, reasoning on $L^2(i\mathbb{R})$, $L^2_{-1}(i\mathbb{R})$, if $f_n \to f$ weakly in $L^2(i\mathbb{R})$, $|\int (f_n - f)\Phi g d\omega| \le \|\Phi\|_\infty \int |(f_n - f)g| d\omega \to 0$ for all g in $L^2(i\mathbb{R})$. Then, if for all $n \in \mathbb{N}$, $\|f_n\|_2 \le M$, there is a subsequence, say $\{f_m\}$, converging weakly in $L^2(i\mathbb{R})$ to a limit f_n such that $\|f_w\|_2 \le M$ (see [28, p. 26]). The weak continuity proved above implies that Φf_m converges weakly in $L^2(i\mathbb{R})$ to Φf_w. However, as f_n converges to f strongly in $L^2_{-1}(i\mathbb{R})$, Φf_n converges strongly to Φf in $L^2(i\mathbb{R})$, and then Φf_n converges weakly to Φf in $L^2(i\mathbb{R})$. As $\{f_m\}$ represents a subsequence of $\{f_n\}$, $\Phi f_w = \Phi f$ (which implies $f_w = f$ in $L^2(i\mathbb{R})$ because $\Phi(\,.\,)$ is a continuous bounded function with no zeros on $i\mathbb{R}$), it follows that $\|f\|_2 \le M$, proving that the closed ball with radius M in $L^2(i\mathbb{R})$ is also closed in $L^2_{-1}(i\mathbb{R})$. The same reasoning applies to $L^2_{-k}(i\mathbb{R})$ for any integer k.

the last integral being strictly positive because $\Phi_{-1}(i\omega)$ is continuous and strictly positive on the real axis. The contrapositive proposition is

$$\text{If } f_n \to f \text{ in } H_+^{2,-1}, \text{ then } \|f\|_\infty \le M,$$

implying that closed balls of H_+^∞ are also closed in the $H_+^{2,-1}$ topology.

Third, if Ω is a bounded closed set in H_+^∞, it is contained in a closed ball in H_+^∞, which is a closed set in $H_+^{2,-1}$. As Ω is closed in a closed subset of a metric subspace of $H_+^{2,-1}$, Ω is also closed in $H_+^{2,-1}$ (see Theorem 2,II,9, 2,b in [25], page 27). ∎

Proof of Remark 5. Let $f_n(s) = (ns+1)^{-1}$, $n \in \mathbb{N}$. These functions belong to H_+^∞ with $\|f_n\|_\infty = f_n(0) = 1$. Also

$$\|f_n\|_2^2 = \int_{-\infty}^{\infty} \frac{(1/n)^2}{(1/n)^2 + \omega^2} d\omega = \frac{\pi}{n}.$$

Therefore, the sequence $f_n(s)$ converges to zero in H_+^2 and, a fortiori, in $H_+^{2,-1}$. But it does not converge to zero in H_+^∞. Now, let $g(s) \in H_+^\infty$ be any function such that $\|g\|_\infty \le 1$. Then $g_n(s) = g(s) + 3f_n(s)$ converges to $g(s)$ in $H_+^{2,-1}$ but does not converge in H_+^∞ because $\|g_n\|_\infty > 2$ for all n. Therefore, any function in the closed unit ball in H_+^∞ can be strongly approximated in $H_+^{2,-1}$ by functions in the exterior of this ball: all the functions in this set are in its $H_+^{2,-1}$ boundary. The H_+^∞ closed balls have an empty interior in the $H_+^{2,-1}$ topology. ∎

Proof of Theorem 4. (a) As continuous linear functionals on Hilbert spaces are uniformly continuous, we need to prove the statement only on R_{1-k}^+, a dense subset of $H_+^{2,-k}$ [38, p. 98]. In this case, as $\gamma(s)$ and $f(s)$ have no poles on the imaginary axis, the integral will be finite if and only if $\partial_r(f) + \partial_r(\gamma) \ge 2$. This occurs for all $f \in R_{1-k}^+$ if and only if $\partial_r(\gamma) \ge 2 - (1-k) = k+1$. Also, $(\Phi_{-k}^*)^{-1}\gamma \in L^2(i\mathbb{R})$ and $\Phi_{-k} f \in L^2(i\mathbb{R})$. Then, by the Cauchy–Schwarz inequality, the linear functional $F(f)$ is continuous on R_{1-k}^+ because

$$\left| \int_{-\infty}^{\infty} f^*(i\omega)\gamma(i\omega)d\omega \right| = \left| \int_{-\infty}^{\infty} (f\Phi_{-k})^*(i\omega)[(\Phi_{-k}^*)^{-1}\gamma](i\omega)d\omega \right|$$
$$\ge \|(\Phi_{-k}^*)^{-1}\gamma\|_2 \, \|f\|_{2,-k}.$$

(b) As a consequence of (a), a rational function $g(s)$ is in the dual space of $H_+^{2,-k}$ if and only if $\partial_r(g) \ge k+1$, i.e., $g \in H_+^{2,k}$. As the dual of $H_+^{2,-k}$ is a Hilbert space, the completion argument proves the statement. ∎

Proof of Theorem 5. (a) The statement is an adaptation of the known Youla Theorem; see [28].

(b) We need to prove the statement only on R_{1-k}^+, a dense subset of $H_+^{2,-k}$ (see [38, p. 100]). Now, if $f(s)$ is a rational function without poles on $i\mathbb{R}$,

$$\int_{-\infty}^{\infty} f^*(i\omega)\Gamma(i\omega)f(i\omega)d\omega = \int_{-\infty}^{\infty} [\Phi f(i\omega)]^*[\Phi f(i\omega)]d\omega = \|\Phi f\|_2^2 < \infty$$

if and only if $\partial_r(f\Phi) \ge 1$, i.e., $\partial_r(f) \ge 1-k$ or $f \in H_+^{2,-k}$.

Also, as $\Phi(s)$ and $\Phi_{-k}(s)$ are rational functions with no poles or zeros on $i\mathbb{R}$, and those functions have the same relative degree, there are real numbers α and β such that

$$0 < \alpha \le |\Phi(i\omega)\Phi_{-k}^{-1}(i\omega)| \le \beta < \infty.$$

This implies that if $f \in R^+_{1-k}$, then

$$\alpha\|f\|^2_{2,-k} \le \int_{-\infty}^{\infty} f^*(i\omega)\Gamma(i\omega)f(i\omega)d\omega = \|\Phi f\|_2^2 \le \beta\|f\|^2_{2,-k}.$$

Thus $\|\Phi f\|_2$ defines a norm equivalent to $\|f\|_{2,-k}$, the quadratic functional being continuous on R^+_{1-k} as the square of an equivalent norm. Finally, if $m < k$ and $f \in H_+^{2,-m}$, $\|f\Phi_{-m}(i\omega)|^2$ and $|\Phi\Phi^{-1}_{-m}(i\omega)|^2$ belong to $L^2(i\mathbb{R})$, then

$$\int_{-\infty}^{\infty} f^*(i\omega)\Gamma(i\omega)f(i\omega)d\omega = \int_{-\infty}^{\infty} [\Phi_{-m}f(i\omega)]^*[\Phi_{-m}f(i\omega)][\Phi\Phi^{-1}_{-m}(i\omega)]^*[\Phi\Phi^{-1}_{-m}(i\omega)]d\omega$$

$$\le \|\Phi\Phi^{-1}_{-m}\|_2^2\|\Phi_{-m}f\|_2^2 = \|\Phi\Phi^{-1}_{-m}\|_2^2\|f\|^2_{2,-m}$$

by the Cauchy–Schwarz inequality. Therefore, the quadratic functional is continuous in $H_+^{2,-m}$ at the origin, then continuous in $H_+^{2,-m}$ for $m < k$.

The coerciveness on $H_+^{2,-k}$ was shown above, where α is the coerciveness constant. For $m < k$ and $f \in H_+^{2,-m}$, let

$$f_n(s) = \Phi^{-1}_{-m}(s)[s\sqrt{n}(s+n)^{-2}], \qquad \Phi(s)\Phi^{-1}_{-m}(s) = g(s)(s+1)^{-1},$$

where $|g(i\omega)|^2 \le \beta^2 < \infty$ for some real number β because $g(s)$ is a proper rational function without poles on the imaginary axis. Straightforward calculations show that

$$0 \le \|\Phi f_n\|_2^2 \le \beta^2 \left\| \frac{1}{s+1}\frac{s\sqrt{n}}{(s+n)^2}\right\|_2^2 = \beta^2\frac{(2n^2-2n+1)\pi}{2(n^2-1)^2},$$

which converges to zero when n goes to infinity. But $\|f_n\|^2_{-m} = \pi/2$ for all n. Then there is no real number α such that $\alpha^2\|f_n\|^2_{-m} \le \|\Phi f_n\|_2^2$ for all n, which shows that the quadratic functional is not coercive on $H_+^{2,-m}$ for $m < k$.

The proof of the strictly convexity is straightforward. □

Proof of Corollary 1. As $\partial_r(\breve{K}) = \partial_r([(\Phi^*)^{-1}\gamma]_+) - k$, then $\partial_r(\breve{K}) \ge 0$ if and only if $\partial_r([(\Phi^*)^{-1}\gamma]_+) \ge k$. If $\partial_r(\gamma) \ge 2k$, then $\partial_r((\Phi^*)^{-1}\gamma) \ge k$, implying that $\partial_r([(\Phi^*)^{-1}\gamma]_+) \ge k$, which proves the sufficiency of the condition. If $k = \partial_r(\Phi) \le 1$, as $\partial_r([(\Phi^*)^{-1}\gamma]_+) \ge 1$, then $\partial_r(\breve{K}) \ge 0$. □

Proof of comments about condition (3.5). We need to prove that condition (3.5) is inherited by a finite sum of quadratic functional as in (3.4). To do that, denote the functional as

$$J[K] = \sum J_n[K], \qquad J_n[K] = \int_{-\infty}^{\infty}\{K^*\Gamma_n K - 2K^*\gamma_n\}d\omega, \quad \Gamma_n = \Phi_n^*\Phi_n.$$

Then

$$J[K] = \int_{-\infty}^{\infty}\{K^*\Gamma K - 2K^*\gamma\}d\omega \qquad \text{for } \Gamma = \Phi^*\Phi = \sum \Phi_n^*\Phi_n, \gamma = \sum \gamma_n.$$

Let $\partial_r(\gamma_n) \ge \partial_r(\Phi_n) + 1$ and assumptions A1 and A2 hold for each n. Then

$$\partial_r\left(\sum \gamma_n\right) \ge \min\{\partial_r(\gamma_n)\},$$

as usual, but

$$\partial_r\left(\sum \Gamma_n\right) = \partial_r\left(\sum \Phi_n^* \Phi_n\right) = \min\{\partial_r(\Gamma_n)\}$$

because the numerator of the first term is a sum of para-Hermitian functions, each one strictly positive on the imaginary axis, which implies that its degree is the maximum degree of the parcels. See [9] for a complete development of this argument. Therefore,

$$\partial_r\left(\sum \gamma_n\right) \geq \min\{\partial_r(\gamma_n)\} \geq \partial_r(\Phi_n) + 1 = \left(\frac{1}{2}\right)\min\{\partial_r(\Gamma_n)\} + 1$$

$$= \left(\frac{1}{2}\right)\min\left\{\partial_r\left(\sum \Gamma_n\right)\right\} + 1 = \partial_r(\Phi_n) + 1,$$

completing the proof. □

Proof of Theorem 8. Here the notations $\|\,.\,\|_\Gamma$ and $\langle\,.\,,.\,\rangle_\Gamma$ from section 4 will be used. The strictly convex criterion in (5.1) is a continuous function because H_n is finite-dimensional. Ω_n is a closed convex set as the interception of the closed convex sets Ω, Θ, and H_n. The set Ω_n is nonempty if the dimension n is sufficiently large because it is the closure of $\bigcup_{n=1}^{\infty} H_n$ in $H_+^{2,-1}$ and in A_0 in the correspondent topologies, and assumption A3 is verified. Therefore, if n is sufficiently large, then (5.1) has one and only one solution $\hat{K}_n$.

(a) For all $V \in H_1$, $\|\hat{K}_n\|_\Gamma \leq \|V\|_\Gamma$ because $\Omega_1 \subset \Omega_2 \subset \cdots \subset \Omega_n \subset \cdots \subset \Omega \cap \Theta$. Then the sequence $\{\hat{K}_n, n \in \mathbb{N}\}$ is bounded, which implies the existence of a weakly convergent subsequence that converges weakly in $H_+^{2,-1}$ to a function, denoted here by $\hat{K}_w$ (see the Bolzano–Weierstrass theorem, [29, p. 26]). This subsequence will be denoted by $\{\hat{K}_m, m \in \mathbb{N}\}$. Note that $\hat{K}_w$ depends on the chosen subsequence.

(b) As $\Omega \cap \Theta$ is convex and strongly closed, it is also weakly closed (see the Mazur theorem, [29, p. 20]). Then $\hat{K}_w \in \Omega \cap \Theta$.

(c) $\hat{K}_n$ is a solution of (5.1) if and only if it verifies the following variational inequality:

$$\langle V_m, V_m - \hat{K}_m\rangle_\gamma \geq 0 \;\forall\; V_m \in \Omega_m$$

(see [31, pp. 9–11] or, in a more general setting [32, p. 76]). The weak convergence of $\hat{K}_m$ implies the convergence of the inequality above to the condition

$$\langle V_m, V_m - \hat{K}_w\rangle_\Gamma \geq 0 \;\forall\; V_m \in \Omega_m$$

for each m used in the subsequence. As the sequence of spaces $\{H_n\}$ increases, then $\bigcup_{m=1}^{\infty} H_m$ is a dense subspace of $H_+^{2,-1}$ and $\bigcup_{m=1}^{\infty} \Omega_m \cup \Omega_m$ is a dense subset of $\Omega \cap \Theta$. Taking the limit in the last inequality, we arrive at

$$\langle V, V - \hat{K}_w\rangle_{2,-1} \geq 0 \;\forall\; V \in \Omega \cap \Theta,$$

a necessary and sufficient condition to $\hat{K}_w$ being the solution of (2.3). Then $\hat{K}_w$ equals $\hat{K}$, the solution of (4.1) for any subsequence $\hat{K}_m$ of the sequence $\hat{K}_n$ generated by the Galerkin method, which implies the weak convergence of this sequence to the optimal solution to (4.1). □

Proof of Theorem 9. First, it will be considered the situation where $\breve{K}_n = \breve{K}$, when (5.2) and (5.3) are essentially the same. Second, note that Theorem 8 can be

generalized to the space $H_+^{2,-k}$ without changes, which proves the weak convergence (in $H_+^{2,-k}$) of the sequences generated by (5.2) and (5.3), when $n \in \mathbb{N}$, meaning that $\hat{K}_n$ converges weakly to $\hat{K}$ and $\hat{G}_n + \breve{K}$ converges weakly to $\hat{G} + \breve{K} = \hat{K}$ in $H_+^{2,-k}$. Under the assumptions of Theorem 9 these sequences will converge strongly in $H_+^{2,-k}$ for the same limit. Indeed, the density of $\bigcup_{n=1}^{\infty} H_n$ in $H_+^{2,-k}$ and the fact that $\hat{G} \in \Omega' \cap \Theta'$, a closed convex set, imply that for all positive real numbers ε, there is an integer N such that $\|\hat{G} - G_n\|_\Gamma < \varepsilon$ for all $n > N$ and $G_n \in \Omega_n'$. Thus, by the triangle inequality,

$$\|G_n\|_\Gamma = \|G_n + \hat{G} - \hat{G}\|_\Gamma \leq \|G_n - \hat{G}\|_\Gamma + \|\hat{G}\|_\Gamma < \|\hat{G}\|_\Gamma + \varepsilon.$$

Squaring this expression and recalling the minimizing property of $\hat{G}$ in $\Omega' \cap \Theta' \subset \Omega_n'$, we have

$$(\|\hat{G}\|_\Gamma + \varepsilon)^2 = \|\hat{G}\|_\Gamma^2 + \varepsilon(2\|\hat{G}\|_\Gamma + \varepsilon) > \|G_n\|_\Gamma^2 \geq \|\hat{G}_n\|_\Gamma^2 \geq \|\hat{G}\|_\Gamma^2.$$

When ε tends to zero, $\|\hat{G}_n\|_\Gamma^2$ converges to $\|\hat{G}\|_\Gamma^2$.

Now an argument due to Riesz shows the strong convergence of $\hat{G}_n$ to $\hat{G}$:

$$\|\hat{G}_n - \hat{G}\|_\Gamma^2 = \langle \hat{G}_n - \hat{G}, \hat{G}_n - \hat{G} \rangle_\Gamma = \|\hat{G}_n\|_\Gamma^2 - 2\langle \hat{G}_n, \hat{G} \rangle_\Gamma + \|\hat{G}\|_\Gamma^2,$$

which goes to $\|\hat{G}\|_\Gamma^2 - 2\langle \hat{G}, \hat{G} \rangle_\Gamma + \|\hat{G}\|_\Gamma^2 = 0$ as n goes to ∞ by the weak convergence of $\hat{G}_n$ to $\hat{G}$ and by the norm convergence (showed above). This ends this part of the proof.

The strong convergence of $\hat{K}_n = \hat{G}_n + \breve{K}$ to $\hat{K} = \hat{G} + \breve{K}$ is a consequence of the continuity of the sum in Hilbert spaces.

Now, if $\breve{K}_n$ is the projection of $\breve{K}$ in Ω_n, then $\hat{K}_n = \hat{G}_n + \breve{K}_n$, where $\{\hat{G}_n\}$ is exactly the sequence considered above. As $\hat{G}_n$ converges strongly to $\hat{G}$ and $\breve{K}_n$ converges strongly to $\breve{K}$ (by the continuity of convex projections in Hilbert spaces [32, pp. 157–158]), $\hat{K}_n$ converges strongly to $\hat{K}$ in $H_+^{2,-k}$.

The strong convergence of $\hat{G}_n$ to $\hat{G}$, in the case where $\breve{K}_n$ is the projection of $\breve{K}$ in Ω_n, is now a consequence of the equivalence between (4.2) and (4.3).

To end the proof, note that $\Omega_n \subset H_+^{2,-1}$, which implies that $\hat{K}_n$ belongs to $H_+^{2,-1}$. Then the convergence of $\hat{K}_n$ in $H_+^{2,-k}$ implies the convergence in $H_+^{2,-1}$ to the same limit by the inverse isometry of Theorem 2(a). □

Proofs of Remark 11 *and Theorem* 10. First, note that

$$H_+^\infty \subset H_+^{2,-1} \approx (H_+^{2,-1})' = H_+^{2,1} \subset (H_+^\infty)',$$

H_+^∞ being dense in $H_+^{2,-1}$ and $(H_+^{2,-1})'$ being weak-star dense in $(H_+^\infty)'$ (apply the corollary in [25, p. 298] and T2, XIX, 7; 5, [25, p. 299]). Then $\hat{K}_n$, $\hat{K}$ above can be identified with functions in $(H_+^{2,-1})' \subset (H_+^\infty)'$ by $K \approx G_K(f) = \langle \Phi_{-1}K, \Phi_{-1}f \rangle_2$ for $f \in H_+^\infty$. Second, "$F_n \in (H_+^\infty)'$ converges to $F \in (H_+^\infty)'$ in the weak-star topology" means $F_n(g) \to F(g)$ for all $g \in H_+^\infty$.

If $\hat{K}_n \to \hat{K}$ weakly in $H_+^{2,-1}$, $\langle \Phi_{-1}\hat{K}_n, \Phi_{-1}g \rangle_2 \to \langle \Phi_{-1}\hat{K}, \Phi_{-1}g \rangle_2$ for each $g \in H_+^\infty$, which proves the sequence weak-star convergence in $(H_+^\infty)'$ and Remark 11.

Now, for Theorem 10, let $\hat{K}_n$ converge to $\hat{K}$ strongly in $H_+^{2,-1}$. For each functional $G \in (H_+^\infty)'$, let F_m be a functional sequence in $(H_+^{2,-1})'$ approaching G in the $(H_+^\infty)'$ weak-star topology, i.e., $F_m(g) \to G(g)$ for each $g \in H_+^\infty$. By the Banach–Steinhaus

theorem [25], the set $\{F_m\}$ is equicontinuous in $H_+^{2,-1}$. Thus $F_n(\hat{K}_n)$ converges to $G(\hat{K})$. Indeed,

$$|G(\hat{K}) - F_n(\hat{K}_n)| \le |F_n(\hat{K}_n) - F_n(\hat{K})| + |F_n(\hat{K}) - G(\hat{K})|,$$

the first term in the right going to zero because $\{F_m\}$ is equicontinuous and $\hat{K}_n \to \hat{K}$ strongly in $H_+^{2,-1}$, the second term in the right going to zero because $F_m(g) \to G(g)$ for each $g \in H_+^\infty$. Therefore, $G(\hat{K}_n)$ converges to $G(\hat{K})$ for each functional $G \in (H_+^\infty)'$, proving the weak convergence in H_+^∞. □

Appendix B. In this appendix we provide the numerical data for the example in section 5. Rational functions described in Table 4 have been calculated from the data $P(s)$, $\phi_w(s)$, $\phi_d(s)$, and $\phi_v(s)$ given in section 5 by solving some diophantine equations (arising from the parameterization of stabilizing controllers), a variable change to reduce the robustness condition to Nehari form was applied, and some cancellations of coincident poles and zeros were made. The first two calculations were performed by state variable methods, as exposed in [6], the cancellation being performed by model order reduction using the Hankel singular value technique. The use of double precision calculations was imperative.

Acknowledgments. The authors are indebted to an unknown referee for his (her) sound criticism and to the encouraging friendship of Professor Carlos Kubrusly.

EXISTENCE OF MINIMIZERS FOR NONCONVEX, NONCOERCIVE SIMPLE INTEGRALS*

P. CELADA† AND S. PERROTTA‡

Abstract. We consider the problem of minimizing autonomous, simple integrals such as

$$(\mathcal{P}) \qquad \min\left\{\int_0^T f\left(x(t)\,,x'(t)\right)\,dt\colon\ x\in AC([0\,,T]),\,x(0)=x_0,\,x(T)=x_T\right\},$$

where $f:\mathbb{R}\times\mathbb{R}\to[0,\infty]$ is a possibly nonconvex function with either superlinear or slow growth at infinity. Assuming that the relaxed problem $(\mathcal{P}^{**})$—obtained from $(\mathcal{P})$ by replacing f with its convex envelope f^{**} with respect to the derivative variable x'—admits a solution, we prove attainment for $(\mathcal{P})$ under mild regularity and growth assumptions on f and f^{**}. We discuss various instances of growth conditions on f that yield solutions to the corresponding relaxed problem $(\mathcal{P}^{**})$, and we present examples that show that the hypotheses on f and f^{**} considered here for attainment are essentially sharp.

Key words. nonconvex and noncoercive minimum problem, simple integrals, existence of solutions

1. Introduction.

This paper deals with the existence of solutions to variational problems for autonomous, simple integrals such as

$$(\mathcal{P}) \qquad \min\left\{\int_0^T f(x(t)\,,x'(t))\,dt\colon\ x\in AC([0\,,T]),\,x(0)=x_0,\,x(T)=x_T\right\},$$

where the Lagrangian function $f\colon\mathbb{R}\times\mathbb{R}\to[0\,,\infty]$ is a possibly nonconvex function of its second argument x'. Though the emphasis here is on the lack of convexity of f, we remark that we wish to consider either problems with slow growth, i.e., $f(\eta\,,\xi)$ has no superlinear growth as $|\xi|\to\infty$, or problems with an extended-valued Lagrangian f as it happens in the case of one-sided constraints on derivatives like $x'\geq 0$ or $x'>0$ almost everywhere on $[0\,,T]$.

As is well known, the lack of convexity of $f(\eta\,,\xi)$ with respect to ξ affects the sequential lower semicontinuity of the integral with respect to weak convergence in $AC([0\,,T])$, thus ruling out the possibility of establishing the existence of optimal configurations by means of the direct method of the calculus of variations. However, attainment is a quite typical behavior for variational, simple integrals, and the basic question for nonconvex minimum problems like $(\mathcal{P})$ becomes that of finding which conditions other than convexity of $f(\eta\,,\xi)$ with respect to ξ yield solutions to $(\mathcal{P})$.

This question has been widely investigated in recent years, mainly when f has a special form like $f(\eta\,,\xi)=h(\xi)+g(\eta)$ or $f(\eta\,,\xi)=g(\eta)h(\xi)$ with nonnegative g and h. In either case, a fairly complete understanding of attainment versus nonattainment

phenomena is now available: roughly speaking, attainment occurs provided $g \in \mathcal{C}(\mathbb{R})$ is such that (i) every point $t \in \mathbb{R}$ lies between two intervals where g is monotone, i.e., g does not oscillate too fast, and (ii) g has no strict, local minima. Moreover, well-known Bolza-type examples such as

$$\min\left\{\int_0^T \left[\left(|x'(t)|^2-1\right)^2+|x(t)|^2\right]\,dt\colon\ x\in AC([0\,,T]),\,x(0)=x(T)=0\right\}$$

and

$$\min\left\{\int_0^T \left(1+|x(t)|^2\right)\left[1+\left(|x'(t)|^2-1\right)^2\right]\,dt\colon\ x\in AC([0\,,T]),\,x(0)=x(T)=0\right\}$$

show that attainment is not to be expected to hold in general if the latter assumption on g is dropped, unless h is supposed to be convex at zero, i.e., the values at zero of h and its convex envelope h^{**} coincide (see [12] and [17] for a complete discussion of this issue). Among the many related papers, we refer to [1], [18], [4], [5], [6], [16], [8], and [9] for sum-like integrals and to [14], [15], and [2] for product-like integrals. We mention also the above-mentioned [12] and [17] for a somewhat different point of view on the subject.

As regards the case of nonconvex Lagrangian functions f of general form, we mention [19], [14], [13], [15], and [20]. Roughly speaking, in these papers, assuming that either f and its convex envelope f^{**} with respect to ξ are smooth, attainment for $(\mathcal{P})$ is proved when the continuous function

$$f^{**}(\eta\,,\xi)-\xi\frac{\partial f^{**}}{\partial\xi}(\eta\,,\xi) \tag{1.1}$$

is either monotone or concave as a function of η for every ξ or possibly on the sections with fixed ξ of the set $\{f^{**}<f\}$ only (see [20]). Note that, letting f^* be the polar function of $f(\eta\,,\xi)$ with respect to ξ, the function above coincides with

$$-f^*\left(\eta\,,\frac{\partial f^{**}}{\partial\xi}(\eta\,,\xi)\right), \tag{1.2}$$

i.e., the value at the origin of the supporting affine function to the graph of $\xi\to f^{**}(\eta\,,\xi)$ through the point $(\eta\,,\xi)$. Hence, according to these papers, attainment for $(\mathcal{P})$ seems to require a very special, global (or possibly local as in [20]) behavior of either (1.1) or (1.2) as a function of η for every ξ like monotonicity or concavity. However, in the special cases of variational problems $(\mathcal{P})$ featuring smooth sum-like or product-like Lagrangian functions f, (1.1) and (1.2) turn in

$$\begin{cases}\left[h^{**}(\xi)-\xi\,(h^{**})'\,(\xi)\right]+g(\eta)=-h^*\left((h^{**})'\,(\xi)\right)+g(\eta),\\ g(\eta)\left[h^{**}(\xi)-\xi\,(h^{**})'\,(\xi)\right]=g(\eta)\left[-h^*\left((h^{**})'\,(\xi)\right)\right],\end{cases}\qquad(\eta\,,\xi)\in\mathbb{R}\times\mathbb{R},$$

respectively. Hence, the monotonicity or concavity assumptions on (1.1) and (1.2) as functions of η reduce to the requirement that g share the same property on the whole real line in cases of sum-like integrals and that g be monotone or possibly convex, provided $h^*\left((h^{**})'\,(\xi)\right)\geq 0$ for every ξ in the product-like case. By contrast, the existence results mentioned before for these special problems call only for weaker properties of g, namely, no oscillations on increasingly smaller scales and no strict local minima.

Thus, there is a gap between the available attainment results for sum- or product-like, nonconvex, variational problems on one hand and the same problems with a Lagrangian f of general form on the other hand, and the aim of this paper is precisely to fill this gap. Indeed, we are going to show that the hypotheses on f^{**} that yield attainment for $(\mathcal{P})$ in the general case actually look even weaker than they appear in the case of sum-like or product-like integrals.

To this aim, provided f enjoys mild regularity and growth assumptions (see Theorem 2.2), we associate with the convex envelope f^{**} of f with respect to ξ a function $Ef^{**}\colon \mathbb{R}\times\mathbb{R} \to [-\infty, \infty]$ whose value at a point (η, ξ) is, roughly speaking, the value at the origin of the supporting affine function to the graph of $\xi \to f^{**}(\eta, \xi)$ through the point (η, ξ) and which reduces to (1.1) and (1.2) for smooth convex envelopes f^{**}. Then, assuming also that the relaxed problem $(\mathcal{P}^{**})$ obtained from $(\mathcal{P})$ by replacing f with its convex envelope f^{**}, i.e.,

$$(\mathcal{P}^{**}) \qquad \min\left\{\int_0^T f^{**}(x(t), x'(t))\,dt\colon\ x \in AC([0,T]),\ x(0) = x_0,\ x(T) = x_T\right\},$$

admits a solution, we prove attainment for $(\mathcal{P})$ provided Ef^{**} and f^{**} have the following qualitative, local behavior on the set $\{f^{**} < f\}$:

(i) If $f^{**}(\eta_0, \xi_0) < f(\eta_0, \xi_0)$, there is $\delta = \delta(\eta_0, \xi_0) > 0$ such that the restriction $\eta \to Ef^{**}(\eta, \xi_0)$ is monotone on both intervals $[\eta_0 - \delta, \eta_0]$ and $[\eta_0, \eta_0 + \delta]$;

and, whenever the section of $\{f^{**} < f\}$ with $\xi = 0$ is not empty,

(ii) the function $\eta \to f^{**}(\eta, 0)$ has no strict, local minima on such sections.

We wish to point out that, in the Bolza-type examples mentioned above, the set $\{f^{**} < f\}$ is given in either case by $\mathbb{R}\times(-1, 1)$, that $f^{**}(\eta, 0)$ is given by η^2 and $1 + \eta^2$, respectively, and that all the other assumptions of our result are satisfied. Thus, nonattainment for those problems is a direct consequence of the failure of (ii).

We refer to section 2 for the exact statement of our result, a more detailed discussion of its hypotheses, and some examples.

Finally, we wish to remark that the existence result for the nonconvex problem $(\mathcal{P})$ we are going to prove is based on the assumption of attainment for the corresponding relaxed problem $(\mathcal{P}^{**})$ and thereby can be applied to nonconvex problems featuring either superlinear or slow growth at infinity, provided the associated relaxed problem admits a solution. Indeed, besides the standard case of functions f having superlinear growth at infinity (see Corollary 2.3) for which the existence of solutions for the corresponding relaxed problem $(\mathcal{P}^{**})$ follows immediately from the direct method of the calculus of variations, we consider also the case of functions f with slow growth at infinity (see Corollary 2.4) for which attainment for the relaxed problem $(\mathcal{P}^{**})$ can be obtained by applying the existence result of [7].

The remaining part of the paper is organized as follows. In the next section, we introduce some notation, we recall some well-known preliminary results, and we state the main result (Theorem 2.2) and prove its consequences (Corollaries 2.3 and 2.4). Then, in section 3, we prove some technical results that will be needed in the proof of Theorem 2.2, presented in section 4.

2. Notation and statement of the main results. We begin by recalling some elementary definitions, notation, and results, mostly from convex analysis and measure theory.

If $A \subset \mathbb{R}^n$, we let $\operatorname{int}(A)$, $\overline{A}$, and ∂A be the interior, the closure, and the boundary of A, respectively.

The *effective domain* of a function $g\colon A \to (-\infty\,,\infty]$ is the subset of A defined by

$$\operatorname{dom}(g) = \{\xi \in A\colon\ g(\xi) < \infty\}\,,$$

and g itself is said to be *proper* whenever its effective domain is not empty. Now, let $g\colon \mathbb{R} \to [0\,,\infty]$ be a proper, lower semicontinuous function. We recall that g is said to be *subdifferentiable* at a point $\xi \in \operatorname{dom}(g)$ if there exists $d \in \mathbb{R}$ such that

$$g(\zeta) \geq g(\xi) + d(\zeta - \xi), \qquad \zeta \in \mathbb{R}. \tag{2.1}$$

Every such d is a *subgradient* of g at ξ, and the set of all such numbers d is the *subdifferential* $\partial g(\xi)$ of g at ξ. When g is also convex, $\partial g(\xi)$ is a nonempty, compact interval for every $\xi \in \operatorname{int}(\operatorname{dom}(g))$, and g turns out to be locally Lipschitz continuous on $\operatorname{int}(\operatorname{dom}(g))$ so that $\partial g(\xi) = \{g'(\xi)\}$ for a.e. $\xi \in \operatorname{int}(\operatorname{dom}(g))$.

We recall also that if $g\colon \mathbb{R} \to [0\,,\infty]$ is proper and lower semicontinuous, the *polar function* of g is the proper, lower semicontinuous convex function $g^*\colon \mathbb{R} \to (-\infty\,,\infty]$ defined by

$$g^*(\zeta) = \sup\{\xi\zeta - g(\xi)\colon\ \xi \in \mathbb{R}\}\,, \qquad \zeta \in \mathbb{R}$$

(see [11]), and that the *bipolar function* or *convex envelope* of g is the polar $g^{**}\colon \mathbb{R} \to [0\,,\infty]$ of g^*. Thus, g^{**} is a proper, lower semicontinuous convex function such that

(2.2) $g^{**}(\xi) \leq g(\xi)$ for every $\xi \in \mathbb{R}$;

(2.3) $g^{**}(\xi) = g(\xi)$ for every $\xi \in \mathbb{R} \setminus \operatorname{int}(\operatorname{dom}(g^{**}))$;

(2.4) the set $\{g^{**} < g\}$ is open;

(2.5) g^{**} is affine on the connected components of $\{g^{**} < g\}$;

(2.6) the closure of each connected component of the set $\{g^{**} < g\}$ is contained in $\operatorname{dom}(g^{**})$.

Moreover, we recall that, whenever $d \in \mathbb{R}$ is a subgradient of g^{**} at some point $\xi \in \operatorname{dom}(g^{**})$, the values of $g^{**}(\xi)$ and $g^*(d)$ are related by

$$g^{**}(\xi) + g^*(d) = d\xi \tag{2.7}$$

(see [11]) because of the equality $g^{***} = g^*$. Hence, writing (2.1) with g^{**} instead of g, it follows that the value at the origin of the supporting affine function to the graph of g^{**} through the point $(\xi\,, g^{**}(\xi))$ with slope d is given by $-g^*(d)$.

As to measure theoretic notations and results, we denote the Lebesgue measure of a measurable subset E of $\mathbb{R}$ by $|E|$, and we recall that a family of nondegenerate, compact intervals $\mathcal{K}$ is said to *shrink* at some point $x \in \mathbb{R}$ if $x \in K$ for every $K \in \mathcal{K}$ and $\inf\{|K|\colon\ K \in \mathcal{K}\} = 0$. We recall also that a *Vitali covering* of a measurable set E is a family of nondegenerate, compact intervals $\mathcal{K}$ such that, for a.e. $x \in E$, the subfamily of those intervals $K \in \mathcal{K}$ containing x shrinks at x itself. We emphasize that in the definitions above, the intervals K associated with x need not be centered at x or nested. Then Vitali's covering theorem states that every such covering contains an (at most) countable subfamily of sets $\{K_n\}_n$ consisting of pairwise disjoint intervals that cover E up to a negligible set, i.e., $|E \setminus (\cup_n K_n)| = 0$. We also recall that a point $x \in \mathbb{R}$ is said to be a *density point* for a measurable set E if

$$\frac{1}{2\varepsilon}\,|(x-\varepsilon\,, x+\varepsilon) \cap E| \to 1 \qquad \text{or, equivalently,} \qquad \frac{1}{2\varepsilon}\,|(x-\varepsilon\,, x+\varepsilon) \setminus E| \to 0$$

as $\varepsilon \to 0_+$ and that Lebesgue's differentiation theorem states that almost every point of E is a density point. It is plain that for every such point x,

$$\frac{|K \setminus E|}{|K|} \to 0 \qquad \text{as } K \in \mathcal{K} \text{ and } |K| \to 0 \tag{2.8}$$

whenever $\mathcal{K}$ shrinks at x.

As regards functional theoretic notations, we let T be a positive number, use standard notations for the Lebesgue space of integrable functions on $[0\,,T]$ and its norm, and write $AC([0\,,T])$ for the space of absolutely continuous functions on $[0\,,T]$, which turns out to be a Banach space with respect to the Sobolev norm

$$\|x\|_{1,1} = \int_0^T \left[|x(t)| + |x'(t)|\right] dt, \qquad x \in AC([0\,,T]).$$

We also denote the space of all smooth, compactly supported functions on the real line by $\mathcal{D}(\mathbb{R})$.

Now, we introduce the class of functionals we are going to consider in what follows. Given a proper and lower semicontinuous function $f\colon \mathbb{R}\times\mathbb{R} \to [0\,,\infty]$ we consider the integral functional

$$I(x) = \int_0^T f(x(t)\,,x'(t))\, dt, \qquad x \in AC([0\,,T]),$$

and the associated minimum problem

$$(\mathcal{P}) \qquad \min\left\{I(x)\colon\ x \in AC([0\,,T]) \text{ with } x(0) = x_0 \text{ and } x(T) = x_T\right\}$$

with x_0, $x_T \in \mathbb{R}$. We denote the polar and the bipolar functions of f with respect to the second variable ξ by $f^*\colon \mathbb{R}\times\mathbb{R} \to (-\infty\,,\infty]$ and $f^{**}\colon \mathbb{R}\times\mathbb{R} \to [0\,,\infty]$, respectively, and, for every $\eta \in \mathbb{R}$, we denote also the subdifferential of $\xi \to f^{**}(\eta\,,\xi)$ at the point $\xi \in \mathbb{R}$ by $\partial f^{**}(\eta\,,\xi)$. Then we consider the functional

$$I^{**}(x) = \int_0^T f^{**}(x(t)\,,x'(t))\, dt, \qquad x \in AC([0\,,T]),$$

and the associated minimum problem

$$(\mathcal{P}^{**}) \qquad \min\left\{I^{**}(x)\colon\ x \in AC([0\,,T]) \text{ with } x(0) = x_0 \text{ and } x(T) = x_T\right\},$$

which we loosely refer to as the relaxed functional and the relaxed minimum problem, respectively. It is plain that $I^{**} \le I$ on $AC([0\,,T])$ so that any solution x to $(\mathcal{P}^{**})$ satisfying $f^{**}(x\,,x') = f(x\,,x')$ almost everywhere on $[0\,,T]$ is a solution to $(\mathcal{P})$ as well. Moreover, I^{**} is sequentially weakly lower semicontinuous on the set of competing functions $\{x \in AC([0\,,T])\colon\ x(0) = x_0 \text{ and } x(T) = x_T\}$.

Throughout this paper, we shall consider the following assumptions on the functions f and f^{**}:

(H1) $\operatorname{dom}(f) = \operatorname{dom}(f^{**}) = \mathbb{R}\times C$, where C is a nondegenerate interval;

(H2) f and f^{**} are continuous on $\mathbb{R}\times\operatorname{int}(C)$.

If the function f satisfies (H1), it follows that $f^{**}(\eta,\xi) = f(\eta,\xi)$ for every $\eta \in \mathbb{R}$ and $\xi \in \mathbb{R} \setminus \operatorname{int}(C)$ because of (2.3); moreover, if f also satisfies (H2), the detachment set $\mathcal{D}$ defined by

$$\mathcal{D} = \{(\eta,\xi) \in \mathbb{R}\times\mathbb{R}\colon\ f^{**}(\eta,\xi) < f(\eta,\xi)\} \tag{2.9}$$

is an open subset of $\mathbb{R} \times \operatorname{int}(C)$. In what follows, we shall denote the sections of the detachment set $\mathcal{D}$ with η and ξ fixed by $\mathcal{D}_\eta = \{\xi \in \mathbb{R}\colon\ (\eta,\xi) \in \mathcal{D}\}$ and $\mathcal{D}^\xi = \{\eta \in \mathbb{R}\colon\ (\eta,\xi) \in \mathcal{D}\}$, respectively.

Now, consider the mapping $Ef^{**}\colon \mathbb{R}\times\mathbb{R} \to [-\infty,\infty]$ defined by

$$Ef^{**}(\eta,\xi) = \sup\{-f^*(\eta,d)\colon\ d \in \partial f^{**}(\eta,\xi)\}, \qquad (\eta,\xi) \in \mathbb{R}\times\mathbb{R},$$

where, as usual, the supremum of the empty set is set equal to $-\infty$. Note that if it happens that f^{**} is smooth, say $f^{**} \in \mathcal{C}^1(\mathbb{R}\times\mathbb{R})$, then Ef^{**} reduces to the continuous function already considered in (1.1), i.e.,

$$Ef^{**}(\eta,\xi) = f^{**}(\eta,\xi) - \xi\frac{\partial f^{**}}{\partial \xi}(\eta,\xi), \qquad (\eta,\xi) \in \mathbb{R}\times\mathbb{R},$$

because of the basic equality (2.7).

On the function f, we shall consider also the following growth assumption:

$$\lim_{|\xi|\to\infty} \sup\{Ef^{**}(\eta,\xi)\colon\ |\eta| \le R\} = -\infty \qquad \text{for every } R \ge 0. \tag{H3}$$

Note that all functions f satisfying (H2) and (H3) have the following property: For every positive number R, there exist two numbers $\alpha > 0$ and $\beta \ge 0$ depending on R such that

$$f^{**}(\eta,\xi) \ge \alpha|\xi| - \beta \qquad \text{for every } |\eta| \le R \text{ and every } \xi \in \mathbb{R}. \tag{2.10}$$

The growth condition (H3) is strictly weaker than superlinearity at infinity. Indeed, it is easy to see that if a proper and lower semicontinuous function $f\colon \mathbb{R}\times\mathbb{R} \to [0,\infty]$ satisfies (H1) and (H2) and has the further property that, for every given $R \ge 0$, $f(\eta,\xi) \ge \theta(|\xi|)$ for every $|\eta| \le R$ and $\xi \in \mathbb{R}$ for some suitable function $\theta\colon [0,\infty) \to \mathbb{R}$ depending on R such that $\theta(|\xi|)/|\xi| \to \infty$ as $|\xi| \to \infty$, then (H3) is also satisfied (see [7], for instance). By contrast, the function

$$f(\eta,\xi) = f(\xi) = |\xi| - \log(1+|\xi|), \qquad \xi \in \mathbb{R},$$

provides a simple example of a convex function satisfying (H3) and having linear growth at infinity. We refer to [3] for interesting results on the relationship between (H3) and the regularity of solutions to $(\mathcal{P}^{**})$.

The properties of the restriction of the function Ef^{**} to the detachment set $\mathcal{D}$ are gathered in the following proposition.

PROPOSITION 2.1. *Let $f\colon \mathbb{R}\times\mathbb{R} \to [0,\infty]$ be a proper and lower semicontinuous function satisfying* (H1) *and* (H2) *and let $\mathcal{D}$ be the detachment set defined by* (2.9). *Then*

(i) *there exists $d\colon \mathcal{D} \to \mathbb{R}$ such that $\partial f^{**}(\eta,\xi) = \{d(\eta,\xi)\}$ for every $(\eta,\xi) \in \mathcal{D}$;*
(ii) *$Ef^{**}(\eta,\xi) = -f^*(\eta, d(\eta,\xi))$ for every $(\eta,\xi) \in \mathcal{D}$;*
(iii) *Ef^{**} is finite-valued on $\mathcal{D}$ and both Ef^{**} and d are continuous on $\mathcal{D}$;*

(iv) *the restrictions* $\xi \in \mathcal{D}_\eta \to Ef^{**}(\eta,\xi)$ *and* $\xi \in \mathcal{D}_\eta \to d(\eta,\xi)$ *are constant on the connected components of* $\mathcal{D}_\eta$*;*

(v) *if* $\mathcal{D}^0 \neq \emptyset$*, then* $Ef^{**}(\eta,0) = f^{**}(\eta,0)$ *for every* $\eta \in \mathcal{D}^0$.

Proof. For every nonempty section $\mathcal{D}_\eta$ the function $\xi \in \mathbb{R} \to f^{**}(\eta,\xi)$ is affine on the connected components of $\mathcal{D}_\eta$ because of (2.5). Hence, it is differentiable at every point ξ of $\mathcal{D}_\eta$ so that (i) holds with $d(\eta,\xi)$ given by the partial derivative of f^{**} with respect to ξ at the point (η,ξ) and (ii) follows from (i) and the definition of Ef^{**}. Then recall that

$$f^*(\eta, d(\eta,\xi)) = \xi d(\eta,\xi) - f^{**}(\eta,\xi), \qquad (\eta,\xi) \in \mathcal{D}, \tag{2.11}$$

because of (2.7). The right-hand side of this equality is finite since $\mathcal{D} \subset \mathbb{R}\times\mathrm{int}\,(C) \subset \mathrm{dom}\,(f^{**})$ and, moreover, f^{**} is continuous on $\mathcal{D}$ because of (H2). As to d, its restriction $\xi \in \mathcal{D}_\eta \to d(\eta,\xi)$ is constant on the connected components of $\mathcal{D}_\eta$ so that for every rectangle $Q = [\eta_1,\eta_2]\times[\xi_1,\xi_2]$ contained in the detachment set $\mathcal{D}$, we have

$$d(\eta,\xi) = \frac{f^{**}(\eta,\xi_1) - f^{**}(\eta,\xi_2)}{\xi_2 - \xi_1}, \qquad (\eta,\xi) \in Q. \tag{2.12}$$

Thus, d too is continuous on $\mathcal{D}$ and (iii) and (iv) follow from (ii), (2.11), and (2.12). Finally, (v) follows immediately from (i) and (2.11). ∎

After these preliminaries, we can state the main result of the paper.

THEOREM 2.2. *Let* $f\colon \mathbb{R}\times\mathbb{R} \to [0,\infty]$ *be a proper and lower semicontinuous function satisfying* (H1)*,* (H2)*, and* (H3)*. Assume also that the following properties hold:*

(2.13) *For every* $(\eta_0,\xi_0) \in \mathcal{D}$*, there is* $\delta = \delta(\eta_0,\xi_0) > 0$ *such that* $[\eta_0-\delta,\eta_0+\delta] \subset \mathcal{D}^{\xi_0}$ *and such that the restriction* $\eta \in [\eta_0-\delta,\eta_0+\delta] \to Ef^{**}(\eta,\xi_0)$ *is monotone on each interval* $[\eta_0-\delta,\eta_0]$ *and* $[\eta_0,\eta_0+\delta]$*;*

and, if $\mathcal{D}^0 \neq \emptyset$*,*

(2.14) *the restriction* $\eta \in \mathcal{D}^0 \to f^{**}(\eta,0)$ *has no strict, local minima on* $\mathcal{D}^0$.

Then, if the relaxed problem $(\mathcal{P}^{**})$ *has a solution, the nonconvex problem* $(\mathcal{P})$ *has a solution too.*

As already pointed out in section 1, the hypothesis (2.14) cannot be dropped without affecting attainment for $(\mathcal{P})$.

Then we complete the previous result by presenting two instances of growth hypotheses on f ensuring the existence of solutions to the relaxed problem $(\mathcal{P}^{**})$ and hence to the nonconvex problem $(\mathcal{P})$ by Theorem 2.2. The first one is the familiar case of functions f having superlinear growth at infinity, whereas the second, a simple application of the existence result of [7], applies to problems featuring Lagrangian functions f with slow growth at infinity. We wish to remark that both results apply to nonconvex problems featuring one-sided constraints on a derivative like $x' \geq 0$ or $x' > 0$ almost everywhere on $[0,T]$.

COROLLARY 2.3. *Let* $f\colon \mathbb{R}\times\mathbb{R} \to [0,\infty]$ *be a proper and lower semicontinuous function such that all the hypotheses of Theorem* 2.2 *hold with* (H3) *replaced by the following:*

(2.15) $f(\eta,\xi) \geq \alpha|\xi| - \beta$*,* $(\eta,\xi) \in \mathbb{R}\times\mathbb{R}$*, for some* $\alpha > 0$ *and* $\beta \geq 0$*;*

(2.16) *for every* $R \geq 0$*, there exists* $\theta\colon [0,\infty) \to \mathbb{R}$ *such that* $f(\eta,\xi) \geq \theta(|\xi|)$ *for every* $|\eta| \leq R$ *and* $\xi \in \mathbb{R}$ *and* $\theta(|\xi|)/|\xi| \to \infty$ *as* $|\xi| \to \infty$*.*

Then the nonconvex problem $(\mathcal{P})$ *admits (at least) a solution for every boundary data* $x_0,\ x_T \in \mathbb{R}$.

Proof. First, recall that (2.16) implies (H3) so that all the hypotheses of Theorem 2.2 hold. Then assume there is some feasible function $\overline{x} \in AC([0\,,T])$ such that $I^{**}(\overline{x}) = c < \infty$; otherwise there is nothing to prove, and set

$$\mathcal{A} = \{x \in AC([0\,,T])\colon\ x(0) = x_0,\ x(T) = x_T \text{ and } I^{**}(x) \le c\}\,.$$

All functions $x \in \mathcal{A}$ are uniformly bounded because of (2.15). Hence, I^{**} is coercive on $\mathcal{A}$ by (2.16) and lower semicontinuous on the same set with respect to weak convergence in $AC([0\,,T])$ (see Theorem 2.1, Chapter 8 in [11], for instance). Thus, $(\mathcal{P}^{**})$ admits a solution and the conclusion follows from Theorem 2.2. □

COROLLARY 2.4. *Let* $f\colon \mathbb{R}\times\mathbb{R} \to [0\,,\infty]$ *be a proper and lower semicontinuous function such that all the hypotheses of Theorem* 2.2 *hold. Assume also that*

(2.17) C *is a cone;*

(2.18) $\partial f^{**}(\eta\,,\xi) \neq \emptyset$ *for every* $(\eta\,,\xi) \in \mathbb{R}\times C$;

(2.19) $f(\eta\,,\xi) \ge \alpha\,|\xi| - \beta$, $(\eta\,,\xi) \in \mathbb{R}\times\mathbb{R}$, *for some* $\alpha > 0$ *and* $\beta \ge 0$.

Then the nonconvex problem $(\mathcal{P})$ *admits (at least) a solution for every boundary data* $x_0,\ x_T \in \mathbb{R}$.

Recall that a cone in $\mathbb{R}$ is either $\mathbb{R}$ itself or any open or closed half line starting at zero. Note that (2.18) is automatically fulfilled if C is open, and recall also that the detachment set $\mathcal{D}$ is contained in $\mathbb{R}\times\operatorname{int}(C)$. Hence, unless C is the whole real line, the section $\mathcal{D}^0$ of $\mathcal{D}$ with $\xi = 0$ is empty so that (2.14) is automatically fulfilled too.

Proof of Corollary 2.4. The very same computations of [2, Corollary 1.4] show that the hypotheses of the existence result of [7] hold for the relaxed problem $(\mathcal{P}^{**})$. Thus, $(\mathcal{P}^{**})$ admits a solution and the conclusion follows from Theorem 2.2. □

Finally, we end this section by presenting two examples of nonconvex problems which the previous results apply to. They are not meant to be meaningful from the point of view of applications. We just want to illustrate the scope of application of the previous results by showing examples of problems to which the previously known attainment results do not apply.

Example 2.5. Let $f\colon \mathbb{R}\times\mathbb{R} \to [0\,,\infty)$ be defined by

$$f(\eta\,,\xi) = [\xi - a(\eta)]^2\,[\xi - b(\eta)]^2 + c(\eta), \qquad (\eta\,,\xi) \in \mathbb{R}\times\mathbb{R},$$

where the coefficients $a\,,b\,,c \in \mathcal{C}(\mathbb{R})$ are such that

$$c(\eta) \ge \alpha \max\{|a(\eta)|\,,|b(\eta)|\}\,, \qquad \eta \in \mathbb{R}, \tag{2.20}$$

for some $\alpha > 0$. Note that if a and b are bounded, the condition above can always be satisfied by any lower bounded function c by possibly adding a positive constant to c itself. Here, we obviously assume that $a(\eta_0) \neq b(\eta_0)$ for some η_0; otherwise f would be convex with respect to ξ and we can also assume without loss of generality that $a(\eta) \le b(\eta)$ for every $\eta \in \mathbb{R}$.

Then the convex envelope f^{**} of f with respect to ξ is given by

$$f^{**}(\eta\,,\xi) = \begin{cases} [\xi - a(\eta)]^2\,[\xi - b(\eta)]^2 + c(\eta), & \xi \le a(\eta) \text{ or } \xi \ge b(\eta), \\ c(\eta), & a(\eta) \le \xi \le b(\eta), \end{cases} \qquad \eta \in \mathbb{R},$$

and the detachment set $\mathcal{D}$ by $\mathcal{D} = \{(\eta\,,\xi)\colon\ a(\eta) < \xi < b(\eta)\}$.

It is clear that (H1) and (H2) hold. Moreover, it is easy to check that (2.20) yields (2.15) and that, for every $R \geq 0$, $f(\eta, \xi) \geq \xi^4/2 - M$ for every $|\eta| \leq R$ and every $\xi \in \mathbb{R}$ for some suitable $M \geq 0$ depending on R.

Now, note that $Ef^{**}(\eta, \xi) = c(\eta)$ for every $(\eta, \xi) \in \mathcal{D}$ so that the main hypotheses (2.13) and (2.14) of Theorem 2.2 are satisfied, for instance, by every smooth function c whose derivative has only isolated zeros and which has no strict, local minima on $\mathcal{D}^0 = \{a < 0\} \cap \{b > 0\}$. In such cases, all the hypotheses of Corollary 2.3 are satisfied and the corresponding nonconvex minimum problem $(\mathcal{P})$ has at least one solution.

Example 2.6. Let $f\colon \mathbb{R} \times \mathbb{R} \to [0, \infty]$ be defined by

$$f(\eta, \xi) = \begin{cases} \infty & \text{for } \eta \in \mathbb{R} \text{ and } \xi \leq 0, \\ \xi - \log \xi + a(\eta) e^{-b(\eta)[\xi - c(\eta)]^2} & \text{for } \eta \in \mathbb{R} \text{ and } \xi > 0, \end{cases}$$

where the coefficients $a, b, c \in \mathcal{C}(\mathbb{R})$ are positive functions. For suitable choices of a, b, and c, f fails to be convex with respect to ξ.

It is plain that (H1) and (H2) hold with $C = (0, \infty)$ so that (2.17) and (2.18) obviously follow. Moreover, the growth assumption (2.19) holds too; choose $\alpha = 1/2$ and $\beta = 0$, for instance. As to (H3), note that Ef^{**} off the set $\mathcal{D}$ is given by

$$Ef^{**}(\eta, \xi) = 1 - \log \xi + a(\eta) \{1 + 2b(\eta)\xi [\xi - c(\eta)]\} e^{-b(\eta)[\xi - c(\eta)]^2}, \qquad (\eta, \xi) \notin \mathcal{D}.$$

Since it is easy to check that, for every $R \geq 0$, there is $M = M(R) > 0$ such that $f(\eta, \xi) = f^{**}(\eta, \xi)$ for every $|\eta| \leq R$ and every $\xi \geq M$, we conclude that (H3) holds.

Now, for every $(\eta, \xi) \in \mathcal{D}$, there is $\xi' > \xi$ such that $(\eta, \xi') \in \partial\mathcal{D}$ and $Ef^{**}(\eta, \xi) = Ef^{**}(\eta, \xi')$. Therefore, (2.13) holds true provided a, b, and c have the appropriate behavior; for instance, they are smooth with only isolated zeros of the derivatives. As $C = (0, \infty)$, the section $\mathcal{D}^0$ of the detachment set $\mathcal{D}$ is empty and the existence of solutions to the corresponding nonconvex problem $(\mathcal{P})$ follows from Corollary 2.4.

3. Some technical results. The proof of our attainment result (Theorem 2.2) is based on the following idea: Let z be a solution to the relaxed problem $(\mathcal{P}^{**})$ and let t be a differentiability point of z such that $(z(t), z'(t))$ lies in the detachment set $\mathcal{D}$. Then we locally modify z around this point t, thus finding a family of new solutions to $(\mathcal{P}^{**})$ which have the further property that they lie, together with their derivatives, on the "boundary" of the detachment set $\mathcal{D}$, i.e., where f and f^{**} coincide, almost everywhere on shrinking neighborhoods of the point t. Then a covering argument allows us to select and glue some of these new solutions so as to find a further new solution x to $(\mathcal{P}^{**})$ satisfying $f^{**}(x, x') = f(x, x')$ almost everywhere on $[0, T]$, thus proving attainment for $(\mathcal{P})$.

The main steps towards the proof of Theorem 2.2 are gathered in this section. Indeed, the program outlined above calls first for a local description of the "boundary" of the detachment set $\mathcal{D}$ which is given in Proposition 3.1 below and then calls for defining new solutions to $(\mathcal{P}^{**})$ which stay locally on the "boundary" of $\mathcal{D}$. These latter functions will be defined as extremal solutions to suitable, convex-valued differential inclusions related to the detachment set $\mathcal{D}$.

PROPOSITION 3.1. *Let $f\colon \mathbb{R} \times \mathbb{R} \to [0, \infty]$ be a proper and lower semicontinuous function satisfying* (H1), (H2), *and* (H3). *Then, for every $(\eta_0, \xi_0) \in \mathcal{D}$, there exists $\delta = \delta(\eta_0, \xi_0) > 0$ and two functions $a, b\colon [\eta_0 - \delta, \eta_0 + \delta] \to \mathbb{R}$ such that*

(i) *$a(\eta) < \xi_0 < b(\eta)$ for every $\eta \in [\eta_0 - \delta, \eta_0 + \delta]$;*

(ii) *a and b are bounded, upper and lower semicontinuous functions, respectively;*

(iii) $\{(\eta\,,\xi)\colon\ |\eta-\eta_0|\le\delta$ *and* $a(\eta)<\xi<b(\eta)\}\subset\mathcal{D}$*;*

(iv) $f^{**}(\eta\,,a(\eta))=f(\eta\,,a(\eta))<\infty$ *and* $f^{**}(\eta\,,b(\eta))=f(\eta\,,b(\eta))<\infty$ *hold for every* $\eta\in[\eta_0-\delta\,,\eta_0+\delta]$.

In other words, (iii) and (iv) of Proposition 3.1 say that every connected component of every sufficiently narrow, vertical strip of $\mathcal{D}$ is the plane set contained between the graphs of two functions a and b satisfying (i) and (ii).

Proof of Proposition 3.1. Let (η_0,ξ_0) be a point of $\mathcal{D}$, choose $\delta=\delta(\eta_0,\xi_0)>0$ such that $(\eta\,,\xi_0)\in\mathcal{D}$ when $|\eta-\eta_0|\le\delta$, and consider the corresponding nonempty, open sections $\mathcal{D}_\eta$.

Since $\xi\in\mathcal{D}_\eta\ \to\ Ef^{**}(\eta\,,\xi)$ is constant on the connected components of $\mathcal{D}_\eta$ by (iv) of Proposition 2.1, the growth assumption (H3) implies that $\mathcal{D}_\eta$ has bounded connected components. Hence, the functions a and b defined by

$$\begin{cases} a(\eta)=\inf\,\{\xi\le\xi_0\colon\ f^{**}(\eta\,,\xi')<f(\eta\,,\xi')\text{ for every }\xi'\in[\xi\,,\xi_0]\}\,,\\ b(\eta)=\sup\,\{\xi\ge\xi_0\colon\ f^{**}(\eta\,,\xi')<f(\eta\,,\xi')\text{ for every }\xi'\in[\xi_0,\xi]\}\,, \end{cases}\qquad |\eta-\eta_0|\le\delta,$$

are finite and properties (i) and (iii) hold by construction. Moreover, the open interval $\big(a(\eta)\,,b(\eta)\big)$ is the connected component of $\mathcal{D}_\eta$ containing ξ_0 whence we obtain the equalities in (iv). Also, the closure of every connected component of $\mathcal{D}_\eta$ is contained in C by (2.6) so that f and f^{**} are finite at the points $(\eta\,,a(\eta))$ and $(\eta\,,b(\eta))$ for every η within δ from η_0 because of (H1).

Thus, we are left to prove (ii). As regards semicontinuity, suppose, for instance, that b fails to be lower semicontinuous at some point η' in $[\eta_0-\delta\,,\eta_0+\delta]$ so that

$$\liminf_{\eta\to\eta'}b(\eta)<M<b(\eta')$$

for some real number $M>\xi_0$. It follows that $f^{**}(\eta',\xi)<f(\eta',\xi)$ for every $\xi\in[\xi_0,M]$. Hence, the compact segment $\{\eta'\}\times[\xi_0,M]$ is contained in the open set $\mathcal{D}$ whence $[\eta'-\sigma\,,\eta'+\sigma]\times[\xi_0,M]$ is in $\mathcal{D}$ too for some positive σ. This yields that $b(\eta)\ge M$ for all η such that $|\eta-\eta'|\le\sigma$ and $|\eta-\eta_0|\le\delta$, and this gives a contradiction. Finally, to prove that a and b are bounded, note that (iii) and (iv) of Proposition 2.1 imply that $Ef^{**}(\eta\,,\xi)\ge-M$ for every $\xi\in\big(a(\eta)\,,b(\eta)\big)$ and every $\eta\in[\eta_0-\delta\,,\eta_0+\delta]$ for some $M\ge0$ and that the growth assumption (H3) yields that

$$\sup\,\{Ef^{**}(\eta\,,\xi)\colon\ |\eta-\eta_0|\le\delta\}<-M,\qquad\qquad |\xi|\ge R,$$

for some large enough R. Thus, $-R<a(\eta)<b(\eta)<R$ for every $|\eta-\eta_0|\le\delta$, completing the proof. □

The following lemma is proved in [2]. It is a technical result whose statement is long though its proof is elementary.

LEMMA 3.2. *Let* $z\in AC([0\,,T])$ *be differentiable at some point* $s\in(0\,,T)$ *and let* α, $\beta\in\mathbb{R}$ *be such that*

$$\alpha<z'(s)<\beta.$$

Then for every $\delta>0$*, there exist* $\varepsilon_0=\varepsilon_0(s\,,\delta)>0$*, two families of compact subintervals* $\mathcal{H}_s^{\pm}=\{H_{s,\varepsilon}^{\pm}\colon\ 0<\varepsilon\le\varepsilon_0\}$ *of* $(0\,,T)$*, and two families of functions* $\mathcal{Z}_s^{\pm}=\{z_{s,\varepsilon}^{\pm}\colon\ 0<\varepsilon\le\varepsilon_0\}$ *in* $AC([0\,,T])$ *such that, setting*

$$\begin{cases} J_{s,\varepsilon}^{+}=\left(s-\dfrac{\varepsilon}{\beta-z'(s)}\,,s+\dfrac{\varepsilon}{z'(s)-\alpha}\right),\\ J_{s,\varepsilon}^{-}=\left(s-\dfrac{\varepsilon}{z'(s)-\alpha}\,,s+\dfrac{\varepsilon}{\beta-z'(s)}\right), \end{cases}\qquad\qquad \varepsilon>0, \tag{3.1}$$

the following properties hold for every $0 < \varepsilon \leq \varepsilon_0$*:*

$$J^{\pm}_{s,\varepsilon/2} \subset H^{\pm}_{s,\varepsilon} \subset J^{\pm}_{s,2\varepsilon} \subset (0\,,T); \tag{3.2}$$

$$z^{\pm}_{s,\varepsilon} = z \text{ on } [0\,,T] \setminus \operatorname{int}\left(H^{\pm}_{s,\varepsilon}\right); \tag{3.3}$$

$$z(t) < z^{+}_{s,\varepsilon}(t) \leq z(t) + \delta \text{ for every } t \in \operatorname{int}\left(H^{+}_{s,\varepsilon}\right); \tag{3.4+}$$

$$z(t) - \delta \leq z^{-}_{s,\varepsilon}(t) < z(t) \text{ for every } t \in \operatorname{int}\left(H^{-}_{s,\varepsilon}\right); \tag{3.4−}$$

$$\varepsilon \geq z^{+}_{s,\varepsilon}(t) - [z(s) + z'(s)(t-s)] \geq \varepsilon/2 \text{ for every } t \in J^{+}_{s,\varepsilon/2}; \tag{3.5+}$$

$$-\varepsilon/2 \geq z^{-}_{s,\varepsilon}(t) - [z(s) + z'(s)(t-s)] \geq -\varepsilon \text{ for every } t \in J^{-}_{s,\varepsilon/2}; \tag{3.5−}$$

$$\left(z^{\pm}_{s,\varepsilon}\right)'(t) \in \{\alpha\,,\beta\} \text{ for a.e. } t \in H^{\pm}_{s,\varepsilon}. \tag{3.6}$$

Setting

$$E = \{s \in (0\,,T)\colon \ z \text{ is differentiable at } s \text{ with } \alpha < z'(s) < \beta\}\,,$$

note in particular that either family of compact sets $\mathcal{H}^{\pm} = \{H^{\pm}_{s,\varepsilon}\colon \ 0 < \varepsilon \leq \varepsilon_0(s\,,\delta), s \in E\}$ constitute a Vitali covering of the measurable set E itself.

Then we construct the local solutions that will be used in the proof of Theorem 2.2. As mentioned above, they will be defined as extremal solutions to suitable, convex-valued differential inclusions.

PROPOSITION 3.3. *Let* $a, b\colon [\eta_0 - \delta\,, \eta_0 + \delta] \to \mathbb{R}$ *be two bounded, upper and lower semicontinuous functions, respectively, such that*

(i) $a(\eta) < \xi_0 < b(\eta)$ *for every* $\eta \in [\eta_0 - \delta\,, \eta_0 + \delta]$

for some $\xi_0 \in \mathbb{R}$ *and assume that there exist* $y \in AC([0\,,T])$ *and* $t_0 \in (0\,,T)$ *such that*

(ii) y *is differentiable at* t_0 *with* $y(t_0) = \eta_0$ *and* $y'(t_0) = \xi_0$.

Then there exist $\varepsilon_0 = \varepsilon_0(t_0, \delta) > 0$*, two families of compact subintervals* $\mathcal{K}^{\pm}_{t_0} = \{K^{\pm}_{t_0,\varepsilon}\colon \ 0 < \varepsilon \leq \varepsilon_0\}$ *of* $(0\,,T)$ *such that*

$$\text{each set } K^{\pm}_{t_0,\varepsilon} \text{ is a neighborhood of } t_0 \text{ and each family } \mathcal{K}^{\pm}_{t_0} \text{ shrinks at } t_0, \tag{3.7}$$

and two families of functions $\mathcal{Y}^{\pm}_{t_0} = \{y^{\pm}_{t_0,\varepsilon}\colon \ 0 < \varepsilon \leq \varepsilon_0\}$ *in* $AC([0\,,T])$ *such that the following properties hold for every* $0 < \varepsilon \leq \varepsilon_0$*:*

$$y^{\pm}_{t_0,\varepsilon} = y \text{ on } [0\,,T] \setminus \operatorname{int}\left(K^{\pm}_{t_0,\varepsilon}\right); \tag{3.8}$$

$$y(t) < y^{+}_{t_0,\varepsilon}(t) \leq y(t) + \varepsilon \text{ for every } t \in \operatorname{int}\left(K^{+}_{t_0,\varepsilon}\right); \tag{3.9+}$$

$$y(t) - \varepsilon \leq y^{-}_{t_0,\varepsilon}(t) < y(t) \text{ for every } t \in \operatorname{int}\left(K^{-}_{t_0,\varepsilon}\right); \tag{3.9−}$$

$$\left|y^{\pm}_{t_0,\varepsilon}(t) - \eta_0\right| \leq \delta \text{ for every } t \in K^{\pm}_{t_0,\varepsilon}; \tag{3.10}$$

$$\left(y^{\pm}_{t_0,\varepsilon}\right)'(t) \in \left\{a\left(y^{\pm}_{t_0,\varepsilon}(t)\right)\,, b\left(y^{\pm}_{t_0,\varepsilon}(t)\right)\right\} \text{ for a.e. } t \in K^{\pm}_{t_0,\varepsilon}. \tag{3.11}$$

Proof. We are going to treat the + case, the other one being entirely equivalent. Therefore, to simplify the notations, we shall drop the superscript + from now on. Our strategy is the following: Relying on Lemma 3.2, for every small enough ε, we are going to define the compact set $K_{t_0,\varepsilon}$ and a sequence of functions $y_{k,t_0,\varepsilon}$ in $AC([0\,,T])$ satisfying (3.8), (3.9+), and (3.10) which are "approximated" solutions to the differential inclusion (3.11). The remarkable point is that although the derivatives of the "approximated" solutions $y_{k,t_0,\varepsilon}$ oscillate faster and faster as $k \to \infty$ in order to solve (3.11), the functions $y_{k,t_0,\varepsilon}$ can be defined in such a way that they do converge strongly in $AC([0\,,T])$. The limit function will be $y_{t_0,\varepsilon}$.

To this purpose, set $I = [\eta_0 - \delta\,, \eta_0 + \delta]$ to simplify the notation and define

$$\text{(3.12)} \qquad \begin{cases} M = \max\{a(\eta)\colon\ \eta \in I\}\,, \\ m = \min\{b(\eta)\colon\ \eta \in I\} \end{cases} \qquad \text{and} \qquad \sigma = \min\{m - \xi_0, \xi_0 - M\}$$

so that $\sigma > 0$ because of (i). Then choose $\varepsilon_0' = \varepsilon_0'(t_0, \delta\,, \sigma) > 0$ small enough so that

$$\text{(3.13)} \qquad \begin{cases} \varepsilon_0' < \min\{\delta/4\,, \sigma/16\,, \sigma t_0/4\,, \sigma(T - t_0)/4\}\,, \\ |t - t_0| \le 4\varepsilon_0'/\sigma \quad \Longrightarrow \quad |y(t) - \eta_0| < \min\{\delta/4\,, \sigma/32\} \end{cases}$$

hold and define also

$$\text{(3.14)} \qquad \begin{cases} a_k(\eta) = \max\{a(\eta') - k\,|\eta' - \eta|\colon\ \eta' \in I\} + \sigma/2k, \\ b_k(\eta), = \min\{b(\eta') + k\,|\eta' - \eta|\colon\ \eta' \in I\} - \sigma/2k, \end{cases} \qquad \eta \in I.$$

These functions a_k and b_k are (up to the constants $\sigma/2k$) the Moreau–Yosida approximations of a and b, respectively. They enjoy the following properties (see [10], for instance):

(3.15) a_k and b_k are Lipschitz continuous on I with Lipschitz constant k;

(3.16) $M + \sigma/2 \ge a_1(\eta)$ and $a_k(\eta) - a_{k+1}(\eta) \ge \Delta_k$ for every $\eta \in I$ and $k \ge 1$;

(3.17) $m - \sigma/2 \le b_1(\eta)$ and $b_{k+1}(\eta) - b_k(\eta) \ge \Delta_k$ for every $\eta \in I$ and $k \ge 1$;

where $\Delta_k = \frac{\sigma}{2k(k+1)}$, $k \ge 1$, and

(3.18) $a_k \to a$ and $b_k \to b$ pointwise on I.

Now, the preparatory work is over and the proof will be completed by proving the following three claims.

Claim 1. There exist $\varepsilon_0 = \varepsilon_0(t_0, \delta\,, \sigma) \in (0\,, \varepsilon_0']$ and a family of compact subintervals $\mathcal{K}_{t_0} = \{K_{t_0,\varepsilon}\colon\ 0 < \varepsilon \le \varepsilon_0\}$ of $(0\,, T)$ satisfying (3.7) with the further property that for every sequence of positive numbers $\{\omega_k\}_{k\ge1}$, the following holds for every $\varepsilon \in (0\,, \varepsilon_0]$: There exists a sequence of functions $\{y_{k,t_0,\varepsilon}\}_{k\ge0}$ in $AC([0\,, T])$ such that $y_{0,t_0,\varepsilon} = y$ and

(3.19) $y_{k,t_0,\varepsilon} = y$ on $[0\,, T] \setminus \text{int}\,(K_{t_0,\varepsilon})$;

(3.20) $0 < y_{k,t_0,\varepsilon}(t) - y_{k-1,t_0,\varepsilon}(t) < \min\left\{\dfrac{\varepsilon}{2^k}\,, \omega_k, \dfrac{\Delta_k}{4(k+1)}\right\}$, $t \in \text{int}\,(K_{t_0,\varepsilon})$;

(3.21) $|y_{k,t_0,\varepsilon}(t) - \eta_0| < \displaystyle\sum_{1\le h\le k} \delta/2^h$, $t \in K_{t_0,\varepsilon}$;

(3.22) $$y'_{k,t_0,\varepsilon}(t) \in \Big(a_{k+1}\left(y_{k,t_0,\varepsilon}(t)\right)\,, a_k\left(y_{k,t_0,\varepsilon}(t)\right)\Big) \cup \Big(b_k\left(y_{k,t_0,\varepsilon}(t)\right)\,, b_{k+1}\left(y_{k,t_0,\varepsilon}(t)\right)\Big) \text{ for a.e. } t \in K_{t_0,\varepsilon}$$

for every $k \ge 1$.

Claim 2. There exists a sequence of positive numbers $\{\omega_k\}_k$ such that for every $\varepsilon \in (0\,, \varepsilon_0]$, the sequence of functions $\{y_{k,t_0,\varepsilon}\}_k$ converges strongly in $AC([0\,, T])$ to a function $y_{t_0,\varepsilon} \in AC([0\,, T])$.

Claim 3. For the same sequence of numbers $\{\omega_k\}_k$, we also have that

$$\begin{cases} a_{k+h}\left(y_{k,t_0,\varepsilon}(t)\right) \to a\left(y_{t_0,\varepsilon}(t)\right), \\ b_{k+h}\left(y_{k,t_0,\varepsilon}(t)\right) \to b\left(y_{t_0,\varepsilon}(t)\right) \end{cases} \qquad \text{as } k \to \infty \tag{3.23}$$

for every $h \geq 0$ and $t \in [0\,,T]$.

Once the previous claims have been proved, we conclude immediately that $y_{t_0,\varepsilon}$ satisfies (3.8), (3.9+), and (3.10) for every $\varepsilon \in (0\,,\varepsilon_0]$ because of the corresponding properties of the functions $y_{k,t_0,\varepsilon}$. Moreover, Claim 2 implies that some subsequence of $\{y'_{k,t_0,\varepsilon}\}_k$ converges to $y'_{t_0,\varepsilon}$ almost everywhere on $[0\,,T]$ so that (3.11) follows from (3.22) and Claim 3.

Proof of Claim 1. We apply Lemma 3.2 in the + case with $s = t_0$, $z = y$ and $\alpha = [a_1(\eta_0) + a_2(\eta_0)]/2$ and $\beta = [b_1(\eta_0) + b_2(\eta_0)]/2$ thus finding $\varepsilon_0 = \varepsilon_0(t_0, \delta\,, \sigma) \in (0\,, \varepsilon'_0]$, a family of compact subintervals $\mathcal{H}_{t_0} = \{H_{t_0,\varepsilon}\colon\ 0 < \varepsilon \leq \varepsilon_0\}$ of $(0\,,T)$ which are all neighborhoods of t_0, and a family of functions $\mathcal{Z}_{t_0} = \{z_{t_0,\varepsilon}\colon\ 0 < \varepsilon \leq \varepsilon_0\}$ in $AC([0\,,T])$ such that (3.2), (3.3), (3.4+), and (3.6) hold. Relying on these properties, it is easy to check that $(z_{t_0,\varepsilon} - y) \to 0_+$ uniformly on $[0\,,T]$ as $\varepsilon \to 0$ so that for every $0 < \varepsilon \leq \varepsilon_0$, we can choose $0 < \varepsilon' \leq \varepsilon$ such that

$$0 < z_{t_0,\varepsilon'}(t) - y(t) < \min\left\{\frac{\varepsilon}{2}\,, \omega_1, \frac{\Delta_1}{4(1+1)}\right\}, \qquad t \in \text{int}\,\left(H_{t_0,\varepsilon'}\right).$$

Hence, recalling that $y_{0,t_0,\varepsilon} = y$ for every $\varepsilon \in (0\,,\varepsilon_0]$ by definition and setting $K_{t_0,\varepsilon} = H_{t_0,\varepsilon'}$ and $y_{1,t_0,\varepsilon} = z_{t_0,\varepsilon'}$ for every $\varepsilon \in (0\,,\varepsilon_0]$, we conclude that $K_{t_0,\varepsilon}$ satisfies (3.7), that $y_{1,t_0,\varepsilon}$ satisfies (3.19) and (3.20) with $k = 1$, and, moreover, that the derivative of $y_{1,t_0,\varepsilon}$ is such that

$$y'_{1,t_0,\varepsilon}(t) \in \left\{\frac{a_1(\eta_0) + a_2(\eta_0)}{2}\,, \frac{b_1(\eta_0) + b_2(\eta_0)}{2}\right\} \qquad \text{for a.e. } t \in K_{t_0,\varepsilon}.$$

As regards (3.21), note that each compact interval $K_{t_0,\varepsilon}$ is contained in H_{t_0,ε_0} and that this latter interval is contained in $[t_0 - 4\varepsilon'_0/\sigma\,, t_0 + 4\varepsilon'_0/\sigma]$ by (3.2). This latter inclusion, together with the equality $y_{0,t_0,\varepsilon} = y$ and the choice of ε'_0 made in (3.13), implies that

$$|y_{0,t_0,\varepsilon}(t) - \eta_0| \leq \min\left\{\frac{\delta}{4}\,, \frac{\Delta_1}{4(1+1)}\right\} \tag{3.24}$$

since $\sigma/32 = \Delta_1/8$. Hence,

$$\begin{aligned} |y_{1,t_0,\varepsilon}(t) - \eta_0| &\leq |y_{1,t_0,\varepsilon}(t) - y_{0,t_0,\varepsilon}(t)| + |y_{0,t_0,\varepsilon}(t) - \eta_0| \\ &< \varepsilon/2 + \delta/4 \leq \delta/4 + \delta/4 = \delta/2 \end{aligned} \tag{3.25}$$

holds for every $t \in K_{t_0,\varepsilon}$ because of (3.20) with $k = 1$ and (3.24). At last, to complete the first step, we have to check that $y_{1,t_0,\varepsilon}$ is an "approximated" solution to the differential inclusion (3.11) on the set $K_{t_0,\varepsilon}$, i.e., that (3.22) holds for $k = 1$. Indeed, let $y_{1,t_0,\varepsilon}$ be differentiable at some point $t \in \text{int}\,(K_{t_0,\varepsilon})$ with derivative $y'_{1,t_0,\varepsilon}(t) = [a_1(\eta_0) + a_2(\eta_0)]/2$. By elementary computations based on (3.15), (3.16), (3.20) for $k = 1$ and (3.24), we get

$$\begin{aligned} a_2\left(y_{1,t_0,\varepsilon}(t)\right) &\leq a_2(\eta_0) + 2\Big(|y_{1,t_0,\varepsilon}(t) - y_{0,t_0,\varepsilon}(t)| + |y_{0,t_0,\varepsilon}(t) - \eta_0|\Big) \\ &< a_2(\eta_0) + \frac{\Delta_1}{2} = \frac{a_1(\eta_0) + a_2(\eta_0)}{2} \end{aligned}$$

and, similarly,

$$a_1\left(y_{1,t_0,\varepsilon}(t)\right) > \frac{a_1(\eta_0)+a_2(\eta_0)}{2}.$$

Thus, $a_2\left(y_{1,t_0,\varepsilon}(t)\right) < y'_{1,t_0,\varepsilon}(t) < a_1\left(y_{1,t_0,\varepsilon}(t)\right)$, and the very same kind of computations in the case that $y'_{1,t_0,\varepsilon}(t)$ is $[b_1(\eta_0)+b_2(\eta_0)]/2$ yield that $b_1\left(y_{1,t_0,\varepsilon}(t)\right) < y'_{1,t_0,\varepsilon}(t) < b_2\left(y_{1,t_0,\varepsilon}(t)\right)$, which is (3.22) for $k=1$.

Next, we go on defining the second "approximated" solution $y_{2,t_0,\varepsilon}$ on the same set $K_{t_0,\varepsilon}$. We shall do this for a fixed $\varepsilon \in (0\,,\varepsilon_0]$.

To this purpose, choose any point $t \in \text{int}\,(K_{t_0,\varepsilon})$ where $y_{1,t_0,\varepsilon}$ is differentiable and (3.22) holds for $k=1$ and set $\eta_t = y_{1,t_0,\varepsilon}(t)$. For every such point t, we apply Lemma 3.2 in the + case again with $s=t$, $z=y_{1,t_0,\varepsilon}$ and $\alpha=[a_2(\eta_t)+a_3(\eta_t)]/2$ and $\beta=[b_2(\eta_t)+b_3(\eta_t)]/2$, thus finding a positive number $\theta_0=\theta_0(t\,,\varepsilon)$, a family of nondegenerate, compact intervals $\mathcal{L}_t=\{L_{t,\theta}\colon\ 0<\theta\le\theta_0\}$ contained in $K_{t_0,\varepsilon}$ and a family of functions $\mathcal{Z}_t=\{z_{t,\theta}\colon\ 0<\theta\le\theta_0\}$ in $AC([0\,,T])$ such that all sets $L_{t,\theta}$ in $\mathcal{L}_t$ are neighborhoods of t and the following properties hold for every $\theta\in(0\,,\theta_0]$:

$$z_{t,\theta} = y_{1,t_0,\varepsilon} \text{ on } [0\,,T]\setminus \text{int}\,(L_{t,\theta}); \tag{3.26}$$

$$0 < z_{t,\theta}(s) - y_{1,t_0,\varepsilon}(s) \le \min\left\{\frac{\varepsilon}{2^2}\,,\omega_2,\frac{\Delta_2}{4(2+1)}\right\} \text{ for every } s\in\text{int}\,(L_{t,\theta}); \tag{3.27}$$

$$z'_{t,\theta}(s) \in \left\{\frac{a_2(\eta_t)+a_3(\eta_t)}{2}\,,\frac{b_2(\eta_t)+b_3(\eta_t)}{2}\right\} \text{ for a.e. } s\in L_{t,\theta}. \tag{3.28}$$

Moreover, we can assume that θ_0 is small enough to have

$$|y_{1,t_0,\varepsilon}(s)-\eta_t| \le \frac{\Delta_2}{4(2+1)} \qquad \text{for every } s\in L_{t,\theta} \text{ and } \theta\in(0\,,\theta_0], \tag{3.29}$$

and we note also that from (3.27), (3.13), and (3.25), it follows that

$$|z_{t,\theta}(s)-\eta_0| \le |z_{t,\theta}(s)-y_{1,t_0,\varepsilon}(s)| + |y_{1,t_0,\varepsilon}(s)-\eta_0| \le \delta/2+\delta/4 \tag{3.30}$$

for every $s\in L_{t,\theta}$ and $\theta\in(0\,,\theta_0]$. Next, we prove that

$$z'_{t,\theta}(s) \in \Big(a_3\left(z_{t,\theta}(s)\right),a_2\left(z_{t,\theta}(s)\right)\Big) \cup \Big(b_2\left(z_{t,\theta}(s)\right),b_3\left(z_{t,\theta}(s)\right)\Big) \tag{3.31}$$

for a.e. $s\in L_{t,\theta}$. Indeed, (3.27), (3.16), and (3.29) yield

$$\begin{aligned} a_3\left(z_{t,\theta}(s)\right) &\le a_3(\eta_t) + 3\Big(|z_{t,\theta}(s)-y_{1,t_0,\varepsilon}(s)| + |y_{1,t_0,\varepsilon}(s)-\eta_t|\Big) \\ &< a_3(\eta_t)+\frac{\Delta_2}{2} \le \frac{a_2(\eta_t)+a_3(\eta_t)}{2} \end{aligned}$$

and, similarly,

$$\frac{a_2(\eta_t)+a_3(\eta_t)}{2} < a_2\left(z_{t,\theta}(s)\right)$$

for a.e. $s\in L_{t,\theta}$. Thus, (3.31) holds if the derivative of $z_{t,\theta}$ exists and is equal to $[a_2(\eta_t)+a_3(\eta_t)]/2$, and a specular argument yields (3.31) if $z'_{t,\theta}(s)$ is $[b_2(\eta_t)+b_3(\eta_t)]/2$.

So far, we have defined a family of functions $z_{t,\theta}$ satisfying (3.19),(3.20), (3.21), and (3.22) for $k=2$ around every "good" point t in the interior of $K_{t_0,\varepsilon}$ and, to complete the definition of $y_{2,t_0,\varepsilon}$, we just have to glue these functions $z_{t,\theta}$ by a covering

argument. Indeed, by the remark following Lemma 3.2, the family of nondegenerate, compact intervals $\mathcal{L} = \{L_{t,\theta}\colon\ 0 < \theta \le \theta_0(t\,,\varepsilon) \text{ and } t \in E_1\}$ constitutes a Vitali covering of the measurable set

$$E_1 = \left\{t \in \text{int }(K_{t_0,\varepsilon})\colon\ y'_{1,t_0,\varepsilon}(t) \text{ exists and (3.22) holds with } k=1\right\},$$

which is a full measure subset of int $(K_{t_0,\varepsilon})$. Hence, Vitali's covering theorem yields (at most) countably many points $t_j \in E_1$ and positive numbers $\theta_j \in (0, \theta_0(t_j, \varepsilon)]$ such that the corresponding compact intervals $L_j = L_{t_j,\theta_j}$ are pairwise disjoint sets that cover E_1, and hence $K_{t_0,\varepsilon}$ as well, up to a null set.

Now, we define the second "approximated" solution $y_{2,t_0,\varepsilon}$ by setting

$$y_{2,t_0,\varepsilon}(t) = y_{1,t_0,\varepsilon}(t) + \sum_{j\ge 1} [z_j(t) - y_{1,t_0,\varepsilon}(t)]\,, \qquad t \in [0\,,T], \tag{3.32}$$

where $z_j = z_{t_j,\theta_j}$. As the supports L_j of the functions $z_j - y_{1,t_0,\varepsilon}$ are disjoint, the series in (3.32) is actually a finite sum for every t and, moreover, the functions $z_j - y_{1,t_0,\varepsilon}$ have (essentially) uniformly bounded derivatives on $[0\,,T]$. Thus, $y_{2,t_0,\varepsilon}$ is Lipschitz continuous on $[0\,,T]$ by the Ascoli–Arzelà theorem, and the fulfillment of (3.19), (3.20), (3.21), and (3.22) for $k = 2$ follows straightforwardly from the corresponding properties (3.26), (3.27), (3.30), and (3.31) of the functions $z_j = z_{t_j,\theta_j}$.

Finally, all the remaining functions $y_{k,t_0,\varepsilon}$ are defined recursively in the very same way we have got $y_{2,t_0,\varepsilon}$ from $y_{1,t_0,\varepsilon}$, and this completes the proof of Claim 1.

Proof of Claim 2. We are going to choose the positive numbers ω_k so as to have strong convergence in $L^1([0\,,T])$ of the derivatives $y'_{k,t_0,\varepsilon}$.

To this purpose, let $\varphi \in \mathcal{D}(\mathbb{R})$ be the standard mollifying kernel and set, as usual, $\varphi_r(t) = r^{-1}\varphi(t/r)$ for every $t \in \mathbb{R}$ and $r > 0$. Choose also a sequence of positive numbers $0 < r_k < 2^{-k}$ in such a way that, extending each function $y_{k,t_0,\varepsilon}$ to the whole real line as a constant function off the interval $[0\,,T]$, the following inequality holds:

$$\int_{\mathbb{R}} \left|\varphi_{r_k} * y'_{k,t_0,\varepsilon}(t) - y'_{k,t_0,\varepsilon}(t)\right|\,dt \le \frac{1}{k}, \qquad k \ge 1. \tag{3.33}$$

Then let $\{\omega_k\}_k$ be the sequence defined by setting $\omega_1 = 1$ and, recursively,

$$\omega_{k+1} = r_k\omega_k, \qquad k \ge 1. \tag{3.34}$$

The reader might think that this way of choosing the numbers ω_k is inconsistent as it requires that the functions $y_{k,t_0,\varepsilon}$ be already defined. This is not the case. Indeed, we set ω_1 to be 1 and then define $y_{1,t_0,\varepsilon}$ so that (3.20) with $k = 1$ holds. Then we compute r_1 according to (3.33) with $k = 1$—which requires only that $y_{1,t_0,\varepsilon}$ be defined—and then we define the number $\omega_2 = r_1\omega_1$. Only then do we choose the function $y_{2,t_0,\varepsilon}$ so that (3.20) with $k = 2$ holds, and we restart the procedure.

Now, we claim that this choice of the numbers ω_k yields the conclusion of Claim 2, and we break the remaining part of the proof into the following three claims.

Claim 2.1. For every $\varepsilon \in (0\,,\varepsilon_0]$, the sequence $\{y_{k,t_0,\varepsilon}\}_k$ converges uniformly on $[0\,,T]$ to some function $y_{t_0,\varepsilon}$.

Indeed,

$$0 \le y_{k+1,t_0,\varepsilon}(t) - y_{k,t_0,\varepsilon}(t) \le \omega_{k+1}, \qquad t \in [0\,,T], \tag{3.35}$$

by (3.19) and (3.20). Since $0 < \omega_{k+1}/\omega_k = r_k \to 0$ as $k \to \infty$, the sequence $\{y_{k,t_0,\varepsilon}\}_k$ is uniformly Cauchy on $[0\,,T]$ and the conclusion follows.

Claim 2.2. $y_{t_0,\varepsilon} \in AC([0\,,T])$.

All the functions $y_{k,t_0,\varepsilon}$ have (essentially) uniformly bounded derivatives on the interval $K_{t_0,\varepsilon}$ since a and b are bounded and

$$a\left(y_{k,t_0,\varepsilon}(t)\right) < a_{k+1}\left(y_{k,t_0,\varepsilon}(t)\right) < y'_{k,t_0,\varepsilon}(t) < b_{k+1}\left(y_{k,t_0,\varepsilon}(t)\right) < b\left(y_{k,t_0,\varepsilon}(t)\right)$$

for a.e. $t \in K_{t_0,\varepsilon}$. Thus, $y_{t_0,\varepsilon}$ is Lipschitz continuous on $K_{t_0,\varepsilon}$. As it coincides with the absolutely continuous function y on $[0\,,T]\setminus \operatorname{int}\left(K_{t_0,\varepsilon}\right)$ because of (3.19), the claim is proved.

Claim 2.3. The sequence $\{y_{k,t_0,\varepsilon}\}_k$ converges strongly in $AC([0\,,T])$.

Indeed,

$$\begin{aligned}&\left\|y'_{k,t_0,\varepsilon} - y'_{t_0,\varepsilon}\right\|_1\\ &\le \left\|y'_{k,t_0,\varepsilon} - \varphi_{r_k} * y'_{k,t_0,\varepsilon}\right\|_1 + \left\|\varphi_{r_k} * y'_{k,t_0,\varepsilon} - \varphi_{r_k} * y'_{t_0,\varepsilon}\right\|_1 + \left\|\varphi_{r_k} * y'_{t_0,\varepsilon} - y'_{t_0,\varepsilon}\right\|_1.\end{aligned}$$

The first and the third summand on the right-hand side go to zero as $k \to \infty$ because of (3.33) and the properties of convolutions with mollifying kernels, respectively. We are thus left to prove that

$$R_k = \left\|\varphi_{r_k} * \left(y'_{k,t_0,\varepsilon} - y'_{t_0,\varepsilon}\right)\right\|_1 \to 0 \qquad \text{as } k \to \infty.$$

To this aim, note that $R_k = C r_k^{-1} \left\|y_{k,t_0,\varepsilon} - y_{t_0,\varepsilon}\right\|_\infty$, where $C = T\left\|\varphi'\right\|_1$, so that (3.34) and (3.35) yield that

$$\begin{aligned}\left\|y_{k,t_0,\varepsilon} - y_{t_0,\varepsilon}\right\|_\infty &\le \sum_{j\ge 1} \left\|y_{k+j,t_0,\varepsilon} - y_{k+j-1,t_0,\varepsilon}\right\|_\infty \le \sum_{j\ge 1} \omega_{k+j}\\ &= \omega_{k+1}\left(1 + \sum_{j\ge 1} r_{k+j}\right) \le 2\omega_{k+1} = 2 r_k \omega_k\end{aligned}$$

because $0 < r_k < 2^{-k}$ by assumption. Thus, $R_k \le 2C\omega_k \to 0$ as $k \to \infty$, and the conclusion follows.

Proof of Claim 3. Let t be in the interior of $K_{t_0,\varepsilon}$; otherwise the conclusion follows immediately from (3.19) and (3.18). For such t, we have

$$\begin{aligned}&\left|a_{k+h}\left(y_{k,t_0,\varepsilon}(t)\right) - a\left(y_{t_0,\varepsilon}(t)\right)\right|\\ &\le \left|a_{k+h}\left(y_{k,t_0,\varepsilon}(t)\right) - a_{k+h}\left(y_{t_0,\varepsilon}(t)\right)\right| + \left|a_{k+h}\left(y_{t_0,\varepsilon}(t)\right) - a\left(y_{t_0,\varepsilon}(t)\right)\right|,\end{aligned}$$

and the second summand at the right-hand side goes to zero as $k \to \infty$ because of (3.18) again, no matter what h is. As to the first one, (3.15) and the very same argument of Claim 2.3 show that it is bounded by $2(k+h)\omega_{k+1}$, and this goes to zero as $k \to \infty$ because (3.34) and the basic assumption $0 < r_k < 2^{-k}$ yield that $\omega_{k+1} \le 2^{-k}$. This proves the a case and nothing changes in the b case. □

4. Proof of the main result. In this final section, we put together and exploit the tools developed in the previous section and prove our attainment result, Theorem 2.2.

Proof of Theorem 2.2. Let R be a bounded, open rectangle whose closure is contained in $\mathcal{D}$. By (iii) and (iv) of Proposition 2.1, the function

$$q(\eta) = Ef^{**}(\eta\,,\xi), \qquad (\eta\,,\xi) \in \overline{R},$$

is well defined, and we claim that it has at most finitely many strict, local extrema in $\overline{R}$. Indeed, should this be false, there would be a converging sequence $\{m_k\}_k$ of strict, local extrema of q, say $m_k \to m_0$, and we could assume also the sequence $\{m_k\}_k$ is strictly monotone. Thus, q would fail to be monotone on both sides of m_0, and this gives a contradiction to (2.13). As $\mathcal{D}$ is a countable union of such rectangles R, we conclude that there exists an (at most) countable family of subsets of $\mathcal{D}$, say $\{m_i\} \times L_i$, with the property that, for every index i, L_i is a connected component of $\mathcal{D}_{m_i}$ and, for every $\xi \in L_i$, m_i is a strict, local extremum point of the mapping $\eta \in \mathcal{D}^\xi \to Ef^{**}(\eta\,,\xi)$. Conversely, if $(\eta\,,\xi) \in \mathcal{D}$ is such that η is a strict, local extremum point for $\eta \in \mathcal{D}^\xi \to Ef^{**}(\eta\,,\xi)$, then $\eta = m_i$ for some index i and the corresponding open interval L_i is the connected component of $\mathcal{D}_{m_i}$ containing ξ. We recall also that according to (v) of Proposition 2.1 and (2.14), a point m_i may be a strict, local minimum point for $\eta \in \mathcal{D}^\xi \to Ef^{**}(\eta\,,\xi)$ for some $\xi \in L_i$ only if $0 \notin L_i$.

