THEOREM 4.8. *Assume that there exists* $\delta > 0$ *such that the set*

$$\begin{aligned}\{(x,y) \in C :{} & (p,q,q^m) \in B(0;\delta), \Psi(x,y,\bar{\alpha}) \le p, H(x,y,\bar{\alpha}) = q,\\ & \min\{y_i, F_i(x,y,\bar{\alpha})\} = q^m_i, i = 1,\dots,m, f(x,y,\bar{\alpha}) \le M\}\end{aligned}$$

is bounded for each M. *Assume also that*

$$\begin{aligned}&0 \in \nabla\Psi(\bar{x},\bar{y},\bar{\alpha})^\top\gamma + \nabla H(\bar{x},\bar{y},\bar{\alpha})^\top\beta + \nabla F(\bar{x},\bar{y},\bar{\alpha})^\top\eta + (0,\xi,0) + N_C(\bar{x},\bar{y}) \times \{0\},\\ &\gamma \ge 0, \langle\Psi,\gamma\rangle(\bar{x},\bar{y},\bar{\alpha}) = 0,\end{aligned}$$

where

$$\begin{aligned}&\eta_i = 0 \quad \forall i \in I_+,\\ &\xi_i = 0 \quad \forall i \in L,\\ &\eta_i = r_i(1-\bar{t}_i), \xi_i = r_i\bar{t}_i \text{ for some } \bar{t}_i \in [0,1], \quad \forall i \in I_0\end{aligned}$$

implies that $\gamma = 0$, $\beta = 0$, $\eta = 0$, $r_i = 0$, $i = 1, \ldots, m$. *Then the value function* V *is lower semicontinuous near* $\bar{\alpha}$, *and*

$$\partial V(\bar{\alpha}) \subseteq \bigcup_{(\bar{x},\bar{y})\in\Sigma(\bar{\alpha})} \{\nabla_\alpha f(\bar{x},\bar{y},\bar{\alpha}) + \nabla_\alpha \Psi(\bar{x},\bar{y},\bar{\alpha})^\top \gamma + \nabla_\alpha H(\bar{x},\bar{y},\bar{\alpha})^\top \beta$$
$$+\nabla_\alpha F(\bar{x},\bar{y},\bar{\alpha})^\top \eta : (\gamma,\beta,\eta) \in M_C^1(\bar{x},\bar{y})\}, \tag{0.4}$$
$$\partial^\infty V(\bar{\alpha}) \subseteq \bigcup_{(\bar{x},\bar{y})\in\Sigma(\bar{\alpha})} \{\nabla_\alpha \Psi(\bar{x},\bar{y},\bar{\alpha})^\top \gamma + \nabla_\alpha H(\bar{x},\bar{y},\bar{\alpha})^\top \beta$$
$$+\nabla_\alpha F(\bar{x},\bar{y},\bar{\alpha})^\top \eta : (\gamma,\beta,\eta) \in M_C^0(\bar{x},\bar{y})\}. \tag{0.5}$$

If the set in the right-hand side of inclusion (0.5) *contains only the zero vector, then the value function* V *is Lipschitz near* $\bar{\alpha}$. *If the set in the right-hand side of inclusion* (0.5) *contains only the zero vector and the set in the right-hand side of inclusion* (0.4) *is a singleton, then the value function is strictly differentiable at* $\bar{\alpha}$.

THEOREM 4.11. *Assume that there exists* $\delta > 0$ *such that, for* $(\bar{x},\bar{y}) \in \Sigma(\bar{\alpha})$ *and each index set* $\sigma \subseteq I_0(\bar{x},\bar{y})$, *the set in Proposition* 4.10 *is bounded for each* M *and*

$$\begin{cases} 0 = \nabla\Psi(\bar{x},\bar{y},\bar{\alpha})^\top \gamma + \nabla H(\bar{x},\bar{y},\bar{\alpha})^\top \beta + \nabla F(\bar{x},\bar{y},\bar{\alpha})^\top \eta + (0,\xi,0) + N_C(\bar{x},\bar{y}) \times \{0\}, \\ \gamma_{J(\Psi)} = 0, \eta_{I_+} = 0, \xi_L = 0, \xi_\sigma \le 0, \eta_{I_0\setminus\sigma} \le 0, \end{cases}$$

implies that $\gamma = 0$, $\beta = 0$, $\eta = 0$. *Then the value function* V *is lower semicontinuous near* $\bar{\alpha}$, *and*

$$\partial V(\bar{\alpha}) \subseteq \bigcup_{(\bar{x},\bar{y})\in\Sigma(\bar{\alpha})} \{\nabla_\alpha f(\bar{x},\bar{y},\bar{\alpha}) + \nabla_\alpha \Psi(\bar{x},\bar{y},\bar{\alpha})^\top \gamma + \nabla_\alpha H(\bar{x},\bar{y},\bar{\alpha})^\top \beta$$
$$+\nabla_\alpha F(\bar{x},\bar{y},\bar{\alpha})^\top \eta : (\gamma,\beta,\eta) \in \cup_{\sigma\subseteq I_0} M_\sigma^1(\bar{x},\bar{y})\}, \tag{0.6}$$
$$\partial^\infty V(\bar{\alpha}) \subseteq \bigcup_{(\bar{x},\bar{y})\in\Sigma(\bar{\alpha})} \{\nabla_\alpha \Psi(\bar{x},\bar{y},\bar{\alpha})^\top \gamma + \nabla_\alpha H(\bar{x},\bar{y},\bar{\alpha})^\top \beta$$
$$+\nabla_\alpha F(\bar{x},\bar{y},\bar{\alpha})^\top \eta : (\gamma,\beta,\eta) \in \cup_{\sigma\subseteq I_0} M_\sigma^0(\bar{x},\bar{y})\}. \tag{0.7}$$

If the set in the right-hand side of inclusion (0.7) *contains only the zero vector, then the value function* V *is Lipschitz near* $\bar{\alpha}$. *If the set in the right-hand side of inclusion* (0.7) *contains only the zero vector and the set in the right-hand side of inclusion* (0.6) *is a singleton, then the value function is strictly differentiable at* $\bar{\alpha}$.

THEOREM 4.13. *In addition to the assumptions of Theorem* 4.11, *assume that* $C = R^n \times R^a \times R^b$ *and, for all* $(\bar{x},\bar{z},\bar{u}) \in \Sigma(\bar{\alpha})$, *the partial MPEC linear independence constraint qualification is satisfied; i.e.,*

$$\begin{cases} 0 = \nabla_{x,y}\Psi(\bar{x},\bar{y},\bar{\alpha})^\top \gamma + \nabla_{x,y} H(\bar{x},\bar{y},\bar{\alpha})^\top \beta + \nabla_{x,y} F(\bar{x},\bar{y},\bar{\alpha})^\top \eta + (0,\xi), \\ \gamma_{J(\Psi)} = 0, \eta_{I_+} = 0, \xi_L = 0, \end{cases}$$

implies that $\eta_{I_0} = 0, \xi_{I_0} = 0$, *where* $J(\Psi) := \{i : \Psi_i(\bar{x},\bar{y},\bar{\alpha}) < 0\}$. *Further assume that*

$$\begin{cases} 0 = \nabla\Psi(\bar{x},\bar{y},\bar{\alpha})^\top \gamma + \nabla H(\bar{x},\bar{y},\bar{\alpha})^\top \beta + \nabla F(\bar{x},\bar{y},\bar{\alpha})^\top \eta + (0,\xi,0), \\ \gamma_{J(\Psi)} = 0, \eta_{I_+} = 0, \xi_L = 0, \eta_{I_0} \le 0, \xi_{I_0} \le 0, \end{cases}$$

implies that $\gamma = 0$, $\beta = 0$, $\eta = 0$. *Then the value function* V *is lower semicontinuous near* $\bar{\alpha}$, *and*

$$\begin{aligned}\partial V(\bar{\alpha}) \subseteq \bigcup_{(\bar{x},\bar{y})\in\Sigma(\bar{\alpha})} &\{\nabla_\alpha f(\bar{x},\bar{y},\bar{\alpha}) + \nabla_\alpha \Psi(\bar{x},\bar{y},\bar{\alpha})^\top \gamma + \nabla_\alpha H(\bar{x},\bar{y},\bar{\alpha})^\top \beta \\ &+\nabla_\alpha F(\bar{x},\bar{y},\bar{\alpha})^\top \eta : (\gamma,\beta,\eta) \in M_S^1(\bar{x},\bar{y})\},\\ \partial^\infty V(\bar{\alpha}) \subseteq \bigcup_{(\bar{x},\bar{y})\in\Sigma(\bar{\alpha})} &\{\nabla_\alpha \Psi(\bar{x},\bar{y},\bar{\alpha})^\top \gamma + \nabla_\alpha H(\bar{x},\bar{y},\bar{\alpha})^\top \beta \\ &+\nabla_\alpha F(\bar{x},\bar{y},\bar{\alpha})^\top \eta : (\gamma,\beta,\eta) \in M_S^0(\bar{x},\bar{y})\}.\end{aligned}$$

Note that the additional assumption (0.1) and its corresponding assumptions in Theorems 4.4., 4.8, 4.11, and 4.13 are automatically satisfied in the case in which the perturbation is additive. In the case of nonadditive perturbations, they are needed even in the case of nonlinear programming, i.e., when $\Omega = R^m$ in Theorem 3.6.

The main error occurs in the proof of Theorem 3.6 when we applied [1, Proposition 2.6] to obtain the partial subdifferentials from the subdifferentials of the fully perturbed value function. The positions of vectors ζ and 0 were switched by mistake. Instead of proving that $(\zeta, 0) \in \partial^\infty \widetilde{V}(0,\bar{\alpha})$ implies $\zeta = 0$, we proved that $(0,\zeta) \in \partial^\infty \widetilde{V}(0,\bar{\alpha})$ implies $\zeta = 0$. Hence, on page 709 in lines 13–18, "For any $(0,0,0,\zeta) \in \partial^\infty \widetilde{V}(0,0,0,\bar{\alpha})$, we have $(0,0,0,\zeta) \in -M^0(\bar{x},\bar{y},\bar{\alpha})$ for some point $(\bar{x},\bar{y},\bar{\alpha}) \in \Sigma(0,0,0,\bar{\alpha})$. Therefore,

$$(0,0,\zeta) \in N_C(\bar{x},\bar{y}) \times \{0\},$$

which implies that $\zeta = 0$" should be changed to "For any $(-\gamma,-\beta,-\eta,0) \in \partial^\infty \widetilde{V}(0,0,0,\bar{\alpha})$, we have $(-\gamma,-\beta,-\eta,0) \in -M^0(\bar{x},\bar{y},\bar{\alpha})$ for some point $(\bar{x},\bar{y},\bar{\alpha}) \in \Sigma(0,0,0,\bar{\alpha})$. Hence $(\gamma,\beta,\eta,0) \in M^0(\bar{x},\bar{y},\bar{\alpha})$, which implies $\gamma = 0$, $\beta = 0$, $\eta = 0$ by assumption (0.1)."

Consider the nonlinear programming formulation of (OPCC) in [1, section 4.1]. Assumption (0.1) amounts to the nonexistence of a nonzero vector $(\gamma,\beta,r^F,r^y,\mu)$ such that

$$\begin{aligned}&0 \in \nabla\Psi(\bar{x},\bar{y},\bar{\alpha})^\top \gamma + \nabla H(\bar{x},\bar{y},\bar{\alpha})^\top \beta\\ &-\nabla F(\bar{x},\bar{y},\bar{\alpha})^\top r^F - \{(0,r^y,0)\} + \mu\nabla\langle y,F\rangle(\bar{x},\bar{y},\bar{\alpha}) + N_C(\bar{x},\bar{y}) \times \{(0)\},\\ &\gamma \geq 0, \langle\gamma,\Psi(\bar{x},\bar{y},\bar{\alpha})\rangle = 0,\\ &r^F \geq 0, r^y \geq 0, \langle r^F, F(\bar{x},\bar{y},\bar{\alpha})\rangle = 0, \langle r^y,\bar{y}\rangle = 0.\end{aligned}$$

However, using [1, Proposition 4.16] with x replaced by (x,α), the above assumption will never be satisfied, and hence [1, Theorem 4.2] does not hold. Consider the following example, which is the example in [1] with the extra constraint $(x,y) \in [-1,1]\times[-1,1]$:

$$\begin{aligned}\text{minimize} \quad & -y\\ \text{subject to} \quad & x - y = 0,\\ & x \geq 0, y \geq 0, xy = 0, (x,y) \in [-1,1]\times[-1,1].\end{aligned}$$

Note that the growth hypothesis holds since the set $[-1,1]\times[-1,1]$ is compact. The normal multiplier set $M_{NLP}^1(0,0) = \emptyset$. So [1, Theorem 4.2] is not true for this example.

That is, the nonlinear programming multipliers may not be useful in the sensitivity analysis.

Acknowledgments. The authors would like to thank the anonymous referees, in particular, referee 2, and the associate editor who suggested listing the statements that should be corrected in the beginning of the erratum.

ADAPTIVE FINITE ELEMENT APPROXIMATION FOR DISTRIBUTED ELLIPTIC OPTIMAL CONTROL PROBLEMS*

RUO LI†, WENBIN LIU‡, HEPING MA§, AND TAO TANG¶

Abstract. In this paper, sharp a posteriori error estimators are derived for a class of distributed elliptic optimal control problems. These error estimators are shown to be useful in adaptive finite element approximation for the optimal control problems and are implemented in the adaptive approach. Our numerical results indicate that the sharp error estimators work satisfactorily in guiding the mesh adjustments and can save substantial computational work.

Key words. mesh adaptivity, optimal control, a posteriori error estimate, finite element method

1. Introduction.

Finite element approximation of optimal control problems has long been an important topic in engineering design work and has been extensively studied in the literature. There have been extensive theoretical and numerical studies for finite element approximation of various optimal control problems; see [2, 12, 13, 15, 20, 23, 37, 44]. For instance, for the optimal control problems governed by some linear elliptic or parabolic state equations, a priori error estimates of the finite element approximation were established long ago; see, for example, [12, 13, 15, 20, 23, 37]. Furthermore, a priori error estimates were established for the finite element approximation of some important flow control problems in [17] and [11]. A priori error estimates have also been obtained for a class of state constrained control problems in [43], though the state equation is assumed to be linear. In [29], this assumption has been removed by reformulating the control problem as an abstract optimization problem in some Banach spaces and then applying nonsmooth analysis. In fact, the state equation there can be a variational inequality.

In recent years, the adaptive finite element method has been extensively investigated. Adaptive finite element approximation is among the most important means to boost the accuracy and efficiency of finite element discretizations. It ensures a higher density of nodes in a certain area of the given domain, where the solution is more difficult to approximate. At the heart of any adaptive finite element method is an a posteriori error estimator or indicator. The literature in this area is extensive. Some of the techniques directly relevant to our work can be found in [1, 5, 6, 7, 28, 32, 34, 42, 47]. It is our belief that adaptive finite element enhancement is one of the future directions to pursue in developing sophisticated numerical methods for optimal design problems.

Although adaptive finite element approximation is widely used in numerical simulations, it has not yet been *fully* utilized in optimal control. Initial attempts in this aspect have been reported only recently for some design problems; see, e.g., [3, 4, 38, 41]. However, a posteriori error indicators of a heuristic nature are widely used in most applications. For instance, in some existing work on adaptive finite element approximation of optimal design, the mesh refinement is guided by a posteriori error estimators *solely* from the state equation (or the displacement) for a fixed control (or design). Thus error information from approximation of the control (design) is not utilized. Although these methods may work well in some particular applications, they cannot be applied confidently in general. It is unlikely that the potential power of adaptive finite element approximation has been fully utilized due to the lack of more sophisticated a posteriori error indicators.

Very recently, some error estimators of residual type were developed in [8, 9, 30, 31, 33]. These error estimators are based on a posteriori estimation of the discretization error for the state *and* the control (design). When there is no constraint in a control problem, normally the optimality conditions consist of coupled partial differential equations only. Consequently, one may be able to write down the dual system of the *whole* optimality conditions and then apply the weighted a posteriori error estimation technique to obtain a posteriori estimators for the *objective functional* approximation error of the control problem; see [8, 9]. In many applications (like parameter estimation), it is more interesting to obtain a posteriori error estimators for the control approximation error [22]. Furthermore, there frequently exist some constraints for the control in applications. In such cases, the optimality conditions often contain a variational inequality and then have some very different properties. Thus it does not always seem to be possible to apply the techniques used in [8, 9] to constrained control problems.

In our work, constrained cases are studied via residual estimation using the norms of energy type. A posteriori error estimators are derived for quite general constrained control problems governed by the elliptic equations (see [30, 31, 33]) with upper error bounds. However, these error estimators have yet to be applied to adaptive finite element methods. Indeed, numerical experiments indicated that these estimators tend to over-refine the computational meshes. Thus the resulting computational meshes may not be efficient in reducing approximation errors. It seems that one has to derive sharper error estimators in order to obtain more efficient meshes. This seems to be possible at least for a class of control problems, which are frequently met in applications. More details on these will be given in section 3.

In this paper, we consider the convex optimal control problem

$$\begin{cases} \min\limits_{u\in K}\{g(y)+h(u)\}, \\ \\ -\mathrm{div}(A\nabla y) = f + Bu \quad \text{in } \Omega,\ y|_{\partial\Omega} = 0, \end{cases} \tag{1.1}$$

where g and h are given convex functionals, K is a closed convex set, and B is a continuous linear operator. The details will be specified later. The main objective of this work is to derive sharp a posteriori error estimators for some frequently met optimal control problems. A number of new techniques have to be introduced in order to obtain such estimators. Our numerical tests indicate that these improved error estimators indeed lead to efficient computational meshes.

The paper is organized as follows: In section 2, we describe the finite element approximation for the convex optimal control problem (1.1). In section 3, we derive

error estimates for the problem with an obstacle constraint. Both upper bounds and lower bounds are established with attention on their equivalence. In section 4, numerical experiments will be carried out, with particular attention to testing the influence of various indicators on the mesh construction.

2. The elliptic optimal control problem and finite element approximation. In this section, we describe the elliptic optimal control problem and its finite element approximation. Let Ω and Ω_U be two bounded open sets in $\mathbf{R}^n (n \leq 3)$ with the Lipschitz boundaries $\partial\Omega$ and $\partial\Omega_U$. We denote by $C^0(\bar{\Omega})$ the space of continuous functions on $\bar{\Omega}$. We adopt the standard notation $W^{m,q}(\Omega)$ for Sobolev spaces on Ω with norm $\|\cdot\|_{m,q,\Omega}$ and seminorm $|\cdot|_{m,q,\Omega}$(see (1.2) of [16, p. 2]). For $q = 2$, we denote $W^{m,2}(\Omega)$ by $H^m(\Omega)$ with norm $\|\cdot\|_{m,\Omega} := \|\cdot\|_{m,2,\Omega}$ and seminorm $|\cdot|_{m,\Omega} := |\cdot|_{m,2,\Omega}$. We set $H_0^1(\Omega) = \{v \in H^1(\Omega) : v|_{\partial\Omega} = 0\}$. In addition, c or C denotes a general positive constant independent of h.

In the rest of the paper, we shall take the state space $Y = H_0^1(\Omega)$, the control space $U = L^2(\Omega_U)$ with the inner product $(\cdot,\cdot)_U$, and $H = L^2(\Omega)$ with the inner product $(\cdot,\cdot)$. We wish to study the finite element approximation of the distributed elliptic convex optimal control problem (1.1). Assume that g and h are convex functionals which are continuously differentiable on $H = L^2(\Omega)$ and $U = L^2(\Omega_U)$, respectively, and h is further strictly convex. Suppose that K is a closed convex set in the control space U, $f \in L^2(\Omega)$, B is a continuous linear operator from U to $H \subset Y'$ (the dual space of Y), and

$$A(\cdot) = (a_{i,j}(\cdot))_{n\times n} \in (L^\infty(\Omega))^{n\times n}$$

such that there is a constant $c > 0$ satisfying, for any vector $\xi \in \mathbf{R}^n$,

$$(A\xi)\cdot\xi \geq c|\xi|^2.$$

We further assume that $h(u) \to +\infty$ as $\|u\|_{0,\Omega_U} \to \infty$, the functional $g(\cdot)$ is bounded below, and

$$|(g'(v) - g'(w), q)| \leq C\|v - w\|_{1,\Omega}\|q\|_{1,\Omega} \qquad \forall v, w, q \in Y. \tag{2.1}$$

To consider the finite element approximation of the above optimal control problem, here we give it a weak formula

$$\text{(CCP)} \begin{cases} \min\limits_{u\in K}\{g(y) + h(u)\}, \\ \\ a(y, w) = (f + Bu, w) \quad \forall w \in Y = H_0^1(\Omega), \end{cases} \tag{2.2}$$

where

$$a(v, w) = \int_\Omega (A\nabla v)\cdot\nabla w \quad \forall v, w \in H^1(\Omega),$$
$$(f, w) = \int_\Omega fw \quad \forall f, w \in L^2(\Omega).$$

Under these assumptions, the control problem (CCP) has a unique solution (y, u), and a pair (y, u) is the solution of (CCP) if and only if there is a costate $p \in Y$ such

that the triplet (y, p, u) satisfies the following optimality conditions (see [27]):

$$\text{(CCP-OPT)}\begin{cases} a(y,w) = (f + Bu, w) \quad \forall w \in Y = H_0^1(\Omega), \\ a(q,p) = (g'(y), p) \quad \forall q \in Y = H_0^1(\Omega), \\ (h'(u) + B^*p, v - u)_U \geq 0 \quad \forall v \in K \subset U = L^2(\Omega_U), \end{cases} \tag{2.3}$$

where B^* is the adjoint operator of B and g' and h' are the derivatives of g and h. Here g' and h' have been viewed as functions in $H = L^2(\Omega)$ and $U = L^2(\Omega_U)$, respectively, using the well-known representation theorem in a Hilbert space.

Let us consider the finite element approximation of the above control problem. For ease of exposition, we consider only n-simplex, conforming Lagrange elements. Also, we assume that Ω and Ω_U are polygonal. Let T^h be a partitioning of Ω into disjoint open regular n-simplices τ so that $\bar{\Omega} = \cup_{\tau \in T^h} \bar{\tau}$. Each element has at most one face on $\partial\Omega$, and the adjoining elements $\bar{\tau}$ and $\bar{\tau}'$ have either only one common vertex or a whole edge or a whole face if τ and $\tau' \in T^h$. Let h_τ denote the diameter of the element τ in T^h. Associated with T^h is a finite dimensional subspace S^h of $C^0(\bar{\Omega})$ such that $v_h|_\tau$ are polynomials of k-order ($k \geq 1$) for all $v_h \in S^h$ and $\tau \in T^h$. Denote $\{P_i\}$ $(i = 1, 2, \ldots, J)$ the vertex set associated with T^h. Let $Y^h = V_0^h := S^h \cap Y$.

Similarly, we have a regular partitioning of Ω_U, and we use the following corresponding notation: T_U^h, τ_U, h_{τ_U} and P_i^U $(i = 1, 2, \ldots, J_U)$. Associated with T_U^h is another finite dimensional subspace W_U^h of $L^2(\Omega_U)$ such that $v_h|_{\tau_U}$ are polynomials of k-order ($k \geq 0$) for all $v_h \in W_U^h$ and $\tau_U \in T_U^h$. Note here that there is no requirement for the continuity or boundary conditions. Let $U^h = W_U^h \subset U = L^2(\Omega_U)$.

Due to the limited regularity of the optimal control u (at most in $H^1(\Omega_U)$ in general), here we will consider only the piecewise constant space for the control approximation, while higher-order finite spaces may be used for the state and costate.

Then a possible finite element approximation of (CCP) is as follows:

$$(\text{CCP})^h \begin{cases} \min\limits_{u_h \in K^h} \{g(y_h) + h(u_h)\}, \\ a(y_h, w_h) = (f + Bu_h, w_h) \quad \forall w_h \in Y^h, \end{cases} \tag{2.4}$$

where K^h is a closed convex set in U^h such that there are $v_h \in K^h$ converging to an element $v \in K$ in U. It follows that the control problem $(\text{CCP})^h$ has a unique solution (y_h, u_h) and that a pair $(y_h, u_h) \in Y^h \times U^h$ is the solution of $(\text{CCP})^h$ if and only if there is a costate $p_h \in Y^h$ such that the triplet (y_h, p_h, u_h) satisfies the following optimality conditions:

$$(\text{CCP-OPT})^h \begin{cases} a(y_h, w_h) = (f + Bu_h, w_h) \quad \forall w_h \in Y^h \subset Y = H_0^1(\Omega), \\ a(q_h, p_h) = (g'(y_h), q_h) \quad \forall q_h \in Y^h \subset Y = H_0^1(\Omega), \\ (h'(u_h) + B^*p_h, v_h - u_h)_U \geq 0 \quad \forall v_h \in K^h \subset U = L^2(\Omega_U). \end{cases} \tag{2.5}$$

It follows that (y_h, p_h, u_h) is uniformly bounded in $Y \times Y \times U$. This is because $g(y_h) + h(u_h)$ is uniformly bounded due to the above assumption on K^h. Thus $\|u_h\|_U$ is also uniformly bounded. Then it follows from (2.5) and (2.1) that $\|y_h\|_Y$ and $\|p_h\|_Y$ are uniformly bounded.

The finite element approximation solution must be solved by using some mathematical programming algorithms such as the conjugate gradient method, the interior point method, and the SQP algorithms. This is a very active research area and is too large to be reviewed here even very briefly. Some of the recent progress in this area has been summarized in [14].

3. Sharp a posteriori error estimators. Deriving a posteriori error estimators for the finite element approximation of the control problem (CCP) is not an easy task since the triplet (y, p, u) is the solution of the coupled system (CCP-OPT). Although there is much work on a priori error estimates for finite element approximation of optimal control problems, as seen in section 1, there are substantial differences between a priori error estimates and a posteriori error estimates for such control problems. Only very recently, some a posteriori error estimators have been derived in the literature. For the control problem (CCP), for instance, the following error estimators have been derived in [31] and [35], assuming that $(h'(u_h) + B^*p_h)|_{\tau_U} \in H^1(\tau_U)$ for any $\tau_U \in T_U^h$:

$$\|u_h - u\|_{0,\Omega_U}^2 + \|y_h - y\|_{1,\Omega}^2 + \|p_h - p\|_{1,\Omega}^2 \le C\left(\bar{\eta}_1^2 + \sum_{i=2}^{5} \eta_i^2\right) = C\bar{\eta}^2, \tag{3.1}$$

where

$$\begin{aligned}
\bar{\eta}_1^2 &= \sum_{\tau_U \in T_U^h} h_{\tau_U}^2 \|\nabla(h'(u_h) + B^*p_h)\|_{0,\tau_U}^2, \\
\eta_2^2 &= \sum_{\tau \in T^h} h_\tau^2 \int_\tau (f + Bu_h + \operatorname{div}(A\nabla y_h))^2, \\
\eta_3^2 &= \sum_{l \in \partial T^h} h_l \int_l [(A\nabla y_h) \cdot \mathbf{n}]^2, \\
\eta_4^2 &= \sum_{\tau \in T^h} h_\tau^2 \int_\tau (g'(y_h) + \operatorname{div}(A^*\nabla p_h))^2, \\
\eta_5^2 &= \sum_{l \in \partial T^h} h_l \int_l [(A^*\nabla p_h) \cdot \mathbf{n}]^2,
\end{aligned} \tag{3.2}$$

where h_l is the diameter of the face l, and the A-normal derivative jump over the interior face l is defined by

$$[(A\nabla v_h) \cdot \mathbf{n}]|_l = ((A\nabla v_h)|_{\partial\tau_l^1} - (A\nabla v_h)|_{\partial\tau_l^2}) \cdot \mathbf{n},$$

with $\mathbf{n}$ being the unit outer normal vector of τ_l^1 on $l = \bar{\tau}_l^1 \cap \bar{\tau}_l^1$. The A^*-normal derivative jump is similarly defined for the transposed matrix A^* of A.

However, major improvements on these error estimators are much needed in order that they can be used to guide mesh adaptivity efficiently in solving the optimal control problem numerically. For example, it does not seem that they are *always* sharp for the constrained cases, and this can be seen from Figures 4.4 and 4.6 in Example 4.1 of section 4, where it is clear that $|u - u_h|$ has a very different profile (the left of Figure 4.4) from that of $\bar{\eta}_1$ (or $\bar{\eta}$) (the left of Figure 4.6). Consequently, the mesh refinement adjustment schemes based on $\bar{\eta}$ may be inefficient. In Example 4.1, the state and costate are very smooth, but the optimal control u has the gradient

jumps across the free boundary, which is the boundary of the zero set $\{x : u(x) = 0\}$, as seen in Figure 4.1. This causes large control approximation errors along the free boundary, as seen from the left of Figures 4.3 and 4.4. Thus an efficient computational mesh for the control should have a higher density of nodes around the free boundary, as those in Figure 4.2. However, the mesh adjustment guided by $\bar{\eta}_1$ did not achieve this goal well, as seen from Figure 4.5. In fact, the resulting mesh even produced a larger approximation error for the control than the uniform mesh of the same size. A sharp error estimator will lead to much more efficient computational meshes, as seen in Figure 4.2.

In this section, we study sharp error estimates for finite element approximation of the convex control problem (CCP). It follows that $\bar{\eta}$ consists of three parts: The part $\bar{\eta}_1$ is contributed from the approximation error of the variational inequality, and $\eta_2^2+\eta_3^2$, $\eta_4^2+\eta_5^2$ result from the approximation error of the state and costate equations. It is well known that $\eta_2^2+\eta_3^2$ and $\eta_4^2+\eta_5^2$ are sharp error estimators for the state and costate equations. Therefore, the key to our purpose is to improve $\bar{\eta}_1^2$. However, it is difficult to derive improved estimates without knowing explicit structures of the control constraint sets K and K^h; the methods and techniques to be developed will depend heavily on these details. Here we derive a posteriori error estimators with both upper bounds and lower bounds for a class of convex sets K of obstacle type, which are most frequently met in real applications. We achieved this by exploring the special structure of the constraint sets. The ideas are applicable to some other control problems, e.g., the boundary control problems.

We shall first consider the constraint of a single obstacle

$$K = \{v \in U : v \geq \phi\}, \qquad K^h = U^h \cap K,$$

and then we will extend the results to more general cases.

We define the coincidence set (contact set) Ω_U^- and the noncoincidence set (noncontact set) Ω_U^+ as follows:

$$\Omega_U^- = \{x \in \Omega_U : u(x) = \phi(x)\}, \quad \Omega_U^+ = \{x \in \Omega_U : u(x) > \phi(x)\}.$$

It can be seen that the inequality in (2.3) is equivalent to the following:

$$h'(u) + B^*p \geq 0, \quad u \geq \phi, \quad (h'(u) + B^*p)(u - \phi) = 0, \quad \text{a.e. in } \Omega_U. \tag{3.3}$$

We shall show that the quantity $(h'(u_h) + B^*p_h)|_{\Omega_U^-}$ can be mostly removed from the error indicator $\bar{\eta}$ in this case, which enables us to obtain sharp error estimates. To make the presentation of our approach clearer and less technical, we shall first derive sharp error estimators containing an a priori quantity and then approximate it using an a posteriori quantity so that the estimators can be easily applied in numerical computations. Let us note that some approximations of a priori quantities are also used in [9].

In the following, we assume that there is a constant $c > 0$ such that

$$(h'(v) - h'(w), v - w)_U \geq c\|v - w\|_{0,\Omega_U}^2 \qquad \forall v, w \in U. \tag{3.4}$$

3.1. Upper error bounds. We first consider the case of a constant obstacle $\phi(x) \equiv \phi_0$. We define

$$\Omega_h^+ = \{\cup\bar{\tau}_U \ : \ \tau_U \subset \Omega_U^+, \ \tau_U \in T_U^h\}, \qquad \Omega_h^- = \{\cup\bar{\tau}_U \ : \ \tau_U \subset \Omega_U^-, \ \tau_U \in T_U^h\},$$
$$\Omega_h^b = \Omega_U \backslash (\Omega_h^+ \cup \Omega_h^-), \qquad \Omega_h^{+b} = \Omega_h^+ \cup \Omega_h^b, \qquad \Omega_h^{-b} = \Omega_h^- \cup \Omega_h^b,$$

and denote by χ_Q the characteristic function of Q. Let ∂T^h be the set consisting of all of the faces l of any $\tau \in T^h$ such that l is not on $\partial\Omega$. Let h_l be the diameter of the face l. We need the following lemmas in deriving residual-type a posteriori error estimates.

LEMMA 3.1 (see [10]). *Let $\pi_h : C^0(\bar{\Omega}) \to S^h$ be the standard Lagrange interpolation operator such that*

$$\pi_h v := \sum_i v(\mathbf{a}_i)\varphi_i,$$

where $\mathbf{a}_i$ are the nodes on $\bar{\Omega}$ and φ_i are the corresponding shape functions. Then, for $m = 0, 1$ and $n/2 < q \le \infty$,

$$\|v - \pi_h v\|_{m,q,\tau} \le C h_\tau^{2-m} |v|_{2,q,\tau} \quad \forall v \in W^{2,q}(\Omega), \tag{3.5}$$

where the constant C depends only on Ω and the minimum angle of the simplices in T^h.

LEMMA 3.2 (see [21]). *For all $v \in W^{1,q}(\Omega), 1 \le q \le \infty$,*

$$\|v\|_{0,q,\partial\tau} \le C(h_\tau^{-1/q}\|v\|_{0,q,\tau} + h_\tau^{1-1/q}|v|_{1,q,\tau}). \tag{3.6}$$

We need another operator $\hat{\pi}_h$: the local averaging interpolation operator defined in [42], which can be applied to functions not necessarily continuous, preserves the homogeneous boundary conditions and is stable in the $W^{1,q}$-norm. The full definition of $\hat{\pi}_h$ is rather long. Thus the readers are referred to [42]. Fortunately, we need only to use one of its properties, which is stated in the following lemma.

LEMMA 3.3. *Let $\hat{\pi}_h : W^{1,q}(\Omega) \to S^h$ be the local averaging interpolation operator defined in* (2.13) *of* [42]. *For $m = 0, 1$ and $1 \le q \le \infty$,*

$$|v - \hat{\pi}_h v|_{m,q,\tau} \le C \sum_{\bar{\tau}' \cap \bar{\tau} \ne \emptyset} h_\tau^{1-m} |v|_{1,q,\tau'} \qquad \forall v \in W^{1,q}(\Omega). \tag{3.7}$$

LEMMA 3.4. *Let $\pi_h^a : L^1(\Omega_U) \to W_U^h$ be the integral averaging operator such that*

$$(\pi_h^a v)|_{\tau_U} := \frac{1}{|\tau_U|} \int_{\tau_U} v \qquad \forall \tau_U \in T_U^h.$$

Then, for $m = 0, 1$ and $1 \le q \le \infty$,

$$\|v - \pi_h^a v\|_{0,q,\tau_U} \le C h_{\tau_U}^m |v|_{m,q,\tau_U} \qquad \forall v \in W^{m,q}(\Omega_U). \tag{3.8}$$

Proof. The result is trivial for $m = 0$. For $m = 1$, we note that $\pi_h^a v|_{\tau_U} = v|_{\tau_U}$ if v is a constant on τ_U. Thus (3.8) can be proved by the standard techniques in the finite element method [10]. ∎

We first give some upper bounds for $u - u_h$ in the L^2-norm and for $y - y_h$, $p - p_h$ in the H^1-norm. We shall use the following inequality:

$$|(Bv, w)| = |(v, B^* w)_U| \le C\|v\|_{0,\Omega_U}\|w\|_{1,\Omega} \qquad \forall v \in U, w \in Y, \tag{3.9}$$

which is held from our assumptions on the operator B.

THEOREM 3.1. *Let (y, p, u) and (y_h, p_h, u_h) be the solutions of* (2.3) *and* (2.5), *respectively. Let the obstacle ϕ be a constant ϕ_0. Assume that conditions* (3.4), (2.1), *and* (3.9) *hold, and $(h'(u_h) + B^* p_h)|_{\tau_U} \in H^1(\tau_U)$ for any $\tau_U \in T_U^h$. Then*

$$\|u_h - u\|_{0,\Omega_U}^2 + \|y_h - y\|_{1,\Omega}^2 + \|p_h - p\|_{1,\Omega}^2 \le C \sum_{i=1}^5 \eta_i^2, \tag{3.10}$$

where

$$\eta_1^2 = \sum_{\tau_U \in T_U^h} h_{\tau_U}^2 \|\nabla(h'(u_h) + B^* p_h)\chi_{\Omega_h^{+b}}\|_{0,\tau_U}^2, \tag{3.11}$$

$$\eta_2^2 = \sum_{\tau \in T^h} h_\tau^2 \int_\tau (f + Bu_h + \operatorname{div}(A\nabla y_h))^2,$$

$$\eta_3^2 = \sum_{l \in \partial T^h} h_l \int_l [(A\nabla y_h)\cdot \mathbf{n}]^2,$$

$$\eta_4^2 = \sum_{\tau \in T^h} h_\tau^2 \int_\tau (g'(y_h) + \operatorname{div}(A^*\nabla p_h))^2,$$

$$\eta_5^2 = \sum_{l \in \partial T^h} h_l \int_l [(A^*\nabla p_h)\cdot \mathbf{n}]^2.$$

Proof. We first estimate the error $\|u - u_h\|_{0,\Omega_U}^2$. It follows from the assumption (3.4) and the inequalities (2.3) and (2.5) that, for any $v_h \in K^h$,

$$\begin{aligned} & c\|u - u_h\|_{0,\Omega_U}^2 \\ &\le (h'(u), u - u_h)_U - (h'(u_h), u - u_h)_U \\ &\le (-B^* p, u - u_h)_U - (h'(u_h), u - u_h)_U + (h'(u_h) + B^* p_h, v_h - u_h)_U \\ &= (h'(u_h) + B^* p_h, v_h - u)_U + (B^*(p_h - p), u - u_h)_U. \end{aligned} \tag{3.12}$$

We introduce y_{u_h} and p_{u_h}, defined by

$$a(y_{u_h}, w) = (f + Bu_h, w) \qquad \forall w \in Y, \tag{3.13}$$

$$a(q, p_{u_h}) = (g'(y_{u_h}), q) \qquad \forall q \in Y. \tag{3.14}$$

It follows from (2.3), (3.13), and (3.14) that

$$a(y_{u_h} - y, w) = (B(u_h - u), w) \qquad \forall w \in Y, \tag{3.15}$$

$$a(q, p_{u_h} - p) = (g'(y_{u_h}) - g'(y), q) \qquad \forall q \in Y. \tag{3.16}$$

Taking $w = p_{u_h} - p$ in (3.15) and $q = y_{u_h} - y$ in (3.16), we have, due to the convexity of g,

$$(B(u_h - u), p_{u_h} - p) = (g'(y_{u_h}) - g'(y), y_{u_h} - y) \ge 0.$$

Using (3.12) together with (3.9) gives

$$\begin{aligned} & c\|u - u_h\|_{0,\Omega_U}^2 \\ &\le (h'(u_h) + B^* p_h, v_h - u)_U + (B^*(p_h - p_{u_h}), u - u_h)_U - (p_{u_h} - p, B(u_h - u)) \\ &\le \sum_{\tau_U \in T_U^h} (h'(u_h) + B^* p_h, v_h - u)_{\tau_U} + C\|p_h - p_{u_h}\|_{1,\Omega}^2 + \frac{c}{2}\|u - u_h\|_{0,\Omega_U}^2. \end{aligned}$$

Now take $v_h = \pi_h^a u \in K^h$ defined in Lemma 3.4. Then we have

$$\begin{aligned} (h'(u_h) + B^* p_h, v_h - u)_{\tau_U} &= ((I - \pi_h^a)(h'(u_h) + B^* p_h), (\pi_h^a - I)(u - u_h))_{\tau_U} \\ &\le Ch_{\tau_U}\|\nabla(h'(u_h) + B^* p_h)\|_{0,\tau_U}\|u - u_h\|_{0,\tau_U} \\ &\le Ch_{\tau_U}^2\|\nabla(h'(u_h) + B^* p_h)\|_{0,\tau_U}^2 + \frac{c}{4}\|u - u_h\|_{0,\tau_U}^2. \end{aligned}$$

Noting that $(v_h - u)|_{\tau_U} = (\pi_h^a - I)u|_{\tau_U} = 0$ for any $\tau_U \in \Omega_U \backslash \Omega_h^{+b}$, we obtain

(3.17)
$$\begin{aligned} \|u - u_h\|_{0,\Omega_U}^2 &\leq C \sum_{\tau_U \in \Omega_h^{+b}} h_{\tau_U}^2 \|\nabla(h'(u_h) + B^* p_h)\|_{0,\tau_U}^2 + C\|p_h - p_{u_h}\|_{1,\Omega_U}^2 \\ &= C\eta_1^2 + C\|p_h - p_{u_h}\|_{1,\Omega_U}^2. \end{aligned}$$

The second step is to estimate the error $\|p_{u_h} - p_h\|_{1,\Omega}$. Let $e_p = p_{u_h} - p_h$. Then it follows from $(2.4)_2$, (3.14), and (2.1) that

$$\begin{aligned} & c\|p_{u_h} - p_h\|_{1,\Omega}^2 \leq a(e_p, p_{u_h}) - a(e_p, p_h) \\ = \; & (g'(y_{u_h}), e_p) - a(e_p - \hat{\pi}_h e_p, p_h) - (g'(y_h), \hat{\pi}_h e_p) \\ = \; & \sum_{\tau \in T^h} \int_\tau (g'(y_h) + \operatorname{div}(A^* \nabla p_h))(e_p - \hat{\pi}_h e_p) \\ & - \sum_{l \in \partial T^h} \int_l [(A^* \nabla p_h) \cdot \mathbf{n}](e_p - \hat{\pi}_h e_p) + (g'(y_{u_h}) - g'(y_h), e_p) \\ \leq \; & C \sum_{\tau \in T^h} h_\tau^2 \int_\tau (g'(y_h) + \operatorname{div}(A^* \nabla p_h))^2 + C \sum_{l \in \partial T^h} h_l \int_l [(A^* \nabla p_h) \cdot \mathbf{n}]^2 \\ & + C\|y_{u_h} - y_h\|_{1,\Omega}^2 + \frac{c}{2}\|e_p\|_{1,\Omega}^2, \end{aligned}$$

where we have used Lemma 3.3 to obtain

$$\|e_p - \hat{\pi}_h e_p\|_{0,\tau} \leq C h_\tau \left(\sum_{\bar{\tau}' \cap \bar{\tau} \neq \emptyset} |e_p|_{1,\tau'}^2 \right)^{1/2} \tag{3.18}$$

and Lemmas 3.2 and 3.3 to have, assuming $l \subset \bar{\tau}$,

$$\begin{aligned} \|e_p - \hat{\pi}_h e_p\|_{0,l} &\leq C(h_\tau^{-1/2}\|e_p - \hat{\pi}_h e_p\|_{0,\tau} + h_\tau^{1/2}|e_p - \hat{\pi}_h e_p|_{1,\tau}) \\ &\leq C h_\tau^{1/2} \left(\sum_{\bar{\tau}' \cap \bar{\tau} \neq \emptyset} |e_p|_{1,\tau'}^2 \right)^{1/2}. \end{aligned} \tag{3.19}$$

Thus we have

$$\|p_{u_h} - p_h\|_{1,\Omega}^2 \leq C(\hat{\eta}_4^2 + \hat{\eta}_5^2) + C\|y_{u_h} - y_h\|_{1,\Omega}^2. \tag{3.20}$$

The third step is thus to estimate the error $\|y_{u_h} - y_h\|_{1,\Omega}$. Let $e_y = y_{u_h} - y_h$, and let $\hat{\pi}_h$ be the interpolator in Lemma 3.3. It can be seen that $a(e_y, \hat{\pi}_h e_y) = 0$ due to the Galerkin orthogonality $a(e_y, w_h) = 0 \; \forall w_h \in Y^h$ from $(2.5)_1$ and (3.13). Then it follows from (2.5), (3.13), (3.6), and (3.7) that

$$
\begin{aligned}
c\|y_{u_h}-y_h\|_{1,\Omega}^2 &\le a(e_y,e_y)=a(e_y,e_y-\hat{\pi}_h e_y)\\
&=\sum_{\tau\in T^h}\int_\tau (f+Bu_h+\operatorname{div}(A\nabla y_h))(e_y-\hat{\pi}_h e_y)\\
&\qquad -\sum_{l\in\partial T^h}\int_l [(A\nabla y_h)\cdot\mathbf{n}](e_y-\hat{\pi}_h e_y)\\
&\le C\sum_{\tau\in T^h} h_\tau^2\int_\tau (f+Bu_h+\operatorname{div}(A\nabla y_h))^2\\
&\qquad +C\sum_{l\in\partial T^h} h_l\int_l [(A\nabla y_h)\cdot\mathbf{n}]^2+\frac{c}{2}\|e_y\|_{1,\Omega}^2,
\end{aligned}
$$

where we have bounded $\|e_y-\hat{\pi}_h e_y\|_{0,\tau}$ and $\|e_y-\hat{\pi}_h e_y\|_{0,l}$ as in (3.18) and (3.19). Thus we have

$$
\|y_{u_h}-y_h\|_{1,\Omega}^2\le C(\hat{\eta}_2^2+\hat{\eta}_3^2). \tag{3.21}
$$

Finally, by noting that, from (3.15), (3.16), (3.9), and (2.1), we have

$$
\|y_{u_h}-y\|_{1,\Omega}\le C\|u_h-u\|_{0,\Omega_U}, \tag{3.22}
$$

$$
\|p_{u_h}-p\|_{1,\Omega}\le C\|y_{u_h}-y\|_{1,\Omega}\le C\|u_h-u\|_{0,\Omega_U}, \tag{3.23}
$$

we combine (3.17), (3.20), and (3.21) to obtain

$$
\begin{aligned}
&\|u-u_h\|_{0,\Omega_U}^2+\|y-y_h\|_{1,\Omega}^2+\|p-p_h\|_{1,\Omega}^2\\
\le\ &\|u-u_h\|_{0,\Omega_U}^2+2\left(\|y-y_{u_h}\|_{1,\Omega}^2+\|p-p_{u_h}\|_{1,\Omega}^2\right)\\
&+2\left(\|y_{u_h}-y_h\|_{1,\Omega}^2+\|p_{u_h}-p_h\|_{1,\Omega}^2\right)\\
\le\ &C\|u-u_h\|_{0,\Omega_U}^2+2\left(\|y_{u_h}-y_h\|_{1,\Omega}^2+\|p_{u_h}-p_h\|_{1,\Omega}^2\right)\le\ C\sum_{i=1}^5\eta_i^2.
\end{aligned}
$$

Therefore, the proof is completed. ∎

In many applications, we are mostly interested in computing the values of the state and the control. In such cases, it is more useful to bound the errors in the L^2-norm to derive sharper estimators, which are given in the following theorem. We shall use the following condition:

$$
|(Bv,w)|=|(v,B^*w)_U|\le C\|v\|_{0,\Omega_U}\|w\|_{0,\Omega}\qquad\forall v\in U, w\in Y, \tag{3.24}
$$

which is held from our assumptions. We shall assume the following condition:

$$
|(g'(v)-g'(w),q)|\le C\|v-w\|_{0,\Omega}\|q\|_{2,\Omega}\qquad\forall v,w\in Y,\ q\in H^2(\Omega). \tag{3.25}
$$

THEOREM 3.2. *Assume that all of the conditions of Theorem* 3.1 *and* (3.25) *are satisfied except that* (3.9) *is replaced with* (3.24). *Assume that* Ω *is convex. Then*

$$
\|u-u_h\|_{0,\Omega_U}^2+\|y-y_h\|_{0,\Omega}^2+\|p-p_h\|_{0,\Omega}^2\le C\left(\eta_1^2+\sum_{i=2}^5\hat{\eta}_i^2\right),
$$

where η_1^2 *is defined in Theorem* 3.1 *and*

$$\hat{\eta}_2^2 = \sum_{\tau\in T^h} h_\tau^4 \int_\tau (f + Bu_h + \operatorname{div}(A\nabla y_h))^2,$$

$$\hat{\eta}_3^2 = \sum_{l\in\partial T^h} h_l^3 \int_l [(A\nabla y_h)\cdot \mathbf{n}]^2,$$

$$\hat{\eta}_4^2 = \sum_{\tau\in T^h} h_\tau^4 \int_\tau (g'(y_h) + \operatorname{div}(A^*\nabla p_h))^2,$$

$$\hat{\eta}_5^2 = \sum_{l\in\partial T^h} h_l^3 \int_l [(A^*\nabla p_h)\cdot \mathbf{n}]^2.$$

Proof. Again, we first estimate the error $\|u-u_h\|^2_{0,\Omega_U}$. By the same argument as in the proof of Theorem 3.1 but using (3.24), we have

$$\|u-u_h\|^2_{0,\Omega_U} \le C\eta_1^2 + C\|p_h - p_{u_h}\|^2_{0,\Omega}. \tag{3.26}$$

To estimate $\|p_h - p_{u_h}\|^2_{0,\Omega}$, we use the dual technique. Consider the following auxiliary problems: Find $\xi \in H_0^1(\Omega)$ and $\zeta \in H_0^1(\Omega)$ such that

$$a(w,\xi) = (f_1, w) \quad \forall w \in Y, \tag{3.27}$$

$$a(\zeta, q) = (f_2, q) \quad \forall q \in Y. \tag{3.28}$$

It follows from the well-known regularity results that

$$\|\xi\|_{2,\Omega} \le C\|f_1\|_{0,\Omega}, \quad \|\zeta\|_{2,\Omega} \le C\|f_2\|_{0,\Omega}.$$

Let $f_2 = p_{u_h} - p_h$ in (3.28) and denote by $\pi_h : C^0(\bar{\Omega}) \to Y^h$ the standard Lagrange interpolation operator. It follows from $(2.5)_2$ and (3.14) that

$$\begin{aligned}
\|p_{u_h} - p_h\|^2_{0,\Omega} &= (f_2, p_h(u_h) - p_h) = a(\zeta, p_{u_h}) - a(\zeta, p_h)\\
&= (g'(y_{u_h}), \zeta) - a(\zeta - \pi_h\zeta, p_h) - (g'(y_h), \pi_h\zeta)\\
&= \sum_{\tau\in T^h}\int_\tau \operatorname{div}(A^*\nabla p_h)(\zeta - \pi_h\zeta) - \sum_{l\in\partial T^h}\int_l [(A^*\nabla p_h)\cdot\mathbf{n}](\zeta - \pi_h\zeta)\\
&\qquad + (g'(y_{u_h}), \zeta) - (g'(y_h), \pi_h\zeta)\\
&= \sum_{\tau\in T^h}\int_\tau (g'(y_h) + \operatorname{div}(A^*\nabla p_h))(\zeta - \pi_h\zeta)\\
&\quad - \sum_{l\in\partial T^h}\int_l [(A^*\nabla p_h)\cdot\mathbf{n}](\zeta - \pi_h\zeta) + (g'(y_{u_h}) - g'(y_h), \zeta).
\end{aligned}$$

By using Lemmas 3.1 and 3.2,

$$\|\zeta - \pi_h\zeta\|_{0,\tau} \le Ch_\tau^2|\zeta|_{2,\tau}, \tag{3.29}$$

$$\|\zeta - \pi_h\zeta\|_{0,l} \le C(h_\tau^{-1/2}\|\zeta - \pi_h\zeta\|_{0,\tau} + h_\tau^{1/2}|\zeta - \pi_h\zeta|_{1,\tau}) \le Ch_\tau^{3/2}|\zeta|_{2,\tau}, \tag{3.30}$$

where $l \subset \bar{\tau}$. Then it follows from (3.25) that

$$\begin{aligned}\|p_{u_h} - p_h\|_{0,\Omega}^2 &\le C \sum_{\tau\in T^h} h_\tau^2 \|g'(y_h) + \operatorname{div}(A^*\nabla p_h)\|_{0,\tau}\|\zeta\|_{2,\tau} \\ &\quad + C \sum_{l\in\partial T^h} h_l^{3/2} \left(\int_l [(A^*\nabla p_n)\cdot \mathbf{n}]^2\right)^{1/2} \|\zeta\|_{2,\tau} + C\|y_{u_h} - y_h\|_{0,\Omega}\|\zeta\|_{2,\Omega} \\ &\le C \sum_{\tau\in T^h} h_\tau^4 \int_\tau (g'(y_h) + \operatorname{div}(A^*\nabla p_h))^2 + C \sum_{l\in\partial T^h} h_l^3 \int_l [(A^*\nabla p_n)\cdot \mathbf{n}]^2 \\ &\quad + C\|y_{u_h} - y_h\|_{0,\Omega}^2 + \frac{1}{2}\|f_2\|_{0,\Omega}^2.\end{aligned}$$

Therefore, we have

$$\|p_{u_h} - p_h\|_{0,\Omega}^2 \le C(\hat{\eta}_4^2 + \hat{\eta}_5^2) + C\|y_{u_h} - y_h\|_{0,\Omega}^2. \tag{3.31}$$

The second step is again to estimate $\|y_{u_h} - y_h\|_{0,\Omega}^2$. Similarly, letting $f_1 = y_{u_h} - y_h$ in (3.27) gives

$$\begin{aligned}\|y_{u_h} - y_h\|_{0,\Omega}^2 = (f, y_{u_h} - y_h) &= a(y_{u_h} - y_h, \xi) = a(y_{u_h} - y_h, \xi - \pi_h\xi) \\ &= \sum_{\tau\in T^h} \int_\tau (f + Bu_h + \operatorname{div}(A\nabla y_h))(\xi - \pi_h\xi) \\ &\quad - \sum_{l\in\partial T^h} \int_l [(A\nabla y_h)\cdot \mathbf{n}](\xi - \pi_h\xi) \\ &\le C \sum_{\tau\in T^h} h_\tau^2 \int_\tau \|f + Bu_h + \operatorname{div}(A\nabla y_h)\|_{0,\tau}\|\xi\|_{2,\tau} \\ &\quad + C \sum_{l\in\partial T^h} h_l^{3/2} \left(\int_l [(A\nabla y_h)\cdot \mathbf{n}]^2\right)^{1/2} \|\xi\|_{2,\tau} \\ &\le C \sum_{\tau\in T^h} h_\tau^4 \int_\tau (f + Bu_h + \operatorname{div}(A\nabla y_h))^2 \\ &\quad + C \sum_{l\in\partial T^h} h_l^3 \int_l [(A\nabla y_h)\cdot \mathbf{n}]^2 + \frac{1}{2}\|f_1\|_{0,\Omega}^2,\end{aligned}$$

where we have estimated $\|\xi - \pi_h\xi\|_{0,\tau}$ and $\|\xi - \pi_h\xi\|_{0,l}$ as in (3.29) and (3.30). The above result leads to

$$\|y_{u_h} - y_h\|_{0,\Omega}^2 \le C(\hat{\eta}_2^2 + \hat{\eta}_3^2). \tag{3.32}$$

Then it follows from (3.26), (3.31), and (3.32) that

$$\|u - u_h\|_{0,\Omega_U}^2 \le C\left(\eta_1^2 + \sum_{i=2}^5 \hat{\eta}_i^2\right). \tag{3.33}$$

Finally, we estimate $\|y_h - y\|_{0,\Omega}$ and $\|p_h - p\|_{0,\Omega}$. It follows from (3.15), (3.16), and (2.1) that

$$\begin{aligned}\|y_h - y\|_{0,\Omega} &\le \|y_h - y_{u_h}\|_{0,\Omega} + \|y_{u_h} - y\|_{0,\Omega} \\ &\le \|y_h - y_{u_h}\|_{0,\Omega} + C\|u_h - u\|_{0,\Omega_U}\end{aligned}$$

and

$$\begin{aligned}\|p_h - p\|_{0,\Omega} &\le \|p_h - p_{u_h}\|_{0,\Omega} + \|p_{u_h} - p\|_{0,\Omega}\\ &\le \|p_h - p_{u_h}\|_{0,\Omega} + C\|y_{u_h} - y\|_{1,\Omega}\\ &\le \|p_h - p_{u_h}\|_{0,\Omega} + C\|u_h - u\|_{0,\Omega_U}.\end{aligned}$$

The above results, together with (3.31)–(3.33), yield

$$\|y_h - y\|_{0,\Omega}^2 + \|p_h - p\|_{0,\Omega}^2 \le C\left(\eta_1^2 + \sum_{i=2}^{5}\hat{\eta}_i^2\right). \tag{3.34}$$

Hence the proof is completed by combining (3.33) and (3.34). ∎

3.2. Lower error bounds. In this subsection, we wish to demonstrate that the error estimates obtained above are quite sharp by establishing lower error bounds for the finite element approximation. We start with the following lemma about the bubble functions, the proof of which can be found in [1, 45].

LEMMA 3.5. *Let $\tau \in T^h$. Let τ_l^1, τ_l^2 be two elements in T^h with a common edge (face) $l = \bar{\tau}_l^1 \cap \bar{\tau}_l^2$. For any constants B_τ and D_l, there exist polynomials $w_\tau \in H_0^1(\tau)$ and $w_l \in H_0^1(\tau_l^1 \cup \tau_l^2)$ such that, for $m = 0, 1$,*

$$\int_\tau B_\tau w_\tau = h_\tau^2 \int_\tau B_\tau^2, \qquad |w_\tau|_{m,\tau}^2 \le C h_\tau^{2(1-m)+2} \int_\tau B_\tau^2,$$

$$\int_l D_l w_l = h_l \int_l D_l^2, \qquad |w_l|_{m,\tau_l^1\cup\tau_l^2}^2 \le C h_l^{2(1-m)+1} \int_l D_l^2.$$

For ease of exposition, we assume that A is a constant matrix and Y^h is the piecewise linear finite element space. We also assume that there exists an integer $k \ge 0$ independent of h such that, for any $\tau_U \in T_U^h$, $(h'(u_h) + B^* p_h)|_{\tau_U}$ is a polynomial of k-order on τ_U. This assumption is needed to apply the inverse property in our proof below, and it may impose an implicit relationship between the meshes for the state and the control. We further assume that

$$\|h'(v) - h'(w)\|_{0,\Omega_U} \le C\|v - w\|_{0,\Omega_U} \qquad \forall v, w \in Y. \tag{3.35}$$

THEOREM 3.3. *Let (y, p, u) and (y_h, p_h, u_h) be the solutions of (2.3) and (2.5), respectively. Assume that A is a constant matrix, Y^h is the piecewise linear finite element space, $f \in L^2(\Omega)$, $\phi \equiv \phi_0$, $(h'(u_h) + B^* p_h)|_{\tau_U}$ is a polynomial of k-order on τ_U for any $\tau_U \in T_U^h$ with $k \ge 0$ independent of h, and the conditions (2.1), (3.24), and (3.35) hold. Then there exists a constant C depending on the matrix A and those constants in (2.1), (3.24), (3.35), and Lemma 3.5 such that*

$$\begin{aligned}\sum_{i=1}^{5}\eta_i^2 \;\le\; & C(\|u - u_h\|_{0,\Omega_U}^2 + \|y - y_h\|_{1,\Omega}^2 + \|p - p_h\|_{1,\Omega}^2)\\ &+ C\sum_{\tau\in T^h} h_\tau^2(\|F - \bar{F}\|_{0,\tau}^2 + \|G - \bar{G}\|_{0,\tau}^2)\\ &+ C\sum_{\tau_U\in T_U^h} h_{\tau_U}^2 \|\nabla(h'(u_h) + B^* p_h)\chi_{\Omega_h^b}\|_{0,\tau_U}^2,\end{aligned}$$

where η_i $(1 \le i \le 5)$ *are defined in Theorem* 3.1, $F = f + Bu_h$, $G = g'(y_h)$, $\bar{F}|_\tau = \int_\tau F/|\tau|$, *and* $\bar{G}|_\tau = \int_\tau G/|\tau|$.

Proof. From the optimality conditions (2.3), we deduce that $(h'(u)+B^*p)|_{\Omega_U^+} = 0$. It follows from the inverse property [10], (3.35), and (3.24) that

$$\begin{aligned}
\eta_1^2 &= \sum_{\tau_U \in T_U^h} h_{\tau_U}^2 (\|\nabla(h'(u_h) + B^*p_h)\chi_{\Omega_h^+}\|_{0,\tau_U}^2 + \|\nabla(h'(u_h) + B^*p_h)\chi_{\Omega_h^b}\|_{0,\tau_U}^2) \\
&\le C\|h'(u_h) + B^*p_h - h'(u) - B^*p\|_{0,\Omega_h^+}^2 + C \sum_{\tau_U \in T_U^h} h_{\tau_U}^2 \|\nabla(h'(u_h) + B^*p_h)\chi_{\Omega_h^b}\|_{0,\tau_U}^2 \\
&\le C(\|u - u_h\|_{0,\Omega_U}^2 + \|p - p_h\|_{1,\Omega}^2) + C \sum_{\tau_U \in T_U^h} h_{\tau_U}^2 \|\nabla(h'(u_h) + B^*p_h)\chi_{\Omega_h^b}\|_{0,\tau_U}^2.
\end{aligned}$$

To bound η_2^2, let w_τ be the bubble function as in Lemma 3.5 with $B_\tau = \bar{F}|_\tau$. It follows from (2.5) and (3.13) that

$$\begin{aligned}
\eta_2^2 &= \sum_{\tau \in T^h} h_\tau^2 \int_\tau F^2 \le 2 \sum_{\tau \in T^h} h_\tau^2 \int_\tau \{\bar{F}^2 + (F - \bar{F})^2\} \\
&= 2 \sum_{\tau \in T^h} \int_\tau \{w_\tau F + w_\tau(\bar{F} - F) + h_\tau^2 (F - \bar{F})^2\} \\
&= 2 \sum_{\tau \in T^h} \int_\tau (A\nabla(y_{u_h} - y_h)) \cdot \nabla w_\tau + 2 \sum_{\tau \in T^h} \int_\tau \{w_\tau(\bar{F} - F) + h_\tau^2 (F - \bar{F})^2\} \\
&\le C \sum_{\tau \in T^h} |y_{u_h} - y_h|_{1,\tau}^2 + \delta \sum_{\tau \in T^h} (|w_\tau|_{1,\tau}^2 + h_\tau^{-2}\|w_\tau\|_{0,\tau}^2) + C \sum_{\tau \in T^h} h_\tau^2 \int_\tau (F - \bar{F})^2 \\
&\le C(|y_{u_h} - y|_{1,\Omega}^2 + |y - y_h|_{1,\Omega}^2) + C\delta\eta_2^2 + C \sum_{\tau \in T^h} h_\tau^2 \int_\tau (F - \bar{F})^2.
\end{aligned}$$

Then it follows from this inequality and (3.22) that

$$\eta_2^2 \le C(\|u - u_h\|_{0,\Omega_U}^2 + \|y - y_h\|_{1,\Omega}^2) + C \sum_{\tau \in T^h} h_\tau^2 \int_\tau (F - \bar{F})^2. \tag{3.36}$$

To estimate η_3, we define the bubble function w_l as in Lemma 3.5 with $D_l = [(A\nabla y_h) \cdot \mathbf{n}]|_l$. By (3.13),

$$\begin{aligned}
\eta_3^2 &= \sum_{l \in \partial T^h} h_l \int_l D_l^2 = \sum_{l \in \partial T^h} \int_l w_l [(A\nabla y_h) \cdot \mathbf{n}] = \sum_{l \in \partial T^h} \int_{\tau_l^1 \cup \tau_l^2} (A\nabla y_h) \cdot \nabla w_l \\
&= \sum_{l \in \partial T^h} \int_{\tau_l^1 \cup \tau_l^2} (A\nabla(y_h - y_{u_h})) \cdot \nabla w_l + \sum_{l \in \partial T^h} \int_{\tau_l^1 \cup \tau_l^2} (f + Bu_h) w_l \\
&\le C \sum_{\tau \in T^h} |y_{u_h} - y_h|_{1,\tau}^2 + \delta \sum_{l \in \partial T^h} (|w_l|_{1,\tau_l^1 \cap \tau_l^2}^2 + h_l^{-2}\|w_l\|_{0,\tau_l^1 \cap \tau_l^2}^2) + C\eta_2^2 \\
&\le C(|y_{u_h} - y|_{1,\Omega}^2 + |y - y_h|_{1,\Omega}^2) + C\delta\eta_3^2 + C\eta_2^2.
\end{aligned}$$

It follows from the above inequality, (3.22), and (3.36) that

$$\eta_3^2 \le C\left(\|u - u_h\|_{0,\Omega_U}^2 + \|y - y_h\|_{1,\Omega}^2\right) + C \sum_{\tau \in T^h} h_\tau^2 \int_\tau (F - \bar{F})^2.$$

For η_4, let w_τ be set as in Lemma 3.5 with $B_\tau = \bar{G}|_\tau$. It follows from (3.14), (2.1), (3.23), and (3.22) that

$$\begin{aligned}
\eta_4^2 &= \sum_{\tau\in T^h} h_\tau^2 \int_\tau G^2 \le 2\sum_{\tau\in T^h} h_\tau^2 \int_\tau \{\bar{G}^2 + (G-\bar{G})^2\} \\
&= 2\sum_{\tau\in T^h} \int_\tau \{w_\tau G + w_\tau(\bar{G}-G) + h_\tau^2 (G-\bar{G})^2\} \\
&= 2\sum_{\tau\in T^h} \int_\tau \{(A\nabla w_\tau)\cdot\nabla(p_{u_h}-p_h) + w_\tau(g'(y_h)-g'(y_{u_h})) \\
&\qquad\qquad + w_\tau(\bar{G}-G) + h_\tau^2(G-\bar{G})^2\} \\
&\le C|p_{u_h}-p_h|_{1,\Omega}^2 + \delta\sum_{\tau\in T^h}(|w_\tau|_{1,\tau}^2 + h_\tau^{-2}\|w_\tau\|_{0,\tau}^2) \\
&\qquad\qquad + C\|y_h - y_{u_h}\|_{1,\Omega}^2 + C\sum_{\tau\in T^h} h_\tau^2 \int_\tau (G-\bar{G})^2 \\
&\le C\left(\|u-u_h\|_{0,\Omega_U}^2 + \|p-p_h\|_{1,\Omega}^2 + \|y-y_h\|_{1,\Omega}^2\right) + C\delta\eta_4^2 + C\sum_{\tau\in T^h} h_\tau^2 \int_\tau (G-\bar{G})^2.
\end{aligned}$$

Thus

$$\eta_4^2 \le C\left(\|u-u_h\|_{0,\Omega_U}^2 + \|y-y_h\|_{1,\Omega}^2 + \|p-p_h\|_{1,\Omega}^2\right) + C\sum_{\tau\in T^h} h_\tau^2 (G-\bar{G})^2. \tag{3.37}$$

To estimate η_5, we set w_l as in Lemma 3.5 with $D_l = [(A^*\nabla p_h)\cdot\mathbf{n}]|_l$. It follows from (3.14), (2.1), (3.23), and (3.22) that

$$\begin{aligned}
\eta_5^2 &= \sum_{l\in\partial T^h} h_l \int_l D_l^2 = \sum_{l\in\partial T^h}\int_l w_l[(A^*\nabla p_h)\cdot\mathbf{n}] = \sum_{l\in\partial T^h}\int_{\tau_l^1\cup\tau_l^2} (A^*\nabla p_h)\cdot\nabla w_l \\
&= \sum_{l\in\partial T^h}\int_{\tau_l^1\cup\tau_l^2} (A\nabla w_l)\cdot\nabla(p_h - p_{u_h}) + \sum_{l\in\partial T^h}\int_{\tau_l^1\cup\tau_l^2} g'(y_{u_h})w_l \\
&\le C|p_h - p_{u_h}|_{1,\Omega}^2 + \delta\sum_{l\in\partial T^h}(|w_l|_{1,\tau_l^1\cap\tau_l^2}^2 + h_l^{-2}\|w_l\|_{0,\tau_l^1\cap\tau_l^2}^2) \\
&\quad + C\|y_{u_h} - y_h\|_{1,\Omega}^2 + C\eta_4^2 \\
&\le C(\|u-u_h\|_{0,\Omega_U}^2 + \|p-p_h\|_{1,\Omega}^2 + \|y-y_h\|_{1,\Omega}^2) + C\delta\eta_5^2 + C\eta_4^2.
\end{aligned}$$

This inequality, combined with (3.37), implies

$$\eta_5^2 \le C(\|u-u_h\|_{0,\Omega_U}^2 + \|y-y_h\|_{1,\Omega}^2 + \|p-p_h\|_{1,\Omega}^2) + C\sum_{\tau\in T^h} h_\tau^2 (G-\bar{G})^2.$$

Thus we proved the desirable result. □

We believe that the error estimator $\eta_1^2 + \sum_{i=2}^5 \hat{\eta}_i^2$ in Theorem 3.2 is also sharp, though we are unable to establish any lower error bound for it. As a matter of fact, to our best knowledge, there exist no lower a posteriori error bounds in the L^2-norm in the literature or for any control problem.

3.3. Sharp a posteriori error estimators. In the above section, we have shown the following error bounds:

(3.38)
$$c\left(\sum_{i=1}^{5}\eta_i^2 \quad - \sum_{\tau\in T^h} h_\tau^2 \int_\tau \{(F-\bar F)^2+(G-\bar G)^2\} - \sum_{\tau\in\Omega_h^b} h_\tau^2 \|\nabla(h'(u_h)+B^*p_h)\|_{0,\tau}^2\right)$$
$$\le \|u-u_h\|_{0,\Omega_U}^2 + \|y-y_h\|_{1,\Omega}^2 + \|p-p_h\|_{1,\Omega}^2 \le C\left(\sum_{i=1}^{5}\eta_i^2\right),$$

provided that the conditions of Theorems 3.1 and 3.3 hold. We note that, if the free boundary $\partial\Omega_U^+$ is regular, for instance, if the free boundary consists of a finite number of smooth surfaces or if the total area of the free boundary is finite, then meas (Ω_h^b) is of the order h as $h\to 0$. Thus the second and third terms of the left side are of higher order as $h\to 0$ if the data are regular. Take the following typical quadratic control as one example: let $\Omega=\Omega_U$; let U^h and Y^h be the piecewise constant and linear spaces, respectively; let $Bu=u$, $f\in H^1(\Omega)$, $h(u)=\int_\Omega u^2$, and $g(y)=\int_\Omega (y-y_0)^2$ with $y_0\in H^1(\Omega)$. Then one has

$$\int_\Omega (F-\bar F)^2+(G-\bar G)^2 \le Ch^2(|f|_{H^1}^2+|y_0|_{H^1}^2)+C\int_\Omega (Bu_h-\overline{Bu_h})^2,$$

$$\sum_{\tau\in\Omega_h^b}\|\nabla(h'(u_h)+B^*p_h)\|_{0,\tau}^2 \le C\left(\int_{\Omega_h^b}|\nabla B^*p|^2+\|p_h-p\|_{H^1(\Omega)}^2\right).$$

Thus it follows that the second and third terms of the left side of (3.38) are not needed in computations. It can be seen that the above observation still holds even if f, y_0 are only piecewise smooth. For more general objective functionals, one can proceed as in Remark 3.4. Therefore, (3.38) gives equivalent a posteriori error estimates in the global sense and thus shows that the estimator $\sum_{i=1}^5\eta_i^2$ is in general quite sharp.

An obvious problem is that the characteristic function $\chi_{\Omega_h^{+b}}$ is not a posteriori in the sense that we usually do not know the position of the free boundary. Nevertheless, one can substitute it with some a posteriori quantities, thus obtaining some a posteriori error indicators, which can then be used in the adaptive finite element method.

One possible idea is to approximate $\chi_{\Omega_h^{+b}}$ by the finite element solution, as suggested in [24] and [32]. The basic idea is to approximate the characteristic function with the a posteriori quantity $\chi_{\Omega_U^+}^h$. For $\alpha>0$, let

$$\chi_{\Omega_U^+}^h = \frac{u_h-\phi_0}{h^\alpha+u_h-\phi_0}.$$

Thus, in computing, we replace η_1^2 by

$$\widetilde{\eta}_1^2 = \sum_{\tau\in T_U^h} h_{\tau_U}^2 \|\nabla(h'(u_h)+B^*p_h)\chi_{\Omega_U^+}^h\|_{0,\tau_U}^2.$$

In the following, we investigate the possible errors caused by this replacement. To this end, we separate Ω_U into three parts:

$$\Omega_h^-, \quad \Omega_U^{\alpha/2} := \{x\in\Omega_U \ : \ u_h(x)<\phi_0+h^{\alpha/2},\ u(x)>\phi_0\}, \text{ and } \Omega_h^{+b}\backslash\Omega_U^{\alpha/2}.$$

Then, for $\tau \in \Omega_h^-$, we have

$$\|\chi^h_{\Omega_U^+} - \chi_{\Omega_h^{+b}}\|_{0,\infty,\tau} = \left\| \frac{u_h - u}{h^\alpha + u_h - u} \right\|_{0,\infty,\tau} \le \min\{1, h^{-\alpha}\|u_h - u\|_{0,\infty,\tau}\},$$

and, for $\tau \in \Omega_h^{+b} \backslash \Omega_U^{\alpha/2}$,

$$\|\chi^h_{\Omega_U^+} - \chi_{\Omega_h^{+b}}\|_{0,\infty,\tau} = \left\| \frac{h^\alpha}{h^\alpha + u_h - \phi_0} \right\|_{0,\infty,\tau} \le h^{\alpha/2}.$$

Therefore, if the error $\|u_h - u\|_{0,\infty,\tau}$ for $\tau \subset \Omega_h^-$ (where $u \equiv \phi_0$) is of the order h^β with $\beta > \alpha$, then the difference caused by the replacement is a high-order small quantity locally for all $\tau \in \Omega_h^- \cup (\Omega_h^{+b} \backslash \Omega_U^{\alpha/2})$. The size of the remaining domain $\Omega_U^{\alpha/2}$ depends on the error $\|u_h - u\|_{0,\infty}$. It can be shown (see, e.g., [32]) that meas $(\Omega_U^{\alpha/2}) \to 0$, as long as $\|u_h - u\|_{0,\infty,\Omega} \to 0$, as $h \to 0$. Thus $\chi^h_{\Omega_U^+}$ is a good approximator to $\chi_{\Omega_h^{+b}}$, and this is confirmed in our numerical tests; see section 4.

Remark 3.1. Generally speaking, for the problem considered here, the costate p is more regular than the solution u. Therefore, we may use p_h instead of u_h to approximate the characteristic function. It can be seen from (2.3) that

$$u = \max\{-(h')^{-1}(B^*p), \phi_0\}.$$

Thus, for example, we can define

$$\widetilde{\chi}^h_{\Omega_U^+} = \frac{\widetilde{u}_h - \phi_0}{h^\alpha + \widetilde{u}_h - \phi_0},$$

where $\widetilde{u}_h = \max\{-(h')^{-1}(B^*p_h), \phi_0\}$. Similarly, we can show

$$\|\widetilde{\chi}^h_{\Omega_U^+} - \chi_{\Omega_h^{+b}}\|_{0,\infty,\tau} \le \begin{cases} \min\{1, h^{-\alpha}\|(h')^{-1}(B^*p_h) - (h')^{-1}(B^*p)\|_{0,\infty,\tau}\} & \forall \tau \in \Omega_h^-, \\ h^{\alpha/2} \qquad \forall \tau \in \Omega_h^{+b} \backslash \Omega_U^{\alpha/2}. \end{cases}$$

3.4. Nonconstant obstacles. If the constraint ϕ_0 is a function $\phi(x)$, one could introduce $u^*(x) = u(x) - \phi(x)$. Then the triplet (y, p, u^*) satisfies the following optimality conditions:

$$\text{(3.39)} \qquad \begin{cases} a(y, w) = (f^* + Bu^*, w) \quad \forall w \in Y = H_0^1(\Omega), \\ a(q, p) = (g'(y), p) \quad \forall q \in Y = H_0^1(\Omega), \\ ((h^*)'(u^*) + B^*p, v - u)_U \ge 0 \quad \forall v \in K \subset U = L^2(\Omega_U), \end{cases}$$

where $f^* = f + B\phi, h^*(v) = h(v + \phi)$, and $K = \{v \in U : v \ge 0\}$. Thus the problem is reduced to the case of (2.3) with $\phi_0 = 0$.

However, this strategy, although simpler, may affect the efficiency of the resulting error estimators. Let us try to explain this: the inactive data $\phi|_{\Omega_U^-}$ on the noncoincidence set does not affect the solution of (CCP) and thus is not expected to play a major role in a sharp error estimator. However, with the transformation $u - \phi$, this data may be brought into the resulting error estimators through f^*. Thus we will directly consider the error $u - u_h$ rather than $u^* - u_h^*$. Let

$$\text{(3.40)} \quad K = \{v \in U : v \ge \phi \text{ a.e. in } \Omega_U\}, \qquad K^h = \{v_h \in U^h : v_h \ge \phi^h \text{ a.e. in } \Omega_U\},$$

where $\phi^h \in U^h$ is an approximation of ϕ. Here we take $\phi^h = \pi_h^a \phi$. It should be noticed that $K^h \not\subset K$ in general.

THEOREM 3.4. *Let (y, p, u) and (y_h, p_h, u_h) be the solutions of (2.3) and (2.5), respectively. Assume that all of the conditions of Theorem 3.1 and (3.35) hold and K^h is defined as in (3.40) with $\phi \in L^2(\Omega_U)$ and $\phi^h = \pi_h^a \phi$. Then*

$$\|u_h - u\|_{0,\Omega_U}^2 + \|y_h - y\|_{1,\Omega}^2 + \|p_h - p\|_{1,\Omega}^2 \le C \sum_{i=1}^{6} \eta_i^2, \tag{3.41}$$

where η_i $(i = 1\text{–}5)$ are defined in Theorem 3.1 and

$$\eta_6^2 = \sum_{\tau_U \in T_U^h} \|(\phi^h - \phi)\chi_{\Omega_h^{-b}}\|_{0,\tau_U}^2.$$

Proof. We will give only the details for the estimation of $\|u - u_h\|_{0,\Omega_U}^2$. The other terms can be estimated similarly as in Theorem 3.1. It should be emphasized that here one cannot take $v = u_h$ in (2.3) since $u_h \ge \phi$ may not be true. It follows from (3.3) that

$$h'(u) + B^* p \ge 0, \quad (h'(u) + B^* p)\chi_{\Omega_U^+} = 0. \tag{3.42}$$

Then it follows from the assumption (3.4), the inequality (2.5), and (3.42) that, for any $v_h \in K^h$,

$$\begin{aligned}
&c\|u - u_h\|_{0,\Omega_U}^2 \\
&\le (h'(u), u - u_h)_U - (h'(u_h), u - u_h)_U + (h'(u_h) + B^* p_h, v_h - u_h)_U \\
&= (h'(u_h) + B^* p_h, v_h - u)_U + (B^*(p_h - p), u - u_h)_U + (h'(u) + B^* p, u - u_h)_U \\
&= ((h'(u_h) + B^* p_h)\chi_{\Omega_h^{+b}}, v_h - u)_U + (B^*(p_h - p), u - u_h)_U \\
&\quad + ((h'(u_h) + B^* p_h - (h'(u) + B^* p))\chi_{\Omega_h^-}, v_h - u)_U \\
&\quad + ((h'(u) + B^* p)\chi_{\Omega_h^-}, v_h - u_h)_U + ((h'(u) + B^* p)\chi_{\Omega_U^- \setminus \Omega_h^-}, u - u_h)_U \\
&\quad := \sum_{i=1}^{5} I_i.
\end{aligned} \tag{3.43}$$

Take $v_h = \pi_h^a u$. Then I_1 and I_2 can be estimated as in the proof of Theorem 3.1 such that

$$I_1 + I_2 \le C(\eta_1^2 + \|p_h - p_{u_h}\|_{1,\Omega}^2) + \delta \|u - u_h\|_{0,\Omega_U}^2,$$

where δ is a small positive constant. It follows from (3.35), (3.24), and (3.23) that

$$\begin{aligned}
I_3 &\le \sum_{\tau_U \in T_U^h} (\|h'(u_h) - h'(u)\|_{0,\tau_U} + \|B^*(p_h - p)\|_{0,\tau_U}) \|(\phi - \phi^h)\chi_{\Omega_h^-}\|_{0,\tau_U} \\
&\le \delta(\|u - u_h\|_{0,\Omega_U}^2 + \|p_h - p_{u_h}\|_{1,\Omega}^2) + C\eta_6^2.
\end{aligned}$$

We note that $I_4 \le 0$ due to (3.42) and the fact that $(v_h - u_h)|_{\Omega_h^-} = (\phi^h - u_h)|_{\Omega_h^-} \le 0$.

Finally, to estimate I_5, we use $u|_{\Omega_U^-} = \phi|_{\Omega_U^-}$, (3.42) and $u_h \geq \phi^h$ to get

$$\begin{aligned}
&((h'(u)+B^*p)\chi_{\Omega_U^-\setminus\Omega_h^-}, u-u_h)_{\tau_U} = ((h'(u)+B^*p)\chi_{\Omega_U^-\setminus\Omega_h^-}, \phi-u_h)_{\tau_U}\\
&\leq ((h'(u)+B^*p)\chi_{\Omega_U^-\setminus\Omega_h^-}, \phi-\phi^h)_{\tau_U} = (h'(u)+B^*p, (\phi-\phi^h)\chi_{\Omega_h^b})_{\tau_U}\\
&= (h'(u)+B^*p-(h'(u_h)+B^*p_h), (\phi-\phi^h)\chi_{\Omega_h^b})_{\tau_U}\\
&\quad + ((I-\pi_h^a)(h'(u_h)+B^*p_h), (\phi-\phi^h)\chi_{\Omega_h^b})_{\tau_U}.
\end{aligned}$$

Thus

$$I_5 \leq \delta(\|u-u_h\|_{0,\Omega_U}^2 + \|p_h - p_{u_h}\|_{1,\Omega}^2) + C(\eta_1^2+\eta_6^2).$$

The rest of the proof is the same as that in Theorem 3.1. □

Remark 3.2. We can approximate the characteristic functions $\chi_{\Omega_h^{+b}}$ and $\chi_{\Omega_h^{-b}}$ by

$$\chi^h_{\Omega_h^{+b}} = \frac{u_h-\phi^h}{h^{\alpha^+}+u_h-\phi^h}, \qquad \chi^h_{\Omega_h^{-b}} = \frac{h^{\alpha^-}}{h^{\alpha^-}+u_h-\phi^h},$$

where α^+ and α^- are positive parameters.

3.5. Double obstacles. We now consider the control problem with the double obstacles: $\phi_1(x) < \phi_2(x)$. Let

$$\begin{aligned}
&K = \{v \in U : \phi_1 \leq v \leq \phi_2 \text{ a.e. in } \Omega_U\},\\
&K^h = \{v_h \in U^h : \phi_1^h \leq v_h \leq \phi_2^h \text{ a.e. in } \Omega_U\},
\end{aligned} \tag{3.44}$$

where $\phi_i^h \in U^h$ is an approximation of ϕ_i $(i=1,2)$. We assume that $\phi_i^h = \pi_h^a\phi_i$ $(i=1,2)$. To generalize the ideas used in Theorem 3.4 to this case, we define

$$\begin{aligned}
&\Omega^-_{\phi_i} = \{x \in \Omega_U : u(x) = \phi_i(x),\}, && \Omega^-_{\phi} = \Omega^-_{\phi_1} \cup \Omega^-_{\phi_2}, && \Omega^+_{\phi} = \Omega_U \setminus \Omega^-_{\phi},\\
&\Omega^-_{\phi_i,h} = \{\cup\bar\tau_U : \tau_U \subset \Omega^-_{\phi_i}, \tau_U \in T_U^h\}, && \Omega^-_{\phi,h} = \Omega^-_{\phi_1,h} \cup \Omega^-_{\phi_2,h}, && \Omega^{+b}_{\phi,h} = \Omega_U \setminus \Omega^-_{\phi,h},\\
&\Omega^{-b}_{\phi_i,h} = \{\cup\bar\tau_U : \bar\tau_U \cap \Omega^-_{\phi_i,h} \neq \emptyset, \tau_U \in T_U^h\}.
\end{aligned}$$

THEOREM 3.5. *Let (y,p,u) and (y_h,p_h,u_h) be the solutions of* (2.3) *and* (2.5)*, respectively. Assume that all of the conditions of Theorem* 3.4 *hold and K and K^h are defined as in* (3.44) *with $\phi_i \in L^2(\Omega_U)$ and $\phi_i^h = \pi_h^a\phi_i$ $(i=1,2)$. Then*

$$\|u_h-u\|_{0,\Omega_U}^2 + \|y_h-y\|_{1,\Omega}^2 + \|p_h-p\|_{1,\Omega}^2 \leq C\sum_{i=1}^6 \eta_i^2, \tag{3.45}$$

where η_i $(i=2$–$5)$ are defined in Theorem 3.1 *and*

$$\eta_1^2 = \sum_{\tau_U \in T_U^h} h_{\tau_U}^2 \|\nabla(h'(u_h)+B^*p_h)\chi_{\Omega^{+b}_{\phi,h}}\|_{0,\tau_U}^2,$$

$$\eta_6^2 = \sum_{\tau_U \in T_U^h} \sum_{i=1,2} \|(\phi_i^h-\phi_i)\chi_{\Omega^{-b}_{\phi_i,h}}\|_{0,\tau_U}^2.$$

Proof. Again, we give only the details for estimation of the error $\|u-u_h\|^2_{0,\Omega_U}$. In this case, we have

$$(h'(u)+B^*p)\chi_{\Omega^-_{\phi_1}} \ge 0, \quad (h'(u)+B^*p)\chi_{\Omega^-_{\phi_2}} \le 0, \quad (h'(u)+B^*p)\chi_{\Omega^+_{\phi}} = 0. \tag{3.46}$$

As in (3.43), it follows from the assumption (3.4), the inequality (2.5), and (3.46) that, for any $v_h \in K^h$,

$$\begin{aligned}
&c\|u-u_h\|^2_{0,\Omega_U} \\
&\le (h'(u),u-u_h)_U - (h'(u_h),u-u_h)_U + (h'(u_h)+B^*p_h, v_h-u_h)_U \\
&= (h'(u_h)+B^*p_h, v_h-u)_U + (B^*(p_h-p),u-u_h)_U + (h'(u)+B^*p,u-u_h)_U \\
&= ((h'(u_h)+B^*p_h)\chi_{\Omega^{+b}_{\phi,h}}, v_h-u)_U + (B^*(p_h-p),u-u_h)_U \\
&\quad +((h'(u_h)+B^*p_h-(h'(u)+B^*p))\chi_{\Omega^-_{\phi,h}}, v_h-u)_U \\
&\quad +((h'(u)+B^*p)\chi_{\Omega^-_{\phi,h}}, v_h-u_h)_U + ((h'(u)+B^*p)\chi_{\Omega^-_{\phi}\setminus\Omega^-_{\phi,h}}, u-u_h)_U \\
&:= \sum_{i=1}^5 J_i.
\end{aligned} \tag{3.47}$$

It is easy to see that for $1 \le i \le 3$, J_i can be estimated as I_i. Thanks to (3.46), we still have $J_4 \le 0$. Also, J_5 can be treated similarly to I_5. For instance, let us consider the case that $\tau_U \subset (\Omega^{-b}_{\phi_2,h}\setminus\Omega^-_{\phi_2,h})$. Assume that $\Omega^{-b}_{\phi_2,h} \cap \Omega^-_{\phi_1} = \emptyset$ for simplicity. We then have, from $u|_{\Omega^-_{\phi_2}} = \phi_2|_{\Omega^-_{\phi_2}}$, (3.46), and $u_h \le \phi^h_2$, that

$$\begin{aligned}
&((h'(u)+B^*p)\chi_{\Omega^{-b}_{\phi_2,h}\setminus\Omega^-_{\phi_2,h}}, u-u_h)_{\tau_U} \\
&\quad = ((h'(u)+B^*p)\chi_{\Omega^{-b}_{\phi_2,h}\setminus\Omega^-_{\phi_2,h}}, \phi_2-u_h)_{\tau_U} \\
&\qquad \le ((h'(u)+B^*p)\chi_{\Omega^{-b}_{\phi_2,h}\setminus\Omega^-_{\phi_2,h}}, \phi_2-\phi^h_2)_{\tau_U} \\
&\quad = (h'(u)+B^*p-(h'(u_h)+B^*p_h), \phi_2-\phi^h_2)_{\tau_U} \\
&\qquad + ((I-\pi^a_h)(h'(u_h)+B^*p_h), \phi_2-\phi^h_2)_{\tau_U}.
\end{aligned}$$

The rest of the proof is the same as that of Theorem 3.4. ∎

Remark 3.3. In computing, we may approximate the characteristic functions $\chi_{\Omega^{+b}_h}$ and $\chi_{\Omega^{-b}_{\phi_i,h}}$ by

$$\chi^h_{\Omega^{+b}_h} = \frac{(u_h-\phi^h_1)(\phi^h_2-u_h)}{h^{\alpha^+}+(u_h-\phi^h_1)(\phi^h_2-u_h)}, \qquad \chi^h_{\Omega^{-b}_{\phi_i,h}} = \frac{h^{\alpha^-}}{h^{\alpha^-}+|u_h-\phi^h_i|},$$

where α^+ and α^- are positive parameters.

Remark 3.4. It is clear that the uniform monotonicity conditions and Lipschitz continuity (2.1), (3.4), (3.25), (3.35), assumed in the proofs of Theorems 3.1–3.3, are needed to hold only in a neighborhood of the true solutions. This observation is useful in some applications involving a nonquadratic objective functional like $g(y) = \int_\Omega (y-y_0)^4$.

For (2.1) and (3.25), let us assume that $g(y) = \int_\Omega j(y)$, where j is twice continuously differentiable on R^1, to just fix the idea. Then it follows from the Sobolev embedding result $H^1(\Omega) \to L^\beta(\Omega)$ ($\beta < \infty$ if $n = 2$, and $\beta = 6$ if $n = 3$) that we have, using the Hölder inequality,

$$\begin{aligned} |(g'(v) - g'(w), q)| &\le \|j''(z)\|_{0,\beta^*,\Omega}\|v - w\|_{0,\beta,\Omega}\|q\|_{0,\beta,\Omega} \\ &\le C\|j''(z)\|_{0,\beta^*,\Omega}\|v - w\|_{1,\Omega}\|q\|_{1,\Omega}, \end{aligned}$$

where $z = \theta v + (1 - \theta)w$ with $\theta \in [0, 1]$, $\beta^* = (1 - 2/\beta)^{-1}$ for any $\beta > 2$ if $n = 2$ and $\beta^* = 3/2$ if $n = 3$.

Also, by using the embedding result $H^2(\Omega) \to L^\infty(\Omega)$ for $n \le 3$, we have

$$|(g'(v) - g'(w), q)| \le \|j''(z)\|_{0,\Omega}\|v - w\|_{0,\Omega}\|q\|_{2,\Omega}.$$

For example, if $g(y) = \int_\Omega (y - y_0)^4$ with $y_0 \in L^4(\Omega)$, we have by $H^1(\Omega) \to L^{2\beta^*}(\Omega)$ that

$$\begin{aligned} |(g'(v) - g'(w), q)| &\le C(\|v^2\|_{0,\beta^*,\Omega} + \|w^2\|_{0,\beta^*,\Omega} + \|y_0^2\|_{0,\beta^*,\Omega})\|v - w\|_{1,\Omega}\|q\|_{1,\Omega}, \\ &\le C(\|v\|_{1,\Omega}^2 + \|w\|_{1,\Omega}^2 + \|y_0\|_{L^4(\Omega)}^2)\|v - w\|_{1,\Omega}\|q\|_{1,\Omega} \end{aligned}$$

and

$$\begin{aligned} |(g'(v) - g'(w), q)| &\le C(\|v^2\|_{0,\Omega} + \|w^2\|_{0,\Omega} + \|y_0^2\|_{0,\Omega})\|v - w\|_{0,\Omega}\|q\|_{2,\Omega}, \\ &\le C(\|v\|_{1,\Omega}^2 + \|w\|_{1,\Omega}^2 + \|y_0\|_{L^4(\Omega)}^2)\|v - w\|_{0,\Omega}\|q\|_{2,\Omega}. \end{aligned}$$

Thus (2.1) and (3.25) hold as long as v, w are in a bounded set of Y. One can discuss (3.4) and (3.35) similarly.

It follows from the proofs of Theorems 3.4–3.5 that Theorem 3.2 can also be generalized to the nonconstant or double obstacle cases in the same way. Thus one can just use $\eta_1^2 + \eta_6^2$ as the error indicator in adaptive finite element methods if only the values of the control and state are important in an application.

4. Numerical experiments. In this section, we carry out some numerical experiments to demonstrate possible applications of the error estimators obtained in section 3. In most control problems, the optimal control is often of prime interest. Thus it is important to develop mesh refinement schemes that efficiently reduce the error $\|u - u_h\|$. In practice, there are four major types of adaptive finite element methods—namely, the h-method (mesh refinement), the p-method (order enrichment), the r-method (mesh redistribution), and the hp-method. A posteriori error estimators can be used as error indicators to guide the mesh refinement in adaptive finite element methods. For our numerical tests, using an adaptive mesh redistribution (AMR) method is advantageous since it can keep the number of the total nodes unchanged while adjusting the distribution of the nodes.

4.1. AMR method. The general idea behind the AMR method is to adjust meshes such that the a posteriori error estimators (the monitor functions to be called) are *equally* distributed over the computational meshes, while the total number of the nodes remains the same. Clearly, this method particularly suits our purposes of testing the efficiency of the known a posteriori error estimators.

In solving the optimal control problem (1.1), we use an iterative method to move the meshes and to redistribute the solutions on the new grid points. The procedure

for the mesh moving part is described in [24, 25, 26]. The key idea here is to use some kind of equivalent error estimators as the monitor function (or moving mesh indicator). More precisely, let $(x(\xi,\eta), y(\xi,\eta))$ be the mesh map in two dimensions. Here (ξ,η) are the computational coordinates. Let $M > 0$ be the monitor function which depends on the physical solution to be adapted. By solving the Euler–Lagrange equation

$$\nabla \cdot (M^{-1}\nabla\xi) = 0, \qquad \nabla \cdot (M^{-1}\nabla\eta) = 0, \tag{4.1}$$

a map between the physical domain Ω and the logical domain Ω_c can be computed. Typically, the map transforms a uniform mesh in the logical domain to cluster grid points at the regions of physical domain where the solutions are of greater physical interest. One of the crucial issues is what monitor functions are to be used. One popular choice in the AMR method literature is a gradient-based monitor function like $M_\tau = \sqrt{1 + |\nabla y_h|^2_\tau}$, which moves more grids to the regions of the largest solution gradients. In [24], it was shown that the gradient-based monitor functions may not be suitable for free boundary problems, and a monitor function associated with a posteriori error estimators is introduced which was found particularly useful in approximating the variational inequalities with free boundaries. In this section, we will use the same solution procedures as described in [24] to obtain the numerical solutions with moving grids, except that monitor functions will be based on the error estimators developed in this work.

4.2. Numerical tests. Our numerical example is the following type of optimal control problem:

$$\text{(OCP)} \qquad \begin{aligned} &\min \frac{1}{2}\int_\Omega (y - y_0)^2 + \frac{1}{2}\int_{\Omega_U} (u - u_0)^2 \\ &\text{s.t.} \quad \begin{cases} -\Delta y = Bu + f, \\ y|_{\partial\Omega} = y_0|_{\partial\Omega} = 0, \\ u \geq 0 \quad \text{in } \Omega_U. \end{cases} \end{aligned}$$

In our example, $\Omega_U = \Omega = [0,1] \times [0,1]$ and $B = I$. We also use the same meshes for the approximation of the state and the control. Thus $\tau_U = \tau$. Let Ω^h be a polygonal approximation to Ω with boundary $\partial\Omega^h$. Let T^h be a partitioning of Ω^h into a disjoint regular triangular τ so that $\bar{\Omega}^h = \cup_{\tau\in T^h}\bar{\tau}$. Assume that the state y is approximated in the finite element space Y^h with Φ^i as basis functions and u is approximated in U^h with Ψ^i as basis functions. Thus the problem (OCP) is discretized as the following optimization problem:

$$\begin{aligned} \min \quad & \tfrac{1}{2}\left\{(Y - Y^0)^T Q (Y - Y^0) + (U - U^0)^T M (U - U^0)\right\} \\ \text{s.t.} \quad & AY = BU + F, \\ & U \geq 0, \end{aligned} \tag{4.2}$$

with

$$Q^{ij} = \int_\Omega \Phi^i \Phi^j dx, \qquad M^{ij} = \int_\Omega \Psi^i \Psi^j dx,$$
$$A^{ij} = \int_\Omega \nabla\Phi^i \nabla\Phi^j dx, \qquad B^{ij} = \int_\Omega \Phi^i \Psi^j dx,$$
$$F_i = \int_\Omega f\Phi^i dx.$$

The finite element solution (y_h, u_h) is given by $y_h = \sum_i Y_i \Phi^i$ and $u_h = \sum_i U_i \Psi^i$, and (y_0, u_0) is approximated by $y_0^h = \sum_i Y_i^0 \Phi^i$ and $u_0^h = \sum_i U_i^0 \Psi^i$.

In solving the above optimization problem, we use a projection gradient method developed by He [19]. The projection method, though simple, is by no means the most efficient algorithm for solving our problem, but the purpose of the experiments in this section is to test the efficiency of the error indicators. The idea in [19] is the first to introduce the Lagrange multiplier P and then to set

$$H = \begin{pmatrix} Q & 0 & -A^T \\ 0 & M & B^T \\ A & -B & 0 \end{pmatrix}, \qquad x = \begin{pmatrix} Y \\ U \\ P \end{pmatrix}, \qquad c = \begin{pmatrix} QY^0 \\ MU^0 \\ F \end{pmatrix}.$$

The algorithm for solving the optimization problem (4.2) is described by the following pseudocode:

```
du = beta*(Hx + c)
e = x - max(x-du,b)
error =||e||
do  while error >= TOL
    d= beta*H^T*e
    g = d + du
    beta=beta*error/||d||
    e = e + d
    rho = error^2/||e||^2
    x = max(x - gamma \rho g,b)
    du = \beta (H x + c)
    e = x - max(x-du,b)
    error = ||e||
end do
```

We now briefly describe the solution algorithm to be used for solving the numerical examples in this section.

ALGORITHM 0

(i) Solve the optimization problem (4.2) with the above optimization code on the current mesh, and calculate the error monitor function M;
(ii) move the mesh to a new location, and update the solution on new meshes using the monitor M, as described in [25].

It is important to note from Theorem 3.2 that the error $\|u - u_h\|_{L^2(\Omega_U)}$ is largely controlled by η_1. Thus, in Algorithm 0, η_1, in (3.11) will be used to construct the

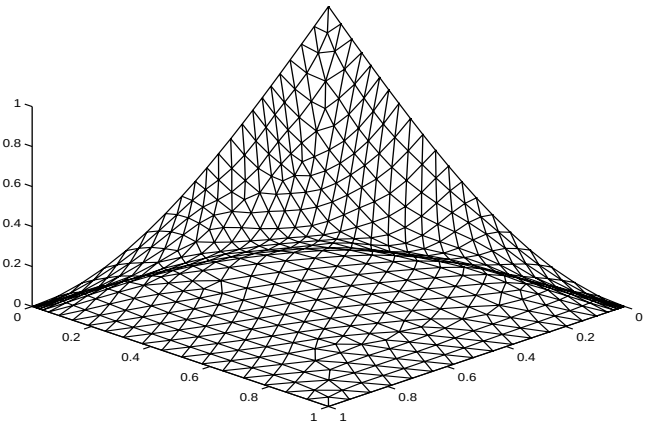

FIG. 4.1. *The surface of the solution u.*

monitor function M discussed in section 4.1,

$$M|_\tau = \sqrt{1 + \lambda \widetilde{\eta}_1^2|_\tau}, \tag{4.3}$$

where $\lambda > 0$ is a positive constant, and

$$\widetilde{\eta}_1^2|_\tau = h_\tau^2 \|\nabla(h'(u_h) + B^* p_h)\chi_{u_h}\|_{0,\tau}^2 . \tag{4.4}$$

In general, λ should be chosen such that $\lambda\|\eta_1\| >> 1$. Here we let $\lambda\|\eta_1\|_2 = 10^4$. As discussed in section 3, in our computation, we approximate the characteristic function used in η_1 by the following approximation:

$$\chi_{u_h} = \frac{u_h}{u_h + \epsilon}, \tag{4.5}$$

where $\epsilon > 0$ is a (small) positive number. In our experiments, we tried a range of values for ϵ between 0.1 and 1, and similar computational results were obtained.

Example 4.1. In this example we have

$$u_0 = 1 - \sin(\pi x_1/2) - \sin(\pi x_2/2), \quad y_0 = 0, \quad p = Z(x_1, x_2), \quad f = 4\pi^4 Z - u,$$

where $Z = \sin \pi x_1 \sin \pi x_2$. The exact solution of this problem is $y = 2\pi^2 Z, u = \max(u_0 - p, 0)$.

20×20 *nodes solution.* We first compute Example 4.1 on a 20×20 uniform mesh and then adjust the mesh by using Algorithm 0. The parameters λ and ϵ in (4.3) and (4.5) are 10^5 and 0.1, respectively. In Figure 4.1, the exact solution u is plotted. It is seen that the free boundary for this problem is just a single curve, and the maximum magnitude of the solution u is 1. The state and costate are approximated by piecewise linear elements. Both piecewise constant and piecewise linear elements are used to approximate the control in this example. In Figure 4.2, the 20×20 adaptive meshes are displayed. The control approximation errors are presented in Figures 4.3 and 4.4. It is observed that the maximum errors are distributed along the free boundary, as seen from Figures 4.3 and 4.4.

The adaptive meshes shown in Figure 4.2 are obtained by using the AMR method with the monitor function defined by (4.3). It is seen that a higher density of node

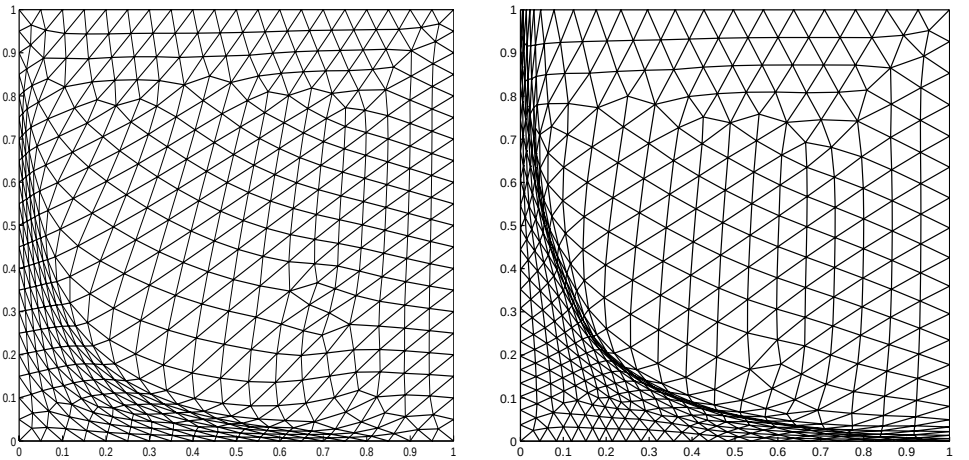

FIG. 4.2. *The adaptive mesh obtained by using piecewise constant elements (left) and piecewise linear elements (right), with* 20×20 *nodes.*

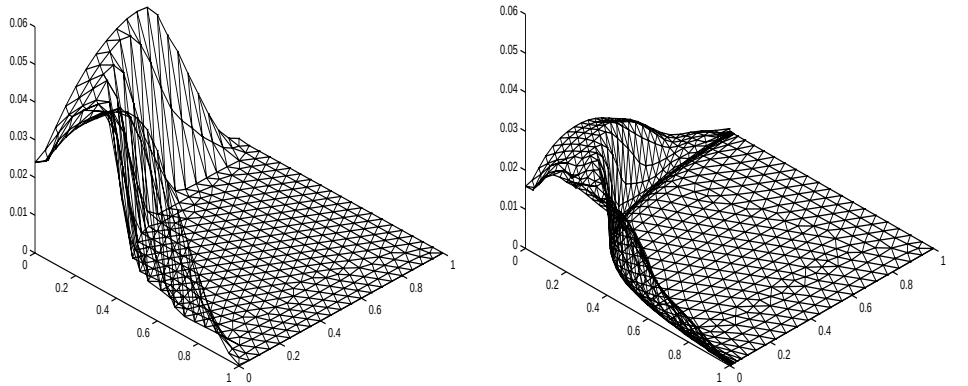

FIG. 4.3. L^2*-error* $\|u - u_h\|$ *with uniform mesh (left) and adaptive mesh (right), obtained by using piecewise constant elements with* 20×20 *nodes.*

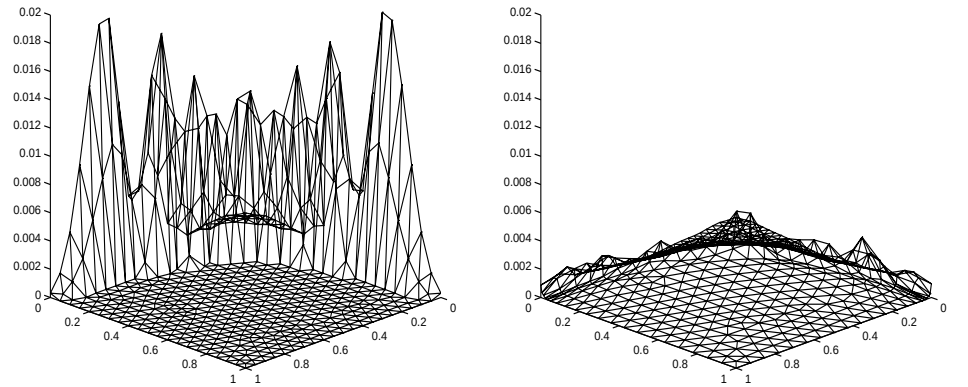

FIG. 4.4. *Same as Figure* 4.3*, except with linear elements.*

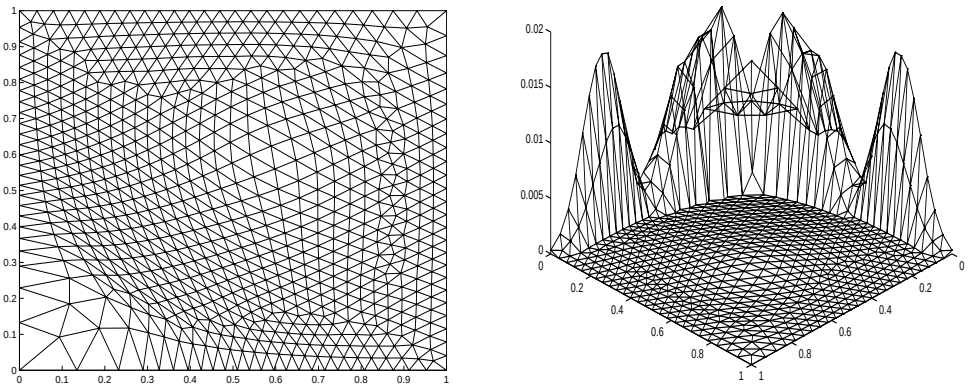

FIG. 4.5. *Example* 4.1 *with* 20×20 *nodes: Mesh (left) and error (right) obtained by using linear elements with unsharp error estimator associated with* $\bar{\eta}_1$*, as defined by* (3.2).

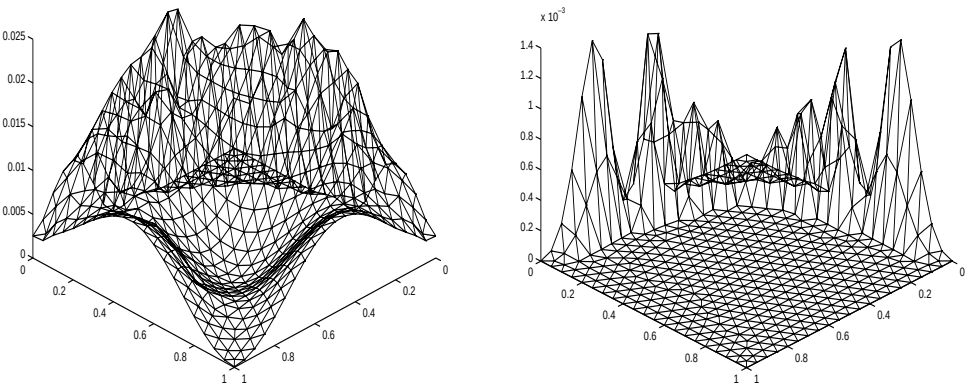

FIG. 4.6. *Profiles of unsharp estimator* $\bar{\eta}_1$ *and the sharp estimator* $\widetilde{\eta}_1$ *obtained by using the linear element with* 20×20 *nodes.*

points are now distributed along the free boundary. Furthermore, the approximation error is substantially reduced, as seen in Figures 4.3 and 4.4. In Figure 4.4, the L^2-norm of $u - u_h$ is 4.3×10^{-3} on the uniform mesh but is reduced 10 times to 4.4×10^{-4} on the adaptive mesh, while the L^2 error of the state approximation becomes slightly larger. It was found that one would need a 100×100 uniform mesh to produce such an error reduction. Thus efficient adaptive meshes can indeed save substantial computational work.

However, if we replace the estimator $\widetilde{\eta}_1$ in the monitor (4.3) with the estimator $\bar{\eta}_1$ given by (3.2), then a very different mesh is obtained; see Figure 4.5. As also seen in Figure 4.5, such a mesh is not efficient in reducing the control error; the error is virtually the same as that on the uniform mesh. The main reason is that the estimator $\bar{\eta}_1$ may not be sharp in this case. In fact, from Figure 4.6, it is clear that $\bar{\eta}_1$ and $|u - u_h|$ have very different profiles, while $\widetilde{\eta}_1$ has a profile similar to that of $|u - u_h|$.

40×40 *nodes solution.* To see the effect of mesh refinement, numerical solutions for Example 4.1 are obtained by using 40×40 linear elements. The control error distributions in this case are plotted in Figure 4.7, while the adapted mesh is plotted

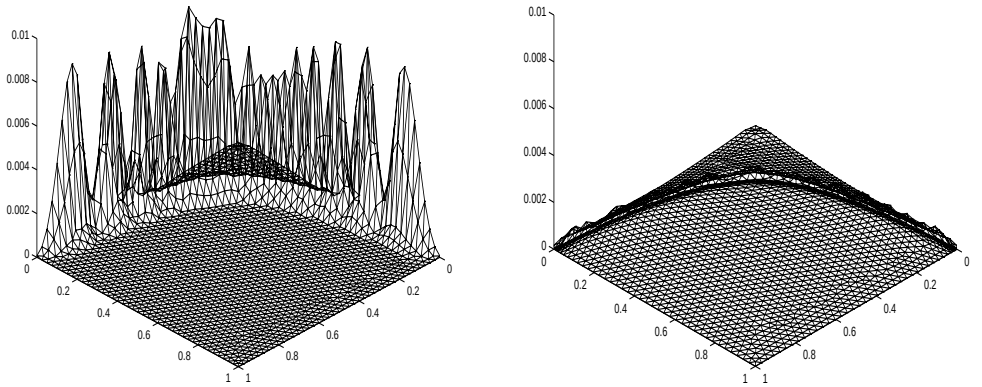

FIG. 4.7. *Same as Figure* 4.4*, except with* 40×40 *nodes.*

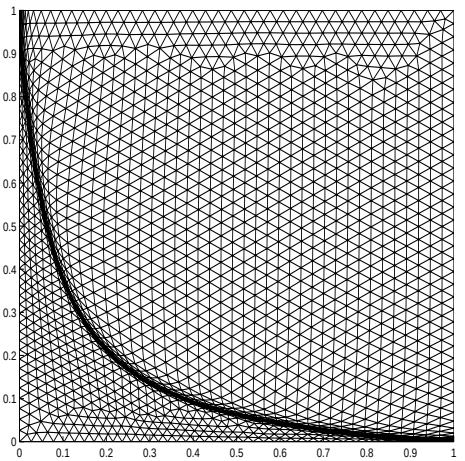

FIG. 4.8. *The adaptive mesh obtained by using piecewise linear elements with* 40×40 *nodes.*

in Figure 4.8. It is clear that the control errors are reduced with the finer mesh and with the use of the adaptive meshes.

5. Conclusion. In this work, we have derived some sharp a posteriori error indicators for the distributed elliptic optimal control problems. It is shown that the error indicators obtained can be applied in adaptive finite element computations and are found efficient in guiding mesh adjustments for our numerical examples. It is clear from the numerical experiments that the AMR methods can substantially increase the approximation accuracy. We point out that the approaches used in this work can be generalized to study other control problems.

SPECTRAL ANALYSIS AND SINGULAR VALUE COMPUTATIONS OF THE NONCOMPACT FREQUENCY RESPONSE AND COMPRESSION OPERATORS IN SAMPLED-DATA SYSTEMS*

TOMOMICHI HAGIWARA†

Abstract. This paper is motivated by the problem of computing the frequency response gain of general sampled-data systems with noncompact frequency response operators. We first show that, with the J-unitary transformation, the computation in the noncompact operator case can be reduced, in principle, to that in the compact operator case, to which an existing efficient and reliable bisection method can be applied. At the same time, however, we point out that there arise some critical problems in this reduction to the compact case which could be serious enough to invalidate the apparent success in the reduction. Through some spectral analysis of operators involving or related to the frequency response operators, we eventually prove that these critical problems can be circumvented after all, and we give an explicit result that shows how to compute the frequency response gain with a bisection method dealing only with finite-dimensional matrices. Extending the arguments, we also give a bisection method to compute the singular values of the frequency response operators and the associated compression operators.

1. Introduction.

1.1. Background and motivation of the study. It is quite common these days to control a continuous-time plant with a digital controller. In such a case, the measurement output y of the plant is detected and the control input u is changed at every sampling period, while the disturbance input w is a continuous-time signal, and it affects the controlled output z, which is also a continuous-time signal. This situation is shown in Figure 1, where P and Ψ denote the continuous-time plant and the digital controller, respectively, and $\mathcal{S}$ and $\mathcal{H}$ denote the ideal sampler and the hold device with sampling period h, respectively. Also, the solid lines denote continuous-time signals, while the dashed lines denote discrete-time signals. Such a system is called a sampled-data system, especially when close attention is paid to the intersample behavior of the continuous-time signals w and z.

The analysis and synthesis of sampled-data systems scored a great success in the past decade, and, for example, the servo problem, the H_∞ control problem, the H_2 control problem, as well as the robust stability problem have been studied (see, e.g., [1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12]). In many of these problems, the frequency response operators of sampled-data systems (with their intersample behavior taken into account), introduced in [13, 14], play an important role and/or provide an insight from the frequency domain, as well as those closely related studies [15, 16] also do.

This paper is motivated by a study on the computation of the gain characteristics of the frequency response of sampled-data systems. By computing the gain (i.e.,

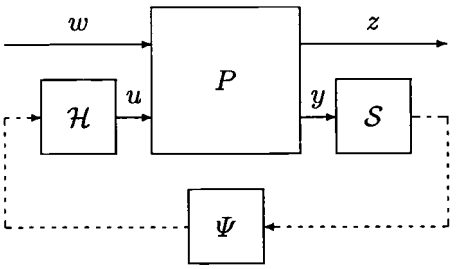

FIG. 1. *Stable sampled-data system* Σ_s.

norm) of the frequency response operator at each angular frequency, we can draw Bode diagrams of sampled-data systems with all of the effects of aliasing taken into account, which should be quite useful for grasping the frequency-domain characteristics of sampled-data systems. The computation methods for the frequency response gain of sampled-data systems have been studied quite intensively [13, 14, 17, 18, 19, 20, 21, 22], and a closed-form formula for the computation is given in [13]. Recently, a quite efficient and reliable method for the computation was derived in [22]. The feature of the latter method is that it is based on a bisection method so that it can compute the gain to any degree of accuracy without numerical problems. The main restriction of this method, however, is that it can be applied only to those sampled-data systems whose frequency response operators are compact operators. It is often the case, however, that the frequency response operator is actually noncompact. In fact, this happens to be the case if and only if there exists a nonzero direct feedthrough matrix from w to z in the continuous-time plant P [13]. Thus, when we consider, e.g., the sensitivity operators of sampled-data systems [14], they are noncompact so that the bisection method of [22] cannot be applied. Even though a closed-form formula exists for this special case (i.e., if we confine ourselves to the sensitivity operators), with which we can compute the frequency response gain exactly [19], more general cases with noncompact operators are hard to deal with in an efficient and reliable way; for example, just considering a *weighted* sensitivity operator makes the computation quite hard if the weight corresponds to a biproper multivariable system.

1.2. The purpose of this paper. This paper mainly focuses on the case in which the frequency response operator is noncompact, and the paper aims at giving a fundamental theoretical result for such a case that readily shows how to compute the frequency response gain with a bisection method. It is expected that such a theoretical result is obtained readily by a simple combination of the method for the compact case [22] and the J-unitary transformation (or the loop-shifting) [5], but, in fact, this combination turns out to lead to some critical theoretical problems. Namely, we need to guarantee that we will never encounter, roughly speaking, the following situations:

- There exists an open interval of positive real numbers such that, for each γ in that interval, a γ-dependent matrix $e^{j\varphi h}I - \mathcal{A}_\gamma$, defined appropriately, has an eigenvalue at γ.
- There exists an open interval of positive real numbers such that, for each γ in that interval, a γ-dependent operator $\mathcal{D}_\gamma$, defined appropriately, has a singular value at γ.

Even though it might look unlikely that we will encounter the above situations, the circumstances here are quite different from the seemingly related case of the H_∞ problem [2]; a different nature of the problem here prevents us from applying the small-gain theorem, which makes it nontrivial to negate the above possibility. Thus we do need to prove with some new approach that this never occurs, since otherwise the implication will be that we cannot derive a bisection method for the noncompact case. Now, the contribution of this paper is twofold: first, we describe the details of the above critical problems and show how we can circumvent them to arrive at a bisection method for the noncompact case. In the course of this study, we will also clarify some useful properties on the singular values of the frequency response operators and compression operators of sampled-data systems together with some related spectral properties; this constitutes the second contribution of this paper.

The contents of this paper are as follows. In section 2, we review the results of [13] about the lifting approach to the frequency response of sampled-data systems with a slight but crucial extension and derive a few fundamental results about some related operators. In section 3, we show that the application of the J-unitary transformation (but in a slightly different way from the H_∞ problem case) reduces the treatment of the noncompact case into that of the compact case in principle, and then we show that a finite-dimensional test can be obtained to examine if the gain at a given angular frequency is smaller than a prescribed positive number γ, *provided that some assumptions are satisfied*. In fact, such assumptions are nothing but the assumptions that neither of the two situations mentioned above occurs. To validate these assumptions, we show in section 4 that the first situation never occurs, while in section 5, we show that the second situation never occurs either. Combining these arguments, eventually we will arrive at a fundamental theoretical result that readily leads to a bisection method for the computation of the frequency response gain. In section 6, we extend some of the arguments used in the preceding sections and give a bisection method for the computation of the singular values of the frequency response operators and the associated compression operators. Finally, in section 7, we summarize the contributions of this paper.

2. Frequency response of sampled-data systems. In this section, we consider the sampled-data system Σ_s shown in Figure 1 and review the associated frequency response operator introduced by Yamamoto and Khargonekar [13] with the lifting technique [1, 2, 3, 13], with a slight but crucial extension. We next study some properties of the spectra of operators involving or related to the frequency response operator.

We assume that the state-space descriptions of P and Ψ are given, respectively, by

$$\begin{aligned} \frac{dx}{dt} &= Ax + B_1 w + B_2 u, \\ z &= C_1 x + D_{11} w + D_{12} u, \\ y &= C_2 x \end{aligned} \tag{1}$$

and

$$\begin{aligned} \xi_{k+1} &= A_\Psi \xi_k + B_\Psi y_k, \\ u_k &= C_\Psi \xi_k + D_\Psi y_k, \end{aligned} \tag{2}$$

where y_k stands for $y(kh)$, while $u(t) = u_k$ $(kh \le t < (k+1)h)$ since $\mathcal{H}$ is the zero-order hold. Throughout the paper, the sampled-data system Σ_s is assumed to be

internally stable.

With a slight abuse of notation, in the following, the Hilbert space of square (Lebesgue) integrable vector functions over the time interval $[0, h)$ with the standard inner product will be denoted by $\mathcal{K}$, whatever the dimension of the vector may be. Similarly, for notational simplicity, every finite-dimensional Euclidean space will be denoted by $\mathcal{F}$.

2.1. Frequency response operators. Now we introduce the matrices A_d, B_{d2}, and C_{d2} and the operators $\mathbf{B}_1$, $\mathbf{C}_1$, $\mathbf{D}_{11}$, and $\mathbf{D}_{12}$ as follows:

$$A_d := \exp(Ah), \quad B_{d2} := \int_0^h \exp(A\sigma)B_2 d\sigma, \quad C_{d2} := C_2, \tag{3}$$

$$\mathbf{B}_1 : \ \mathcal{K} \ni w \mapsto \int_0^h \exp\left(A(h-\sigma)\right)B_1 w(\sigma)d\sigma \in \mathcal{F}, \tag{4}$$

$$\mathbf{C}_1 : \ \mathcal{F} \ni x \mapsto z \in \mathcal{K}, \quad z(\theta) = C_1 \exp\left(A\theta\right)x, \tag{5}$$

$$\mathbf{D}_{11} : \ \mathcal{K} \ni w \mapsto z \in \mathcal{K}, \quad z(\theta) = \int_0^\theta C_1 \exp\left(A(\theta-\sigma)\right)B_1 w(\sigma)d\sigma + D_{11}w(\theta), \tag{6}$$

$$\mathbf{D}_{12} : \ \mathcal{F} \ni u \mapsto z \in \mathcal{K}, \quad z(\theta) = \int_0^\theta C_1 \exp\left(A(\theta-\sigma)\right)B_2 d\sigma\, u + D_{12}u. \tag{7}$$

Then the lifting-based transfer operator $\widehat{G}(z)$ of the sampled-data system Σ_s is defined by

$$\widehat{G}(z) := \mathcal{C}(zI - \mathcal{A})^{-1}\mathcal{B} + \mathcal{D} \tag{8}$$

with

$$\mathcal{A} := \begin{bmatrix} A_d + B_{d2}D_\Psi C_{d2} & B_{d2}C_\Psi \\ B_\Psi C_{d2} & A_\Psi \end{bmatrix} : \ \mathcal{F} \to \mathcal{F}, \tag{9}$$

$$\mathcal{B} := \begin{bmatrix} \mathbf{B}_1 \\ 0 \end{bmatrix} : \ \mathcal{K} \to \mathcal{F}, \tag{10}$$

$$\mathcal{C} := \begin{bmatrix} \mathbf{C}_1 & \mathbf{D}_{12} \end{bmatrix} \begin{bmatrix} I & 0 \\ D_\Psi C_{d2} & C_\Psi \end{bmatrix} : \ \mathcal{F} \to \mathcal{K}, \tag{11}$$

$$\mathcal{D} := \mathbf{D}_{11} : \ \mathcal{K} \to \mathcal{K}. \tag{12}$$

The operator $\mathcal{D}$ is called the compression operator.

Note that $\mathcal{A}$ is a finite-dimensional matrix, and its eigenvalues all lie inside the unit circle by the internal stability assumption of Σ_s. Hence $\widehat{G}(e^{j\varphi h})$ is well defined for each $\varphi \in [0, \omega_s)$, where $\omega_s := 2\pi/h$ denotes the sampling angular frequency. In fact, it defines a bounded operator on $\mathcal{K}$ for each φ and is called the frequency response

operator at angular frequency φ. This terminology is justified by the fact that the asymptotic output z to the "sampled-data (SD)-sinusoid" w is again an "SD-sinusoid" and that these two "SD-sinusoids" are related through $\widehat{G}(e^{j\varphi h})$ in a simple way. What this exactly means is described below in terms of the lifting technique [1, 2, 3, 13]; the discussions here are only a slight modification of that in [13] in the sense that the treatment of the initial state is considered more explicitly. This consideration, however, is crucial to giving a solid basis for the subsequent arguments.

Given a (vector) signal w over the nonnegative time interval $[0, \infty)$, the well-known lifting operation of w is defined as

$$w \mapsto \{\widehat{w}_k\}_{k=0}^{\infty}, \tag{13}$$

where $\widehat{w}_k$ is given by

$$\widehat{w}_k(\theta) = w(kh + \theta) \quad (0 \le \theta < h,\ k = 0, 1, 2, \ldots). \tag{14}$$

The signal w is called an SD-sinusoid of angular frequency φ [14] if its lifted representation satisfies

$$\widehat{w}_k(\theta) = \widehat{w}_0(\theta) e^{j\varphi kh} \quad (0 \le \theta < h) \tag{15}$$

for some $\widehat{w}_0 \in \mathcal{K}$. In this case, the "initial function" $\widehat{w}_0$ represents the "amplitude" and "phase" of the SD-sinusoid. It is a fact that the asymptotic output z of Σ_s to the SD-sinusoid w corresponding to (15) is again an SD-sinusoid of the same angular frequency, where the "initial function" $\widehat{z}_0$ corresponding to the asymptotic output is given by

$$\widehat{z}_0 = \widehat{G}(e^{j\varphi h})\widehat{w}_0. \tag{16}$$

Note carefully that $\widehat{z}_0(\theta)$ $(0 \le \theta < h)$ above is different from the actual response $z(t)$ $(0 \le t < h)$ of Σ_s for the *zero initial state* because z is not exactly an SD-sinusoid, but it just tends to an SD-sinusoid as t goes to infinity.

However, given any $\widehat{w}_0 \in \mathcal{K}$, let us take $\widehat{z}_0$ given by (16) and expand both $\widehat{w}_0$ and $\widehat{z}_0$ into the SD-sinusoids w and z, respectively, with angular frequency φ according to (15) and then (14). Then it is a fact that there exist appropriate initial states $x(0)$ of P and ξ_0 of Ψ such that the above SD-sinusoid input w *together with the initial states* yield exactly the above SD-sinusoid output z over the entire nonnegative time interval $[0, \infty)$. Conversely, if, under some initial states $x(0)$ and ξ_0, the output z to some SD-sinusoid w is exactly an SD-sinusoid over the whole nonnegative time interval $[0, \infty)$, then the "initial functions" of these SD-sinusoids satisfy (16).

These facts justify the following alternative definition for the frequency response gain defined in [13].

DEFINITION 2.1. *Suppose that $e^{j\varphi h} I - \mathcal{A}$ is invertible. Then the frequency response gain of Σ_s at angular frequency φ is given by*

$$\|\widehat{G}(e^{j\varphi h})\| = \sup \frac{\|\widehat{z}_0\|_{\mathcal{K}}}{\|\widehat{w}_0\|_{\mathcal{K}}}, \tag{17}$$

where $\widehat{w}_0$ and $\widehat{z}_0$ are, respectively, the initial functions of the input and output SD-sinusoids of angular frequency φ consistent with the sampled-data system Σ_s. Here, the consistency means that these SD-sinusoids can be the solution of Σ_s under some appropriate initial states.

Remark 2.1. Definition 2.1 is a system-theoretic definition as opposed to the more operator-theoretic one in [13]; unlike the operator-theoretic definition, we can allow nonzero initial states here and also deal with unstable sampled-data systems.[1] This, together with the notion of "consistency," plays a crucial role in the following discussions. See, e.g., the proof of Lemma 3.1 and subsection 4.1.

Here, it should be noted that $\mathcal{D}$ (and hence $\widehat{G}(e^{j\varphi h})$) is a compact operator if and only if $D_{11} = 0$ in (1) [13]. In general, noncompact operators are harder to deal with than compact operators, and we are mainly interested in the computation of the frequency response gain when $\widehat{G}(e^{j\varphi h})$ is not compact (i.e., $D_{11} \neq 0$). Such situations arise, e.g., when we deal with the sensitivity operators [14] among others. Even though there exists an explicit formula [19] for the frequency response gain of (unweighted) sensitivity operators, it is hard to compute the frequency response gain of general sampled-data systems with $D_{11} \neq 0$. The study in the following subsection is motivated by such a research direction.

2.2. Spectral analysis related to the frequency response operators. In this subsection, we derive some facts on the spectra of operators related to the frequency response operator $\widehat{G}(e^{j\varphi h})$. We also study the singular values of $\widehat{G}(e^{j\varphi h})$. Throughout the remainder of this paper, the angular frequency $\varphi \in [0, \omega_s)$ is regarded as an arbitrary fixed number.

If $D_{11} = 0$ so that $\widehat{G}(e^{j\varphi h})$ is compact, then $\widehat{G}(e^{j\varphi h})^*\widehat{G}(e^{j\varphi h})$ is compact, too, and hence it has a maximum eigenvalue. The square root of it is the maximum singular value of $\widehat{G}(e^{j\varphi h})$ and is equal to the frequency response gain $\|\widehat{G}(e^{j\varphi h})\|$ [13].

If $D_{11} \neq 0$, however, the situation becomes much more involved. Although it is known that $\|\widehat{G}(e^{j\varphi h})\|$ is no smaller than $\|D_{11}\|$ [13], the properties of the spectra of operators related to $\widehat{G}(e^{j\varphi h})$, $\widehat{G}(e^{j\varphi h})^*\widehat{G}(e^{j\varphi h})$, or $\mathcal{D}^*\mathcal{D}$ have not necessarily been clarified explicitly enough in the literature. Since we need, in the following arguments, further knowledge on the properties of the spectra of operators involving $\widehat{G}(e^{j\varphi h})$ or $\mathcal{D}$, the remainder of this subsection is devoted to such a study.

With a slight abuse of notation, given a matrix D_{11}, the operator that maps $w(\cdot) \in \mathcal{K}$ to $z(\cdot) = D_{11}w(\cdot) \in \mathcal{K}$ is also denoted by D_{11}. It will be clear from the context whether D_{11} refers to this operator or the underlying matrix. Also, consider replacing the direct feedthrough matrix D_{11} by 0 in the generalized plant (1), and denote the corresponding frequency response operator by $\widehat{G}_c(e^{j\varphi h})$. Then we have

$$\widehat{G}(e^{j\varphi h}) = D_{11} + \widehat{G}_c(e^{j\varphi h}). \tag{18}$$

Note that $\widehat{G}_c(e^{j\varphi h})$ is a compact operator. In the following, the spectrum of an operator is denoted by $\sigma(\cdot)$, and the matrix norm $\|D_{11}\|$ is denoted by d_{11} for simplicity.

LEMMA 2.2. *Suppose that* $\gamma_1^2 \in \partial\sigma(\widehat{G}(e^{j\varphi h})D_{11}^*)$, *where* $\gamma_1 > d_{11}$. *Then* γ_1^2 *is an isolated point of* $\sigma(\widehat{G}(e^{j\varphi h})D_{11}^*)$.

Proof. Since $\widehat{G}_c(e^{j\varphi h})$ is a compact operator, it follows from (18) that

$$\widehat{G}(e^{j\varphi h})D_{11}^* = D_{11}D_{11}^* + K, \tag{19}$$

[1] Unless Σ_s has an unstable mode at $e^{j\varphi h}$, every SD-sinusoid input with angular frequency φ yields an SD-sinusoid output with the same angular frequency provided that the initial state of Σ_s is set appropriately. This situation is quite similar to what we have in unstable continuous-time systems with regard to sinusoid signals.

where K is a compact operator. Hence, by Proposition XI.4.2(e) of [23], we have

$$\sigma_{le}(\widehat{G}(e^{j\varphi h})D_{11}^*) = \sigma_{le}(D_{11}D_{11}^*), \tag{20}$$

$$\sigma_{re}(\widehat{G}(e^{j\varphi h})D_{11}^*) = \sigma_{re}(D_{11}D_{11}^*), \tag{21}$$

$$\sigma_{e}(\widehat{G}(e^{j\varphi h})D_{11}^*) = \sigma_{e}(D_{11}D_{11}^*), \tag{22}$$

where $\sigma_{le}(\cdot)$ and $\sigma_{re}(\cdot)$, respectively, denote the left and the right essential spectra and $\sigma_e(\cdot)$ denotes the essential spectrum. By Proposition XI.4.6 of [23], the right-hand sides of the above three equations all coincide so that we have

$$\sigma_{le}(\widehat{G}(e^{j\varphi h})D_{11}^*) \cap \sigma_{re}(\widehat{G}(e^{j\varphi h})D_{11}^*) = \sigma_e(D_{11}D_{11}^*), \tag{23}$$

which, in turn, is equal to the set of the squared singular values of the matrix D_{11}. Thus we have

$$\gamma_1^2 \notin \sigma_{le}(\widehat{G}(e^{j\varphi h})D_{11}^*) \cap \sigma_{re}(\widehat{G}(e^{j\varphi h})D_{11}^*) \tag{24}$$

since $\gamma_1 > d_{11}$. Hence the assertion follows readily from Theorem XI.6.8 of [23]. □

LEMMA 2.3. *Suppose that $\gamma^2 \in \sigma(\widehat{G}(e^{j\varphi h})D_{11}^*)$, where $\gamma > d_{11}$. Then γ^2 is an isolated point of $\sigma(\widehat{G}(e^{j\varphi h})D_{11}^*)$.*

Proof. If $\gamma^2 \in \partial\sigma(\widehat{G}(e^{j\varphi h})D_{11}^*)$, then the assertion follows readily from Lemma 2.2. If $\gamma^2 \notin \partial\sigma(\widehat{G}(e^{j\varphi h})D_{11}^*)$, on the other hand, then, by definition, there exists some ε-neighborhood of γ^2 that fails to contain a point in the complement of $\sigma(\widehat{G}(e^{j\varphi h})D_{11}^*)$ (i.e., the ε-neighborhood is contained in $\sigma(\widehat{G}(e^{j\varphi h})D_{11}^*)$). This, together with the compactness (boundedness) of $\sigma(\widehat{G}(e^{j\varphi h})D_{11}^*)$, means that we can take some real number $\gamma_1 > \gamma$ such that $\gamma_1^2 \in \partial\sigma(\widehat{G}(e^{j\varphi h})D_{11}^*)$, and, at the same time, γ_1^2 is not an isolated point of $\sigma(\widehat{G}(e^{j\varphi h})D_{11}^*)$. Since $\gamma_1 > d_{11}$, this contradicts Lemma 2.2, and thus $\gamma^2 \notin \partial\sigma(\widehat{G}(e^{j\varphi h})D_{11}^*)$ cannot occur. This completes the proof. □

Similarly, applying Proposition XI.4.6 of [23], we can readily obtain the following result.

PROPOSITION 2.4. *Every $\gamma \in \sigma(\widehat{G}(e^{j\varphi h})^*\widehat{G}(e^{j\varphi h}))$ such that $\gamma > d_{11}^2$ is an isolated point of $\sigma(\widehat{G}(e^{j\varphi h})^*\widehat{G}(e^{j\varphi h}))$ and is in fact an eigenvalue of finite multiplicity.*

Also, by decomposing $\mathbf{D}_{11}$ given by (6) into $\mathbf{D}_{11} = D_{11} + \mathbf{D}_{11c}$ with a compact operator $\mathbf{D}_{11c}$, we can derive the following parallel result.

PROPOSITION 2.5. *Every $\gamma \in \sigma(\mathcal{D}^*\mathcal{D})$ such that $\gamma > d_{11}^2$ is an isolated point of $\sigma(\mathcal{D}^*\mathcal{D})$ and is in fact an eigenvalue of finite multiplicity.*

The square root of each of the eigenvalues of $\widehat{G}(e^{j\varphi h})^*\widehat{G}(e^{j\varphi h})$ described in Proposition 2.4 is a singular value of $\widehat{G}(e^{j\varphi h})$ larger than d_{11}, including multiplicity [24, p. 214]. Furthermore, unless there are infinitely many eigenvalues of $\widehat{G}(e^{j\varphi h})^*\widehat{G}(e^{j\varphi h})$ strictly larger than d_{11}^2, the number d_{11} is also a singular value of $\widehat{G}(e^{j\varphi h})$ (in which case, d_{11} is the smallest singular value of infinite multiplicity). In the following, the ith singular value of an operator is denoted by $s_i(\cdot)$, where $s_1(\cdot) \geq s_2(\cdot) \geq \cdots \geq 0$. Then $\lim_{i\to\infty} s_i(\widehat{G}(e^{j\varphi h})) = d_{11}$, and the maximum singular value $s_1(\widehat{G}(e^{j\varphi h}))$ (which could be equal to d_{11}) equals $\|\widehat{G}(e^{j\varphi h})\|$ [24]. The same holds true for Proposition 2.5 regarding the singular values and norm of $\mathcal{D}$. It will be helpful to keep in mind the above propositions as well as these definitions of singular values in the following arguments.

3. Bisection method and problem descriptions. For the case in which $\widehat{G}(e^{j\varphi h})$ is a compact operator, a quite efficient and reliable method for the computation of $\|\widehat{G}(e^{j\varphi h})\|$ (as well as $s_i(\widehat{G}(e^{j\varphi h}))$) was developed recently [22]. Given $\gamma > 0$, this method reduces the test of the condition $\|\widehat{G}(e^{j\varphi h})\| < \gamma$ or $s_i(\widehat{G}(e^{j\varphi h})) < \gamma$ into a finite-dimensional test, through an infinite-dimensional congruence transformation. Thus a bisection method that deals only with finite-dimensional matrices was established which allows us to compute $\|\widehat{G}(e^{j\varphi h})\|$ or $s_i(\widehat{G}(e^{j\varphi h}))$ to any degree of accuracy.

It is also suggested in [22] that this method can be extended to the noncompact case as well, in principle, to get a finite-dimensional test for $\|\widehat{G}(e^{j\varphi h})\| < \gamma$. In this section, we explicitly describe the extension to the noncompact case; the primary purpose here is to point out that there actually arise a few critical issues in that extension. As it turns out, one might argue that these issues could be serious enough to invalidate the apparent extension to the noncompact case. Indeed, this paper was motivated through an effort to address these issues in full rigor, which will be the topics of the following sections, whereas this section intends to describe the details of the issues.

3.1. Reduction to the compact case. The basic idea for the extension to the noncompact case suggested in [22] is to "remove" the matrix D_{11} so that the resulting frequency response operator becomes compact. This is achieved by the introduction of J-unitary (or unitary) transformations (or loop-shifting) [2, 5]. Note, however, that the way we apply this transformation is quite different from the seemingly related treatment in the sampled-data H_∞ problem [2] in two respects. The first is that we apply it to "remove" D_{11}, while in [2] it was applied to "remove" $\mathcal{D}$. From this difference arises the second difference that γ smaller than $\|\mathcal{D}\|$ (actually, $\|D_{11}\| < \gamma < \|\mathcal{D}\|$) should also be used as opposed to the H_∞ problem setting. Furthermore, we are interested not only in the largest singular value (i.e., the norm) but also in other singular values of the frequency response or compression operator. These differences necessitate quite different arguments in what follows from those in [2], for which basically the small-gain theorem was enough. See, e.g., the proof of Lemma 3.1 and Remark 3.1.

We begin with a routine method of loop-shifting. Suppose that $\gamma > d_{11}(= \|D_{11}\|)$. As is well known, the J-unitary transformation at level γ is

$$\begin{bmatrix} z \\ w \end{bmatrix} = S_\gamma \begin{bmatrix} z_J \\ w_J \end{bmatrix}, \tag{25}$$

where z_J and w_J are newly introduced signals and S_γ is defined by

$$S_\gamma = \begin{bmatrix} \gamma(\gamma^2 I - D_{11}D_{11}^T)^{-1/2} & \gamma(\gamma^2 I - D_{11}D_{11}^T)^{-1/2} D_{11} \\ \gamma^{-1} D_{11}^T(\gamma^2 I - D_{11}D_{11}^T)^{-1/2} & \gamma(\gamma^2 I - D_{11}^T D_{11})^{-1/2} \end{bmatrix}. \tag{26}$$

Defining J_γ as

$$J_\gamma = \begin{bmatrix} I & 0 \\ 0 & -\gamma^2 I \end{bmatrix}, \tag{27}$$

we have

$$S_\gamma^* J_\gamma S_\gamma = J_\gamma. \tag{28}$$

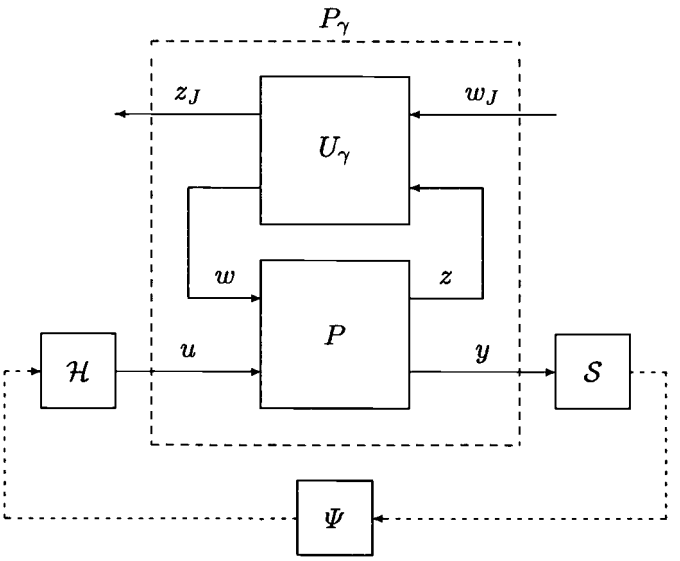

FIG. 2. *J-unitary transformed sampled-data system* Σ_J.

An alternative (equivalent) representation to (25) is

$$\begin{bmatrix} z_J \\ w \end{bmatrix} = U_\gamma \begin{bmatrix} w_J \\ z \end{bmatrix}, \tag{29}$$

where

$$U_\gamma = \begin{bmatrix} -D_{11} & \gamma^{-1}(\gamma^2 I - D_{11}D_{11}^T)^{1/2} \\ \gamma^{-1}(\gamma^2 I - D_{11}^T D_{11})^{1/2} & \gamma^{-2} D_{11}^T \end{bmatrix}. \tag{30}$$

It is easy to see that U_γ is a unitary (orthogonal) matrix when $\gamma = 1$.

Now, the J-unitary transformation at level γ applied to the sampled-data system Σ_s leads to the sampled-data system Σ_J shown in Figure 2. Here, substituting (25) into (1), we can see that P_γ shown in Figure 2 is described by

$$\begin{aligned} \frac{dx}{dt} &= A_\gamma x + B_{1\gamma} w_J + B_{2\gamma} u, \\ z_J &= C_{1\gamma} x + D_{12\gamma} u, \\ y &= C_{2\gamma} x, \end{aligned} \tag{31}$$

where

$$A_\gamma = A + B_1 D_{11}^T (\gamma^2 I - D_{11} D_{11}^T)^{-1} C_1, \tag{32}$$

$$B_{1\gamma} = \gamma B_1 (\gamma^2 I - D_{11}^T D_{11})^{-1/2}, \quad B_{2\gamma} = B_2 + B_1 D_{11}^T (\gamma^2 I - D_{11} D_{11}^T)^{-1} D_{12}, \tag{33}$$

$$C_{1\gamma} = \gamma (\gamma^2 I - D_{11} D_{11}^T)^{-1/2} C_1, \quad C_{2\gamma} = C_2, \tag{34}$$

$$D_{12\gamma} = \gamma (\gamma^2 I - D_{11} D_{11}^T)^{-1/2} D_{12}. \tag{35}$$

Since the sampled-data system Σ_J is nothing but Σ_s with P replaced by P_γ, we can readily introduce the frequency response operator $\widehat{G}_\gamma(e^{j\varphi h})$ for Σ_J. Defining $\mathcal{A}_\gamma$, $\mathcal{B}_\gamma$, $\mathcal{C}_\gamma$, and $\mathcal{D}_\gamma$ corresponding to (9), (10), (11), and (12), respectively, $\widehat{G}_\gamma(e^{j\varphi h})$ is formally given by

$$\widehat{G}_\gamma(e^{j\varphi h}) = \mathcal{C}_\gamma(e^{j\varphi h}I - \mathcal{A}_\gamma)^{-1}\mathcal{B}_\gamma + \mathcal{D}_\gamma. \tag{36}$$

Also, comparing (31) with (1), we can see that "D_{11} has been removed." Therefore, $\mathcal{D}_\gamma$ and hence $\widehat{G}_\gamma(e^{j\varphi h})$ are both compact operators. This is one of the well-known important properties of the J-unitary transformation; the following lemma gives another quite important property, which corresponds to the rigorous arguments for what has been suggested in [17] as to the treatment of nonzero D_{11} matrices. Note, however, that the strengthened assertion for the singular values for the sampled-data system is nontrivial; at least loop-shifting is usually not intended to yield such properties.

LEMMA 3.1. *For each $\gamma > d_{11}$ such that $e^{j\varphi h}I - \mathcal{A}_\gamma$ is invertible, we have that $\|\widehat{G}_\gamma(e^{j\varphi h})\| < \gamma$ if and only if $\|\widehat{G}(e^{j\varphi h})\| < \gamma$. More generally, for each $\gamma > d_{11}$ such that $e^{j\varphi h}I - \mathcal{A}_\gamma$ is invertible and for every positive integer i, we have that $s_i(\widehat{G}_\gamma(e^{j\varphi h})) < \gamma$ if and only if $s_i(\widehat{G}(e^{j\varphi h})) < \gamma$.*

Since $\|\widehat{G}(e^{j\varphi h})\|$ or $s_i(\widehat{G}(e^{j\varphi h}))$ is no less than d_{11} as mentioned in the preceding section, it is enough to use γ larger than d_{11} when we compute $\|\widehat{G}(e^{j\varphi h})\|$ or $s_i(\widehat{G}(e^{j\varphi h}))$ with a bisection method. Thus the above lemma implies that the computation of the norm or singular values of the noncompact operator $\widehat{G}(e^{j\varphi h})$ with a bisection method can be reduced essentially to the computation of those of the compact operator $\widehat{G}_\gamma(e^{j\varphi h})$.

Proof of Lemma 3.1. First note that S_γ is invertible with its inverse given by

$$S_\gamma^{-1} = \begin{bmatrix} \gamma(\gamma^2 I - D_{11}D_{11}^T)^{-1/2} & -\gamma(\gamma^2 I - D_{11}D_{11}^T)^{-1/2}D_{11} \\ -\gamma^{-1}D_{11}^T(\gamma^2 I - D_{11}D_{11}^T)^{-1/2} & \gamma(\gamma^2 I - D_{11}^T D_{11})^{-1/2} \end{bmatrix}. \tag{37}$$

Hence it is easy to see from (25) that w and z are SD-sinusoids of angular frequency φ if and only if w_J and z_J are. In other words, for each $\gamma > d_{11}$, the J-unitary transformation induces a one-to-one correspondence between the input and output SD-sinusoids of angular frequency φ consistent with the sampled-data system Σ_s and those consistent with the sampled-data system Σ_J.

Now, suppose that $s_i(\widehat{G}(e^{j\varphi h})) < \gamma$ or, equivalently (by the min-max characterization of singular values [25]),

$$\inf_{\mathcal{V}} \|\widehat{G}(e^{j\varphi h})|\mathcal{V}\| < \gamma, \tag{38}$$

where $\widehat{G}(e^{j\varphi h})|\mathcal{V}$ stands for the restriction of $\widehat{G}(e^{j\varphi h})$ to $\mathcal{V}$, and $\mathcal{V}$ ranges over the closed subspaces of $\mathcal{K}$ of codimension at most $i-1$. Then there exists some $\mathcal{V}$ of codimension at most $i-1$ such that $\|\widehat{G}(e^{j\varphi h})|\mathcal{V}\| < \gamma$. Hence we have some $\varepsilon > 0$ such that

$$\|\widehat{z}_0\|_{\mathcal{K}}^2 - (\gamma^2 - \varepsilon)\|\widehat{w}_0\|_{\mathcal{K}}^2 \le 0 \tag{39}$$

for every pair of the input and output SD-sinusoids consistent with the sampled-data system Σ_s such that $\widehat{w}_0 \in \mathcal{V}$. Here, by (27), the inequality (39) can be rearranged as

$$\int_0^h \begin{bmatrix} \widehat{z}_0(\theta) \\ \widehat{w}_0(\theta) \end{bmatrix}^* J_\gamma \begin{bmatrix} \widehat{z}_0(\theta) \\ \widehat{w}_0(\theta) \end{bmatrix} d\theta + \varepsilon\|\widehat{w}_0\|_{\mathcal{K}}^2 \le 0. \tag{40}$$

By (25) and (28), this inequality can be rearranged further as

$$\int_0^h \begin{bmatrix} \widehat{z}_{J0}(\theta) \\ \widehat{w}_{J0}(\theta) \end{bmatrix}^* J_\gamma \begin{bmatrix} \widehat{z}_{J0}(\theta) \\ \widehat{w}_{J0}(\theta) \end{bmatrix} d\theta + \varepsilon \|\widehat{w}_0\|_{\mathcal{K}}^2 \le 0 \tag{41}$$

or, equivalently,

$$\|\widehat{z}_{J0}\|_{\mathcal{K}}^2 - \gamma^2 \|\widehat{w}_{J0}\|_{\mathcal{K}}^2 + \varepsilon \|\widehat{w}_0\|_{\mathcal{K}}^2 \le 0. \tag{42}$$

Now, denoting the maximum singular value of S_γ^{-1} by σ_γ, we can see from (25) that

$$\begin{aligned} \|\widehat{w}_{J0}\|_{\mathcal{K}}^2 &\le \left\| \begin{bmatrix} \widehat{z}_{J0} \\ \widehat{w}_{J0} \end{bmatrix} \right\|_{\mathcal{K}}^2 \\ &\le \sigma_\gamma^2 \left\| \begin{bmatrix} \widehat{z}_0 \\ \widehat{w}_0 \end{bmatrix} \right\|_{\mathcal{K}}^2 \\ &= \sigma_\gamma^2 (\|\widehat{z}_0\|_{\mathcal{K}}^2 + \|\widehat{w}_0\|_{\mathcal{K}}^2) \\ &\le \sigma_\gamma^2 (1+\gamma^2) \|\widehat{w}_0\|_{\mathcal{K}}^2. \end{aligned} \tag{43}$$

Substituting the above into (42), we have

$$\|\widehat{z}_{J0}\|_{\mathcal{K}}^2 - \gamma^2 \|\widehat{w}_{J0}\|_{\mathcal{K}}^2 + \varepsilon_1 \|\widehat{w}_{J0}\|_{\mathcal{K}}^2 \le 0, \tag{44}$$

where

$$\varepsilon_1 = \frac{\varepsilon}{\sigma_\gamma^2 (1+\gamma^2)} > 0. \tag{45}$$

As $\widehat{w}_0$ ranges over $\mathcal{V}$, it is obvious that $\widehat{w}_{J0}$ ranges over some closed subspace $\mathcal{V}_J$ of $\mathcal{K}$ of codimension at most $i-1$ since

$$S_\gamma^{-1} \begin{bmatrix} \widehat{G}(e^{j\varphi h}) \\ I \end{bmatrix} \widehat{w}_0 = \begin{bmatrix} \widehat{G}_\gamma(e^{j\varphi h}) \\ I \end{bmatrix} \widehat{w}_{J0}. \tag{46}$$

Hence (44) implies $\|\widehat{G}_\gamma(e^{j\varphi h})|\mathcal{V}_J\| < \gamma$. Thus we have $s_i(\widehat{G}_\gamma(e^{j\varphi h})) < \gamma$.

Conversely, we can show that $s_i(\widehat{G}_\gamma(e^{j\varphi h})) < \gamma$ implies $s_i(\widehat{G}(e^{j\varphi h})) < \gamma$ in a similar way. This completes the proof. □

3.2. Reduction to a finite-dimensional problem. Let us defer the computation of $s_i(\widehat{G}(e^{j\varphi h}))$ to section 6 and confine ourselves to the computation of $\|\widehat{G}(e^{j\varphi h})\|$ here for simplicity. As mentioned before, Lemma 3.1 shows that computing the norm of the noncompact operator $\widehat{G}(e^{j\varphi h})$ can be reduced essentially to computing the norm of the compact operator $\widehat{G}_\gamma(e^{j\varphi h})$. The latter computation has been studied rather intensively in the literature; see, e.g., [13, 14, 18, 20, 21, 22]. Among them, the bisection method developed in [22] will be the best method to use in our context, partly because it is known to be quite efficient, but more importantly because we need only to know whether or not $\|\widehat{G}_\gamma(e^{j\varphi h})\| < \gamma$ for the given number γ; it is meaningless to compute the value itself of $\|\widehat{G}_\gamma(e^{j\varphi h})\|$ exactly. The techniques developed in [22] allow us to check if $\|\widehat{G}_\gamma(e^{j\varphi h})\| < \gamma$ quite efficiently, whereas other methods [13, 14, 18, 20, 21] can compute only the value itself of $\|\widehat{G}_\gamma(e^{j\varphi h})\|$.

Thus, in the following, we focus on the arguments developed in [22]. Also, as in [22], let us introduce the notation $\mathrm{N}(\cdot)$; for a finite-dimensional Hermitian matrix X,

the expression $\mathrm{N}(X) = (q_1, q_2)$ implies that X has q_1 repeated zero eigenvalues, while it has q_2 negative eigenvalues (counted according to multiplicities). Also, the size of the square matrix $\mathcal{A}$ is denoted by n (i.e., $n := \dim(x)+\dim(\xi)$, where x and ξ are as in (1) and (2), respectively). Then we can obtain the following theorem, which provides a method to check if $\|\widehat{G}(e^{j\varphi h})\| < \gamma$ with only finite-dimensional computations.

THEOREM 3.2. *Let $\gamma > d_{11}$. Suppose that $e^{j\varphi h}I - \mathcal{A}_\gamma$ is invertible and γ is not a singular value of $\mathcal{D}_\gamma$. Let ν be the number (counted according to multiplicities) of the singular values of $\mathcal{D}_\gamma$ larger than γ. Then the following three conditions are equivalent:*

$$\text{(i)} \quad \|\widehat{G}(e^{j\varphi h})\| < \gamma, \tag{47}$$

$$\text{(ii)} \quad \|\widehat{G}_\gamma(e^{j\varphi h})\| < \gamma, \tag{48}$$

$$\text{(iii)} \quad N(F_\gamma(e^{j\varphi h}, \gamma)) = (0, n-\nu). \tag{49}$$

Here $F_\gamma(z,\lambda)$ is a Hermitian matrix given by

$$F_\gamma(z,\lambda) = \begin{bmatrix} 0 & zI - \widetilde{E} \\ z^*I - \widetilde{E}^T & 0 \end{bmatrix} - \begin{bmatrix} \widetilde{B} & 0 \\ 0 & \widetilde{C}^T \end{bmatrix} L(\lambda) \begin{bmatrix} \widetilde{B}^T & 0 \\ 0 & \widetilde{C} \end{bmatrix}, \tag{50}$$

$$\widetilde{E} = \begin{bmatrix} 0 & 0 \\ B_\Psi C_{2\gamma} & A_\Psi \end{bmatrix}, \quad \widetilde{B} = \begin{bmatrix} I \\ 0 \end{bmatrix}, \quad \widetilde{C} = \begin{bmatrix} I & 0 \\ D_\Psi C_{2\gamma} & C_\Psi \end{bmatrix}, \tag{51}$$

$$L(\lambda) = \begin{bmatrix} \Gamma_{21} & \Gamma_{22} & \Gamma_{23} \\ I & 0 & 0 \\ \Gamma_{41} & \Gamma_{42} & \Gamma_{43} \end{bmatrix} \begin{bmatrix} \Gamma_{11} & \Gamma_{12} & \Gamma_{13} \\ 0 & I & 0 \\ 0 & 0 & I \end{bmatrix}^{-1}, \tag{52}$$

with Γ_{ij} defined by

$$\begin{bmatrix} \Gamma_{11} & \Gamma_{12} & \Gamma_{13} & 0 \\ \Gamma_{21} & \Gamma_{22} & \Gamma_{23} & 0 \\ 0 & 0 & I & 0 \\ \Gamma_{41} & \Gamma_{42} & \Gamma_{43} & I \end{bmatrix} = \exp\left(\begin{bmatrix} -A_\gamma^T & \frac{1}{\lambda} C_{1\gamma}^T C_{1\gamma} & \frac{1}{\lambda} C_{1\gamma}^T D_{12\gamma} & 0 \\ \frac{1}{\lambda} B_{1\gamma} B_{1\gamma}^T & A_\gamma & B_{2\gamma} & 0 \\ 0 & 0 & 0 & 0 \\ B_{2\gamma}^T & \frac{1}{\lambda} D_{12\gamma}^T C_{1\gamma} & \frac{1}{\lambda} D_{12\gamma}^T D_{12\gamma} & 0 \end{bmatrix} h \right). \tag{53}$$

In this theorem, the equivalence between (i) and (ii) has been proved in Lemma 3.1. On the other hand, the equivalence between (ii) and (iii) follows readily by applying entirely the same arguments as in [22]. Basically, what has been suggested in [22] as to the extension to the noncompact (i.e., nonzero D_{11}) case is just the qualitative fact that these two equivalence relations will still reduce the computation for the noncompact case into finite-dimensional computations.

However, in view of the definite statement of Theorem 3.2, it will be natural to ask the following questions:

- What should we do if $e^{j\varphi h}I - \mathcal{A}_\gamma$ happens to be noninvertible?
- What should we do if γ happens to be a singular value of $\mathcal{D}_\gamma$?

Intuitively, it might be expected that γ could be perturbed slightly to avoid such situations; a bisection method will still work even with such a perturbation on γ. In fact, when $D_{11} = 0$, the first situation never occurs, and the second situation can be avoided by such a perturbation, as can be seen easily. In the noncompact case, however, it is not trivial if a slight perturbation of γ would always resolve the difficulty, especially because $e^{j\varphi h}I - \mathcal{A}_\gamma$ and $\mathcal{D}_\gamma$ are dependent on γ. Even though it might look unlikely, it could possibly be the case that, over an open interval with respect to γ, $e^{j\varphi h}I - \mathcal{A}_\gamma$ is noninvertible and/or $\mathcal{D}_\gamma$ has γ as one of its singular values. If this is really the case, the situation is quite serious since it implies that we have no simple way to check if $\|\widehat{G}(e^{j\varphi h})\| < \gamma$ for such γ lying on the open interval.

Remark 3.1. The situation here is again quite different from the H_∞ problem, in which case the first type of question is always irrelevant. This is because $\gamma > \|\mathcal{D}\|$ can be assumed without loss of generality, and thus the stability of the matrix corresponding to $\mathcal{A}_\gamma$ can be ensured simply by the small-gain theorem (see [2] for details). However, here we need to consider much smaller γ, too, and thus $\mathcal{A}_\gamma$ can become unstable. One trivial example for this instability can be seen by considering the case with $\Psi = 0$, $\dim(x) = \dim(w) = \dim(z) = 1$, and $\gamma \downarrow d_{11}$. In the H_∞ problem, the second question is also irrelevant, which can be seen by Corollary 5.3.

In the first half of the remainder of this paper, we study the above issues and show that a slight perturbation of γ indeed resolves the difficulty; the first question will be dealt with in section 4, and the second will be dealt with in section 5. The second half, section 6, deals with an extension to singular value computations.

4. The case of noninvertible $e^{j\varphi h}I - \mathcal{A}_\gamma$. In this section, we study the case in which $e^{j\varphi h}I - \mathcal{A}_\gamma$ is noninvertible. We first show that such γ is always a strict lower bound of the frequency response gain $\|\widehat{G}(e^{j\varphi h})\|$. From this fact, we further show that the invertibility assumption of $e^{j\varphi h}I - \mathcal{A}_\gamma$ can actually be removed from Theorem 3.2.

4.1. Characterization of γ as a strict lower bound. Let us consider the "unforced" sampled-data system Σ_u shown in Figure 3. It is straightforward to see that the continuous-time part of this system is described by

$$\begin{aligned} \frac{dx}{dt} &= A_\gamma x + B_{2\gamma} u, \\ y &= C_{2\gamma} x, \end{aligned} \tag{54}$$

where A_γ, $B_{2\gamma}$, and $C_{2\gamma}$ are as given in (32), (33), and (34), respectively. Hence it follows that the state transition matrix of the discrete-time system (which we denote by Σ_{ud}) equivalent to Σ_u viewed at every sampling period h is equal to $\mathcal{A}_\gamma$, which has been derived through the application of the J-unitary transformation (recall subsection 3.1). In other words, the assumption that $e^{j\varphi h}I - \mathcal{A}_\gamma$ is noninvertible is nothing but the assumption that Σ_u (or Σ_{ud}) has a mode at $e^{j\varphi h}$. Thus, in this case, the unforced system Σ_{ud} has a nontrivial solution of the following form with some $[x(0)^T,\ \xi_0^T]^T$ $(\neq 0)$:

$$\begin{bmatrix} x(kh) \\ \xi_k \end{bmatrix} = \begin{bmatrix} x(0) \\ \xi_0 \end{bmatrix} e^{j\varphi kh}. \tag{55}$$

On the other hand, the lifted representation of w and z for the unforced system Σ_u can be described, by the linearity of Σ_u, as

$$\widehat{w}_k(\theta) = L_w(\theta) \begin{bmatrix} x(kh) \\ \xi_k \end{bmatrix}, \quad \widehat{z}_k(\theta) = L_z(\theta) \begin{bmatrix} x(kh) \\ \xi_k \end{bmatrix} \quad (0 \le \theta < h) \tag{56}$$

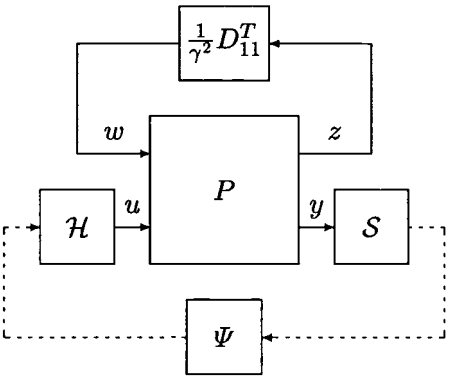

FIG. 3. *Unforced sampled-data system* Σ_u.

with some appropriate matrices $L_w(\theta)$ and $L_z(\theta)$. Substituting (55) into the above equation, we can see that Σ_u has a (nontrivial) solution of the form

$$\widehat{w}_k = \widehat{w}_0 e^{j\varphi kh}, \quad \widehat{z}_k = \widehat{z}_0 e^{j\varphi kh}, \tag{57}$$

where

$$\widehat{w}_0 = L_w \begin{bmatrix} x(0) \\ \xi_0 \end{bmatrix}, \quad \widehat{z}_0 = L_z \begin{bmatrix} x(0) \\ \xi_0 \end{bmatrix}. \tag{58}$$

Since (57) are SD-sinusoids, we have

$$\widehat{z}_0 = \widehat{G}(e^{j\varphi h})\widehat{w}_0 \tag{59}$$

by the definition of the frequency response operator (recall the discussions above Definition 2.1).

Now, from Figure 3, we readily have

$$\widehat{w}_0 = \frac{1}{\gamma^2} D_{11}^* \widehat{z}_0. \tag{60}$$

Substituting the above into (59), we have

$$\left(I - \frac{1}{\gamma^2} \widehat{G}(e^{j\varphi h}) D_{11}^* \right) \widehat{z}_0 = 0. \tag{61}$$

Here we can show that $\widehat{z}_0 \not\equiv 0$. To see this, suppose the contrary. Then we have $\widehat{w}_0 \equiv 0$ by (60), which implies that $w \equiv 0$. In this case, the unforced system Σ_u is nothing but the stable sampled-data system Σ_s so that it can never have the nontrivial solution like (55). By contradiction, we have that $\widehat{z}_0 \not\equiv 0$. Hence (61) implies that γ^2 is an eigenvalue of $\widehat{G}(e^{j\varphi h})D_{11}^*$ with $\widehat{z}_0$ being the corresponding eigenvector. It follows that $\|\widehat{G}(e^{j\varphi h})D_{11}^*\| \geq \gamma^2$, and thus we have

$$\|\widehat{G}(e^{j\varphi h})\| \cdot d_{11} \geq \gamma^2. \tag{62}$$

Since $\gamma > d_{11}$ by assumption, we have

$$\|\widehat{G}(e^{j\varphi h})\| > \gamma. \tag{63}$$

Namely, we have established that such γ that makes $e^{j\varphi h}I - \mathcal{A}_\gamma$ noninvertible is a (strict) lower bound of the frequency response gain $\|\widehat{G}(e^{j\varphi h})\|$.

Furthermore, the above arguments, in particular, lead to the following result.

LEMMA 4.1. *Let Γ be the set of $\gamma > d_{11}$ such that $e^{j\varphi h}I - \mathcal{A}_\gamma$ is noninvertible (for a fixed φ). Then every point in Γ is an isolated point of Γ.*

Proof. The above arguments imply that for every $\gamma \in \Gamma$, γ^2 is an eigenvalue of $\widehat{G}(e^{j\varphi h})D_{11}^*$. Hence the assertion follows readily from Lemma 2.3. □

4.2. Continuity study. The fact shown in the preceding subsection is in some sense enough to answer the first question raised in the preceding section; with the knowledge that γ is a lower bound, a bisection method can be continued without any problem. However, the following further study will be of more interest and value; the aim of this study is to show that we do not need to check if $e^{j\varphi h}I - \mathcal{A}_\gamma$ is invertible after all.

In the following, we assume that γ is such a value that makes $e^{j\varphi h}I - \mathcal{A}_\gamma$ noninvertible. Then, by Lemma 4.1, there exists an open interval $\mathcal{I}$ on the positive real axis containing γ such that $\mathcal{I}$ contains no point in Γ other than γ. Note that we can take $\mathcal{I}$ so that $\|\widehat{G}(e^{j\varphi h})\| > \widetilde{\gamma}$ whenever $\widetilde{\gamma} \in \mathcal{I}$ because of the strict inequality (63). Now, for each $\widetilde{\gamma} \in \mathcal{I} \setminus \{\gamma\}$, the matrix $\mathcal{A}_{\widetilde{\gamma}}$ is invertible by the construction of $\mathcal{I}$. Now let us further assume that γ is not a singular value of $\mathcal{D}$. Note that this assumption is almost always satisfied (Proposition 2.5). Furthermore, as we show in the following section (Proposition 5.1), this assumption is equivalent to the assumption that γ is not a singular value of $\mathcal{D}_\gamma$. Hence, by continuity together with compactness of $\mathcal{D}_\gamma$, we may assume, by taking the interval $\mathcal{I}$ sufficiently small, that the number of the singular values of $\mathcal{D}_{\widetilde{\gamma}}$ larger than $\widetilde{\gamma}$ is constant over $\mathcal{I}$, which we denote by ν. Note that this assumption, in particular, implies that $\widetilde{\gamma}$ is not a singular value of $\mathcal{D}_{\widetilde{\gamma}}$ (for all $\widetilde{\gamma} \in \mathcal{I}$). From all of the considerations above, we can apply Theorem 3.2 for $\widetilde{\gamma}$ to get

$$\mathrm{N}(F_{\widetilde{\gamma}}(e^{j\varphi h}, \widetilde{\gamma})) \neq (0, n-\nu) \quad \forall\, \widetilde{\gamma} \in \mathcal{I} \setminus \{\gamma\}. \tag{64}$$

Now, from the definition of the matrix $F_{\widetilde{\gamma}}(z, \widetilde{\gamma})$ shown in Theorem 3.2 and from the fact that $\widetilde{\gamma}$ is not a singular value of $\mathcal{D}_{\widetilde{\gamma}}$ (for all $\widetilde{\gamma} \in \mathcal{I}$), it follows that the matrix $F_{\widetilde{\gamma}}(e^{j\varphi h}, \widetilde{\gamma})$ has continuous entries over $\mathcal{I}$.

Here let us suppose that $F_\gamma(e^{j\varphi h}, \gamma)$ is invertible because otherwise we would obviously have that

$$\mathrm{N}(F_\gamma(e^{j\varphi h}, \gamma)) \neq (0, n-\nu). \tag{65}$$

Then, by continuity, there exists some open interval $\mathcal{I}_1 (\subset \mathcal{I})$ containing γ such that $F_{\widetilde{\gamma}}(e^{j\varphi h}, \widetilde{\gamma})$ is invertible for every $\widetilde{\gamma} \in \mathcal{I}_1$. Moreover, the number of the negative eigenvalues of $F_{\widetilde{\gamma}}(e^{j\varphi h}, \widetilde{\gamma})$ must be constant over $\mathcal{I}_1$, again by continuity. Since this constant number is not equal to $n - \nu$ by (64), we are led to the same conclusion as (65) after all. Hence we can conclude that (65) holds whenever $e^{j\varphi h}I - \mathcal{A}_\gamma$ is noninvertible as long as γ is not a singular value of $\mathcal{D}_\gamma$.

Thus we arrive at the following theorem, as claimed.

THEOREM 4.2. *Suppose that $\gamma > d_{11}$ and γ is not a singular value of $\mathcal{D}_\gamma$. Let ν be the number of the singular values of $\mathcal{D}_\gamma$ larger than γ. Then conditions* (i) *and* (iii) *of Theorem* 3.2 *are equivalent.*

Proof. Given Theorem 3.2, it is enough to consider the case in which $e^{j\varphi h}I - \mathcal{A}_\gamma$ is noninvertible. In this case, however, condition (iii) of Theorem 3.2 never holds as

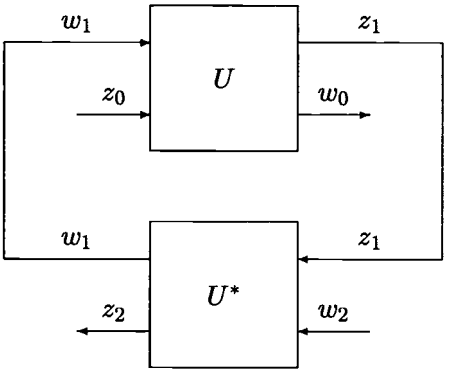

FIG. 4. *Identity system.*

we showed above. Hence it is enough to show that condition (i) never holds either. However, this follows readily from (63). □

5. The relationship between the singular values of $\mathcal{D}$ and $\mathcal{D}_\gamma$. The purpose of this section is to study the second question raised in subsection 3.2. To this end, the following proposition plays a key role, and thus most of this section is devoted to its proof. Note that, unlike in the preceding section, we have no grounds to introduce a nonzero initial state in the arguments of this section, and thus we indeed avoid doing so.

PROPOSITION 5.1. *Suppose that $\gamma > d_{11}$. Then γ is a singular value of $\mathcal{D}_\gamma$ with multiplicity m if and only if it is a singular value of $\mathcal{D}$ with the same multiplicity.*

Since each $\gamma > d_{11}$ in the set of the singular values of $\mathcal{D}$ is an isolated point of this set by Proposition 2.5, the importance of Proposition 5.1 lies in guaranteeing that the second question raised in section 3 can always be circumvented by a slight perturbation of γ. Note that this proposition also played some role in the preceding section, where the first question raised in section 3 was studied.

To prove the above proposition, the following lemma is quite useful.

LEMMA 5.2. *Let $\gamma > d_{11}$, and consider the system shown in Figure* 4, *where U is an operator on $\mathcal{K}$ corresponding to the matrix U given by*

$$U = \begin{bmatrix} -\gamma^{-1}D_{11} & (I-\gamma^{-2}D_{11}D_{11}^T)^{1/2} \\ (I-\gamma^{-2}D_{11}^TD_{11})^{1/2} & \gamma^{-1}D_{11}^T \end{bmatrix}. \tag{66}$$

Then we have $z_0 = z_2$ and $w_0 = w_2$.

Proof. The above matrix U is a unitary matrix with its upper-right block being invertible. Hence, as is well known, e.g., in the circuit theory, we have $z_0(t) = z_2(t)$ and $w_0(t) = w_2(t)$ for each t. Thus the assertion follows readily. □

Given the above lemma, Proposition 5.1 can be proved as follows.

Proof of Proposition 5.1. Comparing the above matrix U with U_γ given in (30), we can see that

$$U = \begin{bmatrix} \gamma^{-1}I & 0 \\ 0 & I \end{bmatrix} U_\gamma \begin{bmatrix} I & 0 \\ 0 & \gamma I \end{bmatrix}. \tag{67}$$

On the other hand, from Figure 4, we have

$$\begin{bmatrix} z_1 \\ w_0 \end{bmatrix} = U \begin{bmatrix} w_1 \\ z_0 \end{bmatrix}. \tag{68}$$

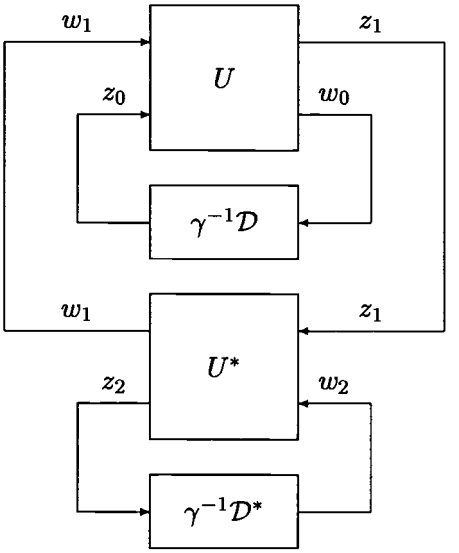

FIG. 5. *System* Σ_{c1}.

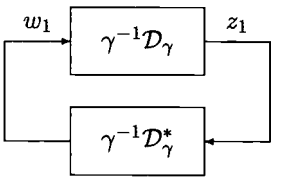

FIG. 6. *System* Σ_{c2}.

Hence, from (67), we obtain

$$\begin{bmatrix} \gamma z_1 \\ w_0 \end{bmatrix} = U_\gamma \begin{bmatrix} w_1 \\ \gamma z_0 \end{bmatrix}. \tag{69}$$

Here let us consider closing the loop between w_0 and z_0 by $z_0 = \gamma^{-1}\mathcal{D}w_0$ as in the system Σ_{c1} shown in Figure 5, and let us rewrite w_0 as w. Then we have $\gamma z_0 = z$, where $z = \mathcal{D}w$ is the output of $\mathcal{D}$ to the input w. Hence (69) can be rewritten as

$$\begin{bmatrix} \gamma z_1 \\ w \end{bmatrix} = U_\gamma \begin{bmatrix} w_1 \\ z \end{bmatrix}. \tag{70}$$

Comparing this equation with (29), we can see that w_1 may be identified with w_J, while z_1 may be identified with γ^{-1} times z_J. Since the J-unitary transformation associated with U_γ transforms $\mathcal{D}$ into $\mathcal{D}_\gamma$, we can see that the map from w_1 to z_1 in Figure 5 is nothing but $\gamma^{-1}\mathcal{D}_\gamma$. Similarly, the map from z_1 to w_1 in the same figure is nothing but $\gamma^{-1}\mathcal{D}_\gamma^*$. Thus we can see that the signals w_1 and z_1 in the system Σ_{c1} shown in Figure 5 are equivalent to those in the system Σ_{c2} shown in Figure 6. On the other hand, the signals w_0 and z_0 in the system Σ_{c1} are equivalent to those in the system Σ_{c3} shown in Figure 7 by Lemma 5.2. Now, since (68) can be rearranged as

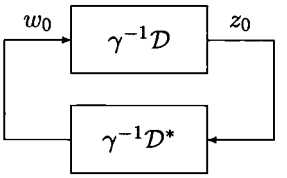

FIG. 7. *System* Σ_{c3}.

$$\begin{bmatrix} z_0 \\ w_0 \end{bmatrix} = S \begin{bmatrix} z_1 \\ w_1 \end{bmatrix}, \tag{71}$$

where S is given by

$$S = \begin{bmatrix} \gamma(\gamma^2 I - D_{11}D_{11}^T)^{-1/2} & (\gamma^2 I - D_{11}D_{11}^T)^{-1/2}D_{11} \\ D_{11}^T(\gamma^2 I - D_{11}D_{11}^T)^{-1/2} & \gamma(\gamma^2 I - D_{11}^T D_{11})^{-1/2} \end{bmatrix} \tag{72}$$

and is invertible, we can see that Σ_{c1} has m pairs of nontrivial solutions (w_0, z_0) if and only if it has m pairs of nontrivial solutions (w_1, z_1). Combining the above arguments, we are led to the conclusion that Σ_{c2} has m nontrivial solutions (w_1 and/or z_1) if and only if Σ_{c3} has the same number of nontrivial solutions (w_0 and/or z_0). Obviously, this implies that γ^2 is an eigenvalue of $\mathcal{D}_\gamma^*\mathcal{D}_\gamma$ with multiplicity m if and only if it is an eigenvalue of $\mathcal{D}^*\mathcal{D}$ with the same multiplicity, which completes the proof of Proposition 5.1. □

COROLLARY 5.3. *Let* $\gamma > d_{11}$. *Then* $\mathcal{D}_\gamma$ *has* ν *singular values larger than* γ *if and only if* $\mathcal{D}$ *has* ν *singular values larger than* γ.

Proof. The assertion follows readily from Proposition 5.1 if we note that the system $(C_{1\gamma}, A_\gamma, B_{1\gamma})$ tends to the γ-independent system (C_1, A, B_1) as $\gamma \to \infty$ and that the singular values of the compact operator $\mathcal{D}_\gamma$ are continuous with respect to γ [26, p. 57]. □

The above result is useful for computing the singular values of the noncompact compression operator $\mathcal{D}$, which will be discussed at the end of the following section. Furthermore, observe that, by Proposition 5.1 and Corollary 5.3, the statement of Theorem 4.2 can be restated further in the following "more natural" form.

THEOREM 5.4. *Suppose that* $\gamma > d_{11}$ *and* γ *is not a singular value of* $\mathcal{D}$. *Let* ν *be the number of the singular values of* $\mathcal{D}$ *larger than* γ. *Then conditions* (i) *and* (iii) *of Theorem* 3.2 *are equivalent.*

This theorem shows that we can check if condition (i) is true only by the finite-dimensional computations regarding condition (iii), where the only difficulty is the computation of the number ν. As will be discussed at the end of the following subsection, however, this can also be carried out with only finite-dimensional computations. Thus the problem of establishing a bisection method for the frequency response gain computation for the noncompact case has now been resolved completely.

6. Computations of the singular values of the frequency response and compression operators. In this section, we study a related topic on the singular values of the frequency response operator $\widehat{G}(e^{j\varphi h})$ and the compression operator $\mathcal{D}$. First, the following result is a direct consequence of Lemma 3.1.

COROLLARY 6.1. *Suppose that $\gamma > d_{11}$ and $e^{j\varphi h}I - \mathcal{A}_\gamma$ is invertible. Then $\widehat{G}_\gamma(e^{j\varphi h})$ has ν singular values larger than γ if and only if $\widehat{G}(e^{j\varphi h})$ has ν singular values larger than γ.*

This, together with Lemma 4.1 and a continuity argument as in the proof of Corollary 5.3, leads to the following result.

PROPOSITION 6.2. *Suppose that $\gamma > d_{11}$ and $e^{j\varphi h}I - \mathcal{A}_\gamma$ is invertible. Then γ is a singular value of $\widehat{G}_\gamma(e^{j\varphi h})$ with multiplicity m if and only if it is a singular value of $\widehat{G}(e^{j\varphi h})$ with the same multiplicity.*

Observe that the order of the discussions here is the opposite of that in the preceding section in that Corollary 5.3 was derived from Proposition 5.1 in the preceding section, while Proposition 6.2 was derived from Corollary 6.1 in this subsection. This is because, in the preceding section, we had to avoid the introduction of a nonzero initial state (and hence such a type of argument similar to Lemma 3.1 was not possible), and thus we had to employ a quite different approach there, even though these two problems are apparently quite similar.

Now, from the study in the case of compact operators [13, 22], it is known that, as long as γ is not a singular value of $\mathcal{D}_\gamma$ (or, equivalently, $\mathcal{D}$), the matrix $F_\gamma(e^{j\varphi h}, \gamma)$ has m repeated eigenvalues at 0 if and only if γ is a singular value of $\widehat{G}_\gamma(e^{j\varphi h})$ with multiplicity m. Hence, by Proposition 6.2 (or Corollary 6.1), we are led to the following result, which can be regarded as a generalization of the state-space formula given in [13] to the noncompact case (see also [27]). Note that the invertibility assumption has been removed in the following result, which can be validated by a continuity argument supported by Lemma 4.1.

COROLLARY 6.3. *Suppose that $\gamma > d_{11}$ and that γ is not a singular value of $\mathcal{D}$. Then γ is a singular value of the frequency response operator $\widehat{G}(e^{j\varphi h})$ with multiplicity m if and only if the finite-dimensional matrix $F_\gamma(e^{j\varphi h}, \gamma)$ has m repeated eigenvalues at 0.*

By definition, all of the singular values of $\widehat{G}(e^{j\varphi h})$ are no smaller than d_{11}, with d_{11} being the smallest singular value with infinite multiplicity if there are only a finite number of singular values strictly larger than d_{11} [24]. This, together with Corollary 6.3, implies that we can compute, in principle, all of the singular values of $\widehat{G}(e^{j\varphi h})$, including their multiplicities. A bisection method for their computation based on Corollary 6.1 is given by the following theorem, which is a generalization of Theorem 5.4.

THEOREM 6.4. *Suppose that $\gamma > d_{11}$ and γ is not a singular value of $\mathcal{D}$. Let ν be the number of the singular values of $\mathcal{D}$ larger than γ. Then the following two conditions are equivalent for any nonnegative integer i, where we define $s_0(\cdot) = +\infty$:*

$$\text{(i)} \quad s_{i+1}(\widehat{G}(e^{j\varphi h})) < \gamma < s_i(\widehat{G}(e^{j\varphi h})), \tag{73}$$

$$\text{(ii)} \quad N(F_\gamma(e^{j\varphi h}, \gamma)) = (0, n + i - \nu). \tag{74}$$

The above theorem follows readily by applying entirely the same arguments as in [22]. The only obstacle in the extension is that, when $e^{j\varphi h}I - \mathcal{A}_\gamma$ happens to be noninvertible, we do not necessarily have $s_i(\widehat{G}(e^{j\varphi h})) > \gamma$, unlike in (63). Hence it is not trivial that we can drop the invertibility assumption of $e^{j\varphi h}I - \mathcal{A}_\gamma$ as we did in subsection 4.2. However, if $s_i(\widehat{G}(e^{j\varphi h})) = \gamma$ for some i, then we are led to the conclusion that $F_\gamma(e^{j\varphi h}, \gamma)$ is noninvertible (Corollary 6.3). Namely, condition (ii) of the above theorem fails for any i. Thus the statement of the above theorem leads to the

conclusion that condition (i) fails for any i, as required (because $s_i(\widehat{G}(e^{j\varphi h})) = \gamma$), which validates the statement. If $s_{i+1}(\widehat{G}(e^{j\varphi h})) < \gamma < s_i(\widehat{G}(e^{j\varphi h}))$, on the other hand, we can still develop a continuity argument, as in subsection 4.2, supported by Lemma 4.1, and, again with the aid of Corollary 6.3, we can show that condition (i) holds if and only if condition (ii) holds, even if $e^{j\varphi h}I - \mathcal{A}_\gamma$ is noninvertible. These considerations show that we can actually drop the invertibility assumption of $e^{j\varphi h}I - \mathcal{A}_\gamma$.

If we apply the above theorem to compute the singular values of $\widehat{G}(e^{j\varphi h})$, then, for each given $\gamma > 0$, we have to know the number ν, which is the number of the singular values of the compression operator $\mathcal{D}$ larger than γ. By Corollary 5.3, the number ν is equal to the number of the singular values of the compression operator $\mathcal{D}_\gamma$ larger than γ. Here $\mathcal{D}_\gamma$ is a compact operator, and, for a compact compression operator, there exists a finite-dimensional method to compute the number of its singular values larger than given $\gamma > 0$; see [22] for details. Hence we can compute the number ν for each $\gamma > 0$, and thus we are led to a bisection method for the computation of the singular values of $\widehat{G}(e^{j\varphi h})$ with only finite-dimensional computations. It should be worthwhile emphasizing that the above-mentioned fact that, for each $\gamma > 0$, we can compute the number of the singular values of $\mathcal{D}$ larger than γ, implies that we can actually develop a bisection method for the computation of the singular values (and hence the norm, as well) of the noncompact compression operator $\mathcal{D}$.

7. Conclusion. In this paper, we studied the problem of computing the frequency response gain (to be more precise, the norm and singular values) of general sampled-data systems with a direct feedthrough matrix D_{11}. We first reviewed in section 2 the frequency response operator $\widehat{G}(e^{j\varphi h})$ of such sampled-data systems, and we made a slight but crucial extension on its definition so that nonzero initial states and unstable sampled-data systems can also be dealt with. We also gave some results on the spectra of operators involving or related to $\widehat{G}(e^{j\varphi h})$ for later use. Then, in section 3, we showed a key result, Theorem 3.2, which is a generalization, to the noncompact case, of the result derived in [22]. Although this result is expected to be a theoretical basis for the development of a bisection method for the computation of the frequency response gain $\|\widehat{G}(e^{j\varphi h})\|$ for noncompact $\widehat{G}(e^{j\varphi h})$, we also pointed out two critical issues that could be serious enough to prevent us from arriving at a bisection method (subsection 3.2). Regarding these issues, however, we clarified in section 4 that the first issue (i.e., whether or not $e^{j\varphi h}I - \mathcal{A}_\gamma$ is invertible) is actually irrelevant, and we gave a refined result (Theorem 4.2); we further showed in section 5 that the second issue (regarding the way the singular values of $\mathcal{D}_\gamma$ are dependent on γ) does not either cause a serious problem in the bisection method after all, where the spectral study in section 2 played important roles for these proofs. Hence, as a whole, we have proved up to the slightest details that the bisection method for the computation of the frequency response gain of sampled-data systems with $D_{11} = 0$ (i.e., the compact case) proposed in [22] can be extended to the case of nonzero D_{11} (i.e., the noncompact case). Finally, in section 6, the result was extended to the computation of the singular values of $\widehat{G}(e^{j\varphi h})$ (Theorem 6.4) as well as those of the compression operator $\mathcal{D}$.

To summarize the results on the singular value computations, we have shown the following: the singular values $s_i(\widehat{G}(e^{j\varphi h}))$ are no smaller than $d_{11}(= \|D_{11}\|)$, and given $\gamma > d_{11}$, the condition

$$s_{i+1}(\widehat{G}(e^{j\varphi h})) < \gamma < s_i(\widehat{G}(e^{j\varphi h})) \tag{75}$$

is equivalent to the condition (in terms of the finite-dimensional matrix given in (50))

$$\mathrm{N}(F_\gamma(e^{j\varphi h},\gamma)) = (0, n+i-\nu), \tag{76}$$

with the only exceptions being for such a countable number of γ that is equal to a singular value of $\mathcal{D}$ (for which the matrix $F_\gamma(z,\gamma)$ in (76) cannot be defined), where ν is the number of the singular values of $\mathcal{D}$ larger than γ. Here, once γ is fixed, we can obtain the number ν by computing the eigenvalues of a single finite-dimensional Hermitian matrix, as long as γ is not a singular value of $\mathcal{D}$, and we will never encounter any sort of critical problem in that process, as shown in [22]. Therefore, the condition (75) can be tested with only finite-dimensional computations, with a possible need for a slight perturbation on γ to avoid the singular values of $\mathcal{D}$. This establishes a complete bisection method for the computation of $\|\widehat{G}(e^{j\varphi h})\|$ and $s_i(\widehat{G}(e^{j\varphi h}))$ even in the case of $D_{11} \neq 0$.

ON THE λ-EQUATIONS FOR MATCHING CONTROL LAWS*

DAVID AUCKLY† AND LEV KAPITANSKI†

Abstract. We discuss matching control laws for underactuated systems. We previously showed that this class of matching control laws is completely characterized by a linear system of first order partial differential equations for one set of variables (λ) followed by a linear system of first order partial differential equations for the second set of variables ($\widehat{g}$, $\widehat{V}$). Here we derive a new first order system of partial differential equations that encodes all compatibility conditions for the λ-equations. We give four examples illustrating different features of matching control laws. The last example is a system with two unactuated degrees of freedom that admits only basic solutions to the matching equations. There are systems with many matching control laws where only basic solutions are potentially useful. We introduce a rank condition indicating when this is likely to be the case.

1. Introduction.

Effective procedures for designing control laws are very important in nonlinear control theory. Explicit analytic formulae for control laws play a role similar to that played by explicit solutions to differential equations. Such formulae exist in only a few special cases, but those that exist serve as simple models to develop and test more general techniques.

In this paper, we discuss a class of full state feedback control laws for underactuated systems. In [5], we showed that this class of matching control laws is completely characterized by a linear system of first order partial differential equations for one set of variables (λ) followed by a linear system of first order partial differential equations for the second set of variables ($\widehat{g}$, $\widehat{V}$). These equations always have a simple family of solutions which we call basic solutions. The system of equations for the first set of variables (λ-equations) is overdetermined. Here we derive a new first order system of partial differential equations that encodes all compatibility conditions for the λ-equations. (We call these the ν-equations.) If only one degree of freedom is unactuated, the solutions to all of these systems of partial differential equations can be completely analyzed. It is often possible to get explicit formulae for the solutions to these equations. We also provide an example of a system with two unactuated degrees of freedom that has only basic solutions. There are systems with many matching control laws where only basic solutions are potentially useful. We write down a rank condition indicating when this is likely to be the case (Remark 5.1).

During the last few years, several researchers have investigated control laws in which the closed loop system assumes a certain structure. Numerous papers have been written on this subject; see [1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13] and the references therein. The control laws that form the subject of this present paper are described by (2.4) and (2.6). These equations were independently derived in [10] and [5]. The λ-equations were first introduced in [5]. Even though the initial

matching equations of [10] and [5] form a highly nonlinear system of partial differential equations, introduction of the λ variables triangulates the system. The system is triangulated in the sense that all solutions are obtained by first solving first order linear equations for λ and then solving first order linear equations for the remaining variables.

This paper is organized as follows. Section 2 reviews matching control laws and the λ-equations and introduces the ν-equations. Section 3 specializes to systems with one unactuated degree of freedom. Sections 4, 5, and 6 contain examples illustrating three different features of matching control laws. The rank condition appears at the end of section 5. Later we apply it in section 6. In section 7, we describe the final example of a system with two unactuated degrees of freedom. We show that this system has only basic matching control laws.

2. Matching equations. We use the following notation.

- n is the number of the degrees of freedom of the mechanical system.
- $x = (x^1, \dots, x^n)$ are configuration variables denoting the position of the system, and $\dot{x} = (\dot{x}^1, \dots, \dot{x}^n)$ are the corresponding velocities.
- $g_{ij}(x)$ is the mass matrix.
- $V(x)$ is the potential energy.
- $C_i(x, \dot{x})$ are the dissipation terms.
- $u_i(x, \dot{x})$ are the control inputs.

Let $m \le n$ be the number of unactuated degrees of freedom. We will assume that degrees of freedom numbered 1 through m are unactuated and use indices $a, b, \dots$ to indicate unactuated degrees of freedom. The indices $i, j, \dots$ will run from 1 to n. We adopt the convention of summation over the repeated indices.

Given this, the equations of motion of the system are

$$g_{rj}\ddot{x}^j + [j\,k,\,r]\,\dot{x}^j\,\dot{x}^k + C_r + \frac{\partial V}{\partial x^r} = u_r\,, \quad r = 1, \dots, n, \tag{2.1}$$

where $[i\,j,\,k]$ is the Christoffel symbol of the first kind,

$$[i\,j,\,k] = \frac{1}{2}\left(\frac{\partial g_{jk}}{\partial x^i} + \frac{\partial g_{ik}}{\partial x^j} - \frac{\partial g_{ij}}{\partial x^k}\right). \tag{2.2}$$

Our assumption that the first m degrees of freedom are not actuated means that

$$u_1 = \cdots = u_m = 0. \tag{2.3}$$

We are looking for control laws u_i such that the closed loop system can be written in the form

$$\widehat{g}_{rj}\ddot{x}^j + \widehat{[j\,k,\,r]}\,\dot{x}^j\,\dot{x}^k + \widehat{C}_r + \frac{\partial \widehat{V}}{\partial x^r} = 0, \quad r = 1, \dots, n,$$

where $\widehat{[i\,j,\,k]}$ is defined as in (2.2) with $\widehat{g}$ in place of g. Such a control law will be given by

$$\begin{aligned} u_\ell = {} & \left([j\,k,\,\ell] - g_{\ell i}\,\widehat{g}^{ir}\,\widehat{[j\,k,\,r]}\right)\dot{x}^j\,\dot{x}^k + \left(C_\ell - g_{\ell i}\,\widehat{g}^{ij}\,\widehat{C}_j\right) \\ & + \left(\frac{\partial V}{\partial x^\ell} - g_{\ell i}\,\widehat{g}^{ij}\,\frac{\partial \widehat{V}}{\partial x^j}\right), \qquad \ell = 1, \dots, n. \end{aligned} \tag{2.4}$$

Condition (2.3) translates into

$$\big([j\,k,\,a] \,-\, g_{ai}\,\widehat{g}^{ir}\,\widehat{[j\,k,\,r]}\,\big)\,\dot{x}^j\,\dot{x}^k \,+\, \big(\,C_a \,-\, g_{ai}\,\widehat{g}^{ij}\,\widehat{C}_j\,\big)$$

$$+\left(\frac{\partial V}{\partial x^a} \,-\, g_{ai}\,\widehat{g}^{ij}\,\frac{\partial \widehat{V}}{\partial x^j}\right) = 0, \qquad a = 1,\dots,m. \tag{2.5}$$

In order to satisfy these equations, it is sufficient to have

$$\begin{aligned} g_{ai}\,\widehat{g}^{ir}\,\widehat{[j\,k,\,r]} \;&=\; [j\,k,\,a], \\ g_{ai}\,\widehat{g}^{ir}\,\widehat{C}_r \;&=\; C_a, \\ g_{ai}\,\widehat{g}^{ir}\,\frac{\partial \widehat{V}}{\partial x^r} \;&=\; \frac{\partial V}{\partial x^a}. \end{aligned} \tag{2.6}$$

These are the *matching equations*; see [5, 10]. Following [5], introduce variables λ_a^j relating the unknown mass matrix $\widehat{g}$ to the original mass matrix g,

$$\lambda_a^r \;=\; g_{ai}\,\widehat{g}^{ir}. \tag{2.7}$$

Using λ_a^j, the matching equations take the form

$$\begin{aligned} \lambda_a^r\,\widehat{[j\,k,\,r]} \;&=\; [j\,k,\,a], \\ \lambda_a^j\,\widehat{C}_j \;&=\; C_a, \\ \lambda_a^j\,\frac{\partial \widehat{V}}{\partial x^j} \;&=\; \frac{\partial V}{\partial x^a}. \end{aligned} \tag{2.8}$$

THEOREM 2.1. *The following equations are equivalent to the matching equations* (2.7), (2.8) *in a neighborhood of a point* x_0.

λ-equations.

$$\frac{\partial}{\partial x^k}\,(\,g_{ai}\,\lambda_b^i) \,-\, [k\,a,\,i]\,\lambda_b^i \,-\, [k\,b,\,i]\,\lambda_a^i \,=\, 0, \qquad \begin{matrix} k = 1,\dots,n, \\ a,b \,=\, 1,\dots,m. \end{matrix} \tag{2.9}$$

$\widehat{g}$-equations.

$$\lambda_a^\ell\,\frac{\partial \widehat{g}_{ij}}{\partial x^\ell} \,+\, \frac{\partial \lambda_a^\ell}{\partial x^i}\cdot\widehat{g}_{\ell j} \,+\, \frac{\partial \lambda_a^\ell}{\partial x^j}\cdot\widehat{g}_{\ell i} \,=\, \frac{\partial g_{ij}}{\partial x^a}\,, \qquad \begin{matrix} a = 1,\dots,m, \\ i,j = 1,\dots,n. \end{matrix} \tag{2.10}$$

$\widehat{V}$-equations.

$$\lambda_a^j\,\frac{\partial \widehat{V}}{\partial x^j} \;=\; \frac{\partial V}{\partial x^a}. \tag{2.11}$$

$\widehat{C}$-equations.

$$\lambda_a^j\,\widehat{C}_j \;=\; C_a. \tag{2.12}$$

Initial compatibility. There exists a hypersurface S containing x_0, transverse to each of the vector-fields $\lambda_a^\ell\frac{\partial}{\partial x^\ell}$, $a = 1,\dots,m$, and on which $\widehat{g}_{ij}$ is invertible and symmetric ($\widehat{g}_{ij} = \widehat{g}_{ji}$), and $g_{ai} = \lambda_a^j\widehat{g}_{ji}$.

That (2.7) and (2.8) imply (2.9), (2.10), (2.11), and (2.12) was originally shown in [5] (for indicial notation, see [1]). In the opposite direction, we show in [4, p. 33] that (2.9), (2.10), and the condition $g_{ai} = \lambda_a^j \widehat{g}_{ji}$ imply the first equation in (2.8). Note that the other two equations in (2.8) are (2.11) and (2.12), and, if $\widehat{g}_{ij}$ is invertible, then (2.7) follows from $g_{ai} = \lambda_a^j \widehat{g}_{ji}$. To complete the proof, we will show now that the *initial compatibility* conditions of the theorem are preserved in some neighborhood of the point x_0 by virtue of (2.9) and (2.10). Indeed, in view of (2.10), each difference $w_{ij} = \widehat{g}_{ij} - \widehat{g}_{ji}$ satisfies m differential equations $\lambda_a^\ell \frac{\partial}{\partial x^\ell} w_{ij} = 0$. Each equation guarantees that $w_{ij}(x) = 0$ in some neighborhood of x_0 provided $w_{ij}(x) = 0$ on the initial hypersurface S. The nondegeneracy of $\widehat{g}$ follows by continuity. Now, denote $\Xi_{ai} = \lambda_a^j \widehat{g}_{ji} - g_{ai}$. Multiplying (2.10) by λ_b^j, summing over j, and rearranging the terms, we obtain

$$\lambda_a^\ell \frac{\partial \Xi_{bi}}{\partial x^\ell} + \frac{\partial \lambda_a^\ell}{\partial x^i} \Xi_{b\ell} + \left[\frac{\partial}{\partial x^i} (\lambda_a^\ell g_{b\ell}) - [ia, \ell]\, \lambda_b^\ell - [ib, \ell]\, \lambda_a^\ell \right] = \left(\lambda_a^\ell \frac{\partial \lambda_b^j}{\partial x^\ell} - \lambda_b^\ell \frac{\partial \lambda_a^j}{\partial x^\ell} \right) \widehat{g}_{ji} - \frac{1}{2} \left\{ \lambda_a^\ell \frac{\partial g_{bi}}{\partial x^\ell} - \lambda_b^\ell \frac{\partial g_{ai}}{\partial x^\ell} - \lambda_a^\ell \frac{\partial g_{b\ell}}{\partial x^i} + \lambda_b^\ell \frac{\partial g_{a\ell}}{\partial x^i} + \lambda_a^\ell \frac{\partial g_{i\ell}}{\partial x^b} - \lambda_b^\ell \frac{\partial g_{i\ell}}{\partial x^a} \right\}.$$

Using (2.9), we simplify this to

$$\lambda_a^\ell \frac{\partial \Xi_{bi}}{\partial x^\ell} + \frac{\partial \lambda_a^\ell}{\partial x^i} \Xi_{b\ell} = \mathcal{R}_{ab},$$

with $\mathcal{R}_{ab}$ antisymmetric in a, b. If $b = a$, this equation reduces to

$$\lambda_a^\ell \frac{\partial \Xi_{ai}}{\partial x^\ell} + \frac{\partial \lambda_a^\ell}{\partial x^i} \Xi_{a\ell} = 0,$$

where *there is no summation over a*. By assumption, $\Xi_{aj}(x) = 0$, $j = 1, \ldots, n$, on the noncharacteristic surface S. Hence $\Xi_{aj}(x) = 0$ in some neighborhood of S. This completes the proof of the theorem.

Remark 2.2. Note that (2.9), (2.10), (2.11), and (2.12) always have a set of solutions of the form

$$\lambda_a^k = \varkappa \delta_a^k, \qquad \widehat{g} = \frac{1}{\varkappa} g + g^o, \qquad \widehat{V} = \frac{1}{\varkappa} V + V^o, \qquad \widehat{C}_j = \frac{1}{\varkappa} C_j$$

with $\varkappa \neq 0$ any constant, V^o an arbitrary function of the variables x^ℓ, $\ell = m+1, \ldots, n$, and g^o any symmetric matrix valued function of the variables x^ℓ such that $g^o_{ia} = 0$. We will call these solutions *basic*.

The λ-equations are a system of $\frac{1}{2} m(m+1) \cdot n$ equations for $n \cdot m$ unknowns. It is not surprising that there are extra compatibility conditions. By viewing system (2.9) in the correct way, we are able to write down the compatibility conditions. Denote

$$\nu_{ab} = g_{ai}\, \lambda_b^i. \tag{2.13}$$

Because the matrix g_{ij} is assumed to be nondegenerate, the matrix comprised of its m first rows has rank m. This implies that m^2 out of $m \cdot n$ λ's can be expressed as linear combinations of ν's; i.e.,

$$\lambda_b^\beta = h^{\beta a}\, \nu_{ab}, \quad \beta \in \mathcal{I}_m, \tag{2.14}$$

where $\mathcal{I}_m$ is some m element subset of $\{1,\dots,n\}$. The indices $\mathcal{I}_m$ are chosen so that the matrix $(g_{a\sigma})$ with $a=1,\dots,m$ and $\sigma\in\mathcal{I}_m$ is nondegenerate; and we denote by $(h^{\beta a})$ the inverse of $(g_{a\sigma})$. Substituting (2.14) in the λ-equations, we obtain

$$\partial_k\,\nu_{ab} \;-\; [a\,k,\,\beta]\,h^{\beta d}\,\nu_{db} \;-\; [b\,k,\,\beta]\,h^{\beta d}\,\nu_{da} \;=\; [a\,k,\,\rho]\,\lambda^{\rho}_{b} \;+\; [b\,k,\,\rho]\,\lambda^{\rho}_{a}, \tag{2.15}$$

where index ρ varies over the remaining $(n-m)$ indices $\{1,\dots,n\}\setminus\mathcal{I}_m$. We will view system (2.15) of $\frac{1}{2}\,m(m+1)\cdot n$ equations as a linear algebraic system for the $m\,(n-m)$ variables λ^{ρ}_{a},

$$\bigl[A_{(k,a,b)}\bigr]^{c}_{\rho}\;\lambda^{\rho}_{c} \;=\; F_{(k,a,b)}. \tag{2.16}$$

Here

$$\bigl[A_{(k,a,b)}\bigr]^{c}_{\rho} \;=\; \delta^{cb}\,[ak,\rho]+\delta^{ca}\,[bk,\rho],$$

and

$$F_{(k,a,b)} \;=\; \partial_k\,\nu_{ab} \;-\; [a\,k,\,\beta]\,h^{\beta d}\,\nu_{db} \;-\; [b\,k,\,\beta]\,h^{\beta d}\,\nu_{da}$$

with δ^{cb} being the Kronecker delta, as usual. Define a linear map A from the vector space of $m\times(n-m)$ two-dimensional arrays into the vector space of $n\times m\times m$ three-dimensional arrays that are symmetric in the last two indices by the coordinate expression

$$[\,A\,\eta\,]_{(k,a,b)} \;=\; \bigl[A_{(k,a,b)}\bigr]^{c}_{\rho}\;\eta^{\rho}_{c}.$$

We know that system (2.16) has at least one solution by Remark 2.2. Thus the rank of the linear map A is at most $m\cdot n$. In order for system (2.16) to have a solution, the vector (three-dimensional array) $F_{(k,a,b)}$ must be perpendicular to the kernel of the adjoint map $A^{\star}$,

$$F \;\perp\; \ker\,A^{\star}. \tag{2.17}$$

Let the kernel of the map $A^{\star}$ be generated by the vectors (three-dimensional arrays) ξ_r. The orthogonality condition (2.17) then takes the form of the following system of linear first order partial differential equations for ν_{ab}:

$$\xi_r^{(k,a,b)}(x)\;\bigl[\,\partial_k\,\nu_{ab} \;-\; [a\,k,\,\beta]\,h^{\beta d}\,\nu_{db} \;-\; [b\,k,\,\beta]\,h^{\beta d}\,\nu_{da}\,\bigr] \;=\; 0. \tag{2.18}$$

THEOREM 2.3. *The general solution to the λ-equations is given by any set of λ^{ρ}_{a} solving the algebraic system* (2.16), *and $\lambda^{\beta}_{b} = h^{\beta a}\,\nu_{ab}$, where ν_{ab} is any solution to* (2.18).

In general, if $m>1$, system (2.17) may be quite complicated, and we do not have a satisfactory description of its solutions.

3. Systems with one unactuated degree of freedom. If only one degree of freedom is unactuated, we do have a reasonable description of all solutions to system (2.18). Assume, for simplicity, that $g_{11}(x)>0$. Then, after rescaling x^1 if necessary, we will have $g_{11}(x)=1$. More precisely, from the very beginning, we could use, instead of $(x^1,x^2,\dots,x^n)$, the coordinates $(z^1,z^2,\dots,z^n)$ which are related to x as follows:

$$\frac{\partial z^1}{\partial x^1} \;=\; \sqrt{g_{11}(x)}, \qquad z^2 \;=\; x^2,\dots,\; z^n \;=\; x^n.$$

In z coordinates, the mass matrix is $\tilde{g}_{ij}(z) = g_{k\ell}(x)\,\frac{\partial x^k}{\partial z^i}\,\frac{\partial x^\ell}{\partial z^j}$, and hence $\tilde{g}_{11}(z) = 1$. On the other hand, the structure of the equations of motion (2.1) does not change because of their tensorial form, and the condition $u_1 = 0$ remains the same again because $\tilde{u}_1 = u_k\,\frac{\partial x^k}{\partial z^1} = u_1\,\sqrt{g_{11}(x)}$. Thus we assume that the coordinates are chosen appropriately, and $g_{11}(x) = 1$.

In the case of one unactuated degree of freedom, one is solving for λ_1^i. The λ-equation reads

$$\frac{\partial \nu}{\partial x^k} = 2\,[k\,1,\,i]\,\lambda_1^i, \tag{3.1}$$

where $\nu = g_{1i}\,\lambda_1^i$. Notice that $[k\,1,\,1] = 0$. View (3.1) as a system of linear algebraic equations for the variables λ_1^ρ, $\rho = 2, \dots, n$. In order for this system of n equations in $(n-1)$ unknowns to have a solution, the vector

$$v = \begin{pmatrix} \partial_1\,\nu \\ \dots \\ \partial_n \nu \end{pmatrix}$$

must be perpendicular to the kernel of the matrix

$$A^\star = \begin{pmatrix} [1\,1,\,2] & \dots & [n\,1,\,2] \\ \dots & \dots & \dots \\ [1\,1,\,n] & \dots & [n\,1,\,n] \end{pmatrix}.$$

Let the kernel of $A^\star$ be generated by the vectors $\xi_r = (\xi_r^1, \dots, \xi_r^n)$. The orthogonality condition for v translates into the system of equations

$$X_r(\nu) \equiv \xi_r^1(x)\,\frac{\partial \nu}{\partial x^1} + \dots + \xi_r^n(x)\,\frac{\partial \nu}{\partial x^n} = 0. \tag{3.2}$$

The standard procedure to solve such a system of equations is to complete the system into an involutive system by adding equations $[X_r,\,X_s](\nu) = 0$, $[[X_r,\,X_s],\,X_t](\nu) = 0$, $\dots$, where $[\eta^i\,\partial_i,\,\zeta^j\,\partial_j] = \big(\eta^i \partial_i(\zeta^k) - \zeta^i\,\partial_i(\eta^k)\big)\,\partial_k$ is the commutator of vector-fields. Recall that a system of equations

$$Y_1(\nu) = 0, \dots, Y_K(\nu) = 0$$

is involutive if $[Y_p,\,Y_q] = f_{pq}^r(x)\,Y_r$.

Thus we have proved the following result.

THEOREM 3.1. *With one unactuated degree of freedom there is a coordinate system such that the ν-equations,* (2.18), *become a homogeneous linear system of equations for one unknown function. This system,* (3.2), *can be completed into an involutive system.*

This theorem extends the general analysis in [4] of systems with two degrees of freedom, one of which is unactuated. Equation (11) of [4] is the analogue of (3.2).

Given any nonzero solution of the λ-equations, there is a local coordinate system $y^1, \dots, y^n$ such that

$$\lambda_1^i(x)\,\frac{\partial y^j}{\partial x^i} = \delta_1^j. \tag{3.3}$$

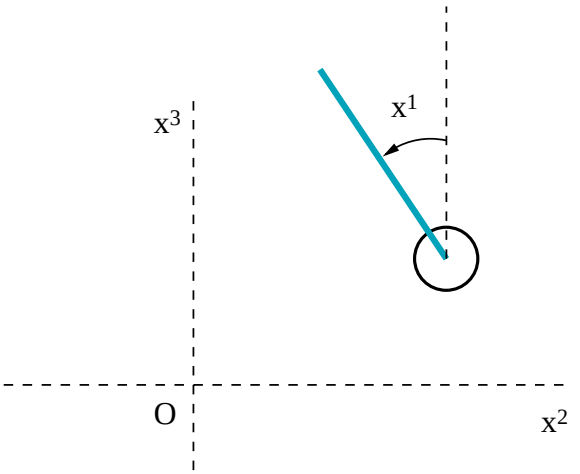

FIG. 4.1.

Let G and $\widehat{G}$ represent g and $\widehat{g}$ in the y-coordinates; i.e., $G_{ij} = g_{kl}\,\frac{\partial x^k}{\partial y^i}\,\frac{\partial x^l}{\partial y^j}$ and similarly for $\widehat{G}$. From (2.7), one gets $g_{1r} = \lambda_1^k\,\widehat{g}_{kr}$. In y-coordinates, we have $g_{1r} = G_{ij}(y)\,\frac{\partial y^i}{\partial x^1}\,\frac{\partial y^j}{\partial x^r}$ and $\lambda_1^k\,\widehat{g}_{kr} = \lambda_1^k\,\widehat{G}_{ij}\,\frac{\partial y^i}{\partial x^k}\,\frac{\partial y^j}{\partial x^r} = \widehat{G}_{1j}\,\frac{\partial y^j}{\partial x^r}$. Thus we obtain

$$G_{ij}(y)\,\frac{\partial y^i}{\partial x^1}\,\frac{\partial y^j}{\partial x^r} = \widehat{G}_{1j}\,\frac{\partial y^j}{\partial x^r}. \tag{3.4}$$

In a similar fashion, one sees that the $\widehat{g}$-equations in y-coordinates read

$$\frac{\partial \widehat{G}_{ij}}{\partial y^1} = \frac{\partial g_{k\ell}}{\partial x^1}\,\frac{\partial x^k}{\partial y^i}\,\frac{\partial x^\ell}{\partial y^j}\,, \tag{3.5}$$

and the $\widehat{V}$-equations become

$$\frac{\partial \widehat{V}}{\partial y^1} = \frac{\partial V}{\partial x^1}\,.$$

It is easy to see now that the following result holds.

THEOREM 3.2. *Given any nonzero solution to the λ-equation, there is a unique solution to the $\widehat{g}$- and $\widehat{V}$-equations with initial data prescribed at $y^1 = 0$.*

Remark 3.3. Note that (3.4) directly gives

$$\widehat{G}_{k1} = G_{ki}\,\frac{\partial y^i}{\partial x^1}\,,$$

and so one needs only to solve (3.5) for $n\,(n-1)/2$ quantities $\widehat{G}_{ij}$, $2 \le i,\, j \le n$.

4. Example 1: Inverted pendulum in a vertical plane. As the first example, we consider the inverted pendulum restricted to a vertical plane with horizontal and vertical actuation of the base; see Figure 4.1.

After rescaling units, the mass matrix and potential energy are given by

$$g = \begin{pmatrix} 1 & -a\,\cos(x^1) & -a\,\sin(x^1) \\ -a\,\cos(x^1) & 1 & 0 \\ -a\,\sin(x^1) & 0 & 1 \end{pmatrix},$$

$$V = b\,x^3 + \cos(x^1).$$

Since only x^1 is unactuated, we will simplify notation and use λ^i to denote λ^i_1. The λ-equations (2.9) are

$$\partial_1 \nu = 2a \sin(x^1)\,\lambda^2 - 2a \cos(x^1)\,\lambda^3, \quad \partial_2 \nu = 0, \quad \partial_3 \nu = 0,$$

with $\nu = \lambda^1 - a\cos(x^1)\,\lambda^2 - a\sin(x^1)\,\lambda^3$. (Note that $\partial_2 \nu = \partial_3 \nu = 0$ are the ν-equations.) It is not difficult to see that the general solution to these equations is

$$\begin{aligned}
\lambda^1 &= \nu(x^1) + \frac{1}{2}\cot(x^1)\,\partial_1\nu(x^1) + a\frac{\lambda^3(x^1,x^2,x^3)}{\sin(x^1)},\\
\lambda^2 &= \frac{1}{2a\sin(x^1)}\,\partial_1\nu(x^1) + \cot(x^1)\,\lambda^3(x^1,x^2,x^3),\\
\lambda^3 &= \lambda^3(x^1,x^2,x^3),
\end{aligned}$$

where $\nu(x^1)$, $\lambda^3(x^1,x^2,x^3)$ are arbitrary. In order to obtain a manageable explicit solution to the matching equations, we will choose

$$\nu(x^1) = a\,\mu_0 \sin^2(x^1) + \sigma_0 - a\,\mu_0, \qquad \lambda^3 = 0,$$

with free parameters σ_0 and μ_0. Then

$$\lambda^1 = \sigma_0, \qquad \lambda^2 = \mu_0 \cos(x^1).$$

The coordinates

$$y^1 = \frac{1}{\sigma_0}\,x^1, \quad y^2 = x^2 - \mu_0 \sin(x^1), \quad y^3 = x^3$$

satisfy (3.3). Following Remark 3.3, we need to solve the $\widehat{g}$-equations only for $\widehat{g}_{22}$, $\widehat{g}_{23}$, and $\widehat{g}_{33}$. These equations are

$$\frac{\partial}{\partial y^1}\,\widehat{g}_{22} = \frac{\partial}{\partial y^1}\,\widehat{g}_{23} = \frac{\partial}{\partial y^1}\,\widehat{g}_{33} = 0.$$

Clearly,

$$\begin{aligned}
\widehat{g}_{22} &= \widehat{g}_{22}(y^2,y^3) = \widehat{g}_{22}(x^2 - \mu_0 \sin(x^1),\ x^3),\\
\widehat{g}_{23} &= \widehat{g}_{23}(x^2 - \mu_0 \sin(x^1),\ x^3),\\
\widehat{g}_{33} &= \widehat{g}_{33}(x^2 - \mu_0 \sin(x^1),\ x^3).
\end{aligned}$$

From $g_{ai} = \lambda^j_a\,\widehat{g}_{ji}$, we obtain the rest of $\widehat{g}_{ij}$:

$$\begin{aligned}
\widehat{g}_{11} &= \frac{1}{\sigma_0} + \frac{a\mu_0}{\sigma_0^2}\cos^2(x^1) + \frac{\mu_0^2}{\sigma_0^2}\cos^2(x^1)\,\widehat{g}_{22},\\
\widehat{g}_{12} &= -\frac{a}{\sigma_0} - \frac{\mu_0}{\sigma_0}\cos(x^1)\,\widehat{g}_{22},\\
\widehat{g}_{13} &= -\frac{a}{\sigma_0}\sin(x^1) - \frac{\mu_0}{\sigma_0}\cos(x^1)\,\widehat{g}_{23}.
\end{aligned}$$

The $\widehat{V}$-equation yields

$$\widehat{V} = \frac{1}{\sigma_0}\cos(x^1) + w(y^2,y^3).$$

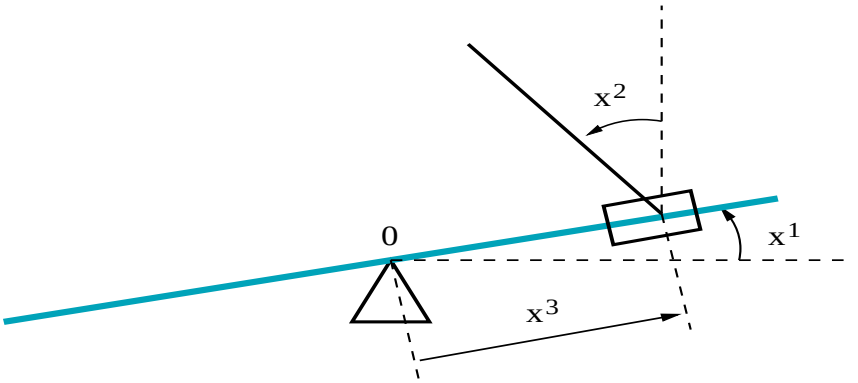

FIG. 5.1.

The $\widehat{C}$-equation reads $\lambda^j \widehat{C}_j = 0$. One solution is

$$\widehat{C} = -\sigma_0 R(x) \begin{pmatrix} \frac{\mu_0^2}{\sigma_0^2}\cos^2(x^1) & -\frac{\mu_0}{\sigma_0}\cos(x^1) & -\frac{\mu_0}{\sigma_0}\cos(x^1) \\ -\frac{\mu_0}{\sigma_0}\cos(x^1) & 1 & 1 \\ -\frac{\mu_0}{\sigma_0}\cos(x^1) & 1 & 1 \end{pmatrix} \cdot \begin{pmatrix} \dot{x}^1 \\ \dot{x}^2 \\ \dot{x}^3 \end{pmatrix}.$$

The resulting control law can be obtained explicitly from (2.4). The expression is too long to be included in this paper.

PROPOSITION 4.1. *If the functions $\widehat{g}_{22}(y^2, y^3)$, $\widehat{g}_{23}(y^2, y^3)$, $\widehat{g}_{33}(y^2, y^3)$, $w(y^2, y^3)$, and $R(x)$ and the parameters μ_0 and σ_0 are chosen so that*

$$\begin{aligned} &\widehat{g}_{22}(0) > 0, \quad \widehat{g}_{23}(0) = 0, \quad \widehat{g}_{33}(0) = 1, \\ &\partial^2_{y^2} w(0) > 0, \quad \partial_{y^2}\partial_{y^3} w(0) = 0, \quad \partial^2_{y^3} w(0) > 0, \qquad R(0) > 0, \\ &\sigma_0 < 0, \quad \widehat{g}_{22}(0)\,\mu_0^2 + a\,\mu_0 + \sigma_0 > 0, \quad \widehat{g}_{22}(0)\,(a\,\mu_0 - \sigma_0) + a^2 < 0, \end{aligned}$$

then $x = \dot{x} = 0$ is a locally asymptotically stable equilibrium of the closed loop system.

It follows from the above inequalities that the function $\widehat{H}(x, \dot{x}) = \frac{1}{2}\widehat{g}_{ij}(x)\,\dot{x}^i\dot{x}^j + \widehat{V}(x)$ has a strict local minimum at $x = \dot{x} = 0$. Also, the matching procedure automatically ensures that $\frac{d}{dt}\widehat{H} = -\widehat{g}(\widehat{C}(x, \dot{x}), \dot{x})$. The above inequalities guarantee that $-\widehat{g}(\widehat{C}(x, \dot{x}), \dot{x}) \leq 0$ in the neighborhood of $x = \dot{x} = 0$. In addition, the set where $\widehat{g}(\widehat{C}(x, \dot{x}), \dot{x}) = 0$ contains no local solutions of the closed loop system except for $x = \dot{x} = 0$. This proves the proposition.

5. Example 2: Inverted pendulum cart on a seesaw. In the previous example, the kernel of the matrix $A^\star$, (2.16), was two-dimensional. Generically, for systems with one unactuated degree of freedom, the dimension of the kernel will be 1. The following example illustrates this situation. The inverted pendulum cart on a seesaw is shown in Figure 5.1. There are several interesting ways to actuate this system. We will consider the case with actuated cart and pendulum, and unactuated seesaw.

The rescaled mass matrix and potential energy of the system are given by

$$g = \begin{pmatrix} b + (x^3)^2 & a\,x^3\sin(x^1 - x^2) & 0 \\ a\,x^3\sin(x^1 - x^2) & 1 & -a\cos(x^1 - x^2) \\ 0 & -a\cos(x^1 - x^2) & 1 \end{pmatrix}$$

and

$$V = x^3 \sin(x^2) + a \cos(x^1).$$

The theory in section 3 was presented with special coordinates so that $g_{11} = 1$. However, in practice, this is not necessary.

As before, we write λ^i for λ_1^i and ν for $g_{1j}\,\lambda^j$. The λ-equations are

$$\begin{aligned}
\partial_1 \nu &= 2a\,x^3 \cos(x^1 - x^2)\,\lambda^2 - 2\,x^3\,\lambda^3,\\
\partial_2 \nu &= 0,\\
\partial_3 \nu &= 2a \sin(x^1 - x^2)\,\lambda^2 + 2\,x^3\,\lambda^1.
\end{aligned}$$

Note that, in this case, the ν-equations (2.17) are simply $\partial_2 \nu = 0$. Hence $\nu = \nu(x^1, x^3)$. Plug in $\lambda^1 = (\nu - g_{12}\,\lambda^2 - g_{13}\,\lambda^3)/g_{11}$, and solve for λ^2 and λ^3:

$$\begin{aligned}
\lambda^1 &= \frac{1}{2b}\,(\,2\nu - x^3 \partial_3\,\nu\,),\\
\lambda^2 &= \frac{1}{2ab\,\sin(x^1 - x^2)}\,(-\,2\,x^3\,\nu + (b + (x^3)^2)\,\partial_3\,\nu),\\
\lambda^3 &= \frac{1}{2b\,x^3\,\sin(x^1 - x^2)}\,(-\,2(x^3)^2 \cos(x^1 - x^2)\,\nu\\
&\qquad + x^3\,(b + (x^3)^2) \cos(x^1 - x^2)\,\partial_3\nu - b \sin(x^1 - x^2)\,\partial_2\nu).
\end{aligned}$$

Notice that λ^2 and λ^3 blow up as x approaches 0 unless $\nu = \kappa\,(b + (x^3)^2)$. Since $g = \widehat{g}\,\lambda$, one must have $\det \widehat{g} \to 0$ as $x \to 0$; i.e., $\widehat{g}$ degenerates at $x = 0$. This means that $\widehat{H}(x, \dot{x}) = \frac{1}{2}\,\widehat{g}_{ij}\,\dot{x}^i\,\dot{x}^j + \widehat{V}$ cannot serve as a Lyapunov function unless $\nu = \kappa\,(b + (x^3)^2)$. This ν corresponds exactly to the basic solutions of the matching equations from Remark 2.2. This illustrates the following general principle.

Remark 5.1. If $(x_0, 0)$ is the desired equilibrium of a system and

$$\operatorname{rank} A^\star(x_0) < \limsup_{x \to x_0} \operatorname{rank} A^\star(x), \tag{5.1}$$

then only basic solutions of the matching equations should be tested to produce a stabilizing control law from (2.4).

6. Example 3: Inverted pendulum cart on a roller coaster. Consider a cart with an inverted pendulum on a roller coaster. Special cases of this mechanical system include the inverted pendulum on a rotor arm, the inverted pendulum on a vertical disk, and the inverted pendulum cart on an incline. By assuming that the size of the base of the cart is relatively small, we may neglect the inertia of the base of the cart. It is therefore sufficient to model the cart with one point mass for the base and one point mass a fixed distance away for the pendulum. The pendulum joint will be unactuated.

The configuration of the system may be described by a position and an angle. Assume that the shape of the roller coaster is given as a curve $x(s)$ in $\mathbb{R}^3$ parametrized by arc length, s, from a fixed point. Assume that the pendulum is always in the plane containing the tangent vector, $\tau(s)$, and the vertical direction, e_3. Let ϕ be the angle between the pendulum and e_3. By rescaling mass, length, and time, we will

write

$$g = \begin{pmatrix} 1 & b\sin(\alpha-\phi) \\ b\sin(\alpha-\phi) & \left(1+k(s)^2\sin^2\phi\left(\frac{\sin^2\alpha-n_3^2}{\sin^4\alpha}\right)\right) \end{pmatrix},$$

$$V = a\,x^3 + \cos\phi,$$

where a and b are positive parameters, $0 < b < 1$, and x^3 is the vertical component of $x(s)$. The (unit) tangent vector to the curve is $\tau(s) = \frac{x'(s)}{|x'(s)|}$, where $'$ stands for the derivative with respect to s. The curvature of the curve is $k(s) = |\tau'(s)|$. Denote by $n(s)$ the principal normal to the curve. Recall that $\tau'(s) = k(s)\,n(s)$. In the formula above, n_3 is the vertical component of the principal normal, and α is the angle between τ and the vertical direction. Index 1 corresponds to ϕ, and index 2 corresponds to s. The unactuated degree of freedom corresponds to the ϕ variable. The λ-equations (3.1) then read as follows:

$$\begin{aligned} \partial_1\nu &= -2\,b\,\cos(\alpha-\phi)\,\lambda_1^2, \\ \partial_2\nu &= k(s)^2\sin(2\,\phi)\left(\frac{\sin^2\alpha-n_3^2}{\sin^4\alpha}\right)\lambda_1^2\,. \end{aligned} \tag{6.1}$$

The orthogonality equation (3.2) then, obviously, is

$$k(s)^2\sin(2\,\phi)\left(\frac{\sin^2\alpha-n_3^2}{\sin^4\alpha}\right)\frac{\partial\nu}{\partial\phi} + 2\,b\,\cos(\alpha-\phi)\,\frac{\partial\nu}{\partial s} = 0. \tag{6.2}$$

It is not clear if all solutions to this equation can be written explicitly for a general curve. We consider here two particular cases when this is possible. The first case is when $\sin^2\alpha = n_3^2$. This occurs exactly when the roller coaster lies in one vertical plane. The second case is when $\alpha(s)$ is constant. This occurs when the track is constantly inclined.

6.1. Case 1: $\sin^2\alpha = n_3^2$. Note that this case includes the interesting examples of an inverted pendulum on a vertical disk and an inverted pendulum cart on an incline.

As is readily seen from (6.2), the general solution of (6.2) in this case is $\nu = \nu(\phi)$, an arbitrary function. Then

$$\lambda_1^2 = -\frac{1}{2\,b\,\cos(\alpha-\phi)}\,\frac{\partial\nu}{\partial\phi},$$

and

$$\lambda_1^1 = \nu(\phi) + \frac{1}{2}\tan(\alpha-\phi)\,\frac{\partial\nu}{\partial\phi}.$$

This is a general solution of the λ-equation. From here, one must solve the $\widehat{g}$- and $\widehat{V}$-equations. For special choices of $\alpha(s)$ and/or $\nu(\phi)$, these equations have explicit closed form solutions.

6.2. Case 2: $\alpha(s) = \alpha_0$. Examples with $\alpha(s)$ constant include an inverted pendulum cart traveling on any path in a horizontal plane and a cart on a vertically oriented circular helix or any constantly inclined track.

Since $\frac{d\alpha}{ds} = -k(s)\frac{n_3(s)}{\sin(\alpha)}$, if $\alpha(s) = \alpha_0$, then we have $k(s)n_3(s) = 0$. To solve (6.2), we introduce new coordinates

$$\begin{aligned} z^1 &= \beta(s), \\ z^2 &= \beta(s) + \cos(\alpha_0)\ln|\csc\phi + \cot\phi| - \sin(\alpha_0)\ln|\sec\phi + \tan\phi|, \end{aligned}$$

where

$$\beta(s) = \int_0^s \frac{k^2(p)}{b\sin^2(\alpha_0)}\,dp.$$

Equation (6.2) is equivalent to the fact that ν is an arbitrary function of z^2. Thus, from (6.1) and the definition of ν, we find

$$\lambda_1^1 = \nu(z^2) - \frac{\sin(\alpha_0 - \phi)}{\sin(2\phi)}\frac{d\,\nu}{d\,z^2}; \qquad \lambda_1^2 = \frac{1}{b\,\sin(2\phi)}\frac{d\,\nu}{d\,z^2}.$$

6.3. End of the roller coaster example. From the computations in case 1 and case 2, one can see that the general solution to the matching equations for the cart on a roller coaster will be fairly complicated. However, we can show that any *linear* control law is the first order germ (linearization) of some matching control law. In fact, the only requirement for this is that there is no rank drop at the equilibrium; i.e.,

$$\operatorname{rank} A^\star(x_0) = \limsup_{x\to x_0} \operatorname{rank} A^\star(x). \tag{6.3}$$

We assume that the dissipative term at the equilibrium satisfies the following natural assumptions:

$$C_\ell(x_0, 0) = 0, \qquad \left.\frac{\partial}{\partial x^i}\right|_{(x_0,0)} C_\ell = 0.$$

LEMMA 6.1. *If condition* (6.3) *is satisfied for a two degree of freedom system, then the first order germs of matching control laws at* $(x_0, 0)$ *exhaust all linear control laws for which the closed loop system has an equilibrium at* $(x_0, 0)$.

Proof. Given a linear control input

$$u_j^{\text{lin}} = v_j + a_{ij}\,(x^i - x_0^i) + b_{ij}\,\dot{x}^i$$

with $u_1^{\text{lin}} = 0$, we will find a matching control law with the same germ. From the general expression (2.4) for the matching control law, we see that the first order germ is

$$u_j^{\text{germ}} = (V_j - g_{j\ell}\,\widehat{g}^{\ell r}\,\widehat{V}_r) + \left(V_{jr} - g_{j\ell}\,\widehat{g}^{\ell i}\,\widehat{V}_{ir}\right)(x^r - x_0^r) + \left(C_{ji} - g_{j\ell}\,\widehat{g}^{\ell r}\,\widehat{C}_{ri}\right)\dot{x}^i,$$

where

$$V_j = \left.\frac{\partial V}{\partial x^j}\right|_{x_0}, \quad V_{jr} = \left.\frac{\partial^2 V}{\partial x^j \partial x^r}\right|_{x_0}, \quad C_{ji} = \left.\frac{\partial C_j}{\partial \dot{x}^i}\right|_{(x_0,0)},$$

and $\widehat{V}_j$, $\widehat{V}_{jr}$, and $\widehat{C}_{ji}$ are defined similarly. Equating like terms gives

$$\widehat{V}_{\ell j} = \widehat{g}_{\ell i}\, g^{ir}\,(V_{rj} - a_{rj}), \quad \widehat{C}_{\ell j} = \widehat{g}_{\ell i}\, g^{ir}\,(C_{rj} - b_{rj}), \quad \widehat{V}_{\ell} = \widehat{g}_{\ell i}\, g^{ir}\,(V_r - v_r) = 0. \tag{6.4}$$

One can see that $\widehat{V}_j$, $\widehat{V}_{jr}$, and $\widehat{C}_{ji}$ are specified once $\widehat{g}_{ij}(x_0)$ is known. Moreover, there exists a nondegenerate symmetric $\widehat{g}_{ij}(x_0)$ such that the resulting $\widehat{V}_{\ell j}$ will be symmetric; see [1, Lemma 1]. To conclude the argument, we now show that any nondegenerate symmetric $\widehat{g}_{ij}(x_0)$ arises as a zero order germ of a solution to the $\widehat{g}$-equation. Also, any $\widehat{V}_\ell$, $\widehat{V}_{\ell j}$ satisfying $\widehat{V}_\ell = \widehat{g}_{\ell i}\, g^{ir}\,(V_r - v_r)$ and $\widehat{V}_{\ell j} = \widehat{g}_{\ell i}\, g^{ir}\,(V_{rj} - a_{rj})$ arises as a solution to the $\widehat{V}$-equation.

Given a nondegenerate $\widehat{g}_{ij}(x_0)$, define the nondegenerate $\lambda_i^j(x_0) = g_{ik}(x_0)\,\widehat{g}^{kj}(x_0)$. Set $\nu_0 = g_{11}(x_0)\,\lambda_1^1(x_0) + g_{12}(x_0)\,\lambda_1^2(x_0)$. The λ-equations in this case are

$$\begin{aligned} \partial_1\nu - 2\,[1\,1,\,2]\,\frac{1}{g_{11}}\,\nu &= 2\,[1\,1,\,2]\,\lambda_1^2, \\ \partial_2\nu - 2\,[1\,2,\,1]\,\frac{1}{g_{11}}\,\nu &= 2\,[2\,1,\,2]\,\lambda_1^2. \end{aligned} \tag{6.5}$$

By the rank condition, we know that the rank of $A^\star$ in the neighborhood of x_0 is either identically 0 or identically 1. If this rank is 0, then ν can be any constant times g_{11}. We simply choose $\nu(x) = (\nu_0/g_{11}(x_0))\,g_{11}(x)$. Any solution to the algebraic equation $\nu(x) = g_{11}(x)\,\lambda_1^1(x) + g_{12}(x)\,\lambda_1^2(x)$ is a solution to the λ-equation. If the rank of $A^\star$ is 1, then the orthogonality condition, (2.17), is

$$[2\,1,\,2]\,\partial_1\nu - [1\,1,\,2]\,\partial_2\nu + 2\,\left([1\,1,\,2]\,[1\,2,\,1] - [2\,1,\,2]\,[1\,1,\,2]\right)\,\frac{1}{g_{11}}\,\nu = 0. \tag{6.6}$$

At $x = x_0$, either ∂_1 or ∂_2 is not parallel to the vector $[2\,1,\,2]\,\partial_1 - [1\,1,\,2]\,\partial_2$. Assume it is ∂_1. Then initial conditions to (6.6) can be specified along the line $x^2 = x_0^2$. In particular, we can choose the initial values so that

$$\left(\partial_1\nu - 2\,[1\,1,\,2]\,\frac{1}{g_{11}}\,\nu\right)\Big|_{x=x_0} = 2\,[1\,1,\,2]\Big|_{x=x_0}\lambda_1^2(x_0), \qquad \nu(x_0) = \nu_0. \tag{6.7}$$

The second equation in (6.5),

$$\left(\partial_2\nu - 2\,[1\,2,\,1]\,\frac{1}{g_{11}}\,\nu\right)\Big|_{x=x_0} = 2\,[2\,1,\,2]\Big|_{x=x_0}\lambda_1^2(x_0),$$

will be satisfied automatically since the rank of $A^\star$ is 1. Let $\nu(x)$ be a solution of (6.6) with initial condition, $\nu(x^1, 0)$, satisfying (6.7). Now one solves (6.5) for $\lambda_1^2(x)$ and then $\nu(x) = g_{11}(x)\,\lambda_1^1(x) + g_{12}(x)\,\lambda_1^2(x)$ for $\lambda_1^1(x)$.

Now that the λ-equations are solved, we turn to the $\widehat{g}$-equations. These equations take the form

$$\frac{\partial}{\partial y^1}\,\widehat{g} + R\,\widehat{g} = S,$$

where $\frac{\partial}{\partial y^1} = \lambda_1^1\,\partial_1 + \lambda_1^2\,\partial_2$. The initial conditions can be set on any line transverse to $\frac{\partial}{\partial y^1}$, in particular, along the line $\lambda_1^1(x_0)\,(x^1 - x_0^1) + \lambda_1^2(x_0)\,(x^2 - x_0^2) = 0$. On this

line, set $\lambda_2^i(x) = \lambda_2^i(x_0)$ and $\widehat{g}(x) = g(x) \cdot (\lambda(x_0))^{-1}$. The solution to (2.10) with this initial data then has the desired value at $x = x_0$.

It remains to show that the $\widehat{V}$-equation has a solution such that $\widehat{V}_\ell = 0$ and

$$\lambda_r^\ell(x_0)\, \widehat{V}_{\ell j} = V_{rj} - a_{rj}, \tag{6.8}$$

where $\lambda_r^\ell(x_0) = g_{rk}(x_0)\, \widehat{g}^{k\ell}(x_0)$. Since $\lambda_r^\ell(x_0)$ is nondegenerate, either $\lambda_1^1(x_0) \neq 0$ or $\lambda_1^2(x_0) \neq 0$. Consider the case with $\lambda_1^2(x_0) \neq 0$. In this case, the line $x^2 = x_0^2$ is noncharacteristic for the $\widehat{V}$-equation

$$\lambda_1^1\, \partial_1 \widehat{V} + \lambda_1^2\, \partial_2 \widehat{V} = \partial_1 V. \tag{6.9}$$

Pick the initial value, $\widehat{V}\big|_{x^2 = x_0^2}$, so that

$$\widehat{V}_1 = 0, \quad \widehat{V}_{11} = \frac{\lambda_2^2\, V_{11} - \lambda_1^2\, (V_{12} - a_{12})}{\lambda_1^1\, \lambda_2^2 - \lambda_2^1\, \lambda_1^2}\bigg|_{x = x_0},$$

and solve (6.9). Since $x = x_0$ is an equilibrium, $V_1 = 0$ and $(V_2 - v_2) = 0$. From the differential equation (6.9), we see that $\widehat{V}_2 = 0$. Differentiating equation (6.9) with respect to x^1 and x^2, we see that $W_{ij} = \widehat{V}_{ij}$ satisfies

$$\begin{aligned} \lambda_1^1(x_0)\, W_{11} + \lambda_1^2(x_0)\, W_{12} &= V_{11}, \\ \lambda_1^1(x_0)\, W_{12} + \lambda_1^2(x_0)\, W_{22} &= V_{12}. \end{aligned} \tag{6.10}$$

By construction,

$$\lambda_2^1(x_0)\, W_{11} + \lambda_2^2(x_0)\, W_{12} = V_{12} - a_{12}. \tag{6.11}$$

Notice that (6.4) implies that $W_{\ell j} = \widehat{g}_{\ell i}\, g^{ir}\, (V_{rj} - a_{rj})$ also satisfy (6.10) and (6.11). Since the solution to the algebraic system (6.10), (6.11) is unique, we conclude that (6.8) is valid, as required.

7. Example 4: A double pendulum on a wheel. Our next example is the system with two unactuated degrees of freedom depicted in Figure 7.1. Only joint **A** is actuated.

After rescaling, the entries g_{ij} of the mass matrix are

$$g_{ij} = m_{ij} \cos(x^i - x^j),$$

and the potential energy is

$$V = a_1 \cos(x^1) + a_2 \cos(x^2) + a_3 \cos(x^3).$$

The parameters $m_{ij} = m_{ji}$ and a_j are positive.

There are six unknown λ_a^i. Define $\nu_{ab} = g_{ai}\, \lambda_b^i$. Note that we must have $\nu_{12} = \nu_{21}$. The computations in this section were performed using Maple. The λ-equations

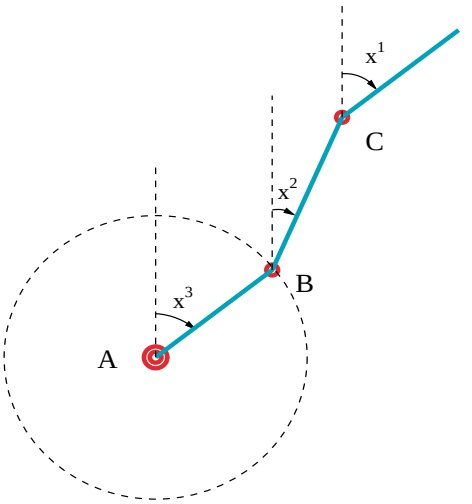

FIG. 7.1.

(2.9) are

$$\begin{aligned}
\partial_1 \nu_{11} &= -2\, m_{12} \sin(x_1 - x_2)\, \lambda_1^2 - 2\, m_{13} \sin(x_1 - x_2)\, \lambda_1^3,\\
\partial_2 \nu_{11} &= 0,\\
\partial_3 \nu_{11} &= 0,
\end{aligned}$$

$$\begin{aligned}
\partial_1 \nu_{22} &= 0,\\
\partial_2 \nu_{22} &= +2\, m_{12} \sin(x_1 - x_2)\, \lambda_2^1 - 2\, m_{23} \sin(x_2 - x_3)\, \lambda_2^3,\\
\partial_3 \nu_{22} &= 0,
\end{aligned}$$

$$\begin{aligned}
\partial_1 \nu_{12} &= -m_{12} \sin(x_1 - x_2)\, \lambda_2^2 - m_{13} \sin(x_1 - x_3)\, \lambda_2^3,\\
\partial_2 \nu_{12} &= +m_{12} \sin(x_1 - x_2)\, \lambda_1^1 - m_{23} \sin(x_2 - x_3)\, \lambda_1^3,\\
\partial_3 \nu_{12} &= 0.
\end{aligned}$$

The second step is to express λ_1^1, λ_2^1, λ_1^2, and λ_2^2 in terms of ν_{11}, ν_{12}, and ν_{22}.

After substitution into the above equations, we obtain

$$\begin{aligned}
\partial_1 \nu_{11} &= D^1_{1,1}\, \nu_{11} + D^2_{1,1}\, \nu_{12} + B^1_{1,1}\, \lambda_1^3,\\
\partial_2 \nu_{11} &= 0,\\
\partial_3 \nu_{11} &= 0,\\
\partial_1 \nu_{22} &= 0,\\
\partial_2 \nu_{22} &= D^2_{3,2}\, \nu_{12} + D^3_{3,2}\, \nu_{22} + B^2_{3,2}\, \lambda_2^3,\\
\partial_3 \nu_{22} &= 0,\\
\partial_1 \nu_{12} &= D^2_{2,1}\, \nu_{12} + D^3_{2,1}\, \nu_{22} + B^2_{2,1}\, \lambda_2^3,\\
\partial_2 \nu_{12} &= D^1_{2,2}\, \nu_{11} + D^2_{2,2}\, \nu_{12} + B^1_{2,2}\, \lambda_1^3,\\
\partial_3 \nu_{12} &= 0.
\end{aligned} \tag{7.1}$$

Here the $D^k_{i,j}$ and $B^k_{i,j}$ are explicit expressions involving x. In section 2, we described a general procedure to obtain compatibility conditions for this system. In this particular case, however, we use a different tactic: we compute and compare the mixed derivatives of ν_{ab}. The first set of equations we obtain is

$$\begin{aligned}\partial_3\partial_1\,\nu_{12} &= K_{11}\,\partial_3\lambda^3_2 + K_{12}\,\lambda^3_2 = 0,\\ \partial_3\partial_2\,\nu_{22} &= K_{21}\,\partial_3\lambda^3_2 + K_{22}\,\lambda^3_2 = 0.\end{aligned}$$

Direct computation shows that $\det(K_{ij}) \neq 0$. Hence $\lambda^3_2 = 0$. Similarly,

$$\begin{aligned}\partial_3\partial_1\,\nu_{11} &= L_{11}\,\partial_3\lambda^3_1 + L_{12}\,\lambda^3_1 = 0,\\ \partial_3\partial_2\,\nu_{12} &= L_{21}\,\partial_3\lambda^3_1 + L_{22}\,\lambda^3_1 = 0,\end{aligned}$$

and $\det(L_{ij}) \neq 0$. Hence $\lambda^3_1 = 0$.

Next we substitute $\lambda^3_1 = \lambda^3_2 = 0$ into (7.1) and solve for ν_{11}, ν_{12}, ν_{22}. This gives

$$\nu_{11} = \text{const}, \qquad \nu_{22} = \frac{m_{22}}{m_{11}}\,\nu_{11}, \qquad \nu_{12} = \frac{m_{12}}{m_{11}}\cos(x^2 - x^1)\,\nu_{11}.$$

Returning to λ-equations, we see that

$$\lambda^1_1 = \lambda^2_2 = \frac{1}{m_{11}}\,\nu_{11}, \qquad \lambda^1_2 = \lambda^2_1 = 0.$$

Our computation shows that the only solutions of the matching equations are the basic solutions defined in Remark 2.2.

8. Conclusion. This paper continues the development of the λ-method for matching control laws for underactuated systems. The matching control laws are those for which the closed loop system retains the structure of the open loop system. The general conditions for such control inputs can be expressed as a nonlinear system of partial differential equations. The λ-method was introduced to replace these nonlinear equations by a sequence of linear systems of partial differential equations, λ-equations, $\widehat{g}$-equations, $\widehat{V}$-equations, and a linear algebraic system (the $\widehat{C}$-equations). The coefficients for the $\widehat{g}$- and $\widehat{V}$-equations are obtained from the solutions of the λ-equations. The λ-equations form an overdetermined system. This paper introduces a new system of equations (the ν-equations) encoding the compatibility conditions of the λ-equations. Four examples are presented to illustrate different aspects of the theory with one or more unactuated degrees of freedom.

GEOMETRIC DESCRIPTION OF VAKONOMIC AND NONHOLONOMIC DYNAMICS. COMPARISON OF SOLUTIONS*

J. CORTÉS†, M. DE LEÓN‡, D. MARTÍN DE DIEGO†, AND S. MARTÍNEZ§

Abstract. We treat the vakonomic dynamics with general constraints within a new geometric framework, which can be useful in the study of optimal control problems. We compare our formulation with the one of Vershik and Gershkovich in the case of linear constraints. We show how nonholonomic mechanics also admits a new geometrical description which allows us to develop an algorithm of comparison between the solutions of both dynamics. Examples illustrating the theory are treated.

Key words. vakonomic dynamics, nonholonomic dynamics, optimal control, symplectic geometry

1. Introduction.

As is well known, the application of tools from modern differential geometry in the fields of mechanics and control theory has caused an important progress in these research areas. For example, the study of the geometrical formulation of the nonholonomic equations of motion has led to a better comprehension of locomotion generation, controllability, motion planning, and trajectory tracking, raising new interesting questions in these subjects (see [4, 5, 26, 28, 35, 47, 49, 50] and references therein). On the other hand, there are by now many papers in which optimal control problems are addressed using geometric techniques (references [8, 23, 24, 59, 60] are good examples).

In this context, we present a unified geometrical formulation of the dynamics of nonholonomic and vakonomic systems. Both kinds of systems have the same mathematical "ingredients": a Lagrangian function and a set of nonintegrable constraints. But the way in which the equations of motion are derived differs. In the case of vakonomic systems, the dynamics is obtained through the application of a constrained variational principle [1]. In particular, an optimal control problem can be seen as a vakonomic one. The term "vakonomic" ("variational axiomatic kind") is inherited from Kozlov [29], who proposed this mechanics as an alternative set of equations of motion for a physical system in the presence of nonholonomic constraints. Nonholonomic equations of motion are deduced using d'Alembert's principle when the constraints are linear or affine.

The two approaches have received a lot of attention in recent years (see [1, 2,

10, 14, 33, 31, 36, 41, 64, 68] and references therein). Vakonomic mechanics (also called dynamical optimization subject to nonholonomic constraints) is used in mathematical economics (growth economic theory), sub-Riemannian geometry, motion of microorganisms, etc., while nonholonomic mechanics provides the evolution equations for wheeled and autonomous vehicles, robotic systems, etc.

Several authors have discussed the domains of validity of both approaches [1, 29, 36, 68]. The solutions of the resulting dynamical systems do not coincide, in general, though there are examples in which the nonholonomic solutions can be seen as solutions of the constrained variational problem. In recent papers [20, 36] the characterization of this situation has been studied. In [36] Lewis and Murray considered the example of a ball on a rotating table and showed that the subset of solutions of the nonholonomic problem is not included in the set of vakonomic ones. In [20] Favretti obtains conditions in some particular cases for the equivalence between both formulations.

Our project of unifying the comparative studies of both types of dynamics from a geometrical point of view has brought us to develop a new geometric setting for vakonomic and nonholonomic mechanics, strongly inspired on the Skinner and Rusk formulation for singular Lagrangian systems [58]. Herewith, we are able to compare them using an algorithm which gives rise, under appropriate conditions, to a final constraint submanifold containing all the nonholonomic solutions which are also vakonomic. As an application of the proposed algorithm, we extend several known results [4, 20, 36]. In particular, we prove that any solution of the unconstrained problem which verifies the constraints is simultaneously a solution of the nonholonomic and the vakonomic problems. This allows us to generalize to arbitrary metrics a result proven in [20] for bundle-like metrics and kinetic energy Lagrangians, $L = \frac{1}{2}g$.

The paper is structured as follows. In section 2, we obtain the equations of motion for vakonomic mechanics, assuming an admissibility condition, which permits us to present them in terms of the restriction of the Lagrangian to the constraint submanifold M. Let us recall that from a geometrical point of view, the Lagrangian L is defined on the tangent bundle TQ of the configuration manifold Q, and M represents the submanifold of TQ determined by the vanishing of the nonholonomic constraint functions. We will deal here with arbitrary submanifolds, that is, the constraints may be nonlinear. It should also be pointed out that we do not consider abnormal solutions. It is interesting to note that our derivation of the equations of motion shows that the information provided by L outside M is completely irrelevant for the vakonomic problem. This fact is not clearly seen in the classical way of writing the equations for vakonomic systems [1, 29].

Section 3 is devoted to a reformulation of vakonomic mechanics in geometric terms. In this section we will use as ambient space the fibered manifold $W_0 = T^*Q \times_Q M$, which is in fact a subbundle of the Whitney sum $T^*Q \oplus TQ$ (the phase space in the Skinner and Rusk approach). Since T^*Q is equipped with a canonical symplectic form we can induce a presymplectic structure ω on $T^*Q \times_Q M$. Moreover, we can consider the Hamiltonian function $H_{W_0} = \langle \pi_1, \pi_2 \rangle - \pi_2^* \tilde{L}$, where π_1 and π_2 are the canonical projections, $\langle \cdot, \cdot \rangle$ denotes the natural pairing between vectors and covectors on Q, and $\tilde{L}$ is the restriction of L to M. Then, we prove that the equations of motion of vakonomic mechanics are intrinsically represented by the presymplectic Hamiltonian equation $i_X \omega = dH_{W_0}$. Since the 2-form ω is presymplectic, a constraint algorithm must be applied in order to obtain well-defined solutions of the dynamics. If the algorithm stabilizes, we obtain a family of explicit solutions on the final constraint

submanifold. In addition, a compatibility condition is found which determines when the first constraint submanifold W_1 is symplectic (and therefore the algorithm stabilizes at the first step). We illustrate in subsections 3.1 and 3.2 how this framework can be of use in the analysis of optimal control problems.

In section 4, we compare our approach with the one of Vershik and Gershkovich [64] for vakonomic systems with linear constraints. We prove that both are related by a convenient presymplectomorphism, so that our approach could be considered as a generalization to the case of nonlinear constraints.

Since we want to compare vakonomic and nonholonomic dynamics, it is necessary to construct a geometrical framework for nonholonomic mechanics using a closed phase space. Indeed, in section 5 it is proved that the nonholonomic dynamics lives on a submanifold $\tilde{M}$ of W_0. In general, we have again a presymplectic system and a constraint algorithm is needed to obtain the dynamics on the final constraint submanifold.

In section 6, assuming that the vakonomic and the nonholonomic dynamics live on W_1 and $\tilde{M}$, respectively, we can compare their solutions by means of the map $\Upsilon : W_1 \to \tilde{M}$, $(\alpha, v) \mapsto (Leg_L(v), v)$. We present here an algorithm that selects those solutions of the nonholonomic problem that can be seen as solutions of the constrained variational one. Several illustrative examples are worked out in order to illustrate the different behaviors, showing that our framework provides a generalization and common context for the equivalence results in [4, 20, 36]. In particular, in the example of the planar mobile robot, we prove that, under an appropriate design of the system, every solution of the nonholonomic problem can be seen as a solution of the vakonomic one.

2. Variational approach to constrained mechanics. Let Q be the configuration manifold with dimension n and $L : TQ \longrightarrow \mathbb{R}$ an autonomous Lagrangian function. If (q^A), $1 \leq A \leq n$, are coordinates on Q, we denote by $(q^A, \dot{q}^A)$ the natural bundle coordinates on TQ in terms of which the tangent bundle projection $\tau_Q : TQ \longrightarrow Q$ reads as $\tau_Q(q^A, \dot{q}^A) = (q^A)$.

Let us suppose that the system is subject to some constraints given by a $(2n-m)$-dimensional submanifold M of TQ, locally defined by $\Phi^\alpha = 0$, $1 \leq \alpha \leq m$, where $\Phi^\alpha : TQ \longrightarrow \mathbb{R}$. Throughout the paper, we will assume the following admissibility condition for the submanifold $M \subseteq TQ$: for all $x \in M$, $\dim T_x M^o = \dim S^* T_x M^o$, where $S = dq^A \otimes \frac{\partial}{\partial \dot{q}^A}$ is the canonical vertical endomorphism (see [34]). This is equivalent to saying that the rank of the matrix

$$\frac{\partial(\Phi^1, \ldots, \Phi^m)}{\partial(\dot{q}^1, \ldots, \dot{q}^n)}$$

is m for any choice of coordinates $(q^A, \dot{q}^A)$ in TQ. Consequently, by the implicit function theorem, we can locally express the constraints (reordering coordinates if necessary) as

$$\dot{q}^\alpha = \Psi^\alpha(q^A, \dot{q}^a), \tag{2.1}$$

where $1 \leq \alpha \leq m$, $m+1 \leq a \leq n$, and $1 \leq A \leq n$. Then, $(q^A, \dot{q}^a)$ are local coordinates for the submanifold M of TQ.

We denote the set of twice differentiable curves connecting two points $x, y \in Q$ as

$$\mathcal{C}^2(x, y) = \{c : [0, 1] \longrightarrow Q \mid c \text{ is } C^2,\ c(0) = x \text{ and } c(1) = y\}.$$

This set is a differentiable infinite-dimensional manifold [3].

Let c be a curve in $\mathcal{C}^2(x,y)$. A variation of c is a curve c_s in $\mathcal{C}^2(x,y)$, that is a differentiable mapping $c_s : (-\epsilon,\epsilon) \to \mathcal{C}^2(x,y)$, $s \mapsto c_s(t)$, such that $c_0 = c$. An infinitesimal variation of c is the tangent vector of a variation of c, that is,

$$u(t) = \frac{dc_s(t)}{ds}\Big|_{s=0} \in T_{c(t)}Q.$$

The tangent space of $\mathcal{C}^2(x,y)$ at c is then given by

$$T_c\mathcal{C}^2(x,y) = \{u : [0,1] \longrightarrow TQ \mid u \text{ is } C^1,\ u(t) \in T_{c(t)}Q,\ u(0) = 0 \text{ and } u(1) = 0\}.$$

Now, we introduce a special subset $\tilde{\mathcal{C}}^2(x,y)$ of $\mathcal{C}^2(x,y)$ which consists of those curves whose velocities belong to the constraint submanifold M:

$$\tilde{\mathcal{C}}^2(x,y) = \{c \in \mathcal{C}^2(x,y) \mid \dot{c}(t) \in M_{c(t)} = M \cap \tau_Q^{-1}(c(t))\ \forall t \in [0,1]\}.$$

Finally, let us consider the action functional $\mathcal{J}$ defined by

$$\mathcal{J} : \mathcal{C}^2(x,y) \longrightarrow \mathbb{R}, \quad c \mapsto \mathcal{J}(c) = \int_0^1 L(\dot{c}(t))\,dt.$$

DEFINITION 2.1. *The vakonomic problem associated with (Q, L, M, x, y) consists of extremizing the functional $\mathcal{J}$ among the curves satisfying the constraints imposed by M, $c \in \tilde{\mathcal{C}}^2(x,y)$. Hence, a curve $c \in \tilde{\mathcal{C}}^2(x,y)$ will be a solution of the vakonomic problem if c is a critical point of $\mathcal{J}_{|\tilde{\mathcal{C}}^2(x,y)}$.*

Remark 2.2. In this paper, we will assume that the solution curves $c \in \tilde{\mathcal{C}}(x,y)$ admit enough nontrivial variations in $\tilde{\mathcal{C}}(x,y)$. These solutions are called normal in the literature, in contrast to the abnormal ones, which are pathological curves which do not admit sufficient nontrivial variations [1]. Several investigators have shown the existence of C^1, stable under perturbations abnormal $\mathcal{J}$-minimizing solutions [37, 45].

Now, we find a characterization for the solutions of the vakonomic problem.

PROPOSITION 2.3. *A curve $c \in \tilde{\mathcal{C}}^2(x,y)$ is a normal solution of the vakonomic problem if and only if there exists $\mu : [0,1] \to \mathbb{R}^m$ such that*

$$\text{(2.2)} \qquad \begin{cases} \dfrac{d}{dt}\left(\dfrac{\partial \tilde{L}}{\partial \dot{q}^a}\right) - \dfrac{\partial \tilde{L}}{\partial q^a} = \mu_\alpha \left[\dfrac{d}{dt}\left(\dfrac{\partial \Psi^\alpha}{\partial \dot{q}^a}\right) - \dfrac{\partial \Psi^\alpha}{\partial q^a}\right] + \dot{\mu}_\alpha \dfrac{\partial \Psi^\alpha}{\partial \dot{q}^a}, \\ \dot{\mu}_\alpha = \dfrac{\partial \tilde{L}}{\partial q^\alpha} - \mu_\beta \dfrac{\partial \Psi^\beta}{\partial q^\alpha}, \\ \dot{q}^\alpha = \Psi^\alpha(q^A, \dot{q}^a), \end{cases}$$

where $\tilde{L} : M \to \mathbb{R}$ is the restriction of L to M.

Proof. The condition for a curve to be a solution of the vakonomic problem is

$$0 = d\mathcal{J}(c) \cdot u = \frac{d}{ds}\mathcal{J}(c_s)\Big|_{s=0},$$

for any variation c_s in $\tilde{\mathcal{C}}^2(x,y)$ of c, where $u = \frac{dc_s}{ds}|_{s=0}$. Then, we have that

$$0 = \frac{d}{ds}\mathcal{J}(c_s)\Big|_{s=0} = \frac{d}{ds}\left(\int_0^1 L(\dot{c}_s(t))\,dt\right)\Big|_{s=0} = \int_0^1 \frac{d}{ds}L(\dot{c}_s(t))\Big|_{s=0} dt.$$

In local coordinates, we obtain

$$
\begin{aligned}
0 &= \int_0^1 \left(\frac{\partial L}{\partial q^A} u^A + \frac{\partial L}{\partial \dot{q}^a} \dot{u}^a + \frac{\partial L}{\partial \dot{q}^\alpha} \frac{\partial \Psi^\alpha}{\partial q^A} u^A + \frac{\partial L}{\partial \dot{q}^\alpha} \frac{\partial \Psi^\alpha}{\partial \dot{q}^a} \dot{u}^a \right) dt \\
&= \int_0^1 \left(\left[\frac{\partial L}{\partial q^A} + \frac{\partial L}{\partial \dot{q}^\alpha} \frac{\partial \Psi^\alpha}{\partial q^A} \right] u^A + \left[\frac{\partial L}{\partial \dot{q}^a} + \frac{\partial L}{\partial \dot{q}^\alpha} \frac{\partial \Psi^\alpha}{\partial \dot{q}^a} \right] \dot{u}^a \right) dt \\
&= \int_0^1 \left(\frac{\partial \tilde{L}}{\partial q^A} u^A + \frac{\partial \tilde{L}}{\partial \dot{q}^a} \dot{u}^a \right) dt.
\end{aligned} \tag{2.3}
$$

From (2.1) we know that the infinitesimal variations u^A, $1 \le A \le n$, are not arbitrary. Consider the functions μ_α defined as the solutions of the following system of first order differential equations

$$
\dot{\mu}_\alpha = \frac{\partial \tilde{L}}{\partial q^\alpha}\Big|_c - \mu_\beta \frac{\partial \Psi^\beta}{\partial q^\alpha}\Big|_c, \qquad 1 \le \alpha \le m.
$$

Then, using the fact that $\dot{u}^\alpha = \frac{\partial \Psi^\alpha}{\partial q^A} u^A + \frac{\partial \Psi^\alpha}{\partial \dot{q}^a} \dot{u}^a$, we get

$$
\frac{d}{dt}(\mu_\alpha u^\alpha) = \mu_\alpha \dot{u}^\alpha + \left(\frac{\partial \tilde{L}}{\partial q^\alpha} - \mu_\beta \frac{\partial \Psi^\beta}{\partial q^\alpha} \right) u^\alpha = u^\alpha \frac{\partial \tilde{L}}{\partial q^\alpha} + \mu_\alpha \frac{\partial \Psi^\alpha}{\partial q^a} u^a + \mu_\alpha \frac{\partial \Psi^\alpha}{\partial \dot{q}^a} \dot{u}^a,
$$

or, equivalently, $u^\alpha \frac{\partial \tilde{L}}{\partial q^\alpha} = \frac{d}{dt}(\mu_\alpha u^\alpha) - \mu_\alpha \frac{\partial \Psi^\alpha}{\partial q^a} u^a - \mu_\alpha \frac{\partial \Psi^\alpha}{\partial \dot{q}^a} \dot{u}^a$. Substituting the last expression in (2.3) and integrating by parts, we obtain

$$
d\mathcal{J}(c) \cdot u = \int_0^1 \left(\left[\frac{\partial \tilde{L}}{\partial q^a} - \mu_\alpha \frac{\partial \Psi^\alpha}{\partial q^a} \right] u^a + \left[\frac{\partial \tilde{L}}{\partial \dot{q}^a} - \mu_\alpha \frac{\partial \Psi^\alpha}{\partial \dot{q}^a} \right] \dot{u}^a \right) dt.
$$

Now, since

$$
\left[\frac{\partial \tilde{L}}{\partial \dot{q}^a} - \mu_\alpha \frac{\partial \Psi^\alpha}{\partial \dot{q}^a} \right] \dot{u}^a = \frac{d}{dt} \left(\left[\frac{\partial \tilde{L}}{\partial \dot{q}^a} - \mu_\alpha \frac{\partial \Psi^\alpha}{\partial \dot{q}^a} \right] u^a \right) - \frac{d}{dt} \left(\frac{\partial \tilde{L}}{\partial \dot{q}^a} - \mu_\alpha \frac{\partial \Psi^\alpha}{\partial \dot{q}^a} \right) u^a,
$$

using again integration by parts, we can write

$$
0 = \int_0^1 \left[\frac{\partial \tilde{L}}{\partial q^a} - \mu_\alpha \frac{\partial \Psi^\alpha}{\partial q^a} - \frac{d}{dt} \left(\frac{\partial \tilde{L}}{\partial \dot{q}^a} - \mu_\alpha \frac{\partial \Psi^\alpha}{\partial \dot{q}^a} \right) \right] u^a \, dt.
$$

As the infinitesimal variations u^a are arbitrary, the fundamental lemma of the calculus of variations applies and we can assert that $d\mathcal{J}(c) \cdot u = 0$ if and only if c and μ_α satisfy (2.2). □

Remark 2.4. The usual way in which the equations of motion for vakonomic mechanics are presented is the following:

$$
\begin{cases}
\dfrac{d}{dt} \left(\dfrac{\partial L}{\partial \dot{q}^A} \right) - \dfrac{\partial L}{\partial q^A} = \dot{\lambda}_\alpha \dfrac{\partial \Phi^\alpha}{\partial \dot{q}^A} + \lambda_\alpha \left[\dfrac{d}{dt} \left(\dfrac{\partial \Phi^\alpha}{\partial \dot{q}^A} \right) - \dfrac{\partial \Phi^\alpha}{\partial q^A} \right], \\
\Phi^\alpha(q, \dot{q}) = 0, \qquad 1 \le \alpha \le m,
\end{cases} \tag{2.4}
$$

where $\Phi^\alpha = \Psi^\alpha - \dot{q}^\alpha$ and $\lambda_\alpha = \frac{\partial L}{\partial \dot{q}^\alpha} - \mu_\alpha$, $1 \leq \alpha \leq m$. Observe that, in contrast to (2.2), (2.4) are expressed in terms of the ambient Lagrangian $L : TQ \to \mathbb{R}$. Equations (2.2) stress how the information given by L outside M is irrelevant to obtain the vakonomic equations, a fact that it is not promptly deduced from (2.4). This is in contrast with what happens in nonholonomic mechanics (see section 5 below).

Equations (2.4) can be seen as the Euler–Lagrange equations for the extended Lagrangian $\mathcal{L} = L + \lambda_\alpha \Phi^\alpha$. We will not follow this approach here, which has been exploited successfully in [20, 28, 42, 43]. Finally, note that if we consider the extended Lagrangian $\lambda_0 L + \lambda_\alpha \Phi^\alpha$, with $\lambda_0 = 1$ or 0, then we recover all the solutions, both the normal and the abnormal ones [1].

3. Geometric approach to vakonomic mechanics. We will develop a geometric characterization of vakonomic mechanics following an approach similar to the formulation given by Skinner and Rusk [58] for singular Lagrangians (see also [15, 22, 38]). This characterization is specially interesting, for it enables us to study both linear and nonlinear constraints in an intrinsic way. Moreover, as we shall discuss later, this formalism will allow to use ideas from geometric mechanics in the treatment of optimal control problems.

Consider the Whitney sum of T^*Q and TQ, $T^*Q \oplus TQ$, and its canonical projections $pr_1 : T^*Q \oplus TQ \longrightarrow T^*Q$, $pr_2 : T^*Q \oplus TQ \longrightarrow TQ$. Let us take the submanifold $W_0 = pr_2^{-1}(M)$, where M is the constraint submanifold, locally determined by the constraint equations $\Phi^\alpha = 0$, $1 \leq \alpha \leq m$. We will denote $W_0 = T^*Q \times_Q M$ and $\pi_1 = pr_{1|W_0}$, $\pi_2 = pr_{2|W_0}$. Now, define on $T^*Q \times_Q M$ the presymplectic 2-form $\omega = \pi_1^* \omega_Q$, where ω_Q is the canonical symplectic form on T^*Q. Observe that the rank of this presymplectic form is equal to $2n$ everywhere. Define also the function

$$H_{W_0} = \langle \pi_1, \pi_2 \rangle - \pi_2^* \tilde{L},$$

where $\langle \cdot, \cdot \rangle$ denotes the natural pairing between vectors and covectors on Q.

If (q^A) are local coordinates on a neighborhood U of Q, $(q^A, \dot{q}^a)$ coordinates on $TU \cap M$, and (q^A, p_A) the induced coordinates on T^*U, then we have induced coordinates $(q^A, p_A, \dot{q}^a)$ on $T^*U \times_Q (TU \cap M)$. Locally, the Hamiltonian function H_{W_0} reads as

$$H_{W_0}(q^A, p_A, \dot{q}^a) = p_a \dot{q}^a + p_\alpha \Psi^\alpha - \tilde{L}(q^A, \dot{q}^a),$$

and the 2-form ω is $\omega = dq^A \wedge dp_A$.

Now, we will see how the dynamics of the vakonomic system (2.2) is determined by the solutions of the equation

$$i_X \omega = dH_{W_0}. \tag{3.1}$$

This then justifies the use of the following terminology.

DEFINITION 3.1. *The presymplectic Hamiltonian system* $(T^*Q \times_Q M, \omega, H_{W_0})$ *will be called vakonomic Hamiltonian system.*

The system $(T^*Q \times_Q M, \omega, H_{W_0})$ being presymplectic, we may apply Gotay Nester's constraint algorithm [21]. First we consider the set of points W_1 of $T^*Q \times_Q M$ where (3.1) has a solution. This first constraint submanifold is determined by

$$W_1 = \{x \in T^*Q \times_Q M \mid dH_{W_0}(x)(V) = 0 \ \forall V \in \ker \omega(x)\}.$$

Locally, $\ker\omega = \operatorname{span}\langle\partial/\partial\dot{q}^a\rangle$. Therefore, the constraint submanifold W_1 is locally characterized by the vanishing of the constraints

$$\varphi_a = p_a + p_\alpha \frac{\partial \Psi^\alpha}{\partial \dot{q}^a} - \frac{\partial \tilde{L}}{\partial \dot{q}^a} = 0, \qquad m+1 \le a \le n,$$

or, equivalently,

$$p_a = \frac{\partial \tilde{L}}{\partial \dot{q}^a} - p_\alpha \frac{\partial \Psi^\alpha}{\partial \dot{q}^a}, \qquad m+1 \le a \le n. \tag{3.2}$$

Expanding the expressions in (3.1) the equations of motion along W_1 are

$$\dot{q}^A = \frac{\partial H_{W_0}}{\partial p_A}, \qquad \dot{p}_A = -\frac{\partial H_{W_0}}{\partial q^A},$$

which is equivalent to

$$\dot{q}^\alpha = \Psi^\alpha(q^A, \dot{q}^a), \tag{3.3}$$

$$\dot{p}_\alpha = \frac{\partial \tilde{L}}{\partial q^\alpha} - p_\beta \frac{\partial \Psi^\beta}{\partial q^\alpha}, \tag{3.4}$$

$$\frac{d}{dt}\left(\frac{\partial \tilde{L}}{\partial \dot{q}^a} - p_\alpha \frac{\partial \Psi^\alpha}{\partial \dot{q}^a}\right) = \frac{\partial \tilde{L}}{\partial q^a} - p_\beta \frac{\partial \Psi^\beta}{\partial q^a}. \tag{3.5}$$

Observe that these equations are precisely the vakonomic equations of motion (2.2), where now $p_\alpha = \mu_\alpha$, $1 \le \alpha \le m$.

Remark 3.2. The momenta p_α, $1 \le \alpha \le m$, play the role of the Lagrange multipliers, but they do not have any physical meaning (see [61]).

Therefore, a vector field X solution of (3.1) will generally be of the form

$$\begin{aligned} X = {} & \dot{q}^a \left(\frac{\partial}{\partial q^a} + \left(\frac{\partial^2 \tilde{L}}{\partial q^a \partial \dot{q}^b} - p_\gamma \frac{\partial^2 \Psi^\gamma}{\partial q^a \partial \dot{q}^b} \right) \frac{\partial}{\partial p_b} \right) \\ & + \Psi^\alpha \left(\frac{\partial}{\partial q^\alpha} + \left(\frac{\partial^2 \tilde{L}}{\partial q^\alpha \partial \dot{q}^b} - p_\gamma \frac{\partial^2 \Psi^\gamma}{\partial q^\alpha \partial \dot{q}^b} \right) \frac{\partial}{\partial p_b} \right) \\ & + \bar{X}^a \left(\frac{\partial}{\partial \dot{q}^a} + \left(\frac{\partial^2 \tilde{L}}{\partial \dot{q}^a \partial \dot{q}^b} - p_\gamma \frac{\partial^2 \Psi^\gamma}{\partial \dot{q}^a \partial \dot{q}^b} \right) \frac{\partial}{\partial p_b} \right) \\ & + \left(\frac{\partial \tilde{L}}{\partial q^\alpha} - p_\beta \frac{\partial \Psi^\beta}{\partial q^\alpha} \right) \left(\frac{\partial}{\partial p_\alpha} - \frac{\partial \Psi^\alpha}{\partial \dot{q}^b} \frac{\partial}{\partial p_b} \right), \end{aligned}$$

where the coefficients $\bar{X}^a$ are still undetermined. The solution on W_1 may not be tangent to W_1. In such a case, we have to restrict W_1 to the submanifold W_2 where this solution is tangent to W_1. Proceeding further, we obtain a sequence of submanifolds (we are assuming that all the subsets generated by the algorithm are submanifolds)

$$\cdots \hookrightarrow W_k \hookrightarrow \cdots \hookrightarrow W_2 \hookrightarrow W_1 \hookrightarrow W_0 = T^*Q \times_Q M.$$

Algebraically, these constraint submanifolds may be described as

$$W_i = \{ x \in T^*Q \times_Q M \mid dH_{W_0}(x)(v) = 0 \ \forall v \in T_x W_{i-1}^\perp \}, \qquad i \ge 1, \tag{3.6}$$

where $T_xW_{i-1}^{\perp} = \{v \in T_x(T^*Q \times_Q M) \mid \omega(x)(u,v) = 0 \ \forall u \in T_xW_{i-1}\}$. If this constraint algorithm stabilizes, i.e., if there exists a positive integer $k \in \mathbb{N}$ such that $W_{k+1} = W_k \neq W_{k-1}$ and $\dim W_k \neq 0$, then we will have obtained a final constraint submanifold $W_f = W_k$ on which a vector field X exists such that

$$(i_X\omega = dH_{W_0})_{|W_f}.$$

Note that on W_f we will have an explicit solution of the vakonomic dynamics. A very important particular case is when the final constraint submanifold is the first one, i.e., $W_f = W_1$. Observe that the dimension of W_1 is even, $\dim W_1 = 2n$. In what follows, we will investigate when this constraint submanifold is equipped with a symplectic 2-form in order to determine a unique solution X of the vakonomic equations. Obviously, this geometrical study is related to the explicit or implicit character of the second order differential equations obtained in (2.2).

Denote by ω_{W_1} the restriction of the presymplectic 2-form ω to W_1.

PROPOSITION 3.3. *(W_1, ω_{W_1}) is a symplectic manifold if and only if for any point of W_1,*

$$\det\left(\frac{\partial^2\tilde{L}}{\partial\dot{q}^a\partial\dot{q}^b} - p_\alpha\frac{\partial^2\Psi^\alpha}{\partial\dot{q}^a\partial\dot{q}^b}\right) \neq 0. \tag{3.7}$$

Proof. ω_{W_1} is symplectic if and only if $T_xW_1 \cap (T_xW_1)^{\perp} = 0$ for all $x \in W_1$. This condition is satisfied if and only if the matrix $d\varphi_a(\frac{\partial}{\partial\dot{q}^b})$ is regular, that is,

$$\det\left(\frac{\partial^2\tilde{L}}{\partial\dot{q}^a\partial\dot{q}^b} - p_\alpha\frac{\partial^2\Psi^\alpha}{\partial\dot{q}^a\partial\dot{q}^b}\right) \neq 0$$

for all $x \in W_1$. □

In this case, (3.5) can be rewritten in explicit form as

$$\ddot{q}^a = -\bar{\mathcal{C}}^{ab}\left[\dot{q}^A\frac{\partial^2\tilde{L}}{\partial q^A\partial\dot{q}^b} - \dot{q}^A p_\alpha\frac{\partial^2\Psi^\alpha}{\partial q^A\partial\dot{q}^b} - \frac{\partial\tilde{L}}{\partial q^b} + p_\alpha\frac{\partial\Psi^\alpha}{\partial q^b} - \left(\frac{\partial\tilde{L}}{\partial q^\gamma} - p_\beta\frac{\partial\Psi^\beta}{\partial q^\gamma}\right)\frac{\partial\Psi^\gamma}{\partial\dot{q}^b}\right], \tag{3.8}$$

where

$$\bar{\mathcal{C}}_{ab} = \frac{\partial^2\tilde{L}}{\partial\dot{q}^a\partial\dot{q}^b} - p_\alpha\frac{\partial^2\Psi^\alpha}{\partial\dot{q}^a\partial\dot{q}^b}, \tag{3.9}$$

and $(\bar{\mathcal{C}}^{ab})$ denotes the inverse matrix of $(\bar{\mathcal{C}}_{ab})$.

Remark 3.4. The characterization found in Proposition 3.3 for the symplectic nature of the manifold (W_1, ω_{W_1}) implies, by the implicit function theorem, that the constraint equations

$$\varphi_a = p_a + p_\alpha\frac{\partial\Psi^\alpha}{\partial\dot{q}^a} - \frac{\partial\tilde{L}}{\partial\dot{q}^a} = 0, \qquad m+1 \leq a \leq n,$$

locally determine the variables $\dot{q}^a$, $m+1 \leq a \leq n$. That is, we have $\dot{q}^a = \varsigma^a(q^A, p_A)$, $m+1 \leq a \leq n$. Therefore, we can also consider local coordinates (q^A, p_A) on W_1. In such a case, the symplectic form and the restriction of the Hamiltonian H_{W_0} to W_1 have the following local expressions:

$$\omega_{W_1} = dq^A \wedge dp_A, \qquad H_{W_1} = p_a\varsigma^a + p_\alpha\Psi^\alpha - \bar{L}(q^A, p_A),$$

where $\bar{L}(q^A, p_A) = \tilde{L}(q^A, \varsigma^a(q^A, p_A))$. Consequently, (3.3)–(3.5) can be rewritten in Hamiltonian form as

$$\dot{q}^A = \frac{\partial H_{W_1}}{\partial p_A}, \qquad \dot{p}_A = -\frac{\partial H_{W_1}}{\partial q^A}.$$

This choice of coordinates is common in optimal control theory.

Now, observe that, if the constraints are linear in the velocities, we can write $\dot{q}^\alpha = \Psi_a^\alpha(q)\dot{q}^a$. Then, from Proposition 3.3, ω_{W_1} is symplectic if and only if

$$\det\left(\frac{\partial^2 \tilde{L}}{\partial \dot{q}^a \partial \dot{q}^b}\right) \neq 0.$$

PROPOSITION 3.5. *Suppose that the constraints are given by* $\dot{q}^\alpha = \Psi_a^\alpha(q)\dot{q}^a$, $1 \leq \alpha \leq m$, *and the Lagrangian* L *is regular. Denote by* (W^{AB}) *the inverse matrix of the Hessian matrix of* L. *In this case,* ω_{W_1} *is symplectic on* W_1 *if and only if the constraints are compatible, that is, the matrix whose entries are*

$$\mathcal{C}^{\alpha\beta} = W^{ab}\Psi_a^\alpha\Psi_b^\beta - W^{\alpha b}\Psi_b^\beta - W^{a\beta}\Psi_a^\alpha + W^{\alpha\beta}$$

is nonsingular.

Proof. See the geometrical proof of Theorem IV.3 in reference [33]. □

Remark 3.6. The compatibility condition guarantees the existence and uniqueness of the solutions for the nonholonomic problem with Lagrangian L and constraint submanifold M [33, 57].

Before ending this section, we would like to make some remarks concerning this geometric approach to vakonomic dynamics. First of all, we must say that it provides an intrinsic formulation of variational problems subject to both linear and *nonlinear* constraints on *manifolds*. In addition, this formulation belongs to the context of Symplectic Geometry and Geometric Mechanics, following previous work by Bloch and Crouch [4, 8, 9], Jurdjevic [23, 24], and others. There is a whole collection of ideas and methods ensuing from these fields that have been used in the treatment of optimal control problems. Apart from being of use as a tool for an algorithmic study of the existence of optimal solutions and their domains of definition, we think that this formulation has something to contribute in at least three directions: the study of the symmetry properties of constrained problems [8, 18, 24, 43] (infinitesimal, Noether and Cartan symmetries, dynamical symmetries, ...), the study of higher order variational problems [6] (since a generalization of our approach to the higher order case seems to be straightforward), and the development of numerical integrators [19, 55, 65, 66, 67] that take into account the geometry of the problem (2-form, Hamiltonian, momentum) and are competitive with the traditional methods.

An immediate outcome of the formulation on $T^*Q \times_Q M$ is that for the study of problems subject to nonlinear constraints we can use similar techniques to those used for the linear case. Finally, this framework will allow us in section 6 to compare vakonomic dynamics with nonholonomic dynamics within a common setting.

In the following, we aim to illustrate some of the above ideas on two examples.

3.1. Applications in economy. The variational calculus is an indispensable tool in many economic problems [25, 39, 52]. In fact, a typical optimization problem in modern economics deals with extremizing the functional

$$\int_0^T D(t)U[f(t, k, \dot{k})]\, dt$$

subject or not to constraints. Here, $D(t)$ is a discount rate factor, U a utility function, f a consumption function, and k the capital-labor ratio. It is common to find dynamical economic models with nonholonomic constraints.

Example 3.7 (closed von Neumann system [53, 54, 56]). Consider the transformation function F on $\mathbb{R}^{2n}$ which relates n capital goods $K_1, K_2, \dots, K_n$ and the net capital formations $\dot{K}_1, \dot{K}_2, \dots, \dot{K}_n$ as

$$F(K_1, \dots, K_n, \dot{K}_1, \dots, \dot{K}_n) = K_1^{\alpha_1} K_2^{\alpha_2} \cdots K_n^{\alpha_n} - \left[\dot{K}_1^2 + \cdots + \dot{K}_n^2\right]^{1/2},$$

with $\alpha_1 + \alpha_2 + \cdots + \alpha_n = 1$. The von Neumann problem consists of maximizing

$$\int_0^T \dot{K}_n \, dt \quad \text{subject to} \quad F(K_1, \dots, K_n, \dot{K}_1, \dots, \dot{K}_n) = 0,$$

with appropriate initial conditions.

Our formalism makes it possible to write this problem as a presymplectic system on $W_0 = \mathbb{R}^{3n-1}$. The constraint $F = 0$ can be rewritten as

$$\dot{K}_1 = \pm \left(K_1^{2\alpha_1} \cdots K_n^{2\alpha_n} - \sum_{i=2}^{n} \dot{K}_i^2 \right)^{1/2} = \pm \Psi(K_1, \dots, K_n, \dot{K}_2, \dots, \dot{K}_n).$$

Here, we restrict the analysis to the component $\dot{K}_1 = \Psi$. Taking coordinates $(K_1, \dots, K_n, \dot{K}_2, \dots, \dot{K}_n, P^1, \dots, P^n)$ we have that

$$\omega = \sum_{j=1}^{n} dK_j \wedge dP^j, \; H_{W_0} = \sum_{i=2}^{n} P^i \dot{K}_i + P^1 \cdot \left(K_1^{2\alpha_1} K_2^{2\alpha_2} \cdots K_n^{2\alpha_n} - \sum_{i=2}^{n} \dot{K}_i^2 \right)^{1/2} - \dot{K}_n.$$

Applying the Gotay and Nester algorithm, new constraints arise,

$$P^i = P^1 \dot{K}_i \left(K_1^{2\alpha_1} K_2^{2\alpha_2} \cdots K_n^{2\alpha_n} - \sum_{i=2}^{n} \dot{K}_i^2 \right)^{-1/2}, \qquad 2 \le i \le n-1,$$

$$P^n = 1 + P^1 \dot{K}_n \left(K_1^{2\alpha_1} K_2^{2\alpha_2} \cdots K_n^{2\alpha_n} - \sum_{i=2}^{n} \dot{K}_i^2 \right)^{-1/2}.$$

Therefore, from (3.3)–(3.5) the initial system is determined by solving the following n differential equations on the variables $(K_1, \dots, K_n, \dot{K}_2, \dots, \dot{K}_n, P^1)$:

(3.10)

$$\begin{cases} \dot{P}^1 = -P^1 \alpha_1 \left(K_1^{2\alpha_1 - 1} K_2^{2\alpha_2} \cdots K_n^{2\alpha_n} \right) G \\ 0 = \dot{P}^1 \dot{K}_i G \\ \qquad + P^1 \left[\left(\ddot{K}_i + \alpha_i \left(K_1^{2\alpha_1} \cdots K_i^{2\alpha_i - 1} \cdots K_n^{2\alpha_n} \right) \right) G + \dot{K}_i \dfrac{d}{dt}(G) \right], \quad 2 \le i \le n, \end{cases}$$

where $G = 1/\Psi$. The presymplectic context for these optimal equations provides us with some new insights into the problem. On the one hand, the existence of well-defined solutions to (3.10) is not guaranteed in general. It can occur, for instance, that an optimal curve starting from a point in W_1 "escapes" from this phase space

after some time because the dynamical vector field is no longer tangent to W_1. But one can indeed eliminate this possibility. Consider the case $n = 2$ for simplicity. Assume $\Psi \neq 0$. Otherwise the dynamics is fully determined and the optimization problem is trivial (we have abnormal solutions). The determinant (3.7) is equal to

$$\frac{P^1}{\Psi^3}(\Psi^2 + \dot{K}_2^2) = \frac{H_{W_1}}{\Psi^2}. \tag{3.11}$$

Therefore, if the optimal curve starts from any point in $x \in W_1$ such that $H_{W_1}(x) \neq 0$, (3.11) guarantees that the dynamics of the vakonomic problem remains tangent to W_1. On the other hand, the optimal solutions with $H_{W_1} = 0$ are stationary curves, $K_1 = \text{const}$, $K_2 = \text{const}$, and $K_1 K_2 = 0$.

This formulation can also shed light on the aspect of symmetries and conservation laws. It is known [53, 54, 56] that the closed von Neumann system possesses, besides the Hamiltonian H, another conservation law, which is usually found by ad hoc methods. However, it is not difficult to define in our context the notion of *Noether symmetry* and verify that the vector field

$$Y = \sum_{j=1}^{n} K_i \frac{\partial}{\partial K^i} \in \mathfrak{X}(Q)$$

indeed corresponds to such a symmetry. The associated conservation law is precisely given by $\Phi = P^1(K_1\Psi + \sum_{j=2}^{n} K_j \dot{K}_j)/\Psi$. In the same way, one can explore the presence of other types of symmetries, like Cartan symmetries, for example, [32, 34, 48].

Finally, obtaining explicit solutions of (3.10) is, in general, a very difficult task. The use of numerical integrators can help in analyzing the behavior of the system. In the last years there has been an increasing activity in the development of integrators that take into account the geometric structures associated with the problem [19, 55, 65, 66, 67]. The proposed formalism offers the possibility of designing such methods for a variety of optimal control problems.

3.2. LC-circuits. The dynamics of nonlinear LC electric circuits [44] can be given a variational interpretation, as discussed in [46]. Here, we treat this class of systems under our vakonomic formalism and study the well-posedness of the optimal equations.

Consider a circuit consisting of capacitors and inductors, which are charge and current controlled. Let $\mathcal{C}$ be the collection of n-capacitor branches and $\mathcal{L}$ the m-inductor branches. Denote by $q \in Q_{\mathcal{C}}$ the vector of capacitor charges and by $i \in Q_{\mathcal{L}}$ the inductor currents. Kirchhoff's current and voltage laws require that $\dot{q} = A_{\mathcal{C}} u$, $i = A_{\mathcal{L}} u$, where $A_{\mathcal{C}}$ and $A_{\mathcal{L}}$ are appropriate linear maps from a vector space $\mathcal{U}$ to $Q_{\mathcal{C}}$ and $Q_{\mathcal{L}}$ characterizing, respectively, the topology of the network and the chosen current reference directions. The new variables $u \in \mathcal{U}$ are usually thought of as a vector of some independent loop currents. The generality of the interconnection structure of the circuit relies on how general the matrices $A_{\mathcal{C}}$, $A_{\mathcal{L}}$ can be. In the following, we will assume that $A_{\mathcal{L}}$ is nonsingular and then the space $\mathcal{U}$ will be identified with $Q_{\mathcal{L}}$ through $A_{\mathcal{L}}$. Finally, denote by $W_e : Q_{\mathcal{C}} \to \mathbb{R}$ the electric energy and by $W_m^* : Q_{\mathcal{L}} \to \mathbb{R}$ the magnetic coenergy of the circuit.

The dynamics of the circuit is governed by the element equations, the equations arising from Kirchhoff's current law, and those arising from Kirchhoff's voltage law.

After some manipulations, these equations may be reduced to

$$\dot{q} = A_{\mathcal{C}} u, \qquad A^*_{\mathcal{L}} \frac{d}{dt} \left(dW^*_m(A_{\mathcal{L}} u) \right) = -A^*_{\mathcal{C}} dW_e(q), \tag{3.12}$$

where the star superscript denotes the transpose of the corresponding matrix operator. However, the well-posedness of this mathematical model for the electric circuit is not guaranteed in general. It could be, for instance, that some specifications of initial conditions $(q(0), u(0))$ turn out to be incompatible with the algebraic constraints embedded in (3.12).

The theoretical setting described above can bring some new insight into this question. Consider as configuration space the product manifold $Q = Q_{\mathcal{C}} \times Q_{\mathcal{L}}$ with coordinates (q^α, u^a). Let $L : TQ \to \mathbb{R}$, $L = W^*_m(A_{\mathcal{L}} u) - W_e(q)$, be the Lagrangian and define $M \subseteq TQ$ by $\dot{q}^\alpha = (A_{\mathcal{C}})^\alpha_b u^b$ as the submanifold of constraints. Then, the dynamics of the LC-circuit is found to be defined on the tertiary constraint submanifold of the presymplectic Hamiltonian system $(T^*Q \times_Q M, \omega, H)$. This means that all initial conditions in W_3 are compatible in the sense of the previous paragraph.

Let $(q^\alpha, u^a, \xi_\alpha, \zeta_a, \dot{u}^a)$ be the local coordinates in $W_0 = T^*Q \times_Q M$. Then,

$$\omega = dq^\alpha \wedge d\xi_\alpha + du^a \wedge d\zeta_a, \qquad H = \zeta_a \dot{u}^a + \xi_\alpha A^\alpha_{\mathcal{C}b} u^b - W^*_m(A_{\mathcal{L}} u) + W_e(q).$$

The first submanifold of constraints is given by $W_1 = \{ x \in W_0 \,|\, dH_x(\frac{\partial}{\partial \dot{u}^a}) = \zeta_a = 0 \}$. After some computations, we find that

$$TW_1 \cap TW_1^\perp = \operatorname{span} \left\{ \frac{\partial}{\partial u^a}, \frac{\partial}{\partial \dot{u}^a} \right\},$$

and hence we must continue with the constraint algorithm. Following (3.6), we have that W_2 is described by the new constraints

$$\frac{\partial H}{\partial u^a} = \left[A^*_{\mathcal{C}} \xi - A^*_{\mathcal{L}} dW^*_m(A_{\mathcal{L}} u) \right]_a = 0. \tag{3.13}$$

Under the additional assumption of invertibility of dW^*_m, or, equivalently, under the assumption that the LC-circuit is also flux controlled, we can ensure that there exists a magnetic energy W_m such that $dW^*_m(A_{\mathcal{L}} u) = \phi \iff A_{\mathcal{L}} u = dW_m(\phi)$. Then, we can rewrite (3.13) as

$$u = A^{-1}_{\mathcal{L}} dW_m((A^{-1}_{\mathcal{L}})^* A^*_{\mathcal{C}} \xi) \equiv F(\xi)$$

and consider $(q^\alpha, \xi_\alpha, \dot{u}^a)$ as a set of coordinates on W_2. The following step of the algorithm leads us to the constraints

$$\frac{\partial H}{\partial \zeta_a} + \frac{\partial F^a}{\partial \xi_\alpha} \frac{\partial H}{\partial q^\alpha} = \dot{u}^a + \frac{\partial F^a}{\partial \xi_\alpha} dW_e(q) = 0.$$

In this way, we have (q^α, ξ_α) as coordinates on W_3, which turns out to be the final constraint submanifold. The dynamics of the system is described on W_3 by the differential equations

$$\dot{q}^\alpha = A_{\mathcal{C}} F(\xi), \qquad \dot{\xi}_\alpha = -dW_e(q). \tag{3.14}$$

Thus, the application of the algorithm allows us to say that, under the given assumptions, the initial conditions in W_3 provide us with consistent optimal solutions of the dynamics of the LC-circuit.

There are, of course, other optimal control problems that can be interpreted in a vakonomic setting and for which this formulation can be of some help. We mention here the optimal control for nonholonomic systems with symmetry, with interesting applications to the locomotion of kinematic and mixed kinematic and dynamic systems [18, 28, 49] or sub-Riemannian geometry [11].

4. Comparison of the Vershik–Gershkovich and the vakonomic Hamiltonian approaches. In the preceding section we have found an intrinsic geometric approach to vakonomic dynamics. It is possible to give an alternative geometric formulation of the vakonomic equations of motion, related to the one of Vershik and Gershkovich [64]. A key element to obtain this alternative description will be the next fibered morphism

$$\begin{array}{rccc} F: & T^*Q \oplus TQ & \longrightarrow & T^*Q \oplus TQ, \\ & (\alpha, v) & \longmapsto & (\alpha - Leg_L(v), v), \end{array}$$

for any $\alpha \in T_x^*Q$, $v \in T_xQ$, and $x \in Q$. Here, $Leg_L : TQ \to T^*Q$ denotes the Legendre transformation associated with the Lagrangian L, which in local coordinates reads $Leg_L(q^A, \dot{q}^A) = (q^A, \frac{\partial L}{\partial \dot{q}^A})$. It is clear that $F(T^*Q \times_Q M) = T^*Q \times_Q M$. We will see how in the case of linear constraints, we "recover" the Vershik–Gershkovich formulation. As a by-product, we will have obtained a generalization of their formulation to the case of nonlinear constraints.

Consider on $T^*Q \oplus TQ$ the presymplectic 2-form $\Omega = pr_1^*\omega_Q$. Let $\omega_L = -dS^*dL$ be the Poincaré–Cartan 2-form on TQ associated with $L : TQ \to \mathbb{R}$ and E_L its energy function. Take also the presymplectic 2-form $pr_2^*\omega_L$ on $T^*Q \oplus TQ$, and define the functions

$$H = \langle pr_1, pr_2 \rangle - pr_2^*L, \qquad \bar{H} = \langle pr_1, pr_2 \rangle - pr_2^*E_L.$$

LEMMA 4.1. *The morphism $F : T^*Q \oplus TQ \to T^*Q \oplus TQ$ is a presymplectomorphism from $(T^*Q \oplus TQ, \Omega)$ onto $(T^*Q \oplus TQ, \Omega + pr_2^*\omega_L)$, i.e., $F^*(\Omega + pr_2^*\omega_L) = \Omega$. Moreover, it verifies $F^*\bar{H} = H$.*

Proof. F is clearly invertible with inverse

$$\begin{array}{rccc} F^{-1}: & T^*Q \oplus TQ & \longrightarrow & T^*Q \oplus TQ, \\ & (\alpha, v) & \longmapsto & (\alpha + Leg(v), v). \end{array}$$

A direct computation shows that $H \circ F^{-1} = \bar{H}$. Moreover, in local coordinates,

$$(F^{-1})^*(dq^A \wedge dp_A) = dq^A \wedge \left[dp_A + d\left(\frac{\partial L}{\partial \dot{q}^A} \right) \right] = dq^A \wedge dp_A + dq^A \wedge d\left(\frac{\partial L}{\partial \dot{q}^A} \right),$$

which implies $F^*(\Omega + pr_2^*\omega_L) = \Omega$. □

Denote by $j : T^*Q \times_Q M \hookrightarrow T^*Q \oplus TQ$ and $i : M \hookrightarrow TQ$ the respective canonical inclusions. Let us define $\bar{\omega} = j^*(\Omega + pr_2^*\omega_L)$. Since $pr_2 \circ j = i \circ \pi_2$, we have that

$$\bar{\omega} = \omega + (i \circ \pi_2)^*\omega_L.$$

PROPOSITION 4.2. *The solutions of the equations*

$$i_X\omega = dH_{W_0} \tag{4.1}$$

and

$$i_Y\bar{\omega} = d(j^*\bar{H}) \tag{4.2}$$

are $F_{|W_0}$-related; that is, if $x \in T^*Q \times_Q M$ is a point where a solution Y of (4.2) exists, then $TF^{-1}(Y)$ is a solution of (4.1) at $F^{-1}(x)$ and, conversely, if X is a solution of (4.1) at $F^{-1}(x)$, then $TF(X)$ is a solution of (4.2) at x.

Proof. The proof readily follows from Lemma 4.1. □

An immediate consequence is the following corollary.