Now, let $y \in AC([0\,,T])$ be a solution to $(\mathcal{P}^{**})$ and assume that $I^{**}(y) < \infty$; otherwise there is nothing else to prove. We are going to prove that y can be modified so as to find a new solution x to $(\mathcal{P}^{**})$ such that

$$f^{**}(x(t)\,,x'(t)) = f(x(t)\,,x'(t)) \qquad \text{for a.e. } t \in [0\,,T], \tag{4.1}$$

thus showing that x is a solution to $(\mathcal{P})$ as well. The proof goes through the following three steps.

Step 1. Let M be the subset of $\mathcal{D}$ defined by $M = \cup_i (\{m_i\} \times L_i)$ and note that $\mathcal{D} \setminus M$ is open. First, we prove that whenever the measurable set

$$E = \big\{t \in (0\,,T)\colon\ y \text{ is differentiable at } t \text{ and } \big(y(t)\,,y'(t)\big) \in \mathcal{D} \setminus M\big\} \tag{4.2}$$

has positive measure, we can use Lemma 3.2 and Proposition 3.3 to associate with every point $s \in E$ a family of new solutions $\mathcal{Y}_s = \{y_{s,\varepsilon}\colon 0 < \varepsilon \le \varepsilon_0(s)\}$ to $(\mathcal{P}^{**})$ such that the sets $K_{s,\varepsilon}$ defined as the closure of $\{y_{s,\varepsilon} \ne y\}$ are nondegenerate, compact intervals that shrink at s and the following properties hold for every $0 < \varepsilon \le \varepsilon_0(s)$:

$$\sup\{|y_{s,\varepsilon}(t) - y(t)|\colon\ 0 \le t \le T\} \le \varepsilon; \tag{4.3a}$$

$$f^{**}(y_{s,\varepsilon}(t)\,,y'_{s,\varepsilon}(t)) = f(y_{s,\varepsilon}(t)\,,y'_{s,\varepsilon}(t)) \text{ for a.e. } t \in K_{s,\varepsilon}. \tag{4.3b}$$

Step 2. Then we use the modified solutions of the previous step and a covering argument to define a new solution x to $(\mathcal{P}^{**})$ such that, setting

$$A = \big\{t \in (0\,,T)\colon\ x \text{ is differentiable at } t \text{ and } \big(x(t)\,,x'(t)\big) \in M\big\}\,, \tag{4.4}$$

we have that

$$f^{**}(x(t)\,,x'(t)) = f(x(t)\,,x'(t)) \qquad \text{for a.e. } t \in [0\,,T] \setminus A. \tag{4.5}$$

Step 3. Finally, we show that A is negligible. Thus, (4.5) reduces to (4.1), and this shows that x is a solution to $(\mathcal{P})$.

Proof of Step 1. Assume that the set E defined by (4.2) has positive measure, fix a point $t_0 \in E$, and set $\eta_0 = y(t_0)$ and $\xi_0 = y'(t_0)$. As $(\eta_0, \xi_0) \in \mathcal{D} \setminus M$ by assumption, the basic hypotheses (2.13) and (2.14) and the very definition of the set M itself imply that the restriction $\eta \in \mathcal{D}^{\xi_0} \to Ef^{**}(\eta\,,\xi_0)$ is monotone on the interval $[\eta_0 - \delta\,,\eta_0 + \delta]$ for some $\delta > 0$. Moreover, by possibly choosing a smaller value of δ, we can describe the upper and the lower parts of the boundary of the connected component of the

vertical strip $\mathcal{D} \cap ([\eta_0 - \delta\,, \eta_0 + \delta] \times \mathbb{R})$ of $\mathcal{D}$ containing (η_0, ξ_0) as in Proposition 3.1, i.e., as the graphs of two functions $a, b\colon [\eta_0 - \delta\,, \eta_0 + \delta] \to \mathbb{R}$ satisfying (i), (ii), (iii), and (iv) of Proposition 3.1. Also, setting $\mathcal{D}' = \{(\eta\,, \xi)\colon\ |\eta - \eta_0| \le \delta \text{ and } a(\eta) \le \xi \le b(\eta)\}$ and recalling (2.5), (2.6), and Proposition 2.1, we can write the convex envelope f^{**} of f on the set $\mathcal{D}'$ as

$$f^{**}(\eta\,, \xi) = d(\eta)\xi + q(\eta), \qquad (\eta\,, \xi) \in \mathcal{D}', \tag{4.6}$$

where the continuous functions $d, q\colon [\eta_0 - \delta\,, \eta_0 + \delta] \to \mathbb{R}$ are defined by $q(\eta) = Ef^{**}(\eta\,, \xi)$ and $d(\eta) = d(\eta\,, \xi)$ for every $(\eta\,, \xi) \in \mathcal{D}'$. Note also that q is monotone on the interval $[\eta_0 - \delta\,, \eta_0 + \delta]$ because of the corresponding property of the restriction $\eta \in \mathcal{D}^{\xi_0} \to Ef^{**}(\eta\,, \xi_0)$, that

$$f^{**}(\eta\,, \xi) \ge d(\eta)\xi + q(\eta) \qquad \text{for every } \eta \in [\eta_0 - \delta\,, \eta_0 + \delta] \text{ and } \xi \in \mathbb{R} \tag{4.7}$$

holds because of (2.1) and (2.7), and that the equalities

$$\begin{cases} f^{**}(\eta\,, a(\eta)) = f(\eta\,, a(\eta)), \\ f^{**}(\eta\,, b(\eta)) = f(\eta\,, b(\eta)), \end{cases} \qquad \eta \in [\eta_0 - \delta\,, \eta_0 + \delta], \tag{4.8}$$

follow from (iv) of Proposition 3.1.

Then we apply Proposition 3.3 and let $\mathcal{K}^{\pm}_{t_0} = \{K^{\pm}_{t_0,\varepsilon}\colon 0 < \varepsilon \le \varepsilon_0(t_0)\}$ and $\mathcal{Y}^{\pm}_{t_0} = \{y^{\pm}_{t_0,\varepsilon}\colon 0 < \varepsilon \le \varepsilon_0(t_0)\}$ be the corresponding intervals and functions. We assume in addition that $\varepsilon_0(t_0)$ is small enough so as to have

$$|y(t) - \eta_0| \le \delta \qquad \text{for every } t \in K^{\pm}_{t_0,\varepsilon} \text{ and } 0 < \varepsilon \le \varepsilon_0(t_0). \tag{4.9}$$

Now, we wish to compare $I^{**}(y^{\pm}_{t_0,\varepsilon})$ with $I^{**}(y)$. To this aim, recalling (3.8), we see that it is enough to compare

$$\int_{K^{\pm}_{t_0,\varepsilon}} f^{**}\left(y^{\pm}_{t_0,\varepsilon}(t)\,, \left(y^{\pm}_{t_0,\varepsilon}\right)'(t)\right) dt \qquad \text{and} \qquad \int_{K^{\pm}_{t_0,\varepsilon}} f^{**}(y(t)\,, y'(t))\, dt.$$

As $(y^{\pm}_{t_0,\varepsilon}(t)\,, (y^{\pm}_{t_0,\varepsilon})'(t))$ can only stay on the upper and lower parts of the boundary of $\mathcal{D}'$ for a.e. $t \in K^{\pm}_{t_0,\varepsilon}$ by (3.10) and (3.11), equation (4.6) shows that the first integral turns in

$$\int_{K^{\pm}_{t_0,\varepsilon}} f^{**}\left(y^{\pm}_{t_0,\varepsilon}(t)\,, \left(y^{\pm}_{t_0,\varepsilon}\right)'(t)\right) dt = \int_{K^{\pm}_{t_0,\varepsilon}} \left[d\left(y^{\pm}_{t_0,\varepsilon}(t)\right)\left(y^{\pm}_{t_0,\varepsilon}\right)'(t) + q\left(y^{\pm}_{t_0,\varepsilon}(t)\right)\right] dt.$$

By the fundamental theorem of calculus, the integrals of $d\left(y^{\pm}_{t_0,\varepsilon}\right)\left(y^{\pm}_{t_0,\varepsilon}\right)'$ and $d(y)y'$ over the interval $K^{\pm}_{t_0,\varepsilon}$ are equal as they are both derivatives of absolutely continuous functions having the same values at the endpoints of the interval $K^{\pm}_{t_0,\varepsilon}$. Hence, the previous computation together with (4.9) and (4.7) yields that

$$\begin{aligned} &\int_{K^{\pm}_{t_0,\varepsilon}} f^{**}\left(y^{\pm}_{t_0,\varepsilon}(t)\,, \left(y^{\pm}_{t_0,\varepsilon}\right)'(t)\right) dt \\ &\le \int_{K^{\pm}_{t_0,\varepsilon}} f^{**}(y(t)\,, y'(t))\, dt + \int_{K^{\pm}_{t_0,\varepsilon}} \left[q\left(y^{\pm}_{t_0,\varepsilon}(t)\right) - q(y(t))\right] dt. \end{aligned} \tag{4.10}$$

Then recall that q is monotone on the interval $[\eta_0 - \delta\,, \eta_0 + \delta]$ and that (3.9+) and (3.9−) hold. Therefore, setting $y_{t_0,\varepsilon} = y^-_{t_0,\varepsilon}$ and $K_{t_0,\varepsilon} = K^-_{t_0,\varepsilon}$ if q is increasing, and $y_{t_0,\varepsilon} = y^+_{t_0,\varepsilon}$ and $K_{t_0,\varepsilon} = K^+_{t_0,\varepsilon}$ otherwise, we conclude that all functions $y_{t_0,\varepsilon}$ are solutions to $(\mathcal{P}^{**})$. Moreover, (4.3a) and (4.3b) follow immediately either from (3.9−) or from (3.9+) and from (3.11) and (4.8), respectively. This completes the proof of the step.

Proof of Step 2. We assume again that the set E defined by (4.2) has positive measure; otherwise the conclusion of the step trivially holds with $x = y$.

Then, for every point $s \in E$, we let $\mathcal{K}_s = \{K_{s,\varepsilon}\colon\ 0 < \varepsilon \le \varepsilon_0(s)\}$ be the family of nondegenerate, compact intervals and $\mathcal{Y}_s = \{y_{s,\varepsilon}\colon\ 0 < \varepsilon \le \varepsilon_0(s)\}$ be the family of new solutions to the relaxed problem $(\mathcal{P}^{**})$ satisfying (4.3) that were constructed in Step 1. Moreover, we can assume that $0 < \varepsilon_0(s) \le 1$ for every $s \in E$.

Now, we are left to prove that we can select and glue some of these functions $y_{s,\varepsilon}$ from $\mathcal{Y}_s$ so as to find a new solution x to $(\mathcal{P}^{**})$ satisfying (4.5).

To this purpose, recall that the intervals $\mathcal{K} = \{K_{s,\varepsilon}\colon\ 0 < \varepsilon \le \varepsilon_0(s) \text{ and } s \in E\}$ defined in the previous step constitute a Vitali covering of E because of (3.7). Hence, Vitali's covering theorem yields (at most) countably many points $s_h \in E$ and numbers $\varepsilon_h \in (0\,, \varepsilon_0(s_h)]$ such that the corresponding intervals $K_h = K_{s_h,\varepsilon_h}$ are pairwise disjoint subsets of $(0\,, T)$ which cover E up to a null set. Also let $y_h = y_{s_h,\varepsilon_h}$ be the corresponding solution to $(\mathcal{P}^{**})$ so that the equality

$$\int_{K_h} f^{**}\left(y_h(t)\,, y_h'(t)\right)\, dt = \int_{K_h} f^{**}\left(y(t)\,, y'(t)\right)\, dt \qquad \text{for every } h \tag{4.11}$$

follows from (3.8) and, moreover,

$$f^{**}\left(y_h(t)\,, y_h'(t)\right) = f\left(y_h(t)\,, y_h'(t)\right) \qquad \text{for a.e. } t \in K_h \tag{4.12}$$

by (4.3b), i.e., the vectors $(y_h(t)\,, y_h'(t))$ keep off the set $\mathcal{D}$ for a.e. $t \in K_h$.

Then we set

$$x(t) = y(t) + \sum_h \left[y_h(t) - y(t)\right], \qquad t \in [0\,, T],$$

and, as in Claim 1 of Proposition 3.3, we show that the series above converges strongly in $AC([0\,, T])$. Indeed, the functions $y_h - y$ are absolutely continuous functions on $[0\,, T]$, whose supports K_h are pairwise disjoint so that the series above actually reduces to a finite sum for every t and its partial sums are bounded by 1 by either (3.9+) or (3.9−) and the choice of $\varepsilon_0(s)$. Thus, the series converges strongly in $L^1([0\,, T])$ by Lebesgue's dominated convergence theorem. As to the derivatives, first recall that the basic assumptions (H2) and (H3) imply that (2.10) holds, i.e., that $f^{**}(\eta\,, \xi)$ has at least linear growth at infinity as $|\xi| \to \infty$, uniformly with respect to η ranging in a bounded interval. Therefore, setting $R = \|y\|_\infty + 1$, for instance, and letting $\alpha > 0$ and $\beta \ge 0$ be the corresponding numbers as in (2.10), we get from (4.11) that

$$\sum_h \int_{K_h} |y_h'(t)|\, dt \le \frac{1}{\alpha}\left[I^{**}(y) + \beta T\right].$$

Hence,

$$\sum_h \int_0^T |y_h'(t) - y'(t)|\, dt = \sum_h \int_{K_h} |y_h'(t) - y'(t)|\, dt$$
$$\leq \sum_h \int_{K_h} |y_h'(t)|\, dt + \|y'\|_1 \leq \frac{1}{\alpha}\,[I^{**}(y) + \beta T] + \|y'\|_1 < \infty;$$

i.e., the series of the derivatives converges strongly in $L^1([0\,,T])$, and this proves the claim about the series defining x.

Finally, it is plain that x is feasible for $(\mathcal{P}^{**})$ because of (3.8) so that, adding (4.11) up for every h, we conclude that x is a solution to $(\mathcal{P}^{**})$. Moreover, $x = y$ on $[0\,,T]\setminus(\cup_h K_h)$, whereas $x = y_h$ on K_h and $x' = y_h'$ almost everywhere on the same set so that the equality $f^{**}(x\,,x') = f(x\,,x')$ almost everywhere on $\cup_h K_h$ follows from (4.12). As the intervals K_h cover E up to a null set, we conclude that (4.5) holds.

Proof of Step 3. Let x be the solution to $(\mathcal{P}^{**})$ satisfying (4.5) that was defined in Step 2 and let A be the set defined by (4.4). We have to show that A is negligible, which we will accomplish by showing that, otherwise, a feasible function $\overline{x}$ such that $I^{**}(\overline{x}) < I^{**}(x)$ would exist.

Indeed, recalling the definitions of the sets A and M in Steps 2 and 1, respectively, we see that set A itself can actually be written, up to a null set, as a countable union of sets

$$B_i = \{t \in (0\,,T)\colon\ x(t) = m_i,\ x \text{ is differentiable at } t \text{ and } x'(t) = 0\}$$

since x' vanishes almost everywhere on each level set $\{x = m_i\}$. Now, assume by contradiction that some set B_i has positive measure and, to simplify notation, set $m = m_i$, $L = L_i$, and $B = B_i$. Note also that (v) of Proposition 2.1 and our assumption (2.14) imply that $0 \in L$ and that m has to be a strict, local maximum point of $\eta \in \mathcal{D}^0 \to Ef^{**}(\eta\,,0)$.

Then, for a sufficiently small $\delta > 0$, there exist two functions $a, b\colon [m - 2\delta\,,m + 2\delta] \to \mathbb{R}$ as in Proposition 3.1 such that the functions $d, q\colon [m - 2\delta\,,m + 2\delta] \to \mathbb{R}$ defined by

$$\begin{cases} d(\eta) = d(\eta\,,\xi), \\ q(\eta) = Ef^{**}(\eta\,,\xi), \end{cases} \qquad \eta \in [m - 2\delta\,,m + 2\delta],$$

are well defined because of Proposition 2.1, no matter what $\xi \in (a(\eta), b(\eta))$ is, and, moreover, the following properties hold:

(4.13a) $(m\,,0) \in \mathcal{D}$;

(4.13b) $a(\eta) < 0 < b(\eta)$ for every $\eta \in [m - 2\delta\,,m + 2\delta]$;

(4.13c) $q(\eta) = f^{**}(\eta\,,0)$ for every $\eta \in [m - 2\delta\,,m + 2\delta]$;

(4.13d) $f^{**}(\eta\,,\xi) = d(\eta)\xi + q(\eta)$ for $\xi \in (a(\eta)\,,b(\eta))$ and $\eta \in [m - 2\delta\,,m + 2\delta]$;

(4.13e) m is a strict, local maximum point of q;

(4.13f) q is increasing on $[m - 2\delta\,,m]$ and decreasing on $[m\,,m + 2\delta]$.

Now, let $s \in B$ be a density point of B and let $\mathcal{H}_s^{\pm} = \left\{H_{s,\varepsilon}^{\pm}\colon\ 0 < \varepsilon \leq \varepsilon_0\right\}$ and $\mathcal{X}_s^{\pm} = \left\{x_{s,\varepsilon}^{\pm}\colon\ 0 < \varepsilon \leq \varepsilon_0\right\}$ be the families of intervals and functions associated with $z = x$, δ, $\alpha = \max\{a(\eta)\colon\ |\eta - m| \leq \delta\} < 0$, and $\beta = \min\{b(\eta)\colon\ |\eta - m| \leq \delta\} > 0$

by Lemma 3.2. Let also $J^{\pm}_{s,\varepsilon}$ be the intervals defined by (3.1) and assume $\varepsilon_0 = \varepsilon_0(s\,,\delta)$ is small enough so as to have $\varepsilon_0 \le 2\delta$ and $|x(t) - m| \le \delta$ for every t in $J^{\pm}_{s,2\varepsilon_0}$. Hence, $\left|x^{\pm}_{s,\varepsilon}(t) - m\right| \le 2\delta$ for every t in $H^{\pm}_{s,\varepsilon}$ and every $0 < \varepsilon \le \varepsilon_0$ by either (3.4+) or (3.4−). Each function $x^{\pm}_{s,\varepsilon}$ is feasible for $(\mathcal{P}^{**})$ because of (3.2) and (3.3) and, in order to compare $I^{**}\left(x^{\pm}_{s,\varepsilon}\right)$ with $I^{**}(x)$, it is enough that we compare

$$\int_{H^{\pm}_{s,\varepsilon}} f^{**}\left(x^{\pm}_{s,\varepsilon}(t)\,,\left(x^{\pm}_{s,\varepsilon}\right)'(t)\right)\,dt \qquad \text{and} \qquad \int_{H^{\pm}_{s,\varepsilon}} f^{**}\left(x(t)\,,x'(t)\right)\,dt.$$

Now, the very same computations of Step 1 yield that

$$\begin{aligned}&\int_{H^{\pm}_{s,\varepsilon}} f^{**}\left(x^{\pm}_{s,\varepsilon}(t)\,,\left(x^{\pm}_{s,\varepsilon}\right)'(t)\right)\,dt\\ &\le \int_{H^{\pm}_{s,\varepsilon}} f^{**}\left(x(t)\,,x'(t)\right)\,dt + \int_{H^{\pm}_{s,\varepsilon}} \left[q\left(x^{\pm}_{s,\varepsilon}(t)\right) - q(x(t))\right]\,dt\end{aligned} \tag{4.14}$$

for every $0 < \varepsilon \le \varepsilon_0$, and we claim that for small enough ε, we can choose either + or − so that the last summand at the right-hand side of (4.14) is negative, thus getting a contradiction.

To see this, choose a decreasing sequence $\{\varepsilon_k\}_k$ in $(0\,,\varepsilon_0]$ such that $\varepsilon_k \to 0$ and set

$$\eta_k = \frac{1}{\varepsilon_k}\sup\left\{|x(t) - m| :\ \ |t - s| < 2p\varepsilon_k\right\} \qquad \text{for every } k,$$

where $p = \max\left\{(\beta - x'(s))^{-1}\,,(x'(s) - \alpha)^{-1}\right\}$. Obviously, $\eta_k \to 0_+$ since x is differentiable at s with $x'(s) = 0$ by assumption and, moreover, $0 < \eta_k\varepsilon_k \le \delta$ by the choice of ε_0. Then, recalling that m is a strict, local maximum point of q and possibly extracting a subsequence that we still label as $\{\varepsilon_k\}_k$, we can assume that the minimum between $q(m - \eta_k\varepsilon_k)$ and $q(m + \eta_k\varepsilon_k)$ is actually achieved for every k by terms with the same sign inside, say $q(m + \eta_k\varepsilon_k)$, so that

$$0 < q(m) - q(m + \eta_k\varepsilon_k) = \max\left\{q(m) - q(m - \eta_k\varepsilon_k), q(m) - q(m + \eta_k\varepsilon_k)\right\} \tag{4.15}$$

holds for every k.

According to this assumption, we choose the + functions and, to simplify notation, we set $x_k = x^{+}_{s,\varepsilon_k}$ and $H_k = H^{+}_{s,\varepsilon_k}$ for every k. Of course, if the minimum between $q(m - \eta_k\varepsilon_k)$ and $q(m + \eta_k\varepsilon_k)$ was achieved by $q(m - \eta_k\varepsilon_k)$ instead, we would have chosen the − functions.

Finally, also set $J_\varepsilon = J^{+}_{s,\varepsilon}$ for $\varepsilon > 0$ and note that (3.2) reduces to

$$J_{\varepsilon_k/2} \subset H_k \subset J_{2\varepsilon_k}. \tag{4.16}$$

We prove the claim by showing that the integral

$$\int_{H_k} \left[q(x_k(t)) - q(x(t))\right]\,dt$$

is eventually negative.

To see this, set

$$A^1_k = \frac{1}{|H_k|}\int_{H_k} \left[q(m) - q(x_k(t))\right]\,dt \qquad \text{and} \qquad A^2_k = \frac{1}{|H_k|}\int_{H_k} \left[q(m) - q(x(t))\right]\,dt$$

for every k so that the claim reduces to proving that eventually $\left|A_k^1 - A_k^2\right| > 0$. Indeed, recalling (4.16), that q is decreasing on the interval $[m\,, m+2\delta]$ by (4.13f) and noting that (3.5+) reduces to

$$2\delta \geq \varepsilon_k \geq x_k(t) - m \geq \varepsilon_k/2, \qquad t \in J_{\varepsilon_k/2},$$

because $s \in B$ and because of the choice of ε_0, we find that

$$\begin{aligned} A_k^1 &\geq \frac{1}{|J_{2\varepsilon_k}|} \int_{J_{\varepsilon_k/2}} [q(m) - q(x_k(t))]\, dt \\ &\geq \frac{1}{|J_{2\varepsilon_k}|} \int_{J_{\varepsilon_k/2}} [q(m) - q(m+\varepsilon_k/2)]\, dt = \frac{1}{4}\,[q(m) - q(m+\varepsilon_k/2)] \end{aligned}$$

for every k since $\left|J_{\varepsilon_k/2}\right| / |J_{2\varepsilon_k}| = 1/4$ by (3.1). As to A_k^2, note that

$$A_k^2 = \frac{1}{|H_k|} \int_{H_k \setminus B} [q(m) - q(x(t))]\, dt \qquad \text{for every } k$$

and that $m - \eta_k\varepsilon_k \leq x(t) \leq m + \eta_k\varepsilon_k$ for $t \in H_k$ by (4.16) and the very definition of η_k. Hence,

$$\begin{aligned} 0 &\leq q(m) - q(x(t)) \leq \max\left\{q(m) - q(m-\eta_k\varepsilon_k)\,, q(m) - q(m+\eta_k\varepsilon_k)\right\} \\ &= q(m) - q(m+\eta_k\varepsilon_k) \end{aligned}$$

for every $t \in H_k$ and every k by (4.13f) and (4.15) whence we obtain

$$0 \leq A_k^2 \leq \frac{|H_k \setminus B|}{H_k}\,[q(m) - q(m+\eta_k\varepsilon_k)] \qquad \text{for every } k.$$

Since $\eta_k \to 0$, it follows that eventually $q(m) - q(m+\varepsilon_k/2) \geq q(m) - q(m+\eta_k\varepsilon_k) > 0$ by (4.13f). As s is a density point of B and the intervals $\{H_k\}_k$ shrink at s, the ratio $|H_k \setminus B| / |H_k|$goes to zero because of (2.8) and the conclusion follows. ∎

FEEDBACKS FOR NONAUTONOMOUS REGULAR LINEAR SYSTEMS*

ROLAND SCHNAUBELT†

Abstract. We introduce nonautonomous well-posed and (absolutely) regular linear systems as quadruples consisting of an evolution family and output, input, and input–output maps subject to natural hypotheses. In the spirit of Weiss' work, these maps are represented in terms of admissible observation and control operators (the latter in an approximate sense) in the time domain. In this setting, the closed-loop system exists for a canonical class of "admissible" feedbacks, and it inherits the absolute regularity and other properties of the given system. In particular, we can iterate feedbacks.

Key words. input–output map, evolution family, Lebesgue extension, representation, closed-loop system, controllable, observable, robustness of exponential dichotomy, input–output stability

AMS subject classifications. Primary, 93C25; Secondary, 47D06

1. Introduction.

As a motivation, we first look at the finite dimensional nonautonomous linear system

$$\begin{aligned} x'(t) &= A(t)x(t) + B(t)u(t), \quad t \geq s \geq 0, \\ y(t) &= C(t)x(t), \quad t \geq s \geq 0, \quad x(s) = x_0, \end{aligned} \tag{1.1}$$

on the state space X with control operators $B(t) : U \to X$, observation operators $C(t) : X \to Y$, the control space U, and the observation space Y. Let $T(t,s)$, $t \geq s \geq 0$, be the evolution family (propagator) on X generated by $A(\cdot)$. Then the output of (1.1) with $u = 0$, the state of (1.1) with $x_0 = 0$, and the input–output operator of (1.1) are given by

$$\begin{aligned} (\Psi_s x_0)(t) &= C(t)T(t,s)x_0, \qquad \Phi_{t,s}u = \int_s^t T(t,\tau)B(\tau)u(\tau)d\tau, \\ (\mathbb{F}_s u)(t) &= C(t)\int_s^t T(t,\tau)B(\tau)u(\tau)d\tau, \qquad t \geq s. \end{aligned} \tag{1.2}$$

If one feeds back the output via $u(t) = \Delta(t)y(t)$, the resulting closed-loop system is described by the perturbed evolution equation

$$x'(t) = [A(t) + B(t)\Delta(t)C(t)]\, x(t), \quad t \geq s \geq 0, \qquad x(s) = x_0. \tag{1.3}$$

Of course, $x(t) = T_\Delta(t,s)x_0$ solves (1.3) if T_Δ is generated by $A(t) + B(t)\Delta(t)C(t)$. This evolution family also satisfies the "variation of constants formulas"

$$T_\Delta(t,s)x = T(t,s)x + \int_s^t T(t,\tau)B(\tau)\Delta(\tau)C(\tau)T_\Delta(\tau,s)x\, d\tau, \tag{1.4}$$

$$T_\Delta(t,s)x = T(t,s)x + \int_s^t T_\Delta(t,\tau)B(\tau)\Delta(\tau)C(\tau)T(\tau,s)x\, d\tau \tag{1.5}$$

for $t \geq s$ and $x \in X$. Identity (1.4) is the integrated version of (1.3). To derive (1.5), we perturb T_Δ by $-B(t)\Delta(t)C(t)$. There are formulas analogous to (1.4) and (1.5) relating the maps from (1.2) with the corresponding ones of the closed-loop system. These formulas are needed to show further properties of the closed-loop system. For instance, the closed-loop system is observable (controllable) if and only if the open-loop system is observable (controllable). In this framework, one can also show the equivalence of internal stability with input/output stability, detectability, and stabilizability. We establish infinite dimensional versions of these results in section 5.

If we pass to an infinite dimensional state space X, it is no longer clear that (1.3) possesses differentiable solutions for "many" initial values even if the Cauchy problem for $A(\cdot)$ is well-posed; cf. [7], [9, section VI.9], [10]. Nevertheless, the formulas (1.2) still work, and there is an evolution family T_Δ fulfilling (1.4) and (1.5). Thus $x(t) = T_\Delta(t,s)x_0$ is the "mild" solution of (1.3) [7]. However, point or boundary control and observation lead to input and output operators $B(t) : U \to \overline{X}_t$ and $C(t) : \underline{X}_t \to Y$ for spaces $\underline{X}_t \subsetneqq X \subsetneqq \overline{X}_t$, where $C(t)$ usually is not closable; see, e.g., [3], [16]. In order to solve (1.4) in this more general setting, we may restrict ourselves to "admissible" observation and control operators—roughly speaking, those for which the expressions (1.2) make sense. Then we are also faced with the question of whether the operators $B(t)$ and $C(t)$ are again admissible for the perturbed evolution family T_Δ, which is necessary to verify (1.5) or to iterate feedbacks.

The resulting perturbation problem (1.3) generalizes the settings of both the Desch–Schappacher theorem (where $\Delta(t) = C(t) = I$) and the Miyadera theorem (where $\Delta(t) = B(t) = I$) from semigroup theory [9, section III.3], [19]. In the control literature, there is a rich perturbation theory for the autonomous case (i.e., $A(t) = A$, $B(t) = B$, $C(t) = C$, $\Delta(t) = \Delta$). Linear systems belonging to the *Pritchard–Salamon class* [18] were exhaustively treated in [6]. Salamon and Weiss introduced the larger class of *well-posed linear systems* in [21] and [28], [29], [30], [31]. Here the semigroup T is given, and the operators Φ, Ψ, and $\mathbb{F}$ are defined in an abstract way by certain algebraic relations. One can then construct admissible control and observation operators B and C and obtain formulas such as (1.2) if the system satisfies a quite natural *regularity* hypothesis. Weiss established a powerful feedback theory for regular systems in the Hilbert space situation [32]. We refer to section 4, [3, section 3.3], [17], [33], and, in particular, to Staffans' monograph [25] for further information and literature.

For nonautonomous systems in variational form, there is the well-known approach due to Lions [16]; see also [1] and [3, Chap. 2]. In a general setting, Hinrichsen, Jacob, and Pritchard [10], [12], [14] constructed an evolution family solving (1.4) for initial values x contained in a dense subspace $\underline{X}$ of X under rather weak assumptions covering autonomous regular systems. However, (1.5) and the admissibility of the perturbed system was investigated only in [12] requiring stronger hypotheses of Pritchard–Salamon type.

In the present work, we combine the direct approach of Hinrichsen, Jacob, and Pritchard with some of Weiss' ideas: In Definition 2.6, we introduce "Lebesgue extensions" of given observation operators $C(t)$ (cf. [28]) which allow the study of (1.4) and (1.5) for all $x \in X$ and simplify several technical details of the proofs considerably. For similar reasons, we mostly work with *nonautonomous (absolutely) regular systems*, which are defined in the spirit of Weiss' work (see Definitions 3.6 and 3.10) as opposed to *admissible systems*, which have been used in [10], [12], [14] and are given directly by operators $B(t)$ and $C(t)$ (see Definition 3.8). In Theorem 2.7, Proposition 3.5, and Theorem 3.11, we represent a given regular system similar as in (1.2). It is known

[27, Ex. 6] that (1.3) can only be solved if the feedback is not "too large." We thus introduce *admissible* feedbacks in Definition 4.1; cf. [25, section 7.1], [32, section 3]. In our main theorem, Theorem 4.4, we then establish the existence of an absolutely regular closed-loop system for a given absolutely regular nonautonomous system with admissible time varying feedback.

However, the extension of Weiss' theory to the nonautonomous case is limited by two serious obstacles: One cannot apply transform methods, and, in contrast to semigroups (see, e.g., [2, Chap. V], [9, section II.5]), we do not have a general extrapolation theory for evolution families. The first point excludes the use of transfer functions (being crucial in [32]) but leads us to arguments which work in a Banach space setting (as in [25, Chap. 7]). The second point forces us to employ approximation formulas for the representation of control systems in Proposition 3.5. A similar problem occurs in the computation of the feedback system and in the context of (1.5); cf. Remark 4.7.

In section 5 we derive analogues of (1.4) and (1.5) for the operators given in (1.2). It is also seen that the closed-loop system is controllable (or observable) if and only if the given system is controllable (or observable). Moreover, iterated feedbacks behave as one would expect. We further prove that the feedback system inherits the exponential dichotomy (or stability) of T. Results of this type are important tools in investigating the long-term behavior of evolution equations but have not yet been obtained for perturbations mapping from a subspace of X to a larger space. Finally, the equivalence of internal stability with input–output stability, detectability, and stabilizability is established, extending theorems from [5], [6], [17], [20], [33] to the present setting. As a sample of possible applications, we treat in section 6 a parabolic problem with point observation and control in space dimension $n \leq 3$ which can be generalized in various directions.

Notation. We denote the space of bounded linear operators from X to Y by $\mathcal{L}(X,Y)$ and put $\mathcal{L}(X) := \mathcal{L}(X,X)$, where X, Y, U, Z always designate Banach spaces. $C_b(\mathbb{R}_+, \mathcal{L}_s(X,Y))$ and $L^\infty(\mathbb{R}_+, \mathcal{L}_s(X,Y))$ are the spaces of (essentially) bounded strongly continuous and strongly measurable operator-valued functions, respectively. We set $a \vee b = \max\{a,b\}$, $a \wedge b = \min\{a,b\}$, $a^+ = a \vee 0$, and $a^- = (-a)^+$ for $a, b \in \mathbb{R}$ and write $\mathbb{1}_N$ for the characteristic function of $N \subset M$. Unless otherwise stated, p is a number contained in $[1,\infty)$. The spaces $L^p_{loc}([s,\infty), Z)$ and $C([s,\infty), Z)$ are endowed with their standard Fréchet topologies. We mostly use the same symbol for a function on $J \subset \mathbb{R}$ and its restrictions to subintervals.

2. Nonautonomous observation systems.

DEFINITION 2.1. *A set* $T = (T(t,s))_{t \geq s \geq 0} \subseteq \mathcal{L}(X)$ *is an* evolution family *if*

(E1) $T(t,s) = T(t,r)T(r,s)$, $T(s,s) = I$,

(E2) $(t,s) \mapsto T(t,s)$ *is strongly continuous, and*

(E3) $\|T(t,s)\| \leq Me^{w(t-s)}$

for $t \geq r \geq s \geq 0$ *and constants* $M \geq 1$ *and* $w \in \mathbb{R}$. *We also define* $(\mathbb{K}_s f)(t) = \int_s^t T(t,\tau) f(\tau)\, d\tau$ *for* $t \geq s \geq 0$ *and* $f \in L^1_{loc}([s,\infty), X)$ *and put* $\mathbb{K} = \mathbb{K}_0$.

Evolution families arise as solution operators of nonautonomous evolution equations, although not every evolution family solves such a problem. We refer to [4], [9, section VI.9], and the references therein for further information. Condition (E3) is needed only in the study of asymptotic properties in section 5; see Remark 4.5.

DEFINITION 2.2. *Let* T *be an evolution family on* X *and* $\Psi_s : X \to L^p_{loc}([s,\infty), Y)$, $s \geq 0$, *be linear operators satisfying*

$$\Psi_s x = \Psi_t T(t,s)x \quad \text{on } [t,\infty) \quad \text{and} \quad \int_s^{s+t_0} \|(\Psi_s x)(t)\|_Y^p \, dt \leq \gamma^p \|x\|_X^p \tag{2.1}$$

for $t \geq s \geq 0$, $x \in X$, and some $t_0 > 0$, $\gamma = \gamma(t_0) > 0$. Then $(T, \Psi) = (T, \{\Psi_s : s \geq 0\})$ is a nonautonomous observation system. *We extend the map $\Psi_s x$ by 0 to $\mathbb{R}$.*

LEMMA 2.3. *Let (T, Ψ) be a nonautonomous observation system. Then one can replace the constant t_0 in (2.1) by every $t_1 > 0$ and $\gamma = \gamma(t_0)$ by $\gamma(t_1) = c_0 M \gamma(t_0) c(t_1)$, where $c(t) = e^{w^+ t}$ for $w \neq 0$, $c(t) = (1 + \frac{t}{t_0})^{\frac{1}{p}}$ for $w = 0$, and c_0 depends on t_0, w, p.*

Proof. The case $t_1 \leq t_0$ is obvious. So let $t_1 = nt_0 + \tau$ for some $n \in \mathbb{N}$ and $\tau \in [0, t_0)$. Setting $I_k = [s + kt_0, s + (k+1)t_0]$, we deduce from Definition 2.2 that

$$\|\Psi_s x\|^p_{L^p([s,s+t_1],Y)} \leq \sum_{k=0}^{n} \|\Psi_{s+kt_0} T(s + kt_0, s)x\|^p_{L^p(I_k,Y)} \leq M^p \, \gamma(t_0)^p \sum_{k=0}^{n} e^{wpt_0 k}$$

for $x \in X$ and $s \geq 0$. The assertion then follows easily. □

DEFINITION 2.4. *Let T be an evolution family on X and $C(s) : D(C(s)) \subseteq X \to Y$, $s \geq 0$, be densely defined linear operators such that $T(\cdot, s)x \in D(C(\cdot), s) := \{f \in L^p_{loc}([s, \infty), X) : f(t) \in D(C(t))$ for a.e. $t \geq s$, $C(\cdot)f(\cdot) \in L^p_{loc}([s, \infty), Y)\}$ and*

$$\int_s^{s+t_0} \|C(t)T(t, s)x\|^p_Y \, dt \leq \gamma^p \, \|x\|^p_X \tag{2.2}$$

for $s \geq 0$, $x \in D(C(s))$, and some constants $\gamma, t_0 > 0$. Then we say that $C(s)$, $s \geq 0$, are (T-)admissible observation operators.

LEMMA 2.5. *Let $C(s)$, $s \geq 0$, be T-admissible observation operators. Then (2.2) holds for all $t_0 > 0$ with a possibly different γ. Let $\Psi_s : X \to L^p_{loc}([s, \infty), Y)$, $s \geq 0$, be the continuous extension of the map $D(C(s)) \ni x \mapsto C(\cdot)T(\cdot, s)x$. Then (T, Ψ) is a nonautonomous observation system.*

Proof. The first claim can be established as Lemma 2.3; one has only to replace $s + kt_0$ by points $s_k \approx s + kt_0$ such that $T(s_k, s)x \in D(C(s_k))$; see [23, Lem. 4.13]. So we can define Ψ_s as in the claim. Given $t \geq s \geq 0$ and $x \in D(C(s))$, we take $z_n \in D(C(t))$ converging in X to $T(t, s)x$ and $t_n \searrow t$ such that $T(t_n, s)x, T(t_n, t)z_n \in D(C(t_n))$. Since $\Psi_t T(t, s)x = \lim_{n\to\infty} \mathbb{1}_{[t_n, t+t_0]} \, C(\cdot)T(\cdot, t)z_n$ in $L^p([t, t + t_0], Y)$, we obtain

$$\begin{aligned}
&\|\Psi_t T(t, s)x - C(\cdot)T(\cdot, s)x\|^p_{L^p([t,t+t_0],Y)} \\
&= \lim_{n\to\infty} \left[\int_{t_n}^{t+t_0} \|C(\tau)T(\tau, t_n) \, [T(t_n, t)z_n - T(t_n, s)x]\|^p d\tau + \int_t^{t_n} \|C(\tau)T(\tau, s)x\|^p d\tau \right] \\
&\leq \gamma^p \lim_{n\to\infty} \|T(t_n, t)z_n - T(t_n, s)x\|^p = 0.
\end{aligned}$$

Therefore, (2.1) holds for $x \in D(C(s))$ and thus for $x \in X$ by approximation. □

We note that different admissible observation operators $C_1(s)$ and $C_2(s)$ may yield the same observation system as shown in [28, Ex. 1.2]. However, if the observation operators $C(s)$ are closable, then one easily verifies that $\Psi_s x = \overline{C(\cdot)}T(\cdot, s)x$ for the induced observation system. We now proceed in the converse direction and represent a given observation system by admissible observation operators; cf. [28, Def. 4.1].

DEFINITION 2.6. *For a nonautonomous observation system (T, Ψ), we define*

$$C(s)x = \lim_{\tau \searrow 0} \frac{1}{\tau} \int_s^{s+\tau} (\Psi_s x)(\sigma) \, d\sigma \qquad \textit{(in } Y\textit{)} \tag{2.3}$$

for $x \in \underline{X}_s := \{x \in X :$ *the limit in* (2.3) *exists*$\}$ *and*

$$\|x\|_{\underline{X}_s} = \|x\|_X + \sup_{0<\tau\le 1} \left\| \frac{1}{\tau} \int_s^{s+\tau} (\Psi_s x)(\sigma)\, d\sigma \right\|_Y$$

for $x \in \underline{X}_s$ *and* $s \ge 0$. *The space* $D(C(\cdot), s)$ *is defined as in Definition* 2.4 *by replacing* $D(C(t))$ *with* $\underline{X}_t$.

Clearly, $\|\cdot\|_{\underline{X}_s}$ is a norm on the subspace $\underline{X}_s$ and $C(s) : \underline{X}_s \to Y$ is linear and continuous. As in [28, Prop. 4.3], one verifies that $(\underline{X}_s, \|\cdot\|_{\underline{X}_s})$ is complete.

We say that $t \in \mathbb{R}$ is a *p-Lebesgue point* of $f \in L^p_{loc}(\mathbb{R}, Z)$, $1 \le p < \infty$, if

$$\lim_{|J|\to 0} \frac{1}{|J|} \int_J \|f(s) - f(t)\|^p\, ds = 0,$$

where the limit is taken over compact intervals J containing t (of length $|J|$). If $p = 1$, then t is called the *Lebesgue point*. Recall that a.e. t is a p-Lebesgue point of $f \in L^p_{loc}(\mathbb{R}, Z)$; see, e.g., [31, Lem. 6.1] or [26, section I.1.8]. The next representation theorem extends [28, Thm. 4.5] to nonautonomous observation systems. A different representation of output functions was given in [11] applying Weiss' theory to the "evolution semigroup" on $L^p([0, t_0], X)$ associated with T; cf. [4].

THEOREM 2.7. *Let* (T, Ψ) *be a nonautonomous observation system, and let* $C(s) \in \mathcal{L}(\underline{X}_s, Y)$ *be given as in Definition* 2.6. *Let* $x \in X$ *and* $t \ge s \ge 0$. *Then* $T(t, s)x \in \underline{X}_t$ *if and only if* $1/\tau \int_0^\tau (\Psi_s x)(t + \sigma)\, d\sigma$ *converges as* $\tau \searrow 0$. *If this is the case, then the limit equals* $C(t)T(t, s)x$. *Thus* $(\Psi_s x)(t) = C(t)T(t, s)x$ *for all Lebesgue points* t *of* $\Psi_s x$.

Proof. The theorem follows from the identity

$$\frac{1}{\tau} \int_t^{t+\tau} [\Psi_s x](\sigma)\, d\sigma = \frac{1}{\tau} \int_t^{t+\tau} [\Psi_t T(t, s)x](\sigma)\, d\sigma. \qquad \square$$

This theorem shows that the operators $C(t)$, $t \ge 0$, introduced in Definition 2.6 are admissible observation operators. According to Lemma 2.5, they generate an observation system $(\tilde{\Psi}, T)$. It is easy to see that, in fact, $(\Psi_s x)(t) = (\tilde{\Psi}_s x)(t)$ for each $x \in X$ and a.e. $t \ge s$. We say that the operators $C(t)$ from Definition 2.6 *represent the observation system* (T, Ψ).

In the remainder of this section, we establish several properties of Ψ_s which will be important for our main perturbation result.

LEMMA 2.8. *Let* (T, Ψ) *be a nonautonomous observation system,* $f \in L^p_{loc}(\mathbb{R}_+, X)$, *and* $t_0 > 0$. *Then the map* $[0, t_0] \ni s \mapsto \Psi_s f(s) \in L^p([0, t_0], Y)$ *is measurable, and*

$$\int_0^{t_0} \|\Psi_s f(s)\|^p_{L^p([0,t_0],Y)}\, ds \le \gamma(t_0)^p \, \|f\|^p_{L^p([0,t_0],X)}\,. \tag{2.4}$$

Proof. For $f \in C(\mathbb{R}_+, X)$, the map $s \mapsto \Psi_s f(s)$ is continuous from the right since

$$\|\Psi_s f(s) - \Psi_r f(r)\|^p_{L^p([0,t_0],Y)} = \|\Psi_s(f(s) - T(s, r)f(r))\|^p_{L^p([s,t_0],Y)} + \|\Psi_r f(r)\|^p_{L^p([r,s],Y)}$$

for $0 \le r \le s \le t_0$. Functions $f \in L^p_{loc}(\mathbb{R}_+, X)$ can be treated by approximation. The estimate (2.4) follows from (2.1). $\square$

The nonclosedness of $C(t)$ is a major obstacle for the analysis of observation systems and input–output operators; for instance, it is a priori not clear whether $C(t)$

can be taken out of an integral. As in the autonomous case (see, e.g., [31, section 4]), such problems can be overcome by employing the operators

$$C_\tau(s)x = \frac{1}{\tau}\int_s^{s+\tau} (\Psi_s x)(\sigma)\,d\sigma, \tag{2.5}$$

$x \in X$, $s \geq 0$, and $\tau \in (0,1]$. Due to this definition, $C_\tau(s)$ belongs to $\mathcal{L}(X,Y)$ with norm less than or equal to $\gamma(1)\tau^{-\frac{1}{p}}$, $C_\tau(s)x$ converges as $\tau \to 0$ if and only if $x \in \underline{X}_s$, and then the limit equals $C(s)x$. Let $C_c(\mathbb{R}_+)$ be the space of continuous functions with compact support in $[0,\infty)$. We also define

$$\mathcal{D}_s = \operatorname{span}\{\varphi(\cdot)T(\cdot,r)x : x \in X,\, r \geq s,\, \varphi \in C_c(\mathbb{R}_+),\, \varphi(t) = 0 \text{ for } s \leq t < r\} \tag{2.6}$$

for $s \geq 0$ (setting $T(t,s) := 0$ for $t < s$), and we put $\mathcal{D} = \mathcal{D}_0$. This space is dense in $L^p([s,\infty),X)$ and in $C_0([s,\infty),X)$, the space of continuous functions vanishing at infinity. This fact can be seen by an obvious modification of the proof of [4, Thm. 3.12].

LEMMA 2.9. *Let (T,Ψ) be a nonautonomous observation system represented by $C(s)$, and let $C_\tau(s)$ be given by (2.5). Then $(s,\tau) \mapsto C_\tau(s)x$ is continuous on $\mathbb{R}_+ \times (0,1]$,*

$$\|C_\tau(\cdot)T(\cdot,s)x\|_{L^p([s,s+t_0],Y)} \leq \gamma(t_0+1)\,\|x\|, \quad \textit{and} \tag{2.7}$$

$$\Psi_s x = \lim_{\tau\to 0} C_\tau(\cdot)T(\cdot,s)x \quad \textit{in} \quad L^p_{loc}([s,\infty),Y) \tag{2.8}$$

for $x \in X$, $s \geq 0$, $\tau \in (0,1]$, and $t_0 > 0$.

Proof. If $f \in \mathcal{D}$, then $(t,\tau) \mapsto C_\tau(t)f(t)$ is continuous since

$$C_\tau(t)f(t) = \sum_{k=1}^n \varphi_k(t)\,\frac{1}{\tau}\int_t^{t+\tau} (\Psi_{r_k}x_k)(\sigma)\,d\sigma$$

for $\tau > 0$, $t \geq 0$, and suitable $n \in \mathbb{N}$, $r_k \geq 0$, $x_k \in X$, $\varphi_k \in C_c(\mathbb{R}_+)$. The first assertion follows by approximation. We further estimate

$$\begin{aligned}&\|C_\tau(\cdot)T(\cdot,s)x\|^p_{L^p([s,s+t_0],Y)}\\ &\leq \int_s^{s+t_0+\tau} \frac{1}{\tau}\int_{\sigma-\tau}^{\sigma} \|(\Psi_s x)(\sigma)\|^p\,dt\,d\sigma \leq \gamma(t_0+1)^p\,\|x\|^p\end{aligned}$$

using Hölder's inequality and Fubini's theorem. Similarly, (2.8) follows from

$$\begin{aligned}&\|C_\tau(\cdot)T(\cdot,s)x - \Psi_s x\|^p_{L^p([s,s+t_0],Y)}\\ &\leq \frac{1}{\tau}\int_0^\tau \int_s^{s+t_0} \|(\Psi_s x)(t+\sigma) - (\Psi_s x)(t)\|^p\,dt\,d\sigma. \qquad \square\end{aligned}$$

We want to show that $C(\cdot)\mathbb{K}_s : L^p([s,s+t_0],X) \to L^p([s,s+t_0],Y)$ is well defined and bounded. This fact is crucial for Theorem 4.4, and its proof is somewhat technical. We set

$$\varphi(t;\,\tau,\sigma,f) = (C_\tau(t) - C_\sigma(t))\int_0^t T(t,s)f(s)\,ds,$$

$$o_f(t) = \overline{\lim_{\tau,\sigma\to 0}}\,\|\varphi(t;\,\tau,\sigma,f)\| = \overline{\lim_{n\to\infty}} \sup_{m\geq n} \sup_{\tau,\sigma\in[1/m,1/n]} \|\varphi(t;\,\tau,\sigma,f)\|$$

for $f \in L^1_{loc}(\mathbb{R}_+, X)$, $t \geq 0$, $\tau, \sigma \in (0,1]$. Observe that o_f is measurable. We further need the *maximal operator* given by

$$M\psi(t) = \sup_{\tau>0} \frac{1}{\tau} \int_t^{t+\tau} |\psi(s)|\, ds \ \in [0,\infty]$$

for all $t \in \mathbb{R}$ and $\psi \in L^1_{loc}(\mathbb{R})$. Recall that

$$\|M\psi\|_{L^p(\mathbb{R})} \leq c_p \, \|\psi\|_{L^p(\mathbb{R})} \tag{2.9}$$

for $\psi \in L^p(\mathbb{R})$, $1 < p \leq \infty$, and a constant c_p; see [26, Thm. I.1].

LEMMA 2.10. *Let (T, Ψ) be a nonautonomous observation system, $p \in (1,\infty)$, and $f \in L^p_{loc}(\mathbb{R}_+, X)$. Then $C_\tau(t)(\mathbb{K}f)(t) \to C(t)(\mathbb{K}f)(t)$ as $\tau \searrow 0$ for a.e. $t \geq 0$.*

Proof. Take $g \in \mathcal{D}$ and $f \in L^p_{loc}(\mathbb{R}_+, X)$. Observe that $o_g = 0$ a.e. because of

$$C_\tau(t)(\mathbb{K}g)(t) = \sum_{k=1}^n \int_0^t \varphi_k(s)\, ds \, \frac{1}{\tau} \int_t^{t+\tau} (\Psi_{r_k} x_k)(\sigma)\, d\sigma$$

for $\tau > 0$, $t \geq 0$, and suitable $n \in \mathbb{N}$, $r_k \geq 0$, $x_k \in X$, and $\varphi_k \in C_c(\mathbb{R}_+)$. Due to Lemma 2.8, there is a measurable function $\psi_{f-g} : \mathbb{R} \times \mathbb{R}_+ \to \mathbb{R}_+$ such that

$$\text{for a.e. } \ s \geq 0, \qquad \|[\Psi_s(f(s) - g(s))](t)\|_Y = \psi_{f-g}(t,s) \quad \text{for a.e. } \ t \geq s.$$

(Here we set $[\Psi_s(f(s) - g(s))](t) = \psi_{f-g}(t,s) = 0$ for $t < s$, $t > t_0$, or $s > t_0$, where $t_0 > 0$ is fixed but arbitrary.) Employing these facts, we estimate

$$\begin{aligned} o_f(t) \leq o_{f-g}(t) &\leq \sup_{\tau,\sigma\in(0,1]} \int_0^t \|(C_\tau(t) - C_\sigma(t))\, T(t,s)(f(s) - g(s))\|\, ds \\ &\leq 2 \sup_{\tau\in(0,1]} \int_0^t \frac{1}{\tau} \int_t^{t+\tau} \|[\Psi_s(f(s) - g(s))](\rho)\|\, d\rho\, ds \\ &\leq 2 \int_0^t [M\psi_{f-g}(\cdot, s)](t)\, ds \end{aligned} \tag{2.10}$$

for t not contained in a set of measure 0 depending on g. Approximating $0 \leq \phi \in L^1_{loc}(\mathbb{R}^2)$ by continuous functions, one sees that $(t,s) \mapsto [M\phi(\cdot,s)](t)$ is measurable. We can now use (2.10), Fubini's theorem, and the maximal inequality (2.9) to derive

$$\begin{aligned} |\{t \in [0,t_0] : o_f(t) > \varepsilon\}| &\leq \frac{2}{\varepsilon} \int_0^{t_0} \int_0^t \left[M\psi_{f-g}(\cdot,s)\right](t)\, ds\, dt \\ &\leq \frac{c}{\varepsilon} \int_0^{t_0} \|M\psi_{f-g}(\cdot,s)\|_{L^p(\mathbb{R})}\, ds \\ &\leq \frac{c'}{\varepsilon} \int_0^{t_0} \|\psi_{f-g}(\cdot,s)\|_{L^p([s,t_0])}\, ds \\ &= \frac{c'}{\varepsilon} \int_0^{t_0} \|\Psi_s(f(s) - g(s))\|_{L^p([s,t_0],Y)}\, ds \\ &\leq \frac{\gamma c'}{\varepsilon} \|f - g\|_{L^1([0,t_0],X)} \end{aligned}$$

for each $\varepsilon > 0$ and constants c, c' not depending on f, g, ε. Since g is arbitrary, the set $\{o_f > \varepsilon\}$ has Lebesgue measure 0. This fact implies the assertion. ∎

PROPOSITION 2.11. *Let (T,Ψ) be a nonautonomous observation system represented by $C(t)$, $p\in(1,\infty)$, and let $C_\tau(t)$ be given by (2.5). Then $\mathbb{K}_s f\in D(C(\cdot),s)$,*

$$\|C(\cdot)\mathbb{K}_s f\|_{L^p([s,s+t_0],Y)}\le c(t_0)\,\|f\|_{L^p([s,s+t_0],X)}\,,$$

and $C_\tau(\cdot)\mathbb{K}_s f\to C(\cdot)\mathbb{K}_s f$ in $L^p_{loc}([s,\infty),Y)$ as $\tau\to 0$ for $s\ge 0$, $t_0>0$, $f\in L^p_{loc}(\mathbb{R}_+,X)$, and a constant $c(t_0)$ independent of f and s.

Proof. By Lemma 2.10, $C(\cdot)\mathbb{K}_s f$ is a well-defined measurable function. Further,

$$\begin{aligned}\int_s^{s+t_0}\|C_\tau(t)(\mathbb{K}_s f)(t)\|^p\,dt &\le c\int_s^{s+t_0}\int_s^t\|C_\tau(t)T(t,r)f(r)\|^p\,dr\,dt\\ &= c\int_s^{s+t_0}\int_r^{s+t_0}\|C_\tau(t)T(t,r)f(r)\|^p\,dt\,dr\\ &\le c\tilde\gamma^p\,\|f\|^p_{L^p([s,s+t_0],X)}\end{aligned}\tag{2.11}$$

for a constant c by Hölder's inequality, Fubini's theorem, and Lemma 2.9. Similarly,

$$\|(C_\tau(\cdot)-C_\sigma(\cdot))\mathbb{K}_s f\|_p^p\le c\int_s^{s+t_0}\int_r^{s+t_0}\|(C_\tau(t)-C_\sigma(t))T(t,r)f(r)\|^p\,dt\,dr,$$

and the right side tends to 0 as $\tau,\sigma\to 0$ by Lemma 2.9 and the dominated convergence theorem. Hence $C_\tau(\cdot)\mathbb{K}_s f$ also converges in $L^p([s,s+t_0],Y)$ to $C(\cdot)\mathbb{K}_s f$. The asserted estimate then follows from (2.11). ∎

3. Well-posed and regular nonautonomous systems.

DEFINITION 3.1. *Let T be an evolution family on X, and let $\Phi_{t,s}=\Phi(t,s):L^p_{loc}([s,\infty),U)\to X$, $t\ge s\ge 0$, be linear operators satisfying*

$$\Phi_{t,s}u=\Phi_{t,r}(u|[r,\infty))+T(t,r)\Phi_{r,s}u,\quad t\ge r\ge s\ge 0,\quad \textit{and}\tag{3.1}$$

$$\|\Phi_{t,s}u\|_X\le\beta\,\|u\|_{L^p([s,t],U)},\quad 0\le t-s\le t_0,\tag{3.2}$$

for $u\in L^p(\mathbb{R}_+,U)$ and constants $t_0>0$, $\beta=\beta(t_0)>0$. Then $(T,\Phi)=(T,\{\Phi_{t,s}:t\ge s\ge 0\})$ is called a nonautonomous control system.

Observe that the above definition implies that $\Phi_{t,t}=0$ and $\Phi_{t,s}u=\Phi_{t,r}u$ if $u=0$ on $[s,r]\subseteq[s,t]$. Thus the control system is *causal*.

LEMMA 3.2. *Let (T,Φ) be a nonautonomous control system. Then*

$$\|\Phi_{t,s}u\|_X\le c_0'M\beta(t_0)\,c(t-s)\,\|u\|_{L^p([s,t],U)},\tag{3.3}$$

$$\|\Phi(\cdot,s)u\|_{L^p([s,t],X)}\le c_0'M\beta(t_0)\,c(t-s)\,\|u\|_{L^p([s,t],U)}\tag{3.4}$$

for $t\ge s\ge 0$, $u\in L^p([s,t],U)$, and $c_0'=c_0'(t_0,w,p)$ ($c(t)$ was defined in Lemma 2.3).

Proof. In Lemma 3.4, we show the measurability of $\Phi(\cdot,s)u$ (of course without referring to (3.4)). The assertion is clear for $s\le t\le s+t_0$. Let $s_k=s+kt_0$ for $k\in\mathbb{N}_0$, let $t\in[s_n,s_{n+1}]$ for some $n\in\mathbb{N}$, and let u_k be the restriction of u to $[s_k,s_{k+1}]\cap[s,t]$ for $k=0,\dots,n$. Then

$$\Phi(t,s)u=\Phi(t,s_n)u_n+\sum_{k=1}^n T(t,s_k)\Phi(s_k,s_{k-1})u_{k-1}\,,\tag{3.5}$$

$$\|\Phi(t,s)u\|\le\beta\,\|u_n\|_p+M\beta\sum_{k=1}^n e^{w(t-s_k)}\,\|u_{k-1}\|_p\le M\beta e^{w^-t_0}\,(a*b)_n\,,$$

where $a_k = e^{wt_0 k}$ if $k = 0, \dots, n$ and $a_k = 0$ otherwise, $b_k = \|u_k\|_p$, $a = (a_k)_k$, and $b = (b_k)_k$. Young's inequality now implies the lemma. ∎

DEFINITION 3.3. *Let T be an evolution family on X, and let $\overline{X}_t$, $t \geq 0$, be Banach spaces in which X is densely and continuously embedded. Assume that $T(t,s)$ has a locally uniformly bounded extension $\overline{T}(t,s) : \overline{X}_s \to \overline{X}_t$ (which then satisfies* (E1) *and is strongly continuous with respect to s). We call $B(t) \in \mathcal{L}(U, \overline{X}_t)$, $t \geq 0$,* (T-)admissible control operators *if the function $\overline{T}(t,\cdot)B(\cdot)u(\cdot)$ is integrable in $\overline{X}_t$,*

$$(\overline{\mathbb{K}}_s B(\cdot)u)(t) := \int_s^t \overline{T}(t,\tau)B(\tau)u(\tau)\,d\tau \in X,$$

and there are constants $t_0, \beta > 0$ such that

$$\|(\overline{\mathbb{K}}_s B(\cdot)u)(t)\|_X \leq \beta \|u\|_{L^p([s,t],U)} \tag{3.6}$$

for all $0 \leq s \leq t \leq s + t_0$ and $u \in L^p([s,t],U)$. (We omit the subscript s if $s = 0$.)

Setting $\Phi_{t,s}u := (\overline{\mathbb{K}}_s B(\cdot)u)(t)$, we obtain, of course, a nonautonomous control system (T, Φ) if $B(t)$, $t \geq 0$, are admissible control operators. Every autonomous control system is given by a T-admissible control operator due to [29, Thm. 3.9], where $\overline{X}_t$, $t \geq 0$, coincide with the extrapolation space X_{-1} of X with respect to the semigroup T (see, e.g., [2, Chap. V], [9, section II.5]). In Proposition 3.5, we extend this result to the time dependent setting but only in an approximate sense because of the lack of an extrapolation theory for evolution families. We first show a preliminary fact.

LEMMA 3.4. *Let (T, Φ) be a nonautonomous control system, and let $u \in L^p_{loc}(\mathbb{R}_+, U)$. Then $t \mapsto \Phi_{t,s}u \in X$ is continuous from the right for $t \geq s$, $s \mapsto \Phi_{t,s}u \in X$ is continuous for $s \in [0,t]$ (locally uniformly in t), and $(t,s) \mapsto \Phi_{t,s}u \in X$ is measurable.*

Proof. Definition 3.1 implies the estimates

$$\begin{aligned}
\|\Phi(t',s)u - \Phi(t,s)u\| &\leq \|\Phi(t',t)u\| + \|(T(t',t) - I)\Phi(t,s)u\| \\
&\leq \beta \|u\|_{L^p([t,t'],U)} + \|(T(t',t) - I)\Phi(t,s)u\|, \\
\|\Phi(t,s)u - \Phi(t,s')u\| &= \|T(t,s')\Phi(s',s)u\| \leq M\beta e^{|w|(t-s)} \|u\|_{L^p([s,s'],U)},
\end{aligned}$$

where $t' \geq t \geq s' \geq s$. Thus the lemma is established. ∎

Let $u \in L^p_{loc}(\mathbb{R}, U)$, $t \geq 0 \geq s$, and $n \in \mathbb{N}$. We define $(B_n u)(t) = n\,\Phi(t, t - \frac{1}{n})u$, where $\Phi(t,s)u := \Phi(t,0)u$. Note that $B_n u \in L^\infty_{loc}(\mathbb{R}_+, X)$ because of the above lemma. To approximate Φ, we introduce

$$\Phi^n(t,s)u = \Phi^n_{t,s}u := \int_s^t T(t,\tau)(B_n u)(\tau)\,d\tau = (\mathbb{K}_s B_n u)(t) \tag{3.7}$$

for $t \geq s \geq 0$, $n \in \mathbb{N}$, and $u \in L^p_{loc}(\mathbb{R}, U)$. These operators can be expressed by

$$\begin{aligned}
\Phi^n(t,s)u &= n \int_s^t \left(\Phi\left(t, \tau - \frac{1}{n}\right) u - \Phi(t,\tau)u \right) d\tau \\
&= n \int_{s-\frac{1}{n}}^{s} \Phi(t,\tau)u\,ds - n \int_{t-\frac{1}{n}}^{t} \Phi(t,\tau)u\,d\tau \\
&= \Phi(t,s)u + nT(t,s) \int_{s-\frac{1}{n}}^{s} \Phi(s,\tau)u\,d\tau - n \int_{t-\frac{1}{n}}^{t} \Phi(t,\tau)u\,d\tau
\end{aligned} \tag{3.8}$$

due to (3.1). If we take a function $u \in L^p_{loc}([s,\infty),U)$ and extend it by 0 to $\mathbb{R}$, then

$$\Phi(t,s)u - \Phi^n(t,s)u = n\int_{t-\frac{1}{n}}^{t} \Phi(t,\tau)u\,d\tau =: r_n(t;\,u). \tag{3.9}$$

To represent Φ approximately, we define operators $B_n(t) \in \mathcal{L}(U,X)$ by

$$B_n(t)z := (B_n u_z)(t) = n\Phi\left(t, t-\frac{1}{n}\right)u_z\,, \qquad \text{where } \ u_z \equiv z,\ z \in U.$$

PROPOSITION 3.5. *Let (T,Φ) be a nonautonomous control system, $n \in \mathbb{N}$, $0 \le s \le t \le s+t_0$, $t_0 > 0$, $z \in U$, and $u \in L^p_{loc}(\mathbb{R},U)$. Then we have the following:*

1. *$\Phi^n(t,s)u \to \Phi(t,s)u$, and $\|\Phi^n(t,s)u\|_X \le 2\beta(t_0)\|u\|_{L^p([s,t],U)}$.*
2. *$(t,s) \mapsto \Phi(t,s)u$, and $t \mapsto B_n(t)z$ are continuous in X.*
3. *$[\mathbb{K}_s B_n(\cdot)u](t) \to \Phi(t,s)u$, and $\|[\mathbb{K}_s B_n(\cdot)u](t)\|_X \le \beta(t_0+1)\,\|u\|_{L^p([s,t],U)}$.*

Here the limits as $n \to \infty$ are taken in X and are locally uniform in (t,s).

Proof. For $u \in L^p_{loc}(\mathbb{R},U)$, we estimate

$$\left\| n\int_{t-\frac{1}{n}}^{t} \Phi(t,\tau)u\,d\tau \right\|_X \le \sup_{t-\frac{1}{n}\le\tau\le t} \|\Phi(t,\tau)u\|_X \le \beta\,\|u\|_{L^p([t-\frac{1}{n},t],U)}\,,$$

$$\left\| nT(t,s)\int_{s-\frac{1}{n}}^{s} \Phi(s,\tau)u\,d\tau \right\|_X \le M\beta e^{w(t-s)}\,\|u\|_{L^p([s-\frac{1}{n},s],U)}\,,$$

which yields the first part of (1) because of (3.8). This fact implies (2). The second part of (1) follows from (3.9) if we extend $u \in L^p([s,\infty),X)$ by 0 to $\mathbb{R}$. We set $\tilde{u}(\tau,\sigma) = u(\tau)$ and $u^{(n)}(\sigma) = n\int_\sigma^{\sigma+\frac{1}{n}} u(\tau)\,d\tau$ for $\sigma \ge \tau \ge 0$ and $n \in \mathbb{N}$. Taking first $u \in W^{1,p}_{loc}(\mathbb{R},U)$, using Hölder's inequality, and interchanging integrals, we estimate

$$\begin{aligned}
\|B_k u - B_k(\cdot)u\|_{L^1([s,s+t_0],X)} &\le k\int_s^{s+t_0} \left\|\Phi\left(\tau,\tau-\frac{1}{k}\right)[u-\tilde{u}(\tau,\cdot)]\right\|_X d\tau \\
&\le \beta k\int_s^{s+t_0} \left(\int_{\tau-\frac{1}{k}}^{\tau}\left(\int_\sigma^\tau \|u'(\rho)\|_U\,d\rho\right)^p d\sigma\right)^{\frac{1}{p}} d\tau \\
&\le \beta k^{1-\frac{1}{p}}\int_s^{s+t_0}\int_0^{\frac{1}{k}} \|u'(\tau-\rho)\|_U\,d\rho\,d\tau \\
&\le c\left(\int_0^{\frac{1}{k}}\int_s^{s+t_0} \|u'(\tau-\rho)\|_U^p\,d\tau\,d\rho\right)^{\frac{1}{p}}
\end{aligned}$$

so that $[\mathbb{K}_s B_k(\cdot)u](t) \to \Phi(t,s)u$ as $k \to \infty$ locally uniformly in this case. Fix now $t > s \ge 0$, and extend $u \in L^p([s,t],X)$ by 0 to $\mathbb{R}$. Then (3.1) and the above results imply

$$
\begin{aligned}
[\mathbb{K}_s B_n(\cdot)u](t) &= n\int_{s-\frac{1}{n}}^{t} \Phi(t,\tau)\left[\tilde{u}\left(\tau+\frac{1}{n},\cdot\right)-\tilde{u}(\tau,\cdot)\right]d\tau \\
&= \lim_{k\to\infty} n\int_{s-\frac{1}{n}}^{t}\int_{\tau}^{t} T(t,\sigma)B_k(\sigma)\left[u\left(\tau+\frac{1}{n}\right)-u(\tau)\right]d\sigma\,d\tau \\
&= \lim_{k\to\infty} n\int_{s-\frac{1}{n}}^{t} T(t,\sigma)B_k(\sigma)\int_{s-\frac{1}{n}}^{\sigma}\left[u\left(\tau+\frac{1}{n}\right)-u(\tau)\right]d\tau\,d\sigma \\
&= \Phi\left(t,s-\frac{1}{n}\right)u^{(n)}.
\end{aligned}
$$

Observing that $\|u^{(n)}\|_{L^p([s,t],U)} \le \|u\|_{L^p([s,t],U)}$, we deduce (3). □

We give, as in [13], the nonautonomous analogue of Weiss' definition of a *well-posed system*; see [30, Def. 1.1].

DEFINITION 3.6. *Let (T,Φ) and (T,Ψ) be nonautonomous control and observation systems. If there are linear operators $\mathbb{F}_s : L^p_{loc}([s,\infty),U) \to L^p_{loc}([s,\infty),Y)$, $s \ge 0$, satisfying*

$$\mathbb{F}_s u = \Psi_t \Phi_{t,s} u + \mathbb{F}_t(u|[t,\infty)) \quad \text{on } [t,\infty) \quad \text{and} \tag{3.10}$$

$$\|\mathbb{F}_s u\|_{L^p([s,s+t_0],Y)} \le \kappa \|u\|_{L^p([s,s+t_0],U)} \tag{3.11}$$

for $u \in L^p_{loc}([s,\infty),U)$, $t \ge s \ge 0$, and constants $t_0 > 0$, $\kappa = \kappa(t_0) > 0$, then $\Sigma = (T,\Phi,\Psi,\mathbb{F}) = (T,\Phi_{t,s},\Psi_s,\mathbb{F}_s)_{t\ge s\ge 0}$ is called a well-posed nonautonomous system, *and $\mathbb{F}_s$, $s \ge 0$, are called* input–output operators. *We put $\mathbb{F} = \mathbb{F}_0$.*

The above definition implies that $\mathbb{F}_s u = 0$ on $[s,t]$ and $\mathbb{F}_s u = \mathbb{F}_t(u|[t,\infty))$ on $[t,\infty)$ if u vanishes on $[s,t]$. Hence $\mathbb{F}_s$ is *causal*, and we can define its restriction as

$$\mathbb{F}_{t,s} = \mathbb{F}(t,s) : L^p([s,t],U) \to L^p([s,t],Y), \qquad t \ge s \ge 0.$$

LEMMA 3.7. *A well-posed nonautonomous linear system Σ satisfies* (3.11) *with t_0 replaced by each $t_1 > 0$ and $\kappa = \kappa(t_0)$ by $\kappa(t_1) = c_0''(\kappa(t_0) \vee M\beta(t_0)\gamma(t_0))c(t_1)$, where $c_0'' = c_0''(w,t_0)$ and $c(t)$ was defined in Lemma* 2.3.

Proof. The assertion is clear for $t_1 \le t_0$. So let $t_1 \in [s_n, s_{n+1})$ for some $n \in \mathbb{N}$, $s_k = s + kt_0$, $I_k = [s_k, s_{k+1}]$, and $u_k = u|I_k$ for $k \in \mathbb{N}_0$, $s \ge 0$, and $u \in L^p_{loc}([s,\infty),U)$. From Definition 3.6 and (3.5), we deduce that

$$\mathbb{F}_s u = \mathbb{F}_{s_k} u_k + \sum_{j=1}^{k} \Psi_{s_k} T(s_k,s_j)\Phi(s_j,s_{j-1})u_{j-1} \quad \text{on } I_k,$$

$$
\begin{aligned}
\|\mathbb{F}_s u\|_{L^p(I_k,Y)} &\le \kappa(t_0)\|u_k\|_p + M\beta(t_0)\gamma(t_0)\sum_{j=1}^{k} e^{wt_0(k-j)}\|u_{j-1}\|_p \\
&\le (\kappa(t_0) \vee M\beta(t_0)\gamma(t_0))\, e^{w^- t_0}\,(a * b)_k\,,
\end{aligned}
$$

$$\|\mathbb{F}_s u\|_{L^p([s,s+t_1],Y)} \le \left(\sum_{k=0}^{n}\|\mathbb{F}_s u\|^p_{L^p(I_k,Y)}\right)^{\frac{1}{p}} \le (\kappa(t_0) \vee M\beta(t_0)\gamma(t_0))\, e^{w^- t_0}\,\|a * b\|_{\ell^p}\,,$$

where the sequences a and b were defined in the proof of Lemma 3.2. Young's inequality now implies the asserted estimate. □

Also, Definition 3.6 is complemented by a concept involving admissible input and output operators; cf. [10], [12, section 1.3], [14].

DEFINITION 3.8. *Let $B(s)$ and $C(s)$, $s \geq 0$, be T-admissible control and observation operators. We call the triple $(T, B(\cdot), C(\cdot))$ an* admissible nonautonomous system *if $\overline{\mathbb{K}}_s B(\cdot)u \in D(C(\cdot), s)$ and $\|C(\cdot)\overline{\mathbb{K}}_s B(\cdot)u\|_{L^p([s,s+t_0],Y)} \leq \kappa \|u\|_{L^p([s,s+t_0],U)}$ for $s \geq 0$, $u \in L^p_{loc}([s,\infty),U)$, and constants $\kappa, t_0 > 0$.*

LEMMA 3.9. *Let $(T, B(\cdot), C(\cdot))$ be an admissible nonautonomous system. Define Ψ_s as in Lemma 2.5, $\Phi_{t,s}u := (\overline{\mathbb{K}}_s B(\cdot)u)(t)$, and $\mathbb{F}_s := C(\cdot)\overline{\mathbb{K}}_s B(\cdot)u$. Then $(T, \Phi, \Psi, \mathbb{F})$ is a well-posed nonautonomous system.*

Proof. In view of Lemma 2.5, we have only to verify (3.10) for $u \in L^p_{loc}([s,\infty),U)$ and $t \geq s \geq 0$. There are $t_n \searrow t$ such that $\Phi_{t_n,t}u, \Phi_{t_n,s}u \in D(C(t_n))$, and hence

$$\mathbb{F}_s u = \mathbb{F}_t u - \Psi_{t_n}\Phi_{t_n,t}u + \Psi_{t_n}\Phi_{t_n,s}u$$

a.e. on $[t_n,\infty)$. The third term on the right-hand side converges in L^p to $\Psi_t\Phi_{t,s}u$ due to Proposition 3.5 and the proof of Lemma 2.8. The assertion then follows from

$$\|\Psi_{t_n}\Phi_{t_n,t}u\|_{L^p([t_n,s+t_0],Y)} \leq \beta\gamma \|u\|_{L^p([t,t_n],U)}\,. \qquad \square$$

In order to prove a converse to the above lemma, we need the first of the following notions, which extends the corresponding concept due to Weiss [30, Def. 4.1].

DEFINITION 3.10. *A well-posed nonautomonous system $\Sigma = (T, \Phi, \Psi, \mathbb{F})$ is called* regular (with feedthrough $D = 0$) *if*

$$\lim_{\tau \searrow 0} \frac{1}{\tau} \int_t^{t+\tau} (\mathbb{F}_t u_z)(\sigma)\, d\sigma = 0 \tag{3.12}$$

(in Y) and absolutely regular *if*

$$\lim_{\tau \searrow 0} \frac{1}{\tau} \int_t^{t+\tau} \|(\mathbb{F}_t u_z)(\sigma)\|_Y^p\, d\sigma = 0 \tag{3.13}$$

for all $t \geq 0$ and $z \in U$, where $u_z(s) := z$ for $s \geq 0$.

We derive several useful properties of a well-posed system Σ. First, (3.11) yields

$$\left\| \frac{1}{\tau} \int_t^{t+\tau} (\mathbb{F}_t u_z)(\sigma)\, d\sigma \right\|_Y^p \leq \frac{1}{\tau} \int_t^{t+\tau} \|(\mathbb{F}_t u_z)(\sigma)\|_Y^p\, d\sigma \leq \kappa^p \|z\|^p \tag{3.14}$$

for $0 < \tau \leq t_0$, $t \geq 0$, and $z \in U$. Take $u \in L^p_{loc}(\mathbb{R}_+, U)$, and set $\tilde{u}(t,\sigma) = u(t)$ for $\sigma \geq t$ and $t \geq 0$. Then the functions

$$t \mapsto F_\tau(t) = \frac{1}{\tau} \int_t^{t+\tau} (\mathbb{F}_t u)(\sigma)\, d\sigma \quad \text{and} \quad t \mapsto \tilde{F}_\tau(t) = \frac{1}{\tau} \int_t^{t+\tau} (\mathbb{F}_t \tilde{u}(t,\cdot))(\sigma)\, d\sigma$$

are measurable for a fixed $\tau > 0$. Indeed, using (3.10), we can write

$$\begin{aligned} \tau\tilde{F}_\tau(t) - \tau\tilde{F}_\tau(r) = &\int_{r+\tau}^{t+\tau} [\mathbb{F}_t \tilde{u}(t,\cdot)](\sigma)\, d\sigma + \int_t^{r+\tau} [\mathbb{F}_t(\tilde{u}(t,\cdot) - \tilde{u}(r,\cdot))](\sigma)\, d\sigma \\ &- \int_t^{r+\tau} [\Psi_t \Phi_{t,r} \tilde{u}(r,\cdot)](\sigma)\, d\sigma - \int_r^t [\mathbb{F}_r \tilde{u}(r,\cdot)](\sigma)\, d\sigma \end{aligned}$$

for $t \geq r \geq t - \tau$. This identity and the straightforward estimates imply the left continuity of $\tilde{F}_\tau$ if u is continuous. Thus $\tilde{F}_\tau$ is measurable by approximation and

(3.14). The function F_τ can be handled in the same way. If Σ is regular, we deduce from Lebesgue's theorem and (3.14) that

$$\lim_{\tau \searrow 0} \int_0^{t_0} \|\tilde{F}_\tau(t)\|_Y^p \, dt = 0. \tag{3.15}$$

Similarly, $\varphi_u(\cdot,\tau)^{\frac{1}{p}}$ is measurable, and absolute regularity yields

$$\lim_{\tau \searrow 0} \int_0^{t_0} \frac{1}{\tau} \varphi_u(t,\tau)\, dt := \lim_{\tau \searrow 0} \int_0^{t_0} \frac{1}{\tau} \int_t^{t+\tau} \|[\mathbb{F}_t \tilde{u}(t,\cdot)](\sigma)\|_Y^p \, d\sigma \, dt = 0. \tag{3.16}$$

We now show a nonautonomous version of Weiss' representation theorem [30, Thm. 4.5].

THEOREM 3.11. *Let $\Sigma = (T, \Phi, \Psi, \mathbb{F})$ be a regular nonautonomous system, and let $C(s)$ and $C_\tau(s)$ be given by Definition 2.6 and (2.5). Then $\Phi(\cdot,s)u \in D(C(\cdot),s)$, and $\mathbb{F}_s u = C(\cdot)\Phi(\cdot,s)u$ for $s \geq 0$ and $u \in L^p_{loc}([s,\infty),U)$. Moreover, $C_\tau(\cdot)\Phi(\cdot,s)u \to \mathbb{F}_s u$ in $L^p_{loc}([s,\infty),Y)$ as $\tau \searrow 0$, and $\|C_\tau(\cdot)\Phi(\cdot,s)u\|_{L^p([s,s+t_0],Y)} \leq c \, \|u\|_{L^p([s,s+t_0],U)}$ for $\tau \in (0,1]$ and a constant $c = c(t_0)$ independent of u and s.*

Proof. Let $t \in [s,\infty)$ be a p-Lebesgue point of u and $\mathbb{F}_s u$ such that the regularity condition (3.12) holds at this point t. Setting $o_t(\sigma) = u(\sigma) - u(t)$ for $\sigma \geq t$, we have

$$\mathbb{F}_s u = \mathbb{F}_t \tilde{u}(t,\cdot) + \mathbb{F}_t o_t + \Psi_t \Phi_{t,s} u \quad \text{on} \quad [t,\infty) \quad \text{and} \tag{3.17}$$

$$\left\| \frac{1}{\tau} \int_t^{t+\tau} (\mathbb{F}_t o_t)(\sigma)\, d\sigma \right\|^p \leq \kappa^p \, \frac{1}{\tau} \int_t^{t+\tau} \|u(\sigma) - u(t)\|^p d\sigma. \tag{3.18}$$

Consequently, $C_\tau(t)\Phi_{t,s}u$ converges in Y to $(\mathbb{F}_s u)(t)$ as $\tau \to 0$ so that the first assertion holds. The estimate (3.18) and Fubini's theorem further yield

$$\begin{aligned} &\int_s^{s+t_0} \left\| \frac{1}{\tau} \int_t^{t+\tau} (\mathbb{F}_t o_t)(\sigma)\, d\sigma \right\|^p dt \leq \frac{\kappa^p}{\tau} \int_0^\tau \int_s^{s+t_0} \|u(t+\sigma) - u(t)\|^p dt \, d\sigma, \\ &\int_s^{s+t_0} \left\| \frac{1}{\tau} \int_t^{t+\tau} [(\mathbb{F}_s u)(\sigma) - (\mathbb{F}_s u)(t)]\, d\sigma \right\|^p dt \\ &\qquad\qquad \leq \frac{\kappa^p}{\tau} \int_0^\tau \int_s^{s+t_0} \|(\mathbb{F}_s u)(t+\sigma) - (\mathbb{F}_s u)(t)\|^p dt \, d\sigma, \end{aligned} \tag{3.19}$$

where both terms on the right-hand side converge to 0 as $\tau \to 0$. Combining these facts with (3.15) and (3.17), we establish that $\mathbb{F}_s u = \lim_\tau C_\tau(\cdot)\Phi(\cdot,s)u$ in $L^p_{loc}([s,\infty),Y)$. The asserted estimate follows in a similar way. ∎

The next approximation result complements Proposition 3.5 for absolutely regular systems. For technical reasons, we have to use the operators $B_n : L^p_{loc}(\mathbb{R}_+,U) \to L^\infty_{loc}(\mathbb{R}_+,X)$ rather than $B_n(t) : U \to X$. Observe that only regularity is used in the proof of estimate (3.20).

PROPOSITION 3.12. *Let Σ be an absolutely regular nonautonomous system, $p \in (1,\infty)$, and let $C(s)$ and $\Phi^n_{t,s}$ be given as in Definition 2.6 and (3.7). Then $\Phi^n(\cdot,s)u \in D(C(\cdot),s)$, $C(\cdot)\Phi^n(\cdot,s)u \to \mathbb{F}_s u$ in $L^p_{loc}([s,\infty),Y)$ as $n \to \infty$, and*

$$\|C(\cdot)\Phi^n(\cdot,s)u\|_{L^p([s,s+t_0],Y)} \leq 2\kappa(t_0) \, \|u\|_{L^p([s,s+t_0],U)} \tag{3.20}$$

for $u \in L^p_{loc}([s,\infty),U)$, $s \geq 0$, $n \in \mathbb{N}$, and $t_0 > 0$.

Proof. Due to Proposition 2.11, we have $\Phi^n(\cdot,s)u = \mathbb{K}_s B_n u \in D(C(\cdot),s)$. Formula (3.9), Proposition 2.11, and Theorem 3.11 further yield

$$\mathbb{F}_s u - C(\cdot)\Phi^n(\cdot,s)u = C(\cdot)r_n(\cdot;u) = \lim_{\tau\to 0} C_\tau(\cdot)r_n(\cdot;u) \quad (\text{in } L^p_{loc}([s,\infty),Y)). \tag{3.21}$$

Using Hölder's inequality, Fubini's theorem, and Theorem 3.11, we now derive

$$\begin{aligned}
\|C(\cdot)r_n(\cdot;u)\|^p_{L^p([s,s+t_0],Y)} &\le \lim_{\tau\to 0} n\int_s^{s+t_0}\int_{t-\frac{1}{n}}^{t} \|C_\tau(t)\Phi_{t,\sigma}u\|^p_Y \,d\sigma\,dt \\
&\le n\int_{s-\frac{1}{n}}^{s+t_0} \|\mathbb{F}_\sigma u\|^p_{L^p([\sigma,\sigma+1/n],Y)}\,d\sigma \\
&\le n\kappa(t_0)\int_0^{\frac{1}{n}}\int_{s-\frac{1}{n}}^{s+t_0} \|u(t+\sigma)\|^p\,d\sigma\,dt \le \kappa(t_0)\,\|u\|^p_p.
\end{aligned} \tag{3.22}$$

(Here we have considered a function $u\in L^p([s,s+t_0],U)$ and extended it by 0 to $\mathbb{R}$.) Thus (3.20) holds. The estimate (3.22) also gives

$$\begin{aligned}
&\|C(\cdot)r_n(\cdot;u)\|_{L^p([s,s+t_0],Y)} \\
&\le \left(\int_{s-\frac{1}{n}}^{s+t_0} n\,\|\mathbb{F}_\sigma o_\sigma\|^p_{L^p([\sigma,\sigma+\frac{1}{n}],Y)}\,d\sigma\right)^{\frac{1}{p}} + \left(\int_{s-\frac{1}{n}}^{s+t_0} n\,\|\mathbb{F}_\sigma \tilde{u}(\sigma,\cdot)\|^p_{L^p([\sigma,\sigma+\frac{1}{n}],Y)}\,d\sigma\right)^{\frac{1}{p}}.
\end{aligned}$$

The right-hand side tends to 0 as in (3.19) and (3.16). ∎

4. The main result and discussion. Let Σ be a regular nonautonomous system, $\Delta(\cdot)\in L^\infty(\mathbb{R}_+,\mathcal{L}_s(Y,U))$, and let $C(s)$ be given by Definition 2.6. For $x\in X$ and $s\ge 0$, we are looking for functions $x(\cdot)\in C([s,\infty),X)\cap D(C(\cdot),s)$ satisfying

$$x(t) = T(t,s)x + \Phi_{t,s}\Delta(\cdot)C(\cdot)x(\cdot), \qquad t\ge s, \tag{4.1}$$

or, if $\Phi(\cdot,s)u = \overline{\mathbb{K}}_s B(\cdot)u(\cdot)$ for admissible control operators $B(s)$,

$$x(t) = T(t,s)x + \int_s^t \to (t,\tau)B(\tau)\Delta(\tau)C(\tau)x(\tau)\,d\tau, \qquad t\ge s. \tag{4.2}$$

As shown by [27, Ex. 6], one cannot allow for every bounded feedback in (4.1) in general. (We note that this example gives rise to an absolutely regular autonomous system with $p=1$ and $\Delta = B = I$.) This fact motivates the next concept.

Definition 4.1. *Let $\Sigma = (T,\Phi,\Psi,\mathbb{F})$ be a well-posed nonautonomous system. We call $\Delta(\cdot)\in L^\infty(\mathbb{R}_+,\mathcal{L}_s(Y,U))$ an* admissible feedback *for Σ if there is $t_0>0$ such that $I-\mathbb{F}(s+t_0,s)\Delta(\cdot)$, $s\ge 0$, have uniformly bounded inverses on $L^p([s,s+t_0],Y)$.*

Of course, $\Delta(\cdot)$ is admissible if

$$\|\Delta(\cdot)\|_\infty < \left[\inf_{t_0>0}\sup_{s\ge 0}\|\mathbb{F}(s+t_0,s)\|\right]^{-1} =: q. \tag{4.3}$$

The right-hand side of this inequality equals ∞ if $B(t)$ and $C(t)$ are of "lower order"; see, e.g., [6] or [23, Ex. 4.11]. We point out that the invertibility of $I-\mathbb{F}(s+t_0,s)\Delta(\cdot)$ is in fact necessary for some properties of the feedback system as shown by Lemma 4.3 and Proposition 5.1. The next lemmas also indicate that our notion of admissibility is

quite flexible; see [21, Lem. 4.1], [25, section 7.1], and [32, section 3] for autonomous analogues.

LEMMA 4.2. *Let $\Delta(\cdot) \in L^\infty(\mathbb{R}_+, \mathcal{L}_s(Y,U))$ and Σ be a well-posed nonautonomous system. If $I - \mathbb{F}(s+t_0,s)\Delta(\cdot)$ is invertible on $L^p([s,s+t_0],Y)$ for all $s \geq 0$ and some $t_0 > 0$, then $I - \mathbb{F}(s+t_1,s)\Delta(\cdot)$ is invertible on $L^p([s,s+t_1],U)$ for all $s \geq 0$ and $t_1 > 0$. The notion of an admissible feedback is independent of $t_0 > 0$.*

Proof. We assume that $U = Y$ and $\Delta(s) = I$ for simplicity. First, let $t_1 \leq t_0$. Extend a given $v \in L^p([s,s+t_1],Y)$ by 0 to $\tilde{v} \in L^p([s,s+t_0],Y)$, and set $\tilde{u} = (I - \mathbb{F}(s+t_0,s))^{-1}\tilde{v}$. Then $(I - \mathbb{F}(s+t_1,s))u = v$ for the restriction u of $\tilde{u}$. If $u = \mathbb{F}(s+t_1,s)u$, then there is a function $u_1 \in L^p([s+t_1,s+t_0],U)$ such that $(I - \mathbb{F}(s+t_0,s+t_1))u_1 = \Psi_{s+t_1}\Phi_{s+t_1,s}u$. Set $\tilde{u} = u$ on $[s,s+t_1]$ and $\tilde{u} = u_1$ on $[s+t_1,s+t_0]$. Hence $\tilde{u} = \mathbb{F}(s+t_0,s)\tilde{u}$ so that $u = 0$.

It remains to consider $t_1 = nt_0$ for $n \in \mathbb{N}$. Proceeding by induction, we assume that the assertion is true for $t_1 = nt_0$. It is then clear that $I - \mathbb{F}(s+(n+1)t_0,s)$ is injective. For $v \in L^p([s,s+(n+1)t_0],Y)$, we set $u_1 = (I - \mathbb{F}(s+nt_0,s))^{-1}(v|[s,s+nt_0])$ and $u_2 = (I - \mathbb{F}(s+(n+1)t_0,s+nt_0))^{-1}\{v|[s+nt_0,s+(n+1)t_0] + \Psi_{s+nt_0}\Phi_{s+nt_0,s}u_1\}$. Putting u_1 and u_2 together, one sees that $I - \mathbb{F}(s+(n+1)t_0,s)$ is surjective. ∎

LEMMA 4.3. *For maps $T : E \to F$ and $V : F \to E$, the following are equivalent:*

1. *$I - VT$ is bijective on E.*
2. *$I - TV$ is bijective on F.*
3. *There is a map $S : E \to F$ such that $S - T = TVS = SVT$.*

Then we have $(I-TV)^{-1} = I + T(I-VT)^{-1}V = I + SV$ and $(I-VT)^{-1} = I + VS$, and S in (3) is uniquely given by $S = (I-TV)^{-1}T = T(I-VT)^{-1}$.

Thus a feedback $\Delta(\cdot)$ is admissible if and only if $I - \Delta(\cdot)\mathbb{F}(s+t_0,s)$, $s \geq 0$, have uniformly bounded inverses for some/all $t_0 > 0$ if and only if for some/all $t_0 > 0$ there are uniformly bounded operators $\mathbb{F}^\Delta(s+t_0,s)$, $s \geq 0$, such that $\mathbb{F}^\Delta(s+t_0,s) - \mathbb{F}(s+t_0,s) = \mathbb{F}^\Delta(s+t_0,s)\Delta(\cdot)\mathbb{F}(s+t_0,s) = \mathbb{F}(s+t_0,s)\Delta(\cdot)\mathbb{F}^\Delta(s+t_0,s)$.

We now solve (4.1) by constructing an evolution family T_Δ on X and show that the feedback system Σ^Δ is again absolutely regular if the unperturbed system is absolutely regular. Proposition 5.1 describes the relations between Σ and Σ^Δ in greater detail.

THEOREM 4.4. *Let $\Sigma = (T,\Phi,\Psi,\mathbb{F})$ be a regular nonautonomous system and $\Delta(\cdot) \in L^\infty(\mathbb{R}_+, \mathcal{L}_s(Y,U))$ be an admissible feedback. Then the following hold:*

(a) *There is an evolution family T_Δ on X such that $T_\Delta(\cdot,s)x \in D(C(\cdot),s)$,*

$$\|C(\cdot)T_\Delta(\cdot,s)x\|_{L^p([s,s+t_0],Y)} \leq \gamma' \|x\|, \tag{4.4}$$

$x(\cdot) = T_\Delta(\cdot,s)x$ is the unique solution of (4.1), and

$$T_\Delta(t,s)x = T(t,s)x + \Phi_{t,s}\Delta(\cdot)C(\cdot)T_\Delta(\cdot,s)x \tag{4.5}$$

for $t \geq s \geq 0$, $x \in X$, and a constant γ'. If, in addition, $\Phi(\cdot,s)u = \overline{\mathbb{K}}_s B(\cdot)u(\cdot)$ for T-admissible control operators $B(t)$, then

$$T_\Delta(t,s)x = T(t,s)x + \int_s^t \to (t,\tau)B(\tau)\Delta(\tau)C(\tau)T_\Delta(\tau,s)x\,d\tau. \tag{4.6}$$

(b) *If the system is absolutely regular and $p \in (1,\infty)$, then*

$$T_\Delta(t,s)x = T(t,s)x + \lim_{n\to\infty} \int_s^t T_\Delta(t,\tau)[B_n(\Delta(\cdot)\Psi_s x)](\tau)\,d\tau \tag{4.7}$$

for $t \geq s \geq 0$ and $x \in X$, where the limit is taken in X and is locally uniform in t. Moreover, $\Sigma^\Delta = (T_\Delta, \Phi^\Delta, \Psi^\Delta, \mathbb{F}^\Delta)$ is an absolutely regular system, where we set

$$\Psi_s^\Delta x = C(\cdot)T_\Delta(\cdot, s)x, \quad \Phi_{t,s}^\Delta u = \lim_{n\to\infty} [\mathbb{K}_s^\Delta B_n u](t),$$
$$\mathbb{F}_s^\Delta u = \lim_{n\to\infty} C(\cdot)\mathbb{K}_s^\Delta B_n u, \quad \mathbb{K}_s^\Delta f\,(t) = \int_s^t T_\Delta(t,\tau)f(\tau)\,d\tau$$

for $t \geq s \geq 0$, $x \in X$, $u \in L^p_{loc}([s,\infty), U)$, and $f \in L^p_{loc}([s,\infty), X)$, where the limits are taken in X and L^p_{loc}, respectively.