COROLLARY 4.3. *F preserves the constraint submanifolds provided by the presymplectic systems $(T^*Q \times_Q M, \omega, H_{W_0})$ and $(T^*Q \times_Q M, \bar{\omega}, j^*\bar{H})$. That is, if*

$$\cdots \hookrightarrow W_k \cdots \hookrightarrow W_1 \hookrightarrow W_0 = T^*Q \times_Q M \quad \textit{and}$$

$$\cdots \hookrightarrow P_k \cdots \hookrightarrow P_1 \hookrightarrow P_0 = T^*Q \times_Q M$$

are the sequences of submanifolds generated by Gotay and Nester's algorithm for the first and the second presymplectic Hamiltonian system, respectively, then $F_i = F_{|W_i} : W_i \longrightarrow P_i$, are diffeomorphisms for all i.

In conclusion, Proposition 4.2 and Corollary 4.3 show that solving the vakonomic Hamiltonian equations (4.1) as in section 3 is equivalent to solving (4.2). Locally, if $(q^A(t), p_A(t), \dot{q}^a(t))$ is an integral curve of X, then

$$\left(q^A(t), p_A - i^* \frac{\partial L}{\partial \dot{q}^A}(q^B(t), \dot{q}^b(t)), \dot{q}^a(t) \right)$$

is an integral curve of Y.

4.1. Vershik–Gershkovich approach. In [64], Vershik and Gershkovich gave a formulation for the "nonholonomic variational problem," i.e., the vakonomic problem, within the framework of the so-called mixed bundle picture, which we briefly review in the following (see also [7]).

If $\mathcal{D} : Q \longrightarrow TQ$ is a differentiable distribution along Q, then the mixed bundle over Q associated with $\mathcal{D}$ is given by $\mathcal{D} \oplus \mathcal{D}^o$, where $\mathcal{D}^o$ is the codistribution annihilating $\mathcal{D}$; the fibers of $\mathcal{D} \oplus \mathcal{D}^o \longrightarrow Q$ are $\mathcal{D}_q \oplus \mathcal{D}_q^o$.

Let $\{ \Phi^\alpha(q^A, \dot{q}^A) = \Psi_a^\alpha(q)\dot{q}^a - \dot{q}^\alpha, 1 \leq \alpha \leq m \}$ be a set of independent functions whose annihilation defines the distribution $\mathcal{D}$, and let $\{ \eta^\alpha = \Psi_a^\alpha dq^a - dq^\alpha, 1 \leq \alpha \leq m \}$ be the corresponding basis of $\mathcal{D}^o$. Regarding $\mathcal{D} \subset TQ$ as the set of admissible velocities, Vershik and Gershkovich write the equations of motion (2.4) for the vakonomic problem $(L, \mathcal{D})$ as follows:

$$\text{(4.3)} \qquad \begin{cases} \left(\dfrac{d}{dt}\left(\dfrac{\partial L}{\partial \dot{q}^A} \right) - \dfrac{\partial L}{\partial q^A} \right) dq^A = \dot{\lambda}_\alpha \eta^\alpha + \lambda_\alpha (i_{\dot{q}} d\eta^\alpha), \\ \\ \langle \dot{q}, \eta^\alpha \rangle = 0, \qquad 1 \leq \alpha \leq m. \end{cases}$$

In this particular case, we obtain that P_1, the first constraint submanifold for the presymplectic Hamiltonian system $(T^*Q \times_Q M, \bar{\omega}, j^*\bar{H})$, is just $\mathcal{D}^o \oplus \mathcal{D}$, since we get $\lambda_a + \lambda_\alpha \Psi_a^\alpha = 0,\ 1 \leq \alpha \leq m$.

If $(P_1 = \mathcal{D}^o \oplus \mathcal{D}, \omega_{P_1})$ is a symplectic manifold (see Proposition 3.5), then the equations of motion (4.3) determine a unique vector field on $\mathcal{D}^o \oplus \mathcal{D}$ and the Lagrange multipliers λ_α are coordinates in $\mathcal{D}^o$ with respect to the basis η^α.

Consequently, the geometrical picture we have developed in section 3 is equivalent to the Vershik–Gershkovich approach. As said above, we have obtained a generalization of the Vershik–Gershkovich formulation to the case of nonlinear constraints, just "translating" things from our approach by the diffeomorphism F.

In the nonlinear case, under the admissibility condition, one can verify that the first constraint submanifold $P_1 = F(W_1)$ can be identified with the manifold $S^*(TM^o) \times_Q M$. In fact, we have that $S^*(TM^o)$ is generated by the 1-forms

$$S^* d\Phi^\alpha = dq^\alpha - \frac{\partial \Psi^\alpha}{\partial \dot{q}^a} dq^a, \qquad 1 \leq \alpha \leq m.$$

If $(q^A, \lambda_A, \dot{q}^a) \in P_1$, then the 1-form $\lambda_A dq^A$ is a linear combination of the 1-forms $S^* d\Phi^\alpha$ in the following manner: $\lambda_A dq^A = \lambda_\alpha S^* d\Phi^\alpha$.

5. Geometric approach to nonholonomic mechanics. A nonholonomic Lagrangian system consists of a Lagrangian $L : TQ \to \mathbb{R}$ subject to nonholonomic constraints defined by m local functions $\Phi^\alpha(q^A, \dot{q}^A)$, $1 \leq \alpha \leq m$. The equations of motion for nonholonomic mechanics are derived assuming that the constraints satisfy d'Alembert's principle, in the linear or affine case. In the nonlinear case, there does not seem to exist a general consensus concerning the correct principle to adopt [41, 51]. The most widely used model is based on Chetaev's principle, which will also be adopted in the present paper. The equations of motion are then given by

$$\frac{d}{dt}\left(\frac{\partial L}{\partial \dot{q}^A}\right) - \frac{\partial L}{\partial q^A} = \lambda_\alpha \frac{\partial \Phi^\alpha}{\partial \dot{q}^A}, \tag{5.1}$$

together with the algebraic equations $\Phi^\alpha(q^A, \dot{q}^A) = 0$. The functions λ_α, $1 \leq \alpha \leq m$, are some Lagrange multipliers to be determined. As in the vakonomic case, we assume the admissibility condition, so it is possible to write the constraints as $\dot{q}^\alpha = \Psi^\alpha(q^A, \dot{q}^a)$, where $1 \leq \alpha \leq m$, $m+1 \leq a \leq n$, and $1 \leq A \leq n$.

The study of nonholonomic systems in the realm of geometric mechanics started with the work by Vershik and Faddeev [62, 63] and has been an active area of research since then, with many contributions from different authors (see [16] for a recent survey). In particular, the role of symmetry has been treated extensively in the literature, starting with the work by Koiller [27] and going through the use of the Hamiltonian formalism [2], Lagrangian reduction [10], the geometry of the tangent bundle [12, 13, 17, 33], or Poisson methods [40], among others.

Nonholonomic mechanics also admits a nice geometrical description on the space $T^*Q \oplus TQ$ inspired on the Skinner and Rusk formalism [58]. In addition, this novel description will be appropriate to compare the solutions of the dynamics between the vakonomic and nonholonomic mechanics. In the following, we will prove that (5.1) can be intrinsically written as

$$\begin{cases} (i_X \Omega - dH)_{|T^*Q \times_Q M} \in F^o, \\ X_{|T^*Q \times_Q M} \in T(T^*Q \times_Q M), \end{cases} \tag{5.2}$$

where Ω is the presymplectic 2-form $\Omega = pr_1^* \omega_Q$ on $T^*Q \oplus TQ$, H the Hamiltonian function $H = \langle pr_1, pr_2 \rangle - pr_2^* L$, and F^o the subbundle of $T^*(T^*Q \oplus TQ)$ along $T^*Q \times_Q M$ defined by $F^o = pr_2^*(S^*(TM^o))$, representing the constraint forces.

Indeed, we have in local coordinates

$$\Omega = dq^A \wedge dp_A, \qquad dH = \dot{q}^A dp_A + p_A d\dot{q}^A - \frac{\partial L}{\partial q^A} dq^A - \frac{\partial L}{\partial \dot{q}^A} d\dot{q}^A,$$

and F^o is generated by the 1-forms

$$\frac{\partial \Phi^\alpha}{\partial \dot{q}^A} dq^A = \frac{\partial \Psi^\alpha}{\partial \dot{q}^a} dq^a - dq^\alpha, \qquad 1 \leq \alpha \leq m.$$

If $X = X^A \frac{\partial}{\partial q^A} + Y^A \frac{\partial}{\partial \dot{q}^A} + Z_A \frac{\partial}{\partial p_A}$ was a solution of (5.2), then

$$X^A = \dot{q}^A, \qquad Z_A = \frac{\partial L}{\partial q^A} + \lambda_\alpha \frac{\partial \Phi^\alpha}{\partial \dot{q}^A}, \tag{5.3}$$

along with the constraints

$$p_A - \frac{\partial L}{\partial \dot{q}^A} = 0, \qquad \Phi^\alpha(q^A, \dot{q}^A) = 0. \tag{5.4}$$

Observe that these constraints determine a submanifold $\tilde{M}$ of $T^*Q \times_Q M$. The submanifold $\tilde{M}$ is diffeomorphic to M since

$$\begin{array}{ccc} M & \longrightarrow & \tilde{M}, \\ m & \longmapsto & (Leg_L(m), m) \end{array}$$

is a diffeomorphism. $\tilde{M}$ is the first constraint submanifold provided by the constraint algorithm applied to (5.2). This algorithm will lead to a final constraint submanifold on which there exists a well-defined dynamics. Obviously, (5.3) and (5.4) are equivalent to the nonholonomic equations of motion (5.1).

In terms of the Ψ^α's the above equations can be written as

$$X^A = \dot{q}^A, \quad Z_a = \frac{\partial L}{\partial q^a} + \lambda_\alpha \frac{\partial \Psi^\alpha}{\partial \dot{q}^a}, \quad Z_\beta = \frac{\partial L}{\partial q^\beta} - \lambda_\beta,$$

together with the constraints

$$p_A - \frac{\partial L}{\partial \dot{q}^A} = 0, \qquad \dot{q}^\alpha - \Psi^\alpha(q^A, \dot{q}^a) = 0. \tag{5.5}$$

Therefore, a solution X of (5.2) is of the form

$$\begin{aligned} X = {} & \dot{q}^a \left(\frac{\partial}{\partial q^a} + \frac{\partial \Psi^\alpha}{\partial q^a} \frac{\partial}{\partial \dot{q}^\alpha} + \left(\frac{\partial^2 L}{\partial \dot{q}^A \partial q^a} + \frac{\partial \Psi^\alpha}{\partial q^a} \frac{\partial^2 L}{\partial \dot{q}^A \partial \dot{q}^\alpha} \right) \frac{\partial}{\partial p_A} \right) \\ & + \Psi^\gamma \left(\frac{\partial}{\partial q^\gamma} + \frac{\partial \Psi^\alpha}{\partial q^\gamma} \frac{\partial}{\partial \dot{q}^\alpha} + \left(\frac{\partial^2 L}{\partial \dot{q}^A \partial q^\gamma} + \frac{\partial \Psi^\alpha}{\partial q^\gamma} \frac{\partial^2 L}{\partial \dot{q}^A \partial \dot{q}^\alpha} \right) \frac{\partial}{\partial p_A} \right) \\ & + Y^a \left(\frac{\partial}{\partial \dot{q}^a} + \frac{\partial \Psi^\alpha}{\partial \dot{q}^a} \frac{\partial}{\partial \dot{q}^\alpha} + \left(\frac{\partial^2 L}{\partial \dot{q}^A \partial \dot{q}^a} + \frac{\partial \Psi^\alpha}{\partial \dot{q}^a} \frac{\partial^2 L}{\partial \dot{q}^A \partial \dot{q}^\alpha} \right) \frac{\partial}{\partial p_A} \right). \end{aligned}$$

Under the regularity assumption, which here means that the matrix

$$\tilde{\mathcal{C}}_{ab} = \frac{\partial^2 \tilde{L}}{\partial \dot{q}^a \partial \dot{q}^b} - i^* \left(\frac{\partial L}{\partial \dot{q}^\alpha} \right) \frac{\partial^2 \Psi^\alpha}{\partial \dot{q}^a \partial \dot{q}^b} \tag{5.6}$$

is invertible (see [57]), there is a unique solution of the dynamics on $\tilde{M}$. In particular, after some computations we obtain

$$Y^a = -\tilde{\mathcal{C}}^{ab} \left[\dot{q}^A \frac{\partial^2 \tilde{L}}{\partial q^A \partial \dot{q}^b} - \dot{q}^A i^* \left(\frac{\partial L}{\partial \dot{q}^\alpha} \right) \frac{\partial^2 \Psi^\alpha}{\partial q^A \partial \dot{q}^b} - \frac{\partial \tilde{L}}{\partial q^b} + i^* \left(\frac{\partial L}{\partial q^\alpha} \right) \left(\frac{\partial \Psi^\alpha}{\partial q^b} - \frac{\partial \Psi^\alpha}{\partial \dot{q}^b} \right) \right],$$

where $i : M \to TQ$ is the canonical inclusion and $(\tilde{\mathcal{C}}^{ab})$ the inverse matrix of $(\tilde{\mathcal{C}}_{ab})$.

Taking coordinates $(q^A, \dot{q}^a)$ on $\tilde{M}$, the equations of motion for a nonholonomic system will be

(5.7)
$$\begin{cases} \dot{q}^\alpha = \Psi^\alpha(q^A, \dot{q}^a), \\ \ddot{q}^a = -\mathcal{C}^{ab}\left[\dot{q}^A \dfrac{\partial^2 \tilde{L}}{\partial q^A \partial \dot{q}^b} - \dot{q}^A i^*\left(\dfrac{\partial L}{\partial \dot{q}^\alpha}\right) \dfrac{\partial^2 \Psi^\alpha}{\partial q^A \partial \dot{q}^b} - \dfrac{\partial \tilde{L}}{\partial q^b} + i^*\left(\dfrac{\partial L}{\partial q^\alpha}\right)\left(\dfrac{\partial \Psi^\alpha}{\partial q^b} - \dfrac{\partial \Psi^\alpha}{\partial \dot{q}^b}\right)\right]. \end{cases}$$

6. Vakonomic and nonholonomic mechanics: Equivalence of dynamics. In this section, we shall investigate the relation between vakonomic and nonholonomic dynamics. Consider a physical system with Lagrangian $L : TQ \to \mathbb{R}$ and constraint submanifold $M \subset TQ$. Let us assume that the vakonomic problem lives on the first constraint submanifold, W_1, and that the nonholonomic one lives on $\tilde{M}$ (this will be the case if the constraints are linear and the admissibility and compatibility conditions are satisfied). As a consequence, we have well-defined vector fields X_{vk} on W_1 and X_{nh} on $\tilde{M}$. It is clear that the mapping $(\pi_2)_{|W_1} : W_1 \to M$ is a surjective submersion and that we can define the mapping $\Upsilon : W_1 \to \tilde{M}$ as

$$\begin{array}{rccc} \Upsilon : & W_1 & \longrightarrow & \tilde{M}, \\ & (\alpha, v) & \longmapsto & (Leg_L(v), v). \end{array}$$

In coordinates, Υ reads as $\Upsilon(q^A, \dot{q}^a, p_\alpha) = (q^A, \dot{q}^a)$.

Our aim is to know whether, given a solution of the nonholonomic problem, we can find initial conditions in the vakonomic Lagrange multipliers, p_α, so that the curve can also be seen as a solution of the vakonomic problem. In order to capture the common solutions to both systems, we have developed the following algorithm. It is inspired on the idea of the Υ-relation of X_{vk} and X_{nh} and the constraint algorithm developed by Krupková [30]. If both fields were Υ-related, then the projection to $\tilde{M}$ of all the vakonomic solutions would be nonholonomic. So, selecting those points where both vector fields are related, we are picking up all the possible good candidates. We write $W_1 = S_0$ and define

$$S_1 = \{w \in S_0 \mid T_w\Upsilon(X_{vk}(w)) = X_{nh}(\Upsilon(w))\}.$$

In general, S_1 is not a submanifold. If $S_1 = \emptyset$, there is no relation between the vakonomic and nonholonomic dynamics. If $S_1 \neq \emptyset$, we apply the following algorithm:

- **Step 1**: For any $w \in S_1$, consider $C_{(w)} = \cup_i C_{(w)i}$, the union of all connected submanifolds $C_{(w)i}$ of maximal dimension lying in S_1, contained in a neighborhood U of w, and passing through w. (Maximal dimension means that if N is a connected submanifold lying in $S_1 \cap U$ passing through w and $C_{(w)i} \subseteq N$, then $C_{(w)i} = N$.)
  Suppose that $C_{(w)} \neq \{w\}$. For each i we consider the subset of $C_{(w)i}$,

  $$\tilde{C}_{(w)i} = \{v \in C_{(w)i} \mid X_{vk}(v) \in T_v C_{(w)i}\}.$$

  If $\tilde{C}_{(w)i} = C_{(w)i}$ then we call the submanifold $C_{(w)i}$ a *final constraint submanifold at* w. If $\tilde{C}_{(w)i} = \emptyset$, we exclude $C_{(w)i}$ from the collection $C_{(w)}$. If $\emptyset \subsetneq \tilde{C}_{(w)i} \subsetneq C_{(w)i}$, then we proceed to the next step.
- **Step 2**: Repeat the Step 1 with $\tilde{C}_{(w)i}$ instead of S_1.

After a sufficient number of steps in this algorithm either we obtain a collection of final constraint submanifolds at w or we find that there is no final constraint submanifold passing through w. Collecting all the points where there exist such final constraint submanifolds, we obtain the subset of W_1 where there is equivalence between vakonomic and nonholonomic dynamics.

Suppose that the constraints Φ^α, $1 \leq \alpha \leq m$, are linear in the velocities so we can write them as $\dot{q}^\alpha = \Psi_a^\alpha(q)\dot{q}^a$. In such a case, the matrices $\mathcal{C}$ and $\tilde{\mathcal{C}}$ defined in (3.9) and (5.6), respectively, are the same (even for constraints affine in the velocities).

PROPOSITION 6.1. *S_1 is locally characterized by the vanishing of the $n-m$ constraints functions on W_1:*

(6.1)
$$g_b = \dot{q}^a \left(p_\alpha - i^* \frac{\partial L}{\partial \dot{q}^\alpha} \right) \left[\frac{\partial \Psi_b^\alpha}{\partial q^a} - \frac{\partial \Psi_a^\alpha}{\partial q^b} + \Psi_a^\beta \frac{\partial \Psi_b^\alpha}{\partial q^\beta} - \Psi_b^\beta \frac{\partial \Psi_a^\alpha}{\partial q^\beta} \right], \qquad m+1 \leq b \leq n.$$

Proof. The comparison between the vector fields X_{vk} and X_{nh} consists of taking the difference between $\ddot{q}^a$'s in the expressions (3.8) and (5.7) and equating the result to zero. □

Consider the local projection $\rho(q^a, q^\alpha) = (q^\alpha)$ and the connection Γ on ρ such that the horizontal distribution $\mathcal{H}$ is given by prescribing its annihilator to be $\mathcal{H}^o = \langle dq^\alpha - \Psi_a^\alpha dq^a, 1 \leq \alpha \leq m \rangle$. Then the curvature R of this connection (see [34]) is given by $R(\frac{\partial}{\partial q^a}, \frac{\partial}{\partial q^b}) = R_{ab}^\alpha \frac{\partial}{\partial q^\alpha}$, where

$$R_{ab}^\alpha = \frac{\partial \Psi_b^\alpha}{\partial q^a} - \frac{\partial \Psi_a^\alpha}{\partial q^b} + \Psi_a^\beta \frac{\partial \Psi_b^\alpha}{\partial q^\beta} - \Psi_b^\beta \frac{\partial \Psi_a^\alpha}{\partial q^\beta}.$$

We say that Γ is flat if the curvature R vanishes identically. The tensor R measures the lack of integrability of the horizontal distribution $\mathcal{H}$, which in our case is the constraint manifold. Then, we can write the constraints determining S_1 as

$$g_b = \dot{q}^a \left(p_\alpha - i^* \frac{\partial L}{\partial \dot{q}^\alpha} \right) R_{ab}^\alpha, \qquad m+1 \leq b \leq n.$$

From this expression we deduce that if the constraints are holonomic, then $R = 0$ and the final constraint submanifold is equal to $S_0 = W_1$. Therefore, every solution of the nonholonomic problem is also a vakonomic solution. Indeed, (3.3)–(3.5) will read as

(6.2)
$$\begin{cases} \dot{q}^\alpha = \Psi_a^\alpha \dot{q}^a, \\ \dot{p}_\alpha = \dfrac{\partial \tilde{L}}{\partial q^\alpha} - p_\beta \dfrac{\partial \Psi_a^\beta}{\partial q^\alpha} \dot{q}^a, \\ \dfrac{d}{dt}\left(\dfrac{\partial \tilde{L}}{\partial \dot{q}^a} \right) - \dfrac{\partial \tilde{L}}{\partial q^a} = \Psi_a^\alpha \dfrac{\partial \tilde{L}}{\partial q^a}. \end{cases}$$

The first and the third set of equations determine the trajectory in M. The Lagrange multipliers p_α are determined by the second set of equations once we know the solution in M. This is the typical behavior of the holonomic case [1, 36]. But, in general, for linear constraints, the first constraint subset in the algorithm is determined by

$$S_1 = \{ g_b = 0, \ m+1 \leq b \leq n \},$$

where $g_b(q^A, \dot{q}^a, p_\alpha) = \dot{q}^a R_{ab}^\alpha(q)(p_\alpha - \frac{\partial L}{\partial \dot{q}^\alpha})$. Note that S_1 will not be a submanifold, because 0 is not a regular value of the functions g_b, $b = m+1, \ldots, n$. Anyway, the

geometric context we have developed can be very useful to tackle the problem of the comparison of the two methods.

PROPOSITION 6.2. *If $c(t) = (q^A(t))$ is a solution of the unconstrained problem which, in addition, verifies all the constraints, i.e.,*

$$\dot{q}^\alpha(t) = \Psi_a^\alpha(q(t))\dot{q}^a(t), \qquad 1 \leq \alpha \leq m,$$

then $c(t)$ is a solution of the nonholonomic and vakonomic problems simultaneously.

Proof. Let us consider the submanifold $S := \{p_\alpha = i^*(\frac{\partial L}{\partial \dot{q}^\alpha})\}$, which is contained in S_1. A natural question is whether the vakonomic vector field will be tangent to S, that is, $X_{vk} \in TS$. From (3.3)–(3.5), we have along any integral curve of the vakonomic vector field

$$X_{vk} \in TS \Longleftrightarrow \frac{d}{dt}\left(p_\alpha - i^*\frac{\partial L}{\partial \dot{q}^\alpha}\right) = 0 \Longleftrightarrow \dot{p}_\alpha = \dot{q}^A \frac{\partial^2 L}{\partial q^A \partial \dot{q}^\alpha} + \ddot{q}^a \frac{\partial^2 L}{\partial \dot{q}^a \partial \dot{q}^\alpha}.$$

On S, we have that

$$\dot{p}_\alpha = \frac{\partial \tilde{L}}{\partial q^\alpha} - p_\beta \frac{\partial \Psi^\beta}{\partial q^\alpha} = \frac{\partial \tilde{L}}{\partial q^\alpha} - \frac{\partial L}{\partial \dot{q}^\beta}\frac{\partial \Psi^\beta}{\partial q^\alpha} = \frac{\partial L}{\partial q^\alpha}.$$

Then the above condition can be rewritten as

$$\frac{\partial L}{\partial q^\alpha} = \frac{d}{dt}\left(\frac{\partial L}{\partial \dot{q}^\alpha}\right),$$

that with (3.5) are precisely the Euler–Lagrange equations. Then, we have proved that a solution $c(t)$ of the unconstrained problem satisfies the constraints if and only if

$$\left(q^A(t), i^*\left(\frac{\partial L}{\partial \dot{q}^\alpha}\right), \dot{q}^a(t)\right)$$

is a solution of the vakonomic equations (3.3). Since the constraints $g_b = 0$ are automatically satisfied for all the points in S we deduce that $c(t)$ is also a solution of the nonholonomic problem. □

Remark 6.3. As a consequence of Proposition 6.2 we obtain that if g is a Riemannian metric on Q, with kinetic energy $L = \frac{1}{2}g$, and if we assume that we are given a distribution $\mathcal{D}$ on Q which is geodesically invariant with respect to the Levi–Civita connection ∇^g, then all the nonholonomic solutions can be seen as vakonomic ones. In fact, they all are solutions of the free problem. This last result was first stated in [20, Theorem 3.2] with additional hypothesis on the nature of the metric g and the integrability of $\mathcal{D}^{\perp_g}$, which are not essential, as we have seen.

Remark 6.4. Let $\Theta : G \times Q \longrightarrow Q$ be a free and proper action on Q. Then $\pi : Q \longrightarrow Q/G$ is a principal G-bundle. Assume that the Lagrangian $L : TQ \longrightarrow \mathbb{R}$ is G-invariant and is subject to equivariant affine constraints, M, such that its linear part $\mathcal{D}$ is the horizontal distribution of a principal connection γ on $\pi : Q \longrightarrow Q/G$. Then, we have the following result, which is an adaptation of Theorem 3.1 in [20] to our geometric description of vakonomic and nonholonomic mechanics.

PROPOSITION 6.5. *Assume that the admissibility and compatibility conditions hold. Then, the following are equivalent:*

1. *The solution of the nonholonomic problem $(q^A(t), \dot{q}^a(t)) \in \tilde{M}$ verifies the condition $g_b(q^A(t), \dot{q}^a(t), p_0) = 0$ for some p_0, $m+1 \leq b \leq n$.*

2. *The curve* $(q^A(t), \dot{q}^a(t), p_0) \in W_1$ *is a vakonomic solution.*

Example 6.6 (rolling penny [4]). Consider a vertical penny constrained to roll without slipping on a horizontal plane. Let (x, y) denote the position of contact of the disk in the plane, θ the orientation of a chosen material point P with respect to the vertical, and ϕ the heading angle of the penny. The configuration space is then $Q = \mathbb{R}^2 \times \mathbb{S}^1 \times \mathbb{S}^1$. The Lagrangian may be written as $L = (\dot{x}^2 + \dot{y}^2 + \dot{\theta}^2 + \dot{\phi}^2)/2$ and the constraints are given by $\dot{x} = \dot{\theta}\cos\phi$, $\dot{y} = \dot{\theta}\sin\phi$. For simplicity, we assume that the mass m, the moments of inertia I, J, and the radius of the penny R are 1.

Applying the algorithm, we obtain the final constraint submanifolds

$$C_{f_1} = \{w \in W_1 \mid \dot{\phi} = 0\}, \qquad C_{f_2} = \{w \in W_1 \mid 2\dot{\theta} = p_x \cos\phi + p_y \sin\phi\},$$
$$C_{f_3} = \{w \in W_1 \mid \dot{\theta} = 0,\ \dot{\phi} = 0\}.$$

The nonholonomic solutions living on C_{f_1} are motions of the penny along a straight line in the horizontal plane. The nonholonomic solutions in C_{f_3} are stationary positions. However, any nonholonomic solution can be seen as a vakonomic one contained in C_{f_2}, with Lagrange multipliers $p_x = 2\dot{\theta}\cos\phi$ and $p_y = 2\dot{\theta}\sin\phi$. In terms of the extended Lagrangian formalism mentioned in Remark 2.4, we have the following Lagrange multipliers:

$$\lambda_x = \frac{\partial L}{\partial x} - p_x = \dot{x} - p_x = -\dot{\theta}\cos\phi, \qquad \lambda_y = \frac{\partial L}{\partial y} - p_y = \dot{y} - p_y = -\dot{\theta}\sin\phi,$$

which is just the result of Bloch and Crouch [4].

Example 6.7 (planar mobile robot). Consider the motion of a two-wheeled planar mobile robot which is able to move in the direction in which it points and, in addition, can spin about a vertical axis [26, 29, 33]. Let P be the intersection point of the horizontal symmetry axis of the robot and the horizontal line connecting the centers of the two wheels. The position and orientation of the robot is determined by $(x, y, \theta) \in SE(2)$, where $\theta \in \mathbb{S}^1$ is the heading angle and the coordinates $(x, y) \in \mathbb{R}^2$ locate the point P. Let ψ_1, $\psi_2 \in \mathbb{S}^1$ denote the rotation angles of the wheels which are assumed to be controlled independently and roll without slipping on the floor. The configuration space of this system is $Q = \mathbb{S}^1 \times \mathbb{S}^1 \times SE(2)$.

The Lagrangian function is the kinetic energy of the system

$$L = \frac{1}{2}m(\dot{x}^2 + \dot{y}^2) + m_0 l\dot{\theta}(\cos\theta\dot{y} - \sin\theta\dot{x}) + \frac{1}{2}J\dot{\theta}^2 + \frac{1}{2}J_2(\dot{\psi}_1^2 + \dot{\psi}_2^2),$$

where $m = m_0 + 2m_1$, m_0 is the mass of the robot without the wheels, J its moment of inertia with respect to the vertical axis, m_1 the mass of each wheel, J_2 the axial moments of inertia of the wheels, and l the distance between the center of mass C of the robot and the point P. The constraints are induced by the conditions that there is no lateral sliding of the robot and that the motion of the wheels also consists of a rolling without sliding,

$$\dot{x} = -R\cos\theta(\dot{\psi}_1 + \dot{\psi}_2)/2, \quad \dot{y} = -R\sin\theta(\dot{\psi}_1 + \dot{\psi}_2)/2, \quad \dot{\theta} = R(\dot{\psi}_2 - \dot{\psi}_1)/(2c),$$

where R is the radius of the wheels and $2c$ the lateral length of the robot.

This example is very interesting because its qualitative behavior changes completely depending on the parameters. If $l = 0$ (namely, the point P is the center of mass of the robot), application of the algorithm yields the following constraint

submanifolds:

$$C_{f_1} = \{w \in W_1 \mid p_x \sin\theta - p_y \cos\theta = 0,\ \dot{\psi}_1 = \dot{\psi}_2\},$$
$$C_{f_2} = \{w \in W_1 \mid p_x = 0,\ p_y = 0\}, \qquad C_{f_3} = \{w \in W_1 \mid \dot{\psi}_1 = 0,\ \dot{\psi}_2 = 0\}.$$

If $l \neq 0$ and $K_1 \neq K_2^2$, with $K_1 = J_2(J_2 + mR^2/2 + R^2J/2c^2) + mR^3J/4c^2$, $K_2 = m_0lR^2/2c$, we find that

$$C_{f_1} = \{w \in W_1 \mid p_x \sin\theta - p_y \cos\theta = 0,\ \dot{\psi}_1 = \dot{\psi}_2\},$$
$$C_{f_2} = \{w \in W_1 \mid \dot{\psi}_1 = 0,\ \dot{\psi}_2 = 0\},$$

whereas if $K_1 = K_2^2$, we obtain an additional final constraint submanifold

$$C_{f_3} = \{w \in W_1 \mid p_x = K_2(\dot{\psi}_1 - \dot{\psi}_2)\sin\theta/R - 2K_2^2(\dot{\psi}_1 + \dot{\psi}_2)\cos\theta/R(2K_1/J_2 - mR^2),$$
$$p_y = -2K_2^2(\dot{\psi}_1 + \dot{\psi}_2)\sin\theta/R(2K_1/J_2 - mR^2) - K_2(\dot{\psi}_1 - \dot{\psi}_2)\cos\theta/R\}.$$

Therefore, in the cases $l = 0$ and $l \neq 0$, $K_1 = K_2^2$, every nonholonomic solution can be seen as a vakonomic one. This has the following interesting physical interpretation: under an appropriate design of the robot (i.e., choice of the parameters), the trajectories that it describes between two points are optimal, in the sense that they minimize the energy cost among all the other possible trajectories satisfying the constraints and connecting the given points.

Example 6.8 (ball on a rotating table [36]). Applying the algorithm to this example, one can recover the result found in [36]. The configuration space is $Q = \mathbb{R}^2 \times SO(3)$ with coordinates (x, y, R). We denote the spatial angular velocity by $\xi \in \mathbb{R}^3$, where $\hat{\xi} = \dot{R}R^T$. The Lagrangian is $L = I((\xi^1)^2 + (\xi^2)^2 + (\xi^3)^2)/2 + m(\dot{x}^2 + \dot{y}^2)/2$, where I and m are the moment of inertia and mass of the ball, respectively. The constraints are $\dot{x} = r\xi^2 - \Omega y$, $\dot{y} = -r\xi^1 + \Omega x$, where r is the radius of the ball and Ω is the angular velocity of the table.

Applying the algorithm, one finds the following final constraint submanifolds

$$C_{f_1} = \{w \in W_1 \mid \dot{x} = \dot{y} = p_x = p_y = 0\}, \qquad C_{f_2} = \{w \in W_1 \mid \xi^3 = \Omega\}.$$

There are nonholonomic solutions that can not be seen as vakonomic ones (see [36]).

Acknowledgments. J. Cortés, S. Martínez, and D. Martín de Diego would like to thank the Department of Mathematical Physics and Astronomy of the University of Ghent for its kind hospitality. We would like to thank F. Cantrijn and E. Martínez for several helpful conversations and the referees for their careful reading of the manuscript and their useful remarks that helped us improve the quality of the paper.

ALGEBRAIC AND SPECTRAL PROPERTIES OF GENERAL TOEPLITZ MATRICES*

A. BULTHEEL† AND P. CARRETTE‡

Abstract. We consider problems related to the generalization of the classical Fourier basis to a basis of rational functions with prescribed poles outside the unit disk. We give some generalizations about the convergence and estimation of the Fourier coefficients with respect to this generalized basis. We also consider a rational generalization of the classical Toeplitz matrices and consider the asymptotic distribution of their spectrum. These bases and general Toeplitz matrices were considered by Ninness et al. in the context of least-squares system estimation where the prescribed poles allow to incorporate a priori knowledge into the system dynamics of the model.

Key words. general Toeplitz matrix, orthogonal rational functions, system identification

1. Introduction.

It is well known that $\{e^{j n\omega}\}_{n\in\mathbb{Z}}$ forms an orthonormal basis in the Hilbert space $\mathcal{L}_2(\mathbb{T})$ of square integrable functions on the unit circle. This basis is also complete in the space $\mathcal{C}_{2\pi}$ of 2π-periodic functions. Moreover, if such a function $f \in \mathcal{C}_{2\pi}$ has absolutely integrable nth derivative, then its Fourier expansion $f(\omega) = \sum_{r\in\mathbb{Z}} c_r e^{jr\omega}$ with $c_r = \langle f, e^{jr\omega}\rangle$ converges uniformly and $|c_{\pm r}| \le \|f^{(n)}\|_1/r^n$ for $r > 0$.

For $f \in \mathcal{C}_{2\pi}$, one can define the Toeplitz matrices associated with the symbol f as

$$M_p(f) = \frac{1}{2\pi}\int_0^{2\pi} \Gamma_p(\omega) f(\omega) \Gamma_p^*(\omega) d\omega, \qquad p \ge 1,$$

where $\Gamma_p(\omega) = [1,\ e^{-j\omega}, \dots, e^{-j(p-1)\omega}]^*$. (The superscript * denotes complex conjugate transpose.) This integral can be approximated by a quadrature formula whose nodes are, for example, the pth roots of unity $\omega_0, \dots, \omega_{p-1}$. This leads to an approximation of the form $\Upsilon_p F_p \Upsilon_p^*$, where Υ_p is a FFT matrix with entries $(\Upsilon_p)_{k,l} = e^{jk\omega_l}/\sqrt{p}$, for $k, l = 0, \dots, p-1$, and $F_p = \mathrm{diag}(f(\omega_0), \dots, f(\omega_{p-1}))$. A bound for the approximation error in this matrix problem can be used in the study of the following asymptotic problems for the matrices.

For general functions $f \in \mathcal{C}_{2\pi}$, the convergence of the Fourier series may not be uniform, and then other summation techniques like Cesàro means are used. It takes only a little thought to see that such a sum can be written as (see, for example, [14])

$$\frac{1}{p}\Gamma_p^*(\omega) M_p(f) \Gamma_p(\omega) = \sum_{k=-(p-1)}^{p-1} \left(1 - \frac{|k|}{p}\right) c_k e^{j\omega k},$$

where the c_k are the Fourier coefficients of f. We know that the limit as $p \to \infty$ in the right-hand side (RHS) gives $f(\omega)$, so that we know the limit in the left-hand side (LHS). This leads to the study of asymptotics for bilinear forms

$$\lim_{p\to\infty} \left(\frac{1}{p}\right) \Gamma_p^*(\sigma) M_p(f) \Gamma_p(\mu),$$

or even more general forms where $M_p(f)$ is replaced by $T(M_p(f))$ with T being an analytic function. Even more general forms are needed. For example, when $M_p(f)$ is replaced by $M_p(f)M_p(g)$, then the limit gives $f(\omega)g(\omega)$ for $\sigma = \mu = \omega$ under appropriate conditions for f and g. So we should be interested in replacing $M_p(f)$ by some analytic *multivariate* function $T(M_p(f^{[1]}), \ldots, M_p(f^{[p]}))$, involving several, possibly different, Toeplitz matrices.

In many applications (see, e.g., [14] and the references mentioned there) it is important to know the asymptotic distribution of the spectrum of these Toeplitz matrices. It is well known that under appropriate conditions on f the eigenvalues of $M_p(f)$ are in the range of f for all p. In this paper we shall generalize results such as the fact that the average of the spectrum of $M_p(f)$ converges to the average value of f, a result due to Grenander and Szegő [11, p. 65].

In this paper we discuss technical results concerning general Toeplitz matrices related to the unifying construction of orthonormal bases presented in [13, 14]. The generalization consists of using rational basis functions where it is allowed to have poles somewhere in the complex plane outside the unit circle. The orthonormal basis functions $\mathrm{e}^{\mathrm{j}n\omega}$ of classical Fourier analysis shall be replaced by orthonormal functions of the form (1.2) below, where the ξ_i are assumed to be arbitrary points in the open unit disk. The motivation for this generalized basis and for the interest in generalizing the above-mentioned properties can be found in papers by Ninness and coworkers [12, 13, 14, 15]; see also [5].

The properties in their generalized form will be summarized in the next section and will be analyzed and proved in the subsequent ones. But let us first recall some of the notation used in [14].

We consider the complex unit circle $\mathbb{T} = \{z \in \mathbb{C} : |z| = 1\}$ and the Hilbert space $\mathcal{L}_2(\mathbb{T})$ of square integrable complex functions defined on $\mathbb{T}$ with inner product

$$\langle F, G\rangle = \frac{1}{2\pi}\int_0^{2\pi} F(\mathrm{e}^{\mathrm{j}\omega})\overline{G(\mathrm{e}^{\mathrm{j}\omega})}\mathrm{d}\omega = \langle f, g\rangle = \frac{1}{2\pi}\int_0^{2\pi} f(\omega)\overline{g(\omega)}\mathrm{d}\omega, \tag{1.1}$$

where the overbar stands for complex conjugation and $f(\omega) = F(\mathrm{e}^{\mathrm{j}\omega})$ and $g(\omega) = G(\mathrm{e}^{\mathrm{j}\omega})$. For simplicity reasons, we shall identify the function $F(z)$ for $z = \mathrm{e}^{\mathrm{j}\omega} \in \mathbb{T}$ with the 2π-periodic function $f(\omega)$, i.e., $f(\omega) = F(\mathrm{e}^{\mathrm{j}\omega})$. We shall, for example, abuse the notation and write $f \in \mathcal{L}_2(\mathbb{T})$.

Now, with $\mathbb{D} = \{z \in \mathbb{C} : |z| < 1\}$, let $\mathcal{H}_2(\mathbb{D}) \subset \mathcal{L}_2(\mathbb{T})$ be the Hardy space of complex functions analytic in $\mathbb{D}$, i.e., for which all the negative Fourier coefficients vanish: $\mathcal{H}_2(\mathbb{D}) = \{f \in \mathcal{L}_2(\mathbb{T}) : \langle f, \mathrm{e}^{-\mathrm{j}k\omega}\rangle = 0,\ k = 1, 2, \ldots\}$. Obviously, $\|f\|_2 < \infty$ for all $f \in \mathcal{H}_2(\mathbb{D})$ where $\|\cdot\|_2$ is the norm induced by the scalar product in (1.1). Also here we identified the 2π-periodic boundary function $f(\omega) = F(\mathrm{e}^{\mathrm{j}\omega})$ and the function F, depending on a complex variable (which is perfectly justified if F is continuous in $\mathbb{D} \cup \mathbb{T}$).

The basis function $\mathcal{B}_n(z)$ with integer $n \geq 0$ is defined as follows:

$$\mathcal{B}_n(z) = \frac{\sqrt{1-|\xi_n|^2}}{1-\overline{\xi}_n z}\prod_{k=0}^{n-1}\frac{z-\xi_k}{1-\overline{\xi}_k z}, \qquad z \in \mathbb{C}, \tag{1.2}$$

where it is assumed that $|\xi_n| \leq c < 1$ for all $n \geq 0$. This ξ_n is called the nth zero. Let us assume that $\xi_0 = 0$, so that $\mathcal{B}_0$ is just the constant 1. Hereby we guarantee that $\{\mathcal{B}_n\}_{n\geq 0}$ can be a basis for $\mathcal{H}_2(\mathbb{D})$ given some technical condition (see below). It is called the Malmquist basis [16, p. 227]. Note that if all the ξ_i are equal to zero, then $\mathcal{B}_n(z) = z^n$ and we are back in the classical Fourier case. It is easily seen that these general basis functions satisfy $\langle \mathcal{B}_n, \mathcal{B}_m \rangle = \delta_{n-m}$ with δ_i, the Kronecker symbol. In other words, they form an orthonormal set.

An important property of the basis functions $\mathcal{B}_n$ is that the set $\{\mathcal{B}_n(\mathrm{e}^{\mathrm{j}\omega}) : n \geq 0\}$ constitutes an orthonormal basis for $\mathcal{H}_2(\mathbb{D})$ if and only if $\sum_{n\geq 0}(1 - |\xi_n|) = \infty$. This means that, under this condition, the following expansion converges on $\mathbb{T}$:

$$f(\omega) = \sum_{n=0}^{\infty} \langle f, \mathcal{B}_n \rangle \, \mathcal{B}_n(\mathrm{e}^{\mathrm{j}\omega}),$$

where f is any function in $\mathcal{H}_2(\mathbb{D})$. This means that the orthonormal basis $\{\mathcal{B}_n(z), n \geq 0\}$ is complete in $\mathcal{H}_2(\mathbb{D})$. For a proof see [1, p. 244], [5, Chap. 7], or [13, App. C].

Moreover, from these references, it also follows that, for any function $f \in \mathcal{L}_2(\mathbb{T})$, the following expansion holds:

$$f(\omega) = \sum_{n\in\mathbb{Z}} \langle f, \mathcal{B}_n \rangle \, \mathcal{B}_n(\mathrm{e}^{\mathrm{j}\omega}), \quad \text{where} \quad \mathcal{B}_{-n}(\mathrm{e}^{\mathrm{j}\omega}) = \overline{\mathcal{B}_n(\mathrm{e}^{\mathrm{j}\omega})}. \tag{1.3}$$

This means that the infinite set $\{\mathcal{B}_k : k \in \mathbb{Z}\}$ constitutes an orthonormal basis for $\mathcal{L}_2(\mathbb{T})$ under the same condition on the zeros ξ_n; see also [3]. One of our concerns will be to prove convergence and order of convergence properties of the above series given some smoothness conditions of the function f, generalizing the classical Fourier results that we mentioned in the beginning of this section.

However, our main concern will be the spectral properties of general Toeplitz matrices. First we introduce the vector

$$\Gamma_p(\omega) = \left[\overline{\mathcal{B}_0(\mathrm{e}^{\mathrm{j}\omega})}, \ldots, \overline{\mathcal{B}_{p-1}(\mathrm{e}^{\mathrm{j}\omega})}\right]^*, \tag{1.4}$$

where the superscript * stands for the conjugate transpose. Then a general Toeplitz matrix is defined as

$$M_p(f) = \frac{1}{2\pi} \int_0^{2\pi} \Gamma_p(\omega) f(\omega) \Gamma_p^*(\omega) \mathrm{d}\omega, \tag{1.5}$$

where $f(\omega)$ is a 2π-periodic function. It is easily seen that, if $f(\omega)$ is real-valued, then the matrix $M_p(f)$ is Hermitian, i.e., $M_p(f) = M_p^*(f)$.

Let $\gamma_p(\omega) = \Gamma_p^*(\omega)\Gamma_p(\omega)$ be the squared 2-norm of the vector Γ_p. It will be shown that the set of associated normalized vectors

$$\tilde{\Gamma}_p(\omega) = \frac{\Gamma_p(\omega)}{\gamma_p^{1/2}(\omega)}, \tag{1.6}$$

evaluated at frequencies ω_i (with $0 \leq i < p$) for which the phase of the Blaschke product

$$\varphi_p(z) = \prod_{k=0}^{p-1} \frac{z - \xi_k}{1 - \bar{\xi}_k z} \tag{1.7}$$

is constant (modulo 2π), induces an orthonormal basis in $\mathbb{C}^p$. The matrix containing these normalized vectors as columns will be denoted Υ_p, i.e., the ith column is $(\Upsilon_p)_i = \tilde{\Gamma}_p(\omega_i)$ with $\omega_i \in [0, 2\pi)$. This notion generalizes the classical situation where the ω_i are the roots of unity (or a constant rotation thereof) and the matrices Υ_p are the (unitary) FFT matrices.

Here, we intend to study the approximation of this general Toeplitz matrix $M_p(f)$ by the matrix $\Upsilon_p F_p \Upsilon_p^*$ with $F_p = \operatorname{diag}(f_p(\omega_0), \ldots, f_p(\omega_{p-1}))$, where $f_p(\omega)$ is the truncated expansion

$$f_p(\omega) = \sum_{|n|<p} \langle f, \mathcal{B}_n \rangle \, \mathcal{B}_n(\mathrm{e}^{\mathrm{j}\omega}). \tag{1.8}$$

The tool for this will be quadrature formulas on the unit circle. Indeed, we can consider

$$\Upsilon_p F_p \Upsilon_p^* = \sum_{i=0}^{p-1} \tilde{\Gamma}_p(\omega_i) f_p(\omega_i) \tilde{\Gamma}_p^*(\omega_i) \tag{1.9}$$

as a quadrature formula with nodes ω_i for the integral (1.5). It is a special case of a rational Szegő formula as studied in [3, 4, 5, 6].

These results will be used in analyzing the asymptotics of bilinear forms whose matrix is a generalized Toeplitz matrix. For reasons that we have given above in the classical Toeplitz case, it is useful to give more general versions of this problem. In summary, it will be shown that

$$\lim_{p\to\infty} \tilde{\Gamma}_p^*(\sigma) T(M_p(f^{[1]}), \ldots, M_p(f^{[n]})) \tilde{\Gamma}_p(\mu) = \begin{cases} \left[T(f^{[1]}, \ldots, f^{[n]})(\mu)\right], & \text{if } \sigma = \mu, \\ 0, & \text{otherwise,} \end{cases} \tag{1.10}$$

where $T(\cdot)$ is an n-variable analytic function (i.e., having convergent Taylor expansion) on the range of the $f^{[k]}$'s and these $f^{[k]}$'s are 2π-periodic functions satisfying appropriate smoothness assumptions that, at least, make the associated error functions $e_{p,k}(\omega) = f^{[k]}(\omega) - f_p^{[k]}(\omega)$ converge to zero uniformly.

Concerning the asymptotics of the average of the spectrum, it will be furthermore shown that if $f(\omega)$ is also positive (real-valued), then it turns out that the eigenvalue distribution of $M_p(f)$ is given by the distribution of the underlying function, i.e.,

$$\lim_{p\to\infty} \frac{1}{p} \sum_{i=0}^{p-1} T\left(\lambda_i\left(M_p(f)\right)\right) = \frac{1}{2\pi} \int_0^{2\pi} T\left(f\left(\tilde{\chi}^{-1}(\omega)\right)\right) \mathrm{d}\omega, \tag{1.11}$$

where now $T(\cdot)$ stands for a continuous function on the range of $f(\omega)$ and $\tilde{\chi}(\omega)$ denotes the asymptotic normalized phase of the Blaschke product evaluated over the (fundamental) unit circle, i.e., $\tilde{\chi}(\omega) = \lim_{p\to\infty} \chi_p(\omega)/p$ with $\chi_p(\omega)$, the phase of $\varphi_p(\mathrm{e}^{\mathrm{j}\omega})$ for $\omega \in [0, 2\pi)$ where $\varphi_p(z)$ is the Blaschke product (1.7). In the classical Fourier case where all $\xi_i = 0$, $\tilde{\chi}(\omega)$ is just ω because $\varphi_p(z) = z^p$, and hence $\chi_p(\omega) = p\omega$. Thus if T is the identity, this property says that the average of the eigenvalues of $M_p(f)$ converges to the average of $f \in \mathcal{C}_{2\pi}$.

Obviously all these results are of crucial importance when studying these specific rational generalized Fourier series. Thus they are important for rational approximation in general, but our main interest is motivated by the paper [14] and the arguments given there, particularly in the context of system identification and models derived

from orthonormal rational bases as they were introduced by several authors with different degrees of generality (see, e.g., [14] for some history). The equation (1.10) is a far reaching generalization of the simple Cesàro sum that we started out with in the classical Fourier case. But as formulated in section 2, we also get bounds for the generalized Fourier coefficients and therefrom obtain the convergence of the generalized Fourier series, including an estimate for the speed of convergence. The spectral properties of the matrix $M_p(f)$ are important from a numerical point of view because the condition number of this matrix will dictate the numerical robustness of the least-squares estimation problem in the underlying model identification.

The structure of the paper is as follows. In section 2, we give a detailed formulation of the results we have obtained. Their proofs are presented in the subsequent sections. In section 3, we consider the convergence of the approximation of 2π-periodic functions by their expansion over the rational basis functions $\mathcal{B}_n(z)$. In section 4, we extract from reproducing kernel properties orthonormal bases of $\mathbb{C}^p$ made of sets of the normalized vector $\tilde{\Gamma}_p(\omega)$ for appropriate ω. This is performed by analyzing the phase of the Blaschke product $\varphi_p(z)$ evaluated over the unit circle. In section 5, we introduce the concept of quadrature formulas on the unit circle and apply it to approximate particular integrals of the basis functions $\mathcal{B}_n(z)$ by use of the derived orthonormal basis of $\mathbb{C}^p$. In section 6, we apply these tailored quadrature formulas to approximate general Toeplitz matrices. Several upper bounds for the norm of the approximation error are also given. By using these bounds, we derive the results about bilinear forms based on functionals of general Toeplitz matrices in section 7. Finally, in section 8, we consider the eigenvalue distribution of general Toeplitz matrices.

2. Main results. In this section, we summarize the results we have achieved concerning the algebraic and spectral properties of general Toeplitz matrices as introduced in (1.5). We give more detailed formulations here. The derivation of these results will be obtained in the subsequent sections.

Before proceeding, let us state a fundamental assumption concerning the poles of the rational basis functions.

Assumption 1. The points ξ_i defining the basis functions $\mathcal{B}_p(z)$ lie in a closed disk of radius $c < 1$, i.e., $|\xi_i| \leq c$ for $i = 0, 1, \ldots$. Further, $\xi_0 = 0$. □

In fact, this is a key assumption for deriving all the results presented in this paper.

2.1. Rational function approximation. Here, we aim at characterizing the functional approximation properties of the rational basis functions. Therefore, we consider the orthonormal set

$$\mathcal{S}_p = \{\mathcal{B}_k : |k| < p\} \quad \text{with} \quad \mathcal{B}_0 \equiv 1 \quad \text{and} \quad \mathcal{B}_{-n}(z) = \overline{\mathcal{B}_n(1/\overline{z})}.$$

Let $a_n = \langle f, \mathcal{B}_n \rangle$ stand for the generalized Fourier coefficient of the function with respect to the rational basis function $\mathcal{B}_n(\mathrm{e}^{\mathrm{j}\omega})$. The convergence analysis of the expansion coefficients $a_{\pm n}$ has led us to the following theorem.

THEOREM 1. *Let Assumption* 1 *be satisfied. Let $f(\omega)$ be a 2π-periodic function having a continuous qth derivative with $q > 2$. Then the generalized Fourier coefficients satisfy*

$$|a_0| \leq \|f\|_1 \quad \textit{and} \quad |a_{\pm n}| \leq \left(K_1 \frac{1}{\ln \tilde{\rho}} + K_2(c) \frac{\epsilon\, n}{q-1} \right) \frac{\|f^{(q)}\|_1}{(\epsilon\, n)^q}, \qquad n \geq 1,$$

where $K_2(0^+) = 0$. *Furthermore,* $\epsilon \triangleq \epsilon(\rho, c) = \ln((\rho + c)/(1 + \rho\, c))/\ln \rho$ *for*

$$\rho \triangleq \rho(c, q, n) = \min\left(\left[\left(\frac{q}{n-1}\,\frac{-4}{\ln c}\right)^{q/4} + \left(\frac{n}{2}\right)^{q/(n-2)}\right] + \left[\frac{1+c}{\sqrt{cq}} + \frac{1}{c(q-1)}\right], e^{q/2}\right)$$

and $\tilde{\rho} \triangleq \tilde{\rho}(c, q) = \lim_{n\to\infty} \rho(c, q, n)$.

This result can be seen as the generalization of the Fourier case for which c is identically zero. It will not be a surprise that the proof is based on the Fourier expansion of the function $f(\omega)$. The proof is given in section 3.

Now, let us denote by $f_p(\omega)$ the partial sum in the expansion of a 2π-periodic function $f \in \mathcal{L}_2(\mathbb{T})$ (see expression (1.8)). Then, as a consequence of Theorem 1, the approximation error

$$e_p(\omega) = f(\omega) - f_p(\omega)$$

of the truncated expansion of the function $f(\omega)$ over the orthonormal set $\mathcal{S}_p$ has the following convergence property.

COROLLARY 2. *With the same assumptions as in Theorem* 1, *the approximation error* $e_p(\omega)$ *converges to zero uniformly in* ω *with increasing values of* p, *i.e.,*

$$\lim_{p\to\infty} |e_p(\omega)| = 0 \qquad \textit{for all } \omega$$

with a convergence rate at least as fast as $1/p^{q-2}$.

Similar to the Fourier case, this result is based on the fact the expansion (1.3) is absolutely convergent and that the limiting set $\mathcal{S} = \bigcup_{p=1}^{\infty} \mathcal{S}_p$ constitutes an orthonormal basis for $\mathcal{L}_2(\mathbb{T})$ (see [3] where no result about the convergence of $e_p(\omega)$ to zero is found).

2.2. General Toeplitz matrix properties. Now, let us concentrate on our contributions to the analysis of the general Toeplitz matrix properties. Let $\tilde{\Gamma}_p(\omega) \in \mathbb{C}^p$ be the normalized vector corresponding to $\Gamma_p(\omega)$ as defined in (1.4) and (1.6). Note that $\gamma_p(\omega) = K_p(\omega, \omega)$, where

$$K_p(\mu, \sigma) = \sum_{n=0}^{p-1} \mathcal{B}_n(\mathrm{e}^{\mathrm{j}\mu})\overline{\mathcal{B}_n(\mathrm{e}^{\mathrm{j}\sigma})}$$

is the *reproducing kernel* [2] of the p-dimensional subspace spanned by the basis functions in $\Gamma_p(\omega)$. By using the Blaschke product $\varphi_p(e^{j\omega})$ as defined in (1.7), it can be brought into a Christoffel–Darboux form (see, e.g., [14, 5]):

$$K_p(\mu, \sigma) = \frac{1 - \varphi_p(\mathrm{e}^{\mathrm{j}\mu})\overline{\varphi_p(\mathrm{e}^{\mathrm{j}\sigma})}}{\mathrm{e}^{\mathrm{j}(\sigma-\mu)} - 1}. \tag{2.1}$$

In section 4, we shall analyze some properties of $K_p(\mu, \sigma)$. The main result is as follows.

LEMMA 3. *Let* $\chi_p(\omega)$ *be the phase of the Blaschke product* $\varphi_p(e^{j\omega})$ *with its zeros satisfying Assumption* 1. *Define for arbitrary real* θ

$$\Omega_p(\theta) = \{\omega \in [0, 2\pi) \,:\, \chi_p(\omega) = \theta \bmod 2\pi\}.$$

Then, the set $\{\tilde{\Gamma}_p(\omega_i) : \omega_i \in \Omega_p(\theta)\}$ *constitutes an orthonormal basis for* $\mathbb{C}^p$. ∎

Note that there is an infinite number of such orthonormal bases because the value of the reference phase $\theta \in [0, 2\pi)$ has been left free.

Before formulating our main results on general Toeplitz matrices, let us state the following assumption on the regularity of the function $f(\omega)$.

Assumption 2. Let $f(\omega)$ be a 2π-periodic function having a continuous qth derivative with $q > 4$. □

THEOREM 4. *Let Assumption* 1 *be satisfied. Let the function* $f^{[k]}(\omega)$ *(with* $k = 1, \ldots, n$*) satisfy Assumption* 2. *Let* $T(\cdot)$ *be an* n*-variable analytic function (i.e., having convergent Taylor expansion) on the range of the* $f^{[k]}(\omega)$*'s. Then,*

$$\lim_{p\to\infty} \tilde{\Gamma}_p^*(\sigma) T\Big(M_p(f^{[1]}), \ldots, M_p(f^{[n]})\Big) \tilde{\Gamma}_p(\mu) = \begin{cases} \left[T(f^{[1]}, \ldots, f^{[n]})(\mu)\right], & \text{if } \sigma = \mu, \\ 0, & \text{otherwise.} \end{cases}$$

The convergence rate to the limiting value is at least as fast as $1/p$ *if* $\sigma = \mu$ *and as* $\ln p/p$ *otherwise.*

Note that the order in which the matrices appear in the serial expansion does not matter for the asymptotic expression since $M_p(f^{[i]})M_p(f^{[j]})$ converges to $M_p(f^{[i]}f^{[j]})$ in the Hilbert Schmidt norm as $p \to \infty$.

Let $\lambda_i(X)$ denote the ith (in any order) eigenvalue of the Hermitian matrix X.

THEOREM 5. *Let Assumption* 1 *be satisfied. Let the real function* $f(\omega)$ *satisfy Assumption* 2. *Let* $T(\cdot)$ *stand for a continuous function on the range of* $f(\omega)$. *Furthermore, let* $\chi_p(\omega)$ *be the phase of* $\varphi_p(\mathrm{e}^{\mathrm{j}\omega})$ *for* $\omega \in [0, 2\pi)$ *where* $\varphi_p(z)$ *is the Blaschke product* (1.7). *Then,* $\tilde{\chi}(\omega) = \lim_{p\to\infty} \chi_p(\omega)/p$ *exists and*

$$\lim_{p\to\infty} \frac{1}{p} \sum_{i=0}^{p-1} T\Big(\lambda_i\big(M_p(f)\big)\Big) = \frac{1}{2\pi} \int_0^{2\pi} T\Big(f\big(\tilde{\chi}^{-1}(\omega)\big)\Big) \mathrm{d}\omega.$$

The convergence rate to the limiting value is at least as fast as $1/p$.

These results are seen as straightforward generalizations of the properties of the Toeplitz matrices based on the Fourier basis functions.

3. Expansion with respect to rational bases. In this section, we analyze the functional approximation properties of the orthonormal basis set $\mathcal{S}_p = \{\mathcal{B}_k : |k| < p\}$. Note from the introduction that, under Assumption 1, the set

$$\mathcal{S} = \{\mathcal{B}_k : k \in \mathbb{Z}\} = \{\ldots, \mathcal{B}_{-p}, \ldots, \mathcal{B}_{-1}, \mathcal{B}_0, \mathcal{B}_1, \ldots, \mathcal{B}_p, \ldots\}, \tag{3.1}$$

where $\mathcal{B}_0 = 1$ and $\mathcal{B}_{-n}(z) = \overline{\mathcal{B}_n(1/\overline{z})}$, is an orthonormal basis for $\mathcal{L}_2(\mathbb{T})$.

More precisely, we show that, under suitable assumptions on the function $f(\omega)$, the approximation error $e_p(\omega) = f(\omega) - f_p(\omega)$ with $f_p(\omega)$ as in (1.8) converges to zero uniformly as p becomes unbounded.

First, we focus our attention on the expansion coefficients

$$a_n = \langle f, \mathcal{B}_n \rangle, \qquad n \in \mathbb{Z},$$

and the asymptotic behavior of these coefficients as presented in Theorem 1. Then, we consider the convergence of the approximation error $e_p(\omega)$ to zero for increasing values of p as in Corollary 2.

Therefore, we should recall some results about Fourier series of 2π-periodic functions (see Edwards [8, 9]). Namely (from Assertions 2.3.2, 2.3.5, and 2.4.3 in

[8, Chap. 2]), for any function $f(\omega) \in \mathcal{C}^q$, i.e., with continuous qth derivative (with $q \geq 2$), we have that

$$f(\omega) = \sum_{k\in\mathbb{Z}} w_k \mathrm{e}^{\mathrm{j}k\omega} \qquad \text{with} \quad w_k = \frac{1}{2\pi}\int_0^{2\pi} f(\omega)\mathrm{e}^{-\mathrm{j}k\omega}\mathrm{d}\omega.$$

The convergence of the Fourier series is uniform in ω and the Fourier coefficients are bounded as

$$|w_0| \leq \|f\|_1 \quad \text{and} \quad |w_{\pm k}| \leq \|f^{(q)}\|_1/k^q, \qquad k > 0, \tag{3.2}$$

where $f^{(q)}(\omega)$ stands for the qth derivative of the function $f(\omega)$.

Prior to prove Theorem 1, let us state the following working result.

LEMMA 6. *Let $x_2 > x_1 > 0$ and $q \geq 2$; then*

$$q\int_{x_1}^{x_2} e^{q(x-\ln x)}\,dx \leq I_{x_1<1}\left[\alpha_1^{-1}\left(1-(x_1/\tilde{x})^{(q-1)\alpha_1}\right)\right]\frac{q}{q-1}\,e^{qx_1-(q-1)\ln x_1} + I_{x_2>1}\left[\alpha_2^{-1}\left(1-e^{-q\alpha_2(x_2-\tilde{x})}\right)\right]\,e^{q(x_2-\ln x_2)},$$

where $\tilde{x} = \max(x_1, \min(1, x_2))$ while

$$\alpha_1 = 1 - \frac{q}{q-1}\tilde{x}\,\frac{1-x_1/\tilde{x}}{\ln(\tilde{x}/x_1)} \quad \textit{and} \quad \alpha_2 = 1 - x_2^{-1}\,\frac{\ln(x_2/\tilde{x})}{1-\tilde{x}/x_2}.$$

The indicator function $I_{x<y}$ is one if $x < y$ and zero otherwise.

Proof. Let us separate the integration interval in two parts, i.e.,

$$q\int_{x_1}^{x_2} e^{q(x-\ln x)}\,dx = q\int_{x_1}^{\tilde{x}} e^{q(x-\ln x)}\,dx + q\int_{\tilde{x}}^{x_2} e^{q(x-\ln x)}\,dx$$

with $\tilde{x}$ as defined above. Note that the cases where $\tilde{x} = x_2$ (resp., x_1) correspond to the situations where the second (resp., first) term in the above RHS is trivially zero because the associated integration interval reduces to one point only.

More generally, the first term is upper bounded as

$$\begin{aligned} q\int_{x_1}^{\tilde{x}} e^{q(x-\ln x)}\,dx &= q\,e^{qx_1-(q-1)\ln x_1}\int_{x_1/\tilde{x}}^{1} e^{(q-2)\ln t - qx_1(1-1/t)}dt \\ &\leq q\,e^{qx_1-(q-1)\ln x_1}\int_{x_1/\tilde{x}}^{1} e^{((q-1)\alpha_1-1)\ln t}dt \\ &= \left[\alpha_1^{-1}\left(1-(x_1/\tilde{x})^{(q-1)\alpha_1}\right)\right]\frac{q}{q-1}\,e^{qx_1-(q-1)\ln x_1} \end{aligned}$$

with $t = x_1/x$. Similarly, an upper bound for the second term is found as follows:

$$\begin{aligned} q\int_{\tilde{x}}^{x_2} e^{q(x-\ln x)}\,dx &\leq q\,e^{q(x_2-\ln x_2)}\int_{\tilde{x}}^{x_2} e^{q\alpha_2(x-x_2)}dx \\ &= \left[\alpha_2^{-1}\left(1-e^{-q\alpha_2(x_2-\tilde{x})}\right)\right]\,e^{q(x_2-\ln x_2)}. \end{aligned}$$

The proof is complete after summing up the above two upper bounds. ∎

Proof of Theorem 1. The statement for a_0 is trivial, so we only consider a_n with $|n| > 0$. Without loss of generality, let us focus on the expansion coefficient a_n with $n > 0$. Indeed, a_{-n} is simply the conjugate of the expansion coefficient of $\overline{f(\omega)}$ with respect to $\mathcal{B}_n(\mathrm{e}^{\mathrm{j}\omega})$. Hence, finding a upper bound for $|a_{-n}|$ is similar to finding an upper bound for $|a_n|$.

First, we consider three parts in the Fourier series of $f(\omega)$, i.e.,

$$f(\omega) = \sum_{k\le k_1} w_k \mathrm{e}^{\mathrm{j}k\omega} + \sum_{k=k_1+1}^{k_3-1} w_k \mathrm{e}^{\mathrm{j}k\omega} + \sum_{k\ge k_3} w_k \mathrm{e}^{\mathrm{j}k\omega}$$

for integers $k_3 > k_1 > 0$ to be specified below. So, using $\mathcal{B}_{-n}(\mathrm{e}^{\mathrm{j}\omega}) = \overline{\mathcal{B}_n(\mathrm{e}^{\mathrm{j}\omega})}$ we successively obtain

$$\begin{aligned} a_n &= \frac{1}{2\pi}\int_0^{2\pi} f(\omega)\overline{\mathcal{B}_n(\mathrm{e}^{\mathrm{j}\omega})}\mathrm{d}\omega \\ &= \frac{1}{2\pi\mathrm{j}}\oint_{|z|=1}\left[\sum_{k\le k_1} w_k z^k + \sum_{k=k_1+1}^{k_3-1} w_k z^k + \sum_{k\ge k_3} w_k z^k\right]\mathcal{B}_{-n}(z)\frac{\mathrm{d}z}{z} \\ &= \frac{1}{2\pi\mathrm{j}}\left[\sum_{k=2}^{k_1} w_k \oint_{|z|=\rho_1} z^k\mathcal{B}_{-n}(z)\frac{\mathrm{d}z}{z} + \sum_{k=k_1+1}^{k_3-1} w_k \oint_{|z|=1} z^k\mathcal{B}_{-n}(z)\frac{\mathrm{d}z}{z}\right. \\ &\qquad\left. + \sum_{k\ge k_3} w_k \oint_{|z|=\rho_3} z^k\mathcal{B}_{-n}(z)\frac{\mathrm{d}z}{z}\right] \end{aligned}$$

with appropriate $\rho_1 \ge 1$ and $c < \rho_3 \le 1$. Note that the summation terms for $k < 2$ have been cancelled out by the residue theorem using the fact that $\xi_0 = 0$.

Then, we upper bound each sum in the brackets separately:
(*First sum*) The modulus of the first sum can thus be bounded as follows:

$$\begin{aligned} \left|\frac{1}{2\pi\mathrm{j}}\sum_{k=2}^{k_1} w_k \oint_{|z|=\rho_1} z^k\mathcal{B}_{-n}(z)\frac{\mathrm{d}z}{z}\right| &\le \sum_{k=2}^{k_1} |w_k|\rho_1^k \left(\frac{1+\rho_1 c}{\rho_1 + c}\right)^{n-1} \frac{1}{2\pi}\int_0^{2\pi} \frac{\beta_n}{|\rho_1 \mathrm{e}^{\mathrm{j}\omega} - \xi_n|}\mathrm{d}\omega \\ &\le \|f^{(q)}\|_1 \left(\frac{1+\rho_1 c}{\rho_1 + c}\right)^{n-1} \rho_1^{-1} \sum_{k=2}^{k_1} \frac{\rho_1^k}{k^q}, \end{aligned} \tag{3.3}$$

where we made use of the fact that if $z = \rho\,\mathrm{e}^{\mathrm{j}\omega}$ with $|\xi| < c < 1 \le \rho$, then

$$\left|\frac{1-\overline{\xi}z}{z-\xi}\right| \le \frac{1+\rho|\xi|}{\rho+|\xi|} \le \frac{1+\rho c}{\rho + c} \le 1,$$

and that, by the Cauchy–Schwarz inequality,

$$\begin{aligned} \left[\frac{1}{2\pi}\int_0^{2\pi} \frac{\beta_n}{|\rho\mathrm{e}^{\mathrm{j}\omega} - \xi_n|}\mathrm{d}\omega\right]^2 &\le \frac{1}{2\pi}\int_0^{2\pi} \frac{\beta_n^2}{|\rho\mathrm{e}^{\mathrm{j}\omega} - \xi_n|^2}\mathrm{d}\omega \\ &= \frac{\beta_n^2}{\rho^2 - |\xi_n|^2} \le \rho^{-2} \quad \text{for } \rho \ge 1 \end{aligned}$$

with $\beta_n = \sqrt{1-|\xi_n|^2}$. We have also used the upper bound for the Fourier coefficients, i.e., $|w_k| \le \|f^{(q)}\|_1/k^q$ for $k > 0$.

The summation factor in expression (3.3) is first simplified into

$$\sum_{k=2}^{k_1} \frac{\rho_1^k}{k^q} \approx q\,(\ln \rho_1)^{q-1}\, e^{-q \ln q} \int_{2 \ln \rho_1/q}^{k_1 \ln \rho_1/q} e^{q(x-\ln x)}\, dx$$

with $x = k \ln \rho_1/q$. By use of Lemma 6 (see notation therein), we then obtain

$$\begin{aligned} & q\,(\ln \rho_1)^{q-1}\, e^{-q \ln q} \int_{x_1}^{x_2} e^{q(x-\ln x)}\, dx \\ & \qquad \le I_{x_1<1} \left[\alpha_1^{-1} \left(1 - \left(\frac{x_1}{\tilde{x}}\right)^{(q-1)\alpha_1}\right)\right] \frac{2}{q-1}\, \frac{\rho_1^2}{2^q} \\ & \qquad\qquad + I_{x_2>1} \left[\alpha_2^{-1} \left(1 - e^{-q\alpha_2(x_2-\tilde{x})}\right)\right] \frac{1}{\ln \rho_1}\, \frac{\rho_1^{k_1}}{{k_1}^q}, \end{aligned} \tag{3.4}$$

where $x_1 = 2 \ln \rho_1/q$ and $x_2 = k_1 \ln \rho_1/q$ while $\tilde{x} = \max(x_1, \min(1, x_2))$. Note that increasing values of ρ_1 make x_1 (resp., x_2) closer to (resp., farther away from) one from below (resp., above) so that the second term in the RHS of expression (3.4) becomes dominant.

The last step of the derivation is to choose the values of ρ_1 and k_1. The choice of k_1 is such that it makes the quantity

$$\rho_1^{k_1-1} \left(\frac{1+\rho_1 c}{\rho_1 + c}\right)^{n-1}$$

less than one, independently of n. This is done by imposing $k_1 = \lfloor \epsilon_1 (n-1) + 1 \rfloor$ with

$$0 < \epsilon_1 = [\ln(\rho_1 + c) - \ln(1 + \rho_1 c)]/\ln \rho_1 \le 1 \quad \text{(because } c < 1 \le \rho_1\text{)}$$

and $\lfloor x \rfloor$ denoting the largest integer not greater than x. Note that if $\rho_1 \gg 1/c$, then ϵ_1 becomes close to zero.

The choice for ρ_1 is

$$\rho_1 = \min\left([(\rho_{11} - 1) + \rho_{12}] + (\rho_{13} - 1), e^{q/2}\right), \tag{3.5}$$

where

$$\rho_{11} = 1 + \left(\frac{q}{n-1}\, \frac{-4}{\ln c}\right)^{q/4}, \quad \rho_{12} = \left(\frac{n}{2}\right)^{q/(n-2)}, \quad \text{and} \quad \rho_{13} = 1 + \frac{1+c}{\sqrt{cq}} + \frac{1}{c(q-1)}.$$

The reason for this choice is the following. For $n \gg (-4/\ln c)\, q$, the upper bound (3.3) receives its main contribution from the second term in the RHS expression (3.4) for which a minimum is obtained for $\rho_1 = \rho_{13}$ (given $k_1(\epsilon_1, n)$ as above). In the other cases, i.e., $n \not\gg (-4/\ln c)\, q$, a small value of the upper bound (3.3) is obtained by compromising the contributions of the two terms in the RHS expression (3.4) while adjusting ρ_1. Depending on values of c, q, and n, the resulting ρ_1 may become very large or stay close to one: namely, ρ_{11} (resp., ρ_{12}) describes the behavior of ρ_1 when it is far from (resp., close to) one. It is further seen that $\rho_{11} \gg \rho_{12} \gg \rho_{13}$ for $n \ll (-4/\ln c)\, q$. The minimum operator in expression (3.5) limits the value of ρ_1 to a maximum of $e^{q/2}$ for which $x_1 = 1$ in expression (3.4) so that only its second term remains. Finally, the expression for ρ_1 sums up the different $\rho_{1\cdot}$'s whose contributions apply in particular n intervals.

Provided these choices for k_1 and ρ_1, the expression (3.3) leads to

$$\left|\frac{1}{2\pi\mathrm{j}}\sum_{k=2}^{k_1} w_k \oint_{|z|=\rho_1} z^k \mathcal{B}_{-n}(z)\frac{\mathrm{d}z}{z}\right| \leq \left[\frac{C_1}{\ln\tilde{\rho}_1}\right] \|f^{(q)}\|_1/(\epsilon_1 n)^q, \tag{3.6}$$

where $\tilde{\rho}_1(c,q) = \lim_{n\to\infty}\rho_1(c,q,n)$. Note that ϵ_1 explicitly appears in the upper bounding expression (3.6). The reason for that is that it is smaller than one and depends on the triplet (c,q,n) via ρ_1.

(*Third sum*) Similarly, the modulus of the third sum in the expression of a_n can be upper bounded as follows:

$$\begin{aligned}\left|\frac{1}{2\pi\mathrm{j}}\sum_{k\geq k_3} w_k \oint_{|z|=\rho_3} z^k \mathcal{B}_{-n}(z)\frac{\mathrm{d}z}{z}\right| &\leq \sum_{k\geq k_3}|w_k|\rho_3^k\left(\frac{1-\rho_3 c}{\rho_3-c}\right)^n \frac{1}{2\pi}\int_0^{2\pi}\frac{\beta_n}{|\rho_3\mathrm{e}^{\mathrm{j}\omega}-\xi_n|}\mathrm{d}\omega \\ &\leq \|f^{(q)}\|_1\left(\frac{1-\rho_3 c}{\rho_3-c}\right)^{n+1/2}\sum_{k\geq k_3}\frac{\rho_3^{k-1/2}}{k^q} \\ &\leq \|f^{(q)}\|_1\left(\frac{1-\rho_3 c}{\rho_3-c}\right)^{n+1/2}\frac{1}{1-\rho_3}\frac{\rho_3^{k_3-1/2}}{k_3^q}, \qquad (3.7)\end{aligned}$$

where we have used the fact that for $z=\rho\mathrm{e}^{\mathrm{j}\omega}$ and $|\xi|<c\leq\rho<1$ we have

$$\left|\frac{1-\bar{\xi}z}{z-\xi}\right| \leq \frac{1-\rho|\xi|}{\rho-|\xi|} \leq \frac{1-\rho c}{\rho-c}$$

and also (by the Cauchy–Schwarz inequality as above)

$$\left[\frac{1}{2\pi}\int_0^{2\pi}\frac{\beta_n}{|\rho\mathrm{e}^{\mathrm{j}\omega}-\xi_n|}\mathrm{d}\omega\right]^2 \leq \frac{1-c^2}{\rho^2-c^2} \leq \rho^{-1}\left(\frac{1-\rho c}{\rho-c}\right) \quad \text{for } c<\rho\leq 1.$$

The choice for k_3 is such that it makes

$$\rho_3^{k_3-1/2}\left(\frac{1-\rho_3 c}{\rho_3-c}\right)^{n+1/2} \leq 1$$

independently of n. This is done by imposing $k_3 = \lceil \epsilon_3(n+1/2)+1/2\rceil$ with

$$\epsilon_3 = [\ln(\rho_3-c)-\ln(1-\rho_3 c)]/\ln\rho_3 \geq 1 \quad (\text{because } c<\rho_3\leq 1)$$

and $\lceil x\rceil$ denoting the smallest integer not smaller than x.

Then, by choosing $\rho_3 = 1-(1-c)^q$ (as it has been left free so far) with $q>2$, the expression (3.7) becomes

$$\begin{aligned}\left|\frac{1}{2\pi\mathrm{j}}\sum_{k\geq k_3} w_k \oint_{|z|=\rho_3} z^k \mathcal{B}_{-n}(z)\frac{\mathrm{d}z}{z}\right| &\leq \|f^{(q)}\|_1\frac{(1-(1-c)^q)^{\tau_3}}{(1-c)^q}\left[\epsilon_3\left(n+\frac{1}{2}\right)+\frac{1}{2}\right]^{-q} \\ &\leq \left[\frac{2}{1+\epsilon_3}\frac{1}{1-c}\right]^q \frac{\|f^{(q)}\|_1}{n^q} \leq \frac{\|f^{(q)}\|_1}{n^q}, \qquad (3.8)\end{aligned}$$

where $0\leq\tau_3 = \lceil\epsilon_3(n+1/2)+1/2\rceil - [\epsilon_3(n+1/2)+1/2] < 1$. The last expression comes from the fact that $\epsilon_3 \geq (1+c)/(1-c)$ for the chosen ρ_3 value. It further tends

to this lower limit for increasing q. Note that, as before, the rate of convergence to zero with n is $1/n^q$.

(*Second sum*) The second sum in expression of a_n is treated as follows:

$$\left|\frac{1}{2\pi \mathrm{j}}\sum_{k=k_1+1}^{k_3-1} w_k \oint_{|z|=1} z^k \mathcal{B}_{-n}(z)\frac{\mathrm{d}z}{z}\right| \le \|f^{(q)}\|_1 \sum_{k=k_1+1}^{k_3-1}\frac{1}{k^q}$$

$$\le \|f^{(q)}\|_1 \frac{C_2}{q-1}\left[\frac{1-\epsilon_1^{q-1}}{\epsilon_1^{q-1}} + \frac{\epsilon_3^{q-1}-1}{\epsilon_3^{q-1}}\right]\frac{1}{n^{q-1}}, \tag{3.9}$$

where we divided the summation interval $[k_1+1, k_3-1]$ into two subintervals, i.e., $[k_1+1, n]$ and $[n+1, k_3-1]$.

(*Overall*) When putting the expression (3.6), (3.8), and (3.9) together, we finally obtain the following upper bound:

$$|a_n| \le \left[\left(\frac{C_1}{\ln\tilde{\rho}_1}+\epsilon_1^q\right) + C_2\,\frac{\epsilon_1 n}{q-1}\left((1-\epsilon_1^{q-1}) + \left(\frac{\epsilon_1}{\epsilon_3}\right)^{q-1}(\epsilon_3^{q-1}-1)\right)\right]\frac{\|f^{(q)}\|_1}{(\epsilon_1 n)^q}$$

$$\le \left[K_1\,\frac{1}{\ln\tilde{\rho}_1} + K_2(c)\,\frac{\epsilon_1 n}{q-1}\right]\frac{\|f^{(q)}\|_1}{(\epsilon_1 n)^q}, \tag{3.10}$$

where K_1 and $K_2(c)$ are defined so that $K_2(0^+) = 0$.

The proof is completed when identifying ϵ, ρ, and $\tilde{\rho}$ to ϵ_1, ρ_1, and $\tilde{\rho}_1$, respectively. □

Proof of Corollary 2. As the function $f(\omega)$ is continuous, the proof requires only the uniform convergence of $\lim_{p\to\infty} f_p(\omega)$. This immediately implies that the limiting function is f, and thus that the error e_p converges uniformly to zero. Indeed, by completeness of the basis (3.1) on which this expansion is constructed, we can derive that if $f(\omega)$ is continuous and all the expansion coefficients are zero, then the function must be identically zero (similar to Assertion 2.4.1 in [8]). Then, in case the expansion $f_p(\omega)$ converges uniformly in ω, this limiting function is continuous and has expansion coefficients identical to those of the expansion itself. Thus, this limiting function and the original function $f(\omega)$ coincide identically (see [8, Assertion 2.4.3]).

Hence, it remains to show that the convergence $\lim_{p\to\infty} f_p(\omega) = f(\omega)$ is uniform in ω. For p large enough, we have that

$$|e_p(\omega)| = \left|\lim_{r\to\infty} f_r(\omega) - f_p(\omega)\right| = \left|\sum_{n\ge p}\left(a_n\mathcal{B}_n(\mathrm{e}^{\mathrm{j}\omega}) + a_{-n}\overline{\mathcal{B}_n(\mathrm{e}^{\mathrm{j}\omega})}\right)\right|$$

$$\le 2\sum_{n\ge p}\max(|a_n|,|a_{-n}|)|\mathcal{B}_n(\mathrm{e}^{\mathrm{j}\omega})|$$

$$\le 2\|f^{(q)}\|_1 \sum_{n\ge p}\left(K_1\,\frac{1}{\ln\tilde{\rho}} + K_2\,\frac{\epsilon\, n}{q-1}\right)/(\epsilon\, n)^q,$$

where K_1, K_2, and $\tilde{\rho}$ do not depend on n or ω (see the notation in Theorem 1). As $q > 2$, the sum in the RHS converges to zero for $p \to \infty$. Furthermore, the convergence rate is at least as fast as $1/p^{q-2}$. This completes the proof. □

4. Reproducing kernel and orthonormal bases of $\mathbb{C}^p$. In section 2.2, we have introduced vectors $\tilde{\Gamma}_p(\omega) \in \mathbb{C}^p$. Their unit norm easily follows from the definition

of $\gamma_p(\omega)$, i.e.,

$$\tilde{\Gamma}_p^*(\omega)\tilde{\Gamma}_p(\omega) = \frac{1}{\gamma_p(\omega)} \sum_{n=0}^{p-1} \left|\mathcal{B}_n(\mathrm{e}^{\mathrm{j}\omega})\right|^2 = 1.$$

Now, in order to prove Lemma 3, let us show how to construct orthonormal bases of $\mathbb{C}^p$ consisting of p such vectors. Therefore we remember that $K_p(\omega,\sigma) = \Gamma_p^*(\sigma)\Gamma_p(\omega)$ so that by (2.1)

$$\Gamma_p^*(\sigma)\Gamma_p(\omega) = 0 \qquad \Longleftrightarrow \qquad \overline{\varphi_p(\mathrm{e}^{\mathrm{j}\sigma})}\varphi_p(\mathrm{e}^{\mathrm{j}\omega}) = 1$$

for appropriate $\sigma \neq \omega$. By the Blaschke product expression, this implies the following condition:

$$\Phi\left(\varphi_p(\mathrm{e}^{\mathrm{j}\sigma})\right) = \Phi\left(\varphi_p(\mathrm{e}^{\mathrm{j}\omega})\right),$$

where $\Phi(\xi)$ denotes the phase of $\xi \in \mathbb{C}$. The phase of $\varphi_p(\mathrm{e}^{\mathrm{j}\omega})$, that we denote from now on by $\chi_p(\omega)$, is written as

$$\chi_p(\omega) = p\omega - 2\sum_{n=0}^{p-1} \Phi\left(1 - \overline{\xi}_n \mathrm{e}^{\mathrm{j}\omega}\right).$$

It satisfies $\chi_p(\omega + 2\pi) = p2\pi + \chi_p(\omega)$. Furthermore, the following result holds for its derivative.

LEMMA 7. *Let the zeros of the Blaschke product $\varphi_p(\mathrm{e}^{\mathrm{j}\omega})$ lie inside the unit disk, i.e., $|\xi_n| \leq c < 1$ with $n = 0, \ldots, p-1$. Then,*

$$0 < \frac{p}{K_c} \leq \frac{\mathrm{d}\chi_p(\omega)}{\mathrm{d}\omega} \leq pK_c \tag{4.1}$$

with $1 \leq K_c := (1+c)/(1-c) < \infty$.

Proof. From the expression of $\chi_p(\omega)$, we successively have

$$\begin{aligned}\frac{\mathrm{d}\chi_p(\omega)}{\mathrm{d}\omega} &= p - 2\sum_{n=0}^{p-1} \frac{\mathrm{d}\Phi\left(1 - \overline{\xi}_n \mathrm{e}^{\mathrm{j}\omega}\right)}{\mathrm{d}\omega} \\ &= p - 2\sum_{n=0}^{p-1} |\xi_n| \frac{|\xi_n| - \cos(\omega - \Phi(\xi_n))}{1 + |\xi_n|^2 - 2|\xi_n|\cos(\omega - \Phi(\xi_n))},\end{aligned}$$

where $\Phi(\xi_n)$ stands for the phase of ξ_n. Hence

$$p - 2\sum_{n=0}^{p-1} \frac{|\xi_n|}{1+|\xi_n|} \leq \frac{\mathrm{d}\chi_p(\omega)}{\mathrm{d}\omega} \leq p + 2\sum_{n=0}^{p-1} \frac{|\xi_n|}{1-|\xi_n|}.$$

Then, the proof is completed by noting that the worst lower and upper bounding case occurs when $|\xi_n| = c$ for all n. ∎

The consequence of this is twofold. First, for a given $\theta \in [0, 2\pi)$, there are exactly p distinct frequencies $\omega_0, \ldots, \omega_{p-1}$ in $[0, 2\pi)$ for which the phase $\chi_p(\omega)$ of the Blaschke product takes this value θ modulo 2π, i.e.,

$$\Omega_p(\theta) = \{\omega \in [0, 2\pi) : \chi_p(\omega) = \theta \bmod 2\pi\} = \{\omega_0, \ldots, \omega_{p-1}\}. \tag{4.2}$$

Second, the distance Δ between two successive frequencies in $\Omega_p(\theta)$ is lower bounded by $2\pi/(pK_c)$. Indeed,

$$2\pi = \chi_p(\mu+\Delta) - \chi_p(\mu) = \int_{\mu}^{\mu+\Delta} \frac{\mathrm{d}\chi_p(\omega)}{\mathrm{d}\omega}\mathrm{d}\omega \leq K_c p\Delta \tag{4.3}$$

for any $\mu, \mu+\Delta \in \Omega_p(\theta)$.

As p increases, this distance decreases because the phase of $\varphi_p(\mathrm{e}^{\mathrm{j}\omega})$ is turning (under the modulo operator) more rapidly in the interval $[0, 2\pi)$. In the limit as p tends to infinity, there is a (countably) infinite number of frequencies in $\Omega_p(\theta)$ (included within $[0, 2\pi)$) and they become infinitely close to each other without inducing any limiting point.

Hence, we have proven the result in Lemma 3.

From now on, we denote by Υ_p the matrix representing such an orthonormal basis. Its ith column is given by $(\Upsilon_p)_i = \tilde{\Gamma}_p(\omega_i)$. This is a unitary matrix so that, by the orthonormality of its rows, we derive that

$$\sum_{i=0}^{p-1} \frac{1}{\gamma_p(\omega_i)} \mathcal{B}_n(\mathrm{e}^{\mathrm{j}\omega_i})\overline{\mathcal{B}_m(\mathrm{e}^{\mathrm{j}\omega_i})} = \delta_{n-m}. \tag{4.4}$$

Finally, as the function $\chi_p(\omega)$ becomes unbounded for increasing p, it is worth defining the following normalized limiting function as mentioned in Theorem 5:

$$\tilde{\chi}(\omega) = \lim_{p\to\infty} \chi_p(\omega)/p.$$

This function $\tilde{\chi}(\omega)$ has values in the interval

$$[\tilde{\chi}(0), \tilde{\chi}(0)+2\pi) \quad \text{with} \quad \tilde{\chi}(0) = -2\lim_{p\to\infty} \sum_{n=0}^{p-1} \Phi(1-\overline{\xi}_n)/p$$

when ω lies in $[0, 2\pi)$. Note that if each complex-valued ξ_n has a conjugate counterpart, then this initial value of $\tilde{\chi}(\omega)$ vanishes.

Before ending this section, let us evaluate the decomposition of any normalized vector $\tilde{\Gamma}_p(\omega)$ in the orthonormal basis $\{\tilde{\Gamma}_p(\omega_i) : \omega_i \in \Omega_p(\theta)\}$.

LEMMA 8. *Let $\alpha_{p,i}(\omega)$ denote the ith decomposition coefficient of $\tilde{\Gamma}_p(\omega)$ in the orthonormal set $\{\tilde{\Gamma}_p(\omega_i) : \omega_i \in \Omega_p(\theta)\}$, i.e., $\alpha_{p,i}(\omega) = \tilde{\Gamma}_p^*(\omega_i)\tilde{\Gamma}_p(\omega)$. Then, $\alpha_{p,i}(\omega_k) = \delta_{k-i}$ and*

$$|\alpha_{p,i}(\omega)| \leq \min\left(1, \frac{K_c}{p}\left|\sin\frac{\omega_i-\omega}{2}\right|^{-1}\right) \qquad \textit{for } \omega \notin \Omega_p(\theta)$$

with $K_c = (1+c)/(1-c)$.

Proof. The case where $\omega = \omega_k$ belongs to $\Omega_p(\theta)$ is trivial. When $\omega \notin \Omega_p(\theta)$, we have by 2-norm properties that $|\alpha_{p,i}(\omega)| \leq \|\tilde{\Gamma}_p^*(\omega_i)\|_2 \|\tilde{\Gamma}_p(\omega)\|_2 \leq 1$. But, by definition of $\tilde{\Gamma}_p(\omega)$, we also have that

$$|\alpha_{p,i}(\omega)| = \frac{|K_p(\omega,\omega_i)|}{\gamma_p^{1/2}(\omega)\gamma_p^{1/2}(\omega_i)} \leq \left|\sin\frac{\omega_i-\omega}{2}\right|^{-1} \max_{\omega} \gamma_p^{-1}(\omega) \tag{4.5}$$

with

$$\gamma_p(\omega) = \sum_{i=0}^{p-1} \frac{1-|\xi_i|^2}{|1-\overline{\xi_i}\mathrm{e}^{\mathrm{j}\omega}|^2} \geq \frac{p}{K_c}$$

so that the proof is completed. □

Furthermore, it is worth evaluating the 1-norm of the sequence of the decomposition coefficients. We have the following result.

LEMMA 9. *With a notation similar to Lemma* 8 *and* $\alpha_p(\omega) = \{\alpha_{p,i}(\omega) : 0 \leq i < p\}$, *we have that*

$$\|\alpha_p(\omega)\|_1 \leq 2 - 2(K_c^2/\pi)\ln[\tan(\pi/2pK_c)] \qquad \textit{for} \;\; p \geq 4,$$

where $\|\alpha_p\|_1$ *stands for the* 1*-norm* $\sum_{k=0}^{p-1}|\alpha_{p,i}|$.

Proof. First, assume that the two frequency points surrounding ω are ω_k and ω_{k+1}. Without loss of generality, we may assume they are somewhere in the middle of the set $\Omega_p(\theta)$ for $p \geq 4$. So, we can successively write

$$\begin{aligned}
\sum_{i=0}^{p-1}|\alpha_{p,i}| &= \sum_{i=k-1}^{k+2}|\alpha_{p,i}| + \left[\sum_{i=0}^{k-2} + \sum_{i=k+3}^{p-1}\right]|\alpha_{p,i}| \\
&\leq 2 + \frac{K_c}{p}\left[\sum_{i'=-k}^{-2} + \sum_{i'=2}^{p-k-2}\right]\left|\sin\frac{i'\pi}{pK_c}\right|^{-1} \\
&\leq 2 + 2\frac{K_c}{p}\sum_{i'=2}^{p/2}\frac{1}{\sin(i'\pi/pK_c)} \leq 2 + 2\frac{K_c^2}{\pi}\int_{\pi/pK_c}^{\pi/2}\frac{\mathrm{d}x}{\sin x} \\
&\leq 2 - 2\left(\frac{K_c^2}{\pi}\right)\ln\left[\tan\left(\frac{\pi}{2pK_c}\right)\right],
\end{aligned}$$

where we have used the fact that $\sum_i |\alpha_{p,i}|^2 = 1$ in upper bounding the first sum in the first expression. We have also taken advantage of

$$\frac{p}{K_c}|\alpha_{p,i}| \leq \left|\sin\left(\frac{\omega_i-\omega}{2}\right)\right|^{-1} \leq \left|\sin\left(\frac{(k-i)\pi}{pK_c}\right)\right|^{-1} \quad \text{or} \quad \left|\sin\left(\frac{(i-(k+1))\pi}{pK_c}\right)\right|^{-1}$$

as the difference between two successive frequency points ω_i is larger than $2\pi/pK_c$. □

Hence, for large p, the 1-norm of the sequence $\alpha_p(\omega)$ diverges like $2(K_c^2/\pi)\ln p$.

5. Quadrature formulas. In the present section, we intend to find approximate quadrature formulas to evaluate integrals of the form[1]

$$\frac{1}{2\pi}\int_0^{2\pi} \mathcal{B}_k(\mathrm{e}^{\mathrm{j}\omega})\overline{\mathcal{B}_l(\mathrm{e}^{\mathrm{j}\omega})}\mathcal{B}_r(\mathrm{e}^{\mathrm{j}\omega})\mathrm{d}\omega, \tag{5.1}$$

where $0 \leq k, l, r < p$.

[1]This generic integral originates from the definition (1.5) of general Toeplitz matrices with the expansion (1.3) for the function $f(\omega)$.

To recall, quadrature formulas [7] are used to approximate the integral of functions as the sum of values of these functions at appropriate points of the integration interval, i.e., generically

$$\int_a^b f(x)\mathrm{d}x \approx \sum_n A_n f(x_n),$$

where x_n are the sampling points inside $[a,b]$ and A_n are appropriate constants related to the functional class to which $f(x)$ belongs. In the case where the integration corresponds to an integration over the complex unit circle, we refer to papers by Bultheel et al. [3, 4, 6].

In the preceding section, we have already derived the quadrature formula corresponding to the integral (5.1) in the particular case where r is zero. Indeed, from the orthonormality of the functions $\mathcal{B}_n(z)$ and of the rows of the unitary matrix Υ_p in (4.4), we obtain that

$$\frac{1}{2\pi}\int_0^{2\pi} \mathcal{B}_n(\mathrm{e}^{\mathrm{j}\omega})\overline{\mathcal{B}_m(\mathrm{e}^{\mathrm{j}\omega})}\mathrm{d}\omega = \delta_{n-m} = \sum_{i=0}^{p-1} \frac{1}{\gamma_p(\omega_i)}\mathcal{B}_n(\mathrm{e}^{\mathrm{j}\omega_i})\overline{\mathcal{B}_m(\mathrm{e}^{\mathrm{j}\omega_i})} \tag{5.2}$$

with ω_i in $\Omega_p(\theta)$ for some θ. The rightmost sum obviously forms a quadrature formula for the leftmost integral.

Now, for $z \in \mathbb{T}$, let us write the basis function $\mathcal{B}_n(z)$ as

$$\mathcal{B}_n(z) = \beta_n \frac{1}{\mu_p(z)}\frac{\mu_p(z)}{\mu_{n+1}(z)}\nu_n(z),$$

where $\beta_n^2 = 1 - |\xi_n|^2$ while

$$\nu_n(z) = \prod_{i=0}^{n-1}(z-\xi_i) \quad \text{and} \quad \mu_n(z) = \prod_{i=0}^{n-1}(1-\overline{\xi}_i z).$$

Similarly, we have

$$\overline{\mathcal{B}_m(z)} = \beta_m \frac{z}{\nu_p(z)}\mu_m(z)\frac{\nu_p(z)}{\nu_{m+1}(z)}.$$

Hence, we can write

$$\mathcal{B}_n(z)\overline{\mathcal{B}_m(z)} = \frac{z}{\mu_p(z)\nu_p(z)}\left[(\beta_n\beta_m)\frac{\mu_p(z)\mu_m(z)}{\mu_{n+1}(z)}\frac{\nu_n(z)\nu_p(z)}{\nu_{m+1}(z)}\right] \tag{5.3}$$

while

$$\mathcal{B}_k(z)\overline{\mathcal{B}_l(z)}\mathcal{B}_r(z) = \frac{z}{\mu_p(z)\nu_p(z)}\left[(\beta_k\beta_l\beta_r)\frac{\mu_p(z)\mu_l(z)}{\mu_{k+1}(z)\mu_{r+1}(z)}\frac{\nu_k(z)\nu_r(z)\nu_p(z)}{\nu_{l+1}(z)}\right].$$

In order to have this last expression written as a sum of terms as in (5.3), i.e.,

$$\mathcal{B}_k(z)\overline{\mathcal{B}_l(z)}\mathcal{B}_r(z) = \sum_{n,m=0}^{p-1}\kappa_{n,m}\mathcal{B}_n(z)\overline{\mathcal{B}_m(z)},$$

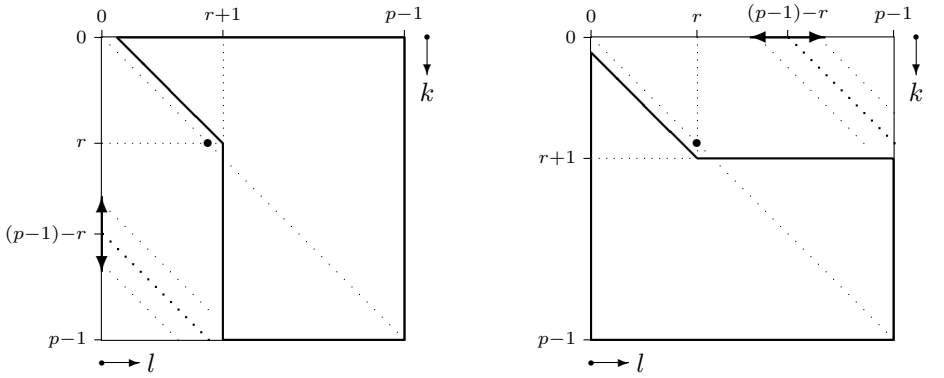

FIG. 5.1. *Admissible (k,l) areas for the quadrature formulas of $\mathcal{B}_k\overline{\mathcal{B}_l}\mathcal{B}_r$ (left) and $\mathcal{B}_k\overline{\mathcal{B}_l}\mathcal{B}_{-r}$ (right) to hold, as functions of r.*

we need that $l > \min(k,r)$ so that the expression between the brackets of its RHS reduces to a polynomial in z only. The coefficients $\kappa_{n,m}$ of this expansion are found by imposing that the zeros of the LHS (being either ξ_i or $1/\overline{\xi}_i$) are reproduced in the RHS.

Hence, the quadrature formula in (5.2) can be applied as follows:

$$\begin{aligned}\frac{1}{2\pi}\int_0^{2\pi}\mathcal{B}_k(\mathrm{e}^{\mathrm{j}\omega})\overline{\mathcal{B}_l(\mathrm{e}^{\mathrm{j}\omega})}\mathcal{B}_r(\mathrm{e}^{\mathrm{j}\omega})\mathrm{d}\omega &= \sum_{n,m=0}^{p-1}\kappa_{n,m}\frac{1}{2\pi}\int_0^{2\pi}\mathcal{B}_n(\mathrm{e}^{\mathrm{j}\omega})\overline{\mathcal{B}_m(\mathrm{e}^{\mathrm{j}\omega})}\mathrm{d}\omega\\ &= \sum_{n,m=0}^{p-1}\kappa_{n,m}\sum_{i=0}^{p-1}\frac{1}{\gamma_p(\omega_i)}\mathcal{B}_n(\mathrm{e}^{\mathrm{j}\omega_i})\overline{\mathcal{B}_m(\mathrm{e}^{\mathrm{j}\omega_i})}\\ &= \sum_{i=0}^{p-1}\frac{1}{\gamma_p(\omega_i)}\mathcal{B}_k(\mathrm{e}^{\mathrm{j}\omega_i})\overline{\mathcal{B}_l(\mathrm{e}^{\mathrm{j}\omega_i})}\mathcal{B}_r(\mathrm{e}^{\mathrm{j}\omega_i}).\end{aligned}\tag{5.4}$$

To summarize, we state the following result.

LEMMA 10. *For $0 \le k,r,l < p$, we have that*

$$\langle\mathcal{B}_k\mathcal{B}_r,\mathcal{B}_l\rangle = \sum_{i=0}^{p-1}\frac{1}{\gamma_p(\omega_i)}\mathcal{B}_k(\mathrm{e}^{\mathrm{j}\omega_i})\overline{\mathcal{B}_l(\mathrm{e}^{\mathrm{j}\omega_i})}\mathcal{B}_r(\mathrm{e}^{\mathrm{j}\omega_i})$$

provided that $l > \min(k,r)$. □

With the help of $\mathcal{B}_k(z)\overline{\mathcal{B}_l(z)}\mathcal{B}_{-r}(z) = \overline{\mathcal{B}_l(z)\overline{\mathcal{B}_k(z)}\mathcal{B}_r(z)}$ (for $z \in \mathbb{T}$) and provided that $k > \min(l,r)$, we can similarly write the following quadrature formula:

$$\langle\mathcal{B}_k\mathcal{B}_{-r},\mathcal{B}_l\rangle = \sum_{i=0}^{p-1}\frac{1}{\gamma_p(\omega_i)}\mathcal{B}_k(\mathrm{e}^{\mathrm{j}\omega_i})\,\overline{\mathcal{B}_l(\mathrm{e}^{\mathrm{j}\omega_i})}\,\overline{\mathcal{B}_r(\mathrm{e}^{\mathrm{j}\omega_i})}.\tag{5.5}$$

Before considering the situation where the index l (resp., k) does not satisfy the previously mentioned condition for $\langle\mathcal{B}_k\mathcal{B}_r,\mathcal{B}_l\rangle$ (resp., $\langle\mathcal{B}_k\mathcal{B}_{-r},\mathcal{B}_l\rangle$), let us draw a picture representing the zones in the (k,l) plane where it indeed satisfies it. It appears in Figure 5.1 that the smaller the value of r, the larger the admitted area in the plane.

Now, let us focus on the other situations, e.g., $l \leq \min(k,r)$ when evaluating the quantity in (5.1). Therefore, we first express the product $\mathcal{B}_k(z)\mathcal{B}_r(z)$ lying in $\mathcal{H}_2(\mathbb{D})$ as an expansion over the basis function $\mathcal{B}_n(z)$ with integer $n \geq 0$, i.e.,

$$\mathcal{B}_k(z)\mathcal{B}_r(z) = \sum_{n=0}^{p-1} \langle \mathcal{B}_k\mathcal{B}_r, \mathcal{B}_n\rangle\, \mathcal{B}_n(z) + \sum_{n\geq p} \langle \mathcal{B}_k\mathcal{B}_r, \mathcal{B}_n\rangle\, \mathcal{B}_n(z).$$

Then, we evaluate this expression at $z = \mathrm{e}^{\mathrm{j}\omega_i}$, we multiply both sides by $[\overline{\mathcal{B}_l(\mathrm{e}^{\mathrm{j}\omega_i})}/\gamma_p(\omega_i)]$ and we sum over $i = 0, \ldots, p-1$. Hence, by taking advantage of the quadrature formula in (5.2), we obtain that

$$\begin{aligned}\frac{1}{2\pi}\int_{-\pi}^{\pi} \mathcal{B}_k(\mathrm{e}^{\mathrm{j}\omega})\overline{\mathcal{B}_l(\mathrm{e}^{\mathrm{j}\omega})}\mathcal{B}_r(\mathrm{e}^{\mathrm{j}\omega})\mathrm{d}\omega &= \sum_{i=0}^{p-1} \frac{1}{\gamma_p(\omega_i)}\mathcal{B}_k(\mathrm{e}^{\mathrm{j}\omega_i})\overline{\mathcal{B}_l(\mathrm{e}^{\mathrm{j}\omega_i})}\mathcal{B}_r(\mathrm{e}^{\mathrm{j}\omega_i}) \\ &\quad - \sum_{n\geq p} \langle \mathcal{B}_k\mathcal{B}_r, \mathcal{B}_n\rangle \sum_{i=0}^{p-1} \frac{1}{\gamma_p(\omega_i)}\mathcal{B}_n(\mathrm{e}^{\mathrm{j}\omega_i})\overline{\mathcal{B}_l(\mathrm{e}^{\mathrm{j}\omega_i})}. \qquad (5.6)\end{aligned}$$

In order to analyze the last summation term in the RHS of this expression, it is helpful to make the following (temporary) assumption.

Assumption 3. The zeros in $\mathcal{B}_n(z)$ for $n \geq p$ are obtained by cyclically repeating the p zeros of $\varphi_p(z)$ in their original order. □

Under this assumption, the basis functions $\mathcal{B}_n(z)$ for $n \geq p$ can easily be written as $\mathcal{B}_n(z) = \mathcal{B}_s(z)\varphi_p^{n'}(z)$ for $n = s + n'p$ with $0 \leq s < p$. Furthermore, we have the following result.

THEOREM 11. *For $0 \leq k, r, l < p$, Assumption* 3 *leads to*

$$\langle \mathcal{B}_k\mathcal{B}_r, \mathcal{B}_l\rangle = \sum_{i=0}^{p-1} \frac{1}{\gamma_p(\omega_i)}\mathcal{B}_k(\mathrm{e}^{\mathrm{j}\omega_i})\overline{\mathcal{B}_l(\mathrm{e}^{\mathrm{j}\omega_i})}\mathcal{B}_r(\mathrm{e}^{\mathrm{j}\omega_i}) - \mathrm{e}^{\mathrm{j}\theta} D_{(k,r),l}, \qquad (5.7)$$

where $D_{(k,r),l} = \langle \mathcal{B}_k\mathcal{B}_r, \mathcal{B}_{l+p}\rangle$ for $l \leq \min(k,r)$ and is identical to zero otherwise.

Proof. First, we have that

$$\sum_{i=0}^{p-1} \frac{1}{\gamma_p(\omega_i)}\mathcal{B}_n(\mathrm{e}^{\mathrm{j}\omega_i})\overline{\mathcal{B}_l(\mathrm{e}^{\mathrm{j}\omega_i})} = \mathrm{e}^{\mathrm{j}n'\theta}\sum_{i=0}^{p-1} \frac{1}{\gamma_p(\omega_i)}\mathcal{B}_s(\mathrm{e}^{\mathrm{j}\omega_i})\overline{\mathcal{B}_l(\mathrm{e}^{\mathrm{j}\omega_i})} = \mathrm{e}^{\mathrm{j}n'\theta}\delta_{l-s},$$

where θ is the reference phase of the Blaschke product $\varphi_p(z)$ while constructing the orthonormal bases of $\mathbb{C}^p$ (see section 4). This implies that n is restricted to $n = l + n'p$ in expression (5.6). Second, it is not difficult to show that

$$\left\langle \mathcal{B}_k\mathcal{B}_r, \mathcal{B}_{\min(k,r)+p+k'}\right\rangle = 0, \qquad \text{for } \; k' > 0,$$

because the integrand corresponding to this scalar product has no poles outside the unit circle so that the residue formula makes the associated integral vanish.

By putting these two results together, we have that n is restricted to $n = l + p$. Then, the proof is completed by making use of Lemma 10. □

As Assumption 3 has no consequences on the first p points ξ_i, the quantity $D_{(k,r),l}$ actually stands for a closed form expression of the last term in the RHS of the expression (5.6).

By complex conjugation, we similarly derive that

$$\langle \mathcal{B}_k \mathcal{B}_{-r}, \mathcal{B}_l \rangle = \sum_{i=0}^{p-1} \frac{1}{\gamma_p(\omega_i)} \mathcal{B}_k(\mathrm{e}^{\mathrm{j}\omega_i}) \overline{\mathcal{B}_l(\mathrm{e}^{\mathrm{j}\omega_i}) \mathcal{B}_r(\mathrm{e}^{\mathrm{j}\omega_i})} - \mathrm{e}^{-\mathrm{j}\theta} \overline{D}_{(l,r),k},$$

for $k \leq \min(l, r)$.

Finally, it is of interest to derive an upper bound on the modulus of $D_{(k,r),l}$ (identical to $D_{(r,k),l}$ by product commutativity) in the case that it is nonzero. This is the purpose of the two following lemmas.

LEMMA 12. *For $0 \leq l \leq k < p$, we have*

$$|D_{(k,l),l}| \leq c\, \beta_c^{-1} \eta^{(p-1)-k},$$

where $\beta_c^2 = 1 - c^2$ and $\eta = 2c/(1 + c^2) < 1$ as $0 \leq c < 1$.

Proof. This comes from the residue theorem. Without loss of generality, we shall again make use of Assumption 3. In detail, we successively have

$$\begin{aligned}
\overline{D}_{(k,l),l} &= \frac{1}{2\pi} \int_0^{2\pi} \overline{\mathcal{B}_k(\mathrm{e}^{\mathrm{j}\omega}) \mathcal{B}_l(\mathrm{e}^{\mathrm{j}\omega})} \mathcal{B}_{p+l}(\mathrm{e}^{\mathrm{j}\omega}) \mathrm{d}\omega \\
&= \frac{1}{2\pi \mathrm{j}} \oint_{|z|=1} \left[\frac{\beta_k}{1 - \overline{\xi}_k z} \prod_{i=k+1}^{p-1} \frac{z - \xi_i}{1 - \overline{\xi}_i z} \right] \frac{\beta_l^2 z}{(z - \xi_l)(1 - \overline{\xi}_l z)} \mathrm{d}z \\
&= \frac{\beta_k}{1 - \overline{\xi}_k \xi_l} \prod_{i=k+1}^{p-1} \frac{\xi_l - \xi_i}{1 - \overline{\xi}_i \xi_l} \xi_l
\end{aligned}$$

because of the contribution of the pole at $z = \xi_l$ only. Then, we easily find that

$$|D_{(k,l),l}| = \frac{\beta_k}{|1 - \overline{\xi}_k \xi_l|} \prod_{i=k+1}^{p-1} \left| \frac{\xi_l - \xi_i}{1 - \overline{\xi}_i \xi_l} \right| |\xi_l| \leq c\, \beta_c^{-1} \eta^{(p-1)-k}.$$

This completes the proof. ∎

Before going into the second lemma, let us introduce the following notation. While denoting by $\tilde{c}_i$ the ith largest value within the set of the zero moduli, i.e., $\{|\xi_k|, 0 \leq k < p\}$, we define

$$\zeta_m^-(\rho) = \prod_{i=1}^{m} \frac{\rho + \tilde{c}_i}{1 + \rho \tilde{c}_i} \quad \text{and} \quad \zeta_n^+(\rho) = \prod_{i=1}^{n} \frac{1 - \rho \tilde{c}_i}{\rho - \tilde{c}_i}. \tag{5.8}$$

Then, we have the following result.

LEMMA 13. *For $0 \leq l < r \leq k < p$, we have*

$$|D_{(k,r),l}| \leq K_c \min_{c < \rho \leq 1} \left[\zeta_m^-(\rho) \zeta_n^+(\rho) I(\rho, c) \right],$$

where $K_c = (1 + c)/(1 - c)$ while

$$I(\rho, c) = \frac{(1 - c)^2 \sqrt{1 - c^2}}{(1 - c\rho)^2 \sqrt{1 - c^2/\rho^2}}.$$

Further, the pair (m, n) (with $m \geq n$) is as follows:

$$(m, n) = \begin{cases} (p - k, r - l), & \text{if } p - k > r - l, \\ (r - l - 1, p - k - 1), & \text{otherwise.} \end{cases}$$

Proof. The derivation of the proof originates from the upper bounding of the value of the unimodular functions (appearing in the definition of the basis functions) outside the unit circle, i.e., $z = \rho\, \mathrm{e}^{\mathrm{j}\omega}$ with $\rho \neq 1$.

First, we can write

$$\overline{\mathcal{B}_k(z)\mathcal{B}_r(z)}\mathcal{B}_{p+l}(z) = \left[\frac{\beta_k z}{1-\overline{\xi}_k z}\prod_{i=k+1}^{p-1}\frac{z-\xi_i}{1-\overline{\xi}_i z}\right]\left[\frac{\beta_r z}{z-\xi_r}\frac{\beta_l}{1-\overline{\xi}_l z}\prod_{i=l}^{r-1}\frac{1-\overline{\xi}_i z}{z-\xi_i}\right].$$

Now, let us consider the case where $p-k > r-l$ for which we choose $c < \rho \leq 1$ in the definition of z. It is easily seen that

$$\frac{\rho-|\xi|}{1-\rho|\xi|} \leq \left|\frac{z-\xi}{1-\overline{\xi}z}\right| \leq \frac{\rho+|\xi|}{1+\rho|\xi|} \leq 1$$

for any $|\xi| \leq c$. The LHS (resp., RHS) inequality of this expression decreases (resp., increases) with $|\xi|$ going from zero to c. It yields

$$\begin{aligned}
|D_{(k,r),l}| &\leq \frac{1}{2\pi\mathrm{j}}\oint_{|z|=\rho}\left|\overline{\mathcal{B}_k(z)\mathcal{B}_r(z)}\mathcal{B}_{p+l}(z)\right|\frac{\mathrm{d}z}{z}\\
&\leq \zeta^-_{(p-1)-k}(\rho)\zeta^+_{r-l}(\rho)\frac{\rho^2}{2\pi\mathrm{j}}\oint_{|z|=\rho}\frac{\beta_k}{|1-\overline{\xi}_k z|}\frac{\beta_r}{|z-\xi_r|}\frac{\beta_l}{|1-\overline{\xi}_l z|}\frac{\mathrm{d}z}{z}\\
&\leq \zeta^-_{(p-1)-k}(\rho)\zeta^+_{r-l}(\rho)\frac{\beta_c^2\rho^2}{(1-c\rho)^2}\left[\frac{1}{2\pi}\int_0^{2\pi}\frac{\beta_r^2}{|\rho\mathrm{e}^{\mathrm{j}\omega}-\xi_r|^2}\mathrm{d}\omega\right]^{1/2}
\end{aligned}$$

by use of $\beta_i/|1-\overline{\xi}_i z| \leq \beta_c/(1-c\rho)$ for $|z| = \rho \in (c,1]$ and the Cauchy–Schwarz inequality for the last expression. With the help of the residue theorem

$$\frac{1}{2\pi}\int_0^{2\pi}\frac{\beta_i^2}{|\rho\mathrm{e}^{\mathrm{j}\omega}-\xi_i|^2}\mathrm{d}\omega = \frac{\beta_i^2}{\rho^2-|\xi_i|^2} \leq \frac{\beta_c^2}{\rho^2-c^2}, \tag{5.9}$$

we obtain

$$\begin{aligned}
|D_{(k,r),l}| &\leq \zeta^-_{p-k}(\rho)\zeta^+_{r-l}(\rho)\frac{\beta_c^3\rho}{(1-c\rho)^2\sqrt{\rho^2-c^2}}\left[\rho\,\frac{1+c\rho}{\rho+c}\right]\\
&\leq \zeta^-_{p-k}(\rho)\zeta^+_{r-l}(\rho)\frac{\beta_c^3}{(1-c\rho)^2\sqrt{1-c^2/\rho^2}} \qquad (5.10)
\end{aligned}$$

as the expression in brackets is less than or identical to one for all $\rho \in (c,1]$. This last expression is straightforwardly put into the form stated in the lemma.

In the case $p-k \leq r-l$, we choose $1 \leq \rho' < 1/c$ for defining $z = \rho'\mathrm{e}^{\mathrm{j}\omega}$. Then, by using the fact that

$$1 \leq \frac{\rho'+|\xi|}{1+\rho'|\xi|} \leq \left|\frac{z-\xi}{1-\overline{\xi}z}\right| \leq \frac{\rho'-|\xi|}{1-\rho'|\xi|}$$

for which the LHS (resp., RHS) inequality of this expression decreases (resp., increases) with $|\xi|$ going from zero to c, we derive that

$$\begin{aligned}
|D_{(k,r),l}| &\leq \zeta^+_{(p-1)-k}\left(\frac{1}{\rho'}\right)\zeta^-_{(r-l)-1}\left(\frac{1}{\rho'}\right)\frac{(\rho')^2}{2\pi\mathrm{j}}\oint_{|z|=\rho'}\frac{\beta_k}{|1-\overline{\xi}_k z|}\frac{\beta_r}{|z-\xi_r|}\frac{\beta_l}{|z-\xi_l|}\frac{\mathrm{d}z}{z}\\
&\leq \zeta^+_{(p-1)-k}\left(\frac{1}{\rho'}\right)\zeta^-_{(r-l)-1}\left(\frac{1}{\rho'}\right)\frac{\beta_c^2(\rho')^2}{(\rho'-c)^2}\left[\frac{1}{2\pi}\int_0^{2\pi}\frac{\beta_k^2}{|1-\overline{\xi}_k\rho'\mathrm{e}^{\mathrm{j}\omega}|^2}\mathrm{d}\omega\right]^{1/2}.
\end{aligned}$$

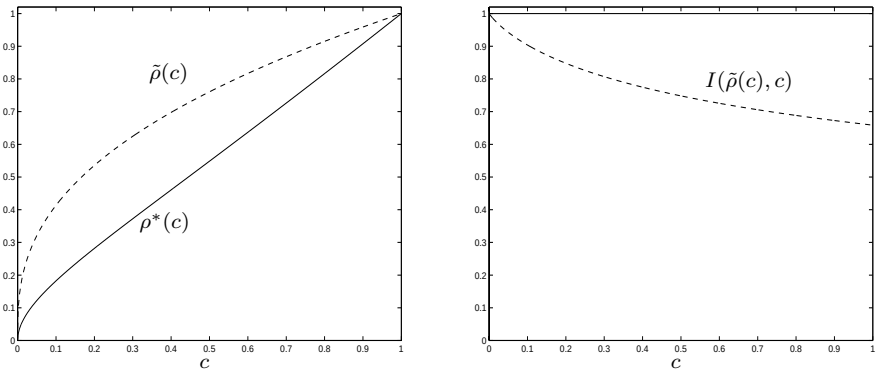

FIG. 5.2. *Characteristics of the convex function $I(\rho, c)$ as functions of c . Left: $\rho^*(c)$ such that $I(\rho^*, c) = 1$ (—) and $\tilde{\rho}(c)$ such that $I(\tilde{\rho}, c)$ is minimal (−−). Right: The value of $I(\tilde{\rho}(c), c)$ (−−).*

From this with $\rho = 1/\rho'$, we obtain that

$$|D_{(k,r),l}| \leq \zeta^+_{(p-1)-k}(\rho)\zeta^-_{(r-l)-1}(\rho)\frac{\beta_c^3}{(1-c\rho)^2\sqrt{1-c^2/\rho^2}}. \tag{5.11}$$

Finally, as ρ is chosen arbitrarily in the interval $(c, 1]$, we can ask for the minimum of the RHS expression (5.10) and (5.11) with respect to such ρ. This completes the proof. □

A characterization of the function $I(\rho, c)$ is given in the following proposition.

PROPOSITION 14. *The function $I(\rho, c)$ is convex for $c < \rho \leq 1$. Furthermore, $I(\rho, c) = 1$ at $\rho^* \in (c, 1)$ for appropriate values of $\rho^* = \rho^*(c)$. Thus, $I(\rho, c) < 1$ for $\rho \in (\rho^*, 1)$.* □

In the left part of Figure 5.2, we have drawn the function $\rho^*(c)$ as well as the value of $\rho \in [\rho^*(c), 1]$, denoted $\tilde{\rho}(c)$, at which $I(\rho, c)$ is minimal. In its right part, we have displayed the value of this minimum, i.e., $I(\tilde{\rho}(c), c)$.

From this proposition, we can state the following lemma.

LEMMA 15. *Let us take the same notation as in Lemma* 13 *and in Proposition* 14. *Then,*

$$|D_{(k,r),l}| \leq K_c\ \eta_0^{m-\min(m,n\epsilon_0)},$$

where $\rho_0 \in [\rho^*, 1)$, $\eta_0 = (\rho_0 + c)/(1 + \rho_0 c) < 1$ and $\epsilon_0 = \epsilon(\rho_0, c)$ is defined as

$$\epsilon(\rho_0, c) = \left\lceil \frac{\ln(1-\rho_0 c) - \ln(\rho_0 - c)}{\ln(1+\rho_0 c) - \ln(\rho_0 + c)} \right\rceil$$

with $\lceil x \rceil$ denoting the smallest integer not less than x.

Proof. First, from the discussion about the function $I(\rho, c)$, we have that $I(\rho_0, c) \leq 1$. Thus, Lemma 13 yields

$$|D_{(k,r),l}| \leq K_c\ \min(1, \zeta^-_m(\rho_0)\zeta^+_n(\rho_0)).$$

Then, by the definition of $\zeta^-_m(\rho)$ and $\zeta^+_n(\rho)$ (see expression (5.8)), the second argument in the RHS minimization is upper bounded as

$$\zeta^-_m(\rho_0)\zeta^+_n(\rho_0) \leq \left(\frac{\rho_0 + c}{1 + \rho_0 c}\right)^m \left(\frac{1-\rho_0 c}{\rho_0 - c}\right)^n.$$

It is easily seen that the RHS expression is less (or identical) to one for $m = n\epsilon_0$ as defined above. Hence, for $m \geq n\epsilon_0$, we successively have

$$\begin{aligned}\zeta_m^-(\rho_0)\zeta_n^+(\rho_0) &= \left[\zeta_m^-(\rho_0)/\zeta_{n\epsilon_0}^-(\rho_0)\right]\left[\zeta_{n\epsilon_0}^-(\rho_0)\zeta_n^+(\rho_0)\right] \\ &\leq \zeta_m^-(\rho_0)/\zeta_{n\epsilon_0}^-(\rho_0) \leq \eta_0^{m-n\epsilon_0}.\end{aligned}$$

Together with the above RHS minimization, this completes the proof. ∎

In summary, in this section we have given exact quadrature formulas (5.7) for the integral of $\mathcal{B}_k\mathcal{B}_r\overline{\mathcal{B}}_l$ if $l > \min(k, r)$. In the case where $l \leq \min(k, r)$, we assume a cyclic repetition of the ξ_k (Assumption 3), and then some error term $D_{(k,r),l}$ appears, which has been bounded in subsequent lemmas. This bound depends on how well the ξ_k are bounded away from the unit circle, which is measured by the paramater c from Assumption 1.

Similar results were obtained for integrals of the form $\mathcal{B}_k\mathcal{B}_{-r}\overline{\mathcal{B}}_l$, in which case a distinction has to be made between $k > \min(l, r)$ and $k \leq \min(l, r)$.

6. General Toeplitz matrix approximation. In this section, we consider general Toeplitz matrices constructed by use of a 2π-periodic function $f(\omega)$. Such a matrix was introduced in section 1 as

$$M_p(f) = \frac{1}{2\pi}\int_0^{2\pi} \Gamma_p(\omega) f(\omega) \Gamma_p^*(\omega) \mathrm{d}\omega.$$

With the help of the quadrature formulas derived in the preceding section, we shall show that any general Toeplitz matrix can be approximated by the matrix $\Upsilon_p F_p \Upsilon_p^*$ of (1.9). Note that the eigenpairs of this matrix are precisely the orthonormal vectors $\tilde{\Gamma}_p(\omega_i)$ with corresponding eigenvalue $f_p(\omega_i)$ (see definition (1.8)) for those particular ω values $\omega_i \in \Omega_p(\theta)$ (defined in (4.2)) that were generalizations of the pth roots of unity. The eigenvalue decomposition is in fact the quadrature formula (1.9), namely,

$$\Upsilon_p F_p \Upsilon_p^* = \sum_{i=0}^{p-1} \tilde{\Gamma}_p(\omega_i) f_p(\omega_i) \tilde{\Gamma}_p^*(\omega_i). \tag{6.1}$$

The approximation error is written as

$$\Delta_p(f) = M_p(f) - \Upsilon_p F_p \Upsilon_p^*.$$

Its (k, l)-element is written as

$$\begin{aligned}[\Delta_p(f)]_{k,l} &= \frac{1}{2\pi}\int_{-\pi}^{\pi} \mathcal{B}_k(\mathrm{e}^{\mathrm{j}\omega}) f(\omega) \overline{\mathcal{B}_l(\mathrm{e}^{\mathrm{j}\omega})} \mathrm{d}\omega - \sum_{i=0}^{p-1} \frac{1}{\gamma_p(\omega_i)} \mathcal{B}_k(\mathrm{e}^{\mathrm{j}\omega_i}) f_p(\omega_i) \overline{\mathcal{B}_l(\mathrm{e}^{\mathrm{j}\omega_i})} \\ &= -\sum_{r=0}^{p-1} \left(a_r \mathrm{e}^{\mathrm{j}\theta} D_{(k,r),l} + a_{-r} \mathrm{e}^{-\mathrm{j}\theta} \overline{D}_{(l,r),k}\right), \end{aligned} \tag{6.2}$$

where we have used the fact that $M_p(e_p) = 0$ by the residue theorem (recall $e_p = f - f_p$). So, it is seen that the closer the position of the $\Delta_p(f)$-elements to the top-right and/or bottom-left corners of the matrix, the larger their modulus because of the contribution of larger $|D_{(k,r),l}|$ terms.

Finally, for future use, let us upper bound the scalar quantities derived from the error matrix $\Delta_p(f)$. The following results hold.

LEMMA 16. *Given expression* (6.2) *together with Lemma* 15*, we have that*

$$\left|\tilde{\Gamma}_p^*(\sigma)\Delta_p(f)\tilde{\Gamma}_p(\mu)\right| \leq K_c^2 K_{f,p}/p \qquad \textit{for any} \quad \sigma,\mu \in [0,2\pi) \tag{6.3}$$

as well as

$$\|\Delta_p(f)\|_F \leq K_{f,p} \quad \textit{and} \quad \|\Delta_p(f)\tilde{\Gamma}_p(\omega)\|_2 \leq K_c K_{f,p}/p^{1/2} \qquad \textit{for} \quad \omega \in [0,2\pi),$$

where $\|.\|_F$ *denotes the Frobenius norm operator while*

$$K_{f,p} = 2K_c \sum_{r=0}^{p-1} K_0(r) \max(|a_r|,|a_{-r}|)$$

with $K_0(r) = [r^2(\epsilon_0 - 1) + (2r+1)/(1-\eta_0)]$.

Proof. First, we write

$$\begin{aligned}\left|\tilde{\Gamma}_p^*(\sigma)\Delta_p(f)\tilde{\Gamma}_p(\mu)\right| &\leq \sum_{k,l} \left|\left[\tilde{\Gamma}_p^*(\sigma)\right]_k [\Delta_p(f)]_{k,l} \left[\tilde{\Gamma}_p(\mu)\right]_l\right| \\ &\leq \max_{\omega,l} \frac{\left|\mathcal{B}_l(\mathrm{e}^{\mathrm{j}\omega})\right|^2}{\gamma_p(\omega)} \sum_{k,l} \left|[\Delta_p(f)]_{k,l}\right| \leq \frac{K_c^2 K_{f,p}}{p},\end{aligned}$$

where $K_{f,p}$ is evaluated as follows:

$$\begin{aligned}\sum_{k,l} \left|[\Delta_p(f)]_{k,l}\right| &\leq \sum_{r=0}^{p-1} \tilde{a}_r \sum_{k,l} \left(|D_{(k,r),l}| + |D_{(l,r),k}|\right) \leq 2\sum_{r=0}^{p-1} \tilde{a}_r \sum_{k,l} |D_{(k,r),l}| \\ &\leq 2K_c \sum_{r=0}^{p-1} K_0(r)\tilde{a}_r =: K_{f,p},\end{aligned}$$

where $\tilde{a}_r = \max(|a_r|,|a_{-r}|)$. This last expression has been obtained by taking advantage of Figure 5.1 in order to evaluate the contribution of the nonzero elements $D_{(k,r),l}$. It is found that

$$\begin{aligned}\sum_{k,l} |D_{(k,r),l}| &= \sum_{l=0}^{r-1} \sum_{k=l+1}^{p-1} |D_{(k,r),l}| + \sum_{k=r}^{p-1} |D_{(k,r),r}| + \sum_{l=0}^{r-1} |D_{(l,r),l}| \\ &\leq \sum_{l=0}^{r-1} \left[\sum_{k=l+1}^{(p-1)-(r-l)} |D_{(k,r),l}| + \sum_{k=(p-1)-(r-l)+1}^{p-1} |D_{(k,r),l}| \right] \\ &\qquad + c\,\beta_c^{-1} \left[\frac{1}{1-\eta} + r\eta^{(p-1)-r}\right] \\ &\leq K_c r \left[r(\epsilon_0 - 1) + \frac{1+\eta_0}{1-\eta_0}\right] + c\,\beta_c^{-1} \left[\frac{1}{1-\eta} + r\eta^{(p-1)-r}\right] \\ &\leq K_c \left[r^2(\epsilon_0 - 1) + \frac{2r+1}{1-\eta_0}\right] \leq K_c K_0(r),\end{aligned}$$

where we have used Lemma 12 and the results in Lemma 15 as follows:

$$\sum_{l=0}^{r-1} \sum_{k=l+1}^{(p-1)-(r-l)} |D_{(k,r),l}| \leq K_c \sum_{n=1}^{r} \sum_{m=n+1}^{(p-1)-(r-n)} \eta_0^{m-\min(m,n\epsilon_0)}$$

$$\leq K_c \sum_{n=1}^{r} \left[n(\epsilon_0 - 1) + \sum_{m=n\epsilon_0+1}^{(p-1)-(r-n)} \eta_0^{m-n\epsilon_0} \right]$$
$$\leq K_c\, r \left[\frac{r+1}{2}(\epsilon_0 - 1) + \frac{\eta_0}{1-\eta_0} \right]$$

as well as

$$\sum_{l=0}^{r-1} \sum_{k=(p-1)-(r-l)+1}^{p-1} |D_{(k,r),l}| \leq K_c \sum_{n=0}^{r-1} \sum_{m=n}^{r-1} \eta_0^{m-\min(m,n\epsilon_0)}$$
$$\leq K_c \sum_{n=0}^{r-1} \left[n(\epsilon_0 - 1) + \sum_{m=n\epsilon_0}^{r-1} \eta_0^{m-n\epsilon_0} \right]$$
$$\leq K_c r \left[\frac{r-1}{2}(\epsilon_0 - 1) + \frac{1}{1-\eta_0} \right].$$

Similarly, it is easy to show that the Frobenius norm of $\Delta_p(f)$ is readily upper bounded by $K_{f,p}$ as well as

$$\left\| \Delta_p(f) \tilde{\Gamma}_p(\omega) \right\|_2 \leq K_c K_{f,p} / p^{1/2}$$

so that the proof is completed. □

Note that this lemma puts into light the dependence between the asymptotic (with p) behavior of the upper bound $K_{f,p}$ and the regularity of the underlying function $f(\omega)$ that is traced in the convergence properties of the decomposition coefficients a_r and a_{-r} (see Theorem 1).

It is also worth mentioning that the (polynomial) upper bound $K_0(r)$ depends on the value of $\rho_0 \in [\rho^*, 1)$ on which a minimization could be performed.

7. General Toeplitz matrix functional. In the present section, we give a proof of Theorem 4. So we consider evaluating quantities of the form

$$\tilde{\Gamma}_p^*(\sigma) M_p(f) \tilde{\Gamma}_p(\mu),$$

making use of the results obtained in the preceding sections. Therefore, we first choose the reference phase θ of the Blaschke product $\varphi_p(e^{j\omega_i})$ so that the frequency point μ belongs to $\Omega_p(\theta)$. In other words, we impose $\tilde{\Gamma}_p(\mu)$ to be one of the column of the related unitary matrix Υ_p.

Then, we immediately have that

$$\tilde{\Gamma}_p^*(\sigma) M_p(f) \tilde{\Gamma}_p(\mu) = f_p(\mu) \tilde{\Gamma}_p^*(\sigma) \tilde{\Gamma}_p(\mu) + \tilde{\Gamma}_p^*(\sigma) \Delta_p(f) \tilde{\Gamma}_p(\mu),$$

where we have used the fact that $[\Upsilon_p F_p \Upsilon_p^*] \tilde{\Gamma}_p(\mu) = f_p(\mu) \tilde{\Gamma}_p(\mu)$. With the help of the upper bound (6.3), the last term in the RHS converges to zero like $1/p$ while the first one is identical to $f(\mu)$ if $\sigma = \mu$. If $\sigma \neq \mu$, this term decreases like $1/p$ by use of the result derived in Lemma 8. More generally, we can derive the following result.

LEMMA 17. *Let Assumptions* 1 *and* 2 *hold. Then*

$$\lim_{p\to\infty} \tilde{\Gamma}_p^*(\sigma) T(M_p(f)) \tilde{\Gamma}_p(\mu) = \begin{cases} T(f(\mu)), & \text{if } \sigma = \mu, \\ 0, & \text{otherwise}, \end{cases} \tag{7.1}$$

where $T(\cdot)$ is an analytic function (i.e., having convergent Taylor expansion) on the range of $f(\omega)$. The convergence rate to the limiting value is at least as fast as $1/p$ for $\sigma = \mu$ and as $\ln p/p$ in the other cases.

Proof. First, we look for the nth term in the Taylor expansion of $T(x)$, say $T_n x^n/n!$. Therefore, we consider $M_p^n(f) := [M_p(f)]^n$ and $f_p^n(\mu) := [f_p(\mu)]^n$ and show that $\tilde{\Gamma}_p^*(\sigma) M_p^n(f) \tilde{\Gamma}_p(\mu)$ converges to $f_p^n(\mu)\tilde{\Gamma}_p^*(\sigma)\tilde{\Gamma}_p(\mu)$. Indeed, we have that

$$\begin{aligned}
&\left|\tilde{\Gamma}_p^*(\sigma)\Big(M_p^n(f) - f_p^n(\mu) I_p\Big)\tilde{\Gamma}_p(\mu)\right| \\
&\quad = \left|\tilde{\Gamma}_p^*(\sigma)\Big(\big(\Upsilon_p F_p \Upsilon_p^* + \Delta_p(f)\big)^n - \Upsilon_p F_p^n \Upsilon_p^*\Big)\tilde{\Gamma}_p(\mu)\right| \\
&\quad \le \sum_{i=0}^{p-1} |\alpha_{p,i}| \left|\tilde{\Gamma}_p^*(\omega_i)\Big(\big(\Upsilon_p F_p \Upsilon_p^* + \Delta_p(f)\big)^n - \Upsilon_p F_p^n \Upsilon_p^*\Big)\tilde{\Gamma}_p(\mu)\right| \\
&\quad \le \sum_{i=0}^{p-1} |\alpha_{p,i}| \left[n\|F_p\|_2^{n-1} \left|\tilde{\Gamma}_p^*(\omega_i)\Delta_p(f)\tilde{\Gamma}_p(\mu)\right| \right. \\
&\qquad\qquad \left. + \sum_{k=2}^{n} C_k^n \|F_p\|_2^{n-k} \|\Delta_p(f)\|_2^{k-2} \|\Delta_p^*(f)\tilde{\Gamma}_p(\omega_i)\|_2 \|\Delta_p(f)\tilde{\Gamma}_p(\mu)\|_2 \right] \\
&\quad \le (K_c^2/p)\left[(f_{p,+} + K_{f,p})^n - f_{p,+}^n\right] \sum_{i=0}^{p-1} |\alpha_{p,i}|,
\end{aligned}$$

where I_p denotes the p-dimensional identity matrix, $f_{p,+} = \max_\omega |f_p(\omega)|$ and $\alpha_{p,i} = \tilde{\Gamma}_p^*(\sigma)\tilde{\Gamma}_p(\omega_i)$ while $C_k^n = n!/k!(n-k)!$ is the binomial function. For bounding the contribution of the $\alpha_{p,i}$'s, we used the results of section 4: namely, the 1-norm of the $\alpha_{p,i}$ sequence is identical to one for $\sigma = \mu$ and diverges at most like $\ln p$ in the other cases. By use of the results in Lemma 16 together with Theorem 1 under Assumption 2, it is easily shown that the term $K_{f,p}$ has bounded limiting values for increasing p. Putting the Taylor expansion terms together, we obtain that

$$\tilde{\Gamma}_p^*(\sigma) T(M_p(f)) \tilde{\Gamma}_p(\mu) = \begin{cases} T(f_p(\mu)) + O(1/p), & \text{if } \sigma = \mu, \\ O(\ln p/p), & \text{otherwise.} \end{cases}$$

Finally, as per Assumption 2, the approximation function $f_p(\omega)$ uniformly converges to $f(\omega)$ for unbounded p (see Corollary 2), so does $T(f_p(\omega))$ to $T(f(\omega))$. This completes the proof. □

It can also be shown that

$$\lim_{p\to\infty} \tilde{\Gamma}_p^*(\sigma) M_p(f) M_p(g) \tilde{\Gamma}_p(\mu) = \begin{cases} f(\mu)g(\mu), & \text{if } \sigma = \mu, \\ 0, & \text{otherwise,} \end{cases}$$

where $g(\omega)$ is a 2π-periodic function satisfying Assumption 2 and for which we define a diagonal matrix G_p and a residual matrix $\Delta_p(g)$ having the same properties as those related to the function $f(\omega)$. This is done as follows:

$$\begin{aligned}
&\left|\tilde{\Gamma}_p^*(\sigma)\Big(M_p(f)M_p(g) - f_p(\mu)g_p(\mu)\Big)\tilde{\Gamma}_p(\mu)\right| \\
&\quad \le \left|\tilde{\Gamma}_p^*(\sigma)\Big(\big(\Upsilon_p F_p \Upsilon_p^* + \Delta_p(f)\big)\big(\Upsilon_p G_p \Upsilon_p^* + \Delta_p(g)\big) - \Upsilon_p F_p G_p \Upsilon_p^*\Big)\tilde{\Gamma}_p(\mu)\right| \\
&\quad \le (K_c^2/p)\left[K_{g,p} f_{p,+} \sum_{i=0}^{p-1} |\alpha_{p,i}| + K_{f,p} g_{p,+} + K_{f,p} K_{g,p}\right]
\end{aligned}$$

with the convergence rate at least as fast as $1/p$ when $\sigma = \mu$ and as $\ln p/p$ in the other cases. Note that this last expression is not symmetric with respect to f and g. The reason for this is that $\mu \in \Omega_p(\theta)$ while nothing similar has been assumed for σ; see also [14, section 5].

Finally, the more general result of Theorem 4 follows easily. It should now be clear that

$$\lim_{p\to\infty} \tilde{\Gamma}_p^*(\sigma) T\Big(M_p(f^{[1]}), \ldots, M_p(f^{[n]})\Big) \tilde{\Gamma}_p(\mu) = \begin{cases} T\left(f^{[1]}, \ldots, f^{[n]}\right)(\mu), & \text{if } \sigma = \mu, \\ 0, & \text{otherwise,} \end{cases}$$

where $T(\cdot)$ is a multivariable analytic function on the range of the functions $f^{[i]}(\omega)$ satisfying Assumption 2. The same remark holds for the convergence rate to the limiting values.

8. General Toeplitz matrix spectrum. For what concerns the spectrum of the general Toeplitz matrix $M_p(f)$, it is possible to derive a result that stipulates that the distribution of its eigenvalues is asymptotically (with p) given by the distribution of those in the diagonal approximation matrix F_p. Remember that these diagonal elements are eigenvalues which are values of the underlying function $f_p(\omega)$ for appropriate frequency points ω_i. Furthermore, a closed form expression can be derived for the asymptotic distribution of these particular values $f_p(\omega_i)$. Here, we assume that the function $f(\omega)$ is not only 2π-periodic but also positive real-valued. We now give the proof of Theorem 5.

Proof of Theorem 5. This result is obtained using the same arguments as for the case of equivalent Toeplitz matrices (see Grenander and Szegő [11, Chap. 5]). Let us expose it in some detail.

First, we denote the ith (in any order) eigenvalue of any Hermitian matrix X by $\lambda_i(X)$. Then, it can be written that

$$\begin{aligned} \frac{1}{p}\sum_{i=0}^{p-1} \lambda_i\left(M_p(f)\right) &= \frac{1}{p}\mathrm{tr}\left(\Upsilon_p^* M_p(f) \Upsilon_p\right) = \frac{1}{p}\left[\sum_{i=0}^{p-1} f_p(\omega_i) + \mathrm{tr}\left(\Upsilon_p^* \Delta_p(f) \Upsilon_p\right)\right] \\ &= \sum_{i=0}^{p-1} \frac{f_p(\omega_i)}{p} + O\left(\frac{1}{p}\right), \end{aligned}$$

where we have used results from the preceding section for bounding the contributions of the error matrix $\Delta_p(f)$, i.e., $p|\tilde{\Gamma}_p^*(\omega)\Delta_p(f)\tilde{\Gamma}_p(\omega)| \le K_c^2 K_{f,p}$ that is upper bounded for all p under Assumption 2 (see Lemma 16 with Theorem 1).

Furthermore, such an expression also holds for any analytic function of the eigenvalues, i.e.,

$$\frac{1}{p}\sum_{i=0}^{p-1} T\left(\lambda_i\left(M_p(f)\right)\right) = \sum_{i=0}^{p-1} \frac{T(f_p(\omega_i))}{p} + O\left(\frac{1}{p}\right), \tag{8.1}$$

where $T(\cdot)$ is analytic over the interval $[f_{p,-}, f_{p,+}] = [\min_\omega f(\omega), \max_\omega f(\omega)]$. In fact, by Weierstrass–Stone's theorem (see, e.g., Gray [10]), this result can be extended to any continuous function over the interval $[f_{p,-}, f_{p,+}]$.

Now, let us write this result in a more convenient way. Therefore, remember from section 4 that the frequency point ω_i corresponds to $\chi_p^{-1}(\theta - i2\pi)$ where $\theta \in [0, 2\pi)$ denotes the reference phase taken for the Blaschke product. This implies that

$$\sum_{i=0}^{p-1} \frac{T(f(\omega_i))}{p} = \frac{1}{2\pi}\sum_{i=0}^{p-1} T\left(f_p\left(\chi_p^{-1}\left(p\left[\frac{\theta}{p} - i\Delta\right]\right)\right)\right)\Delta,$$

where $\Delta = 2\pi/p$. This expression is obviously the discretization of the following integral:

$$\frac{1}{2\pi}\int_{\theta/p-2\pi}^{\theta/p} T\left(f_p\left(\chi_p^{-1}\left(p\omega\right)\right)\right)\mathrm{d}\omega.$$

By continuity of the functions involved and the uniform convergence of the approximation $f_p(\omega)$ to $f(\omega)$ for unbounded p (see Corollary 2 under Assumption 2), we finally end up with an asymptotic expression of the distribution of the eigenvalues of the general Toeplitz matrix $M_p(f)$. It is written as

$$\lim_{p\to\infty}\frac{1}{p}\sum_{i=0}^{p-1} T\left(\lambda_i\left(M_p(f)\right)\right) = \frac{1}{2\pi}\int_0^{2\pi} T\left(f\left(\tilde{\chi}^{-1}\left(\omega\right)\right)\right)\mathrm{d}\omega,$$

where $\tilde{\chi}(\omega)$ satisfies $\tilde{\chi}^{-1}(\omega) = \lim_{p\to\infty}\chi_p^{-1}(p\omega)$ (see section 4). □

EXISTENCE FOR SHAPE OPTIMIZATION PROBLEMS IN ARBITRARY DIMENSION*

W. B. LIU†, P. NEITTAANMÄKI‡, AND D. TIBA§

Abstract. We discuss some existence results for optimal design problems governed by second order elliptic equations with the homogeneous Neumann boundary conditions or with the interior transmission conditions. We show that our continuity hypotheses for the unknown boundaries yield the compactness of the associated characteristic functions, which, in turn, guarantees convergence of any minimizing sequences for the first problem. In the second case, weaker assumptions of measurability type are shown to be sufficient for the existence of the optimal material distribution. We impose no restriction on the dimension of the underlying Euclidean space.

Key words. uniform segment property, compactness, existence of optimal shapers

1. Introduction.

In this paper, we study existence for two shape optimization problems. The first is the following optimal shape design problem:

$$\min_{\Omega\in\mathcal{O}} \int_\Omega (y-y_d)^2\,dx \tag{1.1}$$

(SONB)

$$-\Delta y + y = f, \quad \frac{\partial y}{\partial n}|_{\partial\Omega} = 0, \tag{1.2}$$

where $\mathcal{O}$ is a class of admissible open sets inside a fixed open set D in $\mathbf{R}^m$, and $f, y_d \in L^2(D)$.

The second problem is the following material distribution design problem:

$$\min_{\Omega\in\mathcal{O}} \int_{E\cap\Omega} |y_1 - z_d|^2\,dx + \int_{E\cap(D\setminus\Omega)} |y_2 - z_d|^2\,dx \tag{1.3}$$

(SOTB)

$$-a_1\Delta y_1 + b_1 y_1 = f \quad \text{in } \Omega, \tag{1.4}$$

$$-a_2\Delta y_2 + b_2 y_2 = f \quad \text{in } D\setminus\overline{\Omega}, \tag{1.5}$$

$$a_1\frac{\partial y_1}{\partial n} = a_2\frac{\partial y_2}{\partial n}, \quad y_1 = y_2 \quad \text{in } \partial\Omega\setminus(\partial\Omega\cap\partial D), \tag{1.6}$$

$$a_i\frac{\partial y_i}{\partial n} = 0 \quad \text{in } \Gamma_1, \qquad y_i = 0 \quad \text{in } \Gamma_2, \quad i = 1,2, \tag{1.7}$$

where $E \subset D$ are two given bounded domains in $\mathbf{R}^m$, $\Gamma_1\cup\Gamma_2 = \partial D$ with $\Gamma_1\cap\Gamma_2 = \emptyset$, $z_d \in L^2(E)$, and $\mathcal{O}$ is a class of admissible open sets inside D. The details of the above two problems will be specified in sections 3 and 4.

It is well known that, in general, such shape optimization problems have no solutions without assuming further regularity conditions on the boundaries of the

domain classes; see Pironneau [20] for some counterexamples. Assuming the cone property on $\mathcal{O}$ uniformly, for example, one can prove that the above optimal shape design problem indeed has solutions; see Chenais [6] and Pironneau [20] for the details. Furthermore, much effort has been devoted in the scientific literature to the relaxation of the regularity conditions required for the boundaries of the unknown domains in optimal design problems. This question is discussed in detail in the monographs by Pironneau [20], Haslinger and Neittaanmäki [8], Sokolowski and Zolesio [21], and Tiba [24], for instance. As the range of optimal design problems is very wide, including as well control into coefficients problems, optimization of certain evolution systems, some problems originating in mechanics, etc., there is a rich variety of existence results of interest. We quote here just the recent papers by Sverak [23], Bucur and Zolesio [4, 3, 5], and Henrot [9], where the question of the dependence of solutions of elliptic equations on the underlying domain of definition is discussed in a general setting and various sufficient compactness conditions are introduced. However, a complete solution of the problem seems not to be known, to our knowledge.

In this work, we first prove existence for the above optimal shape design problem governed by the Neumann boundary value problems, under the mere assumption that the unknown open sets are of class $\mathcal{C}$ (or, equivalently, they have the segment property—see Maz'ja [17] and Adams [1]) with some uniformity with respect to the parameters—see section 3 for the details. Our conditions allow cusps or certain oscillations of the boundaries, but cracks or oscillations dense in a set of positive measure (in the sense of Hausdorff–Pompeiu) are not permitted. Then, in section 4, it is shown that, for the material distribution problem, i.e., in the transmission boundary value problems, much weaker assumptions of measurability type are sufficient to obtain existence of the optimal sets. Moreover, all of our results are valid in any space dimension. This is an advantage over much of the existing literature, where very often the case of space dimension two is studied.

The approach that we are using is described in detail in section 2 and has its origin in our previous works—Liu [13], Liu and Rubio [15], Mäkinen, Neittaanmäki, and Tiba [16], and Neittaanmäki and Tiba [19]. Roughly speaking, we replace the extension technique for passing to the limit in the PDEs defined in a sequence of open sets by a local convergence analysis (see Lemma 3.2 and its proof). For set convergence, we introduce a concept of parametric convergence, which can be easily adapted to various possible representations of open sets and preserves some needed properties. As an example, the Hausdorff–Pompeiu convergence is a special case of the parametric convergence, choosing a certain distance function as the parametric representation. Notice that this is essentially different from the one used by Sverak [23]; see Proposition 2.5 and the subsequent remark.

It is recognized in the scientific literature that the a.e. convergence of the corresponding characteristic functions is an essential step in any convergence result for the PDEs defined in a sequence of open sets. Our treatment of this question, appearing mainly in sections 2 and 4, is based on a new technique using the maximal monotone extension of the Heaviside mapping in $\mathbf{R} \times \mathbf{R}$ and the closure properties of monotone operators. We also propose, in this setting, a new approximation procedure for the characteristic functions by means of the Yosida approximation and of the Friedrichs mollifiers. In this respect, we point out the constructive character of our method. Some numerical experiments together with an approximation result are reported in Mäkinen, Neittaanmäki, and Tiba [16].

Finally, we mention that, in the recent paper by Sprekels and Tiba [22], some

design problems, which are formulated as control into coefficients problems, are discussed. It is shown (by different methods) that the boundedness of the coefficients is sufficient to prove existence. An announcement of some of the results from the present work was published in Liu, Neittaanmäki, and Tiba [14] without proofs.

2. Convergence of open sets and of mappings. Let A, B be two open sets contained in the bounded domain D of $\mathbf{R}^m$, $m \in N$. The distance δ between A and B is defined by

$$\rho(A,B) = \sup_{x\in\bar{D}-A} \inf_{y\in\bar{D}-B} \|x-y\|_{\mathbf{R}^m}, \tag{2.1}$$

$$\delta(A,B) = \max\{\rho(A,B), \rho(B,A)\}, \tag{2.2}$$

and it is the Hausdorff–Pompeiu distance between the closed sets $\bar{D} \setminus A$ and $\bar{D} \setminus B$; see Pironneau [20] and Kuratowski [11]. We shall denote by Hlim the limit in the sense of Hausdorff–Pompeiu.

Another frequently used distance notion is

$$\mu(A,B) = \text{meas}[(A \setminus B) \cup (B \setminus A)], \tag{2.3}$$

defined by the Lebesgue measure of the symmetric set difference between A and B; see Hewitt and Stromberg [10, p. 144]. It should be noted that μ coincides with the well-known Ekeland metric in $L^\infty(D)$ applied to characteristic functions:

$$d_E(\chi_A, \chi_B) = \text{meas}\{x \in D \mid \chi_A(x) \neq \chi_B(x)\} = \mu(A,B). \tag{2.4}$$

Relations (2.3), (2.4) are defined up to sets of measure zero. Without supplementary regularity assumptions on the boundaries of the sets, there is no connection between δ and μ. For instance, let $\overline{S(0,1)}$ be the closed unit ball in $\mathbf{R}^m$. Add n (closed) rays of length 2, starting from the origin, into the ball such that the union of the rays is dense in $\overline{S(0,2)}$ as $n \to \infty$, and denote the resulting (closed) sets by A_n. Then

$$\text{Hlim}(A_n) = \overline{S(0,2)} \quad \text{for } n \to \infty, \tag{2.5}$$

$$\mu(A_n, \overline{S(0,1)}) \to 0 \quad \text{for } n \to \infty. \tag{2.6}$$

In Chenais [6], it was proved that, for uniformly Lipschitz domains, convergence in the metric (2.2) yields convergence in the metric (2.4) with the same limit (up to a set with zero measure).

Let us now introduce the mappings $d_\Omega : \bar{D} \to \mathbf{R}$, based on the Euclidean distance functions associated with the domain Ω and its complementary:

$$d_\Omega(x) = \begin{cases} \text{dist}(x, \bar{D} \setminus \Omega) & \text{if } x \in \Omega, \\ 0 & \text{if } x \in \partial\Omega, \\ -\text{dist}(x, \overline{\Omega}) & \text{if } x \in \bar{D} \setminus \overline{\Omega}. \end{cases} \tag{2.7}$$

The mapping d_Ω is uniformly Lipschitzian in $\bar{D}$ for any open subset $\Omega \subset \bar{D}$; see Clarke [7]. Let $\Omega_n \subset D$ be a sequence of open sets, not necessarily connected. Let $d_n = d_{\Omega_n}$ be the associated mappings via (2.7). By the Ascoli theorem, on a subsequence again denoted by n, we have $d_n \to \hat{d}$ uniformly in $\bar{D}$. However, $\hat{d}$ is not necessarily a function of the same type since, in general, the Hlim's of $\overline{\Omega}_n$ and of $\bar{D} \setminus \Omega_n$ may be not complementary to each other (see the above example with the sets A_n). Let $\widehat{\Omega} = \{x \in D \mid \hat{d}(x) > 0\}$ (possibly void).

PROPOSITION 2.1.

$$\widehat{\Omega} = D \setminus \mathrm{Hlim}(\bar{D} \setminus \Omega_n).$$

Proof. Let $x \in D \setminus \mathrm{Hlim}(\bar{D} \setminus \Omega_n)$ so that $x \notin \mathrm{Hlim}(\bar{D} \setminus \Omega_n)$. Then $\lim_{n\to\infty} \mathrm{dist}(x, \bar{D} \setminus \Omega_n) > 0$. Thus $\lim_{n\to\infty} d_n(x) > 0$; i.e., $x \in \widehat{\Omega}$.

Conversely, assume that $x \in \widehat{\Omega}$ and $x \notin D \setminus \mathrm{Hlim}(\bar{D} \setminus \Omega_n)$. Then $\hat{d}(x) > 0$, and $x \in \mathrm{Hlim}(\bar{D} \setminus \Omega_n)$. That is, $\hat{d}(x) > 0$, and there are $x_n \in \bar{D} \setminus \Omega_n$ such that $x_n \to x$. This means that $\hat{d}(x) > 0$, $d_n(x_n) \le 0$, and $x_n \to x$. By the uniform convergence, we have $\hat{d}(x) > 0$ and $\hat{d}(x) \le 0$, which lead to a contradiction. It follows that $\widehat{\Omega} = D \setminus \mathrm{Hlim}(\bar{D} \setminus \Omega_n)$, which is the desired conclusion. □

Remark. The above proposition shows that the well-known compactness property of the Hausdorff–Pompeiu distance is a direct consequence of the Ascoli compactness criteria. A variant of the mapping d_Ω (identically zero outside Ω) was considered by Sverak [23], who also proved a result similar to Proposition 2.1.

PROPOSITION 2.2. *If* $\mathrm{Hlim}(\bar{D} \setminus \Omega_n) = \bar{D} \setminus \widehat{\Omega}$, *then, for any compact* $\mathcal{K} \subset \widehat{\Omega}$, *there is an* $n_{\mathcal{K}} = n(\mathcal{K}) \in N$ *such that* $\mathcal{K} \subset \Omega_n$ *for* $n \ge n_{\mathcal{K}}$.

Proof. We use the same notation as in Proposition 2.1. Since $\hat{d}$ is continuous on $\bar{D}$ and strictly positive on $\mathcal{K}$, there is a $c_{\mathcal{K}} > 0$ such that

$$\hat{d}(x) \ge c_{\mathcal{K}} > 0 \quad \forall x \in \mathcal{K}.$$

By the uniform convergence, for $n \ge n_{\mathcal{K}}$, we obtain $d_n(x) \ge \frac{1}{2} c_{\mathcal{K}} > 0$ for all $x \in \mathcal{K}$. That is, $\mathcal{K} \subset \Omega_n$ for $n \ge n_{\mathcal{K}}$, as required. □

Remark. This property is called the Γ-*property* by Liu [13] and Liu and Rubio [15], and it plays an essential role in the local convergence theory for the solutions of PDEs defined in sequences of bounded domains. The same property is also proved in Pironneau [20], by different methods, together with other domain convergence results.

DEFINITION 2.3. *We say that the sequence of open sets* $\Omega_n \subset D$ *is parametrically convergent to the open set* $\widetilde{\Omega} \subset D$ *if there is a sequence of continuous mappings* $p_n : \bar{D} \to \mathbf{R}$ *such that* $p_n \to \tilde{p}$ *uniformly in* $\bar{D}$ *and*

$$\begin{aligned} \Omega_n &= \{x \in D \mid p_n(x) > 0\}, \\ D \setminus \overline{\Omega}_n &= \{x \in D \mid p_n(x) < 0\}, \\ \widetilde{\Omega} &= \{x \in D \mid \tilde{p}(x) > 0\}, \\ D \setminus \overline{\widetilde{\Omega}} &= \{x \in D \mid \tilde{p}(x) < 0\}. \end{aligned}$$

We denote the limit by $\widetilde{\Omega} = p - \lim \Omega_n$.

Remark. The "parametrization" p_n associated with the domain Ω_n is not unique, and the distance mapping d_n is just one example. The p-limit and the convergence properties depend on the parametrization. If it is different from the function d_Ω, then the convergence may differ from the Hausdorff–Pompeiu convergence. For instance, we choose $\check{p} : \mathbf{R} \to \mathbf{R}$ by

$$\check{p}(x) = \begin{cases} -(x-1)^2 + \frac{1}{2}, & x \ge \frac{1}{2}, \\ x^2, & |x| \le \frac{1}{2}, \\ -(x+1)^2 + \frac{1}{2}, & x \le -\frac{1}{2}, \end{cases}$$

and we rotate its graph to define a continuous mapping $p : \mathbf{R}^2 \to \mathbf{R}$. Take $p_n : \mathbf{R}^2 \to \mathbf{R}$, $p_n(x) = p(x) + \frac{1}{n}$. Then the corresponding domains are $\Omega_n = \{x \in \mathbf{R}^2 \mid |x|_{\mathbf{R}^2} < 1 + \sqrt{\frac{n+2}{2n}}\}$ and $\Omega = \{x \in \mathbf{R}^2 \mid 0 < |x|_{\mathbf{R}^2} < 1 + \frac{1}{\sqrt{2}}\}$. Notice that Ω is nonsmooth, $\Omega = p - \lim \Omega_n$, and $\bar{\Omega} \neq \operatorname{Hlim} \bar{\Omega}_n$. If $\check{p}$ is zero around $x = 0$ on some interval, then $p - \lim \Omega_n$ will be a circular crown, etc. By taking $\sup(p_n, p_k)$ or $\inf(p_n, p_k)$, one can easily "parametrize" $\Omega_n \cup \Omega_k$ or $\Omega_n \cap \Omega_k$.

PROPOSITION 2.4. *The parametric convergence has the* Γ*-property for any parametrization.*

Proof. This is similar to the proof of Proposition 2.2. □

Remark. It is possible to weaken the conditions in Definition 2.3 by replacing the uniform convergence with other types of functional convergence for the mapping p_n. This will be used in section 4 (see Theorem 4.1 and its subsequent remarks).

PROPOSITION 2.5. *If* $\Omega = p - \lim \Omega_n$ *and the closed set* $C = \{x \in \bar{D} \mid \tilde{p}(x) = 0\}$ *has zero measure, then* $\chi_{\Omega_n} \to \chi_\Omega$ *a.e. in* D.

Proof. If $x \in \Omega$, then $\tilde{p}(x) > 0$ so that $p_n(x) > 0$ for $n \geq n_x$ (depending on x). Thus $\chi_{\Omega_n}(x) = \chi_\Omega(x) = 1$ for $n \geq n_x$. If $x \in D \setminus \overline{\Omega}$, then $\tilde{p}(x) < 0$ and $p_n(x) < 0$ for $n \geq n_x$; i.e., $x \in D \setminus \overline{\Omega}_n$ for $n \geq n_x$. Consequently, $\chi_{\Omega_n}(x) = \chi_\Omega(x) = 0$ for $n \geq n_x$.

As the set C has zero measure, we get that $\chi_{\Omega_n}(x) \to \chi_\Omega(x)$ a.e. in D. □

Remark. The family of distance-type mappings used by Sverak [23] does not satisfy this property.

DEFINITION 2.6. *Assume that* $\Omega = p - \lim \Omega_n$, *and let* $y_n \in H^1(\Omega_n)$ *be such that* $\{|y_n|_{H^1(\Omega_n)}\}$ *is bounded. We say that* $\{y_n\}$ *is locally convergent to* $y \in H^1(\Omega)$, *and we write* $y = L - \lim y_n$ *if, for any* $G \subset\subset \Omega$ *(open set compactly embedded in* Ω*), we have*

$$y_n|_G \longrightarrow y|_G \quad \textit{weakly in } H^1(G). \tag{2.8}$$

Remark. This definition is motivated by Proposition 2.4. The limit mapping y is uniquely determined. The convergence in (2.8) is also valid in $L^2(G)$ strongly for any $G \subset\subset \Omega$.

THEOREM 2.7 (compactness). *Assume* $\Omega = p - \lim \Omega_n$. *Suppose that* $y_n \in H^1(\Omega_n)$ *and* $|y_n|_{H^1(\Omega_n)}$ *is uniformly bounded. Then there are a* $y \in H^1(\Omega)$ *and a subsequence still denoted by* y_n *such that* $y = L - \lim y_n$.

Proof. Take a sequence $G_j \subset\subset \Omega$ such that $G_j \subset G_{j+1}$ and $\bigcup G_j = \Omega$. For each j, we take subsequences (one after another and all denoted by n) such that $y_n|_{G_j} \longrightarrow y^j$ weakly in $H^1(G_j)$. We define y on Ω by $y(x) = y^j(x)$ a.e. $x \in G_j$, which is possible by the properties of $\{G_j\}_{j \in \mathcal{N}}$. Clearly, $y \in L^2(\Omega)$ since $|y_n|_{L^2(G_j)}$ is uniformly bounded with respect to n and j. Consider any $\varphi \in \mathcal{D}(\Omega)$. There is a j_0 such that $\varphi \in \mathcal{D}(G_j)$ for all $j \geq j_0$. Therefore,

$$\int_{G_j} \nabla y \varphi = \int_\Omega \nabla y \varphi = -\int_\Omega y \nabla \varphi = -\int_{G_j} y^j \nabla \varphi = \int_{G_j} \nabla y^j \varphi.$$

This yields that $\nabla y = \nabla y^j$ in G_j for all $j \geq j_0$. As $|y^j|_{H^1(G_j)}$ is bounded with respect to j, we obtain that $\nabla y \in L^2(\Omega)^m$; i.e., $y \in H^1(\Omega)$. Relation (2.8) then follows, and the proof is completed. □

THEOREM 2.8 (lower semicontinuity). *If* $l : \mathbf{R}^m \times \mathbf{R} \times \mathbf{R}^m \to \mathbf{R}$ *is nonnegative and measurable,* $l(x, \cdot, \cdot)$ *is continuous on* $\mathbf{R} \times \mathbf{R}^m$, $l(x, s, \cdot)$ *is convex on* $\mathbf{R}^m$, *and*

$\Omega = p - \lim \Omega_n$, *then*

$$\int_\Omega l(x, y, \nabla y)\, dx \le \liminf_{n\to\infty} \int_{\Omega_n} l(x, y_n, \nabla y_n)\, dx \tag{2.9}$$

provided that $y = L - \lim y_n$.

Proof. Let $\{G_j\}$ be selected as in the previous proof. Then we have $\chi_{G_j} \to \chi_\Omega$ a.e. in D. For any fixed G_j, we have that $y_n \to y$ weakly in $H^1(G_j)$, and we obtain

$$\int_{G_j} l(x, y, \nabla y)\, dx \le \liminf_{n\to\infty} \int_{G_j} l(x, y_n, \nabla y_n)\, dx$$

since weak lower semicontinuity is a well-known property of the convex integrals in the fixed domains. Next, Fatou's lemma gives

$$\begin{aligned}
\int_\Omega l(x, y, \nabla y)\, dx &= \int_\Omega \lim_{j\to\infty} \chi_{G_j} l(x, y, \nabla y)\, dx \\
&\le \liminf_{j\to\infty} \int_{G_j} l(x, y, \nabla y)\, dx \\
&\le \liminf_{j\to\infty} \liminf_{n\to\infty} \int_{\Omega_n} l(x, y_n, \nabla y_n)\, dx \\
&= \liminf_{n\to\infty} \int_{\Omega_n} l(x, y_n, \nabla y_n)\, dx.
\end{aligned}$$

The positivity of l is essential in the above proof. □

Remark. Theorems 2.7 and 2.8 are variants or results previously proved by Liu and Rubio [15] and Liu [13]. It should be noted that it is enough to assume the Γ-property for the open sets Ω_n and Ω to prove Theorems 2.7 and 2.8.

3. Equicontinuity. We consider the model problem (SONB). The problem is formulated as

$$\min_\Omega \int_\Omega (y - y_d)^2\, dx, \tag{3.1}$$

subject to the following variational equation with the homogeneous Neumann boundary condition:

$$\int_\Omega \nabla y \nabla v + \int_\Omega yv = \int_\Omega fv \quad \forall v \in H^1(\Omega), \tag{3.2}$$

where Ω is a variable open set such that $\Omega \subset D$ with D being a fixed bounded open set in $\mathbf{R}^m$, and $y_d \in L^2(D)$. For the admissible class of open sets denoted by $\mathcal{O}$, we require that they have the $\mathcal{C}$-property (or, equivalently, the segment property) with some uniform constants:

(H1) We consider a family $\mathcal{F}$ of equibounded and equiuniformly continuous functions $g : S(0,k) \to \mathbf{R}$, with $k > 0$ fixed and $S(0,k) \subset \mathbf{R}^{m-1}$ an open ball. For any $\Omega \in \mathcal{O}$, there is a subset $\mathcal{F}_\Omega \subset \mathcal{F}$, and, for any $g \in \mathcal{F}_\Omega$, we associate an orthogonal system of axes of center $o_g \in \partial\Omega$, "vertical" vector $l_g \in \mathbf{R}^m$ of unit length, and a rotation R_g in $\mathbf{R}^m$ such that $l_g = R_g(0, 0, \dots, 0, 1)$ and

$$\bigcup_{g\in\mathcal{F}_\Omega} \{R_g(s, 0) + o_g + g(s) l_g \mid s \in S(0,k)\} = \partial\Omega.$$

(H2) There is an $a > 0$ such that, for any $\Omega \in \mathcal{O}$ and any $g \in \mathcal{F}_\Omega$, the uniform segment property is valid:

$$\begin{aligned} &R_g(s,0) + o_g + (g(s)+t)l_g \in \mathbf{R}^m \setminus \overline{\Omega} \quad \forall s \in S(0,k),\ \forall t \in]0,a[\,, \\ &R_g(s,0) + o_g + (g(s)-t)l_g \in \Omega \qquad\quad \forall s \in S(0,k),\ \forall t \in]0,a[\,. \end{aligned}$$

These two conditions represent the usual definition of boundaries of class $\mathcal{C}$ with added uniformity assumptions. Notice that, due to the compactness of $\partial\Omega$, it can be covered by a finite number of local charts; therefore, both conditions are automatically satisfied, and the only real requirement is the uniformity with respect to the whole family $\mathcal{O}$, which does not allow the local charts to shrink.

Our specific requirement is that there is a constant $r \in]0,k[$ such that

$$\text{(H3)} \qquad \bigcup_{g\in\mathcal{F}_\Omega} \{R_g(s,0) + o_g + g(s)l_g \mid s \in \overline{S(0,r)}\} = \partial\Omega$$

for any $\Omega \in \mathcal{O}$. This is a uniform restriction (or extension) property for the whole family $\mathcal{F}$ of the local charts. It avoids, for instance, clustering of singularities (like cusps) near the boundary of any local chart. Notice that, due to the finite numbers of the local charts, a positive number $0 < r_\Omega < k$ can be found in each Ω with the above property. We just assume that it can be chosen independent of Ω.

Example. Take $g(x) = x^{\frac{1}{2}}$, $x \in]-\alpha,\alpha[$, to be a local chart with Hölder regularity for some domain in $\mathbf{R}^2$. In $x = 0$, we have a cusp, and the segment property is fulfilled only by the vertical segments. Thus the segment choice for local charts with cusps is unique, and only cusps with the same "axis" may belong to the same local chart. Hypothesis (H3) requires, in particular, that cusps with different "axes" do not cluster. In the common part (which cannot shrink) of neighboring local charts, no cusp can occur.

Remark. In the counterexample of Pironneau [20], with infinitely many oscillations of the boundary in a rectangular region, all of the conditions in (H1)–(H3) are fulfilled except the equicontinuity of the local charts. This shows the essential importance of this assumption, reflected by the title of the section. Examples of continuous oscillating boundaries which are not even of class $\mathcal{C}$ may be found in the book by Maz'ja [17]. It is also known that domains with cuts are not of class $\mathcal{C}$. Notice, however, that our assumptions allow infinitely many oscillations with vanishing amplitude (to preserve equicontinuity).

THEOREM 3.1 (compactness and existence). *Let $\{\Omega_n\}$ be a minimizing sequence of open sets for the problem* (3.1) *satisfying the assumptions* (H1)–(H3). *Then there is an open set $\widehat{\Omega}$ of class $\mathcal{C}$ which is a solution of the problem* (3.1) *and which satisfies* (H1)–(H3). *Furthermore, $\chi_{\Omega_n} \to \chi_{\hat{\Omega}}$ a.e.*

Proof. We may assume that $\bar{D}$ is large enough to include Ω_n and the segments defined in (H2). Denote by d_n the distance-type functions introduced in (2.7) corresponding to Ω_n and by $\hat{d}$ their uniform limit, $\hat{d} \in C(\bar{D})$. Let $\Lambda = \{x \in \bar{D} \mid \hat{d}(x) \geq 0\}$ be a closed set, which is clearly nonvoid. Take $\hat{x} \in \Lambda$ such that $\hat{d}(x) = 0$. Then $d_n(\hat{x}) \to 0$, by the definition of $\hat{d}$. By the definition of d_n, there are $x_n \in \partial\Omega_n$, $x_n \to \hat{x}$ (and $d_n(x_n) = 0$). By (H3), there are $g_n \in \mathcal{F}_{\Omega_n}$ such that $x_n = R_{g_n}(s_n,0) + o_{g_n} + g_n(s_n)l_{g_n}$, $d_n(o_{g_n}) = 0$, and $s_n \in \overline{S(0,r)}$. Under our conditions, we may assume that $s_n \to \hat{s} \in \overline{S(0,r)}$ and $g_n \to \hat{g}$ uniformly in $\overline{S(0,k)}$, with $\hat{g}$ being continuous in $\bar{D}$, $R_{g_n} \to \widehat{R}$, $o_{g_n} \to \hat{o}$ with $\hat{d}(\hat{o}) = 0$, $l_{g_n} \to \hat{l}$ as matrices or

vectors (since all are bounded) with $\widehat{R}(0,0,\dots,0,1)=\hat{l}$, and $|\hat{l}|=1$. We have

$$\hat{x}=\lim x_n=\lim(R_{g_n}(s_n,0)+o_{g_n}+g_n(s_n)l_{g_n})=\widehat{R}(\hat{s},0)+\hat{o}+\hat{g}(\hat{s})\hat{l}, \tag{3.3}$$

$$d_n(R_{g_n}(s,0)+o_{g_n}+g_n(s)l_{g_n})\to\hat{d}(\widehat{R}(s,0)+\hat{o}+\hat{g}(s)\hat{l})=0\quad\forall s\in S(0,k). \tag{3.4}$$

We show the segment property.

Take any $\varepsilon\in\,]0,a[$, and consider the point $\widehat{R}(s,0)+\hat{o}+(\hat{g}(s)-\varepsilon)\hat{l}\in\mathbf{R}^m$. We have that $R_{g_n}(s,0)+o_{g_n}+(g_n(s)-\varepsilon)l_{g_n}\to\widehat{R}(s,0)+\hat{o}+(\hat{g}(s)-\varepsilon)\hat{l}$; that is, $\widehat{R}(s,0)+\hat{o}+(\hat{g}(s)-\varepsilon)\hat{l}\in\bar{D}$ for $s\in S(0,k)$. As $R_{g_n}(s,0)+o_{g_n}+(g_n(s)-\varepsilon)l_{g_n}\in\Omega_n$ by (H2), we have $d_n(R_{g_n}(s,0)+o_{g_n}+(g_n(s)-\varepsilon)l_{g_n})>0$ for $s\in S(0,k)$, $\varepsilon\in\,]0,a[$, $n\geq 1$. It follows that $\hat{d}(\widehat{R}(s,0)+\hat{o}+(\hat{g}(s)-\varepsilon)\hat{l})\geq 0$ for $s\in S(0,k)$, $\varepsilon\in\,]0,a[$; i.e., $(\widehat{R}(s,0)+\hat{o}+(\hat{g}(s)-\varepsilon)\hat{l})\in\Lambda$ for such values of the parameters s, ε.

For the outside segment property, a sharper estimate is needed. By the equicontinuity of g_n, there is an $\delta>0$ (depending only on ε and independent of $s\in S(0,k)$ or $n\in N$) such that

$$|g_n(t)-g_n(s)|<\frac{\varepsilon}{2}\quad\forall n,\ \forall t\in S(s,\delta)\cap S(0,k). \tag{3.5}$$

Then, for $\varepsilon<\frac{2}{3}a$, we get

$$\begin{aligned}\operatorname{dist}[R_{g_n}(s,0)+o_{g_n}+(g_n(s)+\varepsilon)l_{g_n},\partial\Omega_n]\\ \geq\min\left\{\frac{\varepsilon}{2},\delta,a-\frac{3}{2}\varepsilon,\operatorname{dist}(s,\partial S(0,k)\right\}.\end{aligned} \tag{3.6}$$

Here we use the uniform outside segment property for Ω_n, i.e., $R_{g_n}(s,0)+o_{g_n}+(g_n(s)+\varepsilon)l_{g_n}\in D\setminus\overline{\Omega}_n$, for all $s\in S(0,k)$ and for all $\varepsilon\in\,]0,a[$. The inequality (3.6) comes from (3.5), which simply says that the cylinder $[S(0,k)\cap S(s,\delta)]\times[g_n(s)+\frac{\varepsilon}{2},g_n(s)+a-\frac{\varepsilon}{2}]$ after translation o_{g_n} and rotation R_{g_n} cannot intersect $\partial\Omega_n$ for any n. And the right-hand side in (3.6) estimates from below the distance between $(s,g_n(s)+\varepsilon)$ and the boundary of this cylinder. (This point is inside the cylinder for $\varepsilon<\frac{2}{3}a$.)

Then it yields

$$d_n(R_{g_n}(s,0)+o_{g_n}+(g_n(s)+\varepsilon)l_{g_n})\leq-\min\left\{\frac{\varepsilon}{2},\delta,a-\frac{3}{2}\varepsilon,\operatorname{dist}(s,\partial S(0,k))\right\}. \tag{3.7}$$

Inequality (3.7) is independent of n, and we can take the limit, by the uniform convergence, to obtain

$$\hat{d}(\widehat{R}(s,0)+\hat{o}+(\hat{g}(s)+\varepsilon)\hat{l})\leq-\min\left\{\frac{\varepsilon}{2},\delta,a-\frac{3}{2}\varepsilon,\operatorname{dist}(s,\partial S(0,k))\right\}; \tag{3.8}$$

that is, $\hat{d}(\widehat{R}(s,0)+\hat{o}+(\hat{g}(s)+\varepsilon)\hat{l})<0$ for all $s\in S(0,k)$ and for all $\varepsilon\in\,]0,\frac{2}{3}a[$, and, consequently, $(\widehat{R}(s,0)+\hat{o}+(\hat{g}(s)+\varepsilon)\hat{l})\notin\Lambda$ for these values of the parameters s, ε. By choosing a smaller $\delta>0$, if necessary, we can replace $\frac{\varepsilon}{2}$ by $\frac{\varepsilon}{l}$, $l\in N$, and $\frac{3}{2}\varepsilon$ by $\frac{l+1}{l}\varepsilon$ in inequalities (3.5)–(3.8). Finally, we have that $\widehat{R}(s,0)+\hat{o}+(\hat{g}(s)+\varepsilon)\hat{l}\notin\Lambda$ for $s\in S(0,k)$ and $\varepsilon\in\,]0,a[$.

Notice that estimates like (3.8) can also be obtained for $\hat{d}(\widehat{R}(s,0)+\hat{o}+(\hat{g}(s)-\varepsilon)\hat{l})$, $s\in S(0,k)$, $\varepsilon\in\,]0,a[$, with the reversed sign. Then

$$\widehat{\Omega}=\{x\in D\mid\hat{d}(x)>0\}=\operatorname{int}\Lambda \tag{3.9}$$

is a nonvoid open subset of D. The above argument shows that $\partial\widehat{\Omega} = \{x \in D \mid \hat{d}(x) = 0\}$ is of class $\mathcal{C}$ and satisfies (H1)–(H3) with the same constants a, r, k and the same modulus of continuity.

By Proposition 2.1, we see that $\widehat{\Omega} = D \setminus \mathrm{Hlim}(\bar{D} \setminus \Omega_n)$ (and $\widehat{\Omega} = p - \lim \Omega_n$), which proves the compactness of the family $\mathcal{O}$.

Let us also remark that, by Proposition 2.5, we have $\chi_{\Omega_n} \to \chi_{\hat{\Omega}}$ a.e. in D, and, by the Lebesgue theorem, this convergence is valid in any $L^q(D)$, $q \geq 1$. Here we also use the fact that $\partial\widehat{\Omega} = \{x \in D \mid \hat{d}(x) = 0\}$ has zero measure in $\mathbf{R}^m$ since it can be represented as a finite union of graphs of continuous functions.

The fact that $\widehat{\Omega}$ is a solution of the problem (3.1) follows from the subsequent lemma and Theorem 2.8. □

LEMMA 3.2. *Let y_n, $\hat{y}$ denote the unique solutions of* (3.2) *associated with Ω_n, $\widehat{\Omega}$. Then $\hat{y} = L - \lim y_n$ on a subsequence.*

Proof. Clearly, $y_n \in H^1(\Omega_n)$, $\hat{y} \in H^1(\widehat{\Omega})$, and $\{|y_n|_{H^1(\Omega_n)}\}$ is bounded. By Proposition 2.4, for any open set $G \subset\subset \widehat{\Omega}$, there are n_G such that $G \subset \Omega_n$, $n \geq n_G$. We have

$$\int_G (\nabla y_n \nabla v + y_n v) - \int_D \chi_{\Omega_n} f v = \int_{\Omega_n \setminus G} (\nabla y_n \nabla v + y_n v) \quad \forall v \in C^1(\bar{D}). \tag{3.10}$$

We can estimate

$$\left| \int_{\Omega_n \setminus G} (\nabla y_n \nabla v + y_n v) \right| \leq |v|_{C^1(\bar{D})} |y_n|_{H^1(\Omega_n)} \mu(\Omega_n - G)^{\frac{1}{2}}. \tag{3.11}$$

Taking the limit $n \to \infty$ in (3.11), we have that (3.10) yields

$$\left| \int_G \nabla\tilde{y} \nabla v + \int_G \tilde{y} v - \int_{\widehat{\Omega}} f v \right| \leq M |v|_{C^1(\bar{D})} \mu(\widehat{\Omega} - G)^{\frac{1}{2}} \tag{3.12}$$

(due to the convergence of the characteristic functions of Ω_n), where $\tilde{y}$ denotes the L-limit of y_n given by Theorem 2.7. We can take an increasing sequence of open sets $G_j \subset\subset \widehat{\Omega}$ such that $\cup G_j = \widehat{\Omega}$ and (3.12) gives

$$\int_{\widehat{\Omega}} \nabla\tilde{y} \nabla v + \int_{\widehat{\Omega}} \tilde{y} v = \int_{\widehat{\Omega}} f v \quad \forall v \in C^1(\bar{D}). \tag{3.13}$$

Since $\widehat{\Omega}$ has the segment property, $C^1(\bar{D})$ is dense in $H^1(\widehat{\Omega})$ (see Adams [1]) and (3.13) shows that $\tilde{y} = \hat{y}$. This ends the proof.

The semicontinuity result from Theorem 2.8 ensures that $\widehat{\Omega}$ is the desired minimizer for (3.1). □

Remark. The above proof does not use the uniform extension property for functions in $H^1(\Omega)$. We replace it by a density property, which is, in fact, an approximate extension result. This is one of the reasons that we can renounce the cone property for $\partial\Omega$ and use the segment property instead. A more general cost functional, as in (2.9), may be considered in the problem (3.1).

Remark. If we impose uniform Hölder conditions for the family $\mathcal{O}$, the limit domain will satisfy a similar Hölder property. In this case, trace theorems are known (see, e.g., Ladyzenskaya and Uraltseva [12], Pironneau [20]), and the result of Theorem 3.1 can be then extended to Dirichlet boundary value problems.

Example. A special simple case of the family $\mathcal{O}$ is obtained when global representations are given by

$$\mathcal{O}_1 = \{\Omega_g \mid g \in \mathcal{F}_1\},$$
$$\Omega_g = \{(s,\lambda) \in D \mid \lambda < g(s)\},$$

where $D = U \times]0, b[$, $U \subset \mathbf{R}^{m-1}$ open domain, and $\mathcal{F}_1 = \{g : U \to R_+ \mid 0 < c \le g \le b \text{ in } U\}$.

By Theorem 3.1, one can immediately prove the following corollary.

COROLLARY 3.3. *Assume that the family $\mathcal{F}_1$ is equicontinuous. Then the associated problem* (3.1) *has at least one solution in $\mathcal{O}_1$.*

Proof. We indicate a direct argument. The family $\mathcal{F}_1$ is equibounded by definition. We take a minimizing sequence of domains Ω_n associated with g_n. We may assume that $g_n \to \hat{g}$ uniformly in $\overline{U}$ and, clearly, $\hat{g} \in \mathcal{F}_1$. Here it is possible to define the continuous mappings on $\bar{D}$, $p_n(s,\lambda) = g_n(s) - \lambda$, $\hat{p}(s,\lambda) = \hat{g}(s) - \lambda$, and $p_n \to \hat{p}$ uniformly; $\Omega_n = \{(s,\lambda) \in D \mid p_n(s,\lambda) > 0)$, $\widehat{\Omega} = \{(s,\lambda) \in D \mid \hat{p}(s,\lambda) > 0\}$. Finally, $\widehat{\Omega} = p - \lim \Omega_n$, and the results of section 2 may be used directly to end the proof without using the distance functions. ∎

Remark. Another family of domains of interest may be obtained by considering a domain $D \subset \mathbf{R}^m$ such that $D \supset B(0,1)$ (the unit ball) and then defining

$$\mathcal{O}_2 = \{\Omega \subset D \mid \Omega = h(B(0,1))\},$$

where $h : D \to D$ is any homeomorphism, i.e., h and h^{-1} are continuous. This would be a generalization of the mapping method of Murat and Simon [18], where the mappings h were assumed diffeomorphisms.

If $\Omega_h = h_n(B)$ and $h_n \to h$, $h_n^{-1} \to h^{-1}$ uniformly in D, and $\Omega = h(B)$, then it is easy to see that these domains have the Γ-property, and simple representation formulae are valid for $\Omega = hh_n^{-1}(\Omega_n)$, $\partial\Omega = hh_n^{-1}(\partial\Omega_n)$. However, examples from Maz'ja [17] show that, conceptually, $\partial\Omega$ may not be of class $\mathcal{C}$ even when $\partial\Omega_n$ satisfies this assumption. Also, the compactness of $\mathcal{O}_2$ is not clear.

Remark. The examples of the families $\mathcal{O}_1$ and $\mathcal{O}_2$ also indicate that the concept of parametric convergence has enough flexibility to take into account various representation methods of open sets.

4. Measurability. We consider the material distribution problem (SOTB). In this case, it makes sense and is of interest to consider the case where the sets occupied by each material are merely measurable.

We fix $E \subset D$ to be two given bounded domains in $\mathbf{R}^m$ and $\Omega \subset D$ to be a variable measurable subset in some prescribed class $\mathcal{O}$, occupied by one material, while $D \setminus \Omega$ is occupied by another material. Then the physical properties of the two regions are different, and this is expressed by the fact that different coefficients appear in the elliptic equations describing the problem, which (formally) read as

$$-a_1 \Delta y_1 + b_1 y_1 = f \quad \text{in } \Omega, \tag{4.1}$$

$$-a_2 \Delta y_2 + b_2 y_2 = f \quad \text{in } D \setminus \overline{\Omega}, \tag{4.2}$$

$$a_1 \frac{\partial y_1}{\partial n} = a_2 \frac{\partial y_2}{\partial n}, \quad y_1 = y_2 \quad \text{in } \partial\Omega \setminus (\partial\Omega \cap \partial D), \tag{4.3}$$

$$a_i \frac{\partial y_i}{\partial n} = 0 \quad \text{in } \Gamma_1, \qquad y_i = 0 \quad \text{in } \Gamma_2, \quad i = 1, 2, \tag{4.4}$$

where $\Gamma_1 \cup \Gamma_2 = \partial D$ is assumed Lipschitz, $\Gamma_1 \cap \Gamma_2 = \emptyset$, $a_i, b_i > 0$, $i = 1, 2$, are some constants, and $f \in L^2(D)$.

Let y_Ω be defined by

$$y_\Omega(x) = \begin{cases} y_1(x) & \text{in } \Omega, \\ y_2(x) & \text{in } D \setminus \Omega. \end{cases} \tag{4.5}$$

Then the weak formulation of the transmission problem (4.1)–(4.4) reads

$$\int_D \{[a_1\chi_\Omega + a_2(1-\chi_\Omega)]\nabla y_\Omega \cdot \nabla w + [b_1\chi_\Omega + b_2(1-\chi_\Omega)]y_\Omega w\}\, dx$$

$$= \int_D fw\, dx \quad \forall w \in V, \tag{4.6}$$

$$V = \{w \in H^1(D) \mid w = 0 \quad \text{in } \Gamma_2\}. \tag{4.7}$$

For any measurable subset $\Omega \subset D$, the bilinear form governing (4.6) is bounded and coercive in V, and there exists a unique solution $y_\Omega \in V$, which formally satisfies relations (4.1)–(4.5).

In Pironneau [20], by directly interpreting the characteristic function χ_Ω as a control parameter, the following optimization problem is discussed:

$$\min_{\Omega \in \mathcal{O}} \int_E |y_\Omega - z_d|^2\, dx, \tag{4.8}$$

subject to (4.6) and with some prescribed $z_d \in L^2(E)$. However, it is very difficult to impose the constraint that the control should take only the values 0 and 1 in the whole D.

Our approach is to specify the set $\mathcal{O}$ of admissible Ω by requiring that χ_Ω is of the form $H(p_\Omega)$, where $p_\Omega \in U_{ad}$ (some admissible set of mappings will be defined later), and $H \subset \mathbf{R} \times \mathbf{R}$ is the maximal monotone extension of the Heaviside function:

$$H(p) = \begin{cases} 1, & p > 0, \\ [0,1], & p = 0, \\ 0, & p < 0. \end{cases} \tag{4.9}$$

Notice that by taking, for instance, $p_\Omega = \chi_\Omega$, we have representations via H for any measurable Ω. If $\text{meas}(\partial\Omega) = 0$, then we may take $p_\Omega = d_\Omega$, which is even Lipschitzian in D.

For the optimization problem (4.8), we define the class of admissible sets Ω by $\chi_\Omega = H(p_\Omega)$, where $p_\Omega \in U_{ad} \subset H^1_{\text{loc}}(D)$, and $p \in U_{ad}$ iff

$$|p|_{H^{1+\theta_\mathcal{K}}(\mathcal{K})} \le M_\mathcal{K} \qquad \forall \mathcal{K} \subset\subset D,\ \theta_\mathcal{K} > 0, \tag{4.10}$$

$$|p(x)| + |\nabla p(x)|_{\mathbf{R}^m} \ge \nu > 0 \quad \text{a.e. in } D. \tag{4.11}$$

If $\text{meas}(\partial\Omega) = 0$, the mappings d_Ω satisfy (4.11) (see Clarke [7, p. 66]) but do not satisfy (4.10) in general.

Conversely, the condition (4.11) ensures that the set

$$\{x \in D \mid p(x) = 0\} \tag{4.12}$$

has zero measure for $p \in H^1_{\text{loc}}(D)$; see Brezis [2, p. 195].

Remark. Under some stronger smoothness assumptions, condition (4.11) ensures the application of the implicit function theorem and a characterization of the "boundary" given by $\{x \in D \mid p(x) = 0\}$. However, our regularity hypotheses are so weak that even the implicit theorem in Clarke [7, p. 255] for Lipschitzian mappings cannot be applied. The only properties that we have are (4.12) and the measurability of Ω's, which are, in fact, defined up to sets of zero measure. Notice, as well, that the local character of (4.10) allows oscillations of $\partial\Omega$, even under the smoothness assumptions.

We reformulate the problem (4.6)–(4.8) as follows:

$$\min_{p\in U_{ad}} \int_E |y_p - z_d|^2\,dx, \tag{4.13}$$

$$\int_D \{[a_1H(p) + a_2(1 - H(p))]\nabla y_p \nabla w + [b_1H(p) + b_2(1 - H(p))]y_p w\}\,dx = \int_D fw\,dx \quad \forall w \in V. \tag{4.14}$$

THEOREM 4.1. *Under the hypotheses* (4.10)–(4.11)*, the problem* (4.13)–(4.14) *has at least one optimal pair* $[\bar{y}, \bar{p}] \in V \times U_{ad}$.

Proof. Obviously, $U_{ad} \neq \emptyset$ (as constant functions are in U_{ad}), and we may consider a minimizing sequence $[y_n, p_n] \subset V \times U_{ad}$. By taking an increasing sequence of open sets $\mathcal{K}_l \subset D$ such that $\cup\mathcal{K}_l = D$, and by the compactness of $\{p_n|_{\mathcal{K}_l}\}$ in $H^1(\mathcal{K}_l)$, we may define $p \in U_{ad}$ such that $p_n \to p$ strongly in $H^1(\mathcal{K}_l)$ for all $l \in N$, $p_n \to p$, and $\nabla p_n \to \nabla p$ a.e. in D.

Since $a_1H(p_n) + a_2(1 - H(p_n)) \geq ct > 0$ and $b_1H(p_n) + b_2(1 - H(p_n)) \geq ct > 0$, it is easy to infer that $\{y_n\}$ is bounded in $V \subset H^1(D)$, and we may assume that $y_n \to y$ weakly in $H^1(D)$ on a subsequence.

Obviously, $H(p_n)$ is bounded in $L^\infty(D)$; therefore, we may also assume that $H(p_n) \to H(p)$ weakly star in $L^\infty(D)$. The identification of the limit is a consequence of the demiclosedness of the maximal monotone operator H, applied in $L^2(\mathcal{K}) \times L^2(\mathcal{K})$ for any $\mathcal{K} \subset\subset D$. Notice that, by $p \in U_{ad}$ and by (4.12), it follows that $H(p)$ is a characteristic function in D.

We also have that $H(p_n) \to H(p)$ a.e. in D. We know that $p_n(x) \to p(x) \neq 0$ a.e. in D. If $p(x) > 0$, then $p_n(x) > 0$ for $n \geq n_x$ and $H(p_n(x)) = H(p(x)) = 1$ for $n \geq n_x$. If $p(x) < 0$, similarly, we obtain $H(p_n(x)) = H(p(x)) = 0$ for $n \geq n_x$. Consequently, we get that $H(p_n) \to H(p)$ strongly in $L^s(D)$ for all $s \geq 1$ by the Lebesgue dominated convergence theorem.

As $[y_n, p_n]$ satisfies (4.14), the above convergence allows to take the limit and to see that $[y, p]$ also satisfies (4.14) and $p \in U_{ad}$; i.e., the pair $[y, p]$ is admissible. Moreover, for the minimizing sequence, we have

$$\lim_{n\to\infty} \int_E |y_n - z_d|^2\,dx = \int_E |y - z_d|^2\,dx,$$

which shows that the pair $[y, p]$ is optimal for the problem (4.13), (4.14), and we redenote it by $[\bar{y}, \bar{p}]$. □

Remark. The above argument remains valid for any weakly lower semicontinuous cost functional on $H^1(D)$—for instance, for boundary cost functionals. Other boundary conditions may be imposed on ∂D as well.

It is possible to impose (4.10) only for $\mathcal{K} \subset\subset D \setminus C$, where $C \subset D$ is a given closed set of zero measure. This allows cracks in the corresponding $\partial\Omega$'s; see Bucur and Zolesio [3].

Remark. Considering the measurable sets $\Omega_n = \{x \in D \mid p_n(x) > 0\}$, the proof of Theorem 4.1 uses a property of parametric convergence for Ω_n based on a.e. convergence in D of p_n and ∇p_n, and a variant of Definition 2.3.

We continue by describing an approximation procedure which is suggested by our approach to characteristic functions. We denote by H_ε the Yosida approximation of H, given in this case by

$$H_\varepsilon(p) = \begin{cases} 1, & p > \varepsilon, \\ \frac{p}{\varepsilon}, & p \in [0, \varepsilon], \\ 0, & p < 0. \end{cases} \tag{4.15}$$

Notice that H_ε is Lipschitzian with Lipschitz constant $\frac{1}{\varepsilon}$. The approximation of the optimization problem (4.13), (4.14) is obtained by replacing (4.14) with

$$\int_D \{[a_1 H_\varepsilon(p) + a_2(1 - H_\varepsilon(p))]\nabla y_p^\varepsilon \nabla w + [b_1 H_\varepsilon(p) + b_2(1 - H_\varepsilon(p))] y_p^\varepsilon w\}\, dx = \int_D f w\, dx \quad \forall w \in V. \tag{4.14'}$$

By a variant of Theorem 4.1, we have existence of at least one optimal pair $[y_\varepsilon, p_\varepsilon] \in H^1(D) \times U_{ad}$ for the problem (4.13), (4.14').

THEOREM 4.2. *For any open set $\mathcal{K} \subset\subset D$, we have $[y_\varepsilon, p_\varepsilon] \to [\hat{y}, \hat{p}]$ in the weak-strong topology of $H^1(D) \times H^1(\mathcal{K})$ on a subsequence, and $[\hat{y}, \hat{p}]$ is an optimal pair for the problem* (4.13), (4.14).

Proof. By (4.10), we have $p_\varepsilon \to \hat{p}$ strongly in $H^1(\mathcal{K})$ on a subsequence, and $p_\varepsilon \to \hat{p}$, $\nabla p_\varepsilon \to \nabla \hat{p}$ a.e. in D for some $\hat{p} \in U_{ad}$. As $1 \geq H_\varepsilon(p) \geq 0$ a.e. in D, we also obtain that $\{y_\varepsilon\}$ is bounded in $H^1(D)$ by fixing $w = y_\varepsilon$ in (4.14'). We may assume that $y_\varepsilon \to \hat{y}$ weakly in $H^1(D)$ on a subsequence. Moreover, it is known from the theory of maximal monotone operators that $H_\varepsilon(p_\varepsilon) \to H(\hat{p})$ weakly in $L^2(\mathcal{K})$ for any $\mathcal{K} \subset\subset D$ since $\{H_\varepsilon(p_\varepsilon)\}$ is bounded in $L^\infty(D)$ and $p_\varepsilon \to \hat{p}$ strongly in $L^2(\mathcal{K})$, for instance. By the fact that $\hat{p} \in U_{ad}$ and by (4.12), (4.9), we know that $H(\hat{p})$ is a characteristic function in D. We can also prove the pointwise convergence of $H_\varepsilon(p_\varepsilon)$ a.e. in D. If $\hat{p}(x) > 0$, then $p_\varepsilon(x) > \frac{1}{2}\hat{p}(x)$ for $\varepsilon < \varepsilon_x$; that is, $p_\varepsilon(x) > \varepsilon$ for $\varepsilon < \varepsilon_x$ and $H_\varepsilon(p_\varepsilon(x)) = H(\hat{p}(x)) = 1$ by (4.15). If $\hat{p}(x) < 0$, then $p_\varepsilon(x) < 0$ for $\varepsilon < \varepsilon_x$ and $H_\varepsilon(p_\varepsilon(x)) = H(\hat{p}(x)) = 0$ for $\varepsilon < \varepsilon_x$. These two situations are valid a.e. in D by $\hat{p} \in U_{ad}$ and (4.12). Combining these with the Lebesgue theorem, we obtain that $H_\varepsilon(p_\varepsilon) \to H(\hat{p})$ strongly in $L^s(D)$ for all $s \geq 1$. Then we can take the limit in (4.14') and infer that the pair $[\hat{y}, \hat{p}]$ is admissible for the problem (4.13), (4.14). To show that it is optimal, we note that

$$\int_E |y_\varepsilon - z_d|^2\, dx \leq \int_E |y_p^\varepsilon - z_d|^2\, dx, \tag{4.16}$$

where y_p^ε denotes the solution of (4.14') corresponding to some $p \in U_{ad}$. By an argument of the same type as above, we can prove that $y_p^\varepsilon \to y_p$ weakly in $H^1(D)$ on a subsequence, where y_p is the solution of (4.14) associated with p. Taking the limit in (4.16) yields the optimality of $[\hat{y}, \hat{p}]$ in the problem (4.13)–(4.14) and completes the proof. □

COROLLARY 4.3. *On a subsequence, we have*

$$y_\varepsilon \to \hat{y} \quad \textit{strongly in } H^1(D), \tag{4.17}$$

where $\hat{y}$ is some optimal state for the problem (4.13)–(4.14).

Proof. There is a constant $c > 0$ such that

$$
\begin{aligned}
c\,|y_\varepsilon - \hat{y}|^2_{H^1(D)} &\le \int_D [a_1 H_\varepsilon(p_\varepsilon) + a_2(1 - H_\varepsilon(p_\varepsilon))]|\nabla(y_\varepsilon - \hat{y})|^2_{\mathbf{R}^m}\,dx \\
&\quad + \int_D [b_1 H_\varepsilon(p_\varepsilon) + b_2(1 - H_\varepsilon(p_\varepsilon))](y_\varepsilon - \hat{y})^2\,dx \\
&= \int_D \{[a_1 H_\varepsilon(p_\varepsilon) + a_2(1 - H_\varepsilon(p_\varepsilon))]\nabla y_\varepsilon \nabla(y_\varepsilon - \hat{y}) \\
&\qquad + [b_1 H_\varepsilon(p_\varepsilon) + b_2(1 - H_\varepsilon(p_\varepsilon))] y_\varepsilon (y_\varepsilon - \hat{y})\}\,dx \\
&\quad - \int_D \{[a_1 H_\varepsilon(p_\varepsilon) + a_2(1 - H_\varepsilon(p_\varepsilon))]\nabla \hat{y} \nabla(y_\varepsilon - \hat{y})) \\
&\qquad + [b_1 H_\varepsilon(p_\varepsilon) + b_2(1 - H_\varepsilon(p_\varepsilon))]\hat{y}(y_\varepsilon - \hat{y})\}\,dx \\
&= \int_D f(y_\varepsilon - \hat{y})\,dx - \int_D \{[a_1 H_\varepsilon(p_\varepsilon) \\
&\qquad + a_2(1 - H_\varepsilon(p_\varepsilon))]\nabla \hat{y} \nabla(y_\varepsilon - \hat{y})) \\
&\qquad + [b_1 H_\varepsilon(p_\varepsilon) + b_2(1 - H_\varepsilon(p_\varepsilon))]\hat{y}(y_\varepsilon - \hat{y})\}\,dx \\
&= I_1 + I_2.
\end{aligned} \tag{4.18}
$$

By Theorem 4.2, we may assume that $I_1 \to 0$ on a sequence as $\varepsilon \to 0$. For I_2, we first estimate the term

$$
\int_D [a_1 H_\varepsilon(p_\varepsilon) + a_2(1 - H_\varepsilon(p_\varepsilon))]\nabla \hat{y} \nabla(y_\varepsilon - \hat{y})\,dx, \tag{4.19}
$$

which is the most difficult. We know that $\nabla \hat{y} \nabla(y_\varepsilon - \hat{y})$ is weakly convergent in $L^1(D)$ and the coefficients $a_1 H_\varepsilon(p_\varepsilon) + a_2(1 - H_\varepsilon(p_\varepsilon))$ are bounded in $L^\infty(D)$ and strongly convergent in $L^s(D)$ for all $s \ge 1$. On a subsequence, we may assume that $[a_1 H_\varepsilon(p_\varepsilon) + a_2(1 - H_\varepsilon(p_\varepsilon))]\nabla(y_\varepsilon - \hat{y}) \to u$ weakly in $L^2(D)^m$. Egorov's theorem gives that $a_1 H_\varepsilon(p_\varepsilon) + a_2(1 - H_\varepsilon(p_\varepsilon)) \to a_1 H(\hat{p}) + a_2(1 - H(\hat{p}))$ uniformly in D_δ for any $\delta > 0$ and some measurable subset $D_\delta \subset D$ with $\mathrm{meas}(D - D_\delta) < \delta$. Combining this with $\nabla(y_\varepsilon - \hat{y}) \to 0$ weakly in $L^2(D)$, we have that $u = 0$ a.e. in D. Then the limit of the integral (4.19) is zero, and the same is true, by a similar reasoning, for I_2. Finally, (4.18) has limit zero, and this achieves the proof. □

Remark. It is possible to further smooth H_ε by means of a Friedrichs mollifier and to compute the gradient of the smoothed cost functional (4.13) with respect to $p \in U_{ad}$. This shows the constructive character of our approach presented in this paper. Numerical tests for the problem in this section were reported in Mäkinen, Neittaanmäki, and Tiba [16] together with an approximation result.

Remark. In Pironneau [20, p. 134], it is mentioned that, by taking $a_2 \to 0$, $b_2 \to 0$ in (4.14), the Neumann boundary value is approximated. Therefore, the results of this section may open a way to relax the continuity assumptions from section 3. A similar idea is possible for Dirichlet boundary value problems, which could be obtained by taking $a_2 \to \infty$, $b_2 \to \infty$. The hypotheses under which such passages to the limit can be performed are not clear yet.

FLOW STABILITY OF PATCHY VECTOR FIELDS AND ROBUST FEEDBACK STABILIZATION*

FABIO ANCONA† AND ALBERTO BRESSAN‡

Abstract. The paper is concerned with *patchy vector fields*, a class of discontinuous, piecewise smooth vector fields that were introduced by the authors to study feedback stabilization problems. We prove the stability of the corresponding solution set w.r.t. a wide class of impulsive perturbations. These results yield the robustness of *patchy feedback controls* in the presence of measurement errors and external disturbances.

Key words. patchy vector field, impulsive perturbation, feedback stabilization, discontinuous feedback, robustness

1. Introduction and basic notation. The aim of this paper is to establish the stability of the set of trajectories of a patchy vector field w.r.t. various types of perturbations and the robustness of patchy feedback controls.

Patchy vector fields were introduced in [A-B] in order to study feedback stabilization problems. The underlying motivation is the following: The analysis of stabilization problems by means of Lyapunov functions usually leads to stabilizing feedbacks with a wild set of discontinuities. On the other hand, as shown in [A-B], by patching together open-loop controls one can always construct a piecewise smooth stabilizing feedback whose discontinuities have a very simple structure. In particular, one can develop the whole theory by studying the corresponding discontinuous ODEs within the classical framework of Carathéodory solutions. We recall here the main definitions.

DEFINITION 1.1. *By a patch we mean a pair* $\big(\Omega,\, g\big)$*, where* $\Omega \subset \mathbb{R}^n$ *is an open domain with smooth boundary* $\partial\Omega$ *and* g *is a smooth vector field defined on a neighborhood of the closure* $\overline{\Omega}$*, which points strictly inward at each boundary point* $x \in \partial\Omega$*.*

Calling $\mathbf{n}(x)$ the outer normal at the boundary point x, we thus require

$$\big\langle g(x),\ \mathbf{n}(x)\big\rangle < 0 \qquad \text{for all} \quad x \in \partial\Omega. \tag{1.1}$$

DEFINITION 1.2. *We say that* $g : \Omega \mapsto \mathbb{R}^n$ *is a patchy vector field on the open domain* Ω *if there exists a family of patches* $\big\{(\Omega_\alpha,\ g_\alpha);\quad \alpha \in \mathcal{A}\big\}$ *such that*

- $\mathcal{A}$ *is a totally ordered set of indices;*
- *the open sets* Ω_α *form a locally finite covering of* Ω*, i.e.,* $\Omega = \cup_{\alpha\in\mathcal{A}}\Omega_\alpha$ *and every compact set* $K \subset \mathbb{R}^n$ *intersect only a finite number of domains* Ω_α*,* $\alpha \in \mathcal{A}$*;*
- *the vector field* g *can be written in the form*

$$g(x) = g_\alpha(x) \qquad \text{if} \qquad x \in \Omega_\alpha \setminus \bigcup_{\beta>\alpha} \Omega_\beta. \tag{1.2}$$

By setting

$$\alpha^*(x) \doteq \max\big\{\alpha \in \mathcal{A}\,;\quad x \in \Omega_\alpha\big\}, \tag{1.3}$$

we can write (1.2) in the equivalent form

$$g(x) = g_{\alpha^*(x)}(x) \qquad \text{for all} \quad x \in \Omega. \tag{1.4}$$

Remark 1.1. The patches $(\Omega_\alpha,\, g_\alpha)$ are not uniquely determined by the patchy vector field g. Indeed, whenever $\alpha < \beta$, by (1.2) the values of g_α on the set $\Omega_\alpha \cap \Omega_\beta$ are irrelevant. Therefore, if the open sets Ω_α form a locally finite covering of Ω and we assume that, for each $\alpha \in \mathcal{A}$, the vector field g_α satisfies (1.1) at every point $x \in \partial\Omega_\alpha \setminus \bigcup_{\beta>\alpha} \Omega_\beta$, then the vector field g defined according with (1.2) is again a patchy vector field. To see this, it suffices to construct vector fields $\tilde g_\alpha$ which satisfy the inward-pointing property (1.1) at every point $x \in \partial\Omega_\alpha$ and such that $\tilde g_\alpha = g_\alpha$ on $\Omega_\alpha \setminus \bigcup_{\beta>\alpha} \Omega_\beta$. To accomplish this, for each α we first consider a smooth vector field v_α such that $v_\alpha(x) = -\mathbf{n}(x)$ on $\partial\,\Omega_\alpha$. Then we construct a smooth scalar function $\psi_\alpha : \Omega \mapsto [0,1]$ such that

$$\psi_\alpha(x) = \begin{cases} 1 & \text{if} \quad x \in \Omega_\alpha \setminus \bigcup_{\beta>\alpha} \Omega_\beta, \\ 0 & \text{if} \quad x \in \partial\Omega_\alpha, \quad \big\langle g(x),\ \mathbf{n}(x)\big\rangle \geq 0. \end{cases}$$

Finally, for each $\alpha \in \mathcal{A}$ we define the interpolation

$$\tilde g_\alpha(x) \doteq \psi_\alpha(x) g_\alpha(x) + \big(1 - \psi_\alpha(x)\big) v_\alpha(x).$$

The vector fields $\tilde g_\alpha$ thus defined satisfy our requirements.

We shall occasionally adopt the longer notation $\big(\Omega,\ g,\ (\Omega_\alpha,\, g_\alpha)_{\alpha\in\mathcal{A}}\big)$ to indicate a patchy vector field, specifying both the domain and the single patches. If g is a patchy vector field, the differential equation

$$\dot x = g(x) \tag{1.5}$$

has many interesting properties. In particular, in [A-B] it was proved that the set of Carathéodory solutions of (1.5) is closed in the topology of uniform convergence but possibly not connected. Moreover, given an initial condition

$$x(t_0) = x_0, \tag{1.6}$$

the Cauchy problem (1.5)–(1.6) has at least one forward solution and at most one backward solution. For every Carathéodory solution $x = x(t)$ of (1.5), the map $t \mapsto \alpha^*(x(t))$ is left continuous and nondecreasing.

In this paper we study the stability of the solution set for (1.5) w.r.t. various perturbations. Most of our analysis will be concerned with impulsive perturbations, described by

$$\dot y = g(y) + \dot w. \tag{1.7}$$

Here $w = w(t)$ is any left continuous function with bounded variation. By a solution of the perturbed system (1.7) with an initial condition

$$y(t_0) = y_0, \tag{1.8}$$

we mean a measurable function $t \mapsto y(t)$ such that

$$y(t) = y_0 + \int_{t_0}^{t} g\big(y(s)\big)\, ds + \big[w(t) - w(t_0)\big] \tag{1.9}$$

(see [B1]). If $w(\cdot)$ is discontinuous, the system (1.7) has impulsive behavior and the solution $y(\cdot)$ will be discontinuous as well. We choose to work with (1.7) because it provides a simple and general framework to study robustness properties. Indeed, consider a system with both inner and outer perturbations of the form

$$\dot{x} = g\big(x + e_1(t)\big) + e_2(t). \tag{1.10}$$

The map $t \mapsto y(t) \doteq x(t) + e_1(t)$ then satisfies the impulsive equation

$$\dot{y} = g(y) + e_2(t) + \dot{e}_1(t) = g(y) + \dot{w},$$

where

$$w(t) = e_1(t) + \int_{t_0}^{t} e_2(s)\, ds.$$

Therefore, from the stability of solutions of (1.7) w.r.t. perturbations w that have small total variation, one can immediately deduce a result on the stability of solutions of (1.10), when Tot.Var.$\{e_1\}$ and $\|e_2\|_{\mathbf{L}^1}$ are suitably small. Here, Tot.Var.$\{e_1\}$ denotes the total variation of the function e_1 over the whole interval where it is defined, while Tot.Var.$\big\{e_1\,;\,J\,\big\}$ denotes the total variation of e_1 over a subset J. We shall also denote by BV the space of all functions of bounded variation. Any function of bounded variation $w = w(t)$ can be redefined up to $\mathbf{L}^1$-equivalence. For the sake of definiteness, throughout the paper we shall always consider left continuous representatives, so that $w(t) = w(t^-) \doteq \lim_{s\to t-} w(s)$ for every t. The Lebesgue measure of a Borel set $J \subset \mathbb{R}$ will be denoted by meas(J).

We observe that since the Cauchy problem for (1.5) does not have forward uniqueness and continuous dependence, one clearly cannot expect that a single solution of (1.5) be stable under small perturbations. What we establish here is a different stability property, involving not a single trajectory but the whole solution set: If the perturbation w is small in the BV norm, then every solution of (1.7) is close to some solution of (1.5). This is essentially an upper semicontinuity property of the solution set. Namely, we will prove in section 2 the following results.

THEOREM 1.3. *Let g be a patchy vector field on an open domain $\Omega \subset \mathbb{R}^n$. Consider a sequence of solutions $y_\nu(\cdot)$ of the perturbed system*

$$\dot{y}_\nu = g(y_\nu) + \dot{w}_\nu, \qquad\qquad t \in [0,T], \tag{1.11}$$

with Tot.Var.$\{w_\nu\} \to 0$ as $\nu \to \infty$. If the $y_\nu : [0,T] \mapsto \Omega$ converge to a function $y : [0,T] \mapsto \Omega$, uniformly on $[0,T]$, then $y(\cdot)$ is a Carathéodory solution of (1.5) *on* $[0, T]$.

COROLLARY 1.4. *Let g be a patchy vector field on an open domain $\Omega \subset \mathbb{R}^n$. Given any closed subset $A \subset \Omega$, any compact set $K \subset A$, and any $T, \varepsilon > 0$, there exists $\delta = \delta(A, K, T, \varepsilon) > 0$ such that the following holds. If $y : [0,T] \mapsto A$ is a solution of the perturbed system* (1.7), *with $y(0) \in K$ and Tot.Var.$\{w\} < \delta$, then there exists a solution $x : [0,T] \mapsto \Omega$ of the unperturbed equation* (1.5) *with*

$$\big\|x - y\big\|_{\mathbf{L}^\infty([0,T])} < \varepsilon\,. \tag{1.12}$$

We remark that the type of stability described above is precisely what is needed in many feedback control applications. As an example, consider the problem of stabilizing to the origin the control system

$$\dot{x} = f(x,u). \tag{1.13}$$

Given a compact set K and $\varepsilon > 0$, assume that there exists a piecewise constant feedback $u = U(x)$ such that $g(x) \doteq f\big(x, U(x)\big)$ is a patchy vector field and such that every solution of (1.5) starting from a point $x(0) \in K$ is steered inside the ball B_ε centered at the origin with radius ε, within a time $T > 0$. By Corollary 1.4, if the perturbation w is sufficiently small (in the BV norm), every solution of the perturbed system (1.7) will be steered inside the ball $B_{2\varepsilon}$ within time T. In other words, the feedback still performs well in the presence of small perturbations. Applications to feedback control will be discussed in more detail in section 3.

Throughout the paper, by $B(x,r)$ we denote the closed ball centered at x with radius r and, for every given set A, we let $B(A,r) \doteq \cup_{x\in A} B(x,r)$. The closure, the interior, and the boundary of a set Ω are written as $\overline{\Omega}$, $\overset{\circ}{\Omega}$ and $\partial\Omega$, respectively.

2. Stability of patchy vector fields. We begin by proving a local existence result for solutions of the perturbed system (1.7).

PROPOSITION 2.1. *Let g be a patchy vector field on an open domain $\Omega \subset \mathbb{R}^n$. Given any compact set $K \subset \Omega$, there exists $\overline{\chi} = \overline{\chi}_K > 0$ such that, for each $y_0 \in K, t_0 \in \mathbb{R}$, and for every Lipschitz continuous function $w = w(t)$, with Lipschitz constant $\|\dot{w}\|_{\mathbf{L}^\infty} < \overline{\chi}$, the Cauchy problem* (1.7)–(1.8) *has at least one local forward solution.*

Proof. Fix some compact subset $K' \subset \Omega$ whose interior contains K. To prove the local existence of a forward solution to (1.7), first observe that because of the inward-pointing condition (1.1) and the smoothness assumptions on the vector fields g_α, one can find for any $\alpha \in \mathcal{A}$ some constant $\chi_\alpha > 0$ such that

$$\sup_{\substack{x\in\partial\Omega_\alpha\cap K'\\ |v|\leq\chi_\alpha}} \big\langle g_\alpha(x)+v,\, \mathbf{n}_{\boldsymbol{\alpha}}(x)\big\rangle < 0, \tag{2.1}$$

where $\mathbf{n}_{\boldsymbol{\alpha}}(x)$ is the outer normal to $\partial\Omega_\alpha$ at the boundary point x. Since K' is a compact set and $\{\Omega_\alpha\}_\alpha$ is a locally finite covering of Ω, there will be only finitely many elements of $\{\Omega_\alpha\}_\alpha$ that intersect K'. Let

$$\big\{\alpha_1,\ldots,\alpha_{_N}\big\} = \big\{\alpha\in\mathcal{A}\ :\ \Omega_\alpha\cap K'\neq\emptyset\big\}, \tag{2.2}$$

and, by possibly renaming the indices α_i, assume that

$$\alpha_1 < \cdots < \alpha_{_N}. \tag{2.3}$$

Choose a constant $\overline{\chi} > 0$ such that

$$\overline{\chi} \leq \inf\big\{\chi_{\alpha_i}\ :\ i=1,\ldots,N\big\}. \tag{2.4}$$

For any fixed $y_0 \in K$, consider the index

$$\widehat{\alpha}(y_0) \doteq \max\big\{\alpha\ :\ y_0\in\overline{\Omega}_\alpha\big\}.$$

By the definition of $\overline{\chi}$, any solution $y = y(\cdot)$ to the Cauchy problem

$$\dot{y} = g_{\widehat{\alpha}}(y) + \dot{w}, \qquad y(t_0) = y_0,$$

associated to a piecewise Lipschitz map $w = w(t)$ with $\|\dot{w}\|_{\mathbf{L}^\infty} < \overline{\chi}$, remains inside $\Omega_{\widehat{\alpha}}$ for all $t \in [t_0, t_0 + \delta]$ for some $\delta > 0$. Hence, it provides also a solution to (1.6) on some interval $[t_0, t_0 + \delta']$, $0 < \delta' \leq \delta$. □

Toward a proof of Theorem 1.3, we first derive an intermediate result. By the basic properties of a patchy vector field, for every solution $t \mapsto x(t)$ of (1.5) the corresponding map $t \mapsto \alpha^*\big(x(t)\big)$ in (1.3) is nondecreasing. Roughly speaking, a trajectory can move from a patch Ω_α to another patch Ω_β only if $\alpha < \beta$. This property no longer holds in the presence of an impulsive perturbation. However, the next proposition shows that for a solution y of (1.7) the corresponding map $t \mapsto \alpha^*\big(y(t)\big)$ is still nondecreasing, after a possible modification on a small set of times. Alternatively, one can slightly modify the impulsive perturbation w, say replacing it by another perturbation $w^\diamondsuit$, such that the map $t \mapsto \alpha^*\big(y^\diamondsuit(t)\big)$ is monotone along the corresponding trajectory $t \mapsto y^\diamondsuit(t)$.

PROPOSITION 2.2. *Let g be a patchy vector field on an open domain $\Omega \subset \mathbb{R}^n$ determined by the family of patches $\big\{(\Omega_\alpha,\ g_\alpha);\ \alpha \in \mathcal{A}\big\}$. For any $T > 0$ and any compact set $K \subset \Omega$, there exist constants $C, \delta > 0$ and an integer N such that the following hold.*

(i) *For every $w \in \mathrm{BV}$ with Tot.Var.$\{w\} < \delta$, and for every solution $y : [0, T] \mapsto \Omega$ of the Cauchy problem (1.7)–(1.8) with $y_0 \in K$, there is a partition of $[0,\ T]$, $0 = \tau_1 \leq \tau_2 \leq \cdots \leq \tau_{N+1} = T$, and indices*

$$\alpha_1 < \alpha_2 < \cdots < \alpha_N \tag{2.5}$$

such that

$$\alpha^*(y(t)) \geq \alpha_i \qquad \text{for all } t \in \,]\tau_i,\ \tau_{i+1}], \qquad i = 0, \ldots, N, \tag{2.6}$$

$$\text{meas}\Big(\bigcup_{i \geq 0} \big\{t \in [\tau_i,\ \tau_{i+1}]\ :\ \alpha^*(y(t)) > \alpha_i\big\}\Big) < C \cdot \textit{Tot.Var.}\{w\}. \tag{2.7}$$

(ii) *For every BV function $w = w(t)$ with Tot.Var.$\{w\} < \delta$, and for every solution $y : [0, T] \mapsto \Omega$ of the Cauchy problem (1.7)–(1.8) with $y_0 \in K$, there is a BV function $w^\diamondsuit = w^\diamondsuit(t)$ and a solution $y^\diamondsuit : [0, T] \mapsto \Omega$ of*

$$\dot{y}^\diamondsuit = g(y^\diamondsuit) + \dot{w}^\diamondsuit \tag{2.8}$$

so that the map $t \mapsto \alpha^*(y^\diamondsuit(t))$ is nondecreasing and left continuous, and there holds

$$\begin{aligned} \textit{Tot.Var.}\{w^\diamondsuit\} &\leq C \cdot \textit{Tot.Var.}\{w\}, \\ \big\|y^\diamondsuit - y\big\|_{\mathbf{L}^\infty([0,T])} &\leq C \cdot \textit{Tot.Var.}\{w\}. \end{aligned} \tag{2.9}$$

Proof. (i) The proof of (i) will be given in three steps.

Step 1. Since each g_α is a smooth vector field and we are assuming a uniform bound on the total variation of every perturbation $w = w(t)$, there will be some compact subset $K' \subset \overline{\Omega}$ that contains every solution $y : [0, T] \mapsto \Omega$ of (1.7) starting at a point $y_0 \in K$. We will assume without loss of generality that every domain Ω_α is bounded since, otherwise, one can replace Ω_α with its intersection $\Omega_\alpha \cap \Omega'$ with a

bounded domain $\Omega' \subset \Omega$ that contains K', preserving the inward-pointing condition (1.1) (cf. Remark 1.1). For each $\alpha \in \mathcal{A}$, define the map $\varphi_\alpha : \Omega \mapsto \mathbb{R}$ by setting

$$\varphi_\alpha(x) \doteq \begin{cases} d(x,\, \partial\Omega_\alpha) & \text{if} \quad x \in \Omega_\alpha, \\ -d(x,\, \partial\Omega_\alpha) & \text{otherwise,} \end{cases} \tag{2.10}$$

and let

$$\varphi^+_\alpha(x) \doteq \max\{\varphi_\alpha(x),\, 0\}$$

denote the positive part of $\varphi_\alpha(x)$. The regularity assumptions on the patch $(\Omega_\alpha, g_\alpha)$ guarantee that φ_α is smooth if restricted to a sufficiently small neighborhood of the boundary $\partial\Omega_\alpha$. Thus, if $\{\Omega_{\alpha_i} \,:\, i = 1, \dots, N\}$ denotes the finite collection of domains that intersect the compact set K' as in (2.2)–(2.3), there will be some constant $\overline{\rho} > 0$ so that, setting

$$\Omega^{\overline{\rho}}_\alpha \doteq \big\{x \in \Omega \;:\; d(x,\, \partial\Omega_\alpha) \geq \overline{\rho}\big\}, \tag{2.11}$$

the restriction of any map φ_{α_i} to the domain $\Omega \setminus \Omega^{\overline{\rho}}_{\alpha_i}$ will be smooth. In particular, for any $i = 1, \dots, N$, we will have

$$\nabla\varphi_{\alpha_i}(x) = -\mathbf{n}_{\boldsymbol{\alpha_i}}\big(\pi_{\alpha_i}(x)\big) \qquad \text{for all} \quad x \in \Omega \setminus \Omega^{\overline{\rho}}_{\alpha_i}, \tag{2.12}$$

where $\mathbf{n}_{\boldsymbol{\alpha_i}}$ represents as usual the outer normal to $\partial\Omega_{\alpha_i}$, while $\pi_{\alpha_i}(x)$ denotes the projection of the point x onto the set $\partial\Omega_{\alpha_i}$. On the other hand, thanks to the inward-pointing condition (1.1), we can choose the constant $\overline{\rho}$ so that

$$\sup_{\substack{i=1,\dots,N \\ x\in\Omega_{\alpha_i}\setminus\Omega^{\overline{\rho}}_{\alpha_i}}} \big\langle g_{\alpha_i}(x),\, \mathbf{n}_{\boldsymbol{\alpha_i}}(\pi_{\alpha_i}(x))\big\rangle \leq -c' \tag{2.13}$$

for some $c' > 0$. Moreover, the smoothness of the fields g_α on $\overline{\Omega}$ implies the existence of some $c'' > 0$ such that

$$\sup_{\substack{i=1,\dots,N, j>i \\ x\in\Omega_{\alpha_i}}} \Big|\big\langle g_{\alpha_j}(x),\, \mathbf{n}_{\boldsymbol{\alpha_i}}(\pi_{\alpha_i}(x))\big\rangle\Big| \leq c''. \tag{2.14}$$

Step 2. Consider now a left continuous BV function $w = w(t)$ and let $y : [0, T] \mapsto \Omega$ be a solution of the corresponding Cauchy problem (1.7)–(1.8), with $y_0 \in K$. Observe that, for any $i = 1, \dots, N$, and for any interval $J \subset [0, T]$ such that

$$y(t) \in \Omega \setminus \Omega^{\overline{\rho}}_{\alpha_i} \qquad \text{for all} \quad t \in J,$$

the composed map $\varphi^+_{\alpha_i} \circ y : J \mapsto \mathbb{R}$ is also a left continuous BV function whose distributional derivative $\mu_i \doteq D(\varphi^+_{\alpha_i} \circ y)$ is a Radon measure, which can be decomposed into an absolutely continuous μ^{ac}_i and a singular part μ^s_i w.r.t. the Lebesgue measure dt. One can easily verify that for any Borel set $E \subset J$, the absolutely continuous part of μ_i is given by

$$\mu^{ac}_i(E) = \int_{E^+} \big\langle \nabla\varphi_{\alpha_i}(y(t)),\; g(y(t)) + \dot{w}(t)\big\rangle\, dt, \qquad E^+ \doteq \{t \in E \,;\, y(t) \in \Omega_{\alpha_i}\}. \tag{2.15}$$

Moreover, calling μ_w^{ac} and μ_w^s, respectively, the absolutely continuous and the singular part of $\mu_w \doteq \dot{w}$, the following bounds hold:

$$\begin{aligned}\left| \int_{E^+} \big\langle \nabla \varphi_{\alpha_i}(y(t)),\ \dot{w}(t) \big\rangle\ dt + \mu_i^s(E) \right| &\leq c''' \cdot \Big\{ \big|\mu_w^{ac}(E)\big| + \big|\mu_w^s(E)\big| \Big\} \\ &\leq c''' \cdot \text{Tot.Var.}\{w\} \end{aligned} \tag{2.16}$$

for some constant $c''' > 0$ that depends only on the compact set K' and on the time interval $[0, T]$. Let $C_i, \ell_i,\ i = N, N-1, \dots, 1$, be the constants recursively defined by

$$C_N \doteq 1 + c''', \qquad \ell_N \doteq \frac{2C_N}{c'}, \tag{2.17}$$

$$C_i \doteq c'' \cdot \ell_{i+1} + \sum_{j=i+1}^{N} C_j, \qquad \ell_i \doteq \frac{1}{c'} \left(2C_i + c'' \cdot \sum_{j=i+1}^{N} \ell_j \right) \quad \text{if} \quad i < N. \tag{2.18}$$

□

LEMMA 2.3. *Assume that*

$$\textit{Tot. Var.}\{w\} < \delta \doteq \frac{\overline{\rho}}{2C_1}, \tag{2.19}$$

and assume that there exists some interval $[t_1, t_2] \subset [0, T]$ *and some index* $i \in \{1, \dots, N\}$ *such that*

$$\text{meas}\big\{ t \in [t_1, t_2]\ :\ \alpha^*(y(t)) = \alpha_j \big\} \leq \ell_j \cdot \textit{Tot. Var.}\{w\} \qquad \textit{for all}\ \ j > i \tag{2.20$_i$}$$

together with one of the following two conditions:

(a)$_i$

$$\varphi_{\alpha_i}(y(t)) < 2C_i \cdot \textit{Tot. Var.}\{w\} \qquad \textit{for all}\ \ t \in [t_1, t_2], \tag{2.21$_i$}$$

$$\text{meas}\big\{ t \in [t_1, t_2]\ :\ \alpha^*(y(t)) = \alpha_i \big\} > \ell_i \cdot \textit{Tot. Var.}\{w\}. \tag{2.22$_i$}$$

(b)$_i$ *There exists* $\tau \in [t_1, t_2]$ *such that*

$$\varphi_{\alpha_i}(y(\tau)) \geq 2C_i \cdot \textit{Tot. Var.}\{w\}. \tag{2.23$_i$}$$

Then one has

$$\varphi_{\alpha_i}(y(t_2)) \geq C_i \cdot \textit{Tot. Var.}\{w\}. \tag{2.24$_i$}$$

Proof of Lemma 2.3. Observe first that the recursive definition (2.17)–(2.18) of the constants C_i, ℓ_i and the bound (2.19) clearly imply

$$C_i \geq 1 + c''' + c'' \cdot \sum_{j=i+1}^{N} \ell_j, \tag{2.25}$$

$$2C_i \cdot \text{Tot.Var.}\{w\} < \overline{\rho}. \tag{2.26}$$

Assume now that (2.20_i)–(2.22_i) hold. Then, using (2.13)–(2.16) and recalling (2.25)–(2.26), we obtain

$$\begin{aligned}
\varphi^+_{\alpha_i}(y(t_2)) &\geq \varphi^+_{\alpha_i}(y(t_1)) + \int_{\{t\in[t_1,t_2]\,:\,\alpha^*(t)=\alpha_i\}} \big\langle \nabla\varphi_{\alpha_i}(y(t)),\ g_{\alpha_i}(y(t))\big\rangle\, dt \\
&\quad - \sum_{j=i+1}^{N} \int_{\{t\in[t_1,t_2]\,:\,\alpha^*(t)=\alpha_j\}} \Big|\big\langle \nabla\varphi_{\alpha_i}(y(t)),\ g_{\alpha_j}(y(t))\big\rangle\Big|\, dt - c'''\cdot \text{Tot.Var.}\{w\} \\
&\geq \int_{\{t\in[t_1,t_2]\,:\,\alpha^*(t)=\alpha_i\}} -\big\langle \mathbf{n_{\alpha_i}}(\pi_{\alpha_i}(y(t))),\ g_{\alpha_i}(y(t))\big\rangle\, dt \\
&\quad - \Big(c''\cdot \sum_{j=i+1}^{N} \ell_j + c'''\Big)\cdot \text{Tot.Var.}\{w\} \\
&\geq \Big(\ell_i\cdot c' - c''\cdot \sum_{j=i+1}^{N} \ell_j - c'''\Big)\cdot \text{Tot.Var.}\{w\} \\
&\geq C_i\cdot \text{Tot.Var.}\{w\}, \qquad (2.27)
\end{aligned}$$

proving (2.24_i). Next, assume that (2.20_i) and (2.23_i) hold, and let

$$\tau' \doteq \sup\big\{t\in[t_1,\,t_2]\ :\ \varphi_{\alpha_i}(y(t)) > 2C_i\cdot \text{Tot.Var.}\{w\}\big\}. \qquad (2.28)$$

Clearly, the bound (2.24_i) is satisfied if $\tau' = t_2$ since the map φ_{α_i} is left continuous. Next, consider the case $\tau' < t_2$. By computations similar to those in (2.27), using (2.13)–(2.16), and thanks to (2.20_i), (2.25)–(2.26), we get

$$\begin{aligned}
\varphi^+_{\alpha_i}(y(t_2)) &\geq \varphi^+_{\alpha_i}(y(\tau')) + \int_{\{t\in[\tau',t_2]\,:\,\alpha^*(t)=\alpha_i\}} \big\langle \nabla\varphi_{\alpha_i}(y(t)),\ g_{\alpha_i}(y(t))\big\rangle\, dt \\
&\quad - \sum_{j=i+1}^{N} \int_{\{t\in[\tau',t_2]\,:\,\alpha^*(t)=\alpha_j\}} \Big|\big\langle \nabla\varphi_{\alpha_i}(y(t)),\ g_{\alpha_j}(y(t))\big\rangle\Big|\, dt - c'''\cdot \text{Tot.Var.}\{w\} \\
&\geq \left(2C_i - 1 - c''' - c''\cdot \sum_{j=i+1}^{N} \ell_j\right)\cdot \text{Tot.Var.}\{w\} \\
&\geq C_i\cdot \text{Tot.Var.}\{w\}, \qquad (2.29)
\end{aligned}$$

thus concluding the proof of Lemma 2.3. □

Step 3. Assume that the bound (2.19) on the total variation of $w = w(t)$ holds. Set $\tau_1 = 0$, $\tau_{N+1} \doteq T$, and define recursively the points $\tau_N, \tau_{N-1}, \dots, \tau_2$ by setting, for every $1 < i \leq N$,

(2.30_i)

$$\mathcal{T}_i \doteq \Big\{t\in[0,\,\tau_{i+1}]\ :\ \varphi_{\alpha_i}(y(s)) \geq C_i\cdot \text{Tot.Var.}\{w\} \qquad \text{for all}\ \ s\in[t,\,\tau_{i+1}]\Big\},$$

$$\tau_i \doteq \begin{cases} \inf \mathcal{T}_i & \text{if}\quad \mathcal{T}_i \neq \emptyset, \\ \tau_{i+1} & \text{if}\quad \mathcal{T}_i = \emptyset. \end{cases}$$

Applying Lemma 2.3 and proceeding by backward induction on $i = N, N-1, \dots, 2$,

we show now that for any $t < \tau_i$, $i = 2, \dots, N$, one has

$$\begin{aligned} &\text{meas}\big\{s \in [0,\, t] \ :\ \alpha^*(y(s)) = \alpha_i\big\} \leq \ell_i \cdot \text{Tot.Var.}\{w\}, \\ &\varphi_{\alpha_i}(y(t)) < 2C_i \cdot \text{Tot.Var.}\{w\}. \end{aligned} \tag{2.31$_i$}$$

Indeed, if (2.31$_i$) is not satisfied, one of the two conditions (a)$_{\rm N}$ or (b)$_{\rm N}$ must be true on some interval $[0,\, \bar t\,]$, $\bar t < \tau_N$. But then, by (2.24)$_N$, we have

$$\varphi_{\alpha_N}(y(s)) \geq C_N \cdot \text{Tot.Var.}\{w\} \qquad \text{for all} \ \ s \in [\,\bar t,\, T],$$

which contradicts the definition (2.30$_i$). On the other hand, if we assume that (2.31)$_j$ holds for $j = i+1, \dots, N$ but not for $j = i$, then one of the two conditions (a)$_i$ or (b)$_i$ must be true on some interval $[0,\, \bar t\,]$, $\bar t < \tau_i$. Moreover, the inductive assumptions (2.31)$_j$, $j > i$, imply (2.20$_i$) and hence, as above, thanks to (2.24$_i$), we get

$$\varphi_{\alpha_i}(y(s)) \geq C_i \cdot \text{Tot.Var.}\{w\} \qquad \text{for all} \ \ s \in [\bar t,\, T],$$

reaching a contradiction with the definition (2.30$_i$).

To conclude the proof of property (i) stated in Proposition 2.2, observe that, thanks to (2.31$_i$), $i = 2, \dots, N$, we have

$$\text{meas}\big\{s \in [\tau_i,\, \tau_{i+1}] \ :\ \alpha^*(y(s)) > \alpha_i\big\} \leq \left(\sum_{j>i} \ell_j\right) \cdot \text{Tot.Var.}\{w\} \qquad \text{for all} \ \ i \geq 1. \tag{2.32}$$

Therefore, recalling the definitions of the map φ_{α_i} at (2.10), taking δ as in (2.19), and

$$C > (N+1) \cdot \sum_{j=1}^{N} \ell_j, \tag{2.33}$$

from (2.31$_i$) and (2.32) we deduce that the partition $\tau_1 = 0 \leq \tau_2 \leq \cdots \leq \tau_{N+1} = T$ of $[0,\, T]$, defined at (2.30$_i$), satisfies the properties (2.5)–(2.7).

(ii) Concerning (ii), let $C, \delta > 0$ be the constants defined according to (i) and, given a BV function $w = w(t)$ with Tot.Var.$\{w\} < \delta$, and a solution $y : [0, T] \mapsto \Omega$ of the Cauchy problem (1.7)–(1.8) with $y_0 \in K$, consider the partition $0 = \tau_1 \leq \tau_2 \leq \cdots \leq \tau_{N+1} = T$, of $[0,\, T]$, with the properties in (i). Setting

$$\tau_i' \doteq \inf\Big\{t \in [\tau_i,\, \tau_{i+1}] \ :\ \alpha^*(y(t)) = \alpha_i\Big\}, \qquad i = 1, \dots, N,$$

define the map

$$\tau(t) \doteq \begin{cases} \tau_i' & \text{if} \quad t \in \,]\tau_i,\, \tau_i'], \\ \sup\big\{s \in [\tau',\, t] \ :\ \alpha^*(y(s)) = \alpha_i\big\} & \text{if} \quad t \in \,]\tau_i',\, \tau_{i+1}] \end{cases} \tag{2.34}$$

over any interval $]\tau_i,\, \tau_{i+1}]$, $i = 1, \dots, N$. Notice that in the particular case where $\alpha^*(y(t)) > \alpha_i$ for all $t \in \,]\tau_i,\, \tau_{i+1}]$, by the above definitions one has $\tau(t) = \tau_i' = \tau_{i+1}$ for any $t \in \,]\tau_i,\, \tau_{i+1}]$. Then let $y^\diamondsuit : [0, T] \mapsto \Omega$ be the map recursively defined by setting

$$y^\diamondsuit(t) \doteq y(t) \qquad \text{for all} \ \ t \in \,]\tau_N,\, T], \tag{2.35}$$

(2.36)
$$y^\diamond(t) \doteq \begin{cases} y^\diamond(\tau_{i+1}+) & \text{if} \quad \tau_i' = \tau_{i+1}, \\ y(\tau(t)+) & \text{if} \quad \tau_i' < \tau_{i+1}, \quad \alpha^*(y(\tau(t))) > \alpha_i, \\ y(\tau(t)) & \text{if} \quad \tau_i' < \tau_{i+1}, \quad \alpha^*(y(\tau(t))) = \alpha_i, \end{cases} \qquad \text{for all} \quad t \in]\tau_i,\, \tau_{i+1}], \quad i < N,$$

(2.37)
$$y^\diamond(0) \doteq y^\diamond(0^+),$$

and let $w^\diamond = w^\diamond(t)$ be the function defined as

(2.38)
$$w^\diamond(t) \doteq y^\diamond(t) - \int_0^t g\big(y^\diamond(s)\big)\, ds \qquad \text{for all} \quad t \in [0,\, T].$$

Clearly $y^\diamond, w^\diamond$ are both BV functions as well as y, w. Moreover, $y^\diamond$ is a solution of the perturbed equation (2.8). By construction, for every $1 \leq i \leq N$ there holds

(2.39)
$$\alpha^*(y^\diamond(t)) = \begin{cases} \alpha_i & \text{if} \quad \tau_i' < \tau_{i+1}, \\ \alpha^*(y^\diamond({\tau_{i+1}}^+)) & \text{if} \quad \tau_i' = \tau_{i+1}, \end{cases} \qquad \text{for all} \quad t \in]\tau_i,\, \tau_{i+1}].$$

Hence the map $t \mapsto \alpha^*(y^\diamond(t))$ is nonincreasing and left continuous. Next, recalling (2.6) and observing that

(2.40)
$$\alpha^*(y(t)) = \alpha_i \qquad \Longrightarrow \qquad \begin{matrix} \tau(t) = t, \\ y^\diamond(t) = y(t), \end{matrix} \qquad \text{for all} \quad t \in]\tau_i,\, \tau_{i+1}]$$

and defining

(2.41)
$$\mathcal{I} \doteq \bigcup_i \big\{t \in]\tau_i,\, \tau_{i+1}] \ :\ \alpha^*(y(t)) > \alpha_i\big\},$$

we have

(2.42)
$$y(t) = y^\diamond(t) \qquad \text{for all} \quad t \in (0,\, T) \setminus \mathcal{I}.$$

On the other hand, by the above definitions, calling $M \doteq \sup_{y \in \Omega} |g(y)|$, we derive

(2.43)
$$\big|\tau(t) - t\big| \leq \text{meas}(\mathcal{I}) \qquad \text{for all} \quad t \in \mathcal{I},$$

$$\begin{aligned} \big|y^\diamond(t) - y(t)\big| &\leq \int_{\tau(t)}^t \big|g(y(s))\big|\, ds + \text{Tot.Var.}\big\{w\,;\,[0,t]\big\} \\ &\leq M \cdot \text{meas}(\mathcal{I}) + \text{Tot.Var.}\{w\} \qquad \text{for all} \quad t \in \mathcal{I}, \end{aligned} \tag{2.44}$$

and

$$\begin{aligned} \Big|\text{Tot.Var.}\{y^\diamond\} - \text{Tot.Var.}\{y\}\Big| &\leq \text{Tot.Var.}\big\{y\,;\,\mathcal{I}\big\} \\ &\leq M \cdot \text{meas}(\mathcal{I}) + \text{Tot.Var.}\{w\}. \end{aligned} \tag{2.45}$$

Then, using (2.44)–(2.45), we obtain

$$\begin{aligned}\Big|\text{Tot.Var.}\{w^\diamondsuit\} - \text{Tot.Var.}\{w\}\Big| &\leq \int_{\mathcal{I}} \Big|\big|g\big(y^\diamondsuit(s)\big)\big| - \big|g\big(y(s)\big)\big|\Big|\, ds \\ &\quad + \Big|\text{Tot.Var.}\{y^\diamondsuit\} - \text{Tot.Var.}\{y\}\Big| \\ &\leq M' \cdot \Big\{\text{meas}(\mathcal{I}) + \text{Tot.Var.}\{w\}\Big\} \end{aligned} \tag{2.46}$$

for some constant $M' > 0$, depending only on the field g. Hence, from (2.42), (2.44), (2.46), and applying (2.7), it follows that $y^\diamondsuit(\cdot)$ satisfies the estimates in (2.9) for some constant $C' > 0$, which concludes the proof of (ii).

We can now take δ as in (2.19) and choose $C > C'$ according to (2.33). Both properties (i) and (ii) are then satisfied, completing the proof of Proposition 2.2. ∎

Proof of Theorem 1.3. For a given sequence of solutions $y_\nu : [0,T] \mapsto \Omega$ of the perturbed system (1.11) with $\text{Tot.Var.}\{w_\nu\} \leq \delta_\nu$, $\delta_\nu \to 0$ as $\nu \to \infty$, assume that the $y_\nu(\cdot)$ converge to a function $y : [0,T] \mapsto \Omega$ uniformly on $[0,T]$ and that $y_\nu(0)$ belongs to some compact set $K \subset \Omega$ for every ν. Thanks to property (ii) of Proposition 2.2, in connection with any pair $w_\nu(\cdot)$, $y_\nu(\cdot)$, there will be a BV function $w_\nu^\diamondsuit(\cdot)$ and a solution $y_\nu^\diamondsuit(\cdot)$ of (2.8) that satisfy

$$\text{Tot.Var.}\{w_\nu^\diamondsuit\} \leq C' \cdot \delta_\nu, \qquad \big\|y_\nu^\diamondsuit - y_\nu\big\|_{\mathbf{L}^\infty([0,T])} \leq C' \cdot \delta_\nu \tag{2.47}$$

for some constant $C' > 0$ independent of ν. Moreover there exists a partition $0 = \tau_{1,\nu} \leq \tau_{2,\nu} \leq \cdots \leq \tau_{N+1,\nu} = T$ of $[0, T]$ such that

$$\alpha^*(y_\nu^\diamondsuit(t)) = \alpha_i \qquad \text{for all } \ t \in \,]\tau_{i,\nu},\, \tau_{i+1,\nu}], \qquad i = 1, \ldots, N. \tag{2.48}$$

Recalling (1.4) and (1.9), because of (2.48) we have

$$\begin{aligned} y_\nu^\diamondsuit(t) = y_\nu^\diamondsuit(0) \ + \ \sum_{\ell=1}^{i-1} \int_{\tau_{\ell,\nu}}^{\tau_{\ell+1,\nu}} g_{\alpha_\ell}(y_\nu^\diamondsuit(s))\, ds \ + \int_{\tau_{i,\nu}}^{t} g_{\alpha_i}(y_\nu^\diamondsuit(s))\, ds \ + \ [w_\nu^\diamondsuit(t) - w_\nu^\diamondsuit(0)] \\ \text{for all } \ t \in [\tau_{i,\nu},\, \tau_{i+1,\nu}], \qquad i = 1, \ldots, N. \end{aligned} \tag{2.49}$$

By possibly taking a subsequence, we can assume that every sequence $(\tau_{i,\nu})_{\nu \geq 1}$ converges to some limit point, say

$$\overline{\tau}_i \doteq \lim_{\nu \to \infty} \tau_{i,\nu}, \qquad i = 1, \ldots, N+1.$$

We now observe that

$$\,]\overline{\tau}_i,\, \overline{\tau}_{i+1}[\ \subseteq \bigcup_{\mu=1}^{\infty} \bigcap_{\nu=\mu}^{\infty}]\tau_{i,\nu},\, \tau_{i+1,\nu}\,] \qquad \text{for all } \ i.$$

Moreover, the second inequality in (2.47) and the uniform convergence $y_\nu(\cdot) \to y(\cdot)$ yield

$$\lim_{\nu \to \infty} \big\|y_\nu^\diamondsuit - y\big\|_{\mathbf{L}^\infty([0,T])} = 0. \tag{2.50}$$

From the first inequality in (2.47), and from (2.48)–(2.49), we now deduce

(2.51)
$$y(t) \in \overline{\Omega}_{\alpha_i} \setminus \bigcup_{\beta>\alpha_i} \Omega_\beta,$$
$$\text{for all } \ t \in]\overline{\tau}_i,\, \overline{\tau}_{i+1}], \ \text{for all } \ i.$$
$$y(t) = y(0) + \sum_{\ell=1}^{i-1} \int_{\overline{\tau}_\ell}^{\overline{\tau}_{\ell+1}} g_{\alpha_\ell}(y(s))\, ds + \int_{\overline{\tau}_i}^{t} g_{\alpha_i}(y(s))\, ds$$

In particular, on each interval $[\overline{\tau}_i,\, \overline{\tau}_{i+1}]$, the function $y(\cdot)$ is a classical solution of $\dot y = g_{\alpha_i}(y)$ and satisfies

$$\dot y(s^-) = g_{\alpha_i}(y(s)) \qquad \text{for all } \ s \in]\overline{\tau}_i,\, \overline{\tau}_{i+1}].$$

Moreover, observe that because of the inward-pointing condition (1.1), the set $\big\{t \in [\overline{\tau}_i,\, \overline{\tau}_{i+1}] : y(t) \in \partial\,\Omega_{\alpha_i}\big\}$ is nowhere dense in $[\overline{\tau}_i,\, \overline{\tau}_{i+1}]$. Thus, if s is any point in $]\overline{\tau}_i,\, \overline{\tau}_{i+1}]$ such that $y(s) \in \partial\,\Omega_{\alpha_i}$, there will be some increasing sequence $(s_n)_n \subset]\overline{\tau}_i,\, \overline{\tau}_{i+1}[$ converging to s and such that $y(s_n) \in \Omega_{\alpha_i}$ for any n. But this yields a contradiction with (1.1), because

$$0 \leq \lim_{n\to\infty} \Big\langle \frac{y(s) - y(s_n)}{s - s_n},\ \mathbf{n_{\alpha_i}}\big(y(s)\big) \Big\rangle = \Big\langle \dot y(s-),\ \mathbf{n}\big(y(s)\big) \Big\rangle = \Big\langle g_{\alpha_i}\big(y(s)\big),\ \mathbf{n_{\alpha_i}}\big(y(s)\big) \Big\rangle.$$

Hence, recalling the definition (1.2), from (2.51) we conclude

$$y(t) \in \Omega_{\alpha_i} \setminus \bigcup_{\beta>\alpha_i} \Omega_\beta \qquad \text{for all } \ t \in]\overline{\tau}_i,\, \overline{\tau}_{i+1}], \qquad i = 1, \ldots, N,$$

$$y(t) = y(0) + \int_0^t g\big(y(s)\big)\, ds \qquad \text{for all } \ t \in [0,\, T],$$

proving that $y : [0,\, T] \mapsto \Omega$ is a Carathéodory solution of (1.5) on $[0,\, T]$. □

Proof of Corollary 1.4. Assuming that statement is false, we shall reach a contradiction. Fix any closed subset $A \subset \Omega$, any compact set $K \subset A$, and assume that, for some $T, \varepsilon > 0$, there exists a sequence of solutions $y_\nu : [0, T] \mapsto A$ of the perturbed system (1.7), with $y_\nu(0) \in K$, Tot.Var.$\{w_\nu\} \leq \delta_\nu$, $\delta_\nu \to 0$ as $\nu \to \infty$, such that the following property holds.

(P) Every solution $x : [0, T] \mapsto \Omega$ of the unperturbed equation (1.5) satisfies

$$\big\|x - y_\nu\big\|_{\mathbf{L}^\infty([0,T])} \geq \varepsilon \qquad \text{for all } \ \nu. \tag{2.52}$$

For each ν, call $y_\nu^\diamondsuit : [0, T] \mapsto \mathbb{R}^n$ the polygonal curve with vertices at the points $y_\nu(\ell\delta_\nu), \ell \geq 0$, defined by setting

$$y_\nu^\diamondsuit(t) \doteq y_\nu\big(\ell\delta_\nu\big) + \frac{t - \ell\delta_\nu}{\delta_\nu} \cdot \Big(y_\nu\big((\ell+1)\delta_\nu\big) - y_\nu\big(\ell\delta_\nu\big)\Big)$$
$$\text{for all } \ t \in [\ell\delta_\nu,\, (\ell+1)\delta_\nu] \cap [0, T], \qquad 0 \leq \ell \leq \lfloor T/\delta_\nu \rfloor, \tag{2.53}$$

where $\lfloor T/\delta_\nu \rfloor$ denotes the integer part of T/δ_ν. Since every $y_\nu(\cdot)$ is a BV function that solves (1.7), it follows that there will be some constant $C > 0$, independent of ν, such that

$$\text{Tot.Var.}\{y_\nu\ ;\ J\} \leq C \cdot \text{meas}(J) + \text{Tot.Var.}\{w_\nu\ ;\ J\} \tag{2.54}$$

for any interval $J \subset [0,\, T]$. Then, using (2.54), we derive for any fixed $0 \leq \ell < \ell' \leq \lfloor T/\delta_\nu \rfloor$ the bound

$$\begin{aligned}\Big|y_\nu^\diamondsuit(\ell'\delta_\nu) - y_\nu^\diamondsuit(\ell\delta_\nu)\Big| &= \Big|y_\nu(\ell'\delta_\nu) - y_\nu(\ell\delta_\nu)\Big| \\ &\leq \text{Tot.Var.}\big\{y_\nu\,;\ [\ell\delta_\nu,\, \ell'\delta_\nu]\big\} \\ &\leq (1+C)\cdot(\ell'-\ell)\delta_\nu. \end{aligned} \tag{2.55}$$

Therefore $y_\nu^\diamondsuit(\cdot)$ is a uniformly bounded sequence of Lipschitz maps, having Lipschitz constant $\text{Lip}(y_\nu^\diamondsuit) \leq (1+C)$. Hence, applying the Ascoli–Arzelà theorem, we can find a subsequence, which we still denote $y_\nu^\diamondsuit(\cdot)$, that converges to some function $y : [0,\, T] \mapsto \mathbb{R}^n$, uniformly on $[0,\, T]$. On the other hand, by construction, and thanks to (2.54), for any fixed $0 \leq t \leq T$, with $\ell\delta_\nu \leq t < (\ell+1)\delta_\nu$, the following holds:

$$\begin{aligned}\Big|y_\nu(t) - y_\nu^\diamondsuit(t)\Big| &\leq \Big|y_\nu(t) - y_\nu\big(\ell\delta_\nu\big)\Big| + \Big|y_\nu\big(\ell\delta_\nu\big) - y_\nu^\diamondsuit(t)\Big| \\ &\leq \Big|y_\nu(t) - y_\nu(\ell\delta_\nu)\Big| + \Big|y_\nu\big((\ell+1)\delta_\nu\big) - y_\nu\big(\ell\delta_\nu\big)\Big| \\ &\leq 2\cdot\text{Tot.Var.}\big\{y_\nu\,;\ [\ell\delta_\nu,\, (\ell+1)\delta_\nu]\big\} \\ &\leq 2(1+C)\cdot\delta_\nu. \end{aligned} \tag{2.56}$$

Thus, since $\delta_\nu \to 0$ as $\nu \to \infty$, the uniform convergence of $y_\nu^\diamondsuit(\cdot)$ to $y(\cdot)$ implies

$$\lim_{\nu\to\infty} \big\|y_\nu - y\big\|_{\mathbf{L}^\infty([0,T])} = 0. \tag{2.57}$$

By assumption, $\text{Range}(y_\nu) \subset A \subset \Omega$ for every ν, and hence from (2.57) we deduce also that the limit function $y(\cdot)$ takes values inside Ω. We can thus apply Theorem 1.3 to the sequence $y_\nu(\cdot)$ and conclude that the function $y : [0,\, T] \mapsto \Omega$ is a Carathéodory solution of the unperturbed equation (1.5) with

$$\big\|y - y_\nu\big\|_{\mathbf{L}^\infty([0,T])} < \varepsilon$$

for all ν sufficiently large. We thus obtain a contradiction with (2.52), concluding the proof. □

3. Robustness of patchy feedbacks. In this section we apply the previous results on patchy vector fields with impulsive perturbations and construct (discontinuous) stabilizing feedback controls that enjoy robustness properties in the presence of measurement errors and external disturbances. Consider the nonlinear control system on $\mathbb{R}^n$

$$\dot{x} = f(x,u), \qquad\qquad u(t) \in \mathcal{K}, \tag{3.1}$$

assuming that the control set $\mathcal{K} \subset \mathbb{R}^m$ is compact and that the map $f : \mathbb{R}^n \times \mathbb{R}^m \mapsto \mathbb{R}^n$ is smooth. We seek a feedback control $u = U(x) \in \mathcal{K}$ that stabilizes the trajectories of the closed-loop system

$$\dot{x} = f\big(x,\, U(x)\big) \tag{3.2}$$

at the origin. It is well known that even if every initial state $\overline{x} \in \mathbb{R}^n$ can be steered to the origin by an open-loop control $u = u^{\overline{x}}(t)$, a topological obstruction can prevent the existence of a continuous feedback control $u = U(x)$ which (locally) stabilizes the

system (3.1). This fact was first pointed out by Sussmann [Su] for a two-dimensional system ($n = 2,\ \mathcal{K} = \mathbb{R}^2$) and by Sontag and Sussmann [SS] for one-dimensional systems ($n = 1,\ \mathcal{K} = \mathbb{R}$). For general nonlinear systems, it was further analyzed by Brockett [Bro] and Coron [Cor1], [Cor2]. It is thus natural to look for a stabilizing control within a class of discontinuous functions. However, this leads to a theoretical difficulty, because when the function U is discontinuous, the differential equation (3.2) may not admit any Carathéodory solution. To cope with this problem, two different approaches have been pursued.

1. An algorithm is defined which constructs approximate trajectories in connection with an arbitrary (discontinuous) feedback control function. For example, one can sample the feedback control at a discrete set of times. The resulting trajectory, called a sampling solution, was first studied by Krasovskii and Subbotin in the context of positional differential games (see [KS]). In this case, one is not concerned with the existence of exact solutions but only in the asymptotic stabilization properties of all approximate solutions.

2. Alternatively, by the asymptotic controllability to the origin of system (3.1) by means of open-loop controls, one proves the existence of a stabilizing feedback $u = U(x)$ having only a particular type of discontinuities. This feedback thus generates a *patchy vector field*, and the corresponding system (3.2) always admits Carathéodory solutions.

The first approach was initiated in [CLSS] and further developed in [Ri1], [Ri2], [Ri3], [CLRS], [So2]. The second was introduced in [A-B], defining the following class of piecewise constant feedback controls:

DEFINITION 3.1. *Let* $\big(\Omega,\ g,\ (\Omega_\alpha,\ g_\alpha)_{\alpha\in\mathcal{A}}\big)$ *be a patchy vector field. Assume that there exist control values* $k_\alpha \in \mathcal{K}$ *such that for each* $\alpha \in \mathcal{A}$, *there holds*

$$g_\alpha(x) \doteq f(x,\ k_\alpha) \qquad \text{for all } x \in D_\alpha \doteq \Omega_\alpha \setminus \bigcup_{\beta>\alpha} \Omega_\beta. \tag{3.3}$$

Then the piecewise constant map

$$U(x) \doteq k_\alpha \qquad \text{if} \qquad x \in D_\alpha \tag{3.4}$$

is called a patchy feedback control on Ω *and referred to as* $\big(\Omega,\ U,\ (\Omega_\alpha,\ k_\alpha)_{\alpha\in\mathcal{A}}\big)$.

Remark 3.1. From Definitions 1.2 and 3.1, it is clear that the field

$$g(x) = f\big(x,\ U(x)\big)$$

defined in connection with a given patchy feedback $\big(\Omega,\ U,\ (\Omega_\alpha,\ k_\alpha)_{\alpha\in\mathcal{A}}\big)$ is precisely the patchy vector field $\big(\Omega,\ g,\ (\Omega_\alpha,\ g_\alpha)_{\alpha\in\mathcal{A}}\big)$ associated with a family of fields $\big\{g_\alpha : \alpha \in \mathcal{A}\big\}$ satisfying (1.1) Clearly, the patches $(\Omega_\alpha,\ g_\alpha)$ are not uniquely determined by the patchy feedback U. Indeed, whenever $\alpha < \beta$, by (3.3) the values of g_α on the set $\Omega_\alpha \setminus \Omega_\beta$ are irrelevant. Moreover, recalling the notation (1.3) we have

$$U(x) = k_{\alpha^*(x)} \qquad \text{for all } \ x \in \Omega. \tag{3.5}$$

Here, we address the issue of robustness of a stabilizing feedback law $u = U(x)$ w.r.t. small internal and external perturbations

$$\dot{x} = f\big(x,\ U(x + \zeta(t))\big) + d(t), \tag{3.6}$$

where $\zeta = \zeta(t)$ represents a state measurement error and $d = d(t)$ represents an external disturbance of the system dynamics (3.2). Since we are dealing with a discontinuous ODE, one cannot expect the full robustness of the feedback $U(x)$ w.r.t. measurement errors because of possible chattering behavior that may arise at discontinuity points (see [He1], [Ry], [So1], [L-S1], [L-S2], [CR]). Therefore, we shall consider state measurement errors which are small in BV norm, avoiding such phenomena.

Before stating our main result in this direction, we recall here some basic definitions and Proposition 4.2 in [A-B]. This provides the semiglobal practical stabilization (steering all states from a given compact set of initial data into a prescribed neighborhood of zero) of an asymptotically controllable system by means of a patchy feedback control which is robust w.r.t. external disturbances. We consider as (open-loop) *admissible controls* all the measurable functions $u : [0, \infty) \to \mathbb{R}^m$ such that $u(t) \in \mathcal{K}$ for a.e. $t \geq 0$.

DEFINITION 3.2. *The system* (3.1) *is globally asymptotically controllable to the origin if the following holds.*

1. Attractiveness. *For each* $\overline{x} \in \mathbb{R}^n$ *there exists some admissible (open-loop) control* $u = u^{\overline{x}}(t)$ *such that the corresponding trajectory of*

$$\dot{x}(t) = f\big(x(t),\, u^{\overline{x}}(t)\big), \qquad x(0) = \overline{x}, \tag{3.7}$$

either reaches the origin in finite time or tends to the origin as $t \to \infty$.

2. Lyapunov stability. *For each* $\varepsilon > 0$ *there exists* $\delta > 0$ *such that the following holds. For every* $\overline{x} \in \mathbb{R}^n$ *with* $|\overline{x}| < \delta$, *there is an admissible control* $u^{\overline{x}}$ *as in* 1 *steering the system from* $\overline{x}$ *to the origin, so that the corresponding trajectory of* (3.7) *satisfies* $|x(t)| < \varepsilon$ *for all* $t \geq 0$.

PROPOSITION 3.3 (see [A-B, Proposition 4.1]). *Let system* (3.1) *be globally asymptotically controllable to the origin. Then, for every* $0 < r < s$, *one can find* $T > 0$, $\chi > 0$, *and a patchy feedback control* $U : D \mapsto \mathcal{K}$ *defined on some domain*

$$D \supset \big\{x \in \mathbb{R}^n \ ;\ r \leq |x| \leq s\big\} \tag{3.8}$$

so that the following holds. For any measurable map $d : [0, T] \mapsto \mathbb{R}^n$ *such that*

$$\big\|d\big\|_{\mathbf{L}^\infty([0,\,T])} \leq \chi,$$

and for any initial state x_0 *with* $r \leq |x_0| \leq s$, *the perturbed system*

$$\dot{x} = f\big(x,\, U(x)\big) + d(t) \tag{3.9}$$

admits a (forward) Carathéodory trajectory starting from x_0. *Moreover, for any such trajectory* $t \mapsto \gamma(t)$, $t \geq 0$, *one has*

$$\gamma(t) \in D \qquad \text{for all} \quad t \geq 0, \tag{3.10}$$

and there exists $\bar{t}_\gamma < T$ *such that*

$$\big|\gamma(\bar{t}_\gamma)\big| < r. \tag{3.11}$$

Relying on Corollary 1.4 of Theorem 1.3 and on Proposition 3.3, we obtain here the following result concerning robustness of a stabilizing feedback w.r.t. both internal and external perturbations.

THEOREM 3.4. *Let system* (3.1) *be globally asymptotically controllable to the origin. Then, for every* $0 < r < s$, *one can find* $T' > 0$, $\chi' > 0$, *and a patchy*

feedback control $U' : D' \mapsto \mathcal{K}$ defined on some domain D' satisfying (3.8) *so that the following holds. Given any pair of maps $\zeta \in BV([0,\, T'])$, $d \in \mathbf{L}^\infty([0,\, T'])$ such that*

$$\text{Tot.Var.}\{\zeta\} \leq \chi', \qquad \big\|d\big\|_{\mathbf{L}^\infty([0,\, T'])} \leq \chi', \tag{3.12}$$

and any initial state x_0 with $r \leq |x_0| \leq s$, for every solution $t \mapsto x(t)$, $t \geq 0$, of the perturbed system (3.6) *starting from x_0, one has*

$$x(t) \in D' \qquad \text{for all} \quad t \in [0,\, T'], \tag{3.13}$$

and there exists $\bar{t}_x < T'$ such that

$$\big|x(\bar{t}_x)\big| < r. \tag{3.14}$$

Proof. 1. Fix $0 < r < s$. Then, according to Proposition 3.3, we can find $T' > 0$ and a patchy feedback control $U' : D' \mapsto \mathcal{K}$ defined on some domain

$$D' \supset \big\{x \in \mathbb{R}^n \,;\; r/3 \leq |x| \leq s\big\} \tag{3.15}$$

so that the following holds. For every Carathéodory solution $t \mapsto x(t)$, $t \geq 0$, of the unperturbed system (3.2) (with $U = U'$) starting from a point x_0 in the compact set

$$K \doteq \big\{x \in \mathbb{R}^n \,;\; r \leq |x| \leq s\big\}, \tag{3.16}$$

one has

$$x(t) \in D_\rho \doteq \big\{x \in D' \;:\; d\big(x,\, \partial D'\big) > \rho\big\} \qquad \text{for all} \quad t \geq 0 \tag{3.17}$$

for some constant $\rho > 0$. Moreover, there exists $\bar{t}_x < T'$ such that

$$\big|x(\bar{t}_x)\big| < \frac{r}{3}. \tag{3.18}$$

According with Definition 3.1, the field

$$g(x) \doteq f\big(x,\, U'(x)\big) \tag{3.19}$$

is a patchy vector field associated to the family of fields $\big\{g_\alpha : \alpha \in \mathcal{A}\big\}$ defined as in (3.3). The smoothness of f guarantees that for BV perturbations $w = w(t)$ having some uniform bound Tot.Var.$\{w\} \leq \widehat{\chi}$ on the total variation, every (left continuous) solution $y : [0, T'] \mapsto \mathbb{R}^2$ of the impulsive equation (1.7), starting at a point $x_0 \in K$, takes values in the closed set

$$A \doteq B(D_\rho,\, \rho/2). \tag{3.20}$$

Therefore, thanks to Corollary 1.4 of Theorem 1.3, there exists some constant

$$0 < \widehat{\chi}' = \widehat{\chi}'(A,\, K,\, T',\, r/3) < \widehat{\chi} \tag{3.21}$$

such that the following holds. If $y : [0, T'] \mapsto \mathbb{R}^2$ is a (left continuous) solution of the impulsive equation (1.7), with $y(0) \in K$ and Tot.Var.$(w) < \widehat{\chi}'$, then one has

$$y(t) \in A \qquad \text{for all} \quad t \in [0,\, T'], \tag{3.22}$$

and there exists $\bar{t}_y < T'$ such that

$$\big|y(\bar{t}_y)\big| < \frac{2r}{3}. \tag{3.23}$$

2. In connection with the patchy feedback U' introduced above, define the map

$$h(y,z) \doteq f\big(y-z,\, U'(y)\big) - f\big(y,\, U'(y)\big) \tag{3.24}$$

and observe that, by the smoothness of f, there will be some constant $\bar{c} > 0$ such that

$$\big|h(y,z)\big| \leq \bar{c}\cdot|z| \qquad \text{for all } \ y\in A, \quad |z|\leq \widehat{\chi}'. \tag{3.25}$$

Consider now a pair of maps $\zeta \in BV([0,\,T'])$, $d\in \mathbf{L}^\infty([0,\,T'])$ satisfying (3.12) with

$$\chi' < \min\left\{\frac{\widehat{\chi}'}{2(1+T'\bar{c}')},\ \frac{r}{3},\ \frac{\rho}{2}\right\}, \tag{3.26}$$

and let $x = x(t)$ be any Carathéodory solution of the perturbed system (3.6), with an initial condition $x(0) = x_0 \in K$. Then, as observed in the introduction, the map

$$t\mapsto y(t) \doteq x(t) + \zeta(t) \tag{3.27}$$

satisfies the impulsive equation (1.7), where

$$w(t) \doteq \zeta(t) + \int_0^t \big(h\big(y(s),\zeta(s)\big) + d(s)\big)\, ds. \tag{3.28}$$

But then, since (3.12), (3.25), (3.26) together imply

$$\begin{aligned}\text{Tot.Var.}\big\{w\ ;\ [0,\,T']\big\} &\leq \text{Tot.Var.}\big\{\zeta\ ;\ [0,\,T']\big\} + T'\bar{c}\cdot\big\|\zeta\big\|_{\mathbf{L}^\infty([0,\,T'])} + T'\cdot\big\|d\big\|_{\mathbf{L}^\infty([0,\,T'])}\\ &\leq \big(1+T'\bar{c}\big)\cdot\text{Tot.Var.}\big\{\zeta\ ;\ [0,\,T']\big\} + \big\|d\big\|_{\mathbf{L}^\infty([0,\,T'])}\\ &< \widehat{\chi}',\end{aligned}$$

from (3.22)–(3.23) and (3.12), (3.20), (3.26), (3.27) it follows that

$$x(t)\in B(A,\,\rho/2)\subset D' \qquad \text{for all } \ t\in[0,\,T'], \tag{3.29}$$

$$\big|x(\bar{t}_y)\big| < r \qquad \text{for some} \qquad \bar{t}_y < T',$$

which completes the proof of the theorem, taking χ' as in (3.26). □

Remark 3.2. For discontinuous stabilizing feedbacks constructed in terms of sampling solutions, an alternative concept of robustness was introduced in [CLRS], [So1], [So2]. In this case, one considers a partition of the time interval and applies a constant control between two consecutive sampling times. To preserve stability, the measurement error should be sufficiently small compared to the maximum step size. Moreover, each step size should be big enough to prevent possible chattering phenomena. The next result shows that the feedback provided by [A-B, Proposition 4.2] also enjoys this type of robustness. Before stating this result we describe now the concept of a sampling trajectory associated to the perturbed system (3.6) that was introduced in [CLRS], [So2].

Let an initial condition x_0 and a partition $\pi = \{0 = \tau_0 < \tau_1 < \cdots < \tau_{m+1} = T\}$ of the interval $[0, T]$ be given. A sampling trajectory x_π of the perturbed system (3.6), corresponding to a set of measurement errors $\{e_i\}_{i=0}^m$ and an external disturbance $d \in \mathbf{L}^\infty([0, T])$, is defined in a step-by-step fashion as follows. Between τ_0 and τ_1, let $x_\pi(\cdot)$ be a Carathéodory solution of

$$\dot{x} = f\big(x,\ U(x_0 + e_0)\big) + d(t), \qquad t \in [\tau_0,\, \tau_1], \tag{3.30}$$

with initial condition $x_\pi(0) = x_0$. Then, $x_\pi(\cdot)$ is recursively obtained by solving the system

$$\dot{x} = f\big(x,\ U(x_\pi(\tau_i) + e_i)\big) + d(t), \qquad t \in [\tau_i,\, \tau_{i+1}], \quad i > 0. \tag{3.31}$$

The sequence $\{x_\pi(\tau_i) + e_i\}_{i=0}^m$ corresponds to the nonexact measurements used to select control values.

THEOREM 3.5. *Let system* (3.1) *be globally asymptotically controllable to the origin. Then, for every* $0 < r < s$, *one can find* $T'' > 0$, $\chi'' > 0$, $\overline{\delta} > 0$, $\overline{k} > 0$, *and a patchy feedback control* $U'' : D'' \mapsto \mathcal{K}$ *defined on some domain* D'' *satisfying* (3.8) *so that the following holds. Given an initial state* x_0 *with* $r \leq |x_0| \leq s$, *a partition* $\pi = \{\tau_0 = 0,\, \tau_1,\, \ldots,\, \tau_{m+1} = T''\}$ *of the interval* $[0,\, T'']$ *having the property*

$$\frac{\delta}{2} \leq \tau_{i+1} - \tau_i \leq \delta \qquad \textit{for all } \ i \qquad \textit{for some} \qquad \delta \in\ ]0,\, \overline{\delta}\,], \tag{3.32}$$

a set of measurement errors $\{e_i\}_{i=0}^m$, *and an external disturbance* $d \in \mathbf{L}^\infty([0,\, T''])$ *that satisfy*

$$\max_i |e_i| \leq \overline{k} \cdot \delta, \tag{3.33}$$

$$\big\|d\big\|_{\mathbf{L}^\infty} \leq \chi'', \tag{3.34}$$

the resulting sampling solution $x_\pi(\cdot)$ *starting from* x_0 *has the property*

$$x_\pi(t) \in D'' \qquad \textit{for all } \ t \in [0,\, T'']. \tag{3.35}$$

Moreover, there exists $\overline{t}_{x_\pi} < T''$ *such that*

$$\big|x_\pi(\overline{t}_{x_\pi})\big| < r. \tag{3.36}$$

Proof. 1. Fix $0 < r < s$. Then, according with Proposition 3.4, we can find $T' > 0, \chi' > 0$, and a patchy feedback control $U'' : D'' \longmapsto \mathcal{K}$ defined on a domain

$$D'' \supset \big\{x \in \mathbb{R}^n\ ;\ r/3 \leq |x| \leq 2s\big\}$$

so that the following holds. For every external disturbance $d \in \mathbf{L}^\infty$ satisfying (3.34) with $\chi'' \leq \chi'$, and for any Carathéodory solution $t \mapsto x(t)$, $t \geq 0$, of the perturbed system (3.9) (with $U = U''$), starting from a point x_0 with $r \leq |x_0| \leq s$, one has

$$x(t) \in D_{\rho_1} \doteq \big\{x \in D''\ :\ d\big(x,\, \partial D''\big) > \rho_1\big\} \qquad \text{for all } \ t \geq 0 \tag{3.37}$$

for some constant $\rho_1 > 0$. Moreover, there exists $\overline{t}_x < T'$ such that

$$\big|x(\overline{t}_x)\big| < \frac{r}{3}. \tag{3.38}$$

Let

$$\big\{(\Omega_\alpha,\ g_\alpha)\ :\ \alpha = 1, \dots, N\big\}, \qquad g_\alpha(x) = f(x, k_\alpha), \qquad k_\alpha \in \mathcal{K}, \tag{3.39}$$

be the collection of patches associated with the patchy vector field

$$g(x) = f\big(x,\, U''(x)\big). \tag{3.40}$$

We may assume that every vector field g_α is defined on a neighborhood $B(\Omega_\alpha,\, \rho_2)$, $0 < \rho_2 \leq \rho_1$, of the domain Ω_α so that, setting

$$\Omega_\alpha^\rho \doteq \big\{x \in \Omega_\alpha\ ;\ d\big(x,\ \partial\Omega_\alpha\big) > \rho\big\}, \tag{3.41}$$

one has

$$\Omega_\alpha^{\rho_2} \neq \emptyset,$$

and that every g_α is uniformly nonzero on the domain D_α defined in (3.3). Moreover, thanks to the inward-pointing condition (1.1), we may choose the constants $0 < \rho_2 < r/3$ and $\chi'' \leq \chi'$ so that the following hold:

$$\big|g_\alpha(x)\big| \geq 2\chi'' \qquad \text{for all}\ \ x \in B(D_\alpha,\, \rho_2) \tag{3.42}$$

and

$$\big\langle g_\alpha(x) + v,\ \mathbf{n}(x)\big\rangle < 0 \qquad \text{for all}\ \ x \in B(\partial\Omega_\alpha,\, \rho_2), \qquad |v| \leq \chi''. \tag{3.43}$$

For every $d \in \mathbf{L}^\infty$, we denote by $t \mapsto x^\alpha\big(t;\, t_0,\, x_0,\ d\big)$ the solution of the Cauchy problem

$$\dot{x} = g_\alpha(x) + d(t), \qquad x(t_0) = x_0, \tag{3.44}$$

and let $[t_0,\, t^{\max}]$ be the domain of definition of the maximal (forward) solution of (3.44) that is contained in $B(D_\alpha,\, \rho_2)$.

Observe that since every Carathéodory solution of the perturbed system (3.9) (with $U = U''$), starting from a point $x_0 \in B(0, s)\backslash\circ \to B(0,\, r)$, reaches the interior of the ball $B(0,\, r/3)$ in finite time, and because of (3.42), for any $\alpha = 1, \dots, N$ one can find $T_\alpha > 0$ with the following property.

(P)$_1$ For every $x_0 \in B(D_\alpha,\, \rho/2)$, $0 < \rho < \rho_2$, and for any $d \in \mathbf{L}^\infty$ satisfying (3.34), there exists some time $t_\rho \doteq t_\rho(x_0,\, d) < T_\alpha$ such that either one has

$$\big|x^\alpha\big(t_0 + t_\rho;\, t_0,\, x_0,\, d\big)\big| < \frac{2r}{3} \tag{3.45}$$

or else the following holds:

$$x^\alpha\big(t;\, t_0,\, x_0,\, d\big) \in B(D_\alpha,\, \rho_2) \setminus B(D_\alpha,\, \rho) \qquad \text{for all}\ \ t \in [t_0 + t_\rho,\ t^{\max}]. \tag{3.46}$$

On the other hand, relying on the inward-pointing condition (3.43), we deduce two further properties of the solutions of (3.44).

(P)$_2$ The sets Ω_α^ρ, $0 < \rho \leq \rho_2$, defined in (3.41) are positive invariant regions for trajectories of (3.44), i.e., for every $x_0 \in \Omega_\alpha^\rho$, and for any $d \in \mathbf{L}^\infty$ satisfying (3.34), one has

$$x^\alpha\big(t;\, t_0,\, x_0,\, d\big) \in \Omega_\alpha^\rho \qquad \text{for all}\ \ t \geq t_0. \tag{3.47}$$

(P)$_3$ There exists some constant $\overline{c} > 0$ so that, for every $x_0 \in B(\Omega_\alpha, \rho)$, $0 < \rho \leq \rho_2$, such that $d\big(x_0,\ \partial\Omega_\alpha\big) \leq \rho$, and for any $d \in \mathbf{L}^\infty$ satisfying (3.34), one has

$$x^\alpha\big(t;\, t_0,\, x_0,\, d\big) \in \Omega_\alpha^{2\rho} \qquad \text{for all} \quad t \geq t_0 + \overline{c}\cdot\rho\,. \tag{3.48}$$

2. Consider an initial state $x_0 \in B(0,s)\backslash\circ \to B\big(0,\, r\big)$ and a partition $\pi = \{\tau_i\}_{i\geq 0}$ of $[0,\, \infty[$ having the property (3.32), with

$$0 < \delta \leq \overline{\delta} \doteq \min\Big\{\overline{c}\cdot\rho_2,\ \frac{\rho_1}{M}\Big\}, \tag{3.49}$$

$$M \doteq \sup\big\{|g_\alpha(x)| \ :\ x \in B(\Omega_\alpha,\, \rho_2), \quad \alpha = 1, \ldots, N\big\}.$$

Let $x_\pi : [0,\, \infty[\ \mapsto \mathbb{R}^n$ be a sampling solution starting from x_0 and corresponding to a set of measurement errors $\{e_i\}_{i=0}^m$ and to an external disturbance $d(\cdot) \in \mathbf{L}^\infty$ that satisfy (3.33)–(3.34) with

$$\overline{k} \doteq \frac{1}{2\overline{c}}. \tag{3.50}$$

We will first show the following.

LEMMA 3.6. *The map*

$$i \longmapsto \alpha^*(\tau_i) \doteq \alpha^*\big(x_\pi(\tau_i) + e_i\big), \qquad i \geq 0, \tag{3.51}$$

is nondecreasing.

Indeed, assume that $\alpha^*(\tau_i) = \widehat{\alpha}$, which by definitions (1.3), (3.3), (3.5) implies

$$x_\pi(\tau_i) + e_i \in D_{\widehat{\alpha}}, \tag{3.52}$$

$$x_\pi(\tau_{i+1}) = x^{\widehat{\alpha}}\big(\tau_{i+1};\ \tau_i,\, x_\pi(\tau_i),\, d\restriction_{[\tau_i,\,\tau_{i+1}]}\big). \tag{3.53}$$

Then, because of (3.33), (3.49)–(3.50), one has

$$x_i \doteq x_\pi(\tau_i) \in B(D_{\widehat{\alpha}},\ \overline{k}\delta) \subset B(\Omega_{\widehat{\alpha}},\ \rho_2). \tag{3.54}$$

We shall consider separately the case in which

$$x_i \in D_{\widehat{\alpha}}^{\overline{k}\delta} \subset \Omega_{\widehat{\alpha}}^{\overline{k}\delta}, \qquad \overline{k}\delta \leq \rho_2, \tag{3.55}$$

and the case where

$$x_i \in B(D_{\widehat{\alpha}},\ \overline{k}\delta), \qquad d\big(x_i\,,\, \partial\Omega_{\widehat{\alpha}}\big) \leq \overline{k}\delta \leq \rho_2. \tag{3.56}$$

In the first case, using (3.53) and applying (P)$_2$ we deduce that $x_\pi(\tau_{i+1}) \in \Omega_{\widehat{\alpha}}^{\overline{k}\delta}$, which, in turn, because of (3.33), (3.49)–(3.50), implies

$$x_\pi(\tau_{i+1}) + e_{i+1} \in \Omega_{\widehat{\alpha}}. \tag{3.57}$$

From (3.57), by definition (1.3) we derive

$$\alpha^*(\tau_{i+1}) \geq \widehat{\alpha}, \tag{3.58}$$

proving the lemma whenever (3.55) holds. On the other hand, when (3.56) is verified, since by (3.32), (3.50) one has

$$\tau_{i+1} - \tau_i \geq \frac{\delta}{2} = \overline{c}\overline{k} \cdot \delta,$$

applying $(\mathrm{P})_3$, we deduce $x_\pi(\tau_{i+1}) \in \Omega^{2\overline{k}\delta}_{\widehat{\alpha}}$. This again implies (3.57)–(3.58), completing the proof of Lemma 3.6.

Next, relying on $(\mathrm{P})_1$ and setting

$$\begin{aligned} (3.59)\quad i'_\alpha &\doteq \min\big\{\, i \geq 0 \;\;;\;\; \alpha^*(\tau_i) = \alpha, \quad x_\pi(\tau_i) \notin B(0,\, 2r/3)\,\big\}, \\ i''_\alpha &\doteq \max\big\{\, i \geq 0 \;\;;\;\; \alpha^*(\tau_i) = \alpha\,, \quad x_\pi(\tau_i) \notin B(0,\, 2r/3)\,\big\}, \qquad \alpha \in \mathrm{Range}(\alpha^*), \end{aligned}$$

we deduce

$$\tau_{i''_\alpha} - \tau_{i'_\alpha} \leq T_\alpha \qquad \text{for all} \;\; \alpha \in \mathrm{Range}(\alpha^*). \tag{3.60}$$

Indeed, if (3.60) does not hold, by definitions (3.3), (3.5) one has

$$x_{i'_\alpha} \doteq x_\pi(\tau_{i'_\alpha}) \in B(D_\alpha,\, \overline{k}\delta) \subset B(\Omega_\alpha,\, \rho_2/2), \tag{3.61}$$

$$x_\pi(t) = x^\alpha\big(t;\; \tau_{i'_\alpha}\,,\, x_{i'_\alpha},\, d\restriction_{[\tau_{i'_\alpha},\, \tau_{i''_\alpha+1}]}\big) \qquad \text{for all} \;\; t \in [\tau_{i'_\alpha}\,,\; \tau_{i''_\alpha+1}]. \tag{3.62}$$

But then, applying $(\mathrm{P})_1$, one could find some $\widehat{i} \leq i''_\alpha$ such that

$$x_\pi(t) \in B(D_\alpha,\, \rho_2) \setminus B(D_\alpha,\, 2\overline{k}\delta) \qquad \text{for all} \;\; t \in [\tau_{\widehat{i}},\, \tau_{i''_\alpha+1}].$$

By definitions (1.3), (3.51) and because of (3.33), this implies

$$\alpha^*(\tau_i) > \alpha \qquad \text{for all } \widehat{i} \leq i \leq i''_\alpha,$$

providing a contradiction with (3.59).

To conclude the proof of Theorem 3.5, we observe that the monotonicity of the map (3.51), together with the estimate (3.60), implies that there exists some time $\overline{t}_{x_\pi} < T'' \doteq \sum_{\alpha=1}^N T_\alpha$ such that (3.36) is verified. Moreover, (3.35) clearly follows from (3.37) and (3.49). □

Remark 3.3. Consider a partition $\pi = \{\tau_0 = 0,\, \tau_1,\, \ldots,\, \tau_{m+1} = T\}$ of the interval $[0,\, T\,]$ having the property (3.32). If we associate to a set of measurement errors $\{e_i\}_{i=1}^m$ satisfying (3.33) the piecewise constant function $\zeta \;: [0,\, T] \mapsto \mathbb{R}^n$ defined as

$$\zeta(t) = e_i \qquad \text{for all } t \in \;]\tau_i,\, \tau_{i+1}],$$

then

$$\mathrm{Tot.Var.}\{\zeta\} \leq 4\overline{k} \cdot T.$$

Thus, taking the constant $\overline{k}$ sufficiently small we may reinterpret the *discrete* internal disturbance allowed for a sampling solution in Theorem 3 as a particular case of the measurement errors with small total variation considered in Theorem 3.4.

ACCURACY AND CONVERGENCE PROPERTIES OF THE FINITE DIFFERENCE MULTIGRID SOLUTION OF AN OPTIMAL CONTROL OPTIMALITY SYSTEM*

ALFIO BORZÌ†, KARL KUNISCH†, AND DO Y. KWAK‡

Abstract. The finite difference multigrid solution of an optimal control problem associated with an elliptic equation is considered. Stability of the finite difference optimality system and optimal-order error estimates in the discrete L^2 norm and in the discrete H^1 norm under minimum smoothness requirements on the exact solution are proved. Sharp convergence factor estimates of the two grid method for the optimality system are obtained by means of local Fourier analysis. A multigrid convergence theory is provided which guarantees convergence of the multigrid process towards weak solutions of the optimality system.

Key words. optimal control problem, Poisson equation, finite differences, accuracy estimate, convergence theory, multigrid method

1. Introduction.

Optimal control problems involving partial differential equations [17, 18] are nowadays receiving much attention because of their importance in the industrial design process. Especially, the need for accurate and efficient solution methods for these problems has become an important issue.

We consider a finite difference framework and multigrid methods for the case of distributed optimal control of an elliptic problem and provide for this case optimal estimates for the accuracy of the solution and for the convergence factor of the multigrid process. The present work is characterized by the fact that we extend known analytic tools for scalar elliptic problems to the case of a (nonsymmetric) system of elliptic partial differential equations, called an optimality system.

In our finite difference analysis, based on results stated in [14, 20], we prove stability of the finite difference optimality system and prove optimal-order error estimates in the discrete L^2 norm and in the discrete H^1 norm under minimum smoothness requirements on the analytic solution.

It is known that multigrid methods [5, 13, 21] solve elliptic problems with optimal computational order, i.e., the number of computer operations required scales linearly with respect to the number of unknowns. This fact has been demonstrated in the case of multigrid applied to a singular optimal control problem associated with a nonlinear elliptic equation [2]. In particular, results in [2] show that the convergence properties of the multigrid method do not deteriorate as the weight of the cost of the control tends to zero, demonstrating the robustness of this method.

We prove convergence of the multigrid method applied to the optimality system within two analytic frameworks which have complementary features. We use two grid

local Fourier analysis [21, 10] with simplifying assumptions on the boundary conditions to obtain sharp convergence estimates of the multigrid method. These convergence estimates agree very well with results of numerical experiments and appear to be independent of the mesh size and of the value of the control parameter.

While the extension of two grid local Fourier analysis to systems of partial differential equations may be considered straightforward, the extension of the multigrid theory provided in [6, 8, 9, 15] to the case of optimality systems requires additional analysis, which is presented in this paper. The resulting multigrid theory does not require special assumptions on the boundary, it applies to polygonal domains, and guarantees convergence of the multigrid method to weak solutions of the optimality system.

In the following section we introduce and analyze our model problem. The finite difference discretization of this model problem and the corresponding stability and accuracy analysis are considered in section 3. In section 4 we describe the multigrid method and define and analyze its components. Two grid local Fourier analysis is presented in section 5. In section 6, a general convergence theory for multigrid applied to the optimality system is provided.

2. Optimal control problem. We consider the optimal control problem

$$\min J(y,u) = \frac{1}{2}||y-z||^2_{L^2(\Omega)} + \frac{\nu}{2}||u||^2_{L^2(\Omega)}, \tag{2.1}$$

subject to $u \in L^2(\Omega)$ and

$$\begin{aligned} -\Delta y &= u + g \text{ in } \Omega, \\ y &= 0 \text{ on } \partial\Omega, \end{aligned} \tag{2.2}$$

where $\Omega = (0,1)\times(0,1)$, $g \in L^2(\Omega)$, $z \in L^2(\Omega)$ is the objective function, and $\nu > 0$ is the weight of the cost of the control. Existence of a unique solution to (2.1) and its characterization are well known. Let us, for the sake of completeness, give a short derivation and denote by $\hat{J}(u) = J(y(u),u)$, where $y(u)$ denotes the solution of (2.2) as a function of u. Recall that $\Delta : H^1_0(\Omega)\cap H^2(\Omega) \to L^2(\Omega)$ is a homeomorphism. Here we use the fact that Ω is convex. The mapping $u \to y(u)$ from $L^2(\Omega)$ to $H^1_0(\Omega)\cap H^2(\Omega)$ is affine and continuous. Let us denote its first derivative at u in the direction δu by $y'(u,\delta u)$. It is characterized as the solution to

$$\begin{aligned} -\Delta y'(u,\delta u) &= \delta u \text{ in } \Omega, \\ y'(u,\delta u) &= 0 \text{ on } \partial\Omega. \end{aligned} \tag{2.3}$$

The second derivative of $u \to y(u)$ is zero. Hence we find for the second derivative of $u \to \hat{J}(u)$

$$\hat{J}''(u)(\delta u,\delta u) = ||y'(u,\delta u)||^2_{L^2(\Omega)} + \nu||\delta u||^2_{L^2(\Omega)},$$

and thus $u \to \hat{J}(u)$ is uniformly convex. This implies existence of a unique solution u^* to (2.1). Moreover, the solution is characterized by $\hat{J}'(u)(u^*;\delta u) = 0$ for all δu and consequently

$$\hat{J}'(u^*,\delta u) = (y^*-z, y'(u^*,\delta u))_{L^2(\Omega)} + \nu(u^*,\delta u)_{L^2(\Omega)} = 0 \qquad \text{for all } \delta u \in L^2(\Omega),$$

where $y^* = y(u^*)$. Introduce $\lambda^* \in H^1_0(\Omega)\cap H^2(\Omega)$ as the unique solution to

$$\begin{aligned} -\Delta\lambda^* &= -(y^*-z) \text{ in } \Omega, \\ \lambda^* &= 0 \text{ on } \partial\Omega. \end{aligned} \tag{2.4}$$

Then by (2.3) and (2.4) we have

$$\hat{J}'(u^*, \delta u) = -(\lambda^*, \delta u)_{L^2(\Omega)} + \nu(u^*, \delta u)_{L^2(\Omega)} = 0 \qquad \text{for all } \delta u \in L^2(\Omega), \tag{2.5}$$

which constitutes the necessary and sufficient optimality condition for (2.1). In (2.5), λ^* is defined via (2.2) and (2.4).

For later reference let us summarize (2.2), (2.4), and (2.5):

$$\begin{aligned} -\Delta y &= \frac{1}{\nu}\lambda + g \text{ in } \Omega, \\ y &= 0 \text{ on } \partial\Omega, \\ -\Delta\lambda &= -(y - z) \text{ in } \Omega, \\ \lambda &= 0 \text{ on } \partial\Omega, \\ \nu u - \lambda &= 0 \text{ in } \Omega. \end{aligned} \tag{2.6}$$

Here, for convenience, we dropped the $*$-notation. System (2.6) is referred to as the optimality system for (2.1). From the optimality system one concludes the following regularity property.

COROLLARY 2.1. *If z, $g \in L^2(\Omega)$, then $(y^*, u^*, \lambda^*) \in (H_0^1(\Omega) \cap H^2(\Omega))^3$.*

In the following section we address finite difference approximations to (2.1) and (2.6).

3. Finite difference approximation of the optimality system. While finite element approximations to (2.1) are rather well investigated, see [18] and the references given there, much less rigorous analysis is available for finite difference methods. Thus, before addressing multigrid methods in the remainder of the paper, we investigate convergence of finite difference approximations to (2.1). We consider a sequence of grids $\{\Omega_h\}_{h>0}$ defined by

$$\Omega_h = \{\mathbf{x} \in \mathbf{R}^2 : x_i = s_i\, h, \quad s_i \in \mathbb{Z}\} \cap \Omega.$$

Here and below we follow the notation and terminology of [14], especially section 9. To avoid certain technicalities we assume also in this section that Ω is a square and that the values of h are chosen such that the boundaries of Ω coincide with grid lines. The case of general convex domains is addressed in Remark 1 below. The negative Laplacian with homogeneous Dirichlet boundary conditions is approximated by the common five-point stencil as in [14, section 4] and denoted by $-\Delta_h$.

For grid functions v_h and w_h defined on Ω_h we introduce the discrete L^2-scalar product

$$(v_h, w_h)_{L_h^2} = h^2 \sum_{\mathbf{x} \in \Omega_h} v_h(\mathbf{x})\, w_h(\mathbf{x}),$$

with associated norm $|v_h|_0 = (v_h, v_h)_{L_h^2}^{1/2}$. We require as well the discrete H^1-product given by

$$|v_h|_1 = \left(|v_h|_0^2 + \sum_{i=1}^{2} |\partial_i^- v_h|_0^2 \right)^{1/2},$$

where ∂_i^- denotes the backward difference quotient in the x_i direction and v_h is extended by 0 on grid points outside of Ω. The spaces L_h^2 and H_h^1 consist of the sets

of grid functions v_h endowed with $|v_h|_0$, respectively, $|v_h|_1$, as norm. Further denote with M_h the vector space of nodal functions v_h defined on Ω_h which are zero on the boundary. The system of nodal functions (v_h, w_h) is denoted by $\mathcal{M}_h = M_h \times M_h$.

We need the following lemma.

LEMMA 3.1 (Poincaré–Friedrichs inequality for finite differences). *For any grid function $v_h \in M_h$, there exists a constant c_*, independent of v_h and h, such that*

$$|v_h|_0^2 \leq c_* \sum_{i=1}^{2} |\partial_i^- v_h|_0^2, \tag{3.1}$$

where $c_* = \frac{1}{4}$.

Proof. For the proof see [20]. □

Functions in $L^2(\Omega)$ and $H^2(\Omega)$ are approximated by grid functions defined through their mean values with respect to elementary cells $[x_1-\frac{h}{2}, x_1+\frac{h}{2}]\times[x_2-\frac{h}{2}, x_2+\frac{h}{2}]$. This gives rise to the restriction operators $\tilde{R}_h : L^2(\Omega) \to L_h^2$ and $R_h : H_0^1(\Omega)\cap H^2(\Omega) \to L_h^2$ defined in [14, p. 232]. For the definition of H_h^2 we refer to [14], as well. Further, we define $\tilde{R}_h^2 : L^2(\Omega)\times L^2(\Omega) \to L_h^2 \times L_h^2$ by $\tilde{R}_h^2 = (\tilde{R}_h, \tilde{R}_h)$ and analogously $R_h^2 = (R_h, R_h)$.

The discrete optimal control problems are specified next:

$$\begin{cases} \min \frac{1}{2}|y_h - \tilde{R}_h z|_0^2 + \frac{\nu}{2}|u_h|_0^2, \\ \quad -\Delta_h y_h = u_h + \tilde{R}_h g, \qquad u_h \in L_h^2. \end{cases} \tag{3.2}$$

Let u_h^* denote the unique solution to (3.2) and set $y_h^* = y_h(u_h^*)$. The optimality system related to (3.2) is found to be

$$\begin{aligned} -\Delta_h y_h^* &= u_h^* + \tilde{R}_h g, \\ -\Delta_h \lambda_h^* &= -(y_h^* - \tilde{R}_h z), \\ \nu u_h^* - \lambda_h^* &= 0. \end{aligned} \tag{3.3}$$

We can eliminate u_h^* from this system and obtain, dropping the superscript $*$,

$$\begin{cases} -\nu\,\Delta_h y_h - \lambda_h \;=\; \nu\,\tilde{R}_h g, \\ \quad -\Delta_h \lambda_h + y_h \;=\; \tilde{R}_h z. \end{cases} \tag{3.4}$$

To investigate the convergence of the solution of (3.4) to the solution of (2.6) as $h \to 0^+$, we introduce the family of operators

$$\mathcal{A}_h = \begin{pmatrix} -\nu\,\Delta_h & -I_h \\ I_h & -\Delta_h \end{pmatrix}, \tag{3.5}$$

where I_h is the identity operator on grid functions v_h. The operators $\mathcal{A}_h$ are defined between product spaces of grid functions. For us the cases $\mathcal{A}_h : H_h^1 \times H_h^1 \to H_h^{-1} \times H_h^{-1}$ and $\mathcal{A}_h : H_h^2 \times H_h^2 \to L_h^2 \times L_h^2$ are important. Here H_h^{-1} denotes the dual space of H_h^1 with L_h^2 as pivot space.

The family $\{\mathcal{A}_h\}_{h>0}$ is called H_h^1-regular if A_h is invertible and there exists a constant C_1 independent of h such that

$$||\mathcal{A}_h^{-1}||_{\mathcal{L}(H_h^{-1}\times H_h^{-1}, H_h^1 \times H_h^1)} \leq C_1,$$

and analogously it is called H_h^2-regular if

$$||\mathcal{A}_h^{-1}||_{\mathcal{L}(L_h^2\times L_h^2, H_h^2 \times H_h^2)} \leq C_2,$$

for C_2 independent of h.

LEMMA 3.2. *The family of operators $\{\mathcal{A}_h\}_{h>0}$, with h such that the boundaries of Ω are grid lines, is H_h^1-regular.*

Proof. Let $(v_h, w_h) \in \mathcal{M}_h$ be a pair of grid functions. Then

$$\begin{aligned}(\mathcal{A}_h(v_h,w_h),(v_h,w_h))_{L_h^2\times L_h^2} &= \nu(-\Delta_h v_h, v_h)_{L_h^2} + (-\Delta_h w_h, w_h)_{L_h^2}\\ &\geq \min(\nu,1)\, C \sum_{i=1}^{2}(|\partial_i^- v_h|_0^2 + |\partial_i^- w_h|_0^2),\end{aligned} \tag{3.6}$$

where C is independent of h and arises from the coercivity estimate for $-\Delta_h$, i.e.,

$$(-\Delta_h v_h, v_h)_{L_h^2} \geq C \sum_{i=1}^{2} |\partial_i^- v_h|_0^2 \qquad \text{for all } v_h; \tag{3.7}$$

see, e.g., [14, p. 231]. Using Poincaré inequality in (3.6) results in

$$(\mathcal{A}_h(v_h,w_h),(v_h,w_h))_{L_h^2\times L_h^2} \geq C_1^{-2}\,|(v_h,w_h)|^2_{H_h^1\times H_h^1} \qquad \text{for all } (v_h,w_h)\in L_h^2\times L_h^2,$$

with $C_1^{-2} = \min(\nu,1)\, C\, c_0$. Due to the Lax–Milgram lemma $\mathcal{A}_h$ is invertible. Moreover,

$$||\mathcal{A}_h^{-1}||_{\mathcal{L}(H_h^{-1}\times H_h^{-1}, H_h^1\times H_h^1)} \leq C_1 \qquad \text{for all } h. \qquad \square$$

The infinite dimensional analogue of $\mathcal{A}_h$ is the operator

$$\mathcal{A} = \begin{pmatrix} -\nu\,\Delta & -I \\ I & -\Delta \end{pmatrix}, \tag{3.8}$$

where Δ is understood with homogeneous Dirichlet boundary conditions. It is well defined from $H_0^1(\Omega)\times H_0^1(\Omega)$ to $H^{-1}(\Omega)\times H^{-1}(\Omega)$ as well as from $(H^2(\Omega)\cap H_0^1(\Omega))\times (H^2(\Omega)\cap H_0^1(\Omega))$ to $L^2(\Omega)\times L^2(\Omega)$. We have the following consistency result.

LEMMA 3.3. *There exists a constant C_K independent of h such that*

$$||\mathcal{A}_h R_h^2 - \tilde{R}_h^2 \mathcal{A}||_{\mathcal{L}((H^2\cap H_0^1)^2, (H_h^{-1}\times H_h^{-1}))} \leq C_K\, h.$$

Proof. Let $(v,w) \in (H^2(\Omega)\cap H_0^1(\Omega))^2$ and note that, due to the consistency property of $-\Delta_h$ as discretization of $-\Delta$, we have

$$\begin{aligned}&|\mathcal{A}_h R_h^2(v,w) - \tilde{R}_h^2\mathcal{A}(v,w)|^2_{H_h^{-1}\times H_h^{-1}}\\ &\quad\leq \nu\,|(-\Delta_h)R_h v - \tilde{R}_h(-\Delta)v|^2_{H_h^{-1}} + |(-\Delta_h)R_h w - \tilde{R}_h(-\Delta)w|^2_{H_h^{-1}}\\ &\qquad + |R_h v - \tilde{R}_h v|^2_{H_h^{-1}} + |R_h w - \tilde{R}_h w|^2_{H_h^{-1}}\\ &\qquad\leq C_K^2\, h^2\,|(v,w)|_{H^2(\Omega)^2};\end{aligned}$$

see [14, p. 232]. $\square$

THEOREM 3.4. *There exists a constant K_1, depending on Ω, g, z, and independent of h, such that*

$$|y_h^* - R_h y^*|_1 + |u_h^* - R_h u^*|_1 + |\lambda_h^* - R_h\lambda^*|_1 \leq K_1\, h.$$

Proof. From (2.6) and (3.4) we have

$$(y_h^*, \lambda_h^*) - R_h^2\,(y^*, \lambda^*) = \mathcal{A}_h^{-1}(\tilde{R}_h^2 \mathcal{A} - \mathcal{A}_h R_h^2)\,(y^*, \lambda^*). \tag{3.9}$$

Lemmas 3.2 and 3.3 imply the existence of $\bar{K}_1$ such that

$$|y_h^* - R_h y^*|_1 + |\lambda_h^* - R_h \lambda^*|_1 \le \bar{K}_1 h.$$

Using $\nu\, u^* = \lambda^*$ and its discrete analogue, we have the following claim. ∎

Remark 1. In the case of a general convex domain attention must be paid to the discretization of $-\Delta$ along the boundary. The literature offers several options. For the Shortley–Weller discretization, as described in [14, p. 78], $-\Delta_h$ is H_h^1-regular and consistent with $-\Delta$ from $H^2(\Omega)$ to H_h^{-1}. Using these facts the generalization of Theorem 3.4 to convex domains is straightforward.

In the following result the assumption that the boundaries of Ω coincide with grid lines is used.

THEOREM 3.5. *There exists a constant K_2, depending on Ω, g, z, and independent of h, such that*

$$|y_h^* - R_h y^*|_0 + |u_h^* - R_h u^*|_0 + |\lambda_h^* - R_h \lambda^*|_0 \le K_2\, h^2.$$

Proof. We start by showing that $\mathcal{A}_h^T$ is H_h^2-regular. For this purpose it suffices to show the existence of a constant C_2 independent of h such that for all $(f_h, g_h) \in L_h^2 \times L_h^2$

$$|(v_h, w_h)|_{H_h^2 \times H_h^2} \le C_2\, |(f_h, g_h)|_{L_h^2 \times L_h^2}, \tag{3.10}$$

where $\mathcal{A}_h^T(v_h, w_h) = (f_h, g_h)$. Proceeding as in Lemma 3.2 one shows that $\mathcal{A}_h^T$ is H_h^1-regular. In particular, there exists $\tilde{C}_2 \ge 1$, independent of h, such that

$$|(v_h, w_h)|_{H_h^1 \times H_h^1} \le \tilde{C}_2\, |(f_h, g_h)|_{L_h^2 \times L_h^2}. \tag{3.11}$$

Since $-\Delta_h$ is H_h^2-regular [14, p. 242], $\tilde{C}_2$ can also be chosen such that

$$||(-\Delta_h)^{-1}||_{\mathcal{L}(L_h^2, H_h^2)} \le \tilde{C}_2. \tag{3.12}$$

Note that v_h satisfies $\nu\, v_h = (-\Delta_h)^{-1}(f_h - w_h)$. Hence by (3.11) and (3.12)

$$|v_h|_{H_h^2} \le \frac{2}{\nu}\, \tilde{C}_2^2\, |(f_h, g_h)|_{L_h^2 \times L_h^2}. \tag{3.13}$$

Similarly $w_h = (-\Delta_h)^{-1}(g_h + v_h)$ and hence

$$|w_h|_{H_h^2} \le 2\, \tilde{C}_2^2\, |(f_h, g_h)|_{L_h^2 \times L_h^2}. \tag{3.14}$$

Combining (3.13) and (3.14) we have (3.10). From (3.10) it follows by duality that

$$||\mathcal{A}_h^{-1}||_{\mathcal{L}(H_h^{-2} \times H_h^{-2}, L_h^2 \times L_h^2)} \le C_2. \tag{3.15}$$

Turning to consistency, due to the assumption that the boundary of Ω coincides with grid lines, we have

$$||(-\Delta_h) R_h - \tilde{R}_h(-\Delta)||_{\mathcal{L}(H^2, H_h^{-2})} \le K\, h^2, \tag{3.16}$$

$$||R_h - \tilde{R}_h||_{\mathcal{L}(H^2, L_h^2)} \le K\, h^2, \tag{3.17}$$

for a constant K independent of h. Estimate (3.16) is given in [14, p. 239] and (3.17) follows from a direct computation. From (3.9) and (3.16) we have

$$|(y_h^*, \lambda_h^*) - R_h^2 (y^*, \lambda^*)|_{L_h^2 \times L_h^2} \leq C_2 \, |(\tilde{R}_h^2 \mathcal{A} - \mathcal{A}_h R_h^2)(y^*, \lambda^*)|_{H_h^{-2} \times H_h^{-2}}. \tag{3.18}$$

Using (3.16) and (3.17), we proceed as in the proof of Lemma 3.3 to obtain the desired result. □

The approximation results stated in Theorem 3.5 are demonstrated in numerical experiments with global mesh refinement (multigrid); see [2].

4. The multigrid method. Multigrid methods have been extensively used to solve discretized partial differential equations; see, e.g., [21] and the references given there. This fact has motivated intensive research towards the determination of convergence properties of multigrid schemes; see [5, 6, 9, 10, 11, 14, 15]. Multigrid methods have also been used to solve optimal control problems. Most of these contributions except for [12] are rather recent, e.g., [1, 2, 3, 4, 19]. Concerning the convergence theory of multigrid applied to systems of partial differential equations and, in particular, to optimality systems, the theory is far from being complete.

The purpose of the present work is to analyze a multigrid algorithm that solves the optimality system (2.6) with typical multigrid efficiency. We briefly describe the multigrid framework to keep this paper self-contained. Let us index the operators and variables defined on the grid with mesh size $h = h_k = 1/2^k$, $k = 1, \ldots, L$, with the index k, and for simplicity of presentation let us introduce vector notation: we let $\mathbf{w} = (u, v)$ and $|\mathbf{w}|_0 = |(u, v)|_0$, etc.

Consider the discrete problem (3.4) expressed as

$$\mathcal{A}_k \boldsymbol{\phi}_k = \mathbf{f}_k \text{ on } \Omega_k, \tag{4.1}$$

where $\boldsymbol{\phi}_k = (y_k, \lambda_k)$ and $\mathbf{f}_k = (g_k, z_k)$ are defined on the mesh Ω_{h_k}.

For the purpose of multigrid methods it is important to utilize the fact that the solution of (4.1) is equivalent to solve $\mathcal{A}_k \boldsymbol{\phi}_k^e = \mathbf{r}_k$, where $\boldsymbol{\phi}_k^e = \bar{\boldsymbol{\phi}}_k - \boldsymbol{\phi}_k$ is the error grid function between the solution $\bar{\boldsymbol{\phi}}_k$ to (4.1) and its current approximation $\boldsymbol{\phi}_k$, and $\mathbf{r}_k$ is the residual defined by

$$\mathbf{r}_k = \mathbf{f}_k - \mathcal{A}_k \boldsymbol{\phi}_k. \tag{4.2}$$

In fact, the multigrid strategy is to solve for all frequency components of the error using multiple grids.

On the grid of level k, a smoothing procedure is applied in order to solve for the high-frequency components of the error. This is an iterative scheme denoted by $\boldsymbol{\phi}_k^{(m)} = (\mathcal{S}_k)^m (\boldsymbol{\phi}_k, \mathbf{f}_k)$, where $(\mathcal{S}_k)^m$ is a linear smoothing operator applied m times. One sweep of this iteration is written in the form $\boldsymbol{\phi}_k^{(m)} = \boldsymbol{\phi}_k^{(m-1)} + \mathcal{R}_k (\mathbf{f}_k - \mathcal{A}_k \boldsymbol{\phi}_k^{(m-1)})$, where the operator $\mathcal{R}_k$ applies to the residual.

To correct for the smooth components of the error, a coarse grid correction (CGC) is defined. For this purpose a coarse grid problem for the error function is constructed on the grid with mesh size h_{k-1}:

$$\mathcal{A}_{k-1} \boldsymbol{\phi}_{k-1} = \mathcal{I}_k^{k-1} \mathbf{r}_k, \tag{4.3}$$

where $\boldsymbol{\phi}_{k-1}$ aims to represent, on the coarse grid Ω_{k-1}, the error $\boldsymbol{\phi}_k^e$ on the next finer grid. Because of Dirichlet boundary conditions, we have $\boldsymbol{\phi}_{k-1} = 0$ at the boundary.

The operator $\mathcal{I}_k^{k-1} : \mathcal{M}_k \to \mathcal{M}_{k-1}$ restricts the residual computed at level k to the grid with level $k-1$.

Once the coarse grid problem is solved, the CGC follows:

$$\boldsymbol{\phi}_k^{new} = \boldsymbol{\phi}_k + \mathcal{I}_{k-1}^k \, \boldsymbol{\phi}_{k-1}, \tag{4.4}$$

where $\mathcal{I}_{k-1}^k : \mathcal{M}_{k-1} \to \mathcal{M}_k$ is an interpolation operator. Here $\boldsymbol{\phi}_k$ represents the current approximation at level k as it was obtained by the smoothing process and before coarsening. If the high-frequency components of the error on the finer grid k were well damped, then the solution at level $\boldsymbol{\phi}_{k-1}$ should provide enough resolution for the error of $\boldsymbol{\phi}_k$ through $\mathcal{I}_{k-1}^k \boldsymbol{\phi}_{k-1}$.

The idea of transferring to a coarser grid can be applied along the set of nested meshes. One starts at level k with a given initial approximation (zero) and applies the smoothing iteration m_1 times. The residual is then computed and transferred to the next coarser grid while $\boldsymbol{\phi}_k$ obtained by smoothing is left unchanged. On the coarse grid with index $k-1$ the smoothing process is again applied. This procedure is repeated until the coarsest grid is reached.

On the coarsest grid, one solves the problem exactly and the result is used to improve $\boldsymbol{\phi}_k$ via (4.4). The CGC is then followed by m_2 postsmoothing steps at level k before the CGC procedure followed by postsmoothing is repeated for the next (if any) finer level. This entire process represents one multigrid $V(m_1, m_2)$-cycle.

A compact description of the multigrid method is given in section 6.

In the following sections we specify and analyze the multigrid components introduced here.

4.1. Smoothing iterations. Numerical experience [2] has shown that in order to obtain a multigrid algorithm which is robust with respect to changes of ν, care must be taken in the choice of the smoother. For example, when using the Picard–Gauss–Seidel iteration [1, 2], difficulties arise when the value of the weight of the cost of the control is smaller than h^2, which may easily occur when coarse grids are used. On the other hand, the collective Gauss–Seidel (CGS) scheme appears to be a reasonable choice [2]. Notice that this iterative method belongs to the class of Vanka smoothers [22].

To analyze the CGS scheme, let us introduce some notation:

$$\mathcal{A}_h^+ = \begin{bmatrix} \nu\,\Sigma_h^+ & 0 \\ 0 & \Sigma_h^+ \end{bmatrix}, \quad \mathcal{A}_h^- = \begin{bmatrix} \nu\,\Sigma_h^- & 0 \\ 0 & \Sigma_h^- \end{bmatrix}, \quad \mathcal{D}_h = \begin{bmatrix} \nu\,\frac{4}{h^2} I_h & -I_h \\ I_h & \frac{4}{h^2} I_h \end{bmatrix}, \tag{4.5}$$

where I_h is the identity operator on Ω_h and the operators Σ_h^+ and Σ_h^- are given in stencil form by

$$\Sigma_h^+ = \frac{1}{h^2} \begin{bmatrix} 0 & 0 & 0 \\ 1 & 0 & 0 \\ 0 & 1 & 0 \end{bmatrix}, \qquad \Sigma_h^- = \frac{1}{h^2} \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 0 & 0 & 0 \end{bmatrix}. \tag{4.6}$$

Thus a sweep of the forward CGS scheme and of a backward CGS scheme are expressed by

$$(\mathcal{D}_h - \mathcal{A}_h^+)\,\boldsymbol{\phi}^{(1)} - \mathcal{A}_h^-\,\boldsymbol{\phi}^{(0)} = \mathbf{f} \quad \text{and} \quad (\mathcal{D}_h - \mathcal{A}_h^-)\,\boldsymbol{\phi}^{(2)} - \mathcal{A}_h^+\,\boldsymbol{\phi}^{(1)} = \mathbf{f}, \tag{4.7}$$

respectively. In the symmetric version of the CGS smoother, the forward CGS step is followed by a backward CGS step. The resulting iteration can be written in the

linear form

$$\boldsymbol{\phi}^{(2)} = \boldsymbol{\phi}^{(0)} + \mathcal{R}_h\,[f_h - \mathcal{A}_h \boldsymbol{\phi}^{(0)}], \qquad \text{where } \mathcal{R}_h = (\mathcal{D}_h - \mathcal{A}_h^-)^{-1}\,\mathcal{D}_h\,(\mathcal{D}_h - \mathcal{A}_h^+)^{-1},$$

which gives the smoothing operator $\mathcal{S}_h = I_h - \mathcal{R}_h\,\mathcal{A}_h$.

We analyze this iteration by local Fourier analysis [10, 21]. Consider the Fourier space spanned by the functions

$$\boldsymbol{\phi}(\boldsymbol{\theta}, \mathbf{x}) = \mathbf{a}\, e^{i\theta_1 x/h}\, e^{i\theta_2 y/h}, \qquad \boldsymbol{\theta} = (\theta_1, \theta_2),$$

where $\mathbf{a} = (1,1)^T$. One defines

$$\begin{aligned} \boldsymbol{\phi} \text{ low-frequency component } &\iff \boldsymbol{\theta} \in [-\frac{\pi}{2}, \frac{\pi}{2})^2, \\ \boldsymbol{\phi} \text{ high-frequency component } &\iff \boldsymbol{\theta} \in [-\pi, \pi)^2 \setminus [-\frac{\pi}{2}, \frac{\pi}{2})^2. \end{aligned}$$

In the Fourier space consider the symbols of the discrete operators $(\mathcal{D}_h - \mathcal{A}_h^+)$ and $\mathcal{A}_h^-$ for the forward CGS iteration. We have

$$\overline{(\mathcal{D}_h - \mathcal{A}_h^+)}(\boldsymbol{\theta}) = -\frac{1}{h^2}\begin{bmatrix} \nu\,(e^{-i\theta_1} + e^{-i\theta_2} - 4) & h^2 \\ -h^2 & (e^{-i\theta_1} + e^{-i\theta_2} - 4) \end{bmatrix}, \tag{4.8}$$

$$\overline{(\mathcal{A}_h^-)}(\boldsymbol{\theta}) = -\frac{1}{h^2}\begin{bmatrix} \nu\,(e^{i\theta_1} + e^{i\theta_2}) & 0 \\ 0 & (e^{i\theta_1} + e^{i\theta_2}) \end{bmatrix}. \tag{4.9}$$

Thus, the symbol of the forward CGS scheme is given by

$$\overline{\mathcal{S}_h^+}(\boldsymbol{\theta}) = (\overline{(\mathcal{D}_h - \mathcal{A}_h^+)}(\boldsymbol{\theta}))^{-1}\,\overline{(\mathcal{A}_h^-)}(\boldsymbol{\theta}).$$

In this framework, the smoothing factor of the forward CGS scheme for the optimality system is defined by

$$\mu = \mu(\mathcal{S}_h^+) = \sup\{|\rho(\overline{\mathcal{S}_h^+}(\boldsymbol{\theta}))| : \boldsymbol{\theta} \text{ high frequency }\}, \tag{4.10}$$

where ρ denotes the spectral radius. In the same way one defines the smoothing factor for the backward CGS step: $\mathcal{S}_h^- = (\mathcal{D}_h - \mathcal{A}_h^-)^{-1}\,(\mathcal{A}_h^+)$. The symmetric CGS scheme is then given by $\mathcal{S}_h^s = \mathcal{S}_h^-\,\mathcal{S}_h^+$. Since the symbols associated with the CGS iterative schemes considered here are 2×2 operators with entries being functions of (θ_1, θ_2), it is possible, by any symbolical package, to obtain the eigenvalues of the symbols. Thus we have the following.

Remark 2. By inspection in the range of high frequencies for $h \in [0.01, 0.25]$ and ν ranging in the interval $[10^{-6}, 1]$, the following upper bounds for the smoothing factor are found:

$$\mu(\mathcal{S}_h^+) \le 0.5, \quad \mu(\mathcal{S}_h^-) \le 0.5, \quad \text{and } \mu(\mathcal{S}_h^s) \le 0.25.$$

Therefore, we can conclude that the forward CGS, the backward CGS, and the symmetric CGS are all good smoothers for the purpose of the multigrid scheme.

4.2. Intergrid transfer operators. Among two grids $\overline{\Omega}_k$ and $\overline{\Omega}_{k-1}$, corresponding to mesh sizes h_k and h_{k-1}, we define a prolongation operator, $I_{k-1}^k : M_{k-1} \to M_k$, given in stencil form by

$$I_{k-1}^k = \frac{1}{4}\begin{bmatrix} 1 & 2 & 1 \\ 2 & 4 & 2 \\ 1 & 2 & 1 \end{bmatrix}. \tag{4.11}$$

This choice is consistent with the assumption of *bilinear* finite elements on each square partition of the discretization. That is, on each square partition $[x_i, x_{i+1}] \times [y_j, y_{j+1}]$ of $\overline{\Omega}_{k-1}$, the piecewise bilinear function which interpolates U at the nodes is given by

$$\tilde{u}(\tilde{x}, \tilde{y}) = (1-\tilde{x})(1-\tilde{y})\, u_{ij} + \tilde{x}(1-\tilde{y})\, u_{i+1\,j} + \tilde{y}(1-\tilde{x})\, u_{ij+1} + \tilde{x}\tilde{y}\, u_{i+1\,j+1}.$$

Here, $0 \le \tilde{x}, \tilde{y} \le 1$ are local coordinates such that $x = x_i + \tilde{x}\, h_{k-1}$ and $y = y_j + \tilde{y}\, h_{k-1}$. Thus the prolongation of u on a grid point of $\overline{\Omega}_k$ is the value of $\tilde{u}$ corresponding to that grid point.

Next, we define the full-weighting restriction operator, $I_k^{k-1} : M_k \to M_{k-1}$, given in stencil form by

$$I_k^{k-1} = \frac{1}{16}\begin{bmatrix} 1 & 2 & 1 \\ 2 & 4 & 2 \\ 1 & 2 & 1 \end{bmatrix}, \tag{4.12}$$

with the inner product

$$(v, w)_k = \sum_{i=2}^{N_k} \sum_{j=2}^{N_k} h_k^2\, v_{kij}\, w_{kij}, \tag{4.13}$$

where $N_k = 2^k$. We have that the restriction operator is the adjoint of the prolongation operator [13], in the sense that

$$(I_k^{k-1} v_k, w_{k-1})_{k-1} = (v_k, I_{k-1}^k w_{k-1})_k \quad \text{for all } v_k \in M_k,\ w_{k-1} \in M_{k-1}.$$

The action of I_{k-1}^k (resp., I_k^{k-1}) on pairs of grid functions is denoted by $\mathcal{I}_{k-1}^k$ (resp., $\mathcal{I}_k^{k-1}$).

In order to extend the multigrid convergence theory formulated in [9, 15, 6] to the present multigrid method for optimality systems, we need the following lemma [9].

LEMMA 4.1. *Let us introduce the bilinear form* $a_k(u, v) = (-\Delta_k u, v)_k$, $u, v \in M_k$. *The prolongation operator* (4.11) *satisfies the following conditions:*

$$a_k(I_{k-1}^k u_{k-1}, I_{k-1}^k u_{k-1}) \le a_{k-1}(u_{k-1}, u_{k-1}) \qquad \textit{for all } u_{k-1} \in M_{k-1}, \tag{4.14}$$

$$(I_{k-1}^k u_{k-1}, I_{k-1}^k u_{k-1})_k \le (u_{k-1}, u_{k-1})_{k-1} \qquad \textit{for all } u_{k-1} \in M_{k-1}. \tag{4.15}$$

In particular, the result of Lemma 4.1 applied to the operator (3.5) results in the following:

$$(\mathcal{A}_k\, \mathcal{I}_{k-1}^k \mathbf{w}_{k-1}, \mathcal{I}_{k-1}^k \mathbf{w}_{k-1})_k \le (\mathcal{A}_{k-1} \mathbf{w}_{k-1}, \mathbf{w}_{k-1})_{k-1} \tag{4.16}$$

for all $\mathbf{w}_{k-1} = (u_{k-1}, v_{k-1}) \in \mathcal{M}_{k-1}$.

5. Two grid local Fourier analysis. In this section we perform local Fourier analysis [10, 21] of the two grid solution process for the optimal control optimality system. That is, we apply the local Fourier analysis to the two grid operator given by

$$TG_k^{k-1} = \mathcal{S}_k^{m_2} \left[\mathcal{I}_k - \mathcal{I}_{k-1}^k \left(\mathcal{A}_{k-1}\right)^{-1} \mathcal{I}_k^{k-1} \mathcal{A}_k\right] \mathcal{S}_k^{m_1}. \tag{5.1}$$

Here, the coarse grid operator is $CG_k^{k-1} = [\mathcal{I}_k - \mathcal{I}_{k-1}^k \left(\mathcal{A}_{k-1}\right)^{-1} \mathcal{I}_k^{k-1} \mathcal{A}_k]$.

The local Fourier analysis considers infinite grids, $G_k = \{(ih_k, jh_k), i, j \in \mathbb{Z}\}$, and therefore the influence of boundary conditions is not taken into account. Nevertheless, experience shows that local Fourier analysis provides predictions of multigrid convergence which are very sharp. This analysis is based on the quadruples of Fourier components

$$\phi_k(\boldsymbol{\theta}, \mathbf{x}) = e^{i\theta_1 x/h_k}\, e^{i\theta_2 y/h_k}$$

that coincide on G_{k-1}. For any low frequency $\boldsymbol{\theta} = (\theta_1, \theta_2) \in [-\pi/2, \pi/2)^2$, we consider

$$\begin{aligned} \boldsymbol{\theta}^{(0,0)} &:= (\theta_1, \theta_2), \qquad & \boldsymbol{\theta}^{(1,1)} &:= (\overline{\theta_1}, \overline{\theta_2}), \\ \boldsymbol{\theta}^{(1,0)} &:= (\overline{\theta_1}, \theta_2), \qquad & \boldsymbol{\theta}^{(0,1)} &:= (\theta_1, \overline{\theta_2}), \end{aligned}$$

where

$$\overline{\theta_i} = \begin{cases} \theta_i + \pi \text{ if } \theta_i < 0, \\ \theta_i - \pi \text{ if } \theta_i \geq 0. \end{cases}$$

We have $\phi(\boldsymbol{\theta}^{(0,0)}, \cdot) = \phi(\boldsymbol{\theta}^{(1,1)}, \cdot) = \phi(\boldsymbol{\theta}^{(1,0)}, \cdot) = \phi(\boldsymbol{\theta}^{(0,1)}, \cdot)$ for $\boldsymbol{\theta}^{(0,0)} \in [-\pi/2, \pi/2)^2$ and $(x, y) \in G_{k-1}$. Denote with $\boldsymbol{\alpha} = (\alpha_1, \alpha_2)$ and consider $\boldsymbol{\alpha} \in \{(0,0), (1,1), (1,0), (0,1)\}$; then on G_{k-1} we have $\phi_k(\boldsymbol{\theta}^{\boldsymbol{\alpha}}, \mathbf{x}) = \phi_{k-1}(2\boldsymbol{\theta}^{(0,0)}, \mathbf{x})$. The four components $\phi_k(\boldsymbol{\theta}^{\boldsymbol{\alpha}}, \cdot)$ are called harmonics. For a given $\boldsymbol{\theta} = \boldsymbol{\theta}^{(0,0)} \in [-\pi/2, \pi/2)^2$, the four dimensional space of harmonics is defined by

$$E_k^\theta = span[\phi_k(\boldsymbol{\theta}^{\boldsymbol{\alpha}}, \cdot) : \boldsymbol{\alpha} \in \{(0,0), (1,1), (1,0), (0,1)\}].$$

For each θ, the spaces $E_k^\theta \times E_k^\theta$ are invariant under the action of TG_k^{k-1}; see [21]. We now study the action of TG_k^{k-1} on an arbitrary couple $(\psi_y, \psi_\lambda) \in E_k^\theta \times E_k^\theta$, where

$$\psi_y = \sum_{\boldsymbol{\alpha}} A^{\boldsymbol{\alpha}}\, \phi_k(\boldsymbol{\theta}^{\boldsymbol{\alpha}}, \cdot) \quad \text{ and } \quad \psi_\lambda = \sum_{\boldsymbol{\alpha}} B^{\boldsymbol{\alpha}}\, \phi_k(\boldsymbol{\theta}^{\boldsymbol{\alpha}}, \cdot).$$

We analyze how the vector of coefficients $(A^{(0,0)}, \dots, B^{(0,0)}, \dots)$ is transformed if the two grid iteration (5.1) is applied to (ψ_y, ψ_λ). We use the following theorem, which is an extension of Theorem 4.4.1 of [21] to our system of equations.

THEOREM 5.1. *Under the assumption that all multigrid components in* (5.1) *are linear and that* $(\mathcal{A}_{k-1})^{-1}$ *exists, the coarse grid operator* CG_k^{k-1} *is represented on* E_k^θ *by the* 8×8 *matrix* $\widehat{CG}_k^{k-1}(\boldsymbol{\theta})$,

$$\widehat{CG}_k^{k-1}(\boldsymbol{\theta}) = [\hat{\mathcal{I}}_k - \hat{\mathcal{I}}_{k-1}^k(\boldsymbol{\theta}) \left(\widehat{\mathcal{A}}_{k-1}(2\boldsymbol{\theta})\right)^{-1} \hat{\mathcal{I}}_k^{k-1}(\boldsymbol{\theta})\, \widehat{\mathcal{A}}_k(\boldsymbol{\theta})],$$

for each $\boldsymbol{\theta} \in [-\pi/2, \pi/2)^2$. *Here,* $\hat{\mathcal{I}}_k$ *and* $\widehat{\mathcal{A}}_k(\boldsymbol{\theta})$ *are* 8×8 *matrices,* $\hat{\mathcal{I}}_k^{k-1}(\boldsymbol{\theta})$ *is a* 2×8 *matrix,* $\hat{\mathcal{I}}_{k-1}^k(\boldsymbol{\theta})$ *is a* 8×2 *matrix, and* $\widehat{\mathcal{A}}_{k-1}(2\boldsymbol{\theta})$ *is a* 2×2 *matrix.*

If the spaces $E_k^\theta \times E_k^\theta$ are invariant under the smoothing operator $\mathcal{S}_k$, i.e., (the 8×8 matrix) $\hat{\mathcal{S}}_k(\boldsymbol{\theta}) : E_k^\theta \times E_k^\theta \to E_k^\theta \times E_k^\theta$ for all $\boldsymbol{\theta} \in [-\pi/2, \pi/2)^2$, we also have a representation of TG_k^{k-1} on $E_k^\theta \times E_k^\theta$ by a 8×8 matrix given by

$$\widehat{TG}_k^{k-1}(\boldsymbol{\theta}) = \hat{\mathcal{S}}_k(\boldsymbol{\theta})^{m_2}\, \widehat{CG}_k^{k-1}(\boldsymbol{\theta})\, \hat{\mathcal{S}}_k(\boldsymbol{\theta})^{m_1}.$$

We now give the symbols of the operators above in explicit form.

The coarse grid operator $\mathcal{A}_{k-1}$ is

$$\widehat{\mathcal{A}}_{k-1}(2\boldsymbol{\theta}) = \begin{bmatrix} \nu\, \frac{4-2(\cos(2\theta_1)+\cos(2\theta_2))}{h_{k-1}^2} & -1 \\ 1 & \frac{4-2(\cos(2\theta_1)+\cos(2\theta_2))}{h_{k-1}^2} \end{bmatrix}.$$

The fine grid operator is $\mathcal{A}_k$. The symbol $\widehat{\mathcal{A}}_k(\boldsymbol{\theta})$ is given by

$$\begin{bmatrix} \nu\, l(\boldsymbol{\theta}^{(0,0)}) & 0 & 0 & 0 & -1 & 0 & 0 & 0 \\ 0 & \nu\, l(\boldsymbol{\theta}^{(1,1)}) & 0 & 0 & 0 & -1 & 0 & 0 \\ 0 & 0 & \nu\, l(\boldsymbol{\theta}^{(1,0)}) & 0 & 0 & 0 & -1 & 0 \\ 0 & 0 & 0 & \nu\, l(\boldsymbol{\theta}^{(0,1)}) & 0 & 0 & 0 & -1 \\ 1 & 0 & 0 & 0 & l(\boldsymbol{\theta}^{(0,0)}) & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 & l(\boldsymbol{\theta}^{(1,1)}) & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 & l(\boldsymbol{\theta}^{(1,0)}) & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 & 0 & l(\boldsymbol{\theta}^{(0,1)}) \end{bmatrix},$$

where

$$l(\boldsymbol{\theta}^{\boldsymbol{\alpha}}) = \frac{4 - 2(\cos(\theta_1^{\alpha_1}) + \cos(\theta_2^{\alpha_2}))}{h_k^2}.$$

The restriction operator is $\mathcal{I}_k^{k-1}$. The symbol $\hat{\mathcal{I}}_k^{k-1}(\boldsymbol{\theta})$ is given by

$$\begin{bmatrix} I(\boldsymbol{\theta}^{(0,0)}) & I(\boldsymbol{\theta}^{(1,1)}) & I(\boldsymbol{\theta}^{(1,0)}) & I(\boldsymbol{\theta}^{(0,1)}) & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & I(\boldsymbol{\theta}^{(0,0)}) & I(\boldsymbol{\theta}^{(1,1)}) & I(\boldsymbol{\theta}^{(1,0)}) & I(\boldsymbol{\theta}^{(0,1)}) \end{bmatrix},$$

where

$$I(\boldsymbol{\theta}^{\boldsymbol{\alpha}}) = I_k^{k-1}(\boldsymbol{\theta}^{\boldsymbol{\alpha}}) = \frac{1}{4}(1 + \cos(\theta_1^{\alpha_1}))(1 + \cos(\theta_2^{\alpha_2})).$$

For the prolongation operator we have $\hat{\mathcal{I}}_{k-1}^k(\boldsymbol{\theta}) = \hat{\mathcal{I}}_k^{k-1}(\boldsymbol{\theta})^T$.

For the smoothing iteration $\mathcal{S}_k$ consider the forward CGS scheme as described in section 4.1. On $E_k^\theta \times E_k^\theta$ it is given by $(\overline{(\mathcal{D}_h - \mathcal{A}_h^+)}(\boldsymbol{\theta}))^{-1}\, \overline{(\mathcal{A}_h^-)}(\boldsymbol{\theta})$, where $(\overline{(\mathcal{D}_h - \mathcal{A}_h^+)}(\boldsymbol{\theta}))$ is as follows:

$$\frac{1}{h^2}\begin{bmatrix} \nu\, s_+(\boldsymbol{\theta}^{(0,0)}) & 0 & 0 & 0 & -h^2 & 0 & 0 & 0 \\ 0 & \nu\, s_+(\boldsymbol{\theta}^{(1,1)}) & 0 & 0 & 0 & -h^2 & 0 & 0 \\ 0 & 0 & \nu\, s_+(\boldsymbol{\theta}^{(1,0)}) & 0 & 0 & 0 & -h^2 & 0 \\ 0 & 0 & 0 & \nu\, s_+(\boldsymbol{\theta}^{(0,1)}) & 0 & 0 & 0 & -h^2 \\ h^2 & 0 & 0 & 0 & s_+(\boldsymbol{\theta}^{(0,0)}) & 0 & 0 & 0 \\ 0 & h^2 & 0 & 0 & 0 & s_+(\boldsymbol{\theta}^{(1,1)}) & 0 & 0 \\ 0 & 0 & h^2 & 0 & 0 & 0 & s_+(\boldsymbol{\theta}^{(1,0)}) & 0 \\ 0 & 0 & 0 & h^2 & 0 & 0 & 0 & s_+(\boldsymbol{\theta}^{(0,1)}) \end{bmatrix},$$

and the operator $\overline{(\mathcal{A}_h^-)}(\boldsymbol{\theta})$ is given by

$$\frac{1}{h^2}\begin{bmatrix} \nu\, s_-(\boldsymbol{\theta}^{(0,0)}) & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & \nu\, s_-(\boldsymbol{\theta}^{(1,1)}) & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & \nu\, s_-(\boldsymbol{\theta}^{(1,0)}) & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & \nu\, s_-(\boldsymbol{\theta}^{(0,1)}) & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & s_-(\boldsymbol{\theta}^{(0,0)}) & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & s_-(\boldsymbol{\theta}^{(1,1)}) & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & s_-(\boldsymbol{\theta}^{(1,0)}) & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & s_-(\boldsymbol{\theta}^{(0,1)}) \end{bmatrix},$$

TABLE 5.1
Convergence factors and smoothing factors.

	Local Fourier analysis		Experim.
(m_1, m_2)	$\mu_{loc}^{m_1+m_2}$	$\eta(TG_k^{k-1})$	$V(m_1, m_2)$
(1,1)	0.25	0.25	0.30
(2,1)	0.125	0.12	0.12
(2,2)	0.06	0.08	0.08
(3,2)	0.03	0.06	0.06
(3,3)	0.01	0.05	0.05

where

$$s_+(\boldsymbol{\theta}^{\boldsymbol{\alpha}}) = 4 - e^{-i\theta_1^{\alpha_1}} - e^{-i\theta_2^{\alpha_2}} \quad \text{and} \quad s_-(\boldsymbol{\theta}^{\boldsymbol{\alpha}}) = -e^{i\theta_1^{\alpha_1}} - e^{i\theta_2^{\alpha_2}}.$$

Based on the representation on TG_k^{k-1} by a 8×8 matrix $\widehat{TG}_k^{k-1}(\boldsymbol{\theta})$, we can calculate the *convergence factor*:

$$\eta(TG_k^{k-1}) = \sup\{\rho(\widehat{TG}_k^{k-1}(\boldsymbol{\theta})) : \boldsymbol{\theta} \in [-\pi/2, \pi/2)^2\}.$$

Here, $\rho(\widehat{TG}_k^{k-1}(\boldsymbol{\theta}))$ is the spectral radius of $\widehat{TG}_k^{k-1}(\boldsymbol{\theta})$.

Under the invariance property advocated by Theorem 5.1, to measure the smoothing property of the iteration one can assume an *ideal coarse grid correction* which annihilates the low-frequency error components and leaves the high-frequency error components unchanged. That is, one defines the projection operator Q_k^{k-1} on E_k^θ by

$$Q_k^{k-1}\,\phi(\boldsymbol{\theta}, \cdot) = \begin{cases} 0 \text{ if } \boldsymbol{\theta} = \boldsymbol{\theta}^{(0,0)} \in [-\pi/2, \pi/2)^2, \\ \phi(\boldsymbol{\theta}, \cdot) \text{ if } \boldsymbol{\theta} \in \{\boldsymbol{\theta}^{(1,1)}, \boldsymbol{\theta}^{(1,0)}, \boldsymbol{\theta}^{(0,1)}\}. \end{cases}$$

On the space $E_k^\theta \times E_k^\theta$ we then have

$$\widehat{Q}_k^{k-1}(\boldsymbol{\theta}) = \begin{bmatrix} Q_k^{k-1} & 0 \\ 0 & Q_k^{k-1} \end{bmatrix} \qquad \text{for } \boldsymbol{\theta} \in [-\pi/2, \pi/2)^2. \tag{5.2}$$

In this framework the smoothing property of $\mathcal{S}_k$ is defined as follows:

$$\mu_{loc} = \mu(\mathcal{S}_k, m) = \sup\left\{ \sqrt[m]{|\rho(\widehat{Q}_k^{k-1}\,\hat{\mathcal{S}}_k(\boldsymbol{\theta})^m)|} : \boldsymbol{\theta} \in [-\pi/2, \pi/2)^2 \right\}. \tag{5.3}$$

Notice that, assuming an ideal CGC takes place, the convergence factor of the two grid scheme is given by $\mu_{loc}^{m_1+m_2}$.

We complete this section by reporting in Table 5.1 the values of $\eta(TG_k^{k-1})$ and those of $\mu(\mathcal{S}_k, m)$ obtained with the two grid analysis described above. Here the forward Gauss–Seidel smoother is used. For comparison, the observed value of convergence factor defined as the "asymptotic" value of the ratio between the discrete L^2 norms of residuals resulting from two successive multigrid cycles on the finest mesh is reported. Notice that the values reported in Table 5.1 are typical of the standard Poisson model problem. These values have been obtained considering the mesh size value h ranging in the interval $[0.01, 0.25]$ corresponding to the interval of mesh sizes used in the multigrid code. The value of the weight ν has been taken in the interval $[10^{-6}, 1]$.

6. General multigrid convergence theory. In this section, we prove multigrid convergence for the optimal control problem in a more general functional setting. We use the framework in [6, 9, 11] adapted to the nonsymmetric system above. This framework applies directly to elliptic problems with prescribed boundary conditions on bounded polygonal domains.

For the purpose of our analysis, we briefly describe multigrid convergence theory for scalar Poisson equation discretized by the finite difference method on a unit square. Consider

$$\begin{aligned} -\Delta y &= f \text{ in } \Omega, \\ y &= 0 \text{ on } \partial\Omega. \end{aligned} \tag{6.1}$$

The matrix form of this problem is

$$\hat{A}_k y_k = f_k. \tag{6.2}$$

Let $\hat{P}_{k-1} : M_k \to M_{k-1}$ (resp., $I_k^{k-1} : M_k \to M_{k-1}$) be the $\hat{A}_k$ (resp., L_k^2) projections defined by

$$(\hat{A}_{k-1}\hat{P}_{k-1}u, v)_{k-1} = (\hat{A}_k u, I_{k-1}^k v)_k \text{ (resp., } (I_k^{k-1}u, v)_{k-1} = (u, I_{k-1}^k v)_k)$$

for all $u \in M_k$ and $v \in M_{k-1}$. Let $\hat{R}_k : M_k \to M_k$ be an iteration operator. Then the V-cycle multigrid algorithm to solve (6.2) in recursive form is given as follows.

Multigrid Algorithm $V(m_1, m_2)$.

Set $\hat{B}_1 = \hat{A}_1^{-1}$. For $k \geq 2$ define $\hat{B}_k : M_k \to M_k$ in terms of $\hat{B}_{k-1}$ as follows. Let $g \in M_k$.

1. Set $y^0 = 0$.
2. Define y^l for $l = 1, \ldots, m_1$ by
$$y^l = y^{l-1} + \hat{R}_k(g - \hat{A}_k\, y^{l-1}).$$
3. Set $y^{m_1+1} = y^{m_1} + I_{k-1}^k q$, where
$$q = \hat{B}_{k-1} I_k^{k-1}(g - \hat{A}_k\, y^{m_1}).$$
4. Set $\hat{B}_k g = y^{m_1+m_2+1}$, where y^ℓ for $\ell = m_1 + 2, \ldots, m_1 + m_2 + 1$ is given by step 2 ($\hat{R}_k^t$ instead of $\hat{R}_k$).

For the purpose of analysis, we take $m_1 = 1$ and $m_2 = 0$.

From the definition of $\hat{P}_{k-1}$, we see that

$$I_k^{k-1}\hat{A}_k = \hat{A}_{k-1}\hat{P}_{k-1}.$$

Let $\hat{S}_k = I_k - \hat{R}_k\hat{A}_k$ for $k > 1$, where I_k denotes the identity on M_k. Then $\hat{S}_k\, y = y - y^1$. Now for $y \in M_k$, $k = 2, \ldots, L$, we have

$$\begin{aligned} (I_k - \hat{B}_k\hat{A}_k)\, y &= y - y^1 - I_{k-1}^k q \\ &= \hat{S}_k\, y - I_{k-1}^k \hat{B}_{k-1}\hat{A}_{k-1}\hat{P}_{k-1}\hat{S}_k\, y \\ &= [I_k - I_{k-1}^k \hat{B}_{k-1}\hat{A}_{k-1}\hat{P}_{k-1}]\, \hat{S}_k\, y \\ &= [(I_k - I_{k-1}^k\hat{P}_{k-1}) + I_{k-1}^k(I_{k-1} - \hat{B}_{k-1}\hat{A}_{k-1})\, \hat{P}_{k-1}]\hat{S}_k\, y. \end{aligned} \tag{6.3}$$

The convergence results of the multigrid method are expressed in terms of the error operators $\hat{E}_k := I_k - \hat{B}_k\hat{A}_k$ and $\hat{E} := \hat{E}_L$. In the following, let C denote a

generic constant independent of k that can have different values in different places, unless otherwise stated.

In order to prove convergence of the multigrid algorithm, the following two conditions are required. There exists a constant $\bar{C}_{\hat{R}}$ independent of y and k such that

$$\frac{|y|_0^2}{\mu(\hat{A}_k)} \leq \bar{C}_{\hat{R}}(\bar{\hat{R}}y, y) \quad \text{for all } y \in M_k, \tag{6.4}$$

where $\mu(\hat{A}_k)$ denotes the maximum eigenvalue of $\hat{A}_k$, $\bar{\hat{R}} = (I_k - \hat{S}_k^* \hat{S}_k)\,\hat{A}_k^{-1}$, $\hat{S}_k^* = I - \hat{R}_k^t \hat{A}_k$, and $*$ denotes adjoint with respect to the inner product $(\hat{A}_k \cdot, \cdot)$. Next, for $k > 1$ define $\hat{T}_k = \hat{R}_k \hat{A}_k$. We assume that there exists a constant θ, $0 < \theta < 2$, independent of y such that

$$(\hat{A}_k \hat{T}_k\, y, \hat{T}_k\, y)_k \leq \theta(\hat{A}_k \hat{T}_k\, y, y)_k \quad \text{for all } y \in M_k. \tag{6.5}$$

In this paper, we are dealing with multigrid for finite difference method applied to the Poisson equation on rectangular domains. In this case the stiffness matrix is exactly the same as that arising from the finite element case. Hence we have the following result from [9].

THEOREM 6.1. *Let $\hat{R}_k$ satisfy* (6.4) *and* (6.5) *for $k > 1$. Then there exists a positive constant $\hat{\delta} < 1$ such that*

$$(\hat{A}_L \hat{E}_L y, \hat{E}_L y)_L \leq \hat{\delta}^2\,(\hat{A}_L y, y)_L \quad \textit{for all } y \in M_L,$$

where $\hat{\delta} = CL/(CL+1)$.

Remark 3. The dependence of $\hat{\delta}$ on L can be removed by a perturbation analysis given in [16].

Remark 4. For the multigrid algorithm $V(m,0)$ one obtains $\hat{\delta} = CL/(CL+m)$; see [9]. The constant C depends linearly on $\bar{C}_{\hat{R}}$; see [7, 8, 9] to find estimates of these constants. As discussed in [7], the $\hat{\delta}$ estimate in Theorem 6.1 is pessimistic, in the sense that the observed $\hat{\delta}$ is smaller than the theoretical one and their difference becomes larger for larger values of m.

To prove convergence of multigrid for the optimal control optimality system, we first consider the decoupled symmetric system:

$$\begin{aligned} -\nu\Delta y &= \nu g \text{ in } \Omega, \\ y &= 0 \text{ on } \partial\Omega, \\ -\Delta\lambda &= z \text{ in } \Omega, \\ \lambda &= 0 \text{ on } \partial\Omega. \end{aligned} \tag{6.6}$$

This system is exactly two copies of Poisson equation, hence the multigrid convergence theory for this system inherits the properties of the scalar case. In fact, if we define

$$\hat{\mathcal{A}}_k = \begin{pmatrix} \nu\,\hat{A}_k & 0 \\ 0 & \hat{A}_k \end{pmatrix}, \tag{6.7}$$

and analogously $\hat{\mathcal{B}}_k$, $\hat{\mathcal{E}}_k$, etc., as the system counterparts of $\hat{B}_k$, $\hat{E}_k$, etc., then the multigrid algorithm has exactly the same form as (6.3) with $\hat{\mathcal{B}}_k$, $\hat{\mathcal{A}}_k$, etc., replacing $\hat{B}_k$, $\hat{A}_k$, etc. As a consequence we have the following theorem.

THEOREM 6.2. *Under the assumption of Theorem* 6.1, *there exists a positive constant* $\hat{\delta} < 1$ *such that*

$$(\hat{\mathcal{A}}_L\hat{\mathcal{E}}_L(y,\lambda),\hat{\mathcal{E}}_L(y,\lambda))_L \le \hat{\delta}^2(\hat{\mathcal{A}}_L(y,\lambda),(y,\lambda))_L \quad \textit{for all } (y,\lambda)\in\mathcal{M}_L, \tag{6.8}$$

where $\hat{\delta}$ *has the same form as in Theorem* 6.1.

To analyze the optimality system we let

$$\mathcal{A}_k = \hat{\mathcal{A}}_k + d_k,$$

where

$$d_k = \begin{pmatrix} 0 & -I_k \\ I_k & 0 \end{pmatrix}.$$

We note that

$$|(d_k(u,v),(y,\lambda))| \le C\,|(u,v)|_0\,|(y,\lambda)|_0, \tag{6.9}$$

for some constant C. Now, the multigrid algorithm corresponding to this nonsymmetric problem has exactly the same recursive form as (6.3) with $\mathcal{B}_k$, $\mathcal{A}_k$, etc., replacing $\hat{B}_k$, $\hat{A}_k$, etc., and thus,

$$\mathcal{E}_k = \mathcal{I}_k - \mathcal{B}_k\mathcal{A}_k = [\mathcal{I}_k - \mathcal{I}_{k-1}^k\mathcal{P}_{k-1} + \mathcal{I}_{k-1}^k(\mathcal{I}_{k-1} - \mathcal{B}_{k-1}\mathcal{A}_{k-1})\,\mathcal{P}_{k-1}]\,\mathcal{S}_k, \tag{6.10}$$

where $\mathcal{I}_k$ is the identity operator on $\mathcal{M}_k$. We need a subspace decomposition of $\mathcal{M}_k$. Let

$$\mathcal{M}_k = \sum_{i=1}^{\ell}\mathcal{M}_k^i, \tag{6.11}$$

where ℓ is the number of grid points of the discrete domain and $\mathcal{M}_k^i$ is a two dimensional subspace of $\mathcal{M}_k$ consisting of nodal functions with zero nodal values except at the grid point i. Denote the decomposition of $\mathcal{A}_k$ (resp., $\hat{\mathcal{A}}_k$) with respect to the subspace $\mathcal{M}_k^i$ by $\mathcal{A}_k^i : \mathcal{M}_k^i \to \mathcal{M}_k^i$ (resp., $\hat{\mathcal{A}}_k^i$), satisfying

$$(\mathcal{A}_k^i\mathbf{w},\boldsymbol{\chi})_k = (\mathcal{A}_k\mathbf{w},\boldsymbol{\chi})_k \quad \text{for all } \boldsymbol{\chi}\in\mathcal{M}_k^i,\ \mathbf{w}\in\mathcal{M}_k^i.$$

Define $\mathcal{P}_k^i : \mathcal{M}_k \to \mathcal{M}_k^i$ (resp., $\hat{\mathcal{P}}_k^i$) by

$$(\mathcal{A}_k\mathcal{P}_k^i\mathbf{w},\boldsymbol{\chi})_k = (\mathcal{A}_k\mathbf{w},\boldsymbol{\chi})_k \quad \text{for all } \boldsymbol{\chi}\in\mathcal{M}_k^i,\ \mathbf{w}\in\mathcal{M}_k. \tag{6.12}$$

We use the notation $(\mathbf{w},\boldsymbol{\chi})_{0,i} = (\mathbf{w},\boldsymbol{\chi})_0$ and $(\mathbf{w},\boldsymbol{\chi})_{1,i} = (\mathbf{w},\boldsymbol{\chi})_1$ for $\boldsymbol{\chi}\in\mathcal{M}_k^i$. In the case of a CGS smoother, we obtain a product representation (see [8]) of $\mathcal{S}_k$: For this purpose we set $\mathbf{w}^0 = 0$, for $i = 1,\dots,\ell$,

$$\mathbf{w}^i = \mathbf{w}^{i-1} + (\mathcal{A}_k^i)^{-1}\mathcal{Q}_k^i\,(\mathbf{f}_k - \mathcal{A}_k\mathbf{w}^{i-1}), \tag{6.13}$$

and $\mathcal{R}_k\mathbf{f}_k = \mathbf{w}^\ell$. From the identity $\mathcal{A}_k^i\mathcal{P}_k^i = \mathcal{Q}_k^i\mathcal{A}_k$ on $\mathcal{M}_k^i$ it follows that $\mathcal{S}_k = \mathcal{I}_k - \mathcal{R}_k\mathcal{A}_k = \prod_{i=1}^{\ell}(\mathcal{I}_k - \mathcal{P}_k^i)$. Here, the operator $\mathcal{Q}_k^i : \mathcal{M}_k \to \mathcal{M}_k^i$ represents the orthogonal projection onto $\mathcal{M}_k^i$ with respect to $(\cdot,\cdot)_k$. Theorem 3.2 of [8] applies here to prove that (6.13) satisfies (6.4) and (6.5).

LEMMA 6.3. *For* $\mathbf{v}, \mathbf{w} \in \mathcal{M}_k$, *we have*

$$|(\hat{\mathcal{A}}_k \hat{\mathcal{P}}_k^i \mathbf{w}, \mathbf{v})_k| \leq C\, |\mathbf{w}|_1\, |\mathbf{v}|_1 \tag{6.14}$$

and

$$|(\hat{A}_k(\hat{\mathcal{P}}_k^i - \mathcal{P}_k^i)\mathbf{w}, \mathbf{v})| \leq C\, h_k\, |\mathbf{w}|_1\, |\mathbf{v}|_1. \tag{6.15}$$

Proof. By coercivity, Lemma 3.2, and the Poincaré inequality, it follows that there exists a positive constant α such that

$$\begin{aligned} \alpha\, |\hat{\mathcal{P}}_k^i\, \mathbf{w}|_1^2 &\leq (\hat{\mathcal{A}}_k \hat{\mathcal{P}}_k^i \mathbf{w}, \hat{\mathcal{P}}_k^i \mathbf{w})_k = (\hat{\mathcal{A}}_k \mathbf{w}, \hat{\mathcal{P}}_k^i \mathbf{w})_k \\ &\leq C\, |\mathbf{w}|_1\, |\hat{\mathcal{P}}_k^i \mathbf{w}|_1. \end{aligned}$$

Hence $\hat{\mathcal{P}}_k^i$ is bounded in the discrete energy norm and (6.14) is obtained by the Cauchy–Schwarz inequality. For (6.15), we have

$$\begin{aligned} (\hat{\mathcal{A}}_k(\hat{\mathcal{P}}_k^i - \mathcal{P}_k^i)\mathbf{w}, \mathbf{v})_k &= (\hat{\mathcal{A}}_k(\hat{\mathcal{P}}_k^i - \mathcal{P}_k^i)\mathbf{w}, \hat{\mathcal{P}}_k^i \mathbf{v})_k \\ &= (\hat{\mathcal{A}}_k \mathbf{w}, \hat{\mathcal{P}}_k^i \mathbf{v})_k - (\hat{\mathcal{A}}_k \mathcal{P}_k^i \mathbf{w}, \hat{\mathcal{P}}_k^i \mathbf{v})_k \\ &= (\hat{\mathcal{A}}_k \mathbf{w}, \hat{\mathcal{P}}_k^i \mathbf{v})_k - (\mathcal{A}_k \mathbf{w}, \hat{\mathcal{P}}_k^i \mathbf{v})_k + (d_k\, \mathcal{P}_k^i \mathbf{w}, \hat{\mathcal{P}}_k^i \mathbf{v})_k \\ &= -(d_k\, \mathbf{w}, \hat{\mathcal{P}}_k^i \mathbf{v})_k + (d_k\, \mathcal{P}_k^i \mathbf{w}, \hat{\mathcal{P}}_k^i \mathbf{v})_k \\ &= -(d_k\, (\mathcal{I}_k - \mathcal{P}_k^i)\mathbf{w}, \hat{\mathcal{P}}_k^i \mathbf{v})_k. \end{aligned}$$

Taking the absolute value we get by the Poincaré inequality,

$$\begin{aligned} |(\hat{\mathcal{A}}_k(\hat{\mathcal{P}}_k^i - \mathcal{P}_k^i)\mathbf{w}, \mathbf{v})_k| &\leq C\, |(\mathcal{I}_k - \mathcal{P}_k^i)\mathbf{w}|_{0,i}\, |\hat{\mathcal{P}}_k^i \mathbf{v}|_{1,i} \\ &\leq C\, h_k\, |\mathbf{w}|_1\, |\mathbf{v}|_1, \end{aligned}$$

where the boundedness of $\hat{\mathcal{P}}_k^i$ is used for the second inequality. ∎

The proof of the following lemma is based on subspace decomposition and proved with the aid of Lemma 6.3 exactly in the same way as that of Theorem 3.1 in [11]. We skip the details.

LEMMA 6.4. *There exists some constant* $C_{\mathcal{S}}$ *independent of* k *such that*

$$|(\hat{\mathcal{A}}_k(\mathcal{S}_k - \hat{\mathcal{S}}_k)\mathbf{w}, \mathbf{v})_k| \leq C_{\mathcal{S}}\, h_k\, |\mathbf{w}|_1\, |\mathbf{v}|_1 \tag{6.16}$$

for all $\mathbf{w}, \mathbf{v} \in \mathcal{M}_k$.

LEMMA 6.5. *The following inequalities hold:*

$$|(\hat{\mathcal{A}}_{k-1}(\hat{\mathcal{P}}_{k-1} - \mathcal{P}_{k-1})\mathbf{w}, \mathbf{v})_{k-1}| \leq C_{\mathcal{P}}\, h_{k-1}\, |\mathbf{w}|_1 |\mathbf{v}|_1 \text{ for } \mathbf{w} \in \mathcal{M}_k,\ \mathbf{v} \in \mathcal{M}_{k-1} \tag{6.17}$$

and

$$|(\hat{\mathcal{A}}_k(\mathcal{I}_k - \mathcal{I}_{k-1}^k \mathcal{P}_{k-1})\mathbf{w}, \mathbf{v})_k| \leq C_I\, h_k\, |\mathbf{w}|_1\, |\mathbf{v}|_1 \text{ for } \mathbf{w} \in \mathcal{M}_k,\ \mathbf{v} \in \mathcal{M}_k, \tag{6.18}$$

where $C_{\mathcal{P}}$ *and* C_I *are some constants independent of* k.

Proof. Let us first prove (6.17) with $\hat{\mathcal{A}}_{k-1}$ replaced by $\mathcal{A}_{k-1}$. We have for $\mathbf{w} \in \mathcal{M}_k$ and $\mathbf{v} \in \mathcal{M}_{k-1}$,

$$\begin{aligned}
&|(\mathcal{A}_{k-1}\hat{\mathcal{P}}_{k-1}\mathbf{w}, \mathbf{v})_{k-1} - (\mathcal{A}_{k-1}\mathcal{P}_{k-1}\mathbf{w}, \mathbf{v})_{k-1}| \\
&= |(\hat{\mathcal{A}}_{k-1}\hat{\mathcal{P}}_{k-1}\mathbf{w}, \mathbf{v})_{k-1} + (d_{k-1}\,\hat{\mathcal{P}}_{k-1}\mathbf{w}, \mathbf{v})_{k-1} - (\mathcal{A}_k\mathbf{w}, \mathcal{I}_{k-1}^k\mathbf{v})_k| \\
&= |(\hat{\mathcal{A}}_k\mathbf{w}, \mathcal{I}_{k-1}^k\mathbf{v})_k + (d_{k-1}\,\hat{\mathcal{P}}_{k-1}\mathbf{w}, \mathbf{v})_{k-1} - (\mathcal{A}_k\mathbf{w}, \mathcal{I}_{k-1}^k\mathbf{v})_k| \\
&= |(d_{k-1}\,\hat{\mathcal{P}}_{k-1}\mathbf{w}, \mathbf{v})_{k-1} - (d_k\,\mathbf{w}, \mathcal{I}_{k-1}^k\mathbf{v})_k| \\
&= |(d_{k-1}\,\hat{\mathcal{P}}_{k-1}\mathbf{w}, \mathbf{v})_{k-1} - (d_{k-1}\,\mathcal{I}_k^{k-1}\mathbf{w}, \mathbf{v})_{k-1}| \\
&= |(d_{k-1}\,(\hat{\mathcal{P}}_{k-1} - \mathcal{I}_k^{k-1})\mathbf{w}, \mathbf{v})_{k-1}| \\
&\le C\,|(\hat{\mathcal{P}}_{k-1} - \mathcal{I}_k^{k-1})\mathbf{w}|_0\,|\mathbf{v}|_1,
\end{aligned}$$

where the last inequality is obtained as follows: Let us denote by $\bar{\hat{\mathcal{P}}}_{k-1}$ the elliptic projection of the linear finite element method and denote by $\bar{\mathcal{I}}_{k-1} : \mathcal{M}_k \to \mathcal{M}_{k-1}$ the fine-to-coarse injection. We have

$$|(\hat{\mathcal{P}}_{k-1} - \mathcal{I}_k^{k-1})\mathbf{w}|_0 \le |(\hat{\mathcal{P}}_{k-1} - \bar{\hat{\mathcal{P}}}_{k-1})\mathbf{w}|_0 + |(\bar{\hat{\mathcal{P}}}_{k-1} - \bar{\mathcal{I}}_{k-1})\mathbf{w}|_0 + |(\bar{\mathcal{I}}_{k-1} - \mathcal{I}_k^{k-1})\mathbf{w}|_0.$$

Here, inequality (6.7), (6.8), (6.9), and (6.11) of [9], and the approximation property of $\mathcal{I}_k^{k-1}$, are used to obtain the estimate $|(\hat{\mathcal{P}}_{k-1} - \mathcal{I}_k^{k-1})\mathbf{w}|_0 \le C\,h_{k-1}\,|\mathbf{w}|_1$.

It follows that $\|\hat{\mathcal{P}}_{k-1} - \mathcal{P}_{k-1}\|_{\mathcal{A}_{k-1}} \le C\,h_{k-1}$, where $\|\cdot\|_{\mathcal{A}_{k-1}}$ denotes the usual operator norm induced by $\mathcal{A}_{k-1}$. Because $(\mathcal{A}_{k-1}\mathbf{v}, \mathbf{v})_{k-1} = (\hat{\mathcal{A}}_{k-1}\mathbf{v}, \mathbf{v})_{k-1}$ from the definition of d_{k-1}, we also have $\|\hat{\mathcal{P}}_{k-1} - \mathcal{P}_{k-1}\|_{\hat{\mathcal{A}}_{k-1}} \le C\,h_{k-1}$, which is the desired result.

The second assertion (6.18) follows directly from (6.17). ∎

With these preparations we can show the following theorem.

THEOREM 6.6. *There exist positive constants h_0 and $\delta < 1$ such that for all $h_1 < h_0$ we have*

$$(\hat{\mathcal{A}}_L\mathcal{E}_L\mathbf{w}, \mathcal{E}_L\mathbf{w})_L \le \delta^2(\hat{\mathcal{A}}_L\mathbf{w}, \mathbf{w})_L \quad \textit{for all } \mathbf{w} \in \mathcal{M}_L,$$

where $\delta = \hat{\delta} + Ch_1$ and $\hat{\delta}$ is as in Theorem 6.2.

Proof. Denoting the operator norm $\|\cdot\|_{\hat{\mathcal{A}}_k}$ by $\|\cdot\|$, we show that $\|\mathcal{E}_k - \hat{\mathcal{E}}_k\| \le c_k h_1$, where c_k is uniformly bounded. The error operator $\mathcal{E}_k$ can be written as

$$\mathcal{E}_k = (\mathcal{I}_k - \mathcal{I}_{k-1}^k\mathcal{B}_{k-1}\mathcal{A}_{k-1}\mathcal{P}_{k-1})\,\mathcal{S}_k,$$

and $\hat{\mathcal{E}}_k$ has similar representation. We compare the error operators and write their difference as

$$\begin{aligned}
\mathcal{E}_k - \hat{\mathcal{E}}_k = &(\mathcal{I}_k - \mathcal{I}_{k-1}^k\mathcal{B}_{k-1}\mathcal{A}_{k-1}\mathcal{P}_{k-1})\,(\mathcal{S}_k - \hat{\mathcal{S}}_k) \\
&- \mathcal{I}_{k-1}^k\mathcal{B}_{k-1}\mathcal{A}_{k-1}(\mathcal{P}_{k-1} - \hat{\mathcal{P}}_{k-1})\,\hat{\mathcal{S}}_k + \mathcal{I}_{k-1}^k(\mathcal{E}_{k-1} - \hat{\mathcal{E}}_{k-1})\,\hat{\mathcal{P}}_{k-1}\,\hat{\mathcal{S}}_k.
\end{aligned}$$

Thus in terms of the operator norm, we have by (4.16)

$$\begin{aligned}
\|\mathcal{E}_k - \hat{\mathcal{E}}_k\| \le &\|\mathcal{I}_k - \mathcal{I}_{k-1}^k\mathcal{B}_{k-1}\mathcal{A}_{k-1}\mathcal{P}_{k-1}\|\,\|\mathcal{S}_k - \hat{\mathcal{S}}_k\| \\
&+ \|\mathcal{B}_{k-1}\mathcal{A}_{k-1}\|\,\|\mathcal{P}_{k-1} - \hat{\mathcal{P}}_{k-1}\|\,\|\hat{\mathcal{S}}_k\| \\
&+ \|\mathcal{E}_{k-1} - \hat{\mathcal{E}}_{k-1}\|\,\|\hat{\mathcal{P}}_{k-1}\hat{\mathcal{S}}_k\|.
\end{aligned} \tag{6.19}$$

Let us make the induction hypothesis: $\|\mathcal{E}_{k-1} - \hat{\mathcal{E}}_{k-1}\| \le c_{k-1}h_1$, where c_{k-1} is a constant to be defined below. By the triangle inequality and Theorem 6.2,

$$\|\mathcal{E}_{k-1}\| \le \hat{\delta} + c_{k-1}h_1 \tag{6.20}$$

and

$$\|\mathcal{B}_{k-1}\mathcal{A}_{k-1}\| \le 1 + \hat{\delta} + c_{k-1}h_1. \tag{6.21}$$

Using the induction hypothesis, (4.14), Lemma 6.4, and Lemma 6.5, we have

$$\begin{aligned}
&\|\mathcal{I}_k - \mathcal{I}_{k-1}^k \mathcal{B}_{k-1}\mathcal{A}_{k-1}\mathcal{P}_{k-1}\| \\
&\qquad \le \|\mathcal{I}_k - \mathcal{I}_{k-1}^k \mathcal{P}_{k-1}\| + \|\mathcal{I}_{k-1} - \mathcal{B}_{k-1}\mathcal{A}_{k-1}\|\,\|\mathcal{P}_{k-1}\| && (6.22)\\
&\qquad \le C_I h_{k-1} + \|\mathcal{E}_{k-1}\|\,(1 + C_{\mathcal{P}} h_{k-1}) && (6.23)\\
&\qquad \le C_I\,(h_{k-1} + \hat{\delta} + c_{k-1}h_1), && (6.24)
\end{aligned}$$

where we assumed C_I sufficiently large so that $1 + C_{\mathcal{P}} h_{k-1} \le C_I$. To prove the second inequality (6.23) we used the fact that $\|\hat{\mathcal{P}}_{k-1}\| \le 1$ and the chain of inequalities $\|\mathcal{P}_{k-1}\| \le \|\hat{\mathcal{P}}_{k-1}\| + \|\mathcal{P}_{k-1} - \hat{\mathcal{P}}_{k-1}\| \le 1 + C_{\mathcal{P}} h_{k-1}$. The stability of $\hat{\mathcal{P}}_{k-1}$ results from Lemma 4.1 and the identity $(\hat{\mathcal{A}}_{k-1}\hat{\mathcal{P}}_{k-1}\mathbf{w}, \mathbf{v})_{k-1} = (\hat{\mathcal{A}}_k \mathbf{w}, \mathcal{I}_{k-1}^k \mathbf{v})_k$.

Collecting (6.19) through (6.21), and using (4.14), Lemma 6.4, Lemma 6.5, and (6.22)–(6.24), we see that

$$\begin{aligned}
\|\mathcal{E}_k - \hat{\mathcal{E}}_k\| &\le C_I\, C_{\mathcal{S}}\,(h_{k-1} + \hat{\delta} + c_{k-1}h_1)\, h_k \\
&\quad + C_{\mathcal{P}}\,(1 + \hat{\delta} + c_{k-1}h_1)\, h_{k-1} + c_{k-1}h_1 \\
&\le \left(\frac{C_I C_{\mathcal{S}}}{2} + C_{\mathcal{P}}\right) h_{k-1}\,(1 + \hat{\delta} + c_{k-1}h_1) + c_{k-1}h_1
\end{aligned}$$

for all k.

Now let $\hat{C} := \frac{C_I C_{\mathcal{S}}}{2} + C_{\mathcal{P}}$ and define

$$c_k := c_{k-1} + \hat{C}h_1^{-1}h_{k-1}(1 + \hat{\delta} + c_{k-1}h_1). \tag{6.25}$$

To see that the sequence c_k is uniformly bounded in k, one notes that $c_j \le c_k$ for $j \le k$ and hence

$$\begin{aligned}
c_k &= c_{k-1} + \hat{C}h_1^{-1}(1 + \hat{\delta} + c_{k-1}h_1)h_{k-1} \\
&= c_1 + \hat{C}h_1^{-1}\sum_{j=2}^{k}(1 + \hat{\delta} + c_{j-1}h_1)h_{j-1} \\
&\le c_1 + \hat{C}h_1^{-1}\sum_{j=2}^{k}(1 + \hat{\delta} + c_k h_1)h_{j-1} \\
&\le c_1 + 2\hat{C}(1 + \hat{\delta}) + 2\hat{C}h_1 c_k.
\end{aligned}$$

Now move the c_k term to the left to get

$$c_k \le (c_1 + 2\hat{C}(1 + \hat{\delta}))/(1 - 2\hat{C}h_1),$$

provided that h_1 is small enough. Therefore, if the coarsest grid is sufficiently fine, we have $\delta = \hat{\delta} + Ch_1 < 1$. ∎

We conclude this section with remarks on some of the constants appearing in the proofs. In case of collective CGS iteration, the constant $\bar{C}_{\hat{R}}$ appears to be almost independent from the value of the weight of the cost of the control. Its value is close to that of the Gauss–Seidel scheme applied to the scalar Poisson problem.

The constants in (6.16), (6.17), and (6.18) depend on the features of the optimality system as, for example, nonsymmetry. They account for the induction hypothesis where the coarsest mesh size, h_1, enters in the analysis and results in the estimate $\delta = \hat{\delta} + C\,h_1$. The requirement for a sufficiently small h_1 has no correspondence to our numerical experience (using CGS). However, the estimate of Theorem 6.6 states that, for sufficiently small h_1, we have $\delta \approx \hat{\delta}$, that is, the convergence factor of the multigrid method applied to the optimality system is close to the convergence factor of the multigrid scheme applied to the scalar Poisson problem. This fact agrees with our numerical experience and the results reported in Table 5.1.

7. Conclusions. We have presented a systematic study of a finite difference multigrid method for a class of optimality systems arising from optimal control of elliptic partial differential equations. In this emerging field of scientific computing there is an increasing interest in the development of accurate and efficient solution methods for optimal control problems. In the first part we have proved optimal-order error estimates in the discrete L^2 norm and in the discrete H^1 norm under minimum regularity requirements on the data. In the second part, two complementary analytical tools for multigrid convergence theory have been discussed. In the framework of local Fourier analysis it is possible to obtain sharp convergence estimates which are very important in the first phase of development of the multigrid components. The other analytical tool presented here is important from the theoretical point of view. It makes it possible to prove optimal convergence of the multigrid process under weak regularity assumptions. The general multigrid convergence theory discussed in this paper is developed in two steps. First, the multigrid method applied to the uncoupled differential system is considered. Then, the nondifferential coupling part characterizing the optimality system is introduced. By analyzing the difference between the operators obtained with and without coupling, we are able to estimate the convergence factor of multigrid for optimality systems based on the estimates available for the uncoupled problem.

FEEDBACK CLASSIFICATION OF NONLINEAR SINGLE-INPUT CONTROL SYSTEMS WITH CONTROLLABLE LINEARIZATION: NORMAL FORMS, CANONICAL FORMS, AND INVARIANTS*

ISSA AMADOU TALL† AND WITOLD RESPONDEK†

Abstract. We study the feedback group action on single-input nonlinear control systems. We follow an approach of Kang and Krener based on analyzing, step by step, the action of homogeneous transformations on the homogeneous part of the same degree of the system. We construct a dual normal form and dual invariants with respect to those obtained by Kang. We also propose a canonical form and a dual canonical form and show that two systems are equivalent via a formal feedback if and only if their canonical forms (resp., their dual canonical forms) coincide. We give an explicit construction of transformations bringing the system to its normal, dual normal, canonical, and dual canonical forms. We illustrate our results by simple examples on $\mathbb{R}^3$ and $\mathbb{R}^4$.

Key words. feedback equivalence, normal forms, canonical forms, invariants

1. Introduction.

The problem of transforming the nonlinear control single-input system

$$\Sigma \ : \ \dot{\xi} = f(\xi) + g(\xi)u$$

by a feedback transformation of the form

$$\Gamma \ : \quad \begin{array}{l} x = \phi(\xi), \\ u = \alpha(\xi) + \beta(\xi)v \end{array}$$

to a simpler form has been extensively studied during the last twenty years. The transformation Γ brings Σ to the system

$$\tilde{\Sigma} \ : \ \dot{x} = \tilde{f}(x) + \tilde{g}(x)v,$$

whose dynamics are given by

$$\begin{aligned} \tilde{f} &= \phi_*(f + g\alpha), \\ \tilde{g} &= \phi_*(g\beta), \end{aligned}$$

where for any vector field f and any diffeomorphism ϕ we denote

$$(\phi_* f)(x) = d\phi(\phi^{-1}(x)) \cdot f(\phi^{-1}(x)).$$

A natural question to ask is whether we can find a transformation Γ such that the

†Institut National des Sciences Appliquées de Rouen, Laboratoire de Mathématiques de l'INSA, Pl. Emile Blondel, 76 131 Mont Saint Aignan Cedex, France (tall@insa-rouen.fr, wresp@insa-rouen.fr). The first author worked on this paper while on leave from the Department of Mathematics, Université Cheikh Anta Diop, Dakar, Senegal.

transformed system $\tilde{\Sigma}$ is linear, that is, whether we can linearize the system Σ via feedback. Necessary and sufficient geometric conditions for this to be the case have been given in [13] and [18]. Those conditions, except for the planar case, turn out to be restrictive, and a natural problem that arises is to find normal forms for nonlinearizable systems. Although natural, this problem is very involved and has been extensively studied during the last twenty years. Four basic methods have been proposed for studying feedback equivalence problems. The first method is based on the theory of singularities of vector fields and distributions, and their invariants, and using this method a large variety of feedback classification problems have been solved; see, e.g., [4], [7], [14], [15], [18], [19], [27], [29], [32], [38]. The second approach, proposed by Gardner [9], uses Cartan's method of equivalence [6] and describes the geometry of feedback equivalence [10], [11], [12], [28]. The third method, inspired by the Hamiltonian formalism for optimal control problems, was developed by Bonnard [3], [4] and Jakubczyk [16], [17] and has led to a very nice description of feedback invariants in terms of singular extremals. Finally, a very fruitful approach was proposed by Kang and Krener [26] and then followed by Kang [21], [22]. Their idea, which is closely related with Poincaré's classical technique for linearization of dynamical systems (see, e.g., [1]), is to analyze the system Σ and the feedback transformation Γ step by step and, as a consequence, to produce a simpler equivalent system $\tilde{\Sigma}$ also step by step.

Our paper is deeply inspired by those of Kang and Krener [26], [21] and can be considered as a completion of their results. In [21], Kang constructed a normal form for single-input nonlinear control systems with controllable linearization using successively homogeneous feedback transformations, and he proved that the homogeneous terms of a given degree of his normal form are unique under homogeneous feedback transformations of the same degree. He also showed that a nonlinear system can admit different normal forms under feedback resulting from the action of lower order terms of the feedback transformation on higher order terms of the system. The main goal of our paper is to propose a canonical form for the class of single-input systems with controllable linearization and to prove that two systems are equivalent, via a formal feedback, if and only if their canonical forms coincide.

In [26] Kang and Krener constructed two normal forms for the quadratic part of a single-input system. In the first normal form, all components of the linear part of the control vector field are annihilated and all nonremovable quadratic nonlinearities are grouped in the drift; in the second normal form, all quadratic terms of the drift are annihilated and all nonremovable nonlinearities are present in the control vector field. Kang normal form is a generalization, for higher order terms, of the first normal form. In this paper, we generalize the second one and produce a dual normal form for higher order terms. We also construct dual invariants of homogeneous feedback transformations. They contain the same information, as Kang invariants, encoded in a different way. We also give a dual canonical form and prove that two systems are equivalent, via formal feedback, if and only if their dual canonical forms coincide.

The third aim of the paper is to construct explicit homogeneous feedback transformations which bring the homogeneous part of the system of the same degree into its normal, or dual normal, form. For any fixed degree, our transformations are easily computable via differentiation and integration of polynomials. A successive application of those transformations gives formal feedbacks that bring any system to its normal form, dual normal form, canonical form, and dual canonical form.

The theory of normal forms initialized and developed by Kang and Krener [26] and Kang [21], [22] and continued in the present paper (and in [33], [34]) has proved to be very useful in analyzing structural properties of nonlinear control systems. It

has been used to study bifurcations of nonlinear systems [23], [24], [25], has led to a complete description of symmetries around equilibrium [30], [31], and has allowed us to characterize systems equivalent to feedforward forms [35], [36], [37].

The paper is organized as follows. In section 2 we will introduce, following [21] and [26], homogeneous feedback transformations. We give a normal form obtained by Kang and discuss invariants of homogeneous transformations, also obtained by him. We provide an explicit construction of transformations bringing the system to Kang normal form. In section 3 we construct a canonical form and give one of our main results stating that two control systems are feedback equivalent if and only if their canonical forms coincide. Proofs of results presented in sections 2 and 3 are given in section 4.

Section 5 dualizes the main results of section 2: we give a dual normal form, explicitly construct transformations bringing the system to that form, and define dual invariants of homogeneous transformations. Similarly to normal forms, a given system can admit different dual normal forms. In section 6 we thus dualize the results of section 3 by constructing a dual canonical form and proving that two control systems are feedback equivalent if and only if their dual canonical forms coincide. Section 7 contains proofs of results presented in sections 5 and 6. Throughout the paper, we illustrate our results by simple examples on $\mathbb{R}^3$ and $\mathbb{R}^4$.

2. Normal form and m-invariants. All objects, that is, functions, maps, vector fields, control systems, etc., are considered in a neighborhood of $0 \in \mathbb{R}^n$ and assumed to be C^∞-smooth. Let h be a smooth $\mathbb{R}$-valued function. By

$$h(x) = h^{[0]}(x) + h^{[1]}(x) + h^{[2]}(x) + \cdots = \sum_{m=0}^{\infty} h^{[m]}(x)$$

we denote its Taylor series expansion at $0 \in \mathbb{R}^n$, where $h^{[m]}(x)$ stands for a homogeneous polynomial of degree m.

Similarly, for a map ϕ of an open subset of $\mathbb{R}^n$ to $\mathbb{R}^n$ (resp., for a vector field f on an open subset of $\mathbb{R}^n$) we will denote by $\phi^{[m]}$ (resp., by $f^{[m]}$) the homogeneous term of degree m of its Taylor series expansion at $0 \in \mathbb{R}^n$, that is, each component $\phi_j^{[m]}$ of $\phi^{[m]}$ (resp., $f_j^{[m]}$ of $f^{[m]}$) is a homogeneous polynomial of degree m in x.

We will denote by $H^{[m]}(x)$ the space of homogeneous polynomials of degree m of the variables $x_1, \ldots, x_n$ and by $H^{\geq m}(x)$ the space of formal power series of the variables $x_1, \ldots, x_n$ starting from terms of degree m.

Analogously, we will denote by $R^{[m]}(x)$ the space of homogeneous vector fields whose components are in $H^{[m]}(x)$ and by $R^{\geq m}(x)$ the space of vector fields formal power series whose components are in $H^{\geq m}(x)$.

Consider the Taylor series expansion of the system Σ given by

$$\Sigma^\infty \ : \ \dot{\xi} = F\xi + Gu + \sum_{m=2}^{\infty} \left(f^{[m]}(\xi) + g^{[m-1]}(\xi)u \right), \tag{2.1}$$

where $F = \frac{\partial f}{\partial \xi}(0)$ and $G = g(0)$. We will assume throughout the paper that $f(0) = 0$ and $g(0) \neq 0$.

Consider also the Taylor series expansion Γ^∞ of the feedback transformation Γ

given by

$$\Gamma^\infty : \begin{aligned} x &= T\xi + \sum_{m=2}^{\infty} \phi^{[m]}(\xi), \\ u &= K\xi + Lv + \sum_{m=2}^{\infty} \left(\alpha^{[m]}(\xi) + \beta^{[m-1]}(\xi)v\right), \end{aligned} \tag{2.2}$$

where T is an invertible matrix and $L \neq 0$. Let us analyze the action of Γ^∞ on the system Σ^∞ step by step.

To start with, consider the linear system

$$\dot{\xi} = F\xi + Gu.$$

Throughout the paper we will assume that it is controllable. It can be thus transformed by a linear feedback transformation of the form

$$\Gamma^1 : \begin{aligned} x &= T\xi, \\ u &= K\xi + Lv \end{aligned}$$

to the Brunovský canonical form (A, B); see, e.g., [20]. Assuming that the linear part (F, G), of the system Σ^∞ given by (2.1), has been transformed to the Brunovský canonical form (A, B), we follow an idea of Kang and Krener [26], [21] and apply successively a series of transformations

$$\Gamma^m : \begin{aligned} x &= \xi + \phi^{[m]}(\xi), \\ u &= v + \alpha^{[m]}(\xi) + \beta^{[m-1]}(\xi)v \end{aligned} \tag{2.3}$$

for $m = 2, 3, \ldots$. A feedback transformation defined as a series of successive compositions of Γ^m, $m = 1, 2, \ldots$, will also be denoted by Γ^∞ because, as a formal power series, it is of the form (2.2). We will not address the problem of convergence and will call such a series of successive compositions a *formal feedback transformation*.

Observe that each transformation Γ^m for $m \geq 2$ leaves invariant all homogeneous terms of degree smaller than m of the system Σ^∞, and we will call Γ^m a *homogeneous feedback transformation of degree m*. We will study the action of Γ^m on the following *homogeneous system*:

$$\Sigma^{[m]} \ : \ \dot{\xi} = A\xi + Bu + f^{[m]}(\xi) + g^{[m-1]}(\xi)u. \tag{2.4}$$

Consider another homogeneous system, $\tilde{\Sigma}^{[m]}$, given by

$$\tilde{\Sigma}^{[m]} \ : \ \dot{x} = Ax + Bv + \tilde{f}^{[m]}(x) + \tilde{g}^{[m-1]}(x)v. \tag{2.5}$$

We will say that the homogeneous system $\Sigma^{[m]}$ is feedback equivalent to the homogeneous system $\tilde{\Sigma}^{[m]}$ if there exists a homogeneous feedback transformation of the form (2.3), which brings $\Sigma^{[m]}$ into $\tilde{\Sigma}^{[m]}$ modulo terms in $R^{\geq m+1}(x, v)$.

Notation. Because of various normal forms and various transformations that are used throughout the paper, we will keep the following notation. We will denote, respectively, by $\Sigma^{[m]}$ and Σ^{∞} the following systems:

$$\begin{aligned}\Sigma^{[m]} &: \dot{\xi} = A\xi + Bu + f^{[m]}(\xi) + g^{[m-1]}(\xi)u,\\ \Sigma^{\infty} &: \dot{\xi} = A\xi + Bu + \sum_{k=2}^{\infty}\left(f^{[k]}(\xi) + g^{[k-1]}(\xi)u\right).\end{aligned}$$

The systems $\Sigma^{[m]}$ and Σ^{∞} will stand for the systems under consideration. Their state vector will be denoted by ξ and their control by u. The system $\Sigma^{[m]}$ (resp., the system Σ^{∞}) transformed via feedback will be denoted by $\tilde{\Sigma}^{[m]}$ (resp., by $\tilde{\Sigma}^{\infty}$). Its state vector will be denoted by x, its control by v, and the vector fields, defining its dynamics, by $\tilde{f}^{[k]}$ and $\tilde{g}^{[k-1]}$. Feedback equivalence of homogeneous systems $\Sigma^{[m]}$ and $\tilde{\Sigma}^{[m]}$ will be established via a smooth feedback, that is, precisely, via a homogeneous feedback Γ^m. On the other hand, feedback equivalence of systems Σ^{∞} and $\tilde{\Sigma}^{\infty}$ will be established via a formal feedback Γ^{∞}.

We will introduce two kinds of normal forms, Kang normal forms and dual normal forms, as well as canonical forms and dual canonical forms. The "bar" symbol will correspond to the vector field $\bar{f}^{[m]}$ defining the Kang normal forms $\Sigma_{NF}^{[m]}$ and Σ_{NF}^{∞} and the canonical form Σ_{CF}^{∞} as well as to the vector field $\bar{g}^{[m-1]}$ defining the dual normal forms $\Sigma_{DNF}^{[m]}$ and Σ_{DNF}^{∞} and the dual canonical form Σ_{DCF}^{∞}. Analogously, the m-invariants (resp., dual m-invariants) of the system $\Sigma^{[m]}$ will be denoted by $a^{[m]j,i+2}$ (resp., by $b_j^{[m-1]}$) and the m-invariants (resp., dual m-invariants) of the normal form $\Sigma_{NF}^{[m]}$ (resp., dual normal form $\Sigma_{DNF}^{[m]}$) by $\bar{a}^{[m]j,i+2}$ (resp., by $\bar{b}_j^{[m-1]}$).

The starting point is the following result, proved by Kang [21].

PROPOSITION 1. *The homogeneous feedback transformation Γ^m, defined by* (2.3)*, brings the system $\Sigma^{[m]}$, given by* (2.4)*, into $\tilde{\Sigma}^{[m]}$, given by* (2.5)*, if and only if the relations*

$$\begin{cases} L_{A\xi}\phi_j^{[m]}(\xi) - \phi_{j+1}^{[m]}(\xi) = \tilde{f}_j^{[m]}(\xi) - f_j^{[m]}(\xi),\\ L_B\phi_j^{[m]}(\xi) = \tilde{g}_j^{[m-1]}(\xi) - g_j^{[m-1]}(\xi),\\ L_{A\xi}\phi_n^{[m]}(\xi) + \alpha^{[m]}(\xi) = \tilde{f}_n^{[m]}(\xi) - f_n^{[m]}(\xi),\\ L_B\phi_n^{[m]}(\xi) + \beta^{[m-1]}(\xi) = \tilde{g}_n^{[m-1]}(\xi) - g_n^{[m-1]}(\xi)\end{cases} \tag{2.6}$$

hold for any $1 \le j \le n-1$, where $\phi_j^{[m]}$ are the components of $\phi^{[m]}$.

This proposition represents the essence of the method developed by Kang and Krener and used in our paper. The problem of studying the feedback equivalence of two systems Σ and $\tilde{\Sigma}$ requires, in general, solving a system of first order partial differential equations. On the other hand, if we perform the analysis step by step, then the problem of establishing the feedback equivalence of two systems $\Sigma^{[m]}$ and $\tilde{\Sigma}^{[m]}$ reduces to solving the algebraic system (2.6).

Using the above proposition, Kang [21] proved the following result.

THEOREM 1. *The homogeneous system $\Sigma^{[m]}$ can be transformed, via a homogeneous feedback transformation Γ^m, into the normal form*

$$\Sigma_{NF}^{[m]} \; : \; \begin{cases} \dot{x}_1 = x_2 + \sum_{i=3}^{n} x_i^2 P_{1,i}^{[m-2]}(x_1, \dots, x_i), \\ \qquad \vdots \\ \dot{x}_j = x_{j+1} + \sum_{i=j+2}^{n} x_i^2 P_{j,i}^{[m-2]}(x_1, \dots, x_i), \\ \qquad \vdots \\ \dot{x}_{n-2} = x_{n-1} + x_n^2 P_{n-2,n}^{[m-2]}(x_1, \dots, x_n), \\ \dot{x}_{n-1} = x_n, \\ \dot{x}_n = v, \end{cases} \tag{2.7}$$

where $P_{j,i}^{[m-2]}(x_1, \dots, x_i)$ *are homogeneous polynomials of degree* $m-2$ *depending on the indicated variables.*

In order to construct invariants of homogeneous feedback transformations, let us define

$$X_i^{m-1}(\xi) = (-1)^i ad^i_{A\xi + f^{[m]}(\xi)}(B + g^{[m-1]}(\xi))$$

and let $X_i^{[m-1]}$ be its homogeneous part of degree $m-1$. By π_i we will denote the projection on the subspace

$$W_i = \{\xi \in R^n : \quad \xi_{i+1} = \cdots = \xi_n = 0\}, \tag{2.8}$$

that is,

$$\pi_i(\xi) = (\xi_1, \dots, \xi_i, 0, \dots, 0).$$

Following Kang [21], we denote by $a^{[m]j,i+2}(\xi)$ the homogeneous part of degree $m-2$ of the polynomials

$$CA^{j-1}\left[X_i^{m-1}, X_{i+1}^{m-1}\right](\pi_{n-i}(\xi)),$$

where $C = (1, 0, \dots, 0)^T \in \mathbb{R}^n$ and $(j,i) \in \Delta \subset \mathbb{N} \times \mathbb{N}$, defined by

$$\Delta = \{(j,i) \in \mathbb{N} \times \mathbb{N} : \; 1 \le j \le n-2, \; 0 \le i \le n-j-2\}.$$

The homogeneous polynomials $a^{[m]j,i+2}$ for $(j,i) \in \Delta$ will be called *m-invariants* of $\Sigma^{[m]}$.

The following result of Kang [21] asserts that m-invariants $a^{[m]j,i+2}$ for $(j,i) \in \Delta$ are complete invariants of homogeneous feedback and, moreover, illustrates their meaning for the homogeneous normal form $\Sigma_{NF}^{[m]}$.

Consider two homogeneous systems $\Sigma^{[m]}$ and $\tilde{\Sigma}^{[m]}$ and let

$$\{\, a^{[m]j,i+2} : \; (j,i) \in \Delta \,\}$$

and

$$\{\, \tilde{a}^{[m]j,i+2} : \; (j,i) \in \Delta \,\}$$

denote, respectively, their m-invariants. The following theorem was proved by Kang [21].

THEOREM 2. *The m-invariants have the following properties:*

(i) *Two homogeneous systems* $\Sigma^{[m]}$ *and* $\tilde{\Sigma}^{[m]}$ *are equivalent via a homogeneous feedback transformation* Γ^m *if and only if*

$$a^{[m]j,i+2} = \tilde{a}^{[m]j,i+2}$$

for any $(j,i) \in \Delta$.

(ii) *The m-invariants* $\bar{a}^{[m]j,i+2}$ *of the homogeneous normal form* $\Sigma^{[m]}_{NF}$, *defined by* (2.7), *are given by*

$$\bar{a}^{[m]j,i+2}(x) = \frac{\partial^2}{\partial x_{n-i}^2} x_{n-i}^2 P^{[m-2]}_{j,n-i}(x_1, \ldots, x_{n-i}) \tag{2.9}$$

for any $(j,i) \in \Delta$.

Our first aim is to find explicitly feedback transformations bringing the homogeneous system $\Sigma^{[m]}$ to its normal form $\Sigma^{[m]}_{NF}$. Define the homogeneous polynomials $\psi^{[m-1]}_{j,i}(\xi)$ by setting $\psi^{[m-1]}_{j,0}(\xi) = \psi^{[m-1]}_{1,1}(\xi) = 0$,

$$\psi^{[m-1]}_{j,i}(\xi) = -CA^{j-1}\left(ad^{n-i}_{A\xi} g^{[m-1]} + \sum_{t=1}^{n-i} (-1)^t ad^{t-1}_{A\xi} ad_{A^{n-i-t}B} f^{[m]} \right) \tag{2.10}$$

if $1 \le j < i \le n$ and

$$\begin{aligned} \psi^{[m-1]}_{j,i}(\xi) = {} & L_{A^{n-i}B} f^{[m]}_{j-1}(\pi_i(\xi)) + L_{A\xi} \psi^{[m-1]}_{j-1,i}(\pi_i(\xi)) \\ & + \psi^{[m-1]}_{j-1,i-1}(\pi_{i-1}(\xi)) + \int_0^{\xi_i} L_{A^{n-i+1}B} \psi^{[m-1]}_{j-1,i}(\pi_i(\xi)) d\xi_i \end{aligned} \tag{2.11}$$

if $1 \le i \le j$, where $\psi^{[m-1]}_{j,i}(\pi_i(\xi))$ is the restriction of $\psi^{[m-1]}_{j,i}(\xi)$ to the submanifold W_i. Define the components $\phi^{[m]}_j$ of $\phi^{[m]}$ for $1 \le j \le n$ and the feedback $(\alpha^{[m]}, \beta^{[m-1]})$ by

$$\begin{aligned} \phi^{[m]}_j(\xi) &= \sum_{i=1}^{n} \int_0^{\xi_i} \psi^{[m-1]}_{j,i}(\pi_i(\xi)) d\xi_i, \qquad 1 \le j \le n-1, \\ \phi^{[m]}_n(\xi) &= f^{[m]}_{n-1}(\xi) + L_{A\xi} \phi^{[m]}_{n-1}(\xi), \\ \alpha^{[m]}(\xi) &= -\left(f^{[m]}_n(\xi) + L_{A\xi} \phi^{[m]}_n(\xi) \right), \\ \beta^{[m-1]}(\xi) &= -\left(g^{[m-1]}_n(\xi) + L_B \phi^{[m]}_n(\xi) \right). \end{aligned} \tag{2.12}$$

We have the following result.

THEOREM 3. *The homogeneous feedback transformation*

$$\Gamma^m \ : \ \begin{aligned} x &= \xi + \phi^{[m]}(\xi), \\ u &= v + \alpha^{[m]}(\xi) + \beta^{[m-1]}(\xi) v, \end{aligned}$$

where $\alpha^{[m]}$, $\beta^{[m-1]}$, *and the components* $\phi^{[m]}_j$ *of* $\phi^{[m]}$ *are defined by* (2.12), *brings the homogeneous system* $\Sigma^{[m]}$ *into its normal form* $\Sigma^{[m]}_{NF}$ *given by* (2.7).

Proof of Theorem 3. Denote by

$$\tilde{\Sigma}^{[m]} \ : \ \dot{x} = Ax + Bv + \tilde{f}^{[m]}(x) + \tilde{g}^{[m-1]}(x) v$$

the system $\Sigma^{[m]}$ transformed via the feedback transformation Γ^m defined by (2.12).

From the expressions of $\alpha^{[m]}(\xi)$ and $\beta^{[m-1]}(\xi)$ given by (2.12) and the last two equations of (2.6), we get

$$\tilde{f}_n^{[m]}(x) = 0 \qquad \text{and} \qquad \tilde{g}_n^{[m-1]}(x) = 0.$$

Plugging $\phi_j^{[m]}$, defined by (2.12), into the second equation of (2.6) gives

$$\psi_{j,n}^{[m-1]}(x) = \tilde{g}_j^{[m-1]}(x) - g_j^{[m-1]}(x),$$

which, by (2.10), implies $\tilde{g}_j^{[m-1]}(x) = 0$ for $1 \le j \le n-1$. Now we consider the first equation of (2.6). From the expression of $\phi_n^{[m]}$ we get $\tilde{f}_{n-1}^{[m]}(x) = 0$, and for any $1 \le i \le n$, we obtain by differentiating

$$\frac{\partial \tilde{f}_j^{[m]}}{\partial x_i} = \frac{\partial f_j^{[m]}}{\partial x_i} + L_{Ax}\frac{\partial \phi_j^{[m]}}{\partial x_i} + \frac{\partial \phi_j^{[m]}}{\partial x_{i-1}} - \frac{\partial \phi_{j+1}^{[m]}}{\partial x_i}. \tag{2.13}$$

In the above formula, the term $\frac{\partial \phi_j^{[m]}}{\partial x_{i-1}}$ is not present in the case $i = 1$.

If $i \ge j+1$, we get

$$\begin{aligned}\frac{\partial \tilde{f}_j^{[m]}}{\partial x_i}(\pi_{i-1}(x)) &= \left(\frac{\partial f_j^{[m]}}{\partial x_i} + L_{Ax}\frac{\partial \phi_j^{[m]}}{\partial x_i} + \frac{\partial \phi_j^{[m]}}{\partial x_{i-1}} - \frac{\partial \phi_{j+1}^{[m]}}{\partial x_i}\right)(\pi_{i-1}(x)) \\ &= \frac{\partial f_j^{[m]}}{\partial x_i}(\pi_{i-1}(x)) + L_{Ax}\psi_{j,i}^{[m-1]}(\pi_{i-1}(x)) \\ &\quad + \psi_{j,i-1}^{[m-1]}(\pi_{i-1}(x)) - \psi_{j+1,i}^{[m-1]}(\pi_{i-1}(x)).\end{aligned}$$

Hence, by an induction argument, we obtain

$$\frac{\partial f_j^{[m]}}{\partial x_i}(\pi_{i-1}(x)) + L_{Ax}\psi_{j,i}^{[m-1]}(\pi_{i-1}(x)) + \psi_{j,i-1}^{[m-1]}(\pi_{i-1}(x)) - \psi_{j+1,i}^{[m-1]}(\pi_{i-1}(x)) = 0$$

and, finally, we get

$$\frac{\partial \tilde{f}_j^{[m]}}{\partial x_i}(\pi_{i-1}(x)) = 0. \tag{2.14}$$

If $1 \le i \le j$, then, using (2.12) and (2.13), we obtain

$$\begin{aligned}\frac{\partial \tilde{f}_j^{[m]}}{\partial x_i}(\pi_i(x)) &= \left(\frac{\partial f_j^{[m]}}{\partial x_i} + L_{Ax}\frac{\partial \phi_j^{[m]}}{\partial x_i} + \frac{\partial \phi_j^{[m]}}{\partial x_{i-1}} - \frac{\partial \phi_{j+1}^{[m]}}{\partial x_i}\right)(\pi_i(x)) \\ &= \frac{\partial f_j^{[m]}}{\partial x_i}(\pi_i(x)) + L_{Ax}\psi_{j,i}^{[m-1]}(\pi_i(x)) + \psi_{j,i-1}^{[m-1]}(\pi_{i-1}(x)) \\ &\quad + \int_0^{x_i} \frac{\partial \psi_{j,i}^{[m-1]}(\pi_i(x))}{\partial x_{i-1}} dx_i - \psi_{j+1,i}^{[m-1]}(\pi_i(x)).\end{aligned}$$

Using the expression (2.11), it follows that

$$\frac{\partial \tilde{f}_j^{[m]}}{\partial x_i}(\pi_i(x)) = 0. \tag{2.15}$$

From the relations (2.14) and (2.15), we conclude that

$$\tilde{f}_j^{[m]}(x) = \sum_{i=j+2}^{n} x_i^2 P_{j,i}^{[m-2]}(x_1, \dots, x_i),$$

which proves that $\tilde{\Sigma}^{[m]}$ is a normal form satisfying (2.7). Thus the system $\Sigma^{[m]}$ given by (2.4) is feedback equivalent to the normal form $\Sigma_{NF}^{[m]}$ given by (2.7). □

Example 1. To illustrate results of this section, we consider the system $\Sigma^{[m]}$, given by (2.4) on $\mathbb{R}^3$. Theorem 1 implies that the system $\Sigma^{[m]}$ is equivalent, via a homogeneous feedback transformation Γ^m defined by (2.12), to its normal form $\Sigma_{NF}^{[m]}$ (see (2.7))

$$\begin{aligned} \dot{x}_1 &= x_2 + x_3^2 P^{[m-2]}(x_1, x_2, x_3), \\ \dot{x}_2 &= x_3, \\ \dot{x}_3 &= v, \end{aligned}$$

where $P^{[m-2]}(x_1, x_2, x_3)$ is a homogeneous polynomial of degree $m-2$ of the variables x_1, x_2, x_3. □

We would like now to discuss the interest of Theorem 3. As we have already mentioned, Poincaré's method allows us to replace a partial differential equation by solving successively linear algebraic equations defined by the homological equation (2.6); see [26] and [21], and Proposition 1. The solvability of this equation was proved in [26] and [21], while Theorem 3 provides an explicit solution (in the form of the transformations (2.12), which are easily computable via differentiation and integration of homogeneous polynomials) to the homological equation. As a consequence, for any given control system, Theorem 3 gives transformations bringing the homogeneous part of the system to its normal form. For example, if the system is feedback linearizable, up to order $m_0 - 1$ (see [27]), then a diffeomorphism and a feedback compensating all nonlinearities of degree lower than m_0 can be calculated explicitly without solving partial differential equations. More generally, by a successive application of transformations given by (2.12) we can bring the system, without solving partial differential equations, to its normal form given in Theorem 4 below.

Consider the system Σ^∞ of the form (2.1) and recall that we assume the linear part (F, G) to be controllable. Apply successively to Σ^∞ a series of transformations Γ^m, $m = 1, 2, \dots$, such that each Γ^m brings $\Sigma^{[m]}$ to its normal form $\Sigma_{NF}^{[m]}$; for instance we can take a series of transformations defined by (2.12). Successive repeating of Theorem 1 gives the following result of Kang [21].

THEOREM 4. *There exists a formal feedback transformation* Γ^∞ *which brings the*

system Σ^∞ *to a normal form* Σ^∞_{NF} *given by*

$$\Sigma^\infty_{NF}\ :\ \begin{cases} \dot{x}_1 = x_2 + \displaystyle\sum_{i=3}^{n} x_i^2 P_{1,i}(x_1,\dots,x_i), \\ \qquad\vdots \\ \dot{x}_j = x_{j+1} + \displaystyle\sum_{i=j+2}^{n} x_i^2 P_{j,i}(x_1,\dots,x_i), \\ \qquad\vdots \\ \dot{x}_{n-2} = x_{n-1} + x_n^2 P_{n-2,n}(x_1,\dots,x_n), \\ \dot{x}_{n-1} = x_n, \\ \dot{x}_n = v, \end{cases} \tag{2.16}$$

where $P_{j,i}(x_1,\dots,x_i)$ *are formal power series depending on the indicated variables.*

Example 2. Consider a system Σ defined on $\mathbb{R}^3$ whose linear part is controllable. Theorem 4 implies that the system Σ is equivalent, via a formal feedback transformation Γ^∞, to its normal form Σ^∞_{NF}

$$\begin{aligned} \dot{x}_1 &= x_2 + x_3^2 P(x_1,x_2,x_3), \\ \dot{x}_2 &= x_3, \\ \dot{x}_3 &= v, \end{aligned}$$

where $P(x_1,x_2,x_3)$ is a formal power series of the variables x_1,x_2,x_3. □

3. Canonical form. As proved by Kang and recalled in Theorem 2, the normal form $\Sigma^{[m]}_{NF}$ is unique under homogeneous feedback transformation Γ^m. The normal form Σ^∞_{NF} is constructed by a successive application of homogeneous transformations Γ^m for $m \geq 1$ which bring the corresponding homogeneous systems $\Sigma^{[m]}$ into their normal forms $\Sigma^{[m]}_{NF}$. Therefore a natural and fundamental question which arises is whether the system Σ^∞ can admit two different normal forms, that is, whether the normal forms given by Theorem 4 are in fact canonical forms under a general formal feedback transformations of the form Γ^∞. It turns out that a given system can admit different normal forms, as the following example of Kang [21] shows. The main reason for the nonuniqueness of the normal form Σ^∞_{NF} is that, although the normal form $\Sigma^{[m]}_{NF}$ is unique, homogeneous feedback transformation Γ^m bringing $\Sigma^{[m]}$ into $\Sigma^{[m]}_{NF}$ is not. It is this small group of homogeneous feedback transformations of order m that preserve $\Sigma^{[m]}_{NF}$ (described by Proposition 2 below), which causes the nonuniqueness of Σ^∞_{NF}.

The aim of this section is thus to construct a canonical form for Σ^∞ under feedback transformation Γ^∞.

Example 3. Consider the system

$$\begin{aligned} \dot{\xi}_1 &= \xi_2 + \xi_3^2 - 2\xi_1\xi_3^2, \\ \dot{\xi}_2 &= \xi_3, \\ \dot{\xi}_3 &= u \end{aligned} \tag{3.1}$$

on $\mathbb{R}^3$. Clearly, this system is in Kang normal form (compare with Theorem 4). The

feedback transformation

$$\Gamma^{\leq 3}\ :\ \begin{aligned} x_1 &= \xi_1 - \xi_1^2 - \tfrac{4}{3}\xi_2^3,\\ x_2 &= \xi_2 - 2\xi_1\xi_2,\\ x_3 &= \xi_3 - 2(\xi_2^2 + \xi_1\xi_3) - 2\xi_2\xi_3^2,\\ u &= v + 6\xi_2\xi_3 + 12\xi_1\xi_2\xi_3 - 4\xi_3^3 + 2(\xi_1 + 2\xi_1^2 + 2\xi_2\xi_3)v \end{aligned}$$

brings the system (3.1) into the form

$$\begin{aligned} \dot{x}_1 &= x_2 + x_3^2,\\ \dot{x}_2 &= x_3,\\ \dot{x}_3 &= v \end{aligned}$$

modulo terms in $R^{\geq 4}(x, v)$. Applying successively homogeneous feedback transformations Γ^m given, for any $m \geq 4$, by (2.12), we transform the above system into the normal form

$$\begin{aligned} \dot{x}_1 &= x_2 + x_3^2 + x_3^2 P(x),\\ \dot{x}_2 &= x_3,\\ \dot{x}_3 &= v, \end{aligned} \tag{3.2}$$

where P is a formal power series whose 1-jet at $0 \in \mathbb{R}^3$ vanishes. The systems (3.1) and (3.2) are in their normal forms and, moreover, feedback equivalent, but the latter system does not contain any term of degree 3. As a consequence, the normal form Σ^{∞}_{NF} is not unique under formal feedback transformations. □

Consider the system Σ^{∞} of the form (2.1). Since its linear part (F, G) is assumed to be controllable, we bring it, via a linear transformation and linear feedback, to the Brunovský canonical form (A, B). Let the first homogeneous term of Σ^{∞} which cannot be annihilated by a feedback transformation be of degree m_0. As proved by Krener [27], the degree m_0 is given by the largest integer p such that all distributions $\mathcal{D}^k = \operatorname{span}\{g, \dots, ad_f^{k-1} g\}$ for $1 \leq k \leq n-1$ are involutive modulo terms of order $p-2$. We can thus, due to Theorems 1 and 2, assume that, after applying a suitable feedback, Σ^{∞} takes the form

$$\dot{\xi} = A\xi + Bu + \bar{f}^{[m_0]}(\xi) + \sum_{m=m_0+1}^{\infty} \left(f^{[m]}(\xi) + g^{[m-1]}(\xi)u \right),$$

where (A, B) is in Brunovský canonical form and the first nonvanishing homogeneous vector field $\bar{f}^{[m_0]}$ is of the form

$$\bar{f}_j^{[m_0]}(\xi) = \begin{cases} \displaystyle\sum_{i=j+2}^{n} \xi_i^2 P_{j,i}^{[m_0-2]}(\xi_1, \dots, \xi_i), & 1 \leq j \leq n-2,\\ 0, & n-1 \leq j \leq n. \end{cases}$$

Let $(i_1, \dots, i_{n-s})$, where $i_1 + \cdots + i_{n-s} = m_0$ and $i_{n-s} \geq 2$, be the largest, in the lexicographic ordering, $(n-s)$-tuple of nonnegative integers such that for some $1 \leq j \leq n-2$, we have

$$\frac{\partial^{m_0} \bar{f}_j^{[m_0]}}{\partial \xi_1^{i_1} \cdots \partial \xi_{n-s}^{i_{n-s}}} \neq 0.$$

Define

$$j^* = \sup\left\{ j = 1, \dots, n-2 \ : \ \frac{\partial^{m_0} \bar{f}_j^{[m_0]}}{\partial \xi_1^{i_1} \cdots \partial \xi_{n-s}^{i_{n-s}}} \neq 0 \right\}.$$

We have the following result.

THEOREM 5. *The system* Σ^∞ *given by* (2.1) *is equivalent by a formal feedback* Γ^∞ *to a system of the form*

$$\Sigma_{CF}^\infty \ : \ \dot{x} = Ax + Bv + \sum_{m=m_0}^{\infty} \bar{f}^{[m]}(x), \tag{3.3}$$

where, for any $m \geq m_0$,

$$\bar{f}_j^{[m]}(x) = \begin{cases} \displaystyle\sum_{i=j+2}^{n} x_i^2 P_{j,i}^{[m-2]}(x_1, \dots, x_i), & 1 \leq j \leq n-2, \\ 0, & n-1 \leq j \leq n; \end{cases} \tag{3.4}$$

additionally, we have

$$\frac{\partial^{m_0} \bar{f}_{j^*}^{[m_0]}}{\partial x_1^{i_1} \cdots \partial x_{n-s}^{i_{n-s}}} = \pm 1 \tag{3.5}$$

and, moreover, for any $m \geq m_0 + 1$,

$$\frac{\partial^{m_0} \bar{f}_{j^*}^{[m]}}{\partial x_1^{i_1} \cdots \partial x_{n-s}^{i_{n-s}}}(x_1, 0, \dots, 0) = 0. \tag{3.6}$$

The form Σ_{CF}^∞ satisfying (3.4), (3.5), and (3.6) will be called the *canonical form* of Σ^∞. The name is justified by the following.

THEOREM 6. *Two systems* Σ_1^∞ *and* Σ_2^∞ *are formally feedback equivalent if and only if their canonical forms* $\Sigma_{1,CF}^\infty$ *and* $\Sigma_{2,CF}^\infty$ *coincide.*

Proofs of Theorems 5 and 6 are given in section 4.

Kang [21], generalizing [26], proved that any system Σ^∞ can be brought by a formal feedback into the normal form (3.3) for which (3.4) is satisfied. He also observed that his normal forms are not unique; see Example 3. Our results, Theorems 5 and 6, complete his study. We show that for each degree m of homogeneity we can use a one-dimensional subgroup of feedback transformations which preserves the "triangular" structure of (3.4) and at the same time allows us to normalize one higher order term. The form of (3.5) and (3.6) is a result of this normalization. These one-dimensional subgroups of feedback transformations are given by the following proposition.

PROPOSITION 2. *The transformation* Γ^m *given by* (2.3) *leaves invariant the system* $\Sigma^{[m]}$ *defined by* (2.4) *if and only if*

$$\begin{aligned} \phi_j^{[m]} &= a_m L_{A\xi}^{j-1} \xi_1^m, \qquad 1 \leq j \leq n, \\ \alpha^{[m]} &= -a_m L_{A\xi}^n \xi_1^m, \\ \beta^{[m-1]} &= -a_m L_B L_{A\xi}^{n-1} \xi_1^m, \end{aligned} \tag{3.7}$$

where a_m is an arbitrary real parameter.

Proof of Proposition 2. Observe that, following Proposition 1, the transformation Γ^m leaves invariant the system $\Sigma^{[m]}$ if and only if it satisfies the following system of equations:

$$\begin{cases} L_{A\xi}\phi_j^{[m]} - \phi_{j+1}^{[m]}(\xi) = 0, & 1 \le j \le n-1, \\ L_B\phi_j^{[m]} = 0, & 1 \le j \le n-1, \\ L_{A\xi}\phi_n^{[m]} + \alpha^{[m]}(\xi) = 0, \\ L_B\phi_n^{[m]} + \beta^{[m-1]}(\xi) = 0. \end{cases}$$

In order to solve the above system, let us remark, using the second equation of the system, that for any j such that $1 \le j \le n-1$, the component $\phi_j^{[m]}$ does not depend to the variable ξ_n. Putting $j = n-2$ into the first equation, we get

$$\frac{\partial \phi_{n-2}^{[m]}}{\partial \xi_1}\xi_2 + \cdots + \frac{\partial \phi_{n-2}^{[m]}}{\partial \xi_{n-1}}\xi_n = \phi_{n-1}^{[m]}.$$

Since $\phi_{n-1}^{[m]}$ and $\phi_{n-2}^{[m]}$ do not depend on the variable ξ_n, we conclude that $\phi_{n-2}^{[m]}$ does not depend on the variable ξ_{n-1}. An inductive argument shows that $\phi_1^{[m]}$ depends only on the variable ξ_1, that is, $\phi_1^{[m]}(\xi) = a_m\xi_1^m$. Now, all equations of (3.7) follow easily. □

Theorem 5 establishes an equivalence of the system Σ^∞ with its canonical form Σ_{CF}^∞ via a formal feedback. Its direct corollary yields the following result for equivalence under a smooth feedback of the form

$$\Gamma \ : \quad \begin{array}{l} x = \phi(\xi), \\ u = \alpha(\xi) + \beta(\xi)v, \end{array}$$

up to an arbitrary order.

Corollary 1. *Consider a smooth control system*

$$\Sigma \ : \ \dot{\xi} = f(\xi) + g(\xi)u.$$

For any positive integer k we have the following:

(i) *There exists a smooth feedback Γ transforming Σ, locally around $0 \in \mathbb{R}^n$, into its canonical form $\Sigma_{CF}^{\le k}$ given by*

$$\Sigma_{CF}^{\le k} \ : \ \dot{x} = Ax + Bv + \sum_{m=m_0}^{k} \bar{f}^{[m]}(x),$$

modulo $O(x,v)^{k+1}$, where $\bar{f}^{[m]}(x)$, for any $m_0 \le m \le k$, satisfies (3.4), (3.5), (3.6).

(ii) *Feedback equivalence of Σ and $\Sigma_{CF}^{\le k}$, modulo $O(x,v)^{k+1}$, can be established via a polynomial feedback transformation $\Gamma^{\le k}$ of degree k.*

(iii) *Two smooth systems Σ_1 and Σ_2 are feedback equivalent modulo terms of order $O(x,v)^{k+1}$ if and only if their canonical forms $\Sigma_{1,CF}^{\le k}$ and $\Sigma_{2,CF}^{\le k}$ coincide.*

This corollary follows directly from Theorem 5 and its proof, given in section 4, which provides explicit polynomial transformations (4.4)–(4.5) bringing, step by step, the system into its canonical form.

We will illustrate results of this section by two examples.

Example 4. Let us reconsider the system Σ given by Example 2. It is feedback equivalent to the normal form

$$\begin{aligned}\dot{x}_1 &= x_2 + x_3^2 P(x_1, x_2, x_3),\\ \dot{x}_2 &= x_3,\\ \dot{x}_3 &= v,\end{aligned}$$

where $P(x_1, x_2, x_3)$ is a formal power series. Assume, for simplicity, that $m_0 = 2$, which is equivalent to the following generic condition: g, $ad_f g$, and $[g, ad_f g]$ are linearly independent at $0 \in \mathbb{R}^3$. This implies that we can express $P = P(x_1, x_2, x_3)$ as

$$P = c + P_1(x_1) + x_2 P_2(x_1, x_2) + x_3 P_3(x_1, x_2, x_3),$$

where $c \neq 0$ and $P_1(0) = 0$. Observe that any $P(x_1, x_2, x_3)$, of the above form, gives a normal form Σ_{NF}^{∞}. In order to get the canonical form Σ_{CF}^{∞}, we use Theorem 5, which ensures the existence of a feedback transformation Γ^{∞} of the form

$$\begin{aligned}\tilde{x} &= \phi(x),\\ v &= \alpha(x) + \beta(x)\tilde{v},\end{aligned}$$

which normalizes the constant c and annihilates the formal power series $P_1(x_1)$. More precisely, Γ^{∞} transforms Σ into its canonical form Σ_{CF}^{∞},

$$\begin{aligned}\dot{\tilde{x}}_1 &= \tilde{x}_2 + \tilde{x}_3^2 \tilde{P}(\tilde{x}_1, \tilde{x}_2, \tilde{x}_3),\\ \dot{\tilde{x}}_2 &= \tilde{x}_3,\\ \dot{\tilde{x}}_3 &= \tilde{v},\end{aligned}$$

where the formal power series $\tilde{P}(\tilde{x}_1, \tilde{x}_2, \tilde{x}_3)$ is of the form

$$\tilde{P}(\tilde{x}_1, \tilde{x}_2, \tilde{x}_3) = 1 + \tilde{x}_2 \tilde{P}_2(\tilde{x}_1, \tilde{x}_2) + \tilde{x}_3 \tilde{P}_3(\tilde{x}_1, \tilde{x}_2, \tilde{x}_3).$$

Now, we give an example of constructing the canonical form for a physical model of variable length pendulum. □

Example 5. Consider the variable length pendulum of Bressan and Rampazzo [5] (see also [2] and [8]). We denote by ξ_1 the length of the pendulum, by ξ_2 its velocity, by ξ_3 the angle with respect to the horizontal, and by ξ_4 the angular velocity. The control $u = \dot{\xi}_4 = \ddot{\xi}_3$ is the angular acceleration. The mass is normalized to 1. The equations are (compare [5] and [8])

$$\begin{aligned}\dot{\xi}_1 &= \xi_2,\\ \dot{\xi}_2 &= -g \sin \xi_3 + \xi_1 \xi_4^2,\\ \dot{\xi}_3 &= \xi_4,\\ \dot{\xi}_4 &= u,\end{aligned}$$

where g denotes the gravity. Notice that if we suppose to control the angular velocity $\xi_4 = \dot{\xi}_3$, which is the case of [5] and [8], then the system is three-dimensional but the control enters nonlinearly.

At any equilibrium point $\xi_0 = (\xi_{10}, \xi_{20}, \xi_{30}, \xi_{40})^T = (\xi_{10}, 0, 0, 0)^T$, the linear part of the system is controllable. Our goal is to produce, for the variable length pendulum,

a normal form and the canonical form as well as to answer the question whether the systems corresponding to various values of the gravity constant g are feedback equivalent. In order to get a normal form, put

$$\begin{aligned} x_1 &= \xi_1, \\ x_2 &= \xi_2, \\ x_3 &= -g \sin \xi_3, \\ x_4 &= -g\xi_4 \cos \xi_3, \\ v &= g\xi_4^2 \sin \xi_3 - ug \cos \xi_3. \end{aligned}$$

The system becomes

$$\begin{aligned} \dot{x}_1 &= x_2, \\ \dot{x}_2 &= x_3 + x_4^2 \frac{x_1}{g^2 - x_3^2}, \\ \dot{x}_3 &= x_4, \\ \dot{x}_4 &= v, \end{aligned}$$

which gives a normal form. Indeed, we rediscover Σ_{NF}^{∞}, given by (2.16), with $P_{1,3} = 0$, $P_{1,4} = 0$, and

$$P_{2,4} = \frac{x_1}{g^2 - x_3^2}.$$

In order to bring the system to its canonical form Σ_{CF}^{∞}, first observe that $m_0 = 3$. Indeed, the function $x_4^2 \frac{x_1}{g^2 - x_3^2}$ starts with third order terms, which corresponds to the fact that the invariants $a^{[2]j,i+2}$ vanish for any $1 \leq j \leq 2$ and any $0 \leq i \leq 2 - j$. The only nonzero component of $f^{[3]}$ is $f_2^{[3]} = x_4^2 P_{2,4}^{[1]}$. Hence $j^* = 2$ and the only, and thus largest, quadruplet (i_1, i_2, i_3, i_4) of nonnegative integers, satisfying $i_1 + i_2 + i_3 + i_4 = 3$ and such that

$$\frac{\partial^3 f_2^{[3]}}{\partial x_1^{i_1} \cdots \partial x_4^{i_4}} \neq 0,$$

is $(i_1, i_2, i_3, i_4) = (1, 0, 0, 2)$. In order to normalize $f_2^{[3]}$, put

$$\begin{aligned} \tilde{x}_i &= a_1 x_i, \quad 1 \leq i \leq 4, \\ \tilde{v} &= a_1 v, \end{aligned}$$

where $a_1 = 1/g$. We get the following canonical form for the variable length pendulum:

$$\begin{aligned} \dot{\tilde{x}}_1 &= \tilde{x}_2, \\ \dot{\tilde{x}}_2 &= \tilde{x}_3 + \tilde{x}_4^2 \frac{\tilde{x}_1}{1 - \tilde{x}_3^2}, \\ \dot{\tilde{x}}_3 &= \tilde{x}_4, \\ \dot{\tilde{x}}_4 &= \tilde{v}. \end{aligned}$$

Independently of the value of the gravity constant g, all systems are feedback equivalent to each other. □

4. Proofs of Theorems 5 and 6.

Proof of Theorem 5. The proof of this theorem will be done in two steps. In the first step we will deal with terms of degree m_0. Then we will prove the general step by an induction argument.

First step. Let us consider the system Σ^∞ given by (2.1) and let m_0 be the degree of the first nonlinearizable homogeneous part. We can assume that (see Theorems 1 and 2), after applying a suitable feedback transformation, the system Σ^∞ given by (2.1) takes the form

$$\dot{\xi} = A\xi + Bu + \bar{f}^{[m_0]}(\xi) + \sum_{m=m_0+1}^{\infty} \left(f^{[m]}(\xi) + g^{[m-1]}(\xi)u \right), \tag{4.1}$$

where (A, B) is in Brunovský canonical form and the first nonvanishing vector field $\bar{f}^{[m_0]}$ is of the form

$$\bar{f}_j^{[m_0]}(\xi) = \begin{cases} \displaystyle\sum_{i=j+2}^{n} \xi_i^2 P_{j,i}^{[m_0-2]}(\xi_1, \dots, \xi_i), & 1 \le j \le n-2, \\ 0, & n-1 \le j \le n. \end{cases}$$

Notice that the linear feedback transformation

$$\Gamma^1 \ : \ \begin{array}{l} x = a_1 \xi, \\ u = \frac{1}{a_1} v, \end{array}$$

where $a_1 \in \mathbb{R}$ and $a_1 \neq 0$, brings the system (4.1) into the following one:

$$\dot{x} = Ax + Bv + \frac{1}{a_1^{m_0-1}} \bar{f}^{[m_0]}(x) + \sum_{m=m_0+1}^{\infty} \left(\tilde{f}^{[m]}(x) + \tilde{g}^{[m-1]}(x)v \right).$$

By the definitions of $(i_1, \dots, i_{n-s})$ and j^*, we have

$$\frac{\partial^{m_0} \bar{f}_{j^*}^{[m_0]}}{\partial x_1^{i_1} \cdots \partial x_{n-s}^{i_{n-s}}} \neq 0,$$

and thus we can suitably choose the parameter a_1 such that

$$\frac{\partial^{m_0} \bar{f}_{j^*}^{[m_0]}}{\partial x_1^{i_1} \cdots \partial x_{n-s}^{i_{n-s}}} = \pm 1.$$

General step. Now, we assume that, for some $l \ge 1$, the system Σ^∞ given by (2.1), takes the form

$$\Sigma^\infty \ : \ \dot{\xi} = A\xi + Bu + \sum_{m=m_0}^{m_0+l-1} \bar{f}^{[m]}(\xi) + f^{[m_0+l]}(\xi) + g^{[m_0+l-1]}(\xi)u + r(\xi, u), \tag{4.2}$$

where $r(\xi, u) \in R^{\ge m_0+l+1}(\xi, u)$ and the vector fields $\bar{f}^{[m]}(\xi)$ for any m such that $m_0 \le m \le m_0 + l - 1$ satisfy the conditions (3.4), (3.5), and (3.6). We will construct a transformation Γ^∞ which preserves all terms of degree smaller than $m_0 + l$ while taking those of degree $m_0 + l$ into the canonical form defined by (3.4) and (3.6).

Consider the following feedback transformation

$$\Gamma^{\infty} \; : \; \begin{aligned} x &= \xi + \sum_{m=l+1}^{\infty} \phi^{[m]}(\xi), \\ u &= v + \sum_{m=l+1}^{\infty} \left(\alpha^{[m]}(\xi) + \beta^{[m-1]}(\xi) v \right), \end{aligned} \tag{4.3}$$

where, for any m such that $m_0 \leq m \leq m_0 + l - 1$, the triplet $(\phi^{[m]}, \alpha^{[m]}, \beta^{[m-1]})$ is given by (3.7) and $\phi^{[m]} = 0$, $\alpha^{[m]} = 0$, and $\beta^{[m-1]} = 0$ for $m \geq m_0 + l + 1$.

The transformation Γ^{∞} is actually a polynomial transformation $\Gamma^{\leq m_0+l}$ and can be viewed as a composition of a transformation $\Gamma^{\leq m_0+l-1}$ and a homogeneous transformation Γ^{m_0+l} defined, respectively, by

$$\Gamma^{\leq m_0+l-1} \; : \; \begin{aligned} y &= \xi + \sum_{m=l+1}^{m_0+l-1} \phi^{[m]}(\xi), \\ u &= w + \sum_{m=l+1}^{m_0+l-1} \left(\alpha^{[m]}(\xi) + \beta^{[m-1]}(\xi) w \right) \end{aligned} \tag{4.4}$$

and

$$\Gamma^{m_0+l} \; : \; \begin{aligned} x &= y + \phi^{[m_0+l]}(y), \\ w &= v + \alpha^{[m_0+l]}(y) + \beta^{[m_0+l-1]}(y) v. \end{aligned} \tag{4.5}$$

Let us denote by $\tilde{\Sigma}^{\infty}$ the system Σ^{∞}, given by (4.2), transformed via $\Gamma^{\leq m_0+l-1}$. Since

$$\bar{f}^{[m_0]}(\xi) = \bar{f}^{[m_0]}(y - \phi^{[l+1]}(y) - \cdots) = \bar{f}^{[m_0]}(y) - \frac{\partial \bar{f}^{[m_0]}}{\partial y} \phi^{[l+1]}(y) + r_1(y),$$

where $r_1(y) \in R^{\geq m_0+l+1}(y)$ and for any $m \geq m_0 + 1$,

$$\bar{f}^{[m]}(\xi) = \bar{f}^{[m]}(y - \phi^{[l+1]}(y) - \cdots) = \bar{f}^{[m]}(y) + r_2(y),$$

where $r_2(y) \in R^{\geq m_0+l+1}(y)$, we get

$$\tilde{\Sigma}^{\infty} \; : \; \dot{y} = Ay + Bw + \sum_{m=m_0}^{m_0+l-1} \bar{f}^{[m]}(y) + \tilde{f}^{[m_0+l]}(y) + \tilde{g}^{[m_0+l-1]}(y) w + r_3(y, w), \tag{4.6}$$

where $r_3(y, w) \in R^{\geq m_0+l+1}(y, w)$ and

$$\begin{aligned} \tilde{f}^{[m_0+l]} &= f^{[m_0+l]} + [\bar{f}^{[m_0]}, \phi^{[l+1]}], \\ \tilde{g}^{[m_0+l-1]} &= g^{[m_0+l-1]}. \end{aligned}$$

Let

$$\left\{ a^{[m_0+l]j,i+2} \; : \; (j, i) \in \Delta \right\}$$

and

$$\left\{\tilde{a}^{[m_0+l]j,i+2} \ : \ (j,i)\in\Delta\right\}$$

denote, respectively, the sets of (m_0+l)-invariants associated with the homogeneous parts of degree m_0+l of the systems (4.2) and (4.6). We have

$$\tilde{a}^{[m_0+l]j,i+2} = a^{[m_0+l]j,i+2} + \hat{a}^{[m_0+l]j,i+2}, \tag{4.7}$$

where

$$\begin{aligned}\hat{a}^{[m_0+l]j,i+2} = CA^{j-1}\Bigg[&\sum_{k=0}^{i}(-1)^{i+k}\left(ad_{A^iB}ad_{A\xi}^{i-k}ad_{A^kB}\left[\bar{f}^{[m_0]},\phi^{[l+1]}\right]\right)(\pi_{n-i}(\xi))\\ &+\sum_{k=0}^{i-1}(-1)^{i+k}\left(ad_{A^{i+1}B}ad_{A\xi}^{i-k-1}ad_{A^kB}\left[\bar{f}^{[m_0]},\phi^{[l+1]}\right]\right)(\pi_{n-i}(\xi))\Bigg].\end{aligned}$$

Since the identity

$$ad_{A^{n-1}B}^{k}ad_{A\xi}^{i}h = ad_{A\xi}^{i}ad_{A^{n-1}B}^{k}h$$

holds for any vector field h and any $k,i\geq 0$, we get by differentiating

$$\begin{aligned}&L_{A^{n-1}B}^{i_1+l}\hat{a}^{[m_0+l]j,i+2}\\ &= CA^{j-1}\Bigg[\sum_{k=0}^{i}(-1)^{i+k}\left(ad_{A^iB}ad_{A\xi}^{i-k}ad_{A^kB}ad_{A^{n-1}B}^{i_1+l}\left[\bar{f}^{[m_0]},\phi^{[l+1]}\right]\right)(\pi_{n-i}(\xi))\\ &\quad+\sum_{k=0}^{i-1}(-1)^{i+k}\left(ad_{A^{i+1}B}ad_{A\xi}^{i-k-1}ad_{A^kB}ad_{A^{n-1}B}^{i_1+l}\left[\bar{f}^{[m_0]},\phi^{[l+1]}\right]\right)(\pi_{n-i}(\xi))\Bigg].\end{aligned} \tag{4.8}$$

Due to the definition of the $(n-s)$-tuple $(i_1,\dots,i_{n-s})$, we obtain

$$\begin{aligned}ad_{A^{n-1}B}^{i_1+l}\left[\bar{f}^{[m_0]},\phi^{[l+1]}\right] &= c_1\left[ad_{A^{n-1}B}^{i_1}\bar{f}^{[m_0]},ad_{A^{n-1}B}^{l}\phi^{[l+1]}\right]\\ &\quad+c_2\left[ad_{A^{n-1}B}^{i_1-1}\bar{f}^{[m_0]},ad_{A^{n-1}B}^{l+1}\phi^{[l+1]}\right],\end{aligned} \tag{4.9}$$

where c_1 and c_2 are strictly positive integers. From the relations

$$\begin{aligned}ad_{A^{n-1}B}^{l}\phi^{[l+1]} &= a_{l+1}(l+1)!(\xi_1,\xi_2,\dots,\xi_n)^T,\\ ad_{A^{n-1}B}^{l+1}\phi^{[l+1]} &= a_{l+1}(l+1)!(1,0,\dots,0)^T,\end{aligned}$$

one can easily deduce that identity (4.10) can be rewritten as

$$ad_{A^{n-1}B}^{i_1+l}\left[\bar{f}^{[m_0]},\phi^{[l+1]}\right] = \gamma_l ad_{A^{n-1}B}^{i_1}\bar{f}^{[m_0]},$$

where we set $\gamma_l = -a_{l+1}(l+1)!\,(c_1(m_0-i_1+1)+c_2)$. Plugging the above identity into the formula (4.8), we obtain

$$\begin{aligned}&L_{A^{n-1}B}^{i_1+l}\hat{a}^{[m_0+l]j,i+2}\\ &= \gamma_l CA^{j-1}\Bigg[\sum_{k=0}^{i}(-1)^{i+k}\left(ad_{A^{n-1}B}^{i_1}ad_{A^iB}ad_{A\xi}^{i-k}ad_{A^kB}\bar{f}^{[m_0]}\right)(\pi_{n-i}(\xi))\\ &\quad+\sum_{k=0}^{i-1}(-1)^{i+k}\left(ad_{A^{n-1}B}^{i_1}ad_{A^{i+1}B}ad_{A\xi}^{i-k-1}ad_{A^kB}\bar{f}^{[m_0]}\right)(\pi_{n-i}(\xi))\Bigg].\end{aligned}$$

Since $\bar{f}^{[m_0]}$ is of the form (3.4), we get for any k such that $0 \leq k \leq i-1$,

$$ad_{A^kB}\bar{f}^{[m_0]}(\pi_{n-i}(\xi)) = 0$$

and for any $t \geq 0$,

$$\left(ad^t_{A\xi}ad_{A^kB}\bar{f}^{[m_0]}\right)(\pi_{n-i}(\xi)) = 0.$$

Thus, we can deduce the relation

$$\frac{\partial^{i_1+l}\hat{a}^{[m_0+l]j,i+2}}{\partial\xi_1^{i_1+l}} = \gamma_l CA^{j-1}\frac{\partial^{i_1+2}\bar{f}^{[m_0]}}{\partial\xi_1^{i_1}\partial\xi_{n-i}^2}(\pi_{n-i}(\xi)),$$

which leads, after differentiating and setting $j = j^*$ and $i = s$, to the following one:

$$\frac{\partial^{m_0+l-2}\hat{a}^{[m_0+l]j^*,s+2}}{\partial\xi_1^{i_1+l}\partial\xi_2^{i_2}\cdots\partial\xi_{n-s}^{i_{n-s}-2}} = \gamma_l\frac{\partial^{m_0}\bar{f}^{[m_0]}_{j^*}}{\partial\xi_1^{i_1}\partial\xi_2^{i_2}\cdots\partial\xi_{n-s}^{i_{n-s}}}.$$

Differentiating (4.7) and using the above identity, we get

$$\frac{\partial^{m_0+l-2}\tilde{a}^{[m_0+l]j^*,s+2}}{\partial\xi_1^{i_1+l}\partial\xi_2^{i_2}\cdots\partial\xi_{n-s}^{i_{n-s}-2}} = \frac{\partial^{m_0+l-2}a^{[m_0+l]j^*,s+2}}{\partial\xi_1^{i_1+l}\partial\xi_2^{i_2}\cdots\partial\xi_{n-s}^{i_{n-s}-2}} + \gamma_l\frac{\partial^{m_0}\bar{f}^{[m_0]}_{j^*}}{\partial\xi_1^{i_1}\partial\xi_2^{i_2}\cdots\partial\xi_{n-s}^{i_{n-s}}}.$$

We can choose suitably the parameter a_{l+1} (recall the definition of γ_l) such that we obtain

$$\frac{\partial^{m_0+l-2}\tilde{a}^{[m_0+l]j^*,s+2}}{\partial\xi_1^{i_1+l}\partial\xi_2^{i_2}\cdots\partial\xi_{n-i}^{i_{n-i}-2}} = 0.$$

Now, transforming the homogeneous part of degree m_0+l of the system (4.6) to its normal form via a homogeneous transformation Γ^{m_0+l} and taking into account Theorem 2, we bring the system (4.6) into the form

$$\Sigma^\infty \ : \ \dot{x} = Ax + Bv + \sum_{m=m_0}^{m_0+l}\bar{f}^{[m]}(x) + r(x,v),$$

where $r(x,v) \in R^{\geq m_0+l+1}(x,v)$ and the vector fields $\bar{f}^{[m]}$, for any m such that $m_0 \leq m \leq m_0+l$, satisfy the conditions (3.4), (3.5), and (3.6). This completes the proof of Theorem 5. □

In our proof of Theorem 6, we will use the following result.

LEMMA 1. *A transformation Γ^∞ leaves invariant all terms of degree smaller than m_0+l of the system* (4.2) *if and only if Γ^∞ is of the form*

$$\Gamma^\infty \ : \ \begin{aligned} x &= \xi + \sum_{m=l+1}^{\infty}\phi^{[m]}(\xi), \\ u &= v + \sum_{m=l+1}^{\infty}\left(\alpha^{[m]}(\xi) + \beta^{[m-1]}(\xi)v\right), \end{aligned} \tag{4.10}$$

where, for any m such that $m_0 \leq m \leq m_0+l-1$, the triplet $(\phi^{[m]}, \alpha^{[m]}, \beta^{[m-1]})$ is given by (3.7).

Proof of Lemma 1. We have shown, when proving Theorem 5, that the transformation Γ^∞, defined by (4.10) and (3.7), leaves invariant all terms of degree smaller than $m_0 + l$ of the system (4.2).

Conversely, assume that the transformation Γ^∞ leaves invariant all terms of degree smaller than $m_0 + l$ of the system (4.2). Without loss of generality, we can take

$$\Gamma^\infty \ : \begin{aligned} x &= \xi + \sum_{m=k+1}^{\infty} \phi^{[m]}(\xi), \\ u &= v + \sum_{m=k+1}^{\infty} (\alpha^{[m]}(\xi) + \beta^{[m-1]}(\xi)v), \end{aligned}$$

where $k+1$ denotes the smallest degree among degrees of all nonvanishing components $\phi_j^{[m]}$ of the transformation Γ^∞. There is nothing to prove if $k+1 \geq m_0 + l$. We thus focus our attention on the case $k+2 \leq m_0 + l$. Since Γ^∞ leaves invariant all terms of degree smaller than $m_0 + l$ of the system (4.2), in particular it leaves invariant terms of degree $k+1$, which implies that $(\phi^{[k+1]}, \alpha^{[k+1]}, \beta^{[k]})$ satisfies the condition (3.7). By induction, we show that $(\phi^{[m]}, \alpha^{[m]}, \beta^{[m-1]})$ also satisfies the condition (3.7) for any m such that $k+1 \leq m \leq m_0 + k - 1$. Thus it remains only to prove that $k \geq l$. Assume this is false; that is, suppose $k \leq l - 1$. We can see that the transformation Γ^∞ brings the system (4.2) into the following one:

$$\dot{x} = Ax + Bv + \sum_{m=m_0}^{m_0+k-1} \bar{f}^{[m]}(x) + \tilde{f}^{[m_0+k]}(x) + r(x, v), \tag{4.11}$$

where $r(x, v) \in R^{\geq m_0+k+1}(x, v)$ and the vector field $\bar{f}^{[m]}(x)$, for any m such that $m_0 \leq m \leq m_0 + k - 1$, is of the form (3.4) and (3.6) and

$$\tilde{f}^{[m_0+k]} = \bar{f}^{[m_0+k]} + [\bar{f}^{[m_0]}, \phi^{[k+1]}].$$

Since the transformation Γ^∞ leaves invariant all terms of degree smaller than $m_0 + l$ of the system (4.2), in particular it leaves invariant all terms of degree $m_0 + k$, which is equivalent to

$$[\bar{f}^{[m_0]}, \phi^{[k+1]}] = 0.$$

Repeating the calculations done in the proof of Theorem 5 we deduce, by differentiating, the identity

$$\frac{\partial^{m_0+k} C A^{j^*-1} [\bar{f}^{[m_0]}, \phi^{[k+1]}]}{\partial x_1^{i_1+k} \partial x_2^{i_2} \cdots \partial x_{n-s}^{i_{n-s}}} = \gamma_k \frac{\partial^{m_0} \bar{f}_{j^*}^{[m_0]}}{\partial x_1^{i_1} \partial x_2^{i_2} \cdots \partial x_{n-s}^{i_{n-s}}} = 0.$$

Thus, due to the fact that

$$\frac{\partial^{m_0} \bar{f}_{j^*}^{[m_0]}}{\partial x_1^{i_1} \partial x_2^{i_2} \cdots \partial x_{n-s}^{i_{n-s}}} \neq 0,$$

we obtain $\gamma_k = 0$ and hence $(\phi^{[k+1]}, \alpha^{[k+1]}, \beta^{[k]}) = 0$, which contradicts the definition of $k+1$. As a conclusion, it follows that the transformation Γ^∞ is of the form (4.10) and (3.7). □

Proof of Theorem 6. Let us consider two systems Σ_1^∞ and Σ_2^∞ and let

$$\Sigma_{1,CF}^\infty \ : \ \dot{x} = Ax + Bv + \sum_{m=m_0}^{\infty} \bar{f}^{[m]}(x)$$

and

$$\Sigma_{2,CF}^\infty \ : \ \dot{z} = Az + Bw + \sum_{m=m_1}^{\infty} \tilde{f}^{[m]}(z)$$

denote, respectively, their canonical forms, where m_0 and m_1 denote the degrees of the first nonlinearizable homogeneous parts. It is obvious that Σ_1^∞ and Σ_2^∞ are feedback equivalent if their canonical forms $\Sigma_{1,CF}^\infty$ and $\Sigma_{2,CF}^\infty$ coincide. To prove the converse, we assume that the systems Σ_1^∞ and Σ_2^∞ are feedback equivalent while their canonical forms fail to coincide. Since Σ_1^∞ and Σ_2^∞ are feedback equivalent, so are their canonical forms $\Sigma_{1,CF}^\infty$ and $\Sigma_{2,CF}^\infty$. It means that there exists a transformation Γ^∞ which brings $\Sigma_{1,CF}^\infty$ into $\Sigma_{2,CF}^\infty$. First remark that, from the definition of the integers m_0 and m_1, we necessarily have $m_0 = m_1$. Then, Theorem 2 and the fact that the components $\bar{f}_{j^*}^{[m_0]}$ and $\tilde{f}_{j^*}^{[m_0]}$ are normalized (see (3.5)) ensure that $\bar{f}^{[m_0]} = \tilde{f}^{[m_1]}$. Let l be the largest integer such that for any $i \leq l$, we have $\bar{f}^{[m_0+i-1]} = \tilde{f}^{[m_0+i-1]}$. This means that the transformation Γ^∞ leaves invariant all terms of degree smaller than m_0+l of the system $\Sigma_{1,CF}^\infty$. Then Lemma 1 shows that the transformation Γ^∞ is of the form (4.10). Since the transformation Γ^∞ brings $\Sigma_{1,CF}^\infty$ into $\Sigma_{2,CF}^\infty$, we deduce that

$$\tilde{f}^{[m_0+l]} = \bar{f}^{[m_0+l]} + [\bar{f}^{[m_0]}, \phi^{[l+1]}]. \tag{4.12}$$

Following arguments in the proof of Theorem 5, we obtain

$$\frac{\partial^{m_0+l-2}\tilde{a}^{[m_0+l]j^*,s+2}}{\partial x_1^{i_1+l}\partial x_2^{i_2}\cdots\partial x_{n-s}^{i_{n-s}-2}} = \frac{\partial^{m_0+l-2}\bar{a}^{[m_0+l]j^*,s+2}}{\partial x_1^{i_1+l}\partial x_2^{i_2}\cdots\partial x_{n-s}^{i_{n-s}-2}} + \gamma_l \frac{\partial^{m_0}\bar{f}_{j^*}^{[m_0]}}{\partial x_1^{i_1}\partial x_2^{i_2}\cdots\partial x_{n-s}^{i_{n-s}}},$$

where

$$\left\{\bar{a}^{[m_0+l]j,i+2} \ : \ (j,i) \in \Delta\right\}$$

and

$$\left\{\tilde{a}^{[m_0+l]j,i+2} \ : \ (j,i) \in \Delta\right\}$$

denote, respectively, the set of (m_0+l)-invariants associated with the homogeneous parts of degree m_0+l of the systems $\Sigma_{1,CF}^\infty$ and $\Sigma_{2,CF}^\infty$. Using Theorem 2, the last identity can be rewritten as

$$\frac{\partial^{m_0+l}\tilde{f}_{j^*}^{[m_0+l]}}{\partial x_1^{i_1+l}\partial x_2^{i_2}\cdots\partial x_{n-s}^{i_{n-s}}} = \frac{\partial^{m_0+l}\bar{f}_{j^*}^{[m_0+l]}}{\partial x_1^{i_1+l}\partial x_2^{i_2}\cdots\partial x_{n-s}^{i_{n-s}}} + \gamma_l \frac{\partial^{m_0}\bar{f}_{j^*}^{[m_0]}}{\partial x_1^{i_1}\partial x_2^{i_2}\cdots\partial x_{n-s}^{i_{n-s}}}. \tag{4.13}$$

Since

$$\frac{\partial^{m_0}\tilde{f}_{j^*}^{[m_0+l]}}{\partial x_1^{i_1}\cdots\partial x_{n-s}^{i_{n-s}}}(x_1,0,\ldots,0) = \frac{\partial^{m_0}\bar{f}_{j^*}^{[m_0+l]}}{\partial x_1^{i_1}\cdots\partial x_{n-s}^{i_{n-s}}}(x_1,0,\ldots,0) = 0,$$

the identity (4.13) gives

$$\gamma_l \frac{\partial^{m_0} \bar{f}_{j^*}^{[m_0]}}{\partial x_1^{i_1} \partial x_2^{i_2} \cdots \partial x_{n-s}^{i_{n-s}}} = 0,$$

which implies $\gamma_l = 0$, that is (recall the definition of γ_l), we have $a_{l+1} = 0$, and consequently $(\phi^{[l+1]}, \alpha^{[l+1]}, \beta^{[l]}) = 0$. Then the identity (4.12) reduces to

$$\tilde{f}^{[m_0+l]} = \bar{f}^{[m_0+l]},$$

which contradicts the definition of l. We conclude that the canonical forms $\Sigma^{\infty}_{1,CF}$ and $\Sigma^{\infty}_{2,CF}$ coincide. □

5. Dual normal form and dual m-invariants. In the normal form $\Sigma^{[m]}_{NF}$ given by (2.7), all the components of the control vector field $g^{[m-1]}$ are annihilated and all nonremovable nonlinearities are grouped in $f^{[m]}$. Kang and Krener in their pioneering paper [26] showed that it is possible to transform, via a transformation Γ^2 of degree 2, the homogeneous system

$$\Sigma^{[2]}: \ \dot{\xi} = A\xi + Bu + f^{[2]}(\xi) + g^{[1]}(\xi)u$$

into a dual normal form. In that form the components of the drift $f^{[2]}$ are annihilated, while this time all nonremovable nonlinearities are present in $g^{[1]}$. The aim of this section is to propose, for an arbitrary m, a dual normal form for the system $\Sigma^{[m]}$ and a dual normal form for the system Σ^{∞}. Our dual normal form on the one hand generalizes, for higher order terms, that given in [26] for second order terms, and on the other hand dualizes the normal form $\Sigma^{[m]}_{NF}$. The structure of this section will follow that of section 2: we will give the dual normal form, then define and study dual m-invariants; finally, we give an explicit construction of transformations bringing the system into its dual normal form.

Our first result asserts that we can always bring $\Sigma^{[m]}$ to a dual normal form.

THEOREM 7. *The homogeneous system $\Sigma^{[m]}$ is equivalent, via a homogeneous feedback transformation Γ^m, to the dual normal form $\Sigma^{[m]}_{DNF}$ given by*

$$\Sigma^{[m]}_{DNF}: \begin{cases} \dot{x}_1 = x_2, \\ \dot{x}_2 = x_3 + v x_n Q^{[m-2]}_{2,n}(x_1, \dots, x_n), \\ \qquad \vdots \\ \dot{x}_j = x_{j+1} + v \sum_{i=n-j+2}^{n} x_i Q^{[m-2]}_{j,i}(x_1, \dots, x_i), \\ \qquad \vdots \\ \dot{x}_{n-1} = x_n + v \sum_{i=3}^{n} x_i Q^{[m-2]}_{j,i}(x_1, \dots, x_i), \\ \dot{x}_n = v, \end{cases} \tag{5.1}$$

where $Q^{[m-2]}_{j,i}(x_1, \dots, x_i)$ are homogeneous polynomials of degree $m-2$ depending on the indicated variables.

Theorem 7 follows from Theorem 9, which gives explicit transformation bringing $\Sigma^{[m]}$ to its dual normal form $\Sigma^{[m]}_{DNF}$, and thus we omit its proof.

Now we will define dual m-invariants. To start with, recall that the homogeneous vector field $X_i^{[m-1]}$ is defined by taking the homogeneous part of degree $m-1$ of the vector field

$$X_i^{m-1} = (-1)^i ad^i_{A\xi+f^{[m]}}(B + g^{[m-1]}).$$

By $X_i^{[m-1]}(\pi_i(\xi))$ we will denote the vector field $X_i^{[m-1]}$ evaluated at the point $\pi_i(\xi) = (\xi_1, \dots, \xi_i, 0, \dots, 0)$ of the submanifold

$$W_i = \{\xi \in \mathbb{R}^n \ : \ \xi_{i+1} = \cdots = \xi_n = 0 \ \}.$$

Consider the system $\Sigma^{[m]}$ and, for any j such that $2 \leq j \leq n-1$, define the polynomial $b_j^{[m-1]}$ by setting

$$b_j^{[m-1]} = g_j^{[m-1]} + \sum_{k=1}^{j-1} L_B L_{A\xi}^{j-k-1} f_k^{[m]} - \sum_{i=1}^{n} L_B L_{A\xi}^{j-1} \int_0^{\xi_i} CX_{n-i}^{[m-1]}(\pi_i(\xi)) d\xi_i.$$

The homogeneous polynomials $b_j^{[m-1]}$ for $2 \leq j \leq n-1$ will be called the *dual m-invariants* of the homogeneous system $\Sigma^{[m]}$.

Consider two systems $\Sigma^{[m]}$ and $\tilde{\Sigma}^{[m]}$ of the form (2.4) and (2.5). Let

$$\{\, b_j^{[m-1]} \ : \ 2 \leq j \leq n-1 \,\}$$

and

$$\{\, \tilde{b}_j^{[m-1]} \ : \ 2 \leq j \leq n-1 \,\}$$

denote, respectively, their dual m-invariants. The following result gives a dualization of Theorem 2.

THEOREM 8. *The dual m-invariants have the following properties:*

(i) *Two systems $\Sigma^{[m]}$ and $\tilde{\Sigma}^{[m]}$ are equivalent via a homogeneous feedback transformation Γ^m if and only if*

$$b_j^{[m-1]} = \tilde{b}_j^{[m-1]}$$

for any $2 \leq j \leq n-1$.

(ii) *The dual m-invariants $\bar{b}_j^{[m-1]}$ of the dual normal form $\Sigma_{DNF}^{[m]}$, defined by* (5.1)*, are given by*

$$\bar{b}_j^{[m-1]}(x) = \sum_{i=n-j+2}^{n} x_i Q_{j,i}^{[m-2]}(x_1, \dots, x_i)$$

for any $2 \leq j \leq n-1$.

The above result asserts that the dual m-invariants, as do the m-invariants, form a set of complete invariants of the homogeneous feedback transformation. Notice, however, that the same information is encoded in both sets of invariants in different ways. We will give a proof of Theorem 8 in section 7.

Now, we define the following homogeneous polynomials:

$$
\begin{aligned}
\phi_1^{[m]} &= -\sum_{i=1}^{n} \int_0^{\xi_i} CX_{n-i}^{[m-1]}(\pi_i(\xi))d\xi_i, \\
\phi_{j+1}^{[m]} &= f_j^{[m]} + L_{A\xi}\phi_j^{[m]}, \qquad 1 \le j \le n-1, \\
\alpha^{[m]} &= -\left(f_n^{[m]} + L_{A\xi}\phi_n^{[m]}\right), \\
\beta^{[m-1]} &= -\left(g_n^{[m-1]} + L_B\phi_n^{[m]}\right).
\end{aligned} \tag{5.2}
$$

The next result gives an explicit construction of feedback transformations bringing the system $\Sigma^{[m]}$ to its dual normal form $\Sigma_{DNF}^{[m]}$.

THEOREM 9. *The feedback transformation*

$$
\Gamma^m \ : \ \begin{aligned} x &= \xi + \phi^{[m]}(\xi), \\ u &= v + \alpha^{[m]}(\xi) + \beta^{[m-1]}(\xi)v, \end{aligned}
$$

where $\alpha^{[m]}$, $\beta^{[m-1]}$, and the components $\phi_j^{[m]}$ of $\phi^{[m]}$ are defined by (5.2)*, brings the system $\Sigma^{[m]}$ into its dual normal form $\Sigma_{DNF}^{[m]}$ given by* (5.1).

6. Dual canonical form. Consider the system Σ^∞ of the form (2.1) and assume that its linear part (F, G) is controllable. Apply successively to it a series of transformations Γ^m, $m = 1, 2, \ldots$, such that each Γ^m brings $\Sigma^{[m]}$ to its dual normal form $\Sigma_{DNF}^{[m]}$; for instance we can take a series of transformations defined by (5.2). Successive repeating of Theorem 9 gives the following dual normal form.

THEOREM 10. *The system Σ^∞ can be transformed via a formal feedback transformation Γ^∞ into the dual normal form Σ_{DNF}^∞ given by*

$$
\Sigma_{DNF}^\infty \ : \ \begin{cases}
\dot{x}_1 = x_2, \\
\dot{x}_2 = x_3 + vx_nQ_{2,n}(x_1, \ldots, x_n), \\
\qquad \vdots \\
\dot{x}_j = x_{j+1} + v \displaystyle\sum_{i=n-j+2}^{n} x_iQ_{j,i}(x_1, \ldots, x_i), \\
\qquad \vdots \\
\dot{x}_{n-1} = x_n + v\displaystyle\sum_{i=3}^{n} x_iQ_{j,i}(x_1, \ldots, x_i), \\
\dot{x}_n = v,
\end{cases} \tag{6.1}
$$

where $Q_{j,i}(x_1, \ldots, x_i)$ are formal power series depending on the indicated variables.

Naturally, as with normal forms, a given system can admit different dual normal forms. We are thus interested in constructing a dual canonical form. Assuming that the linear part (F, G) of the system Σ^∞, of the form (2.1), is controllable, we denote by m_0 the degree of the first homogeneous term of the system Σ^∞ which cannot be annihilated by a feedback transformation. Thus, using Theorems 8 and 9, we can assume, after applying a suitable feedback, that Σ^∞ takes the form

$$
\Sigma^\infty \ : \ \dot{\xi} = A\xi + Bu + \bar{g}^{[m_0-1]}(\xi)u + \sum_{m=m_0+1}^{\infty} \left(f^{[m]}(\xi) + g^{[m-1]}(\xi)u\right),
$$

where (A, B) is in Brunovský canonical form and the first nonvanishing homogeneous vector field $\bar{g}^{[m_0-1]}$ is of the form

$$\bar{g}_j^{[m_0-1]}(\xi) = \begin{cases} \displaystyle\sum_{i=n-j+2}^{n} \xi_i Q_{j,i}^{[m_0-2]}(\xi_1, \dots, \xi_i), & 2 \le j \le n-1, \\ 0, & j = 1 \text{ and } j = n. \end{cases}$$

Define

$$j_* = \inf \left\{ j = 2, \dots, n-1 \ : \ \bar{g}_j^{[m_0-1]}(\xi) \neq 0 \right\}$$

and let $(i_1, \dots, i_n)$ such that $i_1 + \cdots + i_n = m_0 - 1$ be the largest, in the lexicographic ordering, n-tuple of nonnegative integers such that

$$\frac{\partial^{m_0-1} \bar{g}_{j_*}^{[m_0-1]}}{\partial \xi_1^{i_1} \cdots \partial \xi_n^{i_n}} \neq 0.$$

We get the following result.

THEOREM 11. *There exists a formal feedback transformation Γ^∞ which brings the system Σ^∞ into the following one:*

$$\Sigma_{DCF}^\infty : \dot{x} = Ax + Bv + \sum_{m=m_0}^{\infty} \bar{g}^{[m-1]}(x) v,$$

where for any $m \ge m_0$,

$$\bar{g}_j^{[m-1]} = \begin{cases} \displaystyle\sum_{i=n-j+2}^{n} x_i Q_{j,i}^{[m-2]}(x_1, \dots, x_i), & 2 \le j \le n-1, \\ 0, & j = 1 \text{ and } j = n. \end{cases} \tag{6.2}$$

Moreover,

$$\frac{\partial^{m_0-1} \bar{g}_{j_*}^{[m_0-1]}}{\partial x_1^{i_1} \cdots \partial x_n^{i_n}} = \pm 1, \tag{6.3}$$

and for any $m \ge m_0 + 1$

$$\frac{\partial^{m_0-1} \bar{g}_{j_*}^{[m-1]}}{\partial x_1^{i_1} \cdots \partial x_n^{i_n}}(x_1, 0, \dots, 0) = 0. \tag{6.4}$$

The form Σ_{DCF}^∞, which satisfies (6.2), (6.3), and (6.4), will be called the *dual canonical form* of Σ^∞. The name is justified by the following.

THEOREM 12. *The two systems Σ_1^∞ and Σ_2^∞ are formally feedback equivalent if and only if their dual canonical forms $\Sigma_{1,DCF}^\infty$ and $\Sigma_{2,DCF}^\infty$ coincide.*

Example 6. Let us consider the system

$$\Sigma \ : \ \dot{\xi} = f(\xi) + g(\xi) u, \quad \xi(\cdot) \in \mathbb{R}^3, \ u(\cdot) \in \mathbb{R},$$

whose linear part is assumed to be controllable. Theorem 10 ensures that the system Σ is formally feedback equivalent to the dual normal form Σ^{∞}_{DNF} given by

$$\begin{aligned}\dot{x}_1 &= x_2,\\ \dot{x}_2 &= x_3 + v x_3 Q(x_1, x_2, x_3),\\ \dot{x}_3 &= v,\end{aligned}$$

where $Q(x_1, x_2, x_3)$ is a formal power series of variables x_1, x_2, x_3.

Assume for simplicity that $m_0 = 2$, which is equivalent to the condition that g, $ad_f g$, and $[g, ad_f g]$ are linearly independent at $0 \in \mathbb{R}^3$. This implies that we can represent $Q = Q(x_1, x_2, x_3)$ by

$$Q = c + x_1 Q_1(x_1) + x_2 Q_2(x_1, x_2) + x_3 Q_3(x_1, x_2, x_3),$$

where $c \in \mathbb{R}$, $c \neq 0$.

Observe that any Q of the above form gives a dual normal form Σ^{∞}_{DNF}. In order to get the dual canonical form we use Theorem 11, which ensures that the system Σ is formally feedback equivalent to its dual canonical form Σ^{∞}_{DCF} defined by

$$\begin{aligned}\dot{\tilde{x}}_1 &= \tilde{x}_2,\\ \dot{\tilde{x}}_2 &= \tilde{x}_3 + \tilde{v}\tilde{x}_3 \tilde{Q}(\tilde{x}_1, \tilde{x}_2, \tilde{x}_3),\\ \dot{\tilde{x}}_3 &= \tilde{v},\end{aligned}$$

where $\tilde{Q}(\tilde{x}_1, \tilde{x}_2, \tilde{x}_3)$ is a formal power series such that

$$\tilde{Q}(\tilde{x}_1, \tilde{x}_2, \tilde{x}_3) = 1 + \tilde{x}_2 \tilde{Q}_2(\tilde{x}_1, \tilde{x}_2) + \tilde{x}_3 \tilde{Q}_3(\tilde{x}_1, \tilde{x}_2, \tilde{x}_3). \qquad \square$$

7. Proofs of dual results. In this section, we prove our dual results. The proof of Theorem 7 will be omitted because in the proof of Theorem 9 we give an explicit homogeneous feedback transformation bringing a given homogeneous system into its dual normal form. Theorem 10 follows from a successive application of Theorem 7. We will thus prove Theorems 8, 9, 11, and 12.

Proof of Theorem 8. (i) We will prove that if the system $\Sigma^{[m]}$ is equivalent to $\tilde{\Sigma}^{[m]}$ via a transformation Γ^m, then their dual m-invariants $b_j^{[m-1]}$ and $\tilde{b}_j^{[m-1]}$ coincide. The action of Γ^m can be decomposed into that of a pure feedback of the form

$$u = v + \alpha^{[m]}(\xi) + \beta^{[m-1]}(\xi) v$$

followed by that of a diffeomorphism

$$x = \xi + \phi^{[m]}(\xi)$$

of the state space. Since the first $n-1$ components of the vector fields $f^{[m]}$ and $g^{[m-1]}$, as well as those of $X_{n-i}^{[m-1]}$, are invariant under pure feedback, we can conclude that the functions $b_j^{[m-1]}$ for $2 \leq j \leq n-1$ are invariant under pure feedback. It remains to prove that they are also invariant under any diffeomorphism $x = \Phi(\xi)$ of the form $\Phi(\xi) = \xi + \phi^{[m]}(\xi)$.

The diffeomorphism Φ brings the system $\Sigma^{[m]}$ into the form

$$\tilde{\Sigma}^{[m]} \ : \ \dot{x} = Ax + Bu + \tilde{f}^{[m]}(x) + \tilde{g}^{[m-1]}(x) u,$$

where

$$\tilde{f}^{[m]} = f^{[m]} + [Ax, \phi^{[m]}],$$
$$\tilde{g}^{[m-1]} = g^{[m-1]} + L_B\phi^{[m]}.$$

Denoting by $b_j^{[m-1]}$ and $\tilde{b}_j^{[m-1]}$ for $2 \leq j \leq n-1$ the dual m-invariants associated, respectively, with the homogeneous systems $\Sigma^{[m]}$ and $\tilde{\Sigma}^{[m]}$, we get

$$\tilde{b}_j^{[m-1]} = b_j^{[m-1]} + \hat{b}_j^{[m-1]},$$

where

$$\hat{b}_j^{[m-1]}(x) = L_B\phi_j^{[m]}(x) + \sum_{k=0}^{j-2} L_B L_{Ax}^{j-k-2} C A^k ad_{Ax}\phi^{[m]} - \sum_{i=1}^{n} L_B L_{Ax}^{j-1} \int_0^{x_i} C\hat{X}_{n-i}^{[m-1]}(\pi_i(x))dx_i$$

and

$$\hat{X}_{n-i}^{[m-1]}(x) = (-1)^{n-i} ad_{Ax+[Ax,\phi^{[m]}]}^{n-i}(B + L_B\phi^{[m]}) = (-1)^{n-i}(\Phi_* ad_{A\xi}^{n-i}(B))(x)$$
$$= A^{n-i}B + L_{A^{n-i}B}\phi^{[m]}(x).$$

We can deduce that

$$\hat{b}_j^{[m-1]}(x) = L_B\phi_j^{[m]}(x) + \sum_{k=1}^{j-1} L_B L_{Ax}^{j-k}\phi_k^{[m]} - \sum_{k=2}^{j} L_B L_{Ax}^{j-k}\phi_k^{[m]} - \sum_{i=1}^{n} L_B L_{Ax}^{j-1} \int_0^{x_i} L_{A^{n-i}B}\phi_1^{[m]}(\pi_i(x))dx_i$$
$$= L_B\phi_j^{[m]}(x) + \sum_{k=1}^{j-1} L_B L_{Ax}^{j-k}\phi_k^{[m]} - \sum_{k=2}^{j} L_B L_{Ax}^{j-k}\phi_k^{[m]} - L_B L_{Ax}^{j-1}\phi_1^{[m]}(x) = 0,$$

which gives

$$\tilde{b}_j^{[m-1]} = b_j^{[m-1]}.$$

Thus the functions $b_j^{[m-1]}$ are invariant under any diffeomorphism of the form $x = \Phi(\xi) = \xi + \phi^{[m]}(\xi)$. Therefore they remain invariant under the transformation Γ^m.

The fact that two homogeneous systems, whose dual m-invariants coincide, are feedback equivalent follows clearly from item (ii) of the theorem, which will be proved below. Indeed, by item (ii), both systems coincide when transformed to their canonical forms.

(ii) Denote by $\bar{b}_j^{[m-1]}$ for $2 \leq j \leq n-1$ the dual m-invariants associated with the dual normal form $\Sigma_{DNF}^{[m]}$. They are given by

$$\bar{b}_j^{[m-1]} = \bar{g}_j^{[m-1]} - \sum_{i=1}^{n} L_B L_{Ax}^{j-1} \int_0^{x_i} C\bar{X}_{n-i}^{[m-1]}(\pi_i(x))dx_i,$$

where the components $\bar{g}_j^{[m-1]}$ are given by (5.1) and

$$C\bar{X}_{n-i}^{[m-1]} = (-1)^{n-i} C ad_{Ax}^{n-i} \bar{g}^{[m-1]}.$$

It suffices to observe (see Lemma 2 below) that, on the one hand, $C\bar{X}_{n-i}^{[m-1]}$ is a linear combination of functions $L_{Ax}^s \bar{g}_j^{[m-1]}$ for $0 \le s \le n-i$ and $1 \le j \le n-i+1$ and, on the other hand, $\bar{g}_j^{[m-1]}(\pi_i(x)) = 0$ for all j such that $1 \le j \le n-i+1$. We thus conclude that $C\bar{X}_{n-i}^{[m-1]}(\pi_i(x)) = 0$, which implies

$$\bar{b}_j^{[m-1]} = \bar{g}_j^{[m-1]}$$

for any j such that $2 \le j \le n-1$. □

Proof of Theorem 9. Denote by

$$\tilde{\Sigma}^{[m]} \;:\; \dot{x} = Ax + Bv + \tilde{f}^{[m]}(x) + \tilde{g}^{[m-1]}(x)v$$

the system $\Sigma^{[m]}$ transformed via a homogeneous feedback transformation Γ^m defined by (5.2). From Proposition 1, it follows that for $\tilde{\Sigma}^{[m]}$ we have

$$\begin{aligned} &\tilde{f}_j^{[m]} = 0 \qquad \text{for } \; 1 \le j \le n, \\ &\tilde{g}_j^{[m-1]} = 0 \qquad \text{for } \; j = 1 \text{ and } j = n, \\ &\tilde{g}_j^{[m-1]} = g_j^{[m-1]} + L_B \phi_j^{[m]} \qquad \text{for } \; 2 \le j \le n-1. \end{aligned} \tag{7.1}$$

It thus suffices to show that the components $\tilde{g}_j^{[m-1]}$ for $2 \le j \le n-1$ are in the dual normal form (5.1). We prove easily by an induction argument that

$$\phi_{j+1}^{[m]} = \sum_{k=1}^{j} L_{A\xi}^{j-k} f_k^{[m]} + L_{A\xi}^j \phi_1^{[m]},$$

$$L_B L_{A\xi}^j \phi_1^{[m]} = \sum_{k=0}^{j} \binom{j}{k} L_{A\xi}^{j-k} L_{A^k B} \phi_1^{[m]},$$

which allows us to show that

$$\tilde{g}_{j+1}^{[m-1]} = g_{j+1}^{[m-1]} + \sum_{k=1}^{j} L_B L_{A\xi}^{k-1} f_{j-k+1}^{[m]} + \sum_{k=0}^{j} \binom{j}{k} L_{A\xi}^{j-k} L_{A^k B} \phi_1^{[m]}.$$

Now, from the identity

$$L_{A^k B} \phi_1^{[m]} = -CX_k^{[m-1]}(\pi_{n-k}(\xi)) - \sum_{i=n-k+1}^{n} \int_0^{\xi_i} \frac{\partial CX_{n-i}^{[m-1]}(\pi_i(\xi))}{\partial \xi_{n-k}} d\xi_i,$$

we can deduce that

$$\begin{aligned} \tilde{g}_{j+1}^{[m-1]} = g_{j+1}^{[m-1]} &+ \sum_{k=1}^{j} L_B L_{A\xi}^{k-1} f_{j-k+1}^{[m]} - \sum_{k=0}^{j} \binom{j}{k} L_{A\xi}^{j-k} CX_k^{[m]}(\pi_{n-k}(\xi)) \\ &- \sum_{k=1}^{j} \sum_{i=n-k+1}^{n} \binom{j}{k} L_{A\xi}^{j-k} \left(\int_0^{\xi_i} \frac{\partial CX_{n-i}^{[m-1]}(\pi_i(\xi))}{\partial \xi_{n-k}} d\xi_i \right). \end{aligned}$$

Taking into account that for any k such that $0 \leq k \leq j$ we have

$$L_{A\xi}^{j-k} CX_k^{[m]}(\pi_{n-k} \circ \pi_{n-j}(\xi)) = L_{A\xi}^{j-k} CX_k^{[m]}(\pi_{n-j}(\xi))$$

and that for any $i \geq n-j+1$ we have

$$\left(\int_0^{\xi_i} \frac{\partial CX_{n-i}^{[m-1]}(\pi_i(\xi))}{\partial \xi_{n-k}} d\xi_i \right) (\pi_{n-j}(\xi)) = 0,$$

we can conclude that

$$\tilde{g}_{j+1}^{[m-1]}(\pi_{n-j}(\xi)) = \left(g_{j+1}^{[m-1]} + \sum_{k=1}^{j} L_B L_{A\xi}^{j-k} f_k^{[m]} - \sum_{k=0}^{j} \binom{j}{k} L_{A\xi}^{j-k} CX_k^{[m]} \right) (\pi_{n-j}(\xi)).$$

Using Lemma 2 given below, we thus obtain

$$\tilde{g}_{j+1}^{[m-1]}(\pi_{n-j}(\xi)) = 0,$$

which proves that $\tilde{g}_j^{[m-1]}$ is in the dual normal form (5.1). □

LEMMA 2. *Let $X_i^{[m-1]}$ be the homogeneous part of degree $m-1$ of*

$$X_i^{m-1} = (-1)^i ad_{A\xi + f^{[m]}}^i (B + g^{[m-1]}).$$

Then the following identities hold:

(i) *For any $j \geq 1$, we have*

$$CA^j X_1^{[m-1]} = \sum_{k=1}^{j} L_{AB} L_{A\xi}^{j-k} f_k^{[m]} - \sum_{k=0}^{j} \binom{j}{k} L_{A\xi}^{j-k} CX_{k+1}^{[m-1]}.$$

(ii) *For any j such that $0 \leq j \leq n-1$, we have*

$$\sum_{k=0}^{j} \binom{j}{k} L_{A\xi}^{j-k} CX_k^{[m-1]} = g_{j+1}^{[m-1]} + \sum_{k=1}^{j} L_B L_{A\xi}^{j-k} f_k^{[m]}.$$

Both identities can be proved by a direct calculation.

Proof of Theorem 11. In the first step we will normalize terms of degree at most m_0 while in the general step we will normalize terms of order $m_0 + l$.

First step. Consider the system Σ^∞ and recall that m_0 is the degree of the first nonlinearizable homogeneous part. We can assume (see Theorems 7 and 8) that after applying a suitable feedback transformation, the system Σ^∞ takes the form

$$\dot{\xi} = A\xi + Bu + \bar{g}^{[m_0-1]}(\xi)u + \sum_{m=m_0+1}^{\infty} \left(f^{[m]}(\xi) + g^{[m-1]}(\xi)u \right), \tag{7.2}$$

where the vector field $\bar{g}^{[m_0-1]}$ defined by

$$\bar{g}_j^{[m_0-1]}(\xi) = \begin{cases} \displaystyle\sum_{i=n-j+2}^{n} \xi_i Q_{j,i}^{[m_0-2]}(\xi_1, \ldots, \xi_i), & 2 \leq j \leq n-1, \\ 0, & j = 1 \text{ or } j = n, \end{cases}$$

is the first nonlinearizable homogeneous part. We can notice that the linear feedback transformation

$$\Gamma^1 \ : \quad \begin{aligned} x &= a_1\xi, \\ u &= \tfrac{1}{a_1}v, \end{aligned}$$

where $a_1 \in \mathbb{R}$ and $a_1 \neq 0$, brings the system (7.2) into the following one:

$$\dot{x} = Ax + Bv + \frac{1}{a_1^{m_0-1}}\bar{g}^{[m_0-1]}(x)v + \sum_{m=m_0+1}^{\infty}\left(\tilde{f}^{[m]}(x) + \tilde{g}^{[m-1]}(x)v\right).$$

Due to the definitions of $(i_1, \dots, i_n)$ and j_*, we can suitably choose the parameter a_1 such that

$$\frac{\partial^{m_0-1}\bar{g}_{j_*}^{[m_0-1]}}{\partial x_1^{i_1}\cdots\partial x_n^{i_n}} = \pm 1.$$

General step. Now we assume that, for some $l \geq 1$, the system Σ^∞ takes the form

$$\dot{\xi} = A\xi + Bu + \sum_{m=m_0}^{m_0+l-1}\bar{g}^{[m-1]}(\xi)u + f^{[m_0+l]}(\xi) + g^{[m_0+l-1]}(\xi)u + r(\xi,u), \tag{7.3}$$

where $r(\xi,u) \in R^{\geq m_0+l+1}(\xi,u)$ and, for any m such that $m_0 \leq m \leq m_0+l-1$ and any $1 \leq j \leq n$, the components $\bar{g}_j^{[m-1]}$ satisfy the conditions (6.2), (6.3), and (6.4). Consider the transformation Γ^∞ given by (4.3), satisfying (3.7), and its decomposition $\Gamma^\infty = \Gamma^{\leq m_0+l} = \Gamma^{m_0+l} \circ \Gamma^{\leq m_0+l-1}$ given by (4.4)–(4.5). We can easily see that the transformation $\Gamma^{\leq m_0+l-1}$ brings the system (7.3) into the system

$$\dot{y} = Ay + Bw + \sum_{m=m_0}^{m_0+l-1}\bar{g}^{[m-1]}(y)w + \tilde{f}^{[m_0+l]}(y) + \tilde{g}^{[m_0+l-1]}(y)w + r(y,w), \tag{7.4}$$

where $r(y,w) \in R^{\geq m_0+l+1}(y,w)$ and

$$\begin{aligned} \tilde{f}^{[m_0+l]} &= f^{[m_0+l]} + \bar{g}^{[m_0-1]}\alpha^{[l+1]}, \\ \tilde{g}^{[m_0+l-1]} &= g^{[m_0+l-1]} + \left[\bar{g}^{[m_0-1]}, \phi^{[l+1]}\right] + \bar{g}^{[m_0-1]}\beta^{[l]}. \end{aligned}$$

Let $b_j^{[m_0+l-1]}$ and $\tilde{b}_j^{[m_0+l-1]}$ be the dual (m_0+l)-invariants associated, respectively, to the homogeneous parts of degree m_0+l of the systems (7.3) and (7.4). We thus deduce that

$$\tilde{b}_j^{[m_0+l-1]} = b_j^{[m_0+l-1]} + \hat{b}_j^{[m_0+l-1]}, \tag{7.5}$$

where

$$\hat{b}_j^{[m_0+l-1]} = CA^{j-1}\left[\bar{g}^{[m_0-1]}, \phi^{[l+1]}\right] + \beta^{[l]}\bar{g}_j^{[m_0-1]} - \sum_{i=1}^{n} L_B L_{Ay}^{j-1}\int_0^{y_i} C\hat{X}_{n-i}^{[m-1]}(\pi_i(y))dy_i$$

and

$$\begin{aligned} \hat{X}_{n-i}^{[m-1]} = (-1)^{n-i}ad_{Ay}^{n-i}&\left(\left[\bar{g}^{[m_0-1]}, \phi^{[l+1]}\right] + \bar{g}^{[m_0-1]}\beta^{[l]}\right) \\ &+ \sum_{k=0}^{n-i-1}(-1)^k ad_{Ay}^k ad_{A^{n-i-k-1}B}\left(\bar{g}^{[m_0-1]}\alpha^{[l+1]}\right). \end{aligned}$$

First notice (see Lemma 2) that $C\hat{X}_{n-i}^{[m-1]}$ is a linear combination, over the ring of polynomials, of the components $CA^{j-1}\bar{g}^{[m_0-1]}$ and $CA^{j-1}\left[\bar{g}^{[m_0-1]},\phi^{[l+1]}\right]$, $1\leq j\leq n-i+1$, and their derivatives. Since

$$CA^{j-1}\left[\bar{g}^{[m_0-1]},\phi^{[l+1]}\right]=\sum_{k=1}^{j}\frac{\partial\phi_j^{[l+1]}}{\partial y_k}\bar{g}_k^{[m_0-1]}-\frac{\partial\bar{g}_j^{[m_0-1]}}{\partial y}\phi^{[l+1]},$$

it follows that $C\hat{X}_{n-i}^{[m-1]}$ is a linear combination, over the ring of polynomials, of the components $\bar{g}_j^{[m_0-1]}$, $1\leq j\leq n-i+1$, and their derivatives. Taking into account the fact that $\bar{g}^{[m_0-1]}$ satisfies (6.2), we obtain, for any $1\leq j\leq n-i+1$,

$$\bar{g}_j^{[m_0-1]}(\pi_i(y))=0.$$

Thus, we deduce that

$$\hat{X}_{n-i}^{[m-1]}(\pi_i(y))=0,$$

which leads to the identity

$$\hat{b}_j^{[m_0+l-1]}=CA^{j-1}\left[\bar{g}^{[m_0-1]},\phi^{[l+1]}\right]+\beta^{[l]}\bar{g}_j^{[m_0-1]}.$$

Putting $j=j_*$ and due to the fact that $\bar{g}_1^{[m_0-1]}=\cdots=\bar{g}_{j_*-1}^{[m_0-1]}=0$, we get

$$\hat{b}_{j_*}^{[m_0+l-1]}=-\frac{\partial\bar{g}_{j_*}^{[m_0-1]}}{\partial y}\phi^{[l+1]}+L_{A^{n-j_*}B}(\phi_{j_*}^{[l+1]})\bar{g}_{j_*}^{[m_0-1]}+\beta^{[l]}\bar{g}_{j_*}^{[m_0-1]}.$$

Since the triplet $(\phi^{[l+1]},\alpha^{[l+1]},\beta^{[l]})$ satisfies the condition (3.7), it is easy to see that for any $1\leq j\leq n-1$, we have

$$L_{A^{n-j}B}\phi_j^{[l+1]}+\beta^{[l]}=0$$

and then conclude that

$$\hat{b}_{j_*}^{[m_0+l-1]}=-\frac{\partial\bar{g}_{j_*}^{[m_0-1]}}{\partial y}\phi^{[l+1]}.$$

Now, let us differentiate this last expression, taking into account that $(i_1,\dots,i_n)$ is the largest n-tuple of nonnegative integers such that

$$\frac{\partial^{m_0-1}\bar{g}_{j_*}^{[m_0-1]}}{\partial y_1^{i_1}\cdots\partial y_n^{i_n}}\neq 0.$$

We obtain

$$\frac{\partial^{i_1+l}\hat{b}_{j_*}^{[m_0+l-1]}}{\partial y_1^{i_1+l}}=-\left(d_1\frac{\partial^{i_1+1}\bar{g}_{j_*}^{[m_0-1]}}{\partial y\partial y_1^{i_1}}\frac{\partial^l\phi^{[l+1]}}{\partial y_1^l}+d_2\frac{\partial^{i_1}\bar{g}_{j_*}^{[m_0-1]}}{\partial y\partial y_1^{i_1-1}}\frac{\partial^{l+1}\phi^{[l+1]}}{\partial y_1^{l+1}}\right),\tag{7.6}$$

where d_1 and d_2 are strictly positive integers. Since

$$\frac{\partial^l\phi^{[l+1]}}{\partial y_1^l}=a_{l+1}(l+1)!(y_1,y_2,\dots,y_n)^T$$

and

$$\frac{\partial^{l+1}\phi^{[l+1]}}{\partial y_1^{l+1}} = a_{l+1}(l+1)!(1,0,\dots,0)^T,$$

and due to the fact that

$$\sum_{k=2}^{n}\frac{\partial \bar{g}_{j_*}^{[m_0-1]}}{\partial y_k}y_k = (m_0 - i_1 - 1)\bar{g}_{j_*}^{[m_0-1]},$$

the identity (7.6) gives

$$\frac{\partial^{i_1+l}\bar{b}_{j_*}^{[m_0+l-1]}}{\partial y_1^{i_1+l}} = \theta_l \frac{\partial^{i_1}\bar{g}_{j_*}^{[m_0-1]}}{\partial y_1^{i_1}},$$

where $\theta_l = -a_{l+1}(l+1)!\,(d_1(m_0 - i_1 - 1) + d_2)$. Plugging this last expression into (7.5), where we put $j = j_*$, we obtain, after differentiating, the following relation:

$$\frac{\partial^{m_0+l-1}\tilde{b}_{j_*}^{[m_0+l-1]}}{\partial y_1^{i_1+l}\partial y_2^{i_2}\cdots\partial y_n^{i_n}} = \frac{\partial^{m_0+l-1}\bar{b}_{j_*}^{[m_0+l-1]}}{\partial y_1^{i_1+l}\partial y_2^{i_2}\cdots\partial y_n^{i_n}} + \theta_l\frac{\partial^{m_0-1}\bar{g}_{j_*}^{[m_0-1]}}{\partial y_1^{i_1}\partial y_2^{i_2}\cdots\partial y_n^{i_n}}.$$

Because of the definition of θ_l, we can choose suitably the parameter a_{l+1} such that

$$\frac{\partial^{m_0+l-1}\tilde{b}_{j_*}^{[m_0+l-1]}}{\partial y_1^{i_1+l}\partial y_2^{i_2}\cdots\partial y_n^{i_n}} = 0,$$

which is equivalent to

$$\frac{\partial^{m_0-1}\tilde{b}_{j_*}^{[m_0+l-1]}}{\partial y_1^{i_1}\partial y_2^{i_2}\dots\partial y_n^{i_n}}(y_1,0,\dots,0) = 0.$$

Now, transforming the homogeneous part of degree $m_0 + l$ of the system (7.4) to its normal form via a homogeneous transformation Γ^{m_0+l} and taking into account Theorem 8, we bring the system (7.4) into the form

$$\dot{x} = Ax + Bv + \sum_{m=m_0}^{m_0+l}\bar{g}^{[m-1]}(x)v + r(x,v), \tag{7.7}$$

where $r(x,v) \in R^{\geq m_0+l+1}(x,v)$, and for any m such that $m_0 \leq m \leq m_0 + l$, the components $\bar{g}_j^{[m-1]}$ for $2 \leq j \leq n-1$ satisfy the conditions (6.2), (6.3), and (6.4). This ends the proof of Theorem 11. □

Proof of Theorem 12. The proof of this theorem follows the same line as that of Theorem 6. We notice only that the transformation Γ^{∞} leaves invariant all terms of degree smaller than $m_0 + l$ of the system (7.3) if and only if it is of the form (4.10), given by Lemma 1. □

ON THE GLOBAL CONTROLLABILITY OF NONLINEAR SYSTEMS: FOUNTAINS, RECURRENCE, AND APPLICATIONS TO HAMILTONIAN SYSTEMS*

PETER E. CAINES† AND EKATERINA S. LEMCH‡

Abstract. In this paper, a form of open local accessibility for nonlinear control systems is introduced called the continuous fountain condition. Subject to the conditions that (i) the states of a system are continuous fountains and (ii) one of various recurrence conditions holds, it is established that the system state space is (globally) controllable. It is shown that these controllability results imply the controllability of certain subsets of the state space of Hamiltonian control systems called energy slices. The relations between the notion of a fountain and (i) local accessibility and (ii) the full Lie algebra rank condition for control affine systems are investigated. Finally, the results in this paper are shown to have application to hierarchical hybrid control theory in that they give conditions for a finite analytic partition to satisfy the so-called in-block controllability property; this is illustrated with a linear mass-spring system example.

Key words. nonlinear control systems, controllability, attainable sets, recurrence, hierarchical systems, fountains, accessibility, reachability

1. Introduction.

There is an extensive literature on various forms of the controllability problem for nonlinear systems (see, for example, the texts by Isidori [10], Nijmeijer and van der Schaft [24], and Jurdjevic [11]). In particular, in [11], [12], [13], and [19], it has been shown that control affine systems satisfying a dense recurrence condition and a full Lie algebra rank condition (LARC) are (globally) controllable. In [20], sufficient conditions for the global controllability of conservative systems on a compact manifold are presented. Other results on global controllability based on Poisson stability and local accessibility are presented in [1], [2], and [7]. The notion of weak positive Poisson stability is employed in [18] and [22] for the analysis of the controllability of control affine systems.

In this paper, a form of open local accessibility and coaccessibility for nonlinear control systems is introduced called the continuous fountain condition. Subject to the conditions that (i) the states of a system are continuous fountains and (ii) one of various recurrence conditions holds, it is shown that the system state space is (globally) controllable. As demonstrated in sections 4 and 5, the fountain condition is partially ordered with respect to the local accessibility condition and the LARC condition (i.e., it is not strictly weaker or stronger). In fact, the topological nature of the fountain

notion allows it to be invoked in controllability analysis even for systems that have nonsmooth dynamics. These characteristics of the fountain notion permit it a different domain of application than the classical results based on a recurrence property and the LARC condition. Furthermore, for various classes of smooth systems, we establish several algebraic conditions that give straightforward algorithmic methods for verifying whether a system state is fountain.

In addition to the general relevance of these results to the study of nonlinear systems, they have value in *hierarchical hybrid control theory* (HHCT) (see section 8). This is because the theory presented in [5], [15], [16], and the references therein invokes the so-called hybrid in-block controllability (HIBC) hypothesis; this requires that each of the blocks of a certain class of decompositions (called finite analytic partitions) of the system state space forms a controllable subsystem. To verify the HIBC condition using the theory of this paper, it is sufficient to establish that the fountain condition and one of the recurrence conditions hold. Furthermore, for the so-called energy slice partitions of Hamiltonian control systems, the dense recurrence condition under a distinguished control is an inherent property which does not need explicit verification whenever each slice is precompact.

The paper is organized as follows. In section 2, we introduce the notion of a *(continuous) fountain*; then we show that, for a large class of nonlinear systems, the fountain condition taken together with an additional condition such as (i) existence of orbits, (ii) control recurrence, or (iii) weak positive Poisson stability, implies the global controllability of the systems. In section 3, we generalize the results obtained in section 2 by employing the weaker notion of a *fountain with respect to a trajectory*. In sections 4 and 5, we investigate the relation of the fountain property to that of local accessibility and, for a control affine system, to the LARC condition. It is shown that, in general, the fountain condition is not strictly weaker or stronger than the local accessibility and the LARC conditions. In section 6, some algebraic criteria for verifying the fountain property are presented. These include controllable linearization, symmetry, and full rank conditions. Section 7 is devoted to the global controllability of Hamiltonian control affine systems which satisfy the fountain condition. In this context, the developed results are applied to certain subsets of the state space of Hamiltonian control systems called energy slices in order to establish their controllability. Furthermore, applications of the results of this paper to HHCT as presented in [5], [15], and [16] are discussed in section 8, and, finally, in section 8.2, the theory is illustrated by use of a linear mass-spring system example.

2. Fountains, recurrence, and controllability. We consider nonlinear differential systems on an open connected state space $E \subset \mathbb{R}^n$ of the form

$$\mathcal{S}: \quad \begin{array}{l} \dot{x} = f(x,u), \quad x(0) = x_0 \in E, \\ x \in E,\ u \in \mathbb{R}^m,\ f \in C^r(E \times \mathbb{R}^m, \mathbb{R}^n), \\ r \in \{1, 2, \cdots, \infty, \omega\}, \end{array} \tag{2.1}$$

where C^ω denotes the class of analytic functions on E, and where the set of *admissible control functions* $\mathcal{U}$ satisfies either

(a) $\mathcal{U} = \mathcal{U}^q(\mathbb{R}; \mathbb{R}^m)$, $q \in \{1, 2, \ldots, \infty, \omega\}$, the set of all $\mathbb{R}^m$ valued bounded piecewise C^q functions of time which are continuous from the right, or

(b) $\mathcal{U} = \mathcal{U}^q(\mathbb{R}^n; \mathbb{R}^m)$, $q \in \{1, 2, \ldots, \infty, \omega\}$, the set of all $\mathbb{R}^m$ valued bounded C^q functions of $x \in \mathbb{R}^n$.

Unless otherwise stated, $\mathcal{U} = \mathcal{U}^q(\mathbb{R};\mathbb{R}^m)$. We note, however, that, if u is specified to lie in the state feedback class $\mathcal{U}^q(\mathbb{R}^n;\mathbb{R}^m)$, then, as a function of time along the system trajectory, the resulting function $u(\cdot)$ lies in $\mathcal{U}^q(\mathbb{R};\mathbb{R}^m)$. Furthermore, *unless otherwise stated*, all definitions, theorems, etc. are stated for some system $\mathcal{S}$ of the form (2.1) with the class of controls $\mathcal{U}$.

Take an arbitrary control $u \in \mathcal{U}$ and any $\varepsilon > 0$. We shall say that $\bar{u}$ is an ε-*approximation of* u if (i) $\bar{u}$ belongs to the class of piecewise constant functions which are continuous from the right (denoted $\mathcal{U}_{pwc}$) and (ii) for any t in the domain of u, $\|u(t)-\bar{u}(t)\| \leq \varepsilon$. From the standard results on the continuity of a solution trajectory of a differential equation $\mathcal{S}$ with respect to small perturbations of the control function in $\mathcal{U}^q(\mathbb{R},\mathbb{R}^m)$, it follows that the solution of $\mathcal{S}$ under u can be approximated (with any required accuracy) by the solution of $\mathcal{S}$ under ε-approximating controls in $\mathcal{U}_{pwc}$. In this context, certain properties (such as local accessibility and controllability) of $\mathcal{S}$ with control functions taken in $\mathcal{U}$ can be studied by considering only piecewise constant controls.

Throughout the paper, we use the term *orbit* to denote any nontrivial, possibly self-intersecting, trajectory ϕ_x joining x to itself; i.e., for some $T > 0$, $\phi_x : [0,T] \to E$ is any nonconstant trajectory satisfying $\phi_x(0) = \phi_x(T) = x$. All sets specified in this paper are taken to be nonempty; the term "nonempty set" is merely used for emphasis or to avoid ambiguity. In addition, the symbol $\subset$ denotes not necessarily strict set inclusion.

DEFINITION 2.1. *The set* $A_T^V(x)$ *of* accessible (at time T) from x states (with respect to $V \subset E$) *is defined by*

$$A_T^V(x) \triangleq \{z \in E;\ \exists u \in \mathcal{U},\ \ x(0) = x,\ \phi(T,x,u) = z,\ \phi(t,x,u) \in V \text{ for all } 0 \leq t \leq T\}.$$

The set of accessible states (at time T) from x *is* $A_T(x) \triangleq A_T^E(x)$*; further,* $A^V(x) \triangleq \bigcup_{0\leq T<\infty} A_T^V(x)$ *with* $A(x) \triangleq A^E(x)$. *The set* $R_T^V(x)$ *of* reachable states from x in time T (with respect to V) *is defined by* $R_T^V(x) \triangleq \bigcup_{0\leq t\leq T} A_t^V(x)$. *A state x is called* locally accessible *if the set* $R_T^V(x)$ *contains an open set for every neighborhood V and every time $T > 0$.*

Dually, we have the following definitions.

DEFINITION 2.2. *The set* $CA_T^V(x)$ *of* coaccessible (at time T) to x states (with respect to $V \subset E$) *is defined by*

$$CA_T^V(x) \triangleq \{z \in E;\ \exists u \in \mathcal{U},\ \ x(0) = z,\ \phi(T,z,u) = x,\ \phi(t,z,u) \in V \text{ for all } 0 \leq t \leq T\}.$$

The set of coaccessible states (at time T) to x *is* $CA_T(x) \triangleq CA_T^E(x)$*; further,* $CA^V(x) \triangleq \bigcup_{0\leq T<\infty} CA_T^V(x)$ *with* $CA(x) \triangleq CA^E(x)$.

DEFINITION 2.3. *We say that E is* controllable (with respect to the class of controls $\mathcal{U}$) *if $A(x) = E$ for all $x \in E$, and that E is* controllable on the interval $[0,T]$ *if $A_T(x) = E$ for all $x \in E$. We say that the system is* locally controllable *at p if, for all sufficiently small $\rho' > 0$, there exists ρ, $0 < \rho < \rho'$, such that any two states x, x' in the open ball $B_\rho(p)$ are mutually accessible with respect to $B_{\rho'}(p)$.*

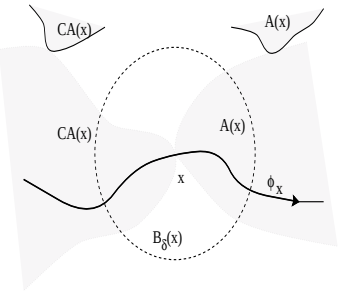

FIG. 2.1. *The fountain condition is satisfied at* x.

DEFINITION 2.4. *A state* $x \in E$ *is called a* fountain *if*

(i) *there exists* $\mu > 0$ *such that, for all* δ, $0 < \delta < \mu$, *the open ball neighborhood* $B_\delta(x)$ *is contained in* E *and* $A^\delta(x) - \{x\}$ *is an open set, where* $A^\delta(x) \underline{\Delta} A^{B_\delta(x)}(x)$ *(in which case* x *is called a* positive fountain*); and*

(ii) *there exists* $\mu' > 0$ *such that, for all* δ', $0 < \delta' < \mu'$, $B_{\delta'}(x) \subset E$ *and* $CA^{\delta'}(x) - \{x\}$ *is an open set, where* $CA^{\delta'}(x) \underline{\Delta} CA^{B_{\delta'}(x)}(x)$ *(in which case* x *is called a* negative fountain*).*

Finally, $\sup\{\mu$; *such that* (i) *holds at* $x\}$ *shall be denoted* $\rho^+(x)$, *and* $\sup\{\mu'$; *such that* (ii) *holds at* $x\}$ *shall be denoted* $\rho^-(x)$; *when* (i) *and* (ii) *hold at* x, *that is, when* x *is a fountain,* $\min(\rho^+(x), \rho^-(x))$ *shall be denoted* $\rho(x)$.

If a set of states $C \subset E$ *(in particular,* E*) is such that each* $x \in C$ *is a fountain, the set* C *is called a fountain.*

Evidently, the fountain definition above requires that, locally (i.e., with respect to all sufficiently small $B_\delta(x)$) the entire accessible set (from a given x, less $\{x\}$) is open; this implies, in particular, that a trajectory ϕ_x passing through x must depart from x within the interior of the accessible set. Clearly, the definition also requires that, locally, the entire coaccessible set (to x, less $\{x\}$) is open, and so such a trajectory ϕ_x must arrive at x within the interior of the coaccessible set. (See Figure 2.1, where the accessible and coaccessible sets are not open, but, at the same time, there exists a sufficiently small neighborhood $B_\delta(x)$ such that the accessibility and coaccessibility sets are open with respect to that neighborhood.)

Example 2.1. Consider the *double integrator* system

$$\begin{aligned} \dot{x} &= u, \quad x(0) = x_0, \\ \dot{y} &= x, \quad y(0) = y_0, \end{aligned} \tag{2.2}$$

where we take $E = \mathbb{R}^2$. Let $p = (x_0, y_0)$ be an arbitrary point in E. In the case when $x_0 > 0$, take $\delta > 0$ sufficiently small so that $B_\delta(p) \subset \{(x, y);\ x > 0\}$. Then, with respect to this δ-ball neighborhood, the accessible set $A^\delta(p) = (\{(x, y);\ y > y_0\} \cup \{p\}) \cap B_\delta(p)$, and the coaccessible set $CA^\delta(p) = (\{(x, y);\ y < y_0\} \cup \{p\}) \cap B_\delta(p)$. This is readily verified by use, for instance, of the parabolic family of controlled trajectories. For any $x_0 < 0$, the situation is reversed with the accessible set lying below and the coaccessible set lying above the y_0 axis. Further, at $p = (0, y_0)$, $A^\delta(p) = B_\delta(p)$ and $CA^\delta(p) = B_\delta(p)$. In all cases, the sets $A^\delta(p) - \{p\}$ and $CA^\delta(p) - \{p\}$ are open. Hence any $p \in E$ is a fountain.

The definition of a positive fountain x is not strictly stronger or weaker than the standard definition of local accessibility from x (see [24]), in that the set of states accessible from a fountain x (relative to the ρ^+ neighborhood in arbitrary time), with

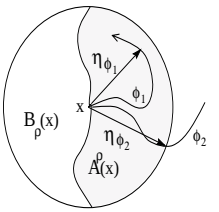

FIG. 2.2. *Throughput function* $\eta_\phi(\cdot)$.

the state x removed, is required to be open; whereas a system is *locally accessible from* x if, for every time $T > 0$ and every neighborhood V of x, the set $R_T^V(x)$ of states reachable from x in time less than or equal to T (with respect to V) contains an open set. The relation of the fountain property to that of local accessibility shall be further discussed in section 4.

Remark. A set of fountains is not necessarily open, which is shown, for instance, by the differential system $\dot{x} = g(x,y)u$, $\dot{y} = 1$, $E = \mathbb{R}^2$, where the function

$$g : E \to \mathbb{R} \text{ is defined to be } g(x,y) = \begin{cases} (x^2 - y^2)^2 & \text{if } x^2 < y^2, \\ 0 & \text{otherwise.} \end{cases}$$

DEFINITION 2.5. *Let $C \subset E$ be an open set of fountains. A state $x \in C$ is called a* continuous positive fountain *if $\rho^+(x)$ is continuous at x, and it is called a* continuous negative fountain *if $\rho^-(x)$ is continuous at x, where a function which is unbounded for all $x \in E$ is taken to be continuous. A fountain is* continuous *if it is both a continuous positive and a continuous negative fountain.*

The set C is called a continuous fountain *if each $x \in C$ is a continuous fountain.*

We observe that, if x is a continuous fountain, then $\rho(x)$ is continuous at x.

For a trajectory ϕ through x, we now introduce a measure of the maximum radius of a ball centered at x which contains an entire segment of ϕ lying in $A^{\rho(x)}(x)$ and $CA^{\rho(x)}(x)$ and is such that the end points of the trajectory segment lie in the boundary of the ball.

DEFINITION 2.6. *For a fountain $x \in E$, the* throughput function on the trajectory $\phi(t,x,u)$ *is defined by $\eta_\phi(x) \underline{\Delta} \sup\{\mu,\ \mu \le \rho(x)$; there exists $T_1 > 0$ such that, for all τ, $0 \le \tau < T_1$, $\phi(\tau,x,u) \in A^\mu(x)$ with $\phi(T_1,x,u) \in \partial B_\mu(x)$; and there exists $T_2 < 0$ such that, for all τ, $T_2 < \tau \le 0$, $\phi(\tau,x,u) \in CA^\mu(x)$ with $\phi(T_2,x,u) \in \partial B_\mu(x)\}$. If $\eta_\phi(x)$ is strictly positive and continuous at x, then x is said to have* continuous strictly positive throughput on the trajectory ϕ.

We observe that throughput functions are strictly positive on any nontrivial trajectory. The definition above is illustrated in Figure 2.2, where η_{ϕ_1}, η_{ϕ_2} represent throughput functions on different trajectories.

LEMMA 2.7. *Let C be an open set of continuous fountains. Then every $x \in C$ has a continuous strictly positive throughput $\eta_\phi(x)$ on any nontrivial trajectory ϕ passing through x; that is, $\eta_\phi(x) > 0$ and*

$$\lim_{n\to\infty} \|\eta_\phi(y_n) - \eta_\phi(x)\| = 0$$

for any sequence $\{y_n;\ y_n \in \phi\}$ converging to x, as $n \to \infty$.

THEOREM 2.8. *Assume that a system $\mathcal{S}$ on the open connected state space E is such that E is a continuous fountain and through each x in E there exists a nontrivial orbit. Then E is controllable.*

Proof. Let Φ_x denote the set of orbits through x. First, we claim that the set $O_x \underline{\Delta} \{z;\ \exists \phi_x \in \Phi_x \text{ s.t. } z \in \phi_x\}$ is open. This is established by showing that any $z \in O_x$ has a neighborhood $N(z)$ contained in O_x.

Consider any $\phi_x \in \Phi_x$. Take an arbitrary point $z \in \phi_x$, and let $z = \phi_x(\tau)$, $0 \leq \tau \leq T$, where the continuous map $\phi_x(\cdot)$ takes $[0,T]$ into the orbit ϕ_x with $\phi_x(0) = \phi_x(T) = x$. Since all states in E are continuous fountains and since ϕ_x is compact (as a continuous image of $[0,T]$ in E), there exists a strictly positive minimum $\eta > 0$ for the function $\eta_{\phi_x}(\cdot)$, which is continuous on ϕ_x by Lemma 2.7.

Then there exist τ_a and τ_b, $\tau_a < \tau < \tau_b$, such that $a = \phi_x(\tau_a) \in B_\eta(z)$ and $b = \phi_x(\tau_b) \in B_\eta(z)$. By the definition of η on ϕ_x, the point z lies in the open set $(A^\eta(a) - \{a\})$ and lies in the open set $(CA^\eta(b) - \{b\})$. Hence there exist open neighborhoods $N_1(z)$ and $N_2(z)$ such that $N_1(z) \subset (A^\eta(a) - \{a\})$ and $N_2(z) \subset (CA^\eta(b) - \{b\})$. Define $N(z) = N_1(z) \cap N_2(z)$. Then, for any $p \in N(z)$, there exists a trajectory from a to p and from p to b; i.e., p lies on a nontrivial orbit through x. Hence $N(z) \subset O_x$. Since this holds for any $\phi_x \in \Phi_x$ and any $z \in \phi_x$, we conclude that O_x is open.

Second, we say that $x, y \in E$ are equivalent, denoted $x \sim y$, if there exists an orbit ϕ such that $x, y \in \phi$. It is clear that $\sim$ is reflexive, symmetric and transitive. Hence the relation $\sim$ defines an equivalence relation on the set E. Thus there exists a partition of the set E into disjoint equivalence classes denoted by $[\cdot]$. For any $x, y \in E$, $y \in [x]$ if and only if $y \in O_x$, i.e., $[x] = O_x$. It follows that the state space E is the disjoint union of open sets. However, E is connected, and hence E consists of just one such orbit class. Now all states $x, y \in E$ lie on orbits passing through each other, and so $A(x) = E$ for all $x \in E$; i.e., E is controllable. □

Example 2.2. Consider the double integrator system described in Example 2.1. As has been shown, every state $p = (x, y) \in \mathbb{R}^2$ is a fountain. Moreover, $\rho(p)$ is unbounded at each p, and hence all states are continuous fountains. Further, applying the state dependent control function $u(x, y) = -y$, we see that there exists a nontrivial orbit trajectory through every state in $\mathbb{R}^2$. Hence, by Theorem 2.8, the system (2.2) is controllable in the space $\mathbb{R}^2$.

2.1. Control recurrence.

DEFINITION 2.9. *A state $x \in E$ is called* control recurrent *if it lies in its nontrivial positive limit set under some control $u \in \mathcal{U}$; i.e., x is not an equilibrium point under u and $x = \lim_{n\to\infty} \phi(t_n, x, u)$ for some sequence $\{t_n;\ n = 1, 2, \cdots\}$ such that $\lim_{n\to\infty} t_n = \infty$.*

Versions of control recurrence have been employed by Lobry [19], [20], Kunita [12], and Jurdjevic [11] to establish the controllability of control affine systems. Using the notion of control recurrence, we obtain the following generalization of Theorem 2.8.

THEOREM 2.10. *Assume that a system $\mathcal{S}$ on the open connected state space E is such that E is a continuous fountain, and, for every x in E there exists a control $u_x \in \mathcal{U}(\mathbb{R}^n; \mathbb{R}^m)$ such that x is control recurrent under u_x. Then E is controllable.*

Proof. Let x be an arbitrary point in E. Consider the associated $u_x(\cdot)$ controlled trajectory ϕ through x. By the fountain condition, there exists a strictly positive radius δ such that the set $N^\delta(x) \underline{\Delta} (CA^\delta(x) - \{x\})$ is open. Take any p such that $p \in \phi$ and $p \in N^\delta(x)$; such a p exists since ϕ is a nontrivial trajectory. Further, let the time interval for the state to pass from p to x be ε. Since x lies in the closure of the forward trajectory, there exists a sequence of instants $\{t_n;\ n = 1, 2, \ldots\}$ such that $\lim_{n\to\infty} t_n = \infty$ and $\lim_{n\to\infty} \phi(t_n, x, u) = x$.

Now consider the sequence $\{\phi(t_n - \varepsilon, x, u_x);\ n = 1, 2, \ldots\}$. By the continuity of solution trajectories with respect to final conditions, this sequence of states converges to p as $n \to \infty$. Hence, for some sufficiently large N, the trajectory ϕ through x over the time interval $[t_n - \varepsilon;\ t_n]$ for all $n > N$ lies in the neighborhood $N^\delta(x)$. Hence, for any such n, the state $\phi(t_n - \varepsilon, x, u_x)$ can be joined to x by a trajectory, using a possibly time-dependent control, where this trajectory segment lies entirely in $N^\delta(x) \cup \{x\}$. This yields a nontrivial orbit through x, and the same construction yields an orbit through any state $y \in E$.

Applying Theorem 2.8, we conclude that E is controllable. □

A vector field F is called *positively Poisson stable* (*PPS*) *on* E (see [24]) if the set of all states $x \in E$ which are control recurrent under F is dense in E. Positive Poisson stability is used by various authors in order to establish the controllability of nonlinear systems. In particular, in [12], it is proven that, if the drift vector field of a control affine system is PPS and the system possesses the LARC condition, then the system is (globally) controllable.

We note that, in the case of the existence of a control u such that the vector field $F \underline{\Delta} f(\cdot, u(\cdot))$ is PPS (in particular, in the case of a control affine system with a PPS drift), the recurrence condition of Theorem 2.10 is satisfied.

DEFINITION 2.11. *A set R is called a* uniform control recurrent set *if there is some state dependent control v such that each $x \in R$ lies in its nontrivial positive limit set under v.*

THEOREM 2.12. *Assume that a system $\mathcal{S}$ on the open connected state space E is such that E is a continuous fountain and there exists a uniform control recurrent set R which is dense in E. Then E is controllable.*

Proof. Take any $x \in E$. By the fountain condition, there exists a strictly positive ρ such that the accessible set $(A^\rho(x) - \{x\})$ and the coaccessible set $(CA^\rho(x) - \{x\})$ are open.

Since R is dense in E, there exists a sequence $\{x_n;\ n = 1, 2, \cdots\} \subset R \cap (CA^\rho(x) - \{x\})$ of control recurrent states converging to x. All x_n are continuous fountains; hence, as has been proved in Theorem 2.10, each x_n lies on a nontrivial orbit ϕ_{x_n}. Moreover, by the recurrence property, the cross-over link creating each orbit can be chosen so that it forms a segment with x_n as the right-hand end point. Hence there exists some interval $[0, \varepsilon]$, where ε is independent of n, such that the trajectory segments commencing at each x_n, subject to the control v, converge uniformly to the trajectory subject to v through x, as $n \to \infty$. So, for some sufficiently large N, the orbit ϕ_{x_N} passes through the set $(A^\rho(x) - \{x\})$, and, since each x_n lies in $(CA^\rho(x) - \{x\})$, the trajectory also passes through this latter set.

Consider any two points p_1 and p_2 such that $p_1, p_2 \in \phi_{x_N}$, $p_1 \in (A^\rho(x) - \{x\})$, $p_2 \in (CA^\rho(x) - \{x\})$. Then there exists an orbit ϕ_x from x to p_1 (since p_1 is accessible from x) to p_2 (since $p_1, p_2 \in \phi_{x_N}$), and then back to x (since p_2 is coaccessible to x).

Hence every state $x \in E$ lies on a nontrivial orbit. Applying Theorem 2.8, we conclude that E is controllable. □

2.2. Weak positive Poisson stability. Let F be a C^r, $r \geq 1$, vector field defined on $E \times \mathbb{R}^1$, and let $\phi^F(t, x)$ denote the flow of F at the time t with the initial condition x; i.e.,

(i) $\phi^F(0, x) = x$,

(ii) $\frac{d}{dt}\phi^F(t, x)|_{t=\tau} = F(\phi^F(\tau, x), \tau)$ for all $\tau \in \mathbb{R}^1$.

Define the set $\phi^F(t, A)$ for $A \subset E$ to be $\{z;\ \exists y \in A,\ \ z = \phi^F(t, y)\}$.

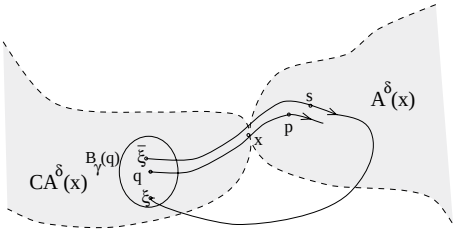

FIG. 2.3. *Theorem* 2.15: *Weak positive Poisson stability.*

DEFINITION 2.13 (see [18]). *A state $x \in E$ is called a* nonwandering state *of F if, for any $T > 0$ and any neighborhood $N(x) \subset E$, there exists a time instant $t > T$, such that $\phi^F(t, N(x)) \cap N(x) \neq \emptyset$. In other words, $\phi^F(t, y) \in N(x)$ for some $y \in N(x)$.*

DEFINITION 2.14 (see [18]). *A smooth (i.e., C^r, $r \geq 1$) vector field F is called* weakly positively Poisson stable (PPS) *if the set of all states which are nonwandering points of F is dense in E.*

The notion of weak positive Poisson stability is employed in [18] and [22] for the analysis of the controllability of control affine systems.

THEOREM 2.15. *For a system $\mathcal{S}$, let there exist a control $\tilde{u} \in \mathcal{U}(\mathbb{R}^n, \mathbb{R}^m)$ such that the vector field $\tilde{X} = f(\cdot, \tilde{u})$ is weakly PPS. Further, let E be a continuous fountain. Then*

(i) *there exists a nontrivial orbit passing through each $x \in E$, and*
(ii) *E is controllable.*

Proof.

(i) Let x be an arbitrary point in E. Choose $\rho > 0$ so that $(A^\rho(x) - \{x\})$ and $(CA^\rho(x) - \{x\})$ are open. Such ρ exists since x is a fountain. Consider the flow $\phi^{\tilde{X}}$ with the initial condition x. Take $p = \phi^{\tilde{X}}(t_1, x)$ and $q = \phi^{\tilde{X}}(t_2, x)$, where $t_1 > 0$ and $t_2 < 0$ are chosen so that $p \in A^\rho(x) - \{x\}$ and $q \in CA^\rho(x) - \{x\}$. Let $t^* = t_1 - t_2$ denote the time needed to reach p from q under the flow $\phi^{\tilde{X}}$. By the continuity of the solution trajectory with respect to initial conditions, there exists an open γ-ball neighborhood $B_\gamma(q) \subset CA^\rho(x) - \{x\}$ such that $\phi^{\tilde{X}}(t^*, B_\gamma(q)) \subset A^\rho(x) - \{x\}$.
Further, since the vector field $\tilde{X}$ is weakly PPS, there exist $\xi, \bar{\xi} \in B_\gamma(q) \subset CA^\rho(x) - \{x\}$ such that $\xi = \phi^{\tilde{X}}(T^*, \bar{\xi})$ for some $T^* > t^*$ (see Figure 2.3). By construction, there exists $s = \phi^{\tilde{X}}(t^*, \bar{\xi}) \in A^\rho(x) - \{x\}$. Hence $\xi = \phi^{\tilde{X}}(T^*, \bar{\xi}) = \phi^{\tilde{X}}(T^* - t^*, s)$, where $T^* - t^* > 0$; i.e., ξ is accessible from s. Therefore, given the facts that ξ is coaccessible to x and s is accessible from x, we conclude that there exists an orbit from x to s to ξ to x.

(ii) The (global) controllability of the state space E follows from part (i) and Theorem 2.8. ∎

Each recurrent point of a vector field F is a nonwandering point of F. Hence we observe that, if a vector field F is PPS (i.e., the set of recurrent points is dense in E), then the nonwandering set is E.

3. Fountains with respect to trajectories. In this section, we assume there exists a compact set $U \subset \mathbb{R}^m$ such that all functions in the set of admissible control functions $\mathcal{U}$ take values in U.

DEFINITION 3.1. *Let x be an arbitrary state in E, and let ϕ_x be an arbitrary trajectory of a system $\mathcal{S}$ passing through x. The state x is called a* fountain with respect to the trajectory ϕ_x *if there exists a time instant $T = T(x, \phi_x) > 0$ such that*

(i) *$\phi_x((0;T))$ lies in the interior of $A(x)$, and*

(ii) *$\phi_x((-T;0))$ lies in the interior of $CA(x)$.*

Further, if $T^* \triangleq \sup\{T;\ \phi_x((0;T)) \subset [A(x)]^\circ$ and $\phi_x((-T;0)) \subset [CA(x)]^\circ\}$ is a continuous function of x, then x is called a continuous fountain with respect to the trajectory ϕ_x.

Note that, by the compactness hypothesis on the set U, T^* is always finite.

Let $x \in E$ be a fountain. Then, as has been noted in section 2, each nontrivial trajectory ϕ_x passing through x has to depart from x within the interior of the accessible set, and it has to arrive at x within the interior of the coaccessible set. Hence x is a fountain with respect to ϕ_x, so Definition 3.1 is a weaker version of Definition 2.4. To illustrate this fact, we consider a simple differential system acting on $\mathbb{R}^2$,

$$\begin{aligned} \dot{x} &= u + 1, \\ \dot{y} &= u^2 x, \end{aligned} \tag{3.1}$$

with the initial condition $p_0 = (1, 0)$. Take a neighborhood $B_\delta(p_0)$ in the open right-half plane $\mathbb{R}^2_+$. Then the accessible set $A^\delta(p_0)$ for all sufficiently small $\delta > 0$ contains a boundary, namely, the set $D \triangleq \{(x, y);\ x > 1; y = 0\} \cap B_\delta(p_0)$. This is because each state p in the topological boundary of D is accessible from p_0 using the control $u = 0$. On the other hand, $A(p_0) = \mathbb{R}^2$, and hence each trajectory lies within the interior of the accessible set. This shows that, for the system (3.1), the state p_0 is not a fountain, but at the same time p_0 is a positive (and, similarly, negative) fountain with respect to any trajectory passing through p_0.

Observe that the fountain property with respect to a specified trajectory is less restrictive than the notion of the *local controllability along a reference trajectory* ϕ (see, for example, [9]), in which the requirement is that all points in some open neighborhood of $\phi(t, x_0)$, $t \geq 0$, can be reached at time t by solutions initiating from x_0. In [23], a sufficient condition for the local controllability along a reference trajectory of an affine control system is formulated in the special case where the reference trajectory is a closed orbit.

THEOREM 3.2. *Assume that a system $\mathcal{S}$ on an open connected state space E is such that, through each state $x \in E$, there exists a nontrivial orbit and every $x \in E$ is a continuous fountain with respect to any orbit $\phi_x \in \Phi(x)$ passing through x. Then E is controllable.*

Proof. Let Φ_x denote the set of orbits through x. First, as in the proof of Theorem 2.8, we claim that the set $O_x \triangleq \{z;\ \exists \phi_x \in \Phi_x$ s.t. $z \in \phi_x\}$ is open. Consider any $\phi_x \in \Phi_x$. Take an arbitrary point $z \in \phi_x$, and let $z = \phi_x(\tau)$, $0 \leq \tau \leq T$, where the continuous map $\phi_x(\cdot)$ takes $[0, T]$ into the orbit ϕ_x with $\phi_x(0) = \phi_x(T) = x$. Since z is a continuous fountain with respect to all orbits passing through z, it is possible to find some q and p on ϕ_x such that some nonempty open neighborhood $N(z)$ is a subset in $[A(q)]^\circ \cap [CA(p)]^\circ$ and hence $N(z) \subset O_x$. We conclude that O_x is open.

As in the proof of Theorem 2.8, the fact that the set O_x is open for any x implies the global controllability of the state space E. ∎

The notion of the fountain with respect to a trajectory can be utilized to establish results similar to the results formulated earlier in this section, namely, in Theorems 2.10, 2.12, and 2.15.

4. Fountain condition for control affine systems. Consider a system $\mathcal{S}$ of the *input-linear* or *control affine* class of nonlinear time-invariant control systems (see [24]),

$$\mathcal{S}: \quad \dot{x} = f(x) + \sum_{i=1}^{m} g_i(x)u_i, \tag{4.1}$$

where we assume that $f, g_1, g_2, \ldots, g_m$ are smooth mappings from $\mathbb{R}^n$ into $\mathbb{R}^n$.

The question of global controllability for control affine systems has been extensively addressed. One of the essential conditions, used for instance in [18] and [20], to establish the controllability of such systems is the (Chow–Hermann) LARC. In [20], it has been proven that any *Poisson stable* system satisfying the LARC is controllable. An extension of this result is presented in [22], where the Poisson stability condition is weakened to the requirement of Poisson stability on the drift vector field $f(x)$ only. One of the most recent of this set of results is to be found in the paper by Lian, Wang, and Fu [18].

THEOREM 4.1 (see [18]). *Consider the system* (4.1) *on the state space* E. *Suppose that* f *is a weakly PPS vector field (see Definition* 2.14*). Then* E *is controllable if the LARC is satisfied.*

Related results can be also found in [3], [1], and [8]. In [21], the LARC condition is used to establish the small-time local controllability for a planar body with unilateral thrusters.

Consequently, it is of interest to investigate the relation between the LARC and the fountain notion. In this section, we show that the fountain condition for control affine systems does not imply the LARC condition and, conversely, the LARC condition does not imply the fountain condition. These facts are illustrated by the following examples.

Example 4.1. Let $h_1(x, y)$, $h_2(x, y)$ be $C^\infty(\mathbb{R} \times \mathbb{R})$ functions such that

(i) $h_1(x, y) \neq 0$, if $(x, y) \in S_1$, and $h_1(x, y) = 0$ if $(x, y) \in \mathbb{R}^2 - S_1$, and

(ii) $h_2(x, y) \neq 0$, if $(x, y) \in S_2$, and $h_2(x, y) = 0$ if $(x, y) \in \mathbb{R}^2 - S_2$,

where $S_1 \subset \mathbb{R}^2$ is the open unit disk with the center at (0,1) and $S_2 \subset \mathbb{R}^2$ is the open unit disk with the center at $(0, -1)$.

Consider the following control affine system:

$$\begin{aligned} \dot{x} &= (h_1(x, y) + h_2(x, y))u, \\ \dot{y} &= 1. \end{aligned} \tag{4.2}$$

Then the accessible set from $p_0 = (0, 0)$ and the coaccessible set to p_0 are such that $A^\delta(p_0) - \{p_0\}$ and $CA^\delta(p_0) - \{p_0\}$ are open for any $\delta > 0$. Hence p_0 is a fountain. On the other hand, the LARC fails at p_0 since the function $g(x, y) \underline{\Delta} h_1(x, y) + h_2(x, y)$ and all of its partial derivatives are equal to zero at p_0 and thus the dimension of the associated Lie algebra of the system (4.2) at p_0 is equal to 1.

Example 4.2. Consider the differential system

$$\begin{aligned} \dot{w} &= z^2 I w + J w, \\ \dot{z} &= u, \end{aligned} \tag{4.3}$$

where $w = [x, y]^T$, $I = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}$, and $J = \begin{bmatrix} 0 & -1 \\ 1 & 0 \end{bmatrix}$.

The system in this example is in the class of control affine systems described by (4.1) with $f = [(z^2 x - y) \quad (z^2 y + x) \quad 0]^T$, $m = 1$, and $g = [0 \quad 0 \quad 1]^T$.

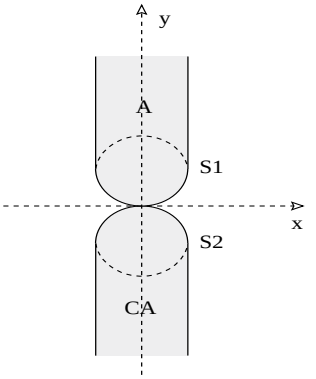

FIG. 4.1. *Example* 4.1: *Fountain condition does not imply LARC.*

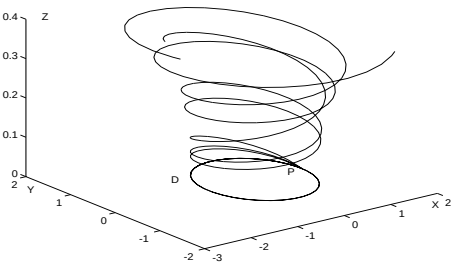

FIG. 4.2. *Example* 4.2: *Fountain condition fails, while the LARC property holds at p.*

The LARC condition holds at the state $p = (1, 0, 0)$. Indeed, $[[f, g], g] = [2x\ 2y\ 0]^T$, and hence, at p, $\dim L(f, g) = \dim span\{[[f, g], g], f, g, \} = 3$.

However, the fountain condition fails at p since the accessible set from p with respect to any neighborhood $B_\delta(p)$ contains accessible boundary states that lie in the set $D \underline{\Delta} \{(x, y, 0);\ x^2 + y^2 = 1\}$ (see Figure 4.2). To verify this, we note that $u \equiv 0$ implies $z \equiv 0$, in which case the motion is a rotation around the unit circle, and so there certainly exist states $p' \epsilon D \cap B_\delta(p)$ accessible under the zero control from p. Next we consider the function $R \underline{\Delta} \frac{1}{2}(x^2 + y^2)$ along any system trajectory. Since $dR = 2z^2 R dt$, R is nondecreasing along all trajectories, and hence any state $p' \epsilon \{(x, y, 0); x^2 + y^2 < 1\}$ is not accessible from p. It follows that any accessible point $p' \epsilon D \cap B_\delta(p)$ does not lie in the interior of the accessible set from p which is consequently not a fountain. □

The above examples show that the fountain condition is neither strictly stronger nor strictly weaker than the LARC.

5. Fountains and local accessibility. As has been noted in section 2, the definition of a positive fountain x is not strictly stronger or weaker than the standard definition of local accessibility from x (see [24]). To illustrate this fact, we present in this section two examples in which only one of these properties is satisfied.

Example 5.1.

$$\dot{x} = \sin^2 u + v_1 z, \quad \dot{y} = \sin^4 u + v_2 z, \quad \dot{z} = g(x, y, z) v_3,$$

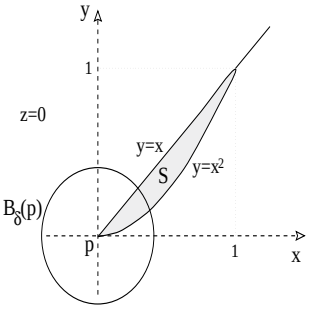

FIG. 5.1. *Example* 5.1: *The local accessibility property fails at the fountain* $p = (0, 0, 0)$.

where $w \underline{\Delta} (u, v_1, v_2, v_3) \epsilon \mathcal{U}$ and the function $g \epsilon C^s(\mathbb{R}^3; \mathbb{R}^1)$, $s \geq 1$, is defined in such a way that $g(x, y, z) = 0$ if $(x, y, z) \epsilon S \underline{\Delta} \{(x, y, 0);\ 0 \leq x \leq 1, x^2 \leq y \leq x\}$ (S is shown in Figure 5.1) and $g(x, y, z) > 0$ otherwise.

For the initial condition $p = (0, 0, 0)$ and an arbitrary control $w \epsilon \mathcal{U}$, denote the corresponding system trajectory as $(x(t), y(t), z(t))$, $t \geq 0$. Then, for any $t \epsilon [0, 1]$,

$$x(t) = \int_0^t \sin^2 u(\tau, x(\tau))d\tau, \quad y(t) = \int_0^t \sin^4 u(\tau, x(\tau))d\tau, \quad z(t) = 0. \tag{5.1}$$

It can be shown (using the Cauchy–Schwarz inequality) that $x(t)$ and $y(t)$ defined by (5.1) satisfy

$$x^2(t) \leq y(t) \leq x(t),$$

and hence $(x(t), y(t), z(t)) \epsilon S$ for any $t \epsilon [0, 1]$.

Hence the system trajectories under various control functions w stay in the set S for any $0 \leq t \leq 1$. This set has an empty interior, and hence the local accessibility condition fails at the origin.

On the other hand, under constant control u and $(v_1, v_2, v_3) = (0, 0, 0)$, the trajectory is such that $y(t) = ax(t)$ (where $a = \sin^2 u$) and $y(1) = x^2(1)$. Hence, for any $\delta > 0$ and any time $T > 1$, there exists a control w under which the trajectory can leave S (in time less than T) without leaving $B_\delta(p)$ and, since $g \neq 0$ outside of S, attain any point in $B_\delta(p)$.

We conclude that the set of accessible from p states (with respect to an arbitrary δ-ball neighborhood $B_\delta(p)$, $\delta > 0$) is equal to the whole $B_\delta(p)$. Hence the fountain condition at the origin is satisfied.

Example 5.2. Consider the system

$$\begin{aligned} \dot{x} &= u^2, \quad x(0) = x_0, \\ \dot{y} &= 1, \quad y(0) = y_0, \end{aligned}$$

where we take $E = \mathbb{R}^2$.

For any $\delta > 0$, the accessibility set is $A_T^\delta(x_0, y_0) = \{(x, y) \epsilon \mathbb{R}^2;\ x \geq x_0; y > y_0; T \geq 0\}$. This set has a nonempty interior, and hence the local accessibility property is satisfied for any state $(x_0, y_0) \epsilon E$. On the other hand, the accessibility set (with the initial state (x_0, y_0) removed) is not open, and thus the positive fountain condition fails.

For nonlinear systems for which the fountain condition is satisfied at some state $x_0 \epsilon E$, it is interesting to investigate under what additional assumptions the local

accessibility property is satisfied at x_0, as well. In this connection, we state the following two lemmas.

LEMMA 5.1 (see [14]). *Assume that, for a system $\mathcal{S}$, there exists a state $x_0 \epsilon E$ at which the fountain condition is satisfied but the local accessibility condition fails. Then*

$$\inf_{u\epsilon\mathcal{U}} \max_{t\epsilon[0,T^*]} \|\phi(t, x_0, u) - x_0\| = 0 \tag{5.2}$$

for some T^*, $0 < T^* < \infty$.

LEMMA 5.2 (see [14]). *Assume that, for a system $\mathcal{S}$, there exists a state $x_0 \epsilon E$ at which the fountain condition is satisfied but the local accessibility condition fails. Then*

$$\inf_{u\epsilon U} \|f(x_0, u)\| = 0, \tag{5.3}$$

where $f(\cdot,\cdot)$ is the vector field of the system $\mathcal{S}$ and $U = \mathbb{R}^m$ is the set of values of admissible control functions.

We conclude that the fountain property, taken together with either of the conditions

$$\text{for all } T^* > 0, \quad \inf_{u\epsilon\mathcal{U}} \max_{t\epsilon[0,T^*]} \|\phi(t, x_0, u) - x_0\| > 0 \tag{5.4}$$

or

$$\inf_{u\epsilon U} \|f(x_0, u)\| > 0, \tag{5.5}$$

implies local accessibility.

6. Algebraic criteria for the fountain condition. In this section, we treat certain classes of nonlinear systems for which it is possible to verify the fountain condition without analyzing the actual geometry of the accessible sets.

6.1. Controllable linearizations. In this section, we take $\mathcal{U}$ to be the set of all admissible time-dependent controls $\mathcal{U}^s(\mathbb{R}; \mathbb{R}^m)$, $s \geq 1$. Let p be an arbitrary state in E, and let a state $q \epsilon E$ be accessible from p. Then there exist a control function $u^0 \epsilon \mathcal{U}$ and a time instant T such that $q = \phi(T, p, u^0)$. Consider the linearization of the system $\mathcal{S}$ along the trajectory $\phi(t, p, u^0)$ on the time interval $[0, T]$ given by

$$\frac{d}{dt} z = A(t)z + B(t)v, \qquad t \epsilon [0, T]. \tag{6.1}$$

The matrices A and B are defined on $[0, T]$ as the derivatives of f with respect to the arguments x and u, respectively:

$$A(t) \underline{\Delta} \left[\frac{\partial f(x,u)}{\partial x}\right] \Big|_{\substack{x=\phi(t,p,u^0)\\ u=u^0(t)}}, \qquad B(t) \underline{\Delta} \left[\frac{\partial f(x,u)}{\partial u}\right] \Big|_{\substack{x=\phi(t,p,u^0)\\ u=u^0(t)}}. \tag{6.2}$$

THEOREM 6.1. *Suppose that a system $\mathcal{S}$ is such that, for each $p \epsilon E \subset \mathbb{R}^n$ and any $q \epsilon A^\rho(p) - \{p\}$ $(\rho > 0)$, the linearization of $\mathcal{S}$ along a trajectory ϕ, joining p to q over a finite time interval $[0, T]$, is controllable on $[0, T]$. Then each state in E is a continuous positive fountain.*

Proof. Take an arbitrary $\rho > 0$ and any $q \epsilon A^\rho(p) - \{p\}$, where $p \epsilon E$. Let $u^0 \epsilon \mathcal{U}$ be such that $q = \phi(T, p, u^0)$ $(0 < T < \infty)$, where the system (6.1) is controllable

along $\phi(t,p,u^0)$ on $[0,T]$. Then there are controls $v_1, v_2, \dots, v_n \in \mathcal{U}$ defined on $[0,T]$ such that the corresponding states $z_i(\cdot)$, $1 \le i \le n$, of (6.1) are linearly independent at time T; i.e.,

$$\frac{d}{dt}z_i = A(t)z_i + B(t)v_i, \qquad z_i(0) = 0, \qquad t \in [0,T]; \quad \text{and}$$
$$\text{for all } \gamma \in \mathbb{R}^n \quad [z_1(T)\cdots z_n(T)]\gamma = 0 \Rightarrow \gamma = 0.$$

Define $u(t,\gamma) = [v_1(t)\cdots v_n(t)]\gamma + u^0(t)$, $\gamma \in \mathbb{R}^n$, $t \in [0,T]$, and consider the state $z(t,p,\gamma)$ of $\mathcal{S}$ corresponding to u. Following the standard arguments (see, e.g., [25]), it can be shown that, for each $x = q + \delta q \in N(q)$, there exist $\gamma = g(x) \in \mathbb{R}^n$ and hence a control $u = u(t,\gamma)$ such that the corresponding trajectory with the initial condition p reaches $q + \delta q$ at time T.

We conclude the proof by noting that

$$\begin{aligned} &\text{for all } \varepsilon > 0 \ \exists\ \delta > 0 \ \text{ such that } \|u_1 - u_2\|_{C_{[0,T]}} < \delta \Rightarrow \\ &\quad \text{for all } t \in [0,T] \ \|\phi(t,x_0,u_1) - \phi(t,x_0,u_2)\| < \varepsilon. \end{aligned} \tag{6.3}$$

Choose $\varepsilon > 0$ to be sufficiently small so that (i) the ε-cylinder of the nominal trajectory $\phi([0,T],p,u^0)$ lies in $B_\rho(p)$, i.e.,

$$\{x;\ \|\phi([0,T],p,u^0) - x\| < \varepsilon\} \subset B_\rho(p),$$

and, furthermore, (ii) $B_\varepsilon(q) \subset N(q)$. For that ε, take $\delta > 0$ for which the property (6.3) is satisfied, and then take α ($\varepsilon > \alpha > 0$) such that, for all $x \in B_\alpha(q)$, $\|u(t,g(x)) - u^0\| = \|[v_1\cdots v_n]g(x)\| < \delta$ (such an α exists since $g(q) = 0$ and $g(\cdot)$ is continuous).

By this construction, the open α-ball neighborhood of q is accessible from p with respect to $B_\rho(p)$. Hence $A^\rho(p) - \{p\}$ is open. Moreover, since this property is satisfied for an arbitrary $\rho > 0$, p is a continuous positive fountain. □

Assume that, for a system $\mathcal{S}: \dot{x} = f(x,u)$ on the state space E, $x_0 \in E$ is a fountain. Let $\Psi : E \to \tilde{E} \triangleq \Psi(E)$ be a diffeomorphism. Consider the system $\tilde{\mathcal{S}}: \dot{z} = \frac{\partial \Psi}{\partial x}(z) f(\Psi^{-1}(z), u)$ on $\tilde{E}$. Since the fountain property is a topological property of the attainable sets, it is preserved under diffeomorphic transformations. Hence the state $\Psi(x_0) \in \tilde{E}$ is also a fountain. In particular, in the case of the existence of a feedback control which, together with a diffeomorphism of the state space, gives rise to a controllable linear system (see [10]), both E and $\tilde{E}$ are fountains, with respect to $\mathcal{S}$ and $\tilde{\mathcal{S}}$, respectively.

6.2. The fountain condition for symmetric systems.

DEFINITION 6.2. *We shall say that a system $\mathcal{S}$ is* symmetric at $x \in E$ *if there exists $\rho > 0$ such that for all $y \in B_\rho(x)$ and $u \in \mathcal{U}$, there exists $u' \in \mathcal{U}$ such that $f(y,u(y)) = -f(y,u'(y))$.*

We note that the definition above is somewhat weaker than the standard definition of a symmetric system (see, for instance, [26]), in which the requirement is that, for all $x \in E$ and $u \in \mathbb{R}^n$, there exists $u' \in \mathbb{R}^n$ such that $f(x,u) = -f(x,u')$.

In [26], a condition for symmetric systems to possess the local controllability property at x is formulated in terms of the Lie algebra of the family $\mathcal{L}_0 \triangleq \{f(\cdot,u);\ u \in \mathbb{R}^n\}$. Namely, for $j = 1, 2, \dots$, let

$$\mathcal{L}_j \triangleq \mathcal{L}_{j-1} \cup \{[f,g](\cdot);\ f(\cdot) \in \mathcal{L}_{j-1}, g(\cdot) \in \mathcal{L}_0 \text{ or } g(\cdot) \in \mathcal{L}_{j-1}, f(\cdot) \in \mathcal{L}_0\}.$$

In addition, define $\mathcal{L}_j(x) \triangleq \{g(x);\ g \in \mathcal{L}_j\}$.

THEOREM 6.3 (see [26]). *Suppose that a system* (2.1) *is symmetric at* x *and the fields* $f(\cdot, u)$, $u \in \mathbb{R}^n$, *are of the class* C^k, $k \geq 2$. *If, for some* $j \leq k$,

$$\dim \mathcal{L}_j(x) = n, \tag{6.4}$$

then the system is locally controllable at x.

THEOREM 6.4. *Suppose that a system* $\mathcal{S}$ *is such that the fields* $f(\cdot, u)$, $u \in \mathcal{U}$, *are of the class* C^k, $k \geq 2$. *Further, let* $x \in E$ *be such that, for some* $\delta > 0$ *and for all states* $y \in A^\delta(x) - \{x\}$,

(i) $\mathcal{S}$ *is symmetric at* y;

(ii) *the condition* (6.4) *is satisfied at* y.

Then x *is a positive fountain.*

Proof. The local controllability at any accessible state $y \in A^\delta(x) - \{x\}$ (which follows from Theorem 6.3) implies that each $y' \in B_\gamma(y)$ (for sufficiently small γ) is accessible from y, and hence from x, with respect to $B_\delta(x)$. Hence the set $A^\delta(x) - \{x\}$ is open, and so x is a positive fountain. ∎

The negative fountain property can be verified by assuming the condition (6.4) and the symmetry property for the reverse time dynamics.

6.3. Full rank condition for systems with time-dependent controls. In this section, the class of admissible control functions, denoted $\mathcal{U}^\omega$, is assumed to be the set of all time-dependent analytic functions taking values in $\mathbb{R}^m$.

Let $f(\cdot, \cdot)$ be an analytic function of the arguments $(x, u) \in E \times \mathbb{R}^m$. Denote the solution trajectory, with the initial condition $x_0 \in E$ under a specified control $u_0(\cdot)$, by $x(\cdot)$. Then $x(\cdot)$ is analytic, and $x(\cdot)$, $u_0(\cdot)$ can be represented locally by the series

$$x(t) = x_0 + \sum_{i=1}^{\infty} x^{(i)}(0)\frac{t^i}{i!}, \qquad u_0(t) = u_0(0) + \sum_{i=1}^{\infty} u_0^{(i)}(0)\frac{t^i}{i!}. \tag{6.5}$$

Denoting $s^i = (x, \lambda_0, \ldots, \lambda_{i-1})$, we define the functions $D_i : \mathbb{R}^n \times \mathbb{R}^{im} \to \mathbb{R}^n$, $i = 1, 2, \cdots$, in the following way:

$$D_1(s^1) = f(x, \lambda_0),$$

$$D_2(s^2) = \frac{\partial D_1}{\partial x}(s^1) f(x, \lambda_0) + \frac{\partial D_1}{\partial \lambda_0}(s^1)\lambda_1$$

$$\cdots$$

$$D_i(s^i) = \frac{\partial D_{i-1}}{\partial x}(s^{i-1}) f(x, \lambda_0) + \frac{\partial D_{i-1}}{\partial \lambda_0}(s^{i-1})\lambda_1 + \cdots + \frac{\partial D_{i-1}}{\partial \lambda_{i-2}}(s^{i-1})\lambda_{i-1} \cdots.$$

THEOREM 6.5. *Let* $x_0 \in E$, *and let* u_0 *be a time-dependent control in* $\mathcal{U}^\omega$. *Suppose that there exist some* $\delta > 0$ *and some integer* $q \geq 0$ *such that, for all* $0 < t < \delta$,

$$\operatorname{rank}\left\{\left[\sum_{i=1}^{\infty} D_i(s_0^i)\frac{t^{i-1}}{(i-1)!} \;\vdots\; \sum_{i=1}^{\infty}\frac{\partial D_i}{\partial \lambda_0}(s_0^i)\frac{t^i}{i!} \;\vdots\; \cdots \;\vdots\; \sum_{i=q+1}^{\infty}\frac{\partial D_i}{\partial \lambda_q}(s_0^i)\frac{t^i}{i!}\right]\right\} = n, \tag{6.6}$$

where we use $u_0 = u_0(0), u_0^{(1)} = \frac{d}{dt}u_0(0), \ldots, u_0^{(q)} = \frac{d^q}{dt^q}u_0(0), \ldots,$ $s_0^i \triangleq (x_0, u_0, u_0^{(1)}, \ldots, u_0^{(i-1)})$, $i \geq 1$, *to simplify the notation. Then* x_0 *is a positive fountain with respect to the trajectory under* u_0 *control.*

Proof. Observe that the functions D_i are defined in such a way that $D_i(s_0^i)$ is equal to the full ith derivative of $x(t)$ with respect to time, evaluated at $t = 0$. Hence the decomposition (6.5) can be rewritten as

$$x(t) = x_0 + \sum_{i=1}^{\infty} D_i(s_0^i)\frac{t^i}{i!}.$$

Next define the function $F : \mathbb{R}^n \times \mathbb{R}^1 \times \mathbb{R}^{(q+1)m} \to \mathbb{R}^n$, $q \geq 0$, as

$$F(x, t, \lambda_0, \lambda_1, \ldots, \lambda_q) \triangleq x - \left\{ x_0 + \sum_{i=1}^{\infty} D_i(p^i)\frac{t^i}{i!} \right\}, \tag{6.7}$$

where $p^i = (\lambda_0, \ldots, \lambda_{i-1}), 1 \leq i \leq q+1$, and $p^i = (\lambda_0, \ldots, \lambda_q, u^{(q+1)}, \ldots, u^{(i-1)}), i > q+1$. Taking an arbitrary $0 < \bar{t} < \delta$ and setting $\bar{x} \triangleq x(\bar{t})$, $p_0 \triangleq (\bar{x}, \bar{t}, u_0, u_0^{(1)}, \ldots, u_0^{(q)})$, we note that

(i) $F(p_0) = \bar{x} - x(\bar{t}) = 0$.

(ii) All first order partial derivatives of F with respect to $x, t, \lambda_0, \ldots, \lambda_q$ are continuous in a neighborhood of the point p_0.

(iii)

$$\left[\frac{\partial F}{\partial t}(p_0) \;\vdots\; \frac{\partial F}{\partial \lambda_0}(p_0) \;\vdots\; \cdots \;\vdots\; \frac{\partial F}{\partial \lambda_q}(p_0) \right]$$

$$= \left[\sum_{i=1}^{\infty} D_i(s_0^i)\frac{\bar{t}^{i-1}}{(i-1)!} \vdots \sum_{i=1}^{\infty} \frac{\partial D_i}{\partial \lambda_0}(s_0^i)\frac{\bar{t}^i}{i!} \vdots \cdots \vdots \sum_{i=q+1}^{\infty} \frac{\partial D_i}{\partial \lambda_q}(s_0^i)\frac{\bar{t}^i}{i!} \right],$$

which, by the condition (6.6), has full rank.

From the implicit function theorem applied to F, it follows that there exist continuous functions $t(r) > 0$ and $\lambda_0(r), \ldots, \lambda_q(r)$ such that

$$F(\bar{x} + r, t(r), \lambda_0(r), \ldots, \lambda_q(r)) = 0$$

for all sufficiently small $r \in \mathbb{R}^n$. Further, define the time-dependent control $v_r \in \mathcal{U}^\omega$ to be

$$\begin{aligned} v_r(t) &= (\lambda_0(r) - u_0) + (\lambda_1(r) - u_0^{(1)})t + \cdots + (\lambda_q(r) - u_0^{(q)})\frac{t^q}{q!} + u_0(t) \\ &= \sum_{i=1}^{q} \lambda_i(r)\frac{t^i}{i!} + \sum_{i=q+1}^{\infty} u_0^{(i)}\frac{t^i}{i!}. \end{aligned} \tag{6.8}$$

Then the solution trajectory under the control v_r drives x_0 to $x(\bar{t}) + r$ at time $t(r)$. Hence each state $x(t)$ (where $t > 0$ is sufficiently small) lies in the interior of the states accessible from x_0, and thus x_0 is a positive fountain with respect to the trajectory under u_0. □

The full rank condition (6.6) can be rewritten (in obvious notation) as

$$\operatorname{rank} \left\{ \sum_{i=0}^{\infty} A_i t^i \right\} = n$$

or, equivalently, as

$$\text{there exists an } n\text{-tuple } k = (k_1, k_2, \dots, k_n),$$
$$1 \le k_i \le n + (q+1)m,\ k_i \ne k_j,\ i \ne j,\ i, j = 1, 2, \dots n, \text{ such that}$$
$$\det\left(\sum_{i=0}^{\infty} P_i^k t^i\right) = \sum_{i=0}^{\infty} p_i^k t^i \not\equiv 0,$$

where $P_i^k \in \mathbb{R}^n \times \mathbb{R}^n$, $i \ge 0$, denotes the submatrix of A_i consisting of the columns $k_1, k_2, \dots, k_n$. We further observe that, for a given k,

$$p_0^k = \det P_0^k, \quad p_\ell^k = \frac{d^{(\ell)}}{dt^\ell}\left\{\det\left(\sum_{i=0}^{\ell} P_i^k t^i\right)\right\}|_{t=0}, \quad \ell \ge 1.$$

Hence a sufficient condition for the fountain property with respect to a specified trajectory to hold can be formulated in terms of the existence of an n-tuple k and an integer $0 \le j < \infty$, such that the coefficient p_j^k (the calculation of which involves only the matrices $D_0, \dots, D_j$) is nonzero.

COROLLARY 6.6. *Let x_0 be an arbitrary state in E. Assume that there exists $\delta > 0$ such that the full rank condition* (6.6) *is satisfied for all $u \in \mathcal{U}^\omega$, for all x in some open neighbourhood $N(x_0)$, and for all t, $t \ne 0$, in the symmetric interval $(-\delta, \delta)$, uniformly in x and u (i.e., δ does not depend on x or u). Then x_0 is a fountain.*

Proof. Consider the set of all states accessible from x_0 with respect to $B_\gamma(x_0)$, where $\gamma > 0$ is chosen so that $B_\gamma(x_0) \subset N(x_0)$. Suppose that there exists a boundary state $y \in A^\gamma(x_0)$. Hence there exists a control $u_0 \in \mathcal{U}^\omega$ and a time instant $0 < T < \infty$ such that $y = \phi(T, x_0, u_0)$. Take $z \triangleq \phi(T - \delta/2, x_0, u_0)$. Then, since $z \in N(x_0)$, any state $y' \in B_\varepsilon(y)$ can be attained from z (and hence from x_0) under the control v_r (defined by (6.8)), $r = y' - y$, in time $t(r)$. Moreover, by the continuity of the functions $t(r), \lambda_0(r), \dots, \lambda_q(r)$, $\varepsilon > 0$ can be chosen so that $\|u_0 - v_r\|$ is sufficiently small and the solution trajectory under v_r does not leave $B_\gamma(x_0)$ on the time interval $[0, t(r)]$. Hence $B_\varepsilon(y) \subset A^\gamma(x_0)$, and x_0 is a positive fountain.

The fact that x_0 is a negative fountain follows from considering the reversed time dynamics. □

Example 6.1. To illustrate the use of Theorem 6.5, we consider the system

$$\dot{x} = 1 + u, \quad \dot{y} = ux^2, \quad u \in \mathbb{R}^1,$$

and test whether the state $p_0 = (1, 0)$ is a fountain with respect to the trajectory under $u_0 \equiv 1$ control. We consecutively compute D_i, $i = 1, 2, 3$:

$$D_1(s^1) = [\lambda_0 + 1\ \ \lambda_0 x^2]^T;\ D_2(s^2) = [0\ \ 2\lambda_0(\lambda_0 + 1)x]^T;\ D_3(s^3) = [0\ \ 2\lambda_0(\lambda_0 + 1)^2]^T;$$

$$\frac{\partial D_1}{\partial \lambda_0} = [1\ \ x^2]^T;\ \frac{\partial D_2}{\partial \lambda_0} = [0\ \ (4\lambda_0 + 2)x]^T.$$

To check the full rank condition, we have to determine the rank of the matrix

$$\left[D_1(s_0^1) + D_2(s_0^2)t + D_3(s_0^3)t^2/2 + o(t) \mid \frac{\partial D_1}{\partial \lambda_0}(s_0^1)t + \frac{\partial D_2}{\partial \lambda_0}(s_0^1)t^2/2 + o(t)\right],$$

where $s_0^1 = (1,1)$, $s^2 = (1,1,0)$, $s^3 = (1,1,0,0)$.

$$\operatorname{rank}\left[\begin{bmatrix}2\\1\end{bmatrix} + \begin{bmatrix}0\\4\end{bmatrix}t + \begin{bmatrix}0\\8\end{bmatrix}t^2/2 \;\middle|\; \begin{bmatrix}1\\1\end{bmatrix}t + \begin{bmatrix}0\\6\end{bmatrix}t^2/2\right] = \operatorname{rank}\begin{bmatrix}2 & t\\ 1+4t+4t^2 & t+3t^2\end{bmatrix} = 2$$

for all sufficiently small $0 < t < \delta$, and hence p_0 is a fountain with respect to the trajectory under the control $u_0 \equiv 1$.

7. Hamiltonian control systems. In this section, we consider an application of the results of section 3 to *affine Hamiltonian control systems* (see [24]), i.e., Hamiltonian control systems with a smooth Hamiltonian of the form

$$H(q,p,u) = H_0(q,p) - \sum_{j=1}^{m} H_j(q,p)u_j,$$

where $H_0(q,p)$ is the *internal Hamiltonian (energy)* and H_j, $j = 1,2,\dots,m$, are the *interaction* or *coupling* Hamiltonians.

For affine Hamiltonian control systems, we have the equations of motion

$$\begin{aligned}\dot{q}_i &= \frac{\partial H_0}{\partial p_i}(q,p) - \sum_{j=1}^{m}\frac{\partial H_j}{\partial p_i}(q,p)u_j,\\ \dot{p}_i &= -\frac{\partial H_0}{\partial q_i}(q,p) + \sum_{j=1}^{m}\frac{\partial H_j}{\partial q_i}(q,p)u_j,\end{aligned} \tag{7.1}$$

where $i = 1,2,\dots,n$.

DEFINITION 7.1. *A u_0 energy slice $ES(H^-,H^+)$ of a Hamiltonian control system is the set of states for which the value of H, under the state-dependent control $u_0 \in \mathcal{U}(\mathbb{R}^n;\mathbb{R}^m)$, lies between some fixed values H^- and H^+,*

$$ES(H^-,H^+) \triangleq \{(p,q);\quad (p,q) \in E \text{ and } H^- < H(p,q,u)_{|_{u=u_0}} < H^+\},$$

where $H(p,q,u)$ is the Hamiltonian function associated with the system (7.1).

We note that, while Definition 7.1 is given in terms of the class $\mathcal{U}(\mathbb{R}^n;\mathbb{R}^m)$, the controllability in the following theorem is with respect to controls in $\mathcal{U} = \mathcal{U}(\mathbb{R};\mathbb{R}^m)$.

THEOREM 7.2. *An affine Hamiltonian control system for which all states are fountains and all equilibrium points under some constant control $u_0 \in \mathbb{R}^m$ are isolated is such that any precompact connected component of a u_0 energy slice is controllable with respect to $\mathcal{U}$.*

Proof. Consider any precompact connected energy slice $ES(H^-,H^+)$, and let $ES_0(H^-,H^+)$ be obtained from $ES(H^-,H^+)$ by removing the (necessarily finite) equilibrium points of the flow under u_0. Since the state space necessarily has dimension greater than 1, we observe that $ES_0(H^-,H^+)$ is also open, precompact, and connected. Now, since $ES_0(H^-,H^+)$ has compact closure, it has finite measure under the density given by H, and, furthermore, the u_0 (i.e., Hamiltonian) flow is Lebesgue measure preserving. It follows by Poincaré's recurrence theorem that almost all states in $ES_0(H^-,H^+)$ are recurrent under the u_0 flow. However, since every state of $ES_0(H^-,H^+)$ is a fountain, and since no state is an equilibrium state under the u_0 flow, Theorem 2.12 implies that $ES_0(H^-,H^+)$ is controllable.

Next consider any equilibrium point $y \in ES(H^-, H^+) - ES_0(H^-, H^+)$ (under u_0). Since all equilibria under u_0 are isolated, there exists a neighborhood $N(y)$ such that $(N(y) - \{y\}) \in ES_0(H^-, H^+)$. Take any $p \in (A^{N(y)}(y) - \{y\})$, which is not empty by the positive fountain condition at y. Then $ES_0(H^-, H^+)$ is a subset $A(p)$ and $p \in A(y)$. Hence $ES_0(H^-, H^+) \subset A(y)$. Finally, consider any equilibrium point $z \in ES(H^-, H^+) - ES_0(H^-, H^+)$ (under u_0). Using analogous arguments and the negative fountain condition at the point z, it can be shown that $ES_0(H^-, H^+) \subset CA(z)$. Since these properties hold for arbitrary equilibria y and z under u_0, it follows that for any $x \in ES(H^-, H^+)$, $ES(H^-, H^+) \subset A(x)$; i.e., $ES(H^-, H^+)$ is controllable. □

We note that the arguments above can be applied to all systems for which there is a measure preserving flow that satisfies the conditions of Theorem 7.2; the theorem is stated for affine Hamiltonian systems because of their importance. We also remark that, in the affine Hamiltonian case, the expression of the linearization condition of section 6.1 for the fountain property takes an interesting symmetric form in terms of the second order partial derivatives of H.

In the case of the existence of a first integral F (which is not necessarily the total energy function) for a dynamical system $\mathcal{S}$, the analogous arguments can be applied to slices based on F or, in the case of the existence of multiple first integrals $F_1, \ldots, F_k$, to intersections of slices based on $F_1, \ldots, F_k$. An example of this is given in [16], where the results of the theory developed in this paper are applied to hybrid systems with disturbances and, in particular, are illustrated on a simplified air traffic system.

8. Applications to hierarchical hybrid control theory (HHCT).

The theory developed in this paper is directly applicable in the analysis of hierarchical hybrid control systems because several of the main results in [5] and [15] employ the HIBC hypothesis (see below). This hypothesis requires that each of the blocks of a given finite analytic partition of the system state space forms a controllable subsystem.

To verify the HIBC condition using the theory of this paper, it is sufficient to establish that the fountain condition holds in E and that one of the recurrence conditions holds for each block of the finite analytic partition under consideration. Furthermore, for the so-called energy slice partitions of affine Hamiltonian systems, the dense recurrence condition under a distinguished constant control is an inherent property which does not need explicit verification whenever each slice is precompact. In this section, we first briefly overview the main concepts of the HHCT developed in [5] and then consider an application of HHCT to a mass-spring system.

8.1. Overview of HHCT.

Consider a system $\mathcal{S}$ of the form (2.1) on some state space $D \in \mathbb{R}^n$. All of the definitions and results here are taken from [5].

DEFINITION 8.1 (see [5]). *A* finite analytic partition *of the state space $D \subset \mathbb{R}^n$ of $\mathcal{S}$ is a pairwise disjoint collection of subsets $\pi = \{X_1, X_2, \ldots, X_{|\pi|}\}$ such that each X_i is nonempty, open, and path-connected and is such that $D = \bigcup_{i=1}^{|\pi|}(X_i \cup \partial X_i)$, where, further, the boundary ∂X_i of every block X_i is a locally finite union of connected components of $n-p$ dimensional, $p \geq 1$, analytic manifolds (possibly with boundary), such that $\partial X_i = \bigcup_{m=1}^{k_i} C_m^i$.*

Henceforth we shall use the following notation for the partition boundary: $\partial\pi = \bigcup_{i=1}^{|\pi|} \partial X_i$.

DEFINITION 8.2 (see [5]). *Let π be a finite analytic partition of D, and let X_i, $1 \le i \le |\pi|$, be any block of π. Then the* interior boundary *∂X_i^{int} of X_i is the set of points $x \in \partial X_i \triangleq \overline{X}_i - \overset{\circ}{X}_i = \overline{X}_i - X_i$ for which there exists a neighborhood N_x meeting only $\overline{X}_i$, and the* exterior boundary *∂X_i^{ext} of X_i is the set complementary to ∂X_i^{int} in ∂X_i; that is, ∂X_i^{ext} is the set of points $x \in \partial X_i$ for which every neighborhood N_x meets $\overline{X}_i^c$.*

For the definition of dynamical consistency, we need the following notion: a state $y \in \partial X_i \cap \partial X_j$ is said to be a *facial (boundary) state of the pair of blocks X_i, X_j* if y lies in the relative interior of the $n-1$ dimensional connected components of the boundaries ∂X_i and ∂X_j. $Facial(\partial X_i \cap \partial X_j)$ shall denote the set of all states that are facial states of the pair X_i, X_j. $NF(\pi)$ shall denote the set of all nonfacial states.

DEFINITION 8.3 (see [5]). *Given a partition π of the set D, $\langle X_i, X_j \rangle \in \pi \times \pi$ is said to be a* dynamically consistent (DC) *pair (with respect to $\mathcal{S}$) if and only if either $i = j$ or, if $i \neq j$, for all x in X_i, there exists $u_x(\cdot) \in \mathcal{U}$, defined upon $[0; T_x]$, $0 < T_x < \infty$, and there exists a facial boundary state $y \in \partial X_i \cap \partial X_j$, such that*

(i) *for all $t \in [0, T_x)$, $\phi(t, x, u_x) \in X_i$, and $\lim_{t \to T_x^-} \phi(t, x, u_x) = y$,*

and, for the state y in (i)*, there exists $u_y \in \mathcal{U}$ defined on $[0, T_y)$, $0 < T_y < \infty$, such that*

(ii) *for all $t \in (0, T_y)$, $\phi(t, y, u_y) \in X_j$,*

where $\phi(\cdot, \cdot, \cdot)$ in (i) *and* (ii) *are the integral curves of the vector field $f(\cdot, \cdot)$ with respect to the controls $u_x, u_y \in \mathcal{U}$ and the initial conditions x, y, respectively.*

DEFINITION 8.4 (see [5]). *Given a partition π of the set D, the* hybrid DC partition machine *$\mathcal{M}^\pi = \langle X^\pi = \{\overline{X}_1, \cdots, \overline{X}_{|\pi|}\}, U = \{\overline{U}_i^j; 1 \le i, j \le |\pi|\}, \Phi^\pi \rangle$, based upon the system $\mathcal{S}$, is the finite state machine defined by $\Phi^\pi(\overline{X}_i, \overline{U}_i^j) = \overline{X}_j$ for all i, j, $1 \le i, j \le |\pi|$, if and only if $\langle X_i, X_j \rangle$ is DC.*

We note that, in the notation introduced in Definition 8.4, if $\langle X_i, X_j \rangle$ is not DC, then the symbol $\overline{U}_i^j$ is not defined.

DEFINITION 8.5 (see [5]). *A hybrid partition machine $\mathcal{M}^\pi$ is called* hybrid in-block controllable *(HIBC) if and only if, for every $X_i \in \pi$ and for all $x, y \in X_i$, the following holds:*

$$\exists u(\cdot) \in \mathcal{U}, \exists T, 0 \le T < \infty, \ (\phi([0; T], x, u) \subset X_i) \wedge (\phi(T, x, u) = y);$$

i.e., each block $X_i \in \pi$ is controllable for the system $\mathcal{S}$.

DEFINITION 8.6. *A hybrid partition machine $\mathcal{M}^\pi$ is called* hybrid between-block controllable *(HBBC) if any block state $\overline{X}_i$ can be reached from any other block state $\overline{X}_j$ by applying a finite number of block transitions.*

We now recall the following result from [5] which characterizes the global controllability of a system $\mathcal{S}$ in terms of the controllability properties of a hierarchical system based upon $\mathcal{S}$. As illustrated in section 8.2, it permits the application of a global controllability analysis to the blocks of a hierarchical system to yield information about the base system and vice versa.

THEOREM 8.7. *An HIBC machine $\mathcal{M}^\pi$ is HBBC if and only if $D^* \triangleq D - \partial\pi$ is controllable for $\mathcal{S}$ with respect to $\tilde{D} \triangleq D - NF(\pi)$, i.e., any two states $x, y \in D^*$ are mutually accessible with respect to $D-$* (nonfacial boundary states).

8.2. Application to a mass-spring system. In this section, we present an illustration of the methodology described in the previous sections for constructing HIBC partitions and the associated partition machines.

Consider N controlled interlinked linear mass-spring systems attached to a moving frame, where the input u determines the velocity of the frame.

Let q_i, $i = 1, \ldots, N$, denote the distance between the ith mass and the frame. Then the Hamiltonian function is given by

$$H(q,p,u) = \frac{1}{2}\sum_{i=1}^{N}\frac{1}{m_i}p_i^2 + \frac{1}{2}\sum_{i=2}^{N}k_i(q_i - q_{i-1})^2 + \frac{1}{2}k_1q_1^2 - \sum_{i=1}^{N}p_iu.$$

The dynamics of the system evolves according to the Hamiltonian system

$$\begin{aligned}\dot{q}_i &= \frac{\partial H}{\partial p_i}(q,p,u) = \frac{1}{m_i}p_i - u,\\ \dot{p}_i &= -\frac{\partial H}{\partial q_i}(q,p,u) + v_i = -k_i(q_i - q_{i-1}) + k_{i+1}(q_{i+1} - q_i) + v_i,\end{aligned} \tag{8.1}$$

where the external forces are interpreted as control variables $v = [v_1 \cdots v_N]^T \in \mathbb{R}^N$ and where we set $q_0 = 0$, $q_{N+1} = 0$, and $k_{N+1} = 0$ to simplify the notation.

We assume that all masses and spring constants of the system are strictly positive. Then the $u^0 = 0, v^0 = 0$ energy slices $ES(H^-, H^+)$ are ellipsoids in the space $\mathbb{R}^{2N}$ (in an appropriate coordinate system $\{\tilde{q}_1, \ldots, \tilde{q}_N, p_1, \ldots, p_n\}$); that is, they have the form

$$\left\{(\tilde{q},p);\ H^- < \frac{1}{2}\sum_{i=1}^{N}\frac{1}{m_i}p_i^2 + \frac{1}{2}\sum_{i=1}^{N}k_i\tilde{q}_i^2 < H^+\right\},$$

where $\{\tilde{q}_1 = q_1, \tilde{q}_i = q_i - q_{i-1}, 2 \le i \le N\}$ is a nonsingular transformation of coordinates.

Let $\{H_1, H_2, \ldots, H_n\}$ be an arbitrary sequence of increasing positive real values. Then π given by the family $\{X_1, X_2, \ldots, X_{n-1}\}$, where X_i is defined to be $ES(H_i, H_{i+1})$, $1 \le i < n$, is a finite analytic partition of the state space $\mathbb{R}^{2N}$.

The fountain property for the system (8.1) can be verified using the technique discussed in section 6.1. The strict positiveness of the masses and spring constants implies that the fountain condition is satisfied for each state $x \in \mathbb{R}^{2N}$. In addition, it can be verified that there exists a unique equilibrium state under the $u^0 = 0$, $v^0 = 0$ control. Consequently, as follows from Theorem 7.2, each block of the partition $\pi \triangleq \{X_1, X_2, \ldots, X_{n-1}\}$ constitutes a controllable set for the linear spring-mass system.

Hence the partition machine $\mathcal{M}^\pi$ based on the energy slice partition π is HIBC. Moreover, by applying the energy slice controllability result of section 7 once more to $E(H)$ defined as the interior of the closure of $\bigcup_{i=1}^{n-1} ES(H_i, H_{i+1})$, i.e., to the interior of the closure of the union of the energy slices, we see that $E(H)$ is controllable.

Further, applying Theorem 8.7, we can conclude that, for the mass-spring system, $\mathcal{M}^\pi$ is HBBC.

Acknowledgments. The authors gratefully acknowledge conversations with Sergej Celikovsky and Robert Hermann concerning parts of this work.

ESCAPE FUNCTION CONDITIONS FOR THE OBSERVATION, CONTROL, AND STABILIZATION OF THE WAVE EQUATION*

LUC MILLER†

Abstract. For the linear wave equation with time-invariant coefficients on a connected compact Riemannian manifold (Ω, g) with C^3 boundary, the geodesics condition of Bardos, Lebeau, and Rauch [*SIAM J. Control Optim.*, 30 (1992), pp. 1024–1065] is characterized in terms of *escape functions*, which are some Lyapunov functions on the phase space $S^*\bar{\Omega}$ (the unit sphere cotangent bundle). Differentiable escape functions yield a sufficient condition which is slightly less sharp but does not refer to geodesics. The escape function condition yields a straightforward geometric proof that the geodesics condition holds in the situations where first order differential multiplier methods apply. Using microlocal control results, it allows us to generalize some control results (that were obtained by multiplier methods) to variable coefficients and lower order terms. It also allows us to prove, in some class of simple situations (e.g., in $\mathbb{R}^2$ with constant coefficients), that no first order differential multiplier method can reach the optimal control time or control regions.

Key words. wave equation, exact controllability, stabilization, multiplier method, geometric optics, escape function

1. Introduction.

This paper is concerned with the widely cited and scarcely used sharp sufficient bicharacteristics condition for the observation, control, and stabilization of the wave equation from the interior or the boundary introduced by Bardos, Lebeau, and Rauch (cf. [2] and the appendix of [21]). Since we shall restrict ourselves to the time-independent coefficients case, this condition can be stated in terms of generalized geodesics (i.e., the rays of geometrical optics) and we shall refer to it as the *geodesics condition*.

While superseding in sharpness and scope earlier results obtained by the "multiplier method" (cf. section 4), the results of [2] are often discarded for reasons already put forward in the introduction of [2]. In the first place, a lot of smoothness is required in [2]. As reviewed in section 1.2, some improvements in this respect have been made thanks to microlocal measures techniques in the last decade. Thus, microlocal techniques apply to the most general geometric situations and have been refined to require less regularity assumptions. The second—more serious—reason is that the explicit computation of the constants appearing in the observation inequalities (which allow us to predict how much energy is needed to control waves of given energy) are out of reach of the closed graph argument in [2] (or the argument by contradiction in the microlocal measures technique). We refer to [23] and [34] for recent significant contributions in this respect using multiplier methods. The third point—to which this article contributes—is that the conditions obtained may not be easy to verify for complicated operators and geometry as acknowledged in [2]. We may add that, even

†Centre de Mathématiques, U.M.R. 7640 du C.N.R.S., Ecole Polytechnique, 91128 Palaiseau Cedex, France and Équipe Modal'X, Bâtiment G, Université de Paris X - Nanterre, 200, Avenue de la République, 92001 Nanterre Cedex, France (miller@math.polytechnique.fr).

in applications in Euclidean geometry (where geodesics are straight lines) of dimension two or three, we are often in the awkward situation in which it is intuitively clear whether the geodesics condition is satisfied but quite intricate to prove rigorously. Other (sufficient) geometric conditions have been obtained independently by first order multiplier methods in the last decade (e.g., [22], [31], [23], [33]). Thus, multiplier methods apply under the most general regularity assumptions and have been refined to cope with more intricate geometric situations.

This paper bridges the geometric gap between the microlocal results and the multiplier results. In section 3, we introduce a new way of formulating the geodesics condition in terms of *escape functions*. For waves evolving on an n-dimensional space, they can be regarded as functions of $2n$ variables which are Lyapunov functions for the phase space dynamics associated with geometrical optics (technically, on the unit sphere cotangent bundle). The definition of differentiable escape functions, which is enough to formulate a sufficient condition, does not even refer to geodesics (cf. the remarks of section 3). In section 4, we consider the geometric conditions that have been obtained by state-of-the-art multiplier methods and obtain them as direct applications of the microlocal results surveyed in section 1.2 by mere examination of well-chosen escape functions (under stronger smoothness assumptions than in [22], [31], [23] but for variable coefficients). This emphasizes that these geometric conditions provide valuable means to verify the geodesics condition and can be obtained without specific P.D.E. analysis. As a by-product, we extend an exact controllability result due to Yao (in [33] by his innovative Riemann multiplier method) to lower order terms and weaker smoothness assumptions (cf. Remark 4 of section 4).

The interest of our paper in terms of applications is twofold. On the one hand, we give some criteria in section 5 which could save us some time by preventing us from trying to apply first order differential multiplier methods to situations which are out of their scope. On the other hand, the escape function condition is a unified geometric framework, which should help experts at the control of P.D.E. problems make new applications of the microlocal results, or detailed comparisons of their results with the microlocal ones. Since it proves so efficient in the linear case (corresponding to first order multipliers; cf. section 4), we intend it as a track to find sufficient geometric conditions (based on explicit classes of nonlinear escape functions and not referring to geodesics) that would be sharper than those obtained by the multiplier methods and easier to verify—albeit less sharp—than the geodesics condition of [2].

In our time-independent coefficients case, it is well known that the tools of symplectic geometry used in [2] can be formulated in the language of Riemannian geometry (e.g., used in [33]). Since it does not appear explicitly in [2], we have included a concise and thorough presentation of this in section 2 for the reader's convenience. In particular, we emphasize the role of the second fundamental form for gliding geodesics (and give an application in a remark). We hope that this paper will contribute to a better understanding of the geometry involved in the control of P.D.E. problems. For some recent contributions in this direction, we refer to [12] and other papers in the same proceedings.

1.1. P.D.E. problems. Let us recall two simple examples of the P.D.E. problems under consideration.

Our first example is a problem of exact controllability from the boundary. Let Ω be a bounded open connected subset of $\mathbb{R}^n$, with C^1 boundary $\partial\Omega$, inside which waves propagate according to the wave equation $\Box u = 0$, where $\Box = \partial_t^2 - \Delta$ is the speed one d'Alembertian. Let $T > 0$ and $\theta \in C_c^0(]0, T[\times \partial\Omega)$ define the boundary region

$\Sigma = \{(t,x) \in \mathbb{R} \times \partial\Omega |\ \theta(t,x) \neq 0\}$, where the Dirichlet boundary condition is controlled. The function θ is said to *control* Ω *exactly* if for all $(u_0,u_1) \in L^2(\Omega) \times H^{-1}(\Omega)$ and all $(w_0,w_1) \in L^2(\Omega) \times H^{-1}(\Omega)$ there is a control function $v \in L^2(\mathbb{R} \times \partial\Omega)$ such that the solution of the mixed Dirichlet–Cauchy problem,

$$\Box u = 0 \quad \text{in }]0,T[\times \Omega, \qquad u = \theta \times v \quad \text{on }]0,T[\times \partial\Omega, \tag{1.1}$$

with Cauchy data $(u, \partial_t u) = (u_0, u_1)$ at $t = 0$, satisfies $(u, \partial_t u) = (w_0, w_1)$ at $t = T$.

Our second example is a problem of exponential internal stabilization. Let (M,g) be a smooth connected compact Riemannian manifold with boundary ∂M and let $\Box_g$ denote the associated d'Alembertian (cf. section 2 for geometric definitions). Let Ω be the complementary set of the support of a nonnegative $a \in C^\infty(\bar{M})$. The function a defines the damping region $\{x \in \bar{M} |\ a(x) > 0\} = \bar{M} \setminus \bar{\Omega}$ (cf. Figure 1.1). It is said to *stabilize* M *exponentially* if for all $(u_0,u_1) \in H_0^1(M) \times L^2(M)$ the energy of the solution to the mixed Dirichlet–Cauchy problem,

$$\Box_g u + 2a\partial_t u = 0 \quad \text{in } \mathbb{R}_+ \times M, \qquad u = 0 \quad \text{on } \mathbb{R}_+ \times \partial M, \tag{1.2}$$

with Cauchy data $(u, \partial_t u) = (u_0, u_1)$ at $t = 0$, decays exponentially, i.e., there exist $\beta > 0$ and $\beta' \geqslant 1$ such that for all $t \geqslant 0$

$$E(t) = \frac{1}{2} \int_M \left\{ |\partial_t u(t,x)|^2 + |\nabla u(t,x)|_x^2 \right\} d_g x \leqslant \beta' e^{-\beta t} E(0). \tag{1.3}$$

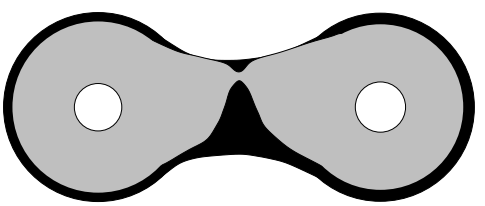

FIG. 1.1. *Ω is light, the damping region $\bar{M} \setminus \bar{\Omega}$ is dark, Γ is the frontier light/dark. The geodesics condition holds.*

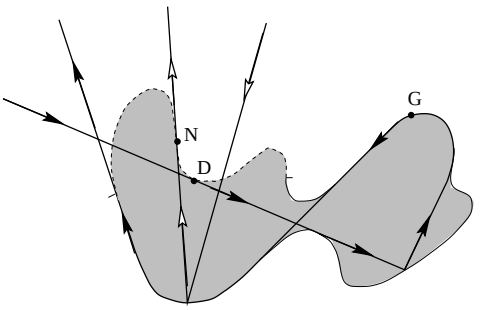

FIG. 1.2. *Two generalized geodesics. Γ is dotted. N: nondiffractive, D: diffractive, G: gliding.*

1.2. Geodesics condition. The common geometric features of these examples are a compact Riemannian manifold (Ω, g) and an open subset Γ of its boundary, if we restrict the first example to a time-independent control region $\Sigma =]0,T[\times \Gamma$, where Γ is an open subset of $\partial\Omega$, and if, in the second example, we denote the part of the boundary of the damping region inside M by $\Gamma = \partial\Omega \cap M$ (cf. Figure 1.1).

In this context, the *generalized geodesics* (cf. Figure 1.2 and Definition 2.1) are continuous trajectories $t \mapsto x(t) \in \bar{\Omega}$ which follow geodesic curves at unit speed in Ω (so that on these intervals $t \mapsto \dot{x}(t)$ is continuous); if they hit $\partial\Omega \setminus \Gamma$ transversely at time t_0, then they reflect as light rays or billiard balls (and $t \mapsto \dot{x}(t)$ is discontinuous at t_0); if they hit Γ transversely at time t_0, then for times $t > t_0$ they have "escaped" from $\bar{\Omega}$; if they hit $\partial\Omega$ tangentially at time t_0, then either there exists a geodesic in Ω which continues $t \mapsto (x(t), \dot{x}(t))$ continuously and they branch onto it, or there is no

such geodesic curve in Ω and—depending on where $\partial\Omega$ was hit—if $x(t_0) \in \Gamma$, then they have "escaped" from $\bar{\Omega}$ at times $t > t_0$; if $x(t_0) \in \Omega \setminus \Gamma$, then they glide at unit speed along the geodesic of $\partial\Omega$, which continues $t \mapsto (x(t), \dot{x}(t))$ continuously until they may branch onto a geodesic in Ω, otherwise they reach $\partial\Gamma$ at a time t_1 and have "escaped" from $\bar{\Omega}$ at times $t > t_1$.

Giving $(x(t_0), \dot{x}(t_0))$ does not always define a unique generalized geodesic (cf. Ex. 24.3.11 in [14] due to M. Taylor). Each of the following assumptions is known to ensure the unique continuation of generalized geodesics (we refer to [4] for (1.6)):

(1.4) g and $\partial\Omega$ are real analytic.

(1.5) g and $\partial\Omega$ are C^∞ and $\partial\Omega$ has no contacts of infinite order with its tangents.

(1.6) g is C^2, $\partial\Omega$ is C^k for some integer $k \geqslant 3$,
and $\partial\Omega$ has no contacts of order $k-1$ with its tangents.

The bicharacteristics condition of Bardos, Lebeau, and Rauch roughly says that every generalized bicharacteristics escapes $\mathbb{R} \times \bar{\Omega}$ through Σ. In our context of time-independent coefficients and region $\Sigma =]0, T[\times \Gamma$, we rephrase the bicharacteristics condition by saying that the time T and the boundary region Γ satisfy the *geodesics condition* if every generalized geodesic starting in $\bar{\Omega}$ has escaped $\bar{\Omega}$ through Γ at time $t = T$; in short, *every generalized geodesic of length T escapes $\bar{\Omega}$ through Γ*. (E.g., in Figure 1.1, this condition is "easily seen" to hold for some T.)

When θ is the characteristic function $\mathbf{1}_\Sigma$ of Σ, it is proved in [2], under (1.4) or (1.5), using microlocal techniques (i.e., the results of [24] and [25] on the propagation of singularities at the boundary and a lifting lemma at nondiffractive points), that the bicharacteristics condition is sufficient and almost necessary for the exact controllability of problem (1.1). Using microlocal measures techniques of Gérard, Tartar, Lions, and Paul (cf. [5] for a survey), Burq obtained the same result in [4] when $\Sigma =]0, T[\times \Gamma$ but $\partial\Omega$ is only C^3 (cf. [11] for propagation results when Ω is convex with $C^{1,1}$ boundary and [6] for results about corners). Moreover, when $\theta \in C_c^0(]0, T[\times \partial\Omega)$, it is proved with the same techniques in [7] under (1.6) that the bicharacteristics condition is both necessary and sufficient for θ to control Ω exactly in problem (1.1), where $\Sigma = \{(t, x) \in \mathbb{R} \times \partial\Omega |\ \theta(t, x) \neq 0\}$. (Note well, if $\mathbf{1}_\Sigma$ controls Ω exactly, then θ does, and if θ does, then so does $\mathbf{1}_{\Sigma'}$ for any open Σ' containing $\bar{\Sigma}$.)

Concerning the stabilization problem in section 1.1 (cf. Figure 1.1), another result of Bardos, Lebeau, and Rauch is that, under (1.4) or (1.5), if there exists a time $T > 0$ such that the geodesics condition holds in Ω with $\Gamma = \partial\Omega \cap M$, then a nonnegative $a \in C^\infty(\bar{M})$ stabilizes M exponentially in problem (1.2) whenever the corresponding damping region $\{x \in \bar{M} |\ a(x) > 0\}$ contains $\bar{M} \setminus \bar{\Omega}$. (Note well, the stabilization of a compact manifold M without boundary corresponds to $\Gamma = \partial\Omega$.) No regularity of $\partial\Omega$ at points of $\bar{\Gamma}$ is required here because there is no boundary condition on Γ. This is the context in which microlocal measures techniques were first applied to control theory, namely by Lebeau in [20], to bound from below the best rate β of exponential decay in (1.3) by some means of a over generalized geodesics.

We refer to [18], [2], [19], [3] for more results allowing observation and stabilization from the boundary, time-dependent coefficients, lower order terms, Neumann and mixed-type boundary conditions, Schrödinger and plate equations, and more. We refer to [27], [26] for results on general boundary conditions and transmission problems and to [8] for general results on systems.

1.3. Escape functions. In this paper, we dwell on pages 1030 and 1031 of [2] which "illustrate the controllability criterion" and end with the following remark: "Our contention is not that we could not do any one of these three [results] with a sufficiently clever differential multiplier. Quite the contrary, the methods of Morawetz, Ralston, and Strauss would surely suffice. However, to create a general result, we would be led inevitably to the same geometric considerations, and avoiding pseudo-differential techniques would only make the task more complicated."

This quote refers to [30], where the decay of solutions of the wave equation outside obstacles with constant coefficients is deduced from some "escape function" which is proved to exist in dimension three under the geodesics condition that the obstacle is "nontrapping." (Melrose later improved on this paper by using the microlocal results of [24] and [25].) Increasingly clever first order differential multipliers had been applied earlier to this problem (radial in [28], gradient of a convex function in [29], "expansive" vector field in [32]) which all correspond to linear escape functions. As Morawetz, Ralston, and Strauss write in [30], "The major point of the present work is that a linear escape function is too special." In the context of resonances for Schrödinger operators with a potential, the same point was made by Helffer and Sjöstrand in [13], where they introduced nonlinear escape functions generalizing the radial case treated earlier by Aguilar and Combes in [1].

Section 5 of this paper makes the same point in the context of the observation, control, and stabilization of waves from the interior or the boundary. In particular, it completes the analysis of [2] by proving that exact controllability cannot be obtained "with a sufficiently clever differential multiplier" of order one in the situation described in Figure 4, p. 1031, of [2]—a disk with some disconnected "minimal" boundary control region which we reproduce in Figure 5.2. This emphasizes the need for new methods to compute explicitly the constants appearing in the observation inequalities in such simple situations.

2. Generalized geodesics. Let (Ω, g) be a connected compact oriented n-dimensional Riemannian manifold with metric g of class C^2 and boundary $\partial\Omega$ of class C^3. Let ν denote the exterior normal vector field and D the Levi–Civita connection of g.

Let $J : X \mapsto \xi$ denote the "flat" isomorphism between the tangent bundle $T\bar{\Omega}$ and cotangent bundle $T^*\bar{\Omega}$ defined by $\xi(Y) = g(X, Y)$, and let a denote the metric on $T^*\bar{\Omega}$ defined by $a(\xi, \eta) = g(X, Y)$, where $\xi = J(X)$ and $\eta = J(Y)$. In local coordinates $(x^1, x^2, \dots, x^n)$, we write a vector field, $X = \sum_i X^i \frac{\partial}{\partial x^i}$, a 1-form, $\xi = \sum_i \xi_i dx^i$, and for each $x \in \bar{\Omega}$ we write the scalar product on the tangent space, $\langle X, Y\rangle_x = \sum_{i,j} g_{i,j}(x) X^i Y^j$, so that $J(X)_j = \sum_i g_{i,j} X^i$ and $J^{-1}(\xi)^j = \sum_i a^{i,j}\xi_i$, where the matrix $A = (a^{i,j})$ is defined by $A^{-1} = (g_{i,j})$. We keep the same notation for the scalar product on the cotangent space $\langle \xi, \eta\rangle_x = {}^t\xi A\eta$ and denote the associated norms by $|\cdot|_x$.

Let $\nabla = J^{-1}d$ denote the gradient operator and Δ_g denote the Laplace–Beltrami operator in (Ω, g). The Sobolev spaces and the energy (1.3) are defined with respect to the measure dx_g. In local coordinates $(x^1, x^2, \dots, x^n)$, $dx_g = \sqrt{\det g}\, dx^1 \cdots dx^n$ and $\Delta_g f = (\sqrt{\det g})^{-1} \sum_{i,j} \partial_{x_j}(a^{i,j}\sqrt{\det g}\,\partial_{x_i} f)$. Let $p \in C^2(T^*(\mathbb{R} \times \bar{\Omega}))$ denote the principal symbol of the d'Alembertian $\Box_g = \partial_t^2 - \Delta_g$. In local coordinates, $p(t, x, \tau, \xi) = \sum_{i,j} a^{i,j}(x)\xi_i\xi_j - \tau^2$ so that p is also the principal symbol of the operator P defined in [2] by $P = \partial_t^2 - \sum_{i,j} a^{i,j}(x)\partial_{x_j}\partial_{x_i} +$ lower order terms.

To link the bicharacteristics of p with the geodesics, it is convenient to consider

the Hamiltonian function $h = p/2$ instead of p. Let H_h denote its Hamiltonian vector field, in local coordinates, $H_h = \partial_{\tau,\xi} h \partial_{t,x} - \partial_{t,x} h \partial_{\tau,\xi}$. The bicharacteristics are integral curves $s \mapsto (t(s), x(s), \tau(s), \xi(s)) = \exp(sH_h)(t(0), x(0), \tau(0), \xi(0))$ of H_h along which $h = 0$. Since p is time-independent, τ is constant along bicharacteristics. By a linear change of parameter, we may restrict ourselves to the bicharacteristics defined on $S = \{(t, x, \tau, \xi) \in h^{-1}(0) | \ -\tau = |\xi|_x = 1\}$. They satisfy $\dot{t}(s) = -\tau(s) = 1$ and $|\dot{x}(s)|_x = |J^{-1}(\xi(s))|_x = |\xi(s)|_x = 1$. Therefore, pushing them through the projections $\pi : T^*(\mathbb{R} \times \bar{\Omega}) \to \bar{\Omega}$ and $\Pi : T^*(\mathbb{R} \times \bar{\Omega}) \to T^*\bar{\Omega}$ (well defined since t is a global coordinate on $\mathbb{R} \times \bar{\Omega}$), we recover the geodesics curves parametrized at unit speed $t \mapsto x(t) = \pi \exp(tH_h)(0, x(0), 0, \xi(0))$ starting from $x(0)$ in the direction $\xi(0)$, which we will sometimes consider as strips $t \to (x(t), J(\dot{x}(t))) = \Pi \exp(tH_h)(0, x(0), 0, \xi(0))$ on the cosphere bundle $S^*\bar{\Omega} = \{(x, \xi) \in T^*\bar{\Omega} | \ |\xi|_x = 1\}$.

Under one of the assumptions (1.4), (1.5), or (1.6), the generalized bicharacteristics introduced in [24] (cf. section 24.3 in [14]) are uniquely defined through each point of $h^{-1}(0)$ (cf. [4] about (1.6)). Let $\mathcal{B}$ denote the second fundamental form, i.e., the symmetric bilinear form $\mathcal{B}_x(X, Y) = -\langle D_X \nu, Y \rangle_x$. Let $\partial\Omega = \phi^{-1}(0)$ be locally defined by a submersion ϕ such that $\Omega = \{\phi(x) > 0\}$. Then $\nabla\phi = -|\nabla\phi|\nu$, $\mathrm{Hess}\phi(X, Y) := D d\phi(X, Y) = -|\nabla\phi| \mathcal{B}_x(X, Y)$, and $H_h^2\phi(x, J(X)) = -|\nabla\phi|_x \mathcal{B}_x(X, X)$. Therefore the *strictly gliding* points of the boundary are the points of $T^*\partial\Omega$ at which the second fundamental quadratic form is positive (cf. Figure 1.2). The Hamiltonian field of h restricted to the symplectic space where $\phi = H_h\phi = 0$ is the gliding vector field $H_h^G = H_h + (H_h^2\phi / H_\phi^2 h) H_\phi$. The gliding bicharacteristics are the trajectories of H_h^G and their image through Π are the geodesic curves of the restriction of g to $\partial\Omega$ parametrized at unit speed.

On a bicharacteristic $t \mapsto (t, x(t), \tau(t), \xi(t))$, the one-sided deleted neighborhoods of the fixed time t_0 are the images of $I \cap \{t > t_0\}$ and the images of $I \cap \{t < t_0\}$ for all neighborhoods I of t_0 in $\mathbb{R}$. Recall that a generalized bicharacteristic pieces together trajectories of H_h in Ω and gliding bicharacteristics in the set $\mathcal{G}_g$ of strictly gliding points: in particular, if at time t it is at $\rho \in T^*\partial\Omega$, then in a one-sided deleted neighborhood of t it coincides with either a bicharacteristic in Ω or a gliding bicharacteristic in $\mathcal{G}_g$. Recall that the *hyperbolic* points of the boundary are the transversal ones (i.e., not in $T^*\partial\Omega$). Recall that $\rho = (x, \xi) \in T^*\bar{\Omega}$ such that $x \in \partial\Omega$ is *nondiffractive* (cf. [2]) if the (nongeneralized) bicharacteristic through ρ at time t is out of $\bar{\Omega}$ at least in one of the one-sided deleted neighborhoods of t (cf. Figure 1.2), i.e., either $\rho \notin T^*\partial\Omega$ is hyperbolic or $\rho \in T^*\partial\Omega$ and the generalized bicharacteristic through ρ at time t is a gliding bicharacteristic in $\mathcal{G}_g$ at least in one of the one-sided deleted neighborhoods of t.

DEFINITION 2.1. *The* generalized geodesic strips *are the images of the generalized bicharacteristics of* $h = (|\xi|_x - \tau^2)/2$ *over* $S = \{-\tau = |\xi|_x = 1\}$ *through the bijection* $\Pi : S \to S^*\bar{\Omega}$. *The* generalized geodesic curves *are the projections of the generalized geodesic strips on* $\bar{\Omega}$.

The generalized geodesic curves are described in section 1.2 for readers not familiar with generalized bicharacteristics. In section 3, it will be convenient to think of generalized geodesics hitting Γ at a nondiffractive point at time $t = t_0$ as having escaped $\bar{\Omega}$ at times $t > t_0$. This interpretation is natural when Ω is an open subset of a larger manifold (M, g): $\partial\Omega \setminus \Gamma$ is a border "obstacle" which confines geodesics inside $\bar{\Omega}$ and Γ is a border "hole" through which the geodesics may "escape" out of $\bar{\Omega}$.

DEFINITION 2.2. *The* geodesics condition $G(T, \Gamma)$ *for the time* $T > 0$ *and the open region* $\Gamma \subset \partial\Omega$ *holds if every generalized geodesic of length greater than* T *passes*

through Γ *at a nondiffractive point (i.e., every generalized geodesic of length greater than* T *escapes* $\bar\Omega$ *through* Γ*).*

As recalled in section 1, $G(T,\Gamma)$ implies, for instance, that all $T'>T$ has the following control property: for all $(u_0,u_1)\in L^2(\Omega)\times H^{-1}(\Omega)$ there exists a control function $v\in L^2(]0,T'[\times\Gamma)$ such that the solution of the mixed Dirichlet–Cauchy problem,

$$\Box_g u=0 \text{ in }]0,T'[\times\Omega,\quad u=v \text{ on }]0,T'[\times\Gamma,\quad u=0 \text{ on }]0,T'[\times\partial\Omega\setminus\Gamma, \tag{2.1}$$

with Cauchy data $(u,\partial_t u)=(u_0,u_1)$ at $t=0$, satisfies $u=\partial_t u=0$ at $t=T'$. Moreover, if T' satisfies this property, then $G(T',\Gamma)$ holds. When $k<\infty$, these results are implicit in [4].

Remark 1. If we also assume Ω to be convex, then the second fundamental form $\mathcal{B}$ is nonnegative on $T^*\partial\Omega$, so that all generalized geodesics starting from $T^*\partial\Omega$ keep gliding on $\partial\Omega$ forever. This answers the question raised in Remark 4.7 of [22]: in a convex open $\Omega\subset\mathbb{R}^n$ satisfying (1.4), (1.5), or (1.6), there is never internal exact controllability for the wave equation with Dirichlet condition on $\partial\Omega$ from a control region G such that $\bar G\subset\Omega$.

3. Escape function condition. In [30], a notion of "escape function" was introduced to characterize the "nontrapping" geodesics condition of Lax and Phillips for exterior problems in $\mathbb{R}^3$ with the Euclidean metric (roughly, $\Gamma=\emptyset$ and there is no specific time, as for stabilization). We adapt the notion of escape function to the geodesics condition of Bardos, Lebeau, and Rauch on a connected compact oriented n-dimensional Riemannian manifold (Ω,g) (with metric g of class C^2 and boundary $\partial\Omega$ of class C^3) by taking T into account.

Definition 3.1. *An* escape function *adapted to* $T>0$ *and* $\Gamma\subset\partial\Omega$ *is a real function* f *defined on* $S^*\bar\Omega$ *such that*

(i) *for all* (x,ξ) *and* (y,η) *in* $S^*\bar\Omega$, $|f(x,\xi)-f(y,\eta)|\leqslant T$;

(ii) f *increases at least as fast as the distance along the closure of any finite interval of geodesic strip in* Ω;

(iii) *for all* $(x,\xi)\in S^*\bar\Omega$ *such that* $x\in\partial\Omega\setminus\Gamma$ *and* $\xi(\nu)>0$, $f(x,\xi')\geqslant f(x,\xi)$ *for* $\xi'=\xi-2\xi(\nu)J^{-1}(\nu)$;

(iv) f *increases at least as fast as the distance along the closure of any finite interval of geodesic strip in* $\partial\Omega\setminus\Gamma$ *on which the second fundamental quadratic form is positive.*

The escape function condition $E(T,\Gamma)$ *holds if there is an escape function adapted to* T *and* Γ.

Note that (i) says that f takes its values in an interval of length less than or equal to T and that (iii) says that f is nondecreasing at reflections on $\partial\Omega\setminus\Gamma$. As such, this definition may appear more intricate than the geodesics condition. If one is only interested in it as a sufficient condition, then it can be simplified by considering only differentiable functions. In the following remarks, the definition of differentiable escape functions is expressed in terms of the values of f and its derivatives and does not refer to geodesics.

Remark 2. When $f\in C^1(T^*\bar\Omega)$, then (ii) says that for all $(x,\xi)\in S^*\Omega$, $H_hf(x,\xi)\geqslant 1$, and (iv) says that for all $(x,\xi)\in S^*\bar\Omega$ such that $x\in\partial\Omega\setminus\Gamma$, $\xi(\nu)=0$, and $\mathcal{B}_x(J^{-1}(\xi),J^{-1}(\xi))>0$, $H_h^Gf(x,\xi)\geqslant 1$. Moreover, (ii) and (iii) imply (iv) by taking a limit as $\xi(\nu)$ tends to 0. Lastly, (iii) is implied by $\nu.\partial_\xi f(x,\xi)\leqslant 0$ for all $x\in\partial\Omega\setminus\Gamma$.

Remark 3. When g is the Euclidean metric, we may consider the unit sphere cotangent bundle as a subspace of $\mathbb{R}^{2n}$, i.e., $S^*\bar{\Omega} = \bar{\Omega} \times \{\xi \in \mathbb{R}^n \mid \sum_{j=1}^n \xi_j^2 = 1\}$. If $f \in C^1(\bar{\Omega} \times \mathbb{R}^n)$, then the four conditions in Definition 3.1 are equivalent to

(i) $f(S^*\bar{\Omega})$ is an interval of length less than or equal to T;

(ii) for all $(x,\xi) \in S^*\bar{\Omega}$, $\xi.\partial_x f(x,\xi) \geqslant 1$;

(iii) for all $(x,\xi) \in S^*\bar{\Omega}$ such that $x \in \partial\Omega \setminus \Gamma$ and $\xi.\nu > 0$, $f(x,\xi') \geqslant f(x,\xi)$ for $\xi' = \xi - 2(\xi.\nu)\nu$.

THEOREM 3.2. *$E(T,\Gamma)$ implies $G(T,\Gamma)$. Under the additional assumption that the generalized geodesics have the uniqueness property (e.g., under one of the assumptions* (1.4), (1.5), *or* (1.6)*), $G(T,\Gamma)$ implies $E(T,\Gamma)$; moreover, f can be chosen continuous outside $\bar{\Gamma}$ and at hyperbolic and strictly gliding points of Γ.*

Proof. We first prove $E(T,\Gamma) \Rightarrow G(T,\Gamma)$. Assume $E(T,\Gamma)$ holds. Let $x : [0,T'] \to \bar{\Omega}$ be a generalized geodesic of length $T' > T$ which does not pass through Γ at a nondiffractive point. From (ii), (iii), and (iv) we deduce that $t \mapsto f(x(t), J(\dot{x}(t)))$ increases at least as fast as t. Hence, $f(x(T'), J(\dot{x}(T'))) - f(x(0), J(\dot{x}(0))) \geqslant T' > T$, which contradicts (i). This proves that such an x does not exist, and therefore $G(T,\Gamma)$ also holds.

We now prove $G(T,\Gamma) \Rightarrow E(T,\Gamma)$. Assume $G(T,\Gamma)$ holds. Let $T' > 0$ and consider a generalized geodesic curve x which does not pass through Γ at a nondiffractive point for $t \in]0,T'[$, such that $x(t) \in \bar{\Gamma}$ for $t \in \{0,T'\}$ and there exists $\epsilon > 0$ satisfying the following properties. If $x(0) \in \Gamma$, then we assume $x(t) \in \Gamma$ for $t \in]-\epsilon,0[$ (in particular, $x(0)$ is nondiffractive) and $x(t) \in \Omega$ for $t \in]0,\epsilon[$. If $x(0) \in \partial\Gamma$, then we assume $x(t) \in \Gamma$ for $t \in]-\epsilon,0[$ and $x(t) \notin \Gamma$ for $t \in]0,\epsilon[$. If $x(T') \in \Gamma$, then we assume $x(t) \in \Gamma$ for $t \in]T',T'+\epsilon[$ (in particular, $x(T')$ is nondiffractive) and $x(t) \in \Omega$ for $t \in]T'-\epsilon,T'[$. If $x(T') \in \partial\Gamma$, then we assume $x(t) \in \Gamma$ for $t \in]T',T'+\epsilon[$ and $x(t) \notin \Gamma$ for $t \in]T'-\epsilon,T'[$.

For each such x, we set $f(x(t), J(\dot{x}(t))) = t$ for $t \in [0,T']$, where the equality is understood as valid for derivatives from both sides at points of reflection except when $t \in \{0,T'\}$. $G(T,\Gamma)$ ensures that $T' < T$ and therefore this f satisfies (i). By definition, this f also satisfies (ii), (iii), and (iv) (with equalities instead of inequalities). The only points of $S^*\bar{\Omega}$ where f has not been yet defined are the points $\rho \in S^*\bar{\Gamma}$ such that the generalized bicharacteristic through ρ at time t is a gliding bicharacteristic in $\mathcal{G}_g$ in both one-sided deleted neighborhoods of t. We set $f = 0$ at those points and recall that strictly gliding points of Γ have this property. The uniqueness property of generalized geodesics ensures that f is well defined.

The continuity of compressed generalized bicharacteristics ensures that f is continuous outside $\bar{\Gamma}$ and at hyperbolic points of Γ. For any point $\rho \in \mathcal{G}_g \cap S^*\Gamma$ and for $\delta > 0$ small enough, there is a neighborhood of ρ in Γ included in the union of $\mathcal{G}_g \cap S^*\Gamma$ and hyperbolic points of Γ which are endpoints of a generalized geodesic x of the preceding type with $T' < \delta$. Therefore f is also continuous at strictly gliding points. □

4. Linear escape functions and the multiplier methods. We discuss the geometrical relationship between the geodesics condition and the situations where first order multiplier techniques apply (cf. the books [21] and [15]). In the framework of escape functions, first order multipliers correspond to escape functions f which are linear with respect to the cotangent variable ξ.

DEFINITION 4.1. *Consider a time $T > 0$ and an open region $\Gamma \subset \partial\Omega$. The* escape vector field condition *$EV(T,\Gamma)$ holds if there is a C^1 section L of $T\bar{\Omega}$ such that*

(i) *for all $x \in \bar{\Omega}$, $|L(x)|_x \leqslant T/2$;*

(ii) *for all* $(x,X)\in S\bar\Omega$, $\langle D_XL,X\rangle_x\geqslant 1$;
(iii) $\{x\in\partial\Omega\,|\,\langle L(x),\nu\rangle_x>0\}\subset\Gamma$.

The escape potential condition $EP(T,\Gamma)$ *holds if there is a function* $\varphi\in C^2(\bar\Omega)$ *such that*

(i) *for all* $x\in\bar\Omega$, $|d\varphi|_x\leqslant T/2$;
(ii) *for all* $(x,X)\in S\bar\Omega$, $\mathrm{Hess}\varphi(X,X):=D d\varphi(X,X)\geqslant 1$;
(iii) $\{x\in\partial\Omega\,|\,\frac{\partial\varphi}{\partial\nu}(x):=d_x\varphi(\nu)>0\}\subset\Gamma$.

When Ω *is a submanifold of* $\mathbb{R}^n$ *with the Euclidean metric, the* radial condition $R(T,\Gamma)$ *holds if there is a point* $x_0\in\mathbb{R}^n$ *such that*

(i) $R(x_0):=\sup\{|x-x_0|\,|\,x\in\bar\Omega\}\leqslant T/2$;
(ii) $\{x\in\partial\Omega\,|\,\langle x-x_0,\nu\rangle>0\}\subset\Gamma$.