Proof. (a) We first prove the uniqueness of solutions to (4.1). If v solves (4.1) with $x = 0$, then $C(\cdot)v = \mathbb{F}_s\Delta(\cdot)C(\cdot)v$ by Theorem 3.11. Since $I - \mathbb{F}(s+t_1, s)\Delta(\cdot)$ is injective, $C(\cdot)v$ has to vanish a.e. on $[s, s+t_1]$, where $t_1 > 0$ can be chosen arbitrarily large by Lemma 4.2. Hence (4.1) implies that $v = 0$. To solve (4.1), we define

$$T_\Delta(t,s)x = T(t,s)x + \Phi_{t,s}\Delta(\cdot)(I - \mathbb{F}(s+t_1,s)\Delta(\cdot))^{-1}\Psi_s x \tag{4.8}$$

for $0 \leq t - s \leq t_1$ and $x \in X$. Clearly, $T_\Delta(t,s)$ is an exponentially bounded linear operator on X, and $T_\Delta(\cdot,s)x$ is continuous in X by Proposition 3.5. Theorems 2.7 and 3.11 further show that $T_\Delta(\cdot,s)x \in D(C(\cdot),s)$ and

$$C(\cdot)T_\Delta(\cdot,s)x = \Psi_s x + \mathbb{F}_s\Delta(\cdot)(I - \mathbb{F}(s+t_1,s)\Delta(\cdot))^{-1}\Psi_s x \tag{4.9}$$
$$= (I - \mathbb{F}(s+t_1,s)\Delta(\cdot))^{-1}\Psi_s x. \tag{4.10}$$

Hence (4.4) holds. Inserting (4.10) into (4.8), we obtain (4.5) and (4.6) and thus have solved (4.1). One verifies (E1) for T_Δ using the uniqueness of (4.1), formula (3.1), and a standard argument. It remains to establish the strong continuity of T_Δ. We first take $(t_n, s_n) \to (s_0, s_0)$ with $t_n \geq s_n \geq 0$. For $\varepsilon > 0$, $x \in X$, and large n, there is $r \in [0, s_0] \cap [0, s_n]$ such that $\|T(s_0, r)x - x\| \leq \varepsilon$. Then (4.8) and (2.1) yield

$$\begin{aligned}\|T_\Delta(t_n,s_n)x - x\| &\leq \|T_\Delta(t_n,s_n)(x - T(s_n,r)x)\| + \|T_\Delta(t_n,s_n)T(s_n,r)x - x\| \\ &\leq c\,\|x - T(s_n,r)x\| + \|T(t_n,r)x - x\| + c\left[\int_{s_n}^{t_n} \|[\Psi_r x](\sigma)\|^p d\sigma\right]^{\frac{1}{p}},\end{aligned}$$

$\overline{\lim_{n\to\infty}} \|T_\Delta(t_n,s_n)x - x\| \leq (c+1)\varepsilon$

for a constant c. Therefore, T_Δ is strongly continuous at (s_0, s_0). If $(t_n, s_n) \to (t_0, s_0)$ for some $t_0 > s_0$, we may assume that $t_n > s_n$ and $t_n > s_0$. We take $t_n \geq r_n \geq s_n \vee s_0$ with $r_n \to s_0$ and derive (E2) from the above results and the expression

$$\begin{aligned}T_\Delta(t_n,s_n)x - T_\Delta(t_0,s_0)x = {} & T_\Delta(t_n,r_n)(T_\Delta(r_n,s_n)x - T_\Delta(r_n,s_0)x) \\ & + T_\Delta(t_n,s_0)x - T_\Delta(t_0,s_0)x.\end{aligned}$$

(b) Define $\mathcal{D}_{\Delta,s}$ as in (2.6) using T_Δ. Then (4.5) and Proposition 3.5 imply that

$$\mathbb{K}_s^\Delta f\,(t) = \mathbb{K}_s f\,(t) + \lim_{n\to\infty} \int_s^t \int_\tau^t T(t,\sigma)B_n(\sigma)\Delta(\sigma)C(\sigma)T_\Delta(\sigma,\tau)f(\tau)\,d\sigma\,d\tau$$

for $f \in \mathcal{D}_{\Delta,s}$ and $s \geq 0$ since the integrand is the sum of functions of the form

$$(\tau,\sigma) \mapsto \gamma(\tau)\,T(t,\sigma)B_n(\sigma)\Delta(\sigma)C(\sigma)T_\Delta(\sigma,r)x. \tag{4.11}$$

For the same reason, $\mathbb{K}_s^\Delta f$ belongs to $D(C(\cdot),s)$, and we can apply Fubini's theorem and take $T(t,\sigma)B_n(\sigma)\Delta(\sigma)C(\sigma) \in \mathcal{L}(\underline{X}_\sigma, X)$ out of the inner integral. So we obtain

$$\mathbb{K}_s^\Delta f = \mathbb{K}_s f + \lim_{n\to\infty} \mathbb{K}_s B_n(\cdot)\Delta(\cdot)C(\cdot)\mathbb{K}_s^\Delta f = \mathbb{K}_s f + \Phi(\cdot,s)\Delta(\cdot)C(\cdot)\mathbb{K}_s^\Delta f \tag{4.12}$$

for $f \in \mathcal{D}_{\Delta,s}$ due to Proposition 3.5. Theorem 3.11 now shows that $C(\cdot)\mathbb{K}_s^\Delta f = C(\cdot)\mathbb{K}_s f + \mathbb{F}_s\Delta(\cdot)C(\cdot)\mathbb{K}_s^\Delta f$. Hence

$$C(\cdot)\mathbb{K}_s^\Delta f = (I - \mathbb{F}(s+t_1,s)\Delta(\cdot))^{-1}C(\cdot)\mathbb{K}_s f \tag{4.13}$$

on $[s, s+t_1]$ for each $t_1 > 0$. Inserting (4.13) into (4.12), we conclude that

$$\mathbb{K}_s^\Delta f = \mathbb{K}_s f + \Phi(\cdot,s)\Delta(\cdot)(I - \mathbb{F}(s+t_1,s)\Delta(\cdot))^{-1}C(\cdot)\mathbb{K}_s f \tag{4.14}$$

on $[s, s+t_1]$ for $f \in \mathcal{D}_{\Delta,s}$. This identity holds for all $f \in L^p_{loc}([s,\infty),X)$ by Proposition 2.11. So we may take $f = B_n u$ for $u \in L^p_{loc}([s,\infty),U)$ and $n \in \mathbb{N}$, and thus

$$\mathbb{K}_s^\Delta B_n u = \mathbb{K}_s B_n u + \Phi(\cdot,s)\Delta(\cdot)(I - \mathbb{F}(s+t_1,s)\Delta(\cdot))^{-1}C(\cdot)\mathbb{K}_s B_n u. \tag{4.15}$$

As a consequence, $\mathbb{K}_s^\Delta B_n u \in D(C(\cdot),s)$ and

$$C(\cdot)\mathbb{K}_s^\Delta B_n u = (I - \mathbb{F}(s+t_1,s)\Delta(\cdot))^{-1}C(\cdot)\mathbb{K}_s B_n u \tag{4.16}$$

by Proposition 2.11 and Theorem 3.11. In view of Propositions 3.5 and 3.12, we can take the limit as $n \to \infty$ in the formulas (4.15) and (4.16) (in $C([s,s+t_1],X)$ and $L^p([s,s+t_1],Y)$, respectively). It is then easy to see that $\Sigma^\Delta = (T_\Delta, \Phi^\Delta, \Psi^\Delta, \mathbb{F}^\Delta)$ defined in the assertion is a well-posed nonautonomous system. Equation (4.16) and Proposition 3.12 further yield

$$\int_t^{t+\tau} \|(\mathbb{F}_t^\Delta u_z)(\sigma)\|^p \, d\sigma \le c \int_t^{t+\tau} \|(\mathbb{F}_t u_z)(\sigma)\|^p \, d\sigma$$

for $t \ge 0$, $\tau > 0$, $u_z \equiv z$, and $z \in U$ so that additionally Σ^Δ is absolutely regular.

We now choose $u = \Delta(\cdot)\Psi_s x$ for $x \in X$ and deduce from (4.15), Propositions 3.5 and 3.12, and (4.8) that

$$\begin{aligned}\lim_{n\to\infty} \mathbb{K}_s^\Delta B_n \Delta(\cdot)\Psi_s x &= \Phi(\cdot,s)\Delta(\cdot)\Psi_s x + \Phi(\cdot,s)\Delta(\cdot)(I - \mathbb{F}(s+t_1,s)\Delta(\cdot))^{-1}\mathbb{F}_s\Delta(\cdot)\Psi_s x \\ &= \Phi(\cdot,s)\Delta(\cdot)(I - \mathbb{F}(s+t_1,s)\Delta(\cdot))^{-1}\Psi_s x = T_\Delta(\cdot,s)x - T(\cdot,s)x,\end{aligned}$$

where the limit is taken in X and is locally uniform in t. Thus (4.7) holds. ∎

We state several variants of Theorem 4.4 and compare them to related results.

REMARK 4.5. *The above theorem remains valid if we do not assume* (E3), *require* β, γ, κ *and* $\|(I - \mathbb{F}(s+t_0,s)\Delta(\cdot))^{-1}\|$ *only to be uniform with respect to* $s \in [0,a]$ *for every* $a > 0$, *and assert for the perturbed problem only the analogous properties. The proof of part* (a) *also works in the case that* T *(and then* T_Δ*) is only strongly continuous in* t *and* s *separately. Part* (a) *can be verified for admissible systems, too, if one considers only* $x \in D(C(s))$ *in* (4.2), (4.4), *and* (4.6)*; see* [23, *Thm.* 4.18] *or* (c) *below.*

REMARK 4.6. *Let* Σ *be a nonautonomous regular system with* $p \in (1,\infty)$. *It can be shown that* $\langle C(\cdot)\mathbb{K}_s B_n u, v\rangle \to \langle \mathbb{F}_s u, v\rangle$ *as* $n \to \infty$ *for all* $v \in L^q([s,s+t_0],Y^*)$, $\frac{1}{p} + \frac{1}{q} = 1$. *Thus, if* Y *is reflexive, the conclusions of Theorem* 4.4(b) *hold for merely*

regular systems except that the limits exist only weakly and that it is not clear whether Σ^Δ *is regular again. In the autonomous case, the regularity of* Σ^Δ *for regular* Σ *was established in* [32, *Thm.* 4.5, 4.7]*, but the proof given there relies on Laplace transforms and a Tauberian theorem* [31, *Thm.* 5.2] *not available here; see also* [25, *section* 7.5].

(a) *Perturbation theory of evolution equations.* Theorem 4.4 is a joint nonautonomous extension of the Desch–Schappacher and Miyadera perturbation theorem from semigroup theory (see, e.g., [9, section III.3]): First, let $B(t)$ be T-admissible control operators, and define $Y = X$, $\Psi_s = T(\cdot, s)$, and $\mathbb{F}_s = \overline{\mathbb{K}}_s B(\cdot)$; i.e., $C(t) \equiv I$. This gives an absolutely regular nonautonomous system with $\kappa(t_0) = \beta t_0^{1/p}$ so that $q = \infty$ in (4.3). Second, let (T, Ψ) be a nonautonomous observation system for $p \in (1, \infty)$ represented by $C(t)$. Setting $U = X$, $\Phi_{t,s} u = (\mathbb{K}_s u)(t)$, and $\mathbb{F}_s = C(\cdot)\mathbb{K}_s$, i.e., $B(t) \equiv I$, we obtain a well-posed nonautonomous system thanks to Proposition 2.11. Approximating u_z by $T(\cdot, t)z$, one verifies that the system is absolutely regular. A nonautonomous Miyadera theorem for closable perturbations $C(t)$ and $p \geq 1$ was proved in [19] by other methods.

(b) *Autonomous controlled systems.* Let $T(t - s) = T(t, s)$ be a C_0-semigroup generated by A and $\Delta(t) \equiv \Delta$. We say that (T, B, C) belongs to the *Pritchard–Salamon class* [18] if (2.2) holds with $\|x\|_X$ replaced by $\|x\|_{\overline{X}}$ and (3.6) holds with $\|\cdot\|_X$ replaced by $\|\cdot\|_{\underline{X}}$. The perturbation theory for this class was developed in detail in [6]. In this case, one can extend $T_\Delta(t)$ to $\overline{X}$, and the number q in (4.3) is equal to ∞.

Weiss introduced autonomous regular systems in [28], [29], [30], [31] similarly as in the above definitions by considering only the initial time $s = 0$. He solved the feedback problem in [32, Thm. 6.1] for a well-posed system with $p = 2$ on Hilbert spaces X, Y, U, allowing for nontrivial feedthrough D and assuming that (roughly speaking) $I - CR(\lambda, A_{-1})B\Delta$ is invertible on a right halfplane; see also [21]. If the system is regular, the feedback system is again regular and can be represented almost in the natural way; see [32, section 7]. The feedback theory for several classes of (non)regular systems is exhaustively studied in Chapter 7 of Staffans' monograph [25] in a Banach space setting and also for $p = 1, \infty$.

The remaining difficulties come from the fact that, in general, $T_\Delta(t)$ cannot be continuously extended to the extrapolation space X_{-1}^A corresponding to T (see [23, Ex. 4.20]); in particular, the extrapolation space X_{-1}^Δ of T_Δ may differ from X_{-1}^A. Weiss constructed subspaces W and W_Δ of X_{-1}^A and X_{-1}^Δ, respectively, such that $Jx := \lim_{\lambda\to\infty} \lambda R(\lambda, A_{-1})x$ (in X_{-1}^Δ) defines an isomorphism $J : W \to W_\Delta$; see [32, Thm. 7.7]. Note that $Jx = x$ for $x \in X$. Then

$$T_\Delta(t)x = T(t)x + \int_0^t T_{\Delta,-1}(t - \tau)JB\Delta CT(\tau)x \, d\tau$$

by (6.11), (6.1), and [32, p. 55]. In other words, Weiss managed to put the limit in (4.7) inside the integral using a different regularization. Identifying B and JB, he represented the feedback system in terms of B and C and computed the generator of T_Δ [32, section 7]; see [25, section 7.4] for a somewhat different approach.

(c) *Nonautonomous controlled systems.* Part (a) of Theorem 4.4 was proved by Hinrichsen, Jacob, and Pritchard for nonautonomous admissible systems in a slightly differing setting; see [10, Thm. 3.2] and [12], [14] also for nonlinear feedback. They work with separately strongly continuous evolution families and have some additional technical assumptions (see, e.g., Hypotheses 4 and 7 of [10]). Moreover, they obtain (4.6) with a pointwise representation of $C(\cdot)T(\cdot, s)x$ only for $x \in D(C(s))$. The

issues investigated in Theorem 4.4(b) were not considered in [10] and [14] and were considered in [12, Thm. 3.4.7] only for systems of Pritchard–Salamon type.

REMARK 4.7. *In addition to the assumptions of Theorem* 4.4(b), *we suppose that* $\Phi_{t,s}$ *is given by admissible observation operators* $B(\cdot) \in L^\infty(\mathbb{R}_+, \mathcal{L}_s(U, \overline{X}))$ *for* $\overline{X}_t \equiv \overline{X}$ *and that* $T_\Delta(t,s)$ *has a locally uniformly bounded extension* $\overline{T}_\Delta(t,s) : \overline{X} \to \overline{X}$. *Thus* $\overline{T}_\Delta$ *satisfies* (E1) *and* (E2). *We set* $(\overline{\mathbb{K}}_s^\Delta f)(t) = \int_s^t \overline{T}_\Delta(t,\tau) f(\tau)\, d\tau$ *for* $t \ge s \ge 0$ *and* $f \in L^1_{loc}([s,\infty), \overline{X})$. *Then* $\Phi^\Delta(\cdot,s)u = \overline{\mathbb{K}}_s^\Delta B(\cdot)u$, $\mathbb{F}_s^\Delta u = C(\cdot)\overline{\mathbb{K}}_s^\Delta B(\cdot)u$, *and*

$$T_\Delta(t,s)x = T(t,s)x + \int_s^t \to_\Delta (t,\tau)B(\tau)\Delta(\tau)C(\tau)T(\tau,s)x\, d\tau \tag{4.17}$$

for $u \in L^p_{loc}([s,\infty), U)$, $x \in X$, *and* $t \ge s \ge 0$.

Proof. Observe that $B_n u \to B(\cdot)u$ as $n \to \infty$ in $L^p_{loc}(\mathbb{R}_+, \overline{X})$ for $u \in L^p_{loc}(\mathbb{R}_+, \overline{X})$ because of the inequality

$$\|B_n u - B(\cdot)u\|^p_{L^p([0,t_0],\overline{X})} \le n \int_0^{\frac{1}{n}} \int_0^{t_0} \|\overline{T}(\tau+\sigma,\tau)B(\tau)u(\tau) - B(\tau+\sigma)u(\tau+\sigma)\|^p_{\overline{X}}\, d\tau\, d\sigma,$$

which is a consequence of Hölder's inequality and Fubini's theorem. Thus $\Phi^\Delta(\cdot,s)u = \overline{\mathbb{K}}_s^\Delta B(\cdot)u$, and (4.17) holds. The identities (4.15) and (4.16) then imply that

$$C(\cdot)\overline{\mathbb{K}}_s^\Delta B(\cdot)u = (I - \mathbb{F}(s+t_1,s)\Delta(\cdot))^{-1}\mathbb{F}_s u = \mathbb{F}_s^\Delta u. \qquad \square$$

The above remark and paragraph (b) indicate that an (absolutely) regular nonautonomous system and the corresponding feedback system can be represented by operators $B(t)$ (and not just approximately by $B_n(t)$) whenever we have a decent extrapolation theory for the given problem. It seems to be reasonable to study first the case that T is generated by operators $A(t)$ and consider spaces $\overline{X}_t$ related to $A(t)$. For various results on parabolic evolution equations and extrapolation spaces, we refer to [1], [2, Chap.V], [23, Prop. 2.1].

5. Further properties of the feedback system. In the setting of Theorem 4.4, we study the relationship between the open- and the closed-loop systems in more detail; see [25, Chap. 7] and [32, section 6] for similar results in the autonomous case. To put the formulas in a concise form, we define $\Psi(t,s)x = \mathbb{1}_{[s,t]}\Psi_s x$ and

$$\Sigma(t,s) = \begin{pmatrix} T(t,s) & \Phi(t,s) \\ \Psi(t,s) & \mathbb{F}(t,s) \end{pmatrix} : X \times L^p([s,t],U) \to X \times L^p([s,t],Y), \quad t \ge s \ge 0.$$

PROPOSITION 5.1. *Let* Σ *be an absolutely regular nonautonomous system, let* $p \in (1,\infty)$, *let* $\Delta(\cdot)$ *be an admissible feedback for* Σ, *and let* Σ^Δ *be the feedback system from Theorem* 4.4. *Then*

$$\mathbb{F}_s^\Delta = (I - \mathbb{F}_s\Delta(\cdot))^{-1}\mathbb{F}_s = \mathbb{F}_s(I - \Delta(\cdot)\mathbb{F}_s)^{-1} = C(\cdot)\Phi^\Delta(\cdot,s), \tag{5.1}$$

$$\Sigma^\Delta(t,s) - \Sigma(t,s) = \Sigma(t,s)\begin{pmatrix} 0 & 0 \\ 0 & \Delta(\cdot) \end{pmatrix}\Sigma^\Delta(t,s) = \Sigma^\Delta(t,s)\begin{pmatrix} 0 & 0 \\ 0 & \Delta(\cdot) \end{pmatrix}\Sigma(t,s). \tag{5.2}$$

Proof. The first equality in (5.1) is an immediate consequence of (4.16) and Proposition 3.12. Lemma 4.3 then yields the second equality in (5.1) and the expressions for $\mathbb{F}^\Delta - \mathbb{F}$ in the lower right corner of (5.2). Taking the limit in (4.15) and using

the formulas for $\mathbb{F}^\Delta$, we deduce the last equality in (5.1). The identities for $T^\Delta - T$ in the upper left corner of (5.2) were established in Theorem 4.4, and they imply the formulas for $\Psi^\Delta - \Psi$ in the lower left corner in (5.2). The first equality in the upper right corner follows from (4.15). Employing the previous results, we finally obtain

$$\begin{aligned}\Phi^\Delta(\cdot,s)\Delta(\cdot)\mathbb{F}_s &= \Phi(\cdot,s)\Delta(\cdot)\mathbb{F}_s + \Phi(\cdot,s)\Delta(\cdot)\mathbb{F}_s^\Delta\Delta(\cdot)\mathbb{F}_s \\ &= \Phi(\cdot,s)\Delta(\cdot)\mathbb{F}_s^\Delta = \Phi^\Delta(\cdot,s) - \Phi(\cdot,s). \qquad \square\end{aligned}$$

The above result allows us to prove that the following control theoretic properties (cf. [7]) remain unchanged under feedback.

DEFINITION 5.2. (a) *A nonautonomous control system* (T,Φ) *is called* exactly (approximately) controllable on $[s,t]$ *if* $\Phi(t,s)$ *is surjective (has dense range) and it is called* exactly (approximately) null controllable on $[s,t]$ *if* $T(t,s)X$ *is contained in the (closure of)* $\Phi(t,s)L^p([s,t],U)$.

(b) *A nonautonomous observation system* (T,Ψ) *is called* (continuously) initially observable on $[s,t]$ *if* $\Psi(t,s)$ *is injective (bounded from below) and* (continuously) finally observable on $[s,t]$ *if* $\ker\Psi(t,s) \subset \ker T(t,s)$ *(if* $\|T(t,s)x\| \le c\,\|\Psi(t,s)x\|_p$ *for a constant* $c>0$ *and* $x \in X$*).*

PROPOSITION 5.3. *Let* Σ *be an absolutely regular nonautonomous system, let* $p \in (1,\infty)$*, let* $\Delta(\cdot)$ *be an admissible feedback for* Σ*, and let* Σ^Δ *be the corresponding feedback system. Then* Σ *possesses one of the properties in Definition* 5.2 *if and only if* Σ^Δ *has the same property.*

Proof. (1) The assertions concerning exact (approximate) controllability and (continuous) initial observability follow from the formulas

$$\begin{aligned}\Phi^\Delta(t,s) &= \Phi(t,s)(I+\Delta(\cdot)\mathbb{F}_s^\Delta), & \Phi(t,s) &= \Phi^\Delta(t,s)(I-\Delta(\cdot)\mathbb{F}_s),\\ \Psi^\Delta(t,s) &= (I+\mathbb{F}_s^\Delta\Delta(\cdot))\Psi(t,s), & \Psi(t,s) &= (I-\mathbb{F}_s\Delta(\cdot))\Psi^\Delta(t,s),\end{aligned}$$

which are immediate consequences of (5.2).

(2) Assume that Σ is null controllable. For $x \in X$, there is $u \in L^p([s,t],U)$ such that $T(t,s)x = \Phi_{t,s}u$. Thus (5.2) yields $T_\Delta(t,s)x = \Phi^\Delta(t,s)[u - \Delta(\cdot)\mathbb{F}_s u + \Delta(\cdot)\Psi_s x]$, and Σ^Δ is null controllable. The converse implication and the equivalence for approximate null controllability are shown in the same way.

(3) Assume that Σ is continuously finally observable. Using (5.2), we estimate

$$\begin{aligned}\|T^\Delta(t,s)x\| &\le \|T(t,s)x\| + \|\Phi(t,s)\Delta(\cdot)\Psi^\Delta(t,s)x\| \\ &\le c\,\|\Psi(t,s)x\|_p + c_1\,\|\Psi^\Delta(t,s)x\|_p \\ &\le (c+c_1)\,\|\Psi^\Delta(t,s)x\|_p + \|\mathbb{F}_s\Delta(\cdot)\Psi^\Delta(t,s)x\|_p \le c_2\,\|\Psi^\Delta(t,s)x\|_p\end{aligned} \tag{5.3}$$

so that Σ^Δ is continuously finally observable. If Σ is finally observable and $\Psi^\Delta(t,s)x = 0$, then $\Psi(t,s)x = -\mathbb{F}_s\Delta(\cdot)\Psi^\Delta(t,s)x = 0$. Hence $T(t,s)x = 0$, and (5.3) yields $T^\Delta(t,s)x = 0$. The converse implications are proved similarly. $\square$

Theorem 4.4 also guarantees that repeated feedbacks behave nicely.

PROPOSITION 5.4. *Let* Σ *be an absolutely regular nonautonomous system with* $p \in (1,\infty)$*, let* $\Delta(\cdot)$ *be an admissible feedback for* Σ*, let* Σ^Δ *be the corresponding feedback system, and let* $\tilde\Delta(\cdot) \in L^\infty(\mathbb{R}_+,\mathcal{L}_s(Y,U))$*. Then* $\tilde\Delta(\cdot)$ *is admissible for* Σ^Δ *if and only if* $\Delta(\cdot)+\tilde\Delta(\cdot)$ *is admissible for* Σ*. If this is the case, then* $\Sigma^{\Delta+\tilde\Delta} = (\Sigma^\Delta)^{\tilde\Delta}$.

Proof. Proposition 5.1 implies that

$$\begin{aligned}&\mathbb{F}_s\,[I-\tilde\Delta(\cdot)\mathbb{F}_s^\Delta] = [I-\mathbb{F}_s(\Delta(\cdot)+\tilde\Delta(\cdot))]\,\mathbb{F}_s^\Delta \quad \text{and}\\ &[I-\mathbb{F}_s^\Delta\tilde\Delta(\cdot)]\,\mathbb{F}_s = \mathbb{F}_s^\Delta\,[I-(\Delta(\cdot)+\tilde\Delta(\cdot))\mathbb{F}_s].\end{aligned} \tag{5.4}$$

Assume that $\Delta(\cdot) + \tilde{\Delta}(\cdot)$ is admissible for Σ. We then deduce from (5.4) and (5.1) that

$$\mathbb{F}_s^{\Delta+\tilde{\Delta}} - \mathbb{F}_s^{\Delta} = \mathbb{F}_s^{\Delta+\tilde{\Delta}}\tilde{\Delta}(\cdot)\mathbb{F}_s^{\Delta} = \mathbb{F}_s^{\Delta}\tilde{\Delta}(\cdot)\mathbb{F}_s^{\Delta+\tilde{\Delta}}$$

so that $\tilde{\Delta}(\cdot)$ is admissible for Σ^{Δ} by Lemma 4.3. The converse implication is proved in the same way. The second claim follows similarly from (5.2) and Lemma 4.3. ∎

We introduce a basic asymptotic property of evolution equations; see, e.g., [4], [9].

DEFINITION 5.5. *An evolution family T has an* exponential dichotomy *(or is called* hyperbolic*) if there are projections $P(t)$, $t \geq 0$, and constants $N, \delta > 0$ such that $P(\cdot) \in C_b(\mathbb{R}_+, \mathcal{L}_s(X))$ and, for $t \geq s \geq 0$ and $Q(t) = I - P(t)$,*

1. *$T(t,s)P(s) = P(t)T(t,s)$,*
2. *the restriction $T_Q(t,s) : Q(s)X \to Q(t)X$ of $T(t,s)$ has the inverse $T_Q(s,t)$,*
3. *$\|T(t,s)P(s)\| \leq Ne^{-\delta(t-s)}$, and $\|T_Q(s,t)Q(t)\| \leq Ne^{-\delta(t-s)}$.*

If $P(t) \equiv I$, then T is called exponentially stable.

Persistence of dichotomy under perturbations mapping from spaces $\underline{X}_t$ into X has been studied intensively; see [4, section 5.2], [22, section 5], and the references given there. The next result also holds for admissible systems; see [23, Thm. 4.23].

THEOREM 5.6. *Assume that $(T, \Phi, \Psi, \mathbb{F})$ is a regular nonautonomous system and that $\Delta(\cdot) \in L^{\infty}(\mathbb{R}_+, \mathcal{L}_s(Y,U))$ is Σ-admissible with $k(t_0) := \sup_s \|(I - \mathbb{F}(s + t_0, s)\Delta(\cdot))^{-1}\|$. Suppose that T has an exponential dichotomy with constants $N, \delta > 0$ and projections $P(t)$. Then there is a number $\varepsilon_0 = \varepsilon_0(N, \delta, t_0) > 0$ such that*

$$k(t_0)\beta(t_0)\gamma(t_0)\,\|\Delta(\cdot)\|_{\infty} \leq \varepsilon_0$$

implies that T_{Δ} is hyperbolic with projections having the same rank as $P(t)$ and $Q(t)$.

Proof. We extend the evolution families T and T_{Δ} to the time interval $\mathbb{R}$ by setting $T(t,s) = T_{\Delta}(t,s) = \exp[(t-s)\delta(Q(0) - P(0))]$ for $0 \geq t \geq s$ and $T_{(\Delta)}(t,s) = T_{(\Delta)}(t,0)\exp[-s\delta(Q(0) - P(0))]$. Observe that we can take $k(t_1) = k(t_0)$ for $0 < t_1 \leq t_0$ by the proof of Lemma 4.2 and that $\exp[t\delta(Q(0) - P(0))] = e^{-\delta t}P(0) + e^{\delta t}Q(0)$. Therefore, (4.8) yields

$$\|T_{\Delta}(s + t_0, s) - T(s + t_0, s)\| \leq (1 + e^{\delta t_0})Nk(t_0)\beta(t_0)\gamma(t_0)\,\|\Delta(\cdot)\|_{\infty}.$$

The assertion then follows from [24, Prop. 2.3] (see also [4, Thm. 5.23] and the references therein), where $\varepsilon_0 := (1 - e^{\delta t_0})^2\,((1 + e^{\delta t_0})8N^3)^{-1}$. ∎

We finally characterize the exponential stability of T from the perspective of control theory using the following notions; cf. [5], [6], [17], [20], [25, section 8.2].

DEFINITION 5.7. *A nonautonomous control system (T, Φ) is called* stabilizable *if there exists an observation system (T_F, Ψ^F) with an exponentially stable evolution family T_F on X such that $T_F(t,s)x = T(t,s)x + \Phi_{t,s}\Psi_s^F x$ for all $x \in X$ and $t \geq s \geq 0$.*

DEFINITION 5.8. *A nonautonomous observation system (T, Ψ) is called* detectable *if there is a control system (T_K, Φ^K) with an exponentially stable evolution family T_K on X such that $T_K(t,s)x = T(t,s)x + \Phi_{t,s}^K\Psi_s x$ for all $x \in X$ and $t \geq s \geq 0$.*

The following theorem relates the exponential stability of T, i.e., *internal stability*, with the boundedness of $\mathbb{F} : L^p(\mathbb{R}_+, U) \to L^p(\mathbb{R}_+, Y)$, the so-called *input–output stability*. Versions of Theorem 5.9 for the autonomous Hilbert space setting are proved in [6, Thm. 5.8] for the Pritchard–Salamon class, in [20, Cor. 1.8] for regular systems, and in [17, Thm. 5.2] and [33, Thm. 5.3] for well-posed systems. In that case, the

input–output stability can be replaced by the equivalent condition that the transfer function $H(\lambda) = CR(\lambda, A_{-1})B$ is bounded for $\operatorname{Re}\lambda > 0$; cf. [31, Thm. 3.1]. In [5, Thm. 4.3], our theorem was shown for bounded control and observation operators using the characterization of exponential stability given in [4, Thm. 3.26]. Here we employ Datko's theorem [8, Thm. 1, Rem. 3] in order to avoid some technical problems. However, we remark that Datko's theorem can be deduced from [4, Thm. 3.26]; see [23, Thm. 1.19]. A variant of the next result holds for admissible systems [23, Thm. 4.29].

THEOREM 5.9. *Let $\Sigma = (T, \Phi, \Psi, \mathbb{F})$ be a regular nonautonomous system. Then the following assertions are equivalent:*

1. *T is exponentially stable.*
2. *(T, Φ) is stabilizable, and $\Phi(\cdot, 0) \in \mathcal{L}(L^p(\mathbb{R}_+, U), L^p(\mathbb{R}_+, X))$.*
3. *(T, Ψ) is detectable, and $\|\Psi_s x\|_{L^p([s,\infty),Y)} \le c\,\|x\|$ for $s \ge 0$ and $x \in X$.*
4. *Σ is detectable and stabilizable, and $\mathbb{F} \in \mathcal{L}(L^p(\mathbb{R}_+, U), L^p(\mathbb{R}_+, Y))$.*

Proof. Let 1 hold. Then Σ is always stabilizable (take $\Psi^F = 0$) and detectable (take $\Phi^K = 0$). The other assertions in 2–4 follow from Lemmas 2.3, 3.2, and 3.7. Extending $u \in L^p([s,\infty), U)$ by 0 to $\mathbb{R}_+$ and using causality, we see that the norms of $\Phi(\cdot, s)$ and $\mathbb{F}_s$ decrease as s increases. The assumptions in 2 and Lemma 2.3 yield $\|T(\cdot, s)x\|_{L^p([s,\infty),X)} \le c\,\|x\|_X$ for $s \ge 0$, $x \in X$, and a constant c. Thus 1 is a consequence of Datko's theorem [8, Thm. 1, Rem. 3]. The implication "3⇒1" can be proved in the same way. If Σ is stabilizable, then Theorems 2.7 and 3.11 show that the operators $C(t)$ representing Ψ are also T_F-admissible, and $\Psi_s x = C(\cdot)T_F(\cdot, s)x - \mathbb{F}_s \Psi^F_s x$ for $s \ge 0$ and $x \in X$. Hence 4 implies 1 by Lemmas 2.3 and 2.5. ∎

6. A parabolic problem with point control and observation. Let $\Omega \subset \mathbb{R}^n$ be a bounded domain with C^2-boundary $\partial\Omega$, and let $a_{kl}, a_k, a_0 : \mathbb{R}_+ \times \overline{\Omega} \to \mathbb{R}$, $k, l = 1, \dots, n$ be bounded and uniformly Hölder continuous such that $\sum_{kl} a_{kl}(t,\xi) v_k v_l \ge \alpha\,|v|^2$ for a constant $\alpha > 0$ and $v \in \mathbb{R}^n$, $t \ge 0$, $\xi \in \overline{\Omega}$. Further, let $b, c : \mathbb{R}_+ \to \Omega$ be uniformly Lipschitz such that $|b(t) - c(t)| \ge \delta > 0$ for $t \ge 0$. Let $\varphi \in C_0(\Omega)$, $s \ge 0$, and $D_k = \frac{\partial}{\partial \xi_k}$. The unique solution $w \in C([s,\infty) \times \overline{\Omega}) \cap C^{1,2}((s,\infty) \times \Omega)$ of the problem

$$
\begin{aligned}
w_t(t,\xi) &= \sum\nolimits_{kl} a_{kl}(t,\xi) D_k D_l w(t,\xi) + \sum\nolimits_k a_k(t,\xi) D_k w(t,\xi) \\
&\quad + a_0(t,\xi) w(t,\xi), \quad t > s, \\
w(t,\xi) &= 0, \quad \xi \in \partial\Omega,\ t \ge s, \qquad w(s,\xi) = \varphi(\xi), \quad \xi \in \Omega,
\end{aligned} \tag{6.1}
$$

is given by $w(t,\xi) = \int_\Omega k(t,s,\xi,\eta)\varphi(\eta)\,d\eta$ for a continuous kernel $k(t,s,\xi,\eta)$, $t > s \ge 0$, $\xi \in \overline{\Omega}$, $\eta \in \Omega$, satisfying the Gaussian estimate

$$
|k(t,s,\xi,\eta)| \le M(t-s)^{-\frac{n}{2}} \exp\left(-\frac{w|\xi-\eta|^2}{t-s} + \tilde{w}(t-s)\right)
$$

for $0 < t - s \le t_0$ and constants $M, w > 0$ and $\tilde{w} \in \mathbb{R}$; see, e.g., [15, section IV.16]. By the uniqueness of solutions, we also have

$$
k(t,s,\xi,\eta) = \int_\Omega k(t,r,\xi,\zeta) k(r,s,\zeta,\eta)\,d\zeta, \quad t > r > s \ge 0,\ \xi,\eta \in \Omega. \tag{6.2}
$$

We take $p, q \in [1, \infty)$ and set $X = L^q(\Omega)$, $U = Y = \mathbb{C}$, $T(s,s) = I$, $\Phi(s,s)u = 0$, and

$$T(t,s)\varphi = \int_\Omega k(t,s,\cdot,\eta)\varphi(\eta)\,d\eta, \qquad \Phi_{t,s}u = \int_s^t k(t,\tau,\cdot,b(\tau))u(\tau)\,d\tau,$$
$$(\Psi_s\varphi)(t) = \int_\Omega k(t,s,c(t),\eta)\varphi(\eta)\,d\eta, \qquad (\mathbb{F}_s u)(t) = \int_s^t k(t,\tau,c(t),b(\tau))u(\tau)\,d\tau$$

for $t > s \geq 0$, $\varphi \in X$, and $u \in L^p_{loc}(\mathbb{R}_+)$. These maps correspond to the PDE (6.1) complemented by the control $B(t)u(t) = \delta_{b(t)}u(t)$ and the output $y(t) = w(t, c(t))$.

The operators $T(t,s)$ yield an evolution family on X due to standard elliptic regularity and, e.g., [2, Thm. II.4.4.1]. Since b is Lipschitz, we have

$$\exp\left(-w\,\frac{|\xi - b(s)|^2}{t-s}\right) \leq c_1 \exp\left(-w\,\frac{|\xi - b(t)|^2}{t-s}\right) \tag{6.3}$$

for $t > s \geq 0$, $\xi \in \Omega$, and a constant c_1. Hence $|(\mathbb{F}_s u)(t)| \leq \varphi * |u|\,(t)$, $s \leq t \leq s + t_0$, where we have extended $u \in L^p_{loc}([s,\infty))$ by 0 and put $\varphi(t) = c_1\, t^{-\frac{n}{2}} \exp(-\frac{w\delta^2}{t} + \tilde{w}t)$ for $t > 0$ and $\varphi(t) = 0$ otherwise. For $1 + \frac{1}{p} = \frac{1}{\lambda} + \frac{1}{\mu}$, Young's inequality yields

$$\|\mathbb{F}_s u\|_{L^p[s,s+t_0]} \leq \|\varphi\|_{L^\lambda[0,t_0]}\, \|u\|_{L^\mu[s,s+t_0]} \tag{6.4}$$

so that (3.11) holds for each $p \in [1,\infty]$. Observe that $\Psi_s\varphi$ is continuous on (s,∞) for each $\varphi \in L^1(\Omega)$ and that $t \mapsto \Phi(t,s)u \in L^1(\Omega)$ is continuous on $[s,\infty)$ for $u \in L^1_{loc}([s,\infty))$. Moreover, (6.2) implies (2.1), (3.1), and (3.10). Using (6.3), Hölder's inequality, and that the norm of the Gaussian kernel in $L^{q'}(\mathbb{R}^n)$ equals $ct^{-n/2q}$, we compute

$$\int_s^t |\Psi_s\varphi(\tau)|^p\,d\tau \leq c\,\|\varphi\|_q^p \int_s^t (\tau - s)^{-\frac{np}{2q}}\,d\tau, \tag{6.5}$$

$$\|\Phi_{t,s}u\|_q \leq c\int_s^t (t-\tau)^{-\frac{n}{2q'}}\,|u(\tau)|\,d\tau \tag{6.6}$$

for $0 < t - s \leq t_0$, $1/q + 1/q' = 1$, and constants c. Thus the operators

$$\Psi_s : L^q(\Omega) \to L^p_{loc}([s,\infty)),\ \ q > \frac{np}{2}, \quad \Phi_{t,s} : L^p_{loc}([s,t]) \to L^q(\Omega),\ \ q' > \frac{np'}{2}, \tag{6.7}$$

are continuous. As a result, $(T, \Phi, \Psi, \mathbb{F})$ is a well-posed nonautonomous system provided that $n = 1$, $q > p/2$, and $q' > p'/2$ (for instance, if $p = q = 2$). In view of (6.4), this system is absolutely regular, and every bounded feedback is admissible.

The restriction $n = 1$ was needed only to obtain the boundedness of Ψ_s and $\Phi_{t,s}$ for the same values of p and q. We now discuss to what extent the assertions of Theorem 4.4 remain valid for $n = 2, 3$. All results dealing with Ψ and Φ *separately* are true for the exponents indicated in (6.7). Observe that $\mathbb{F}_s$ satisfies (3.11), (3.13), and the assertions of Lemma 4.2 for all $p \geq 1$ and that every bounded feedback is admissible. Moreover, the proof and assertion of Theorem 3.11 work as before. Proposition 3.12 holds for $n = 2$, $u \in L^r_{loc}(\mathbb{R}_+)$ with $r > 1$, $X = L^q(\Omega)$ with $q' > r'$, and $p < q$ in the assertions. In fact, we have $B_n u \in L^\infty_{loc}(\mathbb{R}_+, L^q(\Omega))$ for $q' > r'$. So we can apply Proposition 2.11 for $p < q$ to obtain (3.21) and then proceed as before.

We now consider Theorem 4.4, where we restrict ourselves to the case where the state space X equals $L^2(\Omega)$ and the given system Σ is admissible with exponent 2.

We define $T_\Delta(t,s)\varphi$ for $\varphi \in L^q(\Omega)$ with $q > 2n/(4-n)$ as in (4.8). Then $\Psi_s\varphi \in L^p_{loc}([s,\infty))$ for all $p \in (4/(4-n), 2q/n)$, and $T_\Delta(t,s) : L^q(\Omega) \to L^2(\Omega)$ is bounded for $0 \le t-s \le t_0$ due to (6.7). Because of (6.4) with $p=\infty$ and $\mu < 4/n$ and (6.7), we have

$$\|\mathbb{F}_s\Delta(\cdot)(I - \mathbb{F}(s+t_1,s)\Delta(\cdot))^{-1}\Psi_s x\|_{L^\infty[s,s+t_0]} \le c\,\|\Psi_s\varphi\|_{L^\mu[s,s+t_0]} \le c\,\|\varphi\|_2\,.$$

Thus (4.9) and (6.5) yield

$$|C(t)T_\Delta(t,s)\varphi| \le c\,(t-s)^{-\frac{n}{4}}\,\|\varphi\|_2 \tag{6.8}$$

for $0 < t-s \le t_0$. The identity (4.5) (with $\varphi \in L^q(\Omega)$) follows as before. Using (4.5), (6.6), and (6.8), we further estimate $\|T_\Delta(t,s)\varphi\|_2 \le c\,(t-s)^{1-\frac{n}{2}}\,\|\varphi\|_2$. Therefore, we can extend $T_\Delta(t,s)$ and (4.5) to $L^2(\Omega)$. We can now argue as in the proof of Theorem 4.4 and deduce part (a) of the theorem if we replace (4.4) by (6.8), allow for a blow-up of $T_\Delta(t,s)$ as $t \to s$ if $n=3$, and consider solutions $x(\cdot)$ of (4.1) such that $x(\cdot) \in C([s,\infty), L^1(\Omega))$ and $C(\cdot)x(\cdot) \in L^1_{loc}([s,\infty))$.

Now let $n=2$. In part (b), we restrict ourselves in (4.11) to cut-off functions γ with compact support in (r,∞). (One checks as in [4, Thm. 3.12] that the set of resulting functions f is still dense in $L^p_{loc}([s,\infty),X)$. Here we need the strong continuity of $T_\Delta(t,s)$ at $t=s$ and must thus exclude $n=3$.) We proceed as before and deduce (4.15) and (4.16) for $u \in L^p_{loc}([s,\infty))$ with $p > 2$. We can take the limits as $n \to \infty$ in $C([s,s+t_1], L^2(\Omega))$ and $L^2[s,s+t_1]$, respectively, and obtain $\Phi^\Delta u$ and $\mathbb{F}^\Delta u$. Moreover, $\Phi^\Delta u$ satisfies an estimate like (6.6). We can thus apply $\Phi^\Delta_{t,s}$ on $u = \Delta(\cdot)\Psi_s\varphi$ for $\varphi \in L^2(\Omega)$ so that (4.7) holds. The other assertions of Theorem 4.4(b) can be verified as before except that Ψ^Δ and Φ^Δ have the mapping properties from (6.7) with $q=2$.

Acknowledgments. I started this project together with Yuri Latushkin and Timothy Randolph from the University of Missouri, and I profited greatly from many joint discussions.

STABILIZATION OF BEAMS WITH NONLINEAR FEEDBACK*

LARBI BERRAHMOUNE†

Abstract. This paper studies nonlinear feedback stabilization of Euler–Bernoulli beams subject to various pointwise and concentrated actuators. Strong, uniform, and nonuniform stabilization are obtained with explicit decay estimates in appropriate spaces. The results are obtained through the study of an abstract second order distributed system which encompasses the models under investigation.

Key words. stabilization, nonlinear feedback, pointwise actuator, concentrated actuator

1. Introduction and statement of the main abstract results.

1.1. Motivating examples. In this paper, we are concerned with the question of stabilization of second order distributed systems modelling connected vibrating beams provided with various types of actuators. In what follows, $y(x,t)$ represents the displacement of the structure in question at position x and time t. The notation y' denotes the derivative of y with respect to time.

The canonical classes of problems that we have in mind are as follows.

Model 1. *Beam equation with pointwise actuator.* Let $0 < a < 1$; we consider the system of coupled beams with spatial extent from $x = 0$ to $x = a$ and from $x = a$ to $x = 1$. We suppose that the end at $x = 0$ is simply supported and at $x = 1$ there is a shear hinge end. We consider the case where, at $x = a$, we have a rigid support joint with the discontinuity in the shear as control (see [8]). Then y satisfies the following Euler–Bernoulli equation:

$$y'' + \frac{\partial^4 y}{\partial x^4} = 0, \quad t > 0,\ x \in (0,a) \cup (a,1)\,. \tag{1.1}$$

The boundary and joint conditions are given by

$$\begin{cases} y(t,0) = \frac{\partial^2 y}{\partial x^2}(t,0) = 0, \\ \frac{\partial y}{\partial x}(t,1) = \frac{\partial^3 y}{\partial x^3}(t,1) = 0, \\ y(t,a^-) = y(t,a^+), \\ \frac{\partial y}{\partial x}(t,a^-) = \frac{\partial y}{\partial x}(t,a^+), \\ \frac{\partial^2 y}{\partial x^2}(t,a^-) = \frac{\partial^2 y}{\partial x^2}(t,a^+), \end{cases} \tag{1.2}$$

$$\frac{\partial^3 y}{\partial x^3}(t,a^+) - \frac{\partial^3 y}{\partial x^3}(t,a^-) = u(t). \tag{1.3}$$

Model 2. *Beam equation with piezoelectric actuator.* We consider the Euler–Bernoulli beam that is subject to the action of an attached piezoelectric actuator [4]. We suppose that the beam is hinged at both ends and that the actuator is excited in a manner to produce pure bending moments. This leads to the following model [10]:

$$y'' + \frac{\partial^4 y}{\partial x^4} = u(t)\frac{d}{dx}(\delta(x-a_1) - \delta(x-a_2)), \quad t > 0,\ 0 < x < 1, \tag{1.4}$$

$$y(t,0) = y(t,1) = \frac{\partial^2 y}{\partial x^2}(t,0) = \frac{\partial^2 y}{\partial x^2}(t,1) = 0, \tag{1.5}$$

where $\delta(x-a)$ denotes the Dirac mass at a. Here the points $a_1,\ a_2 \in (0,1)$ represent the ends of the actuator and the control function $u(.)$ is the time variation of the voltage applied to the actuator.

Model 3. *Beam equation with concentrated actuator.* We consider the controlled Euler–Bernoulli beam equation

$$y'' + \frac{\partial^4 y}{\partial x^4} = u(t)g(x), \quad t > 0,\ 0 < x < 1, \tag{1.6}$$

with boundary conditions (1.5) and $g \in L^2(0,1)$. As in [12], we shall call the concentrated control (or actuator) the control relevant to (1.6). The introduction of such a system is motivated by the fact that, from an engineering viewpoint, point actuators as in examples (1.1)–(1.3) and (1.4) are idealizations. Indeed, the control actions resulting from such actuators affect a distributed part of the spatial domain and not just points. Thus, although it is generally accepted that point actuators are useful concepts which lead to the so-called unbounded controls, a more realistic model would be to consider concentrated actuators. Such considerations have been studied for beam equations in [12]. In this reference, it is shown that the uniform exponential stability is lost whenever the concentrated actuator concept is adopted for the same linear feedback. In this paper, we shall see that, even when such a concept is adopted, uniform exponential stability can be achieved in appropriate spaces by using unbounded feedbacks.

In the equations above, the function $u : (0,\infty) \to IR$ represents the control, and we suppose that $u \in L^2_{loc}(0,\infty)$. Then we consider the question of explicit (nonlinear) feedback operator based on the velocity

$$u(t) = F(y'(.,t))$$

such that the resulting equation produces a solution which is stable in appropriate spaces. Furthermore, under suitable assumptions, explicit decay estimates will be given.

1.2. Literature. As the foregoing examples indicate, the object of this paper is to study the problem of (nonlinear) feedback stabilization of various Euler–Bernoulli equations with interior control supported by points or zones. Let us state at the outset a part of the abundant literature concerned with the problem of linear feedback stabilization relative to our examples. Model 1 has been studied in [8] and [20]. In the first reference, the tool used is based on a combination of multipliers and the Lyapunov method. In the second one, a frequency domain approach is the main ingredient. As for Model 2, a strong stabilization result has been obtained in [26] via LaSalle's invariance principle. Model 3 can be treated via the general study dealing with the linear bounded feedback case in [21].

The main contributions of this paper are as follows:

(i) The problems above are presented in an abstract framework which encompasses these examples and others as well (wave equation, Kirchhoff models, etc.). Some aspects of this question will be considered in section 4.

(ii) The regularity results relative to the abstract model are sharp. The method used to this end gives an alternative way to obtain in a unified approach regularity properties already studied for their own interest (see [27] for Model 2).

(iii) The nonlinear feedback used to stabilize our models is general and less restrictive compared to those of the existing literature. Furthermore, it enables us to get the linear feedback stabilization results as particular cases (see [1] for Model 1).

(iv) To the author's knowledge and for the models above, the results deduced from the abstract framework are new in the nonlinear feedback stabilization setting. These results can be used to improve some partial results concerned with particular situations (see, for instance, [9], where boundary feedback stabilization is studied).

The plan of the paper is as follows. The rest of this section is devoted to the statement of regularity and stabilization results relative to an abstract formulation of our models. The second section is concerned with the proofs of the abstract results. In the third section, we justify that our problems can be written in abstract form and derive various stabilization results. The fourth section contains some comments on possible extensions and related questions. In the remaining part of this paper, we shall denote by C a generic positive constant which may be different at different occurrences.

1.3. Formulation of the problem and statement of the abstract results. In this subsection, we consider an abstract second order distributed control system subject to certain assumptions. In latter sections, we verify that these assumptions are natural for, and, in fact, automatically satisfied by, the models of our interest.

Let V, H be real Hilbert spaces such that $V \subset H$ with dense, continuous, and compact embedding. We denote by $|.|$ and $\|.\|$ the norms on H and V, respectively. Let us introduce the unique linear bounded operator from V to V' which is characterized by

$$\langle Av, w\rangle_{V',V} = \langle v, w\rangle_V \quad \text{for all } v, w \in V. \tag{1.7}$$

Motivated by the examples given in the introduction, we shall consider the abstract system

$$\begin{cases} y''(t) + Ay(t) = u(t)b, \quad 0 < t < T, \\ y(0) = y_0,\ y'(0) = y_1, \end{cases} \tag{1.8}$$

where $u \in L^2(0,T)$ represents the control and b is given in V'.

Recall that, by identifying H with its dual, we have $V \subset H \equiv H' \subset V'$ and

$$\langle v, w\rangle_H = \langle v, w\rangle \quad \text{for all } v, w \in H, \tag{1.9}$$

where $\langle ., .\rangle$ denotes the V', V duality pairing with respect to the H-topology. Hence, if we consider A as an operator on H with

$$D(A) = A^{-1}(H), \tag{1.10}$$

then A is self-adjoint with compact resolvent on H.

We shall consider the stability of the control system under (possibly nonlinear) feedback control of the form

$$u(t) = -f\left(\frac{d}{dt}\langle b, y(t)\rangle\right), \tag{1.11}$$

where $f : IR \to IR$ is continuous and monotone and satisfies

$$rf(r) \geq 0 \quad \text{for all } r \in IR. \tag{1.12}$$

Thus the resulting system, whose stability properties we shall investigate, is the following:

$$\begin{cases} y''(t) + Ay(t) + f(\frac{d}{dt}\langle b, y(t)\rangle)b = 0, \\ y(0) = y_0,\ y'(0) = y_1. \end{cases} \tag{1.13}$$

The main goal is to characterize those b for which (i) the solutions of (1.8) and (1.13) exist globally and (ii) the energy given by

$$E(t) = \frac{1}{2}(\|y(t)\|^2 + |y'(t)|^2) \tag{1.14}$$

decays to zero when $t \to \infty$ for every solution of (1.13). Furthermore, we shall specify the decay rate in terms of the function f.

Let us introduce the set $\{\lambda_n = \omega_n^2\}_n$ of eigenvalues of A and denote by $\{\psi_n\}_n$ the corresponding orthogonal basis in H. Then we have the standard identifications

$$V \equiv D(A^{\frac{1}{2}}),\ \ \|v\|^2 = \|v\|^2_{D(A^{\frac{1}{2}})} = \sum_n \omega_n^2 \left|\langle v, \psi_n\rangle\right|^2. \tag{1.15}$$

More generally, for $0 < \mu \leq 1$, we shall use the fractional power spaces

$$D(A^\mu) = \left\{ v \in H \,/\, \sum_n \omega_n^{4\mu} \left|\langle v, \psi_n\rangle\right|^2 < \infty \right\},\ \ \|v\|^2_{D(A^\mu)} = \sum_n \omega_n^{4\mu} \left|\langle v, \psi_n\rangle\right|^2. \tag{1.16}$$

The space $D(A^\mu)'$ will denote the dual of $D(A^\mu)$ with respect to the H-topology so that it can be characterized as the completion of H for the norm defined by

$$\|v\|^2_{D(A^\mu)'} = \sum_n \omega_n^{-4\mu} \left|\langle v, \psi_n\rangle\right|^2. \tag{1.17}$$

In the applications, the operator A will stand for $\frac{d^4}{dx^4}$ with appropriate homogenous boundary conditions so that the spaces above can be identified with Sobolev spaces in a standard way [13], [19]. We shall use later the fact that the embedding $H \subset V'$ is also compact.

Let us mention that, from standard theory, the system (1.8) has a unique solution with $y \in C\,(0, T; H) \cap C^1\,(0, T; V')$ [19, p. 311]. In fact, we shall prove that the solution can be more regular. As for the feedback system (1.13), similar regularity results will be obtained under less demanding assumptions.

Below, we shall state our main abstract results, while the proofs are relegated to section 2.

PROPOSITION 1.1 (well posedness of (1.8) on $V \times H$). *Suppose that*

$$\underline{\lim}_n \omega_{n+1} - \omega_n \geq \delta > 0 \tag{1.18}$$

and, for some positive constant C_b,

$$|\langle b, \psi_n \rangle| \leq C_b, \quad \text{for all } n. \tag{1.19}$$

Then, for any $\{y_0, y_1\} \in V \times H$, there exists a unique weak solution to (1.8) such that

$$y \in C\left(0, T; V\right) \cap C^1\left(0, T; H\right). \tag{1.20}$$

Before stating the following corollary, we introduce, for $-1 \leq \theta \leq 1$, the spaces V_θ given by

$$V_\theta = \begin{cases} D(A^\theta), & \text{if } \theta \geq 0, \\ D(A^{-\theta})' & \text{otherwise.} \end{cases} \tag{1.21}$$

Then we have the following corollary.

COROLLARY 1.2. *Suppose that (1.18) holds and, for some $0 < \mu \leq 1$ and some positive constant C_b,*

$$|\langle b, \psi_n \rangle| \leq C_b \lambda_n^\mu \quad \text{for all } n. \tag{1.22}$$

Then, for any $\{y_0, y_1\} \in V_{\frac{1}{2}-\mu} \times D(A^\mu)'$, there exists a unique weak solution to (1.8) such that

$$y \in C(0, T; V_{\frac{1}{2}-\mu}) \cap C^1\left(0, T; D(A^\mu)'\right). \tag{1.23}$$

PROPOSITION 1.3. *Suppose that the assumptions of Proposition 1.1 hold. Moreover, assume that the sequence $\{\sigma_n\}_n$ given by*

$$\sigma_n = \sum_{j \neq n} \frac{1}{\left|\sqrt{\omega_n} - \sqrt{\omega_j}\right|^2} \tag{1.24}$$

is well defined and bounded. Then, for y solution of

$$\begin{cases} y''(t) + Ay(t) = u(t)b, \quad 0 < t < T, \\ y(0) = y'(0) = 0, \end{cases} \tag{1.25}$$

the function $\frac{d}{dt}\langle b, y(.)\rangle$ is well defined in $L^2(0,T)$, and

$$\left\| \frac{d}{dt} \langle b, y(.) \rangle \right\|_{L^2(0,T)} \leq C \left\| u \right\|_{L^2(0,T)} \tag{1.26}$$

for some positive constant C.

PROPOSITION 1.4 (well posedness of (1.13) on $V \times H$). *Let $f : IR \to IR$ be a continuous monotone function satisfying (1.12). Then, for any $\{y_0, y_1\} \in V \times H$, there exists a unique weak solution to (1.13) with the regularity (1.20).*

To state our first stability result for system (1.13), we need the following assumption regarding f:

$$rf(r) > 0 \quad \text{for all } r \neq 0. \tag{1.27}$$

Then we have the following theorem.

THEOREM 1.5 (strong stability for the solution of (1.13)). *Let $f : IR \to IR$ be a continuous monotone function satisfying (1.27). Suppose that the eigenvalues λ_n are simple. Then, for any $\{y_0, y_1\} \in V \times H$, the following conditions are equivalent:*

(i) *The solution of* (1.13) *satisfies* $\lim_{t\to\infty} E(t) = 0$.
(ii) $\langle b, \psi_n\rangle \neq 0$ *for all* n.
(iii) *For any* $\{\varphi_0, \varphi_1\} \in D(A) \times V$, *the only function satisfying the conditions*

$$\begin{cases} \varphi''(t) + A\varphi(t) = 0, \quad 0 < t < \infty, \\ \varphi(0) = \varphi_0,\ \varphi'(0) = \varphi_1, \\ \langle b, \varphi'(t)\rangle = 0, \quad 0 < t < \infty, \end{cases} \tag{1.28}$$

is $\varphi \equiv 0$.

To state our second stabilization result, we consider the assumptions

$$c_f\,|r| \leq |f(r)| \leq C_f\,|r| \quad \text{for all } |r| \geq 1, \tag{1.29}$$

where c_f, C_f are positive constants and there is a concave, strictly increasing function $\xi : IR^+ \to IR$ with $\xi(0) = 0$ such that, for some $\rho \in (0, 1]$,

$$|r|^{2\rho} + |f(r)|^2 \leq \xi(rf(r)) \quad \text{for all } |r| < 1. \tag{1.30}$$

On the other hand, for T satisfying

$$T > \frac{2\pi}{\delta}, \tag{1.31}$$

we set

$$h(s) = s + \xi\left(\frac{s}{T}\right). \tag{1.32}$$

Let p denote the inverse of $C_0 h$ where C_0 is a positive constant to be precise in the proof. Then we have the following theorem.

THEOREM 1.6 (stability and general decay estimate for the solution of (1.13)). *Let* f *be a continuous monotone function satisfying* (1.27), (1.29), *and* (1.30). *Suppose that the eigenvalues* λ_n *are simple, satisfying* (1.18) *and such that the sequence* $\{\sigma_n\}_n$ *is well defined and bounded. Moreover, assume that, for some positive constants* C_b, c_b,

$$c_b \leq |\langle b, \psi_n\rangle| \leq C_b \quad \textit{for all } n. \tag{1.33}$$

Then, for some $T > 0$, *the solution of the system* (1.13) *satisfies*

$$E(t) \leq S\left(\frac{t}{T} - 1\right) \quad \textit{for all } t > T, \tag{1.34}$$

where $S(t) \to 0$ *as* $t \to \infty$ *and is the solution (contraction semigroup) of the differential equation*

$$S'(t) + q(S(t)) = 0,\ S(0) = E(0), \tag{1.35}$$

and q *is given by*

$$q(s) = s - (I + p)^{-1}(s). \tag{1.36}$$

THEOREM 1.7 (stability and decay estimate for the solution of (1.13)). *Let* f *be a continuous monotone function satisfying* (1.27), (1.29), *and the additional hypotheses*

$$\widetilde{c}_f\,|r|^{\alpha+1} \leq rf(r) \quad \textit{for all } |r| < 1, \tag{1.37}$$

$$|f(r)| \leq \widetilde{C}_f \, |r|^{\beta} \quad \textit{for all } |r| < 1, \tag{1.38}$$

where $\widetilde{C}_f$, $\widetilde{c}_f$, α, β *are positive constants with* $0 < \beta \leq 1$ *and* $\alpha \geq \beta$. *Suppose that the eigenvalues* λ_n *satisfy the assumptions of Theorem* 1.6. *Moreover, assume that* (1.33) *holds. Then, for some positive constants* ω, T, *and* K, *the solution of the system* (1.13) *satisfies*

$$E(t) \leq KE(0)e^{-\omega t} \quad \textit{for all } t > T \tag{1.39}$$

if $\alpha = \beta = 1$ *and*

$$E(t) = O(t^{-\frac{2\beta}{\alpha+1-2\beta}}) \; (t \to \infty) \tag{1.40}$$

if $\alpha + 1 > 2\beta$.

The following result gives a nonuniform stability property for (1.13) when the first inequality in (1.33) is not satisfied. More precisely, the decay rates are obtained for initial data lying in a space dense in the energy space.

THEOREM 1.8 (nonuniform stability and decay estimate for the solution of (1.13)). *Let* f *be a continuous monotone function satisfying the assumptions of Theorem* 1.7 *with* $\alpha = \beta = 1$. *Suppose that the eigenvalues* λ_n *satisfy the assumptions of Theorem* 1.6. *Assume that* $b \in H$ *and, for some positive constants* C_b, c_b *and some* $0 < \mu \leq 1$,

$$\frac{c_b}{\lambda_n^{\mu}} \leq |\langle b, \psi_n \rangle| \leq C_b \quad \textit{for all } n. \tag{1.41}$$

Then, for any $\{y_0, y_1\} \in D(A) \times V$, *the solution of the system* (1.13) *satisfies*

$$\begin{cases} E(t) = d(t)(\|y_0\|^2_{D(A)} + \|y_1\|^2), \\ d(t) = O(t^{-\frac{1}{2\mu}}) \;\; (t \to \infty). \end{cases} \tag{1.42}$$

2. Proofs of the main abstract results.

2.1. Well posedness and regularity. Without loss of generality, we shall suppose in subsubsections 2.1.1–2.1.3 that $T > \frac{2\pi}{\delta}$.

2.1.1. Proof of Proposition 1.1. It is standard that (1.8) admits a unique solution satisfying [19, p. 311]

$$y \in C(0, T; H) \cap C^1(0, T; V'). \tag{2.1}$$

On the other hand, if we consider the uncontrolled system

$$\begin{cases} \varphi''(t) + A\varphi(t) = 0, \\ \varphi(0) = \varphi_0, \; \varphi'(0) = \varphi_1, \end{cases} \tag{2.2}$$

and suppose that $\{\varphi_0, \varphi_1\} \in V \times H$, then we have

$$\frac{d}{dt} \langle b, \varphi(t) \rangle = \sum_n \left[-\omega_n \langle \psi_n, \varphi_0 \rangle \sin(\omega_n t) + \langle \psi_n, \varphi_1 \rangle \cos(\omega_n t) \right] \langle b, \psi_n \rangle . \tag{2.3}$$

If we consider the series above as a Fourier series in t and we apply Ingham's inequality, we obtain, for some positive constant C [3],

$$\left\| \frac{d}{dt} \langle b, \varphi(.) \rangle \right\|^2_{L^2(0,T)} \leq C(\|\varphi_0\|^2 + |\varphi_1|^2). \tag{2.4}$$

By adapting Proposition 3.1 in [5, p. 172], we can easily deduce (1.20). ∎

2.1.2. Proof of Corollary 1.2. Let us introduce

$$\widetilde{b} = A^{-\mu} b \tag{2.5}$$

and consider the change of variables

$$\begin{cases} \widetilde{y}(t) = A^{-\mu} y(t), \\ \widetilde{y}_0 = A^{-\mu} y_0, \\ \widetilde{y}_1 = A^{-\mu} y_1. \end{cases} \tag{2.6}$$

Then $\widetilde{b} \in V'$, and $\widetilde{y}$ is the solution of the problem

$$\begin{cases} \widetilde{y}''(t) + A\widetilde{y}(t) = u(t)\widetilde{b} \quad 0 < t < T, \\ \widetilde{y}(0) = \widetilde{y}_0,\ \widetilde{y}'(0) = \widetilde{y}_1. \end{cases} \tag{2.7}$$

On the other hand, for some positive constant C,

$$|\langle \widetilde{b}, \psi_n \rangle| \leq C \quad \text{for all } n. \tag{2.8}$$

Hence Proposition 1.1 yields $\widetilde{y} \in C\left(0, T; V\right) \cap C^1\left(0, T; H\right)$. This completes the proof of the corollary. □

2.1.3. Proof of Proposition 1.3. We first note that, by using the Galerkin method, the solution of (1.25) can be approximated by the sequence of solutions given by

$$\begin{cases} \langle y_m''(t), \psi_k \rangle + \langle A y_m(t), \psi_k \rangle = u(t) \langle b, \psi_k \rangle \quad 0 < t < T, \\ 1 \leq k \leq m,\ y_m(t) \in \mathit{span}\ (\psi_1, \ldots,\ \psi_m), \\ y_m(0) = y_m'(0) = 0. \end{cases} \tag{2.9}$$

Indeed, by adapting the methods performed in [19, chapter 3, section 8], it can be shown that we can extract a subsequence, still denoted by $\{y_m\}_m$, such that

$$y_m \to y \text{ weakly in } L^2(0, T; H), \tag{2.10}$$

$$y_m' \to y' \text{ weakly in } L^2(0, T; V'). \tag{2.11}$$

On the other hand, we notice that, for $u \in H_0^1(0, T)$, we can easily get from above that

$$y' \in C\left(0, T; V\right). \tag{2.12}$$

Hence the function $\frac{d}{dt} \langle b, y(.) \rangle$ is well defined in $C(0, T)$. We shall use the following result.

LEMMA 2.1. *Suppose that $u \in H_0^1(0, T)$. Then the sequence $\{y_m\}_m$ satisfies*

$$\{y_m'\}_m \ \textit{bounded in } C\left(0, T; V\right), \tag{2.13}$$

$$\{y_m''\}_m \ \textit{bounded in } C\left(0, T; H\right). \tag{2.14}$$

Proof. From

$$y'_m(t) = \sum_{k=1}^{m} \left\{ \int_0^t u'(s) \sin \omega_k (t-s) ds \right\} \frac{\langle b, \psi_k \rangle}{\omega_k} \psi_k \tag{2.15}$$

and using (1.19), we get, for some positive constant C,

$$\|y'_m(t)\|_V^2 \leq C \sum_{k=1}^{m} \left\{ \int_0^t u'(s) \sin \omega_k (t-s) ds \right\}^2. \tag{2.16}$$

By an easy adaptation of the auxiliary result in Lemma A.1 (see Appendix A), we obtain, for some positive constant C independent of m,

$$\|y'_m(t)\|_V \leq C \|u'\|_{L^2(0,T)} \quad \text{for all } 0 < t < T. \tag{2.17}$$

The assertion (2.14) can be obtained in the same way. The proof of the lemma is complete. □

In order to complete the proof of (1.26), we notice that, by standard compactness argument [23], there exists a subsequence, still denoted by $\{y'_m\}_m$, such that

$$y'_m \to y' \text{ in } C(0,T;H), \tag{2.18}$$

$$y'_m \to y' \text{ weakly in } L^2(0,T;V). \tag{2.19}$$

Furthermore, from (2.13) we get

$$\langle b, y'_m(.) \rangle \text{ bounded in } L^2(0,T) \tag{2.20}$$

so that we can extract a subsequence such that

$$\langle b, y'_m(.) \rangle \to \langle b, y'(.) \rangle \text{ weakly in } L^2(0,T). \tag{2.21}$$

By a density argument, it is sufficient to establish (1.26) for $u \in H_0^1(0,T)$. Taking into account (2.21) and using a weak compactness argument, this can be reduced to

$$\|\langle b, y'_m(.) \rangle\|_{L^2(0,T)} \leq C \|u\|_{L^2(0,T)} \tag{2.22}$$

for some positive constant C independent of m. To this end, let us denote by $\widetilde{u}$ the extension of u defined by

$$\widetilde{u}(t) = \begin{cases} u(t) & \text{if } 0 < t < T, \\ 0 & \text{otherwise,} \end{cases} \tag{2.23}$$

and consider the sequences $\{s_k\}_k$ and $\{S_m\}_m$ given by

$$s_k(t) = \begin{cases} |\langle b, \psi_k \rangle|^2 e^{i\omega_k t} & \text{if } 0 < t < T, \\ 0 & \text{otherwise,} \end{cases} \tag{2.24}$$

$$S_m(t) = \sum_{k=1}^{m} s_k(t). \tag{2.25}$$

Then, from (2.15), we get

$$\|\langle b, y'_m(.)\rangle\|_{L^2(0,T)} \leq \|(S_m * \widetilde{u})(.)\|_{L^2(IR)}\,. \tag{2.26}$$

For $w \in L^2(IR)$, let $\widehat{w}$ denote the Fourier transform of w defined by

$$\widehat{w}(\tau) = \int_{IR} e^{-it\tau} w(t)dt. \tag{2.27}$$

Then, using Parseval's property, we have

$$\|\langle b, y'_m(.)\rangle\|_{L^2(0,T)} \leq \|\widehat{S}_m \widehat{\widetilde{u}}\|_{L^2(IR)} \tag{2.28}$$

and

$$\|\langle b, y'_m(.)\rangle\|_{L^2(0,T)} \leq \|\widehat{S}_m\|_{L^\infty(IR)} \|\widehat{\widetilde{u}}\|_{L^2(IR)}. \tag{2.29}$$

Hence, it is sufficient to see that, for some positive constant C,

$$\|\widehat{S}_m\|_{L^\infty(IR)} \leq C \quad \text{for all } m. \tag{2.30}$$

By continuity, this can be reduced to see that, for any τ such that

$$\tau \neq \omega_k \quad \text{for all } k,$$

we have

$$|\widehat{S}_m(\tau)| \leq C \quad \text{for all } m. \tag{2.31}$$

In what follows, we shall implicitly consider this case so that

$$\widehat{S}_m(\tau) = \sum_{k=1}^{m} \widehat{s}_k(\tau) = \sum_{k=1}^{m} \frac{e^{i(\omega_k - \tau)T} - 1}{i(\omega_k - \tau)} \left|\langle b, \psi_k\rangle\right|^2. \tag{2.32}$$

If $\tau \leq 0$, then we have

$$|\widehat{S}_m(\tau)| \leq \sum_{k=1}^{m} \frac{2C_b^2}{\omega_k} \leq 2C_b^2 \left(\sigma_1 + \frac{1}{\omega_1}\right) \quad \text{for all } m. \tag{2.33}$$

On the other hand, an easy computation gives

$$\left|\frac{e^{i(\omega_k - \tau)T} - 1}{i(\omega_k - \tau)}\right| = \frac{\left|4\sin^2(\omega_k - \tau)T/2\right|^{\frac{1}{2}}}{|\omega_k - \tau|} = T\frac{|\sin(\omega_k - \tau)T/2|}{|\omega_k - \tau|\, T/2}.$$

Hence we have, for all real τ,

$$|\widehat{s}_k(\tau)| \leq TC_b^2. \tag{2.34}$$

Suppose that $\tau > 0$, and let

$$n(\tau) = \min\{k \,/\, \tau < \omega_k\}\,. \tag{2.35}$$

If $n(\tau) \leq 3$, then

$$|\widehat{S}_m(\tau)| \leq \left|\sum_{k=1}^{n(\tau)} \widehat{s}_k(\tau)\right| + \left|\sum_{k=n(\tau)+1}^{m} \widehat{s}_k(\tau)\right|$$
$$\leq 3TC_b^2 + 2C_b^2 \left|\sum_{k=n(\tau)+1}^{m} \frac{1}{\omega_k - \omega_{n(\tau)}}\right|$$
$$\leq 3TC_b^2 + 2C_b^2 \left[\sum_{k=n(\tau)+1}^{m} \frac{1}{|\sqrt{\omega_k} - \sqrt{\omega_{n(\tau)}}|^2}\right]^{\frac{1}{2}} \left[\sum_{k=n(\tau)+1}^{m} \frac{1}{|\sqrt{\omega_k} + \sqrt{\omega_{n(\tau)}}|^2}\right]^{\frac{1}{2}}.$$

Thus

$$|\widehat{S}_m(\tau)| \leq 3TC_b^2 + 2C_b^2 \sigma_{n(\tau)}. \tag{2.36}$$

If $n(\tau) > 3$, then

$$|\widehat{S}_m(\tau)| \leq \left|\sum_{k=1}^{n(\tau)-2} \widehat{s}_k(\tau)\right| + \left|\widehat{s}_{n(\tau)-1}(\tau)\right| + \left|\widehat{s}_{n(\tau)}(\tau)\right| + \left|\sum_{k=n(\tau)+1}^{m} \widehat{s}_k(\tau)\right|,$$

and, as above, we can easily obtain

$$\left|\sum_{k=1}^{n(\tau)-2} \widehat{s}_k(\tau)\right| \leq \sum_{k=1}^{n(\tau)-2} \frac{2C_b^2}{\omega_{n(\tau)-1} - \omega_k} \leq 2C_b^2 \sigma_{n(\tau)-1}$$

and

$$\left|\sum_{k=n(\tau)+1}^{m} \widehat{s}_k(\tau)\right| \leq 2C_b^2 \sigma_{n(\tau)}.$$

Hence the following holds:

$$|\widehat{S}_m(\tau)| \leq 2C_b^2 \sigma_{n(\tau)-1} + 2TC_b^2 + 2C_b^2 \sigma_{n(\tau)}. \tag{2.37}$$

The inequalities (2.33), (2.36), and (2.37), combined with the boundedness of the sequence (1.24), imply (2.30). This completes the proof of (1.26). Hence the proof of Proposition 1.3 is complete. □

2.1.4. Proof of Proposition 1.4. We shall be concerned with the unbounded case where $b \notin H$. The other case can be proved by similar arguments. Let $\widetilde{A}$ denote the (nonlinear) operator in $V \times H$ defined by

$$\widetilde{A} = \begin{pmatrix} 0 & I \\ -A & -f(\langle b, .\rangle)b \end{pmatrix}, \tag{2.38}$$

$$D(\widetilde{A}) = \{\{y_0, y_1\} \in V \times H \ / \ y_1 \in V,\ Ay_0 + f(\langle b, y_1\rangle)b \in H\}. \tag{2.39}$$

It is sufficient to see that $\widetilde{A}$ is densely defined and maximal dissipative [6]. Since the functional b is not bounded on H, the space $\widetilde{V}$ defined by

$$\widetilde{V} = \{v \in V \ / \ \langle b, v\rangle = 0\} \tag{2.40}$$

is dense in H. Since $D(\widetilde{A}) \supset D(A) \times \widetilde{V}$, $D(\widetilde{A})$ is dense in $V \times H$. On the other hand, the condition Range $(I - \widetilde{A}) = V \times H$ can be reduced to

$$\text{Range } (I + A + f(\langle b, . \rangle\, b) = V'.$$

The latter follows from the coercivity of A and the assumptions on f. Furthermore, the monotonicity results from that of f. This completes the proof of Proposition 1.4. □

2.2. Stabilization.

2.2.1. Proof of Theorem 1.5. (iii) ⇒ (i). Recall that, for $\{y_0, y_1\} \in V \times H$, the strong ω-limit set of $\{y_0, y_1\}$, denoted by $\omega(\{y_0, y_1\})$, is the (possibly empty) set given by those $\{\varphi_0, \varphi_1\} \in V \times H$ such that there exists a sequence $t_n \to \infty$ as $n \to \infty$ for which the solution of (1.13) satisfies

$$\{y(t_n), y'(t_n)\} \to \{\varphi_0, \varphi_1\} \text{ (strongly) in } V \times H \text{ as } n \to \infty.$$

By the invariance principle of LaSalle and following the outline of [11], we can reduce the proof to the following lemmas.

LEMMA 2.2. *Consider the operator defined by* (2.38) *and* (2.39). *Then* $D(\widetilde{A})$ *is compactly embedded in* $V \times H$, *and* $(I - \widetilde{A})^{-1}$ *is compact from* $V \times H$ *into itself.*

Proof. As in the proof of Proposition 1.4, it is easy to see that $(I - \widetilde{A})^{-1}$ maps continuously $V \times H$ onto $D(\widetilde{A})$ and $H \times V'$ onto $V \times H$. Then we can conclude by noting that $V \times H$ is compactly embedded in $H \times V'$. □

LEMMA 2.3. *Suppose that* $\{y_0, y_1\} \in D(\widetilde{A})$. *Then* $\omega(\{y_0, y_1\})$ *is nonempty and satisfies* $\omega(\{y_0, y_1\}) \subset D(A) \times \widetilde{V}$.

Proof. From Lemma 2.2, $\omega(\{y_0, y_1\})$ is nonempty. On the other hand, it is standard that, for all $t \geq 0$, $\{y(t), y'(t)\} \in D(\widetilde{A})$ and (see, for instance, [6, p. 54])

$$\| \widetilde{A}\, \{y(t), y'(t)\} \|_{V \times H} \leq \| \widetilde{A}\, \{y_0, y_1\} \|_{V \times H} \tag{2.41}$$

so that, from the compactness of the embedding $D(\widetilde{A}) \subset V \times H$, it is easy to see that $\omega(\{y_0, y_1\}) \subset D(\widetilde{A})$. Furthermore, from (2.41), we get, for all $t \geq 0$,

$$\| y'(t) \|_V \leq \| \widetilde{A}\, \{y_0, y_1\} \|_{V \times H}. \tag{2.42}$$

Let us consider $\{\varphi_0, \varphi_1\} \in \omega(\{y_0, y_1\})$. Then there exists a sequence $t_n \to \infty$ as $n \to \infty$ such that, as $n \to \infty$,

$$y'(t_n) \to \varphi_1 \text{ in } H. \tag{2.43}$$

From (2.42), we deduce that there exists a subsequence, still denoted by $\{t_n\}_n$, such that, as $n \to \infty$,

$$y'(t_n) \to \varphi_1 \text{ weakly in } V \tag{2.44}$$

so that, as $n \to \infty$,

$$\langle b, y'(t_n) \rangle\, f(\langle b, y'(t_n) \rangle) \to \langle b, \varphi_1 \rangle\, f(\langle b, \varphi_1 \rangle). \tag{2.45}$$

On the other hand, we have, for all $t > 0$,

$$E(t) - E(0) + \int_0^t \langle b, y'(s) \rangle\, f(\langle b, y'(s) \rangle) ds = 0. \tag{2.46}$$

Therefore,

$$\lim_{n\to\infty}\int_{t_n}^{t+t_n}\langle b,y'(s)\rangle\, f(\langle b,y'(s)\rangle)ds=\lim_{n\to\infty}\int_0^t\langle b,y'(s+t_n)\rangle\, f(\langle b,y'(s+t_n)\rangle)ds=0.$$

Let us consider the solution of the equation

$$\begin{cases}\varphi''(t)+A\varphi(t)+f(\frac{d}{dt}\langle b,\varphi(t)\rangle)b=0,\\ \varphi(0)=\varphi_0,\ \varphi'(0)=\varphi_1.\end{cases}\tag{2.47}$$

Then the dominated convergence theorem gives

$$\int_0^t\langle b,\varphi'(s)\rangle\, f\left(\frac{d}{ds}\langle b,\varphi(s)\rangle\right)ds=0\quad\text{for all } t>0.$$

By continuity, this implies that

$$\langle b,\varphi'(t)\rangle\, f(\langle b,\varphi'(t)\rangle)=0\quad\text{for all } t\geq 0.$$

Hence, by assumption (1.27), we get

$$\langle b,\varphi'(t)\rangle=0\quad\text{for all } t\geq 0.\tag{2.48}$$

This completes the proof of the lemma. □

(i) ⇒ (ii). Suppose that condition (ii) is violated for some eigenvector $\widetilde{\psi}$ associated to the eigenvalue $\widetilde{\lambda}$. Then $y(t)=e^{i\sqrt{\widetilde{\lambda}}t}\widetilde{\psi}$ is a constant energy solution of (1.28).

(ii) ⇒ (iii). Suppose that, for $\{\varphi_0,\varphi_1\}\in D(A)\times V$, we have a solution φ satisfying (1.28). Then, for all $t\geq 0$,

$$\sum_n-\omega_n\langle\varphi_0,\psi_n\rangle\langle b,\psi_n\rangle\sin(\omega_n t)+\sum_n\langle\varphi_1,\psi_n\rangle\langle b,\psi_n\rangle\cos(\omega_n t)=0.\tag{2.49}$$

The proof can be reduced to the fact that (2.49) implies

$$\varphi_0=\varphi_1=0.\tag{2.50}$$

It is easy to see that the series in (2.49) is uniformly convergent in $(-\infty,\infty)$. From the uniqueness of the Fourier series expansion for almost periodic functions, we deduce that (2.49) implies, for all n,

$$\langle\varphi_0,\psi_n\rangle\langle b,\psi_n\rangle=\langle\varphi_1,\psi_n\rangle\langle b,\psi_n\rangle=0.\tag{2.51}$$

Thus condition (ii) gives (2.50).

The proof of Theorem 1.5 is complete. □

2.2.2. Proof of Theorem 1.6. For y solution of (1.13) and every $T>0$, the following equality can be deduced by a density argument

$$E(T)+\int_0^T\frac{d}{dt}\langle b,y(t)\rangle\, f\left(\frac{d}{dt}\langle b,y(t)\rangle\right)dt=E(0).\tag{2.52}$$

Let us consider the decomposition

$$y=\varphi+\psi,\tag{2.53}$$

where φ is the solution of

$$\begin{cases} \varphi''(t) + A\varphi(t) = 0, \\ \varphi(0) = y_0,\ \varphi'(0) = y_1, \end{cases} \tag{2.54}$$

and ψ is determined by the problem

$$\begin{cases} \psi'' + A\psi = -f(\frac{d}{dt}\langle b, y(t)\rangle)b, \\ \psi(0) = \psi'(0) = 0. \end{cases} \tag{2.55}$$

Then we have, for $T > \frac{2\pi}{\delta}$ [3],

$$\int_0^T \left| \frac{d}{dt}\langle b, \varphi(t)\rangle \right|^2 dt \geq CE(0) \tag{2.56}$$

so that

$$E(T) = -\int_0^T \frac{d}{dt}\langle b, y(t)\rangle\, f\left(\frac{d}{dt}\langle b, y(t)\rangle\right) dt + E(0)$$

$$\leq C\left\{\int_0^T \frac{d}{dt}\langle b, y(t)\rangle\, f\left(\frac{d}{dt}\langle b, y(t)\rangle\right) dt + \int_0^T \left|\frac{d}{dt}\langle b, \varphi(t)\rangle\right|^2 dt\right\}.$$

On the other hand, by applying (1.26) to system (2.55),

$$\int_0^T \left|\frac{d}{dt}\langle b, \varphi(t)\rangle\right|^2 dt \leq C\left\{\int_0^T \left|\frac{d}{dt}\langle b, \psi(t)\rangle\right|^2 dt + \int_0^T \left|\frac{d}{dt}\langle b, y(t)\rangle\right|^2 dt\right\}$$

$$\leq C\left\{\int_0^T \left|f(\frac{d}{dt}\langle b, y(t)\rangle)\right|^2 dt + \int_0^T \left|\frac{d}{dt}\langle b, y(t)\rangle\right|^2 dt\right\}.$$

Let us consider the decomposition $[0,T] = J_1 \cup J_2$ such that

$$J_1 = \left\{t \in [0,T]\ /\ \left|\frac{d}{dt}\langle b, y(t)\rangle\right| \geq 1\right\},\ J_2 = \left\{t \in [0,T]\ /\ \left|\frac{d}{dt}\langle b, y(t)\rangle\right| < 1\right\}.$$

Then, from (1.29), we get

$$\int_{J_1} \left|f\left(\frac{d}{dt}\langle b, y(t)\rangle\right)\right|^2 dt + \int_{J_1} \left|\frac{d}{dt}\langle b, y(t)\rangle\right|^2 dt \leq C\int_0^T f\left(\frac{d}{dt}\langle b, y(t)\rangle\right)\frac{d}{dt}\langle b, y(t)\rangle\, dt.$$

The hypothesis (1.30) implies

$$\int_{J_2} \left|f\left(\frac{d}{dt}\langle b, y(t)\rangle\right)\right|^2 dt + \int_{J_2} \left|\frac{d}{dt}\langle b, y(t)\rangle\right|^2 dt$$

$$\leq \int_{J_2} \left|f\left(\frac{d}{dt}\langle b, y(t)\rangle\right)\right|^2 dt + \int_{J_2} \left|\frac{d}{dt}\langle b, y(t)\rangle\right|^{2\rho} dt$$

$$\leq \int_0^T \xi\left(f\left(\frac{d}{dt}\langle b, y(t)\rangle\right)\frac{d}{dt}\langle b, y(t)\rangle\right) dt.$$

Applying Jensen's inequality, we obtain

$$\int_0^T \xi\left(f\left(\frac{d}{dt}\langle b,y(t)\rangle\right)\frac{d}{dt}\langle b,y(t)\rangle\right)dt \le T\xi\left(\frac{1}{T}\int_0^T f\left(\frac{d}{dt}\langle b,y(t)\rangle\right)\frac{d}{dt}\langle b,y(t)\rangle\,dt\right).$$

Therefore, for some positive constant C_0, which will be the one introduced in the theorem, we have

$$E(T) \le C_0\left\{\int_0^T f\left(\frac{d}{dt}\langle b,y(t)\rangle\right)\frac{d}{dt}\langle b,y(t)\rangle\,dt + \xi\left(\frac{1}{T}\int_0^T f\left(\frac{d}{dt}\langle b,y(t)\rangle\right)\frac{d}{dt}\langle b,y(t)\rangle\,dt\right)\right\}$$

so that

$$E(T) \le C_0 h(E(0)-E(T)), \tag{2.57}$$

where h is the function given by (1.32). Then the function p (inverse of $C_0 h$) is obviously increasing on $[0,+\infty)$, and (2.57) gives

$$E(T)+p(E(T)) \le E(0). \tag{2.58}$$

As the estimate above remains valid in successive intervals $[kT,(k+1)T]$, we have

$$E((k+1)T)+p(E((k+1)T)) \le E(kT), \quad k=0,1,2,\dots. \tag{2.59}$$

We now apply the result of Lemma 3.3 in [17].

LEMMA 2.4 (see [17]). *Let p denote a positive increasing function such that $p(0)=0$, and consider the function $q(s)=s-(I+p)^{-1}(s)$ and the sequence $\{s_k\}_k$ of positive numbers such that*

$$p(s_{k+1})+s_{k+1} \le s_k, \quad k \ge 0. \tag{2.60}$$

Then $s_k \le S(k)$, where $S(t)$ is the solution of

$$S'(t)+q(S(t))=0, \quad S(0)=s_0. \tag{2.61}$$

Moreover, if $p(s)>0$ for $s>0$, then $S(t)\to 0$ as $t\to\infty$.

Thus applying the lemma to the sequence $s_k=E(kT)$ yields

$$E(kT) \le S(k), \quad k=0,1,2,\dots. \tag{2.62}$$

For any $t>0$, we may write $t=kT+\tau$ for some integer k and $0\le\tau<T$ so that

$$E(t) \le E(kT) \le S(k) \le S\left(\frac{t-\tau}{T}\right) \le S\left(\frac{t}{T}-1\right) \quad \text{for } t>T.$$

This completes the proof of Theorem 1.6. □

2.2.3. Proof of Theorem 1.7. We first construct a function which fulfills the assumptions prescribed for ξ in Theorem 1.6. For $|r| < 1$, the assumptions (1.37) and (1.38) give

$$|r|^{2\beta} + |f(r)|^2 \leq \widetilde{c}_f^{-\frac{2\beta}{\alpha+1}} |rf(r)|^{\frac{2\beta}{\alpha+1}} + \widetilde{C}_f^2 |r|^{2\beta} \leq \widetilde{c}_f^{-\frac{2\beta}{\alpha+1}} (1 + \widetilde{C}_f^2) |rf(r)|^{\frac{2\beta}{\alpha+1}} . \tag{2.63}$$

Therefore, we can choose

$$\xi(s) = \widetilde{c}_f^{-\frac{2\beta}{\alpha+1}} (1 + \widetilde{C}_f^2) s^{\frac{2\beta}{\alpha+1}}, \tag{2.64}$$

and we may define the functions h (which gives p) and q given by (1.32) and (1.36), respectively. We conclude the proof by itemizing as follows.

(i) If $\alpha = \beta = 1$, then p and q have the forms

$$p(s) = c_p s, \ q(s) = \omega s$$

for some positive constants c_p, ω. Then, for some positive constant C, we easily get (1.39).

(ii) If $\alpha + 1 > 2\beta$, by setting $\gamma = \frac{\alpha+1}{2\beta}$ and noting that, for some positive constants C_1, C_2, we have

$$p\left(C_1 s + C_2 \left(\frac{s}{T} \right)^{\frac{1}{\gamma}} \right) = s, \tag{2.65}$$

we obtain

$$p(s) \sim C_p s^\gamma \ \ (s \to 0) \tag{2.66}$$

for some positive constant C_p. Furthermore, from $q(s + p(s)) = p(s)$, we get

$$q(s) \sim C_q s^\gamma \ \ (s \to 0) \tag{2.67}$$

for some positive constant C_q. Then the estimate (1.40) can be deduced from the following lemma, whose proof is given in the Appendix B.

LEMMA 2.5. *Let q denote a positive function such that*

$$q(s) \sim C_q s^\gamma \ \ (s \to 0), \quad \gamma > 1. \tag{2.68}$$

Then the solution of the differential equation (2.61) *satisfies*

$$S(t) = O(t^{\frac{1}{1-\gamma}}) \ \ (t \to \infty). \tag{2.69}$$

This completes the proof of Theorem 1.7. ∎

REMARK 2.1. *Under the assumption* (1.31), *it is easy to see that the solution of* (2.54) *satisfies* (2.56) *if and only if the first inequality in* (1.33) *holds. In other words, this condition is a characterization of the observability of the abstract sytem* (2.2) *with the output*

$$w(t) = \langle b, \varphi'(t) \rangle .$$

REMARK 2.2. *In the case $\alpha = \beta = 1$ and by adapting the results established in* [2], *we can see that the first inequality in* (1.33) *is necessary for the exponential decrease* (1.39) *to hold.*

2.2.4. Proof of Theorem 1.8. One of the ingredients of Theorem 1.8 is the following lemma, whose proof is given in Appendix C.

LEMMA 2.6. *Under the assumptions of Theorem* 1.8*, the solution of* (1.13) *satisfies*

$$\left\| \frac{d}{dt} \langle b, y(.) \rangle \right\|^2_{L^2(0,T)} \geq C(\|y_0\|^2_{V_{\frac{1}{2}-\mu}} + \|y_1\|^2_{D(A^\mu)'}) \tag{2.70}$$

for some positive constant C.

By using (2.52) and (2.70), it is easy to see that

$$E(T) \leq E(0) - C(\|y_0\|^2_{V_{\frac{1}{2}-\mu}} + \|y_1\|^2_{D(A^\mu)'}). \tag{2.71}$$

On the other hand, from the interpolation identities

$$V = D(A^{\frac{1}{2}}) = [D(A), V_{\frac{1}{2}-\mu}]_{\frac{1}{1+2\mu}}, \quad H = [D(A^{\frac{1}{2}}), D(A^\mu)']_{\frac{1}{1+2\mu}},$$

we get the following interpolation inequalities [19, p. 23]:

$$\|y_0\| \leq C \|y_0\|^{\frac{2\mu}{1+2\mu}}_{D(A)} \|y_0\|^{\frac{1}{1+2\mu}}_{V_{\frac{1}{2}-\mu}}, \tag{2.72}$$

$$|y_1| \leq C \|y_1\|^{\frac{2\mu}{1+2\mu}} \|y_1\|^{\frac{1}{1+2\mu}}_{D(A^\mu)'}. \tag{2.73}$$

Then we obtain

$$\|y_0\|^2_{V_{\frac{1}{2}-\mu}} \geq C \frac{\|y_0\|^{2(1+2\mu)}}{\|y_0\|^{4\mu}_{D(A)}}, \tag{2.74}$$

$$\|y_1\|^2_{D(A^\mu)'} \geq C \frac{|y_1|^{2(1+2\mu)}}{\|y_1\|^{4\mu}}. \tag{2.75}$$

Furthermore, it is easy to see that

$$\begin{aligned} \|y_0\|^2_{V_{\frac{1}{2}-\mu}} + \|y_1\|^2_{D(A^\mu)'} &\geq C \left\{ \frac{\|y_0\|^{2(1+2\mu)}}{\|y_0\|^{4\mu}_{D(A)}} + \frac{|y_1|^{2(1+2\mu)}}{\|y_1\|^{4\mu}} \right\} \\ &\geq C \frac{(E(0))^{1+2\mu}}{(\|y_0\|^2_{D(A)} + \|y_1\|^2)^{2\mu}}. \end{aligned}$$

Then the inequality (2.71), combined with the fact that $E(t)$ is nonincreasing, gives

$$E(T) \leq E(0) - C \frac{(E(T))^{1+2\mu}}{(\|y_0\|^2_{D(A)} + \|y_1\|^2)^{2\mu}}. \tag{2.76}$$

The estimate above remains valid in successive intervals $[kT, (k+1)T]$ so that

$$E((k+1)T) \leq E(kT) - C \frac{(E((k+1)T))^{1+2\mu}}{(\|y(kT)\|^2_{D(A)} + \|y'(kT)\|^2)^{2\mu}}, \quad k = 1, 2, \ldots . \tag{2.77}$$

As $\{y(t), y'(t)\}$ defines a (nonlinear) semigroup of contraction in $D(A)\times V$, the relation above gives [6, p. 54]

$$E((k+1)T) \le E(kT) - C\frac{(E((k+1)T))^{1+2\mu}}{(\|y_0\|^2_{D(A)} + \|y_1\|^2)^{2\mu}}, \quad k = 1, 2, \dots . \tag{2.78}$$

Let us consider the function $F(s) = \frac{s}{\|y_0\|^2_{D(A)}+\|y_1\|^2}$. Then relation (2.78) would read $F(E(k+1)T)) \le F(E(kT)) - C(F(E(k+1)T)))^{1+2\mu}$. By using Lemmas 2.4 and 2.5, we can easily deduce (1.42). This completes the proof of Theorem 1.8. □

3. Applications.

3.1. Beam equation with internal pointwise actuator. Consider the system (1.1)–(1.3). By the approach introduced in [14], one can obtain for this system the following state-space equation (see [20] for details):

$$y'' + \frac{\partial^4 y}{\partial x^4} = u(t)\delta(x-a), \quad t > 0,\ 0 < x < 1, \tag{3.1}$$

$$y(t,0) = \frac{\partial^2 y}{\partial x^2}(t,0) = \frac{\partial y}{\partial x}(t,1) = \frac{\partial^3 y}{\partial x^3}(t,1) = 0. \tag{3.2}$$

This formulation has the form (1.8) if we set

$$H = L^2(0,1),\ V = \left\{ v \in H^2(0,1) \ / \ v(0) = \frac{dv}{dx}(1) = 0 \right\}, \tag{3.3}$$

$$A = \frac{d^4}{dx^4},\ D(A) = \left\{ v \in H^4(0,1) \cap V \ / \ \frac{d^2v}{dx^2}(0) = \frac{d^3v}{dx^3}(1) = 0 \right\}, \tag{3.4}$$

$$b = \delta(x-a). \tag{3.5}$$

The eigenvalues $\left\{\lambda_n = \omega_n^2\right\}_n$ and the corresponding eigenfunctions $\{\psi_n\}_n$ are given by

$$\lambda_n = \left(-\frac{\pi}{2} + n\pi\right)^4, \quad n = 1, 2, \dots, \tag{3.6}$$

$$\psi_n(x) = \sin\left(-\frac{\pi}{2} + n\pi\right)x, \quad n = 1, 2, \dots . \tag{3.7}$$

On the other hand, the analogue of the feedback (1.11) is given by

$$u(t) = -f\left(\frac{d}{dt}y(t,a)\right). \tag{3.8}$$

Theorem 1.7 can be adapted to obtain the following stabilization result.

THEOREM 3.1. *Let f be a monotone function satisfying the assumptions of Theorem* 1.7. *Suppose that a is a rational number with coprime factorization*

$$a = \frac{a_1}{a_2} \tag{3.9}$$

such that a_1 is odd. Then, for any initial conditions $\{y_0, y_1\} \in V \times L^2(0,1)$, the solution of the feedback system defined by (3.1), (3.2), *and* (3.8) *satisfies, for some positive constants ω, K, T,*

$$\left\| \frac{\partial^2 y(t,.)}{\partial x^2} \right\|^2_{L^2(0,1)} + \|y'(t,.)\|^2_{L^2(0,1)} \leq K \left\{ \left\| \frac{d^2 y_0}{dx^2} \right\|^2_{L^2(0,1)} + \|y_1\|^2_{L^2(0,1)} \right\} e^{-\omega t} \quad \text{for all } t > T \tag{3.10}$$

if $\alpha = \beta = 1$ and

$$\left\| \frac{\partial^2 y(t,.)}{\partial x^2} \right\|^2_{L^2(0,1)} + \|y'(t,.)\|^2_{L^2(0,1)} = O(t^{-\frac{2\beta}{\alpha+1-2\beta}}) \ (t \to \infty) \tag{3.11}$$

if $\alpha + 1 > 2\beta$.

Proof. We have only to see that, for some positive constant c,

$$\left| \sin\left(-\frac{\pi}{2} + n\pi\right) a \right| \geq c > 0 \quad \text{for all } n. \tag{3.12}$$

This result has been established in [20]. □

3.2. Beam equation with internal piezoelectric actuator. Consider the system defined by (1.4) and (1.5). This system has the form (1.8) if we set

$$H = L^2(0,1),\ V = H^2(0,1) \cap H_0^1(0,1), \tag{3.13}$$

$$A = \frac{d^4}{dx^4},\ D(A) = \left\{ v \in H^4(0,1) \ / \ v(0) = \frac{d^2 v}{dx^2}(0) = v(1) = \frac{d^2 v}{dx^2}(1) = 0 \right\}, \tag{3.14}$$

$$b = \frac{d}{dx}(\delta(x - a_1) - \delta(x - a_2)). \tag{3.15}$$

The eigenvalues $\{\lambda_n = \omega_n^2\}_n$ and the corresponding eigenfunctions $\{\psi_n\}_n$ are given by

$$\lambda_n = (n\pi)^4, \quad n = 1, 2, \ldots, \tag{3.16}$$

$$\psi_n(x) = \sqrt{2} \sin n\pi x, \quad n = 1, 2, \ldots . \tag{3.17}$$

It is easy to see that $b \in D(A^{\frac{1}{2}})'$ and

$$\left| \left\langle \frac{d}{dx}(\delta(x - a_1) - \delta(x - a_2)), \psi_n \right\rangle \right| = \sqrt{2} n\pi \, |\cos n\pi a_1 - \cos n\pi a_2|$$

$$= 2\sqrt{2} n\pi \left| \sin\left(n\pi \frac{a_1 + a_2}{2} \right) \sin\left(n\pi \frac{a_1 - a_2}{2} \right) \right| \leq C \lambda_n^{\frac{1}{4}}.$$

From Corollary 1.2, we deduce that, for $\{y_0, y_1\} \in H_0^1(0,1) \times H^{-1}(0,1)$, the solution of (1.4) satisfies

$$y \in C(0, T; D(A^{\frac{1}{4}}) = H_0^1(0,1)) \cap C^1(0, T; D(A^{\frac{1}{4}})' = H^{-1}(0,1)).$$

Furthermore, an easy application of Theorem 1.5 gives the following result.

THEOREM 3.2. *Let f be a monotone continuous function satisfying* (1.27)*, and consider the feedback*

$$u(t) = -f\left[\frac{d}{dt}\left(\frac{\partial y(t,a_1)}{\partial x} - \frac{\partial y(t,a_2)}{\partial x}\right)\right]. \tag{3.18}$$

Then, for any $\{y_0, y_1\} \in D(A^{\frac{1}{2}}) \times L^2(0,1)$, the solution of the feedback system defined by (1.4)*,* (1.5)*, and* (3.18) *satisfies*

$$y \in C(0,T; D(A^{\frac{1}{2}}) = H^2(0,1) \cap H_0^1(0,1)) \cap C^1(0,T; L^2(0,1)). \tag{3.19}$$

Moreover, $\lim_{t\to\infty} \|\frac{\partial^2 y(t,.)}{\partial x^2}\|^2_{L^2(0,1)} + \|y'(t,.)\|^2_{L^2(0,1)} = 0$ *if and only if*

$$\frac{a_1 + a_2}{2}, \frac{a_1 - a_2}{2} \in IR \backslash IQ. \tag{3.20}$$

In order to get decay estimates related to the position of the actuators, we shall introduce some results from the theory of Diophantine approximations. Such results have been used to derive observability results for parabolic systems in [22], exact controllability properties for system (1.4) in [27], and decay estimate for strings and beams in [15] and [1], respectively.

For a real number θ, we denote by $|||\theta|||$ the difference, taken positively, between θ and the nearest integer, i.e.,

$$|||\theta||| = \min_{n\in Z} |\theta - z|. \tag{3.21}$$

An irrational number $\theta \in (0,1)$ is said to be of constant type if the sequence$\{\theta_n\}_n$, defined by the expansion of θ as a continuous fraction, is bounded. From [16], we quote the following result.

PROPOSITION 3.3. *An irrational number $\theta \in (0,1)$ is of constant type if and only if there exists a positive constant C such that*

$$|||n\theta||| \geq \frac{C}{n}, \quad n = 1, 2, \dots . \tag{3.22}$$

Furthermore, we shall use the following [7].

PROPOSITION 3.4. *For any $\epsilon > 0$, there exists a set $B_\epsilon \subset (0,1)$ having the Lebesgue measure equal to* 1 *and a positive constant C such that, for any $\theta \in B_\epsilon$,*

$$|||n\theta||| \geq \frac{C}{n^{1+\epsilon}}, \quad n = 1, 2, \dots . \tag{3.23}$$

REMARK 3.1. *The property* (3.22) *is satisfied if θ is irrational and is a root of a second degree polynomial with rational coefficients. The property* (3.23) *holds true if θ is an algebraic irrational* [7, p. 104].

Then we have the following stabilization result.

THEOREM 3.5. *Let f satisfy the assumptions of Theorem* 1.8*, and consider the feedback given by*

$$u(t) = -f\left[\frac{d}{dt}\left(\frac{\partial(A^{-1}y)}{\partial x}(t,a_1) - \frac{\partial(A^{-1}y)}{\partial x}(t,a_2)\right)\right]. \tag{3.24}$$

Then, for any $\{y_0, y_1\} \in L^2(0,1) \times D(A^{\frac{1}{2}})'$, *the feedback system defined by* (1.4) *and* (3.24) *admits a unique solution such that*

$$y \in C(0,T; L^2(0,1)) \cap C^1(0,T; D(A^{\frac{1}{2}})'). \tag{3.25}$$

Moreover, for any $\{y_0, y_1\} \in D(A^{\frac{1}{2}}) \times L^2(0,1)$, *we have*

$$\|y(t,.)\|^2_{L^2(0,1)} + \|y'(t,.)\|^2_{D(A^{\frac{1}{2}})'} = d(t)\{\|y(t,.)\|^2_{D(A^{\frac{1}{2}})} + \|y'(t,.)\|^2_{L^2(0,1)}\}, \tag{3.26}$$

where

$$d(t) = O(t^{-\frac{2}{3}}) \ \ (t \to \infty) \tag{3.27}$$

if $\frac{a_1+a_2}{2}$, $\frac{a_1-a_2}{2}$ *are of constant type and*

$$d(t) = O(t^{-\frac{2}{3+2\epsilon}}) \ \ (t \to \infty) \tag{3.28}$$

if $\frac{a_1+a_2}{2}, \frac{a_1-a_2}{2} \in B_\epsilon$.

Proof. Suppose that $\{y_0, y_1\} \in L^2(0,1) \times D(A^{\frac{1}{2}})'$, and consider

$$\widetilde{b} = A^{-\frac{1}{2}} \frac{d}{dx}(\delta(x-a_1) - \delta(x-a_2)) \in L^2(0,1) \tag{3.29}$$

and the change of variables

$$\begin{cases} \widetilde{y}(t) = A^{-\frac{1}{2}} y(t), \\ \widetilde{y}_0 = A^{-\frac{1}{2}} y_0, \\ \widetilde{y}_1 = A^{-\frac{1}{2}} y_1. \end{cases} \tag{3.30}$$

Then we have $\{\widetilde{y}_0, \widetilde{y}_1\} \in D(A^{\frac{1}{2}}) \times L^2(0,1)$, and, by using Proposition 1.4, the feedback system

$$\begin{cases} \widetilde{y}''(t) + A\widetilde{y}(t) + f(\frac{d}{dt}\langle \widetilde{b}, \widetilde{y}(t)\rangle)\widetilde{b} = 0, \\ \widetilde{y}(0) = \widetilde{y}_0, \ \widetilde{y}'(0) = \widetilde{y}_1, \end{cases} \tag{3.31}$$

admits a unique solution satisfying the analogous regularity to the one given by (1.20). This implies that the feedback system defined by (1.4) and (3.24) admits a unique solution satisfying (3.25). Moreover, we have

$$|\langle \widetilde{b}, \psi_n\rangle| = \frac{2\sqrt{2}}{n\pi} \left| \sin\left(n\pi \frac{a_1+a_2}{2}\right) \sin\left(n\pi \frac{a_1-a_2}{2}\right) \right| \leq \frac{2\sqrt{2}}{\pi} \quad \text{for all } n \tag{3.32}$$

and, if $\frac{a_1+a_2}{2}$ and $\frac{a_1-a_2}{2}$ are of constant type,

$$|\langle \widetilde{b}, \psi_n\rangle| \geq C\lambda_n^{-\frac{3}{4}} \quad \text{for all } n. \tag{3.33}$$

Hence, under the assumption $\{y_0, y_1\} \in D(A^{\frac{1}{2}}) \times L^2(0,1)$, we have $\{\widetilde{y}_0, \widetilde{y}_1\} \in D(A) \times D(A^{\frac{1}{2}})$ so that, by using Theorem 1.8, the solution of (3.31) satisfies

$$\begin{cases} \|\widetilde{y}(t)\|^2_{D(A^{\frac{1}{2}})} + \|\widetilde{y}'(t)\|^2_{L^2(0,1)} = d(t)\{\|\widetilde{y}_0\|^2_{D(A)} + \|\widetilde{y}_1\|^2_{D(A^{\frac{1}{2}})}\}, \\ d(t) = O(t^{-\frac{2}{3}}) \ \ (t \to \infty). \end{cases} \tag{3.34}$$

This gives (3.26) and (3.27). The remaining part of the proof can be obtained by similar arguments. This ends the proof of Theorem 3.5. ∎

3.3. Beam equation with concentrated actuator. Consider the system defined by (1.6) with the boundary conditions (1.5). This system has the form (1.8) by setting (3.13), (3.14), and $b = g \in L^2(0,1)$. The appropriate eigenvalues and the corresponding eigenfunctions are given by (3.16) and (3.17). Furthermore, it is standard that, for any $\{y_0, y_1\} \in D(A^{\frac{1}{2}}) \times L^2(0,1)$, there exists a unique solution to (1.5)–(1.6) satisfying (3.19). On the other hand, applying Theorem 1.6, we can obtain the following theorem.

THEOREM 3.6. *Let f be a monotone continuous function satisfying* (1.27)*, and consider the feedback*

$$u(t) = -f\left(\int_0^1 g(x)y'(t,x)dx\right). \tag{3.35}$$

Then, for any $\{y_0, y_1\} \in D(A^{\frac{1}{2}}) \times L^2(0,1)$, the solution of the feedback system defined by (1.5), (1.6)*, and* (3.35) *satisfies* (3.19)*. Moreover,* $\lim_{t\to\infty} \|\frac{\partial^2 y(t,.)}{\partial x^2}\|^2_{L^2(0,1)} + \|y'(t,.)\|^2_{L^2(0,1)} = 0$ *if and only if*

$$\int_0^1 g\psi_n dx \neq 0 \quad \textit{for all } n. \tag{3.36}$$

Before stating a stabilization result which improves the theorem above, let us mention the following regularity result.

PROPOSITION 3.7. *Suppose that, for some positive constant C_g,*

$$|\langle g, \psi_n\rangle| = \left|\int_0^1 g\psi_n dx\right| \leq \frac{C_g}{n^2} \quad \textit{for all } n. \tag{3.37}$$

Then, for any $\{y_0, y_1\} \in D(A) \times D(A^{\frac{1}{2}})$, the system (1.5)–(1.6) *admits a unique solution such that*

$$y \in C(0,T;D(A)) \cap C^1(0,T;D(A^{\frac{1}{2}})). \tag{3.38}$$

Proof. If we set

$$\widetilde{b} = A^{\frac{1}{2}} g \tag{3.39}$$

and consider the change of variables

$$\begin{cases} \widetilde{y}(t) = A^{\frac{1}{2}} y(t), \\ \widetilde{y}_0 = A^{\frac{1}{2}} y_0, \\ \widetilde{y}_1 = A^{\frac{1}{2}} y_1, \end{cases} \tag{3.40}$$

then $\widetilde{b} \in D(A^{\frac{1}{2}})'$, and, for some positive constant $\widetilde{C}_g$,

$$|\langle \widetilde{b}, \psi_n\rangle| \leq \widetilde{C}_g \quad \text{for all } n \tag{3.41}$$

so that, by Proposition 1.1, we have

$$\widetilde{y} \in C(0,T;D(A^{\frac{1}{2}})) \cap C^1(0,T;L^2(0,1)). \tag{3.42}$$

This yields (3.38). ∎

Then we have the following strong stabilization result.

THEOREM 3.8. *Let f be a monotone continuous function satisfying* (1.27)*, and consider the feedback*

$$u(t) = -f\left[\frac{d}{dt}\left(\int_0^1 g(x)\frac{\partial^4 y(t,x)}{\partial x^4}dx\right)\right]. \tag{3.43}$$

Then, for any $\{y_0, y_1\} \in D(A)\times D(A^{\frac{1}{2}})$, the feedback system defined by (1.5)–(1.6) *and* (3.43) *admits a unique solution satisfying* (3.38)*. Moreover,* $\lim_{t\to\infty} \|\frac{\partial^4 y(t,.)}{\partial x^4}\|^2_{L^2(0,1)} + \|\frac{\partial^2 y'(t,.)}{\partial x^2}\|^2_{L^2(0,1)} = 0$ *if and only if* (3.36) *holds.*

Proof. Let us consider the change of variables defined by (3.40). Then the solution of the feedback system

$$\begin{cases} \widetilde{y}''(t) + A\widetilde{y}(t) + f(\frac{d}{dt}\langle\widetilde{b}, \widetilde{y}(t)\rangle)\widetilde{b} = 0, \\ \widetilde{y}(0) = \widetilde{y}_0,\ \widetilde{y}'(0) = \widetilde{y}_1, \end{cases} \tag{3.44}$$

satisfies (3.42). Moreover, $\lim_{t\to\infty} \|\widetilde{y}(t)\|^2_{D(A^{\frac{1}{2}})} + \|\widetilde{y}'(t)\|^2_{L^2(0,1)} = 0$ if and only if

$$\langle\widetilde{b}, \psi_n\rangle = \omega_n \int_0^1 g\psi_n dx \neq 0 \quad \text{for all } n. \tag{3.45}$$

This amounts to saying that there exists a unique solution to the feedback system defined by (1.5), (1.6), and (3.43) and that this solution satisfies the stability of the theorem if and only if (3.36) holds. □

From Theorem 1.8, we can easily deduce the following nonuniform stabilization result.

THEOREM 3.9. *Let f satisfy the assumptions of Theorem* 1.8*. Suppose that, for some positive constant c_g and some $\frac{1}{2} < \mu \leq 4$, we have*

$$\left|\int_0^1 g\psi_n dx\right| \geq \frac{c_g}{n^\mu} \quad \textit{for all } n. \tag{3.46}$$

Then, for any $\{y_0, y_1\} \in D(A) \times D(A^{\frac{1}{2}})$, the solution of the feedback system defined by (1.5)*,* (1.6)*, and* (3.35) *satisfies*

(3.47)

$$\begin{cases} \left\|\frac{\partial^2 y(t,.)}{\partial x^2}\right\|^2_{L^2(0,1)} + \|y'(t,.)\|^2_{L^2(0,1)} = d(t)\left\{\left\|\frac{d^4 y_0}{dx^4}\right\|^2_{L^2(0,1)} + \left\|\frac{d^2 y_1}{dx^2}\right\|^2_{L^2(0,1)}\right\}, \\ d(t) = O(t^{-\frac{2}{\mu}}) \ \ (t \to \infty). \end{cases}$$

Furthermore, Theorem 1.7 enables us to get uniform stabilization with explicit decay estimate for the feedback system defined by (1.5), (1.6), and (3.43).

THEOREM 3.10. *Let f satisfy the assumptions of Theorem* 1.7*. Suppose that, for some positive constants c_g, C_g,*

$$0 < \frac{c_g}{n^2} \leq \left|\int_0^1 g\psi_n dx\right| \leq \frac{C_g}{n^2} \quad \textit{for all } n. \tag{3.48}$$

Then, for some positive constants ω, K, T *and any* $\{y_0, y_1\} \in D(A) \times D(A^{\frac{1}{2}})$, *the solution of the feedback system defined by* (1.5), (1.6), *and* (3.43) *satisfies*

(3.49)

$$\left\| \frac{\partial^4 y(t,.)}{\partial x^4} \right\|^2_{L^2(0,1)} + \left\| \frac{\partial^2 y'(t,.)}{\partial x^2} \right\|^2_{L^2(0,1)} \leq K \left\{ \left\| \frac{d^4 y_0}{dx^4} \right\|^2_{L^2(0,1)} + \left\| \frac{d^2 y_1}{dx^2} \right\|^2_{L^2(0,1)} \right\} e^{-\omega t}$$
$$\text{for all } t > T$$

if $\alpha = \beta = 1$ *and*

$$\left\| \frac{\partial^4 y(t,.)}{\partial x^4} \right\|^2_{L^2(0,1)} + \left\| \frac{\partial^2 y'(t,.)}{\partial x^2} \right\|^2_{L^2(0,1)} = O(t^{-\frac{2\beta}{\alpha+1-2\beta}}) \ (t \to \infty) \tag{3.50}$$

if $\alpha + 1 > 2\beta$.

4. Further extensions and related questions. As mentioned in the introduction, our results deduced from the study of the abstract model may be applied to various hyperbolic-like systems. To illustrate this, we shall consider the plate and the membrane equations with point controls. In what follows, Ω will denote an open bounded domain in IR^2 with sufficiently smooth boundary Γ. For each operator A defined in the examples below, we shall use the same notation relative to the eigenvalues and the corresponding eigenfunctions introduced in subsection 1.3. Every eigenvalue will be supposed simple. Here a is a given point in Ω.

4.1. Plate equation with internal point control. Consider the system

$$\begin{cases} y'' + \Delta^2 y = u(t)\delta(x-a) \ \text{ in } (0,\infty) \times \Omega, \\ y = \Delta y = 0 \ \text{ on } (0,\infty) \times \Gamma, \\ y(0,x) = y_0(x), \ y'(0,x) = y_1(x) \ \text{ in } \Omega. \end{cases} \tag{4.1}$$

This system has the form (1.8) if we set

$$A = \Delta^2, \ D(A) = \left\{ v \in H^4(\Omega) \ / \ y = \Delta y = 0 \text{ on } \Gamma \right\}, \tag{4.2}$$

$$H = L^2(\Omega), \ V = D(A^{\frac{1}{2}}) = H^2(\Omega) \cap H_0^1(\Omega), \tag{4.3}$$

$$b = \delta(x-a) \in V'. \tag{4.4}$$

Then, for f satisfying the assumptions of Theorem 1.5 and any $\{y_0, y_1\} \in H^2(\Omega) \cap H_0^1(\Omega) \times L^2(\Omega)$, the solution of the feedback system defined by (4.1) and

$$u(t) = -f\left(\frac{d}{dt} y(t,a) \right) \tag{4.5}$$

satisfies $\lim_{t\to\infty} \|\Delta y(t,.)\|^2_{L^2(\Omega)} + \|y'(t,.)\|^2_{L^2(\Omega)} = 0$ if and only if

$$\psi_n(a) \neq 0 \quad \text{for all } n. \tag{4.6}$$

4.2. Wave equation with internal point control. Consider the system

$$\begin{cases} y'' - \Delta y = u(t)\delta(x-a) \ \text{ in } (0,\infty)\times\Omega, \\ y = 0 \ \text{ on } (0,\infty)\times\Gamma, \\ y(0,x) = y_0(x),\ y'(0,x) = y_1(x) \ \text{ in } \Omega. \end{cases} \tag{4.7}$$

If we consider the setting defined by

$$A = -\Delta,\ D(A) = H^2(\Omega)\cap H_0^1(\Omega), \tag{4.8}$$

$$H = L^2(\Omega),\ V = D(A^{\frac{1}{2}}) = H_0^1(\Omega), \tag{4.9}$$

then we have $\delta(x-a)\notin D(A^{\frac{1}{2}})'$. Furthermore, we cannot readily apply the results of subsection 1.3 since, from [18], [24], and [25], we have the following sharp regularity result:

$$y\in C(0,T;D(A^{\frac{1}{4}}))\cap C^1(0,T;D(A^{\frac{1}{4}})').$$

However, exploiting the fact that, for $\epsilon>0$ arbitrarily small, $A^{-\epsilon}\delta(x-a)\in D(A^{\frac{1}{2}})'$, we can consider the change of variables

$$\begin{cases} \widetilde{y}(t) = A^{-\epsilon}y(t), \\ \widetilde{y}_0 = A^{-\epsilon}y_0, \\ \widetilde{y}_1 = A^{-\epsilon}y_1 \end{cases} \tag{4.10}$$

and the auxiliary feedback system

$$\begin{cases} \widetilde{y}''(t) + A\widetilde{y}(t) + f(\frac{d}{dt}\langle\widetilde{b},\widetilde{y}(t)\rangle)\widetilde{b} = 0, \\ \widetilde{y}(0) = \widetilde{y}_0,\ \widetilde{y}'(0) = \widetilde{y}_1, \end{cases} \tag{4.11}$$

where $\widetilde{b} = A^{-\epsilon}\delta(x-a)$. Then Theorem 1.5 may be applied to obtain that, for any $\{y_0,y_1\}\in D(A^{\frac{1}{2}-\epsilon})\times D(A^{\epsilon})'$ and for f satisfying the assumptions of Theorem 1.5, the feedback system defined by (4.7) and

$$u(t) = -f\left(\frac{d}{dt}\left\langle A^{-\epsilon}\delta(x-a), A^{-\epsilon}y(t)\right\rangle\right) \tag{4.12}$$

admits a unique solution $y\in C(0,T;D(A^{\frac{1}{2}-\epsilon}))\cap C^1(0,T;D(A^{\epsilon})')$. Moreover, $\lim_{t\to\infty}\|y(t)\|^2_{D(A^{\frac{1}{2}-\epsilon})} + \|y'(t)\|^2_{D(A^{\epsilon})'} = 0$ if and only if the analogous condition to (4.6) holds.

Appendix A.

LEMMA A.1. *For $v\in L^2(0,T)$, consider*

$$v_k = \int_0^T v(t)e^{-i\omega_k t}dt, \quad 1\le k\le m. \tag{A.1}$$

Then, for any $v\in L^2(0,T)$, we have

$$\sum_{k=1}^{m}|v_k|^2 \le C\|v\|^2_{L^2(0,T)} \tag{A.2}$$

for some positive constant C independent of m.

Proof. For $w = (w_1, \dots, w_m) \in IR^m$, we introduce

$$W_m(t) = \sum_{k=1}^{m} w_k e^{i\omega_k t}. \tag{A.3}$$

Then the following holds:

$$\left| \int_0^T v(t)\overline{W_m(t)}dt \right| = \left| \sum_{k=1}^{m} v_k w_k \right| \le \|v\|_{L^2(0,T)} \|W_m\|_{L^2(0,T)}.$$

On the other hand, for some positive constant C independent of m, we have [3]

$$\|W_m\|^2_{L^2(0,T)} \le C \sum_{k=1}^{m} |w_k|^2.$$

This yields (A.2). ∎

Appendix B. Proof of Lemma 2.5. Let us consider the function

$$g(s) = \int_s^\zeta \frac{d\tau}{q(\tau)}, \quad 0 < s < \zeta. \tag{B.1}$$

Then g is a decreasing function and $g(\zeta) = 0$, $g(0+) = +\infty$. Thus $[0, +\infty)$ is in the range of g, and the solution of (2.61) is given by

$$X(t) = g^{-1}(t), \quad t \ge 0. \tag{B.2}$$

Since $g(0+) = +\infty$,

$$\lim_{t\to\infty} X(t) = \lim_{t\to\infty} g^{-1}(t) = 0.$$

Let $0 < \epsilon < 1$. There exists $\delta(\epsilon) > 0$ such that, if $0 < s < \delta(\epsilon)$,

$$|q(s) - C_q s^\gamma| < \epsilon C_q s^\gamma. \tag{B.3}$$

Moreover, there exists $t_0(\epsilon) > 0$ such that $0 < X(t) < \delta(\epsilon)$ for $t \ge t_0(\epsilon)$. Therefore, if $t \ge t_0(\epsilon)$, we have

$$-q(X(t)) \le C_q(\epsilon - 1)(X(t))^\gamma. \tag{B.4}$$

Hence

$$X'(t) + C_q(1 - \epsilon)(X(t))^\gamma \le 0, \quad t \ge t_0(\epsilon). \tag{B.5}$$

This yields (2.69) and completes the proof of the lemma. ∎

Appendix C. Proof of Lemma 2.6. Let us consider the decomposition defined by (2.53), (2.54), and (2.55). Then the assumptions (1.31) and (1.41) give, for some positive constant C [3],

$$\int_0^T \left| \frac{d}{dt} \langle b, \varphi(t) \rangle \right|^2 dt \ge C(\|\varphi_0\|^2_{V_\mu} + \|\varphi_1\|^2_{D(A^\mu)'}). \tag{C.1}$$

On the other hand, Proposition 1.3 implies

$$\int_0^T \left| \frac{d}{dt}(\langle b, \varphi(t)\rangle - \langle b, y(t)\rangle)\right|^2 dt \leq C \int_0^T \left| \frac{d}{dt} \langle b, y(t)\rangle \right|^2 dt \tag{C.2}$$

so that, for some positive constant C,

$$\left\| \frac{d}{dt} \langle b, \varphi(.)\rangle \right\|_{L^2(0,T)} \leq C \left\| \frac{d}{dt} \langle b, y(.)\rangle \right\|_{L^2(0,T)}. \tag{C.3}$$

This yields (2.70). □

AN INVERSE INITIAL BOUNDARY VALUE PROBLEM FOR THE WAVE EQUATION IN THE PRESENCE OF IMPERFECTIONS OF SMALL VOLUME*

HABIB AMMARI†

Dedicated to Jean-Claude Nédélec for his 60th birthday

Abstract. We consider for the wave equation the inverse problem of identifying locations and certain properties of the shapes of small conductivity inhomogeneities in a homogeneous background medium from dynamic boundary measurements on part of the boundary and for a finite interval in time. Using as weights particular background solutions constructed by a geometrical control method, we develop an asymptotic method based on appropriate averaging of the partial dynamic boundary measurements. Our approach is expected to lead to very effective computational identification algorithms.

Key words. inverse problem, wave equation, reconstruction, geometric control

1. The inverse initial boundary value problem. Let Ω be a bounded, smooth subdomain of $\mathbf{R}^2$. For simplicity, we take $\partial\Omega$ to be $\mathcal{C}^\infty$, but this condition could be considerably weakened. Let n denote the outward unit normal to $\partial\Omega$. We suppose that Ω contains a finite number of inhomogeneities, each of the form $z_j + \alpha B_j$, where $B_j \subset \mathbf{R}^2$ is a bounded, smooth domain containing the origin. The total collection of inhomogeneities thus takes the form $\mathcal{B}_\alpha = \cup_{j=1}^m (z_j + \alpha B_j)$. The points $z_j \in \Omega, j = 1, \ldots, m$ that determine the location of the inhomogeneities are assumed to satisfy

$$|z_j - z_l| \geq d_0 > 0 \quad \forall\, j \neq l \quad \text{and} \quad \operatorname{dist}(z_j, \partial\Omega) \geq d_0 > 0 \quad \forall\, j.$$

As a consequence of this assumption, it follows immediately that $m \leq \frac{4|\Omega|}{\pi d_0^2}$. We also assume that $\alpha > 0$, the common order of magnitude of the diameters of the inhomogeneities, is sufficiently small so that these are disjoint and their distance to $\mathbf{R}^2 \setminus \overline{\Omega}$ is larger than $d_0/2$. Let γ_0 denote the conductivity of the background medium; for simplicity, we shall assume in this paper that it is constant. Let γ_j denote the constant conductivity of the jth inhomogeneity, $z_j + \alpha B_j$. Using this notation, we introduce the piecewise constant conductivity

$$\gamma_\alpha(x) = \begin{cases} \gamma_0, & x \in \Omega \setminus \overline{\mathcal{B}_\alpha}, \\ \gamma_j, & x \in z_j + \alpha B_j,\ j = 1, \ldots, m. \end{cases}$$

Consider the initial boundary value problem for the (scalar) wave equation

$$\text{(1)}\qquad \begin{cases} (\partial_t^2 - \text{ div } \gamma_\alpha \,\text{grad})u_\alpha = 0 \quad \text{in } \Omega \times (0,T), \\ u_\alpha|_{t=0} = \varphi, \partial_t u_\alpha|_{t=0} = \psi \quad \text{in } \Omega, \\ u_\alpha|_{\partial\Omega\times(0,T)} = f. \end{cases}$$

Define u to be the solution of the wave equation in the absence of any inhomogeneities. Thus u satisfies

$$\text{(2)}\qquad \begin{cases} (\partial_t^2 - \gamma_0\Delta)u = 0 \quad \text{in } \Omega \times (0,T), \\ u|_{t=0} = \varphi, \partial_t u|_{t=0} = \psi \quad \text{in } \Omega, \\ u|_{\partial\Omega\times(0,T)} = f. \end{cases}$$

Here $T > 0$ is a final observation time, and the initial conditions $\varphi, \psi \in \mathcal{C}^\infty(\overline{\Omega})$ and the boundary condition $f \in \mathcal{C}^\infty(0,T;\mathcal{C}^\infty(\partial\Omega))$ are subject to the compatibility conditions

$$\partial_t^{2l} f|_{t=0} = (\gamma_0)^l(\Delta^l\varphi)|_{\partial\Omega} \text{ and } \partial_t^{2l+1} f|_{t=0} = (\gamma_0)^l(\Delta^l\psi)|_{\partial\Omega}, \quad l = 1, 2, \ldots.$$

From the above compatibility conditions on φ, ψ and f, it follows that the initial boundary value problem (2) has a unique solution in $\mathcal{C}^\infty([0,T]\times\overline{\Omega})$; see [14]. It is also classical to prove that the transmission problem for the wave equation (1) has a unique weak solution $u_\alpha \in \mathcal{C}^0(0,T;H^1(\Omega)) \cap \mathcal{C}^1(0,T;L^2(\Omega))$; see, for example, [19]. Indeed, Lions proved in [19, Chapter VI, Theorem 4.1, p. 369] that $\frac{\partial u_\alpha}{\partial n}|_{\partial\Omega}$ belongs to $L^2(0,T;L^2(\partial\Omega))$. His proof is based on an extension of the multiplier method.

Throughout this paper, we shall use quite standard L^2-based Sobolev spaces to measure regularity. The notation H^s is used to denote those functions which, along with all their derivatives of order less than or equal to s, are in L^2. H_0^1 denotes the closure of $\mathcal{C}_0^\infty$ in the norm of H^1. Sobolev spaces with negative indices are in general defined by duality, using an L^2-inner product. We shall only need two such spaces, namely, H^{-1}, which is defined as the dual of H_0^1, and H^{-2}, which is defined as the dual of H_0^2 that is the closure of $\mathcal{C}_0^\infty$ in the norm of H^2.

Define ν_j to be the outward unit normal to $\partial(z_j + \alpha B_j)$ for $j = 1, \ldots, m$. Let $\Gamma \subset \Omega$ be a given part of the boundary $\partial\Omega$. The aim of this paper is to identify the location and certain properties of the shapes of the inhomogeneities $\mathcal{B}_\alpha$ from only knowledge of boundary measurements of

$$\frac{\partial u_\alpha}{\partial n} \quad \text{on } \Gamma \times (0,T),$$

i.e., on the part Γ of the boundary $\partial\Omega$ and on the finite interval in time $(0,T)$. For this purpose, we develop an asymptotic method based on appropriate averaging, using particular background solutions as weights. These particular solutions are constructed by a control method as was done in the original work [32].

The first fundamental step in the design of our reconstruction method is the derivation of an asymptotic formula for $\frac{\partial u_\alpha}{\partial \nu_j}|_{\partial(z_j+\alpha B_j)^+}$ in terms of the reference solution u, the location z_j of the imperfection $z_j + \alpha B_j$, and the geometry of B_j. The second step consists of the use of this asymptotic formula to derive integral boundary formulae with a convenient choice of test functions, which is based on a geometrical control method and solving Volterra-type integral equations. We expect that these

boundary integral formulae will form the basis of very effective computational identifying algorithms. A similar approach may be applied to the full (time-dependent) Maxwell equations with small inhomogeneities of different electric permittivity or magnetic permeability (or both). This will be discussed in a forthcoming paper. The elastodynamic inverse problem will also be considered.

Whereas the determination of conductivity profiles from knowledge of boundary measurements has received a great deal of attention (see, for example, [1], [4], [9], [12], [15], and [34]), the reconstruction of imperfections within dynamics is much less investigated. To the best of our knowledge, the present paper is the first attempt to design an effective method to determine the location and the size of small conductivity imperfections inside a homogeneous medium from the dynamical measurements on part of the boundary.

The inverse problem considered in this paper is more complicated from the mathematical point of view and more interesting in applications than the one solved in [4] and [34] because, in many applications, one cannot get measurements for all t or on the whole boundary, and so one cannot, by taking a Fourier transform in the time variable, reduce our dynamic inverse problem to the inverse problem for the Helmholtz equation considered in [4] and [34].

The general approach we will take to recuperate the locations and shapes of the imperfections is to integrate the solution against special test functions. Our method is quite similar to the ideas used (in the time-independent case) by Calderón [11] in his proof of uniqueness of the linearized conductivity problem and later by Sylvester and Uhlmann in their important work [29] on uniqueness of the three-dimensional inverse conductivity problem (see Nachman [21] for the two-dimensional problem). It is also closely related to ideas used by Yamamoto in his original work [32] on inverse source hyperbolic problems and by Rakesh and Symes [27]. For discussions on other interesting inverse source hyperbolic problems, the reader is referred, for example, to Isakov [17], Belishev and Kurylev [8], Romanov and Kabanikhin [28], Yamamoto [31], [33], Puel and Yamamoto [23], [24], [25], [26], Grasselli and Yamamoto [16], Bruckner and Yamamoto [10], Nicaise [22], and Sun [30].

2. An energy estimate. We start the derivation of the asymptotic formula for $\frac{\partial u_\alpha}{\partial \nu_j}|_{\partial(z_j+\alpha B_j)^+}$ with the following energy estimate of $u_\alpha - u$.

PROPOSITION 2.1. *There exist constants $0 < \alpha_0$ and C such that, for $0 < \alpha < \alpha_0$, the following energy estimate holds:*

$$||\partial_t(u_\alpha - u)||_{L^\infty(0,T;H^{-1}(\Omega))} + ||u_\alpha - u||_{L^\infty(0,T;L^2(\Omega))} \leq C\alpha. \tag{3}$$

The constants α_0 and C depend on the domains $\{B_j\}_{j=1}^m$, the domain Ω, d_0, T, γ_0, $\{\gamma_j\}_{j=1}^m$, the data φ, ψ, and f but are otherwise independent of the points $\{z_j\}_{j=1}^m$.

Proof. Since $u_\alpha - u \in H_0^1(\Omega)$, we have, for any $v \in H_0^1(\Omega)$,

$$\int_\Omega \partial_t^2(u_\alpha - u)v + \int_\Omega \gamma_\alpha \operatorname{grad}(u_\alpha - u) \cdot \operatorname{grad} v = \sum_{j=1}^m (\gamma_0 - \gamma_j) \int_{z_j+\alpha B_j} \operatorname{grad} u \cdot \operatorname{grad} v. \tag{4}$$

Let v_α be defined by

$$\begin{cases} v_\alpha \in H_0^1(\Omega), \\ \operatorname{div} \gamma_\alpha \operatorname{grad} v_\alpha = \partial_t(u_\alpha - u) \quad \text{in } \Omega. \end{cases}$$

Then

$$\int_\Omega \gamma_\alpha \operatorname{grad}(u_\alpha - u)\cdot \operatorname{grad} v_\alpha = -\int_\Omega \partial_t(u_\alpha - u)(u_\alpha - u) = -\frac{1}{2}\partial_t \int_\Omega (u_\alpha - u)^2$$

and

$$\begin{aligned}\int_\Omega \partial_t^2(u_\alpha - u)v_\alpha &= \int_\Omega \operatorname{div}\gamma_\alpha \operatorname{grad}\partial_t v_\alpha\ v_\alpha \\ &= -\int_\Omega \gamma_\alpha \operatorname{grad}\partial_t v_\alpha \cdot \operatorname{grad} v_\alpha \\ &= -\frac{1}{2}\partial_t \int_\Omega \gamma_\alpha |\operatorname{grad} v_\alpha|^2.\end{aligned}$$

Thus it follows that

$$\partial_t \int_\Omega \gamma_\alpha |\operatorname{grad} v_\alpha|^2 + \partial_t \int_\Omega (u_\alpha - u)^2 = -2\sum_{j=1}^m (\gamma_0 - \gamma_j)\int_{z_j+\alpha B_j} \operatorname{grad} u\cdot \operatorname{grad} v_\alpha.$$

Next

$$\left|\sum_{j=1}^m (\gamma_0 - \gamma_j)\int_{z_j+\alpha B_j} \operatorname{grad} u\cdot \operatorname{grad} v_\alpha\right| \le C||\operatorname{grad} u||_{L^2(\mathcal{B}_\alpha)}||\operatorname{grad} v_\alpha||_{L^2(\Omega)}.$$

Since $u \in \mathcal{C}^\infty([0,T]\times\overline{\Omega})$, we have

$$||\operatorname{grad} u||_{L^2(\mathcal{B}_\alpha)} \le ||\operatorname{grad} u||_{L^\infty(\mathcal{B}_\alpha)}\alpha\left(\sum_{j=1}^m |B_j|\right)^{\frac{1}{2}} \le C\alpha,$$

which gives

$$\left|\sum_{j=1}^m (\gamma_0 - \gamma_j)\int_{z_j+\alpha B_j} \operatorname{grad} u\cdot \operatorname{grad} v_\alpha\right| \le C\alpha||\operatorname{grad} v_\alpha||_{L^2(\Omega)},$$

and so

$$\partial_t \int_\Omega \gamma_\alpha |\operatorname{grad} v_\alpha|^2 + \partial_t \int_\Omega (u_\alpha - u)^2 \le C\alpha\left(\int_\Omega \gamma_\alpha |\operatorname{grad} v_\alpha|^2 + \int_\Omega (u_\alpha - u)^2\right)^{1/2}.$$

From the Gronwall lemma, it follows that

$$\left(\int_\Omega \gamma_\alpha |\operatorname{grad} v_\alpha|^2\right)^{1/2} + \left(\int_\Omega (u_\alpha - u)^2\right)^{1/2} \le C\alpha.$$

Combining this last estimate with the fact that

$$||\partial_t(u_\alpha - u)||_{L^\infty(0,T;H^{-1}(\Omega))} \le C||\operatorname{grad} v_\alpha||_{L^\infty(0,T;L^2(\Omega))},$$

we obtain the desired estimate (3). We remark that, taking (at least formally) $v = \partial_t(u_\alpha - u)$ in (4), we arrive at

$$\partial_t \int_\Omega \left[|\partial_t(u_\alpha - u)|^2 + \gamma_\alpha |\operatorname{grad}(u_\alpha - u)|^2\right] = 2\sum_{j=1}^m (\gamma_0 - \gamma_j)\int_{z_j+\alpha B_j} \operatorname{grad} u\cdot \operatorname{grad}\partial_t(u_\alpha - u).$$

Using now the regularity of u in Ω and estimate (3) given above, we see that

$$\left|\sum_{j=1}^{m}(\gamma_0-\gamma_j)\int_{z_j+\alpha B_j}\operatorname{grad}u\cdot\operatorname{grad}\partial_t(u_\alpha-u)\right| \le C||\operatorname{grad}u||_{H^2(\mathcal{B}_\alpha)}||\partial_t(u_\alpha-u)||_{H^{-1}(\Omega)} \le C\alpha^2,$$

where C is independent of t and α, and so we obtain

$$\partial_t\int_\Omega\left[|\partial_t(u_\alpha-u)|^2+\gamma_\alpha|\operatorname{grad}(u_\alpha-u)|^2\right]\le C\alpha^2,$$

which yields the estimate

$$||\partial_t(u_\alpha-u)||_{L^\infty(0,T;L^2(\Omega))}+||u_\alpha-u||_{L^\infty(0,T;H_0^1(\Omega))}\le C\alpha,$$

where C is independent of α and the points $\{z_j\}_{j=1}^m$. □

3. An asymptotic formula. Before formulating the main result of this section, we need to introduce some additional notation. For any $1\le j\le m$, let Φ_j denote the vector-valued solution to

$$\text{(5)}\qquad\begin{cases}\Delta\Phi_j=0 \text{ in } B_j, \text{ and } \mathbf{R}^2\setminus\overline{B_j},\\ \Phi_j \text{ is continuous across } \partial B_j,\\ \dfrac{\gamma_0}{\gamma_j}\dfrac{\partial\Phi_j}{\partial\nu_j}\Big|_+-\dfrac{\partial\Phi_j}{\partial\nu_j}\Big|_-=-\nu_j,\\ \lim\limits_{|y|\to+\infty}|\Phi_j(y)|=0.\end{cases}$$

The existence and uniqueness of this Φ_j can be established using single layer potentials with suitably chosen densities; see [12]. In terms of this function, we are able to prove the following result about the asymptotic behavior of $\frac{\partial u_\alpha}{\partial\nu_j}|_{\partial(z_j+\alpha B_j)^+}$.

PROPOSITION 3.1. *For $y\in\partial B_j$, we have, in the weak sense,*

$$\text{(6)}\qquad\frac{\partial u_\alpha}{\partial\nu_j}|_{\partial(z_j+\alpha B_j)^+}(z_j+\alpha y,t)=\left[\nu_j+\left(\frac{\gamma_0}{\gamma_j}-1\right)\frac{\partial\Phi_j}{\partial\nu_j}|_+(y)\right]\cdot\operatorname{grad}u(z_j,t)+o(1).$$

The term $o(1)$ depends on the shapes of the domains $\{B_j\}_{j=1}^m$ and Ω, the constants d_0, T, γ_0, $\{\gamma_j\}_{j=1}^m$, the data φ,ψ, and f but is otherwise independent of the points $\{z_j\}_{j=1}^m$.

For simplicity, let us restrict our attention to the case of a single inhomogeneity, i.e., the case $m=1$. The proof, for any fixed number m of well-separated inhomogeneities, follows by iteration of the argument that we will present for the case $m=1$. In order to further simplify notation, we assume that the single inhomogeneity has the form αB; that is, we assume it is centered at the origin. We denote the conductivity inside αB by γ_* and define Φ_* to be the same as Φ_j, defined in (5), but with B_j and γ_j replaced by B and γ_*, respectively. Define ν to be the outward unit normal to ∂B. Let $U_\alpha=\operatorname{grad}u_\alpha(x,t)$ and $U_0=\operatorname{grad}u(x,t)$ in $\Omega\times(0,T)$.

We start with a formal derivation of the asymptotic formula (6). Following a common practice in multiscale expansions, we introduce the local variable $y=\frac{x}{\alpha}$. We expect that $U_\alpha(x,t)$ will differ appreciably from $U_0(x,t)$ for x near the origin,

but it will differ little from $U_0(x,t)$ for x far from the origin. Therefore, in the spirit of matched asymptotic expansions, we shall represent $U_\alpha(x,t)$ by two different expansions: an inner expansion for x near the origin and an outer expansion for x far from the origin. The outer expansion must begin with U_0, so we write

$$U_\alpha(x,t) = U_0(x,t) + \beta_1(\alpha)U_1(x,t) + \beta_2(\alpha)U_2(x,t) + \cdots \quad \text{for } |x| >> O(\alpha),\ t \in (0,T),$$

where the gauge functions $\beta_1(\alpha), \beta_2(\alpha), \ldots$ and the functions $U_1, U_2, \ldots$ are to be found. We write the inner expansion as

$$U_\alpha(z_j + \alpha y, t) = V_0(y,t) + \mu_1(\alpha)V_1(y,t) + \mu_2(\alpha)V_2(y,t) + \cdots \quad \text{for } |y| = O(1),\ t \in (0,T),$$

where the gauge functions $\mu_1(\alpha), \mu_2(\alpha), \ldots$ and the functions $V_0, V_1, V_2, \ldots$ are to be found. Here the gauge functions $\beta_i(\alpha)$ and $\mu_i(\alpha)$ satisfy $\beta_i(\alpha) >> \beta_{i+1}(\alpha)$ and $\mu_i(\alpha) >> \mu_{i+1}(\alpha)$ as α tends to 0.

The inner and outer expansions must be asymptotically equal in some overlap domain within which the stretched variable $|y|$ is large and $|x|$ is small. In this domain, the matching condition is

$$U_0(x,t) + \beta_1(\alpha)U_1(x,t) + \cdots \sim V_0(y,t) + \mu_1(\alpha)V_1(y,t) + \cdots.$$

From the terms of order α^0, we obtain the first matching condition

$$V_0(y,t) \to U_0(0,t) \text{ as } |y| \to +\infty \text{ (for } t \in (0,T)).$$

Since

$$\partial_t^2 u_\alpha - \ \text{div}\ \gamma_\alpha U_\alpha = 0 \text{ and } \ \text{curl}\ U_\alpha = 0, \tag{7}$$

by substituting the inner and outer expansions into these equations and formally equating coefficients of α^{-1}, we get

$$\text{curl}\ {}_y V_0 = 0,\ \text{div}\ {}_y\gamma(y)V_0 = 0 \text{ in } \mathbf{R}^2,$$

where

$$\gamma(y) = \begin{cases} \gamma_0 \text{ in } \mathbf{R}^2 \setminus \overline{B}, \\ \gamma_* \text{ in } B. \end{cases}$$

Therefore,

$$V_0(y) = \text{grad}\left(\left(\frac{\gamma_0}{\gamma_*} - 1\right)\Phi_*(y) + y\right) \cdot \text{grad}\, u(0,t),$$

and so, by multiplying by ν_j, we arrive at

$$\frac{\partial u_\alpha}{\partial \nu}\bigg|_{\partial(\alpha B)^+}(\alpha y, t) = \nu \cdot \text{grad}\, u(0,t) + \left(\frac{\gamma_0}{\gamma_*} - 1\right)\frac{\partial \Phi_*}{\partial \nu}\bigg|_+ (y) \cdot \text{grad}\, u(0,t) + o(1). \tag{8}$$

In the case of m (well-separated) inhomogeneities $z_j + \alpha B_j$, $j = 1, \ldots, m$, we (formally) obtain from (8) that the following asymptotic formula holds for any $y \in \partial B_j$:

$$\frac{\partial u_\alpha}{\partial \nu_j}\bigg|_{\partial(z_j+\alpha B_j)^+}(z_j + \alpha y, t) = \nu_j \cdot \text{grad}\, u(z_j,t) + \left(\frac{\gamma_0}{\gamma_j} - 1\right)\frac{\partial \Phi_j}{\partial \nu_j}\bigg|_+ (y) \cdot \text{grad}\, u(z_j,t) + o(1).$$

Proof of Proposition 3.1. Let θ be given in $\mathcal{C}_0^\infty(]0,T[)$. For any function $v \in L^1(0,T;L^2(\Omega))$, we define

$$\hat{v}(x) = \int_0^T v(x,t)\,\theta(t)\,dt \in L^2(\Omega).$$

We remark that $\widehat{\partial_t v}(x) = -\int_0^T v(x,t)\theta'(t)\,dt$. So we deduce from (7) that $\hat{U}_\alpha$ satisfies

$$\begin{cases} \text{div } \gamma_\alpha \hat{U}_\alpha = \displaystyle\int_0^T u_\alpha\,\theta''(t)\,dt & \text{in } \Omega, \\ \text{curl } \hat{U}_\alpha = 0 & \text{in } \Omega. \end{cases}$$

Analogously, $\hat{U}_0 = \int_0^T U_0(x,t)\,\theta(t)\,dt$ satisfies

$$\begin{cases} \gamma_0 \text{ div } \hat{U}_0 = \displaystyle\int_0^T u\,\theta''(t)\,dt & \text{in } \Omega, \\ \text{curl } \hat{U}_0 = 0 & \text{in } \Omega. \end{cases}$$

Indeed, we have $\hat{U}_\alpha \times n = \hat{U}_0 \times n = \text{grad}_{\partial\Omega}\,\hat{f} \times n$ on the boundary $\partial\Omega$, where $\text{grad}_{\partial\Omega}$ is the tangential gradient. Following [6], we introduce q_α^* as the unique solution to the following problem:

$$\begin{cases} \Delta q_\alpha^* = 0 & \text{in } \widetilde{\Omega} = \left(\dfrac{\Omega}{\alpha}\right) \Big\backslash\, \overline{B} \text{ and in } B, \\ q_\alpha^* \text{ is continuous across } \partial B, \\ \gamma_0 \dfrac{\partial q_\alpha^*}{\partial \nu}\Big|_+ - \gamma_* \dfrac{\partial q_\alpha^*}{\partial \nu}\Big|_- = -(\gamma_0 - \gamma_*)\hat{U}_0(\alpha y)\cdot\nu & \text{on } \partial B, \\ q_\alpha^* = 0 & \text{on } \partial\widetilde{\Omega}. \end{cases}$$

The jump condition

$$\gamma_0 \frac{\partial q_\alpha^*}{\partial \nu}\Big|_+ - \gamma_* \frac{\partial q_\alpha^*}{\partial \nu}\Big|_- = -(\gamma_0 - \gamma_*)\hat{U}_0(\alpha y)\cdot\nu \quad \text{on } \partial B$$

guarantees that $\hat{U}_\alpha(x) - \hat{U}_0(x) - \text{grad}_y\, q_\alpha^*(\frac{x}{\alpha})$ belongs to the functional space

$$Z_\alpha(\Omega) = \{v \in L^2(\Omega),\ \text{div } (\gamma_\alpha v) \in L^2(\Omega),\ \text{curl } v \in L^2(\Omega), v \times n = 0 \text{ on } \partial\Omega\}.$$

Since

$$\text{(9)} \qquad \begin{cases} \text{div } \gamma_\alpha \left(\hat{U}_\alpha - \hat{U}_0 - \text{grad}_y\, q_\alpha^*\left(\dfrac{x}{\alpha}\right)\right) \\ \qquad = \displaystyle\int_0^T \left[u_\alpha - \chi(\Omega \setminus \overline{\alpha B})u - \frac{\gamma_*}{\gamma_0}\chi(\alpha B)u\right]\theta''(t)\,dt & \text{in } \Omega, \\ \text{curl } \left(\hat{U}_\alpha - \hat{U}_0 - \text{grad}_y\, q_\alpha^*\left(\dfrac{x}{\alpha}\right)\right) = 0 & \text{in } \Omega, \\ \left(\hat{U}_\alpha - \hat{U}_0 - \text{grad}_y\, q_\alpha^*\left(\dfrac{x}{\alpha}\right)\right) \times n = 0 & \text{on } \partial\Omega, \end{cases}$$

where $\chi(\omega)$ is the characteristic function of the domain ω, we arrive, as a consequence of the energy estimate (3), at the following:

$$\begin{cases} \left(\hat{U}_\alpha - \hat{U}_0 - \operatorname{grad}_y q_\alpha^*\left(\frac{x}{\alpha}\right)\right) \in Z_\alpha(\Omega), \\ \operatorname{div} \gamma_\alpha \left(\hat{U}_\alpha - \hat{U}_0 - \operatorname{grad}_y q_\alpha^*\left(\frac{x}{\alpha}\right)\right) = 0(\alpha) \quad \text{in } \Omega, \\ \operatorname{curl} \left(\hat{U}_\alpha - \hat{U}_0 - \operatorname{grad}_y q_\alpha^*\left(\frac{x}{\alpha}\right)\right) = 0 \quad \text{in } \Omega, \\ \left(\hat{U}_\alpha - \hat{U}_0 - \operatorname{grad}_y q_\alpha^*\left(\frac{x}{\alpha}\right)\right) \times n = 0 \quad \text{on } \partial\Omega. \end{cases}$$

From [6], we know that this yields the estimate

$$\left\| \operatorname{div} \gamma_\alpha \left(\hat{U}_\alpha - \hat{U}_0 - \operatorname{grad}_y q_\alpha^*\left(\frac{x}{\alpha}\right)\right)\right\|_{L^2(\Omega)} + \left\|\hat{U}_\alpha - \hat{U}_0 - \operatorname{grad}_y q_\alpha^*\left(\frac{x}{\alpha}\right)\right\|_{L^2(\Omega)} \leq C\alpha,$$

and so

$$\left(\hat{U}_\alpha - \hat{U}_0 - \operatorname{grad}_y q_\alpha^*\left(\frac{x}{\alpha}\right)\right) \cdot \nu|_+ = 0(\alpha) \quad \text{on } \partial(\alpha B).$$

Let q_* be the unique (scalar) solution to

$$\begin{cases} \Delta q_* = 0 \quad \text{in } \mathbf{R}^2 \setminus \overline{B} \text{ and in } B, \\ q_* \text{ is continuous across } \partial B, \\ \gamma_0 \dfrac{\partial q_*}{\partial \nu}\bigg|_+ - \gamma_* \dfrac{\partial q_*}{\partial \nu}\bigg|_- = -(\gamma_0 - \gamma_*)\hat{U}_0(0) \cdot \nu \quad \text{on } \partial B, \\ \lim\limits_{|y| \to +\infty} q_* = 0. \end{cases}$$

From [12, Theorem 1], it follows that

$$\left\|(\operatorname{grad}_y q_* - \operatorname{grad}_y q_\alpha^*)\left(\frac{x}{\alpha}\right)\right\|_{L^2(\Omega)} \leq C\alpha^{1/2},$$

which yields

$$\left(\hat{U}_\alpha - \hat{U}_0 - \operatorname{grad}_y q_*\left(\frac{x}{\alpha}\right)\right) \cdot \nu = o(1) \quad \text{on } \partial(\alpha B).$$

Writing q_* in terms of Φ_* gives

$$\int_0^T \left[\frac{\partial u_\alpha}{\partial \nu}\bigg|_{\partial(\alpha B)^+}(\alpha y) - \nu \cdot \operatorname{grad} u(0,t) - \left(\frac{\gamma_0}{\gamma_*} - 1\right)\frac{\partial \Phi_*}{\partial \nu}\bigg|_+ (y) \cdot \operatorname{grad} u(0,t)\right] \theta(t)\, dt = o(1)$$

for any $\theta \in \mathcal{C}_0^\infty(]0,T[)$. In view of (9), the remainder $o(1)$ in the above asymptotic formula is bounded by $C_\alpha ||\theta||_{H^2(0,T)}$, where the constant C_α is independent of θ and goes to zero as $\alpha \to 0$. Therefore,

$$\frac{\partial u_\alpha}{\partial \nu}\bigg|_{\partial(\alpha B)^+}(\alpha y) - \nu \cdot \operatorname{grad} u(0,t) - \left(\frac{\gamma_0}{\gamma_*} - 1\right)\frac{\partial \Phi_*}{\partial \nu}\bigg|_+ (y) \cdot \operatorname{grad} u(0,t) = o(1)$$

holds in a weak sense, and so, by iterating the same argument for the case of m (well-separated) inhomogeneities $z_j + \alpha B_j, j = 1, \ldots, m$, we arrive at the promised asymptotic formula (6). □

4. The identification procedure. Let $\beta(x) \in \mathcal{C}_0^\infty(\Omega)$ be a cutoff function such that $\beta(x) \equiv 1$ in a subdomain Ω' of Ω that contains the inhomogeneities $\mathcal{B}_\alpha$. For an arbitrary $\eta \in \mathbf{R}^2$, we assume that we are in possession of the boundary measurements of

$$\frac{\partial u_\alpha}{\partial n} \quad \text{on } \Gamma \times (0,T)$$

for

$$\varphi(x) = \varphi_\eta(x) = e^{i\eta\cdot x}, \psi(x) = \psi_\eta(x) = -i\sqrt{\gamma_0}|\eta|e^{i\eta\cdot x}$$
$$\text{and } f(x,t) = f_\eta(x,t) = e^{i\eta\cdot x - i\sqrt{\gamma_0}|\eta|t}.$$

This particular choice of data φ, ψ, and f implies that the background solution u of the wave equation (2) in the absence of any inhomogeneity is given by

$$u(x,t) = u_\eta(x,t) = e^{i\eta\cdot x - i\sqrt{\gamma_0}|\eta|t} \quad \text{in } \Omega \times (0,T).$$

Suppose that T and the part Γ of the boundary $\partial\Omega$ are such that they geometrically control Ω, which roughly means that every geometrical optic ray, starting at any point $x \in \Omega$ at time $t = 0$, hits Γ before time T at a nondiffractive point; see [7]. Then, from [19, Theorem 6.4, p. 75] and [7], it follows that, for any $\eta \in \mathbf{R}^2$, we can construct by the Hilbert uniqueness method a unique $g_\eta \in H_0^1(0,T;L^2(\Gamma))$ in such a way that the unique weak solution w_η in $\mathcal{C}^0(0,T;L^2(\Omega)) \cap \mathcal{C}^1(0,T;H^{-1}(\Omega))$ of the wave equation

$$\text{(10)} \qquad \begin{cases} (\partial_t^2 - \gamma_0\Delta)w_\eta = 0 \quad \text{in } \Omega \times (0,T), \\ w_\eta|_{t=0} = \beta(x)e^{i\eta\cdot x} \in H_0^1(\Omega), \\ \partial_t w_\eta|_{t=0} = 0 \quad \text{in } \Omega, \\ w_\eta|_{\Gamma\times(0,T)} = g_\eta, \\ w_\eta|_{\partial\Omega\setminus\overline{\Gamma}\times(0,T)} = 0, \end{cases}$$

satisfies $w_\eta(T) = \partial_t w_\eta(T) = 0$. Let $v_{\alpha,\eta} \in \mathcal{C}^0(0,T;L^2(\Omega)) \cap \mathcal{C}^1(0,T;H^{-1}(\Omega))$ be defined by

$$\begin{cases} (\partial_t^2 - \gamma_0\Delta)v_{\alpha,\eta} = 0 \quad \text{in } \Omega \times (0,T), \\ v_{\alpha,\eta}|_{t=0} = 0 \quad \text{in } \Omega, \\ \partial_t v_{\alpha,\eta}|_{t=0} = \displaystyle\sum_{j=1}^m i\left(1 - \frac{\gamma_0}{\gamma_j}\right)\eta \cdot \left(\nu_j + \left(\frac{\gamma_0}{\gamma_j} - 1\right)\frac{\partial\Phi_j}{\partial\nu_j}|_+\right) e^{i\eta\cdot z_j}\delta_{\partial(z_j+\alpha B_j)} \quad \text{in } \Omega, \\ v_{\alpha,\eta}|_{\partial\Omega\times(0,T)} = 0. \end{cases}$$

Since $\frac{\partial\Phi_j}{\partial\nu_j}|_+(y)\delta_{\partial(z_j+\alpha B_j)} \in H^{-1}(\Omega)$ for $j = 1,\dots,m$, the existence and uniqueness of a solution $v_{\alpha,\eta}$ can be established by transposition; see [20] and [19, Theorem 4.2, p. 46]. Indeed, we can prove that $\frac{\partial v_{\alpha,\eta}}{\partial n}|_\Gamma \in H^{-1}(0,T;L^2(\Gamma))$. To do so, let θ be defined as

$$\begin{cases} \theta \in H_0^1(\Omega), \\ \gamma_0\,\Delta\theta = \displaystyle\sum_{j=1}^m i\left(1 - \frac{\gamma_0}{\gamma_j}\right)\eta \cdot \left(\nu_j + \left(\frac{\gamma_0}{\gamma_j} - 1\right)\frac{\partial\Phi_j}{\partial\nu_j}|_+\right) e^{i\eta\cdot z_j}\delta_{\partial(z_j+\alpha B_j)} \in H^{-1}(\Omega) \quad \text{in } \Omega, \end{cases}$$

and introduce

$$z(x,t) = \int_0^t v_{\alpha,\eta}(x,s)\, ds + \theta(x) \in L^2(\Omega).$$

It is easy to see that z satisfies the initial boundary value problem

$$\begin{cases} (\partial_t^2 - \gamma_0\Delta)z = 0 \quad \text{in } \Omega, \\ z|_{t=0} = \theta \in H_0^1(\Omega), \partial_t z|_{t=0} = 0 \quad \text{in } \Omega, \\ z|_{\partial\Omega\times(0,T)} = 0. \end{cases}$$

Classical regularity results (see [19, Theorem 4.1, p. 44]) yield

$$\frac{\partial z}{\partial n}|_\Gamma \in L^2(0,T;L^2(\Gamma)),$$

and so $\frac{\partial v_{\alpha,\eta}}{\partial n}|_\Gamma = \partial_t(\frac{\partial z}{\partial n}|_\Gamma) \in H^{-1}(0,T;L^2(\Gamma))$.

The following holds.

PROPOSITION 4.1. *Suppose that Γ and T geometrically control Ω. For any $\eta \in \mathbf{R}^2$, we have*

$$\alpha \sum_{j=1}^m i\left(1 - \frac{\gamma_0}{\gamma_j}\right) e^{2i\eta\cdot z_j}\eta \cdot \int_{\partial B_j} \left(\nu_j + \left(\frac{\gamma_0}{\gamma_j} - 1\right)\frac{\partial \Phi_j}{\partial \nu_j}|_+(y)\right) e^{i\alpha\eta\cdot y}\, ds_j(y)$$

$$= -\gamma_0 \int_0^T \int_\Gamma g_\eta \frac{\partial v_{\alpha,\eta}}{\partial n}.$$

Here $\int_0^T \int_\Gamma g_\eta \frac{\partial v_{\alpha,\eta}}{\partial n}$ is in the sense of the duality pairing between $H_0^1(0,T)$ and $H^{-1}(0,T)$. Proposition 4.1 is obtained by multiplying $(\partial_t^2 - \gamma_0\Delta)v_{\alpha,\eta} = 0$ by w_η and integrating by parts over $(0,T)\times\Omega$. In fact, we have

$$-\gamma_0 \int_0^T \int_\Gamma g_\eta \frac{\partial v_{\alpha,\eta}}{\partial n} = \alpha \sum_{j=1}^m i\left(1 - \frac{\gamma_0}{\gamma_j}\right) e^{i\eta\cdot z_j}\eta$$
$$\cdot \int_\Omega \left(\nu_j + \left(\frac{\gamma_0}{\gamma_j} - 1\right)\frac{\partial \Phi_j}{\partial \nu_j}|_+\left(\frac{x - z_j}{\alpha}\right)\right) \delta_{\partial(z_j+\alpha B_j)} e^{i\eta\cdot x}\beta(x)\, dx,$$

where the integral on the right-hand side is in the sense of the duality pairing between $H_0^1(\Omega)$ and $H^{-1}(\Omega)$. Thus

$$-\gamma_0 \int_0^T \int_\Gamma g_\eta \frac{\partial v_{\alpha,\eta}}{\partial n} = \alpha \sum_{j=1}^m i\left(1 - \frac{\gamma_0}{\gamma_j}\right) e^{i\eta\cdot z_j}\eta$$
$$\cdot \int_{\partial(z_j+\alpha B_j)} \left(\nu_j + \left(\frac{\gamma_0}{\gamma_j} - 1\right)\frac{\partial \Phi_j}{\partial \nu_j}|_+\left(\frac{x - z_j}{\alpha}\right)\right) e^{i\eta\cdot x}\, ds_j(x)$$

since $\beta(x) \equiv 1$ in a subdomain Ω' of Ω that contains the inhomogeneities $\mathcal{B}_\alpha$. By a change of variables, the above identity leads to the desired formula.

Taking now Taylor expansion of $e^{i\alpha\eta\cdot y}$ and having in mind that [12]

$$\int_{\partial B_j} \left(\nu_j + \left(\frac{\gamma_0}{\gamma_j} - 1\right)\frac{\partial \Phi_j}{\partial \nu_j}|_+(y)\right) ds_j(y) = 0,$$

we obtain the more convenient asymptotic formula.

PROPOSITION 4.2. *Suppose that Γ and T geometrically control Ω. For any $\eta \in \mathbf{R}^2$, we have*

$$\alpha^2 \sum_{j=1}^{m} \left(1 - \frac{\gamma_0}{\gamma_j}\right) e^{2i\eta\cdot z_j} \eta \cdot \int_{\partial B_j} \left(\nu_j + \left(\frac{\gamma_0}{\gamma_j} - 1\right) \frac{\partial \Phi_j}{\partial \nu_j}|_+(y)\right) \eta \cdot y \, ds_j(y) = \gamma_0 \int_0^T \int_\Gamma g_\eta \frac{\partial v_{\alpha,\eta}}{\partial n} + o(\alpha^2).$$

Next, for any $\eta \in \mathbf{R}^2$, let θ_η denote the solution to the Volterra equation of the second kind:

$$\text{(11)} \quad \begin{cases} \partial_t \theta_\eta(x,t) + \displaystyle\int_t^T e^{-i\sqrt{\gamma_0}|\eta|(s-t)} (\theta_\eta(x,s) - i\sqrt{\gamma_0}|\eta| \partial_t \theta_\eta(x,s)) \, ds = g_\eta(x,t) \\ \quad \text{for } x \in \Gamma, t \in (0,T), \\ \theta_\eta(x,0) = 0 \quad \text{for } x \in \Gamma. \end{cases}$$

The existence and uniqueness of this θ_η in $H^1(0,T;L^2(\Gamma))$ for any $\eta \in \mathbf{R}^2$ can be established using the resolvent kernel. Since $g_\eta \in H_0^1(0,T;L^2(\Gamma))$, the solution θ_η belongs, in fact, to $H^2(0,T;L^2(\Gamma))$. Note that it was Yamamoto [32] who first conceived the idea of using such a Volterra equation to apply the geometrical control for solving inverse source problems. We also note from differentiation of (11) with respect to t that θ_η is the unique solution of the ODE

$$\text{(12)} \quad \begin{cases} \partial_t^2 \theta_\eta - \theta_\eta = e^{i\sqrt{\gamma_0}|\eta|t} \partial_t (e^{-i\sqrt{\gamma_0}|\eta|t} g_\eta) \quad \text{for } x \in \Gamma, \ t \in (0,T), \\ \theta_\eta(x,0) = 0, \partial_t \theta_\eta(x,T) = 0 \quad \text{for } x \in \Gamma. \end{cases}$$

Therefore, the function θ_η may be found in practice explicitly with variation of parameters. It also immediately follows from this observation that θ_η belongs to $H^2(0,T;L^2(\Gamma))$ since $g_\eta \in H_0^1(0,T;L^2(\Gamma))$.

To identify the locations and certain properties of the small inhomogeneities $\mathcal{B}_\alpha$, let us view the averaging of the boundary measurements $\frac{\partial u_\alpha}{\partial n}|_{\Gamma\times(0,T)}$, using the solution θ_η to the Volterra equation (11) or, equivalently, the ODE (12) as a function of η. The following holds.

THEOREM 4.3. *Let $\eta \in \mathbf{R}^2$. Let u_α be the unique solution in $\mathcal{C}^0(0,T;H^1(\Omega)) \cap \mathcal{C}^1(0,T;L^2(\Omega))$ to the wave equation* (1) *with*

$$\varphi(x) = e^{i\eta\cdot x}, \psi(x) = -i\sqrt{\gamma_0}|\eta| e^{i\eta\cdot x}, \text{ and } f(x,t) = e^{i\eta\cdot x - i\sqrt{\gamma_0}|\eta|t}.$$

Suppose that Γ and T geometrically control Ω; then we have

$$\text{(13)} \quad \begin{aligned} &\int_0^T \int_\Gamma \left[\theta_\eta \left(\frac{\partial u_\alpha}{\partial n} - \frac{\partial u}{\partial n}\right) + \partial_t \theta_\eta \partial_t \left(\frac{\partial u_\alpha}{\partial n} - \frac{\partial u}{\partial n}\right)\right] \\ &= -\int_0^T \int_\Gamma e^{i\sqrt{\gamma_0}|\eta|t} \partial_t (e^{-i\sqrt{\gamma_0}|\eta|t} g_\eta) \left(\frac{\partial u_\alpha}{\partial n} - \frac{\partial u}{\partial n}\right) \\ &= \alpha^2 \sum_{j=1}^{m} \left(\frac{\gamma_0}{\gamma_j} - 1\right) e^{2i\eta\cdot z_j} \left[M_j(\eta)\cdot\eta - |\eta|^2 |B_j|\right] \\ &\quad + o(\alpha^2), \end{aligned}$$

where θ_η is the unique solution to the ODE (12)*, with g_η defined as the boundary control in* (10)*, and M_j is the polarization tensor of B_j, defined by*

$$(M_j)_{k,l} = e_k \cdot \left(\int_{\partial B_j} \left(\nu_j + \left(\frac{\gamma_0}{\gamma_j} - 1 \right) \frac{\partial \Phi_j}{\partial \nu_j}|_+(y) \right) y \cdot e_l \, ds_j(y) \right). \tag{14}$$

Here (e_1, e_2) is an orthonormal basis of $\mathbf{R}^2$.

Proof. The first identity in (13) follows from integration by parts and use of the fact that θ_η is the solution to the ODE (12).

From $\partial_t \theta_\eta(T) = 0$ and $(\frac{\partial u_\alpha}{\partial n} - \frac{\partial u}{\partial n})|_{t=0} = 0$, the term $\int_0^T \int_\Gamma \partial_t \theta_\eta \partial_t (\frac{\partial u_\alpha}{\partial n} - \frac{\partial u}{\partial n})$ has to be interpreted as follows:

$$\int_0^T \int_\Gamma \partial_t \theta_\eta \partial_t \left(\frac{\partial u_\alpha}{\partial n} - \frac{\partial u}{\partial n} \right) = - \int_0^T \int_\Gamma \partial_t^2 \theta_\eta \left(\frac{\partial u_\alpha}{\partial n} - \frac{\partial u}{\partial n} \right). \tag{15}$$

Next, introducing

$$\widetilde{u}_{\alpha,\eta}(x,t) = u(x,t) - \gamma_0 \int_0^t e^{-i\sqrt{\gamma_0}|\eta|s} v_{\alpha,\eta}(x, t-s) \, ds, x \in \Omega, t \in (0,T),$$

we rewrite

$$\begin{aligned}
&\int_0^T \int_\Gamma \left[\theta_\eta \left(\frac{\partial u_\alpha}{\partial n} - \frac{\partial u}{\partial n} \right) + \partial_t \theta_\eta \partial_t \left(\frac{\partial u_\alpha}{\partial n} - \frac{\partial u}{\partial n} \right) \right] \\
&= \int_0^T \int_\Gamma \left[\theta_\eta \left(\frac{\partial u_\alpha}{\partial n} - \frac{\partial \widetilde{u}_{\alpha,\eta}}{\partial n} \right) + \partial_t \theta_\eta \partial_t \left(\frac{\partial u_\alpha}{\partial n} - \frac{\partial \widetilde{u}_{\alpha,\eta}}{\partial n} \right) \right] \\
&- \gamma_0 \int_0^T \int_\Gamma \left[\theta_\eta \int_0^t e^{-i\sqrt{\gamma_0}|\eta|s} \frac{\partial v_{\alpha,\eta}}{\partial n}(x, t-s) \, ds + \partial_t \theta_\eta \partial_t \int_0^t e^{-i\sqrt{\gamma_0}|\eta|s} \frac{\partial v_{\alpha,\eta}}{\partial n}(x, t-s) \, ds \right].
\end{aligned}$$

Since θ_η satisfies the Volterra equation (11) and

$$\begin{aligned}
&\partial_t \left(\int_0^t e^{-i\sqrt{\gamma_0}|\eta|s} \frac{\partial v_{\alpha,\eta}}{\partial n}(x, t-s) \, ds \right) = \partial_t \left(e^{-i\sqrt{\gamma_0}|\eta|t} \int_0^t e^{i\sqrt{\gamma_0}|\eta|s} \frac{\partial v_{\alpha,\eta}}{\partial n}(x,s) \, ds \right) \\
&= -i\sqrt{\gamma_0}|\eta| e^{-i\sqrt{\gamma_0}|\eta|t} \int_0^t e^{i\sqrt{\gamma_0}|\eta|s} \frac{\partial v_{\alpha,\eta}}{\partial n}(x,s) \, ds + \frac{\partial v_{\alpha,\eta}}{\partial n}(x,t),
\end{aligned}$$

we obtain by integrating by parts over $(0,T)$ that

$$\begin{aligned}
&\int_0^T \int_\Gamma \left[\theta_\eta \int_0^t e^{-i\sqrt{\gamma_0}|\eta|s} \frac{\partial v_{\alpha,\eta}}{\partial n}(x, t-s) \, ds + \partial_t \theta_\eta \partial_t \int_0^t e^{-i\sqrt{\gamma_0}|\eta|s} \frac{\partial v_{\alpha,\eta}}{\partial n}(x, t-s) \, ds \right] \\
&= \int_0^T \int_\Gamma \frac{\partial v_{\alpha,\eta}}{\partial n}(x,t) \left(\partial_t \theta_\eta + \int_t^T \theta_\eta(s) e^{i\sqrt{\gamma_0}|\eta|(t-s)} \, ds \right) \\
&\quad - i\sqrt{\gamma_0}|\eta| (e^{-i\sqrt{\gamma_0}|\eta|t} \partial_t \theta_\eta(t)) \int_0^t e^{i\sqrt{\gamma_0}|\eta|s} \frac{\partial v_{\alpha,\eta}}{\partial n}(x,s) \, ds \, dt \\
&= \int_0^T \int_\Gamma \frac{\partial v_{\alpha,\eta}}{\partial n}(x,t) \left(\partial_t \theta_\eta + \int_t^T (\theta_\eta(s) - i\sqrt{\gamma_0}|\eta| \partial_t \theta_\eta(s)) e^{i\sqrt{\gamma_0}|\eta|(t-s)} \, ds \right) dt \\
&= \int_0^T \int_\Gamma g_\eta(x,t) \frac{\partial v_{\alpha,\eta}}{\partial n}(x,t) \, dt,
\end{aligned}$$

and so, from Proposition 4.2, we obtain that

$$\begin{aligned}
&\int_0^T \int_\Gamma \left[\theta_\eta \left(\frac{\partial u_\alpha}{\partial n} - \frac{\partial u}{\partial n}\right) + \partial_t \theta_\eta \partial_t \left(\frac{\partial u_\alpha}{\partial n} - \frac{\partial u}{\partial n}\right)\right] \\
(16) \quad &= -\alpha^2 \sum_{j=1}^m \left(1 - \frac{\gamma_0}{\gamma_j}\right) e^{2i\eta\cdot z_j} \eta \cdot \int_{\partial B_j} \left(\nu_j + \left(\frac{\gamma_0}{\gamma_j} - 1\right) \frac{\partial \Phi_j}{\partial \nu_j}|_+(y)\right) \eta \cdot y \, ds_j(y) \\
&+ \int_0^T \int_\Gamma \left[\theta_\eta \left(\frac{\partial u_\alpha}{\partial n} - \frac{\partial \widetilde{u}_{\alpha,\eta}}{\partial n}\right) + \partial_t \theta_\eta \partial_t \left(\frac{\partial u_\alpha}{\partial n} - \frac{\partial \widetilde{u}_{\alpha,\eta}}{\partial n}\right)\right] + o(\alpha^2).
\end{aligned}$$

In order to prove Theorem 4.1, it suffices then to find the leading order term in the asymptotic expansion of

$$\int_0^T \int_\Gamma \left[\theta_\eta \left(\frac{\partial u_\alpha}{\partial n} - \frac{\partial \widetilde{u}_{\alpha,\eta}}{\partial n}\right) + \partial_t \theta_\eta \partial_t \left(\frac{\partial u_\alpha}{\partial n} - \frac{\partial \widetilde{u}_{\alpha,\eta}}{\partial n}\right)\right].$$

Let $h_{\alpha,\eta} \in \mathcal{C}^0(0,T;H_0^1(\Omega)) \cap \mathcal{C}^1(0,T;L^2(\Omega))$ be the solution to

$$\begin{cases}
(\partial_t^2 - \gamma_0 \Delta) h_{\alpha,\eta} = 0 \quad \text{in } \Omega \times (0,T), \\
h_{\alpha,\eta}|_{t=0} = 0 \quad \text{in } \Omega, \\
\partial_t h_{\alpha,\eta}|_{t=0} = -\gamma_0 |\eta|^2 \displaystyle\sum_{j=1}^m \left(1 - \frac{\gamma_0}{\gamma_j}\right) e^{i\eta\cdot x} \chi(z_j + \alpha B_j) \quad \text{in } \Omega, \\
h_{\alpha,\eta}|_{\partial\Omega\times(0,T)} = 0,
\end{cases}$$

where $\chi(z_j + \alpha B_j)$ denotes the characteristic function of the inhomogeneity $z_j + \alpha B_j$. Since

$$\begin{cases}
(\partial_t^2 - \gamma_0 \Delta) \left(\displaystyle\int_0^t e^{-i\sqrt{\gamma_0}|\eta| s} v_{\alpha,\eta}(x, t-s)\, ds\right) \\
= \displaystyle\sum_{j=1}^m i \left(1 - \frac{\gamma_0}{\gamma_j}\right) \eta \cdot \left(\nu_j + \left(\frac{\gamma_0}{\gamma_j} - 1\right) \frac{\partial \Phi_j}{\partial \nu_j}|_+(y)\right) e^{i\eta\cdot z_j} \delta_{\partial(z_j+\alpha B_j)} e^{-i\sqrt{\gamma_0}|\eta| t} \\
\quad \text{in } \Omega \times (0,T), \\
\left(\displaystyle\int_0^t e^{-i\sqrt{\gamma_0}|\eta| s} v_{\alpha,\eta}(x, t-s)\, ds\right)|_{t=0} = 0, \\
\partial_t \left(\displaystyle\int_0^t e^{-i\sqrt{\gamma_0}|\eta| s} v_{\alpha,\eta}(x, t-s)\, ds\right)|_{t=0} = 0 \quad \text{in } \Omega, \\
\left(\displaystyle\int_0^t e^{-i\sqrt{\gamma_0}|\eta| s} v_{\alpha,\eta}(x, t-s)\, ds\right)|_{\partial\Omega\times(0,T)} = 0
\end{cases}$$

and

$$\begin{cases} (\partial_t^2 - \gamma_0\Delta)\left(\displaystyle\int_0^t e^{-i\sqrt{\gamma_0}|\eta|s} h_{\alpha,\eta}(x,t-s)\,ds\right) \\ = -\gamma_0|\eta|^2 \displaystyle\sum_{j=1}^m \left(1-\frac{\gamma_0}{\gamma_j}\right) e^{i\eta\cdot x}\chi(z_j+\alpha B_j) e^{-i\sqrt{\gamma_0}|\eta|t} \quad \text{in } \Omega\times(0,T), \\ \left(\displaystyle\int_0^t e^{-i\sqrt{\gamma_0}|\eta|s} h_{\alpha,\eta}(x,t-s)\,ds\right)|_{t=0} = 0, \\ \partial_t\left(\displaystyle\int_0^t e^{-i\sqrt{\gamma_0}|\eta|s} h_{\alpha,\eta}(x,t-s)\,ds\right)|_{t=0} = 0 \quad \text{in } \Omega, \\ \left(\displaystyle\int_0^t e^{-i\sqrt{\gamma_0}|\eta|s} h_{\alpha,\eta}(x,t-s)\,ds\right)|_{\partial\Omega\times(0,T)} = 0, \end{cases}$$

setting $\widetilde{h}_{\alpha,\eta} = \int_0^t e^{-i\sqrt{\gamma_0}|\eta|s} h_{\alpha,\eta}(x,t-s)\,ds$, it follows that

$$\begin{aligned} &(\partial_t^2 - \gamma_0\Delta)(u_\alpha - \widetilde{u}_{\alpha,\eta} - \widetilde{h}_{\alpha,\eta}) \\ &= \gamma_0 \sum_{j=1}^m i\left(1-\frac{\gamma_0}{\gamma_j}\right)\left[-\frac{\partial u_\alpha}{\partial n}|_+ + \eta\cdot\left(\nu_j + \left(\frac{\gamma_0}{\gamma_j}-1\right)\frac{\partial \Phi_j}{\partial \nu_j}|_+(y)\right) e^{i\eta\cdot z_j} e^{-i\sqrt{\gamma_0}|\eta|t}\right]\delta_{\partial(z_j+\alpha B_j)} \\ &+ \sum_{j=1}^m \left(1-\frac{\gamma_0}{\gamma_j}\right)(\partial_t^2 u_\alpha + |\eta|^2\gamma_0 e^{i\eta\cdot x - i\sqrt{\gamma_0}|\eta|t})\chi(z_j+\alpha B_j), \end{aligned}$$

and, therefore, by Propositions 3.1 and 2.1, we readily get that

$$\begin{cases} (\partial_t^2 - \gamma_0\Delta)(u_\alpha - \widetilde{u}_{\alpha,\eta} - \widetilde{h}_{\alpha,\eta}) = o(\alpha^2) \quad \text{in } \Omega\times(0,T), \\ (u_\alpha - \widetilde{u}_{\alpha,\eta} - \widetilde{h}_{\alpha,\eta})|_{t=0} = 0, \partial_t(u_\alpha - \widetilde{u}_{\alpha,\eta} - \widetilde{h}_{\alpha,\eta})|_{t=0} = 0 \quad \text{in } \Omega, \\ (u_\alpha - \widetilde{u}_{\alpha,\eta} - \widetilde{h}_{\alpha,\eta})|_{\partial\Omega\times(0,T)} = 0, \end{cases} \tag{17}$$

where the right-hand side in the first equation in (17) is of order $o(\alpha^2)$ in the $H^{-2}(0,T;H^{-1}(\Omega))$ norm.

Following the proof of Proposition 2.1, we immediately obtain that

$$||u_\alpha - \widetilde{u}_{\alpha,\eta} - \widetilde{h}_{\alpha,\eta}||_{L^2(\Omega)} = o(\alpha^2), \quad t\in(0,T),\ x\in\Omega,$$

where the remainder $o(\alpha^2)$ is independent of the points $\{z_j\}_{j=1}^m$.

We now show that the estimate

$$\left\|\frac{\partial}{\partial n}(u_\alpha - \widetilde{u}_{\alpha,\eta} - \widetilde{h}_{\alpha,\eta})\right\|_{L^2(0,T;L^2(\Gamma))} = o(\alpha^2) \tag{18}$$

holds, which will immediately imply that

$$\begin{aligned} &\int_0^T\int_\Gamma \left[\theta_\eta\left(\frac{\partial u_\alpha}{\partial n} - \frac{\partial \widetilde{u}_{\alpha,\eta}}{\partial n}\right) + \partial_t\theta_\eta\partial_t\left(\frac{\partial u_\alpha}{\partial n} - \frac{\partial \widetilde{u}_{\alpha,\eta}}{\partial n}\right)\right] \\ &= \int_0^T\int_\Gamma \theta_\eta\frac{\partial \widetilde{h}_{\alpha,\eta}}{\partial n} + \partial_t\theta_\eta\partial_t\frac{\partial \widetilde{h}_{\alpha,\eta}}{\partial n} + o(\alpha^2). \end{aligned} \tag{19}$$

Let θ be given in $\mathcal{C}_0^\infty(]0,T[)$, and define

$$\hat{\widetilde{u}}_{\alpha,\eta}(x) = \int_0^T \widetilde{u}_{\alpha,\eta}(x,t)\theta(t)\,dt,$$

$$\hat{\widetilde{h}}_{\alpha,\eta}(x) = \int_0^T \widetilde{h}_{\alpha,\eta}(x,t)\theta(t)\,dt,$$

and

$$\hat{u}_\alpha(x) = \int_0^T u_\alpha(x,t)\theta(t)\,dt.$$

We have

$$\begin{cases} \operatorname{div}\gamma_\alpha \operatorname{grad}(\hat{u}_\alpha - \hat{\widetilde{u}}_{\alpha,\eta} - \hat{\widetilde{h}}_{\alpha,\eta}) = o(\alpha^2) \in L^2(\Omega\setminus\overline{\Omega'}) \cap H^{-1}(\Omega), \\ (\hat{u}_\alpha - \hat{\widetilde{u}}_{\alpha,\eta} - \hat{\widetilde{h}}_{\alpha,\eta}) = 0 \quad \text{on } \partial\Omega, \end{cases}$$

which implies from [34] that

$$\left\| \frac{\partial}{\partial n}(\hat{u}_\alpha - \hat{\widetilde{u}}_{\alpha,\eta} - \hat{\widetilde{h}}_{\alpha,\eta}) \right\|_{L^2(\Gamma)} = o(\alpha^2)$$

for all $\theta \in \mathcal{C}_0^\infty(]0,T[)$, whence

$$\left\| \frac{\partial}{\partial n}(u_\alpha - \widetilde{u}_{\alpha,\eta} - \widetilde{h}_{\alpha,\eta}) \right\|_{L^2(\Gamma)} = o(\alpha^2) \text{ a.e. in } t \in (0,T),$$

and so the desired estimate (18) holds.

On the other hand, analogously to Proposition 4.1, by integration by parts and taking the Taylor expansion of $e^{i\eta\cdot x}$ in $z_j + \alpha B_j$, the following holds:

$$\int_0^T \int_\Gamma g_\eta(x,t) \frac{\partial h_{\alpha,\eta}}{\partial n}(x,t)\,dt = \alpha^2 \sum_{j=1}^m \left(1 - \frac{\gamma_0}{\gamma_j}\right) e^{2i\eta\cdot z_j} |\eta|^2 |B_j| + o(\alpha^2). \tag{20}$$

However,

$$\int_0^T \int_\Gamma g_\eta(x,t) \frac{\partial h_{\alpha,\eta}}{\partial n}(x,t)\,dt = \int_0^T \int_\Gamma \theta_\eta \frac{\partial \widetilde{h}_{\alpha,\eta}}{\partial n} + \partial_t\theta_\eta \partial_t \frac{\partial \widetilde{h}_{\alpha,\eta}}{\partial n}, \tag{21}$$

and so, combining (16), (19), (20), and (21), we arrive at our promised asymptotic formula (13). The proof of Theorem 4.1 is then over. □

We are now in position to describe our identification procedure, which is based on Theorem 4.1. Let us neglect the asymptotically small remainder in the asymptotic formula (13) and define $\Lambda_\alpha(\eta)$ by

$$\Lambda_\alpha(\eta) = \int_0^T \int_\Gamma \left[\theta_\eta \left(\frac{\partial u_\alpha}{\partial n} - \frac{\partial u}{\partial n} \right) + \partial_t\theta_\eta \partial_t \left(\frac{\partial u_\alpha}{\partial n} - \frac{\partial u}{\partial n} \right) \right].$$

The function $\Lambda_\alpha(\eta)$ is computed in the following way. First, we construct the control g_η in (10) for given $\eta \in \mathbf{R}^2$. Then we solve the ODE (12) to find the auxiliary test

function θ_η. From the boundary measurements $\frac{\partial u_\alpha}{\partial n}|_{\Gamma\times(0,T)}$, we form the integrals that come in the expression of $\Lambda_\alpha(\eta)$.

Recall that the function $e^{2i\eta\cdot z_j}$ is exactly the Fourier transform (up to a multiplicative constant) of the Dirac function δ_{-2z_j} (a point mass located at $-2z_j$). From Theorem 4.3, it follows that the function $\Lambda_\alpha(\eta)$ is (approximately) the Fourier transform of a linear combination of derivatives of point masses, or

$$\breve{\Lambda}_\alpha(\eta) \approx \alpha^2 \sum_{j=1}^{m} L_j \delta_{-2z_j},$$

where L_j is a second order constant coefficient, differential operator whose coefficients depend on the polarization tensor M_j defined by (14) (see [12] for its properties) and $\breve{\Lambda}_\alpha(\eta)$ represents the inverse Fourier transform of $\Lambda_\alpha(\eta)$. The reader is referred to [12] for properties of the tensor polarization M_j.

The method of reconstruction we propose here consists, as in [4], in sampling values of $\breve{\Lambda}_\alpha(\eta)$ at some discrete set of points and then calculating the corresponding discrete inverse Fourier transform. After a rescaling by $-\frac{1}{2}$, the support of this discrete inverse Fourier transform yields the location of the small inhomogeneities $\mathcal{B}_\alpha$. This procedure generalizes the approach that we developed in [4] for the two-dimensional (time-independent) inverse conductivity problem. On other terms, once $\Lambda_\alpha(\eta)$ is computed from dynamic boundary measurements on Γ, we calculate its inverse Fourier transform. The asymptotic formula (13) in Theorem 4.1 asserts that this inverse Fourier transform is a distribution supported at the locations $(z_j)_{j=1}^m$.

Once the locations are known, we may calculate the polarization tensors $(M_j)_{j=1}^m$ by solving an appropriate linear system arising from (13). These polarization tensors give ideas on the orientation and relative size of the inhomogeneities [18]. We wish to point out that, from the leading order term of $\Lambda_\alpha(\eta)$ given by (13), we cannot reconstruct more details of the shapes of the domains B_j. Higher order terms in the asymptotic expansion of $\Lambda_\alpha(\eta)$, with respect to α, are needed to reconstruct the domains B_j with high resolution.

The number of data (sampling) points needed for an accurate discrete Fourier inversion of $\Lambda_\alpha(\eta)$ follows from Shannon's sampling theorem [13]. We need (conservatively) order $(\frac{h}{\delta})^2$ sampled values of $\Lambda_\alpha(\eta)$ to reconstruct, with resolution δ, a collection of inhomogeneities that lie inside a square of side h. In order to simulate errors in the measurements of $\frac{\partial u_\alpha}{\partial n}$ on $\Gamma\times(0,T)$, as well as the errors inherent in the approximation (13) and in the calculations of g_η, θ_η, and $\Lambda_\alpha(\eta)$ (by some quadrature rules), we should add random noise to the values of $\Lambda_\alpha(\eta)$. Numerical experiments in [4] for the two-dimensional (time-independent) inverse conductivity problem seem to suggest that the method is quite stable with respect to noise in measurements and errors in the different approximations.

We are convinced that the use of approximate formulae such as (13) represents a very promising approach to the dynamical identification of small inhomogeneities that are embedded in a homogeneous medium. In particular, our method can be extended to solve the dynamical identification problem of small incompressible or rigid inclusions. Formally, we can recover these two cases by letting γ_j tend to $+\infty$ or 0 in (5) and the asymptotic formula (13). Rigorously, to assert that (13) is still valid for incompressible or rigid inclusions, we should prove that the term $o(\alpha^2)$ is uniform in γ_j as $\gamma_j \to +\infty$ or 0. We also believe that our method yields a good approximation to small amplitude perturbations in the conductivity ($\gamma_\alpha(x) = \gamma_0 + \alpha\gamma_1(x)$) from the measurements of $\frac{\partial u_\alpha}{\partial n}$ on $\Gamma\times(0,T)$. Our method may yield the Fourier transform of

the perturbation $\gamma_1(x)$. This inverse problem is considered in [2].

Finally, we wish to emphasize the fact that, in the algorithm described in this paper, the locations z_j, $j = 1, \ldots, m$, of the inhomogeneities are found with an error $O(\alpha)$, and only the polarization tensors of the domains B_j can be reconstructed. Making use of higher order terms in the asymptotic expansion of $\frac{\partial u_\alpha}{\partial \nu_j}|_{\partial(z_j+\alpha B_j)^+}$, we certainly would be able to reconstruct the small inhomogeneities with higher resolution from dynamical boundary measurements on part of the boundary and capture more details of the geometries of the domains B_j. Perhaps, more importantly, this would also allow us to identify quite general conductivity inhomogeneities without restrictions on their sizes. Results in this direction are now available for the conductivity problem. In [3], based on layer potential techniques, high order terms in the asymptotic expansions of the steady-state voltage potentials in the presence of a finite number of diametrically small inhomogeneities with conductivities different from the background conductivity are rigorously derived. In [5], similar accurate asymptotic formulae are applied for the purpose of identifying the location and certain properties of the shape of the conductivity inhomogeneities. A real-time algorithm with a very high resolution and accuracy that makes use of constant current sources is designed. We believe that the results and techniques of [3] and [5] could be combined with the approach developed in this paper for recovering the small electromagnetic inhomogeneities from dynamic boundary measurements with higher resolution and accuracy. This very important issue will be considered in a forthcoming work.