Thanks to Theorem 3.2, a straightforward computation is enough to prove that these conditions are sufficient to apply the microlocal results surveyed in section 1.2.

PROPOSITION 4.2. $R(T,\Gamma)\Rightarrow EP(T,\Gamma)\Rightarrow EV(T,\Gamma)\Rightarrow E(T,\Gamma)$.

Proof. To prove $R(T,\Gamma)\Rightarrow EP(T,\Gamma)$, take $\varphi(x)=|x-x_0|^2/2$: $d\varphi(x)=x-x_0$ and $\mathrm{Hess}\varphi$ is the identity matrix. To prove $EP(T,\Gamma)\Rightarrow EV(T,\Gamma)$, take $L(x)=\nabla\varphi$: $\langle L,X\rangle_x=d\varphi(X)$ and $\langle D_XL,X\rangle_x=\mathrm{Hess}\varphi(X,X)$.

Assume $EV(T,\Gamma)$ holds. To prove $E(T,\Gamma)$, take $f(x,\xi)=\xi(L(x))$ and, since this function is C^1, use Remark 2 after Definition 3.1. For all $(x,\xi)\in S^*\bar\Omega$, we have $|f(x,\xi)|\leqslant|\xi|_x|L(x)|_x=|L(x)|_x\leqslant T/2$, so that (i) in $E(T,\Gamma)$ holds. Let $t\mapsto x(t)$ be a geodesic curve, i.e., $D_{\dot x}\dot x=0$. Since D is the Levi–Civita connection of g, $D_X\langle L,X\rangle_x=\langle D_XL,X\rangle_x+\langle L,D_XX\rangle_x$. In particular, $D_{\dot x}f=\langle D_{\dot x}L,\dot x\rangle_x\geqslant 1$, so that (ii) in $E(T,\Gamma)$ holds. By linearity, $f(x,\xi-2\xi(\nu)J^{-1}(\nu))-f(x,\xi)=-2\xi(\nu)f(x,J^{-1}(\nu))=-2\xi(\nu)\langle L(x),\nu\rangle_x<0$ whenever $\xi(\nu)>0$, so that (iii) in $E(T,\Gamma)$ holds. □

The radial multiplier was introduced by Morawetz in [28] for exterior problems and condition $R(T,\Gamma)$ is a variation on her "star-shape" condition. Using this radial multiplier, sufficient conditions for exact controllability from the boundary were obtained by Chen (1979) and Ho (1986) and condition $R(T,\Gamma)$ is their sharper form due to Lions (cf. [21] and [15]). The condition $EP(T,\Gamma)$ is adapted from the convex function condition of Morawetz in [29] for exterior problems with Euclidean metric. There are interesting remarks about global conditions for the existence of potential escape functions in [33]. The condition $EV(T,\Gamma)$ is adapted from the condition of Strauss in [32] for exterior problems with Euclidean metric. The condition of Strauss was used by Chen in [9] for boundary stabilization with Euclidean metric, and later by Lagnese in [16] with less restrictive assumptions and hints for general metrics.

Remark 4. In [33], Yao introduced a "Riemann multiplier method" under the condition $EV(T,\Gamma)$ for smooth $\partial\Omega$ and g. His Theorem 1.1 proves exact controllability under these geometric and regularity assumptions, i.e., for all $(u_0,u_1)\in L^2(\Omega)\times H^{-1}(\Omega)$ there is a control function $v\in L^2(\mathbb{R}\times\Gamma)$ such that the solution of the problem, $\Box_g u=0$ in $]0,T[\times\Omega$, $u=0$ on $]0,T[\times(\partial\Omega\setminus\Gamma)$, $u=v$ on $]0,T[\times\Gamma$, with Cauchy data $(u,\partial_t u)=(u_0,u_1)$ at $t=0$, satisfies $u=\partial_t u=0$ at $t=T$. Under the stronger geometric condition $EP(T,\Gamma)$, the same result has been proved in [17] when $\partial\Omega$ is only C^2 and the operator is $\partial_t^2-\sum_{i,j}a^{i,j}(x)\partial_{x_j}\partial_{x_i}+$ lower order terms, where $a^{i,j}$ are C^1 coefficients and lower order terms have bounded coefficients. On the contrary, it is mentioned on p. 19 of [17] that "in its original form [33], this approach also cannot handle genuine first-order" terms. On the one hand, Theorem 3.2 and Proposition 4.2 prove that Yao's theorem is still true with first order terms, thanks to [2]. On the other hand, Theorem 3.2 and Proposition 4.2 prove that Yao's theorem

is still true when $\partial\Omega$ is of class C^3 and g is of class C^2, thanks to [4]. Moreover, the microlocal measure method of [4] extends to lower order terms (cf. [8]) and should allow us to prove Yao's theorem with lower order terms when $\partial\Omega$ is of class C^3 and g is of class C^2.

Remark 5. If L_2 is a vector field satisfying $\langle D_X L_2, X\rangle_x = 0$ for all $(x,X) \in S\bar{\Omega}$, then adding L_2 to an escape vector field L_1 modifies the boundary condition (iii) without modifying the interior condition (ii). Hence the escape vector field $L = L_1 + L_2$ yields control regions which could not be obtained with L_1. The "multipliers with rotated direction" introduced by Osses (e.g., $L(x) = M(\theta)(x - x_0)$ where $M(\theta)$ is the rotation of angle θ) build on this remark: in [31], Ω is a submanifold of $\mathbb{R}^n$ with the Euclidean metric, $L_1(x) = x - x_0$, and $L_2(x) = A(x - x_0)$, where A is a skew-symmetric matrix.

Remark 6. In [22], Liu introduced a "piecewise multiplier method" for internal exact controllability in a bounded connected open $M \subset \mathbb{R}^n$ with Euclidean metric, with Dirichlet condition on ∂M, from a control region $G \subset M$ under the following geometric condition: there exist open sets $\Omega_j \subset M$ and points $x_j \in \mathbb{R}^n$ (for $j = 1, \dots, J$) such that $\Omega_i \cap \Omega_j = \emptyset$ for $i \neq j$ and $G \supset M \cap \mathcal{N}_\epsilon[(\cup_j \Gamma_j) \cup (M \setminus \cup_j \Omega_j)]$ for some $\epsilon > 0$, where $\mathcal{N}_\epsilon[S]$ denotes an ϵ neighborhood of the set S and $\Gamma_j = \{x \in \partial\Omega_j \mid \langle x - x_j, \nu_j\rangle > 0\}$, where ν_j is the unit exterior normal to $\partial\Omega_j$. Remark 4.7 of [22] calls for a geometric argument proving that this condition implies the geodesics condition when ∂M is sufficiently smooth. Let Ω denote a connected component of $\bar{M}\setminus G$ and $\Gamma = \partial\Omega \cap \partial G \subset \partial G \cap M$. It is included in one of the Ω_j only and we fix this j henceforth. $(T_j, \partial\Omega_j \cap G)$ satisfies the radial condition in Ω_j with $T_j = 2R(x_j)$ since $\Gamma_j \subset G$, hence it also satisfies the geodesics condition. Every generalized geodesic of length T_j starting in $\bar{\Omega}$ and reflecting on $\partial\Omega \setminus \partial G \subset \partial\Omega_j \setminus (\partial\Omega_j \cap G) \subset \partial M$ reaches $\partial\Omega_j \cap G$ and a fortiori escapes $\bar{\Omega}$ through Γ. Therefore every generalized geodesics in $\bar{M}$ of length greater than $\max_j T_j$ reaches G, which proves that the condition of Liu implies the geodesics condition. (No regularity of $\partial\Omega_j$ outside ∂M is needed since it carries no boundary condition.) In the framework of escape functions, the corresponding idea is to consider $f(x,\xi) = (x - \sum_j \mathbf{1}_{\Omega_j}(x) x_j).\xi$ on $S^*(\bar{M} \setminus G)$. Note that the lower bound $\max_j 2R(x_j)$ on the control time could be improved by the microlocal results, e.g., if Ω_1 is star-shaped with respect to x_1, then we can replace $2R(x_1)$ by the length $\mathrm{diam}(\bar{\Omega}_1)$ of the longest segment in $\bar{\Omega}_1$. ($\mathrm{diam}(\bar{\Omega}_1) \leqslant 2R(x_1)$ always holds, and the equality does not hold for any x_1 in Figure 5.1, for example.)

Remark 7. In [23], Martinez introduced the "almost star-shaped" condition for boundary stabilization when g is the Euclidean metric: there exists $\phi \in C^2(\bar{\Omega})$ and $c > 0$ such that $\Delta\phi = 1$ in Ω; $\lambda_1(x) \geqslant c$ in Ω; $\frac{\partial\phi}{\partial\nu}(x) \geqslant 0$ on $\partial\Omega \setminus \Gamma$; $\frac{\partial\phi}{\partial\nu}(x) \leqslant 0$ on Γ, where $\lambda_1(x)$ is the smallest eigenvalue of the matrix $\mathrm{Hess}\phi$ of second order partial derivatives of ϕ. Taking $\varphi = \phi/c$, the second and third requirements are equivalent to the requirements (ii) and (iii) in condition $EP(T,\Gamma)$. This emphasizes that the first requirement $\Delta\phi = 1$ is only useful for explicit computation of the stabilization rate.

5. Linear escape functions are too special. We describe situations where linear escape functions (and therefore all the multiplier methods discussed in section 4) are too special to reach the optimal control time (cf. Proposition 5.1 and Figure 5.1) or the optimal control region (cf. Proposition 5.2 and Figure 5.2). This contrasts with the context of exterior problems where the geodesics condition implies the existence of a linear escape function in dimension $n = 2$ (cf. section 4 of [30]).

Let $\mathrm{diam}_g(\bar{\Omega})$ denote the supremum of the lengths of the geodesics in Ω. A diameter of $\bar{\Omega}$ is a geodesic in Ω whose closure is of length $\mathrm{diam}_g(\bar{\Omega})$. (If $\mathrm{diam}_g(\bar{\Omega})$ is

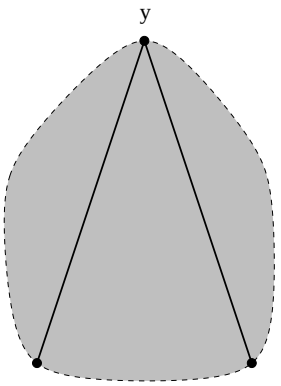

FIG. 5.1. *Segments are diameters of length T. By Proposition* 5.1, *$G(T,\partial\Omega)$ holds but $EV(T,\partial\Omega)$ does not. Here g is Euclidean.*

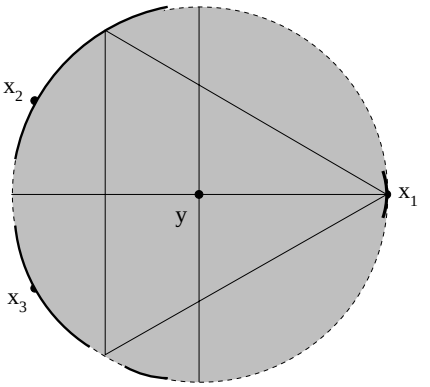

FIG. 5.2. *Segments explain why $G(T,\Gamma)$ holds for some T. $EV(T,\Gamma)$ does not hold for any T by Proposition* 5.2, *with $J=3$ and g Euclidean.*

finite, then there are no closed geodesics and there is at least one diameter of $\bar{\Omega}$ since it is compact.)

PROPOSITION 5.1. *If there exist $y\in\bar{\Omega}$ and two distinct geodesics in Ω of length $T>0$ issued from y, then $EV(T,\partial\Omega)$ does not hold. In particular, if $T=\operatorname{diam}_g(\bar{\Omega})$ and there are two diameters of $\bar{\Omega}$ issued from the same point $y\in\bar{\Omega}$, then $E(T,\partial\Omega)$ holds but $EV(T,\partial\Omega)$ does not.*

Proof. Assume L satisfies $EV(T,\partial\Omega)$. Denote by $[0,T]\ni t\mapsto x(t)$ the geodesic from $x(0)=z$ to $x(T)=y$. By (ii), $\langle L(y),\dot{x}(T)\rangle_y-\langle L(z),\dot{x}(0)\rangle_z\geqslant T$, and by (i), we know that $\langle L(y),\dot{x}(T)\rangle_y\leqslant|L(y)|_y\leqslant T/2$ and $-\langle L(z),\dot{x}(0)\rangle_z\leqslant|L(z)|_z\leqslant T/2$, so that $\langle L(y),\dot{x}(T)\rangle_y=|L(y)|_y=T/2=|L(z)|_z=-\langle L(z),\dot{x}(T)\rangle_z$ and therefore $L(y)=\dot{x}(T)$. The same argument with the other geodesic proves both geodesics have the direction $L(y)$ at y which contradicts that they are distinct. □

PROPOSITION 5.2. *If there are J geodesics in Ω which are issued from points $x_j\in\partial\Omega\setminus\Gamma$ $(j=1,\dots,J)$ with directions normal to the boundary and cross at $y\in\Omega$ with directions ξ_j such that the complementary set in $T_y\Omega$ of their polar cone $C=\{Y\in T_y\Omega\,|\,\forall j,\xi_j(Y)\leqslant 0\}$ is empty, then $EV(T,\Gamma)$ does not hold for any $T>0$.*

Proof. Assume L satisfies $EV(T,\Gamma)$. Denote by $[0,T]\ni t\to x(t)$ the geodesic from $x(0)=x_j$ to $x(T)=y$. Since $\dot{x}(0)=-\nu(x_j)$, (iii) implies $\langle L(x_j),\dot{x}(0)\rangle_{x_j}\geqslant 0$. But by (ii), we know that $\langle L(y),\dot{x}(T)\rangle_y>\langle L(x_j),\dot{x}(0)\rangle_{x_j}$, so that $\langle L(y),\xi_j\rangle_y>0$ since $\dot{x}(T)=\xi_j$. Repeating the argument with all j proves $L(y)\notin C$, which is a contradiction. □

Note that the proofs of these propositions also apply to escape functions of the escape vector field form $f(x,\xi)=\xi(L(x))$ without assuming any regularity on the section L of $T\bar{\Omega}$. Also note that Figure 5.1 is a counterexample to the conjecture (cf. Remark 3.2 in [17]) that the control time in the escape potential condition is optimal.

Remark 8. In the introduction to chapter four of their book *Controllability of Evolution Equations* [10], Fursikov and Imanuvilov mention "a very interesting (and still open to the author's knowledge) question: Does the fulfillment of non-trapping condition imply the existence of pseudoconvex function?". Proposition 5.2 and Figure 5.2 answer this question negatively once it is translated in our terms. On the one hand, the *nontrapping condition* for the control region Γ means that the geodesics

condition $G(T,\Gamma)$ holds for some time $T>0$, or equivalently (cf. Theorem 3.2) that $E(T,\Gamma)$ holds for some time $T>0$. On the other hand, the *existence of a pseudoconvex function* adapted to Γ means that the escape potential condition $EP(T,\Gamma)$ holds for some time $T>0$, and implies (cf. Proposition 4.2) that $EV(T,\Gamma)$ holds for some time $T>0$. Therefore, the situation described in Figure 5.2 (a disk with some disconnected boundary control region as in Figure 4, p. 1031, of [2]) satisfies the nontrapping condition but precludes any pseudoconvex function.

Acknowledgments. I am thankful to N. Burq, G. Lebeau, and C. Margerin for stimulating discussions. N. Burq triggered this investigation by mentioning the function $f(x,\xi)=\xi.(x-x_0)$ as I was asking him whether he knew of a straightforward proof that the radial multiplier condition as found in [21] implies the bicharacteristics condition of [2]. References [23] and [34] were pointed out to me by one of the referees.

POSITIVE DEFINITENESS OF FORMS: NUMERICAL IDENTIFICATION*

ARAM V. ARUTYUNOV† AND ALEXEY F. IZMAILOV‡

Abstract. The question about positive definiteness or semidefiniteness of quadratic forms (or, more generally, polynomial homogeneous forms of an even degree) arises in numerous fields of mathematics and its applications. This is certainly the case for optimization theory, including calculus of variations and optimal control. Effective methods intended to obtain a reliable answer to this question for a given form are of doubtless theoretical and practical interest. For that purpose, we propose to use the traditional unconstrained optimization technique, namely, the steepest descent and the conjugate gradient methods. The effectiveness of this approach is justified by theoretical analysis and computational experiments.

Key words. quadratic form, polynomial homogeneous form, positive definiteness, positive semidefiniteness, steepest descent, conjugate gradients, optimal control, calculus of variations, finite-dimensional approximation

1. Introduction.

The need to verify positive definiteness or semidefiniteness of (real) polynomial homogeneous forms arises in numerous fields of mathematics and its applications. In particular, this is certainly the case for optimization theory, including calculus of variations and optimal control. For instance, second-order optimality conditions are normally stated in terms of positive semidefiniteness or definiteness of particular quadratic forms. Moreover, sometimes one has to deal with forms of an even degree higher than 2. As will be shown below, for the quadratic form arising from calculus of variations on an infinite time interval, the analysis can be reduced to the corresponding considerations for the particular finite-dimensional form of degree 4. Efficient methods intended to obtain a reliable answer to the question about the "sign" for a given form are of doubtless theoretical and practical interest. Unfortunately, in most cases it is not possible to find the answer by analytical considerations only, and numerical methods have to be involved.

Procedures for verification of second-order optimality conditions can be used as (part of) a stopping test in numerical optimization, but this seems too costly. Probably, main applications of such procedures arise in the context of "postoptimal analysis": they can help when one needs to check whether the candidate for a solution (found by analytic or numerical methods) is an actual solution.

Note that in the optimal control theory, it is often needed to test the definiteness of a certain quadratic form on a subspace rather than on the entire space. However, this problem can be reduced to the case of the entire space using, e.g., Finsler's theorem [3], or by "reducing" the Hessian. In [8, 9, 17], the definiteness of the reduced Hessian for

discretized optimal control problems is analyzed by means of numerical approximation of the eigenvalues.

First let us give a few words about basic assumptions and notation. All matrices in this paper are supposed to have real entries. Let $\mathcal{M}(n, m)$ stand for the set of all $n \times m$ matrices, let $\mathcal{S}(n)$ stand for the set of symmetric $n \times n$ matrices, and let $\mathcal{A}(n)$ stand for the set of antisymmetric $n \times n$ matrices. A real homogeneous form defined on a linear space is referred to as positively semidefinite if it is nonnegative everywhere on this space, and positively definite if it is positive everywhere on this space except the zero point. Recall that finite-dimensional quadratic forms are generated by symmetric matrices, and it is commonly accepted to use the term "positive definiteness" or "semidefiniteness" with respect to such matrices rather than only with respect to forms. In what follows, we use the same symbol for the (polynomial homogeneous) form of degree l and the corresponding symmetric l-linear form.

In what follows (excluding the last section), we basically consider two main objects. The first one is an abstract continuous quadratic form $q : U \to \mathbf{R}$ defined on a Hilbert space U. Let $Q : U \to U$ stand for the (uniquely defined) continuous self-adjoint linear operator such that

$$q(u) = \langle Qu, u\rangle, \quad u \in U. \tag{1.1}$$

We assume that q is at least weakly lower semicontinuous. In particular, special attention will be paid to the case of finite-dimensional U.

Another object is the quadratic form arising from optimal control, and it is much more specific:

$$q(u) = \int_0^1 (\langle A(t)u(t), u(t)\rangle + 2\langle C(t)u(t), x(t)\rangle + \langle B(t)x(t), x(t)\rangle)\, dt, \quad u \in U, \tag{1.2}$$

with $U = L_{2,\,r}[0, 1]$. Here $x(\cdot) \in W^1_{2,\,m}[0, 1]$ is defined by the initial value problem

$$\dot{x} = G(t)x + \Gamma(t)u(t), \quad x(0) = 0. \tag{1.3}$$

The matrix functions $A : [0, 1] \to \mathcal{S}(r)$, $B : [0, 1] \to \mathcal{S}(m)$, $C : [0, 1] \to \mathcal{M}(m, r)$, $G : [0, 1] \to \mathcal{M}(m, m)$, and $\Gamma : [0, 1] \to \mathcal{M}(m, r)$ are supposed to be piecewise continuous. It is well known that this quadratic form is weakly lower semicontinuous on U if and only if the so-called *Legendre condition* is satisfied, i.e., the matrix $A(t)$ is positively semidefinite for almost all $t \in [0, 1]$. The Legendre condition is also necessary (but certainly not sufficient) for q to have a finite index and, in particular, to be positively semidefinite (for the detailed discussion of these questions, see [13, 15]).

For the quadratic form q on the finite-dimensional U, several traditional algebraic approaches to the problem under consideration are well known, such as the Sylvester criterion, numerical methods for computing or approximating the eigenvalues of Q, etc. However, these approaches are too costly, especially when the dimension n is large. Note that the methods for computing the eigenvalues are iterative by nature [21], while the methods we discuss below are finite.

Apparently, the most effective known finite method appropriate for our purpose is the Cholesky (square root) algorithm. For the case of positively definite q, application of this algorithm to Q results in its LL^{T} decomposition, and this requires approximately $n^3/6$ multiplication and the same number of additions [21]. (Here L is a lower triangular matrix with positive diagonal entries.) If q is not positively definite, then

the algorithm will be terminated at some stage because of the necessity to compute the square root from a negative number or to divide by zero.

However, all approaches mentioned above are completely finite-dimensional and, in particular, cannot be applied directly to the quadratic form q given by (1.2), (1.3). Moreover, these approaches assume that the matrix Q is given explicitly, while determination of this matrix can be a rather complicated problem. In particular, this is normally the case for finite-dimensional approximations of q given by (1.2), (1.3) (see section 4). Finally, all these approaches are applicable to quadratic forms only and cannot be applied to forms of an even degree higher than 2.

The alternative approach (free from the disadvantages mentioned above) can be based on optimization methods for the following problem:

$$\begin{array}{ll} \text{minimize} & q(u) \\ \text{subject to} & u \in D, \end{array} \tag{1.4}$$

where $D \subset U$ is a closed convex set such that $0 \in \operatorname{int} D$ or is the boundary of such a set. For instance, one can take the unite ball or the unite sphere in U as D. With this choice, each local solution to problem (1.4) is actually global. Hence, every method which is (globally) convergent to a (local) minimizer will yield the needed result. Note, however, that for forms of degree 4, this is already not the case: such a form can have local minimizers on the unite sphere with positive values of q and, at the same time, can be even not positively semidefinite; see section 5.

This observation is one of the reasons why we propose in this paper to take $D = U$, i.e., to consider the unconstrained optimization problem, q being the objective function. Note that if q is not positively semidefinite, then problem (1.4) with $D = U$ has no (even local) solutions. Nevertheless, as we are going to show, application of the standard unconstrained optimization technique can help to distinguish between cases when q is positively definite, positively semidefinite, or not positively semidefinite, and can do so quite effectively.

Specifically, we consider the steepest descent and the conjugate gradient methods (see, e.g., [18, 20, 12, 5, 7]), though there is a wide range of different unconstrained optimization algorithms applicable in this context. Note that both methods use gradients of q at particular points only, and computation of Q is not necessary for that purpose. Moreover, both methods are correctly defined in the infinite-dimensional setting, at least formally, and both are applicable not only to quadratic forms. Both methods will be described in the next section in the framework of the basic algorithm.

2. The basic algorithm. We introduce our *basic algorithm* for an abstract quadratic form $q : U \to \mathbf{R}$, U being a Hilbert space. The initial *step* 0 of the algorithm consists of fixing two index sets K_1 and K_2 such that $K_1 \cup K_2 = \{0, 1, \ldots\}$, $0 \in K_1$, with an arbitrary initial point $u^0 \in U \setminus \{0\}$.

After k steps of the algorithm, the following elements are supposed to be computed: $u^0, u^1, \ldots, u^k \in U$ and $g^0, g^1, \ldots, g^{k-1} \in U$, and if $k \geq 1$, then

$$q(u^i) > 0, \quad q(g^i) > 0 \quad \forall\, i = 0, 1, \ldots, k-1, \tag{2.1}$$

and

$$\langle q'(u^k), g^{k-1} \rangle = 0. \tag{2.2}$$

Step $k+1$. Compute $q(u^k)$. If $q(u^k) < 0$, then stop. Let $q(u^k) \geq 0$, then compute $q'(u^k) = 2Qu^k$. If $q'(u^k) = 0$, then stop. Let $q'(u^k) \neq 0$. If $q(u^k) = 0$, then stop. Let

$q(u^k) > 0$, then compute

$$g^k = -q'(u^k) + \beta_{k-1} g^{k-1}, \tag{2.3}$$

where

$$\beta_{k-1} = \begin{cases} 0 & \text{if } k \in K_1, \\ \frac{\langle q'(g^{k-1}), q'(u^k)\rangle}{2q(g^{k-1})} & \text{if } k \in K_2. \end{cases} \tag{2.4}$$

(It is known that $\beta_{k-1} > 0$ for $k \in K_2$; see (5.4) below.) Compute $q(g^k)$. If $q(g^k) \le 0$, then stop. Let $q(g^k) > 0$, then take

$$u^{k+1} = u^k + \alpha_k g^k,$$

with $\alpha_k \ge 0$ being defined by the condition

$$q(u^k + \alpha_k g^k) = \min_{\alpha \ge 0} q(u^k + \alpha g^k),$$

and proceed to the next step.

Note that α_k can be given by the explicit formula

$$\alpha_k = -\frac{\langle q'(u^k),\, g^k\rangle}{2q(g^k)} > 0,$$

where the inequality follows from (2.2) and (2.3), as $\langle q'(u^k),\, g^k\rangle = \langle q'(u^k),\, -q'(u^k) + \beta_{k-1} g^{k-1}\rangle = -\|q'(u^k)\|^2$.

Obviously, if $K_2 = \emptyset$, then the underlying iteration of the algorithm described above is the pure steepest descent iteration. We refer to this variant as the *SD-algorithm*. In the opposite case $K_1 = \{0\}$, the algorithm is based on the pure conjugate gradient method. This variant will be referred to as the *CG-algorithm*.

Suppose that the algorithm was stopped at step $k+1$. The following cases are possible. If $q(u^k) < 0$, then q is not positively semidefinite. Let $q(u^k) \ge 0$. If $q'(u^k) = 0$, then with $u^k = 0$ we claim q to be positively definite, and with $u^k \ne 0$ we claim it to be positively semidefinite but not definite. Let $q'(u^k) \ne 0$. If $q(u^k) = 0$, then q is not positively semidefinite. Indeed, in this case $q(u^k + \alpha g^k) = q(g^k)\alpha^2 - \|q'(u^k)\|^2 \alpha < 0$ for each $\alpha > 0$ sufficiently small. Let $q(u^k) > 0$. If $q(g^k) \le 0$, then again q is not positively semidefinite. Indeed, if $q(g^k) = 0$, then $q(u^k + \alpha g^k) = -\|q'(u^k)\|^2 \alpha + q(x^k) < 0$ for each $\alpha > 0$ sufficiently large.

To apply the algorithm to quadratic form q given by (1.2), (1.3), one needs a formula for the gradient of q. This formula is well known [18, 20]; we provide it here for the sake of completeness:

$$q'(u) = 2(A(\cdot)u(\cdot) + (C(\cdot))^{\mathrm{T}} x(\cdot)) - (\Gamma(\cdot))^{\mathrm{T}} \psi(\cdot), \quad u \in U,$$

where $\psi(\cdot) \in W^1_{2,m}[0, 1]$ is defined by the initial value problem

$$\dot\psi = -(G(t))^{\mathrm{T}} \psi + 2(C(t)u(t) + B(t)x(t)), \quad \psi(1) = 0. \tag{2.5}$$

Of course, implementation of the algorithm in this case will require solving the (linear) initial value problems (1.3) and (2.5) and evaluating the integrals (in particular, in (1.2)) on each step. This can hardly be done precisely, except in the most simple cases; hence, some approximation technique will have to be involved.

We proceed with justification of the algorithm. In the rest of this section, we deal mainly with the SD-algorithm, even though some results for the basic algorithm will also be provided. In the next section, the CG-algorithm will be justified in the finite-dimensional setting, and computational results will be reported. Section 4 is devoted to the application of the algorithms to quadratic form defined by (1.2), (1.3) via the direct finite-dimensional approximation. Finally, in section 5, we present the application of the basic algorithm to forms of degree 4.

The following lemma will play a central role in justification of the algorithm.

LEMMA 2.1. *Let $q : U \to \mathbf{R}$ be a continuous quadratic form, and let $Q : U \to U$ be the continuous self-adjoint linear operator associated with q according to* (1.1). *Assume that q is weakly lower semicontinuous and is not positively semidefinite. Then*

(i) *Q has an eigenvalue $\lambda < 0$ with the associated eigenelement $v \in U$;*

(ii) *if the basic algorithm was not stopped on the first k steps, then there exist numbers $\mu_i > 0$ such that*

$$\langle u^i, v\rangle = \left(1 + \sum_{j=1}^{i} \mu_j\right) \langle u^0, v\rangle \quad \forall\, i = 1, \ldots, k.$$

Proof. Consider the optimization problem

$$\begin{array}{ll} \text{minimize} & q(u) \\ \text{subject to} & \|u\|^2 \le 1. \end{array}$$

By weak semicontinuity of q, this problem has a solution v. Obviously, $\|v\| = 1$, and from the Lagrange principle it easily follows that v is an eigenelement of Q associated with some eigenvalue λ. Moreover,

$$0 > q(v) = \langle Qv, v\rangle = \lambda \|v\|^2 = \lambda.$$

This completes the proof of (i).

Assertion (ii) can be proved by induction. For $k = 1$,

$$\langle u^1, \xi\rangle = \langle u^0 - 2\alpha_0 Q u^0, v\rangle = \langle u^0, v\rangle - 2\alpha_0 \lambda \langle u^0, v\rangle = (1 + \mu_1)\langle u^0, v\rangle$$

with $\mu_1 = -2\alpha_0\lambda > 0$.

Suppose that (ii) holds true $\forall\, k \in \{1, \ldots, s\}$ with some s, and let $k = s+1$. Then there exist numbers $\mu_i > 0$ such that

$$\langle u^i, v\rangle = \left(1 + \sum_{j=1}^{i} \mu_j\right) \langle u^0, v\rangle \quad \forall\, i = 1, \ldots, s.$$

Hence

$$\begin{aligned} \langle u^{s+1}, v\rangle &= \langle u^s + \alpha_s g^s, v\rangle \\ &= \left\langle u^s + \alpha_s \left(-2Qu^s + \frac{\beta_{s-1}}{\alpha_{s-1}}(u^s - u^{s-1})\right), v \right\rangle \\ &= \langle u^s, v\rangle - 2\alpha_s\lambda\langle u^s, v\rangle + \frac{\alpha_s}{\alpha_{s-1}}\beta_{s-1}(\langle u^s, v\rangle - \langle u^{s-1}, v\rangle) \\ &= (1 - 2\alpha_s\lambda)\left(1 + \sum_{i=1}^{s} \mu_i\right)\langle u^0, v\rangle + \frac{\alpha_s}{\alpha_{s-1}}\beta_{s-1}\mu_s\langle u^0, v\rangle \\ &= \left(1 + \sum_{i=1}^{s+1} \mu_i\right)\langle u^0, v\rangle, \end{aligned}$$

where

$$\mu_{s+1} = -2\alpha_s\lambda\left(1 + \sum_{i=1}^{s}\mu_i\right) + \frac{\alpha_s}{\alpha_{s-1}}\beta_{s-1}\mu_s > 0.$$

This completes the proof of (ii). □

The following theorem shows that if q is not positively semidefinite, this fact will be identified by the SD-algorithm after a finite number of steps for any choice of the initial point u^0, except the points from a proper closed linear subspace in U.

THEOREM 2.2. *Let $q : U \to \mathbf{R}$ be a continuous quadratic form, and let $Q : U \to U$ be the continuous self-adjoint linear operator associated with q according to* (1.1). *Then*

(i) *for every $u^0 \in U$, either the SD-algorithm will be stopped on some step or $\{q'(u^k)\} = \{2Qu^k\} \to 0$ as $k \to \infty$;*

(ii) *if q is weakly lower semicontinuous and is not positively semidefinite, then the set of initial points $u^0 \in U$—such that either the basic algorithm will be stopped at some point in $\ker Q$ or $\{Qu^k\} \to 0$ as $k \to \infty$—is contained in a proper closed linear subspace in U. Specifically, this subspace is the orthogonal complement to the subspace spanned by the eigenelements of Q associated with the negative eigenvalues.*

Proof. Let us prove (i). Suppose that the algorithm generates the infinite sequence $\{u^k\}$. Then

$$q(u^k) - q(u^{k+1}) \geq \|Q\|^{-1}\|Qu^k\|^2 \quad \forall\, k = 0, 1, \ldots. \tag{2.6}$$

This estimate for the steepest descent trajectories is well known. (One should take into account that $q'(\cdot)$ is Lipschitz-continuous on U with the constant $2\|Q\|$.) On the other hand, this estimate can be easily derived by direct evaluation.

The sequence $\{q(u^k)\}$ is bounded from below, because in the opposite case there would exist some k such that $q(u^k) < 0$, and the algorithm would be stopped. Hence, taking into account the monotonicity of this sequence, it converges, and from (2.6) it follows that $\{Qu^k\} \to 0$ as $k \to \infty$.

To prove (ii), suppose again that the algorithm generates the infinite sequence $\{u^k\}$. Fix an arbitrary eigenelement $v \in U$ of Q associated with a negative eigenvalue λ (which exists, according to assertion (i) of Lemma 2.1). According to assertion (ii) of Lemma 2.1, there exist numbers $\nu_k \geq 0$ such that

$$\langle Qu^k, v\rangle = \lambda\langle u^k, v\rangle = \lambda(1 + \nu_k)\langle u^0, v\rangle \quad \forall\, k = 0, 1, \ldots.$$

Hence, $\{Qu^k\} \to 0$ as $k \to \infty$ takes place if and only if $\langle u^0, v\rangle = 0$. This is certainly also true for the case when $Qx^k = 0$ for some k. This completes the proof. □

When q is positively definite or semidefinite, the behavior of the steepest descent is well known (see, e.g., [18, 20, 12, 5, 7]). First, let U be finite-dimensional. If q is positively definite, then $\forall\, u^0 \in U$ the SD-algorithm will either be stopped on some step at the zero point 0 or will generate the sequence $\{u^k\}$ such that $\{u^k\} \to 0$ as $k \to \infty$, and the rate of convergence is geometric. If q is positively semidefinite but not definite, then $\forall\, u^0 \in U$ the SD-algorithm will either be stopped on some step at the point $\bar{u} = \bar{u}(u^0)$, which is a unique intersection point of $\ker Q$ and $u^0 + (\ker Q)^\perp$, or generate the sequence $\{u^k\}$ converging geometrically to $\bar{u}$. Here we take into account the following observation: $q'(u) = 2Qu \in (\ker Q)^\perp\ \forall\, u \in U$; hence, all the points generated by the SD-algorithm (and the CG-algorithm as well) belong to $u^0 + (\ker Q)^\perp$. Note that $\bar{u}(u^0) = 0$ if and only if $u^0 \in (\ker Q)^\perp$; hence, the set of

"bad" initial points u^0 (such that the SD-algorithm will incorrectly identify the form q as positively definite) is a proper subspace in U.

Hence, in the finite-dimensional setting, the SD-algorithm can be used for our purposes as soon as it is equipped with an additional procedure intended to analyze convergence properties of the sequence being generated. The main problem here is that the number of steps needed to identify the absence of positive semidefiniteness can be arbitrary large, even though it is always finite. This problem will be resolved in the next section in the context of the CG-algorithm.

In the case of infinite-dimensional U, the situation is somewhat more involved, of course. Namely, for our justification above to hold true, one should additionally assume the following property: if q is positively semidefinite, then it is strongly positive on $(\ker Q)^\perp$, i.e., there exists $\gamma > 0$ such that

$$q(u) \geq \gamma \|u\|^2 \quad \forall\, u \in (\ker Q)^\perp.$$

Without this condition, the behavior of the algorithm in the positively semidefinite case can be quite unpredictable.

3. Conjugate gradient method for the finite-dimensional case. In this section, let $U = \mathbf{R}^n$. Let $q : \mathbf{R}^n \to \mathbf{R}$ be an abstract quadratic form, and let $Q \in \mathcal{S}(n)$ be the matrix associated with q. The following simple lemma will be needed.

LEMMA 3.1. *Let $q : \mathbf{R}^n \to \mathbf{R}$ be a quadratic form. If q is nonnegative everywhere on a linear manifold (plane) $V \subset \mathbf{R}^n$, then it is positively semidefinite on* $\operatorname{span} V$.

Proof. For an arbitrary integer s, fix arbitrary points $v^1, \ldots, v^s \in V$ and numbers $\lambda_1, \ldots, \lambda_s$ such that $\mu = \sum_{i=1}^s \lambda_i \neq 0$. Since $\sum_{i=1}^s (\lambda_i/\mu) v^i \in V$ (as V is a linear manifold), for the point $u = \sum_{i=1}^s \lambda_i v^i$ we have

$$q(u) = q\left(\mu \sum_{i=1}^s \frac{\lambda_i}{\mu} v^i\right) = \mu^2 q\left(\sum_{i=1}^s \frac{\lambda_i}{\mu} v^i\right) \geq 0.$$

Obviously, $\operatorname{span} V$ is the closure of the set of such points u. Positive semidefiniteness of q on $\operatorname{span} V$ follows now from continuity of q. ∎

Recall that the index $\operatorname{ind} q$ of a quadratic form q is the maximum dimension of a subspace in $\mathbf{R}^n$ such that q is negatively definite on this subspace. The equivalent definition for $\operatorname{ind} q$ is the minimum codimension of the subspace such that q is positively semidefinite on this subspace.

The following theorem coupled with assertion (ii) of Theorem 2.2 shows that if q is not positively semidefinite, this fact will be identified by the CG-algorithm after not more than $n - \operatorname{ind} q + 1$ steps for almost any choice of the initial point u^0.

THEOREM 3.2. *Let $q : \mathbf{R}^n \to \mathbf{R}$ be a quadratic form. Then for every $u^0 \in U$, the CG-algorithm will be stopped not later than on step $n - \operatorname{ind} q + 1$.*

Proof. Suppose that the CG-algorithm was not stopped on the first k steps, and the elements $u^0, u^1, \ldots, u^k \in \mathbf{R}^n$ and $g^0, g^1, \ldots, g^{k-1} \in \mathbf{R}^n$ were generated, satisfying (2.1). We can consider the case $k \geq 2$ only, because $n - \operatorname{ind} q + 1 \geq 1$, and if the inequality holds as equality, the algorithm would necessarily be stopped on step 1.

By the standard argument for the conjugate gradient method for quadratic functions (see, e.g., [20]), the following can be shown: the vectors $g^0, g^1, \ldots, g^{k-1}$ are linearly independent, and for the linear manifolds $V_i = u^0 + \operatorname{span}\{g^0, g^1, \ldots, g^{i-1}\}$ it holds that

$$q(u^i) = \min_{u \in V_i} q(u) \quad \forall\, i = 1, \ldots, k.$$

In particular, according to (2.1),

$$0 < q(u^{k-1}) = \min_{u \in V_{k-1}} q(u); \tag{3.1}$$

hence

$$q(u) > 0 \quad \forall\, u \in V_{k-1}.$$

By Lemma 3.1, it follows that

$$q(u) \geq 0 \quad \forall\, x \in \operatorname{span} V_{k-1}. \tag{3.2}$$

Suppose for a moment that $u^0 \in \operatorname{span}\{g^0, g^1, \ldots, g^{k-2}\}$. Then V_{k-1} is a linear subspace in $\mathbf{R}^n$, which is in contradiction with (3.1), as $q(0) = 0$. Hence, $u^0 \notin \operatorname{span}\{g^0, g^1, \ldots, g^{k-2}\}$, and $\dim \operatorname{span} V_{k-1} = k$. Thus, according to (3.2), q is positively semidefinite on the subspace of dimension k. Hence, $k \leq n - \operatorname{ind} q$. This completes the proof. □

For example, if $n = 2$, then the absence of positive semidefiniteness will be identified by the algorithm for almost any initial point after, at worst, one step (actually, this will be the steepest descent step). This assertion can also be easily verified directly, using the canonical representation of a quadratic form.

If q is positively definite, then $\forall\, u^0 \in \mathbf{R}^n$ the CG-algorithm will be stopped at 0 not later than on step $n+1$, and positive definiteness will be identified. If q is positively semidefinite but not definite, then $\forall\, u^0 \in U$ the CG-algorithm will be stopped at $\bar{u}$ not later than on step n (recall that $\bar{u} = \bar{u}(u^0)$ is the intersection point of $\ker Q$ and $u^0 + (\ker Q)^\perp$). Similarly to the SD-algorithm, the set of "bad" initial points u^0 (such that the CG-algorithm will incorrectly identify the form q as positively definite) is contained in a proper subspace $(\ker Q)^\perp$ in $\mathbf{R}^n$.

Summarizing, we have proved that for almost any choice of the initial point u^0, the CG-algorithm will completely identify the presence or the absence of positive definiteness or semidefiniteness of a quadratic form after not more than n steps. (If the algorithm was not stopped after n steps, it is not necessary to make step $n + 1$, as by necessity $x^n = 0$, and the form should be claimed positively definite.)

Note that the conjugate gradient step is not much more costly than the steepest descent step, and the CG-algorithm seems to be definitely preferable when compared with the SD-algorithm, at least in the finite-dimensional setting.

Another point is that our justification of the algorithm deals with the idealized situation: it is assumed that all the computations are precise. The question about the influence of computational errors and perturbations of another kind is beyond the scope of this paper, even though this question is certainly important, especially for those forms which are degenerate or nearly degenerate. Here, we mention only that in our computational experiments, any failure evidently caused by inexactness of computations never occurred.

We complete this section with a brief report on computational experiments which were carried out in order to confirm the theoretically justified properties of the algorithm and to compare the two variants of the algorithm with each other and with the Cholesky method (for the latter, the standard realization in Maple V Release 5 was used).

Dimensions in the experiments being reported were up to $n = 100$. The following scheme was used to generate the matrix $Q \in \mathcal{S}(n)$: $Q = S^{\mathrm{T}} \hat{Q} S$, where $\hat{Q}$ is a fixed diagonal $n \times n$ matrix, and S is a nondegenerate $n \times n$ matrix. The effectiveness of

our algorithms can depend drastically on the choice of the initial point, which is why a comparison of our algorithms with the Cholesky method has restricted reliability, of course.

In our experiments, various $\hat{Q}$ were taken, though special attention was paid to matrices with a small number of negative diagonal elements. The algorithms were multiply started with random initial points, and the average characteristics were computed. General conclusions are as follows. For any dimension, both the SD-algorithm and the CG-algorithm are quite competitive in comparison with the Cholesky method, and the CG-algorithm normally requires substantially less CPU time than the Cholesky method. This can be explained by the observation that in large dimensions, the number of steps required by the CG-algorithm is normally substantially less than one guaranteed by the estimate in Theorem 3.2. Moreover, the number of steps needed for the SD-algorithm is usually also substantially less than n. This compensates the necessity of two costly matrix-vector multiplications on every step of the algorithm.

As an example, let us report the typical results for one of the series of experiments. One diagonal entry of $\hat{Q}$ was taken equal to -1, and the others were taken as random numbers in $(0, 10)$. Clearly, this choice of $\hat{Q}$ is quite unfavorable for identification of the absence of positive semidefiniteness. Next, S was taken as the random matrix with entries in $(-1, 1)$. These two objects where used to compute Q as suggested above, and the algorithms were multiply started with random initial points with components in $(-10, 10)$. For $n = 100$, the minimum number of steps for the SD-algorithm is 17, the maximum number is 93, and the average number is 46. For the CG-algorithm, the corresponding numbers are 8, 24, and 14.

4. Finite-dimensional approximation for the optimal control quadratic form. In this section, we deal with the quadratic form $q : U \to \mathbf{R}$ given by (1.2), (1.3), $U = L_{2,r}[0, 1]$. Recall that the matrix functions $A(\cdot)$, $B(\cdot)$, $C(\cdot)$, $G(\cdot)$, and $\Gamma(\cdot)$ in (1.2), (1.3) are supposed to be piecewise continuous.

Consider the simplest finite-dimensional approximation of q. Namely, for every integer n, take a mesh $\{t_0^n, t_1^n, \ldots, t_n^n\}$ on $[0, 1]$ such that $0 = t_0^n < t_1^n < \ldots t_n^n = 1$ and the following hypotheses are satisfied:

(H1) All points of discontinuity of $A(\cdot)$, $B(\cdot)$, $C(\cdot)$, $G(\cdot)$, and $\Gamma(\cdot)$ belong to the mesh for n sufficiently large. (We emphasize that this requirement is the only serious reason why we consider the mesh which is not uniform, in general.)

(H2) There exists a constant $c > 0$ such that $\Delta_n \le c/n \ \forall\, n$, where

$$\Delta_n = \max_{i=0,\,1,\,\ldots,\,n-1} \Delta_i^n, \quad \Delta_i^n = t_{i+1}^n - t_i^n, \quad i = 0, 1, \ldots, n-1.$$

Take $U_n = \prod_{i=0}^{n-1} \mathbf{R}^r$, $X_n = \prod_{i=0}^{n} \mathbf{R}^m$, $q_n : U_n \to \mathbf{R}$,

$$q_n(u^n) = \sum_{i=0}^{n-1} \Delta_i^n (\langle A_i^n u_i^n, u_i^n \rangle + 2\langle C_i^n u_i^n, x_i^n \rangle + \langle B_i^n x_i^n, x_i^n \rangle), \quad u^n = (u_0^n, u_1^n, \ldots, u_{n-1}^n) \in U_n, \tag{4.1}$$

where $x^n = (x_0^n, x_1^n, \ldots, x_n^n) \in X_n$ is defined by the discrete initial value problem given by the explicit Euler scheme for (1.3):

$$x_{i+1}^n = x_i^n + \Delta_i^n (G_i^n x_i^n + \Gamma_i^n u_i^n), \quad i = 0, 1, \ldots, n-1, \quad x_0^n = 0. \tag{4.2}$$

Here $A_i^n = A(t_i^n + 0)$, $i = 0, 1, \ldots, n-1$, and the same notation is used for matrix functions $B(\cdot)$, $C(\cdot)$, $G(\cdot)$, and $\Gamma(\cdot)$.

THEOREM 4.1. *Under the assumptions imposed, the following hold:*

(i) *If q is not positively semidefinite, then q_n is not positively semidefinite for every n sufficiently large.*

(ii) *If q is strongly positive, i.e., there exists $\gamma > 0$ such that*

$$q(u) \geq \gamma \|u\|^2 \quad \forall\, u \in U, \tag{4.3}$$

then for any $\varepsilon > 0$,

$$q_n(u^n) \geq (\gamma - \varepsilon)\|u^n\|^2 \quad \forall\, u^n \in U_n$$

for every n sufficiently large.

As is well known, condition (4.3) is equivalent to saying that q is positively definite, and the *strengthened Legendre condition* is satisfied, i.e., there exists $\tilde{\gamma} > 0$ such that the matrix $A(t) - \tilde{\gamma}E$ is positively semidefinite for almost all $t \in [0, 1]$.

Results similar to Theorem 4.1 can be found in the literature (see, e.g., [11, 16]). In particular, Lemma 11 in [11] contains our assertion (ii), assuming the continuity of the matrix functions involved. However, we include the proof for the sake of completeness.

Proof. In order to prove (i), let us fix $u \in U$ such that $q(u) < 0$. Since continuous functions comprise a dense subset in $L_{2,\,r}[0, 1]$ (see [19]) and q is continuous, we can suppose $u(\cdot)$ to be continuous on $[0, 1]$.

Next, let $x(\cdot) \in W^1_{2,\,m}[0, 1]$ be defined by (1.3) for the given $u(\cdot)$. For each n, take $u^n = (u(t_0^n), u(t_1^n), \ldots, u(t_{n-1}^n)) \in U_n$ and define $x^n \in X_n$ according to (4.2). Clearly, it suffices to show that

$$q_n(u^n) \to q(u) \quad \text{as } n \to \infty.$$

According to (1.2) and (4.1), $\forall\, n$

$$\begin{aligned}
q_n(u^n) - q(u) = \sum_{i=0}^{n-1} \int_{t_i^n}^{t_{i+1}^n} \big(& \langle A_i^n u_i^n,\, u_i^n \rangle - \langle A(t)u(t),\, u(t) \rangle \\
& + 2(\langle C_i^n u_i^n,\, x_i^n \rangle - \langle C(t)u(t),\, x(t) \rangle) \\
& + \langle B_i^n x_i^n,\, x_i^n \rangle - \langle B(t)x(t),\, x(t) \rangle \big)\, dt \\
= \sum_{i=0}^{n-1} \int_{t_i^n}^{t_{i+1}^n} \big(& \langle A_i^n u(t_i^n),\, u(t_i^n) \rangle - \langle A(t)u(t),\, u(t) \rangle \\
& + 2(\langle C_i^n u(t_i^n),\, x(t_i^n) \rangle - \langle C(t)u(t),\, x(t) \rangle) \\
& + \langle B_i^n x(t_i^n),\, x(t_i^n) \rangle - \langle B(t)x(t),\, x(t) \rangle \big)\, dt \\
+ \sum_{i=0}^{n-1} \int_{t_i^n}^{t_{i+1}^n} \big(& 2\langle C_i^n u(t_i^n),\, x_i^n - x(t_i^n) \rangle \\
& + \langle B_i^n x_i^n,\, x_i^n \rangle - \langle B_i^n x(t_i^n),\, x(t_i^n) \rangle \big)\, dt.
\end{aligned}$$

From continuity of $u(\cdot)$ and $x(\cdot)$, piecewise continuity of $A(\cdot)$, $B(\cdot)$, $C(\cdot)$, the definition of A_i^n, B_i^n, C_i^n, $i = 0, 1, \ldots, n$, and the hypotheses (H1) and (H2), it follows that

the first sum on the right-hand side of the last equality tends to zero as $n \to \infty$. To prove that the second sum also tends to zero, it suffices to show that

$$\max_{i=0,\,1,\,\ldots,\,n} |x_i^n - x(t_i^n)| \to 0 \quad \text{as } n \to \infty.$$

But under our assumptions, this is the standard convergence result for the Euler scheme (see, e.g., [11] or [20, p. 358]). This completes the proof of (i).

We proceed with the proof of (ii). Suppose that for every n sufficiently large, there exists $u^n \in U_n \setminus \{0\}$ such that $q_n(u^n) \le 0$. We may suppose that u^n is normalized in the following sense:

$$\|u^n\| = \sqrt{\sum_{i=0}^{n-1} \Delta_i^n |u_i^n|^2} = 1.$$

Define the piecewise constant function $u_n(\cdot) : [0,\,1] \to \mathbf{R}^r$, $u_n(t) = u_i^n$, $t \in [t_i^n,\,t_{i+1}^n)$, $i = 0,\,1,\,\ldots,\,n-1$. Note that

$$\Delta_i^n |u_i^n| = \sqrt{\Delta_i^n}\sqrt{\Delta_i^n |u_i^n|^2} \le \sqrt{\Delta_i^n}\|u^n\| = \sqrt{\Delta_n} \quad \forall\, i = 0,\,1,\,\ldots,\,n-1, \tag{4.4}$$

$$\sum_{i=0}^{n-1} \Delta_i^n |u_i^n| = \|u_n\|_{L_1} \le \|u_n\|_{L_2} = \|u^n\| = 1. \tag{4.5}$$

In particular, from (4.3) it follows that $q(u_n) \ge \gamma$. Now it is clear that in order to come to a contradiction, it suffices to show that

$$q_n(u^n) - q(u_n) \to 0 \quad \text{as } n \to \infty.$$

For every n sufficiently large, let $x^n \in X_n$ be defined according to (4.2), and let $x_n(\cdot) \in W_{2,\,m}^1[0,\,1]$ be defined by (1.3) for $u(\cdot) = u_n(\cdot)$. Let $\bar G = \sup_{t\in[0,\,1]} \|G(t)\|$, $\bar\Gamma = \sup_{t\in[0,\,1]} \|\Gamma(t)\|$. Now, from the Gronwall inequality (in its discrete and continuous forms; see [20]), hypothesis (H2), and (4.5), the following estimates can be derived:

$$\max_{i=0,\,1,\,\ldots,\,n} |x_i^n| \le \bar\Gamma e^{c\bar G}, \quad \|x_n\|_C \le \bar\Gamma e^{\bar G}. \tag{4.6}$$

According to (1.2) and (4.1), for every n sufficiently large

$$\begin{aligned}
q_n(u^n) - q(u_n) = \sum_{i=0}^{n-1} \int_{t_i^n}^{t_{i+1}^n} &\big(\langle A_i^n u_i^n,\, u_i^n\rangle - \langle A(t)u_n(t),\, u_n(t)\rangle \\
&+ 2(\langle C_i^n u_i^n,\, x_i^n\rangle - \langle C(t)u_n(t),\, x_n(t)\rangle) \\
&+ \langle B_i^n x_i^n,\, x_i^n\rangle - \langle B(t)x_n(t),\, x_n(t)\rangle\big)\, dt \\
= \sum_{i=0}^{n-1} \int_{t_i^n}^{t_{i+1}^n} &\big(\langle (A_i^n - A(t))u_i^n,\, u_i^n\rangle \\
&+ 2\langle (C_i^n - C(t))u_i^n,\, x_i^n\rangle + \langle (B_i^n - B(t))x_i^n,\, x_i^n\rangle\big)\, dt \\
+ \sum_{i=0}^{n-1} \int_{t_i^n}^{t_{i+1}^n} &\big(\langle C(t)u_i^n,\, x_i^n - x_n(t)\rangle \\
&+ \langle B(t)(x_i^n - x_n(t)),\, x_i^n\rangle + \langle B(t)x_n(t),\, x_i^n - x_n(t)\rangle\big) dt.
\end{aligned}$$

The first sum on the right-hand side of the last equality tends to zero as $n \to \infty$. This follows from piecewise continuity of $A(\cdot)$, $B(\cdot)$, $C(\cdot)$, the definition of A_i^n, B_i^n, C_i^n, $i = 0, 1, \ldots, n$, hypotheses (H1) and (H2), and (4.5), (4.6). To prove that the second sum also tends to zero, it suffices to show that

$$\max_{i=0,\,1,\,\ldots,\,n-1} \max_{t\in[t_i^n,\,t_{i+1}^n]} |x_i^n - x_n(t)| \to 0 \quad \text{as } n \to \infty.$$

For every n sufficiently large, and for arbitrary $t \in [t_i^n, t_{i+1}^n)$, $i = 0, 1, \ldots, n-1$, set $\varphi_n(t) = |x_i^n - x_n(t)|$. Then, according to (1.3) and (4.2),

$$\begin{aligned}
\varphi_n(t) &\le \sum_{j=0}^{i-1} \int_{t_j^n}^{t_{j+1}^n} (|G_j^n x_j^n - G(\tau)x_n(\tau)| + |\Gamma_j^n u_j^n - \Gamma(\tau)u_j^n|)\,d\tau \\
&\quad + \int_{t_i^n}^{t} (|G(\tau)x_n(\tau)| + |\Gamma(\tau)u_i^n|)\,d\tau \\
&\le \sum_{j=0}^{i-1} \int_{t_j^n}^{t_{j+1}^n} (\|G_j^n - G(\tau)\||x_j^n| + \|\Gamma_j^n - \Gamma(\tau)\||u_j^n|)\,d\tau \\
&\quad + \sum_{j=0}^{i-1} \int_{t_j^n}^{t_{j+1}^n} \bar{G}\varphi_n(\tau)\,d\tau + \int_{t_i^n}^{t} \bar{G}\varphi_n(\tau)\,d\tau \\
&\quad + \int_{t_i^n}^{t} (\bar{G}|x_i^n| + \bar{\Gamma}|u_i^n|)\,d\tau \\
&\le \sum_{j=0}^{i-1} |x_j^n| \int_{t_j^n}^{t_{j+1}^n} \|G_j^n - G(\tau)\|\,d\tau + \sum_{j=0}^{i-1} |u_j^n| \int_{t_j^n}^{t_{j+1}^n} \|\Gamma_j^n - \Gamma(\tau)\|\,d\tau \\
&\quad + \Delta_i^n(\bar{G}|x_i^n| + \bar{\Gamma}|u_i^n|) + \int_0^t \bar{G}\varphi_n(\tau)\,d\tau \\
&= \omega_n + \int_0^t \bar{G}\varphi_n(\tau)\,d\tau,
\end{aligned}$$

where $\omega_n \to 0$ as $n \to \infty$. This follows from piecewise continuity of $G(\cdot)$, $\Gamma(\cdot)$, the definition of G_i^n, Γ_i^n, $i = 0, 1, \ldots, n$, hypotheses (H1) and (H2), and (4.4)–(4.6). By the Gronwall inequality,

$$\varphi_n(t) \le \omega_n e^{\bar{G}} \to 0 \quad \text{as } n \to \infty.$$

This completes the proof of (ii). □

By Theorem 4.1, the question about the "sign" of q is reduced to the same question for the finite-dimensional form q_n for n sufficiently large. More precisely, by analyzing the "sign" of q_n, one can distinguish between the case when q is strongly positive and the case when it is not positively semidefinite.

For finite-dimensional q_n, the SD-algorithm and the CG-algorithm are applicable. For that purpose, a formula for the gradient of q_n is needed:

$$(q_n'(u^n))_i = 2\Delta_i^n(A_i^n u_i^n + (C_i^n)^{\mathrm{T}} x_i^n) - \Delta_i^n(\Gamma_i^n)^{\mathrm{T}}\psi_{i+1}^n, \quad i = 0, 1, \ldots, n-1, \quad u^n \in U_n,$$

where $\psi^n \in X_n$ is defined by the discrete initial value problem

$$\psi_{i-1}^n = \psi_i^n + \Delta_{i-1}^n (G_{i-1}^n)^{\mathrm{T}}\psi_i^n - 2\Delta_i^n(C_{i-1}^n u_{i-1}^n + B_{i-1}^n x_{i-1}^n), \;\; i = 1, \ldots, n-1, \;\; \psi_n^n = 0$$

(see [18, 20]). Again we emphasize that we do not need the symmetric matrix associated with q_n and that it would by quite costly to compute this matrix, especially for large n.

5. Forms of degree 4. Consider the following quadratic form, arising in various applications, particularly in the study of degenerate quadratic forms in calculus of variations [22, 1]: $q : W \to \mathbf{R}$,

$$q(x) = \int_0^{+\infty} (\langle A\dot{x}(t),\, \dot{x}(t)\rangle + 2\langle C\dot{x}(t),\, x(t)\rangle + \langle Bx(t),\, x(t)\rangle)\, dt, \quad x \in W,$$

where W is the space comprised by absolutely continuous functions $x(\cdot) : [0, +\infty) \to \mathbf{R}^m$ such that $x(\cdot)$ and $\dot{x}(\cdot)$ belong to $L_{2,\,m}[0,\, 1]$, $A,\, B \in \mathcal{S}(m)$, $C \in \mathcal{A}(m)$, and A is assumed to be positively semidefinite (Legendre condition). It follows from the results in [22, 1, 10] that q is positively definite (semidefinite) if and only if the form $\tilde{q} : U \to \mathbf{R}$ is positively definite (semidefinite), where $U = \mathbf{R}^m \times \mathbf{R}^m$,

$$\begin{aligned} \tilde{q}(u) &= \tilde{q}_{A,\,B,\,C}(u) \\ &= (\langle A\xi,\, \xi\rangle + \langle A\eta,\, \eta\rangle)(\langle B\xi,\, \xi\rangle + \langle B\eta,\, \eta\rangle) \\ &\quad -4\langle C\xi,\, \eta\rangle^2, \quad u = (\xi,\, \eta) \in U. \end{aligned} \tag{5.1}$$

Thus, the question about the "sign" for the infinite-dimensional quadratic form q is reduced to the same question for the form $\tilde{q}$ of degree 4 on the space U of dimension $2m$.

Clearly, for $\tilde{q}$ to be positively definite, the matrices A and B should be positively definite. For $m = 2$, the simple criterion for positive definiteness of $\tilde{q}$ is known.

PROPOSITION 5.1. *If $m = 2$ and matrices A and B are positively definite, then the form $\tilde{q}$ defined by* (5.1) *is positively semidefinite if and only if*

$$4 \det C \le \det A \left(\operatorname{tr} \sqrt{A^{-1/2} B A^{-1/2}}\right)^2, \tag{5.2}$$

and positively definite if and only if (5.2) *holds as a strict inequality.*

Inequality (5.2) can be rewritten in the form

$$4 \det C \le \det B \operatorname{tr}(B^{-1}A) + 2\sqrt{\det A \det B}.$$

Note that the right-hand side of the last inequality is actually symmetric with respect to A and B, as for 2×2 matrices the following holds: $\det B \operatorname{tr}(B^{-1}A) = \det A \operatorname{tr}(A^{-1}B)$.

The proof of Proposition 5.1 is quite long and involved; see [2]. Moreover, to our knowledge, for $m > 2$ no analytical criterion is available. That is why it would be desirable to develop a numerical technique appropriate for identification of positive definiteness of $\tilde{q}$.

From now on, let $U = \mathbf{R}^n$, and let $q : \mathbf{R}^n \to \mathbf{R}$ be a (polynomial homogeneous) form of degree 4. The basic algorithm introduced in section 2 can be formally extended to this case with the following natural modifications.

First, $q'(\cdot)$ is now defined by the relation

$$\langle q'(u),\, v\rangle = 4q(u,\, u,\, u,\, v), \quad u,\, v \in \mathbf{R}^n.$$

Note that normally it is not that difficult to obtain explicit formulas for the gradient and higher differentials of a given form.

Next, if the algorithm will be stopped on step $k+1$ because of the equality $q'(u^k) = 0$, one should be more careful with conclusions (the same is true for the case when $\{q'(u^k)\} \to 0$ as $k \to \infty$). For example, the form $q : \mathbf{R}^2 \to \mathbf{R}$, $q(u) = u_1 u_2 (u_1 - u_2)^2$ is not positively semidefinite, though at the same time all the points on the line $u_1 = u_2$ are zeros and local minimizers for q. If u^k belongs to this line, then $q'(u^k) = 0$, and the algorithm will be stopped with the wrong conclusion that q is positively semidefinite. Moreover, it is easy to see that in this example, the set of initial points such that the algorithm will be stopped on the mentioned line after one step is quite wide. The need to consider such situations can be avoided by the assumption that q is *nondegenerate*, namely,

$$q'(u) \neq 0 \quad \forall\, u \in \mathbf{R}^n \setminus \{0\}. \tag{5.3}$$

Note that nondegeneracy is a generic condition in the corresponding space of forms; this follows from the parametric transversality theorem [14]. On the other hand, if one assumes this condition to be satisfied, then the cases of semidefiniteness, but not definiteness, are immediately excluded from consideration. Under the nondegeneracy condition, equality $q'(u^k) = 0$ means that $u^k = 0$ (respectively, relation $\{q'(u^k)\} \to 0$ as $k \to \infty$ means that $\{u^k\} \to 0$ as $k \to \infty$), and q is declared positively definite in this case.

If $k \in K_2$, then one of the following formulas can be used for β_{k-1} instead of (2.4):

$$\beta_{k-1} = \frac{\langle q'(u^k),\, q'(u^k) - q'(u^{k-1})\rangle}{|q'(u^{k-1})|^2},$$

$$\beta_{k-1} = \frac{|q'(u^k)|^2}{|q'(u^{k-1})|^2}, \tag{5.4}$$

or

$$\beta_{k-1} = \frac{\langle q''(u^k) g^{k-1},\, q'(u^k)\rangle}{\langle q''(u^k) g^{k-1},\, g^{k-1}\rangle}.$$

(In the quadratic case, all these representations of β_{k-1} are actually the same and are equivalent to (2.4).) Furthermore, in the literature on the conjugate gradient method, it is usually recommended to take an infinite K_1 in the nonquadratic case. The most customary choice is $K_1 = \{0,\, n,\, 2n,\, \ldots\}$, i.e., the method is "renewed" after every n steps, and we accept this choice in what follows.

If $q(u^k) > 0$, $q(g^k) = 0$, the algorithm should not be stopped automatically on step $k+1$. One should compute

$$c_2 = \frac{1}{3!}(q'''(u^k))(g^k,\, g^k,\, g^k) = 4q(u^k,\, g^k,\, g^k,\, g^k).$$

If $c_2 \neq 0$, then q is not positively semidefinite, because $q(x^k + \alpha g^k)$ is a polynomial of degree 3 with respect to α, and it always takes negative values. Let $c_2 = 0$, then compute

$$c_1 = \frac{1}{2!}\langle q''(u^k) g^k,\, g^k\rangle = 6q(u^k,\, u^k,\, g^k,\, g^k).$$

If $c_1 \le 0$, then q is evidently not positively semidefinite. On the other hand, if $c_1 > 0$, then the algorithm should not be stopped. Note that in this case,

$$\alpha_k = \frac{c_0}{2c_1},$$

where

$$c_0 = -\langle q'(u^k),\, g^k\rangle = |q'(u^k)|^2.$$

Finally, if $q(u^k) > 0$, $q(g^k) > 0$, then α_k should be computed as the nonnegative minimizer to the polynomial

$$q(u^k + \alpha g^k) = q(g^k)\alpha^4 + c_2\alpha^3 + c_1\alpha^2 + c_0\alpha + q(u^k)$$

of degree 4.

Of course, the algorithm can be applied to forms of an even degree higher than 4, but in that case, in order to compute the step-length parameter, one would have to deal with the polynomial equation of degree 5 or higher.

A form q of degree 4 satisfying the nondegeneracy condition (5.3) has a unique critical point at zero. This point is a global minimizer, provided q is positively definite, and is not even a local minimizer, provided q is not positively definite. Because of this observation, one can expect the reasonable behavior of the algorithm.

Note that the gradient of a nontrivial form of degree 4 cannot be Lipschitzian on the entire space. This fact results in additional difficulties in theoretical analysis of the algorithm for such forms; for instance, results from [6] cannot be applied here.

THEOREM 5.2. *Let $q : \mathbf{R}^n \to \mathbf{R}$ be a nondegenerate form of degree 4.*

Then for every $u^0 \in \mathbf{R}^n$, either the SD-algorithm will be stopped on some step or $\{u^k\} \to 0$ as $k \to \infty$.

Proof. Suppose that the SD-algorithm generates an infinite sequence $\{u^k\}$. If this sequence is bounded, then from the results in [4] it follows that $\{q'(u^k)\} \to 0$ as $k \to \infty$. Taking into account nondegeneracy of q, $\{u^k\}$ converges to zero.

Thus, we have only to prove that $\{u^k\}$ is bounded. Suppose that this is not the case, i.e., there exists a subsequence $\{u^{k_i}\}$ such that $|u^{k_i}| \to \infty$ as $i \to \infty$.

From (5.3) it follows that

$$|q'(u)| \ge \gamma |u|^3 \quad \forall\, u \in \mathbf{R}^n$$

with some $\gamma > 0$. It is easy to see now that there exist constants C_1, C_2, $C_3 > 0$ such that $\forall\, \alpha \ge 0$

$$\begin{aligned} q(u^{k_i} - \alpha q'(u^{k_i})) &\le q(u^{k_i}) - |q'(u^{k_i})|^2\alpha + C_1|u^{k_i}|^8\alpha^2 \\ &\quad + C_2|u^{k_i}|^{10}\alpha^3 + C_3|u^{k_i}|^{12}\alpha^4 \\ &\le |u^{k_i}|^4 \left(\frac{q(u^{k_i})}{|u^{k_i}|^4} - \gamma^2\alpha|u^{k_i}|^2 + C_1\alpha^2|u^{k_i}|^4 \right. \\ &\quad \left. + C_2\alpha^3|u^{k_i}|^6 + C_3\alpha^4|u^{k_i}|^8 \right). \end{aligned} \tag{5.5}$$

Choose $t > 0$ satisfying the inequality $-\gamma^2 + C_1 t + C_2 t^2 + C_3 t^3 < 0$, and set $\alpha = t|u^{k_i}|^{-2}$; then

$$q(u^{k_i} - \alpha q'(u^{k_i})) \le |u^{k_i}|^4 \left(\frac{q(u^{k_i})}{|u^{k_i}|^4} - \gamma^2 t + C_1 t^2 + C_2 t^3 + C_3 t^4 \right) < 0 \tag{5.6}$$

for i large enough. Here we take into account that $|u^{k_i}|^{-4}q(u^{k_i}) \to 0$ as $i \to \infty$, because $\{q(u^k)\}$ is a bounded sequence (as it is monotonically decreasing and composed of positive numbers).

Inequality (5.6) means that the algorithm would be stopped on step $k_i + 1$, which contradicts the assumption that $\{u^k\}$ is infinite. This completes the proof. □

Unfortunately, for the CG-algorithm, a complete analogue of Theorem 5.2 was not proved by the authors. It can be shown that for a nondegenerate form, if the CG-algorithm generates an infinite sequence, then the latter can have a limit point only at zero. This follows from results in [4], and it is important here that the algorithm is "renewed" on steps kn, $k = 0, 1, \ldots$. Moreover, the argument used in the proof of Theorem 5.2 actually shows that $\{u^{kn}\} \to 0$ as $k \to \infty$, and hence 0 is indeed a limit point for $\{u^k\}$. At the same time, we cannot prove that the entire sequence $\{u^k\}$ is bounded, even though in our computational experiments, the case of unbounded $\{u^k\}$ has never occurred.

Generally speaking, the advantages of the conjugate gradient method in the nonquadratic case are normally theoretically justified only locally, near the solution being sought. Reasonable global behavior (which is of primary interest in the context of this paper) is usually ensured precisely by the "renewing" gradient steps; see [4]. That is why theoretical questions are discussed below mainly for the SD-algorithm, even though, by the evidence of computational experiments, the CG-algorithm is preferable here, as well as in the quadratic case.

Unfortunately, however, even for the SD-algorithm, in the nonquadratic case one cannot guarantee the correct identification with almost any choice of the initial point. If q is positively definite, then for every initial point, the SD-algorithm will either be stopped at zero on some step or generate the sequence convergent to zero. Note that the rate of convergence is normally rather low, as zero is a degenerate critical point for q. However, if q is not positively semidefinite, computational experiments show that there can exist "wide" sets (of nonzero measure) such that starting from them, the SD-algorithm will generate a sequence convergent to zero, and the form will be incorrectly identified as positively definite. We proceed with the example for which this "bad" behavior can be detected.

First, consider the form $q : \mathbf{R}^2 \to \mathbf{R}$, $q(u) = (au_1^2 + u_2^2)(u_1^2 - u_2^2)$, with $0 < a < 1/3$. This form is not positively semidefinite. Note that for problem (1.4) with D equal to the unit sphere in $\mathbf{R}^2$, the points $\pm(1, 0)$ are local solutions, and the value of q at these points is positive (recall that this is not possible for quadratic forms). To construct the example we need, let us now increase the dimension by 1, and take $q : \mathbf{R}^3 \to \mathbf{R}$, $q(u) = (au_1^2 + u_2^2 + bu_3^2)(u_1^2 - u_2^2 + u_3^2)$, with $b > 0$ being large enough. Geometrical analysis of level surfaces for this form, combined with numerical experiments, shows that the point (1, 0, 0), e.g., belongs to the closure of an open set of "bad" initial points.

According to the discussion above, the estimates for sets of appropriate initial points can be of interest. The next proposition contains the estimates for the sets of initial points such that the SD-algorithm will give a correct answer not later than steps 2 and 3, respectively. Set

$$\theta = \max_{t \geq 0} t(\gamma^2 - C_1 t - C_2 t^2 - C_3 t^3) > 0,$$

where γ, C_1, C_2, and C_3 are taken from the proof of Theorem 5.2.

PROPOSITION 5.3. *Assume that a nondegenerate form $q : \mathbf{R}^n \to \mathbf{R}$ of degree 4 is not positively semidefinite.*

Then for every $u^0 \in \mathbf{R}^n \setminus \{0\}$ *such that*

$$q(u^0/|u^0|) + 32\theta\varphi^2(u^0)(1 - 8\varphi^2(u^0)) < 2\theta \tag{5.7}$$

with

$$\varphi(u^0) = \frac{q(u^0/|u^0|)}{|q'(u^0/|u^0|)|},$$

the SD-algorithm will be stopped at some point distinct from zero not later than step 3. *In particular, if*

$$q(u^0/|u^0|) < \theta, \tag{5.8}$$

then the algorithm will be stopped not later than step 2.

It is easy to see that the second term on the left-hand side of (5.7) is less than or equal to θ, and hence (5.8) implies (5.7).

Proof. Suppose that the SD-algorithm was not stopped on the first $k+1$ steps, and the following points were generated: $u^0, u^1, \dots, u^k \in \mathbf{R}^n$ (distinct from zero) and $u^{k+1} \in \mathbf{R}^n$. Replace u^{k_i} in (5.5) by x^i and set $t = \alpha|u^{k_i}|^2$; then

$$\begin{aligned} q(u^{i+1}) &= \min_{\alpha \ge 0} q(u^i - \alpha q'(u^i)) \\ &\le q(u^i) - |u^i|^4 \max_{t \ge 0}(\gamma^2 t - C_1 t^2 - C_2 t^3 - C_3 t^4) \\ &= q(u^i) - \theta|u^i|^4 \\ &\le \cdots \\ &\le q(u^0) - \theta \sum_{j=0}^{i} |u^j|^4 \quad \forall\, i = 0, 1, \dots, k. \end{aligned}$$

Hence, provided

$$q(u^0) - \theta \sum_{i=0}^{k} |u^i|^4 < 0, \tag{5.9}$$

on step $k+2$ the algorithm will necessarily be stopped at a point distinct from zero. In particular, under the condition (5.8), (5.9) holds with $k = 0$; i.e., the algorithm will be stopped on step 2, unless it was stopped on step 1.

Furthermore,

$$\begin{aligned} |u^{i+1}|^2 &= |u^i|^2 - 2\langle q'(u^i), u^i\rangle\alpha_i + |q'(u^i)|^2\alpha_i^2 \\ &= |u^i|^2 - 8q(u^i)\alpha_i + |q'(u^i)|^2\alpha_i^2 \\ &\ge |u^i|^2 - \max_{\alpha \ge 0} \alpha(8q(u^i) - |q'(u^i)|^2\alpha) \\ &= |u^i|^2 - 16\left(\frac{q(u^i)}{|q'(u^i)|}\right)^2 \quad \forall\, i = 0, 1, \dots, k. \end{aligned}$$

It follows that

$$\begin{aligned} q(u^0) - \theta(|u^0|^4 + |u^1|^4) &\le q(u^0) - \theta\left(2|u^0|^4 - 32\left(\frac{q(u^0)}{|q'(u^0)|}\right)^2 |u^0|^2 \right. \\ &\qquad \left. + 16^2\left(\frac{q(u^0)}{|q'(u^0)|}\right)^4\right) \\ &= q(u^0) + 32\theta\varphi^2(u^0)(1 - 8\varphi^2(u^0))|u^0|^4 - 2\theta|u^0|^4, \end{aligned}$$

and hence (5.7) implies (5.9) with $k = 1$; i.e., the algorithm will be stopped on step 3, unless it was stopped earlier. This completes the proof. □

In several series of computational experiments, the forms of the following type were considered:

$$q(u) = \langle Q_1 u,\, u\rangle \langle Q_2 u,\, u\rangle, \quad u \in \mathbf{R}^n,$$

where matrices $Q_1,\, Q_2 \in \mathcal{S}(n)$ were generated in the same manner as Q in the experiments with quadratic forms. For instance, let $\hat{Q}_1$ and $\hat{Q}_2$ be diagonal $n \times n$ matrices. Let the diagonal entries of the first matrix be random numbers in (0, 10), and for the second matrix, let it be the same, except for one diagonal entry equal to -1. Fix random $n \times n$ matrices S_1 and S_2 with entries in $(-1,\, 1)$, and then set $Q_1 = S_1^{\mathrm{T}} \hat{Q}_1 S_1$, $Q_2 = S_2^{\mathrm{T}} \hat{Q}_2 S_2$. Further, the algorithms were multiply started with random initial points with components in $(-1,\, 1)$. For $n = 10$, computations were terminated if the number of steps exceeded 50. (It was considered that in this case, the algorithm failed to identify the absence of positive semidefiniteness.) Typical results are as follows. The SD-algorithm failed for 36% of trials, and when it did not fail, identification required 8 steps on average. For the CG-algorithm, the last number is 11, though the algorithm failed for 8% of trials only. Thus, the CG-algorithm turns out to be more robust with respect to the choice of the initial point, though the required number of steps for the CG-algorithm can even exceed the corresponding number for the SD-algorithm.

Recall the form $\tilde{q} = \tilde{q}_{A,\,B,\,C} : U \to \mathbf{R}$ defined in (5.1). Let $\mathcal{P}(m) \subset \mathcal{S}(m)$ stand for the cone of positively definite matrices, equipped with the metrics induced from $\mathcal{S}(m)$.

PROPOSITION 5.4. *The set of triples* $(A,\, B,\, C) \in \mathcal{P}(m) \times \mathcal{P}(m) \times \mathcal{A}(m)$ *such that the form* $\tilde{q}_{A,\,B,\,C}$ *of degree* 4 *defined in* (5.1) *is nondegenerate is open and dense in* $\mathcal{P}(m) \times \mathcal{P}(m) \times \mathcal{A}(m)$.

The proof easily follows from the parametric transversality theorem [14].

In the computational experiments, matrices A, B, and C were generated, e.g., in the following way. Fix diagonal $m \times m$ matrices $\hat{A}$ and $\hat{B}$, the diagonal entries of both being random numbers in (0, 10), except for the first two diagonal entries. Let the first two diagonal entries of $\hat{A}$ be equal to 1, and let the corresponding diagonal entries b_1 and b_2 of $\hat{B}$ be considered as parameters. Further, define a matrix $\hat{C} \in \mathcal{A}(m)$ such that the upper left 2×2 submatrix of $\hat{C}$ is

$$\begin{pmatrix} 0 & c \\ -c & 0 \end{pmatrix},$$

c being a parameter. Fix random $m \times m$ matrix S with elements in $(-1,\, 1)$, and set $A = S^{\mathrm{T}} \hat{A} S$, $B = S^{\mathrm{T}} \hat{B} S$, $C = S^{\mathrm{T}} \hat{C} S$. Choosing parameters b_1, b_2, and c in accordance with criteria from Proposition 5.1, one can obtain the form with the known answer to the question about the "sign" for any m.

The algorithms were multiply started with random initial points with components in $(-1,\, 1)$. For $n = 10$, computations were terminated if the number of steps exceeded 100. Let us report the typical results for $b_1 = 1$, $b_2 = 4$, $c = 2$ (the form is not positively semidefinite with this choice). The SD-algorithm failed for 35% of trials, and when it did not fail, identification required 28 steps on average. The CG-algorithm never failed, and the required number of steps was 16 on average. Note that for the same b_1 and b_2, and $c = 1.6$, the SD-algorithm failed for 87% of trials, though the CG-algorithm failed for 3% of trials only. (The form is still not positively semidefinite with this choice, but c is close to the "critical" value 1.5.)

Acknowledgments. The authors thank the anonymous referees, whose valuable comments significantly improved the presentation of the paper.

IDENTIFICATION FOR CONTROL: OPTIMAL INPUT DESIGN WITH RESPECT TO A WORST-CASE ν-GAP COST FUNCTION*

ROLAND HILDEBRAND† AND MICHEL GEVERS‡

Abstract. Parameter identification experiments deliver an identified model together with an ellipsoidal uncertainty region in parameter space. The objective of robust controller design is thus to stabilize all plants in the identified uncertainty region. The subject of the present contribution is to design an identification experiment such that the worst-case ν-gap over all plants in the resulting uncertainty region between the identified plant and plants in this region is as small as possible. The experiment design is performed via input power spectrum optimization. Two cost functions are investigated, which represent different levels of trade-off between accuracy and computational complexity. It is shown that the input optimization problem with respect to these cost functions is amenable to standard numerical algorithms used in convex analysis.

1. Introduction.

This paper continues the line of research that aims at connecting prediction error identification methods with robust control theory ([2], [3], [4], [10]). Subject to investigation are discrete time SISO real-rational stable linear time invariant (LTI) plants, which are to be identified in open loop within an autoregressive with exogeneous input (ARX) model structure. We assume the true plant to lie in the model set. Hence the model error is determined only by the covariance of the estimated parameter vector.

Since the aim of the identification experiment is control design, it is desirable to obtain an uncertainty region with good stability robustness properties. By this is meant that the set of controllers that stabilize all models in the uncertainty set should be as large as possible. A suitable measure of robust stability that allows one to connect the "size" of an uncertainty set with a set of robustly stabilizing controllers is the worst-case ν-gap $\delta_{WC}(\hat{G}, \mathcal{D})$ introduced in [10]. It is the supremum of the Vinnicombe ν-gap (see, e.g., [28]) between the identified model $\hat{G}$ and all plants in the uncertainty set $\mathcal{D}$. Specifically, if $\delta_{WC}(\hat{G}, \mathcal{D}) = \beta$, then all controllers C that stabilize the model $\hat{G}$ with a stability margin $b_{\hat{G},C} > \beta$ stabilize all plants in $\mathcal{D}$.

In previous papers ([3], [4], [10]) a special type of uncertainty set $\mathcal{D}$ of transfer functions, which emerges from prediction error identification experiments, was described and investigated. It is given by an ellipsoid in parameter space and is determined by the covariance matrix of the parameter vector and the prespecified confidence level. The latter is defined to be the probability with which the true plant is lying inside the considered uncertainty set.

‡CESAME, Université Catholique de Louvain, Bâtiment EULER, 4 av. Georges Lemaitre, 1348 Louvain-la-Neuve, Belgium (Gevers@auto.ucl.ac.be).

The goal of this paper is to minimize the worst-case ν-gap of such uncertainty regions $\mathcal{D}$ by choosing a suitable input $u(t)$ for the identification experiment. To restrict the class of admissible inputs we assume the total input energy to be bounded.

The problem setting of experiment design first arose in statistics and was extensively studied throughout the last century. Important results were obtained by Kiefer [15], Kiefer and Wolfowitz [16], Fedorov (e.g., [9]), Mehra (e.g., [20], [21]), Goodwin, Zarrop, and Payne [12], Zarrop [30], and others.

We shall adopt the most common viewpoint and study input optimization in the frequency domain, i.e., optimize the input power spectrum with respect to a cost function that depends on the average per data sample information matrix $\bar{M}$ of the experiment. This matrix is defined as the limit of the ratio between the information matrix and the number of data as the number of data tends to infinity (see, e.g., [30]). For typical number of data, this leads to a sufficiently good approximation of the optimal input. The latter can be obtained only by computationally expensive time domain optimization (see, e.g., [11], [23], [26], [6]). Thus we will essentially regard the average information matrix instead of the input power spectrum as the quantity that is going to be optimized. Once the optimal average information matrix, i.e., the one that minimizes the considered cost function, is found, we proceed by construction of an input power spectrum that produces this information matrix.

For different classes of cost functions iterative procedures were designed to find the optimal input power spectrum up to a prespecified precision. Most common cost functions are $\ln(\det \bar{M}^{-1})$ (D-optimality), $\mathrm{tr}\bar{M}^{-1}$ (A-optimality), $\mathrm{tr}W\bar{M}^{-1}$, where $W \geq 0$ (L-optimality), $\lambda_{\max}(\bar{M}^{-1})$ (E-optimality), $\Phi_s = (p^{-1}\mathrm{tr}\bar{M}^{-s})^{1/s}$, where p is the dimension of the parameter vector and $s = 0, 1, \ldots, \infty$ (Φ-optimality). All mentioned cost functions except $\Phi_\infty = \lambda_{\max}(\bar{M}^{-1})$ depend analytically on the entries of $\bar{M}$ and Kiefer–Wolfowitz theory can effectively be applied to them (see [15]). All above-mentioned criteria are convex and monotonic with respect to $\bar{M}$ (see [30, p. 39]).

In this paper, we optimize the input power spectrum with respect to the worst-case ν-gap of the uncertainty region $\mathcal{D}$. This is a nonstandard cost function, which is nonsmooth and thus more difficult to treat than the common above-mentioned criteria. We shall also introduce another cost function, which approximates the worst-case ν-gap, but is somewhat simpler. Nevertheless, both cost functions are compound criteria (see [15, section 4G]) and application of Kiefer–Wolfowitz theory does not make them more tractable. However, the proposed criteria satisfy the natural condition of monotonicity with respect to $\bar{M}$, as well as the condition of quasiconvexity, which is slightly weaker than convexity.

It follows from a classical result on trigonometric moment spaces (see [14, Chapter VI, Theorem 4.1]) that the set of possible average information matrices $\bar{M}$ can be represented as the feasible set of a linear matrix inequality (LMI). For a survey on LMIs, see, e.g., [5]. Since the worst-case ν-gap and the other proposed criteria are quasiconvex with respect to the input power spectrum, the apparatus of convex analysis and the theory of LMIs can be applied to solve this optimization problem. For recent results in convex optimization, see, e.g., [22].

In the last years several authors successfully treated input design problems arising in identification for control with convex optimization methods. In [18], the input spectrum for an open loop identification experiment was designed to minimize the closed loop system performance. By a Taylor series truncation, the cost function reduced to the weighted-trace criterion (L-optimality). However, the input spectra

were restricted to those which can be realized by white noise filtered through a finite impulse response (FIR) filter. An LMI description of the corresponding set of information matrices can be derived from the positive-real lemma [5], [29].

In this paper we optimize over the whole set of nonnegative input power spectra. It can be shown [30] that under the assumptions made above the corresponding set of admissible average information matrices, over which the optimization is performed, represents a moment space of a trigonometric Tchebycheff system. The foundations of the theory of moment spaces are classical. In the last century important contributions were made by Krein (see, e.g., [17]), Karlin and Shapley [13], and others. For a comprehensive treatment, see the textbook [14] by Karlin and Studden. It follows from a well-known fact of Tchebycheff system theory (see, e.g., [14]) that any admissible average information matrix $\bar{M}$ can be obtained by applying an input with discrete power spectrum, and that there exist admissible $\bar{M}$ which can be realized only by discrete power spectra. A restatement of this assertion is provided in Theorem 3.6 in this paper. In view of this, we propose an algorithm that yields optimal input power spectra which are discrete. Given the result just quoted, this is in no way a restriction. There are different ways to choose an input sequence with a desired power spectrum. We can choose the input, e.g., as a multisine function. However, in many cases one could use also binary signals (see, e.g., [30, p. 29]) or other functions.

Another approach, which leads to a suboptimal discrete input power spectrum, was proposed by Schoukens, Guillaume, and Pintelon [25] and van den Eijnde and Schoukens [27]. Here a finite subset of frequencies is prespecified and the optimal input power spectrum is sought within this subset. Advantages of this suboptimal method are less computational effort and an easier way to generate an input signal with the desired spectrum.

Let us also mention the paper [7], where identification in the ν-gap metric was treated outside the context of input design. The identification of a model was performed from a set of frequency response measurements in a way that aimed at minimizing the ν-gap between the true plant and the model.

We stress that the assumption of an ARX model structure and an input energy constraint are in no way restrictive. The ideas and methods proposed in the present paper easily carry over to other model structures and to input power or output power/energy constraints.

The remainder of the paper is structured as follows. In the next section the considered identification problem as well as the cost functions will be formally defined. In section 3 we will show that the set over which the optimization takes place is amenable to an LMI formulation. In section 4 we prove that the optimization problem is quasiconvex. In section 5 we show how to construct cutting planes to the different cost functions. Sections 3 to 5 are the key parts of the paper. The results obtained therein allow the problem to be treated with standard convex analysis methods. In section 6 we provide some results that are useful for designing stopping criteria for iterative search algorithms and quality assessment of the solution. Since the optimization takes place in an abstract parameter space, it is necessary to convert values in this space into power spectra and input sequences. This task is accomplished in section 7. In section 8 we present a simulation example, which demonstrates the superiority of the proposed cost functions over the classical design criteria D- and E-optimality. Finally, in section 9 we draw some conclusions.

2. Problem setting. Let us consider an ARX model structure

$$y(t) + a_1 y(t-1) + \cdots + a_{n_a} y(t-n_a) = b_1 u(t-n_k) + \cdots + b_{n_b} u(t-n_k-n_b+1) + e(t),$$

where $u(t)$ is the input signal, $y(t)$ is the output signal, both one-dimensional, $\theta = (a_1, \dots, a_{n_a}, b_1, \dots, b_{n_b})^T$ is the parameter vector, and $e(t)$ is normally distributed white noise with covariance λ_0. Let us assume that the true system dynamics can be described within this structure and corresponds to a parameter value $\theta = \theta_0$. Assume further that the true system is stable. Denote by z^{-1} the delay operator. Then we can write

$$\begin{aligned} y &= z^{-n_k+1}\frac{b_1 z^{-1} + \cdots + b_{n_b} z^{-n_b}}{1 + a_1 z^{-1} + \cdots + a_{n_a} z^{-n_a}} u + \frac{1}{1 + a_1 z^{-1} + \cdots + a_{n_a} z^{-n_a}} e \\ &= z^{-n_k+1}\frac{B(\theta)}{A(\theta)} u + \frac{1}{A(\theta)} e = G(\theta) u + \frac{1}{A(\theta)} e, \end{aligned}$$

where A, B are obviously defined polynomials in the delay operator with coefficients depending on the parameter vector. Note that by our stability assumption A has no zeros on the unit circle and hence $|A|^2$ is strictly positive there.

Suppose an identification experiment with input $(u(1), \dots, u(N))$ is performed, leading to an observed output $(y(1), \dots, y(N))$ with N data samples, where $u(t)$ is a realization of a quasi-stationary stochastic process with power spectrum Φ_u. Suppose a parameter estimate $\hat{\theta}$ is obtained by least squares prediction error minimization. Then it is well known (see [19]) that the estimate $\hat{\theta}$ is asymptotically unbiased as $N \to \infty$ and its covariance for large N is given by $E(\theta_0 - \hat{\theta})(\theta_0 - \hat{\theta})^T \approx \frac{\lambda_0}{N}(\bar{E}\psi\psi^T)^{-1}$, where $\psi^T = (-z^{-1}y, \dots, -z^{-n_a}y, z^{-n_k}u, \dots, z^{-n_k-n_b+1}u)$ is the gradient of the predictor with respect to θ at $\theta = \theta_0$. The power spectrum of ψ is given by

$$\Phi_\psi = \begin{pmatrix} -z^{-n_k}\frac{B}{A} \\ \vdots \\ -z^{-n_a-n_k+1}\frac{B}{A} \\ z^{-n_k} \\ \vdots \\ z^{-n_k-n_b+1} \end{pmatrix} \Phi_u \left(-z^{n_k}\frac{\bar{B}}{\bar{A}} \cdots z^{n_k+n_b-1} \right) + \begin{pmatrix} -\frac{z^{-1}}{A} \\ \vdots \\ -\frac{z^{-n_a}}{A} \\ 0 \\ \vdots \\ 0 \end{pmatrix} \lambda_0 \left(-\frac{z}{\bar{A}} \cdots 0 \right).$$

This yields the following asymptotic expression for the parameter covariance:

$$E(\theta_0 - \hat{\theta})(\theta_0 - \hat{\theta})^T \approx \left(\frac{N}{2\pi} \int_{-\pi}^{\pi} \frac{1}{|A|^2} \left(\frac{\Phi_u}{\lambda_0} \begin{pmatrix} -z^{-1}B \\ \vdots \\ -z^{-n_a}B \\ z^{-1}A \\ \vdots \\ z^{-n_b}A \end{pmatrix} \begin{pmatrix} -z^{-1}B \\ \vdots \\ -z^{-n_a}B \\ z^{-1}A \\ \vdots \\ z^{-n_b}A \end{pmatrix}^* + \begin{pmatrix} -z^{-1} \\ \vdots \\ -z^{-n_a} \\ 0 \\ \vdots \\ 0 \end{pmatrix} \begin{pmatrix} -z^{-1} \\ \vdots \\ -z^{-n_a} \\ 0 \\ \vdots \\ 0 \end{pmatrix}^* \right) d\omega \right)^{-1} = M^{-1},$$

where $z = e^{j\omega}$. The inverse of the parameter covariance matrix is the Fisher information matrix. Let us denote the asymptotic expression for the information matrix by

M and the average information matrix per data sample (see, e.g., [30, p. 24]) by $\bar{M}$, $\bar{M} = \frac{1}{N}M$. We obtain

$$\bar{M} = \frac{1}{2\pi}\int_{-\pi}^{\pi} \frac{\Phi_u}{\lambda_0 |A|^2} \begin{pmatrix} |B|^2 \begin{pmatrix} 1 & \cdots & z^{n_a-1} \\ \vdots & \ddots & \vdots \\ z^{-n_a+1} & \cdots & 1 \end{pmatrix} & -B\bar{A} \begin{pmatrix} 1 & \cdots & z^{n_b-1} \\ \vdots & \ddots & \vdots \\ z^{-n_a+1} & \cdots & z^{n_b-n_a} \end{pmatrix} \\ -\bar{B}A \begin{pmatrix} 1 & \cdots & z^{n_a-1} \\ \vdots & \ddots & \vdots \\ z^{-n_b+1} & \cdots & z^{n_a-n_b} \end{pmatrix} & |A|^2 \begin{pmatrix} 1 & \cdots & z^{n_b-1} \\ \vdots & \ddots & \vdots \\ z^{-n_b+1} & \cdots & 1 \end{pmatrix} \end{pmatrix}$$

$$+ \frac{1}{|A|^2} \begin{pmatrix} 1 & \cdots & z^{n_a-1} & \\ \vdots & \ddots & \vdots & 0 \\ z^{-n_a+1} & \cdots & 1 & \\ & 0 & & 0 \end{pmatrix} d\omega. \tag{2.1}$$

Note that in the expansion of $\bar{M}$, we have $A = A(\theta_0)$, $B = B(\theta_0)$. Since the parameter estimate $\hat{\theta}$ is asymptotically normally distributed (see [19]), we can assume, following [10], that the true parameter vector θ_0 lies with a prespecified probability $\alpha \in (0,1)$ in the uncertainty ellipsoid

$$U = \left\{ \theta | \frac{N}{\chi^2_{n_a+n_b}(\alpha)} (\theta - \hat{\theta})^T \bar{M} (\theta - \hat{\theta}) < 1 \right\}, \tag{2.2}$$

where χ^2_l is the χ^2 probability distribution with l degrees of freedom.

The uncertainty ellipsoid U corresponds to an uncertainty set

$$\mathcal{D} = \left\{ G(z,\theta) = z^{-n_k+1} \frac{B(\theta)}{A(\theta)} | \theta \in U \right\} = \left\{ G(z,\theta) = \frac{Z_N(z)\theta}{1 + Z_D(z)\theta} | \theta \in U \right\}$$

in the space of transfer functions. Here

$$Z_N = z^{-n_k+1}(0 \ \cdots \ 0 \ z^{-1} \ \cdots \ z^{-n_b}), \qquad Z_D = (z^{-1} \ \cdots \ z^{-n_a} \ 0 \ \cdots \ 0) \tag{2.3}$$

are row vectors of dimension $n_a + n_b$. The set $\mathcal{D}$ belongs to the class of generic prediction error model uncertainty sets as defined in [10].

The worst-case ν-gap between the identified model $G(\hat{\theta})$ and the uncertainty region $\mathcal{D}$ is defined by

$$\delta_{WC}(G(\hat{\theta}), \mathcal{D}) = \sup_{\theta \in U} \delta_\nu(G(\hat{\theta}), G(\theta)), \tag{2.4}$$

where δ_ν denotes the Vinnicombe ν-gap between two plants (see [28]). Since $G(\hat{\theta})$ belongs to $\mathcal{D}$, the worst-case ν-gap can be expressed in the following way (see [10, Lemma 5.1]):

$$\delta_{WC}(G(\hat{\theta}), \mathcal{D}) = \sup_{\omega \in [0,\pi]} \kappa_{WC}(G(e^{j\omega}, \hat{\theta}), \mathcal{D}), \tag{2.5}$$

where $\kappa_{WC}(G(e^{j\omega}, \hat{\theta}), \mathcal{D})$ is called the worst-case chordal distance between $G(\hat{\theta})$ and $\mathcal{D}$ at frequency ω and is defined by

$$\kappa_{WC}(G(e^{j\omega}, \hat{\theta}), \mathcal{D}) = \sup_{\theta \in U} \frac{|G(e^{j\omega}, \hat{\theta}) - G(e^{j\omega}, \theta)|}{\sqrt{(1 + |G(e^{j\omega}, \hat{\theta})|^2)(1 + |G(e^{j\omega}, \theta)|^2)}}. \tag{2.6}$$

The worst-case ν-gap is directly related to the robustness properties of the uncertainty region $\mathcal{D}$. The smaller it is, the larger is the set of controllers stabilizing simultaneously all plants in $\mathcal{D}$. Therefore our primary goal shall be to minimize the quantity $\delta_{WC}(G(\hat{\theta}), \mathcal{D}) = \max_{\omega\in[0,\pi]} \kappa_{WC}(G(e^{j\omega}, \hat{\theta}), \mathcal{D})$ by choosing an input with an appropriate power spectrum.

To be more precise, by input spectrum we mean a nonnegative measure on $[-\pi, \pi]$ such that the equality $\int_{-\pi}^{\pi} \Phi_u \varphi(\omega)\, d\omega = \int_{-\pi}^{\pi} \Phi_u \varphi(-\omega)\, d\omega$ holds for all functions $\varphi(\omega) \in C^\infty([-\pi, \pi])$. To any such measure Φ_u on $[-\pi, \pi]$ corresponds a unique nonnegative measure $\bar{\Phi}_u$ on $[0, \pi]$ such that $\int_{-\pi}^{\pi} \Phi_u \varphi(\omega)\, d\omega = \int_0^{\pi} \bar{\Phi}_u \frac{\varphi(\omega)+\varphi(-\omega)}{2}\, d\omega$ for all $\varphi \in C^\infty([-\pi, \pi])$. For details on constructing $\bar{\Phi}_u$ from Φ_u, see, e.g., [30, p. 23]. In what follows we will denote the single-sided measure $\bar{\Phi}_u$ also by Φ_u. Since the measures are defined on different intervals, confusion is excluded.

To restrict the class of admissible power spectra we impose an input energy constraint

$$\frac{1}{2\pi} \int_{-\pi}^{\pi} \Phi_u(\omega) d\omega \le c, \tag{2.7}$$

where $c > 0$ is a prespecified positive constant.

The worst-case ν-gap depends on Φ_u via the average per data sample information matrix $\bar{M}$, which enters in the expression for the set U. Furthermore, it depends via $\bar{M}$ on the unknown true parameter value θ_0 and noise covariance λ_0. In addition it depends on the identified parameter value $\hat{\theta}$, which is naturally not available before the identification experiment is performed. All these three quantities have to be approximated with values derived from previous knowledge about the system, for instance from a preliminary identification experiment. Since the expectation of $\hat{\theta}$ equals θ_0, these two quantities can be approximated by the same value. Denote this value by $\bar{\theta}$, and denote the approximation of λ_0 by $\bar{\lambda}$.

We can now formulate our main problems.

PROBLEM 1. *Find Φ_u satisfying* (2.7) *such that $\bar{M}(\Phi_u)$ defined by* (2.1) *minimizes the cost function $\mathcal{J}_1 = \delta_{WC}(G(\hat{\theta}), \mathcal{D})$ defined by* (2.5), (2.6).

Along with the worst-case ν-gap of the uncertainty region $\mathcal{D}$, we will consider another cost function, which is easier to compute and is an approximation of δ_{WC}.

Let us approximate cost function $\mathcal{J}_1 = \mathcal{J}_1(\bar{M})$ by its asymptotic expression for large information matrices. For a fixed positive definite matrix $\bar{M}_0$ the size of the parameter ellipsoid U defined by any multiple $\bar{M} = \beta \bar{M}_0$ of $\bar{M}_0$, where $\beta > 0$, is proportional to $\beta^{-1/2}$. Since for small ellipsoids the worst-case ν-gap is asymptotically proportional to the size of the former, it follows that for large β the value of $\mathcal{J}_1(\bar{M})$ diminishes asymptotically proportionately to $\beta^{-1/2}$. Thus we can approximate $\mathcal{J}_1$ by

$$\mathcal{J}_2 = \lim_{\varepsilon\to 0} \frac{\mathcal{J}_1(\varepsilon^{-2}\bar{M})}{\varepsilon}. \tag{2.8}$$

PROBLEM 2. *Find Φ_u satisfying* (2.7) *such that $\bar{M}(\Phi_u)$ defined by* (2.1) *minimizes cost function $\mathcal{J}_2$ defined by* (2.8).

The goal of the present paper is the development of numerical algorithms for solving both Problems 1 and 2. There is a twofold reason for introducing cost function $\mathcal{J}_2$. Beside its much lower computational complexity, it turns out that identification with an input power spectrum minimizing $\mathcal{J}_2$ in many cases gives better results than one with an input power spectrum minimizing $\mathcal{J}_1$. This apparently counterintuitive observation has the following reason. Both cost functions depend on the identified

parameter value $\hat{\theta}$, the true parameter value θ_0, and the noise covariance λ_0. As mentioned above, these quantities are unknown and must be replaced by estimates obtained, e.g., from a preliminary identification experiment. This approximation introduces an error to the argument of the minimum of the cost functions $\mathcal{J}_1$ and $\mathcal{J}_2$, i.e., to the solutions of Problems 1 and 2. Now simulations show that the impact of this effect on $\arg\min \mathcal{J}_2$ is lower than that on $\arg\min \mathcal{J}_1$ and that this difference as a rule outweighs the error introduced by approximating cost function $\mathcal{J}_1$ by $\mathcal{J}_2$. We will address this issue again in the simulation section.

3. LMI description of the search space. In this section we shall describe the set of possible average information matrices $\bar{M}$, over which the optimization takes place, as the feasible set of an LMI.

The following fact is due to Payne and Goodwin [24].

PROPOSITION 3.1. *The average information matrix $\bar{M}$ is contained in a (n_a+n_b)-dimensional affine subspace of the space of symmetric $(n_a+n_b)\times(n_a+n_b)$-matrices.*

We find it convenient to give a proof here in order to provide explicit expressions that clarify the structure of $\bar{M}$.

Proof. Define $a_0 = 1$ and $n = n_a + n_b - 1$. Then we have

$$
\begin{aligned}
|B|^2 &= \sum_{k=-(n_b-1)}^{n_b-1} \left(\sum_{j=\max(1,1-k)}^{\min(n_b,n_b-k)} b_{j+k} b_j \right) z^k, \\
-B\bar{A} &= \sum_{k=-n_b}^{n_a-1} \left(\sum_{j=\max(1,-k)}^{\min(n_b,n_a-k)} -a_{j+k} b_j \right) z^k, \\
|A|^2 &= \sum_{k=-n_a}^{n_a} \left(\sum_{j=\max(0,-k)}^{\min(n_a,n_a-k)} a_{j+k} a_j \right) z^k. \qquad (3.1)
\end{aligned}
$$

Using (3.1) in (2.1) and ordering by powers of z, we can rewrite (2.1) as $\bar{M} = \frac{1}{2\pi}\int_{-\pi}^{\pi} \frac{\Phi_u}{\lambda_0|A|^2}(\sum_{i=-n}^{n} \tilde{M}_i z^i)\, d\omega + \tilde{M}$. The matrices $\tilde{M}_i$ are constant and depend only on the coefficients of A and B. By $\tilde{M}$ the integral over the second term in (2.1) is denoted. It is a constant matrix and independent of Φ_u. $\tilde{M}$ is most easily computed using the method proposed in [19, p. 50]. Note that $\tilde{M}_i = \tilde{M}_{-i}^T$. Hence we obtain

$$
\begin{aligned}
\bar{M} &= \frac{1}{2\pi}\int_{-\pi}^{\pi} \frac{\Phi_u}{\lambda_0|A|^2}\, d\omega \tilde{M}_0 + \sum_{i=1}^{n} \left(\frac{1}{2\pi}\int_{-\pi}^{\pi} \frac{\Phi_u}{\lambda_0|A|^2} z^i\, d\omega (\tilde{M}_i + \tilde{M}_i^T) \right) + \tilde{M} \\
&= \frac{1}{\pi}\int_{0}^{\pi} \frac{\Phi_u}{\lambda_0|A|^2}\, d\omega \frac{\tilde{M}_0}{2} + \sum_{i=1}^{n} \left(\frac{1}{\pi}\int_{0}^{\pi} \frac{\Phi_u}{\lambda_0|A|^2} \cos(i\omega)\, d\omega \frac{\tilde{M}_i + \tilde{M}_i^T}{2} \right) + \tilde{M}. \qquad (3.2)
\end{aligned}
$$

Thus $\bar{M}$ is contained in the $(n+1)$-dimensional affine subspace that is spanned by $\tilde{M}_0, \tilde{M}_i + \tilde{M}_i^T$, $i = 1, \ldots, n$, and shifted by $\tilde{M}$. This completes the proof. ∎

Let us compose a vector $\tilde{x} \in \mathbf{R}^{n+1}$ of real numbers $\tilde{x}_i$, $i = 0, \ldots, n$, defined by $\tilde{x}_i = \frac{1}{\pi}\int_0^{\pi} \frac{\Phi_u}{\lambda_0|A|^2} \cos(i\omega)\, d\omega$.

DEFINITION 3.2. *The quantities $\tilde{x}_k = \frac{1}{\pi}\int_0^{\pi} \frac{\Phi_u}{\lambda_0|A|^2} \cos(k\omega)\, d\omega$, $k \in \mathbf{N}$, are called* trigonometric moments *of the measure $\frac{\Phi_u}{\pi\lambda_0|A|^2}$.*

Since $\frac{1}{\pi\lambda_0|A|^2}$ is strictly positive on $\omega \in [0, \pi]$, we have the following result [30].

PROPOSITION 3.3. *The set* $\{\tilde{x}(\Phi_u) \,|\, \Phi_u$ *is a nonnegative measure on* $[0,\pi]\}$ *equals the moment space* $\mathcal{M}^{(n+1)}$ *of the Tchebycheff system* $\{1, \cos\omega, \ldots, \cos n\omega\}$ *on* $[0,\pi]$.

For definition and properties of moment spaces, see, e.g., [14].

The characterization of the space $\mathcal{M}^{(n+1)}$ is a special case of the extensively studied classical trigonometric moment problem. The following theorem is a consequence of the general result [14, Chapter VI, Theorem 4.1]. It asserts that $\mathcal{M}^{(n+1)}$ can be characterized as the feasible set of an LMI.

THEOREM 3.4. *A point* $\tilde{x} \in \mathbf{R}^{n+1}$ *belongs to the space* $\mathcal{M}^{(n+1)}$ *if and only if the Töplitz matrix composed of the elements of* $\tilde{x}$ *is positive semidefinite, i.e.,*

$$T(\tilde{x}) = \begin{pmatrix} \tilde{x}_0 & \tilde{x}_1 & \ddots & \tilde{x}_n \\ \tilde{x}_1 & \tilde{x}_0 & \ddots & \tilde{x}_{n-1} \\ \ddots & \ddots & \ddots & \ddots \\ \tilde{x}_n & \tilde{x}_{n-1} & \ddots & \tilde{x}_0 \end{pmatrix} \geq 0. \qquad \square \tag{3.3}$$

Since $n+1 \geq 2$, the strict LMI $T(\tilde{x}) > 0$ is feasible. Hence the feasible set of the strict version is the interior of $\mathcal{M}^{(n+1)}$ (see [5, section 2.5]). By $\mathcal{M}$ denote the set of average information matrices corresponding to the interior of $\mathcal{M}^{(n+1)}$. From (3.2) we have

$$\mathcal{M} = \left\{ \bar{M}(\tilde{x}) = \tilde{x}_0 \frac{\tilde{M}_0}{2} + \sum_{i=1}^{n} \tilde{x}_i \frac{\tilde{M}_i + \tilde{M}_i^T}{2} + \tilde{M} \,|\, T(\tilde{x}) > 0 \right\}.$$

DEFINITION 3.5. *Let* Φ_u *be a discrete double-sided power spectrum with support* $\operatorname{supp}\Phi_u \subset [-\pi,\pi]$. *The number of points in the intersection* $\operatorname{supp}\Phi_u \cap [-\pi,\pi)$, *divided by two, is called the index of* Φ_u: *index*$(\Phi_u) = \frac{1}{2}\#(\operatorname{supp}\Phi_u \cap [-\pi,\pi))$. *The index of a single-sided nonnegative discrete measure on* $[0,\pi]$ *is defined as the index of the corresponding double-sided power spectrum.*

Remark. This definition of the index is consistent with its definition for nonnegative discrete measures on the interval $[0,\pi]$ (see, e.g., [14]).

The notion of the index also allows us to characterize the interior of the moment space $\mathcal{M}^{(n+1)}$. The following theorem is a standard result on moment spaces.

THEOREM 3.6 (see, e.g., [14]). *Let* $\tilde{x}$ *be a point in* $\mathcal{M}^{(n+1)}$. *Then the following conditions hold:*

(i) $\tilde{x} \in \mathrm{Bd}(\mathcal{M}^{(n+1)})$ *if and only if there exists a discrete nonnegative measure on* $[0,\pi]$ *with index less than* $\frac{n+1}{2}$ *that induces* $\tilde{x}$. *This measure is unique.*

(ii) $\tilde{x} \in \mathrm{Int}(\mathcal{M}^{(n+1)})$ *if and only if there exists a discrete nonnegative measure on* $[0,\pi]$ *with index* $\frac{n+1}{2}$ *that induces* $\tilde{x}$. *There are exactly two such measures. Exactly one of them contains the frequency* π.

(iii) *Let* $\tilde{x} \in \mathrm{Int}(\mathcal{M}^{(n+1)})$ *and* $\omega \in [0,\pi]$. *Then there exists a unique discrete nonnegative measure on* $[0,\pi]$ *which induces* $\tilde{x}$, *has index not exceeding* $\frac{n+2}{2}$, *and contains the frequency* ω. $\square$

Remark. Measures with index $\frac{n+1}{2}$ which induce $\tilde{x}$ are called *principal realizations* of $\tilde{x}$. The one containing π is called *upper principal*, the other *lower principal*, realization. Measures with index not exceeding $\frac{n+2}{2}$ are called *canonical*.

We see that the interior of $\mathcal{M}^{(n+1)}$ is characterized by those points $\tilde{x}$ which can be represented by a discrete measure with index not less than $\frac{n+1}{2}$.

Now we shall characterize the set of input power spectra Φ_u that lead to nonsingular average information matrices $\bar{M}$.

PROPOSITION 3.7. *Let Φ_u be a power spectrum and $\bar{M}$ the corresponding average information matrix. Then $\bar{M}$ is singular if and only if Φ_u is discrete and its index is less than $\frac{n_b}{2}$.*

Proof. "⇒": Suppose $\bar{M}(\Phi_u)$ is singular. Then there exists a nonzero vector $v = (v_1, \dots, v_{n_a+n_b})^T \in \mathbf{R}^{n_a+n_b}$ such that $v^T \bar{M} v = 0$. Expanding $\bar{M}$, we obtain

$$v^T \bar{M} v = \frac{1}{2\pi} \int_{-\pi}^{\pi} \left(\frac{\Phi_u}{\lambda_0 |A|^2} | -v_1 z^{-1} B - \dots - v_{n_a} z^{-n_a} B + v_{n_a+1} z^{-1} A + \dots + v_{n_a+n_b} z^{-n_b} A|^2 \right.$$
$$\left. + \frac{1}{|A|^2} | - v_1 z^{-1} - \dots - v_{n_a} z^{-n_a}|^2 \right) d\omega = 0$$

with $z = e^{j\omega}$. This yields $-v_1 z^{-1} - \dots - v_{n_a} z^{-n_a} = 0$ for all z on the unit circle and $-v_1 z^{-1} B - \dots - v_{n_a} z^{-n_a} B + v_{n_a+1} z^{-1} A + \dots + v_{n_a+n_b} z^{-n_b} A = 0$ for all $z = e^{j\omega}$ such that $\omega \in \operatorname{supp} \Phi_u$. From the first identity we obtain $v_1 = \dots = v_{n_a} = 0$. Inserting this in the second equality, we get $v_{n_a+1} + \dots + v_{n_a+n_b} z^{-n_b+1} = 0$. Since $v \neq 0$, this equation can have at most $n_b - 1$ different roots. Since Φ_u has to be concentrated at these roots, it is discrete and its index cannot exceed $\frac{n_b-1}{2}$.

"⇐": Suppose Φ_u is discrete with index less than $\frac{n_b}{2}$. Denote the frequencies of Φ_u by $\omega_1, \dots, \omega_{k'}$. They correspond to k different points $z_1, \dots, z_k$ on the unit circle, where $k < n_b$. We have

$$\bar{M} = \frac{1}{2\pi} \sum_{i=1}^{k} \frac{\alpha_i}{\lambda_0 |A(z_i)|^2} \begin{pmatrix} -z_i^{-1} B(z_i) \\ \vdots \\ -z_i^{-n_a} B(z_i) \\ z_i^{-1} A(z_i) \\ \vdots \\ z_i^{-n_b} A(z_i) \end{pmatrix} \begin{pmatrix} -z_i^{-1} B(z_i) \\ \vdots \\ -z_i^{-n_a} B(z_i) \\ z_i^{-1} A(z_i) \\ \vdots \\ z_i^{-n_b} A(z_i) \end{pmatrix}^* + \frac{1}{2\pi} \int_{-\pi}^{\pi} \frac{1}{|A|^2} \begin{pmatrix} -z^{-1} \\ \vdots \\ -z^{-n_a} \\ 0 \\ \vdots \\ 0 \end{pmatrix} \begin{pmatrix} -z^{-1} \\ \vdots \\ -z^{-n_a} \\ 0 \\ \vdots \\ 0 \end{pmatrix}^* d\omega.$$

Here $\alpha_i > 0$ are the weightings of the different frequencies. It is easily seen that the matrices under the sign of the sum are of (complex) rank one, while the integral is a matrix which has a rank of at most n_a. Thus the rank of $\bar{M}$ does not exceed $n_a + n_b - 1$ and $\bar{M}$ is singular. This concludes the proof. ∎

COROLLARY 3.8. *Any $\bar{M} \in \mathcal{M}$ is strictly positive definite.* ∎

This corollary ensures the existence of the inverse $\bar{M}^{-1}$ in the interior of the search space.

By inspecting (2.2), (2.4), and (2.8), the reader will have no difficulty in proving the following monotonicity property.

PROPOSITION 3.9. *Let $\bar{M}_1, \bar{M}_2$ be two positive semidefinite average information matrices, and suppose $\bar{M}_1 \leq \bar{M}_2$. Then the values of the cost functions $\mathcal{J}_1, \mathcal{J}_2$ at $\bar{M}_2$ do not exceed the respective values at $\bar{M}_1$.* ∎

Now we shall include the input energy constraint (2.7) into our framework. By Proposition 3.9, for any constant $\beta > 1$ the value of each of the considered cost functions at a particular input power spectrum Φ_u will be not less than its value at the input power spectrum $\beta \Phi_u$. Thus we can replace constraint (2.7) by

$$\frac{1}{2\pi} \int_{-\pi}^{\pi} \Phi_u(\omega) d\omega = c. \tag{3.4}$$

In [30] it was shown that relations like (3.4) determine affine hyperplanes in the space of feasible average information matrices. Indeed, we have

$$\frac{1}{2\pi}\int_{-\pi}^{\pi}\Phi_u(\omega)d\omega = \frac{\lambda_0}{2\pi}\int_{-\pi}^{\pi}\frac{\Phi_u}{\lambda_0|A|^2}\left(\sum_{i=0}^{n_a}a_i^2+\sum_{i=1}^{n_a}\left(2\sum_{k=0}^{n_a-i}a_{k+i}a_k\right)\cos i\omega\right)d\omega$$
$$= \lambda_0\left(\tilde{x}_0\sum_{i=0}^{n_a}a_i^2+\sum_{i=1}^{n_a}\tilde{x}_i\left(2\sum_{k=0}^{n_a-i}a_{k+i}a_k\right)\right)=c.$$

Thus we get

$$\tilde{x}_0 = \frac{1}{\sum_{i=0}^{n_a}a_i^2}\left(\frac{c}{\lambda_0}-\sum_{i=1}^{n_a}\tilde{x}_i\left(2\sum_{k=0}^{n_a-i}a_{k+i}a_k\right)\right). \tag{3.5}$$

Inserting (3.5) into (3.3), we obtain an LMI on the variables $\tilde{x}_1,\dots,\tilde{x}_n$, i.e., in an n-dimensional space instead of the initial $n+1$-dimensional one. The feasible set of LMI (3.5), (3.3) is a subset of $\mathbf{R}^n$, parametrized by new variables $x_1,\dots,x_n$, which we define by $x_1=\tilde{x}_1,\dots,x_n=\tilde{x}_n$. Denote by $\mathcal{X}_c$ the interior of this set and by $\mathcal{M}_c$ the set of average information matrices corresponding to points in $\mathcal{X}_c$. Thus the optimization takes place over the closure of $\mathcal{X}_c$. Let us stack the variables $x_1,\dots,x_n$ into a vector $x\in\mathbf{R}^n$, to be distinguished from $\tilde{x}\in\mathbf{R}^{n+1}$. While the latter parametrizes the set $\mathcal{M}$, the former parametrizes the set $\mathcal{M}_c$ or $\mathcal{X}_c$.

Using (3.5), we can represent average information matrices in the closure of $\mathcal{M}_c$ as affine functions of the variables $x_1,\dots,x_n$. We have

$$\bar{M} = \bar{M}_0+\sum_{i=1}^{n}x_i\bar{M}_i, \tag{3.6}$$

where

$$\bar{M}_0 = \frac{c}{2\lambda_0\sum_{i=0}^{n_a}a_i^2}\tilde{M}_0+\tilde{M},$$
$$\bar{M}_i = \frac{\tilde{M}_i+\tilde{M}_i^T}{2}-\frac{\sum_{k=0}^{n_a-i}a_{k+i}a_k}{\sum_{i=0}^{n_a}a_i^2}\tilde{M}_0, \qquad i=1,\dots,n_a,$$
$$\bar{M}_i = \frac{\tilde{M}_i+\tilde{M}_i^T}{2}, \qquad i=n_a+1,\dots,n.$$

Thus the closure of $\mathcal{M}_c$ is contained in an n-dimensional affine subspace of the space of symmetric $(n_a+n_b)\times(n_a+n_b)$-matrices.

PROPOSITION 3.10. *The search space of Problems* 1 *and* 2 *can be represented as a section of the trigonometric moment cone* $\mathcal{M}^{(n+1)}$ *and is thus a bounded closed* n*-dimensional convex set. It is parametrized by the variables* $x_1,\dots,x_n$.

Proof. What is left to prove is that relation (3.5) defines a section of the moment cone $\mathcal{M}^{(n+1)}$. Let $\tilde{x}$ be an arbitrary nonzero moment point and $\Phi_u(\omega)$ a measure generating this moment point. Then the ray $\beta\tilde{x}$, $\beta>0$, will be generated by the ray $\beta\Phi_u(\omega)$ of measures. On the latter, exactly one measure satisfies relation (3.4). Therefore exactly one point on the ray $\beta\tilde{x}$ satisfies relation (3.5). ∎

In this section we reduced the infinite-dimensional problem of searching the minimum of the cost functions over the set of all admissible input power spectra to the finite-dimensional problem of searching the minimum over a section of a moment cone. Moreover, we described the search space as an LMI, namely (3.3), (3.5), and showed that it is bounded.

4. Quasiconvexity. In the previous section we proved the search space to be a bounded convex set. In this section we prove quasiconvexity of cost functions $\mathcal{J}_1, \mathcal{J}_2$ and thus of Problems 1 and 2.

PROPOSITION 4.1. *On $\mathcal{M}$ cost function $\mathcal{J}_1$ is quasiconvex with respect to $\bar{M}$.*

Proof. The worst-case chordal distance can be expressed as a solution to a generalized eigenvalue problem (GEVP) [10, Theorem 5.1]. We have $\kappa_{WC}(G(e^{j\omega}, \hat{\theta}), \mathcal{D}) = \sqrt{\gamma_{opt}}$, where γ_{opt} is the solution of the GEVP

$$\text{minimize } \gamma \text{ subject to } \quad F_0 + \gamma F_1 + \tau R \geq 0, \quad \tau \geq 0. \tag{4.1}$$

Here F_0, F_1, R are symmetric matrices given by

$$F_0 = V \begin{pmatrix} -1 & 0 & -\mathrm{Im}G(e^{j\omega}, \hat{\theta}) & \mathrm{Re}G(e^{j\omega}, \hat{\theta}) \\ 0 & -1 & \mathrm{Re}G(e^{j\omega}, \hat{\theta}) & \mathrm{Im}G(e^{j\omega}, \hat{\theta}) \\ -\mathrm{Im}G(e^{j\omega}, \hat{\theta}) & \mathrm{Re}G(e^{j\omega}, \hat{\theta}) & -|G(e^{j\omega}, \hat{\theta})|^2 & 0 \\ \mathrm{Re}G(e^{j\omega}, \hat{\theta}) & \mathrm{Im}G(e^{j\omega}, \hat{\theta}) & 0 & -|G(e^{j\omega}, \hat{\theta})|^2 \end{pmatrix} V^T,$$

$$F_1 = (1 + |G(e^{j\omega}, \hat{\theta})|^2) V V^T,$$

$$R = \begin{pmatrix} I_{n_a+n_b} \\ -\hat{\theta}^T \end{pmatrix} \bar{M} \begin{pmatrix} I_{n_a+n_b} & -\hat{\theta} \end{pmatrix} - \begin{pmatrix} 0 & \cdots & 0 \\ \vdots & \ddots & \vdots \\ 0 & \cdots & \frac{\chi^2_{n_a+n_b}(\alpha)}{N} \end{pmatrix}, \tag{4.2}$$

where V is a $(n_a + n_b + 1) \times 4$-matrix defined by

$$V = \begin{pmatrix} \mathrm{Re}Z_N^T & \mathrm{Im}Z_N^T & \mathrm{Im}Z_D^T & \mathrm{Re}Z_D^T \\ 0 & 0 & 0 & 1 \end{pmatrix}$$

with Z_N, Z_D given by (2.3).

We will now show that γ_{opt} is quasiconvex with respect to R. Choose $\lambda \in (0,1)$ and let R_1, R_2 be symmetric matrices of appropriate dimension. Suppose γ, τ_1, τ_2 are nonnegative numbers such that $F_0 + \gamma F_1 + \tau_1 R_1 \geq 0, F_0 + \gamma F_1 + \tau_2 R_2 \geq 0$. We have to show that there exists $\tau \geq 0$ such that $F_0 + \gamma F_1 + \tau(\lambda R_1 + (1-\lambda) R_2) \geq 0$. If $\tau_1 = 0$ or $\tau_2 = 0$, then we can choose $\tau = 0$. Let $\tau_1 \tau_2 > 0$. Define

$$\lambda' = \frac{\lambda \tau_2}{\lambda \tau_2 + (1-\lambda)\tau_1}, \quad \tau = \frac{\tau_1 \tau_2}{\lambda \tau_2 + (1-\lambda)\tau_1}.$$

Obviously $\lambda' \in (0,1)$ and $\tau > 0$. It is easily verified that $\lambda\tau = \lambda'\tau_1, (1-\lambda)\tau = (1-\lambda')\tau_2$. Hence we have

$$F_0 + \gamma F_1 + \tau(\lambda R_1 + (1-\lambda) R_2) = \lambda'(F_0 + \gamma F_1 + \tau_1 R_1) + (1-\lambda')(F_0 + \gamma F_1 + \tau_2 R_2) \geq 0.$$

Thus if γ is feasible for $R = R_1$ and for $R = R_2$, then it is also feasible for any linear convex combination of R_1, R_2. It follows that $\gamma_{opt}|_{R=\lambda R_1 + (1-\lambda) R_2} \leq \max\{\gamma_{opt}|_{R=R_1}, \gamma_{opt}|_{R=R_2}\}$, i.e., quasiconvexity of γ_{opt} with respect to R.

Suppose $\omega \in [0, \pi]$ is fixed. Note that R affinely depends on $\bar{M}$, while F_0 and F_1 are constant for given ω. Therefore γ_{opt} is quasiconvex with respect to $\bar{M}$ for fixed ω. But quasiconvexity is preserved under the operation of taking the maximum over a family of functions and under rescaling by a strictly monotonic function (in this case the square root). This completes the proof. ∎

PROPOSITION 4.2. *On $\mathcal{M}$, cost function $\mathcal{J}_2$ is quasiconvex with respect to $\bar{M}$.*

Proof. Let us compute cost function $\mathcal{J}_2$.

$$\mathcal{J}_2 = \lim_{\varepsilon\to 0}\frac{\mathcal{J}_1(\varepsilon^{-2}\bar{M})}{\varepsilon} = \sup_{\omega\in[0,\pi]}\lim_{\varepsilon\to 0}\left(\varepsilon^{-1}\sup_{z\in U_\varepsilon(\omega)}\frac{|G(e^{j\omega},\hat{\theta})-z|}{\sqrt{1+|G(e^{j\omega},\hat{\theta})|^2}\sqrt{1+|z|^2}}\right)$$
$$= \sup_{\omega\in[0,\pi]}\frac{d}{d\varepsilon}|_{\varepsilon=0}\sup_{z\in U_\varepsilon(\omega)}\frac{|G(e^{j\omega},\hat{\theta})-z|}{\sqrt{1+|G(e^{j\omega},\hat{\theta})|^2}\sqrt{1+|z|^2}}.$$

Here $U_\varepsilon(\omega)$ denotes the set $\{z = G(e^{j\omega},\theta)|\frac{N}{\chi^2_{n_a+n_b}(\alpha)}(\theta-\hat{\theta})^T\bar{M}(\theta-\hat{\theta}) < \varepsilon^2\}$. The expression $\sqrt{1+|z|^2}$ tends to $\sqrt{1+|G(e^{j\omega},\hat{\theta})|^2}$ as $\varepsilon\to 0$; therefore

$$\mathcal{J}_2 = \sup_{\omega\in[0,\pi]}\frac{\frac{d}{d\varepsilon}|_{\varepsilon=0}\sup_{z\in U_\varepsilon(\omega)}|z-G(e^{j\omega},\hat{\theta})|}{1+|G(e^{j\omega},\hat{\theta})|^2} = \sup_{\omega\in[0,\pi]}\frac{\varepsilon^{-1}\sup_{z\in U_\varepsilon(\omega)}|T(\theta-\hat{\theta})|}{1+|G(e^{j\omega},\hat{\theta})|^2},$$

where the $2\times(n_a+n_b)$-matrix T is given by

$$T = \begin{pmatrix} \mathrm{Re}\frac{\partial G(e^{j\omega},\theta)}{\partial\theta}|_{\theta=\hat{\theta}} \\ \mathrm{Im}\frac{\partial G(e^{j\omega},\theta)}{\partial\theta}|_{\theta=\hat{\theta}} \end{pmatrix}.$$

If T has full rank, then, following [2], we can write the term $\varepsilon^{-1}\sup_{z\in U_\varepsilon(\omega)}|T(\theta-\hat{\theta})|$ as

$$\left(\lambda_{\min}\left(\left(T\left(\frac{N}{\chi^2_{n_a+n_b}(\alpha)}\bar{M}\right)^{-1}T^T\right)^{-1}\right)\right)^{-1/2} = \sqrt{\frac{\chi^2_{n_a+n_b}(\alpha)}{N}}(\lambda_{\max}(T\bar{M}^{-1}T^T))^{1/2}.$$

By $\lambda_{\min}$ and $\lambda_{\max}$ the minimal and maximal eigenvalues, respectively, are denoted.

If T is rank deficient, we can find vectors $w\in\mathbf{R}^{n_a+n_b}$ and $w_1\in\mathbf{R}^2$ such that $|w_1|=1$ and $T = w_1w^T$. We exclude the trivial case $T=0$ from consideration and assume $w\neq 0$. Then

$$\varepsilon^{-1}\sup_{z\in U_\varepsilon(\omega)}|T(\theta-\hat{\theta})| = \left(\left(w^T\left(\frac{N}{\chi^2_{n_a+n_b}(\alpha)}\bar{M}\right)^{-1}w\right)^{-1}\right)^{-1/2}$$
$$= \sqrt{\frac{\chi^2_{n_a+n_b}(\alpha)}{N}}(w^T\bar{M}^{-1}w)^{1/2}.$$

But we have anyway $w^T\bar{M}^{-1}w = \lambda_{\max}(T\bar{M}^{-1}T^T)$.

Hence in either case we obtain

$$\mathcal{J}_2 = \sqrt{\frac{\chi^2_{n_a+n_b}(\alpha)}{N}}\sup_{\omega\in[0,\pi]}\frac{(\lambda_{\max}(T(\omega)\bar{M}^{-1}T(\omega)^T))^{1/2}}{1+|G(e^{j\omega},\hat{\theta})|^2}. \tag{4.3}$$

It is well known that the inverse P^{-1} of a symmetric positive definite matrix P and the maximal eigenvalue $\lambda_{\max}(Q)$ of a symmetric positive semidefinite matrix Q are convex functions with respect to P or Q, respectively (see, e.g., [8]). Hence $\lambda_{\max}(T\bar{M}^{-1}T^T)$ is convex with respect to $\bar{M}$ for fixed ω. Since the operation of taking

the maximum over a family of functions preserves convexity, we have that $\mathcal{J}_2^2$ is a convex function with respect to $\bar{M}$. By strict monotonicity of the square root, this yields quasiconvexity of $\mathcal{J}_2$. ∎

In the preceding two sections we have shown that Problems 1 and 2 stated in section 2 are quasiconvex. In the next section we will provide the necessary tools that allow the user to apply standard convex algorithms to solve these problems numerically.

5. Cutting planes. Most methods in convex analysis are based on the notion of a cutting plane (see, e.g., [5]). Suppose $S \subset \mathbf{R}^m$ is a convex set and $f : S \to \mathbf{R}$ is a quasiconvex function defined on S.

DEFINITION 5.1. *A cutting plane to f at a point $x^{(0)} \in S$ is defined by a nonzero vector $g \in \mathbf{R}^m$ such that $f(x^{(0)}) \leq f(x)$ for any $x \in S$ satisfying the inequality $g^T(x - x^{(0)}) \geq 0$.*

Thus the global minimum of f on S lies in the half-space $\{x \,|\, g^T(x - x^{(0)}) \leq 0\}$. By definition of quasiconvexity, a cutting plane always exists.

In this section we will compute cutting planes for cost functions $\mathcal{J}_1, \mathcal{J}_2$ at an arbitrary point $x^{(0)} \in \mathcal{X}_c$.

Let $\bar{M}^{(0)}$ be the average information matrix corresponding to $x^{(0)}$. By Corollary 3.8 the matrix $\bar{M}^{(0)}$ is positive definite.

We shall now compute a cutting plane for $\mathcal{J}_1 = \max_{\omega \in [0,\pi]} \kappa_{WC}(G(e^{j\omega}, \hat{\theta}), \mathcal{D})$. Denote by $\omega^{(0)}$ the frequency where the worst-case chordal distance κ_{WC} attains its maximum. The value of $\omega^{(0)}$ can be found, e.g., by a grid search with subsequent refinement using a denser grid in the vicinity of the maximum. It is easily seen that a cutting plane to the function $\kappa_{WC}(G(e^{j\omega^{(0)}}, \hat{\theta}), \mathcal{D})$ or its square will also be a cutting plane to $\mathcal{J}_1$. In what follows we will assume that ω is equal to $\omega^{(0)}$ and omit it as an argument.

Thus our goal is to find a cutting plane for the optimum value γ_{opt} of GEVP (4.1), (4.2), considered as a function of x. Note that F_0, F_1 are independent of x, while R depends on x via $\bar{M}$. By (3.6), we can represent R as $R(x) = R_0 + \sum_{i=1}^n x_i R_i$ with

$$R_0 = \begin{pmatrix} I_{n_a+n_b} \\ -\hat{\theta}^T \end{pmatrix} \bar{M}_0 \begin{pmatrix} I_{n_a+n_b} & -\hat{\theta} \end{pmatrix} - \begin{pmatrix} 0 & \cdots & 0 \\ \vdots & \ddots & \vdots \\ 0 & \cdots & \frac{\chi^2_{n_a+n_b}(\alpha)}{N} \end{pmatrix},$$

$$R_i = \begin{pmatrix} I_{n_a+n_b} \\ -\hat{\theta}^T \end{pmatrix} \bar{M}_i \begin{pmatrix} I_{n_a+n_b} & -\hat{\theta} \end{pmatrix}.$$

Let $\gamma_{opt}^{(0)}, \tau_{opt}^{(0)}$ be the optimal values for γ, τ in GEVP (4.1), (4.2) at $x = x^{(0)}$. Then the matrix $F_0 + \gamma_{opt}^{(0)} F_1 + \tau_{opt}^{(0)} R$ is both singular and positive semidefinite. Let V^0 be the nullspace of this matrix.

PROPOSITION 5.2. *If $\tau_{opt}^{(0)} > 0$, then there exists a unit length vector $v \in V^0$ such that $v^T R v = 0$. If $\tau_{opt}^{(0)} = 0$, then there exists a unit length vector $v \in V^0$ such that $v^T R v \leq 0$. In either case the vector $g \in \mathbf{R}^n$ given componentwise by $g_i = -v^T R_i v$, if it is nonzero, defines a cutting plane for the function $\mathcal{J}_1$. If g is zero, $\mathcal{J}_1$ achieves a minimum at $x^{(0)}$.*

The proof of this proposition can be found in the appendix.

Let us now compute a cutting plane for cost function $\mathcal{J}_2$, which is given by (4.3). Denote by $\omega^{(0)}$ the frequency at which the function $\frac{\lambda_{\max}(T(\omega)\bar{M}^{-1}T(\omega)^T)}{(1+|G(e^{j\omega},\hat{\theta})|^2)^2}$ attains its

maximum. Let $v \in \mathbf{R}^2$ be a unit length eigenvector to the maximal eigenvalue of the matrix $T(\omega^{(0)})\bar{M}^{-1}T(\omega^{(0)})^T$.

PROPOSITION 5.3. *Let $g \in \mathbf{R}^n$ be defined componentwise by $g_i = -v^T T(\omega^{(0)}) \cdot \bar{M}^{-1}\bar{M}_i\bar{M}^{-1}T(\omega^{(0)})^T v$. Then g defines a cutting plane for the cost function $\mathcal{J}_2$ at $x^{(0)}$, if $g \neq 0$, and $\mathcal{J}_2$ attains a minimum at $x^{(0)}$, if $g = 0$.*

Proof. Consider

$$f(x) = \sqrt{\frac{\chi^2_{n_a+n_b}(\alpha)}{N}} \frac{\left(v^T T(\omega^{(0)}) \left(\bar{M}_0 + \sum_{i=1}^n x_i \bar{M}_i\right)^{-1} T(\omega^{(0)})^T v\right)^{1/2}}{1 + |G(e^{j\omega^{(0)}}, \hat{\theta})|^2}.$$

By definition we have $f(x^{(0)}) = \mathcal{J}_2(x^{(0)})$, but $f(x) \leq \mathcal{J}_2(x)$ for any $x \in \mathcal{X}_c$.

Let $x \in \mathcal{X}_c$ be a point such that $g^T(x - x^{(0)}) \geq 0$. We shall show that $f(x^{(0)}) \leq f(x)$, which would imply $\mathcal{J}_2(x^{(0)}) \leq \mathcal{J}_2(x)$. This is equivalent to $\tilde{f}(x^{(0)}) \leq \tilde{f}(x)$, where $\tilde{f}$ is defined by

$$\begin{aligned}
\tilde{f}(x) &= \frac{N}{\chi^2_{n_a+n_b}(\alpha)}(1 + |G(e^{j\omega^{(0)}}, \hat{\theta})|^2)^2 f^2(x) \\
&= v^T T(\omega^{(0)}) \left(\bar{M}_0 + \sum_{i=1}^n x_i \bar{M}_i\right)^{-1} T(\omega^{(0)})^T v \\
&= \operatorname{tr}\left(T(\omega^{(0)})^T v v^T T(\omega^{(0)}) \left(\bar{M}_0 + \sum_{i=1}^n x_i \bar{M}_i\right)^{-1}\right).
\end{aligned}$$

In other words, we have to show that g defines a cutting plane for $\tilde{f}$. It is well known (see, e.g., [30, p. 39]) that $\tilde{f}$, being of the form $\operatorname{tr} W\bar{M}^{-1}$ with $W \geq 0$, is a smooth convex function on $\mathcal{X}_c$. Hence a cutting plane to $\tilde{f}$ is defined by its gradient, which is identical to g.

If $g = 0$, then $\tilde{f}$ attains a minimum at $x^{(0)}$. Hence f attains a minimum at $x^{(0)}$, which yields $\mathcal{J}_2(x^{(0)}) \leq \mathcal{J}_2(x)$ for any $x \in \mathcal{X}_c$. This concludes the proof. ∎

The results of sections 3 to 5, i.e., the LMI description of the feasible set and the knowledge of cutting planes, allow the user to apply a whole range of convex optimization methods for solving Problems 1 and 2. For a description of different methods, see, e.g., [5], [22].

6. Error assessment of the solution. Suppose we seek the minimum of a quasiconvex cost function $\mathcal{J}(x)$ on the closure of $\mathcal{X}_c$. Let us assume that with some method an approximation $x^{(0)} \in \mathcal{X}_c$ of the optimal value x^* was obtained together with an upper bound on the scalar product $g^T(x^{(0)} - x^*)$ (which is usually delivered by standard convex analysis methods), where g is a vector defining a cutting plane to $\mathcal{J}$ at $x^{(0)}$.

In this section we assess the quality of the approximation $x^{(0)}$, i.e., we derive a bound on the error $\mathcal{J}(x^{(0)}) - \mathcal{J}(x^*)$. The results presented can be used for designing termination criteria for iterative optimization algorithms, guaranteeing a prespecified level of accuracy.

PROPOSITION 6.1. *Let $x^{(0)} \in \mathcal{X}_c$ be a feasible point and $\omega^{(0)}$ a frequency at which the worst-case chordal distance $\kappa_{WC}(G(e^{j\omega}, \hat{\theta}), \mathcal{D}(x^{(0)}))$ attains its maximum. Suppose cost function $\mathcal{J}_1$ attains its minimum at x^*. Let vectors v and g be defined as in Proposition 5.2. If $v^T F_1 v > 0$, then the following bound on the error $\mathcal{J}_1(x^{(0)}) -$*

$\mathcal{J}_1(x^*)$ *holds:*

$$\mathcal{J}_1^2(x^{(0)}) - \mathcal{J}_1^2(x^*) \leq N \frac{\mathcal{J}_1^2(x^{(0)})}{\chi^2_{n_a+n_b}(\alpha) v^T F_1 v} (1 + |G(e^{j\omega^{(0)}}, \hat{\theta})|^2)^2 |1 + Z_D \hat{\theta}|^2 g^T (x^{(0)} - x^*),$$

where Z_D *is defined in* (2.3).

Note that the condition $v^T F_1 v > 0$ is satisfied whenever $\mathcal{J}_1(x^{(0)}) < 1$. This inequality holds at least in the vicinity of x^* if $\mathcal{J}_1$ is not identically 1 on $\mathcal{X}_c$.

Proof of Proposition 6.1. Denote by γ^*_{opt} the square of the worst-case chordal distance $\kappa_{WC}(G(e^{j\omega^{(0)}}, \hat{\theta}), \mathcal{D}(x^*))$ at frequency $\omega^{(0)}$ and at the point x^*. Let τ^*_{opt} be the corresponding optimal value of τ. Then we have $\mathcal{J}_1^2(x^*) \geq \gamma^*_{opt}$.

By definition we have at frequency $\omega^{(0)}$ the relations $v^T(F_0 + \gamma^{(0)}_{opt} F_1 + \tau^{(0)}_{opt} R)v = 0$, $(\tau - \tau^{(0)}_{opt}) v^T R(x^{(0)}) v \leq 0$ for any $\tau \geq 0$, and $v^T(R(x) - R(x^{(0)}))v \leq -g^T(x - x^{(0)})$ for any x. Hence

$$v^T(F_0 + \gamma^*_{opt} F_1 + \tau^*_{opt} R(x^*))v \leq (\gamma^*_{opt} - \gamma^{(0)}_{opt}) v^T F_1 v - \tau^*_{opt} g^T (x^* - x^{(0)}).$$

Since the left-hand side of this inequality is nonnegative, we obtain

$$\mathcal{J}_1^2(x^{(0)}) - \mathcal{J}_1^2(x^*) \leq \gamma^{(0)}_{opt} - \gamma^*_{opt} \leq \frac{\tau^*_{opt}}{v^T F_1 v} g^T (x^{(0)} - x^*).$$

Let us now derive a bound on τ^*_{opt}. We have $(v')^T(F_0 + \gamma^*_{opt} F_1 + \tau^*_{opt} R)v' \geq 0$ for any vector $v' \in \mathbf{R}^{n_a+n_b+1}$. Choose $v' = (\hat{\theta}^T \ 1)^T$. By direct calculation one can show that $(v')^T F_0 v' = 0, (v')^T F_1 v' = (1 + |G|^2)^2 |1 + Z_D \hat{\theta}|^2, (v')^T R v' = -\frac{\chi^2_{n_a+n_b}(\alpha)}{N}$. Thus we have

$$\tau^*_{opt} \leq \frac{N}{\chi^2_{n_a+n_b}(\alpha)} \gamma^*_{opt} (1 + |G|^2)^2 |1 + Z_D \hat{\theta}|^2 \leq \frac{N}{\chi^2_{n_a+n_b}(\alpha)} \gamma^{(0)}_{opt} (1 + |G|^2)^2 |1 + Z_D \hat{\theta}|^2.$$

Combining the obtained inequalities, we complete the proof. ∎

PROPOSITION 6.2. *Let* $x^{(0)} \in \mathcal{X}_c$ *be a feasible point. Let* $\omega^{(0)}$ *be a frequency at which the quantity* $\frac{\lambda_{\max}(T(\omega)\bar{M}^{-1}(x^{(0)})T(\omega)^T)}{(1+|G(e^{j\omega}, \hat{\theta})|^2)^2}$ *attains its maximum. Suppose cost function* $\mathcal{J}_2$ *attains its minimum at* x^*. *Let* g *be defined as in Proposition* 5.3. *Then the following bound on the error* $\mathcal{J}_2(x^{(0)}) - \mathcal{J}_2(x^*)$ *holds:*

$$\mathcal{J}_2^2(x^{(0)}) - \mathcal{J}_2^2(x^*) \leq \frac{\chi^2_{n_a+n_b}(\alpha)}{N(1 + |G(e^{j\omega^{(0)}}, \hat{\theta})|^2)^2} g^T (x^{(0)} - x^*).$$

Proof. Recall that we defined two functions $f(x), \tilde{f}(x)$ in the proof of Proposition 5.3 and identified g as the gradient of $\tilde{f}$. Since $\tilde{f}$ is convex, we can bound it by its first order Taylor polynomial, i.e., $\tilde{f}(x^{(0)}) - \tilde{f}(x^*) \leq g^T(x^{(0)} - x^*)$. Therefore we have

$$\begin{aligned}\mathcal{J}_2^2(x^{(0)}) - \mathcal{J}_2^2(x^*) \leq f^2(x^{(0)}) - f^2(x^*) &= \frac{\chi^2_{n_a+n_b}(\alpha)}{N(1 + |G(e^{j\omega^{(0)}}, \hat{\theta})|^2)^2} (\tilde{f}(x^{(0)}) - \tilde{f}(x^*)) \\ &\leq \frac{\chi^2_{n_a+n_b}(\alpha)}{N(1 + |G(e^{j\omega^{(0)}}, \hat{\theta})|^2)^2} g^T (x^{(0)} - x^*). \qquad ∎\end{aligned}$$

The propositions proven in this section enable the user to tell whether a given solution $x^{(0)}$, delivered, e.g., by the current iteration step, satisfies the prespecified accuracy requirements. This information can be used, e.g., to decide whether further iterations are necessary.

7. Design of input signals. Let us now turn to the question of how to design an input signal from $x^{(0)}$. By Theorem 3.6, there exist moment points which can be realized only by discrete spectra. On the other hand, any moment point can be realized by a discrete spectrum. Therefore we propose here the following two-step procedure. First a discrete input power spectrum generating the moment point $x^{(0)}$ is computed, and then a multisine input with the desired spectrum is generated. This procedure in no way restricts the optimality of the solution.

We weaken the condition $x^{(0)} \in \mathcal{X}_c$ and suppose that $x^{(0)}$ is in the closure of $\mathcal{X}_c$. The point $x^{(0)}$ corresponds to a point $\tilde{x} = (\tilde{x}_0, \tilde{x}_1, \ldots, \tilde{x}_n)$ in moment space $\mathcal{M}^{(n+1)}$. Here $\tilde{x}_i$ equals the ith component of $x^{(0)}$ for $i = 1, \ldots, n$, and $\tilde{x}_0$ is given by (3.5).

Our goal will be to construct a realization of $\tilde{x}$. By Theorem 3.6, there exists a discrete realization with index not greater than $\frac{n+1}{2}$.

Denote by $\tilde{x}^s(\omega) \in \mathcal{M}^{(n+1)}$ the moment point induced by the design measure that satisfies constraint (3.4) and concentrates all power at the single frequency ω. Then the ith entry of $\tilde{x}^s(\omega)$ is given by $\frac{c}{\lambda_0 |A(\omega)|^2} \cos(i\omega)$. Since (3.4) defines an affine section of the convex cone $\mathcal{M}^{(n+1)}$ and $\tilde{x}$ satisfies (3.4), $\tilde{x}$ is a convex combination of points on the curve $\{\tilde{x}^s(\omega) \,|\, \omega \in [0, \pi]\}$.

If $\tilde{x}$ equals $\tilde{x}^s(\pi)$, then we have already found a realization of index $\frac{1}{2}$. In this case this is the only possible realization.

Suppose now that $\tilde{x}$ is not equal to $\tilde{x}^s(\pi)$. To construct a realization of $\tilde{x}$, we will exploit an idea that is used to prove Theorem 3.6 (see, e.g., [14]).

Consider the line going through the points $\tilde{x}$ and $\tilde{x}^s(\pi)$. This line has an interval in common with the convex set $\mathcal{M}^{(n+1)}$. This interval is finite, because it lies on the section defined by (3.4), and nondegenerated, because it contains two different points $\tilde{x}$ and $\tilde{x}^s(\pi)$. By Theorem 3.6 part (i), $\tilde{x}^s(\pi)$ is one of the endpoints of this interval. Denote the other endpoint by $\tilde{x}^{bd}$. The computation of $\tilde{x}^{bd}$ from $\tilde{x}$ and $\tilde{x}^s(\pi)$ can be reduced to a standard GEVP using LMI description (3.3) of the set $\mathcal{M}^{(n+1)}$. For treatment of this type of problem, see, e.g., [5].

Thus $\tilde{x}$ is a linear convex combination of the points $\tilde{x}^s(\pi)$ and $\tilde{x}^{bd}$. Any realization of $\tilde{x}^{bd}$ will deliver us a realization of $\tilde{x}$. Note that $\tilde{x}^{bd}$ lies on the boundary of $\mathcal{M}^{(n+1)}$. By Theorem 3.6 part (i) it has only one realization, which is of index less than $\frac{n+1}{2}$. Hence the realization of $\tilde{x}$ that we obtain with the described procedure will have an index not exceeding $\frac{n+1}{2}$. If $\tilde{x}$ lies in the interior of $\mathcal{M}^{(n+1)}$, then this realization contains the frequency π and is therefore the upper principal realization of $\tilde{x}$.

We shall now construct the realization of $\tilde{x}^{bd}$. Denote the frequencies which are involved in this realization by ω_i, $i = 1, \ldots, k$. Then the point $\tilde{x}^{bd}$ is a nondegenerated linear convex combination of $\tilde{x}^s(\omega_1), \ldots, \tilde{x}^s(\omega_k)$. We can write $\tilde{x}^{bd} = \sum_{i=1}^{k} \lambda_i \tilde{x}^s(\omega_i)$, where $\lambda_i > 0$ and $\sum_{i=1}^{k} \lambda_i = 1$.

Since $\tilde{x}^{bd}$ lies on the boundary of $\mathcal{M}^{(n+1)}$, there exists a supporting hyperplane E at $\tilde{x}^{bd}$. Note that E is a linear subspace, because $\mathcal{M}^{(n+1)}$ is a convex cone. The construction of a supporting hyperplane proceeding from LMI description (3.3) of $\mathcal{M}^{(n+1)}$ is a standard procedure and is described, e.g., in [5].

LEMMA 7.1. *The points $\tilde{x}^s(\omega_1), \ldots, \tilde{x}^s(\omega_k)$ lie in E.*

Proof. Denote by n_E the normal vector to E that points toward $\mathcal{M}^{(n+1)}$ and by L_E the linear functional $x \mapsto \langle n_E, x \rangle$ defined by n_E. For any $\omega \in [0, \pi]$ we have $L_E(\tilde{x}^s(\omega)) \geq 0$. On the other hand, $L_E(\tilde{x}^{bd}) = \sum_{i=1}^{k} \lambda_i L_E(\tilde{x}^s(\omega_i)) = 0$, because $\tilde{x}^{bd}$ lies in E. Hence for all i we have $L_E(\tilde{x}^s(\omega_i)) = 0$, i.e., $\tilde{x}^s(\omega_i) \in E$. ∎

LEMMA 7.2. *There exist maximally $\frac{n}{2} + 1$ frequencies such that the corresponding points $\tilde{x}^s(\omega)$ lie in E.*

Proof. Consider $p_E : [0, \pi] \to \mathbf{R}$ defined by $p_E(\omega) = L_E(\tilde{x}^s(\omega))\frac{\lambda_0 |A(\omega)|^2}{c}$. By definition, p_E is a trigonometric polynomial. Since $L_E(\tilde{x}^s(\omega))$ is nonnegative for all ω, p_E is too. Now we can apply a classical result from Tchebycheff system theory which states that p_E can have at most $\frac{n}{2} + 1$ zeros. But the zeros of p_E lie exactly at those frequencies whose corresponding points $\tilde{x}^s(\omega)$ lie in E. □

Now we are able to obtain a finite set of frequencies that is guaranteed to contain $\omega_1, \ldots, \omega_k$. Namely, we have to find the zeros, which are at the same time local minima, of the trigonometric polynomial $p_E(\omega)$.

Once we have found a set of frequencies $\omega_1, \ldots, \omega_k, \omega_{k+1}, \ldots, \omega_{k+k'}$ such that the convex hull of the points $\tilde{x}^s(\omega_1), \ldots, \tilde{x}^s(\omega_{k+k'})$ contains $\tilde{x}^{bd}$, it is a standard linear quadratic (LQ) programming problem to find the weights associated with the different frequencies. Namely, the weights λ_j minimize the squared distance $|\tilde{x}^{bd} - \sum_{j=1}^{k+k'} \lambda_j \tilde{x}^s(\omega_j)|^2$, which is a quadratic polynomial in the λ_j. Note that the number of frequencies involved is not greater than $\frac{n}{2} + 1$ and hence not greater than n. Therefore the points $\tilde{x}^s(\omega_1), \ldots, \tilde{x}^s(\omega_{k+k'})$ are linearly independent and the minimized polynomial has a positive definite quadratic part. An efficient algorithm for solving this type of problems is, e.g., the Beale algorithm (see [1]).

Suppose that a discrete realization of $\tilde{x}$ with frequencies $\omega_1, \ldots, \omega_m$ and associated weights $\lambda_1, \ldots, \lambda_m$ is available. Then the multisine input $u(t) = \sum_{i=1}^{m} \alpha_i \sin(t\omega_i + \phi_i)$ with $\alpha_i = \sqrt{2c\lambda_i}$, ϕ_i arbitrary, if $\omega_i \neq 0, \pi$, and $\alpha_i = \sqrt{c\lambda_i}$, $\phi_i = \pm\frac{\pi}{2}$, if $\omega_i \in \{0, \pi\}$, has the desired input power spectrum (see, e.g., [30]).

Often it is also possible to obtain the desired power spectrum by using binary signals (see [30, p. 29] and references cited therein).

8. Simulation results. Consider the true system $y = G_0 u + H_0 e = \frac{B(z)}{A(z)} u + \frac{1}{A(z)} e$ with $G_0 = \frac{B(z)}{A(z)} = \frac{0.1047z^{-1} + 0.0872z^{-2}}{1 - 1.5578z^{-1} + 0.5769z^{-2}}$. Here u is the input, subject to the energy constraint $\bar{E}u^2(t) = 1$, and e is white Gaussian noise with variance 0.1.

The system is to be identified within an ARX model structure of order two. The number of data points to be collected is $N = 1000$. The aim is to minimize the worst-case ν-gap of the uncertainty region around the identified model corresponding to a confidence level of $\alpha = 0.95$.

In a Monte-Carlo simulation, 500 runs were performed. Each run consisted of five identification experiments: one preliminary experiment and four mutually independent secondary experiments based on this preliminary experiment, corresponding to the four different cost functions $\mathcal{J}_1$, $\mathcal{J}_2$, D-optimality, and E-optimality.

In the preliminary experiment, the input was chosen to be white Gaussian noise with variance 1. The parameter vector and noise variance identified in the preliminary experiment were used as a priori estimates of the true parameter vector and the true noise variance for designing the input power spectrum for the series of second experiments. In two of the second experiments, the input power spectrum minimized the cost functions $\mathcal{J}_1, \mathcal{J}_2$, respectively. The actual input sequence was a multisine having the evaluated optimal power spectrum. For comparison, two other second experiments with D-optimal and E-optimal input power spectra were performed. After each identification experiment the worst-case ν-gap of the identified uncertainty region was recorded.

The noise realizations for the five experiments within one run and for different runs were different, as well as the input realizations for the preliminary experiments of the different runs.

In Figure 8.1 the worst-case ν-gap obtained from the preliminary experiment with

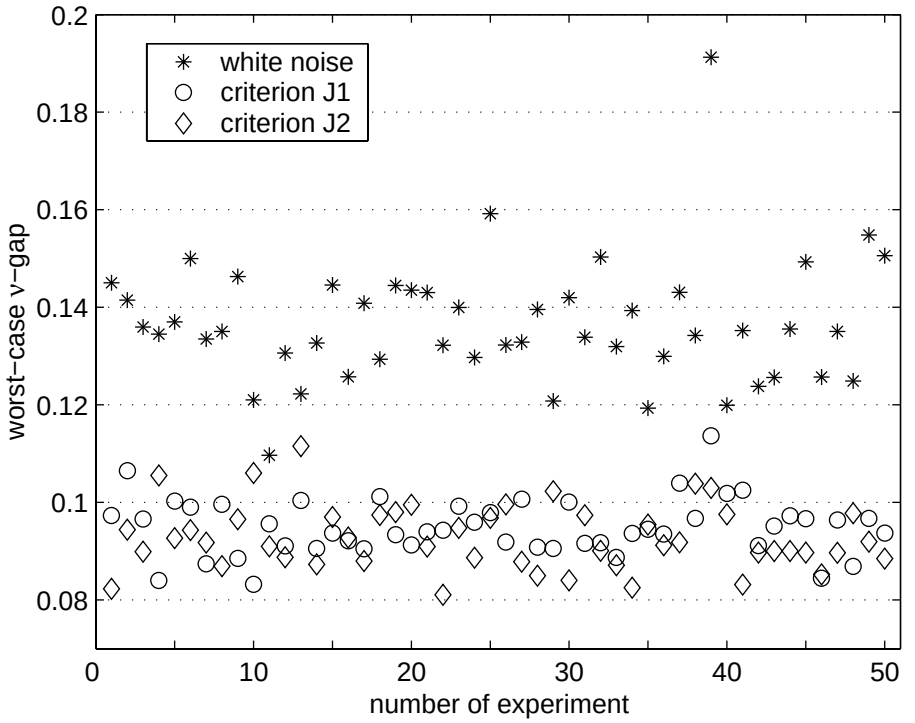

FIG. 8.1. *Identification with white and subsequently estimated optimal input.*

white noise input, as well as from the experiments with inputs optimized with respect to $\mathcal{J}_1$ and $\mathcal{J}_2$, respectively, is shown for the first 50 simulation runs. The mean over 500 runs of the worst-case ν-gap resulting from the preliminary experiments equals 0.1345. The means of the worst-case ν-gap resulting from the experiments with multisine input optimized with respect to criteria $\mathcal{J}_1, \mathcal{J}_2$ are 0.0937 and 0.0927, respectively. The difference between them is statistically significant (2×1.64 standard deviations). The means of the worst-case ν-gap resulting from the experiments with D- and E-optimal multisine input are equal to 0.1434 and 0.1055, respectively.

It is evident that using inputs optimized with respect to criteria $\mathcal{J}_1, \mathcal{J}_2$ gives better results than using white noise input or input optimized with respect to the classical D- and E-optimality criteria. Note also that the inputs optimized with respect to the cost function $\mathcal{J}_2$, which is a first order approximation of the exact cost function $\mathcal{J}_1$, give better results than $\mathcal{J}_1$, despite the fact that the plotted quantity is in fact $\mathcal{J}_1$. As mentioned already in section 2, this tendency was observed also in simulations with other systems. The reason is that the optimum of the input power spectrum with respect to $\mathcal{J}_2$ is less dependent on the preliminary estimate $\bar{\theta}$ of the true parameter vector than the optimum with respect to $\mathcal{J}_1$. Given the lower complexity of $\mathcal{J}_2$ and hence the lower computational effort in comparison with $\mathcal{J}_1$, it is preferable to use primarily the former.

9. Conclusions. Let us summarize the results obtained in the present paper. We have to design an input sequence for an identification experiment that makes the worst-case ν-gap between the identified model and the uncertainty region around it as small as possible. The design takes place via power spectrum optimization. Two

nonstandard cost criteria $\mathcal{J}_1$ and $\mathcal{J}_2$ are defined, which reflect the optimization task with different accuracy. $\mathcal{J}_1$ is the exact worst-case ν-gap one would want to minimize, while $\mathcal{J}_2$ is an approximation of $\mathcal{J}_1$. These functions fulfill the natural conditions of monotonicity and quasiconvexity with respect to the power spectrum.

It was shown that optimization of the input power spectrum with respect to these cost criteria can be reduced to a standard convex optimization problem involving LMI constraints. In Propositions 5.2 and 5.3 we demonstrate how to construct cutting planes to the cost functions $\mathcal{J}_1, \mathcal{J}_2$, which is essential for applying standard numerical methods such as the ellipsoid algorithm. In Propositions 6.1 and 6.2 we derive bounds on the difference between the actually achieved and the optimal value of the cost functions, which allows us to estimate the quality of the optimization result and to design stopping criteria for iterative search algorithms. We have also briefly touched on the problem of designing an input sequence with a prespecified power spectrum.

Simulations show clearly the superiority of the proposed cost functions over classical design criteria. They also suggest using cost function $\mathcal{J}_2$ rather than $\mathcal{J}_1$, due to both lower computational effort and higher performance.

Appendix A. Proof of Proposition 5.2.

LEMMA A.1. *Let γ_{opt}, τ_{opt} be the optimal values of γ, τ in GEVP* (4.1), (4.2). *Then the following conditions hold:*

(i) *The matrix F_0 is negative semidefinite.*
(ii) *The nullspace of F_1 is a subset of the nullspace of F_0.*
(iii) *The matrix $F_0 + F_1$ is positive semidefinite.*
(iv) *The nullspace of F_1 is a strict subset of the nullspace of $F_0 + F_1$.*
(v) *$\tau_{opt} > 0$ if and only if the restriction of R on the nullspace of $F_0 + F_1$ is strictly positive definite.*
(vi) *$\gamma_{opt} = 1$ if and only if $\tau_{opt} = 0$.*

Proof. (i) follows from the representation $F_0 = -VWW^TV^T$, where W is a 4×2-matrix given by

$$W = \begin{pmatrix} 1 & 0 \\ 0 & 1 \\ \mathrm{Im}G(\hat{\theta}) & -\mathrm{Re}G(\hat{\theta}) \\ -\mathrm{Re}G(\hat{\theta}) & -\mathrm{Im}G(\hat{\theta}) \end{pmatrix}.$$

The nullspace of F_1 is given by the kernel of V^T. The latter is contained in the kernel of F_0, which yields (ii).

(iii) follows from the representation

$$F_0 + F_1 = V \begin{pmatrix} |G(\hat{\theta})|^2 & 0 & -\mathrm{Im}G(\hat{\theta}) & \mathrm{Re}G(\hat{\theta}) \\ 0 & |G(\hat{\theta})|^2 & \mathrm{Re}G(\hat{\theta}) & \mathrm{Im}G(\hat{\theta}) \\ -\mathrm{Im}G(\hat{\theta}) & \mathrm{Re}G(\hat{\theta}) & 1 & 0 \\ \mathrm{Re}G(\hat{\theta}) & \mathrm{Im}G(\hat{\theta}) & 0 & 1 \end{pmatrix} V^T = VW_\perp W_\perp^T V^T,$$

where $W_\perp$ is a 4×2-matrix given by

$$W_\perp = \begin{pmatrix} |G(\hat{\theta})| & 0 \\ 0 & |G(\hat{\theta})| \\ -\sin \arg G(\hat{\theta}) & \cos \arg G(\hat{\theta}) \\ \cos \arg G(\hat{\theta}) & \sin \arg G(\hat{\theta}) \end{pmatrix}.$$

Here $\arg G(\hat{\theta})$ is an arbitrary number if $G(\hat{\theta}) = 0$. Note that $W^T W = (1 + |G(\hat{\theta})|^2) I_2$, $W^T W_\perp = 0$, and $W_\perp^T W_\perp = (1 + |G(\hat{\theta})|^2) I_2$.

By (ii) the nullspace of F_1 is a subset of the nullspace of $F_0 + F_1$. We shall now show that the vector $v = (\zeta, 0, \dots, 0, 1, 0, \dots, 0, -\cos n_k\omega \operatorname{Re} G(\hat{\theta}) + \sin n_k\omega \operatorname{Re} G(\hat{\theta}) - \zeta \cos\omega)^T \in \mathbf{R}^{n_a+n_b+1}$, where $\zeta = -\cot n_k\omega \operatorname{Im} G(\hat{\theta}) - \operatorname{Re} G(\hat{\theta})$ if $\omega \in (0, \pi)$ and ζ arbitrary otherwise, is not contained in the kernel of V^T but is contained in the kernel of $W_\perp^T V^T$. The "1" in v is situated at position $n_a + 1$. Indeed, by (2.3) we obtain

$$V^T v = \begin{pmatrix} \cos n_k\omega \\ -\sin n_k\omega \\ -\zeta \sin\omega \\ -\cos n_k\omega \operatorname{Re} G(\hat{\theta}) + \sin n_k\omega \operatorname{Im} G(\hat{\theta}) \end{pmatrix}$$

$$= \cos n_k\omega \begin{pmatrix} 1 \\ 0 \\ \operatorname{Im} G(\hat{\theta}) \\ -\operatorname{Re} G(\hat{\theta}) \end{pmatrix} - \sin n_k\omega \begin{pmatrix} 0 \\ 1 \\ -\operatorname{Re} G(\hat{\theta}) \\ \operatorname{Im} G(\hat{\theta}) \end{pmatrix} \neq 0,$$

because $\cos n_k\omega$, $-\sin n_k\omega$ cannot both vanish. In case $\omega \in \{0, \pi\}$ the equality holds by $\operatorname{Im} G(\hat{\theta}) = 0$. On the other hand, we have $W_\perp^T V^T v = W_\perp^T W (\cos n_k\omega, -\sin n_k\omega)^T = 0$. This concludes the proof of (iv).

Let us prove (v) and (vi). Denote the nullspace of $F_0 + F_1$ by $\bar{V}^0$ and its orthogonal complement by $\bar{V}^\perp$. By definition there exists a positive number β_1 such that for any $v^\perp \in \bar{V}^\perp$ we have $(v^\perp)^T (F_0 + F_1) v^\perp \geq \beta_1 |v^\perp|^2$.

Suppose the restriction of R on $\bar{V}^0$ is strictly positive definite. Then there exists a positive number β_2 such that for any $v^0 \in \bar{V}^0$ we have $(v^0)^T R v^0 \geq \beta_2 |v^0|^2$. Let $v = v^0 + v^\perp$ be an arbitrary vector with v^0, $v^\perp$ being its orthogonal projections on $\bar{V}^0$, $\bar{V}^\perp$, respectively. Let $\tau > 0$ be a positive number. Then we have

$$v^T (F_0 + F_1 + \tau R) v = (v^\perp)^T (F_0 + F_1) v^\perp + \tau((v^\perp)^T R v^\perp + 2(v^0)^T R v^\perp + (v^0)^T R v^0)$$

$$\geq \beta_1 |v^\perp|^2 + \tau(\lambda_{\min}(R)|v^\perp|^2 - 2\min\{\lambda_{\min}(R), -\lambda_{\max}(R)\}|v^\perp||v^0| + \beta_2 |v^0|^2)$$

$$= \begin{pmatrix} |v^\perp| \\ |v^0| \end{pmatrix}^T \begin{pmatrix} \beta_1 + \tau\lambda_{\min}(R) & -\tau \min\{\lambda_{\min}(R), -\lambda_{\max}(R)\} \\ -\tau \min\{\lambda_{\min}(R), -\lambda_{\max}(R)\} & \tau\beta_2 \end{pmatrix} \begin{pmatrix} |v^\perp| \\ |v^0| \end{pmatrix}.$$

It is easily seen that the 2×2-matrix in the middle is positive definite if τ is small enough. Therefore there exists $\tau > 0$ such that the matrix $F_0 + F_1 + \tau R$ is strictly positive definite, while the matrix $F_0 + F_1$ is not. Thus in this case we have $\tau_{opt} \neq 0$ and $\gamma_{opt} < 1$.

Now suppose the restriction of R on $\bar{V}^0$ is not strictly positive definite. Since $\bar{M}$ is strictly positive definite, it follows from expression (4.2) that R has $n_a + n_b$ positive eigenvalues and one negative eigenvalue. Thus it can be represented as a difference $R = R_+ - R_-$, where R_+, R_- are positive semidefinite matrices of rank $n_a + n_b, 1$, respectively, and the linear hulls $\bar{V}_+, \bar{V}_-$ of their columns are orthogonal to each other. The whole space $\mathbf{R}^{n_a+n_b+1}$ splits into a direct sum $\bar{V}_+ \oplus \bar{V}_-$.

Let $v^0 \in \bar{V}^0$ be a nonzero vector such that $(v^0)^T R v^0 \leq 0$. The vector v^0 can be represented as a sum $v^0 = v_+ + v_-$, where $v_+ \in \bar{V}_+$, $v_- \in \bar{V}_-$. Since $(v^0)^T R v^0 =$

$(v_+)^T R_+ v_+ - (v_-)^T R_- v_- \leq 0$, the assumption $v_- = 0$ would imply $v_+ = 0$, which contradicts $v^0 \neq 0$. Hence $v_- \neq 0$. We can represent v_- as a sum $v_- = v_-^0 + v_-^\perp$, where $v_-^0 \in \bar{V}^0, v_-^\perp \in \bar{V}^\perp$. Let $\varepsilon > 0$ be a positive number and consider the vector $v = v^0 + \varepsilon v_-$. We have $v = v_+ + (1+\varepsilon)v_-$. Hence $v^T R v = (v_+)^T R_+ v_+ - (1+\varepsilon)^2 (v_-)^T R_- v_- = (v^0)^T R v^0 - (2\varepsilon + \varepsilon^2)(v_-)^T R_- v_-$. On the other hand, $v = (v^0 + \varepsilon v_-^0) + \varepsilon v_-^\perp$. Since $v^0 + \varepsilon v_-^0 \in \bar{V}^0$, this yields $v^T(F_0 + F_1)v = \varepsilon^2 (v_-^\perp)^T (F_0 + F_1) v_-^\perp$. We obtain

$$v^T(F_0 + F_1 + \tau R)v \leq \varepsilon^2 (v_-^\perp)^T (F_0 + F_1) v_-^\perp - \tau(2\varepsilon + \varepsilon^2)(v_-)^T R_- v_-.$$

Note that $(v_-)^T R_- v_-$ is strictly positive. Hence for any prespecified $\tau > 0$ we can choose a small $\varepsilon > 0$ such that $v^T(F_0 + F_1 + \tau R)v < 0$. Thus for any positive τ the matrix $F_0 + F_1 + \tau R$ is not positive semidefinite, while $F_0 + F_1$ is. This implies $\tau_{opt} = 0$. $\gamma_{opt} = 1$ now follows from (iv).

The proof of the lemma is complete. □

Proof of Proposition 5.2. Denote the orthogonal complement of V^0 by $V^\perp$. Then the restriction on $V^\perp$ of the quadratic form defined by the matrix $F_0 + \gamma_{opt}^{(0)} F_1 + \tau_{opt}^{(0)} R$ is strictly positive definite. Hence there exists a positive number β_1 such that for any vector $v^\perp \in V^\perp$ we have $(v^\perp)^T (F_0 + \gamma_{opt}^{(0)} F_1 + \tau_{opt}^{(0)} R) v^\perp \geq \beta_1 |v^\perp|^2$.

Suppose the restriction on V^0 of the quadratic form defined by the matrix R is strictly positive definite. Then there exists a positive number β_2 such that for any vector $v^0 \in V^0$ we have $(v^0)^T R v^0 \geq \beta_2 |v^0|^2$.

Let $v = v^0 + v^\perp$ be an arbitrary vector, where $v^0 \in V^0$ and $v^\perp \in V^\perp$ are its orthogonal projections on the subspaces V^0 and $V^\perp$, respectively. Let $\varepsilon > 0$ be a positive number. Then we have

$$\begin{aligned}
&v^T(F_0 + \gamma_{opt}^{(0)} F_1 + (\tau_{opt}^{(0)} + \varepsilon) R)v \\
&= (v^\perp)^T (F_0 + \gamma_{opt}^{(0)} F_1 + \tau_{opt}^{(0)} R) v^\perp + \varepsilon((v^\perp)^T R v^\perp + 2(v^0)^T R v^\perp + (v^0)^T R v^0) \\
&\geq \beta_1 |v^\perp|^2 + \varepsilon(\lambda_{\min}(R)|v^\perp|^2 + 2\min\{\lambda_{\min}(R), -\lambda_{\max}(R)\}|v^\perp||v^0| + \beta_2 |v^0|^2) \\
&= \begin{pmatrix} |v^\perp| \\ |v^0| \end{pmatrix}^T \begin{pmatrix} \beta_1 + \varepsilon\lambda_{\min}(R) & \varepsilon \min\{\lambda_{\min}(R), -\lambda_{\max}(R)\} \\ \varepsilon \min\{\lambda_{\min}(R), -\lambda_{\max}(R)\} & \varepsilon\beta_2 \end{pmatrix} \begin{pmatrix} |v^\perp| \\ |v^0| \end{pmatrix}.
\end{aligned}$$

It is easily seen that the 2×2-matrix in the middle is positive definite if ε is small enough. This implies that there exists a number $\tau > \tau_{opt}^{(0)}$ such that the matrix $F_0 + \gamma_{opt}^{(0)} F_1 + \tau R$ is strictly positive definite. This contradicts the optimality of $\gamma_{opt}^{(0)}$.

In a similar way it is shown that if the restriction on V^0 of the quadratic form R is strictly negative definite, then there exists a number $\varepsilon > 0$ such that for any $\tau \in [\tau_{opt}^{(0)} - \varepsilon, \tau_{opt}^{(0)})$ the matrix $F_0 + \gamma_{opt}^{(0)} F_1 + \tau R$ is strictly positive definite.

Thus the restriction on V^0 of the quadratic form R is neither strictly positive nor strictly negative definite if $\tau_{opt}^{(0)} > 0$ and it is negative semidefinite if $\tau_{opt}^{(0)} = 0$. This proves the first part of the proposition.

Now let $v \in V^0$ be a unit length vector satisfying the conditions of Proposition 5.2. Let $g \in \mathbf{R}^n$ be given componentwise by $g_i = -v^T R_i v$. Let $x \in \mathcal{X}_c$ be a vector satisfying the inequality $g^T(x - x^{(0)}) \geq 0$. Let τ be a nonnegative number and let γ be strictly less than $\gamma_{opt}^{(0)}$.

By assumption we have $v^T(F_0 + \gamma_{opt}^{(0)} F_1 + \tau_{opt}^{(0)} R(x^{(0)}))v = 0$. We obtain

$$v^T(F_0 + \gamma F_1 + \tau R(x))v = v^T((\gamma - \gamma_{opt}^{(0)})F_1 + \tau(R(x) - R(x^{(0)})) + (\tau - \tau_{opt}^{(0)})R(x^{(0)}))v$$

$$= (\gamma - \gamma_{opt}^{(0)})v^T F_1 v + (-\tau g^T(x - x^{(0)})) + (\tau - \tau_{opt}^{(0)})v^T R(x^{(0)})v \leq 0.$$

The last inequality follows from the fact that none of the three terms on the left-hand side exceeds zero. The first term is nonpositive because F_1 is positive semidefinite. The second term does not exceed zero by assumption on x. The third term is not greater than zero because by assumption on v we have $v^T R(x^{(0)})v \leq 0$ and the condition $\tau - \tau_{opt}^{(0)} < 0$ yields $\tau_{opt}^{(0)} > 0$ and hence $v^T R(x^{(0)})v = 0$. If the inequality is strict, then $F_0 + \gamma F_1 + \tau R(x)$ is not positive semidefinite.

Now assume that $v^T(F_0 + \gamma F_1 + \tau R(x))v = 0$. Then we have $v^T F_1 v = 0$ and v is an element of the nullspace of F_1. By Lemma A.1, part (iv), it is also an element of the nullspace of $F_0 + F_1$. Note that $v^T R(x^{(0)})v \leq 0$. By Lemma A.1, part (v), we then have $\tau_{opt}^{(0)} = 0$ and by part (vi) $\gamma_{opt}^{(0)} = 1$. Further we have either $\tau = \tau_{opt}^{(0)}$ or $v^T R(x^{(0)})v = 0$.

If $\tau = \tau_{opt}^{(0)} = 0$, then by Lemma A.1, parts (iii) and (iv), the matrix $F_0 + \gamma F_1 = F_0 + \gamma F_1 + \tau R(x)$ is not positive semidefinite.

If $\tau > 0$, then $v^T R(x^{(0)})v = 0$ and $v^T R(x)v = v^T(R(x) - R(x^{(0)}))v = -g^T(x - x^{(0)}) \leq 0$. Since v belongs to the nullspace of $F_0 + F_1$, by Lemma A.1, part (v) we have $\tau_{opt}(x) = 0$ and by part (vi) $\gamma_{opt}(x) = 1 > \gamma$. Hence the pair (γ, τ) is again not feasible for GEVP (4.1), (4.2) at x.

Thus in any case $\gamma_{opt}(x)$ is not less than $\gamma_{opt}^{(0)}$ and the vector g, if nonzero, defines a cutting plane for γ_{opt} and hence for $\mathcal{J}_1$.

If $g = 0$, however, then any x satisfies the relation $g^T(x - x^{(0)}) \geq 0$ and $\gamma_{opt}^{(0)}$ does not exceed γ_{opt} at any other point $x \in \mathcal{X}_c$. Hence we have $\mathcal{J}_1(x) \geq \kappa_{WC}(G(e^{j\omega^{(0)}}, \hat{\theta}), \mathcal{D}) = \sqrt{\gamma_{opt}(x)} \geq \sqrt{\gamma_{opt}^{(0)}} = \mathcal{J}_1(x^{(0)})$ and $\mathcal{J}_1$ attains a minimum at $x^{(0)}$.

This concludes the proof of the second part of Proposition 5.2. ∎

STABILITY ANALYSIS OF SECOND-ORDER SWITCHED HOMOGENEOUS SYSTEMS*

DAVID HOLCMAN† AND MICHAEL MARGALIOT‡

Abstract. We study the stability of second-order switched homogeneous systems. Using the concept of *generalized first integrals* we explicitly characterize the "most destabilizing" switching-law and construct a Lyapunov function that yields an easily verifiable, necessary and sufficient condition for asymptotic stability. Using the duality between stability analysis and control synthesis, this also leads to a novel algorithm for designing a stabilizing switching controller.

Key words. absolute stability, switched linear systems, robust stability, hybrid systems, hybrid control

1. Introduction.

We consider the *switched homogeneous system*

$$\dot{\mathbf{x}}(t) \in \mathbf{\Omega}(\mathbf{x}(t)), \quad \mathbf{\Omega}(\mathbf{x}) := Co\{\mathbf{f}_1(\mathbf{x}), \mathbf{f}_2(\mathbf{x}), \ldots, \mathbf{f}_q(\mathbf{x})\}, \tag{1.1}$$

where $\mathbf{x}(t) = (x_1(t), \ldots, x_n(t))^T$, the $\mathbf{f}_i(\cdot)$'s are homogeneous functions (with equal degree of homogeneity), and *Co* denotes the convex hull. An important special case is $\mathbf{f}_i(\mathbf{x}) = A_i\mathbf{x}$, $i = 1, \ldots, q$, for which (1.1) reduces to a *switched linear system*.

Switched systems appear in many fields of science ranging from economics to electrical and mechanical engineering [15], [18]. In particular, switched linear systems were studied in the literature under various names, e.g., polytopic linear differential inclusions [4], linear polysystems [6], bilinear systems [5], and uncertain linear systems [20].

If $\mathbf{f}_i(\mathbf{0}) = \mathbf{0}$ for all i, then $\mathbf{0}$ is an equilibrium point of (1.1). Analyzing the stability of this equilibrium point is difficult because the system admits infinitely many solutions for every initial value.[1]

Stability analysis of switched *linear* systems can be traced back to the 1940s since it is closely related to the well-known *absolute stability problem* [4], [19]. Current approaches to stability analysis include (i) deriving sufficient but *not* necessary and sufficient stability conditions, and (ii) deriving necessary and sufficient stability conditions for the particular case of low-order systems. Popov's criterion, the circle criterion [19, Chapter 5], and the positive-real lemma [4, Chapter 2] can all be considered as examples of the first approach. Many other sufficient conditions exist in the literature.[2] Nevertheless, these conditions are sufficient but not necessary and sufficient and are known to be rather conservative conditions.

[1] An analysis of the computational complexity of some closely related problems can be found in [2].
[2] See, for example, the recent survey paper by Liberzon and Morse [11].

Far more general results were derived for the second approach, namely, the particular case of low-order linear switched systems. The basic idea is to single out the "most unstable" solution $\tilde{\mathbf{x}}(t)$ of (1.1), that is, a solution with the following property: If $\tilde{\mathbf{x}}(t)$ converges to the origin, then so do *all* the solutions of (1.1). Then, all that is left to analyze is the stability of this single solution (see, e.g., [3]).

Pyatnitskiy and Rapoport [16] and Rapoport [17] were the first to formulate the problem of finding the "most unstable" solution of (1.1) using a variational approach. Applying the maximum principle, they developed a characterization of this solution in terms of a two-point boundary value problem. Their characterization is not explicit but, nevertheless, using tools from convex analysis they proved the following result. Let Γ be the collection of all the q-sets of *linear* functions $\{A_1\mathbf{x},\ldots,A_q\mathbf{x}\}$ for which (1.1) is asymptotically stable, and denote the boundary[3] of Γ by $\partial\Gamma$. Pyatnitskiy and Rapoport proved that if $\{A_1\mathbf{x},\ldots,A_q\mathbf{x}\}\in\partial\Gamma$, then the "most unstable" solution of (1.1) is a *closed* trajectory. Intuitively, this can be explained as follows. If $\{A\mathbf{x},B\mathbf{x}\}\in\Gamma$, then, by the definition of Γ, $\tilde{\mathbf{x}}(t)$ converges to the origin; if $\{A\mathbf{x},B\mathbf{x}\}\notin(\Gamma\cup\overline{\Gamma})$, then $\tilde{\mathbf{x}}(t)$ is unbounded. Between these two extremes, that is, when $\{A\mathbf{x},B\mathbf{x}\}\in\partial\Gamma$, $\tilde{\mathbf{x}}(t)$ is a closed solution. This leads to a *necessary and sufficient* stability condition for second- and third-order switched linear systems [16], [17]; however, the condition is a nonlinear equation in several unknowns and, since solving this equation turns out to be difficult, it cannot be used in practice.

Margaliot and Langholz [14] introduced the novel concept of *generalized first integrals* and used it to provide a different characterization of the closed trajectory. Unlike Pyatnitskiy and Rapoport, the characterization is *constructive* and leads, for second-order switched linear systems, to an *easily verifiable*, necessary and sufficient stability condition. Furthermore, their approach yields an *explicit* Lyapunov function for switched linear systems.

In the general homogeneous case, the functions $\mathbf{f}_i(\cdot)$ are *nonlinear* functions, and therefore the approaches used for switched linear systems cannot be applied. Filippov [7] derived a necessary and sufficient stability condition for second-order switched homogeneous systems. However, his proof uses a Lyapunov function that is not constructed explicitly.

In this paper we combine Filippov's approach with the approach developed by Margaliot and Langholz to provide a necessary and sufficient condition for asymptotic stability of second-order switched homogeneous systems. We construct a suitable *explicit* Lyapunov function and derive a condition that is easy to check in practice.

A closely related problem is the stabilization of several unstable systems using switching. This problem has recently regained interest with the discovery that there are systems that can be stabilized by *hybrid controllers* whereas they cannot be stabilized by continuous state-feedback [18, Chapter 6]. To analyze the stability of (1.1), we synthesize the "most unstable" solution $\tilde{\mathbf{x}}(t)$ by switching between several asymptotically stable systems. Designing a switching controller is equivalent to synthesizing the "most stable" solution by switching between several unstable systems. These problems are dual and, therefore, a solution of the first is also a solution of the second. Consequently, we use our stability analysis to develop a novel procedure for designing a stabilizing switching controller for second-order homogeneous systems.

The rest of this paper is organized as follows. Section 2 includes some notations and assumptions. Section 3 develops the *generalized first integral* which will serve as our main analysis tool. Section 4 analyzes the sets Γ and $\partial\Gamma$. Section 5 provides an

[3]The set Γ is open [17].

explicit characterization of the "most destabilizing" switching-law. Section 6 presents an easily verifiable, *necessary and sufficient* stability condition. Section 7 describes a new algorithm for designing a switching controller. Section 8 summarizes.

2. Notations and assumptions. For $\beta > 1$, let

$$P_\beta := \left\{ f(\cdot,\cdot) : f(cx_1, cx_2) = c^\beta f(x_1, x_2) \text{ for all } c, x_1, x_2 \right\},$$

that is, the set of homogeneous functions of degree β. We denote by E_β the set of functions $\mathbf{f} : \mathbb{R}^2 \to \mathbb{R}^2$ such that $\mathbf{f}(x_1, x_2) = (f_1(x_1, x_2), f_2(x_1, x_2))^T$ with $f_1, f_2 \in P_\beta$.

Consider the system $\dot{\mathbf{x}} = \mathbf{f}(\mathbf{x})$, where $\mathbf{x} = (x_1, x_2)^T$ and $\mathbf{f} \in E_\beta$. Transforming to polar coordinates,

$$r(t) = \sqrt{x_1^2(t) + x_2^2(t)}, \qquad \theta(t) = \arctan\left(\frac{x_2(t)}{x_1(t)}\right),$$

we get

$$\dot{r} = r^\beta R(\theta), \qquad \dot{\theta} = r^{\beta-1} A(\theta), \tag{2.1}$$

where $R(\theta)$ and $A(\theta)$ are homogeneous functions of degree $\beta+1$ in the variables $\cos(\theta)$ and $\sin(\theta)$.

Following [9, Chapter III], we analyze the stability of (2.1) by considering two cases. If $A(\cdot)$ has no zeros, then the origin is a focus and (2.1) yields $r(\theta) = r_0 e^{\int_{\theta_0}^{\theta} \frac{R(u)}{A(u)} du} = r_0 p(\theta;\theta_0) e^{h\theta}$, where p is periodic in θ with period 2π, and $h := \frac{1}{2\pi}\int_0^{2\pi} \frac{R(u)}{A(u)} du$. Hence, $r(t) \to 0$ ($r(t) \to \infty$) if $sgn(h) \neq sgn(A)$ ($sgn(h) = sgn(A)$).

If A has zeros, say $A(\overline{\theta}) = 0$, then the line $\theta = \overline{\theta}$ is a solution of (2.1) (the origin is a node) and along this line $r(t) \to 0$ ($r(t) \to \infty$) if $R(\overline{\theta}) < 0$ ($R(\overline{\theta}) > 0$).

Hence, if $ES_\beta := \{\mathbf{f} \in E_\beta : \dot{\mathbf{x}} = \mathbf{f}(\mathbf{x})$ is asymptotically stable$\}$, then $ES_\beta = ES_\beta^F \cup ES_\beta^N$,[4] where

$$ES_\beta^F := \left\{ \mathbf{f} \in E_\beta : A(\theta) \text{ has no zeros and } sgn(h) \neq sgn(A) \right\},$$
$$ES_\beta^N := \left\{ \mathbf{f} \in E_\beta : R(\overline{\theta}) < 0 \text{ for all } \overline{\theta} \text{ such that } A(\overline{\theta}) = 0 \right\}.$$

Given $\mathbf{f}(\mathbf{x}) \in E_\beta$, we denote its differential at $\mathbf{x}$ by

$$(D\mathbf{f})(\mathbf{x}) := \begin{pmatrix} \frac{\partial f_1(\mathbf{x})}{\partial x_1} & \frac{\partial f_1(\mathbf{x})}{\partial x_2} \\ \frac{\partial f_2(\mathbf{x})}{\partial x_1} & \frac{\partial f_2(\mathbf{x})}{\partial x_2} \end{pmatrix}.$$

The differential's norm is $||(Df)(\mathbf{x})|| := \sup_{\mathbf{h}\in\mathbb{R}^2, ||\mathbf{h}||=1} ||(Df)(\mathbf{x})\mathbf{h}||$, where $||\cdot|| : \mathbb{R}^2 \to \mathbb{R}_+$ is some vector norm on $\mathbb{R}^2$. The distance between two functions $\mathbf{f}, \mathbf{g} \in E_\beta$ is defined by [10]

$$d(\mathbf{f}, \mathbf{g}) := \sup_{\mathbf{x}\,:\,||\mathbf{x}||<1} (||\mathbf{f}(\mathbf{x}) - \mathbf{g}(\mathbf{x})|| + ||(D\mathbf{f})(\mathbf{x}) - (D\mathbf{g})(\mathbf{x})||). \tag{2.2}$$

Note that $(E_\beta, d(\cdot,\cdot))$ is a Banach space and that in the topology induced by $d(\cdot,\cdot)$ the set ES_β is *open*.

[4] Here F stands for focus and N for node.

For simplicity,[5] we consider the differential inclusion (1.1) with $q = 2$:

$$\dot{\mathbf{x}}(t) \in \mathbf{\Omega}(\mathbf{x}(t)), \quad \mathbf{\Omega}(\mathbf{x}) := Co\{\mathbf{f}(\mathbf{x}), \mathbf{g}(\mathbf{x})\} \tag{2.3}$$

with $\mathbf{f}, \mathbf{g} \in ES_\beta$.

Given an initial condition $\mathbf{x}_0$, a solution of (2.3) is an absolutely continuous function $\mathbf{x}(t)$, with $\mathbf{x}(0) = \mathbf{x}_0$, that satisfies (2.3) for almost all t. Clearly, there is an infinite number of solutions for any initial condition. To differentiate the possible solutions we use the concept of a switching-law.

DEFINITION 2.1. *A* switching-law *is a piecewise constant function* $\eta : [0, +\infty) \to [0, 1]$. *We refer to the solution of* $\dot{\mathbf{x}} = \eta(t)\mathbf{f}(\mathbf{x}) + (1 - \eta(t))\mathbf{g}(\mathbf{x})$ *as the solution corresponding to the switching-law* η.

The solution $\mathbf{x}(t) \equiv \mathbf{0}$ is said to be *uniformly*[6] *locally asymptotically stable* if

- given any $\epsilon > 0$, there exists $\delta(\epsilon) > 0$ such that *every* solution of (2.3) with $||\mathbf{x}(0)|| < \delta(\epsilon)$ satisfies $||\mathbf{x}(t)|| < \epsilon$ for all $t \geq 0$,
- there exists $c > 0$ such that *every* solution of (2.3) satisfies $\lim_{t\to\infty} \mathbf{x}(t) = \mathbf{0}$ if $||\mathbf{x}(0)|| < c$.

Since $\mathbf{f}$ and $\mathbf{g}$ are homogeneous, local asymptotic stability of (2.3) implies global asymptotic stability. Hence, when the above conditions hold, the system is uniformly globally asymptotically stable (UGAS).

DEFINITION 2.2. *A set* $P \subset \mathbb{R}^2$ *is an* invariant set *of* (2.3) *if* every *solution* $\mathbf{x}(t)$, *with* $\mathbf{x}(0) \in P$, *satisfies* $\mathbf{x}(t) \in P$ *for all* $t \geq 0$.

DEFINITION 2.3. *We will say that* $\mathbf{\Omega}(\mathbf{x}) = Co\{\mathbf{f}(\mathbf{x}), \mathbf{g}(\mathbf{x})\}$ *is* singular *if there exists an invariant set that does not contain an open neighborhood of the origin.*

We assume the following from here on.

Assumption 1. The set $\mathbf{\Omega}(\mathbf{x})$ is not singular.

The role of Assumption 1 will become clear in the proof of Lemma 5.4 below. Note that it is easy to check if the assumption holds by transforming the two systems $\dot{\mathbf{x}} = \mathbf{f}(\mathbf{x})$ and $\dot{\mathbf{x}} = \mathbf{g}(\mathbf{x})$ to polar coordinates and examining the set of points where $\dot{\theta} = 0$ for each system. For example, if there exists a line l that is an invariant set for both $\dot{\mathbf{x}} = \mathbf{f}(\mathbf{x})$ and $\dot{\mathbf{x}} = \mathbf{g}(\mathbf{x})$, then l is an invariant set of (2.3) and Assumption 1 does not hold.

To make the stability analysis nontrivial, we also assume the following.

Assumption 2. For any *fixed* $\overline{\eta} \in [0, 1]$, the origin is a globally asymptotically stable equilibrium point of $\dot{\mathbf{x}} = \overline{\eta}\mathbf{f}(\mathbf{x}) + (1 - \overline{\eta})\mathbf{g}(\mathbf{x})$.

3. The generalized first integral.

If the system

$$\dot{\mathbf{x}} = \mathbf{f}(\mathbf{x}) \tag{3.1}$$

is Hamiltonian [8], then it admits a *classical* first integral, that is, a function $H(\mathbf{x})$ which satisfies $H(\mathbf{x}(t)) \equiv H(\mathbf{x}(0))$ along the trajectories of (3.1). In this case, the study of (3.1) is greatly simplified since its trajectories are nothing but the contours $H(\mathbf{x}) = \text{const}$. In particular, it turns out that the first integral provides a crucial analysis tool for switched linear systems [14]. The purpose of this section is to extend this idea to the case where $\mathbf{f} \in ES_\beta$ and, therefore, (3.1) is not Hamiltonian.

Let $v := x_2/x_1$; then

$$\frac{dv}{\frac{dx_2}{dx_1} - v} = \frac{dx_1}{x_1}.$$

[5] Our results can be easily generalized to the case $q > 2$.

[6] The term "uniform" is used here to describe uniformity with respect to switching signals.

If $\mathbf{f} \in ES_\beta$, then f_1 and f_2 are both homogeneous functions of degree β and, therefore, the ratio $\frac{f_2(x_1,x_2)}{f_1(x_1,x_2)}$ is a function of v only, which we denote by $\alpha(v)$. Hence, along the trajectories of (3.1), $\frac{dv}{\alpha(v)-v} = \frac{dx_1}{x_1}$, that is, $e^{\int \frac{dv}{v-\alpha(v)}}|x_1| = \text{const}$. Thus, we define the *generalized first integral* of (3.1) by

$$H(x_1, v) := \left(x_1 e^{L(v)}\right)^{2k}, \tag{3.2}$$

where $L(v) := \int \frac{dv}{v-\alpha(v)}$ and k is a positive integer. Note that we can write $H = H(x_1, x_2)$ by substituting $v = x_2/x_1$. Note also that $H(\lambda x_1, \lambda x_2) = \lambda^{2k} H(x_1, x_2)$.

Let S be the collection of points where $H(x_1, x_2)$ is not defined or not continuous; then, by construction, $H : \mathbb{R}^2 \setminus S \to \mathbb{R}_+$ is *piecewise constant* along the trajectories of (3.1). If $S = \emptyset$, then H is a classical first integral of the system. In general, however, $S \neq \emptyset$. Nevertheless, this does not imply that H cannot be used in the analysis of (3.1). Consider, for example, the case where S is a line and a trajectory $\mathbf{x}(t)$ of (3.1) can cross S but not stay on S. Then, $H(\mathbf{x}(t))$ will remain constant except perhaps at a crossing time where its value can "jump."[7] Thus, a trajectory of the system is a concatenation of several contours of H. This motivates the term *generalized first integral*.

To clarify the relationship between the trajectories of $\dot{\mathbf{x}} = \mathbf{f}(\mathbf{x})$ and the contours $H(\mathbf{x}) = \text{const}$, we consider an example.

EXAMPLE 1. *Consider the system*

$$\begin{pmatrix} \dot{x}_1 \\ \dot{x}_2 \end{pmatrix} = \begin{pmatrix} -x_2^3 - 2x_1^3 \\ x_1 x_2^2 \end{pmatrix}. \tag{3.3}$$

Here (3.2) *yields*

$$H(x_1, v) = \left(x_1 \frac{v(2 - v + v^2)^{\frac{1}{8}}}{(1+v)^{\frac{1}{4}}} e^{-\frac{3}{4\sqrt{7}} \arctan((-1+2v)/\sqrt{7})} \right)^{2k},$$

and using $k = 2$ *and* $v = x_2/x_1$ *we get*

$$H(x_1, x_2) = \frac{x_2^4 \sqrt{2x_1^2 - x_1 x_2 + x_2^2}}{x_1 + x_2} e^{-\frac{3}{\sqrt{7}} \arctan(\frac{2x_2 - x_1}{\sqrt{7} x_1})}.$$

In this case $S = l_1 \cup l_2$, *where* $l_1 := \{\mathbf{x} : x_1 + x_2 = 0\}$ *and* $l_2 := \{\mathbf{x} : x_1 = 0\}$. *It is easy to verify that* l_1 *is an invariant set of* (3.3), *that is,* $\mathbf{x}(t) \cap l_1 = \emptyset$ *(except for the trivial trajectory that starts and stays on* l_1*). Furthermore, it is easy to see that a trajectory of* (3.3) *cannot stay on the line* l_2.

Figure 1 *shows the trajectory* $\mathbf{x}(t)$ *of* (3.3) *for* $\mathbf{x}_0 = (3, 1)^T$. *Figure* 2 *displays* $H(\mathbf{x}(t))$ *as a function of time. It may be seen that* $H(\mathbf{x}(t))$ *is a piecewise constant function that attains two values. Note that the "jump" in* $H(\mathbf{x}(t))$ *occurs when* $x_1(t) = 0$, *that is, when* $\mathbf{x}(t) \in S$.

4. The boundary of stability. Let Γ be the set of all pairs $(\mathbf{f}, \mathbf{g})$ for which (2.3) is UGAS. In this section we study Γ and its boundary $\partial\Gamma$. Our first result, whose proof is given in the appendix, is an inverse Lyapunov theorem.

LEMMA 4.1. *If* $(\mathbf{f}, \mathbf{g}) \in \Gamma$, *then there exists a* C^1 *positive-definite function* $V(\mathbf{x}) : \mathbb{R}^2 \to [0, +\infty)$ *such that for all* $\mathbf{x} \in \mathbb{R}^2 \setminus \mathbf{0}$, $\nabla V(\mathbf{x})\mathbf{f}(\mathbf{x}) < 0$ *and* $\nabla V(\mathbf{x})\mathbf{g}(\mathbf{x}) < 0$. *Furthermore,* $V(\mathbf{x})$ *is positively homogeneous of degree one.*[8]

[7] That is, a time t_0 such that $\mathbf{x}(t_0) \in S$.

[8] That is, $V(c\mathbf{x}) = cV(\mathbf{x})$ for all $c > 0$ and all $\mathbf{x} \in \mathbb{R}^2$.

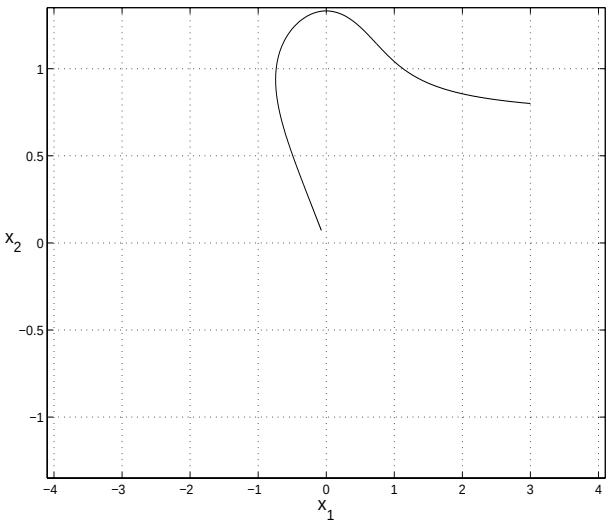

FIG. 1. *The trajectory of* (3.3) *for* $\mathbf{x}_0 = (3,1)^T$.

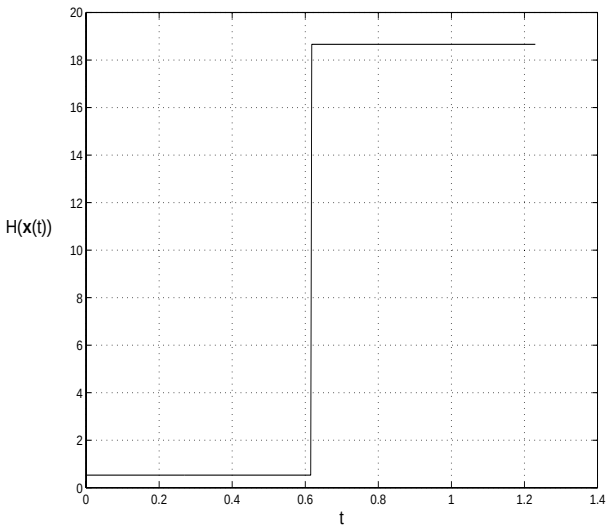

FIG. 2. $H(\mathbf{x}(t))$ *as a function of time.*

LEMMA 4.2. Γ *is an open cone.*

Proof. Let $(\mathbf{f},\mathbf{g}) \in \Gamma$. Clearly, $(c\mathbf{f}, c\mathbf{g}) \in \Gamma$ for all $c > 0$. Hence, Γ is a cone.

To prove that Γ is open, we use the common Lyapunov function V from Lemma 4.1. Denote $\gamma := \{\mathbf{x} : V(\mathbf{x}) = 1\}$, so γ is a closed curve encircling the origin. Hence, there exists $a < 0$ such that for all $\mathbf{x} \in \gamma$,

$$\nabla V(\mathbf{x})\mathbf{f}(\mathbf{x}) < a \quad \text{and} \quad \nabla V(\mathbf{x})\mathbf{g}(\mathbf{x}) < a. \tag{4.1}$$

If $\tilde{\mathbf{f}} \in ES_\beta$ and $\tilde{\mathbf{g}} \in ES_\beta$ are such that $d(\tilde{\mathbf{f}},\mathbf{f}) < \epsilon$ and $d(\tilde{\mathbf{g}},\mathbf{g}) < \epsilon$, with $\epsilon > 0$ sufficiently small, then for all $\mathbf{x} \in \gamma$, $\nabla V(\mathbf{x})\tilde{\mathbf{f}}(\mathbf{x}) < a/2 < 0$ and $\nabla V(\mathbf{x})\tilde{\mathbf{g}}(\mathbf{x}) < a/2 < 0$. It follows from the homogeneity of V, $\tilde{\mathbf{f}}$, and $\tilde{\mathbf{g}}$ that $(\tilde{\mathbf{f}},\tilde{\mathbf{g}}) \in \Gamma$. ∎

5. The worst-case switching-law. In this section we provide two explicit characterizations of the switching-law that yields the "most unstable" solution of (2.3).

Let $H^{\mathbf{f}}(\mathbf{x})$ ($H^{\mathbf{g}}(\mathbf{x})$) be the generalized first integral of $\dot{\mathbf{x}} = \mathbf{f}(\mathbf{x})$ ($\dot{\mathbf{x}} = \mathbf{g}(\mathbf{x})$).

DEFINITION 5.1. *Define the* worst-case switching-law (WCSL) *by*

$$\lambda(\mathbf{x}) := \begin{cases} 0 & \text{if } \nabla H^{\mathbf{f}}(\mathbf{x})\mathbf{g}(\mathbf{x}) \geq 0, \\ 1 & \text{if } \nabla H^{\mathbf{f}}(\mathbf{x})\mathbf{g}(\mathbf{x}) < 0. \end{cases} \tag{5.1}$$

We denote

$$\mathbf{h}(\mathbf{x}) := \lambda(\mathbf{x})\mathbf{f}(\mathbf{x}) + (1 - \lambda(\mathbf{x}))\mathbf{g}(\mathbf{x})$$

so the solution corresponding to the WCSL satisfies $\dot{\mathbf{x}} = \mathbf{h}(\mathbf{x})$. Note that the WCSL is a *state-dependent* switching-law and that since $\lambda(\mathbf{x}) = 0$ or $\lambda(\mathbf{x}) = 1$, then $\mathbf{h}(\mathbf{x}) = \mathbf{g}(\mathbf{x})$ or $\mathbf{h}(\mathbf{x}) = \mathbf{f}(\mathbf{x})$, respectively, that is, the vertices of $\mathbf{\Omega}$. Furthermore, it is easy to see that $\mathbf{h}(\mathbf{x})$ is homogeneous of degree β.

Intuitively, the WCSL can be explained as follows. Consider a point $\mathbf{x}$ where $\mathbf{f}(\mathbf{x})$ and $\mathbf{g}(\mathbf{x})$ are as shown in Figure 3. A solution of $\dot{\mathbf{x}} = \mathbf{f}(\mathbf{x})$ follows the contour $H^{\mathbf{f}}(\mathbf{x}) = \text{const}$, whereas a solution of $\dot{\mathbf{x}} = \mathbf{g}(\mathbf{x})$ crosses this contour going further away from the origin. In this case, $\nabla H^{\mathbf{f}}(\mathbf{x})\mathbf{g}(\mathbf{x}) > 0$, so the WCSL is $\lambda(\mathbf{x}) = 0$, which corresponds to setting $\dot{\mathbf{x}} = \mathbf{g}(\mathbf{x})$. Thus, the WCSL "pushes" the trajectory away from the origin as much as possible.

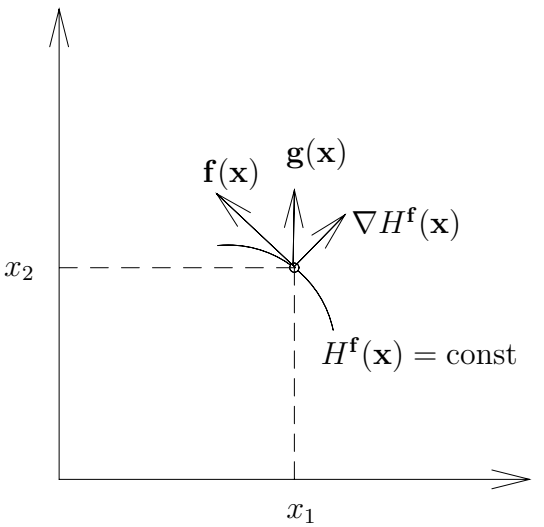

FIG. 3. *Geometrical explanation of the WCSL when* $\nabla H^{\mathbf{f}}(\mathbf{x})\mathbf{g}(\mathbf{x}) > 0$.

Note that the definition of WCSL using (5.1) is meaningful only for $\mathbf{x} \in \mathbb{R}^2 \setminus S$ since $\nabla H^{\mathbf{f}}(\mathbf{x})$ is not defined for $\mathbf{x} \in S$. However, extending the definition of WCSL to any $\mathbf{x} \in \mathbb{R}^2$ is immediate since $\mathbf{x} \in S$ implies one of two cases. In the first case, $\mathbf{x} \in l$, where l is a line in $\mathbb{R}^2$ which is an invariant set of $\dot{\mathbf{x}} = \mathbf{f}(\mathbf{x})$, that is, $\mathbf{f}(\mathbf{x}) = c\mathbf{x}$ (with $c < 0$ since $\mathbf{f}$ is asymptotically stable), so clearly the WCSL must use $\mathbf{g}$. In the second case, the trajectory of $\dot{\mathbf{x}} = \mathbf{f}(\mathbf{x})$ crosses S so the value of the switching-law on the single point $\mathbf{x}$ can be chosen arbitrarily.

We expect the WCSL to remain unchanged if we swap the roles of $\mathbf{f}$ and $\mathbf{g}$. Indeed, this is guaranteed by the following lemma, whose proof is given in the appendix.

LEMMA 5.2. *For all* $\mathbf{x} \in D := \{\mathbf{x} : \mathbf{f}^T(\mathbf{x})\mathbf{g}(\mathbf{x}) > 0\}$

$$sgn(\nabla H^{\mathbf{f}}(\mathbf{x})\mathbf{g}(\mathbf{x})) = -sgn(\nabla H^{\mathbf{g}}(\mathbf{x})\mathbf{f}(\mathbf{x})), \tag{5.2}$$

where $sgn(\cdot)$ *is the sign function.*

We can now state the main result of this section.

THEOREM 5.3. $(\mathbf{f}, \mathbf{g}) \in \partial\Gamma$ *if and only if the solution corresponding to the WCSL is closed.*[9]

Proof. Denote the solution corresponding to the WCSL by $\mathbf{x}(t)$ and suppose that $\mathbf{x}(t)$ is closed. Let γ be the closed curve $\{\mathbf{x}(t) : t \in [0, T]\}$, where $T > 0$ is the smallest time such that $\mathbf{x}(T) = \mathbf{x}(0)$. Note that using the explicit construction of $\lambda(\mathbf{x})$ (see (5.1)) we can easily define γ *explicitly* as a concatenation of several contours of $H^{\mathbf{f}}(\mathbf{x})$ and $H^{\mathbf{g}}(\mathbf{x})$. Note also that the switching between $\dot{\mathbf{x}} = \mathbf{f}(\mathbf{x})$ and $\dot{\mathbf{x}} = \mathbf{g}(\mathbf{x})$ takes place at points $\mathbf{x}$ where $\nabla H^f(\mathbf{x})\mathbf{g}(\mathbf{x}) = 0$ (see (5.1)), that is, when $\mathbf{g}(\mathbf{x})$ and $\mathbf{f}(\mathbf{x})$ are collinear. Hence, the curve γ has no corners.

We define the function $V(\mathbf{x})$ by $V(\mathbf{0}) = 0$, and for all $\mathbf{x} \neq \mathbf{0}$

$$V(\mathbf{x}) = k \quad \text{such that} \quad \mathbf{x} \in k\gamma, \tag{5.3}$$

that is, the contours of V are obtained by scaling γ (see [1]). The function $V(\mathbf{x})$ is positively homogeneous (that is, for any $c \geq 0$, $V(c\mathbf{x}) = cV(\mathbf{x})$), radially unbounded, and differentiable on $\mathbb{R}^2 \setminus \{\mathbf{0}\}$.

Let $\mathbf{p}(\mathbf{x}) = ||\mathbf{x}||^{\beta-1}\mathbf{x}$ and denote $\mathbf{f}^\epsilon(\mathbf{x}) := \mathbf{f}(\mathbf{x}) + \epsilon\mathbf{p}(\mathbf{x})$ and $\mathbf{g}^\epsilon(\mathbf{x}) := \mathbf{g}(\mathbf{x}) + \epsilon\mathbf{p}(\mathbf{x})$. Note that both $\mathbf{f}^\epsilon(\mathbf{x})$ and $\mathbf{g}^\epsilon(\mathbf{x})$ belong to E_β. We use $V(\mathbf{x})$ to analyze the stability of the perturbed system $\dot{\mathbf{x}} \in \mathbf{\Omega}^\epsilon(\mathbf{x}) := Co\{\mathbf{f}^\epsilon(\mathbf{x}), \mathbf{g}^\epsilon(\mathbf{x})\}$. Consider the derivative of V along the trajectories of $\dot{\mathbf{x}} \in \mathbf{\Omega}^\epsilon(\mathbf{x})$:

$$\begin{aligned}\dot{V}(\mathbf{x}) &= \nabla V(\mathbf{x})\left(\eta(t)(\mathbf{f}^\epsilon(\mathbf{x}) + (1-\eta(t))\mathbf{g}^\epsilon(\mathbf{x})\right) \\ &= \epsilon\nabla V(\mathbf{x})\mathbf{p}(\mathbf{x}) + \eta(t)\nabla V(\mathbf{x})\mathbf{f}(\mathbf{x}) + (1-\eta(t))\nabla V(\mathbf{x})\mathbf{g}(\mathbf{x}),\end{aligned}$$

where $\eta(t) \in [0, 1]$ for all t. If at some $\mathbf{x}$, $V(\mathbf{x})$ corresponds to a contour $H^{\mathbf{f}}(\mathbf{x}) = \text{const}$, then $\nabla V(\mathbf{x})\mathbf{f}(\mathbf{x}) = 0$ and, by the definition of WCSL (see (5.1)), $\nabla V(\mathbf{x})\mathbf{g}(\mathbf{x}) \leq 0$ so $\dot{V}(\mathbf{x}) \leq \epsilon\nabla V(\mathbf{x})\mathbf{p}(\mathbf{x})$. Otherwise, $V(\mathbf{x})$ corresponds to a contour $H^{\mathbf{g}}(\mathbf{x}) = \text{const}$, so $\nabla V(\mathbf{x})\mathbf{g}(\mathbf{x}) = 0$, $\nabla V(\mathbf{x})\mathbf{f}(\mathbf{x}) \leq 0$, and again $\dot{V}(\mathbf{x}) \leq \epsilon\nabla V(\mathbf{x})\mathbf{p}(\mathbf{x})$. Hence, for any $\epsilon < 0$ we have

$$\dot{V}(\mathbf{x}) \leq \epsilon\nabla V(\mathbf{x})\mathbf{p}(\mathbf{x}) = \epsilon||\mathbf{x}||^{\beta-1}\nabla V(\mathbf{x})\mathbf{x} < 0;$$

since this holds for all $\mathbf{x}$ and all $\eta(t) \in [0, 1]$, we get that for $\epsilon < 0$, $\mathbf{\Omega}^\epsilon \in \Gamma$.

On the other hand, for $\epsilon > 0$ and $\eta(t) = \lambda(\mathbf{x}(t))$ we have

$$\dot{V}(\mathbf{x}) = \epsilon\nabla V(\mathbf{x})\mathbf{p}(\mathbf{x}) = \epsilon||\mathbf{x}||^{\beta-1}\nabla V(\mathbf{x})\mathbf{x} > 0;$$

since this holds for all $\mathbf{x}$, $\dot{\mathbf{x}} \in \mathbf{\Omega}^\epsilon(\mathbf{x})$ admits an unbounded solution for $\epsilon > 0$. The derivations above hold for arbitrarily small ϵ and, therefore, $\mathbf{\Omega} \in \partial\Gamma$.

For the opposite direction, assume that $(\mathbf{f}, \mathbf{g}) \in \partial\Gamma$, and let $\mathbf{x}(t)$ be the solution corresponding to the WCSL, that is, $\mathbf{x}(t)$ satisfies $\dot{\mathbf{x}} = \mathbf{h}(\mathbf{x}) := \lambda(\mathbf{x})\mathbf{f}(\mathbf{x}) +$

[9] We omit specifying the initial condition because the fact that $\mathbf{h}(\mathbf{x})$ is homogeneous implies that, if the solution starting at some $\mathbf{x}_0$ is closed, then all solutions are closed.

$(1-\lambda(\mathbf{x}))\mathbf{g}(\mathbf{x})$. To prove that $\mathbf{x}(t)$ is a closed trajectory, we use the following lemma, whose proof appears in the appendix.

LEMMA 5.4. *If* $(\mathbf{f},\mathbf{g}) \in \partial\Gamma$*, then the solution corresponding to the WCSL rotates around the origin.*

Thus, for a given $\mathbf{x}_0 \neq \mathbf{0}$, there exists $t_1 > 0$ such that $\mathbf{x}(t)$, with $\mathbf{x}(0) = \mathbf{x}_0$, satisfies $\mathbf{x}(t_1) = c\mathbf{x}_0$, and since $\mathbf{h}(\mathbf{x})$ is homogeneous, we get $\mathbf{x}(nt_1) = c^n\mathbf{x}(0)$, $n = 1, 2, 3, \ldots$. We consider two cases. If $c > 1$, then $\mathbf{x}(t)$ is unbounded, and using the homogeneity of $\mathbf{h}(\mathbf{x})$ we conclude that $\mathbf{0}$ is a (spiral) source. It follows from the theory of structural stability (see, e.g., [10]) that there exists an $\epsilon > 0$ such that for *all* $(\tilde{\mathbf{f}},\tilde{\mathbf{g}})$ with $d(\tilde{\mathbf{f}},\mathbf{f}) < \epsilon$ and $d(\tilde{\mathbf{g}},\mathbf{g}) < \epsilon$, the origin is a source of the perturbed dynamical system $\dot{\mathbf{x}} = \lambda(x)\tilde{\mathbf{f}}(\mathbf{x}) + (1-\lambda(x))\tilde{\mathbf{g}}(\mathbf{x})$. This implies that $(\mathbf{f},\mathbf{g}) \notin \partial\Gamma$, which is a contradiction.

If $c < 1$, then $\mathbf{x}(t)$ converges to the origin and, by the construction of the WCSL, so does any other solution, so $(\mathbf{f},\mathbf{g}) \in \Gamma$, which is again a contradiction. Hence, $c = 1$, that is, $\mathbf{x}(t)$ is closed. □

The characterization of the WCSL using the generalized first integrals leads to a simple and *constructive* proof of Theorem 5.3. However, to actually check whether the solution corresponding to the WCSL is closed, a characterization of the WCSL in polar coordinates is more suitable.

Representing (2.3) in polar coordinates, we get

$$\begin{pmatrix} \dot{r} \\ \dot{\theta} \end{pmatrix} \in \begin{pmatrix} \cos\theta & \sin\theta \\ -\frac{\sin\theta}{r} & \frac{\cos\theta}{r} \end{pmatrix} Co\{\mathbf{f}(r,\theta),\mathbf{g}(r,\theta)\}. \tag{5.4}$$

If $(\mathbf{f},\mathbf{g}) \in \partial\Gamma$, then the WCSL yields a closed solution. By using the transformation $\overline{r} = r$, $\overline{\theta} = -\theta$ (if necessary), we may always assume that this solution rotates around the origin in a counterclockwise direction, that is, $\dot{\theta}(r,\theta) > 0$ for all $\theta \in [0, 2\pi)$. Note that this implies that if at some point $\mathbf{x}$ the trajectories of one of the systems are in the clockwise direction, then the WCSL will use the second system. Hence, determining the WCSL is nontrivial only at points where the trajectories of both systems rotate in the same direction, and we assume from here on that both rotate in a clockwise direction. (Note that this explains why in Lemma 5.2 it is enough to consider $\mathbf{x} \in D$.)

Let $\mathbf{j}_\eta(r,\theta) := \eta\mathbf{f}(r,\theta) + (1-\eta)\mathbf{g}(r,\theta)$ and

$$F(r,\theta) := \{\eta \in [0,1] : (-\sin\theta \quad \cos\theta)\mathbf{j}_\eta(r,\theta) > 0\} \tag{5.5}$$

so F is a parameterization of the set of directions in $\boldsymbol{\Omega}$ for which $\dot{\theta} > 0$.

For any (r,θ) we define the switching-law

$$\zeta(r,\theta) := \arg\max_{\eta\in F} \frac{1}{r}\frac{\dot{r}}{\dot{\theta}};$$

that is, ζ is the switching-law that selects, among all the directions which yield $\dot{\theta} > 0$, the direction that maximizes $\frac{d\ln r}{d\theta}$. Using (5.4), we get

$$\zeta(r,\theta) = \arg\max_{\eta\in F} \frac{(\cos\theta \quad \sin\theta)\mathbf{j}_\eta(r,\theta)}{(-\sin\theta \quad \cos\theta)\mathbf{j}_\eta(r,\theta)}. \tag{5.6}$$

Let

$$m(r,\theta) := \frac{(\cos\theta \quad \sin\theta)\mathbf{j}_\zeta(r,\theta)}{(-\sin\theta \quad \cos\theta)\mathbf{j}_\zeta(r,\theta)} \tag{5.7}$$

so that along the trajectory corresponding to ζ, $\frac{1}{r}\dot{r}/\dot{\theta} = m$. Note that since $\mathbf{f}$ and $\mathbf{g}$ are homogeneous, $\zeta = \zeta(\theta)$ and $m = m(\theta)$.

It is easy to verify that the function $q(y) := \frac{ay+b(1-y)}{cy+d(1-y)}$, $y \in [0,1]$ (where c and d are such that the denominator is never zero), is monotonic and, therefore, $\zeta(r,\theta)$ in (5.6) is always 0 or 1 and $m(r,\theta)$ in (5.7) is always one of the two values,

$$m_0(\theta) := \frac{(\cos\theta \quad \sin\theta)\mathbf{g}(r,\theta)}{(-\sin\theta \quad \cos\theta)\mathbf{g}(r,\theta)}, \qquad m_1(\theta) := \frac{(\cos\theta \quad \sin\theta)\mathbf{f}(r,\theta)}{(-\sin\theta \quad \cos\theta)\mathbf{f}(r,\theta)},$$

respectively.

The next lemma, whose proof is given in the appendix, shows that the switching-law ζ is just the WCSL λ.

LEMMA 5.5. *The switching-law ζ yields a closed solution if and only if λ yields a closed solution.*

Let

$$\begin{aligned} I &:= \int_0^{2\pi} m(\theta)d\theta \\ &= \int_0^{2\pi} \frac{d\ln r}{d\theta}d\theta \\ &= \ln(r(T)) - \ln(r(0)), \end{aligned} \tag{5.8}$$

where $(r(t),\theta(t))$ is the solution corresponding to the switching-law ζ, and T is the time needed to complete a rotation around the origin. This solution is closed if and only if $\ln(r(T)) - \ln(r(0)) = 0$. Combining this with Lemma 5.5 and Theorem 5.3, we immediately obtain the following.

THEOREM 5.6. $(\mathbf{f},\mathbf{g}) \in \partial\Gamma$ *if and only if* $I = 0$.

It is easy to calculate I numerically and, therefore, Theorem 5.6 provides us with a simple recipe for determining whether $(\mathbf{f},\mathbf{g}) \in \partial\Gamma$. However, note that we assumed throughout that the closed solution of the system rotates in a counterclockwise direction. Thus, to use Theorem 5.6 correctly, I has to be computed twice: first for the original system and then for the transformed system $r' = r$, $\theta' = -\theta$ (denote this value by I'). $(\mathbf{f},\mathbf{g}) \in \partial\Gamma$ if and only if $\max(I, I') = 0$. In this way, we find whether the system has a closed trajectory, rotating around the origin in a clockwise or counterclockwise direction.

The following example demonstrates the use of Theorem 5.6.

EXAMPLE 2 (detecting the boundary of stability). *Consider the system*

$$\dot{\mathbf{x}} \in \Omega_k(\mathbf{x}) := Co\{\mathbf{f}(\mathbf{x}), \mathbf{g}_k(\mathbf{x})\}, \tag{5.9}$$

where

$$\mathbf{f}(\mathbf{x}) = \begin{pmatrix} -x_2^3 - 2x_1^3 \\ x_1x_2^2 \end{pmatrix}, \qquad \mathbf{g}_k(\mathbf{x}) = \begin{pmatrix} (kx_1 - x_2)^3 - 2x_1^3 \\ x_1(x_2 - kx_1)^2 \end{pmatrix}. \tag{5.10}$$

It is easy to verify that $\mathbf{f} \in ES_3^N$, and since $\mathbf{g}_0(\mathbf{x}) = \mathbf{f}(\mathbf{x})$, we have $\Omega_0 \in \Gamma$. The problem is to determine the smallest $k^* > 0$ such that $(\mathbf{f}(\mathbf{x}), \mathbf{g}_{k^*}(\mathbf{x})) \in \partial\Gamma$.

Transforming to polar coordinates we get

$$\mathbf{f}(r,\theta) = r^3 \begin{pmatrix} -\sin^3\theta - 2\cos^3\theta \\ \cos\theta\sin^2\theta \end{pmatrix}, \quad \mathbf{g}_k(r,\theta) = r^3 \begin{pmatrix} (k\cos\theta - \sin\theta)^3 - 2\cos^3\theta \\ \cos\theta(\sin\theta - k\cos\theta)^2 \end{pmatrix},$$

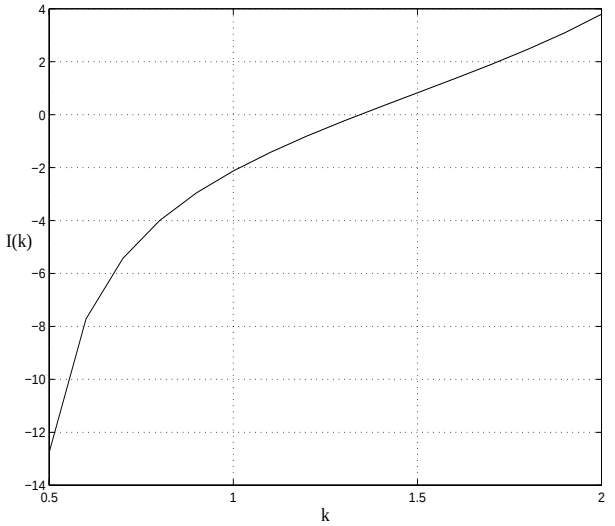

FIG. 4. *$I(k)$ as a function of k.*

so

$$j_\eta(r,\theta) = r^3\eta \begin{pmatrix} -\sin^3\theta - 2\cos^3\theta \\ \cos\theta\sin^2\theta \end{pmatrix} + r^3(1-\eta)\begin{pmatrix} (k\cos\theta - \sin\theta)^3 - 2\cos^3\theta \\ \cos\theta(\sin\theta - k\cos\theta)^2 \end{pmatrix}$$

and

$$I = \int_0^{2\pi} m(\theta)d\theta = \int_0^{2\pi} \max_{\eta\in F(\theta)} \frac{(\cos\theta \quad \sin\theta)\mathbf{j}_\eta(r,\theta)}{(-\sin\theta \quad \cos\theta)\mathbf{j}_\eta(r,\theta)}d\theta, \tag{5.11}$$

where $F(\theta)$ includes 0 if $(-\sin\theta \quad \cos\theta)\mathbf{j}_0(r,\theta) > 0$ and 1 if $(-\sin\theta \quad \cos\theta)\mathbf{j}_1(r,\theta) > 0$. Note that although j_η is a function of both r and θ, the integrand in (5.11) *is a function of θ (and k) but not of r.*

We calculated $I(k)$ numerically for different values of k. The results are shown in Figure 4. *The value k^* for which $I(k^*) = 0$ is*

$$k^* = 1.3439$$

(to four-digit accuracy), and it may be seen that for $k < k^*$ ($k > k^*$), $I(k) < 0$ ($I(k) > 0$). We repeated the computation for the transformed system $\overline{r} = r$, $\overline{\theta} = -\theta$ and found that there exists no closed solution rotating around the origin in a clockwise direction. Hence, the system (5.9) *and* (5.10) *is UGAS for all $k \in [0, k^*)$ and unstable for all $k > k^*$.*

The WCSL (see (5.6)*) for $k = k^*$ is*

$$\zeta(\theta) = \begin{cases} 0 & \text{if } \theta \in [0, 0.6256) \cup [1.1811, 3.7672) \cup [4.3227, 2\pi), \\ 1 & \text{otherwise.} \end{cases} \tag{5.12}$$

Figure 5 *depicts the solution of the system given by* (5.9) *and* (5.10) *with $k =$ 1.3439, WCSL* (5.12)*, and $\mathbf{x}_0 = (1,0)^T$. It may be seen that the solution is a closed trajectory, as expected. Note that this trajectory is* not *convex, which implies that the Lyapunov function used in the proof of Theorem* 5.3 *(see* (5.3)*) is not convex. This is*

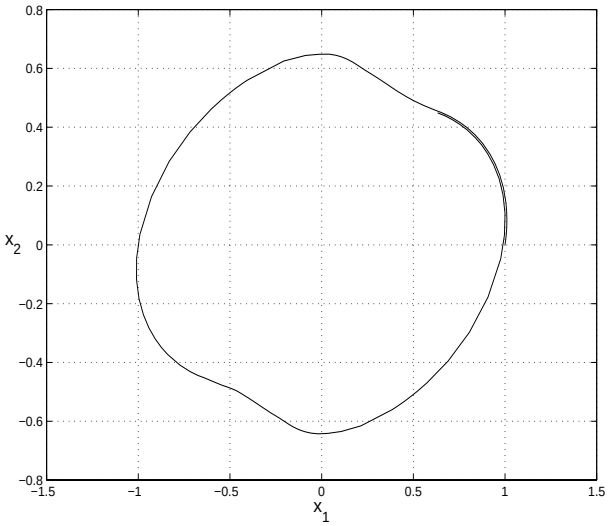

FIG. 5. *The solution of* (5.9) *and* (5.10) *for* $k = k^*$ *and the WCSL, with* $\mathbf{x}_0 = (1,0)^T$.

a phenomenon that is unique to nonlinear systems. For switched linear *systems the closed trajectory is convex and, therefore, so is the Lyapunov function* V *that yields a sufficient and necessary stability condition* [14].

6. Stability analysis. In this section we transform the original problem of analyzing the stability of (2.3) to one of detecting the boundary of stability $\partial\Gamma$. The latter problem was solved in section 5.

Given $\mathbf{\Omega} = Co\{\mathbf{f}, \mathbf{g}\}$, we define a new homogeneous function $\mathbf{h}_k(\mathbf{x})$ with the following properties: (1) $\mathbf{h}_0(\mathbf{x}) = \mathbf{f}(\mathbf{x})$; (2) $\mathbf{h}_1(\mathbf{x}) = \mathbf{g}(\mathbf{x})$; and (3) for all $k_1 < k_2$, $\{\mathbf{h}_k(\mathbf{x}) : 0 \le k \le k_1\} \subset \{\mathbf{h}_k(\mathbf{x}) : 0 \le k \le k_2\}$. One possible example that satisfies the above is

$$\mathbf{h}_k(\mathbf{x}) := \mathbf{f}(\mathbf{x}) + k(\mathbf{g}(\mathbf{x}) - \mathbf{f}(\mathbf{x})).$$

Consider the switched homogeneous system

$$\dot{\mathbf{x}}(t) \in \mathbf{\Omega}_k(\mathbf{x}(t)), \quad \mathbf{\Omega}_k := Co\{\mathbf{f}(\mathbf{x}), \mathbf{h}_k(\mathbf{x})\}. \tag{6.1}$$

The *absolute stability problem* is to find the smallest $k^* > 0$, when it exists, such that $\mathbf{\Omega}_{k^*} \in \partial\Gamma$. Noting that $\mathbf{\Omega}_0 = Co\{\mathbf{f}(\mathbf{x}), \mathbf{f}(\mathbf{x})\} \in \Gamma$, $\mathbf{\Omega}_1 = Co\{\mathbf{f}(\mathbf{x}), \mathbf{g}(\mathbf{x})\} = \mathbf{\Omega}$, and $\mathbf{\Omega}_{k_1} \subset \mathbf{\Omega}_{k_2}$ for all $k_1 < k_2$, we immediately obtain the following result.

LEMMA 6.1. *The system* (2.3) *is UGAS if and only if* $k^* > 1$.

Thus, we can always transform the problem of analyzing the stability of a switched dynamical system into an absolute stability problem. We already know how to solve the latter problem for second-order homogeneous systems. To illustrate this consider the following example.

EXAMPLE 3. *Consider the system* (2.3) *with*

$$\mathbf{f}(\mathbf{x}) = \begin{pmatrix} -x_2^3 - 2x_1^3 \\ x_1 x_2^2 \end{pmatrix}, \qquad \mathbf{g}(\mathbf{x}) = \begin{pmatrix} (x_1 - x_2)^3 - 2x_1^3 \\ x_1(x_2 - x_1)^2 \end{pmatrix}. \tag{6.2}$$

It is easy to verify that $\mathbf{f}(\mathbf{x})$ *and* $\mathbf{g}(\mathbf{x})$ *belong to* ES_3 *and that both Assumptions* 1 *and* 2 *are satisfied.*

To analyze the stability of the system we use Lemma 6.1. *Defining*

$$\mathbf{h}_k(\mathbf{x}) = \begin{pmatrix} (kx_1 - x_2)^3 - 2x_1^3 \\ x_1(x_2 - kx_1)^2 \end{pmatrix}, \tag{6.3}$$

we must find the smallest k^* *such that* $(\mathbf{f}, \mathbf{h}_{k^*}) \in \partial\Gamma$. *We already calculated* k^* *in Example* 2 *and found that* $k^* = 1.3439 > 1$. *Hence, the system* (2.3) *with* $\mathbf{f}$ *and* $\mathbf{g}$ *given in* (6.2) *is UGAS.*

7. Designing a switching controller. In this section we employ our results to derive an algorithm for designing a switching controller for stabilizing homogeneous systems. To be concrete, we focus on linear systems rather than on the general homogeneous case. Hence, consider the system

$$\dot{\mathbf{x}} = A\mathbf{x} + B\mathbf{u}, \quad \mathbf{u} \in \mathcal{U} := Co\{K_1\mathbf{x}, K_2\mathbf{x}\}, \tag{7.1}$$

where K_1 and K_2 are given matrices that represent constraints on the possible controls.[10] We would like to design a stabilizing state-feedback controller $\mathbf{u}(t) = \mathbf{u}(\mathbf{x}(t))$ that satisfies the constraint $\mathbf{u}(t) \in \mathcal{U}$ for all t.

We assume that for any fixed matrix $K \in Co\{K_1, K_2\}$ the matrix $A + BK$ is strictly unstable and, therefore, a linear controller $\mathbf{u} = K\mathbf{x}$ will not stabilize the system. However, it is still possible that a switching controller will stabilize the system, and designing such a controller (if one exists) is the purpose of this section.

Roughly speaking, we are trying to find a switching-law that yields an asymptotically stable solution of $\dot{\mathbf{x}} \in \mathbf{\Omega} := Co\{A + BK_1, A + BK_2\}\mathbf{x}$, where each matrix in $\mathbf{\Omega}$ is strictly unstable. Using the transformation $\bar{t} = -t$, we see that such a solution exists if and only if this switching-law yields an unstable solution of $\dot{\mathbf{x}} \in \mathbf{\Omega}^- := Co\{-(A + BK_1), -(A + BK_2)\}\mathbf{x}$. Clearly, every matrix in $\mathbf{\Omega}^-$ is asymptotically stable. Hence, we obtain the main result of this section.

THEOREM 7.1. *Let* $\lambda = \lambda(\mathbf{x})$ *be the WCSL for the system*

$$\dot{\mathbf{x}} \in Co\{-(A + BK_1), -(A + BK_2)\}$$

and let $\tilde{\mathbf{x}}$ *be the corresponding solution. There exists a switching controller that asymptotically stabilizes* (7.1) *if and only if* $\tilde{\mathbf{x}}$ *is unbounded and, in this case,* $\mathbf{u}(\mathbf{x}) = \lambda(\mathbf{x})K_1\mathbf{x} + (1 - \lambda(\mathbf{x}))K_2\mathbf{x}$ *is a stabilizing controller.*

Note that Theorem 7.1 provides an algorithm for designing a stabilizing switching controller whenever such a controller exists. We already solved the problem of analyzing $\tilde{\mathbf{x}}$ for second-order systems.

EXAMPLE 4 (designing a stabilizing switching controller). *Consider the system* (7.1) *with*

$$A = \begin{pmatrix} 0 & 1 \\ -2 & 1 \end{pmatrix}, \quad B = \begin{pmatrix} 0 & 0 \\ -1 & 0 \end{pmatrix}, \quad K_1 = \begin{pmatrix} 0 & 0 \\ 0 & 0 \end{pmatrix}, \quad K_2 = \begin{pmatrix} k & 0 \\ 0 & 0 \end{pmatrix}, \tag{7.2}$$

where $k > 0$ *is a constant. It is easy to verify that for any fixed* $K \in Co\{K_1, K_2\}$, *the matrix* $A + BK$ *is unstable and, therefore, no linear controller* $\mathbf{u} = K\mathbf{x}$ *can stabilize the system. Therefore, we design a switching controller. By Theorem* 7.1 *we must analyze the stability of the switched system* (6.1) *with*

$$\mathbf{f}(\mathbf{x}) = -\begin{pmatrix} 0 & 1 \\ -2 & 1 \end{pmatrix}\mathbf{x}, \qquad \mathbf{h}_k(\mathbf{x}) = -\begin{pmatrix} 0 & 1 \\ -(2+k) & 1 \end{pmatrix}\mathbf{x}.$$

[10] Determined, for example, by the physical limitations of the actuators.

Transforming $\dot{\mathbf{x}} = \mathbf{f}(\mathbf{x})$ *to polar coordinates, we get*

$$\begin{pmatrix} \dot{r} \\ \dot{\theta} \end{pmatrix} = \begin{pmatrix} (\cos\theta - \sin\theta) r \sin\theta \\ (\sin\theta - \frac{1}{2}\cos\theta)^2 + \frac{7}{4}\cos^2\theta \end{pmatrix},$$

whereas $\dot{\mathbf{x}} = \mathbf{h}_k(\mathbf{x})$ *becomes*

$$\begin{pmatrix} \dot{r} \\ \dot{\theta} \end{pmatrix} = \begin{pmatrix} ((1+k)\cos\theta - \sin\theta) r \sin\theta \\ (\sin\theta - \frac{1}{2}\cos\theta)^2 + (\frac{7}{4}+k)\cos^2\theta \end{pmatrix}.$$

Clearly, the solutions of both these systems always rotate in a counterclockwise direction ($\dot{\theta} > 0$ *for all* θ) *and, therefore, for all* θ, *we have* $m(\theta) = \max(m_0(\theta), m_1(\theta))$, *where*

$$m_0(\theta) = \frac{((1+k)\cos\theta - \sin\theta)\sin\theta}{(\sin\theta - \frac{1}{2}\cos\theta)^2 + (\frac{7}{4}+k)\cos^2\theta}, \qquad m_1(\theta) = \frac{(\cos\theta - \sin\theta)\sin\theta}{(\sin\theta - \frac{1}{2}\cos\theta)^2 + \frac{7}{4}\cos^2\theta}.$$

It is easily verified that $m_1(\theta) \le m_0(\theta)$ *if and only if* $\tan\theta \ge 0$. *Hence, the WCSL is*

$$\zeta(\theta) = \begin{cases} 0 & \text{if } \tan\theta \ge 0, \\ 1 & \text{otherwise} \end{cases} = \begin{cases} 0 & \text{if } \theta \in [0, \pi/2) \cup [\pi, 3\pi/2), \\ 1 & \text{otherwise} \end{cases}$$

and

$$I(k) = \int_0^{\pi/2} m_0(\theta)d\theta + \int_{\pi/2}^{\pi} m_1(\theta)d\theta + \int_{\pi}^{3\pi/2} m_0(\theta)d\theta + \int_{3\pi/2}^{2\pi} m_1(\theta)d\theta.$$

Computing numerically, we find that the value of k *for which* $I = 0$ *is* $k^* = 6.98513$. *Hence, there exists a switching controller that asymptotically stabilizes* (7.1) *and* (7.2) *if and only if* $k > 6.98513$ *and*

$$\mathbf{u}(\mathbf{x}) = \begin{cases} K_2\mathbf{x} & \text{if } \arctan(x_2/x_1) \in [0, \pi/2) \cup [\pi, 3\pi/2), \\ K_1\mathbf{x} & \text{otherwise} \end{cases} \tag{7.3}$$

is a stabilizing controller.

Figure 6 *depicts the trajectory of the closed-loop system given by* (7.1) *and* (7.2) *with* $k = 10$, *the switching controller* (7.3), *and* $\mathbf{x}_0 = (1, 0)^T$. *As we can see, the system is indeed asymptotically stable.*

8. Summary. We presented a new approach to stability analysis of second-order switched homogeneous systems based on the idea of generalized first integrals. Our approach leads to an explicit Lyapunov function that provides an easily verifiable, *necessary and sufficient* stability condition.

Using our stability analysis, we designed a novel algorithm for constructing a *switching controller* for stabilizing second-order homogeneous systems. The algorithm determines whether the system can be stabilized using switching, and if the answer is affirmative, outputs a suitable controller.

Interesting directions for further research include the complete characterization of the boundary of stability $\partial\Gamma$ and the study of higher-order switched homogeneous systems.

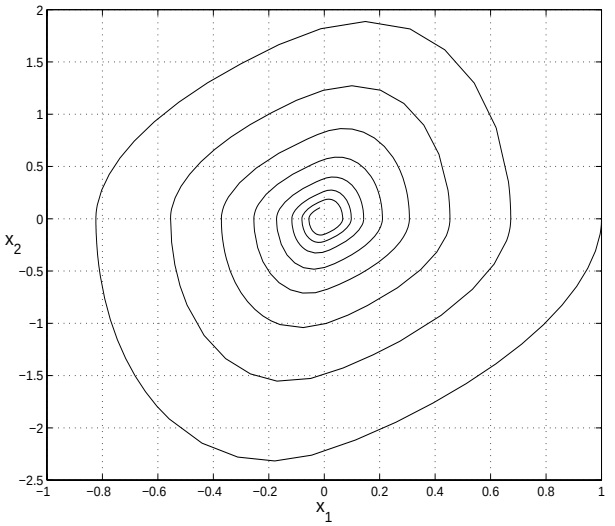

FIG. 6. *Trajectory of the closed-loop system with the switching controller with* $\mathbf{x}_0 = (1,0)^T$.

Appendix.

Proof of Lemma 4.1. The existence of a common Lyapunov function $V'(\mathbf{x})$ follows from Theorem 3.1 in [13] (see also [12]). However, V' is not necessarily homogeneous. Denote $\gamma := \{\mathbf{x} : V'(\mathbf{x}) = 1\}$ so γ is a closed curve encircling the origin. We define a new function $V(\mathbf{x})$ by $V(\mathbf{0}) = 0$ and, for all $\mathbf{x} \neq \mathbf{0}$,

$$V(\mathbf{x}) = k \quad \text{such that} \quad \mathbf{x} \in k\gamma;$$

that is, the contours of V are obtained by scaling γ (see [1]). $V(\mathbf{x})$ is differentiable on $\mathbb{R}^2 \setminus \{\mathbf{0}\}$, positively homogeneous of order one, and radially unbounded.

For any $\mathbf{x} \in \gamma$ we have $\nabla V(\mathbf{x})\mathbf{f}(\mathbf{x}) = \nabla V'(\mathbf{x})\mathbf{f}(\mathbf{x}) < 0$, and using the homogeneity of $V(\mathbf{x})$ and $\mathbf{f}(\mathbf{x})$ this holds for any $\mathbf{x} \in \mathbb{R}^2 \setminus \{\mathbf{0}\}$. Similarly, $\nabla V(\mathbf{x})\mathbf{g}(\mathbf{x}) < 0$ for all $\mathbf{x} \in \mathbb{R}^2 \setminus \{\mathbf{0}\}$. □

Proof of Lemma 5.2. Let $\mathbf{v}(\mathbf{x}) = \frac{\mathbf{f}(\mathbf{x})}{||\mathbf{f}(\mathbf{x})||}$ and $\mathbf{w}(\mathbf{x}) = \frac{(\nabla H^{\mathbf{f}}(\mathbf{x}))^T}{||\nabla H^{\mathbf{f}}(\mathbf{x})||}$. These two vectors form an orthonormal basis of $\mathbb{R}^2$ and, therefore, $\mathbf{g}(\mathbf{x}) = a_1\mathbf{v}(\mathbf{x}) + a_2\mathbf{w}(\mathbf{x})$ and $(\nabla H^{\mathbf{g}}(\mathbf{x}))^T = b_1\mathbf{v}(\mathbf{x}) + b_2\mathbf{w}(\mathbf{x})$, where $a_1 = \mathbf{g}^T(\mathbf{x})\mathbf{v}(\mathbf{x})$, $a_2 = \mathbf{g}^T(\mathbf{x})\mathbf{w}(\mathbf{x})$, $b_1 = \nabla H^{\mathbf{g}}(\mathbf{x})\mathbf{v}(\mathbf{x})$, and $b_2 = \nabla H^{\mathbf{g}}(\mathbf{x})\mathbf{w}(\mathbf{x})$. Now $\nabla H^{\mathbf{g}}(\mathbf{x})\mathbf{g}\mathbf{x} = 0$ yields

$$a_1 b_1 + a_2 b_2 = 0. \tag{8.1}$$

For any $\mathbf{x} \in D$ we have $a_1 > 0$ and since $\nabla H^{\mathbf{f}}(\mathbf{x})$ $(\nabla H^{\mathbf{g}}(\mathbf{x}))$ is orthogonal to $\mathbf{f}(\mathbf{x})$ $(\mathbf{g}(\mathbf{x}))$, we also have $b_2 > 0$. Substituting in (8.1) yields $sgn(a_2) = -sgn(b_1)$, which is just (5.2). □

Proof of Lemma 5.4. The system $\dot{\mathbf{x}} = \mathbf{h}(\mathbf{x})$ is homogeneous and we can represent it in polar coordinates as in (2.1). If $A(\overline{\theta}) = 0$ for some $\overline{\theta} \in [0, 2\pi]$, then the solution corresponding to the WCSL follows the line $l := \theta = \overline{\theta}$. If $R(\overline{\theta}) < 0$, then the solution follows the line l to the origin. However, by the definition of WCSL this is possible only if both the solutions of $\dot{\mathbf{x}} = \mathbf{f}(\mathbf{x})$ and $\dot{\mathbf{x}} = \mathbf{g}(\mathbf{x})$ coincide with the line l. Thus, the line l is an invariant set of the system which is a contradiction to

Assumption 1. If $R(\bar{\theta}) \geq 0$, then we get a contradiction of Assumption 2. Hence, $A(\theta) \neq 0$ for all $\theta \in [0, 2\pi]$ and, therefore, there exists $c > 0$ such that $A(\theta) > c$ or $A(\theta) < -c$ for all $\theta \in [0, 2\pi]$. Thus, the solution rotates around the origin. ∎

Proof of Lemma 5.5. Suppose that the WCSL yields a closed trajectory $\tilde{\mathbf{x}}(t)$ that rotates around the origin in a counterclockwise direction ($\dot{\theta} > 0$). Assume that at some point $\mathbf{x}$ along this trajectory, $\lambda(\mathbf{x}) = 1$, that is,

$$\nabla H^{\mathbf{f}}(\mathbf{x})\mathbf{g}(\mathbf{x}) < 0. \tag{8.2}$$

Note that by the definition of the generalized first integral, $\nabla H^{\mathbf{f}}(\mathbf{x})\mathbf{f}(\mathbf{x}) = 0$ for any $\mathbf{x} \in \mathbb{R}^2 \setminus S$. This implies that $\nabla H^{\mathbf{f}}(\mathbf{x}) = k(f_2(\mathbf{x}), -f_1(\mathbf{x}))$ for some $k > 0$, so (8.2) yields

$$f_2(\mathbf{x})g_1(\mathbf{x}) - f_1(\mathbf{x})g_2(\mathbf{x}) < 0. \tag{8.3}$$

Let r, θ be the polar coordinates of $\mathbf{x}$. Since $\tilde{\mathbf{x}}(t)$ rotates around the origin in a counterclockwise direction and satisfies $\dot{\tilde{\mathbf{x}}} = \mathbf{f}(\tilde{\mathbf{x}})$ at $\mathbf{x}$, we have $(-\sin\theta \quad \cos\theta)\mathbf{f}(r, \theta) > 0$. If $(-\sin\theta \quad \cos\theta)\mathbf{g}(r, \theta) < 0$, then $0 \notin F(r, \theta)$ and, therefore, $\zeta(\theta) = 1$. If, on the other hand, $(-\sin\theta \quad \cos\theta)\mathbf{g}(r, \theta) > 0$, then by the definition of ζ (see (5.6)), $\zeta(\theta) = 1$ if and only if

$$\frac{(\cos\theta \quad \sin\theta)\mathbf{f}(r, \theta)}{(-\sin\theta \quad \cos\theta)\mathbf{f}(r, \theta)} > \frac{(\cos\theta \quad \sin\theta)\mathbf{g}(r, \theta)}{(-\sin\theta \quad \cos\theta)\mathbf{g}(r, \theta)}. \tag{8.4}$$

Simplifying, we see that (8.4) is equivalent to $f_1(r, \theta)g_2(r, \theta) - f_2(r, \theta)g_1(r, \theta) > 0$, which is just (8.3), hence, $\zeta(r, \theta) = 1$. Summarizing, we proved that $\lambda(\mathbf{x}) = 1$ if and only if $\zeta(\theta) = 1$. ∎

MINIMAX CONTROL OF DISCRETE-TIME STOCHASTIC SYSTEMS*

J. I. GONZÁLEZ-TREJO†, O. HERNÁNDEZ-LERMA‡, AND L. F. HOYOS-REYES†

Abstract. This paper gives a unified, self-contained presentation of minimax control problems for discrete-time stochastic systems on Borel spaces, with possibly unbounded costs. The main results include conditions for the existence of minimax strategies for finite-horizon problems and infinite-horizon discounted and undiscounted (average) cost criteria. The results are specialized to control systems with *unknown* disturbance distributions—also known as *games against nature*. Two examples illustrate the theory, one of them on the *mold level control problem*, which is a key problem in the steelmaking industry.

Key words. minimax control problems, Markov games with complete information, discrete-time stochastic control systems, games against nature

1. Introduction.

This paper has several aims. First, it is a survey of results on minimax control problems for discrete-time, stochastic, Markov-like systems in Borel spaces, with possibly unbounded costs. Second, for such systems, it presents a unified, self-contained study that extends virtually all of the results known to date on the minimax control theory, including finite- and infinite-horizon (discounted and undiscounted) problems. It also includes stochastic control problems with unknown disturbance distribution—also known as *games against nature*. And, third, we use the developed theory to analyze a mold level control problem, which is a key problem in the steelmaking industry, and which provided the initial motivation for this paper.

In contrast to the standard optimal control problem, in which there is a *single* decision-maker, in a minimax control problem there are two decision-makers, namely, the controller himself and an "opponent." Thus, in the discrete-time stochastic case that we are concerned with, the system's state process $\{x_t\}$ typically evolves according to a model of the form, say,

$$x_{t+1} = F(x_t, a_t, b_t, \xi_t), \qquad t = 0, 1, \dots, \tag{1.1}$$

where $\pi = \{a_t\}$ and $\gamma = \{b_t\}$ are strategies for the controller and the opponent, and $\{\xi_t\}$ is a sequence of random disturbances. Then if $K(x, \pi, \gamma)$ denotes the system's performance criterion for each initial state $x_0 = x$, the controller's problem is to find a *minimax strategy* π^*, which means that π^* guarantees the best performance in the worst possible situation in the sense that it minimizes

$$K^{\#}(x, \pi) := \sup_{\gamma} K(x, \pi, \gamma) \qquad \forall x \tag{1.2}$$

The research of this author was performed partially during a visit to the LAAS-CNRS, Toulouse, France, under the auspices of the CONACyT (México)–CNRS (France) Scientific Cooperation Program and was also partially supported by CONACyT grants 32299-E and 37355-E.

over the set of all admissible strategies π. Hence π^* is a "minimax" strategy because it minimizes the maximum expected cost $K^{\#}(x,\cdot)$, where the maximum is taken over all possible strategies γ of the opponent. On the other hand, it follows from the above description that a minimax control problem is a special class of a two-person zero-sum stochastic game. In fact, defining this game's *upper value* as usual, i.e.,

$$U(x) := \inf_{\pi} \sup_{\gamma} K(x,\pi,\gamma) = \inf_{\pi} K^{\#}(x,\pi),$$

we can see that a minimax strategy π^* is precisely one that attains the upper value because

$$K^{\#}(x,\pi^*) = \inf_{\pi} K^{\#}(x,\pi) = U(x) \qquad \forall x. \tag{1.3}$$

A standard application of the minimax approach is to control systems that depend on *unknown* parameters. In this case, the opponent is the "nature," which somehow chooses the unknown parameters at each time t. For example, instead of (1.1) consider the usual, single-controller system

$$x_{t+1} = F(x_t, a_t, \xi_t), \qquad t = 0, 1, \dots, \tag{1.4}$$

and suppose that the disturbances ξ_t are independent random variables with *unknown distributions*. Then a nature's strategy, say $\gamma = \{b_t\}$, would choose a distribution b_t for ξ_t at each time $t = 0, 1, \dots$. Problems of this kind are naturally called *games against nature*.

As far as we can tell, except for some results by Küenle [32, 33, 34] and Kurano [35], there is no *general* theory for minimax control problems in Borel spaces. In fact, all of the previous literature consists either of results specialized from the theory of zero-sum games (which we can argue are not "true" minimax problems—see the next-to-last paragraph in section 2.1 and Remark 2.2) or of minimax problems for particular classes of controlled systems, for instance, queueing and inventory models; see [1, 2, 6, 22, 24, 36] and their references.

Here we propose a general theory for minimax control problems based on the weighted supremum norm approach, which can be traced back (at least) to Wessels [64], and further developed by many authors for different classes of Markov games and control processes, e.g., [2, 12, 13, 14, 17, 18, 19, 23, 25, 31, 32, 33, 34, 35, 42, 46, 48, 64]. This theory is presented in sections 2 to 5. After introducing the basic setup and performance criteria in section 2, in section 3 we first state our main hypothesis (Assumption 3.1), and then we present a full solution (Theorem 3.1) of the finite-horizon, *n-stage problem* ($n = 1, 2, \dots$). In section 4 we consider the infinite-horizon *α-discounted cost* (α-DC), with a "discount factor" α in (0,1). Our main results include the existence of minimax strategies and the approximation of the optimal α-DC by finite-horizon costs (Theorem 4.2), as well as the convergence, in a suitable sense (Definition 4.5), of finite-horizon minimax strategies to an infinite-horizon one (Corollary 4.6). Similar results are presented in section 5 for the *average cost* (AC) problem (Theorem 5.2 and Corollary 5.4).

In section 6 we turn our attention to the games against nature concerning a system of the form (1.4) with unknown disturbance distribution. Here we give conditions that ensure (most of) the requirements in Assumption 3.1, which in turn guarantees that (most of) the results in sections 3 to 5 hold for the games against nature.

Finally, in section 7, we thoroughly analyze two examples, obtaining the corresponding optimal cost functions and minimax strategies. The first one, Example 7.1,

gives a solution to the *mold level control problem*, which essentially consists of controlling a valve to regulate the mold level in a continuous casting machine. From a mathematical viewpoint this problem looks deceptively simple, but it has many critical implications for steelmaking [26, 47]. For instance, from an operational point of view the mold level must be kept constant to avoid molten steel overflows, mold emptying, or strand breakouts, which may cause significant economic losses [9, 28, 30]. From a metallurgical perspective, regulation of the mold is important to avoid slag trapping and steel oxidizing. Moreover, from the quality viewpoint the mold level must be kept constant to obtain a final product that is free of internal and surface cracks [5]. The problem is greatly complicated by many uncertainties and unknown parameters coming into play. For example, measuring the level of molten steel in the mold is not an easy task because the environment is very harsh (over 1600 degrees Celsius), and the molten surface is covered with an insulating powder [62]. In addition, the caster dynamic performance is affected by the material's clogging and unclogging in the valve's nozzle [29, 54]. These complications, among others, naturally induced us to pose the mold level control problem as a minimax problem. To our surprise, the minimax strategy turned out to be an easy-to-compute *myopic* strategy. For other approaches to the mold level control problem, see, for instance, [3, 9, 20, 27] and their references. In the second example, Example 7.2, we study a general, scalar LQ (linear systems, quadratic cost) minimax problem. Although the latter problem is scalar (i.e., the state space is $X = \mathbb{R}$), it clearly shows how one can deal with the vector case.

Before getting into details, a word needs to be said concerning our approach vs. other approaches in the related literature.

Existence and computation of values and minimax strategies. As happens with many mathematical problems, it is one thing to give conditions for a zero-sum game to have a value and/or minimax or maximin strategies (see Remark 2.2 below), and another—sometimes quite different—story to give conditions for the existence and *computation* of the game's value and optimal strategies. For instance, Rieder's [50] Example 4.1 shows a zero-sum game (with a Borel measurable payoff function) for which the value function exists, but it is *not* universally measurable. On the other hand, Küenle [31], Maitra and Sudderth [38], Nowak [43, 44], and other authors give conditions for a zero-sum game to have an either upper or lower semianalytic—hence universally measurable—value function, which is *not* necessarily Borel measurable.

As a consequence, in all of these cases it is, of course, unclear that one can in fact *compute* the value function. Similarly, in, for instance, the latter references one can find conditions for the existence of ε-optimal (for each $\varepsilon > 0$) *universally*—or even *limit*—measurable strategies; and, again, the question of how to *compute* these strategies remains open.

Actually, the existence of the value function and minimax/maximin strategies has been studied in an almost incredible generality. For instance, extending a result by Martin [41] for games on finite sets, Maitra and Sudderth [40] recently proved that a two-person, zero-sum stochastic game with *arbitrary* state and action spaces, a *finitely additive* law of motion, and a bounded Borel measurable payoff has a value. Moreover, the payoff function may depend on the *whole history* of the game (i.e., as in (2.4) with $n = \infty$), and so the main result in [40] is a vast improvement of Theorem 2.1 in [37] on games with a so-called lim sup payoff, which *includes, e.g., discounted and average cost games* (see (2.6) and (2.7) below). A countably additive (as opposed to finitely

additive) version of lim sup games is provided by Maitra and Sudderth in [38]—see also [39]—in which the state and action spaces are Borel spaces, with some additional requirements of compactness and continuity. In the latter case, Maitra and Sudderth give a *transfinite* algorithm for calculating the value; this algorithm, however, may not "terminate" if the state space is not finite.

Another work of extreme generality is Rieder's [51]. He considers zero- and nonzero-sum, *nonstationary* stochastic games, with a *non-Markov* transition law and utility functions that may depend on the *whole story* of the game. Under several different sets of assumptions, for each stage of the nonstationary game he shows the existence of values, the existence of optimal strategies, and the convergence of the value iteration algorithm.

Our paper is at a more mundane level: we consider a standard, time-homogeneous minimax control model with Borel state and action spaces (see (2.1)), and we are interested in the existence of *Borel measurable*—as opposed to, say, semianalytic or universally measurable—value functions and optimal strategies. This "loss" of generality, however, is compensated by the fact that our assumptions are reasonably mild and not hard to verify, and, at the same time, they are sufficiently general to include most of the minimax control problems that appear in applications; and above all, they allow us to obtain computable results, at least in principle. Moreover, replacing our Assumption 3.1 with the standard continuity/compactness conditions (see, e.g., [18, 25, 45, 46, 61]) the results in sections 3, 4, 5 can be extended in the obvious manner to get both minimax and maximin strategies for zero-sum games.

2. Minimax control problems. In this section we introduce the basic components of a minimax control problem, namely, the minimax control model, the sets of admissible strategies, and the performance criteria. We will use the following notation.

REMARK 2.1. *If X is a Borel space (that is, a Borel subset of a complete and separable metric space), its Borel σ-algebra is denoted by $\mathfrak{B}(X)$. Let X and Y be Borel spaces. Then a transition probability (or stochastic kernel) from Y to X is a function $\varphi(D \mid y)$ such that $\varphi(\cdot \mid y)$ is a probability measure on $\mathfrak{B}(X)$ for each $y \in Y$, and $\varphi(D \mid \cdot)$ is a measurable function on Y for each $D \in \mathfrak{B}(X)$. If $Y = X$, then φ is called a* Markov transition probability.

2.1. The minimax control model. As we have already noted, a minimax control problem is in fact a special class of a two-person zero-sum dynamic game. Thus the corresponding minimax control model is (as in [32, 33, 34, 35]) of the form

$$MCM := (X, A, B, \mathbb{K}_A, \mathbb{K}, Q, c), \tag{2.1}$$

where X is the *state space*, A is the *controller's* (player 1) *action space*, and B is the *opponent's* (player 2) *action space*. These spaces are all assumed to be Borel spaces. In addition we have the following:

(a) $\mathbb{K}_A \in \mathfrak{B}(X \times A)$ is the *constraint set for the controller*. That is, for each state $x \in X$, the x-section

$$A(x) := \{a \in A \mid (x, a) \in \mathbb{K}_A\} \tag{2.2}$$

represents the set of admissible actions for the controller in the state x. We assume that $\mathbb{K}_A$ contains the graph of a measurable function from X to A. (This will indeed be the case under Assumption 3.1 below.)

(b) $\mathbb{K} \in \mathfrak{B}(X \times A \times B)$ is the *constraint set for the opponent*, so that for each pair (x, a) in $\mathbb{K}_A$ the (x, a)-section

$$B(x, a) := \{b \in B \mid (x, a, b) \in \mathbb{K}\} \tag{2.3}$$

is the set of admissible actions for the opponent when the state is $x \in X$ and the controller uses the action $a \in A(x)$. We suppose that $\mathbb{K}$ contains the graph of a measurable map from $\mathbb{K}_A$ to B. (This, again, will be the case under Assumption 3.1.)

(c) Q or, more explicitly, $Q(D \mid x, a, b)$, denotes the *transition law*, a stochastic kernel from $\mathbb{K}$ to X.

(d) $c : \mathbb{K} \to \mathbb{R}$ stands for the *cost-per-stage* function.

The above minimax control model is also known as a *Markov* (or *stochastic*) *game with complete information* [32, 33, 34]. If the opponent's action set $B(x, a)$ in (2.3) does not depend on $a \in A(x)$, we then obtain the usual zero-sum Markov game in which the players choose their actions $a \in A(x)$ and $b \in B(x)$ independently.

The minimax control model represents a dynamic game that evolves in discrete time ($n = 0, 1, \dots$) as follows: if the state at time n is $x_n = x \in X$, then the controller chooses an action $a_n = a$ in $A(x)$, and the opponent chooses an action $b_n = b$ in $B(x, a)$. As a consequence of this, two things happen: (1) the controller pays $c(x, a, b)$ to the opponent, and (2) the system moves to a new state $x_{n+1} \in X$ with probability $Q(\cdot \mid x, a, b)$.

2.2. Strategies. Let $H_0 := X$, $H_0^\# := \mathbb{K}_A$, and for $n \geq 1$ let $H_n := \mathbb{K}^n \times X$ and $H^\# := \mathbb{K}^n \times \mathbb{K}_A$. Generic elements of H_n and $H_n^\#$ are "histories" of the form

$$h_n = (x_0, a_0, b_0, \dots, x_{n-1}, a_{n-1}, b_{n-1}, x_n) \qquad \text{and} \qquad h_n^\# = (h_n, a_n), \tag{2.4}$$

respectively.

A *strategy for the controller* is a sequence $\pi = \{\pi_n\}$ of stochastic kernels from H_n to A that satisfy the constraint

$$\pi_n(A(x_n) \mid h_n) = 1 \qquad \forall h_n \in H_n \qquad \text{and} \qquad n = 0, 1, \dots .$$

We shall denote by Π the set of all the strategies (or control policies) for the controller.

A *strategy for the opponent* is a sequence $\gamma = \{\gamma_n\}$ of stochastic kernels γ_n from $H_n^\#$ to B such that $\gamma_n(B(x_n, a_n) \mid h_n^\#) = 1$ for all $h_n^\# \in H_n^\#$ and $n = 0, 1, \dots$. The set of all these strategies is denoted by Γ.

DEFINITION 2.1. *$\mathbb{F}_A$ denotes the set of all measurable functions $f : X \to A$ such that $f(x)$ is in $A(x)$ for all $x \in X$, and $\mathbb{F}_B$ stands for the set of measurable functions g from $X \times A$ to B such that $g(x, a)$ is in $B(x, a)$ for all $(x, a) \in \mathbb{K}_A$.*

A strategy $\pi = \{\pi_n\}$ for the controller is said to be a *Markov strategy* if there is a sequence of functions $f_n \in \mathbb{F}_A$ such that $\pi_n(\cdot \mid h_n)$ is concentrated at $f_n(x_n)$ for all $n = 0, 1, \dots$. In this case we shall identify π_n with f_n. Moreover, if $\pi = \{f_n\}$ is a Markov strategy and $f_n = f_0$ for all $n \geq 0$, then π is called a *stationary strategy*, and we shall identify π with $f_0 \in \mathbb{F}_A$. In other words, $\mathbb{F}_A$ will be identified with the family of stationary strategies for the controller.

The Markov and stationary strategies for the opponent are defined similarly, replacing $f_n \in \mathbb{F}_A$ with $g_n \in \mathbb{F}_B$.

Let $(\Omega, \mathfrak{F})$ be the (canonical) measurable space consisting of the sample space $\Omega := (X \times A \times B)^\infty$ and its product σ-algebra $\mathfrak{F}$. Then, by a theorem of Ionescu-Tulcea [4, 32] for each pair of strategies $\pi \in \Pi$ and $\gamma \in \Gamma$, and each initial state $x \in X$,

there is a probability measure $\mathbb{P}_x^{\pi,\gamma}$ and a stochastic process $\{(x_t, a_t, b_t), t = 0, 1, \dots\}$ defined on $(\Omega, \mathfrak{F})$ in a canonical way, where x_t, a_t, and b_t represent the state and the actions of the controller and the opponent, respectively, at each time $t = 0, 1, \dots$. The expectation operator with respect to $\mathbb{P}_x^{\pi,\gamma}$ is denoted by $\mathbb{E}_x^{\pi,\gamma}$.

2.3. Performance criteria. Let α be a given positive number. We shall consider three performance criteria, each depending on the initial state $x_0 = x \in X$, and strategies $\pi \in \Pi$ for the controller and $\gamma \in \Gamma$ for the opponent.

- The finite-horizon *n-stage cost* ($n = 1, 2, \dots$):

$$V_{n,\alpha}(x, \pi, \gamma) := \mathbb{E}_x^{\pi,\gamma}\left[\sum_{t=0}^{n-1} \alpha^t c(x_t, a_t, b_t)\right]. \tag{2.5}$$

  For $\alpha = 1$ we shall write $V_{n,1}(x, \pi, \gamma) \equiv J_n(x, \pi, \gamma)$.
- The infinite-horizon *α-discounted cost* (α-DC) with $0 < \alpha < 1$:

$$V_\alpha(x, \pi, \gamma) := \mathbb{E}_x^{\pi,\gamma}\left[\sum_{t=0}^{\infty} \alpha^t c(x_t, a_t, b_t)\right]. \tag{2.6}$$

- The infinite-horizon expected *average cost* (AC):

$$J(x, \pi, \gamma) := \limsup_{n\to\infty} \frac{1}{n} J_n(x, \pi, \gamma). \tag{2.7}$$

DEFINITION 2.2. *Let $K(x, \pi, \gamma)$ be any of the cost functions in* (2.5)–(2.7)*, and let*

$$K^{\#}(x, \pi) := \sup_{\gamma\in\Gamma} K(x, \pi, \gamma). \tag{2.8}$$

A strategy $\pi^* \in \Pi$ (for the controller) is said to be a minimax strategy with respect to the cost function K if π^* minimizes $K^{\#}(x, \cdot)$ over Π for all $x \in X$, that is,

$$K^{\#}(x, \pi^*) = \inf_{\pi\in\Pi} K^{\#}(x, \pi) = \inf_{\pi\in\Pi} \sup_{\gamma\in\Gamma} K(x, \pi, \gamma) \qquad \forall x \in X. \tag{2.9}$$

REMARK 2.2. *In game-theoretic terminology the function on the right-hand side of* (2.9)*, i.e.,*

$$U(x) := \inf_{\pi\in\Pi} \sup_{\gamma\in\Gamma} K(x, \pi, \gamma), \tag{2.10}$$

is called the zero-sum game's upper value *(with respect to K). Thus a minimax strategy is one that attains the game's upper value. On the other hand, one could consider the "dual,"* maximin problem *in which* (2.8) *is replaced with*

$$K_{\#}(x, \gamma) := \inf_{\pi\in\Pi} K(x, \pi, \gamma).$$

Then the game's lower value *(with respect to K) is*

$$L(x) := \sup_{\gamma\in\Gamma} K_{\#}(x, \gamma) = \sup_{\gamma\in\Gamma} \inf_{\pi\in\Pi} K(x, \pi, \gamma),$$

and $\gamma^* \in \Gamma$ is called a maximin strategy *if*

$$K_{\#}(x, \gamma^*) = L(x) \qquad \forall x \in X. \tag{2.11}$$

In general $L(\cdot) \le U(\cdot)$, and if the equality holds, then $L(\cdot) = U(\cdot)$ is called the game's value function. If in addition π^* and γ^* satisfy (2.9) *and* (2.11)*, then the pair (π^*, γ^*) is said to be a* saddle point *or a* noncooperative equilibrium.

3. Finite-horizon minimax problems. The following assumption is supposed to hold throughout the remainder of the paper. Except for parts (f) and (g) in this assumption, all of the conditions concern the usual continuity/compactness hypotheses for Markov control processes and Markov games [1, 2, 10, 11, 12, 17, 18, 23, 31, 32, 33, 34, 35, 45, 46, 48, 51, 52, 55, 56, 61, 64].

Assumption 3.1. Let MCM be as in (2.1).

(a) $c(x, a, b)$ is lower semicontinuous (l.s.c.) on $\mathbb{K}$.

(b) There is a constant $\bar{c} \geq 0$ and a measurable function $w(\cdot) \geq 1$ on X such that

$$|c(x, a, b)| \leq \bar{c} w(x) \qquad \forall (x, a, b) \in \mathbb{K}. \tag{3.1}$$

(c) The transition law Q is weakly continuous, that is, for each continuous bounded function $u : X \to \mathbb{R}$, the function

$$\hat{u}(x, a, b) := \int_X u(y) Q(dy|x, a, b) \tag{3.2}$$

is continuous on $\mathbb{K}$.

(d) The function $w(\cdot) \geq 1$ in (b) as well as $\hat{w}(x, a, b) := \int w(y) Q(dy|x, a, b)$ are continuous on X and $\mathbb{K}$, respectively. (See Remark 3.1(a).)

(e) There is a constant $\beta > 0$ such that $\hat{w}(x, a, b) \leq \beta w(x)$ for all (x, a, b) in $\mathbb{K}$.

(f) The set $A(x) \subset A$ in (2.2) is compact for each $x \in X$, and in addition the set-valued mapping $x \mapsto A(x)$ is upper semicontinuous (u.s.c.), that is, if $x^k \to x$ and $a^k \in A(x^k)$ is such that $a^k \to a$, then a is in $A(x)$. (See Remark 3.1(c).)

(g) The set $B(x, a)$ in (2.3) is σ-compact for each $(x, a) \in \mathbb{K}_A$, and, moreover, the set-valued mapping $(x, a) \mapsto B(x, a)$ is l.s.c., that is, if $(x^k, a^k) \in \mathbb{K}_A$ converges to $(x, a) \in \mathbb{K}_A$ and b is in $B(x, a)$, then there exists b^k in $B(x^k, a^k)$ such that $b^k \to b$.

Before stating our optimality result for the finite-horizon criterion (2.5), we shall make some comments on Assumption 3.1 and introduce some useful concepts.

REMARK 3.1. (a) *If the cost-per-stage* $c(x, a, b)$ *is* bounded below, *then part* (d) *in Assumption* 3.1 *is* not *required. (Indeed, if* $c(x, a, b) \geq -k$ *for all* (x, a, b) *in* $\mathbb{K}$ *and some constant* k, *then* $\hat{c}(x, a, b) := c(x, a, b) + k$ *is nonnegative, and so the fact that Assumption* 3.1(d) *is not required follows from the proof of Lemma* 3.2(b), *below. Observe that replacing* c *with* $\hat{c}$ *in* (2.5)–(2.7) *does not essentially alter the corresponding minimax control problem.) Furthermore, if* c *is* bounded *(above and below), then the "weight" or "bounding" function* $w(\cdot)$ *can be taken as a* constant, *for instance,* $w(\cdot) \equiv 1$, *and so Assumption* 3.1(e) *can be omitted.*

(b) *Consider the dynamic model* (1.1) *and suppose that* $\{\xi_t\}$ *is a sequence of independently and identically distributed (i.i.d.) random variables in a Borel space* S. *Let* μ *be the common probability distribution of the* ξ_t. *Then the function* $\hat{u}$ *in* (3.2) *becomes*

$$\hat{u}(x, a, b) = \mathbb{E}\left[u(x_{t+1}) \mid (x_t, a_t, b_t) = (x, a, b)\right] = \int_S u[F(x, a, b, s)]\mu(ds). \tag{3.3}$$

Therefore, by the dominated convergence theorem, Assumption 3.1(c) *holds if the measurable function* $F : \mathbb{K} \times S \to X$ *is continuous in* $(x, a, b) \in \mathbb{K}$ *for each* $s \in S$.

(c) *A set-valued mapping is said to be* continuous *if it is l.s.c. and u.s.c. Thus the semicontinuity requirements in Assumption* 3.1(f) *and* (g) *will be trivially verified in many cases because the mappings* $x \mapsto A(x)$ *and* $(x, a) \mapsto B(x, a)$ *are continuous*

in most applications (see (7.6) *and* (7.18)*, for instance). In fact, it is not uncommon to find situations in which they are* constant*—hence continuous—mappings, that is, $A(x) = A$ for all $x \in X$ or $B(x,a) = B$ for all $(x,a) \in \mathbb{K}_A$.*

Let $w(\cdot) \geq 1$ be as in Assumption 3.1*. We shall denote by $\mathbb{B}_w(X)$ the Banach space of measurable functions u on X that have a finite w-norm, $\|u\|_w < \infty$, which is defined as*

$$\|u\|_w := \sup_{x \in X} [|u(x)|/w(x)]. \tag{3.4}$$

For each $u \in \mathbb{B}_w(X)$, $0 \leq \alpha \leq 1$, and $(x,a,b) \in \mathbb{K}$ let

$$H_\alpha(u;x,a,b) := c(x,a,b) + \alpha \int_X u(y) Q(dy|x,a,b), \tag{3.5}$$

$$H_\alpha^\#(u;x,a) := \sup_{b \in B(x,a)} H_\alpha(u;x,a,b), \tag{3.6}$$

$$T_\alpha u(x) := \inf_{a \in A(x)} H_\alpha^\#(u;x,a). \tag{3.7}$$

More explicitly, we can write (3.7) as

$$T_\alpha u(x) = \inf_{a \in A(x)} \sup_{b \in B(x,a)} \left[c(x,a,b) + \alpha \int_X u(y) Q(dy|x,a,b) \right]. \tag{3.8}$$

The operator T_α is usually referred to as the *dynamic programming* (DP) *operator.*

We shall denote by $\mathbb{B}_{lsc}$ the family of l.s.c. functions in $\mathbb{B}_w(X)$.

THEOREM 3.1. *Fix $\alpha > 0$, and define on X the functions*

$$v_{n,\alpha} := T_\alpha v_{n-1,\alpha} = T_\alpha^n v_{0,\alpha} \qquad \forall n = 1,2,\dots, \tag{3.9}$$

with $v_{0,\alpha}(\cdot) \equiv 0$. Then for each $n = 1,2,\dots,$

(a) *$v_{n,\alpha}$ is in $\mathbb{B}_{lsc}$;*

(b) *there exists $f_n \in \mathbb{F}_A$ such that*

$$v_{n,\alpha}(x) = H_\alpha^\#(v_{n-1,\alpha};x,f_n(x)) \qquad \forall x \in X,$$

i.e.,

$$v_{n,\alpha}(x) = \sup_{b \in B(x,f_n(x))} \left[c(x,f_n(x),b) + \alpha \int_X v_{n-1,\alpha}(y) Q(dy|x,f_n(x),b) \right], \tag{3.10}$$

and, moreover,

$$v_{n,\alpha}(x) = \min_{a \in A(x)} \sup_{b \in B(x,a)} \left[c(x,a,b) + \alpha \int_X v_{n-1,\alpha}(y) Q(dy|x,a,b) \right]; \tag{3.11}$$

(c) *$v_{n,\alpha}$ is the optimal n-stage cost, that is, from* (2.5) *and* (2.9)*,*

$$v_{n,\alpha}(x) = \inf_{\pi \in \Pi} \sup_{\gamma \in \Gamma} V_{n,\alpha}(x,\pi,\gamma) \qquad \forall x \in X;$$

(d) *the Markov policy* $\pi^n := \{f_n, f_{n-1}, \dots, f_1\}$ *is a minimax strategy for the* n*-stage problem; that is, by* (c) *and Definition* 2.2,

$$v_{n,\alpha}(x) = \sup_{\gamma\in\Gamma} V_{n,\alpha}(x, \pi^n, \gamma) \qquad \forall x \in X.$$

To prove Theorem 3.1 we shall state first some useful preliminary results. Observe in particular that the following lemma gives the existence of minimax strategies for a *single-stage minimax problem* with cost function $v(x, a, b)$, say.

LEMMA 3.2. *Let* $v : \mathbb{K} \to \mathbb{R}$ *be an l.s.c. function such that*

$$|v(x, a, b)| \le \bar{v}w(x) \qquad \forall (x, a, b) \in \mathbb{K} \tag{3.12}$$

for some constant $\bar{v} \ge 0$. *Let*

$$v^{\#}(x, a) := \sup_{b\in B(x,a)} v(x, a, b) \qquad \textit{and} \qquad v^*(x) := \inf_{a\in A(x)} v^{\#}(x, a).$$

Then

(a) $v^{\#}$ *is l.s.c. on* $\mathbb{K}_A$ *and satisfies that*

$$|v^{\#}(x, a)| \le \bar{v}w(x) \qquad \forall (x, a) \in \mathbb{K}_A; \tag{3.13}$$

(b) v^* *is in* $\mathbb{B}_{lsc}$ *and there exists* $f \in \mathbb{F}_A$ *such that*

$$v^*(x) = \min_{a\in A(x)} v^{\#}(x, a) = v^{\#}(x, f(x)) \qquad \forall x \in X, \tag{3.14}$$

that is, by definition of $v^{\#}$,

$$v^*(x) = \sup_{b\in B(x,f(x))} v(x, f(x), b) \qquad \forall x \in X.$$

Proof. (a) The inequality (3.13) obviously follows from (3.12). Now, to prove that $v^{\#}$ is l.s.c., let $(x^k, a^k) \in \mathbb{K}_A$ be a sequence converging to $(x, a) \in \mathbb{K}_A$. Choose an arbitrary $b \in B(x, a)$. Then, by Assumption 3.1(g), there exists $b^k \in B(x^k, a^k)$ such that $b^k \to b$. Therefore, as $v^{\#}(x^k, a^k) \ge v(x^k, a^k, b^k)$ and v is l.s.c., we have

$$\liminf_{k\to\infty} v^{\#}(x^k, a^k) \ge v(x, a, b).$$

Thus, as $b \in B(x, a)$ was arbitrary, we obtain $\liminf v^{\#}(x^k, a^k) \ge v^{\#}(x, a)$; that is, $v^{\#}$ is l.s.c.

(b) By (a) and the continuity of $w(\cdot)$ (Assumption 3.1(d)), the function $v^{\#}(x, a) + \bar{v}w(x)$ is *nonnegative* and l.s.c. on $\mathbb{K}_A$. Combining this fact with Assumption 3.1(f), a well-known result of Schäl [55] (reproduced in [16, Proposition D.5]) yields that the function

$$\inf_{a\in A(x)} [v^{\#}(x, a) + \bar{v}w(x)] \tag{3.15}$$

is l.s.c. and that there exists $f \in \mathbb{F}_A$ that realizes the minimum in (3.15), i.e.,

$$\min_{a\in A(x)} [v^{\#}(x, a) + \bar{v}w(x)] = v^{\#}(x, f(x)) + \bar{v}w(x) \qquad \forall x \in X.$$

This gives (3.14). Finally, (3.13) gives that $|v^*(\cdot)| \le \bar{v}w(\cdot)$, and so we conclude that v^* is in $\mathbb{B}_{lsc}$. □

In part (b) of the following lemma we replace the function v in (3.12) with the function $H_\alpha(u;\cdot)$ in (3.5), with u in $\mathbb{B}_{lsc}$. This yields in particular that *the DP operator T_α maps $\mathbb{B}_{lsc}$ into itself.*

LEMMA 3.3. *Let u be an arbitrary function in $\mathbb{B}_{lsc}$, and let $\hat{u}$ and $T_\alpha u$ be as in* (3.2) *and* (3.7), (3.8)*, respectively. Then*

(a) *$\hat{u}$ is l.s.c. on $\mathbb{K}$, and, therefore,*

(b) *$H_\alpha(u;x,a,b)$ is l.s.c. on $\mathbb{K}$, and*

$$|H_\alpha(u;x,a,b)| \le [\bar{c} + \alpha\beta\|u\|_w]w(x) \qquad \forall (x,a,b) \in \mathbb{K}; \tag{3.16}$$

(c) *$T_\alpha u$ is in $\mathbb{B}_{lsc}$, and, furthermore, there exists $f \in \mathbb{F}_A$ such that, for all $x \in X$,*

$$T_\alpha u(x) = \sup_{b \in B(x,f(x))} \left[c(x,f(x),b) + \alpha \int_X u(y) Q(dy|x,f(x),b) \right], \tag{3.17}$$

and (3.8) *holds with "min" in lieu of "inf," i.e.,*

$$T_\alpha u(x) = \min_{a \in A(x)} \sup_{b \in B(x,f(x))} \left[c(x,a,b) + \alpha \int_X u(y) Q(dy|x,a,b) \right]. \tag{3.18}$$

Proof. (a) Let u be in $\mathbb{B}_{lsc}$, and let us assume for a moment that u is *nonnegative*. Then there exists a sequence $\{u^n\}$ of continuous bounded functions such that $u^n \uparrow u$ pointwise. Hence, as $\int u(y)Q(dy|x,a,b) \ge \int u^n(y)Q(dy|x,a,b)$ for all n, if $(x^k,a^k,b^k) \to (x,a,b)$ we get from Assumption 3.1(c) that

$$\liminf_{k\to\infty} \int_X u(y)Q(dy|x^k,a^k,b^k) \ge \int_X u^n(y)Q(dy|x,a,b) \qquad \forall n.$$

Thus, letting $n \to \infty$ we conclude that $\hat{u}$ is l.s.c. on $\mathbb{K}$, when u is nonnegative. Consider now an *arbitrary* function u in $\mathbb{B}_{lsc}$. Then, by (3.4) and the continuity of $w(\cdot)$, the function $u(\cdot) + \|u\|_w w(\cdot)$ is l.s.c. and nonnegative. Therefore, by the result in the nonnegative case and the continuity of $\hat{w}$ (Assumption 3.1(d)), it follows that $\hat{u}$ is l.s.c.

(b) By (a) and Assumption 3.1(a), the function $H_\alpha(u;\cdot)$ is l.s.c. on $\mathbb{K}$. On the other hand, from (3.4) and Assumption 3.1(e),

$$\int |u(y)|Q(dy|x,a,b) \le \|u\|_w \int w(y)Q(dy|x,a,b) \le \|u\|_w \beta w(x) \tag{3.19}$$

for all (x,a,b) in $\mathbb{K}$. From the latter inequality together with (3.1) and (3.5) we get (3.16).

(c) This follows from (b) and Lemma 3.2(b) with $v(\cdot) = H_\alpha(u;\cdot)$. □

Using Lemma 3.3 we can now easily prove Theorem 3.1.

Proof of Theorem 3.1. Part (a) can be obtained by induction. As $v_{0,\alpha}(\cdot) \equiv 0$, (a) trivially holds for $n = 0$. Suppose now that $v_{n-1,\alpha}$ is in $\mathbb{B}_{lsc}$ for some $n \ge 1$. Then (3.9) and Lemma 3.3(c) yield that $v_{n,\alpha}$ is in $\mathbb{B}_{lsc}$, and (a) follows. In turn, (a) and Lemma 3.3(c) again yield (b). Finally, (c) and (d) follow from (b) and standard dynamic programming arguments (see, for instance, Theorem 3.2.1 in [16]). □

4. Infinite-horizon discount cost. In this section we consider the α-DC in (2.6), with $0 < \alpha < 1$. The clue to our optimality result is provided by the following fact due to Küenle [32, 33].

THEOREM 4.1. *Suppose that there exists a measurable function* $v^* : X \to \mathbb{R}$ *and a stationary policy* $f^* \in \mathbb{F}_A$ *such that, for all* $x \in X$,

$$v^*(x) = \sup_{b \in B(x, f^*(x))} \left[c(x, f^*(x), b) + \alpha \int_X v^*(y) Q(dy|x, f^*(x), b) \right] \tag{4.1}$$

and

$$\lim_{n \to \infty} \alpha^n \mathbb{E}_\alpha^{\pi,\gamma}[v^*(x_n)] = 0 \qquad \forall \pi \in \Pi, \gamma \in \Gamma, x \in X. \tag{4.2}$$

Then

$$v^*(x) = \sup_{\gamma \in \Gamma} V_\alpha(x, f^*, \gamma) \qquad \forall x \in X. \tag{4.3}$$

If in addition v^* *satisfies that (with* T_α *as in* (3.7), (3.8)*)*

$$v^* = T_\alpha v^*, \tag{4.4}$$

then v^* *is the optimal* α*-DC function, and* f^* *is an* α*-DC minimax strategy, that is,* (4.3) *holds and also*

$$v^*(x) = \inf_{\pi \in \Pi} \sup_{\gamma \in \Gamma} V_\alpha(x, \pi, \gamma) \qquad \forall x \in X. \tag{4.5}$$

To obtain (4.1), (4.2), and (4.4) it suffices to impose an additional condition on Assumption 3.1. The precise result is as follows. (Recall that $\mathbb{B}_{lsc}$ denotes the family of l.s.c. functions in $\mathbb{B}_w(X)$.)

THEOREM 4.2. *Suppose that Assumption* 3.1 *holds but, in addition, the constant* β *in part* (e) *satisfies that*

$$1 \le \beta < 1/\alpha. \tag{4.6}$$

Then there exist a function $v^* : X \to \mathbb{R}$ *and a stationary policy* $f^* \to \mathbb{F}_A$ *such that the following hold:*

(a) v^**is the unique function in* $\mathbb{B}_{lsc}$ *that satisfies* (4.4). *Moreover, it satisfies* (4.2), *and*

$$\|v_{n,\alpha} - v^*\|_w \le \bar{c}(\alpha\beta)^n/(1 - \alpha\beta) \qquad \forall n \ge 0, \tag{4.7}$$

with $\bar{c}$ *and* $v_{n,\alpha}$ *as in* (3.1) *and* (3.9), *respectively, with* $v_{0,\alpha} \equiv 0$.

(b) v^* *and* f^* *satisfy* (4.1).

Hence, v^* *and* f^* *satisfy the conclusions of Theorem* 4.1.

To prove Theorem 4.2 we will first state a few general results, some of which are in fact well known, but we include them here for completeness and ease of reference. After the proof of the theorem we state an interesting consequence (Corollary 4.6) of (4.7).

LEMMA 4.3. (a) *If* $\{v_n\}$ *is a sequence in* $\mathbb{B}_{lsc}$ *and* $\|v_n - v\|_w \to 0$, *then* v *is in* $\mathbb{B}_{lsc}$. *Hence,* (b) $\mathbb{B}_{lsc}$ *is a* complete *subset of* $\mathbb{B}_w(X)$, *that is, if* $\{v_n\} \subset \mathbb{B}_{lsc}$ *is a Cauchy sequence in* w*-norm, then it converges in* w*-norm to some function in* $\mathbb{B}_{lsc}$.

Proof. (a) The proof follows from the inequality $v(\cdot) \ge -\|v_n - v\|_w w(\cdot) + v_n(\cdot)$ and the continuity of w (Assumption 3.1(d)). Part (b) follows from (a) and the fact that $\mathbb{B}_w(X)$ is a Banach space. □

LEMMA 4.4. *Let $\mathbb{B}_0$ be a complete subset of $\mathbb{B}_w(X)$, and let T be a mapping from $\mathbb{B}_0$ into itself. Suppose that* (i) *T is monotone (i.e., $u \le u'$ implies $Tu \le Tu'$), and* (ii) *there is a constant $0 < \tau < 1$ such that*

$$T(u + rw) \le Tu + \tau rw \qquad \forall u \in \mathbb{B}_0 \qquad \text{and} \qquad r \ge 0. \tag{4.8}$$

Then T is a contraction mapping with modulus τ, i.e.,

$$\|Tu - Tu'\|_w \le \tau \|u - u'\|_w \qquad \forall u, u' \in \mathbb{B}_0, \tag{4.9}$$

and, therefore, there is a unique function u^* in $\mathbb{B}_0$ that satisfies

$$\text{(a)} \quad u^* = Tu^* \quad \text{and} \quad \text{(b)} \quad \|T^n u - u^*\|_w \le \tau^n \|u - u^*\|_w \quad \forall u \in \mathbb{B}_0, n \ge 0. \tag{4.10}$$

Further, if there is a constant $k \ge 0$ such that

$$\|Tu\|_w \le k + \tau \|u\|_w \qquad \forall u \in \mathbb{B}_0, \tag{4.11}$$

then

$$\|u^*\|_w \le k/(1 - \tau). \tag{4.12}$$

Proof. By (3.4), for any two functions u and u' in $\mathbb{B}_w(X)$ we have $u \le u' + \|u - u'\|_w w$. Hence, by (i) and (4.8) with $r := \|u - u'\|_w$, we obtain

$$Tu \le Tu' + \tau \|u - u'\|_w w,$$

so that $Tu - Tu' \le \tau \|u - u'\|_w w$. Similarly, $Tu - Tu' \ge -\tau \|u - u'\|_w w$, and (4.9) follows. Finally, (4.10) follows from Banach's fixed point theorem, whereas (4.12) follows from (4.11) and (4.10)(a). □

Lemma 4.4 is essentially the same as Proposition 7.2.9 in [17, p. 6], but the latter is *incorrectly stated* (!): it requires $r \in \mathbb{R}$, rather than $r \ge 0$ as in (4.8).

Finally, before passing to the proof of Theorem 4.2 we should mention that (4.2) holds for all u in $\mathbb{B}_w$, $\pi \in \Pi$, $\gamma \in \Gamma$, *and* $x \in X$, i.e.,

$$\lim_{n \to \infty} \alpha^n \mathbb{E}_x^{\pi,\gamma}[u(x_n)] = 0. \tag{4.13}$$

Indeed, using Assumption 3.1(e), a straightforward calculation gives

$$\mathbb{E}_x^{\pi,\gamma}[w(x_{n+1})] \le \beta \mathbb{E}_x^{\pi,\gamma}[w(x_n)] \qquad \forall n = 0, 1, \dots,$$

and so

$$\mathbb{E}_x^{\pi,\gamma}[w(x_n)] \le \beta^n w(x). \tag{4.14}$$

Hence, by (4.6),

$$\lim_{n \to \infty} \alpha^n \mathbb{E}_x^{\pi,\gamma}[w(x_n)] = 0.$$

This implies (4.13) because, by (3.4),

$$\mathbb{E}_x^{\pi,\gamma}[u(x_n)] \le \|u\|_w \mathbb{E}_x^{\pi,\gamma}[w(x_n)] \qquad \forall u \in \mathbb{B}_w(X). \tag{4.15}$$

Proof of Theorem 4.2. (a) We shall first use Lemma 4.4 to show that T_α is a contraction mapping on $\mathbb{B}_0 := \mathbb{B}_{lsc}$ with modulus $\tau := \alpha\beta < 1$, that is,

$$\|T_\alpha u - T_\alpha u'\|_w \le \tau \|u - u'\|_w \qquad \forall u, u' \in \mathbb{B}_{lsc}. \tag{4.16}$$

(Observe that T_α may not map all of $\mathbb{B}_w(X)$ into itself because for an arbitrary function u in $\mathbb{B}_w(X)$, the function $T_\alpha u$ is not necessarily measurable.) Now, by Lemma 4.3, $\mathbb{B}_{lsc}$ is a complete subset of $\mathbb{B}_w(X)$, whereas by Lemma 3.3, T_α maps $\mathbb{B}_{lsc}$ into itself. On the other hand, it is evident that T_α is monotone. Thus, to obtain (4.16) it suffices to verify that T_α satisfies (4.8). To do this, note that Assumption 3.1(e) yields

$$\sup_{b \in B(x,a)} \int_X w(y) Q(dy|x,a,b) \le \beta w(x) \qquad \forall (x,a) \in \mathbb{K}_A. \tag{4.17}$$

This inequality and (3.8) give (4.8) for $T = T_\alpha$ and $\tau := \alpha\beta$, and so (4.16) follows. Hence, there is a unique function v^* in $\mathbb{B}_{lsc}$ that satisfies (4.4), and, moreover (taking $u = v_{0,\alpha}$ in (4.10)(b)),

$$\|v_{n,\alpha} - v^*\|_w \le \tau^n \|v^*\|_w \qquad \forall n \ge 0, \quad \text{with } \tau = \alpha\beta. \tag{4.18}$$

Finally, observe that (3.16) gives

$$\|T_\alpha u\|_w \le \bar{c} + \tau \|u\|_w \qquad \forall u \in \mathbb{B}_{lsc},$$

which in turn, by (4.12), gives

$$\|v^*\|_w \le \bar{c}/(1-\tau). \tag{4.19}$$

From the latter inequality and (4.18) we obtain (4.7). Therefore, as v^* satisfies (4.2) (by (4.13)), the proof of part (a) is complete.

(b) The proof follows from (a) and Lemma 3.3(c). □

It is worth noting that (4.7) yields the *geometric convergence*, in the w-norm, of the so-called *value iteration* (or *successive approximations*) procedure $T_\alpha^n v_{0,\alpha} \to v^*$, where $v_{0,\alpha}(\cdot) \equiv 0$. Another noteworthy fact is Corollary 4.6 below, in which we use the following concept.

DEFINITION 4.5. *A sequence of stationary strategies $\{f_n\} \subset \mathbb{F}_A$ is said to converge in the sense of Schäl* [55] *if there exist $f_* \in \mathbb{F}_A$ such that $f_*(x) \in A(x)$ is an accumulation point of $\{f_n(x)\} \subset A(x)$ for each $x \in X$; that is, for each $x \in X$ there is a subsequence $\{n_i(x)\}$ of $\{n\}$ such that*

$$f_{n_i(x)}(x) \to f_*(x) \qquad as \qquad i \to \infty. \tag{4.20}$$

For example, *under Assumption* 3.1(f)*, any sequence in $\mathbb{F}_A$ converges in the sense of Schäl.* This is a special case of a result in [55], reproduced in [16, Proposition D.7]. This result trivially holds, and in fact it takes a *stronger* form, if the state space X is a *countable set* (with the discrete topology) and $A(x)$ is compact for each $x \in X$. Indeed, in the latter, countable case, a standard "diagonalization" argument shows that for any sequence $\{f_n\}$ in $\mathbb{F}_A$ there exists $f_* \in \mathbb{F}_A$ and a subsequence $\{n_i\} \subset \{n\}$ *independent of* $x \in X$ such that $f_{n_i}(x) \to f_*(x)$ for all $x \in X$.

COROLLARY 4.6. *Suppose that the hypotheses of Theorem* 4.2 *are satisfied. For each $n = 1, 2, \ldots$, let $f_n \in \mathbb{F}_A$ be as in* (3.10)*. Then*

(a) $\{f_n\}$ *converges in the sense of Schäl to some* $f_* \in \mathbb{F}_A$, *and*
(b) f_* *is a minimax strategy for the infinite-horizon* α*-DC problem.*

Proof. As mentioned in the previous paragraph, part (a) comes from [55]. To prove (b), first observe that (4.14), (4.6), and (3.1) yield

$$|V_{n,\alpha}(x,\pi,\gamma)| \le w(x)\bar{c}\sum_{t=0}^{n-1}(\alpha\beta)^t \le w(x)\bar{c}/(1-\tau), \qquad \text{with } \tau := \alpha\beta,$$

for all $n \ge 1$, π, γ, and x. Therefore the sequence $\{v_{n,\alpha}\}$ of optimal n-stage costs is *bounded in the* w*-norm*, i.e.,

$$\|v_{n,\alpha}\|_w \le \bar{c}/(1-\tau) \qquad \forall n. \tag{4.21}$$

Moreover, from (3.10),

$$v_{n,\alpha}(x) \ge c(x, f_n(x), b) + \alpha \int_X v_{n-1,\alpha}(y)Q(dy|x, f_n(x), b) \tag{4.22}$$

for all b in $B(x, f_n(x))$. Now choose an arbitrary $x \in X$, and let $n_i \equiv n_i(x)$ be as in (4.20), so that $(x, f_{n_i}(x)) \to (x, f_*(x))$. Next, choose an arbitrary b_* in $B(x, f_*(x))$. By Assumption 3.1(g), there exists b_{n_i} in $B(x, f_{n_i}(x))$ such that $b_{n_i} \to b_*$, and so $(x, f_{n_i}(x), b_{n_i}) \to (x, f_*(x), b_*)$. Finally, in (4.22) replace n, $f_n(x)$, and b with n_i, $f_{n_i}(x)$, and b_{n_i}, respectively, and let $i \to \infty$. Then, by (4.7) and the extension of Fatou's lemma in [17, Lemma 8.3.7, p. 48] (which is applicable in the present case because of (4.21)), we obtain

$$v^*(x) \ge c(x, f_*(x), b_*) + \alpha \int_X v^*(y)Q(dy|x, f_*(x), b_*).$$

Actually, as $b_* \in B(x, f_*(x))$ was arbitrary,

$$v^*(x) \ge \sup_{b \in B(x, f_*(x))} \left[c(x, f_*(x), b) + \alpha \int_X v^*(y)Q(dy|x, f_*(x), b) \right]. \tag{4.23}$$

Therefore, as x was also arbitrary, (4.23) holds for all $x \in X$. On the other hand, by the definition (3.8) of T_α, together with (4.4), the right-hand side of (4.23) is minorized by $T_\alpha v^* = v^*$, and so the equality (4.1) follows. Hence, by Theorem 4.2, f_* is a minimax strategy. □

5. Infinite-horizon AC. For the AC criterion in (2.7), Küenle [32, 33] and Kurano [35] give the following analogue of Theorem 4.1, in which $T \equiv T_1$ is the DP operator in (3.7), (3.8) when $\alpha = 1$. (In fact, Küenle assumes that the function h^* in Theorem 5.1 is *bounded*, but, as in [18], it is easy to verify that the boundedness of h^* can be replaced with (5.2). On the other hand, Kurano assumes that $c(x,a,b)$ is *nonnegative* and that $B(x,a) \equiv B$ does not depend on (x,a). Combining their techniques, we get Theorem 5.1.)