Acknowledgments. The author expresses his thanks to M. Vogelius for various interesting discussions. He is also very grateful to the referees for their comments, which enabled him to make many improvements to the presentation.

NECESSARY AND SUFFICIENT CONDITIONS FOR OPTIMAL OFFERS IN ELECTRICITY MARKETS*

EDWARD J. ANDERSON† AND HUIFU XU†

Abstract. In this paper, we consider the optimal policy for a generator offering power into a wholesale electricity market operating under a pool arrangement. Anderson and Philpott [*Math. Oper. Res.*, 27 (2002), pp. 82–100] recently discussed necessary conditions for an optimal offer curve when there is uncertainty in the demand and in the behavior of other participants in the market. They show that the objective function in these circumstances can be expressed as a line integral along the offer curve of a profit function integrated with respect to a market distribution function. In this paper, we prove the existence of an optimal offer stack, and we extend the analysis of [*Math. Oper. Res.*, 27 (2002), pp. 82–100] to include necessary conditions of a higher order in the presence of horizontal and/or vertical sections in an offer curve. Finally, we establish sufficient conditions for an offer curve to be locally optimal.

1. Introduction.

In the past few years, there has been an enormous change in the way that wholesale prices for electricity are determined in many parts of the world. Increasingly, market mechanisms are being set up in which the clearing price for electricity is determined by some sort of auction process. The book by Chao and Huntington [3] gives a useful overview of the nature of electricity markets, and the working paper by von der Fehr and Harbord [4] is another useful starting point as it reviews the form of a variety of markets as they existed in 1998. In this paper, we consider a model of the operation of such a market which captures some important features of the electricity markets which operate in the UK, Australia, New Zealand, and parts of the US. The model was introduced in a recent paper by Anderson and Philpott [1]. We begin by reviewing this model before going on to extend the results of Anderson and Philpott on the form of the optimal solutions for generators operating in a market of this sort.

Generators in an electricity market offer energy into the market at prices that they determine. We take this offer as having the form of an offer curve linking quantity and price. We can write the quantity of electricity offered as a nondecreasing function of price, $S(p)$. $S(p)$ is the quantity of electricity that will be delivered by the generator in question if the clearing price is p. In some markets, power is offered in blocks, which will imply that $S(p)$ has the form of a step function. The clearing price is determined by a market mechanism that incorporates consideration of the offers made by all the generators, transmission constraints operating within the electricity network, and the demand (which may have price dependence for some large consumers).

The model we consider represents a market operating under pool arrangements. In some markets, there are more bilateral trading arrangements, and our model will

not apply in these cases. In a pool arrangement, some form of independent system operator (ISO) is responsible for determining which generators are dispatched and will do this in a way which satisfies demand at least cost, using the generator bids as proxies for cost. If the spot market consists of a pool located at a single node, then the price of electricity can be computed by successively dispatching generation from the offers with the lowest price until all of the demand is met. The price of the marginal offer, the system marginal price, is then the price that is paid for all the electricity dispatched. Thus a low cost generator can choose to offer power at its real marginal cost and will be very likely dispatched and paid a substantial premium over its marginal generating cost.

Following Anderson and Philpott [1], we will be interested in finding an optimal offer for a generator when there is uncertainty about the demand and the behavior of the other generators. This takes a different approach than that considered by Gross and Finlay [6], who assume perfect competition so that the clearing price is unaffected by any single generator's offer. In our model, the offer that a generator makes has a direct influence on the clearing price, but we will not consider the equilibrium framework that would arise if we were to consider the optimal response of other generators to our offer curve. In fact, the majority of papers dealing with electricity markets have studied equilibria, often with the aim of assessing the degree of market power implied by different market structures. See, for example, the papers by Hobbs [7], Bolle [2], Green and Newbery [5], Rudkevich, Duckworth, and Rosen [8], and Wei and Smeers [9].

Our work is more directly concerned with the problem faced by a generator in deciding on an offer. In this case, the generator might take an equilibrium solution as an indication of where things may end up in the long term, but the immediate problem will be to respond to the current environment, which will involve uncertainty in demand and in other generators' offers. Such uncertainty arises partly because of possible outages and partly because generators' bidding behavior is not stable. Concentration only on an equilibrium solution is problematic: this assumes that other generators are behaving in a fully rational way and that we have access to all relevant information. Moreover, in many circumstances, there will be more than one equilibrium possible; which one should guide the offer behavior for a generator? Finally, we should observe that the actual computation of equilibria in these markets with many participants is extremely hard. Of course, since offers are repeated many times a day and there is often considerable similarity between outcomes at the same hour on different days, we should expect electricity markets to move toward some sort of equilibrium behavior. Thus we are not arguing here against the importance of understanding equilibria but merely that the problem we address is of importance. Indeed, a good understanding of this problem will be helpful in moving forward in the analysis of equilibrium models.

Anderson and Philpott have explored the problem of finding an offer curve that maximizes the expected value of the profit made by an individual generator. The offer curve is simply a monotonic continuous curve in the two-dimensional (quantity, price) space. This curve need not be smooth; indeed, it will often in practice take the form of a series of steps. Anderson and Philpott show how the problem of maximizing expected profit is, in some circumstances, equivalent to maximizing the line integral along the offer curve of a market distribution function defined in the (quantity, price) space. The market distribution function captures all the elements of uncertainty in either demand or the other players' behavior.

Anderson and Philpott give necessary conditions for an optimal offer curve in this framework. In this paper, we make a number of contributions. First, in section 2, we demonstrate the existence of an optimal solution. Second, in section 3, we extend the necessary conditions given previously. In section 4, we give sufficient conditions for an offer curve to be locally optimal. Finally, in section 5, we give an example to demonstrate the application of these conditions.

The analysis we give is quite general and has some interest apart from its electricity market context. The necessary and sufficient conditions apply to the problem of finding a choice of monotonic curve within a bounded region in order to maximize a line integral along the curve. In the absence of monotonicity constraints, this is a problem in the calculus of variations. However, the requirement for monotonicity is fundamental and implies additional conditions that apply on sections of the curve which are either horizontal or vertical (and hence at points where monotonicity acts as a binding constraint). The results we give are proved by relatively direct and elementary methods involving consideration of perturbations of an offer curve. It is interesting that sufficient conditions for optimality can be obtained in this way.

2. Problem formulation and fundamentals. In this section, we will introduce some notation and formulate the problem that we shall consider. Let $R(q,p)$ be the return function: that is, $R(q,p)$ denotes the profit we make if we are dispatched an amount q at a clearing price p. We will assume that R has continuous partial derivatives. This function captures not only the cost of generating an amount q and the proceeds pq which arise from the sale of this electricity but also the effects of any hedging contracts the generator holds which depend on the market clearing price.

Rather than dealing with a supply function $S(\cdot)$ directly, it is convenient to model the offer using a continuous curve $\mathbf{s} = \{(x(t), y(t)), 0 \le t \le T\}$, in which the components $x(t)$ and $y(t)$ are continuous monotonic increasing functions of t, and $x(t)$ and $y(t)$ trace, respectively, the quantity and price components. Without loss of generality we may take $x(0) = y(0) = 0$ and $y(T) \le p_M$, where p_M is a bound on the price of any offer. We also assume that q_m is a bound on the generation capacity of the generator, so $x(T) \le q_M$.

We use a single *market distribution function* $\psi(q,p)$ to describe the uncertainty in the market. $\psi(q,p)$ is defined as the probability of not being fully dispatched if we offer generation q at price p. It turns out that knowledge of the single function $\psi(q,p)$ is enough to determine the expected profit for a generator. In practice, a generator will estimate the market distribution function from knowledge of the distribution of demand and from repeated observations of the behavior of other generators. This estimation problem will depend on the information released to market participants about other players' bids (something which varies between different markets). Another issue will be to decide the class of functions from which an estimate is to be chosen. However, subject to these considerations, either Bayesian or maximum likelihood estimation techniques can be used.

Since $\psi(q,p)$ is a probability, it takes values between 0 and 1. Let $\Psi = \{(q,p), 0 < \psi(q,p) < 1\}$. Throughout, we assume that ψ is continuously differentiable on $\Psi \cap \{(q,p), 0 \le q \le q_M, 0 \le p \le p_M\}$. The first key result, which we repeat from Anderson and Philpott [1], demonstrates that the expected return if a generator offers in a supply curve $\mathbf{s}$ can be expressed as a line integral along $\mathbf{s}$. This can be established by showing that a generator can only be dispatched at price-quantity points lying on its offer curve and observing that the derivative of the market distribution function ψ captures the appropriate probability density.

LEMMA 1 (see [1, Theorem 2]). *If a generator offers in a curve* $\mathbf{s}$ *and the market distribution function* ψ *is continuous, then the expected return is the line integral*

$$v(\mathbf{s}) = \int_{\mathbf{s}} R(q,p)d\psi(q,p).$$

Anderson and Philpott [1] treat $v(\mathbf{s})$ as an objective function and investigate the necessary conditions for an offer curve $\mathbf{s}$ to be a local maximizer. However, there is an important question that they do not address explicitly: does there exist a maximum over the set of curves which are considered? We begin by answering this question before discussing optimality conditions.

A generator need not offer all of its generation capacity into the market; the offer curve will start at some point $(0, y(0))$ and finish at $(x(T), y(T))$. However, the clearing price is determined as though the offer curve began with a vertical segment from the origin to $(0, y(0))$ and finished with a vertical segment from $(x(T), y(T))$ to $(x(T), p_M)$. Hence we assume that Ω, the set of curves, has these characteristics.

LEMMA 2. *Let* Ω *be the set of monotonic continuous curves starting at the origin and ending on the closed line segment,* $\mathcal{L}$*, from* $(0, p_M)$ *to* (q_M, p_M)*. Then* Ω *is compact under the Hausdorff metric:*

$$|\mathbf{s}_1 - \mathbf{s}_2|_H = \max_{(x_1,y_1)\in\mathbf{s}_1} \min_{(x_2,y_2)\in\mathbf{s}_2} \sqrt{(x_1-x_2)^2 + (y_1-y_2)^2}.$$

Proof. Let $\mathbf{s} \in \Omega$ and $L(\mathbf{s})$ be the arc length of $\mathbf{s}$. By the monotonicity of $\mathbf{s}$,

$$p_M \le L(\mathbf{s}) \le p_M + q_M.$$

For any $\mathbf{s} \in \Omega$, we may use the arc length measured from the origin as a parameter and write $\mathbf{s} = \{(x(t), y(t)), 0 \le t \le L(\mathbf{s})\}$. For $0 \le t_1 < t_2 \le L(\mathbf{s})$, we have

$$t_2 - t_1 \ge \max\left(x(t_2) - x(t_1), y(t_2) - y(t_1)\right).$$

Thus both x and y are Lipschitz with respect to t. By replacing t with $\frac{T}{L(\mathbf{s})}t$, we obtain a representation of $\mathbf{s}$ with both x and y defined on $[0, T]$. The scaled x and y are still Lipschitz and monotonic. It is well known that the class of monotonic Lipschitz functions defined on $[0, T]$ forms a compact set. Thus the set of curves Ω, when represented as pairs of (Lipschitz) functions, is compact with the metric

$$|\mathbf{s}_1 - \mathbf{s}_2| = \max\left(\sup_{0\le t\le T} |x_1(t) - x_2(t)|, \sup_{0\le t\le T} |y_1(t) - y_2(t)|\right).$$

Since $|s_1 - s_2|_H \le \sqrt{2}|s_1 - s_2|$, this implies compactness of Ω with the Hausdorff metric. □

Anderson and Philpott [1] introduced the notation

$$Z(q,p) \equiv \begin{cases} R_q\psi_p - R_p\psi_q, & (q,p) \in \Psi, \\ 0 & \text{otherwise} \end{cases}$$

and observed that

$$\int\int_{\mathcal{S}} Z(q,p)dpdq = \int_{\mathcal{C}} R(q,p)d\psi(q,p), \tag{1}$$

where $\mathcal{S}$ is a region enclosed by a curve $\mathcal{C}$. Relation (1) follows immediately from Green's theorem and plays an important role in the investigation of optimality conditions. The scalar function Z can be thought of as indicating the direction in which the offer curve needs to move to produce an improvement in expected profit. If $Z > 0$, then a move of the offer curve down and to the left in the (q, p) plane will produce an improvement, while $Z < 0$ indicates that the offer curve should move up and to the right. Consequently, when monotonicity constraints are not binding, it will be optimal to follow a $Z = 0$ curve.

Using Lemma 2 and (1), we are able to obtain the following result.

THEOREM 3. *Let Ω be defined as above, and let v be the expected return function given in Lemma* 1. *Then v achieves its maximum on Ω.*

Proof. By Lemma 2, Ω is a compact set. It suffices to prove that v is continuous with the Hausdorff metric. Let $\tilde{\mathbf{s}} \in \Omega$, and assume without loss of generality that $\mathcal{S}$ is the region surrounded by $\tilde{\mathbf{s}}$, $\mathbf{s}$. Thus, as $\tilde{\mathbf{s}}$ is close to $\mathbf{s}$, the area $\mathcal{S}$ is small. By (1), the boundedness of Ψ, and the continuous differentiability ψ and R, we know that the integral of Z over $\mathcal{S}$ will be arbitrarily small when the area of $\mathcal{S}$ shrinks to zero. On the other hand, the line integral at the right side of (1) over the segment of $\mathcal{L}$ between $\mathbf{s}$ and $\tilde{\mathbf{s}}$ tends to zero as $\tilde{\mathbf{s}} \to \mathbf{s}$. This implies that $v(\tilde{\mathbf{s}})$ tends to $v(\mathbf{s})$. □

Given this theorem, the maximization problem

$$\text{maximize } v(\mathbf{s}), \quad \text{subject to } \mathbf{s} \in \Omega$$

is well defined. In the rest of this paper, we will discuss the necessary and sufficient conditions for an offer curve $\mathbf{s}$ to be a local maximizer.

3. Necessary conditions. We turn now to necessary conditions for optimality. Anderson and Philpott [1] establish a set of conditions which we will extend. Such conditions are important in the development of algorithms to solve the generator's maximization problem. Later we will illustrate their use by considering a simple example. In general, more complete optimality conditions will serve to eliminate more potential candidate optimal offer curves. It is convenient to restate the result of [1] in a slightly different form in order to show how it is related to the results that we prove in this paper.

Throughout, we need to use the line integral of Z along a curve $\{(x(t), y(t)) : 0 \leq t \leq T\}$ which is defined by

$$w(t) = \int_0^t Z(x(\tau), y(\tau))(x'(\tau) + y'(\tau))d\tau.$$

In some cases, we will write $w(x(t), y(t))$ to denote $w(t)$ for clarity.

THEOREM 4. *Suppose that $\mathbf{s} = \{x(t), y(t), 0 \leq t \leq T\}$ is an increasing continuous offer curve. Suppose that there exist m numbers $0 \leq t_1 < t_2 < \cdots < t_m \leq T$ with $0 < x(t) < q_M$ and $0 < y(t) < p_M$ for $t_1 < t < t_m$ and such that, on each section (t_{i-1}, t_i), $i = 2, \ldots, m$, $\mathbf{s}$ is either strictly increasing in both components or horizontal or vertical, with different characteristics in successive segments. If $\mathbf{s}$ is optimal, then each of the $w(t_i)$, $i = 1, 2, \ldots, m$, takes the same value, say, w_0, and, for each interval I, being one of (t_{i-1}, t_i), $i = 2, \ldots, m$, $(0, t_1)$, or (t_m, T), one of the following holds:*

(i) $\mathbf{s}$ *is strictly increasing in both components, and $Z(x(t), y(t)) = 0$ for $t \in I$;*

(ii) $\mathbf{s}$ *is horizontal on I, and $w(t) \leq w_0$ for $t \in I$;*

(iii) $\mathbf{s}$ *is vertical on I, and $w(t) \geq w_0$ for $t \in I$.*

Anderson and Philpott [1] show, in addition, that, when $\mathbf{s}$ is neither horizontal nor vertical, then there are sign constraints on the partial derivatives of Z if they exist. In fact, the existence of partial derivatives for Z will allow us to extend the results of Theorem 4 provided that Z is well behaved enough.

We will need to make an assumption about the partial derivatives of Z. We give the weakest form of this required for our results; it is stronger than continuous differentiability, requiring also a uniformity condition on horizontal and vertical sections of $\mathbf{s}$. This condition will be implied, for example, by Z having continuous second derivatives.

Assumption 1. Z is continuously differentiable on Ψ. If $\mathbf{s}$ is horizontal on $[t_{i-1}, t_i]$, then, for every $\eta > 0$, there is a $\tau_0 > 0$ with

$$|Z(x(t), y(t_i) + \tau) - Z(x(t), y(t_i)) - Z_p(x(t), y(t_i))\tau| \leq \eta|\tau|$$

for every $t \in [t_{i-1}, t_i]$ and $|\tau| < \tau_0$. Similarly, if $\mathbf{s}$ is vertical on $[t_{i-1}, t_i]$, then, for every $\eta > 0$, there is a $\tau_0 > 0$ with

$$|Z(x(t_i) + \tau, y(t)) - Z(x(t_i), y(t)) - Z_q(x(t_i), y(t))\tau| \leq \eta|\tau|$$

for every $t \in [t_{i-1}, t_i]$ and $|\tau| < \tau_0$.

The theorem below extends Theorem 4, but there is a key difference that is worth pointing out before stating the result. In the previous theorem, the values t_i are defined as corresponding to points where the curve changes characteristic, say, from horizontal to vertical. In the theorem we give next, we will define the values t_i in terms of the w values instead. Thus suppose we have a horizontal segment within which $w(t) \leq w_0$: then, in Theorem 4, the t_i values mark either end of this segment, but in the next theorem we add to this any other values of t at which $w(t) = w_0$, between the end points. Thus we may have a point t_i, with $\mathbf{s}$ horizontal on either side of it. It will be convenient to distinguish those values of t_i such that the curve $\mathbf{s}$ changes its characteristics at $(x(t_i), y(t_i))$, for instance, from vertical to horizontal or strictly increasing in both components. For convenience, we call both the parameter t_i and the point $(x(t_i), y(t_i))$ a *turning point.*

THEOREM 5. *Suppose that* $\mathbf{s} = \{x(t), y(t), 0 \leq t \leq T\}$ *is an increasing continuous offer curve. Suppose that there exist* m *numbers* $0 \leq t_1 < t_2 < \cdots < t_m \leq T$ *such that each of the* $w(t_i)$, $i = 1, 2, \ldots, m$, *takes the same value, say,* w_0, *and, on each section* $[t_{i-1}, t_i]$, $i = 2, \ldots, m$, $\mathbf{s}$ *is either strictly increasing in both components or horizontal or vertical. Suppose that* $\mathbf{s}$ *is an optimal offer stack. Then, under Assumption* 1, *for each section* (t_{i-1}, t_i), *the following hold:*

(i) *if* $\mathbf{s}$ *is strictly increasing on* (t_{i-1}, t_i), *then* $Z_p(x(t), y(t)) \geq 0$ *and* $Z_q(x(t), y(t)) \leq 0$ *for* $t \in (t_{i-1}, t_i)$;

(ii) *if* $\mathbf{s}$ *is horizontal on* (t_{i-1}, t_i) *and one of* t_{i-1} *or* t_i *is a turning point, then*

$$\int_{x(t_{i-1})}^{x(t_i)} Z_p(x, y(t_i))dx \geq 0; \tag{2}$$

further, if $\mathbf{s}$ *turns from horizontal to vertical at* t_i, *then*

$$\int_{x(t_{i-1})}^{x(t_i)} Z_p(x, y(t_i))dx - \int_{y(t_i)}^{y(t_{i+1})} Z_q(x(t_i), y)dy \geq 2Z(x(t_i), y(t_i)); \tag{3}$$

(iii) *if* $\mathbf{s}$ *is vertical on* (t_{i-1}, t_i) *and one of* t_{i-1} *or* t_i *is a turning point, then*

$$\int_{y(t_{i-1})}^{y(t_i)} Z_q(x(t_i), y)dy \leq 0; \tag{4}$$

further, if $\mathbf{s}$ *turns from vertical to horizontal at* t_i*, then*

$$\int_{y(t_{i-1})}^{y(t_i)} Z_q(x(t_i), y)dy - \int_{x(t_i)}^{x(t_{i+1})} Z_p(x, y(t_i))dx \leq 2Z(x(t_i), y(t_i)). \tag{5}$$

Before giving a proof of this result, it may be helpful to discuss the conditions (2), (3), (4), and (5).

If $\mathbf{s}$ is horizontal on (t_{i-1}, t_i), then, since $w(t_{i-1}) = w(t_i) = w_0$,

$$\int_{x(t_{i-1})}^{x(t_i)} Z(x, y(t_i))dx = 0.$$

This integral captures the first order effect of a move of the horizontal segment up or down by a small amount. Given that the integral is zero, we can look at the second order effects of the same move, and these are given by the integral in (2). The same argument applied to a vertical segment leads to the integral in (4).

The stronger conditions (3) and (5), which apply when there is a turn from horizontal to vertical (or vice versa), arise from considering a move of a horizontal segment at the same time as a vertical segment. Notice that, if $\mathbf{s}$ turns from horizontal to vertical at t_i, then $Z(x(t_i), y(t_i)) \geq 0$. This follows from the observation that Theorem 4 implies that $w(t)$ is increasing at $t = t_i$. In the same way, $Z(x(t_i), y(t_i)) \leq 0$ if there is a turn from vertical to horizontal at t_i.

Proof. Part (i) was already established by Anderson and Philpott [1]. We will prove part (ii); part (iii) follows in exactly the same way. For the sake of contradiction, assume that (2) does not hold and $\mathbf{s}$ is horizontal on (t_{i-1}, t_i) but not horizontal on (t_i, t_{i+1}). Let $\delta > 0$ be sufficiently small, and consider a vertical perturbation of $\mathbf{s}$ by an amount δ between t_{i-1} and t_i. We can make this explicit as follows. Define $t_i(+\delta) = y^{-1}(y(t_i) + \delta)$, and let

$$\tilde{\mathbf{s}}(t) = \begin{cases} (x(t), y(t)), & t \leq t_{i-1}, \\ (x(t_{i-1}), t - t_{i-1} + y(t_{i-1})), & t_{i-1} \leq t \leq t_{i-1} + \delta, \\ (x(t-\delta), y(t_{i-1}) + \delta), & t_{i-1} + \delta \leq t \leq t_i(+\delta) + \delta, \\ (x(t-\delta), y(t-\delta)), & t_i(+\delta) + \delta \leq t \leq T + \delta, \end{cases}$$

be a perturbation of $\mathbf{s}$. This is illustrated in Figure 1. For $0 \leq \tau \leq \delta$, we consider the line integral

$$I(\tau) = \int_{x(t_{i-1})}^{x(t_i)} Z(x, y(t_i) + \tau)dx.$$

Let $\epsilon > 0$ be such that $\int_{x(t_{i-1})}^{x(t_i)} Z_p(x, y(t_i))dx < -\epsilon < 0$. By Assumption 1, for τ sufficiently small and $x \in [x(t_{i-1}), x(t_i)]$,

$$Z(x, y(t_i) + \tau) \leq Z(x, y(t_i)) + Z_p(x, y(t_i))\tau + \frac{\tau\epsilon}{x(t_i) - x(t_{i-1})}.$$

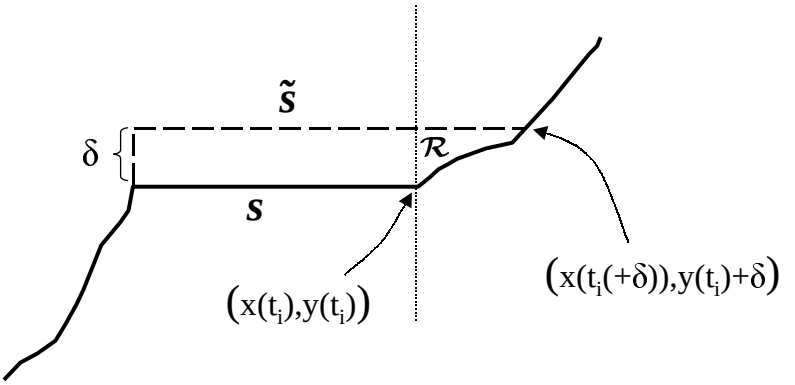

FIG. 1. *Perturbation of a horizontal section of* **s**.

Thus

$$I(\tau) \le w(t_i) - w(t_{i-1}) + \tau \int_{x(t_{i-1})}^{x(t_i)} Z_p(x, y(t_i))dx + \tau\epsilon.$$

Consequently, we have, for all τ, $I(\tau) < 0$ when δ is sufficiently small. The area integral of Z over the region surrounded by $\mathbf{s}$, $\tilde{\mathbf{s}}$, $x = x(t_{i-1})$, and $x = x(t_i)$ can be written as $\int_0^\delta I(\tau)d\tau$, which is not larger than $\frac{\delta^2}{2}[\int_{x(t_{i-1})}^{x(t_i)} Z_p(x, y(t_i))dx + \epsilon]$.

Now we need to consider the region, namely, $\mathcal{R}$, to the right of $x = x(t_i)$ surrounded by $\mathbf{s}$ and $\tilde{\mathbf{s}}$. This area exists only when $\mathbf{s}$ is strictly increasing in each component on the interval (t_i, t_{i+1}). In this case, the area is of order $o(\delta)$. On the other hand, since $Z(x(t), y(t)) = 0$ along the lower boundary of the region,

$$Z(x(t), y(t_i) + \tau) = Z_p(x(t), y(t))(y(t_i) + \tau - y(t)) + o(\tau) < Z_p(x(t), y(t))\tau + o(\tau)$$

for all $t_i \le t \le t_i(+\delta)$, $0 \le \tau \le \delta$, such that $(x(t), y(t_i) + \tau) \in \mathcal{R}$. Note that Z_p is continuous, and the distance between any point $(x, y) \in \mathcal{R}$ and $(x(t_i), y(t_i))$ tends to 0 as $\delta \to 0$. Consequently, the integral of Z over $\mathcal{R}$ is at most of order $o(\delta^2)$. Thus we have

$$v(\mathbf{s}) - v(\tilde{\mathbf{s}}) \le \int_0^\delta I(\tau)d\tau + o(\delta^2) = \frac{\delta^2}{2} \int_{x(t_{i-1})}^{x(t_i)} Z_p(x, y(t_i))dx + \frac{\delta^2}{2}\epsilon + o(\delta^2)$$

for δ small enough. From the choice of ϵ, this contradicts the optimality of $\mathbf{s}$ for δ small enough.

In the case that $\mathbf{s}$ is not horizontal on (t_{i-2}, t_{i-1}), we can obtain the same result by considering a vertical perturbation of $\mathbf{s}$ between t_{i-1} and t_i downward by an amount δ.

Now suppose that t_i is a corner where $\mathbf{s}$ turns from horizontal to vertical. We will assume that (3) does not hold and derive a contradiction. Let η be a scalar such that

$$(6)\quad \int_{x(t_{i-1})}^{x(t_i)} Z_p(x, y(t_i))dx - \int_{y(t_i)}^{y(t_{i+1})} Z_q(x(t_i), y)dy - 2Z(x(t_i), y(t_i)) < -2\eta < 0.$$

We consider a perturbation that moves the horizontal section between t_{i-1} and t_i upward by a small amount δ and the vertical section between t_i and t_{i+1} to the

left by the same amount δ. We can make this explicit as follows. Define $t_i(-\delta) = x^{-1}(x(t_i) - \delta)$, and let

$$\tilde{\mathbf{s}}(t) = \begin{cases} (x(t), y(t)), & t \le t_{i-1}, \\ (x(t_{i-1}), t - t_{i-1} + y(t_{i-1})), & t_{i-1} \le t \le t_{i-1} + \delta, \\ (x(t-\delta), y(t_{i-1}) + \delta), & t_{i-1} + \delta \le t \le t_i(-\delta) + \delta, \\ (x(t_i) - \delta, y(t + k - \delta)), & t_i(-\delta) + \delta \le t \le t_{i+1} - k + \delta, \\ (x(t_{i+1}) + t - 2\delta + k - t_{i+1}, y(t_{i+1})), & t_{i+1} - k + \delta \le t \le t_{i+1} - k + 2\delta, \\ (x(t + k - 2\delta), y(t + k - 2\delta))), & t_{i+1} - k + 2\delta \le t \le T - k + 2\delta, \end{cases}$$

be a perturbation of $\mathbf{s}$, where $k = t_i(+\delta) - t_i(-\delta)$.

First observe that

$$\begin{aligned} w(t_i(-\tau)) - w(t_i(+\tau)) &= -\int_{x(t_i)-\tau}^{x(t_i)} Z(x, y(t_i))dx - \int_{y(t_i)}^{y(t_i)+\tau} Z(x(t_i), y)dy \\ &\le -2\tau Z(x(t_i), y(t_i)) + \eta\tau/2 \end{aligned} \tag{7}$$

for τ sufficiently small, using the mean value theorem and the continuity of Z. On the other hand, under Assumption 1, for the given η, there exists $\delta > 0$ sufficiently small such that, for $0 < \tau \le \delta$, the line integral

$$\begin{aligned} I(\tau) &\equiv \int_{x(t_{i-1})}^{x(t_i)-\tau} Z(x, y(t_i) + \tau)dx + \int_{y(t_i)+\tau}^{y(t_{i+1})} Z(x(t_i) - \tau, y)dy \\ &\le w(t_i(-\tau)) - w(t_{i-1}) + w(t_{i+1}) - w(t_i(+\tau)) \\ &\quad + \tau \int_{x(t_{i-1})}^{x(t_i)-\tau} Z_p(x, y(t_i))dx - \tau \int_{y(t_i)+\tau}^{y(t_{i+1})} Z_q(x(t_i), y)dy + \eta\tau/2. \end{aligned} \tag{8}$$

Since Z_p and Z_q are continuous, it follows from (6) that, for δ sufficiently small and $\tau \le \delta$,

$$\int_{x(t_{i-1})}^{x(t_i)-\tau} Z_p(x, y(t_i))dx - \int_{y(t_i)+\tau}^{y(t_{i+1})} Z_q(x(t_i), y)dy - 2Z(x(t_i), y(t_i)) < -\eta. \tag{9}$$

Combining (7)–(9) and noticing that $w(t_{i-1}) = w(t_{i+1}) = w_0$, we have $I(\tau) < 0$ for δ sufficiently small and all $0 \le \tau \le \delta$.

Now the area integral of Z over the region surrounded by $\mathbf{s}$ and $\tilde{\mathbf{s}}$ can be written as $\int_0^\delta I(\tau)d\tau$ and hence is strictly negative. Thus we have constructed a perturbed curve which leads to a larger value for v, which is a contradiction. This completes the proof. □

4. Sufficient conditions. In this section, we discuss sufficient conditions for an offer curve $\mathbf{s}$ to be locally optimal. This involves a more complex set of conditions than were required for the necessary conditions. To establish this result, we will have to consider all possible monotonic perturbations around the offer curve $\mathbf{s}$. As we shall see, considerable care is needed in the argument required to prove this result.

THEOREM 6. *Let $\mathbf{s} = \{x(t), y(t), 0 \le t \le T\}$ be an increasing and continuous offer stack. Suppose that there exist finite numbers $0 = t_0 < t_1 < t_2 < \cdots < t_M = T$ such that, for $i = 1, \ldots, M-1$, $w(t_i)$ takes a common value, say, w_0, and on each*

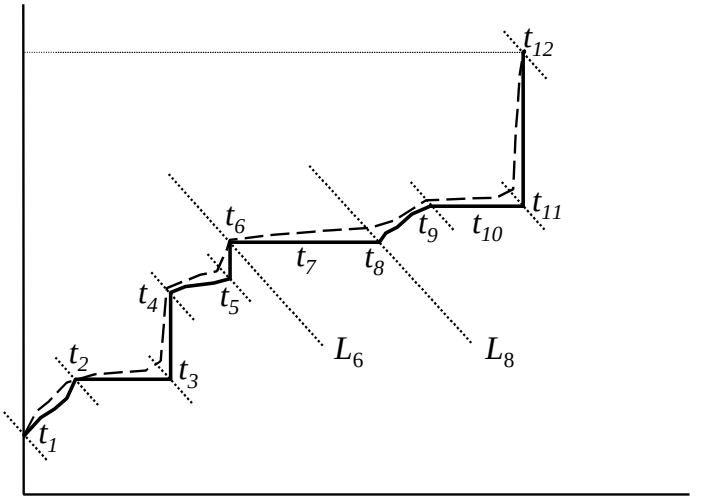

FIG. 2. *Area of perturbation split into subregions.*

section (t_{i-1}, t_i), $i = 1, \ldots, M$, $\mathbf{s}$ *is either strictly increasing in both components or horizontal or vertical. Suppose also that Assumption* 1 *and the following hold:*

(i) *if* $\mathbf{s}$ *is increasing in both components on* (t_{i-1}, t_i), *then, for* $t \in (t_{i-1}, t_i)$, $Z(x(t), y(t)) = 0$, $Z_p(x(t), y(t)) > 0$, *and* $Z_q(x(t), y(t)) < 0$;

(ii) *if* $\mathbf{s}$ *is horizontal on* (t_{i-1}, t_i), *then, for* $t \in (t_{i-1}, t_i)$, $w(t) < w_0$; *moreover, for any* $j < k$ *such that* $\mathbf{s}$ *is horizontal from* t_j *to* t_k *with at least one of* t_j *and* t_k *a turning point,*

$$\int_{x(t_j)}^{x(t_k)} Z_p(x, y(t_j))dx > Z(x(t_k), y(t_k)) - Z(x(t_j), y(t_j)); \tag{10}$$

(iii) *if* $\mathbf{s}$ *is vertical on* (t_{i-1}, t_i), *then, for* $t \in (t_{i-1}, t_i)$, $w(t) > w_0$; *moreover, for any* $j < k$ *such that* $\mathbf{s}$ *is vertical from* t_j *to* t_k *with at least one of* t_j *and* t_k *a turning point,*

$$\int_{y(t_j)}^{y(t_k)} Z_q(x(t_j), y)dy < Z(x(t_k), y(t_k)) - Z(x(t_j), y(t_j)); \tag{11}$$

(iv) *if* $(x(t_i), y(t_i))$ *is a point where the curve turns from horizontal to vertical, then either* $Z(x(t_i), y(t_i)) > 0$ *or* $Z(x(t_i), y(t_i)) = 0$ *and* $Z_p(x(t_i), y(t_i)) > 0$, $Z_q(x(t_i), y(t_i)) < 0$; *if* $(x(t_i), y(t_i))$ *is a point where the curve turns from vertical to horizontal, then either* $Z(x(t_i), y(t_i)) < 0$ *or* $Z(x(t_i), y(t_i)) = 0$ *and* $Z_p(x(t_i), y(t_i)) > 0$, $Z_q(x(t_i), y(t_i)) < 0$.

Then s *is a locally optimal offer stack.*

Proof. In order to prove that $\mathbf{s}$ is locally optimal, it suffices to prove that, for any local perturbation $\tilde{\mathbf{s}}$ which is sufficiently close to $\mathbf{s}$, $v(\tilde{\mathbf{s}}) < v(\mathbf{s})$. By Green's theorem, this is equivalent to proving that the area integral of Z over any region surrounded by $\tilde{\mathbf{s}}$ and $\mathbf{s}$ is positive if the region is above or to the left of the curve $\mathbf{s}$ and negative if under or to the right of $\mathbf{s}$. We discuss only the case that the perturbed region is above or to the left of the curve $\mathbf{s}$, and the other case can be dealt with similarly.

We define a line $y = y(t_i) - (x - x(t_i))$ at every turning point and call this line L_i. Figure 2 illustrates this with $\mathbf{s}$ shown bold and $\tilde{\mathbf{s}}$ as a dashed line. Assume the

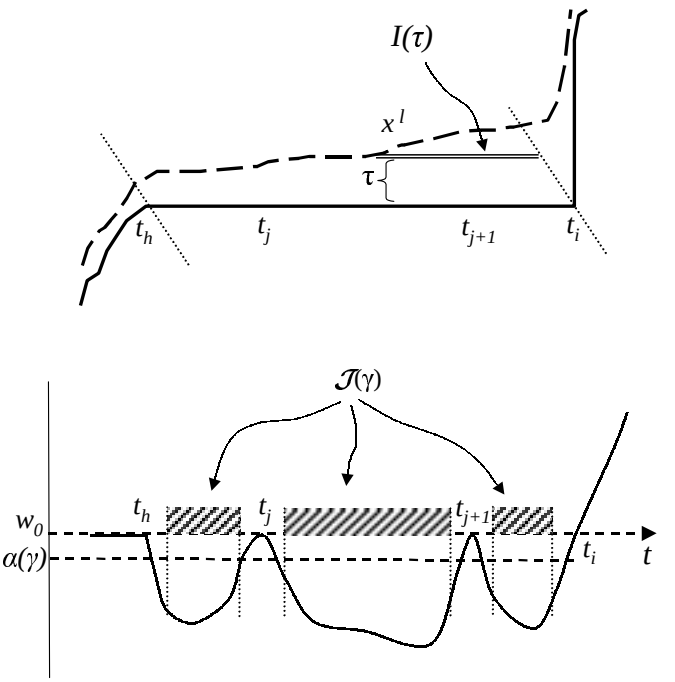

FIG. 3. *Comparison between* w *and* $\mathbf{s}$.

maximum distance between $\mathbf{s}$ and $\tilde{\mathbf{s}}$ is no larger than δ_0. The idea of the proof is to deal separately with different parts of the region between $\mathbf{s}$ and $\tilde{\mathbf{s}}$. In fact, we divide this region into subregions using the lines L_i and show that the area integral of Z is positive over each nonempty subregion. To accomplish this, we will consider integrals along horizontal (or vertical) segments with an end point on one of the lines L_i and show that each of these has positive value. One of these integrals $I(\tau)$ is illustrated in Figure 3. Since the perturbation is monotonic, the horizontal line segments will finish on an L_i, while the vertical line segments will start on an L_i.

Suppose first that $\mathbf{s}$ is strictly increasing in both components on (t_{i-1}, t_i). By assumption (i), it is easy to verify that $Z(x, y) > 0$ for any (x, y) within the region surrounded by $\mathbf{s}$, $\tilde{\mathbf{s}}$, and lines L_{i-1} and L_i provided δ_0 is chosen small enough. Consequently, the area integral of Z over the region surrounded by $\mathbf{s}$, $\tilde{\mathbf{s}}$, and these lines, if not empty, is positive.

Now we turn to the central part of the proof, and we consider the case that $\mathbf{s}$ is horizontal between t_h and t_i, and $(x(t_h), y(t_h))$ and $(x(t_i), y(t_i))$ are turning points. We observe first from (i) and (iv) that

$$Z(x(t_h), y(t_h)) \leq 0 \tag{12}$$

and

$$Z(x(t_i), y(t_i)) \geq 0. \tag{13}$$

We will need to keep track of the parameter t at points on $\mathbf{s}$ which are a distance γ to the right or left of one of the t_i values in this horizontal segment. We let $t_k(-\gamma)$ denote $x^{-1}(x(t_k) - \gamma)$ for $k = h + 1, \ldots, i$, and $t_j(+\gamma) = x^{-1}(x(t_j) + \gamma)$ for $j = h, \ldots, i - 1$.

The proof proceeds in two major steps. In step 1, we construct a value of δ sufficiently small for the $I(\tau)$ integrals to be positive when $\delta_0 < \delta$; then, in step 2, we demonstrate this inequality.

Step 1. To define δ appropriately, we need first to define some intermediate quantities γ and ϵ. Choose $\gamma > 0$ small enough so that, for all $x \in (x(t_i) - \gamma, x(t_i))$,

$$Z(x, y(t_i)) > 0,\ Z_p(x, y(t_i)) > 0, \tag{14}$$

and for $x^u \in [x(t_i) - \gamma, x(t_i)]$, $x^l \in [x(t_j) - \gamma, x(t_j) + \gamma]$, $j = h+1, \ldots, i-1$,

$$\int_{x^l}^{x^u} Z_p(x, y(t_i))dx - Z(x(t_i), y(t_i)) > 0, \tag{15}$$

and for $x^l \in [x(t_h), x(t_h) + \gamma]$,

$$\int_{x^l}^{x^u} Z_p(x, y(t_i))dx + Z(x(t_h), y(t_h)) - Z(x(t_i), y(t_i)) > 0. \tag{16}$$

The existence of a γ satisfying (14) is guaranteed by conditions (i) and (iv) and (13), while the existence of a γ satisfying (15) and (16) follows from (10) after observing that $Z(x(t_j), y(t_j)) = 0$ since $w(t_j)$ is a local maximum of $w(\cdot)$ for $j = h+1, \ldots, i-1$.

Given such a γ, choose $\epsilon > 0$ small enough so that

$$w_0 - \alpha(\gamma) > \epsilon,$$

where

$$\alpha(\gamma) = \sup_{x(t) \in \mathcal{J}(\gamma)} w(t),$$

and

$$\mathcal{J}(\gamma) = \bigcup_{h \le j \le i-1} [x(t_j) + \gamma, x(t_{j+1}) - \gamma];$$

and for $x^u \in [x(t_i) - \gamma, x(t_i)]$, $x^l \in [x(t_j) - \gamma, x(t_j) + \gamma]$, $j = h+1, \ldots, i-1$,

$$\int_{x^l}^{x^u} Z_p(x, y(t_i))dx - Z(x(t_i), y(t_i)) > 2\epsilon, \tag{17}$$

and for $x^l \in [x(t_h), x(t_h) + \gamma]$,

$$\int_{x^l}^{x^u} Z_p(x, y(t_i))dx + Z(x(t_h), y(t_h)) - Z(x(t_i), y(t_i)) > 3\epsilon. \tag{18}$$

The definitions of $\alpha(\gamma)$ and $\mathcal{J}(\gamma)$ are illustrated in Figure 3.

Having chosen ϵ and γ, now let $\delta > 0$ be chosen small enough such that the following six conditions (a)–(f) hold.

(a)

$$\delta < \frac{1}{2\epsilon} \left(w_0 - \alpha(\gamma) - \epsilon \right). \tag{19}$$

(b) For $x^l \in \mathcal{J}(\gamma)$ and $x^u \in [x(t_i) - \gamma, x(t_i)]$,

$$\delta \left| \int_{x^l}^{x^u} Z_p(x, y(t_i))dx - Z(x(t_i), y(t_i)) \right| < \epsilon. \tag{20}$$

This follows from the fact that Z_p is continuous.

(c) For $0 \le \tau \le \delta$,

$$w_0 - w(t_i(-\tau)) \le \tau Z(x(t_i), y(t_i)) + \epsilon\tau. \tag{21}$$

This can be proved using continuity of Z and the mean value theorem.

(d) For $0 \le \tau \le \delta$ and $t \in [t_h, t_i]$,

$$Z(x(t), y(t_i) + \tau) \ge Z(x(t), y(t_i)) + Z_p(x(t), y(t_i))\tau - \frac{\epsilon\tau}{(x(t_i) - x(t_h))}. \tag{22}$$

This follows from Assumption 1.

(e) For $x \in (x(t_i) - \gamma, x(t_i))$, $0 \le \tau \le \delta$,

$$Z(x, y(t_i) + \tau) > 0. \tag{23}$$

This follows from (14) and Assumption 1.

(f) For $0 \le \tau_1, \tau_2 \le \delta$,

$$Z(x(t_h) - \tau_1, y(t_h) + \tau_2) > Z(x(t_h), y(t_h)) - \epsilon. \tag{24}$$

This follows from the continuity of Z.

Step 2. For $0 < \tau \le \delta$, we consider the integral

$$I(\tau) = \int_{x^l}^{x(t_i)-\tau} Z(x, y(t_i) + \tau)dx.$$

We shall prove that $I(\tau) > 0$ for all $x^l \in [x(t_h) - \tau, x(t_i) - \tau]$. To do this, we need to consider four cases depending on the position of x^l. When $x^l \in \mathcal{J}(\gamma)$, we will show that the value of the integral $I(\tau)$ is dominated by $I(0)$, which is a similar integral of Z but shifted down by an amount τ. Now $I(0) = w_0 - w(x^l, y(t_i))$, which is positive. However, when x^l is near t_h, t_i, or one of the intermediate t_j, then $I(0)$ is near zero, and we need to consider more precisely the difference between $I(\tau)$ and $I(0)$. This difference will be determined by the integral of Z_p along the line segment.

Suppose first that $x^l \ge x(t_h)$. By (22), we have

$$I(\tau) \ge w(x(t_i) - \tau, y(t_i)) - w(x^l, y(t_i)) + \tau \int_{x^l}^{x(t_i)-\tau} Z_p(x, y(t_i))dx - \epsilon\tau. \tag{25}$$

Case A. For $x^l \in [x(t_h), x(t_i) - \gamma] \backslash \mathcal{J}(\gamma)$, since $w(x^l, y(t_i)) \le w(x(t_i), y(t_i)) = w_0$, it follows from (21) and (25) that

$$I(\tau) \ge \tau \left(\int_{x^l}^{x(t_i)-\tau} Z_p(x, y(t_i))dx - Z(x(t_i), y(t_i)) \right) - 2\epsilon\tau. \tag{26}$$

Thus (using (17), (18), and (12)), $I(\tau) > 0$.

Case B. For $x^l \in \mathcal{J}(\gamma)$, combining (19), (20), (21), and (25), we have

$$\begin{aligned} I(\tau) &\geq w_0 - \alpha(\gamma) + \tau \left(\int_{x^l}^{x(t_i)-\tau} Z_p(x, y(t_i))dx - Z(x(t_i), y(t_i)) \right) - 2\epsilon\tau \\ &\geq w_0 - \alpha(\gamma) - \epsilon - 2\tau\epsilon \\ &> 0. \end{aligned}$$

Case C. For $x^l \in [x(t_i) - \gamma, x(t_i) - \tau]$, $0 \leq \tau \leq \delta$, it follows immediately from (23) that $I(\tau)$ is positive.

Case D. For $x^l < x(t_h)$, we must have $x^l \in [x(t_h) - \tau, x(t_h)]$, $0 \leq \tau \leq \delta$, and

$$I(\tau) = \int_{x^l}^{x(t_h)} Z(x, y(t_i) + \tau)dx + \int_{x(t_h)}^{x(t_i)-\tau} Z(x, y(t_i) + \tau)dx.$$

By (26),

$$\int_{x(t_h)}^{x(t_i)-\tau} Z(x, y(t_i) + \tau)dx \geq \tau \left(\int_{x(t_h)}^{x(t_i)-\tau} Z_p(x, y(t_i))dx - Z(x(t_i), y(t_i)) \right) - 2\epsilon\tau.$$

On the other hand, it follows from (24) that

$$\int_{x^l}^{x(t_h)} Z(x, y(t_i) + \tau)dx \geq (Z(x(t_h), y(t_h)) - \epsilon)\tau.$$

Thus

$$I(\tau) \geq \tau \left(\int_{x(t_h)}^{x(t_i)-\tau} Z_p(x, y(t_i))dx - Z(x(t_i), y(t_i)) + Z(x(t_h), y(t_h)) - 3\epsilon \right) > 0.$$

The last inequality is due to (18).

Now that we have established that $I(\tau)$ is positive, we are almost done. Let $\mathcal{L}$ be any horizontal line segment with a distance less than δ_0 above $\mathbf{s}$ and lying between the lines L_h and L_i, and with its right-hand end on the line L_i. The above discussion shows that, when $\delta_0 \leq \delta$, the line integral of Z along $\mathcal{L}$ is positive. Let $\tilde{\mathcal{R}}$ denote the region surrounded by $\tilde{\mathbf{s}}$, $\mathbf{s}$, L_h, and L_i. Since $\tilde{\mathbf{s}}$ is monotonic increasing and the maximum distance between $\tilde{\mathbf{s}}$ and $\mathbf{s}$ is not larger than δ_0, any intersection of a horizontal line and $\tilde{\mathcal{R}}$ will take the form $\mathcal{L}$. This implies that the area integral of Z over $\tilde{\mathcal{R}}$ is positive.

The argument for a vertical section is similar, but the integral $I(\tau)$ takes the form

$$I(\tau) = \int_{y(t_i)+\tau}^{y^u} Z(x(t_i) - \tau, y)dy.$$

This completes the proof. □

The conditions of Theorem 6 are stronger than the necessary conditions of Theorems 4 and 5, and it is worth discussing the differences. First observe that the necessary conditions of Theorem 4 (i) and Theorem 5 (i) carry over as we would expect after a change to strict inequalities for Z_p and Z_q.

When we come to consider conditions (ii) and (iii) of Theorems 4 and 5, the position is more complex. We replace the condition $w(t) \leq w(t_1)$ on a horizontal

section with the condition $w(t) < w(t_1)$ except at identified points among the t_j, $j = 1, \ldots,$ where $w(t_j) = w(t_1)$. The same thing happens on a vertical section. However, there is no direct equivalence of conditions (3) and (5) (though these inequalities can be derived from adding (10) and (11) in an appropriate way). Consider the inequality (10). As we have already observed, $Z(x(t_k), y(t_k)) \geq 0$, and $Z(x(t_j), y(t_j)) \leq 0$. So inequality (10) is strictly stronger than inequality (2). Similarly, inequality (11) is stronger than inequality (4).

Condition (iv) of Theorem 6 strengthens the inequality $Z(x(t_i), y(t_i)) \geq 0$ (or $Z(x(t_i), y(t_i)) \leq 0$), which can be derived from the necessary conditions at a turning point from horizontal to vertical (or vertical to horizontal).

5. An example. To illustrate the application of these necessary and sufficient conditions, we consider a small example based on one given in [1]. We define the market distribution function ψ via an intermediate function ϕ, which is defined as

$$\phi(q,p) = ((q-p)^2 - 1)((q-p)^2 - 0.7) - 1.59p^2 - 1.11q^2.$$

Then we set $\psi\,(q,p) = pq + 0.045\phi(q,p) - 0.1$. We suppose that the cost function is given by the quadratic $C(q) = 0.08q^2$. We also suppose that the generator has a two-way hedging contract for a quantity 0.15 and thus makes payments under these contracts of $0.15(f-p)$ where f is the contract price. Since f is fixed, we can ignore this term in seeking an optimal solution, and so we can take the profit function as $R(q,p) = (q - 0.15)p - C(q)$.

The first step in understanding the behavior of this example is to look at the values of the function Z over the region Ψ. This is shown in Figure 4, where the dashed lines show that $Z = 0$ and divide Ψ into regions where Z is either positive or negative. Also shown in the figure are three solid lines AB, CD, and EF, which connect the lower boundary of Ψ, $\psi = 0$, with its upper boundary, $\psi = 1$. These are candidate offer curves. AB runs along a $Z = 0$ line, and EF runs along another $Z = 0$ line for most of its length. It is clear that AB will satisfy all of the conditions used in this paper and is a local optimum, but the position is less clear for the other two curves.

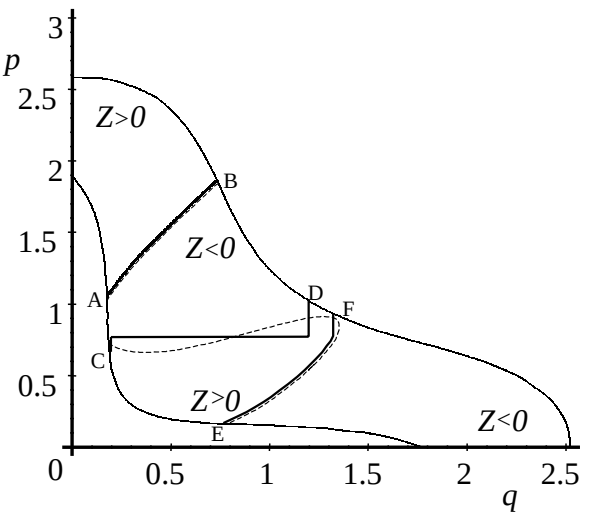

FIG. 4. *Candidate supply curves for the example.*

First we look at the CD offer curve. This starts with a vertical section from $(0.1858, 0.68244)$ to $(0.1858, 0.75685)$, then has a horizontal section to the point $(1.1972, 0.75685)$, and then finishes with a vertical section to hit the boundary of Ψ at the point $(1.1972, 1.0245)$. These points have been chosen so that the solution satisfies all of the conditions of Theorem 4. Each of the three sections has the property that the integral of Z along the section is zero, which is what is required for w to take the same value w_0 at the endpoints of each section. Moreover, the fact that the two vertical sections move from $Z > 0$ to $Z < 0$, while the horizontal section does the reverse, will ensure that w is no less than w_0 on the vertical sections and no more than w_0 on the horizontal section. Once it is decided to search for an offer curve of this general form, these conditions can be used to find the exact curve. Starting from different points on the $\psi = 0$ curve, we can let the w condition determine when to switch from vertical to horizontal and then back to vertical. We then iterate amongst possible starting positions to search for a solution which achieves a zero Z integral on the final vertical section; i.e., it makes $w = w_0$ at the point where the vertical section crosses the $\psi = 1$ curve. (All of the numerical calculations for this example were performed using Maple.)

The next step is to check the second order conditions of Theorem 5. We require that the integral of Z_q on the first vertical section be no greater than zero, and, in fact,

$$\int_{0.68244}^{0.75685} Z_q(0.1858, y)dy = -5.408 \times 10^{-3},$$

so this condition is satisfied. We also require that the integral of Z_p along the horizontal section be no less than zero, but

$$\int_{0.1858}^{1.1972} Z_p(x, 0.75685)dx = -0.16526,$$

so this condition fails. Moreover, the integral of Z_q on the last vertical section is greater than zero so that this condition fails as well. Finally, both the conditions (3) and (5) involving the value of Z at the corner points fail. So we know from the theorem that this solution is not a local optimum.

Next we consider the EF solution. The final vertical section of this is chosen in such a way that the integral of Z on this vertical section is zero. It starts at the point $(1.365, 0.82561)$ and moves vertically until meeting the $\psi = 1$ boundary at $(1.365, 0.90056)$ Since the rest of the curve is on the $Z = 0$ curve, the conditions of Anderson and Philpott will be satisfied. We check the conditions of Theorem 5. We have

$$\int_{0.82561}^{0.90056} Z_q(1.365, y)dy = -9.4287 \times 10^{-3} < 0$$

as required.

The next step is to check the sufficient conditions of Theorem 6. Most of the conditions of this theorem will hold trivially, but we need to check that

$$\int_{0.82561}^{0.90056} Z_q(1.365, y)dy < Z(1.365, 0.90056) - Z(1.365, 0.82561).$$

Now $Z(1.365, 0.82561) = 0$, and $Z(1.365, 0.90056) = -1.3136 \times 10^{-3}$, so this condition will hold.

Hence both the curves AB and EF are locally optimal: to choose between them, we must evaluate the objective function for each. In fact, the objective function value along the curve AB is 0.5183, while the value along EF is 0.4857. So the curve AB is the (global) optimum for this problem.

AN OPTIMAL CONTROL PROBLEM GOVERNED BY QUASI-LINEAR VARIATIONAL INEQUALITIES*

HONGWEI LOU†

Abstract. An optimal control problem governed by quasi-linear variational inequality is considered. The cost functional to be minimized contains the solution of a quasi-linear variational inequality. To get the existence, regularity, and necessary condition for the optimal pair, a new related control problem is introduced. By proving the existence of an optimal pair to such a new problem, the existence and regularity of the optimal pair to the original problem are obtained. It turns out that the regularity obtained is sharp in general. Some necessary conditions of the optimal pair are also obtained.

Key words. optimal control, quasi-linear, variational inequality, existence, regularity, necessary condition

1. Introduction.

In this paper, we consider the following optimal control problem.

Problem (C). Find a $\bar{y} \in W_0^{1,p}(\Omega)$ such that

$$I(\bar{y}) = \inf_{y \in W_0^{1,p}(\Omega)} I(y), \tag{1.1}$$

where

$$I(y) = I(y; z, p, \Omega) \stackrel{\triangle}{=} \frac{1}{p} \int_\Omega \{|T(y) - z|^p + |\nabla y|^p\} dx, \quad y \in W_0^{1,p}(\Omega), \tag{1.2}$$

$1 < p < +\infty$, $\Omega \subset \mathbb{R}^n$ is a bounded domain with $C^{1,1}$ boundary $\partial\Omega$, $z \in L^p(\Omega)$ is a given target profile, y is a function in Sobolev space $W_0^{1,p}(\Omega)$, ∇y denotes its generalized gradient, and $\psi \equiv T(y)$ is the state corresponding to the control y satisfying the following quasi-linear variational inequality:

$$\begin{cases} \psi \in \mathbb{K}(y) \stackrel{\triangle}{=} \{\varphi \in W_0^{1,p}(\Omega) | \varphi \geq y, \text{ a.e. } \Omega\}, \\ \displaystyle\int_\Omega |\nabla\psi|^{p-2} \nabla\psi \cdot \nabla(\varphi - \psi) dx \geq 0 \quad \forall\, \varphi \in \mathbb{K}(y). \end{cases} \tag{1.3}$$

It is well known that for any $y \in W_0^{1,p}(\Omega)$, (1.3) admits a unique solution (see [5], [24], [25], for example) and ψ is the solution of (1.3) if and only if ψ minimizes the functional $\varphi \mapsto \int_\Omega |\nabla\varphi|^p dx$ over $\mathbb{K}(y)$. Moreover, replacing φ by $\psi + v$ in (1.3), we see that ψ satisfies

$$-\mathrm{div}(|\nabla\psi|^{p-2}\nabla\psi) \geq 0 \quad \text{in } \Omega \tag{1.4}$$

in the weak sense. We denote $\mathcal{H}_+^p(\Omega)$ to be the set of all $\psi \in W_0^{1,p}(\Omega)$ satisfying (1.4). Any $\psi \in \mathcal{H}_+^p(\Omega)$ is called a p-superharmonic function.

If one wants to design a membrane having an expected shape, one needs to choose a suitable obstacle. In this case, the obstacle can be looked at as a control, and the membrane can be looked at as the state. Then our aim is to find an optimal obstacle control minimizing some cost functional.

In the literature, many other authors have discussed similar problems concerning different aspects. See [3], [13], [14], [15], [16], [17], [18], [23], [28], for example. They considered optimal control problems for obstacle problems (or variational inequalities). Usually, the obstacle functions are fixed at 0, and the control variables appear in the variational inequality. In other words, controls do not change the obstacle. They change only the functional of obstacle problems. For general cases of the obstacle problem, when the obstacles are smooth enough, they can be reduced to the case of the obstacle being 0 by simple translations (see [30, Chap. 1]). Similarly, by suitable translations, we can reformulate most optimal control problems such that the controls change only the obstacles but not the functionals of the obstacle problems. In case an optimal control does not exist (or we do not know whether it exists or not), we can consider the problem with controls being in a larger space (see [4], for example) as we consider relaxed controls in existence theory of optimal control problems. In these cases, reformulating the obstacle problems and considering obstacles as controls (or depending on controls) will be more convenient.

In mathematical finance, the problem of American option pricing is an obstacle problem (see [20], [21], for example). Researching in optimal obstacle control is also useful in the theory of designing and pricing American-type contingent claims.

In case $p = 2$, the optimal obstacle control problem was studied by Adams, Lenhart, and Yong [1], Chen [8], [9], [10], and Lou [26]. The cases of $p \neq 2$ are related to the so-called non-Newtonian fluids. The quantity p is a characteristic of the medium. Media with $p > 2$ are called dilatant fluids and those with $p < 2$ are called pseudoplastics. For $p = 2$, they are Newtonian fluids (see [11]).

The main purpose of this paper is to establish the existence, regularity, and necessary condition of an optimal pair to Problem (C).

By the fact that an optimal control, if it exists, must be equal to the corresponding optimal state, we can see that finding an optimal pair $(\bar{y}, \bar{\psi})$ to Problem (C) is equivalent to finding a minimizer $\bar{y}$ such that (see the next section for details)

$$\tilde{I}(\bar{y}) = \inf_{y \in \mathcal{H}_+^p(\Omega)} \tilde{I}(y),$$

with

$$\tilde{I}(y) = \frac{1}{p} \int_\Omega \{|y - z|^p + |\nabla y|^p\} dx. \tag{1.5}$$

Thus, it is not very hard to prove that Problem (C) admits a unique optimal pair when $p = 2$. The cases of $p \neq 2$ are quite different. The difficulty is that when $p \neq 2$ and $n \neq 1$, $\mathcal{H}_+^p(\Omega)$ is not a convex set (and we do not know whether it is weakly closed in $W_0^{1,p}(\Omega)$). Thus the standard method of getting the existence of an optimal control is not valid. The main idea of getting the existence and regularity of an optimal pair is to establish the existence theorem for a new related control problem. More precisely, we introduce the following optimal control problem.

Problem (C*). Find a $\bar{u} \in L_+^{p'}(\Omega) \stackrel{\triangle}{=} \{v \in L^{p'}(\Omega) | v \geq 0, \text{ a.e. } \Omega\}$ such that

$$I^*(\bar{u}) = \inf_{u \in L_+^{p'}(\Omega)} I^*(u),$$

where $p' = \frac{p}{p-1}$,

$$I^*(u) = I^*(u; z, p, \Omega) \triangleq \frac{1}{p}\int_\Omega \{|T^*(u) - z|^p + uT^*(u)\}dx, \quad u \in L^{p'}(\Omega), \tag{1.6}$$

with $y \equiv T^*(u) \in W_0^{1,p}(\Omega)$ being the unique solution of the following equation:

$$\begin{cases} -\mathrm{div}(|\nabla y|^{p-2}\nabla y) = u \ \text{ in } \Omega, \\ y|_{\partial\Omega} = 0. \end{cases} \tag{1.7}$$

We will show that $\bar{u}$ is an optimal control to Problem (C*) if and only if $\bar{y} \equiv T^*(\bar{u})$ is an optimal control to Problem (C). Because of this fact, we are able to get $C^{1,\alpha}$-regularity of $\bar{y}$ by the results of [12]. Furthermore, it turns out that such a regularity is the best possible result in general.

The difficulty in getting the necessary condition of optimality $\bar{y}$ is to give a characterization of the singular set $\{x \in \Omega | \nabla\bar{y}(x) = 0\}$ of $\bar{y}$. Without a proper characterization to the singular set, the necessary condition of the optimal control is far from completely determining it. For some special cases, we do get characterizations of optimal controls.

Now we state our main results.

THEOREM 1.1. *Let $1 < p < +\infty$, $z \in L^p(\Omega)$. Then Problem* (C) *admits an optimal control.*

Theorem 1.1 is an existence theorem. The following theorem gives the regularity of an optimal control.

THEOREM 1.2. *Suppose $1 < p < +\infty$, $z \in L^p(\Omega)$, and $z^+ \in L^q(\Omega)$ for some $q \geq p$. Let $\bar{y}$ be an optimal control to Problem* (C). *Then there exists a $\bar{u} \in L_+^{\frac{q}{p-1}}(\Omega)$ such that*

$$\begin{cases} -\mathrm{div}(|\nabla\bar{y}|^{p-2}\nabla\bar{y}) = \bar{u} \ \ \textit{in } \Omega, \\ \bar{y}|_{\partial\Omega} = 0. \end{cases} \tag{1.8}$$

Consequently, if $q > pn$, then $\bar{y} \in C^{1,\alpha}(\bar{\Omega})$ for some $\alpha \in (0,1)$.

In this paper, for $1 \leq q \leq +\infty$, we denote

$$L_+^q(\Omega) \triangleq \{v \in L^q(\Omega) | v \geq 0, \text{ a.e. } \Omega\}. \tag{1.9}$$

For $1 < p < +\infty$, $\varepsilon \geq 0$, $y \in W_0^{1,p}(\Omega)$, define operator $\mathbf{L}$ by

$$\begin{aligned} \mathbf{L}(\varphi; y, p, \varepsilon) \triangleq & -\mathrm{div}[(\varepsilon^2 + |\nabla y|^2)^{\frac{p-2}{2}}\nabla\varphi] \\ & -(p-2)\mathrm{div}[(\varepsilon^2 + |\nabla y|^2)^{\frac{p-4}{2}}(\nabla y \cdot \nabla\varphi)\nabla y] \end{aligned} \tag{1.10}$$

and denote

$$\begin{aligned} \mathbf{L}(\varphi; y, p) \triangleq & \mathbf{L}(\varphi; y, p, 0) \equiv -\mathrm{div}(|\nabla y|^{p-2}\nabla\varphi) \\ & -(p-2)\mathrm{div}[|\nabla y|^{p-4}(\nabla y \cdot \nabla\varphi)\nabla y]. \end{aligned} \tag{1.11}$$

For $\varphi \in W_0^{1,p}(\Omega)$ and $\mu \in W^{-1,p'}(\Omega)$, we always write $\langle \mu, \varphi \rangle$ in the integral form $\int_\Omega \mu\varphi \, dx$.

The positive part and the negative part of a function f will be denoted by f^+, f^-, respectively, i.e., $f^+ = \max(f, 0)$, $f^- = \max(-f, 0)$.

When the domain Ω is clear from the context, the sets $\{x \in \Omega | f(x) < 0\}$ and $\{x \in \Omega | f(x) = 0\}$ will be denoted by $\{f < 0\}$ and $\{f = 0\}$, respectively. The characteristic function of E will be denoted by χ_E. Hereafter, by a solution of a differential equation we mean a weak solution.

The rest of the paper is organized as follows. In section 2, we will transform the original problem to a new related problem. In section 3, we will introduce an approximate problem and give estimates of optimal pairs for the approximate problem. In section 4, we use the results obtained in section 3 to obtain the existence and regularity of the solution to the original problem. An example is presented to show that such regularity is the best possible in general. Finally, in section 5, necessary conditions of optimality in some special cases are derived.

2. Transformation of the problem. As is in the case of $p = 2$ (see [1]), we will prove that if $\bar{y}$ minimizes $I(\cdot)$, then $T(\bar{y})$ must be equal to $\bar{y}$. To see this, let us introduce the following lemma, which will reveal some basic properties of the operator T.

LEMMA 2.1. *Given $1 < p < +\infty$.*

(i) *Suppose $y \in W_0^{1,p}(\Omega)$. Then $T(y) = y$ if and only if $y \in \mathcal{H}_+^p(\Omega)$.*

(ii) $T^2(y) = T(y)$ $\forall y \in W_0^{1,p}(\Omega)$.

(iii) $T[W_0^{1,p}(\Omega)] = \mathcal{H}_+^p(\Omega)$.

Proof. (i) Let $y \in W_0^{1,p}(\Omega)$ satisfy $T(y) = y$. Then by the definition of T, we have $y = T(y) \in \mathcal{H}_+^p(\Omega)$.

On the other hand, let $y \in \mathcal{H}_+^p(\Omega)$. Noting that for any $v \in \mathbb{K}(y)$, we have $v - y \in W_0^{1,p}(\Omega)$ and $v - y \geq 0$, a.e. Ω, thus, it follows that

$$\int_\Omega |\nabla y|^{p-2} \nabla y \cdot \nabla (v - y) dx \geq 0 \quad \forall v \in \mathbb{K}(y).$$

Consequently, $T(y) = y$ by the definition.

(ii) Let $y \in W_0^{1,p}(\Omega)$. We have $T(y) \in \mathcal{H}_+^p(\Omega)$. Consequently, $T^2(y) = T(y)$ by (i).

(iii) First, $T[W_0^{1,p}(\Omega)] \subseteq \mathcal{H}_+^p(\Omega)$. Next, by (i), we have

$$\mathcal{H}_+^p(\Omega) = T[\mathcal{H}_+^p(\Omega)] \subseteq T[W_0^{1,p}(\Omega)],$$

proving the result. □

Now we can establish the following proposition, which shows that an optimal control to Problem (C) must be equal to the corresponding optimal state.

PROPOSITION 2.2. *Given $1 < p < +\infty$, $z \in L^p(\Omega)$, suppose $\bar{y}$ is an optimal control to Problem* (C)*. Then $T(\bar{y}) = \bar{y}$. Consequently, $\bar{y}$ is an optimal control to Problem* (C) *if and only if $\bar{y}$ minimizes $\tilde{I}(\cdot)$ over $\mathcal{H}_+^p(\Omega)$ (see* (1.5) *for the definition of $\tilde{I}(\cdot)$).*

Proof. By the definition of $\bar{y}$, we have

$$\int_\Omega \{|T(\bar{y}) - z|^p + |\nabla \bar{y}|^p\} dx \leq \int_\Omega \{|T(y) - z|^p + |\nabla y|^p\} dx \quad \forall\, y \in W_0^{1,p}(\Omega).$$

Let $y = T(\bar{y})$. By Lemma 2.1, $T(y) = T(\bar{y})$. Therefore

$$\int_\Omega \{|T(\bar{y}) - z|^p + |\nabla \bar{y}|^p\} dx \leq \int_\Omega \{|T(\bar{y}) - z|^p + |\nabla [T(\bar{y})]|^p\} dx.$$

Thus

$$\int_\Omega |\nabla \bar{y}|^p dx \le \int_\Omega |\nabla (T(\bar{y}))|^p dx \le \int_\Omega |\nabla \varphi|^p dx \quad \forall\ \varphi \in \mathbb{K}(\bar{y}).$$

That is, $T(\bar{y}) = \bar{y}$. □

From (1.2), (1.5), and Lemma 2.1, we see that

$$\tilde{I}(y) = I(y) \quad \forall\ y \in \mathcal{H}_+^p(\Omega).$$

Because of Proposition 2.2, we need only consider $\tilde{I}(\cdot)$ over $\mathcal{H}_+^p(\Omega)$. When $p = 2$, $\mathcal{H}_+^p(\Omega)$ is a closed and convex set. Then by the results in [22, Chap. 1], we can prove that the minimizer uniquely exists. But when $p \neq 2$ and $n \neq 1$, $\mathcal{H}_+^p(\Omega)$ is not convex. Here is a counterexample for Ω being a ball. The general cases are similar.

Example 1. Let $n = 2$, $1 < p < +\infty$, $p \neq 2$, and $\Omega = B_4$ be the ball of radius 4 in $\mathbb{R}^2$, centered at the origin. Define

$$u_1(x_1, x_2) = \begin{cases} -x_1^2 + x_2^2 + 16x_1 + 81 & \text{if } p > 2 \\ x_1^2 - x_2^2 - 16x_1 + 64 & \text{if } p < 2 \end{cases} \quad \text{in } \bar{\Omega},$$

$$u_2(x_1, x_2) = \begin{cases} -16x_1 + 65 & \text{if } p > 2 \\ 16x_1 + 65 & \text{if } p < 2 \end{cases} \quad \text{in } \bar{\Omega},$$

and

$$\varphi(x_1, x_2) = 6(16 - x_1^2 - x_2^2) \ \text{ in } \bar{\Omega}.$$

By a straightforward computation, we have

$$-\mathrm{div}(|\nabla u_i|^{p-2}\nabla u_i) \ge 0 \quad \text{in } \Omega, \quad i = 1, 2,$$

$$-\mathrm{div}(|\nabla \varphi|^{p-2}\nabla \varphi) \ge 0 \quad \text{in } \Omega.$$

Let $\omega_i = \min(u_i, \varphi)$. Then $\omega_i \in W_0^{1,\infty}(\Omega) \subset W_0^{1,p}(\Omega)$ and

$$\omega_i = \begin{cases} u_i & \text{in } \Omega_1^i, \\ \varphi & \text{in } \Omega_2^i, \end{cases}$$

where Ω_1^i is an ellipse in Ω and $\Omega_2^i = \Omega \setminus \Omega_1^i$.

Let ν_i be the outer normal of $\partial\Omega_1^i$. We have

$$\nu_i = \frac{-\nabla\varphi + \nabla u_i}{|-\nabla\varphi + \nabla u_i|} \quad \text{on } \partial\Omega_1^i, \quad i = 1, 2.$$

Therefore (see Lemma 3.3),

$$(-|\nabla\varphi|^{p-2}\nabla\varphi + |\nabla u_i|^{p-2}\nabla u_i) \cdot \nu_i \ge 0 \quad \text{on } \partial\Omega_1^i, \quad i = 1, 2.$$

Thus, for any $v \in W_0^{1,p'}(\Omega)$ satisfying $v \ge 0$, a.e. in Ω,

$$\begin{aligned} &\int_\Omega |\nabla\omega_i|^{p-2}\nabla\omega_i \cdot \nabla v dx \\ &= \int_{\Omega_1^i} [-\mathrm{div}(|\nabla u_i|^{p-2}\nabla u_i)] v dx + \int_{\Omega_2^i} [-\mathrm{div}(|\nabla\varphi|^{p-2}\nabla\varphi)] v dx \\ &\quad + \int_{\partial\Omega_1^i} v(-|\nabla\varphi|^{p-2}\nabla\varphi + |\nabla u_i|^{p-2}\nabla u_i) \cdot \nu_i ds \ge 0. \end{aligned}$$

Therefore $\omega_i \in \mathcal{H}_+^p(\Omega)$, $i = 1, 2$.

Since

$$\omega_1+\omega_2=\begin{cases} x_2^2-x_1^2+146 & \text{if } p>2 \\ x_1^2-x_2^2+129 & \text{if } p<2 \end{cases} \quad \text{in } B_{\frac{1}{2}}(0)$$

in this neighborhood, therefore $\frac{1}{2}(\omega_1+\omega_2)\notin\mathcal{H}_+^p(\Omega)$. Thus, $\mathcal{H}_+^p(\Omega)$ is not convex.

Let us rewrite $\tilde{I}(\cdot)$ as follows:

$$\begin{aligned}\tilde{I}(y)&=\frac{1}{p}\int_\Omega\{|y-z|^p+|\nabla y|^p\}dx \\ &=\frac{1}{p}\int_\Omega\{|y-z|^p+[-\mathrm{div}(|\nabla y|^{p-2}\nabla y)]\cdot y\}dx.\end{aligned} \tag{2.1}$$

Next, we introduce Problem (C*) stated in the introduction. It is clear that

$$T^*[L_+^{p'}(\Omega)]\subset\mathcal{H}_+^p(\Omega). \tag{2.2}$$

By (2.1) and (1.7), we have

$$\tilde{I}[T^*(u)]=I^*(u)\quad\forall\ u\in L^{p'}(\Omega). \tag{2.3}$$

Then the existence of an optimal control to Problem (C*) means not only the existence of an optimal control to Problem (C) but also that the optimal control is in the set

$$\{y\in W_0^{1,p}(\Omega)|\ -\mathrm{div}(|\nabla y|^{p-2}\nabla y)\in L_+^{p'}(\Omega)\}.$$

Thus, its regularity is better than $W^{1,p}$-regularity. For example, when $p=2$, it means that an optimal control to Problem (C) belongs to $H_0^1(\Omega)\cap H^2(\Omega)$. To reveal the relation between Problems (C) and (C*), we give the following proposition.

PROPOSITION 2.3. *Given $1<p<+\infty$, $z\in L^p(\Omega)$, suppose $\bar{y}$ is an optimal control to Problem* (C) *and $\bar{u}\equiv-\mathrm{div}(|\nabla\bar{y}|^{p-2}\nabla\bar{y})\in L^{p'}(\Omega)$. Then $\bar{u}\in L_+^{p'}(\Omega)$ and $\bar{u}$ is an optimal control to Problem* (C*).

On the other hand, suppose $\bar{u}$ is an optimal control to Problem (C*). *Then $T^*(\bar{u})$ is an optimal control to Problem* (C).

Proof. Suppose $\bar{y}$ is an optimal control to Problem (C) and $\bar{u}=-\mathrm{div}(|\nabla\bar{y}|^{p-2}\nabla\bar{y})\in L^{p'}(\Omega)$. Then $\bar{u}\in L_+^{p'}(\Omega)$ by $\bar{y}\in\mathcal{H}_+^p(\Omega)$. Now, for any $u\in L_+^{p'}(\Omega)$, we have $T^*(u)\in\mathcal{H}_+^p(\Omega)$. Hence

$$\begin{aligned}&I^*(\bar{u})=I(\bar{y})\le I(T^*(u))=\frac{1}{p}\int_\Omega\{|T(T^*(u))-z|^p+|\nabla[T^*(u)]|^p\}dx \\ &=\frac{1}{p}\int_\Omega\{|T^*(u)-z|^p+uT^*(u)\}dx=I^*(u)\quad\forall\ u\in L_+^{p'}(\Omega).\end{aligned}$$

Thus $\bar{u}$ is an optimal control to Problem (C*).

Similarly, let $\bar{u}$ be an optimal control to Problem (C*). Then for any $u\in L_+^{p'}(\Omega)$,

$$\tilde{I}(T^*(\bar{u}))=I^*(\bar{u})\le I^*(u)=\tilde{I}(T^*(u)).$$

This means $T^*(\bar{u})$ minimizes $\tilde{I}(\cdot)$ over $\{T^*(u)|u\in L_+^{p'}(\Omega)\}$. By density (see Corollary 3.5 for details), $T^*(\bar{u})$ minimizes $\tilde{I}(\cdot)$ over $\mathcal{H}_+^p(\Omega)$. Hence $T^*(\bar{u})$ is an optimal control to Problem (C). ∎

3. Approximate problem. To get the existence, regularity, and necessary condition of an optimal control, we establish the following theorem for an approximate problem. Let us denote $\mathcal{U}_{M,\delta} \equiv \{v : \Omega \to [\delta, M] | v \text{ measurable } \}$ for $0 \le \delta < M < +\infty$.

THEOREM 3.1. *Let $z \in L^\infty(\Omega)$, $1 < p < +\infty$, $0 < \delta < 1$, and $p\|z\|^{p-1}_{L^\infty(\Omega)} + 2p \le M < +\infty$. Then there exists at least one $\bar{u} \in \mathcal{U}_{M,\delta}$ such that*

$$I^*(\bar{u}) = \inf_{u \in \mathcal{U}_{M,\delta}} I^*(u). \tag{3.1}$$

Moreover, if $\bar{u} \in \mathcal{U}_{M,\delta}$ satisfies (3.1), *then*

$$|\bar{u}(x)| \le |z^+(x)|^{p-1} + \delta, \quad \text{a.e. } \Omega. \tag{3.2}$$

It is crucial that in (3.2), the estimate of $\bar{u}$ is independent of $\delta > 0$ (we can replace δ by 1 in (3.2)) and $M \gg 1$. By this fact, we finally get the existence and regularity of an optimal pair for Problem (C).

To prove Theorem 3.1, we need some preliminary lemmas.

LEMMA 3.2. *Let C be a constant. If $\varphi \in W^{m,p}(\Omega)$, $p \ge 1, m \ge 1$, then*

$$\partial^\beta \varphi(x) = 0, \quad \text{a.e. in } \{\varphi = C\} \quad \forall\ 1 \le |\beta| \le m,$$

where $\beta = (\beta_1, \dots, \beta_n)$ is an n-tuple of nonnegative integers β_i, $|\beta| = \sum_{i=1}^n \beta_i$.

The above lemma can be found in ([26, p. 69]; see also [29]). It tells us that for any element z in $W^{m,1}(\Omega)$, on its level set, we can calculate its mth generalized derivatives just as we calculate classical derivatives.

LEMMA 3.3. *Let $1 < p < +\infty$. Then*

(i) *for any $a, b \in \mathbb{R}^m, m \in \mathcal{N}$,*

$$(|a|^{p-2}a - |b|^{p-2}b) \cdot (a - b) \ge 0, \tag{3.3}$$

and the equality holds if and only if $a = b$;

(ii) *for any $\varepsilon > 0$, $a \in \mathbb{R}^m, m \in \mathcal{N}$,*

$$(\varepsilon^2 + |a|^2)^{\frac{p-2}{2}} |a|^2 \ge |a|^p - \varepsilon^p. \tag{3.4}$$

Proof. (i) We omit the proof since it is straightforward.

(ii) If $p \ge 2$ or $|a| \le \varepsilon$, then (3.4) holds obviously. Now, we suppose that $1 < p < 2$ and $|a| > \varepsilon$. Then

$$\begin{aligned}(\varepsilon^2 + |a|^2)^{p/2}|a|^2 + (\varepsilon^2 + |a|^2)\varepsilon^p &\ge |a|^{p+2} + |a|^2\varepsilon^p \\ &\ge |a|^{p+2} + |a|^p\varepsilon^2 = |a|^p(\varepsilon^2 + |a|^2).\end{aligned}$$

That is (3.4). □

Let $\varepsilon \ge 0$. For $\mu \in W^{-1,p'}(\Omega)$, define $y_\varepsilon \equiv T^*_\varepsilon(\mu)$ to be the unique solution of the following quasi-linear elliptic equation:

$$\begin{cases} -\mathrm{div}[(\varepsilon^2 + |\nabla y_\varepsilon|^2)^{\frac{p-2}{2}} \nabla y_\varepsilon] = \mu & \text{in } \Omega, \\ y_\varepsilon|_{\partial\Omega} = 0. \end{cases} \tag{3.5}$$

The following two lemmas give some basic properties of the operator T^*_ε (recall that $T^*_0 = T^*$).

LEMMA 3.4. *Let $\varepsilon \geq 0$, $p \in (1, +\infty)$, $\mu \in W^{-1,p'}(\Omega)$.*

(i) *Equation (3.5) admits a unique solution $T^*_\varepsilon(\mu)$ in $W^{1,p}_0(\Omega)$. Moreover, there exists a positive constant $C = C(p, \Omega)$, independent of $\varepsilon \geq 0$, such that*

$$\|T^*_\varepsilon(\mu)\|_{W^{1,p}_0(\Omega)} \leq C \left(\|\mu\|^{\frac{1}{p-1}}_{W^{-1,p'}(\Omega)} + \varepsilon \right). \tag{3.6}$$

(ii) *Suppose (as $\varepsilon \to 0^+$)*

$$\mu_\varepsilon \to \mu \quad \textit{strongly in } W^{-1,p'}(\Omega).$$

Then

$$T^*_\varepsilon(\mu_\varepsilon) \to T^*(\mu) \quad \textit{strongly in } W^{1,p}_0(\Omega). \tag{3.7}$$

In particular, if $\mu_\varepsilon \to \mu$ weakly in $L^{p'}(\Omega)$, then (3.7) holds.

(iii) *Fix $\varepsilon \geq 0$. Suppose (as $k \to +\infty$)*

$$\mu^k \to \mu \quad \textit{strongly in } W^{-1,p'}(\Omega) \textit{ or } \textit{ weakly in } L^{p'}(\Omega).$$

Then

$$T^*_\varepsilon(\mu^k) \to T^*_\varepsilon(\mu) \quad \textit{strongly in } W^{1,p}_0(\Omega). \tag{3.8}$$

Proof. (i) The results can be obtained easily since y_ε satisfies (3.5) if and only if y_ε minimizes the functional $\varphi \mapsto \int_\Omega \{\frac{1}{p}(\varepsilon^2 + |\nabla\varphi|^2)^{\frac{p}{2}} - \varphi\mu\} dx$ over $W^{1,p}_0(\Omega)$.

(ii) Denote $y_\varepsilon = T^*_\varepsilon(\mu_\varepsilon)$, $y = T^*(\mu)$. By (3.6), we know that for $\varepsilon \in (0, 1)$, y_ε is bounded uniformly in $W^{1,p}_0(\Omega)$. Consequently, by the Banach–Alaoglu theorem (see [31]) and the Sobolev imbedding theorem (see [2]), y_ε has a subsequence which converges weakly in $W^{1,p}_0(\Omega)$ and strongly in $L^p(\Omega)$. Thus, it is sufficient to prove that $y^* = y$ and

$$\lim_{\varepsilon \to 0^+} \|\nabla y_\varepsilon\|_{L^p(\Omega)} = \|\nabla y\|_{L^p(\Omega)} \tag{3.9}$$

if

$$y_\varepsilon \to y^* \quad \text{weakly in } W^{1,p}_0(\Omega), \quad \text{strongly in } L^p(\Omega).$$

To see this, noting that

$$\int_\Omega \left\{ \frac{1}{p}(\varepsilon^2 + |\nabla y_\varepsilon|^2)^{\frac{p}{2}} - y_\varepsilon \mu_\varepsilon \right\} dx \leq \int_\Omega \left\{ \frac{1}{p}(\varepsilon^2 + |\nabla\varphi|^2)^{\frac{p}{2}} - \varphi\mu_\varepsilon \right\} dx \quad \forall\, \varphi \in W^{1,p}_0(\Omega),$$

$$\int_\Omega |\nabla y^*|^p dx \leq \liminf_{\varepsilon \to 0+} \int_\Omega (\varepsilon^2 + |\nabla y_\varepsilon|^2)^{\frac{p}{2}} dx, \tag{3.10}$$

and

$$\lim_{\varepsilon \to 0+} \int_\Omega y_\varepsilon \mu_\varepsilon dx = \int_\Omega y^* \mu dx, \tag{3.11}$$

we have

$$\int_\Omega \left\{ \frac{1}{p}|\nabla y^*|^p - y^*\mu \right\} dx \leq \int_\Omega \left\{ \frac{1}{p}|\nabla\varphi|^p - \varphi\mu \right\} dx \quad \forall \varphi \in W^{1,p}_0(\Omega).$$

Hence $y^* = y$.

On the other hand, by Lemma 3.3(ii),

$$\int_\Omega y_\varepsilon \mu_\varepsilon dx = \int_\Omega (\varepsilon^2 + |\nabla y_\varepsilon|^2)^{\frac{p-2}{2}} |\nabla y_\varepsilon|^2 dx \geq \int_\Omega (|\nabla y_\varepsilon|^p - \varepsilon^p) dx.$$

Therefore

$$\limsup_{\varepsilon \to 0^+} \int_\Omega |\nabla y_\varepsilon|^p dx \leq \int_\Omega y\mu dx = \int_\Omega |\nabla y|^p dx.$$

Consequently,

$$\lim_{\varepsilon \to 0^+} \int_\Omega |\nabla y_\varepsilon|^p dx = \int_\Omega |\nabla y|^p dx.$$

Thus, (3.9) holds and we get the proof.

(iii). The proof is similar to that of (ii). □

COROLLARY 3.5. *Let $p \in (1, +\infty)$. Then the set $\{T^*(u) | u \in L^{p'}_+(\Omega)\}$ is dense in $\mathcal{H}^p_+(\Omega)$.*

Proof. It is easy to see that

$$\mathcal{H}^p_+(\Omega) = \{T^*(\mu) | \mu \in W^{-1,p'}(\Omega), \mu \geq 0 \text{ in the weak sense}\}.$$

Thus, we need only to prove that for any $\mu \in W^{-1,p'}(\Omega)$, $\mu \geq 0$, there exists a sequence $u_j \in L^{p'}_+(\Omega)$ such that $T^*(u_j) \to T^*(\mu)$ strongly in $W^{1,p}_0(\Omega)$.

To see this, let

$$\Psi(x) = \begin{cases} k \ \exp\left(-\dfrac{1}{1-|x|^2}\right) & \text{if } |x| < 1, \\ 0 & \text{if } |x| \geq 1, \end{cases}$$

where $k > 0$ is chosen to satisfy the condition

$$\int_{\mathbb{R}^n} \Psi(x) dx = 1.$$

For $j \in \mathcal{N}$, denote $\Psi_j(x) \equiv j^{\,n} \Psi(jx)$, and $v_j \equiv \mu * \Psi_j$. Then we can verify that $v_j \in C^\infty(\bar{\Omega}) \bigcap L^{p'}_+(\Omega)$ and

$$v_j \to \mu \ \text{ weakly in } W^{-1,p'}(\Omega).$$

By Mazur's theorem, there exists $\alpha_{j,i} \geq 0$, $\sum_{i=1}^{K_j} \alpha_{j,i} = 1$ such that

$$u_j \equiv \sum_{i=1}^{K_j} \alpha_{j,i} v_{j+i} \to \mu \ \text{ strongly in } W^{-1,p'}(\Omega).$$

We have $u_j \in L^p_+(\Omega)$. By Lemma 3.4(iii), we get

$$T^*(u_j) \to T^*(\mu) \quad \text{strongly in } W^{1,p}_0(\Omega),$$

completing the proof. □

LEMMA 3.6. *Let $\varepsilon \geq 0$, $p \in (1, +\infty)$.*

(i) *Suppose $y_\varepsilon \in W_0^{1,p}(\Omega)$, $-\mathrm{div}[(\varepsilon^2 + |\nabla y_\varepsilon|^2)^{\frac{p-2}{2}} \nabla y_\varepsilon] \geq 0$. Then $y_\varepsilon \geq 0$, a.e. Ω.*

(ii) *Suppose $q > p'n$, $u \in L^q(\Omega)$. Let $y_\varepsilon = T_\varepsilon^*(u)$. Then $y_\varepsilon \in C^{1,\alpha}(\bar{\Omega})$, where $\alpha = \alpha(p, q, \|u\|_{L^q(\Omega)}, \Omega) \in (0, 1)$ is independent of $\varepsilon \geq 0$. Moreover, there exists a positive constant $C = C(p, q, \|u\|_{L^q(\Omega)}, \Omega)$ such that*

$$|D_i y_\varepsilon(x) - D_i y_\varepsilon(x')| \leq C|x - x'|^\alpha \quad \forall\ x, x' \in \bar{\Omega}; \qquad i = 1, 2, \ldots, n. \tag{3.12}$$

Proof. (i) Since $y_\varepsilon^- \in W_0^{1,p}(\Omega)$ and $y_\varepsilon^- \geq 0$, a.e. Ω, we have

$$\begin{aligned} 0 &\leq \int_\Omega (\varepsilon^2 + |\nabla y_\varepsilon|^2)^{\frac{p-2}{2}} \nabla y_\varepsilon \cdot \nabla y_\varepsilon^- dx \\ &= -\int_\Omega (\varepsilon^2 + |\nabla y_\varepsilon|^2)^{\frac{p-2}{2}} |\nabla y_\varepsilon^-|^2 dx. \end{aligned}$$

Therefore $\nabla y_\varepsilon^- = 0$, a.e. Ω. Consequently, $y_\varepsilon^- = 0$, a.e. Ω, i.e., $y_\varepsilon \geq 0$, a.e. Ω.

(ii) The result is an immediate corollary of the interior $C^{1,\alpha}$-regularity of the quasi-linear equations with the homogenous boundary condition (see [12] and [33]).

LEMMA 3.7. *Suppose $0 < \alpha < 1$, $f \in C^\alpha(\bar{\Omega}, \mathbb{R}^n)$. Then*

(i) *$\forall \beta > -1$, there exists a $\gamma \in (0, 1)$ such that $|f|^\beta f \in C^\gamma(\bar{\Omega}, \mathbb{R}^n)$;*

(ii) *$\forall \delta > 0$, $\beta > -1$, there exists a $\gamma \in (0, 1)$ and $C > 0$, independent of $\varepsilon \in [0, 1]$, such that*

$$|h_\varepsilon(\tilde{x}) - h_\varepsilon(x)| \leq C|\tilde{x} - x|^\gamma \quad \forall\ \tilde{x},\ x \in \bar{\Omega},$$

where $h_\varepsilon = (\varepsilon^2 + |f|^\delta)^{\frac{\beta}{\delta}} f$.

(iii) *$\forall k \geq 0$, $2s + k + 1 > 0$, there exists a $\gamma \in (0, 1)$ and $C > 0$, independent of $\varepsilon \in [0, 1]$, such that*

$$|g_\varepsilon(\tilde{x}) - g_\varepsilon(x)| \leq C|\tilde{x} - x|^\gamma \quad \forall\ \tilde{x},\ x \in \bar{\Omega},$$

where $g_\varepsilon = (\varepsilon^2 + |f|^2)^s |f|^k f$.

Proof. The proofs of (i) and (ii) are straightforward, and (i) is in fact a special case of (ii). Finally, (iii) follows from (i) and (ii) since $(\varepsilon^2 + |f|^2)^s |f|^k f = (\varepsilon^2 + |g|^{\frac{2}{k+1}})^s g$ with $g = |f|^k f$. □

The following lemma has a result similar to that of Lemma 3.2, which shows some crucial information about the so-called singular set.

LEMMA 3.8. *Suppose $u \in L^\infty(\Omega)$, and $y \in W_0^{1,p}(\Omega)$ is a solution of the following equation:*

$$\begin{cases} -\mathrm{div}(|\nabla y|^{p-2} \nabla y) = u & \text{in } \Omega, \\ y|_{\partial\Omega} = 0. \end{cases}$$

Then

$$u(x) = 0, \quad \text{a.e. } x \in \{\nabla y = 0\}.$$

For a proof of the above lemma, see [27]. As a consequence of the above lemma, the singular set $\{\nabla y = 0\}$ must have Lebesgue measure zero if $u(x) > 0$, a.e. Ω.

Now, let us give a proof of Theorem 3.1.

Proof of Theorem 3.1. First, by (2.3), for any $u \in \mathcal{U}_{M,\delta}$, $I^*(u) \geq 0$. Thus, we have $u_k \in \mathcal{U}_{M,\delta}$ satisfying

$$\lim_{k\to+\infty} I^*(u_k) = \inf_{u\in\mathcal{U}_{M,\delta}} I^*(u).$$

Moreover, we can suppose that

$$u_k \to \bar{u} \quad \text{weakly in } L^{p'}(\Omega).$$

Since $\mathcal{U}_{M,\delta}$ is convex, $\bar{u} \in \mathcal{U}_{M,\delta}$. On the other hand, by Lemma 3.4(ii) (for the case $\varepsilon = 0$), we can obtain that

$$T^*(u_k) \to \bar{y} \equiv T^*(\bar{u}) \quad \text{strongly in } W_0^{1,p}(\Omega).$$

Thus, by the definition of I^*, we have

$$I^*(\bar{u}) = \lim_{k\to+\infty} I^*(u_k) = \inf_{u\in\mathcal{U}_{M,\delta}} I^*(u).$$

Therefore, there exists at least one $\bar{u} \in \mathcal{U}_{M,\delta}$ satisfying (3.1).

Now, let $\bar{u} \in \mathcal{U}_{M,\delta}$ be an optimal control satisfying (3.1), $\bar{y} = T^*(\bar{u})$. By Lemma 3.6(ii), we have $\bar{y} \in C^{1,\alpha}(\bar{\Omega})$ for some $\alpha \in (0,1)$. We will prove (3.2) in three steps.

Step I: *First approximation.* Let $(\bar{y}, \bar{u})$ be described as above. Fix

$$\eta \in \left(0, \frac{1}{1 + \|\bar{y}\|^{p-1}_{L^{+\infty}(\Omega)}}\right).$$

For $\theta > 0$, consider the equation

$$\begin{cases} -\mathrm{div}(|\nabla y_\theta|^{p-2}\nabla y_\theta) + \theta y_\theta = u \ \text{ in } \Omega, \\ y_\theta|_{\partial\Omega} = 0. \end{cases} \tag{3.13}$$

Similar to the existence of a $\bar{u} \in \mathcal{U}_{M,\delta}$ satisfying (3.1), it is easy to prove that there exists a $(\bar{y}_\theta, \bar{u}_\theta) \in W_0^{1,p}(\Omega) \times \mathcal{U}_{M,\delta}$ satisfying (3.13) and

$$\begin{aligned} &\frac{1}{p}\int_\Omega \{|\bar{y}_\theta - z|^p + \eta|\bar{y}_\theta - \bar{y}|^p + \bar{u}_\theta\bar{y}_\theta\}dx \\ &\leq \frac{1}{p}\int_\Omega \{|y_\theta - z|^p + \eta|y_\theta - \bar{y}|^p + uy_\theta\}dx \end{aligned} \tag{3.14}$$

for all $(y_\theta, u) \in W_0^{1,p}(\Omega) \times \mathcal{U}_{M,\delta}$ satisfying (3.13).

For any $k > 0$, by (3.13), we have

$$\begin{aligned} \theta k \int_\Omega (\bar{y}_\theta - k)^+ dx &\leq \theta \int_\Omega \bar{y}_\theta(\bar{y}_\theta - k)^+ dx \\ &\leq \int_\Omega \{|\nabla[(\bar{y}_\theta - k)^+]|^p + \theta\bar{y}_\theta(\bar{y}_\theta - k)^+\}dx \\ &= \int_\Omega \bar{u}_\theta(\bar{y}_\theta - k)^+ dx \leq M\int_\Omega (\bar{y}_\theta - k)^+ dx. \end{aligned}$$

Therefore,

$$\theta\bar{y}_\theta \leq M, \quad \text{a.e. } \Omega. \tag{3.15}$$

Similarly,

$$\theta\bar{y}_\theta \geq 0, \quad \text{a.e. } \Omega. \tag{3.16}$$

Thus, $\|\bar{u}_\theta - \theta\bar{y}_\theta\|_{L^\infty(\Omega)} \leq M$. By Lemma 3.6, we see that $\bar{y}_\theta$ is uniformly bounded in $C^{1,\alpha}(\bar{\Omega})$ for some $\alpha \in (0,1)$. Then we can suppose that, at least in the sense of a subsequence (as $\theta \to 0^+$),

$$\begin{cases} \bar{u}_\theta \to \hat{u} & \text{weakly in } \ L^q(\Omega) \quad \forall\ 1 < q < +\infty, \\ \bar{y}_\theta \to \hat{y} & \text{uniformly in } \ C^1(\bar{\Omega}). \end{cases}$$

Thus, $\hat{u} \in \mathcal{U}_{M,\delta}$. By Lemma 3.4(ii), $\hat{y} = T^*(\hat{u})$. Moreover, by (3.14),

$$\begin{aligned} &\frac{1}{p}\int_\Omega \{|\hat{y} - z|^p + \eta|\hat{y} - \bar{y}|^p + \hat{u}\hat{y}\}dx \\ \leq\ &\frac{1}{p}\int_\Omega \{|y - z|^p + \eta|y - \bar{y}|^p + uy\}dx \quad \forall\ u \in \mathcal{U}_{M,\delta}, \end{aligned}$$

where $y = T^*(u)$. If $\hat{y} \not\equiv \bar{y}$ (i.e., $\hat{u} \not\equiv \bar{u}$), replacing u by $\bar{u}$ in the above inequality, we get

$$\frac{1}{p}\int_\Omega \{|\hat{y} - z|^p + \hat{u}\hat{y}\}dx < \frac{1}{p}\int_\Omega \{|\bar{y} - z|^p + \bar{u}\bar{y}\}dx;$$

this contradicts the optimality of $\bar{u}$ (see (3.1)). Therefore, we have $\hat{u} \equiv \bar{u}$, $\hat{y} \equiv \bar{y}$. Consequently, not only in the sense of a subsequence, we get (as $\theta \to 0^+$),

$$\begin{cases} \bar{u}_\theta \to \bar{u} & \text{weakly in } \ L^q(\Omega) \quad \forall\ 1 < q < +\infty, \\ \bar{y}_\theta \to \bar{y} & \text{uniformly in } \ C^1(\bar{\Omega}). \end{cases} \tag{3.17}$$

Consequently, there exists a $\theta_0 > 0$ such that

$$\theta\|\bar{y}_\theta\|_{L^\infty(\Omega)} < \frac{\delta}{2}, \quad \|\bar{y}_\theta\|^{p-1}_{L^\infty(\Omega)} < \|\bar{y}\|^{p-1}_{L^\infty(\Omega)} + 1 \quad \forall\ 0 < \theta \leq \theta_0. \tag{3.18}$$

In this case, we have (see (3.13))

$$-\mathrm{div}(|\nabla\bar{y}_\theta|^{p-2}\nabla\bar{y}_\theta) = \bar{u}_\theta - \theta\bar{y}_\theta \geq \frac{\delta}{2} > 0 \quad \text{in } \Omega.$$

Thus, by Lemma 3.8, the set $E_\theta \equiv \{\nabla\bar{y}_\theta = 0\}$ has n-dimensional Lebesgue measure zero. On the other hand, E_θ is closed since $\bar{y}_\theta \in C^{1,\alpha}(\bar{\Omega})$.

Step II: *Second approximation.* For $0 < \theta < \theta_0$, $\varepsilon > 0$, consider the equation

$$\begin{cases} -\mathrm{div}[(\varepsilon^2 + |\nabla y_{\theta,\varepsilon}|^2)^{\frac{p-2}{2}}\nabla y_{\theta,\varepsilon}] + \theta y_{\theta,\varepsilon} = u \ \text{ in } \Omega, \\ y_{\theta,\varepsilon}|_{\partial\Omega} = 0. \end{cases} \tag{3.19}$$

Similar to Step I, there exists a $(\bar{y}_{\theta,\varepsilon}, \bar{u}_{\theta,\varepsilon}) \in W_0^{1,p}(\Omega) \times \mathcal{U}_{M,\delta}$ satisfying (3.19) and

$$\begin{aligned} &\frac{1}{p}\int_\Omega \{|\bar{y}_{\theta,\varepsilon} - z|^p + \eta|\bar{y}_{\theta,\varepsilon} - \bar{y}|^p + \eta|\bar{y}_{\theta,\varepsilon} - \bar{y}_\theta|^p + \bar{u}_{\theta,\varepsilon}\bar{y}_{\theta,\varepsilon}\}dx \\ \leq\ &\frac{1}{p}\int_\Omega \{|y_{\theta,\varepsilon} - z|^p + \eta|y_{\theta,\varepsilon} - \bar{y}|^p + \eta|y_{\theta,\varepsilon} - \bar{y}_\theta|^p + uy_{\theta,\varepsilon}\}dx \end{aligned}$$

for any $(y_{\theta,\varepsilon}, u) \in W_0^{1,p}(\Omega) \times \mathcal{U}_{M,\delta}$ satisfying (3.19). Moreover, there exists a $\bar{\varphi}_{\theta,\varepsilon} \in W_0^{1,2}(\Omega)$ such that (see (1.10) for the definition of $\mathbf{L}$)

$$\begin{cases} \mathbf{L}(\bar{\varphi}_{\theta,\varepsilon}; \bar{y}_{\theta,\varepsilon}, p, \varepsilon) + \theta\bar{\varphi}_{\theta,\varepsilon} = f_{\theta,\varepsilon} - \bar{u}_{\theta,\varepsilon} \ \text{ in } \Omega, \\ \bar{\varphi}_{\theta,\varepsilon}|_{\partial\Omega} = 0, \end{cases} \tag{3.20}$$

and

$$\int_\Omega (\bar{\varphi}_{\theta,\varepsilon} - \bar{y}_{\theta,\varepsilon})(u - \bar{u}_{\theta,\varepsilon})dx \le 0 \quad \forall\ u \in \mathcal{U}_{M,\delta}, \tag{3.21}$$

where

$$\begin{aligned} f_{\theta,\varepsilon} = {} & p|z - \bar{y}_{\theta,\varepsilon}|^{p-2}(z - \bar{y}_{\theta,\varepsilon}) + p\eta|\bar{y} - \bar{y}_{\theta,\varepsilon}|^{p-2}(\bar{y} - \bar{y}_{\theta,\varepsilon}) \\ & + p\eta|\bar{y}_\theta - \bar{y}_{\theta,\varepsilon}|^{p-2}(\bar{y}_\theta - \bar{y}_{\theta,\varepsilon}) \quad \text{ in } \ \Omega. \end{aligned} \tag{3.22}$$

Similarly to (3.15)–(3.16) and (3.17), we have $0 \le \theta\bar{y}_{\theta,\varepsilon} \le M$, and (as $\varepsilon \to 0^+$)

$$\begin{cases} \bar{u}_{\theta,\varepsilon} \to \bar{u}_\theta \quad \text{weakly in } L^q(\Omega) \quad \forall\ 1 < q < +\infty, \\ \bar{y}_{\theta,\varepsilon} \to \bar{y}_\theta \quad \text{uniformly in } C^1(\bar{\Omega}). \end{cases} \tag{3.23}$$

Therefore, there exists a $C_\theta > 0$, independent of $\varepsilon \in (0,1)$, such that (see (3.18) and (3.22))

$$\begin{aligned} & -C_\theta \le f_{\theta,\varepsilon} \le p(z^+)^{p-1} + p\eta(\bar{y})^{p-1} + p\eta(\bar{y}_\theta)^{p-1} \\ & \le p\|z\|^{p-1}_{L^\infty(\Omega)} + p\eta(2\|\bar{y}\|^{p-1}_{L^\infty(\Omega)} + 1) \le p\|z\|^{p-1}_{L^\infty(\Omega)} + 2p \le M \quad \text{ in } \Omega. \end{aligned} \tag{3.24}$$

Thus, as in (3.15), we have

$$-\frac{1}{\theta}C_\theta \le \varphi_{\theta,\varepsilon} \le \frac{1}{\theta}M.$$

By the $W^{2,q}$-estimate for linear elliptic equation (3.20), we obtain the following estimate:

$$\|\bar{\varphi}_{\theta,\varepsilon}\|_{W^{2,q}(\Omega_0)} \le C(\theta, q, \Omega_0) \ \ \forall\ \Omega_0 \subset\subset (\Omega \setminus E_\theta), \quad 1 < q < +\infty,$$

where the constant $C(\theta, q, \Omega_0)$ is independent of $\varepsilon \in (0,1)$ (see [19]). Then we can suppose that (at least for a subsequence)

$$\begin{aligned} \bar{\varphi}_{\theta,\varepsilon} \to \bar{\varphi}_\theta \quad & \text{weakly in } L^q(\Omega) \quad \forall\ 1 < q < +\infty, \\ & \text{uniformly in } C^1(\bar{\Omega}_0) \ \ \forall\ \Omega_0 \subset\subset (\Omega \setminus E_\theta). \end{aligned} \tag{3.25}$$

Passing to the limit and noting that (3.21) still holds by replacing the integral domain Ω by $\Omega_0 \subset \Omega$ (just let $u = \bar{u}_{\theta,\varepsilon}$ on the set $\Omega \setminus \Omega_0$), we get from (3.20)–(3.22) that

$$\mathbf{L}(\bar{\varphi}_\theta; \bar{y}_\theta, p) + \theta\bar{\varphi}_\theta = f_\theta - \bar{u}_\theta \ \text{ in } \Omega \setminus E_\theta, \tag{3.26}$$

and

$$\int_{\Omega_0} (\bar{\varphi}_\theta - \bar{y}_\theta)(u - \bar{u}_\theta)dx \le 0 \ \ \forall\ u \in \mathcal{U}_{M,\delta},\ \Omega_0 \subset\subset (\Omega \setminus E_\theta), \tag{3.27}$$

where

$$f_\theta = p|z - \bar{y}_\theta|^{p-2}(z - \bar{y}_\theta) + p\eta|\bar{y} - \bar{y}_\theta|^{p-2}(\bar{y} - \bar{y}_\theta) \quad \text{ in } \ \Omega.$$

One can easily see that (3.27) still holds if the integral domain Ω_0 is replaced by Ω, since E_θ has Lebesgue measure zero.

Step III: *Applying the maximum principles for approximate problems.* First, we want to prove that $\bar{\varphi}_\theta(x) \le \bar{y}_\theta(x)$, and then we want to get a useful estimate of $\bar{u}_\theta$. Equations (3.20)–(3.21) and (3.26)–(3.27) are maximum principles for approximate problems. We notice that in (3.26)–(3.27), no boundary condition is posed for $\bar{\varphi}_\theta$. Thus, as a maximum principle, (3.26)–(3.27) is incomplete (see similar results in [6], [7]).

By (3.21),

$$\begin{cases} \bar{u}_{\theta,\varepsilon}(x) = M, & \text{a.e. } x \in \{\bar{\varphi}_{\theta,\varepsilon} > \bar{y}_{\theta,\varepsilon}\}, \\ \bar{u}_{\theta,\varepsilon}(x) = \delta, & \text{a.e. } x \in \{\bar{\varphi}_{\theta,\varepsilon} < \bar{y}_{\theta,\varepsilon}\}. \end{cases}$$

Therefore, by (3.24),

$$f_{\theta,\varepsilon}(x) - \bar{u}_{\theta,\varepsilon}(x) \le 0, \quad \text{a.e. } x \in \{\bar{\varphi}_{\theta,\varepsilon} > \bar{y}_{\theta,\varepsilon}\}.$$

Thus, it follows from (3.20) that

$$\begin{aligned} \int_\Omega \Big\{ & (\varepsilon^2 + |\nabla \bar{y}_{\theta,\varepsilon}|^2)^{\frac{p-2}{2}} \nabla \bar{\varphi}_{\theta,\varepsilon} \cdot \nabla \left((\bar{\varphi}_{\theta,\varepsilon} - \bar{y}_{\theta,\varepsilon})^+ \right) \\ & + (p-2)(\varepsilon^2 + |\nabla \bar{y}_{\theta,\varepsilon}|^2)^{\frac{p-4}{2}} (\nabla \bar{y}_{\theta,\varepsilon} \cdot \nabla \bar{\varphi}_{\theta,\varepsilon}) \left[\nabla \bar{y}_{\theta,\varepsilon} \cdot \nabla \left((\bar{\varphi}_{\theta,\varepsilon} - \bar{y}_{\theta,\varepsilon})^+ \right) \right] \\ & + \theta \bar{\varphi}_{\theta,\varepsilon} (\bar{\varphi}_{\theta,\varepsilon} - \bar{y}_{\theta,\varepsilon})^+ \Big\} \le 0. \end{aligned} \tag{3.28}$$

On the other hand, by (3.18) and (3.23), we have $\varepsilon_0 > 0$ such that

$$\theta \|\bar{y}_{\theta,\varepsilon}\|_{L^\infty(\Omega)} < \delta \quad \forall\, \varepsilon \in (0, \varepsilon_0).$$

Consequently, by (3.19),

$$-\mathrm{div}[(\varepsilon^2 + |\nabla \bar{y}_{\theta,\varepsilon}|^2)^{\frac{p-2}{2}} \nabla \bar{y}_{\theta,\varepsilon}] = \bar{u}_{\theta,\varepsilon} - \theta \bar{y}_{\theta,\varepsilon} > 0 \quad \forall\, \varepsilon \in (0, \varepsilon_0).$$

Therefore

$$(p-1) \int_\Omega (\varepsilon^2 + |\nabla \bar{y}_{\theta,\varepsilon}|^2)^{\frac{p-2}{2}} \nabla \bar{y}_{\theta,\varepsilon} \cdot \nabla [(\bar{\varphi}_{\theta,\varepsilon} - \bar{y}_{\theta,\varepsilon})^+] dx \ge 0. \tag{3.29}$$

Noting that $\bar{y}_{\theta,\varepsilon} \ge 0$, we have

$$\theta \int_\Omega \bar{y}_{\theta,\varepsilon} (\bar{\varphi}_{\theta,\varepsilon} - \bar{y}_{\theta,\varepsilon})^+ dx \ge 0. \tag{3.30}$$

Combining (3.28)–(3.30), we get

$$\begin{aligned} & \int_\Omega (\varepsilon^2 + |\nabla \bar{y}_{\theta,\varepsilon}|^2)^{\frac{p-2}{2}} |\nabla [(\bar{\varphi}_{\theta,\varepsilon} - \bar{y}_{\theta,\varepsilon})^+]|^2 dx \\ & + (p-2) \int_\Omega (\varepsilon^2 + |\nabla \bar{y}_{\theta,\varepsilon}|^2)^{\frac{p-4}{2}} |\nabla \bar{y}_{\theta,\varepsilon} \cdot \nabla [(\bar{\varphi}_{\theta,\varepsilon} - \bar{y}_{\theta,\varepsilon})^+]|^2 dx \\ & + \int_\Omega \theta [(\bar{\varphi}_{\theta,\varepsilon} - \bar{y}_{\theta,\varepsilon})^+]^2 dx \\ & \le (p-2) \int_\Omega \varepsilon^2 (\varepsilon^2 + |\nabla \bar{y}_{\theta,\varepsilon}|^2)^{\frac{p-4}{2}} \nabla \bar{y}_{\theta,\varepsilon} \cdot \nabla [(\bar{\varphi}_{\theta,\varepsilon} - \bar{y}_{\theta,\varepsilon})^+] dx. \end{aligned} \tag{3.31}$$

Thus,

$$\min(p-1,1)\int_\Omega (\varepsilon^2+|\nabla\bar y_{\theta,\varepsilon}|^2)^{\frac{p-2}{2}}|\nabla[(\bar\varphi_{\theta,\varepsilon}-\bar y_{\theta,\varepsilon})^+]|^2dx \tag{3.32}$$
$$\le |p-2|\int_\Omega (\varepsilon^2+|\nabla\bar y_{\theta,\varepsilon}|^2)^{\frac{p-2}{2}}|\nabla\bar y_{\theta,\varepsilon}|\ |\nabla[(\bar\varphi_{\theta,\varepsilon}-\bar y_{\theta,\varepsilon})^+]|dx.$$

Consequently, by Hölder's inequality and (3.19),

$$\int_\Omega (\varepsilon^2+|\nabla\bar y_{\theta,\varepsilon}|^2)^{\frac{p-2}{2}}|\nabla[(\bar\varphi_{\theta,\varepsilon}-\bar y_{\theta,\varepsilon})^+]|^2dx \tag{3.33}$$
$$\le C_p\int_\Omega (\varepsilon^2+|\nabla\bar y_{\theta,\varepsilon}|^2)^{\frac{p}{2}}dx\le\tilde C_p$$

for some $C_p,\tilde C_p>0$ independent of $\varepsilon\in(0,\varepsilon_0)$. Therefore, we can suppose that

$$(\varepsilon^2+|\nabla\bar y_{\theta,\varepsilon}|^2)^{\frac{p-2}{4}}\nabla[(\bar\varphi_{\theta,\varepsilon}-\bar y_{\theta,\varepsilon})^+]\to g_\theta\quad\text{ weakly in } L^2(\Omega;\mathbb{R}^n).$$

On the other hand, since $\bar y_{\theta,\varepsilon}$ is bounded uniformly in $C^{1,\alpha}(\bar\Omega)$, by Lemma 3.7, both

$$(\varepsilon^2+|\nabla\bar y_{\theta,\varepsilon}|^2)^{\frac{p-2}{4}}\nabla\bar y_{\theta,\varepsilon}\quad\text{and}\quad(\varepsilon^2+|\nabla\bar y_{\theta,\varepsilon}|^2)^{\frac{p-6}{4}}|\nabla\bar y_{\theta,\varepsilon}|^2\nabla\bar y_{\theta,\varepsilon}$$

are bounded uniformly in $C^\beta(\bar\Omega;\mathbb{R}^n)$ for some $\beta\in(0,1)$ independent of ε. Thus, their difference

$$\varepsilon^2(\varepsilon^2+|\nabla\bar y_{\theta,\varepsilon}|^2)^{\frac{p-6}{4}}\nabla\bar y_{\theta,\varepsilon}$$

is also bounded uniformly in $C^\beta(\bar\Omega;\mathbb{R}^n)$. Then we can suppose that

$$\varepsilon^2(\varepsilon^2+|\nabla\bar y_{\theta,\varepsilon}|^2)^{\frac{p-6}{4}}\nabla\bar y_{\theta,\varepsilon}\to h_\theta\quad\text{ uniformly in } C(\bar\Omega;\mathbb{R}^n).$$

Noting that $\nabla\bar y_{\theta,\varepsilon}(x)\to\nabla\bar y_\theta(x)\ne0$ for $x\in(\Omega\setminus E_\theta)$, we get $h_\theta=0$ in $\Omega\setminus E_\theta$. Moreover, there exists an $\varepsilon_0>0$, and $C_1>C_2>0$, independent of $\varepsilon\in(0,\varepsilon_0)$, such that

$$C_2\le|\nabla\bar y_{\theta,\varepsilon}|\le C_2\quad\text{ in }\Omega_0\subset\subset(\Omega\setminus E_\theta)\quad\forall\ \varepsilon\in(0,\varepsilon_0).$$

Thus, by (3.33) and (3.31), there exists a $C>0$, independent of $\varepsilon\in(0,\varepsilon_0)$, such that

$$C\int_{\Omega_0}|\nabla[(\bar\varphi_{\theta,\varepsilon}-\bar y_{\theta,\varepsilon})^+]|^2dx\le\tilde C_p, \tag{3.34}$$

and

$$C\int_{\Omega_0}|\nabla[(\bar\varphi_{\theta,\varepsilon}-\bar y_{\theta,\varepsilon})^+]|^2dx \tag{3.35}$$
$$\le(p-2)\int_\Omega\varepsilon^2(\varepsilon^2+|\nabla\bar y_{\theta,\varepsilon}|^2)^{\frac{p-4}{2}}\nabla\bar y_{\theta,\varepsilon}\cdot\nabla[(\bar\varphi_{\theta,\varepsilon}-\bar y_{\theta,\varepsilon})^+]dx.$$

Combining (3.34) with (3.23) and (3.25), we have

$$(\bar\varphi_{\theta,\varepsilon}-\bar y_{\theta,\varepsilon})^+\to(\bar\varphi_\theta-\bar y_\theta)^+\quad\text{ weakly in }\ W^{1,2}(\Omega_0).$$

Then, by (3.35), we get

$$C\int_{\Omega_0}|\nabla[(\bar\varphi_\theta-\bar y_\theta)^+]|^2dx\le C\liminf_{\varepsilon\to0^+}\int_{\Omega_0}|\nabla[(\bar\varphi_{\theta,\varepsilon}-\bar y_{\theta,\varepsilon})^+]|^2dx$$
$$\le(p-2)\int_\Omega h_\theta\cdot g_\theta dx=0.$$

Thus,

$$\nabla[(\bar\varphi_\theta-\bar y_\theta)^+]=0,\quad \text{a.e. } \Omega\setminus E_\theta.$$

Therefore, for any ball $B\subset(\Omega\setminus E_\theta)$,

$$(\bar\varphi_\theta-\bar y_\theta)^+=C_B,\quad \text{a.e. } B.$$

We claim that $C_B=0$. Otherwise, suppose that $C_B>0$ for some $B\subset(\Omega\setminus E_\theta)$. Then

$$\bar\varphi_\theta=\bar y_\theta+C_B,\quad \text{a.e. } B.$$

Noting that $\nabla\bar y_\theta\neq0$ in $\Omega\setminus E_\theta$ and $\bar y_\theta\in C^{1,\alpha}(\bar\Omega)$, we can easily prove that $\bar y_\theta,\bar\varphi_\theta\in W^{2,q}(B)$ for some $q>1$ (see (3.13) and (3.26)). Then by Lemma 3.2 and (3.26), we have

$$-(p-1)\mathrm{div}(|\nabla\bar y_\theta|^{p-2}\nabla\bar y_\theta)+\theta\bar y_\theta+\theta C_B$$
$$=p|z-\bar y_\theta|^{p-2}(z-\bar y_\theta)+p\eta|\bar y-\bar y_\theta|^{p-2}(\bar y-\bar y_\theta)-\bar u_\theta\quad\text{in } B.$$

Therefore, by (3.13), and noting that $\bar y_\theta\ge0$,

$$\bar u_\theta=|z-\bar y_\theta|^{p-2}(z-\bar y_\theta)+\eta|\bar y-\bar y_\theta|^{p-2}(\bar y-\bar y_\theta)+\frac{p-2}{p}\theta\bar y_\theta-\frac1p\theta C_B \tag{3.36}$$
$$\le(z^+)^{p-1}+\eta(\bar y)^{p-1}+\theta\bar y_\theta\le(z^+)^{p-1}+2<M\quad\text{in } B.$$

On the other hand, by (3.27),

$$\begin{cases}\bar u_\theta=M, & \text{a.e. } \{\bar\varphi_\theta>\bar y_\theta\}\setminus E_\theta,\\ \bar u_\theta=\delta, & \text{a.e. } \{\bar\varphi_\theta<\bar y_\theta\}\setminus E_\theta.\end{cases} \tag{3.37}$$

This contradicts (3.36) since $B\subset(\{\bar\varphi_\theta>\bar y_\theta\}\setminus E_\theta)$. Thus, we prove that

$$(\bar\varphi_\theta-\bar y_\theta)^+=0,\quad \text{a.e. } \Omega\setminus E_\theta.$$

That is,

$$\bar\varphi_\theta\le\bar y_\theta,\quad \text{a.e. } \Omega\setminus E_\theta. \tag{3.38}$$

Similarly to (3.36), we have

$$\bar u_\theta\le(z^+)^{p-1}+\eta(\bar y)^{p-1}+\theta\bar y_\theta,\quad \text{a.e. } \{\bar\varphi_\theta=\bar y_\theta\}\setminus E_\theta.$$

Combining the above with (3.37)–(3.38) and noting that $|E_\theta|=0$, we get

$$\bar u_\theta\le(z^+)^{p-1}+\eta\bar y^{p-1}+\theta\bar y_\theta+\delta,\quad \text{a.e. } \Omega. \tag{3.39}$$

Let $\theta\to0^+$; by (3.17), we get

$$\bar u\le(z^+)^{p-1}+\eta\bar y^{p-1}+\delta,\quad \text{a.e. } \Omega.$$

Finally, let $\eta\to0^+$; then (3.2) follows and we get the proof. □

4. Existence and regularity of an optimal control. In this section, we will prove the main results of this paper.

Proof of Theorem 1.1. We first suppose that $z \in L^\infty(\Omega)$. Let $M > p\|z^+\|^{p-1}_{L^\infty(\Omega)} + 2p$, $0 < \delta < 1$. By Theorem 3.1, there exists a $\bar{u}^{M,\delta} \in \mathcal{U}_{M,\delta}$ such that (3.1) and (3.2) hold with $\bar{u}$ being replaced by $\bar{u}^{M,\delta}$. Thus, we have a subsequence $\delta_j \to 0^+$ such that

$$\bar{u}^{M,\delta_j} \to \bar{u}^M \quad \text{weakly in } L^q(\Omega) \quad \forall\ 1 < q < +\infty.$$

It is not very hard to see that $\bar{u}^M$ minimizes $I^*(\cdot)$ over $\mathcal{U}_{M,0}$ and by (3.2), $\bar{u}^M \le (z^+)^{p-1}$. Similarly, for any $S > M$, there exists a $\bar{u}^S$ minimizing $I^*(\cdot)$ over $\mathcal{U}_{S,0}$ and satisfying $\bar{u}^S \le (z^+)^{p-1}$. Consequently, $\bar{u}^S \in \mathcal{U}_{M,0}$. Therefore $I^*(\bar{u}^M) \le I^*(\bar{u}^S)$. That is, $\bar{u} \equiv \bar{u}^M$ also minimizes $I^*(\cdot)$ over $\mathcal{U}_{S,0}$ for any $S > M$. Then it must minimize $I^*(\cdot)$ over $L^{p'}_+(\Omega)$.

Now, suppose $z \in L^p(\Omega)$. For $\varepsilon > 0$, denote

$$z_\varepsilon(x) = \begin{cases} z(x) & \text{if } |z(x)| \le \frac{1}{\varepsilon}, \\ 0 & \text{if } |z(x)| > \frac{1}{\varepsilon}. \end{cases} \tag{4.1}$$

Then there exists a $\bar{u}_\varepsilon$ which minimizes $I^*(\cdot; z_\varepsilon, p, \Omega)$ over $L^{p'}_+(\Omega)$ such that $0 \le \bar{u}_\varepsilon \le (z^+_\varepsilon)^{p-1}$. Thus,

$$\|\bar{u}_\varepsilon\|_{L^{p'}(\Omega)} \le \|z^+\|^{p-1}_{L^p(\Omega)}. \tag{4.2}$$

Hence, we can suppose that

$$\bar{u}_\varepsilon \to \bar{u} \quad \text{weakly in } L^{p'}(\Omega). \tag{4.3}$$

Therefore,

$$0 \le \bar{u} \le (z^+)^{p-1}, \quad \text{a.e. } \Omega. \tag{4.4}$$

Consequently, $\bar{u} \in L^{p'}_+(\Omega)$. Denote $\bar{y}_\varepsilon = T^*(\bar{u}_\varepsilon), \bar{y} = T^*(\bar{u})$. By Lemma 3.4(iii),

$$\bar{y}_\varepsilon \to \bar{y} \quad \text{strongly in } W^{1,p}_0(\Omega). \tag{4.5}$$

Thus,

$$\begin{aligned} I^*(\bar{u}) &= \frac{1}{p}\int_\Omega \{|\bar{y} - z|^p + \bar{y}\bar{u}\}dx = \lim_{\varepsilon\to 0^+} \frac{1}{p}\int_\Omega \{|\bar{y}_\varepsilon - z_\varepsilon|^p + \bar{y}_\varepsilon\bar{u}_\varepsilon\}dx \\ &\le \lim_{\varepsilon\to 0^+} \frac{1}{p}\int_\Omega \{|T^*(u) - z_\varepsilon|^p + uT^*(u)\}dx \\ &= \frac{1}{p}\int_\Omega \{|T^*(u) - z|^p + uT^*(u)\}dx = I^*(u) \quad \forall\ u \in L^{p'}_+(\Omega). \end{aligned}$$

That is, $\bar{u}$ is an optimal control to Problem (C*). Consequently, $\bar{y}$ is an optimal control to Problem (C).

Proof of Theorem 1.2. If $\bar{y}$ is the limit of $\bar{y}_\varepsilon$ as in (4.5), then we have proved that $\bar{u} \equiv -\mathrm{div}(|\nabla\bar{y}|^{p-2}\nabla\bar{y})$ satisfies (4.4).

If $z^+ \in L^q(\Omega)$ and $q > pn$, then $\bar{u} \in L^{\frac{q}{p-1}}_+(\Omega)$ and $\frac{q}{p-1} > \frac{p}{p-1}n = p'n$. Consequently, by Lemma 3.6(ii), $\bar{y} \in C^{1,\alpha}(\bar{\Omega})$ for some $\alpha \in (0,1)$.

In general, let $\bar{y}$ be an optimal control to Problem (C). Then it is easy to see that $\bar{y}$ must be the unique minimizer of the functional $y \mapsto \tilde{I}(y) + \int_\Omega |y - \bar{y}|^p dx$ over $\mathcal{H}^p_+(\Omega)$. Replacing $I^*(\cdot)$ by $I^*(\cdot) + \int_\Omega |T^*(\cdot) - \bar{y}|^p dx$, we can get the desired regularity of $\bar{y}$ by a discussion similar to that above.

The $C^{1,\alpha}$-regularity of $\bar{y}$ is the best possible result in general. To see this, let us first establish the following theorem.

THEOREM 4.1. *Let $1 < p < +\infty$, $z \in L^p(\Omega)$. Let $\bar{y}$ be an optimal control to Problem* (C) *and let Z minimize $\tilde{I}(\cdot)$ over $W^{1,p}_0(\Omega)$, i.e.,*

$$\begin{cases} -\mathrm{div}(|\nabla Z|^{p-2}\nabla Z) = |z - Z|^{p-2}(z - Z) \quad \text{in } \Omega, \\ Z|_{\partial\Omega} = 0. \end{cases} \tag{4.6}$$

Then $\bar{y} = Z$ if and only if $Z \le z$.

Proof. Suppose $\bar{y} = Z$. Then $Z = \bar{y} \le z$ since

$$|z - \bar{y}|^{p-2}(z - \bar{y}) = -\mathrm{div}(|\nabla \bar{y}|^{p-2}\nabla \bar{y}) \ge 0.$$

Now, suppose $Z \le z$. Then $Z \in \mathcal{H}^p_+(\Omega)$. Since Z minimizes $\tilde{I}(\cdot)$ over $W^{1,p}_0(\Omega)$, it must minimize $\tilde{I}(\cdot)$ over $\mathcal{H}^p_+(\Omega)$. Thus, $\tilde{I}(Z) = \tilde{I}(\bar{y})$. Therefore $\bar{y}$ also minimizes $\tilde{I}$ over $W^{1,p}_0(\Omega)$. Since $\tilde{I}$ is strictly convex in $W^{1,p}_0(\Omega)$, we get $\bar{y} = Z$. □

By the previous theorem, we can see that the $C^{1,\alpha}$-regularity of $\bar{y}$ is the best possible result in general. In fact, it is well known that a p-harmonic function may have no $C^{1,\alpha}$-regularity provided $\alpha > \alpha_p$, where $\alpha_p \to \frac{1}{3}$ as $p \to +\infty$ (see [22]). The case in our problem is quite similar. When $p = 2$, examples in [26] show that the $C^{1,1}$-regularity of $\bar{y}$ is the best possible result in general. The following is an example for the case $p > 2$.

Example 2. Let $2 < p < +\infty$, $\Omega = B_1$, $z \equiv 1$. Then by Theorem 4.1, we can prove that the minimizer $\bar{y}$ of $I(\cdot)$ corresponding to z satisfies

$$\begin{cases} -\mathrm{div}(|\nabla \bar{y}|^{p-2}\nabla \bar{y}) = |z - \bar{y}|^{p-2}(z - \bar{y}) \quad \text{in } \Omega, \\ \bar{y}|_{\partial\Omega} = 0. \end{cases}$$

It is easy to see that $\bar{y}$ is a radial function. Denote $\bar{y}(x) = h(|x|)$. We have

$$-h'(r) = \left\{ r^{1-n} \int_0^r \xi^{n-1}[1 - h(\xi)]^{p-1} d\xi \right\}^{\frac{1}{p-1}}. \tag{4.7}$$

Therefore

$$-h'(r) \le \left[r^{1-n} \int_0^r \xi^{n-1} d\xi \right]^{\frac{1}{p-1}} = \left(\frac{r}{n} \right)^{\frac{1}{p-1}} \tag{4.8}$$

and

$$h(r) \le h(0) = \int_0^1 -h'(r) dr \le \int_0^1 \left(\frac{r}{n} \right)^{\frac{1}{p-1}} dr = \left(\frac{1}{n} \right)^{\frac{1}{p-1}} \cdot \frac{p-1}{p} < 1.$$

Thus, by (4.7),

$$-h'(r) \ge [1 - h(0)] \left(\frac{r}{n} \right)^{\frac{1}{p-1}}. \tag{4.9}$$

Combining (4.8) with (4.9), we see that $h \notin C^{1,\alpha}[0,1)$ $\forall \alpha \in (\frac{1}{p-1}, 1]$. Consequently, $\bar{y} \notin C^{1,\alpha}(B_1)$ when $\alpha \in (\frac{1}{p-1}, 1]$.

5. Necessary condition. In section 3, we obtained the existence theorem and the necessary condition for a minimizer of the approximate problem. In section 4, we obtained the regularity of an optimal control to the original problem. However, it is difficult to characterize an optimality $\bar{y}$. The difficulty comes when we attempt to characterize the singular set $\{\nabla \bar{y} = 0\}$. But, in some special cases, we do get a characterization of $\bar{y}$.

LEMMA 5.1. *Let $-\infty < a < b < +\infty$, $1 < p < +\infty$. Suppose that $y \in W_0^{1,p}(a,b)$. Then, in the weak sense,*

$$-(|y'|^{p-2}y')' \geq 0 \quad \text{in } (a,b) \Longleftrightarrow -y'' \geq 0 \quad \text{in } (a,b). \tag{5.1}$$

Consequently, $\mathcal{H}_+^p(a,b)$ is convex.

Proof. We first suppose that in the weak sense,

$$-(|y'|^{p-2}y')' \geq 0 \quad \text{in } (a,b).$$

Denote

$$\mu = -(|y'|^{p-2}y')'.$$

Then $\mu \in W^{-1,p'}(a,b)$ and $\mu \geq 0$. As in the proof of Corollary 3.5, we have $u_\varepsilon \in C^\infty[a,b] \bigcap L_+^{p'}(\Omega)$ for any $\varepsilon > 0$ such that

$$\|u_\varepsilon - \mu\|_{W^{-1,p'}(a,b)} \leq \varepsilon.$$

Let y_ε satisfy (recalling that $y \in W^{1,p}(a,b) \hookrightarrow C[a,b]$)

$$\begin{cases} -[(\varepsilon^2 + |y_\varepsilon'|^2)^{\frac{p-2}{2}} y_\varepsilon']' = u_\varepsilon & \text{in } (a,b), \\ y_\varepsilon(a) = 0,\ y_\varepsilon(b) = 0. \end{cases} \tag{5.2}$$

By Lemma 3.4(ii), we have

$$y_\varepsilon \to y \quad \text{strongly in } W_0^{1,p}(a,b).$$

It is easy to see that $y_\varepsilon \in C^\infty(a,b)$. Therefore,

$$-(\varepsilon^2 + |y_\varepsilon'|^2)^{\frac{p-4}{2}}(\varepsilon^2 + (p-1)|y_\varepsilon'|^2)y_\varepsilon'' = u_\varepsilon \geq 0 \quad \text{in } (a,b).$$

Thus,

$$-y_\varepsilon'' \geq 0 \quad \text{in } (a,b).$$

Passing to the limit, we get

$$-y'' \geq 0 \quad \text{in } (a,b).$$

The remainder can be proved by a discussion similar to the above. □

THEOREM 5.2. *Let $-\infty < a < b < +\infty$, $\Omega = (a,b)$, $z \in L^p(a,b)$. Then Problem* (C) *admits a unique optimal control $\bar{y}$ and there exist a $\bar{\varphi} \in W_0^{1,p'}(a,b) \cap W^{2,p'}(a,b)$ such that*

$$\bar{\varphi} \leq 0 \quad \text{in } (a,b), \tag{5.3}$$

$$\begin{cases} -(|\bar{y}'|^{p-2}\bar{y}')' = |z - \bar{y}|^{p-2}(z - \bar{y})\chi_{\{\bar{\varphi}=0\}} & \text{in } (a,b), \\ \bar{y}(a) = \bar{y}(b) = 0, \end{cases} \tag{5.4}$$

and

$$\begin{cases} -\bar{\varphi}'' = |z-\bar{y}|^{p-2}(z-\bar{y})\chi_{\{\bar{\varphi}<0\}} \quad \text{in } (a,b), \\ \bar{\varphi}(a) = \bar{\varphi}(b) = 0. \end{cases} \tag{5.5}$$

Moreover, the pair $(\bar{y},\bar{\varphi}) \in \mathcal{H}_+^p(a,b)\times [W_0^{1,p'}(a,b)\cap W^{2,p'}(a,b)]$ *satisfying* (5.3)–(5.5) *is unique.*

On the other hand, if $z \in L^\infty(a,b)$, *then* $\bar{\varphi} \in C^{1,1}[a,b]$.

If $p \in (1,2]$ *and* $z^+ \in L^q(a,b)$ *for some* $p \le q \le +\infty$, *then* $\bar{y} \in W^{2,\frac{q}{p-1}}(a,b)$.

Proof. Obviously, $\mathcal{H}_+^p(a,b)$ is closed in $W_0^{1,p}(a,b)$ and $\tilde{I}(\cdot)$ is a strictly convex functional. By Lemma 5.1, $\mathcal{H}_+^p(a,b)$ is convex. Thus, we can prove that Problem (C) admits a unique optimal control $\bar{y}$ by the discussion in section 2. By Theorem 1.2, $\bar{u} \equiv -(|\bar{y}'|^{p-2}\bar{y}')' \in L_+^{p'}(a,b)$.

Let $y \in \mathcal{H}_+^p(a,b)$. Then

$$\bar{y} + \alpha(y-\bar{y}) \in \mathcal{H}_+^p(a,b) \quad \forall\ \alpha \in (0,1).$$

By the optimality of $\bar{y}$, we have

$$0 \le \frac{1}{p\alpha}\int_a^b \{|\bar{y}+\alpha(y-\bar{y})-z|^p + |\nabla\bar{y}+\alpha(\nabla y-\nabla\bar{y})|^p - |\bar{y}-z|^p - |\nabla\bar{y}|^p\}dx.$$

Let $\alpha \to 0^+$; we then get

$$\begin{aligned} 0 &\le \int_a^b \{|\bar{y}-z|^{p-2}(\bar{y}-z)(y-\bar{y}) + |\nabla\bar{y}|^{p-2}\nabla\bar{y}\cdot(\nabla y-\nabla\bar{y})\}dx \\ &= \int_a^b \{|\bar{y}-z|^{p-2}(\bar{y}-z)+\bar{u}\}(y-\bar{y})dx. \end{aligned} \tag{5.6}$$

Let $\bar{\varphi}$ be the solution of the following equation:

$$\begin{cases} -\bar{\varphi}'' = |z-\bar{y}|^{p-2}(z-\bar{y}) - \bar{u} \ \text{ in } (a,b), \\ \bar{\varphi}(a) = \bar{\varphi}(b) = 0. \end{cases} \tag{5.7}$$

Then (5.6) becomes

$$0 \le \int_a^b \bar{\varphi}''(y-\bar{y})dx = -\int_a^b \bar{\varphi}[(-y'')-(-\bar{y}'')]dx. \tag{5.8}$$

Consequently, by choosing $-y'' = -\bar{y}'' + v$, $v \in L_+^\infty(a,b)$, we get (5.3).

On the other hand, choosing $y = \frac{1}{2}\bar{y}$ in (5.8), we have

$$0 \le \frac{1}{2}\int_a^b \bar{\varphi}(-\bar{y}'')dx.$$

By (5.7), we have $\bar{\varphi} \in C^1[a,b]$. Thus $\{\bar{\varphi}<0\}$ is open and we have $\{\bar{\varphi}<0\} = \cup_k(a_k,b_k)$, where (a_k,b_k) are mutually disjoint. Combining (5.3) with $-\bar{y}'' \ge 0$, we get

$$\text{supp } \bar{y}'' \subseteq \{\bar{\varphi}=0\}.$$

Then, for any k, there exists a constant C_k such that

$$\bar{y}' = C_k, \quad \text{a.e. } (a_k,b_k).$$

That is,

$$|\bar{y}'|^{p-2}\bar{y}' = |C_k|^{p-2}C_k, \quad \text{a.e. } (a_k, b_k),$$

and we get

$$\bar{u} = 0, \quad \text{a.e. } (a_k, b_k).$$

On the other hand, by (5.7) and Lemma 3.2, we have

$$\bar{u} = |z - \bar{y}|^{p-2}(z - \bar{y}), \quad \text{a.e. } \{\bar{\varphi} = 0\}.$$

Thus, we get (5.4)–(5.5).

When $z \in L^\infty(a, b)$, we see that $\bar{\varphi} \in W^{2,\infty}(a, b) = C^{1,1}[a, b]$ by (5.5).

When $p \in (1, 2]$ and $z^+ \in L^q(a, b)$ for some $p \le q \le +\infty$, we have

$$-\bar{y}'' = \frac{1}{p-1}|\bar{y}'|^{2-p}|z - \bar{y}|^{p-2}(z - \bar{y})\chi_{\{\bar{\varphi}=0\}} \in L^{\frac{q}{p-1}}(a, b)$$

by (5.4). Consequently, $\bar{y} \in W^{2,\frac{q}{p-1}}(a, b)$.

Now, we prove the uniqueness. Suppose

$$(\tilde{y}, \tilde{\varphi}) \in \mathcal{H}_+^p(\Omega) \times W_0^{1,p'}(a, b)$$

satisfies (5.3)–(5.5) too. Then

$$\begin{aligned}
(5.9) \qquad & \int_a^b \{[|z - \tilde{y}|^{p-2}(z - \tilde{y}) - |z - \bar{y}|^{p-2}(z - \bar{y})][(z - \tilde{y}) - (z - \bar{y})] \\
& \qquad + (|\bar{y}'|^{p-2}\bar{y}' - |\tilde{y}'|^{p-2}\tilde{y}')(\bar{y}' - \tilde{y}')\}dx \\
& = \int_a^b \{-(|\bar{y}'|^{p-2}\bar{y}')' - |z - \bar{y}|^{p-2}(z - \bar{y}) \\
& \qquad + (|\tilde{y}'|^{p-2}\tilde{y}')' + |z - \tilde{y}|^{p-2}(z - \tilde{y})\}(\bar{y} - \tilde{y})dx \\
& = \int_a^b (\bar{\varphi}'' - \tilde{\varphi}'')(\bar{y} - \tilde{y})dx.
\end{aligned}$$

Since $\bar{\varphi} \in W_0^{1,p'}(a, b)$, $\bar{\varphi}$ is continuous. Therefore $\{\bar{\varphi} < 0\}$ is an open subset of (a, b). Thus $\{\bar{\varphi} < 0\} = \cup_k (a_k, b_k)$, where (a_k, b_k) are mutually disjoint. For each (a_k, b_k),

$$-(|\bar{y}'|^{p-2}\bar{y}')' = 0 \ \text{ in } (a_k, b_k).$$

Hence

$$\bar{y}' = C_k \ \text{ in } (a_k, b_k)$$

for some constant C_k. Noting that $\bar{\varphi}(a_k) = \bar{\varphi}(b_k) = 0$, $\bar{y} \in W_0^{1,p}(a, b)$, and $\bar{\varphi}' = 0$, a.e. in $\{\bar{\varphi} = 0\}$, by Lemma 3.2, we have

$$\begin{aligned}
& \int_a^b -\bar{\varphi}''\bar{y}dx = \int_a^b \bar{\varphi}'\bar{y}'dx = \int_{\{\bar{\varphi}<0\}} \bar{\varphi}'\bar{y}'dx = \sum_k \int_{a_k}^{b_k} \bar{\varphi}'\bar{y}'dx \\
& = \sum_k \int_{a_k}^{b_k} \bar{\varphi}'C_k dx = \sum_k C_k[\bar{\varphi}(a_k) - \bar{\varphi}(b_k)] = 0.
\end{aligned}$$

Similarly,

$$\int_a^b -\tilde{\varphi}''\tilde{y}dx = 0.$$

Therefore, by (5.3), (5.9), and Lemma 5.1,

$$\begin{aligned}&\int_a^b \{[|z-\tilde{y}|^{p-2}(z-\tilde{y}) - |z-\bar{y}|^{p-2}(z-\bar{y})][(z-\tilde{y}) - (z-\bar{y})] \\ &\qquad + (|\bar{y}'|^{p-2}\bar{y}' - |\tilde{y}'|^{p-2}\tilde{y}')(\bar{y}'-\tilde{y}')\}dx \\ &= \int_a^b \{-\bar{\varphi}''\tilde{y} - \tilde{\varphi}''\bar{y}\}dx = \int_a^b \{-\bar{\varphi}'\tilde{y}' - \tilde{\varphi}'\bar{y}'\}dx \le 0.\end{aligned}$$

Hence, by Lemma 3.3, $\bar{y} = \tilde{y}$. We complete the proof. □

When the domain is B_R and z is a radial function, we are interested in finding a minimizer of I over $W_0^{1,p}(B_R) \cap S_R$, where S_R denotes the set of all radial functions in B_R. We can also give results similar to those of Theorem 5.2.

THEOREM 5.3. *Suppose $1 < p < +\infty$ and $z \in L^p(B_R) \cap S_R$. Then $I(\cdot)$ admits a unique minimizer $\bar{y}$ over $W_0^{1,p}(B_R) \cap S_R$. We have $\bar{y} \in \mathcal{H}_+^p(B_R) \cap C^1(B_R \setminus \{0\})$. Moreover, if $z^+ \in L^q(B_R)$ for some $q > (p-1)n$, then $\bar{y} \in C^{1,\alpha}(\bar{B}_R)$ for some $\alpha \in (0,1)$.*

In the following theorems, $\bar{y}$ denotes the minimizer of $I(\cdot)$ over $W_0^{1,p}(B_R) \cap S_R$ corresponding to $z \in L^p(B_R) \cap S_R$.

THEOREM 5.4. *Let*

$$\bar{\psi}(x) = \bar{\psi}(|x|) = \int_{|x|}^R dr \int_0^r \xi^{n-1}|z(\xi)|^{p-2}z(\xi)r^{\frac{1-n}{p-1}}d\xi, \quad 0 < |x| \le R. \tag{5.10}$$

Then, $\bar{y} \equiv 0$ if and only if $\bar{\psi} \le 0$ in $\bar{B}_R \setminus \{0\}$.

THEOREM 5.5. *Suppose $1 < p < 2$, $\bar{\psi} \not\equiv 0$, where $\bar{\psi}$ is defined by (5.10) in $\bar{B}_R \setminus \{0\}$. Denote*

$$s = \sup\{r \in [0,R] | \nabla\bar{y} = 0, \text{ a.e. in } B_r\}. \tag{5.11}$$

Then $s \in [0,R)$, and

$$\nabla\bar{y} \ne 0 \quad \text{in } B_R \setminus \bar{B}_s. \tag{5.12}$$

(i) *If $s = 0$, then there exists a $\bar{\varphi} \in W_0^{1,\frac{p+1}{2}}(B_R) \cap C^1(\bar{B}_R \setminus \{0\})$ such that*

$$\bar{\varphi} \le 0 \quad \text{in } \bar{B}_R \setminus \{0\}, \tag{5.13}$$

$$\begin{cases} -\mathrm{div}(|\nabla\bar{y}|^{p-2}\nabla\bar{\varphi}) = |z-\bar{y}|^{p-2}(z-\bar{y})\chi_{\{\bar{\varphi}<0\}} & \text{in } B_R, \\ \bar{\varphi}|_{\partial B_R} = 0, \end{cases} \tag{5.14}$$

$$\begin{cases} -\mathrm{div}(|\nabla\bar{y}|^{p-2}\nabla\bar{y}) = |z-\bar{y}|^{p-2}(z-\bar{y})\chi_{\{\bar{\varphi}=0\}} & \text{in } B_R, \\ \bar{y}|_{\partial B_R} = 0. \end{cases} \tag{5.15}$$

Moreover, if $z \in L^q(B_R)$ for some $q > n(p-1)$, then $\bar{\varphi} \in C^1(\bar{B}_R)$. Consequently, $\bar{\varphi}(0) = 0$, $\nabla\bar{\varphi}(0) = 0$.

(ii) *If $s > 0$, then*

$$\int_{B_s} |z-\bar{y}|^{p-2}(z-\bar{y})dx = 0, \tag{5.16}$$

and there exists a $\bar{\varphi} \in C^1(\bar{B}_R \setminus B_s)$ such that

$$\bar{\varphi} \le 0 \quad \text{in } B_R \setminus \bar{B}_s, \tag{5.17}$$

$$\begin{cases} -\mathrm{div}(|\nabla\bar{y}|^{p-2}\nabla\bar{\varphi}) = |z-\bar{y}|^{p-2}(z-\bar{y})\chi_{\{\bar{\varphi}<0\}} & \text{in } B_R \setminus \bar{B}_s, \\ \bar{\varphi}|_{\partial B_R \cup \partial B_s} = 0, \nabla\bar{\varphi}|_{\partial B_s} = 0, \end{cases} \tag{5.18}$$

and

$$\begin{cases} -\mathrm{div}(|\nabla\bar{y}|^{p-2}\nabla\bar{y}) = |z-\bar{y}|^{p-2}(z-\bar{y})\chi_{\{\bar{\varphi}=0\}\cap(B_R\setminus\bar{B}_s)} & \text{in } B_R, \\ \bar{y}|_{\partial B_R} = 0. \end{cases} \tag{5.19}$$

THEOREM 5.6. *Suppose $2 < p < +\infty$. Then there exists a $\bar{\varphi} \in W_0^{1,p'}(B_R) \cap C^1(\bar{B}_R \setminus \{0\})$ such that*

$$\bar{\varphi} \le 0 \quad \text{in } \bar{B}_R, \tag{5.20}$$

$$\begin{cases} -\mathrm{div}(|x|^{-\gamma}\nabla\bar{\varphi}) = |z-\bar{y}|^{p-2}(z-\bar{y})\chi_{\{\bar{\varphi}<0\}} & \text{in } B_R, \\ \bar{\varphi}|_{\partial B_R} = 0, \end{cases} \tag{5.21}$$

$$\begin{cases} -\mathrm{div}(|\nabla\bar{y}|^{p-2}\nabla\bar{y}) = |z-\bar{y}|^{p-2}(z-\bar{y})\chi_{\{\bar{\varphi}=0\}} & \text{in } B_R, \\ \bar{y}|_{\partial B_R} = 0, \end{cases} \tag{5.22}$$

where $\gamma = \frac{(n-1)(p-2)}{p-1}$.

Though $\mathcal{H}_+^p(B_R)$ is not convex when $p \neq 2$ and $n > 1$, $\mathcal{H}_+^p(B_R) \cap S_R$ is convex by a straightforward computation. The proof of Theorem 5.3 is based on the fact that $\mathcal{H}_+^p(B_R) \cap S_R$ is a closed and convex subset of $W_0^{1,p}(B_R)$. The proofs of Theorems 5.4–5.6, which are somewhat similar to the proof of Theorem 5.2, need careful calculations. We omit the proofs.

REMARK 5.7. *If $\bar{\psi}$ in Theorem* 5.4 *has good regularity, then it is a solution of an equation like* (5.21) *in Theorem* 5.6.

REMARK 5.8. *Comparing Theorem* 5.5(ii) *with Theorems* 5.2 *and* 5.6, *we can see that the condition we get in case $1 < p < 2$ on the singular set $\{\nabla\bar{y} = 0\}$ is relatively weak. Roughly speaking,* (5.16) *is equivalent to $\bar{\varphi}(s) = 0$.*

REMARK 5.9. *In Theorem* 5.5, *if $\bar{u} \neq 0$, a.e. in $B_{s+\delta} \setminus B_s$ for some $\delta > 0$, then in* (5.14) *and* (5.18), $-\mathrm{div}(|\nabla\bar{y}|^{p-2}\nabla\bar{\varphi})$ *can be replaced by* $-\mathrm{div}(|x|^{-\gamma}\nabla\bar{\varphi})$ *as in* (5.21).

The results in Theorems 5.2, 5.5, and 5.6 are somewhat surprising. We guessed that on the singular set $\Omega_0 \equiv \{\nabla\bar{y} = 0\}$, $\bar{\varphi}$ in these theorems would satisfy $\bar{\varphi} \le 0$ and (if Ω_0 is a domain)

$$\begin{cases} -\triangle\bar{\varphi} = |z-\bar{y}|^{p-2}(z-\bar{y}) & \text{in } \Omega_0, \\ \bar{\varphi}|_{\partial\Omega_0} = 0. \end{cases}$$

Theorems 5.3 and 5.6 show that this is not the case. Though $\bar{y}_\varepsilon \to \bar{y}$ uniformly in $C^1(\bar{\Omega})$ under proper conditions, the set $\{\nabla\bar{y} = 0\}$ may be quite different from $\{\nabla\bar{y}_\varepsilon = 0\}$.

Acknowledgments. This paper was written under the guidance of Professor Jiongmin Yong. Many valuable suggestions were offered by Professor Xunjing Li. The author thanks both of them for their help.

ASYMPTOTIC CONTROL OF PAIRS OF OSCILLATORS COUPLED BY A REPULSION, WITH NONISOLATED EQUILIBRIA I: THE REGULAR CASE*

ALEXANDRE CABOT† AND MARC-OLIVIER CZARNECKI†

Abstract. Let $\phi : H \to \mathbb{R}$ be a $\mathcal{C}^1$ function on a real Hilbert space H and let $\gamma > 0$ be a positive damping parameter. For any repulsive potential $V : H \to \mathbb{R}_+$ and any control function $\varepsilon : \mathbb{R}_+ \to \mathbb{R}_+$ which tends to zero as $t \to +\infty$, we study the asymptotic behavior of the trajectories of the coupled dissipative system of nonlinear oscillators

$$\text{(HBFC}^2\text{)} \qquad \begin{cases} \ddot{x} + \gamma\dot{x} + \nabla\phi(x) + \varepsilon(t)\nabla V(x-y) = 0, \\ \ddot{y} + \gamma\dot{y} + \nabla\phi(y) - \varepsilon(t)\nabla V(x-y) = 0. \end{cases}$$

We first provide general existence results and show that $\nabla\phi(x(t)) \to 0$ and $\nabla\phi(y(t)) \to 0$ when $t \to +\infty$, assuming either that the trajectory (x, y) is bounded, or that the potential V is bounded and that ϕ satisfies the following limit condition:

(LIM) For every sequence $(z_n) \subset H$ such that $\lim_{n\to+\infty} |z_n| = +\infty$, there exists a subsequence $(z_{\varphi(n)})$ such that

$$\lim_{n\to+\infty} \phi(z_{\varphi(n)}) = +\infty \qquad \text{or} \qquad \lim_{n\to+\infty} \nabla\phi(z_{\varphi(n)}) = 0.$$

If $\varepsilon(t)$ does not tend to zero too rapidly as $t \to +\infty$, then the term $\varepsilon(t)\nabla V(x-y)$ asymptotically repulses the trajectories one from the other. Precisely, when $H = \mathbb{R}$, and if ε is a "slow" control, i.e., $\int_0^{+\infty} \varepsilon(t)dt = +\infty$, then the trajectories x and y converge to extremal points of the set $S = \{\lambda \in \mathbb{R}, \nabla\phi(\lambda) = 0\}$ of the equilibria of ϕ (when $S \neq \emptyset$), or they have the same limit. In particular, when S is reduced to an interval—for example, if ϕ is convex—this allows us to obtain a global description of the set S. We provide numerical experiments which make our convergence results more precise.

Key words. nonlinear oscillator, coupled system, slow control, heavy ball with friction, global optimization

1. Introduction.

(a) Let H be a real Hilbert space, with scalar product and corresponding norm, respectively, denoted by $\langle ., . \rangle$ and $|\ .\ |$. Let $\phi : H \to \mathbb{R}$ be a given $\mathcal{C}^1$ real-valued function called the potential function. An important problem is the search for the equilibria of the function ϕ (i.e., the solutions of the equation $\nabla\phi(x) = 0$, where $\nabla\phi$ is the gradient of ϕ), among which the minima (global or local) play a particular role in the fields of optimization, physics, and economics, to name a few. To obtain equilibria or minima of the function ϕ, a powerful method is to follow the trajectories of an associated dissipative gradient-like dynamical system, possibly discretized for numerical applications. In many practical problems (for example, minimizing a convex function which is not strictly convex), the function ϕ has nonisolated equilibria, and one wants to choose a particular equilibrium or minimum. One may also desire a full and global description of the set of equilibria or minima of ϕ, and also estimations of its size. We provide some examples in section 3.1.

It is not obvious that a dynamical system may help in these last cases, since a trajectory would likely lead to a single equilibrium at the limit when $t \to +\infty$. However, one could conceive, for example, that the cluster points of a dynamical system associated to the function ϕ could correspond exactly to the set of its minima. Even so, numerical applications might be tricky since the cluster points are likely to be more difficult to identify than simply limits. Another direction, which is our concern in this paper, is to consider coupled dynamical systems, which exchange information and thus are more able to globally explore the function ϕ than a single noncoupled system. Precisely, in order to obtain a global dynamical approach of the equilibria of the function ϕ, we study the asymptotic behavior of the following second order (in time) coupled gradient-like system:

$$\text{(HBFC}^2\text{)} \qquad \begin{cases} \ddot{x} + \gamma\dot{x} + \nabla\phi(x) + \varepsilon(t)\nabla V(x-y) = 0, \\ \ddot{y} + \gamma\dot{y} + \nabla\phi(y) - \varepsilon(t)\nabla V(x-y) = 0, \end{cases}$$

where $\gamma > 0$ is a positive damping parameter, $\varepsilon : \mathbb{R}_+ \to (0, +\infty)$ is a control function such that $\lim_{t\to+\infty} \varepsilon(t) = 0$, and $V : H \to \mathbb{R}_+$ is a (coupling) potential function.

(b) Let us briefly explain what led us to consider the (HBFC^2) system. To simply obtain equilibria or local minima of the function ϕ, the classical steepest descent method

$$\text{(SD)} \qquad \dot{x}(t) + \nabla\phi(x(t)) = 0$$

gives positive results (see Bruck's theorem [11], Lojasiewicz theorem [19, 20]; see also [9, 10], etc.) and is a descent method which corresponds to the motion of a drop of water on the graph of ϕ. Introducing acceleration in the motion, precisely considering a second order in time dynamical system, is likely to lead to more global exploration properties since it would not necessarily stop at the first equilibrium that it encounters. A particularly important system, the Heavy Ball with Friction system,

$$\text{(HBF)} \qquad \ddot{x}(t) + \gamma\dot{x}(t) + \nabla\phi(x(t)) = 0,$$

corresponds to the motion of a material point with positive mass, subjected to stay on the graph of ϕ. It is not a descent method but still a dissipative system ($\gamma > 0$ is the friction parameter) and enjoys many minimizing properties (see the recent papers of Alvarez [1], Attouch, Goudou, and Redont [6], Goudou [15], Haraux and Jendoubi [17], and Jendoubi [18]). However, only the first problem of reaching one—nonspecified—minimum of the function ϕ is answered.

In order to obtain more specifications on the properties of the equilibria which are selected as limits of the trajectories, Attouch and Czarnecki [4] consider the system

$$\text{(HBFC)} \qquad \ddot{x}(t) + \gamma\dot{x}(t) + \nabla\phi(x(t)) + \varepsilon(t)x(t) = 0$$

(Heavy Ball with Friction and Control) by introducing a Tikhonov-like[1] asymptotic regularization term $\varepsilon(t)x(t)$. When ϕ is convex and $\varepsilon : \mathbb{R}_+ \to \mathbb{R}_+$ is a $\mathcal{C}^1$ control function which tends to zero slowly, i.e., such that $\int_0^{+\infty} \varepsilon(t)dt = +\infty$, they proved that each trajectory of the (HBFC) system strongly converges to the point of minimal norm of the set $S = \operatorname{argmin}\phi$ [2] (which is assumed to be nonempty). The condition

[1] For the theory of Tikhonov regularization, we refer to [24].

[2] Precisely defined by $\operatorname{argmin}\phi = \{z \in H | \forall z' \in H, \phi(z) \leq \phi(z')\}$.

$\int_0^{+\infty} \varepsilon(t)dt = +\infty$ corresponds to the fact that $\varepsilon(t)$ does not tend to zero too rapidly, thus allowing the Tikhonov regularization term $\varepsilon(t)x(t)$ to be effective asymptotically.

This result shows in fact an asymptotic selection property: the effect of such a slow control ε forces all the trajectories to converge to the same equilibrium, namely, the equilibrium of minimal norm. This situation sharply contrasts with the noncontrolled situation (or fast control) where the limits of the trajectories are only weak limits, depend on the initial data, and may also be difficult to identify. The idea of coupling approximation methods with the dynamics of a gradient-like system had already been considered at the first order for the steepest descent by Attouch and Cominetti [3] (for related topics, see also Furuya, Miyashiba, and Kenmochi [14] and Baillon and Cominetti [8]).

(c) It is then a natural question to know if it is possible to adapt the selection properties of the Tikhonov regularization with a coupling potential in order to allow two different trajectories to "exchange" information so that they explore different parts of the set of equilibria $S = \{\lambda \in \mathbb{R}, \nabla\phi(\lambda) = 0\}$. Note that the (HBFC^2) system has a similar mechanical interpretation as the (HBF) system with an extra repulsion force—deriving from the potential V—between the two "balls" (for example, in the case where $V(z) = 1 - |z|^2$ ($|z| < 1$), it corresponds to a repulsive spring of varying stiffness $\varepsilon(t)$). One can easily conceive that if $\varepsilon(t)$ does not tend to zero too rapidly, the mechanical system will select two equilibria as far as possible from each other. Note also that the coupling term $\varepsilon(t)\nabla V(x-y)$ can be viewed as a time-varying feedback (see Coron [12] for a survey on stabilization of nonlinear systems by nonautonomous feedbacks).

The first main result of the paper (corresponding to Proposition 2.1 and part of Theorem 2.1 below) shows that $\nabla\phi(x(t)) \to 0$ and $\nabla\phi(y(t)) \to 0$ when $t \to +\infty$.

THEOREM A. *Assume that $\phi : H \to \mathbb{R}$ is a $\mathcal{C}^1$ function, bounded from below, such that $\nabla\phi$ is Lipschitz continuous on the bounded sets. Let $V : H \to \mathbb{R}_+$ be a C^1 function such that ∇V is locally Lipschitz continuous on H and bounded on the bounded subsets of H. Let $\varepsilon : [0, +\infty) \to \mathbb{R}_+$ be a C^1 function such that $\lim_{t\to+\infty} \varepsilon(t) = 0$ and $\dot\varepsilon(t) \le 0$ for every $t \in \mathbb{R}_+$. Then, for every $((x_0, y_0), (\dot x_0, \dot y_0)) \in H^2 \times H^2$, there is a unique solution $(x, y) : [0, +\infty) \to H^2$ of the* (HBFC^2) *Cauchy problem:*

$$\text{(HBFC}^2\text{)} \qquad \begin{cases} \ddot x + \gamma\dot x + \nabla\phi(x) + \varepsilon(t)\nabla V(x-y) = 0, \\ \ddot y + \gamma\dot y + \nabla\phi(y) - \varepsilon(t)\nabla V(x-y) = 0, \\ \Big(x(0), y(0), \dot x(0), \dot y(0)\Big) = \Big(x_0, y_0, \dot x_0, \dot y_0\Big). \end{cases}$$

Moreover,

$$\lim_{t\to+\infty} \nabla\phi(x(t)) = \lim_{t\to+\infty} \nabla\phi(y(t)) = 0$$

if one of the two following assumptions holds:

(a) *The trajectory (x, y) is bounded.*

(b) *The map $t \mapsto V(x(t) - y(t))$ is bounded and the map ϕ satisfies the limit condition*

(LIM) *for every sequence $(z_n) \subset H$ such that $\lim_{n\to+\infty} |z_n| = +\infty$, there exists a subsequence $(z_{\varphi(n)})$ such that*

$$\lim_{n\to+\infty} \phi(z_{\varphi(n)}) = +\infty \qquad \text{or} \qquad \lim_{n\to+\infty} \nabla\phi(z_{\varphi(n)}) = 0.$$

The second main result of the paper (corresponding to Theorem 2.2 and Corollary 2.4 below) is the convergence of the trajectories in the one-dimensional case. Let

$$\widehat{S} = \left\{ \overline{z} \in \overline{\mathbb{R}}, \lim_{z \to \overline{z}} \phi'(z) = 0 \right\}.$$

THEOREM B. *Under the assumptions of Theorem* A, *additionally assume that* $H = \mathbb{R}$ *and that* $zV'(z) \leq 0$ *for every* $z \in \mathbb{R}$ *(repulsion). Then the solution* (x, y) *satisfies the following asymptotical behavior:*

(i) *If* ϕ *satisfies* (LIM) *or if the trajectory* (x, y) *is bounded, there exists* $(x_\infty, y_\infty) \in \widehat{S} \times \widehat{S}$ *such that* $\lim_{t \to +\infty}(x(t)\,,\, y(t)) = (x_\infty\,,\, y_\infty)$.

(ii) *(Slow parametrization.) Additionally assume that* $\int_0^{+\infty} \varepsilon(t)\, dt = +\infty$, *that* $\widehat{S}$ *is an interval, and that for every* $z \neq 0$, $V'(z) \neq 0$. *Then one of the following cases holds:*

- $\lim_{t \to +\infty}(x(t)\,,\, y(t)) = (\sup \widehat{S}\,,\, \inf \widehat{S})$;
- $\lim_{t \to +\infty}(x(t)\,,\, y(t)) = (\inf \widehat{S}\,,\, \sup \widehat{S})$;
- $\lim_{t \to +\infty} x(t) = \lim_{t \to +\infty} y(t) \in \widehat{S}$.

In fact our convergence results are more precise and are not restricted to the case where $\widehat{S}$ is a nonempty interval. The first two cases give a global description of the set $\widehat{S}$ and give an answer to the initial problem of the global exploration of the equilibria of the potential ϕ. The last case does not provide global information and could be viewed as a drawback of our results. But numerical experiments (with different potentials ϕ and V) lead to the conjecture that this last case only happens on a negligible set of initial data, with a possibly fractal structure.

In order to precisely determine the convergence properties of the (HBFC^2) system in the infinite-dimensional setting, we show the weak convergence of the trajectories with a convex potential ϕ, and a "fast" control ε, i.e., such that $\int_0^{+\infty} \varepsilon(t)\, dt < +\infty$ (Proposition 2.2). But with a "fast" control, the (weak) limits depend on the initial data and are in general difficult to identify.

The one-dimensional case should be seen as a first step in which we are able to give precise results concerning the convergence, with a "slow control" ε. Though we provide remarks and counterexamples for such precision in higher dimensions, we believe that our paper could give a direction and justification for further extension of the global exploration of the equilibria of a (possibly nonconvex) function ϕ. Our numerical experiments seem to indicate that in "most" cases the coupled systems would lead to a full description of the set of the minima of ϕ, possibly involving a coupled finite number N of systems, with N greater than 2.

In numerical applications and simulations, the system (HBFC^2) is approximated by a discretized system, thus requiring one to compute only the potential on the sequence (x_n, y_n) of the discretized trajectory. For studies in this direction, see, for example, [2]. Note that the control term $\varepsilon(t)\nabla V(x-y)$ can be viewed as a perturbation term and thus allows us to take into account other perturbations (for example, of the potential ϕ). From the numerical point of view, it is essential to study the stability of the trajectory behavior of the (discretized) system under a perturbation of the potential, thus allowing for errors on the computation of ϕ and $\nabla\phi$ (which also can be interesting for the speed of computations). These studies are beyond the scope of our paper, but encouraging results are obtained in [21] by using incomplete sensitivities.

Besides its first optimization scope, note that applications are also to be found in the study of physical coupled systems, which of course requires results in higher dimensions.

(d) The paper is organized as follows. In section 2.1, we precisely state the global existence results and general asymptotic properties (Proposition 2.1 and Theorem 2.1), which are not reduced to the one-dimensional case. In section 2.2, we precisely state the asymptotic convergence results (Theorems 2.2 and 2.3 and Corollaries 2.3 and 2.4). In section 3, we provide remarks on and counterexamples of our results. The results are proved in section 4 (global existence) and section 5 (asymptotic convergence). Finally, in section 6, we give numerical results making our theoretical results more precise, and we indicate some possible directions for further research on the subject.

2. Main results. In this paper, we assume the following (rather standard) set of hypotheses.

HYPOTHESIS 1. *Let H be a real Hilbert space. Let us consider a map $\phi : H \to \mathbb{R}$ of class $\mathcal{C}^1$ which satisfies the following conditions:*

$$(\mathcal{H}_\phi) \quad \begin{cases} \text{(i)} & \text{the map } \phi \text{ is bounded from below on } H; \\ \text{(ii)} & \text{the map } \nabla\phi \text{ is Lipschitz continuous on the bounded subsets of } H. \end{cases}$$

Let $V : H \to \mathbb{R}_+$ be a map of class $\mathcal{C}^1$ such that

$$(\mathcal{H}_V) \quad \begin{cases} \text{(i)} & \text{the map } \nabla V \text{ is locally Lipschitz continuous on } H; \\ \text{(ii)} & \text{the map } \nabla V \text{ is bounded on the bounded subsets of } H. \end{cases}$$

Let $\varepsilon : [0, +\infty) \to \mathbb{R}_+$ be a function of class $\mathcal{C}^1$ such that

$$(\mathcal{H}_\varepsilon) \quad \begin{cases} \text{(i)} & \text{the function } \varepsilon \text{ is nonincreasing, i.e., } \forall t \in \mathbb{R}_+,\ \dot{\varepsilon}(t) \leq 0; \\ \text{(ii)} & \lim_{t \to +\infty} \varepsilon(t) = 0. \end{cases}$$

Let $\gamma > 0$, $((x_0, y_0), (\dot{x}_0, \dot{y}_0)) \in H^2 \times H^2$; the (HBFC^2) *system is defined as follows:*

$$\text{(HBFC}^2\text{)} \quad \begin{cases} \ddot{x} + \gamma\dot{x} + \nabla\phi(x) + \varepsilon(t)\nabla V(x - y) = 0, \\ \ddot{y} + \gamma\dot{y} + \nabla\phi(y) - \varepsilon(t)\nabla V(x - y) = 0, \\ \Big(x(0), y(0), \dot{x}(0), \dot{y}(0)\Big) = \Big(x_0, y_0, \dot{x}_0, \dot{y}_0\Big). \end{cases} \tag{2.1}$$

Remark. For the sake of readability, we take 0 as initial time. All the results of the paper clearly hold by taking any other initial time $t_0 \in \mathbb{R}$ and making the corresponding adaptations in the statements.

2.1. Global properties. The following proposition ensures the global existence of the solutions of the (HBFC^2) system.

PROPOSITION 2.1 (global existence). *Assume Hypothesis* 1. *Then*

(i) *there exists a unique maximal solution $(x, y) : [0, +\infty) \to H \times H$ of* (HBFC^2) *which is of class $\mathcal{C}^2$;*

(ii) $(\dot{x}, \dot{y}) \in L^\infty([0, +\infty); H \times H) \cap L^2([0, +\infty); H \times H)$ *and* $(\phi(x), \phi(y)) \in L^\infty([0, +\infty); \mathbb{R} \times \mathbb{R})$.

Proposition 2.1 is proved in section 4.1. The next result summarizes the global (convergence) properties of the solutions of the (HBFC^2) system.

THEOREM 2.1. *Under the assumptions of Proposition* 2.1 *(Hypothesis* 1*), additionally assume one of the two following assumptions:*

(a) *The trajectory (x, y) is bounded.*

(b) *The map $t \mapsto V(x(t) - y(t))$ is bounded and the map ϕ satisfies the limit condition*

(LIM) *For every sequence* $(z_n) \subset H$ *such that* $\lim_{n\to+\infty} |z_n| = +\infty$, *there exists a subsequence* $(z_{\varphi(n)})$ *such that*

$$\lim_{n\to+\infty} \phi(z_{\varphi(n)}) = +\infty \qquad \text{or} \qquad \lim_{n\to+\infty} \nabla\phi(z_{\varphi(n)}) = 0.$$

Then

(iii) $\lim_{t\to+\infty} \dot{x}(t) = \lim_{t\to+\infty} \dot{y}(t) = 0$;

(iv) $\lim_{t\to+\infty} \nabla\phi(x(t)) = \lim_{t\to+\infty} \nabla\phi(y(t)) = 0$.

Additionally assume that the map ϕ *is convex. Then, with* $S = \{z \in H, \nabla\phi(z) = 0\}$,

(v) *if* x *(resp.,* y*) is bounded, then* $\lim_{t\to+\infty} \phi(x(t)) = \inf \phi$ *(resp.,* $\lim_{t\to+\infty} \phi(y(t)) = \inf \phi$*)*;

(vi) *if* x_∞ *(resp.,* y_∞*) is a weak cluster point of* x *(resp.,* y*), then* x_∞ *(resp.,* y_∞*) belongs to* S.

Theorem 2.1 is proved in section 4.2. Note that Proposition 2.1 and Theorem 2.1 clearly imply Theorem A in the introduction.

Remark. Note that the condition (LIM) is equivalent to the following assertion:

$$\forall \alpha > 0,\ \forall A \in \mathbb{R}, \qquad \text{the set } \{z \in H, \phi(z) \le A \text{ and } |\nabla\phi(z)| \ge \alpha\} \text{ is bounded.}$$

The condition (LIM) is clearly satisfied in the two following simpler cases:

(c) The map ϕ is coercive, i.e., $\lim_{|z|\to+\infty} \phi(z) = +\infty$.

(d) $\lim_{|z|\to+\infty} \nabla\phi(z) = 0$.

In view of Proposition 2.1(ii), the map ϕ is bounded and the assumption (c) implies that the trajectory (x, y) is bounded. In this case, the assumption that the map $t \mapsto V(x(t) - y(t))$ is bounded is automatically satisfied.

We provide additional remarks and counterexamples in section 3.2.

2.2. Convergence in the one-dimensional case. Once the (global) existence is acquired, the main point in the study of a dissipative system is to investigate the convergence properties of the solution map. In this section, we explore the convergence and stabilizing properties of the solutions of the (HBFC^2) system under additional assumptions. We assume that the space H is one-dimensional (i.e., $H = \mathbb{R}$). Note that since the map $V' : \mathbb{R} \to \mathbb{R}$ is continuous, it is bounded on the bounded sets and assumption $(\mathcal{H}_V)$(ii) is automatically satisfied. Since our point is a global exploration, and in order to push the trajectories away one from another, we consider the case where the potential V is a repulsion, i.e., satisfies

$$(\mathcal{H}_V)\text{(iii)} \qquad \forall z \in \mathbb{R}, \quad zV'(z) \le 0.$$

2.2.1. Convergence of the trajectory. The next result gives the general convergence and stabilizing properties of the solutions of the (HBFC^2) system without further assumptions on the control ε. In the following, S denotes the set of the equilibria of ϕ: $S = \{z \in \mathbb{R}, \phi'(z) = 0\}$. In order to give a unified presentation of our results, we define the set $\widehat{S}$ as the union of S, of $\{+\infty\}$ if $\lim_{z\to+\infty} \phi'(z) = 0$, and of $\{-\infty\}$ if $\lim_{z\to-\infty} \phi'(z) = 0$. Equivalently,

$$\widehat{S} = \left\{ \overline{z} \in \overline{\mathbb{R}}, \lim_{z\to\overline{z}} \phi'(z) = 0 \right\}.$$

Finally, in order to include the case where the trajectories x and y may not be bounded, we consider the limit condition (LIM). Since $H = \mathbb{R}$, the limit condition (LIM) is satisfied if the map ϕ is convex and bounded from below.

THEOREM 2.2 (convergence of the solutions). *Assume Hypothesis* 1, *with* $H = \mathbb{R}$, *together with* $(\mathcal{H}_V)$(iii), $\forall z \in \mathbb{R},\ zV'(z) \leq 0$.

Assume that the map ϕ *satisfies* (LIM) *(for example, if* ϕ *is convex) or that the trajectory* (x, y) *is bounded.*[3] *Let (x,y) be the solution of the* (HBFC^2) *system. Then there exists* $(x_\infty, y_\infty) \in \widehat{S} \times \widehat{S}$ *such that*

$$\lim_{t \to +\infty} (x(t)\,,\, y(t)) = (x_\infty\,,\, y_\infty).$$

Theorem 2.2 is proved in section 5.1 and commented on in section 3.4. When ϕ is convex, the trajectory minimizes ϕ. The following corollary states this precisely.

COROLLARY 2.1. *Under the assumptions of Theorem* 2.2, *additionally assume that the map* ϕ *is convex. Then*

$$\lim_{t \to +\infty} (\phi(x(t))\,,\, \phi(y(t))) = (\inf \phi\,,\, \inf \phi).$$

Proof of Corollary 2.1. Consider the different cases (i) $x_\infty \in \mathbb{R}$ (hence x is bounded), (ii) $x_\infty = -\infty$ (hence $\phi' \geq 0$), (iii) $x_\infty = +\infty$ (hence $\phi' \leq 0$). ∎

Corollary 2.1 is commented on in section 3.5. As a consequence of Theorem 2.2, we deduce the convergence result of Haraux [16, Example 2.2.6] for the (not controlled) (HBF) system in dimension one.

COROLLARY 2.2 (Haraux [16]). *Let* $f \in \mathcal{C}^1(\mathbb{R})$ *and* $\gamma > 0$*; then every bounded solution of*

$$\ddot{x}(t) + \gamma \dot{x}(t) = f(x(t))$$

converges to some $x_\infty \in \mathbb{R}$ *such that* $f(x_\infty) = 0$.

Proof of Corollary 2.2. In Theorem 2.2, consider the (not controlled) case where $\varepsilon(t) = 0$ for every t, with a bounded $\mathcal{C}^2$ potential ϕ such that $\phi(z) = -\int_0^z f(u)du$ for $|z| \leq \|x\|_\infty$. ∎

2.2.2. Slow control. The results in this section specify the convergence of the solution map (x, y) toward specific points of $\widehat{S}$ with a "slow" control ε. For every $\lambda \in \overline{\mathbb{R}}$, we denote by $P^+(\lambda)$ (resp., $P^-(\lambda)$) the following proposition:

$$\text{For every neighborhood } V(\lambda) \text{ of } \lambda \quad \exists \mu \in V(\lambda) \cap \mathbb{R}, \quad \phi'(\mu) > 0 \quad (\text{resp., } \phi'(\mu) < 0).$$

THEOREM 2.3 (slow parametrization). *Under the assumptions of Theorem* 2.2, *additionally assume that*

$$(\mathcal{H}_\varepsilon)\text{(iii)} \qquad \int_0^{+\infty} \varepsilon(t)\, dt = +\infty.$$

$$(\mathcal{H}_V)\text{(iv)} \qquad \forall z \in \mathbb{R} \setminus \{0\}, \quad V'(z) \neq 0.$$

Let $m_\infty = \min\{x_\infty, y_\infty\}$ *and* $M_\infty = \max\{x_\infty, y_\infty\}$, *where* $(x_\infty, y_\infty) \in \widehat{S} \times \widehat{S}$ *are the limits of the trajectories. Then the solution* (x, y) *of the* (HBFC^2) *system satisfies the following properties:*

- *If* $-\infty < m_\infty < M_\infty < +\infty$, *then we have* $P^-(m_\infty)$ *and* $P^+(M_\infty)$.
- *If* $m_\infty = -\infty$ *and* $M_\infty < +\infty$, *then we have* $P^+(m_\infty)$ *or* $P^+(M_\infty)$.
- *If* $m_\infty > -\infty$ *and* $M_\infty = +\infty$, *then we have* $P^-(m_\infty)$ *or* $P^-(M_\infty)$.

[3] In fact this last case could be deduced from the previous one—the (LIM) assumption—by changing the map ϕ.

Theorem 2.3 is proved in section 5.2. In fact Theorem 2.3 specifies the points of $\widehat{S}$ where the trajectories x and y converge. In order to ensure readability, we consider only the special case below (see Corollary 3.1 for a more extensive description).

COROLLARY 2.3 (slow parametrization). *Under the assumptions of Theorem* 2.3, *let* $I(\lambda)$ *be the connected component of* λ *in* $\widehat{S}$. *If* $y_\infty < x_\infty$ *and if one of the conditions*

(a) $-\infty < y_\infty$;

(b) $y_\infty = -\infty$ *and* $\exists \lambda \in \mathbb{R}$, $\phi'((-\infty, \lambda]) \leq 0$

is satisfied, then the trajectory x *converges to an extremal point of* $I(x_\infty)$; *precisely,*

$$x_\infty \in \{\inf I(x_\infty), \sup I(x_\infty)\}.$$

Corollary 2.3 is proved in section 5.3 and commented on in section 3.6. When the set of equilibria is an interval, the behavior of the trajectories is more precise.

COROLLARY 2.4 (slow parametrization with a connected set of equilibria). *Under the assumptions of Theorem* 2.3, *additionally assume that the set* $\widehat{S}$ *is an interval (in* $\overline{\mathbb{R}}$*) (for example, if* ϕ *is convex). Then the solution (x,y) of the* (HBFC^2) *system satisfies one of the following cases:*

(i) $\lim_{t\to+\infty}(x(t)\,,\, y(t)) = (\sup \widehat{S}\,,\, \inf \widehat{S})$.

(ii) $\lim_{t\to+\infty}(x(t)\,,\, y(t)) = (\inf \widehat{S}\,,\, \sup \widehat{S})$.

(iii) *There exists* $x_\infty \in \widehat{S}$ *such that* $\lim_{t\to+\infty} x(t) = \lim_{t\to+\infty} y(t) = x_\infty$.

Note that Theorem 2.2 and Corollary 2.4 clearly imply Theorem B in the introduction.

Remark. In Corollary 2.4, the three cases reduce to only one when $\widehat{S}$ is reduced to a singleton. But then other simple methods of optimization (like the steepest descent method in the convex case) also apply. In the general case where $\widehat{S}$ is not reduced to a singleton, the three cases are disjoint.

Remark. When case (i) or (ii) of Corollary 2.4 holds, one obtains a global description of the set $\widehat{S}$ since the trajectories converge toward the extremal points of $\widehat{S}$. After some numerical experiments, we conjecture that case (iii) only happens for initial data in a negligible set (see section 6.2).

To illustrate Corollary 2.4 (hence Theorem 2.3 and Corollaries 2.3 and 3.1), we represent some trajectories $(x(t), y(t))$ in the plane $\mathbb{R}^2$. We take $\phi(z) = (z+1)^2$ if $z \leq -1$, $\phi(z) = 0$ if $z \in [-1, 1]$, $\phi(z) = (z-1)^2$ if $z \geq 1$, $V(z) = \frac{1}{2}e^{\frac{-z^2}{10}}$, $\varepsilon(t) = \frac{1}{\log(t+2)}$, and $\gamma = 0.4$. On Figure 2.1, we draw the trajectories $(x(t), y(t))$ for the three different initial conditions $(x(0), y(0), \dot{x}(0), \dot{y}(0)) = (0, 1.9, 0, 0)$, respectively, $(1.5, -2.5, 0, 0)$, respectively, $(2.5, 1.525718, 0, 0)$ corresponding to case (i), respectively, (ii), respectively, (iii). The gray square is the set $S \times S = [-1, 1] \times [-1, 1]$.

As a (clear) consequence of Corollary 2.4, the limit of the difference of the trajectories either maximizes the diameter of the set S or is equal to 0.

COROLLARY 2.5. *Under the assumptions of Theorem* 2.3, *additionally assume that* S *is a nonempty interval and that* $\widehat{S} = \mathrm{cl}_{\overline{\mathbb{R}}}(S)$. *Then the solution* (x, y) *of the* (HBFC^2) *system satisfies*

$$\lim_{t\to+\infty} |x(t) - y(t)| = \mathrm{diam}\,(S) \qquad \textit{or} \qquad \lim_{t\to+\infty} |x(t) - y(t)| = 0.$$

The proof of Corollary 2.5 is immediate.

Remark. Corollary 2.5 may not hold if we do not assume $\widehat{S} = \mathrm{cl}_{\overline{\mathbb{R}}}(S)$, even if S is a nonempty interval. Consider the counterexample in section 3.5.

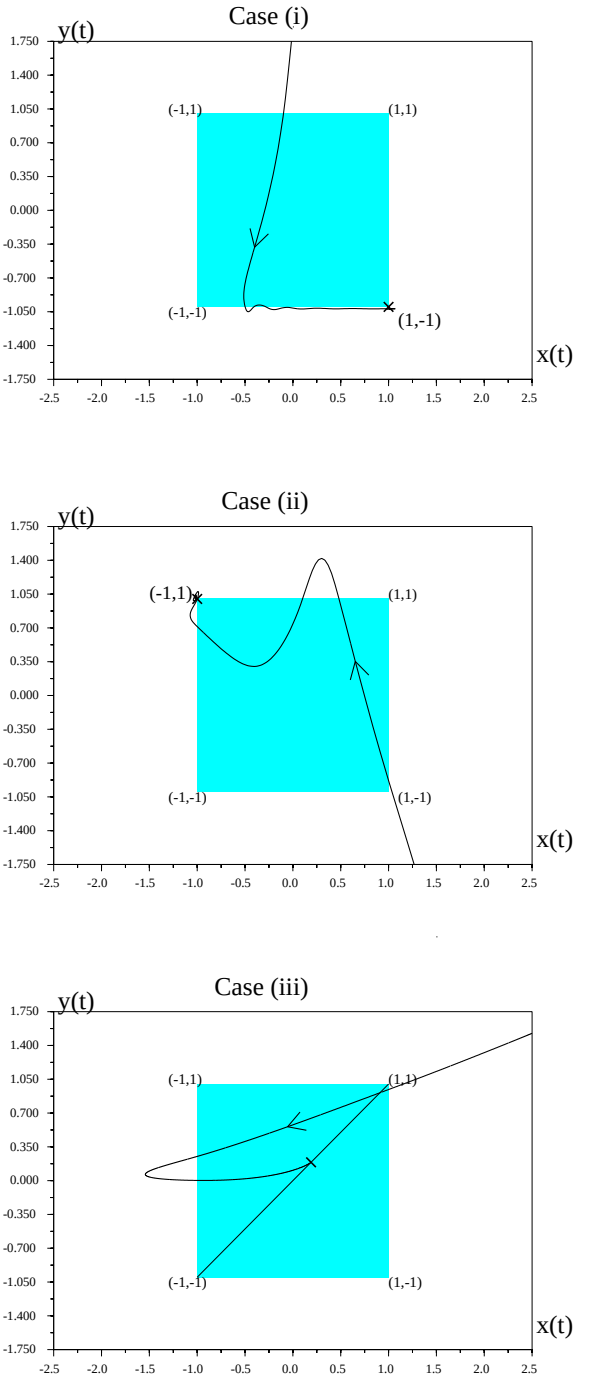

FIG. 2.1. *Illustration of the three cases* (i), (ii), *and* (iii).

2.3. Fast convergence in the convex and infinite-dimensional case. In order to precisely determine the convergence properties of the (HBFC^2) system, we show that the solutions of the (HBFC^2) system weakly converge, with a convex potential and a "fast control." Note that in this section we do not necessarily assume the potential V to be repulsive.

PROPOSITION 2.2 (fast parametrization in the convex case). *Assume Hypothesis* 1, *that* ϕ *is convex with* $S = \operatorname{argmin}\phi \neq \emptyset$, *and that*

$$(\mathcal{H}_\varepsilon)(\text{iv}) \qquad \int_0^{+\infty} \varepsilon(t)\,dt < +\infty.$$

Additionally assume that the trajectories x *and* y *are bounded. Then there exists some* $(x_\infty, y_\infty) \in S \times S$ *such that* (x, y) *weakly converges to* (x_∞, y_∞)*; precisely,* $w - \lim_{t\to+\infty}(x(t), y(t)) = (x_\infty, y_\infty)$ *and* $\lim_{t\to+\infty}\phi(x(t)) = \lim_{t\to+\infty}\phi(y(t)) = \min\phi$.

Proposition 2.2 is proved in section 5.5.

3. Remarks and counterexamples.

3.1. Some applications. In this section, we give some illustrations of practical cost or potential functions with nonunique and nonisolated equilibria. These are of course academic examples, while examples closer to real-world applications would require considering higher dimensions, PDEs, and also constraints (for example, if one needs to describe the full optimal face in mathematical programming). As pointed out in [5], this last study raises nontrivial difficulties, since the existence of constraints implies the possibility of shocks, with $\dot{x}$, $\dot{y}$ being discontinuous and $\ddot{x}$, $\ddot{y}$ being measures in the (HBFC^2) system.

Example. Let us consider the minimization problem

$$(\text{P}) \qquad \min_{x\in\mathbb{R}^n}\{\alpha\,||Ax - b||^2 + \beta\,d_C^2(x)\},$$

where A is an $(m\times n)$ matrix, $b \in \mathbb{R}^m$ is a vector, α and β are nonnegative coefficients, and d_C stands for the distance function of a convex set C, which should be seen as a penalization. When $\beta = 0$, (P) reduces to the classical least-squares resolution of the equation $Ax = b$. The optimal set S is then an affine subspace $F \subset \mathbb{R}^n$. On the other hand, when $\alpha = 0$, the optimal set clearly coincides with the set C. Now suppose we mix both problems by taking $\alpha > 0$ and $\beta > 0$. Assuming moreover that $C \cap F \neq \emptyset$, the optimal set S is equal to $C \cap F$: our problem then amounts to solving the linear system $Ax = b$ by a least-squares technique under the constraint $[x \in C]$. One question which naturally arises here concerns the size of the set $C \cap F$. We can then use the (HBFC)^2 system with $\phi(x) = \alpha\,||Ax - b||^2 + \beta\,d_C^2(x)$ to obtain a global exploration of the set $C \cap F$, and possibly its diameter. A second important question concerns the full description of the affine space F. This can be achieved by using N coupled system (for N larger than $\dim F$) and taking $C = \overline{B}(0, M)$ (with M large enough). If they do not collapse, the limit points of the trajectories will generate (by affine combination) the space F.

Example. An investor who wants to set up a firm will face and minimize an aggregate cost function, which is likely to have nonisolated equilibria. For example, the cost of linking to various utilities (water, electricity, etc.) is usually constant in a city, while outside the city the cost depends on the distance to the existing network. The same applies for employment costs, due to the existence of public transportation, but also due to possible differences of wage policies in different states.

3.2. On the global existence results.

Remark. Proposition 2.1 holds without assuming that the map ∇V is bounded on the bounded subsets of H ($(\mathcal{H}_V)$(ii)) and that $\lim_{t\to+\infty} \varepsilon(t) = 0$ ($(\mathcal{H}_\varepsilon)$(ii)).

Remark. If one does not assume that the trajectory (x, y) is bounded, then assertion (iv) of Theorem 2.1 may not hold, even in dimension one. Consider indeed a C^2 potential $\phi : \mathbb{R} \to \mathbb{R}$ such that $\phi' > 0$, $\lim_{z\to-\infty} \phi(z) = -1$, $\lim_{z\to+\infty} \phi(z) = 1$, $\limsup_{z\to-\infty} \phi'(z) \geq 1$. Take as initial conditions $x_0 = y_0$ and $\dot{x}_0 = \dot{y}_0 = 0$. Then by the Cauchy–Lipschitz theorem, $x \equiv y$. Then x satisfies $\ddot{x}(t) + \gamma\dot{x}(t) + \phi'(x(t)) = 0$. Since $\phi' > 0$, then $\ddot{x} + \gamma\dot{x} < 0$. We deduce that the map $\dot{x} + \gamma x$ converges (in $\overline{\mathbb{R}}$). Since $\dot{x}$ is bounded, $\ddot{x}$ is bounded from above. Since $\dot{x} \in L^2([0, +\infty), \mathbb{R})$, $\lim_{t\to+\infty} \dot{x}(t) = 0$, and the trajectory x converges (in $\overline{\mathbb{R}}$). Then $\liminf_{t\to+\infty} \phi'(x(t)) \leq 0$ (otherwise we would have $\lim_{t\to+\infty} \dot{x}(t) = -\infty$), and we obtain $\lim_{t\to+\infty} x(t) = -\infty$; hence $\limsup_{t\to+\infty} \phi'(x(t)) \geq 1$, a contradiction with assertion (iv).