THEOREM 5.1 (see [32, 33, 34, 35]). *Suppose that there exists a constant* ρ^*, *a measurable function* h^* *on* X, *and a stationary strategy* $f^* \in \mathbb{F}_A$ *such that, for all* $x \in X$,

$$\rho^* + h^*(x) = \sup_{b \in B(x, f^*(x))} \left[c(x, f^*(x), b) + \int_X h^*(y)Q(dy|x, f^*(x), b) \right] \tag{5.1}$$

and

$$\lim_{n\to\infty}\frac{1}{n}\mathbb{E}_x^{\pi,\gamma}[h^*(x_n)]=0 \qquad \forall \pi\in\Pi,\ \gamma\in\Gamma. \tag{5.2}$$

Then

$$\rho^*=\sup_{\gamma\in\Gamma}J(x,f^*,\gamma) \qquad \forall x\in X. \tag{5.3}$$

If in addition

$$\rho^*+h^*(x)=Th^*(x) \qquad \forall x\in X, \tag{5.4}$$

then ρ^* is the optimal AC, and f^* is a minimax strategy for the AC criterion, that is, (5.3) *holds and also*

$$\rho^*=\inf_{\pi\in\Pi}\sup_{\gamma\in\Gamma}J(x,\pi,\gamma) \qquad \forall x\in X. \tag{5.5}$$

We will next give conditions for the existence of a "triplet" (ρ^*,h^*,f^*) that satisfies (5.1), (5.2), and (5.4). We shall use the notation $\mu(v):=\int v\,d\mu$ whenever the integral is well defined.

First of all, throughout this section we suppose that Assumption 3.1 holds except for part (e). (Actually, (e) can be obtained from the following assumption taking $\beta:=\theta+\nu(w)/\nu(X)$ because $\delta(x,a,b)\le 1/\nu(X)$. Assumption 5.1(c) also implies (4.6) for suitable values of α; see Remark 8.3.5(a) in [17], for instance.) In addition we suppose the following.

Assumption 5.1. There exists a measure ν on X, with $\nu_*:=\nu(X)>0$, a nonnegative u.s.c. function δ on $\mathbb{K}$, and a constant $0<\theta<1$ such that

(a) $Q(D\mid x,a,b)\ge\delta(x,a,b)\,\nu(D)$ for all $(x,a,b)\in\mathbb{K}$ and $D\in\mathfrak{B}(X)$;
(b) $\nu(w):=\int_X w(x)\nu(dx)<\infty$;
(c) $\int_X w(y)Q(dy\mid x,a,b)\le\theta w(x)+\delta(x,a,b)\,\nu(w)$ for all $(x,a,b)\in\mathbb{K}$; and
(d) $\int_X\delta(x,f(x),g(x,f(x)))\nu(dx)>0$ for each $f\in\mathbb{F}_A$ and $g\in\mathbb{F}_B$.

See Remark 5.3 for comments on Assumption 5.1 and other similar hypotheses used in the literature on stochastic games and Markov control problems under the AC criterion.

THEOREM 5.2. *If Assumptions* 3.1 *and* 5.1 *hold, then there is a constant ρ^*, a function h^* in $\mathbb{B}_{lsc}$, and a stationary policy $f^*\in\mathbb{F}_A$ that satisfy* (5.1), (5.2), *and* (5.4). *Hence the conclusions of Theorem* 5.1 *hold.*

To prove Theorem 5.2 we shall first introduce some notation and a preliminary result.

For any real-valued measurable function u on $\mathbb{K}$ and any two stationary policies $f\in\mathbb{F}_A$ and $g\in\mathbb{F}_B$ we write

$$u(x,f,g):=u(x,f(x),g(x,f(x))) \qquad \forall x\in X.$$

In particular, $c(x,f,g):=c(x,f(x),g(x,f(x)))$ and similarly for $Q(\cdot\mid x,f,g)$ and $\delta(x,f,g)$. The following result can be proved as Vega-Amaya's [61] Theorem 3.3 and Lemma 4.3.

LEMMA 5.3. *Suppose that Assumption* 5.1 *holds. Then for each pair of stationary strategies $f\in\mathbb{F}_A$ and $g\in\mathbb{F}_B$ we have the following:*

(a) *$Q(\cdot\mid x,f,g)$ is positive Harris recurrent—hence, in particular, $Q(\cdot\mid x,f,g)$ admits a unique invariant probability measure (i.p.m.), say $\mu_{f,g}$. Moreover,*

(b) $\mu_{f,g}(w) := \int w\, d\mu_{f,g} < \infty$, *and*
(c) *the function* $\delta(x,a,b)$ *and the constant* $\mu_{f,g}(\delta) := \int \delta(x,f,g)\mu_{f,g}(dx)$ *satisfy*

$$\mu_{f,g}(\delta) = \lim_{n\to\infty} \frac{1}{n} E_x^{f,g}\left[\sum_{t=0}^{n-1} \delta(x_t,f,g)\right] \qquad \forall x \in X.$$

(d) *If in addition* (3.1) *holds, then (by* (b)*)*

$$J(f,g) := \int_X c(x,f,g)\mu_{f,g}(dx) \qquad \textit{and} \qquad \rho^* := \inf_{f\in\mathbb{F}_A} \sup_{g\in\mathbb{F}_B} J(f,g) \tag{5.6}$$

are both finite.

Observe that the constant $J(f,g)$ in (5.6) coincides with the average cost (2.7) if $\pi = f$ and $\gamma = g$, i.e.,

$$J(x,f,g) = J(f,g) \qquad \forall x \in X.$$

On the other hand, integrating with respect to the i.p.m. $\mu_{f,g}$ both sides of the inequality in Assumption 5.1(c), we obtain that

$$\mu_{f,g}(\delta) \geq \mu_{f,g}(w)(1-\theta)/\nu(w).$$

Hence, as $w(\cdot) \geq 1$, letting $\delta_* := (1-\theta)/\nu(w)$ we get

$$\mu_{f,g}(\delta) \geq \delta_* > 0 \qquad \forall f \in \mathbb{F}_A,\ g \in \mathbb{F}_B. \tag{5.7}$$

Furthermore, if $\hat{Q}$ denotes the substochastic kernel

$$\hat{Q}(\cdot \mid x,a,b) := Q(\cdot \mid x,a,b) - \delta(x,a,b)\nu(\cdot) \tag{5.8}$$

(see Assumption 5.1(a)), then we may express the Assumption 5.1(c) as

$$\int_X w(y)\hat{Q}(dy \mid x,a,b) \leq \theta w(x) \qquad \forall (x,a,b) \in \mathbb{K}. \tag{5.9}$$

From these facts we may obtain the proof of Theorem 5.2 as follows.

Proof of Theorem 5.2. Let ρ^* and $\hat{Q}$ be as in (5.6) and (5.8), respectively, and for each function u in $\mathbb{B}_{lsc}$ and $x \in X$ let

$$Mu(x) := \inf_{a\in A(x)} \sup_{b\in B(x,a)} \left[c(x,a,b) + \int_X u(y)\hat{Q}(dy \mid x,a,b) - \rho^*\right] \tag{5.10}$$

or, more explicitly,

$$Mu(x) = \inf_{a\in A(x)} \sup_{b\in B(x,a)} \left[c(x,a,b) + \int_X u(y)Q(dy \mid x,a,b) - \delta(x,a,b)\nu(u) - \rho^*\right].$$

It is easily seen that M is a *contraction mapping* from $\mathbb{B}_{lsc}$ into itself. Indeed, by Assumption 5.1, the function δ is u.s.c., and so $-\delta$ is l.s.c. Thus, as in Lemma 3.3, it follows that if u is in $\mathbb{B}_{lsc}$, then so is Mu. Moreover, it is obvious that M is monotone, and, on the other hand, by (5.9),

$$M(u + rw) \leq Mu + \theta rw \qquad \forall u \in \mathbb{B}_{lsc}, r \geq 0.$$

Thus Lemma 4.4 yields that M is a contraction mapping on $\mathbb{B}_{lsc}$ with modulus θ, and it follows that M has a unique fixed point h^* in $\mathbb{B}_{lsc}$, i.e., $h^* = Mh^*$, or, equivalently,

(5.11)
$$\rho^* + h^*(x) = \inf_{a\in A(x)} \sup_{b\in B(x,a)} \left[c(x,a,b) + \int_X h^*(y) Q(dy \mid x,a,b) - \delta(x,a,b)\nu(h^*) \right].$$

We will next show that

$$\nu(h^*) = 0 \tag{5.12}$$

so that (5.11) reduces to the AC "optimality equation" (5.4).

To this end, first note that as in Lemma 3.3(c) (or Lemma 3.2(b)) there exists a stationary strategy f^* in $\mathbb{F}_A$ such that

(5.13)
$$\rho^* + h^*(x) = \sup_{b\in B(x,f^*(x))} \left[c(x,f^*(x),b) + \int_X h^*(y) Q(dy \mid x, f^*(x), b) - \delta(x,f^*(x),b)\nu(h^*) \right]$$

for all $x \in X$. Therefore, for any strategy $g \in \mathbb{F}_B$ we have

$$\rho^* + h^*(x) \geq c(x,f^*,g) + \int_X h^*(y) Q(dy \mid x, f^*, g) - \delta(x,f^*,g)\nu(h^*),$$

and integrating both sides of this inequality with respect to $\mu_{f^*,g}$ we get

$$\rho^* \geq J(f^*,g) - \mu_{f^*,g}(\delta)\nu(h^*) \qquad \forall g \in \mathbb{F}_B.$$

Now suppose that $\nu(h^*) < 0$. Hence, by (5.7),

$$-\mu_{f^*,g}(\delta)\nu(h^*) > -\delta_*\nu(h^*) > 0,$$

and so

$$\rho^* \geq J(f^*,g) - \delta_*\nu(h^*) > J(f^*,g) \qquad \forall g \in \mathbb{F}_B.$$

This inequality contradicts the definition of ρ^* in (5.6), according to which

$$\rho^* \leq \sup_{g\in\mathbb{F}_B} J(f,g) \qquad \forall f \in \mathbb{F}_A.$$

As a consequence, $\nu(h^*)$ cannot be negative; that is, necessarily $\nu(h^*) \geq 0$. Hence suppose that $\nu(h^*) > 0$, and let us go back to (5.11). By well-known measurable selection theorems—see, e.g., Corollary 4.3 in [49]—for each $\varepsilon > 0$ there exists an ε-maximizer $g_\varepsilon \in \mathbb{F}_B$ of the right-hand side of (5.11), i.e.,

$$\sup_{b\in B(x,a)} \left[c(x,a,b) + \int_X h^*(y) Q(dy \mid x,a,b) - \delta(x,a,b)\nu(h^*) \right]$$
$$\leq c(x,a,g_\varepsilon(x,a)) + \int_X h^*(y) Q(dy \mid x,a,g_\varepsilon(x,a)) - \delta(x,a,g_\varepsilon(x,a))\nu(h^*) + \varepsilon$$

for all $(x,a) \in \mathbb{K}_A$. The latter inequality and (5.11) yield that for any stationary strategy $f \in \mathbb{F}_A$ and $x \in X$,

$$\rho^* + h^*(x) \leq c(x,f,g_\varepsilon) + \int_X h^*(y) Q(dy \mid x, f, g_\varepsilon) - \delta(x,f,g_\varepsilon)\nu(h^*) + \varepsilon,$$

and so integration with respect to the i.p.m. μ_{f,g_ε} gives

$$\rho^* \le J(f, g_\varepsilon) - \mu_{f,g_\varepsilon}(\delta)\nu(h^*) + \varepsilon \qquad \forall f \in \mathbb{F}_A.$$

Hence, as we have assumed that $\nu(h^*) > 0$, from (5.7) we get

$$\rho^* \le \inf_{f\in\mathbb{F}_A} J(f, g_\varepsilon) - \delta_*\nu(h^*) + \varepsilon.$$

In particular, if we take $0 < \varepsilon < \delta_*\nu(h^*)$, there exists $g_\varepsilon \in \mathbb{F}_B$ such that

$$\rho^* < \inf_{f\in\mathbb{F}_A} J(f, g_\varepsilon),$$

which again contradicts the definition of ρ^* in (5.6), because the latter gives us

$$\rho^* \ge \inf_{f\in\mathbb{F}_A} J(f, g) \qquad \forall g \in \mathbb{F}_B.$$

Thus, necessarily (5.12) holds, and so (5.11) and (5.13) yield (5.4) and (5.1), respectively. Finally, using (4.15) and Assumption 5.1(c) a straightforward calculation shows that (5.2) *holds for any function in* $\mathbb{B}_w(X)$. This completes the proof of Theorem 5.2. □

A special case. The contraction mapping in (5.10) gives the desired theoretical results in Theorem 5.2, but for practical purposes it is not very useful because it is defined in terms of ρ^*, which is precisely what we would like to compute! Hence, to show a "computable" case, *throughout the rest of this section we consider the special case in which Assumption* 5.1 *holds with*

$$\delta(x, a, b) \equiv 1 \qquad \forall (x, a, b) \in \mathbb{K}. \tag{5.14}$$

Now let $v_n \equiv v_{n,1}$ be the optimal n-stage cost when $\alpha = 1$ (see Theorem 3.1(c)), with $v_0 \equiv 0$. We denote by $\{u_n\}$ the sequence in $\mathbb{B}_{lsc}$ defined as $u_0 := v_0$, $u_1 := v_1$, and for $n \ge 2$

$$u_n := v_n - m_n, \qquad \text{with} \qquad m_n := \sum_{j=1}^{n-1} (1 - \nu_*)^{n-1-j}\nu(v_j), \tag{5.15}$$

where $\nu_* := \nu(X)$. Furthermore, let

$$\rho_n := \nu(u_n) = \nu(v_n) - \nu_* m_n \qquad \forall n \ge 0. \tag{5.16}$$

Observe that all of these quantities are indeed "computable." Moreover, they yield a solution h^*, ρ^* of (5.4) as follows.

COROLLARY 5.4. *Suppose that the hypotheses of Theorem* 5.2 *are satisfied, with* δ *as in* (5.14). *Then there exist* $\rho^* \in \mathbb{R}$, $h^* \in \mathbb{B}_{lsc}$, *and* $f^* \in \mathbb{F}_A$ *as in Theorem* 5.2 *and, in addition, for all* $n = 0, 1, \ldots$, *we have*

$$\|u_n - h^*\|_w \le \theta^n \bar{c}/(1 - \theta), \tag{5.17}$$

$$|\rho_n - \rho^*| \le \theta^n \nu(w)\bar{c}/(1 - \theta). \tag{5.18}$$

Proof. Instead of the mapping Mu in (5.10), consider

$$Nu(x) := \inf_{a\in A(x)} \sup_{b\in B(x,a)} \left[c(x,a,b) + \int_X u(y)\hat{Q}(dy \mid x,a,b) \right] \tag{5.19}$$

for each $u \in \mathbb{B}_{lsc}$, with $\hat{Q}(\cdot \mid x,a,b) := Q(\cdot \mid x,a,b) - \nu(\cdot)$; see (5.8) and (5.14). Then, arguing exactly as in the proof of Theorem 5.2, it follows that N is a contraction mapping from $\mathbb{B}_{lsc}$ into itself, with modulus θ. Therefore, there is a unique function h^* in $\mathbb{B}_{lsc}$ such that $h^* = Nh^*$; equivalently, letting $\rho^* := \nu(h^*)$, the pair (h^*, ρ^*) is the unique solution of (5.4). Hence, as the existence of $f^* \in \mathbb{F}_A$ satisfying (5.1) follows from Theorem 5.2, to complete the proof it remains only to consider (5.17) and (5.18).

To this end, let $T := T_1$ be the DP operator in (3.8) when $\alpha = 1$, and note that (5.19) can be written as

$$Nu = Tu - \nu(u). \tag{5.20}$$

Now let $u_0 := 0$, and for $n \geq 1$ define u_n in $\mathbb{B}_{lsc}$ as

$$u_n := Nu_{n-1} = N^n u_0, \tag{5.21}$$

which, by (5.20), we can also write as $u_n = Tu_{n-1} - \nu(u_{n-1})$. Then, as (3.9) gives (with $\alpha = 1$) $v_n = Tv_{n-1} = T^n v_0$, a direct induction argument shows that the sequence in (5.21) is precisely the sequence $\{u_n\}$ in (5.15). Consequently, the contraction property of N and (4.10)(b) with $u = u_0 = 0$ give

$$\|u_n - h^*\|_w \leq \theta^n \|h^*\|_w.$$

Thus to get (5.17) it suffices to show that $\|h^*\|_w \leq \bar{c}/(1-\theta)$. To obtain the latter inequality note that (3.1), (3.4), and (5.9) yield

$$\|Nu\|_w \leq \bar{c} + \theta\|u\|_w \qquad \forall u \in \mathbb{B}_{lsc}. \tag{5.22}$$

This inequality and (4.11)–(4.12) give that $\|h^*\|_w \leq \bar{c}/(1-\theta)$, and so (5.17) follows.

Finally, since $\rho^* := \nu(h^*)$, from (5.16) we obtain

$$|\rho_n - \rho^*| \leq \int |u_n - h^*| d\nu \leq \|u_n - h^*\|_w \int w d\nu.$$

This inequality and (5.17) give (5.18) because $\nu(w) := \int w d\nu$. □

REMARK 5.1. *We should mention that although the "contraction approach" is quite standard, the convergence estimates in* (5.17) *and* (5.18) *are new, even for the standard (or one-player) AC control problem. As in the α-DC case, obtaining h^* and ρ^* via u_n and ρ_n is also called the* value iteration *(or* successive approximations*) procedure for the AC problem.*

Of course, (5.17) and (5.18) yield for the AC problem an analogue of Corollary 4.6, as follows.

COROLLARY 5.5. *Suppose that the hypotheses of Corollary* 5.4 *hold, and let $v_n \equiv v_{n,1}$ and f_n be as in* (3.10) *with $\alpha = 1$, for each $n = 1, 2, \ldots$, with $v_0 \equiv 0$. Then*

(a) *$\{f_n\}$ converges in the sense of Schäl to some stationary strategy $f_* \in \mathbb{F}_A$, and*

(b) *f_* is a minimax strategy for the AC problem.*

Proof. Part (a) is obtained as in the paragraph after Definition 4.5. To prove (b) note that (5.15) and (5.16) give

$$m_{n+1} - m_n = \rho_n \qquad \forall n \geq 2.$$

Using this equality and (5.15) we may express (3.10), when $\alpha = 1$, as

$$\rho_{n-1} + u_n(x) = \sup_{b \in B(x, f_n(x))} \left[c(x, f_n(x), b) + \int_X u_{n-1}(y) Q(dy|x, f_n(x), b) \right] \tag{5.23}$$

for all $x \in X$ and $n \geq 3$. Finally, (5.22) and the first equality in (5.21) yield

$$\|u_n\|_w \leq \bar{c} + \theta \|u_{n-1}\|_w \qquad \forall n \geq 1 \tag{5.24}$$

and, therefore,

$$\|u_n\|_w \leq \bar{c}/(1-\theta) \qquad \forall n \geq 0;$$

that is, the sequence $\{u_n\}$ *is bounded in the w-norm* (compare (5.24) with (4.21)). Hence, as (5.23) yields

$$\rho_{n-1} + u_n(x) \geq c(x, f_n(x), b) + \int_X u_{n-1}(y) Q(dy \mid x, f_n(x), b) \qquad \forall b \in B(x, f_n(x)),$$

using (5.17) and (5.18) the proof of (b) can now be completed "exactly" as the proof of Corollary 4.6(b) (after (4.22)), with the obvious changes. □

REMARK 5.2. *Concerning Assumption* 5.1(a)*, with* $\delta \equiv 1$ *as in* (5.14)*, Kurano* [35] *introduced an interesting approach that might be particularly useful if one does not know in advance that the said assumption holds. The idea is to introduce, for each* $0 < \varepsilon < 1$*, an auxiliary game model in which the transition law* Q *is replaced with*

$$Q_\varepsilon(\cdot \mid x, a, b) := (1-\varepsilon) Q(\cdot \mid x, a, b) + \varepsilon \psi(\cdot) \qquad [\geq \varepsilon \psi(\cdot)]$$

for some suitable probability measure ψ *on* X*. As* Q_ε *satisfies the Assumption* 5.1(a) *and* (5.14)*, one can solve (as in Corollary* 5.4*, say) the corresponding minimax control problem, and, finally, one should verify that the original problem is indeed solved in the limit as* $\varepsilon \to 0$*.*

The following proposition gives a couple of restrictive but easy-to-verify conditions that guarantee Assumption 5.1(a) with $\delta \equiv 1$.

PROPOSITION 5.6 (cf. Theorem 3.2 in [19]). *Suppose that* $Q(\cdot \mid x, a, b)$ *has a density* $q(x, a, b, \cdot)$ *with respect to a* σ*-finite measure* m *on* X*, that is,*

$$Q(D \mid x, a, b) = \int_D q(x, a, b, y) m(dy) \qquad \forall (x, a, b) \in \mathbb{K}, D \in \mathfrak{B}(X). \tag{5.25}$$

Then the following two conditions satisfy that (a) $\Rightarrow$ (b) $\Rightarrow$ *Assumption* 5.2(a) *with* $\delta \equiv 1$*.*

(a) *There exists a number* $\varepsilon > 0$ *and a set* $D_0 \in \mathfrak{B}(X)$ *with* $m(D_0) > 0$ *such that*

$$q(x, a, b, y) \geq \varepsilon \qquad \forall (x, a, b) \in \mathbb{K},\ y \in D_0. \tag{5.26}$$

(b) *There exists a nonnegative measurable function* q_0 *on* X *such that*

$$q(x, a, b, y) \geq q_0(y) \qquad \forall (x, a, b) \in \mathbb{K},\ y \in X \tag{5.27}$$

and

$$\int_X q_0(y)m(dy) > 0.$$

Proof. (a) *implies* (b): If (a) holds, then $q_0(y) := \varepsilon I_{D_0}(y)$ satisfies (b), where I_D stands for the indicator function of a set D.

(b) *implies Assumption* 5.1(a) *with* $\delta \equiv 1$: By (5.25) and (5.27), the measure $\nu(D) := \int_D q_0(y)m(dy)$ satisfies the desired conclusion. □

For examples satisfying (5.25)–(5.27), see [11, 17, 23, 35], for instance, or Examples 7.1 and 7.2 below.

REMARK 5.3. *Hypotheses similar to Assumption* 5.1 *have been used to study several classes of AC Markov games and control processes—see, e.g.,* [1, 2, 14, 17, 18, 22, 23, 25, 31, 32, 33, 34, 35, 42, 46, 48, 56, 61]*—but with some important differences. For instance, in* [18] *the inequality* $\int \delta(x,f,g)\nu(dx) > 0$ *in Assumption* 5.1(d) *is supposed to hold* uniformly *in* $f \in \mathbb{F}_A$ *and* $g \in \mathbb{F}_B$*, but Vega-Amaya* [61] *noted that it suffices to take the inequality in our present form, that is, for* each *pair of strategies* $f \in \mathbb{F}_A$*,* $g \in \mathbb{F}_B$*. On the other hand, instead of our Assumptions* 5.1(c) *and* (a)*, Jaśkiewicz and Nowak* [25] *use conditions of the form*

$$\int_X w(y)Q(dy \mid x,a,b) \le \theta w(x) + \eta I_C(x) \tag{5.28}$$

for some fixed Borel subset C *of* X*, and*

$$Q(D \mid x,f,g) \ge \delta\nu_{f,g}(D) \qquad \forall D \subset C, D \in \mathfrak{B}(X), \tag{5.29}$$

respectively, where $\nu_{f,g}$ *is a probability measure on* X *concentrated on* C*, for each* $f \in \mathbb{F}_A$ *and* $g \in \mathbb{F}_B$*. In the latter case, when* $\nu_{f,g}$ *depends on the strategies* f *and* g*, our fixed-point approach to prove Theorem* 5.2 *is* not *applicable. Another different form of* (5.28), (5.29) *has been introduced in* [31]*, allowing multichain Markov games. This basically means that there is a measurable partition* $D_0, \dots, D_m$ *of* X *such that for every pair of stationary strategies* $f \in \mathbb{F}_A$ *and* $g \in \mathbb{F}_B$ *the corresponding Markov chain has the same set* D_0 *of transient states and the same recurrent sets which consist of several cyclic sets* $D_1, \dots, D_m$*. A little more precisely, there is an integer* $k \ge 1$ *and measures* $\nu_1, \dots, \nu_m$ *on* X*, with* ν_i *concentrated on* D_i $(i = 1, \dots, m)$ *such that*

$$Q^k(\cdot \mid x,f,g) \ge \sum_{i=1}^m I_{D_i}(x)\nu_i(\cdot) \tag{5.30}$$

for each $x \in X$*,* $f \in \mathbb{F}_A$*, and* $g \in \mathbb{F}_B$*, where* I_D *denotes the indicator function of the set* D*. When* $k = m = 1$ *and* $D_1 = X$*,* (5.30) *reduces to Assumption* 5.1(a) *with* $\delta \equiv 1$ *as in* (5.14)*; in other words,* (5.30) *is a generalization of our special case* (5.14)*. In general, however, since the right-hand side of* (5.30) *does not depend on the players' actions/strategies, the relation (if any) between* (5.30) *and either* (5.29) *or our Assumption* 5.1(a) *is unclear. For other, detailed comments on Assumption* 5.1*, see* [25] *and* [61].

Finally, we mention also that the special case (5.14) has been used by many authors; see, e.g., [11, 15, 19, 32, 50, 52] and the references therein.

6. Systems with unknown disturbance distribution. In this section we consider the control system

$$x_{t+1} = F(x_t, a_t, \xi_t), \qquad t = 0, 1, \dots, \tag{6.1}$$

in which the ξ_t are independent random variables with values in a Borel space S and with *unknown* probability distributions. More precisely, the distributions may change from period to period, but they are restricted to lie in a certain class B specified below. The initial state x_0 is supposed to be independent of the sequence $\{\xi_t\}$, and F is a measurable function from $X \times A \times S$ to X.

REMARK 6.1. *Control problems in which the random variables are i.i.d. with a common but* unknown *distribution μ are usually referred to as (nonparametric)* adaptive control problems. *They are so named because at each decision time $t = 0, 1, \ldots$, the controller determines an estimate of the distribution of ξ_t, say $\hat{\xi}_t$, and then he/she "adapts" his/her actions to the given estimate. But, of course, this approach requires the disturbances to be "observable" because the estimate $\hat{\xi}_t$ is typically computed using realizations $\xi_0, \ldots, \xi_t$* [15, 21, 42]. *This observability condition occurs in many situations. For example, in control of inventories, queues, and water reservoirs, the disturbances are, respectively, the product's demand, the arrival process, and the water inflow, which can be safely assumed to be observable. However, there are other cases in which the disturbances are "really" random noises and it is impossible to "observe" them. For example, in economics, finance, and control of populations (fisheries, epidemics, and so on) there are so many external factors influencing the system's dynamics that it is practically necessary to model the disturbances as a "real" (unobservable) random noise. This is precisely the kind of situation that we have in mind in this section: the controller's opponent is the "nature" that at each period t picks (from a given set) a distribution for ξ_t.*

We shall denote by $\mathbb{P}(S)$ the family of probability measures on S, endowed with the topology of weak convergence. Thus, a sequence $\{\mu_n\}$ in $\mathbb{P}(S)$ *converges weakly* to μ if

$$\int_S h\, d\mu_n \to \int_S h\, d\mu \qquad \forall h \in C_b(S), \tag{6.2}$$

where $C_b(S)$ is the space of real-valued continuous bounded functions on S. As S is a Borel space, so is $\mathbb{P}(S)$ (see [4]).

We shall consider the game model in (2.1) except that now we suppose the following:

(a) B is a Borel subset of $\mathbb{P}(S)$ such that $B(x, a) = B$ for all $(x, a) \in \mathbb{K}_A$.

(b) The transition law $Q(\cdot \mid x, a, b)$ is the conditional distribution of x_{t+1} given that $(x_t, a_t) = (x, a) \in \mathbb{K}_A$ and that ξ_t has distribution $b \in \mathbb{P}(S)$; hence, by (6.1),

$$Q(D|x, a, b) = \int_S I_D[F(x, a, s)]b(ds) \qquad \forall D \in \mathfrak{B}(X). \tag{6.3}$$

(c) Similarly, for some given measurable function $\hat{c}$ on $\mathbb{K}_A \times S$,

$$c(x, a, b) = \int_S \hat{c}(x, a, s)b(ds). \tag{6.4}$$

We shall refer to this model as a *game against nature*. In the remainder of this section we give conditions under which the latter game satisfies some parts of Assumptions 3.1 and 5.1. The simplest—actually, trivial—is the following.

PROPOSITION 6.1. *Assumption* 3.1(b) *holds for the game against nature if there exists a constant $\bar{c} \geq 0$ and a measurable function $w(\cdot) \geq 1$ on X such that*

$$|\hat{c}(x, a, s)| \leq \bar{c}w(x) \qquad \forall (x, a, s) \in \mathbb{K}_A \times S. \tag{6.5}$$

Proof. The proof is trivial. □

To obtain other parts of Assumption 3.1 the game against nature requires more structure, as in the following proposition.

PROPOSITION 6.2. *Assumption* 3.1(c) *holds for the transition law in* (6.3) *if*

(a) *X, A, and S are locally compact separable metric spaces, and $\mathbb{K}_A$ is a closed subset of $X \times A$; and*

(b) *$F : \mathbb{K}_A \times S \to X$ is continuous.*

Proof. First note that the integrand in (6.3) can be written as a Dirac measure concentrated at $F(x, a, s)$, i.e.,

$$I_D[F(x, a, s)] = \delta_{F(x,a,s)}(D).$$

Suppose now that $(x^n, a^n, b^n) \to (x, a, b)$ in $\mathbb{K}_A \times B$, and define the stochastic kernels

$$\varphi_n(D \mid s) := \delta_{F(x^n,a^n,s)}(D) \qquad \text{and} \qquad \varphi(D \mid s) := \delta_{F(x,a,s)}(D). \tag{6.6}$$

Then, in particular, we can write (6.3) as a so-called *b-mixture of φ*, that is,

$$Q(D \mid x, a, b) = \int_S \varphi(D \mid s) b(ds).$$

Therefore, as the hypothesis (a) ensures that $\mathbb{K}_A \times S \to X$ is a locally compact and separable metric space and, on the other hand, we are assuming that $b^n \to b$ weakly, the proposition will follow from Serfozo's [57] Theorem 4.1 provided that

$$\varphi_n(\cdot \mid s^n) \to \varphi(\cdot \mid s) \qquad \text{weakly if} \qquad s^n \to s.$$

The latter condition, however, is obvious because by (6.6) and the hypothesis (b) we get

$$\int_X u(y)\varphi_n(dy|s^n) = u[F(x^n, a^n, s^n)] \to u[F(x, a, s)] = \int_X u(y)\varphi(dy|s)$$

for any continuous bounded function u on X. □

To get conditions under which the cost function in (6.4) satisfies Assumption 3.1(a) we shall assume that $\hat{c}$ is "separable" in (x, a) and s, that is,

$$\hat{c}(x, a, s) = c_1(x, a) + c_2(s) \qquad \forall (x, a, s) \in \mathbb{K}_A \times S. \tag{6.7}$$

In this case, (6.4) becomes

$$c(x, a, b) = c_1(x, a) + \int_S c_2(s) b(ds). \tag{6.8}$$

It is well known that if $b^n \to b$ weakly and $h : S \to \mathbb{R}$ is l.s.c. and bounded below, then

$$\liminf_{n\to\infty} \int_S h db^n \geq \int_S h db. \tag{6.9}$$

This fact yields the following.

PROPOSITION 6.3. *Assumption* 3.1(a) *holds for the function c in* (6.8) *if c_1 is l.s.c. on $\mathbb{K}_A$ and c_2 is l.s.c. and bounded below on S.*

Proposition 6.6, below, does not require c_2 to be bounded below. To state this, let us first recall the following concept.

DEFINITION 6.4. *Let $\{b^n\}$ be a sequence in $\mathbb{P}(S)$. A function u on S is said to be $\{b^n\}$-*uniformly integrable *if*

$$\lim_{\eta\to\infty} \sup_n \int_{N(u,\eta)} |u(s)| b^n(ds) = 0, \tag{6.10}$$

where, for $\eta > 0$,

$$N(u,\eta) := \{s \in S \mid |u(s)| \geq \eta\}.$$

For example, (6.10) holds if

$$\sup_n \int_S |u(s)|^{1+\varepsilon} b^n(ds) < \infty \tag{6.11}$$

for some $\varepsilon > 0$ because in this case

$$\int_{N(u,\eta)} |u(s)| b^n(ds) \leq (1/\eta^{\varepsilon}) \int_S |u(s)|^{1+\varepsilon} b^n(ds).$$

At any rate, the fact we are interested in is the following, whose proof can be found in [57], for instance.

LEMMA 6.5. *Suppose that $u : S \to \mathbb{R}$ is continuous and that it satisfies* (6.10). *If in addition $b^n \to b$ weakly, then $\int u\, db^n \to \int u\, db$.*

Replacing the function u in Lemma 6.5 with c_2 we obtain the following.

PROPOSITION 6.6. *Assumption* 3.1(a) *holds for the function c in* (6.8) *if c_1 is l.s.c. on $\mathbb{K}_A$ and, furthermore,*

(a) *c_2 is continuous on S;*

(b) *if $(x^n, a^n) \to (x, a)$ and b^n is in B for all n, then c_2 is $\{b^n\}$-uniformly integrable.*

EXAMPLE 6.1. *Suppose that $S = \mathbb{R}$ and let $c_2(s) := s^2$. From* (6.9) *we obtain that if $b^n \to b$ weakly, then*

$$\liminf_{n\to\infty} \int s^2 b^n(ds) \geq \int s^2 b(ds). \tag{6.12}$$

On the other hand, if, for instance,

$$\sup_n \int |s|^3 b^n(ds) < \infty, \tag{6.13}$$

and $b^n \to b$ weakly, then instead of (6.12) *we obtain the stronger result:*

$$\lim_{n\to\infty} \int s^2 b^n(ds) = \int s^2 b(ds). \tag{6.14}$$

This result comes from Lemma 6.5 *and* (6.11) *with $\varepsilon = 1$. In other words,* (6.14) *states that the mapping $b \mapsto \int s^2 db$ is continuous, whereas* (6.12) *gives that it is l.s.c.*

Finally, note that for "separable" functions as in (6.8) we have

$$\inf_{a\in A(x)} \sup_{b\in B} c(x,a,b) = \inf_{a\in A(x)} c_1(x,a) + \sup_{b\in B} \int c_2(s) b(s). \tag{6.15}$$

7. Examples. We will now present two examples on the game against nature introduced in section 6. In both examples, the state space X and the control set A are Borel subsets of $\mathbb{R}$. Moreover, to fix ideas we will choose a particular set B of admissible noise distributions, but the reader should note that such a set B can be replaced with *any family* of compactly supported distributions with zero mean, finite second moment, and strictly positive densities (for instance, uniform distributions). Further, the choice of zero-mean distributions is simply to facilitate calculations.

Throughout this section, the disturbance set S in (6.3), (6.4) is the compact interval $S := [-\hat{s}, \hat{s}]$ for some $\hat{s} > 0$, and the set $B \subset \mathbb{P}(S)$ of admissible disturbance distributions is the family $N(0, \sigma^2; \underline{\sigma}, \bar{\sigma})$ of truncated Gaussian distributions on S, with zero mean and standard deviation σ in $[\underline{\sigma}, \bar{\sigma}]$, where $0 < \underline{\sigma} \leq \bar{\sigma} < \infty$. In other words, a probability measure, denoted by b_σ, in B is of the form $b_\sigma(ds) = g_\sigma(s)ds$, where g_σ is the density function given by

$$g_\sigma(s) := k(\sigma)^{-1} e^{-s^2/2\sigma^2} I_S(s) \qquad \forall s \in \mathbb{R}, \tag{7.1}$$

with

$$k(\sigma) := \int_{-\hat{s}}^{\hat{s}} e^{-s^2/2\sigma^2} ds. \tag{7.2}$$

We shall denote by $\xi(\sigma)$ a generic random variable with distribution b_σ in B. It is evident that the second moments

$$E[\xi(\sigma)^2] = \int_{-\hat{s}}^{\hat{s}} s^2 g_\sigma(s) ds \qquad \text{for} \qquad \sigma \in [\underline{\sigma}, \bar{\sigma}] \tag{7.3}$$

are continuous in σ and uniformly bounded above. On the other hand, as $S = [-\hat{s}, \hat{s}]$ is a compact set, so is $\mathbb{P}(S)$ and also $B \subset \mathbb{P}(S)$. Therefore, there exists $\xi_*^2 > 0$ such that

$$\max_{\underline{\sigma} \leq \sigma \leq \bar{\sigma}} E[\xi(\sigma)^2] = \xi_*^2. \tag{7.4}$$

EXAMPLE 7.1. *This example was motivated by the mold level control problem briefly described in section* 1. *The underlying idea is that the state variable x stands for the height of a certain object that we wish to keep as close as possible to a nominal height x_*. Thus we consider the discrete-time model*

$$x_{t+1} = x_t + a_t + \xi_t \qquad for \qquad t = 0, 1, \dots, \tag{7.5}$$

with independent disturbances $\xi_t \equiv \xi(\sigma)$ as in the previous paragraph, and state space $X := [x_* - \underline{x}, x_* + \bar{x}]$, where $\underline{x}$ and $\bar{x}$ are given positive numbers. For each state x, the control set is

$$A(x) := [x_* - x, 0] \quad if \quad x \geq x_*, \quad and \quad A(x) := [0, x_* - x] \quad if \quad x \leq x_*. \tag{7.6}$$

The rationale is that if $x \geq x_*$, then we choose a control action $a \in A(x)$ to decrease x down to a point $x + a$ in $[x_*, x]$, whereas if $x \leq x_*$, then $a \in A(x)$ increases x up to a point $x + a$ in $[x, x_*]$. Moreover, to ensure that x_t is indeed in X for all $t \geq 0$ whenever x_0 is in X, we will assume that the disturbance set $S = [-\hat{s}, \hat{s}]$ is such that

$$0 < \hat{s} \leq \min\{\underline{x}, \bar{x}\}. \tag{7.7}$$

On the other hand, observe that as the disturbances $\xi(\sigma)$ have zero mean, (7.5) *gives that $E(x_{t+1}) = x + a$ if $x_t = x$ and $a_t = a$. Therefore it is natural to consider the cost function*

$$\hat{c}(x, a, s) := (x + a - x_*)^2 + s^2, \tag{7.8}$$

so that, by (7.3) *and* (6.8),

$$c(x, a, b_\sigma) = (x + a - x_*)^2 + E[\xi(\sigma)^2]. \tag{7.9}$$

We next verify that the corresponding minimax control problems satisfy Assumptions 3.1 *and* 5.1.

Verification of Assumption 3.1. Assumption 3.1(a) obviously follows from Proposition 6.3. In fact, it also follows from Proposition 6.6 because $c_2(s) := s^2$ is continuous on the *compact* set S. To verify Assumption 3.1(b) note that

$$-\underline{x} \le x + a - x_* \le \bar{x} \qquad \forall x \in X,\ a \in A(x). \tag{7.10}$$

This inequality and (7.4) yield that the *nonnegative* cost c in (7.9) is *bounded above* by $\bar{c} := \max\{\underline{x}^2, \bar{x}^2\} + \xi_*^2$. This yields Assumption 3.1(b) and also (d) and (e) with $w(\cdot) \equiv 1$ and $\beta = 1$. Observe that $\beta = 1$ also satisfies (4.6). On the other hand, Proposition 6.2 yields Assumption 3.1(c), and finally, parts (f) and (g) in Assumption 3.1 follow from the definitions of X, $A(x)$ and $B(x, a) \equiv B$—see Remark 3.1(c).

Verification of Assumption 5.1. Recall that $w(\cdot) \equiv 1$. We now wish to verify Assumption 5.1 in the special case (5.14), that is, $\delta \equiv 1$, assuming that $\underline{x} = \bar{x} =: \hat{x}$ and that, moreover, in lieu of (7.7) we have

$$\hat{s} < \hat{x} < 2\hat{s}. \tag{7.11}$$

Now, using (7.5), (7.1), and (6.3), we get the transition law

$$Q(D \mid x, a, b_\sigma) = \int_S I_D(x + a + s) g_\sigma(s) ds \qquad \forall D \in \mathfrak{B}(X). \tag{7.12}$$

Hence, as $S = [-\hat{s}, \hat{s}]$, using the change of variable $y := x + a + s$ we can write Q as in (5.25), i.e.,

$$Q(D \mid x, a, b_\sigma) = \int_D q(x, a, b_\sigma, y) dy,$$

where q is the transition density

$$q(x, a, b_\sigma, y) := I_{D(x,a)}(y) g_\sigma(y - (x + a)), \tag{7.13}$$

with $D(x, a) := [x + a - \hat{s}, x + a + \hat{s}]$. Furthermore, as

$$-\hat{s} \le y - (x + a) \le \hat{s} \qquad \forall y \in D(x, a),\ x \in X,\ a \in A(x), \tag{7.14}$$

$D(x, a)$ contains the interval $D_1 := [x_* - \hat{s}, x_* - \hat{x} + \hat{s}]$ if $x \le x_*$, and the interval $D_2 := [x_* + \hat{x} - \hat{s}, x_* + \hat{s}]$ if $x \ge x_*$. Hence

$$I_{D(x,a)} \ge I_{D_1} + I_{D_2}.$$

On the other hand, by (7.1), there exists $\varepsilon > 0$ such that $g_\sigma(y-(x+a)) \geq \varepsilon g_\sigma(y)$ for all x, a, y as in (7.14) and all σ in $[\underline{\sigma}, \bar{\sigma}]$. Therefore, the transition density in (7.13) satisfies an inequality of the form (5.27) with

$$q_0(y) := \varepsilon \left[I_{D_1}(y) + I_{D_2}(y) \right] g_\sigma(y).$$

Consequently, by Proposition 5.6, we get Assumption 5.1(a) with $\delta(x,a,b) \equiv 1$.

Summarizing, Assumptions 3.1 and 5.1 hold in the present example, and therefore all of the optimality results in sections 3, 4, and 5 are satisfied. In fact, as we show next, getting the optimal cost function turns out to be surprisingly simple because there exists a *myopic* minimax strategy! (See Remark 7.1 below.)

Computation of the minimax strategy and the optimal costs. Let f_n and $v_{n,\alpha}$ be as in (3.10) with $v_{0,\alpha} \equiv 0$. Then from (7.9), (7.4), and (6.15) we get that

$$f_1(x) := x_* - x, \qquad \text{and} \qquad v_{1,\alpha}(x) = \xi_*^2 \qquad \forall x \in X. \tag{7.15}$$

Similarly, a straightforward induction argument using (3.11) yields that

$$f_n(\cdot) \equiv f_1(\cdot) \qquad \text{and} \qquad v_{n,\alpha}(\cdot) \equiv \xi_*^2 \sum_{j=0}^{n-1} \alpha^j \qquad \forall n \geq 1, \alpha \in (0,1]. \tag{7.16}$$

It follows from Theorem 3.1 that the *constant function* $v_{n,\alpha}$ is the optimal n-stage cost and that the *stationary strategy* f_1 is minimax *for all* $n \geq 1$ *and all* α *in* (0,1].

In turn, from (7.16) and (4.7) it follows that the optimal α-DC is the *constant function* $v_\alpha^*(\cdot) \equiv \xi_*^2/(1-\alpha)$ *for all* $0 < \alpha < 1$, and so, by Theorem 4.2, $f_\alpha^*(\cdot) \equiv f_1(\cdot)$ is an α-DC minimax strategy *for all* $0 < \alpha < 1$.

Finally, from (5.15) and (5.17) we obtain that also the function h^* in (5.4) is constant, and so (5.4) reduces to $\rho^* = v_1(\cdot) \equiv \xi_*^2$. That is, the optimal AC is $\rho^* = \xi_*^2$, and $f^*(\cdot) \equiv f_1(\cdot)$ is a minimax strategy for the AC criterion.

REMARK 7.1. *A minimax strategy is said to be* myopic *if it can be obtained by solving a static (i.e., a one-period) optimization problem. Myopic policies, if they exist, are usually "problem-dependent"—for instance, in the* α*-DC case they depend on* α*. Thus, it is truly surprising that the myopic strategy* f_1 *in* (7.15) *is minimax for all of the problems associated to* (7.5), (7.6), (7.8)*, finite- or infinite-horizon, discounted or average. It is worth noting, on the other hand, that myopic behavior has been observed by many authors (see, e.g.,* [7, 8, 36, 53, 63]*), but as far as we can tell, it has been determined only for* particular *classes of problems, and* a posteriori*, that is, after one has actually solved the problem, as in Example* 7.1. *An interesting* open problem *would be to find a priori conditions—i.e., exclusively based on the problem data—for the existence of myopic strategies. The existing results in that direction* [58, 59, 60] *are not sufficiently general to include, for instance, the minimax model in Example* 7.1.

On the other hand, one might be willing to conjecture that the myopic property of f_1 is due to the fact that the system in (7.5) is linear and that the cost (7.9) is quadratic. These conditions, however, in general are not sufficient to have myopic behavior: for instance, the following example shows another LQ (i.e., linear system, quadratic cost) problem in which the minimax strategies are not myopic.

EXAMPLE 7.2. *Consider the linear system*

$$x_{t+1} = k_1 x_t + k_2 a_t + \xi_t \tag{7.17}$$

with state space $X := \mathbb{R}$*, and disturbances* $\xi_t \equiv \xi(\sigma) \in B$*, as at the beginning of this section. The coefficients* k_1 *and* k_2 *are given positive constants. For each state* x*, the control set* $A(x) \subset A := \mathbb{R}$ *is the interval*

$$A(x) := [-k_1|x|/k_2, k_1|x|/k_2]. \tag{7.18}$$

(Actually, in (7.18) *we may take* $A(x) := [-g_1(x), g_2(x)]$*, where* g_1 *and* g_2 *are nonnegative continuous functions such that* $g_i(x) \geq |k_1 x/k_2|$ *for all* $x \in X$ *and* $i = 1, 2$*. However, the choice in* (7.18) *greatly simplifies the calculations below.) To complete the specification of the minimax model we introduce the cost-per-stage*

$$\hat{c}(x, a, s) := c_1 x^2 + c_2 a^2 + s^2 \qquad \forall (x, a) \in \mathbb{K},\ s \in S,$$

where c_1 *and* c_2 *are positive constants. Thus, by* (7.3) *and* (6.8)*,*

$$c(x, a, b_\sigma) = c_1 x^2 + c_2 a^2 + E[\xi(\sigma)^2]. \tag{7.19}$$

The plan now is as in Example 7.1*: first we will verify the Assumptions* 3.1 *and* 5.1*, and then we will compute the optimal cost function and the minimax strategies for each of the problems in sections* 3*,* 4*,* 5*.*

Verification of Assumption 3.1. As in Example 7.1, part (a) in Assumption 3.1 follows from either Proposition 6.3 or Proposition 6.6. Now let ξ_*^2 be as in (7.4), and define

$$w_1 := c_1 + c_2(k_1/k_2)^2, \qquad \overline{w} := \max\{1, \xi_*^2, w_1\}$$

and, for some $\gamma \geq 2$,

$$w(x) := \overline{w} e^{\gamma|x|} \qquad \forall x \in X. \tag{7.20}$$

Therefore, by (7.18) and (7.19),

$$0 \leq c(x, a, b_\sigma) \leq w_1 x^2 + \xi_*^2 \leq w(x),$$

and so Assumption 3.1(b) holds with $\bar{c} := 1$. Furthermore, Assumption 3.1(c) follows from Proposition 6.2, whereas, as $c(x, a, b_\sigma)$ is nonnegative, Assumption 3.1(d) is not required in the present case (see Remark 3.1(a)). On the other hand, parts (f) and (g) are obvious (see Remark 3.1(c)), and so it only remains to verify Assumption 3.1(e), which can be done as follows.

LEMMA 7.1. *Let* $w(x)$ *be as in* (7.20)*, and suppose that*

$$0 < k_1 < 1/2. \tag{7.21}$$

Then Assumption 3.1(e) *holds with* $\beta := e^{\gamma \hat{s}}$*, i.e.,*

$$\hat{w}(x, a, b_\sigma) \leq \beta w(x), \tag{7.22}$$

where $\hat{w}(x, a, b_\sigma) := \int w(y) Q(dy|x, a, b_\sigma)$*. If in addition* $\gamma \hat{s} < -\log \alpha$*, then we also obtain* (4.6)*, i.e.,* $1 \leq \beta < 1/\alpha$*.*

Proof. By (7.18),

$$|k_1 x + k_2 a| \leq 2k_1|x| \qquad \forall (x, a) \in \mathbb{K}_A. \tag{7.23}$$

On the other hand, by (7.20),

$$\begin{aligned}\hat{w}(x,a,b_\sigma) &= E[w(k_1x+k_2a+\xi_0)]\\ &\le \overline{w}e^{\gamma|k_1x+k_2a|}E(e^{\gamma|\xi_0|})\\ &\le \overline{w}e^{2\gamma k_1|x|}e^{\gamma\hat{s}} \qquad \text{[by (7.23)]}\\ &= w(x)e^{-\gamma|x|}e^{\gamma|x|}\beta \qquad \text{[by (7.21) and (7.20)]}.\end{aligned} \tag{7.24}$$

This gives (7.22). The last statement in the lemma is obvious. □

Verification of Assumption 5.1. Let us replace (7.21) with the stronger condition

$$0 < k_1 < 1/6. \tag{7.25}$$

Consider the intervals $D_0 := [-\hat{s}/2, \hat{s}/2], D_1 := [-\hat{s}/4k_1, \hat{s}/4k_1]$, and let $\delta(x)$ be the indicator function of D_1. Observe that, by (7.23),

$$D_2(x,a) \supset D_0 \qquad \text{if} \qquad x \in D_1, \tag{7.26}$$

with $D_2(x,a) := [k_1x + k_2a - \hat{s}, k_1x + k_2a + \hat{s}]$. Moreover, as in Example 7.1 (see (7.12), (7.13)), one can see that the transition law Q for the system (7.17) has the density

$$q(x,a,b_\sigma,y) = I_{D_2(x,a)}(y)g_\sigma(y-(k_1x+k_2a)).$$

We can now verify Assumption 5.1 with

$$\delta(x,a,b_\sigma) \equiv \delta(x) \qquad \text{and} \qquad \nu(B) := \varepsilon \cdot m(B \cap D_0), \tag{7.27}$$

where $m(dy) = dy$ denotes the Lebesgue measure on X, and $\varepsilon > 0$ is a lower bound for $g_\sigma(\cdot)$ on S. (Observe that a point y is in $D_2(x,a)$ if and only if $y-(k_1x+k_2a)$ is in $S = [-\hat{s}, \hat{s}]$.) Indeed, by (7.26), Assumption 5.1(a) follows because

$$\begin{aligned}Q(B|x,a,b_\sigma) &= \int_B I_{D_2(x,a)}(y)g_\sigma(y-(k_1x+k_2a))dy\\ &\ge \delta(x)\int_B I_{D_0}(y)\cdot\varepsilon dy\\ &= \delta(x)\nu(B).\end{aligned}$$

Further, parts (b) and (d) in Assumption 5.1 are obvious. To verify part (c) we shall use the notation $\hat{w}(x,a,b_\sigma)$ in (7.22). Let us first consider the case $\delta(x) = 0$, that is, $|x| > \hat{s}/4k_1$. Then as in (7.24) we obtain

$$\begin{aligned}\hat{w}(x,a,b_\sigma) &\le w(x)e^{-\gamma|x|(1-2k_1)}e^{\gamma\hat{s}}\\ &\le w(x)e^{-\gamma\hat{s}(1-2k_1)/4k_1}e^{\gamma\hat{s}}\\ &=: \theta w(x)\end{aligned}$$

with $\theta := \exp[-\gamma\hat{s}(1-6k_1)/4k_1] < 1$. A similar calculation gives us

$$\hat{w}(x,a,b_\sigma) \le \theta w(x) + \nu(w)$$

if $\delta(x) = 1$, that is, $|x| \le \hat{s}/4k_1$. This completes the verification of Assumption 5.1.

We next compute the optimal cost functions and the minimax strategies for the system (7.17)–(7.19).

Finite-horizon case. Let $v_{n,\alpha}$ and f_n be as (3.10), (3.11) for $n \geq 1$, with $v_{0,\alpha}(\cdot) \equiv 0$.

PROPOSITION 7.2. *For all $n = 1, 2, \ldots$ and $x \in X$,*

$$v_{n,\alpha}(x) = v_1(n,\alpha)x^2 + v_2(n,\alpha) \qquad \text{and} \qquad f_n(x) = -f(n,\alpha)x \tag{7.28}$$

with coefficients given by $v_1(0,\alpha) = v_2(0,\alpha) = 0$, and for $n \geq 0$,

$$f(n+1,\alpha) := [c_2 + \alpha v_1(n,\alpha)k_2^2]^{-1}\alpha v_1(n,\alpha)k_1k_2, \tag{7.29}$$

$$v_1(n+1,\alpha) := c_1 + c_2 f(n+1,\alpha)^2 + \alpha v_1(n,\alpha)(k_1 - k_2 f(n+1,\alpha))^2, \tag{7.30}$$

$$v_2(n+1,\alpha) := (1 + \alpha v_1(n,\alpha))\xi_*^2 + \alpha v_2(n,\alpha). \tag{7.31}$$

As $c_2 > 0$, (7.29) implies that $|f(n,\alpha)| \leq k_1/k_2$, and therefore $f_n(x)$ is indeed in the interval $A(x)$ (in (7.18)) for all $x \in X$ and $n \geq 1$.

Proof. For $n = 1$, from (3.11), (6.15), and (7.19) we get $v_{1,\alpha}(x) = c_1x^2 + \xi_*^2$ and $f_1(x) = 0$ for all $x \in X$, with ξ_*^2 as in (7.4). That is, (7.28)–(7.31) hold with $v_1(1,\alpha) = c_1, v_2(1,\alpha) = \xi_*^2$, and $f(1,\alpha) = 0$. Now, by induction, let us suppose that (7.28) holds for some $n \geq 1$. Thus, by (7.23),

$$\int_X v_{n,\alpha}(y)Q(dy|x,a,b_\sigma) = v_1(n,\alpha)(k_1x + k_2a)^2 + v_1(n,\alpha)E[\xi(\sigma)^2] + v_2(n,\alpha),$$

and replacing this expression in (3.11) and using (6.15) we obtain

$$v_{n+1,\alpha}(x) = \min_{a \in A(x)} [c_1x^2 + c_2a^2 + \alpha v_1(n,\alpha)(k_1x + k_2a)^2] + \xi_*^2(1 + \alpha v_1(n,\alpha)) + \alpha v_2(n,\alpha).$$

Finally, a straightforward calculation gives

$$v_{n+1,\alpha}(x) = v_1(n+1,\alpha)x^2 + v_2(n+1,\alpha) \qquad \text{and} \qquad f_{n+1}(x) = -f(n+1,\alpha)x$$

with coefficients as in (7.29)–(7.31). □

The infinite-horizon α-discounted case ($0 < \alpha < 1$). Let us suppose that the number β in (7.25) satisfies (4.6). Then, by (7.28) and (4.7), we may "guess" that there is a unique function

$$v^*(x) = v_1(\alpha)x^2 + v_2(\alpha) \qquad \forall x \in X \tag{7.32}$$

in $\mathbb{B}_{lsc}$ that satisfies (4.4), i.e., using (7.28) and (7.19),

$$\begin{aligned} v^*(x) = \min_a \max_b \big\{ & c_1x^2 + c_2a^2 + E[\xi(\sigma)^2] + \alpha v_1(\alpha)(k_1x + k_2a)^2 \\ & + \alpha v_1(\alpha)E[\xi(\sigma)^2] + \alpha v_2(\alpha) \big\}. \end{aligned} \tag{7.33}$$

Moreover, from (6.15), a direct calculation shows that the minimum in (7.33) is attained when $a = f_\alpha(x)$ is the minimax strategy given by

$$f_\alpha(x) = -f(\alpha)x \qquad \forall x \in X, \tag{7.34}$$

with coefficient (cf. (7.29))

$$f(\alpha) := [c_2 + \alpha v_1(\alpha)k_2^2]^{-1}\alpha v_1(\alpha)k_1k_2. \tag{7.35}$$

As $c_2 > 0$, we have $|f(\alpha)| \leq |k_1/k_2|$, and so $f_\alpha(x)$ is indeed in $A(x)$ for all $x \in X$. Substituting (7.34) and (7.4) in (7.33), and then comparing the result with (7.32), we conclude that the coefficients $v_1(\alpha)$ and $v_2(\alpha)$ in (7.32) are given by the equations (similar to (7.30), (7.31))

$$v_1(\alpha) = c_1 + c_2 f(\alpha)^2 + \alpha v_1(\alpha)(k_1 - k_2 f(\alpha))^2, \tag{7.36}$$

$$v_2(\alpha) = (1 + \alpha v_1(\alpha))\xi_*^2 + \alpha v_2(\alpha). \tag{7.37}$$

Observe that (7.37) can be solved for $v_2(\alpha)$ in terms of $v_1(\alpha)$, i.e.,

$$v_2(\alpha) = (1 - \alpha)^{-1}(1 + \alpha v_1(\alpha))\xi_*^2, \tag{7.38}$$

whereas inserting (7.35) in (7.36) we obtain a quadratic equation for $v_1(\alpha)$:

$$\alpha k_2^2 v_1(\alpha)^2 + (c_2 - \alpha c_1 k_2^2 - \alpha c_2 k_1^2)v_1(\alpha) - c_1 c_2 = 0. \tag{7.39}$$

This equation has a *unique positive solution*, which is the value of the coefficient $v_1(\alpha)$ in (7.32), (7.35), and (7.38). In other words, the latter equations and (7.39) give an explicit solution for the α-discounted minimax problem in terms of the coefficients in (7.17) and (7.19).

The average cost (AC) case. We shall assume that (7.25) holds. To solve the minimax problem in the AC case we shall proceed as in the discounted cost problem. Namely, in light of (5.17) and (5.18), taking $\alpha = 1$ in (7.28)–(7.31) we "guess" that the solution $\rho^*, h^*(x)$ of (5.4) consists of some constant ρ^* and a quadratic function $h^*(x) = h_* x^2$ for some constant h_*. (Adding a constant to $h^*(x)$ does not alter the fact that $h^*(x)$ is a solution to (5.4); hence we take such a constant to be zero.) Now, substitution of

$$\rho^* \qquad \text{and} \qquad h^*(x) = h_* x^2 \tag{7.40}$$

in (5.4) yields, with the usual calculations,

$$\rho^* + h_* x^2 = \min_{a \in A(x)} [c_1 x^2 + c_2 a^2 + h_*(k_1 x + k_2 a)^2] + (1 + h_*)\xi_*^2 \tag{7.41}$$

and that the minimum is realized when $a = f^*(x)$ is the minimax strategy

$$f^*(x) = -f_* x, \qquad \text{with} \qquad f_* := (c_2 + h_* k_2^2)^{-1} h_* k_1 k_2. \tag{7.42}$$

Substitution of (7.42) in (7.41) yields that

$$\rho^* = (1 + h_*)\xi_*^2, \tag{7.43}$$

$$h_* = c_1 + c_2 f_*^2 + h_*(k_1 - k_2 f_*)^2. \tag{7.44}$$

Moreover, substitution of (7.42) in (7.44) gives the following quadratic equation for h_*:

$$k_2^2 h_*^2 + (c_2 - c_1 k_2^2 - c_2 k_1^2)h_* - c_1 c_2 = 0, \tag{7.45}$$

and the *unique positive solution* of (7.45) is the coefficient h_* in (7.40), (7.42), and (7.43). Thus, the optimal cost and the minimax strategy for the AC problem are as in (7.43) and (7.42), respectively.

8. Concluding remarks. We have presented in this paper a unified, self-contained study of minimax control problems for discrete-time stochastic systems in Borel spaces, allowing unbounded cost functions. Our results can be extended to maximin problems by modifying Assumption 3.1 in the obvious manner. Our study includes finite- and infinite-horizon problems. In fact, Theorem 4.2 (on the α-discounted case) and Corollary 5.4 (for AC problems) give precise estimates for the convergence of finite-horizon optimal cost functions to their infinite-horizon counterparts. Moreover, for the special case of stochastic systems with unknown disturbance distribution, in which the minimax problem is a "game against nature," we have presented (in section 6) sufficient conditions for the assumptions that ensure our optimality results in sections 3, 4, and 5. These sufficient conditions are used in section 7 to make a detailed analysis of two particular minimax control problems (Examples 7.1 and 7.2).

Finally, in connection with Example 7.1 and Remark 7.1 we should mention once again an important problem that remains open: determining conditions for the existence of *myopic* minimax strategies.

ROBUST DISSIPATIVITY OF INTERVAL UNCERTAIN LINEAR SYSTEMS*

FLORIN DAN BARB†, AHARON BEN-TAL‡, AND ARKADI NEMIROVSKI‡

Abstract. In this paper we are concerned with the problem of robust dissipativity of linear systems with parameters affected by box uncertainty; our major goal is to evaluate the largest uncertainty level for which all perturbed instances share a common dissipativity certificate. While it is NP-hard to compute this quantity exactly, we demonstrate that under favorable circumstances one can build an $O(1)$-tight lower bound of this "intractable" quantity by solving an explicit semidefinite program of the size polynomial in the size of the system. We consider a number of applications, including the robust versions of the problems of extracting nearly optimal available storage, providing nearly optimal required supply, Lyapunov stability analysis, and linear-quadratic control.

Key words. interval matrices, dissipative linear systems, interval uncertain LMIs, positive-real systems, contractive systems, Riccati equation, semidefinite programming

1. Introduction and motivation.

An important requirement of any modern control system is its robustness. In many system theory and control applications, the concept of robustness is related to the stability of the closed-loop system and its performance measured with respect to a certain objective function.

In this paper, we focus on robustness with respect to unknown-but-bounded (and possibly time-varying) perturbations of the entries in the matrix $\Sigma = \begin{bmatrix} A & B \\ C & D \end{bmatrix}$ of a continuous-time linear dynamical system

$$\begin{aligned} \dot{z} &= Az + Bu, \\ y &= Cz + Du. \end{aligned}$$

For the time being, we assume the simplest *interval* model of perturbations—every entry Σ_{ij} in Σ, independently of all other entries, can vary in the interval $\Sigma_{ij} \pm \rho d\Sigma_{ij}$, where Σ_{ij} are the nominal data, $d\Sigma_{ij}$ are given scale factors, and ρ is the uncertainty level. The set of matrices just defined will be referred to as *interval matrix* and will be denoted by $\mathcal{U}_\rho$.

The question we are addressing is as follows:

(?) *What is the supremum $\rho^\star$ of those uncertainty levels ρ under which all perturbations of level ρ preserve a particular property of the system, such as stability, passivity, contractiveness, etc.?*

Typically, it is computationally intractable to give a *precise* answer to such a question. For example, it is known to be NP-hard to check the stability of all instances of an interval matrix $\mathcal{U}_\rho$ [7]. In other words, we do not know how to check efficiently whether every one of the Lyapunov linear matrix inequalities (LMIs)

$$\text{find } X \text{ such that } X \succ 0 \text{ and } A^T X + XA \prec 0^1$$

corresponding to the instances A of an interval square matrix is solvable.

The situation does not improve at all when we pass from the question "whether all instances of an interval matrix are stable" to the seemingly simpler question "whether all instances of an interval matrix admit a common quadratic Lyapunov stability certificate," or, which is the same, whether the aforementioned LMIs have a *common* solution. Although in the new form the question is to check the solvability of a *finite* system of LMIs

$$X \succ 0, \quad A^T X + XA \prec 0 \quad \forall (A \in \mathcal{V}),$$

where $\mathcal{V}$ is the (finite!) set of the extreme points of the original interval matrix, the number of LMIs in this system blows up exponentially with the size of the matrix (unless the number of uncertain entries in the matrix remains once and for ever fixed). It turns out that in general it is already NP-hard to check whether a given candidate solution X is feasible for the above system of LMIs.[2]

The difficulty arising when checking stability of (all instances of) an interval matrix is typical for other problems of the aforementioned type: the property of interest is equivalent to the solvability of certain LMI $\mathcal{L}_\Sigma(X) \succ 0$ with the data coming from the matrix Σ of the system in question. When Σ is subject to interval uncertainty, both of the following tasks become NP-hard:

(1.A) Checking whether every one of the LMIs

$$\mathcal{L}_\Sigma(X) \succ 0 \tag{1}$$

with $\Sigma \in \mathcal{U}_\rho$ is solvable (i.e., to verify that the desired property is possessed by all instances), and

(1.B) Checking whether the infinite system of LMIs

$$\mathcal{L}_\Sigma(X) \succ 0 \qquad \forall (\Sigma \in \mathcal{U}_\rho)$$

is solvable, i.e., whether all instances of our interval matrix share a common certificate for the property of interest (which normally is a *sufficient* condition for the property to be preserved also by dynamic perturbations).

Now, in light of the fact that it is NP-hard to answer questions (1.A), (1.B) *exactly*, a natural course of action is to *relax* the questions in order to make them tractable. We are not aware of any good relaxation of question (1.A). In contrast to this, recent progress in what is called robust semidefinite programming [1, 5, 6] (specifically, the matrix cube theorem [3]) leads to "tight" tractable relaxations of question (1.B). It turns out that *under favorable circumstances* (which do take place for a wide family of "properties of interest") *one can build efficiently a lower bound* $\widehat{\rho}$ *on the supremum* $\rho^\star$ *of those uncertainty levels* ρ *for which the answer to the question* (1.B) *is affirmative, and this lower bound is tight within an absolute constant factor* (the latter is in most of the cases $\frac{\pi}{2} = 1.57\ldots$). The goal of this paper is to justify the above claim.

[1] We write $A \succeq B$ ($A \succ B$) to express that A, B are symmetric matrices of the same size such that $A - B$ is positive semidefinite (respectively, positive definite).

[2] This "analysis" problem is not simpler than checking whether all instances of a given interval symmetric matrix are positive semidefinite; it is shown in [7] that the latter problem is NP-hard already in the case when all entries in the interval matrix, except for those from the first two rows and columns, are fixed.

A convenient general framework for our study is the dissipativity-based approach, as developed in the seminal papers of Willems [9, 10]. The notion of dissipativity is one of the most important concepts in systems and control theory, both from the theoretical point of view as well as from the practical perspective. In many mechanical and electrical engineering applications, dissipativity is related to the notion of energy. Here, a dissipative system is characterized by the following property: at any moment of time, the amount of energy which the system can supply to its environment cannot exceed the amount of energy that has been supplied to it. However, the dissipativity-based framework is not restricted to the energy-related issues; it allows us to investigate stability analysis and linear-quadratic control as well.

The rest of the paper is organized as follows. In section 2, we review basic notions and results from dissipativity theory. In section 3, we present the box model of uncertainty (which is slightly more general than the simple interval model) and pose and motivate three basic dissipativity-related versions of question (1.B): finding a common dissipativity certificate for all instances of a given uncertain system (a particular case of this problem is the Lyapunov stability analysis under box uncertainty); extracting available storage/providing required supply in the face of uncertainty (this covers, in particular, the optimal linear-quadratic control of uncertain systems). In the central section 4, we develop "tractable tight relaxations" of the problems posed in section 3. Finally, in section 5, we present several illustrating numerical examples.

On many occasions in this paper we use the term "efficient computability" of various quantities. An appropriate definition of this notion does exist,[3] but for our purposes here it suffices to agree that all "LMI-representable" quantities—those which can be represented as optimal values in semidefinite programs

$$\min_x \left\{ c^T x : A_0 + \sum_{i=1}^N x_i A_i \succeq 0 \right\}$$

or generalized eigenvalue problems

$$\min_{x,\omega} \left\{ \omega : \begin{array}{c} A(x) \equiv A_0 + \sum_{i=1}^N x_i A_i \succeq 0 \\ B(x) \equiv B_0 + \sum_{i=1}^N x_i B_i \preceq \omega A(x) \\ C(x) \equiv C_0 + \sum_{i=1}^N x_i C_i \succeq 0 \end{array} \right\}$$

—are efficiently computable functions of the data $c, \{A_i \in \mathbf{S}^n\}_{i=0}^N$, respectively, $\{A_i, B_i, C_i \in \mathbf{S}^n\}_{i=0}^N$; where $\mathbf{S}^n$ is the space of real symmetric $n \times n$ matrices. From now on, missing blocks in block matrices are assumed to be zero.

2. Dissipative systems. In this section, we shall briefly review the dissipativity theory for linear systems with quadratic storage and supply functions as developed in [10]. The readers less familiar with the topic are referred to [8] for details.

Consider a continuous-time linear time-invariant dynamical system given by

$$\begin{array}{ll} \dot{z}(t) = Az(t) + Bu(t), & z(0) = \zeta, \\ y(t) = Cz(t) + Du(t), & \end{array} \tag{2}$$

[3]For a definition which fits best of all the contents of the paper, see [2, Chapter 5].

where $\Sigma \equiv \left[\begin{smallmatrix} A & B \\ C & D \end{smallmatrix}\right] \in \mathbf{R}^{(n+p)\times(n+m)}$ is the matrix of system coefficients, $u(\cdot) \in \mathbf{R}^m$ is the *input* (which henceforth is assumed to be locally square integrable), $z(\cdot) \in \mathbf{R}^n$ is the *state*, and $y(\cdot) \in \mathbf{R}^p$ is the *output*. In what follows we refer to system (2) given by a matrix Σ as "system Σ."

Let us fix a quadratic *supply function*

$$\mathfrak{S} : \mathbf{R}^{p+m} \to \mathbf{R}, \qquad \mathfrak{S}(y,u) = \begin{bmatrix} y \\ u \end{bmatrix}^T \begin{bmatrix} Q & L \\ L^T & R \end{bmatrix} \begin{bmatrix} y \\ u \end{bmatrix}; \tag{3}$$

here

$$\mathfrak{P} = \begin{bmatrix} Q & L \\ L^T & R \end{bmatrix}$$

is a symmetric *supply matrix* (Q is $p\times p$, R is $m\times m$). Given a trajectory $(z(\cdot), y(\cdot), u(\cdot))$ of (2) and two time instants $t_0 \le t_1$, we interpret the corresponding *supply*

$$\int_{t_0}^{t_1} \mathfrak{S}(y(t), u(t))dt$$

as the work carried on the system in the time interval $[t_0, t_1]$ along the trajectory in question, if the supply is nonnegative, and as minus the energy extracted from the system, if the supply is negative.

Note that along a trajectory of (2) the supply can be expressed in terms of the state and the input:

$$\begin{aligned} \mathcal{S}_\Sigma(z,u) &\equiv \mathfrak{S}(Cz+Du,u) \\ &= \begin{bmatrix} z \\ u \end{bmatrix}^T \underbrace{\begin{bmatrix} C^TQC & C^T(L+QD) \\ (L+QD)^TC & D^TQD + L^TD + D^TL + R \end{bmatrix}}_{\mathbf{S}_\Sigma} \begin{bmatrix} z \\ u \end{bmatrix}. \end{aligned} \tag{4}$$

Definition 2.1. *System Σ is called dissipative with respect to supply $\mathfrak{S}$, if there exists a nonnegative storage function $V(z)$, $V(0) = 0$, such that*

$$V(z(0)) + \int_0^T \mathfrak{S}(y(t), u(t))dt \ge V(z(T)) \tag{5}$$

for all $T \ge 0$ and all trajectories $(z(\cdot), y(\cdot), u(\cdot))$ of the system.

The standard interpretation of a storage function is that $V(z)$ is the internal energy stored by system in state z; with this interpretation, (5) means that the work W on the system needed to move it from one state to another is at least the resulting change ΔV in the internal energy stored by the system; the excess $W - \Delta V \ge 0$ is thought of to be dissipated by the system.

The summary of facts on dissipativity we need in what follows is as follows. *Assume that system Σ is controllable*, and let $\mathfrak{S}$ be a quadratic supply:

D.1. $(\Sigma, \mathfrak{S})$ is dissipative if and only if $(\Sigma, \mathfrak{S})$ admits a quadratic storage function $V(z) = z^TZz$, where $Z \in \mathbf{S}^n_+$ (from now on, $\mathbf{S}^n_+$ is the cone of positive semidefinite matrices from $\mathbf{S}^n$).

D.2. A quadratic function $V(z) = z^TZz$ is a storage function for $(\Sigma, \mathfrak{S})$ if and only if $Z \in \mathbf{S}^n_+$ and

$$\mathfrak{S}(y(t), u(t)) - \frac{d}{dt}(z^T(t)Zz(t)) \ge 0$$

for all trajectories $(z(\cdot), y(\cdot), u(\cdot))$, or, which is the same, if and only if $Z \in \mathbf{S}^n$ solves the system of matrix inequalities (MIs)

$$Z \succeq 0, \tag{6a}$$

$$\mathbb{D}_\Sigma[Z] \equiv \mathbf{S}_\Sigma - \begin{bmatrix} A^T Z + ZA & ZB \\ B^T Z & \end{bmatrix} \succeq 0 \tag{6b}$$

(for notation, see (4)). Note that MI (6b) expresses a very transparent requirement that

$$\mathcal{S}_\Sigma(z(t), u(t)) \geq \frac{d}{dt}(z^T(t) Z z(t)) \tag{7}$$

for all t and all trajectories $(z(t), y(t), u(t))$ of Σ. In what follows, we call the solutions of (6) the *dissipativity certificates* for $(\Sigma, \mathfrak{S})$.

D.3. If $(\Sigma, \mathfrak{S})$ is dissipative, then we have the following:

(a) among the associated storage functions there exist the (pointwise) minimal one,

$$V_{av}(z) = \sup_{(z(\cdot),y(\cdot),u(\cdot))} \left\{ -\int_0^{t_1} \mathfrak{S}(y(t), u(t))dt : \begin{array}{l} (z(\cdot), y(\cdot), u(\cdot)) \text{ is a trajectory,} \\ z(0) = z \end{array} \right\}$$

("available storage"), and the (pointwise) maximal one,

$$V_{req}(z) = \inf_{(z(\cdot),y(\cdot),u(\cdot))} \left\{ \int_0^{t_1} \mathfrak{S}(y(t), u(t))dt : \begin{array}{l} (z(\cdot), y(\cdot), u(\cdot)) \text{ is a trajectory,} \\ z(0) = 0, z(t_1) = z \end{array} \right\}$$

("required supply"). Every storage function $V(\cdot)$ for $(\Sigma, \mathfrak{S})$ satisfies the relations $V_{av}(z) \leq V(z) \leq V_{req}(z)$ for all z, and every convex combination of $V_{av}(\cdot)$ and $V_{req}(\cdot)$ is a storage function for $(\Sigma, \mathfrak{S})$.

(b) Both the available storage and the required supply are quadratic functions of the state:

$$\begin{array}{rcl} V_{av}(z) & = & z^T Z_{av} z, \\ V_{req}(z) & = & z^T Z_{req} z, \end{array}$$

where the positive semidefinite matrices Z_{av}, Z_{req} are, respectively, the $\succeq$-minimal and the $\succeq$-maximal solutions of (6). The set of solutions to (6) is exactly the "matrix interval" $\{Z : Z_{av} \preceq Z \preceq Z_{req}\}$.

D.4. Assume that $(\Sigma, \mathfrak{S})$ is dissipative and that the matrix $D^T Q D + L^T D + D^T L + R$ is positive definite. Then the state feedback

$$u = F_{av} z, \quad F_{av} = -(D^T Q D + L^T D + D^T L + R)^{-1}(B^T Z_{av} - (L + QD)^T C)$$

stabilizes the system (i.e., the real parts of all eigenvalues of the matrix $A + BF_{av}$ of the closed-loop system are negative), and with this feedback, the energy extracted from the system, the initial state of the system being $\zeta \in \mathbb{R}^n$, is exactly the available storage $V_{av}(\zeta)$:

$$-\int_0^\infty \mathfrak{S}(y(t), u(t))dt = \zeta^T Z_{av} \zeta,$$

where $(y(t), u(t))$ are given by

$$\begin{aligned} \dot{z}(t) &= Az(t) + Bu(t), \qquad z(0) = \zeta, \\ u(t) &= F_{av} z(t), \\ y(t) &= Cz(t) + Du(t). \end{aligned}$$

Similarly, the state feedback

$$u = F_{req} z, \quad F_{req} = -(D^T Q D + L^T D + D^T L + R)^{-1}(B^T Z_{req} - (L + QD)^T C)$$

stabilizes the "backward time" system (i.e., the real parts of all eigenvalues of the matrix $-(A + BF_{req})$ of the closed-loop system with backward time are negative), and with this feedback the supply required to move the system from the origin to a state ζ is exactly the required supply $V_{req}(\zeta)$:

$$\int_0^\infty \mathfrak{S}(y(t), u(t))dt = \zeta^T Z_{req} \zeta,$$

where $(y(t), u(t))$ are given by

$$\begin{aligned} \dot{z}(t) &= -[Az(t) + Bu(t)], \qquad z(0) = \zeta, \\ u(t) &= F_{req} z(t), \\ y(t) &= Cz(t) + Du(t). \end{aligned}$$

Let us list several important examples of supply functions.

EXAMPLE 1 (positive-real systems). *Here $m = p$, and the supply matrix is $\mathfrak{P} = \left[\begin{smallmatrix} 0 & I \\ I & 0 \end{smallmatrix}\right]$*, i.e.,

$$\mathfrak{S}(y, u) = 2y^T u.$$

Assuming that A is stable and (A, B, C) is minimal, the pair $(\Sigma, \mathfrak{S})$ is dissipative if and only if (2) is passive, i.e., $\int_0^T y^T(t) v(t) dt \geq 0$ for all $T \geq 0$ and all trajectories $(z(t), y(t), v(t))$ with $z(0) = 0$. Under the same assumptions on A, B, C, the frequency domain characterization of passivity is that the transfer function

$$H(s) = C(sI - A)^{-1} B + D$$

of the system is such that

$$\Re(s) \geq 0 \Rightarrow H(s) + H^*(s) \succeq 0,$$

where $H^*(s)$ is the Hermitian conjugate of $H(s)$ and $\Re(s)$ is the real part of $s \in \mathbb{C}$.

EXAMPLE 2 (nonexpansive systems [4]). *Here the supply matrix is $\mathfrak{P} = \left[\begin{smallmatrix} I_p & 0 \\ 0 & -I_m \end{smallmatrix}\right]$ (I_k is the $k \times k$ unit matrix), i.e.,*

$$\mathfrak{S}(y, u) = u^T u - y^T y.$$

Assuming again that A is stable and (A, B, C) is minimal, dissipativity of $(\Sigma, \mathfrak{S})$ is equivalent to the fact that

$$\int_0^T y^T(t) y(t) dt \leq \int_0^T u^T(t) u(t) dt$$

for all $T \geq 0$ and trajectories $(z(t), y(t), u(t))$ of (2) with $z(0) = 0$. Under the same assumption on A, B, C, the frequency domain characterization of nonexpansivity is that the transfer function $H(s)$ of the system is such that

$$\Re(s) \geq 0 \Rightarrow H^*(s)H(s) \preceq I.$$

EXAMPLE 3 (linear-quadratic control [4]). *Here the supply matrix $\mathfrak{P}$ is positive semidefinite. Assuming that (A, B) is controllable, the pair $(\Sigma, \mathfrak{S})$ is always dissipative, with the available storage $V_{av}(z) \equiv 0$. The required supply $V_{req}(z)$ is the optimal value in the problem of optimal control where the goal is to minimize $\int_0^T \mathfrak{S}(y(t), u(t))dt$ when moving the system from the origin at time 0 to the state z at time T (to be chosen).*

3. Dissipativity under uncertainty. Now assume that the linear dynamic system in question is *uncertain*, so that all we know about the matrix Σ is that Σ belongs to a given *uncertainty set* $\mathcal{U}_\rho$ in the space of $(n+p) \times (m+p)$ real matrices. In this paper we focus on the case of *box uncertainty*:

$$\mathcal{U}_\rho = \left\{ \Sigma = \Sigma + \sum_{\ell=1}^{L} u_\ell d\Sigma_\ell : -\rho \leq u_\ell \leq \rho,\ \ell = 1, \ldots, L \right\}, \tag{8}$$

where

- $\Sigma = \left[\begin{smallmatrix} \mathbf{A} & \mathbf{B} \\ \mathbf{C} & \mathbf{D} \end{smallmatrix}\right]$ is the *nominal* system;
- $d\Sigma_\ell = \left[\begin{smallmatrix} dA_\ell & dB_\ell \\ dC_\ell & dD_\ell \end{smallmatrix}\right]$, $\ell = 1, \ldots, L$, are *basic perturbation matrices*;
- $\rho > 0$ is the *uncertainty level*.

In what follows, we refer to matrices $\Sigma \in \mathcal{U}_\rho$ as to *instances* of the uncertain system associated with the uncertainty set $\mathcal{U}_\rho$.

Let us fix a quadratic supply function (3); in what follows, when speaking about the dissipativity of a certain system, we mean the dissipativity with respect to this supply function. We assume from now on that the nominal pair $(\mathbf{A}, \mathbf{B})$ is controllable, and the nominal system Σ is dissipative, with the minimal and maximal dissipativity certificates $\mathbf{Z}_{av}$, $\mathbf{Z}_{req}$, respectively.

We intend to focus on three dissipativity-related problems for uncertain systems, specifically, the following problems:

1. Common dissipativity certificate. Find a common dissipativity certificate for all instances of the uncertain system.
2. Extracting available storage. Given $\epsilon \in (0, 1)$, find a feedback which stabilizes all instances of the uncertain system and allows us to extract from the initial state ζ of any instance energy at least $(1 - \epsilon)\zeta^T \mathbf{Z}_{av} \zeta$.
3. Providing required supply. Given $\delta > 0$, find a feedback which stabilizes in backward time all instances of the uncertain system and allows to move every instance from the origin to a given state ζ with total supply at most $(1 + \delta)\zeta^T \mathbf{Z}_{req} \zeta$.

Our next goal is to motivate and to model the outlined problems.

3.1. Common dissipativity certificate. The problem of finding a common dissipativity certificate for all instances of an uncertain system is as follows.

PROBLEM 1. *Given a supply $\mathfrak{S}$, a convex set $\mathcal{I}$ in the cone $\mathbf{S}^n_+$, and the data specifying $\mathcal{U}_\rho$, find the supremum of those $\rho \geq 0$ for which all instances from $\mathcal{U}_\rho$ admit a common dissipativity certificate in $\mathcal{I}$, or, which is the same in view of* D.2*, find the*

supremum of those $\rho \geq 0$ for which the system of constraints

$$Z \in \mathcal{I}, \tag{9a}$$

$$\mathbb{D}_\Sigma[Z] \equiv \begin{bmatrix} C^TQC - A^TZ - ZA & C^T(L+QD) - ZB \\ (L+QD)^TC - B^TZ & D^TQD + L^TD + D^TL + R \end{bmatrix} \succeq 0 \tag{9b}$$

$$\forall \Sigma = \begin{bmatrix} A & B \\ C & D \end{bmatrix} \in \mathcal{U}_\rho$$

(see (6)*) in matrix variable Z is solvable.*

The motivation behind Problem 1 is quite transparent: there are cases when the dissipativity is a highly desirable property, and in these cases it is worthy of knowing what are the largest perturbations which for sure preserve this property. With this motivation, however, it remains unclear why we should be interested in a *common* dissipativity certificate for all $\Sigma \in \mathcal{U}_\rho$ rather than to ask what is the largest ρ for which every instance from $\mathcal{U}_\rho$ admits a dissipativity certificate (perhaps depending on the instance). The motivation behind seeking a common dissipativity certificate comes from the fact that such a certificate ensures dissipativity of the uncertain *time-varying* system

$$\begin{array}{l} \dot{z}(t) = A(t)z(t) + B(t)u(t), \\ y(t) = C(t)z(t) + D(t)u(t), \end{array} \tag{10}$$

where the dependence of $\Sigma(t) \equiv \left[\begin{smallmatrix} A(t) & B(t) \\ C(t) & D(t) \end{smallmatrix}\right]$ on t is not known in advance; all we know is that $\Sigma(t)$ is a measurable function of t taking values in $\mathcal{U}_\rho$. The precise meaning of the claim "existence of a common dissipativity certificate for all instances $\Sigma \in \mathcal{U}_\rho$ implies dissipativity of the uncertain time-varying system (10)" is given by the following simple statement.

PROPOSITION 3.1. *Let Z be a common dissipativity certificate for all instances $\Sigma \in \mathcal{U}_\rho$, i.e., let $Z \succeq 0$ satisfy* (9b)*. Then for every $T \geq 0$ and every trajectory $(z(t), y(t), u(t))$ of the time-varying system* (10) *with $\Sigma(t) \in \mathcal{U}_\rho$ for all t, one has*

$$z^T(0)Zz(0) + \int_0^T \mathfrak{S}(y(t), u(t))dt \geq z^T(T)Zz(T). \tag{11}$$

Proof. It is immediately seen that (9b) implies that

$$\mathfrak{S}(y(t), u(t)) \geq \frac{d}{dt}(z^T(t)Zz(t))$$

for all t. Integrating this inequality, we arrive at (11). ∎

EXAMPLE 4 (Lyapunov stability analysis under box uncertainty). *Assume that we have designed a controller for a linear dynamical system, and let*

$$\dot{z} = Az$$

be the description of the closed-loop system (so that some components of z represent states of the plant, while the remaining components of z represent states of the controller). After the design is completed, a natural question is how the performance of the system can be affected by perturbations in A (i.e., in the parameters of the plant and of the controller). Assuming a box model of perturbations

$$A \in \mathcal{V}_\rho = \left\{ A = \mathbf{A} + \sum_{\ell=1}^{L} u_\ell dA_\ell : -\rho \leq u_\ell \leq \rho,\ \ell = 1, \ldots, L \right\},$$

an important component of the above question is, What is the supremum $\rho^\star$ of those uncertainty levels ρ for which all instances $A \in \mathcal{V}_\rho$ remain stable, moreover, such that

$$z^T(t)\mathbf{Z}z(t) \le \beta \exp\{-\alpha t\} z^T(0)\mathbf{Z}z(0) \qquad \forall t \ge 0 \tag{12}$$

for all trajectories $z(\cdot)$ of all perturbed instances? Here $\mathbf{Z} \succ 0$, $\beta > 1$, and $\alpha > 0$ are given in advance. A well-known sufficient condition for (12) *is the existence of an appropriate quadratic Lyapunov stability certificate, namely, a matrix Z satisfying the relations*

$$\beta^{-1}\mathbf{Z} \preceq Z \preceq \mathbf{Z}, \tag{13a}$$

$$A^T Z + ZA \preceq -\alpha \mathbf{Z} \qquad \forall A \in \mathcal{V}_\rho. \tag{13b}$$

Indeed, if Z satisfies (13) *and $z(t)$ is a trajectory of the time-varying system*

$$\dot{z}(t) = A(t)z(t) \qquad (A(t) \in \mathcal{V}_\rho \qquad \forall t),$$

then

$$\begin{aligned} \tfrac{d}{dt}(z^T(t)Zz(t)) &= z^T(t)[A^T(t)Z + ZA(t)]z(t) \\ &\le -\alpha z^T(t)\mathbf{Z}z(t) && \text{(cf. (13b))} \\ &\le -\alpha z^T(t)Zz(t) && \text{(cf. (13a));} \end{aligned}$$

hence

$$\begin{aligned} z^T(t)Zz(t) &\le \exp\{-\alpha t\} z^T(0)Zz(0) \\ &\le \exp\{-\alpha t\} z^T(0)\mathbf{Z}z(0) \quad \text{(cf. (13a))} \end{aligned}$$

and therefore

$$\begin{aligned} z^T(t)\mathbf{Z}z(t) &\le \beta z^T(t)Zz(t) && \text{(cf. (13a))} \\ &\le \beta \exp\{-\alpha t\} z^T(0)\mathbf{Z}z(0). \end{aligned}$$

On the other hand, it is immediately seen that relations (13) *say exactly that Z is a common dissipativity certificate, belonging to the matrix interval $\mathcal{I} = \{Z : \beta^{-1}\mathbf{Z} \preceq Z \preceq \mathbf{Z}\}$ for all instances $\Sigma \in \mathcal{U}_\rho$ of the system*

$$\begin{aligned} \dot{z} &= Az + 0_{n\times 1} \cdot u, \\ y &= z + 0_{n\times 1} \cdot u \end{aligned} \tag{14}$$

when the supply matrix is specified as

$$\mathfrak{P} = \begin{bmatrix} -\alpha\mathbf{Z} & \\ & I \end{bmatrix}; \tag{15}$$

here $\mathcal{U}_\rho$ is the box uncertainty given by

$$d\Sigma_\ell = \begin{bmatrix} dA_\ell & 0_{n\times 1} \\ 0_{n\times n} & 0_{n\times 1} \end{bmatrix}, \qquad \ell = 1, \dots, L.$$

We see that Problem 1 *can be used to find the largest uncertainty level ρ for which the validity of* (13) *can be guaranteed by a quadratic Lyapunov stability certificate.*

3.2. Extracting available storage. Assume that we are interested in retrieving the energy stored in the initial state ζ. If there were no perturbations, the maximal amount of energy we could retrieve would be the nominal available storage $\zeta^T \mathbf{Z}_{av} \zeta$, and the corresponding control could be chosen in the state feedback form (see D.4). With perturbations, we hardly could guarantee the same amount of retrieved energy; however, it is reasonable to look for a state feedback which stabilizes all instances of the uncertain system in question and allows us to retrieve, whatever is an instance and an initial state ζ, at least a given fraction $(1-\epsilon)\zeta^T \mathbf{Z}_{av} \zeta$ of the nominal available storage. To model this target mathematically, we start with the following simple observation.

PROPOSITION 3.2. *Assume that $0 \prec \mathbf{Z}_{av}$, and let $\epsilon \in [0,1)$, $\rho \geq 0$ be given. Assume that matrices $G, H \in \mathbf{S}^n_+$ and a state feedback $u = Fz$ are such that*

1.

(16)
$$\begin{bmatrix} C^TQC & C^T(L+QD) \\ (L+QD)^TC & D^TQD + L^TD + D^TL + R \end{bmatrix} - \begin{bmatrix} A^TG + GA & GB \\ B^TG & \end{bmatrix} \succeq 0 \quad \forall \begin{bmatrix} A & B \\ C & D \end{bmatrix} \in \mathcal{U}_\rho,$$

i.e., G is a common dissipativity certificate for all instances of $\mathcal{U}_\rho$;

2.

(17)
$$\begin{bmatrix} I & F^T \end{bmatrix} \begin{bmatrix} C^TQC & C^T(L+QD) \\ (L+QD)^TC & D^TQD + L^TD + D^TL + R \end{bmatrix} \begin{bmatrix} I \\ F \end{bmatrix} \prec \left[(A+BF)^TH + H(A+BF)\right] \quad \forall \begin{bmatrix} A & B \\ C & D \end{bmatrix} \in \mathcal{U}_\rho;$$

3.

(18)
$$(1-\epsilon)\mathbf{Z}_{av} \preceq H \prec G.$$

Then all instances of the uncertain time-varying closed-loop system

(19)
$$\begin{array}{rcl} \dot{z}(t) & = & A(t)z(t) + B(t)u(t), \\ y(t) & = & C(t)z(t) + D(t)u(t), \\ u(t) & = & Fz(t), \end{array} \qquad \begin{bmatrix} A(t) & B(t) \\ C(t) & D(t) \end{bmatrix} \in \mathcal{U}_\rho \qquad \forall t$$

share a common quadratic Lyapunov function $z^T(G-H)z$. Moreover, for every initial state $\zeta = z(0)$ of (19), one has

(20)
$$-\int_0^\infty \mathfrak{S}(y(t),u(t))dt \geq \zeta^T H \zeta \geq (1-\epsilon)\zeta^T \mathbf{Z}_{av} \zeta,$$

i.e., the state feedback F allows us to extract at least $(1-\epsilon)$ times the nominal available storage $\zeta^T \mathbf{Z}_{av} \zeta$.

Proof. Consider a time-invariant instance $\Sigma = \left[\begin{smallmatrix} A & B \\ C & D \end{smallmatrix}\right]$ of (19), and let $(z(t), y(t), u(t))$ be a trajectory of this instance. By (16), the quadratic function $V(z) = z^TGz$ is a storage function for $(\Sigma, \mathfrak{S})$; hence for every $t_0 \leq t_1$

(21)
$$z^T(t_0)Gz(t_0) + \int_{t_0}^{t_1} \mathfrak{S}(y(t),u(t))dt \geq z^T(t_1)Gz(t_1).$$

On the other hand, (17) implies that

$$\mathfrak{S}(y(t),u(t)) \le \frac{d}{dt}\left(z^T(t)Hz(t)\right) - \theta z^T(t)z(t)$$

for certain $\theta > 0$; hence

$$\int_{t_0}^{t_1} \mathfrak{S}(y(t),u(t))dt \le \left[z^T(t_1)^T Hz(t_1) - z^T(t_0)^T Hz(t_0)\right] - \theta \int_{t_0}^{t_1} z^T(t)z(t)dt.$$

Substituting this inequality into (21), we see that for every trajectory of every time-invariant instance of (19) and every pair $t_0 \le t_1$ of time instants one has

$$z^T(t_0)[G-H]z(t_0) - \theta \int_{t_0}^{t_1} z^T(t)z(t)dt \ge z^T(t_1)[G-H]z(t_1);$$

hence $\frac{d}{dt}(z^T(t)[G-H]z(t)) \le -\theta z^T(t)z(t)$ for all $t \ge 0$ and all trajectories, so that

$$(A+BF)^T[G-H] + [G-H](A+BF) \preceq -\theta I.$$

Since this relation is valid for all $\Sigma \in \mathcal{U}_\rho$, and since $G - H \succ 0$ by (18), $G - H$ is indeed a quadratic Lyapunov stability certificate for (19).

Now consider a trajectory $(z(t), y(t), u(t))$ of (19). Same as above, we have

$$\mathfrak{S}(y(t),u(t)) \le \frac{d}{dt}\left(z^T(t)Hz(t)\right).$$

Integrating both sides of this inequality from 0 to ∞ and taking into account that $(z(t), y(t), u(t))$ converges exponentially fast to 0 as $t \to \infty$ (we have seen that (19) admits quadratic Lyapunov stability certificate!), we get

$$\int_0^\infty \mathfrak{S}(y(t),u(t))dt \le -z^T(0)Hz(0),$$

as required in the first inequality in (20); the second inequality in (20) is readily given by (18). □

In view of Proposition 3.2, we could pose the problem of extracting available storage as the problem of finding the supremum of those uncertainty levels ρ for which the semi-infinite system of MIs (16), (17), (18) in matrix variables G, H, F is solvable. This problem, however, is too difficult; it is completely unclear how to check efficiently the solvability of this *nonlinear* in F, H MI even in the nominal case $\rho = 0$. This is why we are forced to simplify our task by assuming that either F or H are given in advance. With this simplification, we arrive at the following pair of problems.

PROBLEM 2A. *Given a supply $\mathfrak{S}$, a feedback matrix F, parameter $\epsilon \in (0,1)$, and the data specifying $\mathcal{U}_\rho$, find the supremum of those $\rho \ge 0$ for which the system of MIs* (16)–(18) *in matrix variables G, H is solvable.*

With F specified as the ideal nominal feedback F_{av}, see D.4, Problem 2A becomes a quite natural question of finding the largest uncertainty level for which we can certify the fact that whatever is an initial state ζ of an instance of the uncertain system, the nominal feedback allows us to extract at least the fraction $(1-\epsilon)$ of the corresponding nominal available storage $\zeta^T \mathbf{Z}_{av}\zeta$.

PROBLEM 2B. *Given a supply $\mathfrak{S}$, parameter $\epsilon \in (0,1)$, an $n \times n$ positive definite matrix $H \succeq (1-\epsilon)\mathbf{Z}_{av}$, and the data specifying $\mathcal{U}_\rho$, find the supremum of those $\rho \ge 0$ for which the system of MIs* (16), (18) *in matrix variables G and F is solvable.*

A simple choice for the matrix H in Problem 2B is the solution of Problem 2A.

3.3. Providing required supply. The motivation behind this problem is completely similar to the one for the extracting storage problem; the only difference is that now we want to drive the system from the origin to a given state ζ and we are interested in achieving this target with the total supply not exceeding $(1+\delta)$ times the nominal required supply $\zeta^T\mathbf{Z}_{req}\zeta$. We have the following analogy of Proposition 3.2.

PROPOSITION 3.3. *Assume that $0 \prec \mathbf{Z}_{req}$, and let $\delta \in [0,1)$, $\rho \geq 0$ be given. Assume that matrices $G, H \in \mathbf{S}^n_+$ and a state feedback $u = Fz$ are such that the conditions* (16), (17) *and the condition*

$$G \prec H \preceq (1+\delta)\mathbf{Z}_{req} \tag{22}$$

are satisfied.

Then all instances of the uncertain time-varying closed-loop system

$$\begin{array}{l} \dot{z}(t) = -[A(t)z(t) + B(t)u(t)], \\ y(t) = C(t)z(t) + D(t)u(t), \\ u(t) = Fz(t), \end{array} \qquad \begin{bmatrix} A(t) & B(t) \\ C(t) & D(t) \end{bmatrix} \in \mathcal{U}_\rho \qquad \forall t \tag{23}$$

(which is the backward time version of system (19)*) share a common quadratic Lyapunov function $z^T[H-G]z$. Moreover, for every initial state $\zeta = z(0)$ of* (23)*, one has*

$$\int_0^\infty \mathfrak{S}(y(t),u(t))dt \leq (1+\delta)\zeta^T\mathbf{Z}_{req}\zeta, \tag{24}$$

i.e., the state feedback F allows us to move system (19) *from the origin to a given state ζ with total supply at most $(1+\delta)$ times the nominal required supply $\zeta^T\mathbf{Z}_{req}\zeta$.*

The proof is similar to the one of Proposition 3.2.

In view of Proposition 3.3, a natural way to model the providing required supply problem would be to look for the largest ρ for which the semi-infinite system (16), (17), (22) in matrix variables F, G, H is solvable; however, "tractability reasons" similar to those in section 3.2 force us to simplify the setting and restrict ourselves to the following pair of problems.

PROBLEM 3A. *Given a supply $\mathfrak{S}$, a feedback matrix F, parameter $\delta > 0$, and the data specifying $\mathcal{U}_\rho$, find the supremum of those $\rho \geq 0$ for which the system of MIs* (16), (17), (22) *in matrix variables G, H is solvable.*

PROBLEM 3B. *Given a supply $\mathfrak{S}$, parameter $\delta > 0$, an $n \times n$ positive definite matrix $H \preceq (1+\delta)\mathbf{Z}_{req}$, and the data specifying $\mathcal{U}_\rho$, find the supremum of those $\rho \geq 0$ for which the system of MIs* (16), (17) *in matrix variables G, $0 \preceq G \prec H$, and F is solvable.*

In contrast to the situation of section 3.2, now there exists a particular "tractable case" where one can treat in the system of interest (which is now the system (16), (17), (22)) both F and H as design variables; this is the case of positive semidefinite supply matrix $\left[\begin{smallmatrix} Q & L \\ L^T & R \end{smallmatrix}\right]$ (as it happens in linear-quadratic control).[4] In this case it makes sense to specify the common dissipativity certificate G of the perturbed instances as the zero matrix; this choice ensures the validity of (16) and is "ideal" from the viewpoint of the constraint (22). Setting $G = 0$ and treating F, H as the design variables in the

[4]Note that this case makes no sense in the extracting storage problem, since there it would imply that "there is nothing to extract" – $\mathbf{Z}_{av} = 0$

system (16), (17), (22), we arrive at the following version of the problem of providing required supply.

PROBLEM 3C. *Given a supply* $\mathfrak{S}$ *such that the supply matrix* $\mathfrak{P}$ *is positive semidefinite, parameter* $\delta > 0$*, and the data specifying* $\mathcal{U}_\rho$*, find the supremum of those* $\rho \geq 0$ *for which the system comprised of semi-infinite MI* (17) *and the LMI*

$$0 \prec H \preceq (1+\delta)\mathbf{Z}_{req} \tag{25}$$

in matrix variables F, H *is solvable.*

4. Processing the problems. Every one of Problems 1, 2A, 2B, 3A, 3B, and 3C asks for finding the largest ρ such that a given system of MIs (depending on ρ as on a parameter) is solvable. The systems in question are *semi-infinite*—they involve infinitely many MIs with the data running through the uncertainty sets. It is well known that semi-infinite systems of MIs are, in general, NP-hard; it is easy to show that in general this is the case with the specific semi-infinite systems arising in Problems 1, 2A, 2B, 3A, 3B, and 3C. What we intend to do is to replace these NP-hard systems with their computationally tractable *conservative approximations*, the latter notion being defined as follows.

DEFINITION 4.1. *Let* $\mathcal{S}$ *be a system of constraints on a design vector* x*. We say that a system* $\mathcal{A}$ *of constraints on* x *and a vector of additional variables* y *is a conservative approximation of* $\mathcal{S}$ *if the* x*-component of every feasible solution* (x, y) *of the approximating system* $\mathcal{A}$ *is a feasible solution of the original system* $\mathcal{S}$*.*

Our plan for processing Problems 1, 2A, 2B, 3A, 3B, and 3C is as follows: we start with reviewing the basic results we intend to use when building computationally tractable approximations of the problems and then apply these results to the problems of interest.

4.1. The matrix cube theorem. Consider an uncertain LMI with affine box uncertainty

$$\mathcal{A}^0(x) + \sum_{\ell=1}^{L} u_\ell \mathcal{A}^\ell(x) \succeq 0 \qquad \forall (u : \|u\|_\infty \leq \rho), \tag{26}$$

where

- $x \in \mathbf{R}^d$ is the vector of decision variables;
- $\mathcal{A}^\ell(x)$, $\ell = 0, 1, \ldots, L$, are symmetric $m \times m$ matrices affinely depending on x;
- $u_1, \ldots, u_L$ are *perturbations*, and $\rho \geq 0$ is the *uncertainty level*.

It is known that in general, it is NP-hard to solve (26) or even to check whether a given candidate solution x is feasible. However, (26) admits a computationally tractable conservative approximation which is a system of LMIs in original variables x and additional symmetric matrix variables $X_1, \ldots, X_L$. Let us write $X \succeq \pm Y$ as a shortcut for the system of two matrix inequalities $X \succeq Y$, $X \succeq -Y$. The aforementioned conservative approximation of (26) is as follows:

$$X_\ell \succeq \pm \mathcal{A}^\ell(x), \qquad \ell = 1, \ldots, L; \tag{27a}$$

$$\rho \sum_{\ell=1}^{L} X_\ell \preceq \mathcal{A}^0(x). \tag{27b}$$

The fact that (27) is indeed a conservative approximation of (26) is evident: if x can be extended by appropriately chosen $X_1, \dots, X_L$ to a feasible solution of (27), then from (27a) it follows that $u_\ell \mathcal{A}^\ell(x) \succeq -\rho X_\ell$ for all u_ℓ such that $|u_\ell| \le \rho$; hence

$$\mathcal{A}^0(x) + \sum_{\ell=1}^{L} u_\ell \mathcal{A}^\ell(x) \succeq \mathcal{A}^0(x) - \rho \sum_{\ell=1}^{L} X_\ell \qquad \forall (u : \|u\|_\infty \le \rho);$$

the right-hand side matrix in the latter relation is $\succeq 0$ by (27b), so that x indeed satisfies (26).

It turns out that the "level of conservativeness" of the approximation (27) is not too big, provided that the matrices $\mathcal{A}^1(x), \dots, \mathcal{A}^L(x)$ are of small ranks.

PROPOSITION 4.1 (matrix cube theorem [3]). *Let* $\mu = \max_x \max_{\ell \ge 1} \operatorname{Rank}(\mathcal{A}^\ell(x))$. *(Note* $\ell \ge 1$ *in the* max*!). Then the relation between the feasible sets of* (26) *and* (27) *is as follows:*

1. *If* x *can be extended to a feasible solution of* (27)*, then* x *is feasible for* (26).
2. *If* x *cannot be extended to a feasible solution of* (27)*, then* x *is infeasible for* (26) *with* ρ *replaced by* $\vartheta(\mu)\rho$*, where* $\vartheta(\cdot)$ *is certain universal function such that* $\vartheta(\mu) \le \frac{\pi\sqrt{\mu}}{2}$ *for all* μ *and*

$$\vartheta(1) = 1, \quad \vartheta(2) = \frac{\pi}{2} = 1.57\dots, \quad \vartheta(3) = 1.73\dots, \quad \vartheta(4) = 2.$$

In particular, for every set $\mathcal{X} \subset \mathbf{R}^d$ *one has*

$$1 \le \frac{\sup\{\rho : (26) \text{ has a solution in } \mathcal{X}\}}{\sup\{\rho : (27) \text{ has a solution in } \mathcal{X}\}} \le \vartheta(\mu)$$

provided that the numerator in the fraction is positive.

Remark 1. Sometimes we shall be interested in a sufficient condition for the strict version

$$\mathcal{A}^0(x) + \sum_{\ell=1}^{L} u_\ell \mathcal{A}^\ell(x) \succ 0 \qquad \forall (u : \|u\|_\infty \le \rho)$$

of the semi-infinite LMI (26). Such a sufficient condition can be obtained from (27) by replacing the nonstrict LMI (27b) with its strict version. For the resulting pair of conditions, a statement completely similar to the matrix cube theorem takes place.

4.2. Approximating Problem 1. Let

$$Q = Q_+ - Q_-$$

be the representation of Q as a difference of two positive semidefinite symmetric matrices with orthogonal image spaces, and let

$$S_+ = Q_+^{1/2}, \qquad S_- = Q_-^{1/2}.$$

From now on, we assume that the set $\mathcal{I}$ in Problem 1 is *LMI-representable*, i.e., it can be specified by LMI $\{Z : \mathcal{Z}[Z] \succeq 0\}$, where $\mathcal{Z}[\cdot]$ is an affine function taking values in the space of symmetric matrices. With this assumption, Problem 1 becomes the problem of finding the supremum $\rho_1^\star$ of those $\rho > 0$ for which the system of LMIs

$$\mathcal{Z}[Z] \succeq 0, \tag{28a}$$

$$\begin{bmatrix} -A^T Z - ZA & C^T L - ZB \\ L^T C - B^T Z & L^T D + D^T L + R \end{bmatrix} + \begin{bmatrix} C^T \\ D^T \end{bmatrix} Q \begin{bmatrix} C & D \end{bmatrix} \succeq 0 \tag{28b}$$

$$\forall (A, B, C, D) \in \mathcal{U}_\rho$$

in symmetric matrix variable Z has a solution. This system can be equivalently rewritten as

(29a)
$$\mathcal{Z}[Z] \succeq 0,$$

$$\left[\begin{array}{c|c} \delta C^T Q\mathbf{C} + \mathbf{C}^T Q\delta C + \mathbf{C}^T Q\mathbf{C} & \delta C^T Q\mathbf{D} + \mathbf{C}^T Q\delta D + \mathbf{C}^T Q\mathbf{D} \\ -A^T Z - ZA & +C^T L - ZB \\ \hline \mathbf{D}^T Q\delta C + \delta D^T Q\mathbf{C} + \mathbf{D}^T Q\mathbf{C} & \delta D^T Q\mathbf{D} + \mathbf{D}^T Q\delta D + \mathbf{D}^T Q\mathbf{D} \\ +L^T C - B^T Z & +L^T D + D^T L + R \end{array}\right]$$

(29b)
$$-\left[\begin{array}{c} \delta C^T S_- \\ \delta D^T S_- \end{array}\right]\left[\begin{array}{cc} S_-\delta C & S_-\delta D \end{array}\right] + \left[\begin{array}{c} \delta C^T \\ \delta D^T \end{array}\right] Q_+ \left[\begin{array}{cc} \delta C & \delta D \end{array}\right] \succeq 0$$

$$\forall \left[\begin{array}{cc} A = \mathbf{A} + \delta A & B = \mathbf{B} + \delta B \\ C = \mathbf{C} + \delta C & D = \mathbf{D} + \delta D \end{array}\right] \in \mathcal{U}_\rho.$$

Since $Q_+ \succeq 0$, the last term in the left-hand side of (29b) is positive semidefinite. Eliminating this term, we pass from (29) to a conservative approximation of this system. By the Schur complement lemma,[5] this approximation is equivalent to the system of LMIs

(30a)
$$\mathcal{Z}[Z] \succeq 0,$$

(30b)
$$\left[\begin{array}{c|c|c} \delta C^T Q\mathbf{C} + \mathbf{C}^T Q\delta C + \mathbf{C}^T Q\mathbf{C} & \delta C^T Q\mathbf{D} + \mathbf{C}^T Q\delta D + \mathbf{C}^T Q\mathbf{D} & \delta C^T S_- \\ -A^T Z - ZA & +C^T L - ZB & \\ \hline \mathbf{D}^T Q\delta C + \delta D^T Q\mathbf{C} + \mathbf{D}^T Q\mathbf{C} & \delta D^T Q\mathbf{D} + \mathbf{D}^T Q\delta D & \\ +L^T C - B^T Z & +\mathbf{D}^T Q\mathbf{D} & \delta D^T S_- \\ & +L^T D + D^T L + R & \\ \hline S_-\delta C & S_-\delta D & I_p \end{array}\right] \succeq 0$$

$$\forall \left[\begin{array}{cc} A = \mathbf{A} + \delta A & B = \mathbf{B} + \delta B \\ C = \mathbf{C} + \delta C & D = \mathbf{D} + \delta D \end{array}\right] \in \mathcal{U}_\rho.$$

Taking into account (8), we see that the latter semi-infinite system of LMIs is in the form of (26), and we can use the construction from section 4.1 to build a computationally tractable conservative approximation of this system (and thus of (28)). The approximation is the following system of LMIs in matrix variables $Z, \{X_\ell\}$:

(31)
$$\mathcal{Z}[Z] \succeq 0,$$

$$X_\ell \succeq \pm \overbrace{\left[\begin{array}{c|c|c} dC_\ell^T Q\mathbf{C} + \mathbf{C}^T Q dC_\ell & dC_\ell^T [L + Q\mathbf{D}] & dC_\ell^T S_- \\ -dA_\ell^T Z - Z dA_\ell & +\mathbf{C}^T Q dD_\ell - Z dB_\ell & \\ \hline [L + Q\mathbf{D}]^T dC_\ell & dD_\ell^T [L + Q\mathbf{D}] & dD_\ell^T S_- \\ +dD_\ell^T Q\mathbf{C} - dB_\ell^T Z & +[L + Q\mathbf{D}]^T dD_\ell & \\ \hline S_- dC_\ell & S_- dD_\ell & 0_{pp} \end{array}\right]}^{\mathcal{A}^\ell[Z]}, \quad \ell = 1, \ldots, L,$$

$$\rho \sum_{\ell=1}^{L} X_\ell \preceq \left[\begin{array}{c|c|c} \mathbf{C}^T Q\mathbf{C} - \mathbf{A}^T Z - Z\mathbf{A} & \mathbf{C}^T [L + Q\mathbf{D}] - Z\mathbf{B} & \\ \hline [L + Q\mathbf{D}]^T \mathbf{C} - \mathbf{B}^T Z & L^T \mathbf{D} + \mathbf{D}^T L & \\ & +\mathbf{D}^T Q\mathbf{D} + R & \\ \hline & & I_p \end{array}\right].$$

[5] The Schur complement lemma (see, e.g., [2, Chapter 4]) states that a symmetric block matrix $\left[\begin{smallmatrix} P & L \\ L^T & Q \end{smallmatrix}\right]$ with $Q \succ 0$ is positive definite (positive semidefinite) if and only if the matrix $P - LQ^{-1}L^T$ is positive definite (positive semidefinite).

Note that the supremum $\widehat{\rho}_1$ of those $\rho \geq 0$ for which system (31) is solvable is efficiently computable—it is the optimal value in the problem

$$\max_{\rho,\{X_\ell\},Z} \{\rho : (\rho, \{X_\ell\}, Z) \text{ solves (31)}\}.$$

The latter is a generalized eigenvalue problem, so that its optimal value is efficiently computable. We intend to use the efficiently computable quantity $\widehat{\rho}$ as a bound for the "quantity of interest" $\rho_1^\star$. The properties of this bound are described in the following statement.

PROPOSITION 4.2. (i) *System* (31) *is a conservative approximation of* (28)*, so that the Z-component of a feasible solution to* (31) *is a feasible solution of* (28)*. In particular, $\widehat{\rho}_1$ is a lower bound for $\rho_1^\star$.*

(ii) *If either*

(a) *$Q \preceq 0$ (i.e., $Q_+ = 0$) (as it is the case, e.g., in Examples* 1, 2, 4*)*

or

(b) *D and C are certain (i.e., $dC_\ell = 0$, $dD_\ell = 0$ for all ℓ),*

then

$$1 \leq \frac{\rho_1^\star}{\widehat{\rho}_1} \leq \vartheta(\mu) \tag{32}$$

provided that $\rho_1^\star > 0$. Here $\vartheta(\mu)$ is the function from Proposition 4.1 *and*

$$\mu = \max_{\ell=1,\dots,L} \max_{Z} \operatorname{Rank}(\mathcal{A}^\ell[Z]);$$

see (31)*.*

Proof. The validity of the first claim is readily given by the origin of (31). To justify the second claim, note that in the case of $Q \preceq 0$, same as in the case when C, D are certain, system (30) is solvable if and only if (28) is solvable, so that $\rho_1^\star$ is the supremum of those $\rho \geq 0$ for which (30) is solvable; with this observation, (32) is readily given by Proposition 4.1. □

Unfortunately, we cannot bound from above fraction (32) in the case of uncertain C, D and $Q_+ \neq 0$, since here the derivation of the approximating system includes a step (passing from (28) to (30)) with an unknown "level of conservativeness."

4.3. Approximating Problems 2A and 3A. It suffices to process Problem 2A, since Problem 3A can be treated in a completely similar fashion. The semi-infinite LMI (16), similar to the semi-infinite LMI (28), admits the conservative approximation (cf. (30))

(33)

$$\left[\begin{array}{c|c|c} \delta C^T Q\mathbf{C} + \mathbf{C}^T Q\delta C + \mathbf{C}^T Q\mathbf{C} \\ -A^T G - GA & \delta C^T Q\mathbf{D} + \mathbf{C}^T Q\delta D + \mathbf{C}^T Q\mathbf{D} \\ & +C^T L - GB & \delta C^T S_- \\ \hline \mathbf{D}^T Q\delta C + \delta D^T Q\mathbf{C} + \mathbf{D}^T Q\mathbf{C} \\ +L^T C - B^T G & \delta D^T Q\mathbf{D} + \mathbf{D}^T Q\delta D \\ & +\mathbf{D}^T Q\mathbf{D} \\ & +L^T D + D^T L + R & \delta D^T S_- \\ \hline S_-\delta C & S_-\delta D & I_p \end{array}\right] \succeq 0$$

$$\forall \left[\begin{array}{cc} A = \mathbf{A} + \delta A & B = \mathbf{B} + \delta B \\ C = \mathbf{C} + \delta C & D = \mathbf{D} + \delta D \end{array}\right] \in \mathcal{U}_\rho,$$

which is equivalent to (16) in the case of $Q_+ = 0$, as well as in the case of certain C, D. The semi-infinite LMI (17) can be rewritten as

(34)
$$\begin{bmatrix} I & F^T \end{bmatrix} \begin{bmatrix} \mathbf{C}^TQ\mathbf{C} + \delta C^TQ\mathbf{C} + \mathbf{C}^TQ\delta C & \mathbf{C}^T(L+Q\mathbf{D}) + \delta C^T(L+Q\mathbf{D}) \\ (L+QD)^T\mathbf{C} + (L+Q\mathbf{D})^T\delta C & \delta D^T(L+Q\mathbf{D}) + (L+Q\mathbf{D})^T\delta D + \mathbf{D}^TQ\mathbf{D} + \mathbf{D}^TL + L^T\mathbf{D} + R \end{bmatrix} \begin{bmatrix} I \\ F \end{bmatrix}$$
$$+ (\delta C + \delta DF)^T S_+^2 (\delta C + \delta DF)$$
$$- (\delta C + \delta DF)^T S_-^2 (\delta C + \delta DF) \prec \big[(A+BF)^TH + H(A+BF)\big]$$
$$\forall \begin{bmatrix} A = \mathbf{A} + \delta A & B = \mathbf{B} + \delta B \\ C = \mathbf{C} + \delta C & D = \mathbf{D} + \delta D \end{bmatrix} \in \mathcal{U}_\rho.$$

The third term in the left-hand side of this MI is negative semidefinite; eliminating this term, we get a conservative approximation of (34), and this approximation, by the Schur complement lemma, is equivalent to the following semi-infinite LMI, where we set

$$\mathcal{F} = \left[\begin{array}{c|c} I_n & \\ F & \\ \hline & I_p \end{array}\right]:$$

(35)
$$\mathcal{F}^T \left[\begin{array}{cc|c} A^TH + HA - \mathbf{C}^TQ\mathbf{C} & HB - \mathbf{C}^T(L+QD) & \delta C^TS_+ \\ -\delta C^TQ\mathbf{C} - \mathbf{C}^TQ\delta C & -\delta C^T(L+Q\mathbf{D}) & \\ \hline B^TH - (L+QD)^T\mathbf{C} & -\delta D^T(L+Q\mathbf{D}) - (L+Q\mathbf{D})^T\delta D & \delta D^TS_+ \\ -(L+Q\mathbf{D})^T\delta C & -\mathbf{D}^TL + L^T\mathbf{D} - \mathbf{D}^TQ\mathbf{D} - R & \\ \hline S_+\delta C & S_+\delta D & I_p \end{array}\right] \mathcal{F} \succ 0$$
$$\forall \begin{bmatrix} A = \mathbf{A} + \delta A & B = \mathbf{B} + \delta B \\ C = \mathbf{C} + \delta C & D = \mathbf{D} + \delta D \end{bmatrix} \in \mathcal{U}_\rho$$

in matrix variable H. Thus, the system of semi-infinite LMIs (33), (35) in matrix variables G, H is a conservative approximation of (16), (17); in the cases when $Q = 0$ and/or C, D are certain, the former system in fact is equivalent to the latter one. The semi-infinite system (33), (35) is in the form of (26). Applying the construction from section 4.1, we end up with computationally tractable conservative approximation of the system (16), (17), (18). The approximation is the following system of LMIs in matrix variables $G, H, \{X_\ell, Y_\ell\}$:

(36a)
$$X_\ell \succeq \pm \overbrace{\left[\begin{array}{cc|c} dC_\ell^TQ\mathbf{C} + \mathbf{C}^TQdC_\ell - dA_\ell^TG - GdA_\ell & dC_\ell^T(L+Q\mathbf{D}) + \mathbf{C}^TQdD_\ell - GdB_\ell & dC_\ell^TS_- \\ \hline (L+Q\mathbf{D})^TdC_\ell + dD_\ell^TQ\mathbf{C} - dB_\ell^TG & dD_\ell^T(L+Q\mathbf{D}) + (L+Q\mathbf{D})^TdD_\ell & dD_\ell^TS_- \\ \hline S_-dC_\ell & S_-dD_\ell & \end{array}\right]}^{B^\ell[G]}, \quad \ell = 1, \dots, L,$$

(36b)
$$\rho \sum_{\ell=1}^{L} X_\ell \preceq \left[\begin{array}{cc|c} \mathbf{C}^TQ\mathbf{C} - \mathbf{A}^TG - G\mathbf{A} & \mathbf{C}^T(L+Q\mathbf{D}) - G\mathbf{B} & \\ \hline (L+Q\mathbf{D})^T\mathbf{C} - \mathbf{B}^TG & \mathbf{D}^TQ\mathbf{D} + L^T\mathbf{D} + \mathbf{D}^TL + R & \\ \hline & & I_p \end{array}\right],$$

(36c)

$$Y_\ell \succeq \pm \mathcal{F}^T \overbrace{\left[\begin{array}{c|c|c} dA_\ell^T H + H dA_\ell & H dB_\ell & dC_\ell^T S_+ \\ -dC_\ell^T Q\mathbf{C} - \mathbf{C}^T Q dC_\ell & -dC_\ell^T(L+Q\mathbf{D}) - \mathbf{C}^T Q dD_\ell & \\ \hline dB_\ell^T H & -dD_\ell^T(L+Q\mathbf{D}) & dD_\ell^T S_+ \\ -(L+Q\mathbf{D})^T dC_\ell - dD_\ell^T Q\mathbf{C} & -(L+Q\mathbf{D})^T dD_\ell & \\ \hline S_+ dC_\ell & S_+ dD_\ell & \end{array}\right]}^{\mathcal{C}^\ell[H]} \mathcal{F},$$

(36d)

$$\rho \sum_{\ell=1}^{L} Y_\ell \prec \mathcal{F}^T \left[\begin{array}{c|c|c} \mathbf{A}^T H + H\mathbf{A} - \mathbf{C}^T Q\mathbf{C} & H\mathbf{B} - \mathbf{C}^T(L+Q\mathbf{D}) & \\ \hline \mathbf{B}^T H - (L+Q\mathbf{D})^T\mathbf{C} & -\mathbf{D}^T Q\mathbf{D} - L^T\mathbf{D} - \mathbf{D}^T L - R & \\ \hline & & I_p \end{array}\right] \mathcal{F},$$

(36e)

$$(1-\epsilon)\mathbf{Z}_{av} \preceq H \prec G.$$

The supremum $\widehat{\rho}_{2A}$ of those $\rho \geq 0$ for which system (36) is solvable is efficiently computable, and this efficiently computable quantity can be used as a bound for the optimal value $\rho^\star_{2\mathrm{A}}$ in Problem 2A. The properties of this bound are described in the following.

PROPOSITION 4.3. (i) *System* (36) *is a conservative approximation of* (16), (17), (18) *so that the* G, H*-components of a feasible solution to* (36) *are a feasible solution of* (16), (17), (18). *In particular,* $\widehat{\rho}_{2A}$ *is a lower bound for* $\rho^\star_{2\mathrm{A}}$.

(ii) *If either*

(a) $Q = 0$ *(i.e.,* $Q_+ = Q_- = 0$*),*

or

(b) D *and* C *are certain (i.e.,* $dC_\ell = 0$, $dD_\ell = 0$ *for all* ℓ*),*

then

$$1 \leq \frac{\rho^\star_{2\mathrm{A}}}{\widehat{\rho}_{2A}} \leq \vartheta(\mu) \tag{37}$$

provided that $\rho^\star_{2\mathrm{A}} > 0$. *Here* $\vartheta(\mu)$ *is the function from Proposition* 4.1 *and*

$$\mu = \max\left[\max_{\ell\geq 1, G} \mathrm{Rank}(\mathcal{B}^\ell[G]), \max_{\ell\geq 1, H} \mathrm{Rank}(\mathcal{C}^\ell[H])\right];$$

see (36).

Tractable conservative approximation of Problem 3A looks exactly as (36), up to the constraint (36e), which should be replaced with the constraint

$$0 \preceq G \prec H \preceq (1+\delta)\mathbf{Z}_{req}.$$

The properties of this approximation are completely similar to those established in Proposition 4.3.

4.4. Approximating Problems 2B and 3B. Our current goal is to build a tractable conservative approximation of the semi-infinite system of MIs associated with Problems 2B and 3B. Both problems have the same structure, so that it suffices to consider the system associated with Problem 2B, i.e., the system (16), (17), (22) in variables G, F (H now is fixed). We have already built a tractable conservative approximation of the semi-infinite MI (16); it is given by system of LMIs (36a), (36b) in matrix variables $G, \{X_\ell\}$. Let us focus on the semi-infinite MI (17) in variable F.

We can rewrite this inequality equivalently as

(38)
$$(S_+\delta C + S_+\delta DF)^T(S_+\delta C + S_+\delta DF) - (S_-\delta C + S_-\delta DF)^T(S_-\delta C + S_-\delta DF)$$
$$+\begin{bmatrix} I & F^T \end{bmatrix}\left[\begin{array}{c|c} \delta C^T Q\mathbf{C} + \mathbf{C}^T Q\delta C + \mathbf{C}^T Q\mathbf{C} & \mathbf{C}^T(L+Q\mathbf{D}) + \delta C^T(L+Q\mathbf{D}) + \mathbf{C}^T Q\delta D \\ \hline (L+Q\mathbf{D})^T\mathbf{C} + (L+Q\mathbf{D})^T\delta C + \delta D^T Q\mathbf{C} & \mathbf{D}^T Q\mathbf{D} + L^T\mathbf{D} + \mathbf{D}^T L + R + \delta D^T Q\mathbf{D} + \mathbf{D}^T Q\delta D + L^T\delta D + \delta D^T L \end{array}\right]\begin{bmatrix} I \\ F \end{bmatrix}$$
$$\prec \left([A+BF]^T H + H[A+BF]\right)$$
$$\forall \begin{bmatrix} A = \mathbf{A} + \delta A & B = \mathbf{B} + \delta B \\ C = \mathbf{C} + \delta C & D = \mathbf{D} + \delta D \end{bmatrix} \in \mathcal{U}_\rho.$$

The second term in the left-hand side of the latter MI always is negative semidefinite; eliminating this term, we come to a conservative approximation of (38) as follows:

(39)
$$(S_+\delta C + S_+\delta DF)^T(S_+\delta C + S_+\delta DF)$$
$$+\begin{bmatrix} I & F^T \end{bmatrix}\left[\begin{array}{c|c} \overbrace{\delta C^T Q\mathbf{C} + \mathbf{C}^T Q\delta C + \mathbf{C}^T Q\mathbf{C}}^{J_{00}[\Sigma]} & \overbrace{\mathbf{C}^T(L+Q\mathbf{D}) + \delta C^T(L+Q\mathbf{D}) + \mathbf{C}^T Q\delta D}^{J_{01}[\Sigma]} \\ \hline \underbrace{(L+Q\mathbf{D})^T\mathbf{C} + (L+Q\mathbf{D})^T\delta C + \delta D^T Q\mathbf{C}}_{J_{10}[\Sigma]} & \underbrace{\mathbf{D}^T Q\mathbf{D} + L^T\mathbf{D} + \mathbf{D}^T L + R + \delta D^T Q\mathbf{D} + \mathbf{D}^T Q\delta D + L^T\delta D + \delta D^T L}_{J_{11}[\Sigma]} \end{array}\right]\begin{bmatrix} I \\ F \end{bmatrix}$$
$$\prec \left([A+BF]^T H + H[A+BF]\right)$$
$$\forall\Sigma \equiv \begin{bmatrix} A = \mathbf{A} + \delta A & B = \mathbf{B} + \delta B \\ C = \mathbf{C} + \delta C & D = \mathbf{D} + \delta D \end{bmatrix} \in \mathcal{U}_\rho.$$

Note that the matrices $J_{ij}[\Sigma]$ are affine in Σ.

Observe that (39) is exactly the semi-infinite MI

$$\begin{aligned} &[A+BF]^T H + H[A+BF] - J_{00}[\Sigma] - F^T J_{10}[\Sigma] - J_{01}[\Sigma]F \\ &\quad -(S_+\delta C + S_+\delta DF)^T(S_+\delta C + S_+\delta DF) - F^T J_{11}[\Sigma]F \succ 0 \\ &\qquad \forall\Sigma \equiv \begin{bmatrix} A = \mathbf{A} + \delta A & B = \mathbf{B} + \delta B \\ C = \mathbf{C} + \delta C & D = \mathbf{D} + \delta D \end{bmatrix} \in \mathcal{U}_\rho. \end{aligned} \tag{40}$$

Now assume that $J_{11}[\Sigma] \succ 0$. Note that this assumption is quite natural—the matrix $J_{11}[\Sigma]$ should be positive semidefinite already to make feasible (16) with $\rho = 0$. Let

$$\mathbf{K} = J_{11}^{-1}[\Sigma], \qquad \delta J_{11}[\delta\Sigma] = J_{11}[\Sigma + \delta\Sigma] - J_{11}[\Sigma].$$

We claim that the following relations hold true:

$$\mathbf{K} - \mathbf{K}\delta J_{11}[\delta\Sigma]\mathbf{K} \succ 0 \qquad \forall\Sigma \equiv \Sigma + \delta\Sigma \in \mathcal{U}_\rho \tag{41a}$$

$$\Updownarrow$$

$$J_{11}[\Sigma] \succ 0 \qquad \forall\Sigma \in \mathcal{U}_\rho \tag{41b}$$

$$\Downarrow$$

$$[\mathbf{K} - \mathbf{K}\delta J_{11}[\delta\Sigma]\mathbf{K}]^{-1} \succeq [J_{11}[\Sigma]]^{-1} \succ 0 \qquad \forall \Sigma \equiv \Sigma + \delta\Sigma \in \mathcal{U}_\rho. \tag{41c}$$

Indeed, the equivalence between (41a) and (41b) follows from the identity

$$\mathbf{K} - \mathbf{K}\delta J_{11}[\delta\Sigma]\mathbf{K} = \mathbf{K}J_{11}[\Sigma - \delta\Sigma]\mathbf{K}$$

(which is readily given by the definition of $\mathbf{K}$), combined with the fact that $\mathcal{U}_\rho$ is symmetric with respect to Σ. To see that (41b) implies (41c), observe, first, that

$$X \succ \pm Y \Rightarrow [X^{-1} - X^{-1}YX^{-1}]^{-1} \succeq X + Y \succ 0. \tag{42}$$

Indeed, assuming $X \succ \pm Y$ and setting $Z = X^{-1/2}YX^{-1/2}$ (so that $I \succ \pm Z$), we have

$$\begin{aligned}(X+Y)^{-1} - [X^{-1} - X^{-1}YX^{-1}] &= [X^{1/2}(I+Z)X^{1/2}]^{-1} - X^{-1/2}[I-Z]X^{-1/2} \\ &= X^{-1/2}[(I+Z)^{-1} - (I-Z)]X^{-1/2} \\ &= X^{-1/2}Z(I+Z)^{-1}ZX^{-1/2} \succeq 0,\end{aligned}$$

hence $(X+Y)^{-1} \succeq [X^{-1} - X^{-1}YX^{-1}]$ and thus $[X^{-1} - X^{-1}YX^{-1}]^{-1} \succeq X + Y \succ 0$, as required in (42). Now let $\delta\Sigma$ be such that $\Sigma + \delta\Sigma \in \mathcal{U}_\rho$. Since $\mathcal{U}_\rho$ is symmetric with respect to Σ, we have $\Sigma - \delta\Sigma \in \mathcal{U}_\rho$ as well. In the case of (41b) it follows that $J_{11}[\Sigma \pm \delta\Sigma] \succ 0$ or, which is the same, $J_{11}[\Sigma] \succ \pm\delta J_{11}[\delta\Sigma]$. Applying (42), we arrive at (41c).

By (41), in the case of (41a) the semi-infinite MI

$$\begin{gathered}[A+BF]^T H + H[A+BF] - J_{00}[\Sigma] - F^T J_{10}[\Sigma] - J_{01}[\Sigma]F \\ - (S_+\delta C + S_+\delta DF)^T(S_+\delta C + S_+\delta DF) - F^T[\mathbf{K} - \mathbf{K}\delta J_{11}[\delta\Sigma]\mathbf{K}]^{-1}F \succ 0 \\ \forall \Sigma \equiv \Sigma + \delta\Sigma \equiv \left[\begin{array}{ll} A = \mathbf{A} + \delta A & B = \mathbf{B} + \delta B \\ C = \mathbf{C} + \delta C & D = \mathbf{D} + \delta D \end{array}\right] \in \mathcal{U}_\rho\end{gathered}$$

is a conservative approximation of (40), which in turn is a conservative approximation of (17). Applying the Schur complement lemma, the resulting semi-infinite MI can be rewritten as

$$\left[\begin{array}{c|c|c} [A+BF]^T H + H[A+BF] & (S_+\delta C + S_+\delta DF)^T & F^T \\ -J_{00}[\Sigma] - F^T J_{10}[\Sigma] - J_{01}[\Sigma]F & & \\ \hline (S_+\delta C + S_+\delta DF) & I & \\ \hline F & & \mathbf{K} - \mathbf{K}\delta J_{11}[\delta\Sigma]\mathbf{K} \end{array}\right] \succ 0 \tag{43}$$

$$\forall \Sigma \equiv \Sigma + \delta\Sigma \equiv \left[\begin{array}{ll} A = \mathbf{A} + \delta A & B = \mathbf{B} + \delta B \\ C = \mathbf{C} + \delta C & D = \mathbf{D} + \delta D \end{array}\right] \in \mathcal{U}_\rho.$$

Note that the validity of this semi-infinite LMI automatically implies (41a). Further, the matrix in the left-hand side of the resulting semi-infinite LMI is affine in Σ, so that we can apply the scheme from section 4.1 to build a computationally tractable conservative approximation of this semi-infinite LMI. The approximation is the following

system of LMIs in matrix variables $F, \{Y_\ell\}$:

(44)

$$Y_\ell \succeq \pm \overbrace{\left[\begin{array}{c|c|c} [dA_\ell + dB_\ell F]^T H + H[dA_\ell + dB_\ell F] & & \\ -dC_\ell^T Q\mathbf{C} - \mathbf{C}^T Q dC_\ell & dC_\ell^T S_+ & \\ -\left\{dC_\ell^T[L+Q\mathbf{D}] + \mathbf{C}^T Q dD_\ell\right\} F & +F^T dD_\ell^T S_+ & \\ -F^T\left\{dC_\ell^T[L+Q\mathbf{D}] + \mathbf{C}^T Q dD_\ell\right\}^T & & \\ \hline S_+ dC_\ell & & \\ +S_+ dD_\ell F & & \\ \hline & & -\mathbf{K}dD_\ell^T[L+Q\mathbf{D}]\mathbf{K} \\ & & -\mathbf{K}[L+Q\mathbf{D}]^T dD_\ell \mathbf{K} \end{array}\right]}^{\mathcal{D}^\ell[F]},$$

$$\ell = 1, \ldots, L,$$

$$\rho \sum_{\ell=1}^{L} Y_\ell \prec \left[\begin{array}{c|c|c} [\mathbf{A}+\mathbf{B}F]^T H + H[\mathbf{A}+\mathbf{B}F] - \mathbf{C}^T Q\mathbf{C} & & F^T \\ -F^T[L+Q\mathbf{D}]^T\mathbf{C} - \mathbf{C}^T[L+Q\mathbf{D}]F & & \\ \hline & I & \\ \hline F & & \mathbf{K} \end{array}\right].$$

We arrive at the following result.

PROPOSITION 4.4. *Assume that the matrix*

$$\mathbf{K}^{-1} \equiv \mathbf{D}^T Q\mathbf{D} + L^T\mathbf{D} + \mathbf{D}^T L + R \tag{45}$$

is positive definite. Then

(i) *The system of LMIs* (36a), (36b), (44) *and the LMI*

$$H \prec G \tag{46}$$

in matrix variables $G, F, \{X_\ell, Y_\ell\}$ is a conservative approximation of the system (16), (17), (18) *associated with Problem* 2B. *In particular, the efficiently computable supremum $\widehat{\rho}$ of those $\rho \geq 0$ for which the approximating system is solvable is a lower bound on the optimal value $\rho^\star_{2\mathrm{B}}$ of Problem* 2B.

(ii) *If either*

(a) *C, D are certain (i.e., $dC_\ell = 0$, $dD_\ell = 0$ for all ℓ)*

or

(b) *$Q = 0$ and D is certain,*

then

$$1 \leq \frac{\rho^\star_{2\mathrm{B}}}{\widehat{\rho}} \leq \vartheta(\mu), \tag{47}$$

provided that $\rho^\star_{2\mathrm{B}} > 0$. Here $\vartheta(\mu)$ is the function from Proposition 4.1 *and*

$$\mu = \max\left[\max_{\ell\geq 1, G} \mathrm{Rank}(\mathcal{B}^\ell[G]), \max_{\ell\geq 1, F} \mathrm{Rank}(\mathcal{D}^\ell[F])\right];$$

see (36a), (44) *for the definitions of $\mathcal{B}^\ell[G]$ and $\mathcal{D}^\ell[F]$.*

Tractable conservative approximation of Problem 3B looks exactly like the one for Problem 2B, with the only difference that the LMI (46) should now be replaced with the LMIs

$$0 \preceq G \prec H.$$

The properties of this approximation are completely similar to those established in Proposition 4.4.

4.5. Approximating Problem 3C. Now consider Problem 3C. The system of MIs to be approximated is now comprised of the semi-infinite MI (17) in matrix variables F, H and the LMI $0 \prec H \preceq (1+\delta)\mathbf{Z}_{req}$. The system in question can be rewritten equivalently as

(48)
$$\begin{array}{rcl}
\left[\begin{array}{cc} I & F^T \end{array}\right]\left[\begin{array}{cc} C^T & \\ D^T & I \end{array}\right]\left[\begin{array}{cc} Q & L \\ L^T & R \end{array}\right]\left[\begin{array}{cc} C & D \\ & I \end{array}\right]\left[\begin{array}{c} I \\ F \end{array}\right] & \prec & [(A+BF)^T H + H(A+BF)] \\
& & \forall \left[\begin{array}{cc} A & B \\ C & D \end{array}\right] \in \mathcal{U}_\rho, \\
0 \prec H & \preceq & (1+\delta)\mathbf{Z}_{req}.
\end{array}$$

We can assume that $\mathbf{Z}_{req} \succ 0$—otherwise the system clearly is unsolvable. Let us use the standard change of variables $(H, F) \mapsto (U = H^{-1}, V = FH^{-1})$. Multiplying both sides of (48) from the right and from the left by H^{-1}, we rewrite (48) in the new variables as

(49)
$$\begin{array}{rcl}
\left[\begin{array}{cc} U & V^T \end{array}\right]\left[\begin{array}{cc} C^T & \\ D^T & I \end{array}\right]\underbrace{\left[\begin{array}{cc} Q & L \\ L^T & R \end{array}\right]}_{\mathfrak{P}}\left[\begin{array}{cc} C & D \\ & I \end{array}\right]\left[\begin{array}{c} U \\ V \end{array}\right] & \prec & [AU + UA^T + BV + V^T B^T] \\
& & \forall \left[\begin{array}{cc} A & B \\ C & D \end{array}\right] \in \mathcal{U}_\rho, \\
U & \succeq & (1+\delta)^{-1}\mathbf{Z}_{req}^{-1}.
\end{array}$$

Setting $M \equiv \begin{bmatrix} M_{yy} & M_{yu} \\ M_{yu}^T & M_{uu} \end{bmatrix} = \mathfrak{P}^{1/2}$ (recall that we are in the case of $\mathfrak{P} \succeq 0$) and applying the Schur complement lemma, we can rewrite the latter system equivalently as

(50)
$$\left[\begin{array}{c|c|c}
\begin{array}{c} AU + UA^T \\ +BV + V^T B^T \end{array} & \begin{array}{c} UC^T M_{yy} \\ +V^T[M_{yy}D + M_{yu}]^T \end{array} & \begin{array}{c} UC^T M_{yu} \\ +V^T[M_{yu}^T D + M_{uu}]^T \end{array} \\ \hline
\begin{array}{c} M_{yy}CU \\ +[M_{yy}D + M_{yu}]V \end{array} & I_p & \\ \hline
\begin{array}{c} M_{yu}^T CU \\ +[M_{yu}^T D + M_{uu}]V \end{array} & & I_m
\end{array}\right] \succeq 0$$
$$\forall \left[\begin{array}{cc} A & B \\ C & D \end{array}\right] \in \mathcal{U}_\rho,$$
$$U \succeq (1+\delta)^{-1}\mathbf{Z}_{req}^{-1}.$$

System (50) is in the form of (26); applying the construction from section 4.1, we end up with a tractable conservative approximation of (49), which is the following system of LMIs in matrix variables $U, V, \{X_\ell\}$:

(51)
$$U \succeq (1+\delta)^{-1}\mathbf{Z}_{req}^{-1},$$
$$X_\ell \succeq \pm \underbrace{\left[\begin{array}{c|c|c}
\begin{array}{c} dA_\ell U + UdA_\ell^T \\ +dB_\ell V + V^T dB_\ell^T \end{array} & \begin{array}{c} UdC_\ell^T M_{yy} \\ +V^T dD_\ell^T M_{yy} \end{array} & \begin{array}{c} UdC_\ell^T M_{yu} \\ +V^T dD_\ell^T M_{yu} \end{array} \\ \hline
\begin{array}{c} M_{yy}dC_\ell U \\ +M_{yy}dD_\ell V \end{array} & 0_{p\times p} & \\ \hline
\begin{array}{c} M_{yu}^T dC_\ell U \\ +M_{yu}^T dD_\ell V \end{array} & & 0_{m\times m}
\end{array}\right]}_{\mathcal{E}^\ell[U,V]}, \quad \ell = 1, \ldots, L,$$

$$\rho \sum_{\ell=1}^{L} X_\ell \preceq \left[\begin{array}{c|c|c} \mathbf{A}U + U\mathbf{A}^T & UC^T M_{yy} & UC^T M_{yu} \\ +\mathbf{B}V + V^T\mathbf{B}^T & +V^T[M_{yy}\mathbf{D} + M_{yu}]^T & +V^T[M_{yu}^T\mathbf{D} + M_{uu}]^T \\ \hline M_{yy}\mathbf{C}U & I_p & \\ +[M_{yy}\mathbf{D} + M_{yu}]V & & \\ \hline M_{yu}^T\mathbf{C}U & & I_m \\ +[M_{yu}^T\mathbf{D} + M_{uu}]V & & \end{array}\right].$$

We arrive at the following.

PROPOSITION 4.5. *Assume that the supply matrix* $\mathfrak{P} = \left[\begin{smallmatrix} Q & L \\ L^T & R \end{smallmatrix}\right]$ *is positive semidefinite and that* $\mathbf{Z}_{req} \succ 0$. *Then the system of LMIs* (51) *in matrix variables* $U, V, \{X_\ell\}$ *is a conservative approximation of the system associated with Problem* 3C. *In particular, the efficiently computable supremum* $\widehat{\rho}$ *of those* $\rho \geq 0$ *for which the approximating system is solvable is a lower bound on the optimal value* $\rho^\star_{3C}$ *of Problem* 3C. *For this lower bound, one has*

$$1 \leq \frac{\rho^\star_{3C}}{\widehat{\rho}} \leq \vartheta(\mu), \tag{52}$$

provided that $\rho^\star_{3C} > 0$. *Here* $\vartheta(\mu)$ *is the function from Proposition* 4.1 *and*

$$\mu = \max_{\ell \geq 1, U, V} \mathrm{Rank}(\mathcal{E}^\ell[U, V]);$$

see (51).

4.6. Simplifying approximating systems. A severe practical disadvantage of the tractable approximations of Problems 1, 2A, 2B, 3A, 3B, and 3C we have built is that the sizes of these approximations, although polynomial in the sizes m, n, p, L of the underlying dynamical system and uncertainty set, are quite large. For example, approximation (31) has a single $(m+n+p) \times (m+n+p)$ symmetric matrix variable X_ℓ and two $(m+n+p) \times (m+n+p)$ LMIs per every basic perturbation in the data, so that the design dimension of the approximation is of order of $L(m+n+p)^2$, a quantity which typically is prohibitively large for practical computations. We are about to demonstrate that under favorable circumstances the sizes of the approximating systems can be reduced dramatically. For the sake of simplicity, we restrict our considerations to the case of the approximation (31) associated with Problem 1; the approximations associated with other problems can be processed in a completely similar fashion.

System (31) is of the generic form

$$\mathcal{P}(x) \succeq 0, \tag{53a}$$

$$U_\ell \succeq \pm \mathcal{Q}_\ell(x), \qquad \ell = 1, \ldots, M, \tag{53b}$$

$$V_\ell \succeq \pm R_\ell, \qquad \ell = 1, \ldots, N, \tag{53c}$$

$$\rho \left[\sum_\ell U_\ell + \sum_\ell V_\ell\right] \preceq \mathcal{S}(x), \tag{53d}$$

where

- x is the collection of the original design variables (for (31), $x = Z$);
- U_ℓ, V_ℓ are additional $K \times K$ matrix variables (for (31), $K = m + n + p$, $M + N = L$, the U-variables are those of X_ℓ for which $\mathcal{A}^\ell[Z]$ indeed depends on Z, while the V-variables correspond to those of X_ℓ for $\mathcal{A}^\ell[Z]$ in fact does not depend on Z);

- $\mathcal{P}(x)$, $\mathcal{Q}_\ell(x)$, $\mathcal{S}(x)$ are affine functions of x taking values in the spaces of symmetric matrices of appropriate sizes, and R_ℓ are given $K \times K$ symmetric matrices.

Note that in the situations we are interested in, the ranks of the matrices $\mathcal{Q}_\ell(x)$, R_ℓ are small, provided that the ranks of basic perturbation matrices $dA_\ell, dB_\ell, dC_\ell, dD_\ell$ are small (as indeed is the case in applications). The undesirable large sizes of the approximating system (53) come exactly from the necessity to introduce large-size "matrix bounds" U_ℓ, V_ℓ on the small rank matrices $\mathcal{Q}_\ell(x)$, R_ℓ.

Note that in our applications all we are interested in are the x-components of the feasible solutions of (53). Thus, for our purposes (53) can be replaced with any *x-equivalent* system of LMIs—a system of LMIs $\mathcal{L}(x,y) \succeq 0$ in the original variables x and additional variables y such that the set of x-components of feasible solutions to the latter system is exactly the same as the set of x-components of feasible solutions of (53). What we intend to do is to demonstrate that under favorable circumstances we can build a system of LMIs which is x-equivalent to (53), while being "much smaller" than the latter system. The key to our construction is given by the following two observations.

LEMMA 4.6 (see [3, Lemma 3.1 and Proposition 2.1]). (i) *Let a, b be two nonzero vectors. A symmetric matrix X satisfies the relation*

$$X \succeq \pm[ab^T + ba^T]$$

if and only if there exists positive λ such that

$$X \succeq \lambda aa^T + \frac{1}{\lambda} bb^T.$$

(ii) *Let A be a $n \times n$ symmetric matrix of rank $k > 0$, so that $A = P^T \widehat{A} P$ for appropriately chosen $k \times k$ matrix $\widehat{A}$ and $k \times n$ matrix P of rank k. A symmetric matrix X satisfies the relation*

$$X \succeq \pm A$$

if and only if there exists $k \times k$ symmetric matrix $\widehat{X}$ such that

$$\begin{array}{l} X \succeq P^T \widehat{X} P, \\ \widehat{X} \succeq \pm \widehat{A}. \end{array} \tag{54}$$

Now assume that the matrices $\mathcal{Q}_\ell(x)$ are of the from

$$\mathcal{Q}_\ell(x) = a_\ell b_\ell^T(x) + b_\ell(x) a_\ell^T, \tag{55}$$

where $a_\ell \neq 0$, $b_\ell(x) \not\equiv 0$ are, respectively, a vector and an affine vector-valued function of x. Let also

$$R_\ell = P_\ell^T \widehat{R}_\ell P_\ell : \quad \widehat{R}_\ell = \widehat{R}_\ell^T \in \mathbf{S}^{k_\ell}, \qquad k_\ell = \mathrm{Rank}(R_\ell) > 0.$$

Applying Lemma 4.6, we see that (53) is x-equivalent to the following system of constraints in the original variables x and the additional variables $\lambda_\ell \geq 0$, $\widehat{V}_\ell \in \mathbf{S}^{k_\ell}$:

$$\begin{array}{c} \mathcal{P}(x) \succeq 0, \\ \widehat{V}_\ell \succeq \pm \widehat{R}_\ell, \qquad \ell = 1, \ldots, N, \\ \rho\left[\sum_\ell \left[\lambda_\ell a_\ell a_\ell^T + \frac{1}{\lambda_\ell} b_\ell(x) b_\ell^T(x)\right] + \sum_\ell P_\ell^T \widehat{V}_\ell P_\ell\right] \preceq \mathcal{S}(x) \end{array}$$

(where $\frac{1}{0}bb^T$ is 0 for $b = 0$ and is undefined for $b \neq 0$). The resulting system, via the Schur complement lemma, is x-equivalent to the system of LMIs

$$\mathcal{P}(x) \succeq 0, \tag{56a}$$

$$\left[\begin{array}{c|cccc} X - \sum\limits_{\ell=1}^{M} \lambda_\ell a_\ell a_\ell^T & b_1(x) & b_2(x) & \dots & b_M(x) \\ \hline b_1^T(x) & \lambda_1 & & & \\ b_2^T(x) & & \lambda_2 & & \\ \vdots & & & \ddots & \\ b_M^T(x) & & & & \lambda_M \end{array}\right] \succeq 0, \tag{56b}$$

$$\widehat{V}_\ell \succeq \pm \widehat{R}_\ell, \qquad \ell = 1, \dots, N, \tag{56c}$$

$$\rho\left[X + \sum_\ell P_\ell^T \widehat{V}_\ell P_\ell\right] \preceq \mathcal{S}(x) \tag{56d}$$

in the original variables x and additional scalar variables $\{\lambda_\ell\}_{\ell=1}^M$ and matrix variables X, $\{\widehat{V}_\ell\}_{\ell=1}^N$.

System (56) is x-equivalent to our original system (53) and is usually much better suited for numerical processing than the original system. Indeed, as compared to (53), in (56) there are

- a single $K \times K$ matrix variable X and M scalar variables $\{\lambda_\ell\}_{\ell=1}^M$ instead of M $K \times K$ matrix variables U_ℓ;
- $k_\ell \times k_\ell$ matrix variables $\widehat{V}_\ell$ instead of $K \times K$ matrix variables V_ℓ, and $k_\ell \times k_\ell$ LMIs (56c) instead of $K \times K$ LMIs (53c) (recall that k_ℓ are assumed to be small as compared to K);
- a single LMI (56b) instead of M LMIs (53b). Although the size of LMI (56b) is larger than those of LMIs (53b), the LMI is of very simple arrow structure and is extremely sparse.

It remains to understand what should be required from the uncertainty set $\mathcal{U}_\rho$ in order to ensure that the approximations associated with Problems 1, 2A, 2B, 3A, 3B, and 3C possess property (55) and thus admit the outlined simplification. The corresponding requirements are as follows:

A. In the case of Problems 1, 2A, 3A, it suffices to assume the following:
   - A.1. The parts $[A, B]$ and $[C, D]$ of the matrix $\Sigma = \left[\begin{smallmatrix} A & B \\ C & D \end{smallmatrix}\right]$ are perturbed independently (i.e., for every ℓ exactly one of the matrices $[dA_\ell, dB_\ell]$, $[dC_\ell, dD_\ell]$ is nonzero).
   - A.2. The basic perturbations of the part $[A, B]$ of Σ are of ranks ≤ 1.

   Note that under these assumptions the quantity μ in Propositions 4.2, 4.3 and the above quantities k_ℓ satisfy the relation

$$k_\ell \leq \mu \leq 2 \max\left[1, \max_\ell (\mathrm{Rank}(dC_\ell) + \mathrm{Rank}(dD_\ell))\right].$$

B. In the case of Problems 2B, 3B, it suffices to assume the following.
   - B.1. The parts A, B, C, D of Σ are perturbed independently (i.e., for every ℓ exactly one of the matrices dA_ℓ, dB_ℓ, dC_ℓ, dD_ℓ is nonzero).
   - B.2. The basic perturbations of the parts A, B, C, D of Σ are of ranks ≤ 1 and
     - i. either $Q = 0$

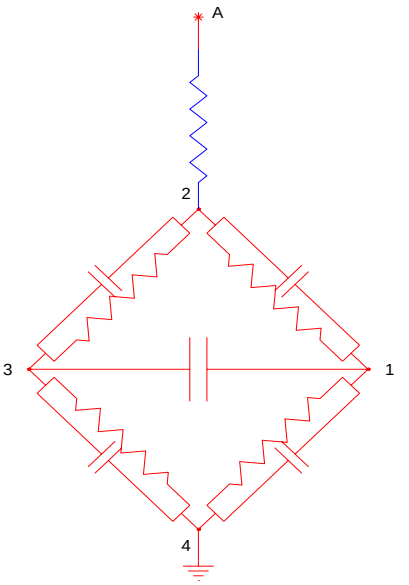

FIG. 1. *"Bridge."*

ii. or D is certain.

Note that under these assumptions the quantity μ in Proposition 4.4 and the above quantities k_ℓ satisfy the relation

$$k_\ell \le \mu \le 2.$$

C. In the case of Problem 3C, it suffices to assume that

C.1. the basic perturbations $d\Sigma_\ell$ are of ranks ≤ 1.

Note that under these assumptions the quantity μ in Proposition 4.5 equals 2.

Note that the sets A.1–A.2, B.1–B.2, C.1 of the assumptions are satisfied in the simplest case of the *interval uncertainty*—every entry in Σ, independently of other entries, runs through a given interval. In this case, $k_\ell \le \mu = 2$, and the corresponding "tightness bound" $\vartheta(\mu)$ (see (32), (37), (47), (52)) becomes $\frac{\pi}{2}$.

5. Illustrating examples. Here we present three simple illustrations of the proposed approach. The first two of them correspond to the positive-real case, while the third has to do with the linear-quadratic case.

5.1. Positive-real case. Consider the simple RC circuit ("bridge") presented in Figure 1. The input is the outer voltage applied between the node A and the ground, the output is the current through the circuit. The state variables are the potentials at the nodes 1, 2, 3 (normalized by the condition that the potential of the ground is identically zero). Applying the Kirchoff laws, the description of the system becomes

$$\begin{aligned} \dot z(t) &= A_{c,r} z(t) + B_{c,r} u(t), \\ y(t) &= C_r z(t) + D_r u(t), \end{aligned} \tag{57}$$

where we have the following:

- $c \in \mathbf{R}^{10}$ is the vector of capacitances of the capacitors in the 10 arcs of the circuit (9 "visible arcs" and the external arc from node 2 via point A to the ground; for arc i with no capacitor, $c_i = 0$).
- $r \in \mathbf{R}^{10}$ is the vector of conductances of the resistors in the 10 arcs of the circuit (for arc i with no resistor, $r_i = 0$).
- the matrix $\Sigma = \left[\begin{smallmatrix} A & B \\ C & D \end{smallmatrix}\right]$ is given by

$$\Sigma = \Sigma_{c,r} \equiv \left[\begin{array}{c|c} -[P^T\mathrm{Diag}\{c\}P]^{-1}[P^T\mathrm{Diag}\{r\}P] & [P^T\mathrm{Diag}\{c\}P]^{-1}[P^T\mathrm{Diag}\{r\}J], \\ \hline -[P^T\mathrm{Diag}\{r\}J], & J^T\mathrm{Diag}\{r\}J, \end{array}\right],$$

where $\mathrm{Diag}\{p\}$ denotes the diagonal matrix with diagonal entries given by vector p and

- P is the *incidence matrix*. The rows of P are indexed by the 10 arcs in the circuit, the columns are indexed by the 3 nonground nodes 1, 2, 3 and the element P_{ij} is equal to $+1$, -1 or 0 depending on whether node # j starts arc # i, ends this arc, or is not incident to the arc. For our circuit, P is as follows (R stands for arcs with resistors, C for arcs with capacitors):

Arcs			Nodes		
Origin	Destination	Type	1	2	3
1	2	R	1	−1	0
1	2	C	1	−1	0
2	3	R	0	1	−1
2	3	C	0	1	−1
3	4	R	0	0	1
3	4	C	0	0	1
4	1	R	−1	0	0
4	1	C	−1	0	0
1	3	C	1	0	−1
2	→ A → 4	R	0	1	0

- $J = (0, \ldots, 0, 1)^T \in \mathbf{R}^{10}$ "points" to the external arc (which in our enumeration is the last of the 10 arcs of the circuit).

We treat as the uncertain parameters the capacitances of the capacitors and the conductances of the resistors (except for the "outer" resistor in the external arc; it represents the inner resistance of the outer supply and is assumed to be certain) and assume that every one of these parameters can vary, independently of others, by at most ρ times the nominal value of the parameter, where ρ is the uncertainty level in question. The nominal values of the data are given in Table 1. Here is the nominal instance (entries are rounded to 4 digits after the dot):

$$\Sigma = \left[\begin{array}{rrr|r} -0.5005 & -50.0000 & -0.4995 & 50.0000 \\ 0.1000 & -101.1000 & 0.0000 & 100.0000 \\ -0.4995 & -50.0000 & -0.5005 & 50.0000 \\ \hline 0 & -100.0000 & 0 & 100.0000 \end{array}\right].$$

The elements of the matrix $\Sigma_{c,r}$ are nonlinear functions of the "physical data" c, r, so that an interval uncertainty in the latter data is not equivalent to a box uncertainty in $\Sigma_{c,r}$. We neglect this phenomenon by linearizing $\Sigma_{r,c}$ at the nominal data, thus

TABLE 1
Nominal values for the bridge circuit.

Element	Nominal value	Element	Nominal value
R_{12}	1.2	C_{12}	1.0
R_{23}	1.0	C_{23}	1.0
R_{34}	1.0	C_{34}	1.0
R_{41}	1.0	C_{41}	1.0
R_{2A}	100	C_{13}	1000

arriving at a box uncertainty set with $L = 9$ basic perturbation matrices, according to the number of uncertain capacitances and conductances in the circuit. Note that for our particular circuit, the resulting uncertainty affects only the $[A, B]$-part of Σ, and the basic perturbation matrices $[dA_\ell, dB_\ell]$ are of rank 1.

Recall that the supply in the SISO positive-real case is $2yu$, i.e.,

$$\mathfrak{P} = \left[\begin{array}{cc} Q = 0 & L = 1 \\ L^T = 1 & R = 0 \end{array} \right];$$

for our RC circuit, the supply is nothing but (twice) the electrical power pumped into the circuit by the external voltage.

We have carried out two experiments with the outlined system: the first deals with extracting the energy stored in the circuit, and the second with moving the circuit from the zero initial state to a given state.

Extracting available energy. The question we are addressing is to find the largest level $\rho^\star_{av}$ of uncertainty for which the "performance" Θ of the "ideal extracting feedback" $\mathbf{F}_{av}$ (see D.4) corresponding to the nominal instance is at least $1 - \epsilon$, i.e., this feedback still allows, for every perturbed instance and every initial state ζ of the circuit, to extract at least $(1 - \epsilon)$-part of the nominal available storage $\zeta^T \mathbf{Z}_{av} \zeta$. In our experiment, we set $\epsilon = 0.1$. Solving the conservative approximation

$$\max_{\rho, G, H, \{X_\ell, Y_\ell\}} \{\rho : \ (\rho, G, H, \{X_\ell, Y_\ell\}) \text{ satisfies (36)}\}$$

of the associated Problem 2A, we end up with a lower bound

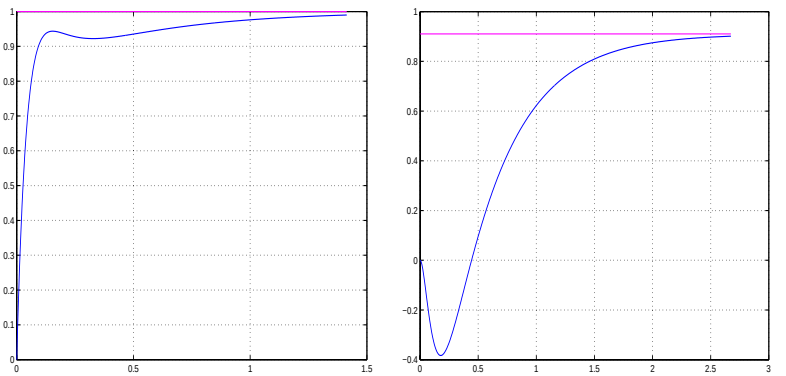
$$\widehat{\rho} = 1.1\mathsf{e}{-3}$$

on $\rho^\star_{av}$; in other words, we can be sure that with 0.11% perturbations of the uncertain capacitances and conductances, the nominal feedback $\mathbf{F}_{av}$ still allows us to extract at least 90% of the nominal available storage, whatever is the initial state of the circuit. A natural question arises, How conservative is our bound? Recall that there are two reasons for it to be conservative:

- First, the bound comes from solving a conservative approximation of Problem 2A rather than from solving the problem itself; according to Proposition 4.3, the true optimal value in the problem is at most $\frac{\pi}{2}$ times larger than the bound (recall that we are in the situation of $Q = 0$ and $\mu = 2$).
- Second, and worse, even the true optimal value in Problem 2A is a lower bound on $\rho^\star_{av}$, since the problem comes from the *sufficient* condition, stated by Proposition 3.2, for "good" performance of the nominal feedback $\mathbf{F}_{av}$ under data perturbations. Note that we have no idea how conservative this sufficient condition is.

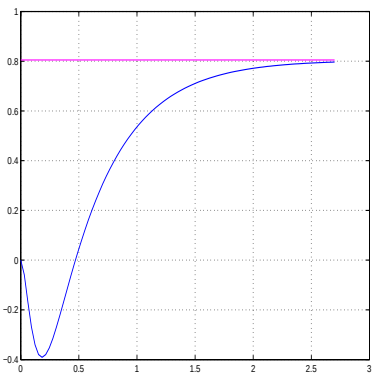
TABLE 2
Performance of the nominal feedback $\mathbf{F}_{av}$ *versus uncertainty level.*

ρ	$1.2\widehat{\rho} = 1.3\mathsf{e}{-3}$	$2.2\widehat{\rho} = 2.3\mathsf{e}{-3}$	$3\widehat{\rho} = 3.2\mathsf{e}{-3}$
Θ	0.893	0.805	0.736



$\rho = 0$
$\Theta = 1$

$\rho = \widehat{\rho} = 1.1\mathsf{e}{-3}$
$\Theta = 0.910$



$\rho = 2.2\widehat{\rho} = 2.3\mathsf{e}{-3}$
$\Theta = 0.805$

FIG. 2. *Sample plots of* $\frac{E_{av}(t)}{z^T(0)\mathbf{Z}_{av}z(0)}$.

In spite of these pessimistic considerations, the experiment shows that our bound is pretty tight. Looking through all $2^L = 512$ "extreme" perturbations of the data, and playing with the initial state of the circuit, we found out that the worst-case (with respect to relative perturbations of the uncertain entries in c, r of level ρ and initial states) performance Θ of the ideal nominal feedback is *at most* as given in Table 2. In particular, we see that with the level of perturbations $1.2\widehat{\rho}$, the worst-case performance of the ideal nominal feedback is less than 0.9 ($\equiv 1-\epsilon$) times the nominal available storage. It follows that $\rho^\star_{av} \leq 1.2\widehat{\rho}$, i.e., our bound $\widehat{\rho}$ is within 20% margin of the quantity of interest.

Figure 2 represents three sample plots of the extracted energy $E_{av}(t)$ as a function of time for the feedback $\mathbf{F}_{av}$.

TABLE 3
Price of the nominal feedback $\mathbf{F}_{req}$ versus uncertainty level.

ρ	$1.2\widehat{\rho} = 5.5\mathtt{e}{-4}$	$2.2\widehat{\rho} = 1.0\mathtt{e}{-3}$	$3\widehat{\rho} = 1.4\mathtt{e}{-3}$
Γ	1.056	1.105	1.148

Moving the circuit to a given state. Now let us try to find the largest uncertainty level $\rho^\star_{req}$ for which the "price" Γ of the "ideal driving feedback" $\mathbf{F}_{req}$ (see D.4) corresponding to the nominal instance is at most $1+\delta$, i.e., this feedback still allows, for every perturbed instance and every target state ζ of the circuit, to move the circuit from the zero initial state to the state ζ while pumping into the circuit at most $(1+\delta)$ times the nominal required energy $\zeta^T\mathbf{Z}_{req}\zeta$. In our experiment, we set $\delta = 0.1$. Solving the conservative approximation of the associated Problem 3A (see the end of section 4.3), we end up with a lower bound

$$\widehat{\rho} = 4.6\mathtt{e}{-4}$$

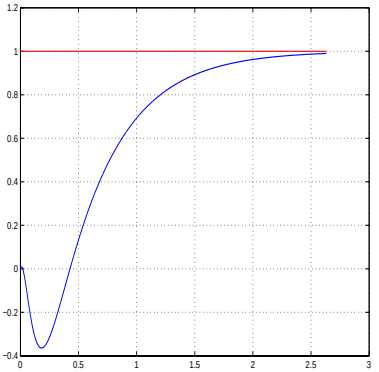
on $\rho^\star_{req}$; thus, we can be sure that with 0.046% perturbations of the uncertain capacitances and conductances, the ideal nominal feedback $\mathbf{F}_{req}$ still allows us to move the circuit from the zero state to (any) target one while pumping into the circuit at most 110% of the nominal required energy. It turns out that our bound is perhaps not as tight as in the previous case, but still is good enough. Indeed, looking at the data in Table 3, which represent *lower* bounds on the price of the ideal nominal driving feedback $\mathbf{F}_{req}$ under different levels of perturbations, we see that with the perturbations of the level $2.2\widehat{\rho}$ the price of moving the circuit to certain target state ζ by the feedback $\mathbf{F}_{req}$ can be larger than 1.1 ($\equiv 1+\delta$) times the nominal required energy $\zeta^T\mathbf{Z}_{req}\zeta$; hence $\rho^\star_{req} \le 2.2\widehat{\rho}$. Note that, in the case in question, the conservative approximation of Problem 3A contributes to the ratio $\rho^\star_{req}/\widehat{\rho} \approx 2.2$ a factor $\le \frac{\pi}{2} = 1.57$; the remaining factor in the ratio (which is at least $2.2/1.57 \approx 1.4$) comes from the conservativeness of the sufficient condition expressed in Proposition 3.3 and underlying Problem 3A.

Figure 3 presents three sample plots of the pumped energy $E_{req}(t)$ as a function of time for the feedback $\mathbf{F}_{req}$.

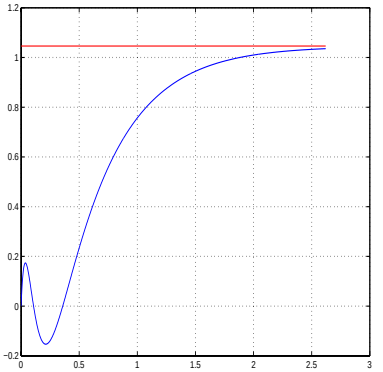
5.2. Linear-quadratic case. Consider the mechanical system shown on Figure 4; it consists of 5 material points in a two-dimensional plane linked to each other by elastic springs as shown on the figure; the points can slide without friction along the respective axes $01, \dots, 05$. The nominal data for the system are given in Table 4. The system is controlled by two external forces acting at the masses 1 and 5. The first 5 components of the state vector are the shifts x_i of the points from their equilibrium positions along the lines of motion, and the next 5 components are the linear velocities $\dot{x}_i$ of the points; these velocities are the outputs of the system. With respect to these states, the dynamical system in question is

$$\begin{array}{rcl} \frac{d}{dt}\left[\begin{array}{c} x \\ \dot{x} \end{array}\right] &=& \left[\begin{array}{c|c} & I_5 \\ \hline -M^{-1}E & \end{array}\right]\left[\begin{array}{c} x \\ \dot{x} \end{array}\right] + Bu, \\ y &=& \dot{x}, \end{array} \tag{58}$$

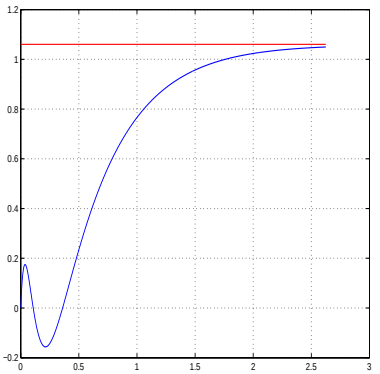
where M is the diagonal matrix with the masses $m(i)$ of the points as the diagonal entries, E is the *stiffness matrix* readily given by the rigidities of the springs and the equilibria positions of the points, and B is the 10×2 matrix with two nonzero



$\rho = 0$
$\Gamma = 1$



$\rho = \widehat{\rho} = 4.6\mathsf{e}{-4}$
$\Gamma = 1.046$



$\rho = 2.2\widehat{\rho} = 1.0\mathsf{e}{-3}$
$\Gamma = 1.105$

FIG. 3. *Sample plots of* $\frac{E_{req}(t)}{z^T(0)\mathbf{Z}_{req}z(0)}$.

entries $B_{5,1} = m^{-1}(1)$ and $B_{10,2} = m^{-1}(5)$. Here is the nominal instance (entries are rounded to 4 digits after the dot):

$$\Sigma = \left[\begin{array}{ccccc|cccccc|c|c} & & & & & 1 & & & & & & & \\ & & & & & & 1 & & & & & & \\ & & & & & & & 1 & & & & & \\ & & & & & & & & 1 & & & & \\ & & & & & & & & & 1 & & & \\ -2.5647 & -1.0797 & & & -1.0890 & & & & & & & 1.9637 & \\ -0.6038 & -0.8206 & -0.4766 & & & & & & & & & & \\ & -0.6009 & -1.5044 & -0.4808 & & & & & & & & & \\ & & -0.4300 & -1.1142 & -0.5131 & & & & & & & & \\ -0.6190 & & & -0.4626 & -0.8352 & & & & & & & 1.1161 & \\ \hline & & & & & 1 & & & & & & & \\ & & & & & & 1 & & & & & & \\ & & & & & & & 1 & & & & & \\ & & & & & & & & 1 & & & & \\ & & & & & & & & & 1 & & & \end{array}\right].$$

We are interested to bring the system from the equilibrium to a given state while

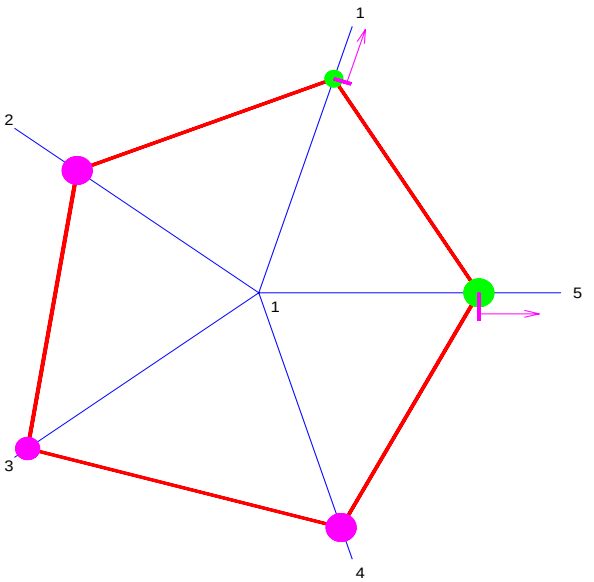


FIG. 4. 5 *masses linked by elastic springs*

TABLE 4
The nominal data.

Point	Mass	Distance to the origin at equilibrium	Spring	Rigidity
1	0.5093	0.8034	1 - 2	1.461
2	0.9107	0.7430	2 - 3	1.369
3	0.7224	0.9456	3 - 4	1.088
4	0.8077	0.8810	4 - 5	1.203
5	0.8960	0.7282	5 - 1	1.468

minimizing the cost functional

$$\int_0^\infty \left[\sum_{i=1}^{5}(\dot{x}_i)^2(t) + \sum_{i=1}^{2} u_i^2(t)\right] dt,$$

which is equivalent to the providing required supply problem with the supply matrix

$$\mathfrak{P} = \left[\begin{array}{c|c} Q = I_5 & L = 0_{5\times 2} \\ \hline L^T = 0_{2\times 5} & R = I_2 \end{array}\right].$$

In our experiment, we treat as uncertain parameters the masses of the points and the rigidities of the springs and assume that every one of these parameters can vary, independently of others, by at most ρ times the nominal value of the parameter. Note that the perturbations affect only the $[A, B]$-part of the matrix Σ of the system and that the dependence of Σ on the masses and rigidities is nonlinear (although both M and E in (58) are affine in the parameters). As in the previous example, we neglect this phenomenon by linearizing Σ at the nominal data, and end up with a box

uncertainty set with $L = 10$ basic perturbation matrices, according to the number of uncertain parameters; all these perturbation matrices turn out to be of rank 1. The outlined model underlies two numerical experiments we are about to report.

Designing robust feedback with "nearly optimal" performance. For the nominal system, there exists the ideal state feedback $u = \mathbf{F}z$ which moves the system from the equilibrium to (any) given initial state ζ at the minimum possible cost $\zeta^T \mathbf{Z}_{req}\zeta$. What we are interested in now is to find the largest uncertainty level for which there still exists an instance-independent state feedback with a given *performance index* $1+\delta$; the latter means that the feedback allows to move every instance of the perturbed system from the equilibrium to (any) given state ζ at the cost at most $(1+\delta)$ times the "ideal nominal cost" $\zeta^T \mathbf{Z}_{req}\zeta$. In our experiment, we set $\delta = 0.1$ and get the desired feedback by solving the conservative approximation (50) of Problem 3C associated with the outlined model. As a result, we get

(a) state feedback with the matrix

$$F = \begin{bmatrix} -0.0396 & 0.0220 & -0.3685 & -0.8069 & -0.4099 & 0.0152 & -0.3694 & 0.0647 & -0.0498 & 1.3167 \\ -0.3993 & -0.6453 & -0.4886 & -0.2269 & -0.0322 & 1.1859 & -0.5896 & -0.2165 & -0.3263 & 0.0268 \end{bmatrix},$$

which is slightly different from the ideal nominal feedback

$$\mathbf{F} = \begin{bmatrix} -0.0281 & 0.0289 & -0.4196 & -0.8948 & -0.4551 & 0.0063 & -0.3897 & 0.0628 & -0.0558 & 1.3826 \\ -0.4467 & -0.7133 & -0.5466 & -0.2423 & -0.0311 & 1.2269 & -0.6375 & -0.2570 & -0.3520 & 0.0111 \end{bmatrix},$$

and

(b) the "safe" uncertainty level $\widehat{\rho} = 0.0048$, which is a lower bound on the optimal value $\rho^\star_{3C}$ in Problem 3C.

What we know about F and $\widehat{\rho}$ from their origin is the following:

- The performance index of the state feedback $u = Fz$ is no worse than $1 + \delta$, provided that the level of perturbations does not exceed 0.48% (which is our $\widehat{\rho}$). Note that this statement remains true even for dynamical perturbations.
- The true optimal value $\rho^\star_{3C}$ in Problem 3C is at most $\frac{\pi}{2}$ times larger than $\widehat{\rho}$ (see Proposition 4.5; note that our basic perturbation matrices are of rank 1, so that the quantity μ in (52) equals 2 by item C of Section 4.6).

What we are interested in now is how conservative are our results, specifically, what is the actual value of the ratio $\rho^\star_{3C}/\widehat{\rho}$. An even more important question is as follows. The optimal value $\rho^\star_{3C}$ of Problem 3C is itself no more than a lower bound on the supremum $\rho^\star$ of those perturbation levels for which there still exists a state feedback with performance index $1 + \delta = 1.1$ (since what underlies Problem 3C is no more than a sufficient condition for good performance under uncertainty). How large is the ratio $\rho^\star/\widehat{\rho}$, or, in other words, how far is the robustness of our feedback F from the "ideal" robustness compatible with the prescribed performance index 1.1? It turns out that the answers to these questions are quite assuring. Indeed, looking at a large enough number of randomly perturbed instances with different perturbation levels and computing the required supply for these instances, one can find out that already at the perturbation level $1.2\widehat{\rho} = 0.0058$ there exist perturbed instances Σ and target states ζ such that Σ cannot be moved from the equilibrium to the state ζ at the cost $\leq 1.1\zeta^T \mathbf{Z}_{req}\zeta$. It follows that

$$\rho^\star_{3C} \leq \rho^\star < 1.2\widehat{\rho},$$

which is much better than we could expect.

Lyapunov stability analysis. Here we use the data yielded by the previous experiment for illustrating another application of the proposed approach, namely,

estimating the level of perturbations which keep the closed-loop system stable. This problem was the subject of Example 4 in section 3.1, where it was shown that the problem can be posed as the one of finding the supremum of those uncertainty levels for which all perturbed instances of the system share a common dissipativity certificate. As our sample closed-loop system, we used the outlined mechanical system equipped with the state feedback F found in the previous experiment. Our uncertainty model for the matrix

$$\widehat{A} = A + BF$$

of the closed-loop system is as follows: we use the aforementioned "physical" model of perturbations in $[A, B]$ and assume, in addition, that the entries in F also are subject to perturbations. Since we have no physical model of the controller, we assume that the entries F_{ij} in F can vary, independently of each other (and independently of the perturbations in $[A, B]$), in the intervals $[F^c_{ij} - \rho|F^c_{ij}|, F^c_{ij} + \rho|F^c_{ij}|]$, where ρ is the uncertainty level, and F^c_{ij} are the "nominal" values as computed in the previous experiment.

As in the previous cases, we linearized the dependence of $\widehat{A}$ on the perturbations, thus arriving at a box model of perturbations in the matrix of the closed-loop system. Then we solved the conservative approximation (31) of Problem 1 associated with system (14) and the supply matrix (15). Since we were interested solely in the stability of the closed-loop system under perturbations and did not care of any kind of performance, we looked for the common dissipativity certificate Z in a pretty wide "matrix interval" $\mathcal{I} = \{Z : 10^{-7}\mathbf{Z} \preceq Z \preceq \mathbf{Z}\}$, which in the situation of Example 4 basically means that we do not impose restrictions on Z except for being positive definite.

The results of our experiment are as follows. The solution of (31) yields a level of perturbations $\widehat{\rho} = 0.041$ and a positive definite matrix Z, which is a common Lyapunov stability certificate for all perturbed instances of the matrix $\widehat{A}$ of the closed-loop system when the level of perturbations is $\widehat{\rho}$. Thus, we can be sure that the closed-loop system remains stable whatever are 4.1% perturbations of the physical parameters of our mechanical system and 4.1% perturbations of the coefficient in the feedback matrix, even when these perturbations are dynamical. A natural question is, How conservative is this conclusion? Note that, a priori, there is no reason to be too optimistic in this respect, since the existence of a common Lyapunov stability certificate, as a sufficient condition for stability, may be quite conservative already by itself, and we are dealing with conservative approximation of this condition. However, the experiment demonstrates that we are lucky: simulating about 1,000 random perturbations of the closed-loop system at different uncertainty levels, it turns out that at the uncertainty level $1.6\widehat{\rho} = 0.065$ there already exist perturbations which make the closed-loop system unstable. Thus, the closed-loop system definitely survives perturbations not exceeding 4.1% and can be crushed by 6.5% perturbations.

6. Conclusions. We have developed techniques for specifying the magnitudes of dynamic perturbations in the parameters of a linear system which preserve a desired property of the system (such as positive-realness, nonexpansiveness, etc.). The standard sufficient condition for this is the solvability of an associated *infinite* system $\mathcal{S}$ of linear matrix inequalities. The latter condition, however, is usually NP-hard to verify, so that one is forced to look for *efficiently verifiable* sufficient conditions for $\mathcal{S}$ to be solvable. We propose such a condition and demonstrate that in many cases it is *provably tight, within an absolute constant factor*, $\frac{\pi}{2}$ in most cases (for details, see

Propositions 4.2, 4.3, 4.4, 4.5). This "guaranteed tightness" is a specific (and, to the best of our knowledge, unique) feature of the paper.

Recently, it turned out that the matrix cube theorem, which underlies all our developments, can be extended to the complex case and even with a model of uncertainty richer than the interval one. These extensions could then imply corresponding extensions of the results we have presented here.

MULTIDIMENSIONAL BACKWARD STOCHASTIC RICCATI EQUATIONS AND APPLICATIONS*

MICHAEL KOHLMANN† AND SHANJIAN TANG‡

Abstract. Backward stochastic Riccati differential equations (BSRDEs for short) arise from the solution of general linear quadratic optimal stochastic control problems with random coefficients. The existence and uniqueness question of the global adapted solutions has been open since Bismut's pioneering research publication in 1978 [*Séminaire de Probabilités* XII, Lecture Notes in Math. 649, C. Dellacherie, P. A. Meyer, and M. Weil, eds., Springer–Verlag, Berlin, 1978, pp. 180–264]. One distinguishing difficulty lies in the quadratic nonlinearity of the drift term in the second unknown component. In a previous article [*Stochastic Process. Appl.*, 97 (2002), pp. 255–288], the authors solved the one-dimensional case driven by Brownian motions. In this paper the multidimensional case driven by Brownian motions is studied. A closeness property for solutions of BSRDEs with respect to their coefficients is stated and is proved for general BSRDEs, which is used to obtain the existence of a global adapted solution to some BSRDEs. The global existence and uniqueness results are obtained for two classes of BSRDEs, whose generators contain a quadratic term of L (the second unknown component). More specifically, the two classes of BSRDEs are (for the regular case $N > 0$)

$$\begin{cases} dK = -[A^*K + KA + Q - LD(N + D^*KD)^{-1}D^*L]\,dt + L\,dw, \\ K(T) = M, \end{cases}$$

under the condition $d = 1$, and (for the singular case)

$$\begin{cases} dK = -[A^*K + KA + C^*KC + Q + C^*L + LC \\ \qquad -(KB + C^*KD + LD)(D^*KD)^{-1}(KB + C^*KD + LD)^*]\,dt + L\,dw, \\ K(T) = M, \end{cases}$$

under the condition $d = 1$ and $m = n$. The arguments given in this paper are completely new, and they consist of some simple techniques of algebraic matrix transformations and direct applications of the closeness property mentioned above. We make full use of the special structure (the nonnegativity of the quadratic term, for example) of the underlying Riccati equation. Applications in optimal stochastic control are exposed.

1. Introduction.

Let d and d_0 be two nonnegative integers with $d_0 \le d$. Let $(\Omega, \mathcal{F}, P, \{\mathcal{F}_t, 0 \le t \le T\})$ be a fixed complete probability space on which is defined a standard d-dimensional $\mathcal{F}_t$-adapted Brownian motion $w(t) \equiv (w_1(t), \dots, w_d(t))^*$. Assume that $\{\mathcal{F}_t, 0 \le t \le T\}$ is the completion, by the totality $\mathcal{N}$ of all null sets of $\mathcal{F}$, of the natural filtration $\{\mathcal{F}_t^w, 0 \le t \le T\}$ generated by w. Denote by $\{\mathcal{G}_t, 0 \le t \le T\}$ the P-augmented natural filtration generated by the $(d - d_0)$-dimensional Brownian motion $(w_{d_0+1}, \dots, w_d)$. Assume that all the coefficients A, B, C_i, and D_i

are $\{\mathcal{F}_t, , 0 \le t \le T\}$-progressively measurable bounded matrix-valued processes, defined on $\Omega \times [0,T]$, of dimensions $n \times n$, $n \times m$, $n \times n$, and $n \times m$, respectively, with $i = 1, \dots, d$. Also assume that M is an $\mathcal{F}_T$-measurable nonnegative bounded $n \times n$ random matrix, and Q and N are $\{\mathcal{F}_t, 0 \le t \le T\}$-progressively measurable, bounded, nonnegative, and uniformly positive $n \times n$ and $m \times m$ matrix processes, respectively.

Consider the following backward stochastic Riccati differential equation (BSRDE for short):

(1)
$$\begin{cases} dK = -\left[A^*K + KA + \sum_{i=1}^{d} C_i^* K C_i + Q + \sum_{i=1}^{d} (C_i^* L_i + L_i C_i)\right. \\ \qquad -\left(KB + \sum_{i=1}^{d} C_i^* K D_i + \sum_{i=1}^{d} L_i D_i\right)\left(N + \sum_{i=1}^{d} D_i^* K D_i\right)^{-1} \\ \qquad \left.\times \left(KB + \sum_{i=1}^{d} C_i^* K D_i + \sum_{i=1}^{d} L_i D_i\right)^*\right] dt + \sum_{i=1}^{d} L_i\, dw_i, \qquad 0 \le t < T, \\ K(T) = M. \end{cases}$$

It will be called the BSRDE $(A, B; C_i, D_i, i = 1, \dots, d; Q, N, M)$ in the following for convenience of indicating the concerned coefficients. When the coefficients A, B, C_i, D_i, Q, N, and M are all deterministic, then $L_1 = \cdots = L_d = 0$ and BSRDE (1) is reduced to the following nonlinear matrix ordinary differential equation:

(2)
$$\begin{cases} dK = -\left[A^*K + KA + \sum_{i=1}^{d} C_i^* K C_i + Q - \left(KB + \sum_{i=1}^{d} C_i^* K D_i\right)\right. \\ \qquad \left.\times \left(N + \sum_{i=1}^{d} D_i^* K D_i\right)^{-1} \left(KB + \sum_{i=1}^{d} C_i^* K D_i\right)^*\right] dt, \\ \qquad 0 \le t < T, \\ K(T) = M, \end{cases}$$

which was solved by Wonham [31] by applying Bellman's principle of quasi linearization and a monotone convergence approach. Bismut [2, 3] initially studied the case of random coefficients, but he could solve only some special simple cases. He always assumed that the randomness of the coefficients comes only from a smaller filtration $\{\mathcal{G}_t\}$, which leads to $L_1 = \cdots = L_{d_0} = 0$. He further assumed in his paper [2] that

$$C_{d_0+1} = \cdots = C_d = 0, \qquad D_{d_0+1} = \cdots = D_d = 0, \tag{3}$$

under which BSRDE (1) becomes the following one:

(4)
$$\begin{cases} dK = -\left[A^*K + KA + \sum_{i=1}^{d_0} C_i^* K C_i + Q\right. \\ \qquad -\left(KB + \sum_{i=1}^{d_0} C_i^* K D_i\right)\left(N + \sum_{i=1}^{d_0} D_i^* K D_i\right)^{-1} \left.\left(KB + \sum_{i=1}^{d_0} C_i^* K D_i\right)^*\right] dt \\ \qquad + \sum_{i=d_0+1}^{d} L_i\, dw_i, \qquad 0 \le t < T, \\ K(T) = M, \end{cases}$$

and the generator does not involve L at all. In his work [3] he assumed that

$$D_{d_0+1} = \cdots = D_d = 0, \tag{5}$$

under which BSRDE (1) becomes the following one:

(6)
$$\begin{cases} dK = -\left[A^*K + KA + \sum_{i=1}^{d} C_i^* K C_i + Q + \sum_{i=d_0+1}^{d} (C_i^* L_i + L_i C_i) \right. \\ \qquad - \left. \left(KB + \sum_{i=1}^{d_0} C_i^* K D_i\right)\left(N + \sum_{i=1}^{d_0} D_i^* K D_i\right)^{-1}\left(KB + \sum_{i=1}^{d_0} C_i^* K D_i\right)^*\right] dt \\ \qquad + \sum_{i=d_0+1}^{d} L_i\, dw_i, \qquad 0 \le t < T, \\ K(T) = M, \end{cases}$$

and the generator depends on the second unknown variable $(L_{d_0+1}, \ldots, L_d)^*$ only in a linear way. His method consists of constructing an appropriate contraction mapping. Later, Peng [20] gave a nice treatment on the proof of existence and uniqueness for BSRDE (6) by using Bellman's principle of quasi linearization and a method of monotone convergence—a generalization of Wonham's approach to the random situation.

As early as 1978, Bismut [3] commented on page 220, "Nous ne pourrons pas démontrer l'existence de solution pour l'équation (2.49) dans le cas général." In English, it reads, "We could not prove the existence of solution for equation (2.49) for the general case." On page 238, he further pointed out that the essential difficulty for solution of the general BSRDE (2.49) lies in the fact that the integrand of the martingale term appears in the generator in a quadratic way. Note that Bismut [3] referred to the more general case: the concerned system is allowed to have jumps and the associated BSRDE is driven by a Martingale with possible jumps. BSRDE (1) is only a particular case of BSRDE (2.49) in [3]. However, BSRDE (1) possesses the difficult nature described by Bismut [3].

Two decades later in 1998, Peng [21] included the existence and uniqueness question for BSRDE (1) in his list of open problems on backward stochastic differential equations (BSDEs for short), which will be called the Bismut–Peng problem hereafter to be distinguished from Bismut's original problem (the latter is more general). Subsequently, there appear related discussions concerning the problem, for which the reader is referred to Chen, Li, and Zhou [4] and Chen and Yong [5].

Recently, the authors [14] solved the one-dimensional case of the Bismut–Peng problem with an approximation approach.

In this paper, we are concerned with the multidimensional case. We prove the global existence and uniqueness result for BSRDE (1) for the following class of multidimensional case:

$$d = 1, \quad B = C = 0.$$

That is, we solve the following BSRDE:

$$\begin{cases} dK = -\left[A^*K + KA + Q - LD(N + D^*KD)^{-1}D^*L\right] dt + L\, dw, \\ \qquad\qquad 0 \le t < T, \\ K(T) = M. \end{cases} \tag{7}$$

This BSRDE is special but typical, for the generator contains a quadratic term of L. This result is stated as Theorem 2.3.

Consider then the case where the control weight matrix N reduces to zero. Kohlmann and Zhou [16] discussed such a case under the following three assumptions: (a) all the coefficients involved are deterministic; (b) $C_1 = \cdots = C_d = 0, D_1 = \cdots = D_d = I_{m\times m}$, and $M = I$; (c) $A + A^* \geq BB^*$. Their arguments are based on applying a result of Chen, Li, and Zhou [4]. The authors [13] considered a general framework along those of an analogue of Bismut [3] and Peng [20], which has the following features: (a) the coefficients A, B, C, D, N, Q, M are allowed to be random, but are only $\{\mathcal{G}_t, 0 \leq t \leq T\}$-progressively measurable processes or $\mathcal{G}_T$-measurable random variable; (b) the assumptions in [16] are dispensed with or generalized; (c) the condition (5) is assumed to be satisfied. In [13], we generalized Bismut's previous result on existence and uniqueness of a solution of BSRDE (6) to the singular case under the following additional two assumptions:

$$M \geq \varepsilon I_{n\times n},\ \sum_{i=1}^{d} D_i^* D_i(t) \geq \varepsilon I_{m\times m} \text{ for some deterministic constant } \varepsilon > 0. \tag{8}$$

Later, the authors [14] proved the existence and uniqueness result for the one-dimensional singular case $N = 0$ under the assumption (8), but for a more general framework: the coefficients A, B, C, D, N, Q, M are allowed to be $\{\mathcal{F}_t, 0 \leq t \leq T\}$-progressively measurable processes or an $\mathcal{F}_T$-measurable random variable, and all the coefficients D_i, $i = 1, \ldots, d$, may be nonzero matrices.

In this paper we also obtain the global existence and uniqueness for the following multidimensional singular case:

$$\begin{gathered} d = 1, \quad m = n, \quad N = 0, \quad D^*D \geq \varepsilon I_{m\times m}, \\ M \geq \varepsilon I_{n\times n} \text{ for some deterministic constant } \varepsilon > 0. \end{gathered}$$

That is, we solve the following BSRDE:

$$\begin{cases} dK = -\,[A^*K + KA + C^*KC + Q + C^*L + LC \\ \qquad\quad -\,(KB + C^*KD + LD)(D^*KD)^{-1}(KB + C^*KD + LD)^*]\,dt + L\,dw, \\ \qquad\quad 0 \leq t < T, \\ K(T) = M. \end{cases} \tag{9}$$

This result is stated as Theorem 2.2.

BSRDE (1) arises from the solution of the optimal control problem

$$\inf_{u\in\mathcal{L}^2_{\mathcal{F}}(0,T;R^m)} J(u; 0, x), \tag{10}$$

where, for $t \in [0, T]$ and $x \in R^n$,

$$\begin{aligned} &J(u; t, x) \\ &:= E^{\mathcal{F}_t}\left[\int_t^T [\langle Nu, u\rangle + \langle QX^{t,x;u}, X^{t,x;u}\rangle]\,ds + \langle MX^{t,x;u}(T), X^{t,x;u}(T)\rangle\right] \end{aligned} \tag{11}$$

and $X^{t,x;u}(\cdot)$ solves the following stochastic differential equation:

$$\begin{cases} dX = (AX + Bu)\,ds + \sum_{i=1}^{d}(C_iX + D_iu)\,dw_i, \qquad t \leq s \leq T, \\ X(t) = x. \end{cases} \tag{12}$$

The following heuristic connection is well known: if BSRDE (1) has a solution (K, L), the solution for the above linear quadratic optimal control problem (LQ problem for short) has the following closed form (also called the feedback form):

$$u(t) = -\left(N + \sum_{i=1}^{d} D_i^* K D_i\right)^{-1} \left[B^* K + \sum_{i=1}^{d} D_i^* K C_i + \sum_{i=1}^{d} D_i^* L_i\right] X(t), \tag{13}$$

and the associated value function V has the following quadratic form:

$$V(t,x) := \operatorname*{essinf}_{u \in \mathcal{L}^2_{\mathcal{F}}(t,T;R^m)} J(u;t,x) = \langle K(t)x, x\rangle, \qquad 0 \le t \le T, x \in R^n. \tag{14}$$

In this way, on the one hand, solution of the above LQ problem is reduced to solving BSRDE (1). On the other hand, formula (14) actually provides a representation—of Feynman–Kac type—for the solution of BSRDE (1). The reader will see that this kind of representation plays an important role in the proofs given here for Theorems 2.1, 2.2, and 2.3.

The arguments given in this paper are completely new. They result from two observations. The first one is that in the following simple case,

$$\begin{aligned} &A = B = C = 0, \quad d = 1, m = n, \\ &D \text{ is nonsingular, and } D \text{ and } N \text{ are constant matrices,} \end{aligned} \tag{15}$$

the difficult quadratic term of L can be removed by doing some simple algebraic transformation, and the resulting BSRDE is globally solvable in view of the result of Bismut [3] and Peng [20]. As a consequence, the above simple case is globally solved. However, this case is too restricted. Then comes the second observation: by using some other tricks and by applying Theorem 2.1, some more general cases can be solved. Specifically, the following restrictions,

$$A = 0, \ m = n, \text{ and } D \text{ is nonsingular,} \tag{16}$$

are all removed, and the restrictive condition that

$$D \text{ and } N \text{ are constant matrices} \tag{17}$$

is improved. For the singular case, we have only the two restrictions $d = 1$ and $n = m$ remaining. Theorem 2.1 provides a way to obtain the solvability of more general BSRDEs from that of simple ones. We hope that the Bismut–Peng problem will be completely solved in the near future by using the above-mentioned methodology.

It is worth noting that backward stochastic differential equations were originally formulated in a linear form by Bismut [1] and then well studied in a Lipschitz nonlinear form by Pardoux and Peng [19].

It might be helpful to the reader to give the following remarks.

Yong and Zhou [32] give a good account of the stochastic LQ theory for the case of deterministic coefficients, with emphasis on the indefinite feature of the quadratic cost functional. Several recent papers are also devoted to the stochastic LQ problem, among which we cite Chen and Zhou [8] and Chen and Yong [5, 6, 7] for the reader's convenience. The papers [8, 6, 7] are mainly devoted to the study of the associated BSRDEs (or simply of the deterministic Riccati differential equations). Their existence and uniqueness results on BSRDEs could not cover ours. All of their global existence and uniqueness results are concerned with the case of deterministic coefficients, which exclude the quadratic growth in L of BSRDE—the main interesting and

difficult feature of this paper. The local existence and uniqueness results in [6] require either the condition $D_1 = D_2 = \cdots = D_d \equiv 0$—which also excludes the quadratic growth in L of BSRDE—or an additional regularity of the coefficients (that is, the conditions on the Malliavin derivatives of the coefficients), which is unnecessary in this paper even for the global existence and uniqueness assertions. Moreover, our approach is different from theirs.

The results of this paper were briefly reviewed in [15], which was presented at the Workshop on Mathematical Finance, held in Konstanz, Germany, on October 5–7, 2000.

When this second version was prepared in January and February, 2002, one year had passed since the submission of the original manuscript, and the Bismut–Peng problem has been closed in [28] by the second author by developing a different approach. A presentation more general than [28], incorporating the singular case, is available in Tang [29], which was reported at the International Conference on Mathematical Finance, held on May 10–13, 2001, at Fudan University, Shanghai, China. However, a complete solution of the Bismut–Peng problem in the spirit of either this paper or the authors' previous paper [14] is still interesting.

The rest of the paper is organized as follows. Section 2 contains a list of notation, two preliminary propositions, and the statement of the main results, which consist of Theorems 2.1–2.3. The proofs of these three theorems are given in sections 3–5, respectively. Finally, in section 6, application of Theorems 2.2 and 2.3 is given to the regular and singular stochastic LQ problems, both with and without constraint.

2. Preliminaries and the main results. Throughout this paper, we make the following assumptions. Let d and d_0 be two nonnegative integers with $d_0 \leq d$. Let $(\Omega, \mathcal{F}, P, \{\mathcal{F}_t, 0 \leq t \leq T\})$ be a fixed complete probability space on which is defined a standard d-dimensional $\mathcal{F}_t$-adapted Brownian motion $w(t) \equiv (w_1(t), \ldots, w_d(t))^*$. Assume that $\{\mathcal{F}_t, 0 \leq t \leq T\}$ is the completion, by the totality $\mathcal{N}$ of all null sets of $\mathcal{F}$, of the natural filtration $\{\mathcal{F}_t^w, 0 \leq t \leq T\}$ generated by w. Denote by $\{\mathcal{G}_t, 0 \leq t \leq T\}$ the P-augmented natural filtration generated by the $(d - d_0)$-dimensional Brownian motion $(w_{d_0+1}, \ldots, w_d)$. Assume that all the coefficients A, B, C_i, and D_i are $\{\mathcal{F}_t, , 0 \leq t \leq T\}$-progressively measurable bounded matrix-valued processes, defined on $\Omega \times [0, T]$, of dimensions $n \times n$, $n \times m$, $n \times n$, and $n \times m$, respectively, with $i = 1, \ldots, d$. Also assume that M is an $\mathcal{F}_T$-measurable nonnegative bounded $n \times n$ random matrix, and Q and N are $\{\mathcal{F}_t, 0 \leq t \leq T\}$-progressively measurable, bounded, and nonnegative matrix processes of dimensions $n \times n$ and $m \times m$, respectively.

Notation. Throughout this paper, the following additional notation will be used:

M^*:	the transpose of any vector or matrix M;
$\lvert M\rvert$:	equals $\sqrt{\sum_{ij} m_{ij}^2}$ for any vector or matrix $M = (m_{ij})$;
$\langle M_1, M_2\rangle$:	the inner product of the two vectors M_1 and M_2;
R^n:	the n-dimensional Euclidean space;
R_+:	the set of all nonnegative real numbers;
$\mathcal{S}^n$:	the Euclidean space of all $n \times n$ symmetric matrices;
$\mathcal{S}_+^n$:	the set of all $n \times n$ nonnegative definite matrices;
$C([0, T]; H)$:	the Banach space of H-valued continuous functions on $[0, T]$, endowed with the maximum norm for a given Hilbert space H;
$\mathcal{L}_{\mathcal{F}}^2(0, T; H)$:	the Banach space of H-valued $\{\mathcal{F}_t, 0 \leq t \leq T\}$-adapted square -integrable stochastic processes f on $[0, T]$, endowed with the norm $(E\int_0^T \lvert f(t)\rvert^2\, dt)^{1/2}$ for a given Euclidean space H;

$\mathcal{L}^\infty_{\mathcal{F}}(0,T;H)$: the Banach space of H-valued, $\{\mathcal{F}_t, 0 \le t \le T\}$-adapted, essentially bounded stochastic processes f on $[0,T]$, endowed with the norm $\operatorname{ess\,sup}_{t,\omega} |f(t)|$ for a given Euclidean space H;

$L^2(\Omega,\mathcal{F},P;H)$: the Banach space of H-valued norm-square-integrable random variables on the probability space $(\Omega,\mathcal{F},P)$ for a given Banach space H;

and $L^\infty(\Omega,\mathcal{F},P;C([0,T];\mathcal{S}^n))$ is the Banach space of $C([0,T];\mathcal{S}^n)$-valued, essentially maximum-norm-bounded random variables f on the probability space $(\Omega,\mathcal{F},P)$, endowed with the norm $\operatorname{ess\,sup}_{\omega\in\Omega} \max_{0\le t\le T} |f(t,\omega)|$. The definitions of $\mathcal{L}^\infty_{\mathcal{F}}(0,T;\mathcal{S}^n_+)$ and $L^\infty(\Omega,\mathcal{F},P;C([0,T];\mathcal{S}^n_+))$ are obvious.

PROPOSITION 2.1. *Assume that the coefficients A, B, C_i, and D_i are $\{\mathcal{G}_t, 0 \le t \le T\}$-progressively measurable bounded matrix-valued processes, defined on $\Omega \times [0,T]$, of dimensions $n \times n$, $n \times m$, $n \times n$, $n \times m$, respectively, with $i = 1, \dots, d$. Assume that M is a $\mathcal{G}_T$-measurable, nonnegative, and bounded $n \times n$ random matrix. Assume that Q and N are $\mathcal{G}_t$-progressively measurable, bounded, nonnegative and uniformly positive, $n \times n$ and $m \times m$ matrix processes, respectively. Then, BSRDE* (6) *has a unique $\{\mathcal{G}_t, 0 \le t \le T\}$-adapted global solution (K, L) with*

$$K \in \mathcal{L}^\infty_{\mathcal{G}}(0,T;\mathcal{S}^n_+) \cap L^\infty(\Omega,\mathcal{G}_T,P;C([0,T];\mathcal{S}^n_+)), \qquad L \in \mathcal{L}^2_{\mathcal{G}}(0,T;\mathcal{S}^n).$$

Proposition 2.1 and its proof can be found in Bismut [3] and Peng [20].

For $t \in [0,T]$ and $x \in R^n$, the following stochastic differential equation,

$$\begin{cases} dX = (AX + Bu)\,ds + \displaystyle\sum_{i=1}^{d} (C_i X + D_i u)\,dw_i, & t \le s \le T, \\ X(t) = x \end{cases} \tag{18}$$

has a unique solution (see Gal'chuk [10]) denoted by $X^{t,x;u}(\cdot)$. Define

$$J(u;t,x) := E^{\mathcal{F}_t}\left[\int_t^T [\langle Nu, u\rangle + \langle QX^{t,x;u}, X^{t,x;u}\rangle]\,ds + \langle MX^{t,x;u}(T), X^{t,x;u}(T)\rangle\right]. \tag{19}$$

Consider the optimal control problem

$$\inf_{u\in\mathcal{L}^2_{\mathcal{F}}(0,T;R^m)} J(u;0,x). \tag{20}$$

PROPOSITION 2.2. *Let (K, L) be an $\{\mathcal{F}_t, 0 \le t \le T\}$-adapted solution of BSRDE* (1) *with*

$$K \in \mathcal{L}^\infty_{\mathcal{F}}(0,T;\mathcal{S}^n_+) \cap L^\infty(\Omega,\mathcal{F}_T,P;C([0,T];\mathcal{S}^n_+)), \qquad L \in \mathcal{L}^2_{\mathcal{F}}(0,T;\mathcal{S}^n),$$

and $N(t) + \sum_{i=1}^d D_i^* K D_i(t)$ being uniformly positive. Then, the value function $V(t,x)$ defined by

$$V(t,x) := \operatorname*{essinf}_{u\in\mathcal{L}^2_{\mathcal{F}}(t,T;R^m)} J(u;t,x) \qquad \forall (t,x) \in [0,T] \times R^n$$

has the following quadratic form:

$$V(t,x) = \langle K(t)x, x\rangle.$$

The detailed proof can be found in [13].

The main results of this paper consist of the following three theorems.

THEOREM 2.1. *We make the following six assumptions:*

(i) *For all* $\gamma \geq 0$, *the coefficients* $A^\gamma, B^\gamma, C_i^\gamma, D_i^\gamma, Q^\gamma$, *and* N^γ *are* $\{\mathcal{F}_t, 0 \leq t \leq T\}$-*progressively measurable matrix-valued processes, defined on* $\Omega \times [0,T]$, *of dimensions* $n \times n$, $n \times m$, $n \times n$, $n \times m$, $n \times n$, *and* $m \times m$, *respectively.*

(ii) M^γ *is an* $\mathcal{F}_T$-*measurable and nonnegative* $n \times n$ *random matrix.*

(iii) Q^γ *is a.s. a.e. nonnegative.*

(iv) *There are two deterministic positive constants* ε_1 *and* ε_2, *which are independent of the parameter* γ, *such that*

$$|A^\gamma(t)|, |B^\gamma(t)|, |C_i^\gamma(t)|, |D_i^\gamma(t)|, |Q^\gamma(t)|, |N^\gamma(t)|, |M^\gamma| \leq \varepsilon_1$$

and

$$N^\gamma \geq \varepsilon_2 I_{m\times m}.$$

(v) *As* $\gamma \to 0$, $A^\gamma(t), B^\gamma(t), C_i^\gamma(t), D_i^\gamma(t), Q^\gamma(t)$, *and* $N^\gamma(t)$ *converge uniformly in* (t,ω) *to* $A^0(t), B^0(t), C_i^0(t), D_i^0(t), Q^0(t)$, *and* $N^0(t)$, *respectively. Moreover,* M^γ *converges uniformly in* ω *to* M^0 *as* $\gamma \to 0$.

(vi) *For all* $\gamma > 0$ *the BSRDE* $(A^\gamma, B^\gamma; C_i^\gamma, D_i^\gamma, i = 1, \ldots, d; Q^\gamma, N^\gamma, M^\gamma)$ *has a unique* $\{\mathcal{F}_t, 0 \leq t \leq T\}$-*adapted global solution* (K^γ, L^γ) *with*

$$K^\gamma \in \mathcal{L}^\infty_{\mathcal{F}}(0,T;\mathcal{S}^n_+) \cap L^\infty(\Omega, \mathcal{F}_T, P; C([0,T];\mathcal{S}^n_+)), \qquad L^\gamma \in \mathcal{L}^2_{\mathcal{F}}(0,T;\mathcal{S}^n).$$

Then, there is a pair of processes (K,L) *with*

$$K \in \mathcal{L}^\infty_{\mathcal{F}}(0,T;\mathcal{S}^n_+) \cap L^\infty(\Omega, \mathcal{F}_T, P; C([0,T];\mathcal{S}^n_+)), \qquad L \in (\mathcal{L}^2_{\mathcal{F}}(0,T;\mathcal{S}^n))^d,$$

such that

$$\begin{aligned} &\lim_{\gamma\to 0} K^\gamma = K \quad \text{strongly in } \mathcal{L}^\infty_{\mathcal{F}}(0,T;\mathcal{S}^n_+) \cap L^\infty(\Omega, \mathcal{F}_T, P; C([0,T];\mathcal{S}^n_+)),\\ &\lim_{\gamma\to 0} L^\gamma = L \quad \text{strongly in } (\mathcal{L}^2_{\mathcal{F}}(0,T;\mathcal{S}^n))^d. \end{aligned} \tag{21}$$

Moreover, (K,L) *is a unique* $\{\mathcal{F}_t, 0 \leq t \leq T\}$-*adapted global solution of the BSRDE* $(A^0, B^0, C^0, D^0, Q^0, N^0, M^0)$.

If the above assumption of uniform convergence of $(A^\gamma, C^\gamma, Q^\gamma, M^\gamma)$ *is replaced with the following one:*

$$\lim_{\gamma\to 0} \operatorname*{esssup}_{\omega\in\Omega} \int_0^T (|A^\gamma - A^0| + |C^\gamma - C^0|^2 + |Q^\gamma - Q^0|)\, ds + |M^\gamma - M^0| \to 0, \tag{22}$$

then the above assertions still hold.

Remark 2.1. When the assumption of uniform positivity on the control weight matrix N is relaxed to nonnegativity, Theorem 2.1 still holds with the additional assumption that there is a deterministic positive constant ε_3, being independent of γ, such that

$$\sum_{i=1}^d (D_i^\gamma)^* D_i^\gamma \geq \varepsilon_3 I_{m\times m}, \quad M^\gamma \geq \varepsilon_3 I_{n\times n} \quad \forall \gamma > 0.$$

THEOREM 2.2 (the singular case). *Assume that $N \equiv 0$, $d = 1$, $n = m$, and $Q(t) \geq 0$. Also assume that there is a deterministic positive constant ε_3 such that*

$$M \geq \varepsilon_3 I_{n\times n} \tag{23}$$

and

$$D^*D \geq \varepsilon_3 I_{m\times m}. \tag{24}$$

Then, BSRDE (9) *has a unique $\{\mathcal{F}_t, 0 \leq t \leq T\}$-adapted global solution (K, L) with*

$$K \in \mathcal{L}^\infty_{\mathcal{F}}(0,T;\mathcal{S}^n_+) \cap L^\infty(\Omega,\mathcal{F}_T,P;C([0,T];\mathcal{S}^n_+)), \qquad L \in \mathcal{L}^2_{\mathcal{F}}(0,T;\mathcal{S}^n),$$

and $K(t,\omega)$ being uniformly positive with respect to (t,ω).

THEOREM 2.3 (the regular case). *Assume that $d = 1$, $M \geq 0$, $Q(t) \geq 0$, and $N(t) \geq \varepsilon_3 I_{m\times m}$ for some positive constant ε_3. Further assume that $B = C = 0$, and D and N satisfy the following:*

$$\begin{aligned} &\lim_{h\to 0+} \operatorname*{esssup}_{\omega\in\Omega} \max_{t_1,t_2\in[0,T];\,|t_1-t_2|\leq h} |D(t_1) - D(t_2)| = 0,\\ &\lim_{h\to 0+} \operatorname*{esssup}_{\omega\in\Omega} \max_{t_1,t_2\in[0,T];\,|t_1-t_2|\leq h} |N(t_1) - N(t_2)| = 0. \end{aligned} \tag{25}$$

Then, BSRDE (7) *has a unique $\{\mathcal{F}_t, 0 \leq t \leq T\}$-adapted global solution (K, L) with*

$$K \in \mathcal{L}^\infty_{\mathcal{F}}(0,T;\mathcal{S}^n_+) \cap L^\infty(\Omega,\mathcal{F}_T,P;C([0,T];\mathcal{S}^n_+)), \qquad L \in \mathcal{L}^2_{\mathcal{F}}(0,T;\mathcal{S}^n).$$

The proofs of the above three theorems are given in sections 3, 4, and 5, respectively.

3. The proof of Theorem 2.1. For all $(t, K, L) \in [0,T] \times \mathcal{S}^n_+ \times (\mathcal{S}^n)^d$, write

$$\begin{aligned} F^\gamma(t,K,L) := &-[KB^\gamma(t) + \sum_{i=1}^d C_i^\gamma(t)^* K D_i^\gamma(t) + \sum_{i=1}^d L_i D_i^\gamma(t)]\\ &\times [N^\gamma(t) + \sum_{i=1}^d D_i^\gamma(t)^* K D_i^\gamma(t)]^{-1}\\ &\times \left[KB^\gamma(t) + \sum_{i=1}^d C_i^\gamma(t)^* K D_i^\gamma(t) + \sum_{i=1}^d L_i D_i^\gamma(t)\right]^*. \end{aligned} \tag{26}$$

The generator of the BSRDE $(A^\gamma, B^\gamma; C_i^\gamma, D_i^\gamma, i = 1,\dots,d; Q^\gamma, N^\gamma, M^\gamma)$ is

$$\begin{aligned} G^\gamma(t,K,L) := &(A^\gamma)^*K + KA^\gamma + \sum_{i=1}^d (C_i^\gamma)^* K C_i^\gamma + Q^\gamma\\ &+ \sum_{i=1}^d ((C_i^\gamma)^* L_i + L_i C_i^\gamma) + F^\gamma(t,K,L). \end{aligned} \tag{27}$$

We have the following a priori estimates.

LEMMA 3.1. *Let the set of coefficients $(A^\gamma, B^\gamma; C_i^\gamma, D_i^\gamma, i = 1,\dots,d; Q^\gamma, N^\gamma, M^\gamma)$ satisfy the assumptions made in Theorem* 2.1. *Let (K^γ, L^γ) be a global $\{\mathcal{F}_t, 0 \leq t \leq T\}$-adapted solution to the BSRDE $(A^\gamma, B^\gamma; C_i^\gamma, D_i^\gamma, i = 1,\dots,d; Q^\gamma, N^\gamma, M^\gamma)$ with*

$$K^\gamma \in \mathcal{L}^\infty_{\mathcal{F}}(0,T;\mathcal{S}^n_+) \cap L^\infty(\Omega,\mathcal{F}_T,P;C([0,T];\mathcal{S}^n_+)) \quad \text{and} \quad L^\gamma \in (\mathcal{L}^2_{\mathcal{F}}(0,T;\mathcal{S}^n))^d.$$

Then, there is a deterministic positive constant ε_0, which is independent of γ, such that for all $\gamma > 0$, the following estimates hold:

$$0 \le K^\gamma(t) \le \varepsilon_0 I_{n\times n}, \quad E^{\mathcal{F}_t}\left(\int_t^T |L^\gamma|^2\,ds\right)^p \le \varepsilon_0 \quad \forall p \ge 1. \tag{28}$$

Proof of Lemma 3.1. Note that (K^γ, L^γ) satisfies the BSRDE:

$$\begin{cases} dK^\gamma = -\Big[(A^\gamma)^* K^\gamma + K^\gamma A^\gamma + \sum_{i=1}^d (C_i^\gamma)^* K^\gamma C_i^\gamma + Q^\gamma + \sum_{i=1}^d ((C_i^\gamma)^* L_i^\gamma + L_i^\gamma C_i^\gamma) \\ \qquad\qquad + F^\gamma(t, K^\gamma, L^\gamma)\Big]\,dt + \sum_{i=1}^d L_i^\gamma\,dw_i, \qquad 0 \le t < T, \\ K^\gamma(T) = M^\gamma. \end{cases} \tag{29}$$

Using Itô's formula, we get

$$\begin{cases} d|K^\gamma|^2 = -\Big[4\,\mathrm{tr}\,\big[(K^\gamma)^2 A^\gamma\big] + \sum_{i=1}^d 2\,\mathrm{tr}\,[K^\gamma (C_i^\gamma)^* K^\gamma C_i^\gamma] + 2\,\mathrm{tr}\,(K^\gamma Q^\gamma) \\ \qquad\qquad + \sum_{i=1}^d 4\,\mathrm{tr}\,(K^\gamma L_i^\gamma C_i^\gamma) + 2\,\mathrm{tr}\,[K^\gamma F^\gamma(t, K^\gamma, L^\gamma)] - |L^\gamma|^2\Big]\,dt \\ \qquad\qquad + \sum_{i=1}^d 2\,\mathrm{tr}\,(K^\gamma L_i^\gamma)\,dw_i, \qquad 0 \le t < T, \\ |K^\gamma|^2(T) = |M^\gamma|^2. \end{cases} \tag{30}$$

We observe that since

$$F^\gamma(t, K^\gamma, L^\gamma) \le 0, \qquad K^\gamma \ge 0,$$

we have

$$2\,\mathrm{tr}\,[K^\gamma F^\gamma(t, K^\gamma, L^\gamma)] = 2\,\mathrm{tr}\,\Big[(K^\gamma)^{\frac{1}{2}} F^\gamma(t, K^\gamma, L^\gamma)\,(K^\gamma)^{\frac{1}{2}}\Big] \le 0. \tag{31}$$

Hence,

$$\begin{aligned} |K^\gamma|^2(t) + \int_t^T |L^\gamma|^2\,ds \le |M^\gamma|^2 + \int_t^T \Big[4\,\mathrm{tr}\,\big[(K^\gamma)^2 A^\gamma\big] + \sum_{i=1}^d 2\,\mathrm{tr}\,[K^\gamma (C_i^\gamma)^* K^\gamma C_i^\gamma] \\ + 2\,\mathrm{tr}\,(K^\gamma Q^\gamma) + \sum_{i=1}^d 4\,\mathrm{tr}\,(K^\gamma L_i^\gamma C_i^\gamma)\Big]\,ds \\ - \int_t^T \sum_{i=1}^d 2\,\mathrm{tr}\,(K^\gamma L_i^\gamma)\,dw_i, \qquad 0 \le t < T. \end{aligned} \tag{32}$$

Using the elementary inequality

$$2ab \le a^2 + b^2$$

and taking the expectation on both sides with respect to $\mathcal{F}_r$ for $r \geq t$, we obtain that

(33)
$$E^{\mathcal{F}_r}|K^\gamma|^2(t) + \frac{1}{2}E^{\mathcal{F}_r}\int_t^T |L^\gamma|^2\,ds \leq \varepsilon_4 + \varepsilon_4 \int_t^T E^{\mathcal{F}_r}|K^\gamma|^2(s)\,ds, \qquad 0 \leq r \leq t < T.$$

Using Gronwall's inequality, we derive from the last inequality the first one of the estimates (28). In return, we derive from the second last inequality that

$$\int_t^T |L^\gamma|^2\,ds \leq \varepsilon_5 + \varepsilon_5 \int_0^T |L^\gamma|\,ds - \int_t^T \sum_{i=1}^d 2\,\mathrm{tr}\ (K^\gamma L_i^\gamma)\ dw_i. \tag{34}$$

Therefore,

$$\begin{aligned} &E^{\mathcal{F}_t}\left(\int_t^T |L^\gamma|^2\,ds\right)^p \\ &\leq 3^p\left[\varepsilon_5^p + \varepsilon_5^p E^{\mathcal{F}_t}\left(\int_t^T |L^\gamma|\,ds\right)^p + E^{\mathcal{F}_t}\left|\int_t^T \sum_{i=1}^d 2\mathrm{tr}(K^\gamma L_i^\gamma)\,dw_i\right|^p\right]. \end{aligned} \tag{35}$$

We have from the Burkhölder–Davis–Gundy inequality the following:

$$E^{\mathcal{F}_t}\left|\int_t^T \sum_{i=1}^d 2\,\mathrm{tr}\ (K^\gamma L_I^\gamma)\ dw_i\right|^p \leq 2^p E^{\mathcal{F}_t}\left|\int_t^T |K^\gamma|^2|L^\gamma|^2\,ds\right|^{p/2},$$

while from the Cauchy–Schwarz inequality, we have

$$E^{\mathcal{F}_t}\left(\int_t^T |L^\gamma|\,ds\right)^p \leq T^{p/2}E^{\mathcal{F}_t}\left(\int_t^T |L^\gamma|^2\,ds\right)^{p/2}.$$

Finally, we get

$$E^{\mathcal{F}_t}\left(\int_t^T |L^\gamma|^2\,ds\right)^p \leq 3^p\varepsilon_5^p + [3^pT^{p/2}\varepsilon_5^p + 6^p n^{p/2}\varepsilon_0^p]E^{\mathcal{F}_t}\left(\int_t^T |L^\gamma|^2\,ds\right)^{p/2}, \tag{36}$$

which implies the last estimate of the lemma.

Now, consider the optimal control problem,

$$\text{Problem } \mathcal{P}_\gamma\text{:} \qquad \inf_{u\in\mathcal{L}^2_{\mathcal{F}}(0,T;R^m)} J^\gamma(u;0,x), \tag{37}$$

where for $t \in [0,T]$ and $x \in R^n$,

(38)
$$J^\gamma(u;t,x) := E^{\mathcal{F}_t}\left\{\int_t^T [\langle N^\gamma u, u\rangle + \langle Q^\gamma X_\gamma^{t,x;u}, X_\gamma^{t,x;u}\rangle]\,ds + \langle M^\gamma X_\gamma^{t,x;u}(T), X_\gamma^{t,x;u}(T)\rangle\right\}$$

and $X_\gamma^{t,x;u}(\cdot)$ solves the following stochastic differential equation:

$$\begin{cases} dX = (A^\gamma X + B^\gamma u)\,ds + \sum_{i=1}^d (C_i^\gamma X + D_i^\gamma u)\,dw_i, & t \leq s \leq T, \\ X(t) = x. \end{cases} \tag{39}$$

The associated value function V^γ is defined as

$$V^\gamma(t,x) := \operatorname*{essinf}_{u\in\mathcal{L}^2_{\mathcal{F}}(t,T;R^m)} J^\gamma(u;t,x), \qquad (t,x)\in[0,T]\times R^n. \tag{40}$$

Then, from Proposition 2.2, we have

$$\langle K^\gamma(t)x,x\rangle = V^\gamma(t,x) \qquad \forall (t,x)\in[0,T]\times R^n.$$

From Lemma 3.1, we deduce

$$V^\gamma(t,x)\le \varepsilon_0|x|^2 \qquad \forall (t,x)\in[0,T]\times R^n.$$

So, the optimal control $\widehat{u}^\gamma$ for problem $\mathcal{P}_\gamma$ satisfies

$$\varepsilon_2 E^{\mathcal{F}_t}\int_t^T |\widehat{u}^\gamma|^2\,ds = E^{\mathcal{F}_t}\int_t^T \langle N^\gamma\widehat{u}^\gamma,\widehat{u}^\gamma\rangle\,ds \le \varepsilon_0|x|^2.$$

Set

$$\mathcal{U}^x_{ad}(t,T) := \left\{ u\in\mathcal{L}^2_{\mathcal{F}}(t,T;R^m) : \varepsilon_2 E^{\mathcal{F}_t}\int_t^T |u|^2\,ds \le \varepsilon_0|x|^2 \right\} \qquad \forall x\in R^n. \tag{41}$$

Then, we have

$$V^\gamma(t,x) := \operatorname*{essinf}_{u\in\mathcal{U}^x_{ad}(t,T)} J^\gamma(u;t,x). \tag{42}$$

Define

$$\begin{aligned} &K^{\gamma\tau} := K^\gamma - K^\tau, \quad L_i^{\gamma\tau} := L_i^\gamma - L_i^\tau, \quad X^{t,x;u}_{\gamma\tau} := X^{t,x;u}_\gamma - X^{t,x;u}_\tau,\\ &A^{\gamma\tau} := A^\gamma - A^\tau, \quad B^{\gamma\tau} := B^\gamma - B^\tau, \quad C_i^{\gamma\tau} := C_i^\gamma - C_i^\tau,\\ &D^{\gamma\tau} := D^\gamma - D^\tau, \quad Q^{\gamma\tau} := Q^\gamma - Q^\tau, \quad N^{\gamma\tau} := N^\gamma - N^\tau,\\ &M^{\gamma\tau} := M^\gamma - M^\tau. \end{aligned} \tag{43}$$

LEMMA 3.2. *Let the assumptions of Theorem* 2.1 *be satisfied. Then, there are three deterministic positive constants* ε_6, ε_7, *and* ε_8, *which are independent of the parameters* γ *and* τ, *such that the following three estimates hold:*

(i) *For each* $(t,x)\in[0,T]\times R^n$, *a.s.*

$$E^{\mathcal{F}_t}\max_{t\le s\le T}|X^{t,x;u}_\gamma(s)|^2 \le \varepsilon_6|x|^2 + \varepsilon_6 E^{\mathcal{F}_t}\int_t^T |u(s)|^2\,ds. \tag{44}$$

(ii) *For each* $(t,x)\in[0,T]\times R^n$, *a.s.*

$$\begin{aligned} E^{\mathcal{F}_t}\max_{t\le s\le T}|X^{t,x;u}_{\gamma\tau}(s)|^2 \le{}& \varepsilon_7 E^{\mathcal{F}_t}\int_t^T (|A^{\gamma\tau}|+|C^{\gamma\tau}|^2)|X^{t,x;u}_\gamma(s)|^2\,ds\\ &+ \varepsilon_7 E^{\mathcal{F}_t}\int_t^T (|B^{\gamma\tau}|+|D^{\gamma\tau}|^2)|u(s)|^2\,ds. \end{aligned} \tag{45}$$

(iii) *For each* $(t,x)\in[0,T]\times R^n$, *a.s.*

$$\begin{aligned} &|J^\gamma(u;t,x) - J^\tau(u;t,x)|\\ &\le \varepsilon_8 E^{\mathcal{F}_t}[|M^{\gamma\tau}||X^{t,x;u}_\gamma(T)|^2 + |X^{t,x;u}_{\gamma\tau}(T)|(|X^{t,x;u}_\gamma(T)| + |X^{t,x;u}_\tau(T)|)]\\ &\quad + \varepsilon_8 E^{\mathcal{F}_t}\int_t^T |X^{t,x;u}_{\gamma\tau}(s)|[|X^{t,x;u}_\gamma(s)| + |X^{t,x;u}_\tau(s)|]\,ds\\ &\quad + \varepsilon_8 E^{\mathcal{F}_t}\int_t^T |Q^{\gamma\tau}||X^{t,x;u}_\gamma(s)|^2\,ds + \varepsilon_8 E^{\mathcal{F}_t}\int_t^T |N^{\gamma\tau}||u(s)|^2\,ds. \end{aligned} \tag{46}$$

Proof of Lemma 3.2. Note that $X_{\gamma\tau}^{t,x;u}$ satisfies the following stochastic differential equation:

$$\begin{cases} dX_{\gamma\tau} = (A^\tau X_{\gamma\tau} + A^{\gamma\tau} X_\gamma + B^{\gamma\tau} u)\, ds + \sum_{i=1}^{d} (C_i^\tau X_{\gamma\tau} + C_i^{\gamma\tau} X_\gamma + D_i^{\gamma\tau} u)\, dw_i, \\ X_{\gamma\tau}(t) = 0. \end{cases}$$

So, in view of the assumptions of Theorem 2.1, the first two estimates are actually a consequence of the continuous dependence upon the parameters of the solution of a stochastic differential equation, and the proof is standard. The last estimate results from an immediate application of the mean-value formula for a differential function.

LEMMA 3.3. *Let the assumptions of Theorem* 2.1 *be satisfied. Then, we have the following three inequalities:*

(i) *For each* $(t,x) \in [0,T] \times R^n$, *for all* $u \in \mathcal{U}_{ad}^x(t,T)$,

$$E^{\mathcal{F}_t} \max_{t \le s \le T} |X_\gamma^{t,x;u}(s)|^2 \le \varepsilon_6 (1 + \varepsilon_2^{-1} \varepsilon_0) |x|^2. \tag{47}$$

(ii) *For each* $(t,x) \in [0,T] \times R^n$, *for all* $u \in \mathcal{U}_{ad}^x(t,T)$,

$$\begin{aligned} E^{\mathcal{F}_t} \max_{t \le s \le T} |X_{\gamma\tau}^{t,x;u}(s)|^2 \le{}& \varepsilon_7 \varepsilon_6 (1 + \varepsilon_2^{-1} \varepsilon_0) |x|^2 \operatorname*{esssup}_\omega \int_0^T (|A^{\gamma\tau}| + |C^{\gamma\tau}|^2)\, ds \\ &+ \varepsilon_7 \varepsilon_2^{-1} \varepsilon_0 |x|^2 \operatorname*{esssup}_{s,\omega} [|B^{\gamma\tau}(s)| + |D^{\gamma\tau}(s)|^2]. \end{aligned} \tag{48}$$

(iii) *For each* $(t,x) \in [0,T] \times R^n$, *for all* $u \in \mathcal{U}_{ad}^x(t,T)$,

$$\begin{aligned} &|J^\gamma(u;t,x) - J^\tau(u;t,x)| \\ &\le \varepsilon_8 \operatorname*{esssup}_\omega |M^{\gamma\tau}|\ E^{\mathcal{F}_t} |X_\gamma^{t,x;u}(T)|^2 \\ &\quad + \varepsilon_8 \left[E^{\mathcal{F}_t} |X_{\gamma\tau}^{t,x;u}(T)|^2\right]^{1/2} \left[E^{\mathcal{F}_t} (2|X_\gamma^{t,x;u}(T)|^2 + 2|X_\tau^{t,x;u}(T)|^2)\right]^{1/2} \\ &\quad + \varepsilon_8 T \left[E^{\mathcal{F}_t} \sup_{t \le s \le T} |X_{\gamma\tau}^{t,x;u}(s)|^2\right]^{1/2} \left[E^{\mathcal{F}_t} \sup_{t \le s \le T} [2|X_\gamma^{t,x;u}(s)|^2 + 2|X_\tau^{t,x;u}(s)|^2]\right]^{1/2} \\ &\quad + \varepsilon_8 \operatorname*{esssup}_\omega \int_0^T |Q^{\gamma\tau}|\, ds\ E^{\mathcal{F}_t} \sup_{t \le s \le T} |X_\gamma^{t,x;u}(s)|^2 + \varepsilon_8 \varepsilon_2^{-1} \varepsilon_0 |x|^2 \operatorname*{esssup}_{s,\omega} |N^{\gamma\tau}(s)|. \end{aligned} \tag{49}$$

Proof of Lemma 3.3. Since $u \in \mathcal{U}_{ad}^x(t,T)$, we have

$$E^{\mathcal{F}_t} \int_t^T |u|^2\, ds \le \varepsilon_2^{-1} \varepsilon_0 |x|^2. \tag{50}$$

Putting (50) into the first estimate of Lemma 3.2, we get the first inequality of Lemma 3.3. Putting (50) and the first inequality of Lemma 3.3 into the second estimate of Lemma 3.2, we get the second one. The last one is derived from (50) and applying the Cauchy–Schwarz inequality in the third estimate of Lemma 3.2.

Now we are in a position to prove Theorem 2.1.

Combining the first and the last inequalities of Lemma 3.3, we conclude that for each $(t,x)\in[0,T]\times R^n$, for all $u\in\mathcal{U}_{ad}^x(t,T)$,

$$
\begin{aligned}
&|J^\gamma(u;t,x)-J^\tau(u;t,x)|\\
&\le \varepsilon_8\varepsilon_6(1+\varepsilon_2^{-1}\varepsilon_0)|x|^2\operatorname*{esssup}_\omega|M^{\gamma\tau}|\\
&\quad+2|x|\varepsilon_8(T+1)\sqrt{\varepsilon_6(1+\varepsilon_2^{-1}\varepsilon_0)}\left[E^{\mathcal{F}_t}\sup_{t\le s\le T}|X_{\gamma\tau}^{t,x;u}(s)|^2\right]^{1/2}\\
&\quad+\varepsilon_8\varepsilon_6(1+\varepsilon_2^{-1}\varepsilon_0)|x|^2\operatorname*{esssup}_\omega\int_0^T|Q^{\gamma\tau}|\,ds+\varepsilon_8\varepsilon_2^{-1}\varepsilon_0|x|^2\operatorname*{esssup}_{s,\omega}|N^{\gamma\tau}(s)|.
\end{aligned}
\tag{51}
$$

Noting the second inequality of Lemma 3.3, we have

$$
\begin{aligned}
&|J^\gamma(u;t,x)-J^\tau(u;t,x)|\\
&\le \varepsilon_8\varepsilon_6(1+\varepsilon_2^{-1}\varepsilon_0)|x|^2\operatorname*{esssup}_\omega|M^{\gamma\tau}|+2|x|\varepsilon_8(T+1)\sqrt{\varepsilon_6(1+\varepsilon_2^{-1}\varepsilon_0)}\\
&\quad\times\left[\varepsilon_7\varepsilon_6(1+\varepsilon_2^{-1}\varepsilon_0)|x|^2\operatorname*{esssup}_\omega\int_0^T(|A^{\gamma\tau}|+|C^{\gamma\tau}|^2)\,ds\right.\\
&\quad\left.+\varepsilon_7\varepsilon_2^{-1}\varepsilon_0|x|^2\operatorname*{esssup}_{s,\omega}[|B^{\gamma\tau}(s)|+|D^{\gamma\tau}(s)|^2]\right]^{1/2}\\
&\quad+\varepsilon_8\varepsilon_6(1+\varepsilon_2^{-1}\varepsilon_0)|x|^2\operatorname*{esssup}_\omega\int_0^T|Q^{\gamma\tau}|\,ds+\varepsilon_8\varepsilon_2^{-1}\varepsilon_0|x|^2\operatorname*{esssup}_{s,\omega}|N^{\gamma\tau}(s)|
\end{aligned}
\tag{52}
$$

for each $(t,x)\in[0,T]\times R^n$, for all $u\in\mathcal{U}_{ad}^x(t,T)$. Therefore, we have

$$
\begin{aligned}
&|V^\gamma(t,x)-V^\tau(t,x)|\\
&\le \varepsilon_8\varepsilon_6(1+\varepsilon_2^{-1}\varepsilon_0)|x|^2\operatorname*{esssup}_\omega|M^{\gamma\tau}|+2|x|\varepsilon_8(T+1)\sqrt{\varepsilon_6(1+\varepsilon_2^{-1}\varepsilon_0)}\\
&\quad\times\left[\varepsilon_7\varepsilon_6(1+\varepsilon_2^{-1}\varepsilon_0)|x|^2\operatorname*{esssup}_\omega\int_0^T(|A^{\gamma\tau}|+|C^{\gamma\tau}|^2)\,ds\right.\\
&\quad\left.+\varepsilon_7\varepsilon_2^{-1}\varepsilon_0|x|^2\operatorname*{esssup}_{s,\omega}[|B^{\gamma\tau}(s)|+|D^{\gamma\tau}(s)|^2]\right]^{1/2}\\
&\quad+\varepsilon_8\varepsilon_6(1+\varepsilon_2^{-1}\varepsilon_0)|x|^2\operatorname*{esssup}_\omega\int_0^T|Q^{\gamma\tau}|\,ds+\varepsilon_8\varepsilon_2^{-1}\varepsilon_0|x|^2\operatorname*{esssup}_{s,\omega}|N^{\gamma\tau}(s)|
\end{aligned}
\tag{53}
$$

for each $(t,x)\in[0,T]\times R^n$.

In view of the assumptions of Theorem 2.1, (53) implies that for each $(t,x)\in[0,T]\times R^n$, $V^\gamma(t,x)$ converges to $V^0(t,x)$ as $\gamma\to0$. Moreover, this convergence is uniform in (t,ω). Hence, K^γ converges to some K^0 in the set

$$
\mathcal{L}_{\mathcal{F}}^\infty(0,T;\mathcal{S}_+^n)\cap L^\infty(\Omega,\mathcal{F}_T,P;C([0,T];\mathcal{S}_+^n)).
$$

In the following, we show the strong convergence of L^γ. Note that $(K^{\gamma\tau},L^{\gamma\tau})$ satisfies the BSDE

$$
\begin{cases}
dK^{\gamma\tau}(t)=-\left[G^\gamma(t,K^\gamma,L^\gamma)-G^\tau(t,K^\tau,L^\tau)\right]\,dt+\displaystyle\sum_{i=1}^d L_i^{\gamma\tau}\,dw_i,\\
K^{\gamma\tau}(T)=M^{\gamma\tau}.
\end{cases}
\tag{54}
$$

Using Itô's formula, we have

$$\begin{aligned} &E|K^{\gamma\tau}(t)|^2 + E\int_t^T |L^{\gamma\tau}(s)|^2\,ds \\ &= E|M^{\gamma\tau}|^2 + E\int_t^T \operatorname{tr}\,\{K^{\gamma\tau}[G^\gamma(s,K^\gamma,L^\gamma) - G^\tau(t,K^\tau,L^\tau)]\}\,ds. \end{aligned} \tag{55}$$

Since

$$|G^\gamma(s,K^\gamma,L^\gamma) - G^\tau(t,K^\tau,L^\tau)| \le \varepsilon(1+|L^\gamma|^2+|L^\tau|^2) \tag{56}$$

for some deterministic constant ε, which is independent of γ and τ, we have

$$E\int_t^T |L^{\gamma\tau}(s)|^2\,ds \le E|M^{\gamma\tau}|^2 + \varepsilon \operatorname*{esssup}_{s,\omega} |K^{\gamma\tau}(s)| E\int_t^T (1+|L^\gamma|^2+|L^\tau|^2)\,ds. \tag{57}$$

From the second a priori estimate of Lemma 3.1, we conclude that L^γ converges to some L^0 strongly in $\mathcal{L}^2_{\mathcal{F}}(0,T;\mathcal{S}^n)$. By passing to the limit in the BSRDE $(A^\gamma, B^\gamma; C_i^\gamma, D_i^\gamma, i=1,\dots,d; Q^\gamma, N^\gamma, M^\gamma)$, we show that (K^0,L^0) is an $\{\mathcal{F}_t, 0\le t\le T\}$-adapted global solution of the BSRDE $(A^0,B^0;C_i^0,D_i^0,i=1,\dots,d;Q^0,N^0,M^0)$.

4. The proof of Theorem 2.2. This section gives the proof of Theorem 2.2. The main idea is to do the matrix inverse transformation

$$\widetilde{K} := K^{-1}, \tag{58}$$

which turns out to satisfy a Riccati equation whose generator depends on the martingale term only in a linear way.

First, note that D has an inverse. We can rewrite the BSRDE (9) as

$$\begin{cases} dK = -[-\widetilde{A}^*K - K\widetilde{A} + Q - K\widetilde{B}K^{-1}\widetilde{B}^*K - LK^{-1}L \\ \qquad\quad + K\widetilde{B}K^{-1}L + LK^{-1}\widetilde{B}^*K]\,dt + L\,dw, \\ K(T) = M, \end{cases} \tag{59}$$

where

$$\widetilde{A} := -A + BD^{-1}C, \qquad \widetilde{B} := -BD^{-1}.$$

We have the following rules for the first-order and the second-order differentials of the inverse of a positive matrix as a matrix-valued function defined on the set of all $n\times n$ positive matrices:

$$\begin{aligned} d\left(K^{-1}\right) &= -K^{-1}(dK)K^{-1}, \\ d^2\left(K^{-1}\right) &= d\left(d\left(K^{-1}\right)\right) \\ &= -d\left(K^{-1}(dK)K^{-1}\right) \\ &= -d(K^{-1})(dK)K^{-1} - K^{-1}(dK)d(K^{-1}) \\ &= 2K^{-1}(dK)K^{-1}(dK)K^{-1}. \end{aligned} \tag{60}$$

Here, $d(K^{-1})$ is defined as the matrix whose (i,j)-component is the first-order differential of the (i,j)-component of K^{-1}, and $d^2(K^{-1})$ is defined as the matrix whose

(i,j)-component is the second-order differential of the (i,j)-component of K^{-1}. Using Itô's formula, we can write the equation for the inverse $\widetilde{K}$ of K:

$$\begin{cases} d\widetilde{K} = -[\widetilde{K}\widetilde{A}^* + \widetilde{A}\widetilde{K} - \widetilde{K}Q\widetilde{K} + \widetilde{B}\widetilde{K}\widetilde{B}^* + \widetilde{B}\widetilde{L} + \widetilde{L}\widetilde{B}^*]\,dt + \widetilde{L}\,dw, \\ \widetilde{K}(T) = M^{-1}, \end{cases} \tag{61}$$

where

$$\widetilde{L} := -K^{-1}LK^{-1}.$$

In what follows, we shall show how to construct an $\{\mathcal{F}_t, 0 \le t \le T\}$-adapted global solution for BSRDE (9), starting from the preceding BSRDE $(\widetilde{A}, Q^{1/2}; \widetilde{B}, 0; 0, I_{m\times m}, M^{-1})$, that is, BSRDE (61).

From Proposition 2.1, the above BSRDE $(\widetilde{A}, Q^{1/2}; \widetilde{B}, 0; 0, I_{m\times m}, M^{-1})$ has a unique $\{\mathcal{F}_t, 0 \le t \le T\}$-adapted global solution $(\widetilde{K}, \widetilde{L})$ with

$$\widetilde{K} \in \mathcal{L}^\infty_{\mathcal{F}}(0,T;\mathcal{S}^n_+) \cap L^\infty(\Omega, \mathcal{F}_T, P; C([0,T];\mathcal{S}^n_+)) \quad \text{and} \quad \widetilde{L} \in \mathcal{L}^2_{\mathcal{F}}(0,T;\mathcal{S}^n).$$

Proposition 2.1 does not assert that $\widetilde{K}$ is uniformly positive. However, from the fact that $\widetilde{K}(T) = M^{-1} \ge \varepsilon_1^{-1} I_{n\times n}$, we derive that $\widetilde{K}$ is uniformly positive. Define

$$K := \widetilde{K}^{-1} \quad \text{and} \quad L := -\widetilde{K}^{-1}\widetilde{L}\widetilde{K}^{-1}. \tag{62}$$

Then,

$$K \in \mathcal{L}^\infty_{\mathcal{F}}(0,T;\mathcal{S}^n_+) \cap L^\infty(\Omega, \mathcal{F}_T, P; C([0,T];\mathcal{S}^n_+)) \quad \text{and} \quad L \in \mathcal{L}^2_{\mathcal{F}}(0,T;\mathcal{S}^n). \tag{63}$$

Moreover, $K(t)$ is uniformly positive in (t,ω).

Again using Itô's formula, in view of BSRDE (61), we show that (K,L) is a global $\{\mathcal{F}_t, 0 \le t \le T\}$-adapted solution of BSRDE (9).

The uniqueness is derived from Proposition 2.2. In fact, assume that $(\widehat{K}, \widehat{L})$ is another global $\{\mathcal{F}_t, 0 \le t \le T\}$-adapted solution of BSRDE (9) with

$$\widehat{K} \in \mathcal{L}^\infty_{\mathcal{F}}(0,T;\mathcal{S}^n_+) \cap L^\infty(\Omega, \mathcal{F}_T, P; C([0,T];\mathcal{S}^n_+)) \quad \text{and} \quad \widehat{L} \in \mathcal{L}^2_{\mathcal{F}}(0,T;\mathcal{S}^n). \tag{64}$$

Then, from Proposition 2.2, we see that

$$\langle K(t)x, x\rangle = V(t,x) = \langle \widehat{K}(t)x, x\rangle, \quad \text{a.s.,} \quad \forall (t,x) \in [0,T] \times R^n.$$

Therefore we have $K(t) = \widehat{K}(t)$ almost surely for all $t \in [0,T]$. Set

$$\delta K := K - \widehat{K}, \quad \delta L_i := L_i - \widehat{L}_i, \quad \delta G := G(t,K,L) - G(t,\widehat{K},\widehat{L}).$$

On the one hand, we have $\delta K = 0$. On the other hand, the pair $(\delta K, \delta L)$ satisfies the following BSDE:

$$\begin{cases} d\delta K(t) = -\delta G\,dt + \displaystyle\sum_{i=1}^d \delta L_i(t)\,dw_i(t), \qquad 0 \le t < T, \\ \delta K(T) = 0. \end{cases} \tag{65}$$

Using Itô's formula, we have

$$E\int_t^T |\delta L(s)|^2\,ds \le E|\delta K(T)|^2 + \varepsilon \operatorname*{esssup}_{s,\omega} |\delta K(s)| E\int_t^T (1 + |L|^2 + |\widehat{L}|^2)\,ds = 0. \tag{66}$$

Here, ε is a positive constant. Hence, $\delta L = L - \widehat{L} = 0$.

The proof is complete.

5. The proof of Theorem 2.3. For the regular case, the situation is a little complex: we easily see that the above matrix inverse transformation on the first unknown matrix variable cannot eliminate the quadratic term of the second unknown variable. However, we can still solve some classes of BSRDEs through doing other appropriate matrix transformations.

PROPOSITION 5.1. *Assume that* $Q \geq A^*(D^{-1})^*ND^{-1} + (D^{-1})^*ND^{-1}A, \quad m = n$, *and* D *and* N *are nonsingular constant matrices. Then, Theorem* 2.3 *holds.*

Proof of Proposition 5.1. Write

$$\widehat{N} := (D^{-1})^*ND^{-1}. \tag{67}$$

Then BSRDE (7) is equivalent to the BSRDE $(A, 0; 0, I_{n\times n}; Q, \widehat{N}, M)$, i.e.,

$$\begin{cases} dK = -[A^*K + KA + Q - L(\widehat{N} + K)^{-1}L]\,dt + L\,dw, \\ \qquad\qquad 0 \leq t < T, \\ K(T) = M. \end{cases} \tag{68}$$

Define

$$\widehat{Q} := Q - A^*\widehat{N} - \widehat{N}A, \qquad \widehat{M} := \widehat{N} + M. \tag{69}$$

It is easy to see that $\widehat{Q}$ is nonnegative and $\widehat{M}$ is uniformly positive.

We also see that if (K, L) is a global $\{\mathcal{F}_t, 0 \leq t \leq T\}$-adapted solution of the BSRDE $(A, 0; 0, I_{n\times n}; Q, \widehat{N}, M)$ such that

$$K \in \mathcal{L}^\infty_{\mathcal{F}}(0, T; \mathcal{S}^n_+) \cap L^\infty(\Omega, \mathcal{F}_T, P; C([0, T]; \mathcal{S}^n_+)) \quad \text{and} \quad L \in \mathcal{L}^2_{\mathcal{F}}(0, T; \mathcal{S}^n), \tag{70}$$

then the pair $(\widehat{K}, \widehat{L})$, defined by $\widehat{K} := \widehat{N} + K$ and $\widehat{L} := L$, is a global $\{\mathcal{F}_t, 0 \leq t \leq T\}$-adapted solution of the BSRDE $(A, 0; 0, I_{n\times n}; \widehat{Q}, 0, \widehat{M})$, i.e.,

$$\begin{cases} d\widehat{K} = -[A^*\widehat{K} + \widehat{K}A + \widehat{Q} - \widehat{L}\widehat{K}^{-1}\widehat{L}]\,dt + \widehat{L}\,dw, \qquad 0 \leq t < T, \\ \widehat{K}(T) = \widehat{M}. \end{cases} \tag{71}$$

Moreover, $\widehat{K} \in \mathcal{L}^\infty_{\mathcal{F}}(0, T; \mathcal{S}^n_+) \cap L^\infty(\Omega, \mathcal{F}_T, P; C([0, T]; \mathcal{S}^n_+))$, $\widehat{L} \in \mathcal{L}^2_{\mathcal{F}}(0, T; \mathcal{S}^n)$, and $\widehat{K}$ is uniformly positive.

Inversely, if $(\widehat{K}, \widehat{L})$ is a global $\{\mathcal{F}_t, 0 \leq t \leq T\}$-adapted solution of BSRDE (71) such that $\widehat{K} \in \mathcal{L}^\infty_{\mathcal{F}}(0, T; \mathcal{S}^n_+) \cap L^\infty(\Omega, \mathcal{F}_T, P; C([0, T]; \mathcal{S}^n_+))$, $\widehat{L} \in \mathcal{L}^2_{\mathcal{F}}(0, T; \mathcal{S}^n)$, and $\widehat{K}$ is uniformly positive, then the pair (K, L), defined by $K := \widehat{K} - \widehat{N}$ and $L := \widehat{L}$, is a global $\{\mathcal{F}_t, 0 \leq t \leq T\}$-adapted solution of the BSRDE $(A, 0; 0, I_{n\times n}; Q, \widehat{N}, M)$, satisfying the following:

$$K \in \mathcal{L}^\infty_{\mathcal{F}}(0, T; \mathcal{S}^n) \cap L^\infty(\Omega, \mathcal{F}_T, P; C([0, T]; \mathcal{S}^n)) \quad \text{and} \quad L \in \mathcal{L}^2_{\mathcal{F}}(0, T; \mathcal{S}^n). \tag{72}$$

At the moment, it is not clear that K is nonnegative. However, it is clear that $\widehat{N} + K$ is uniformly positive. Making use of the nonnegativity of Q, M, and $\widehat{N}$, we can deduce that K is nonnegative. In fact, according to our previous paper [13], since $(\widehat{K}, \widehat{L})$ is a global $\{\mathcal{F}_t, 0 \leq t \leq T\}$-adapted solution of BSRDE (71) such that $\widehat{K} \in \mathcal{L}^\infty_{\mathcal{F}}(0, T; \mathcal{S}^n_+) \cap L^\infty(\Omega, \mathcal{F}_T, P; C([0, T]; \mathcal{S}^n_+))$, $\widehat{L} \in \mathcal{L}^2_{\mathcal{F}}(0, T; \mathcal{S}^n)$, and $\widehat{K}$ is uniformly positive, the following closed system (it is a homogeneous matrix-valued stochastic differential equation with possibly unbounded coefficients!),

$$\begin{cases} dU(s) = A(s)U(s)\,ds - [\widehat{K}(s)]^{-1}\widehat{L}(s)U(s)\,dw(s), \qquad s \in (t, T] \\ \qquad\quad = A(s)U(s)\,ds - [\widehat{N}(s) + K(s)]^{-1}L(s)U(s)\,dw(s), \qquad s \in (t, T], \\ U(t) = I_{n\times n}, \end{cases} \tag{73}$$

has a solution $\{U(s,t), t \le s \le T\}$ for each $t \in [0,T]$, satisfying the following:

$$E \max_{t \le s \le T} |U(s,t)|^2 < \infty, \qquad E \int_t^T |L(s)U(s,t)|^2 \, ds < \infty. \tag{74}$$

Therefore, we can use Itô's formula to derive from BSRDE (68) the representation

$$K(t) = U(t,t)^* K(t) U(t,t) = E^{\mathcal{F}_t} \Bigg\{ U(T,t)^* M U(T,t) + \int_t^T U(s,t)^* [Q + L(s)(\widehat{N}+K)^{-1} \widehat{N} (\widehat{N}+K)^{-1} L(s)] U(s,t) \, ds \Bigg\} \qquad \forall\, t \in [0,T]. \tag{75}$$

This formula implies that $K(t)$ is nonnegative for each $t \in [0,T]$.

While from Theorem 2.2, we see that BSRDE (71) has a unique global $\{\mathcal{F}_t, 0 \le t \le T\}$-adapted solution $(\widehat{K}, \widehat{L})$ such that $\widehat{K} \in \mathcal{L}^\infty_{\mathcal{F}}(0,T;\mathcal{S}^n_+) \cap L^\infty(\Omega, \mathcal{F}_T, P; C([0,T];\mathcal{S}^n_+))$, $\widehat{L} \in \mathcal{L}^2_{\mathcal{F}}(0,T;\mathcal{S}^n)$, and $\widehat{K}$ is uniformly positive. Therefore $(\widehat{K} - \widehat{N}, \widehat{L})$ is a global $\{\mathcal{F}_t, 0 \le t \le T\}$-adapted solution of BSRDE (7), satisfying the following:

$$\widehat{K} - \widehat{N} \in \mathcal{L}^\infty_{\mathcal{F}}(0,T;\mathcal{S}^n_+) \cap L^\infty(\Omega, \mathcal{F}_T, P; C([0,T];\mathcal{S}^n_+)) \quad \text{and} \quad \widehat{L} \in \mathcal{L}^2_{\mathcal{F}}(0,T;\mathcal{S}^n). \tag{76}$$

The proof is then complete.

PROPOSITION 5.2. *Assume that $A = 0$ and D and N are constant matrices. Then, Theorem* 2.3 *holds.*

Proof of Proposition 5.2. First assume $m = n$. Consider the following approximating BSRDEs:

$$\begin{cases} dK = -[Q - LD_\gamma (N + D_\gamma^* K D_\gamma)^{-1} D_\gamma^* L] \, dt + L \, dw, \\ K(T) = M, \end{cases} \tag{77}$$

where

$$D_\gamma := D + \gamma I_{m \times m}, \gamma > 0.$$

As γ is sufficiently small, D_γ is nonsingular. From Proposition 5.1, we see that BSRDE (77) has a unique global $\{\mathcal{F}_t, 0 \le t \le T\}$-adapted solution (K_γ, L_γ) for sufficiently small $\gamma > 0$, such that

$$K_\gamma \in \mathcal{L}^\infty_{\mathcal{F}}(0,T;\mathcal{S}^n_+) \cap L^\infty(\Omega, \mathcal{F}_T, P; C([0,T];\mathcal{S}^n_+)) \quad \text{and} \quad L_\gamma \in \mathcal{L}^2_{\mathcal{F}}(0,T;\mathcal{S}^n). \tag{78}$$

From Theorem 2.1, we see that as γ tends to zero, K_γ uniformly converges to some $K \in \mathcal{L}^\infty_{\mathcal{F}}(0,T;\mathcal{S}^n_+) \cap L^\infty(\Omega, \mathcal{F}_T, P; C([0,T];\mathcal{S}^n_+))$ and L_γ strongly converges to some $L \in \mathcal{L}^2_{\mathcal{F}}(0,T;\mathcal{S}^n)$, and that (K,L) is an $\{\mathcal{F}_t, 0 \le t \le T\}$-adapted solution of the BSRDE (7) with $A = 0$.

Consider the case $n > m$. Then consider the $n \times n$ matrices $\widetilde{D}$, whose first m columns are D and whose last $(n-m)$ columns are zero column vectors, and $\widetilde{N}$, which is defined as

$$\widetilde{N} := \begin{pmatrix} R & 0 \\ 0 & I \end{pmatrix}.$$

BSRDE (7) with $A = 0$ is rewritten as

$$\begin{cases} dK = -[Q - L\widetilde{D}(\widetilde{N} + \widetilde{D}^* K \widetilde{D})^{-1} \widetilde{D}^* L]\, dt + L\, dw, \\ K(T) = M. \end{cases}$$

From the preceding result, we obtain the desired existence result.

Consider the case $n < m$. Then, there is an $m \times m$ orthogonal transformation matrix T such that

$$D = [\widehat{D}, 0]T, \qquad \widehat{D} \in R^{n \times n} \text{ and is nonsingular.}$$

Write

$$\widetilde{N} := (T^{-1})^* N T^{-1} := \begin{pmatrix} \widehat{N}_{11} & \widehat{N}_{12} \\ \widehat{N}_{12}^* & \widehat{N}_{22} \end{pmatrix} > 0.$$

Then, $\widehat{N}_{11} > 0$. BSRDE (7), when $A = 0$, is rewritten as

$$\begin{cases} dK = -[Q - L\widehat{D}(\widetilde{N}_{11} + \widehat{D}^* K \widehat{D})^{-1} \widehat{D}^* L]\, dt + L\, dw, \\ K(T) = M. \end{cases}$$

From the preceding result, we obtain the desired existence result.

PROPOSITION 5.3. *Assume that $A = 0$ and D and N are piecewisely constant $\{\mathcal{F}_t, 0 \le t \le T\}$-adapted bounded matrix processes. Then, Theorem* 2.3 *holds.*

Proof of Proposition 5.3. Since D and N are piecewisely constant $\{\mathcal{F}_t, 0 \le t \le T\}$-adapted bounded matrix processes, there is a finite partition,

$$0 =: t_0 < t_1 < \cdots < t_J := T,$$

such that on each interval $[t_i, t_{i+1}] \subset [0, T]$, D and N are constant $\mathcal{F}_{t_i}$-measurable bounded random matrices. From Proposition 5.2, the BSRDE

$$\begin{cases} dK = -[Q - LD(N + D^* K D)^{-1} D^* L]\, dt + L\, dw, \\ \qquad\qquad t_{J-1} \le t < T, \\ K(T) = M \end{cases} \tag{79}$$

has a unique $\{\mathcal{F}_t, t_{J-1} \le t \le T\}$-adapted solution (K^J, L^J) with

$$K^J \in \mathcal{L}^\infty_{\mathcal{F}}(t_{J-1}, T; \mathcal{S}^n_+) \cap L^\infty(\Omega, \mathcal{F}_T, P; C([t_{J-1}, T]; \mathcal{S}^n_+)), \qquad L^J \in \mathcal{L}^2_{\mathcal{F}}(t_{J-1}, T; \mathcal{S}^n).$$

Assume that for some $i = 2, \ldots, J$, the BSRDE

$$\begin{cases} dK = -[Q - LD(N + D^* K D)^{-1} D^* L]\, dt + L\, dw, \\ \qquad\qquad t_{i-1} \le t < t_i, \\ K(t_i) = K^{i+1}(t_i) \end{cases} \tag{80}$$

has a unique $\{\mathcal{F}_t, t_{i-1} \le t \le t_i\}$-adapted solution (K^i, L^i) with

$$K^i \in \mathcal{L}^\infty_{\mathcal{F}}(t_{i-1}, t_i; \mathcal{S}^n_+) \cap L^\infty(\Omega, \mathcal{F}_{t_i}, P; C([t_{i-1}, t_i]; \mathcal{S}^n_+)), \qquad L^i \in \mathcal{L}^2_{\mathcal{F}}(t_{i-1}, t_i; \mathcal{S}^n).$$

Note that when $i = J$, we use the convention $K^{J+1}(t_J) := M$. Then, we conclude from Proposition 5.2 that the BSRDE

$$\begin{cases} dK = -[Q - LD(N + D^* K D)^{-1} D^* L]\, dt + L\, dw, \\ \qquad\qquad t_{i-2} \le t < t_{i-1}, \\ K(t_{i-1}) = K^i(t_{i-1}) \end{cases} \tag{81}$$

has a unique $\{\mathcal{F}_t, t_{i-2} \le t \le t_{i-1}\}$-adapted solution (K^{i-1}, L^{i-1}) with

$$K^{i-1} \in \mathcal{L}^{\infty}_{\mathcal{F}}(t_{i-2}, t_{i-1}; \mathcal{S}^n_+) \cap L^{\infty}(\Omega, \mathcal{F}_{t_{i-1}}, P; C([t_{i-2}, t_{i-1}]; \mathcal{S}^n_+)),$$
$$L^{i-1} \in \mathcal{L}^{2}_{\mathcal{F}}(t_{i-2}, t_{i-1}; \mathcal{S}^n).$$

In this backward inductive way, we may define J pairs of processes $\{(K^i, L^i)\}_{i=1}^J$. Define on the whole time interval $[0, T]$ the pair of $\{\mathcal{F}_t, 0 \le t \le T\}$-adapted processes (K, L) as follows:

$$K(t) := \sum_{i=1}^{J} K^i(t)\chi_{[t_{i-1}, t_i)}(t), \qquad L(t) := \sum_{i=1}^{J} L^i(t)\chi_{[t_{i-1}, t_i)}(t).$$

We see that (K, L) solves BSRDE (7). We then obtain the desired existence result.

PROPOSITION 5.4. *Assume that $A = 0$. Then, Theorem 2.3 holds.*

Proof of Proposition 5.4. For an arbitrary positive integer k, consider the 2^k-partition of the time interval. Define

$$D^k(t) = D\left(\frac{i-1}{2^k}T\right) \qquad \forall t \in \left[\frac{i-1}{2^k}T, \frac{i}{2^k}T\right),\ i = 1, 2, \ldots, 2^k,$$

and

$$N^k(t) = N\left(\frac{i-1}{2^k}T\right) \qquad \forall t \in \left[\frac{i-1}{2^k}T, \frac{i}{2^k}T\right),\ i = 1, 2, \ldots, 2^k.$$

For each k, D^k and N^k are piecewisely constant, $\{\mathcal{F}_t, 0 \le t \le T\}$-adapted, bounded matrix processes. Further, in view of (25), $D^k(t)$ and $N^k(t)$ converge respectively to D and N, uniformly in (t, ω). That is, we have

$$\lim_{k\to\infty} \operatorname*{esssup}_{\omega\in\Omega} \max_{t\in[0,T]} |D^k(t) - D(t)| = 0, \qquad \lim_{k\to\infty} \operatorname*{esssup}_{\omega\in\Omega} \max_{t\in[0,T]} |N^k(t) - N(t)| = 0.$$

From Proposition 5.3, we see that the BSRDE $(0, 0, 0, D^k; Q, N^k; M)$ has a global $\{\mathcal{F}_t, 0 \le t \le T\}$-adapted solution (K^k, L^k), and then from Theorem 2.1, we see that Theorem 2.3 holds.

Proof of Theorem 2.3. The case $A = 0$ is solved by Proposition 5.4. For the case $A \neq 0$, consider the following transformation:

$$\widetilde{K} := \Phi^* K \Phi, \qquad \widetilde{L} := \Phi^* L \Phi,$$

where Φ is the solution of the differential matrix equation

$$\begin{cases} \dfrac{d\Phi}{dt}(t) = A(t)\Phi(t), \quad t \in (0, T], \\ \Phi(0) = I_{n\times n}. \end{cases}$$

Using Itô's formula, we get the BSDE for $(\widetilde{K}, \widetilde{L})$:

$$\begin{cases} d\widetilde{K}(t) = -[\widetilde{Q} - \widetilde{L}\widetilde{D}(N + \widetilde{D}^*\widetilde{K}\widetilde{D})^{-1}\widetilde{D}\widetilde{L}]\,dt + \widetilde{L}\,dw(t), \qquad t \in (0, T], \\ \widetilde{K}(T) = \widetilde{M}, \end{cases}$$

where $\widetilde{Q} := \Phi^* Q \Phi$, $\widetilde{M} := \Phi(T)^* M \Phi(T)$, $\widetilde{D} := \Phi^{-1} D$. Note that the trajectories of $\widetilde{D}$ are still uniformly continuous like D. From Proposition 5.4, we see that the BSRDE $(0, 0, 0, \widetilde{D}; \widetilde{Q}, N, \widetilde{M})$ has a global adapted solution $(\widetilde{K}, \widetilde{L})$, and thus the pair

$$((\Phi^*)^{-1}\widetilde{K}\Phi^{-1}, (\Phi^*)^{-1}\widetilde{L}\Phi^{-1})$$

solves the original BSRDE $(A, 0, 0, D; Q, N, M)$.

The uniqueness can be proved in the same way as in the proof of Theorem 2.2.

6. Application to stochastic LQ problems.

6.1. The unconstrained stochastic LQ problem.

Assume that

$$\xi \in L^2(\Omega, \mathcal{F}_T, P; R^n), \qquad q, f, g_i \in \mathcal{L}^2_{\mathcal{F}}(0, T; R^n). \tag{82}$$

Consider the following optimal control problem (denoted by $\mathcal{P}_0$):

$$\min_{u \in \mathcal{L}^2_{\mathcal{F}}(0,T;R^m)} J(u; 0, x), \tag{83}$$

with

$$\begin{aligned} J(u; t, x) = {} & E^{\mathcal{F}_t} \langle M(X^{t,x;u}(T) - \xi), X^{t,x;u}(T) - \xi \rangle \\ & + E^{\mathcal{F}_t} \int_t^T [\langle Q(X^{t,x;u} - q), X^{t,x;u} - q \rangle + \langle Nu, u \rangle] \, ds \end{aligned} \tag{84}$$

and $X^{t,x;u}$ being the solution of the stochastic differential equation

$$\begin{cases} dX = (AX + Bu + f) \, ds + \sum_{i=1}^d (C_i X + D_i u + g_i) \, dw_i, & t < s \le T, \\ X(t) = x, \qquad u \in \mathcal{L}^2_{\mathcal{F}}(t, T; R^m). \end{cases} \tag{85}$$

The value function V is defined as

$$V(t, x) := \operatorname*{essinf}_{u \in \mathcal{L}^2_{\mathcal{F}}(t,T;R^m)} J(u; t, x), \qquad (t, x) \in [0, T] \times R^n. \tag{86}$$

Define $\Gamma : [0, T] \times \mathcal{S}^n_+ \times R^{n \times d} \to R^{m \times n}$ by

$$\Gamma(\cdot, S, L) = -\left(N + \sum_{i=1}^d D_i^* S D_i \right)^{-1} \left(B^* S + \sum_{i=1}^d D_i^* S C_i + \sum_{i=1}^d D_i^* L_i \right) \tag{87}$$

and

$$\widehat{A} := A + B\Gamma(\cdot, K, L), \quad \widehat{C}_i := C_i + D_i \Gamma(\cdot, K, L), \quad i = 1, \dots, d. \tag{88}$$

We have the following theorem.

THEOREM 6.1. *Suppose that the assumptions of Theorem* 2.2 *or Theorem* 2.3 *are satisfied. Let* (K, L) *be the unique* $\{\mathcal{F}_t, 0 \le t \le T\}$*-adapted solution of BSRDE* (1) *such that* $K \in \mathcal{L}^\infty_{\mathcal{F}}(0, T; \mathcal{S}^n_+) \cap L^\infty(\Omega, \mathcal{F}_T, P; C([0, T]; \mathcal{S}^n_+))$ *and* $L \in \mathcal{L}^2_{\mathcal{F}}(0, T; \mathcal{S}^n)$*. Let* (ψ, ϕ) *be the* $\{\mathcal{F}_t, 0 \le t \le T\}$*-adapted solution of the BSDE*

$$\begin{cases} d\psi(t) = -\left[\widehat{A}^* \psi + \sum_{i=1}^d \widehat{C}_i^* (\phi_i - K g_i) - K f - \sum_{i=1}^d L_i g_i + Q q \right] dt + \sum_{i=1}^d \phi_i \, dw_i, \\ \psi(T) = M\xi, \quad \phi := (\phi_1, \dots, \phi_d) \end{cases} \tag{89}$$

such that $(\psi, \phi) \in (\mathcal{L}^2_{\mathcal{F}}(0, T; R^n))^{(n+1)}$.

Then, the optimal control $\widehat{u}$ for the nonhomogeneous stochastic LQ problem $\mathcal{P}_0$ exists uniquely and has the following feedback law:

$$\begin{aligned}\widehat{u} = -\left(N+\sum_{i=1}^{d} D_i^* K D_i\right)^{-1}\Bigg[\left(B^*K+\sum_{i=1}^{d} D_i^* K C_i+\sum_{i=1}^{d} D_i^* L_i\right)\widehat{X}\\ -B^*\psi+\sum_{i=1}^{d} D_i^*(Kg_i-\phi_i)\Bigg].\end{aligned}\tag{90}$$

The value function $V(t,x),(t,x)\in[0,T]\times R^n$, has the following explicit formula:

$$V(t,x)=\langle K(t)x,x\rangle-2\langle\psi(t),x\rangle+V^0(t),\qquad (t,x)\in[0,T]\times R^n,\tag{91}$$

with

$$\begin{aligned}V^0(t) :=\ & E^{\mathcal{F}_t}\langle M\xi,\xi\rangle+E^{\mathcal{F}_t}\int_t^T\langle Qq,q\rangle\,ds-2E^{\mathcal{F}_t}\int_t^T\langle\psi,f\rangle\,ds\\ &+E^{\mathcal{F}_t}\int_t^T\sum_{i=1}^{d}[\langle Kg_i,g_i\rangle-2\langle\phi_i,g_i\rangle]\,ds\\ &-E^{\mathcal{F}_t}\int_t^T\left\langle\left(N+\sum_{i=1}^{d} D_i^* K D_i\right)u^0,u^0\right\rangle ds\end{aligned}\tag{92}$$

and

$$u^0:=\left(N+\sum_{i=1}^{d} D_i^* K D_i\right)^{-1}\left[B^*\psi+\sum_{i=1}^{d} D_i^*(\phi_i-Kg_i)\right],\qquad t\le s\le T.\tag{93}$$

The reader is referred to our previous paper [13] for a detailed proof.

6.2. The constrained stochastic LQ problem. Fix $x_T\in R^n$. Define

$$U_{\rm ad}(t,x):=\{u\in\mathcal{L}^2_{\mathcal{F}}(t,T;R^m):EX^{t,x;u}(T)=x_T\}\quad\forall(t,x)\in[0,T]\times R^n,\tag{94}$$

where $X^{t,x;u}$ is the solution of stochastic differential equation (85). Then, consider the following constrained LQ problem (denoted by $\mathcal{P}_c^{t,x}$):

$$\inf_{u\in U_{\rm ad}(0,x)} J(u;0,x),\tag{95}$$

where the cost functional $J(u;t,x)$ is defined by (84). Note that the set of admissible controls $U_{\rm ad}(t,x)$ contains the terminal expected constraint.

Let $\Psi(\cdot,t)$ be the unique solution of the stochastic differential equation:

$$\begin{cases}dY_s=A(s)Y_s\,ds+\sum_{i=1}^{d} C_i(s)Y_s\,dw_i(s),\qquad t\le s\le T,\\ Y_t=I_{n\times n}.\end{cases}\tag{96}$$

To guarantee that $U_{\rm ad}(t,x)$ is not empty, assume that the matrix

$$\Delta(t):=E\int_t^T E^{\mathcal{F}_s}\Psi(T,s)B(s)B^*(s)E^{\mathcal{F}_s}\Psi^*(T,s)\,ds\tag{97}$$

is nonsingular. Then, for all $x \in R^n$, the following control,

$$u(s) := B^*(s)E^{\mathcal{F}_s}\Psi^*(T,s)\Delta(t)^{-1}\left[x_T - E\int_t^T \Psi(T,s)f(s)\,ds\right], \qquad s \in (t,T], \tag{98}$$

belongs to $U_{\mathrm{ad}}(t,x)$.

We have the following existence result.

THEOREM 6.2. *Let the assumptions of Theorem* 2.2 *or Theorem* 2.3 *be satisfied. Assume that* $U_{\mathrm{ad}}(0,x)$ *is not empty. Then, the problem* $\mathcal{P}_c^{0,x}$ *has a unique optimal control.*

Proof of Theorem 6.2. The main idea is to choose a sequence $\{u^k; k = 1,2,\ldots\}$ such that

$$u^k \in U_{\mathrm{ad}}(0,x), \qquad \lim_{k\to\infty} J(u^k;0,x) = \inf_{u\in U_{\mathrm{ad}}(0,x)} J(u;0,x).$$

Define $X^k := x^{0,x;u^k}$. Note that $U_{\mathrm{ad}}(0,x)$ is close and convex. Therefore, $\frac{1}{2}(u^k+u^l) \in U_{\mathrm{ad}}(0,x)$. The LQ structure implies the following equality:

$$\begin{aligned} &2E\left\langle M\left(\frac{X^k(T)-X^l(T)}{2}\right), \frac{X^k(T)-X^l(T)}{2}\right\rangle \\ &+2E\int_0^T\left[\left\langle Q\left(\frac{X^k-X^l}{2}\right), \frac{X^k-X^l}{2}\right\rangle + \left\langle N\left(\frac{u^k-u^l}{2}\right), \frac{u^k-u^l}{2}\right\rangle\right] ds \\ &= J(u^k;0,x) + J(u^l;0,x) - 2J\left(\frac{u^k+u^l}{2};0,x\right). \end{aligned} \tag{99}$$

Then, we have for a positive constant ε,

$$E\int_0^T |u^k-u^l|^2\,ds \le \varepsilon\left[J(u^k;0,x) + J(u^l;0,x) - 2J\left(\frac{u^k+u^l}{2};0,x\right)\right], \tag{100}$$

which implies that $E\int_0^T |u^k-u^l|^2\,ds \to 0$ as $k,l\to\infty$. (100) is obvious for the regular case. For the singular case, we deduce it using the estimate

$$E\int_0^T |u^k-u^l|^2\,ds \le \varepsilon E|X^k(T)-X^l(T)|^2 \quad \text{for a positive constant } \varepsilon,$$

which is derived from [13, Lemma 2.2].

Hence the sequence $\{u^k, k = 1,2,\ldots\}$ is a Cauchy sequence, and it has a limit $u \in U_{\mathrm{ad}}(0,x)$. Then u is an optimal control.

It remains to show the uniqueness. Let u^1 and u^2 be both optimal. Then similar to that above, we have

$$E\int_0^T |u^1-u^2|^2\,ds \le \varepsilon\left[J(u^1;0,x) + J(u^2;0,x) - 2J\left(\frac{u^1+u^2}{2};0,x\right)\right] \le 0. \tag{101}$$

So, $u^1 = u^2$. The proof is complete.

Due to the limitation of space, we will, in what follows, just sketch how to solve the unique optimal control of Theorem 6.2 in terms of the solution of the associated BSRDE.

Using the stochastic maximum principle (see Peng [22], and Tang and Li [30], for example), we have the following. Let $\widetilde{u}$ be the optimal control, and $\widetilde{X} := X^{0,x;\widetilde{u}}$. Then, there is some $\lambda \in R^n$, and a pair of processes $(\widetilde{p}, \widetilde{q})$, such that

(102)
$$\begin{cases} d\widetilde{p} = -\left[A^*\widetilde{p} + Q(\widetilde{X} - q) + \sum_{i=1}^{d} C_i^*\widetilde{q}_i\right] ds + \sum_{i=1}^{d} \widetilde{q}_i\, dw_i, \qquad 0 < s \le T, \\ \widetilde{p}(T) = M(\widetilde{X}(T) - \xi) - \lambda \end{cases}$$

and

$$B^*\widetilde{p} + \sum_{i=1}^{d} D_i^*\widetilde{q}_i + N\widetilde{u} = 0. \tag{103}$$

Using Itô's formula and equality (103), we get the equation for $\widetilde{\psi} := K\widetilde{X} - \widetilde{p}$:

(104)
$$\begin{cases} d\widetilde{\psi}(t) = -\left[\widehat{A}^*\widetilde{\psi} + \sum_{i=1}^{d} \widehat{C}_i^*(\widetilde{\phi}_i - Kg_i) - Kf - \sum_{i=1}^{d} L_i g_i + Qq\right] dt + \sum_{i=1}^{d} \widetilde{\phi}_i\, dw_i, \\ \widetilde{\psi}(T) = M\xi + \lambda \end{cases}$$

where (K, L) is the unique $\{\mathcal{F}_t, 0 \le t \le T\}$-adapted solution of BSRDE (1), and the explicit formula of the optimal control,

$$\begin{aligned} \widetilde{u} = -\left(N + \sum_{i=1}^{d} D_i^* K D_i\right)^{-1} \Bigg[\left(B^*K + \sum_{i=1}^{d} D_i^* K C_i + \sum_{i=1}^{d} D_i^* L_i\right)\widehat{X} \\ -B^*\widetilde{\psi} + \sum_{i=1}^{d} D_i^*(Kg_i - \widetilde{\phi}_i)\Bigg], \end{aligned} \tag{105}$$

where the Lagrange multiple λ is determined such that the terminal constraint $E\widetilde{X}(T) = x_T$ is satisfied.

6.3. A comment on application of the LQ theory in mathematical finance. One-dimensional singular LQ problems arise from mathematical finance. The mean-variance hedging problem and the dynamic version of Markowitz's mean-variance portfolio selection problem are one-dimensional singular LQ problems.

The mean-variance hedging problem was extensively studied, among others, by Duffie and Richardson [9], Schweizer [25, 26, 27], Hipp [12], Monat and Stricker [18], Pham, Rheinländer, and Schweizer [23], Gourieroux, Laurent, and Pham [11], and Laurent and Pham [17]. Most of these works use a projection argument. Recently, Kohlmann and Zhou [16] used a natural LQ theory approach to solve the case of deterministic market conditions. Kohlmann and Tang [13, 14] used a natural LQ theory approach to solve the case of stochastic market conditions, and the optimal hedging portfolio and the variance-optimal martingale measure are characterized in terms of the solution of the associated BSRDE.

The study on continuous time mean-variance portfolio selection problem is dated back to Richardson [24]. The reader is referred to Zhou and Li [33] for recent developments on this problem.

Acknowledgment. The second author would like to thank the hospitality of Department of Mathematics and Statistics and the Center of Finance and Econometrics, Universität Konstanz, Germany.

ADAPTIVE LOW-GAIN INTEGRAL CONTROL OF MULTIVARIABLE WELL-POSED LINEAR SYSTEMS*

HARTMUT LOGEMANN† AND STUART TOWNLEY‡

To Ruth F. Curtain, on the occasion of her 60th birthday

Abstract. The principle of low-gain integral control for finite-dimensional systems is well known. More recently, low-gain integral control results have been obtained for classes of infinite-dimensional systems. In this paper we show that integral control with a simple and natural adaptation of the integrator gain achieves tracking of constant reference signals for every exponentially stable, multivariable, well-posed, infinite-dimensional, linear system whose steady-state gain matrix has its spectrum in the open right-half plane. Our results considerably extend, improve, and simplify previous work by the authors [*SIAM J. Control Optim.* 35 (1997), pp. 78–116].

Key words. adaptive control, adaptive tracking, integral control, well-posed infinite-dimensional systems

1. Introduction.

There has been much interest over the last twenty-five years in low-gain integral control. Indeed, the following principle has become well established (see Davison [2], Lunze [7], and Morari [10]): closing the loop around an asymptotically stable, finite-dimensional, continuous-time plant, with transfer-function matrix $\mathbf{G}(s)$, compensated by an integrator $(k/s)I$ (see Figure 1), will result in an asymptotically stable closed-loop system which achieves asymptotic tracking of arbitrary constant reference signals, provided that the gain parameter $k > 0$ is sufficiently small and the eigenvalues of the steady-state gain matrix $\mathbf{G}(0)$ have positive real parts, i.e.,

$$\text{spectrum}(\mathbf{G}(0)) \subset \{s \in \mathbb{C} \mid \operatorname{Re} s > 0\}. \tag{1.1}$$

This principle has been extended to various classes of infinite-dimensional systems; see Logemann and Townley [6] and the references therein. The generalization in [6] applies to so-called regular well-posed systems. We remark that the class of well-posed linear systems is the largest class of infinite-dimensional systems for which a well-developed state-space and frequency-domain theory exists; see Curtain and Weiss [3], Salamon [15], Staffans and Weiss [19], and Weiss [20], to mention just a few references. Well-posed systems are rather general in the sense that they capture most distributed parameter systems and all time-delay systems (retarded and neutral) which are of interest in applications. A well-posed system is called regular if the average of its step-response over $[0, t]$ converges as $t \to 0$ (equivalently, if its transfer functions $\mathbf{G}(s)$ converges as $s \to \infty$ on the positive real axis). Whilst the authors believe that any physically motivated well-posed linear system is regular, for a given well-posed system, regularity can be difficult to check.

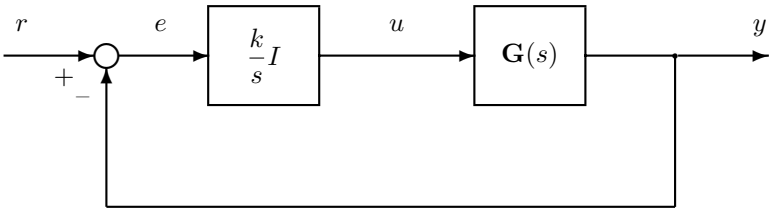

FIG. 1. *Low-gain control system.*

One of the main issues in the design of low-gain integral controllers is the tuning of the integrator gain k. There have been two basic approaches to the tuning problem—either steady-state data from the plant is used off-line to determine suitable ranges for the gain k (see, for example, [2], Logemann, Ryan, and Townley [5], or [7]) or else simple on-line adaptive tuning of k is used (see, for example, Miller and Davison [8, 9] in the finite-dimensional case and [6] in the infinite-dimensional case). Of particular relevance here is a result in [6] which shows that the adaptive integral controller

$$\dot{u}(t) = \gamma^{-p}(t)(r - y(t))\,, \qquad \dot{\gamma}(t) = \|r - y(t)\|^2 \tag{1.2}$$

achieves asymptotic tracking of arbitrary constant reference signals r, provided that the following three assumptions are satisfied:

(i) the plant is an exponentially stable, regular, well-posed, infinite-dimensional system;
(ii) the steady-state gain matrix $\mathbf{G}(0)$ is symmetric and positive definite;
(iii) the parameter p in (1.2) satisfies $p \in (0, 1/2)$.

We note that earlier work by Cook [1] shows that in the finite-dimensional single-input single-output case, assumption (iii) can be relaxed to $p \in (0, 1]$. Of course, the symmetry assumption in (ii) is restrictive and highly nonrobust, essentially limiting the applications of the above result to single-input single-output systems. The main result of this note (Theorem 3.1) shows that assumption (ii) can be replaced by the considerably weaker assumption (1.1), that the regularity assumption in (i) can be dropped, and that (iii) can replaced by $p \in (0, 1]$. Furthermore, in comparing the results we present here to those in [6], the proofs are dramatically simplified and more importantly give a clearer insight into the structure of the resulting closed-loop system. We emphasize that our main result is new even in the finite-dimensional case.

Notation. $\mathbb{R}_+ := [0, \infty)$; for $\alpha \in \mathbb{R}$, set $\mathbb{C}_\alpha := \{s \in \mathbb{C} \mid \operatorname{Re} s > \alpha\}$; let Z be a real or complex Banach space; for $\alpha \in \mathbb{R}$, we define the exponentially weighted L^p-space $L^p_\alpha(\mathbb{R}_+, Z) := \{f \in L^p_{\mathrm{loc}}(\mathbb{R}_+, Z) \mid f(\cdot)\exp(-\alpha\,\cdot) \in L^p(\mathbb{R}_+, Z)\}$ and endow it with the norm $\|f\|_{p,\alpha} := \|e^{-\alpha\,\cdot} f(\cdot)\|_{L^p}$; let $H^2(\mathbb{C}_\alpha, Z)$ denote the Hardy–Lebesgue space of square-integrable holomorphic functions defined on $\mathbb{C}_\alpha$ with values in Z; $H^\infty(\mathbb{C}_\alpha, Z)$ denotes the space of bounded holomorphic functions defined on $\mathbb{C}_\alpha$ with values in Z; $\mathcal{B}(Z_1, Z_2)$ denotes the space of bounded linear operators from a Banach space Z_1 to a Banach space Z_2; we write $\mathcal{B}(Z)$ for $\mathcal{B}(Z, Z)$; let $A : \operatorname{dom}(A) \subset Z \to Z$ be a linear operator, where $\operatorname{dom}(A)$ denotes the domain of A; the resolvent set of A and the spectrum of A is denoted by $\varrho(A)$and $\sigma(A)$, respectively; the Laplace transform is denoted by $\mathfrak{L}$.

2. Preliminaries on well-posed sytems. There are a number of equivalent definitions of well-posed systems; see [3, 14, 15, 16, 17, 18, 19, 20, 21]. We will be

brief in the following and refer the reader to the above references for more details. Throughout this section, we shall be considering a well-posed system Σ with state-space X, input space $\mathbb{R}^m$, and output space $\mathbb{R}^m$, generating operators (A, B, C), input-output operator G, and transfer function $\mathbf{G}$. Here X is a real Hilbert space with norm denoted by $\|\cdot\|$, A is the generator of a strongly continuous semigroup $\mathbf{T} = (\mathbf{T}_t)_{t\geq 0}$ on X, $B \in \mathcal{B}(\mathbb{R}^m, X_{-1})$, and $C \in \mathcal{B}(X_1, \mathbb{R}^m)$, where X_1 denotes the space $\mathrm{dom}(A)$ endowed with the norm $\|x\|_1 := \|x\| + \|Ax\|$ (the graph norm of A), whilst X_{-1} denotes the completion of X with respect to the norm $\|x\|_{-1} = \|(\lambda I - A)^{-1}x\|$, where $\lambda \in \varrho(A)$ (different choices of λ lead to equivalent norms). Clearly, $X_1 \subset X \subset X_{-1}$ and the canonical injections are bounded and dense. The semigroup $\mathbf{T}$ restricts to a strongly continuous semigroup on X_1 and extends to a strongly continuous semigroup on X_{-1} with the exponential growth constant being the same on all three spaces; the generator of the restriction (extension) of $\mathbf{T}$ is a restriction (extension) of A; we shall use the same symbol $\mathbf{T}$ (respectively, A) for the original semigroup (respectively, generator) and the associated restrictions and extensions: with this convention, we may write $A \in \mathcal{B}(X, X_{-1})$ (considered as a generator on X_{-1}, the domain of A is X). Moreover, the operator B is an *admissible control operator* for $\mathbf{T}$, i.e., for each $t \in \mathbb{R}_+$ there exists $\alpha_t \geq 0$ such that

$$\left\| \int_0^t \mathbf{T}_{t-\tau} B u(\tau) d\tau \right\| \leq \alpha_t \|u\|_{L^2([0,t],\mathbb{R}^m)} \quad \forall\, u \in L^2([0,t], \mathbb{R}^m)\,.$$

The operator C is an *admissible observation operator* for $\mathbf{T}$, i.e., for each $t \in \mathbb{R}_+$ there exists $\beta_t \geq 0$ such that

$$\left(\int_0^t \|C\mathbf{T}_\tau x\|^2 d\tau \right)^{1/2} \leq \beta_t \|x\| \quad \forall\, x \in X_1\,.$$

The control operator B is said to be *bounded* if it is so as a map from the input space $\mathbb{R}^m$ to the state-space X; otherwise, it is said to be *unbounded*; the observation operator C is said to be *bounded* if it can be extended continuously to X; otherwise, C is said to be *unbounded*.

The so-called Λ-*extension* C_Λ of C is defined by

$$C_\Lambda x = \lim_{s\to\infty,\, s\in\mathbb{R}} Cs(sI - A)^{-1}x\,,$$

with $\mathrm{dom}(C_\Lambda)$ consisting of all $x \in X$ for which the above limit exists. For every $x \in X$, $\mathbf{T}_t x \in \mathrm{dom}(C_\Lambda)$ for a.a. $t \in \mathbb{R}_+$, and, if $\omega > \omega(\mathbf{T})$, then $C_\Lambda \mathbf{T} x \in L^2_\omega(\mathbb{R}_+, \mathbb{R}^m)$, where

$$\omega(\mathbf{T}) := \lim_{t\to\infty} \frac{1}{t} \ln \|\mathbf{T}_t\|$$

denotes the exponential growth constant of $\mathbf{T}$. The transfer function $\mathbf{G}$ satisfies

$$\frac{1}{s-\lambda}\left(\mathbf{G}(s) - \mathbf{G}(\lambda)\right) = -C(sI - A)^{-1}(\lambda I - A)^{-1}B \quad \forall\, s, \lambda \in \mathbb{C}_{\omega(\mathbf{T})},\ s \neq \lambda\,, \tag{2.1}$$

and $\mathbf{G} \in H^\infty(\mathbb{C}_\omega, \mathbb{R}^{m\times m})$ for every $\omega > \omega(\mathbf{T})$. Moreover, the input-output operator $G : L^2_{\mathrm{loc}}(\mathbb{R}_+, \mathbb{R}^m) \to L^2_{\mathrm{loc}}(\mathbb{R}_+, \mathbb{R}^m)$ is continuous and shift-invariant; for every $\omega > \omega(\mathbf{T})$, $G \in \mathcal{B}(L^2_\omega(\mathbb{R}_+, \mathbb{R}^m))$ and

$$(\mathfrak{L}(Gu))(s) = \mathbf{G}(s)(\mathfrak{L}(u))(s) \quad \forall\, s \in \mathbb{C}_\omega,\ \forall\, u \in L^2_\omega(\mathbb{R}_+, \mathbb{R}^m)\,.$$

In the following, let $\lambda \in \mathbb{C}_{\omega(\mathbf{T})}$ be fixed but arbitrary. For $x^0 \in X$ and $u \in L^2_{\mathrm{loc}}(\mathbb{R}_+, \mathbb{R}^m)$, let x and y denote the state and output functions of Σ, respectively, corresponding to the initial condition $x(0) = x^0 \in X$ and the input function u. Then $x(t) = \mathbf{T}_t x^0 + \int_0^t \mathbf{T}_{t-\tau} B u(\tau) d\tau$ for all $t \in \mathbb{R}_+$, $x(t) - (\lambda I - A)^{-1} B u(t) \in \mathrm{dom}(C_\Lambda)$ for a.a. $t \in \mathbb{R}_+$,[1] and

$$\dot{x}(t) = Ax(t) + Bu(t)\,, \quad x(0) = x^0\,, \quad \text{for a.a. } t \in \mathbb{R}_+\,, \tag{2.2a}$$

$$y(t) = C_\Lambda \big(x(t) - (\lambda I - A)^{-1} B u(t)\big) + \mathbf{G}(\lambda) u(t)\,, \quad \text{for a.a. } t \geq 0\,. \tag{2.2b}$$

Of course, the differential equation (2.2a) has to be interpreted in X_{-1}. Note that the output equation (2.2b) yields the following formula for the input-output operator G:

$$(Gu)(t) = C_\Lambda \left[\int_0^t \mathbf{T}_{t-\tau} B u(\tau) d\tau \; - (\lambda I - A)^{-1} B u(t) \right] + \mathbf{G}(\lambda) u(t) \tag{2.3}$$
$$\forall\, u \in L^2_{\mathrm{loc}}(\mathbb{R}_+, \mathbb{R}^m), \text{ for a.a. } t \in \mathbb{R}_+.$$

In the following, we identify Σ and (2.2) and refer to (2.2) as a well-posed system. We say that the well-posed system (2.2) is *exponentially stable* if $\omega(\mathbf{T}) < 0$. If the well-posed system (2.2) is *regular*, i.e., the following limit

$$\lim_{s \to \infty,\, s \in \mathbb{R}} \mathbf{G}(s) = D$$

exists, then $x(t) \in \mathrm{dom}(C_\Lambda)$ for a.a. $t \in \mathbb{R}_+$, the output equation (2.2b) simplifies to

$$y(t) = C_\Lambda x(t) + Du(t)\,, \quad \text{for a.a. } t \geq 0,$$

and

$$(Gu)(t) = C_\Lambda \int_0^t \mathbf{T}_{t-\tau} B u(\tau) d\tau + Du(t) \quad \forall\, u \in L^2_{\mathrm{loc}}(\mathbb{R}_+, \mathbb{R}^m)\,, \text{ for a.a. } t \in \mathbb{R}_+\,.$$

Moreover, in the regular case, we have that $(sI - A)^{-1} B \mathbb{R}^m \subset \mathrm{dom}(C_\Lambda)$ for all $s \in \varrho(A)$ and

$$\mathbf{G}(s) = C_\Lambda (sI - A)^{-1} B + D \quad \forall\, s \in \mathbb{C}_{\omega(\mathbf{T})}\,.$$

The matrix $D \in \mathbb{R}^{m \times m}$ is called the *feedthrough matrix* of (2.2). We mention that if the control operator B or the observation operator C is bounded, then (2.2) is regular.

3. Main result. We consider adaptive low-gain integral control of an exponentially stable well-posed system of the form (2.2). By exponential stability, we may assume w.l.o.g. that $\lambda = 0$ in (2.2b), and hence the plant equations are given by

$$\dot{x} = Ax + Bu\,, \quad x(0) = x^0 \in X\,, \tag{3.1a}$$

$$y = C_\Lambda (x + A^{-1} B u) + \mathbf{G}(0) u\,. \tag{3.1b}$$

Let $r \in \mathbb{R}^m$ be a given reference vector and consider the following simple adaptive low-gain integral controller:

$$\dot{u} = \gamma^{-p} (r - y)\,, \quad u(0) = u^0 \in \mathbb{R}^m\,, \tag{3.2a}$$

$$\dot{\gamma} = \|r - y\|^2\,, \quad \gamma(0) = \gamma^0 > 0\,, \tag{3.2b}$$

[1] It was stated in [21] (without proof) that, for arbitrary $u \in L^2_{\mathrm{loc}}(\mathbb{R}_+, \mathbb{R}^m)$, $x(t) - (\lambda I - A)^{-1} B u(t) \in \mathrm{dom}(C_\Lambda)$ for a.a. $t \in \mathbb{R}_+$ and the output formula (2.2b) holds. The proof can be found in [19].

where $0 < p \leq 1$. The closed-loop system is then given by

$$\dot{x} = Ax + Bu\,, \quad x(0) = x^0 \in X\,, \tag{3.3a}$$

$$\dot{u} = \gamma^{-p}\left(r - C_\Lambda(x + A^{-1}Bu) - \mathbf{G}(0)u\right)\,, \quad u(0) = u^0 \in \mathbb{R}^m\,, \tag{3.3b}$$

$$\dot{\gamma} = \|r - C_\Lambda(x + A^{-1}Bu) - \mathbf{G}(0)u\|^2\,, \quad \gamma(0) = \gamma^0 > 0\,. \tag{3.3c}$$

Let $T > 0$. A continuous function $(x, u, \gamma) : [0, T) \to X \times \mathbb{R}^m \times \mathbb{R}$ is called a *solution* of (3.3) if $(x(0), u(0), \gamma(0)) = (x^0, u^0, \gamma^0)$, (x, u, γ) is absolutely continuous on $[0, t]$ as a $(X_{-1} \times \mathbb{R}^m \times \mathbb{R})$-valued function for every $t \in (0, T)$ and the differential equations in (3.3) are satisfied almost everywhere on $[0, T)$.

Our main result, Theorem 3.1, shows that the controller (3.2) achieves tracking of constant reference signals for all exponentially stable well-posed systems (3.1) whose steady-state gain matrix $\mathbf{G}(0)$ satisfies $\sigma(\mathbf{G}(0)) \subset \mathbb{C}_0$.

THEOREM 3.1. *Assume that the well-posed system* (3.1) *is exponentially stable with* $\sigma(\mathbf{G}(0)) \subset \mathbb{C}_0$ *and that* $0 < p \leq 1$ *in* (3.2). *Let* $r \in \mathbb{R}^m$ *be given and define* $u^r := [\mathbf{G}(0)]^{-1}r$. *Then, for all* $(x^0, u^0, \gamma^0) \in X \times \mathbb{R}^m \times (0, \infty)$, *there exists a unique solution* $(x, u, \gamma) : \mathbb{R}_+ \to X \times \mathbb{R}^m \times (0, \infty)$ *of the closed-loop system* (3.3) *and the following statements hold:*

(1) $\lim_{t\to\infty} \gamma(t) = \gamma^\infty < \infty$ *;*
(2) $u - u^r \in L^2(\mathbb{R}_+, \mathbb{R}^m)$ *and* $\lim_{t\to\infty} u(t) = u^r$ *;*
(3) $x + A^{-1}Bu^r \in L^2(\mathbb{R}_+, X)$ *and* $\lim_{t\to\infty} \|x(t) + A^{-1}Bu^r\| = 0$ *;*
(4) $e := r - y \in L^2(\mathbb{R}_+, \mathbb{R}^m)$ *and* e *admits a decomposition of the form* $e = e_1 + e_2$, *where* $e_1 \in C(\mathbb{R}_+, \mathbb{R}^m)$, $e_2 \in L^2_\omega(\mathbb{R}_+, \mathbb{R}^m)$ *for every* $\omega > \omega(\mathbf{T})$, *and* $\lim_{t\to\infty} e_1(t) = 0$ *; moreover, if there exists* $t_0 \geq 0$ *such that* $\mathbf{T}_{t_0}(Ax^0 + Bu^0) \in X$, *then* $e \in C([t_0, \infty), \mathbb{R}^m)$ *and* $\lim_{t\to\infty} e(t) = 0$.

Proof. As in [6] it can be proved that there exists a unique maximally defined solution $(x, u, \gamma) : [0, T) \to X \times \mathbb{R}^m \times (0, \infty)$ to the closed-loop system (3.3), where $T = \infty$ if γ is bounded on $[0, T)$. To analyze the stability of the closed-loop system (3.3), we use a change of coordinates. Define

$$z(t) := x(t) + A^{-1}Bu(t)\,, \qquad v(t) := u(t) - u^r\,; \tag{3.4}$$

it follows from (3.1) and (3.2) that

$$\dot{z}(t) = Az(t) + \gamma^{-p}(t)A^{-1}Be(t)\,, \quad \text{for a.a. } t \in [0, T)\,, \tag{3.5a}$$

$$\dot{v}(t) = \gamma^{-p}(t)e(t)\,, \quad \text{for a.a. } t \in [0, T)\,, \tag{3.5b}$$

where

$$e(t) := r - y(t) = -\left(C_\Lambda z(t) + \mathbf{G}(0)v(t)\right)\,, \quad \text{for a.a. } t \in [0, T)\,. \tag{3.6}$$

Of course, the derivative on the left-hand side of (3.5a) has to be interpreted in X_{-1}. There are two advantages to viewing the closed-loop system in the coordinates (3.4): the unbounded B in (3.1a) is replaced by a bounded $A^{-1}B$ and it turns out that the stability of $-\mathbf{G}(0)$ is easier to exploit in the (z, v)-coordinates than in the (x, u)-coordinates.

To proceed, we use the stability of $-\mathbf{G}(0)$ to obtain the existence of $Q = Q^T \in \mathbb{R}^{m\times m}$ with $Q > 0$ such that

$$Q\mathbf{G}(0) + \mathbf{G}(0)^T Q = I. \tag{3.7}$$

Furthermore, using the exponential stability of $\mathbf{T}$ and the admissibility of C, a standard argument (see the appendix) shows that there exists $P = P^* \in \mathcal{B}(X)$ with $P \geq 0$ and such that

$$\langle Ax_1, Px_2\rangle + \langle Px_1, Ax_2\rangle = -\langle x_1, x_2\rangle - \langle Cx_1, Cx_2\rangle \quad \forall\, x_1, x_2 \in X_1\,. \tag{3.8}$$

Our aim is to show that γ is bounded on $[0,T)$, from which we will deduce that $T = \infty$ and that statements (1)–(4) hold. To this end, define a function $V : [0,T) \to \mathbb{R}_+$ by

$$V(t) = \langle z(t), Pz(t)\rangle + \langle v(t), Qv(t)\rangle \quad \forall\, t \in [0,T)\,,$$

where the first inner product is taken in X and the second inner product is the standard inner product in $\mathbb{R}^m$. Since, due to lack of regularity of z as a X-valued function, V is in general not differentiable, we adopt an approximation argument. Define

$$z_n(t) := \mathbf{T}_t z_n^0 + A^{-1}\int_0^t \mathbf{T}_{t-\tau} B\gamma^{-p}(\tau)e(\tau)d\tau \quad \forall\, t \in [0,T)\,,$$

where $z_n^0 \in X_1$ is such that $z_n^0 \to z(0) = x^0 + A^{-1}Bu^0$ as $n \to \infty$. Clearly, $z_n(t) \in X_1$ for all $t \in [0,T)$. It follows from the admissibility of B and well-known results on abstract Cauchy problems (see [11, p. 109]) that z_n is absolutely continuous as a X-valued function and

$$\dot{z}_n(t) = Az_n(t) + \gamma^{-p}(t)A^{-1}Be(t)\,, \quad \text{for a.a. } t \in [0,T)\,.$$

Therefore, the function

$$V_n : [0,T) \to \mathbb{R}_+\,, \quad t \mapsto \langle z_n(t), Pz_n(t)\rangle + \langle v(t), Qv(t)\rangle$$

is absolutely continuous. Invoking (3.5)–(3.8), we compute the derivative of V_n to be

$$\dot{V}_n = -\|z_n\|^2 - \|Cz_n\|^2 + 2\gamma^{-p}\langle z_n, PA^{-1}Be\rangle - \gamma^{-p}\|v\|^2 - 2\gamma^{-p}\langle v, QC_\Lambda z\rangle. \tag{3.9}$$

Integrating (3.9) from s to t, where $0 \leq s \leq t < T$, we obtain

$$\begin{aligned} V_n(t) - V_n(s) = -\int_s^t \big(&\|z_n(\tau)\|^2 + \|Cz_n(\tau)\|^2 + \gamma^{-p}\|v(\tau)\|^2 \\ &- 2\gamma^{-p}(\tau)\langle z_n(\tau), PA^{-1}Be(\tau)\rangle + 2\gamma^{-p}(\tau)\langle v(\tau), QC_\Lambda z(\tau)\rangle\big)\, d\tau. \end{aligned} \tag{3.10}$$

It follows from (3.5a) that $z(t) := \mathbf{T}_t z(0) + A^{-1}\int_0^t \mathbf{T}_{t-\tau}B\gamma^{-p}(\tau)e(\tau)d\tau$, showing that $z(t) - z_n(t) = \mathbf{T}_t(z(0) - z_n^0)$ for all $t \in [0,T)$ and hence for all $t \in [0,T)$

$$\lim_{n\to\infty}\|z(t) - z_n(t)\| = 0, \quad \lim_{n\to\infty}\|z - z_n\|_{L^2(0,t)} = 0, \quad \lim_{n\to\infty}\|C_\Lambda z - C_\Lambda z_n\|_{L^2(0,t)} = 0,$$

where the last limit follows from the admissibility of C. Consequently, letting $n \to \infty$ in (3.10), we may conclude that

$$\begin{aligned} V(t) - V(s) = -\int_s^t \big(&\|z(\tau)\|^2 + \|C_\Lambda z(\tau)\|^2 + \gamma^{-p}\|v(\tau)\|^2 \\ &- 2\gamma^{-p}(\tau)\langle z(\tau), PA^{-1}Be(\tau)\rangle + 2\gamma^{-p}(\tau)\langle v(\tau), QC_\Lambda z(\tau)\rangle\big)\, d\tau. \end{aligned} \tag{3.11}$$

Denoting the integrand on the right-hand side of (3.11) by $f(\tau)$ and using (3.6), routine estimates give

$$\begin{aligned} f &\geq \|z\|^2 + \|C_\Lambda z\|^2 + c_1\gamma^{-p}\|\mathbf{G}(0)v\|^2 \\ &\quad - c_2\gamma^{-p}\left(\|z\|\|C_\Lambda z\| + \|z\|\|\mathbf{G}(0)v\| + \|C_\Lambda z\|\|\mathbf{G}(0)v\|\right) \\ &\geq \|z\|^2 + \|C_\Lambda z\|^2 + c_1\gamma^{-p}\|\mathbf{G}(0)v\|^2 - c_2\gamma^{-p}\left(\|z\|^2 + \|C_\Lambda z\|^2\right) \\ &\quad - c_2\gamma^{-p}\left(\lambda\|z\|^2 + \|\mathbf{G}(0)v\|^2/\lambda\right) - c_2\gamma^{-p}\left(\lambda\|C_\Lambda z\|^2 + \|\mathbf{G}(0)v\|^2/\lambda\right), \end{aligned} \tag{3.12}$$

where $c_1, c_2 > 0$ are suitable constants and $\lambda > 0$ is arbitrary. In the following we choose

$$\lambda = 4c_2/c_1\,. \tag{3.13}$$

We show that γ is bounded on $[0,T)$. If

$$\gamma^{-p}(\tau) > 1/[2c_2(1+\lambda)] \quad \forall\, t \in [0,T)\,, \tag{3.14}$$

then there is nothing to prove. So assume that (3.14) does not hold. Then, by monotonicity of γ, there exists $t_0 \in [0,T)$ such that

$$\gamma^{-p}(\tau) \leq 1/[2c_2(1+\lambda)] \quad \forall\, t \in [t_0,T)\,.$$

Combining this with (3.12) and (3.13) yields

$$\begin{aligned} f(\tau) &\geq \left(\|z(\tau)\|^2 + \|C_\Lambda z(\tau)\|^2 + c_1\gamma^{-p}(\tau)\|\mathbf{G}(0)v(\tau)\|^2\right)/2 \\ &\geq c_3\gamma^{-p}(\tau)\left(\|C_\Lambda z(\tau)\|^2 + \|\mathbf{G}(0)v(\tau)\|^2\right) \qquad \forall\, t \in [t_0,T)\,, \end{aligned}$$

where $c_3 > 0$ is a suitable constant. Noting that

$$\|r-y\|^2 = \|e\|^2 = \|C_\Lambda z + \mathbf{G}(0)v\|^2 \leq 2\left(\|C_\Lambda z\|^2 + \|\mathbf{G}(0)v\|^2\right),$$

we see that there exists a constant $c_4 > 0$ such that

$$f(\tau) \geq c_4\gamma^{-p}(\tau)\|r-y(\tau)\|^2 \quad \forall\, \tau \in [t_0,T)\,.$$

Therefore, by (3.11),

$$V(t) - V(t_0) = -\int_{t_0}^{t} f(\tau)d\tau \leq -c_4\int_{t_0}^{t}\gamma^{-p}(\tau)\|r-y(\tau)\|^2 d\tau \quad \forall\, t \in [t_0,T)\,. \tag{3.15}$$

But $\dot\gamma = \|r-y\|^2$, and hence, by (3.15),

$$\int_{\gamma(t_0)}^{\gamma(t)} w^{-p}dw = \int_{t_0}^{t}\gamma^{-p}(\tau)\dot\gamma(\tau)d\tau \leq V(t_0)/c_4 \quad \forall\, t \in [t_0,T)\,.$$

Since $0 < p \leq 1$, this inequality implies that γ is bounded on $[0,T)$, showing that $T = \infty$ and also establishing statement (1).

To prove statements (2) and (3) note that

$$e \in L^2(\mathbb{R}_+, \mathbb{R}^m)\,, \tag{3.16}$$

which follows immediately from the boundedness of γ and the fact that $\dot{\gamma} = \|e\|^2$. Since $(A, A^{-1}B, C)$ are the generators of an exponentially stable regular system (with zero feedthrough), it follows from (3.5a) and (3.16) that

$$\lim_{t\to\infty} \|z(t)\| = 0\,, \quad z \in L^2(\mathbb{R}_+, X)\,, \quad C_\Lambda z \in L^2(\mathbb{R}_+, \mathbb{R}^m). \tag{3.17}$$

Using that $C_\Lambda z \in L^2(\mathbb{R}_+, \mathbb{R}^m)$, it follows from (3.6), (3.16), and the invertibility of $\mathbf{G}(0)$ that $v \in L^2(\mathbb{R}_+, \mathbb{R}^m)$. But by (3.5b) and (3.16) we also have that $\dot{v} \in L^2(\mathbb{R}_+, \mathbb{R}^m)$, showing that $\lim_{t\to\infty} v(t) = 0$ and completing the proof of statement (2). Since $x + A^{-1}Bu^r = z + A^{-1}B(u^r - u)$, statement (3) follows from statement (2) and (3.17).

To prove statement (4), we first note that we have already shown that $e \in L^2(\mathbb{R}_+, \mathbb{R}^m)$, and so

$$\dot{u} \in L^2(\mathbb{R}_+, \mathbb{R}^m)\,. \tag{3.18}$$

We recall that G denotes the input-output operator of (3.1). Define a shift-invariant operator $H : L^2_{\mathrm{loc}}(\mathbb{R}_+, \mathbb{R}^m) \to L^2_{\mathrm{loc}}(\mathbb{R}_+, \mathbb{R}^m)$ by setting

$$(Hw)(t) := \int_0^t \left((Gw)(\tau) - \mathbf{G}(0)w(\tau)\right) d\tau \quad \forall\, w \in L^2_{\mathrm{loc}}(\mathbb{R}_+, \mathbb{R}^m) \quad \forall\, t \in \mathbb{R}_+\,.$$

The transfer function $\mathbf{H}$ of H is given by $\mathbf{H}(s) = (\mathbf{G}(s) - \mathbf{G}(0))/s$. Clearly, for every $\omega > \omega(\mathbf{T})$

$$\mathbf{H} \in H^2(\mathbb{C}_\omega, \mathbb{C}^{m\times m}) \cap H^\infty(\mathbb{C}_\omega, \mathbb{C}^{m\times m})\,,$$

showing in particular that H is bounded, i.e., $H \in \mathcal{B}(L^2(\mathbb{R}_+, \mathbb{R}^m))$. Using that G commutes with the integration operator (by shift-invariance), a routine calculation gives

$$Gu = H\dot{u} + \mathbf{G}(0)u + G(u^0\theta) - \mathbf{G}(0)u^0\,,$$

where θ denotes the unit-step function. Invoking the output formula $y = C_\Lambda \mathbf{T}x^0 + Gu$, we may write $e = r - y = e_1 + e_2$, where

$$e_1 := \mathbf{G}(0)(u^r - u) - H\dot{u}\,, \quad e_2 := \mathbf{G}(0)u^0 - G(u^0\theta) - C_\Lambda \mathbf{T}x^0\,.$$

Clearly, e_1 is continuous. Using (3.18) and the boundedness of H and G, it follows that $H\dot{u}$ and $(d/dt)(H\dot{u})$ are in $L^2(\mathbb{R}_+, \mathbb{R}^m)$ and hence $\lim_{t\to\infty}(H\dot{u})(t) = 0$. Combining this with statement (2) shows that $\lim_{t\to\infty} e_1(t) = 0$. Let $\omega > \omega(\mathbf{T})$. To prove that $e_2 \in L^2_\omega(\mathbb{R}_+, \mathbb{R}^m)$, it is sufficient to show that $g := \mathbf{G}(0)u^0 - G(u^0\theta) \in L^2_\omega(\mathbb{R}_+, \mathbb{R}^m)$. But $(\mathfrak{L}g)(s) = -\mathbf{H}(s)u^0$, and so $\mathfrak{L}g \in H^2(\mathbb{C}_\omega, \mathbb{C}^m)$, which in turn implies (by a well-known result of Paley and Wiener, see [12, p. 405]) that $g \in L^2_\omega(\mathbb{R}_+, \mathbb{R}^m)$. Finally, assume that there exists $t_0 \geq 0$ such that $\mathbf{T}_{t_0}(Ax^0 + Bu^0) \in X$. Taking the Laplace transform of e_2 gives

$$(\mathfrak{L}e_2)(s) = \left(\mathbf{G}(0) - \mathbf{G}(s)\right) u^0/s - C(sI - A)^{-1}x^0 \quad \forall\, s \in \mathbb{C}_\omega\,.$$

Invoking (2.1) leads to

$$\begin{aligned}(\mathfrak{L}e_2)(s) &= -C(sI - A)^{-1}A^{-1}Bu^0 - C(sI - A)^{-1}x^0 \\ &= -C(sI - A)^{-1}A^{-1}(Ax^0 + Bu^0) \quad \forall\, s \in \mathbb{C}_\omega,\end{aligned}$$

implying that $e_2(t) = -C_\Lambda \mathbf{T}_t A^{-1}(Ax^0 + Bu^0)$ for a.a. $t \in \mathbb{R}_+$. Hence, since $\mathbf{T}_{t_0}(Ax^0 + Bu^0) \in X$,

$$e_2(t) = -C\mathbf{T}_{t-t_0} A^{-1} \mathbf{T}_{t_0}(Ax^0 + Bu^0)\,, \quad \text{for a.a. } t \geq t_0\,,$$

showing that e_2, and hence e, is continuous on $[t_0, \infty)$ and $\lim_{t\to\infty} e_2(t) = 0 = \lim_{t\to\infty} e(t)$. □

Remark 3.2. (1) Statement (4) in Theorem 3.1 shows that the tracking error e becomes small in the sense that $e = e_1 + e_2$, where $e_1(t)$ converges to 0 as $t \to \infty$, $e_1 \in L^2(\mathbb{R}_+, \mathbb{R}^m)$, and $e_2 \in L^2_\omega(\mathbb{R}_+, \mathbb{R}^m)$ for $\omega > \omega(\mathbf{T})$. This implies, in particular, "tracking in measure," i.e., for all $\varepsilon > 0$ we have that

$$\lim_{\tau\to\infty} \mu_L\left(\{t \geq \tau \,|\, \|e(t)\| \geq \varepsilon\}\right) = 0\,,$$

where μ_L denotes the Lebesgue measure on $\mathbb{R}_+$. The last part of statement (4) shows that "asymptotic tracking" (i.e., $\lim_{t\to\infty} e(t) = 0$) is guaranteed, provided that $\mathbf{T}_{t_0}(Ax^0 + Bu^0) \in X$ for some $t_0 \geq 0$ (which, for example, is the case if $\mathbf{T}$ is holomorphic).

(2) Under the conditions of Theorem 3.1, it is easy to see that if $\mathbf{T}_{t_0} x^0 \in X_1$ for some $t_0 \geq 0$ and the convolution kernel of G is a finite (matrix-valued) Borel measure, then $\lim_{t\to\infty} e(t) = 0$.

(3) Combining the above change of coordinates technique with the approach in [4], it can be shown that the adaptation law (3.2b) can be generalized to $\dot\gamma(t) = \|r - y(t)\|^q$ for arbitrary $q \geq 1$.

(4) Theorem 3.1 remains true if we replace the finite-dimensional input space $\mathbb{R}^m$ by an arbitrary real Hilbert space; the proof carries over word for word to this more general situation.

(5) Suppose that the parameter p in (3.2a) satisfies $p \in (0, 1]$. Then, by Theorem 3.1, for the adaptive low-gain integral controller (3.2) to achieve its objective, it is sufficient that the following two assumptions are satisfied:

(i) the semigroup generated by A is exponentially stable;

(ii) $\sigma(\mathbf{G}(0)) \subset \mathbb{C}_0$.

It can be shown that if the well-posed system (2.2) is low-gain integral stabilizable, i.e., there exists $k^* \in (0, \infty]$ such that (2.2) is exponentially stabilized by the integrator $\dot u = -ky$ for all $k \in (0, k^*)$, then $\sigma(A) \cap \mathbb{C}_0 = \emptyset$ and $\sigma(\mathbf{G}(0)) \subset \overline{\mathbb{C}}_0$. Note that these necessary conditions for low-gain integral stabilizability are only "slightly weaker" than the sufficient conditions (i) and (ii) for adaptive low-gain integral control. Simple counterexamples (see the appendix) show that low-gain integral stabilizability does not imply either of the above conditions (i) or (ii).

(6) If, in (3.2a), $p > 1$, then in general the adaptive controller fails, that is, the conclusions of Theorem 3.1 are not valid. To see this, consider the case of an exponentially stable regular single-input single-output system with $C = 0$ and feedthrough $D = 1$. Then $\mathbf{G}(s) \equiv \mathbf{G}(0) = D = 1$. Suppose that $r = 0$, so that $y(t) = u(t)$. Let $p = 1 + \varepsilon$, where $\varepsilon > 0$. Then (3.2) becomes

$$\begin{aligned} \dot u &= -\gamma^{-(1+\varepsilon)} u\,, \quad u(0) \in \mathbb{R}\,, \\ \dot\gamma &= u^2\,, \qquad\qquad \gamma(0) > 0\,, \end{aligned}$$

from which it follows that $u\dot u = -\gamma^{-(1+\varepsilon)}\dot\gamma$. Integration from 0 to t yields

$$u^2(t) = u^2(0) + \frac{2}{\varepsilon}\left(\gamma^{-\varepsilon}(t) - \gamma^{-\varepsilon}(0)\right).$$

If $u(0) > \sqrt{2\gamma^{-\varepsilon}(0)/\varepsilon}$, then $\lim_{t\to\infty} u(t) > 0$, and so the tracking of $r = 0$ is not achieved.

4. Appendix.

Existence of a self-adjoint positive semidefinite solution to the Lyapunov equation (3.8). It follows from the exponential stability of $\mathbf{T}$ and the admissibility of C that the bilinear form $F : X \times X \to \mathbb{R}$ defined by

$$F(x_1, x_2) := \int_0^\infty \langle \mathbf{T}_t x_1, \mathbf{T}_t x_2 \rangle dt + \int_0^\infty \langle C_\Lambda \mathbf{T}_t x_1, C_\Lambda \mathbf{T}_t x_2 \rangle dt$$

is bounded. Consequently, there exists $P \in \mathcal{B}(X)$ such that $F(x_1, x_2) = \langle x_1, Px_2 \rangle$ for all $x_1, x_2 \in X$ (see [13, Theorem 12.8, p. 296]). It is clear that $P = P^* \geq 0$. Moreover,

$$\begin{aligned}\langle Ax_1, Px_2 \rangle + \langle Ax_2, Px_1 \rangle &= \int_0^\infty \frac{d}{dt} \langle \mathbf{T}_t x_1, \mathbf{T}_t x_2 \rangle + \int_0^\infty \frac{d}{dt} \langle C\mathbf{T}_t x_1, C\mathbf{T}_t x_2 \rangle \\ &= -\langle x_1, x_2 \rangle - \langle Cx_1, Cx_2 \rangle \quad \forall\, x_1, x_2 \in \mathrm{dom}(A^2)\,.\end{aligned}$$

Since $\mathrm{dom}(A^2)$ is dense in X_1, $A \in \mathcal{B}(X_1, X)$, and $C \in \mathcal{B}(X_1, \mathbb{R}^m)$ the above identity extends to all of X_1, showing that (3.8) holds.

Counterexamples showing that low-gain integral stabilizability does not imply conditions (i) or (ii) in part (5) of Remark 3.2. Consider the finite-dimensional system (with zero feedthrough) given by

$$A = \begin{pmatrix} 0 & 1 \\ 0 & -1 \end{pmatrix}, \quad B = \begin{pmatrix} 0 \\ 1 \end{pmatrix}, \quad C = (1/2, 1).$$

This system is integral stabilizable (with $k^* = \infty$), but $0 \in \sigma(A)$, showing that condition (i) in part (5) of Remark 3.2 does not hold.

The finite-dimensional system given by

$$A = \begin{pmatrix} -2 & 0 \\ 0 & -2 \end{pmatrix}, \quad B = \begin{pmatrix} 0 & -1 \\ -1 & 0 \end{pmatrix}, \quad C = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}, \quad D = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}$$

is integral stabilizable (with $k^* = \infty$). However, the transfer function is given by

$$\mathbf{G}(s) = C(sI - A)^{-1}B + D = \begin{pmatrix} 0 & -\dfrac{s+1}{s+2} \\ \dfrac{s+1}{s+2} & 0 \end{pmatrix},$$

and thus $\sigma(\mathbf{G}(0)) = \{\pm i/2\}$, showing that condition (ii) in part (5) of Remark 3.2 does not hold.

OPTIMAL SHAPE CONTROL PROBLEM FOR THE NAVIER–STOKES EQUATIONS*

BUI AN TON†

Abstract. Optimal control techniques are used to find approximate solutions of an inverse problem for a plane nonstationary flow. The shape of the region, the inflow, and the outflow are determined from partial measurements of the flow in a fixed subdomain.

Key words. shape control, optimal design, open loop, multicontrols, inverse problem, Navier–Stokes

1. Introduction.

In this paper, we shall apply optimal control techniques to find an approximate solution to an inverse problem for nonstationary plane Navier–Stokes equations. One wishes to determine the optimal shape and the boundary velocity controls from partial measurements of the velocity in a subregion, with the flow having a minimum drag.

Pioneering work on optimal shape designs for the Navier–Stokes equations was done by Pironneau [13], where a minimum drag profile submerged in a homogeneous, steady, viscous fluid was obtained using optimal control techniques. In [4], Gunzburger and Kim studied a two-dimensional channel flow of an incompressible, stationary, viscous flow to determine the shape of a bump on a part of the boundary that minimizes the viscous drag. Optimal shape control problems associated with the Navier–Stokes equations may have wide applications to aerodynamic and hydrodynamic problems. An application of optimal shape theory in fluid mechanics to the design of riblets as a drag reduction device can be found in Armugan and Pironneau [1].

Optimal control techniques have been used to approximate solutions of inverse problems. The approach has been developed by Chavent [3], James and Sepulveda [6], Lenhart, Protopopescu, and Yong [8], [9], [10].

In all the cited works, a single control problem was considered as a single cost function was involved, even in the case of several controls. It is known that for multicontrols problems, open and closed loops are two different notions. In [15], we have established the existence of an open loop for a general class of evolution inclusions.

In this paper, we shall apply the multicontrol open loop technique to find an approximate solution to an inverse problem for a nonstationary two-dimensional channel flow of an incompressible, viscous fluid. One wants to find the shape of a bump on a part of the boundary, the inflow and the outflow velocity, from partial measurements of the velocity in a fixed subdomain. The work of Gunzburger and Kim [4] on the optimal shape for the stationary Navier–Stokes equations is extended to the time-dependent case.

2. Setting of the problem. We consider the two-dimensional incompressible flow of a viscous fluid passing through a channel having a finite depth. Let $\mathbf{v}^2, \mathbf{v}^3$ be the velocities at the inflow Γ_1 and at the outflow Γ_2 of the channel, respectively, with

$$\Gamma_1 = \{(\psi,\eta):\ \psi = -2; \eta \in [-2,0]\}, \qquad \Gamma_2 = \{(\psi,\eta):\ \psi = 2,\ \eta \in [-2,0]\},$$
$$\Gamma = \Gamma_1 \cup \Gamma_2.$$

Along the top and the bottom sides Γ_3, $\Gamma(u_1)$ of the channel, the velocity vanishes with

$$\Gamma_3 = \{(\psi,\eta) : |\ \psi\ | \leq 2,\ \eta = 0\},$$

and

$$\Gamma(u^1) = \{(\psi,\ \eta):\ \eta = u^1(\psi),\ |\ \psi\ | \leq 2,\ \eta \in [-2,-1],\ u^1 \in U_1\}$$

represents the bump, which is to be determined.

The domain bounded by the curves $\Gamma, \Gamma(u^1)$ is $Q(u^1)$.

We denote by $\mathcal{U}_1$ the following compact subset of $L^2(I)$:

$$\begin{aligned}\mathcal{U}_1 = \{u^1:\ &\|u^1\|_{H^2(I)} \leq C,\ -2 \leq u^1(\psi) \leq -1,\ \forall \psi \in I\\ &I = [-2,2],\ u^1(\pm 1) = -2,\ u^1_\psi(\pm 1) = 0,\ u^1 = -2\\ &\text{for } 1 \leq |\ \psi\ | \leq 2\}.\end{aligned} \tag{2.1}$$

Thus, u^1 is in $C^1(I)$ and there is no excessive oscillation on the bump $\Gamma(u^1)$.

For the inflow and outflow $\mathbf{v}^2, \mathbf{v}^3$, we shall assume that $\mathbf{v}^j$ belongs to the set $\mathcal{U}_j$ with

$$\mathcal{U}_j = \Big\{\mathbf{u}^j:\ \mathbf{u}^j = (u^j_1, u^j_2),\ \|\mathbf{u}^j\|_{H^2(\Gamma_{j-1})} \leq C,$$
$$\int_{\Gamma_j} \mathbf{u}^j.\mathbf{n} d\sigma = 0,\ \text{support } \mathbf{u}^j \subset \Gamma_j\Big\}. \tag{2.2}$$

Let $\mathcal{H}(Q(u^1))$ be the $L^2(Q(u^1))$-closure of the set

$$\{\mathbf{y}:\ \mathbf{y} = (y_1, y_2),\ \mathbf{y} \in C_0^\infty(Q(u^1)),\ \text{div}(\mathbf{y}) = 0 \text{ in } Q(u^1)\},$$

and $\mathcal{H}^k(Q(u^1))$ is the space

$$\{\mathbf{y}:\ \mathbf{y} \in H^k(Q(u^1)),\ \text{div}(\mathbf{y}) = 0 \text{ in } Q(u^1),\ \mathbf{y} = 0 \text{ on } \Gamma_3 \cup \Gamma(u^1)\}.$$

Set

$$\mathcal{H}^k_0(Q(u^1)) = \{\mathbf{y}:\ \mathbf{y} \in H^k_0(Q(u^1)) \cap \mathcal{H}(Q(u^1))\}.$$

We shall write $\mathbf{v}$ for $(\mathbf{v}^2, \mathbf{v}^3)$. We consider, for each $\{u^1, \mathbf{v}\} \in U$, the nonstationary Navier–Stokes equations:

$$\begin{aligned}\mathbf{y}' - \nu\Delta\mathbf{y} + (\mathbf{y}.\nabla)\mathbf{y} + \nabla p &= \mathbf{f} \text{ in } Q(u^1) \times (0,T),\\ \nabla.\mathbf{y} &= 0 \text{ in } Q(u^1) \times (0,T),\\ \mathbf{y}(.,0) &= \mathbf{y}_0 \text{ in } Q(u^1),\\ \mathbf{y} = \mathbf{v}^j \text{ on } \Gamma_{j-1} \times (0,T),\ \mathbf{y} &= 0 \text{ on } \Gamma(u^1) \cup \Gamma_3,\ j = 2,3.\end{aligned} \tag{2.3}$$

DEFINITION 2.1. *The vector function* $\mathbf{y}$ *is said to be a weak solution of* (2.3) *with controls* $\{u^1, \mathbf{v}\}$ *if*

- $\{\mathbf{y},\, \mathbf{y}'\} \in L^2(0,T;\mathcal{H}^1(Q(u^1)) \cap L^\infty(0,T;\mathcal{H}(Q(u^1))) \times L^2(0,T;\mathcal{H}(Q(u^1))^*)$,
- $\mathbf{y}$ *satisfies* (2.3).

Let

$$\Omega \subset Q(u^1)\ \ \forall u^1 \in \mathcal{U}_1;\ \ \mathbf{h},\mathbf{k} \in L^2(0,T;L^2(\Omega)) \times L^2(0,T;L^2(\omega)).$$

The vector functions $\mathbf{h},\mathbf{k}$ represent the experimental measurements of the velocity of the fluid in the subregion Ω and the measurement of the flow at

$$\omega = \{(\psi,\eta):\ \psi = 3/2,\ \eta \in [-1,0]\}.$$

We shall associate with (2.3) the cost functionals

$$J_1(\mathbf{y};u^1;\mathbf{v}) = \int_0^T \int_\Omega \mid \mathbf{y}(\,,t) - \mathbf{h}(\,.,t) \mid^2 d\psi d\eta dt \tag{2.4}$$

and

$$J_2(\mathbf{y};\, u^1;\, \mathbf{v}) = \int_0^T \int_\omega \mid \mathbf{y}(\,.,t) - \mathbf{k}(\,.,t) \mid^2 d\eta dt. \tag{2.5}$$

Let $D(\mathbf{y})$ be the deformation tensor of the flow $\mathbf{y}$; it represents the rate of energy dissipation due to the deformation and is given by

$$D(\mathbf{y}) = \frac{1}{2}(\nabla\mathbf{y} + (\nabla\mathbf{y})^t).$$

We shall associate with (2.3) the cost functional

$$J(\mathbf{y};u^1\,;\mathbf{v}) = \int_0^T \int_{Q(u^1)} (D(\mathbf{y}))^2 d\psi d\eta dt + J_1(\mathbf{y};\, u^1;\, \mathbf{v}) + J_2(\mathbf{y};\, u^1;\, \mathbf{v}). \tag{2.6}$$

The aim of this paper is to show the existence of an open loop of (2.3)–(2.5) and to establish the existence of an optimal control of (2.3)–(2.6), thereby extending Gunzburger and Kim's result.

DEFINITION 2.2. *A control* $\vec{u}_* = (u^1_*,\, \mathbf{u}_*)$ *is said to be an open loop control of* (2.3)–(2.5) *if*

- *there exists* $\tilde{\mathbf{y}}$*, weak solution of* (2.3) *in* $Q(u^1_*)$ *with inflow* $\mathbf{u}^2_*$ *and outflow* $\mathbf{u}^3_*$*, and*
- $$\begin{aligned} &J_1(\tilde{\mathbf{y}};\, u^1_*;\, \mathbf{u}_*) \le J_1(\mathbf{y};u^1_*;\, \mathbf{v}) \qquad \forall \mathbf{v} \in \mathcal{U}_2 \times \mathcal{U}_3, \\ &J_2(\tilde{\mathbf{y}};\, u^1_*;\, \mathbf{u}_*) \le J_2(\mathbf{x};\, u^1;\, \mathbf{u}_*) \qquad \forall u^1 \in \mathcal{U}_1. \end{aligned} \tag{2.7}$$

  $\mathbf{y}$ *is the solution of* (2.3) *with controls* $\{u^1_*,\, \mathbf{v}\}$*. Similarly for* $\mathbf{x}$*.*

We denote by $\tilde{Q}$ the rectangle with vertices at $(-2,2)$, $(-2,0)$, $(2,0)$, $(2,-2)$. We shall now state the main result of the paper.

THEOREM 2.1. *Let* $\{\mathbf{f},\, \mathbf{y}_0, \mathbf{h}, \mathbf{k}\}$ *be in*

$$L^2(0,T;L^2(\tilde{Q})) \times (\tilde{Q}) \times L^2(0,T;L^2(\Omega)) \times L^2(0,T;L^2(\omega))$$

and let J_1, J_2 *be as in* (2.4)–(2.5)*. Then there exists an open loop control* $\{\tilde{u}^1,\, \tilde{\mathbf{u}}\} \in \mathcal{U}$ *of* (2.3)–(2.5).

For the optimal control problem (2.3), (2.6) we have the following.

THEOREM 2.2. *Suppose all the hypotheses of Theorem* 2.1 *are satisfied. Then there exists*

- *a control* $\{\hat{u}^1, \hat{\mathbf{u}}\} \in \mathcal{U}$,
- *a weak solution* $\hat{\mathbf{y}}$ *of* (2.3), *in the sense of Definition* 2.1, *with controls* $\{\hat{u}^1, \hat{\mathbf{u}}\}$ *such that*

$$J(\hat{\mathbf{y}};\, \hat{u}^1;\, \hat{\mathbf{u}}) \le J(\mathbf{x};\, v^1;\, \mathbf{v}) \qquad \forall \{v^1,\, \mathbf{v})\} \in \mathcal{U}.$$

Consider the initial boundary-value problem for the Stokes equations:

$$\begin{gathered} \mathbf{w}' - \nu\Delta\mathbf{w} + \nabla p = 0 \ \text{ in } Q(u^1) \times (0,T), \\ \mathbf{w} = \mathbf{v}^j \ \text{ on}\, \Gamma_{j-1},\ \mathbf{w} = 0 \ \text{ on } \partial Q(u^1)/\Gamma_j,\ j = 2,3, \\ \nabla.\mathbf{w} = 0,\ \mathbf{w}(\,.\,,0) = 0 \ \text{ in } Q(u^1). \end{gathered} \tag{2.8}$$

We have the following result.

LEMMA 2.1. *Let* $\mathbf{v} = (\mathbf{v}^2, \mathbf{v}^3)$ *be in* $\mathcal{U}_2 \times \mathcal{U}_3$*; then there exists a unique solution* $\mathbf{w}$ *of* (2.8) *with*

$$\{\mathbf{w}, \mathbf{w}'\} \in L^2(0,T;{}^4(Q(u^1))) \times L^2(0,T;L^2(Q(u^1))).$$

Moreover,

$$\|\mathbf{w}\|^2_{L^2(0,T;{}^4(Q(u^1)))} + \|\mathbf{w}'\|^2_{L^2(0,T;L^2(Q(u^1)))} \le C\{1 + \|\mathbf{v}\|^2_{H^2(\Gamma)}\}.$$

The lemma is an immediate result of the theory of Stokes equations; cf. [14].

Set $\hat{\mathbf{y}} = \mathbf{y} - \mathbf{w}$; then (2.3) becomes

$$\begin{gathered} \hat{\mathbf{y}}' - \nu\Delta\hat{\mathbf{y}} + (\hat{\mathbf{y}}.\nabla)\hat{\mathbf{y}} + L(\hat{\mathbf{y}};u^1;\,\mathbf{v}) + \nabla p = \mathbf{f} \text{ in } Q(u^1) \times (0,T), \\ \nabla.\hat{\mathbf{y}} = 0;\ \hat{\mathbf{y}} = 0 \ \text{ on } \partial Q(u^1) \times (0,T), \\ \hat{\mathbf{y}}(\,.\,,0) = \mathbf{y}_0 \text{ in } Q(u^1) \end{gathered} \tag{2.9}$$

with

$$L(\hat{\mathbf{y}};\mathbf{v};\,u^1) = (\hat{\mathbf{y}}.\nabla)\mathbf{w} + (\mathbf{w}.\nabla)\hat{\mathbf{y}} + (\mathbf{w}.\nabla)\mathbf{w}. \tag{2.10}$$

The extension method, used in [4] and in many optimal design stationary problems, gives rise to difficulties when applied to time-dependent problems. In the case of the Navier–Stokes equations, one needs an estimate on the time derivative of the solution in a *control-free* space. We shall follow Lenhart, Protopopescu, and Yong [8] and transform (2.9) into a problem in a fixed domain by making a change of variable.

Let

$$\zeta = 2\eta/u^1(\psi), \qquad \psi \in I. \tag{2.11}$$

Set

$$\mathbf{y}(\psi,\zeta,t) = \mathbf{Y}(\psi,\eta,t) = \mathbf{Y}(\psi,\zeta u^1/2;\,t) \qquad \forall (t,\,\psi,\zeta) \in [0,T] \times Q, \tag{2.12}$$

where Q is the rectangle with vertices at $(-2,0), (-2,2), (2,0), (2,2)$. A calculation as in [8, p. 946] gives

$$\nabla_{\psi,\eta}\mathbf{Y}(\psi,\eta,t) = U(\psi,\zeta;u^1)\nabla_{\psi,\zeta}\mathbf{y}(\psi,\zeta;t)$$

with

$$U(\psi,\zeta;u^1) = \begin{pmatrix} I & -\zeta u^1_\psi/u^1 \\ 0 & 2/u^1 \end{pmatrix}.$$

Throughout the paper, we shall write U for $U(\psi, \zeta; u^1)$. Furthermore

$$\nabla_{\psi,\eta}.\mathbf{Y} = \nabla_{\psi,\zeta}.(U^t\mathbf{y}) + (U^t\mathbf{y}.\nabla_{\psi,\zeta}u^1)/u^1 \tag{2.13}$$

and, as computed in [8, p. 946],

$$\operatorname{div}(\mathbf{Y}) = (U\nabla).\mathbf{y} = \nabla.U^t\mathbf{y} + (U^t\mathbf{y}.\nabla u^1)/u^1. \tag{2.14}$$

U^t denotes the transpose of U.

In order to operate in a control-free space, we shall consider an approximate system of Cauchy–Kowaleska type, introduced by Lions [11, pp. 466–469]. Consider the system

$$\begin{aligned} &\hat{\mathbf{y}}'_\varepsilon - \nu\nabla(F(u^1)\nabla\hat{\mathbf{y}}_\varepsilon) + (\hat{\mathbf{y}}_\varepsilon.U\nabla)\hat{\mathbf{y}}_\varepsilon + \hat{L}(\hat{\mathbf{y}}_\varepsilon; u^1, \mathbf{v}) + \frac{1}{2}\{(\nabla.U)\hat{\mathbf{y}}_\varepsilon\}\hat{\mathbf{y}}_\varepsilon \\ &\qquad + (\nabla U)p_\varepsilon = \mathbf{f} \text{ in } Q \times (0,T), \\ &\hat{\mathbf{y}}_\varepsilon = 0 \text{ on } \partial Q \times (0,T), \qquad \hat{\mathbf{y}}_\varepsilon(.0) = \mathbf{y}_0 \text{ in } Q, \end{aligned} \tag{2.15}$$

and

$$\varepsilon p'_\varepsilon + (U\nabla).\hat{\mathbf{y}}_\varepsilon = 0 \text{ in } Q \times (0,T);\ p_\varepsilon(.,0) = 0, \tag{2.16}$$

with

$$\hat{L}(\hat{\mathbf{y}};\ \mathbf{w}; u^1) = (\mathbf{w}.u\nabla)\mathbf{w} + (\mathbf{y}.U\nabla)\mathbf{w} + (\mathbf{w}.U\nabla)\mathbf{w} - (F(u^1)\nabla\hat{\mathbf{y}}.\nabla u^1)/u^1. \tag{2.17}$$

We denote by $F(u^1)$ the matrix

$$\begin{pmatrix} 1 & -\zeta u^1_\psi/u^1 \\ 0 & \zeta^2 \mid \nabla u^1 \mid^2 /(u^1)^2 + 4/(u^1)^2 \end{pmatrix}.$$

DEFINITION 2.3. *Let* $\{\mathbf{f}, \mathbf{y}_0, \mathbf{v}^j, u^1\}$ *be as in Theorem* 2.1. *Then* $\{\mathbf{y}_\varepsilon, p_\varepsilon\}$ *is said to be a weak solution of* (2.15)–(2.16) *if*

- $\{\mathbf{y}_\varepsilon, p_\varepsilon\} \in L^2(0,T; H_0^1(Q)) \cap L^\infty(0,T; L^2(Q)) \times L^\infty(0,T; L^2(Q))$,
- $\{D_t^\gamma \mathbf{y}_\varepsilon, D_t^\gamma p_\varepsilon\} \in L^2(0,T; L^2(Q)) \times L^2(0,T; L^2(Q))$, $0 < \gamma < 1/4$, *with*
- $$\begin{aligned} -\int_0^T (\mathbf{y}_\varepsilon, \phi')dt + \nu\int_0^T (F(u^1)\nabla\mathbf{y}_\varepsilon, \phi)dt + \int_0^T ((\mathbf{y}_\varepsilon.U\nabla)\mathbf{y}_\varepsilon, \phi)dt \\ + \int_0^T (\hat{L}(\mathbf{y}_\varepsilon; u^1; \mathbf{w}),\ \phi)dt + \frac{1}{2}\int_0^T (\mathbf{y}_\varepsilon(U\nabla.\mathbf{y}_\varepsilon),\ \phi)dt \\ - \int_0^T (p_\varepsilon, U\nabla.\mathbf{y}_\varepsilon)dt \\ = (\mathbf{y}_0,\ \phi(0)) + \int_0^T (\mathbf{f},\ \phi)dt \end{aligned}$$

and

$$-\varepsilon\int_0^T (p_\varepsilon, q')dt + \int_0^T (u\nabla._\varepsilon,\ q)dt = 0$$

for all

$$\{\phi, q\} \in L^2(0,T; H_0^1(Q)) \times L^2(0,T; L^2(Q)), \quad \{\phi',\ q'\} \in (L^2(0,T; L^2(Q)))^2,$$

and $\phi(.,T) = 0 = q(.,T)$.

We shall show the existence of an open loop for the approximating system (2.15)–(2.16) and Theorem 2.1 is obtained by letting $\varepsilon \to 0$.

3. The approximating system. The main result of the section is the following theorem.

THEOREM 3.1. *Suppose all the hypotheses of Theorem* 2.1 *are satisfied. Then for each* ε, *there exists a weak solution*

$$\{\mathbf{y}_\varepsilon, p_\varepsilon\} \in L^2(0,T;H_0^1(Q)) \cap L^\infty(0,T;L^2(Q)) \times L^\infty(0,T;L^2(Q))$$

of (2.15)–(2.16) *in the sense of Definition* 2.3. *Moreover,*

$$\|\mathbf{y}_\varepsilon\|^2_{L^2(0,T;H_0^1(Q))} + \|\mathbf{y}_\varepsilon\|^2_{L^\infty(0,T;L^2(Q))} + \varepsilon\|p_\varepsilon\|^2_{L^\infty(0,T;L^2(Q))}$$

$$\le C\{1 + \|\mathbf{f}\|^2_{L^2(0,T;L^2(Q))} + \|\mathbf{y}_0\|^2_{L^2(Q)}\exp(\|\mathbf{v}\|^2_{H^2(\Gamma)} + \|u^1\|^2_{H^2(I)})\}.$$

The constant C *is independent of* $\varepsilon, \mathbf{v}, u^1$. *Furthermore*

$$\|D_t^\gamma \mathbf{y}_\varepsilon\|^2_{L^2(0,T;L^2(Q))} + \|\varepsilon\|D_t^\gamma p_\varepsilon\|^2_{L^2(0,T;L^2(Q))} \le C, \qquad 0 < \gamma < \frac{1}{4}.$$

We shall follow Lions's proof [11, pp. 466–469] and make the necessary modifications using Lenhart, Protopopescu, and Yong's [8] estimates.

LEMMA 3.1. *Suppose all the hypotheses of Theorem* 3.1 *are satisfied. Then there exists a positive constant* c, *independent of* u^1, $\mathbf{v}$ *such that*

$$(F(u^1)\nabla\mathbf{y}, \nabla\mathbf{y}) = \int_Q F(u^1) \mid \nabla\mathbf{y} \mid^2 d\psi d\zeta \ge c\|\mathbf{y}\|^2_{H_0^1(Q)} \qquad \forall \mathbf{y} \in H_0^1(Q).$$

Proof. In [8, p. 952], it was shown that

$$\begin{aligned}(F(u^1)\nabla\mathbf{y}, \nabla\mathbf{y}) &\ge c\int_Q \mid U\nabla\mathbf{y} \mid^2 d\psi d\zeta \\ &\ge \int_Q \{\mid \mathbf{y}_\psi - \zeta\mathbf{y}_\zeta u^1_\psi/u^1 \mid^2 + \mid \mathbf{y}_\zeta \mid^2\} d\psi d\zeta \\ &\ge \int_Q \mid \mathbf{y}_\zeta \mid^2 d\psi d\zeta \qquad \forall \mathbf{y} \in H_0^1(Q).\end{aligned}$$

On the other hand,

$$\begin{aligned}\|\mathbf{y}_\psi\|_{L^2(Q)} &\le \|\mathbf{y}_\psi - \zeta\mathbf{y}_\zeta u^1_\psi/u^1\|_{L^2(Q)} + \|\zeta u^1_\psi \mathbf{y}_\zeta/u^1\|_{L^2(Q)} \\ &\le C\{1 + \|u^1\|_{H^{1,\infty}(I)}\|U\nabla\mathbf{y}\|_{L^2(Q)}\} \\ &\le C\{1 + \|u^1\|_{H^2(I)}\|U\nabla\mathbf{y}\|_{L^2(Q)}\}.\end{aligned}$$

The lemma is proved.

LEMMA 3.2. *Suppose all the hypotheses of Theorem* 3.1 *are satisfied. Let* $\hat{L}(\mathbf{y}, u^1, \mathbf{w})$ *be as in* (2.17). *Then*

$$\|\hat{L}(\mathbf{y}; u^1; \mathbf{w})\|_{L^2(Q)} \le C\{1 + \|u^1\|_{H^2(I)} + \|\mathbf{v}^j\|_{H^2(\Gamma)}\}^2(1 + \|\mathbf{y}\|_{H^1(Q)}) \quad \forall \mathbf{y} \in H_0^1(Q).$$

The constant C *is independent of* u^1, $\mathbf{v}$.

Proof. The proof is trivial and we shall not reproduce it.

LEMMA 3.3. *Let* $U, \mathbf{y}$ *be as in Theorem* 3.1; *then*

$$((\mathbf{y}.U\nabla)\mathbf{y}, \mathbf{y}) = -\frac{1}{2}(\mathbf{y},\ \mathbf{y}(U\nabla.\mathbf{y})). \tag{3.1}$$

The inner product in $L^2(Q)$ *is denoted by* $(\ .,\ .)$.

Proof. A simple but lengthy calculation using (2.14) gives the stated result.

To prove Theorem 3.1, we shall use the Faedo–Galerkin method and establish the existence of $\{\mathbf{y}_\varepsilon, p_\varepsilon\}$, a weak solution of (2.15)–(2.16) in the sense of Definition 2.3.

LEMMA 3.4. *Let* $\{\mathbf{y}_\varepsilon^n,\ p_\varepsilon^n\}$ *be the approximate solution of* (2.15)–(2.16) *obtained from the Galerkin method. Then*

$$\|\mathbf{y}_\varepsilon^n\|^2_{L^2(0,T;H_0^1(Q))} + \|\mathbf{y}_\varepsilon^n\|^2_{L^\infty(0,T;L^2(Q))} + \varepsilon\|p_\varepsilon^n\|^2_{L^\infty(0,T;L^2(Q))}$$

$$\leq C\{1 + \|\mathbf{f}\|^2_{L^2(0,T;L^2(Q))}\} + \|\mathbf{y}_0\|^2_{L^2(Q)}\exp(1 + \|u^1\|_{H^2(I)} + \|\mathbf{v}\|^2_{H^2(\Gamma)}).$$

The constant C *is independent of* $\varepsilon, n, u^1,\ \mathbf{v}^j$.

Proof. With (2.14) and with Lemmas 3.1 and 3.2, the proof is almost the same as the one given in [11, pp. 466–469]. We shall not reproduce it.

LEMMA 3.5. *Let* $\{\mathbf{y}_\varepsilon^n,\ p_\varepsilon^n\}$ *be as in Lemma* 3.4. *Then*

$$\|D_t^\gamma \mathbf{y}_\varepsilon^n\|_{L^2(0,T;L^2(Q))} + \|D_t^\gamma p_\varepsilon^n\|_{L^2(0,T;L^2(Q))} \leq C.$$

The constant C *is independent of* $n,\ \varepsilon, u^1,\ \mathbf{v}$ *and* γ *is any number in* $(0, 1/4)$.

Proof. The proof is as that done in [11, pp. 466–469]. The changes are minor.

Proof of Theorem 3.1. Let $\{\mathbf{y}^n, p^n\}$ be as in Lemmas 3.4 and 3.5. From the estimates of the lemmas, we obtain, by taking subsequences if necessary,

$$\{\mathbf{y}^n, D_t^\gamma \mathbf{y}^n, p^n, D_t^\gamma p^n\} \to \{\mathbf{y}, D^\gamma \mathbf{y},\ y, D_t^\gamma p\}$$

in

$$(L^2(0,T;H_0^1(Q)))_{weak} \cap (L^\infty(0,T;L^2(Q)))_{weak^*} \times (L^2(0,T:L^2(Q)))_{weak}$$
$$\times (L^\infty(0,T;L^2(Q)))_{weak^*} \times (L^2(0,T;L^2(Q)))_{weak}.$$

Since the injection mapping of $H^1(Q)$ onto $L^4(Q)$ is compact, it follows from the above estimates and from [11, p. 61, Theorem 5.2] that

$$\mathbf{y}^n \to \mathbf{y} \text{ in } L^2(0,T;L^4(Q)) \text{ and a.e.}$$

Now a standard proof (e.g., [11, pp. 78–79]) shows that $\{\mathbf{y}, p\}$ is a solution of (2.14)–(2.15). The estimates of the theorem are direct consequences of those of Lemmas 3.4 and 3.5. The theorem is proved.

4. The equation (2.3) in a fixed domain. In this section, we shall study the problem (2.3) in the fixed domain $Q \times (0,T)$. Consider the initial boundary-value problem

$$\begin{aligned} &\mathbf{y}' - \nu\nabla.(F(u^1)\nabla\mathbf{y}) + (\mathbf{y}.U\nabla)\mathbf{y} + U\nabla p + \hat{L}(\mathbf{y}; u^1; \mathbf{w}) = \mathbf{y} \text{ in } Q \times (0,T), \\ &U\nabla.\mathbf{y} = 0 \text{ in } Q \times (0,T), \qquad \mathbf{y} = 0 \text{ on } \partial Q \times (0,T), \\ &\mathbf{y}(\ .,0) = \mathbf{y}_0 \text{ in } Q. \end{aligned} \tag{4.1}$$

DEFINITION 4.1. *The vector function* $\mathbf{y} \in L^2(0,T;H_0^1(Q)) \cap L^\infty(0,T;L^2(Q))$ *with* $D_t^\gamma \mathbf{y} \in L^2(0,T;L^2(Q))$ *is said to be a weak solution of* (4.1) *if*

$$-\int_0^T (\mathbf{y},\phi')dt + \nu\int_0^T (F(u^1)\nabla\mathbf{y},\nabla\phi)dt + \int_0^T ((\mathbf{y}.U\nabla)\mathbf{y},\phi)dt + \int_0^T (\hat{L}(\mathbf{y};u^1;\mathbf{w}),\phi)dt = (\mathbf{y}_0,\phi(\,.,0)) + \int_0^T (\mathbf{f},\phi)dt$$

for all

$$\phi \in L^2(0,T;H_0^1(Q)\cap H^2(Q)),\quad \phi' \in L^2(0,T;L^2(Q)),\quad \phi(\,.,T)=0,\quad U\nabla.\phi = 0.$$

The main result of the section is the following theorem.

THEOREM 4.1. *Suppose all the hypotheses of Theorem* 2.1 *are satisfied. Then there exists a weak solution of* (4.1) *in the sense of Definition* 4.1. *Moreover,*

$$\|\mathbf{y}\|^2_{L^2(0,T;H_0^1(Q))} + \|\mathbf{y}\|^2_{L^\infty(0,T;L^2(Q))} + \|D_t^\gamma\mathbf{y}\|^2_{L^2(0,T;L^2(Q))} \le C\{1+\|\mathbf{f}\|^2_{L^2(0,T;L^2(Q))}\} + C\|\mathbf{y}_0\|^2_{L^2(Q)}\exp(\|u^1\|^2_{H^2(I)} + \|\mathbf{v}^j\|^2_{H^2(\Gamma)})$$

with $0<\gamma<1/4$. *The constant* C *is independent of* $u^1,\mathbf{v}$.

Proof. (1) Let $\{\mathbf{y}_\varepsilon,\, p_\varepsilon\}$ be as in Theorem 3.1. From the estimates of the theorem, we obtain, by taking subsequences,

$$\{\mathbf{y}_\varepsilon,\, D_t^\gamma\mathbf{y}_\varepsilon,\, \varepsilon p_\varepsilon\} \to \{\mathbf{y},\, D_t^\gamma\mathbf{y}, 0\}$$

in

$$(L^2(0,T;H_0^1(Q)))_{weak} \cap (L^\infty(0,T;L^2(Q)))_{weak^*} \times (L^2(0,T;L^2(Q)))_{weak} \times L^2(0,T;L^2(Q)).$$

With our estimate on the fractional time derivative of $\mathbf{y}_\varepsilon$, it follows from the Sobolev imbedding theorem and from [11, p. 61, Theorem 5.2] that

$$\mathbf{y}_\varepsilon \to \mathbf{y} \text{ in } L^2(0,T;L^4(Q)) \text{ and a.e.}$$

The estimates of the theorem are direct consequences of those of Theorem 3.1.

(2) Since

$$\sqrt{\varepsilon}p_\varepsilon \to 0 \text{ in } (L^\infty(0,T;L^2(Q)))_{weak^*},$$

we have $\varepsilon p_\varepsilon' \to 0$ in the distribution sense in $Q\times(0,T)$. Hence

$$U\nabla.\mathbf{y}_\varepsilon \to U.\nabla\mathbf{y} \text{ in } (L^2(0,T;L^2(Q)))_{weak}.$$

Thus, $U\nabla.\mathbf{y} = 0$ in $Q\times(0,T)$.

(3) Since Q is a bounded subset of the plane, an application of the Sobolev imbedding theorem yields

$$\|\mathbf{y}_\varepsilon U\nabla.\mathbf{y}_\varepsilon\|_{H^{-1}(Q)} \le C\|\mathbf{y}_\varepsilon\|^{\frac12}_{L^2(0,T;L^2(Q))}\|\mathbf{y}_\varepsilon\|^{\frac32}_{H_0^1(Q)}.$$

Hence

$$\|\mathbf{y}_\varepsilon U\nabla.\mathbf{y}_\varepsilon\|_{L^{\frac43}(0,T;H^{-1}(Q))} \le C\{1+\|\mathbf{y}_\varepsilon\|^2_{L^\infty(0,T;L^2(Q))}\}\|\mathbf{y}_\varepsilon\|^2_{L^{\frac43}(0,T;H_0^1(Q))} \le C.$$

There exists a subsequence such that

$$\mathbf{y}_\varepsilon(U\nabla.\mathbf{y}_\varepsilon) \to \Psi \text{ in } (L^{\frac{4}{3}}(0,T;H^{-1}(Q)))_{weak},$$

and from part 2, we deduce that $\Psi = 0$.

(4) A similar argument shows that

$$(\mathbf{y}_\varepsilon.U\nabla)\mathbf{y}_\varepsilon \to (\mathbf{y}.U\nabla)\mathbf{y} \text{ in } (L^{\frac{4}{3}}(0,T;H^{-1}(Q)))_{weak}.$$

It is now trivial to check that $\mathbf{y}$ is a solution of (4.1) in the sense of Definition 4.1.

LEMMA 4.1. *The weak solution* $\mathbf{y}$ *of* (4.1)*, given by Theorem* 4.1*, is unique.*

Proof. (1) we have, by a simple calculation,

$$\begin{aligned}((\mathbf{y}.U\nabla),\,\phi) &= \sum_{j,k=1}^{2}(y_j(U\nabla)_j y_k,\,\phi_k)\\ &= -\sum_{k=1}^{2}(y_k,\phi_k\{\nabla.U^t\mathbf{y} + (U^t\mathbf{y}.\nabla u^1)/u^1\}) - ((\mathbf{y}.U\nabla)\phi,\mathbf{y})\\ &= -(\mathbf{y}U\nabla.\mathbf{y},\phi) - ((\mathbf{y}.U\nabla)\phi,\mathbf{y}) = -((\mathbf{y}.U\nabla)\phi,\,\mathbf{y}).\end{aligned}$$

Thus it follows from the Sobolev imbedding theorem that

$$\begin{aligned}\mid((\mathbf{y}.U\nabla)\mathbf{y},\phi)\mid &\le C\|\mathbf{y}\|^2_{L^4(Q)}\|\phi\|_{H^1_0(Q)}\\ &\le C\|\mathbf{y}\|_{L^2(Q)}\|\mathbf{y}\|_{H^1_0(Q)}\|\phi\|_{H^1_0(Q)}.\end{aligned}$$

(2) Let (u^1) be the completion of the set

$$\{\phi:\ \phi\in C_0^\infty(Q),\ U\nabla.\phi = 0\}$$

in the $H^1(Q)$-norm. Then we deduce from the above that

$$\|(\mathbf{y}.U\nabla)\mathbf{y}\|_{L^2(0,T;(\mathcal{V}(u^1))^*)} \le C\|\mathbf{y}\|_{L^\infty(0,T;L^2(Q))}\|\mathbf{y}\|_{L^2(0,T;H^1_0(Q))}.$$

It follows from (4.1) that $\mathbf{y}'$ exists and is in $L^2(0,T;((u^1))^*)$.

(3) Suppose that $\mathbf{x},\mathbf{y}$ are two solutions of (4.1), given by Theorem 4.1; then

$$\begin{aligned}(\mathbf{y}'-\mathbf{x}',\mathbf{y}-\mathbf{x}) &+ \nu(F(u^1)\nabla(\mathbf{y}-\mathbf{x}),\,\nabla(\mathbf{y}-\mathbf{x})) + ((\mathbf{y}-\mathbf{x}).U\nabla\mathbf{y},\mathbf{y}-\mathbf{x})\\ &+ (\mathbf{x}.U\nabla(\mathbf{y}-\mathbf{x}),\mathbf{y}-\mathbf{x}) + (\mathbf{y}-\mathbf{x}.U\nabla\mathbf{w},\mathbf{y}-\mathbf{x})\\ &+ (\mathbf{w}.U\nabla(\mathbf{y}-\mathbf{x}),\mathbf{y}-\mathbf{x}) = 0.\end{aligned}$$

We deduce that

$$\frac{d}{dt}\|\mathbf{y}-\mathbf{x}\|^2_{L^2(Q)} \le C\|\mathbf{y}-\mathbf{x}\|^2_{L^2(Q)}.$$

Hence $\mathbf{y}-\mathbf{x} = 0$. The lemma is proved.

5. Optimal control. The main results of the paper, which are Theorem 2.1 and Theorem 2.2, will be proved in this section. Let $\mathbf{y}$ be the solution of (4.1) with controls $\{u^1, \mathbf{v}\}$ and let

$$J_1(\mathbf{y}; u^1; \mathbf{v}) = \int_0^T \int_\Omega \mid \mathbf{Y}(\psi, 2\eta/u^1; t) - \mathbf{h}(\psi, \eta; t) \mid^2 d\psi d\eta dt, \tag{5.1}$$

$$J_2(\mathbf{y}; u^1; \mathbf{v}) = \int_0^T \int_\omega \mid \mathbf{Y}(3/2; 2\eta/u^1(3/2); t) - \mathbf{k}(\eta, t) \mid^2 d\eta dt$$

with

$$\mathbf{Y}(\psi, \eta; t) = \mathbf{y}(\psi, \zeta; t) + \mathbf{w}. \tag{5.2}$$

Set

$$\Psi(\vec{u}, \vec{v}) = J_1(; \mathbf{u}; v^1) + J_2(\mathbf{x}; u^1; \mathbf{v}),$$

where $\vec{u} = (u^1, \mathbf{u})$, $\vec{v} = (v^1, \mathbf{v})$ are in $\mathcal{U}$ and $\mathbf{x}$ is the unique solution of (4.1) with controls $\{v^1, \mathbf{u}\}$.

LEMMA 5.1. *Suppose all the hypotheses of Theorem* 4.1 *are satisfied. Then for each given* $\vec{u} = \{u^1, \mathbf{u}\}$ *in* $\mathcal{U}$, *there exists* $\vec{v}_* \in \mathcal{U}$ *such that*

$$\Psi(\vec{u}; \vec{v}_*) = d(u) = \inf\{\Psi(\vec{u}, \vec{v}) : \ \vec{v} \in \mathcal{U}\}. \tag{5.3}$$

Proof. First we note that the infimum exists. Let $\{\vec{v}_n\}$ be a minimizing sequence of the optimization problem (5.3) with

$$d(\vec{u}) \leq \Psi(\vec{u}; \vec{v}_n) \leq d(\vec{u}) + \frac{1}{n}.$$

Since $\{\vec{v}_n\}$ is in $\mathcal{U}$ and $\mathcal{U}$ is a compact subset of $H^1(I) \times H^1(\Gamma)$, we get, by taking subsequences,

$$\vec{v}_n \to \vec{v}_* \text{ in } H^1(I) \cap (H^2(I))_{weak} \times H^1(\Gamma) \cap (H^2(\Gamma))_{weak}$$

with $\vec{v}_* \in$. Let $\{\mathbf{y}_n, \mathbf{x}_n\}$ be the solutions of (4.1) with controls $\{u^1, \mathbf{v}_n\}$, $\{v_n^1, \mathbf{u}\}$, respectively. It follows from Theorem 4.1 that

$$\|\{\mathbf{y}_n, \mathbf{x}_n\}\|_{L^2(0,T;H_0^1(Q))} + \|\{\mathbf{y}_n, \mathbf{x}_n\}\|_{L^\infty(0,T;L^2(Q))} + \|\{D_t^\gamma \mathbf{y}_n, D_t^\gamma \mathbf{x}_n\}\|_{L^2(0,T;L^2(Q))} \leq C,$$

where C is independent of n.

Since the injection mapping of $H_0^1(Q)$ into $L^4(Q)$ is compact, it follows from the above estimates and from [11, p. 62, Theorem 5.2] that

$$\{\mathbf{y}_n, \mathbf{x}_n\} \to \{\mathbf{y}_*, \mathbf{x}_*\}$$
$$\text{in } (L^2(0,T; H_0^1(Q)))_{weak} \cap L^2(0,T; L^2(Q)) \cap (L^\infty(0,T; L^2(Q)))_{weak^*}$$

and a.e. with

$$\{\mathbf{y}_n, \mathbf{x}_n\} \mid_{\psi=3/2} \to \{\mathbf{y}_*, \mathbf{x}_*\} \mid_{\psi=3/2} \text{ in } L^2(0,T; L^2(0,2)).$$

Now we consider a typical term of (4.1). We have

$$\begin{aligned} &\|\mathbf{x}_n . U(v_n^1)\mathbf{x}_n\|_{L^{\frac{4}{3}}(0,T;H^{-1}(Q))} \\ &\quad \leq C\|U(v_n^1)\|_{L^\infty(Q)}(1 + \|\mathbf{x}_n\|^2_{L^\infty(0,T;L^2(Q))}\|\mathbf{x}_n\|^2_{L^{\frac{4}{3}}(0,T;H_0^1(Q))}) \\ &\quad \leq C. \end{aligned}$$

Since

$$\mathbf{x}_n.U(v_n^1)\nabla\mathbf{x}_n \to \mathbf{x}_*.U(v_*^1)\nabla\mathbf{x}_* \text{ a.e. in } Q\times(0,T),$$

it follows from the above estimate that

$$\mathbf{x}_n.U(v_n^1)\nabla\mathbf{x}_n \to \mathbf{x}_*.U(v_*^1)\nabla\mathbf{x}_* \text{ in } (L^{\frac{4}{3}}(0,T;H^{-1}(Q)))_{weak}.$$

It is now easy to check that $\{\mathbf{y}_*, \mathbf{x}_*\}$ is the unique solution of (4.1) with the corresponding controls. Moreover,

$$J_1(\mathbf{y}_*;\mathbf{u};v_*^1)+J_2(\mathbf{x};\mathbf{v}_*;u^1)\le \liminf \Psi(\vec{u};\vec{v}_n)\le d(\vec{u}).$$

It follows from the definition of $d(\vec{u})$ that

$$d(\vec{u})=\Psi(\vec{u};\vec{v}_*).$$

The lemma is proved.

Let

$$S=\{\vec{v}_*:\ \vec{v}_* \text{ as in (5.3)}\}.$$

LEMMA 5.2. *Suppose all the hypotheses of Theorem* 4.1 *are satisfied. Let* g_1, g_j^k *be weakly continuous functions from* $\mathcal{U}_1$, $_j^k$; $j=2,3,k=1,2$ *into* R^+, *and suppose that* g_1, g_j^k *are one-to-one. Then there exists a unique* $\vec{v}\in S$ *such that*

$$\begin{aligned} &g_1(\tilde{v}^1)=\alpha_1=\inf\{g_1(v^1):\ \forall\vec{v}\in S\},\\ &g_j^k(\tilde{v}_k^j)=\alpha_j^k=\inf\{g_j^k(v_k^j):\ \forall\vec{v}\in S\}, \qquad j=2,3,k=1,2. \end{aligned} \tag{5.4}$$

Proof. (1) First we note that there exists functions g_1, g_j^k satisfying the hypotheses of the lemma. If S is a finite set, then it is trivial to show the stated results. Let $\{\vec{v}_n\}$ be a minimizing sequence of the optimization problem (5.4) with

$$\alpha_1\le g_1(v_n^1)\le \alpha_1+\frac{1}{n}.$$

Since $\vec{v}_n$ are in $\mathcal{U}$, and since by hypothesis $\mathcal{U}$ is a compact subset of $H^2(I)\times H^2(\Gamma)$, there exists a subsequence such that

$$\vec{v}_n\to\hat{\vec{v}} \text{ in } H^1(I)\times\{H^1\cap(H^2(I))_{weak}\}\times(H^2(I))_{weak}.$$

It is clear that

$$g_1(v_n^1)\to g_1(\hat{v}^1)=\alpha_1.$$

We now show that $\hat{\vec{v}}\in S$, i.e., is such that

$$\Psi(\vec{u};\hat{\vec{v}})\le\Psi(\vec{u};\vec{v}) \qquad \forall\vec{v}\in\mathcal{U}.$$

From the definition of $\vec{v}_n$, we get

$$\begin{aligned}\Psi(\vec{u};\vec{v}_n)&=J_1(\mathbf{y}_n;v_n^1;\mathbf{u})+J_2(\mathbf{x}_n;u^1;\mathbf{v}_n)\\ &\le\Psi(\vec{u};\vec{v}) \qquad \forall\vec{v}\in\mathcal{U},\end{aligned}$$

where $\{\mathbf{y}_n, \mathbf{x}_n\}$ are the solutions of (4.1) with the controls $\{u^1, \mathbf{v}_n\}$, $\{v_n^1, \mathbf{u}\}$, respectively. An argument like that of Lemma 5.1 gives

$$\{\mathbf{y}_n, \mathbf{x}_n\} \to \{\mathbf{y}_*, \mathbf{x}_*\} \text{ in } L^2(0,T;L^2(Q)) \cap (L^2(0,T;H_0^1(Q)))_{weak}$$

and

$$\{\mathbf{y}_n, \mathbf{x}_n\} \mid_{\psi=3/2} \to \{\mathbf{y}_*, \mathbf{x}_*\} \mid_{\psi=3/2} \text{ in } L^2(0,T;L^2(0,2)).$$

Moreover, $\{\mathbf{y}_*, \mathbf{x}_*\}$ are the solutions of (4.1) with the corresponding controls. From the definition of J_1, J_2 and from the above, we deduce that

$$\Psi(\vec{u};\, \hat{\vec{v}}) \le \liminf \Psi(\vec{u};\, \vec{v}_n) \le \Psi(\vec{u};\, \vec{v}) \qquad \forall \vec{v} \in \mathcal{U}.$$

Since g_1 is one-to-one, $\hat{v}^1$ is unique.

(2) Now let

$$\alpha_2^1 = \inf\{g_2^1(v_1^2) :\ \forall \vec{\hat{v}} \in S \text{ with } \vec{\hat{v}} = (\hat{v}^1, .\,, .)\}.$$

Repeating the same argument as above, we have $\vec{v}^* \in S$ such that

$$\alpha_2^1 = g_2^1(v_1^{*,2}) = \inf\{g_2^1(v_1^2) :\ \forall \vec{\hat{v}} \in S,\, \vec{\hat{v}} = (\hat{v}^1, ., .)\}.$$

Then

$$g_2^1(v_1^{*,2}) = \alpha_2^1, \qquad g_1(v_*^1) = \alpha_1.$$

Repeating the process three more times, we get the stated result.

Let A be the nonlinear mapping of U, considered as a compact convex subset of $L^2(I) \times L^2(\Gamma)$ into $\mathcal{U}$, given by

$$A(\vec{u}) = \vec{\hat{v}}, \tag{5.5}$$

where $\vec{\hat{v}}$ is the unique element of $\mathcal{U}$ given by Lemma 5.2.

LEMMA 5.3. *Let A be as in* (5.5)*; then A has a fixed point $\vec{u}^* \in \mathcal{U}$.*

Proof. The nonlinear operator A, given by (5.5), maps a compact convex set U into itself. To show that A has a fixed point, we shall apply Schauder's theorem. Since U is compact, it suffices to show that it is continuous.

Let

$$\vec{v}_n^* = A(\vec{u}_n), \qquad \vec{u}_n \in \mathcal{U}.$$

Since both $\vec{u}_n$, $\vec{v}_n^*$ are in $\mathcal{U}$, we obtain, by taking subsequences,

$$\{\vec{u}_n, \vec{v}_n^*\} \to \{\vec{u}^*, \vec{v}^*\} \text{ in } H^1(I) \times \{H^1(\Gamma) \cap (H^2(I))_{weak}\} \times (H^2(I))_{weak}.$$

By definition, we have

$$\Psi(\vec{u}_n;\, \vec{v}_n^*) \le \Psi(\vec{u}_n;\, \vec{v}) \qquad \forall \vec{v} \in \mathcal{U}.$$

Thus, as in the proof of Lemma 5.1, we get

$$\Psi(\vec{u} :\, \vec{v}^*) \le \liminf \Psi(\vec{u}_n;\, \vec{v}_n^*). \tag{5.6}$$

It follows from the definition of $\vec{v}_n^*$ and from (5.6) that

$$\Psi(\vec{u};\, \vec{v}^*) \le \liminf \Psi(\vec{u}_n;\, \vec{v}) \qquad \forall \vec{v} \in \mathcal{U}. \tag{5.7}$$

On the other hand,

$$\Psi(\vec{u}_n;\, \vec{v}) = J_1(\mathbf{y}_n;\, {}_n; v^1) + J_2(\mathbf{x}_n;\, u_n^1;\, \mathbf{v}),$$

where $\{\mathbf{y}_n,\, \mathbf{x}_n\}$ are the solutions of (4.1) with controls $\{u_n^1,\, \mathbf{v}\}$, $\{v^1,\, \mathbf{u}_n\}$, respectively. A proof like that of Lemma 5.1 yields

$$\Psi(\vec{u};\, \vec{v}) = \lim \Psi(\vec{u}_n;\, \vec{v}) \qquad \forall \vec{v} \in \mathcal{U}. \tag{5.8}$$

It follows from (5.7)–(5.8) that

$$\Psi(\vec{u};\, \vec{v}^*) \le \Psi(\vec{u};\, \vec{v}) \qquad \forall \vec{v} \in \mathcal{U}.$$

The nonlinear mapping A satisfies all the hypotheses of the Schauder fixed point theorem. There exists $\vec{u}_* = \{u_*^1,\, \mathbf{u}_*\} \in \mathcal{U}$ such that $A(\vec{u}_*) = \vec{u}_*$.

Set $\vec{v} = (u^1,\, \mathbf{u}_*)$ in the formula and we obtain

$$\begin{aligned} &\Psi(\vec{u}_*;\, \vec{u}_*) \le \Psi(\vec{u}_*;\, \vec{v}), \\ &J_1(\mathbf{y};\, u_*^1;\, \mathbf{u}_*) \le J_1(\mathbf{x};\, u^1;\, \mathbf{u}_*) \qquad \forall u^1 \in \mathcal{U}_1. \end{aligned}$$

With $\vec{v} = (u_*^1,\, \mathbf{v})$, we have

$$J_2(\mathbf{y};\, u_*^1;\, \mathbf{u}_*) \le J_2(\mathbf{x};\, u_*^1;\, \mathbf{v}) \qquad \forall \mathbf{v} \in \mathcal{U}_2 \times \mathcal{U}_3.$$

The lemma is proved.

Proof of Theorem 2.1. From Theorem 4.1 and from Lemma 5.3, we deduce that there exists $\mathbf{y}$ and $\vec{u}_* = (u_*^1,\, \mathbf{u}_*) \in \mathcal{U}$ with $\mathbf{y}$ being the unique solution of (4.1) with control $\vec{u}_*$. Moreover,

$$\begin{aligned} &J_1(\tilde{\mathbf{y}};\, u_*^1;\, \mathbf{u}_*) \le J_1(\mathbf{x};\, u^1;\, \mathbf{u}_*) \qquad \forall u^1 \in \mathcal{U}_1, \\ &J_2(\tilde{\mathbf{y}};\, u_*^1;\, \mathbf{u}_*) \le J_2(\mathbf{z};\, u_*^1;\, \mathbf{v}) \qquad \forall \mathbf{v} \in \mathcal{U}_2 \times \mathcal{U}_3; \end{aligned}$$

$\mathbf{x}$, $\mathbf{z}$ are the unique solutions of (4.1) with the indicated controls.

Set

$$\begin{aligned} \mathbf{Y}(\psi; \eta; t) &= \tilde{\mathbf{y}}(\psi, \zeta, t) + \mathbf{w} \\ &= \tilde{\mathbf{y}}(\psi;\, 2\eta / u_*^1(\psi); t) + \mathbf{w}, \end{aligned}$$

where $\mathbf{w}$ is the solution of the Stokes equations, given by Lemma 2.1, with boundary controls $\mathbf{v} = \mathbf{u}_*$. Then $\mathbf{Y}$ is the solution of (2.3) and $\{u_*^1,\, \mathbf{u}_*\}$ is the open loop of the problem.

The theorem is proved.

We now turn to the case when the deformation vector function is involved in the cost functional. The open loop problem is open in that case as we have only weak convergence of the first order derivatives of the approximating sequences. Let

$$\tilde{J}(\mathbf{y};\, u^1;\, \mathbf{v}) = \int_0^T \int_Q \{U \nabla \mathbf{y} + (U \nabla \mathbf{y})^t\}^2 2u^1 d\psi d\zeta dt + J_1(\mathbf{y};\, u^1;\, \mathbf{v}) + J_2(\mathbf{y};\, u^1;\, \mathbf{v})$$

and consider the problem

$$\alpha = \inf\{\tilde{J}(\mathbf{y};\, u^1;\, \mathbf{u}) :\ \vec{u} \in \}, \tag{5.9}$$

where $\mathbf{y}$ is the unique solution of (4.1) with controls $\vec{u} = (u^1,\, \mathbf{u})$, given by Theorem 4.1 and by Lemma 4.1.

LEMMA 5.4. *Suppose all the hypotheses of Theorem* 4.1 *are satisfied. Then there exists* $\{\hat{\mathbf{y}},\, \hat{u}^1,\, \hat{\mathbf{u}}\}$ *such that*

$$\tilde{J}(\hat{\mathbf{y}};\, \hat{u}^1;\, \hat{\mathbf{u}}) = \alpha = \inf\{\tilde{J}(\mathbf{y};\, u^1;\, \mathbf{u}) :\ \forall \vec{u} \in \mathcal{U}\}.$$

Proof. It is clear that α is finite. Let $\{\vec{u}_n\}$ be a minimizing sequence of the optimization problem (5.8) with

$$\alpha \le \tilde{J}(\mathbf{y}_n;\, u_n^1;\, \mathbf{u}_n) \le \alpha + \frac{1}{n}.$$

Since $\vec{u}_n \in \mathcal{U}$, with our hypotheses on $\mathcal{U}$, we obtain, by taking subsequences if necessary,

$$\vec{u}_n \to \vec{u}_* \qquad \text{in } H^1(I) \times H^1(\Gamma).$$

From Theorem 4.1, we have the estimate

$$\|\mathbf{y}_n\|_{L^2(0,T;H^1(Q))} + \|\mathbf{y}_n\|_{L^\infty(0,T;L^2(Q))} + \|D_t^\gamma \mathbf{y}_n\|_{L^2(0,T;L^2(Q))} \le C.$$

Again by taking subsequences, we get

$$\mathbf{y}_n \to \hat{\mathbf{y}} \text{ in } L^2(0,T;L^2(Q)) \cap (L^2(0,T;H^1(Q)))_{weak} \cap (L^\infty(0,T;L^2(Q)))_{weak^*}$$

with

$$\mathbf{y}_n \to \hat{\mathbf{y}} \text{ a.e.}, \qquad \mathbf{y}_n\,|_{\psi=1.5} \to \hat{\mathbf{y}}\,|_{\psi=1.5} \qquad \text{in } L^2(0,T;L^2(0,2)).$$

It is not difficult to check that $\hat{\mathbf{y}}$ is the solution of (4.1) with control $\vec{u}_*$. We now have

$$\alpha = \lim \tilde{J}(\mathbf{y}_n;\, u_n^1;\, \mathbf{u}_n) = \tilde{J}(\hat{\mathbf{y}};\, u_*^1;\, \mathbf{u}_*).$$

Thus, by definition

$$\tilde{J}(\hat{\mathbf{y}};\, u_*^1;\, \mathbf{u}_*) \le \tilde{J}(\mathbf{x};\, v^1;\, \mathbf{v}) \qquad \forall \vec{v} \in \mathcal{U},$$

where $\mathbf{x}$ is the solution of (4.1) with control $\vec{v}$.

Proof of Theorem 2.2. Let $\hat{\mathbf{y}}$, $\mathbf{u}_*$ be as in Lemma 5.4 and set

$$\begin{aligned}\hat{\mathbf{Y}}(\psi;\, \eta, t) &= \hat{\mathbf{y}}(\psi; \zeta, t) + \mathbf{w} \\ &= \hat{\mathbf{y}}(\psi; 2\eta/u_*^1(\psi);\, t) + \mathbf{w},\end{aligned}$$

where $\mathbf{w}$ is the solution of the Stokes equations of Lemma 2.1 with $\mathbf{v} = \mathbf{u}_*$. Then $\{\hat{\mathbf{Y}},\, \mathbf{u}_*\}$ is the sought solution of the theorem.

Acknowledgment. The author wishes to thank the referees for their comments.

EXACT BOUNDARY CONTROLLABILITY FOR QUASI-LINEAR HYPERBOLIC SYSTEMS*

TA-TSIEN LI† AND BO-PENG RAO‡

Abstract. Using a result on the existence and uniqueness of the semiglobal C^1 solution to the mixed initial-boundary value problem for first order quasi-linear hyperbolic systems with general nonlinear boundary conditions, we establish the exact boundary controllability for quasi-linear hyperbolic systems if the C^1 norm of initial and final states is small enough.

Key words. semiglobal C^1 solution, exact boundary controllability, quasi-linear hyperbolic system

1. Introduction and main result.

Consider the first order quasi-linear hyperbolic system

$$\frac{\partial u}{\partial t} + A(u)\frac{\partial u}{\partial x} = F(u), \tag{1.1}$$

where $u = (u_1, \dots, u_n)^T$ is a vector valued function of (t, x), $A(u) = (a_{ij}(u))$ is an $n \times n$ matrix with suitably smooth elements $a_{ij}(u)(i, j = 1, \dots, n)$, $F : \mathbb{R}^n \to \mathbb{R}^n$ is a vector valued function with suitably smooth components $f_i(u)(i = 1, \dots, n)$, and

$$F(0) = 0. \tag{1.2}$$

By the definition of hyperbolicity, on the domain under consideration, the matrix $A(u)$ has n real eigenvalues $\lambda_i(u)$ $(i = 1, \dots, n)$ and a complete set of left eigenvectors $l_i(u) = (l_{i1}(u), \dots, l_{in}(u))$ $(i = 1, \dots, n)$:

$$l_i(u)A(u) = \lambda_i(u)l_i(u), \tag{1.3}$$

and a complete set of right eigenvectors $r_i(u) = (r_{i1}(u), \dots r_{in}(u))^T$ $(i = 1, \dots, n)$:

$$A(u)r_i(u) = \lambda_i(u)r_i(u). \tag{1.4}$$

We have

$$\det |l_{ij}(u)| \neq 0 \qquad (\text{resp., } \det |r_{ij}(u)| \neq 0). \tag{1.5}$$

Without loss of generality, we may assume that

$$l_i(u)r_j(u) \equiv \delta_{ij} \qquad (i, j = 1, \dots n), \tag{1.6}$$

$$r_i^T(u)r_i(u) \equiv 1 \qquad (i = 1, \dots, n), \tag{1.7}$$

where δ_{ij} stands for the Kronecker symbol. Moreover, we assume that, on the domain under consideration, the eigenvalues satisfy the following conditions:

$$\lambda_r(u) < 0 < \lambda_s(u) \qquad (r = 1, \dots, m; \quad s = m+1, \dots, n). \tag{1.8}$$

Let

$$v_i = l_i(u)u \qquad (i = 1, \dots, n). \tag{1.9}$$

We consider the mixed initial-boundary value problem for the quasi-linear hyperbolic system (1.1) with the initial condition

$$t = 0: \quad u = \phi(x), \qquad 0 \le x \le 1, \tag{1.10}$$

and the boundary conditions

$$x = 0: \quad v_s = G_s(t, v_1, \dots, v_m) + H_s(t) \quad (s = m+1, \dots, n), \tag{1.11}$$

$$x = 1: \quad v_r = G_r(t, v_{m+1}, \dots, v_n) + H_r(t) \quad (r = 1, \dots, m). \tag{1.12}$$

Without loss of generality, we assume that

$$G_i(t, 0, \dots, 0) \equiv 0 \qquad (i = 1, \dots, n). \tag{1.13}$$

Let us recall the following result of Li–Jin [9] on the semiglobal C^1 solution, which will be used as the main tool in what follows.

LEMMA 1.1. *Assume that $l_{ij}(u), \lambda_i(u), f_i(u), G_i(t, \cdot), H_i(t)$ $(i, j = 1, \dots, n)$, and $\phi(x)$ are all C^1 functions with respect to their arguments. Assume, furthermore, that* (1.2), (1.5), (1.8), *and* (1.13) *hold. Assume finally that the conditions of C^1 compatibility are satisfied at the points $(0, 0)$ and $(0, 1)$, respectively. Then, for a given $T_0 > 0$, the mixed initial-boundary value problem* (1.1) *and* (1.10)–(1.12) *admits a unique C^1 solution $u = u(t, x)$ (called the semiglobal C^1 solution) with sufficiently small C^1 norm on the domain*

$$R(T_0) = \{(t, x) | \quad 0 \le t \le T_0, \quad 0 \le x \le 1\}, \tag{1.14}$$

provided that the C^1 norms $\|\phi\|_{C^1[0,1]}$ and $\|H\|_{C^1[0,T_0]}$ are small enough (depending on T_0). In particular, for any given $\epsilon_0 > 0$, we have

$$|u(t, x)| \le \epsilon_0 \tag{1.15}$$

on the domain $R(T_0)$ if $\|\phi\|_{C^1[0,1]}$ and $\|H\|_{C^1[0,T_0]}$ are small enough (depending on T_0 and ϵ_0).

Based on this result, we can consider the following problem of local exact boundary controllability.

For any given initial data $\phi \in C^1[0, 1]$ and final data $\psi \in C^1[0, 1]$ with small C^1 norm, can we find a time $T_0 > 0$ and boundary input controls $H_i \in C^1[0, T_0]$ $(i = 1, \dots, n)$ with small C^1 norm, such that the mixed initial-boundary value problem (1.1) *and* (1.10)–(1.12) *admits a unique C^1 solution $u = u(t, x)$ on the domain $R(T_0)$, which verifies the final condition*

$$u(T_0, x) = \psi(x), \quad 0 \le x \le 1? \tag{1.16}$$

Notice that, because of the finiteness of the speed of wave propagation, the exact boundary controllability of a hyperbolic system requires that the controllability time T_0 must be greater than a given constant. Let

$$T_0 > \max_{i=1,\dots,n} \frac{1}{|\lambda_i(0)|}. \tag{1.17}$$

In this paper, we will give an affirmative answer to the above problem of exact boundary controllability. The main result is the following theorem.

THEOREM 1.2. *Assume that $l_{ij}(u), \lambda_i(u), f_i(u), G_i(t,\cdot)$, and $H_i(t)$ $(i,j=1,\dots,n)$ are all C^1 functions with respect to their arguments. Assume, furthermore, that* (1.2), (1.5), (1.8), *and* (1.13) *hold. Let T_0 be defined by* (1.17). *Then, for any given initial data $\phi \in C^1[0,1]$ and final data $\psi \in C^1[0,1]$ with small C^1 norm, there exist boundary controls $H_i(t) \in C^1[0,T_0]$ $(i=1,\dots,n)$ with small C^1 norm, such that the mixed initial-boundary value problem* (1.1) *and* (1.10)–(1.12) *admits a unique C^1 solution $u = u(t,x)$ on the domain $R(T_0)$, which verifies the final condition* (1.16).

Remark 1.1. The exact controllability time T_0 given in this theorem is optimal.

Remark 1.2. The results given in [7], [8] can be regarded as a direct consequence of this theorem.

Remark 1.3. In some special cases, it is possible to use only boundary controls $H_s(t)$ $(s=m+1,\dots,n)$ on $x=0$ or $H_r(t)$ $(r=1,\dots,m)$ on $x=1$ to realize the exact boundary controllability, but the controllability time T_0 must be doubled (see [10]).

There are a number of publications concerning the exact controllability and the uniform stabilization for linear hyperbolic systems (see [11], [12], and the references therein). Furthermore, using the Hilbert uniqueness method (HUM) suggested by J.-L. Lions [11] and Schauder's fixed point theorem, Zuazua [13] proved the global (resp., local) exact boundary controllability for semilinear wave equations in the asymptotically linear case (resp., the superlinear case with suitable growth conditions). Later, using a global inversion theorem, Lasiecka–Triggiani [4] established an abstract result on the exact controllability for semilinear equations. As an application, they gave the global exact boundary controllability for the wave and plate equations in the asymptotically linear case. However, only a few results are known for quasi-linear hyperbolic systems. In the case in which $n=2$, the exact boundary controllability for *reducible* quasi-linear hyperbolic systems was proved in Li–Zhang [6] and Li–Rao–Jin [7], [8] by a constructive method which does not work in the general case of quasi-linear hyperbolic systems that we consider in this paper. A similar consideration can be found in Fursikov–Imanuvilov [3] for a class of one-dimensional semilinear wave equations. In earlier work, M-Cirinà [1], [2] considered the zero exact controllability for quasi-linear hyperbolic systems with linear boundary controls; however, his results are essentially valid only for the system of diagonal form. Moreover, if one applies the result of [1] twice for getting the general controllability, then the corresponding controllability time must be doubled. In this work, based on the existence result [9] for the semiglobal C^1 solution to the mixed initial-boundary value problem of quasi-linear hyperbolic systems, we establish the local exact boundary controllability for general quasi-linear hyperbolic systems with general nonlinear boundary controls.

2. Reduction of the problem. In order to prove the main theorem, it suffices to establish the following proposition.

PROPOSITION 2.1. *Let T_0 be defined by* (1.17), *and let $\epsilon_0 > 0$ be a given small number. For any given initial data $\phi \in C^1[0,1]$ and final data $\psi \in C^1[0,1]$ with small*

C^1 norm, the quasi-linear hyperbolic system (1.1) *admits a C^1 solution $u = u(t,x)$ on the domain $R(T_0)$ such that*

$$u(0,x) = \phi(x), \qquad 0 \le x \le 1, \tag{2.1}$$

$$u(T_0,x) = \psi(x), \qquad 0 \le x \le 1, \tag{2.2}$$

the C^1 norm of $u = u(t,x)$ is suitably small, and $u = u(t,x)$ satisfies (1.15) *on the domain $R(T_0)$.*

In fact, let $u = u(t,x)$ be a C^1 solution of (1.1) on the domain $R(T_0)$, given by Proposition 2.1. Set

$$H_r(t) = \big(v_r - G_r(t, v_{m+1}, \dots, v_n)\big)|_{x=1} \quad (r = 1, \dots, m), \tag{2.3}$$

$$H_s(t) = \big(v_s - G_s(t, v_1, \dots, v_m)\big)|_{x=0} \quad (s = m+1, \dots, n), \tag{2.4}$$

where v_i $(i = 1, \dots, n)$ are defined by (1.9). Noting (1.13), the C^1 norm of H_i $(i = 1, \dots, n)$ is small. Then, by Lemma 1.1, $u = u(t,x)$ is the semiglobal C^1 solution to the corresponding mixed initial-boundary value problem (1.1) and (1.10)–(1.12) on the domain $R(T_0)$, which also satisfies the final condition (2.2). Therefore, we obtain the desired exact boundary controllability, and the boundary controls H_i $(i = 1, \dots, n)$ are given by (2.3)–(2.4).

3. Exact boundary controllability. In this section, we will prove Proposition 2.1.

First, noting (1.17), there exists an $\epsilon_0 > 0$ so small that

$$T_0 > \max_{|u| \le \epsilon_0,\ i=1,\dots,n} \frac{1}{|\lambda_i(u)|}. \tag{3.1}$$

Let

$$T_1 = \max_{|u| \le \epsilon_0,\ i=1,\dots,n} \frac{1}{2|\lambda_i(u)|}. \tag{3.2}$$

We divide the proof into several steps.

(i) We first consider the forward auxiliary mixed initial-boundary value problem of (1.1) with the initial condition

$$t = 0: \quad u = \phi(x), \qquad 0 \le x \le 1, \tag{3.3}$$

and the boundary conditions

$$x = 0: \quad v_s = f_s(t) \quad (s = m+1, \dots, n), \tag{3.4}$$

$$x = 1: \quad v_r = \overline{f}_r(t) \quad (r = 1, \dots, m), \tag{3.5}$$

where v_i $(i = 1, \dots, n)$ are defined by (1.9) and $f_s, \overline{f}_r$ $(r = 1, \dots, m; s = m+1, \dots, n)$ are any given functions of t with small $C^1[0, T_1]$ norm. We assume that the conditions of C^1 compatibility are satisfied at the points $(0,0)$ and $(0,1)$, respectively. By Lemma 1.1, there exists a unique semiglobal C^1 solution $u = u^{(1)}(t,x)$ with small C^1 norm on the domain

$$\{(t,x)| \quad 0 \le t \le T_1, \quad 0 \le x \le 1\}. \tag{3.6}$$

In particular, the solution $u = u^{(1)}(t,x)$ satisfies (1.15) on the domain (3.6). Thus we can uniquely determine the corresponding value of u on $x = \frac{1}{2}$ as

$$x = \frac{1}{2}: \quad u = a(t), \quad 0 \le t \le T_1, \tag{3.7}$$

and the $C^1[0,T_1]$ norm of $a(t)$ is suitably small.

(ii) Similarly, we consider the backward auxiliary initial-boundary value problem of (1.1) with the initial condition

$$t = T_0: \quad u = \psi(x), \qquad 0 \le x \le 1, \tag{3.8}$$

and the boundary conditions

$$x = 0: \quad v_r = g_r(t) \quad (r = 1, \dots, m), \tag{3.9}$$

$$x = 1: \quad v_s = \overline{g}_s(t) \quad (s = m+1, \dots, n), \tag{3.10}$$

where v_i $(i = 1, \dots, n)$ are defined by (1.9) and $g_r, \overline{g}_s$ $(r = 1, \dots, m; s = m+1, \dots, n)$ are any given functions of t with small $C^1[T_0 - T_1, T_0]$ norm. We assume that the conditions of C^1 compatibility are satisfied at the points $(T_0, 0)$ and $(T_0, 1)$, respectively. Once again, by Lemma 1.1, there exists a unique semiglobal C^1 solution $u = u^{(2)}(t,x)$ with small C^1 norm on the domain

$$\{(t,x) | \quad T_0 - T_1 \le t \le T_0, \quad 0 \le x \le 1\}. \tag{3.11}$$

In particular, the solution $u = u^{(2)}(t,x)$ satisfies (1.15) on the domain (3.11). Thus we can uniquely determine the corresponding value of u on $x = \frac{1}{2}$ as

$$x = \frac{1}{2}: \quad u = b(t), \quad T_0 - T_1 \le t \le T_0, \tag{3.12}$$

and the $C^1[T_0 - T_1, T_0]$ norm of $b(t)$ is suitably small.

(iii) Now we change the order of variables t and x, and then the system (1.1) is rewritten in the following form:

$$\frac{\partial u}{\partial x} + A^{-1}(u)\frac{\partial u}{\partial t} = \widetilde{F}(u) := A^{-1}(u)F(u). \tag{3.13}$$

We notice that

$$\widetilde{F}(0) = 0. \tag{3.14}$$

Noting (1.8), the eigenvalues of the inverse matrix $A^{-1}(u)$ satisfy

$$\frac{1}{\lambda_r(u)} < 0 < \frac{1}{\lambda_s(u)} \qquad (r = 1, \dots, m; \quad s = m+1, \dots, n). \tag{3.15}$$

Moreover, since the matrices $A(u)$ and $A^{-1}(u)$ have the same left eigenvectors, we can still define the variables v_i $(i = 1, \dots, n)$ by the same formula (1.9).

Now we consider the mixed initial-boundary value problem for system (3.13) with the initial condition

$$x = \frac{1}{2}: \quad u = c(t), \qquad 0 \le t \le T_0, \tag{3.16}$$

and the boundary conditions

$$t = 0: \quad v_r = \Phi_r(x) \quad (r = 1, \dots, m), \quad 0 \le x \le \frac{1}{2}, \tag{3.17}$$

$$t = T_0: \quad v_s = \Psi_s(x) \quad (s = m+1, \dots, n), \quad 0 \le x \le \frac{1}{2}, \tag{3.18}$$

where $c(t)$ is a $C^1[0, T_0]$ function with small C^1 norm such that (noting (1.17))

$$c(t) = \begin{cases} a(t), & 0 \le t \le T_1, \\ b(t), & T_0 - T_1 \le t \le T_0; \end{cases} \tag{3.19}$$

moreover,

$$\Phi_i(x) = l_i(\phi(x))\phi(x) \qquad (i = 1, \dots, n), \tag{3.20}$$

$$\Psi_i(x) = l_i(\psi(x))\psi(x) \qquad (i = 1, \dots, n), \tag{3.21}$$

the $C^1[0, 1]$ norm of which is also small. Noting (3.19)–(3.21), we easily check that the mixed initial-boundary value problem (3.13) and (3.16)–(3.18) satisfies the conditions of C^1 compatibility at the points $(0, \frac{1}{2})$ and $(T_0, \frac{1}{2})$, respectively. Therefore, by Lemma 1.1, there exists a unique semiglobal C^1 solution $u = u_l(t, x)$ with small C^1 norm on the domain

$$R_l(T_0) = \left\{ (t, x) | \quad 0 \le t \le T_0, \quad 0 \le x \le \frac{1}{2} \right\}. \tag{3.22}$$

Moreover, $u = u_l(t, x)$ can be asked to satisfy (1.15) on the domain (3.22) if the C^1 norm of $\phi, \psi, \bar{f}_r, f_s, g_r$, and $\bar{g}_s (r = 1, \dots, m; s = m+1, \dots, n)$ is small enough.

(iv) Similarly, the mixed initial-boundary value problem (3.13) with the initial condition (3.16) and the boundary conditions

$$t = 0: \quad v_s = \Phi_s(x) \quad (s = m+1, \dots, n), \quad \frac{1}{2} \le x \le 1, \tag{3.23}$$

$$t = T_0: \quad v_r = \Psi_r(x) \quad (r = 1, \dots, m), \quad \frac{1}{2} \le x \le 1, \tag{3.24}$$

admits a unique semiglobal C^1 solution $u = u_r(t, x)$ with small C^1 norm on the domain

$$R_r(T_0) = \left\{ (t, x) | \quad 0 \le t \le T_0, \quad \frac{1}{2} \le x \le 1 \right\}, \tag{3.25}$$

and $u = u_r(t, x)$ can also be asked to satisfy (1.15) on the domain (3.25).

(v) Let

$$u(t, x) = \begin{cases} u_l(t, x), & (t, x) \in R_l(T_0), \\ u_r(t, x), & (t, x) \in R_r(T_0). \end{cases} \tag{3.26}$$

To complete the proof of Proposition 2.1, it is only necessary to check that

$$t = 0: \quad u = \phi(x), \qquad 0 \le x \le 1, \tag{3.27}$$

$$t = T_0: \quad u = \psi(x), \qquad 0 \le x \le 1. \tag{3.28}$$

In fact, the C^1 solutions $u = u_l(t,x)$ (resp., $u = u_r(t,x)$) and $u = u^{(1)}(t,x)$ satisfy the system (3.13) (and thus (1.1)), the initial condition

$$x = \frac{1}{2}: \quad u = a(t), \quad 0 \le t \le T_1, \tag{3.29}$$

and the boundary conditions

$$\begin{aligned} &t = 0: \quad v_r = \Phi_r(x) \quad (r = 1, \dots m), \quad \frac{1}{2} \le x \le 1 \\ &\left(\text{resp.,} \quad t = 0: \quad v_s = \Phi_s(x) \quad (s = m+1, \dots n), \quad \frac{1}{2} \le x \le 1\right). \end{aligned} \tag{3.30}$$

Because of the finiteness of the speed of wave propagation and the choice of T_1 given by (3.1), the mixed initial-boundary value problem (3.13) and (3.29)–(3.30) has a unique C^1 solution on the domain

$$\begin{aligned} &\left\{(t,x)| \quad 0 \le t \le 2T_1 x, \quad 0 \le x \le \frac{1}{2}\right\} \\ &\left(\text{resp.,} \quad \left\{(t,x)| \quad 0 \le t \le 2T_1(1-x), \quad \frac{1}{2} \le x \le 1\right\}\right) \end{aligned} \tag{3.31}$$

(see Li–Yu [5]). Then

$$u(t,x) \equiv u^{(1)}(t,x) \tag{3.32}$$

on these domains, and, in particular, we obtain (3.27).

On the other hand, the C^1 solutions $u = u_l(t,x)$ (resp., $u = u_r(t,x)$) and $u = u^{(2)}(t,x)$ satisfy the system (3.13) (and thus (1.1)), the initial condition

$$x = \frac{1}{2}: \quad u = b(t), \quad T_0 - T_1 \le t \le T_0, \tag{3.33}$$

and the boundary conditions

$$\begin{aligned} &t = T_0: \quad v_s = \Psi_s(x) \quad (s = m+1, \dots, n), \quad 0 \le x \le \frac{1}{2} \\ &\left(\text{resp.,} \quad t = T_0: \quad v_r = \Psi_r(x) \quad (r = 1, \dots, m), \quad \frac{1}{2} \le x \le 1\right). \end{aligned} \tag{3.34}$$

Similarly, the mixed initial-boundary value problem (3.13) and (3.33)–(3.34) has a unique C^1 solution on the domain

$$\begin{aligned} &\left\{(t,x)| \quad T_0 - 2T_1 x \le t \le T_0, \quad 0 \le x \le \frac{1}{2}\right\} \\ &\left(\text{resp.,} \quad T_0 + 2T_1(x-1) \le t \le T_0, \quad \frac{1}{2} \le x \le 1\right). \end{aligned} \tag{3.35}$$

Then it follows that

$$u(t,x) \equiv u^{(2)}(t,x) \tag{3.36}$$

on these domains, and, in particular, we obtain (3.28).

Thus we have finished the proof of Proposition 2.1, and then we get the local exact boundary controllability. In view of the proof, we see that the boundary controls are certainly not unique.

4. Remarks. We can consider the mixed initial-boundary value problem for the quasi-linear hyperbolic system (1.1) with the initial condition (1.10) and the following boundary conditions:

$$x = 0: \quad \widetilde{v}_s = \widetilde{g}_s(t, \widetilde{v}_1, \ldots, \widetilde{v}_m) + \widetilde{h}_s(t) \quad (s = m+1, \ldots, n), \tag{4.1}$$

$$x = 1: \quad \widetilde{v}_r = \widetilde{g}_r(t, \widetilde{v}_{m+1}, \ldots, \widetilde{v}_n) + \widetilde{h}_r(t) \quad (s = 1, \ldots, m), \tag{4.2}$$

where

$$\widetilde{v}_i = l_i(\phi(x))u \qquad (i = 1, \ldots, n), \tag{4.3}$$

and, without loss of generality, we assume that

$$\widetilde{g}_i(t, 0, \ldots, 0) \equiv 0 \qquad (i = 1, \ldots, n). \tag{4.4}$$

Following [9], for the C^1 solution $u = u(t, x)$ satisfying (1.15) with suitably small $\epsilon_0 > 0$, the mixed initial-boundary value problem (1.1), (1.10), and (4.1)–(4.2) is equivalent to the mixed initial-boundary value problem (1.1) and (1.10)–(1.12). Then we can also establish the exact boundary controllability for this problem. More precisely, T_0 being given by (1.17), for any given initial data ϕ and final data ψ with small $C^1[0, 1]$ norm, there exist boundary controls $\widetilde{h}_i$ $(i = 1, \ldots, n)$ with suitably small $C^1[0, T_0]$ norm such that the mixed initial-boundary value problem (1.1), (1.10), and (4.1)–(4.2) admits a unique C^1 solution $u = u(t, x)$ on the domain $R(T_0)$, which verifies the final condition (1.16).

Acknowledgments. The authors would like to thank the referees for their kind and valuable suggestions.

IMMERSION OF NONLINEAR SYSTEMS INTO LINEAR SYSTEMS MODULO OUTPUT INJECTION*

PHILIPPE JOUAN†

Abstract. The problem of the immersion of a SISO system into a linear up to an output injection one is studied in order to design Luenberger-like observers. Necessary and sufficient conditions are stated within a very general framework. Effective computations and examples are then provided.

Key words. immersion of nonlinear systems, linearization, output injection, observability

1. Introduction.

It has been well known for a long time that a controlled and observed system in $\mathbb{R}^n$ whose nonlinear part depends only upon the output admits Luenberger-like observers. More specifically, let us consider

$$\begin{cases} \dot{z} = Az + \varphi(u, Cz), \\ \xi = Cz, \end{cases} \tag{1.1}$$

where $z \in \mathbb{R}^n$, $\xi \in \mathbb{R}$, $u \in \mathbb{R}^p$, $A \in \mathcal{M}(n, \mathbb{R})$, and $C \in \mathcal{M}(1 \times n, \mathbb{R})$. Such a system will be referred to as a linear up to an output injection system. If the pair (C, A) is observable, we can choose a vector-column K such that the eigenvalues of $A - KC$ have arbitrary prescribed values. If their real parts are negative, then the system

$$\dot{\widehat{z}} = A\widehat{z} + \varphi(u, \xi) - K(C\widehat{z} - \xi) \tag{1.2}$$

is an observer for (1.1): denoting the error by $e = \widehat{z} - z$, it is straightforward that

$$\dot{e} = (A - KC)e.$$

Thus the error dynamics is linear and the error converges exponentially to zero.

Up to now, mainly the possibility to transform a given system into the form (1.1) by diffeomorphism was studied. In the paper [KI83], Krener and Isidori gave necessary and sufficient conditions to transform an uncontrolled, single-output system into (1.1). Then Krener and Respondek extended the results to MIMO systems (see [KR85]). In these two papers the transformations under consideration are (local) diffeomorphisms in the state space, together with a diffeomorphism in the output space in the second one (see also [BZ83], [XG89], [Phe91], [GMP96], [HG88], [HP99]).

Some generalizations of the output injection method have been recently proposed in order to enlarge the class of systems for which one can design an observer with linear error dynamics. Among them let us quote the output-dependent time-scale transformation [Gua01], the generalized output injection (after transformation the nonlinear term depends upon the output, the input, and some of its derivatives) [Kel87], and the completely generalized output injection [LPG99] (the nonlinear term

†Lab. R. Salem, CNRS UMR 6085, Université de Rouen, Mathématiques, site Colbert, 76821 Mont-Saint-Aignan Cedex, France (Philippe.Jouan@univ-rouen.fr).

depends, moreover, upon the derivatives of the output). In these papers, as well as in the previous ones, the state space is transformed by (local) diffeomorphism.

In the present paper we deal with the problem of the immersion of a given system into a linear up to an output injection one whose state space dimension may be greater, or lower, than the dimension of the initial state space. The precise definition of an immersion will be stated later (see Definition 2.2), but roughly speaking, a system Σ can be immersed into a system S if the input-output mapping of Σ, possibly followed by a diffeomorphism ψ of $\mathbb{R}$, is a restriction of the input-output mapping of S. The interest is twofold: on the one hand the class of systems into consideration is much wider; on the other hand it is well known that a generic uncontrolled system can be globally put in observable form by embedding but generically not by diffeomorphism. Therefore the transformation of systems by diffeomorphism will always keep a local character.

Among the literature let us mention [FK83], where the problem of the immersion into a bilinear system is studied, and [BRG89], where the immersion of a control-affine system into a linear up to an output injection one is studied under the very strong hypothesis that the drift system is linearizable.

We consider herein a smooth system defined on a manifold X,

$$\Sigma = \begin{cases} \dot{x} = f(x,u), \\ y = h(x), \end{cases}$$

where $u \in \mathbb{R}$ and $y \in \mathbb{R}$. (The paper mainly deals with control-affine systems; however, we start with general ones because the first reduction, stated in Theorem 2.3, is true in the general case.) This system will be said to be LIS (for the French *linéarisable par injection de sortie*) if it can be immersed into a linear up to an output injection one.

For instance, the reader can check that the uncontrolled system defined in $\mathbb{R}^2$ by

$$\begin{cases} \dot{x}_1 = x_2 \exp(-x_1), \\ \dot{x}_2 = \frac{1}{2}x_2^2 \exp(-x_1) + x_2 \exp(x_1) + 1, \\ y = h(x_1, x_2) = \exp(x_1) \end{cases}$$

is LIS because it can be immersed into the system defined in $\mathbb{R}^3$ by

$$\begin{cases} \dot{z_1} = z_2 + \frac{5}{6}y^2, \\ \dot{z_2} = z_3 + \ln y - \frac{2}{9}y^3, \\ \dot{z_3} = \quad -\frac{2}{3}y, \\ y = z_1, \end{cases}$$

the immersion being

$$\begin{cases} z_1 = \exp(x_1), \\ z_2 = x_2 - \frac{5}{6}\exp(2x_1), \\ z_3 = \frac{1}{2}x_2^2 \exp(-x_1) - \frac{2}{3}x_2 \exp(x_1) + \frac{2}{9}\exp(3x_1) - x_1 + 1. \end{cases}$$

We want to thank the anonymous reviewer who gave us this example, in a somewhat different form.

First at all we state in Theorem 2.3 that whenever this system is LIS, it can be

immersed into a system "in canonical form," that is, in the form

$$\begin{cases} \dot{z}_1 & = z_2 + \varphi_1(u, z_1), \\ \dot{z}_2 & = z_3 + \varphi_2(u, z_1), \\ \vdots & \vdots \\ \dot{z}_{n-1} & = z_n + \varphi_{n-1}(u, z_1), \\ \dot{z}_n & = \quad +\varphi_n(u, z_1), \\ \xi & = z_1. \end{cases}$$

This result leads in the uncontrolled case to Theorem 2.6: *An uncontrolled system is LIS if and only if there exist a smooth function ψ and n smooth functions φ_1, $\varphi_2, \ldots, \varphi_n$ such that*

$$(F) \qquad L_f^n \tilde{h} = L_f^{n-1}(\varphi_1 \circ \tilde{h}) + L_f^{n-2}(\varphi_2 \circ \tilde{h}) + \cdots + L_f(\varphi_{n-1} \circ \tilde{h}) + \varphi_n \circ \tilde{h},$$

where $\tilde{h} = \psi \circ h$.

Although this characterization involves unknown functions φ_i and ψ, it is fundamental for several reasons. In the first place it is very general because it is just as well global than local and because no assumption of observability is needed; then formula (F) will be systematically used to implement the computations; finally it is the starting point of the control-affine case. This last is studied in section 2.4, where Theorem 2.7 is stated: *A control-affine system whose dynamics is $\dot{x} = f(x) + ug(x)$ is LIS if and only if the following hold:*

1. *The uncontrolled part of the system is LIS.*
2. *If we denote by $\tau = (\tau_1, \ldots, \tau_n)$ the immersion of the uncontrolled part into a canonical system in $\mathbb{R}^n$, then for $i = 1, \ldots, n$ $L_g\tau_i$ is a smooth function of h.*

Moreover, at points x such that $dh(x) \neq 0$, condition 2 is equivalent to

$$dL_g\tau_i \wedge dh = 0.$$

After these theoretical results the second part of the paper is devoted to computational ones. The actual computation of the functions φ_i involved in formula (F), necessary to decide whether a given system can be immersed into a linear up to an output injection one, is not easy and we start with systems whose drift part is in observable form:

$$\Sigma = \begin{cases} \dot{x}_1 = x_2 & + ug_1(x), \\ \dot{x}_2 = x_3 & + ug_2(x), \\ \cdots & \cdots \\ \dot{x}_d = \Phi(x_1, x_2, \ldots, x_d) & + ug_d(x), \\ y = h(x) = x_1, \end{cases}$$

where $d = \dim(X)$, this last condition ensuring the uniqueness of $\Phi(x_1, x_2, \ldots, x_d)$. We also assume that no diffeomorphism in the output space is necessary ($\psi = Id_{\mathbb{R}}$). It turns out that the control-affine case is easier to deal with than the uncontrolled one because there are additional conditions that avoid to solve (untractable) differential equations. Thus the computation process is complete in the SISO control-affine case (with the slight restriction $g_1 \neq 0$).

2. Theoretical results.

2.1. Definitions and notations. Let X be a $\mathcal{C}^\infty$, connected manifold. We consider on X the system

$$\Sigma = \begin{cases} \dot{x} = f(x,u), \\ y = h(x), \end{cases} \tag{2.1}$$

where $x \in X$, $u \in \mathbb{R}$, and $y \in \mathbb{R}$. The parametrized vector field f and the output function h are assumed to be $\mathcal{C}^\infty$. We define the open interval $I_o =]a,b[$, where $a, b \in \overline{\mathbb{R}}$, w.r.t. the range $h(X)$ of h in the following way: if the lower bound α of $h(X)$ is finite and $h(X)$ is closed at α, then $a = -\infty$, otherwise $a = \alpha$; if the upper bound β of $h(X)$ is finite and $h(X)$ is closed at β, then $b = +\infty$, otherwise $b = \beta$.

In view of Definition 2.1 we denote by A_c the (n-dimensional) antishift matrix, that is, the $n \times n$ matrix

$$A_c = \begin{pmatrix} 0 & 1 & 0 & \cdots & 0 \\ 0 & 0 & 1 & \cdots & 0 \\ \vdots & \vdots & & \ddots & \vdots \\ & & & \ddots & 1 \\ 0 & 0 & & & 0 \end{pmatrix},$$

and by C_c the $1 \times n$ matrix $C_c = (1, 0, \ldots, 0)$.

Definition 2.1. *Let E be a finite-dimensional vector space; let $A \in L(E)$ be an endomorphism of E and $C \in L(E, \mathbb{R})$ be a linear form. Let I be an open interval and $\varphi \in \mathcal{C}^\infty(I \times \mathbb{R}; E)$. The system Σ_L,*

$$\Sigma_L = \begin{cases} \dot{z} = Az + \varphi(Cz, u), \\ \xi = Cz, \end{cases} \tag{2.2}$$

defined on the pullback L of I by C is said to be linear up to an output injection.

When $E = \mathbb{R}^n$, the linear mappings A and C are identified with their matrices in the canonical basis, and Σ_L is said to be in canonical form if $A = A_c$ and $C = C_c$.

Remarks.

1. When a linear up to an output injection system Σ_{Lc} is in canonical form, the output function is $z \longmapsto z_1$ and the state space is $L = I \times \mathbb{R}^{n-1}$.
2. We will say that Σ_L is observable if so is the pair (C, A). It is easy to check that as well as in the linear case, whenever Σ_L is observable, it is observable for every input in the sense that for a L^∞ input being given, any two different states are distinguished by the output on any nontrivial time interval. Notice that, in particular, Σ_{Lc} is observable.

Let $u \in L^\infty([0, T_u[)$ be an input and let $x \in X$ (resp., $z \in E$). We denote by $x(t)$ (resp., $z(t)$) the solution of (2.1) (resp., (2.2)) for this input that verifies the initial condition $x(0) = x$ (resp., $z(0) = z$). These solutions are, respectively, defined on $[0, T_x[$ and $[0, T_z[$.

Definition 2.2. *An* immersion *of the system Σ into the system Σ_L is a couple (τ, ψ), where τ is a $\mathcal{C}^\infty$ mapping from X into E and ψ is a $\mathcal{C}^\infty$ diffeomorphism from I_o onto $\psi(I_o) \subset I$, that verifies the following property.*

For every input $u \in L^\infty([0, T_u[)$ and for every initial condition $x \in X$, if $z = \tau(x)$, then $T_x \leq T_z$ and

$$\psi \circ h[x(t)] = Cz(t) \qquad \forall t \in [0, T_x[.$$

This definition is rather weak because only the input-output mappings are involved; for a stronger one we could require that the trajectories of Σ are applied on those of Σ_L. But it is a general fact that these two requirements are equivalent whenever Σ_L is observable for every input and the forthcoming reduction will show that Σ_L can always be so chosen.

In what follows, a system that can be immersed into a linear up to an output injection one will be called LIS. A linear up to an output injection system in canonical form will be called a LIS system in canonical form.

2.2. First reduction.

THEOREM 2.3. *If the system Σ is LIS, then it can be immersed into a linear up to an output injection system in canonical form (hence observable). Moreover, the mapping τ applies in that case the trajectories of* (2.1) *onto the trajectories of* (2.2), *i.e., for every input $u \in L^\infty([0, T_u[)$ and for every initial condition $x \in X$ the image $\tau[x(t)]$ of $x(t)$ by τ is a trajectory of* (2.2).

In order to prove this theorem we state two very simple lemmas.

LEMMA 2.4. *If the system Σ can be immersed into a linear up to an output injection system, then it can be immersed into an observable one.*

Proof of Lemma 2.4. Let us assume that (τ, ψ) is an immersion of Σ into Σ_L and let

$$V = \bigcap_{i=0}^{+\infty} \ker CA^i$$

be the unobservable subspace of (C, A). If Σ_L is not observable, then $V \neq \{0\}$, but we can define an observable, linear up to an output injection system on the quotient space E/V in the same way as in the linear case. Let p be the projection of E onto E/V and consider

$$\begin{array}{lll} \widetilde{A} \in L(E/V) & \text{defined by} & \widetilde{A}(pz) = p(Az); \\ \widetilde{C} \in L(E/V; \mathbb{R}) & \text{defined by} & \widetilde{C}(pz) = Cz; \\ \widetilde{\varphi} \in \mathcal{C}^\infty(I \times \mathbb{R}; E/V) & \text{defined by} & \widetilde{\varphi} = p \circ \varphi; \\ \widetilde{\tau} \in \mathcal{C}^\infty(X; E/V) & \text{defined by} & \widetilde{\tau} = p \circ \tau. \end{array}$$

We have to show that the couple $(\widetilde{\tau}, \psi)$ is an immersion of Σ into the system

$$\widetilde{\Sigma}_L = \begin{cases} \dot{\widetilde{z}} = \widetilde{A}\widetilde{z} + \widetilde{\varphi}(\widetilde{C}\widetilde{z}, u), \\ \xi = \widetilde{C}\widetilde{z} \end{cases} \tag{2.3}$$

in the sense of Definition 2.2.

Let $u \in L^\infty([0, T_u[)$, $x \in X$, and $z = \tau(x)$. The solution of (2.3) issued from $p(z)$ is $p[z(t)]$; therefore

$$\forall t \in [0, T_x[\qquad \widetilde{C}p[z(t)] = Cz(t) = \psi \circ h[x(t)]$$

and Lemma 2.4 is proved. □

LEMMA 2.5. *We keep the conditions and notations of Lemma* 2.4. *Then for every $u \in L^\infty([0, T_u[)$ and $x \in X$*

$$\widetilde{\tau}[x(t)] = p[z(t)].$$

Proof of Lemma 2.5. Let $u \in L^\infty([0, T_u[)$ and $x \in X$. We want to show that

$$\forall t \in [0, T_x[\qquad \widetilde{\tau}[x(t)] = p[z(t)].$$

Let $t_0 \in [0, T_x[$, let $\widetilde{z}_0 = \widetilde{\tau}(x(t_0))$, and let $t \longmapsto \widetilde{z}(t)$ be the trajectory of (2.3) issued from $\widetilde{z}_0$ for the input v defined on $[0, T_u - t_0[$ by $v(t) = u(t_0 + t)$. We have

$$\begin{aligned} \forall t \in [0, T_x - t_0[\qquad \widetilde{C}\widetilde{z}(t) &= \psi \circ h[x(t_0 + t)] \\ &= Cz(t_0 + t) \\ &= \widetilde{C}p[z(t_0 + t)]. \end{aligned}$$

But the system $\widetilde{\Sigma}_L$ is observable and this equality implies

$$\widetilde{z}(0) = p[z(t_0)].$$

Therefore

$$\widetilde{\tau}(x(t_0)) = p[z(t_0)]. \qquad \square$$

Proof of Theorem 2.3. The system $\widetilde{\Sigma}_L$ being observable, so is the pair (C, A). We know by the linear theory that we can choose a basis in E/V in which

$$\widetilde{A} \equiv \begin{pmatrix} * & 1 & 0 & \cdots & 0 \\ * & 0 & 1 & \cdots & 0 \\ \vdots & \vdots & & \ddots & \vdots \\ & & & \ddots & 1 \\ * & 0 & & & 0 \end{pmatrix} \qquad \text{and } \widetilde{C} \equiv (1, 0, \ldots, 0).$$

The first column of $\widetilde{A}$ is a linear function of the output and can be added to $\widetilde{\varphi}$ in order to obtain in $\mathbb{R}^{\dim E/V}$ a system in canonical form. This choice of coordinates induces an isomorphism between E/V and $\mathbb{R}^{\dim E/V}$; $\widetilde{\tau}$ followed by this isomorphism, together with ψ, is clearly a suitable immersion. $\square$

Observability. This first reduction has some immediate consequences on the observability of LIS systems. Let us recall that an input is universal if it distinguishes between any two states that can be distinguished by at least one input (see [Sus79]). As a first result of Theorem 2.3 we can see at once that every input is universal for a LIS system. In particular, an observable and LIS system is observable for every input in the sense defined in the above remarks.

However, the universality of all inputs is not a characterization of LIS systems. Pick any uncontrolled system in observable form: it can be the drift part of a uniformly observable control affine system (see [GHO92]) without being LIS.

Despite this fact, no assumption of observability will be needed in the forthcoming results.

2.3. The uncontrolled case.

2.3.1. Main result. In this section we deal with uncontrolled systems:

$$\Sigma_u = \begin{cases} \dot{x} = f(x), \\ y = h(x). \end{cases} \tag{2.4}$$

THEOREM 2.6. *The uncontrolled system Σ_u is LIS if and only if there exist a function ψ belonging to $\mathcal{C}^\infty(I_o,\mathbb{R})$, an integer n, and n functions φ_1, $\varphi_2,\ldots,$ φ_n belonging to $\mathcal{C}^\infty(\psi(I_o),\mathbb{R})$ such that*

$$(F)\qquad L_f^n\tilde{h} = L_f^{n-1}(\varphi_1\circ\tilde{h}) + L_f^{n-2}(\varphi_2\circ\tilde{h}) + \cdots + L_f(\varphi_{n-1}\circ\tilde{h}) + \varphi_n\circ\tilde{h},$$

where $\tilde{h} = \psi\circ h$.

Proof of Theorem 2.6. Let us assume that Σ_u is LIS. Then, by Theorem 2.3, it can be immersed into a canonical system:

$$(2.5)\qquad \Sigma_{uc} = \begin{cases} \dot{z} = A_c z + \varphi(C_c z), \\ \xi = C_c z \end{cases} = \begin{cases} \dot{z}_1 &= z_2 + \varphi_1(z_1), \\ \dot{z}_2 &= z_3 + \varphi_2(z_1), \\ &\vdots \\ \dot{z}_{n-1} &= z_n + \varphi_{n-1}(z_1), \\ \dot{z}_n &= \varphi_n(z_1), \\ \xi = z_1. \end{cases}$$

Let (τ,ψ), with $\tau = (\tau_1,\ldots,\tau_n)$, be the immersion of Σ_u into Σ_{uc}. We have $\psi\circ h = C_c\circ\tau = \tau_1$.

Let us assume that for an index k, $1\le k<n$, the following equality holds:

$$(2.6)\qquad \tau_k = L_f^{k-1}\tilde{h} - L_f^{k-2}(\varphi_1\circ\tilde{h}) - \cdots - L_f(\varphi_{k-2}\circ\tilde{h}) - \varphi_{k-1}\circ\tilde{h}.$$

Let $x\in X$ and let us denote by $x(t)$ the solution of $\dot{x}=f(x)$ that verifies $x(0)=x$. Then

$$\begin{aligned}\tau_{k+1}(x) &= \frac{d}{dt}\tau_k(x(t))|_{t=0} - \varphi_k(\psi\circ h(x)) \\ &= L_f^k\tilde{h}(x) - L_f^{k-1}(\varphi_1\circ\tilde{h})(x) - \cdots - L_f(\varphi_{k-1}\circ\tilde{h})(x) - (\varphi_k\circ\tilde{h})(x).\end{aligned}$$

Moreover,

$$\begin{aligned}\varphi_n(\tilde{h}(x)) &= \frac{d}{dt}\tau_n(x(t))|_{t=0} \\ &= L_f^n\tilde{h}(x) - L_f^{n-1}(\varphi_1\circ\tilde{h})(x) - \cdots - L_f(\varphi_{n-1}\circ\tilde{h})(x)\end{aligned}$$

and formula (F) holds.

Conversely, if formula (F) holds, let

$$\begin{cases} \tau_1 = \psi\circ h, \\ \tau_{k+1} = L_f\tau_k - \varphi_k\circ\psi\circ h \qquad \text{for } 1\le k<n. \end{cases}$$

Let $\tau=(\tau_1,\ldots,\tau_n)$ and $\tilde{h}=\psi\circ h$.

For $k=1,\ldots,n-1$ we have by induction

$$\frac{d}{dt}\tau_k(x(t)) = L_f\tau_k(x(t)) = \tau_{k+1}(x(t)) + \varphi_k(\tilde{h}(x(t)));$$

hence

$$\tau_{k+1} = L_f^k\tilde{h} - L_f^{k-1}(\varphi_1\circ\tilde{h}) - \cdots - L_f(\varphi_{k-1}\circ\tilde{h}) - \varphi_k\circ\tilde{h}.$$

In the end

$$\begin{aligned}\frac{d}{dt}\tau_n(x(t)) &= L_f\tau_n(x(t))\\ &= \left(L_f^n\tilde{h} - L_f^{n-1}(\varphi_1\circ\tilde{h}) - L_f^{n-2}(\varphi_2\circ\tilde{h}) - \cdots - L_f(\varphi_{n-1}\circ\tilde{h})\right)(x(t))\\ &= \varphi_n(\tilde{h}(x(t)))\end{aligned}$$

and (τ,ψ) is an immersion of Σ_u into

$$\Sigma_{uc} = \begin{cases} \dot{z} = A_c z + \varphi(C_c z),\\ \xi = z_1, \end{cases}$$

where $\varphi = {}^T(\varphi_1,\ldots,\varphi_n)$. □

Remarks.

1. Clearly the functions $\varphi_1,\ldots,\varphi_{n-1}$ are defined up to a constant. But they need not be unique, even up to a constant, as the forthcoming Example 1 will show.
2. Formula (2.6), which gives τ_k as a function of the φ_i's, will be useful later to do the effective computations.

2.3.2. Existence of LIS systems. At a point x^0 where $f(x^0)\neq 0$ we can choose coordinates $(x_1,\ldots,x_d)$ such that $f\equiv\frac{\partial}{\partial x_1}$ in a neighborhood of x^0. In these coordinates, and in the case where $\psi = Id$, formula (F) becomes

$$(F') \qquad \frac{\partial^n}{\partial x_1^n}h = \frac{\partial^{n-1}}{\partial x_1^{n-1}}(\varphi_1\circ h) + \cdots + \frac{\partial}{\partial x_1}(\varphi_{n-1}\circ h) + \varphi_n\circ h.$$

Now we can consider $\varphi_1,\ldots,\varphi_n$ (defined on an interval I) as data and (F') as a differential equation whose unknown is h. Setting $\widehat{x} = (x_2,\ldots,x_d)$, we can choose initial conditions x_1^0 and $y_k(\widehat{x})$, for $k=0,\ldots,n-1$, defined in an open subset U of I^{d-1} and smoothly depending on $\widehat{x}$. Then there exists a smooth function h defined in a neighborhood of $\{x_1^0\}\times U$ that is solution of (F') and verifies

$$\frac{\partial^k h}{\partial x_1^k}(x_1^0,\widehat{x}) = y_k(\widehat{x}) \qquad \text{for } k=0,\ldots,n-1.$$

Thus for any choice of the integer n and of the functions φ_i, there exist functions h that verify equation (F'). All these solutions of (F'), possibly composed with diffeomorphisms ψ, form the class of the universal solutions of the LIS problem at a regular point of the vector field. Notice that we can, moreover, choose the $y_k(\widehat{x})$'s in such a way that the system is observable (if $n\geq d$), at least in a neighborhood of $\{x_1^0\}\times U$.

2.4. The control-affine case. In this section we consider systems whose vector field is affine w.r.t. the control. The general setting of these systems is

$$\Sigma = \begin{cases} \dot{x} = f(x) + ug(x),\\ y = h(x), \end{cases} \tag{2.7}$$

where f and g belong to $V^\infty(X)$, the set of C^∞-vector fields on X.

Let us assume that Σ is LIS and can be immersed into the system in canonical form:

$$S = \begin{cases} \dot{z} = A_c z + \varphi(C_c z) + u\gamma(C_c z), \\ \xi = C_c z, \end{cases} \tag{2.8}$$

where $z \in \mathbb{R}^n$.

Clearly the uncontrolled system

$$\Sigma U = \begin{cases} \dot{x} = f(x), \\ y = h(x) \end{cases} \tag{2.9}$$

is also LIS and can be immersed into

$$SU = \begin{cases} \dot{z} = A_c z + \varphi(C_c z), \\ \xi = C_c z. \end{cases} \tag{2.10}$$

This remark leads to the following statement.

THEOREM 2.7. *The control-affine system Σ is LIS if and only if the following hold:*

1. *The drift system ΣU is LIS.*
2. *If we denote by (τ, ψ), with $\tau = (\tau_1, \dots, \tau_n)$, the immersion of ΣU into a LIS system in canonical form in $\mathbb{R}^n$, then there exist smooth functions γ_i, $i = 1, \dots, n$, such that*

$$L_g \tau_i = \gamma_i \circ (\psi \circ h).$$

Moreover, at points x such that $dh(x) \neq 0$, condition 2 is locally equivalent to

$$dL_g \tau_i \wedge dh = 0.$$

Proof of Theorem 2.7.

(i) Proof of the necessity part. As we have just remarked, if (τ, ψ) is an immersion of Σ into S, then it is also an immersion of ΣU into SU and condition 1 holds. Let us show that condition 2 holds as well.

Let u be a constant control and $x \in X$. Let $x(t)$ be the solution of Σ for the constant input u and for the initial condition $x(0) = x$. By Theorem 2.3 the solution of S for the input u and the initial condition $z(0) = \tau(x)$ is $z(t) = \tau[x(t)]$.

Differentiating $\tau_i[x(t)] = z_i(t)$ at $t = 0$, we get for all x, u, and i

$$L_f \tau_i(x) + uL_g \tau_i(x) = L_F z_i(\tau(x)) + uL_\gamma z_i(\tau(x)),$$

where F (resp., γ) stands for the vector field $z \longmapsto A_c z + \varphi(C_c z)$ (resp., $z \longmapsto \gamma(C_c z)$) in $\mathbb{R}^n$.

Therefore

$$\begin{aligned} \forall x \in X \qquad L_g \tau_i(x) &= L_\gamma z_i(\tau(x)) \\ &= \gamma_i(C_c \tau(x)) \\ &= \gamma_i(\psi \circ h)(x), \end{aligned}$$

where γ_i denotes the ith component of γ.

(ii) Sufficiency. We assume now that conditions 1 and 2 hold. By condition 1, and because SU is observable, we know by Theorem 2.3 that the trajectories of the uncontrolled system ΣU are applied by τ on those of SU. Therefore we have

$$\forall x \in X \qquad L_f \tau_i(x) = L_F z_i(\tau(x)),$$

where again F stands for the vector field $z \longmapsto A_c z + \varphi(C_c z)$.

We also know that $C_c \circ \tau = \psi \circ h$ and, in order to prove that (τ, ψ) is an immersion of Σ into S, it is enough to show that for any input the mapping τ applies the trajectories of Σ onto those of S, where the vector field γ is defined by

$$\gamma(z) = (\gamma_1(C_c z), \gamma_2(C_c z), \ldots, \gamma_n(C_c z)) .$$

Let $u \in L^\infty[0, T_u[$ be an input and $t \mapsto x(t)$ a trajectory of Σ for this input.

We have almost everywhere

$$\begin{aligned} \frac{d}{dt}\tau_i[x(t)] &= L_f \tau_i[x(t)] + u(t) L_g \tau_i[x(t)] \\ &= L_F z_i[\tau(x(t))] + u(t)(\gamma_i \circ (\psi \circ h))[x(t)] \\ &= L_F z_i[\tau(x(t))] + u(t)\gamma_i(C_c \tau)[x(t)]. \end{aligned}$$

This computation proves that $\tau[x(t)]$ is a solution of S and ends the proof.

(iii) Regular points. The condition

$$L_g \tau_i = \gamma_i \circ (\psi \circ h)$$

always implies

$$dL_g \tau_i \wedge dh = d(\gamma_i \circ (\psi \circ h)) \wedge dh = 0.$$

Conversely let us assume that locally $dh(x) \neq 0$ and

$$dL_g \tau_i \wedge dh = 0.$$

Let us choose local coordinates $x_1, x_2, \ldots, x_d$ such that $h(x) = x_1$. In these coordinates, $L_g \tau_i$ is a function of x_1, hence, a function γ_i of $\psi \circ h = \psi(x_1)$. □

Remarks.

1. The conditions stated in Theorem 2.7 are very strong. Let us, for instance, assume that τ is an embedding from X into $\mathbb{R}^n$; $\tau(X)$ is then a submanifold of $\mathbb{R}^n$. The value of $\tau_* g$ at a point $z \in \tau(X)$ depends only on the value z_1 of the first coordinate of z. Thus all the subspaces of $\mathbb{R}^n$ tangent to $\tau(X)$ at points z such that $z_1 = z_1^0$ contain $\tau_* g(z^0)$ and, if we assume $\tau_* g(z^0) \neq 0$, their intersection must be different from $\{0\}$.
   These conditions, somewhat hidden, are used further to compute the immersion τ in the control-affine case.
2. In the paper [BRG89] the immersion of a control-affine system into a linear up to an output injection one is studied in the case where the drift system is linearizable. The necessary and sufficient conditions stated in that paper seem to be more intrinsic than those of Theorem 2.7 because they do not involve the immersion τ of the drift system. More specifically, the drift system is assumed to be linearizable, and the conditions stated in [BRG89] turn out to be

$$d\left(L_g L_f^k h\right) \wedge dh = 0 \quad \forall k.$$

But these conditions are no longer true in the more general case dealt with herein.

Example.

$$\Sigma = \begin{cases} \dot{z}_1 &= z_2 + z_1^2 + uz_1, \\ \dot{z}_2 &= z_3 + z_1^2 + uz_1, \\ & . \\ & . \\ \dot{z}_{n-1} &= z_n + z_1^2 + uz_1, \\ \dot{z}_n &= z_1^2 + uz_1, \\ y &= h(z) = z_1. \end{cases} \tag{2.11}$$

The system is LIS. However,

$$\begin{aligned} L_f h(z) &= z_2 + z_1^2, \\ L_f^2 h(z) &= z_3 + z_1^2 + 2z_1(z_2 + z_1^2) \\ &= z_3 + z_1^2 + 2z_1^3 + 2z_1 z_2, \\ L_g L_f^2 h(z) &= (1 + 2z_1 + 6z_1^2 + 2z_1 + 2z_2)z_1 \\ &= z_1 + 4z_1^2 + 6z_1^3 + 2z_1 z_2. \end{aligned}$$

Hence

$$dL_g L_f^2 h \wedge dh = -2z_1 dz_1 \wedge dz_2 \neq 0.$$

3. Computational results. The purpose of this section is to actually check if a given system is LIS and to compute the functions φ_k or, equivalently, the coordinate functions τ_k of the immersion in an LIS system in canonical form.

We shall always start with a system whose drift part is in observable form, that is, a system in the form

$$\Sigma = \begin{cases} \dot{x}_1 &= x_2 &+ ug_1(x), \\ \dot{x}_2 &= x_3 &+ ug_2(x), \\ \cdots & & \cdots \\ \cdots & & \cdots \\ \dot{x}_d &= \Phi(x) &+ ug_d(x), \\ y &= h(x) &= x_1, \end{cases} \tag{3.1}$$

where $x = (x_1, \ldots, x_d)$ and where d is the dimension of the state space X. This is of course a restriction because generically there exist points of the state space where the observable form can be obtained only in dimension strictly greater than the dimension of the state space, but at the present time we do not know how to do the computations at these points. Moreover, we shall always assume the function ψ that appears in Definition 2.2 to be equal to the identity of $\mathbb{R}$.

The computations are easier in the controlled case, but they make use of a general form of certain extensions of the drift system, and in the first place we are going to study uncontrolled systems.

3.1. The uncontrolled case. As we have just said, we assume that the system Σ is in observable form:

$$\Sigma = \begin{cases} \dot{x}_1 = x_2, \\ \dot{x}_2 = x_3, \\ \cdots \\ \dot{x}_d = \Phi(x_1, x_2, \dots, x_d), \\ y = h(x) = x_1. \end{cases} \tag{3.2}$$

The requirement $d = \dim X$, i.e., the requirement that the observable form is obtained by diffeomorphism, is very important because in that case the function Φ is unique. If Σ can be embedded in the system

$$\Sigma_n = \begin{cases} \dot{x}_1 = x_2, \\ \dot{x}_2 = x_3, \\ \cdots \\ \dot{x}_n = \theta(x_1, x_2, \dots, x_n), \\ y = h(x) = x_1, \end{cases} \tag{3.3}$$

we will say that Σ_n is *an extension at the order* n of Σ. If Σ_n is, moreover, LIS by diffeomorphism, we will say that Σ_n is *a LIS extension at the order* n of Σ. We can use existing algorithms to check whether Σ_n is LIS by diffeomorphism or not (see, for instance, [KI83], [Phe91], [GMP96]). But of course such an extension at order n is not unique as soon as $n > d$ and the problem is to choose the function θ in order to get an LIS one if it exists.

Let us denote by

$$f = \sum_{i=1}^{d-1} x_{i+1} \frac{\partial}{\partial x_i} + \Phi(x_1, x_2, \dots, x_d) \frac{\partial}{\partial x_d}$$

the vector field of (3.2) and by

$$F = \sum_{i=1}^{n-1} x_{i+1} \frac{\partial}{\partial x_i} + \theta(x_1, x_2, \dots, x_n) \frac{\partial}{\partial x_n}$$

the one of (3.3).

The first thing to notice is that (3.3) is an extension at the order n of (3.2) if and only if

$$\theta(x, L_f^d h(x), L_f^{d+1} h(x), \dots, L_f^{n-1} h(x)) = L_f^n h(x), \tag{3.4}$$

where $x = (x_1, x_2, \dots, x_d)$.

If, moreover, (3.3) is LIS by a change of variables, we can find functions φ_i, $i = 1, \dots, n$, such that

$$\theta(x_1, \dots, x_n) = L_F^{n-1}[\varphi_1(x_1)] + \cdots + L_F[\varphi_{n-1}(x_1)] + \varphi_n(x_1). \tag{3.5}$$

In this formula, we can compute the terms where $x_{d+1}, \dots, x_n$ appear, and then, combining this with formula (3.4), we can obtain the general form of θ in the case where (3.3) is an LIS extension of (3.2).

Let us first consider the case $n = d + 1$.

3.1.1. Extension at order $d+1$.

PROPOSITION 3.1. *If* (3.2) *admits an LIS extension* (3.3) *at order* $d+1$*, then the mapping* θ *that appears in* (3.3) *has the following form:*

$$\theta = L_f^{d+1}h(x) + \varphi_1'(x_1)\left(x_{d+1} - L_f^d h(x)\right),$$

where $x = (x_1, x_2, \dots, x_d)$*. Moreover,* φ_1' *is equal to*

$$\varphi_1' = \frac{\partial^2 L_f^{d+1}h}{\partial x_d^2}\left(\frac{\partial^2 L_f^d h}{\partial x_d^2}\right)^{-1}$$

if $\frac{\partial^2}{\partial x_d^2}L_f^d h(x) \neq 0$ *and* $d > 2$*. Otherwise* φ_1' *is solution of the first order linear differential equation*

$$\varphi_1'' + \varphi_1'\frac{\partial^2}{\partial x_2 \partial x_d}L_f^d h = \frac{\partial^2}{\partial x_2 \partial x_d}L_f^{d+1}h$$

if $d > 2$*, and*

$$2\varphi_1'' + \varphi_1'\frac{\partial^2}{\partial x_2^2}L_f^d h = \frac{\partial^2}{\partial x_2^2}L_f^{d+1}h$$

if $d = 2$.

Proof of Proposition 3.1.

1. Let us prove the first assertion: the only term of formula (3.5) in which x_{d+1} appears is $L_F^d[\varphi_1(x_1)]$ (see the appendix):

$$L_F^d[\varphi_1(x_1)] = x_{d+1}\varphi_1'(x_1) + \text{terms in } x_1, \dots, x_d.$$

Therefore we have

$$\theta(x, x_{d+1}) = x_{d+1}\varphi_1'(x_1) + \Lambda(x),$$

where Λ does not depend on x_{d+1}, and

$$L_f^{d+1}h(x) = \theta(x, L_f^d h(x)) = L_f^d h(x)\varphi_1'(x_1) + \Lambda(x).$$

Consequently

$$\Lambda(x) = L_f^{d+1}h(x) - L_f^d h(x)\varphi_1'(x_1)$$

and

$$\theta(x, x_{d+1}) = L_f^{d+1}h(x) + \varphi_1'(x_1)\left(x_{d+1} - L_f^d h(x)\right).$$

2. Let us now compute φ_1'. In formula (3.5) x_d appears only in the terms

$$L_F^d[\varphi_1(x_1)] = x_{d+1}\varphi_1'(x_1) + x_2 x_d \varphi_1''(x_1) + \text{terms in } x_1, \dots, x_{d-1}$$

and

$$L_F^{d-1}[\varphi_2(x_1)] = x_d\varphi_2'(x_1) + \text{terms in } x_1, \dots, x_{d-1}.$$

Replacing x_{d+1} by $L_f^d h(x)$ we get

$$L_f^{d+1}h(x) = L_f^d h(x)\varphi_1'(x_1) + x_2 x_d \varphi_1''(x_1) + x_d \varphi_2'(x_1) + \text{terms in } x_1, \ldots, x_{d-1}$$

and then, differentiating w.r.t. x_d,

$$\frac{\partial L_f^{d+1}h}{\partial x_d} = \frac{\partial L_f^d h}{\partial x_d}\varphi_1'(x_1) + x_2\varphi_1''(x_1) + \varphi_2'(x_1)$$

if $d > 2$, and

$$\frac{\partial L_f^3 h}{\partial x_2} = \frac{\partial L_f^2 h}{\partial x_2}\varphi_1'(x_1) + 2x_2\varphi_1''(x_1) + \varphi_2'(x_1)$$

if $d = 2$.

If $d > 2$ let us differentiate one more time w.r.t x_d. We get

$$\frac{\partial^2 L_f^{d+1}h}{\partial x_d^2} = \frac{\partial^2 L_f^d h}{\partial x_d^2}\varphi_1'$$

and, if $\frac{\partial^2}{\partial x_d^2}L_f^d h(x) \neq 0$, this equality gives the result.

Otherwise, differentiating w.r.t x_2 we get

$$\varphi_1'' + \varphi_1' \frac{\partial^2}{\partial x_2 \partial x_d} L_f^d h = \frac{\partial^2}{\partial x_2 \partial x_d} L_f^{d+1} h$$

if $d > 2$, and

$$2\varphi_1'' + \varphi_1' \frac{\partial^2}{\partial x_2^2} L_f^2 h = \frac{\partial^2}{\partial x_2^2} L_f^3 h$$

if $d = 2$. □

Example 1. Let us consider the system defined in $]-1, +\infty[\times\mathbb{R}$ by

$$\left\{ \begin{array}{l} \dot{x}_1 = x_2, \\ \dot{x}_2 = \frac{x_2^2}{2x_1+2} + x_1 x_2 + x_2 + 1, \\ y = h(x_1, x_2) = x_1. \end{array} \right. \tag{3.6}$$

Thus we have

$$L_f^2 h(x) = \frac{x_2^2}{2x_1 + 2} + x_1 x_2 + x_2 + 1$$

and we can first remark that the system (2.11) is not LIS by diffeomorphism; hence in dimension 2, in any open subset of $]-1, +\infty[\times\mathbb{R}$, because we would have in that case

$$\begin{aligned} \Phi(x_1, x_2) = L_f^2 h(x) &= L_f[\varphi_1(h(x))] + \varphi_2(h(x)) \\ &= \varphi_1'(x_1)x_2 + \varphi_2(x_1), \end{aligned}$$

one has

$$L_f^3 h(x) = \frac{5}{2}x_2^2 + \frac{x_2}{x_1+1} + x_1^2 x_2 + 2x_1 x_2 + x_1 + x_2 + 1,$$

$$\frac{\partial L_f^3 h}{\partial x_2}(x) = 5x_2 + \frac{1}{x_1+1} + x_1^2 + 2x_1 + 1,$$

$$\frac{\partial^2 L_f^3 h}{\partial x_2^2}(x) = 5.$$

If the system is LIS at order 3, then φ_1 must verify

$$\varphi_1'' + \frac{1}{2}\frac{\partial^2 L_f^2 h}{\partial x_2^2}\varphi_1' = \frac{1}{2}\frac{\partial^2 L_f^3 h}{\partial x_2^2},$$

that is,

$$\varphi_1'' + \frac{1}{2(x_1+1)}\varphi_1' = \frac{5}{2}.$$

The general solution of this equation is

$$\varphi_1' = \frac{C}{\sqrt{x_1+1}} + \frac{5}{3}(x_1+1),$$

where $C \in \mathbb{R}$, and we set

$$\theta(x_1, x_2, x_3) = L_f^3 h + \varphi_1'(x_3 - \Phi).$$

In order to check whether the system is LIS at order 3 and to compute φ_2 and φ_3, we have to compute $\theta - L_F^2(\varphi_1(x))$, where F is the vector field of the system

$$\begin{cases} \dot{x}_1 = x_2, \\ \dot{x}_2 = x_3, \\ \dot{x}_3 = \theta(x_1, x_2, x_3), \\ y = x_1. \end{cases}$$

We get

$$\begin{aligned} \theta - L_F^2(\varphi_1(x_1)) &= x_2\left(\tfrac{1}{x_1+1} + x_1^2 + 2x_1 + 1 - \tfrac{5}{3}(x_1+1)^2\right) \\ &\quad + x_1 + 1 - \tfrac{5}{3}(x_1+1) \\ &\quad - \tfrac{C}{\sqrt{x_1+1}}(x_1x_2 + x_2 + 1). \end{aligned}$$

Let us take $C = 0$, hence $\varphi_1' = \frac{5}{3}(x_1+1)$, and

$$\theta - L_F^2(\varphi_1(x_1)) = x_2\left(\frac{1}{x_1+1} - \frac{2}{3}x_1^2 - \frac{4}{3}x_1 - \frac{2}{3}\right) - \frac{2}{3}(x_1+1).$$

We obtain

$$\begin{aligned} &\varphi_2 = \ln(x_1+1) - \tfrac{2}{9}x_1^3 - \tfrac{2}{3}x_1^2 - \tfrac{2}{3}x_1, \\ &\varphi_3 = -\tfrac{2}{3}(x_1+1). \end{aligned}$$

At the end the system can be immersed into

$$\begin{cases} \dot{z}_1 = z_2 + \frac{5z_1^2}{6} + \frac{5z_1}{3}, \\ \dot{z}_2 = z_3 + \ln(z_1+1) - \frac{2}{9}z_1^3 - \frac{2}{3}z_1^2 - \frac{2}{3}z_1, \\ \dot{z}_3 = \quad -\frac{2}{3}(z_1+1), \end{cases}$$

the immersion being given by

$$\begin{aligned} &\tau_1 = x_1, \\ &\tau_2 = x_2 - \frac{5x_1^2}{6} - \frac{5x_1}{3}, \\ &\tau_3 = \frac{x_2^2}{2x_1+2} - \frac{2}{3}x_1x_2 - \frac{2}{3}x_2 - \ln(x_1+1) + \frac{2}{9}x_1^3 + \frac{2}{3}x_1^2 + \frac{2}{3}x_1 + 1. \end{aligned}$$

In order to verify the result, one can differentiate τ_1, τ_2, and τ_3. As expected we obtain

$$\begin{cases} \dot{\tau_1} = \tau_2 + \frac{5y^2}{6} + \frac{5y}{3}, \\ \dot{\tau_2} = \tau_3 + \ln(y+1) - \frac{2}{9}y^3 - \frac{2}{3}y^2 - \frac{2}{3}y, \\ \dot{\tau_3} = \quad -\frac{2}{3}(y+1). \end{cases}$$

Remark on the nonuniqueness. In fact it is possible to give any value to the integration constant C of the differential equation. Let us set

$$\varphi' = \frac{C}{\sqrt{x_1+1}}.$$

This function φ' verifies the homogeneous equation

$$\varphi'' + \frac{1}{2(x_1+1)}\varphi' = 0;$$

hence the degree of

$$L_f^2\varphi = (x_1x_2 + x_2 + 1)\varphi'$$

w.r.t. x_2 is one. Therefore we can add φ' to φ_1' if we modify φ_2 and φ_3. This is due to the fact that the degree of Φ w.r.t. x_2 is 2: if φ' is a solution of the homogeneous equation

$$\varphi'' + \frac{1}{2}\frac{\partial\Phi}{\partial x_2^2}\varphi' = 0,$$

then $L_f^2\varphi$ verifies

$$L_f^2\varphi = \left(-\frac{x_2^2}{2}\frac{\partial\Phi}{\partial x_2^2} + \Phi\right)\varphi',$$

where the second degree term w.r.t. x_2 clearly vanishes.

3.1.2. Extension at order $n \geq d+2$. We can compute the general form of the function θ of an LIS extension in the same manner as in the case of the extension at order $d+1$. Each term of the formula

$$\theta(x_1, \dots, x_n) = L_F^{n-1}[\varphi_1(x_1)] + \cdots + L_F[\varphi_{n-1}(x_1)] + \varphi_n(x_1)$$

is a polynomial in $x_{d+1}, \dots, x_n$ with coefficients in $\mathcal{C}^\infty(\mathbb{R})[x_2, \dots, x_d]$. Therefore θ can be written

$$\theta(x, x_{d+1}, \dots, x_n) = P_{n,d}(x_{d+1}, \dots, x_n) + \Lambda(x),$$

where $P_{n,d}$ is a polynomial in the variables $x_{d+1}, \dots, x_n$ without constant term. These polynomials are universal and their computation is postponed to the appendix. Now we have also

$$\theta(x, L_f^d h(x), L_f^{d+1}h(x), \dots, L_f^{n-1}h(x)) = L_f^n h(x);$$

hence

$$L_f^n h(x) = P_{n,d}(L_f^d h(x), L_f^{d+1}h(x), \dots, L_f^{n-1}h(x)) + \Lambda(x)$$

and

$$\Lambda(x) = L_f^n h(x) - P_{n,d}(L_f^d h(x), L_f^{d+1} h(x), \dots, L_f^{n-1} h(x)).$$

In the end we get

$$\begin{aligned} \theta(x, x_{d+1}, \dots, x_n) &= L_f^n h(x) + P_{n,d}(x_{d+1}, \dots, x_n) \\ &\quad - P_{n,d}(L_f^d h(x), L_f^{d+1} h(x), \dots, L_f^{n-1} h(x)). \end{aligned} \tag{3.7}$$

In particular, if $n < 2d$, the degree of the polynomial $P_{n,d}$ w.r.t. each of the variables $x_{d+1}, \dots, x_n$ is one (see the appendix):

$$P_{n,d} = x_{d+1} Q_{n,d}^{d+1}(x) + \cdots + x_n Q_{n,d}^n(x),$$

where $Q_{n,d}^k \in \mathcal{C}^\infty(\mathbb{R})[x_2, \dots, x_d]$, $k = d+1, \dots, n$, and θ becomes

$$\theta(x, x_{d+1}, \dots, x_n) = L_f^n h(x) + \sum_{k=d+1}^{n} (x_k - L_f^{k-1} h(x)) Q_{n,d}^k(x).$$

At this point we would like to get some equation allowing us to compute at least φ_1 or one of its derivatives. But whenever $n > d+1$, it turns out that the above formulas lead to partial differential equations, involving not only at least φ_1 and φ_2, but also the equivalent of the function θ in an intermediate extension, and we do not know how to solve these equations in the uncontrolled case.

Fortunately there are additional conditions in the controlled one and these can be used to compute the functions φ_i in most cases.

3.2. The controlled case. We consider controlled systems in observable form,

$$\Sigma = \begin{cases} \dot{x}_1 = x_2 & + u g_1(x), \\ \dot{x}_2 = x_3 & + u g_2(x), \\ \cdots & \cdots \\ \cdots & \cdots \\ \dot{x}_d = \Phi(x_1, x_2, \dots, x_d) & + u g_d(x), \\ y = h(x) = x_1, & \end{cases} \tag{3.8}$$

where d is again equal to the dimension of the state space X.

Following the results of section 2.4, if there exists an embedding $\tau = (\tau_1, \dots, \tau_n)$ into an n-dimensional system in LIS canonical form, then this mapping must verify

$$dL_g \tau_i \wedge dx_1 = 0 \qquad \text{for } i = 1, \dots, n.$$

But, by section 2.3, we also know that

$$\tau_k = L_f^{k-1} h - L_f^{k-2}(\varphi_1 \circ h) - \cdots - L_f(\varphi_{k-2} \circ h) - \varphi_{k-1} \circ h$$

for $k = 1, \dots, n$.

Let us first notice the following proposition.

PROPOSITION 3.2. *If Σ is LIS, then*

(i) *g_1 and g_2 are functions of x_1 only;*

(ii) *for $k = 3, \dots, d$, g_k depends on $x_1, \dots, x_{k-1}$ only; more specifically g_k is a polynomial in the variables $x_2, \dots, x_{k-1}$ and its degree is one w.r.t. x_{k-1}.*

In particular, g does not depend on x_d.

Proof of Proposition 3.2. The proof merely uses the fact that $L_g \tau_k$ is a function of x_1 only.

- $\tau_1 = x_1$; hence $L_g\tau_1 = g_1$ and g_1 is a function of x_1 only.
- $\tau_2 = L_f h - \varphi_1(x_1) = x_2 - \varphi_1(x_1)$; hence $L_g\tau_2 = g_2 - \varphi_1'(x_1)g_1(x_1)$ and $g_2 = L_g\tau_2 + \varphi_1'(x_1)g_1(x_1)$ is a function of x_1 only.
- Let $3 \le k \le d$ and let us assume the property true for $g_1, \dots, g_{k-1}$. We have

$$\begin{aligned}\tau_k &= x_k - L_f^{k-2}(\varphi_1(x_1)) - \cdots - L_f(\varphi_{k-2}(x_1)) - \varphi_{k-1}(x_1)\\ &= x_k - x_{k-1}\varphi_1'(x_1) + \text{terms without } x_k, x_{k-1}.\end{aligned}$$

  Therefore

$$\begin{aligned}L_g\tau_k = g_k - x_{k-1}\varphi_1''(x_1)g_1(x_1) - \varphi_1'(x_1)g_{k-1}(x_1, \dots, x_{k-2})\\ + \text{terms in } x_1, \dots, x_{k-2} \text{ and } g_1, \dots, g_{k-2}.\end{aligned}$$

  The fact that g_k is a polynomial in the variables $x_2, \dots, x_{k-1}$ comes from the similar property for the functions $L_f^p(\varphi_i(x_1))$. □

Remarks.

1. The independence of g on x_d is crucial in the forthcoming computations.
2. The necessary conditions of Proposition 3.2 are stronger than the criterion of uniform observability stated in [GHO92]: a control affine SISO system whose drift part is in observable form is uniformly observable if and only if g_k is a function of $x_1, \dots, x_k$ only for $k = 1, \dots, d$.

Now the same kind of computations of the τ_k's for $k \ge d+1$ will give conditions on the φ_i's. For instance,

$$\begin{aligned}\tau_{d+1} &= L_f^d h - L_f^{d-1}(\varphi_1(x_1)) - \cdots - \varphi_d(x_1)\\ &= L_f^d h - x_d\varphi_1'(x_1) + \text{ terms without } x_d.\end{aligned}$$

Therefore

$$L_g\tau_{d+1} = L_g L_f^d h - x_d\varphi_1''(x_1)g_1(x_1) + \text{ terms without } x_d.$$

Since $L_g\tau_{d+1}$ has to be a function of x_1 only, we have

$$\frac{\partial}{\partial x_d} L_g L_f^d h = \varphi_1''(x_1)g_1(x_1). \tag{3.9}$$

If the system is LIS, the left-hand side of (3.9) does depend only upon x_1, and, if $g_1(x_1) \neq 0$, this provides $\varphi_1''(x_1)$, hence $\varphi_1'(x_1)$ up to a constant.

We can check if the drift system is LIS at order $d+1$ for a value of this constant. If not, we do the same with τ_{d+2}:

$$\begin{aligned}\tau_{d+2} &= L_f^{d+1}h - L_f^d(\varphi_1(x_1)) - L_f^{d-1}(\varphi_2(x_1)) - \cdots - \varphi_{d+1}(x_1)\\ &= L_f^{d+1}h - L_f^d(\varphi_1(x_1)) - x_d\varphi_2'(x_1) + \text{ terms without } x_d\end{aligned}$$

and

$$L_g\tau_{d+1} = L_g\left(L_f^{d+1}h - L_f^d(\varphi_1(x_1))\right) - x_d\varphi_2''(x_1)g_1(x_1) + \text{ terms without } x_d.$$

As $L_g\tau_{d+2}$ has to be a function of x_1 only, we have

$$\varphi_2''(x_1)g_1(x_1) = \frac{\partial}{\partial x_d}\left(L_g\left(L_f^{d+1}h - L_f^d(\varphi_1(x_1))\right)\right)$$

and, again, $\varphi_2'(x_1)$ is known up to a constant if $g_1(x_1) \neq 0$ and if the right-hand side depends only on x_1 for a value of the constant of φ_1'.

We know $\varphi_1'(x_1)$ and $\varphi_2'(x_1)$ up to constants, and we can check if the drift system is LIS at order $d+2$ for some values of these constants.

By induction we will have

$$\begin{aligned}\tau_{k+1} &= L_f^k h - L_f^{k-1}(\varphi_1(x_1)) - \cdots - L_f^{d-1}(\varphi_{k-d+1}(x_1)) - \cdots - \varphi_k \circ h \\ &= \zeta(x) - x_d \varphi_{k-d+1}'(x_1) + \text{ terms without } x_d,\end{aligned}$$

where $\zeta = L_f^k h - L_f^{k-1}(\varphi_1(x_1)) - \cdots - L_f^d(\varphi_{k-d+2}(x_1))$ is known up to some constants. If the system is LIS we must have

$$\varphi_{k-d+1}''(x_1) g_1(x_1) = \frac{\partial}{\partial x_d}\zeta.$$

If it is not possible to choose the constants in such a way that $\frac{\partial}{\partial x_d}\zeta$ is a function of x_1 only, then the system is not LIS. If this function depends on x_1 only, one has to check whether the system is LIS at order $k+1$. If the answer is negative, the computation continues at order $k+2$.

Thus the computation of the functions φ_i is quite easy whenever the first component g_1 of the vector field g vanishes on no nontrivial interval.

Example 2. Let us consider the system defined by

$$\left\{\begin{array}{l} \dot{x}_1 = x_2 + u\gamma(x_1), \\ \dot{x}_2 = \sqrt{1-(x_1+x_2-\delta(x_1))^2} + (\delta'(x_1)-1)x_2 \\ \qquad\qquad + u(\delta'(x_1)-1)\gamma(x_1), \\ y = h(x_1,x_2) = x_1, \end{array}\right. \tag{3.10}$$

where γ and δ are smooth functions from $\mathbb{R}$ into $\mathbb{R}$. The system is defined for

$$-1 < x_1 + x_2 - \delta(x_1) < 1$$

and we assume that γ vanishes on no nontrivial interval.

If an immersion $\tau = (\tau_1, \tau_2, \tau_3, \dots)$ into an LIS canonical system exists, then $L_g\tau_3$ is a function of x_1 only. Hence we compute

$$\begin{aligned}\tau_3 &= L_f^2 h - L_f(\varphi_1 \circ h) - \varphi_2 \circ h \\ &= \sqrt{1-(x_1+x_2-\delta(x_1))^2} + (\delta'(x_1)-1)x_2 - x_2\varphi_1'(x_1) - \varphi_2(x_1)\end{aligned}$$

and

$$\begin{aligned}L_g\tau_3 = {} & x_2\delta''(x_1)\gamma(x_1) + (\delta'(x_1)-1)^2\gamma(x_1) - x_2\varphi_1''(x_1)\gamma(x_1) \\ & - \varphi_1'(x_1)\gamma(x_1)(\delta'(x_1)-1) - \varphi_2'(x_1)\gamma(x_1).\end{aligned}$$

As $L_g\tau_3$ does not depend on x_2 we get $\delta''(x_1) - \varphi_1''(x_1) = 0$; hence

$$\varphi_1(x_1) = \delta(x_1) + Cx_1,$$

where C is a constant to be determined.

If the drift part of the system is LIS at order 3, the extension will be

$$\left\{\begin{array}{l} \dot{x}_1 = x_2, \\ \dot{x}_2 = x_3, \\ \dot{x}_3 = L_f^3 h + \varphi_1'\left(x_3 - L_f^2 h\right). \end{array}\right.$$

An easy computation gives

$$\begin{aligned} L_f^3 h + \varphi_1' \left(x_3 - L_f^2 h\right) = & -x_1 - x_2 + \delta(x_1) + \delta''(x_1) x_2^2 + (\delta'(x_1) - 1)^2 x_2 \\ & - (C+1)\sqrt{1 - (x_1 + x_2 - \delta(x_1))^2} \\ & + (\delta'(x_1) + C)((x_3 - \delta'(x_1) x_2 + x_2). \end{aligned}$$

As this expression must be polynomial w.r.t. x_2, we take $C = -1$, we get

$$L_f^3 h + \varphi_1' \left(x_3 - L_f^2 h\right) = -x_1 - x_2 + \delta(x_1) + \delta''(x_1) x_2^2 + (\delta'(x_1) - 1) x_3,$$

and, as $\varphi_1(x_1) = \delta(x_1) - x_1$,

$$L_f^3 h + \varphi_1' \left(x_3 - L_f^2 h\right) - L_F^2(\varphi_1(x_1)) = -x_1 - x_2 + \delta(x_1).$$

Consequently

$$\begin{aligned} \varphi_2(x_1) &= -x_1, \\ \varphi_3(x_1) &= \delta(x_1) - x_1 \end{aligned}$$

and the drift system can be immersed into

$$\left\{ \begin{array}{l} \dot{z_1} = z_2 + \delta(z_1) - z_1, \\ \dot{z_2} = z_3 - z_1, \\ \dot{z_3} = \qquad \delta(z_1) - z_1. \end{array} \right.$$

The immersion is given by

$$\begin{array}{rcl} \tau_1 & = & x_1, \\ \tau_2 & = & L_f h - \varphi_1(x_1), \\ & = & x_1 + x_2 - \delta(x_1), \\ \tau_3 & = & L_f^2 h - L_f(\varphi_1(x_1)) - \varphi_2(x_1), \\ & = & x_1 + \sqrt{1 - (x_1 + x_2 - \delta(x_1))^2}; \end{array}$$

hence

$$\begin{array}{rcl} L_g \tau_1 & = & \gamma(x_1), \\ L_g \tau_2 & = & 0, \\ L_g \tau_3 & = & \gamma(x_1) \end{array}$$

and the system can be immersed into

$$\left\{ \begin{array}{l} \dot{z_1} = z_2 + \delta(z_1) - z_1 + u\gamma(x_1), \\ \dot{z_2} = z_3 - z_1, \\ \dot{z_3} = \qquad \delta(z_1) - z_1 + u\gamma(x_1). \end{array} \right.$$

□

Appendix. In what follows F stands for the vector field

$$F = \sum_{i=1}^{n-1} x_{i+1} \frac{\partial}{\partial x_i},$$

the possible last term $\theta(x_1, x_2, \ldots, x_n) \frac{\partial}{\partial x_n}$ being of no importance.

In order to compute the universal polynomials $P_{n,d}$ of section 3.1.2, the simplest way is to compute $L_F^k\varphi_{n-k}$ for $k = d, \dots, n-1$ and to sum the terms where $x_{d+1}, \dots, x_n$ appear on $k = d, \dots, n-1$. For example, let us compute $P_{4,2}$:

$$\begin{aligned} L_F^2\varphi_2 &= L_F(x_2\varphi_2') \\ &= x_3\varphi_2' + x_2^2\varphi_2'', \\ L_F^3\varphi_1 &= L_F(x_3\varphi_1' + x_2^2\varphi_1'') \\ &= x_4\varphi_1' + 3x_2x_3\varphi_1'' + x_2^3\varphi_1^{(3)}; \end{aligned}$$

hence

$$P_{4,2} = x_4\varphi_1' + x_3(3x_2\varphi_1'' + \varphi_2').$$

Of course this computation can be rather long, and, if d is great but n is not too much greater than d, it is more interesting to obtain $P_{n,d}$ without completely computing the $L_F^k\varphi_{n-k}$'s.

First of all we have the following lemma.

LEMMA A.1. *Let I be an open interval and $\varphi \in \mathcal{C}^\infty(I;\mathbb{R})$. Then, for $1 \le k \le n-1$,*

$$L_F^k(\varphi \circ h) = \sum_{p=1}^{k} Q_p^k \varphi^{(p)}(x_1),$$

where Q_p^k is a polynomial in the variables $x_2, \dots, x_n$, the monomials of which are

$$\zeta_{k,p,r} x_2^{r_2} x_3^{r_3} \dots x_{k+1}^{r_{k+1}},$$

where

$$\begin{aligned} r_2 + r_3 + \dots + r_{k+1} &= p, \\ r_2 + 2r_3 + \dots + kr_{k+1} &= k, \end{aligned}$$

$r = (r_2, r_3, \dots, r_{k+1})$, and $\zeta_{k,p,r}$ is an integer. We set $r = e_j$ if $r_j = 1$ and $r_i = 0$ for $i \ne j$, and we have the following:

- *If $p = 1$, then*

$$\zeta_{k,1,e_{k+1}} = 1$$

  and $\zeta_{k,1,r}$ vanishes for $r \ne e_{k+1}$.
- *If $p > 1$, then $\zeta_{k,p,r}$ can be defined by induction:*

$$\begin{aligned} \zeta_{k,p,(r_2,..,r_{k+1})} = \nu_2 \zeta_{k-1,p-1,(r_2-1,..,r_{k+1})} \\ + \textstyle\sum_{j=3}^{k+1} \nu_j (r_{j-1}+1) \zeta_{k-1,p,(..,r_{j-1}+1,r_j-1,...)}, \end{aligned}$$

  where $\nu_j = 1$ if $r_j > 0$; $\nu_j = 0$ otherwise.

Proof of Lemma A.1. As $L_F(\varphi \circ h) = x_2\varphi'(x_1)$, the lemma is clearly true for $k = 1$.

Let $\zeta x_2^{r_2} x_3^{r_3} \dots x_{k+1}^{r_{k+1}} \varphi^{(p)}$ be a monomial of $L_F^k(\varphi \circ h)$. The differentiation of this monomial along the vector field F gives monomials where $x_j^{r_j} x_{j+1}^{r_{j+1}}$ (with $r_j > 0$) is replaced by $x_j^{r_j-1} x_{j+1}^{r_{j+1}+1}$ and a monomial where $x_2^{r_2}\varphi^{(p)}(x_1)$ is replaced by

$x_2^{r_2+1}\varphi^{(p+1)}(x_1)$. This gives by induction the result about the r_j's and it remains to evaluate the $\zeta_{k,p,r}$'s.

If $p = 1$, the only nonzero monomial is $\zeta x_{k+1}\varphi'(x_1)$ and it is obtained by differentiating $k-1$ times $x_2\varphi'(x_1)$, so $\zeta_{k,1,e_{k+1}} = 1$ and $\zeta_{k,1,r} = 0$ if $r \neq e_{k+1}$.

If $p > 1$, the result is obtained by considering the monomials of $L_F^{k-1}(\varphi \circ h)$ whose differentiation along F gives the desired monomial. □

As a first consequence of Lemma A.1, $P_{n,d}$ is of the first degree w.r.t. $x_{d+1}, \ldots, x_n$ if $n \leq 2d-1$ because $r_j \geq 2$ with $j \geq d+1$ implies

$$n \geq k \geq (j-1)r_j \geq 2d.$$

We can then compute $P_{n,d}$ for $n = d+1, d+2, d+3, \ldots$.

1. $n = d+1$. The computation of $P_{d+1,d}$ involves only $L_f^d\varphi_1$ and the only term of this last quantity where x_{d+1} appears is $x_{d+1}\varphi_1'$. So we obtain the previously used formula:

$$P_{d+1,d} = x_{d+1}\varphi_1'.$$

2. $n = d+2$.

$$\begin{aligned} L_F^{d+1}\varphi_1 &= x_{d+2}\varphi_1' + \alpha x_{d+1}x_2\varphi_1'' + \ldots, \\ L_F^d\varphi_2 &= x_{d+1}\varphi_2' + \ldots, \end{aligned}$$

where $\alpha = \zeta_{d+1,2,(1,0,..,r_{d+1}=1,0)}$. But

$$\begin{aligned} \zeta_{d+1,2,(1,0,..,r_{d+1}=1,0)} &= \zeta_{d,1,(0,0,..,r_{d+1}=1,0)} + \zeta_{d,2,(1,0,..,r_d=1,0,0)} \\ &= 1 + \zeta_{d,2,(1,0,..,r_d=1,0,0)} \end{aligned}$$

and by induction

$$\zeta_{d+1,2,(1,0,..,r_{d+1}=1,0)} = d+1.$$

Hence

$$P_{d+2,d} = x_{d+2}\varphi_1' + x_{d+1}\left((d+1)x_2\varphi_1'' + \varphi_2'\right).$$

3. In the same manner, the reader can check that for $n = d+3$ (with $d \geq 3$),

$$\begin{aligned} P_{d+3,d} = {} & x_{d+3}\varphi_1' + x_{d+2}\left((d+2)x_2\varphi_1'' + \varphi_2'\right) \\ & + x_{d+1}\left(\tfrac{(d+1)(d+2)}{2}x_3\varphi_1'' + \tfrac{(d+1)(d+2)}{2}x_2^2\varphi_1^{(3)} + (d+1)x_2\varphi_2'' + \varphi_3'\right). \end{aligned}$$

OPTIMAL STRATEGIES FOR RISK-SENSITIVE PORTFOLIO OPTIMIZATION PROBLEMS FOR GENERAL FACTOR MODELS*

HIDEO NAGAI†

Abstract. We consider constructing optimal strategies for risk-sensitive portfolio optimization problems on an infinite time horizon for general factor models, where the mean returns and the volatilities of individual securities or asset categories are explicitly affected by economic factors. The factors are assumed to be general diffusion processes. In studying the ergodic type Bellman equations of the risk-sensitive portfolio optimization problems, we introduce some auxiliary classical stochastic control problems with the same Bellman equations as the original ones. We show that the optimal diffusion processes of the problem are ergodic and that under some condition related to integrability by the invariant measures of the diffusion processes we can construct optimal strategies for the original problems by using the solution of the Bellman equations.

Key words. portfolio optimization, risk-sensitive control, infinite time horizon, Bellman equations, factor models

1. Introduction.

Risk-sensitive portfolio optimization problems for factor models have been studied by several authors, e.g., [4], [5], [7], [8], [9], [11], [12], [14], [15], etc., as the study of infinite time horizon versions of Merton terminal wealth problems for incomplete market models. In those works the problems have been mostly formulated for such models that the mean returns of the individual securities depend linearly on underlying economic factors formulated as the solutions of linear stochastic differential equations, except [15], which treats the case of discrete time and nonlinear factors. For these models they considered the problem maximizing the risk-sensitized expected growth rate per unit time:

$$J_\infty(v,x;h) = \liminf_{T\to\infty}\left(-\frac{2}{\theta T}\right)\log E\left[e^{-(\frac{2}{\theta})\log V_T(h)}\right], \tag{1.1}$$

where $V_T(h)$ denotes the capital at time T a investor possesses by selecting a portfolio proportion h. To discuss such portfolio optimization problems, employing the idea of Bellman's dynamic programming principle, they have constructed optimal strategies by using the solutions of relevant ergodic type Bellman equations, or more directly the ones of Riccati equations which express the solutions of the Bellman equations in the case of linear Gaussian factor models. However, it is to be noted that the solutions don't always straightforwardly construct the optimal strategies for the problems. In the case of linear Gaussian factor models, in [5], [9] they actually constructed nearly optimal strategies or optimal ones for small θ, while in [12], [14] the construction was done for general $\theta > 0$ under some condition related to integrability of the criterion function.

In the present paper we formulate a general factor model where the mean returns as well as the volatilities of security prices depend nonlinearly on the economic factors which are formulated as the solutions of general stochastic differential equations. For such a general model we consider the above-mentioned risk-sensitized portfolio optimization problem on infinite time horizon without strategy constraints. We shall study the ergodic type Bellman equation of the risk-sensitive control problem relevant to the portfolio optimization through asymptotic analysis of the solution of the Bellman equation corresponding to the portfolio optimization on a finite time horizon. Then, by using the solution of the ergodic type equation, we construct the optimal strategy for the problem on infinite time horizon under a similar condition to what was assumed in [12], [14]. We here notice that the condition suggests an integrability by the invariant measure of an underlying ergodic diffusion process. The ergodic diffusion process is the optimal one of the other classical ergodic control problem with the same Bellman equation of ergodic type as the original one. Furthermore, the integrability condition is checked precisely in the case of linear Gaussian models in section 5. We remark that such a situation occurs in discussing other stochastic control problems with an exponential type criterion as well (cf. [11]).

2. Finite time horizon case. We consider a market with $m+1 \geq 2$ securities and $n \geq 1$ factors. We assume that the set of securities includes one bond, whose price is defined by ordinary differential equation:

$$dS^0(t) = r(X_t)S^0(t)dt, \qquad S^0(0) = s^0, \tag{2.1}$$

where $r(x)$ is a nonnegative bounded function. The other security prices S^i_t, $i = 1, 2, \ldots, m$, and factors X_t are assumed to satisfy the following stochastic differential equations:

$$\begin{aligned} &dS^i(t) = S^i(t)\{g^i(X_t)dt + \textstyle\sum_{k=1}^{n+m} \sigma^i_k(X_t)dW^k_t\}, \\ &S^i(0) = s^i, \qquad i = 1, \ldots, m, \end{aligned} \tag{2.2}$$

and

$$\begin{aligned} &dX_t = b(X_t)dt + \lambda(X_t)dW_t, \\ &X_0 = x \in R^n, \end{aligned} \tag{2.3}$$

where $W_t = (W^k_t)_{k=1,\ldots,(n+m)}$ is an $m+n$ dimensional standard Brownian motion process defined on a filtered probability space $(\Omega, \mathcal{F}, P, \mathcal{F}_t)$. Here σ and λ are, respectively, $m \times (m+n)$, $n \times (m+n)$ matrix valued functions. We assume that

$$\begin{aligned} &g,\ \sigma,\ b,\ \lambda \ \text{ are locally Lipschitz}, \\ &c_1|\xi|^2 \leq \xi^*\sigma\sigma^*(x)\xi \leq c_2|\xi|^2, \qquad c_1, c_2 > 0, \\ &x^*b(x) + \tfrac{1}{2} \parallel \lambda\lambda^*(x) \parallel \leq K(1+|x|^2), \end{aligned} \tag{2.4}$$

where σ^* stands for the transposed matrix of σ.

Let us denote by $h^i(t)$ a portion of the capital invested to the ith security $S^i(t)$, $i = 0, 1, \ldots, m$ and set

$$\begin{aligned} &S(t) = (S^1(t), S^2(t), \ldots, S^m(t))^*, \\ &h(t) = (h^1(t), h^2(t), \ldots, h^m(t))^* \end{aligned}$$

and

$$\mathcal{G}_t = \sigma(S(u), X(u); u \le t).$$

Here S^* stands for transposed matrix of S.

DEFINITION 2.1. *$(h^0(t), h(t)^*)_{0\le t\le T}$ is called an investment strategy if the following conditions are satisfied:*

(i) *$h(t)$ is a R^m valued $\mathcal{G}_t$ progressively measurable stochastic process such that*

$$\sum_{i=1}^{m} h^i(t) + h^0(t) = 1; \tag{2.5}$$

(ii)

$$P\left(\int_0^T |h(s)|^2 ds < \infty\right) = 1.$$

The set of all investment strategies will be denoted by $\mathcal{H}(T)$. When $(h^0(t), h(t)^*)_{0\le t\le T} \in \mathcal{H}(T)$, we will often write $h \in \mathcal{H}(T)$ for simplicity since h^0 is determined by (2.5).

For given $h \in \mathcal{H}(T)$ the process $V_t = V_t(h)$ representing the investor's capital at time t is determined by the stochastic differential equation:

$$\begin{aligned} \frac{dV_t}{V_t} &= \textstyle\sum_{i=0}^m h^i(t) \dfrac{dS^i(t)}{S^i(t)} \\ &= h^0(t) r(X_t) dt + \textstyle\sum_{i=1}^m h^i(t)\{g^i(X_t)dt + \sum_{k=1}^{m+n} \sigma_k^i(X_t) dW_t^k\}, \\ V_0 &= v. \end{aligned}$$

Then, taking (2.5) into account, we find that it turns out to be a solution of

$$\begin{aligned} \frac{dV_t}{V_t} &= r(X_t)dt + h(t)^*(g(X_t) - r(X_t)\mathbf{1})dt + h(t)^*\sigma(X_t)dW_t, \\ V_0 &= v, \end{aligned} \tag{2.6}$$

where $\mathbf{1} = (1, 1, \ldots, 1)^*$.

We first consider the following problem. For a given constant $\theta > -2$, $\theta \ne 0$ maximize the following risk-sensitized expected growth rate up to time horizon T:

$$J(v, x; h; T) = -\frac{2}{\theta} \log E[e^{-\frac{\theta}{2} \log V_T(h)}], \tag{2.7}$$

where h ranges over the set $\mathcal{A}(T)$ of all admissible strategies defined later. Then we consider the problem of maximizing the risk-sensitized expected growth rate per unit time,

$$J(v, x; h) = \liminf_{T\to\infty} \left(\frac{-2}{\theta T}\right) \log E[e^{-\frac{\theta}{2} \log V_T(h)}], \tag{2.8}$$

where h ranges over the set of all investment strategies such that $h \in \mathcal{A}(T)$ for each T.

Since V_t satisfies (2.6) we have

$$\begin{aligned} V_t^{-\frac{\theta}{2}} &= v^{-\frac{\theta}{2}} \exp\{\tfrac{\theta}{2} \textstyle\int_0^t \eta(X_s, h_s) ds \\ &\quad - \tfrac{\theta}{2} \textstyle\int_0^t h_s^* \sigma(X_s) dW_s - \tfrac{\theta^2}{8} \int_0^t h_s^* \sigma\sigma^*(X_s) h_s ds\}, \end{aligned}$$

where

$$\eta(x,h)=\left(\frac{\theta+2}{4}\right)h^*\sigma\sigma^*(x)h-r(x)-h^*(g(x)-r(x)\mathbf{1}).$$

If a given investment strategy h satisfies

$$E[e^{-\frac{\theta}{2}\int_0^T h(s)^*\sigma^*(X_s)dW_s-\frac{\theta^2}{8}\int_0^T h(s)^*\sigma\sigma^*(X_s)h(s)ds}]=1, \tag{2.9}$$

then we can introduce a probability measure P^h given by

$$P^h(A)=E[e^{-\frac{\theta}{2}\int_0^T h^*(s)\sigma(X_s)dW_s-\frac{\theta^2}{8}\int_0^T h^*(s)\sigma\sigma^*(X_s)h(s)ds};A]$$

for $A\in\mathcal{F}_T$, $T>0$. By the probability measure P^h our criterion $J(v,x;h;T)$ and $J(v,x;h)$ can be written as follows:

$$J(v,x;h,T)=\log v-\frac{2}{\theta}\log E^h[e^{\frac{\theta}{2}\int_0^T \eta(X_s,h(s))ds}] \tag{2.7$'$}$$

and

$$J(v,x;h)=\liminf_{T\to\infty}-\frac{2}{\theta T}\log E^h[e^{\frac{\theta}{2}\int_0^T \eta(X_s,h(s))ds}]. \tag{2.8$'$}$$

On the other hand, under the probability measure,

$$\begin{aligned}W_t^h&=W_t-\langle W_\cdot,-\tfrac{\theta}{2}\textstyle\int_0^\cdot h^*(s)\sigma(X_s)dW_s\rangle_t\\&=W_t+\tfrac{\theta}{2}\textstyle\int_0^t\sigma^*(X_s)h(s)ds\end{aligned}$$

is a standard Brownian motion process, and therefore the factor process X_t satisfies the following stochastic differential equation:

$$dX_s=\left(b(X_s)-\frac{\theta}{2}\lambda\sigma^*(X_s)h(s)\right)ds+\lambda(X_s)dW_s^h. \tag{2.10}$$

We regard (2.10) as a stochastic differential equation controlled by h and the criterion function is written by P^h as follows:

$$J(v,x;h;T-t)=\log v-\frac{2}{\theta}\log E^h[e^{\frac{\theta}{2}\int_0^{T-t}\eta(X_s,h(s))ds}] \tag{2.11}$$

and the value function

$$u(t,x)=\sup_{h\in\mathcal{H}(T-t)}J(v,x;h;T-t),\qquad 0\le t\le T. \tag{2.12}$$

Then, according to Bellman's dynamic programming principle, it should satisfy the following Bellman equation:

$$\begin{aligned}&\frac{\partial u}{\partial t}+\sup_{h\in R^m}L^hu=0,\\&u(T,x)=\log v,\end{aligned} \tag{2.13}$$

where L^h is defined by

$$L^hu(t,x)=\frac{1}{2}\mathrm{tr}(\lambda\lambda^*(x)D^2u)+\left(b(x)-\frac{\theta}{2}\lambda\sigma^*(x)h\right)^*Du-\frac{\theta}{4}(Du)^*\lambda\lambda^*(x)Du-\eta(x,h).$$

Note that $\sup_{h\in R^m} L^h u$ can be written as

$$\sup_{h\in R^m} L^h u(t,x) = \tfrac{1}{2}\mathrm{tr}(\lambda\lambda^*(x)D^2u) + (b - \tfrac{\theta}{\theta+2}\lambda\sigma^*(\sigma\sigma^*)^{-1}(g - r\mathbf{1}))^* Du$$
$$- \tfrac{\theta}{4}(Du)^*\lambda(I - \tfrac{\theta}{\theta+2}\sigma^*(\sigma\sigma^*)^{-1}\sigma)\lambda^* Du + \tfrac{1}{\theta+2}(g - r\mathbf{1})^*(\sigma\sigma^*)^{-1}(g - r\mathbf{1}).$$

Therefore our Bellman equation (2.13) is written as follows:

$$\begin{aligned} &\tfrac{\partial u}{\partial t} + \tfrac{1}{2}\mathrm{tr}(\lambda\lambda^* D^2u) + B(x)^* Du - (Du)^*\lambda N^{-1}\lambda^* Du + U(x) = 0,\\ &u(T,x) = \log v, \end{aligned} \tag{2.14}$$

where

$$\begin{aligned} B(x) &= b(x) - \tfrac{\theta}{\theta+2}\lambda\sigma^*(\sigma\sigma^*)^{-1}(g(x) - r(x)\mathbf{1}),\\ N^{-1}(x) &= \tfrac{\theta}{4}(I - \tfrac{\theta}{\theta+2}\sigma^*(\sigma\sigma^*)^{-1}\sigma(x)),\\ U(x) &= \tfrac{1}{\theta+2}(g - r\mathbf{1})^*(\sigma\sigma^*)^{-1}(g - r\mathbf{1}) + r(x). \end{aligned} \tag{2.15}$$

As for (2.14), we note that if $\theta > 0$, then

$$\frac{\theta}{2(\theta+2)} I \le N^{-1} \le \frac{\theta}{4} I$$

and therefore we have

$$-\frac{\theta}{4}\lambda\lambda^* \le -\lambda N^{-1}\lambda^* \le -\frac{\theta}{2(\theta+2)}\lambda\lambda^*.$$

Such kinds of equations have been studied in Nagai [13], or Bensoussan, Frehse, and Nagai [3]. Here we can obtain the following result along the line of [3, Theorem 5.1] with refinement on estimate (2.17).

THEOREM 2.1. (i) *If, in addition to* (2.4), $\theta > 0$ *and*

$$\nu_r|\xi|^2 \le \xi^*\lambda\lambda^*(x)\xi \le \mu_r|\xi|^2, \quad r = |x|, \quad \nu_r,\ \mu_r > 0, \tag{2.16}$$

then we have a solution of (2.14) *such that*

$$\begin{aligned} &u,\ \tfrac{\partial u}{\partial t},\ D_k u,\ D_{kj}u \in L^p(0,T;L^p_{loc}(R^n)), \qquad 1 < \forall p < \infty,\\ &\tfrac{\partial^2 u}{\partial t^2},\ \tfrac{\partial D_k u}{\partial t},\ \tfrac{\partial D_{kj}u}{\partial t}, D_{kjl}u \in L^p(0,T;L^p_{loc}(R^n)), \qquad 1 < \forall p < \infty,\\ &u \ge \log v, \quad \tfrac{\partial u}{\partial t} \le 0. \end{aligned}$$

Furthermore, we have the estimate

$$\begin{aligned} |\nabla u|^2(t,x) - \frac{c_0}{\nu_r}\frac{\partial u}{\partial t}(t,x) &\le c_r(|\nabla Q|^2_{2r} + |Q|^2_{2r} + |\nabla(\lambda\lambda^*)|^2_{2r}\\ &\quad + |\nabla B|_{2r} + |B|^2_{2r} + |U|_{2r} + |\nabla U|^2_{2r} + 1), \qquad x \in B_r,\ \ t \in [0,T), \end{aligned} \tag{2.17}$$

where

$$\begin{aligned} &Q = \lambda N^{-1}\lambda^*, \quad c_0 = \tfrac{4(1+c)(\theta+2)}{\theta}, \quad c > 0,\\ &|\cdot|_{2r} = \|\cdot\|_{L^\infty(B_{2r})}, \end{aligned}$$

and c_r is a positive constant depending on n, r, ν_r, μ_r, and c.

(ii) *If, in addition to the above conditions,*

$$\inf_{|x|\geq r} U(x),\ \ \frac{r^2}{\mu_r}\inf_{|x|\geq r} U(x),\ \ r\inf_{|x|\geq r}\frac{U(x)}{|B(x)|}\to\infty,\quad as\ \ r\to\infty,$$

then the above solution u satisfies

$$\inf_{|x|\geq r, t\in(0,T)} u(x,t)\to\infty \qquad as\ \ r\to\infty.$$

Moreover, there exists at most one such solution in $L^\infty(0,T;W^{1,\infty}_{loc}(R^n))$.

Proof. We need only prove (2.17). Let us set

$$F(t,x)=t\left(|\nabla u|^2-\gamma\frac{\partial u}{\partial t}\right),\qquad \gamma>0,$$

and

$$\Gamma(F)=\frac{1}{2}(\lambda\lambda^*)^{ij}D_{ij}F+B^iD_iF-Q^{ij}D_juD_iF+\frac{\partial F}{\partial s}-\frac{F}{s},$$

where $\Lambda=\lambda\lambda^*$. Then, in a similar way to [3], [13] we have

$$\begin{aligned}\Gamma(F)\geq{}&\tfrac{2s}{n\mu_r}(\tfrac{\partial u}{\partial s}+B^iD_iu-\tfrac{1}{2}(Du)^*QDu+U)^2\\&-\tfrac{sn|\nabla\lambda\lambda^*|^2}{2\nu_r}|\nabla u|^2-2s|\nabla B||\nabla u|^2-2s|\nabla Q||\nabla u|^3-2s|\nabla u||\nabla U|.\end{aligned}$$

Note that

$$\frac{\theta\nu_r}{2(\theta+2)}|\nabla u|^2\leq\frac{1}{2}(Du)^*QDu\leq\frac{\theta\mu_r}{2}|\nabla u|^2$$

and that

$$-\frac{1}{2\delta}|B|^2-\frac{\delta}{2}|\nabla u|^2\leq B^*Du\leq\frac{1}{2\delta}|B|^2+\frac{\delta}{2}|\nabla u|^2.$$

By taking δ such that

$$\delta<\frac{\theta\nu_r}{2(\theta+2)},$$

we have

$$-\frac{3\theta\mu_r}{4(\theta+2)}|\nabla u|^2-\frac{1}{\delta}|B|^2\leq B^*Du-\frac{1}{2}(Du)^*QDu-\frac{1}{2\delta}|B|^2\leq-\frac{\theta\nu_r}{4(\theta+2)}|\nabla u|^2.$$

Set

$$|\nabla u|^2=\beta F$$

and take γ such that

$$\gamma=\frac{4(1+c)(\theta+2)}{\theta\nu_r},\qquad c>0;$$

then

$$\frac{1}{\gamma} < \frac{\theta\nu_r}{4(\theta+2)}$$

and we have

$$\frac{\partial u}{\partial s} + B^*Du - \frac{1}{2}(Du)^*QDu - \frac{1}{2\delta}|B|^2 \le -\left[\left(\frac{\theta\nu_r}{4(\theta+2)} - \frac{1}{\gamma}\right)\beta + \frac{1}{s\gamma}\right]F$$

and

$$-\left[\left(\frac{3\theta\mu_r}{4(\theta+2)} - \frac{1}{\gamma}\right)\beta + \frac{1}{s\gamma}\right]F - \frac{1}{\delta}|B|^2 \le \frac{\partial u}{\partial s} + B^*Du - \frac{1}{2}(Du)^*QDu - \frac{1}{2\delta}|B|^2.$$

Thus we obtain

$$\begin{aligned}
\Gamma(F) &\ge \tfrac{2s}{n\mu_r}\left(\tfrac{\partial u}{\partial s} + B^*Du - \tfrac{1}{2}(Du)^*QDu - \tfrac{1}{2\delta}|B|^2\right)^2 \\
&\quad - \tfrac{4s}{n\mu_r}\left(U + \tfrac{1}{2\delta}|B|^2\right)\left|\tfrac{\partial u}{\partial s} + B^*Du - \tfrac{1}{2}(Du)^*QDu - \tfrac{1}{2\delta}|B|^2\right|^2 \\
&\quad - \tfrac{sn|\nabla\lambda\lambda^*|^2}{2\nu_r}|\nabla u|^2 - 2s|\nabla B||\nabla u|^2 - 2s|\nabla Q||\nabla u|^3 - 2s|\nabla u||\nabla U| \\
&\ge \tfrac{2s}{n\mu_r}[(k_r - \tfrac{1}{\gamma})\beta + \tfrac{1}{s\gamma}]^2F^2 - \tfrac{4s}{n\mu_r}\left(U + \tfrac{1}{2\delta}|B|^2\right)[(k_r' - \tfrac{1}{\gamma})\beta + \tfrac{1}{s\gamma}]F \\
&\quad - \tfrac{4s}{n\mu_r\delta}|B|^2\left(U + \tfrac{1}{2\delta}|B|^2\right) - s(\tfrac{n|\nabla\lambda\lambda^*|^2}{2\nu_r} + 2|\nabla B|)\beta F \\
&\quad - 2s|\nabla Q|\beta^{\frac{3}{2}}F^{\frac{3}{2}} - 2s|\nabla U|\beta^{\frac{1}{2}}F^{\frac{1}{2}},
\end{aligned} \tag{2.18}$$

where

$$k_r = \frac{\theta\nu_r}{4(\theta+2)}, \qquad k_r' = \frac{3\theta\nu_r}{4(\theta+2)}.$$

Let $\alpha \in B_r$ and define the function

$$\tau = \begin{cases} (\frac{|x-\alpha|^2}{r^2} - 1)^2, & |x-\alpha| \le r, \\ 0, & |x-\alpha| > r. \end{cases}$$

Then we have

$$\begin{aligned}
\operatorname{tr}(\lambda\lambda^*D^2\tau) &\ge -\frac{4n}{r^2}\mu_r, \\
(D\tau)^*\lambda\lambda^*D\tau &\le \frac{16\mu_r}{r^2}\tau, \\
|D\tau|^2 &\le \frac{16\mu_r}{\nu_r r^2}\tau.
\end{aligned}$$

Now let (s,x) be a maximum point of τF in $[0,t) \times B_r(\alpha)$; then it suffices to prove that

$$\tau F(s,x) \le sc_r(|\nabla Q|^2 + |Q|^2 + |\nabla\lambda\lambda^*|^2 + |\nabla B| + |B|^2 + |U| + |\nabla U|^2 + 1)(x) \tag{2.19}$$

because

$$F(t,\alpha) = (\tau F)(t,\alpha) \le (\tau F)(s,x), \qquad s \le t, \;\; x \in B_{2r}.$$

Note that

$$D(\tau F)(s,x)=0,\quad \frac{\partial F}{\partial s}(s,x)\le 0,\quad \mathrm{tr}(\lambda\lambda^* D^2(\tau F))(s,x)\le 0.$$

Therefore

$$\begin{aligned}-\tfrac{\tau F}{s} &\ge \tfrac{1}{2}(\lambda\lambda^*)^{ij}D_{ij}(\tau F)+B^iD_i(\tau F)-Q^{ij}D_juD_i(\tau F)+\tau\tfrac{\partial F}{\partial s}-\tfrac{\tau F}{s}\\ &=\tau\Gamma(F)+(\tfrac{1}{2}(\lambda\lambda^*)^{ij}D_{ij}\tau)F-(\lambda\lambda^*)^{ij}\tfrac{D_i\tau D_j\tau}{\tau}F+(B^iD_i\tau-Q^{ij}D_juD_i\tau)F.\end{aligned}$$

Thus we obtain

$$-\frac{\tau F}{s}\ge\tau\Gamma(F)-\frac{c_1\mu_r}{r^2}F-(|B|+|Q|\beta^{\frac12}F^{\frac12})\frac{c_2\sqrt{\mu_r}}{r\sqrt{\nu_r}}\sqrt{\tau}F,$$

where c_1 and c_2 are global constants. Therefore

$$\begin{aligned}-\tfrac{\tau F}{s}\ge{}&\tfrac{2s}{n\mu_r}[(k_r-\tfrac{1}{\gamma})\beta+\tfrac{1}{s\gamma}]^2\tau F^2-\tfrac{4s}{n\mu_r}(U+\tfrac{1}{2\delta}|B|^2)[(k_r'-\tfrac{1}{\gamma})\beta+\tfrac{1}{s\gamma}]\tau F\\ &-(2s|\nabla Q|\beta^{\frac32}\tau+|Q|\beta^{\frac12}\tfrac{c_2\sqrt{\mu_r}}{r\sqrt{\nu_r}}\sqrt{\tau})F^{\frac32}\\ &-\{s(\tfrac{n|\nabla\lambda\lambda^*|^2}{2\nu_r}+2|\nabla B|)\beta\tau+\tfrac{c_1\mu_r}{r^2}+|B|\tfrac{c_2\sqrt{\mu_r}}{r\sqrt{\nu_r}}\sqrt{\tau}\}F\\ &-2s|\nabla U|\beta^{\frac12}\tau F^{\frac12}-\tfrac{4s}{n\mu_r\delta}|B|^2(U+\tfrac{1}{2\delta}|B|^2)\tau.\end{aligned}$$

We can asssume that

$$F\ge s|B|^2,\qquad F^{\frac12}\ge s^{\frac12}|\nabla U|. \tag{2.20}$$

Indeed, otherwise (2.19) is already proved. Then

$$\begin{aligned}-\tau\ge{}&\tfrac{2}{n\mu_r}[(k_r-\tfrac{1}{\gamma})\beta s+\tfrac{1}{\gamma}]^2\tau F-\tfrac{4s}{n\mu_r}(U+\tfrac{1}{2\delta}|B|^2)[(k_r'-\tfrac{1}{\gamma})\beta s+\tfrac{1}{\gamma}]\\ &-(2s^2|\nabla Q|\beta^{\frac32}+s|Q|\beta^{\frac12}\tfrac{c_2\sqrt{\mu_r}}{r\sqrt{\nu_r}})(\tau F)^{\frac12}\\ &-\{s^2(\tfrac{n|\nabla\lambda\lambda^*|^2}{2\nu_r}+2|\nabla B|)\beta+s\tfrac{c_1\mu_r}{r^2}+s|B|\tfrac{c_2\sqrt{\mu_r}}{r\sqrt{\nu_r}}\}\\ &-2s^{\frac32}\beta^{\frac12}-\tfrac{4s}{n\mu_r\delta}(U+\tfrac{1}{2\delta}|B|^2).\end{aligned}$$

Setting $X=(\tau F)^{\frac12}$, we have

$$\begin{aligned}0\ge{}&\tfrac{2}{n\mu_r}[(k_r-\tfrac{1}{\gamma})\beta s+\tfrac{1}{\gamma}]^2X^2-s^{\frac12}(2|\nabla Q|(\beta s)^{\frac32}+|Q|(\beta s)^{\frac12}\tfrac{c_2\sqrt{\mu_r}}{r\sqrt{\nu_r}})X\\ &-\tfrac{4s}{n\mu_r}(U+\tfrac{1}{2\delta}|B|^2)[(k_r'-\tfrac{1}{\gamma})\beta s+\tfrac{1}{\gamma}]\\ &-s\{(\tfrac{n|\nabla\lambda\lambda^*|^2}{2\nu_r}+2|\nabla B|)\beta s+\tfrac{c_1\mu_r}{r^2}+|B|\tfrac{c_2\sqrt{\mu_r}}{r\sqrt{\nu_r}}\}\\ &-2s((\beta s)^{\frac12}+\tfrac{2}{n\mu_r\delta}(U+\tfrac{1}{2\delta}|B|^2)).\end{aligned}$$

Since

$$\begin{aligned}&\tfrac{2}{n\mu_r}[(k_r-\tfrac{1}{\gamma})\beta s+\tfrac{1}{\gamma}]^2X^2-s^{\frac12}(2|\nabla Q|(\beta s)^{\frac32}+|Q|(\beta s)^{\frac12}\tfrac{c_2\sqrt{\mu_r}}{r\sqrt{\nu_r}})X\\ &\ge\tfrac{2}{n\mu_r\gamma^2}\{\tfrac12(k_r\gamma-1)\beta s+1\}\{(k_r\gamma-1)\beta s+1\}X^2-\tfrac{s\gamma^2(2\beta s|\nabla Q|+\frac{c_2\sqrt{\mu_r}}{r\sqrt{\nu_r}}|Q|)^2}{4(k_r\gamma-1)\{(k_r\gamma-1)\beta s+1\}}\end{aligned}$$

and $k_r\gamma - 1 = c > 0$, $k_r'\gamma - 1 = 2 + 3c$, we obtain

$$X^2 \le \frac{n\mu_r\gamma^2 s}{(c\beta s+2)(c\beta s+1)} \Big[(U + \tfrac{1}{2\delta}|B|^2)\tfrac{(2+3c)\beta s+1}{\gamma} + \{(\tfrac{n|\nabla\lambda\lambda^*|^2}{2\nu_r} + 2|\nabla B|)\beta s + \tfrac{c_1\mu_r}{r^2} + |B|\tfrac{c_2\sqrt{\mu_r}}{r\sqrt{\nu_r}}\} + 2\{(\beta s)^{\frac{1}{2}} + \tfrac{2}{n\mu_r\delta}(U + \tfrac{1}{2\delta}|B|^2)\} + \frac{\gamma^2(2\beta s|\nabla Q| + \frac{c_2\sqrt{\mu_r}}{r\sqrt{\nu_r}}|Q|)^2}{4c(c\beta s+1)} \Big].$$

Taking into account that

$$\frac{\beta s}{c\beta s+1}, \quad \frac{(\beta s)^{\frac{1}{2}}}{c\beta s+1}, \quad \frac{1}{c\beta s+1}$$

are bounded, we see that

$$X^2 \le sc_r(U + |B|^2 + |\nabla B| + |\nabla\lambda\lambda^*|^2 + |\nabla Q|^2 + |Q|^2 + 1)(x),$$

where c_r is a constant depending on n, r, c, ν_r, and μ_r. Including the other cases where (2.20) does not hold, we conclude (2.19). □

Remark. (i) If

$$\frac{1}{\nu_r},\ \mu_r \le M(1 + r^m), \qquad \exists m \ge 0, \tag{2.21}$$

then we have

$$c_r \le M'(1 + r^{m'}), \qquad \exists m'$$

in estimate (2.17). In particular, if $m = 0$, namely ν_r and μ_r are constants, then c_r can be taken independent of r.

(ii) In [13], [3] we have gotten a similar estimate to (2.17), where the dependence on the coefficients of the equation was not clear. However, to check the condition (2.22) in the following proposition, we need a precise estimate such as (2.17), which makes clear the dependence on the coefficients of (2.14). It is a key estimate to prove that the strategy defined by the solution of (2.14) forms the optimal one as we shall see in the following proposition. It is also the case in the proof of Theorem 4.1 since the estimate holds for the solution w of the limit equation (2.29) of (2.14).

Let us define a class of admissible investment strategy $\mathcal{A}_T$ as the set of investment strategies satisfying (2.9). Then, thanks to the above Theorem 2.1 and the above remark we have the following proposition.

PROPOSITION 2.1. (i) *We assume the assumptions in the above theorem and let u be a solution of* (2.14). *Define*

$$\hat{h}_t = \hat{h}(t, X_t),$$
$$\hat{h}(t,x) = \tfrac{2}{\theta+2}(\sigma\sigma^*)^{-1}(g - r\mathbf{1} - \tfrac{\theta}{2}\sigma\lambda^* Du)(t,x),$$

where X_t is the solution of (2.3); *then, under the assumption that*

$$E[e^{-\int_0^T (2N^{-1}\lambda^* Du+\theta K)^*(x_s)dW_s - \frac{1}{2}\int_0^T (2N^{-1}\lambda^* Du+\theta K)^*(2N^{-1}\lambda^* Du+\theta K)(x_s)ds}] = 1, \tag{2.22}$$

where

$$K = \frac{1}{\theta+2}\sigma^*(\sigma\sigma^*)^{-1}(g - r\mathbf{1}),$$

$\hat{h}_t \in \mathcal{A}_T$ *is an optimal strategy for the portfolio optimization problem of maximizing the criterion* (2.7).

(ii) *If*

$$\begin{aligned} &\nu_r \text{ and } \mu_r \text{ in (2.16) are constants and} \\ &g,\ b,\ \lambda,\ \sigma \text{ are globally Lipschitz,} \end{aligned} \tag{2.23}$$

then (2.22) *is valid.*

Proof. (i) Set

$$Z_T(\hat{h}) = \frac{\theta}{2}\int_0^T \eta(X_s, \hat{h}_s)ds - \frac{\theta}{2}\int_0^T \hat{h}_s^*\sigma(X_s)dW_s - \frac{\theta^2}{8}\int_0^T \hat{h}_s^*\sigma\sigma^*(X_s)\hat{h}_s ds.$$

Since $\hat{h}(t,x)$ attains the supremum in (2.13) we have

$$e^{Z_T(\hat{h})} = e^{\frac{\theta}{2}\{\log v - u(0,x) - \int_0^T [(Du)^*\lambda + \hat{h}_s^*\sigma]dW_s - \frac{\theta}{4}\int_0^T [(Du)^*\lambda + \hat{h}_s^*\sigma][(Du)^*\lambda + \hat{h}_s^*\sigma]^* ds\}}.$$

Note that

$$2N^{-1}\lambda^* Du + \theta K = \frac{\theta}{2}\lambda^* Du + \frac{\theta}{\theta+2}(\sigma\sigma^*)^{-1}\left(g - r\mathbf{1} - \frac{\theta}{2}\sigma\lambda^* Du\right);$$

then, under assumption (2.22), we obtain

$$-\frac{2}{\theta}\log E_x[e^{Z_T(\hat{h})}] = u(0,x) - \log v,$$

namely,

$$\frac{2}{\theta}\log E_x[e^{-\frac{\theta}{2}V_t(\hat{h})}] = -\frac{2}{\theta}\log E_x[v^{-\frac{\theta}{2}}e^{Z_T(\hat{h})}] = u(0,x).$$

On the other hand, for each h_s satisfying (2.9), we have

$$-\frac{2}{\theta}\log E_x[e^{Z_T(h)}] \le u(0,x) - \log v$$

in a similar way to the above because

$$\frac{\partial u}{\partial t} + L^h u \le 0$$

for each $h \in R^m$. Thus, we see that $\hat{h}_t$ is optimal.

(ii) Thanks to (2.17) and the above remark we see that $|Du|$ has at most linear growth under assumption (2.23) and so does $\hat{h}(t,x)^*\sigma(x)$. Moreover, $b(x)$ is globally Lipschitz and we can see that (2.22) holds under these conditions in a similar way to Lemma 4.1.1 in [2]. □

To discuss the problem on infinite time horizon we introduce another stochastic control problem on a finite time horizon with the same Bellman equation as (2.14) and then consider its ergodic counterpart. For that let us set

$$G = b - \lambda\sigma^*(\sigma\sigma^*)^{-1}(g - r\mathbf{1})$$

and rewrite (2.14) as

$$
\begin{aligned}
&\frac{\partial u}{\partial t} + \frac{1}{2}\mathrm{tr}(\lambda\lambda^*(x)D^2u) + G(x)^*Du \\
&\quad - (-\lambda^*Du + NK)^*N^{-1}(-\lambda^*Du + NK)(x) + \frac{\theta+2}{2}K^*NK(x) + r(x) = 0, \\
&u(T,x) = \log v.
\end{aligned} \tag{2.24}
$$

Since

$$
-(-\lambda^*Du + NK)^*N^{-1}(-\lambda^*Du + NK) = \inf_{z\in R^{n+m}}\{z^*Nz + 2z^*NK - 2(\lambda z)^*Du\},
$$

we can regard (2.24) as the Bellman equation of the following stochastic control problem. Set

$$
\begin{aligned}
&u(t,x) \\
&= \inf_{Z_\cdot} E_x\left[\int_0^{T-t}\left\{Z_s^*N(Y_s)Z_s + 2Z_s^*NK(Y_s) + \frac{\theta+2}{2}K^*NK(Y_s) + r(Y_s)\right\}ds + \log v\right],
\end{aligned} \tag{2.25}
$$

where Y_t is a controlled process governed by the stochastic differential equation

$$
dY_t = \lambda(Y_t)dW_t + (G(Y_t) - 2\lambda(Y_t)Z_t)dt, \qquad Y_0 = x, \tag{2.26}
$$

and Z_t is a control taking its value on R^{n+m}. We define the set of admissible controls Z_t as all progressively measurable processes satisfying

$$
E_x\left[\int_0^T |Z_s|^{2q}ds\right] < \infty \qquad \forall q \geq 1.
$$

An ergodic counterpart of the above problem is formulated as follows. Consider the problem

$$
\chi = \inf_{Z_\cdot}\liminf_{T\to\infty}\frac{1}{T}E_x\left[\int_0^T\left\{Z_s^*N(Y_s)Z_s + 2Z_s^*NK(Y_s) + \frac{\theta}{2}K^*NK(Y_s) + r(Y_s)\right\}ds\right] \tag{2.27}
$$

with controlled process Y_t governed by (2.26). Then, the corresponding Bellman equation is written as

$$
\begin{aligned}
\chi &= \frac{1}{2}\mathrm{tr}(\lambda\lambda^*(x)D^2w) + G(x)^*Dw \\
&\quad - (-\lambda^*Dw + NK)^*N^{-1}(-\lambda^*Dw + NK)(x) + \frac{\theta+2}{2}K^*NK(x) + r(x),
\end{aligned} \tag{2.28}
$$

whose original one is

$$
\chi = \frac{1}{2}\mathrm{tr}(\lambda\lambda^*(x)D^2w) + B(x)^*Dw - (Dw)^*\lambda N^{-1}\lambda^*(x)Dw + U(x) = 0, \tag{2.29}
$$

namely,

$$\chi = \frac{1}{2}\mathrm{tr}(\lambda\lambda^*(x)D^2w) + (b - \tfrac{\theta}{\theta+2}\lambda\sigma^*(\sigma\sigma^*)^{-1}(g - r\mathbf{1}))^*Dw$$
$$- \tfrac{\theta}{4}(Dw)^*\lambda(I - \tfrac{\theta}{\theta+2}\sigma^*(\sigma\sigma^*)^{-1}\sigma)\lambda^*Dw + \tfrac{1}{\theta+2}(g - r\mathbf{1})^*(\sigma\sigma^*)^{-1}(g - r\mathbf{1}) + r(x).$$

In the following section we shall analyze the Bellman equation of ergodic type (2.28). Indeed, we shall deduce (2.28), accordingly (2.29), as the limit of parabolic type equation (2.24) as $T \to \infty$ under suitable conditions.

Remark. To regard our Bellman equation as (2.24) has a meaning from a financial point of view. Indeed, under the minimal martingale measure $\tilde{P}$ (cf. [6, Proposition 1.8.2] as for minimal martingale measures), which is defined by

$$\left.\frac{d\tilde{P}}{dP}\right|_{\mathcal{F}_T} = e^{-\int_0^T \zeta(X_s)^* dW_s - \frac{1}{2}\int_0^T |\zeta(X_s)|^2 ds},$$

$\zeta(x) = \sigma^*(\sigma\sigma^*)^{-1}(x)(g(x) - r(x)\mathbf{1})$ factor process X_t is the diffusion process with the generator

$$L = \frac{1}{2}\mathrm{tr}(\lambda\lambda^*(x)D^2) + G(x)^*D,$$

namely, it is governed by the stochastic differential equation

$$dX_t = \lambda(X_t)d\tilde{W}_t + G(X_t)dt.$$

Here $\tilde{W}_t = W_t + \int_0^t \zeta(X_s)ds$ and it is a Brownian motion under the probability measure $\tilde{P}$.

3. Ergodic type Bellman equation. In what follows we assume that

$$\frac{1}{2}\mathrm{tr}(\lambda\lambda^*(x)) + x^*G(x) + \frac{\kappa}{2}\frac{x^*\lambda\lambda^*(x)x}{\sqrt{1+|x|^2}} \le 0, \qquad |x| \ge \exists r_0 > 0, \ \ \kappa > 0, \tag{3.1}$$

and set

$$L = \frac{1}{2}\mathrm{tr}(\lambda\lambda^*(x)D^2) + G^*(x)D.$$

Proposition 3.1. *We assume* (2.4), (3.1), *and* (2.16) *with*

$$\nu_r \ge e^{-\frac{\kappa - c}{8}r}, \qquad c > 0, \ \ r \ge \exists r_1 > 0; \tag{3.2}$$

then L diffusion process $(\tilde{P}_x, X_t)$ *is ergodic, namely, recurrent and admits a finite invariant measure (unique up to a constant multiple). Furthermore, it satisfies*

$$\tilde{E}_x[e^{\kappa\sqrt{1+|X_t|^2}}] \le e^{\kappa\sqrt{1+|x|^2}}. \tag{3.3}$$

Proof. Let us set

$$\alpha(r) = \inf_{|x|=r} \frac{x^*\lambda\lambda^*(x)x}{|x|^2},$$

and

$$I(u) = \int_{r_0}^{\infty} \frac{\beta(u)}{u} du,$$

where

$$\beta(r) = \sup_{|x|=r} \frac{\mathrm{tr}(\lambda\lambda^*(x)) - \frac{x^*\lambda\lambda^*(x)x}{|x|^2} + 2x^*G(x)}{\frac{x^*\lambda\lambda^*(x)x}{|x|^2}}.$$

According to [1], it is known that, if

$$\int_{r_0}^{\infty} e^{-I(u)} du = \infty \tag{3.4}$$

and

$$\int_{r_0}^{\infty} \frac{1}{\alpha(u)} e^{I(u)} du < \infty, \tag{3.5}$$

then the diffusion process with the generator

$$L = \frac{1}{2}\mathrm{tr}(\lambda\lambda^*(x)D^2) + G^*(x)D$$

is ergodic. From (3.1) it follows that

$$\mathrm{tr}(\lambda\lambda^*(x)) - \frac{x^*\lambda\lambda^*(x)x}{|x|^2} + 2x^*G(x) \le -\frac{\kappa}{4}\frac{x^*\lambda\lambda^*(x)x}{\sqrt{1+|x|^2}}, \qquad |x| > r_0.$$

Namely, we have

$$\frac{\mathrm{tr}(\lambda\lambda^*(x)) - \frac{x^*\lambda\lambda^*(x)x}{|x|^2} + 2x^*G(x)}{\frac{x^*\lambda\lambda^*(x)x}{|x|^2}} \le -\frac{\kappa|x|^2}{4\sqrt{1+|x|^2}}$$

and so $\beta(r) \le -\frac{\kappa r^2}{4\sqrt{1+r^2}}$, $r \ge r_0$. Then

$$I(r) \le -\int_{r_0}^{r} \frac{\kappa u}{4\sqrt{1+u^2}} du \le -\frac{\kappa}{8}(r - r_0), \qquad r > r_0 > 0,$$

which implies that

$$\int_{r_0}^{\infty} e^{-I(r)} dr = \infty.$$

On the other hand, because of (2.16), we have $\alpha(r) \ge \nu_r$ and obtain

$$\begin{aligned} \textstyle\int_{r_1}^{\infty} \frac{1}{\alpha(r)} e^{I(u)} du &\le \textstyle\int_{r_1}^{\infty} \frac{1}{\nu_r} e^{-\frac{\kappa}{8}(r-r_1)} dr \\ &= \textstyle\int_{r_1}^{\infty} e^{-\log \nu_r - \frac{\kappa}{8}(r-r_1)} dr < \infty \end{aligned}$$

by using (3.2). Hence we see that the diffusion process $(\tilde{P}_x, X_t)$ with the generator L is ergodic.

To see (3.3), let us set

$$\varphi(x) = e^{\kappa(1+|x|^2)^{\frac{1}{2}}};$$

then by Itô's formula we have

$$\begin{aligned}
&\varphi(X_t) - \varphi(X_0) \\
&\quad = \frac{\kappa\varphi(X_t)}{\sqrt{1+|X_t|^2}}\{\tfrac{1}{2}\mathrm{tr}(\lambda\lambda^*(X_t)) + X_t^* G(X_t) - \frac{X_t^*\lambda\lambda^*(X_t)X_t}{2(1+|X_t|^2)} + \frac{\kappa X_t\lambda\lambda^*(X_t)X_t}{2\sqrt{1+|X_t|^2}}\}dt \\
&\quad + \frac{\kappa\varphi(X_t)}{\sqrt{1+|X_t|^2}} X_t\lambda(X_t)d\tilde{W}_t.
\end{aligned}$$

Thus, we obtain

$$\tilde{E}_x[\varphi(X_{t\wedge\tau_R})] \le \varphi(x), \qquad \tau_R = \inf\{t; |X_t| \ge R\},$$

and so

$$\tilde{E}_x[\varphi(X_t)] \le \varphi(x). \qquad \square$$

THEOREM 3.1. *Assume the assumptions of Theorem* 2.1, (3.1) *and that*

$$\begin{aligned}
&\frac{1}{\nu_r},\ \mu_r \le K(1+r^m), \\
&|Q|,\ |\nabla Q|,\ |B|,\ |\nabla B|,\ U,\ |\nabla U|,\ |\nabla(\lambda\lambda^*)| \le K(1+|x|^m);
\end{aligned}$$

then, as $T \to \infty$,

$$\begin{aligned}
&u(0,x;T) - u(0,0;T) \to w(x), \\
&\tfrac{1}{T}u(0,x;T) \to \chi,
\end{aligned}$$

uniformly on each compact set, where (w,χ) *is the solution of* (2.28) *such that* $w \in C^2(R^n)$.

Proof. In a similar way to Lemma 3.1 in [13], we can see that there exists a subsequence $\{T_i\} \subset R_+$ such that $u(0,x;T_i) - u(0,0;T_i)$ converges to a function $w(x) \in C^2(R^n)$ uniformly on each compact set and strongly in $W^1_{2,loc}$ and $\frac{\partial u}{\partial t}(0,x;T_i)$ to $\chi(x) \in C(R^n)$ uniformly on each compact set by using estimate (2.17). We shall see that $\chi(x) = \chi$, a constant, in what follows.

We need the following lemma.

LEMMA 3.1. *Let* $\tilde{m}$ *be an invariant measure of* L *diffusion process* $(\tilde{P}_x, X_t)$*; then we have the following estimate:*

$$\tilde{m}(|x| \ge R) \le e^{\kappa - \kappa\sqrt{1+R^2}}. \tag{3.6}$$

Proof. Because of (3.3) we have

$$E_0[e^{\kappa\sqrt{1+|X_t|^2}}; |X_t| \ge R] \le e^{\kappa}.$$

Then we obtain

$$\tilde{P}_0(|X_t| \ge R) \le e^{\kappa - \kappa\sqrt{1+R^2}}.$$

Since the left-hand side converges to $\tilde{m}(|x| \ge R)$ as $t \to \infty$, we conclude our present lemma. $\square$

COROLLARY 3.1. *If* $|q(x)| \le c(1+|x|^l)$ *for* $\exists l > 0$, *then* $\int q(x)\tilde{m}(dx) < \infty$.

Now we shall complete the proof of Theorem 3.1. Let us introduce a function γ, which is a solution of the following linear partial differential equation:

$$\begin{aligned}&\tfrac{\partial\gamma}{\partial t} + \tfrac{1}{2}\mathrm{tr}(\lambda\lambda^*(x)D^2\gamma) + G(x)^*D\gamma + \tfrac{\theta+2}{2}K^*NK(x) = 0,\\ &u(T,x) = \log v.\end{aligned}$$

Then we have

$$\begin{aligned}&\tfrac{\partial(\gamma-u)}{\partial t} + \tfrac{1}{2}\mathrm{tr}(\lambda\lambda^*(x)D^2(\gamma-u))\\ &\quad + G(x)^*D(\gamma-u) + (-\lambda^*Du + NK)^*N^{-1}(-\lambda^*Du + NK) = 0,\\ &(\gamma-u)(T,x) = 0\end{aligned}$$

and so we see that

$$\gamma(t,x) \ge u(t,x) \ge \log v. \tag{3.7}$$

On the other hand, γ has an expression by L diffusion process $(\tilde{P}_x, X_t)$ such as

$$\gamma(t,x) = \tilde{E}_x\left[\int_0^{T-t} \frac{\theta+2}{2}K^*NK(X_s)ds\right] + \log v.$$

Therefore, by ergodic theorem

$$\begin{aligned}\lim_{T\to\infty}\tfrac{\gamma(0,x;T)}{T} &= \lim_{T\to\infty}\tfrac{1}{T}\tilde{E}_x[\textstyle\int_0^T \frac{\theta+2}{2}K^*NK(X_s)ds]\\ &= \textstyle\int \frac{\theta+2}{2}K^*NK(x)\tilde{m}(dx).\end{aligned} \tag{3.8}$$

Note that [10, IV, Theorem 5.1], and therefore its Corollary 1, extend to the present case (cf. also Proof of Theorem 3.5 in [1]) by using the above Corollary 3.1. Set

$$\bar{u}(T) = \frac{1}{|B_1|}\int_{B_1} u(0,y;T)dy.$$

Since

$$|u(0,x;T) - u(0,y;T)| \le K_R, \qquad x,y \in B_R,$$

because of (2.17), we have

$$|u(0,x;T) - \bar{u}(T)| \le K_R, \qquad x,y \in B_R, \tag{3.9}$$

for $R > 1$. Noting that $\{\frac{\bar{u}(T)}{T}\}_T$ is bounded due to (3.7) and (3.8), take a subsequence $T_i \subset R_+$ such that

$$\lim_{T_i\to\infty}\frac{\bar{u}(T_i)}{T_i} = \chi.$$

Then (3.9) implies that

$$\lim_{T_i\to\infty}\sup_{x\in B_R}\left|\frac{u(0,x;T_i)}{T_i} - \chi\right| = 0 \qquad \forall R.$$

Hence

$$\chi(x) = \lim_{T_i} \frac{\partial u}{\partial t}(0, x, T_i) = \lim_{T_i \to \infty} \frac{u(0, x; T_i)}{T_i} = \chi$$

uniformly on each compact set. On the other hand, in a similar way to Lemma 3.3 in [13], we can see that $w(x)$ is bounded below and so $w(x) \to \infty$ as $|x| \to \infty$ (cf. Remark 3.2 in [13]). Furthermore, such a solution (w, χ) is unique up to additive constant with respect to a function w (cf. Lemma 3.2 in [13]) and we conclude our present theorem. □

Our Bellman equation of ergodic type (2.28) is rewritten as

$$\begin{aligned} \chi = {} & \tfrac{1}{2}\mathrm{tr}(\lambda\lambda^*(x)D^2 w) + G(x)^* Dw \\ & + \inf_{z \in R^{n+m}} \{z^* N z + 2z^* N K - 2(\lambda z)^* Dw\} + \tfrac{\theta+2}{2} K^* N K(x), \end{aligned} \tag{3.10}$$

and the infimum is attained by

$$\hat{z}(x) = N^{-1}\lambda^*(x) Dw(x) - K(x),$$

which define the following elliptic operator considered as the generator of the optimal diffusion for (2.27):

$$\hat{L} = \frac{1}{2}\mathrm{tr}(\lambda\lambda^*(x)D^2) + G^*(x)D - 2(\lambda N^{-1}\lambda^*(x) Dw(x) - \lambda K(x))^* D.$$

Then we have the following proposition.

PROPOSITION 3.2. *Under the assumptions of Theorem* 3.1, $\hat{L}$ *diffusion process is ergodic.*

Proof. Thanks to Theorem 3.1 and our assumptions, the coefficients of $\hat{L}$ are locally Lipschitz and $\lambda\lambda^*$ is uniformly positive definite on each compact set. Then, we can check Has'minskii's conditions [10] for ergodicity as follows (cf. [10, III Theorem 7.1], its Corollary 1 and Theorem 4.1). Since $w(x) \to \infty$ as $|x| \to \infty$, it is bounded below. Moreover, by calculation we see that

$$\begin{aligned} \hat{L}w &= -\{(Dw)^*\lambda N^{-1}\lambda^* Dw + \tfrac{\theta}{2} K^* N K\} + \chi \\ &= -\tfrac{\theta}{4}(Dw)^*\lambda(I - \tfrac{\theta}{\theta+2}\sigma^*(\sigma\sigma^*)^{-1}\sigma)\lambda^* Dw - \tfrac{1}{\theta+2}(g - r\mathbf{1})^*(\sigma\sigma^*)^{-1}(g - r\mathbf{1}) + \chi. \end{aligned}$$

Since

$$\frac{1}{\theta+2}(g - r\mathbf{1})^*(\sigma\sigma^*)^{-1}(g - r\mathbf{1}) \to \infty, \qquad |x| \to \infty,$$

we see that

$$\hat{L}w \le -C, \ \ |x| >> 1, \quad C > 0.$$

Thus we conclude our present proposition. □

4. Optimal strategy for portfolio optimization on infinite time horizon. Define the set of admissible strategies $\mathcal{A}$ by

$$\mathcal{A} = \{h : h \in \mathcal{A}(T) \ \forall T\}$$

and set

$$\hat{H}_t = \hat{H}(X_t),$$
$$\hat{H}(x) = \tfrac{2}{\theta+2}(\sigma\sigma^*)^{-1}(g - r\mathbf{1} - \tfrac{\theta}{2}\sigma\lambda^* Dw)(x),$$

where X_t is the solution of stochastic differential equation (2.3); then we have the following theorem.

THEOREM 4.1. *In addition to the assumptions of Theorem* 3.1, *we assume* (2.23) *and that*

$$\frac{4}{\theta^2}(g - r\mathbf{1})^*(\sigma\sigma)^{-1}(g - r\mathbf{1}) - (Dw)^*\lambda\sigma^*(\sigma\sigma^*)^{-1}\sigma\lambda^* Dw \to \infty, \qquad |x| \to \infty; \tag{4.1}$$

then $\hat{H}_t$ *is an optimal strategy for portfolio optimization maximizing long run criterion* (2.8):

$$J(v, x; \hat{H}) = \sup_{h \in \mathcal{A}} J(v, x; h).$$

Proof. The Bellman equation (2.28) has the original form

$$\chi = \frac{1}{2}\mathrm{tr}(\lambda\lambda^*(x)D^2 w) + B(x)^* Dw - \frac{\theta}{4}(Dw)^*\lambda\lambda^*(x)Dw + \sup_{h \in R^m}\left\{-\frac{\theta}{2}(\lambda\sigma^* h)^* Dw - \eta(x, h)\right\}$$

and the supremum in this equation is attained by

$$\hat{H}(x) = \frac{2}{\theta+2}(\sigma\sigma^*)^{-1}\left(g - r\mathbf{1} - \frac{\theta}{2}\sigma\lambda^* Dw\right)(x).$$

We consider the stochastic differential equation

$$dX_t = \left(b(X_t) - \frac{\theta}{2}\lambda\sigma^*\hat{H}(X_t)\right)dt + \lambda(X_t)dW_t^{\hat{H}},$$

where

$$W_t^{\hat{H}} = W_t + \frac{\theta}{2}\int_0^t \sigma^*(X_s)\hat{H}(X_s)ds.$$

Then

$$\begin{aligned} w(X_t) - w(X_0) &= \int_0^t \{\tfrac{1}{2}\mathrm{tr}(\lambda\lambda^* D^2 w)(X_s) + (b^* - \tfrac{\theta}{2}\hat{H}^*\sigma\lambda^*)Dw(X_s)\}ds \\ &\quad + \int_0^t (Dw)^*\lambda(X_s)dW_s^{\hat{H}} \\ &= \int_0^t \{\chi + \tfrac{\theta}{4}(Dw)^*\lambda\lambda^* Dw(X_s) + \eta(X_s, \hat{H}_s)\}ds + \int_0^t (Dw)^*\lambda(X_s)dW_s^{\hat{H}}. \end{aligned} \tag{4.2}$$

Therefore, we have

$$\begin{aligned} &E_x^{\hat{H}}\left[e^{\frac{\theta}{2}\int_0^T \eta(X_s, \hat{H}_s)ds}\right] \\ &= E_x^{\hat{H}}\left[e^{-\frac{\theta}{2}\{\chi T + \int_0^T (Dw)^*\lambda(X_s)dW_s^{\hat{H}} + \frac{\theta}{4}\int_0^T (Dw)^*\lambda\lambda^* Dw(X_s)ds - w(X_T) + w(x)\}}\right]. \end{aligned}$$

We define new probability measure $\hat{P}$ by

$$\left.\frac{d\hat{P}}{dP^{\hat{H}}}\right|_{\mathcal{F}_t} = e^{-\frac{\theta}{2}\int_0^T (Dw)^*\lambda(X_s)dW_s^{\hat{H}} - \frac{\theta^2}{8}\int_0^T (Dw)^*\lambda\lambda^* Dw(X_s)ds}; \tag{4.3}$$

then $\hat{W}_t$ defined by

$$\hat{W}_t = W_s^{\hat{H}} + \frac{\theta}{2}\int_0^t \lambda^* Dw(X_s)ds$$

is a Brownian motion under the probability measure $\hat{P}$ and the above stochastic differential equation is described, by using $\hat{W}_t$, as

$$dX_t = \left(b(X_t) - \frac{\theta}{2}\lambda\sigma^*\hat{H}(X_t) - \frac{\theta}{2}\lambda\lambda^* Dw(X_t)\right)dt + \lambda(X_t)d\hat{W}_t.$$

Note that we can see that $|\nabla w|$ is at most linear growth because of the estimate (2.17) under the assumption (2.23) and the right-hand side of (4.3) is a martingale in a similar way to the proof of Proposition 2.1 (ii) (cf. the remark after Theorem 2.1). Thus,

$$E_x^{\hat{H}}[e^{\frac{\theta}{2}\int_0^T \eta(X_s,\hat{H}_s)ds}] = e^{-\frac{\theta}{2}\chi T - \frac{\theta}{2}w(x)}\hat{E}[e^{\frac{\theta}{2}w(X_T)}].$$

Then

$$\begin{aligned} e^{\frac{\theta}{2}w(X_T)} - e^{\frac{\theta}{2}w(X_0)} &= \tfrac{\theta}{2}\int_0^T e^{\frac{\theta}{2}w(X_s)}(Dw)^*\lambda(X_s)d\hat{W}_s \\ &\quad + \int_0^T e^{\frac{\theta}{2}w(X_s)}\{\tfrac{\theta}{4}\mathrm{tr}(\lambda\lambda^* D^2 w) + \tfrac{\theta^2}{8}(Dw)^*\lambda\lambda^* Dw \\ &\quad + \tfrac{\theta}{2}(B - \tfrac{\theta}{2}\lambda\sigma^*\hat{H} - \tfrac{\theta}{2}\lambda\lambda^* Dw)^* Dw\}(X_s)ds. \end{aligned}$$

Note that

$$\frac{\theta}{4}\mathrm{tr}(\lambda\lambda^* D^2 w) - \frac{\theta^2}{8}(Dw)^*\lambda\lambda^* Dw + \frac{\theta}{2}\left(B - \frac{\theta}{2}\lambda\sigma^*\hat{H}\right)^* Dw = \frac{\theta}{2}(\eta(x,\hat{H}(x)) + \chi)$$

and

$$\begin{aligned} \eta(x,\hat{H}(x)) &= \tfrac{\theta+2}{4}\hat{H}^*\sigma\sigma^*\hat{H}(x) - \hat{H}^*(g - r\mathbf{1})(x) - r(x) \\ &= -\tfrac{1}{\theta+2}(g - r\mathbf{1})^*(\sigma\sigma^*)^{-1}(g - r\mathbf{1})(x) \\ &\quad + \tfrac{\theta^2}{4(\theta+2)}(Dw)^*\lambda\sigma^*(\sigma\sigma^*)^{-1}\sigma\lambda^* Dw(x) - r(x). \end{aligned}$$

Then, under assumption (4.1), we see that

$$\eta(x,\hat{H}(x)) + \chi \le 0, \qquad x \in B_R^c, \ \ \exists R > 0,$$

which implies, by the arguments using a stopping time,

$$\hat{E}[e^{\frac{\theta}{2}w(X_T)}] \le e^{\frac{\theta}{2}w(x)} + MT, \qquad \exists M > 0.$$

Hence we conclude that

$$\lim_{T\to\infty} -\frac{2}{\theta T}\log E_x^{\hat{H}}[e^{\frac{\theta}{2}\int_0^T \eta(X_s,\hat{H}_s)ds}] = \lim_{T\to\infty} -\frac{2}{\theta T}\log\{e^{-\frac{\theta}{2}\chi T - \frac{\theta}{2}w(x)}\hat{E}[e^{\frac{\theta}{2}w(X_T)}]\} = \chi.$$

For $h \in \mathcal{A}$, inequality $\leq$ holds in (4.2) and we can see that

$$J(v, x; h) \leq \chi$$

in a similar way to the above since w is bounded below. □

Remark. Under the probability measure $\hat{P}_x$, the factor process is an ergodic diffusion process with the generator $\hat{L}$. In fact, by calculation, we can see that

$$\begin{aligned}&\tfrac{1}{2}\mathrm{tr}(\lambda\lambda^* D^2) + (b - \tfrac{\theta}{2}\lambda\sigma^*\hat{H} - \tfrac{\theta}{2}\lambda\lambda^* Dw)^* D \\ &\quad = \tfrac{1}{2}\mathrm{tr}(\lambda\lambda^*(x)D^2) + G^*(x)D - 2(\lambda N^{-1}\lambda^*(x)Dw(x) - \lambda K(x))^* D.\end{aligned}$$

Then, under assumption (4.1), $\hat{L}$ diffusion process $(\hat{P}_x, X_t)$ satisfies

$$\hat{E}_x[e^{\frac{\theta}{2}w(X_T)}] \to \int e^{\frac{\theta}{2}w(x)}\mu(dx) < \infty \qquad \text{as } T \to \infty,$$

where μ is the invariant measure of (P_x, X_t).

5. Example.

Example (linear Gaussian case). Let us consider the case where

$$\begin{aligned} g(x) = a + Ax,\ \sigma(x) = \Sigma, \\ b(x) = b + Bx,\ \lambda(x) = \Lambda, \\ r(x) = r, \end{aligned}$$

where A, B, Σ, Λ are all constant matrices and a and b are constant vectors. Such a case has been considered by Bielecki and Pliska [4], [5], Fleming and Sheu [8], [9], and Kuroda and Nagai [12].

In this case the solution $u(t, x)$ of (2.14) has the following explicit form:

$$u(t, x) = \frac{1}{2}x^* P(t)x + q(t)^* x + k(t),$$

where $P(t)$ is a solution of the Riccati differential equation

$$\begin{aligned} &\dot{P}(t) - P(t)K_0 P(t) + K_1^* P(t) + P(t)K_1 + \tfrac{2}{\theta+2}A^*(\Sigma\Sigma^*)^{-1}A = 0, \\ &P(T) = 0, \end{aligned} \tag{5.1}$$

and

$$\begin{aligned} K_0 &= \tfrac{\theta}{2}\Lambda(I - \tfrac{\theta}{\theta+2}\Sigma^*(\Sigma\Sigma^*)^{-1}\Sigma)\Lambda^*, \\ K_1 &= B - \tfrac{\theta}{\theta+2}\Lambda\Sigma^*(\Sigma\Sigma^*)^{-1}A. \end{aligned}$$

The term $q(t)$ is a solution of linear differential equation

$$\begin{aligned} &\dot{q}(t) + (K_1^* - P(t)K_0)q(t) + P(t)b + (\tfrac{2}{\theta+2}A^* - \tfrac{\theta}{\theta+2}P(t)\Lambda\Sigma^*)(\Sigma\Sigma^*)^{-1}(a - r\mathbf{1}) = 0, \\ &q(T) = 0 \end{aligned}$$

and $k(t)$ a solution of

$$\begin{aligned} &\dot{k}(t) + \frac{1}{2}\mathrm{tr}(\Lambda\Lambda^* P(t)) - \frac{\theta}{4}q(t)^*\Lambda\Lambda^* q(t) + b^* q(t) + r + \frac{1}{\theta+2}(a - r\mathbf{1})^*(\Sigma\Sigma^*)^{-1}(a - r\mathbf{1}) \\ &\quad + \frac{\theta^2}{4(\theta+2)}q(t)^*\Lambda\Sigma^*(\Sigma\Sigma^*)^{-1}\Sigma\Lambda^* q(t) - \frac{\theta}{\theta+2}(a - r\mathbf{1})^*(\Sigma\Sigma^*)^{-1}\Sigma\Lambda^* q(t) = 0, \\ &k(T) = \log v. \end{aligned}$$

If

$$G \equiv B - \Lambda\Sigma^*(\Sigma\Sigma^*)^{-1}A \quad \text{is stable,}$$

then

(i) $P(0) = P(0;T)$ converges, as $T \to \infty$, to a nonnegative definite matrix $\tilde{P}$, which is a solution of algebraic Riccati equation

$$K_1^*\tilde{P} + \tilde{P}K_1 - \tilde{P}K_0\tilde{P} + \frac{2}{\theta+2}A^*(\Sigma\Sigma^*)^{-1}A = 0.$$

Moreover, $\tilde{P}$ satisfies the estimate

$$0 \le \tilde{P} \le \frac{2}{\theta}\int_0^\infty e^{sG^*}A^*(\Sigma\Sigma^*)^{-1}Ae^{sG}ds. \tag{5.2}$$

(ii) $q(0) = q(0;T)$ converges, as $T \to \infty$, to a constant vector $\tilde{q}$, which satisfies

$$(K_1^* - \tilde{P}K_0)\tilde{q} + \tilde{P}b + \left(\frac{2}{\theta+2}A^* - \frac{\theta}{\theta+2}\tilde{P}\Lambda\Sigma^*\right)(\Sigma\Sigma^*)^{-1}(a - r\mathbf{1}) = 0.$$

(iii) $\frac{k(0;T)}{T}$ converges to a constant $\rho(\theta)$ defined by

$$\begin{aligned}\rho(\theta) = {} & \frac{1}{2}\mathrm{tr}(\tilde{P}\Lambda\Lambda^*) - \frac{\theta}{4}\tilde{q}^*\Lambda\Lambda^*\tilde{q} + b^*\tilde{q} + r + \frac{1}{\theta+2}(a - r\mathbf{1})^*(\Sigma\Sigma^*)^{-1}(a - r\mathbf{1}) \\ & + \tfrac{\theta^2}{4\theta+8}\tilde{q}^*\Lambda\Sigma^*(\Sigma\Sigma^*)^{-1}\Sigma\Lambda^*\tilde{q} - \tfrac{\theta}{\theta+2}(a - r\mathbf{1})^*(\Sigma\Sigma^*)^{-1}\Sigma\Lambda^*\tilde{q}.\end{aligned}$$

If, moreover,

$$(B^*, A^*(\Sigma\Sigma^*)^{-1}\Sigma) \text{ is controllable,} \tag{5.3}$$

then

(iv) the solution $\tilde{P}$ of the above algebraic Riccati equation is strictly positive definite.

Finally, if, in addition to the above conditions,

$$(B, \Lambda) \text{ is controllable,} \tag{5.4}$$

then

(v) the investment strategy $\tilde{h}_t$ defined by

$$\tilde{h}_t = \frac{2}{\theta+2}(\Sigma\Sigma^*)^{-1}\left[a - r\mathbf{1} - \frac{\theta}{2}\Sigma\Lambda^*\tilde{q} + \left(A - \frac{\theta}{2}\Sigma\Lambda^*\tilde{P}\right)X_t\right]$$

is optimal for the portfolio optimization on infinite time horizon maximizing the criterion (2.8)

$$\sup_{h\in\mathcal{A}} J(v,x;h) = J(v,x;\tilde{h}_\cdot) = \rho(\theta)$$

if and only if

$$\hat{P}\Lambda\Sigma^*(\Sigma\Sigma^*)^{-1}\Sigma\Lambda^*\hat{P} < A^*(\Sigma\Sigma^*)^{-1}A, \tag{5.5}$$

where $\hat{P} = \frac{\theta}{2}\tilde{P}$ (cf. [12]).

Set

$$w(x) = \frac{1}{2}x^*\tilde{P}x + \tilde{q}^*x;$$

then $w(x)$ satisfies (2.28) and (5.5) is equivalent to

$$\int e^{\frac{\theta}{2}w(x)}\mu(dx) < \infty$$

under the assumptions (5.3) and (5.4), where $\mu(dx)$ is the invariant measure of $\hat{L}$ diffusion process. We consider the case where $n = m = 1$. Then $\Sigma\Sigma^*$, $\Lambda\Sigma^*$, A, B are all scalars and (5.5) is written as

$$\frac{\theta^2}{4}\tilde{P}^2(\Lambda\Sigma^*)^2 < A^2. \tag{5.5$'$}$$

We can find sufficient condition for (5.5′) by using estimate (5.2). Indeed, If

$$A^2(\Lambda\Sigma^*)^2(\Sigma\Sigma^*)^{-2}\left(\int_0^\infty e^{2sG}ds\right)^2 < 1, \tag{5.6}$$

then (5.5′) holds. (5.6) is equivalent to

$$(2B(\Sigma\Sigma^*) - 3(\Lambda\Sigma^*)A)(2B(\Sigma\Sigma^*) - (\Lambda\Sigma^*)A) > 0,$$

which indicates that

$$B < \frac{1}{2}\Lambda\Sigma^*(\Sigma\Sigma^*)^{-1}A \quad \text{if} \quad \Lambda\Sigma^*A > 0, \tag{5.7}$$

$$B < \frac{3}{2}\Lambda\Sigma^*(\Sigma\Sigma^*)^{-1}A \quad \text{if} \quad \Lambda\Sigma^*A < 0 \tag{5.8}$$

since $G = B - \Lambda\Sigma^*(\Sigma\Sigma^*)^{-1}A < 0$ by the stability assumption.

We illustrate an example where (5.5′) is violated as follows. Set $\theta = 4$ and $B = \frac{2}{3}\Lambda\Sigma^*(\Sigma\Sigma^*)^{-1}A$; then we have

$$\tilde{P}^2(6\Lambda\Lambda^*\Sigma\Sigma^* - 4(\Lambda\Sigma^*)^2) = A^2$$

and therefore (5.5′) is violated if and only if

$$6\Lambda\Lambda^*\Sigma\Sigma^* - 4(\Lambda\Sigma^*)^2 \le 4(\Lambda\Sigma^*)^2,$$

namely,

$$4(\Lambda\Sigma^*)^2 \ge 3\Lambda\Lambda\Sigma\Sigma^*. \tag{5.9}$$

Set $\Lambda = (1, \lambda)$, $\Sigma = (1, \sigma)$; then (5.9) is equivalent to

$$\{\lambda\sigma + 1 + \sqrt{3}(\lambda - \sigma)\}\{\lambda\sigma + 1 - \sqrt{3}(\lambda - \sigma)\} \ge 0.$$

APPROXIMATE NONLINEAR FILTERING FOR A TWO-DIMENSIONAL DIFFUSION WITH ONE-DIMENSIONAL OBSERVATIONS IN A LOW NOISE CHANNEL*

PAULA MILHEIRO DE OLIVEIRA† AND JEAN PICARD‡

Abstract. The asymptotic behavior of a nonlinear continuous time filtering problem is studied when the variance of the observation noise tends to 0. We suppose that the signal is a two-dimensional process from which only one of the components is noisy and that a one-dimensional function of this signal, depending only on the unnoisy component, is observed in a low noise channel. An approximate filter is considered in order to solve this problem. Under some detectability assumptions, we prove that the filtering error converges to 0, and an upper bound for the convergence rate is given. The efficiency of the approximate filter is compared with the efficiency of the optimal filter, and the order of magnitude of the error between the two filters, as the observation noise vanishes, is obtained.

Key words. stochastic differential models, nonlinear filtering, approximate filters

1. Introduction.

Due to its vast application in engineering, the problem of filtering a random signal X_t from noisy observations of a function $h(X_t)$ of this signal has been considered by several authors. In particular, the case of small observation noise has been widely studied, and several articles are devoted to the research of approximate filters which are asymptotically efficient when the observation noise vanishes. Among them, one notices a first group in which a one-dimensional system is observed through an injective observation function h (see [4, 5, 7, 1]); in this case, the filtering error is small when the observation noise is small, and one can find efficient suboptimal finite-dimensional filters. The multidimensional case appears later with [8, 9], but an assumption of injectivity of h is again required; in particular, the extended Kalman filter is studied in [9]. See also previous work by Krener [6] for systems with linear observations. When h is not injective, the process $\{X_t\}$ cannot always be restored from the observation of $\{h(X_t)\}$, so the filtering error is not always small; such a case is studied in [3]. However, there are some classes of problems in which $\{X_t\}$ can be restored from $\{h(X_t)\}$; in these cases, the filtering error is small, and one again looks for efficient suboptimal filters. For instance, $\{X_t\}$ is sometimes obtained from $\{h(X_t)\}$ and its quadratic variation; see [2, 10, 11, 13]. Here, we are interested in another case in which $h(X_t)$ is differentiable with respect to the time t, and $\{X_t\}$ is obtained from $\{h(X_t)\}$ and its derivative. As opposed to [9], the existence of a Lipschitz inverse of h is not assumed in this paper, as the dimension of the measurements that we consider is lower than that of the state. More precisely, we consider the framework of [12], which we now describe.

We consider the two-dimensional process $X_t = (x_t^{(1)}, x_t^{(2)})$ given by the Itô equa-

tion

$$\left\{\begin{array}{rcl} dx_t^{(1)} &=& f_1(x_t^{(1)}, x_t^{(2)})\, dt, \\ dx_t^{(2)} &=& f_2(x_t^{(1)}, x_t^{(2)})\, dt + \sigma(x_t^{(1)}, x_t^{(2)})\, dw_t, \end{array}\right. \tag{1.1}$$

with initial condition $X_0 = (x_0^{(1)}, x_0^{(2)})$, and we are concerned by the problem of estimating the signal X_t when the observation process is modelled by the equation

$$dy_t = h(x_t^{(1)})\, dt + \varepsilon\, d\bar{w}_t, \tag{1.2}$$

where $\{w_t\}$ and $\{\bar{w}_t\}$ are standard independent real-valued Wiener processes and ε is a small nonnegative parameter. In particular, if $f_1(x_1, x_2) = x_2$, then $x_t^{(1)}$ is the position of some moving body on $\mathbf{R}$, $x_t^{(2)}$ is its speed, the body is submitted to a dynamical force described by f_2 and to a random force described by σ, and one has a noisy observation of the position. This class of problems arises in practice in tracking RADAR applications, for instance, as well as in control and communications engineering. The use of the method of proof introduced in [7] and later extended to [9] in the class of systems (1.1)–(1.2) is not covered by previous work.

If $\varepsilon = 0$ and if the functions h and $x_2 \mapsto f_1(x_1, x_2)$ are injective, then the signal X_t can (at least theoretically) be exactly restored from the observation; we are here interested by the asymptotic case $\varepsilon \to 0$, and we look for a good approximation of the optimal filter

$$\hat{X}_t = (\hat{x}_t^{(1)}, \hat{x}_t^{(2)}) = E\big[X_t \;\big|\; y_s, 0 \le s \le t\big].$$

This approximation should be finite-dimensional (a solution of a finite-dimensional equation driven by y_t).

The same problem has been dealt with in [12] (with σ constant) by means of a formal asymptotic expansion of the optimal filter in a stationary situation. Our aim is to work out a rigorous mathematical study of the filter proposed by [12], namely the solution $M_t = (m_t^{(1)}, m_t^{(2)})$ of

$$dM_t = f(M_t)dt + R_t[dy_t - h(m_t^{(1)})dt], \tag{1.3}$$

$$R_t \stackrel{def}{=} \left[\begin{array}{c} \sqrt{\dfrac{2\sigma(M_t)F_{12}(M_t)}{h'(m_t^{(1)})\,\varepsilon}} \\ \dfrac{\sigma(M_t)}{\varepsilon} \end{array}\right], \tag{1.4}$$

with $F_{12} = \partial f_1/\partial x_2$ and with initial condition $M_0 = E[X_0]$. This filter does in fact correspond to the extended Kalman filter with stationary gain if one neglects the contribution of the derivatives of f other than $\partial f_1/\partial x_2$. The stability of this filter is not evident and requires some assumptions. When it is stable, we prove in this work that

$$x_t^{(1)} - m_t^{(1)} = \mathcal{O}(\varepsilon^{3/4}), \quad x_t^{(2)} - m_t^{(2)} = \mathcal{O}(\varepsilon^{1/4}), \tag{1.5}$$

and

$$\hat{x}_t^{(1)} - m_t^{(1)} = \mathcal{O}(\varepsilon), \quad \hat{x}_t^{(2)} - m_t^{(2)} = \mathcal{O}(\sqrt{\varepsilon}). \tag{1.6}$$

We also verify that (1.6) can be improved when σ is constant, h is linear, and f_1 is linear with respect to x_2. (This case will be referred to as the almost linear case.) The proofs follow the method of [9].

The contents are organized as follows. In section 2, we introduce the assumptions which will be needed in what follows, and we study the filtering error as ε converges to zero; more precisely, we obtain the rate (1.5). In section 3, the error between the approximate filter and the optimal filter is studied, and we prove (1.6). Section 4 is devoted to the almost linear case. Results of numerical simulations that illustrate the performance of this approach are included in section 5.

Notation. The following notation is used:

$$f = \begin{bmatrix} f_1 \\ f_2 \end{bmatrix}, \quad \Sigma = \begin{bmatrix} 0 \\ \sigma \end{bmatrix}, \quad H = \begin{bmatrix} h' & 0 \end{bmatrix};$$

$F = \begin{smallmatrix} F_{11} & F_{12} \\ F_{21} & F_{22} \end{smallmatrix}$ and $\Sigma' = \begin{smallmatrix} 0 & 0 \\ \Sigma'_{21} & \Sigma'_{22} \end{smallmatrix}$ are the Jacobian matrices of f and Σ; $\nabla_0 \Phi = \frac{\partial \Phi}{\partial X_0}$ is either a 2×2 matrix (if Φ is $\mathbf{R}^2$-valued) or a line-vector (if Φ is real-valued); see section 3. The symbol * is used for the transposition of matrices.

When describing the behavior of approximate filters, we will write asymptotic expressions with the meaning given by the following definition.

DEFINITION 1.1. *Consider a real- or vector-valued stochastic process $\{\xi_t\}$. If β is real and $p \geq 1$, we will write that*

$$\xi_t = \mathcal{O}(\varepsilon^\beta) \quad \textit{in} \quad L^p$$

when, for some $q \geq 0$, $\alpha > 0$, and some positive constants C_1, C_2, c_3,

$$E\big[\|\xi_t\|^p\big]^{1/p} \leq \frac{C_1}{\varepsilon^q} e^{-c_3 t/\varepsilon^\alpha} + C_2 \varepsilon^\beta$$

for $t \geq 0$ and ε small. In this situation, the process $\{\xi_t\}$ is usually said to converge to zero with rate of order ε^β, in a time scale of order ε^α.

2. Estimation of $X_t - M_t$. The following assumptions will be used throughout this article. The last one depends on a parameter $\delta \geq 1$.

(H1) X_0 is a random variable, the moments of which are finite.

(H2) $\{w_t\}$ and $\{\bar{w}_t\}$ are standard independent Wiener processes independent of X_0.

(H3) The function h is C^3 with bounded derivatives, and h' is positive.

(H4) The function f is C^3 with bounded partial derivatives, and $F_{12} = \partial f_1 / \partial x_2$ is positive.

(H5) The function σ is C^2 with bounded partial derivatives.

(H6.δ) One has

$$\frac{1}{\delta} \leq \sigma(x) \leq \delta, \quad \frac{1}{\delta} \leq h'(x_1) \leq \delta, \quad \frac{1}{\delta} \leq F_{12}(x) \leq \delta$$

for any $x = (x_1, x_2)$.

Remark 2.1. In order to reduce the notation in (H6.δ), system (1.1)–(1.2) has been rescaled. Indeed, if we assume instead that one has

$$\frac{1}{\delta} \leq \frac{\sigma(x)}{\bar{\sigma}} \leq \delta, \quad \frac{1}{\delta} \leq \frac{h'(x_1)}{\bar{H}} \leq \delta, \quad \frac{1}{\delta} \leq \frac{F_{12}(x)}{\bar{F}} \leq \delta$$

for any $x = (x_1, x_2)$ and for some positive $\bar\sigma$, $\bar H$, and $\bar F$ and if we replace the processes $x_t^{(1)}$, $x_t^{(2)}$, and y_t by $x_t^{(1)}/(\bar\sigma\bar F)$, $x_t^{(2)}/\bar\sigma$, and $y_t/(\bar\sigma\bar F\bar H)$, then the functions f_1, f_2, σ, and h are replaced, respectively, by

$$f_1(\bar\sigma\bar F x_1, \bar\sigma x_2) \,/\, (\bar\sigma\bar F), \quad f_2(\bar\sigma\bar F x_1, \bar\sigma x_2) \,/\, \bar\sigma,$$

$$\sigma(\bar\sigma\bar F x_1, \bar\sigma x_2) \,/\, \bar\sigma, \quad h(\bar\sigma\bar F x) \,/\, (\bar\sigma\bar F\bar H),$$

and ε is replaced by $\varepsilon/(\bar\sigma\bar F\bar H)$. We can apply the filter (1.3) to this new system, and we obtain $m_t^{(1)}/(\bar\sigma\bar F)$ and $m_t^{(2)}/\bar\sigma$. This shows that the problem can be reduced to the case $\bar\sigma = \bar F = \bar H = 1$.

Assumption (H6.δ) says that the system does not contain too much nonlinearity; when it is not satisfied, there may be a small positive probability for the filter to lose the signal (see [10] for a similar problem). This is a rather restrictive condition, so we discuss at the end of the section the general case in which it does not hold.

We consider the system (1.1)–(1.2) and the filter (1.3). We let $\mathcal{F}_t$ be the filtration generated by $(X_0, w_t, \bar w_t)$ and $\mathcal{Y}_t$ the filtration generated by (y_t).

THEOREM 2.1. *Assume* (H1)–(H5). *For* $1 < \delta < 2^{1/5}$, *if* (H6.δ) *holds, then one has*

$$x_t^{(1)} - m_t^{(1)} = \mathcal{O}(\varepsilon^{3/4}), \quad x_t^{(2)} - m_t^{(2)} = \mathcal{O}(\varepsilon^{1/4})$$

in L^p *for any* $p \geq 1$.

Consider a change of basis defined by a matrix T and its inverse T^{-1}, where

$$T \overset{def}{=} \begin{bmatrix} \sqrt{2/\varepsilon} & -1 \\ 0 & 1 \end{bmatrix}, \qquad T^{-1} = \begin{bmatrix} \sqrt{\varepsilon/2} & \sqrt{\varepsilon/2} \\ 0 & 1 \end{bmatrix}.$$

Then consider the process

$$Z_t \overset{def}{=} T(X_t - M_t). \tag{2.1}$$

We are going to check that Z_t is the solution of a linear stochastic differential equation; the study of the exponential stability of this equation will enable the estimation of both components of Z_t, and the theorem will immediately follow.

An equation for Z_t. From (1.1)–(1.3), we have

$$\begin{aligned} d(X_t - M_t) = {} & \big(f(X_t) - f(M_t)\big)dt - R_t\big(h(x_t^{(1)}) - h(m_t^{(1)})\big)dt \\ & + \begin{bmatrix} 0 & -\sqrt{\dfrac{2\varepsilon\,\sigma(M_t)F_{12}(M_t)}{h'(m_t^{(1)})}} \\ \sigma(X_t) & -\sigma(M_t) \end{bmatrix} \begin{bmatrix} dw_t \\ d\bar w_t \end{bmatrix}. \end{aligned}$$

In this equation, we introduce the Taylor expansions for the functions f and h,

$$f(X_t) - f(M_t) = F(\xi_t, \mu_t)(X_t - M_t)$$

and

$$h(x_t^{(1)}) - h(m_t^{(1)}) = h'(\eta_t)(x_t^{(1)} - m_t^{(1)}),$$

where $\{\xi_t\}$, $\{\mu_t\}$, and $\{\eta_t\}$ are $\mathbf{R}^2$- and $\mathbf{R}$-valued processes depending on $\{X_t\}$ and $\{M_t\}$, and

$$F(\xi_t, \mu_t) \stackrel{def}{=} \begin{bmatrix} F_{11}(\xi_t) & F_{12}(\xi_t) \\ \\ F_{21}(\mu_t) & F_{22}(\mu_t) \end{bmatrix}.$$

We obtain a linear equation for $X_t - M_t$. By applying the transformation (2.1), we deduce for Z_t an equation of the type

$$dZ_t = A_t\, Z_t\, dt + U_t \begin{bmatrix} dw_t \\ d\bar{w}_t \end{bmatrix}. \tag{2.2}$$

The precise computation shows that

$$A_t = T\big(F(\xi_t, \mu_t) - R_t H(\eta_t)\big)T^{-1} = \frac{\bar{A}_t}{\sqrt{2\varepsilon}} + \widetilde{A}_t\,,$$

with

$$\bar{A}_t^{(11)} = -2h'(\eta_t)\sqrt{\frac{F_{12}(M_t)\sigma(M_t)}{h'(m_t^{(1)})}} + h'(\eta_t)\sigma(M_t), \quad \bar{A}_t^{(12)} = \bar{A}_t^{(11)} + 2F_{12}(\xi_t),$$

$$\bar{A}_t^{(21)} = \bar{A}_t^{(22)} = -h'(\eta_t)\sigma(M_t),$$

and where $\widetilde{A}_t$ is a 2×2 matrix-valued process which is uniformly bounded as ε converges to 0; similarly, the matrix-valued process U_t is also uniformly bounded.

Stability of A_t. If $\delta = 1$, then $h' = F_{12} = \sigma = 1$, so $\bar{A}_t$ is the constant matrix

$$\bar{A}_t = \begin{bmatrix} -1 & 1 \\ -1 & -1 \end{bmatrix},$$

and

$$\bar{A}_t + \bar{A}_t^* = -2\, I.$$

In the general case $\delta > 1$, the coefficients of $\bar{A}_t + \bar{A}_t^*$ can be controlled so that this matrix is uniformly close to $-2I$ if δ is close to 1; in particular, for $1 < \delta < 2^{1/5}$, there exists $0 < \alpha < \alpha' < \sqrt{2}$ such that

$$\bar{A}_t + \bar{A}_t^* \leq -\alpha'\sqrt{2}\, I$$

and, therefore,

$$A_t + A_t^* \leq -\frac{\alpha}{\sqrt{\varepsilon}} I \tag{2.3}$$

if ε is small.

End of the proof of Theorem 2.1. Our goal is now to deduce an estimate of Z_t in L^{2p} for the p integer. From Itô's formula and (2.2), the process $\|Z_t\|^2 = Z_t^* Z_t$ is the solution of

$$d\|Z_t\|^2 = Z_t^*(A_t + A_t^*)Z_t\, dt + \operatorname{trace}(U_t^* U_t)\, dt + 2\, Z_t^* U_t \begin{bmatrix} dw_t \\ d\bar{w}_t \end{bmatrix}.$$

We deduce that the moment of order p of $\|Z_t\|^2$ is finite and that

$$\frac{d}{dt}E[\|Z_t\|^{2p}] = p\,E[\|Z_t\|^{2p-2}Z_t^*(A_t+A_t^*)Z_t] + p\,E[\|Z_t\|^{2p-2}\mathrm{trace}(U_t^*U_t)]$$
$$+2\,p\,(p-1)\,E[\|Z_t\|^{2p-4}\,\|U_t^*Z_t\|^2]\,.$$

From (2.3), one has

$$Z_t^*(A_t+A_t^*)Z_t \le -\frac{\alpha}{\sqrt{\varepsilon}}\,\|Z_t\|^2.$$

As a consequence of the Cauchy–Schwarz inequality, one has

$$\|U_t^*Z_t\|^2 \le \mathrm{trace}(U_t^*U_t)\,\|Z_t\|^2\,.$$

Thus we obtain the inequality

$$\frac{d}{dt}E[\|Z_t\|^{2p}] \le -p\,\frac{\alpha}{\sqrt{\varepsilon}}E[\|Z_t\|^{2p}] + p\,(2p-1)E[\|Z_t\|^{2p-2}\mathrm{trace}(U_t^*U_t)]$$
$$\le -p\,\frac{\alpha}{\sqrt{\varepsilon}}E[\|Z_t\|^{2p}] + C_pE[\|Z_t\|^{2p-2}]\,.$$

Moreover, there exists C_p' such that

$$C_p\|Z_t\|^{2p-2} \le p\,\frac{\alpha}{2\sqrt{\varepsilon}}\|Z_t\|^{2p} + C_p'\varepsilon^{(p-1)/2},$$

and so

$$\frac{d}{dt}E[\|Z_t\|^{2p}] \le -\frac{\alpha}{2\sqrt{\varepsilon}}\,p\,E[\|Z_t\|^{2p}] + C_p'\varepsilon^{(p-1)/2}\,.$$

By solving this differential inequality, one obtains that, for some $C_p'' > 0$,

$$E[\|Z_t\|^{2p}] \le C_p''\varepsilon^{p/2} + C_p''\,E[\|Z_0\|^{2p}]\,e^{-\alpha\,p\,t/(2\sqrt{\varepsilon})}\,. \tag{2.4}$$

Thus Z_t is $\mathcal{O}(\varepsilon^{1/4})$, and the order of magnitude of the components of $X_t - M_t$ follows from (2.1) and the form of T^{-1}. □

We remark in (2.4) that the time scale of the estimation is of order $\sqrt{\varepsilon}$; one can compare it with the time scale ε obtained when the observation function is injective (see, for instance, [7]). This means that here it takes more time to estimate the signal, and this is not surprising since the second component of the signal is not well observed. There are also other systems where the time scale is not the same for the different components of the signal (see [10]).

In Theorem 2.1, we need the assumption (H6.δ), which is a restriction to the nonlinearity of the system; otherwise, it is difficult to ensure that the filter does not lose the signal. (This problem also occurs in [10].) Actually, we have chosen the filter (1.3) because it gives a good approximation of $\hat{X}_t$ (see the next section), but it is not the most stable one. If in (1.4) we replace the processes $\sigma(M_t)$, $F_{12}(M_t)$, and $h'(m_t^{(1)})$ by constant numbers $\bar{\sigma}$, $\bar{F}$, and $\bar{H}$, then we obtain a filter with constant gain; we can again work out the previous estimations and prove that the result of Theorem 2.1 holds for this filter without (H6.δ) as soon as

$$\frac{\max F_{12}}{\bar{F}} < 2\frac{\min h'}{\bar{H}}.$$

Thus we have two filters—a filter which is stable and tracks the signal under rather weak assumptions and the filter (1.3) which seems more fragile but gives (under good stability assumptions) a better approximation of the optimal filter.

3. Estimation of $\hat{X}_t - M_t$. The main result contained in this section is Theorem 3.1, which states the rate of convergence of the approximate filter considered in this paper toward the optimal filter. In order to give a proof of this theorem, a sequence of steps is needed: a change of probability measure, the differentiation with respect to the initial condition, and an integration by parts formula. A similar method of proof is adopted in [9]. As in Theorem 2.1, we may have a problem of stability in the general nonlinear case.

THEOREM 3.1. *Consider a finite time interval* $[0,\tau]$. *Assume* (H1)–(H6.δ) *and the following:*

(H7) *The law of* X_0 *has a* C^1 *positive density* p_0 *with respect to the Lebesgue measure and* $\nabla p_0(X_0)/p_0(X_0)$ *is in* L^2.

If δ *in* (H6.δ) *is close enough to* 1, *in the sense that* $1 < \delta < 2^{2/9}$, *then the filter* M_t *given by* (1.3) *satisfies*

$$\hat{x}_t^{(1)} - m_t^{(1)} = \mathcal{O}(\varepsilon), \qquad \hat{x}_t^{(2)} - m_t^{(2)} = \mathcal{O}(\sqrt{\varepsilon})$$

in L^2.

The rest of this section is devoted to the proof of this theorem.

Consider the matrix

$$P_t \overset{def}{=} \begin{bmatrix} \dfrac{1}{h'(m_t^{(1)})}\sqrt{\dfrac{2\sigma(M_t)F_{12}(M_t)}{h'(m_t^{(1)})}}\,\varepsilon^{3/2} & \dfrac{\sigma(M_t)}{h'(m_t^{(1)})}\varepsilon \\ \dfrac{\sigma(M_t)}{h'(m_t^{(1)})}\varepsilon & \sigma(M_t)\sqrt{\dfrac{2\sigma(M_t)}{h'(m_t^{(1)})F_{12}(M_t)}}\,\varepsilon^{1/2} \end{bmatrix},$$

which depends only on M_t. Notice that P_t is the solution of the stationary Riccati equation

$$-\frac{1}{\varepsilon^2}P_t H^*(M_t)H(M_t)P_t + \widetilde{F}(M_t)P_t + P_t\widetilde{F}^*(M_t) + \Sigma(M_t)\Sigma^*(M_t) = 0 \tag{3.1}$$

with

$$\widetilde{F}(M_t) = \begin{bmatrix} 0 & F_{12}(M_t) \\ 0 & 0 \end{bmatrix}$$

and that the process R_t of (1.4) is

$$R_t = \frac{P_t}{\varepsilon^2}H^*(M_t). \tag{3.2}$$

We will also need the inverse of P_t, namely,

$$P_t^{-1} = \begin{bmatrix} h'(m_t^{(1)})\sqrt{\dfrac{2h'(m_t^{(1)})}{\sigma(M_t)F_{12}(M_t)}}\,\varepsilon^{-3/2} & -\dfrac{h'(m_t^{(1)})}{\sigma(M_t)}\varepsilon^{-1} \\ -\dfrac{h'(m_t^{(1)})}{\sigma(M_t)}\varepsilon^{-1} & \dfrac{1}{\sigma(M_t)}\sqrt{\dfrac{2h'(m_t^{(1)})F_{12}(M_t)}{\sigma(M_t)}}\,\varepsilon^{-1/2} \end{bmatrix}.$$

Change of probability measure. Our random variables can be viewed as functions of the initial condition X_0 and of the Wiener processes w and $\bar{w}$. We are going to

make a change of variables; in view of the Girsanov theorem, this can be viewed as a change of probability measure; however, all the estimations will be made under the original probability P. Thus consider the new probability measure which is given on $\mathcal{F}_t$ by

$$\left.\frac{d\dot{P}}{dP}\right|_{\mathcal{F}_t} = L_t^{-1}\,,$$

where

$$L_t^{-1} = \exp\left\{-\frac{1}{\varepsilon}\int_0^t h(x_s^{(1)})\,d\bar{w}_s - \frac{1}{2\varepsilon^2}\int_0^t h^2(x_s^{(1)})\,ds\right\}.$$

The probability $\dot{P}$ is the so-called reference probability, and one checks easily from the Girsanov theorem that y_t/ε and w_t are standard independent Wiener processes under $\dot{P}$. Let us define now the probability measure $\widetilde{P}$ on $\mathcal{F}_t$ by

$$\left.\frac{d\widetilde{P}}{d\dot{P}}\right|_{\mathcal{F}_t} = \Lambda_t^{-1}\,,$$

where

$$\Lambda_t^{-1} = \exp\left\{\int_0^t \Sigma^*(M_s)P_s^{-1}(X_s - M_s)\,dw_s - \frac{1}{2}\int_0^t (\Sigma^*(M_s)P_s^{-1}(X_s - M_s))^2\,ds\right\}.$$

Then the processes

$$\widetilde{w}_t = w_t - \int_0^t \Sigma^*(M_s)P_s^{-1}(X_s - M_s)\,ds$$

and y_t/ε are standard independent Wiener processes under $\widetilde{P}$. On the other hand, one has

$$dX_t = f(X_t)\,dt + \Sigma(X_t)\Sigma^*(M_t)P_t^{-1}(X_t - M_t)\,dt + \Sigma(X_t)\,d\widetilde{w}_t \tag{3.3}$$

and

$$\begin{aligned}\log(L_t\Lambda_t) = {}& \frac{1}{\varepsilon^2}\int_0^t h(x_s^{(1)})\,dy_s - \frac{1}{2\varepsilon^2}\int_0^t h^2(x_s^{(1)})\,ds - \int_0^t \Sigma^*(M_s)P_s^{-1}(X_s - M_s)\,d\widetilde{w}_s \\ & -\frac{1}{2}\int_0^t (\Sigma^*(M_s)P_s^{-1}(X_s - M_s))^2\,ds\,.\end{aligned} \tag{3.4}$$

Differentiation with respect to the initial condition and an estimation. The random variables involved in our computation can now be viewed as functions of X_0, $\{\widetilde{w}_t\}$, and $\{y_t\}$; let us denote by ∇_0 the differentiation with respect to the initial condition X_0 (computed in L^p). In particular, we can see on (3.3) and (3.4) that the processes X_t and $\log(L_t\Lambda_t)$ are differentiable, and we obtain matrix- and vector-valued processes, respectively. Our aim is to estimate the process

$$V_t \overset{def}{=} (\nabla_0 \log(L_t\Lambda_t)\,(\nabla_0 X_t)^{-1} + (X_t - M_t)^* P_t^{-1})U \tag{3.5}$$

with

$$U \overset{def}{=} \begin{bmatrix} 1 & 1 \\ 0 & \sqrt{2/\varepsilon} \end{bmatrix}, \qquad U^{-1} = \begin{bmatrix} 1 & -\sqrt{\varepsilon/2} \\ 0 & \sqrt{\varepsilon/2} \end{bmatrix}.$$

Then an integration by parts will enable us to conclude.

By applying the operator ∇_0 to (3.4), one gets

$$\begin{aligned} \nabla_0 \log(L_t\Lambda_t) &= \frac{1}{\varepsilon^2}\int_0^t h'(x_s^{(1)})\nabla_0 x_s^{(1)}\,(dy_s - h(x_s^{(1)})ds) \\ &\quad - \int_0^t \Sigma^*(M_s)P_s^{-1}\nabla_0 X_s\,(d\widetilde{w}_s + \Sigma^*(M_s)P_s^{-1}(X_s - M_s)ds) \\ &= \frac{1}{\varepsilon}\int_0^t h'(x_s^{(1)})\nabla_0 x_s^{(1)}\,d\bar{w}_s - \int_0^t \Sigma^*(M_s)P_s^{-1}\nabla_0 X_s\,dw_s\,. \end{aligned} \tag{3.6}$$

We can also differentiate (3.3), and, if Σ' is the Jacobian matrix of Σ, we obtain

$$d(\nabla_0 X_t) = [F(X_t) + \Sigma(X_t)\Sigma^*(M_t)P_t^{-1}]\nabla_0 X_t\,dt + \Sigma'(X_t)\nabla_0 X_t\,dw_t.$$

The matrix $\nabla_0 X_t$ is invertible, and Itô's calculus shows that

$$\begin{aligned} d(\nabla_0 X_t)^{-1} &= -(\nabla_0 X_t)^{-1}[F(X_t) + \Sigma(X_t)\Sigma^*(M_t)P_t^{-1} - \Sigma'^2(X_t)]\,dt \\ &\quad -(\nabla_0 X_t)^{-1}\Sigma'(X_t)dw_t\,. \end{aligned} \tag{3.7}$$

From this equation and (3.6), one can write that

$$\begin{aligned} d\left(\nabla_0 \log(L_t\Lambda_t)(\nabla_0 X_t)^{-1}\right) &= \frac{1}{\varepsilon}H(X_t)\,d\bar{w}_t - \Sigma^*(M_t)P_t^{-1}\,dw_t \\ &\quad -\nabla_0 \log(L_t\Lambda_t)(\nabla_0 X_t)^{-1}\Sigma'(X_t)\,dw_t \\ &\quad -\nabla_0 \log(L_t\Lambda_t)(\nabla_0 X_t)^{-1} \\ &\qquad .[F(X_t) + \Sigma(X_t)\Sigma^*(M_t)P_t^{-1} - \Sigma'^2(X_t)]dt \\ &\quad +\Sigma^*(M_t)P_t^{-1}\Sigma'(X_t)dt \end{aligned} \tag{3.8}$$

since one has $h'(x_t^{(1)})\nabla_0 x_t^{(1)}(\nabla_0 X_t)^{-1} = H(X_t)$.

On the other hand, from the equations of X_t and M_t ((1.1) and (1.3), respectively), one has

$$d(X_t - M_t) = [f(X_t) - f(M_t)]\,dt - R_t[h(x_t^{(1)}) - h(m_t^{(1)})]\,dt - R_t\varepsilon\,d\bar{w}_t + \Sigma(X_t)\,dw_t\,.$$

By writing the differential of P_t^{-1} in the form

$$dP_t^{-1} = J_t^{(1)}\,dt + J_t^{(2)}\,d\bar{w}_t,$$

we obtain

$$\begin{aligned} d\left((X_t - M_t)^*P_t^{-1}\right) &= [f^*(X_t) - f^*(M_t) - R_t^*(h(x_t^{(1)}) - h(m_t^{(1)}))]P_t^{-1}\,dt \\ &\quad +\Sigma^*(X_t)P_t^{-1}\,dw_t - \varepsilon\,R_t^*P_t^{-1}\,d\bar{w}_t \\ &\quad +(X_t - M_t)^*[J_t^{(1)}\,dt + J_t^{(2)}\,d\bar{w}_t] - \varepsilon\,R_t^*J_t^{(2)}\,dt\,. \end{aligned} \tag{3.9}$$

One can write the Taylor expansions for f and h,

$$f(X_t) - f(M_t) = F(M_t)(X_t - M_t) + \phi_t\,,$$
$$h(x_t^{(1)}) - h(m_t^{(1)}) = H(M_t)(X_t - M_t) + \gamma_t,$$

with

$$\|\phi_t\| \le C\|X_t - M_t\|^2, \quad |\gamma_t| \le C|x_t^{(1)} - m_t^{(1)}|^2.$$

By using these expansions together with the consequence of (3.2),

$$H^*(M_t)R_t^*P_t^{-1} = \frac{1}{\varepsilon^2}H^*(M_t)H(M_t),$$

in (3.9), we obtain

$$\begin{aligned} d((X_t - M_t)^*P_t^{-1}) = (X_t - M_t)^*\left(F^*(M_t)P_t^{-1} - \frac{1}{\varepsilon^2}H^*(M_t)H(M_t)\right)dt \\ +\Sigma^*(X_t)P_t^{-1}\,dw_t - \varepsilon\,R_t^*P_t^{-1}d\bar{w}_t \\ +(X_t - M_t)^*[J_t^{(1)}\,dt + J_t^{(2)}\,d\bar{w}_t] - \varepsilon\,R_t^*J_t^{(2)}\,dt \\ +(\phi_t^* - \gamma_t R_t^*)P_t^{-1}\,dt\,. \end{aligned}$$

By adding this equation to (3.8), we obtain that the process V_t of (3.5) satisfies

$$\begin{aligned} d\big(V_tU^{-1}\big) = -V_tU^{-1}[F(X_t) + \Sigma(X_t)\Sigma^*(M_t)P_t^{-1} - \Sigma'^2(X_t)]dt - V_tU^{-1}\,\Sigma'(X_t)\,dw_t \\ +\frac{1}{\varepsilon}H(X_t)d\bar{w}_t - \Sigma^*(M_t)P_t^{-1}dw_t + \Sigma^*(M_t)P_t^{-1}\Sigma'(X_t)dt \\ +(X_t - M_t)^*S_tdt + (X_t - M_t)^*P_t^{-1}\Sigma'(X_t)dw_t + \Sigma^*(X_t)P_t^{-1}dw_t \\ -\varepsilon R_t^*P_t^{-1}d\bar{w}_t + (X_t - M_t)^*[J_t^{(1)}dt + J_t^{(2)}d\bar{w}_t] - \varepsilon R_t^*J_t^{(2)}dt \\ +(\phi_t^* - \gamma_t R_t^*)P_t^{-1}dt, \end{aligned} \tag{3.10}$$

where S_t is the matrix given by

$$\begin{aligned} S_t \stackrel{def}{=} -\frac{1}{\varepsilon^2}H^*(M_t)H(M_t) + F^*(M_t)P_t^{-1} + P_t^{-1}F(X_t) \\ +P_t^{-1}\Sigma(X_t)\Sigma^*(M_t)P_t^{-1} - P_t^{-1}\Sigma'^2(X_t)\,. \end{aligned} \tag{3.11}$$

Consider also the matrix-valued process

$$A_t \stackrel{def}{=} -U^{-1}[F(X_t) + \Sigma(X_t)\Sigma^*(M_t)P_t^{-1} - \Sigma'^2(X_t)]U\,. \tag{3.12}$$

Then (3.10) can be written in the form

$$\begin{aligned} dV_t &= V_tA_tdt - V_tU^{-1}\Sigma'(X_t)Udw_t + J_t^{(3)}dt + J_t^{(4)}dw_t + J_t^{(5)}d\bar{w}_t, \\ V_0 &= (X_0 - M_0)^*P_0^{-1}U, \end{aligned} \tag{3.13}$$

where

$$\begin{aligned} J_t^{(3)} &= \Sigma^*(M_t)P_t^{-1}\Sigma'(X_t)U + (X_t - M_t)^*S_tU + (X_t - M_t)^*J_t^{(1)}U \\ &\quad -\varepsilon R_t^*J_t^{(2)}U + (\phi_t^* - \gamma_t R_t^*)P_t^{-1}U, \\ J_t^{(4)} &= (\Sigma^*(X_t) - \Sigma^*(M_t))P_t^{-1}U + (X_t - M_t)^*P_t^{-1}\Sigma'(X_t)U, \\ J_t^{(5)} &= \frac{1}{\varepsilon}H(X_t)U - \varepsilon R_t^*P_t^{-1}U + (X_t - M_t)^*J_t^{(2)}U \\ &= \frac{1}{\varepsilon}(H(X_t) - H(M_t))U + (X_t - M_t)^*J_t^{(2)}U \end{aligned}$$

(apply (3.2) for the last line). We deduce that $E[\|V_0\|^2]$ is of order ε^{-3} and that

$$\begin{aligned}\frac{d}{dt}E[\|V_t\|^2] &= E[V_t(A_t + A_t^*)V_t^*] + 2E[J_t^{(3)}V_t^*] \\ &\quad + E[\|V_tU^{-1}\Sigma'(X_t)U + J_t^{(4)}\|^2] + E[\|J_t^{(5)}\|^2]\,.\end{aligned} \tag{3.14}$$

We have to estimate the terms of the right-hand side.

By computing the matrix A_t, we obtain that

$$A_t = \frac{\bar{A}_t}{\sqrt{2\varepsilon}} + \widetilde{A}_t$$

with

$$\bar{A}_t^{(11)} = -\bar{A}_t^{(21)} = -h'(m_t^{(1)})\sigma(X_t)\,,$$

$$\bar{A}_t^{(12)} = -2\,F_{12}(X_t) - h'(m_t^{(1)})\sigma(X_t) + 2\,\sigma(X_t)\sqrt{\frac{h'(m_t^{(1)})F_{12}(M_t)}{\sigma(M_t)}}\,,$$

$$\bar{A}_t^{(22)} = h'(m_t^{(1)})\sigma(X_t) - 2\,\sigma(X_t)\sqrt{\frac{h'(m_t^{(1)})F_{12}(M_t)}{\sigma(M_t)}}\,,$$

and $\widetilde{A}_t$ is uniformly bounded. As in the proof of Theorem 2.1, we see that, if $\delta = 1$, then the matrix $\bar{A}_t$ is simply

$$\bar{A}_t = \begin{bmatrix} -1 & -1 \\ 1 & -1 \end{bmatrix},$$

which satisfies

$$\bar{A}_t + \bar{A}_t^* = -2\,I\,.$$

Thus, for $0 < \alpha < \sqrt{2}$, when δ is close enough to 1, that is, $1 < \delta < 2^{2/9}$, and when ε is small enough, we have

$$A_t + A_t^* \le -\frac{\alpha}{\sqrt{\varepsilon}}I\,. \tag{3.15}$$

We also notice that

$$2J_t^{(3)}V_t^* \le \frac{\alpha}{3\sqrt{\varepsilon}}\|V_t\|^2 + C\sqrt{\varepsilon}\|J_t^{(3)}\|^2$$

and that

$$\|V_tU^{-1}\Sigma'(X_t)U + J_t^{(4)}\|^2 \le C\|V_t\|^2 + 2\|J_t^{(4)}\|^2$$

because $U^{-1}\Sigma'(X_t)U$ is bounded. Thus (3.14) implies that, for small ε,

$$\begin{aligned}\frac{d}{dt}E[\|V_t\|^2] &\le -\frac{\alpha}{3\sqrt{\varepsilon}}E[\|V_t\|^2] + C\sqrt{\varepsilon}\,E[\|J_t^{(3)}\|^2] \\ &\quad + 2\,E[\|J_t^{(4)}\|^2] + E[\|J_t^{(5)}\|^2]\,.\end{aligned} \tag{3.16}$$

Let us first estimate $J_t^{(3)}$. We deduce from the Riccati equation (3.1) satisfied by P_t that the process S_t defined in (3.11) satisfies

$$S_t = \big(F^*(M_t) - \widetilde{F}^*(M_t)\big)P_t^{-1} + P_t^{-1}\big(F(X_t) - \widetilde{F}(M_t)\big) \\ +P_t^{-1}\big(\Sigma(X_t) - \Sigma(M_t)\big)\Sigma^*(M_t)P_t^{-1} - P_t^{-1}\Sigma'^2(X_t).$$

By computing this matrix and applying Theorem 2.1, we check that

$$S_t = \begin{bmatrix} \mathcal{O}(\varepsilon^{-7/4}) & \mathcal{O}(\varepsilon^{-5/4}) \\ \mathcal{O}(\varepsilon^{-5/4}) & \mathcal{O}(\varepsilon^{-3/4}) \end{bmatrix}$$

in the spaces L^p. Thus

$$(X_t - M_t)^* S_t U = \mathcal{O}(\varepsilon^{-1}).$$

The term $\Sigma^*(M_t)P_t^{-1}\Sigma'(X_t)U$ is easily shown to have the same order of magnitude. On the other hand, by looking at the equation of M_t and by applying Itô's formula, we can prove that, for any C^2 function ρ with bounded derivatives, one has

$$d\rho(M_t) = \mathcal{O}(\varepsilon^{-1/4})dt + \mathcal{O}(1)d\bar{w}_t.$$

By applying this result to the functions involved in P_t^{-1}, it appears that

$$J_t^{(1)} = \begin{bmatrix} \mathcal{O}(\varepsilon^{-7/4}) & \mathcal{O}(\varepsilon^{-5/4}) \\ \mathcal{O}(\varepsilon^{-5/4}) & \mathcal{O}(\varepsilon^{-3/4}) \end{bmatrix}, \quad J_t^{(2)} = \begin{bmatrix} \mathcal{O}(\varepsilon^{-3/2}) & \mathcal{O}(\varepsilon^{-1}) \\ \mathcal{O}(\varepsilon^{-1}) & \mathcal{O}(\varepsilon^{-1/2}) \end{bmatrix}.$$

We deduce that the terms of $J_t^{(3)}$ involving $J_t^{(1)}$ and $J_t^{(2)}$ are also of order ε^{-1}. Finally, ϕ_t and γ_t are, respectively, of order $\varepsilon^{1/2}$ and $\varepsilon^{3/2}$, and so the last term is of order ε^{-1}, and we deduce that

$$J_t^{(3)} = \mathcal{O}(\varepsilon^{-1}).$$

We can also estimate $J_t^{(4)}$ and $J_t^{(5)}$ and check that they are of order $\varepsilon^{-3/4}$. Thus (3.16) enables us to conclude that

$$V_t = \mathcal{O}(1/\sqrt{\varepsilon})$$

in L^2. We can take the conditional expectation with respect to $\mathcal{Y}_t$ in this estimation because the conditional expectation is a contraction in L^2; thus $E[V_t|\mathcal{Y}_t]$ is $\mathcal{O}(1/\sqrt{\varepsilon})$ in L^2, and, therefore, we obtain from the definition (3.5) that

$$(\hat{X}_t - M_t)^* P_t^{-1} U = -E[\nabla_0 \log(L_t\Lambda_t)(\nabla_0 X_t)^{-1}U|\mathcal{Y}_t] + \mathcal{O}(1/\sqrt{\varepsilon}). \tag{3.17}$$

Application of an integration by parts formula. The estimation of the right-hand side of (3.17) can be completed by means of an integration by parts formula. It is proved in Lemma 3.4.2 of [9] that, if $G = G(X_0, \widetilde{w}, y)$ is a functional defined on the probability space which is differentiable with respect to the initial condition (in the spaces L^p) and if ∇_0^i is the differentiation with respect to the ith component of X_0, then

$$E[G\nabla_0^i \log(L_t\Lambda_t) + G(p_0^{-1}\,\partial p_0/\partial x_i)(X_0) + \nabla_0^i G|\mathcal{Y}_t] = 0. \tag{3.18}$$

We can write (3.7) in the form

$$\begin{aligned} d(\nabla_0 X_t)^{-1} = &-(\nabla_0 X_t)^{-1}(F(X_t) + \Sigma(X_t)\Sigma^*(M_t)P_t^{-1} - \Sigma'^2(X_t) \\ &+\Sigma'(X_t)(\Sigma^*(M_t)P_t^{-1}(X_t - M_t)))dt \\ &-(\nabla_0 X_t)^{-1}\Sigma'(X_t)d\widetilde{w}_t \end{aligned} \tag{3.19}$$

with $(\nabla_0 X_0)^{-1} = I$. This equation can be differentiated with respect to X_0, and so we can apply the integration by parts formula (3.18) to the coefficients of the matrix $(\nabla_0 X_t)^{-1}$. Denote by $(\nabla_0 X_t)_i^{-1}$ its ith line. Then

$$E[(\nabla_0 X_t)_i^{-1}\nabla_0^i \log(L_t\Lambda_t) + (\nabla_0 X_t)_i^{-1}(p_0^{-1}\,\partial p_0/\partial x_i)(X_0) + \nabla_0^i(\nabla_0 X_t)_i^{-1}|\mathcal{Y}_t] = 0.$$

By summing on i and multiplying by U, we have

$$\begin{aligned} E\Bigg[&\nabla_0 \log(L_t\Lambda_t)(\nabla_0 X_t)^{-1}U + (p_0^{-1}p_0')(X_0)(\nabla_0 X_t)^{-1}U \\ &+\sum_i \nabla_0^i(\nabla_0 X_t)_i^{-1}U \;\Big|\; \mathcal{Y}_t\Bigg] = 0. \end{aligned} \tag{3.20}$$

The first term of (3.20) is exactly the term that we want to estimate in (3.17).

For the second term of (3.20), if

$$\Psi_t \overset{def}{=} (p_0^{-1}p_0')(X_0)\,(\nabla_0 X_t)^{-1}U,$$

we have from (3.7) and (3.12) that

$$\Psi_0 = (p_0^{-1}p_0')(X_0)U, \quad d\Psi_t = \Psi_t A_t\,dt - \Psi_t U^{-1}\Sigma'(X_t)U\,dw_t.$$

We proceed as in the study of (3.13). The stability of the matrix A_t, which has been obtained in (3.15), and the boundedness of $U^{-1}\Sigma'(X_t)U$ imply that $(\nabla_0 X_t)^{-1}$ is exponentially small in L^2, and so the second term is negligible.

Let us study the third term of (3.20). If

$$\Phi_t^i = \nabla_0^i(\nabla_0 X_t)_i^{-1}U,$$

then by differentiating (3.19) and transforming $\widetilde{w}$ back into w, we get

$$\begin{aligned} d\Phi_t^i = &\Phi_t^i A_t dt - \Phi_t^i\,U^{-1}\Sigma'(X_t)U\,dw_t - (\nabla_0 X_t)_i^{-1}\,\nabla_0^i\rho(X_t, M_t)U\,dt \\ &-\Sigma^*(M_t)P_t^{-1}\nabla_0^i X_t(\nabla_0 X_t)_i^{-1}\Sigma'(X_t)U\,dt - (\nabla_0 X_t)_i^{-1}\nabla_0^i\big(\Sigma'(X_t)\big)U\,dw_t \end{aligned}$$

with

$$\rho(X_t, M_t) \overset{def}{=} F(X_t) + \Sigma(X_t)\Sigma^*(M_t)P_t^{-1} - \Sigma'^2(X_t).$$

By summing on i and using

$$\sum_i (\nabla_0 X_t)_i^{-1}\nabla_0^i\rho(X_t, M_t) = \sum_{i,j} \nabla_0^i X_t^j (\nabla_0 X_t)_i^{-1}\frac{\partial\rho}{\partial x_j}(X_t, M_t) = \sum_j \frac{\partial\rho_j}{\partial x_j}(X_t, M_t),$$

where ρ_j is the jth line of ρ, we obtain that $\Phi_t = \sum \Phi_t^i$ is the solution of

$$\begin{aligned}\Phi_0 = 0, \quad d\Phi_t = \Phi_t A_t\,dt - \Phi_t U^{-1}\Sigma'(X_t)U\,dw_t - \sum_j \frac{\partial \rho_j}{\partial x_j}(X_t, M_t)U\,dt \\ -\Sigma^*(M_t)P_t^{-1}\Sigma'(X_t)U\,dt - \frac{\partial \sigma'}{\partial x_2}(X_t)U\,dw_t,\end{aligned} \tag{3.21}$$

where σ' is the Jacobian of σ. A computation shows that

$$\frac{\partial \rho_j}{\partial x_j}(X_t, M_t) = \begin{bmatrix} \mathcal{O}(1) & \mathcal{O}(1) \\ \mathcal{O}(\varepsilon^{-1}) & \mathcal{O}(\varepsilon^{-1/2}) \end{bmatrix}.$$

The multiplication on the right by U yields a process of order ε^{-1}; the term $\Sigma^*(M_t)$ $.P_t^{-1}\Sigma'(X_t)U$ is also $\mathcal{O}(\varepsilon^{-1})$, and the term involving the second derivative of σ is $\mathcal{O}(\varepsilon^{-1/2})$. By proceeding again as in the study of (3.13), we deduce that Φ_t is of order $\varepsilon^{-1/2}$.

Thus (3.17), (3.20), and the estimation of Ψ_t and Φ_t yield

$$(\hat{X}_t - M_t)^* P_t^{-1} U = \mathcal{O}(1/\sqrt{\varepsilon}).$$

We multiply on the right by the matrix $U^{-1}P_t$, the coefficients of which are of order $\varepsilon^{3/2}$ for the first column and ε for the second column, and we deduce the order of $\hat{X}_t - M_t$ which was claimed in the theorem. ∎

4. An almost linear case. It is interesting to consider a particular case in which σ, h', and F_{12} are constant so that the system (1.1)–(1.2) is

$$\begin{cases} dx_t^{(1)} &= \big(f_1^0(x_t^{(1)}) + F_{12}x_t^{(2)}\big)\,dt, \\ dx_t^{(2)} &= f_2(x_t^{(1)}, x_t^{(2)})\,dt + \sigma\,dw_t, \\ dy_t &= h'x_t^{(1)}\,dt + \varepsilon\,d\bar{w}_t. \end{cases} \tag{4.1}$$

In particular, (H6.δ) holds with $\delta = 1$. Then it is possible to improve the upper bounds given in Theorem 3.1. The time interval that we consider may be infinite. The result is stated in the following proposition.

PROPOSITION 4.1. *Assuming that* (H1)–(H7) *hold for* (4.1)*, the filter* M_t *given by* (1.3) *verifies*

$$\hat{x}_t^{(1)} - m_t^{(1)} = \mathcal{O}(\varepsilon^{5/4}), \qquad \hat{x}_t^{(2)} - m_t^{(2)} = \mathcal{O}(\varepsilon^{3/4})$$

in L^2.

Proof. The proof closely follows the sequence of steps adopted in Theorem 3.1. The matrices $P_t = P$ and $R_t = R$ are now constant; the processes $J_t^{(1)}$, $J_t^{(2)}$, $J_t^{(4)}$, and $J_t^{(5)}$ are zero. The order of S_t is improved into

$$S_t = \begin{bmatrix} \mathcal{O}(\varepsilon^{-3/2}) & \mathcal{O}(\varepsilon^{-1}) \\ \mathcal{O}(\varepsilon^{-1}) & \mathcal{O}(\varepsilon^{-1/2}) \end{bmatrix},$$

and

$$|\phi_t^{(1)}| \le C|x_t^{(1)} - m_t^{(1)}|^2 = \mathcal{O}(\varepsilon^{3/2}), \quad |\phi_t^{(2)}| \le C\|X_t - M_t\|^2 = \mathcal{O}(\varepsilon^{1/2})$$

so that

$$J_t^{(3)} = (X_t - M_t)^* S_t U + \phi_t^* P^{-1} U$$

is of order $\varepsilon^{-3/4}$. Thus V_t is $\mathcal{O}(\varepsilon^{-1/4})$, and we obtain $\mathcal{O}(\varepsilon^{-1/4})$ in (3.17).

For the end of the proof, we see that

$$\rho(X_t, M_t) = F(X_t) + \Sigma\Sigma^* P^{-1},$$

and so

$$\frac{\partial \rho_j}{\partial x_j}(X_t, M_t) = \frac{\partial F_j}{\partial x_j}(X_t)$$

is bounded. Multiplication by U yields a process of order $\varepsilon^{-1/2}$, and so the process Φ_t of (3.21) is bounded for small ε. We can conclude that

$$(\hat{X}_t - M_t)^* P_t^{-1} U = \mathcal{O}(\varepsilon^{-1/4})$$

and deduce the proposition. □

With more computational effort, it is possible to extend these results to the case in which the component $x^{(1)}$ is driven by low noise:

$$\text{(4.2)} \qquad \begin{cases} dx_t^{(1)} &= \big(f_1^0(x_t^{(1)}) + F_{12} x_t^{(2)}\big)\, dt + \varepsilon^\gamma\, dw_t^{(1)}, \\ dx_t^{(2)} &= f_2(x_t^{(1)}, x_t^{(2)})\, dt + \sigma\, dw_t^{(2)}, \\ dy_t &= h' x_t^{(1)}\, dt + \varepsilon\, d\bar{w}_t \end{cases}$$

with M_t given by (1.5) and with the gain R_t given by (1.4), as before, if $\gamma > 1/2$, and with R_t given by

$$R_t \stackrel{def}{=} \begin{bmatrix} \sqrt{\dfrac{2\sigma F_{12}}{h'} + 1}\, \dfrac{1}{\sqrt{\varepsilon}} \\ \dfrac{\sigma}{\varepsilon} \end{bmatrix}$$

if $\gamma = 1/2$.

Clearly, Theorem 2.1 extends to system (4.2) as soon as $\gamma \geq 1/2$. This results from the fact that, in the SDE of Z_t, the matrices involved in the martingale terms are still uniformly bounded as ε converges to 0, and the matrix A_t of (2.2) has the same stability property as before.

Regarding the extension of Proposition 4.1 to system (4.2), one can see that, assuming $\gamma \geq 3/4$, the estimation in Proposition 4.1 still holds. This happens because the matrix $\bar{A}_t$ in the decomposition of A_t remains the same. More effort is needed if one considers the cases $1/2 < \gamma < 3/4$ and $\gamma = 1/2$.

Another class of almost linear filtering problems when some of the observations and driving noises are small is considered by Krener [6]. Krener studied the multidimensional case, where nonlinearities depend only on state variables which can be estimated quickly and accurately; that is, the only nonlinearity allowed in (4.2) is that of the function f_2 with respect to $x_t^{(1)}$. Observations with at least two components, instead of one, are also assumed.

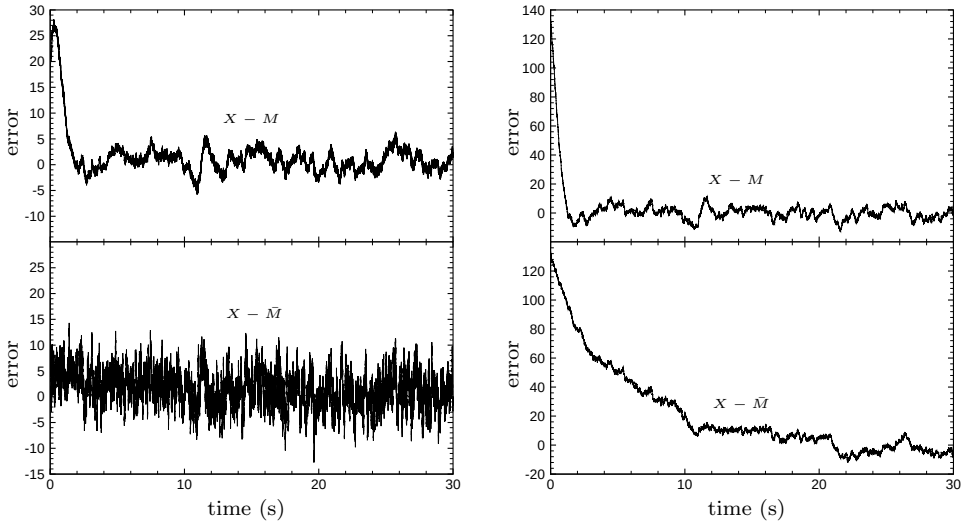

FIG. 5.1. *Estimation errors for the* (a) *first and* (b) *second components of X computed on a single trajectory.*

5. Numerical simulation results. Let us consider the following example illustrating the case of free fall of a body through the atmosphere:

$$\left\{ \begin{array}{rcl} dx_t^{(1)} & = & x_t^{(2)} dt, \\ dx_t^{(2)} & = & (\rho_0 e^{-x_t^{(1)}/k} (x_t^{(2)})^2/(2\beta) - g)\, dt + \sigma dw_t \end{array} \right.$$

and

$$dy_t = \sqrt{(x_t^{(1)})^2 + a^2}\, dt + \varepsilon\, d\bar{w}_t,$$

where $x_t^{(1)}$ is the position of the moving body and $x_t^{(2)}$ is its speed, ρ_0 being the reference air density, k the atmosphere thickness, β the ballistic coefficient of the body, g the acceleration due to gravity, and a the horizontal distance between the body and the measuring device ($\rho_0 = 3.4 \times 10^{-3}\, lb\, s^2/ft^4$, $k = 22 \times 10^3\, ft$, $\beta = 1.6 \times 10^3\, lb^2/ft^4$, $g = 32.2\, ft/s^2$, $\sigma = 5\, ft/s$, and $a = 10^4\, ft$). Figure 5.1 shows the estimation errors obtained from applying the two approximate filters (filter (1.5), noted M_t, and the constant gain filter mentioned at the end of section 2 with $\bar{H} = 0.02$, noted $\bar{M}_t$) to a single trajectory of the state with measurements taken each 0.001 s. The parameter ε is equal to 1 and

$$X_0 \sim \mathcal{N}\left(\left[\begin{array}{c} 3 \times 10^5 \\ -10^3 \end{array} \right], \left[\begin{array}{cc} 900 & 0 \\ 0 & 2 \times 10^4 \end{array} \right] \right).$$

It illustrates the fact that the errors get small very quickly, and one notices that the constant gain filter needs more time than filter (1.5) to attain small errors in the second component.