Remark. Proposition 2.1 and Theorem 2.1 can easily be generalized to the case of N coupled oscillators with different potentials $\phi_1, \ldots, \phi_N$, with $N \geq 2$. For example, taking $\phi_2 = -\phi_1$ should lead to the exploration of saddle points, but this study is beyond the scope of this paper.

3.3. On condition (LIM).

Remark. When $H = \mathbb{R}$, note that the limit condition (LIM) is satisfied if

$$(\mathrm{LIM}_{strong}) \qquad \begin{cases} \lim_{z\to-\infty} \phi(z) = +\infty \text{ or } \lim_{z\to-\infty} \phi'(z) = 0, \\ \lim_{z\to+\infty} \phi(z) = +\infty \text{ or } \lim_{z\to+\infty} \phi'(z) = 0. \end{cases}$$

The converse is not true. Consider, for example, a $\mathcal{C}^2$ convolution-type approximation ϕ of the function $f + g$, where f is the simplest continuous piecewise affine function such that $f(2^{2n}) = n$ and $f(2^{2n+1}) = 0$, and g is the simplest continuous piecewise affine function such that $g(2^{2n}) = 1$, $g([2^{2n} + 1/2^n, 2^{2(n+1)} - 1/2^{n+1}]) = 0$. Note also that the natural generalization of (LIM_{strong}) in higher dimensions would be

$$\forall z \in H \setminus \{0\}, \qquad \lim_{\lambda\to+\infty} \phi(\lambda z) = +\infty \qquad \text{or} \qquad \lim_{\lambda\to+\infty} \nabla\phi(\lambda z) = 0.$$

But contrary to the one-dimensional case, the above condition does not imply (LIM). For example, consider $H = \mathbb{R}^2$ and $\phi(x, y) = x^2$.

Remark. Condition (LIM) can be generalized as follows:

$$(\mathrm{LIM}_{weak}) \qquad \begin{array}{l} \forall \alpha > 0, \forall A \in \mathbb{R}, \text{ for every connected component} \\ \Gamma_A \text{ of the set } \{z \in H, \phi(z) \leq A\}, \text{ the set} \\ \{z \in \Gamma_A, |\nabla\phi(z)| \geq \alpha\} \text{ is bounded.} \end{array}$$

Then all the results in this paper hold by replacing (LIM) by (LIM_{weak}). When $H = \mathbb{R}$, (LIM_{weak}) is equivalent to

$$\begin{cases} (\exists (z_n) \subset \mathbb{R}, \lim_{n\to+\infty} z_n = -\infty \text{ and } \lim_{n\to+\infty} \phi(z_n) = +\infty) \text{ or } \lim_{z\to-\infty} \phi'(z) = 0, \\ (\exists (z_n) \subset \mathbb{R}, \lim_{n\to+\infty} z_n = +\infty \text{ and } \lim_{n\to+\infty} \phi(z_n) = +\infty) \text{ or } \lim_{z\to+\infty} \phi'(z) = 0. \end{cases}$$

3.4. On Theorem 2.2.

Remark. It is possible to obtain the convergence of the solutions (but not necessarily in $\widehat{S}$; see below) under other sets of assumptions (for example, $\phi(z)$ converges when $z \to -\infty$, and when $z \to +\infty$). But our concern being the exploration of the equilibria of ϕ by the (HBFC^2) system, the extensive study of the converging properties of (HBFC^2) is beyond the scope of this paper.

3.5. On Corollary 2.1.

Remark. Corollary 2.1 may not hold if the map ϕ is not assumed to be convex, even if it is quasi-convex. Consider indeed the map $\phi : \mathbb{R} \to \mathbb{R}$ defined by $\phi(z) = 1 - e^{-z^2}$, a C^1 repulsion V such that $V(z) = 1/z$ if $z \geq 1$. Then ϕ is quasi-convex and $(x(t)\,,\, y(t)) = (\log t, -\log t)$ (for t large enough) is a solution of the corresponding (HBFC^2) system with $\varepsilon(t) = (\log t)^2(\frac{1}{t} - \frac{1}{t^2} + 2e^{-(\log t)^2}\log t)$ and $\gamma = 1$. One easily finds that when $t \to +\infty$, $\varepsilon(t) \sim \frac{(\log t)^2}{t}$ and $\dot{\varepsilon}(t) \sim \frac{\log t}{t^2}(2 - \log t)$, and hence that $\varepsilon(t) > 0$ and $\dot{\varepsilon}(t) < 0$ for t large enough. Moreover, note that $\int_0^{+\infty} \varepsilon(t)\, dt = +\infty$. The solution map $(x(t)\,,\, y(t)) = (\log t, -\log t)$ clearly does not satisfy the conclusion of Corollary 2.1.

3.6. On Corollary 2.3.

Remark. The conclusion of Corollary 2.3 may not be more precise in general. Precisely, one cannot replace the conclusion $x_\infty \in \{\inf I(x_\infty), \sup I(x_\infty)\}$ by $x_\infty = \sup I(x_\infty)$. Indeed, consider the even $\mathcal{C}^1$ map $\phi : \mathbb{R} \to \mathbb{R}$ defined by $\phi(z) = z^2 - \frac{1}{2}$ for $0 \leq z \leq \frac{1}{2}$, $\phi(z) = -(z-1)^2$ for $\frac{1}{2} \leq z \leq 1$, $\phi(z) = 0$ for $z \geq 1$. Let $x(t) = 1 - \frac{1}{t}$ for $t \geq 2$ and $y(t) = -x(t)$. Then (x, y) is a solution of the corresponding (HBFC^2) system, with $V(z) = \frac{1}{z}$ for $z \geq 1$ and $\varepsilon(t) = (2 - \frac{2}{t})^2(\frac{2}{t} + \frac{1}{t^2} - \frac{2}{t^3})$. Note that when $t \to +\infty$, $\varepsilon(t) \sim \frac{8}{t}$ and $\dot{\varepsilon}(t) \sim -\frac{8}{t^2}$, and hence $\int_0^{+\infty} \varepsilon(t)\, dt = +\infty$ and $\dot{\varepsilon}(t) < 0$ for t large enough.

Remark. The conclusion of Corollary 2.3 does not hold if $y_\infty = -\infty$ and there exists no $\lambda \in \mathbb{R}$ such that $\phi'((-\infty, \lambda]) \leq 0$. Indeed, consider a $\mathcal{C}^1$ increasing map $\phi : \mathbb{R} \to \mathbb{R}$ such that $\phi(z) = e^z$ for $z \leq 0$, $\phi(z) = 2$ for $z \geq 1$, and such that $S = [1, +\infty)$. Let $\gamma = 1$, $V(z) = e^{-z}$ for $z \geq 1$. Let $y(t) = -(1 + \frac{2}{t})\log(t)$ for $t \geq 1$. Then there is a map $x : [1, +\infty) \to \mathbb{R}$ such that $x(t) = 2 - \frac{1}{t} + o(\frac{1}{t})$ and such that (x, y) is a solution of the corresponding (HBFC^2) system for t large enough, with a control ε which satisfies $\varepsilon(t) \sim \frac{1}{C_2 t}$ and $\dot{\varepsilon}(t) \sim \frac{-1}{C_2 t^2}$ for some $C_2 > 0$. Precisely, $x(t) = x(1) + \int_1^t e^{-s} \int_1^s -e^u(\ddot{y}(u) + \dot{y}(u) + e^{y(u)})du ds$ and $\varepsilon(t) = \frac{\ddot{y}(t) + \dot{y}(t) + e^{y(t)}}{V'(x(t) - y(t))}$. Then $\widehat{S} = \{-\infty\} \cup [1, +\infty]$ and $\lim_{t \to +\infty} x(t) = 2$, which is clearly not an extremal point of its connected component $[1, +\infty]$.

Remark. From Corollary 2.3, one can deduce a full description of the different cases, as seen more precisely in the following corollary.

COROLLARY 3.1 (slow parametrization). *Under the assumptions of Theorem* 2.3*, the solution (x,y) of the* (HBFC^2) *system satisfies one of the following cases:*

(i) $y_\infty < x_\infty$
- (a) *if* $-\infty < y_\infty$, *or* ($y_\infty = -\infty$ *and* $\exists \lambda \in \mathbb{R}$, $\phi'((-\infty, \lambda]) \leq 0$), *then* $x_\infty \in \{\inf I(x_\infty), \sup I(x_\infty)\}$;
- (b) *if* $x_\infty < +\infty$, *or* ($x_\infty = +\infty$ *and* $\exists \lambda \in \mathbb{R}$, $\phi'([\lambda, +\infty)) \geq 0$), *then* $y_\infty \in \{\inf I(y_\infty), \sup I(y_\infty)\}$.

(ii) $x_\infty < y_\infty$
- (a) *if* $-\infty < x_\infty$, *or* ($x_\infty = -\infty$ *and* $\exists \lambda \in \mathbb{R}$, $\phi'((-\infty, \lambda]) \leq 0$), *then* $y_\infty \in \{\inf I(y_\infty), \sup I(y_\infty)\}$;
- (b) *if* $y_\infty < +\infty$, *or* ($y_\infty = +\infty$ *and* $\exists \lambda \in \mathbb{R}$, $\phi'([\lambda, +\infty)) \geq 0$), *then* $x_\infty \in \{\inf I(x_\infty), \sup I(x_\infty)\}$.

(iii) $x_\infty = y_\infty$.

Proof of Corollary 3.1. Let $\tilde{\phi}(z) = \phi(-z)$ and $\tilde{V}(z) = V(-z)$. If (x, y) is a solution of the (HBFC^2) system associated to ϕ and V, $(-y, -x)$ is a solution of the (HBFC^2) system associated to $\tilde{\phi}$ and V, which proves (ii)(b), and (y, x) is a solution

of the (HBFC^2) system associated to ϕ and $\tilde{V}$, which proves (ii)(a). Assertion (i)(b) follows. ∎

3.7. On Corollary 2.5.

Remark. The formulation of Theorem 2.3 and Corollaries 2.3, 2.4, and 3.1 is specific to dimension one. This is not the case for Corollary 2.5, even if this last one may not remain true in higher dimensions. Indeed, in $\mathbb{R}^2$, consider the set $C = [-1,1] \times [-1,1]$, the function $\phi = d_C^2$, and $V(z) = e^{-|z|^2}$. Take any $\gamma > 0$ and slow control function ε (satisfying the assumptions $(\mathcal{H}_\varepsilon)$(i)(ii)(iii)). Let (x,y) be the solution of the corresponding (HBFC^2) system for initial data $x(0) \in \{0\} \times \mathbb{R}$, $y(0) \in \{0\} \times \mathbb{R}$, $\dot{x}(0) \in \{0\} \times \mathbb{R}$, $\dot{y}(0) \in \{0\} \times \mathbb{R}$. It is then clear that the trajectories of x and y are one-dimensional, and from Corollary 2.4 one easily shows that either $\lim_{t\to+\infty} x(t) = \lim_{t\to+\infty} y(t)$ or x and y converge toward the extremities of the segment $[(0,-1),(0,1)]$. In this last case, $\lim_{t\to+\infty} |x(t)-y(t)| = 2 \neq 2\sqrt{2} = \operatorname{diam}(S)$.

3.8. On Proposition 2.2.

Remark. In general, it does not seem possible to obtain a better result (in the sense of the specification of the limit point, or by obtaining strong convergence rather than weak convergence) without further assumptions. Indeed, if $x = y$, a case which happens if and only if $(x_0, \dot{x}_0) = (y_0, \dot{y}_0)$, then the (HBFC^2) system reduces to a (HBF) system. It is then known (see Baillon [7] and [6]) that the trajectory (x,y) may not strongly converge and that the weak limits depend on the initial data.

Remark. If the map ϕ is not assumed to be convex, the trajectories (x,y) may not weakly converge. Considering again the case where $x = y$, we refer to the counterexample of Redont [23] (see also [6]).

4. Proof of the global existence and of the main properties.

4.1. Proof of Proposition 2.1. Let

$$X = (x,y) \in H^2, \qquad \Phi(X) = \phi(x) + \phi(y), \qquad U(X) = V(x-y),$$
$$X_0 = (x_0, y_0), \qquad \dot{X}_0 = (\dot{x}_0, \dot{y}_0).$$

The system (HBFC^2) then reduces to:

$$\text{(HBFC)} \qquad \begin{cases} \ddot{X} + \gamma \dot{X} + \nabla\Phi(X) + \varepsilon(t)\nabla U(X) = 0, \\ X(0) = X_0, \quad \dot{X}(0) = \dot{X}_0. \end{cases}$$

4.1.1. Proof of (i). The second order system (HBFC) can be written as a first order system in $H^2 \times H^2$:

$$\dot{Y} = F(t,Y)$$

with

$$Y(t) = \begin{pmatrix} X(t) \\ \dot{X}(t) \end{pmatrix} \qquad \text{and} \qquad F(t,u,v) = \begin{pmatrix} v \\ -\gamma v - \nabla\Phi(u) - \varepsilon(t)\nabla U(u) \end{pmatrix}. \tag{4.1}$$

For $Y_0 = \binom{X_0}{\dot{X}_0}$ given in $H^2 \times H^2$, the Cauchy–Lipschitz theorem and Hypothesis 1 ensure the existence of a unique local solution to the problem

$$\begin{cases} \dot{Y} = F(t,Y), \\ Y(0) = Y_0. \end{cases} \tag{4.2}$$

Let X denote the maximal solution defined on the interval $[0, T_{max})$ with $0 < T_{max} \leq +\infty$. In order to prove that $T_{max} = +\infty$, let us show that the map $\dot{X}$ is bounded. We first observe that (HBFC) and the regularity assumptions on ϕ, V, and ε automatically imply that the map X is $\mathcal{C}^2$ on $[0, T_{max})$.

Along every trajectory of (HBFC), we define the energy by

$$E(t) = \frac{1}{2}|\dot{X}(t)|^2 + \Phi(X(t)) + \varepsilon(t)U(X(t)).$$

By differentiation of $E(t)$, and in view of (HBFC), we obtain for every $t \in [0, T_{max})$

$$\begin{aligned} \dot{E}(t) &= \langle \dot{X}(t), \ddot{X}(t) + \nabla\Phi(X(t)) + \varepsilon(t)\nabla U(X(t))\rangle + \dot{\varepsilon}(t)U(X(t)) \\ &= -\gamma|\dot{X}(t)|^2 + \dot{\varepsilon}(t)U(X(t)). \end{aligned} \tag{4.3}$$

Since $\dot{\varepsilon}(t) \leq 0$ (assumption $(\mathcal{H}_\varepsilon)$(i)) and $U \geq 0$, we have $\dot{E}(t) \leq 0$. Hence the function E is nonincreasing and for every $t \in [0, T_{max})$, $E(t) \leq E(0)$. Equivalently,

$$\frac{1}{2}|\dot{X}(t)|^2 + \Phi(X(t)) + \varepsilon(t)U(X(t)) \leq E(0). \tag{4.4}$$

Since Φ is bounded from below, $U \geq 0$, and $\varepsilon \geq 0$, we obtain

$$\sup_{t\in[0,T_{max})} |\dot{X}(t)| < +\infty.$$

By a standard argument, we derive that $T_{max} = +\infty$. Indeed, assume that $T_{max} < +\infty$. Since

$$|X(t) - X(t')| \leq ||\dot{X}||_\infty |t - t'|$$

and since $T_{max} < +\infty$, $\lim_{t\to T_{max}} X(t) := X_\infty$ exists. Hence, the maps X and $\dot{X}$ are bounded on $[0, T_{max})$. Since $\lim_{t\to T_{max}} X(t) = X_\infty$, the map

$$\nabla\Phi(X) + \varepsilon\nabla U(X) \quad \text{ is bounded on } [0, T_{max}).$$

From (HBFC), we deduce that $\ddot{X}$ is bounded on this interval. Hence $\lim_{t\to T_{max}} \dot{X}(t) = \dot{X}_\infty$ exists. Applying again the local existence theorem with initial data $(X_\infty, \dot{X}_\infty) \in H^2 \times H^2$, we can extend the maximal solution to a strictly larger interval, a contradiction. Hence $T_{max} = +\infty$, which completes the proof of Proposition 2.1(i). □

4.1.2. Proof of (ii). We already proved that the function E is nonincreasing. For every $t \geq 0$, $E(0) \geq E(t) \geq \Phi(X(t))$, which implies that the map Φ is bounded from above, and hence bounded. Moreover, the function E is also bounded from below. Hence, there exists $E_\infty \in \mathbb{R}$ such that $\lim_{t\to+\infty} E(t) = E_\infty$. From (4.4), and since Φ is bounded from below and $U \geq 0$, we obtain, for every $t \geq 0$,

$$\frac{1}{2}|\dot{X}(t)|^2 \leq E(0) - \inf\Phi.$$

Hence $\dot{X} \in L^\infty([0, +\infty); H^2)$. From (4.3) and the fact that $\dot{\varepsilon} \leq 0$ and $U \geq 0$, we derive, for every $t \geq 0$,

$$\int_0^t |\dot{X}(s)|^2 ds \leq \frac{1}{\gamma}(E(0) - E(t)).$$

Since $E(t)$ decreases to E_∞ as t increases to $+\infty$, we obtain

$$\int_0^{+\infty} |\dot{X}(s)|^2 ds \leq \frac{1}{\gamma}(E(0) - E_\infty),$$

and $\dot{X} \in L^2([0,+\infty); H^2)$. The inequality (4.4) implies, for every $t \geq 0$,

$$\Phi(X(t)) \leq E(0),$$

i.e., $\Phi(X)$ is bounded. □

4.2. Proof of Theorem 2.1.

4.2.1. Proof of (iii). We first claim that the maps $\nabla\Phi(X)$ and $U(X)$ are bounded. To prove it, we distinguish the two cases (a) and (b).

Case (a). Since the map $\nabla\Phi$ is Lipschitz continuous on the bounded sets, it is bounded on the bounded sets. Since the map ∇U is bounded on the bounded sets, the map U is Lipschitz continuous on the bounded sets, and hence bounded on the bounded sets. Since the trajectory $X = (x, y)$ is bounded, the maps $\nabla\Phi(X)$ and $U(X)$ are bounded.

Case (b). In this case, the map $U(X)$ is assumed to be bounded. From Proposition 2.1(ii), the map $\phi(x)$ is bounded. The condition (LIM) implies that the set

$$C = \{z \in H, \phi(z) \leq \|\phi(x)\|_\infty \text{ and } |\nabla\phi(z)| \geq 1\}$$

is bounded. Since the map $\nabla\phi$ is bounded on the bounded sets, it is bounded on C. If $x(t) \notin C$, since $\phi(x(t)) \leq \|\phi(x)\|_\infty$, we deduce $|\nabla\phi(x(t))| < 1$. Hence the map $\nabla\phi(x)$ is bounded, and so is the map $\nabla\phi(y)$. We now conclude the proof thanks to the following claim. □

CLAIM 4.1. *If the maps $\nabla\Phi(X)$ and $U(X)$ are bounded, then $\lim_{t\to+\infty} \dot{X}(t) = 0$.*

Proof of Claim 4.1. Since the map $\nabla\Phi(X)$ is bounded, and since the map $\dot{X}$ is bounded (Proposition 2.1(ii)), the map $t \mapsto \Phi(X(t))$ is Lipschitz continuous. Let us recall that the energy function

$$E(t) = \frac{1}{2}|\dot{X}(t)|^2 + \Phi(X(t)) + \varepsilon(t)U(X(t))$$

converges to some $E_\infty \in \mathbb{R}$. Since $t \mapsto U(X(t))$ is bounded, $\lim_{t\to+\infty} \varepsilon(t)U(X(t)) = 0$. Hence, the map $|\dot{X}|^2$ is the sum of a convergent map and of a Lipschitz continuous map. From Proposition 2.1(ii), $|\dot{X}|^2 \in L^1([0,+\infty), H)$. By a classical argument, we deduce that $\lim_{t\to+\infty} |\dot{X}(t)|^2 = 0$, and hence deduce also that the map $\Phi(X(t))$ converges when $t \to +\infty$. □

4.2.2. Proof of (iv). We distinguish the two cases (a) and (b).

Proof in Case (a). The trajectory X is bounded, and $\lim_{t\to+\infty} \nabla\Phi(X(t)) = 0$—which proves (iv)—is an immediate consequence of the following lemma. □

LEMMA 4.1. *Assume Hypothesis* 1. *Let $(t_n) \subset \mathbb{R}_+$ be a sequence such that $\lim_{n\to+\infty} t_n = +\infty$ and $X(t_n)$ is bounded. Then $\lim_{n\to+\infty} \nabla\Phi(X(t_n)) = 0$.*

Proof of Lemma 4.1. Assume that it is not true. Then there exist $\alpha > 0$ and a subsequence of (t_n), still denoted by (t_n), such that $\lim_{n\to+\infty} t_n = +\infty$ and $|\nabla\Phi(X(t_n))| \geq \alpha$ for every n. By assumption, the map $\nabla\Phi$ is K-Lipschitz continuous on the bounded set

$$C = \{Z \in H \times H, \quad \exists n \in \mathbb{N}, \quad |Z - X(t_n)| \leq 1\}$$

for some $K > 0$. Let $\tau = \frac{\alpha}{K\|\dot{X}\|_\infty}$ (assuming without any loss of generality that $\|\dot{X}\|_\infty \neq 0$) and let $t \in [t_n, t_n + \tau]$. Then

$$|X(t) - X(t_n)| \leq \|\dot{X}\|_\infty \tau = \frac{\alpha}{K}. \tag{4.5}$$

Assuming without any loss of generality that $\frac{\alpha}{K} \leq 1$, then from (4.5), $X(t) \in C$ and

$$|\nabla\Phi(X(t)) - \nabla\Phi(X(t_n))| \leq K|X(t) - X(t_n)| \leq K\frac{\alpha}{K} = \alpha. \tag{4.6}$$

Let us now integrate (HBFC) on the interval $[t_n, t_n + \tau]$:

$$\begin{aligned}\dot{X}(t_n + \tau) - \dot{X}(t_n) + \gamma \int_{t_n}^{t_n+\tau} \dot{X}(t)\, dt + \int_{t_n}^{t_n+\tau} \nabla\Phi(X(t))\, dt \\ + \int_{t_n}^{t_n+\tau} \varepsilon(t)\nabla U(X(t))\, dt = 0.\end{aligned} \tag{4.7}$$

From (iii), $\lim_{n\to+\infty} \sup_{t\in[t_n,t_n+\tau]} \dot{X}(t) = 0$ and therefore

$$\lim_{n\to+\infty} \dot{X}(t_n + \tau) - \dot{X}(t_n) + \gamma \int_{t_n}^{t_n+\tau} \dot{X}(t)\, dt = 0.$$

Since the map ∇U is bounded on the bounded set C, we obtain

$$\lim_{n\to+\infty} \int_{t_n}^{t_n+\tau} \varepsilon(t)\nabla U(X(t))\, dt = 0.$$

Noticing that

$$\begin{aligned}\left| \int_{t_n}^{t_n+\tau} \nabla\Phi(X(t))\, dt - \int_{t_n}^{t_n+\tau} \nabla\Phi(X(t_n))\, dt \right| &\leq K\|\dot{X}\|_\infty \int_{t_n}^{t_n+\tau} |t - t_n|\, dt \\ &\leq \frac{K\|\dot{X}\|_\infty \tau^2}{2} = \frac{\alpha\tau}{2}\end{aligned}$$

and that $\left| \int_{t_n}^{t_n+\tau} \nabla\Phi(X(t_n))\, dt \right| \geq \alpha\tau$, we obtain

$$\left| \int_{t_n}^{t_n+\tau} \nabla\Phi(X(t))\, dt \right| \geq \frac{\alpha\tau}{2}.$$

Taking the limit in equation (4.7) when $n \to +\infty$, we obtain a contradiction. Hence $\lim_{t\to+\infty} |\nabla\Phi(X(t))| = 0$. □

Proof in Case (b). Let us argue by contradiction and assume that it is not true; i.e., there exists $\alpha > 0$ and a sequence $(t_n) \subset \mathbb{R}_+$ such that $\lim_{n\to+\infty} t_n = +\infty$ and $|\nabla\Phi(X(t_n))| \geq \alpha$. Without any loss of generality, we may assume that $|\nabla\phi(x(t_n))| \geq \alpha$. Since the map $\phi(x)$ is bounded (Proposition 2.1(ii)) and since the map ϕ satisfies the condition (LIM), the sequence $(x(t_n))$ is bounded. The following lemma shows that the sequence $(y(t_n))$ is also bounded. From Lemma 4.1, $\lim_{n\to+\infty} \nabla\Phi(X(t_n)) = 0$, a contradiction. Hence $\lim_{t\to+\infty} \nabla\Phi(X(t)) = 0$. □

LEMMA 4.2. *Assume Hypothesis* 1, *and that the map ϕ satisfies the limit condition* (LIM). *Let $\alpha > 0$ and $(t_n) \subset \mathbb{R}_+$ be a sequence such that $\lim_{n\to+\infty} t_n = +\infty$, $(x(t_n))$ is bounded and $|\nabla\phi(x(t_n))| \geq \alpha$. Then the sequence $(y(t_n))$ is also bounded.*

Proof of Lemma 4.2. By assumption, the map $\nabla\phi$ is K-Lipschitz continuous on the bounded set $C = \{z \in H, \quad \exists n \in \mathbb{N}, \quad |z - x(t_n)| \leq 1\}$ for some $K > 0$. Let $\tau = \frac{\alpha}{2K\|\dot{x}\|_\infty}$ (assuming without any loss of generality that $\|\dot{x}\|_\infty \neq 0$) and let $t \in [t_n, t_n + \tau]$. Then

$$|x(t) - x(t_n)| \leq \|\dot{x}\|_\infty \tau = \frac{\alpha}{2K}. \tag{4.8}$$

Assuming without any loss of generality that $\frac{\alpha}{2K} \leq 1$, $x(t) \in C$, and

$$|\nabla\phi(x(t)) - \nabla\phi(x(t_n))| \leq K|x(t) - x(t_n)| \leq K\frac{\alpha}{2K} = \frac{\alpha}{2}. \tag{4.9}$$

By adding the two equations of (HBFC^2), we obtain

$$\ddot{x}(t) + \ddot{y}(t) + \gamma(\dot{x}(t) + \dot{y}(t)) + \nabla\phi(x(t)) + \nabla\phi(y(t)) = 0. \tag{4.10}$$

Integrating (4.10) between t_n and $t_n + \tau$, we obtain

$$\begin{aligned}\dot{x}(t_n + \tau) + \dot{y}(t_n + \tau) - (\dot{x}(t_n) + \dot{y}(t_n)) + \gamma \int_{t_n}^{t_n+\tau} \dot{x}(t) + \dot{y}(t)\, dt \\ + \int_{t_n}^{t_n+\tau} \nabla\phi(x(t)) + \nabla\phi(y(t))\, dt = 0.\end{aligned} \tag{4.11}$$

From assertion (iii), $\lim_{t\to+\infty} \dot{x}(t) + \dot{y}(t) = 0$; hence $\lim_{n\to+\infty} \sup_{t\in[t_n,t_n+\tau]} \dot{x}(t) + \dot{y}(t) = 0$. Therefore,

$$\lim_{n\to+\infty} \dot{x}(t_n + \tau) + \dot{y}(t_n + \tau) - (\dot{x}(t_n) + \dot{y}(t_n)) + \gamma \int_{t_n}^{t_n+\tau} \dot{x}(t) + \dot{y}(t)\, dt = 0$$

and

$$\lim_{n\to+\infty} \int_{t_n}^{t_n+\tau} \nabla\phi(x(t)) + \nabla\phi(y(t))\, dt = 0. \tag{4.12}$$

Writing

$$\nabla\phi(x(t_n)) = \nabla\phi(x(t_n)) - \nabla\phi(x(t)) \; + \; \nabla\phi(x(t)) + \nabla\phi(y(t)) \; - \; \nabla\phi(y(t)),$$

we obtain

$$\begin{aligned}\left|\int_{t_n}^{t_n+\tau} \nabla\phi(x(t_n))\, dt\right| \leq \left|\int_{t_n}^{t_n+\tau} \nabla\phi(x(t_n)) - \nabla\phi(x(t))\, dt\right| \\ + \left|\int_{t_n}^{t_n+\tau} \nabla\phi(x(t)) + \nabla\phi(y(t))\, dt\right| + \left|\int_{t_n}^{t_n+\tau} \nabla\phi(y(t))\, dt\right|.\end{aligned}$$

Now using $|\nabla\phi(x(t_n))| \geq \alpha$, (4.9), and (4.12), we deduce

$$\liminf_{n\to+\infty} \left|\int_{t_n}^{t_n+\tau} \nabla\phi(y(t))\, dt\right| \geq \frac{\alpha}{2}\tau,$$

and therefore, for n large enough,

$$\int_{t_n}^{t_n+\tau} |\nabla\phi(y(t))|\, dt \geq \frac{\alpha}{3}\tau. \tag{4.13}$$

From the above inequality, we deduce that there exists $\theta_n \in [t_n, t_n+\tau]$ such that, for n large enough, $|\nabla\phi(y(\theta_n))| \geq \frac{\alpha}{3}$. Indeed, if it were not true, up to a subsequence, then for every n and for every $t \in [t_n, t_n+\tau]$, $|\nabla\phi(y(t))| < \frac{\alpha}{3}$, which contradicts (4.13). Since the map $\phi(y)$ is bounded (Proposition 2.1(ii)) and since the map ϕ satisfies the condition (LIM), the sequence $(y(\theta_n))$ is bounded. Since $|y(t_n) - y(\theta_n)| \leq ||\dot{y}||_\infty \tau$, we deduce that the sequence $(y(t_n))$ is also bounded. □

4.2.3. Proof of (v) and (vi). Let us write the classical convexity inequality

$$\forall \xi \in H, \qquad \phi(\xi) \geq \phi(x(t)) + \langle \nabla\phi(x(t)), \xi - x(t)\rangle.$$

By noticing that in the duality bracket $\langle \nabla\phi(x(t)), \xi - x(t)\rangle$ the two terms are, respectively, norms converging to zero and bounded, we can pass to the upper limit to obtain

$$\forall \xi \in H, \qquad \phi(\xi) \geq \limsup_{t\to+\infty} \phi(x(t)) \geq \liminf_{t\to+\infty} \phi(x(t)) \geq \inf \phi.$$

This being true for any $\xi \in H$, we deduce that $\lim_{t\to+\infty} \phi(x(t)) = \inf \phi$, which proves assertion (v).

From assertion (iv), $\nabla\phi(x(t)) \to 0$ as $t \to +\infty$. If $x(t_n) \rightharpoonup x_\infty$ weakly, by using the graph closedness property of the maximal monotone operator $\nabla\phi$ in $w-H \times s-H$, we conclude that $\nabla\phi(x_\infty) = 0$, i.e., $x_\infty \in S$. □

5. Proof of the convergence results. In this section, we consider the one-dimensional case, i.e., $H = \mathbb{R}$.

5.1. Proof of Theorem 2.2. The proof of the convergence of the trajectories goes in three steps. We first establish the inequality fulfilled by the map $\max\{x, y\}$. Then we deduce the convergence of the maps $\max\{x, y\}$ and $\min\{x, y\}$. Finally we check the convergence of the trajectories.

5.1.1. Properties of the map $\max\{x, y\}$.

LEMMA 5.1. *Under the assumptions of Theorem* 2.2, *let* (x, y) *be the unique solution of the* (HBFC^2) *system. Then*

(i) *there exists a discrete and closed set* $\mathcal{D} \subset \mathbb{R}_+$ *such that the map* $w = \max\{x, y\}$ *is of class* $\mathcal{C}^2$ *on* $\mathbb{R}_+ \setminus \mathcal{D}$, *and for every* $t \in \mathbb{R}_+ \setminus \mathcal{D}$,

$$\ddot{w}(t) + \gamma\dot{w}(t) + \phi'(w(t)) \geq 0; \tag{5.1}$$

(ii) *for every* $(t, t') \in \mathbb{R}_+ \times \mathbb{R}_+$ *such that* $t' \leq t$, *the following inequality holds:*

$$w(t) \geq w(t') - \frac{1}{\gamma}(\dot{w}_-(t) - \dot{w}_+(t')) - \frac{1}{\gamma}\int_{t'}^{t} \phi'(w(s))\, ds.$$

Proof of Lemma 5.1.

Proof of (i). Let us remark at once that if $\forall t \in \mathbb{R}_+$, $x(t) = y(t)$, then we obviously have

$$\forall t \in \mathbb{R}_+, \qquad \ddot{w}(t) + \gamma\dot{w}(t) + \phi'(w(t)) = 0.$$

We can then take $\mathcal{D} = \emptyset$. Assume now that $x \not\equiv y$. Let us prove that the set $\mathcal{D} = \{t \in \mathbb{R}_+,\ x(t) = y(t)\}$ satisfies the conditions of the statement. Since x and y are continuous, the set $\mathcal{D}$ is closed. Let $t_0 \in \mathcal{D}$, i.e., such that $x(t_0) = y(t_0)$.

Necessarily $\dot{x}(t_0) \neq \dot{y}(t_0)$; in fact, in the opposite case, one would have $x \equiv y$ by the Cauchy–Lipschitz theorem. Indeed, take the solution z of $\ddot{z}(t) + \gamma\dot{z}(t) + \phi'(z(t)) = 0$, $z(t_0) = x(t_0)$ $\dot{z}(t_0) = \dot{x}(t_0)$ and note that (z, z) is a solution of (HBFC^2), and hence that $(x, y) = (z, z)$. Then there exists $\varepsilon > 0$ such that $\forall t \in [t_0-\varepsilon, t_0[\cup]t_0, t_0+\varepsilon]$, $x(t) \neq y(t)$, i.e., $[t_0 - \varepsilon, t_0 + \varepsilon] \cap \mathcal{D} = \{t_0\}$, which proves that the point t_0 is isolated.

Let us now verify (5.1); let $t_0 \in \mathbb{R}_+ \setminus \mathcal{D}$. There exists a neighborhood $\mathcal{V}$ of t_0 such that w coincides with x (resp., y) on $\mathcal{V}$. We then have $x(t_0) \geq y(t_0)$ (resp., $y(t_0) \geq x(t_0)$) and therefore, using assumption $(\mathcal{H}_V)$(iii), $V'(x - y)(t_0) \leq 0$ (resp., $V'(x-y)(t_0) \geq 0$). We then deduce from the first (resp., second) equation of (HBFC^2) that

$$\ddot{w}(t_0) + \gamma\dot{w}(t_0) + \phi'(w(t_0)) \geq 0.$$

Proof of (ii). Let us remark at once that the set $\mathcal{D} \cap [t', t]$ is discrete and compact, and hence finite. Relation (5.1) is then true on $[t', t]$ outside a finite number of points. Let us denote by $a_1, \dots, a_n$ the elements of $\mathcal{D} \cap]t', t[$ and set $a_0 = t'$ and $a_{n+1} = t$. We now integrate the inequality (5.1) on each interval $]a_k, a_{k+1}[$, $0 \leq k \leq n$. By adding the obtained inequalities, one finds

$$\sum_{k=0}^{n} \int_{a_k}^{a_{k+1}} \ddot{w}(s)\, ds \, + \gamma \sum_{k=0}^{n} \int_{a_k}^{a_{k+1}} \dot{w}(s)\, ds \, + \sum_{k=0}^{n} \int_{a_k}^{a_{k+1}} \phi'(w(s))\, ds \, \geq 0. \tag{5.2}$$

Since the functions $w = \max\{x, y\}$ and $\phi'(w)$ are continuous on $[t', t]$, we have

$$\sum_{k=0}^{n} \int_{a_k}^{a_{k+1}} \dot{w}(s)\, ds \, = \sum_{k=0}^{n} \Big(w(a_{k+1}) - w(a_k) \Big) = w(t) - w(t') \tag{5.3}$$

and

$$\sum_{k=0}^{n} \int_{a_k}^{a_{k+1}} \phi'(w(s))\, ds \, = \, \int_{t'}^{t} \phi'(w(s))\, ds. \tag{5.4}$$

On the other hand, the map $w = \max\{x, y\}$ verifies $\dot{w}_+ \geq \dot{w}_-$, and hence

$$\begin{aligned} \sum_{k=0}^{n} \int_{a_k}^{a_{k+1}} \ddot{w}(s)\, ds \, &= \sum_{k=0}^{n} \dot{w}_-(a_{k+1}) - \dot{w}_+(a_k) \\ &= \dot{w}_-(t) - \dot{w}_+(t') - \sum_{k=1}^{n} \Big(\dot{w}_+(a_k) - \dot{w}_-(a_k) \Big) \leq \dot{w}_-(t) - \dot{w}_+(t'). \end{aligned} \tag{5.5}$$

By combining (5.2), (5.3), (5.4), and (5.5), we obtain the expected formula. ∎

5.1.2. Convergence of $\max\{x, y\}$ and $\min\{x, y\}$.

LEMMA 5.2. *Under the assumptions of Theorem* 2.2, *the maps* $\max\{x, y\}$ *and* $\min\{x, y\}$ *converge in* $\overline{\mathbb{R}}$.

Proof of Lemma 5.2. Without any loss of generality, we prove the convergence of the map $w = \max\{x, y\}$ only. Assume that it is not true, i.e., $\liminf_{t\to+\infty} w(t) < \limsup_{t\to+\infty} w(t)$. Let us first prove that $]\liminf_{t\to+\infty} w(t), \limsup_{t\to+\infty} w(t)[\subset S$. Let $\lambda \in]\liminf_{t\to+\infty} w(t), \limsup_{t\to+\infty} w(t)[$. There is a sequence (t_n) in $\mathbb{R}$ such that $\lim_{n\to+\infty} t_n = +\infty$ and $\lim_{n\to+\infty} w(t_n) = \lambda$. Without any loss of generality, up to a subsequence, we may assume that $w(t_n) = x(t_n)$ for every n; hence from Theorem 2.1(iv), $\phi'(\lambda) = \lim_{n\to+\infty} \phi'(w(t_n)) = \lim_{n\to+\infty} \phi'(x(t_n)) = 0$.

Now consider λ and μ in $\mathbb{R}$ such that

$$\liminf_{t\to+\infty} w(t) < \lambda < \mu < \limsup_{t\to+\infty} w(t).$$

Since $\mu < \limsup_{t\to+\infty} w(t)$, there exists a sequence (t_n) such that $t_n \to +\infty$ and $w(t_n) > \mu$. Let

$$T_n = \sup\left\{u \geq t_n,\ w([t_n,u]) \geq \lambda\right\}.$$

Since $\liminf_{t\to+\infty} w(t) < \lambda$, then $T_n < +\infty$. By the continuity of w, we have $w(T_n) = \lambda$. Let

$$\tau_n = \inf\left\{u \in [t_n,T_n],\ w([u,T_n]) \leq \limsup_{t\to+\infty} w(t)\right\}.$$

If $\tau_n = t_n$ then $w(\tau_n) = w(t_n) > \mu$. If $\tau_n > t_n$, then $w(\tau_n) = \limsup_{t\to+\infty} w(t) > \mu$. Hence, in both cases, $w(\tau_n) > \mu$. For every $u \in [\tau_n, T_n]$,

$$\liminf_{t\to+\infty} w(t) < \lambda \leq w(u) \leq \limsup_{t\to+\infty} w(t);$$

hence $\phi'(w(u)) = 0$. We then deduce from Lemma 5.1 that $w(T_n) \geq w(\tau_n) - \frac{1}{\gamma}(\dot{w}_-(T_n) - \dot{w}_+(\tau_n))$, and since $w(T_n) = \lambda$ and $w(\tau_n) > \mu$,

$$\lambda > \mu - \frac{1}{\gamma}(\dot{w}_-(T_n) - \dot{w}_+(\tau_n)). \tag{5.6}$$

Since $\lim_{t\to+\infty} \dot{x}(t) = \lim_{t\to+\infty} \dot{y}(t) = 0$ (Theorem 2.1(iii)), then $\lim_{t\to+\infty} \dot{w}_-(t) = \lim_{t\to+\infty} \dot{w}_+(t) = 0$. Passing to the limit when $n \to +\infty$, (5.6) then yields $\lambda \geq \mu$, a contradiction. □

5.1.3. Convergence of the trajectories. We now come back to the proof of Theorem 2.2. In view of Lemma 5.2, the maps $\max\{x,y\}$ and $\min\{x,y\}$, respectively, converge to some m_∞ and M_∞ in $\overline{\mathbb{R}}$. If $m_\infty < M_\infty$, we directly deduce the convergence of the trajectories x and y. If $m_\infty = M_\infty = +\infty$ (resp., $-\infty$), then clearly $\lim_{t\to+\infty} x(t) = \lim_{t\to+\infty} y(t) = +\infty$ (resp., $-\infty$). Let us now examine the case $m_\infty = M_\infty \in \mathbb{R}$. The functions $x + y = \max\{x,y\} + \min\{x,y\}$ and $|x - y| = \max\{x,y\} - \min\{x,y\}$, respectively, converge to $2\,m_\infty (= 2\,M_\infty)$ and 0. Hence, $\lim_{t\to+\infty} x(t) = \lim_{t\to+\infty} y(t) = m_\infty = M_\infty$. Consequently, in all cases, there exists $(x_\infty, y_\infty) \in \overline{\mathbb{R}} \times \overline{\mathbb{R}}$ such that $\lim_{t\to+\infty} x(t) = x_\infty$ and $\lim_{t\to+\infty} y(t) = y_\infty$. Since $\lim_{t\to+\infty}(\phi'(x(t)), \phi'(y(t))) = (0,0)$ (Theorem 2.1(iv)), then $(x_\infty, y_\infty) \in \widehat{S} \times \widehat{S}$, which ends the proof of Theorem 2.2. □

5.2. Proof of Theorem 2.3. Let us first assume that $-\infty < m_\infty < M_\infty < +\infty$. Without any loss of generality, we prove only the assertion $P^+(M_\infty)$. Let us argue by contradiction and assume that there exists a neighborhood $V(M_\infty)$ of M_∞ such that $\phi'_{|V(M_\infty)} \leq 0$. Setting $w = \max\{x,y\}$, there exists $t_0 \geq 0$ such that, $\forall t \geq t_0$, $w(t) \in V(M_\infty)$, and hence

$$\forall t \geq t_0, \qquad \phi'(w(t)) \leq 0. \tag{5.7}$$

Since, by assumption, $-\infty < m_\infty < M_\infty < +\infty$, there exist $\alpha > 0$, $M > 0$, and $t_1 \geq t_0$ such that, $\forall t \geq t_1$, $\alpha \leq |x(t) - y(t)| \leq M$. From $(\mathcal{H}_V)$(iv), there exists $\eta > 0$ such that

$$\forall t \geq t_1, \qquad |V'(x(t) - y(t))| \geq \inf_{\alpha \leq |z| \leq M} |V'(z)| = \eta. \tag{5.8}$$

On the other hand, since $x(t) \neq y(t)$ for every $t \geq t_1$, then $w(t) = x(t)$ for every $t \geq t_1$ or $w(t) = y(t)$ for every $t \geq t_1$. Hence the map w is of class $\mathcal{C}^2$ on $[t_1, +\infty)$. In view of (HBFC^2) and $(\mathcal{H}_V)$(iii), the map w verifies the following differential equation:

$$\ddot{w} + \gamma \dot{w} + \phi'(w) - \varepsilon(t)|V'(x - y)| = 0. \tag{5.9}$$

In view of (5.7), (5.8), and (5.9), we find

$$\forall t \geq t_1, \qquad \ddot{w}(t) + \gamma \dot{w}(t) \geq \eta \varepsilon(t).$$

In view of Claim 5.1 below, we obtain $\lim_{t \to +\infty} w(t) = +\infty$, a contradiction.

Claim 5.1. *Let $u : [0, +\infty[\to \mathbb{R}$ be a function of class $\mathcal{C}^2$ and let $\varepsilon : [0, +\infty) \to \mathbb{R}_+$ be a continuous function such that*

$$\forall t \geq 0, \qquad \ddot{u}(t) + \gamma \dot{u}(t) \geq \eta \varepsilon(t),$$

where $\eta > 0$, $\gamma > 0$, and $\int_0^{+\infty} \varepsilon(t)\, dt = +\infty$. Then $\lim_{t \to +\infty} u(t) = +\infty$.

Proof of Claim 5.1. Let us multiply the differential inequality by $e^{\gamma s}$ and integrate twice; we find

$$u(t) \geq u(0) + \frac{\dot{u}(0)}{\gamma}(1 - e^{-\gamma t}) + \eta \int_0^t \int_0^u e^{-\gamma(u-s)} \varepsilon(s)\, ds\, du.$$

On the other hand,

$$\lim_{t \to +\infty} \int_0^t \int_0^u e^{-\gamma(u-s)} \varepsilon(s)\, ds\, du = \frac{1}{\gamma} \int_0^{+\infty} \varepsilon(s)\, ds = +\infty.$$

Hence, $\lim_{t \to +\infty} u(t) = +\infty$. ∎

Let us now assume that $m_\infty = -\infty$ and $M_\infty < +\infty$. Let us argue by contradiction and assume that we have neither $P^+(m_\infty)$ nor $P^+(M_\infty)$. Then there exists a neighborhood $V(M_\infty)$ of M_∞, respectively, $V(m_\infty)$ of m_∞, such that ${\phi'}_{|V(M_\infty)} \leq 0$, respectively, ${\phi'}_{|V(m_\infty)} \leq 0$. Consequently there exists $t_0 \geq 0$ such that, for every $t \geq t_0$,

$$\phi'(x(t)) \leq 0 \quad \text{and} \quad \phi'(y(t)) \leq 0.$$

By adding the two equations of (HBFC^2), we deduce that

$$\forall t \geq t_0, \qquad \ddot{x}(t) + \ddot{y}(t) + \gamma(\dot{x}(t) + \dot{y}(t)) \geq 0.$$

A direct computation shows that $x + y$ is bounded from below, a contradiction with $m_\infty = -\infty$. The proof of the last case $m_\infty > -\infty$ and $M_\infty = +\infty$ goes along the same lines. ∎

5.3. Proof of Corollary 2.3. Let $I(x_\infty)$ be the connected component of x_∞ in $\widehat{S}$. Let us argue by contradiction and assume that $x_\infty \notin \{\inf I(x_\infty), \sup I(x_\infty)\}$. In particular, we have $x_\infty < +\infty$. If condition (a) is satisfied, we obtain by Theorem 2.3 the assertions $P^-(y_\infty)$ and $P^+(x_\infty)$. If condition (b) is satisfied, the assertion $P^+(y_\infty)$ is false and then, by Theorem 2.3, we obtain the assertion $P^+(x_\infty)$. In both cases, we have $P^+(x_\infty)$, which is inconsistent with $x_\infty \in \operatorname{int} I(x_\infty)$, a contradiction. ∎

5.4. Proof of Corollary 2.4. We assume that the third conclusion of Corollary 2.4 does not hold, i.e., $x_\infty \neq y_\infty$. Without any loss of generality, we may assume that $x_\infty > y_\infty$. Since $\widehat{S}$ is connected, $I(x_\infty) = \widehat{S}$. From Corollary 2.3, $x_\infty \in \{\inf \widehat{S}, \sup \widehat{S}\}$. But $x_\infty > y_\infty$ with $y_\infty \in \widehat{S}$ implies that $x_\infty = \sup \widehat{S}$. ∎

5.5. Proof of Proposition 2.2. Not surprisingly, our proof of Proposition 2.2 is greatly inspired by the proof of the Alvarez theorem given in [6] and its extension to the controlled case in [4]. The Alvarez theorem is itself an extension of Bruck's theorem [11] (first order steepest descent method) to the second order dissipative (HBF) system. For the sake of completeness, we recall the outline of the proof. We refer to [4] for further details.

Let $z \in S$; we define the function $h_z : [0, +\infty) \to \mathbb{R}_+$ by

$$h_z(t) = \frac{1}{2}|x(t) - z|^2.$$

Since $\dot{h}_z(t) = \langle x(t) - z, \dot{x}(t)\rangle$ and $\ddot{h}_z(t) = |\dot{x}(t)|^2 + \langle x(t) - z, \ddot{x}(t)\rangle$, and since the map x is the solution of the (HBFC^2) system, we have

$$\ddot{h}_z(t) + \gamma \dot{h}_z(t) = |\dot{x}(t)|^2 - \langle x(t) - z, \nabla\phi(x(t))\rangle - \varepsilon(t)\langle x(t) - z, \nabla V(x(t) - y(t))\rangle.$$

Since $z \in S$, we have $\nabla\phi(z) = 0$. From the monotonicity of $\nabla\phi$, we have, for every t, $\langle x(t) - z, \nabla\phi(x(t))\rangle = \langle x(t) - z, \nabla\phi(x(t)) - \nabla\phi(z)\rangle \geq 0$. Since the trajectories x and y are bounded and since ∇V is bounded on the bounded sets, there is $C > 0$ such that $|\langle x(t) - z, \nabla V(x(t) - y(t))\rangle| \leq C$ for every t. Hence

$$\ddot{h}_z(t) + \gamma \dot{h}_z(t) \leq |\dot{x}(t)|^2 + C\varepsilon(t). \tag{5.10}$$

Since $|\dot{x}|^2 \in L^1([t_0, +\infty), \mathbb{R}_+)$ and $\varepsilon \in L^1([t_0, +\infty), \mathbb{R}_+)$, in view of [6, Lemma 4.2], the above equation implies that h_z converges. Since the function x is bounded, from Theorem 2.1(vi) it follows that for every sequence $(t_n) \subset [0, +\infty)$ such that $t_n \to +\infty$ and $x(t_n) \rightharpoonup \bar{x}$ weakly in H, we have $\bar{x} \in S$ and $\lim_{n\to+\infty} \phi(x(t_n)) = \min \phi$. Since, from above, $\lim_{t\to+\infty} |x(t) - z|$ exists for every $z \in S$, we deduce from Opial's lemma (given below) that the map x weakly converges to some element x_∞ of S.

Lemma 5.1 (Opial [22]). *Let H be a Hilbert space and let $x : [0, +\infty) \to H$ be a function such that there exists a nonempty set $S \subset H$ which verifies*

(i) *$\forall t_n \to +\infty$ with $x(t_n) \rightharpoonup \bar{x}$ weakly in H, we have $\bar{x} \in S$;*

(ii) *$\forall z \in S$, $\lim_{t\to+\infty} |x(t) - z|$ exists.*

Then $x(t)$ weakly converges as $t \to +\infty$ to some element x_∞ of S.

6. Further remarks: Precisions and generalizations. In this paper the convergence results are restricted to the one-dimensional case. They clearly call for precisions and generalizations. With numerical applications in mind, an important issue is the study and the control of the rates of convergence of the solutions, of the exponential decay of the energy, etc.

6.1. Toward higher dimensions. To obtain further results, it is natural to directly study the map $x-y$ in order to obtain more general conclusions on the maps x and y. The function $h(t) := \frac{1}{2}|x(t)-y(t)|^2$ satisfies the following equation:

$$\begin{aligned}\ddot{h}(t)+\gamma\dot{h}(t) &= |\dot{x}(t)-\dot{y}(t)|^2 - \langle \nabla\phi(x(t)) - \nabla\phi(y(t)), x(t)-y(t)\rangle \\ &\quad - 2\varepsilon(t)\langle \nabla V(x(t)-y(t)), x(t)-y(t)\rangle. \end{aligned} \tag{6.1}$$

First recall that from Proposition 2.1, $|\dot{x}-\dot{y}|^2 \in L^1([0,+\infty),\mathbb{R}_+)$. We then obtain positive results when $\phi = 0$. In the general case, it seems difficult to deduce global information from (6.1). If we assume the map ϕ to be convex, $\langle \nabla\phi(x(t)) - \nabla\phi(y(t)), x(t)-y(t)\rangle \geq 0$. But the inequality that follows from (6.1) may at most lead to upper bounds on the map h. On the other hand, since the map $\nabla\phi$ is Lipschitz continuous on the bounded sets, $\langle \nabla\phi(x(t)) - \nabla\phi(y(t)), x(t)-y(t)\rangle \leq Kh(t)$ if the maps x and y are bounded. However, even in the slow case the term $\varepsilon(t)$ is then negligible in front of K and the effect of the "slow" control does not appear in the equation deduced from (6.1).

But, as we have seen in the proof of the global existence results (section 4.1), it is possible to rewrite the (HBFC^2) system as a (HBFC) system in $H \times H$. It then seems to be natural to adapt the proofs of the convergence results of [4] for the (HBFC) system in order to obtain convergence results for the (HBFC^2) system. This direction gives indeed positive results in the case where $H = \mathbb{R}$ but does not lead to all the conclusions of Theorems 2.2 and 2.3 because of the problems arising from the direct study of the map $x - y$. But taking into account the remark in section 3.7, this method could likely help to generalize some of our results to a higher, possibly infinite dimension, of course obtaining more possible cases than in Theorem 2.3.

6.2. Numerical experiments: The three cases in Corollary 2.4. When $\widehat{S}$ is a nonempty interval, for example, when ϕ is convex, the conclusion of Corollary 2.4 shows that either the solutions x and y of the (HBFC^2) system globally explore the set $\widehat{S}$ or converge to the same limit in $\widehat{S}$. In this last case, the (HBFC^2) system does not provide more information than a simple (noncoupled) (HBF) system. A first investigation would be to find, numerically and theoretically, when this "bad" case happens—hopefully on a negligible set. A natural way is to distinguish the sets where each case happens:

$$\begin{aligned} C_i &= \{(x_0,y_0,\dot{x}_0,\dot{y}_0)\in\mathbb{R}^4, \lim_{t\to+\infty}(x(t),y(t)) = (\sup\widehat{S},\inf\widehat{S})\};\\ C_{ii} &= \{(x_0,y_0,\dot{x}_0,\dot{y}_0)\in\mathbb{R}^4, \lim_{t\to+\infty}(x(t),y(t)) = (\inf\widehat{S},\sup\widehat{S})\};\\ C_{iii} &= \{(x_0,y_0,\dot{x}_0,\dot{y}_0)\in\mathbb{R}^4, \lim_{t\to+\infty}x(t) = \lim_{t\to+\infty}y(t)\}, \end{aligned}$$

where (x,y) denotes the solution of the (HBFC^2) system with initial data $(x_0,y_0,\dot{x}_0,\dot{y}_0)$. Then from Corollary 2.4, $C_i \cup C_{ii} \cup C_{iii} = \mathbb{R}^4$ and the sets C_i, C_{ii}, and C_{iii} form a partition of $\mathbb{R}^4$ when the set $\widehat{S}$ is not reduced to a singleton. Since each case is characterized by the value $\lim_{t\to+\infty} x(t)-y(t)$, we obtain equivalently

$$\begin{aligned} C_i &= \{(x_0,y_0,\dot{x}_0,\dot{y}_0)\in\mathbb{R}^4, \lim_{t\to+\infty}x(t)-y(t) = \sup\widehat{S}-\inf\widehat{S}\};\\ C_{ii} &= \{(x_0,y_0,\dot{x}_0,\dot{y}_0)\in\mathbb{R}^4, \lim_{t\to+\infty}x(t)-y(t) = \inf\widehat{S}-\sup\widehat{S}\};\\ C_{iii} &= \{(x_0,y_0,\dot{x}_0,\dot{y}_0)\in\mathbb{R}^4, \lim_{t\to+\infty}x(t)-y(t) = 0\}. \end{aligned}$$

Numerically, we approximate the function $\Delta : (x_0,y_0,\dot{x}_0,\dot{y}_0) \mapsto \lim_{t\to+\infty} x(t)-y(t)$ by the functions $\Delta_t : (x_0,y_0,\dot{x}_0,\dot{y}_0) \mapsto x(t)-y(t)$, which converge to Δ as $t\to+\infty$. We obtain positive (numerical) results on the example considered for the illustration

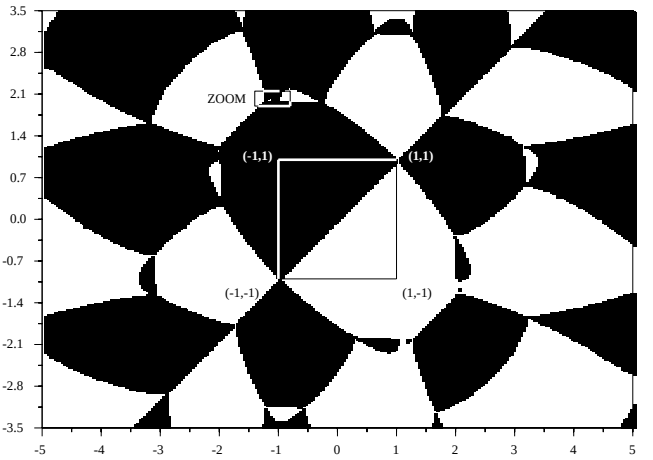

FIG. 6.1. *Case* (i) *in white and case* (ii) *in black.*

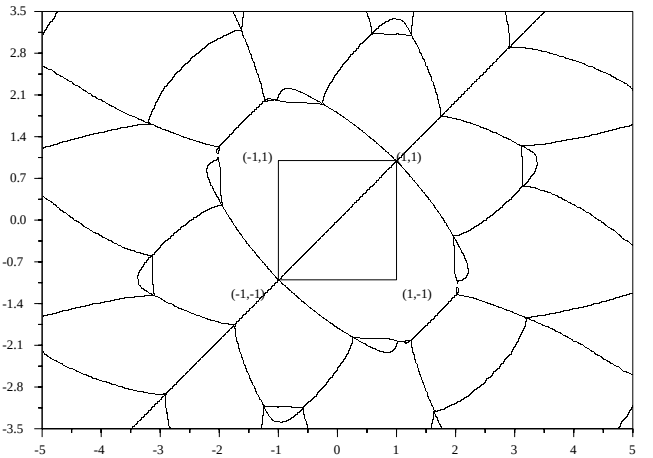

FIG. 6.2. *Cases* (i) *and* (ii) *in white and case* (iii) *in black.*

of Corollary 2.4 ($\phi(z) = (z+1)^2$ if $z \leq -1$, $\phi(z) = 0$ if $z \in [-1,1]$, $\phi(z) = (z-1)^2$ if $z \geq 1$, $V(z) = \frac{1}{2}e^{\frac{-z^2}{10}}$, $\varepsilon(t) = \frac{1}{\log(t+2)}$, $\gamma = 0.4$).

6.2.1. About the structure of the sets C_i, C_{ii}, and C_{iii}. To give an idea of the possible structure of the sets C_i, C_{ii}, and C_{iii}, we compute the function $\Delta_t : (x_0, y_0, \dot{x}_0, \dot{y}_0) \mapsto x(t) - y(t)$ for initial data $(x_0, y_0, \dot{x}_0, \dot{y}_0)$ in the set $[-5,5] \times [-3.5, 3.5] \times \{0\} \times \{0\}$ and for different times t. Figures 6.1 and 6.2 correspond to $t = 60$, respectively with a grid of 62500 points (250×250) and a grid of 10^6 points (1000×1000). On Figure 6.1, the white parts correspond to the set C_i (case (i)), and the black parts to the set C_{ii} (case (ii)). The set C_{iii} (case (iii)) is easier to visualize in Figure 6.2, where it appears in black. Note that the symmetries in the figures are only due to the symmetries in ϕ and V in our example (if $(x(t), y(t))$ is a solution, then $(y(t), x(t))$ and $(-x(t), -y(t))$ are also solutions).

Enlarging a part of Figure 6.1 (precisely, with a computation on a new grid

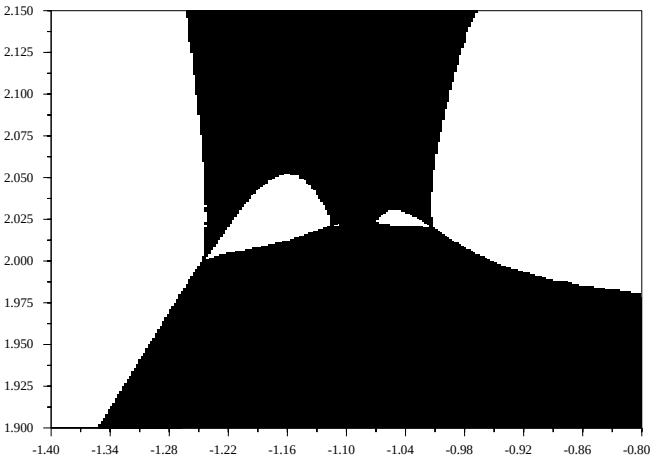

FIG. 6.3. *Zoom on the set* $[-1.4, -0.8] \times [1.9, 2.15]$. *Case* (i) *in white and case* (ii) *in black.*

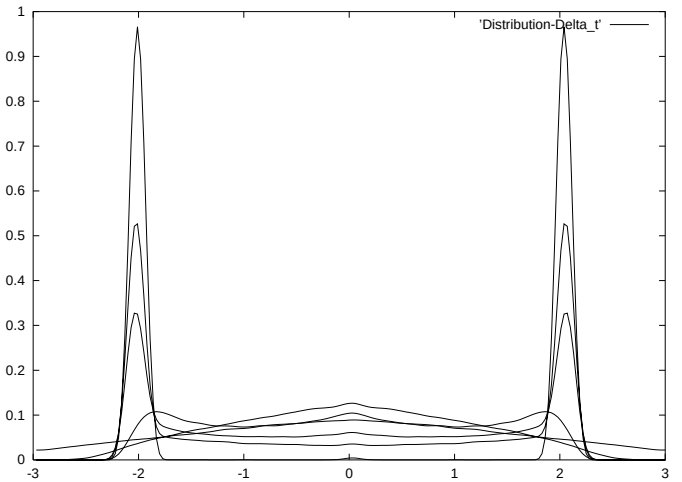

FIG. 6.4. *Distribution of the function* $x(t) - y(t)$ *at times* 0, 5, 10, 15, 20, 25, *and* 30.

of 62500 points corresponding to the zoomed part) suggests in Figure 6.3 a fractal structure of the sets C_i, C_{ii}, and C_{iii}. This also happens with other potentials ϕ and V (for example, $\phi = d^{\alpha}_{[a,b]}$ with $\alpha \geq 2$, etc.).

6.2.2. Relative weight of the sets C_i, C_{ii}, and C_{iii}. The second numerical experiment illustrates on Figure 6.4 the relative weight of the sets C_i, C_{ii}, and C_{iii} and also gives an idea of the rates of convergence. It precisely consists of evaluating the distribution of the function $x(t) - y(t)$. For initial data $(x_0, y_0, \dot{x}_0, \dot{y}_0)$ in the set $[-5, 5] \times [-5, 5] \times [-5, 5] \times [-5, 5]$ and for different times t, we compute the function Δ_t and, for a given number $p > 0$, the proportion of points which belong to an interval $[\frac{k}{p}, \frac{k+1}{p})$ for $k \in \mathbf{Z}$. In our example, the values 2 and -2, respectively, correspond to cases (i) and (ii), and the value 0 corresponds to case (iii). The experiments are computed on a grid of 10^4 points, and we limited the representation at $t = 30$ for a

matter of readability. Again, the symmetries in the figure are due to the symmetries in ϕ and V. The function corresponding at $t = 0$ is simply the density of probability $p(z = x - y)$ for $(x, y) \in [-5, 5] \times [-5, 5]$.

6.3. The singular case to avoid case (iii). An idea to avoid case (iii) consists of preventing the solutions x and y from collapsing by taking a "singular" potential V, precisely defined on $\mathbb{R} \setminus \{0\}$ and such that $\lim_{z \to 0} V(z) = +\infty$. Then the trajectories x and y never cross, and this effect could hopefully influence the asymptotic behavior of the solutions and thus avoid the case $\lim_{t \to +\infty} x(t) - y(t) = 0$ (see [13]). Note, however, that the regular case studied in this paper is still relevant from a numerical point of view since a singular potential would be numerically approximated by a regular potential.

Acknowledgment. We wish to thank Hedy Attouch for suggesting the global approach of equilibria by coupled systems and for useful comments.

FEEDBACK SPREADING CONTROL UNDER SPEED CONSTRAINTS*

K. KASSARA†

Abstract. This paper is concerned with the control of spread in semilinear parabolic systems. It first introduces a formula in order to measure the speed of a spread. Then feedback spreading control laws under speed constraints are studied by a set-valued approach. The optimality of such laws is examined in the case in which the system is affine dependent upon the control.

Key words. semilinear parabolic systems, spreading control, lower semicontinuity of maps, constrained optimization

1. Introduction.

Spreadable distributed parameter systems provide a mathematical context for modeling expansion phenomena which may arise in spatially distributed processes; cf. [6, 7] and the references therein.

In handling the control aspects of that concept, a first attempt has been made in [8], where it is shown that spreading control can be determined by minimizing a rather unusual criterion, which is partly quadratic but contains a nonquadratic term. Conditions for a solution are given, the optimality system is derived, and algorithms for the resolution are determined. It is even of interest to cite [9], which relates spreading control to actuators for a class of linear distributed parameter systems.

Nevertheless, all of the approaches cited above have the disadvantage of being restricted to linear systems and concern only a few situations. In a recent study [13], it has been pointed out that feedback spreading controls for semilinear partial differential equations may be investigated in the framework of *monotone* solutions with respect to a *preorder*; cf. [1, 17]. Then the application of some results on monotonicity by [4] has allowed us to characterize these controls as selections of a certain set-valued map, which is defined by a set of tangential conditions.

The present study continues the investigation of the field as expounded in [13] by essentially concentrating on the speed of a spread. For this, we are motivated by the technical need to design spreads, taking into consideration both the speed and the time of spreading; cf. [8]. First, we propose a convenient setting in which the measure of the spread speed can be rigorously made. Then, due to some set-valued analysis facts, we examine the existence of feedback spreading control laws, which generate a spread either slower or quicker than a desired given speed.

In this paper, the following definitions and notation are used. Let Y be a Hilbert space; then a set-valued map $Q : \mathcal{S} \to 2^Y \setminus \{\emptyset\}$ is said to be lower semicontinuous (lsc) whenever the following property holds: For each $z_0 \in \mathcal{S}$ and any sequence of elements $z_n \in \mathcal{S}$ converging to z_0, for every $y_0 \in Q(z_0)$, there exists a sequence of elements $y_n \in Q(z_n)$ which converges to y_0.

The graph of Q is denoted by

$$\operatorname{graph}(Q) \doteq \{(z,y) \in \mathcal{S} \times Z \mid y \in Q(z)\}.$$

The inverse of Q is the map $Q^{-1} : Y \to 2^{\mathcal{S}}$ defined by

$$Q^{-1}(y) \doteq \{z \in \mathcal{S} \mid y \in Q(z)\} \quad \text{for each } y \in Y.$$

A selection of the map Q is a mapping $\nu : \mathcal{S} \to Y$, which satisfies

$$\nu(z) \in Q(z) \quad \text{for each } z \in \mathcal{S}.$$

We quote Michael's selection theorem, which states that any lsc set-valued map with closed convex values has a continuous selection; cf. [5].

A mapping from Z to Y is said to be demicontinuous if it maps strongly convergent sequences in Z into weakly convergent sequences in Y; cf. [15].

When the scalar product in Y is clear from the context, it is denoted by $\langle\ ;\ \rangle$.

The projector of best approximation on a closed convex subset $\mathcal{K}$ of Y will be denoted by $\pi_{\mathcal{K}}(\cdot)$.

The directional derivative of a functional $\ell : \mathcal{S} \to \mathbb{R}$ in the direction of $y \in Y$, if it exists at a point $z \in \mathcal{S}$, is denoted by

$$d\ell(z)(y) \doteq \liminf_{h \downarrow O} \frac{\ell(z+hy) - \ell(z)}{h}. \tag{1.1}$$

Note that, if ℓ is Gâteaux differentiable at z, then we get

$$d\ell(z)(y) = \langle \nabla \ell(z), y \rangle \quad \text{for each } y \in Y,$$

where $\nabla \ell$ denotes the Gâteaux derivative of ℓ; cf. [11].

The paper is organized as follows: In section 2, we set the spreading control problems in their open loop form. Then section 3 gives the basic results on feedback spreading control laws. In section 4, we state the speed functional and show some results which justify its definition. In section 5, we deal with feedback spreading control laws under speed constraints. Finally, section 6 is devoted to the optimality of these control laws.

2. Statement of the problem. Let $\Omega \subset \mathbb{R}^n$ be an open and bounded domain with sufficiently smooth boundary $\partial\Omega$, and set $Q = \Omega \times (0, \infty[$. Let A be a second order elliptic operator on Ω given in the form

$$A \doteq -\sum_{i,j=1}^{n} \frac{\partial}{\partial x_i}\left(a_{ij}(x)\frac{\partial}{\partial x_j}\right) + \sum_{i=1}^{n} a_i(x)\frac{\partial}{\partial x_i} + a_0(x), \tag{2.1}$$

with the smooth functions a_{ij}, a_i, and a_0. For convenient boundary data, it can be assumed that the operator $-A$ stands for an unbounded densely defined linear operator which generates a $\mathcal{C}_0$ analytic semigroup $(S(t))_{t \geq 0}$ on $Z = L^2(\Omega)$; cf. [2, 3].

We consider the semilinear parabolic control system

$$\frac{\partial z}{\partial t} + Az = \varphi(z,v) \qquad \text{in } Q \tag{2.2a}$$

with initial data

$$z(x,0) = z_0(x) \qquad \text{in } \Omega, \tag{2.2b}$$

where $z_0 \in \mathrm{dom}(A)$ (i.e., the domain of A) and φ denotes a nonlinear operator which maps $\mathcal{S} \times V$ into Z, with V another Hilbert space and $\mathcal{S}$ a closed subset of Z. Let ω be a map defined as follows:

$$\omega : \mathcal{S} \subset Z \to 2^{\Omega}. \tag{2.3}$$

DEFINITION 2.1 (cf. [6]). *A measurable function $\bar{v} : [0, t_1[\to V$ is called a spreading control with respect to ω if there exists a solution $\bar{z}$ which satisfies*

$$\bar{z}(t) \in \mathcal{S} \quad \textit{for all } t \in [0, t_1[\tag{2.4a}$$

and

$$(\omega(\bar{z}(t)))_{0 \le t < t_1} \textit{ is nondecreasing.} \tag{2.4b}$$

As an instance of the map ω, we consider the pollution process; cf. [8, 12]. It takes place when the system which describes the *concentration of pollutant* is spreadable with respect to ω, with

$$\omega(z) \doteq \{x \in \Omega \mid z(x) > z_{\max}\},$$

where $z_{\max}$ is a tolerance coefficient. Let $t_1 > 0$, and set

$$\mathcal{V}^s_{t_1} \doteq \{v \in L^2(0, t_1, V) \mid v \text{ is a spreading control with respect to } \omega\}.$$

For each control $v \in \mathcal{V}^s_{t_1}$, denote by $z(\cdot, v)$ the solution of (2.2) on the interval $[0, t_1[$; then a natural way to define the speed of the generated spread $(\omega(z(t, v)))_t$ may be

$$\mathrm{speed}(t, v) \doteq \liminf_{h \downarrow O} \frac{\lambda(\omega(z(t+h, v)) \setminus \omega(z(t, v)))}{h} \ge 0 \quad \text{for each } t \in [0, t_1[\,, \tag{2.5}$$

where λ stands for the Lebesgue measure on Ω. Then, roughly, the control problems we shall consider in this paper are stated as follows:

$$P^+_m \qquad \begin{array}{l} \text{Find a control } v^+_m \in \mathcal{V}^s_{t_1} \text{ such that} \\ \mathrm{speed}(t, v^+_m) \ge m(t) \text{ for all } t \in [0, t_1[\end{array}$$

and

$$P^-_m \qquad \begin{array}{l} \text{Find a control } v^-_m \in \mathcal{V}^s_{t_1} \text{ such that} \\ \mathrm{speed}(t, v^-_m) \le m(t) \text{ for all } t \in [0, t_1[\,, \end{array}$$

where $m : [0, t_1[\to \mathbb{R}^+$ stands for a measurable function. Also, we are concerned with investigating the optimal control problems

$$P^+_{\theta,m} \qquad \begin{array}{l} \min \|v_s\|^2_{L^2(0,t_1,V)} \text{ subject to} \\ v_s \text{ is a solution of } P^+_m \end{array}$$

and

$$P^-_{\theta,m} \qquad \begin{array}{l} \min \|v_s\|^2_{L^2(0,t_1,V)} \text{ subject to} \\ v_s \text{ is a solution of } P^-_m. \end{array}$$

Note that there are two technical notes which might be taken into account:

(i) According to [13], it should be of interest to seek feedback spreading control laws in the form

$$v_s = \psi(z) \quad \text{for each } z \in \mathcal{S}. \tag{2.6}$$

(ii) In general, the Lebesgue measure λ does not provide a well-defined function $\mathrm{speed}(\cdot, \cdot)$. That, a priori, depends upon the differentiability of $\lambda \circ \omega$ in the sense of Dini; cf. [11].

3. Preliminaries on feedback spreading control laws. In this section, we present a summary of the main definitions and results related to the concept of feedback spreading control. Let ω be as in (2.3).

DEFINITION 3.1 (cf. [13]). *The mapping $\varsigma : \mathcal{S} \to V$ is said to be a feedback spreading control (fsc) law with respect to ω if, for all initial data z_0 in $\mathcal{S}$, there exists a solution $\bar{z}$ which satisfies*

$$\bar{z}(t) \in \mathcal{S} \quad \textit{for all } t \in [0, t_1[\tag{3.1a}$$

and

$$\bar{v} = \varsigma(\bar{z}) \textit{ is a spreading control.} \tag{3.1b}$$

Next, for each couple $(y, z) \in Z \times \mathcal{S}$, consider the following tangential condition:

$$\begin{array}{l} \text{for all } \delta > 0, \exists\ 0 < h < \delta, \text{ and } \|p\| \le \delta \text{ such that} \\ S(h)z + h(y+p) \in \mathcal{S} \text{ and} \\ \omega(S(h)z + h(y+p)) \supset \omega(z). \end{array} \tag{3.2}$$

Then define the set-valued maps

$$\mathcal{T}_\omega(z) \doteq \{y \in Z \mid \text{ (3.2) holds with } (y, z)\} \quad \text{for each } z \in \mathcal{S} \tag{3.3}$$

and

$$\mathcal{F}_\omega(z) \doteq \{v \in V \mid \varphi(z, v) \in \mathcal{T}_\omega(z)\} \quad \text{for each } z \in \mathcal{S}. \tag{3.4}$$

Also, we need to let

$$\Sigma_\omega \doteq \{(y, z) \in \mathcal{S}^2 \mid \omega(y) \supset \omega(z)\} \tag{3.5}$$

and make the following assumption.

Assumption 3.2. The semigroup $S(\cdot)$ is compact.

We are ready to present the following basic result which characterizes fsc laws.

THEOREM 3.3. *Let Assumption* 3.2 *hold, and let $\varsigma : \mathcal{S} \to V$ be a measurable function. Furthermore, assume that*

(i) *Σ_ω is closed,*

(ii) *$\varphi(\cdot, \varsigma(\cdot))$ is demicontinuous on $\mathcal{S}$.*

Then ς is an fsc law with respect to ω iff ς is a selection of $\mathcal{F}_\omega$.

Proof. See [13, Theorem 3.1]. □

It should be convenient to emphasize that, in Theorem 3.3, only $\varphi(\cdot, \varsigma(\cdot))$ is required to be demicontinuous, and there are no continuity assumptions on φ or ς. Also, note that Assumption 3.2 is generic for parabolic systems; cf. [3, 16].

Remark 3.4. It is useful to notice that the subset $\mathcal{T}_\omega(z)$ may be expressed in terms of contingent subsets [17], which are given by

$$T_D^A(z) = \left\{ y \in Z \mid \liminf_{h \downarrow 0} \frac{d(S(h)z + hy, D)}{h} = 0 \right\}.$$

We have, by considering (3.2),

$$\mathcal{T}_\omega(z) = T^A_{P_\omega(z)}(z) \quad \text{for each } z \in \mathcal{S},$$

where

$$P_\omega(z) = \{y \in Z \mid \omega(y) \supset \omega(z)\} \quad \text{for each } z \in \mathcal{S}. \tag{3.6}$$

In the preliminary result below, we use the following assumption.

Assumption 3.5. Σ_ω is closed, and the map ω^{-1} has convex values.

LEMMA 3.6.

(i) *The map $\mathcal{T}_\omega$ has closed values.*

(ii) *Under Assumption* 3.5*, the map $\mathcal{T}_\omega$ has convex values.*

Proof. Let z belong to $\mathcal{S}$; then the tangential condition (3.2) yields

$$\mathcal{T}_\omega(z) = \bigcap_{\delta>0} cl \bigcup_{h\in(0,\delta)} \frac{1}{h}[P_\omega(z) - S(h)z].$$

Then it is obvious that $\mathcal{T}_\omega(z)$ is closed.

Regarding (ii), let $y, \bar{y} \in \mathcal{T}_\omega(z)$, and $\alpha, \beta \geq 0$ such that $\alpha + \beta = 1$. It follows that

$$S(h)z + h(\alpha y + \beta\bar{y}) = \alpha(S(h)z + hy) + \beta(S(h)z + h\bar{y}).$$

Now it is not hard to show that Assumption 3.5 implies that the map P_ω has closed convex values. It follows that the function

$$y \in Z \to d(y, P_\omega(z))$$

is convex, and therefore we get

$$d(S(h)z + h(\alpha y + \beta\bar{y}), P_\omega(z)) \leq \alpha d(S(h)z + hy, P_\omega(z)) + \beta d(S(h)z + h\bar{y}, P_\omega(z)).$$

Consequently, Remark 3.4 yields the result. ∎

4. The speed functional. Let μ be a measure on Ω. By the *speed functional*, we mean the functional defined on graph$(\mathcal{T}_\omega)$ by

$$\theta(y,z) \doteq \liminf_{h\downarrow 0, \|p\|\to 0} \frac{\mu(\omega(S(h)z + h(y+p)) \setminus \omega(z))}{h} \quad \text{for each } z \in \mathcal{S} \text{ and } y \in \mathcal{T}_\omega(z). \tag{4.1}$$

Let

$$\tau_\omega \doteq \mu \circ \omega : \begin{array}{ll} \mathcal{S} & \to \mathbb{R}^+, \\ z & \to \mu(\omega(z)). \end{array}$$

Next, we prove some immediate properties which are verified by the speed functional.

PROPOSITION 4.1.

(i) *θ is well defined and has values ranging in $[0, \infty]$.*

(ii) *Assume τ_ω to be locally Lipschitz on $\mathcal{S}$. Let $\bar{v}$ and $\bar{z}$ be as in Definition* 2.1*, with μ instead of λ; then we have*

$$\text{speed}(t, \bar{v}) = \theta(\varphi(\bar{z}(t), \bar{v}(t)), \bar{z}(t)) \quad \textit{for each } t \in [0, t_1[\,. \tag{4.2}$$

(iii) *Suppose that $\mathcal{S}$ and τ_ω are convex; then we have*

$$\theta(y,z) = d\tau_\omega(z)(y - Az) \quad \textit{for each } y \in \mathcal{T}_\omega(z) \textit{ and } z \in \mathcal{S} \cap \text{dom}(A). \tag{4.3}$$

Proof. First, note that (i) is simply a consequence of (3.2) and (3.3). To show (ii), let $\bar{v}$ and $\bar{z}$ be as in Definition 2.1, and denote $\bar{\varphi}(\cdot) \doteq \varphi(\bar{z}(\cdot), \bar{v}(\cdot))$. For $t \in [0, t_1[$, we get

$$\bar{z}(t+h) = \bar{z}(t) + h(\bar{\varphi}(t) + p_h) \quad \text{with } p_h \to 0 \text{ when } h \to 0.$$

Then, applying formula (4.1) yields

$$\begin{aligned} \theta(\varphi(\bar{z}(t), \bar{v}(t)), \bar{z}(t)) &= \liminf_{h \downarrow 0, \|p\| \to 0} \frac{\tau_\omega(S(h)\bar{z}(t) + h(\bar{\varphi}(t) + p)) - \tau_\omega(\bar{z}(t))}{h} \\ &= \liminf_{h \downarrow 0, \|p\| \to 0} \frac{\tau_\omega(\bar{z}(t+h) + h(p - p_h)) - \tau_\omega(\bar{z}(t))}{h}. \end{aligned}$$

Now, we observe that

$$\begin{aligned} \tau_\omega(\bar{z}(t+h) + h(p-p_h)) - \tau_\omega(\bar{z}(t)) &= \tau_\omega(\bar{z}(t+h)) - \tau_\omega(\bar{z}(t)) \\ &\quad + \tau_\omega(\bar{z}(t+h) + h(p-p_h)) - \tau_\omega(\bar{z}(t+h)). \end{aligned}$$

We use the fact that τ_ω is locally Lipschitz to obtain

$$\lim_{h \downarrow 0, \|p\| \to 0} \frac{\tau_\omega(\bar{z}(t+h) + h(p-p_h)) - \tau_\omega(\bar{z}(t))}{h} = 0.$$

Therefore, (ii) is proved if we refer to (2.5).

Regarding statement (iii), we first remark that, due to its convexity, the mapping τ_ω has a directional derivative on $\mathcal{S}$, and $d\tau_\omega(z)(\cdot)$ is continuous for each z; cf. [11]. On the other hand, we have

$$S(h)z = z - hAz + hp_h \quad \text{for each } h \geq 0, \quad \text{with } p_h \to 0 \text{ when } h \to 0.$$

It follows that

$$\theta(y, z) = \liminf_{h \downarrow 0, \|p\| \to 0} \frac{\tau_\omega(z + h(y - Az + p)) - \tau_\omega(z)}{h}.$$

Therefore, we have

$$\theta(y, z) = \liminf_{\|p\| \to 0} d\tau_\omega(z)(y - Az + p),$$

and consequently we obtain (4.3) thanks to the continuity of the directional derivative. □

As an important consequence, we stress that the speed functional provides a proper tool in order to measure the speed of the spread generated by a spreading control, especially when τ_ω has a directional derivative, in which case formula (4.3) can easily be used.

Remark 4.2. Note that in (iii) the assumption "τ_ω is convex" may be replaced by "τ_ω is Gâteaux differentiable." In this case, we obtain the formula

$$\theta(y, z) = \langle \nabla \tau_\omega(z); y - Az \rangle \quad \text{for each } y \in \mathcal{T}_\omega(z) \text{ and } z \in \mathcal{S} \cap \operatorname{dom}(A). \tag{4.4}$$

Next, we show a technical result to be used in the subsequent sections. To this end, let us consider the following assumption.

Assumption 4.3. For each sequence $(z_n)_n \subset \mathcal{S}$ and $(y_n)_n \subset Z$ such that $y_n \in \mathcal{T}_\omega(z_n)$ for every n, we have

$$\begin{array}{l} z_n \to z \text{ (strong)} \\ y_n \to y \text{ (weak)} \end{array} \implies y \in \mathcal{T}_\omega(z), \text{ and } \theta(y_n, z_n) \to \theta(y, z).$$

Then we can prove the following result, which studies the convexity of the mapping $\theta(\cdot, z)$ on $\mathcal{T}_\omega(z)$.

LEMMA 4.4. *Let Assumptions* 3.5 *and* 4.3 *be satisfied; then we have the following statements:*

(i) *If τ_ω is convex, then $\theta(\cdot, z)$ is convex on $\mathcal{T}_\omega(z)$ for each $z \in \mathcal{S}$.*

(ii) *If τ_ω is Gâteaux differentiable, then, for each $\alpha, \beta > 0$ with $\alpha + \beta = 1$, we have*

$$\theta(\alpha y + \beta \bar{y}, z) = \alpha\theta(y, z) + \beta\theta(\bar{y}, z) \quad \textit{for each } z \in \mathcal{S} \textit{ and } y, \bar{y} \in \mathcal{T}_\omega(z).$$

Proof. For $z \in \mathcal{S} \cap \operatorname{dom}(A)$, by considering Proposition 4.1(iii), we can easily see that $\theta(\cdot, z)$ is convex on $\mathcal{T}_\omega(z)$ because $d\tau_\omega(z)$ is such. Now let $z \in \mathcal{S}$; then $z = \lim_{n\to\infty} z_n$ for a sequence $(z_n)_n \subset \mathcal{S} \cap \operatorname{dom}(A)$. Let $\alpha, \beta \geq 0$ such that $\alpha + \beta = 1$ and $y, \bar{y} \in \mathcal{T}_\omega(z)$; then using Assumption 4.3 yields

$$\begin{aligned} \theta(\alpha y + \beta \bar{y}, z) &= \lim_{n\to\infty} \theta(\alpha y + \beta \bar{y}, z_n) \\ &\leq \alpha \lim_{n\to\infty} \theta(y, z_n) + \beta \lim_{n\to\infty} \theta(\bar{y}, z_n) \\ &\leq \alpha\theta(y, z) + \beta\theta(\bar{y}, z), \end{aligned}$$

and hence (i) is shown. Similarly, statement (ii) easily follows from Remark 4.2 and Assumption 4.3. ∎

5. Feedback spreading controls with constraints on the speed. In this section, based on the results provided by Theorem 3.3 and Proposition 4.1, we suitably restate the spreading control problems P_m^+ and P_m^- of section 2 in their feedback version. Let ν be a nonnegative measurable function on $\mathcal{S}$; then problem P_m^+ may read as follows:

$$\mathbb{P}_\nu^+ \qquad \begin{array}{l} \text{Find an fsc law } v = \varsigma_\nu^+(z) \text{ such that} \\ \rho(z, v) \geq \nu(z) \text{ for each } z \in \mathcal{S}. \end{array}$$

Also, problem P_m^- can be reformulated as

$$\mathbb{P}_\nu^- \qquad \begin{array}{l} \text{Find an fsc law } v = \varsigma_\nu^-(z) \text{ such that} \\ \rho(z, v) \leq \nu(z) \text{ for each } z \in \mathcal{S}, \end{array}$$

where the functional ρ is defined according to (4.2) by

$$\rho(z, v) \doteq \theta(\varphi(z, v), z) \quad \text{for each } z \in \mathcal{S} \text{ and } v \in \mathcal{F}_\omega(z), \tag{5.1}$$

and $\mathcal{F}_\omega(\cdot)$ is as in (3.4). Now define the following maps for each $z \in \mathcal{S}$:

$$\mathcal{T}_\omega^{\nu^+}(z) \doteq \{y \in \mathcal{T}_\omega(z) \mid \theta(y, z) \geq \nu(z)\} \tag{5.2a}$$

and

$$\mathcal{F}_\omega^{\nu^+}(z) \doteq \{v \in V \mid \varphi(z, v) \in \mathcal{T}_\omega^{\nu^+}(z)\}. \tag{5.2b}$$

We also need to set

$$\mathcal{T}_\omega^{\nu^-}(z) \doteq \{y \in \mathcal{T}_\omega(z) \mid \theta(y,z) \leq \nu(z)\} \tag{5.3a}$$

and

$$\mathcal{F}_\omega^{\nu^-}(z) \doteq \{v \in V \mid \varphi(z,v) \in \mathcal{T}_\omega^{\nu^-}(z)\}. \tag{5.3b}$$

Consequently, providing that the assumptions of Theorem 3.3 are satisfied by ς_ν^ϵ (with ϵ denoting $+$ or $-$), the following statement holds:

$$\varsigma_\nu^\epsilon \text{ is a solution of problem } \mathbb{P}_\nu^\epsilon \iff \varsigma_\nu^\epsilon \text{ is a selection of } \mathcal{F}_\omega^{\nu^\epsilon}. \tag{5.4}$$

For both problems $\mathbb{P}_\nu^+$ and $\mathbb{P}_\nu^-$, we respectively define the subsets of admissible speeds ν as follows:

$$\mathcal{A}_\omega^+ \doteq \{\nu : \mathcal{S} \to \mathbb{R}^+ \mid \text{for all } z \in \mathcal{S}, \exists y \in \mathcal{T}_\omega(z) \text{ such that } \theta(y,z) > \nu(z)\} \tag{5.5a}$$

and

$$\mathcal{A}_\omega^- \doteq \{\nu : \mathcal{S} \to \mathbb{R}^+ \mid \text{for all } z \in \mathcal{S}, \exists y \in \mathcal{T}_\omega(z) \text{ such that } \theta(y,z) < \nu(z)\}. \tag{5.5b}$$

In order to state an existence result for problem $\mathbb{P}_\nu^+$ for appropriate speeds ν, we first begin by proving the following lemma, which studies the lower semicontinuity of the map $\mathbb{P}_\nu^+$.

LEMMA 5.1. *Let Assumptions* 3.5 *and* 4.3 *be satisfied. Furthermore, suppose that*

(i) $\mathcal{T}_\omega$ *is lsc,*
(ii) τ_ω *is Gâteaux differentiable,*
(iii) $\nu \in \mathcal{A}_\omega^+$ *and is upper semicontinuous.*

Then the map $\mathcal{T}_\omega^{\nu^+}$ *is lsc.*

Proof. Since $\nu \in \mathcal{A}_\omega^+$, it can easily be seen that $\mathcal{T}_\omega^{\nu^+}(z) \neq \emptyset$ for each $z \in \mathcal{S}$. Now, to see that this map is lsc, it suffices to show that the functional

$$\jmath : z \in \mathcal{S} \to d(y_0, \mathcal{T}_\omega^{\nu^+}(z))^2$$

is upper semicontinuous for each $y_0 \in Y$; cf. [5, Lemma 4.2]. Indeed, given $y_0 \in Y$ and $z \in Z$, we have

$$\jmath(z) = \min_{\substack{y \in \mathcal{T}_\omega(z) \\ \nu(z) - \theta(y,z) \leq 0}} \|y_0 - y\|^2. \tag{5.6}$$

By virtue of Lemma 3.6, $\mathcal{T}_\omega(z)$ is closed and convex. On the other hand, the function $\nu(z) - \theta(\cdot, z)$ is continuous (by Assumption 4.3) and convex (due to Lemma 4.4). Then there is a unique $y_+(z) \in \mathcal{T}_\omega(z)$ which solves the optimization problem (5.6). For such a problem, the fact that $\nu \in \mathcal{A}_\omega^+$ obviously provides the Slater condition as in [11, Theorem 6.7] yields the formula

$$\jmath(z) = \sup_{\lambda \geq 0} \inf_{y \in \mathcal{T}_\omega(z)} \{\|y_0 - y\|^2 + \lambda(\nu(z) - \theta(y,z))\} \quad \text{for each } z \in \mathcal{S}. \tag{5.7}$$

Now let $(z_n)_n$ be a sequence in $\mathcal{S}$ which converges to z. By condition (i) and the fact that $y_+(z) \in \mathcal{T}_\omega(z)$, there exists a sequence $y_n \in \mathcal{T}_\omega(z)$ which converges to $y_+(z)$. It follows that

$$\inf_{y \in \mathcal{T}_\omega(z_n)} \{\|y_0 - y\|^2 + \lambda(\nu(z_n) - \theta(y,z_n))\} \leq \|y_0 - y_n\|^2 + \lambda(\nu(z_n) - \theta(y_n,z_n)) \tag{5.8}$$

for each $\lambda \geq 0$ and $n \in \mathbb{N}$. However, since ν is upper semicontinuous and

$$\theta(y_n, z_n) \to \theta(y_+(z), z),$$

we get

$$\limsup_{n\to\infty}(\nu(z_n) - \theta(y_n, z_n)) \leq \nu(z) - \theta(y_+(z), z) \leq 0.$$

Consequently, by passing to the lim sup in (5.8), we obtain

$$\limsup_{n\to\infty} \inf_{y\in\mathcal{T}_\omega(z_n)} \{\|y_0 - y\|^2 + \lambda(\nu(z_n) - \theta(y, z_n))\} \leq \|y_0 - y_+(z)\|^2 \tag{5.9}$$

for each $\lambda \geq 0$. Next, by writing $\jmath(z_n)$ by (5.7) and noting that

$$\limsup_{n\to\infty} \sup_{\lambda\geq 0}[\cdot] \leq \sup_{\lambda\geq 0} \limsup_{n\to\infty}[\cdot],$$

we get the desired inequality

$$\limsup_{n\to\infty} \jmath(z_n) \leq \jmath(z),$$

ending the proof of the lemma. □

Now we turn our attention to examine the lower semicontinuity of the map $\mathcal{T}_\omega^{\nu^-}$ as defined by (5.3a). Arguing as in the proof of Lemma 5.1, we can easily show the following result.

LEMMA 5.2. *Let Assumptions* 3.5 *and* 4.3 *be satisfied. Furthermore, suppose that*

(i) $\mathcal{T}_\omega$ *is lsc,*
(ii) τ_ω *is convex or Gâteaux differentiable,*
(iii) $\nu \in \mathcal{A}_\omega^-$ *and is lsc.*

Then the map $\mathcal{T}_\omega^{\nu^-}$ *is lsc.*

Consequently, we are in a position to provide existence results for problems $\mathbb{P}_\nu^+$ and $\mathbb{P}_\nu^-$. For that purpose, we need to take into consideration the following hypothesis.

Assumption 5.3. For each $z \in \mathcal{S}$ and $y \in \mathcal{T}_\omega(z)$, there exists $v \in V$ such that $\varphi(z, v) = y$.

PROPOSITION 5.4. *Let Assumptions* 3.2 *and* 5.3 *hold, and assume that all of the conditions of Lemma* 5.1 *(resp., Lemma* 5.2*) are satisfied. Then there exists an fsc law which solves problem* $\mathbb{P}_\nu^+$ *(resp., problem* $\mathbb{P}_\nu^-$*).*

Proof. By Lemma 5.1 (resp., Lemma 5.2), the map $\mathcal{T}_\omega^{\nu^+}$ (resp., $\mathcal{T}_\omega^{\nu^-}$) is lsc. Moreover, due to Assumption 4.3 and Lemma 4.4, it has closed convex values. Then, thanks to Michael's selection theorem which is stated in section 1, the map $\mathcal{T}_\omega^{\nu^+}$ (resp., $\mathcal{T}_\omega^{\nu^-}$) admits a continuous selection $y_+(\cdot)$ (resp., $y_-(\cdot)$). Next, we can use Assumption 5.3 to construct a mapping $\varsigma_\nu^+ : \mathcal{S} \to V$ (resp., ς_ν^-) in such a manner that

$$\varphi(z, \varsigma_\nu^\epsilon(z)) = y_\epsilon(z) \quad \text{for each } z \in \mathcal{S} \text{ with } \epsilon \in \{+, -\}.$$

Consequently, by using Theorem 3.3, it follows that ς_ν^+ (resp., ς_ν^-) stands for the desired fsc law. □

6. Optimality of fsc laws with speed constraints. In the same spirit of section 5, we investigate in this section the feedback versions of optimal control problems $P^+_{\theta,m}$ and $P^-_{\theta,m}$, which are stated in section 2. Let ν be a measurable function defined from $\mathcal{S}$ with nonnegative values; then problem $P^+_{\theta,m}$ may read as follows:

$$\mathbb{P}^+_{\theta,\nu} \quad \begin{array}{l} \text{Find an fsc law } v = \hat{\varsigma}_+(z) \text{ which solves} \\ \min \|v\|^2 \text{ subject to } \varphi(z,v) \in \mathcal{T}_\omega^{\nu^+}(z) \text{ for each } z \in \mathcal{S}. \end{array}$$

Also, problem $P^-_{\theta,m}$ can be restated as

$$\mathbb{P}^-_{\theta,\nu} \quad \begin{array}{l} \text{Find an fsc law } v = \hat{\varsigma}_-(z) \text{ which solves} \\ \min \|v\|^2 \text{ subject to } \varphi(z,v) \in \mathcal{T}_\omega^{\nu^-}(z) \text{ for each } z \in \mathcal{S}. \end{array}$$

By virtue of Theorem 3.3, the above problems can be treated through satisfying what follows.