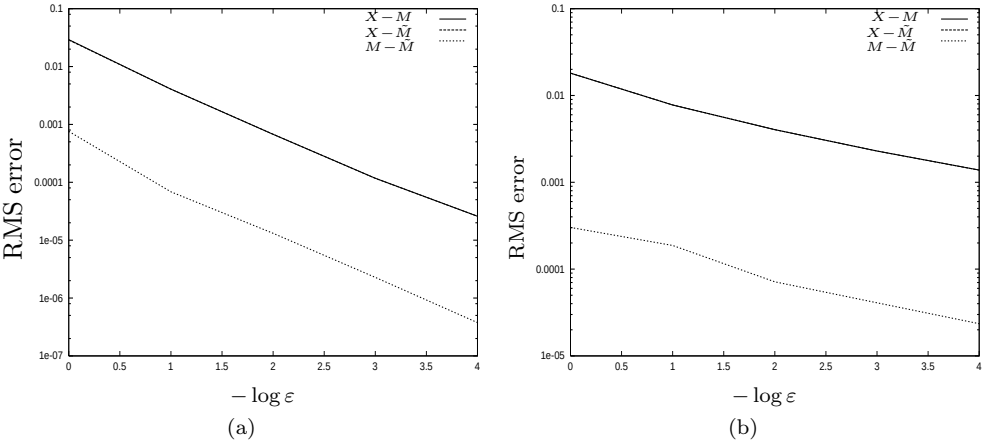

FIG. 5.2. *Estimation errors for the* (a) *first and* (b) *second components of* X.

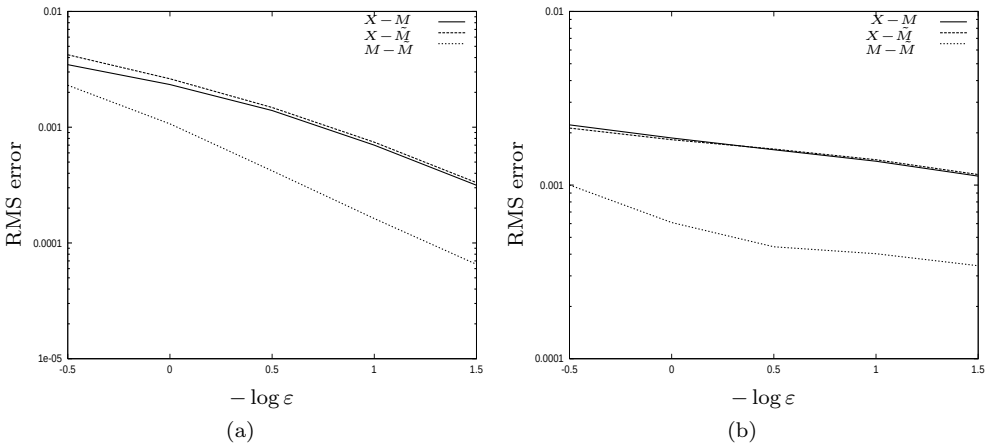

FIG. 5.3. *Estimation errors for the* (a) *first and* (b) *second components of* X ($G = 0.5$).

Figure 5.2 illustrates the asymptotic behavior of the estimation errors when system (1.1)–(1.2) with $f(x_1, x_2) = [x_2 \quad -1.5 \times 10^{-3} x_1^2]^*$, $\sigma = 2$, and $h(x_1) = \sqrt{x_1^2 + 10^8}$ is considered. Although f and h' fail to verify assumption (H3) and, in fact, $\inf h' = 0$, we will assume that the state remains in a bounded domain with high probability, thus assuming that $\inf h' > 1/\sqrt{120}$. The root mean square error between the two approximate filters (with $\bar{H} = 0.18$) was computed for $\varepsilon = 1, 10^{-1}, \ldots, 10^{-4}$ over 200 simulations for both components in the time interval $[0, 5]$. The solid lines exhibit approximate slopes of -0.76 (first component) and -0.28 (second component) which agree with the results in section 2. The error associated with the constant gain filter and that associated to filter (1.5) are very similar.

Figures 5.3–5.5 illustrate the van der Pol oscillator example presented in [12, section 6]: $f(x_1, x_2) = [x_2 \quad -x_1 - x_2]^*$, $\sigma = 1$, and $h(x_1) = 0.606(1 - G)x_1 +$

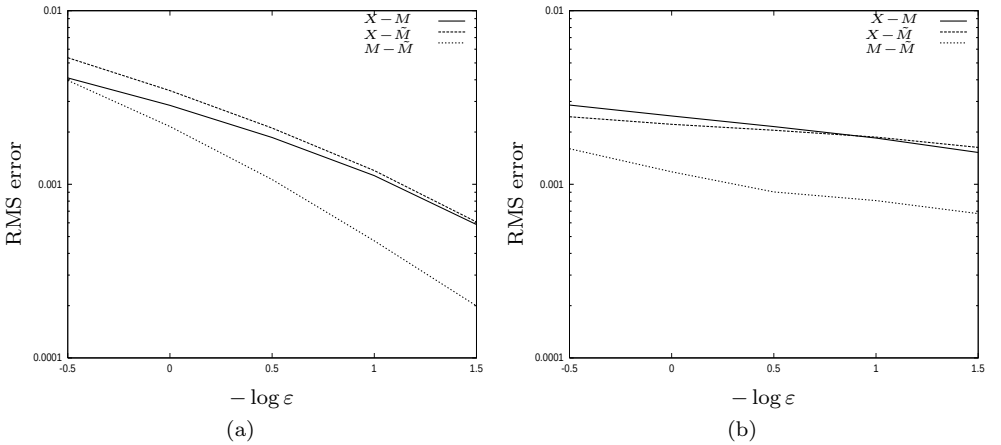

FIG. 5.4. *Estimation errors for the* (a) *first and* (b) *second components of* X $(G = 0.8)$.

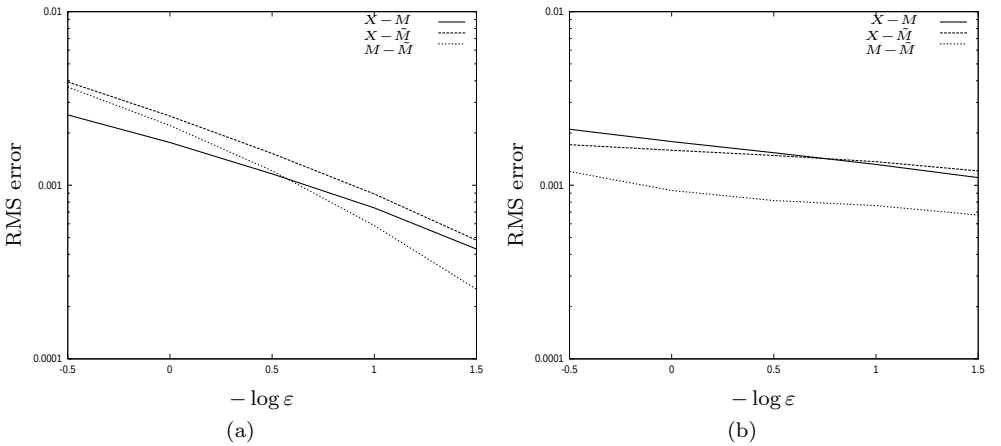

FIG. 5.5. *Estimation errors for the* (a) *first and* (b) *second components of* X $(G = 0.9)$.

Gx_1^3 with $G = 0.5, 0.8, 0.9$, respectively. The time interval $[0, 100]$ was considered. One can observe the increasing benefit of using filter (1.5) as the nonlinearity in the observations gets stronger. The results obtained by using the extended Kalman filter (EKF) are also shown in [12] for comparison.

WEAK CONVERGENCE OF HYBRID FILTERING PROBLEMS INVOLVING NEARLY COMPLETELY DECOMPOSABLE HIDDEN MARKOV CHAINS*

G. YIN† AND S. DEY‡

Abstract. Concentrating on a class of hybrid discrete-time filtering problems that are modulated by a Markov chain, this work aims to reduce the complexity of the underlying problems. Since the Markov chain has a large state space, the solution of the problem relies on solving a large number of filtering equations. Exploiting the hierarchical structure of the system, it is noted that the transition probability matrix of the Markov chain can be viewed as a nearly decomposable one. It is shown that a reduced system of filtering equations can be obtained by aggregating the states of each recurrent class into one state. Extensions to inclusion of transient states and nonstationary cases are also treated.

Key words. Markov chain, filtering, near complete decomposability, weak convergence

1. Introduction.

In this work, we concern ourselves with hybrid filtering problems in discrete time. Since a wide variety of problems arising in target tracking, speech recognition, telecommunication, and manufacturing requires solutions of filtering problems involving a hidden Markov chain, in addition to the usual random system disturbances and observation noise, we assume that the system under consideration is influenced by a hidden Markov chain with finite state space. Due to the rapid advances in science and technology, various systems tend to be rather complex and large-scale in nature. As a result, although the state space of the Markov chain is finite, it inevitably contains a large number of states. Our main effort is devoted to reducing the complexity of such filtering problems involving large-scale hidden Markov chains.

In a recent paper, linear systems with coefficients driven by a hidden Markov chain were considered [21]. Discrete-time systems were studied in [1, 6, 12, 28] among others. In [33], Zhang studied hybrid filters in continuous time and treated problems involving non-Gaussian noise. Our study is motivated by these recent developments and stems from the needs in many applications mentioned above.

In the seminal paper [26], Simon and Ando pointed out that various large-scale systems have hierarchical structures. Some of the states vary rapidly, and others change slowly. In addition, these states are also naturally decomposable into different layers or a hierarchy. Such a hierarchy allows one to take advantage and to organize and reorganize the systems accordingly. Based on such ideas, Courtois dealt with the so-called *nearly completely decomposable* Markov chain models [7]. Recently, Dey derived reduced-complexity filtering results for hidden Markov models, in which the underlying Markov chains are nearly completely decomposable [9]. Such hierarchical

Markov chains have numerous applications in queueing and computer systems [7], multiple time-scale heterogeneous traffic modelling (e.g., variable bit rate video traffic [27]), manufacturing systems, operations research, and many other biological and physical systems in which a multiple time-scale or hierarchical behavior is involved; see also related work in [3, 5, 14, 18, 22, 23, 25] and the references therein. Taking the approaches of [7] and [9] as our point of departure, to reduce the complexity of the underlying problem, we introduce a small parameter $\varepsilon > 0$ into the system. Note that the small parameter is used to reflect the high contrast of the transition rates of the Markov chain. For the subsequent asymptotic analysis, to obtain the desired results, it is necessary to send $\varepsilon \to 0$, which can serve as a guideline for various applications and for approximation and heuristics. In real applications, however, ε might be a fixed constant, and only the relative order of magnitude of this parameter matters. In our setup, we also consider a nearly completely decomposable Markovian model, in which the hidden Markov chain has a large state space. The transition probability matrix is a sum of a completely decomposable transition matrix and a generator of a continuous-time Markov chain. Following our systematic studies on singularly perturbed Markov chains in both continuous time and discrete time [16, 29, 30, 31, 34], we investigate the asymptotic properties of the filtering problem by means of weak convergence methods. We show that a limit filtering problem can be derived in which the underlying Markov chain is replaced by an averaged chain and the system coefficients are averaged out with respect to the stationary measures of each ergodic class. The reduction of complexity is particularly pronounced when the transition matrix of the Markov chain consists of only one ergodic class. In this case, the limit filtering problem becomes a standard Kalman filter free of Markovian jump processes.

The rest of the paper is arranged as follows. Section 2 presents the precise formulation of the problem and a number of preliminary results that are to be used in our study. Section 3 is concerned with weak convergence analysis and the derivation of limit filtering problems or reduced systems. In order not to disrupt the flow of presentation, all proofs are placed in an appendix. Section 4 proceeds with numerical experiments and simulation studies that demonstrate the relationship between the original system and that of a reduced system. Section 5 gives remarks and a few extensions.

Throughout the paper, we use K to denote a generic positive constant, whose values may be different for different usage. For any $z \in \mathbb{R}^{\ell_1 \times \ell_2}$ with some positive integers ℓ_1 and ℓ_2, z' denotes its transpose. For a suitable function f, f_x and f_{xx} denote its first-order and second-order partial derivatives with respect to x.

2. Formulation and preliminaries. This section gives the precise formulation of the problem to be studied. It also presents some preliminary results needed in the analysis to follow.

2.1. Hybrid filtering problem. Let $\varepsilon > 0$ be a small parameter, and let $\{\alpha_n^\varepsilon\}$ be a (time) homogeneous singularly perturbed Markov chain in discrete time with a finite state space $\mathcal{M}$ having m elements and a transition matrix

$$P^\varepsilon = \widetilde{P} + \varepsilon Q, \tag{2.1}$$

where $\widetilde{P}$ is an $m \times m$ transition matrix and $Q = (q_{\iota\ell})$ is a generator of a continuous-time homogeneous Markov chain, i.e., $q_{\iota\ell} \geq 0$ for $\iota \neq \ell$ and $\sum_\ell q_{\iota\ell} = 0$ for each ι.

Suppose that, for some $T > 0$ and $0 \le n \le \lfloor T/\varepsilon \rfloor$ (where $\lfloor z \rfloor$ denotes the largest integer part of z), $x_n^\varepsilon \in \mathbb{R}^r$ is the state to be estimated, y_n^ε is the corresponding observation, and $A(\iota)$, $C(\iota)$, $\sigma_w(\iota)$, and $\sigma_v(\iota)$ are well defined for each $\iota \in \mathcal{M}$ (i.e., they are finite for each $\iota \in \mathcal{M}$). With initial data x_0 and y_0, the hybrid filtering problem is concerned with the linear system of equations

$$\begin{aligned} x_{n+1}^\varepsilon &= x_n^\varepsilon + \varepsilon A(\alpha_n^\varepsilon) x_n^\varepsilon + \sqrt{\varepsilon}\sigma_w(\alpha_n^\varepsilon) w_n, \\ y_{n+1}^\varepsilon &= y_n^\varepsilon + \varepsilon C(\alpha_n^\varepsilon) x_n^\varepsilon + \sqrt{\varepsilon}\sigma_v(\alpha_n^\varepsilon) v_n, \end{aligned} \tag{2.2}$$

where $\{w_n\}$ and $\{v_n\}$ are the system disturbance and the observation noise, respectively. For ease of presentation, in what follows, we will suppress the floor-function notation $\lfloor \cdot \rfloor$ and write it as $0 \le n \le T/\varepsilon$ throughout. The use of the $\sqrt{\varepsilon}$ in the noise terms stems from the central limit scaling. Precise conditions on the noises will be provided later. In what follows, we will show that, as $\varepsilon \to 0$, the above filtering problem has a limit. The limit filtering problem is still modulated by a Markov chain. However, the total number of states of the limit Markov chain is equal to the number of recurrent groups or clusters l. As mentioned before, typically $l \ll m$, and by considering this limit filtering problem, substantial computational savings can be obtained. Although (2.2) is a discrete-time filtering problem, the limit under appropriate scaling is a continuous-time hybrid filtering problem. In the rest of the paper, our main effort is devoted to deriving the limit filtering problem. For solutions of continuous-time hybrid filtering problems involving jump Markov processes, see [4, 8, 11, 12, 21]; see also [2, 10] and the references therein for discrete-time results.

2.2. Nearly completely decomposable Markov chain $\boldsymbol{\alpha_n^\varepsilon}$. In view of (2.1), the transition probabilities of α_n^ε are dominated by $\widetilde{P}$. The structure of $\widetilde{P}$ is thus important. Since α_n^ε is a finite-state Markov chain, the Markov chain corresponding to the transition matrix $\widetilde{P}$ either consists of all recurrent states or includes transient states in addition to recurrent states (see [15]). We first consider the case of inclusion of recurrent states only. Later we will discuss a generalization to the case in which transient states are also included. Suppose that the matrix $\widetilde{P}$ is given by

$$\widetilde{P} = \operatorname{diag}(\widetilde{P}^1, \dots, \widetilde{P}^l) = \begin{pmatrix} \widetilde{P}^1 & & \\ & \ddots & \\ & & \widetilde{P}^l \end{pmatrix}, \tag{2.3}$$

where each $\widetilde{P}^i \in \mathbb{R}^{m_i \times m_i}$ is itself a transition matrix and $\sum_{i=1}^l m_i = m$. Here and henceforth, by $\operatorname{diag}(Z^1, \dots, Z^l)$, we mean a diagonal block matrix with matrix entries Z^1 through Z^l of appropriate dimensions. It is clear that, for sufficiently small $\varepsilon > 0$, P^ε is close to $\widetilde{P}$, and so P^ε is a nearly completely decomposable transition matrix (see [7]). Note that, typically for large scale Markovian systems, $l \ll m$, and therein lies the motivation for reducing computational complexity. Concerning the Markov chain, we assume the following condition.

(A1) The transition probability matrix of the Markov chain α_n^ε is given by (2.1) with $\widetilde{P}$ specified in (2.3), and the state space of the Markov chain is

$$\begin{aligned} \mathcal{M} &= \mathcal{M}_1 \cup \mathcal{M}_2 \cap \cdots \cup \mathcal{M}_l \\ &= \{s_{11}, \dots, s_{1m_1}\} \cup \cdots \cup \{s_{l1}, \dots, s_{lm_l}\}. \end{aligned} \tag{2.4}$$

For each $i = 1, \dots, l$, $\mathcal{M}_i = \{s_{i1}, \dots, s_{im_i}\}$ is the state space corresponding to the transition matrix $\widetilde{P}^i$, and $\widetilde{P}^i$ is irreducible and aperiodic.

Note that the probability vector

$$p_n^\varepsilon = (P(\alpha_n^\varepsilon = s_{11}), \dots, P(\alpha_n^\varepsilon = s_{1m_1}), \dots, P(\alpha_n^\varepsilon = s_{l1}), \dots, P(\alpha_n^\varepsilon = s_{lm_l})) \in \mathbb{R}^{1\times m}$$

satisfies

$$p_{n+1}^\varepsilon = p_n^\varepsilon P^\varepsilon, \qquad p_0^\varepsilon = p_0, \tag{2.5}$$

such that p_0 is the initial probability distribution. By (A1), the result in [30] yields the following lemma.

LEMMA 2.1. *Assume condition* (A1). *Then the following assertions hold:*

(1) *Denote by* ν^i *the stationary distribution corresponding to the transition matrix* $\widetilde{P}_i$ *for each* $i = 1, \dots, l$. *Then, for some* $0 < \lambda < 1$,

$$p_n^\varepsilon = \theta(t)\,\mathrm{diag}(\nu^1, \dots, \nu^l) + O(\varepsilon + \lambda^n), \tag{2.6}$$

where $\theta(t) = (\theta_1(t), \dots, \theta_l(t)) \in \mathbb{R}^{1\times l}$ *(with* $t = \varepsilon n$*) satisfies*

$$\frac{d\theta(t)}{dt} = \theta(t)\overline{Q}, \quad \theta_i(0) = x_0^i \mathbf{1}_{m_i},$$

with

$$\begin{aligned} \overline{Q} &= \mathrm{diag}(\nu^1, \dots, \nu^l) Q \widetilde{\mathbf{1}}, \\ \widetilde{\mathbf{1}} &= \mathrm{diag}(\mathbf{1}_{m_1}, \dots, \mathbf{1}_{m_l}), \end{aligned} \tag{2.7}$$

where $\mathbf{1}_\ell$ *denotes an* ℓ*-dimensional column vector with all entries being* 1.

(2) *For* $n \le T/\varepsilon$, *the n-step transition probability matrix* $(P^\varepsilon)^n$ *satisfies*

$$(P^\varepsilon)^n = \Phi(t) + O\left(\varepsilon + \lambda^n\right), \tag{2.8}$$

where

$$\begin{aligned} P^0\Phi(t) &= \widetilde{\mathbf{1}}\Theta(t)\,\mathrm{diag}(\nu^1, \dots, \nu^l), \\ \frac{d\Theta(t)}{dt} &= \Theta(t)\overline{Q}, \quad \Theta(0) = I. \end{aligned} \tag{2.9}$$

Remark 2.2. Since we are primarily concerned with the form of the limit distribution, only the leading terms are presented in the lemma, although a full asymptotic expansion can be obtained. See [30] for more details.

Starting from the Markov chain α_n^ε, define an aggregated process $\overline{\alpha}_n^\varepsilon$ by setting $\overline{\alpha}_n^\varepsilon = i$ if $\alpha_n^\varepsilon \in \mathcal{M}_i$. Define piecewise constant interpolated processes $\alpha^\varepsilon(\cdot)$ and $\overline{\alpha}^\varepsilon(\cdot)$ by

$$\alpha^\varepsilon(t) = \alpha_n, \ \overline{\alpha}^\varepsilon(t) = \overline{\alpha}_n^\varepsilon, \quad t \in [n\varepsilon, n\varepsilon + \varepsilon).$$

Lemma 2.1 is mainly deterministic, whereas the following lemma is a weak convergence result on the aggregated process. Its proof is provided in [32]; a continuous-time counterpart can be found in [29, pp. 170–171].

LEMMA 2.3. *Under* (A1), *as* $\varepsilon \to 0$, $\overline{\alpha}^{\varepsilon}(\cdot)$ *converges weakly to* $\overline{\alpha}(\cdot)$, *which is a continuous-time Markov chain with state space* $\overline{\mathcal{M}} = \{1, \ldots, l\}$ *and generator* $\overline{Q}$ *given by* (2.7). *Moreover, for the occupation measures defined by*

$$o^{\varepsilon}_{n,ij} = \varepsilon \sum_{k=0}^{n} [I_{\{\alpha^{\varepsilon}_k = s_{ij}\}} - \nu^i_j I_{\{\alpha^{\varepsilon}_k \in \mathcal{M}_i\}}] \quad \textit{for each} \quad i = 1, \ldots, l, \ j = 1, \ldots, m_i,$$

the following mean square estimates hold:

$$\sup_{0 \le n \le T/\varepsilon} E|o^{\varepsilon}_{n,ij}|^2 = O(\varepsilon). \tag{2.10}$$

To proceed, we give additional conditions needed for the filtering problem.

(A2) $E|x_0|^2 < \infty$ and $E|y_0|^2 < \infty$. For each $\iota \in \mathcal{M}$, $A(\iota)$, $C(\iota)$, $\sigma_w(\iota)$, and $\sigma_v(\iota)$ are finite; $\sigma_w(\iota)\sigma'_w(\iota)$ and $\sigma_v(\iota)\sigma'_v(\iota)$ are positive definite matrices.

(A3) The sequences $\{w_n\}$ and $\{v_n\}$ are independent of $\{\alpha^{\varepsilon}_n\}$ and independent of each other. The $\{w_n\}$ and $\{v_n\}$ are stationary martingale difference sequences (with zero mean) such that

$$Ew_n w'_n = I, \ Ev_n v'_n = I,$$
$$E|w_n|^{2+\Delta} < \infty, \quad \text{and} \quad E|v_n|^{2+\Delta} < \infty \quad \text{for some} \quad \Delta > 0.$$

Remark 2.4. For simplicity and ease of presentation, we assume that the noises are stationary martingale difference sequences and that the covariance of w_n and v_n is the identity matrix. Even though no Gaussian assumption is used, as a result of the scaling, these noise processes will be asymptotically normal thanks to the functional central limit theorem.

In what follows, we use the weak convergence method to establish the desired results. Further details on the weak convergence method, which is an extension of convergence in distribution, can be found in, for example, [13, Chapter 3] or [19, Chapters 7 and 8].

3. Limit filtering problem. This section is devoted to the derivation of the limit filtering problem. In lieu of treating the discrete-time iterates, our analysis focuses on suitable continuous-time interpolations of piecewise constant processes.

For $0 \le n \le T/\varepsilon$, define the interpolations $x^{\varepsilon}(\cdot)$ and $y^{\varepsilon}(\cdot)$ as

$$x^{\varepsilon}(t) = x^{\varepsilon}_n, \quad y^{\varepsilon}(t) = y^{\varepsilon}_n, \quad t \in [n\varepsilon, n\varepsilon + \varepsilon), \tag{3.1}$$

where x^{ε}_n and y^{ε}_n are given in (2.2). Then $x^{\varepsilon}(\cdot)$ and $y^{\varepsilon}(\cdot) \in D^r[0,T]$, which is the space of $\mathbb{R}^r$-valued functions that are right continuous and have left limits, endowed with the Skorohod topology [13, p. 122]. Using weak convergence methods, we will show that the interpolated processes converge weakly to $x(\cdot)$ and $y(\cdot)$, which satisfy continuous-time hybrid Kalman filtering equations. Following the approach of weak convergence methods [13, 17], we first show that the sequences of interests are tight, and then we characterize the limit processes by using martingale averaging techniques.

Owing to the assumption on the system and observation noise and $\sqrt{\varepsilon}$ scaling, the following lemma, known as the functional central limit theorem or Donsker's invariance theorem, holds. Its proof is standard; see, for example, [13, Theorem 3.1, p. 351].

LEMMA 3.1. *Define*

$$w^\varepsilon(t) = \sqrt{\varepsilon} \sum_{j=0}^{t/\varepsilon-1} w_j \quad \text{and} \quad v^\varepsilon(t) = \sqrt{\varepsilon} \sum_{j=0}^{t/\varepsilon-1} v_j. \tag{3.2}$$

Under (A3), $w^\varepsilon(\cdot)$ *and* $v^\varepsilon(\cdot)$ *converge weakly to standard* r*-dimensional Brownian motions* $w(\cdot)$ *and* $v(\cdot)$*, respectively.*

In fact, correlated φ-mixing noises may be dealt with, and the corresponding central limit result can be obtained, but the notation will be much more complex for the subsequent averaging. Thus we decide to work with the martingale difference sequences $\{w_n\}$ and $\{v_n\}$. In the analysis to follow, we need the a priori bounds on $\{x_n^\varepsilon\}$ and $\{y_n^\varepsilon\}$, which are presented in the form of the following lemma. The proof is provided in the appendix.

LEMMA 3.2. *Assume* (A1)–(A3). *For* $\{x_n^\varepsilon\}$ *and* $\{y_n^\varepsilon\}$ *defined in* (2.2)*, the following bounds hold:*

$$\sup_{0\le n\le T/\varepsilon} E|x_n^\varepsilon|^2 < \infty \quad \text{and} \quad \sup_{0\le n\le T/\varepsilon} E|y_n^\varepsilon|^2 < \infty. \tag{3.3}$$

3.1. Tightness and weak convergence. To proceed, let $\mathcal{F}_n$ be the σ-algebra generated by $\{\alpha_j^\varepsilon, w_j, v_j : j \le n\}$, and let E_n be the conditional expectation with respect to $\mathcal{F}_n$; let $\mathcal{F}_t^\varepsilon$ be the σ-algebra generated by $\{\alpha^\varepsilon(s), w^\varepsilon(s), v^\varepsilon(s) : s \le t\}$, and let E_t^ε be the conditional expectation with respect to $\mathcal{F}_t^\varepsilon$. We are to derive the tightness of $\{x^\varepsilon(\cdot)\}$ and $\{y^\varepsilon(\cdot)\}$. This is a compactness result, which is established by verifying a tightness criterion; the proof is in the appendix.

THEOREM 3.3. *Assume* (A1)–(A3). *Then* $\{x^\varepsilon(\cdot)\}$ *is tight in* $D^r[0,T]$*, and so is* $\{y^\varepsilon(\cdot)\}$*, where* $D^r[0,T]$ *is the space of* $\mathbb{R}^r$*-valued functions that are right continuous and have left limits, endowed with the Skorohod topology.*

We are now in a position to obtain the weak convergence of the sequences $\{x^\varepsilon(\cdot)\}$ and $\{y^\varepsilon(\cdot)\}$. To prove the assertion, we use a martingale problem formulation. Thus our task becomes to figure out the limit by characterizing the operator of the limit martingale problem. The technique used is essentially an averaging approach. Different from the diffusion approximation in wideband noise systems [17], the limit $\overline{\alpha}^\varepsilon(\cdot)$ also contributes to the limit process and adds further complication. The result is recorded in the following theorem, whose proof is in the appendix as well.

THEOREM 3.4. *Suppose the conditions of Theorem* 3.3 *hold. Then* $x^\varepsilon(\cdot)$ *and* $y^\varepsilon(\cdot)$ *converge weakly to* $x(\cdot)$ *and* $y(\cdot)$*, respectively, such that* $x(\cdot)$ *and* $y(\cdot)$ *are solutions of the filtering equations*

$$\begin{aligned} dx &= \overline{A}(\overline{\alpha}(t))x\,dt + \overline{\sigma_w}(\overline{\alpha}(t))dw, \\ dy &= \overline{C}(\overline{\alpha}(t))x\,dt + \overline{\sigma_v}(\overline{\alpha}(t))dv, \end{aligned} \tag{3.4}$$

where $w(\cdot)$ *and* $v(\cdot)$ *are the independent* r*-dimensional standard Brownian motions given by Lemma* 3.1*,*

$$\overline{A}(i) = \sum_{j=1}^{m_i} \nu_j^i A(s_{ij}),\ \overline{B}(i) = \sum_{j=1}^{m_i} \nu_j^i B(s_{ij}) \quad \text{for each } i \in \overline{\mathcal{M}}, \tag{3.5}$$

and, for each $i \in \overline{\mathcal{M}}$, $\overline{\sigma}_w(i)$ *and* $\overline{\sigma}_v(i)$ *satisfy*

$$\overline{\sigma}_w(i)\overline{\sigma}'_w(i) = \sum_{j=1}^{m_i} \nu_j^i \sigma_w(s_{ij})\sigma'_w(s_{ij}), \tag{3.6}$$
$$\overline{\sigma}_v(i)\overline{\sigma}'_v(i) = \sum_{j=1}^{m_i} \nu_j^i \sigma_v(s_{ij})\sigma'_v(s_{ij}).$$

3.2. Markov chains with one ergodic class. The reduction of complexity is particularly pronounced if the transition matrix (2.3) consists of only one ergodic class (i.e., P in (2.3) consists of only one block). That is, $P^\varepsilon = P + \varepsilon Q$ such that P is irreducible and aperiodic. It is easily seen that, for sufficiently small $\varepsilon > 0$, P^ε is also irreducible. Consider the filtering problem (2.2). Similarly to the previous case, define $x^\varepsilon(\cdot)$ and $y^\varepsilon(\cdot)$ as the piecewise constant interpolations of x_k^ε and y_k^ε, respectively. Replace $\overline{A}(\cdot)$ and $\overline{\sigma}_w(\cdot)$ by

$$\overline{A}^0 = \sum_{j=1}^{m} A(j)\nu_j \quad \text{and} \quad \overline{\sigma_w}^0(\overline{\sigma_w}^0)' = \sum_{j=1}^{m} \nu_j \sigma_w(j)\sigma'_w(j), \tag{3.7}$$

with $\nu = (\nu_1, \ldots, \nu_m)$ denoting the stationary distribution of P. Similarly replace $\overline{C}(\cdot)$ and $\overline{\sigma}_v(\cdot)$ by $\overline{C}^0$ and $\overline{\sigma}_v^0$, respectively. The weak convergence of $(x^\varepsilon(\cdot), y^\varepsilon(\cdot))$ will still be obtained. The proofs are similar to the previous case. In fact, it is readily seen that Lemma 3.2 and Theorem 3.3 continue to hold. Lemma 2.1 still holds with obvious modifications, and (2.10) (in Lemma 2.3) is changed to

$$\sup_{0 \le n \le T/\varepsilon} E\left[\varepsilon \sum_{k=0}^{n} [I_{\{\alpha_k^\varepsilon = j\}} - \nu_j]\right]^2 = O(\varepsilon).$$

Using this mean square estimate and similar arguments as before, we can show that Theorem 3.4 continues to hold. It is interesting to note that the limit filtering problem becomes a standard Kalman filter, in which the jump process effect has been completely averaged out. We state this as the following result.

COROLLARY 3.5. *Consider the filtering problem* (2.2) *such that* P *is irreducible and aperiodic. Then* $(x^\varepsilon(\cdot), y^\varepsilon(\cdot))$ *converges weakly to* $(x(\cdot), y(\cdot))$*, that is, the solution of the filtering problem*

$$dx(t) = \overline{A}^0 x(t)dt + \overline{\sigma_w}^0 dw(t), \tag{3.8}$$
$$dy(t) = \overline{C}^0 x(t)dt + \overline{\sigma_v}^0 dv(t).$$

4. Simulation studies. In this section, we demonstrate the relationship between the full-order discrete-time system (2.2) and the reduced-order limit filtering equations (3.4) through simulation examples. All results are averaged over 50 trials.

For (2.2), we simulate a discrete-time Markov chain with four states (with two blocks, $m_1 = m_2 = 2$) for which the transition probability matrices are

$$\widetilde{P}^1 = \begin{pmatrix} 0.9 & 0.1 \\ 0.2 & 0.8 \end{pmatrix}, \ \widetilde{P}^2 = \begin{pmatrix} 0.25 & 0.75 \\ 0.68 & 0.32 \end{pmatrix}$$

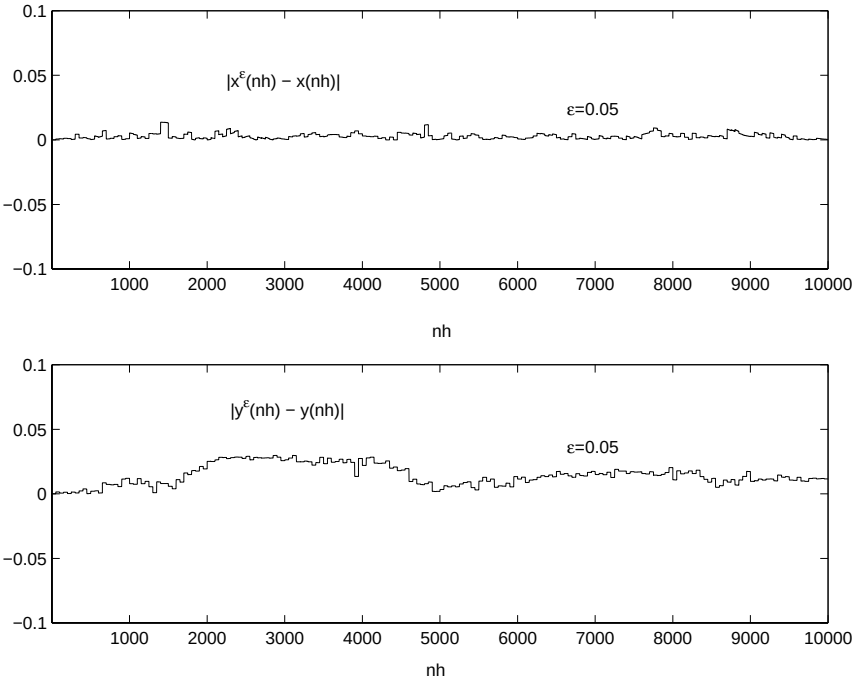

FIG. 4.1. *Absolute error between the piecewise constant interpolated full-order system and the reduced-order limit filtered system,* $\varepsilon = 0.05$.

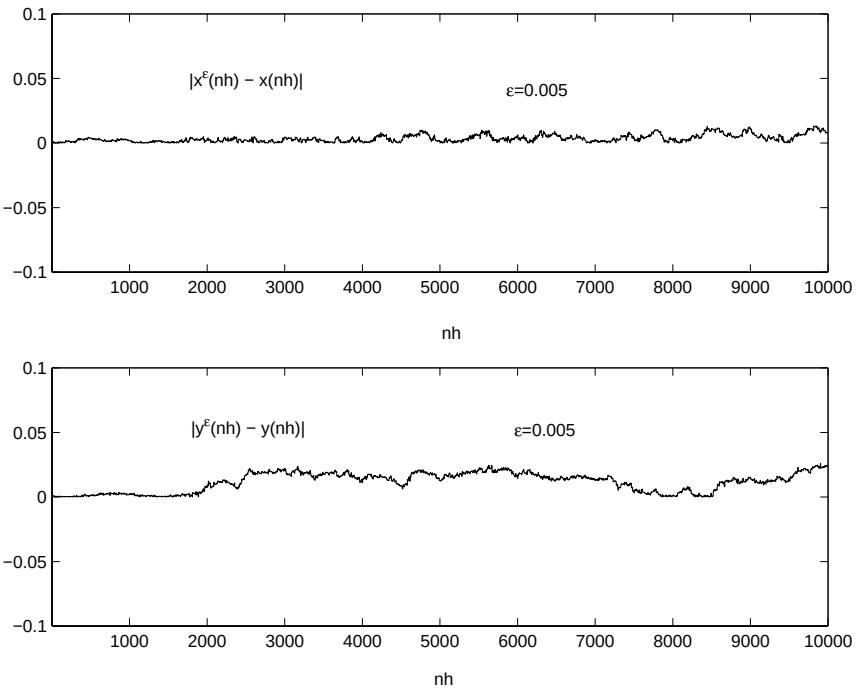

FIG. 4.2. *Absolute error between the piecewise constant interpolated full-order system and the reduced-order limit filtered system,* $\varepsilon = 0.005$.

and the generator is

$$Q = \begin{pmatrix} -0.6 & 0.4 & 0.1 & 0.1 \\ 0.05 & -0.4 & 0.05 & 0.3 \\ 0.1 & 0.2 & -0.7 & 0.4 \\ 0.15 & 0.05 & 0.1 & -0.3 \end{pmatrix}.$$

We take $(A(1)\ A(2)\ A(3)\ A(4)) = (-4.0\ -1.0\ -2.0\ -3.0)$, $(C(1)\ C(2)\ C(3)\ C(4)) = (0.2\ 0.5\ 0.1\ 1.0)$. Also, $(\sigma_w(1)\ \sigma_w(2)\ \sigma_w(3)\ \sigma_w(4)) = (0.2\ 0.5\ 0.1\ 1.0)$, $\sigma_v(i) = \sigma_w(i)$, for $i = 1, 2, 3, 4$. The noise sequences $\{w_n\}$ and $\{v_n\}$ are simulated as Gaussian random variables with zero mean and unity variance. The piecewise constant interpolated processes $x^\varepsilon(t)$ and $y^\varepsilon(t)$ are constructed from (3.1). The time horizon is taken to be $T = 10$. To simulate (3.4), a continuous-time Markov chain is used with a generator $\overline{Q}$. This is then discretized with a discretization interval $h = 0.001$. Figures 4.1 and 4.2 show the difference $|x^\varepsilon(\cdot) - x(\cdot)|$ and $|y^\varepsilon(\cdot) - y(\cdot)|$ for $\varepsilon = 0.05$ and $\varepsilon = 0.005$, respectively.

5. Remarks and extensions. This section is devoted to several remarks regarding the approximation issue. They include reduction of complexity as well as ramifications of the results we have obtained thus far.

Reduction of complexity. One of the main motivations of the current study is the effort of reduction of complexity. Regarding (2.2), note that the time horizon we are working with is $0 \le n \le \lfloor T/\varepsilon \rfloor$. As pointed out in [24], if we treat the discrete-time case directly, it can be reduced to an $m^{\lfloor T/\varepsilon \rfloor}$-dimensional recursive system of equations, where m is the total number of states of the Markov chain. For us, m is a fairly large number. As a result, the amount of computation becomes practically untrackable. One cannot complete the computation in polynomial time. By weak convergence methods, we have obtained a reduced or limit system of filtering equations. This limit system of equations allows us to find nearly optimal filtering, and the limit system has reduced complexity. In particular, if the transition matrix P given in (2.1) is irreducible, the limit becomes a Kalman filter (see Proposition 3.5).

For continuous-time Kalman filter problems with Markovian switching, it has been recognized (see [4, 11, 21]) that, in general, the problem is an infinite-dimensional one just as in the nonlinear filter case [20]. Nevertheless, Björk [4] proved that a finite-dimensional filter exists for a linear hybrid system if and only if the observation is independent of the state variable. For the filtering problem considered in this paper, this requires the observation process in the limit problem being independent of state. Corresponding to such a requirement, we can consider

$$\begin{aligned} x^\varepsilon_{n+1} &= x^\varepsilon_n + \varepsilon A(\alpha^\varepsilon_n) x^\varepsilon_n + \sqrt{\varepsilon}\sigma_w(\alpha^\varepsilon_n) w_n, \\ y^\varepsilon_{n+1} &= y^\varepsilon_n + \varepsilon C(\alpha^\varepsilon_n) + \sqrt{\varepsilon}\sigma_v v_n. \end{aligned} \tag{5.1}$$

Similar to the derivation of Theorem 3.4, we obtain the limit filtering equations

$$\begin{aligned} dx &= \overline{A}(\overline{\alpha}(t))x\,dt + \overline{\sigma_w}(\overline{\alpha}(t))dw, \\ dy &= \overline{C}(\overline{\alpha}(t))dt + \sigma_v dv. \end{aligned} \tag{5.2}$$

Note that the calculation of (5.1) leads to recursive filters of dimension $m^{\lfloor T/\varepsilon \rfloor}$, whereas (5.2) yields a finite-dimensional filtering problem.

Inclusion of transient states. In the previous sections, the main ingredient is the aggregation of states in each recurrent classes. The results obtained can be extended to the case in which the Markov chain has finite state space with inclusion of transient states. To be more specific, Let the transition probability be of the form (2.1). However, in lieu of (2.3), suppose the transition matrix $\widetilde{P}$ in (2.1) is given by

$$\widetilde{P} = \begin{pmatrix} \widetilde{P}^1 & & & \\ & \ddots & & \\ & & \widetilde{P}^l & \\ \widetilde{P}^1_* & \cdots & \widetilde{P}^l_* & \widetilde{P}_* \end{pmatrix}. \tag{5.3}$$

In lieu of (A1), assume (A1').

(A1') α^ε_n is a Markov chain with a transition probability matrix given by (2.1) and (5.3), and with state space

$$\begin{aligned} \mathcal{M} &= \mathcal{M}_1 \cup \mathcal{M}_2 \cap \cdots \cup \mathcal{M}_l \cup \mathcal{M}_* \\ &= \{s_{11}, \ldots, s_{1m_1}\} \cup \cdots \cup \{s_{l1}, \ldots, s_{lm_l}\} \cup \{s_{*1}, \ldots, s_{*m_*}\}, \end{aligned} \tag{5.4}$$

where, for each $i = 1, \ldots, l$, $\mathcal{M}_i = \{s_{i1}, \ldots, s_{im_i}\}$ is the state space corresponding to the transition matrix $\widetilde{P}^i$ and where the subspace $\mathcal{M}_* = \{s_{*1}, \ldots, s_{*m_*}\}$ collects the transient states. Moreover, $\widetilde{P}^i$ is irreducible for each $i = 1, \ldots, l$, and all eigenvalues of $\widetilde{P}_*$ are inside the unit disk.

To obtain the desired asymptotics, we still use aggregations. However, we aggregate only the states in each recurrent class. Partition the matrix Q as

$$Q = \begin{pmatrix} Q^{11} & Q^{12} \\ Q^{21} & Q^{22} \end{pmatrix}, \tag{5.5}$$

where

$$\begin{aligned} &Q^{11} \in \mathbb{R}^{(m-m_*)\times(m-m_*)},\ Q^{12} \in \mathbb{R}^{(m-m_*)\times m_*}, \\ &Q^{21} \in \mathbb{R}^{m_*\times(m-m_*)}, \text{ and } Q^{22} \in \mathbb{R}^{m_*\times m_*}. \end{aligned}$$

Set

$$\overline{Q}_* = \operatorname{diag}(\nu^1, \ldots, \nu^l)(Q^{11}\widetilde{\mathbf{1}} + Q^{12}A_*), \tag{5.6}$$

with

$$\begin{aligned} &A_* = (a_1, \ldots, a_l) \in \mathbb{R}^{m_*\times l} \quad \text{and} \\ &a_i = -(\widetilde{P}_* - I)^{-1}\widetilde{P}^i_*\mathbf{1}_{m_i} \text{ for } i = 1, \ldots, l. \end{aligned} \tag{5.7}$$

Let U be a random variable uniformly distributed over $[0,1]$. For each $j = 1, \ldots, m_*$, define an integer-valued random variable ξ_j by

$$\xi_j = I_{\{0\le U\le a_{m_1,j}\}} + 2I_{\{a_{1,j}<U\le a_{1,j}+a_{2,j}\}} + \cdots + lI_{\{a_{1,j}+\cdots+a_{l-1,j}<U\le 1\}}.$$

Define the aggregated process and its interpolation by

$$\begin{aligned} \overline{\alpha}^\varepsilon_n &= \begin{cases} i & \text{if } \alpha_n \in \mathcal{M}_i, \\ U_j & \text{if } \alpha^\varepsilon_n = s_{*j}, \end{cases} \\ \overline{\alpha}^\varepsilon(t) &= \overline{\alpha}^\varepsilon_n \quad \text{for} \quad t \in [n\varepsilon, n\varepsilon+\varepsilon). \end{aligned} \tag{5.8}$$

Then we can show that $\overline{\alpha}^{\varepsilon}(\cdot)$ converges weakly to $\overline{\alpha}(\cdot)$ and that the limit is still a Markov chain with state space $\overline{\mathcal{M}}$. Furthermore, we can obtain similar limit results for the filtering problems. The notation is more involved, but the main idea and the averaging techniques are as in the previous case. Loosely, the transient states are asymptoticly negligible. In the limit (reduced) system, only the states in the recurrent states are important. The limit is still an average with respect to the stationary measures of each recurrent class.

THEOREM 5.1. *Assume* (A1'), (A2), *and* (A3). *Then the conclusions of Theorems* 3.3 *and* 3.4 *continue to hold with* $\overline{Q}$ *replaced by* $\overline{Q}_*$ *defined in* (5.6).

Nonstationary Markov chains. Generally, nonstationary or time-inhomogeneous cases are much more difficult to deal with. However, for a class of problems, it can be worked out. The main setup is similar to that of [30]. In lieu of (2.1), assume that the transition probability matrix is nonstationary and given by

$$P^{\varepsilon}(\varepsilon n) = \widetilde{P}(\varepsilon n) + \varepsilon Q(\varepsilon n),$$

where $\widetilde{P}(\varepsilon n)$ is the dominating part of the transition matrix. In this case, we can carry out the analysis as in the previous case, although the details and notation are more involved.

Continuous-time problems. So far, we have considered discrete-time filtering problems exclusively. There is also a continuous-time analogue of the hybrid filtering problems. In place of (2.2), for $t \in [0, T]$, consider

$$\begin{aligned} dx^{\varepsilon}(t) &= A(\alpha^{\varepsilon}(t))x^{\varepsilon}(t)dt + \sigma_w(\alpha^{\varepsilon}(t))dw, \\ dy^{\varepsilon}(t) &= C(\alpha^{\varepsilon}(t))x^{\varepsilon}(t)dt + \sigma_v(\alpha^{\varepsilon}(t))dv, \end{aligned} \tag{5.9}$$

where $w(\cdot)$ and $v(\cdot)$ are independent standard Brownian motions, and where $\alpha^{\varepsilon}(\cdot)$ is a continuous-time singularly perturbed Markov chain with finite state space $\mathcal{M}$ and with generator

$$Q^{\varepsilon}(t) = \frac{\widetilde{Q}(t)}{\varepsilon} + \widehat{Q}(t), \tag{5.10}$$

where both $\widetilde{Q}(t)$ and $\widehat{Q}(t)$ are generators. The state space $\mathcal{M}$ can be of the form of either (2.4) (with recurrent states only) or (5.4) (inclusion of transient states). We can follow our approach of averaging and aggregation to reduce the complexity of the underlying system and obtain a limit system with much reduced state space. Various results on the asymptotic properties of $\alpha^{\varepsilon}(\cdot)$ can be found in [29, 31] among others. The proof of the following result is similar to the discrete-time case; we omit the details. Note that, since the problem is in continuous time, no interpolations are needed, however. For definiteness, we state the result for decomposition of the form (5.4). The matrix $\widetilde{Q}(t)$ has the form

$$\widetilde{Q}(t) = \begin{pmatrix} \widetilde{Q}^1(t) & & & \\ & \ddots & & \\ & & \widetilde{Q}^l(t) & \\ \widetilde{Q}^1_*(t) & \cdots & \widetilde{Q}^l_*(t) & \widetilde{Q}_*(t) \end{pmatrix}. \tag{5.11}$$

For each $i \in \{1, \ldots, l\}$, let $\widetilde{Q}^i_*(t) = B(t)\widetilde{Q}^i_{*,c}$, $\widetilde{Q}_*(t) = B(t)\widetilde{Q}_{*,c}$, where $B(t)$ is an $\mathbb{R}^{m_* \times m_*}$ matrix-valued function, and $\widetilde{Q}^i_{*,c} \in \mathbb{R}^{m_* \times m_i}$ and $\widetilde{Q}_{*,c} \in \mathbb{R}^{m_* \times m_*}$ are

constant matrices. It is readily seen that $B(t)$ is invertible for each $t \in [0,T]$, and, for each i,

$$a_i(t) \stackrel{\text{def}}{=} -\widetilde{Q}_*^{-1}(t)\widetilde{Q}_*^i(t)\mathbf{1}_{m_i} = -\widetilde{Q}_{*,c}^{-1}\widetilde{Q}_{*,c}^i\mathbf{1}_{m_i} = a_i \tag{5.12}$$

is a time-independent vector. Define $\overline{Q}_*(t)$ and $\overline{\alpha}^\varepsilon(t)$ as in (5.6) and (5.8) with $Q^{\iota\ell}$ (the partition of Q) replaced by $\widehat{Q}^{\iota\ell}(t)$ (the partition of $\widehat{Q}(t)$) and with a_i in (5.7) replaced by (5.12). Then we have the following theorem and its corollary.

THEOREM 5.2. *Suppose that, for each $i \in \{1,\dots,l\}$, $\widetilde{Q}^i(t)$ is weakly irreducible (see* [29, pp. 21–22] *for a definition of weak irreducibility and quasi-stationary distribution), that $\widetilde{Q}_*(t)$ has all of its eigenvalues on the left half of the complex plan, that $\widetilde{Q}(\cdot)$ and $\widehat{Q}(\cdot)$ are bounded and Borel measurable, and that $\widetilde{Q}(\cdot)$ is Lipschitz continuous on $[0,T]$. Then $(x^\varepsilon(\cdot), y^\varepsilon(\cdot))$ converges weakly to $(x(\cdot), y(\cdot))$ such that $(x(\cdot), y(\cdot))$ is a solution of the averaged filtering equations* (3.4), *where $\overline{A}(\cdot)$, $\overline{\sigma}_w(\cdot)$, $\overline{C}(\cdot)$, and $\overline{\sigma}_v(\cdot)$ are defined as before with time-dependent quasi-stationary distributions $\nu^i(t)$ used.*

COROLLARY 5.3. *Suppose that $Q^\varepsilon(t)$ is given by* (5.10) *such that $\widetilde{Q}(t)$ is weakly irreducible. Suppose that all other conditions in Theorem* 5.2 *are satisfied. Then $(x^\varepsilon(\cdot), y^\varepsilon(\cdot))$ converges weakly to $(x(\cdot), y(\cdot))$, satisfying*

$$\begin{aligned} dx(t) &= \overline{A}^0(t)x(t)dt + \overline{\sigma_w}^0(t)dw(t), \\ dy(t) &= \overline{C}^0(t)x(t)dt + \overline{\sigma_v}^0(t)dv(t), \end{aligned} \tag{5.13}$$

where $\overline{A}^0$, $\overline{C}^0$, $\overline{\sigma_w}^0$, and $\overline{\sigma_v}^0$ are defined as in (3.7) *with the time-dependent quasi-stationary distribution $\nu(t) = (\nu_1(t),\dots,\nu_m(t))$ used.*

Appendix. Proofs of results.

Proof of Lemma 3.2. We first work with x_n^ε. Iterating on the first equation in (2.2), for $0 \le n \le T/\varepsilon$,

$$x_{n+1}^\varepsilon = x_0^\varepsilon + \varepsilon\sum_{j=0}^n A(\alpha_j^\varepsilon)x_j^\varepsilon + \sqrt{\varepsilon}\sum_{j=0}^n \sigma_w(\alpha_j^\varepsilon)w_j.$$

Note that, for any $z \in \mathbb{R}^r$, $|z|^2 = \operatorname{tr}(zz')$, where $\operatorname{tr}(zz')$ denotes the trace of zz'. Consequently (recall that K is a generic positive constant),

$$\begin{aligned} E|x_{n+1}^\varepsilon|^2 &\le K\left(E|x_0^\varepsilon|^2 + \varepsilon^2 E\left|\sum_{j=0}^n A(\alpha_j^\varepsilon)x_j^\varepsilon\right|^2 + \varepsilon E\left|\sum_{j=0}^n \sigma_w(\alpha_j^\varepsilon)w_j\right|^2\right) \\ &\le KE|x_0^\varepsilon|^2 + K\varepsilon\sum_{j=0}^n E|x_j^\varepsilon|^2 + \varepsilon K\sum_{j=0}^n\sum_{k=0}^n E\operatorname{tr}\left(\sigma_w(\alpha_j^\varepsilon)w_j w_k'\sigma_w'(\alpha_k^\varepsilon)\right). \end{aligned} \tag{A.1}$$

Using the independence of $\{\alpha_n^\varepsilon\}$ and $\{w_n\}$ and the boundedness of $\sigma_w(\iota)$ for each

$\iota \in \mathcal{M}$ and noting that $Ew_j w_k' = 0$ if $j \neq k$,

$$\begin{aligned}
&\varepsilon \sum_{j=0}^{n}\sum_{k=0}^{n} \operatorname{tr}\left(E\sigma_w(\alpha_j^\varepsilon) w_j w_k' \sigma_w'(\alpha_k^\varepsilon)\right) \\
&\le \varepsilon K \left| \sum_{j=0}^{n}\sum_{k=0}^{n} E\{\sigma_w(\alpha_j^\varepsilon)[Ew_j w_k']\sigma_w'(\alpha_k^\varepsilon)\}\right| \\
&\le \varepsilon K \sum_{k=0}^{n} |Ew_k w_k'| \\
&\le \varepsilon K \frac{T}{\varepsilon} \le K < \infty.
\end{aligned} \tag{A.2}$$

Combining this with (A.1), an application of Gronwall's inequality yields

$$E|x_{n+1}^\varepsilon|^2 \le K + K\varepsilon \sum_{j=0}^{n} E|x_j^\varepsilon|^2 \le K\exp(K\varepsilon n) \le K < \infty.$$

Moreover, the bound holds uniformly in n for $0 \le n \le T/\varepsilon$.

As for y_n^ε, using the bound of $\sup_{0\le n\le T/\varepsilon} E|x_n^\varepsilon|^2$, we have

$$\begin{aligned}
E|y_{n+1}^\varepsilon|^2 &\le K\left(E|y_0^\varepsilon|^2 + \varepsilon^2 E\left|\sum_{j=0}^{n} C(\alpha_j^\varepsilon)x_j^\varepsilon\right|^2 + \varepsilon E\left|\sum_{j=0}^{n}\sigma_v(\alpha_j^\varepsilon)v_j\right|^2\right) \\
&\le KE|y_0^\varepsilon|^2 + K\varepsilon\sum_{j=0}^{n} E|x_j^\varepsilon|^2 + \varepsilon K\sum_{j=0}^{n}\sum_{k=0}^{n} E\operatorname{tr}\left(\sigma_v(\alpha_j^\varepsilon)v_j v_k'\sigma_v'(\alpha_k^\varepsilon)\right) \\
&\le K < \infty.
\end{aligned} \tag{A.3}$$

Moreover, the bound holds uniformly in $0 \le n \le T/\varepsilon$. □

Proof of Theorem 3.3. Let us first deal with the sequence $\{x^\varepsilon(\cdot)\}$. For any $\delta > 0$, $t > 0$, and $s > 0$ with $s \le \delta$, consider

$$\begin{aligned}
E_t^\varepsilon|x^\varepsilon(t+s) - x^\varepsilon(t)|^2 &= E_t^\varepsilon\left|\varepsilon\sum_{j=t/\varepsilon}^{(t+s)/\varepsilon-1} A(\alpha_j^\varepsilon)x_j^\varepsilon + \sqrt{\varepsilon}\sum_{j=t/\varepsilon}^{(t+s)/\varepsilon-1}\sigma_w(\alpha_j^\varepsilon)w_j\right|^2 \\
&= \varepsilon^2\sum_{j=t/\varepsilon}^{(t+s)/\varepsilon-1}\sum_{k=t/\varepsilon}^{(t+s)/\varepsilon-1} E_t^\varepsilon\operatorname{tr}[A(\alpha_j^\varepsilon)x_j^\varepsilon x_k^{\varepsilon\prime}A'(\alpha_k^\varepsilon)] \\
&\quad + 2\sqrt{\varepsilon^3}\sum_{j=t/\varepsilon}^{(t+s)/\varepsilon-1}\sum_{k=t/\varepsilon}^{(t+s)/\varepsilon-1} E_t^\varepsilon\operatorname{tr}[A(\alpha_j^\varepsilon)x_j^\varepsilon w_k'\sigma_w'(\alpha_k^\varepsilon)] \\
&\quad + \varepsilon\sum_{j=t/\varepsilon}^{(t+s)/\varepsilon-1}\sum_{k=t/\varepsilon}^{(t+s)/\varepsilon-1} E_t^\varepsilon\operatorname{tr}[\sigma_w(\alpha_j^\varepsilon)w_j w_k'\sigma_w'(\alpha_k^\varepsilon)]
\end{aligned} \tag{A.4}$$

$$\stackrel{\text{def}}{=} I_1^\varepsilon(t,s) + I_2^\varepsilon(t,s) + I_3^\varepsilon(t,s), \tag{A.5}$$

where $I_\ell^\varepsilon(t,s)$ for $\ell = 1,2,3$ are defined in an obvious manner.

Consider each of the terms on the right-hand side of (A.4) separately as follows. First, by the finiteness of $A(\iota)$ for each $\iota \in \mathcal{M}$,

$$I_1^\varepsilon(t,s) = \varepsilon^2 \sum_{j=t/\varepsilon}^{(t+s)/\varepsilon-1} \sum_{k=t/\varepsilon}^{(t+s)/\varepsilon-1} \operatorname{tr}\left(E_t^\varepsilon[A(\alpha_j^\varepsilon)x_j^\varepsilon x_k^{\varepsilon,\prime} A'(\alpha_k^\varepsilon)]\right)$$
$$\leq K\varepsilon^2 \sum_{j=t/\varepsilon}^{(t+s)/\varepsilon-1} \sum_{k=t/\varepsilon}^{(t+s)/\varepsilon-1} E_t^\varepsilon |x_j^\varepsilon||x_k^\varepsilon|.$$

By virtue of Lemma 3.2, an application of the Cauchy–Schwarz inequality then yields

$$EI_1^\varepsilon(t,s) \leq K\varepsilon^2 \sum_{j=t/\varepsilon}^{(t+s)/\varepsilon-1} \sum_{k=t/\varepsilon}^{(t+s)/\varepsilon-1} E^{1/2}|x_j^\varepsilon|^2 E^{1/2}|x_k^\varepsilon|^2$$
$$\leq K\varepsilon^2 \left(\frac{t+s}{\varepsilon} - \frac{t}{\varepsilon}\right)^2 \leq Ks^2 = O(\delta^2).$$

Thus

$$\lim_{\delta\to 0} \limsup_{\varepsilon\to 0} EI_1^\varepsilon(t,s) = \lim_{\delta\to 0} O(\delta^2) = 0. \tag{A.6}$$

As for the second term on the right-hand side of (A.4), note that x_j^ε and $A(\alpha_j^\varepsilon)$ are $\mathcal{F}_j$-measurable. Since, for $j < k$, $E_j w_k = 0$, the independence of $\{\alpha_n^\varepsilon\}$ and $\{w_n\}$ in (A3) and the finiteness of $A(\iota)$ and $\sigma_w(\iota)$ for each $\iota \in \mathcal{M}$ lead to

$$I_2^\varepsilon(t,s) = 2\sqrt{\varepsilon^3} \sum_{j=t/\varepsilon}^{(t+s)/\varepsilon-1} \sum_{k=t/\varepsilon}^{(t+s)/\varepsilon-1} \operatorname{tr} E_t^\varepsilon[A(\alpha_j^\varepsilon)x_j^\varepsilon w_k' \sigma_w'(\alpha_k^\varepsilon)]$$
$$\leq K\sqrt{\varepsilon^3} \sum_{j=t/\varepsilon}^{(t+s)/\varepsilon-1} \sum_{k\geq j} \left|\operatorname{tr}\left[E_t^\varepsilon A(\alpha_j^\varepsilon)x_j^\varepsilon (E_j w_k')(E_j \sigma_w'(\alpha_k^\varepsilon))\right]\right|$$
$$\leq K\sqrt{\varepsilon^3} \sum_{k=t/\varepsilon}^{(t+s)/\varepsilon-1} \sqrt{E_t^\varepsilon |x_k^\varepsilon|^2}\sqrt{E_t^\varepsilon |w_k|^2}.$$

Therefore, an application of the Cauchy–Schwarz inequality yields

$$\lim_{\delta\to 0} \limsup_{\varepsilon\to 0} EI_2^\varepsilon(t,s) = \lim_{\delta\to 0} \limsup_{\varepsilon\to 0} O(\sqrt{\varepsilon}) = 0. \tag{A.7}$$

Next, we consider the last term of (A.4). Using the martingale difference property, the independence of $\{\alpha_n^\varepsilon\}$ and $\{w_n\}$, and $E_j w_k = 0$ for $j < k$ and $E_k w_j = 0$ for $k < j$, we obtain

$$I_3^\varepsilon(t,s) = \varepsilon \sum_{j=t/\varepsilon}^{(t+s)/\varepsilon-1} \sum_{k=t/\varepsilon}^{(t+s)/\varepsilon-1} \operatorname{tr}\left(E_t^\varepsilon \sigma_w(\alpha_j^\varepsilon) w_j w_k' \sigma_w'(\alpha_k^\varepsilon)\}\right)$$
$$= \varepsilon \sum_{k=t/\varepsilon}^{(t+s)/\varepsilon-1} \left|\operatorname{tr}[E_t^\varepsilon \sigma_w(\alpha_k^\varepsilon) w_k w_k' \sigma_w'(\alpha_k^\varepsilon)]\right|,$$

and so

$$EI_3^\varepsilon(t,s) \le K\varepsilon\left(\frac{t+s}{\varepsilon} - \frac{t}{\varepsilon}\right) = O(\delta).$$

As a result,

$$\lim_{\delta\to 0}\limsup_{\varepsilon\to 0} EI_3^\varepsilon(t,s) = \lim_{\delta\to 0} O(\delta) = 0. \tag{A.8}$$

Combining (A.6), (A.7), and (A.8), we obtain

$$\lim_{\delta\to 0}\limsup_{\varepsilon\to 0} E|x^\varepsilon(t+s) - x^\varepsilon(t)|^2 = 0.$$

The criteria due to Kurtz [17, p. 47] then yields that $\{x^\varepsilon(\cdot)\}$ is tight in $D^r[0,T]$.

As far as the estimates of $y^\varepsilon(\cdot)$ are concerned, we merely note that

$$\begin{aligned} &E_t^\varepsilon|y^\varepsilon(t+s) - y^\varepsilon(t)|^2 \\ &\qquad = E_t^\varepsilon\left|\varepsilon\sum_{k=t/\varepsilon}^{(t+s)/\varepsilon-1} C(\alpha_k^\varepsilon)x_k^\varepsilon + \sqrt{\varepsilon}\sum_{k=t/\varepsilon}^{(t+s)/\varepsilon-1}\sigma_v(\alpha_k^\varepsilon)v_k\right|^2 \\ &\qquad \le KE_t^\varepsilon\left|\varepsilon\sum_{k=t/\varepsilon}^{(t+s)/\varepsilon-1} C(\alpha_k^\varepsilon)x_k^\varepsilon\right|^2 + KE_t^\varepsilon\left|\sqrt{\varepsilon}\sum_{k=t/\varepsilon}^{(t+s)/\varepsilon-1}\sigma_v(\alpha_k^\varepsilon)v_k\right|^2. \end{aligned}$$

The rest of the estimates are all similar to the previous case. Thus we also have that $\{y^\varepsilon(\cdot)\}$ is tight in $D^r[0,T]$. □

Proof of Theorem 3.4. Consider $\{x^\varepsilon(\cdot)\}$ first. In fact, we work with the pair $(x^\varepsilon(\cdot),\overline{\alpha}^\varepsilon(\cdot))$. Owing to the tightness of $\{x^\varepsilon(\cdot)\}$ and the weak convergence of $\{\overline{\alpha}^\varepsilon(\cdot)\}$, $\{(x^\varepsilon(\cdot),\overline{\alpha}^\varepsilon(\cdot))\}$ is tight. By virtue of the Prohorov theorem [13, p. 104], we can extract a weakly convergent subsequence. Select such a subsequence, and still denote it by $\{(x^\varepsilon(\cdot),\overline{\alpha}^\varepsilon(\cdot))\}$ for simplicity. Denote the limit of the sequence by $(x(\cdot),\overline{\alpha}(\cdot))$. By the Skorohod representation [13, p. 102], we may assume without loss of generality that $(x^\varepsilon(\cdot),\overline{\alpha}^\varepsilon(\cdot))$ converges to $(x(\cdot),\overline{\alpha}(\cdot))$ with probability one (w.p.1). Moreover, the convergence is uniform on each bounded time interval. We proceed to use martingale averaging techniques to figure out the limit.

To obtain the desired limit, it suffices to show that the limit $(x(\cdot),\overline{\alpha}(\cdot))$ is the solution of a martingale problem with operator $\mathcal{L}$ given by

$$\mathcal{L}f(x,i) = f_x'(x,i)\overline{A}(i)x + \frac{1}{2}\mathrm{tr}[f_{xx}(x,i)\overline{\sigma_w}(i)\overline{\sigma_w}'(i)] + \overline{Q}f(x,\cdot)(i), \quad i\in\overline{\mathcal{M}}, \tag{A.9}$$

where

$$\overline{Q}f(x,\cdot)(i) = \sum_{j\in\overline{\mathcal{M}}}\overline{q}_{ij}f(x,j) = \sum_{j\in\overline{\mathcal{M}},\ j\neq i}\overline{q}_{ij}(f(x,j)-f(x,i))$$

for each $i\in\overline{\mathcal{M}}$, and $f(\cdot,i)\in C_0^2$ (twice continuously differentiable function with compact support). Since the filtering equation is linear in the state variable, by using a similar argument to that in [29, Lemma 7.18], the corresponding martingale problem with operator $\mathcal{L}$ given in (A.9) has a unique solution.

To obtain the desired results, it suffices to show (see [19, Chapters 7 and 8]), for any positive integer k_0, any bounded and continuous function $h_\kappa(\cdot)$ with $\kappa \le k_0$, any $t, s > 0$, and $t_\kappa \le t \le t+s$, that the following equation holds:

$$E\prod_{\kappa=1}^{k_0} h_\kappa(x(t_\kappa),\overline{\alpha}(t_\kappa))\Bigg(f(x(t+s),\overline{\alpha}(t+s)) - f(x(t),\overline{\alpha}(t)) - \int_t^{t+s}\mathcal{L}f(x(u),\overline{\alpha}(u))du\Bigg) = 0. \tag{A.10}$$

To obtain (A.10), we begin with the pair $(x^\varepsilon(\cdot),\alpha^\varepsilon(\cdot))$. For each x, define $\check{f}$ by

$$\check{f}(x,\alpha) = \sum_{i=1}^{l} f(x,i)I_{\{\alpha\in\mathcal{M}_i\}} \quad \text{for each} \quad \alpha\in\mathcal{M}. \tag{A.11}$$

Note that, for each $\alpha = s_{ij} \in \mathcal{M}_i$, $\check{f}(x,\alpha)$ takes a constant value $f(x,i)$. Note also that, at any time instant t, $\alpha^\varepsilon(t) = \alpha^\varepsilon_{t/\varepsilon}$ takes on one of the m possible values from $\mathcal{M}$.

Note that $\check{f}(x^\varepsilon_k,\alpha^\varepsilon_k) = f(x^\varepsilon_k,\overline{\alpha}^\varepsilon_k)$ for each k. Choose a sequence of positive integers $\{n_\varepsilon\}$ such that $n_\varepsilon \to \infty$ but $\delta_\varepsilon = \varepsilon n_\varepsilon \to 0$ as $\varepsilon \to 0$. The piecewise constant interpolation implies that

$$\begin{aligned}
&\check{f}(x^\varepsilon(t+s),\alpha^\varepsilon(t+s)) - \check{f}(x^\varepsilon(t),\alpha^\varepsilon(t))\\
&= \sum_{l:t\le l\delta_\varepsilon\le(t+s)-\varepsilon}[\check{f}(x^\varepsilon_{ln_\varepsilon+n_\varepsilon},\alpha^\varepsilon_{ln_\varepsilon+n_\varepsilon}) - \check{f}(x^\varepsilon_{ln_\varepsilon+n_\varepsilon},\alpha^\varepsilon_{ln_\varepsilon})]\\
&\quad + \sum_{l:t\le l\delta_\varepsilon\le(t+s)-\varepsilon}[\check{f}(x^\varepsilon_{ln_\varepsilon+n_\varepsilon},\alpha^\varepsilon_{ln_\varepsilon}) - \check{f}(x^\varepsilon_{ln_\varepsilon},\alpha^\varepsilon_{ln_\varepsilon})],
\end{aligned} \tag{A.12}$$

and hence

$$\begin{aligned}
&\lim_{\varepsilon\to0} E\prod_{\kappa=1}^{k_0} h_\kappa(x^\varepsilon(t_\kappa),\overline{\alpha}^\varepsilon(t_\kappa))[\check{f}(x^\varepsilon(t+s),\alpha^\varepsilon(t+s)) - \check{f}(x^\varepsilon(t),\alpha^\varepsilon(t))]\\
&= \lim_{\varepsilon\to0} E\prod_{\kappa=1}^{k_0} h_\kappa(x^\varepsilon(t_\kappa),\overline{\alpha}^\varepsilon(t_\kappa)) \sum_{l:t\le l\delta_\varepsilon\le(t+s)-\varepsilon}[\check{f}(x^\varepsilon_{ln_\varepsilon+n_\varepsilon},\alpha^\varepsilon_{ln_\varepsilon+n_\varepsilon}) - \check{f}(x^\varepsilon_{ln_\varepsilon+n_\varepsilon},\alpha^\varepsilon_{ln_\varepsilon})]\\
&\quad + \lim_{\varepsilon\to0} E\prod_{\kappa=1}^{k_0} h_\kappa(x^\varepsilon(t_\kappa),\overline{\alpha}^\varepsilon(t_\kappa)) \sum_{l:t\le l\delta_\varepsilon\le(t+s)-\varepsilon}[\check{f}(x^\varepsilon_{ln_\varepsilon+n_\varepsilon},\alpha^\varepsilon_{ln_\varepsilon}) - \check{f}(x^\varepsilon_{ln_\varepsilon},\alpha^\varepsilon_{ln_\varepsilon})]\\
&\stackrel{\text{def}}{=} \lim_{\varepsilon\to0} E\prod_{\kappa=1}^{k_0} h_\kappa(x^\varepsilon(t_\kappa),\overline{\alpha}^\varepsilon(t_\kappa))[g^\varepsilon_1 + g^\varepsilon_2].
\end{aligned} \tag{A.13}$$

In the above, $\sum_{l:t\le l\delta_\varepsilon\le(t+s)-\varepsilon}$ can also be written as $\sum_{ln_\varepsilon=t/\varepsilon}^{((t+s)/\varepsilon)-1}$. We proceed to obtain the desired limit by examining g^ε_i $(i=1,2)$ in (A.13).

By virtue of a Taylor expansion, rewrite g_2^ε as

$$\begin{aligned} g_2^\varepsilon &= \sum_{l:t\le l\delta_\varepsilon\le(t+s)-\varepsilon} \check{f}_x'(x_{ln_\varepsilon},\alpha_{ln_\varepsilon}^\varepsilon)[x_{ln_\varepsilon+n_\varepsilon}^\varepsilon - x_{ln_\varepsilon}^\varepsilon] \\ &\quad + \frac{1}{2}\sum_{l:t\le l\delta_\varepsilon\le(t+s)-\varepsilon} [x_{ln_\varepsilon+n_\varepsilon}^\varepsilon - x_{ln_\varepsilon}^\varepsilon]'\check{f}_{xx}(x_{ln_\varepsilon}^+,\alpha_{ln_\varepsilon}^\varepsilon)[x_{ln_\varepsilon+n_\varepsilon}^\varepsilon - x_{ln_\varepsilon}^\varepsilon] \\ &= \sum_{l:t\le l\delta_\varepsilon\le(t+s)-\varepsilon}\sum_{k=ln_\varepsilon}^{ln_\varepsilon+n_\varepsilon-1} \check{f}_x'(x_{ln_\varepsilon}^\varepsilon,\alpha_{ln_\varepsilon}^\varepsilon)[\varepsilon A(\alpha_k^\varepsilon)x_k^\varepsilon + \sqrt{\varepsilon}\sigma_w(\alpha_k^\varepsilon)w_k] \\ &\quad + \frac{1}{2}\sum_{l:t\le l\delta_\varepsilon\le(t+s)-\varepsilon}\sum_{k=ln_\varepsilon}^{ln_\varepsilon+n_\varepsilon-1} [\varepsilon A(\alpha_k^\varepsilon)x_k^\varepsilon + \sqrt{\varepsilon}\sigma_w(\alpha_k^\varepsilon)w_k]'\check{f}_{xx}(x_{ln_\varepsilon}^+,\alpha_{ln_\varepsilon}^\varepsilon) \\ &\quad \times \sum_{k_1=ln_\varepsilon}^{ln_\varepsilon+n_\varepsilon-1} [\varepsilon A(\alpha_{k_1}^\varepsilon)x_{k_1}^\varepsilon + \sqrt{\varepsilon}\sigma_w(\alpha_{k_1}^\varepsilon)w_{k_1}] \qquad \text{(A.14)} \\ &\stackrel{\text{def}}{=} \left[g_{2,1}^\varepsilon + \frac{1}{2}g_{2,2}^\varepsilon\right], \qquad \text{(A.15)} \end{aligned}$$

where $x_{ln_\varepsilon}^+$ is on the line segment joining $x_{ln_\varepsilon}^\varepsilon$ and $x_{ln_\varepsilon+n_\varepsilon}^\varepsilon$.

Then we have

$$\begin{aligned} &E\prod_{\kappa=1}^{k_0} h_\kappa(x^\varepsilon(t_\kappa),\overline{\alpha}^\varepsilon(t_\kappa))\left[\sqrt{\varepsilon}\sum_{l:t\le l\delta_\varepsilon\le(t+s)-\varepsilon}\check{f}_x'(x_{ln_\varepsilon}^\varepsilon,\alpha_{ln_\varepsilon}^\varepsilon)\sum_{k=ln_\varepsilon}^{ln_\varepsilon+n_\varepsilon-1}\sigma_w(\alpha_k^\varepsilon)w_k\right] \\ &= E\prod_{\kappa=1}^{k_0} h_\kappa(x^\varepsilon(t_\kappa),\overline{\alpha}^\varepsilon(t_\kappa))\left[\sqrt{\varepsilon}\sum_{l:t\le l\delta_\varepsilon\le(t+s)-\varepsilon}\check{f}_x'(x_{ln_\varepsilon},\alpha_{ln_\varepsilon}^\varepsilon)\right. \\ &\qquad\left.\times\sum_{k=ln_\varepsilon}^{ln_\varepsilon+n_\varepsilon-1}E_{ln_\varepsilon}\sigma_w(\alpha_k^\varepsilon)E_{ln_\varepsilon}w_k\right]. \end{aligned}$$

In the above, the second line is a consequence of the independence of $\{\alpha_n^\varepsilon\}$ and $\{w_n\}$ and the measurability of $x_{ln_\varepsilon}^\varepsilon$ and $\alpha_{ln_\varepsilon}^\varepsilon$ with respect to $\mathcal{F}_{ln_\varepsilon}$. In view of the boundedness of $h_\kappa(\cdot)$ and $\check{f}_x(\cdot)$ and the finiteness of $\sigma_w(\alpha_k^\varepsilon)$, we obtain

$$\begin{aligned} &E\prod_{\kappa=1}^{k_0} h_\kappa(x^\varepsilon(t_\kappa),\overline{\alpha}^\varepsilon(t_\kappa))\left[\sqrt{\varepsilon}\sum_{l:t\le l\delta_\varepsilon\le(t+s)-\varepsilon}\sum_{k=ln_\varepsilon}^{ln_\varepsilon+n_\varepsilon-1}\check{f}_x'(x_{ln_\varepsilon},\alpha_{ln_\varepsilon}^\varepsilon)E_{ln_\varepsilon}\sigma_w(\alpha_k^\varepsilon)E_{ln_\varepsilon}w_k\right] \\ &\to 0 \quad \text{as} \quad \varepsilon\to 0. \end{aligned} \qquad \text{(A.16)}$$

Next, let us treat the term on the second line of (A.14). First note that

$$\begin{aligned} &E\left|\varepsilon\sum_{i=1}^{l}\sum_{j=1}^{m_i}\sum_{k=ln_\varepsilon}^{ln_\varepsilon+n_\varepsilon-1}A(s_{ij})x_k^\varepsilon[I_{\{\alpha_k^\varepsilon=s_{ij}\}} - \nu_j^i I_{\{\alpha_k^\varepsilon\in\mathcal{M}_i\}}]\right| \\ &\le K\sum_{i=1}^{l}\sum_{j=1}^{m_i}E\left|\varepsilon\sum_{k=ln_\varepsilon}^{ln_\varepsilon+n_\varepsilon-1}A(s_{ij})x_k^\varepsilon[I_{\{\alpha_k^\varepsilon=s_{ij}\}} - \nu_j^i I_{\{\alpha_k^\varepsilon\in\mathcal{M}_i\}}]\right|. \end{aligned}$$

Thus we need only examine the terms with fixed indices i and j. By a partial summation,

$$
\begin{aligned}
&E\left|\varepsilon \sum_{k=ln_\varepsilon}^{ln_\varepsilon+n_\varepsilon-1} A(s_{ij})x_k^\varepsilon[I_{\{\alpha_k^\varepsilon=s_{ij}\}}-\nu_j^i I_{\{\alpha_k^\varepsilon\in\mathcal{M}_i\}}]\right| \\
&\le KE\left|\varepsilon A(s_{ij})x^\varepsilon_{ln_\varepsilon+n_\varepsilon-1}\sum_{k=0}^{ln_\varepsilon+n_\varepsilon-1}[I_{\{\alpha_k^\varepsilon=s_{ij}\}}-\nu_j^i I_{\{\alpha_k^\varepsilon\in\mathcal{M}_i\}}]\right| \\
&\quad + KE\left|\varepsilon A(s_{ij})x^\varepsilon_{ln_\varepsilon-1}\sum_{k=0}^{ln_\varepsilon-1}[I_{\{\alpha_k^\varepsilon=s_{ij}\}}-\nu_j^i I_{\{\alpha_k^\varepsilon\in\mathcal{M}_i\}}]\right| \\
&\quad + KE\left|\varepsilon \sum_{k=ln_\varepsilon}^{ln_\varepsilon+n_\varepsilon-2}(x_k^\varepsilon-x_{k+1}^\varepsilon)\sum_{k_0=0}^{k}[I_{\{\alpha_{k_0}^\varepsilon=s_{ij}\}}-\nu_j^i I_{\{\alpha_{k_0}^\varepsilon\in\mathcal{M}_i\}}]\right|.
\end{aligned}
$$

Using the mean square estimates on the occupation measures (2.10) and Lemma 3.2,

$$
\begin{aligned}
&E\left|\varepsilon A(s_{ij})x^\varepsilon_{ln_\varepsilon+n_\varepsilon-1}\sum_{k=0}^{ln_\varepsilon+n_\varepsilon-1}[I_{\{\alpha_k^\varepsilon=s_{ij}\}}-\nu_j^i I_{\{\alpha_k^\varepsilon\in\mathcal{M}_i\}}]\right| \\
&\le KE^{1/2}\left|x^\varepsilon_{ln_\varepsilon+n_\varepsilon-1}\right|^2 E^{1/2}\left|\varepsilon\sum_{k=0}^{ln_\varepsilon+n_\varepsilon-1}[I_{\{\alpha_k^\varepsilon=s_{ij}\}}-\nu_j^i I_{\{\alpha_k^\varepsilon\in\mathcal{M}_i\}}]\right|^2 \\
&= O(\sqrt{\varepsilon})\to 0 \quad \text{as} \quad \varepsilon\to 0.
\end{aligned}
$$

Similarly,

$$
E\left|\varepsilon A(s_{ij})x^\varepsilon_{ln_\varepsilon-1}\sum_{k=0}^{ln_\varepsilon-1}[I_{\{\alpha_k^\varepsilon=s_{ij}\}}-\nu_j^i I_{\{\alpha_k^\varepsilon\in\mathcal{M}_i\}}]\right|\to 0 \quad \text{as} \quad \varepsilon\to 0.
$$

Using (2.2), the Cauchy–Schwarz inequality, and the mean square estimates (2.10),

$$
\begin{aligned}
&E\left|\varepsilon \sum_{k=ln_\varepsilon}^{ln_\varepsilon+n_\varepsilon-2}(x_k^\varepsilon-x_{k+1}^\varepsilon)\sum_{k_0=0}^{k}[I_{\{\alpha_{k_0}^\varepsilon=s_{ij}\}}-\nu_j^i I_{\{\alpha_{k_0}^\varepsilon\in\mathcal{M}_i\}}]\right| \\
&\le \sum_{k=ln_\varepsilon}^{ln_\varepsilon+n_\varepsilon-2} E^{1/2}|x_k^\varepsilon-x_{k+1}^\varepsilon|^2 E^{1/2}\left|\varepsilon\sum_{k_0=0}^{k}[I_{\{\alpha_{k_0}^\varepsilon=s_{ij}\}}-\nu_j^i I_{\{\alpha_{k_0}^\varepsilon\in\mathcal{M}_i\}}]\right|^2 \\
&\le \sum_{k=ln_\varepsilon}^{ln_\varepsilon+n_\varepsilon-2} E^{1/2}|\varepsilon A(\alpha_k^\varepsilon)x_k^\varepsilon+\sqrt{\varepsilon}\sigma_w(\alpha_k^\varepsilon)w_k|^2 \\
&\times E^{1/2}\left|\varepsilon\sum_{k_0=0}^{k}[I_{\{\alpha_{k_0}^\varepsilon=s_{ij}\}}-\nu_j^i I_{\{\alpha_{k_0}^\varepsilon\in\mathcal{M}_i\}}]\right|^2 \\
&\to 0 \quad \text{as} \quad \varepsilon\to 0.
\end{aligned}
$$

Using the above estimates and the continuity of $\check{f}_x(\cdot,\alpha)$ for each $\alpha \in \mathcal{M}$,

$$
\begin{aligned}
&E\prod_{\kappa=1}^{k_0} h_\kappa(x^\varepsilon(t_\kappa),\overline{\alpha}^\varepsilon(t_\kappa))\left[\varepsilon \sum_{l:t\le l\delta_\varepsilon\le (t+s)-\varepsilon} \check{f}'_x(x^\varepsilon_{ln_\varepsilon},\alpha^\varepsilon_{ln_\varepsilon}) \sum_{k=ln_\varepsilon}^{ln_\varepsilon+n_\varepsilon-1} A(\alpha^\varepsilon_k)x^\varepsilon_k\right]\\
&= E\prod_{\kappa=1}^{k_0} h_\kappa(x^\varepsilon(t_\kappa),\overline{\alpha}^\varepsilon(t_\kappa))\left[\sum_{l:t\le l\delta_\varepsilon\le (t+s)-\varepsilon}\sum_{i=1}^{l}\sum_{j=1}^{m_i} \check{f}'_x(x_{ln_\varepsilon},\alpha^\varepsilon_{ln_\varepsilon})\right.\\
&\qquad\left.\times \frac{\delta_\varepsilon}{n_\varepsilon}\sum_{k=ln_\varepsilon}^{ln_\varepsilon+n_\varepsilon-1} A(s_{ij})x^\varepsilon_{ln_\varepsilon}\nu^i_j I_{\{\alpha^\varepsilon_k\in\mathcal{M}_i\}}\right]+o(1),
\end{aligned}
\tag{A.17}
$$

where $o(1)\to 0$ as $\varepsilon\to 0$. Then, as $\varepsilon\to 0$, letting $\varepsilon l n_\varepsilon \to u$, and using the techniques of [19, Chapter 8], (A.17) together with (A.16) leads to

$$
\begin{aligned}
&E\prod_{\kappa=1}^{k_0} h_\kappa(x^\varepsilon(t_\kappa),\overline{\alpha}^\varepsilon(t_\kappa))g^\varepsilon_{2,1}\\
&\to E\prod_{\kappa=1}^{k_0} h_\kappa(x(t_\kappa),\overline{\alpha}(t_\kappa))\left(\int_t^{t+s} f'_x(x(u),\overline{\alpha}(u))A(\overline{\alpha}(u))x(u)du\right)\quad\text{as}\quad \varepsilon\to 0.
\end{aligned}
\tag{A.18}
$$

As for $g^\varepsilon_{2,2}$, we have, by the continuity of $f_{xx}(\cdot,\alpha)$ for each $\alpha\in\mathcal{M}$, $x^+_{ln_\varepsilon}-x^\varepsilon_{ln_\varepsilon}\to 0$ in probability as $\varepsilon\to 0$. Consequently,

$$
E\prod_{\kappa=1}^{k_0} h_\kappa(x^\varepsilon(t_\kappa),\overline{\alpha}^\varepsilon(t_\kappa))g^\varepsilon_{2,2} \stackrel{\text{def}}{=} \widetilde{g}^\varepsilon_{2,2}+o(1),
$$

where $o(1)\to 0$ as $\varepsilon\to 0$ uniformly in t, and

$$
\begin{aligned}
\widetilde{g}^\varepsilon_{2,2} &= E\prod_{\kappa=1}^{k_0} h_\kappa(x^\varepsilon(t_\kappa),\overline{\alpha}^\varepsilon(t_\kappa))\\
&\times\left[\sum_{l:t\le l\delta_\varepsilon\le (t+s)-\varepsilon}\sum_{k=ln_\varepsilon}^{ln_\varepsilon+n_\varepsilon-1}[\varepsilon A(\alpha^\varepsilon_k)x^\varepsilon_k+\sqrt{\varepsilon}\sigma_w(\alpha^\varepsilon_k)w_k]'\check{f}_{xx}(x^\varepsilon_{ln_\varepsilon},\alpha^\varepsilon_{ln_\varepsilon})\right.\\
&\qquad\left.\times\sum_{k_1=ln_\varepsilon}^{ln_\varepsilon+n_\varepsilon-1}[\varepsilon A(\alpha^\varepsilon_{k_1})x^\varepsilon_{k_1}+\sqrt{\varepsilon}\sigma_w(\alpha^\varepsilon_{k_1})w_{k_1}]\right].
\end{aligned}
$$

It then follows that

$$\begin{aligned}
\widetilde{g}^{\varepsilon}_{2,2} &= E\prod_{\kappa=1}^{k_0} h_\kappa(x^\varepsilon(t_\kappa),\overline{\alpha}^\varepsilon(t_\kappa))\\
&\quad\times\Bigg[\varepsilon^2\sum_{l:t\le l\delta_\varepsilon\le(t+s)-\varepsilon}\sum_{k=ln_\varepsilon}^{ln_\varepsilon+n_\varepsilon-1}(A(\alpha^\varepsilon_k)x^\varepsilon_k)'\check{f}_{xx}(x^\varepsilon_{ln_\varepsilon},\alpha^\varepsilon_{ln_\varepsilon})\sum_{k_1=ln_\varepsilon}^{ln_\varepsilon+n_\varepsilon-1}A(\alpha^\varepsilon_{k_1})x^\varepsilon_{k_1}\\
&\quad+\sqrt{\varepsilon^3}\sum_{l:t\le l\delta_\varepsilon\le(t+s)-\varepsilon}\sum_{k=ln_\varepsilon}^{ln_\varepsilon+n_\varepsilon-1}(A(\alpha^\varepsilon_k)x^\varepsilon_k)'\check{f}_{xx}(x^\varepsilon_{ln_\varepsilon},\alpha^\varepsilon_{ln_\varepsilon})\sum_{k_1=ln_\varepsilon}^{ln_\varepsilon+n_\varepsilon-1}\sigma_w(\alpha^\varepsilon_{k_1})w_{k_1}\\
&\quad+\sqrt{\varepsilon^3}\sum_{l:t\le l\delta_\varepsilon\le(t+s)-\varepsilon}\sum_{k=ln_\varepsilon}^{ln_\varepsilon+n_\varepsilon-1}(\sigma_w(\alpha^\varepsilon_k)w_k)'\check{f}_{xx}(x^\varepsilon_{ln_\varepsilon},\alpha^\varepsilon_{ln_\varepsilon})\sum_{k_1=ln_\varepsilon}^{ln_\varepsilon+n_\varepsilon-1}A(\alpha^\varepsilon_{k_1})x^\varepsilon_{k_1}\\
&\quad+\varepsilon\sum_{l:t\le l\delta_\varepsilon\le(t+s)-\varepsilon}\sum_{k=ln_\varepsilon}^{ln_\varepsilon+n_\varepsilon-1}(\sigma_w(\alpha^\varepsilon_k)w_k)'\check{f}_{xx}(x^\varepsilon_{ln_\varepsilon},\alpha^\varepsilon_{ln_\varepsilon})\sum_{k_1=ln_\varepsilon}^{ln_\varepsilon+n_\varepsilon-1}\sigma_w(\alpha^\varepsilon_{k_1})w_{k_1}\Bigg]\\
&= E\prod_{\kappa=1}^{k_0} h_\kappa(x^\varepsilon(t_\kappa),\overline{\alpha}^\varepsilon(t_\kappa))\\
&\quad\times\Bigg[\varepsilon\sum_{l:t\le l\delta_\varepsilon\le(t+s)-\varepsilon}\sum_{k=ln_\varepsilon}^{ln_\varepsilon+n_\varepsilon-1}(\sigma_w(\alpha^\varepsilon_k)w_k)'\check{f}_{xx}(x^\varepsilon_{ln_\varepsilon},\alpha^\varepsilon_{ln_\varepsilon})\sigma_w(\alpha^\varepsilon_k)w_k\Bigg]+o(1),
\end{aligned}$$

where $o(1)\to 0$ as $\varepsilon\to 0$. Furthermore, using the idea of the estimates leading to (A.17) and the mean square estimates (2.10), it can be shown that

$$\begin{aligned}
&\varepsilon\sum_{l:t\le l\delta_\varepsilon\le(t+s)-\varepsilon}\sum_{k=ln_\varepsilon}^{ln_\varepsilon+n_\varepsilon-1}(\sigma_w(\alpha^\varepsilon_k)w_k)'\check{f}_{xx}(x^\varepsilon_{ln_\varepsilon},\alpha^\varepsilon_{ln_\varepsilon})\sigma_w(\alpha^\varepsilon_k)w_k\\
&=\sum_{l:t\le l\delta_\varepsilon\le(t+s)-\varepsilon}\sum_{i=1}^{l}\sum_{j=1}^{m_i}\frac{\delta_\varepsilon}{n_\varepsilon}\sum_{k=ln_\varepsilon}^{ln_\varepsilon+n_\varepsilon-1}\mathrm{tr}[\check{f}_{xx}(x^\varepsilon_{ln_\varepsilon},s_{ij})\sigma_w(s_{ij})w_kw_k'\sigma_w'(s_{ij})]I_{\{\alpha^\varepsilon_k=s_{ij}\}}\\
&=\sum_{l:t\le l\delta_\varepsilon\le(t+s)-\varepsilon}\sum_{i=1}^{l}\sum_{j=1}^{m_i}\frac{\delta_\varepsilon}{n_\varepsilon}\sum_{k=ln_\varepsilon}^{ln_\varepsilon+n_\varepsilon-1}\mathrm{tr}[\check{f}_{xx}(x^\varepsilon_{ln_\varepsilon},\alpha^\varepsilon_{ln_\varepsilon})\sigma_w(s_{ij})w_kw_k'\sigma_w'(s_{ij})]\\
&\quad\times\nu^i_jI_{\{\alpha^\varepsilon_k\in\mathcal{M}_i\}}+o(1),
\end{aligned}$$

where $o(1)\to 0$ in probability as $\varepsilon\to 0$ uniformly in t. It then follows that

$$\begin{aligned}
\lim_{\varepsilon\to 0}&E\prod_{\kappa=1}^{k_0} h_\kappa(x^\varepsilon(t_\kappa),\overline{\alpha}^\varepsilon(t_\kappa))\\
&\times\Bigg[\varepsilon\sum_{l:t\le l\delta_\varepsilon\le(t+s)-\varepsilon}\sum_{k=ln_\varepsilon}^{ln_\varepsilon+n_\varepsilon-1}(\sigma_w(\alpha^\varepsilon_k)w_k)'\check{f}_{xx}(x^\varepsilon_{ln_\varepsilon},\alpha^\varepsilon_{ln_\varepsilon})\sigma_w(\alpha^\varepsilon_k)w_k\Bigg]\\
&=E\prod_{\kappa=1}^{k_0} h_\kappa(x(t_\kappa),\overline{\alpha}(t_\kappa))\left[\int_t^{t+s}\mathrm{tr}[f_{xx}(x(u),\overline{\alpha}(u))\sigma_w(\overline{\alpha}(u))\sigma_w'(\overline{\alpha}(u))]du\right].
\end{aligned}\tag{A.19}$$

Next, we consider the term g^ε_1. Using the continuity of $\check{f}(\cdot,\alpha)$ for each $\alpha\in\mathcal{M}$, the Markov property of α^ε_n, the mean square estimate (2.10) of the occupation measures,

(2.1), and Lemma 2.1, we have

$$
\begin{aligned}
(\text{A.20})\ & E\prod_{\kappa=1}^{k_0} h_\kappa(x^\varepsilon(t_\kappa),\overline{\alpha}^\varepsilon(t_\kappa))g_1^\varepsilon \\
&= E\prod_{\kappa=1}^{k_0} h_\kappa(x^\varepsilon(t_\kappa),\overline{\alpha}^\varepsilon(t_\kappa))\left[\sum_{l:t\le l\delta_\varepsilon\le(t+s)-\varepsilon}(\check{f}(x^\varepsilon_{ln_\varepsilon},\alpha^\varepsilon_{ln_\varepsilon+n_\varepsilon})-\check{f}(x^\varepsilon_{ln_\varepsilon},\alpha^\varepsilon_{ln_\varepsilon}))\right] \\
&= E\prod_{\kappa=1}^{k_0} h_\kappa(x^\varepsilon(t_\kappa),\overline{\alpha}^\varepsilon(t_\kappa))\left[\sum_{l:t\le l\delta_\varepsilon\le(t+s)-\varepsilon}\sum_{k=ln_\varepsilon}^{ln_\varepsilon+n_\varepsilon-1}\sum_{i_1=1}^{l}\sum_{j_1=1}^{m_{i_1}}\left[\sum_{i=1}^{l}\sum_{j=1}^{m_i}\check{f}(x^\varepsilon_{ln_\varepsilon},s_{ij})\right.\right. \\
&\qquad \left.\left.\times P(\alpha^\varepsilon_{k+1}=s_{ij}|\alpha^\varepsilon_k=s_{i_1j_1})-\check{f}(x^\varepsilon_{ln_\varepsilon},s_{i_1j_1})\right]I_{\{\alpha^\varepsilon_k=s_{i_1j_1}\}}\right] \\
&= E\prod_{\kappa=1}^{k_0} h_\kappa(x^\varepsilon(t_\kappa),\overline{\alpha}^\varepsilon(t_\kappa))\left[\varepsilon\sum_{l:t\le l\delta_\varepsilon\le(t+s)-\varepsilon}\sum_{k=ln_\varepsilon}^{ln_\varepsilon+n_\varepsilon-1}(P-I+\varepsilon Q)\check{f}(x^\varepsilon_{ln_\varepsilon},\cdot)(\alpha^\varepsilon_k)\right] \\
&= E\prod_{\kappa=1}^{k_0} h_\kappa(x^\varepsilon(t_\kappa),\overline{\alpha}^\varepsilon(t_\kappa))\left[\varepsilon\sum_{l:t\le l\delta_\varepsilon\le(t+s)-\varepsilon}\sum_{k=ln_\varepsilon}^{ln_\varepsilon+n_\varepsilon-1}Q\check{f}(x^\varepsilon_{ln_\varepsilon},\cdot)(\alpha^\varepsilon_k)\right] \\
&\quad \to \int_t^{t+s}\overline{Q}f(x(u),\overline{\alpha}(u))du \ \text{ as } \ \varepsilon\to 0.
\end{aligned}
$$

Combining (A.18), (A.19), and (A.20),

$$
\begin{aligned}
(\text{A.21})\qquad & \lim_{\varepsilon\to 0} E\prod_{\kappa=1}^{k_0} h_\kappa(x^\varepsilon(t_\kappa),\overline{\alpha}^\varepsilon(t_\kappa))\left[\check{f}(x^\varepsilon(t+s),\overline{\alpha}^\varepsilon(t+s))-\check{f}(x^\varepsilon(t),\overline{\alpha}^\varepsilon(t))\right] \\
&\qquad = E\prod_{\kappa=1}^{k_0} h_\kappa(x(t_\kappa),\overline{\alpha}(t_\kappa))\left[\int_t^{t+s}\mathcal{L}f(x(u),\overline{\alpha}(u))du\right].
\end{aligned}
$$

On the other hand, by the weak convergence of $(x^\varepsilon(\cdot),\overline{\alpha}^\varepsilon(\cdot))$ to $(x(\cdot),\overline{\alpha}(\cdot))$, the Skorohod representation, and the definition of $\check{f}(\cdot)$, we have

$$
\begin{aligned}
(\text{A.22})\qquad & \lim_{\varepsilon\to 0} E\prod_{\kappa=1}^{k_0} h_\kappa(x^\varepsilon(t_\kappa),\overline{\alpha}^\varepsilon(t_\kappa))[\check{f}(x^\varepsilon(t+s),\alpha^\varepsilon(t+s))-\check{f}(x^\varepsilon(t),\alpha^\varepsilon(t))] \\
&\qquad = E\prod_{\kappa=1}^{k_0} h_\kappa(x(t_\kappa),\overline{\alpha}(t_\kappa))[f(x(t+s),\overline{\alpha}(t+s))-f(x(t),\overline{\alpha}(t))].
\end{aligned}
$$

By (A.21) and (A.22), (A.10) holds. Using the same techniques, detailed estimates yield the second equation in (3.4). Thus the desired results follow. □

ON STABILITY OF BANG-BANG TYPE CONTROLS*

URSULA FELGENHAUER†

Abstract. From the theory of nonlinear optimal control problems it is known that the solution stability w.r.t. data perturbations and conditions for strict local optimality are closely related facts. For important classes of control problems, sufficient optimality conditions can be formulated as a combination of the independence of active constraints' gradients and certain coercivity criteria. In the case of discontinuous controls, however, common pointwise coercivity approaches may fail.

In the paper, we consider sufficient optimality conditions for strong local minimizers which make use of an integrated Hamilton–Jacobi inequality. In the case of linear system dynamics, we show that the solution stability (including the switching points localization) is ensured under relatively mild regularity assumptions on the switching function zeros. For the objective functional, local quadratic growth estimates in L_1 sense are provided. An example illustrates stability as well as instability effects in case the regularity condition is violated.

Key words. optimal control, optimality conditions, strong local minimality, control stability, solution structure stability

1. Introduction.

The paper is devoted to optimality conditions and the solution stability for certain linear, linear-quadratic, or linear time-optimal control problems with typically discontinuous optimal control functions. At the present time, optimal controls with bang-bang structure are intensively studied, which is reflected in the growing number of publications on the topic. Second-order sufficient conditions are derived, e.g., by Noble and Schaettler [28], Schättler [36], or Ledzewicz and Schaettler [15], by using the method of characteristics in adapted form for analyzing the flow of extremals. In his paper [35], Sarychev introduced special first- and second-order variations including measure type additives at the switching points in order to handle control discontinuities. Very recently, Agrachev, Stefani, and Zezza [3] proposed an approach treating the switching times as the main unknown. In their work, ideas of the so-called symplectic geometry going back to [1] (also [2]) are basically involved. A comprehensive theory of second-order conditions in optimal control is given by Milyutin and Osmolovskii in [27] and Osmolovskii [29]. The central feature in their book is the analysis of Pontryagin minima. The criteria derived are of high generality and strong in their closeness to necessary optimality conditions but partly difficult to check in applications. It was shown, e.g., in [30], [31] how they can be applied to bang-bang control regimes.

Our paper starts from weak duality relations going back to the work of Klötzler and his group ([13], [32], and [14], e.g.). It has been modified and extensively used in the recent past for deriving weak local optimality conditions, cf. [34], [26], [33]. The criteria obtained are often given in terms of the independence of the gradients of the active constraints w.r.t. the control, together with certain coercivity properties of the Hamilton function. For the class of problems considered in sections 3–5, however, in

†Institut für Mathematik, Brandenburgische Technische Universität Cottbus, Germany, PF 101344, 03013 Cottbus (felgenh@math.tu-cottbus.de).

particular the classical Legendre–Clebsch condition ([4], e.g.) is not fulfilled, so that the optimality test requires alternative estimation techniques.

In [11], [12] we have shown that the optimality criteria in their integrated version from [8] are, in principle, applicable to problems with discontinuous optimal control regimes. In section 2 this approach is shortly described, and the basic Hamilton–Jacobi inequality in integrated form is given (Theorem 2.2). Subsequently, local quadratic growth estimates for the objective functionals are obtained in the bang-bang case for soft termination control problems with linear systems dynamics (section 3), and also for a related time-optimal problem (section 5).

The investigation is restricted to nonsingular extremals having only finitely many switching points (Assumption 1) with regular zeros of the switching function components (Assumption 2). Under these conditions, the solution is proved to be a strict strong local minimizer such that the objective functional satisfies a local quadratic growth estimation in $L_2 \times L_1$ sense (Theorem 3.4). The proof uses a direct estimation technique for admissible variations without involving approximation cones. Although the obtained characterization of the optimum could be strengthened by means of the theory developed in [27] and [29] (see also section 7), the method presented here is of interest as a self-contained and easy to prove alternative way of analyzing strong local minimizers.

In section 4 it is proved that, under the given assumptions, the switching structure of the optimal control behaves stably w.r.t. small data perturbations (Theorem 4.1). The result is independent of the previous section. As a supplement, in section 5 the time-optimal problem is analyzed. Introducing an additional state variable for the free final time, one can find an extended dual formulation and derive appropriate optimality conditions. Although the estimates obtained (see Lemma 5.3) are slightly weaker than the requirements in Theorem 2.2, a local quadratic growth estimation results whenever (x, T) is close to the reference state and end-time solution (cf. Theorem 5.4). In addition, a sensitivity result for the optimal time (Lemma 5.5) is derived.

Finally, section 6 is devoted to the example of a two-dimensional chain problem with fixed end-time T. If T is smaller than the optimal termination time, the solution is locally strict and stable. When the optimal end-time T^* is reached, the solution becomes singular and instable: for $T > T^*$, the solution is no longer unique, and the switching structure shows serious bifurcations.

2. Local optimality criteria in integrated form. In this section, it will be shortly explained how sufficient optimality criteria and related growth estimates can be obtained from an abstract dualization for optimal control problems. The approach goes back to Klötzler [13], and it has been repeatedly used and described in detail, e.g., in [14], [32], [34], or [26]. In [8] or [11], variants of the basically parametric criteria have been considered in integrated form.

First, let be given a general nonlinear constrained optimal control problem (*primal* problem formulation):

$$\text{(P)} \qquad \min\ J(x,u) \ =\ k(x(0),x(T)) \ +\ \int_0^T r(t,x(t),u(t))\,dt$$

$$\text{(2.1)} \qquad \text{subject to (s.t.)} \quad \dot{x} \ = f(t,x(t),u(t)) \qquad \text{a.e. in } [0,T],$$

$$\text{(2.2)} \qquad \beta(x(0),x(T)) \ =\ 0,$$

$$\text{(2.3)} \qquad g(t,x(t),u(t)) \ \le\ 0 \qquad \text{a.e. in } [0,T]\,,$$

where $T > 0$ is given.

The pair $(x,u) \in W^1_\infty(0,T;R^n) \times L_\infty(0,T;R^k)$ is called *admissible* for (P) if the state equation (2.1) together with the boundary condition (2.2) and the inequality constraints (2.3) (where $g : [0,T] \times R^n \times R^k \to R^m$, $\beta : R^n \times R^n \to R^s$) is fulfilled. All data functions are assumed to be sufficiently smooth. An admissible pair (x_0,u_0) is called a (*global*) minimizer for (P) if $J(x_0,u_0) \le J(x,u)$ for all admissible (x,u). For characterizing *local* minimizers, the following definitions are used (see, e.g., [27], [31]).

DEFINITION 2.1. *The pair (x_0,u_0) is called a weak local minimizer of* (P) *if it is admissible and if a constant $\epsilon > 0$ exists such that $J(x_0,u_0) \le J(x,u)$ for any admissible pair (x,u) with $\| x - x_0\|_\infty + \| u - u_0\|_\infty < \epsilon$.*

An admissible pair (x_0,u_0) is called a strong local minimizer if $J(x_0,u_0) \le J(x,u)$ for any admissible (x,u) with $\| x - x_0\|_\infty < \epsilon$. If, for each positive M, an $\epsilon > 0$ exists such that $J(x_0,u_0) \le J(x,u)$ is satisfied for any admissible pair (x,u) with $\| x - x_0\|_\infty < \epsilon$ and $\|u\|_\infty \le M$, then (x_0,u_0) is a bounded-strong minimizer.

If, in addition, for $(x,u) \ne (x_0,u_0)$ (resp., $x \ne x_0$) the inequality $J(x_0,u_0) < J(x,u)$ holds true, (x_0,u_0) is a strict weak (resp., strict strong or strict bounded-strong) local minimizer.

Denote by H the Hamiltonian and by $\hat{H}$ the *augmented* Hamiltonian related to (P):

$$H(t,x,u,p) \;=\; r(t,x,u) \;+\; p^T f(t,x,u)\;,$$

$$\hat{H}(t,x,u,p,\mu) \;=\; H(t,x,u,p) \;+\; \mu^T g(t,x,u)\;, \qquad \mu \ge 0.$$

Further, let W stand for the set

$$W(t) \;=\; \{\,(x,u) :\; g(t,x,u) \le 0\,\}.$$

Second, let us consider a dual variable S given as a function $S : [0,T] \times R^n \to R$ and the auxiliary functional θ (for $\xi_{1,2} \in R^n$, resp.):

$$\theta(\xi_1,\xi_2;\,S) \;=\; k(\xi_1,\xi_2) \;+\; S(0,\xi_1) - S(T,\xi_2).$$

We assume that S is continuously differentiable w.r.t. x and at least piecewise continuously differentiable w.r.t. t. Define

$$T(S) \;=\; \inf_{(\xi_1,\xi_2)} \{\theta(\xi_1,\xi_2;\,S) \;:\; \beta(\xi_1,\xi_2) = 0\,\}.$$

Then the following problem is a dual to the original control problem (P):

$$\begin{aligned} \text{(D)} \quad & \max\; T(S) \\ & \text{s.t. } H(t,x,u,S_x(t,x)) \;+\; S_t(t,x) \;\ge\; 0 \qquad \forall\,(x,u) \in W(t) \;\text{ a.e. on }\; [0,T]\,. \end{aligned}$$

In the case of control problems without inequality constraints, the dual function S satisfies the Hamilton–Jacobi equation and can be interpreted as a *verification function* (see [5], e.g.). The dual problem formulation by Klötzler [13], or Pickenhain [32], thus allows for generalizing this variational approach to constrained control problems.

It is easy to see that $J(x,u) \geq T(S)$ whenever (x,u) is admissible for problem (P) and S is feasible for (D): denoting $x(0) = x_1, x(T) = x_2$ for admissible (x,u), we have

$$\begin{aligned} J(x,u) - T(S) &= \int_0^T r(t,x(t),u(t))\,dt + k(x_1,x_2) - T(S) \\ &= \int_0^T \left[H(t,x(t),u(t),S_x(t,x(t))) + S_t(t,x(t))\right]\,dt \\ &\quad - \int_0^T \left[S_x(t,x(t))^T \dot{x}(t) + S_t(t,x(t))\right]\,dt + k(x_1,x_2) - T(S) \\ &= \int_0^T \left[H(t,x(t),u(t),S_x(t,x(t))) + S_t(t,x(t))\right]\,dt \\ &\qquad + \theta(x_1,x_2;\,S) - \inf_{(\xi_1,\xi_2)} \theta(\xi_1,\xi_2;\,S) \geq 0\,. \end{aligned} \tag{2.4}$$

Thus, a weak duality relation holds for the problem pair (P), (D) (see [13], also [32], [8]). Let us introduce

$$\begin{aligned} \Psi(x,u;\,S) &= \int_0^T \left[\, H(t,x(t),u(t),S_x(t,x(t))) + S_t(t,x(t))\,\right]\,dt\,, \\ \psi(\xi_1,\xi_2;\,S) &= \theta(\xi_1,\xi_2;\,S) - T(S)\,. \end{aligned} \tag{2.5}$$

Then, the duality gap $(J(x,u) - T(S))$ equals zero if and only if for some admissible (x_0,u_0) and feasible dual S, $\Psi(x_0,u_0;\,S) = 0$ and $\psi(x_0(0),x_0(T);\,S) = 0$. In this case, the pair (x_0,u_0) is a solution of (P).

The analysis of the behavior of Ψ and ψ can be used to verify local minimality of a solution including estimates for local growth terms if available (cf., e.g., [12]). It can be applied to *weak* as well as to *strong* local optima in dependence of the reference sets choice. For example, consider the sets

$$\begin{aligned} W_\epsilon(t) = W(t) \cap B_\epsilon(x_0(t),u_0(t))\,, \qquad \hat{W}_\epsilon(t) &= W(t) \cap \left(B_\epsilon(x_0(t)) \times R^k\right), \\ \tilde{W}_{\epsilon,M}(t) &= W(t) \cap \left(B_\epsilon(x_0(t)) \times B_M(0)\right), \end{aligned}$$

where $B_r(z)$ denotes closed balls of radius r in the related Euclidean spaces.

The following result then characterizes general strict local optima.

THEOREM 2.2 (see [26], [12]). *Let (x_0,u_0) be admissible for* (P). *Suppose that a function $S : [0,T] \times R^n \to R$ exists which is Lipschitz continuous w.r.t. x and piecewise continuously differentiable w.r.t. t such that for suitably chosen positive constants c and ϵ the following relations hold with $1 \leq p < \infty$, $\gamma = 1$, $D(t) = W_\epsilon(t)$, and $D_\pi = B_\epsilon(x_0(0),x_0(T)) \cap \{\xi = (\xi_1,\xi_2) : \beta(\xi) = 0\}$:*

(R1) $$\Psi(x,u;S) \geq c\left(\|x - x_0\|_2^2 + \gamma\,\|u - u_0\|_p^2\right)$$
$$\forall \text{ admissible } (x,u) \text{ with } (x(t),u(t)) \in D(t) \quad \text{a.e. in } [0,T];$$

(R2) $$\Psi(x_0,u_0;S) = 0\,, \qquad \psi(x_0(0),x_0(T);\,S) = 0;$$

(R3) $$\psi(\xi_1,\xi_2;\,S) \geq 0 \qquad \forall\,\xi \in D_\pi\,.$$

Then (x_0,u_0) is a strict weak local minimizer of (P).

If (R1)–(R3) *hold true for a certain constant $\epsilon > 0$ with $\gamma = 0$, $D(t) = \hat{W}_\epsilon(t)$, and D_π given above, then (x_0,u_0) is a (strict) strong local minimizer.*

If, for arbitrary $M > 0$, a positive ϵ exists such that (R1)–(R3) *are satisfied with $D(t) = \tilde{W}_{\epsilon,M}(t)$, the point (x_0, u_0) is a (strict) bounded-strong local optimum.*

Furthermore,

$$J(x,u) - J(x_0,u_0) \;\geq\; c'\left(\|x - x_0\|_2^2 \;+\; \gamma\,\|u - u_0\|_p^2\right). \tag{2.6}$$

holds true for all admissible (x,u) on the related reference set, i.e., with $(x(t),u(t)) \in D(t)$ a.e. on $[0,T]$, and $(x(0),x(T)) \in D_\pi$, respectively.

The proof of the theorem follows from (2.4) together with the description of the functionals in (2.5). Under condition (R2), in particular, $J(x_0,u_0) = T(S)$ holds true. The above theorem differs from formulations given in [32], [26], e.g., mainly by the consequent usage of the Hamilton–Jacobi inequality (cf. (D)) in its *integrated* instead of its *parametric* form. This relaxation was already used in [8] for analyzing Ritz type discretization methods in optimal control.

Let us mention the fact that the local growth estimate for J is formulated in terms of L_2 (resp., L_p) topology whereas the reference sets are L_∞-neighborhoods w.r.t. x in particular. This effect is well known as part of the *two-norm discrepancy* in optimal control problems (see, e.g., [16]).

Starting from abstract results like Theorem 2.2, one can establish sufficient optimality conditions for general control problems in a form which in principle is suitable for numerical tests (see [26], [20], also [18] and [21]). The known criteria include independence of the (nearly) active constraints as well as certain coercivity conditions.

The independence conditions are usually given in terms of the *invertibility* w.r.t. control for the (nearly) active inner constraints and a certain *controllability* assumption. Using Pontryagin's maximum principle, the following system of first-order necessary optimality conditions is obtained for a weak local minimizer:

Canonical system (complementarity formulation):

$$\begin{aligned}
\dot{x} \;&= \hat{H}_p \;=\; f\,, \qquad \beta(x(0),x(T)) = 0\,;\\
\dot{p} \;&= -\hat{H}_x;\\
p(0) &= -\nabla_1 k - \nabla_1\beta\cdot\rho, \quad p(T) = \nabla_2 k + \nabla_2\beta\cdot\rho\,, \qquad \rho \in R^s;\\
\hat{H}_u \;&= 0\,;\\
\mu^T g &= 0\,, \quad \mu \geq 0\,, \quad g \leq 0.
\end{aligned} \tag{2.7}$$

Sufficient conditions are usually given as second-order criteria including, first, the so-called Legendre–Clebsch condition, and, second, the solvability of a certain Riccati matrix differential (in)equality on a parameter function Q. As a rule, these characterizations are strongly local w.r.t. (x,u) and thus are mainly related to weak local optima (cf. [26], also [22] and [23].

The matrix function Q and the terms in (2.7) are connected with the optimal S as follows (see [8]):

$$\dot{S}(t,x_0) = -r_0[t]\,, \quad S_x(t,x_0) = p_0(t)\,, \quad S_{xx}(t,x_0) = Q(t).$$

(Here r_0 stands for r evaluated along $(x_0(t),u_0(t))$, and p_0 is the related costate trajectory.)

It has been shown that the independence and the coercivity conditions are not only sufficient for the solution optimality: they are also sufficient for the stability of the solutions in L_∞ sense under reasonable small data perturbations [17], [19], [21]. The conditions are further proved to be also necessary for Lipschitz stability of solutions over a certain class of perturbations [7]. In the case of continuous controls, local

convergence of Euler's and related discretization methods [20], [8], [6] can be guaranteed. Furthermore, estimates of the form (2.6) are of practical interest, e.g., for analyzing the convergence of minimizing sequences [9], [11].

Consider the auxiliary functional Ψ from (2.5) with its integrand

$$R[t] \;=\; (\, H(t,x,u,S_x) \;+\; S_t \,)\;[t]\;. \tag{2.8}$$

As has been shown in [12] using $\Psi(x_0,u_0;\,S)=0$ together with the ansatz

$$S(t,x) \;=\; S_0(t) \;+\; p_0(t)^T(x-x_0(t)) \;+\; 0.5\,(x-x_0(t))^T Q(t)\,(x-x_0(t))$$

and $S_x = p_0 + Q(x-x_0)$, the function R can be expressed by

$$\begin{aligned} R[t] = \hat H(x,u,p_0,\mu_0) - \hat H(x_0,u_0,p_0,\mu_0) - \hat H_x(x_0,u_0,p_0,\mu_0)^T(x-x_0) \\ +\, 0.5\,(x-x_0)^T\dot Q(x-x_0) \;+\; (x-x_0)^T Q\,(\,f(x,u)-f(x_0,u_0)\,) \\ -\,\mu_0^T\,(\,g(x,u)-g(x_0,u_0))\,. \end{aligned} \tag{2.9}$$

For $z=(x,u)$ near $z_0=(x_0,u_0)$, the Taylor expansion yields $R = R^{(2)} + \mathrm{o}(|z-z_0|^2)$,

$$R^{(2)}[t] = 0.5 \begin{pmatrix} x-x_0 \\ u-u_0 \end{pmatrix}^T \begin{pmatrix} \hat H_{xx} + Qf_x + f_x^T Q + \dot Q & \hat H_{xu} + Qf_u \\ \hat H_{ux} + f_u^T Q & \hat H_{uu} \end{pmatrix} \begin{pmatrix} x-x_0 \\ u-u_0 \end{pmatrix}.$$

If the Hessian herein is positive definite, an estimate of type (R1) holds true with $p=2$, $\gamma=1$. In particular, the Legendre–Clebsch condition $\hat H_{uu} \succ 0$ together with a Riccati equation for Q resulting from a Schur complement approach are sufficient [32], [26] for weak local optimality then.

If we allow for more general variations in u under the restriction $x \approx x_0$, then the following decomposition is useful: $R[t] \;=\; R_1[t] \;+\; R_2[t]$, where

$$\begin{aligned} R_1[t] = \hat H(x,u_0,p_0,\mu_0) - \hat H(x_0,u_0,p_0,\mu_0) - \hat H_x(x_0,u_0,p_0,\mu_0)^T(x-x_0) \\ +\, 0.5\,(x-x_0)^T\dot Q(x-x_0) \;+\; (x-x_0)^T Q\,(f(x,u_0)-f(x_0,u_0)) \\ -\;\mu_0^T\,(g(x,u_0)-g(x_0,u_0))\,; \end{aligned} \tag{2.10}$$

$$\begin{aligned} R_2[t] = \hat H(x,u,p_0,\mu_0) - \hat H(x,u_0,p_0,\mu_0) \;+\; (x-x_0)^T Q(f(x,u)-f(x,u_0)) \\ -\;\mu_0^T\,(\,g(x,u)-g(x,u_0)\,)\,. \end{aligned}$$

The term R_1 is the variation in R w.r.t. x, and for x sufficiently close to x_0 we have

$$R_1[t] \;=\; 0.5\,(x-x_0)^T\left(\dot Q \;+\; Q\,f_x \;+\; f_x^T Q \;+\; \hat H_{xx}\right)(x-x_0) \;+\mathrm{o}(|x-x_0|^2). \tag{2.11}$$

Thus, R_1 is positive in the case that Q satisfies a certain *reduced* Riccati differential inequality. The analysis of R_2, however, essentially depends of the kind of minimum achieved in $\hat H$ at $u=u_0(t)$. In [12] and [11], typical cases with inner and boundary optima (related to the actual control set) are discussed in detail.

The problem class and examples considered in [12] and partly in [10] in general satisfy weak local optimality criteria including the Legendre–Clebsch condition. Instead, the problems considered in the present paper are linear in the control with a zero Hessian $\hat H_{uu}$ so that pointwise coercivity conditions necessarily fail. In the next section we will show how to overcome this difficulty.

3. Soft termination control problem. Bang-bang type controls are typical optimal regimes in problems, where the system dynamics are linear in control, and the control set is a box or polyhedron in R^k. Our aim is to consider problems with linear, in both state and control, state equation and given initial position. We will ask for a control which in a prescribed time gains the system as close as possible to a given final state (mostly zero). The control function herein is subject to componentwise upper and lower bounds, which for simplicity are given in normalized form.

Not always, the terminal state can be reached, for a given end-time. Since some deviation from the desired final position is allowed, this problem class is also called *soft termination control*. The model problem can be written in the form

$$(\mathrm{P}_S) \qquad \min\ J(x,u)\ =\ 0.5\,\|\,x(T)-b\,\|^2$$

$$\text{s.t. } \dot{x}(t)\ = A(t)x(t)\ +\ B(t)u(t) \quad \text{a.e. in } [0,T]; \tag{3.1}$$

$$x(0)\ =\ a\,; \tag{3.2}$$

$$|\,u_i(t)\,|\ \le 1, \quad i=1,\dots,k, \qquad \text{a.e. in } [0,T]\,. \tag{3.3}$$

It will be assumed that $a \neq b$ and that the matrix functions A and B are continuously differentiable on $[0,T]$.

The Hamilton function related to (P_S) is given by

$$H(t,x,u,p)\ =\ p^T A(t)\,x\ +\ p^T B(t)\,u\ ,$$

whereas the *augmented* Hamiltonian for $\mu_{1,2} \ge 0$ and $e=(1,1,\dots,1)^T$ reads as

$$\hat{H}(t,x,u,p,\mu)\ =\ H\ +\ \mu_1^T(u-e)\ -\ \mu_2^T(u+e)\ .$$

Notice that for the above problem the so-called independence condition for (nearly) active constraints always holds true. Thus, from Pontryagin's maximum principle we obtain the *switching function*

$$\sigma(t)\ =\ B(t)^T p(t)\ , \tag{3.4}$$

where the costate p satisfies the adjoint equation

$$\dot{p}(t)\ =\ -A(t)^T p(t), \qquad p(T)=x(T)-b,$$

and the optimal control is given by

$$u_{0,i}(t)\ \in\ \begin{cases} \{\,-sign\,\sigma_i(t)\,\} & \text{if} \quad \sigma_i(t)\ \neq\ 0, \\ [-1,+1] & \text{if} \quad \sigma_i(t)\ =\ 0, \end{cases} \qquad i=1,\dots,k\ . \tag{3.5}$$

Further, the multiplier functions μ_j suffice the relations

$$\mu_1(t)\ =\ \big(\,B(t)^T p(t)\,\big)_-\ , \qquad \mu_2(t)\ =\ \big(\,B(t)^T p(t)\,\big)_+$$

with right-hand sides denoting componentwise positive, respectively, negative, parts.

The Hesse matrix of $\hat{H}$ w.r.t. u is zero everywhere on $[0,T]$ so that the classical Legendre–Clebsch condition is not fulfilled (and this is true even when we consider its stable subspace formulation, e.g., [20], [8], or [7]). Thus, in general the usual stable weak optimality criteria are not fulfilled—a property corresponding to the obvious fact that, as a rule, the optimal controls are unstable in L_∞ under shifts of the switching

points caused by data perturbations. However, under rather mild conditions on the solution structure, quadratic estimates of type (2.6) can be proved, e.g., in $L_2 \times L_1$-norm. To this aim suppose the following.

Assumption 1. The optimal control has no singular arcs. The set of switching points $\Sigma = \{ t \in [0,T] : \exists\, i \in \{1,\dots,m\}$ with $\sigma_i(t) = 0 \}$ is finite, and $0, T$ do not belong to Σ. In particular, $\Sigma = \{ t_s : 1 \le s \le l \}$ for some $l \in N$.

Second, a restriction on the switching functions zeros is required.

Assumption 2. On $[0,T]$, the functions $\sigma_i,\ i = 1,\dots,k$, are continuously differentiable. For $I(s) = \{i : \sigma_i(t_s) = 0\}$, the term $\min_{1\le s\le l}\ \min_{i\in I(s)} |\,\dot\sigma_i(t_s)\,| = m_0$ is positive.

A first direct conclusion from Assumption 2 consists of the following invertibility result for σ.

LEMMA 3.1. *Let $\sigma(t) = B(t)^T p(t)$ satisfy Assumptions* 1 *and* 2. *If $t_s \in \Sigma$ is a point such that $\sigma_i(t_s) = 0$, then for arbitrary continuously differentiable $\hat B, \hat p$ close to B and p in C^0 sense, in every sufficiently small neighborhood of t_s the function $\hat\sigma_i(t) = (\hat B(t)^T \hat p(t))_i$ has a unique zero $\hat t_s$. Further, with the supremum norm $\|\cdot\|_\infty$ on C^0, we have*

$$\left|\,\hat t_s - t_s\right| \;=\; O(\,\|\hat B - B\|_\infty + \|\hat p - p\|_\infty)\,.$$

Proof. Consider the mapping $F_i : \ C^1(0,T;R^{n\times k}) \times C^1(0,T;R^n) \times [0,T] \ \to R$ defined by $F_i(M,\eta,t) = (M(t)^T\eta(t))_i$. This mapping is differentiable w.r.t. all components in $(M,\eta,t) = (B,p,t_s)$, and the derivative $(\partial/\partial t)\,F_i$ is continuous near this point. Further, $(\partial F_i/\partial t)(B,p,t_s) : \ R \to R$ is surjective due to Assumption 2. By the implicit function theorem in Banach spaces, the equation $F_i = 0$ near (B,p,t_s) is invertible w.r.t. t, and we end up with a first-order approximation for $\hat t_s$:

$$\hat t_s - t_s \doteq -\,(\dot\sigma_i(t_s))^{-1}\,\Big(\,(\partial F_i/\partial B)\,(\hat B - B)\;+\;(\partial F_i/\partial p)\,(\hat p - p)\Big)\;. \tag{3.6}$$

Thus, the assertion of the lemma holds true. □

The above lemma will be used in the next section for further investigation of the switching structure stability.

Now, let us reconsider the auxiliary functional Ψ from (2.5) and the related integrand $R[t]$ in (2.8). We refer to the representation of R in the form of a sum $R_1 + R_2$ given in the previous section. The approximation (2.11) for R_1 motivates consideration of the reduced Riccati equation for $Q = S_{xx}$ together with appropriate boundary restrictions (cf. [26]), which in case of problem (P_S) take the form

$$\begin{aligned} \dot Q \;+\; A^T Q \;+\; Q\,A \succeq \gamma\, I \qquad &\text{a.e.},\\ I \;-\; Q(T) \succeq 0\;. \end{aligned} \tag{3.7}$$

LEMMA 3.2. *For arbitrary $\gamma \in (0, 0.5)$, the system* (3.7) *has a bounded on $[0,T]$ solution Q satisfying $\|Q\|_\infty = O(\gamma)$.*

Proof. Consider the equality case in (3.7) with $\gamma = 0.5$ and $Q(T) = 0.5\,I$. Since the differential equation in this special case is linear w.r.t. Q, a solution $Q = Q_1 \in C^1(0,T;R^{n\times n})$ exists. Now, setting $Q = Q_\gamma = 2\,\gamma\,Q_1$, it is easy to see that Q_γ solves the inequalities (3.7) for arbitrary $\gamma \in (0, 0.5)$.
In addition, $\|Q_\gamma\|_\infty = 2\,\gamma\|Q_1\|_\infty = \mathrm{O}(\gamma)$. □

Our main result in preparing a local quadratic growth estimation in the spirit of Theorem 2.2 consists of the following statement.

LEMMA 3.3. *Let Assumptions* 1 *and* 2 *hold true. Then a matrix function* Q *and positive constants* ϵ, c *exist such that for all admisssible* (x,u) *satisfying* $(x(t),u(t)) \in \tilde{W}_{\epsilon,1}(t)$ *a.e. on* $[0,T]$,

$$\int_0^T R[t]\,dt \;\geq\; c\,\big(\,\|\,x-x_0\|_2^2 + \|\,u-u_0\|_1^2\,\big)\,. \tag{3.8}$$

Proof. Starting with $R[t] = R_1[t] + R_2[t]$ from (2.10) and the abbreviations $y = x - x_0$, $v = u - u_0$, for (P_S) we have

$$R_1 \;=\; 0.5\,y^T(\dot{Q} + A^TQ + Q\,A)\,y\,, \qquad R_2 = (p_0 + Qy)^TBv.$$

Remember that

$$\begin{aligned}
\big(B^Tp_0\big)_i > 0 \quad &\Rightarrow \quad (u_0)_i = -1 \quad \Rightarrow \qquad v_i \geq 0,\\
\big(B^Tp_0\big)_i < 0 \quad &\Rightarrow \quad (u_0)_i = +1 \quad \Rightarrow \qquad v_i \leq 0.
\end{aligned}$$

Choose $Q \equiv 0$ first. Then,

$$\int_0^T R[t]\,dt \;=\; \int_0^T p_0^TBv\,dt \;=\; \int_0^T \left(\sum_{i=1}^n |\,\sigma_i|\,\cdot\,|\,v_i|\right) dt \;\geq\; 0\,.$$

Under Assumption 1, it follows in particular that

$$\int_0^T R[t]\,dt \;=\; \Psi(x,u;S) \;>\; 0 \qquad \forall\,(x,u) \text{ such that } u \neq u_0\,. \tag{3.9}$$

Although this relation is weaker than (R1), together with appropriate boundary inequalities it already allows us to deduce strict optimality of (x_0,u_0). In order to obtain the estimate (3.8) of type (R1), let us take $Q = Q_\gamma$ from Lemma 3.2. Then we get

$$\int_0^T R_1[t]\,dt \;\geq\; \frac{\gamma}{2}\,\|\,x-x_0\|_2^2\,. \tag{3.10}$$

Further, the part R_2 can be expressed by

$$R_2[t] \;=\; \big(B^Tp_0\big)^T\,v \;+\; y^TQ\,B\,v \;\geq\; \sum_{i=1}^m \big|\,B^Tp_0\big|_i\cdot\,|\,v_i| \;-\; \big|\,y^TQ\,B\,v\,\big|\,, \tag{3.11}$$

so that for the integral over R_2 we obtain $\int_0^T R_2[t]\,dt \;\geq\; J_2 \;-\; J_1$ with

$$J_1 = \int_0^T |\,y^TQ\,B\,v\,|\,dt, \qquad J_2 = \int_0^T \sum_{i=1}^m |\,B^Tp_0|_i\,|\,v_i|\,dt. \tag{3.12}$$

From the state equation for admissible x and x_0 we know that $\dot{y} \;-\; A\,y \;=\; B\,v$ and $y(0) = 0$. If $\Phi(t)$ denotes the fundamental solution for this linear system, then

$$y(t) \;=\; \Phi(t)\int_0^t \Phi^{-1}(s)\,B(s)v(s)\,ds.$$

Consequently, y can be estimated by

$$\|y\|_\infty \le \|\Phi\|_\infty \int_0^T \|\Phi^{-1}\|_\infty \|B\|_\infty |v| \, dt = c(A,B)\|v\|_1. \tag{3.13}$$

Thus, the integral J_1 from (3.12) satisfies the inequality

$$J_1 \le c(A,B)\|Q\|_\infty \|B\|_\infty \|v\|_1^2 \le \gamma c_1 \|v\|_1^2. \tag{3.14}$$

For the second part J_2, from Assumption 2 the following property of $B^T p_0 = \sigma$ follows: For given $\delta > 0$ denote $\omega_\delta = \bigcup_{1\le s\le l}(t_s - \delta, t_s + \delta)$. Then a constant $\bar\delta$ exists such that for all $\delta \in (0, \bar\delta)$,

$$\min_i \left| \left(B^T p(t) \right)_i \right| \ge 0.5\, m_0 \delta \qquad \forall\, t \in [0,T]\backslash\omega_\delta.$$

Inserting this estimate into the formula (3.12) for J_2, we arrive at

$$J_2 \ge 0.5\, m_0 \delta \int_{[0,T]\backslash\omega_\delta} |v(t)| \, dt\,. \tag{3.15}$$

But the variation terms v are bounded in L_∞-norm by $2M = 2$, so that

$$\begin{aligned} \|v\|_1 = \int_0^T |v(t)|\, dt &= \int_{[0,T]\backslash\omega_\delta} |v(t)|\, dt + \int_{\omega_\delta} |v(t)|\, dt \\ &\le \int_{[0,T]\backslash\omega_\delta} |v(t)|\, dt + 4l\,\delta \end{aligned}$$

follows from Assumption 1. Using this relation together with (3.15), we obtain

$$J_2 \ge 0.5\, m_0 \delta \, (\|v\|_1 - 4l\delta)\,. \tag{3.16}$$

Combining now the inequalities (3.14), (3.16) for J_1 and J_2, the following estimate for $\int R_2\, dt$ results:

$$\int_0^T R_2[t]\, dt \ge 0.5\, m_0 \delta \, (\|v\|_1 - c_2\delta) - c_1\gamma \|v\|_1^2 \tag{3.17}$$

with $c_2 = 4l$ and c_1 from (3.14). We will choose δ such that

$$\delta = \min\left\{ \frac{1}{2\,c_2}, \frac{\bar\delta}{2T} \right\} \|v\|_1 =: c_3 \|v\|_1,$$

and $\gamma < \bar c = (m_0 c_3)/(8c_2)$. Then, from (3.10) and (3.17) we get

$$\int_0^T R[t]\, dt \ge \bar c\, \|v\|_1^2\,.$$

Taking into account (3.13), the desired estimate (3.8) follows immediately, e.g., with $c = 0.5\bar c \, \min\{1, c(A,B)^{-2}\}$. □

Finally, as a direct consequence of Theorem 2.2, Lemma 3.3, and (3.9), we obtain the following.

THEOREM 3.4. *Let (x_0, u_0) be an extremal point of (P_S) with the related adjoint function p, and $\sigma = B^T p$. Suppose Assumption 1 holds true. Then (x_0, u_0) is a strict strong local minimizer.*

If, in addition, Assumption 2 is fulfilled for the switching function, then for each $M > 0$, positive constants ϵ and c' exist such that

$$J(x,u) - J(x_0,u_0) \;\geq\; c' \left(\|x - x_0\|_2^2 \;+\; \|u - u_0\|_1^2 \right)$$

for all admissible (x,u) satisfying $(x(t),u(t)) \in \tilde{W}_{\epsilon,M}$ a.e. on $[0,T]$.

Remark. Since the control set in the problem under consideration is compact, the definitions of strong and of bounded-strong local optimality coincide. For the above result, however, the boundedness of u is essential.

4. Structural stability of the control. In this section, under which conditions the structure of the optimal control function is stable w.r.t. perturbations in the problem data will be analyzed. Notice that the growth condition of Theorem 3.4 can be read as a first stability result, which in particular yields the local convergence of minimizing sequences (cf. [11], [10]) for (P_S) when the approximations are taken from sufficiently small neighborhoods of the solution in $L_\infty \times L_1$, e.g. In particular, such variations may differ in the switching points and thus violate closeness conditions w.r.t. the L_∞ topology in the control component.

Denote the reference data for (P_S) by $(\bar{a}, \bar{b}, \bar{A}, \bar{B})$, and consider problems with the same type of linear dynamics but for $(a,b,A,B) \approx (\bar{a}, \bar{b}, \bar{A}, \bar{B})$ in the sense of $R^n \times R^n \times C^0(0,T;R^{n\times n}) \times C^1(0,T;R^{n\times k})$. For the perturbation analysis, the classical implicit function theorem will be used.

Let us start with the *canonical system* related to (P_S), i.e.,

$$\begin{array}{lll} \dot{x}(t) = A(t)x(t) \;+\; B(t)u(t)\,, & x(0) = a\,, & \\ \dot{p}(t) = -A(t)^T p(t)\,, & p(T) = x(T) - b\,, & \\ \sigma(t) = B(t)^T p(t)\,, & u_i(t) = -sign\,(\sigma_i(t)) & \text{for } t \notin \Sigma. \end{array} \tag{4.1}$$

Assume for the moment that besides $x(0) = a$ the initial condition for p is known, e.g., $p(0) = z \in R^n$. Then the above system can be interpreted as follows: The data set (z,a,A,B) defines $p = p(\cdot\,; z, a, A, B)$ from the adjoint equation and, subsequently, u via the switching condition. Thus, the function $x = x(\cdot\,; z, a, A, B)$ is uniquely determined from the state equation provided the control does not include singular arcs. The system (4.1) is solved if and only if

$$F(z,a,b,A,B) \;=\; x(T;z,a,A,B) \;-\; p(T;z,a,A,B) \;-\; b \;=\; 0\,. \tag{4.2}$$

If we can show that small changes in (a,b,A,B) cause only small perturbations in the solution z of (4.2) and the resulting switching functions, then the set Σ of the points of control discontinuity, in accordance to Lemma 3.1, will be stable w.r.t. (a,b,A,B). Let us start with defining fundamental solutions for the canonical equations by

$$\begin{array}{ll} \dot{\Phi} \;+\; A^T\Phi = 0\,, & \Phi(0) \;=\; I\,, \\ \dot{\Psi} \;-\; A\Psi = 0\,, & \Psi(0) \;=\; I\,. \end{array} \tag{4.3}$$

Formally, these matrix functions can be given as $\Phi(t) \;=\; \exp\{-\int_0^t A^T(s)\,ds\}$, $\Psi(t) \;=\; \exp\{\int_0^t A(s)\,ds\}$, and in particular we have $\Psi(t)^T\Phi(t) \equiv I$ (I—the unit matrix). Then

we can express $p = p(\cdot; z, a, A, B)$ and $x = x(\cdot; z, a, A, B)$ as

$$
\begin{aligned}
p(t) &= \Phi(t)\, z\,, \\
x(t) &= \Psi(t)\, a \,+\, \Psi(t) \int_0^t \Psi^{-1}(s) B(s) u(s)\, ds \\
&= \Psi(t)\, a \,-\, \Psi(t) \int_0^t \Phi^T(s) B(s)\, sign\left(B(s)^T \Phi(s)\, z \right)\, ds\,.
\end{aligned} \tag{4.4}
$$

Consequently, with the abbreviation $B(t)^T \Phi(t) = \Gamma(t)$,

$$
F(z, a, b, A, B) \,=\, \Psi(T)\, a \,-\, \Phi(T)\, z \,-\, b \,-\, \Psi(T) \int_0^T \Gamma^T(t)\, sign\left(\Gamma(t)\, z \right)\, dt\,. \tag{4.5}
$$

Notice that the dependency of F on (A, B) herein is "hidden" in the construction of the fundamental solution functions Φ, Ψ and the term $\Gamma = B^T \Phi$, which all smoothly depend on the input data. The same holds true for F then.

The smoothness of F as a function of z is less obvious. Starting from (4.2), let us rewrite F as $F_1 + F_2$, where

$$
F_1(z, a, b, A) \,=\, \Psi(T)\, a \,-\, \Phi(T)\, z \,-\, b \tag{4.6}
$$

is continuously differentiable in all variables. The second part $F_2 = F - F_1$ is given by

$$
F_2(z, A, B) \,=\, -\Psi(T) \int_0^T \Gamma^T(t)\, sign\left(\Gamma(t)\, z \right)\, dt\,.
$$

In order to analyze the differentiability of F w.r.t. z, consider $\Delta F_2 = F_2(z, \bar{A}, \bar{B}) - F_2(\bar{z}, \bar{A}, \bar{B})$:

$$
\Delta F_2 \,=\, -\,\bar{\Psi}(T) \int_0^T \bar{\Gamma}^T(t)\, \left[\, sign\left(\bar{\Gamma}(t)\, z \right) - sign\left(\bar{\Gamma}(t)\, \bar{z} \right) \right]\, dt, \tag{4.7}
$$

where $\bar{\Psi}$ and $\bar{\Gamma} = \bar{B}^T \bar{\Phi}$ are constructed in accordance to (4.3) with $A = \bar{A}$ and $B = \bar{B}$.

The difference ΔF_2 is essentially determined by the change of the switching function $\sigma = B^T p = \Gamma\, z$ for different z. Under Assumptions 1 and 2, it follows from Lemma 3.1 that for z near $\bar{z}$ the signs of $\sigma_i(t) = \left(\bar{\Gamma}(t)\, z \right)_i$ and $\bar{\sigma}_i(t) = \left(\bar{\Gamma}(t)\, \bar{z} \right)_i$ differ each from the other only near t_s and for $i \in I(s)$. In detail, if, e.g., t_i' is a zero of σ_i close to t_s and such that $t_i' < t_s$, then for $\dot{\bar{\sigma}}_i(t_s) > 0$ the difference of signs is equal to 2 on (t_i', t_s) and -2 in the case $\dot{\bar{\sigma}}_i < 0$. In general,

$$
sign\left(\sigma_i(s) \right) \,-\, sign\left(\bar{\sigma}_i(s) \right) \,=\, 2\, sign\left(\dot{\bar{\sigma}}_i(t_s) \right) \,\cdot\, sign(t_s - t_i')
$$

for all s between t_s and t_i'. Outside this interval, σ_i and $\bar{\sigma}_i$ are of the same sign. With this information, from (4.7) we obtain

$$
\begin{aligned}
\Delta F_2 &= -\bar{\Psi}(T) \int_0^T \sum_{i=1}^{n} \bar{\Gamma}_i^T(\tau)\, \left[\, sign\left(\sigma_i(\tau) \right) \,-\, sign\left(\bar{\sigma}_i(\tau) \right) \right]\, d\tau \\
&= -2\, \bar{\Psi}(T) \sum_{s=1}^{l} \sum_{i \in I(s)} sign(\dot{\bar{\sigma}}_i(t_s)) \int_{t_i'}^{t_s} \bar{\Gamma}_i^T(\tau)\, d\tau \\
&= \,2\, \bar{\Psi}(T) \sum_{s=1}^{l} \sum_{i \in I(s)} sign(\dot{\bar{\sigma}}_i(t_s))\, \bar{\Gamma}_i^T(t_s)\, \left(t_i' - \, t_s \right) \,+\, \mathrm{o}(\, |t_i' - t_s|\,)
\end{aligned}
$$

(where $\bar{\Gamma}_i$ denotes the ith row of $\bar{\Gamma} = \bar{B}^T \bar{\Phi}$, and thus $\bar{\sigma}_i(t)$ is equal to $\bar{\Gamma}_i(t) z$.)

From Lemma 3.1 it follows that the difference $(t_i' - t_s)$ can be approximated by

$$t_i' - t_s \;=\; -(\dot{\bar\sigma}_i(t_s))^{-1}\bar B^i(t_s)^T(p(t_s) - \bar p(t_s))$$

($\bar B^i$—the ith column of $\bar B$, or equal to $\partial F_i/\partial p$). Using $p = \bar\Phi\, z$, we see that

$$\begin{aligned}\Delta F_2 &= -2\,\bar\Psi(T)\sum_{s=1}^{l}\sum_{i\in I(s)} |\,\dot{\bar\sigma}_i(t_s)|^{-1}\bar\Gamma_i(t_s)^T\bar B^i(t_s)^T(p(t_s)-\bar p(t_s)) \;+\; \mathrm{o}(\,\|p-\bar p\|_\infty)\,,\\ &= -2\,\bar\Psi(T)\sum_{s=1}^{l}\sum_{i\in I(s)} |\,\dot{\bar\sigma}_i(t_s)|^{-1}\bar\Gamma_i(t_s)^T\bar\Gamma_i(t_s)(z-\bar z) \;+\; \mathrm{o}(\,|z-\bar z|\,)\,.\end{aligned}$$

Finally, with $F = F_1 + F_2$, from (4.6) and the last expression we obtain

$$\frac{\partial F}{\partial z} \;=\; -\bar\Phi(T) - 2\;\bar\Psi(T)\sum_{s=1}^{l}\sum_{i\in I(s)} (\,|\,\dot{\bar\sigma}_i(t_s)\,|\,)^{-1}\,\bar\Gamma_i(t_s)^T\bar\Gamma_i(t_s)\,. \tag{4.8}$$

Therefore, the mapping F is differentiable in all variables at $(\bar z, \bar a, \bar b, \bar A, \bar B)$, and the derivative $\partial F/\partial z$ is continuous near the given point.

After these preliminaries, we are able to formulate a structural stability result for bang-bang type optimal controls in (P_S).

THEOREM 4.1. *Let (x_0, u_0) be a solution of (P_S) without singular arcs and the related set of switching points given by $\Sigma = \{t_s :\; 1 \le s \le l\}$. Suppose that A, B are continuously differentiable in t and let Assumptions 1 and 2 of section 3 hold true. Then the switching structure of u_0 is stable in the following sense: For arbitrary positive ϵ, one can find a constant $\delta > 0$ such that for all $(\hat A, \hat B, \hat a, \hat b)$ with*

$$\|\,\hat A - A\,\|_0 + \|\,\hat B - B\,\|_{C^1} \;+\; |\hat a - a| \;+\; |\hat b - b| \;\le\; \delta,$$

the problem has a unique solution $(\hat x, \hat u)$ in a certain $L_\infty \times L_1$-neighborhood of (x_0, u_0) with $\hat u$ having the same number of switching points as u_0, and dist$\{\hat\Sigma, \Sigma\} < \epsilon$.

Remark. The norms figuring in the theorem and the proof below are the maximal over $[0,T]$ matrix norm $\|\cdot\|_0$ in C^0, and for R^n the Euclidean norm $|\cdot|$.

Proof. Consider (4.2) as an equation for z depending on the parameters $a, b \in R^n$, $A \in C^0(0,T;R^{n\times n})$, and $B \in C^1(0,T;R^{n\times k})$. The mapping F is continuously differentiable w.r.t. all variables. Moreover, by the construction of Φ and Ψ from (4.3) and from (4.8) one can see that

$$\frac{\partial F}{\partial z} \;=\; -2\,\Phi^{-T}(T)\,M,$$

where

$$M \;=\; 1/2\,\Phi(T)^T\Phi(T) + \sum_{s=1}^{l}\sum_{i\in I(s)} (\,|\,\dot\sigma_i(t_s)\,|\,)^{-1}\,\Gamma_i(t_s)^T\Gamma_i(t_s)$$

is positive definite. Thus, it represents a surjective map from R^n to R^n. From the implicit function theorem it can be deduced, first, that the equation $F(z, \hat a, \hat b, \hat A, \hat B) = 0$ for arbitrary $(\hat a, \hat b, \hat A, \hat B)$ near (a, b, A, B) has a solution $\hat z \in R^n$, which is unique in a certain neighborhood of $z\,(= p(0))$. Second, a constant $c_F > 0$ exists such that

$$|\,\hat z - z\,| \;\le\; c_F\,\Big(\,\|\,\hat A - A\,\|_0 + \|\,\hat B - B\,\|_0 \;+\; |\hat a - a| \;+\; |\hat b - b|\Big)\,.$$

Further, by $p(t) = \Phi(t)\, z$, $\sigma(t) = B(t)^T p(t) = \Gamma(t)\, z$ we obtain the C^1 error estimate

$$|\,\hat{p} - p\,\|_{C^1} + \|\,\hat{\sigma} - \sigma\,\|_{C^1} \le c_{sw} \left(\|\,\hat{A} - A\,\|_0 + \|\,\hat{B} - B\,\|_{C^1} + |\hat{a} - a| + |\hat{b} - b| \right). \tag{4.9}$$

Using Lemma 3.1 we may deduce that for every switching point t_s of u_0 there exists a locally unique switching point $\hat{t}_s$ of the perturbed solution $\hat{u}$ with

$$|\,\hat{t}_s - t_s| \le c_t \left(\|\,\hat{A} - A\,\|_0 + \|\,\hat{B} - B\,\|_{C^1} + |\hat{a} - a| + |\hat{b} - b| \right), \tag{4.10}$$

so that for sufficiently small δ the conclusion of the theorem follows. □

5. Linear time-optimal termination problem. Let us reconsider the steering problem from section 3 but now with the requirement to finish the process at $x = b$ in minimal time T:

$$(\mathrm{P}_T) \qquad \min \ T$$

$$\text{s.t. } \dot{x}(t) = A(t)x(t) + B(t)u(t) \quad \text{a.e. in } [0,T]; \tag{5.1}$$

$$x(0) = a\,, \ x(T) = b\,, \quad T > 0; \tag{5.2}$$

$$|\,u_i(t)\,| \le 1, \ i = 1, \dots, k, \qquad \text{a.e. in } [0,T]\,. \tag{5.3}$$

Consider the case that $a \neq b$, and A, B are continuously differentiable for $t \ge 0$. Further, we will always assume existence of admissible state-control pairs (i.e., the *controllability* of the system).

If $b = 0$, (P_T) is also called *hard termination control* problem.

By setting $T = \int_0^T dt$, the objective functional can be rewritten in Lagrange form. The Hamilton function then turns into

$$H(t,x,u,p) = 1 + p^T A(t)\, x + p^T B(t)\, u. \tag{5.4}$$

Consequently, the adjoint equation and transversality conditions are

$$\dot{p}(t) = -A(t)^T p(t), \qquad H[T] = 0,$$

whereas $p(0)$, $p(T)$, and the final time T are free. The switching function for u is given as before by (3.4), i.e.,

$$\sigma(t) = B(t)^T p(t), \qquad u(t) = -sign\ (\,\sigma(t)\,).$$

There are several ways to reduce (P_T) to a problem on a fixed time interval. Following Hestenes in [24] and [25], a new time variable was introduced by

$$t = T\,\tau\,, \qquad 0 \le \tau \le 1,$$

together with the extended state vector

$$y(\tau) = (y'(\tau),\, y_{n+1}) := (x(T\tau),\, T)$$

and the transformed control v with $v(\tau) := u(T\tau)$, respectively. The state equation after this transformation turns into

$$\dot{y} = \frac{dy}{d\tau} = \tilde{f}(\tau, y, v) = \begin{pmatrix} T\, f(T\tau, x, u) \\ 0 \end{pmatrix}$$

with $f(t,x,u) = A(t)x + B(t)u$, whereas the objective functional is rewritten as

$$\tilde{J}(y,v) \;=\; \int_0^1 T\, d\tau.$$

If we consider the related Hamiltonian functions, for $\tilde{p} = (p\,,\, p_{n+1})$ we get

$$\begin{aligned} H^+(\tau,y,v,\tilde{p}) &= T\, H(T\tau,x,u,p), \\ \hat{H}^+(\tau,y,v,\tilde{p},\tilde{\mu}) &= T\, \hat{H}(T\tau,x,u,p,\mu)\,, \quad \mu \;=\; \tilde{\mu}/T\,. \end{aligned} \tag{5.5}$$

From these relations one can easily reformulate the optimality conditions for a problem with free final time now (cf. [24], e.g.). In the maximum principle (PMP), the additional transversality condition w.r.t. to the free final time is usually given by $\hat{H}[T] \;=\; 0$. Equivalently, with the above state transformation we obtain a boundary value problem for the additional adjoint component, i.e.,

$$\dot{p}_{n+1} = \; -\hat{H} \;-\; T\tau\, \hat{H}_t\,, \qquad p_{n+1}(0) = p_{n+1}(1) = 0\,.$$

The (first-order) *independence* conditions for the transformed problem are equivalent to the formulations related to (P_S). For the example problem (P_T), under Assumption 1 they are automatically fulfilled. Second-order *coercivity* type conditions, however, have to be suitably modified.

Notice that in the case of linear systems dynamics as in (P_T), the Hessian w.r.t. u of $\hat{H}$ is not positive definite. In order to derive optimality conditions and obtain second-order local growth estimates for $\tilde{J} = T$, we will use again the duality approach explained in section 1 but with an appropriate *extended* dual formulation now.

Let (x_0, u_0, T) be an extremal of (P_T) for which Assumptions 1 and 2 are fulfilled, and denote by p the corresponding adjoint function. We will assume that (x, u, T') is admissible for (P_T), and that at least (x, T') are close to (x_0, T), e.g., in $C^0 \times R$ sense. Let us introduce the dual variable in the form

$$\tilde{S} \;= \tilde{S}(\tau,y) = \tilde{S}_0(\tau) \;+\; \tilde{p}_0^T(y - y_0) \;+\; 0.5(y-y_0)^T \tilde{Q}(y-y_0),$$

where $\tilde{p}_0 = \tilde{p}_0(\tau) = (p^T(T\tau), \lambda(\tau))^T$, $y_0 = y_0(\tau) = (x_0^T(T\tau), T)^T$, and

$$\tilde{Q} = \tilde{Q}(\tau) = \begin{pmatrix} Q(T\tau) & \eta(\tau) \\ \eta^T(\tau) & q(\tau) \end{pmatrix}. \tag{5.6}$$

These expressions are related to the original data as follows:

$$\begin{aligned} \tilde{S}(\tau,y) &= S_0(T\tau) + p(T\tau)^T(x - x_0) \;+\; \lambda(\tau)(T' - T) \;+\; (x-x_0)^T \eta(\tau)(T'-T) \\ &\quad + 0.5(x-x_0)^T Q(T\tau)(x-x_0) \;+\; 0.5(T'-T)^2 q(\tau), \\ \tilde{S}_y \;&= \tilde{p}_0 + \tilde{Q}(y-y_0) \;=\; \begin{pmatrix} p + Q(x-x_0) + (T'-T)\eta \\ \lambda + (x-x_0)^T\eta + (T'-T)\, q \end{pmatrix}, \\ \tilde{S}_\tau \;&= \dot{\tilde{S}}_0 + \dot{\tilde{p}}_0^T(y-y_0) \;+\; 0.5(y-y_0)^T \dot{\tilde{Q}}(y-y_0) \\ &\qquad\qquad - (\,\tilde{p}_0 + \tilde{Q}(y-y_0)\,)^T (dy_0/d\tau)\,. \end{aligned}$$

(Here and in the following the symbol "dot" ($\dot{}$) is used for derivatives w.r.t. $\tau = t/T$.) In analogy to section 2, next consider the auxiliary functional $\tilde{\Psi}$ from the *duality gap*,

$$\tilde{\Psi}(y,v;\tilde{S}) \;=\; \int_0^1 \Big[\, H^+(\tau,y,v,\tilde{S}_y) \;+\; \tilde{S}_\tau(\tau,y) \Big]\, d\tau \;=:\; \int_0^1 \tilde{R}[\tau]\, d\tau\,, \tag{5.7}$$

and the boundary term related to (R3), i.e., $\tilde{\psi}(\tilde{\xi}_1, \tilde{\xi}_2; \tilde{S}) = \tilde{S}(0, \tilde{\xi}_1) - \tilde{S}(1, \tilde{\xi}_2) - T$ with

$$\begin{aligned} \tilde{\psi}(y(0), y(1); \tilde{S}) &= \tilde{S}(0; a, T') - \tilde{S}(1; b, T') - T \\ &= 0.5 \ (\, q(0) - q(1) \,) \ (T' - T)^2, \end{aligned} \tag{5.8}$$

due to $\dot{S}_0 = -r_0 = -1$. For $\tilde{z} = (x, u, T')$ near $\tilde{z}_0 = (x_0, u_0, T)$, the Taylor formula for the integrand in (5.7) says that $\tilde{R} = \tilde{R}^{(2)} + \mathrm{o}(|\tilde{z} - \tilde{z}_0|^2)$, (cf. (2.9)), where

$$\tilde{R}^{(2)}[t] = 0.5 \begin{pmatrix} y - y_0 \\ v - v_0 \end{pmatrix}^T \begin{pmatrix} \hat{H}^+_{yy} + \tilde{Q}\tilde{f}_y + \tilde{f}_y^T\tilde{Q} + \dot{\tilde{Q}} & \hat{H}^+_{yv} + \tilde{Q}\tilde{f}_v \\ \hat{H}^+_{vy} + \tilde{f}_v^T\tilde{Q} & \hat{H}^+_{vv} \end{pmatrix} \begin{pmatrix} y - y_0 \\ v - v_0 \end{pmatrix}.$$

If the Hessian herein is positive definite for a certain matrix function $\tilde{Q}$ (satisfying $q(0) - q(1) > 0$ in addition), then the triple (x_0, u_0, T) in accordance to (5.7), (5.8), and Theorem 2.2 is a *weak* local minimizer to (P_T). Sufficient conditions of coercivity type using an *extended* Riccati differential system have been derived and discussed for the general (i.e., possibly nonlinear) case in [25]. They include, in particular, the assumption $\hat{H}^+_{vv} = T\hat{H}_{uu} \succeq 0$, which is violated in the linear case. Therefore, we will return to the integrand $\tilde{R}$ in (5.7) and analyze it for (P_T) in its extended form.

For simplicity, the following considerations are restricted to the *autonomous case*, i.e., to problems with constant matrices $A \in R^{n\times n}$ and $B \in R^{n\times m}$.

Consider the decomposition $\tilde{R}[t] = \tilde{R}_1[t] + \tilde{R}_2[t]$ induced by (2.10). In the linear autonomous case with free final time we have

$$\begin{aligned} \tilde{R}_2[\tau] &= \hat{H}^+(\tau, y, v, \tilde{p}_0, \tilde{\mu}_0) - \hat{H}^+(\tau, y, v_0, \tilde{p}_0, \tilde{\mu}_0) - \tilde{\mu}_0^T \, (g(y, v) - g(y, v_0)) \\ &\qquad + (y - y_0)^T \tilde{Q} (\tilde{f}(y, v) - \tilde{f}(y, v_0)) \\ &= \ T' \, p^T B(u - u_0) \ + \ T' \, (\, Q(x - x_0) + (T' - T)\eta \,)^T \, B(u - u_0), \end{aligned} \tag{5.9}$$

and, for (x, T') sufficiently close to the reference data (x_0, T),

$$\tilde{R}_1[\tau] \ = \ 0.5 \, (y - y_0)^T \left(\hat{H}^+_{yy} + \tilde{Q} \, \tilde{f}_y + \tilde{f}_y^T \tilde{Q} \ + \dot{\tilde{Q}} \right) (y - y_0) \ + \ \mathrm{o}(|y - y_0|^2) \tag{5.10}$$

with

$$\tilde{f}_{y'} \ = \ \begin{pmatrix} T f_x \\ 0 \end{pmatrix} \ = \ T \begin{pmatrix} A \\ 0 \end{pmatrix}, \qquad \tilde{f}_{y_{n+1}} \ = \ \begin{pmatrix} f \\ 0 \end{pmatrix} \ = \ \begin{pmatrix} Ax + Bu \\ 0 \end{pmatrix}$$

and

$$\begin{aligned} \hat{H}^+_{y'y'} = T \, \hat{H}_{xx} \ = \ 0 \, , \qquad \hat{H}^+_{y'y_{n+1}} \ = \ \hat{H}_x \ = \ A^T p \, , \\ \hat{H}^+_{y_{n+1}y_{n+1}} = 0 \, . \end{aligned}$$

Inserting these expressions together with (5.6) into (5.10), we obtain

$$\begin{aligned} \tilde{R}_1 &= 0.5 \, (y - y_0)^T \, M \, (y - y_0) \ + \ \mathrm{o}(|y - y_0|^2) \\ &= 0.5 \begin{pmatrix} x - x_0 \\ T' - T \end{pmatrix}^T \begin{pmatrix} M_1 & M_2 \\ M_2^T & M_3 \end{pmatrix} \begin{pmatrix} x - x_0 \\ T' - T \end{pmatrix} \\ &\qquad + \mathrm{o}(|x - x_0|^2 + |T' - T|^2), \end{aligned} \tag{5.11}$$

where the matrix blocs M_i of the Hessian M are given by

$$\begin{aligned} M_1 &= \dot{Q} \,+\, T\,\left(Q\,A \,+\, A^T Q\right), \\ M_2 &= \dot{\eta} \,+\, T\,A^T\eta \,+\, A^T p \,+\, Q(Ax_0 + Bu_0)\,, \\ M_3 &= \dot{q} \,+\, 2\,\eta^T(Ax_0 + Bu_0)\,. \end{aligned}$$

In order to ensure the positive definiteness of M it will be sufficient to solve appropriate linear differential equations for the components of $\tilde{Q}$, so that the only crucial point would be the boundary restriction on q (cf. (5.8)). However, as will be shown in the following, for the time-optimal termination problem (P_T) a relaxation becomes possible which can be trivially fulfilled for linear state equations.

LEMMA 5.1. *For every $\gamma \in (0,1)$, the matrix differential equation $M = \gamma I$, i.e.,*

$$\dot{Q} \,+\, T\,\left(Q\,A \,+\, A^T Q\right) = \gamma\, I\,, \tag{5.12}$$

$$\dot{\eta} \,+\, T\,A^T\eta = -A^T p \,-\, Q(Ax_0 + Bu_0)\,, \tag{5.13}$$

$$\dot{q} = \gamma \,-\, 2\,\eta^T(Ax_0 + Bu_0)\,, \tag{5.14}$$

has a bounded on $[0,T]$ solution $\tilde{Q} = \left(\begin{smallmatrix} Q & \eta \\ \eta^T & q \end{smallmatrix}\right)$. In particular, the solution can be chosen such that for $\gamma \to 0$ the components η and q are uniformly bounded, and Q satisfies $\|Q\|_\infty = O(\gamma)$.

Proof. Denote by Q_1 the solution of the initial value problem for the linear equation (5.12) with $\gamma = 1$ and $Q(0) = I$. Setting next $Q = \gamma\, Q_1$, we can solve the (linear) equations for η and q, e.g., with $\eta(0) = 0$ and $q(0) = 0$ then. The solutions satisfy

$$\begin{aligned} \|Q\|_\infty &= \gamma\,\|Q_1\|_\infty \;=\; \mathrm{O}(\gamma)\,, \\ \|\eta\|_\infty &\le c_1\|p\|_1 + \mathrm{O}(\gamma) \;\le\; M_\eta\,, \\ \|q\|_\infty &\le c_2\|\eta\|_1 + \gamma \;\le\; M_q \end{aligned}$$

for positive constants $c_{1,2}$ and M_η, M_q not depending of γ for $\gamma \in [0,1]$. Thus, the conclusion follows. □

LEMMA 5.2. *Let the solution (x_0, u_0, T) of (P_T) satisfy Assumption 1. Then, for every $\gamma \in (0,1)$, positive constants ϵ, $\tilde{c}_1$ exist such that*

$$\tilde{R}_1[\tau] \;\ge\; 0.25\,\gamma\,\left(\,|\,x(T'\tau) - \,x_0(T\,\tau)\,|^2 \,+\, |T' - T|^2\right) \tag{5.15}$$

holds together with $|\psi| \;\le\; \tilde{c}_1|T' - T|^2$ for arbitrary admissible (x, u, T') satisfying $\|x' - x_0\|_\infty + |T' - T| \,<\, \epsilon$ (where x' stands for the transformed state $x'(t) = x(T't/T)$ on $[0,T]$).

Proof. Let the matrix parameter $\tilde{S}_{yy} = \tilde{Q}$ in (5.6) be chosen in accordance to Lemma 5.1. Then the proof of the first part of this lemma follows immediately from (5.11) and Lemma 5.1. The second part is a direct consequence of relation (5.8) and the estimate for q from the above lemma. □

LEMMA 5.3. *Suppose that (x_0, u_0, T) suffices the Assumptions 1 and 2 of section 3. Further, let $\tilde{Q}$ be determined from Lemma 5.1, where γ is chosen sufficiently small. Then there exist positive constants ϵ', $\tilde{c}_2$, and $\tilde{c}_3$ such that*

$$\int_0^1 \tilde{R}_2[\tau]\,d\tau \;\ge\; \tilde{c}_2\|u' - \,u_0\|_1^2 \,-\, \tilde{c}_3|T' - T|^2 \tag{5.16}$$

for arbitrary admissible (x, u, T') *with* $\|x' - x_0\|_\infty + |T' - T| < \epsilon'$ *(where* $x'(t) = x(T't/T)$ *and* $u'(t) = u(T't/T)$ *are the transformed state and control, resp.).*

Proof. The proof follows the line from Lemma 3.3 but uses the extended dual formulation with $\tilde{S}$, respectively, $\tilde{Q}$.

Under Assumption 2, from the expression (5.9) for $\tilde{R}_2[t]$ in analogy to (3.17) we obtain the following estimate for sufficiently small $\delta > 0$:

$$(T')^{-1} \int_0^1 \tilde{R}_2[\tau]\, d\tau \geq 0.5\, m_0\, \delta\ (\, \|v - v_0\|_1 - c_1\, \delta\,) \\ - c_2 \|Q\|_\infty \|B\| \cdot \|v - v_0\|_1^2 \ - \ \|\eta^T B\|_\infty \|v - v_0\|_1\, |T' - T|\,.$$

Since $B = \text{const}$ and $\|\eta\|_\infty \leq M_\eta$ for arbitrary $\gamma \in (0, 1)$ (cf. Lemma 5.1), the last term can be estimated by

$$\|\eta^T B\|_\infty \|v - v_0\|_1\, |T' - T| \ \leq\ c_3 \left(\, \rho\, \|v - v_0\|_1^2 + (4\rho)^{-1} |T' - T|^2 \,\right)$$

with a certain constant c_3 and arbitrary positive ρ. Moreover,

$$\|Q\|_\infty \|B\| \cdot \|v - v_0\|_1^2 \ \leq\ c_4 \gamma \|v - v_0\|_1^2$$

for small positive γ. Thus one can choose, first, $\delta = c' \|v - v_0\|_1$ with sufficiently small c', and subsequently γ and ρ small enough so that the estimate (5.16) follows. ∎

Our final result is given by the next theorem.

THEOREM 5.4. *Let* (x_0, u_0, T) *be an extremal point of* (P_T) *with constant* A *and* B*, and assume Assumptions* 1 *and* 2 *hold true. Then the triple* (x_0, u_0, T) *is a strict local minimizer, and for some positive constants* $\tilde{c}$ *and* $\tilde{\epsilon}$ *the estimate*

$$T' - T \ =\ J(x, u) - J(x_0, u_0) \ \geq\ \tilde{c}\, \left(\, \|x' - x_0\|_2^2 + \|u' - u_0\|_1^2 \,\right)$$

is valid for all admissible (x, u, T') *with* $\|x' - x_0\|_\infty + |T' - T| < \tilde{\epsilon}$ *(with the notations* $x'(t) = x(T't/T)$ *and* $u'(t) = u(T't/T)$ *on* $[0, T]$*, resp.).*

Proof. Let (x, u) be an arbitrary admissible state-control pair corresponding to the final time $T' > 0$, and denote the related extended state and control functions by y, respectively, v. First, consider the functional $\tilde{J}(y, v) = \int_0^1 T' d\tau$ reformulated in terms of $\tilde{S}$ and H^+ from (5.5) (see also (2.4)):

$$\begin{aligned} \tilde{J}(y, v) &= \int_0^1 H^+(\tau, y, v, \tilde{S}_y(\tau, y))\, d\tau \ - \ \int_0^1 \tilde{S}_y(\tau, y)^T \tilde{f}(\tau, y, v)\, d\tau \\ &= \int_0^1 \left(\, H^+(\tau, y, v, \tilde{S}_y) \ + \ \tilde{S}_\tau \,\right)\, d\tau \ + \ \tilde{S}(0, y(0)) - \tilde{S}(1, y(1)). \end{aligned}$$

Denoting by (y_0, v_0) the extended trajectories related to (x_0, u_0, T), from (5.7), (5.8) we deduce

$$T' - T \ =\ \tilde{J}(y, v) \ - \ \tilde{J}(y_0, v_0) \ =\ \tilde{\Psi}(y, v; \tilde{S}) \ + \ \tilde{\psi}(y(0), y(1); \tilde{S})\,.$$

Using Lemma 5.2 and 5.3, for sufficiently small $\gamma > 0$ we obtain the estimate

$$\begin{aligned} T' - T &\geq \int_0^1 \tilde{R}[\tau]\, d\tau \ + \ \tilde{\psi}(y(0), y(1), \tilde{S}) \\ &\geq\ \frac{\gamma}{4}\, \|x' - x_0\|_2^2 + \tilde{c}_2 \|u' - u_0\|_1^2 \ - \ (\tilde{c}_1 + \tilde{c}_3)\, |T' - T|^2 \end{aligned} \tag{5.17}$$

(with the notations x', u' used in the statement of the theorem).

Assume for the moment that $T' < T$: From (5.17) it follows that

$$(T' - T)\ (\,1 + (\tilde{c}_1 + \tilde{c}_3)(T' - T)\,)\ \geq\ 0\,.$$

In the case that $|T' - T| < \tilde{\epsilon} \leq 0.5(\tilde{c}_1 + \tilde{c}_3)^{-1}$, this leads to a contradiction. Consequently, Assumptions 1 and 2 are sufficient for the local optimality of (x_0, u_0) and the related final time T.

With $T' \geq T$, from $|T' - T| < \tilde{\epsilon}$ chosen above we now arrive at

$$(T' - T)\ +\ (\tilde{c}_1 + \tilde{c}_3)(T' - T)^2\ \leq\ (3/2)\,(T' - T)\,,$$

so that finally for some positive $\tilde{c}$ we end up with

$$T' - T\ \geq\ \frac{\gamma}{6}\,\|x' - x_0\|_2^2 + (2\tilde{c}_2/3)\,\|u' - u_0\|_1^2\ \geq\ \tilde{c}\,\left(\,\|x' - x_0\|_2^2 +\ \|u' - u_0\|_1^2\,\right),$$

i.e., the desired result. □

We will accomplish Theorem 5.4 by a sensitivity result concerning the optimal time.

LEMMA 5.5. *Let $(x_0, u_0; T)$ be a solution of (P_T) satisfying Assumptions 1 and 2. Further, let (x, u) be an admissible pair corresponding to the final time T' (with $x(T') = b$ in particular). Then positive constants ρ and c exist such that*

$$|\,T' - T\,|\ \leq\ c\,\|u - u_0\|_1 \qquad \forall\, T' \ \text{ with } \ \ |\,T' - T\,| < \rho\,.$$

Remark. The L_1-norm on the right-hand side is related to the interval $[0, T']$, where for $T' > T$ the function u_0 is continued to $[T, T']$ as a constant. The function x_0 then denotes the corresponding solution of the state equation on the larger interval $[0, T']$.

Proof. Notice first that from the transversality condition $H[T] = 1 + p^T \dot{x}_0 = 0$ it follows that $\dot{x}_0(T) \neq 0$.

Let i be an index with $|\dot{x}_{0,i}(T)| = \max_j\{|\dot{x}_{0,j}(T)|\} = m > 0$. Then, in a sufficiently small neighborhood $(T - \rho, T + \rho)$ of T, $\dot{x}_{0,i}$ does not change its sign, and the estimate $|\dot{x}_{0,i}(t)| \geq m/2$ holds true. Consequently, for $0 < |t - T| < \rho$,

$$|\,x_{0,i}(t)\ - x_{0,i}(T)| \geq\ (m/2)\,|t - T|\,.$$

Taking in particular $t = T'$, with $x_{0,i}(T) = x_i(T') = b_i$ and $c_m = 2/m$ we get

$$|T' - T|\ \leq\ c_m\ |\,x_{0,i}(T') - x_{0,i}(T)\,|\ =\ c_m\ |\,x_{0,i}(T') - x_i(T')\,|\,.$$

Since the state equation is linear, we arrive at the assertion

$$|T' - T|\ \leq\ c_m\,\|\,x - x_0\,\|_\infty \leq\ c(A, B, m)\|\,u - u_0\,\|_1\,. \qquad \square$$

6. Test example. This section is devoted to the stability analysis of *hard* and of *soft* termination control problems for a simple two-dimensional chain (cf. [30]). It will be shown that failures in the stability assumptions may cause serious instabilities of the solution structure even in elementary model cases.

Consider a particular problem of type (P),

$$(\mathrm{P}^0) \qquad \min\ 0.5\,\|x(T) - b\|^2 \quad \text{s.t.} \quad \dot{x}_1(t)\ =\ x_2(t)\,,\ \ \dot{x}_2(t)\ =\ u(t) \quad \text{a.e. in } [0, T],$$
$$x(0)\ =\ a\,; \qquad |\,u(t)\,|\ \leq 1 \qquad \text{a.e. in } [0, T].$$

(This problem is also known as the rocket car problem, where x_1 stands for the position, x_2 for the velocity, and u for the acceleration of the vehicle.) We will restrict ourselves to the case that a_2, b_2 are positive, and $b_1 > a_1$. According to the results of section 4, the adjoint equation together with the transversality condition take the form

$$\dot{p}_1 \equiv 0\,, \quad \dot{p}_2 = -p_1, \quad p(T) \,=\, x(T) - b,$$

so that with $p_1(0) = z_1,\ p_2(0) = z_2$ the *switching function* reads as

$$\sigma(t) \,= p_2(t) \,=\, -z_1 t \,+\, z_2\,.$$

Therefore we have $t_s = z_2/z_1$ whenever $z_1 \neq 0$, i.e., the extremal trajectories cannot have more than one switching point on $[0, T]$.

Consider the solution representation (4.4) from section 4: The fundamental solutions to the equations (4.3) are given by

$$\Psi(t) \,=\, \begin{pmatrix} 1 & t \\ 0 & 1 \end{pmatrix}, \qquad \Phi(t) \,=\, \begin{pmatrix} 1 & 0 \\ -t & 1 \end{pmatrix}$$

so that $\Gamma(t) = (\,-t\ \ 1\,)$. Consequently,

$$\begin{aligned} p_1(t) &= z_1\,, \qquad p_2(t) \,=\, z_2 - z_1 t\,, \\ x_1(t) &= a_1 + a_2 t \,-\, \int_0^t sign\,(\,z_2 - z_1 s\,)\,\cdot\,(t-s)\,ds\,, \\ x_2(t) &= a_2 \,-\, \int_0^t sign\,(\,z_2 - z_1 s\,)\,ds\,. \end{aligned}$$

Thus, any discontinuous nonsingular extremal belongs to one of the following types:

Type 1: $\quad z_1 < 0\,,\ \ z_2 < 0 \quad$ or $\quad u_0 = \begin{cases} +1 & \text{for } 0 \le t < t_s, \\ -1 & \text{for } t_s \le t \le T. \end{cases}$

In the first part, the object moves with maximal acceleration, and the trajectory is part of a parabola $P_1 :\ x_1 = 0.5x_2^2 + \alpha$ in the phase plane, whereas $x \in P_2 :\ x_1 = -0.5x_2^2 + \beta$ (with appropriately chosen α, β) in the second (retardation) part. Denoting the switching point by x^S, the arcs may be written as

$$\begin{aligned} P_1 :\quad & x_1(t) = x_1^S - x_2^S(t_s - t) + 0.5(t - t_s)^2, \\ & x_2(t) = x_2^S - (t_s - t), \qquad 0 \le t \le t_s\,; \\ P_2 :\quad & x_1(t) = x_1^S + x_2^S(t - t_s) - 0.5(t - t_s)^2, \\ & x_2(t) = x_2^S - (t - t_s), \qquad t_s \le t \le T\,. \end{aligned} \tag{6.1}$$

Notice that $z_1 \equiv p_1(t)$ with $p_1(T) = x_1(T) - b_1$ so that $x_1(T) < b_1$ for this situation.

Type 2: $\quad z_1 > 0\,,\ \ z_2 > 0 \quad$ or $\quad u_0 = \begin{cases} -1 & \text{for } 0 \le t < t_s, \\ +1 & \text{for } t_s \le t \le T. \end{cases}$

The switching structure says that, in the phase plane, the points move with retardation along $x_1 = -0.5x_2^2 + \beta'$ in the first part and accelerating along $x_1 = +0.5x_2^2 + \alpha'$ in the second part. The condition $0 < z_1 \equiv p_1(t)$ says that $x_1(T) > b_1$ holds true for the second type.

In both cases, one can find explicit formulas for $p,\ x$, and the function F in (4.5). Indeed, for type 2, e.g., we have for $t > t_s = z_2/z_1$ that

$$
\begin{aligned}
x_1(t) &= a_1 + a_2 t + \frac{t^2}{2} - \frac{2tz_2}{z_1} + \left(\frac{z_2}{z_1}\right)^2, \qquad p_1(t) \;=\; z_1,\\
x_2(t) &= a_2 + t - \frac{2z_2}{z_1}, \qquad\qquad\qquad\quad p_2(t) \;=\; z_2 - tz_1\,.
\end{aligned}
\tag{6.2}
$$

From the first equation taken at $t = T$ we see that $t_s = z_2/z_1$ satisfies

$$
T(a_2 - t_s) \;=\; x_1(T) - a_1 - \frac{t_s^2}{2} - \frac{(T - t_s)^2}{2} \;\le\; 0
$$

due to $|u| \le 1$, so that $t_s \ge a_2$ follows. Taking into account (6.2), we see that $x_2(t_s) \le 0$. Notice that thus the type 2 trajectories switch to the second parabola not in the first point of intersection (which is in the upper half plane) but only when these curves intersect in the lower part of the phase plane. This effect had been earlier discussed for the time-optimal case; cf., e.g., [30].

Using (6.2), the Jacobian of $F = x(T) - p(T) - b$ now can be expressed as

$$
\frac{\partial F}{\partial z} \;=\; -\begin{pmatrix} 1 & 0 \\ -T & 1 \end{pmatrix} - \frac{2}{z_1^3}\begin{pmatrix} z_2^2 - Tz_1z_2 & Tz_1^2 - z_1z_2 \\ -z_1z_2 & z_1^2 \end{pmatrix}
$$

(and the same result may be obtained from (4.8) with $|\dot\sigma(t_s)| = |\,z_1| = -z_1$ and $t_s = z_2/z_1$).

It follows from the proof of Theorem 4.1 that $\partial F/\partial z$ is a regular matrix. In the example case, it is easy to confirm this fact by calculating the determinant:

$$
\left|\frac{\partial F}{\partial z}\right| \;=\; 1 \;+\; \frac{2}{|z_1|}\left(1 \;+\; (T - z_2/z_1)^2\right) \;>\; 0\,.
$$

Therefore, any solution of the structural type 2 is a stable solution in the sense of section 4. Moreover, Assumptions 1 and 2 hold true for such trajectories so that Theorem 3.4 can be applied to show the strong local optimality.

Analogous arguments show the stability of extremal trajectories of type 1.

In order to find locally optimal solutions of (P^0), let us first consider the related time-optimal problem

$$
\begin{aligned}
(\mathrm{P}^0_T) \qquad \min\ T \qquad \text{s.t.}\quad & \dot x_1(t) \;=\; x_2(t)\,,\ \ \dot x_2(t) \;=\; u(t) \quad \text{a.e. in } [0,T];\\
& x(0) \;=\; a\,,\ \ x(T) = b, \quad |\,u(t)\,| \le 1 \quad \text{a.e. in } [0,T]\,.
\end{aligned}
$$

As before, we will consider extremals without singular arcs, i.e., trajectories which are synthesized from parabolas of the type P_1 or P_2, respectively. Depending on the end points localization we have the following.

If $b_1 - a_1 > l = 0.5\,|\,a_2^2 - b_2^2|$, then the point b is attainable with trajectories of the structural type 1. If, in addition, $b_1 - a_1 < L = 0.5\,(\,a_2^2 + b_2^2)$, then the target can be reached by type 2 curves too, so that two extremals exist. We denote the corresponding time values by T^* and T^+. The type 1 extremal with the higher velocity components $x_2(t)$ is the global minimizer of (P^0_T). (For a detailed analysis see [30].) Due to $x_1^s \in (a_1, b_1)$, $x_2^s \ge \max\{a_2, b_2\} > 0$ we have $p_1 \equiv z_1 = -1/x_2(t_s^*) < 0$ and $\dot\sigma(t_s^*) = z_1 < 0$, so that this solution satisfies all assumptions of Theorems 5.4 and 4.1 and the minimum is locally strong and stable.

For the second extremal, where, in the phase plane, the points move under retardation in the first part and with acceleration in the second part, we have $p_1 \equiv z_1 = -1/x_2(t_s^+) > 0$, i.e., $\dot\sigma(t_s^+) = z_1 > 0$ in particular. Therefore, again we can apply the theory of section 5, respectively, 4 to see that this suboptimal extremal also gives a strict locally strong minimizer with stable switching structure.

Let us return now to problem (P^0) with given end-time T. We will mainly consider T near the local optimizers T^* or T^+ and, without loss of generality, assume that $T > |\,b_2 - a_2|$.

If the time parameter T is smaller than T^*, the target point b cannot be reached. The solution can be constructed as a trajectory of type 1 by finding the switching time t_s. Using for the trajectories analogous formulas as in (6.2), and abbreviating $r = T - t_s$, we get

$$J(x,u) \;=\; \frac{1}{2}\,\|\,x(T) - b\,\|^2 \;=\; \frac{1}{2}\,\big(\,(c_1 - r^2)^2 + (c_2 - 2r)^2\big) \;=:\; 2\,\phi(r),$$

with $c_1 = T^2/2 + a_2T + a_1 - b_1$, $c_2 = T + a_2 - b_2 > 0$. Since $\lim_{r\to\infty}\phi(r) = +\infty$ and $\phi'(0) = -c_2 < 0$, a positive minimum point r_s exists. From $\phi'(r_s) = 0$ the representation $r_s = -(c_2 - 2r_s)/(c_1 - r_s^2)$ follows. Using that $(c_1 - r_s^2) = x_1(T) - b_1 = z_1 < 0$ holds true for type 1 solutions, we get

$$r_s \;<\; 0.5c_2 = \;0.5(T \;+\; (b_2 - a_2)) \;<\; T\,.$$

Furthermore, the relation $t_s \;>\; 0.5\,(T \;+\; (b_2 - a_2))$ is characteristic for the solution trajectory in case $T < T^*$.

Consider next the situation $T^* \ll T < T^+$: naturally, we will ask for a solution of type 2 now. The approach used above leads to the auxiliary problem of minimizing $\phi(r)$ from

$$J(x,u) \;=\; \frac{1}{2}\,\big(\,(\hat c_1 + r^2)^2 + (2r - \hat c_2)^2\big) \;\;=:\; 2\hat\phi(r)$$

with the notations $\hat c_1 = \,-0.5\,T^2 + a_2T + a_1 - b_1$, $\hat c_2 = \,T - a_2 + b_2$, and $r = T - t_s$. For a minimizer t_s from $(0,T)$ in analogy to case 1 it can be proved that

$$t_s \;>\; 0.5\,(T \;-\; (b_2 - a_2)).$$

In both cases discussed so far, due to $T < \bar T \in \{T^*, T^+\}$, the condition $\dot\sigma(t_s) = z_1 \neq 0$ is fulfilled so that the solutions are stable in their structure in the sense of Theorem 4.1. Moreover, they are strict strong local minimizers of (P^0) satisfying the local quadratic growth estimate from Theorem 3.4. The situation changes when we consider $T = T^*$ or $T = T^+$: In this case, the solution of (P^0) terminates in b, and we have $z_1 = p_1 \equiv p_1(\bar T) = x_1(\bar T) - b_1 = 0$ so that in fact we have to do with a (completely) singular optimal control solution: $\sigma(t) \equiv 0$. Due to the coincidence with the time-optimal case, however, the solution is uniquely determined and represents the limit of solutions for $T \uparrow \bar T$.

The singularity mentioned for (P^0) with $T = \bar T$ causes instabilities in the behavior of the solutions when the problem data are changed. To see this, consider, e.g., $T = T^* + \delta$ with small positive δ: obviously, the optimal value of the objective function in the soft termination problem is zero (which means that the final state position $x(T) = b$ is attainable). One way for constructing optimal trajectories in the case $T = T^* + \delta$ consists of the following approach.

Consider, first, the time-optimal path along the parabolas P_1 on $[0, t_s]$ and along P_2 for $(t_s, T^*]$; cf. (6.1). On P_1, let a point $x^H = x(t_H)$ be chosen such that $v_H =$

$x_2^H > \max\{a_2, b_2\}$, and $t_H < t_s$. The point with the same x_2-component on P_2 denote by x^R. With $d = t_s - t_H = x_2^S - x_2^H$, its distance to x^H can be calculated from (6.1) as

$$L \;=\; x_1^R \;-\; x_1^H \;=\; 2x_2^S d \;-\; d^2\;.$$

Assume that the point moves for $0 \le t \le t_H$ with maximal acceleration along P_1, but then with constant velocity v_H over a distance $l \in (0, L)$. When the motion is then continued with $u = 1$, the point follows a parabola P_1' determined by

$$x_1 \;=\; 0.5\,(x_2)^2 + \; x_1^S - 0.5\,(x_2^S)^2 \;+\; l, \tag{6.3}$$

which meets P_2 at a point x^B with $x_2^H < x_2^B = v_B < x_2^S$. From this point on we set $u = -1$ and, following the parabola P_2, achieve b.

The time delay caused by breaking the acceleration and holding the velocity v_H on a certain interval of length l is given by

$$\Delta_H(l) \;=\; l/v_H \;-\; 2\,(x_2^S - x_2^B).$$

Denoting $d_B = x_2^S - x_2^B$ $(= t_B - t_s$ from the time-optimal trajectory), we see from (6.1) and (6.3) that

$$x_1^B - x_1^S \;= 0.5\,l \;=\; x_2^S d_B - 0.5\,d_B^2\,,$$

consequently,

$$\Delta_H(l) \ge\; l/v_B \;-\; 2\,d_B \;=\; \frac{l - 2x_2^S d_B + 2d_B^2}{x_2^S - d_B} \;=\; \frac{d_B^2}{v_B} \;>\; 0.$$

On the other hand, for $d = x_2^S - x_2^H$ it follows analogously that

$$\Delta_H(l) \le \frac{L}{v_H} - 2\,d \;=\; \frac{d^2}{v_H} \;=:\; D_H.$$

Summing up, we see that in dependence of the choice of x^H and the length l of the singular arc with $u \equiv 0$, a small but arbitrary time delay $\Delta_H(l) \in (0, D_H)$ can be realized. Moreover, this technique can be repeatedly applied for finitely or even countably many points on the remaining acceleration parabolas of type P_1, respectively, P_1', before their switching point to the parabola P_2 is reached. We have only to make sure that the sum of the individual time delays equals $\delta = T - T^*$.

The arguments show that near the time parameter $T = T^*$, where the stability condition contained in Assumption 2 fails, for $T^* < T \ll T^+$ one can observe bifurcations of the optimal solution including essential changes in the structure of the optimal control behavior. The same qualitative result can be obtained (by a slightly modified construction) for T near the second local optimizer T^+ satisfying $T > T^+$.

7. Conclusion. The stability analysis of bang-bang control regimes is of practical as well as of theoretical interest. A thorough comparison of the different approaches appearing in the literature could lead to better insights and should be a field for further investigations. The benefit for constructing robust and efficient numerical algorithms is another, widely open question.

In addition to the remarks in the introduction, some comments have to be added concerning the local growth results in Theorem 3.4 and Theorem 5.4: as it was pointed out by one of the referees, the estimate in Theorem 3.4 is a consequence of Theorem 5.2, [27]. Further, the statement of Theorem 5.4 could be also obtained from Theorem 13.1, [27], and the results on linear time-optimal problems from [29].

Acknowledgments. The author is very grateful to the anonymous referees for their detailed and helpful remarks. In particular, they have led to substantial improvements in the presentation of section 2 and of some of the proofs in sections 3 and 5.

GLOBAL WEAK SHARP MINIMA ON BANACH SPACES*

KUNG FU NG† AND XI YIN ZHENG†

Abstract. We consider a proper lower semicontinuous function f on a Banach space X with $\lambda = \inf\{f(x) : x \in X\} > -\infty$. Let $\alpha \geq \lambda$ and $S_\alpha = \{x \in X : f(x) \leq \alpha\}$. We define the lower derivative of f at the set S_α by

$$\underline{D}(f, S_\alpha) = \liminf_{x \to S_\alpha} \frac{f(x) - \alpha}{dist(x, S_\alpha)},$$

where $x \to S_\alpha$ can be interpreted in various ways. We show that, when f is convex and $\alpha = \lambda$, it is equal to the largest weak sharp minima constant. In terms of these derivatives and subdifferentials, we present several characterizations for convex f to have global weak sharp minima. Some of these results are also shown to be valid for nonconvex f. As applications, we give error bound results for abstract linear inequality systems.

Key words. weak sharp minima, error bound, Banach spaces, Asplund space

1. Introduction.

Throughout this paper, let X be a Banach space and $f : X \to R\bigcup\{+\infty\}$ a proper lower semicontinuous function; we always assume that f is bounded below and denote by λ the infimum of f on X. For each $\alpha \in R$, let

$$S_\alpha := \{x \in X : f(x) \leq \alpha\};$$

in particular,

$$S_\lambda = \{x \in X : f(x) \leq \lambda\} = \{x \in X : f(x) = \lambda\}.$$

We say that f has global weak sharp minima if $S_\lambda \neq \emptyset$ and there exists $\tau > 0$ such that

$$\tau dist(x, S_\lambda) \leq f(x) - \lambda \qquad \forall x \in X. \tag{1.1}$$

In this case, τ is called a weak sharp minima constant; and $\tau_f := \sup\{\tau : \tau \text{ satisfies } (1.1)\}$ is called the largest weak sharp minima constant of f.

Weak sharp minima occur in many optimization problems; in particular, they are related to the convergence analysis of iterative procedures. Several authors [1, 2, 4, 6, 13, 18, 19, 20] studied such minima (but only local ones). Among these, [1, 2, 6, 13, 18] considered the unique minimizer solution set case. Burke and Ferris [4] extended it to the nonunique minimizer solution set case; Studniarski and Ward [19] and Ward [20] studied local weak sharp minima with a nonunique minimizer solution set. Most previous works add assumptions on the minimizer solution set S_λ and

require the space X to be finite dimensional. In this paper, we consider global weak sharp minima on a Banach space and add no assumptions on S_λ. In section 2, we first prove a characterization for a proper lower semicontinuous function on a Banach space to have global weak sharp minima. Using this characterization and a recent significant result (local Lipschitz fuzzy sum rule of Fréchet subdifferential) on Asplund spaces, we give a sufficient condition in terms of Fréchet subdifferential for a proper lower semicontinuous function on an Asplund space to have global weak sharp minima. Moreover, we consider weak sharp minima with constraint for a locally Lipschitz function. In section 3, we discuss weak sharp minima of a lower semicontinuous convex function and give several equivalent conditions for such a function to have weak sharp minima. In section 4, as applications of results in sections 2 and 3, we establish some error bound results for abstract linear inequality systems, which are more general than previous linear inequality systems considered by other authors.

We conclude this section with a compilation of some notations which will be used throughout the paper. For $x \in \mathrm{dom}(f) := \{x \in X : \ f(x) < +\infty\}$ and $\varepsilon \geq 0$, let $\tilde{\partial}_\varepsilon f(x)$ denote the set

$$\left\{x^* \in X^* : \ \liminf_{y \to x} \frac{f(y) - f(x) - \langle x^*, y - x\rangle}{\|y - x\|} \geq -\varepsilon\right\}.$$

$\tilde{\partial} f(x)$ stands for $\tilde{\partial}_0 f(x)$ and is called the Fréchet subdifferential of f at x. Let

$$\begin{aligned}\partial f(x) &:= \limsup_{y \overset{f}{\to} x} \tilde{\partial} f(y)\\ &:= \{x^* \in X^* : \ x_n^* \overset{w^*}{\to} x^* \text{ with } x_n^* \in \tilde{\partial} f(x_n),\ x_n \to x \text{ and } f(x_n) \to f(x)\}.\end{aligned}$$

$\partial f(x)$ is called the limiting Fréchet subdifferential of f at x. If X is an Asplund space, $\partial f(x) = \limsup_{y \overset{f}{\to} x, \varepsilon \downarrow 0} \tilde{\partial}_\varepsilon f(y)$ (see [14, Theorem 2.9]). Clearly, $\tilde{\partial} f(x) \subset \partial f(x)$. It is known that if f is convex, then

$$\tilde{\partial} f(x) = \partial f(x) = \{x^* \in X^* : \ \langle x^*, y - x\rangle \leq f(y) - f(x) \qquad \forall y \in X\}.$$

For more discussions on generalized differentials, see [5] and [12]. For a closed subset K of X and $x \in K$, define $N(K, x) := \partial \delta_K(x)$, where δ_K is the indicator function of K. It is known [14] that $N(K, x) = \bigcup_{\lambda > 0} \lambda \partial dist(x, K)$. Recall that X is called an Asplund space if every continuous convex function on an open convex subset D of X is Fréchet differentiable on a dense G_δ subset of D. It is well known [17] that each Banach space with an equivalent Fréchet smooth norm, each Banach space with separable dual, and each reflexive Banach space are examples of Asplund spaces.

2. Weak sharp minima for lower semicontinuous functions. We first present a general characterization for f to have global weak sharp minima, which is also a tool to prove other results in this section.

THEOREM 2.1. *f has global weak sharp minima with a constant $\tau > 0$ if and only if there exists a sequence $\{\lambda_n\}$ in R such that $\lambda_n \to \lambda^+$ and for each $x \in X$ with $f(x) > \lambda$,*

$$\tau \liminf_{n \to \infty} dist(x, S_{\lambda_n}) \leq f(x) - \lambda. \tag{2.1}$$

Proof. It is clear that (2.1) holds if f has global weak sharp minima with a constant $\tau > 0$. Conversely, suppose that (2.1) holds. We need only show that $S_\lambda \neq \emptyset$

and that for each $\gamma \in (0,\ \tau)$ and each $x \in X \setminus S_\lambda$,

$$\gamma dist(x, S_\lambda) \le f(x) - \lambda.$$

Fixing $\gamma \in (0,\ \tau)$, for each $y \in \mathrm{dom}(f)$, let

$$F(y) = \{y' \in X :\ \gamma\|y - y'\| \le f(y) - f(y')\}.$$

Then $F(y)$ is a nonempty closed subset of X for each $y \in \mathrm{dom}(f)$. Since $\lambda = \inf\{f(z) : z \in X\} > -\infty$, one can inductively construct a sequence $\{x_n\}$ such that

(i) $x_0 = x$,
(ii) $x_n \in F(x_{n-1})$,
(iii) $f(x_n) \le \inf\{f(y) :\ y \in F(x_{n-1})\} + \frac{1}{n}$.

By (ii) and the definition of F, it is easy to verify that $F(x_n) \subset F(x_{n-1})$. This and (iii) imply that $F(x_n) \subset B(x_n, \frac{1}{\gamma n})$, where $B(x_n, \frac{1}{\gamma n})$ denotes the ball with center x_n and radius $\frac{1}{\gamma n}$. It follows from the completeness of X that there exists $z \in X$ such that $\{z\} = \bigcap_{n=0}^{\infty} F(x_n) \subset F(x)$. Thus $F(z) = \{z\}$ and $\gamma\|x - z\| \le f(x) - f(z)$. It remains to show that $f(z) = \lambda$. If this is not the case, then $f(z) > \lambda$. By (2.1) and passing to a subsequence if necessary, we can assume that the lower limit on the left-hand side of (2.1) is the full limit. By lower semicontinuity of f and $\lambda_n \to \lambda^+$, one has $\lim_{n\to\infty} dist(z, S_{\lambda_n}) > 0$. Since $\gamma \in (0,\ \tau)$, it follows that

$$\gamma dist(z, S_{\lambda_n}) < f(z) - \lambda \qquad \forall \text{ large enough } n.$$

Therefore, for each large enough n there exists $z_n \in S_{\lambda_n} \setminus \{z\}$ such that

$$\gamma\|z - z_n\| < f(z) - \lambda_n \le f(z) - f(z_n),$$

and so $z_n \in F(z) = \{z\}$; thus $z_n = z$, contradicting our choice of z_n.

THEOREM 2.2. *Let X be an Asplund space and $\tau > 0$ be such that*

$$\inf\{\|x^*\| :\ x^* \in \tilde{\partial} f(x),\ x \in X \text{ and } f(x) > \lambda\} \ge \tau. \tag{2.2}$$

Then f has global weak sharp minima with a constant τ.

Proof. Suppose not; then by Theorem 2.1 there exist $x_0 \in X$ and $\lambda_0 > \lambda$ such that

$$\tau dist(x_0, S_{\lambda_0}) > f(x_0) - \lambda,$$

that is,

$$f(x_0) < \inf\{f(x) :\ x \in X\} + \tau dist(x_0, S_{\lambda_0}).$$

Pick $\alpha > 0$ such that

$$f(x_0) < \inf\{f(x) :\ x \in X\} + (\tau - \alpha)(dist(x_0, S_{\lambda_0}) - \alpha).$$

By the Ekeland variational principle (cf. [5, Theorem 7.5.1]), there exists $v \in X$ such that

(i) $\|v - x_0\| < dist(x_0, S_{\lambda_0}) - \alpha$,
(ii) $f(v) < f(x) + (\tau - \alpha)\|x - v\|$ for each $x \in X \setminus \{v\}$.

Since X is an Asplund space, it follows from (ii) and Theorem 2.12 in [22] that there exist $u_i \in X$ and $x_i^* \in X^*$ $(i = 1, 2)$ such that

$$\|u_i - v\| < \alpha \quad (i = 1, 2), \tag{2.3}$$

$$x_1^* \in \tilde{\partial} f(u_1), \quad x_2^* \in (\tau - \alpha)\partial(\|\cdot - v\|)(u_2), \quad \text{and} \quad \|x_1^* + x_2^*\| < \alpha.$$

It follows from the fact that $\partial(\|\cdot - v\|)(u_2) \subset \{x^* \in X^* : \|x^*\| \le 1\}$ that

$$\|x_1^*\| < \|x_2^*\| + \alpha \le \tau.$$

Therefore,

$$\inf\{\|x^*\| : x^* \in \tilde{\partial} f(u_1)\} < \tau. \tag{2.4}$$

On the other hand, by (2.3) and (i), one has that $u_1 \notin S_{\lambda_0}$, and so $f(u_1) > \lambda_0 > \lambda$. Thus (2.4) contradicts the given assumption (2.2).

The following result concerns the constrained case.

THEOREM 2.3. *Let X be an Asplund space, K a closed nonempty subset of X, and f a locally Lipschitz function on X. Let $\lambda_K := \inf\{f(x) : x \in K\}$ be finite. Assume that there exists $\tau > 0$ such that for each $x \in K$ with $f(x) > \lambda_K$,*

$$\inf\{\|x^* + y^*\| : x^* \in \partial f(x) \text{ and } y^* \in N(K, x)\} \ge \tau. \tag{2.5}$$

Then $S(\lambda_K) := \{x \in K : f(x) = \lambda_K\} \ne \emptyset$ and

$$\tau dist(x, S(\lambda_K)) \le f(x) - \lambda_K \qquad \forall x \in K.$$

Proof. Let $\phi = f + \delta_K$. Then ϕ is a proper lower semicontinuous function on X, $\inf\{\phi(x) : x \in X\} = \lambda_K$, and $S(\lambda_K) = \{x \in X : \phi(x) = \lambda_K\}$. It suffices to show that ϕ has global weak sharp minima with constant τ. By Theorem 4.1 in [14], for each $x \in K$

$$\partial\phi(x) = \partial(f + \delta_K)(x) \subset \partial f(x) + \partial\delta_K(x) = \partial f(x) + N(K, x).$$

Thus (2.5) reads $\inf\{\|z^*\| : z^* \in \partial\phi(x)\} \ge \tau$ for each $x \in K$ with $f(x) > \lambda_K$. Since $\tilde{\partial}\phi(x) = \emptyset$ for each $x \notin K$ and since $\tilde{\partial}\phi(x) \subset \partial\phi(x)$ for each $x \in K$ with $\phi(x) > \lambda_K$, it follows that

$$\inf\{\|z^*\| : z^* \in \tilde{\partial}\phi(x), x \in X \text{ and } \phi(x) > \lambda_K\} \ge \tau.$$

Thus Theorem 2.2 imples that ϕ has global weak sharp minima with the constant τ.

Remark. From the proofs of Theorems 2.2 and 2.3, it is clear that we can generalize these two theorems to any triple $(X, \mathcal{F}, \partial_a)$, where X is a Banach space, $\mathcal{F}$ a function space on X, and ∂_a is an abstract subdifferential operator with appropriate properties. For example, we can take $\mathcal{F}$ to be the set of all proper lower semicontinuous functions from X to $R \cup \{\infty\}$ and $\partial_a : \mathcal{F} \times X \to 2^{X^*}$ with the following properties:

(i) For each equivalent norm $\|\cdot\|_e$ of X and each $x \in X$,

$$\partial_a\|\cdot\|_e(x) = \{x^* : \langle x^*, h\rangle \le \|x + h\|_e - \|x\|_e, \ h \in X\}.$$

(ii) For any $g \in \mathcal{F}$ and any equivalent norm $\|\cdot\|_e$ of X, if $v \in X$ is a minimum point of $g + \|\cdot\|_e$ on X, then for any $\varepsilon > 0$ there exist $v_1, v_2 \in X$ and $x_1^*, x_2^* \in X^*$ such that

$$\|v_i - v\| < \varepsilon \ \ (i = 1, 2), \ \ x_1^* \in \partial_a g(v_1), \ \ x_2^* \in \partial_a\|\cdot\|_e(v_2), \text{ and } \|x_1^* + x_2^*\| < \varepsilon.$$

In this setup, following the proof of Theorem 2.2 one can obtain the following result: $f \in \mathcal{F}$ has weak sharp minimum with a constant $\tau > 0$ if

$$\inf\{\|x^*\| : x^* \in \partial_a f(x),\ x \in X \text{ with } f(x) > \lambda\} \geq \tau.$$

After the completion of our first draft, we learnt that Wu and Ye [21] have obtained an error bound result similar to Theorem 2.2 in terms of the abstract subdifferential. Jourani [11] also proved an error bound result similar to Theorem 2.2, but some stronger assumptions are added on the abstract subdifferential. In the approach of both [21] and [11], the solution set S is required to be nonempty as an assumption (the proof of [11] requires this assumption though it is not explicitly mentioned). Theorem 2.2 allows us to show that this assumption is automatically satisfied.

The following two propositions tell us that the scenario of weak sharp minima only happens for nonsmooth functions when either f is convex or X is finite dimensional.

PROPOSITION 2.4. *Let X be a finite dimensional space. Suppose that f is a differentiable function on X and that $f(\cdot)$ is not constant on X. Then f has no weak sharp minina.*

Proof. Suppose to the contrary that f has global weak sharp minima with constant $\tau > 0$. Then

$$\tau dist(x, S_\lambda) \leq f(x) - \lambda \qquad \forall x \in X. \tag{2.6}$$

Since f is not constant, one can pick $z \notin S_\lambda$. Since S_λ is a nonempty closed subset of the finite dimensional space X, there exists $x_0 \in S_\lambda$ such that $\|z - x_0\| = dist(z, S_\lambda)$. It follows that for each $t \in (0,\ 1]$,

$$\tau t\|z-x_0\| = \tau dist(x_0+t(z-x_0), S_\lambda) \leq f(x_0+t(z-x_0))-\lambda = f(x_0+t(z-x_0))-f(x_0).$$

Thus $0 < \tau\|z - x_0\| \leq df(x_0)(z - x_0) = \bigtriangledown f(x_0)(z - x_0)$, and so $\bigtriangledown f(x_0) \neq 0$, contradicting the fact that x_0 is a minimizer of f.

PROPOSITION 2.5. *Let f be a differentiable convex function on a Banach space X. Suppose that $f(\cdot)$ is not constant on X. Then f has no weak sharp minima.*

Proof. Suppose to the contrary that (2.6) holds. By the convexity and continuity of f, S_λ is a closed convex subset of X. Noting that ∂S_λ is nonempty, it follows from the Bishop–Phelps theorem that S_λ has support points, that is, there exist $x_0 \in S_\lambda$ and $x^* \in X^*$ with $\|x^*\| = 1$ such that

$$\langle x^*, x_0\rangle = \sup\{\langle x^*, x\rangle : x \in S_\lambda\}. \tag{2.7}$$

Pick $h \in X$ such that $\|h\| = 1$ and $\langle x^*, h\rangle > \frac{1}{2}$. This implies that $dist(th, \ker(x^*)) > \frac{1}{2}t$ for each $t \in (0,\ 1]$, where $\ker(x^*) = \{x \in X : \langle x^*, x\rangle = 0\}$. It is easy to verify from (2.7) that for each $t \in (0,\ 1]$,

$$\frac{1}{2}t \leq dist(th, \ker(x^*)) = dist(x_0 + th, x_0 + \ker(x^*)) \leq dist(x_0 + th, S_\lambda).$$

This and (2.6) imply that for each $t \in (0,\ 1)$,

$$\frac{1}{2}t\tau \leq f(x_0 + th) - \lambda = f(x_0 + th) - f(x_0).$$

It follows that $\frac{1}{2}\tau \leq df(x_0)(h) = \bigtriangledown f(x_0)(h)$, and so $\bigtriangledown f(x_0) \neq 0$. This contradicts the fact that x_0 is a minimizer of f.

3. Characterizations of weak sharp minima for convex functions. Throughout this section, we assume that X is a Banach space, $f : X \to R \cup \{\infty\}$ is a proper lower semicontinuous convex function and that $\lambda = \inf\{f(x) : \ x \in X\} > -\infty$. Let $\mathrm{dom}(f) := \{x \in X : \ f(x) < \infty\}$. Thus f is continuous on each line segment contained in $\mathrm{dom}(f)$. For $x_1, x_2 \in X$, $(x_1, \ x_2]$ denotes the line segment $\{tx_1 + (1-t)x_2 : \ 0 < t \leq 1\}$. Similar notations $(x_1, \ x_2)$ and $[x_1, \ x_2]$ are self-explanatory. For any $\alpha \geq \lambda$, let $S_\alpha := \{x \in X : \ f(x) \leq \alpha\}$. We write

$$\begin{aligned} x \to S_\alpha \ \text{ if } x \notin S_\alpha \text{ and } dist(x, S_\alpha) \to 0, \\ x_f \to S_\alpha \ \text{ if } x \notin S_\alpha \text{ and } f(x) \to \alpha, \\ \text{and } \ x \xrightarrow{f} S_\alpha \ \text{ if } x \to S_\alpha \text{ and } x_f \to S_\alpha. \end{aligned}$$

For an extended real-valued function ϕ on X, $\delta > 0$ and $\alpha \geq \lambda$, let

$$\begin{aligned} &\phi_\alpha^{(1)}(\delta) := \inf\{\phi(x) : \ x \in X \text{ with } 0 < dist(x, S_\alpha) < \delta\}, \\ &\phi_\alpha^{(2)}(\delta) := \inf\{\phi(x) : \ x \in X \text{ with } 0 < f(x) - \alpha < \delta\}, \\ \text{and} \quad &\phi_\alpha^{(1,2)}(\delta) := \inf\{\phi(x) : \ x \in X \text{ with } 0 < \max\{dist(x, S_\alpha), f(x) - \alpha\} < \delta\}. \end{aligned}$$

Thus, one has that

$$\begin{aligned} \liminf_{x \to S_\alpha} \phi(x) &= \lim_{\delta \to 0^+} \phi_\alpha^{(1)}(\delta), \\ \liminf_{x_f \to S_\alpha} \phi(x) &= \lim_{\delta \to 0^+} \phi_\alpha^{(2)}(\delta), \\ \text{and} \quad \liminf_{x \xrightarrow{f} S_\alpha} \phi(x) &= \lim_{\delta \to 0^+} \phi_\alpha^{(1,2)}(\delta). \end{aligned}$$

Below we introduce various kinds of "lower derivatives" of f at the set S_α (rather than the usual ones at a point) with $\alpha \geq \lambda$. These derivatives are defined by

$$\begin{aligned} \underline{D}_1(f, S_\alpha) &:= \liminf_{x \to S_\alpha} \frac{f(x) - \alpha}{dist(x, S_\alpha)}, \\ \underline{D}_2(f, S_\alpha) &:= \liminf_{x_f \to S_\alpha} \frac{f(x) - \alpha}{dist(x, S_\alpha)}, \\ \text{and} \ \ \underline{D}_{1,2}(f, S_\alpha) &:= \liminf_{x \xrightarrow{f} S_\alpha} \frac{f(x) - \alpha}{dist(x, S_\alpha)}. \end{aligned}$$

If $\alpha \in (\lambda, \ \infty)$, then $S_\alpha \neq \emptyset$ and so $\underline{D}_1(f, S_\alpha)$, $\underline{D}_2(f, S_\alpha)$, and $\underline{D}_{1,2}(f, S_\alpha)$ are well defined. If $\alpha = \lambda$, it is possible that $S_\alpha = \emptyset$; in this case, we define $dist(x, S_\alpha) = \infty$ and these lower derivatives are to be understood as 0. Note also that

$$\underline{D}_{1,2}(f, S_\alpha) \geq \max\{\underline{D}_1(f, S_\alpha), \ \underline{D}_2(f, S_\alpha)\}.$$

Remark. By definition, $\underline{D}_{1,2}(f, S_\alpha) > 0$ means $S_\alpha \neq \emptyset$ and that there exist $\delta > 0$ and $\tau > 0$ such that

$$\tau dist(x, S_\alpha) \leq f(x) - \alpha \ \text{ for any } x \in X \text{ with } \max\{dist(x, S_\alpha), f(x) - \alpha\} < \delta.$$

Similar observations can be made for the case when $\underline{D}_1(f, S_\alpha) > 0$ or $\underline{D}_2(f, S_\alpha) > 0$. The following lemma will be a useful tool for us.

LEMMA 3.1. *Let $\alpha \geq \lambda$, $S_\alpha \neq \emptyset$, and $x \in \mathrm{dom}(f) \setminus S_\alpha$. Let $\varepsilon > 0$ and $\delta > 0$ be such that*

$$\delta < \max\{dist(x, S_\alpha),\ f(x) - \alpha\}. \tag{3.1}$$

Then there exist $s \in S_\alpha$ with $f(s) = \alpha$, and $y \in (s,\ x)$ such that

(a) $\delta = \max\{dist(y, S_\alpha), f(y) - \alpha\}$,
(b) $(s,\ x] \cap S_\alpha = \emptyset$,
(c) $\|y - s\| < (1 + \varepsilon) dist(y, S_\alpha)$,
(d) $\|x - s\| < (1 + \varepsilon) dist(x, S_\alpha)$,
(e)

$$\frac{f(y) - \alpha}{dist(y, S_\alpha)} \leq (1 + \varepsilon) \frac{f(x) - \alpha}{dist(x, S_\alpha)}.$$

Proof. Take a sequence $\{s_n\}$ in S_α such that

$$\|x - s_n\| \to dist(x, S_\alpha). \tag{3.2}$$

For each n, we may assume without loss of generality that $(s_n,\ x] \cap S_\alpha = \emptyset$ and $f(s_n) = \alpha$. It follows from (3.1) and the intermediate value theorem that there exists $y_n \in (s_n,\ x)$ such that

$$\delta = \max\{dist(y_n, S_\alpha),\ f(y_n) - \alpha\}. \tag{3.3}$$

Write $y_n = s_n + t_n(x - s_n)$ for some $t_n \in (0,\ 1)$; it follows from the convexity of f that

$$f(y_n) \leq (1 - t_n) f(s_n) + t_n f(x) = \alpha + t_n(f(x) - \alpha). \tag{3.4}$$

We claim that

$$\frac{t_n \|x - s_n\|}{dist(y_n, S_\alpha)} \to 1. \tag{3.5}$$

Indeed, if this is not the case, then, by $dist(y_n, S_\alpha) \leq \|y_n - s_n\| = t_n \|x - s_n\|$, one can assume that

$$\frac{t_n \|x - s_n\|}{dist(y_n, S_\alpha)} \to \beta > 1 \tag{3.6}$$

(passing to a subsequence if necessary). Since $\|s_n - x\| \to dist(x, S_\alpha)$, one can assume without loss of generality that for each n

$$t_n > \frac{dist(y_n, S_\alpha)}{dist(x, S_\alpha)}. \tag{3.7}$$

By (3.4), one also has that $t_n \geq \frac{f(y_n) - \alpha}{f(x) - \alpha}$ for each n. Setting $r = \min\{\frac{1}{dist(x, S_\alpha)}\ ,\ \frac{1}{f(x) - \alpha}\}$, it follows from (3.7) and (3.3) that for each n,

$$t_n \geq r \max\{dist(y_n, S_\alpha),\ f(y_n) - \alpha\} = r\delta.$$

Since $t_n \in (0,\ 1)$, one can assume without loss of generality that $t_n \to t$ for some t. Then $t \geq r\delta > 0$. Since

$$dist(x, S_\alpha) \leq \|x - y_n\| + dist(y_n, S_\alpha) = (1 - t_n)\|x - s_n\| + dist(y_n, S_\alpha),$$

$$\frac{dist(x, S_\alpha)}{\|x - s_n\|} \leq 1 - t_n + \frac{dist(y_n, S_\alpha)}{\|x - s_n\|}.$$

Letting $n \to \infty$, it follows from (3.2) and (3.6) that $1 \leq 1 - t + \frac{t}{\beta}$. This is not possible as $\beta > 1$ and $t > 0$. Therefore (3.5) is true and so

$$\frac{\|y_n - s_n\|}{dist(y_n, S_\alpha)} \to 1. \tag{3.8}$$

Moreover, rewrite (3.4) in the form

$$\frac{f(y_n) - \alpha}{dist(y_n, S_\alpha)} \leq \frac{t_n(f(x) - \alpha)}{dist(y_n, S_\alpha)} \frac{\|x - s_n\|}{\|x - s_n\|}$$

and note that the right-hand side converges to $\frac{f(x)-\alpha}{dist(x,S_\alpha)}$ by (3.5) and (3.2). It follows from (3.8) and (3.2) that if we take $y = y_n$ for large enough n, then (e), (d), and (c) are satisfied.

PROPOSITION 3.2. *$\underline{D}_1(f, S_\alpha)$, $\underline{D}_2(f, S_\alpha)$, and $\underline{D}_{1,2}(f, S_\alpha)$ are increasing on the interval $[\lambda, \infty)$ with respect to α.*

Proof. We need only show the conclusion to hold for $\underline{D}_1$ as proofs are similar for $\underline{D}_2$ and $\underline{D}_{1,2}$. Let $\alpha_1 > \alpha_2 \geq \lambda$. By way of contradiction we suppose that

$$\underline{D}_1(f, S_{\alpha_1}) < r < \underline{D}_1(f, S_{\alpha_2}) \tag{3.9}$$

for some $r \in R$. Then there exists $z \in \mathrm{dom}(f) \setminus S_{\alpha_1}$ such that

$$\frac{f(z) - \alpha_1}{dist(z, S_{\alpha_1})} < r. \tag{3.10}$$

By Lemma 3.1, for every natural number n there exist $x_n \in S_{\alpha_2}$ with

$$f(x_n) = \alpha_2 \quad \text{and} \quad (x_n,\ z] \cap S_{\alpha_2} = \emptyset$$

and $y_n \in (x_n,\ z]$ such that

$$\|y_n - x_n\| < \left(1 + \frac{1}{n}\right) dist(y_n, S_{\alpha_2}) \tag{3.11}$$

and

$$\max\{dist(y_n, S_{\alpha_2}), f(y_n) - \alpha_2\} = \frac{\alpha_1 - \alpha_2}{2n}. \tag{3.12}$$

In particular, $dist(y_n, S_{\alpha_2}) \to 0$ and by definition,

$$\underline{D}_1(f, S_{\alpha_2}) \leq \liminf_{n\to\infty} \frac{f(y_n) - \alpha_2}{dist(y_n, S_{\alpha_2})}.$$

By (3.12), one has that $f(y_n) < \alpha_1 < f(z)$. Take w_n in the open segment $(y_n,\ z)$ such that $f(w_n) = \alpha_1$. Since f is convex and since $w_n \in (y_n,\ z] \subset (x_n,\ z]$, one has

$$\frac{f(z) - f(w_n)}{\|z - w_n\|} \geq \frac{f(y_n) - f(x_n)}{\|y_n - x_n\|},$$

that is,

$$\frac{f(z)-\alpha_1}{\|z-w_n\|} \geq \frac{f(y_n)-\alpha_2}{\|y_n-x_n\|}.$$

Thus,

$$\frac{f(z)-\alpha_1}{dist(z,S_{\alpha_1})} \geq \frac{f(y_n)-\alpha_2}{\|y_n-x_n\|}.$$

It follows from (3.10) and (3.11) that

$$\left(1+\frac{1}{n}\right) r \geq \frac{f(y_n)-\alpha_2}{dist(y_n,S_{\alpha_2})} \qquad \text{for each } n$$

and so

$$r \geq \liminf_{n\to\infty} \frac{f(y_n)-\alpha_2}{dist(y_n,S_{\alpha_2})} \geq \underline{D}_1(f,S_{\alpha_2}),$$

contradicting (3.9).

THEOREM 3.3. *Let $\tau > 0$ be a constant. The following statements are equivalent.*

(i) $\inf\{\|x^*\| :\ x^* \in \partial f(X \setminus S_\lambda)\} \geq \tau$.
(ii) $\liminf_{x\ f\to S_\lambda} \inf\{\|x^*\| :\ x^* \in \partial f(x)\} \geq \tau$.
(iii) $S_\lambda \neq \emptyset$ *and* $\liminf_{x\to S_\lambda} \inf\{\|x^*\| :\ x^* \in \partial f(x)\} \geq \tau$.
(iv) $S_\lambda \neq \emptyset$ *and* $\liminf_{x\xrightarrow{f} S_\lambda} \inf\{\|x^*\| :\ x^* \in \partial f(x)\} \geq \tau$.
(v) $S_\lambda \neq \emptyset$ *and* $\underline{D}_1(f,S_\lambda) \geq \tau$.
(vi) $S_\lambda \neq \emptyset$ *and* $\underline{D}_2(f,S_\lambda) \geq \tau$.
(vii) $S_\lambda \neq \emptyset$ *and* $\underline{D}_{1,2}(f,S_\lambda) \geq \tau$.
(viii) *f has global weak sharp minima with constant τ.*

Consequently $\underline{D}_1(f,S_\lambda)$, $\underline{D}_2(f,S_\lambda)$, and $\underline{D}_{1,2}(f,S_\lambda)$ coincide: all equal zero if f does not have global weak sharp minima, and otherwise all equal the largest weak sharp minimum constant of f.

Proof. We need only prove the equivalence of (i)–(viii). It is clear that (i)⇒(ii) (and hence (i)⇒(iii) by virtue of the implication (ii)⇒(iv) to be proved below), (iii)⇒(iv), (v)⇒(vii), (vi)⇒(vii), (viii)⇒(v), and (viii)⇒(vi).

(ii)⇒(iv). Suppose that (ii) holds. We need only show that $S_\lambda \neq \emptyset$. Let $r \in (0,\ \tau)$; then by (ii) there exists $\delta > 0$ such that for each $x \in X \setminus S_\lambda$ with $f(x) < \lambda + \delta$

$$\inf\{\|x^*\| :\ x^* \in \partial f(x)\} > r. \tag{3.13}$$

Pick $x_1 \in X$ such that $f(x_1) < \lambda + \min\{\delta,\ r\}$. By the Ekeland variational principle there exists $y_1 \in X$ such that

(a) $f(y_1) \leq f(x_1)$,
(b) $f(y_1) < f(x) + \min\{\delta,\ r\}\|x - y_1\|$ for any $x \neq y_1$.

By (a), $f(y_1) < \lambda + \delta$; by (b), one has that

$$\inf\{\|x^*\| :\ x^* \in \partial f(y_1)\} \leq r.$$

It follows from (3.13) that $y_1 \in S_\lambda$, and so $S_\lambda \neq \emptyset$.

(iv)⇒(vii). Suppose that (iv) holds. Let $r \in (0,\ \tau)$. Then there exists $\delta > 0$ such that for any $x \in X \setminus S_\lambda$ with $\max\{dist(x,S_\lambda), f(x) - \lambda\} < \delta$,

$$\inf\{\|x^*\| :\ x^* \in \partial f(x)\} > r. \tag{3.14}$$

We claim that $\underline{D}_{1,2}(f, S_\lambda) \geq r$. To see this, suppose to the contrary that there exists $x_1 \in X \setminus S_\lambda$ with

$$\max\{dist(x_1, S_\lambda),\ f(x_1) - \lambda\} < \frac{\delta}{2}$$

such that $\frac{f(x_1)-\lambda}{dist(x_1,S_\lambda)} < r$, that is,

$$f(x_1) < \lambda + r dist(x_1, S_\lambda).$$

Using the Ekeland variational principle, there exists $y_1 \in X$ such that

(c) $f(y_1) \leq f(x_1)$,
(d) $\|y_1 - x_1\| < dist(x_1, S_\lambda) < \frac{\delta}{2}$,
(e) $f(y_1) < f(x) + r\|x - y_1\|$ for all $x \neq y_1$.

Note that (d) and (c) imply that $y_1 \in X \setminus S_\lambda$ and that $\max\{dist(y_1, S_\lambda), f(y_1) - \lambda\} < \delta$; (e) entails that

$$\inf\{\|y^*\| :\ y^* \in \partial f(y_1)\} \leq r.$$

This contradicts (3.14). Therefore $\underline{D}_{1,2}(f, S_\lambda) \geq r$ whenever $r \in (0, \tau)$, and (vii) is seen to hold.

(vii)⇒(viii). Suppose that (vii) holds. Let $r \in (0,\ \tau)$. Then there exists $\delta > 0$ such that for each $x \in X \setminus S_\lambda$ with $\max\{dist(x, S_\lambda), f(x) - \lambda\} \leq \delta$,

$$\frac{f(x) - \lambda}{dist(x, S_\lambda)} > r. \tag{3.15}$$

On the other hand, let $z \in X$ with $\max\{dist(z, S_\lambda), f(z) - \lambda\} > \delta$. Let $\varepsilon > 0$. By Lemma 3.1 there exists $y \in X$ such that

$$\max\{dist(y, S_\lambda), f(y) - \lambda\} = \delta \qquad \text{and} \qquad \frac{f(y) - \lambda}{dist(y, S_\lambda)} \leq (1 + \varepsilon)\frac{f(z) - \lambda}{dist(z, S_\lambda)}.$$

It follows from (3.15) that $r dist(z, S_\lambda) \leq (1+\varepsilon)(f(z)-\lambda)$. Letting $\varepsilon \to 0$, $r dist(z, S_\lambda) \leq f(z) - \lambda$. This and (3.15) imply that $r dist(\cdot, S_\lambda) \leq f(\cdot) - \lambda$ on X. Letting $r \to \tau$, (viii) is seen to hold.

(viii)⇒(i). Suppose that (viii) holds: for any $x \in X \setminus S_\lambda$

$$\tau dist(x, S_\lambda) \leq f(x) - \lambda.$$

Let $r \in (0,\ \tau)$. Then there exists $x_\lambda \in S_\lambda$ such that

$$r\|x - x_\lambda\| < \tau dist(x, S_\lambda) \leq f(x) - \lambda = f(x) - f(x_\lambda).$$

It follows that for any $x^* \in \partial f(x)$,

$$\langle x^*, x_\lambda - x\rangle \leq f(x_\lambda) - f(x) \leq -r\|x - x_\lambda\|,$$

and so $\|x^*\| \geq r$. This shows that

$$\inf\{\|x^*\| :\ x^* \in \partial f(x)\} \geq r.$$

Letting $r \to \tau$, (i) is seen to hold. This completes the proof.

Remarks. (i) Let $\mu := \sup\{f(x) : x \in \mathrm{dom}(f)\}$, and for each $\alpha \in [\lambda, \mu)$, let $f_\alpha(x) = \max\{f(x), \alpha\}$ $(x \in X)$. Then f_α is a proper lower semicontinuous convex function, $\inf\{f_\alpha(x) : x \in X\} = \alpha$. By definition,

$$\underline{D}_1(f, S_\alpha) = \underline{D}_1(f_\alpha, S_\alpha), \ \underline{D}_2(f, S_\alpha) = \underline{D}_2(f_\alpha, S_\alpha), \text{ and } \underline{D}_{1,2}(f, S_\alpha) = \underline{D}_{1,2}(f_\alpha, S_\alpha)$$

for any $\alpha \in [\lambda, \mu)$. By Theorem 3.3, these lower derivatives coincide: all equal zero if f_α does not have weak sharp minima, and otherwise all equal the largest weak sharp minima constant of f_α.

(ii) If $\mu \neq \infty$, then, for any $\alpha \in [\mu, \infty)$, $S_\alpha = S_\mu = \mathrm{dom}(f) \neq \emptyset$ and $f(x) - \alpha = \infty$ for any $x \notin S_\alpha$. Thus, by definition, for any $\alpha \in [\mu, \infty)$,

$$\underline{D}_1(f, S_\alpha) = \underline{D}_2(f, S_\alpha) = \underline{D}_{1,2}(f, S_\alpha) = \infty. \tag{3.16}$$

(iii) By virtue of the preceding remarks (i) and (ii), we shall write $\underline{D}$ in place of $\underline{D}_1$, $\underline{D}_2$, and $\underline{D}_{1,2}$.

The first assertion of following corollary is a consequence of remarks (i) and (ii), while the second assertion is that of Proposition 3.2.

COROLLARY 3.4. *For any $\alpha \in [\lambda, \infty)$, let*

$$\Gamma_\alpha := \{\gamma \geq 0 : \gamma dist(x, S_\alpha) \leq [f(x) - \alpha]_+ \text{ for any } x \in X\}$$

and $\tau_\alpha = \sup\{\gamma : \gamma \in \Gamma_\alpha\}$. Then

$$\underline{D}(f, S_\alpha) = \tau_\alpha.$$

Consequently, $\tau_\alpha \leq \tau_\beta$ whenever $\beta \geq \alpha \geq \lambda$.

COROLLARY 3.5. *Let $\lambda \leq \beta < \infty$. Then $\lim_{\alpha \to \beta^+} \underline{D}(f, S_\alpha) = \underline{D}(f, S_\beta)$.*

Proof. In view of (3.16), we need only consider the case when $\beta \in [\lambda, \mu)$. Then by Proposition 3.2,

$$\lim_{\alpha \to \beta^+} \underline{D}(f, S_\alpha) \geq \underline{D}(f, S_\beta). \tag{3.17}$$

If inequality in (3.17) is strict, then there exists $\tau \in R$ such that

$$\lim_{\alpha \to \beta^+} \underline{D}(f, , S_\alpha) > \tau > \underline{D}(f, S_\beta) \ (\geq 0). \tag{3.18}$$

Take a sequence $\{\alpha_n\}$ in (β, μ) with $\alpha_n \to \beta^+$. Then $\underline{D}(f, S_{\alpha_n}) > \tau$. By Corollary 3.4, this implies that $\tau \in \Gamma_{\alpha_n}$ and hence

$$\tau dist(x, S_{\alpha_n}) \leq [f(x) - \alpha_n]_+ \leq [f(x) - \beta]_+ \qquad \forall x \in X.$$

It follows that

$$\tau \liminf_{n \to \infty} dist(x, S_{\alpha_n}) \leq [f(x) - \beta]_+ \qquad \forall x \in X.$$

By Theorem 2.1 (applying to $[f(x) - \beta]_+$), one can show easily that

$$\tau dist(x, S_\beta) \leq [f(x) - \beta]_+ \qquad \forall x \in X.$$

Therefore, $\tau \in \Gamma_\beta$ and hence $\underline{D}(f, S_\beta) \geq \tau$, contradicting (3.18).

Corollary 3.5 and Theorem 3.3 imply that f has weak sharp minimum if and only if $\lim_{\alpha\to\lambda^+} \underline{D}(f, S_\alpha) > 0$.

If X is assumed to be reflexive, one has the following characterization.

THEOREM 3.6. *Let X be a reflexive Banach space and $S_\lambda \neq \emptyset$. Then f has global weak sharp minima with constant $\tau > 0$ if and only if for each $x \in S_\lambda$ there exists $\delta_x > 0$ such that*

$$\inf\{\|x^*\| : x^* \in \partial f(B(x, \delta_x) \setminus S_\lambda)\} \geq \tau. \tag{3.19}$$

Proof. The necessity is a consequence of Theorem 3.3.

For any $x \in \mathrm{dom}(f) \setminus S_\lambda$, there exists $x_0 \in S_\lambda$ such that $f(x_0) = \lambda$, $(x_0,\ x] \cap S_\lambda = \emptyset$, and $\|x - x_0\| = dist(x, S_\lambda)$ (because of the lower semicontinuity and convexity of f and the reflexivity of X). It is clear that $\|y - x_0\| = dist(y, S_\lambda)$ for each $y \in (x_0,\ x]$. We assert that

$$\tau dist(y, S_\lambda) \leq f(y) - \lambda \text{ for each } y \in (x_0,\ x] \cap B\left(x_0, \frac{\delta_{x_0}}{2}\right). \tag{3.20}$$

Granting this, one sees that the convexity of f implies that for each $y \in (x_0,\ x] \cap B(x_0, \frac{\delta_{x_0}}{2})$

$$\tau \leq \frac{f(y) - \lambda}{dist(y, S_\lambda)} = \frac{f(y) - f(x_0)}{\|y - x_0\|} \leq \frac{f(x) - f(x_0)}{\|x - x_0\|} = \frac{f(x) - \lambda}{dist(x, S_\lambda)}$$

and so $\tau dist(x, S_\lambda) \leq f(x) - \lambda$. Thus it remains to show that (3.20) holds. Suppose to the contrary that there exists $y_0 \in (x_0,\ x] \cap B(x_0, \frac{\delta_{x_0}}{2})$ and $0 < \gamma < \tau$ such that $f(y_0) < \lambda + \gamma\|y_0 - x_0\|$. By the Ekeland variational principle, there exists $v \in X$ such that

(a) $\|v - y_0\| < \|y_0 - x_0\|$,

(b) $f(v) < f(z) + \gamma\|z - v\|$ for all $z \neq v$.

Since $dist(y_0, S_\lambda) = \|y_0 - x_0\| < \frac{\delta_{x_0}}{2}$,

(a) implies that $v \in B(x_0, \delta_{x_0}) \setminus S_\lambda$. On the other hand,

(b) implies that $\inf\{\|v^*\| : v^* \in \partial f(v)\} \leq \gamma < \tau$.

This contradicts (3.19).

If f is further assumed to be continuous, one can obtain another characterization. For any $\alpha > \lambda$, let $L_\alpha := \{x \in X : f(x) = \alpha\}$.

THEOREM 3.7. *Let X be a reflexive Banach space and f a continuous convex function on X, and let $\tau > 0$ be a constant. Then f has weak sharp minimum with the constant τ if and only if there exists a sequence $\{\lambda_n\}$ with $\lambda_n \to \lambda^+$ such that*

$$\limsup_{n\to\infty} \inf\{\|x^*\| : x^* \in \partial f(L_{\lambda_n})\} \geq \tau. \tag{3.21}$$

Proof. Suppose that (3.21) holds for some sequence $\{\lambda_n\}$ with $\lambda_n \to \lambda^+$. Then

$$\tau \liminf_{n\to\infty} dist(x, S_{\lambda_n}) \leq f(x) - \lambda. \tag{3.22}$$

Indeed, if this is not the case, then there exist $\tau_0 \in (0,\ \tau)$ and $x_0 \in X$ with $f(x_0) > \lambda$ such that

$$\tau_0 \liminf_{n\to\infty} dist(x_0, S_{\lambda_n}) > f(x_0) - \lambda.$$

Since $\lambda_n \to \lambda_+$, we can assume without loss of generality that for all n, $f(x_0) > \lambda_n$ and

$$\tau_0 dist(x_0, S_{\lambda_n}) > f(x_0) - \lambda_n. \tag{3.23}$$

By the convexity of f and the reflexivity of X, there exists $x_n \in X$ with $f(x_n) = \lambda_n$ such that $\|x_0 - x_n\| = dist(x_0, S_{\lambda_n})$; thus

$$\mathrm{int}(B(x_0, \|x_0 - x_n\|)) \bigcap S_{\lambda_n} = \emptyset.$$

By the separation theorem there exists $z^* \in X^*$ with $\|z^*\| = 1$ such that

$$\langle z^*, x_0\rangle - \|x_0 - x_n\| = \langle z^*, x_n\rangle = \sup\{\langle z^*, x\rangle : \ x \in S_{\lambda_n}\}.$$

Thus $z^* \in N(S_{\lambda_n}, x_n)$. Since f is continuous and $\lambda_n > \lambda$, $N(S_{\lambda_n}, x_n) = \mathrm{cone}(\partial f(x_n))$. Hence there exist $r > 0$ and $y^* \in \partial f(x_n)$ such that $y^* = rz^*$. Therefore,

$$\|y^*\| dist(x_0, S_{\lambda_n}) = \|y^*\|\|x_0 - x_n\| = \langle y^*, x_0 - x_n\rangle \le f(x_0) - f(x_n) = f(x_0) - \lambda_n.$$

This and (3.23) imply that $\|y^*\| \le \tau_0$, and so

$$\inf\{\|x^*\| : \ x^* \in \partial f(x) \text{ and } x \in X \text{ with } f(x) = \lambda_n\} \le \tau_0,$$

contradicting (3.21). Therefore (3.22) holds, and it follows from Theorem 2.1 that f has global weak sharp minima with the constant τ. The sufficiency part is proved. The necessity part follows easily from Theorem 3.3.

From Theorem 3.3 and Theorem 3.7, one has the following result.

COROLLARY 3.8. *Let X be a reflexive Banach space and f a continuous convex function. Then $\lim_{\beta\to\alpha^+} \inf\{\|x^*\| : \ x^* \in \partial f(L_\beta)\}$ exists for each $\alpha \in [\lambda, \infty)$.*

Proof. Let τ_α be as in Corollary 3.4. Applying Theorem 3.7 to f_α, one can easily check that

$$\limsup_{\beta\to\alpha^+} \inf\{\|x^*\| : \ x^* \in \partial f(L_\beta)\} = \tau_\alpha. \tag{3.24}$$

On the other hand, by Theorem 3.3 (also applied to f_α), one has that $\tau_\alpha \le \inf\{\|x^*\| : x^* \in \partial f(X \setminus S_\alpha)\}$. Hence

$$\liminf_{\beta\to\alpha^+} \inf\{\|x^*\| : \ x^* \in \partial f(L_\beta)\} \ge \tau_\alpha.$$

It follows from (3.24) that

$$\lim_{\beta\to\alpha^+} \inf\{\|x^*\| : \ x^* \in \partial f(L_\beta)\} = \tau_\alpha.$$

This completes the proof.

Remark. Adopting the approach of Theorem 3.1 in [15], one sees that some other characterizations for f to have weak sharp minima can be given in terms of either local versions or the directional derivatives.

Let $x_i^* \in X^*$ and $c_i \in R$ for $i = 1, \ldots, n$. Define $\phi(x) = \max\{\langle x_i^*, x\rangle + c_i : \ i = 1, \ldots, n\}$ for each $x \in X$. Then, ϕ is convex but is in general not Fréchet differentiable on X. Moreover, ϕ has global weak sharp minima if (and only if) ϕ is bounded below. Indeed, let $I(x) = \{i \in I : \ \langle x_i^*, x\rangle + c_i = \phi(x)\}$ for each $x \in X$, where $I = \{1, \ldots, n\}$. Note that $0 \notin \partial\phi(x) = \mathrm{co}\{x_i^* : \ i \in I(x)\}$ for each $x \in X$ with $\phi(x) > \lambda$. It follows from the fact that $\{I(x) : \ x \in X \text{ with } \phi(x) > \lambda\}$ is a finite set that

$$\inf\{\|x^*\| : \ x^* \in \partial\phi(x) \text{ and } x \in X \text{ with } \phi(x) > \lambda\} > 0.$$

This and Theorem 3.6 imply that ϕ has global weak sharp minima.

4. Application to an abstract Hoffman error bound. In 1952, Hoffman [8] established an error bound for a finite system of linear inequalities. Since then, his pioneering work has been generalized in numerous ways. For details, readers may see Pang's survey paper [16]. Recently, Hu and Wang [10], Goberna, Lopez, and Todorov [7], and Hu [9] considered an error bound for the following infinite system of linear inequalities. Let U be an index set; $\mathcal{B}(U, R^n)$ denotes the set of bounded functions $a : U \to R^n$, that is, $a(U) := \{a(u) : u \in U\}$ is bounded. For $a \in \mathcal{B}(U, R^n)$ and $b \in \mathcal{B}(U, R^1)$, define a system of linear inequalities by

$$a(u)^T x \le b(u) \qquad \forall u \in U, \tag{4.1}$$

where $x \in R^n$ and $a(u)^T$ denotes the transpose of $a(u)$.

In this section, applying results in section 3, we will establish error bounds for a more general class of linear inequality systems. Let X and Y be Banach spaces. Let $C \subset Y$ be a closed convex cone, which specifies a preorder "$\le_C$" as follows: for $y_1, y_2 \in Y$, $y_1 \le_C y_2$ if and only if $y_2 - y_1 \in C$. Let $A : X \to Y$ be a bounded linear operator and $b \in Y$. Define an abstract linear inequality system (A, C, b) by

$$A(x) \le_C b, \tag{4.2}$$

where $x \in X$. Let $S_C := \{x \in X : A(x) \le_C b\}$ be the solution set of the system. The system (A, C, b) is said to have an error bound if there exists $\tau > 0$ such that

$$dist(x, S_C) \le \tau dist(Ax - b, -C) \qquad \forall x \in X.$$

In general such a constant τ does not necessarily exist even if X, Y are finite dimensional. In the following we present two sufficient conditions to ensure that (A, C, b) has an error bound.

If $X = R^n$, Y is the space $\mathcal{B}(U, R)$ of all bounded functions on the index set U equipped with the supremum norm, and the cone $C_U := \{y \in \mathcal{B}(U, R) : y(u) \ge 0$ for all $u \in U\}$, and if $A_U : R^n \to \mathcal{B}(U, R)$ is such that $A_U(x)(u) = a(u)^T x$ for each $x \in X$, then it is easily seen that the system (A_U, C_U, b) defined by (4.2) is exactly the system (4.1). Thus (4.2) may be viewed as a generalization of (4.1).

Let C^+ denote the dual cone of C, that is,

$$C^+ := \{y^* \in Y^* : \langle y^*, y\rangle \ge 0 \text{ all } x \in C\}.$$

DEFINITION 4.1. *The system (A, C, b) is said to have property (P) if there exist finitely many closed convex cones $C_1, \ldots, C_m$ in Y satisfying the following conditions:*

(i) *$C \subset C_i$ and $\text{int}C_i \ne \emptyset$ for each $i \in I := \{1, \ldots, m\}$.*

(ii) *$0 \notin A^*(C_i^+ \setminus \{0\})$ for each $i \in I$.*

(iii) *There exists $\alpha > 0$ such that $dist(x, S_C) \le \alpha \max\{dist(x, S_{C_i}) : i \in I\}$ for all $x \in X$, where $S_{C_i} = \{x \in X : A(x) \le_{C_i} b\}$.*

PROPOSITION 4.2. *Let $A : X \to R^m$ be a bounded linear operator and $b = (r_1, \ldots, r_m) \in R^m$. Then (A, R^m_+, b) has property (P).*

Proof. Pick $a_1^*, \ldots, a_m^* \in X^*$ such that $A(x) = (\langle a_1^*, x\rangle, \ldots, \langle a_m^*, x\rangle)$ for each $x \in X$. Write $S_{R^m_+}$ for the set $\{x \in X : Ax \le_C b\}$ with $C = R^m_+$. Let $\mathcal{J} = \{D \subset I : \{a_i^* : i \in D\}$ is linearly independent and $\langle a_i^*, x\rangle = r_i$ for some $x \in S_{R^m_+}$ and each $i \in D\}$. For each $D \in \mathcal{J}$, let $C_D = \{y \in R^m :$ the ith component of y is nonnegative for each $i \in D\}$; then $R^m_+ \subset C_D$, $\text{int}(C_D) \ne \emptyset$, and $C_D^+ = \{y \in R^m_+ :$ the ith component of y is

zero for each $i \in I \setminus D\}$. Therefore, for each $D \in \mathcal{J}$,

$$A^*(C_D^+ \setminus \{0\}) = \left\{ \sum_{i\in D} t_i a_i^* : \ t_i \geq 0 \text{ and } \sum_{i\in D} t_i \neq 0 \right\}.$$

Since $\{a_i^* : \ i \in D\}$ is linearly independent, it follows that $0 \notin A^*(C_D^+ \setminus \{0\})$. Let $X_0 = \{x \in X : \ \langle a_i^*, x\rangle = 0 \text{ for each } i \in I\}$. Then X/X_0 is finite dimensional. For each $x \in X$, let $[x]$ denote the equivalence class containing x in X/X_0, that is, $[x] = x + X_0$. Define $\hat{a}_i^* \in (X/X_0)^*$ such that $\langle \hat{a_i}^*, [x]\rangle = \langle a_i^*, x\rangle$ for each $x \in X$ and $i \in I$. Then, for any $D \subset I$, $\{\hat{a}_i^* : \ i \in D\}$ is linearly independent if and only if $\{a_i^* : \ i \in D\}$ is linearly independent. Let $\hat{S}_{R_+^m} = \{[x] : \ \langle \hat{a}_i^*, [x]\rangle \leq r_i \text{ for each } i \in I\}$ and $\hat{S}_{C_D} = \{[x] : \ \langle \hat{a}_i^*, [x]\rangle \leq r_i \text{ for each } i \in D\}$ for each $D \in \mathcal{J}$. It is easy to verify that $\hat{S}_{R_+^m} = \{[x] : \ x \in S_{R_+^m}\}$ and $\hat{S}_{C_D} = \{[x] : \ x \in S_{C_D}\}$ for each $D \in \mathcal{J}$. Equip X/X_0 with the norm $|||\cdot|||$: $|||[x]||| = \inf\{\|z\| : \ z \in [x] = x + X_0\}$ for each $x \in X$. Then for each $x \in X$ and $D \in \mathcal{J}$,

$$dist([x], \hat{S}_{R_+^m}) = dist(x, S_{R_+^m}) \text{ and } dist([x], \hat{S}_{C_D}) = dist(x, S_{C_D}).$$

Since X/X_0 is finite dimensional, and by [3, Corollary 1.1], one has that for each $x \in X$ there exists $D \in \mathcal{J}$ such that $dist([x], \hat{S}_{R_+^m}) = dist([x], \hat{S}_{C_D})$, that is, $dist(x, S_{R_+^m}) = dist(x, S_{C_D})$. It follows that $dist(x, S_{R_+^m}) \leq \max\{dist(x, S_{C_D}) : \ D \in \mathcal{J}\}$ for each $x \in X$. This shows that (A, R_+^m, b) has property (P).

LEMMA 4.3. *Let Y be a Banach space, $C \subset Y$ a closed convex cone, and $B(C^+) := \{y^* \in C^+ : \ \|y^*\| = 1\}$. Let $g(y) = dist(y, -C)$ for each $y \in Y$. Then the following assertions hold.*

(a) *$\partial g(y) \subset B(C^+)$ for each $y \in Y$ with $g(y) > 0$.*

(b) *$g(y) = \lim_{k\to\infty} \langle y^*, y - h_k\rangle$ for each $y^* \in \partial g(y)$ and each sequence $\{h_k\}$ in $-C$ with $g(y) = \lim_{k\to\infty} \|y - h_k\|$.*

Proof. Let $y \in Y$ and $y^* \in \partial g(y)$. It is easy to verify that $\|y^*\| \leq 1$. Let $\{h_k\}$ be a sequence in $-C$ with $\|y - h_k\| \to dist(y, -C) = g(y)$. Then $g(h_k) = 0$ and

$$\langle y^*, h_k - y\rangle \leq g(h_k) - g(y) = -dist(y, -C).$$

Passing to the limits in

$$g(y) = dist(y, -C) \leq \langle y^*, y - h_k\rangle \leq \|y - h_k\|,$$

it follows that

$$g(y) = \lim_{k\to\infty} \langle y^*, y - h_k\rangle = \lim_{k\to\infty} \|y - h_k\|, \tag{4.3}$$

proving (b). Moreover, if $g(y) > 0$, then (4.3) also entails that $\|y^*\| \geq 1$ and so $\|y^*\| = 1$. It remains to show that $y^* \in C^+$. To do this, let $h \in C$ and $t > 0$. Then $g(-th) = 0$ and $\langle y^*, -th - y\rangle \leq -g(y)$. Letting $t \to +\infty$ in $\langle y^*, h\rangle \geq \frac{g(y) - \langle y^*, y\rangle}{t}$, one has that $\langle y^*, h\rangle \geq 0$ and so $y^* \in C^+$.

THEOREM 4.4. *Let $A : X \to Y$ be a bounded linear operator, $C \subset Y$ a closed convex cone, and $b \in Y$. Assume that the system (A, C, b) has property (P) and $S_C = \{x \in X : \ A(x) \leq_C b\} \neq \emptyset$. Then there exists $\tau \in (0, \ +\infty)$ such that for each $x \in X$,*

$$dist(x, S_C) \leq \tau dist(A(x) - b, -C).$$

Proof. Let $C_1, \ldots, C_m$ be closed convex cones in Y which satisfy (i)–(iii) of Definition 4.1. For each $i \in I = \{1, \ldots, m\}$, pick a $c_i \in \text{int}(C_i)$ and let $\Theta_i := \{y^* \in C_i^+ : \langle y^*, c_i\rangle = 1\}$; it is easy to verify that Θ_i is a bounded weak*-closed (so weak*-compact) subset of Y^* and $C_i^+ = \{ty^* : t \geq 0 \text{ and } y^* \in \Theta_i\}$. For each $i \in I$, let $B_i = \{y^* \in C_i^+ : \|y^*\| = 1\}$; then there exist $0 < \alpha_i < \beta_i < +\infty$ such that

$$B_i \subset [\alpha_i,\ \beta_i]\Theta_i. \tag{4.4}$$

To see (4.4) we use U to denote the unit ball of Y and take $r > 0$ such that $c_i + rU \subset C_i$. Then, for each $y^* \in B_i$, one has that $\langle y^*, c_i - ru\rangle \geq 0$ for each $u \in U$. It follows from $\|y^*\| = 1$ that $\|c_i\| \geq \langle y^*, c_i\rangle \geq r$. Since $\frac{y^*}{\langle y^*, c_i\rangle} \in \Theta_i$, (4.4) is seen to hold with $[\alpha_i,\ \beta_i] = [r,\ \|c_i\|]$. Since the conjugate operator A^* is weak*-weak* continuous, $A^*(\Theta_i)$ is a weak*-compact (hence norm-closed). By (ii) of Definition 4.1, one has that $0 \notin A^*(\Theta_i)$. Therefore,

$$\inf\{\|x^*\| :\ x^* \in A^*(\Theta_i)\} > 0.$$

This and (4.4) imply that

$$\tau_i := \inf\{\|x^*\| :\ x^* \in A^*(B_i)\} > 0, \tag{4.5}$$

valid for each $i \in I$. For each $i \in I$, define $f_i(x) := dist(Ax - b, -C_i)$ and $g_i(y) := dist(y, -C_i)$ for each $x \in X$ and $y \in Y$. Note that f_i and g_i are continuous convex functions, $f_i(x) = g_i(Ax - b)$, $S_{C_i} = \{x \in X :\ f_i(x) \leq 0\}$, and $0 = \inf\{f_i(x) :\ x \in X\}$. Since $\partial f_i(x) = A^*(\partial g_i(Ax - b))$, it follows from Lemma 4.3 that $\partial f_i(x) \subset A^*(B_i)$ for each $x \in X$ with $f_i(x) > 0$. This and (4.5) imply that $\inf\{\|x^*\| :\ x^* \in \partial f_i(x)\} \geq \tau_i$ for each $x \in X$ with $f_i(x) > 0$. It follows from Theorem 3.3 that

$$dist(x, S_{C_i}) \leq \frac{1}{\tau_i} f_i(x) \qquad \forall x \in X.$$

By (iii) of Definition 4.1, one has that for each $x \in X$,

$$dist(x, S_C) \leq \tau \max\{f_i(x) :\ i \in I\},$$

where $\tau = \max\{\frac{\alpha}{\tau_i} :\ i \in I\}$. Since $C \subset C_i$,

$$f_i(x) = dist(Ax - b, -C_i) \leq dist(Ax - b, -C).$$

Hence,

$$dist(x, S_C) \leq \tau dist(Ax - b, -C) \qquad \forall x \in X.$$

This completes the proof.

If X, Y, A, and cone C are, respectively, taken as R^n, $\mathcal{B}(U, R)$, A_U, and C_U in the beginning of this section, then $dist(A_U x - b, -C_U) = \|(A_U x - b)_+\|_\infty$. In view of this and Proposition 4.2, we see that Theorem 4.4 is a generalization of Hoffman's error bound result.

THEOREM 4.5. *Let* $\text{Im}(A) := \{Ax :\ x \in X\}$ *be closed and suppose that* $C + b \subset \text{Im}(A)$. *Then there exists* $\tau \in [0,\ +\infty)$ *such that for each* $x \in X$,

$$dist(x, S_C) \leq \tau dist(Ax - b, -C).$$

Proof. Let $f(x) = dist(Ax - b, -C)$ and $g(x) = dist(y, -C)$ for each $x \in X$ and $y \in Y$. Then $\partial f(x) = A^*(\partial g(Ax - b))$ for each $x \in X$. Let

$$\tau := \sup\{dist(0, A^{-1}(y)) : \ y \in \mathrm{Im}(A) \text{ and } \|y\| = 1\}.$$

It follows from the closedness of $\mathrm{Im}(A)$ and the open mapping theorem that $\tau < +\infty$. For each $x \in X$ with $f(x) > 0$ and $x^* \in \partial f(x)$ there exists $y^* \in \partial g(Ax - b)$ such that $x^* = A^*(y^*)$. Pick a sequence $\{h_k\}$ in $-C$ such that

$$\|Ax - b - h_k\| \to dist(Ax - b, -C) = f(x). \tag{4.6}$$

Since $C + b \subset \mathrm{Im}(A)$, $Ax - b - h_k \in \mathrm{Im}(A)$ for each k. By the definition of τ, for each k there exists $x_k \in X$ such that $Ax_k = Ax - b - h_k$ and $\|x_k\| \le (1 + \frac{1}{k})\tau\|Ax - b - h_k\|$. It follows from $y^* \in \partial g(Ax - b)$ that

$$\begin{aligned} f(x) = g(Ax - b) &\le \langle y^*, Ax - b - h_k\rangle = \langle y^*, Ax_k\rangle = \langle A^*(y^*), x_k\rangle = \langle x^*, x_k\rangle \\ &\le \|x^*\|\|x_k\| \le \|x^*\| \left(1 + \frac{1}{k}\right) \tau\|Ax - b - h_k\|. \end{aligned}$$

This and (4.6) imply that $\|x^*\| \ge \frac{1}{\tau}$. This shows that $\inf\{\|x^*\| : \ x^* \in \partial f(x)\} \ge \frac{1}{\tau}$ for each $x \in X$ with $f(x) > 0$. Since $0 = \inf\{f(x) : \ x \in X\}$ and $S_C = \{x \in X : \ f(x) \le 0\}$, it follows from Theorem 3.3 that for each $x \in X$,

$$dist(x, S_C) \le \tau f(x) = \tau dist(Ax - b, -C).$$

CONTROLLABILITY OF THE SEMILINEAR PARABOLIC EQUATION GOVERNED BY A MULTIPLICATIVE CONTROL IN THE REACTION TERM: A QUALITATIVE APPROACH*

A. Y. KHAPALOV†

Abstract. In this paper we are concerned with the global "nonnegative" approximate controllability property of a rather general semilinear heat equation with superlinear term, governed in a bounded domain $\Omega \subset R^n$ by a multiplicative (bilinear) control in the reaction term like $vu(x,t)$, where v is the control. We show that any nonnegative target state in $L^2(\Omega)$ can approximately be reached from any nonnegative, nonzero initial state by applying at most three static bilinear $L^\infty(\Omega)$-controls subsequently in time. This result is further applied to discuss the controllability properties of the nonhomogeneous version of this problem with bilinear term like $v(u(x,t)-\theta(x))$, where θ is given. Our approach is based on an asymptotic technique allowing us to distinguish and make use of the pure diffusion and/or pure reaction parts of the dynamics of the system at hand, while suppressing the effect of a (general) nonlinear term.

Key words. semilinear parabolic equation, approximate controllability, bilinear control

1. Introduction.

We consider the following Dirichlet boundary problem, governed in a bounded domain $\Omega \subset R^n$ by a multiplicative (*bilinear*) control $v \in L^\infty(Q_T)$ in the reaction term:

$$\text{(S)} \qquad \frac{\partial u}{\partial t} = \Delta u + vu - f(x,t,u,\nabla u) \quad \text{in} \quad Q_T = \Omega \times (0,T),$$

$$u = 0 \quad \text{in} \ \Sigma_T = \partial\Omega \times (0,T), \qquad u\,|_{t=0} = u_0 \in L^2(\Omega),$$

assuming that f is the given function satisfying the following conditions:

- $f(x,t,q,p)$ is Lebesgue's measurable in x,t,q,p, is continuous in q,p for almost all $(x,t) \in Q_T$;
- there exists a nonnegative function ψ in $L^{1+n/(n+4)}(\Omega)$, $\beta > 0$, and

$$\text{(1.1a)} \qquad r_1 \in \left[0, 1+\frac{4}{n}\right), \qquad r_2 \in \left[0, 1+\frac{2}{n+2}\right)$$

such that

$$\text{(1.1b)} \qquad |f(x,t,q,p)| \le \psi(x,t) + \beta|q|^{r_1} + \beta\|p\|_{R^n}^{r_2} \quad \text{a.e. in } Q_T \text{ for } q \in R,\ p \in R^n;$$

- there exist $\rho > 0$ and $\nu > 0$ such that

$$\text{(1.1c)} \qquad \int_\Omega f(x,t,\phi,\nabla\phi)\phi\,dx \ge (\nu-1)\int_\Omega \|\nabla\phi\|_{R^n}^2 dx - \rho\int_\Omega (1+\phi^2)dx \qquad \forall \phi \in H_0^1(\Omega).$$

†Department of Pure and Applied Mathematics, Washington State University, Pullman, WA 99164-3113 (khapala@wsu.edu).

For $n = 1$ a simple example of a function f satisfying conditions (1.1a)–(1.1c) is $f(u) = u^3$.

Here and below we use the standard notations for Sobolev spaces such as $H_0^{1,0}(Q_T) = \{\phi | \phi, \phi_{x_i} \in L^2(Q_T),\ i = 1, \dots, n,\ \phi|_{\Sigma_T} = 0\}$ and $H_0^1(\Omega) = \{\phi | \phi, \phi_{x_i} \in L^2(\Omega),\ i = 1, \dots, n,\ \phi|_{\partial\Omega} = 0\}$.

We refer, e.g., to [19, p. 466], where it was shown that system (S), (1.1a)–(1.1c) admits at least one generalized solution in $C([0,T]; L^2(\Omega)) \bigcap H_0^{1,0}(Q_T) \bigcap L^{2+4/n}(Q_T)$, while its uniqueness is not guaranteed.

The multiplicative (bilinear) controls are essential in modeling reaction-diffusion-convection processes controlled by means of so-called catalysts that can accelerate or decelerate the reaction at hand, e.g., various chemical or biological chain reactions. In the context of heat-transfer, v is proportional to the heat-transfer coefficient, which depends on the substance at hand, its surface area, and the environment. If the heat-transfer (or mass-transfer in the case of the diffusion process) involves fluids (air), v also depends on the speed of the fluid. Alternatively, the surface area can be changed when the substance at hand is a polymer (e.g., a planar array of gel fibers can be controlled to maximize the surface area exposed to the surrounding fluid). We also refer to the so-called extended surface applications (fins, pins, studs, etc.) allowing one to increase or decrease the heat-exchange with an ambient fluid.

In this paper we intend to analyze the global controllability properties of the homogeneous bilinear system (S) and its nonhomogeneous version (NHS), given in the next section.

2. Main results. Let us remind the reader that it is said that the system at hand is globally *approximately* controllable in the given (*linear* phase) space H at time $T > 0$ if, by selecting a suitable available control, it can be steered in H from any given initial state into any desirable neighborhood of any desirable target state at time T.

It is immediate that, in general, system (S) is not approximately controllable in any (reasonable) linear space. This can be illustrated by a quick analysis of the linear truncated version of (S) with $f = 0$ (as in (3.2) below). Indeed, in this case the zero-state is the fixed point of the solution mapping, regardless of the choice of control v. In other words, the truncated linear version of (S) cannot be steered anywhere from the zero-state by applying any bilinear control. Furthermore, due to the maximum principle, if, e.g., the initial state $u_0(x)$ is nonnegative, then the maximum principle implies that the corresponding solution $u(x,t)$ to the truncated linear version of (S) must remain nonnegative for all $t > 0$, regardless of the choice of v. Hence, one is unable to reach any of the "negative" target states from a nonnegative initial state.

However, we showed in [15] that in the linear case, i.e., with $f = 0$, the one-dimensional (1-D) version of (S) can be steered in $L^2(0,1)$ from any nonzero, nonnegative initial state u_0 into any desirable neighborhood of any nonnegative target state u_d at a time $T > 0$, which depends on the choice of (u_0, u_d) and the desirable precision of steering, by means of static controls $v = v(x)$, $v \in L^\infty(0,1)$ only. By making use of at most three static bilinear controls, applied subsequently in time, this "nonnegative controllability" result was further extended in [15] to prove the nonnegative controllability of the 1-D semilinear parabolic equation like (S), (1.1a)–(1.1c), admitting multiple solutions, in the case when $n = 1$, $\psi = 0$, $\nu = 1$, and $\rho = 0$ in the sense of the following definition.

DEFINITION 2.1 (see [15]). *We will say that system* (S), (1.1a)–(1.1c), *generally admitting multiple solutions, is nonnegatively globally approximately controllable in*

$L^2(\Omega)$ if for every $\varepsilon > 0$ and nonnegative $u_0, u_d \in L^2(\Omega), u_0 \neq 0$ there exist a $T = T(\varepsilon, u_0, u_d)$ and a bilinear control $v \in L^\infty(Q_T)$ such that for all (i.e., possibly multiple) solutions of (S), (1.1a)–(1.1c), *corresponding to the latter,*

$$\|u(\cdot, T) - u_d\|_{L^2(\Omega)} \leq \varepsilon.$$

The central idea of the method in [15] is to select the bilinear control $v = v(x)$ in such a way that the target state (or its "close" approximation) becomes colinear to the first (nonnegative) eigenfunction for the truncated linear version of (S), which is then approached by the system at hand as t increases. Thus, on the one hand, this method allows one to deal with "practical" relatively small and simple static controls, but, on the other hand, the control time can be relatively large. Moreover, such an approach requires the first eigenvalues to be always simple—hence one needs to assume that $n = 1$.

In the semilinear case another principal limitation of the method of [15] is the assumption that the nonlinear term must be superlinear near the origin as well (i.e., in particular, it must vanish at the origin, which is an equilibrium in this case). In this way it can be assured that the system at hand behaves "almost" like a linear one near the origin, which enabled us to make use of the bilinear controllability properties of the latter. However, this limitation did not allow us to extend the methods of [15] to a nonhomogeneous bilinear system like

$$\text{(NHS)} \qquad \frac{\partial z}{\partial t} = \Delta z + v(z - \theta(x)) - f(x, t, z, \nabla z) \qquad \text{in } Q_T,$$

$$z = 0 \quad \text{in } \Sigma_T, \qquad z\,|_{t=0} = z_0 \in L^2(\Omega),$$

where f does not necessarily vanish at the origin and $\theta \neq 0$ is given.

In the context of heat-transfer the term $v(x,t)(z(x,t) - \theta(x))$ in (NHS) can model the heat-exchange at point x at time t of the given substance with the surrounding medium of temperature $\theta(x)$ according to Newton's law (the classical examples here are the heat equations for a rod or a plate [23]).

In this paper we intend to prove the same, as in [15], nonnegative controllability result, but now (a) in *any* space dimension and (b) within *an arbitrarily small time-interval* $(0, T)$ given in advance. We employ a different qualitative approach which allows us to *eliminate the assumptions of* [15] *on the one dimensionality* of the system at hand and (c) to *get rid of the superlinearity assumption on the nonlinear term near the origin*. Our central idea below is to view the evolution of system (S) as an interaction of the following three dynamics associated with the three terms in the right-hand side of (S):

- *Pure diffusion dynamics*—when $v = 0$ and $f = 0$;
- *Pure reaction dynamics*—caused by the reaction term only, namely, we further associate it with the system

$$\frac{\partial y}{\partial t} = vy \qquad \text{in} \quad Q_T, \tag{2.1}$$

$$y\,|_{t=0} = y_0.$$

- *Nonlinear "disturbance"*—the dynamics caused by the nonlinear term of class (1.1a)–(1.1c).

Accordingly, our strategy to achieve the desirable controllability result will be to try to select the bilinear control in such a way that the corresponding trajectories of (S) can be approximated by those associated with the pure diffusion and/or the pure reaction like in (2.1), while the effect of nonlinearity is to be suppressed. The latter appears to be unavoidable when dealing with a general class of highly nonlinear terms like in (1.1a)–(1.1c).

Our main results are as follows.

THEOREM 2.1. *Let $T > 0$ be given and the pair of the initial and target states $u_0 \in H_0^1(\Omega)$ and $u_d \in L^2(\Omega)$ be such that*

$$\frac{u_d}{u_0} \in H^2(\Omega), \qquad \nabla\left(\frac{u_d}{u_0}\right) \in [L^\infty(\Omega)]^n, \qquad \Delta\left(\frac{u_d}{u_0}\right) \in L^\infty(\Omega), \tag{2.2a}$$

and

$$0 < c_1 \le \frac{u_d(x)}{u_0(x)} \le c_2 < 1 \quad \text{a.e. in } \Omega, \tag{2.2b}$$

where c_1 and c_2 are some positive constants. Then for every $\varepsilon > 0$ there is a $T_* \in (0, T)$ such that for all, i.e., possibly multiple, solutions to (S), (1.1a)–(1.1c) *generated by control*

$$v(x) = \frac{1}{T_*} \ln\left(\frac{u_d(x)}{u_0(x)}\right), \tag{2.3}$$

we have the same uniform estimate

$$\|u(\cdot, T_*) - u_d\|_{L^2(\Omega)} \le \varepsilon. \tag{2.4}$$

Theorem 2.1 can be reformulated as follows.

THEOREM 2.2. *Given $T > 0$, let $v_*(x)$ be any function such that*

$$v_* \in L^\infty(\Omega) \bigcap H^2(\Omega),\ \nabla v_* \in [L^\infty(\Omega)]^n,\ \Delta v_* \in L^\infty(\Omega),\ v_*(x) \le L < 0 \quad \text{a.e. in } \Omega,$$

where L is some negative constant. Then for any $u_0 \in H_0^1(\Omega)$ and every $\varepsilon > 0$ there is a $T_* \in (0, T)$ such that for all, i.e., possibly multiple, solutions to (S), (1.1a)–(1.1c) *with control*

$$v(x) = \frac{1}{T_*} v_*(x),$$

we have the same estimate

$$\|u(\cdot, T_*) - e^{v_*(\cdot)} u_0\|_{L^2(\Omega)} \le \varepsilon.$$

Theorems 2.1 and 2.2 provide the basis for the following nonnegative controllability result within any time-interval $(0, T)$ given in advance.

THEOREM 2.3 (nonnegative controllability of (S)). *Given $T > 0$, assume that the boundary $\partial\Omega$ of domain Ω is of class $C^{3+[n/2]}$ (where $[n/2]$ denotes the largest nonnegative integer which does not exceed $n/2$). Then for every $\varepsilon > 0$ and nonnegative $u_0, u_d \in L^2(\Omega)$, $u_0 \not\equiv 0$, there exists a $T_* = T_*(\varepsilon, u_0, u_d) \in (0, T)$ and a bilinear control $v \in L^\infty(Q_{T_*})$ such that for all (i.e., possibly multiple) solutions of* (S), (1.1a)–(1.1c), *corresponding to the latter,* (2.4) *holds. Suitable v can be selected as a combination of at most three static controls applied subsequently in time.*

An immediate consequence of Theorem 2.3 for the nonhomogeneous system (NHS) is as follows.

THEOREM 2.4 (nonhomogeneous case (NHS)). *Given $T > 0$, let $\theta \in H^2(\Omega) \bigcap H_0^1(\Omega)$ and the boundary $\partial\Omega$ of domain Ω be of class $C^{3+[n/2]}$. For every $\varepsilon > 0$ and $z_0, z_d \in L^2(\Omega)$, $z_0 \neq \theta$, $z_0(x) \geq \theta(x)$, $z_d(x) \geq \theta(x)$, a.e. in Ω, there exist a $T_* = T_*(\varepsilon, z_0, z_d) \in (0, T)$ and a bilinear control $v \in L^\infty(Q_{T_*})$ such that for all (i.e., possibly multiple) solutions of* (NHS), (1.1a)–(1.1c), *corresponding to the latter,* (2.4) *holds with z_0, z_d in place of u_0, u_d. Again, suitable v can be selected as a combination of at most three static controls applied subsequently in time.*

Indeed, to prove Theorem 2.4 it is sufficient to notice that the substitution $w = z - \theta$ transforms (NHS) into

$$\frac{\partial w}{\partial t} = \Delta w + vw - f_*(x, t, w, \nabla w) \text{ in } Q_T, \tag{2.5}$$

$$w = 0 \qquad \text{in } \Sigma_T, \qquad w\,|_{t=0} = z_0 - \theta \in L^2(\Omega),$$

where $f_*(x, t, w, \nabla w) = -\Delta\theta + f(x, t, w+\theta, \nabla w+\theta)$. Making use of Young's inequality and the inequality $(a + b)^\gamma \leq C(a^\gamma + b^\gamma)$ $(a, b, \gamma \geq 0,\ C = C(\gamma) > 0)$, one can check that conditions (1.1a)–(1.1c) hold for this function as well (in general, with a different set of parameters β, ν, ρ). Then Theorem 2.4 follows immediately from Theorem 2.3 applied to (2.5).

Remark 2.1 (some references on bilinear controllability).

- In the pioneering work [4] by Ball, Mardsen, and Slemrod the global approximate controllability of the rod equation $u_{tt} + u_{xxxx} + k(t)u_{xx} = 0$ with hinged ends and of the wave equation $u_{tt} - u_{xx} + k(t)u = 0$ with Dirichlet boundary conditions, where k is control (the axial load), was shown by making use of the nonharmonic Fourier series approach under the additional (nontraditional) assumption that all the modes in the initial data are active. We also refer to [18] exploring the ideas of [4] in the context of simultaneous control of the rod equation and Schrödinger equation.
- In [14] the global approximate controllability of a semilinear heat equation like (S), (1.1a)–(1.1c) was established at any positive time $T > 0$ (fixed in advance) in the case when a *pair* of controls govern the system at hand: (a) the traditional internal either locally distributed or lumped control *and* (b) a piecewise constant bilinear control v. (Recall along these lines that without the latter one does not have the global approximate controllability for this class of PDEs [6], [12], [8].) In one space dimension the method of [14] was further extended in [15] to the case dealing with bilinear controls only, as we discussed in detail in the beginning of this section.
- The works [9] and [16] deal with a different approach to the bilinear controllability, which is as follows. It is known that a rather general class of semilinear parabolic equations with globally Lipschitz terms is approximately controllable by the traditional additive locally distributive controls (see, e.g., [6], [12], [10], [7], [8] and the references therein), while a system like (S), (1.1a)–(1.1c) is globally approximately controllable by the additive static controls with support everywhere in Ω [13]. Denote, e.g., in the latter case, the additive static control by $\alpha(x)$. Then a suitable bilinear control for (S) can be sought as some "well-posed modification" of the expression $v(x, t) = \alpha(x)/u(x, t)$ in the homogeneous case and of the expression $v(x, t) = \alpha(x)/(z(x, t) - \theta(x))$ in the

nonhomogeneous case (NHS). In this way the "original" additive static control $\alpha(x)$ is "transformed," respectively, into the homogeneous bilinear term $v(x,t)u(x,t)$ or into its nonhomogeneous version $v(x,t)(z(x,t)-\theta)$. Note, however, that this approach deals with essentially more "complex" controls (e.g., in terms of numerical implementation), namely, as functions of both x and t. In the paper [9] it was applied in the context of the nonnegative approximate controllability and in [16] it was used to investigate the exact null-controllability of a nonhomogeneous bilinear problem.

- Aside from bilinear controllability, a very close issue is *stabilization* by means of bilinear controls. We can point out only a very limited number of publications in this area in terms of PDEs; see [2], [3], [22]. Regarding the issues of optimal control for bilinear systems, we refer to [20], [5], and the references therein.
- An extensive and thorough bibliography on controllability on bilinear *ODEs* is available; see, e.g., the survey in [1]. On the issue of the qualitative approach in the context of controllability for bilinear ODEs, we refer to [17].

The remainder of this paper is organized as follows. In section 3 we introduce several auxiliary technical estimates, proven in Appendices A and B. In section 4 we prove Theorems 2.1 and 2.2, while Theorem 2.3 is proven in section 5.

3. Auxiliary estimates. In this section we formulate three lemmas containing several estimates, which are heavily used in the proofs of our main results.

Denote $\mathcal{B}(0,T) = C([0,T];\, L^2(\Omega)) \bigcap H_0^{1,0}(Q_T)$ and

$$\|\phi\|_{\mathcal{B}(0,T)} = \left(\max_{t\in[0,T]} \|\phi(\cdot,t)\|^2_{L^2(\Omega)} + 2\nu \int_0^T \int_\Omega \|\nabla\phi\|^2_{R^n} dxds \right)^{1/2},$$

where $\nu > 0$ is from (1.1c).

LEMMA 3.1. *Given $T > 0$ and $v \in L^\infty(\Omega)$, any solution to system* (S), (1.1a)–(1.1c) *(if there are multiple solutions), satisfies the following* two *estimates:*

$$\|u\|_{\mathcal{B}(0,T)}, \qquad \|u\|_{L^{2+4/n}(Q_T)} \le Ce^{(\alpha+\rho)T} \left(\|u_0\|^2_{L^2(\Omega)} + 2\rho T \right)^{1/2}, \tag{3.1}$$

where $\alpha = \|v\|_{L^\infty(\Omega)}$ and C is a generic positive constant (it does not depend on v).

Consider now the truncated version of system (S) as follows:

$$h_t = \Delta h + vh \qquad \text{in} \quad Q_T, \tag{3.2}$$

$$h = 0 \text{ in } \Sigma_T, \qquad h\,|_{t=0} = h_0 \in L^2(\Omega).$$

LEMMA 3.2. *Given $T > 0$, $v \in L^\infty(\Omega)$, $\delta \in (0, 1/4)$, we have the following two estimates for the difference $\xi = u - h$ between any corresponding solution u to* (S), (1.1a)–(1.1c) *(if there are multiple ones), and the unique corresponding solution to* (3.2)*:*

$$\begin{aligned} \|\xi\|_{\mathcal{B}(0,T)}, \|\xi\|_{L^{2+4/n}(Q_T)} \le Ce^{2\sqrt{2}\alpha T} \Bigg\{ & \|u_0 - h_0\|^2_{L^2(\Omega)} \\ & + \frac{1}{\sqrt{\delta}} T^{\frac{n+4}{2(n+2)}(1-\frac{r_1 n}{n+4})} \|u\|^{r_1}_{L^{2+4/n}(Q_T)} \\ & + T^{\frac{n+4}{2(n+2)}(1-\frac{(n+2)r_2}{(n+4)})} \|\nabla u\|^{r_2}_{[L^2(Q_T)]^n} + \|\psi\|_{L^{1+n/(n+4)}(Q_T)} \Bigg\}, \end{aligned} \tag{3.3}$$

where the (generic) constant C does not depend on $\alpha = \|v\|_{L^\infty(\Omega)}$.

Lemmas 3.1 and 3.2 are proven in Appendix A.

Next we have the following result, proven in Appendix B, based on Lemma 3.1.

LEMMA 3.3. *Given $T > 0$, the following estimate holds for solutions to* (3.2) *with $h_0 \in H_0^1(\Omega)$, $v \in L^\infty(\Omega) \bigcap H^2(\Omega)$, $\nabla v \in [L^\infty(\Omega)]^n$, $\Delta v \in L^\infty(\Omega)$, $v(x) \le 0$:*

$$\begin{aligned} &\int\int_{Q_T} (\Delta h)^2 dxdt \ + \ \frac{1}{2}\int_\Omega \|\nabla h(x,T)\|^2_{R^n} dx \\ &\le \frac{1}{2}\int_\Omega \|\nabla h_0\|^2_{R^n} dx + \frac{1}{2}\|\Delta v\|_{L^\infty(\Omega)} TC^2 e^{2\alpha T} \|h_0\|^2_{L^2(\Omega)}, \end{aligned} \tag{3.4}$$

where C is from Lemma 3.1 *and $\alpha = \|v\|_{L^\infty(\Omega)}$.*

4. Proofs of Theorems 2.1 and 2.2.

4.1. Proof of Theorem 2.1: The case $f = 0$. In this subsection we consider the truncated version (3.2) of system (S).

Step 1. Consider h_0 and h_d satisfying the assumptions of Theorem 2.1 in place of u_0 and u_d.

Denote

$$v_*(x) = \ln\left(\frac{h_d(x)}{h_0(x)}\right). \tag{4.1}$$

Then

$$h_d(x) = e^{v_*(x)} h_0(x). \tag{4.2}$$

Remark 4.1. Note that, since (2.1) is, in fact, a linear ODE in $L^2(\Omega)$, in view of (4.1) and (4.2), its solution y satisfies the following property:

$$y(x, 1/s) = h_d(x) \qquad \text{when } y_0 = h_0, v(x) = sv_*(x) \tag{4.3}$$

for any number $s > 0$.

Step 2. To prove Theorem 2.1, we need to show that h_d can be approximated by a suitable solution to (3.2). To this end we intend to study the difference between the solutions to (3.2) and to (2.1) on $(0, T)$.

Consider any $v \in L^\infty(\Omega)$ and denote $g = h - y$. Then, assuming that $y_0 = h_0$ in (2.1) and (3.2), we obtain

$$g_t = vg + \Delta h \qquad \text{in} \quad Q_T,$$

$$g|_{t=0} = 0.$$

Thus

$$g(x,t) = \int_0^t e^{v(x)(t-\tau)} \Delta h(x,\tau) d\tau, \qquad t \in [0,T]. \tag{4.4}$$

Let now v be of the form as in (4.3), namely,

$$v(x) = sv_*(x),$$

where we now treat the positive number s as a parameter (its value will be selected later in Step 4).

Then, since (see (2.2b))

$$\ln c_1 \le v_* \le \ln c_2 < 0,$$

formula (4.4) yields

$$\|g(\cdot,t)\|^2_{L^2(\Omega)} \le \left(\frac{e^{2st\ln c_2}-1}{s\ln c_2}\right)\|\Delta h\|^2_{L^2(Q_t)}, \qquad Q_t=\Omega\times(0,t),\ t\in[0,T]. \tag{4.5}$$

Step 3. Making use of the estimate (3.4) from Lemma 3.3 applied with $v = sv_*$, we derive from (4.5) that

$$\begin{aligned}\|g(\cdot,t)\|^2_{L^2(\Omega)} \ &\le\ \left(\frac{e^{2st\ln c_2}-1}{s\ln c_2}\right)\\ &\times\left(\frac{1}{2}\int_\Omega\|\nabla h_0\|^2_{R^n}dx\ +\ \frac{1}{2}s\|\Delta v_*\|_{L^\infty(\Omega)}tC^2e^{2\alpha st}\|h_0\|^2_{L^2(\Omega)}\right),\end{aligned} \tag{4.6}$$

where $\alpha = \|v_*\|_{L^\infty(\Omega)}$.

Step 4. Select now $s > 0$ and $T_* \in (0,T)$ such that

$$T_* = \frac{1}{s} \text{ or } T_*s = 1. \tag{4.7}$$

Then we obtain from (4.6), (4.7), and the property (4.3) that

$$\|g(\cdot,T_*)\|_{L^2(\Omega)} = \|h(\cdot,T_*)-y(\cdot,T_*)\|_{L^2(\Omega)} = \|h(\cdot,T_*)-h_d\|_{L^2(\Omega)} \to 0 \tag{4.8}$$

as $s\to\infty$ (or $T_*\to 0+$), which ensures (2.4) for any given in advance ε for some pair (s,T_*) as in (4.7). This ends the proof of Theorem 2.1 when $f = 0$. □

4.2. Proof of Theorem 2.1: The general case. It follows from the above argument by making use of Lemma 3.2, in which we evaluated the difference between the (possible multiple) solutions u to (S) and h to (3.2) in a uniform way as given in (3.3). It follows from (3.3) that under condition (4.7) and with $h_0 = u_0$,

$$\|u(\cdot,T_*)-h(\cdot,T_*)\|_{L^2(\Omega)}\ \to\ 0$$

as $s = 1/T_* \to \infty$, which ensures (2.4) whenever it holds for h as in (4.8). This ends the proof of Theorem 2.1 in the general case. □

4.3. Proof of Theorem 2.2. It is immediate from the proof of Theorem 2.1, since the assumptions on h_0 and h_d in the latter are used specifically to ensure the properties of v_* required in Theorem 2.2. □

5. Proof of Theorem 2.3.

5.1. Proof of Theorem 2.3: The case $f = 0$. Again we study first the truncated problem (3.2).

Consider any pair of initial and target states h_0, $h_d \in L^2(\Omega)$, which are nonnegative (almost everywhere) in Ω and $h_0 \ne 0$. Since we study the issue of approximate controllability and because the set of infinitely differentiable functions with compact

support (denoted by $C_0^\infty(\Omega)$) is dense in $L^2(\Omega)$, without loss of generality we can further assume that

$$h_d \in C_0^\infty(\Omega), \qquad h_d \neq 0, \quad h_d(x) \geq 0 \quad \forall x \in \Omega. \tag{5.1}$$

We plan to approximate h_d by using three static bilinear controls, applied subsequently in time:

(a) First, we will use $v = 0$ on some time-interval $(0, t_1)$ to steer our system to a state $h(\cdot, t_1)$, which is strictly positive in the interior of Ω.

(b) Second, we will use a relatively "large" positive constant control v on some time-interval (t_1, t_2) to steer our system to a state which is "larger" than the given h_d in (5.1).

(c) Finally, we will use a static control as described in Theorem 2.1 on some time-interval (t_2, t_3) to steer our system further to a desirable neighborhood of h_d.

Step 1. Pick any $t_1 > 0$ and apply in (3.2) the zero bilinear control $v = 0$ on $(0, t_1)$. Then, at time t_1 system (3.2) reaches the state

$$h(\cdot, t_1) \in H_0^1(\Omega) \bigcap H^{3+[n/2]}(\Omega) \subset C^2(\bar{\Omega}). \tag{5.2}$$

(We refer, e.g., to [21] for the corresponding regularity and embedding results.)

Note also that, due to the smoothing effect, the solution h to (3.2) is classical in $\bar{\Omega} \times [\beta, t_1]$, for any $\beta \in (0, t_1]$ [21]. Furthermore, due to the strong maximum principle (see, e.g., [11]),

$$h(x, t_1) > 0 \quad \text{in the interior of } \Omega, \qquad h(x, t_1)|_{\partial\Omega} = 0. \tag{5.3}$$

Step 2. Consider any $t_2 > t_1$. On the interval (t_1, t_2) we apply a positive constant control $v(x) = v$ (its value will be chosen later). Then for the corresponding solution h to (3.2) on (t_1, t_2) we have

$$h(x, t_2) = e^{v(t_2 - t_1)} \sum_{k=1}^{\infty} e^{\lambda_k (t_2 - t_1)} \left(\int_\Omega h(r, t_1) \omega_k(r) dr \right) \omega_k(x), \tag{5.4}$$

where λ_k ($\lambda_k \to -\infty$ as $k \to \infty$) and $\omega_k(x)$ ($\|\omega_k\|_{L^2(\Omega)} = 1$), $k = 1, \ldots$, are, respectively, the eigenvalues and eigenfunctions associated with the spectral problem $\Delta\omega = \lambda\omega$, $\omega|_{\partial\Omega} = 0$ in $H_0^1(\Omega)$.

Consider any number $\gamma > 1$ (its value will be chosen more precisely a little bit later) and select a constant (in t and x) control $v > 0$ such that

$$e^{v(t_2 - t_1)} = \gamma, \text{ namely, } v = \frac{\ln \gamma}{t_2 - t_1}. \tag{5.5a}$$

(Thus, v depends on γ and $t_2 - t_1$.)

Then, it follows from (5.4) that with this control

$$h(\cdot, t_2) \to \gamma h(\cdot, t_1) \text{ as } t_2 \to t_1 + \text{ in } C(\bar{\Omega}), \tag{5.5b}$$

as implied by the estimate

$$\|h(\cdot, t_2) - \gamma h(\cdot, t_1)\|_{C(\bar{\Omega})} \leq C \|h(\cdot, t_2) - \gamma h(\cdot, t_1)\|_{H^{1+[n/2]}(\Omega)}$$

$$\leq C \left(\sum_{k=1}^{\infty} \lambda_k^{1+[n/2]} \left(e^{\lambda_k (t_2 - t_1)} - 1 \right)^2 \left(\int_\Omega h(r, t_1) \omega_k(r) dr \right)^2 \right)^{1/2},$$

where $C > 0$ is a (generic) constant associated with the continuous embedding $H^{1+[n/2]}(\Omega) \subset C(\bar{\Omega})$ (see, e.g., [21]).

Select now the value of $\gamma > 1$ in such a way that

$$\gamma h(x, t_1) \geq h_d(x) + 1 \qquad \forall x \in \operatorname{supp} h_d,$$

which is possible due to (5.3) and (5.1), where supp h_d stands for the set of all x where $h_d(x) \neq 0$ (i.e., where $h_d(x) > 0$).

For this γ and any given $\sigma \in (0, 1)$ (to be selected more precisely later) select any positive number $t_2 > t_1, t_2 = t_2(\gamma, \sigma)$ and v as in (5.5a) such that

$$\gamma h(x, t_1) + \sigma/2 \geq h(x, t_2) \geq \gamma h(x, t_1) - \sigma/2 \geq -\sigma/2 \qquad \forall x \in \Omega, \tag{5.6a}$$

$$h(x, t_2) \geq h_d(x) \qquad \forall x \in \text{ supp } h_d. \tag{5.6b}$$

This is possible due to (5.1), (5.3), and (5.5b).

Step 3. We will now apply Theorem 2.2 to the system (3.2) on some interval (t_2, t_3) with the initial state $h(x, t_2)$ and the static control

$$v(x) = \frac{1}{t_3 - t_2} v_\sigma(x),$$

where

$$v_\sigma = \ln\left(\frac{h_d + \sigma^2/2}{h(\cdot, t_2) + \sigma}\right) \in C^2(\bar{\Omega}).$$

(Note that the additional "regularizing" terms $\sigma^2/2$ and σ ensure that the argument of the logarithmic function in the above is positive everywhere in $\bar{\Omega}$.)

Since, in view of (5.6a)–(5.6b),

$$\frac{\sigma^2/2}{\max_{x\in\bar{\Omega}} h(x, t_2) + \sigma} \leq \frac{h_d(x) + \sigma^2/2}{h(x, t_2) + \sigma}$$

$$\leq \begin{cases} \frac{h(x,t_2)+\sigma-\sigma+\sigma^2/2}{h(x,t_2)+\sigma} \leq 1 - \frac{\sigma-\sigma^2/2}{\max_{x\in\bar{\Omega}} h(x,t_2)+\sigma} & \text{for } \in \text{ supp } h_d, \\ \frac{\sigma^2/2}{-\sigma/2+\sigma} = \sigma & \text{for } x \in \Omega \backslash \text{ supp } h_d, \end{cases}$$

we have

$$\ln\left(\frac{\sigma^2/2}{\max_{x\in\bar{\Omega}} h(x, t_2) + \sigma}\right) < v_\sigma(x)$$

$$\leq \ln\left(\max\left\{s, 1 - \frac{\sigma - \sigma^2/2}{\max_{x\in\bar{\Omega}} h(x, t_2) + \sigma}\right\}\right) < 0 \qquad \text{in } \Omega.$$

According to Theorem 2.2, this v will steer (3.2) in $L^2(\Omega)$ at some time t_3 from $h(\cdot, t_2) \in H_0^1(\Omega)$ as close as we wish to a state

$$e^{v_\sigma(x)} h(x, t_2) = h(x, t_2)\left(\frac{h_d(x) + \sigma^2/2}{h(x, t_2) + \sigma}\right), \tag{5.7}$$

provided that t_3 is sufficiently close to t_2 from the right. For example, there is a $t_3 > t_2$ ($t_3 = t_3(\sigma)$) such that

$$\left\| h(\cdot, t_3) - h(\cdot, t_2)\left(\frac{h_d + \sigma^2/2}{h(\cdot, t_2) + \sigma}\right)\right\|_{L^2(\Omega)} \leq \sigma. \tag{5.8}$$

To finish the proof of Theorem 2.3 for the case $f = 0$, it remains to notice that, in view of (5.6a)–(5.6b), the expression in (5.7) converges in $L^2(\Omega)$ to the desirable target state h_d as $\sigma \to 0+$.

Indeed, we have

$$\begin{aligned}\left|h(x,t_2)\left(\frac{h_d(x)+\sigma^2/2}{h(x,t_2)+\sigma}\right)-h_d(x)\right| &= \left|\frac{h(x,t_2)\sigma^2/2-h_d(x)\sigma}{h(x,t_2)+\sigma}\right| \\ &\le \sigma^2/2\frac{h(x,t_2)}{h(x,t_2)+\sigma}+\sigma\frac{h_d(x)}{h(x,t_2)+\sigma} \le \sigma^2/2+\sigma\end{aligned} \tag{5.9}$$

for all $x \in \operatorname{supp} h_d$, where, in view of (5.6b), $h(x,t_2) \ge h_d(x) > 0$ and hence

$$0 \le \frac{h(x,t_2)}{h(x,t_2)+\sigma} \le 1, \tag{5.10}$$

and

$$0 \le \frac{h_d(x)}{h(x,t_2)+\sigma} \le \frac{h(x,t_2)+\sigma}{h(x,t_2)+\sigma} = 1. \tag{5.11}$$

In turn, since h_d vanishes elsewhere, for $x \in \Omega\setminus \operatorname{supp} h_d$ we have

$$h(x,t_2)\left(\frac{h_d(x)+\sigma^2/2}{h(x,t_2)+\sigma}\right)-h_d(x) = h(x,t_2)\left(\frac{\sigma^2/2}{h(x,t_2)+\sigma}\right), \tag{5.12}$$

where, due to (5.6a),

$$\left|h(x,t_2)\left(\frac{\sigma^2/2}{h(x,t_2)+\sigma}\right)\right| \le \left|h(x,t_2)\left(\frac{\sigma^2/2}{-\sigma/2+\sigma}\right)\right| \le (\gamma\|h(\cdot,t_1)\|_{C(\bar\Omega)}+\sigma/2)\sigma. \tag{5.13}$$

Thus, combining (5.9)–(5.13), we obtain that

$$\left\|h(\cdot,t_2)\left(\frac{h_d+\sigma^2/2}{h(\cdot,t_2)+\sigma}\right)-h_d\right\|_{C(\bar\Omega)} \le \sigma^2+\sigma+\sigma\gamma\|h(\cdot,t_1)\|_{C(\bar\Omega)} \to 0$$

as $\sigma \to 0+$, which, in view of (4.8), completes the proof of Theorem 2.3 in the case when $f = 0$. □

5.2. Proof of Theorem 2.3: The general case. As in the case of Theorem 2.1, it follows from estimate (3.3) evaluating the difference between the solutions u to (S) and h to (3.2) (uniformly with respect to possible multiple solutions to (S)).

It follows from (3.3) that whenever the product of the $L^\infty(\Omega)$-norm of the static bilinear control $v(x)$, applied, say, on the time-interval (a,b), and its duration $(b-a)$, namely, $\|v\|_{L^\infty(\Omega)}(b-a)$ remains bounded, we have

$$\|u(\cdot,b)-h(\cdot,b)\|_{L^2(\Omega)} \to 0,$$

provided that $b \to a+$ and $\|u(\cdot,a)-h(\cdot,a)\|_{L^2(\Omega)} \to 0$.

Indeed, in the above,

- on the interval $(0,t_1)$ we used $v = 0$ and can select t_1 as small as we wish;
- on the interval (t_1,t_2) we applied a constant v as in (5.5a) such that for any (fixed) $\gamma > 1$ we have $v(t_2-t_1) = \ln\gamma$;

- on the interval (t_2, t_3) we used the condition like in (4.7), exactly as it is described in the proof of Theorem 2.1 in the general case. Again, $(t_3 - t_2)$ can be arbitrarily small.

Thus applying (3.3) subsequently three times on the aforementioned intervals, while selecting sufficiently small t_i, $i = 1, 2, 3$, and the bilinear controls as described in the above, we can ensure (2.4). This completes the proof of Theorem 2.3 in the general case. □

Appendix A. Proof of Lemmas 3.1 and 3.2.

A.1. Proof of Lemma 3.1. Recall (see, e.g., [19]) that $f(\cdot, \cdot, u, \nabla u) \in L^{1+n/(n+4)}(Q_T)$ and that the following energy equality holds for (S) treated as a linear equation with the source term $f(x, t, u, \nabla u)$, e.g., [19, p. 142]:

$$\frac{1}{2}\|u\|^2_{L^2(\Omega)}|_0^t + \int_0^t \int_\Omega \left(\|\nabla u\|^2_{R^n} - vu^2 + f(x, s, u, \nabla u)u\right) dxds = 0 \qquad \forall t \in [0, T]. \tag{A.1}$$

Here and everywhere below, if there exist several solutions to (S), we always deal separately with a selected one, while noticing that all the estimates hold uniformly.

Combining (A.1) and (1.1c) yields for $t \in [0, T]$

$$\begin{aligned} &\|u(\cdot, t)\|^2_{L^2(\Omega)} + 2\nu \int_0^t \int_\Omega \|\nabla u\|^2_{R^n}\, dxds \\ &\le \|u_0\|^2_{L^2(\Omega)} + 2(\alpha + \rho) \int_0^t \int_\Omega u^2 dxds + 2\rho T \\ &\le \left(\|u_0\|^2_{L^2(\Omega)} + 2\rho T\right) + 2(\alpha + \rho) \int_0^t \left(\|u(\cdot, \tau)\|^2_{L^2(\Omega)} + 2\nu \int_0^\tau \int_0^1 \|\nabla u\|^2_{R^n}\, dxds\right) d\tau. \end{aligned} \tag{A.2}$$

Applying the Gronwall–Bellman inequality to (A.2) yields the first estimate in (3.1) with respect to the $\mathcal{B}(0, T)$-norm with $C = \sqrt{2}$. The second estimate follows by the continuity of the embedding of $\mathcal{B}(0, T)$ into $L^{2+4/n}(Q_T)$ (e.g., [19, pp. 467, 475]), due to which

$$\|\xi\|_{L^{2+4/n}(Q_T)} \le c\|\xi\|_{\mathcal{B}(0,T)} \tag{A.3}$$

for some constant $c > 0$ independent of T. In this case $C = c\sqrt{2}$ in (3.1). This ends the proof of Lemma 3.1. □

A.2. Proof of Lemma 3.2. We now intend to evaluate the difference between any possible (multiple) solution u to (S) and its truncated version (3.2).

Denote $\xi = u - h$; then

$$\xi_t = \Delta\xi + v\xi - f(x, t, u, \nabla u) \qquad \text{in} \quad Q_T, \tag{A.4}$$

$$\xi|_{\Sigma_T} = 0, \qquad \xi\,|_{t=0} = u_0 - h_0.$$

Multiplying (A.4) by ξ and integrating it by parts in $Q_t = \Omega \times (0, t)$, we obtain

the following chain of estimates for all $t \in [0,T]$:

$$\begin{aligned}
&\|\xi(\cdot,t)\|^2_{L^2(\Omega)} + 2\nu \int_0^t \int_\Omega \|\nabla\xi\|^2_{R^n}(x,s)\, dxds \\
&= \|\xi(\cdot,0)\|^2_{L^2(\Omega)} + 2\int_0^t \int_\Omega v\xi^2 dxds - 2\int_0^t \int_\Omega \xi f(x,s,u,\nabla u) dxds \\
&\le \|\xi(\cdot,0)\|^2_{L^2(\Omega)} + 2\alpha \int_0^t \int_0^1 \xi^2 dxds + 2\|\xi\|_{L^{2+4/n}(Q_t)} \|f(x,t,u,\nabla u)\|_{L^{1+n/(n+4)}(Q_t)} \\
&\le \|\xi(\cdot,0)\|^2_{L^2(\Omega)} + 2\alpha \int_0^t \int_\Omega \xi^2 dxds + 2c\|\xi\|_{\mathcal{B}(0,t)} \|f(x,t,u,\nabla u)\|_{L^{1+n/(n+4)}(Q_T)} \\
&\le \|\xi(\cdot,0)\|^2_{L^2(\Omega)} + 2\alpha \int_0^t \|\xi\|^2_{\mathcal{B}(0,s)} ds + \delta\|\xi\|^2_{\mathcal{B}(0,t)} + \frac{c^2}{\delta} \|f(\cdot,\cdot,u,\nabla u)\|^2_{L^{1+n/(n+4)}(Q_T)},
\end{aligned} \tag{A.5}$$

where we made use of (A.3) and Hölder's and Young's inequalities.

It follows from (A.5) that we have

$$\|\xi\|^2_{\mathcal{B}(0,t)} \le 2\|\xi(\cdot,0)\|^2_{L^2(\Omega)} + 4\alpha \int_0^t \|\xi\|^2_{\mathcal{B}(0,s)} ds + 2\delta\|\xi\|^2_{\mathcal{B}(0,t)}$$

$$+ \frac{2c^2}{\delta} \|f(\cdot,\cdot,u,\nabla u)\|^2_{L^{1+n/(n+4)}(Q_T)} \qquad \forall t \in [0,T].$$

Thus,

$$\begin{aligned}
\|\xi\|^2_{\mathcal{B}(0,t)} \le 4\|\xi(\cdot,0)\|^2_{L^2(\Omega)} &+ 8\alpha \int_0^t \|\xi\|^2_{\mathcal{B}(0,s)} ds \\
&+ \frac{4c^2}{\delta} \|f(\cdot,\cdot,u,\nabla u)\|^2_{L^{1+n/(n+4)}(Q_T)},
\end{aligned} \tag{A.6}$$

provided that $0 < \delta < \frac{1}{4}$.

Making use of the Gronwall–Bellman inequality, we derive from (A.6) that

$$\|\xi\|_{\mathcal{B}(0,T)} \le e^{2\sqrt{2}\alpha T} \left(2\|\xi(\cdot,0)\|_{L^2(\Omega)} + \frac{2c}{\sqrt{\delta}} \|f(\cdot,\cdot,u,\nabla u)\|_{L^{1+n/(n+4)}(Q_T)} \right). \tag{A.7}$$

Now, using (1.1b) and Hölder's inequality (as in [19, p. 469], [13, p. 863]), we obtain

$$\begin{aligned}
\|f(\cdot,\cdot,u,\nabla u)\|_{L^{1+n/(n+4)}(Q_T)} &\le \beta T^{\frac{n+4}{2(n+2)}(1-\frac{r_1 n}{n+4})} \|u\|^{r_1}_{L^{2+4/n}(Q_T)} \\
&+ \beta T^{\frac{n+4}{2(n+2)}(1-\frac{(n+2)r_2}{(n+4)})} \|\nabla u\|^{r_2}_{[L^2(Q_T)]^n} + \|\psi\|_{L^{1+n/(n+4)}(Q_T)}.
\end{aligned} \tag{A.8}$$

Combining (A.8), (A.7) yields the result of Lemma 3.2. □

Appendix B. Proof of Lemma 3.3. We need to evaluate Δh in $L^2(Q_T)$, where h satisfies (3.2) with $h_0 \in H^1_0(\Omega)$.

Consider any

$$v \in L^\infty(\Omega) \bigcap H^2(\Omega), \quad \nabla v \in [L^\infty(\Omega)]^n, \quad \Delta v \in L^\infty(\Omega), \quad v(x) \le 0 \qquad \text{in } \Omega. \tag{B.1}$$

Multiplying (3.2) by Δh and further integrating it over Q_T yields

$$\int\int_{Q_T} \left(-h_t \Delta h + (\Delta h)^2\right) dxdt = -\int\int_{Q_T} vh\Delta h dxdt. \tag{B.2}$$

In turn,

$$-\int\int_{Q_T} h_t \Delta h dxdt = \frac{1}{2}\int_\Omega \sum_{k=1}^n h_{x_k}^2(x,T)dx - \frac{1}{2}\int_\Omega \sum_{k=1}^n h_{x_k}^2(x,0)dx,$$

while, having (B.1) in mind,

$$-\int\int_{Q_T} vh\Delta h dxdt = -\int\int_{Q_T} \sum_{k=1}^n vhh_{x_k x_k} dxdt$$

$$= \int\int_{Q_T} \sum_{k=1}^n vh_{x_k}^2 dxdt + \frac{1}{2}\int\int_{Q_T} \sum_{k=1}^n v_{x_k}(h^2)_{x_k} dxdt \le \frac{1}{2}\|\Delta v\|_{L^\infty(\Omega)} \int\int_{Q_T} h^2 dxdt.$$

Combining all the above yields

$$\begin{aligned} &\int\int_{Q_T} (\Delta h)^2 dxdt + \frac{1}{2}\int_\Omega \|\nabla h(x,T)\|_{R^n}^2 dx \\ &\le \frac{1}{2}\int_\Omega \|\nabla h_0\|_{R^n}^2 dx + \frac{1}{2}\|\Delta v\|_{L^\infty(\Omega)} \int\int_{Q_T} h^2 dxdt \\ &\le \frac{1}{2}\int_\Omega \|\nabla h_0\|_{R^n}^2 dx + \frac{1}{2}\|\Delta v\|_{L^\infty(\Omega)} T \max_{t\in[0,T]} \int_\Omega h^2(x,t)dx. \end{aligned} \tag{B.3}$$

From (B.3) and estimate (3.1) (applied to system (3.2)) we obtain the estimate (3.4). This ends the proof of Lemma 3.3. □

CONFIGURATION CONTROLLABILITY OF MECHANICAL SYSTEMS UNDERACTUATED BY ONE CONTROL*

JORGE CORTÉS† AND SONIA MARTÍNEZ‡

Abstract. We investigate local configuration controllability for mechanical control systems within the affine connection formalism. We rely on previous results on controllability and series expansions for the evolution of mechanical systems starting from rest. Extending the work by Lewis for the single-input case, we are able to characterize local configuration controllability for systems with n degrees of freedom and $n-1$ input forces.

Key words. nonlinear control, configuration controllability, symmetric product

1. Introduction.

Mechanical control systems belong to a class of nonlinear systems whose controllability properties have not been fully characterized yet. Much work has been devoted to the study of their rich geometrical structure, both in the Hamiltonian framework (see [30] and references therein) and in the Lagrangian one, which has been receiving increasing attention in the last few years [5, 8, 17, 21, 23, 24, 25, 31]. This research is providing new insights and a bigger understanding of the accessibility and controllability aspects associated with them. In particular, the affine connection formalism was revealed to be very useful for modeling different types of mechanical systems, such as natural ones (Lagrangian equal to kinetic energy minus potential energy) [24, 25], with symmetries [5, 9], with nonholonomic constraints [6, 23], etc. and, on the other hand, it has led to the development of some new techniques and control algorithms for approximate trajectory generation in controller design [4, 37]. Certainly, we shall see further progress in these directions in future years.

Underactuated mechanical control systems are interesting to study both from a theoretical and a practical point of view. From a theoretical perspective, they offer a control challenge as they have nonzero drift, their linearization at zero velocity is not controllable, they are not static feedback linearizable, and it is not known if they are dynamic feedback linearizable. That is, they are not amenable to standard techniques in control theory [13, 30]. From the practical point of view, they appear in numerous applications as a result of design choices motivated by the search for less costly devices, or as a result of a failure regime in fully actuated mechanical systems.

The work by Lewis and Murray [24, 25] on simple mechanical control systems has rendered strong conditions for configuration accessibility and sufficient conditions

for configuration controllability. The conditions for the latter are based on the sufficient conditions that Sussmann obtained for general affine control systems [35]. It is worth noting that these conditions are not invariant under input transformations. As controllability is the more interesting property in practice, more research is needed in order to sharpen the configuration controllability conditions. Whatever these conditions might be, they will be harder to check than the ones for accessibility, since controllability is inherently a more difficult property to establish [14, 33]. Lewis [21] investigated the single-input case, building on previous results by Sussmann for general scalar-input systems [34]. The recent work by Bullo [3] on series expansions for the evolution of a mechanical control system starting from rest gave the necessary tools to tackle this problem in the much more involved multi-input case. In this paper, we characterize local configuration controllability for systems whose number of inputs and degrees of freedom differ by one. Examples include autonomous vehicles (like aircraft takeoff and landing models [11, 28], underwater vehicles [32]), robotic manipulators with a passive joint [26], and locomotion devices (such as the robotic leg [23] or the quadrotor [29]). In addition, fully actuated mechanical systems may temporarily suffer from an actuator failure turning them into underactuated systems by one control, in which case the knowledge of their controllability properties becomes relevant within a robust design perspective. Interestingly, the differential flatness properties of this type of underactuated mechanical control systems have also been characterized in intrinsic geometric terms [32].

Both results, Lewis's and ours, can be seen as particular cases of the following conjecture, which remains open: *The system is locally configuration controllable at a point if and only if there exists a basis of inputs satisfying the sufficient conditions for local configuration controllability at that point.* The conjecture relies on the fact we have mentioned before: the lack of invariance of the sufficient conditions under input transformations. It is remarkable to note that local controllability has not been characterized yet for general control systems, even for the single-input case (in this regard see [12, 34, 35]).

The paper is organized as follows. In section 2, we describe the affine connection framework for mechanical control systems and recall the controllability notions we shall consider on them. In section 3 we review the existing results concerning configuration controllability [24, 25] and the series expansion for the evolution of a mechanical control system starting from rest developed by Bullo in [3]. In section 4 we briefly recall the single-input case solved by Lewis and properly state his conjecture. Section 5 contains the main contributions of this paper. In section 6 we treat two examples to illustrate the results. Finally, we present our conclusions in section 7.

2. Simple mechanical control systems. Let Q be a n-dimensional manifold. We will denote by TQ the tangent bundle of Q, by $\mathfrak{X}(Q)$ the set of vector fields on Q, and by $C^\infty(Q)$ the set of smooth functions on Q. Throughout the paper, the manifold Q and the mathematical objects defined on it will be assumed analytic.

A *simple mechanical control system* is defined by a triple $(Q, g, \mathcal{F})$, where Q is the manifold of configurations of the system, g is a Riemannian metric on Q, and $\mathcal{F} = \{F^1, \ldots, F^m\}$ is a set of m linearly independent 1-forms on Q, which physically correspond to forces or torques.

Associated with the metric g is a natural affine connection, called the *Levi–Civita* connection. An *affine connection* [1, 18] is defined as an assignment

$$\begin{array}{rccc} \nabla : & \mathfrak{X}(Q) \times \mathfrak{X}(Q) & \longrightarrow & \mathfrak{X}(Q), \\ & (X, Y) & \longmapsto & \nabla_X Y, \end{array}$$

which is $\mathbb{R}$-bilinear and satisfies $\nabla_{fX}Y = f\nabla_X Y$ and $\nabla_X(fY) = f\nabla_X Y + X(f)Y$, for any $X,\ Y \in \mathfrak{X}(Q)$, $f \in C^\infty(Q)$. A curve $c : [a,b] \longrightarrow Q$ is a *geodesic* for ∇ if $\nabla_{\dot c(t)}\dot c(t) = 0$. Locally, the condition for a curve $t \longmapsto (q^1(t), \dots, q^n(t))$ to be a geodesic can be expressed as

$$\ddot q^a + \Gamma^a_{bc}\dot q^b \dot q^c = 0\,, \qquad 1 \le a \le n\,, \tag{2.1}$$

where the $\Gamma^a_{bc}(q)$ are the Christoffel symbols of the affine connection, that is, they are given by $\nabla_{\frac{\partial}{\partial q^b}}\frac{\partial}{\partial q^c} = \Gamma^a_{bc}\frac{\partial}{\partial q^a}$. The geodesic equation (2.1) is a first-order differential equation on TQ. The vector field corresponding to this first-order equation is given in coordinates by

$$S = v^a\frac{\partial}{\partial q^a} - \Gamma^a_{bc}v^b v^c\frac{\partial}{\partial v^a}$$

and is called the *geodesic spray* of the affine connection ∇. Hence, the integral curves of the geodesic spray S, $(q^a, \dot q^a)$ are the solutions of the geodesic equation.

The Levi–Civita connection ∇^g is determined by the formula

$$\begin{aligned} 2\,g(\nabla^g_X Y, Z) = {} & (X(g(Y,Z)) + Y(g(Z,X)) - Z(g(X,Y)) \\ & + g(Y,[Z,X]) - g(X,[Y,Z]) + g(Z,[X,Y]))\,, \qquad X,Y,Z \in \mathfrak{X}(Q)\,. \end{aligned}$$

One can compute the Christoffel symbols of ∇^g to be

$$\Gamma^a_{bc} = \frac{1}{2}g^{ad}\left(\frac{\partial g_{db}}{\partial q^c} + \frac{\partial g_{dc}}{\partial q^b} - \frac{\partial g_{bc}}{\partial q^d}\right),$$

where (g^{ad}) denotes the inverse of the inertia matrix $(g_{da}) = (g(\frac{\partial}{\partial q^d}, \frac{\partial}{\partial q^a}))$.

The metric tensor g induces a bundle isomorphism $\flat_g : TQ \longrightarrow T^*Q$ given by $\flat_g(X)(Y) = g(X,Y)$. Instead of the input forces $F^1, \dots, F^m$, we shall make use of the vector fields $Y_1, \dots, Y_m$, defined as $Y_i = \flat_g^{-1}(F^i)$. Roughly speaking, this corresponds to considering "accelerations" rather than forces. If $Y_i = Y_i^a(q)\frac{\partial}{\partial q^a}$, the control equations for the simple mechanical control system read in coordinates as

$$\begin{aligned} \dot q^a &= v^a\,, \\ \dot v^a &= -\Gamma^a_{bc}\dot q^b \dot q^c + \sum_{i=1}^m u_i(t)Y_i^a(q)\,, \qquad 1 \le a \le n\,. \end{aligned}$$

These equations can be written in a coordinate-free way as

$$\nabla^g_{\dot c(t)}\dot c(t) = \sum_{i=1}^m u^i(t)Y_i(c(t))\,. \tag{2.2}$$

The inputs we will consider come from the set $\mathcal{U} = \{u : [0,T] \to \mathbb{R}^m \mid T > 0,\ u \text{ is measurable and } \|u\| \le 1\}$, where

$$\|u\| = \sup_{t\in[0,T]}\|u(t)\|_\infty = \sup_{t\in[0,T]}\max_{l=1,\dots,m}|u_l(t)|\,.$$

We can use a general affine connection in (2.2) instead of the Levi–Civita connection without changing the structure of the equation. This is particularly interesting, since nonholonomic mechanical control systems also give rise to equations of

the form (2.2) by means of the so-called nonholonomic affine connection (see [23]). Therefore, the discussion throughout the paper is carried out for a general affine connection ∇.

We can turn (2.2) into a general affine control system with drift

$$\dot{x}(t) = f(x(t)) + \sum u^i(t) g_i(x(t)) \,. \tag{2.3}$$

To do this we need another bit of notation. The vertical lift of a vector field X on Q is the vector field X^v on TQ defined as

$$X^v(v_q) = \frac{d}{dt}\Big|_{t=0} (v_q + tX(q)) \,.$$

In coordinates, if $X = X^a \frac{\partial}{\partial q^a}$, one can check that $X^v = X^a \frac{\partial}{\partial v^a}$. Then, the second-order equation (2.2) on Q can be written as the first-order system on TQ:

$$\dot{v} = S(v) + \sum_{i=1}^{m} u^i(t) Y_i^v(v) \,, \tag{2.4}$$

where S is the geodesic spray associated with the affine connection ∇.

2.1. Controllability notions. The control equations for the mechanical system (2.4) are nonlinear. The standard techniques in control theory [30], like, for example, the linearization around an equilibrium point or linearization by feedback, do not yield satisfactory results in the analysis of its controllability properties, in the sense that they do not provide necessary and sufficient conditions characterizing them.

The point in the approach of Lewis and Murray to simple mechanical control systems is precisely to focus on what is happening to configurations, rather than to states, since in many of these systems, configurations may be controlled, but not configurations and velocities at the same time. The basic question they pose is, What is the set of configurations which are attainable from a given configuration starting from rest? Moreover, since we deal with objects defined on the configuration manifold Q, we expect to find answers on Q, although the control system (2.4) lives in TQ.

DEFINITION 2.1. *A* solution *of* (2.2) *is a pair* (c, u)*, where* $c : [0, T] \longrightarrow Q$ *is a piecewise smooth curve and* $u \in \mathcal{U}$ *such that* $(\dot{c}, u)$ *satisfies the first-order control system* (2.4)*.*

Consider $q_0 \in Q$, $(q_0, 0_{q_0}) \in T_{q_0}Q$ and let $U \subset Q$, $\overline{U} \subset TQ$ be neighborhoods of q_0 and $(q_0, 0_{q_0})$, respectively. Define

$$\mathcal{R}_Q^U(q_0, T) = \left\{ q \in Q \,\middle|\, \begin{array}{c} \text{there exists a solution } (c,u) \text{ of (2.2) such that} \\ \dot{c}(0) = 0_{q_0},\ c(t) \in U \text{ for } t \in [0,T], \text{ and } \dot{c}(T) \in T_qQ \end{array} \right\},$$

$$\mathcal{R}_{TQ}^{\overline{U}}(q_0, T) = \left\{ (q, v) \in TQ \,\middle|\, \begin{array}{l} \text{there exists a solution } (c,u) \text{ of (2.2) such that } \dot{c}(0) = \\ 0_{q_0},\ (c(t), \dot{c}(t)) \in \overline{U} \text{ for } t \in [0,T], \text{ and } \dot{c}(T) = v \in T_qQ \end{array} \right\}$$

and denote

$$\mathcal{R}_Q^U(q_0, \leq T) = \cup_{0 \leq t \leq T} \mathcal{R}_Q^U(q_0, t) \,, \qquad \mathcal{R}_{TQ}^{\overline{U}}(q_0, \leq T) = \cup_{0 \leq t \leq T} \mathcal{R}_{TQ}^{\overline{U}}(q_0, t) \,.$$

Now, we recall the notions of accessibility considered in [24].

DEFINITION 2.2. *The system* (2.2) *is* locally configuration accessible (LCA) at $q_0 \in Q$ *if there exists* $T > 0$ *such that* $\mathcal{R}^U_Q(q_0, \leq t)$ *contains a nonempty open set of* Q, *for all neighborhoods* U *of* q_0 *and all* $0 \leq t \leq T$. *If this holds for any* $q_0 \in Q$, *then the system is called LCA.*

DEFINITION 2.3. *The system* (2.2) *is* locally accessible (LA) at $q_0 \in Q$ and zero velocity *if there exists* $T > 0$ *such that* $\mathcal{R}^{\overline{U}}_{TQ}(q_0, \leq t)$ *contains a nonempty open set of* TQ, *for all neighborhoods* $\overline{U}$ *of* $(q_0, 0_{q_0})$ *and all* $0 \leq t \leq T$. *If this holds for any* $q_0 \in Q$, *then the system is called LA at zero velocity.*

We shall focus our attention on the following concepts of controllability [24].

DEFINITION 2.4. *The system* (2.2) *is* small-time locally configuration controllable (STLCC) at $q_0 \in Q$ *if there exists* $T > 0$ *such that* $\mathcal{R}^U_Q(q_0, \leq t)$ *contains a nonempty open set of* Q *to which* q_0 *belongs, for all neighborhoods* U *of* q_0 *and all* $0 \leq t \leq T$. *If this holds for any* $q_0 \in Q$, *then the system is called STLCC.*

DEFINITION 2.5. *The system* (2.2) *is* small-time locally controllable (STLC) at $q_0 \in Q$ and zero velocity *if there exists* $T > 0$ *such that* $\mathcal{R}^{\overline{U}}_{TQ}(q_0, \leq t)$ *contains a nonempty open set of* TQ *to which* $(q_0, 0_{q_0})$ *belongs, for all neighborhoods* $\overline{U}$ *of* $(q_0, 0_{q_0})$ *and all* $0 \leq t \leq T$. *If this holds for any* $q_0 \in Q$, *then the system is called STLC at zero velocity.*

3. Existing results. Here we review some accessibility and controllability results obtained in [24, 25] and summarize the work by Bullo [3] in describing the evolution of mechanical control systems via a series expansion.

3.1. On controllability. Given an affine connection ∇ on Q, the *symmetric product* of two vector fields $X, Y \in \mathfrak{X}(Q)$ is defined by

$$\langle X : Y \rangle = \nabla_X Y + \nabla_Y X \,.$$

The geometric meaning of the symmetric product is the following [22]: a *geodesically invariant* distribution $\mathcal{D}$ is a distribution such that for every geodesic $c(t)$ of ∇ starting from a point in $\mathcal{D}$, $\dot{c}(0) \in \mathcal{D}_{c(0)}$, we have that $\dot{c}(t) \in \mathcal{D}_{c(t)}$. Then, one can prove that $\mathcal{D}$ is geodesically invariant if and only if $\langle X : Y \rangle \in \mathcal{D}$, for all X, $Y \in \mathcal{D}$.

Given the input vector fields $\mathcal{Y} = \{Y_1, \ldots, Y_m\}$, let us denote by $\overline{Sym}(\mathcal{Y})$ the distribution obtained by closing the set $\mathcal{Y}$ under the symmetric product and by $\overline{Lie}(\mathcal{Y})$ the involutive closure of $\mathcal{Y}$. With these ingredients, one can prove the following theorem.

THEOREM 3.1 (see [24]). *The control system* (2.2) *is LCA at* q *(respectively, LA at* q *and zero velocity) if* $\overline{Lie}(\overline{Sym}(\mathcal{Y}))_q = T_qQ$ *(respectively,* $\overline{Sym}(\mathcal{Y})_q = T_qQ$*).*

If P is a symmetric product of vector fields in $\mathcal{Y}$, we let $\gamma_i(P)$ denote the number of occurrences of Y_i in P. The *degree* of P will be $\gamma_1(P) + \cdots + \gamma_m(P)$. We shall say that P is *bad* if $\gamma_i(P)$ is even for each $1 \leq i \leq m$. We say that P is *good* if it is not bad. The following theorem gives sufficient conditions for STLCC.

THEOREM 3.2. *Suppose that the system* (2.2) *is LCA at* q *(respectively, LA at* q *and zero velocity) and that* $\mathcal{Y}$ *is such that every bad symmetric product* P *at* q *in* $\mathcal{Y}$ *can be written as a linear combination of good symmetric products at* q *of lower degree than* P. *Then* (2.2) *is STLCC at* q *(respectively, STLC at* q *and zero velocity).*

This theorem was proved in [24], adapting previous work by Sussmann [35] on general control systems of the form (2.3). Throughout the paper, we will refer to the conditions of every bad symmetric product at q being a linear combination of good symmetric products at q of lower degree as the *sufficient conditions for STLCC.*

3.2. Series expansion. Within the realm of geometric control theory, series expansions play a key role in the study of nonlinear controllability [2, 15, 34, 35], trajectory generation and motion planning problems [4, 19, 20, 29], etc. In [27], Magnus describes the evolution of systems on a Lie group. In [7, 10, 16, 36] a general framework is developed to describe the evolution of a nonlinear system via the so-called Chen–Fliess series and its factorization.

In the context of mechanical control systems, the work by Bullo in [3] describes the evolution of the trajectories with zero initial velocity via a series expansion on the configuration manifold Q. In this section we describe the series expansion, which will be key in the subsequent discussion. Before doing so, however, we need to introduce some notation on analyticity over complex neighborhoods.

Let $q_0 \in Q$. By selecting a coordinate chart around q_0, we locally identify $Q \equiv \mathbb{R}^n$. In this way, we write $q_0 \in \mathbb{R}^n$. Let σ be a positive scalar, and define the complex σ-neighborhood of q_0 in $\mathbb{C}^n$ as $B_\sigma(q_0) = \{z \in \mathbb{C}^n \mid \|z - q_0\| < \sigma\}$. Let f be a real analytic function on $\mathbb{R}^n$ that admits a bounded analytic continuation over $B_\sigma(q_0)$. The norm of f is defined as

$$\|f\|_\sigma \triangleq \max_{z \in B_\sigma(q_0)} |f(z)| \,,$$

where f denotes both the function over $\mathbb{R}^n$ and its analytic continuation. Given a time-varying vector field $(q,t) \mapsto Z(q,t) = Z_t(q)$, let Z_t^i be its ith component with respect to the usual basis on $\mathbb{R}^n$. Assuming $t \in [0,T]$, and assuming that every component function Z_t^i is analytic over $B_\sigma(q_0)$, we define the norm of Z as

$$\|Z\|_{\sigma,T} \triangleq \max_{t\in[0,T]} \max_{i\in\{1,\dots,n\}} \|Z_t^i\|_\sigma \,.$$

In what follows, we will often simplify notation by neglecting the subscript T in the norm of a time-varying vector field. Finally, given an affine connection ∇ with Christoffel symbols $\{\Gamma^i_{jk} \mid i,j,k \in \{1,\dots,n\}\}$, we introduce the following notation:

$$\|\Gamma\|_\sigma \triangleq \max_{i,j,k} \|\Gamma^i_{jk}\|_\sigma \,.$$

In what follows, we let

$$Z(q,t) = \sum_{i=1}^m u_i(t) Y_i(q) \,.$$

THEOREM 3.3 (see [3]). *Let $c(t)$ be the solution of (2.2) with input given by $Z(q,t)$ and with initial conditions $c(0) = q_0$, $\dot c(0) = 0$. Let the Christoffel symbols $\Gamma^i_{jk}(q)$ and the vector field $Z(q,t)$ be uniformly integrable and bounded analytic in Q. Define recursively the time-varying vector fields*

$$\begin{aligned} V_1(q,t) &= \int_0^t Z(q,s) ds \,, \\ V_k(q,t) &= -\frac{1}{2} \sum_{j=1}^{k-1} \int_0^t \langle V_j(q,s) : V_{k-j}(q,s) \rangle ds \,, \qquad k \geq 2 \,, \end{aligned}$$

where q is maintained fixed at each integral. Select a coordinate chart around the point $q_0 \in Q$, let $\sigma > \sigma'$ be two positive constants, and assume that

$$\|Z\|_\sigma T^2 < L \triangleq \min \left\{ \frac{\sigma - \sigma'}{2^4 n^2 (n+1)}, \frac{1}{2^4 n (n+1) \|\Gamma\|_\sigma}, \frac{\eta^2 (\sigma' n^2 \|\Gamma\|_{\sigma'})}{n^2 \|\Gamma\|_{\sigma'}} \right\} . \tag{3.1}$$

Then the series $(q,t) \longmapsto \sum_{k=1}^{\infty} V_k(q,t)$ *converges absolutely and uniformly in* t *and* q, *for all* $t \in [0,T]$ *and for all* $q \in B_{\sigma'}(q_0)$, *with the* V_k *satisfying the bound*

$$\|V_k\|_{\sigma'} \leq L^{1-k}\, \|Z\|_{\sigma}^{k}\, t^{2k-1}\,, \tag{3.2}$$

Over the same interval, the solution $c(t)$ *satisfies*

$$\dot{c}(t) = \sum_{k=1}^{\infty} V_k(c(t),t)\,. \tag{3.3}$$

This theorem generalizes previous results obtained in [4] under the assumption of small amplitude forcing. The first few terms of the series (3.3) can be computed to obtain

(3.4)

$$\begin{aligned}\dot{c}(t) = {} & \overline{Z}(c(t),t) - \frac{1}{2}\overline{\langle \overline{Z} : \overline{Z} \rangle}(c(t),t) + \frac{1}{2}\overline{\left\langle \langle \overline{Z} : \overline{Z} \rangle : \overline{Z} \right\rangle}(c(t),t) \\ & - \frac{1}{2}\overline{\left\langle \left\langle \langle \overline{Z} : \overline{Z} \rangle : \overline{Z} \right\rangle : \overline{Z} \right\rangle}(c(t),t) - \frac{1}{8}\overline{\left\langle \langle \overline{Z} : \overline{Z} \rangle : \langle \overline{Z} : \overline{Z} \rangle \right\rangle}(c(t),t) + O(\|Z\|_{\sigma}^{5} t^{9})\,,\end{aligned}$$

where $\overline{Z}(q,t) \equiv \int_0^t Z(q,s)ds$ and so on.

4. The single-input case. Theorem 3.2 gives us sufficient conditions for STLCC. A natural concern both from the theoretical and the practical points of view is to try to sharpen this controllability test. Lewis [21] investigated the single-input case and proved the next result.

THEOREM 4.1. *Let* (Q,g) *be an analytic manifold with an affine connection* ∇. *Let* Y *be an analytic vector field on* Q *and* $q_0 \in Q$. *Then the system*

$$\nabla_{\dot{c}(t)}\dot{c}(t) = u(t)Y(c(t))$$

is locally configuration controllable at $q_0 \in Q$ *if and only if* $\dim Q = 1$.

The fact of being able to completely characterize STLCC in the single-input case (something which has not been accomplished yet for general control systems of the form (2.3)) suggests that understanding local configuration controllability for mechanical systems may be possible. More precisely, examining the single-input case, one can deduce that if (2.2) is STLCC at q_0, then $\dim Q = 1$, which implies $\langle Y : Y \rangle(q_0) \in \operatorname{span}\{Y(q_0)\}$, i.e., sufficient conditions for STLCC are also necessary. Can this be extrapolated to the multi-input case? The following conjecture was posed by Lewis:

> *Let a mechanical control system* (2.2) *be LCA at* $q_0 \in Q$. *Then it is STLCC at* q_0 *if and only if there exists a basis of input vector fields which satisfies the sufficient conditions for STLCC at* q_0.

Theorem 4.1 implies that the conjecture is true for $m = 1$. In the following section we prove that this conjecture is also valid for $m = n - 1$.

5. Mechanical systems underactuated by one control. Here we focus our attention on mechanical control systems of the form (2.2) which have n degrees of freedom and $m = n - 1$ control input vector fields. The following lemma, taken from [34], will be helpful in the proof of the theorem of this section.

LEMMA 5.1. *Let* Q *be a* n*-dimensional analytic manifold. Given* $q_0 \in Q$ *and* $X_1, \ldots, X_p \in \mathfrak{X}(Q)$, $p \leq n$, *linearly independent vector fields, there exists a function* $\phi : Q \longrightarrow \mathbb{R}$ *satisfying the properties*

1. ϕ *is analytic,*
2. $\phi(q_0) = 0$*,*
3. $X_1(\phi) = \cdots = X_{p-1}(\phi) = 0$ *on a neighborhood* V *of* q_0*,*
4. $X_p(\phi)(q_0) = -1$*,*
5. *within any neighborhood of* q_0 *there exist points* q*, where* $\phi(q) < 0$ *and* $\phi(q) > 0$*.*

Proof. Let $Z_1, \ldots, Z_n$ be vector fields defined in a neighborhood of q_0 such that $\{Z_1(q_0), \ldots, Z_n(q_0)\}$ forms a basis for $T_{q_0}Q$ and $Z_i = X_i$, $1 \leq i \leq p-1$, $Z_p = -X_p$. Let $t_i \longmapsto \Psi_i(t)$ be the flow of Z_i, $1 \leq i \leq n$. In a sufficiently small neighborhood V of q_0, any point q may be expressed as $q = \Psi_1(t_1) \circ \cdots \circ \Psi_n(t_n)(q_0)$ for some unique n-tuple $(t_1, \ldots, t_n) \in \mathbb{R}^n$. Define $\phi(q) = t_p$. It is a simple exercise to verify that ϕ satisfies the required properties. □

Next, we state and prove the main result of the paper.

THEOREM 5.2. *Let* Q *be a* n*-dimensional analytic manifold and let* $Y_1, \ldots, Y_{n-1}$ *be analytic vector fields on* Q*. Consider the control system*

$$\nabla_{\dot{c}(t)}\dot{c}(t) = \sum_{i=1}^{n-1} u_i(t) Y_i(c(t)), \tag{5.1}$$

and assume that it is LCA at $q_0 \in Q$*. Then the system is locally configuration controllable at* q_0 *if and only if there exists a basis of input vector fields satisfying the sufficient conditions for STLCC at* q_0*.*

A rough sketch of the proof is the following: because of the hypotheses of the theorem, we need only to check that the symmetric products of degree two of a given basis of the input distribution, when evaluated at q_0, are linear combinations of good products of degree one. To verify this, we associate with the given basis a symmetric matrix A, in such a way that this basis satisfies the sufficient conditions for STLCC if and only if the diagonal elements of A are all zero. If this is not the case, we search for a change of basis B such that the new basis has an associated matrix A with zeros in its diagonal. This is equivalent to solving a quadratic equation in B. In order to ensure that a solution to this equation exists, we have to explore the different possibilities that may occur regarding the various radicands involved. Finally, we discard the situations in which the equation is not solvable by a contradiction argument with the controllability assumption (see Figure 5.1).

Proof. We need only to prove one implication (the other one is Theorem 3.2). Let us suppose that the system is locally configuration controllable at q_0. Let $\mathcal{D}$ denote the input distribution. One of the following is true:

1. For all $Y_1, Y_2 \in \mathcal{D}$, $\langle Y_1 : Y_2 \rangle(q_0) \in \mathcal{D}_{q_0}$.
2. There exist Y_1, $Y_2 \in \mathcal{D}$ such that $\langle Y_1 : Y_2 \rangle(q_0) \notin \mathcal{D}_{q_0}$.

In case 1, there is nothing to prove since any basis of input vector fields satisfies the sufficient conditions for STLCC at q_0. In case 2, it is clear that one can choose Y_1, $Y_2 \in \mathcal{D}$, linearly independent at q_0 and such that $\langle Y_1 : Y_2 \rangle(q_0) \notin \mathcal{D}_{q_0}$. (If Y_1, Y_2 in case 2 are linearly dependent, then $\langle Y_1 : Y_1 \rangle(q_0) \notin \mathcal{D}_{q_0}$. Take any Y_2 linearly independent with Y_1. If $\langle Y_1 : Y_2 \rangle(q_0) \in \mathcal{D}_{q_0}$, define a new Y_2' by $Y_1 + Y_2$.) Therefore, we can complete the set $\{Y_1(q_0), Y_2(q_0)\}$ to a basis of $\mathcal{D}_{q_0}$,

$$\{Y_1(q_0), Y_2(q_0), \ldots, Y_m(q_0)\}$$

such that $\operatorname{span}\{Y_1(q_0), Y_2(q_0), \ldots, Y_m(q_0), \langle Y_1 : Y_2 \rangle(q_0)\} = T_{q_0}Q$. In this basis, the

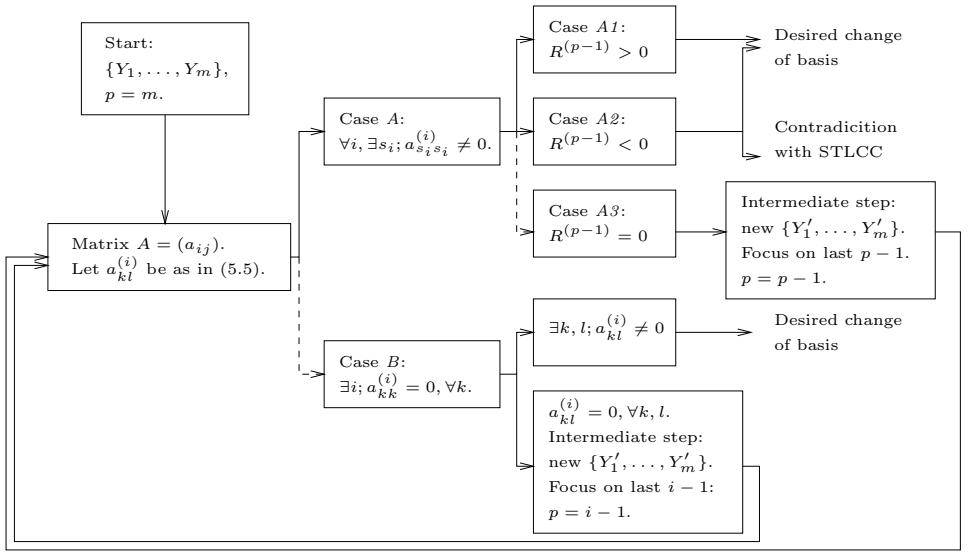

FIG. 5.1. *Illustration of the proof of Theorem* 5.2. $R^{(p-1)}$ *denotes* $(a^{(p-1)}_{s_{p-1}s_p})^2 - a^{(p-1)}_{s_{p-1}s_{p-1}} a^{(p-1)}_{s_p s_p}$. *The dashed lines mean that one cannot fall repeatedly in Cases* A3 *or* B *without contradicting STLCC.*

symmetric products of degree two of the vector fields $\{Y_1, \ldots, Y_m\}$ at q_0 are expressed,

$$\begin{aligned}
\langle Y_1 : Y_1 \rangle(q_0) &= lc(Y_1(q_0), \ldots, Y_m(q_0)) + a_{11} \langle Y_1 : Y_2 \rangle(q_0)\,, \\
&\vdots \\
\langle Y_m : Y_m \rangle(q_0) &= lc(Y_1(q_0), \ldots, Y_m(q_0)) + a_{mm} \langle Y_1 : Y_2 \rangle(q_0)\,, \\
\langle Y_1 : Y_2 \rangle(q_0) &= a_{12} \langle Y_1 : Y_2 \rangle(q_0)\,, \\
\langle Y_1 : Y_3 \rangle(q_0) &= lc(Y_1(q_0), \ldots, Y_m(q_0)) + a_{13} \langle Y_1 : Y_2 \rangle(q_0)\,, \\
&\vdots \\
\langle Y_{m-1} : Y_m \rangle(q_0) &= lc(Y_1(q_0), \ldots, Y_m(q_0)) + a_{m-1\,m} \langle Y_1 : Y_2 \rangle(q_0)\,,
\end{aligned}$$

where $lc(Y_1(q_0), \ldots, Y_m(q_0))$ means a linear combination of $Y_1(q_0), \ldots, Y_m(q_0)$. The coefficients a_{ij} define a symmetric matrix $A = (a_{ij}) \in \mathbb{R}^{m \times m}$. Observe that if $a_{11} = \cdots = a_{mm} = 0$, then the bad symmetric products $\langle Y_i : Y_i \rangle(q_0)$ are in $\mathcal{D}_{q_0}$ and we have finished. Suppose then that the opposite situation is true, that is, there exists $s = s_1$ such that $a_{s_1 s_1} \neq 0$.

What we are going to prove now is that, under the hypothesis of STLCC at q_0, there exists a change of basis $B = (b_{jk})$, $\det B \neq 0$, providing new vector fields in $\mathcal{D}$,

$$Y'_j = \sum_{k=1}^{m} b_{jk} Y_k\,, \qquad 1 \leq j \leq m\,,$$

which satisfy the sufficient conditions for STLCC at q_0. Since

$$\begin{aligned}\langle Y_j' : Y_j' \rangle(q_0) &= \sum_{k,l=1}^{m} b_{jk} b_{jl} \langle Y_k : Y_l \rangle(q_0) \\ &= \sum_{k=1}^{m} b_{jk}^2 \langle Y_k : Y_k \rangle(q_0) + 2 \sum_{1 \le k < l \le m} b_{jk} b_{jl} \langle Y_k : Y_l \rangle(q_0) \\ &= lc(Y_1'(q_0), \dots, Y_m'(q_0)) + \left(\sum_{k=1}^{m} b_{jk}^2 a_{kk} + 2 \sum_{1 \le k < l \le m} b_{jk} b_{jl} a_{kl} \right) \langle Y_1 : Y_2 \rangle(q_0) \,,\end{aligned} \tag{5.2}$$

the matrix B we are looking for must fulfill

$$\sum_{k=1}^{m} b_{jk}^2 a_{kk} + 2 \sum_{1 \le k < l \le m} b_{jk} b_{jl} a_{kl} = 0 \,, \qquad 1 \le j \le m \,, \tag{5.3}$$

or, equivalently,

$$(BAB^T)_{jj} = 0 \,, \qquad 1 \le j \le m \,.$$

Note that, since $a_{s_1 s_1} \neq 0$, this is equivalent to

$$\begin{aligned} b_{j s_1} = & \frac{-\sum_{k \neq s_1} b_{jk} a_{k s_1}}{a_{s_1 s_1}} \\ & \pm \frac{\sqrt{(\sum_{k \neq s_1} b_{jk} a_{k s_1})^2 - a_{s_1 s_1} (\sum_{k \neq s_1} b_{jk}^2 a_{kk} + 2 \sum_{k<l,\, k,l \neq s_1} b_{jk} b_{jl} a_{kl})}}{a_{s_1 s_1}} \,, \end{aligned}$$

for each $1 \le j \le m$. After some computations, the radicand of this expression becomes

$$\sum_{k \neq s_1} b_{jk}^2 (a_{k s_1}^2 - a_{s_1 s_1} a_{kk}) + 2 \sum_{k<l,\, k,l \neq s_1} b_{jk} b_{jl} (a_{k s_1} a_{l s_1} - a_{s_1 s_1} a_{kl}) \,.$$

If this radicand is zero, it would imply that the matrix B should be singular in order to satisfy (5.3). We must ensure then that it is possible to select B such that the radicand is different from zero. We do this in the following, studying several cases that can occur. Letting

$$a_{kl}^{(2)} = a_{k s_1} a_{l s_1} - a_{s_1 s_1} a_{kl} \,, \qquad k,l \in \{1, \dots, m\} \setminus \{s_1\} \,,$$

we have that the radicand would vanish if

$$\sum_{k \neq s_1} b_{jk}^2 a_{kk}^{(2)} + 2 \sum_{k<l,\, k,l \neq s_1} b_{jk} b_{jl} a_{kl}^{(2)} = 0 \,. \tag{5.4}$$

Note the similarity between (5.3) and (5.4). Define recursively

$$\begin{aligned} & a_{kl}^{(1)} = a_{kl} \,, \\ & a_{kl}^{(i)} = a_{k s_{i-1}}^{(i-1)} a_{l s_{i-1}}^{(i-1)} - a_{s_{i-1} s_{i-1}}^{(i-1)} a_{kl}^{(i-1)} \,, \quad i \ge 2 \,, \quad k,l \in \{1, \dots, m\} \setminus \{s_1, \dots, s_{i-1}\} \,. \end{aligned} \tag{5.5}$$

Case A. Here we treat the case when for each i there exists s_i such that $a^{(i)}_{s_i s_i} \neq 0$. Several subcases are discussed.

Reasoning as before, (5.4) would imply that for $1 \leq j \leq m$

$$b_{js_2} = lc(b_{j1}, \ldots, \hat{b}_{js_1}, \ldots, \hat{b}_{js_2}, \ldots, b_{jm}) \pm \frac{1}{a^{(2)}_{s_2 s_2}} \sqrt{\sum_{k \neq s_1, s_2} b^2_{jk} a^{(3)}_{kk} + 2 \sum_{k<l,\, k,l \neq s_1, s_2} b_{jk} b_{jl} a^{(3)}_{kl}},$$

where the symbol $\hat{b}$ means that the term b has been removed. Iterating this procedure, we finally obtain the following equations for the $b_{js_{m-1}}$:

$$b_{js_{m-1}} = b_{js_m} \frac{-a^{(m-1)}_{s_{m-1}s_m} \pm \sqrt{(a^{(m-1)}_{s_{m-1}s_m})^2 - a^{(m-1)}_{s_{m-1}s_{m-1}} a^{(m-1)}_{s_m s_m}}}{a^{(m-1)}_{s_{m-1}s_{m-1}}}, \quad 1 \leq j \leq m\,.$$

Let $(b_{js_m})_{1 \leq j \leq m}$ be a nonzero vector in $\mathbb{R}^m$. Now, we distinguish three possibilities.

Case A1. We show that if the radicand $(a^{(m-1)}_{s_{m-1}s_m})^2 - a^{(m-1)}_{s_{m-1}s_{m-1}} a^{(m-1)}_{s_m s_m}$ is positive, then it is possible to obtain the desired change of basis.

If $(a^{(m-1)}_{s_{m-1}s_m})^2 - a^{(m-1)}_{s_{m-1}s_{m-1}} a^{(m-1)}_{s_m s_m} > 0$, then the quadratic polynomial in $b_{js_{m-1}}$,

$$a^{(m-1)}_{s_{m-1}s_{m-1}} b^2_{js_{m-1}} + 2a^{(m-1)}_{s_{m-1}s_m} b_{js_{m-1}} b_{js_m} + a^{(m-1)}_{s_m s_m} b^2_{js_m}\,, \tag{5.6}$$

has two real roots and we can choose $(b_{js_{m-1}})_{1 \leq j \leq m} \in \mathbb{R}^m$, linearly independent with $(b_{js_m})_{1 \leq j \leq m}$ such that (5.6) is positive for all $1 \leq j \leq m$. As this polynomial is the radicand of the preceding one,

$$\sum_{k \neq s_1, \ldots, s_{m-3}} b^2_{jk} a^{(m-2)}_{kk} + 2 \sum_{k<l,\, k,l \neq s_1, \ldots, s_{m-3}} b_{jk} b_{jl} a^{(m-2)}_{kl}\,, \tag{5.7}$$

our choice of $(b_{js_{m-1}})_{1 \leq j \leq m}$ ensures that we can again take $(b_{js_{m-2}})_{1 \leq j \leq m} \in \mathbb{R}^m$, linearly independent with $(b_{js_{m-1}})_{1 \leq j \leq m}$ and $(b_{js_m})_{1 \leq j \leq m}$ such that (5.7) is positive for all $1 \leq j \leq m$. This is propagated step by step through the iteration process and we are able to choose a nonsingular matrix (b_{jk}) satisfying (5.3).

Case A2. We show that when the radicand $(a^{(m-1)}_{s_{m-1}s_m})^2 - a^{(m-1)}_{s_{m-1}s_{m-1}} a^{(m-1)}_{s_m s_m}$ is negative, then either it is possible to find the change of basis or the system is not STLCC at q_0.

If $(a^{(m-1)}_{s_{m-1}s_m})^2 - a^{(m-1)}_{s_{m-1}s_{m-1}} a^{(m-1)}_{s_m s_m} < 0$, then for all $b_{js_{m-1}}$, b_{js_m} (5.6) does not change its sign. If this sign is positive, the same argument as in Case A1 ensures us the choice of the desired matrix. If negative, it implies that for all $b_{js_{m-2}}$, $b_{js_{m-1}}$, b_{js_m} (5.7) does not change its sign. Then, the unique problem we must face is when, through the iteration process, all the radicands are negative. In the following, we discard this latter case by contradiction with the hypothesis of controllability. Apply Lemma 5.1 to the vector fields $\{Y_1, \ldots, Y_m, \langle Y_1 : Y_2 \rangle\}$ to find a function ϕ satisfying properties 1–5. By (3.4), we have that

$$\begin{aligned}\dot{c}(t) &= \sum_{i=1}^m \bar{u}_i Y_i - \frac{1}{2} \overline{\left\langle \sum_{j=1}^m \bar{u}_j Y_j : \sum_{k=1}^m \bar{u}_k Y_k \right\rangle} + O(\|Z\|^3_\sigma t^5) \\ &= \sum_{i=1}^m \bar{u}_i Y_i - \frac{1}{2} \left(\overline{\sum_{j=1}^m \bar{u}_j^2 \langle Y_j : Y_j \rangle - \sum_{j<k} \bar{u}_j \bar{u}_k \langle Y_j : Y_k \rangle} \right) + O(\|Z\|^3_\sigma t^5)\,,\end{aligned}$$

where $Z = \sum_{i=1}^m u_i Y_i$. Now, observe that $\frac{d}{dt}(\phi(c(t))) = \dot{c}(t)(\phi)$. Then, using properties 3 and 4 of ϕ, we get

$$\frac{d}{dt}(\phi(c(t))) = \frac{1}{2}\left(\overline{\sum_{j=1}^m a_{jj}\bar{u}_j^2 + 2\sum_{j<k} a_{jk}\bar{u}_j\bar{u}_k}\right) + O(\|Z\|_\sigma^3 t^5)\,.$$

The expression $\sum_{j=1}^m a_{jj}\bar{u}_j^2 + 2\sum_{j<k} a_{jk}\bar{u}_j\bar{u}_k$ does not change its sign, whatever the functions $u_1(t), \ldots, u_m(t)$ might be, because as a quadratic polynomial in $\bar{u}_{s_1}$ its radicand is always negative. Therefore, $\frac{d}{dt}(\phi(c(t)))$ has constant sign for sufficiently small t, since $\overline{\sum_{j=1}^m a_{jj}\bar{u}_j^2 + 2\sum_{j<k} a_{jk}\bar{u}_j\bar{u}_k}$ is $O(\|u\|^2 t^3)$ and dominates $O(\|Z\|_\sigma^3 t^5) = O(\|u\|^3 t^5)$ when $t \to 0$. Finally,

$$\phi(c(t)) = \phi(q_0) + \int_0^t \frac{d}{ds}(\phi(c(s))) = \int_0^t \frac{d}{ds}(\phi(c(s)))$$

will have constant sign for t small enough. As a consequence, all the points in a neighborhood of q_0 where ϕ has the opposite sign (property 5) are unreachable in small time, which contradicts the hypothesis of controllability.

Case A3. We show that if the radicand $(a^{(m-1)}_{s_{m-1}s_m})^2 - a^{(m-1)}_{s_{m-1}s_{m-1}} a^{(m-1)}_{s_m s_m}$ vanishes, then an intermediate change of basis reduces the problem to considering $m-1$ input vector fields. The preceding discussion can be then reproduced.

The situation now is similar to that of Case A2. However, the argument employed above to discard the possibility of all the radicands being negative does not apply, since in this case there *do* exist controls such that $\sum_{j=1}^m a_{jj}\bar{u}_j^2 + 2\sum_{j<k} a_{jk}\bar{u}_j\bar{u}_k$ is zero, and hence we should really investigate the sign of $O(\|Z\|_\sigma^3 t^5)$ to reach a contradiction. Instead, what we are going to do is to get a new basis $\{Y'_j\}$ such that $\langle Y'_1 : Y'_j\rangle(q_0) \in \mathcal{D}_{q_0}$, $1 \le j \le m$, and thus remove one vector field (Y'_1) from the discussion. By repeating this procedure, we finally come to consider a limit case, which we will discard by contradiction with the controllability hypothesis.

For $j = 1$, we choose $b_{1s_m} \neq 0$ and

$$\begin{aligned}
b_{1s_{m-1}} &= -b_{1s_m}\frac{a^{(m-1)}_{s_{m-1}s_m}}{a^{(m-1)}_{s_{m-1}s_{m-1}}} = C_{s_{m-1}} b_{1s_m}\,,\\
b_{1s_{m-2}} &= -\frac{a^{(m-2)}_{s_{m-2}s_{m-1}} b_{1s_{m-1}} + a^{(m-2)}_{s_{m-2}s_m} b_{1s_m}}{a^{(m-2)}_{s_{m-2}s_{m-2}}} = C_{s_{m-2}} b_{1s_m}\,,\\
&\vdots\\
b_{1s_1} &= -\frac{\sum_{k\neq s_1} b_{1k} a_{ks_1}}{a_{s_1 s_1}} = C_{s_1} b_{1s_m}\,.
\end{aligned} \tag{5.8}$$

We denote $C_{s_m} = 1$. For $j > 1$, we select the $(b_{jk})_{1\le k\le m}$ such that the matrix B is nonsingular. Consequently, we change our original basis $\{Y_1, \ldots, Y_m\}$ to a new one $\{Y'_1, \ldots, Y'_m\}$. In this basis, following (5.2), one has

$$\begin{aligned}
&\langle Y'_1 : Y'_1\rangle(q_0) = lc(Y'_1(q_0), \ldots, Y'_m(q_0))\,,\\
&\langle Y'_j : Y'_j\rangle(q_0) = lc(Y'_1(q_0), \ldots, Y'_m(q_0)) + a'_{jj}\langle Y_1 : Y_2\rangle(q_0)\,, \qquad 2 \le j \le m\,.
\end{aligned}$$

In addition, one can check that for each $2 \le j \le m$,

$$\begin{aligned}\langle Y_1' : Y_j' \rangle(q_0) &= lc(Y_1'(q_0), \dots, Y_m'(q_0)) + \left(\sum_{k,l} a_{kl} b_{1k} b_{jl} \right) \langle Y_1 : Y_2 \rangle(q_0) \\ &= lc(Y_1'(q_0), \dots, Y_m'(q_0)) + b_{1 s_m} \left(\sum_l b_{jl} \left(\sum_k a_{kl} C_k \right) \right) \langle Y_1 : Y_2 \rangle(q_0) \,.\end{aligned}$$

Now, when the C_k are given by (5.8), we have

$$\sum_k a_{kl} C_k = 0 \,, \qquad 1 \le l \le m$$

(see Lemma A.1 in the appendix), and this guarantees that

$$\langle Y_1' : Y_j' \rangle(q_0) = lc(Y_1'(q_0), \dots, Y_m'(q_0)) \,, \qquad 2 \le j \le m \,.$$

If the $a'_{jj} = 0$, $2 \le j \le m$, we are done. Assume then that $a'_{33} \neq 0$, reordering the input vector fields if necessary. Assume further that $\langle Y_2' : Y_3' \rangle(q_0)$ is not a linear combination of $\{Y_1', \dots, Y_m'\}$ (otherwise, redefine a new Y_2'' as $Y_2' + Y_3'$). Then,

$$\begin{aligned}\langle Y_2' : Y_2' \rangle(q_0) &= lc(Y_1'(q_0), \dots, Y_m'(q_0)) + a'_{22} \langle Y_2' : Y_3' \rangle(q_0) \,, \\ &\vdots \\ \langle Y_m' : Y_m' \rangle(q_0) &= lc(Y_1'(q_0), \dots, Y_m'(q_0)) + a'_{mm} \langle Y_2' : Y_3' \rangle(q_0) \,, \\ \langle Y_2' : Y_3' \rangle(q_0) &= a'_{23} \langle Y_2' : Y_3' \rangle(q_0) \,, \\ \langle Y_2' : Y_4' \rangle(q_0) &= lc(Y_1'(q_0), \dots, Y_m'(q_0)) + a'_{24} \langle Y_2' : Y_3' \rangle(q_0) \,, \\ &\vdots \\ \langle Y_{m-1}' : Y_m' \rangle(q_0) &= lc(Y_1'(q_0), \dots, Y_m'(q_0)) + a'_{m-1m} \langle Y_2' : Y_3' \rangle(q_0) \,,\end{aligned}$$

where we have denoted with a slight abuse of notation by a'_{jk} the new coefficients corresponding to $\langle Y_2' : Y_3' \rangle$. Consequently, we can now reproduce the preceding discussion, but with the $m-1$ vector fields $\{Y_2', \dots, Y_m'\}$. That is, we look for one change of basis B' in the vector fields $\{Y_2', \dots, Y_m'\}$ such that the new ones $\{Y_2'', \dots, Y_m''\}$ together with Y_1' verify the sufficient conditions for STLCC at q_0. Accordingly, we must consider the vanishing of the new polynomials

$$\sum_{k=2}^{m} {b_{jk}^2}' a'_{kk} + 2 \sum_{2 \le k < l \le m} b'_{jk} b'_{jl} a'_{kl} = 0 \,, \quad 2 \le j \le m \,.$$

The cases in which the last radicand $(a_{s_{m-1} s_m}^{(m-1)\prime})^2 - a_{s_{m-1} s_{m-1}}^{(m-1)\prime} a_{s_m s_m}^{(m-1)\prime}$ does not vanish are treated as before (Cases A1 and A2). When it vanishes, we obtain a new basis $\{Y_1'' = Y_1', Y_2'', \dots, Y_m''\}$ such that

$$\begin{aligned}&\langle Y_1'' : Y_1'' \rangle(q_0) \,, \langle Y_2'' : Y_2'' \rangle(q_0) \in \mathcal{D}_{q_0} \,, \\ &\langle Y_j'' : Y_j'' \rangle(q_0) = lc(Y_1''(q_0), \dots, Y_m''(q_0)) + c'_{jj} \langle Y_2' : Y_3' \rangle(q_0) \,, \qquad 3 \le j \le m \,, \\ &\langle Y_1'' : Y_j'' \rangle \,, \langle Y_2'' : Y_{j+1}'' \rangle \in \mathcal{D}_{q_0} \,, \qquad 2 \le j \le m \,,\end{aligned}$$

where there could exist some $3 \le j \le m$ such that $c'_{jj} \neq 0$. By an induction procedure, we finally come to consider discarding the case of a certain basis $\{Z_1 = Y_1', Z_2 = Y_2'',$

$\dots, Z_m\}$ of $\mathcal{D}$ satisfying $\langle Z_i : Z_j\rangle(q_0) \in \operatorname{span}\{Z_1(q_0), \dots, Z_m(q_0)\}$, $1 \le i < j \le m$, and the sufficient conditions for STLCC at q_0 for $Z_1, \dots, Z_{m-1}$, but such that $\langle Z_m : Z_m\rangle(q_0) \notin \operatorname{span}\{Z_1(q_0), \dots, Z_m(q_0)\}$. Similarly as we have done above, the application of Lemma 5.1 with the vector fields $\{Z_1, \dots, Z_m, \langle Z_m : Z_m\rangle\}$ implies that the system is not controllable at q_0, yielding a contradiction.

Case B. Finally, we prove that if there exists an $i \ge 2$ such that $a^{(i)}_{kk} = 0$ for all $k \in \{1, \dots, m\} \setminus \{s_1, \dots, s_{i-1}\}$, then either the desired change of basis is straightforward or an intermediate step can be done that reduces the problem to considering $i-1$ input vector fields.

In this case, the polynomial

$$\sum_{k \neq s_1, \dots, s_{i-1}} b^2_{jk} a^{(i)}_{kk} + \quad 2 \sum_{k<l,\, k,l \neq s_1, \dots, s_{i-1}} b_{jk} b_{jl} a^{(i)}_{kl}$$

takes the form

$$2 \sum_{k<l,\, k,l \neq s_1, \dots, s_{i-1}} b_{jk} b_{jl} a^{(i)}_{kl}\,. \tag{5.9}$$

If any of the $a^{(i)}_{kl}$ are different from zero, then it is clear that we can choose the b_{jk}, $k \notin \{s_1, \dots, s_{i-1}\}$, such that (5.9) is positive. Then, reasoning as before, we find a regular matrix B yielding the desired change of basis. If this is not the case, i.e., $a^{(i)}_{kl} = 0$, for all $k < l$, $k, l \notin \{s_1, \dots, s_{i-1}\}$, we can do the following. Choose $\{(b_{jk})_{1 \le j \le m}\}$, with $k \notin \{s_1, \dots, s_{i-1}\}$, $m-i+1$ linearly independent vectors in $\mathbb{R}^m$, such that the minor $\{b_{jk}\}^{k \neq s_1, \dots, s_{i-1}}_{1 \le j \le m-i+1}$ is regular. Now, let j in (5.8) vary between 1 and $m-i+1$; that is, take

$$\begin{aligned} b_{js_{i-1}} &= -\frac{\sum^m_{k \neq s_1, \dots, s_{i-1}} b_{jk} a^{(i-1)}_{s_{i-1}k}}{a^{(i-1)}_{s_{i-1}s_{i-1}}}\,, \\ b_{js_{i-2}} &= -\frac{\sum^m_{k \neq s_1, \dots, s_{i-2}} b_{jk} a^{(i-2)}_{s_{i-2}k}}{a^{(i-2)}_{s_{i-2}s_{i-2}}}\,, \quad \dots, \quad b_{js_1} = -\frac{\sum_{k \neq s_1} b_{jk} a_{ks_1}}{a_{s_1 s_1}}\,, \end{aligned} \tag{5.10}$$

for $1 \le j \le m-i+1$. Finally, for $j > m-i+1$, we select the b_{jk} such that the matrix B is nonsingular. In this manner, in a unique step, we would change to a new basis $\{Y'_1, \dots, Y'_m\}$ verifying

$$\begin{aligned} &\langle Y'_1 : Y'_1\rangle(q_0), \dots, \langle Y'_{m-i+1} : Y'_{m-i+1}\rangle(q_0) \in \mathcal{D}_{q_0}\,, \\ &\langle Y'_j : Y'_j\rangle(q_0) = lc(Y'_1(q_0), \dots, Y'_m(q_0)) + a'_{jj}\langle Y_1 : Y_2\rangle(q_0)\,, \qquad m-i+2 \le j \le m\,, \\ &\langle Y'_k : Y'_l\rangle(q_0) \in \mathcal{D}_{q_0}\,, \qquad k < l,\ 1 \le k \le m-i+1\,, \end{aligned}$$

with possibly some of the $(a'_{jj})_{m-i+1 \le j \le m}$ being different from zero. Now, the above discussion can be redone in this context to assert the validity of the theorem. That is, we have to look for a change of basis B' in the vector fields $\{Y'_{m-i+2}, \dots, Y'_m\}$ such that the new ones, $\{Y''_{m-i+2}, \dots, Y''_m\}$, together with $\{Y'_1, \dots, Y'_{m-i+1}\}$, verify the sufficient conditions for STLCC at q_0. To find the change of basis for $\{Y'_{m-i+2}, \dots, Y'_m\}$, we have to consider the corresponding versions of Cases A and B. If we repeatedly fall into Case B, then we come to discard the same possibility that we encountered in the treatment of Case A3, which can be done again by means of Lemma 5.1. □

To recap, the steps of the proof can be summarized as follows (see Figure 5.1). First, we have considered the case when there exists for all i an s_i such that $a^{(i)}_{s_i s_i} \neq 0$. We have seen that this case can be subdivided into three: one (Case A1) ensuring the desired change of basis, another one (Case A2) in which either one obtains the basis or one contradicts the hypothesis of STLCC, and a third one (Case A3), where an intermediate change of basis is performed that allows us to focus on the search for a change of basis for $m-1$ of the new vector fields. Then, under the same assumption on the new coefficients, a'_{jk} (i.e., for all i, there exists an s_i such that $a^{(i)\prime}_{s_i s_i} \neq 0$), we can reproduce the former discussion. We cannot repeatedly fall into Case A3, since we would contradict the controllability assumption. Finally, we have treated the case when this type of "circular" process is broken (Case B); that is, when there exists an i such that $a^{(i)}_{kk} = 0$ for all $k \neq s_1, \ldots, s_{i-1}$. What we have shown then is that this leads to either a new basis of input vector fields satisfying the sufficient conditions for STLCC or a reduced situation where we can at the same time "get rid" of the problems associated with $m-i+1$ vector fields.

Remark 5.3. Notice that the proof of this result can be reproduced for the corresponding notions of accessibility and controllability at zero velocity. Indeed, a mechanical control system of the form (2.2) with $m = n-1$, which is STLC at q_0 and zero velocity is, in particular, STLCC at q_0. Then, Theorem 5.2 implies that there exists a basis of input vector fields $\mathcal{Y}$ satisfying the sufficient conditions of Theorem 3.2, so the same result is also valid for local controllability at zero velocity.

COROLLARY 5.4. *Let Q be a three-dimensional analytic manifold and let Y_1, Y_2 be analytic vector fields on Q. Consider the control system* (5.1) *and assume that it is LCA at $q_0 \in Q$. Let A be the 2×2 symmetric matrix whose elements are given by*

$$\begin{aligned}
\langle Y_1 : Y_1 \rangle(q_0) &= lc(Y_1(q_0), Y_2(q_0)) + a_{11}\langle Y_1 : Y_2 \rangle(q_0)\,,\\
\langle Y_2 : Y_2 \rangle(q_0) &= lc(Y_1(q_0), Y_2(q_0)) + a_{22}\langle Y_1 : Y_2 \rangle(q_0)\,,\\
\langle Y_1 : Y_2 \rangle(q_0) &= a_{12}\langle Y_1 : Y_2 \rangle(q_0)\,.
\end{aligned}$$

Then the system is locally configuration controllable at q_0 if and only if $\det A < 0$.

Proof. The result follows from the proof of Theorem 5.2 by noting that $\det A < 0$ corresponds to Case A1, $\det A > 0$ to Case A2, and $\det A = 0$ to Case A3. ∎

Remark 5.5. Note that Corollary 5.4 together with Theorem 5.2 completely characterize the configuration controllability properties of mechanical control systems with three degrees of freedom, since fully actuated systems are obviously STLCC.

6. Examples.

6.1. The planar rigid body. Consider a planar rigid body [24]. Fix a point $P \in \mathbb{R}^2$ and let $\{e_1, e_2\}$ be the standard orthonormal frame at that point. Let $\{d_1, d_2\}$ be an orthonormal frame attached to the body at its center of mass. The configuration manifold is then $SE(2)$, with coordinates (x, y, θ), where (x, y) describe the position of the center of mass and θ the orientation of the frame $\{d_1, d_2\}$ with respect to $\{e_1, e_2\}$.

The inputs of the system consist of a force F^1 applied at a distance h from the center of mass CM and a torque, F^2, about CM (see Figure 6.1). In coordinates, the input forces are given by

$$F^1 = -\sin\theta dx + \cos\theta dy - h d\theta\,, \qquad F^2 = d\theta\,.$$

The Riemannian metric is

$$g = m dx \otimes dx + m dy \otimes dy + J d\theta \otimes d\theta\,,$$

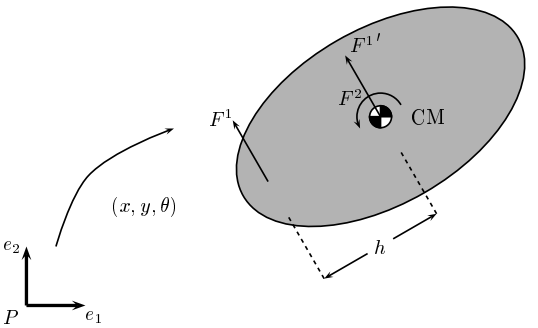

FIG. 6.1. *The planar rigid body.*

where m is the mass of the body and J its moment of inertia.

The input vector fields can be computed via $\flat_g^{-1}$ as

$$Y_1 = -\frac{\sin\theta}{m}\frac{\partial}{\partial x} + \frac{\cos\theta}{m}\frac{\partial}{\partial y} - \frac{h}{J}\frac{\partial}{\partial\theta}d\theta\,, \qquad Y_2 = \frac{1}{J}\frac{\partial}{\partial\theta}\,.$$

One can easily show that the planar body is LCA [24]. However, the inputs Y_1, Y_2 fail to satisfy the sufficient conditions for STLCC. In fact,

$$\begin{aligned}
\langle Y_1 : Y_1\rangle &= \frac{2h\cos\theta}{mJ}\frac{\partial}{\partial x} + \frac{2h\sin\theta}{mJ}\frac{\partial}{\partial y}\,,\\
\langle Y_1 : Y_2\rangle &= -\frac{\cos\theta}{mJ}\frac{\partial}{\partial x} - \frac{\sin\theta}{mJ}\frac{\partial}{\partial y}\,,\\
\langle Y_2 : Y_2\rangle &= 0\,.
\end{aligned}$$

Therefore, $\{Y_1, Y_2, \langle Y_1 : Y_2\rangle\}$ are linearly independent and $\langle Y_1 : Y_1\rangle = -2h\langle Y_1 : Y_2\rangle$. Theorem 5.2 ensures STLCC if and only if there exists a basis of input vector fields satisfying the sufficient conditions. We have that

$$\det A = \det\begin{pmatrix} -2h & 1\\ 1 & 0\end{pmatrix} = -1 < 0\,,$$

and consequently, by Corollary 5.4, the system is locally configuration controllable. Indeed, this example falls into Case A1 of the proof of Theorem 5.2. Accordingly, we obtain the change of basis $Y_1' = Y_1 + hY_2$, $Y_2' = Y_2$. This yields

$$\langle Y_1' : Y_1'\rangle = \langle Y_2' : Y_2'\rangle = 0\,, \qquad \langle Y_1' : Y_2'\rangle = \langle Y_1 : Y_2\rangle\,,$$

which satisfies the sufficient conditions for STLCC. The new input vector field precisely corresponds to the force $F^{1'}$ in Figure 6.1.

6.2. A simple example. The following example does not necessarily correspond to a physical example, but it illustrates the proof of Theorem 5.2. Consider a mechanical control system on $\mathbb{R}^3$, with coordinates (x, y, z). The Riemannian metric is given by

$$g = dx \otimes dx + dy \otimes dy + dz \otimes dz$$

and the input vector fields are

$$Y_1 = z\frac{\partial}{\partial x} + \frac{\partial}{\partial y} + \frac{1}{4}\frac{\partial}{\partial z}\,, \qquad Y_2 = y\frac{\partial}{\partial x} + \frac{1}{4}\frac{\partial}{\partial y} - \frac{1}{2}\frac{\partial}{\partial z}\,.$$

In coordinates, we have the following control equations:

$$\ddot{x} = u_1 z + u_2 y\,, \quad \ddot{y} = u_1 + \frac{u_2}{4}\,, \quad \ddot{z} = \frac{u_1}{4} - \frac{u_2}{2}\,. \tag{6.1}$$

Since

$$\langle Y_1 : Y_1\rangle = \langle Y_1 : Y_2\rangle = \langle Y_2 : Y_2\rangle = \frac{1}{2}\frac{\partial}{\partial x}\,,$$

we deduce that $\operatorname{span}\{Y_1(q), Y_2(q), \langle Y_1 : Y_2\rangle(q)\} = T_qQ$ for all $q \in Q$ and the system (6.1) is LCA. However, Corollary 5.4 implies that it is not STLCC, since $\det A = 0$. Going through the proof of Theorem 5.2, we see that this example falls into Case A3. Choosing the change of basis

$$B = \begin{pmatrix} -1 & 1 \\ 1 & 1 \end{pmatrix},$$

we get the new input vector fields $Y_1' = -Y_1 + Y_2$ and $Y_2' = Y_1 + Y_2$. Now, we have

$$\langle Y_1' : Y_1'\rangle = 0\,, \quad \langle Y_1' : Y_2'\rangle = 0\,, \quad \langle Y_2' : Y_2'\rangle = 2\frac{\partial}{\partial x}\,.$$

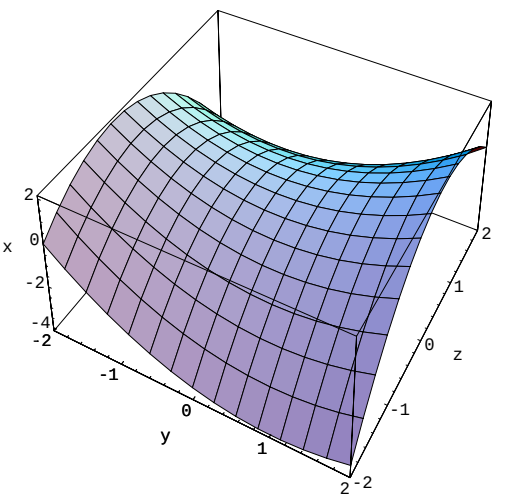

FIG. 6.2. *The level surface* $\phi(x, y, z) = 0$.

We can compute explicitly the function ϕ of Lemma 5.1 for this example. The flows of $Z_1 = Y_1'$, $Z_2 = Y_2'$, $Z_3 = -\langle Y_2' : Y_2'\rangle$ are given by

$$\begin{aligned}
\Psi_1(t)(x, y, z) &= (x + (y - z)t, y - 3t/4, z - 3t/4)\,,\\
\Psi_2(t)(x, y, z) &= (x + (y + z)t + t^2/2, y + 5t/4, z - t/4)\,,\\
\Psi_3(t)(x, y, z) &= (x - 2t, y, z)\,.
\end{aligned}$$

Letting (x_0, y_0, z_0) be an arbitrary point, one verifies

$$\begin{aligned}\Psi_1(t_1) \circ \Psi_2(t_2) \circ \Psi_3(t_3)(x_0, y_0, z_0) \\ = \left(x_0 - 2t_3 + \left(y_0 + z_0 + \frac{1}{2} t_2 \right) t_2 + t_1 \left(y_0 - z_0 - \frac{3}{2} t_2 \right), \right. \\ \left. y_0 - \frac{3}{4} t_1 + \frac{5}{4} t_2, z_0 - \frac{3}{4} t_1 - \frac{1}{4} t_2 \right).\end{aligned}$$

We may solve for $\phi(x, y, z) = t_3$ as

$$\begin{aligned}&\phi(x, y, z) \\ &= \frac{1}{18} \left(-9(x - x_0) + 4(y^2 - y y_0 + yz - 5 y_0 z - 2z^2 + y z_0 + 3 y_0 z_0 + 5 z z_0 - 3 z_0^2) \right).\end{aligned}$$

In Figure 6.2, we show the level set $\phi(x, y, z) = 0$ for $(x_0, y_0, z_0) = (0, 0, 0)$. The locally accessible configurations from $(0, 0, 0)$ are contained below the surface, where $\phi(x, y, z) \geq 0$.

7. Conclusions. In this paper, we have built on previous results on controllability and series expansions for the evolution of mechanical control systems within the affine connection formalism to demonstrate that the sufficient conditions encountered in [24] for STLCC are also necessary when the configuration manifold is n-dimensional and the system is actuated by $n - 1$ inputs, in the sense that there exists some basis of input vector fields that verifies them.

However $n - 1$ controls is a special case and is the simplest case next to fully actuated systems, which are always STLCC. For an arbitrary number of inputs, higher-order controllability will necessarily play a key role. Future research will be devoted to investigating the validity of the controllability conjecture in the full general case.

Appendix A. A simple lemma.

LEMMA A.1. *With the notation of Theorem* 5.2, *assume that* $(a^{(m-1)}_{s_{m-1}s_m})^2 - a^{(m-1)}_{s_{m-1}s_{m-1}} a^{(m-1)}_{s_m s_m} = 0$. *Then the coefficients* C_k *given by* (5.8) *verify*

$$\sum_{k=1}^{m} a_{kl} C_k = 0\,, \qquad 1 \leq l \leq m\,.$$

Proof. From (5.8), one can obtain the following recurrence formula for the coefficients C_k:

$$C_{s_m} = 1\,, \quad C_{s_j} = -\frac{1}{a^{(j)}_{s_j s_j}} \left(\sum_{i=j+1}^{m} a^{(j)}_{s_i s_j} C_{s_i} \right), \quad 1 \leq j \leq m-1\,. \tag{A.1}$$

Let us denote

$$\Sigma(l) = \sum_{k=1}^{m} a_{kl} C_k\,.$$

It is easy to see that $\Sigma(s_1) = 0$. Indeed, using (A.1), we have that

$$\Sigma(s_1) = a_{s_1 s_1} C_{s_1} + \sum_{i=2}^{m} a_{s_i s_1} C_{s_i} = -\sum_{i=2}^{m} a_{s_i s_1} C_{s_i} + \sum_{i=2}^{m} a_{s_i s_1} C_{s_i} = 0\,.$$

To prove the result for the remaining indices we can do the following. First, note that

$$a_{s_1 s_j} C_{s_1} = -\frac{a_{s_1 s_j}}{a_{s_1 s_1}} \left(\sum_{i=2}^{m} a_{s_i s_j} C_{s_i} \right) = -\sum_{i=2}^{m} \left(\frac{a_{s_1 s_j} a_{s_i s_j}}{a_{s_1 s_1}} \right) C_{s_i} \,.$$

Then, substituting in $\Sigma(s_j)$, we get

$$\begin{aligned} \Sigma(s_j) &= -\sum_{i=2}^{m} \left(\frac{a_{s_1 s_j} a_{s_i s_j}}{a_{s_1 s_1}} \right) C_{s_i} + \sum_{i=2}^{m} a_{s_i s_j} C_{s_i} \\ &= \sum_{i=2}^{m} \left(\frac{a_{s_i s_j} a_{s_1 s_1} - a_{s_1 s_j} a_{s_i s_j}}{a_{s_1 s_1}} \right) C_{s_i} = -\frac{1}{a_{s_1 s_1}} \left(\sum_{i=2}^{m} a^{(2)}_{s_i s_j} C_{s_i} \right), \end{aligned}$$

where we have used the definition (5.5) for the coefficients $a^{(j)}_{kl}$. This procedure can be iterated to obtain the general expression

$$\Sigma(s_j) = \frac{(-1)^k}{a_{s_1 s_1} a^{(2)}_{s_2 s_2} \dots a^{(k)}_{s_k s_k}} \left(\sum_{i=k+1}^{m} a^{(k+1)}_{s_i s_j} C_{s_i} \right), \tag{A.2}$$

which is valid for any $1 \le k \le m-2$.

Now, consider the cases $2 \le j \le m-1$. Take $k = j-1$. Then, using (A.2),

$$\begin{aligned} \Sigma(s_j) &= \frac{(-1)^{j-1}}{a_{s_1 s_1} a^{(2)}_{s_2 s_2} \dots a^{(j-1)}_{s_{j-1} s_{j-1}}} \left(\sum_{i=j}^{m} a^{(j)}_{s_i s_j} C_{s_i} \right) \\ &= \frac{(-1)^{j-1}}{a_{s_1 s_1} a^{(2)}_{s_2 s_2} \dots a^{(j-1)}_{s_{j-1} s_{j-1}}} \left(a^{(j)}_{s_j s_j} C_{s_j} + \sum_{i=j+1}^{m} a^{(j)}_{s_i s_j} C_{s_i} \right) = 0 \,, \end{aligned}$$

where in the last equality we have used (A.1). Finally, if $j = m$, we have that

$$\begin{aligned} \Sigma(s_m) &= \frac{(-1)^{m-2}}{a_{s_1 s_1} a^{(2)}_{s_2 s_2} \dots a^{(m-2)}_{s_{m-2} s_{m-2}}} \left(a^{(m-1)}_{s_{m-1} s_m} C_{s_{m-1}} + a^{(m-1)}_{s_m s_m} C_{s_m} \right) \\ &= \frac{(-1)^{m-2}}{a_{s_1 s_1} a^{(2)}_{s_2 s_2} \dots a^{(m-2)}_{s_{m-2} s_{m-2}}} \left(-\frac{(a^{(m-1)}_{s_{m-1} s_m})^2}{a^{(m-1)}_{s_{m-1} s_{m-1}}} + a^{(m-1)}_{s_m s_m} \right). \end{aligned}$$

From the hypothesis $(a^{(m-1)}_{s_{m-1} s_m})^2 - a^{(m-1)}_{s_{m-1} s_{m-1}} a^{(m-1)}_{s_m s_m} = 0$, we conclude that $\Sigma(s_m) = 0$, and this completes the proof. □

TRAJECTORY-BASED LOCAL APPROXIMATIONS OF ORDINARY DIFFERENTIAL EQUATIONS*

LUC MOREAU† AND DIRK AEYELS†

Abstract. The present paper introduces a new definition of local approximation for ordinary differential equations locally around an equilibrium point. This definition generalizes the well-known linear and homogeneous approximations. The approach is based on approximating trajectories near the origin. This concept of local approximation is applied to the study of local uniform asymptotic stability, leading to alternative proofs for and extensions of several existing stability results.

Key words. asymptotic stability, ordinary differential equations, averaging, perturbations

1. Introduction.

It is of course well-known that in general the solutions of a nonlinear differential equation cannot be obtained in closed form. Accordingly, various methods have been developed to approximate these solutions. Apart from numerical integration techniques, several asymptotic methods are available. These asymptotic methods typically reflect the structural properties possessed by the differential equation under consideration. Averaging techniques [24], for example, are applicable when the time variation in the constitutive relation is much faster then the rate of change of the state with time. Singular perturbation techniques [10] may be applied when some components of the state evolve on a much faster time scale than other state components.

In a standard setting, asymptotic methods are concerned with differential equations depending on a small parameter. Asymptotic methods enable us to approximate the solutions of this equation by the solutions of a simpler equation (or several simpler equations). Standard results in this context are concerned with closeness properties of solutions. Typically, it is proven that solutions of the original equation converge uniformly on compact time-intervals to solutions of the simpler, limiting equation as the parameter tends to zero.

A different class of results that has been obtained in the literature on asymptotic methods is concerned with stability properties. The subject of these studies is the extent to which stability properties of the original differential equation (for small enough values of the parameter) may be inferred from stability properties of the simpler, limiting system. These results are typically obtained by means of Lyapunov techniques, as in [9, 13, 20], or by means of generalized Lyapunov techniques, as in [4] and [1, 23, 22].

In previous papers [17, 18] we have initiated a new approach to obtain such sta-

bility results. This approach is centered around the observation that many of these stability results may be obtained directly as a consequence of the closeness property for solutions, even if the convergence is only proven to be uniform on compact time-intervals. In other words, stated as a general principle, *it is possible to deduce stability properties for a dynamical system based upon an approximate analysis of its trajectories, even if this approximation is only proven to be valid on finite time-intervals.* Important features of the present approach are that it only makes use of elementary mathematical techniques and that, in contrast with other approaches based on (generalized) Lyapunov techniques, the present approach does not rely on converse Lyapunov theorems. Consequently, the present approach lends itself naturally to generalizations to differential equations with delay and to the study of input-to-state stability. (Such extensions are being studied in [19] and [29].)

The present work is a continuation of this line of research initiated in [17, 18]. In those papers, the original system, whose stability properties are to be analyzed, depends on a small parameter—recall that this is the natural setting for asymptotic methods. In the present paper we show that the presence of a small parameter is not always needed; the general principle mentioned above may also be applicable when the original system does not depend on a small parameter. In this case, instead of assuming the presence of a small parameter, we typically impose appropriate *homogeneity* assumptions on the right-hand side (RHS) of the differential equation. The stability property that will be studied in this case is local uniform asymptotic stability.

The paper is organized as follows. After the preliminaries in section 2, we present in section 3 the main theorem of the paper. This theorem relates closeness properties for trajectories with stability properties. It states that, if the solutions of an ordinary differential equation starting near the origin (which is assumed to be an equilibrium point) are sufficiently close (in some well-defined sense) to the solutions of another differential equation, which has a locally uniformly asymptotically stable equilibrium point at the origin, then the origin of the original system is also locally uniformly asymptotically stable. This result leads to the introduction of a new notion of local approximation for ordinary differential equations, whose definition is based on approximating trajectories near the origin. This new notion generalizes the well-known linear and homogeneous approximations. As an immediate consequence of our main result, we obtain that the null-solution of a given system is locally uniformly asymptotically stable if the origin of its local approximation is locally uniformly asymptotically stable. In section 4 we show how this concept of local approximation relates to more standard closeness results for differential equations depending on a small parameter. This relation is made explicit by means of a rescaling mechanism. Applications are given in section 5, where it is shown how the general theory of the paper enables us to recover and extend several known stability results. We conclude the paper in section 6.

We end this introduction with some references to related work. A rescaling mechanism similar to the present one has been used, for example, in [3] and [30, p. 227] in the context of, respectively, bifurcation analysis and renormalization techniques. The rescaling mechanism featuring in the present paper is more general, since we will associate different scaling factors with different coordinate axes. The fact that the presence of a small parameter is not needed in order to obtain stability results was already observed in [28] and [23] in the context of averaging theory. These references make use of, respectively, center manifold theory and generalized Lyapunov theorems. Related but independent work may be found in [13] and [25]. The first reference makes

use of Lyapunov theory; the second studies periodic differential equations (with period, say, 1) by means of nonlinear Floquet theory, the time-1-map being calculated by means of Lie and chronologico-algebraic tools.

2. Preliminary definitions. The state space of all dynamical systems in the present paper is $\mathbb{R}^n$ with $n \in \mathbb{N}$.

2.1. Homogeneity. Homogeneity refers to symmetry properties with respect to a family of dilation mappings. Homogeneity plays a prominent role in various aspects of nonlinear control theory. See, for example, [6, 8, 14, 20] for some applications in feedback control. In the present paper, homogeneity will play an important role in section 5, where the general theory of the paper is applied to particular examples.

Consider an n-tuple $r = (r_1, \ldots, r_n) \in ((0, \infty))^n$. We define the family of *dilation mappings* δ_λ^r $(\lambda \in (0, \infty))$ as

$$\delta_\lambda^r : \mathbb{R}^n \to \mathbb{R}^n : x \mapsto \delta_\lambda^r x = (\lambda^{r_1} x_1, \ldots, \lambda^{r_n} x_n). \tag{1}$$

A continuous function $h : \mathbb{R}^n \to \mathbb{R}$ is *r-homogeneous of degree $m \in [0, \infty)$* if $h(\delta_\lambda^r x) = \lambda^m h(x)$ for all $\lambda \in (0, \infty)$ and $x \in \mathbb{R}^n$. A continuous function $f : \mathbb{R}^n \to \mathbb{R}^n$ is *r-homogeneous of order $\tau \in [0, \infty)$* if $f(\delta_\lambda^r x) = \lambda^\tau \delta_\lambda^r f(x)$ for all $\lambda \in (0, \infty)$ and $x \in \mathbb{R}^n$. An *r-homogeneous norm* ρ is a continuous function $\rho : \mathbb{R}^n \to \mathbb{R}$ which is zero at the origin, strictly positive elsewhere, and r-homogeneous of degree 1.

Remark 1. A continuous function $f : \mathbb{R}^n \to \mathbb{R}^n$ which is r-homogeneous of order $\tau \geq 0$ will typically not be locally Lipschitz at the origin if $\tau < \max\{r_1, \ldots, r_n\} - \min\{r_1, \ldots, r_n\}$. When f is continuously differentiable on $\mathbb{R}^n \setminus \{0\}$, this follows from the homogeneity properties of the partial derivatives:

$$\frac{\partial f_i}{\partial x_j}(\delta_\lambda^r x) = \lambda^{\tau + r_i - r_j} \frac{\partial f_i}{\partial x_j}(x) \tag{2}$$

for all $x \in \mathbb{R}^n \setminus \{0\}$, $\lambda \in (0, \infty)$, and $i, j \in \{1, \ldots, n\}$. Indeed, if $\tau + r_i - r_j < 0$ for some pair of indices (i, j), then $\frac{\partial f_i}{\partial x_j}(\delta_\lambda^r x)$ may blow up as $\lambda \downarrow 0$ with x fixed. In the statements of the various results in the paper, we will therefore always take into account the possibility of the vectorfield being non-Lipschitz at the origin.

Remark 2. An r-homogeneous norm is not necessarily a norm in the topological sense since it might not satisfy the triangle inequality. For some considerations, however, an r-homogeneous norm ρ and the Euclidean norm $\|\cdot\|$ may be used interchangeably. For example, it is easy to see that

$$\rho(x) \to 0 \Leftrightarrow \|x\| \to 0, \tag{3}$$

$$\rho(x) \to \infty \Leftrightarrow \|x\| \to \infty. \tag{4}$$

In these cases it may be convenient to pass from an r-homogeneous norm to the Euclidean norm, since the Euclidean norm does satisfy the triangle inequality.

2.2. Dynamical systems and flows. All dynamical systems in the present paper are described by ordinary differential equations

$$\dot{x} = f(t, x),$$

where, by assumption, f is a continuous map from $\mathbb{R} \times \mathbb{R}^n$ to $\mathbb{R}^n$ and $\dot{x} = f(t, x)$ has the uniqueness property of solutions.[1] Recall that existence of solutions is guaranteed by

[1] That is, for every $(t_0, x_0) \in \mathbb{R} \times \mathbb{R}^n$, there is a solution $\xi : \mathrm{Dom}\,(\xi) \to \mathbb{R}^n$ of $\dot{x} = f(t, x)$ with $\xi(t_0) = x_0$ such that (i) $\mathrm{Dom}\,(\xi)$ is an open interval containing t_0 and (ii) for any other solution $\bar{\xi} : \mathrm{Dom}\,(\bar{\xi}) \to \mathbb{R}^n$ of $\dot{x} = f(t, x)$ with $\bar{\xi}(t_0) = x_0$, (a) $\mathrm{Dom}\,(\bar{\xi}) \subset \mathrm{Dom}\,(\xi)$ and (b) $\bar{\xi}$ and ξ coincide on $\mathrm{Dom}\,(\bar{\xi})$. We call ξ the *trajectory* of this system passing through state x_0 at time t_0.

continuity of f. These dynamical systems will be referred to as *admissible dynamical systems on* $\mathbb{R}^n$. We do not assume completeness of solutions; that is, we do not exclude finite escape times. Before we explicitly state sufficient conditions for uniqueness of solutions, we first introduce an interesting class of functions from $\mathbb{R} \times \mathbb{R}^n$ to $\mathbb{R}^n$.

DEFINITION 2.1 (class-$\mathcal{CLB}$ function). *A function* $f : \mathbb{R} \times \mathbb{R}^n \to \mathbb{R}^n : (t, x) \mapsto f(t, x)$ *is a class-*$\mathcal{CLB}$ *function if the following three conditions are all satisfied:*

1. f *is continuous in* (t, x)*;*
2. f *is locally Lipschitz in* $x \in \mathbb{R}^n \setminus \{0\}$ *uniformly with respect to* $t \in \mathbb{R}$*; that is, for each compact set* $K \subset \mathbb{R}^n \setminus \{0\}$*, there exists* $k \in [0, \infty)$ *such that*

$$\|f(t, x_1) - f(t, x_2)\| \leq k\|x_1 - x_2\| \qquad \forall t \in \mathbb{R} \quad \forall x_1, x_2 \in K;$$

3. f *is bounded in* $t \in \mathbb{R}$ *uniformly with respect to* x *in compact subsets of* $\mathbb{R}^n$*; that is, for each compact set* $K \subset \mathbb{R}^n$*, there exists* $M \in [0, \infty)$ *such that*

$$\|f(t, x)\| \leq M \qquad \forall t \in \mathbb{R} \quad \forall x \in K.$$

The following lemma provides sufficient conditions for uniqueness of solutions. It will be used in various proofs and may be of independent interest.

LEMMA 2.2. *Let* $r \in ((0, \infty))^n$ *and* $f : \mathbb{R} \times \mathbb{R}^n \to \mathbb{R}^n : (t, x) \mapsto f(t, x)$*. Assume that*

(a) $f \in \mathcal{CLB}$*;*

(b) $\delta^r_{1/\lambda} f(t, \delta^r_\lambda x)$ *remains bounded as* $\lambda \downarrow 0$*, uniformly with respect to* $t \in \mathbb{R}$ *and* x *in compact subsets of* $\mathbb{R}^n$*.*

Then the ordinary differential equation

$$\dot{x} = f(t, x) \tag{5}$$

has the uniqueness property of solutions.

Assumption (a) of the lemma implies uniqueness of solutions in the region $\mathbb{R}^n \setminus \{0\}$ of the state space, but does not exclude nonunique behavior at the origin. The possibility of nonuniqueness at the origin is ruled out by assumption (b). This may be seen as follows. First of all, notice that the origin is an equilibrium point by continuity of f and assumption (b). Suppose that the null solution is not unique, say, in forward time. That is, assume the existence of a solution $t \mapsto \zeta(t)$ that starts in the origin and leaves the origin in forward time. It is not difficult to see that this implies that $\sup\{||(\mathrm{d}/\mathrm{d}t)\delta^r_{1/\lambda}\zeta(t)|| : \delta^r_{1/\lambda}\zeta(t) \in K\} \to \infty$ as $\lambda \downarrow 0$, where K is a small neighborhood around the origin. This yields a contradiction, since $t \mapsto \delta^r_{1/\lambda}\zeta(t)$ is a solution of $\dot{x} = \delta^r_{1/\lambda} f(t, \delta^r_\lambda x)$, and the RHS of this equation is assumed to be bounded as $\lambda \downarrow 0$ as stated in assumption (b). A rigorous proof along these lines is given in Appendix A.

Remark 3. Lemma 2.2 is a modest extension of [14, Lemma 2]. In that reference, assumption (b) is replaced by the stronger assumption that f is r-homogeneous of order 0 in x. The present result includes this as a particular case but extends it, for example, to functions f which are r-homogeneous of order $\tau \geq 0$ in x, or to sums of functions which are r-homogeneous of various nonnegative orders.

Consider an admissible dynamical system on $\mathbb{R}^n$ and let $\phi(t, t_0, x_0)$ be the trajectory of this system passing through state x_0 at time t_0 evaluated at time t. The function $\phi : (t, t_0, x_0) \mapsto \phi(t, t_0, x_0)$ is the *flow* of this system. The domain of ϕ is open and ϕ is continuous on its domain [5, Chapter 5, Theorem 2.1].

Let $r \in ((0, \infty))^n$ and $\tau \in [0, \infty)$. An admissible dynamical system $\dot{x} = f(t, x)$ on $\mathbb{R}^n$ is *r-homogeneous of order τ* if f is r-homogeneous of order τ in x for all t. An admissible dynamical system $\dot{x} = f(t, x)$ on $\mathbb{R}^n$ and its corresponding flow ϕ are said to have the *(r, τ)-scaling property of trajectories* if

$$\phi(t, t_0, \delta_\lambda^r x_0) = \delta_\lambda^r \phi(\lambda^\tau t, \lambda^\tau t_0, x_0). \tag{6}$$

This means that, modulo a scaling of time, δ_λ^r maps trajectories to trajectories. As may be expected, there is a relationship between homogeneity properties of a vector-field and scaling properties of the corresponding trajectories. An admissible dynamical system $\dot{x} = f(t, x)$ on $\mathbb{R}^n$ that is r-homogeneous of order 0 has the $(r, 0)$-scaling property of trajectories, and an admissible dynamical system on $\mathbb{R}^n$ that is r-homogeneous of order $\tau > 0$ has the (r, τ)-scaling property of trajectories if the differential equation does not depend explicitly on time. These statements may be proven by verifying that the RHS of (6) viewed as a function of t is the solution of $\dot{x} = f(t, x)$ that passes through state $\delta_\lambda^r x_0$ at time t_0. It is important to notice that admissible dynamical systems on $\mathbb{R}^n$ that are r-homogeneous of order $\tau > 0$ in general do not have the (r, τ)-scaling property of trajectories if the differential equation depends explicitly on time.

3. Approximation of dynamical systems. We start this section with the main theorem of the paper: consider two admissible dynamical systems on $\mathbb{R}^n$ having an equilibrium point at the origin,

$$\dot{x} = f(t, x) \tag{7}$$

and

$$\dot{x} = g(t, x). \tag{8}$$

Assume that (8) has the (r, τ)-scaling property of trajectories for some $r \in ((0, \infty))^n$ and $\tau \geq 0$, and assume that the origin of (8) is locally uniformly asymptotically stable (LUAS). Theorem 3.1 states that, if trajectories of (7) that start near the origin are sufficiently close to trajectories of (8), then the origin of (7) is also LUAS. This theorem is the basis for all further result of the paper.

THEOREM 3.1. *Consider an admissible dynamical system $\dot{x} = g(t, x)$ on $\mathbb{R}^n$ with flow ψ having an equilibrium point at the origin. Consider also $r \in ((0, \infty))^n$, $\tau \geq 0$, and an r-homogeneous norm ρ. Assume that*

(a) *$\dot{x} = g(t, x)$ has the (r, τ)-scaling property of trajectories, and*

(b) *the origin of $\dot{x} = g(t, x)$ is LUAS.*

Then there exist $T \in [0, \infty)$ and $d \in (0, \infty)$ such that for every admissible dynamical system $\dot{x} = f(t, x)$ on $\mathbb{R}^n$ with flow ϕ having an equilibrium point at the origin, the following holds: if there exists $\sigma \in (0, \infty)$ such that for all $t_0 \in \mathbb{R}$ and $x_0 \in \mathbb{R}^n$ with $0 < \rho(x_0) \leq \sigma$

$$\begin{cases} \phi(t, t_0, x_0) \text{ exists} & \forall t \in [t_0, t_0 + \frac{T}{\rho(x_0)^\tau}], \\ \rho(\phi(t, t_0, x_0) - \psi(t, t_0, x_0)) < \rho(x_0) d & \forall t \in [t_0, t_0 + \frac{T}{\rho(x_0)^\tau}], \end{cases} \tag{9}$$

then the origin of $\dot{x} = f(t, x)$ is LUAS, and $\{x_0 \in \mathbb{R}^n : \rho(x_0) \leq \sigma\}$ is contained in its region of attraction.

Proof. We begin with studying the implications of assumptions (a) and (b) for the flow ψ of $\dot{x} = g(t, x)$. Since the origin of $\dot{x} = g(t, x)$ is assumed to be a LUAS

equilibrium point, there exist $c \in (0, \infty)$, $m \in [1, \infty)$, and $T \in (0, \infty)$ such that

$$\forall t_0 \in \mathbb{R}, \quad \forall x_0 \in \mathbb{R}^n \text{ with } \rho(x_0) = c, \quad \rho(\psi(t, t_0, x_0)) \leq \begin{cases} cm & \forall t \geq t_0, \\ c\frac{1}{2} & \forall t \geq t_0 + \frac{T}{c^\tau}. \end{cases} \tag{10}$$

(The particular choice for the constants cm, $c/2$, and T/c^τ in (10) is inspired by expression (11), which we are about to prove.) We show that, by the scaling property of trajectories of ψ, (10) implies

(11)

$$\forall t_0 \in \mathbb{R}, \quad \forall x_0 \in \mathbb{R}^n \text{ with } x_0 \neq 0, \quad \rho(\psi(t, t_0, x_0)) \leq \begin{cases} \rho(x_0)m & \forall t \geq t_0, \\ \rho(x_0)\frac{1}{2} & \forall t \geq t_0 + \frac{T}{\rho(x_0)^\tau}. \end{cases}$$

Indeed, for $x_0 \neq 0$,

$$\rho(\psi(t, t_0, x_0))$$

may be rewritten as

$$\rho\left(\psi(t, t_0, \delta^r_{\rho(x_0)/c}\delta^r_{c/\rho(x_0)}x_0)\right)$$

or, by the scaling property of trajectories of ψ, as

$$\rho\left(\delta^r_{\rho(x_0)/c}\psi\left((\rho(x_0)/c)^\tau t, (\rho(x_0)/c)^\tau t_0, \delta^r_{c/\rho(x_0)}x_0\right)\right)$$

and, since ρ is r-homogeneous of degree 1, as

$$\frac{\rho(x_0)}{c}\rho\left(\psi\left((\rho(x_0)/c)^\tau t, (\rho(x_0)/c)^\tau t_0, \delta^r_{c/\rho(x_0)}x_0\right)\right).$$

Since $\rho(\delta^r_{c/\rho(x_0)}x_0) = c$, we apply (10) and obtain

$$\begin{aligned} &\forall t_0 \in \mathbb{R}, \quad \forall x_0 \in \mathbb{R}^n \text{ with } x_0 \neq 0, \\ &\qquad \rho(\psi(t, t_0, x_0)) = \frac{\rho(x_0)}{c}\rho\left(\psi\left((\rho(x_0)/c)^\tau t, (\rho(x_0)/c)^\tau t_0, \delta^r_{c/\rho(x_0)}x_0\right)\right) \\ &\qquad\qquad \leq \begin{cases} \frac{\rho(x_0)}{c}cm & \forall\, (\rho(x_0)/c)^\tau t \geq (\rho(x_0)/c)^\tau t_0, \\ \frac{\rho(x_0)}{c}c\frac{1}{2} & \forall\, (\rho(x_0)/c)^\tau t \geq (\rho(x_0)/c)^\tau t_0 + \frac{T}{c^\tau}, \end{cases} \end{aligned}$$

yielding (11).

Next we derive some "triangle-like" inequalities for the r-homogeneous norm ρ. Let $d \in (0, \infty)$ be such that

$$\forall x_1, x_2 \in \mathbb{R}^n, \qquad \left.\begin{matrix} \rho(x_1) \leq \frac{1}{2} \\ \rho(x_2 - x_1) < d \end{matrix}\right\} \Rightarrow \rho(x_2) \leq \frac{3}{4}. \tag{12}$$

Equation (12) implies that for any $\lambda \in (0, \infty)$

$$\forall x_1, x_2 \in \mathbb{R}^n, \qquad \left.\begin{array}{r} \rho(x_1) \leq \lambda \frac{1}{2} \\ \rho(x_2 - x_1) < \lambda d \end{array}\right\} \Rightarrow \rho(x_2) \leq \lambda \frac{3}{4}. \tag{13}$$

Indeed, $\rho(x_1) \leq \lambda \frac{1}{2}$ iff $\rho\big(\delta^r_{1/\lambda} x_1\big) \leq \frac{1}{2}$ since ρ is r-homogeneous of degree 1. Similarly, $\rho(x_2 - x_1) < \lambda d$ iff $\rho\big(\delta^r_{1/\lambda}(x_2 - x_1)\big) < d$, which, by linearity of δ^r_λ, is equivalent to $\rho\big(\delta^r_{1/\lambda} x_2 - \delta^r_{1/\lambda} x_1\big) < d$. Therefore, it follows from (12) that $\rho\big(\delta^r_{1/\lambda} x_2\big) \leq \frac{3}{4}$. This, in turn, is equivalent to $\rho(x_2) \leq \lambda \frac{3}{4}$, from which (13) follows. Let $M \in (1, \infty)$ be such that

$$\forall x_1, x_2 \in \mathbb{R}^n, \qquad \left.\begin{array}{r} \rho(x_1) \leq m \\ \rho(x_1 - x_2) < d \end{array}\right\} \Rightarrow \rho(x_2) \leq M. \tag{14}$$

As above, this implies that for any $\lambda \in (0, \infty)$

$$\forall x_1, x_2 \in \mathbb{R}^n, \qquad \left.\begin{array}{r} \rho(x_1) \leq \lambda m \\ \rho(x_1 - x_2) < \lambda d \end{array}\right\} \Rightarrow \rho(x_2) \leq \lambda M. \tag{15}$$

Notice that the numbers $T \in [0, \infty)$ and $d \in (0, \infty)$ we have introduced so far are independent of $\dot{x} = f(t, x)$, as required in the statement of the theorem. We now turn our attention to $\dot{x} = f(t, x)$ and assume that there exists $\sigma \in (0, \infty)$ such that

$$\forall t_0 \in \mathbb{R}, \quad \forall x_0 \in \mathbb{R}^n \text{ with } 0 < \rho(x_0) \leq \sigma, \qquad \left\{\begin{array}{ll} \phi(t, t_0, x_0) \text{ exists} & \forall t \in [t_0,\, t_0 + \frac{T}{\rho(x_0)^\tau}], \\ \rho(\phi(t, t_0, x_0) - \psi(t, t_0, x_0)) < \rho(x_0) d & \forall t \in [t_0,\, t_0 + \frac{T}{\rho(x_0)^\tau}]. \end{array}\right. \tag{16}$$

We prove that this implies LUAS for the origin of $\dot{x} = f(t, x)$. Indeed, estimates (11), (13), (15), and (16) yield

$$\forall t_0 \in \mathbb{R}, \quad \forall x_0 \in \mathbb{R}^n \text{ with } 0 < \rho(x_0) \leq \sigma, \qquad \rho(\phi(t, t_0, x_0)) \leq \left\{\begin{array}{ll} \rho(x_0) M & \forall t \in [t_0,\, t_0 + \frac{T}{\rho(x_0)^\tau}], \\ \rho(x_0) \frac{3}{4} & \text{for } t = t_0 + \frac{T}{\rho(x_0)^\tau}. \end{array}\right. \tag{17}$$

The first inequality in (17) gives an upper bound for $\rho(\phi(t, t_0, x_0))$ on the interval $[t_0,\, t_0 + \frac{T}{\rho(x_0)^\tau}]$. The second inequality says that, after a time $\frac{T}{\rho(x_0)^\tau}$, the r-homogeneous norm ρ has at least decreased with a factor $\frac{3}{4}$ along trajectories of the system with initial state $0 < \rho(x_0) \leq \sigma$. We may then apply estimate (17) again with $\phi(t_0 + \frac{T}{\rho(x_0)^\tau}, t_0, x_0)$ as the new initial state, and so forth. This process of iterated applications of (17) may be formalized as follows: associated with a particular $t_0 \in \mathbb{R}$ and $x_0 \in \mathbb{R}^n$ satisfying $0 < \rho(x_0) \leq \sigma$ we introduce a sequence of times $t_0^{t_0,x_0} < t_1^{t_0,x_0} < t_2^{t_0,x_0} < \cdots \to \infty$ according to

$$\begin{aligned} t_0^{t_0,x_0} &= t_0, \\ t_i^{t_0,x_0} - t_{i-1}^{t_0,x_0} &= \tfrac{T}{\rho(x_0)^\tau} \big((\tfrac{4}{3})^\tau\big)^{i-1} \qquad \forall i \in \mathbb{N}. \end{aligned}$$

Then, applying (17) iteratively yields

$$\forall t_0 \in \mathbb{R}, \quad \forall x_0 \in \mathbb{R}^n \text{ with } 0 < \rho(x_0) \leq \sigma, \qquad \rho(\phi(t, t_0, x_0)) \leq \rho(x_0) (\tfrac{3}{4})^{i-1} M \qquad \forall t \in [t_{i-1}^{t_0,x_0},\, t_i^{t_0,x_0}] \quad \forall i \in \mathbb{N}. \tag{18}$$

This proves that the equilibrium point $x = 0$ of $\dot{x} = f(t, x)$ is LUAS and that $\{x_0 \in \mathbb{R}^n : \rho(x_0) \leq \sigma\}$ is contained in its region of attraction. ∎

Remark 4. If $\tau = 0$, then all the $t_i^{t_0,x_0}$ introduced in the proof above are equidistant with distance T. Estimate (18) then implies that the equilibrium point $x = 0$ of $\dot{x} = f(t, x)$ is locally uniformly exponentially stable with respect to the r-homogeneous norm ρ; that is, there exist $\mu \in [1, \infty)$, $\nu \in (0, \infty)$ such that

(19)
$$\forall t_0 \in \mathbb{R}, \quad \forall x_0 \in \mathbb{R}^n \text{ with } \rho(x_0) \leq \sigma, \quad \rho(\phi(t, t_0, x_0)) \leq \rho(x_0)\mu e^{-\nu(t-t_0)} \quad \forall t \geq t_0.$$

Notice that the number T in the statement of Theorem 3.1 depends on the dynamics of $\dot{x} = g(t, x)$ and thus may be hard to determine. Cases where the existence of σ is guaranteed for each $T \in [0, \infty)$ and $d \in (0, \infty)$ are therefore of particular interest. This leads to the following definition.

DEFINITION 3.2 ((r, τ)-approximation). *Consider admissible dynamical systems $\dot{x} = f(t, x)$ and $\dot{x} = g(t, x)$ on $\mathbb{R}^n$ with respective flows ϕ and ψ having an equilibrium point at the origin. Consider also $r \in ((0, \infty))^n$, $\tau \geq 0$, and an r-homogeneous norm ρ. System $\dot{x} = g(t, x)$ is an* (r, τ)-approximation *of $\dot{x} = f(t, x)$ if the following two conditions are both satisfied:*

Condition 1. *$\dot{x} = g(t, x)$ has the (r, τ)-scaling property of trajectories.*

Condition 2. *For each $T \in [0, \infty)$ satisfying $\{(t, t_0, x_0) \in \mathbb{R} \times \mathbb{R} \times \mathbb{R}^n : t \in [t_0, t_0 + T],\ \rho(x_0) = 1\} \subset \operatorname{Dom} \psi$ and for each $d \in (0, \infty)$, there exists $\sigma \in (0, \infty)$ such that for all $t_0 \in \mathbb{R}$ and $x_0 \in \mathbb{R}^n$ with $0 < \rho(x_0) \leq \sigma$*

$$\text{(20)} \qquad \begin{cases} \phi(t, t_0, x_0) \text{ exists} & \forall t \in [t_0, t_0 + \frac{T}{\rho(x_0)^\tau}], \\ \rho(\phi(t, t_0, x_0) - \psi(t, t_0, x_0)) < \rho(x_0)d & \forall t \in [t_0, t_0 + \frac{T}{\rho(x_0)^\tau}]. \end{cases}$$

Remark 5. An extra assumption on T is introduced in Condition 2 since solutions of $\dot{x} = g(t, x)$ need not be forward complete in general. This is in contrast with Theorem 3.1 where solutions of $\dot{x} = g(t, x)$ are guaranteed to be forward complete by assumption (b). Notice that, if $\{(t, t_0, x_0) \in \mathbb{R} \times \mathbb{R} \times \mathbb{R}^n : t \in [t_0, t_0 + T],\ \rho(x_0) = 1\} \subset \operatorname{Dom} \psi$, then $\{(t, t_0, x_0) \in \mathbb{R} \times \mathbb{R} \times \mathbb{R}^n : t \in [t_0, t_0 + \frac{T}{\rho(x_0)^\tau}],\ x_0 \neq 0\} \subset \operatorname{Dom} \psi$ by the (r, τ)-scaling property of trajectories, and the second expression in (20) indeed makes sense.

Remark 6. The definition of an (r, τ)-approximation is independent of the particular r-homogeneous norm ρ used. This may be proven based on the fact that for each two r-homogeneous norms ρ_1 and ρ_2, there exist $a, b \in (0, \infty)$ such that $a\rho_1(x) \leq \rho_2(x) \leq b\rho_1(x)$ for all $x \in \mathbb{R}^n$.

The definition of (r, τ)-approximation includes linear and homogeneous approximations as a particular case but is more general, as will be shown in section 5. It follows immediately from Theorem 3.1 that (r, τ)-approximations are useful for the purpose of stability analysis.

COROLLARY 3.3. *Consider an admissible dynamical system $\dot{x} = f(t, x)$ on $\mathbb{R}^n$ with an equilibrium point at the origin. This equilibrium point is LUAS if there exists, for some $r \in ((0, \infty))^n$ and $\tau \in [0, \infty)$, an (r, τ)-approximation of $\dot{x} = f(t, x)$ whose origin is a LUAS equilibrium point.*

Corollary 3.3 states that stability properties of a dynamical system—LUAS of the equilibrium point—may be inferred from stability properties of an (r, τ)-approximation. This may constitute an important simplification, since an (r, τ)-approximation is assumed to have the (r, τ)-scaling property of trajectories. In section 5 we will show

that Corollary 3.3 leads to alternative proofs for and generalizations of several existing stability results.

Remark 7. If $\tau = 0$, then the conclusion of Corollary 3.3 may be strengthened according to Remark 4. Consider an admissible dynamical system $\dot{x} = f(t,x)$ on $\mathbb{R}^n$ with an equilibrium point at the origin. This equilibrium point is locally uniformly *exponentially* stable with respect to an r-homogeneous norm if there exists, for some $r \in ((0,\infty))^n$, an $(r,0)$-approximation of $\dot{x} = f(t,x)$ whose origin is a LUAS equilibrium point.

Remark 8. It is instructive to notice that, by the (r,τ)-scaling property of trajectories, LUAS for the equilibrium point $x = 0$ of the (r,τ)-approximation actually implies global uniform asymptotic stability. Furthermore, if $\tau = 0$, then we actually have global uniform exponential stability with respect to an r-homogeneous norm. Both observations follow readily from estimate (11) in the proof of Theorem 3.1.

4. On the convergence analysis of trajectories. In the previous section, we have introduced (r,τ)-approximations and clarified their role in stability analysis. In order to apply this theory, we need to be able to verify Conditions 1 and 2 featuring in the definition of (r,τ)-approximation (Definition 3.2). In the present section, we discuss the second of these two conditions.

A possible approach to verify Condition 2 is based on the Gronwall lemma—this is the approach that will be taken in the present paper. It turns out, however, that a direct verification of Condition 2 based on the Gronwall lemma is complicated by the possible non-Lipschitz character of the vectorfields near the origin (see Remark 1). In order to avoid these complications, we introduce a rescaling mechanism that is adapted to the underlying family of dilation mappings. This rescaling mechanism "desingularizes" the non-Lipschitz behavior around the origin. Furthermore, this rescaling mechanism will reveal a close relationship between stability results and (r,τ)-approximations on the one hand and convergence results for trajectories of systems depending on a small parameter on the other hand.

Recall Condition 2 of Definition 3.2. As a first step, we reformulate this condition, introducing $\overline{x}_0$ and ε according to $\overline{x}_0 = \delta^r_{1/\rho(x_0)} x_0$ and $\varepsilon = \rho(x_0)$: for each $T \in [0,\infty)$ satisfying $\{(t,t_0,x_0) \in \mathbb{R}\times\mathbb{R}\times\mathbb{R}^n : t \in [t_0,\, t_0+T],\ \rho(x_0) = 1\} \subset \operatorname{Dom}\psi$ and for each $d \in (0,\infty)$, there exists $\sigma \in (0,\infty)$ such that for all $t_0 \in \mathbb{R}$ and $\overline{x}_0 \in \mathbb{R}^n$ with $\rho(\overline{x}_0) = 1$ and for all $\varepsilon \in (0,\sigma]$

$$\text{(21)}\qquad \begin{cases} \phi(t,t_0,\delta^r_\varepsilon \overline{x}_0) \text{ exists} & \forall t \in [t_0,\, t_0 + \frac{T}{\varepsilon^\tau}], \\ \rho(\phi(t,t_0,\delta^r_\varepsilon \overline{x}_0) - \psi(t,t_0,\delta^r_\varepsilon \overline{x}_0)) < \varepsilon d & \forall t \in [t_0,\, t_0 + \frac{T}{\varepsilon^\tau}]. \end{cases}$$

By homogeneity of ρ and linearity of $\delta^r_{1/\varepsilon}$, expression (21) is equivalent to

$$\text{(22)}\qquad \begin{cases} \delta^r_{1/\varepsilon}\phi(t,t_0,\delta^r_\varepsilon \overline{x}_0) \text{ exists} & \forall t \in [t_0,\, t_0 + \frac{T}{\varepsilon^\tau}], \\ \rho(\delta^r_{1/\varepsilon}\phi(t,t_0,\delta^r_\varepsilon \overline{x}_0) - \delta^r_{1/\varepsilon}\psi(t,t_0,\delta^r_\varepsilon \overline{x}_0)) < d & \forall t \in [t_0,\, t_0 + \frac{T}{\varepsilon^\tau}]. \end{cases}$$

Replacing the dummy variables t and t_0 by $\frac{t}{\varepsilon^\tau}$ and $\frac{t_0}{\varepsilon^\tau}$, respectively, this may be rewritten as

$$\text{(23)}\qquad \begin{cases} \delta^r_{1/\varepsilon}\phi(\frac{t}{\varepsilon^\tau}, \frac{t_0}{\varepsilon^\tau}, \delta^r_\varepsilon \overline{x}_0) \text{ exists} & \forall t \in [t_0,\, t_0 + T], \\ \rho(\delta^r_{1/\varepsilon}\phi(\frac{t}{\varepsilon^\tau}, \frac{t_0}{\varepsilon^\tau}, \delta^r_\varepsilon \overline{x}_0) - \delta^r_{1/\varepsilon}\psi(\frac{t}{\varepsilon^\tau}, \frac{t_0}{\varepsilon^\tau}, \delta^r_\varepsilon \overline{x}_0)) < d & \forall t \in [t_0,\, t_0 + T]. \end{cases}$$

Estimate (23) suggests the introduction of time-functions $\zeta^\varepsilon(\cdot, t_0, \overline{x}_0)$ and $\xi^\varepsilon(\cdot, t_0, \overline{x}_0)$ according to

$$\zeta^\varepsilon(t, t_0, \overline{x}_0) = \delta^r_{1/\varepsilon}\phi\left(\frac{t}{\varepsilon^\tau}, \frac{t_0}{\varepsilon^\tau}, \delta^r_\varepsilon \overline{x}_0\right), \tag{24}$$

$$\xi^\varepsilon(t, t_0, \overline{x}_0) = \delta^r_{1/\varepsilon}\psi\left(\frac{t}{\varepsilon^\tau}, \frac{t_0}{\varepsilon^\tau}, \delta^r_\varepsilon \overline{x}_0\right). \tag{25}$$

The function ζ^ε satisfies the differential relation

$$\frac{\partial}{\partial t}\zeta^\varepsilon(t, t_0, \overline{x}_0) = \frac{\partial}{\partial t}\delta^r_{1/\varepsilon}\phi\left(\frac{t}{\varepsilon^\tau}, \frac{t_0}{\varepsilon^\tau}, \delta^r_\varepsilon \overline{x}_0\right) \tag{26}$$

$$= \delta^r_{1/\varepsilon}\frac{\partial}{\partial t}\phi\left(\frac{t}{\varepsilon^\tau}, \frac{t_0}{\varepsilon^\tau}, \delta^r_\varepsilon \overline{x}_0\right) \tag{27}$$

$$= \delta^r_{1/\varepsilon} f\left(\frac{t}{\varepsilon^\tau}, \phi\left(\frac{t}{\varepsilon^\tau}, \frac{t_0}{\varepsilon^\tau}, \delta^r_\varepsilon \overline{x}_0\right)\right)\frac{1}{\varepsilon^\tau} \tag{28}$$

$$= \frac{1}{\varepsilon^\tau}\delta^r_{1/\varepsilon} f\left(\frac{t}{\varepsilon^\tau}, \delta^r_\varepsilon \zeta^\varepsilon(t, t_0, \overline{x}_0)\right) \tag{29}$$

and the initial condition

$$\zeta^\varepsilon(t_0, t_0, \overline{x}_0) = \delta^r_{1/\varepsilon}\phi\left(\frac{t_0}{\varepsilon^\tau}, \frac{t_0}{\varepsilon^\tau}, \delta^r_\varepsilon \overline{x}_0\right) \tag{30}$$

$$= \delta^r_{1/\varepsilon}\delta^r_\varepsilon \overline{x}_0 \tag{31}$$

$$= \overline{x}_0. \tag{32}$$

The function ξ^ε satisfies

$$\xi^\varepsilon(t, t_0, \overline{x}_0) = \psi(t, t_0, \overline{x}_0) \tag{33}$$

since ψ is assumed to have the (r, τ)-scaling property of trajectories.

Finally, measuring the distance between trajectories in terms of the Euclidean norm $\|\cdot\|$ instead of the r-homogeneous norm ρ (see Remark 2) and omitting the bar in the notation of the initial state, we conclude that Condition 2 of Definition 3.2 is equivalent to the following condition:

Condition 2bis. For each $T \in [0, \infty)$ satisfying $\{(t, t_0, x_0) \in \mathbb{R}\times\mathbb{R}\times\mathbb{R}^n : t \in [t_0, t_0 + T],\ \rho(x_0) = 1\} \subset \operatorname{Dom}\psi$, for each $d \in (0, \infty)$, there exists $\sigma \in (0, \infty)$ such that for all $t_0 \in \mathbb{R}$ and $x_0 \in \mathbb{R}^n$ with $\rho(x_0) = 1$ and for all $\varepsilon \in (0, \sigma]$

$$\begin{cases} \zeta^\varepsilon(t, t_0, x_0) \text{ exists} & \forall t \in [t_0, t_0 + T], \\ \|\zeta^\varepsilon(t, t_0, x_0) - \psi(t, t_0, x_0)\| < d & \forall t \in [t_0, t_0 + T], \end{cases} \tag{34}$$

where ζ^ε is the flow of

$$\dot{x} = \frac{1}{\varepsilon^\tau}\delta^r_{1/\varepsilon} f\left(\frac{t}{\varepsilon^\tau}, \delta^r_\varepsilon x\right) \tag{35}$$

and ψ the flow of

$$\dot{x} = g(t, x). \tag{36}$$

This shows that (r, τ)-approximations are related to convergence results for trajectories of systems depending on a small parameter ε: trajectories of (35) converge uniformly on compact time-intervals to trajectories of (36) as $\varepsilon \downarrow 0$.

5. Applications. In this section we give three particular examples of (r, τ)-approximations, leading to three corresponding stability results. As we have seen in the previous section, (r, τ)-approximations are related to convergence results for trajectories of systems depending on a small parameter. The three examples given here are, respectively, related to perturbation theory, averaging theory, and the theory of highly oscillatory systems [11, 27, 12]. This will lead to alternative proofs for several existing results, as well as to extensions of these results.

5.1. Zero-order approximations. Consider a dynamical system on $\mathbb{R}^n$ of the form

$$\dot{x} = X(t,x) + Y(t,x), \tag{37}$$

where X and Y are class-$\mathcal{CLB}$ functions. Assume that

(a) X is r-homogeneous of order zero in x for all t, and

(b) $\delta^r_{1/\lambda} Y(t, \delta^r_\lambda x) \to 0$ as $\lambda \downarrow 0$, uniformly with respect to $t \in \mathbb{R}$ and x in compact subsets of $\mathbb{R}^n$.

Assumption (b) is satisfied, for example, if Y is r-homogeneous of positive order in x, or if Y is a sum of functions which are r-homogeneous in x, possibly with different, positive orders. In other words, X is a zero-order approximation of $X+Y$ with respect to x near the origin. Consider the associated dynamical system on $\mathbb{R}^n$,

$$\dot{x} = X(t,x). \tag{38}$$

The assumptions imply that both (37) and (38) have the uniqueness property of solutions (see Lemma 2.2) and an equilibrium point at the origin.

THEOREM 5.1. *Let $r \in ((0,\infty))^n$. Consider systems* (37) *and* (38) *satisfying the assumptions introduced above. If the origin of* (38) *is LUAS, then the origin of* (37) *is locally uniformly exponentially stable with respect to an r-homogeneous norm.*

Theorem 5.1 generalizes several known stability results. For the particular case that X and Y are assumed to be time-invariant, we recover [7, Theorem 1] with $k = 1$. For the particular case that X and Y are assumed to be periodic in t, we recover a result that has been reported by Morin and Samson [21, Proposition 2, Part 2]. Also, the linearization principle corresponds to the special case where $r = (1, \ldots, 1)$ and X is assumed to be linear in x.

Remark 9. It is instructive to recall that LUAS for the origin of (38) actually implies that this equilibrium point is globally uniformly exponentially stable with respect to an r-homogeneous norm since (38) has the $(r, 0)$-scaling property of trajectories by assumption (a) of the theorem. Theorem 5.1 would not be true, in general, if the null-solution were only assumed to be (nonuniformly) exponentially stable with respect to an r-homogeneous norm. When X is linear in x, this issue is related to the notion of Lyapunov regularity, which plays a central role in the Lyapunov stability theory. It is known that the linearization principle requires a somewhat sophisticated assumption (Lyapunov regularity) to hold, if the null-solution of the linearized equation is only assumed to be (nonuniformly) exponentially stable [2, Theorem 1.1.2]. Lyapunov regularity, however, need not be assumed when the null-solution of the linearized equation is uniformly exponentially stable [2, Theorem 1.4.2]. Accordingly, Lyapunov regularity (or its appropriate generalization) need not be assumed in Theorem 5.1.

Theorem 5.1 is proven by showing that (38) is an $(r, 0)$-approximation of (37). Following the approach outlined in section 4, this turns out to be related to perturbation theory.

Proof. We prove that (38) is an $(r, 0)$-approximation of (37). As Condition 1 of Definition 3.2 is readily verified (see section 2.2), we focus upon Condition 2. Following the approach outlined in section 4 we prove the equivalent Condition 2bis instead. For the present particular case system (35) becomes

$$\begin{aligned} \dot{x} &= \delta^r_{1/\varepsilon} X(t, \delta^r_\varepsilon x) + \delta^r_{1/\varepsilon} Y(t, \delta^r_\varepsilon x) \\ &= X(t, x) + \delta^r_{1/\varepsilon} Y(t, \delta^r_\varepsilon x), \end{aligned} \tag{39}$$

since X is r-homogeneous of order 0. The second term in the RHS tends to zero as $\varepsilon \downarrow 0$ by assumption (b). In other words, system (39) is a perturbed version of system (38). We prove in Appendix B.1 that trajectories of (39) converge to trajectories of (38) as $\varepsilon \downarrow 0$ in the sense of Condition 2bis.[2] Theorem 5.1 now follows from Corollary 3.3 and Remark 7. ∎

5.2. Approximation and averaging. Consider a dynamical system on $\mathbb{R}^n$ of the form

$$\dot{x} = X(t, x) + Y(t, x), \tag{40}$$

where X and Y are class-$\mathcal{CLB}$ functions. Assume that

(a) X is r-homogeneous of order $\tau > 0$ in x for all t, and
(b) $\frac{1}{\lambda^\tau} \delta^r_{1/\lambda} Y(t, \delta^r_\lambda x) \to 0$ as $\lambda \downarrow 0$, uniformly with respect to $t \in \mathbb{R}$ and x in compact subsets of $\mathbb{R}^n$.

Assumption (b) is satisfied, for example, if Y is r-homogeneous of order $\tau' > \tau$ in x, or if Y is a sum of functions which are r-homogeneous in x with (possibly different) orders strictly larger than τ.

We introduce the average of X as the map

$$X_{\mathrm{av}} : \mathbb{R}^n \to \mathbb{R}^n : x \mapsto X_{\mathrm{av}}(x) = \lim_{T \to \infty} \frac{1}{T} \int_0^T X(t, x)\, \mathrm{d}t, \tag{41}$$

where it is assumed that this limit exists for all x. The assumptions on X imply that X_{av} is continuous, locally Lipschitz in $x \in \mathbb{R}^n \setminus \{0\}$, and r-homogeneous of order τ. Assume in addition that

(c) for each $T \in [0, \infty)$ and for each compact subset $K \in \mathbb{R}^n$,

$$\int_{t_0+\varsigma_1}^{t_0+\varsigma_2} \left\{ X\left(\frac{s}{\varepsilon^\tau}, x\right) - X_{\mathrm{av}}(x) \right\} \mathrm{d}s \to 0 \tag{42}$$

as $\varepsilon \downarrow 0$ uniformly with respect to $t_0 \in \mathbb{R}$, $\varsigma_1, \varsigma_2 \in [0, T]$, and $x \in K$.

Consider the associated averaged system on $\mathbb{R}^n$,

$$\dot{x} = X_{\mathrm{av}}(x). \tag{43}$$

The assumptions imply that both (40) and (43) have the uniqueness property of solutions (see Lemma 2.2) and an equilibrium point at the origin.

THEOREM 5.2. *Let $r \in ((0, \infty))^n$ and $\tau \in (0, \infty)$. Consider systems* (40) *and* (43) *satisfying the assumptions introduced above. If the origin of* (43) *is LUAS, then the origin of* (40) *is also LUAS.*

[2] Convergence results are available in the literature on perturbation theory, but, to the best of our knowledge, none of these results yields exactly the required convergence property Condition 2bis.

Remark 10. It is instructive to recall that LUAS for the origin of (43) actually implies that this equilibrium point is globally uniformly asymptotically stable since the assumptions of the theorem imply that (43) has the (r,τ)-scaling property of trajectories.

This theorem generalizes some known results from the literature. For the special case that X and Y are independent of t (and hence X_{av} coincides with X), we recover a well-known result by Hermes; see, for example, [7, Theorem 1] with $k > 1$. For the special case that Y vanishes identically and X is locally Lipschitz in x on the complete state space $\mathbb{R}^n$ (and hence also at the origin), we recover [23, Theorem 1]. Whereas the proof technique of [23] is based on generalized Lyapunov theorems, the present proof is based on closeness results for trajectories of fast time-varying systems via a rescaling mechanism. As already mentioned before, this rescaling mechanism enables us to relax the Lipschitz assumption at the origin.

Proof. We prove that (43) is an (r,τ)-approximation of (40). As Condition 1 of Definition 3.2 is readily verified (see section 2.2), we focus upon Condition 2. Following the approach outlined in section 4 we prove the equivalent Condition 2bis instead. For the present particular case system (35) becomes

$$\begin{aligned}\dot{x} &= \frac{1}{\varepsilon^\tau}\delta^r_{1/\varepsilon}X\left(\frac{t}{\varepsilon^\tau},\delta^r_\varepsilon x\right)+\frac{1}{\varepsilon^\tau}\delta^r_{1/\varepsilon}Y\left(\frac{t}{\varepsilon^\tau},\delta^r_\varepsilon x\right)\\ &= X\left(\frac{t}{\varepsilon^\tau},x\right)+\frac{1}{\varepsilon^\tau}\delta^r_{1/\varepsilon}Y\left(\frac{t}{\varepsilon^\tau},\delta^r_\varepsilon x\right),\end{aligned} \tag{44}$$

where we have used the homogeneity property of X. This is a fast time-varying differential equation since the RHS depends on time through $\frac{t}{\varepsilon^\tau}$, where ε is a small parameter. In addition the second term tends to zero as $\varepsilon \downarrow 0$ by assumption (b). We prove in Appendix B.2 that trajectories of (44) converge to trajectories of (43) as $\varepsilon \downarrow 0$ in the sense of Condition 2bis.[3] Theorem 5.2 now follows from Corollary 3.3. ∎

5.3. Approximation and Lie brackets. Consider a dynamical system on $\mathbb{R}^n$ of the form

$$\dot{x} = \sqrt{\gamma}\cos(\gamma t)X_1(x) + \sqrt{\gamma}\sin(\gamma t)X_2(x) + X_3(x), \tag{45}$$

where X_1, X_2, and X_3 are continuous on $\mathbb{R}^n$ and X_1 and X_2 (respectively, X_3) are of class C^2 (respectively, of class C^1) on $\mathbb{R}^n \setminus \{0\}$ and where γ is a strictly positive parameter. It is important to emphasize that γ is *not* assumed to be very large or very small. Let $\tau > 0$ and assume that

(a) X_1 and X_2 are r-homogeneous of order $\frac{\tau}{2}$,

(b) X_3 is r-homogeneous of order τ.

We introduce the *Lie bracket* of X_1 and X_2 as the map

$$[X_1,X_2]:\mathbb{R}^n\to\mathbb{R}^n:\quad x\mapsto[X_1,X_2](x)=\begin{cases}DX_2(x)\cdot X_1(x)-DX_1(x)\cdot X_2(x) & \forall x\in\mathbb{R}^n\setminus\{0\},\\ 0 & \text{for } x=0,\end{cases} \tag{46}$$

[3] Convergence results are available in the literature on averaging theory, but, to the best of our knowledge, none of these results yields exactly the required convergence property Condition 2bis.

where $DX_i(x)$ is the Jacobian of X_i evaluated at x and $\cdot$ indicates the matrix product. The assumptions on X_1 and X_2 imply that $[X_1, X_2]$ is continuous on $\mathbb{R}^n$, of class C^1 on $\mathbb{R}^n \setminus \{0\}$, and r-homogeneous of order τ. Consider the following system on $\mathbb{R}^n$:

$$\dot{x} = \frac{1}{2}[X_1, X_2](x) + X_3(x). \tag{47}$$

The assumptions imply that both (45) and (47) have the uniqueness property of solutions (see Lemma 2.2) and an equilibrium point at the origin.

THEOREM 5.3. *Let $r \in ((0, \infty))^n$ and $\tau \in (0, \infty)$. Consider systems* (45) *and* (47) *satisfying the assumptions introduced above. If the origin of* (47) *is LUAS, then the origin of* (45) *is also LUAS.*

Remark 11. It is instructive to recall that LUAS for the origin of (47) actually implies that this equilibrium point is globally uniformly asymptotically stable since, by the assumptions of the theorem, (47) has the (r, τ)-scaling property of trajectories.

Independently of the present research, closely related results have been reported by M'Closkey and Morin [13] and by Sarychev [25]. The approach in [13] is based on Lyapunov considerations; the approach in [25] is based on nonlinear Floquet theory. We also mention that this stability result may be applied to the constructive stabilization of driftless control affine systems; see [16].

Theorem 5.3 is proven by showing that (47) is an (r, τ)-approximation of (45). Following the approach outlined in section 4, this turns out to be related to the theory of highly oscillatory differential equations [11, 27, 12].

Proof. We prove that (47) is an (r, τ)-approximation of (45). As Condition 1 of Definition 3.2 is readily verified (see section 2.2), we focus upon Condition 2. Following the approach outlined in section 4 we prove the equivalent Condition 2bis instead. For the present particular case system (35) becomes

$$\begin{aligned}\dot{x} &= \frac{\sqrt{\gamma}}{\varepsilon^\tau}\delta^r_{1/\varepsilon}\cos\left(\gamma\frac{t}{\varepsilon^\tau}\right)X_1(\delta^r_\varepsilon x) + \frac{\sqrt{\gamma}}{\varepsilon^\tau}\delta^r_{1/\varepsilon}\sin\left(\gamma\frac{t}{\varepsilon^\tau}\right)X_2(\delta^r_\varepsilon x) + \frac{1}{\varepsilon^\tau}\delta^r_{1/\varepsilon}X_3(\delta^r_\varepsilon x)\\ &= \sqrt{\frac{\gamma}{\varepsilon^\tau}}\cos\left(\gamma\frac{t}{\varepsilon^\tau}\right)X_1(x) + \sqrt{\frac{\gamma}{\varepsilon^\tau}}\sin\left(\gamma\frac{t}{\varepsilon^\tau}\right)X_2(x) + X_3(x),\end{aligned} \tag{48}$$

where we have used the homogeneity properties of the X_i. Systems of the form (48) with ε a small parameter are studied in the literature on highly oscillatory systems. We prove in Appendix B.3 that trajectories of (48) converge to trajectories of (47) as $\varepsilon \downarrow 0$ in the sense of Condition 2bis.[4] Theorem 5.3 now follows from Corollary 3.3. ∎

In addition, we also prove the following semiglobal result, which is original.

THEOREM 5.4. *Consider the same data and assumptions of Theorem* 5.3. *If the origin of* (47) *is LUAS, then the origin of* (45) *is semiglobally uniformly asymptotically stable as $\gamma \to \infty$.*

Remark 12. A similar semiglobal result has been obtained in the context of averaging if, using the notation of section 5.2, $Y(t, x)$ vanishes identically and t is replaced by γt in (40); see [23].

Proof. The proof of Theorem 5.3, in particular, the proof of Condition 2bis given in Appendix B.3, reveals that for each $T \in [0, \infty)$ satisfying $\{(t, t_0, x_0) \in \mathbb{R} \times \mathbb{R} \times \mathbb{R}^n :$

[4] Convergence results are available in the literature on highly oscillatory systems but, to the best of our knowledge, none of these results yields exactly the required convergence property Condition 2bis.

$t \in [t_0,\, t_0+T],\ \rho(x_0)=1\} \subset \mathrm{Dom}\,\psi$, for each $d \in (0,\,\infty)$, there exists $\beta \in (0,\,\infty)$ such that for all $t_0 \in \mathbb{R}$ and $x_0 \in \mathbb{R}^n$ with $\rho(x_0)=1$ and for all $\varepsilon \in (0,\ \sqrt[\tau]{\gamma\beta}]$

$$\begin{cases} \zeta^\varepsilon(t,t_0,x_0) \text{ exists} & \forall t \in [t_0,\, t_0+T], \\ \rho(\zeta^\varepsilon(t,t_0,x_0)-\psi(t,t_0.x_0)) < d & \forall t \in [t_0,\, t_0+T], \end{cases} \tag{49}$$

with ζ^ε and ψ, respectively, the flow of (48) and (47), and where we have replaced the Euclidean norm by the r-homogeneous norm ρ in the second expression of (49)—see Remark 2. Following the manipulations of section 4, this may be restated as follows: for each $T \in [0,\,\infty)$ satisfying $\{(t,t_0,x_0) \in \mathbb{R}\times\mathbb{R}\times\mathbb{R}^n : t \in [t_0,\, t_0+T],\ \rho(x_0) = 1\} \subset \mathrm{Dom}\,\psi$, for each $d \in (0,\,\infty)$, there exists $\beta \in (0,\,\infty)$ such that for all $t_0 \in \mathbb{R}$ and $x_0 \in \mathbb{R}^n$ with $0 < \rho(x_0) \le \sqrt[\tau]{\gamma\beta}$

$$\begin{cases} \phi(t,t_0,x_0) \text{ exists} & \forall t \in [t_0,\, t_0+\frac{T}{\rho(x_0)^\tau}], \\ \rho(\phi(t,t_0,x_0)-\psi(t,t_0,x_0)) < \rho(x_0)d & \forall t \in [t_0,\, t_0+\frac{T}{\rho(x_0)^\tau}], \end{cases} \tag{50}$$

where ϕ is the flow of (45). In particular, there corresponds a β^* to the particular values of T and d associated with $\dot{x} = \frac{1}{2}[X_1,X_2](x)+X_3(x)$ according to Theorem 3.1. It then follows from Theorem 3.1 that the origin of (45) is LUAS with $\{x_0 \in \mathbb{R}^n : \rho(x_0) \le \sqrt[\tau]{\gamma\beta^*}\}$ contained in the region of attraction. The observation that $\sqrt[\tau]{\gamma\beta^*} \to \infty$ as $\gamma \to \infty$ completes the proof. □

As mentioned above, Theorems 5.3 and 5.4 are related to convergence results for trajectories of highly oscillatory systems. Here we have considered the particular case of one generated Lie bracket, but the theory of [27, 12] covers the general case of how to generate any number of (iterated) Lie brackets. We are therefore inclined to believe that, incorporating ideas from [27, 12], the present theory may be generalized to the case where several (iterated) Lie brackets are featuring in the local approximation.

6. Concluding remarks. The present paper has introduced a new method for proving local stability results for ordinary differential equations. The present approach is based on closeness results for trajectories on finite time intervals. This approach may serve as an alternative for other, Lyapunov-based techniques. A distinctive feature of the present approach is that it does not rely on converse Lyapunov theorems.

Instrumental for our approach is a rescaling mechanism. With this rescaling mechanism we avoid complications that would otherwise arise from the possible non-Lipschitz behavior of homogeneous vectorfields near the origin. This rescaling mechanism also reveals the close relationship between stability results and closeness results for trajectories of systems depending on a small parameter.

By means of several applications, we have shown that this approach enables us to recover and extend several existing stability results. Future research may focus on possible generalizations of this approach to the study of differential equations with delay.

Appendix A. Proof of Lemma 2.2. We start with the observation that the dynamical system obtained from (5) by restricting the state space to $\mathbb{R}^n \setminus \{0\}$ has the uniqueness property of solutions by assumption (a) of the lemma—see, for example, [26]. Furthermore, assumption (b) of the lemma implies that the origin is an equilibrium point of (5); that is, $f(t,0) = 0$. It therefore suffices to prove that no solution of (5) can leave the origin or reach the origin in finite time.

First we prove by contradiction that no solution of (5) starting at the origin can leave the origin in forward time. Indeed, if this is not true, then there exist a solution

ζ of (5) and time-instants $t_0 < t_1$ in the domain of ζ such that $\zeta(t_0) = 0$ and $\zeta(t) \neq 0$ for all $t \in (t_0, t_1]$. Let c be defined by

$$c = ||\zeta(t_1)||.$$

We introduce the family of time-functions ζ_λ defined by

$$\zeta_\lambda(t) = \delta^r_{1/\lambda}\zeta(t),$$

with $\lambda > 0$. Associated with these time-functions is the family of real numbers T_λ defined by

$$T_\lambda = \min\{t > t_0 : ||\zeta_\lambda(t)|| = c\}.$$

Based on the continuity of ζ and expression (1) for the dilation map, it is easy to see that T_λ is a well-defined number between t_0 and t_1, that $T_\lambda \downarrow t_0$ as $\lambda \downarrow 0$, and thus that $\max\{||\dot{\zeta}_\lambda(t)|| : t \in [t_0, T_\lambda]\} \to \infty$ as $\lambda \downarrow 0$. Since ζ_λ satisfies the differential equation

$$\begin{aligned}\dot{\zeta}_\lambda(t) &= \delta^r_{1/\lambda}\dot{\zeta}(t)\\ &= \delta^r_{1/\lambda} f(t, \zeta(t))\\ &= \delta^r_{1/\lambda} f(t, \delta^r_\lambda \zeta_\lambda(t)),\end{aligned}$$

we therefore conclude that necessarily

$$\max\{||\delta^r_{1/\lambda} f(t, \delta^r_\lambda x)|| : t \in \mathbb{R},\ ||x|| \leq c\} \to \infty$$

as $\lambda \downarrow 0$. This yields a contradiction with assumption (b) of the lemma.

We have thus proven that no solution starting in the origin can leave the origin in forward time. By means of similar arguments, it may be shown that no solution starting away from the origin can reach the origin in finite time. This concludes the proof of Lemma 2.2.

Appendix B. Convergence analysis of trajectories. Throughout Appendix B, ρ is an r-homogeneous norm that is assumed to be continuously differentiable on $\mathbb{R}^n \setminus \{0\}$—the particular choice is irrelevant by Remark 6. Also, we regard ζ^ε and ψ as functions of t and write $\zeta^\varepsilon(t)$ and $\psi(t)$ instead of $\zeta^\varepsilon(t, t_0, x_0)$ and $\psi(t, t_0, x_0)$ for notational convenience.

B.1. Proof of Condition 2bis: Perturbed systems. Let $T \in [0, \infty)$ be such that $\{(t, t_0, x_0) \in \mathbb{R} \times \mathbb{R} \times \mathbb{R}^n : t \in [t_0, t_0 + T],\ \rho(x_0) = 1\} \subset \operatorname{Dom}\psi$. Consider arbitrary $d \in (0, \infty)$, $t_0 \in \mathbb{R}$, and $x_0 \in \mathbb{R}^n$ with $\rho(x_0) = 1$. Condition 2bis is proven by showing the existence of $\sigma \in (0, \infty)$ independent of t_0 and x_0 such that for all $\varepsilon \in (0, \sigma]$

$$\left\{\begin{array}{ll}\zeta^\varepsilon(t) \text{ exists} & \forall t \in [t_0, t_0 + T],\\ \|\zeta^\varepsilon(t) - \psi(t)\| < d & \forall t \in [t_0, t_0 + T].\end{array}\right. \tag{51}$$

For that purpose, we analyze ζ^ε and ψ on the time-interval $[t_0, t_0 + T]$.

ζ^ε satisfies

$$\zeta^\varepsilon(t) = x_0 + \int_{t_0}^{t} X(s, \zeta^\varepsilon(s))\,\mathrm{d}s + \int_{t_0}^{t} \delta^r_{1/\varepsilon} Y(s, \delta^r_\varepsilon \zeta^\varepsilon(s))\,\mathrm{d}s \tag{52}$$

for all $t \in \operatorname{Dom}\zeta^\varepsilon \cap [t_0,\, t_0 + T]$. ψ satisfies

$$\psi(t) = x_0 + \int_{t_0}^{t} X(s, \psi(s))\,\mathrm{d}s \tag{53}$$

for all $t \in [t_0,\, t_0 + T]$. Subtracting (53) from (52) gives

$$\zeta^\varepsilon(t) - \psi(t) = \int_{t_0}^{t} \{X(s, \zeta^\varepsilon(s)) - X(s, \psi(s))\}\,\mathrm{d}s + \int_{t_0}^{t} \delta^r_{1/\varepsilon} Y(s, \delta^r_\varepsilon \zeta^\varepsilon(s))\,\mathrm{d}s \tag{54}$$

for all $t \in \operatorname{Dom}\zeta^\varepsilon \cap [t_0,\, t_0 + T]$.

A bound on $\zeta^\varepsilon(t) - \psi(t)$ will be obtained from the Gronwall lemma. First introduce two real numbers $0 < c_1 < c_2$ independent of t_0 and x_0 such that

$$0 < c_1 \le \|\psi(t)\| \le c_2 \qquad \forall t \in [t_0,\, t_0 + T]. \tag{55}$$

Assume for the time being the existence of these numbers. Next take $0 < d' < c_1$.

Let $[t_0,\, t_e]$ be the largest time-interval contained in $\operatorname{Dom}\zeta^\varepsilon \cap [t_0,\, t_0 + T]$ satisfying

$$0 < c_1 - d' \le \|\zeta^\varepsilon(t)\| \le c_2 + d' \qquad \forall t \in [t_0,\, t_e]. \tag{56}$$

Notice that in general the time t_e depends on t_0, x_0, and ε. Since $X \in \mathcal{CLB}$, there exists a Lipschitz constant $k \in [0,\, \infty)$ for X with respect to x on the set $\{(t, x) \in \mathbb{R} \times \mathbb{R}^n : c_1 - d' \le \|x\| \le c_2 + d'\}$. Notice that k is independent of t_0 and x_0.

Then by (54)

$$\|\zeta^\varepsilon(t) - \psi(t)\| \le \int_{t_0}^{t} k\|\zeta^\varepsilon(s) - \psi(s)\|\,\mathrm{d}s + \left\| \int_{t_0}^{t} \delta^r_{1/\varepsilon} Y(s, \delta^r_\varepsilon \zeta^\varepsilon(s))\,\mathrm{d}s \right\| \tag{57}$$

for all $t \in [t_0,\, t_e]$. Notice that the second term in the RHS of (57) is a function of $(\varepsilon, t, t_0, x_0)$ since it depends explicitly on ε, t, and t_0 and implicitly on t_0 and x_0 via ζ^ε. By (56) and assumption (b) of subsection 5.1, this term tends to zero as $\varepsilon \downarrow 0$ uniformly with respect to $t \in [t_0,\, t_e]$, $t_0 \in \mathbb{R}$, and $x_0 \in \mathbb{R}^n$ with $\rho(x_0) = 1$.

Hence, by the Gronwall lemma, there exists $\sigma \in (0,\, \infty)$ independent of t_0 and x_0 such that for all $\varepsilon \in (0,\, \sigma]$

$$\|\zeta^\varepsilon(t) - \psi(t)\| < \min\{d, d'\} \qquad \forall t \in [t_0,\, t_e]. \tag{58}$$

We show by contradiction that $t_e = t_0 + T$ if $\varepsilon \in (0,\, \sigma]$: indeed, from the definition of t_e it follows that if $t_e < t_0 + T$, then necessarily $\|\zeta^\varepsilon(t_e)\| = c_1 - d'$ or $\|\zeta^\varepsilon(t_e)\| = c_2 + d'$ and thus $\|\zeta^\varepsilon(t_e) - \psi(t_e)\| \ge d'$ by (55), which contradicts (58). We conclude that for all $\varepsilon \in (0,\, \sigma]$

$$\begin{cases} \zeta^\varepsilon(t) \text{ exists} & \forall t \in [t_0,\, t_0 + T], \\ \|\zeta^\varepsilon(t) - \psi(t)\| < d & \forall t \in [t_0,\, t_0 + T]. \end{cases} \tag{59}$$

The proof is completed by proving the existence of the real numbers c_1 and c_2 introduced above. For this purpose we study the evolution of the r-homogeneous

norm ρ along ψ. By uniqueness of solutions, $\psi(t) \in \mathbb{R}^n \setminus \{0\}$ for all $t \in [t_0,\, t_0 + T]$ and thus $\rho(\psi(\cdot))$ satisfies

$$\frac{\mathrm{d}}{\mathrm{d}t}\rho(\psi(t)) = \alpha(t)\rho(\psi(t)) \tag{60}$$

for all $t \in [t_0,\, t_0 + T]$, where $\alpha : [t_0,\, t_0 + T] \to \mathbb{R}$ is a continuous function given by

$$\alpha(t) = \sum_{i=1}^{n} \frac{\partial \rho}{\partial x_i}(\delta^r_{1/\rho(\psi(t))}\psi(t)) \frac{1}{\rho(\psi(t))^{r_i}} X_i(t, \delta^r_{\rho(\psi(t))}\delta^r_{1/\rho(\psi(t))}\psi(t)). \tag{61}$$

By homogeneity of X, (61) may be simplified:

$$\alpha(t) = \sum_{i=1}^{n} \frac{\partial \rho}{\partial x_i}(\delta^r_{1/\rho(\psi(t))}\psi(t)) X_i(t, \delta^r_{1/\rho(\psi(t))}\psi(t)). \tag{62}$$

Observe that $\delta^r_{1/\rho(\psi(t))}\psi(t)$ belongs to the compact set $\{x \in \mathbb{R}^n : \rho(x) = 1\}$. Since $\frac{\partial \rho}{\partial x_i}$ is assumed to be continuous on $\mathbb{R}^n \setminus \{0\}$ and since X is assumed to be a class-$\mathcal{CLB}$ function, we conclude the existence of $M \in [0,\, \infty)$ independent of t_0 and x_0 such that $|\alpha(t)| \leq M$ for all $t \in [t_0,\, t_0 + T]$. Together with (60) this implies that for all $t \in [t_0,\, t_0 + T]$

$$0 < e^{-MT} \leq e^{-M(t-t_0)} \leq \rho(\psi(t)) \leq e^{M(t-t_0)} \leq e^{MT}. \tag{63}$$

Passing to the Euclidean norm $\|\cdot\|$—see Remark 2—we conclude the existence of c_1 and c_2 as required.

B.2. Proof of Condition 2bis: Fast time-varying systems. The proof is along the lines of the previous proof in Appendix B.1. Let $T \in [0,\, \infty)$ be such that $\{(t, t_0, x_0) \in \mathbb{R} \times \mathbb{R} \times \mathbb{R}^n : t \in [t_0,\, t_0 + T],\ \rho(x_0) = 1\} \subset \operatorname{Dom} \psi$. Consider arbitrary $d \in (0,\, \infty)$, $t_0 \in \mathbb{R}$, and $x_0 \in \mathbb{R}^n$ with $\rho(x_0) = 1$.

ζ^ε satisfies

$$\zeta^\varepsilon(t) = x_0 + \int_{t_0}^{t} X\left(\frac{s}{\varepsilon^\tau}, \zeta^\varepsilon(s)\right) \mathrm{d}s + \int_{t_0}^{t} \frac{1}{\varepsilon^\tau}\delta^r_{1/\varepsilon} Y\left(\frac{s}{\varepsilon^\tau}, \delta^r_\varepsilon \zeta^\varepsilon(s)\right) \mathrm{d}s \tag{64}$$

for all $t \in \operatorname{Dom} \zeta^\varepsilon \cap [t_0,\, t_0 + T]$. ψ satisfies

$$\psi(t) = x_0 + \int_{t_0}^{t} X_{\mathrm{av}}(\psi(s))\, \mathrm{d}s \tag{65}$$

for all $t \in [t_0,\, t_0 + T]$. Subtracting (65) from (64) and adding terms that cancel out gives

(66)

$$\begin{aligned}
\zeta^\varepsilon(t) - \psi(t) &= \int_{t_0}^{t} X\left(\frac{s}{\varepsilon^\tau}, \zeta^\varepsilon(s)\right) \mathrm{d}s - \int_{t_0}^{t} X_{\mathrm{av}}(\psi(s))\, \mathrm{d}s + \int_{t_0}^{t} \frac{1}{\varepsilon^\tau}\delta^r_{1/\varepsilon} Y\left(\frac{s}{\varepsilon^\tau}, \delta^r_\varepsilon \zeta^\varepsilon(s)\right) \mathrm{d}s \\
&= \int_{t_0}^{t} \left\{ X\left(\frac{s}{\varepsilon^\tau}, \zeta^\varepsilon(s)\right) - X\left(\frac{s}{\varepsilon^\tau}, \psi(s)\right) \right\} \mathrm{d}s \\
&\quad + \int_{t_0}^{t} \left\{ X\left(\frac{s}{\varepsilon^\tau}, \psi(s)\right) - X_{\mathrm{av}}(\psi(s)) \right\} \mathrm{d}s + \int_{t_0}^{t} \frac{1}{\varepsilon^\tau}\delta^r_{1/\varepsilon} Y\left(\frac{s}{\varepsilon^\tau}, \delta^r_\varepsilon \zeta^\varepsilon(s)\right) \mathrm{d}s
\end{aligned}$$

for all $t \in \operatorname{Dom} \zeta^\varepsilon \cap [t_0,\, t_0 + T]$.

A bound on $\zeta^\varepsilon(t) - \psi(t)$ will be obtained from the Gronwall lemma. First introduce two real numbers $0 < c_1 < c_2$ independent of t_0 and x_0 such that

$$0 < c_1 \leq \|\psi(t)\| \leq c_2 \qquad \forall t \in [t_0,\, t_0 + T]. \tag{67}$$

These numbers indeed exist since, by time-invariance of $\dot{x} = X_{\mathrm{av}}(x)$ and continuity of its flow, all states that are reached from initial states x_0 with $\rho(x_0) = 1$ in times $t \in [t_0,\, t_0 + T]$ form a compact set which, by uniqueness of solutions, does not contain the origin. Next take $0 < d' < c_1$.

Let $[t_0,\, t_e]$ be the largest time-interval contained in $\mathrm{Dom}\,\zeta^\varepsilon \cap [t_0,\, t_0 + T]$ satisfying

$$0 < c_1 - d' \leq \|\zeta^\varepsilon(t)\| \leq c_2 + d' \qquad \forall t \in [t_0,\, t_e]. \tag{68}$$

Since $X \in \mathcal{CLB}$, there exists a Lipschitz constant $k \in [0,\, \infty)$ for X with respect to x on the set $\{(t, x) \in \mathbb{R} \times \mathbb{R}^n : c_1 - d' \leq \|x\| \leq c_2 + d'\}$ and an upper bound $M \in [0,\, \infty)$ for $\|X\|$ on the set $\{(t, x) \in \mathbb{R} \times \mathbb{R}^n : c_1 - d' \leq \|x\| \leq c_2 + d'\}$. Notice that both k and M are independent of t_0 and x_0. It follows from the definition of X_{av} that k (respectively, M) is also a Lipschitz constant for X_{av} (respectively, an upper bound for $\|X_{\mathrm{av}}\|$) on the set $\{x \in \mathbb{R}^n : c_1 - d' \leq \|x\| \leq c_2 + d'\}$.

Then by (66)

$$\begin{aligned} \|\zeta^\varepsilon(t) - \psi(t)\| &\leq \int_{t_0}^{t} k\|\zeta^\varepsilon(s) - \psi(s)\|\,\mathrm{d}s \\ &+ \left\| \int_{t_0}^{t} \left\{ X\left(\frac{s}{\varepsilon^\tau}, \psi(s)\right) - X_{\mathrm{av}}(\psi(s)) \right\} \mathrm{d}s \right\| + \left\| \int_{t_0}^{t} \frac{1}{\varepsilon^\tau} \delta^r_{1/\varepsilon} Y\left(\frac{s}{\varepsilon^\tau}, \delta^r_\varepsilon \zeta^\varepsilon(s)\right) \mathrm{d}s \right\| \end{aligned} \tag{69}$$

for all $t \in [t_0,\, t_e]$. We now show that the second and the third terms in the RHS of this expression tend to zero as $\varepsilon \downarrow 0$. By (68) and assumption (b) of subsection 5.2

$$\left\| \int_{t_0}^{t} \frac{1}{\varepsilon^\tau} \delta^r_{1/\varepsilon} Y\left(\frac{s}{\varepsilon^\tau}, \delta^r_\varepsilon \zeta^\varepsilon(s)\right) \mathrm{d}s \right\| \to 0 \tag{70}$$

as $\varepsilon \downarrow 0$ uniformly with respect to $t \in [t_0,\, t_e]$, $t_0 \in \mathbb{R}$, and $x_0 \in \mathbb{R}^n$ with $\rho(x_0) = 1$. Bounding the second term using assumption (c) of subsection 5.2 is more complicated, since $\psi(s)$ featuring in the integrand of the second term varies with time s, whereas x featuring in the integrand of (42) is fixed. This problem may be overcome by sampling the trajectory ψ with sample period $\theta \in (0,\, \infty)$: define ψ_{sa} by

$$\psi_{\mathrm{sa}}(t) = \psi(t_0 + i\theta) \quad \forall t \in [t_0 + i\theta,\, t_0 + (i+1)\theta) \cap [t_0,\, t_0 + T] \quad \forall i \in \{0\} \cup \mathbb{N}. \tag{71}$$

Notice that $\psi_{\mathrm{sa}}(t)$ is related to $\psi(t)$ by the inequality

$$\|\psi_{\mathrm{sa}}(t) - \psi(t)\| \leq M\theta \tag{72}$$

for all $t \in [t_0,\, t_0 + T]$. Then

$$\begin{aligned} &\left\| \int_{t_0}^{t} \left\{ X\left(\frac{s}{\varepsilon^\tau}, \psi(s)\right) - X_{\mathrm{av}}(\psi(s)) \right\} \mathrm{d}s \right\| \leq \left\| \int_{t_0}^{t} \left\{ X\left(\frac{s}{\varepsilon^\tau}, \psi(s)\right) - X\left(\frac{s}{\varepsilon^\tau}, \psi_{\mathrm{sa}}(s)\right) \right\} \mathrm{d}s \right\| \\ &+ \left\| \int_{t_0}^{t} \left\{ X\left(\frac{s}{\varepsilon^\tau}, \psi_{\mathrm{sa}}(s)\right) - X_{\mathrm{av}}(\psi_{\mathrm{sa}}(s)) \right\} \mathrm{d}s \right\| + \left\| \int_{t_0}^{t} \{ X_{\mathrm{av}}(\psi_{\mathrm{sa}}(s)) - X_{\mathrm{av}}(\psi(s)) \}\, \mathrm{d}s \right\|. \end{aligned} \tag{73}$$

By (72) the first and the third terms in the RHS of (73) are both bounded by $TkM\theta$ and thus can be made as small as required by choosing the sample period θ sufficiently small. The second term in the RHS of (73) may be bounded as follows:

$$\begin{aligned}(74)\quad &\left\| \int_{t_0}^{t} \left\{ X\left(\frac{s}{\varepsilon^\tau}, \psi_{\mathrm{sa}}(s)\right) - X_{\mathrm{av}}(\psi_{\mathrm{sa}}(s)) \right\} \mathrm{d}s \right\| \\ &\qquad \le \left\| \int_{t_0}^{t_0+\theta} \left\{ X\left(\frac{s}{\varepsilon^\tau}, \psi_{\mathrm{sa}}(s)\right) - X_{\mathrm{av}}(\psi_{\mathrm{sa}}(s)) \right\} \mathrm{d}s \right\| \\ &\qquad + \left\| \int_{t_0+\theta}^{t_0+2\theta} \left\{ X\left(\frac{s}{\varepsilon^\tau}, \psi_{\mathrm{sa}}(s)\right) - X_{\mathrm{av}}(\psi_{\mathrm{sa}}(s)) \right\} \mathrm{d}s \right\| \\ &\qquad\qquad + \cdots + \left\| \int_{t_0+p\theta}^{t} \left\{ X\left(\frac{s}{\varepsilon^\tau}, \psi_{\mathrm{sa}}(s)\right) - X_{\mathrm{av}}(\psi_{\mathrm{sa}}(s)) \right\} \mathrm{d}s \right\|\end{aligned}$$

with $p \in \{0\} \cup \mathbb{N}$ defined by $t_0 + p\theta \le t < t_0 + (p+1)\theta$. For a given choice of θ the number of terms in the RHS of (74) is bounded for $t \in [t_0, t_0 + T]$, and thus by (67), (71), and assumption (c) of subsection 5.2 the RHS of (74) tends to zero as $\varepsilon \downarrow 0$ uniformly with respect to $t \in [t_0, t_0 + T]$, $t_0 \in \mathbb{R}$, and $x_0 \in \mathbb{R}^n$ with $\rho(x_0) = 1$. We finally conclude that

$$(75)\qquad \left\| \int_{t_0}^{t} \left\{ X\left(\frac{s}{\varepsilon^\tau}, \psi(s)\right) - X_{\mathrm{av}}(\psi(s)) \right\} \mathrm{d}s \right\| \to 0$$

as $\varepsilon \downarrow 0$ uniformly with respect to $t \in [t_0, t_0 + T]$, $t_0 \in \mathbb{R}$, and $x_0 \in \mathbb{R}^n$ with $\rho(x_0) = 1$.

Recall (69), (70), and (75). Hence, by the Gronwall lemma, there exists $\sigma \in (0, \infty)$ independent of t_0 and x_0 such that for all $\varepsilon \in (0, \sigma]$

$$(76)\qquad \|\zeta^\varepsilon(t) - \psi(t)\| < \min\{d, d'\} \qquad \forall t \in [t_0, t_e].$$

As in Appendix B.1, we conclude that for all $\varepsilon \in (0, \sigma]$

$$(77)\qquad \begin{cases} \zeta^\varepsilon(t) \text{ exists} & \forall t \in [t_0, t_0 + T], \\ \|\zeta^\varepsilon(t) - \psi(t)\| < d & \forall t \in [t_0, t_0 + T]. \end{cases}$$

B.3. Proof of Condition 2bis: Highly oscillatory systems. The proof is along the lines of the proofs in Appendices B.1 and B.2. Let $T \in [0, \infty)$ be such that $\{(t, t_0, x_0) \in \mathbb{R} \times \mathbb{R} \times \mathbb{R}^n : t \in [t_0, t_0 + T],\ \rho(x_0) = 1\} \subset \mathrm{Dom}\,\psi$. Consider arbitrary $d \in (0, \infty)$, $t_0 \in \mathbb{R}$, and $x_0 \in \mathbb{R}^n$ with $\rho(x_0) = 1$.

ζ^ε satisfies

$$\begin{aligned}(78)\quad \zeta^\varepsilon(t) = x_0 &+ \int_{t_0}^{t} \frac{1}{\sqrt{\mu}} \cos\left(\frac{s}{\mu}\right) X_1(\zeta^\varepsilon(s))\,\mathrm{d}s \\ &+ \int_{t_0}^{t} \frac{1}{\sqrt{\mu}} \sin\left(\frac{s}{\mu}\right) X_2(\zeta^\varepsilon(s))\,\mathrm{d}s + \int_{t_0}^{t} X_3(\zeta^\varepsilon(s))\,\mathrm{d}s\end{aligned}$$

for all $t \in \mathrm{Dom}\,\zeta^\varepsilon \cap [t_0, t_0 + T]$, where we have introduced the notation $\mu = \frac{\varepsilon^\tau}{\gamma}$.

Integrating the second and the third terms in the RHS of (78) by parts yields

(79)
$$\begin{aligned}\zeta^\varepsilon(t) &= x_0 + \sqrt{\mu}\sin\left(\frac{s}{\mu}\right) X_1(\zeta^\varepsilon(s))|_{s=t_0}^t \\ &\quad - \int_{t_0}^t \sqrt{\mu}\sin\left(\frac{s}{\mu}\right) DX_1\cdot\left\{\frac{1}{\sqrt{\mu}}\cos\left(\frac{s}{\mu}\right)X_1 + \frac{1}{\sqrt{\mu}}\sin\left(\frac{s}{\mu}\right)X_2 + X_3\right\}(\zeta^\varepsilon(s))\,\mathrm{d}s \\ &\quad - \sqrt{\mu}\cos\left(\frac{s}{\mu}\right) X_2(\zeta^\varepsilon(s))|_{s=t_0}^t \\ &\quad + \int_{t_0}^t \sqrt{\mu}\cos\left(\frac{s}{\mu}\right) DX_2\cdot\left\{\frac{1}{\sqrt{\mu}}\cos\left(\frac{s}{\mu}\right)X_1 + \frac{1}{\sqrt{\mu}}\sin\left(\frac{s}{\mu}\right)X_2 + X_3\right\}(\zeta^\varepsilon(s))\,\mathrm{d}s \\ &\quad + \int_{t_0}^t X_3(\zeta^\varepsilon(s))\,\mathrm{d}s.\end{aligned}$$

Applying the geometric identities $\cos^2(\phi) = \frac{1}{2} + \frac{1}{2}\cos(2\phi)$, $\sin^2(\phi) = \frac{1}{2} - \frac{1}{2}\cos(2\phi)$, and $\sin(\phi)\cos(\phi) = \frac{1}{2}\sin(2\phi)$ and rearranging terms gives

$$\zeta^\varepsilon(t) = x_0 + \int_{t_0}^t \left(\frac{1}{2}DX_2\cdot X_1 - \frac{1}{2}DX_1\cdot X_2 + X_3\right)(\zeta^\varepsilon(s))\,\mathrm{d}s + J_1 + J_2 + J_3 \tag{80}$$

with

$$\begin{aligned}J_1 &= \int_{t_0}^t \frac{1}{2}\sin\left(2\frac{s}{\mu}\right)\{DX_2\cdot X_2 - DX_1\cdot X_1\}(\zeta^\varepsilon(s))\,\mathrm{d}s, \\ J_2 &= \int_{t_0}^t \frac{1}{2}\cos\left(2\frac{s}{\mu}\right)\{DX_1\cdot X_2 + DX_2\cdot X_1\}(\zeta^\varepsilon(s))\,\mathrm{d}s, \\ J_3 &= \sqrt{\mu}\bigg(\int_{t_0}^t \left\{\cos\left(\frac{s}{\mu}\right)DX_2\cdot X_3(\zeta^\varepsilon(s)) - \sin\left(\frac{s}{\mu}\right)DX_1\cdot X_3(\zeta^\varepsilon(s))\right\}\mathrm{d}s \\ &\qquad + \sin\left(\frac{s}{\mu}\right)X_1(\zeta^\varepsilon(s))|_{s=t_0}^t - \cos\left(\frac{s}{\mu}\right)X_2(\zeta^\varepsilon(s))|_{s=t_0}^t\bigg).\end{aligned}$$

ψ satisfies

$$\begin{aligned}\psi(t) &= x_0 + \int_{t_0}^t \left(\frac{1}{2}[X_1, X_2] + X_3\right)(\psi(s))\,\mathrm{d}s \\ &= x_0 + \int_{t_0}^t \left(\frac{1}{2}DX_2\cdot X_1 - \frac{1}{2}DX_1\cdot X_2 + X_3\right)(\psi(s))\,\mathrm{d}s\end{aligned} \tag{81}$$

for all $t \in [t_0,\, t_0 + T]$, where we used the definition of $[X_1, X_2]$ taking into account that $\psi(s) \in \mathbb{R}^n \setminus \{0\}$ by the uniqueness property of solutions. Subtracting (81) from (80) gives

$$\begin{aligned}\zeta^\varepsilon(t) - \psi(t) = \int_{t_0}^t \bigg\{ &\left(\frac{1}{2}DX_2\cdot X_1 - \frac{1}{2}DX_1\cdot X_2 + X_3\right)(\zeta^\varepsilon(s)) \\ &- \left(\frac{1}{2}DX_2\cdot X_1 - \frac{1}{2}DX_1\cdot X_2 + X_3\right)(\psi(s))\bigg\}\,\mathrm{d}s + J_1 + J_2 + J_3\end{aligned} \tag{82}$$

for all $t \in \operatorname{Dom}\zeta^\varepsilon \cap [t_0,\, t_0 + T]$.

A bound on $\zeta^\varepsilon(t)-\psi(t)$ will be obtained from the Gronwall lemma. First introduce two real numbers $0 < c_1 < c_2$ independent of t_0 and x_0 such that

$$0 < c_1 \le \|\psi(t)\| \le c_2 \qquad \forall t \in [t_0,\, t_0+T]. \tag{83}$$

These numbers indeed exist since, by time-invariance of $\dot{x} = \frac{1}{2}[X_1, X_2](x)+X_3(x)$ and continuity of its flow, all states that are reached from initial states x_0 with $\rho(x_0) = 1$ in times $t \in [t_0,\, t_0+T]$ form a compact set which, by uniqueness of solutions, does not contain the origin. Next take $0 < d' < c_1$.

Let $[t_0,\, t_e]$ be the largest time-interval contained in $\operatorname{Dom}\zeta^\varepsilon \cap [t_0,\, t_0+T]$ satisfying

$$0 < c_1 - d' \le \|\zeta^\varepsilon(t)\| \le c_2 + d' \qquad \forall t \in [t_0,\, t_e]. \tag{84}$$

By the smoothness assumptions on the X_i, there exists a Lipschitz constant $k \in [0,\, \infty)$ for $\frac{1}{2}DX_2\cdot X_1 - \frac{1}{2}DX_1\cdot X_2 + X_3$ on the set $\{x \in \mathbb{R}^n : c_1 - d' \le \|x\| \le c_2 + d'\}$. Notice that k is independent of t_0 and x_0.

Then by (82)

$$\|\zeta^\varepsilon(t) - \psi(t)\| \le \int_{t_0}^{t} k\|\zeta^\varepsilon(s) - \psi(s)\|\,\mathrm{d}s + \|J_1\| + \|J_2\| + \|J_3\| \tag{85}$$

for all $t \in [t_0,\, t_e]$. Notice that the J_i are functions of (μ, t, t_0, x_0) since J_i depends explicitly on μ, t, and t_0 and implicitly on t_0 and x_0 via $\zeta^\varepsilon(s)$. We now show that the $\|J_i\|$ converge to zero as $\mu \downarrow 0$, uniformly with respect to $t \in [t_0,\, t_e]$, $t_0 \in \mathbb{R}$, and $x_0 \in \mathbb{R}^n$ with $\rho(x_0) = 1$. This is easily verified for $\|J_3\|$: J_3 is the product of $\sqrt{\mu}$ with a factor that is bounded on $\{(\mu, t, t_0, x_0) : t \in [t_0,\, t_e],\ \rho(x_0) = 1\}$ by the smoothness assumptions on the X_i. Next we focus on J_1: integration by parts yields

$$\begin{aligned}
J_1 &= -\frac{\mu}{4}\cos\left(2\frac{s}{\mu}\right)\{DX_2\cdot X_2 - DX_1\cdot X_1\}(\zeta^\varepsilon(s))|_{s=t_0}^{t} \\
&\quad + \int_{t_0}^{t} \frac{\mu}{4}\cos\left(2\frac{s}{\mu}\right) D\{DX_2\cdot X_2 - DX_1\cdot X_1\}\cdot \\
&\qquad\qquad \left\{\frac{1}{\sqrt{\mu}}\cos\left(\frac{s}{\mu}\right)X_1 + \frac{1}{\sqrt{\mu}}\sin\left(\frac{s}{\mu}\right)X_2 + X_3\right\}(\zeta^\varepsilon(s))\,\mathrm{d}s \\
&= \mu\bigg(-\frac{1}{4}\cos\left(2\frac{s}{\mu}\right)\{DX_2\cdot X_2 - DX_1\cdot X_1\}(\zeta^\varepsilon(s))|_{s=t_0}^{t} \\
&\qquad + \int_{t_0}^{t}\frac{1}{4}\cos\left(2\frac{s}{\mu}\right) D\{DX_2\cdot X_2 - DX_1\cdot X_1\}\cdot X_3(\zeta^\varepsilon(s))\,\mathrm{d}s\bigg) \\
&\quad + \sqrt{\mu}\bigg(\int_{t_0}^{t}\frac{1}{4}\cos\left(2\frac{s}{\mu}\right) D\{DX_2\cdot X_2 - DX_1\cdot X_1\} \\
&\qquad\qquad \cdot\left\{\cos\left(\frac{s}{\mu}\right)X_1 + \sin\left(\frac{s}{\mu}\right)X_2\right\}(\zeta^\varepsilon(s))\,\mathrm{d}s\bigg).
\end{aligned} \tag{86}$$

Both factors between brackets in the second RHS of (86) are bounded on the set $\{(\mu, t, t_0, x_0) : t \in [t_0,\, t_e],\ \rho(x_0) = 1\}$ by the smoothness assumptions on the X_i. We thus see that $\|J_1\|$ also converges to zero as $\mu \downarrow 0$, uniformly with respect to $t \in [t_0,\, t_e]$, $t_0 \in \mathbb{R}$, and $x_0 \in \mathbb{R}^n$ with $\rho(x_0) = 1$. Finally, a similar argument shows that $\|J_2\|$ also converges to zero as $\mu \downarrow 0$, uniformly with respect to $t \in [t_0,\, t_e]$, $t_0 \in \mathbb{R}$, and $x_0 \in \mathbb{R}^n$ with $\rho(x_0) = 1$.

Hence, by the Gronwall lemma, there exists $\beta \in (0, \infty)$ independent of t_0 and x_0 such that for all $\mu \in (0, \beta]$

$$\|\zeta^\varepsilon(t) - \psi(t)\| < \min\{d, d'\} \qquad \forall t \in [t_0, t_e]. \tag{87}$$

As in Appendix B.1, we conclude that for all $\mu \in (0, \beta]$ or, equivalently since $\mu = \frac{\varepsilon^\tau}{\gamma}$ for all $\varepsilon \in (0, \sqrt[\tau]{\gamma\beta}]$,

$$\begin{cases} \zeta^\varepsilon(t) \text{ exists} & \forall t \in [t_0, t_0 + T], \\ \|\zeta^\varepsilon(t) - \psi(t)\| < d & \forall t \in [t_0, t_0 + T]. \end{cases} \tag{88}$$

Acknowledgment. The authors would like to thank the anonymous reviewers for their constructive comments that have helped to improve the paper. In particular we thank one of the reviewers for providing an alternative proof of Lemma 2.2, which has been incorporated in the present version of the paper.

A DIFFUSION MODEL FOR OPTIMAL DIVIDEND DISTRIBUTION FOR A COMPANY WITH CONSTRAINTS ON RISK CONTROL*

TAHIR CHOULLI†, MICHAEL TAKSAR‡, AND XUN YU ZHOU§

Abstract. This paper investigates a model of a corporation which faces constant liability payments and which can choose a production/business policy from an available set of control policies with different expected profits and risks. The objective is to find a business policy and a dividend distribution scheme so as to maximize the expected present value of the total dividend distributions. The main feature of this paper is that there are constraints on business activities such as inability to completely eliminate risk (even at the expense of reducing the potential profit to zero) or when such a risk cannot exceed a certain level. The case in which there is no restriction on the dividend pay-out rates is dealt with. This gives rise to a mixed regular-singular stochastic control problem. First the value function is analyzed in great detail and in particular is shown to be a viscosity solution of the corresponding Hamilton–Jacobi–Bellman (HJB) equation. Based on this it is further proved that the value function must be twice continuously differentiable. Then a delicate analysis is carried out on the HJB equation, leading to an explicit expression of the value function as well as the optimal policies.

Key words. diffusion model, dividend distribution, risk control, optimal stochastic control, HJB equation, viscosity solution, Skorohod problem

1. Introduction.

Recently there has been an upsurge of interest in diffusion models for optimal dividend optimization and/or risk control techniques (see Jeanblanc–Piqué and Shiryaev [11], Asmussen and Taksar [2], Radner and Shepp [16], Boyle, Elliott, and Yang [3], Højgaard and Taksar [8], [9], [10], Paulsen and Gjessing [13], and Taksar and Zhou [18]). In those models the liquid assets of the company are modeled by a Brownian motion with constant drift and diffusion coefficients. The drift term corresponds to the expected (potential) profit per unit time, while the diffusion term is interpreted as risk. The larger the diffusion coefficient the greater the business risk the company takes on. If the company wants to decrease the risk from its business activities, it also faces a decrease in its potential profit. In other words, different business activities in this model correspond to changing *simultaneously* the drift and the diffusion coefficients of the underlying process. This sets a scene for an optimal stochastic control model where the controls affect not only the drift but also the diffusion part of the dynamic of the system.

Another important feature of our paper is dividend distribution. Dividends are paid from the liquid reserve of the company and distributed to the shareholders.

In the control model the dividend distribution plan is represented by an increasing functional, C_t, whose meaning is the cumulative amount of dividends paid out up to time t. In this paper the dividend pay-out rate is unbounded which, together with the risk control part, leads to a mixed regular-singular stochastic control model. The risk control/dividend distribution policy determines uniquely the dynamics of the liquid reserve. The company is bankrupt when its liquid assets vanish. The objective is to find the policy which maximizes the expected cumulative discounted dividend pay-outs up to the time of the bankruptcy.

Insurance is one of the natural areas where those models become widely applied. The risk control in insurance takes on the form of reinsurance. Specifically, if at any fixed time both the drift and diffusion coefficients of the controlled stochastic process are multiples of one and the same control parameter a, $0 \leq a \leq 1$, then this would be the case of the so-called *proportional reinsurance*, which is employed by a *cedent* in order to reduce the insurance risks. Other types of reinsurance schemes result in different types of drift/diffusion control models (see, e.g., [1], [17], [4]).

In this paper we consider a company whose business activities are modeled by a control process a_t, $t \geq 0$, which takes on values in the interval $[\alpha, \beta]$, $0 < \alpha < \beta < +\infty$, with risk and potential profit at any time t proportional to a_t. The restriction $\alpha > 0$ reflects the fact that there are institutional or statutory reasons (e.g., the company is public) that its business activities cannot be reduced to zero, unless the company faces bankruptcy. In addition, in our model the company has a constant rate of liability payments, such as mortgage payments on its property or amortization of bonds. In the case of an insurance company, when the control parameter a_t lies within $[0, 1]$ this problem was considered by Taksar and Zhou [18]. In this regard, the model treated in [18] can be viewed as a limiting case of $\alpha \to 0+$ and $\beta = 1$. However, the strictly positive lower bound treated in this paper renders the argument in [18] invalid and imposes a great difficulty for the problem. It is interesting to observe that the analytic expression for the optimal return function (value function) obtained in this paper, in the limiting case of $\alpha \to 0+$, $\beta = 1$, looks completely different from that in [18]. However, we will show via a detailed analysis that these are two analytic expressions for one and the same function.

We start our analysis with the value function v of the underlying stochastic control model. We first show that v is a viscosity solution of the corresponding Hamilton–Jacobi–Bellman (HJB) equation, which is interesting in its own right as the underlying stochastic control model is of a mixed regular-singular type. Based on this fact, along with the concavity of the value function, we prove a priori that v must be twice continuously differentiable (and hence, as a by-product, must be a classical solution to the HJB equation). The proof is very general and should be applicable to a large set of problems whenever concavity can be proved in advance. Afterwards we perform a delicate analysis on the HJB equation, which leads to explicit expressions of the value function for all the possible parameter values. Once this is done, optimal risk control and dividend policies are constructed via the verification theorem and the solution to a Skorohod problem.

The paper is structured as follows. In the next section we give a rigorous mathematical formulation of the problem and analyze the structure of the value function. We show that it is concave and is twice continuously differentiable. In section 3 we analyze the case without liability, which is interesting in its own right and inspiring in treating more general cases. In section 4 we extend the results to the case of a constant liability payments. Section 5 is devoted to the construction of optimal policies

based on the results of the preceding sections. The last section is devoted to economic interpretation of the obtained results, along with some concluding remarks.

2. Properties of the optimal return function. We start with a filtered probability space $(\Omega, \mathcal{F}, \mathcal{F}_t, P)$ and a one-dimensional standard Brownian motion W_t (with $W_0 = 0$) on it, adapted to the filtration $\mathcal{F}_t$. We denote by R_t^π the reserve of the company at time t under a control policy $\pi = (a_t^\pi, C_t^\pi; t \geq 0)$ (to be specified below). The dynamics of the reserve process R_t^π is described by

$$dR_t^\pi = (a_t^\pi \mu - \delta)dt + a_t^\pi \sigma dW_t - dC_t^\pi, \tag{2.1}$$

with initial condition

$$R_{0-}^\pi = x, \tag{2.2}$$

where μ is the expected profit per unit time (profit rate) and σ is the volatility rate of the reserve process in the absence of any risk control, δ represents the amount of money the company has to pay per unit time (the debt rate) irrespective of what business activities it chooses, and x is the initial reserve. It should be noted that a dividend distribution (see below) may take place at the initial time, hence the notation R_{0-}^π represents the initial reserve level *before* such a distribution has ever occurred.

The control in this model is described by a pair of $\mathcal{F}_t$-adapted measurable processes $\pi = (a_t^\pi, C_t^\pi; t \geq 0)$. A control $\pi = (a_t^\pi, C_t^\pi; t \geq 0)$ is admissible if $\alpha \leq a_t^\pi \leq \beta$ for all $t \geq 0$, and C_t^π is nondecreasing, right continuous having left limits process, where $0 < \alpha < \beta < +\infty$ are given scalars. In addition it is required that the state process R_t^π is nonnegative for all $t \leq \tau$, where τ is the time of bankruptcy given by (2.3) below. The last condition describes the requirement that one cannot have a negative reserve even at the time of bankruptcy. Thus if at time t a lump sum payment of dividends is made, then it cannot be in excess of the reserve at hand. We denote the set of all admissible controls by $\mathcal{A}$. The control component a_t^π represents one of the possible business activities available for the company at time t, and the component C_t^π corresponds to the total amount of dividends paid out by the company up to time t. For any admissible C^π and any $t < 0$ we set $C_t^\pi = 0$. Thus $C_{0-}^\pi = 0$ and if $C_0^\pi > 0$, then $R_0 = x - C_0^\pi$. The latter corresponds to the policy π, which pays a lump sum dividend of C_0^π at time 0.

Given a control policy π, the time of bankruptcy is defined as

$$\tau^\pi = \inf\{t \geq 0 : R_t^\pi = 0\}. \tag{2.3}$$

We make the convention that

$$R_t^\pi = 0 \qquad \forall t \geq \tau^\pi. \tag{2.4}$$

The *performance functional* associated with each control π is

$$J_x(\pi) = E\left(\int_0^{\tau^\pi} e^{-\gamma t} dC_t^\pi\right), \tag{2.5}$$

where $\gamma > 0$ is an a priori given discount factor (used in calculating the present value of the future dividends), and the subscript x denotes the initial state in the right-hand side of (2.2). To simplify notation, in what follows we will omit the superscript π in τ^π, a^π, etc. when it is clear from the context which policy we are dealing with.

The integral in (2.5) is understood as an integral on $[0, \tau]$ with respect to the measure whose distribution function is C_t. In particular, if $C_0 > 0$, this measure has an atomic mass of C_0 at 0 and this quantity is included in the integral. Likewise if $C_{\tau-} < C_\tau$, then $e^{-c\tau}(C_\tau - C_{\tau-})$ is included in the integral in the right-hand side of (2.5). The objective is to find the *value function* (also known as *optimal return function*)

$$v(x) = \sup_{\pi \in \mathcal{A}} J_x(\pi) \tag{2.6}$$

and the optimal policy π^* such that

$$J_x(\pi^*) = v(x). \tag{2.7}$$

It is worthwhile to mention that from the requirement of nonnegativity of the reserve one can deduce that C_t does not exceed the running maximum of a Brownian motion with drift coefficient $\beta\mu - \delta$ and diffusion coefficient $\beta\sigma$. From this it is easy to see that for each policy π

$$J_x(\pi) \le \int_0^\infty e^{-\gamma t} \max_{0 \le u \le t} [x + (\beta\mu - \delta)u + \beta\sigma W_u] dt.$$

From the above inequality one can deduce that $v(x)$ is finite. However, more elaborate arguments are not needed since the finiteness of v will be also implied from the results of sections 3 and 4. The exogenous parameters of the problem are $\mu, \sigma, \delta, \alpha, \beta$, and γ. The aim of this paper is to obtain the value function v and the optimal policy *explicitly* in terms of these parameters.

A few remarks on the control component a_t are in order. The way this quantity enters into the dynamics (2.1) clearly shows that it reduces or increases the risk simultaneously reducing or increasing the expected profit rate at the same scale. In other words, the diffusion coefficient of the system (2.1) depends on the control component a_t. In [18], the problem is formulated in the context of an insurance company where $1 - a_t$ signifies the reinsurance fraction and the constraint $0 \le a_t \le 1$ is imposed, which is a limiting case of $\alpha \to 0+$ and $\beta = 1$. (Note that while in our analysis below we require $\alpha > 0$, the solution we obtain does have a limit when $\alpha \to 0+$ and this limit coincides with the solution in [18]. In this sense the model in [18] is indeed a special case of the model presented here.) It is certainly meaningful to relax this constraint to one with any arbitrary upper and lower bounds. For example, for the insurance company case, $\beta > 1$ would mean that the company can take an extra insurance business from other companies (that is, act as a reinsurer for other cedents). Moreover, our formulation can model risk control problems for companies other than insurance ones. On the other hand, the two general bounds α and β add a new, nontrivial feature to this model, as will be evident in what follows.

The main tools for solving the problem are the dynamic programming and the HJB equation (see Fleming and Rishel [6], Fleming and Soner [7], and Yong and Zhou [19], as well as relevant discussions in [2], [9], and [18]). To analyze the value function, we need the following lemma.

LEMMA 1. *Let X_t be Ito's process on a positive half line,*

$$X_t = x + \int_0^t m(u)du + \int_0^t s(u)dW_u, \tag{2.8}$$

where

$$0 < d \le s(u) \le g, \qquad b \le m(u) \le c, \tag{2.9}$$

for some constants $b, c, d,$ and g. Let $h > 0$ and $\zeta_h = \inf\{t \geq 0 : X_t = h\}$. Then for any fixed $t > 0$,

$$P(\zeta_0 < \zeta_h \wedge t) \to 1, \tag{2.10}$$

$$E\left(\max_{0\leq s\leq \zeta_0\wedge t} X_s\right) \to 0 \tag{2.11}$$

as $x \downarrow 0$ uniformly over all the processes X_t with the drift and diffusion terms subject to (2.9).

Proof. Let $\tilde{t}(r) = \int_0^r s(u)^2 du$ and $\hat{t}(v) = \tilde{t}^{-1}(v), Y(v) = X(\hat{t}(v))$. Then, in view of [14, Theorem 3.6, Corollary 3.7],

$$dY(v) = \hat{m}(v)dv + d\hat{W}_v,$$

where $\hat{W}$ is a standard Brownian motion. On the other hand, (2.9) shows $\frac{1}{d^2} \geq \frac{d\hat{t}(v)}{dv} \geq \frac{1}{g^2}$. Thus $|\hat{m}(v)| \leq \frac{1}{d^2}(|b| \vee |c|) \equiv K$,

$$X(s) = Y(\tilde{t}(s)), \qquad Y(s) \leq x + Ks + \hat{W}_s,$$

and

$$\max_{0\leq s\leq t} X(s) = \max_{0\leq v\leq \tilde{t}(t)} Y(v) \leq \max_{0\leq v\leq \tilde{t}(t)} (x + Kv + \hat{W}_v) \leq \max_{0\leq v\leq g^2 t} (x + Kv + \hat{W}_v). \tag{2.12}$$

Therefore, if $0 < x < h$, then

$$\tilde{t}(\zeta_0) \leq \hat{\zeta}_0, \qquad \tilde{t}(\zeta_h) \geq \hat{\zeta}_h, \tag{2.13}$$

where $\hat{\zeta}_h$ is the first hitting time of h by the process $x + Kv + \hat{W}_v$. As a result,

$$P(\zeta_0 < \zeta_h \wedge t) \geq P(\hat{\zeta}_0 < \hat{\zeta}_h \wedge d^2 t)$$

and

$$\max_{0\leq s\leq \zeta_0\wedge t} X_s \leq \max_{0\leq v\leq \hat{\zeta}_0\wedge g^2 t} (x + Kv + \hat{W}_v).$$

Thus the statement of the proposition follows from a similar statement for a standard Brownian motion with a constant drift. The latter is trivial since $x + Kv + \hat{W}_v$ decreases as $x \downarrow 0$ and the law of iterated logarithm (see [14, section II, Theorem 1.9]) implies that $\hat{\zeta}_0 \to 0$, wherefrom (2.10) follows. On the other hand, since $x + Kv + \hat{W}_v$ is a continuous process, $\max_{0\leq v\leq \hat{\zeta}_0\wedge g^2 t}(x + Kv + \hat{W}_v) \downarrow 0$ as $x \downarrow 0$. Moreover, this maximum is majorized by $\max_{0\leq v\leq g^2 t}(h + Kv + \hat{W}_v)$; hence (2.11) follows. ∎

Now we show that the value function v has the following basic properties.

PROPOSITION 1. *The value function v is a continuous, nondecreasing function subject to*

$$v(0+) = 0. \tag{2.14}$$

Proof. If $y > x$, then for any $\pi = (a_t, C_t)$, we can put $\hat{\pi} = (a_t, C_t + y - x)$. The policy $\hat{\pi}$ corresponds to instantaneously paying dividends in the amount of $y - x$,

thus instantaneously changing the initial reserve from y into x and then following the policy π. If R_t is the process satisfying (2.1), (2.2) and $\hat{R}_t$ is the process satisfying (2.1) and (2.2) with π replaced by $\hat{\pi}$ and x replaced by y in (2.2), then $R_t = \hat{R}_t$ for all $t > 0$. Obviously $J_y(\hat{\pi}) = (y - x) + J_x(\pi)$. This shows that

$$v(y) \geq (y - x) + v(x) \tag{2.15}$$

and, in particular, v is nondecreasing.

To prove (2.14), let $\pi = (a_t, C_t)$ be an arbitrary policy and R_t be given by (2.1), (2.2) while $X_t = R_t + C_t$. Thus X is the process governed by (2.8) with $m(u) = \mu a_u - \delta$ and $s(u) = \sigma a_u$. From the condition $\alpha \leq a_u \leq \beta$ follows (2.9). Fix $t > 0$. In view of Lemma 1, for any $0 < \varepsilon < 1$ choose x such that the expression in the left-hand side of (2.10) is greater than $1 - \varepsilon$ and the expression in the left-hand side of (2.11) is less than ε.

Fix $h > 0$ and let $\eta = \tau \wedge \zeta_h \wedge t$. Since $R_t \leq X_t$, we see that $\tau \leq \zeta_0$ and $P(\tau < \zeta_h \wedge t) > P(\zeta_0 < \zeta_h \wedge t) > 1 - \varepsilon$. Due to the requirement that $R_s = X_s - C_s \geq 0$ for all $s \leq \tau$, we have $C_\eta \leq X_\eta \leq \max_{0 \leq u \leq \eta} X_u$. Therefore $EC_\eta < \varepsilon$. As a result

$$\begin{aligned} J_x(\pi) &= E \int_0^\tau e^{-\gamma s} dC_s = E \int_0^\eta e^{-\gamma s} dC_s + E \left(1_{\tau > \eta} \int_\eta^\tau e^{-\gamma s} dC_s \right) \\ &\leq EC_\eta + E \left(1_{\tau > \eta} E \left(\int_\eta^\tau e^{-\gamma s} dC_s | \mathcal{F}_\eta \right) \right) \leq \varepsilon + E \left(1_{\tau > \eta} e^{-\gamma \eta} v(R_\eta) \right). \end{aligned} \tag{2.16}$$

The last inequality in (2.16) is due to the definition of the value function v. Since $R_\eta \leq X_\eta \leq h$, and the function v is increasing, $v(R_\eta) \leq v(h)$. Consequently,

$$J_x(\pi) \leq \varepsilon + E(1_{\tau > \eta} e^{-\gamma \eta} v(h)) \leq \varepsilon + v(h) P(\tau > \eta) \leq \varepsilon(1 + v(h)). \tag{2.17}$$

In view of arbitrariness of ε, we conclude the validity of (2.14).

Finally, we prove that v is continuous at any $y > 0$. Let $\pi = (a_t, C_t)$ be a control admissible from y and R_t is the corresponding process with the initial position y (that is, $R_{0-} = y$). Let $0 < x < y$ be such that the expression in the left-hand side of (2.10) is greater than $1 - \varepsilon$ and the expression in the left-hand side of (2.11) is less than ε. Suppose $\xi \geq 0$ is any stopping time such that $R_\xi \leq x$. Then, following exactly the same line of proof as for (2.17), we can show that

$$E \left(\int_\xi^\tau e^{-\gamma t} dC_t \right) \leq \varepsilon(1 + v(h)), \tag{2.18}$$

where $h > 0$ is fixed. Let $\hat{y} = y - x$ and $\hat{\pi} = (\hat{a}_t, \hat{C}_t)$ be the control which makes the resulting state process $\hat{R}$ "trail" the process R at the constant distance of x until the bankruptcy of the tracing process. That is, $(\hat{a}_t, \hat{C}_t) = (a_t, C_t)$, $t < \zeta$, where $\zeta = \inf\{t \geq 0 : \hat{R}_t \leq 0\}$ and

$$\hat{R}_t = y - x + \int_0^t (a_s \mu - \delta) ds + \int_0^t a_s \sigma dW_s - C_t.$$

We set $\hat{C}_\zeta = C_{\zeta -} + \hat{R}_{\zeta -}$. Obviously $\hat{R}_t = R_t - x$ for $t < \zeta$ and $\hat{R}_\zeta = 0$. Since $\hat{R}_{\zeta -} = R_{\zeta -} - x$ and $\hat{R}_{\zeta -} - (C_\zeta - C_{\zeta -}) \leq 0$, we conclude that

$$R_\zeta = R_{\zeta -} - (C_\zeta - C_{\zeta -}) \leq x. \tag{2.19}$$

On the other hand, since $R_\zeta = R_{\zeta-} - (C_\zeta - C_{\zeta-}) = \hat{R}_{\zeta-} + x - (C_\zeta - C_{\zeta-}) \geq 0$, we also have

$$(C_\zeta - C_{\zeta-}) - \hat{R}_{\zeta-} \leq x. \tag{2.20}$$

Then

$$\begin{aligned} J_y(\pi) &= E\left(\int_0^\tau e^{-\gamma t} dC_t\right) = E\left(\int_0^\zeta e^{-\gamma t} dC_t + \int_\zeta^\tau e^{-\gamma t} dC_t\right) \\ &= E\left[\int_0^{\zeta-} e^{-\gamma t} dC_t + e^{-\gamma\zeta}(C_\zeta - C_{\zeta-}) + \int_\zeta^\tau e^{-\gamma t} dC_t\right] \\ &= E\left\{\int_0^{\zeta-} e^{-\gamma t} dC_t + e^{-\gamma\zeta}\hat{R}_{\zeta-} + e^{-\gamma\zeta}[(C_\zeta - C_{\zeta-}) - \hat{R}_{\zeta-}] + \int_\zeta^\tau e^{-\gamma t} dC_t\right\} \\ &= J_{y-x}(\hat{\pi}) + E\left\{e^{-\gamma\zeta}[(C_\zeta - C_{\zeta-}) - \hat{R}_{\zeta-}] + \int_\zeta^\tau e^{-\gamma t} dC_t\right\}. \end{aligned}$$

In view of (2.19) we see that (2.18) is true with $\xi = \zeta$. This, together with (2.20), yields

$$J_y(\pi) \leq J_{y-x}(\hat{\pi}) + x + \varepsilon(1 + v(h)).$$

Thus

$$0 \leq v(y) - v(y-x) \leq x + \varepsilon(1 + v(h)),$$

which shows continuity of v. □

Since the value function has been proved to be continuous, the following dynamic programming principle holds:

$$v(x) = \sup_{\pi\in\mathcal{A}}\left[E\int_0^{\tau\wedge\theta} e^{-\gamma t} dC_t + Ee^{-\gamma(\tau\wedge\theta)} v(R_{\tau\wedge\theta})\right] \tag{2.21}$$

for every $x \geq 0$ and $\mathcal{F}_t$-stopping time θ (which may depend on the policy π); see [7, p. 333] for details.

PROPOSITION 2. *The value function v is a concave function.*

Proof. First note that the dynamic programming principle (2.21) implies that if $0 < y < x$, then

$$v(x) = \sup_{\pi\in\mathcal{A}} E_x\left(\int_0^{\chi_y} e^{-\gamma t} dC_t + e^{-\gamma\chi_y} v(R_{\chi_y})\right), \tag{2.22}$$

where $\chi_y = \inf\{t \geq 0 : R_t \leq y\}$ with R_t the reserve process corresponding to π. Since $x > y$ and the process R_t can have only the downward jumps, we have

$$R_{\chi_y} \leq y \tag{2.23}$$

and $R_{\chi_y} \equiv R_{\chi_y-} - \Delta C_{\chi_y} < y$ only if $\Delta C_{\chi_y} = C_{\chi_y} - C_{\chi_y-} > 0$. Put $\Delta' C_{\chi_y} = R_{\chi_y-} - y$ and $\Delta'' C_{\chi_y} = \Delta C_{\chi_y} - \Delta' C_{\chi_y}$. In view of (2.23) we have $\Delta' C_{\chi_y} \leq \Delta C_{\chi_y}$, $\Delta'' C_{\chi_y} \geq 0$ and

$$R_{\chi_y-} - \Delta' C_{\chi_y} = y, \qquad y - \Delta'' C_{\chi_y} = R_{\chi_y}. \tag{2.24}$$

Taking into account (2.24), we have for any $\pi \in \mathcal{A}$

$$
\begin{aligned}
& E_x\left(\textstyle\int_0^{\chi_y} e^{-\gamma t} dC_t + e^{-\gamma\chi_y} v(R_{\chi_y})\right) \\
= \; & E_x\left(\textstyle\int_0^{\chi_y -} e^{-\gamma t} dC_t + e^{-\gamma\chi_y}\Delta C_{\chi_y} + e^{-\gamma\chi_y}[v(y) + v(R_{\chi_y}) - v(y)]\right) \\
= \; & E_x\Big(\textstyle\int_0^{\chi_y -} e^{-\gamma t} dC_t + e^{-\gamma\chi_y}(\Delta' C_{\chi_y} + \Delta'' C_{\chi_y}) \\
& \qquad + e^{-\gamma\chi_y}[v(y) + v(y - \Delta'' C_{\chi_y}) - v(y)]\Big) \\
= \; & E_x\Big(\textstyle\int_0^{\chi_y -} e^{-\gamma t} dC_t + e^{-\gamma\chi_y}\Delta' C_{\chi_y} + e^{-\gamma\chi_y} v(y) \\
& \qquad + e^{-\gamma\chi_y}[v(y - \Delta'' C_{\chi_y}) - v(y) + \Delta'' C_{\chi_y}]\Big).
\end{aligned} \tag{2.25}
$$

In view of (2.15),

$$v(y - \Delta'' C_{\chi_y}) - v(y) \le -\Delta'' C_{\chi_y};$$

therefore (2.25) implies

$$
\begin{aligned}
& E_x\left(\int_0^{\chi_y} e^{-\gamma t} dC_t + e^{-\gamma\chi_y} v(R_{\chi_y})\right) \\
& \le E_x\left(\int_0^{\chi_y -} e^{-\gamma t} dC_t + e^{-\gamma\chi_y}\Delta' C_{\chi_y} + e^{-\gamma\chi_y} v(y)\right) \\
& = E_x\left(\int_0^{\chi_y} e^{-\gamma t} dC'_t + e^{-\gamma\chi_y} v(y)\right),
\end{aligned} \tag{2.26}
$$

where

$$
\begin{aligned}
C'_s &= C_s \qquad \forall s < \chi_y, \\
C'_{\chi_y} &= C_{\chi_y -} + \Delta' C_{\chi_y}.
\end{aligned}
$$

Thus if $(a_t, C_t) \in \mathcal{A}$, then by changing C_t into C'_t (that is, not changing control C_t until χ_y and only changing the jump at the time χ_y from ΔC_{χ_y} to $\Delta' C_{\chi_y}$) we can only increase the left-hand side of (2.25). Therefore the supremum in the right-hand side of (2.22) can be taken over only those controls in $\mathcal{A}$ for which ΔC_{χ_y} is replaced by $\Delta' C_{\chi_y}$. Note that an easy calculation shows that under the control (a_t, C'_t) the corresponding reserve process *always* satisfies

$$R_{\chi_y} = y. \tag{2.27}$$

Consequently, for the right-hand side of the dynamic programming equation (2.22) we need only consider those controls π for which (2.27) holds.

For $h > 0$, let $\mathcal{A}^h$ be the set of controls (a_t, C_t) such that

$$\int_0^\zeta \mu a(s) ds + \int_0^\zeta \sigma a(s) dW_s - \delta\zeta - C_\zeta = -h$$

on the set $\{\zeta < \infty\}$, where

$$\zeta = \inf\left\{t \ge 0 : \int_0^t \mu a(s) ds + \int_0^t \sigma a(s) dW_s - \delta t - C_t \le -h\right\}.$$

From (2.22) and the argument above, we can write (putting $h = x - y$)

$$v(x) = \sup_{(a_t, C_t) \in \mathcal{A}^h} E_x \left(\int_0^\zeta e^{-\gamma t} dC_t + e^{-\gamma \zeta} v(y) \right). \tag{2.28}$$

Thus, by putting $y = x - h$ in (2.28), we have

$$v(x) - v(x-h) = \sup_{(a_t, C_t) \in \mathcal{A}^h} E_x \left(\int_0^\zeta e^{-\gamma t} dC_t + (e^{-\gamma \zeta} - 1) v(x-h) \right). \tag{2.29}$$

Since $e^{-\gamma\zeta} - 1 \leq 0$ and $v(x)$ is a nondecreasing function as shown earlier, the right-hand side of (2.29) is a nonincreasing function of x. Thus $v(x) - v(x-h)$ is a nonincreasing function of x, which shows the concavity of v. □

Remark 1. Normally a proof for the concavity of the value function is straightforward if the dynamics of the underlying stochastic control model is linear and is on, say, an infinite time horizon. In such a case there is no need to employ the dynamic programming approach. In the present case, however, the random time horizon terminated by a stopping time, the constraint that a_t must be *strictly* positive as well as the presence of $\delta > 0$ render the normal approach invalid. Here, we use the dynamic programming principle to overcome the difficulty in proving the concavity of the value function, which is new according to our best knowledge.

THEOREM 1. *The value function v is a viscosity solution of the HJB equation*

$$\begin{aligned} &\max\left(\max_{\alpha \leq a \leq \beta} \left(\tfrac{1}{2}\sigma^2 a^2 V''(x) + (a\mu - \delta) V'(x) - \gamma V(x) \right),\ 1 - V'(x) \right) = 0, \quad x > 0, \\ &V(0) = 0. \end{aligned} \tag{2.30}$$

That is,

(i) *for any $x_0 > 0$ and any C^2 function f such that $f(x_0) = v(x_0)$ and $f(x) \geq v(x)$ for all x in the neighborhood of x_0,*

$$\max\left(\max_{\alpha \leq a \leq \beta} \left(\frac{1}{2}\sigma^2 a^2 f''(x_0) + (a\mu - \delta) f'(x_0) - \gamma f(x_0) \right),\ 1 - f'(x_0) \right) \geq 0; \tag{2.31}$$

(ii) *for any $x_0 > 0$ and any C^2 function f such that $f(x_0) = v(x_0)$ and $f(x) \leq v(x)$ for all x in the neighborhood of x_0,*

$$\max\left(\max_{\alpha \leq a \leq \beta} \left(\frac{1}{2}\sigma^2 a^2 f''(x_0) + (a\mu - \delta) f'(x_0) - \gamma f(x_0) \right),\ 1 - f'(x_0) \right) \leq 0. \tag{2.32}$$

Moreover, if v is twice differentiable at the point x_0, then v satisfies (2.30) *at x_0.*

Proof. For any $a \in [\alpha, \beta]$ denote the operator

$$L^a = \frac{1}{2}\sigma^2 a^2 \frac{d^2}{dx^2} + (a\mu - \delta)\frac{d}{dx} - \gamma. \tag{2.33}$$

Fix $x_0 > 0$. Dynamic programming principle yields

$$v(x_0) = \sup_{\pi \in \mathcal{A}} \left[E \int_0^{\tau \wedge \tau'} e^{-\gamma t} dC_t + E e^{-\gamma(\tau \wedge \tau')} v(R_{\tau \wedge \tau'}) \right] \tag{2.34}$$

for any $\mathcal{F}_t$-stopping time τ' (which may depend on the policy π).

For any C^2 function f such that $f(x_0) = v(x_0)$ and $f(x) \le v(x)$ for all x in the neighborhood of x_0, let $O_\varepsilon(x_0) = [x_0-\varepsilon, x_0+\varepsilon]$ be the small interval, where $\varepsilon > 0$, such that $f(x) \le v(x)$ and $x > 0$ for all $x \in O_\varepsilon(x_0)$. Fix a policy $\pi = (a_t, C_t; t \ge 0) \in \mathcal{A}$, where $C_t = \begin{cases} 0 \text{ if } t = 0-, \\ \eta \text{ if } t \ge 0, \end{cases}$ with $0 \le \eta < \varepsilon$. Let θ be the exit time of the corresponding reserve process R_t from $O_\varepsilon(x_0)$, namely, $\theta = \inf\{t \ge 0 : R_t \notin O_\varepsilon(x_0)\}$. By the choice of $O_\varepsilon(x_0)$ above, $\theta \le \tau$. It is also easily seen that the corresponding reserve process R_t has at most one jump at $t = 0$ while remaining continuous on $(0, \theta]$ (hence staying in $O_\varepsilon(x_0)$ at or before θ). Now, taking $\tau' = \theta \wedge h$ in (2.34), where $h > 0$ is a deterministic quantity, and noting that $R_{\theta\wedge h} \in O_\varepsilon(x_0)$, we have

$$\begin{aligned} f(x_0) = v(x_0) &\ge E[\textstyle\int_0^{\theta\wedge h} e^{-\gamma s} dC_s + e^{-\gamma(\theta\wedge h)} v(R_{\theta\wedge h})] \\ &\ge E[\textstyle\int_0^{\theta\wedge h} e^{-\gamma s} dC_s + e^{-\gamma(\theta\wedge h)} f(R_{\theta\wedge h})] \qquad \forall h > 0. \end{aligned} \tag{2.35}$$

Applying a generalized Ito formula (see Dellacherie and Meyer [5, Theorem VIII.27]) to the process $e^{-\gamma t} f(R_t)$, we get (below C_t^c stands for the continuous part of the increasing process C_t)

$$\begin{aligned} e^{-\gamma(\theta\wedge h)} f(R_{\theta\wedge h}) &= f(x_0) + \int_0^{\theta\wedge h} e^{-\gamma s} \sigma a_s f'(R_s) dW_s \\ &\quad + \int_0^{\theta\wedge h} e^{-\gamma s} L^{a_s} f(R_s) ds - \int_0^{\theta\wedge h} e^{-\gamma s} f'(R_s) dC_s \\ &\quad + \sum_{s \le \theta\wedge h} e^{-\gamma s} [f(R_s) - f(R_{s-}) - f'(R_{s-})(R_s - R_{s-})] \\ &= f(x_0) + \int_0^{\theta\wedge h} e^{-\gamma s} \sigma a_s f'(R_s) dW_s + \int_0^{\theta\wedge h} e^{-\gamma s} L^{a_s} f(R_s) ds \\ &\quad - \int_0^{\theta\wedge h} e^{-\gamma s} f'(R_s) dC_s^c + \sum_{s \le \theta\wedge h} e^{-\gamma s} [f(R_s) - f(R_{s-})], \end{aligned} \tag{2.36}$$

where we used the equality $R_s - R_{s-} = -(C_s - C_{s-})$. Since f is C^2 and R_s stays in the bounded region $O_\varepsilon(x_0)$ for $s \le \theta$, we conclude that $f'(R_s)$ is bounded on $[0, \theta \wedge h]$ and hence the stochastic integral in (2.36) is a square integrable martingale whose expectation vanishes. Taking the expectation of (2.36) and substituting it into (2.35), we obtain

$$\begin{aligned} &E\textstyle\int_0^{\theta\wedge h} e^{-\gamma s} dC_s + E\int_0^{\theta\wedge h} e^{-\gamma s} L^{a_s} f(R_s) ds \\ &\quad - E\textstyle\int_0^{\theta\wedge h} e^{-\gamma s} f'(R_s) dC_s^c + E\sum_{s \le \theta\wedge h} e^{-\gamma s} [f(R_s) - f(R_{s-})] \le 0 \qquad \forall h > 0. \end{aligned} \tag{2.37}$$

In the above, taking $a_t \equiv a$ and $C_t \equiv 0$ (i.e., $\eta = 0$), where $a \in [\alpha, \beta]$, we have $E\int_0^{\theta\wedge h} e^{-\gamma s} L^a f(R_s) ds = E\int_0^h e^{-\gamma s} L^a f(R_s) 1_{s \le \theta} ds \le 0$ for all $h > 0$. Note that in this case R_s is continuous at $s = 0$ and the integrand, $e^{-\gamma s} L^a f(R_s) 1_{s \le \theta}$, converges to $L^a f(x_0)$ almost surely as $s \to 0$. Dividing the above inequality by h and sending h to zero, we conclude by the uniform boundedness of the above integrand that

$$L^a f(x_0) \le 0 \qquad \forall a \in [\alpha, \beta]. \tag{2.38}$$

On the other hand, in (2.37) taking $a_t \equiv a$ and $\eta > 0$, we obtain

$$E\int_0^{\theta\wedge h} e^{-\gamma s} L^a f(R_s) ds + \eta + f(x_0 - \eta) - f(x_0) \le 0 \qquad \forall h > 0 \ \ \forall 0 < \eta < \varepsilon.$$

First letting $h \to 0$, then dividing by η and finally sending η to 0, we obtain

$$1 - f'(x_0) \leq 0. \tag{2.39}$$

Combining (2.38) and (2.39) we arrive at (2.32).

To prove (2.31), let a C^2 function f be such that $f(x_0) = v(x_0)$ and $f(x) \geq v(x)$ for all x in the neighborhood of $x_0 > 0$. If (2.31) is not true, then there is $A > 0$ such that

$$\max\left(\max_{\alpha\leq a\leq\beta}\left(\frac{1}{2}\sigma^2a^2f''(x) + (a\mu - \delta)f'(x) - \gamma f(x)\right),\ 1 - f'(x)\right) \leq -A < 0 \tag{2.40}$$

for all $x \in O_\varepsilon(x_0) = [x_0 - \varepsilon, x_0 + \varepsilon]$, where $\varepsilon > 0$. As before we can make ε sufficiently small so that $f(x) \geq v(x)$ and $x > 0$ for all $x \in O_\varepsilon(x_0)$. Given a policy $\pi \in \mathcal{A}$, let $\theta = \inf\{t \geq 0 : R_t \notin O_\varepsilon(x_0)\}$. Note that it is possible that $\theta = 0+$, meaning that there is a jump at $t = 0$ getting the reserve process out of $O_\varepsilon(x_0)$ instantly. However, by definition R_s stays in $O_\varepsilon(x_0)$ so long as $s < \theta$. Once again, $\theta \leq \tau$. (If there is a jump at $t = 0$ making the reserve process zero instantly, then $\theta = \tau = 0+$.) Now, the generalized Ito formula yields

$$\begin{aligned} &Ee^{-\gamma\theta}f(R_{\theta-}) - f(x_0) + E\textstyle\int_0^{\theta-} e^{-\gamma s}dC_s \\ &\quad = E\textstyle\int_0^{\theta-} e^{-\gamma s}L^{a_s}f(R_s)ds - E\int_0^{\theta-} e^{-\gamma s}f'(R_s)dC_s^c \\ &\qquad + E\textstyle\sum_{s<\theta} e^{-\gamma s}[f(R_s) - f(R_{s-})] + E\int_0^{\theta-} e^{-\gamma s}dC_s. \end{aligned} \tag{2.41}$$

First we have

$$\begin{aligned} f(R_s) - f(R_{s-}) &= (R_s - R_{s-})\textstyle\int_0^1 f'(R_{s-} + z(R_s - R_{s-}))dz \\ &= -(C_s - C_{s-})\int_0^1 f'(R_{s-} + z(R_s - R_{s-}))dz \\ &\leq -(1 + A)(C_s - C_{s-}), \end{aligned} \tag{2.42}$$

where the last inequality is due to (2.40). Going back to (2.41), noting (2.40) and (2.42), we have

$$\begin{aligned} &Ee^{-\gamma\theta}f(R_{\theta-}) - f(x_0) + E\textstyle\int_0^{\theta-} e^{-\gamma s}dC_s \\ \leq\ &-AE\textstyle\int_0^\theta e^{-\gamma s}ds - (1 + A)E\int_0^{\theta-} e^{-\gamma s}dC_s^c - (1 + A)E\sum_{s<\theta} e^{-\gamma s}(C_s - C_{s-}) \\ &+E\textstyle\int_0^{\theta-} e^{-\gamma s}dC_s \\ =\ &-AE\textstyle\int_0^\theta e^{-\gamma s}ds - (1 + A)E\int_0^{\theta-} e^{-\gamma s}dC_s + E\int_0^{\theta-} e^{-\gamma s}dC_s \\ =\ &-AE\textstyle\int_0^\theta e^{-\gamma s}ds - AE\int_0^{\theta-} e^{-\gamma s}dC_s. \end{aligned} \tag{2.43}$$

To proceed, note that $R_\theta \leq R_{\theta-} \in O_\varepsilon(x_0)$ while R_θ may be out of $O_\varepsilon(x_0)$. However, one can always find a point x_λ on the boundary of $O_\varepsilon(x_0)$ such that

$$x_\lambda = R_{\theta-} + \lambda(R_\theta - R_{\theta-}) \equiv R_{\theta-} - \lambda(C_\theta - C_{\theta-}) \in \{x_0 - \varepsilon, x_0 + \varepsilon\}, \tag{2.44}$$

where $\lambda \in [0, 1]$ is a random variable. Clearly we have $R_\theta \leq x_\lambda \leq R_{\theta-}$, and $x_\lambda = x_0 - \epsilon$ if $R_\theta \notin O_\epsilon(x_0)$. Now, similar to (2.42), we have

$$f(R_{\theta-}) - f(x_\lambda) \geq (1 + A)(R_{\theta-} - x_\lambda) = \lambda(1 + A)(C_\theta - C_{\theta-}). \tag{2.45}$$

Moreover, since $R_\theta \le x_\lambda$ we have by (2.15) that

$$v(x_\lambda) \ge x_\lambda - R_\theta + v(R_\theta) = (1-\lambda)(C_\theta - C_{\theta-}) + v(R_\theta). \tag{2.46}$$

Combining (2.43), (2.45), and (2.46), we derive

(2.47)
$$\begin{aligned} v(x_0) = f(x_0) &\ge E\int_0^{\theta-} e^{-\gamma s}dC_s + Ee^{-\gamma\theta}f(R_{\theta-}) \\ &\quad + A\big[E\int_0^{\theta} e^{-\gamma s}ds + E\int_0^{\theta-} e^{-\gamma s}dC_s\big] \\ &\ge E\int_0^{\theta-} e^{-\gamma s}dC_s + Ee^{-\gamma\theta}f(x_\lambda) + \lambda(1+A)Ee^{-\gamma\theta}(C_\theta - C_{\theta-}) \\ &\quad + A\big[E\int_0^{\theta} e^{-\gamma s}ds + E\int_0^{\theta-} e^{-\gamma s}dC_s\big] \\ &\ge E\int_0^{\theta-} e^{-\gamma s}dC_s + Ee^{-\gamma\theta}v(x_\lambda) + \lambda(1+A)Ee^{-\gamma\theta}(C_\theta - C_{\theta-}) \\ &\quad + A\big[E\int_0^{\theta} e^{-\gamma s}ds + E\int_0^{\theta-} e^{-\gamma s}dC_s\big] \\ &\ge E\int_0^{\theta-} e^{-\gamma s}dC_s + Ee^{-\gamma\theta}v(R_\theta) + (1-\lambda)Ee^{-\gamma\theta}(C_\theta - C_{\theta-}) \\ &\quad + \lambda(1+A)Ee^{-\gamma\theta}(C_\theta - C_{\theta-}) \\ &\quad + A\big[E\int_0^{\theta} e^{-\gamma s}ds + E\int_0^{\theta-} e^{-\gamma s}dC_s\big] \\ &= E\int_0^{\theta} e^{-\gamma s}dC_s + Ee^{-\gamma\theta}v(R_\theta) \\ &\quad + A\big[E\int_0^{\theta} e^{-\gamma s}ds + E\int_0^{\theta-} e^{-\gamma s}dC_s + \lambda Ee^{-\gamma\theta}(C_\theta - C_{\theta-})\big]. \end{aligned}$$

Next we are going to show that there is a constant $k_0 > 0$ such that

$$E\int_0^{\theta} e^{-\gamma s}ds + E\int_0^{\theta-} e^{-\gamma s}dC_s + \lambda Ee^{-\gamma\theta}(C_\theta - C_{\theta-}) \ge k_0 \qquad \forall \pi \in \mathcal{A}. \tag{2.48}$$

To this end, define a C^2 function

$$w(x) = K_0(|x - x_0|^2 - \varepsilon^2), \tag{2.49}$$

where

(2.50)
$$K_0 = \min\left\{ \frac{1}{\sup_{|x-x_0|\le\delta,\alpha\le a\le\beta}\left[\sigma^2a^2 + \gamma\varepsilon^2 + 2|(a\mu-\delta)(x-x_0)|\right]}, \frac{1}{2\varepsilon} \right\} > 0.$$

From the definition of $w(\cdot)$ it is easy to verify that

$$L^a w(x) \le 1 \quad \text{and} \quad |w'(x)| \le 1 \qquad \forall x \in O_\varepsilon(x_0)\ \ \forall a \in [\alpha,\beta]. \tag{2.51}$$

Now applying the generalized Ito formula, we have

$$\begin{aligned} &E[e^{-\gamma\theta}w(R_{\theta-}) - w(x_0)] \\ &= E\int_0^{\theta-} e^{-\gamma s}L^{a_s}w(R_s)ds - E\int_0^{\theta-} e^{-\gamma s}w'(R_s)dC_s^c \\ &\qquad + E\textstyle\sum_{s<\theta} e^{-\gamma s}[w(R_s) - w(R_{s-})] \\ &\le E\int_0^{\theta} e^{-\gamma s}ds + E\int_0^{\theta-} e^{-\gamma s}dC_s, \end{aligned} \tag{2.52}$$

where the last inequality is due to (2.51). However, since $w'(x) \ge -1$, we have

$$w(R_{\theta-}) - w(x_\lambda) \ge -(R_{\theta-} - x_\lambda) = -\lambda(C_\theta - C_{\theta-}). \tag{2.53}$$

Substituting (2.53) into (2.52) we obtain

(2.54)
$$E\int_0^{\theta} e^{-\gamma s}ds + E\int_0^{\theta-} e^{-\gamma s}dC_s \geq E[e^{-\gamma\theta}w(x_\lambda) - w(x_0)] - \lambda E e^{-\gamma\theta}(C_\theta - C_{\theta-}).$$

Noting that $w(x_\lambda) = 0$ and $w(x_0) = -K_0\varepsilon^2$, we prove (2.48) with $k_0 := K_0\varepsilon^2 > 0$.

Thus, (2.47) gives

$$v(x_0) \geq E\int_0^{\theta} e^{-\gamma s}dC_s + Ee^{-\gamma\theta}v(R_\theta) + Ak_0, \tag{2.55}$$

which holds true for any $\pi \in \mathcal{A}$. Taking supremum over $\pi \in \mathcal{A}$ on both sides and appealing to (2.34), we have

$$v(x_0) \geq v(x_0) + Ak_0,$$

which is a contradiction. This proves that (2.40) is invalid.

Finally, if v is twice differentiable at x_0, then by definition we have $(v'(x_0), v''(x_0)) \in D^{2,+}v(x_0)$, the latter being the second-order superdifferential of v at x_0. Hence, by [19, p. 193, Lemma 5.4], there is a C^2 function f such that $v - f$ attains a strict maximum at x_0 and $(v(x_0), v'(x_0), v''(x_0)) = (f(x_0), f'(x_0), f''(x_0))$. By (i) proved above, f satisfies (2.31) at x_0, hence so does v at x_0. On the other hand, we also have $(v'(x_0), v''(x_0)) \in D^{2,-}v(x_0)$, the latter being the second-order subdifferential of v at x_0. Thus a symmetric reasoning leads to that v satisfies (2.32) at x_0. This proves the last claim of the theorem. □

Remark 2. It is proved in Fleming and Soner [7, chapter VIII] that the value function of a *pure* singular control problem is a viscosity solution of the corresponding HJB equation. The proof there is very involved as it is for a multidimensional problem. Our proof here is for a mixed regular-singular problem and is relatively simple by greatly exploiting the special structure of the single dimensionality.

Remark 3. Technically speaking the boundary condition in (2.30) should be $V(0+) = 0$ as (2.14) shows, rather than $V(0) = 0$. However, here and in what follows we will always adopt a convention that the solution of the HJB equation is extended to 0 by continuity and the value of V at 0 is its limit from the right.

Based on the fact that the value function is a concave viscosity solution of the HJB equation, we are able to show that it is in fact C^2. To this end we need the following lemma.

LEMMA 2. *Suppose g is a concave function such that $g(x) = g(x_0) + a(x - x_0)$ for $x \leq x_0$ and $g(x) = g(x_0) + b(x - x_0)$ for $x \geq x_0$, where $a > b$. Then for each sufficiently small $\varepsilon > 0$ there exists a concave C^2 function $f \geq g$ such that $f(x_0) = g(x_0)$, $f'(x) = a$, $x < x_0 - \varepsilon$, $f'(x) = b$, $x \geq x_0 + \varepsilon$, $f'(x_0) = (b + a)/2$, and $f''(x_0) \leq -\varepsilon^{-1}$.*

Proof. Choose $F(x)$ to be a nonincreasing continuously differentiable function, such that $F(x) = a$ for $x \leq x_0 - \varepsilon$, $F(x) = b$ for $x \geq x_0 + \varepsilon$, and $F(x) = -\frac{2}{\varepsilon}(x - x_0) + (b + a)/2$ for $-\varepsilon^2/2 < x - x_0 < \varepsilon^2/2$. Then $f(x) := g(x_0) + \int_{x_0}^{x} F(y)dy$ is the desired function. □

THEOREM 2. *The value function $v(x)$ is twice continuously differentiable for all $x > 0$.*

Proof. We divide the proof into several steps.

Step 1°. In view of concavity, the function v is a continuous function on $(0,\infty)$. First we show that v is a C^1 function. Let $D_+v(x)$ and $D_-v(x)$ be the right and the left derivatives of v at x. In view of concavity of v, the derivatives $D_+v(x)$ and $D_-v(x)$ exist for any $x>0$ and $D_-v(x)\geq D_+v(x)$. By virtue of (2.15) $D_+v(x)\geq 1$ for all $x>0$. Suppose x_0 is such that $D_-v(x_0)>D_+v(x_0)\geq 1$. Then $v(x)\leq g(x)$, where $g(x)=v(x_0)+D_+v(x_0)(x-x_0)$ for $x\geq x_0$ and $g(x)=v(x_0)+D_-v(x_0)(x-x_0)$ for $x\leq x_0$. Lemma 2 guarantees an existence of a concave C^2 function f such that $f(x)\geq g(x)\geq v(x)$, $f(x_0)=g(x_0)=v(x_0)$, $f'(x_0)=(D_+v(x_0)+D_-v(x_0))/2>1$, and $f''(x_0)\leq -\varepsilon^{-1}$. Theorem 1 shows that f must satisfy (2.31). Since $f'(x_0)>1$ we must have

$$\frac{1}{2}\sigma^2a^2f''(x_0)+(a\mu-\delta)f'(x_0)-\gamma f(x_0)\geq 0 \tag{2.56}$$

for some $\alpha\leq a\leq\beta$. However, $|(a\mu-\delta)f'(x_0)-\gamma f(x_0)|\leq|(a\mu-\delta)f'(x_0)|+\gamma v(x_0)\leq(\beta\mu-\delta)D_-v(x_0)+\gamma v(x_0)$ while $\frac{1}{2}\sigma^2a^2f''(x_0)<-\frac{1}{2}\alpha^2\sigma^2\frac{1}{\varepsilon}$. Thus choosing ε sufficiently small, we can see that (2.56) is violated. This shows that $D_-v(x_0)=D_+v(x_0)$.

Step 2°. Inequality (2.15) shows that $v'(x)\geq 1$ for all $x>0$. Let $x_1=\min\{x: v'(x)=1\}$. Since v' is a nonincreasing function, we have $v'(x)>1$ for all $x<x_1$. If f is subject to condition (i) of Theorem 1, then $f'(x_0)=v'(x_0)>1$ for $x_0<x_1$. Therefore (2.31) implies

$$\max_{\alpha\leq a\leq\beta}\left(\frac{1}{2}\sigma^2a^2f''(x_0)+(a\mu-\delta)f'(x_0)-\gamma f(x_0)\right)\geq 0. \tag{2.57}$$

Since v is concave, existence of the derivative of v everywhere implies that v' is a continuous nonincreasing function. Let $\mathcal{B}$ be the set of points x where $v''(x)$ exists. In view of [15, chapter 5, Theorem 3] the Lebesgue measure of the complement of $\mathcal{B}$ is zero. Thus $\mathcal{B}$ is an everywhere dense set.

Suppose $y_n\in\mathcal{B}, y_n<x_1$ and $y_n\to x_0$. Then by Theorem 1,

$$\max_{\alpha\leq a\leq\beta}\left(\frac{1}{2}\sigma^2a^2v''(y_n)+(a\mu-\delta)v'(y_n)-\gamma v(y_n)\right)=0. \tag{2.58}$$

Let $a^*(y_n)$ be the maximizer of the left-hand side of (2.58). Since $v(y_n)\to v(x_0)$, $v'(x_n)\to v'(x_0)$, and $\beta\geq a^*(y_n)\geq\alpha>0$ we see that $v''(y_n)$ is a bounded sequence. Choosing a subsequence if necessary, we can assume that $v''(y_n)\to q$. The expression which is maximized in the left-hand side of (2.58) is a quadratic polynomial of a on the interval $[\alpha,\beta]$ with convergent coefficients. Therefore we can pass to a limit and conclude

$$\max_{\alpha\leq a\leq\beta}\left(\frac{1}{2}\sigma^2a^2q+(a\mu-\delta)v'(x_0)-\gamma v(x_0)\right)=0. \tag{2.59}$$

If there exists another sequence $z_n\in\mathcal{B}, z_n<x_1$, such that $z_n\to x_0$ and $v''(z_n)\to q_1\neq q$, then the same arguments show that

$$\max_{\alpha\leq a\leq\beta}\left(\frac{1}{2}\sigma^2a^2q_1+(a\mu-\delta)v'(x_0)-\gamma v(x_0)\right)=0. \tag{2.60}$$

However,

$$\begin{aligned}&\left|\frac{1}{2}\sigma^2a^2q+(a\mu-\delta)v'(x_0)-\gamma v(x_0)-\frac{1}{2}\sigma^2a^2q_1-(a\mu-\delta)v'(x_0)-\gamma v(x_0)\right|\\ &=\frac{1}{2}\sigma^2a^2|q-q_1|\geq\frac{1}{2}\sigma^2\alpha^2|q-q_1|>0\end{aligned}$$

for all $a \in [\alpha, \beta]$. This inequality shows that (2.59) and (2.60) cannot hold simultaneously. Therefore $q = q_1$. As a result $v''(x)$ is a continuous function on $\mathcal{B}$ which can be extended to a continuous function on $(0, x_1)$. Consequently, v' is continuously differentiable on $(0, x_1)$.

Step 3°. The function v' is nonincreasing and $v'(x) \geq 1$ for all $x > 0$, while $v'(x) \leq 1$ for all $x \geq x_1$. Thus, $v'(x) = 1$ for all $x \geq x_1$. Therefore $v''(x) = 0$ for $x > x_1$. It is left only to show that $v''(x_1)$ exists.

Using the same arguments as in Step 2°, we can prove that $q = \lim_{y \uparrow x_1} v''(y)$ exists and (2.59) is true if we replace x_0 by x_1 in the left-hand side. Since v is concave, $q \leq 0$. Suppose $q < 0$. Then from (2.59) follows (recall that $v'(x_1) = 1$)

$$\begin{aligned}
&\max_{\alpha \leq a \leq \beta}[(a\mu - \delta) - \gamma v(x_1)] \\
&= \max_{\alpha \leq a \leq \beta}[(a\mu - \delta)v'(x_1) - \gamma v(x_1)] \\
&\geq \max_{\alpha \leq a \leq \beta}[\tfrac{1}{2}\sigma^2 a^2 q + (a\mu - \delta)v'(x_1) - \gamma v(x_1)] - \max_{\alpha \leq a \leq \beta}[\tfrac{1}{2}\sigma^2 a^2 q] \\
&= -\tfrac{1}{2}\sigma^2 \alpha^2 q \equiv K > 0.
\end{aligned}$$

Continuity of v implies that there exists $y > x_1$ such that $\gamma(v(y) - v(x_1)) < K/2$. Consequently,

$$\max_{\alpha \leq a \leq \beta}\left[\frac{1}{2}\sigma^2 a^2 v''(y) + (\mu a - \delta)v'(y) - \gamma v(y)\right] = \max_{\alpha \leq a \leq \beta}[(\mu a - \delta) - \gamma v(y)] > K/2 > 0.$$

The above inequality contradicts the last statement of Theorem 1. This contradiction proves that $q = v''(x_1-) = 0$. Therefore v'' can be continuously extended to the point x_1 and as a result v has a second derivative at x_1. □

In view of the last statement of Theorem 1, the following corollary is straightforward.

COROLLARY 1. *The value function v is the classical (i.e., C^2) solution to the HJB equation* (2.30).

Note that we do not know a priori whether the HJB equation has any C^2 solution other than the value function. However, the following verification theorem, which says that *any* concave solution V to the HJB equation (2.30) whose derivative is finite at 0 majorizes the performance functional for any policy π, is sufficient for us to identify optimal policies.

THEOREM 3. *Let V be a concave, twice continuously differentiable solution of* (2.30)*, such that $V'(0+) < +\infty$. Then for any policy $\pi = (a_t, C_t; t \geq 0)$,*

$$V(x) \geq J_x(\pi). \tag{2.61}$$

Proof. Let R_t be the reserve process given by (2.1) and (2.2) corresponding to a given policy π. Then applying the generalized Ito formula to the process $e^{-\gamma t}V(R_t)$, we get

(2.62)

$$\begin{aligned}
e^{-\gamma(t\wedge\tau)}V(R_{t\wedge\tau}) = V(x) &+ \int_0^{t\wedge\tau} e^{-\gamma s}\sigma a_s V'(R_s)dW_s + \int_0^{t\wedge\tau} e^{-\gamma s}L^{a_s}V(R_s)ds \\
&- \int_0^{t\wedge\tau} e^{-\gamma s}V'(R_s)dC_s^c + \sum_{s \leq t\wedge\tau} e^{-\gamma s}[V(R_s) - V(R_{s-})].
\end{aligned}$$

In view of the HJB equation (2.30), the quantity $L^{a_s}V(R_s)$ is always nonpositive. Taking expectations of both sides of (2.62), we get

$$E(e^{-\gamma(t\wedge\tau)}V(R_{t\wedge\tau})) \le V(x) - E\int_0^{t\wedge\tau} e^{-\gamma s}V'(R_s)dC_s^c + E\sum_{s\le t\wedge\tau} e^{-\gamma s}[V(R_s) - V(R_{s-})]. \tag{2.63}$$

Since $V'(x) \ge 1$, the mean-value theorem implies $V(R_s) - V(R_{s-}) \le R_s - R_{s-} = -(C_s - C_{s-})$. Thus in (2.63), we can replace $\sum_{s\le t\wedge\tau} e^{-\gamma s}[V(R_s) - V(R_{s-})]$ by $-\sum_{s\le t\wedge\tau} e^{-\gamma s}(C_s - C_{s-})$ with inequality preserved. Also the right-hand side of (2.63) will not decrease if we replace $V'(R_s)$ in the first integral by 1 because $V'(x) \ge 1$. As a result we get

$$\begin{aligned} E(e^{-\gamma(t\wedge\tau)}V(R_{t\wedge\tau})) &\le V(x) - E\int_0^{t\wedge\tau} e^{-\gamma s}dC_s^c - E\sum_{s\le t\wedge\tau} e^{-\gamma s}(C_s - C_{s-}) \\ &= V(x) - E\int_0^{t\wedge\tau} e^{-\gamma s}dC_s, \end{aligned}$$

or

$$E(e^{-\gamma(t\wedge\tau)}V(R_{t\wedge\tau})) + E\int_0^{t\wedge\tau} e^{-\gamma s}V'(R_s)dC_s \le V(x). \tag{2.64}$$

Note that in view of boundedness of V',

$$e^{-\gamma(t\wedge\tau)}V(R_{t\wedge\tau}) \le e^{-\gamma t}K(1 + R_{t\wedge\tau}) \le e^{-\gamma t}K(1 + |R_t|)$$

for some constant K. Since R_t is a diffusion process with uniformly bounded drift and diffusion coefficient, standard arguments yield $E|R_t| \le x + K_1 t$ for some constant K_1. Therefore

$$Ee^{-\gamma(t\wedge\tau)}V(R_{t\wedge\tau}) \to 0 \tag{2.65}$$

as $t \to \infty$. Thus taking limit in (2.64) as $t \to \infty$ we arrive at

$$V(x) \ge E\int_0^{\tau} e^{-\gamma s}V'(R_s)dC_s \ge J_\pi(x). \qquad \square$$

The idea of solving the original optimization problem is to first find a concave, smooth solution to the HJB equation (2.30) and then construct a control policy (via solving a Skorohod problem; for details see section 5) whose performance functional can be shown to coincide with the bounded solution to (2.30). Then, the above verification theorem establishes the optimality of the constructed control policy. As a by-product, we have a proof that there is no concave solution to (2.30) other than the value function.

3. Case of no liability. In this section we study the case where there is no debt liability, namely, $\delta = 0$. While being part of a more general case, it is interesting in its own right and will provide some valuable insights into the resolution of the general problem.

In this case, the HJB equation reads

(3.1)
$$\max\left(\max_{\alpha\le a\le\beta}\left(\tfrac{1}{2}\sigma^2a^2V''(x)+a\mu V'(x)-\gamma V(x)\right),\ 1-V'(x)\right)=0,\quad x>0,$$
$$V(0)=0.$$

As mentioned above, the key is to find a concave, smooth function V satisfying (3.1). While we could have presented such a solution immediately without any explanation (one would need only to check if it does satisfy (3.1), which is a relatively easy task), we believe that it is better to unfold the entire process of finding the solution for the benefit of the readers. Therefore, what we are going to present below is indeed the original process of tracking down the solution. Suppose such a solution, V, to the HJB equation (3.1) is found. Then due to concavity, V' is a nonincreasing function. Let $x_1=\inf\{x\ge 0\ :\ V'(x)\le 1\}$. Suppose $x_1>0$. Since V is concave we have $V'(x)>1$ for all $x<x_1$. In view of (3.1), V satisfies

$$\max_{\alpha\le a\le\beta}\left(\frac{1}{2}\sigma^2a^2V''(x)+a\mu V'(x)-\gamma V(x)\right)=0\qquad\forall x<x_1. \tag{3.2}$$

Note that if V satisfies (3.2) and $V''(x)=0$ on an open interval, then the maximum in the right-hand side of (3.2) is attained at $a=\beta$. Therefore on this interval the function V satisfies the first-order linear differential equation whose solution is $C\exp(\frac{\gamma}{\beta\mu}x)$, which contradicts concavity. Let

$$a(x)\equiv-\frac{\mu V'(x)}{\sigma^2V''(x)}>0,\qquad x<x_1, \tag{3.3}$$

be the maximizer of $\frac{1}{2}\sigma^2a^2V''(x)+a\mu V'(x)-\gamma V(x)$ over all $a\ge 0$, which is defined for those x for which $V''(x)\neq 0$. If $\alpha<a(x)<\beta$, then we can substitute the expression for $a(x)$ given by (3.3) back into (3.2) to get

$$-\frac{\mu^2(V'(x))^2}{2\sigma^2V''(x)}-\gamma V(x)=0.$$

Replacing $-\frac{\mu V'(x)}{\sigma^2V''(x)}$ in the above equation by $a(x)$ again, we get $\mu a(x)V'(x)/2-\gamma V(x)=0$ or

$$a(x)=\frac{2\gamma V(x)}{\mu V'(x)}.$$

For a concave nondecreasing function V the numerator of the above expression is a nondecreasing function, while the denominator is nonincreasing. Therefore $a(x)$ should be a nondecreasing function of x on the set where $\alpha<a(x)<\beta$. On the other hand continuity of V, V', and V'' implies that $a(x)$ is a continuous function of x for all $x>0$. Therefore, if $a(\bar{x})=\alpha$ for some $\bar{x}$, then $a(x)\le\alpha$ for all $x<\bar{x}$. Indeed, suppose $a(\bar{y})>\alpha$ for some $\bar{y}<\bar{x}$. Define $\hat{y}=\inf\{y>\bar{y}:a(y)\le\alpha\}\le\bar{x}$. Since $a(x)$ is continuous, $\alpha<a(z)<\beta$ whereas $a(z)$ is not nondecreasing for z in a left neighborhood of $\hat{y}$, leading to a contradiction. Likewise if $a(\bar{x})=\beta$ for some $\bar{x}$, then $a(x)\ge\beta$ for all $x>\bar{x}$.

Since $V''(x)\le 0$, the expression $\frac{1}{2}\sigma^2a^2V''(x)+a\mu V'(x)-\gamma V(x)$ as a function of a increases on $[0,\ a(x)]$ and decreases on $[a(x),\ \infty)$. As was just shown there exist

x_α and x_β, $0 \le x_\alpha < x_\beta \le +\infty$, such that $a(x) \le \alpha$ for all $x \le x_\alpha$ and $a(x) \ge \beta$ for all $x \ge x_\beta$; and $a(x)$ is nondecreasing from α to β on $[x_\alpha,\ x_\beta]$. Our next step is to show that $x_\alpha > 0$. To this end it is sufficient to analyze $a(0)$.

PROPOSITION 3. *The following holds:*

$$a(0) = \frac{1}{2}\alpha. \tag{3.4}$$

Proof. Put

$$\phi(x,\ a) = \frac{1}{2}\sigma^2 a^2 V''(x) + a\mu V'(x) - \gamma V(x), \qquad x \ge 0,\ a \ge 0. \tag{3.5}$$

It follows from (3.2) that $\max_{\alpha \le a \le \beta} \phi(0,\ a) = 0$. Let $\tilde{a} \in [\alpha,\ \beta]$ be such that $\phi(0,\ \tilde{a}) = \max_{\alpha \le a \le \beta} \phi(0,\ a) = 0$. Since $V(0) = 0$ we conclude

$$\tilde{a} = \frac{-2\mu V'(0)}{\sigma^2 V''(0)} \equiv 2a(0).$$

On the other hand, $\phi(0, a) = a[\frac{1}{2}\sigma^2 a V''(0) + \mu V'(0)]$, where $\frac{1}{2}\sigma^2 V''(0) \le 0$. Hence the maximum of $\phi(0, \cdot)$ is attained at the lower end of the interval $[\alpha, \beta]$, namely, $\tilde{a} = \alpha$. This proves (3.4). □

Continuity of $a(x)$ and the inequality $a(0) < \alpha$ show that for all x in a right neighborhood of 0, the maximum over $a \in [\alpha, \beta]$ in (3.2) is attained at α. Substituting $a = \alpha$ into (3.2) and solving the resulting second-order linear ordinary differential equation (ODE), we get

$$V(x) = k_1(\alpha,\ \beta)\left(e^{r_+(\alpha)x} - e^{r_-(\alpha)x}\right), \tag{3.6}$$

where $k_1(\alpha,\ \beta)$ is a free constant to be determined, and

$$r_+(z) \equiv \frac{-\mu + [\mu^2 + 2\sigma^2\gamma]^{1/2}}{z\sigma^2} > 0, \quad r_-(z) \equiv \frac{-\mu - [\mu^2 + 2\sigma^2\gamma]^{1/2}}{z\sigma^2} < 0 \qquad \forall z > 0. \tag{3.7}$$

From (3.6) and (3.3) it follows that

$$a'(x) = \frac{-\mu r_-(\alpha) r_+(\alpha) k_1^2(\alpha,\ \beta) e^{(r_+(\alpha)+r_-(\alpha))x} \left(r_+(\alpha) - r_-(\alpha)\right)^2}{(\sigma V''(x))^2} > 0$$

for all x in the right neighborhood of 0. Therefore in the right neighborhood of 0 the function $a(x)$ increases. Let x_α be such that $a(x_\alpha) = \alpha$. From (3.3) and (3.6), we obtain

$$x_\alpha = \frac{1}{r_+(\alpha) - r_-(\alpha)} \ln\left(-\frac{r_-(\alpha)}{r_+(\alpha)}\right) > 0. \tag{3.8}$$

PROPOSITION 4. *For each $x \ge x_\alpha$,*

$$a(x) \ge \alpha. \tag{3.9}$$

Proof. Suppose that there exists $x_0 > x_\alpha$ such that $a(x_0) < \alpha$. Then there exists $\varepsilon > 0$ such that $a(x) < \alpha$ for each x with $|x - x_0| < \varepsilon$. Let $x' = \sup\{x < x_0 : a(x) = \alpha\}$.

Then $x_\alpha \le x' < x_0 < x_0 + \varepsilon$ and $a(x') = \alpha$. Since $a(x) \le \alpha$ for all $x \in [x',\ x_0 + \varepsilon)$, the function V satisfies (3.2) with the maximum there attained at $a = \alpha$. Therefore

$$V(x) = K_1 e^{r_+(\alpha)(x-x')} + K_2 e^{r_-(\alpha)(x-x')} \qquad \forall x \in [x',\ x_0 + \varepsilon). \tag{3.10}$$

From (3.10) and (3.3), the equation $a(x') = \alpha$ can be rewritten as

$$K_1 r_+(\alpha) = -K_2 r_-(\alpha) \frac{\mu + \alpha\sigma^2 r_-(\alpha)}{\mu + \alpha\sigma^2 r_+(\alpha)},$$

which establishes a relation between the constants K_1 and K_2. Using this relation, we calculate

(3.11)

$$\begin{aligned} a(x) &= \frac{-\mu V'(x)}{\sigma^2 V''(x)} \\ &= \frac{-\mu \left(e^{(r_+(\alpha)-r_-(\alpha))(x-x')} - \frac{\mu+\alpha\sigma^2 r_+(\alpha)}{\mu+\alpha\sigma^2 r_-(\alpha)} \right)}{\sigma^2 \left(r_+(\alpha) e^{(r_+(\alpha)-r_-(\alpha))(x-x')} - r_-(\alpha) \frac{\mu+\alpha\sigma^2 r_+(\alpha)}{\mu+\alpha\sigma^2 r_-(\alpha)} \right)} \qquad \forall x \in [x',\ x_0 + \varepsilon). \end{aligned}$$

However, we have $a(x) < \alpha$ for $x > x'$, which after a simple algebraic transformation of (3.11) is equivalent to $e^{(r_+(\alpha)-r_-(\alpha))(x-x')} < 1$. This leads to a contradiction. Therefore (3.9) holds. □

In view of $a(x_\alpha) = \alpha < \beta$ and (3.9), we have

$$\alpha \le a(x) < \beta$$

in the right neighborhood of x_α. Therefore

$$\phi(x,\ a(x)) = \max_{\alpha \le a \le \beta} \phi(x,\ a) = 0. \tag{3.12}$$

From (3.3), we have $V''(x) = -\frac{\mu V'(x)}{\sigma^2 a(x)}$. Substituting this expression for V'' into (3.12), we get

$$\mu a(x) V'(x)/2 = \gamma V(x). \tag{3.13}$$

Differentiating this equation and again using $V''(x) = -\frac{\mu V'(x)}{\sigma^2 a(x)}$, we arrive at

$$a'(x) = \frac{\mu^2 + 2\sigma^2\gamma}{\mu\sigma^2}.$$

Integrating this equation results in (recall that $a(x_\alpha) = \alpha$)

$$a(x) = \frac{\mu^2 + 2\sigma^2\gamma}{\mu\sigma^2}(x - x_\alpha) + \alpha. \tag{3.14}$$

Let

$$x_\beta = \frac{\mu\sigma^2}{\mu^2 + 2\sigma^2\gamma}(\beta - \alpha) + x_\alpha, \tag{3.15}$$

which is obtained by setting $a(x_\beta) = \beta$. Then $\alpha \le a(x) < \beta$ for all $x \in [x_\alpha,\ x_\beta)$. It follows from (3.13) that (noting $a(x_\alpha) = \alpha$)

$$\frac{V(x_\alpha)}{V'(x_\alpha)} = \frac{\mu\alpha}{2\gamma} \equiv \frac{y_\alpha}{(1-\Gamma)}, \tag{3.16}$$

where

$$0 < \Gamma \equiv \frac{\mu^2}{\mu^2 + 2\sigma^2\gamma} < 1, \qquad y_\alpha \equiv \frac{\mu\sigma^2\alpha}{\mu^2 + 2\sigma^2\gamma}. \tag{3.17}$$

Substituting the expression (3.14) for $a(x)$ into (3.3) and then solving the resulting equation for $V(x)$ on $[x_\alpha,\ x_\beta)$, while taking into account (3.16), we get

$$V(x) = \frac{\mu\alpha}{2\gamma} V'(x_\alpha) \left(\frac{x - x_\alpha + y_\alpha}{y_\alpha} \right)^{1-\Gamma}, \qquad x_\alpha \le x < x_\beta, \tag{3.18}$$

where the free constant $V'(x_\alpha)$ can be determined by

$$V'(x_\alpha) = k_1(\alpha,\beta)(r_+(\alpha)e^{r_+(\alpha)x_\alpha} - r_-(\alpha)e^{r_-(\alpha)x_\alpha}), \tag{3.19}$$

in view of (3.6) and a smooth fit at $x = x_\alpha$. Straightforward computations show that the function V defined by (3.6) and (3.18) is continuous with continuous first and second derivatives at x_α.

So far, we have obtained the forms of V on two intervals, $[0, x_\alpha)$ and $[x_\alpha, x_\beta)$, by (3.6) and (3.18), respectively. Now we proceed to the interval beyond x_β. To this end, we first have the following.

PROPOSITION 5. *For all $x \ge x_\beta$*

$$a(x) \ge \beta.$$

Proof. By virtue of Proposition 4, $a(x) \ge \alpha$ for all $x \ge x_\beta$. Suppose there exists $x' > x_\beta$ such that $a(x') < \beta$. Then there exists $\varepsilon > 0$ such that $a(x) < \beta$ for all $x < x' + \varepsilon$. Let $\bar{x} = \sup\{x < x' \ :\ a(x) = \beta\}$. Then $x_\beta \le \bar{x} < x'$ and $a(\bar{x}) = \beta$. In addition, $\alpha \le a(x) < \beta$ for all $\bar{x} < x \le x'$. Repeating the same arguments as in the proof of (3.9) we get $a(x) = \frac{\mu^2 + 2\sigma^2\gamma}{\mu\sigma^2}(x - \bar{x}) + \beta > \beta$ for each $x > \bar{x}$, which is a contradiction. □

The above proposition implies that the maximum in (3.2) is obtained at $a = \beta$ for $x \ge x_\beta$. The resulting equation of (3.2) then becomes a second-order linear ODE, whose solution is of the form

$$V(x) = k_1(\beta)e^{r_+(\beta)(x - x_1)} + k_2(\beta)e^{r_-(\beta)(x-x_1)}, \qquad x_\beta \le x < x_1, \tag{3.20}$$

where $x_1 > x_\beta$, as defined earlier, is also the first point such that $V''(x_1) = 0$ (see Proposition 6 below).

PROPOSITION 6. *Let $x_1 > x_\beta$ be the first point where V'' vanishes. Then $V'(x_1) = 1$.*

Proof. Suppose $V'(x_1) > 1$. Then there exists $\varepsilon > 0$ such that $V'(x) > 1$ for all $x_1 \le x \le x_1 + \varepsilon$. Therefore on the interval $[x_1, x_1 + \varepsilon]$ the function V satisfies (3.2). In view of Proposition 5, $a(x) \ge \beta$, and hence on the interval $[x_1, x_1 + \varepsilon]$, V is of the form given by (3.20). Since $V''(x_1) = 0$, we conclude $k_1(\beta)r_+^2(\beta) = -k_2(\beta)r_-^2(\beta) > 0$. (The positivity of $k_1(\beta)$ follows from $V' > 0$.) Thus $V''(x) =$

$k_1(\beta)r_+^2(\beta)\left(e^{(r_+(\beta)-r_-(\beta))(x-x_1)}-1\right)$. This expression is positive for each $x > x_1$. This contradicts the concavity of V. □

The following corollary is straightforward in view of the above proposition and the inequality $V'(x) \geq 1$.

COROLLARY 2. *Under the assumption of Proposition* 6,

$$V'(x) = 1 \qquad \forall x \geq x_1.$$

The analysis so far shows that the function V is of the following form:

$$V(x) = \begin{cases} k_1(\alpha,\ \beta)(e^{r_+(\alpha)x} - e^{r_-(\alpha)x}), & 0 \leq x < x_\alpha, \\ \frac{\mu\alpha}{2\gamma}V'(x_\alpha)\left(\frac{x-x_\alpha+y_\alpha}{y_\alpha}\right)^{1-\Gamma}, & x_\alpha \leq x < x_\beta, \\ k_1(\beta)e^{r_+(\beta)(x-x_1)} + k_2(\beta)e^{r_-(\beta)(x-x_1)}, & x_\beta \leq x < x_1, \\ k_1(\beta) + k_2(\beta) + x - x_1, & x_1 \leq x, \end{cases} \tag{3.21}$$

where $r_+(\alpha)$, $r_-(\alpha)$, $r_+(\beta)$, $r_-(\beta)$, x_α and x_β, and Γ and y_α are given by (3.7), (3.8), (3.15), and (3.17), respectively.

The next step is to determine the remaining constants in (3.21). To do so we use the principle of smooth fit at the points x_β and x_1. Namely, we have to choose the unknown constants $k_1(\beta), k_2(\beta), k_1(\alpha,\beta)$, and x_1 in such a way that the function V and its first and second derivatives are continuous at these points. To this end, first for V of the form (3.20) the condition

$$V'(x_1) = 1, \qquad V''(x_1) = 0$$

can be written as

$$k_1(\beta)r_+(\beta) + k_2(\beta)r_-(\beta) = 1, \qquad k_1(\beta)r_+^2(\beta) + k_2(\beta)r_-^2(\beta) = 0.$$

As a result,

$$k_1(\beta) = \frac{-r_-(\beta)}{r_+(\beta)(r_+(\beta)-r_-(\beta))}, \qquad k_2(\beta) = \frac{r_+(\beta)}{r_-(\beta)(r_+(\beta)-r_-(\beta))}. \tag{3.22}$$

Next, let $\Delta = x_\beta - x_1$; then we can calculate V' and V'' at x_β as

$$\begin{aligned} V'(x_\beta) &= k_1(\beta)r_+(\beta)e^{r_+(\beta)\Delta} + k_2(\beta)r_-(\beta)e^{r_-(\beta)\Delta}, \\ V''(x_\beta) &= k_1(\beta)r_+^2(\beta)e^{r_+(\beta)\Delta} + k_2(\beta)r_-^2(\beta)e^{r_-(\beta)\Delta}. \end{aligned} \tag{3.23}$$

Recall that $V''(x_\beta) = \frac{-\mu V'(x_\beta)}{\sigma^2 a(x_\beta)} = \frac{-\mu V'(x_\beta)}{\sigma^2\beta}$, which results in

$$x_\beta - x_1 \equiv \Delta = \frac{\beta\sigma^2}{[\mu^2+2\sigma^2\gamma]^{1/2}} \log\left(\frac{-\mu+[\mu^2+2\sigma^2\gamma]^{1/2}}{\mu+[\mu^2+2\sigma^2\gamma]^{1/2}}\right) < 0. \tag{3.24}$$

On the other hand, a smooth fit, in terms of $V'(x_\beta)$, for (3.18) and (3.23) with (3.19) taken into consideration yields

$$\begin{aligned} &\frac{\alpha\mu}{2\gamma y_\alpha}k_1(\alpha,\ \beta)\left(r_+(\alpha)e^{r_+(\alpha)x_\alpha} - r_-(\alpha)e^{r_-(\alpha)x_\alpha}\right)\left(\frac{\beta}{\alpha}\right)^{-\Gamma} \\ &\quad = k_1(\beta)r_+(\beta)e^{r_+(\beta)\Delta} + k_2(\beta)r_-(\beta)e^{r_-(\beta)\Delta}. \end{aligned} \tag{3.25}$$

Formulas (3.24) and (3.25) determine x_1 and $k_1(\alpha,\beta)$. Note that from (3.22) and (3.24) it follows that

$$\frac{V(x_\beta)}{V'(x_\beta)} = \frac{k_1(\beta)e^{r_+(\beta)\Delta} + k_2(\beta)e^{r_-(\beta)\Delta}}{k_1(\beta)r_+(\beta)e^{r_+(\beta)\Delta} + k_2(\beta)r_-(\beta)e^{r_-(\beta)\Delta}} = \frac{e^{(r_+(\beta)-r_-(\beta))\Delta} - \frac{r_-(\beta)}{r_+(\beta)}}{r_+(\beta)e^{(r_+(\beta)-r_-(\beta))\Delta} - r_-(\beta)} = \frac{\mu\beta}{2\gamma}.$$

Therefore $\lim_{x\to x_\beta,\ x<x_\beta} V(x) = \frac{\mu\alpha}{2\gamma}V'(x_\alpha)(\frac{\beta}{\alpha})^{1-\Gamma} = \frac{\mu\beta}{2\gamma}V'(x_\beta) = V(x_\beta)$, which proves the continuity of V at x_β.

These calculations enable us to formulate the main result of this section.

THEOREM 4. *Let $r_+(\alpha)$, $r_-(\alpha)$, $r_+(\beta)$ and $r_-(\beta)$, Γ and y_α, x_α, x_β, x_1, $k_1(\beta)$ and $k_2(\beta)$, and $k_1(\alpha,\ \beta)$ be given by* (3.7), (3.17), (3.8), (3.15), (3.24), (3.22), *and* (3.25), *respectively. Then $V(x)$ given by* (3.21) *is a concave, twice continuously differentiable solution of the HJB equation* (3.1).

Proof. From the way we constructed V, it must be a twice continuously differentiable solution to the HJB equation (3.1). What remains to show is the concavity. From (3.21), we deduce that

$$V'''(x) = k_1(\alpha,\ \beta)\left(r_+^3(\alpha)e^{r_+(\alpha)x} - r_-^3(\alpha)e^{r_-(\alpha)x}\right) > 0 \qquad \forall 0 \le x < x_\alpha,$$

due to $r_-(\alpha) < 0 < k_1(\alpha,\ \beta)$. Hence on this interval V'' is increasing and

$$V''(x) < V''(x_\alpha) = k_1(\alpha,\ \beta)\left(r_+^2(\alpha)e^{r_+(\alpha)x_\alpha} - r_-^2(\alpha)e^{r_-(\alpha)x_\alpha}\right) < 0,$$

due to $\frac{r_-(\alpha)}{r_+(\alpha)} = e^{(r_+(\alpha)-r_-(\alpha))x_\alpha}$ and $|r_-(\alpha)| > r_+(\alpha)$.

For $x_\alpha \le x < x_\beta$, $V''(x) = \frac{-\mu V'(x)}{\sigma^2 a(x)} < 0$. For $x_\beta \le x <\ x_1$,

$$V'''(x) = k_1(\beta)r_+^3(\beta)e^{r_+(\beta)(x-x_1)} + k_2(\beta)r_-^3(\beta)e^{r_-(\beta)(x-x_1)} > 0,$$

since $k_2(\beta)$ and $r_-(\beta)$ are of the same signs. Thus $V''(x) < V''(x_1) = 0$ for all $x_\beta \le x <\ x_1$. Finally, $V''(x) = 0$ for all $x \ge x_1$. This establishes the concavity of V. ∎

4. Case with nonzero liability. This section deals with the general model (2.1) where $\delta > 0$. In this case the HJB equation is given by (2.30). Again we are looking for a smooth concave function that solves this equation. As before, suppose that such a solution V exists and consider $x_1 = \inf\{x \ge 0\ :\ V'(x) \le 1\}$. Then it is obvious that $x_1 = 0$ if and only if $V(x) = x$ for all $x \ge 0$. Our first step is to characterize the existence of such a trivial solution to (2.30).

THEOREM 5. *$V(x) = x$ for all $x \ge 0$ if and only if*

$$\beta\mu \le \delta. \tag{4.1}$$

Proof. Suppose $V(x) = x$ for each $x \ge 0$. Then in view of (2.30)

$$\max_{\alpha\le a\le\beta}\left(\frac{1}{2}\sigma^2a^2V''(0) + (a\mu-\delta)V'(0) - \gamma V(0)\right) \equiv \beta\mu - \delta \le 0.$$

Conversely, if $\beta\mu \le \delta$, then due to concavity

$$\max_{\alpha\le a\le\beta}\left(\frac{1}{2}\sigma^2a^2V''(x) + (a\mu-\delta)V'(x) - \gamma V(x)\right) \le -\gamma V(x) < 0 \qquad \forall x > 0.$$

Thus, (2.30) is satisfied only if $V'(x) = 1$ for all $x > 0$. □

In the rest of this section we assume $\beta\mu > \delta$. In view of (2.30)

$$0 = \max_{\alpha \le a \le \beta} \left(\frac{1}{2}\sigma^2 a^2 V''(x) + (a\mu - \delta)V'(x) - \gamma V(x) \right) \qquad \forall x < x_1. \tag{4.2}$$

For each $x \ge 0$ and $a \ge 0$ define

$$\phi(x,\ a) = \frac{1}{2}\sigma^2 a^2 V''(x) + (a\mu - \delta)V'(x) - \gamma V(x). \tag{4.3}$$

The maximizer of the function $\phi(x,\ a)$ over $a \ge 0$ is given by

$$a(x) = -\frac{\mu V'(x)}{\sigma^2 V''(x)} > 0, \qquad x \ge 0. \tag{4.4}$$

Following the same scheme as in the no-liability case, we will prove that there exist $x_\alpha \le x_\beta < x_1$ such that $a(x) \le \alpha$ for all $x \le x_\alpha$, and $a(x) \ge \beta$ for all $x \ge x_\beta$, and the function $a(x)$ increases from α to β on the interval $[x_\alpha,\ x_\beta]$.

As before we start with analyzing $a(0)$.

PROPOSITION 7. *Let $\beta\mu > \delta$. Then*

(i) $\frac{2\delta}{\mu} < \alpha$ *if and only if* $a(0) < \alpha$. *In this case* $a(0) = \frac{\mu\alpha^2}{2(\mu\alpha - \delta)}$.

(ii) $\alpha \le \frac{2\delta}{\mu} < \beta$ *if and only if* $\alpha \le a(0) < \beta$. *In this case* $a(0) = 2\frac{\delta}{\mu}$.

(iii) $\beta \le \frac{2\delta}{\mu}$ *if and only if* $a(0) \ge \beta$. *In this case* $a(0) = \frac{\mu\beta^2}{2(\mu\beta - \delta)}$.

Proof. Let $\tilde{a} \in [\alpha,\ \beta]$ be such that

$$0 = \max_{\alpha \le a \le \beta} \left(\frac{1}{2}\sigma^2 a^2 V''(0) + (a\mu - \delta)V'(0) \right) = \frac{1}{2}\sigma^2 \tilde{a}^2 V''(0) + (\tilde{a}\mu - \delta)V'(0). \tag{4.5}$$

Comparing (4.5) with (4.4) we obtain

$$\tilde{a}^2 - 2a(0)\tilde{a} + \frac{2\delta}{\mu}a(0) = 0. \tag{4.6}$$

From (4.6), it follows that $a(0) \ge \frac{2\delta}{\mu}$. Moreover, by definition, $a(0) \in [\alpha,\ \beta]$ is equivalent to $\tilde{a} = a(0)$, which is further equivalent to $a(0) = \frac{2\delta}{\mu} \in [\alpha,\ \beta]$. Thus we conclude:

(i) If $a(0) < \alpha$, then $\frac{2\delta}{\mu} \le a(0) < \alpha$. Conversely, suppose $\frac{2\delta}{\mu} < \alpha$. If $a(0) \in [\alpha,\ \beta]$, then by the above $a(0) = \frac{2\delta}{\mu} < \alpha$, which is a contradiction. Thus either $a(0) < \alpha$ or $a(0) > \beta$. Suppose $a(0) > \beta$; then $\tilde{a} = \beta$ and by (4.6), $a(0) = \frac{\mu\beta^2}{2(\mu\beta - \delta)} < \beta$ (due to $\frac{2\delta}{\mu} < \alpha < \beta$). This is again a contradiction. Hence we have $a(0) < \alpha$. Then $\tilde{a} = \alpha$ and in view of (4.6), we get $a(0) = \frac{\mu\alpha^2}{2(\alpha\mu - \delta)}$.

(ii) Suppose $\alpha \le \frac{2\delta}{\mu} < \beta$. Then due to (i) we have $a(0) \ge \alpha$. Now we proceed to prove that $a(0) \le \frac{2\delta}{\mu} < \beta$. Suppose $a(0) > \frac{2\delta}{\mu}$. Then $a(0) > \beta \equiv \tilde{a}$. On the other hand, in view of (4.6) we have $a(0) = \frac{\mu\beta^2}{2(\beta\mu - \delta)}$; thus $\frac{\mu\beta^2}{2(\beta\mu - \delta)} \ge \beta$, which is equivalent to $2\frac{\delta}{\mu} \ge \beta$. This, however, is a contradiction and therefore $a(0) = \frac{2\delta}{\mu} \in [\alpha,\ \beta)$. Conversely, if $a(0) \in [\alpha,\ \beta)$, then $a(0) = \frac{2\delta}{\mu} \in [\alpha,\ \beta)$.

(iii) Suppose $\beta \le \frac{2\delta}{\mu}$. Then $a(0) \ge \frac{2\delta}{\mu} \ge \beta$, leading to $\tilde{a} = \beta$ and $a(0) = \frac{\mu\beta^2}{2(\beta\mu - \delta)} \ge \beta$. Conversely, if $a(0) \ge \beta$, then $\tilde{a} = \beta$ and $a(0) = \frac{\mu\beta^2}{2(\mu\beta - \delta)} \ge \beta$, which is equivalent to $\frac{2\delta}{\mu} \ge \beta$. □

As it will be seen in what follows, the structure of the solution to our original optimization problem depends on three cases specified by (i), (ii), and (iii) above. Accordingly in the rest of the section we will analyze these three cases.

4.1. Case of $\frac{2\delta}{\mu} < \alpha$. We begin our analysis with an observation that in this case, in view of Proposition 7(i), $a(x) < \alpha$ for all x in the right neighborhood of 0. Substituting $a = \alpha$ in (4.2) and solving the resulting second-order linear ODE, we obtain

$$V(x) = k_1(\alpha,\ \beta)(e^{r_+(\alpha)x} - e^{r_-(\alpha)x}), \tag{4.7}$$

where $k_1(\alpha,\ \beta)$ is a free constant to be determined, and

$$\begin{aligned} r_+(z) &= \frac{-(z\mu-\delta) + [(z\mu-\delta)^2 + 2\sigma^2 z^2\gamma]^{1/2}}{\sigma^2 z^2}, \\ r_-(z) &= \frac{-(z\mu-\delta) - [(z\mu-\delta)^2 + 2\sigma^2 z^2\gamma]^{1/2}}{\sigma^2 z^2}, \qquad z > 0. \end{aligned} \tag{4.8}$$

Due to (4.4) and (4.7),

$$\begin{aligned} a'(x) &= \frac{-\mu}{\sigma^2}\frac{(V''(x))^2 - V'(x)V^{(3)}(x)}{(V''(x))^2} \\ &= \frac{-\mu r_+(\alpha)r_-(\alpha)e^{(r_+(\alpha)+r_-(\alpha))x}\left(r_+(\alpha) - r_-(\alpha)\right)^2}{\sigma^2(V''(x))^2} > 0 \end{aligned}$$

for each x in the right neighborhood of 0. Therefore $a(x)$ increases and reaches α at the point x_α given by

$$x_\alpha = \frac{1}{r_+(\alpha) - r_-(\alpha)} \log\left(\frac{r_-(\alpha)\left(\mu + \alpha\sigma^2 r_-(\alpha)\right)}{r_+(\alpha)\left(\mu + \alpha\sigma^2 r_+(\alpha)\right)}\right) > 0. \tag{4.9}$$

PROPOSITION 8. *For each $x \in [x_\alpha, x_1]$,*

$$a(x) \geq \alpha.$$

Proof. Suppose there exists $x' > x_\alpha$ such that $a(x) < \alpha$ and let $\bar{x} = \sup\{x < x' \ :\ a(x) = \alpha\}$. Then $x_\alpha \leq \bar{x} < x'$, $a(\bar{x}) = \alpha$, and $a(x) < \alpha$ for $\bar{x} < x \leq x'$. Substituting $a = \alpha$ into (4.2) and solving the resulting second-order linear ODE, we get $V(x) = k_1 e^{r_+(\alpha)(x-\bar{x})} + k_2 e^{r_-(\alpha)(x-\bar{x})}$. Therefore

$$a(x) = \frac{-\mu V'(x)}{\sigma^2 V''(x)} = -\frac{\mu}{\sigma^2}\frac{k_1 r_+(\alpha)e^{(r_+(\alpha)-r_-(\alpha))(x-\bar{x})} + k_2 r_-(\alpha)}{k_1 r_+^2(\alpha)e^{(r_+(\alpha)-r_-(\alpha))(x-\bar{x})} + k_2 r_-^2(\alpha)}, \qquad \bar{x} < x \leq x'.$$

Since $a(\bar{x}) = \alpha$, we have

$$k_1 r_+(\alpha)\left(1 + \frac{\alpha\sigma^2 r_+(\alpha)}{\mu}\right) = -k_2 r_+(\alpha)\left(1 + \frac{\alpha\sigma^2 r_-(\alpha)}{\mu}\right).$$

Thus, for $\bar{x} < x \leq x'$ the inequality $a(x) < \alpha$ is equivalent to $e^{(r_+(\alpha)-r_-(\alpha))(x-\bar{x})} < 1$, which is a contradiction. □

By virtue of Proposition 8, $\alpha \leq a(x) < \beta$ in the right neighborhood of x_α. In this case we have

$$\phi(x,\ a(x)) = \max_{\alpha \leq a \leq \beta} \phi(x,\ a) = 0. \tag{4.10}$$

Substituting

$$V''(x) = \frac{-\mu V'(x)}{\sigma^2 a(x)} \tag{4.11}$$

into (4.10), differentiating the resulting equation, and substituting $V''(x) = \frac{-\mu V'(x)}{\sigma^2 a(x)}$ once more, we arrive at $\frac{\mu a'(x)}{2} + \frac{\mu\delta}{\sigma^2 a(x)} = \frac{\mu^2+2\gamma\sigma^2}{2\sigma^2}$. As a result

$$a'(x) = \frac{\mu^2 + 2\gamma\sigma^2}{\mu\sigma^2}\left(1 - \frac{c}{a(x)}\right) \tag{4.12}$$

with

$$c \equiv 2\delta\mu/(\mu^2 + 2\gamma\sigma^2). \tag{4.13}$$

Integrating (4.12), we get $G(a(x)) \equiv \frac{\mu^2+2\gamma\sigma^2}{\mu\sigma^2}(x - x_\alpha) + G(\alpha)$, where

$$G(u) = u + c\log(u - c). \tag{4.14}$$

Therefore

$$a(x) = G^{-1}\left(\frac{\mu^2 + 2\gamma\sigma^2}{\mu\sigma^2}(x - x_\alpha) + G(\alpha)\right). \tag{4.15}$$

Thus $a(x)$ is increasing and $a(x_\beta) = \beta$ for

$$x_\beta \equiv \frac{\mu\sigma^2}{\mu^2 + 2\gamma\sigma^2}[G(\beta) - G(\alpha)] + x_\alpha = \frac{\mu\sigma^2}{\mu^2 + 2\gamma\sigma^2}(\beta - \alpha) + \frac{\mu\sigma^2 c}{\mu^2 + 2\gamma\sigma^2}\log\left(\frac{\beta - c}{\alpha - c}\right). \tag{4.16}$$

Solving (4.11), we obtain

$$V(x) = V(x_\alpha) + V'(x_\alpha)\int_{x_\alpha}^{x} \exp\left(-\frac{\mu}{\sigma^2}\int_{x_\alpha}^{y}\frac{du}{a(u)}\right)dy, \qquad x_\alpha \le x < x_\beta, \tag{4.17}$$

where $V(x_\alpha)$ and $V'(x_\alpha)$ are free constants. Choosing $V(x_\alpha)$ and $V'(x_\alpha)$ as the value and the derivative, respectively, of the right-hand side of (4.7) at x_α, we can ensure that the function V given by (4.7) and (4.17) is continuous with its first and second derivatives at the point x_α no matter what the choice of $k(\alpha, \beta)$ is. (Note that due to the HJB equation, continuity of V and its first derivative at x_α automatically implies continuity of the second derivative as well.)

Next we are to simplify (4.17). First, changing variables $a(u) = \theta$ we get

$$\begin{aligned}\int_{x_\alpha}^{x} &\exp\left(-\frac{\mu}{\sigma^2}\int_{x_\alpha}^{y}\frac{du}{a(u)}dy\right)\\ &= \frac{\mu\sigma^2}{\mu^2 + 2\gamma\sigma^2}\int_{\alpha}^{a(x)}\left(1 + \frac{c}{\theta - c}\right)\left(\frac{\theta - c}{\alpha - c}\right)^{-\Gamma}d\theta, \qquad x_\alpha \le x < x_\beta.\end{aligned}$$

On the other hand, relations (4.9) and (4.7) imply

$$V(x_\alpha) = \frac{\alpha\mu - 2\delta}{2\gamma}V'(x_\alpha).$$

Simple algebraic transformations yield

$$\left(\frac{\mu\sigma^2}{\mu^2+2\gamma\sigma^2}\right)\left(\frac{c}{\Gamma}-\frac{z-c}{1-\Gamma}\right)=\frac{z\mu-2\delta}{2\gamma}\qquad \forall z>0, \tag{4.18}$$

where c is given by (4.13) and

$$\Gamma=\frac{\mu^2}{\mu^2+2\gamma\sigma^2}. \tag{4.19}$$

Therefore

$$V(x)=V'(x_\alpha)\frac{\mu a(x)-2\delta}{2\gamma}\left(\frac{a(x)-c}{\alpha-c}\right)^{-\Gamma},\qquad x_\alpha\le x<x_\beta. \tag{4.20}$$

Now, we proceed to the next piece of V on the interval beyond x_β.

PROPOSITION 9. *For each $x\in[x_\beta,x_1]$,*

$$a(x)\ge\beta.$$

Proof. Suppose that there exists $x'>x_\beta$ such that $a(x)<\beta$. Since $x'\ge x_\alpha$, we have $\beta>a(x)\ge\alpha$. Denote $\bar{x}=\sup\{x<x' \ : \ a(x)=\beta\}$. Then $x_\beta\le\bar{x}<x'$, $a(\bar{x})=\beta$, and $\alpha\le a(x)<\beta$ for $\bar{x}<x\le x'$. Thus $a(x)$ satisfies (4.12) for $\bar{x}<x\le x'$ and

$$a(x)=G^{-1}\left(\frac{\mu^2+2\gamma\sigma^2}{\mu\sigma^2}(x-\bar{x})+G(\beta)\right)>\beta.$$

This is a contradiction. □

In view of the above proposition,

$$\phi(x,\ \beta)=\max_{\alpha\le a\le\beta}\phi(x,\ a)=0,\qquad x_\beta\le x<x_1, \tag{4.21}$$

where x_1, which is defined earlier, is also the first point such that $V''(x_1)=0$. This results in

$$V(x)=k_1(\beta)e^{r_+(\beta)(x-x_1)}+k_2(\beta)e^{r_-(\beta)(x-x_1)},\qquad x_\beta\le x<x_1, \tag{4.22}$$

where $k_1(\beta)$ and $k_2(\beta)$ are two free constants also to be determined.

PROPOSITION 10. *For $x\ge x_1$,*

$$V'(x)=1.$$

Proof. Suppose that there exists $x'\ge x_1$ such that $V''(x')<0$. Since $x'\ge x_\beta$, inequality $a(x)\ge\beta$ holds. Let $\bar{x}=\sup\{x<x' \ : \ V''(x)=0\}$. For any $x\in(\bar{x},\ x']$, we have $V(x)=K_1'e^{r_+(\beta)(x-\bar{x})}+K_2'e^{r_-(\beta)(x-\bar{x})}$. Equality $V''(\bar{x})=0$ results in $0<K_1'r_+^2(\beta)=-K_2'r_-^2(\beta)$. Consequently $V''(x)=K_1'r_+^2(\beta)e^{r_+(\beta)(x-\bar{x})}+K_2'r_-^2(\beta)e^{r_-(\beta)(x-\bar{x})}=K_1'r_+^2(\beta)\left(e^{r_+(\beta)(x-\bar{x})}-e^{r_-(\beta)(x-\bar{x})}\right)>0$. This contradicts the concavity of the function V. □

From Proposition 10 it follows that

$$V(x)=x-x_1+k_1(\beta)+k_2(\beta),\qquad x\ge x_1.$$

To compute the free constants $k_1(\beta)$ and $k_2(\beta)$, we use the relationship

$$V'(x_1) = 1, \qquad V''(x_1) = 0.$$

From (4.22) it follows that

$$k_1(\beta)r_+(\beta) + k_2(\beta)r_-(\beta) = 1, \qquad k_1(\beta)r_+^2(\beta) + k_2(\beta)r_-^2(\beta) = 0.$$

As a result

$$k_1(\beta) = \frac{-r_-(\beta)}{r_+(\beta)(r_+(\beta) - r_-(\beta))} > 0, \tag{4.23}$$
$$k_2(\beta) = \frac{r_+(\beta)}{r_-(\beta)(r_+(\beta) - r_-(\beta))} < 0.$$

To determine the remaining unknown constants we apply the principle of smooth fit at the point x_β. Let $\Delta = x_\beta - x_1$. By (4.22) we have

$$V'(x_\beta) = k_1(\beta)r_+(\beta)e^{r_+(\beta)\Delta} + k_2(\beta)r_-(\beta)e^{r_-(\beta)\Delta}, \tag{4.24}$$
$$V''(x_\beta) = k_1(\beta)r_+^2(\beta)e^{r_+(\beta)\Delta} + k_2(\beta)r_-^2(\beta)e^{r_-(\beta)\Delta}.$$

However, the relation (4.11) (recall that $a(x_\beta) = \beta$) yields $V''(x_\beta) = \frac{-\mu V'(x_\beta)}{\sigma^2\beta}$. This leads to

$$x_\beta - x_1 = \Delta = \frac{1}{r_+(\beta) - r_-(\beta)} \log\left(\frac{\frac{1}{r_-(\beta)} + \frac{\sigma^2\beta}{\mu}}{\frac{1}{r_+(\beta)} + \frac{\sigma^2\beta}{\mu}}\right) < 0, \tag{4.25}$$

which determines x_1 and, in turn, determines $V'(x_\beta)$ via (4.24). To proceed, simple but tedious algebraic transformations show that from (4.20) and (4.17) it follows that

$$V'(x_\alpha) = V'(x_\beta)\left(\frac{\beta - c}{\alpha - c}\right)^\Gamma. \tag{4.26}$$

As in the previous section this implies the continuity of V at x_β. Finally, the continuity of V at x_α gives rise to

$$k_1(\alpha,\ \beta) = \frac{V'(x_\beta)\left(\frac{\beta-c}{\alpha-c}\right)^\Gamma}{r_+(\alpha)e^{r_+(\alpha)x_\alpha} - r_-(\alpha)e^{r_-(\alpha)x_\alpha}}. \tag{4.27}$$

This enables us to establish the main result of this section.

THEOREM 6. *Suppose* $\frac{2\delta}{\mu} < \alpha$. *Let* $k_1(\alpha,\ \beta)$, $r_+(\alpha)$, $r_-(\alpha)$, $r_+(\beta)$, $r_-(\beta)$, x_α, x_β, x_1 $k_1(\beta)$, $k_2(\beta)$, $a(x)$, c, Γ, *and* $V'(x_\alpha)$ *be given by* (4.27), (4.8), (4.9), (4.16), (4.25), (4.23), (4.15), (4.13), (4.19), *and* (4.26), *respectively. Then*

$$V(x) = \begin{cases} k_1(\alpha,\ \beta)\left(e^{r_+(\alpha)x} - e^{r_-(\alpha)x}\right), & 0 \le x < x_\alpha, \\ V'(x_\alpha)\frac{\mu a(x) - 2\delta}{2\gamma}\left(\frac{a(x)-c}{\alpha-c}\right)^{-\Gamma}, & x_\alpha \le x < x_\beta, \\ k_1(\beta)e^{r_+(\beta)(x-x_1)} + k_2(\beta)e^{r_-(\beta)(x-x_1)}, & x_\beta \le x < x_1, \\ k_1(\beta) + k_2(\beta) + x - x_1, & x \ge x_1, \end{cases} \tag{4.28}$$

is a concave, twice continuously differentiable solution of the HJB equation (2.30).

Proof. As before we need only show the concavity. To do this consider V'''. From (4.28), we get

$$\begin{aligned}
V'''(x) &= k_1(\alpha,\ \beta)\left(r_+^3(\alpha)e^{r_+(\alpha)x} - r_-^3(\alpha)e^{r_-(\alpha)x}\right) > 0, && 0 \le x < x_\alpha,\\
V'''(x) &= \tfrac{-\mu V''(x)}{\sigma^2 a(x)} + \tfrac{\mu a'(x)V'(x)}{\sigma^2(a(x))^2} > 0, && x_\alpha \le x < x_\beta,\\
V'''(x) &= k_1 r_+^3(\beta)e^{r_+(\beta)(x-x_1)} + k_2(\beta)r_-^3(\beta)e^{r_-(\beta)(x-x_1)} > 0, && x_\beta \le x < x_1.
\end{aligned}$$

Thus $V''(x) < V''(x_1) = 0$ for each $x < x_1$. On the other hand, $V''(x) = 0$ for each $x \ge x_1$. These lead to the concavity of V. □

4.2. Case of $\alpha \le \frac{2\delta}{\mu} < \beta$. Applying Propositions 7 and 8, we see that in this case $a(0) = \frac{2\delta}{\mu} \ge \alpha$ and $a(x) \ge \alpha$ for all $x \ge 0$. Then in the right neighborhood of 0, $\alpha \le a(x) < \beta$. It follows that for ϕ given by (4.3), equation (4.10) holds. Proceeding as in section 4.1, we see that $a(x)$ satisfies (4.12). Therefore

$$a(x) = G^{-1}\left(\frac{\mu^2 + 2\gamma\sigma^2}{\mu\sigma^2}x + G(2\delta/\mu)\right) \in [2\delta/\mu,\ \ \infty), \tag{4.29}$$

where G is given by (4.14). As a result $a(x)$ increases and $a(x_\beta) = \beta$, where

$$\begin{aligned}
x_\beta &= \frac{\mu\sigma^2}{\mu^2 + 2\gamma\sigma^2}[G(\beta) - G(2\delta/\mu)]\\
&= \frac{\mu\sigma^2}{\mu^2 + 2\gamma\sigma^2}(\beta - 2\delta/\mu) + \frac{2\delta\mu c}{\mu^2 + 2\gamma\sigma^2}\log\left(\frac{\beta - c}{2\delta/\mu - c}\right).
\end{aligned} \tag{4.30}$$

Integrating (4.4), we get

$$V(x) = V'(0)\frac{\mu a(x) - 2\delta}{2\gamma}\left(\frac{a(x) - c}{2\delta/\mu - c}\right)^{-\Gamma}, \qquad 0 \le x < x_\beta. \tag{4.31}$$

By virtue of Proposition 9 we have $a(x) \ge \beta$ for $x \in [x_\beta, x_1]$. Let x_1 be such that $V''(x_1) = 0$. Then for $x_\beta \le x < x_1$,

$$V(x) = k_1(\beta)e^{r_+(\beta)(x-x_1)} + k_2(\beta)e^{r_-(\beta)(x-x_1)}. \tag{4.32}$$

Using the principle of smooth fit for V in (4.32) at x_1, we see that $k_1(\beta)$ and $k_2(\beta)$ are given by (4.23). Put $\Delta = x_\beta - x_1$. Applying the principle of smooth fit at x_β for V' and V'', we deduce that Δ is given by (4.25). Therefore

$$x_1 = x_\beta + \Delta = x_\beta + \frac{1}{r_+(\beta) - r_-(\beta)}\log\left(\frac{\frac{1}{r_-(\beta)} + \frac{\sigma^2\beta}{\mu}}{\frac{1}{r_+(\beta)} + \frac{\sigma^2\beta}{\mu}}\right). \tag{4.33}$$

THEOREM 7. *Suppose $\alpha \le \frac{2\delta}{\mu} < \beta$. Let $a(x)$, c, Γ, x_β, x_1, $r_+(\beta)$, $r_-(\beta)$, $k_1(\beta)$, and $k_2(\beta)$ be given by* (4.29), (4.13), (4.19), (4.30), (4.33), (4.8), *and* (4.23), *respectively. Let $V'(0)$ be determined from* (4.26), *in which x_α and α are replaced by 0 and $2\delta/\mu$, respectively. Then*

$$V(x) = \begin{cases} V'(0)\frac{\mu a(x) - 2\delta}{2\gamma}\left(\frac{a(x) - c}{2\delta/\mu - c}\right)^{-\Gamma}, & 0 \le x < x_\beta,\\ k_1(\beta)e^{r_+(\beta)(x-x_1)} + k_2(\beta)e^{r_-(\beta)(x-x_1)}, & x_\beta \le x < x_1,\\ k_1(\beta) + k_2(\beta) + x - x_1, & x \ge x_1, \end{cases} \tag{4.34}$$

is a concave, twice continuously differentiable solution of the HJB equation (2.30).

Proof. The proof of this theorem is similar to that of Theorem 6. (One needs only to repeat the proof of Theorem 6, substituting x_α, x_β, and x_1 by 0, x_β, and x_1, respectively.) □

Remarks 1. Denote by $V_{\alpha,\,\beta}(x)$ the concave solution to the HJB equation (2.30) corresponding to the parameters (α, β). Then the results of this section show that

$$V_{\alpha,\,\beta}(x) = V_{\frac{2\delta}{\mu},\,\beta}(x), \qquad x \geq 0,$$

for each $\alpha \leq \frac{2\delta}{\mu}$. One can verify that as $\alpha \to 0+$ and $\beta = 1$, the expression (4.34) becomes the value function for the problem with $\alpha = 0$, $\beta = 1$, even though our methodology cannot be applied in the case of $\alpha = 0$.

It is interesting to notice that in the case of $\alpha = 0$, $\beta = 1$, and $\frac{2\delta}{\mu} < 1$ a different approach used in [18] yields

$$V_{TZ}(x) = \begin{cases} \int_0^x X^{-1}(y)dy, & 0 \leq x < x_\beta, \\ k_1(\beta)e^{r_+(\beta)(x-x_1)} + k_2(\beta)e^{r_-(\beta)(x-x_1)}, & x_\beta \leq x < x_1, \\ k_1(\beta) + k_2(\beta) + x - x_1, & x \geq x_1, \end{cases} \tag{4.35}$$

where $X(z) = Cz^{-1-\frac{2\gamma\sigma^2}{\mu^2}} + C_1 - \frac{\delta}{\mu^2/(2\sigma^2)+\gamma}\ln z$ for some constants C and C_1. The expression for the case $0 \leq x < x_\beta$ in (4.35) is very different from that in (4.34). However, the following result shows that they are in fact the same.

Proposition 11.

$$V(x) = V_{TZ}(x) \quad \textit{when } \alpha = 0,\ \beta = 1,\ \textit{and } \frac{2\delta}{\mu} < 1. \tag{4.36}$$

Proof. First note that $V(x)$ and $V_{TZ}(x)$ coincide for $x \geq x_\beta$. Due to the continuity of both V' and V'_{TZ} at x_β, we deduce that

$$V'(x_\beta) = V'_{TZ}(x_\beta) \equiv X^{-1}(x_\beta). \tag{4.37}$$

Now we prove that (4.36) holds if and only if

$$a(x) = \frac{\mu}{\sigma^2}\left(\frac{C}{\Gamma}\left(X^{-1}(x)\right)^{-1/\Gamma} + \frac{2\delta\sigma^2}{\mu^2 + 2\gamma\sigma^2}\right), \qquad 0 \leq x \leq x_\beta. \tag{4.38}$$

To this end, first suppose that (4.38) holds. Since $V(x)$ is derived from (4.4) after calculating $a(x)$, we insert in (4.4) the right-hand side of (4.38) and derive

$$\begin{aligned} \log\left(\frac{V'(x_\beta)}{V'(x)}\right) &= -\int_x^{x_\beta} \frac{dx}{\frac{C}{\Gamma}\left(X^{-1}(x)\right)^{-1/\Gamma} + \frac{2\delta\sigma^2}{\mu^2+2\gamma\sigma^2}} \\ &= \log\left(\frac{X^{-1}(x_\beta)}{X^{-1}(x)}\right) \qquad \forall 0 \leq x \leq x_\beta, \end{aligned}$$

where the second equality follows by considering the change of variable $y = X^{-1}(x)$. By (4.37), we conclude that $V'(x) = X^{-1}(x) \equiv V'_{TZ}(x)$ for all $0 \leq x \leq x_\beta$. This together with the fact that $V(0) = V_{TZ}(0) = 0$ leads to (4.36). Conversely, suppose $V(x) = V_{TZ}(x)$ for all $0 \leq x \leq x_\beta$. By differentiating V twice, we get

$$V'(x) = X^{-1}(x), \qquad V''(x) = -\frac{X^{-1}(x)}{\frac{C}{\Gamma}\left(X^{-1}(x)\right)^{-1/\Gamma} + \frac{2\delta\sigma^2}{\mu^2+2\gamma\sigma^2}}.$$

These two equations combined with (4.4) imply that (4.38) holds.

So now we need only to prove the validity of (4.38). Let

$$Z(x) = \frac{\mu}{\sigma^2}\left(\frac{C}{\Gamma}\left(X^{-1}(x)\right)^{-1/\Gamma} + \frac{2\delta\sigma^2}{\mu^2+2\gamma\sigma^2}\right), \qquad 0 \le x \le x_\beta. \tag{4.39}$$

Since $V(x) = V_{TZ}(x)$ for $x \ge x_\beta$ and V' and V'' are continuous at x_β, we obtain via a similar calculation as above that $Z(x_\beta) = a(x_\beta)$. On the other hand, by differentiating $Z(x)$, we derive

$$Z'(x) = \frac{\mu}{\sigma^2\Gamma}\frac{\frac{C}{\Gamma}\left(X^{-1}(x)\right)^{-1/\Gamma}}{\frac{C}{\Gamma}\left(X^{-1}(x)\right)^{-1/\Gamma} + \frac{2\delta\sigma^2}{\mu^2+2\gamma\sigma^2}} = \frac{\mu}{\sigma^2\Gamma} - \frac{2\delta\sigma^2}{\mu^2+2\gamma\sigma^2}\frac{1}{Z(x)\Gamma} \quad \forall 0 \le x \le x_\beta.$$

Therefore, $Z(x)$ satisfies (4.12) with the boundary condition $Z(x_\beta) = a(x_\beta)$. This leads to (4.38) and the proof is completed. □

4.3. Case of $\beta \le \frac{2\delta}{\mu}$. Since in this case $a(0) \ge \beta$, we can apply Proposition 9 to conclude $a(x) \ge \beta$ for all $x \ge 0$. Substituting $a = \beta$ in (4.2), we get

$$V(x) = k_1(\beta)e^{r_+(\beta)(x-x_1)} + k_2(\beta)e^{r_-(\beta)(x-x_1)}, \qquad 0 \le x < x_1. \tag{4.40}$$

Using the principle of smooth fit at x_1, we get that $k_1(\beta)$ and $k_2(\beta)$ are given by (4.23). Using the initial condition $V(0) = 0$, we obtain

$$\Delta = -x_1 = \frac{1}{r_+(\beta) - r_-(\beta)}\log\left(\frac{r_+^2(\beta)}{r_-^2(\beta)}\right). \tag{4.41}$$

Note that the expression on the right-hand side of (4.41) is negative if and only if $|r_+(\beta)| < |r_-(\beta)|$. The latter is true if and only if

$$\frac{\delta}{\mu} < \beta; \tag{4.42}$$

see (4.8).

THEOREM 8. *Suppose $\frac{\delta}{\mu} < \beta \le \frac{2\delta}{\mu}$. Let $k_1(\beta)$, $k_2(\beta)$, $r_+(\beta)$, $r_-(\beta)$, and x_1 be given by* (4.23), (4.8), *and* (4.41), *respectively. Then*

$$V(x) = \begin{cases} k_1(\beta)e^{r_+(\beta)(x-x_1)} + k_2(\beta)e^{r_-(\beta)(x-x_1)}, & 0 \le x < x_1, \\ k_1(\beta) + k_2(\beta) + x - x_1, & x \ge x_1, \end{cases} \tag{4.43}$$

is a concave, twice continuously differentiable solution of the HJB equation (2.30).

Proof. The proof of this theorem follows the lines of the proof of Theorem 7, in which one replaces x_β by 0. □

Remark 4. The case when (4.42) fails is a trivial case; see Theorem 5.

Remark 5. From the expressions for $V_{\alpha,\,\beta}$ obtained in this subsection and the previous subsection, one can see that

$$\lim_{\beta\to\infty} V_{\alpha,\,\beta}(x) = \infty, \qquad \lim_{\alpha\to 0,\ \beta\to 0} V_{\alpha,\,\beta}(x) = 0 \qquad \forall x > 0.$$

5. Optimal policies. In this section we construct the optimal control policies based on the solutions to the HJB equations obtained in the previous sections. Recall that x_1 is the smallest number such that V'' vanishes. For each $x \le x_1$ define

$$a^*(x) \equiv \arg \max_{\alpha \le a \le \beta} \left(\frac{1}{2}\sigma^2 a^2 V''(x) + (a\mu - \delta)V'(x) - \gamma V(x) \right). \tag{5.1}$$

As evident from below the function $a^*(x)$ represents the optimal feedback control function for the control component a_t^π, $t \ge 0$. More precisely, the value $a^*(x)$ is the optimal risk that one should take when the value of the current reserve is x. From the analysis in section 4, it follows that $a^*(x)$ can be represented as

$$a^*(x) = \begin{cases} \alpha, & 0 \le x \le x_\alpha, \\ a(x), & x_\alpha \le x \le x_\beta, \\ \beta, & x \ge x_\beta. \end{cases} \tag{5.2}$$

Note that the values of the critical points x_α, x_β as well as the function $a(x)$ depend on the three different cases studied in section 4. Specifically, in the case of $\frac{2\delta}{\mu} < \alpha$ the values of x_α and x_β are specified by Theorem 6 while $a(x)$ is given by (4.15); in the case of $\alpha \le \frac{2\delta}{\mu} < \beta$, $x_\alpha = 0$ and x_β is given by Theorem 7 while $a(x)$ is determined by (4.29); in the case of $\beta \le \frac{2\delta}{\mu}$, $x_\alpha = x_\beta = 0$.

To determine the other component of the optimal control, C_t^π, $t \ge 0$, which is the singular control in the terminology of control theory, we need to involve the reflection processes which solve the so-called Skorohod problem for the one-dimensional diffusion. Let (R_t^*, C_t^*) be a solution to the following Skorohod problem on $t \ge 0$:

$$\begin{aligned} &R_t^* = x + \textstyle\int_0^t (a^*(R_s^*)\mu - \delta)ds + \int_0^t a^*(R_s^*)\sigma dW_s - C_t^*, \\ &R_t^* \le x_1, \\ &\textstyle\int_0^\infty 1_{\{R_s^* < x_1\}} dC_s^* = 0. \end{aligned} \tag{5.3}$$

This solution yields two processes R_t^* and C_t^*. The first is a diffusion process on $(-\infty, x_1]$ reflected at the upper boundary, and the second is an increasing process. Subtracting C_t^* from R_t^* results in the reflection of R_t^* from x_1. The last condition is the requirement that this functional increases only when the controlled process is at the boundary x_1, thus not affecting the dynamics of R_t^* whenever R_t^* is below x_1. Existence of a solution to such a Skorohod problem follows from Theorem 3.1 in [12]. For a process R_t with a constant drift and diffusion term ($R_t = x + \mu t + \sigma W_t$), a solution to the Skorohod problem can be written in a closed form via the so-called running maximum

$$R_t^* = x + \mu t + \sigma W_t - C_t^*, \qquad C_t^* = \max_{0 \le s \le t} [(x + \mu s + \sigma W_t - x_1)^+].$$

In the case when drift and diffusion coefficients are not constants, by and large the solution to the equations (5.3) cannot be found in a closed form. An ε-approximation to the solution to the Skorohod problem by a jump diffusion R_t^ε can be the following. The process R_t^ε is a diffusion on $(-\infty, x_1]$, and whenever this process reaches x_1, it jumps down to $x_1 - \varepsilon$. The corresponding process C_t^ε in this case is a purely discontinuous functional which increases by ε when R_t^ε reaches x_1. The solution (R_t^*, C_t^*) to (5.3) can be viewed as a limiting case of $\varepsilon \to 0$.

THEOREM 9. *Let V be a concave, twice continuously differentiable solution of the HJB equation* (2.30) *and* $(R_t^*, C_t^*; t \geq 0)$ *be a solution to the Skorohod problem* (5.3). *Then for* $\pi^* = (a^*(R_t^*), C_t^*; t \geq 0)$, *we have*

$$J_x(\pi^*) = V(x) \qquad \forall x \geq 0. \tag{5.4}$$

Proof. For simplicity assume that the initial position $x \leq x_1$. In this case both processes R_t^* and C_t^* as a solution to the Skorohod problem are continuous. In view of (5.1),

$$L^{a^*(R_s^*)} V(R_s^*) = 0, \tag{5.5}$$

where the operator L^a is defined in (2.33). Repeating the argument in proving (2.62) and applying (5.5), we see that

$$E(e^{-\gamma(t\wedge\tau)} V(R_{t\wedge\tau}^*)) = V(x) - E\int_0^{t\wedge\tau} e^{-\gamma s} V'(R_s^*) dC_s^*. \tag{5.6}$$

Since $V'(x_1) = 1$ and in view of (5.3),

$$1_{\{R_s^* = x_1\}} dC_s^* = dC_s^*, \tag{5.7}$$

we can replace $V'(R_s^*)$ in the integrand on the right-hand side of (5.6) by $V'(R_s^*)1_{\{R_s^*=x_1\}} = V'(x_1)1_{\{R_s^*=x_1\}}$ to obtain

$$\begin{aligned} E(e^{-\gamma(t\wedge\tau)} V(R_{t\wedge\tau}^*)) &= V(x) - E\int_0^{t\wedge\tau} e^{-\gamma s} V'(x_1) 1_{\{R_s^*=x_1\}} dC_s^* \\ &= V(x) - E\int_0^{t\wedge\tau} e^{-\gamma s} V'(x_1) dC_s^* = V(x) - E\int_0^{t\wedge\tau} e^{-\gamma s} dC_s^*, \end{aligned} \tag{5.8}$$

where in the last two equalities we used once more (5.7) and the condition $V'(x_1) = 1$. Taking limit as $t \to \infty$, and applying (2.65), we obtain the desired result. □

Combining Theorems 3 and 9, we get the following result immediately.

COROLLARY 3. *The function V presented in the previous sections is the value function and π^* is the optimal policy.*

Remark 6. Theorem 9 and Corollary 3 also imply that the HJB equation (2.30) has a unique solution in the class of concave, twice continuously differentiable functions.

Next we summarize all the results we obtained in Table 1 for easy reference.

6. Economic interpretation and conclusions. The optimal policies obtained in the previous sections have clear economic meaning and are very easy to implement. Let us now elaborate.

Theorem 5 is a mathematical formulation of the intuition that if a company has a liability rate not smaller than the maximal expected profit rate, then it is optimal to declare bankruptcy immediately, distributing the whole reserve as the dividend. In this case the risk control policy is irrelevant.

When an immediate bankruptcy is not optimal, the optimal risk control policy is characterized by two critical reserve levels: x_α and x_β. The values of these two levels are further determined by three parameters: the minimum risk allowed (α), the maximum risk allowed (β), and the ratio between the debt rate and profit rate ($\frac{\delta}{\mu}$). If the company has very little debt compared to the potential profit (so that $\frac{2\delta}{\mu} \leq \alpha$),

TABLE 1
Summary of results.

Range for $\frac{\delta}{\mu}$	x_α	x_β	$a^*(x)$	Risk α ever attained	x_1
$\frac{2\delta}{\mu} < \alpha$	positive and finite; see (4.9)	positive and finite; see (4.16)	(i) α, for $x \in [0, x_\alpha]$; (ii) increases from α to β on $[x_\alpha,\ x_\beta]$; see (4.15); (iii) β, for $x \geq x_\beta$	yes	positive; see (4.25)
$\frac{2\delta}{\mu} = \alpha$ / $\alpha < \frac{2\delta}{\mu} < \beta$	0	positive and finite; see (4.30)	(i) increases from $2\delta/\mu$ to β on $[0,\ x_\beta]$; (ii) β, for $x \geq x_\beta$	yes / no	positive; see (4.33)
$\frac{\delta}{\mu} < \beta \leq \frac{2\delta}{\mu}$	0	0	β	no	positive; see (4.41)
$\frac{\delta}{\mu} \geq \beta$ (trivial case)	0	0	any	N/A	0

then both the critical reserve levels, x_α and x_β, are positive and finite. In this case, the company will minimize the business activity (i.e., take the minimum risk α) when the reserve is below the level x_α, then gradually increase the business activity when the reserve is between x_α and x_β, and then maximize the business activity (i.e., take the maximum risk β) when the reserve ever reaches or goes beyond the level x_β.

Next, if the company has a higher debt-profit ratio (so that $\alpha < \frac{2\delta}{\mu} < \beta$), then the company has to be a bit more aggressive in the sense that $x_\alpha = 0$ and x_β is positive and finite. In this case, no matter how small the reserve is the company will never take the minimum risk; rather it will start with the risk level $\frac{2\delta}{\mu}$ and gradually increase to the maximum risk level β when the reserve hits the level x_β and goes above this level. This can be explained by the fact that when the debt rate is high one needs to gamble on the higher potential profits in order to get out of the "bankruptcy zone" as fast as possible, even at the expense of assuming higher risk. The company becomes more aggressive when the debt-profit ratio is even higher (precisely when $\frac{\delta}{\mu} < \beta \leq \frac{2\delta}{\mu}$), in which case the maximum allowable risk β is taken throughout while the two critical levels x_α and x_β are both zero. Finally, when the debt-profit ratio is so high that the debt-profit ratio is greater than the maximum risk possible, then the company should declare bankruptcy and go out of business immediately. This is due to the fact that the expected net cash flow is negative in this case, no matter what the company's policy might be.

On the other hand, the optimal dividend policy is always of a threshold type with the threshold being equal to x_1. Namely, the reserve should be kept below the critical level x_1 while distributing any excess as dividends. A simple realistic approximation of this policy is distributing a small amount of dividends whenever the process reaches x_1. If the initial reserve x exceeds x_1, then the optimal policy requires to distribute instantaneously all the excess above x_1. From the structure of our solution we also see that the maximum business activity is always taken on *before* dividend distributions take place.

In conclusion, we would like to point out an intricate interplay between the liability and restrictions on the risk control of a financial company. The sheer number of qualitatively different optimal policies, which appears due to different possible relationships between exogenous parameters, shows the multiplicity of different economic environments which a financial company faces depending on the size of the debt and on the size of available business activity.

Acknowledgments. We thank the associate editor and the two reviewers for their careful reading of an earlier version of the paper and for their constructive comments that led to an improved version.