(a) The involved parameterized minimization problems

$$\min \|v\|^2 \text{ subject to } \varphi(z,v) \in \mathcal{T}_\omega^{\nu^\epsilon}(z) \quad \text{for each } z \in \mathcal{S} \tag{6.1}$$

uniquely have solutions $\hat{\varsigma}_\epsilon(\cdot)$ for each $z \in \mathcal{S}$ and $\epsilon \in \{+,-\}$.

(b) Let the mappings $\varphi(\cdot, \hat{\varsigma}_\epsilon(\cdot))$ be demicontinuous.

Next, we need to assume that (2.2a) is affine in the controls; i.e.,

$$\varphi(z,v) = B(z)v + f(z) \quad \text{for each } z \in \mathcal{S} \text{ and } v \in V, \tag{6.2}$$

where f and B act in $\mathcal{S}$ and have images, respectively, in Z and $\mathcal{L}(V,Z)$.

First, we show a result on the optimization technique to be used in order to solve the problems (6.1).

LEMMA 6.1. *Let $f \in Z$ and $\mathcal{T}$ be a closed convex subset of Z. Let $B \in \mathcal{L}(V,Z)$ be a linear operator satisfying the following condition:*

$$\|B^\star \mu\|^2 \geq m\|\mu\|^2 \quad \textit{for each } \mu \in Z \textit{ with } m > 0. \tag{6.3}$$

Then the minimization problem

$$\min_{Bv+f \in \mathcal{T}} \|v\|^2 \tag{6.4}$$

has a unique solution $v_0 = -B^\star \mu_0$, where μ_0 is uniquely given by the optimality system

$$\begin{array}{l} \|B^\star \mu_0\|^2 \leq \langle \mu_0, f - y \rangle \quad \textit{for each } y \in \mathcal{T}, \\ f - BB^\star \mu_0 \in \mathcal{T}. \end{array} \tag{6.5}$$

Proof. See the appendix. □

Now we consider the following assumption.

Assumption 6.2.

(i) The mapping $f : \mathcal{S} \to Z$ is continuous.

(ii) For each sequence $(z_n)_n \subset \mathcal{S}$, $(v_n)_n \subset V$, and $(\mu_n)_n \subset Z$,

$$\begin{array}{l} z_n \to z \text{ (strong) and } v_n \to v \text{ (weak)} \implies B(z_n)v_n \to B(z)v \text{ (weak)}, \\ z_n \to z \text{ (strong) and } \mu_n \to \mu \text{ (weak)} \implies B^\star(z_n)\mu_n \to B^\star(z)\mu \text{ (weak)}. \end{array}$$

(iii) For each $z \in \mathcal{S}$, the operator $B^\star(z)$ satisfies the coercivity condition which is required in (6.3),

$$\|B^\star(z)\mu\|^2 \geq m_z\|\mu\|^2 \quad \text{for each } \mu \in Z, \tag{6.6}$$

where the coefficient $m_z > 0$ is such that, for each $\alpha > 0$, there exists $M > 0$ such that $m_z > M$ for each $z \in \mathcal{S}, \|z\| < \alpha$.

Then we are ready to examine problem $\mathbb{P}^+_{\theta,\nu}$.

THEOREM 6.3. *Let Assumptions* 3.2, 3.5, *and* 6.2 *be satisfied. In addition, suppose that*

(i) *the map* $\mathcal{T}_\omega$ *is lsc,*

(ii) τ_ω *is Gâteaux differentiable,*

(iii) $\nu \in \mathcal{A}^+_\omega$ *and is upper semicontinuous.*

Then the mapping $\hat{\varsigma}_+(\cdot)$ *of* (6.1) *stands for the unique solution of problem* $\mathbb{P}^+_{\theta,\nu}$.

Proof. By Lemma 4.4, the map $\mathcal{T}_\omega$ has closed convex values. Then the map $\mathcal{T}_\omega^{\nu^+}$ of (5.2a) also has closed convex values. This results, respectively, from Assumption 4.3 and Lemma 4.4 (ii). Therefore, all conditions of Lemma 6.1 are satisfied for each $z \in \mathcal{S}$ with $B \doteq B(z)$, $f \doteq f(z)$, $\mathcal{T} \doteq \mathcal{T}_\omega^{\nu^+}(z)$, and the coercivity condition (6.6). Hence the minimization problem (6.1) has $\hat{\varsigma}_+(z)$ as a unique solution for each $z \in \mathcal{S}$. In addition, by using Lemma 6.1, we have

$$\hat{\varsigma}_+(z) = -B^\star(z)\mu_0(z) \quad \text{for each } z \in \mathcal{S}, \tag{6.7}$$

where $\mu_0(z) \doteq \mu_0$ is uniquely determined by

$$\begin{aligned} &\|B^\star(z)\mu_0\|^2 \leq \langle \mu_0, f(z) - y\rangle \quad \text{for each } y \in \mathcal{T}_\omega^{\nu^+}(z) \text{ and } z \in \mathcal{S}, \\ &f(z) - B(z)B^\star(z)\mu_0 \in \mathcal{T}_\omega^{\nu^+}(z). \end{aligned} \tag{6.8}$$

Now it remains to show that $\hat{\varsigma}_+(\cdot)$ stands for an fsc law. According to (b) above, this holds if the mapping

$$\phi_s \doteq f + B(\cdot)\hat{\varsigma}_+ = f - B(\cdot)B^\star(\cdot)\mu_0(\cdot)$$

is demicontinuous.

Indeed, let $(z_n)_n$ be a sequence with (strong) limit $z \in \mathcal{S}$ and $y \in \mathcal{T}_\omega^{\nu^+}(z)$. Due to Lemma 5.1, the map $\mathcal{T}_\omega^{\nu^+}$ is lsc; then there exists a sequence $(y_n)_n$ which converges to y and satisfies

$$y_n \in \mathcal{T}_\omega^{\nu^+}(z_n) \quad \text{for each } n.$$

Therefore, by (6.8), we have

$$\|B^\star(z_n)\mu_0(z_n)\|^2 \leq \langle \mu_0(z_n), f(z_n) - y_n\rangle \quad \text{for each } n.$$

Consequently, since the sequence $(f(z_n))_n$ is bounded (due to Assumption 6.2 (i)), it follows that the sequence $(\mu_0(z_n))_n$ is bounded too. It therefore has a subsequence $(\mu_0(z_k))_k$ which is weakly convergent to $\bar{\mu}_0 \in Z$.

Now, since $\langle \mu_0(z_k); f(z_k) - y_k\rangle \to \langle \bar{\mu}_0; f(z) - y\rangle$ (because $f(z_k) - y_k \to f(z) - y$ strongly and $\mu_0(z_k) \to \bar{\mu}_0$ weakly), we get by passing to the lim inf in the last inequality

$$\liminf \|B^\star(z_k)\mu_0(z_k)\|^2 \leq \langle \bar{\mu}_0; f(z) - y\rangle.$$

Therefore, due to Assumption 6.2 (ii), it follows that

$$\|B^\star(z)\bar{\mu}_0\|^2 \leq \liminf \|B^\star(z_k)\mu_0(z_k)\|^2 \leq \langle \bar{\mu}_0; f(z) - y\rangle \tag{6.9}$$

for every $y \in \mathcal{T}_\omega^{\nu^+}(z)$. By using Assumption 6.2 (ii), we get

$$\phi_s(z_k) = f(z_k) - B(z_k)B^\star(z_k)\mu_0(z_k) \overset{we}{\to} f(z) - B(z)B^\star(z)\bar{\mu}_0.$$

This implies, due to Assumption 3.5 and the upper semicontinuity of ν, that

$$f(z) - B(z)B^\star(z)\bar{\mu}_0 \in \mathcal{T}_\omega^{\nu^+}(z).$$

Therefore, by (6.9), $\bar{\mu}_0$ satisfies the optimality system (6.8), and then we obtain, by uniqueness,

$$\bar{\mu}_0 = \mu_0(z) \text{ and } f(z) - B(z)B^\star(z)\bar{\mu}_0 = \phi_s(z).$$

Consequently, the sequences $(\mu_0(z_n))_n$ and $(\phi_s(z_n))_n$ are, respectively, weakly convergent to $\mu_0(z)$ and $\phi_s(z)$. Thus, as desired, the mapping ϕ_s is demicontinuous on the subset $\mathcal{S}$. □

Remark 6.4. From the proof of Theorem 6.3, it follows by Assumption 6.2 that the minimal fsc law

$$\hat{\varsigma}_\cdot = -B^\star(\cdot)\mu_0(\cdot)$$

is also demicontinuous.

Remark 6.5. The proof of Lemma 6.1 in the appendix is informative on the technique to use in order to compute $\hat{\varsigma}_\cdot$. In fact, we can use the optimality system (A.3), from which a sequence of suboptimal fsc laws can be derived by successive approximation.

Similarly, we can follow the same approach to examine problem $\mathbb{P}^-_{\theta,\nu}$.

THEOREM 6.6. *Let Assumptions* 3.2, 3.5, 5.3, *and* 6.2 *be satisfied. In addition, suppose that*

(i) *the map* $\mathcal{T}_\omega$ *is lsc,*
(ii) τ_ω *is convex or Gâteaux differentiable,*
(iii) $\nu \in \mathcal{A}_\omega^-$ *and is lsc.*

Then the mapping $\hat{\varsigma}_-(\cdot)$ *of* (6.1) *stands for the unique solution of problem* $\mathbb{P}^-_{\theta,\nu}$.

Also, note that Remarks 6.4 and 6.5 remain valid regarding problem $\mathbb{P}^-_{\theta,\nu}$.

Appendix. Proof of Lemma 6.1. Since $\mathcal{C} = \{v \in V \mid Bv + f \in \mathcal{T}\}$ is a nonempty closed convex subset in V, (6.4) has a unique solution which is $v_0 = \pi_{\mathcal{C}}(0)$. Now we can use a saddle point method to compute v_0. Define the Lagrangian functional (cf. [10, 14])

$$L(v, y, \mu) = \frac{1}{2}\|v\|^2 + \langle Bv + f - y; \mu\rangle \quad \text{for each } v \in V, y \in \mathcal{T}, \mu \in Z.$$

In fact, it can be easily shown that, if (u_0, y_0, μ_0) is a saddle point for L, i.e.,

$$\max_{\mu \in Z} L(u_0, y_0, \mu) = L(u_0, y_0, \mu_0) = \min_{v \in V, y \in \mathcal{T}} L(v, y, \mu_0),$$

then u_0 is a solution of (6.4), and, by uniqueness, $u_0 = v_0$. Now, since both L and $\mathcal{T}$ are convex, the saddle point (v_0, y_0, μ_0) is characterized by

$$\frac{\partial L}{\partial v}(v_0, y_0, \mu_0) = 0,$$

$$\left\langle \frac{\partial L}{\partial y}(v_0, y_0, \mu_0); y - y_0 \right\rangle \geq 0 \quad \text{for each } y \in \mathcal{T},$$

$$\frac{\partial L}{\partial \mu}(v_0, y_0, \mu_0) = 0$$

so that we have

$$\begin{aligned} &v_0 + B^\star \mu_0 = 0, \\ &\langle \mu_0; y - y_0 \rangle \leq 0 \quad \text{for each } y \in \mathcal{T}, \\ &Bv_0 + f = y_0 \in \mathcal{T}. \end{aligned}$$

Therefore, in an equivalent way, we get $v_0 = -B^\star \mu_0$, where μ_0 is uniquely given by the system

$$\begin{aligned} &-BB^\star \mu_0 + f = y_0, \\ &\langle \mu_0, y - y_0 \rangle \leq 0 \quad \text{for each } y \in \mathcal{T}, \\ &y_0 \in \mathcal{T}, \end{aligned} \tag{A.1}$$

which is equivalent to

$$\begin{aligned} &\|B^\star \mu_0\|^2 \leq \langle \mu_0, f - y \rangle \quad \text{for each } y \in \mathcal{T}, \\ &f - BB^\star \mu_0 \in \mathcal{T}. \end{aligned} \tag{A.2}$$

Now it remains to show that such a μ_0 exists. In fact, by multiplying by $\rho > 0$ in (A.1) and using the operator of best approximation $\pi_{\mathcal{T}}$, we obtain the equivalent system

$$\begin{aligned} &v_0 = B^\star R^{-1}(y_0 - f), \\ &y_0 = \pi_{\mathcal{T}}[(1 - \rho R^{-1})y_0 + \rho R^{-1} f] \end{aligned} \tag{A.3}$$

for some $\rho > 0$, where the operator $R = BB^\star$. Then we are led to seek a fixed point of the mapping

$$\begin{aligned} \Theta_\rho : \quad \mathcal{T} &\to \mathcal{T} \\ y &\to \pi_{\mathcal{T}}[(1 - \rho R^{-1})y + \rho R^{-1} f]. \end{aligned}$$

Indeed, we have

$$\begin{aligned} \|\Theta_\rho(y) - \Theta_\rho(\bar{y})\|^2 &\leq \|(1 - \rho R^{-1})e\|^2 \\ &= \|e\|^2 - 2\rho \langle R^{-1} e; e \rangle + \rho^2 \|R^{-1} e\|^2, \end{aligned}$$

where $y, \bar{y} \in \mathcal{T}$, and $e = y - \bar{y}$.

Since the operator R^{-1} is coercive, we have, for some $m' > 0$,

$$\langle R^{-1} y; y \rangle \geq m' \|y\|^2 \quad \text{for each } y \in Z.$$

It follows that

$$\|\Theta_\rho(y) - \Theta_\rho(\bar{y})\|^2 \leq (1 - 2\rho m' + \rho^2 \|R^{-1}\|^2) \|y - \bar{y}\|^2.$$

Therefore, Θ_ρ is a contraction for $\rho < 2m'/\|R^{-1}\|^2$, and thereby it has a unique fixed point y_0, which belongs to $\mathcal{T}$. This ends the proof of Lemma 6.1.

Acknowledgments. The author is grateful to the unknown reviewers for their careful reading of the original manuscript, constructive criticism, and helpful suggestions.

ON THE OBSERVABILITY AND DETECTABILITY OF CONTINUOUS-TIME MARKOV JUMP LINEAR SYSTEMS*

EDUARDO F. COSTA† AND JOÃO B. R. DO VAL†

Abstract. The paper introduces a new detectability concept for continuous-time Markov jump linear systems with finite Markov space that generalizes previous concepts found in the literature. The detectability in the weak sense is characterized as mean square detectability of a certain related stochastic system, making both detectability senses directly comparable. The concept can also ensure that the solution of the coupled algebraic Riccati equation associated to the quadratic control problem is unique and stabilizing, making other concepts redundant. The paper also obtains a set of matrices that plays the role of the observability matrix for deterministic linear systems, and it allows geometric and qualitative properties. Tests for weak observability and detectability of a system are provided, the first consisting of a simple rank test, similar to the usual observability test for deterministic linear systems.

Key words. Markov jump systems, detectability and observability of stochastic systems, optimal control, stochastic systems, quadratic control

1. Introduction.

The concepts of observability and detectability play an important role in the theory of dynamic systems. For instance, in optimal control problems, these concepts provide a connection between closed-loop stability and finiteness of the cost functional, and they ensure uniqueness of the solution to the algebraic Riccati equation. This is the scenario in the theory of deterministic time-invariant linear systems (see [14]), deterministic linear time-varying systems (see [1], [2] or [11]), and to some extent, in Markov jump linear systems (MJLS) (see [7], [9], [13], [16], and [17]).

Thanks to those developments, a number of well-established results concerning detectability and the good behavior of solutions of filtering and control problems exist today which can be found in a literature that spans more than four decades. Among the results we refer to concerning linear time-invariant deterministic systems are the following: (I) invariance of nonobserved trajectories, (II) existence of a simple rank-test condition for observability, (III) correspondence between nonobserved trajectories and stable modes of detectable systems, and (IV) relationship between observability and detectability. However, it was not known to this date how properties (I)–(IV) extend to MJLS.

Consider the continuous-time MJLS written as

$$\Phi : \begin{cases} \dot{x}(t) = A_{\theta(t)}x(t), & t \geq 0, \\ y(t) = C_{\theta(t)}x(t), & x(0) = x_0, \quad \theta(0) = \theta_0, \end{cases} \tag{1}$$

defined in a fundamental probability space $(\Omega, \mathcal{F}, \{\mathcal{F}_t\}, P)$, where $\mathcal{F}_t$ denotes the σ-field generated by $\{x(s), \theta(s), 0 \leq s \leq t\}$. The variables $x \in \mathbb{R}^n$ and $y \in \mathbb{R}^q$ are the

continuous state and the output, respectively; x_0 is a second order random variable. The mode θ is the state of an underlying continuous-time homogeneous Markov chain $\Theta = \{\theta(t); t \geq 0\}$ having $\mathcal{S} = \{1, \ldots, N\}$ as state space and $\Lambda = [\lambda_{ij}]$, $i, j = 1, \ldots, N$, as the transition rate matrix. The initial distribution of Θ is determined by $\mu_i = P(\theta_0 = i)$, $i = 1, \ldots, N$. Matrices A_i and C_i, $1 \leq i \leq N$, belong to the collections of N real matrices: $A = (A_1, \ldots, A_N)$, $\dim(A_i) = n \times n$, and $C = (C_1, \ldots, C_N)$, $\dim(C_i) = q \times n$. Consider also the functional

$$W^t(x, \theta) = E\left\{\int_0^t x(\tau)' C'_{\theta(\tau)} C_{\theta(\tau)} x(\tau) d\tau | \mathcal{F}_0\right\} \tag{2}$$

defined for $x(0) = x$ and $\theta(0) = \theta$. Here we consider the following concept of observability, which is drawn from the observability concept for time-variant MJLS that appears, for instance, in [16]. The concept is more general than other observability concepts for MJLS, like the ones in [13].

Definition 1 (W-observability). *We say that (A, C, Λ) is weakly (W-) observable when there exist scalars $t_d \geq 0$ and $\gamma > 0$ such that $W^{t_d}(x, \theta) \geq \gamma |x|^2$ for each $x \in \mathbb{R}^n$ and $\theta \in \mathcal{S}$.*

In this paper, for the time-invariant system Φ, we present a collection of matrices $\mathcal{O} = (\mathcal{O}_1, \ldots, \mathcal{O}_N)$ associated to the W-observability concept that resembles observability matrices of deterministic linear systems. Then we provide extensions of properties (I) and (II) mentioned above, respectively: we show that nonobserved trajectories are invariant in the sense that, if $x(s)$ is in the kernel of $\mathcal{O}_{\theta(s)}$ for some $s \geq 0$, then $x(t)$ is in the kernel of $\mathcal{O}_{\theta(t)}$ for any $t \geq s$ (see Corollary 15), and we show that (A, C, Λ) is W-observable if and only if each of the matrices of the set $\mathcal{O}$ is of full rank. We also demonstrate that the largest attainable dimensionality of $\mathcal{O}$ is constrained by the system dimensions n and N (see Lemma 12) in a similar manner to observability matrices of deterministic systems.

Regarding the detectability of MJLS, before the work in [4] for discrete-time MJLS, the most general detectability concept available was the dual of the stabilizability concept, known as mean square (MS-) detectability (see [7], [9], or [16]). The concept is as follows.

Definition 2 (MS-stability). *We say that (A, Λ) is MS-stable if, for system Φ and for each $x_0 \in \mathbb{R}^n$ and $\theta_0 \in \mathcal{S}$,*

$$\lim_{t \to \infty} E\{|x(t)|^2\} = 0.$$

Definition 3 (MS-detectability). *We say that (A, C, Λ) is MS-detectable when there exists $G = \{G_1, \ldots, G_N\}$ of appropriate dimension for which $(A - GC, \Lambda)$ is MS-stable.*

In connection with the MS-detectability concept, we have that none of the well-known properties (III) and (IV) mentioned above hold. Moreover, W-observability is not comparable to MS-detectability. In Example 2, we present a system that is W-observable but is not MS-detectable. It is also simple to provide a converse example: if one takes (A, Λ) as MS-stable and $C = 0$, one has that (A, C, Λ) is MS-detectable but is not W-observable. This lack of structure sometimes compels authors to consider either a detectability or an observability hypothesis (see, for example, [9] and [16]), where these conditions appear as sufficient conditions for uniqueness of solutions to coupled algebraic Riccati equations (CAREs) arising in the optimal linear quadratic problem.

In this paper, we develop the following associate concept of W-detectability from the W-observability concept. We mention that it is analogous to a concept for time-varying systems that appears in [1].

DEFINITION 4 (W-detectability). *We say that* (A, C, Λ) *is W-detectable if there exist scalars* $t_d, s_d \geq 0$, $\gamma > 0$, *and* $0 \leq \delta < 1$ *such that* $W^{t_d}(x_0, \theta_0) \geq \gamma |x_0|^2$ *whenever* $E\{|x(s_d)|^2\} \geq \delta |x_0|^2$.

We show that W-detectability generalizes and can retrieve each of the properties (III) and (IV), respectively: for every nonobserved trajectory, a contraction condition holds, ensuring that the trajectory converges in the MS sense (see Lemma 20); W-detectability generalizes W-observability. Moreover, in one of the main results of this paper, we characterize W-detectability by means of MS-detectability as follows: (A, C, Λ) is W-detectable if and only if $(A, \mathcal{O}, \Lambda)$ is MS-detectable (see Theorem 24). This result allows us to clarify the conservativeness of MS-detectability when compared with W-detectability, and, at same time, it provides a testable condition for W-detectability; see section 4.1.

For the controlled MJLS, we show that the W-detectability concept ensures that finite cost implies stable trajectories in the MS sense and, in particular, that the solution to the CARE arising in optimal control problems is unique and stabilizing; see section 5. This result generalizes previous characterizations in [9], [13], [16], and [17].

The paper is organized as follows. In section 2 basic results and relevant definitions are introduced, and, in section 3, we introduce the observability matrices and related properties. In section 4, some characterizations of W-detectability are presented, and, in section 4.1, it is shown that W-detectability generalizes MS-detectability. In section 5, we set up the link between W-detectability and stabilizing quadratic control.

2. Notation, concepts, and basic results. Let $\mathbb{R}^n$ be the nth dimensional Euclidean space. Let $\mathcal{R}^{n,q}$ (respectively, $\mathcal{R}^n$) represent the normed linear space formed by all $n \times q$ (respectively, $n \times n$) real matrices and $\mathcal{R}^{n0}$ ($\mathcal{R}^{n+}$) the closed convex cone $\{U \in \mathcal{R}^n : U = U' \geq 0\}$ (the open cone $\{U \in \mathcal{R}^n : U = U' > 0\}$), where U' denotes the transpose of U; $U \geq V$ ($U > V$) signifies that $U - V$ is positive semidefinite (definite). For $U \in \mathcal{R}^{n,q}$, $\mathcal{N}\{U\}$ and $\mathcal{R}\{U\}$ represent the kernel and the range of U, respectively.

Let $\mathcal{M}^{n,q}$ denote the linear space formed by a number N of matrices such that $\mathcal{M}^{n,q} = \{U = (U_1, \ldots, U_N) : U_i \in \mathcal{R}^{n,q}, i = 1, \ldots, N\}$; also, $\mathcal{M}^n \equiv \mathcal{M}^{n,n}$. We denote by $\mathcal{M}^{n0}$ ($\mathcal{M}^{n+}$) the set $\mathcal{M}^n$ when it is made up by some $U_i \in \mathcal{R}^{n0}$ ($U_i \in \mathcal{R}^{n+}$) for all $i = 1, \ldots, N$. Analogously, for $U, V \in \mathcal{M}^{n0}$ $U \geq V$ ($U > V$) signifies that $U - V \in \mathcal{M}^{n0}$ ($U - V \in \mathcal{M}^{n+}$). It is known that $\mathcal{M}^{n,q}$ equipped with the inner product

$$\langle U, V \rangle = \sum_{j=1}^{N} \operatorname{tr}\{U_j' V_j\}$$

forms a Hilbert space. Let us define the norm $\|U\| = \langle U, I \rangle$ on $\mathcal{M}^{n0}$.

Consider system Φ in (1). For $i = 1, \ldots, N$, we define

$$X_i(t) = E\{x(t)x(t)' 1_{\{\theta(t)=i\}} | \mathcal{F}_0\}, \quad t \geq 0. \tag{3}$$

With this notation, we can write, for instance, $E\{|x(t)|^2 | \mathcal{F}_0\} = \langle X(t), I \rangle = \|X(t)\|$.

Now let us introduce the operators $\mathcal{L} : \mathcal{M}^n \to \mathcal{M}^n$ and their adjoint in the inner

product sense $\mathcal{T} : \mathcal{M}^n \to \mathcal{M}^n$ as

$$\mathcal{L}_i(U) = A_i'U_i + U_iA_i + \sum_{j=1}^{N} \lambda_{ij}U_j, \tag{4a}$$

$$\mathcal{T}_i(U) = A_iU_i + U_iA_i' + \sum_{j=1}^{N} \lambda_{ji}U_j, \quad i = 1, \ldots, N. \tag{4b}$$

Let also $L(t)$ and $U(t)$, $t \geq 0$, be defined by the matrix linear differential equations

$$\dot{L}_i(t) := \mathcal{L}_i(L(t)) + C_i'C_i, \quad L(0) = 0,\ t \geq 0, \tag{5a}$$

$$\dot{U}_i(t) := \mathcal{T}_i(U(t)), \quad U(0) = U \in \mathcal{M}^{n0}, \tag{5b}$$

for each $i = 1, \ldots, N$. The operators $\mathcal{L}$ and $\mathcal{T}$ are linear, and $L(t)$ and $U(t)$ defined by (5) are unique. The following results are adapted from [6] and [13]; the proof is omitted.

PROPOSITION 5. *The following assertions hold:*

(i)

$$\dot{X}_i(t) = \mathcal{T}_i(X(t)), \quad t \geq 0, \quad i = 1, \ldots, N, \tag{6}$$

for $X(0) \in \mathcal{M}^{n0}$*, such that* $X_i(0) = x_0x_0'1_{\{\theta(0)=i\}}$, $i = 1, \ldots, N$*;*

(ii)

$$W^t(x, i) = \int_0^t \langle X(\tau), C'C\rangle d\tau = \langle X(0), L(t)\rangle. \tag{7}$$

Consider the corresponding generalization of (7)

$$W^t(U) = \int_0^t \langle U(\tau), C'C\rangle d\tau = \langle U, L(t)\rangle, \tag{8}$$

where $L(\cdot)$ and $U(\cdot)$ are given by (5).

LEMMA 6. $U(\cdot) \in \mathcal{M}^{n0}$ *and* $L(s) \geq L(t)$ *whenever* $s \geq t$.

Proof. Notice that, for any $U \in \mathcal{M}^{n0}$, one can adopt the following representation (cf. Theorem 7.5.2 of [12]):

$$U_i = x_i^1x_i^{1\prime} + \cdots + x_i^{r_i}x_i^{r_i\prime},$$

where $x_i^k \in \mathbb{R}^n, k = 1, \ldots, r$ and $r_i = \operatorname{rank}(U_i) \leq n$. In connection, we can define $X_i^{j,k}(\cdot)$ as the solution of (6) with $X_i^{i,k}(0) = x_i^kx_i^{k\prime}$; it is clear from the second moment definition in (3) that $X_i^{j,k}(\cdot) \in \mathcal{M}^{n0}$. Also, from the linearity of the operator $\mathcal{T}$, we have that

$$U_i(t) = \sum_{j=1}^{N}\sum_{k=1}^{r_j} X_i^{j,k}(t), \quad t \geq 0,$$

and $U(\cdot) \in \mathcal{M}^{n0}$, which proves the first assertion.

From the expression (8) and the first assertion, it is simple to check the result for $L(\cdot)$. In fact, whenever $s \geq t$, one has that $W^s(U) \geq W^t(U)$ for each $U \in \mathcal{M}^{n0}$, and thus $\langle U, L(s) - L(t) \rangle \geq 0$. The assertion follows from the Fejer's trace theorem; cf. [12]. □

It is well known that the MS-stability of A is equivalent to the requirement that $\mathrm{Re}\{\lambda(\mathcal{T})\} < 0$; see, for instance, [6]. Then we can rewrite the MS-stability concept as follows.

DEFINITION 7 (MS-stability). *We say that* (A, Λ) *is MS-stable if*

$$\lim_{t \to \infty} \|X(t)\| = 0 \quad \forall X \in \mathcal{M}^{n0}.$$

Remark 1. Feng et al. in [10] have shown that the MS-stability concept is equivalent to other second moment stability concepts, such as exponential stability. Thus the system is MS-stable if and only if there exist $0 < \xi < 1$ and $\alpha \geq 1$ such that $\|X(t)\| \leq \alpha \xi^t \|X(0)\|$ for every $X(0) \in \mathcal{M}^{n0}$. It is also known that, if (A, Λ) is not MS-stable, then there exists $X(0) \in \mathcal{M}^{n0}$ such that $\|X(t)\| \geq \beta \zeta^t \|X(0)\|$ for some $\zeta \geq 1$ and $0 < \beta \leq 1$.

3. W-observability and observability matrices. In this section, we introduce a collection of observability matrices, and, in one of the main results, we derive a test for observability based on the rank of these matrices, in a parallel with the observability test for deterministic linear systems. We also derive a counterpart for MJLS for the well-known result for linear deterministic systems that nonobserved trajectories are invariant. An illustrative example is also provided.

Let us introduce the matrices $\mathcal{O}_i \in \mathcal{R}^{n(n^2N),n}$, defined for each $i = 1, \ldots, N$, as

$$\mathcal{O}_i := [O_i(0)\, O_i(1) \cdots O_i(n^2N - 1)]', \tag{9}$$

where each matrix $O_i(\cdot)$ belongs to the sequence of matrices on $\mathcal{M}^{n0}$ defined as

$$O_i(k) := \mathcal{L}_i(O(k-1)), \quad k > 0, \tag{10}$$

with $O_i(0) := C_i' C_i$, for each $i = 1, \ldots, N$. Notice by inspection of (5a) that

$$O_i(k) = \frac{d^{k+1} L}{dt^{k+1}}(0). \tag{11}$$

The collection of matrices $\mathcal{O} \in \mathcal{M}^{n0}$ is called the set of observability matrices of system Φ. In fact, $\mathcal{O}$ resembles the observability matrices of linear deterministic systems in many aspects, as we shall see in this section. We can mention in passing that, for an isolated Markov state i, namely, $\lambda_{ji} = 0$, $j = 1, \ldots, N$, a direct equivalence is retrieved: the pair (A_i, C_i) is observable in the deterministic sense if and only if $\mathcal{O}_i$ is a full rank matrix.

Next we present some preliminary results.

For $V \in \mathcal{R}^n$, let us identify the columns of $V = [v_1 \vdots v_2 \vdots \cdots \vdots v_n]$. For $U = (U_1, \ldots, U_N)$ and following [5], we introduce the linear and invertible operator $\widehat{\varphi} : \mathcal{M}^{n0} \to \mathbb{R}^{n^2 N}$ as

$$\widehat{\varphi}(U) = \begin{bmatrix} \varphi(U_1) \\ \vdots \\ \varphi(U_N) \end{bmatrix}, \quad \text{where} \quad \varphi(V) = \begin{bmatrix} v_1 \\ \vdots \\ v_n \end{bmatrix}.$$

Let $V \otimes Z$ represent the Kronecker tensor product of matrices V and Z. From (4a), using basic properties of the Kronecker product [3], we obtain

$$\varphi(\mathcal{L}_i(U)) = (I_n \otimes A_i')\varphi(U_i) + (A_i' \otimes I_n)\varphi(U_i) + \sum_{j=1}^{N} \lambda_{ij}\varphi(U_j),$$

and one can check that

$$\widehat{\varphi}(\mathcal{L}(U)) = \mathcal{A}\widehat{\varphi}(U), \tag{12}$$

where $\mathcal{A} \in \mathcal{R}^{n^2N}$ is the matrix defined by

$$\begin{bmatrix} \hat{A}_1 + \lambda_{11}I_{n^2} & \lambda_{12}I_{n^2} & \cdots & \lambda_{1N}I_{n^2} \\ \lambda_{21}I_{n^2} & \hat{A}_2 + \lambda_{22}I_{n^2} & & \\ \vdots & & \ddots & \\ \lambda_{N1}I_{n^2} & & & \hat{A}_N + \lambda_{NN}I_{n^2} \end{bmatrix}$$

and $\hat{A}_i = (I_n \otimes A_i' + A_i' \otimes I_n)$. Applying the operator $\widehat{\varphi}$ in (5a) and employing (12), we obtain

$$\begin{aligned} \dot{\ell}(t) &= \widehat{\varphi}[C'C + \mathcal{L}(L(t))] \\ &= q + \mathcal{A}\widehat{\varphi}(L(t)) = q + \mathcal{A}\ell(t), \quad t \geq 0, \end{aligned} \tag{13}$$

where $\ell(t) \in \mathbb{R}^{n^2N}$ and $q \in \mathbb{R}^{n^2N}$ are defined by

$$\ell(t) = \widehat{\varphi}(L(t)), \quad q = \widehat{\varphi}(C'C).$$

Notice by inspection of (13) that

$$\frac{d^k\ell(0)}{dt^k} = \mathcal{A}^k q. \tag{14}$$

We also introduce the following representation for the expression $\langle U, L(t)\rangle$:

$$\langle U, L(t)\rangle = \widehat{\varphi}(U)'\ \ell(t). \tag{15}$$

LEMMA 8. *Consider $x \in \mathbb{R}^n$ and $i \in \mathcal{S}$; define $X \in \mathcal{M}^{n0}$ as $X_i = xx'$ and $X_j = 0$ for all $j \neq i$. Set $w \in \mathbb{R}^{n^2N}$ as $w = \hat{\varphi}(X)$. The following assertions are equivalent:*

(i) *$x'L_i(s)x = 0$ or, equivalently, $w'\ell(s) = 0$ for some $s > 0$;*

(ii) *$w'd^m\ell/dt^m(0) = 0$ for $m = 1, \ldots, n^2N$;*

(iii) *$w'\mathcal{A}^{m-1}q = 0$ for $m = 1, \ldots, n^2N$;*

(iv) *$x \in \mathcal{N}(L_i(t))$ or, equivalently, $w'\ell(t) = 0$ for all $t \geq 0$;*

(v) *$x \in \mathcal{N}(\mathcal{O}_i)$.*

Proof. (i) $\Rightarrow$ (ii): From Lemma 6, $L(t) \leq L(s)$ for $t \leq s$; from (15), we evaluate $w'\ell(t) = \langle\widehat{\varphi}^{-1}(w), L(t)\rangle \leq \langle\widehat{\varphi}^{-1}(w), L(s)\rangle = w'\ell(s) = 0$, $t \leq s$. In addition, noticing that $w'\ell(t) \geq 0$ and recalling that $L(0) = 0$, we can write $w'\ell(t) = 0$ for all $0 \leq t \leq s$, which leads to

$$w'\frac{d^m\ell}{dt^m}(0) = 0 \quad \forall m \geq 0.$$

(ii) ⇒ (iii): The result follows immediately from (14).

(iii) ⇒ (iv): For the linear deterministic system in (13), we can write for any $t \geq 0$

$$\ell(t) = \int_0^t e^{\mathcal{A}(t-\tau)} q d\tau = \int_0^t \sum_{m=1}^{n^2N} \alpha_m(\tau) \mathcal{A}^{m-1} q d\tau$$
$$= \sum_{m=1}^{n^2N} \mathcal{A}^{m-1} q \int_0^t \alpha_m(\tau) d\tau = \sum_{m=1}^{n^2N} \hat{\alpha}_m(t) \mathcal{A}^{m-1} q,$$

where α_m and $\hat{\alpha}_m$ are scalar functions. Then we get that

$$w'\ell(t) = \sum_{m=1}^{n^2N} \hat{\alpha}_m(t) w' \mathcal{A}^{m-1} q = 0.$$

(iv) ⇒ (i): This part of the proof is trivial.

(ii) ⇔ (v): Employing (15), we write

$$w' \frac{d^m \ell}{dt^m}(0) = 0 \Leftrightarrow \left\langle X, \frac{d^m L}{dt^m}(0) \right\rangle = 0 \Leftrightarrow \frac{d^m L_i}{dt^m}(0) x = 0 \tag{16}$$

for $m = 1, \ldots, n^2N$. The proof is easily completed by noticing from (11) that

$$\mathcal{O}_i = \begin{bmatrix} O_i(0) \\ \vdots \\ O_i(n^2N-1) \end{bmatrix} = \begin{bmatrix} \frac{d^1 L_i}{dt}(0) \\ \vdots \\ \frac{d^{n^2N} L_i}{dt^{n^2N}}(0) \end{bmatrix}. \qquad \square$$

The next corollary restates some assertions in Lemma 8 for further use.

COROLLARY 9. *The following assertions are equivalent:*

(i) $x \in \mathcal{N}\{\mathcal{O}_i\}$;

(ii) $W^s(x,i) = 0$ *for some* $s > 0$;

(iii) $W^t(x,i) = 0$ *for all* $t \geq 0$.

Remark 2. Notice from Corollary 9 that if the conditions in Definitions 1 or 4 hold for some $t_d \geq 0$, then they hold for all $t \geq 0$.

The next theorem provides a rank test on the set of observability matrices $\mathcal{O}$. First, let us rewrite the W-observability concept in terms of the notation introduced in section 2.

DEFINITION 10 (W-observability). *We say that* (A, C, Λ) *is W-observable when there exist scalars* $t_d \geq 0$ *and* $\gamma > 0$ *such that* $W^{t_d}(X) \geq \gamma \|X\|$ *for each initial condition* X.

THEOREM 11. *Consider system* Φ. (A, C, Λ) *is W-observable if and only if* $\mathcal{O}_i$ *has full rank for each* $i = 1, \ldots, N$.

Proof. From (8), we can write the condition in Definition 1 equivalently as

$$\langle X, L(t_d) \rangle \geq \gamma \|X\| \quad \forall X \in \mathcal{M}^{n0}.$$

This is equivalent to requiring that $L_i(t_d)$ be positive definite for each $i = 1, \ldots, N$. The equivalencies (i) and (v) of Lemma 8 complete the proof. $\square$

Example 1. Let $N = 2$, $n = 2$, and set

$$A_1 = I_2;\ A_2 = \begin{bmatrix} 1 & 1 \\ 0 & 1; \end{bmatrix};\ C_1 = [1\ 0];\ C_2 = 0;\ \Lambda = \begin{bmatrix} -1 & 1 \\ 1 & -1 \end{bmatrix}.$$

From (9), one evaluates $\operatorname{rank}(\mathcal{O}_1) = \operatorname{rank}(\mathcal{O}_2) = 2$, and Theorem 11 ensures that (A, C, Λ) is W-observable.

Remark 3. It is known that (A, C, Λ) is W-observable if each pair (A_i, C_i), $i = 1, \ldots, N$, is observable; see, e.g., [16]. However, this condition is not necessary; for instance, in Example 1, none of the pairs (A_i, C_i) are observable.

3.1. Properties of the observability matrices and pathwise invariance of nonobserved trajectories. The next lemma establishes a counterpart for the well-known result about the largest attainable dimensionality of observability matrices.

LEMMA 12.

$$\mathcal{N}\{\mathcal{O}_i\} = \mathcal{N}\{[O_i(0)\vdots\cdots\vdots O_i(k)]'\} \quad \forall k \geq n^2N - 1.$$

Proof. For $x \in \mathcal{N}(\mathcal{O}_i)$, let $X_i = xx'$ and $X_j = 0$ for all $j \neq i$, and let $w = \widehat{\varphi}(X)$. From Lemma 8 (iii) and (v), we have that $\mathcal{O}_i x = 0$ is equivalent to $w'\mathcal{A}^{r-1}q = 0$, $r = 1, \ldots, n^2N$. From the Cayley–Hamilton lemma, $\mathcal{A}^m = \sum_{r=0}^{n^2N-1} \alpha_r \mathcal{A}^r$ for each $m \geq 0$, and we obtain

$$\begin{cases} w'q = 0, \\ w'\mathcal{A}q = 0, \\ \vdots \\ w'\mathcal{A}^m q = 0, \end{cases} \tag{17}$$

which, from (14), is equivalent to $w'd^m\ell(0)/dt^m = 0$, $m \geq 0$. Finally, applying (16) for a generic $m \geq 0$, we obtain $d^m L_i(0)/dt^m x = 0$, and from (11) we write $O_i(m)x = d^{m+1}L_i(0)/dt^{m+1}x = 0$ for $m \geq 0$ and, in particular, for $m \geq n^2N - 1$. Thus $\mathcal{N}\{\mathcal{O}_i\} \subset \mathcal{N}\{[O_i(0)\vdots\cdots\vdots O_i(k)]'\}$ for all $k \geq n^2N - 1$; the opposite relation holds trivially. ∎

Next we present a relation between the null spaces of the observability matrices which will be useful in what follows. The following preliminary result is needed.

PROPOSITION 13. *For each scalar $M > 0$, there exists $t_M > 0$ for which $\|x(t) - x_0\| \leq M\|x_0\|$ almost surely (a.s.) for all $t \leq t_M$.*

LEMMA 14. *Assume that the Markov state j is accessible from the state i. Then $\mathcal{N}\{\mathcal{O}_i\} \subset \mathcal{N}\{\mathcal{O}_j\}$.*

Proof. Let us deny the assertion of the lemma; that is, we assume that there exist a scalar $m > 0$ and $x_0 \in \mathbb{R}^n$ such that

$$x_0 \in \mathcal{N}\{\mathcal{O}_i\} \tag{18}$$

for which $|x_0 - x| \geq m$, for all $x \in \mathcal{N}\{\mathcal{O}_j\}$. Notice that $x_0 \neq 0$, and let x_0 and $\theta_0 = i$ be initial conditions.

We start the proof by setting $M = m/(2|x_0|)$ in Proposition 13 to obtain that there exists t_M for which $x(t) \in B_{m/2}(x_0)$, $t \leq t_M$, where $B_{m/2}(x_0) = \{x : |x - x_0| \leq m/2\}$. Let $\tilde{x}(t_M)$ and $\hat{x}(t_M)$ be the orthogonal projection of $x(t_M)$ on $\mathcal{N}\{\mathcal{O}_j\}$ and $\mathcal{R}\{\mathcal{O}_j'\}$, respectively. Notice that $\tilde{x}(t_M) \perp \hat{x}(t_M)$ and $|\tilde{x}(t_M)| \geq m/2$; see Figure 1.

From Lemma 8 (i) and (v), one has that $\mathcal{N}\{O_j\} = \mathcal{N}\{L_j(s)\}$ for $s \geq 0$, and thus $\mathcal{R}\{\mathcal{O}_j'\} = \mathcal{R}\{L_j'(s)\}$. In this situation, we can write

$$x(t_M)'L_j(s)x(t_M) = \hat{x}(t_M)'L_j(s)\hat{x}(t_M) \geq \mu|\hat{x}(t_M)|^2 \geq \mu(m/2)^2,$$

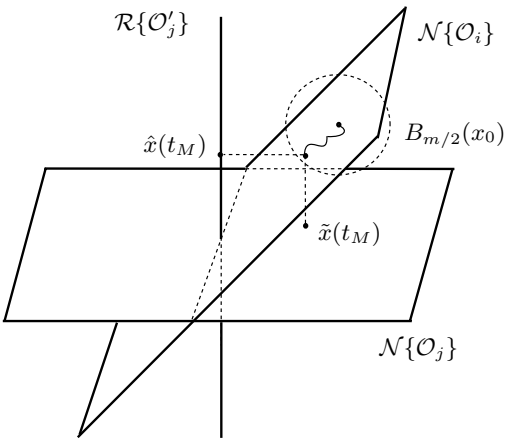

FIG. 1. *The geometry of Lemma* 14.

where μ is the smallest strictly positive eigenvalue of $L_j(s)$, and Proposition 5 leads to

$$W^s(x(t_M), j) \geq \mu m^2/4 \quad \text{a.s.}$$

Now we evaluate

$$\begin{aligned} E\{W^s(x(t_M), \theta(t_M))|\mathcal{F}_0\} &\geq E\{W^s(x(t_M), \theta(t_M))1_{\{\theta(t_M)=j\}}|\mathcal{F}_0\} \\ &\geq \frac{\mu m^2}{4} E\{1_{\{\theta(t_M)=j\}}|\mathcal{F}_0\} > 0, \end{aligned}$$

where the last inequality comes from the assumption of the lemma. Finally, we can write that

$$\begin{aligned} W^{s+t_M}(x_0, \theta_0) &= E\{W^{s+t_M}(x_0, \theta_0)|\mathcal{F}_0\} \\ &= E\{W^{t_M}(x_0, \theta_0)|\mathcal{F}_0\} + E\{W^s(x(t_M), \theta(t_M))|\mathcal{F}_0\} \\ &\geq E\{W^s(x(t_M), \theta(t_M))|\mathcal{F}_0\} > 0, \end{aligned}$$

and, from Corollary 9 (i) and (iii), it follows that $x_0 \notin \mathcal{N}\{\mathcal{O}_{\theta_0}\}$, which is a contradiction in view of (18). □

The next corollary establishes that nonobserved trajectories are pathwise invariant.

COROLLARY 15. *If* $x(t) \in \mathcal{N}\{\mathcal{O}_{\theta(t)}\}$, *then* $x(s) \in \mathcal{N}\{\mathcal{O}_{\theta(s)}\}$ *a.s. for all* $s \geq t$.

4. W-detectability. Let us start this section by rewriting the concept of W-detectability in terms of the notation introduced in section 2.

DEFINITION 16 (W-detectability). *We say that* (A, C, Λ) *is W-detectable if there exist scalars* $t_d, s_d \geq 0$, $\gamma > 0$, *and* $0 \leq \delta < 1$ *such that* $W^{t_d}(X) \geq \gamma \|X\|$ *whenever* $\|X(s_d)\| \geq \delta \|X\|$, *with* $X(0) = X$.

Notice that W-detectability requires positivity of $W^{t_d}(\cdot)$ only when the condition $\|X(s_d)\| \geq \delta \|X\|$, related to stability of the system, is satisfied. The next result is immediate; the proof is omitted.

LEMMA 17. *If* (A, C, Λ) *is W-observable, then* (A, C, Λ) *is W-detectable.*

The concept of W-detectability resembles standard concepts of detectability for linear discrete time-varying systems; see, e.g., [1] or [11]. As we shall see in Lemma 19, the concept retrieves the idea that every nonobserved state corresponds to stable modes of the system. Notice that every MS-stable MJLS is W-detectable with t_d and γ arbitrary and δ and s_d such that $\delta = \alpha\xi^{s_d} < 1$, where α and ξ are as in Remark 1.

In what follows, basic properties of W-detectability are derived. We start with some properties of the functional $W^t(X)$. In this section, the initial condition $X(0) \in \mathcal{M}^{n0}$ is denoted by X; $W^t(X(s)) = W^t(X)$ whenever $X(s) = X$.

LEMMA 18. *Let $T > 0$. The following assertions hold:*

(i) *$W^t(X)$ is continuous on X.*

(ii) *Assume that $W^T(X) = 0$ for some $T \geq 0$; then $W^t(X(s)) = 0$ for all $t, s \geq 0$.*

Proof. (i) The assertion follows immediately from the representation in (8), $W^t(X) = \langle X, L(t)\rangle$, and the continuity of the inner product.

(ii) Since $W^T(X) = 0$ for some $T > 0$, from Corollary 9 (ii) and (iii), we conclude that $W^{s+t}(X) = 0$. Now let us define $U(0) = U = X(s)$; since $U(t)$ is defined by $\dot{U}_i(t) = \mathcal{T}_i(U(t))$ and, from Proposition 5 (i), it holds that $\dot{X}_i(t) = \mathcal{T}_i(X(t))$, we have that $U(\tau) = X(\tau + s)$ for $0 \leq \tau \leq t$. Then, from the definition of W in (8), we can write that

$$\begin{aligned} W^t(X(s)) &= \int_0^t \langle U(\tau), C'C\rangle d\tau \\ &= \int_s^{s+t} \langle X(\tau), C'C\rangle d\tau \\ &\leq \int_0^{s+t} \langle X(\tau), C'C\rangle d\tau = W^{s+t}(X) = 0. \end{aligned}$$ □

The result in the next lemma parallels the known result in deterministic linear systems theory that every nonobserved trajectory corresponds to stable modes of the system. The proof is a counterpart of the discrete-time case presented in [4, Lemma 8].

LEMMA 19. *Consider system Φ, and let $T > 0$. (A, C, Λ) is W-detectable if and only if $\|X(t)\| \to 0$ as $t \to \infty$ whenever $W^T(X) = 0$.*

Proof. Sufficiency. Let us consider the set

$$\mathbb{Z} = \{Z : \|Z\| = 1, W^T(Z) = 0\}, \tag{19}$$

and let us denote as $Z(t)$ the trajectory corresponding to an initial condition $Z \in \mathbb{Z}$. By hypothesis, $\|Z(t)\| \to 0$ as $t \to \infty$, and we can write as in Remark 1 that there exist $0 < \xi < 1$ and $\alpha \geq 1$ such that $\|Z(t)\| \leq \alpha\xi^t$. Consequently, there exist $s_d \geq 0$ and $0 \leq \delta < 1$ such that $\|Z(s_d)\| < \delta$ for all $Z \in \mathbb{Z}$, and we can write

$$\mathbb{Z} \subset \bar{\mathbb{C}} = \{Z : \|Z\| = 1, \|Z(s_d)\| < \delta\}.$$

In this proof, we shall demonstrate that there exists $\gamma > 0$ such that, whenever $\|X(s_d)\| \geq \delta$, then $W^T(X) \geq \gamma \|X\|$, and consequently (A, C, Λ) is W-detectable. Let us deny the assertion and suppose that, for each $\gamma > 0$, there exists X, $\|X\| = 1$ such that $W^T(X) < \gamma$ and $\|X(s_d)\| \geq \delta$, i.e., $X \in \mathbb{C}$, where

$$\mathbb{C} = \{X : \|X\| = 1, \|X(s_d)\| \geq \delta\}.$$

Notice that, since $X(s_d)$ is solution of the differential equation (6), $X(s_d)$ is continuous on the initial condition X, and hence the set $\mathbb{C}$ is a compact set. Then we can take a

sequence $X_n \in \mathbb{C}$ with $\gamma_n \to 0$ as $n \to \infty$ in such a manner that, from the compactness of $\mathbb{C}$, there exists a subsequence X_m, which converges to some $\widehat{X} \in \mathbb{C}$, and, from the continuity of W^T (see Lemma 18),

$$\lim_{m\to\infty} W^T(X_m) = W^T(\widehat{X}) = 0.$$

In view of (19), $\widehat{X} \in \mathbb{Z} \subset \bar{\mathbb{C}}$, which completes the proof by contradiction.

Necessity. We shall show that, under W-detectability of (A, C, Λ), $\|X(t)\| \to 0$ as $t \to \infty$ when $W^T(X) = 0$. Since $W^T(X) = 0$, from Lemma 18, we have that $W^T(X(t)) = 0$ for all $t \geq 0$. Then, in view of the W-detectability of (A, C, Λ), we have that $\|X(t + s_d)\| < \delta \|X(t)\|$ for all $t \geq 0$ and some $s_d \geq 0$ and $0 \leq \delta < 1$; consequently, $\|X(t + ns_d)\| < \delta^n \|X(t)\|$, and hence

$$\lim_{n\to\infty} \sup_{0\leq t\leq s_d-1} \|X(t + ns_d)\| \leq \lim_{n\to\infty} \delta^n \sup_{0\leq t\leq s_d-1} \|X(t)\| = 0,$$

and the result follows in a straightforward manner. □

The next lemma presents a second version of the previous result, coined here in terms of the set of observability matrices $\mathcal{O}$.

LEMMA 20. *(A, C, Λ) is W-detectable if and only if $\lim_{t\to\infty} E\{|x(t)|^2\} = 0$ whenever $x_0 \in \mathcal{N}(\mathcal{O}_{\theta_0})$.*

Proof. Necessity. We show that $\lim_{t\to\infty} \|X(t)\| = 0$ whenever $x_0 \in \mathcal{N}(\mathcal{O}_{\theta_0})$, provided (A, C, Λ) is W-detectable. For the initial condition x_0, θ_0, we have that $X_j(0) = 0$, $j \neq \theta_0$, and $X_{\theta_0}(0) = x_0 x_0'$, and since $x_0 \in \mathcal{N}(\mathcal{O}_{\theta_0})$, Corollary 9 yields $W^t(X(0)) = 0$; Lemma 19 completes the proof.

Sufficiency. Let us assume that $W^T(X) = 0$. Any such $X \in \mathcal{M}^{n0}$ can be written in the following form (see Theorem 7.5.2 of [12]):

$$X_i = x_i^1 x_i^{1\prime} + \cdots + x_i^{r_i} x_i^{r_i\prime}, \tag{20}$$

where $x_i^k \in \mathbb{R}^n, k = 1, \ldots, r$, and $r_i = \operatorname{rank}(X_i) \leq n$. From (8), we have that $\langle X, L(T)\rangle = W^T(X) = 0$, and we can write that $W^T(x_i^k, i) \leq \langle X, L(T)\rangle = 0$ for any i and k. Thus (i) and (ii) of Corollary 9 provide

$$x_i^k \in \mathcal{N}(\mathcal{O}_i), \quad i = 1, \ldots, N, \;\; k = 1, \ldots, r_i.$$

Now let $v^{i,k}(0) = x_i^k \in \mathcal{N}(\mathcal{O}_i)$. Let $v^{i,k}(t) \in \mathbb{R}^n$, $k = 1, \ldots, r_i$, be given by the differential equation $\dot{v}^{i,k}(t) = A_{\theta(t)} v^{i,k}(t)$, $\theta(0) = i$. Since $x^{i,k}(0) \in \mathcal{N}(\mathcal{O}_{\theta(0)})$, from the assumption of the lemma, we have that

$$\lim_{t\to\infty} E\{|v^{i,k}(t)|^2\} = 0, \quad i = 1, \ldots, N, \;\; k = 1, \ldots, r_i. \tag{21}$$

Let $X^{i,k}(t) \in \mathcal{M}^{n0}$ be the second moment matrix $X_j^{i,k}(t) = E\{v^{i,k}(t) v^{i,k}(t)' 1_{\{\theta(t)=j\}}\}$, $j = 1, \ldots, N$. Notice that $X_i^{i,k}(0) = x_i^k x_i^{k\prime}$ and $X_j^{i,k}(0) = 0$ for $j \neq i$; in view of (20), we can write $X_i = \sum_{j=1}^N \sum_{k=1}^{r_j} X_i^{j,k}$. Then, from (6) and the linearity of the operator $\mathcal{T}$, we have that

$$X_i(t) = \sum_{j=1}^{N} \sum_{k=1}^{r_j} X_i^{j,k}(t),$$

and from (21) we evaluate

$$\lim_{t\to\infty}\|X(t)\| \le \sum_{j=1}^{N}\sum_{k=1}^{r_j}\lim_{t\to\infty}\|X^{j,k}(t)\| = \sum_{j=1}^{N}\sum_{k=1}^{r_j}\lim_{t\to\infty}E\{|v^{j,k}(t)|^2\} = 0.$$

We have shown, under the assumption of the lemma, that $\|X(t)\| \to 0$ as $t \to \infty$ for each $X \in \mathcal{M}^{n0}$ such that $W^T(X) = 0$; Lemma 19 provides that (A, C, Λ) is W-detectable. □

COROLLARY 21. *If the triplet (A, C, Λ) is not W-detectable, then there exist $i \in \mathcal{S}$ and $x_0 \in \mathcal{N}(\mathcal{O}_i)$ such that $\lim_{t\to\infty} E\{|x(t)|^2\} \neq 0$, for the initial condition $x(0) = x_0$ and $\theta(0) = i$.*

4.1. W-detectability and MS-detectability. This section deals with the relation between the concepts of MS-detectability and W-detectability. In the main result of this section, we show that W-detectability of (A, C, Λ) is equivalent to MS-detectability of $(A, \mathcal{O}, \Lambda)$. From the main result, we also derive a computational test for W-observability.

We start by dealing with the following closed-loop version of the MJLS:

$$\Phi_o : \dot{x}(t) = (A_{\theta(t)} + G_{\theta(t)}\mathcal{O}_{\theta(t)})x(t), \quad x(0) = x_0,\ \theta(0) = \theta_0. \tag{22}$$

For each $i = 1, \ldots, N$, we set

$$G_i = (-A_i - I)\mathcal{O}_i^+, \tag{23}$$

where $\mathcal{O}_i^+$ denotes the pseudoinverse of $\mathcal{O}_i$.

Let us present some properties of system Φ_o with G given in (23). First, one has that $\mathcal{O}_i^+\mathcal{O}_i x$ is the orthogonal projection of x onto $\mathcal{R}\{\mathcal{O}_i'\}$ and $I - \mathcal{O}_i^+\mathcal{O}_i$ is the projection onto $\mathcal{N}\{\mathcal{O}_i\}$. Notice that we can write $x(t) = \hat{x}(t) + \tilde{x}(t)$, where $\hat{x}(t) = \mathcal{O}_{\theta(t)}^+\mathcal{O}_{\theta(t)}x(t)$ and $\tilde{x}(t) = (I - \mathcal{O}_{\theta(t)}^+\mathcal{O}_{\theta(t)})x(t)$, and one can easily check that

$$\hat{x}(t) \perp \tilde{x}(t). \tag{24}$$

In what follows, we study each component $\hat{x}$ and $\tilde{x}$ separately. For ease of notation, we denote $\mathcal{O}_{\theta(t^-)} = \lim_{s\uparrow t}\mathcal{O}_{\theta(s)}$ and similarly for $\hat{x}(\cdot)$ and $\tilde{x}(\cdot)$. Let us define the sequence of jump times $t_1, t_2, \ldots$, as

$$\begin{cases} t_0 = 0, \\ t_{m+1} = \inf\{t > t_m : \mathcal{N}\{\mathcal{O}_{\theta(t^-)}\} \neq \mathcal{N}\{\mathcal{O}_{\theta(t)}\}\}, \quad m \ge 0. \end{cases} \tag{25}$$

LEMMA 22. *Consider system Φ_o with G given in (23). Then $|\hat{x}(t)| \le e^{-t}|\hat{x}(0)|$ a.s.*

Proof. From (23) and (22), it is a simple matter to check that, for $t_{m-1} \le t < t_m$, $\dot{\hat{x}}(t) = -\hat{x}(t)$ with a given condition $\hat{x}(t_{m-1})$ due to the strong Markov property of MJLS [8] and the linearity of Φ_o; this means that

$$\hat{x}(t) = e^{-(t-t_{m-1})}\hat{x}(t_{m-1}), \quad t_{m-1} \le t < t_m \text{ a.s.} \tag{26}$$

Regarding the sequence of jump times, from (25) and Lemma 14, we have that $\mathcal{N}\{\theta(t_m^-)\} \subset \mathcal{N}\{\theta(t_m)\}$ holds strictly, which yields that the projection of $\tilde{x}(t_m^-)$ onto $\mathcal{R}\{\mathcal{O}_{\theta(t_m)}'\}$ is null and $\hat{x}(t_m)$ is simply the result of the orthogonal projection of $\hat{x}(t_m^-)$

onto $\mathcal{R}\{\mathcal{O}'_{\theta(t_m)}\}$. Then the value of the Euclidean norm of $\hat{x}(\cdot)$ decreases at the sequence of jump times,

$$|\hat{x}(t_m)| \leq |\hat{x}(t_m^-)| \text{ a.s.} \tag{27}$$

The result follows from (26) and (27). ∎

LEMMA 23. *Consider system Φ_o with G given in* (23), *and assume that (A, C, Λ) is W-detectable. Then $E\{|\tilde{x}(t)|^2\} \to 0$ as $t \to \infty$.*

Proof. In this proof, $P_{t_m} = (I - \mathcal{O}^+_{\theta(t_m)}\mathcal{O}_{\theta(t_m)})$ stands for the orthogonal projection onto $\mathcal{N}\{\mathcal{O}_{\theta(t_m)}\}$. We start showing inductively that $E\{|\tilde{x}(t_m)|^2\} < \infty$. For $m = 0$, the result is immediate since $E\{|\tilde{x}(0)|^2\} \leq |x_0|^2$. Now we assume that $E\{|\tilde{x}(t_{m-1})|^2\} < \infty$. At time instant t_m, the orthogonal projection of $\hat{x}(t_m^-)$ onto $\mathcal{N}\{\mathcal{O}_{\theta(t_m)}\}$ is added to $\tilde{x}$; that is,

$$\tilde{x}(t_m) = \tilde{x}(t_m^-) + P_{t_m}\hat{x}(t_m^-). \tag{28}$$

Notice that $P_{t_{m-1}}P_{t_m} = P_{t_{m-1}}$ since $\mathcal{N}\{\mathcal{O}_{\theta(t_{m-1})}\} \subset \mathcal{N}\{\mathcal{O}_{\theta(t_m)}\}$, and we write $P_{t_{m-1}}P_{t_m}\hat{x}(t_m^-) = P_{t_{m-1}}\hat{x}(t_m^-) = 0$; notice that $P_{t_m}\hat{x}(t_m^-) \in \mathcal{R}\{\mathcal{O}'_{\theta(t_{m-1})}\}$ or, equivalently,

$$\tilde{x}(t_m^-) \perp P_{t_m}\hat{x}(t_m^-). \tag{29}$$

On the other hand, from (22) and (23), it is easy to check that, for $t_{m-1} \leq t < t_m$, $\dot{\tilde{x}}(t) = A_{\theta(t)}\tilde{x}(t)$ with given condition $\tilde{x}(t_{m-1})$ due to the strong Markov property of MJLS [8] and the linearity of Φ_o. Recalling that $\tilde{x}(t) \in \mathcal{N}\{\mathcal{O}_{\theta(t)}\}$ for $t_m \leq t < t_{m+1}$, Lemma 20, Remark 1, and the strong Markov property yield

$$E\{|\tilde{x}(t)|^2 1_{\{t_m \leq t < t_{m+1}\}}\} \leq \alpha E\{\xi^{t-t_m}|\tilde{x}(t_m)|^2 1_{\{t_m \leq t < t_{m+1}\}}\}, \tag{30}$$

where $0 < \xi < 1$ and $\alpha \geq 1$. Then, from (28), by employing (29) and (30) and from Lemma 22, we evaluate

$$\begin{aligned} E\{|\tilde{x}(t_m)|^2\} &= E\{|\tilde{x}(t_m^-) + P_{t_m}\hat{x}(t_m^-)|^2\} = E\{|\tilde{x}(t_m^-)|^2\} + E\{|P_{t_m}\hat{x}(t_m^-)|^2\} \\ &\leq \alpha E\{\xi^{t-t_{m-1}}|\tilde{x}(t_{m-1})|^2\} + E\{|\hat{x}(t_m^-)|^2\} \\ &< \alpha E\{|\tilde{x}(t_{m-1})|^2\} + E\{|\hat{x}(t_m^-)|^2\} < \infty, \end{aligned} \tag{31}$$

and the induction is complete. From (30) and (31), we can find $o(t) > 0$ for which

$$E\{|\tilde{x}(t)|^2 1_{\{t_m \leq t < t_{m+1}\}}\} \leq \alpha E\{\xi^{t-t_m}|\tilde{x}(t_m)|^2 1_{\{t_m \leq t < t_{m+1}\}}\} \leq o(t)$$

holds for each interval $t_{m-1} < t < t_m$, where $o(t) \to 0$ as $t \to \infty$. Then we can write

$$\begin{aligned} E\{|\tilde{x}(t)|^2\} &= E\{|\tilde{x}(t)|^2 1_{\{t_0 \leq t < t_1\}}\} + E\{|\tilde{x}(t)|^2 1_{\{t_1 \leq t < t_2\}}\} + \cdots \\ &\leq \alpha E\{\xi^{t-t_0}|\tilde{x}(t_0)|^2 1_{\{t_0 \leq t < t_1\}}\} + \alpha E\{\xi^{t-t_1}|\tilde{x}(t_1)|^2 1_{\{t_1 \leq t < t_2\}}\} + \cdots \\ &\leq o(t) + o(t) + \cdots . \end{aligned} \tag{32}$$

Finally, it can be checked that (32) has at most n elements. Indeed, from (25) and Lemma 14, it is simple to check that $\mathcal{N}\{\theta(t_0)\} \subset \mathcal{N}\{\theta(t_1)\} \subset \cdots \subset \mathcal{N}\{\theta(t_m)\}$ strictly, which yields $m \leq \dim\mathcal{N}\{\mathcal{O}_{\theta(t_m)}\} \leq n$, where the limit comes from the fact that $\mathcal{O}_i \in \mathcal{R}^{n(n^2N),n}$ for all i. Hence

$$\lim_{t\to\infty} E\{|\tilde{x}(t)|^2\} \leq n \lim_{t\to\infty} o(t) = 0. \qquad \blacksquare$$

Now we are ready to present the main result of the section.

THEOREM 24. *The triplet* (A, C, Λ) *is W-detectable if and only if the triplet* $(A, \mathcal{O}, \Lambda)$ *is MS-detectable.*

Proof. Necessity. Consider system Φ_o, let G be defined as in (23), and assume that (A, C, Λ) is W-detectable. From (24) and Lemmas 22 and 23, we evaluate

$$\lim_{t\to\infty} E\{|x(t)|^2\} = \lim_{t\to\infty} E\{|\hat{x}(t)|^2\} + \lim_{t\to\infty} E\{|\tilde{x}(t)|^2\}$$
$$\leq \lim_{t\to\infty} e^{-2t} E\{|x(0)|^2\} + \lim_{t\to\infty} E\{|\tilde{x}(t)|^2\} = 0.$$

Thus $(A + G\mathcal{O}, \Lambda)$ is MS-stable, which implies that $(A, \mathcal{O}, \Lambda)$ is MS-detectable.

Sufficiency. We show that $(A, \mathcal{O}, \Lambda)$ is not MS-detectable provided the triplet (A, C, Λ) is not W-detectable. Consider $i \in \mathcal{S}$ and $x_0 \in \mathcal{N}(\mathcal{O}_i)$ as in Corollary 21. For the initial condition $x(0) = x_0$ and $\theta(0) = i$, we have from Corollary 15 that $\mathcal{O}_{\theta(t)} x(t) = 0$, $t \geq 0$. Then the term $G_{\theta(t)}\mathcal{O}_{\theta(t)}x(t)$ vanishes in (22), and $x(t)$ evolves according to $\dot{x}(t) = A_{\theta(t)}x(t)$ for any $G \in \mathcal{M}^n$ in such a manner that the system Φ_o behaves as its open-loop version Φ no matter how G is chosen. Finally, from Corollary 21, we have that $\lim_{t\to\infty} E\{|x(t)|^2\} \neq 0$, and we conclude that there is no $G \in \mathcal{M}^n$ such that $A + G\mathcal{O}$ is MS-stable; hence $(A, \mathcal{O}, \Lambda)$ is not MS-detectable. □

The relationship between MS-detectability and W-detectability is established as follows.

THEOREM 25. *If* (A, C, Λ) *is MS-detectable, then* (A, C, Λ) *is W-detectable.*

Proof. It follows from the definition of $\mathcal{O}$ that $\mathcal{N}\{\mathcal{O}_i\} \subset \mathcal{N}\{C_i\}$. In view of this fact, it is simple to check that, given $K \in \mathcal{M}^{n,q}$, there always exists $G \in \mathcal{M}^{n,n^3N}$ such that $G_i\mathcal{O}_i = K_iC_i$, $i = 1, \ldots, N$; hence we have that MS-detectability of (A, C, Λ) implies MS-detectability of $(A, \mathcal{O}, \Lambda)$. Theorem 24 completes the proof. □

Notice that the converse of Theorem 25 does not hold in general since it is a simple matter to find situations for which $\mathcal{N}\{C_i\} \subset \mathcal{N}\{\mathcal{O}_i\}$ strictly.

Remark 4. Theorem 24 allows one to test the W-detectability of the triplet (A, C, Λ) by checking the MS-detectability of the triplet $(A, \mathcal{O}, \Lambda)$. For a downsizing in the dimensionality, one can check alternatively if the triplet $(A, \mathcal{O}'\mathcal{O}, \Lambda)$ is MS-detectable. The following computational form for the MS-detectability test, posed in terms of linear matrix inequalities, is an adaptation of the results in [17]: the MS-detectability of (A, C, Λ) is equivalent to the feasibility of the set

$$A_i'X_i + X_iA_i + C_i'L_i' + L_iC_i + \mathcal{E}_i(X) < 0, \quad i = 1, \ldots, N,$$

in the unknowns $X_i \in \mathcal{R}^{n0}$ and L_i of appropriate dimensions.

Example 2. Let $N = 2$, $n = 1$, and set

$$A_1 = -2;\ A_2 = 2;\ C_1 = 1;\ C_2 = 0;\ \Lambda = \begin{bmatrix} -1 & 1 \\ 1 & -1 \end{bmatrix}.$$

From (9), we evaluate $\mathcal{O}_1 = [1\ -5]'$ and $\mathcal{O}_2 = [0\ 1]'$, and Theorem 11 ensures that (A, C, Λ) is W-observable. Notice also that the condition in Lemma 20 is trivially satisfied. On the other hand, one can check by employing the result in Remark 4 that (A, C, Λ) is not MS-detectable.

Remark 5. It can be shown that matrix $\mathcal{O}_i$ is full rank if the pair (A_i, C_i) is observable. From this result and the result in Lemma 14, we conclude that a sufficient condition for W-observability of (A, C, Λ) is that the pair (A_i, C_i) is observable and $\lambda_{ji} > 0$ for all $j \neq i$. For instance, this is the scenario in Example 2.

Remark 6. For the deterministic linear system described by the pair (A_i, C_i), let N_i stand for the observability matrix $N_i = [C_i \vdots A_i C_i \vdots \cdots \vdots A_i^{n-1} C_i]$. It is widely known that the detectability of (A_i, N_i) is equivalent to the detectability of (A_i, C_i). This property is not mirrored by the MS-detectability concept since Theorem 24 states that the MS-detectability of $(A, \mathcal{O}, \Lambda)$ is equivalent to the W-detectability of (A, C, Λ), which is more general than the MS-detectability of (A, C, Λ). The scenario of MJLS with W-detectability is as follows:

$$\text{W-detectable } (A, \mathcal{O}, \Lambda) \;\Leftrightarrow\; \text{W-detectable } (A, C, \Lambda) \;\Leftrightarrow\; \text{MS-detectable } (A, \mathcal{O}, \Lambda),$$

where the first equivalence follows from Lemma 12.

Remark 7. For the degenerate case $\Lambda = 0$, we can show that W-detectability is equivalent to MS-detectability. This relation is exposed by the following equivalencies; most of them are simple to verify and are stated without further reference. We use a concise but self-evident notation; as in the remark above, N_i denotes the observability matrix of the system described by (A_i, C_i).

(i) MS-detec$(A, C, \Lambda) \;\Leftrightarrow\;$ detec(A_i, C_i) for all $i \;\Leftrightarrow\;$ detec(A_i, N_i) for all i;

(ii) $\mathcal{N}(N_i) \equiv \mathcal{N}(\mathcal{O}_i)$ for all i;

(iii) detec$(A_i, N_i) \;\Leftrightarrow$ detec$(A_i, \mathcal{O}_i)$;

(iv) detec$(A_i, \mathcal{O}_i)$ for all $i \;\Leftrightarrow$ MS-detec$(A, \mathcal{O}, \Lambda) \;\Leftrightarrow$ W-detec(A, C, Λ) (Theorem 24).

5. W-detectability and the LQ problem. In this section, we consider the linear quadratic control for system Φ. Under the W-detectability assumption, we show that the closed-loop system is MS-stable if a set of coupled algebraic matrix equations associated with the closed-loop system has a solution. In particular, we conclude that the solution to the CARE arising in the LQ problem is a unique stabilizing solution. Thus W-detectability not only generalizes MS-detectability but also plays the same role of MS-detectability in optimal LQ problems; see [7] and [9].

We start with some preliminary results for the open-loop system Φ. Consider the cost functional

$$J^T(X) = \int_0^T \langle U(\tau), S\rangle d\tau = E\left\{\int_0^T x(\tau)' S_{\theta(\tau)} x(\tau) d\tau | \mathcal{F}_0\right\} \tag{33}$$

defined whenever $U(0) = X$, where $S \in \mathcal{M}^{n0}$. Notice that the functionals J^T and W^T are closely related. In fact, it is easy to check that, when $C = S^{1/2}$, $W^T(X)$ and $J^T(X)$ coincide.

Let us consider the following coupled equation in the unknown $P \in \mathcal{M}^n$:

$$0 = \mathcal{L}_i(P) + S_i, \quad i = 1, \ldots, N, \tag{34}$$

with $S \in \mathcal{M}^{n0}$. The following results are derived from [6] and [13].

PROPOSITION 26. *Consider system* Φ *and the set of equations* (34). *Then the following assertions hold:*

(i) *If there exists* $P \in \mathcal{M}^{n0}$ *satisfying* (34), *then*

$$J^\infty(X) = \lim_{T\to\infty} J^T(X) \le \langle X, P\rangle. \tag{35}$$

(ii) *Assume that* A *is MS-stable. Then there exists a unique* P *satisfying* (34) *and* $P \in \mathcal{M}^{n0}$; *moreover,*

$$J^\infty(X) = \langle X, P\rangle.$$

LEMMA 27. *Assume that $(A, S^{1/2}, \Lambda)$ is W-detectable and that there exists $P \in \mathcal{M}^{n0}$ such that $J^\infty(X) < \langle X, P\rangle$. Then A is MS-stable.*

Proof. Let t_d, s_d, δ, and γ be as in Definition 16. Let us assume that A is not MS-stable; in this situation, there exists $X(0) \neq 0$ such that

$$\|X(t)\| \geq \beta\zeta^t \|X(0)\| \tag{36}$$

for some $0 < \beta \leq 1$ and $\zeta \geq 1$; see Remark 1. Let us define the sequence $\mathcal{N} = \{n_0, n_1, \dots\}$, where $n_0 = 0$ and each n_m, $m = 1, 2, \dots$, is the smallest integer such that $n_m > n_{m-1}$ and

$$\|X((n_m + 1)s_d)\| \geq \delta \|X(n_m s_d)\|$$

hold. It is easy to check that, if the number of elements of $\mathcal{N}$ is finite, then

$$\lim_{m\to\infty} \|X(m\, s_d)\| = 0,$$

which contradicts (36) and we conclude that $\mathcal{N}$ has infinitely many elements. Hence we can take a subsequence with infinitely many elements $\mathcal{N}' = \{n_{m_0}, n_{m_1}, \dots\}$, where $n_{m_0} = m_0 = 0$ and each m_k, $k = 1, 2, \dots$, is the smallest integer, such that $n_{m_k} \geq n_{m_{k-1}} + \max\{1, t_d/s_d\}$. In view of the W-detectability, we can evaluate

$$\begin{aligned} J^T(X) &= \int_0^T \langle X(\tau), S\rangle d\tau \geq \sum_{k=0}^{k'} \int_{n_{m_k} s_d}^{n_{m_k} s_d + t_d} \langle X(\tau), S\rangle d\tau \\ &= \sum_{k=0}^{k'} W^{t_d}(X(n_{m_k} s_d)) \geq \sum_{k=0}^{k'} \gamma \|X(n_{m_k} s_d)\| \\ &\geq \gamma \sum_{k=0}^{k'} \beta\zeta^{(n_{m_k} s_d)} \|X(0)\| \geq \gamma\, \beta\zeta^{(n_{m_0} s_d)}(k' + 1) \|X(0)\|, \end{aligned}$$

where k' is the largest integer for which $n_{m_{k'}} s_d + t_d \leq T$, in such a manner that $k' \to \infty$ as $T \to \infty$, and we conclude that $J^\infty(X) = \infty$, which, from Proposition 26 (i), contradicts the hypothesis of the lemma. □

Now we consider the system Φ in closed-loop form. Recall that we assumed in section 1 that both the state x and the jump variable θ are accessible for control. In this situation, it is well known that the optimal control is in linear state feedback form; see, e.g., [13]. Then we consider the following closed-loop version of system Φ:

$$\Phi_c \ : \ \dot{x}(t) = (A_{\theta(t)} + B_{\theta(t)} G_{\theta(t)})x(t), \tag{37}$$

where $B \in \mathcal{M}^{n,r}$ is given and $G \in \mathcal{M}^{r,n}$ can be regarded as a linear state feedback control. The associated infinite horizon cost functional is

$$J^\infty(X) = \lim_{t\to\infty} \int_0^T \langle U(\tau), Q + G'RG\rangle d\tau, \tag{38}$$

where $Q \in \mathcal{M}^{n0}$ and $R \in \mathcal{M}^{r+}$, defined whenever $U(0) = X$. The system Φ_c is said to be MS-stabilizable when there exists $G \in \mathcal{M}^{r,n}$ such that $A + BG$ is MS-stable. In what follows, $\mathcal{L}_G$ refers to the operator $\mathcal{L}$ associated to the closed-loop system with gain G; namely,

$$\mathcal{L}_{Gi}(U) = \widehat{A}_i' U_i + U_i \widehat{A}_i + \sum_{j=1}^{N} \lambda_{ij} U_j, \tag{39}$$

where $\widehat{A}_i = A_i + B_iG_i$ for each i. The same notation applies to $\mathcal{T}_G$.

A question that arises is whether a W-detectable open-loop triplet (A, C, Λ) can turn into a non-W-detectable closed-loop triplet $((A + BG), C, \Lambda)$. The next lemma gives an answer to this conjecture.

LEMMA 28. *If $(A, Q^{1/2}, \Lambda)$ is W-detectable, then $(A + BG, (Q + G'RG)^{1/2}, \Lambda)$ is W-detectable for any $G \in \mathcal{M}^{r,n}$ and $R \in \mathcal{M}^{r+}$.*

Proof. In this proof, $\mathcal{T}$ and W refer to the system Φ, and $\mathcal{T}_G$ and W_G refer to Φ_c; $X(\cdot)$ represents the trajectory of system Φ_c. We show that $\|X(t)\| \to 0$ as $t \to \infty$ whenever $W_G^T(X) = 0$. From Lemma 18, we can write for all $t \geq 0$ that

$$0 = W_G^t(X) = \int_0^t \langle X(\tau), (Q + G'RG)'^{1/2}(Q + G'RG)^{1/2}\rangle d\tau \tag{40}$$
$$= \int_0^t \langle X(\tau), Q + G'RG\rangle d\tau \geq \int_0^t \langle X(\tau), G'RG\rangle d\tau.$$

From the continuity of $X(t)$, we can evaluate

$$\langle X(t), G'RG\rangle = \langle R^{1/2}GX(t)^{1/2}, R^{1/2}GX(t)^{1/2}\rangle = 0$$

for all $t \geq 0$, and, since $R_i > 0$, we get that $G_iX(t) = 0$ for all $t \geq 0$ and i. Then we can write

$$\mathcal{T}_{Gi}(X(t)) = \widehat{A}_iX_i(t) + X_i\widehat{A}_i' + \sum_{j=1}^N \lambda_{ji}X_j$$
$$= A_iX_i(t) + X_iA_i' + \sum_{j=1}^N \lambda_{ji}X_j = \mathcal{T}_i(X(t))$$

for all $t \geq 0$, and, in view of Proposition 5 with $\widehat{A}_i = (A_i + B_iG_i)$ for $i = 1, \ldots, N$, we have that such trajectories of systems Φ_c and Φ coincide whenever the initial conditions coincide. We set $C = Q^{1/2}$ in system Φ to conclude, similarly to (40), that

$$W^T(X) = \int_0^T \langle X(\tau), C'C\rangle d\tau = \int_0^T \langle X(\tau), Q\rangle d\tau \leq W_G^T(X) = 0$$

for any $s > 0$, and the detectability of $(A, Q^{1/2}, \Lambda)$ ensures that $\|X(t)\| \to 0$ as $t \to \infty$. ∎

THEOREM 29. *Consider the closed-loop system Φ_c with a linear state feedback control $G \in \mathcal{M}^{r,n}$. Assume that $(A, Q^{1/2}, \Lambda)$ is W-detectable. If there exists a solution $P \in \mathcal{M}^{n0}$ of*

$$\mathcal{L}_{Gi}(P) + Q_i + G_i'R_iG_i = 0, \quad i = 1, \ldots, N, \tag{41}$$

then $A + BG$ is MS-stable.

Proof. Set $S = Q + G'RG$, and notice, from Lemma 28 and the assumption in the theorem, that $(\hat{A}, S^{1/2}, \Lambda)$ is W-detectable, where $\widehat{A} = (A + BG)$. Then, from Proposition 26 (i), we have that $J_G^\infty(X) \leq \langle X, P\rangle$, and Lemma 27 states that $\widehat{A}$ is MS-stable. ∎

THEOREM 30. *Consider the system*

$$\dot{x}(t) = A_{\theta(t)}x(t) + B_{\theta(t)}u(t), \tag{42}$$

the associated infinite-horizon linear quadratic cost $J^\infty(X)$, *and the CARE in the unknown* $P \in \mathcal{M}^{n0}$:

$$A_i'P_i + P_iA_i + \sum_{j=1}^{N} \lambda_{ij}P_j - P_iB_iR_i^{-1}B_i'P_i + Q_i = 0. \tag{43}$$

Assume that $(A, Q^{1/2}, \Lambda)$ *is W-detectable. Then the following assertions hold:*

(i) *There exists a solution* $P \in \mathcal{M}^{n0}$ *of* (43) *if and only if the system is MS-stabilizable;*

(ii) *If* P *is a solution of* (43), *then it is unique. The optimal state feedback control*

$$u(t) = -R_i^{-1}B_i'P_ix(t) \quad \textit{whenever } \theta(t) = i \tag{44}$$

is such that

$$\lim_{t\to\infty} E\{|x(t)|^2\} = 0.$$

Proof. The sufficiency part of assertion (i) is a well-known result; see, e.g., [17, Theorem 3.1]. Notice that, if we denote $G_i = -R_i^{-1}B_i'P_i$, we can write (43) equivalently as

$$\mathcal{L}_{Gi}(P) + G_i'R_iG_i + Q_i = 0, \quad i = 1, \dots, N, \tag{45}$$

and, from Theorem 29, we have that $A + BG$ is MS-stable. This argument completes the proof of assertion (i) and also part of the assertion (ii) regarding the MS-stability of the closed-loop system defined by (44). Let us show now that P is unique. Suppose that $\bar{P} \in \mathcal{M}^{n0}$ is a solution of (43). In a similar fashion to (45), we can write

$$\mathcal{L}_{\bar{G}i}(\bar{P}) + \bar{G}_i'R_i\bar{G}_i + Q_i = 0, \quad i = 1, \dots, N, \tag{46}$$

where $\bar{G}_i = -R_i^{-1}B_i'\bar{P}_i$; notice that, from Theorem 29, the system with gain $\bar{G}$ is also MS-stable. Subtracting (46) from (45), we get, after some manipulations, that

$$\mathcal{L}_{Gi}(P - \bar{P}) + (G_i - \bar{G}_i)'R_i(G_i - \bar{G}_i) = 0, \quad i = 1, \dots, N,$$

and we identify $S_i = (G_i - \bar{G}_i)'R_i(G_i - \bar{G}_i)$ in (34) to get, from Proposition 26 (ii), that $P - \bar{P} \in \mathcal{M}^{n0}$; that is, $P_i - \bar{P}_i \geq 0$, $i = 1, \dots, N$. Now, subtracting (45) from (46), we get similarly that $\bar{P}_i - P_i \geq 0$, $i = 1, \dots, N$, and we conclude that $\bar{P} = P$. It remains only to show that the feedback control (44) is optimal. Let us suppose that there exist $X \in \mathcal{M}^{n0}$ and $\bar{G} \in \mathcal{M}^{r,n}$ such that $J_{\bar{G}}^\infty(X) < J_G^\infty(X)$. From Proposition 26 (ii), we have that $J_{\bar{G}}^\infty(X) < J_G^\infty(X) = \langle X, P\rangle$, and, since $(A + B\bar{G}, Q + \bar{G}'R\bar{G}, \Lambda)$ is W-detectable (see Lemma 28), Lemma 27 ensures that the closed-loop system with gain $\bar{G}$ is MS-stable. Then, from Proposition 26 (ii), we have that there exists a unique solution $\bar{P}$ to (46) and $J_{\bar{G}}^\infty(X) = \langle X, \bar{P}\rangle$. Once again, subtracting (45) from (46), we obtain $\bar{P} \geq P$, and we conclude that $J_{\bar{G}}^\infty(X) = \langle X, \bar{P}\rangle \geq \langle X, P\rangle = J_G^\infty(X)$, which denies the initial hypothesis, and hence

$$J_G^\infty(X) \leq J_K^\infty(X) \quad \forall K \in \mathcal{M}^{r,n}.$$

The fact that the optimal control action is in linear state feedback form is a well-established result which comes from dynamic programming arguments and from the fact that the system is Markovian; see, for instance, [13] and [15]. ∎

6. Conclusions. This paper introduces the concept of W-detectability and the set of observability matrices $\mathcal{O}$ that is related to the concept of W-observability for continuous-time MJLS.

We show that the concepts of W-observability and W-detectability reproduce geometric and qualitative properties of the deterministic concepts within the MJLS setting. In particular, we show how the properties (I)–(IV) mentioned in section 1 extend to MJLS; respectively, we have shown that

- if $x(t) \in \mathcal{N}\{\mathcal{O}_{\theta(t)}\}$, then $x(s) \in \mathcal{N}\{\mathcal{O}_{\theta(s)}\}$ a.s. for all $s \geq t$;
- (A, C, Λ) is W-observable if and only if $\mathcal{O}_i$ has full rank for each $i = 1, \ldots, N$;
- (A, C, Λ) is W-detectable if and only if $\lim_{t\to\infty} E\{|x(t)|^2\} = 0$ whenever $x_0 \in \mathcal{N}(\mathcal{O}_{\theta_0})$; and
- (A, C, Λ) is W-detectable provided (A, C, Λ) is W-observable.

We also show that those concepts generalize the previous concepts encountered in the literature and that they play the same role in the quest for stabilizing solutions of quadratic control problems. Regarding the concept of MS-detectability, in one of the main results of this paper, we show that (A, C, Λ) is W-detectable if and only if $(A, \mathcal{O}, \Lambda)$ is MS-detectable. The result provides a testable condition for W-detectability. Moreover, the kernel of $\mathcal{O}$ is in general smaller than that of the original matrices C, henceforth making W-detectability and MS-detectability directly comparable.

Testable conditions for the concept of W-observability is also developed in terms of the set of observability matrices $\mathcal{O}$. The test of W-observability in Theorem 11 for MJLS and the observability test for N deterministic time-invariant linear systems, each with dimension n, are alike.

ERRATUM: SENSITIVITY ANALYSIS OF THE VALUE FUNCTION FOR OPTIMIZATION PROBLEMS WITH VARIATIONAL INEQUALITY CONSTRAINTS*

YVES LUCET† AND JANE J. YE‡

Abstract. In our paper [*SIAM J. Control Optim.*, 40 (2001), pp. 699–723], due to an error in the proof, an additional assumption is needed for the conclusion of Theorem 3.6 to hold. In this erratum, we restate and prove Theorem 3.6 and correct other related mistakes accordingly.

PII. S036301290139926X

In our paper [1], due to an error in the proof, an additional assumption is needed for the conclusion of Theorem 3.6 to hold. As a consequence, Theorem 4.2 does not hold, each of Theorems 4.4, 4.8, 4.11, and 4.13 requires an additional assumption, and the last two lines on page 701 and the first two lines on page 702 should be changed to

$$M^1 = M^1_{CD}(\Sigma), M^1_C(\Sigma), M^1_S(\Sigma),$$
$$M^0 = M^0_{CD}(\Sigma), M^0_C(\Sigma), M^0_S(\Sigma).$$

We first correct Theorem 3.6 by adding the additional assumption (0.1) as follows.

THEOREM 3.6. *In addition to the basic assumption* (BH), *assume that there exists* $\delta > 0$ *such that the set*

$$\{(x,y) \in C \ : \ \Psi(x,y,\bar\alpha) \le p, H(x,y,\bar\alpha) = q, r \in F(x,y,\bar\alpha) + N_\Omega(y), f(x,y,\bar\alpha) \le M, \\ (p,q,r) \in B(0;\delta)\}$$

is bounded for each M *and the following assumption holds:*

$$(\gamma,\beta,\eta,0) \in M^0(\bar x,\bar y,\bar\alpha) \text{ implies } \gamma = 0,\ \beta = 0,\ \eta = 0. \tag{0.1}$$

Then the value function $V(\alpha)$ *is lower semicontinuous near* $\bar\alpha$, *and*

$$\partial V(\bar\alpha) \subseteq \bigcup_{(\bar x,\bar y)\in\Sigma(\bar\alpha)} \{-\zeta : (\gamma,\beta,\eta,\zeta) \in M^1(\bar x,\bar y,\bar\alpha)\},$$
$$\partial^\infty V(\bar\alpha) \subseteq \bigcup_{(\bar x,\bar y)\in\Sigma(\bar\alpha)} \{-\zeta : (\gamma,\beta,\eta,\zeta) \in M^0(\bar x,\bar y,\bar\alpha)\},$$

where $M^\lambda(\bar x,\bar y,\bar\alpha)$ *is the set of index* λ *multipliers for problem* GP(p,q,r,α) *at* $(0,0,0,\bar\alpha)$, *i.e., vectors* $(\gamma,\beta,\eta,\zeta)$ *in* $R^d \times R^l \times R^m \times R$ *satisfying*

$$\begin{cases} 0 \in \lambda\partial f(\bar x,\bar y,\bar\alpha) + \partial\langle\Psi,\gamma\rangle(\bar x,\bar y,\bar\alpha) + \partial\langle H,\beta\rangle(\bar x,\bar y,\bar\alpha) + \partial\langle F,\eta\rangle(\bar x,\bar y,\bar\alpha) \\ +\{0\}\times D^*N_\Omega(\bar y,-F(\bar x,\bar y,\bar\alpha))(\eta)\times\{0\} + \{(0,0,\zeta)\} + N_C(\bar x,\bar y)\times\{0\}, \\ \gamma \ge 0 \text{ and } \langle\Psi(\bar x,\bar y,\bar\alpha),\gamma\rangle = 0, \end{cases}$$

*Received by the editors December 6, 2001; accepted for publication (in revised form) May 20, 2002; published electronically December 3, 2002. This work was partly supported by an NSERC research grant.

and $\Sigma(\bar{\alpha})$ *is the set of solutions of problem* $GP(\bar{\alpha})$.

We now make the correct statements for Theorems 4.4, 4.8, 4.11, and 4.13 by translating assumption (0.1) to the case of CD, C, P, and S multipliers, respectively. Unless otherwise indicated, we denote by $\nabla f(x,y,\alpha)$ the gradient of function f with respect to (x,y,α) and not the gradient of f with respect to (x,y) as in section 4 of [1].

THEOREM 4.4. *Assume that there exists* $\delta > 0$ *such that the set*

$$\begin{aligned}\{(x,y) \in C :{} & (p,q,r) \in B(0;\delta), \Psi(x,y,\bar{\alpha}) \le p, H(x,y,\bar{\alpha}) = q,\\ & y \ge 0,\ F(x,y,\bar{\alpha}) \ge r, \langle y, F(x,y,\bar{\alpha}) - r\rangle = 0, f(x,y,\bar{\alpha}) \le M\}\end{aligned}$$

is bounded for each M. *Assume also that*

$$\begin{aligned}&0 \in \nabla\Psi(\bar{x},\bar{y},\bar{\alpha})^\top\gamma + \nabla H(\bar{x},\bar{y},\bar{\alpha})^\top\beta + \nabla F(\bar{x},\bar{y},\bar{\alpha})^\top\eta + (0,\xi,0) + N_C(\bar{x},\bar{y}) \times \{0\},\\ &\gamma \ge 0 \text{ and } \langle\Psi(\bar{x},\bar{y},\bar{\alpha}),\gamma\rangle = 0,\\ &\xi_i = 0 \qquad \text{if } \bar{y}_i > 0 \text{ and } F_i(\bar{x},\bar{y},\bar{\alpha}) = 0,\\ &\eta_i = 0 \qquad \text{if } \bar{y}_i = 0 \text{ and } F_i(\bar{x},\bar{y},\bar{\alpha}) > 0,\\ &\text{either } \xi_i < 0, \eta_i < 0 \text{ or } \xi_i\eta_i = 0 \qquad \text{if } \bar{y}_i = 0 \text{ and } F_i(\bar{x},\bar{y}) = 0\end{aligned}$$

implies that $\gamma = 0$, $\beta = 0$, $\eta = 0$. *Then the value function* V *is lower semicontinuous near* $\bar{\alpha}$, *and*

$$\begin{aligned}\partial V(\bar{\alpha}) \subseteq \bigcup_{(\bar{x},\bar{y})\in\Sigma(\bar{\alpha})} &\{\nabla_\alpha f(\bar{x},\bar{y},\bar{\alpha}) + \nabla_\alpha\Psi(\bar{x},\bar{y},\bar{\alpha})^\top\gamma + \nabla_\alpha H(\bar{x},\bar{y},\bar{\alpha})^\top\beta\\ &+\nabla_\alpha F(\bar{x},\bar{y},\bar{\alpha})^\top\eta : (\gamma,\beta,\eta) \in M^1_{CD}(\bar{x},\bar{y})\},\end{aligned} \tag{0.2}$$

$$\begin{aligned}\partial^\infty V(\bar{\alpha}) \subseteq \bigcup_{(\bar{x},\bar{y})\in\Sigma(\bar{\alpha})} &\{\nabla_\alpha\Psi(\bar{x},\bar{y},\bar{\alpha})^\top\gamma + \nabla_\alpha H(\bar{x},\bar{y},\bar{\alpha})^\top\beta\\ &+\nabla_\alpha F(\bar{x},\bar{y},\bar{\alpha})^\top\eta : (\gamma,\beta,\eta) \in M^0_{CD}(\bar{x},\bar{y})\}.\end{aligned} \tag{0.3}$$

If the set in the right-hand side of inclusion (0.3) *contains only the zero vector, then the value function* V *is Lipschitz near* $\bar{\alpha}$. *If the set in the right-hand side of inclusion* (0.3) *contains only the zero vector and the set in the right-hand side of inclusion* (0.2) *is a singleton, then the value function is strictly differentiable at* $\bar{\alpha}$.
